
MAIN EQUIPMENT CENTER

1 CABIN ATTENDANT HANDSETS ARE AT EACH ATTENDANT STATION.

2 THERE IS ONE ZMU IN EACH ZONE.

23-42-00-003.018 Rev 0 12/22/1997

CIS - COMPONENT LOCATIONS - CABIN AND MAIN EQUIPMENT CENTER

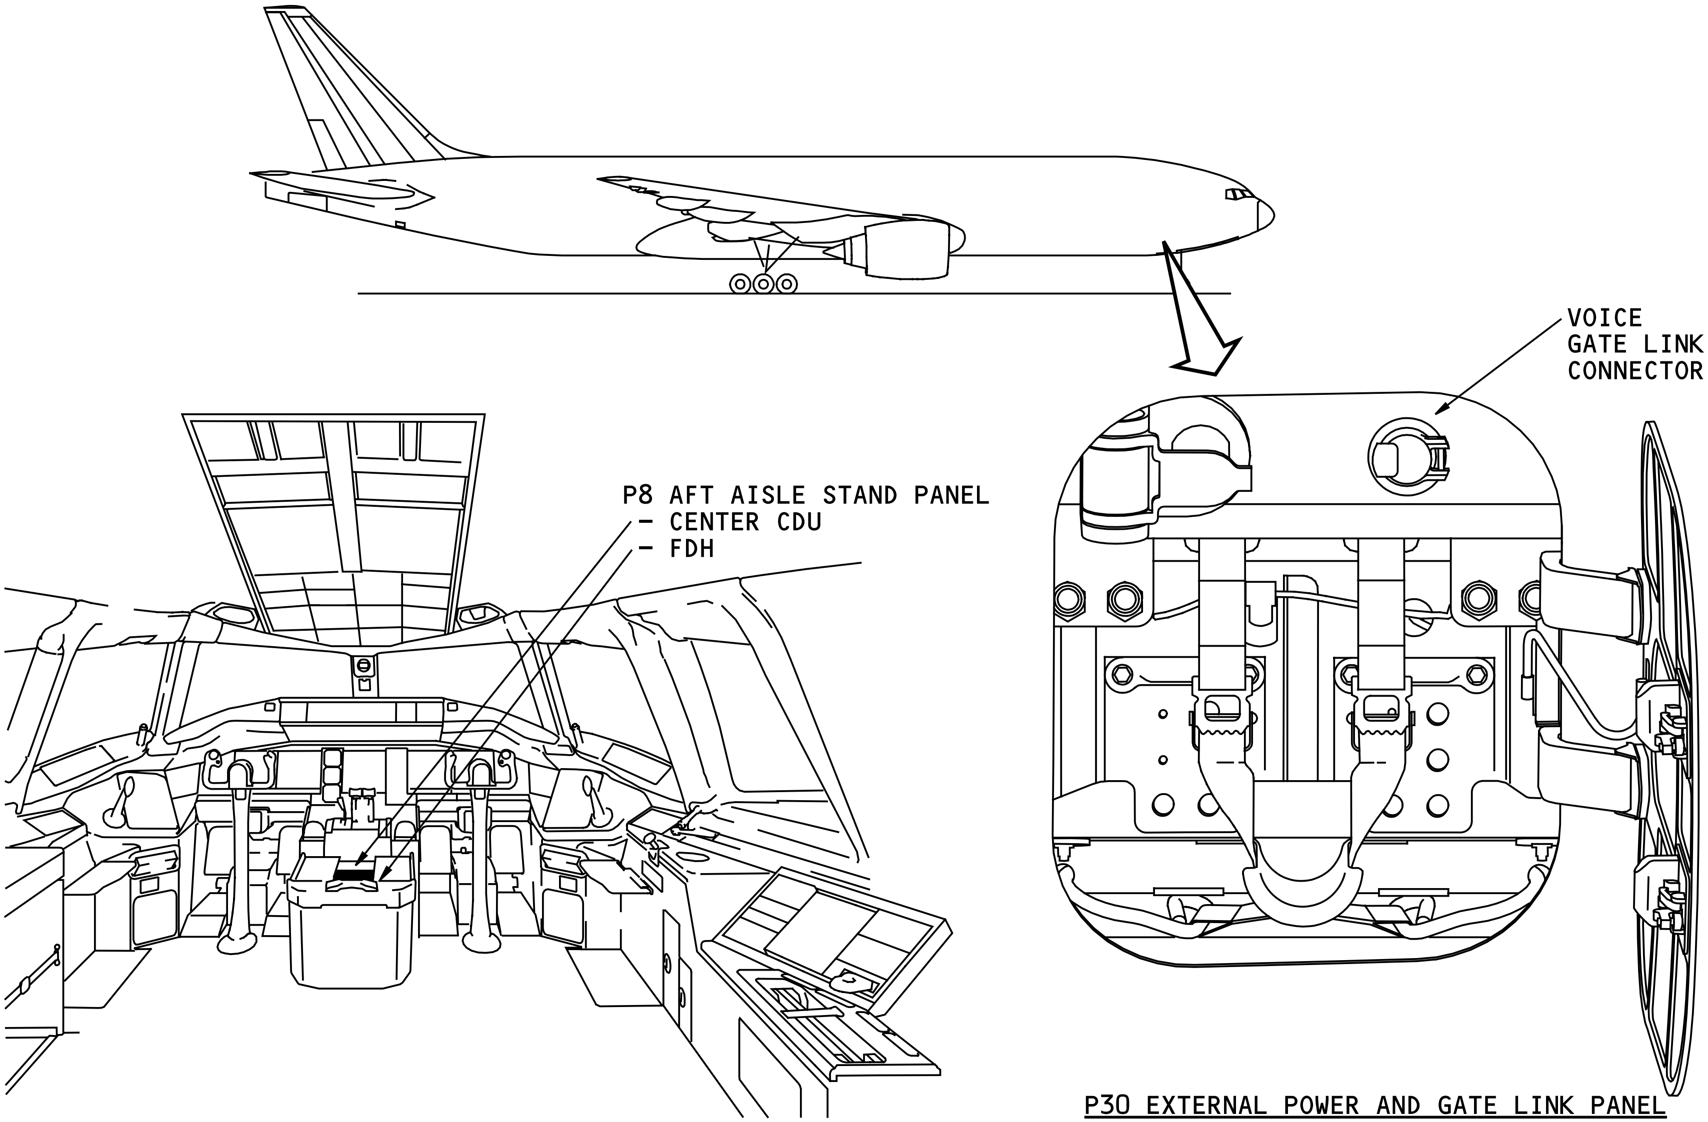
CIS - COMPONENT LOCATIONS - FLIGHT DECK AND P30

Flight Deck

The flight deck handset (FDH) and center control display unit (CDU) are on the aft aisle stand panel.

P30 External Power and Gate Link Panel

The external power and gate link panel has two telephone jacks on it. The jacks connect the passenger address/cabin (PA/CI) controller to land telephone networks.



CIS - COMPONENT LOCATIONS - FLIGHT DECK AND P30

CIS - POWER INTERFACE

General

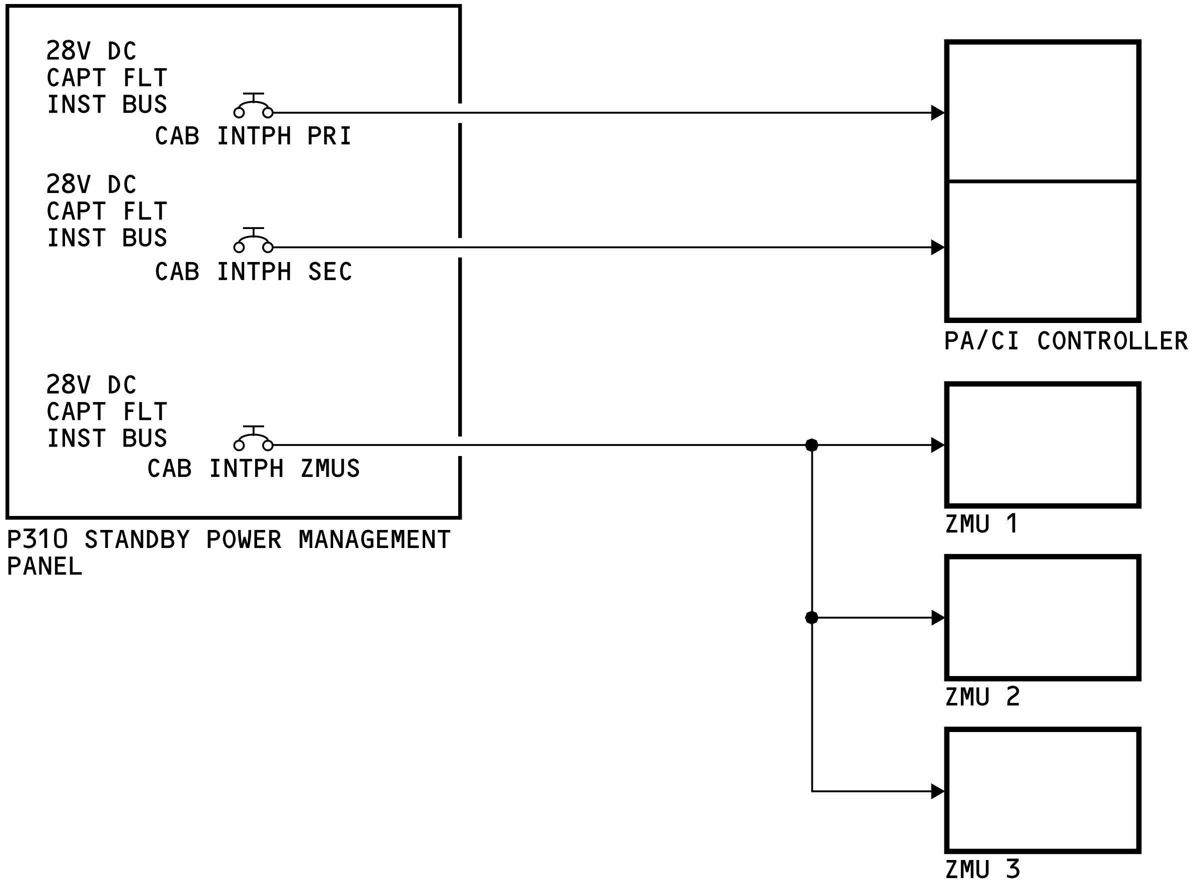
The standby power management panel has three circuit breakers that connect power to the CIS components.

PA/CI Controller

The passenger address/cabin interphone (PA/CI) controller uses two 28 volt inputs for the cabin interphone function. One input supplies power to the normal cabin interphone controller. The other supplies power to the alternate cabin interphone controller.

ZMUs

The zone management units (ZMUs) get 28v dc for their cabin interphone circuits.



23-42-00-005 Rev 1 07/02/1997

CIS - POWER INTERFACE

THIS PAGE INTENTIONALLY LEFT BLANK

CIS - PA/CI CONTROLLER INTERFACES

General

The passenger address/cabin interphone (PA/CI) controller has interfaces to connect the flight attendant and flight crew stations.

Flight Crew

The flight crew can use the flight deck handset (FDH) or the flight interphone system to talk on the cabin interphone system (CIS).

The FDH sends mic audio and dial code signals to the PA/CI controller. It also sends a push to talk (PTT) for passenger address announcements. The PA/CI controller sends receiver audio to the FDH.

To use the flight interphone system, the flight crew selects a dial code on the center control display unit (CDU). The center CDU shows call messages and data from the PA/CI controller.

The audio management unit (AMU) sends and receives the audio from the PA/CI controller. It also sends a PTT.

The in-flight entertainment system (IFE) sends a signal to the CSMU when the video system is on. The CSMU sends the signal to the center CDU to show VIDEO IN USE. The PA/CI controller also sends a signal to show PA IN USE when the passenger address system is on.

When a call goes to the flight deck, the PA/CI controller:

- Sends a cabin call discrete to the AMU
- Sends a discrete to the AIMS cabinets
- Shows a message on the center CDU.

The audio control panel (ACP) call lights come on. The AMU controls the call lights. When a pilot selects CAB on an ACP, the AMU sends an off-hook signal to the PA/CI controller. The PA/CI controller sends a cabin reset signal to the AMU. The call lights go off.

To make a priority line call, push the CAB transmit switch twice. The AMU sends a priority line signal to the PA/CI controller. The priority line call goes to a station defined by the configuration database.

When the ground crew calls the flight deck from the service and APU shutdown panel, the flight crew gets a call light on their ACPs and a message on EICAS. The PA/CI controller sends a flight deck call signal to the AMU. It also sends a signal to the AIMS cabinets. When a pilot selects FLT on an ACP, the AMU sends a flight deck reset signal to the PA/CI controller. This ends the flight call signal.

Cabin

The PA/CI controller connects to the zone management units (ZMUs) to connect cabin handsets. Each ZMU has a digital interface with the PA/CI controller. The ZMU sends digital audio and dial codes to the PA/CI controller. The PA/CI controller makes the internal connection and sends digital audio to the ZMU. It also sends cabin interphone master call light data to the ZMUs.

External Panels

When the ground crew calls the flight deck, the P40 service and APU shutdown panel sends a signal to the PA/CI controller. When the flight crew calls the ground crew, the PA/CI controller sends a signal to the standby power management panel. This causes the ground crew call horn to sound.

There are two telephone lines that connect to the P30 external power and gate link panel. This permits the cabin interphone system to connect to public telephone systems.

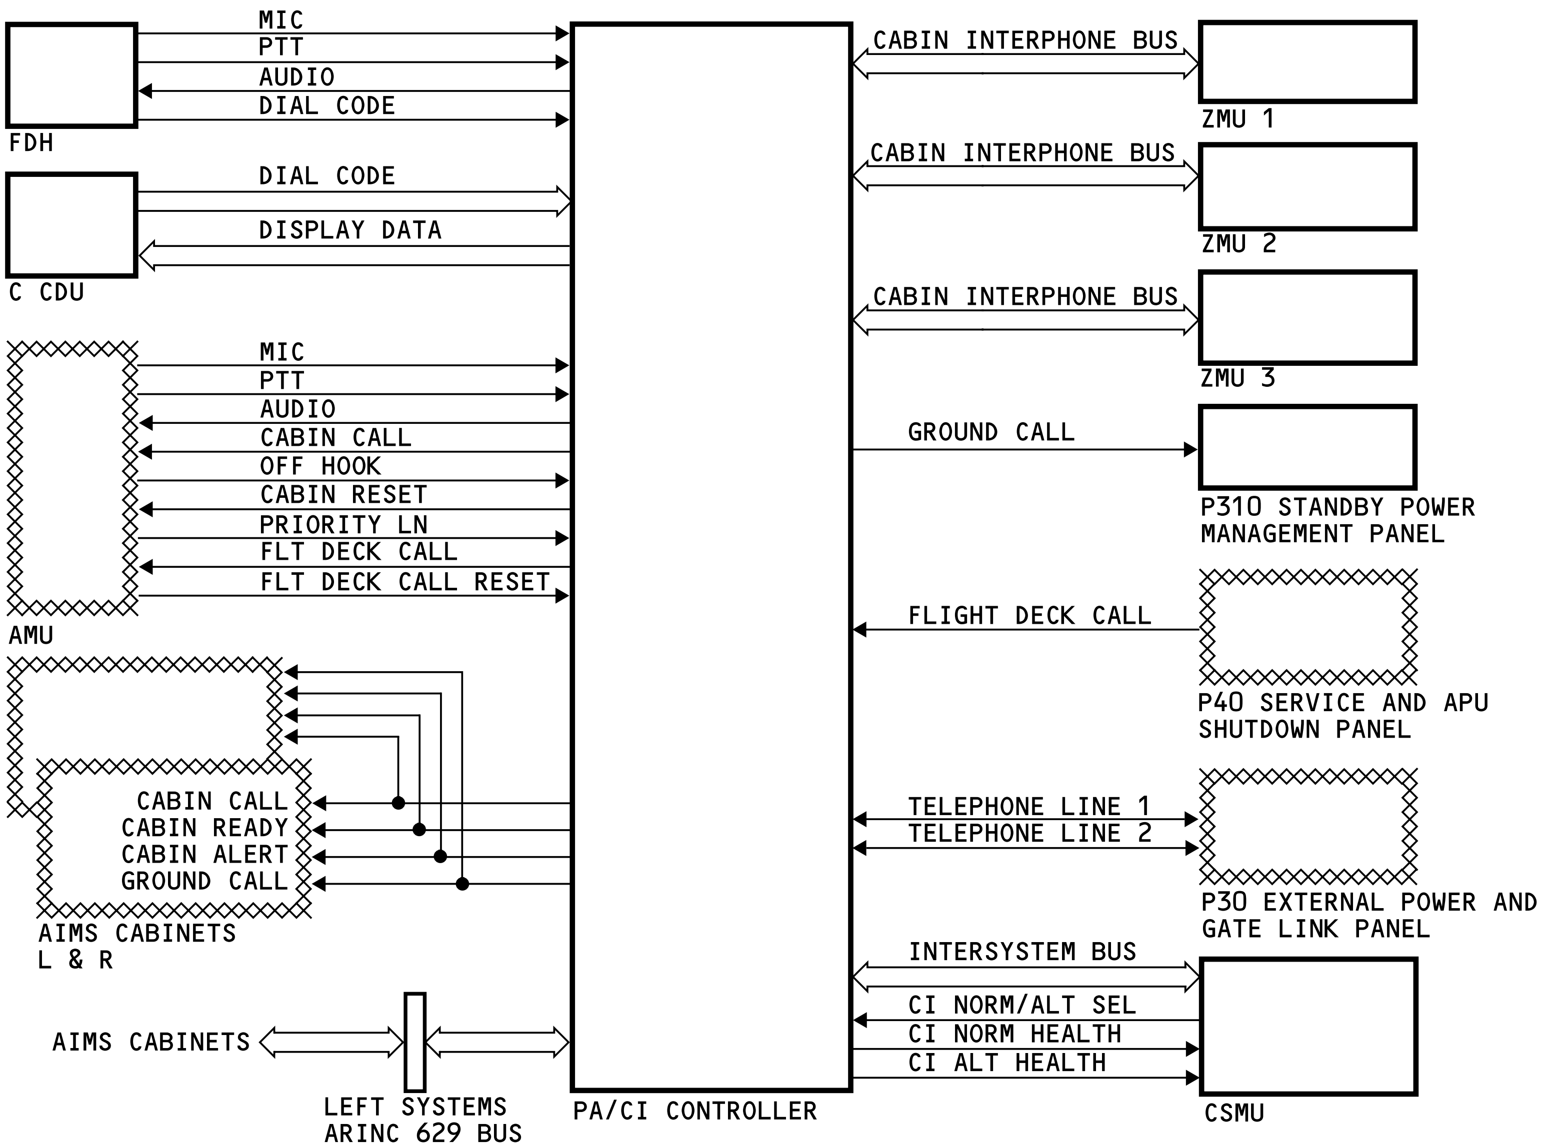
CSMU

The cabin system management unit (CSMU) sends and gets both test and software installation data on the intersystem bus from the PA/CI controller.

The PA/CI controller has two cabin interphone controllers, normal and alternate. Only one operates at a time. If the normal controller fails, flight attendants select the alternate from the attendant switch panel (ASP).

Each controller monitors its operation. If it finds a failure, it sets a discrete. The discrete is a health discrete and it goes to the CSMU. The CSMU and the PA/CI controller send the failure information on the intersystem bus. The cabin system control panel and cabin area control panels show a failure message.

The PA/CI controller sends failure data to the AIMS on the left systems ARINC 629 bus. The CSMU also sends failure information to the AIMS when either cabin interphone controller fails.



CIS - PA/CI CONTROLLER INTERFACES

CIS - ZMU INTERFACES

General

The zone management units (ZMUs) supply an interface between the passenger address/cabin interphone (PA/CI) controller and the cabin attendant handsets (CAHs).

The ZMUs digitize analog audio from the CAHs. They change digital audio from the PA/CI controller to analog.

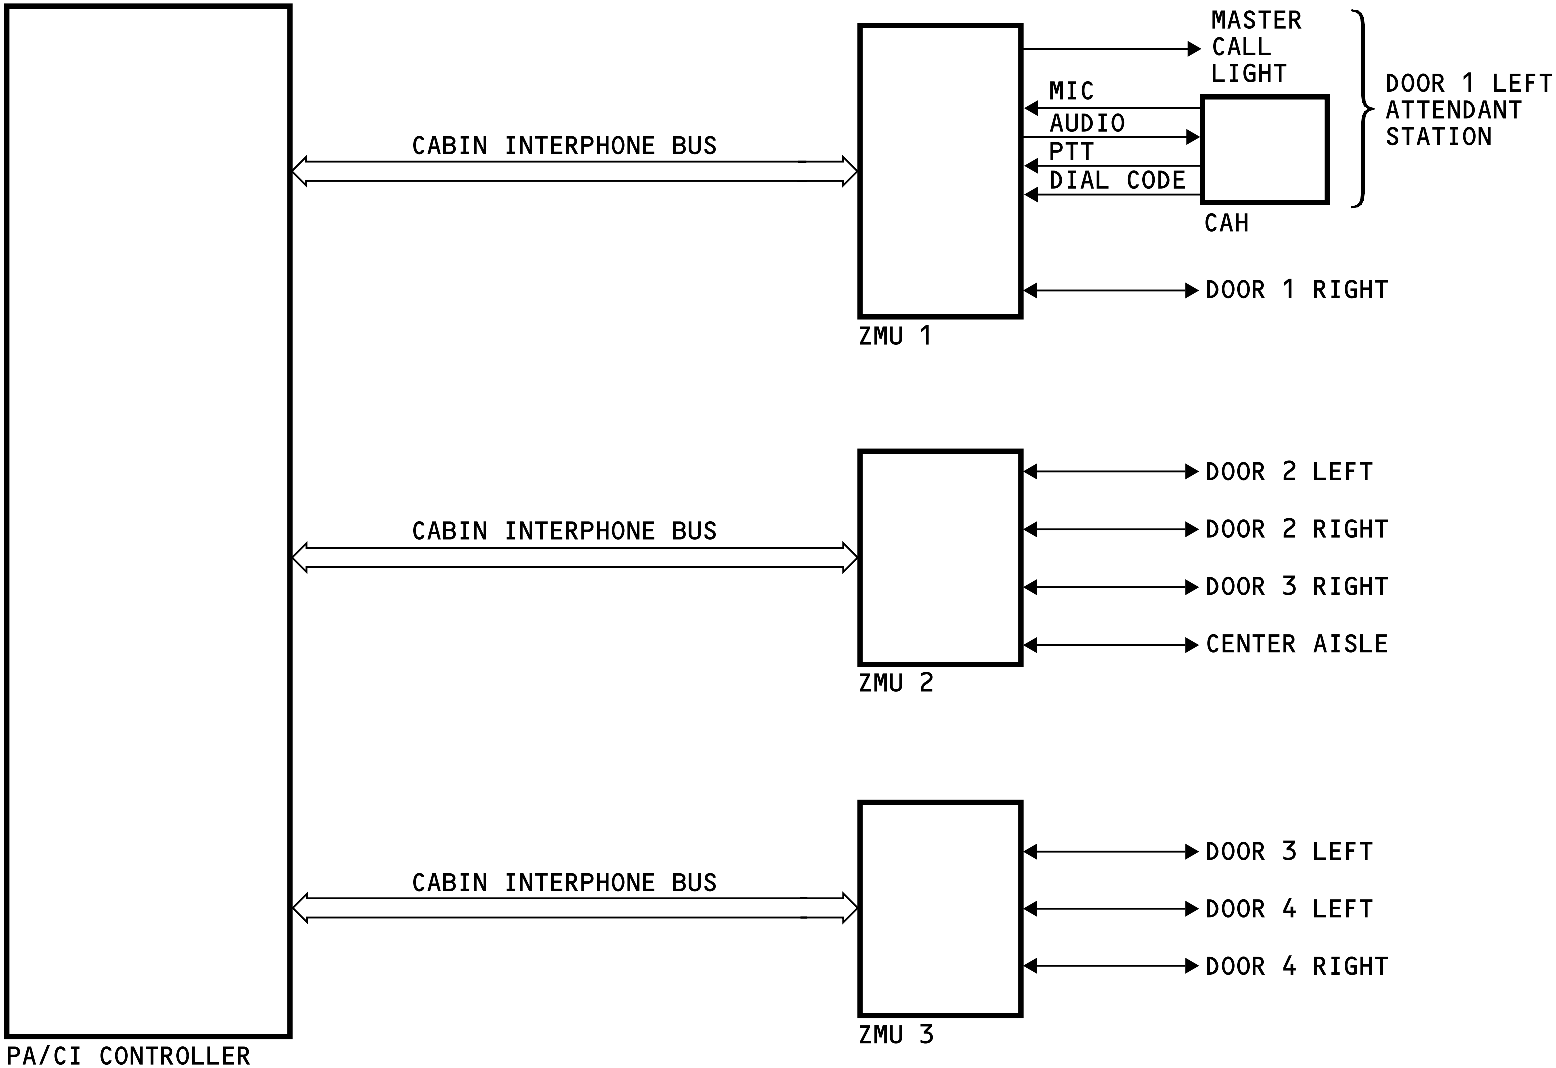
ZMU Interfaces

ZMU 1 gets microphone audio and dial codes from the CAH at door 1 left. It also gets a PTT for passenger address announcements. The ZMU digitizes the inputs and sends the data to the PA/CI controller.

The PA/CI controller makes the internal connection between the calling CAH and the called CAH. It sends the digital audio to the applicable ZMU. The ZMU changes the audio back to analog and sends it to the CAH.

The PA/CI controller also sends data to the ZMU. An incoming call makes the master call light at door 1 left come on.

The interfaces for other CAHs operate in the same way as the door 1 left interface.



NOTE: ALL ATTENDANT STATION INTERFACES ARE SIMILAR TO DOOR 1 LEFT

CIS - ZMU INTERFACES

CIS - CABIN ATTENDANT HANDSET/FLIGHT DECK HANDSET

Purpose

The crew uses cabin attendant handsets (CAH) and the flight deck handset (FDH) to speak with each other. They also use them to make an announcement on the passenger address system.

Physical Description

The CAH and the FDH are the same.

The CAH/FDH is like a telephone handset. It has these features:

- Earpiece
- Microphone
- Standard 12 digit keypad
- Reset switch.

It also has a PTT switch for use with the passenger address system.

The back of each handset has a directory that shows all the dial codes.

Location

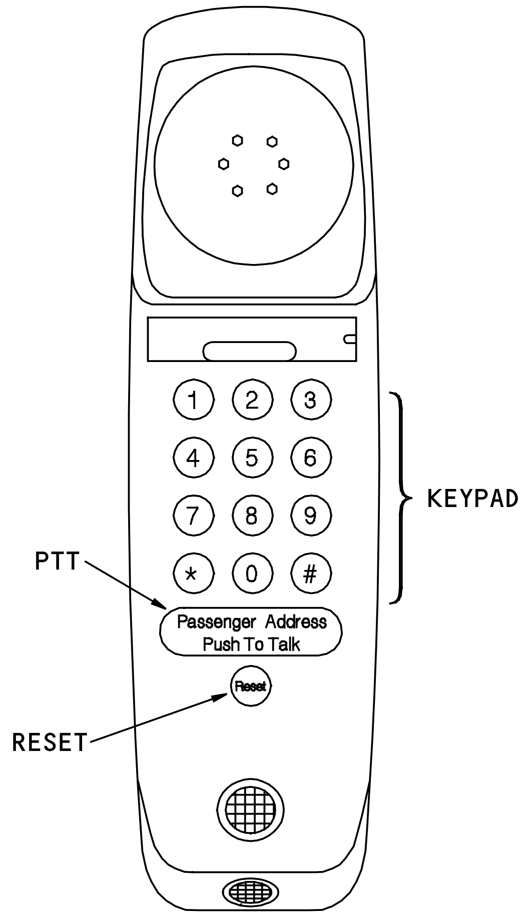
There is a CAH on the attendant seat at each door. The FDH is on the aisle stand in the flight deck.

Operation

All calls use a two digit dial code. To make a call, push the first key of the code, then push the second.

Functional Description

The CAH/FDH sends and receives analog audio. It also sends dial codes and a PTT signal.



CAH/FDH

CIS - CABIN ATTENDANT HANDSET/FLIGHT DECK HANDSET

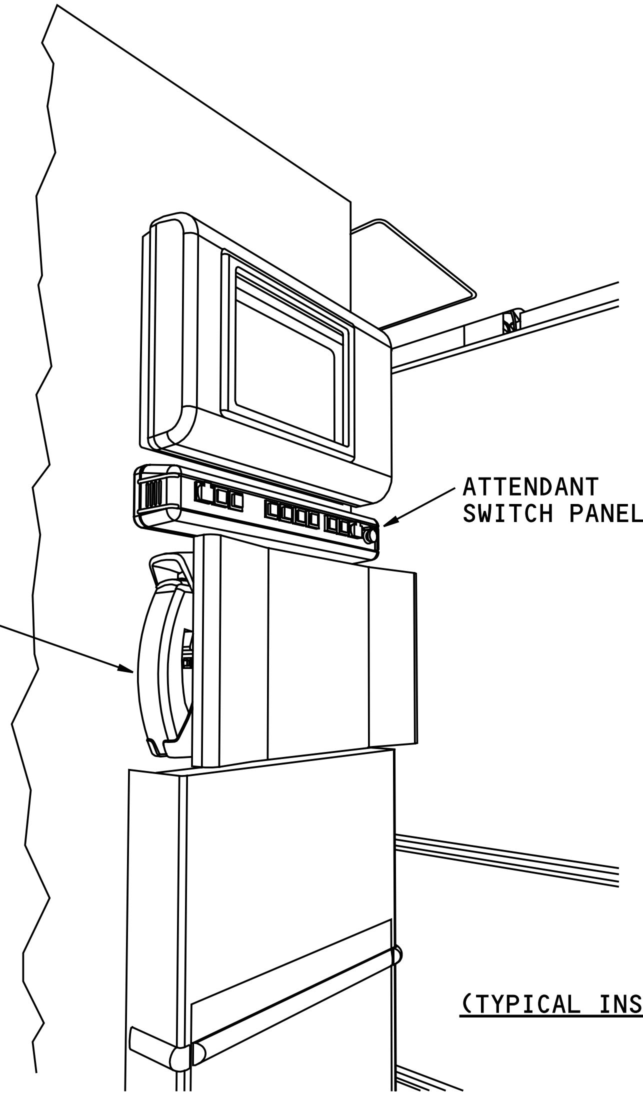
CIS - CAH AND ASP INSTALLATION

Cabin Attendant Handsets

The cabin attendant handsets (CAHs) are at the attendant seats at each door. The cradle and CAH is behind the headrest of the seat.

Attendant Switch Panel

The attendant switch panel (ASP) is at door 2 left. It has the cabin interphone normal/alternate switch on it.

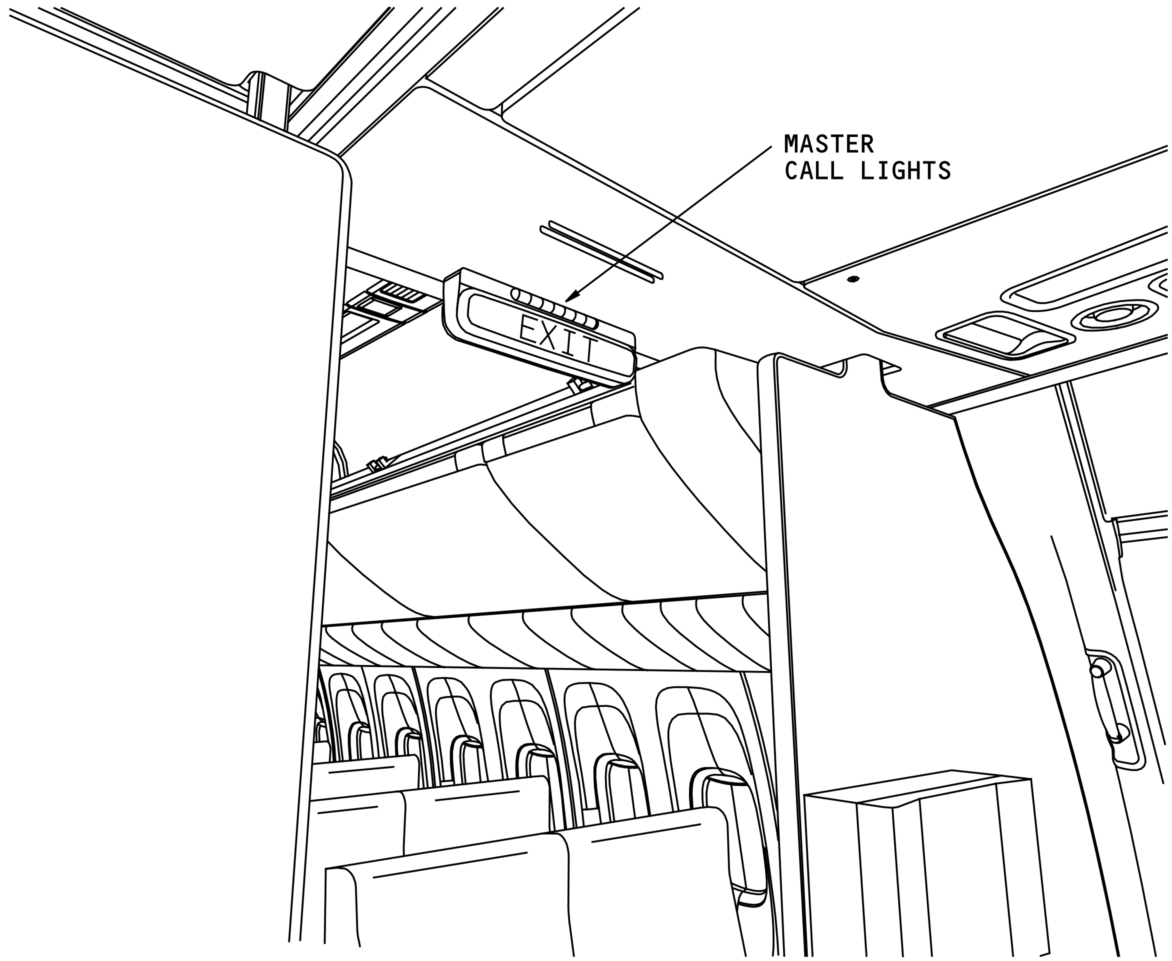


CIS - CAH AND ASP INSTALLATION

CIS - MASTER CALL LIGHTS

Operation

When an attendant gets a cabin interphone call, a pink master call light comes on. The call light is on the EXIT sign module near the station that gets the call.



CIS - MASTER CALL LIGHTS

CIS - CABIN INTERPHONE FAILURE MESSAGE

General

Each cabin interphone controller (CIC) of the PA/CI controller monitors its internal operation. If it finds a failure, it sends a message to the cabin system control panel (CSCP) and the cabin area control panels (CACPs). The CSCP and all the CACPs show a pop up window.

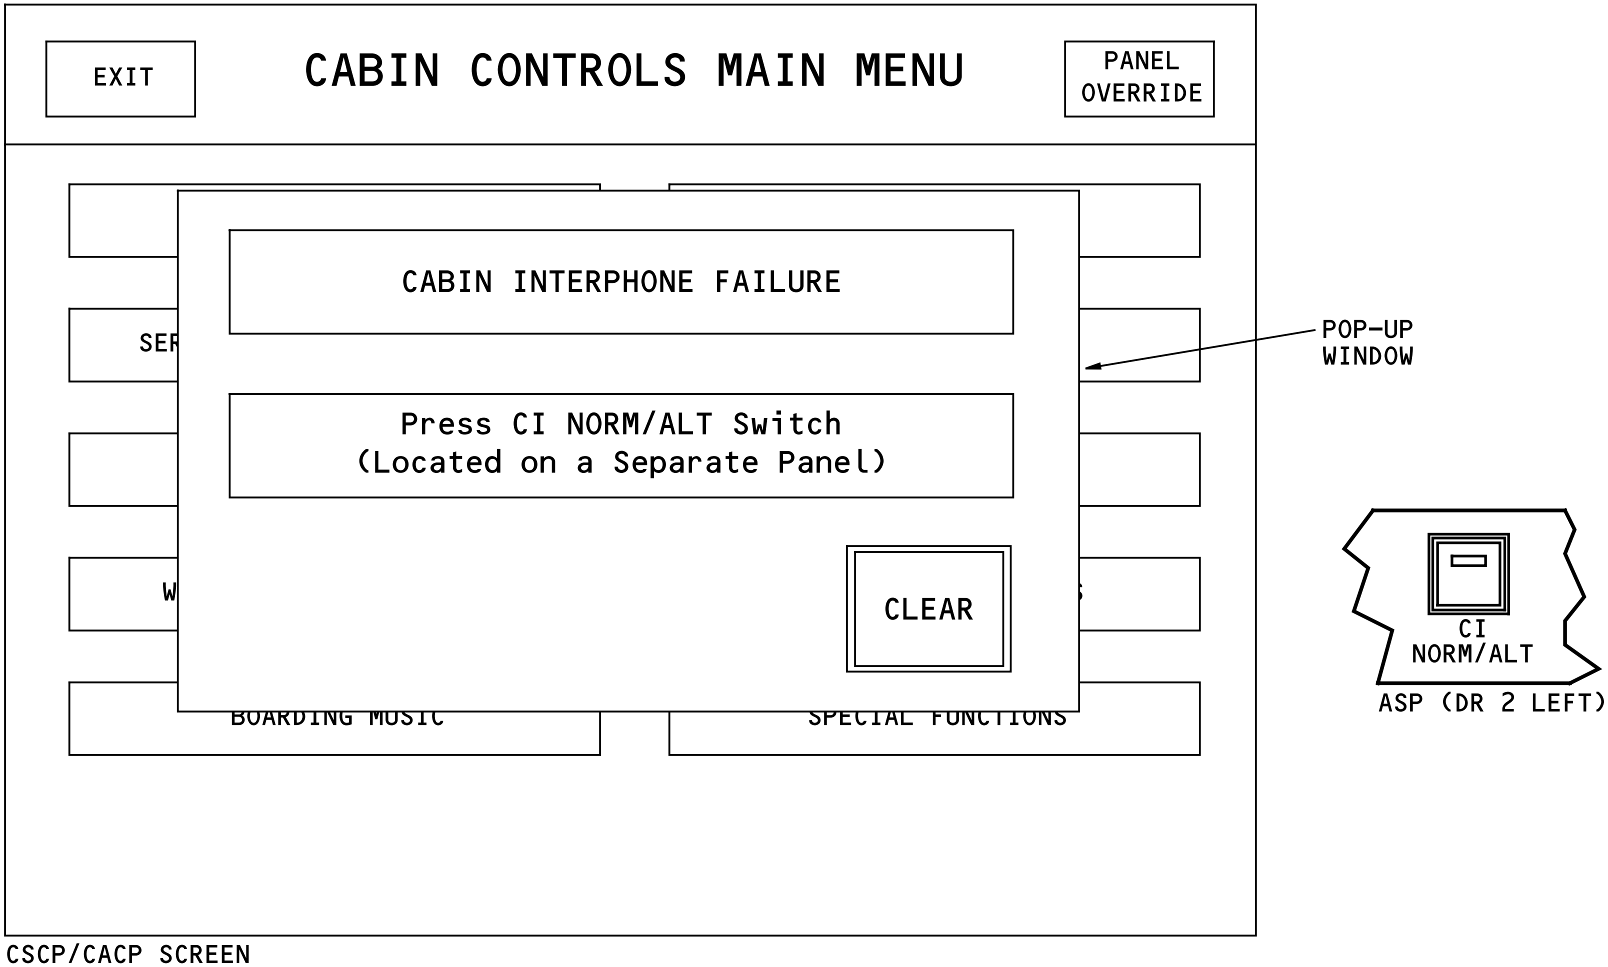
Message

The pop up window tells the flight attendants to push the CI NORM/ALT switch.

To clear the window, touch CLEAR or push the CI NORM/ALT switch. The CI NORM/ALT switch is on the attendant switch panel at door 2 left.

If you touch CLEAR and do not push the CI NORM/ALT switch, the CSCP and CACPs show this message at the bottom of the screen - CABIN INTERPHONE FAILURE Press CI NORM/ALT Switch. The message goes away when you push the CI NORM/ALT switch.

The CIC also sends a message to the AIMS for both EICAS and the central maintenance computing function (CMCF).



23-42-00-011 Rev 6 11/27/1996

CIS - CABIN INTERPHONE FAILURE MESSAGE

CIS - NORMAL/ALTERNATE CIC FUNCTIONAL DESCRIPTION

General

The PA/CI controller has two cabin interphone controllers (CICs), normal and alternate. Only one CIC operates at a time. If the normal CIC fails, the flight attendants select the alternate CIC. They do this from a switch on the attendant switch panel (ASP).

The interfaces to both CICs are the same.

Operation

The CI NORM/ALT switch is an alternate action switch. It sends a discrete signal to the cabin system management unit (CSMU).

During normal operation, the switch signal goes through a switch in the CSMU to the PA/CI controller. When you install software or test the system, the CSMU controls the selection of normal or alternate CIC.

Normal CIC

With the switch in the normal position, an open signal goes to the PA/CI controller. This causes the PA/CI to use the normal CIC. The alternate CIC is off.

Alternate CIC

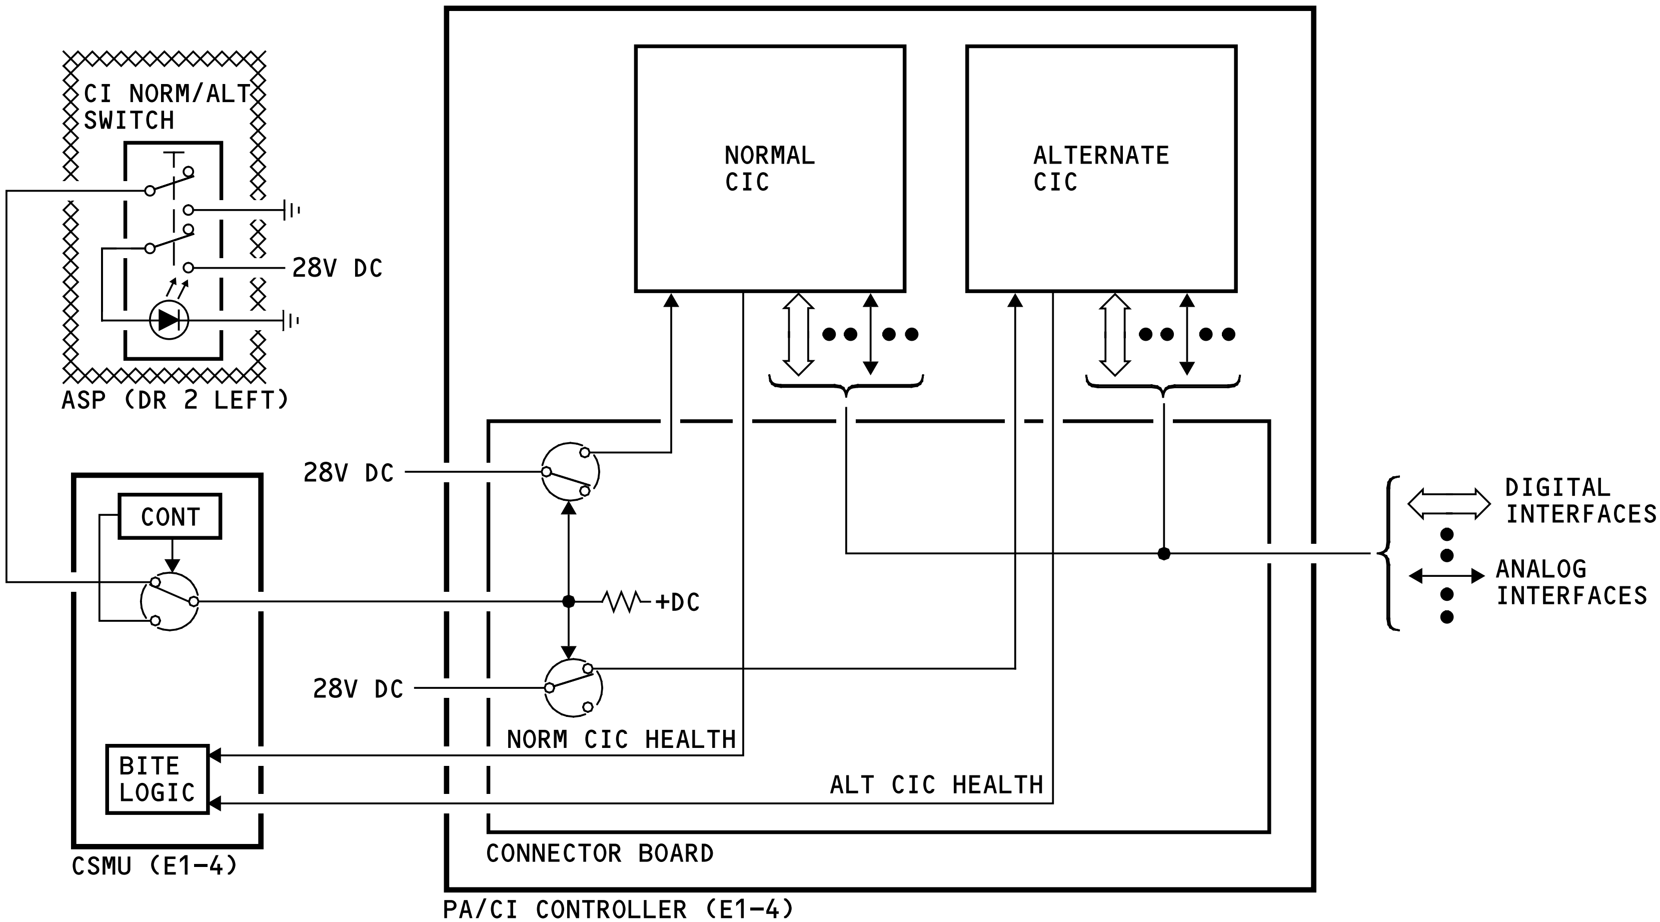
When you push the switch in, a ground signal goes to the PA/CI controller. The LED in the switch comes on. A ground signal causes the PA/CI controller to use the alternate CIC. The normal CIC is off.

Health Signals

Both CICs monitor their operation. Each CIC sends a health discrete to the CSMU. If the CIC finds a failure, it sets the health discrete. The CSMU sends a message to the CSCP and CACPs. The CSMU also sends a signal to the AIMS.

Training Information Point

Because only one CIC operates at a time, you can use the CI NORM/ALT switch to help isolate cabin interphone system problems. If the problem goes away when the other CIC is active, the problem is in the PA/CI controller.



23-42-00-012 Rev 10 10/21/96

CIS - NORMAL/ALTERNATE CIC FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

CIS - ZMU AND CAH FUNCTIONAL DESCRIPTION

General

The zone management units (ZMUs) supply an interface between the passenger address/cabin interphone (PA/CI) controller and the cabin attendant handsets (CAHs). The ZMUs also control the master call lights.

Each ZMU can connect to as many as five CAHs.

Zone Management Unit

The ZMU has circuits for the CIS. The ZMU digitizes CAH mic audio and changes PA/CI controller call audio to analog.

The ZMU receives data and digital audio from the PA/CI controller. The EIA-485 interface sends the digital audio to the multiplexer/demultiplexer. The multiplexer/demultiplexer isolates the different channels of audio. It sends each channel to the applicable CAH interface.

The CAH interface has a digital to analog (D/A) converter that changes the digital audio to analog. The CAH interface sends the analog signal to the CAH.

The CAH sends mic audio to the ZMU. The CAH interface has an analog to digital (A/D) converter that digitizes the audio signal. The digital signal goes to the multiplexer. The CAH interface also supplies the bias voltage for the CAH microphone.

The CAH sends dial codes and a PTT to the ZMU. The CAH interface has a PTT/dial code interface that digitizes the inputs. It sends the data to the multiplexer/demultiplexer.

The multiplexer/demultiplexer adds the signals together and sends it to the EIA-485 interface. The EIA-485 interface sends it to the PA/CI controller.

Each ZMU connects to one CAH that supplies a direct access input to the passenger address system. Normally the mic audio and PTT go through the direct access relay to the CAH interface. The direct access function sends the mic and PTT to the passenger address system.

Master Call Lights

The ZMU controls the master call lights. The EIA-485 interface isolates call light on/off data from the PA/CI controller. The EIA-485 interface sends the data to the master call light driver. The master call light driver controls the lights.

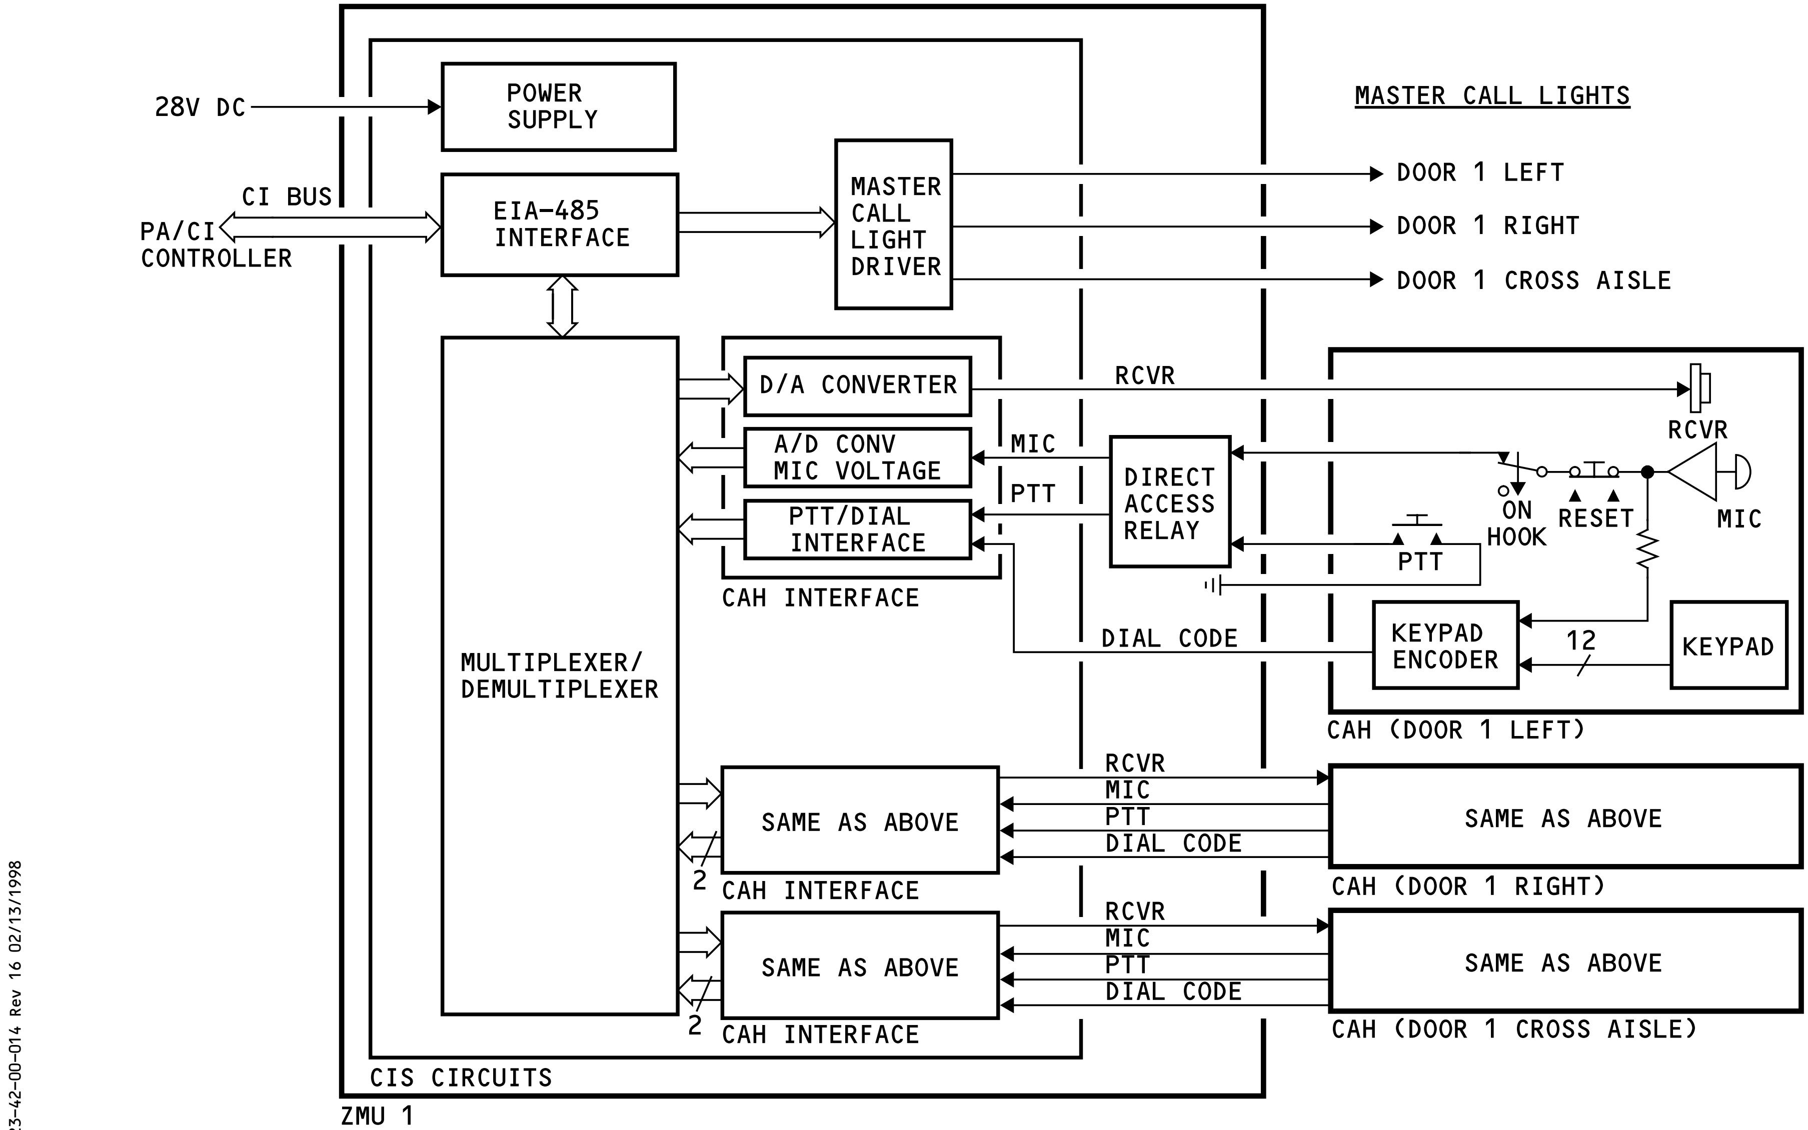
Cabin Attendant Handset

The CAH gets receiver audio from the ZMU. Mic audio goes through an amplifier. It passes through the RESET switch and on-hook switch. The RESET and on-hook switches stop the call.

The PTT sends a ground signal to the ZMU. It is for passenger address announcements.

CIS - ZMU AND CAH FUNCTIONAL DESCRIPTION

The CAH keypad has twelve momentary switches. They send signals to the keypad encoder. The keypad encoder sends dial code signals to the ZMU. The keypad encoder gets power from the mic line.



CIS - ZMU AND CAH FUNCTIONAL DESCRIPTION

CIS - TYPES OF CALLS

General

The CIS has different types of calls between cabin interphone stations. A station is any station with a cabin attendant handset (CAH) or the flight deck handset (FDH). The flight crew can also use the flight interphone system for CIS calls.

Call Types

The CIS has these three basic types of calls:

- Pilot alert call
- Conference call
- Station-to-station call.

Pilot Alert

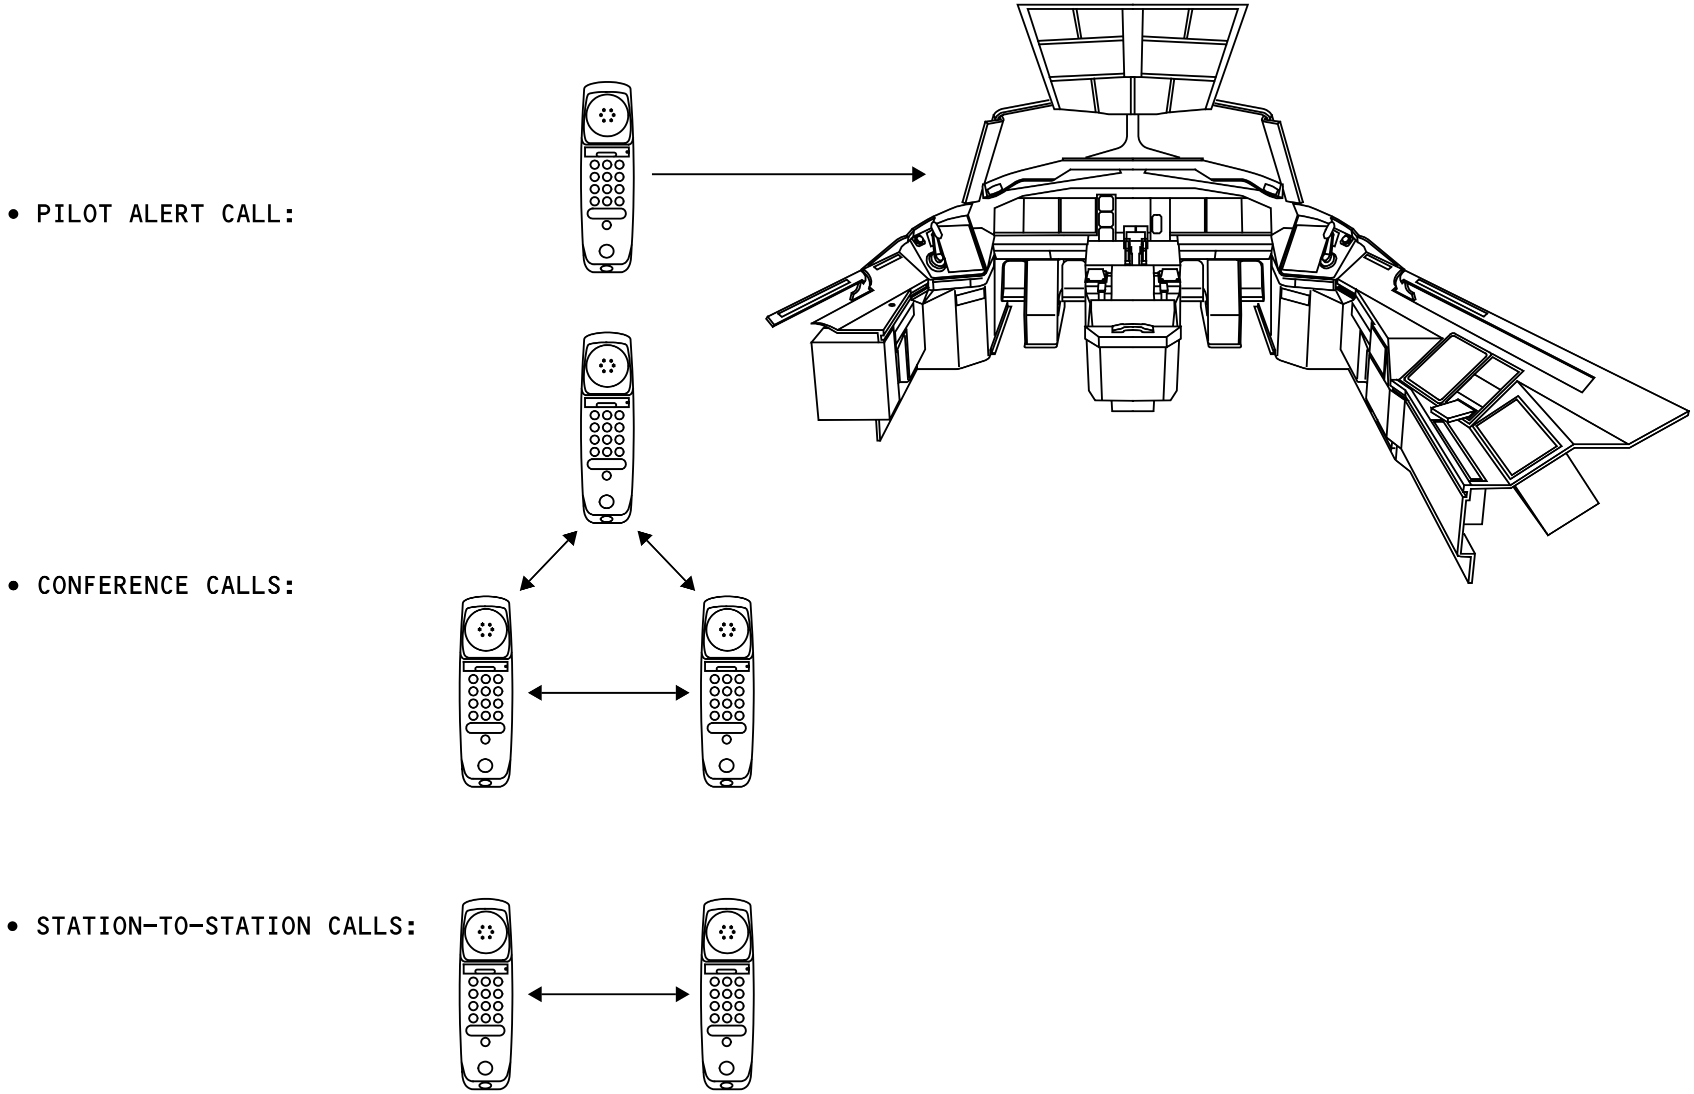
The flight attendants use the pilot alert call to tell the flight crew about an emergency. A pilot alert replaces all other calls to the flight deck. Any CAH can make a pilot alert call.

Conference Calls

A conference call connects a group of stations in one CIS call. The stations connect to the same line. Each conference call has one dial code for all stations included in the conference call.

Station-to-Station Calls

A station-to-station call is a normal two way call. Any station can make a call to any other station with a two digit dial code. Once you make a station-to-station call, you can add one or two more stations to the connection.



23–42–00–015 Rev 0

CIS – TYPES OF CALLS

CIS - DIAL CODES

General

The flight crew and flight attendants use two digit dial codes to make cabin interphone calls.

Station to Station Calls

Most station-to-station codes relate the location of the handset to the code.

To call the handset, push the first dial code key then the second for the station.

Conference Calls

Conference calls include a set number of stations. The configuration database identifies the stations.

To make a conference call, push the first dial code key then the second. The call can come from any handset.

Passenger Address Codes

The passenger address codes are for passenger address announcements.

Pilot Calls

The pilot call codes are for calls from the cabin to the flight deck.

The ground crew code is only for the flight crew to call the ground crew.

Land Line Calls

The external power and gate link panel has two telephone jacks. If you connect a local telephone network to a jack, you can access the network by dialing *9. With the system connected to a telephone network, you use the handset like a telephone.

Configuration Database

The configuration database identifies all types of calls and their dial codes. The configuration database also enables or disables the landline calls.

TYPICAL

CIS - DIAL CODES

CIS - FLIGHT DECK CONTROLS

General

The flight crew can use either the flight deck handset (FDH) or flight interphone system to connect to the CIS. The FDH is the same as the cabin attendant handsets.

To use the flight interphone system, select CAB on an audio control panel (ACP). Use the center control display unit (CDU) to select dial codes and receive CIS messages.

Audio Control Panel

The cabin interphone transmitter select switch connects the crew member to the CIS.

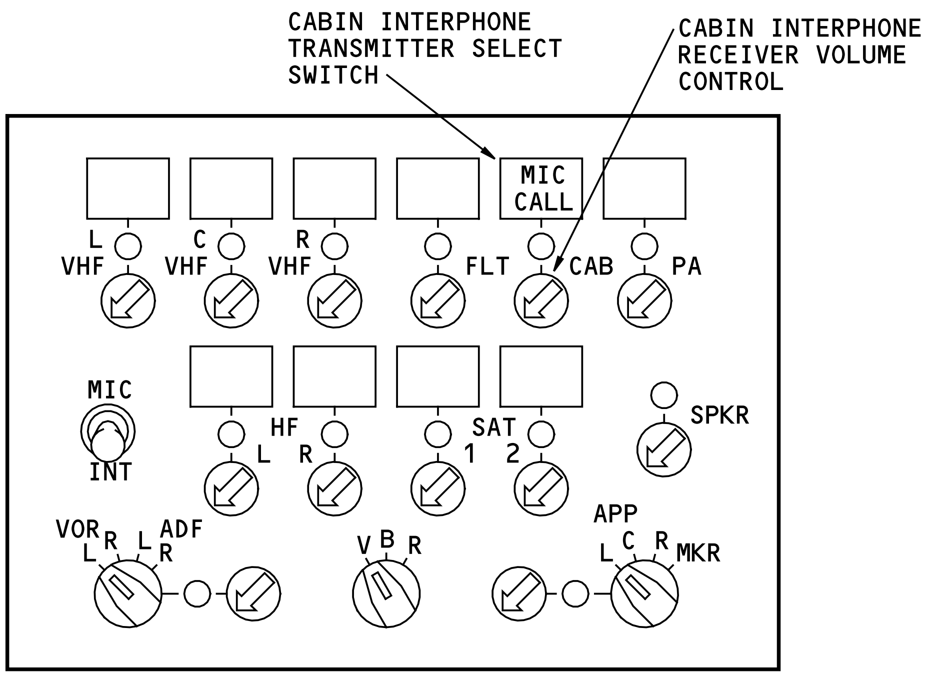
When a call comes to the flight deck, the ACP CALL light comes on. To answer the call, push the cabin interphone transmitter select switch. This also causes the CALL light to go off. The cabin interphone receiver volume control sets the volume.

To make a call, push the cabin interphone transmitter select switch. Then use the center CDU to select a dial code.

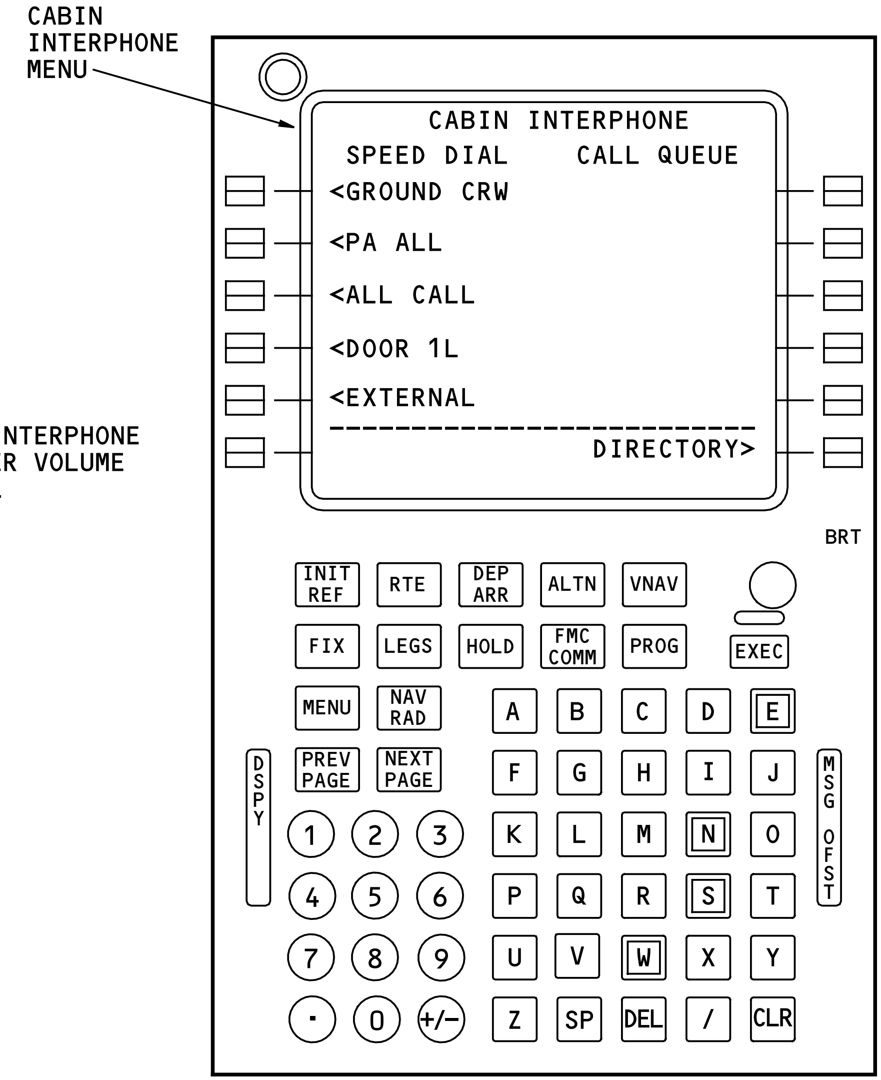
Push the cabin interphone transmitter select switch two times in one second to make a call to door 1 left.

Center Control Display Unit

Flight crew uses the center CDU to select dial codes. It also shows directories and incoming call data.



AUDIO CONTROL PANEL



CENTER CONTROL DISPLAY UNIT

CIS - FLIGHT DECK CONTROLS

23-42-00-021 Rev 2 03/18/96

CIS - CDU OPERATION - CABIN INTERPHONE MENU

General

The flight crew can use the center control display unit (CDU) to operate the CIS. The center CDU also shows CIS call data.

To show the cabin interphone menu, push the line select key (LSK) next to <CAB INT on the CDU menu.

The configuration database identifies all the selections on the cabin interphone CDU pages.

Cabin Interphone Menu

The cabin interphone menu has different selections. LSKs 1 left through 5 left are for speed dial selections. LSKs 1 right through 5 right are for stored messages. Use LSK 6 left to make a call. LSK 6 right selects the directory.

Speed Dial

The flight crew uses the speed dial selections to make a call. To make a call, push the LSK next to the call selection.

Send

The flight crew can make a call to any station from the cabin interphone menu. To call a station, push the station code numbers on CDU keys. The dial code and station shows in the scratch pad. <SEND shows next to LSK 6 left. Push LSK 6 left to make the call.

Call Queue

The call queue shows calls that came to the flight deck while the line was busy. The CDU shows the station that made the call. When the current call is over, the flight crew can call the station back. They push the LSK next to the stored message to make the call.

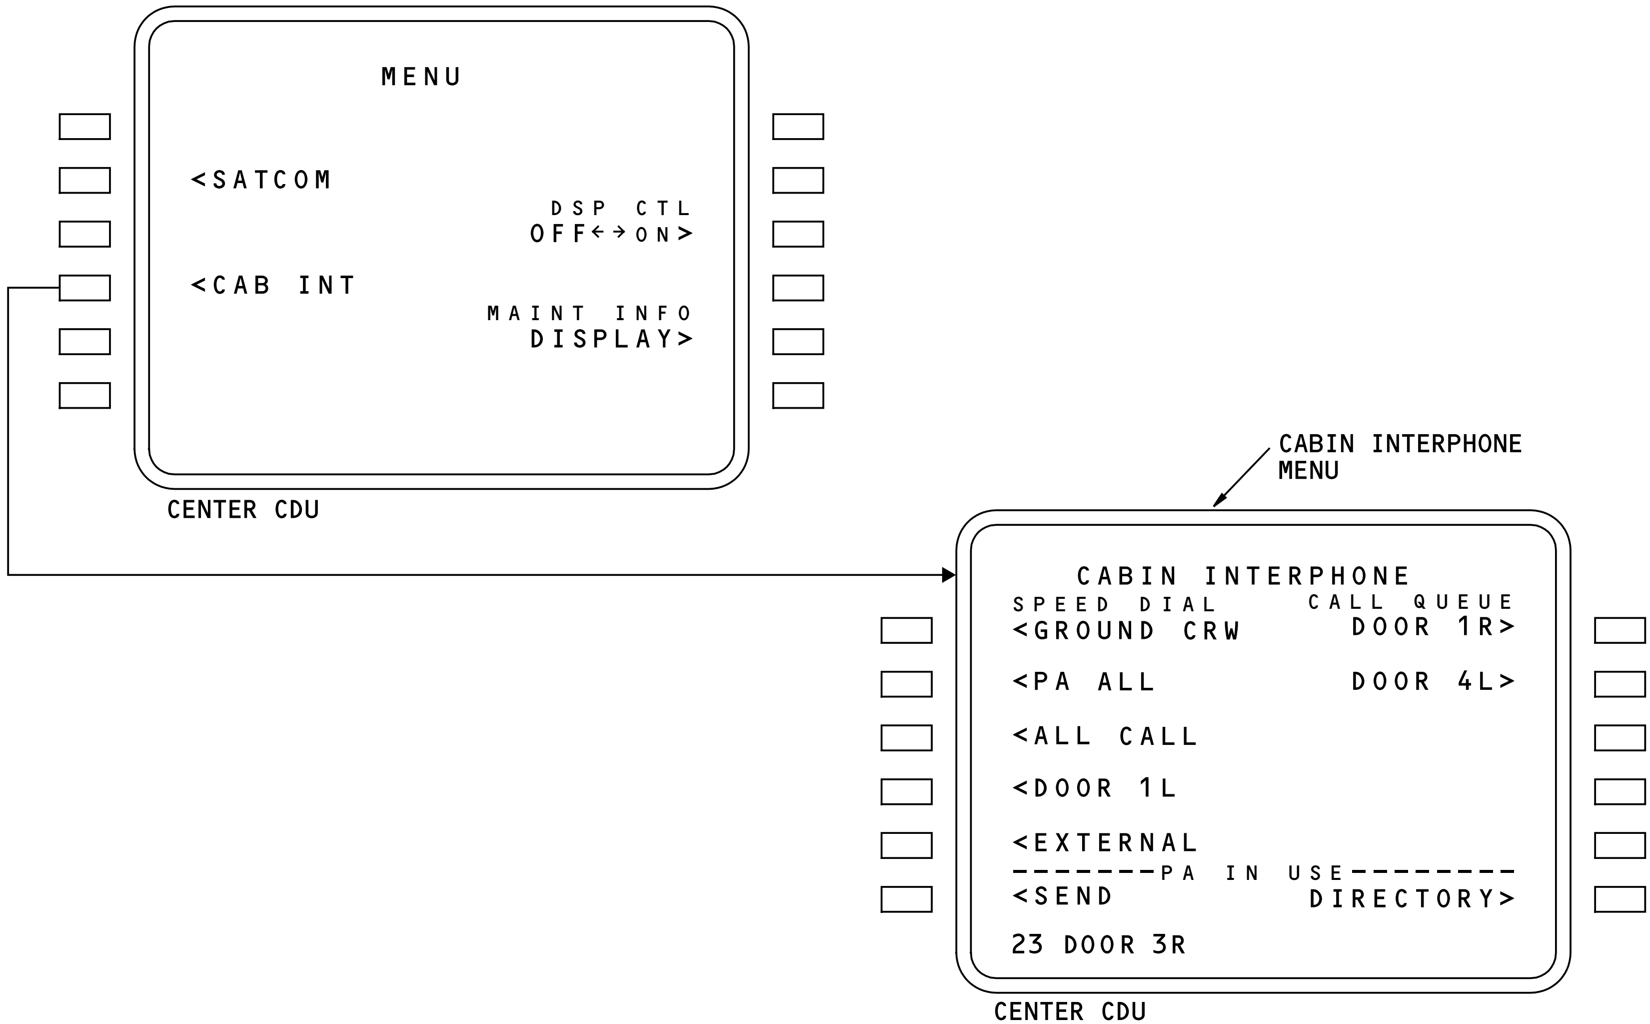
If more than one call goes to the flight deck while the line is busy, the CDU shows them in the call queue. The first message shows at LSK 1 right. The second message shows at LSK 2 right, and so on.

PA/Video In Use

The cabin interphone pages on the CDU show passenger address and video system activity. When the passenger address system is in use, PA IN USE shows above the scratch pad. When the video system is on, VIDEO IN USE shows above the scratch pad. When both the passenger address system and the video system are on, PA IN USE shows.

Directory

The directory pages give selections to call other stations. Push LSK 6 right to show the directory.



23-42-00-022 Rev 1 06/21/96

CIS - CDU OPERATION - CABIN INTERPHONE MENU

CIS - CDU OPERATION - MAIN DIRECTORY

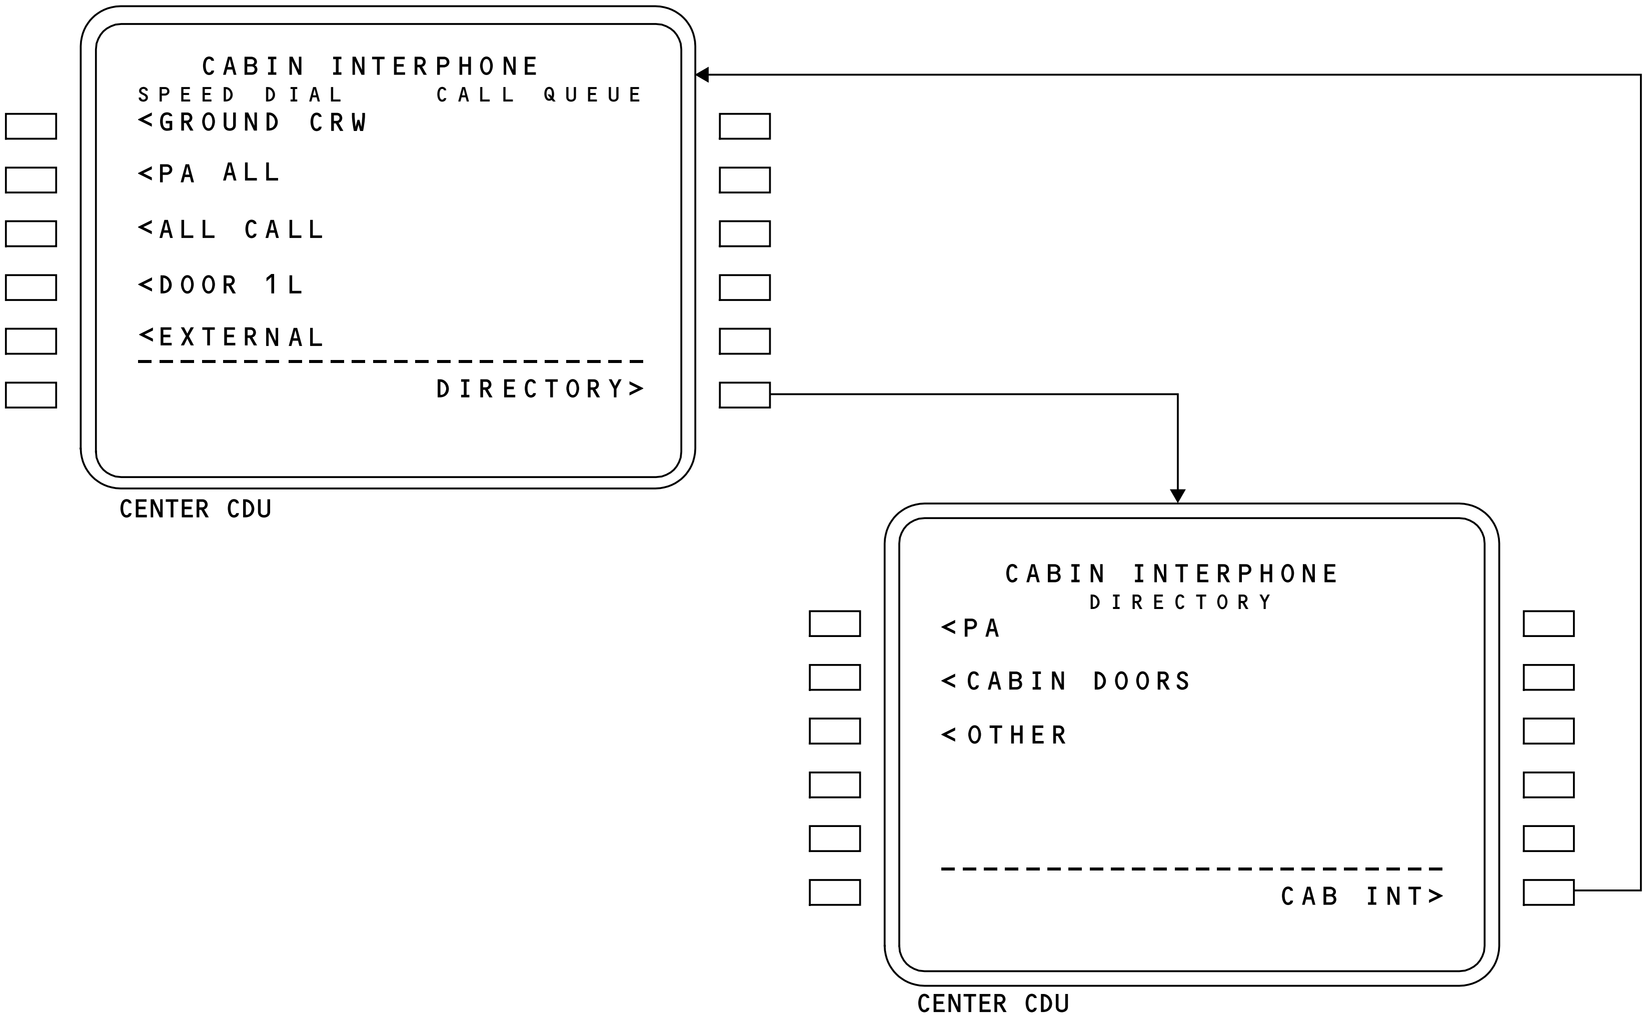
General

The flight crew uses the directory pages to make CIS calls. The main directory gives access to sub-directories.

Main Directory

To show the main directory, push line select key (LSK) 6 right on the cabin interphone menu. To show a sub-directory, push the LSK next to the applicable directory title.

To return to the cabin interphone menu, push LSK 6 right.



23-42-00-023 Rev 1 06/21/96

CIS - CDU OPERATION - MAIN DIRECTORY

CIS - CDU OPERATION - DOORS SUB-DIRECTORY

General

The flight crew uses the doors sub-directory to make station-to-station calls to handsets at the cabin doors.

Directory Access

To show the cabin doors sub-directory, push line select key (LSK) 2 left.

The other directories operate in the same way.

Push LSK 6 right to return to the cabin interphone menu.

23-42-00-024 Rev 2 07/08/1997

CIS - CDU OPERATION - DOORS SUB-DIRECTORY

CIS - CONFIGURATION DATABASE PROGRAMMED ITEMS

General

The CMS configuration database supplies details of CMS operation. For the CIS, the database gives configuration data for:

- Cabin attendant handsets (CAHs)
- Dial codes
- Conference calls
- Chimes
- Call lights
- CDU selections.

Cabin Attendant Handsets

The configuration database identifies the number of CAHs. It also supplies the location of each handset.

Dial Codes

The configuration database identifies the dial code for each station. It also identifies the dial code for conference calls and special function calls.

Conference Calls

The configuration database identifies the stations included in each conference call. A conference call has two or more stations on the same call. The call uses one dial code that can come from any station. The CIS can have as many as ten conference calls.

Chime Types and Count

The configuration database identifies the chime type and number of chimes for each type of call. When a station receives a call, it normally gets a single high-low chime. Special calls, such as an all call, may use different chimes. The station can get more than one chime. It can also get low-high chimes, instead of high-low chimes.

Call Lights

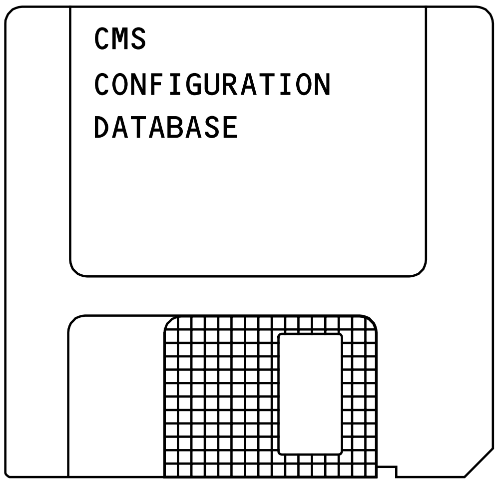
The configuration database identifies the flashing or non-flashing condition of call lights for each type of call. When a station receives a call, it normally gets a non-flashing call light. Special calls, such as an all call, may use a flashing call light.

CDU Selections

The configuration database identifies the selections available on the center control display unit (CDU). It identifies the calls that have a speed dial on the cabin interphone menu. It also supplies the selections on the directory page and sub-directory pages.

Priority Line Connection

When the flight crew pushes the CAB button twice on their audio control panel, they make a call to the priority station. The configuration database identifies where the call goes.



- NUMBER AND LOCATION OF CAH(S)
- DIAL CODES
- CONFERENCE CALLS
- CHIME TYPES AND COUNT
- FLASHING OR NON-FLASHING CALL LIGHTS
- CDU SELECTIONS
- PRIORITY LINE CONNECTION

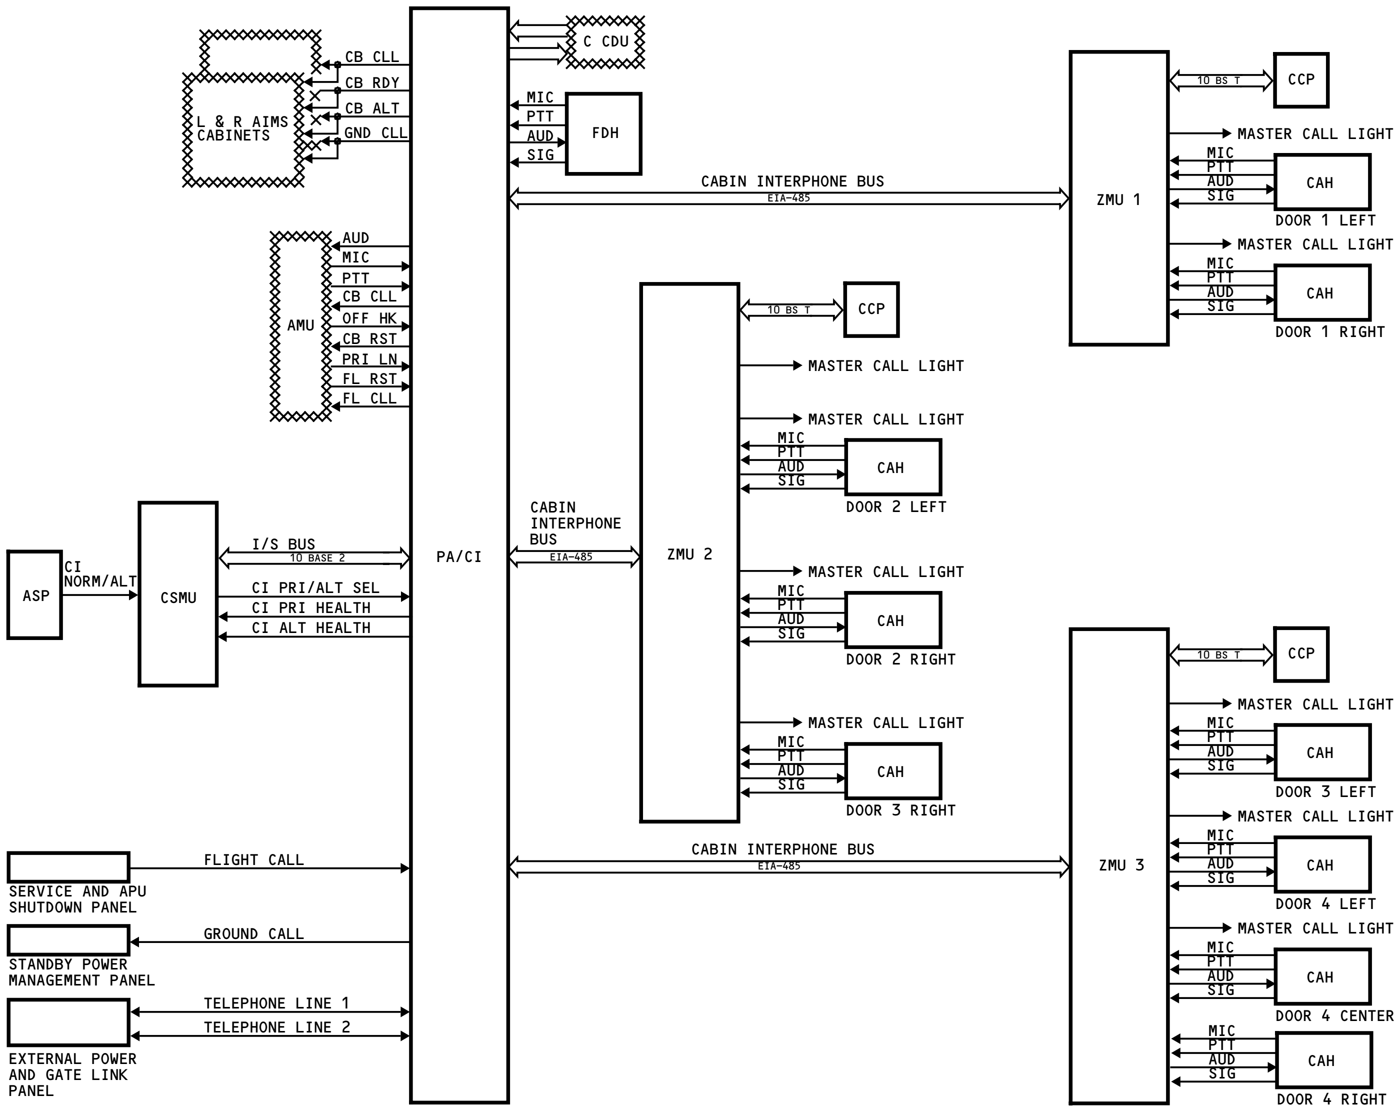
Interface Diagram

This interface diagram is for reference purposes.



CIS - INTERFACE DIAGRAM

CIS - CABIN TESTS

General

Use the cabin system control panel (CSCP) to do the cabin test for the cabin interphone system (CIS).

See the cabin services system (CSS) section for more information about tests (AMM PART I 23-39).

Quick Test

Use quick test to quickly find major faults. This test checks these CIS components:

- Passenger address/cabin interphone (PA/CI) controller
- Zone management units (ZMUs).

This test collects continuous monitor data for as long as 20 seconds. The CSCP shows the failures.

To start a quick test, touch START QUICK TEST.

All Test

Use all test for a more complete test. All test starts a complete BITE of the system. The screen shows all the failures the BITE finds.

To start an all test, touch START ALL TEST.

Engineering Tests

Use engineering tests for more detailed tests.

Touch ENGINEERING TESTS to show the engineering tests menu.

Lamps Test

The lamps test does not test the CIS.

PASSENGER ADDRESS SYSTEM - INTRODUCTION

Purpose

The passenger address system (PAS) lets the crew send announcements and other audio to the passenger cabin.

Announcement Types

The PAS sends these types of audio to the cabin:

- Flight crew announcements
- Flight attendant announcements
- Recorded announcements
- Video system audio
- Boarding music.

The PAS also makes chime sounds.

PASSENGER ADDRESS SYSTEM - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

PAS - GENERAL DESCRIPTION

General

The passenger address system (PAS) receives audio inputs and sends them to the passenger cabin. The cabin can have as many as six passenger address areas.

The PAS has interfaces with the in-flight entertainment (IFE) system on ARINC 628 head-end buses for PAS functions.

Components

The PAS uses these components:

- Passenger address/cabin interphone (PA/CI) controller
- Ambient noise sensors (ANSs)
- Speaker drive modules (SDMs)
- Zone management units (ZMUs)
- Cabin attendant handsets (CAHs)
- Cabin speakers.

These other components and systems connect to the PAS:

- Audio management unit (AMU)
- Left systems ARINC 629 bus
- In-flight entertainment (IFE) system
- Cabin system management unit (CSMU)
- Right systems ARINC 629 bus
- Attendant switch panel (ASP)
- Audio entertainment players (AEPs)
- Cabin control panels (CCPs).

Audio Inputs

All passenger address audio goes to the PA/CI controller.

The flight crew uses the flight interphone system to make announcements. The announcement audio goes from the AMU to the PA/CI controller.

The flight attendants use CAHs to make announcements.

Priorities

The PAS has these priorities:

- 1 - From flight interphone system
- 2A - Direct access
- 2B - From cabin interphone system
- 3A - Recorded announcements
- 3B - Video system audio
- 4 - Boarding music.

Audio Outputs

The PA/CI controller selects the audio with the highest priority and digitizes it. It sends the signal to the SDMs. The SDMs change the signal to analog and send it to one or two speakers.

The PA/CI controller also sends the announcement audio to the IFE system. This system then sends the audio over the passenger entertainment system so the passengers hear the announcement on their headphones.

PAS - GENERAL DESCRIPTION

The PAS also makes a chime sound for attendant calls and passenger information signs. The PA/CI controller sends chime signals to the SDMs.

Volume Control

The configuration database gives the normal volume level. The PAS makes automatic adjustments based on either cabin noise level inputs from the ANSs or flight data inputs. In addition, flight attendants use the CCPs to adjust the volume manually.

Pause Signals

When an announcement goes to all areas, the CSMU sends a pause signal to the IFE system.

Other Interfaces

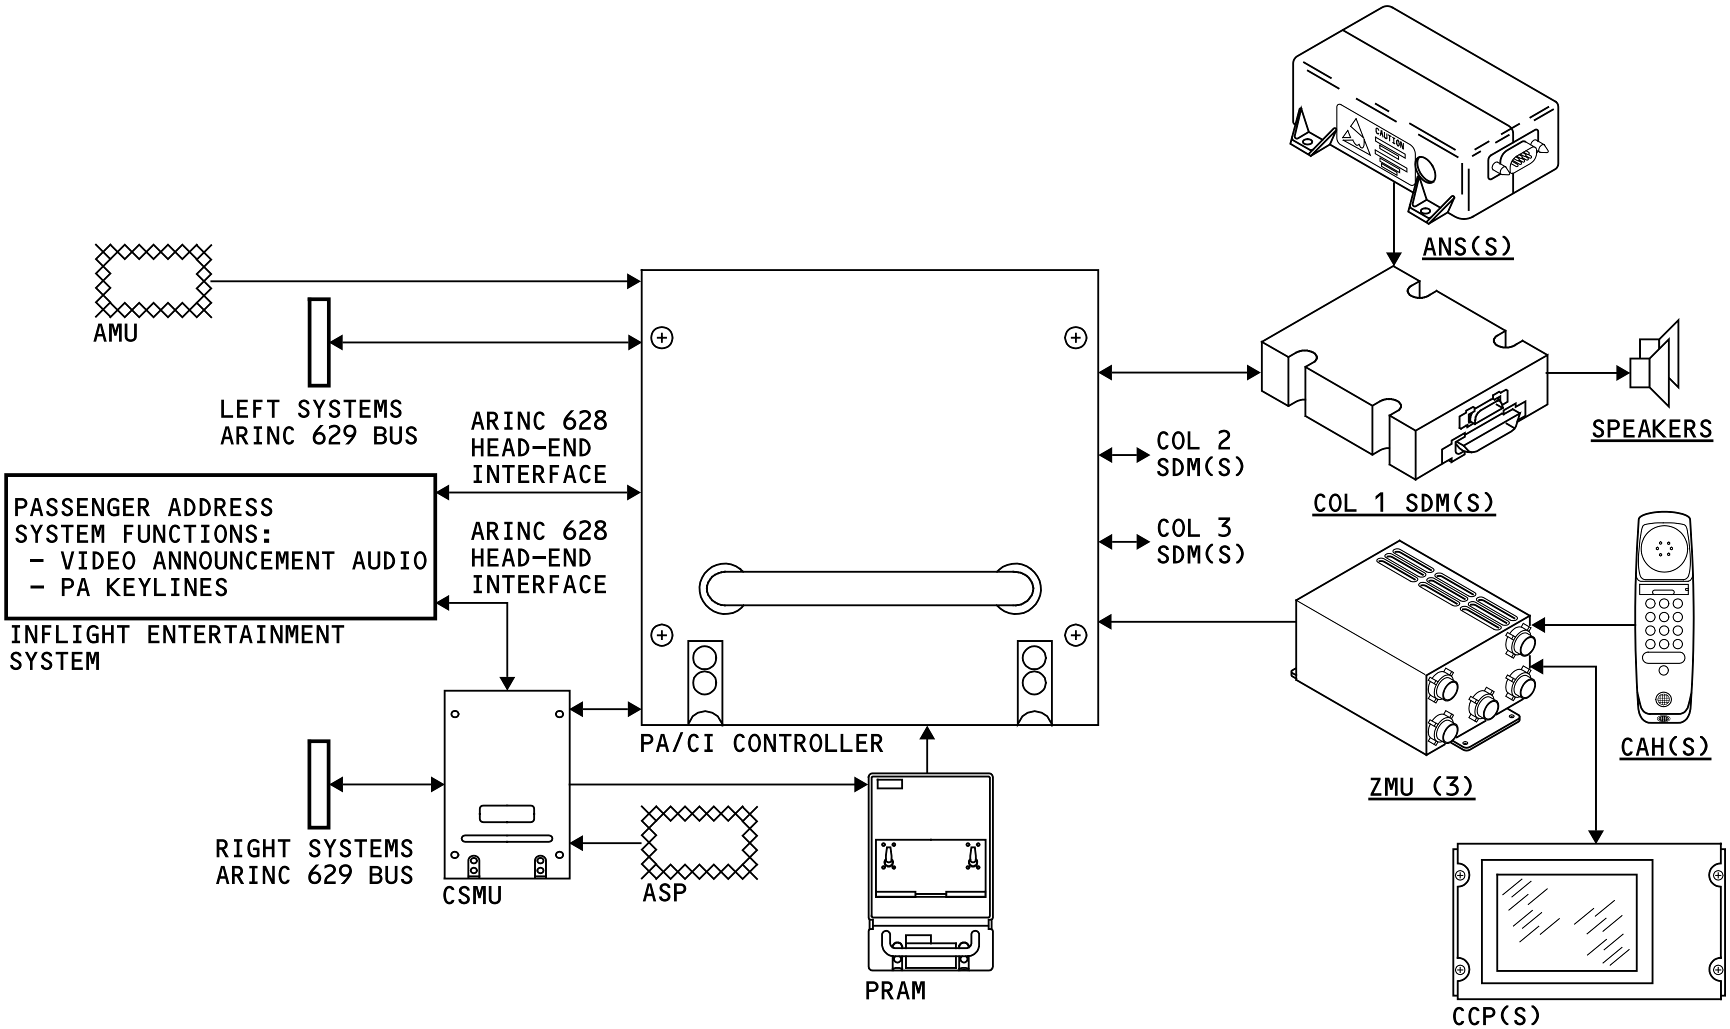
The PA/CI controller has an interface with the left systems ARINC 629 bus. It uses airplane system data to adjust volume and to control chime sounds.

You use the cabin control panels (CCPs) to control the PAS. A CCP operates as a cabin area control panel (CACP) or as a cabin system control panel (CSCP), depending upon it configuration.

The PA/CI controller has an alternate passenger address controller. If there is a failure on the normal passenger address controller, the flight attendants get a message on the cabin control panels (CCPs). The flight attendant pushes a button on the attendant switch panel (ASP) to select the alternate passenger address controller.

The CSMU sends the passenger address controller selection to the PA/CI controller. You use the CSCP to do tests and install software.

The CSMU connects to the IFE system with an ARINC 628 head-end interface. It sends airplane system data and cabin services system (CSS) configuration data to the IFE system.



PAS - GENERAL DESCRIPTION

PAS - COMPONENT LOCATIONS

PAS Components

These are the types of passenger address system (PAS) components in the cabin and crown:

- Speaker drive modules (SDMs)
- Speakers
- Ambient noise sensors (ANSs)
- PA NORM/ALT switch.

There are three columns of SDMs.

These PAS components are in the main equipment center:

- Passenger address/cabin interphone (PA/CI) controller
- Prerecorded announcement machine (PRAM).

Other Components

These are the other CSS components in the cabin:

- Cabin system control panel (CSCP)
- Cabin area control panels (CACPs).

You find the exact locations of the components with the wiring diagram and functional schematic.

PAS - POWER INTERFACES

General

Circuit breakers in two panels control power to the passenger address system.

Standby Power Management Panel

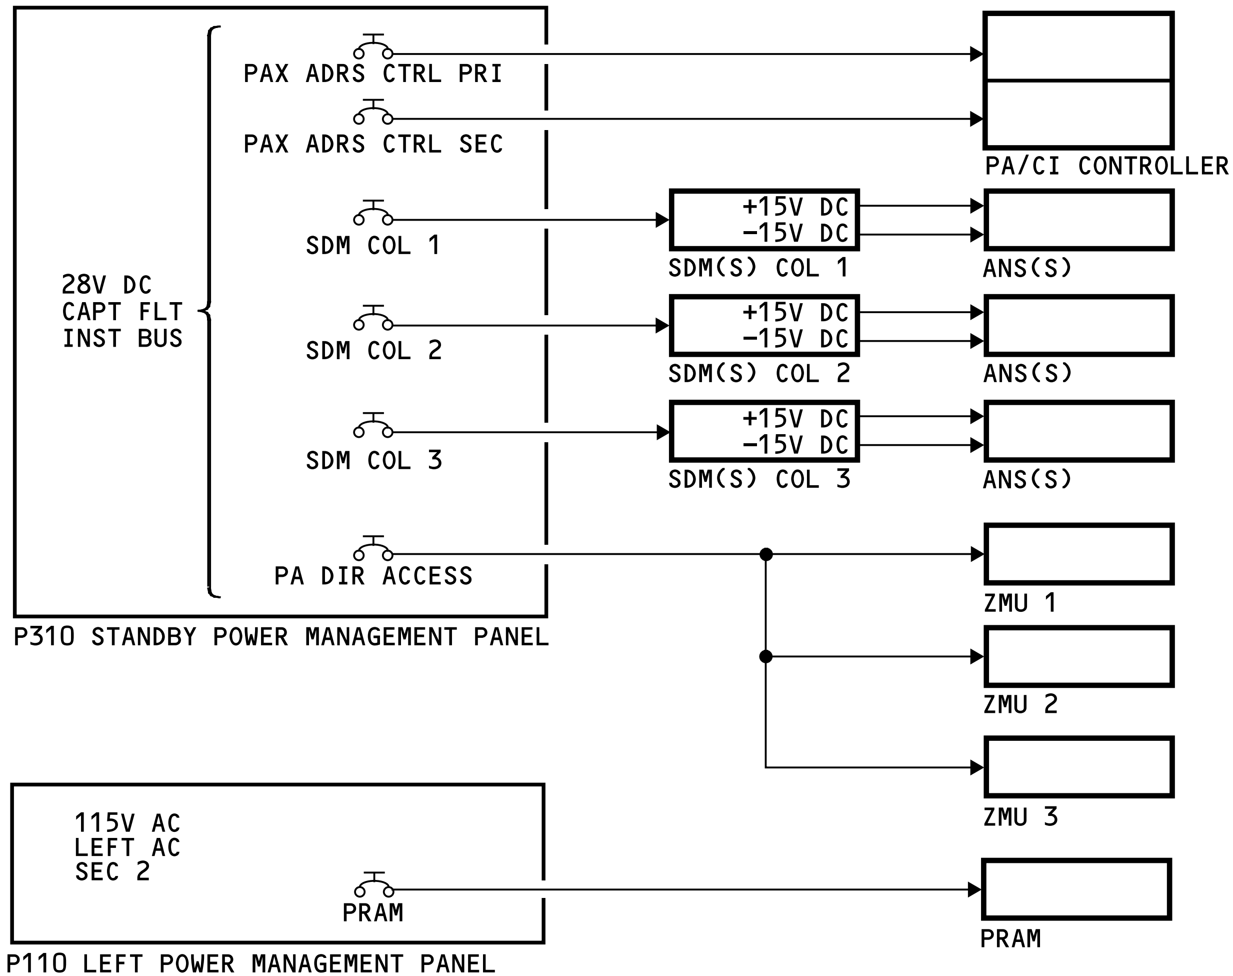
The passenger address/cabin interphone (PA/CI) controller uses two 28v dc inputs for the passenger address function. One input supplies power to the normal passenger address controller. The other supplies power to the alternate passenger address controller.

There is a circuit breaker for each column of speaker drive modules (SDMs). The ambient noise sensors (ANSs) get a positive 15v and a negative 15v from the connected SDM.

The zone management units (ZMUs) get 28v dc for the circuitry that does the direct access function.

Left Power Management Panel

The prerecorded announcement machine (PRAM) uses 115v ac.



23-31-00-004 Rev 10 07/02/1997

PAS - POWER INTERFACES

PAS - PRIORITY 1, 2A, AND 2B INTERFACES

General

The passenger address system accepts and sends announcements at these levels of priority:

- Flight interphone (priority 1)
- Direct access (priority 2A)
- Cabin interphone (priority 2B)
- Recorded announcements (priority 3A)
- Video system audio (priority 3B)
- Boarding music (priority 4).

Announcements from the flight crew and attendants have the three highest priority levels.

Priority 1 - Flight Interphone

The flight crew normally uses the flight interphone system to make passenger address announcements. The audio management unit (AMU) sends microphone audio and PTT to the passenger address/cabin interphone (PA/CI) controller. The PA/CI controller sends sidetone back to the AMU.

Priority 2A - Direct Access

Flight attendants normally use the cabin interphone system (CIS) to make PA announcements.

The direct access function lets attendant announcements go around the CIS circuits and connect directly to the PAS. They use direct access if there is a failure of the CIS.

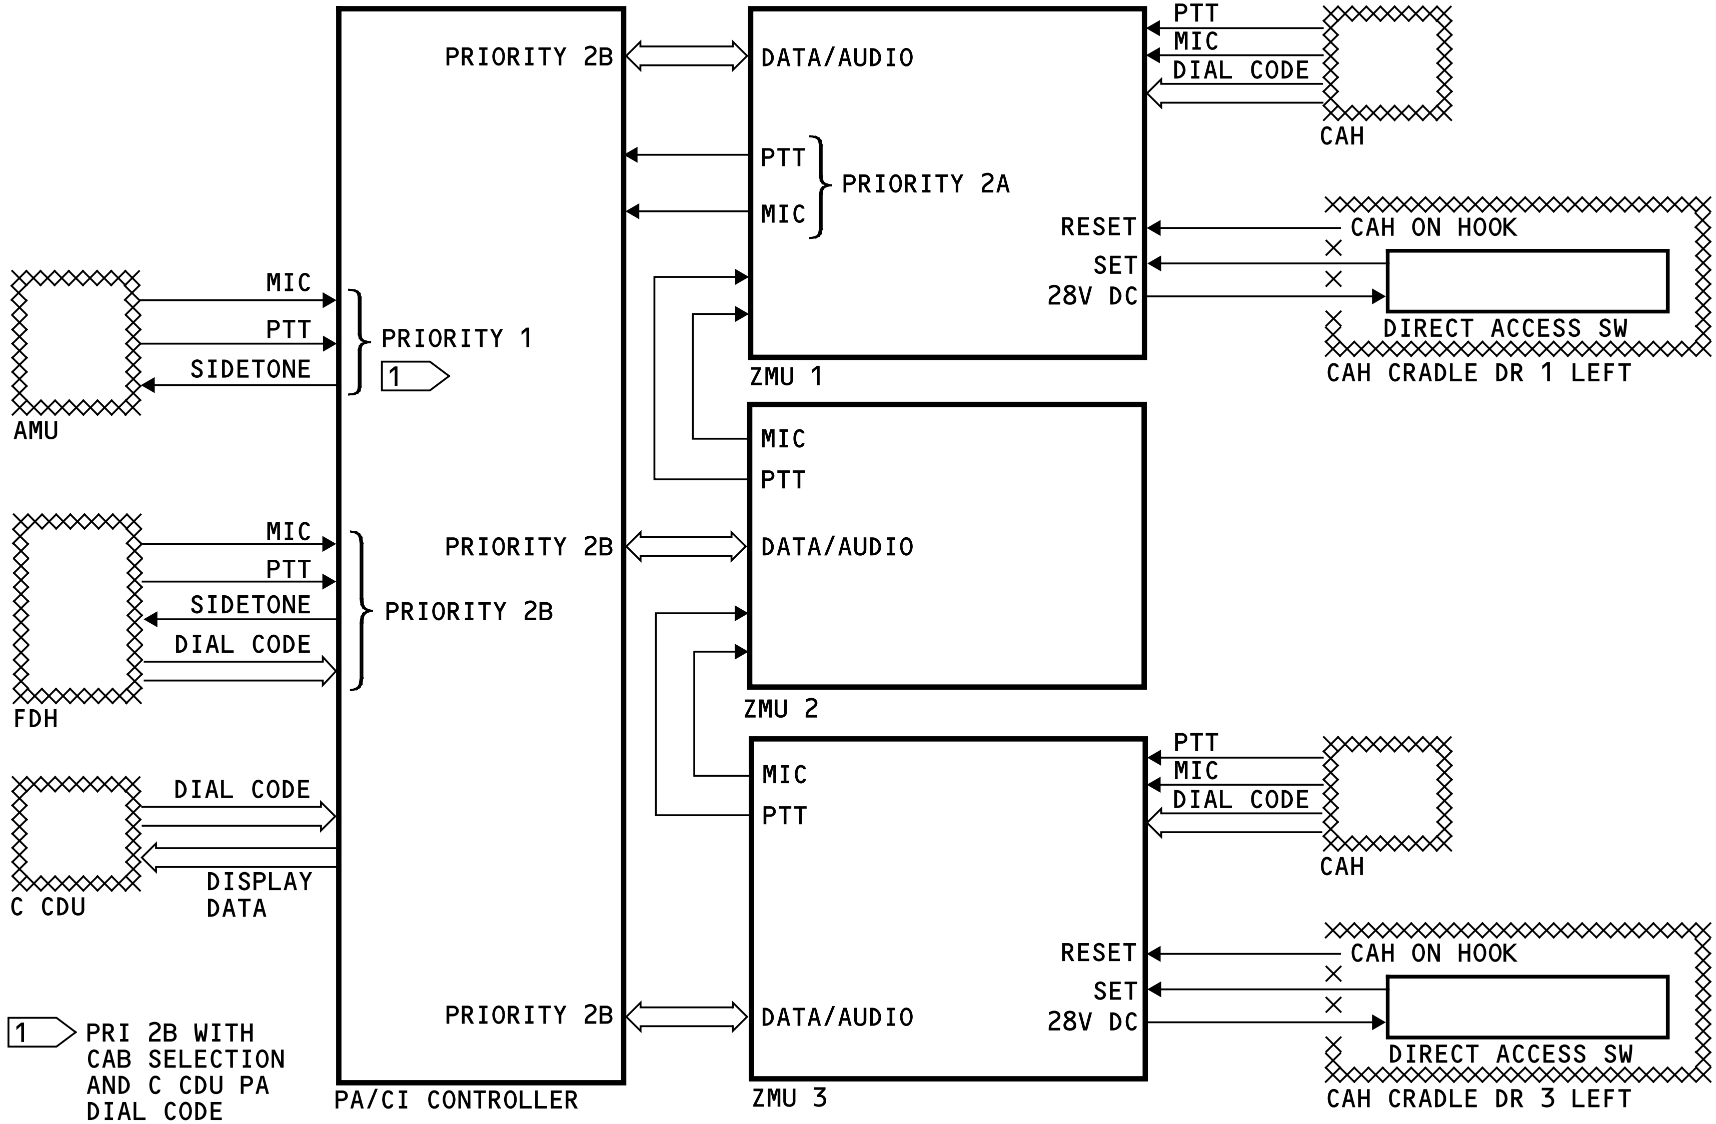
Only two of the cabin attendant handsets (CAHs) have the direct access function. They are at door 1 left and door 3 left.

To make a direct access announcement, you push a direct access switch on the cabin attendant handset (CAH) cradle. This energizes a relay in the ZMU and sends the audio past the CIS circuits to the PA/CI controller.

Priority 2B - Cabin Interphone

Flight attendants normally use the CIS to make passenger address (PA) announcements. They use any CAH to make an announcement and select a PA area. The attendant dials a PA code. This connects the mic and PTT to the CIS circuits in the zone management unit (ZMU).

The flight crew also uses the cabin interphone system to make announcements in a selected area. To do this, the flight crew uses either the flight deck handset (FDH) or the flight interphone system. To use the flight interphone system, they dial the area on the center control display unit (CDU).



PAS - PRIORITY 1, 2A, AND 2B INTERFACES

PAS - PRIORITY 3 AND 4 INTERFACES

General

These three lower priorities are for recorded announcements, video audio and boarding music.

Priority 3A - Recorded Announcements

The prerecorded announcement machine (PRAM) sends recorded announcements to the PA/CI controller. It also sends a keyline signal when a recorded announcement is in progress.

If cabin decompression occurs, the PA/CI controller sends a signal to the PRAM. This causes the PRAM to play an emergency announcement.

During a priority 1, 2A, or 2B announcement to all areas, the PA/CI controller sends a pause signal to stop the recorded announcement.

Priority 3B - Video Audio

The IFE system sends video audio to the PA/CI controller. The IFE system has a separate audio output and separate keyline for each video area. Attendants use the IFE system to select the video.

The cabin system management unit (CSMU) sends cabin services system (CSS) configuration data to the IFE system. This data includes video audio areas definition.

Priority 4 - Boarding Music

The PRAM also supplies boarding music. It sends boarding music and its keyline to the PA/CI controller. The CSCP permits selection of boarding music.

Chimes

The PAS makes chimes for these functions:

- Passenger to attendant calls
- Cabin interphone calls
- Passenger information signs.

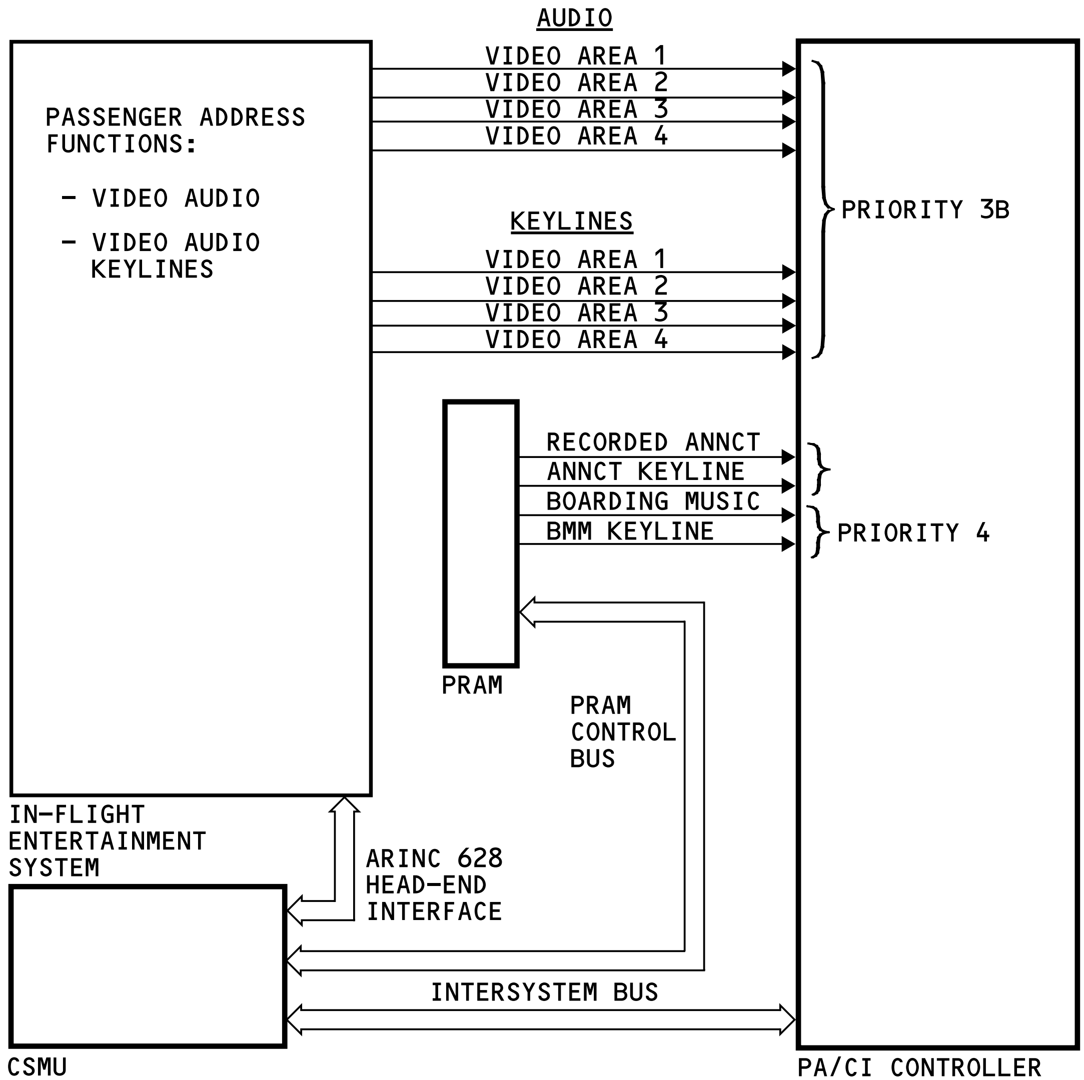
The PA/CI controller gets chime data for passenger to attendant calls from the ZMUs on the intersystem bus.

The passenger address function of the PA/CI controller gets cabin interphone call chime data from the cabin interphone function of the PA/CI controller.

The passenger information sign chime data comes from different airplane systems.

Pause Signals

During all area announcements, the PA/CI controller sends a PA-all keyline to the IFE system. This system pauses the entertainment equipment for priority 1, 2A, and 2B all area announcements.



PAS - PRIORITY 3 AND 4 INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

PAS - OUTPUT INTERFACES

General

The passenger address/cabin interphone (PA/CI) controller gets all audio inputs. It selects the input with the highest priority and sends it to speaker drive modules (SDMs) and to the in-flight entertainment (IFE) system.

Speaker Drive Modules

There are three columns of SDMs in the cabin, one column for each zone. There can be as many as 25 SDMs in each column. Usually, each column has ten to thirteen SDMs.

The PA/CI controller selects the audio with the highest priority. The controller digitizes the audio and sends it to the SDMs.

The speaker drive module changes digital audio to analog audio. The PAS can have up to six passenger address (PA) areas. The SDM changes the audio for each speaker assigned to an area. Each SDM controls one or two speakers.

When the LLAR is not installed, the S23093 (PA) switch in the P325 LLAR umbilical panel terminates the audio and data buses.

The PAS uses the token signal for software installation.

Ambient Noise Sensor

The ambient noise sensors (ANSs) monitor cabin noise levels. They send a signal in proportion to the measured noise level to a nearby SDM. The SDMs send the data to the PA/CI controller. The PA/CI controller uses the data to set volume levels.

There are three to five ANSs in each column.

In-flight Entertainment System

The in-flight entertainment (IFE) system sends passenger entertainment audio to the cabin. When a PA all area announcement occurs, the PA/CI controller sends the PA audio to the IFE system. The passengers hear the announcement in their headphones.

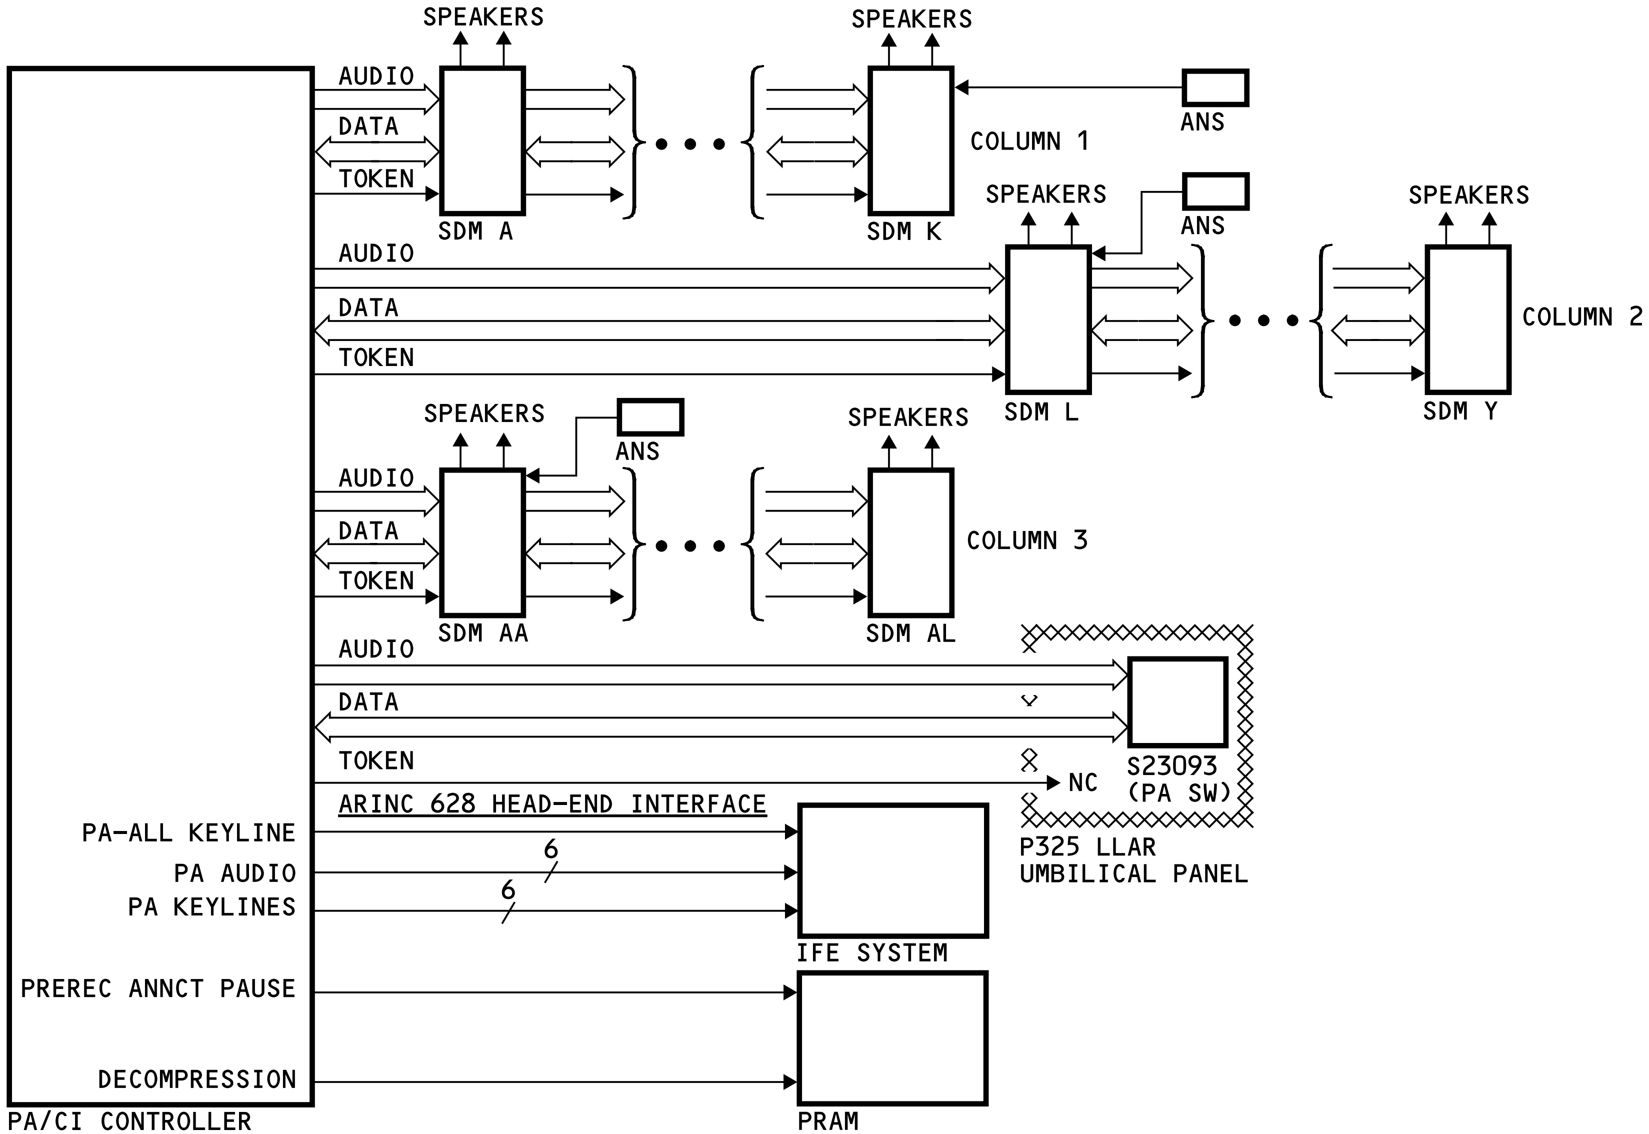
The PA/CI controller has seven keylines to the IFE system, one for each PA area and one for a PA-all area announcement.

Pause Signals

During all area announcements, the PA/CI controller sends a pause signal to the prerecorded announcement machine (PRAM).

Cabin Decompression

For a cabin decompression, the PA/CI controller sends a decompression signal to the prerecorded announcement machine (PRAM). The PRAM starts an emergency announcement and sends it to the PA/CI controller.



PAS - OUTPUT INTERFACES

23-31-00-007 Rev 14 09/16/1997

PAS - AIRPLANE SYSTEMS AND CSMU INTERFACES

General

The passenger address/cabin interphone (PA/CI) controller has interfaces with different airplane systems and with the cabin system management unit (CSMU).

Airplane Systems

The PA function of the PA/CI controller receives inputs from these airplane systems on the left systems ARINC 629 bus:

- ARINC signal gateway (ASG) card
- Proximity sensor electronics unit (PSEU)
- Overhead panel ARINC 629 system (OPAS)
- Flap/slat electronics unit (FSEU)
- Warning electronic system (WES)
- Airplane information management system (AIMS)
- Electrical load management system (ELMS).

The PA/CI controller uses these inputs to make chimes when the FASTEN SEAT BELTS and NO SMOKING signs go on or off. The PA/CI controller also uses airplane system data to adjust volume levels. The PA/CI controller uses flight data to set volume levels.

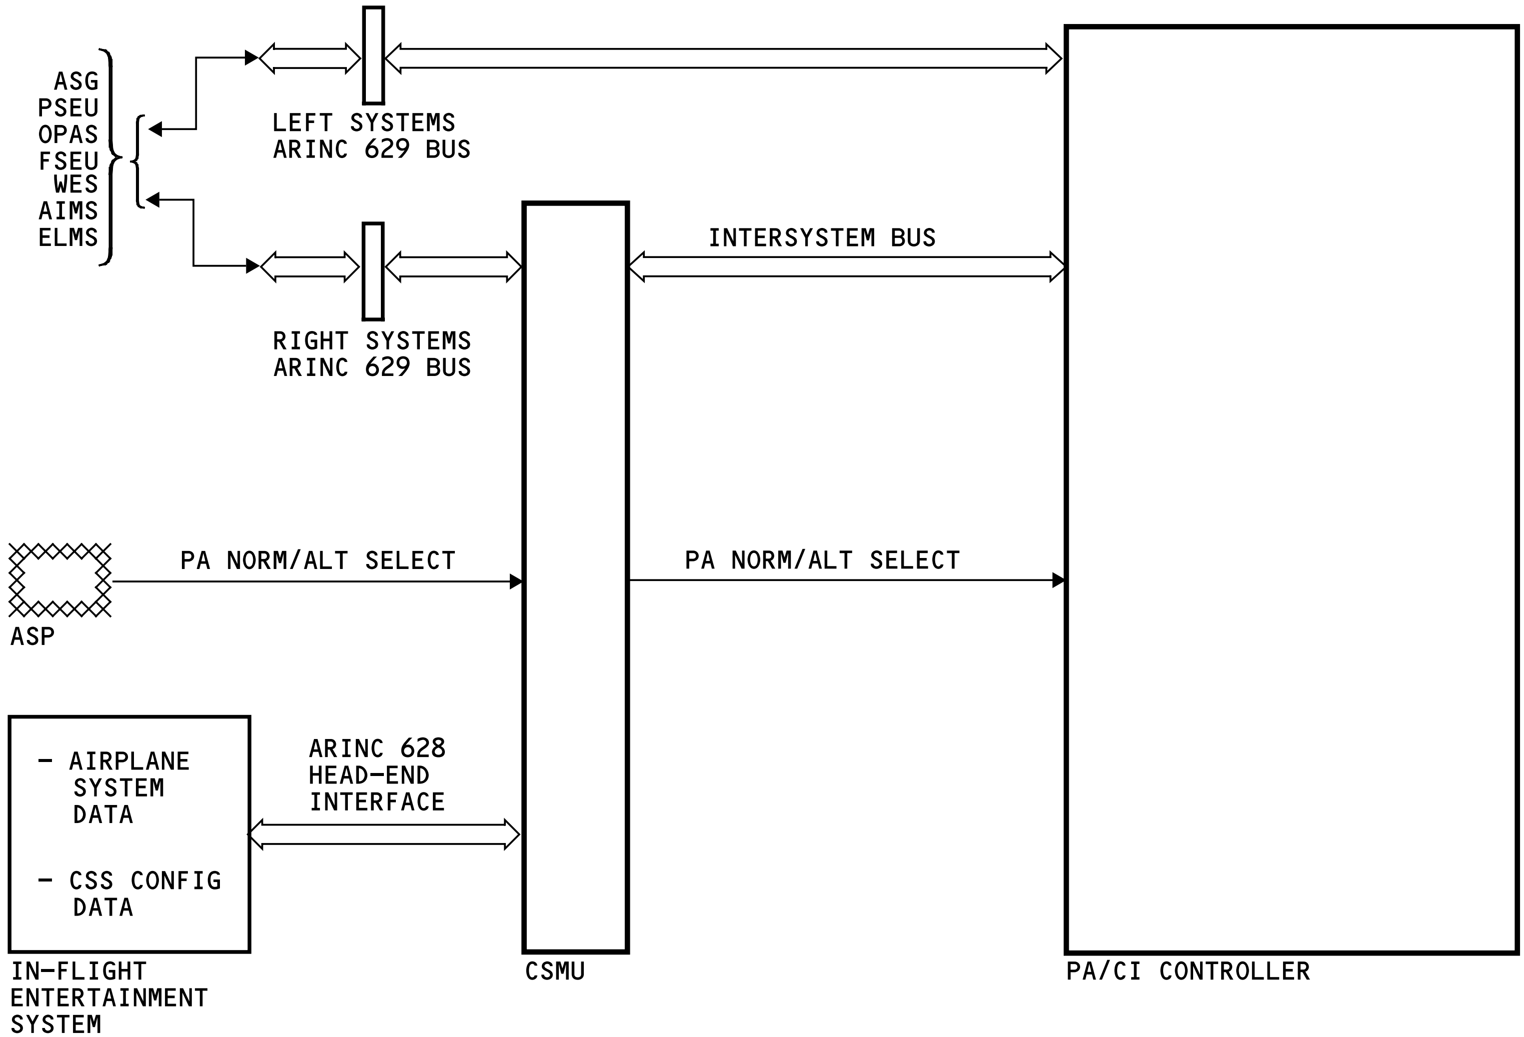
CSMU

There are two passenger address controllers in the PA/CI controller. They are normal and alternate. Only one controller operates at a time. If the normal controller fails, the crew selects the alternate controller at the attendant switch panel (ASP). The ASP sends a discrete to the cabin system management unit (CSMU). The CSMU sends a discrete to the PA/CI controller. The PA/CI controller then changes to the alternate PA controller.

The PA/CI controller also sends and receives data on the intersystem bus. The CSMU sends software installation data and test commands on the intersystem bus. The PA/CI controller sends fault status and test results to the CSMU on the intersystem bus.

The CSMU receives the same inputs from airplane systems on the right system ARINC 629 bus as the PA/CI controller does on the left systems ARINC 629 bus. If the left systems ARINC 629 bus fails, the PA function of the PA/CI controller gets right systems ARINC 629 bus information from the CSMU on the intersystem bus.

The CSMU sends airplane system data and cabin services system (CSS) configuration data to the in-flight entertainment (IFE) system.



23-31-00-008 Rev 10 10/31/1997

PAS - AIRPLANE SYSTEMS AND CSMU INTERFACES

PAS - PRERECORDED ANNOUNCEMENT MACHINE CONTROL PANEL

Purpose

The prerecorded announcement machine control panel (PRAM/CP)sends boarding music and announcment requests to the prerecorded announcment machine (PRAM).

General

The PRAM/CP controls the selection of emergency announcments and as many as 14 more announcements such as seat belt sign on/off and no smoking sign on/off announcements. The PRAM/CP also controls the boarding music in the PRAM.

Boarding music

To play boarding music, push the music on/off switch. When the music is on, volume 3 shows.

Music select

To select a boarding music channel, push the music select switch. The display shows the sequence of channels from the lowest to highest.

Music volume

Push the UP or the DOWN volume key to change the boarding music volume. Each time you push the UP or DOWN key it will increase or decrease the music volume. The volume range is 21db in five steps.

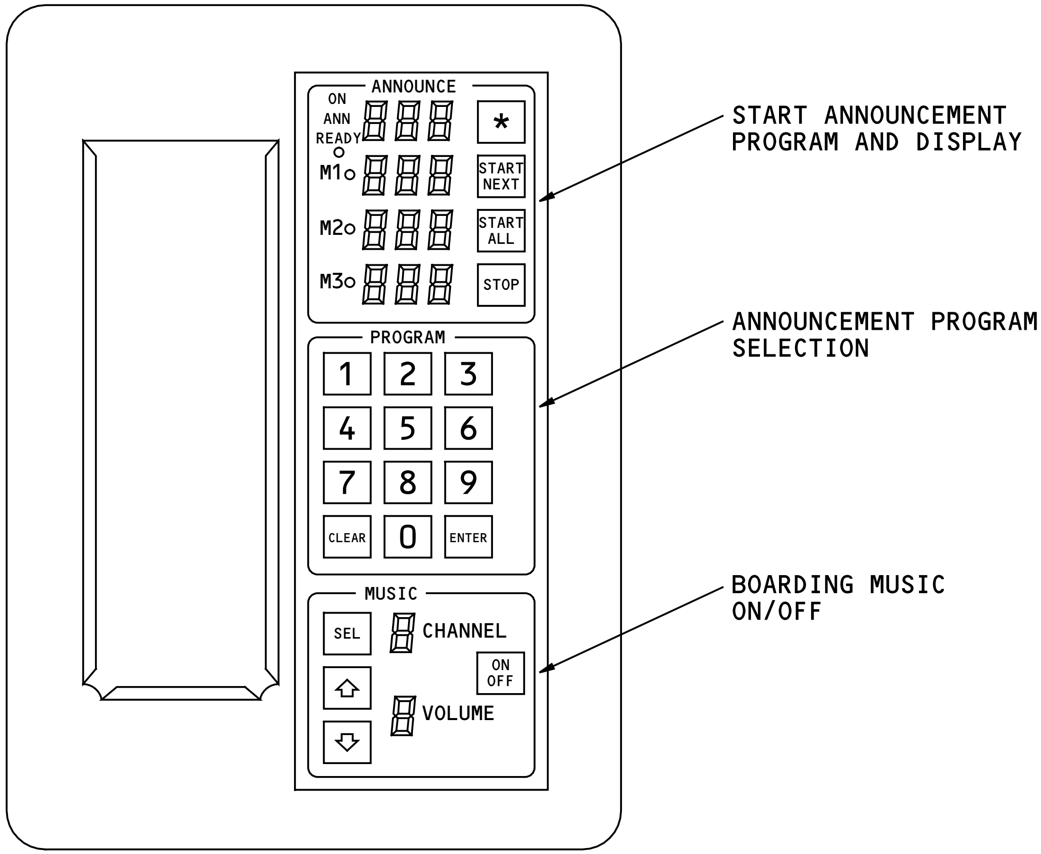
Recorded announcements

You use the PRAM/CP to program the PRAM to play the announcments that you want.

Controls

These are the announcement controls on the PRAM control panel:

- The ENTER pushbutton to enter programming data and to step the cursor to the next memory.
- The CLEAR pushbutton erases all data in the current memory.
- The START NEXT pushbutton (when the ready light is on) sends one play command to the A/R and updates the display.
- The START ALL pushbutton (when the ready light is on) sends sequential play commands to the A/R and updates the display.
- The STOP pushbutton interrupts the START ALL commands.



23-31-00-031 Rev 0 10/11/1997

PAS - PRERECORDED ANNOUNCEMENT MACHINE CONTROL PANEL

PAS - SPEAKER DRIVE MODULE

Purpose

The speaker drive modules (SDMs) send passenger address (PA) audio to the PA speakers. They also send inputs from ambient noise sensors (ANSs) to the PA/CI controller.

Physical Description

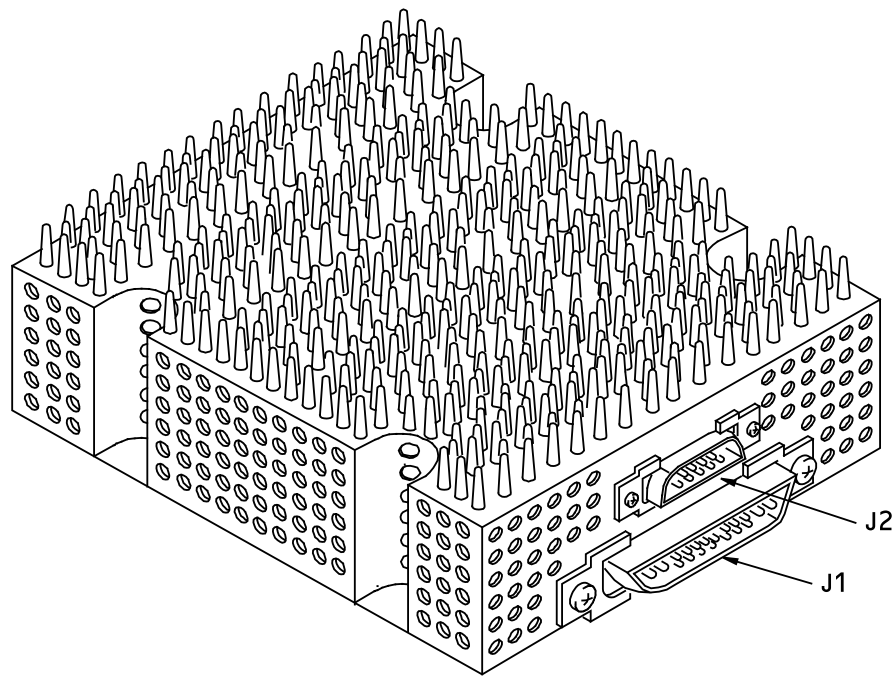
An SDM is about six inches wide and seven inches long. It weighs about one and a half pounds.

Functional Description

The SDMs get digital audio from the PA/CI controller and change it to analog audio. Each SDM can control as many as two speakers independently.

The SDMs also have a chime generator to make chime sounds.

Some SDMs connect to an ANS. The SDM supplies power to the ANS. The ANS sends a signal proportional to the cabin noise level. The SDM digitizes the signal and sends it to the PA/CI controller.



23-31-00-009 Rev 0

PAS - SPEAKER DRIVE MODULE

PAS - AMBIENT NOISE SENSOR

Purpose

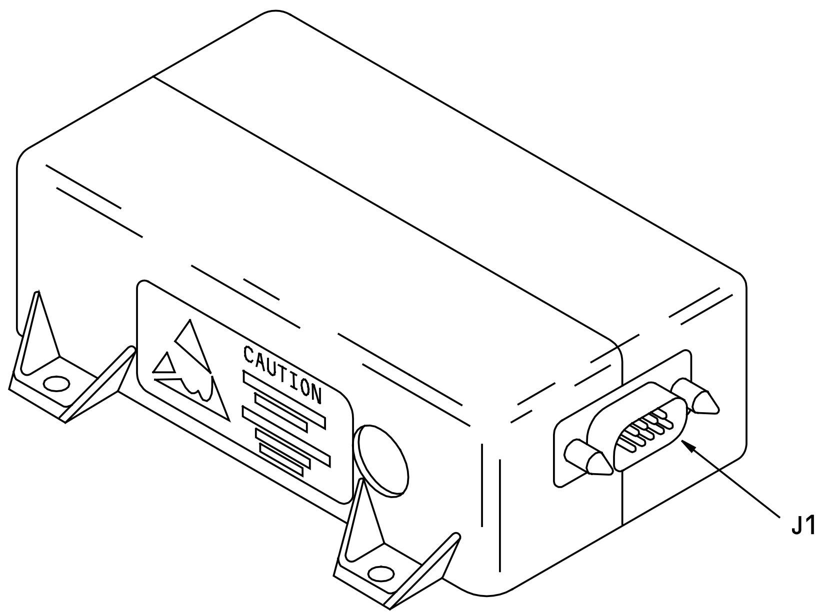
The ambient noise sensors (ANSs) measure cabin noise levels. The passenger address system uses ANS data to automatically adjust the PA volume.

Physical Description

The ANS is about four inches wide and five inches long. It weighs about 1/3 pound.

Functional Description

The ANS has a microphone that monitors cabin sounds. It makes a dc signal in proportion to the cabin noise level. The ANS sends the signal to the nearest speaker drive module.



PAS - AMBIENT NOISE SENSOR

PAS - SPEAKERS

Purpose

The speakers produce the passenger address audio in the passenger cabin.

Locations

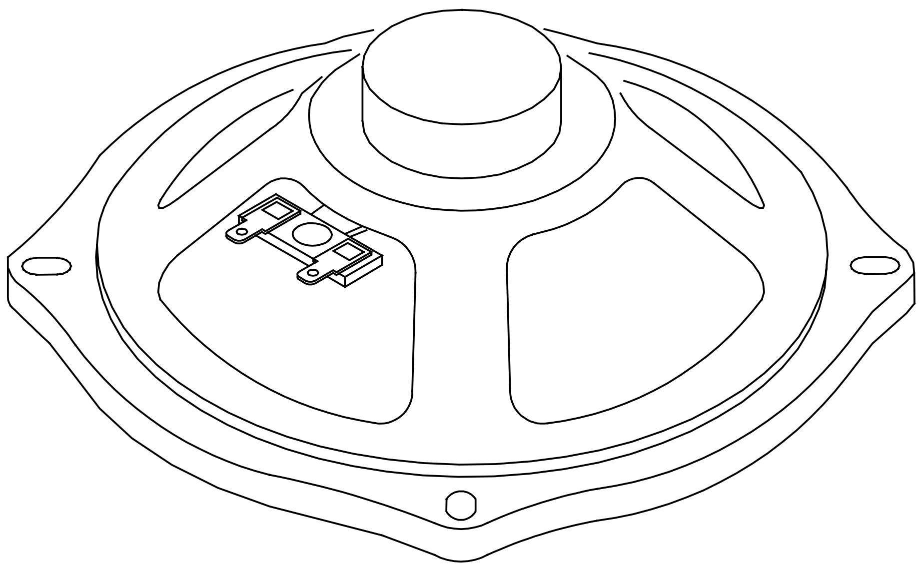
Most speakers are in the ceiling panels over the passenger seats and aisles. There are also speakers in the galleys, above the doors, and in each lavatory.

Functional Description

The speakers get audio signals from the speaker drive modules (SDMs). They change the electrical signal into an acoustic signal.

Training Information Point

A dot on one speaker terminal identifies it as positive. Connect the red lead to the positive terminal.



CABIN SPEAKER

23-31-00-011 Rev 1

PAS - SDM, ANS, AND SPEAKER INSTALLATION

SDM Installation

The speaker drive modules (SDMs) are above the cabin ceiling panels on the left side of the stow bin support assembly. Four screws attach the SDM to the support assembly.

Training Information Point

You must remove ceiling panels to get access to a SDM.

ANS Installation

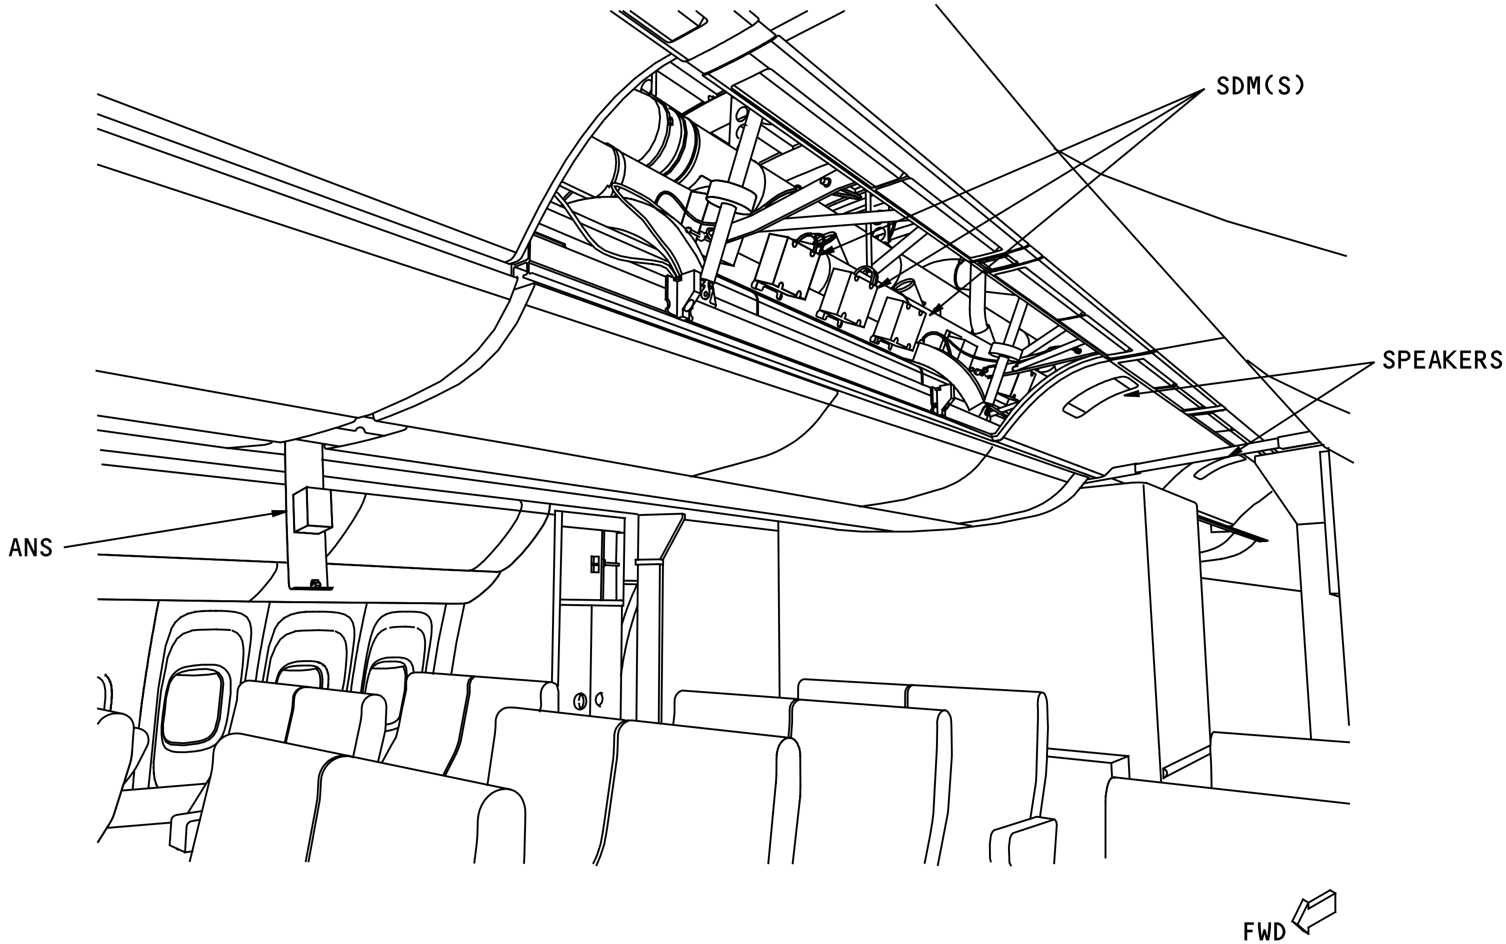
There are twelve ambient noise sensors. They are in the center passenger service unit rail.

Training Information Point

You must lower a passenger service unit panel to get access to an ANS.

Speakers

Most speakers are in the overhead panels. There are also speakers in the galleys and lavatories.



PAS - SDM, ANS, AND SPEAKER INSTALLATION

PAS - FLIGHT INTERPHONE ANNOUNCEMENT - OPERATION

General

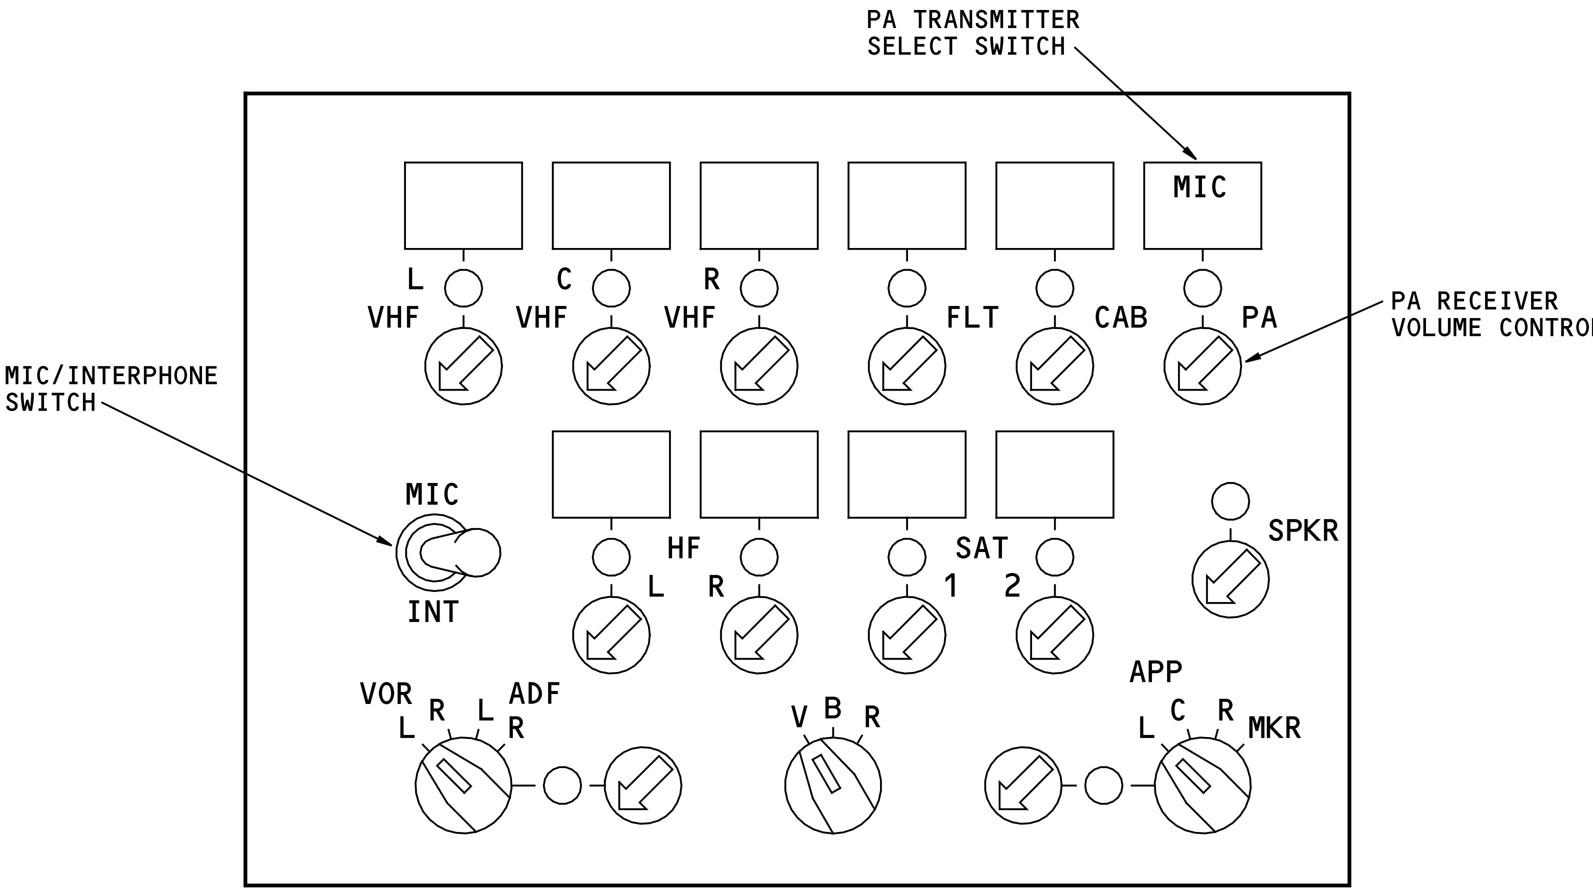
The audio control panel (ACP) lets the flight crew make priority 1 announcements.

Control and Indications

Push the PA receiver switch to listen to PA audio. The green PA receiver light above the receiver volume control comes on when the PA receive is on.

Push the PA transmitter select switch to make a priority 1 announcement. The white MIC light comes on. Push the MIC/interphone switch to connect the microphone to the PA/CI controller.

Priority 1 announcements go to all passenger address areas.



AUDIO CONTROL PANEL

23-31-00-013 Rev 1 08/08/96

PAS - FLIGHT INTERPHONE ANNOUNCEMENT - OPERATION

PAS - DIRECT ACCESS FUNCTIONAL DESCRIPTION

General

Flight attendants normally make PA announcements through the cabin interphone system (CIS) (priority 2B). If the CIS has a failure, attendants can make direct access announcements (priority 2A). Direct access announcements go around the CIS.

CIS Announcements

When an attendant selects a passenger address dial code, the CIS circuits in the zone management unit (ZMU) send digital audio to the PA/CI controller. The cabin interphone controller (CIC) sends the audio to the passenger address controller (PAC) in the PA/CI controller.

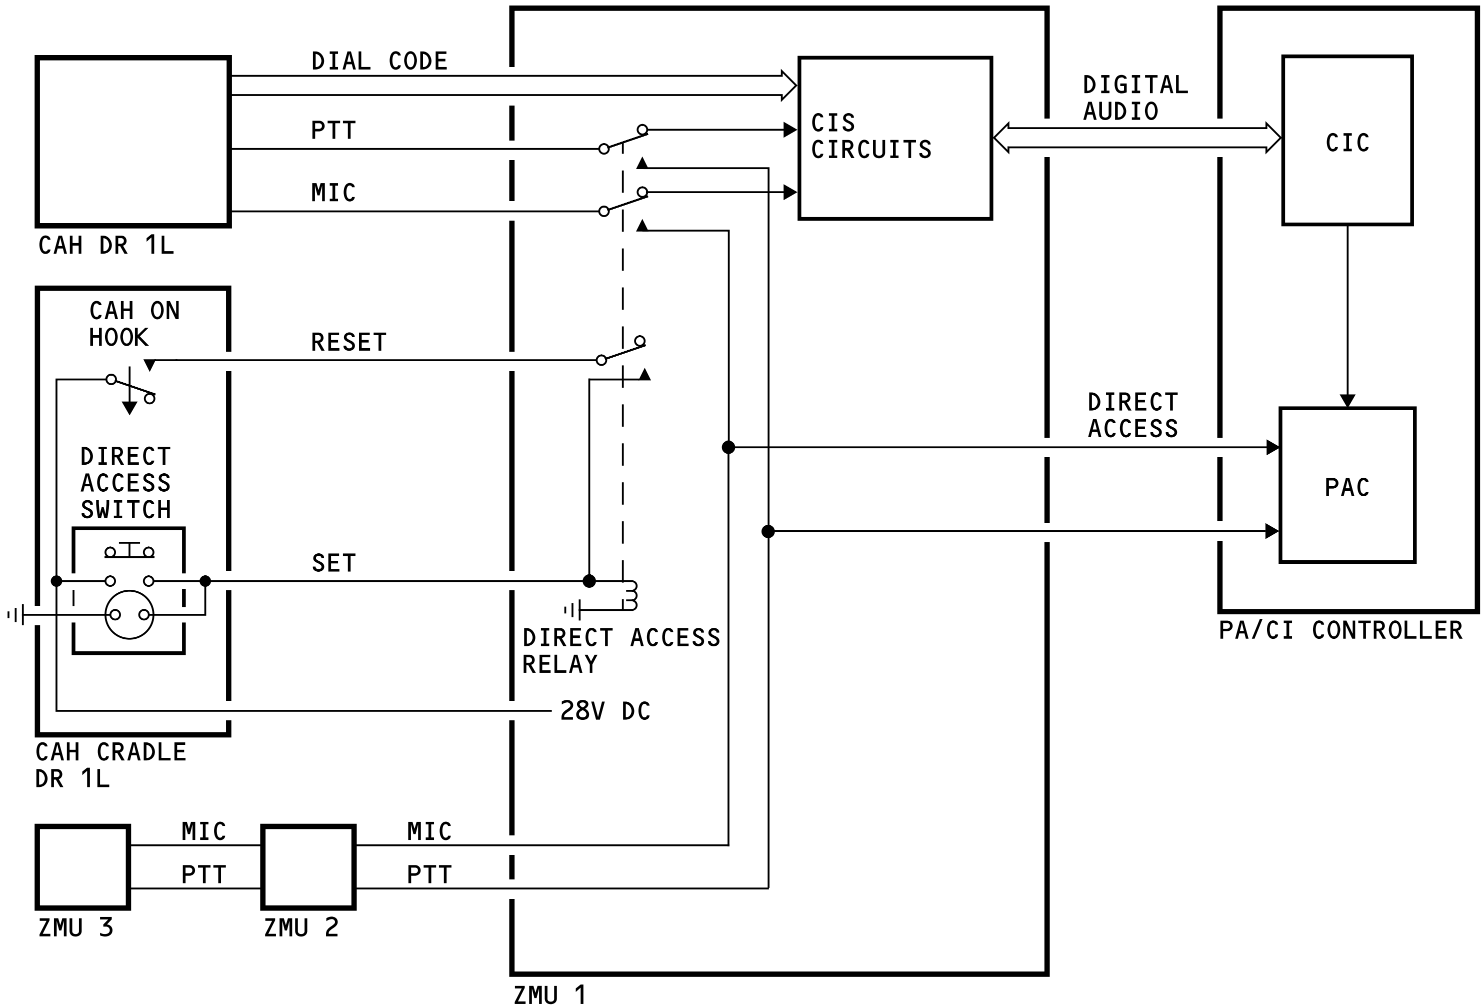
Direct Access

Two of the cabin attendant handsets (CAHs) have the direct access function. They are at door 1 left and door 3 left. Only one direct access handset may connect to a ZMU. The handset at door 1 left connects to ZMU 1. The handset at door 3 left connects to ZMU 3. There is no direct access handset connected to ZMU 2.

A momentary DIRECT ACCESS switch is on the front of the CAH cradle. When you push the switch, 28v dc goes though the contacts to the relay in the zone management unit (ZMU). The relay energizes. The 28v dc goes through the reset line and latches the relay in the energized position.

When the relay energizes, the CAH microphone audio and PTT signals go around the CIS circuits. In each ZMU, the direct access mic and PTT signals from the CAH mix with the signals from the previous ZMU. The direct access outputs from ZMU 1 connect directly to the PAC in the PA/CI controller.

When the CAH goes back in the cradle, it opens the CAH on hook switch. When the CAH on hook switch opens, this deenergizes the direct access relay.



23-31-00-014 Rev 7 02/25/1998

PAS - DIRECT ACCESS FUNCTIONAL DESCRIPTION

PAS - DIRECT ACCESS AND CABIN INTERPHONE ANNOUNCEMENT - OPERATION

General

You use cabin attendant handsets (CAHs) for both direct access and cabin interphone announcements.

Cabin Interphone

Flight attendants normally use the cabin interphone system (CIS) to make PA announcements (priority 2B). They can use any CAH to make a CIS announcement.

CIS announcements go to selected PA areas or all areas. To select a PA area, dial the code. These are typical PA dial codes:

- Area 1 - 41
- Area 2 - 42
- Area 3 - 43
- Area 4 - 44
- Area 5 - 45
- Area 6 - 46
- All areas - 40
- Priority all areas - 47.

To make a CIS announcement, dial the code for the area and push the PTT. To end the announcement, either push the RESET button or put the handset back in the cradle.

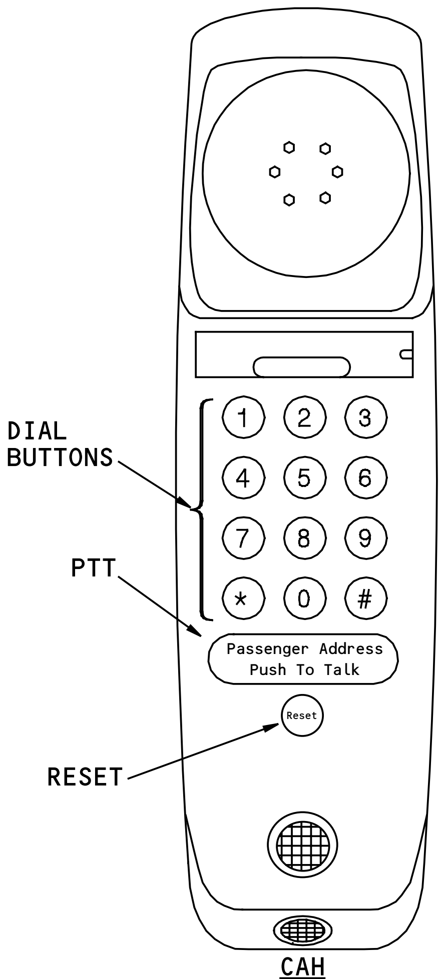
Direct Access

Flight attendants use CAHs at doors 1 left and 3 left to make direct access announcements (priority 2A).

The direct access CAH cradle has a PA switch. To make a direct access announcement, push the PA switch. Then push and hold the PTT. This connects the CAH microphone to the PA/CI controller.

Direct access announcements go to all PA areas.

To end the direct access announcement, put the handset back in the cradle.



PA DIAL CODES (TYPICAL)

AREA 1 - 41
AREA 2 - 42
AREA 3 - 43
AREA 4 - 44
AREA 5 - 45
AREA 6 - 46
ALL AREAS - 40
PRIORITY ALL AREAS - 47

PAS - DIRECT ACCESS AND CABIN INTERPHONE ANNOUNCEMENT - OPERATION

PAS - BOARDING MUSIC SELECTION

General

Flight attendants use the cabin system control panel (CSCP) or cabin area control panels (CACPs) to select boarding music (priority 4).

Access

Touch BOARDING MUSIC on the cabin controls main menu to show the boarding music screen.

Controls

The boarding music selection screen gives control of these functions:

- Boarding music on/off
- Channel selection
- Volume.

Touch ON to cause the boarding music to come on. Touch OFF to cause the boarding music to go off.

There are four channels of boarding music from each. Touch 1, 2, 3, or 4 to select a channel.

The volume indication shows green vertical bars to show the current volume.

Touch the left arrow to decrease the volume. Touch the right arrow to increase the volume.

PAS - BOARDING MUSIC SELECTION

THIS PAGE INTENTIONALLY LEFT BLANK

PAS - CONFIGURATION DATABASE PROGRAMMED ITEMS

General

The configuration database supplies details of the system operation. For the PAS, the database gives configuration data for:

- Speaker drive modules (SDMs)
- Speakers
- Ambient noise sensors (ANS)
- Passenger address areas
- Volume
- Chimes.

SDMs, Speakers, and ANSs

The configuration database identifies the number of SDMs, speakers, and ANSs. It assigns as many as two speakers to a SDM and identifies the type of announcements each speaker transmits. The database assigns each ANS to a SDM.

The database also identifies the location of each component.

Speaker Mute Assignments

When an attendant makes an announcement, the PAS mutes up to three nearby speakers. This prevents speaker feedback. The configuration database assigns the speakers to a cabin attendant handset.

Passenger Address Areas

The PAS can have up to six passenger address areas. The configuration database assigns each speaker to a PA area.

Announcement Types for Each Speaker

The configuration database identifies the announcement types (priority 1, 2A, 2B, 3A, 3B, 4) each speaker plays.

Volume Control Areas

The PAS adjusts the volume in an area. The configuration database identifies the speakers assigned to a volume control area.

Volume Reference Level

The PAS uses a volume reference level to adjust the volume above or below reference level. The reference level is the normal in-flight volume. The configuration database gives the reference level.

ANS Reference Level

The configuration database identifies the reference level each ANS uses to measure noise.

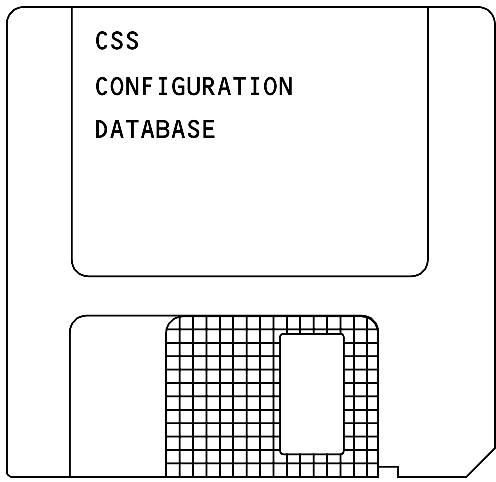
PAS - CONFIGURATION DATABASE PROGRAMMED ITEMS

Chimes Types and Count

The configuration database identifies the types of chimes the PAS makes for each chime condition. It also identifies the number of chimes for each chime condition.

PA Area to Video Area Assignment

The configuration database matches PA areas to video areas. The configuration database assigns each PA area to one video area. It assigns each video area to one or more PA areas.



- NUMBER OF SDM(S), SPEAKERS, AND ANS(S)
- SPEAKER MUTE ASSIGNMENTS
- PASSENGER ADDRESS AREAS
- TYPES OF ANNOUNCEMENTS FOR EACH SPEAKER
- VOLUME CONTROL AREAS
- VOLUME REFERENCE LEVEL
- ANS REFERENCE LEVEL
- CHIME TYPES AND COUNT
- PA AREA TO VIDEO AREA ASSIGNMENTS

23-31-00-017 Rev 2 09/16/1997

PAS - CONFIGURATION DATABASE PROGRAMMED ITEMS

PAS - PASSENGER ADDRESS FAILURE MESSAGE

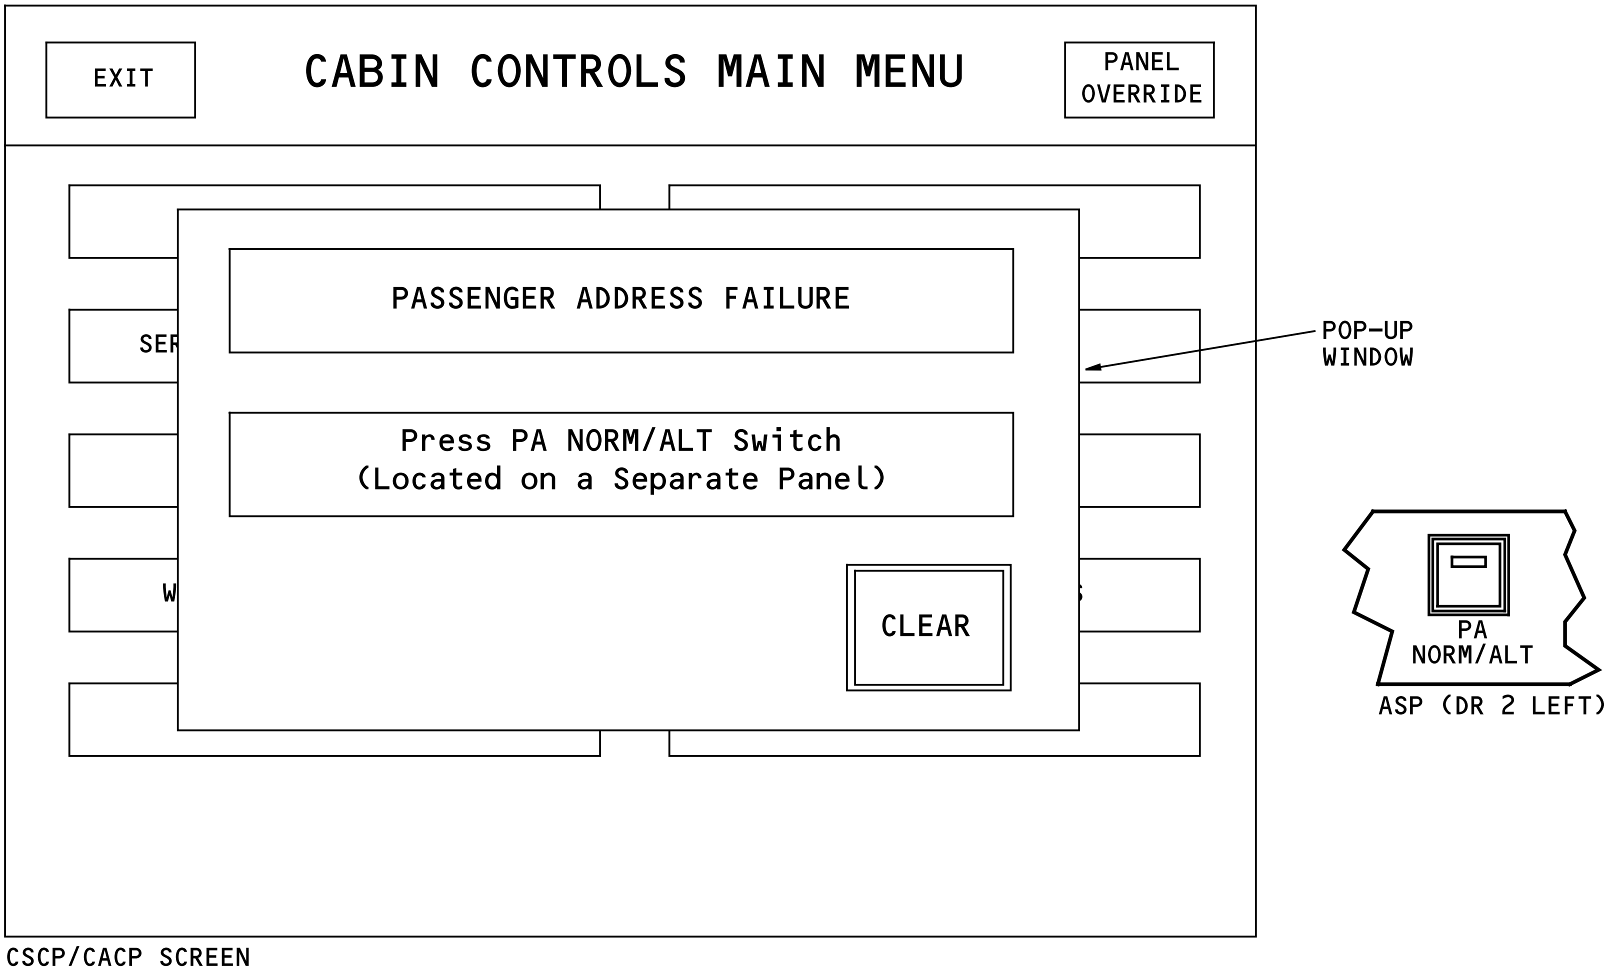
Operation

The passenger address controller (PAC) of the PA/CI controller has continuous BITE. If the BITE finds a failure, the PAC sends a message to the cabin system control panel (CSCP) and the cabin area control panels (CACPs). This causes the CSCP and all CACPs to show a PA failure message on a pop-up window.

The pop-up window tells the flight attendants to push the PA NORM/ALT switch.

To clear the pop-up window, touch CLEAR or push the PA NORM/ALT switch. The PA NORM/ALT switch makes the alternate PAC operational. The PA NORM/ALT switch is on the attendant switch panel (ASP) at door 2 left.

The PAC also sends a message to the AIMS for both EICAS and the central maintenance computing function (CMCF).



23-31-00-018 Rev 4 10/21/96

PAS - PASSENGER ADDRESS FAILURE MESSAGE

PAS - PASSENGER ADDRESS CONTROL SCREEN

General

The passenger address screen permits you to adjust the PA volume. It also permits you to disable the ambient noise sensors (ANS).

You can access the screen on the CSCP or on any CACP.

Access

Touch PASSENGER ADDRESS on the cabin controls main menu screen to show the passenger address screen.

Volume Control

Touch the area selection arrows to select an area.

The configuration database identifies the airborne volume reference level. The volume indication shows the current volume above the reference level. Green vertical bars show the volume for the area selected.

The STEPS ABOVE MINIMUM shows the number of increments above the reference level. The range is from 0 to 16. The configuration data base determines the amount each increment increases the volume.

To increase the volume, touch the right arrow. To lower the volume, touch the left arrow. You cannot lower the volume level below the reference level.

Touch AREA RESET to return the volume to the reference level.

Ambient Noise Sensor Control

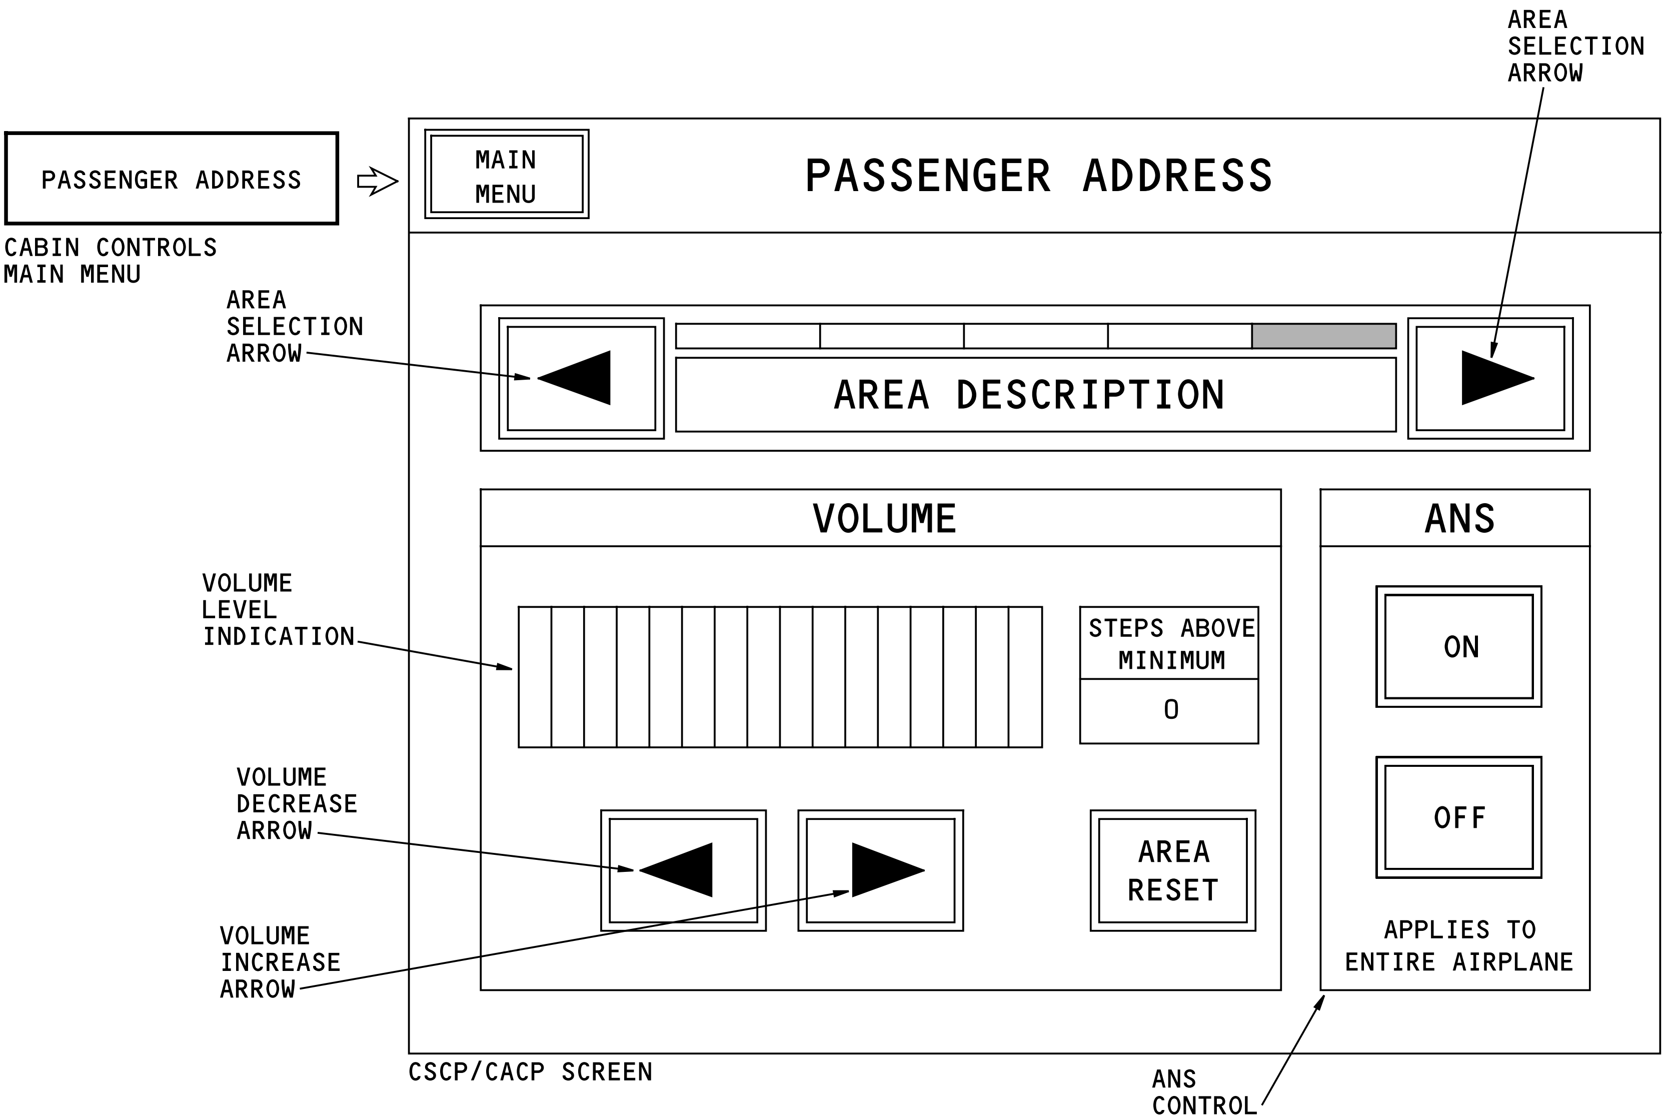
The ANS section permits you to enable or disable the ANSs. The ANS control goes to all ANSs in the airplane.

Touch ON to enable the ANSs. The PAS uses ANS inputs to calculate the volume levels.

Touch OFF to disable the ANSs. The PAS uses flight inputs to calculate the volume.

Training Information Point

It is normal to have the ambient noise sensors (ANSs) on. If the volume changes are too large, turn the ANSs off.



23-31-00-022 Rev 5 03/18/96

PAS - PASSENGER ADDRESS CONTROL SCREEN

PAS - NOISE GENERATION

General

Use the command output - speaker drive module (SDM) screen to make PAS noise for audio tests.

Access

Use these steps on the CSCP to select the screen:

- Touch CABIN MAINTENANCE on the CSCP main menu
- Touch CABIN TESTS on the cabin maintenance menu
- Touch ENGINEERING TESTS on the cabin tests menu
- Touch COMMAND OUTPUT on the engineering tests menu
- Touch SPEAKER DRIVE MODULE (SDM) on the command output menu.

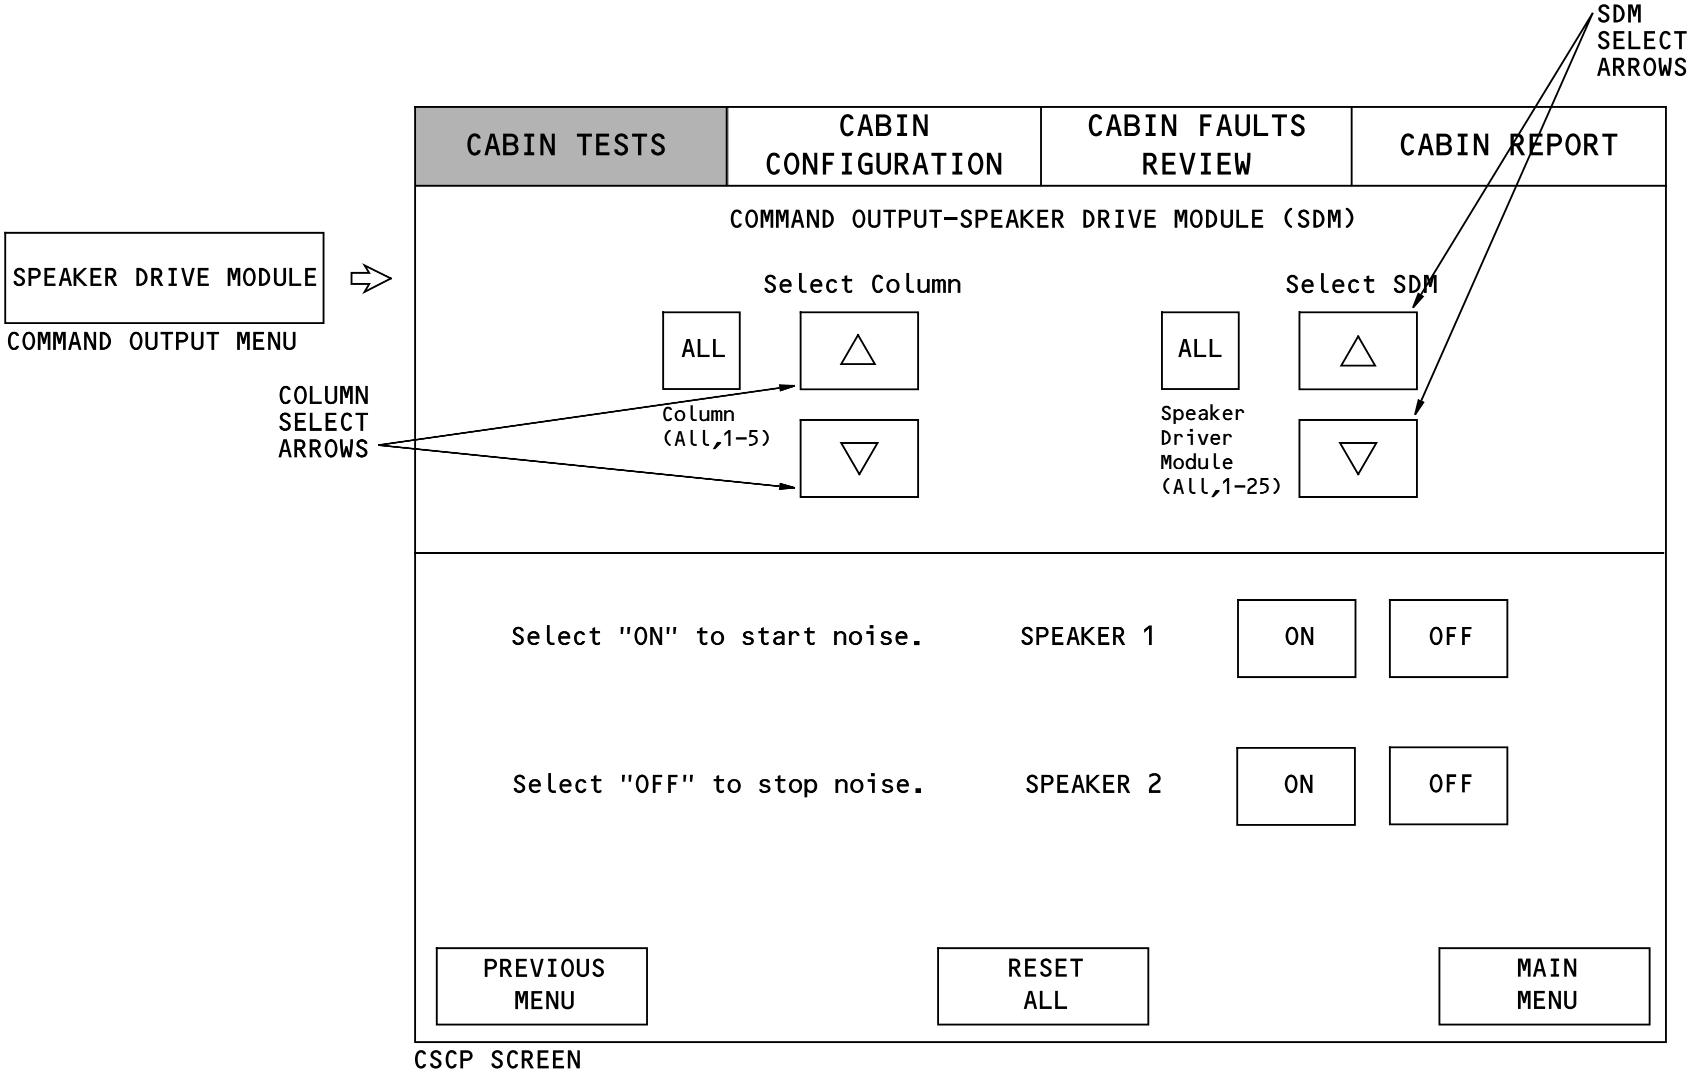
Command Output - Speaker Drive Modules Screen

Touch the column select arrows to select one or all columns (zones).

Touch the SDM select arrows to select one or more SDMs.

Touch SPEAKER 1 ON and SPEAKER 2 ON to cause the SDMs to make noise.

Touch RESET ALL to stop the random noise.



23-31-00-023 Rev 1 03/18/96

PAS - NOISE GENERATION

PAS - CABIN TESTS

General

Use the cabin system control panel (CSCP) to do the cabin test for the passenger address system (PAS).

See the cabin services system (CSS) section for more information about tests (AMM PART I 23-39).

Quick Test

Use quick test to quickly find major faults. This test does a check of these PAS components:

- Passenger address/cabin interphone (PA/CI) controller
- Speaker drive modules (SDMs).

This test collects continuous monitor data for as long as 20 seconds. The CSCP shows the failures.

To start a quick test, touch START QUICK TEST.

All Test

Use all test for a more complete test. All test starts a complete BITE of the system. The screen shows all the failures the BITE finds.

To start an all test, touch START ALL TEST.

Engineering Tests

Use engineering tests for more detailed tests.

Touch ENGINEERING TESTS to show the engineering tests menu.

Lamps Test

The lamps test does not do a test of the PAS.

PASSENGER SERVICE SYSTEM - INTRODUCTION

Introduction

The passenger service system (PSS) has these three functions:

- Lets passengers call flight attendants for cabin service
- Gives passengers control of reading lights
- Shows passengers information on cabin signs.

The flight attendants use the PSS to do these functions:

- Turn off passenger to attendant call chimes
- Control no smoking areas
- Control passenger reading lights.

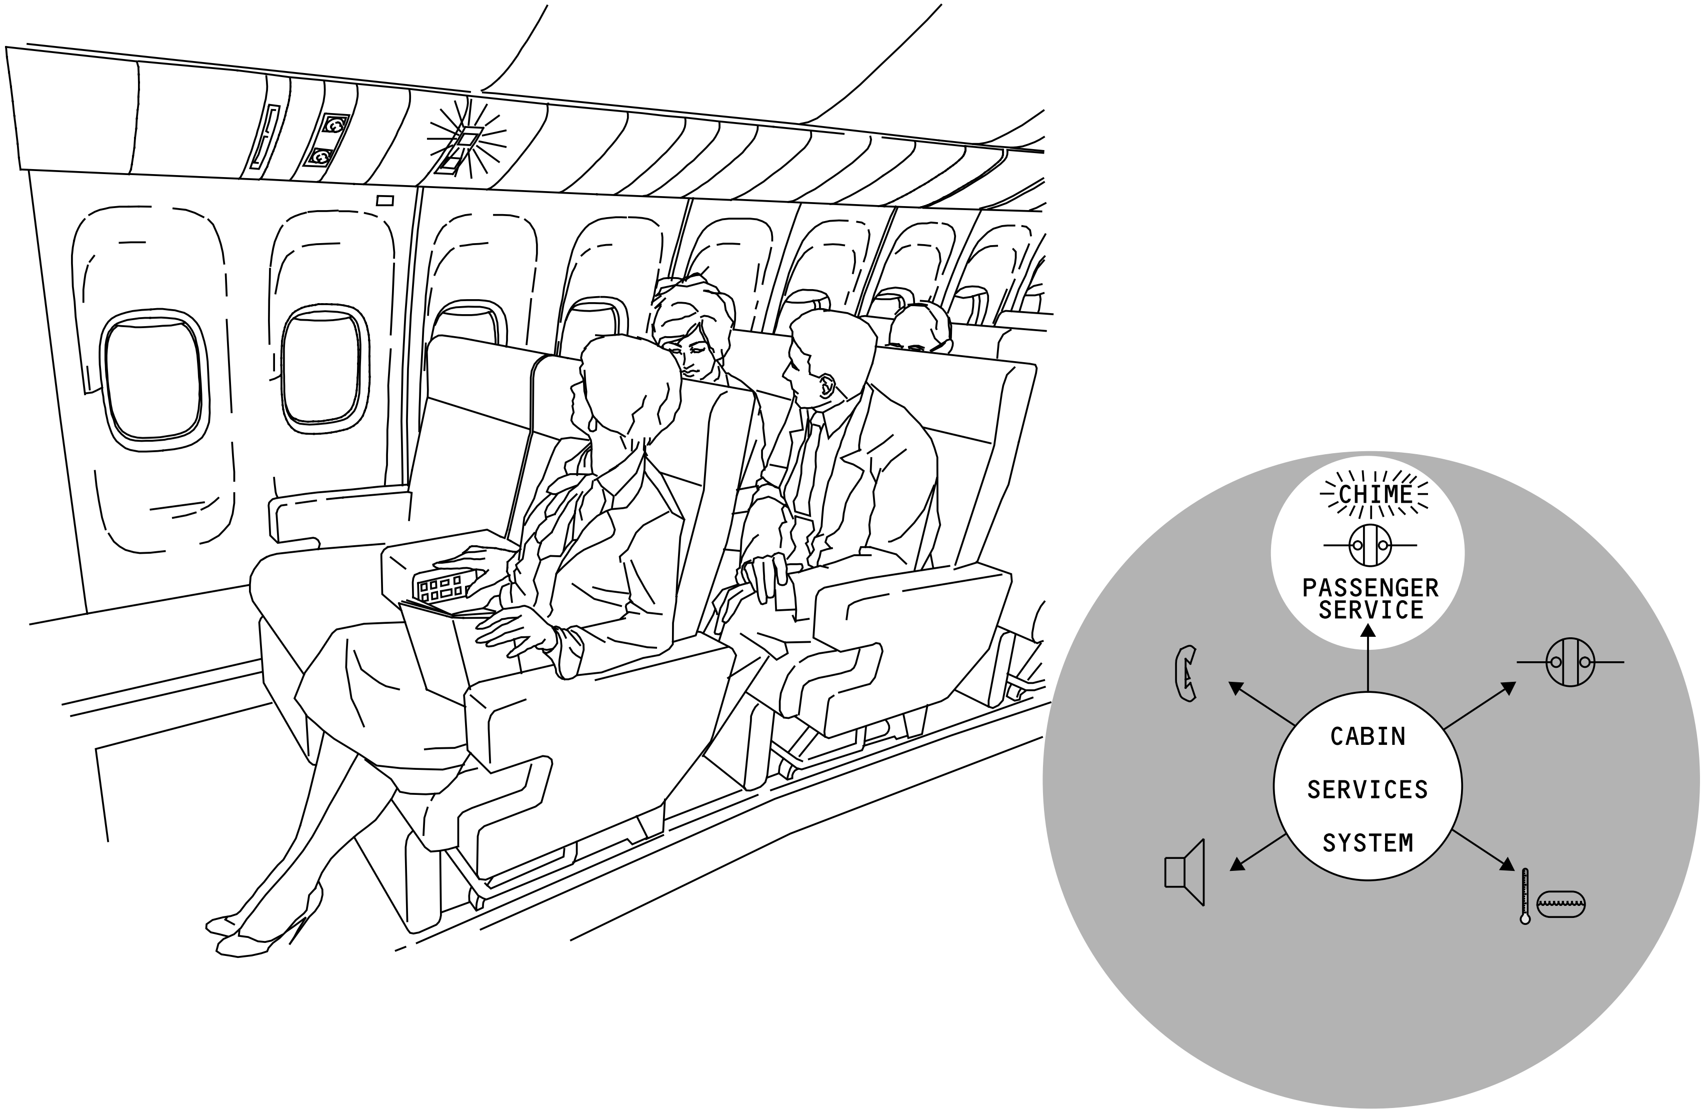
ZMU	- zone management unit



PASSENGER SERVICE SYSTEM - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

PSS - GENERAL DESCRIPTION

General

The passenger services system (PSS) has head-end and zone interfaces with the in-flight entertainment (IFE) system for PSS functions.

The PSS gets inputs from the left and right systems ARINC 629 buses and flight attendants to control passenger information signs.

The PSS also gets data from passengers to control reading lights and attendant call lights.

The PSS sends configuration database information and status information to the IFE.

Components

These are the main components of the passenger service system (PSS):

- Zone management units (ZMUs)
- Cabin control panels (CCPs)
- Overhead electronics units (OEUs)

These other systems and components connect with the PSS:

- Cabin system management unit (CSMU)
- Passenger address/cabin interphone (PA/CI) controller
- Right and left systems ARINC 629 buses
- Lavatory modules
- Reading and call lights.

Passenger Service/Entertainment On/Off

Attendants may use the CCPs to enable or disable the reading lights and attendant call lights. They may also use a panel to turn off the attendant call and reading lights.

Passenger Information Signs

The PSS gets inputs from other systems to control passenger information signs. The OEUs send signals to control these types of signs:

- Lavatory
- Return to seat
- Fasten seat belts
- No smoking.

Reading Light Control

Passengers use controls at their seat to control reading lights. The reading light selection goes through the IFE seat components to the ZMU. The ZMU sends the on or off signal to an OEU to control the reading light.

Passenger to Attendant Call

Passengers use controls at their seat to call a flight attendant. When the passenger pushes the attendant call button:

PSS - GENERAL DESCRIPTION

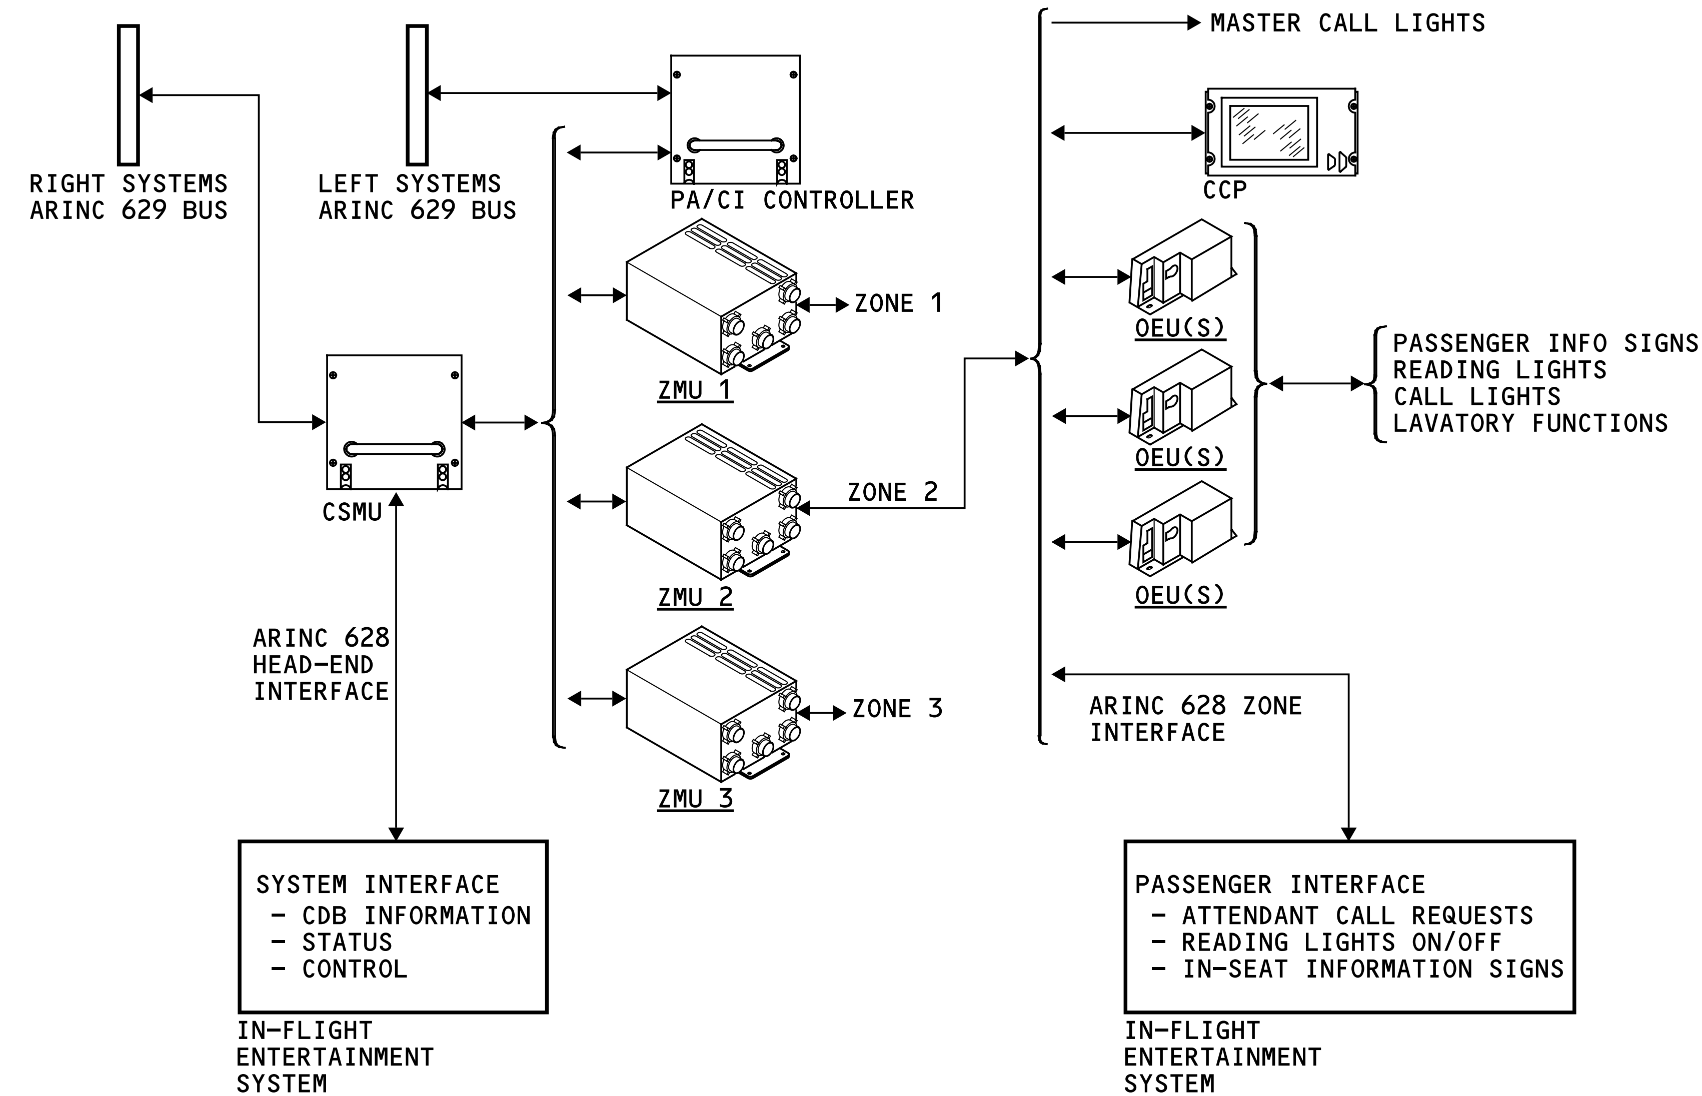
- A row call light in the passenger service unit (PSU) comes on
- A master call light at an attendant station comes on
- The passenger address system makes a chime.

Chime Cut-Off Function

Attendants use the CCPs to disable the chime related to a passenger-to-attendant call. Each CCP controls the chimes in an area identified by the configuration database.

Lavatory Functions

The lavatories connect with OEUs for lavatory to attendant calls and lavatory status signals.



PSS - GENERAL DESCRIPTION

PSS - POWER INTERFACE - ZONE 1

PSS - POWER INTERFACE - ZONE 2

General

Circuit breakers on the right power management panel control power to these zone 2 components:

- Zone management unit (ZMU) 2
- Overhead electronics units (OEUs).

The P210 right power management panel has these components:

- PAX MASTER CALL LT circuit breaker
- ZONE MGMT UNIT 2 circuit breaker
- OEU ZONE2 LEFT MAIN BUS circuit breaker
- OEU ZONE2 CENTER MAIN BUS circuit breaker
- OEU ZONE2 RIGHT MAIN BUS circuit breaker
- OEU ZONE2 XFER BUS circuit breaker.

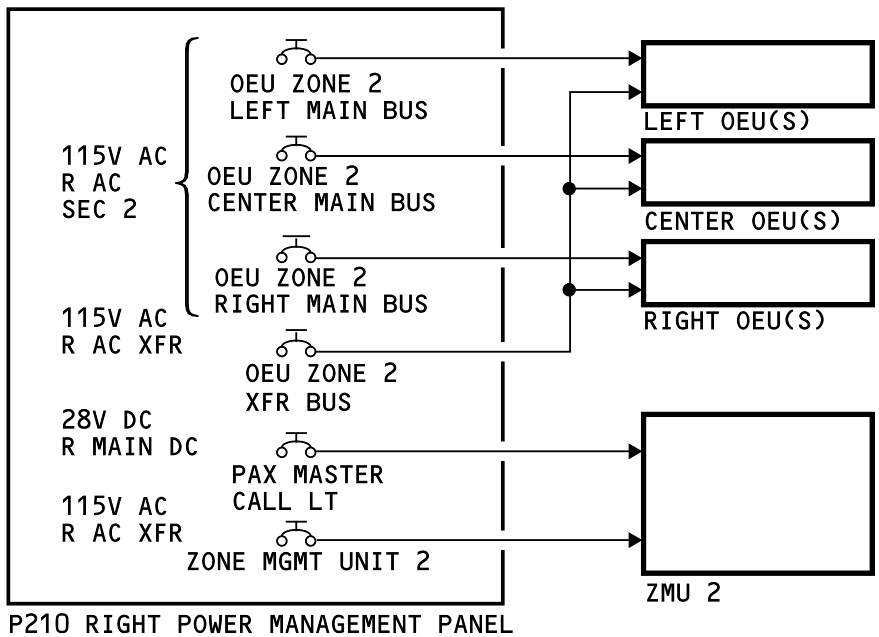
P210 Right Power Management Panel

The PAX MASTER CALL LT circuit breaker connects 28v dc to ZMU 2. The ZONE MGMT UNIT 2 circuit breaker connects 115v ac to the ZMU.

These circuit breakers each connect 115v ac power to a column of OEUs:

- OEU ZONE2 LEFT MAIN BUS to the left OEUs
- OEU ZONE2 CENTER MAIN BUS to the center OEUs
- OEU ZONE2 RIGHT MAIN BUS to the right OEUs.

The OEU ZONE2 XFER BUS circuit breaker connects 115v ac power to all of the OEUs in zone 2.



23-33-00-005 Rev 7 10/28/1997

PSS - POWER INTERFACE - ZONE 2

PSS - POWER INTERFACE - ZONE 3

General

Circuit breakers on the left and right power management panels control power to these zone 3 components:

- Zone management unit (ZMU) 3
- Overhead electronics units (OEUs).

The P110 left power management panel has these components:

- ZONE MGMT UNIT 3 circuit breaker
- OEU ZONE3 LEFT MAIN BUS circuit breaker
- OEU ZONE3 CENTER MAIN BUS circuit breaker
- OEU ZONE3 RIGHT MAIN BUS circuit breaker
- OEU ZONE 3 XFER BUS circuit breaker

The PAX MASTER CALL LT circuit breaker is on the P210 right power management panel.

P110 Left Power Management Panel

The ZONE MGMT UNIT 3 circuit breaker connects 115v ac to the ZMU.

These circuit breakers each connect 115v ac power to a column of OEUs:

- OEU ZONE 3 LEFT MAIN BUS to the left OEUs
- OEU ZONE 3 CENTER MAIN BUS to the center OEUs
- OEU ZONE 3 RIGHT MAIN BUS to the right OEUs.

The OEU ZONE 3 XFER BUS circuit breaker connects 115v ac power to all of the OEUs in zone 3.

P210 Right Power Management Panel

The PAX MASTER CALL LT circuit breaker connects 28v dc to the ZMU.

PSS - POWER INTERFACE - ZONE 3

THIS PAGE INTENTIONALLY LEFT BLANK

PSS - INTERFACES

General

The passenger service system (PSS) uses an ARINC 629 interface and an in-flight entertainment (IFE) system ARINC 628 head-end interface to get data from other systems. An intersystem (I/S) bus connects the three cabin zones. Other buses connect the other PSS components.

The passenger interface for PSS is through an IFE system ARINC 628 zone interface.

The diagram shows zone 1 interfaces. The other zones are the same.

ARINC 629

The passenger address/cabin interphone (PA/CI) controller connects to the left systems ARINC 629 bus. The cabin system management unit (CSMU) connects to the right systems ARINC 629 bus. The PA/CI and CSMU get data from these systems to control the passenger information signs:

- Airplane information management system (AIMS)
- Electrical load management system (ELMS)
- Overhead panel ARINC 629 system (OPAS)
- Flap/slat electronics unit (FSEU)
- Proximity sensor electronics unit (PSEU).

ARINC 628 Interface

PSS sends smoking area information and a no smoking signal to the IFE system on the ARINC 628 head-end interface.

The passenger interface for PSS is through an ARINC 628 zone interface to the IFE system. PSS gets attendant call requests and reading light inputs. PSS sends reset information and seat call status on the zone interface.

Intersystem Bus

Each of these components connects to the intersystem bus to control PSS functions:

- CSMU
- PA/CI controller
- Zone management units (ZMUs).

The intersystem bus passes through the components it connects. A failure of any component cannot cause a failure of the bus.

Other Buses

The cabin control panel (CCP) sends command signals to the ZMU on a panel bus. The ZMU sends display data to the CCP.

The ZMUs get commands and data from the I/S bus to control data to the OEUs and IFE. Each ZMU has an EIA-

PSS - INTERFACES

485 bus to each column of overhead electronics units (OEUs).

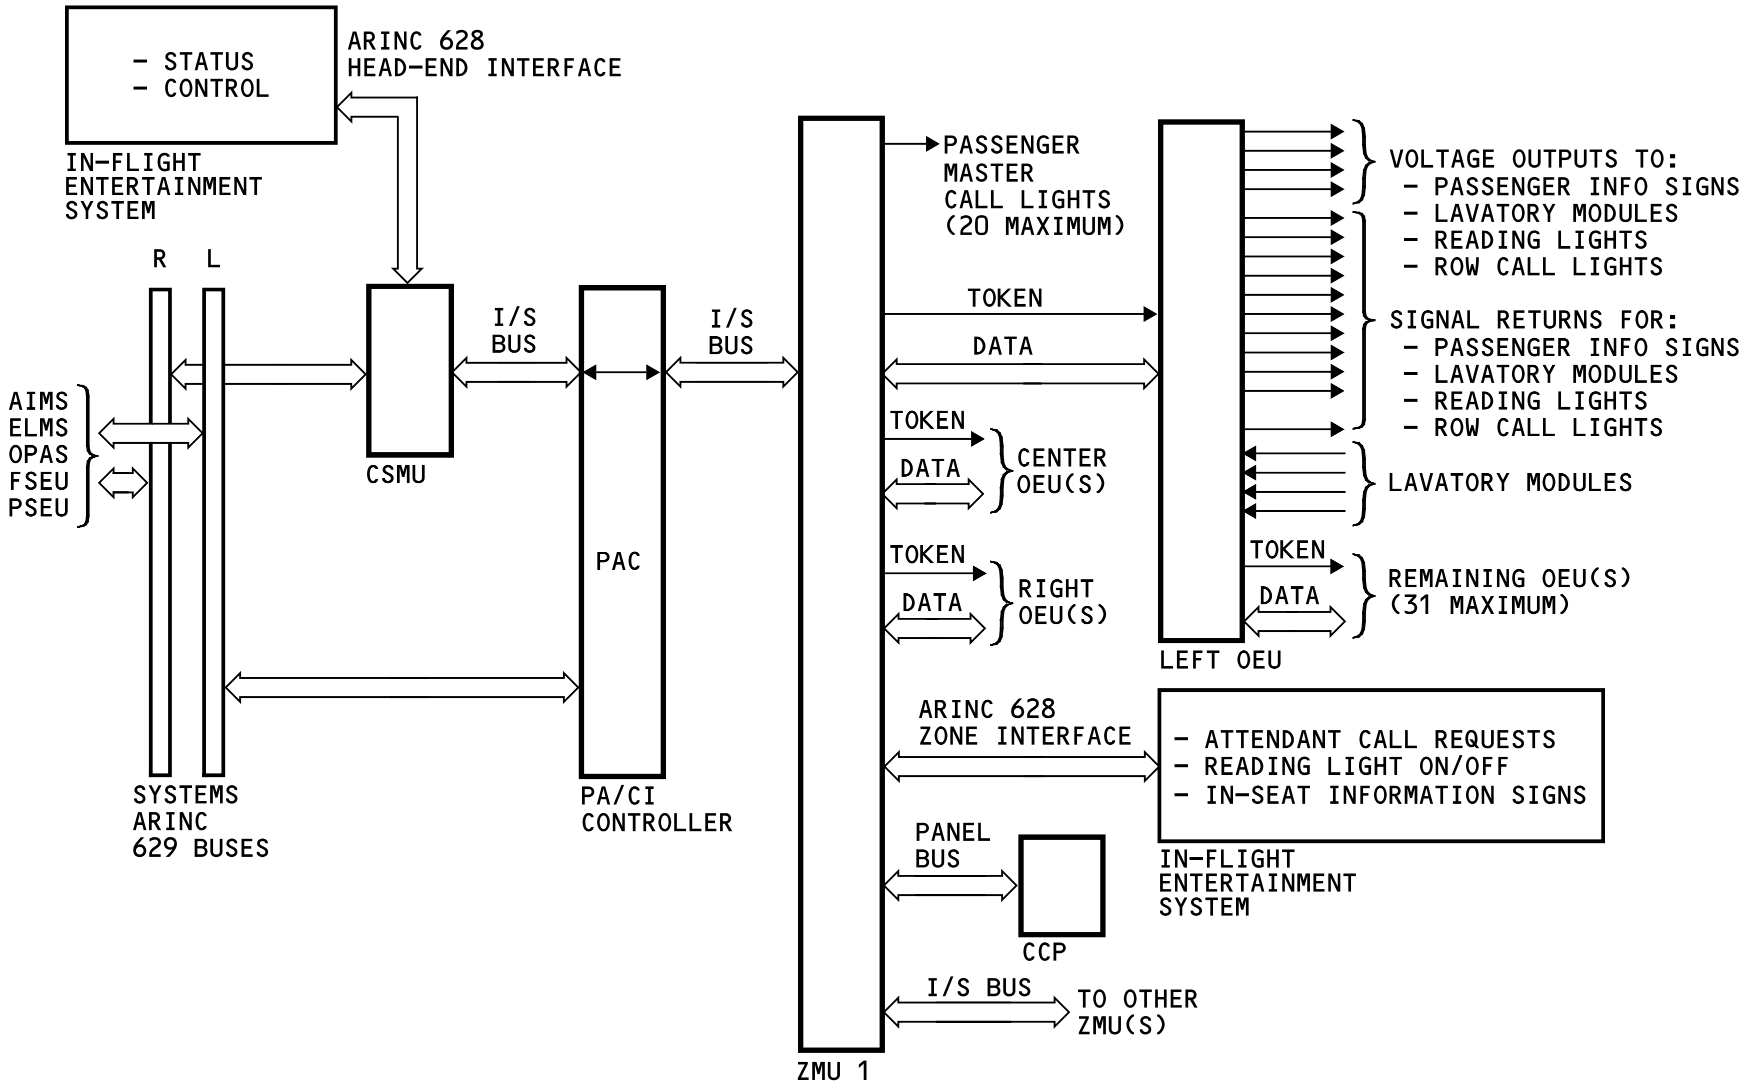
Discretes

Each ZMU can control as many as 20 passenger master call lights. The ZMU also sends a token signal to each column of OEUs for software installation.

Each OEU has four voltage outputs and twelve signal returns. The OEU controls the signal returns for these passenger service items:

- Passenger information signs
- Return to seat and lock door signs in the lavatories
- Reading lights
- Row call lights.

Each OEU has four inputs to monitor signals from lavatory modules.



23-33-00-007 Rev 9 10/28/1997

PSS - INTERFACES

PSS - LLAR INTERFACES

General

Zone management unit (ZMU) 3 has an interface with the P325 lower lobe attendant rest (LLAR) umbilical panel.

You use a switch on the P325 LLAR umbilical panel to control the OEU interfaces to LLAR components. A termination plug terminates the IFE system signals.

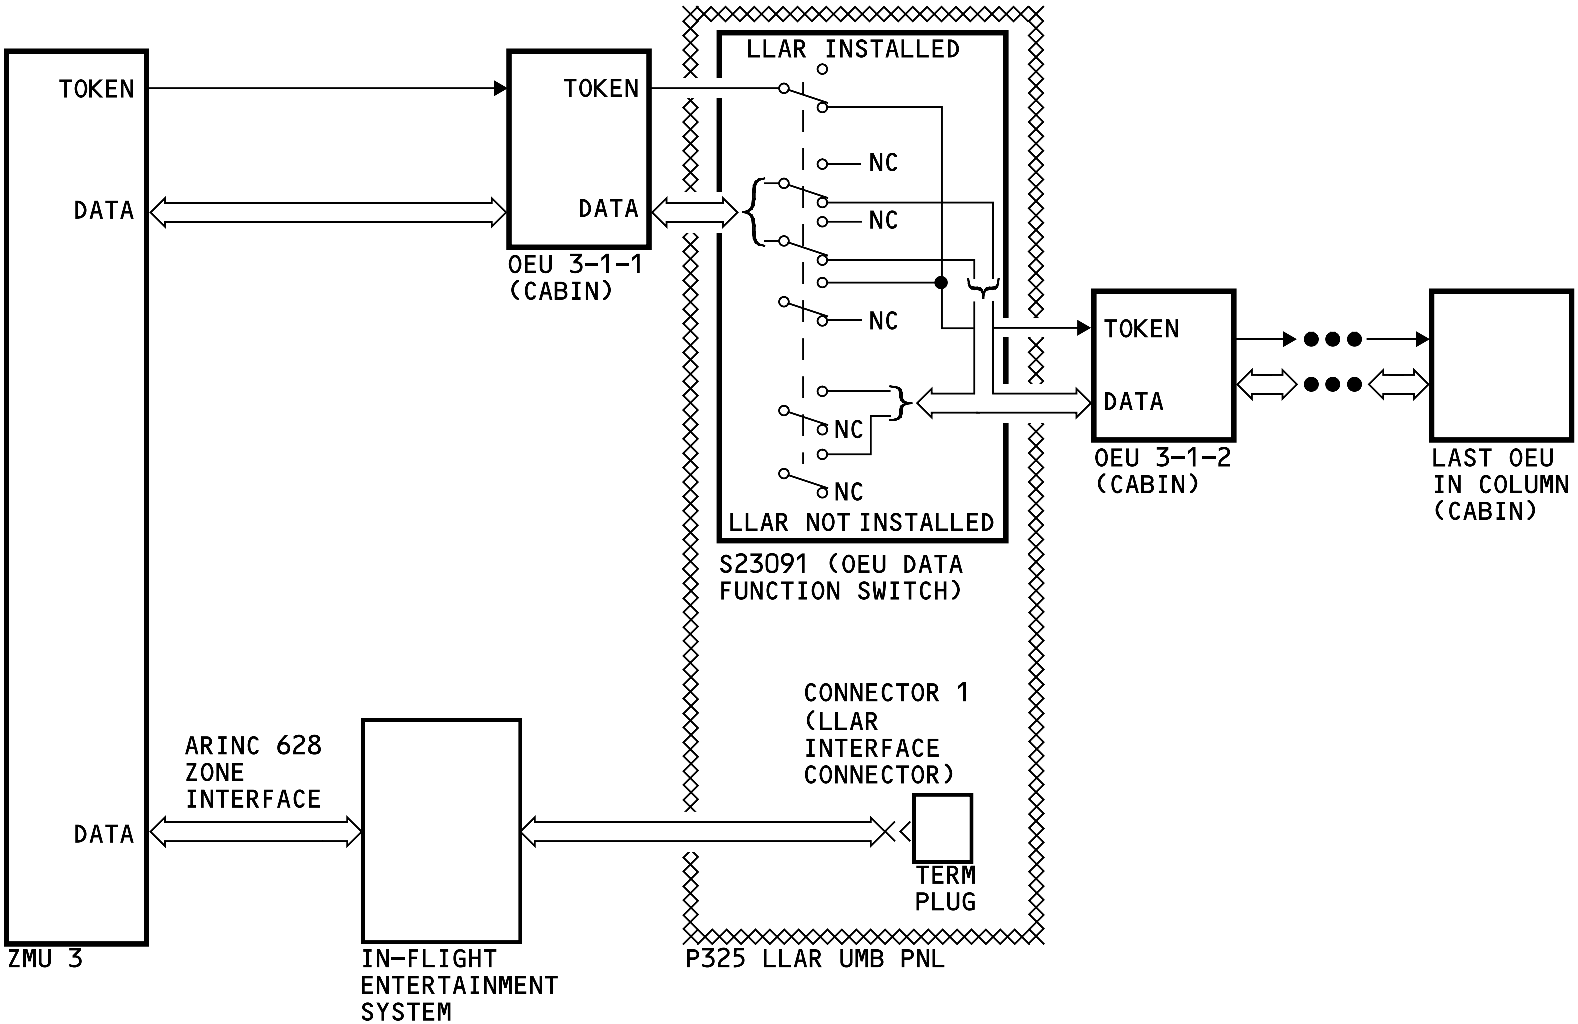
OEU Interface

When S23091 (OEU data function switch) on the P325 LLAR umbilical panel is in the LLAR NOT INSTALLED position, the signals go from OEU 3-1-1 to OEU 3-1-2 and then to the other OEUs in the column.

IFE System Interface

ZMU 3 sends data to the IFE system components in the cabin and to the P325 LLAR umbilical panel.

When the LLAR is not installed, the IFE system signals terminate at a termination plug on the LLAR interface connector.



23-33-00-034 Rev 6 04/10/1997

PSS - LLAR INTERFACES

PSS - OVERHEAD ELECTRONICS UNIT

General

The overhead electronics units (OEUs) control these components:

- Reading lights
- Call lights
- Passenger information signs.

They also monitor signals from lavatories and waste tanks.

Physical Description

The OEU weighs 1.7 pounds. It has these dimensions:

- Length - 8.7 inches
- Width - 2.75 inches
- Height - 4 inches.

The OEU has three connectors. J1 is the voltage and data bus input/output. It receives data from the ZMU or another OEU and sends it to the next OEU through the same connector. For correct operation, install a jumper plug when you remove an OEU.

J2 provides voltage and signal outputs.

J3 provides voltage and signal outputs and gets discrete inputs.

Functional Description

The OEUs change 115v ac power to these voltages:

- 28v ac for lavatory and passenger information signs
- 12v ac for reading lamps
- 5v ac for row call lights.

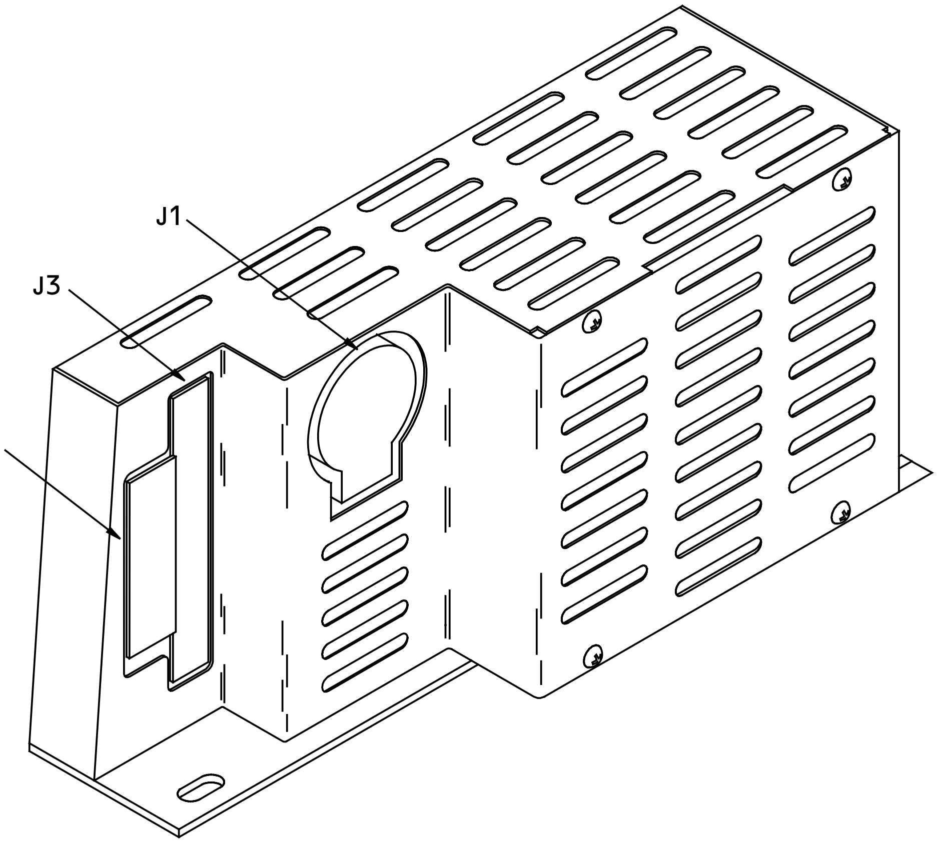
The OEUs get signals from the ZMU to control these PSS related items:

- Reading lights
- Call lights
- Passenger information signs.

The OEUs monitor lavatory-to-attendant calls and door latch discretes from the lavatory modules.

These systems and components also connect to OEUs:

- Lavatory and crew rest smoke detectors
- Water and waste system
- Cabin lighting system.



23-33-00-009 Rev 0

PSS - OVERHEAD ELECTRONICS UNIT

PSS - OEU INSTALLATION - PASSENGER SERVICE UNITS

General

There are overhead electronics units (OEUs) in the center and outboard passenger service units (PSUs). There are also OEUs in other cabin locations. Three screws attach the OEU to a panel.

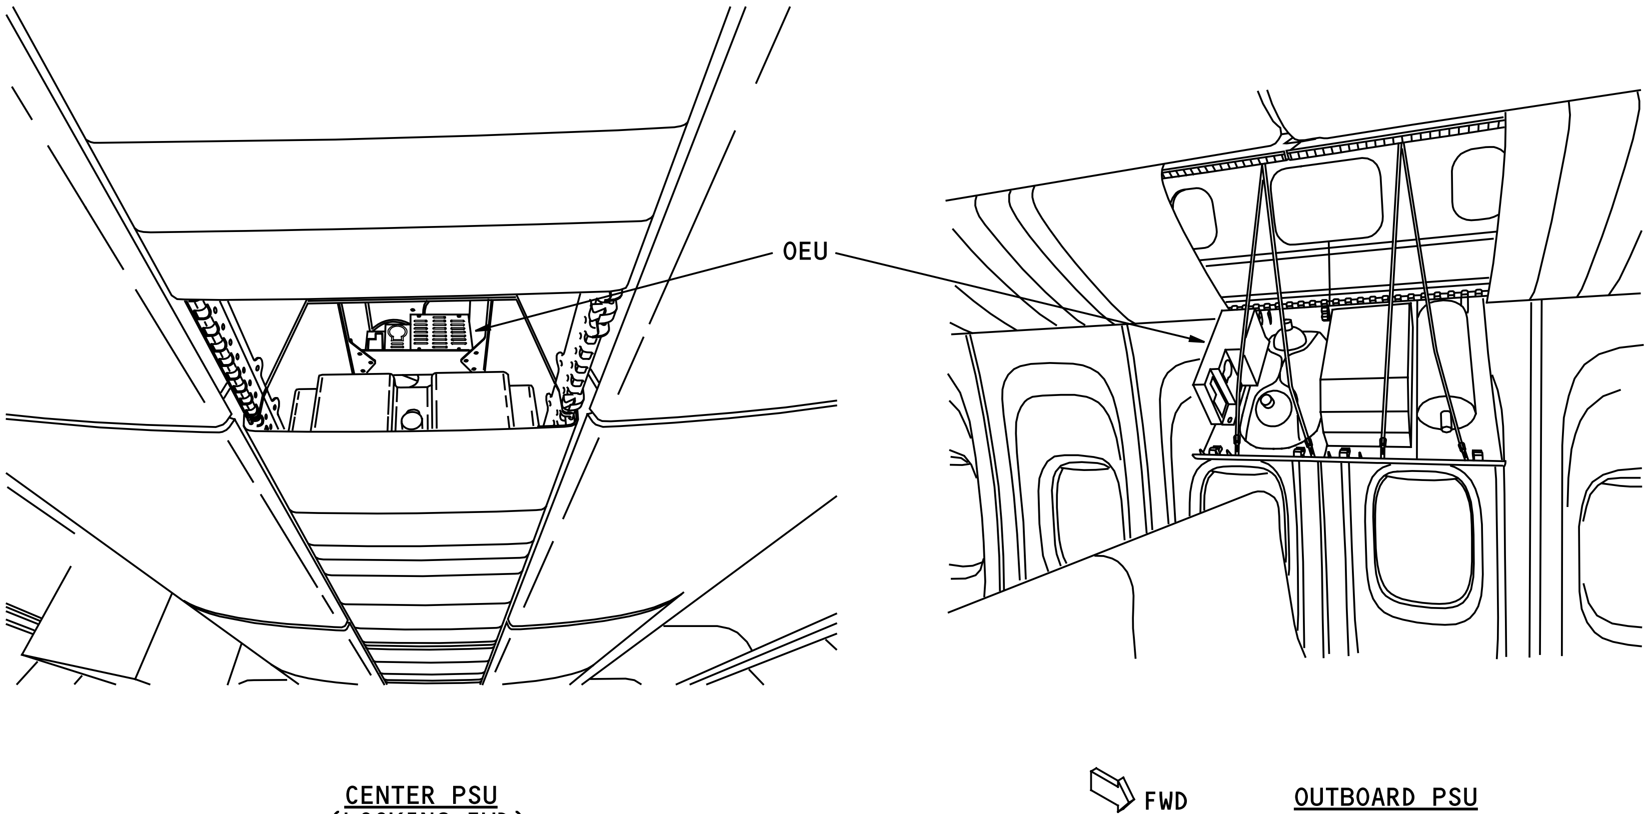
Center PSU

Release the PSU panel latches and lower the PSU to get to the OEU. The OEU is on a bracket approximately eight inches above the PSU panel.

Outboard PSU

The left and right OEUs are on outboard PSUs.

Release the panel latches and lower the PSU. The OEU is on the PSU panel.



23-33-00-010 Rev 2 05/03/95

PSS - OEU INSTALLATION - PASSENGER SERVICE UNITS

PSS - OEU INSTALLATION - LAVATORIES AND LOWERED CEILING AREAS

General

There are overhead electronics units (OEUs) in these locations:

- Each lavatory
- Above each passenger door
- Some lowered ceiling panels.

The diagram shows a typical lavatory and typical door area with lowered ceiling panels.

Lavatories

The lavatory OEUs mount to a passenger service unit (PSU) rail adjacent to the lavatory.

Training Information Point

You must remove ceiling panels adjacent to the lavatory to get to the OEU.

Overdoor Panels

Panels over each passenger door have an OEU.

Release the latches of the overdoor panel and lower it to get access to the OEU.

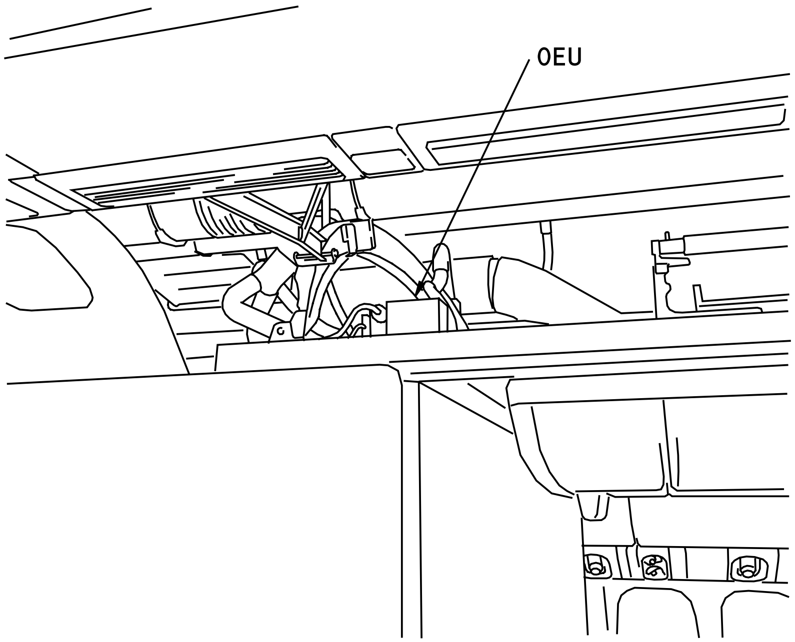
Lowered Ceiling Panels

The flight deck aisle access panel (near door 1 left) and a lowered ceiling panel at door 4 left have OEUs.

Training Information Point

Lower the flight deck aisle access panel to get access to the OEUs in the door 1 area.

Release the latches of the door 4L overdoor panel and lower it to get access to the OEU on the lowered ceiling panel.



TYPICAL LAVATORY MODULE

PSS - PASSENGER SERVICE UNIT

PSS - PASSENGER INFORMATION SIGNS

General

The passenger information signs show passengers these PSS conditions:

- No smoking
- Lavatory occupied
- Fasten seat belt.

TYPICAL PASSENGER INFORMATION SIGN

23-33-00-013 Rev 1

PSS - TYPICAL LAVATORY COMPONENTS

General

These lavatory components send and get signals through an overhead electronics unit (OEU):

- Lavatory call light/reset switch
- Return to seat sign
- Lavatory call switch
- Lock door sign
- Lavatory door latch.

Lavatory Call Light/Reset Switch

The lavatory call light comes on when you push the lavatory call switch. Attendants push this light/switch to cancel lavatory calls.

Return to Seat Sign

The return to seat sign comes on when the fasten seat belt signal is active and and cabin pressure is normal.

Lavatory Call Switch

Passengers use the lavatory call switch to call an attendant. The lavatory call switch makes the PSS do these things:

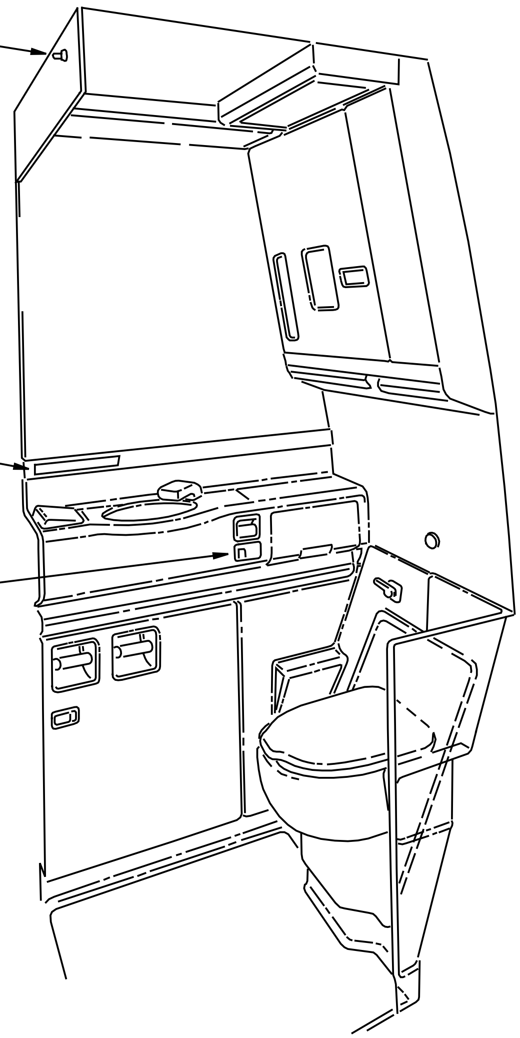
- The lavatory call light outside the lavatory comes on
- A lavatory master call light at an attendant station comes on
- A signal goes to the passenger address system for a chime.

Lock Door Sign

The lock door sign is on when the lavatory door is not locked.

Lavatory Door Latch

The lavatory door latch sends a signal to the PSS to make the lock door sign go off and a lavatory occupied sign come on.



NOT SHOWN:
- LOCK DOOR SIGN
- LAVATORY DOOR LATCH

PSS - TYPICAL LAVATORY COMPONENTS

PSS - CONFIGURATION DATABASE PROGRAMMED ITEMS

General

The cabin management system (CMS) configuration database supplies details of CMS operation. For the PSS, the database gives configuration data for these items:

- Master call light assignments
- Row call light assignments
- Lavatory call light assignments
- Reading light assignments
- Chime mute areas
- Passenger information sign control
- Panels for PSS on/off control
- OEU configuration.

Master Call Light Assignments

A passenger-to-attendant call or lavatory call makes a master call light come on. The configuration database specifies which master call lights come on in an area.

Row and Lavatory Call Light Assignments

The database specifies the relation of the attendant call button on each passenger control unit and the adjacent row call light on a passenger service unit.

The database also specifies which lavatory call light comes on when a passenger makes a call from a lavatory.

Reading Light Assignments

When a passenger pushes a reading light switch on the passenger control unit (PCU), a reading light comes on. The configuration database specifies which reading light comes on or goes off.

Chime Mute Areas

The configuration database specifies the chime mute areas for cabin control panels (CCPs).

Passenger Information Sign Control

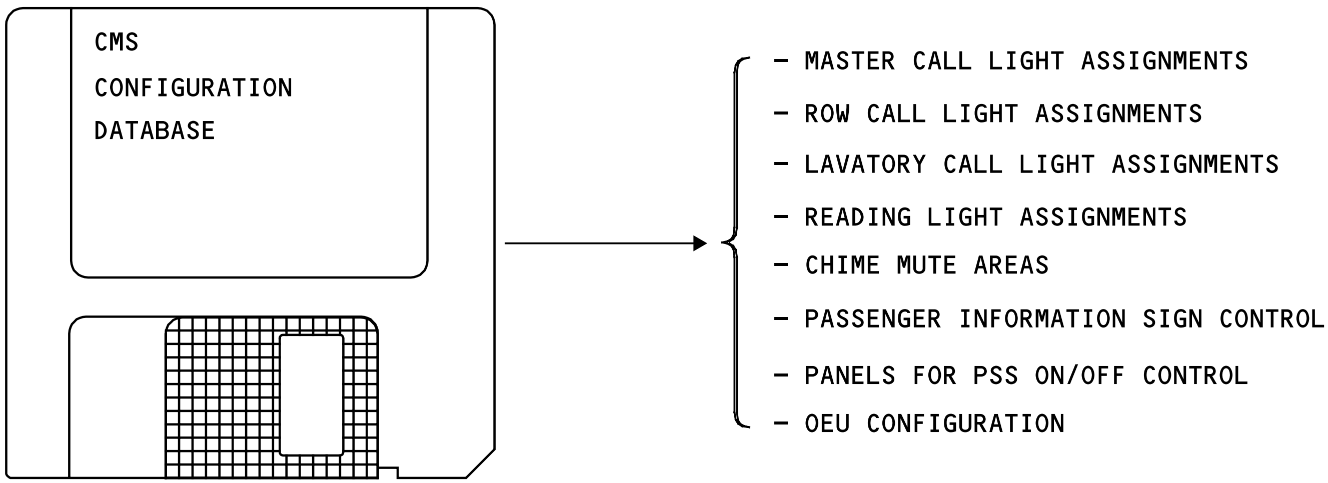
The database specifies the conditions that control all of the passenger information signs.

Panels for PSS On/Off Control

The configuration database specifies which control panels can turn the passenger service system on and off.

OEU Configuration

The database specifies how many OEUs are in each column. It also tells which components connect to each OEU.



23-33-00-015 Rev 2 04/24/1997

PSS - CONFIGURATION DATABASE PROGRAMMED ITEMS

PSS - OPERATION - CABIN CONTROLS MAIN MENU SCREEN

General

Attendants use the cabin controls main menu on the cabin system control panel (CSCP) or cabin area control panels (CACPs) to select screens that control PSS functions. Touch any one of these to show PSS related screens:

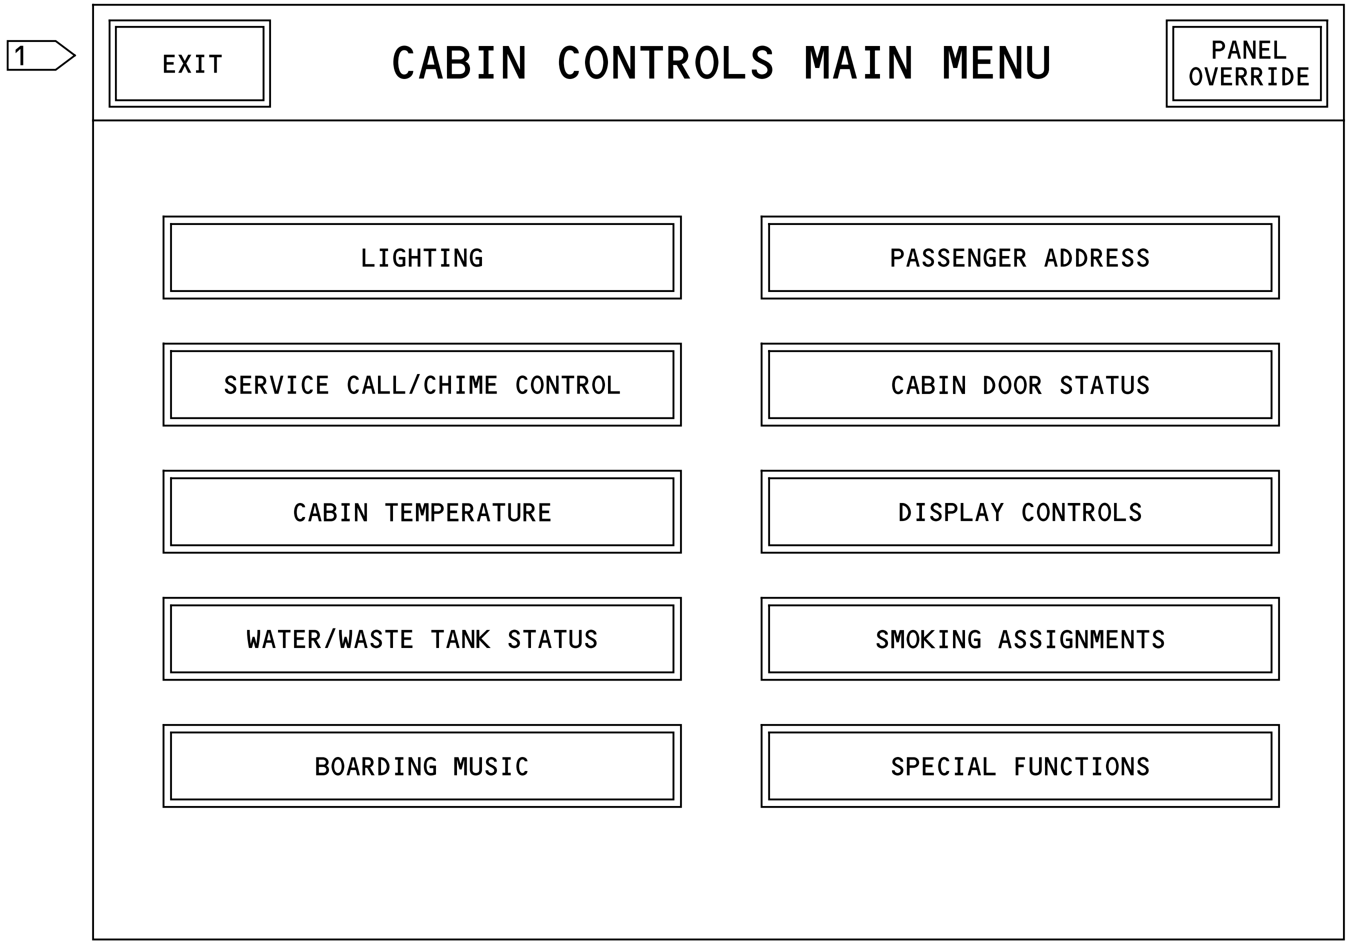
- LIGHTING
- SERVICE CALL/CHIME CONTROL
- SMOKING ASSIGNMENTS.

Access

Touch CABIN CONTROLS on the CSCP main menu to show this screen.

On the CACP, the cabin controls main menu is the highest level menu. It shows automatically when you apply power to the CSS.

The CACPs do not have the EXIT selection.



CSCP/CACP SCREEN

1 THE EXIT SELECTION IS NOT ON THE CACP.

PSS – OPERATION – CABIN CONTROLS MAIN MENU SCREEN

PSS - OPERATION - LIGHTING MENU SCREEN

General

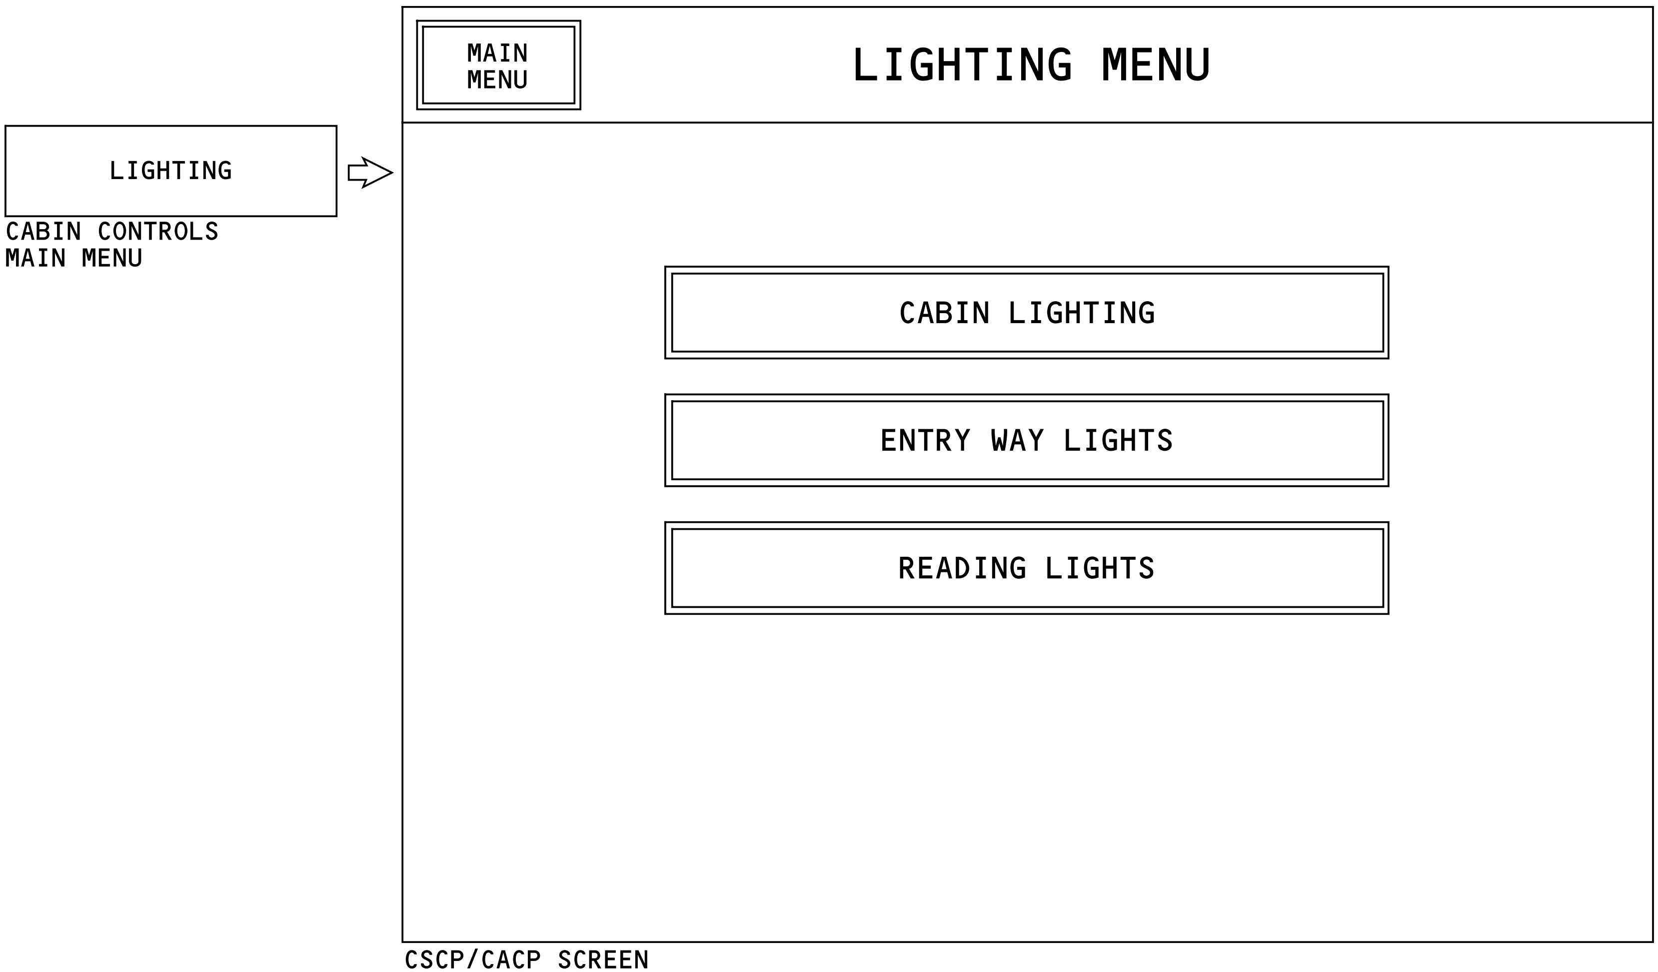
Attendants use the lighting menu on the cabin system control panel (CSCP) or cabin area control panels (CACPs) to select the reading lights control screen.

Access

Touch the LIGHTING selection on the cabin controls main menu to show this screen.

Controls and Indications

Touch READING LIGHTS to show the screen you use to control passenger reading lights.



23-33-00-021 Rev 1 03/26/96

PSS - OPERATION - LIGHTING MENU SCREEN

PSS - OPERATION - READING LIGHTS SCREEN

General

You use the reading lights screen to control the passenger reading lights.

Access

Touch LIGHTING on the cabin controls main menu. Then touch READING LIGHTS to show the reading lights screen.

Controls and Indications

Use the left and right arrows to select the cabin area. The space between the arrows shows the selected cabin area description.

Use the selections below the cabin area description to control the reading lights.

Latched Mode Operation

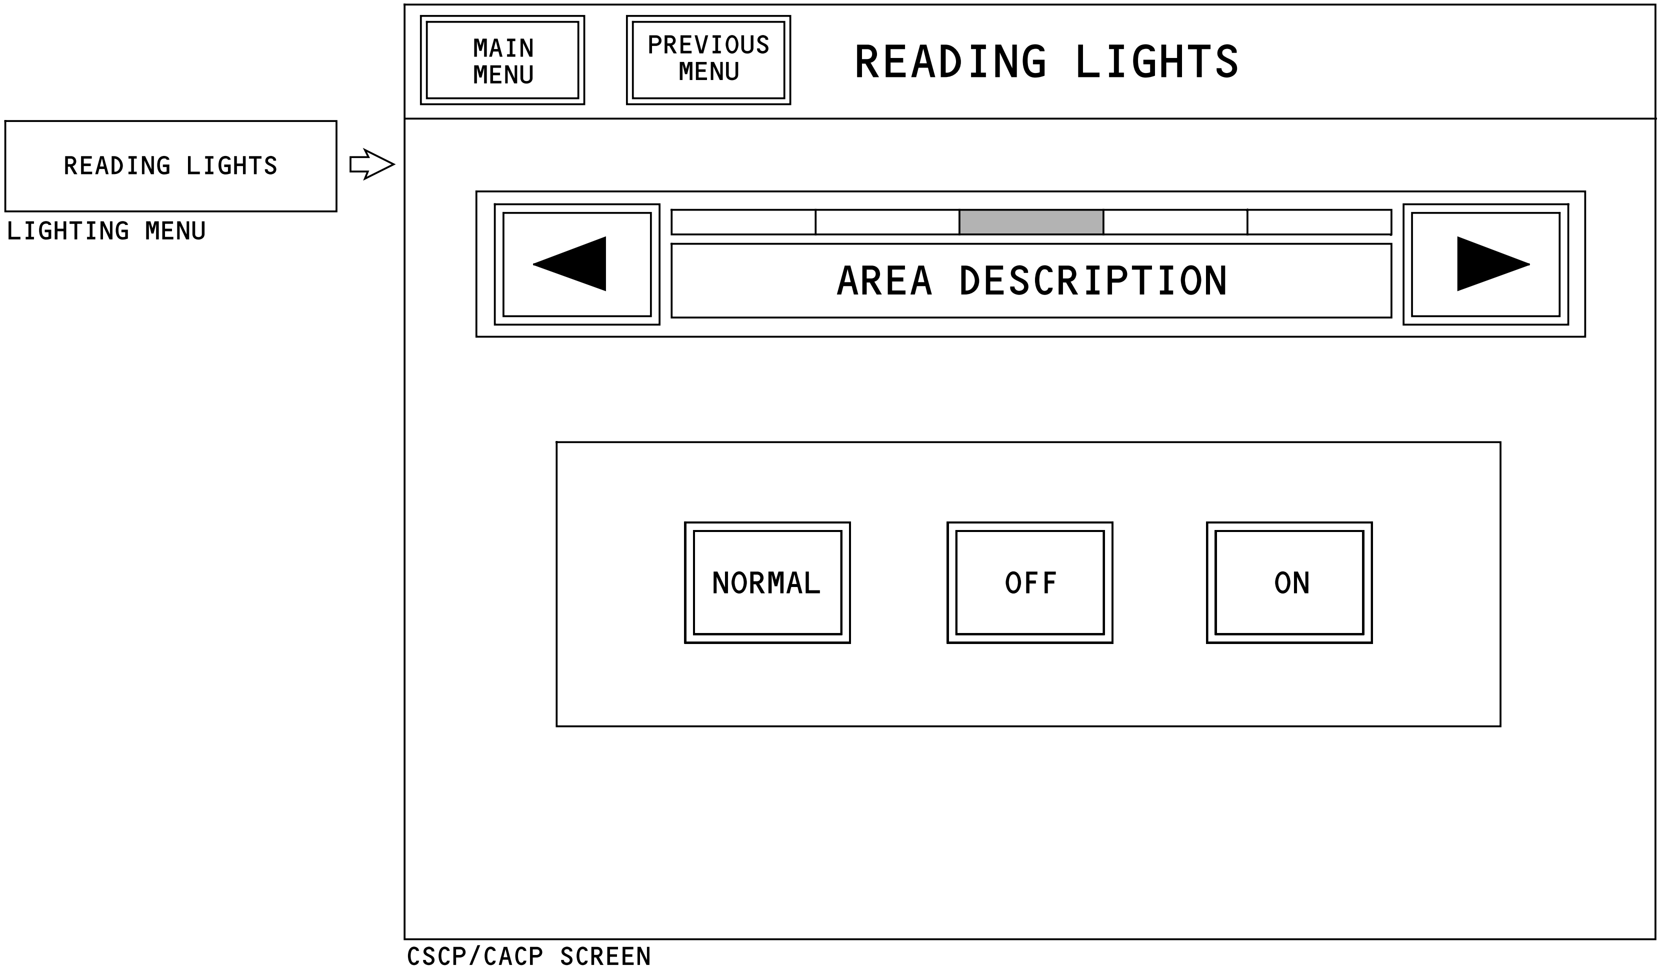
Touch NORMAL to let the passengers control their reading lights.

Touch OFF or ON to turn all reading lights in the selected area off or on. The screen selection shows green and the reading lights stay in the commanded mode until you make another selection.

Momentary Mode Operation

Touch ON or OFF to turn all reading lights in the selected area on or off. The screen selection changes to green for one-half second and the reading lights go to the commanded mode.

After one-half second, passengers can control their reading lights and the NORMAL selection on the panel changes to green.



23-33-00-022 Rev 1 03/26/96

PSS - OPERATION - READING LIGHTS SCREEN

PSS - OPERATION - SERVICE CALL/CHIME CONTROL MENU SCREEN

General

Attendants use the service call/chime control menu to select a screen that shows passenger calls. They can also select screens to control chimes.

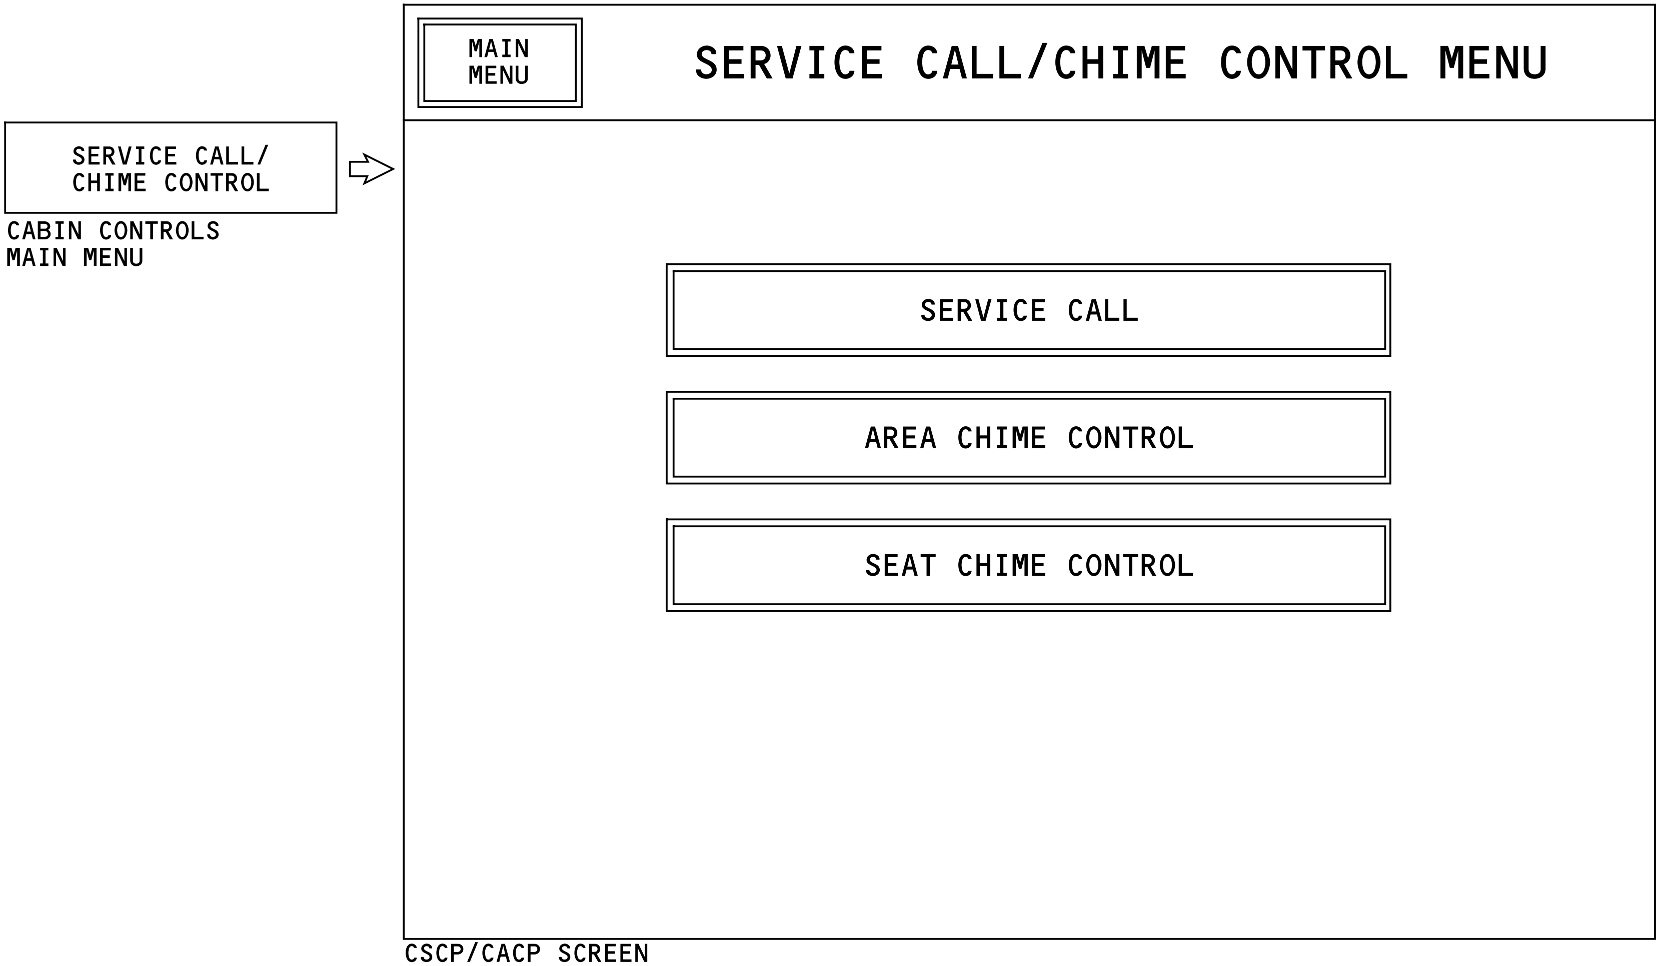
Access

Touch SERVICE CALL/CHIME CONTROL on the cabin controls main menu to show this screen.

Controls and Indications

Touch these selections to go to the screen that controls the related function:

- SERVICE CALL - to see passenger call data
- AREA CHIME CONTROL - to disable passenger-to-attendant chimes in a selected area
- SEAT CHIME CONTROL - to disable each passenger-to-attendant chime.



23-33-00-023 Rev 1 03/26/96

PSS - OPERATION - SERVICE CALL/CHIME CONTROL MENU SCREEN

PSS - OPERATION - SERVICE CALL SCREEN

General

Attendants use the service call screen to see active passenger-to-attendant calls and lavatory calls.

Access

Touch SERVICE CALL/CHIME CONTROL on the cabin controls main menu. Then touch SERVICE CALL to show this screen.

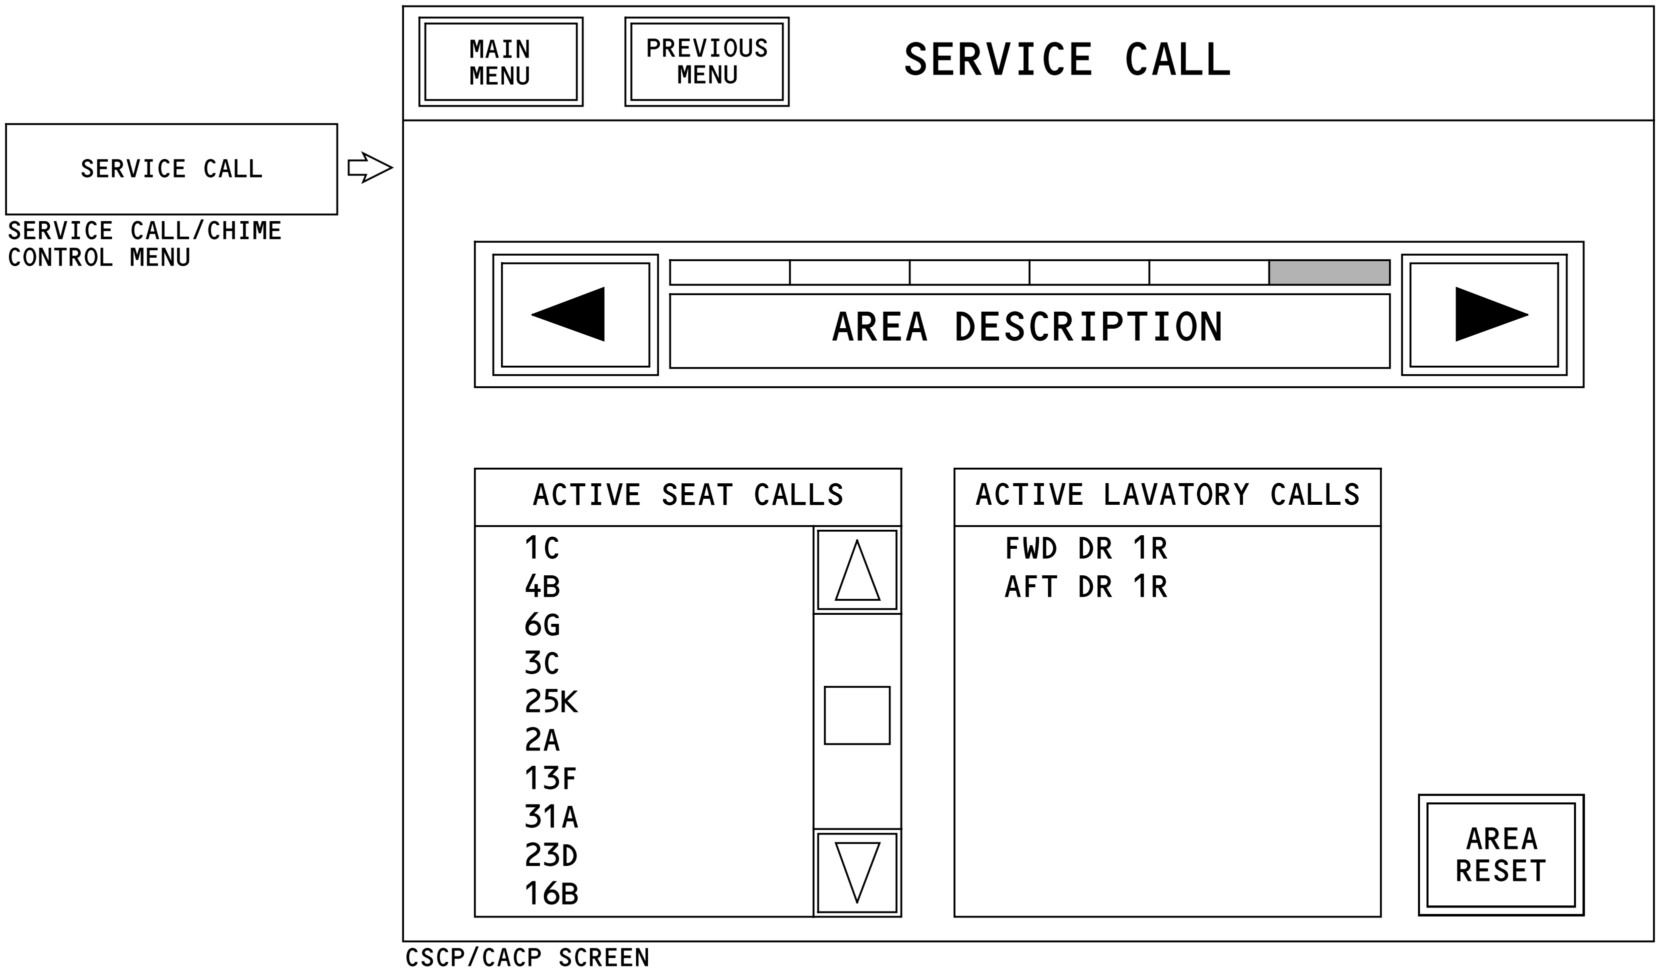
Controls and Indications

Use the left and right arrows to select the cabin areas. The space between the arrows shows the selected cabin area description.

The active seat calls and active lavatory calls areas on the screen show all active calls from the selected cabin area. The data on the display shows the locations of the calls in the order they were received.

Use the up and down arrows to scroll through the data in the active calls area.

Touch AREA RESET to cancel all active calls for the selected area.



PSS - OPERATION - SERVICE CALL SCREEN

23-33-00-024 Rev 1 03/26/96

PSS - OPERATION - AREA CHIME CONTROL SCREEN

General

Attendants use the area chime control screen to disable the passenger-to-attendant chimes in selected areas of the cabin.

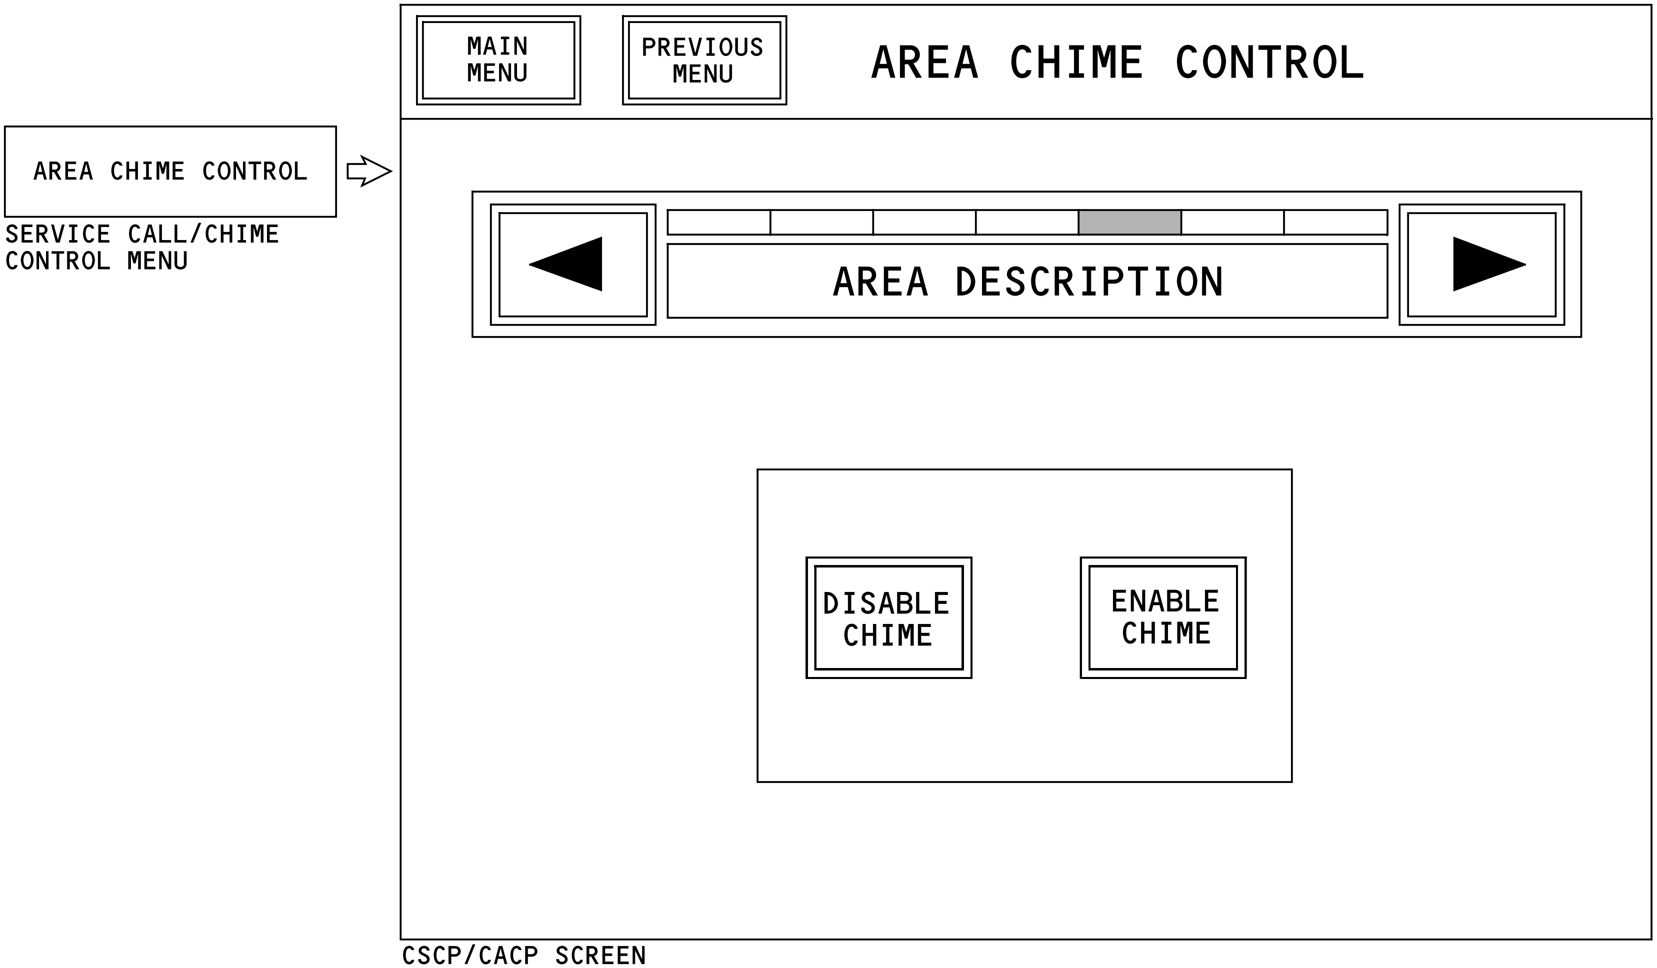
Access

Touch SERVICE CALL/CHIME CONTROL on the cabin controls main menu. Then touch AREA CHIME CONTROL on the service call/chime control menu to show this screen.

Controls and Indications

Touch the left or right arrow to select a cabin area. The space between the two arrows shows the cabin area description.

Touch ENABLE CHIME or DISABLE CHIME to enable or disable the passenger-to-attendant call chime for the selected area. These selections change to green to show the condition of the selected area.



23-33-00-025 Rev 1 03/26/96

PSS - OPERATION - AREA CHIME CONTROL SCREEN

PSS - OPERATION - SEAT CHIME CONTROL SCREEN

General

Attendants use the seat chime control screen to disable the passenger-to-attendant chimes at selected seats in the cabin.

Access

Touch SERVICE CALL/CHIME CONTROL on the cabin controls main menu. Then touch SEAT CHIME CONTROL to show this screen.

Controls and Indications

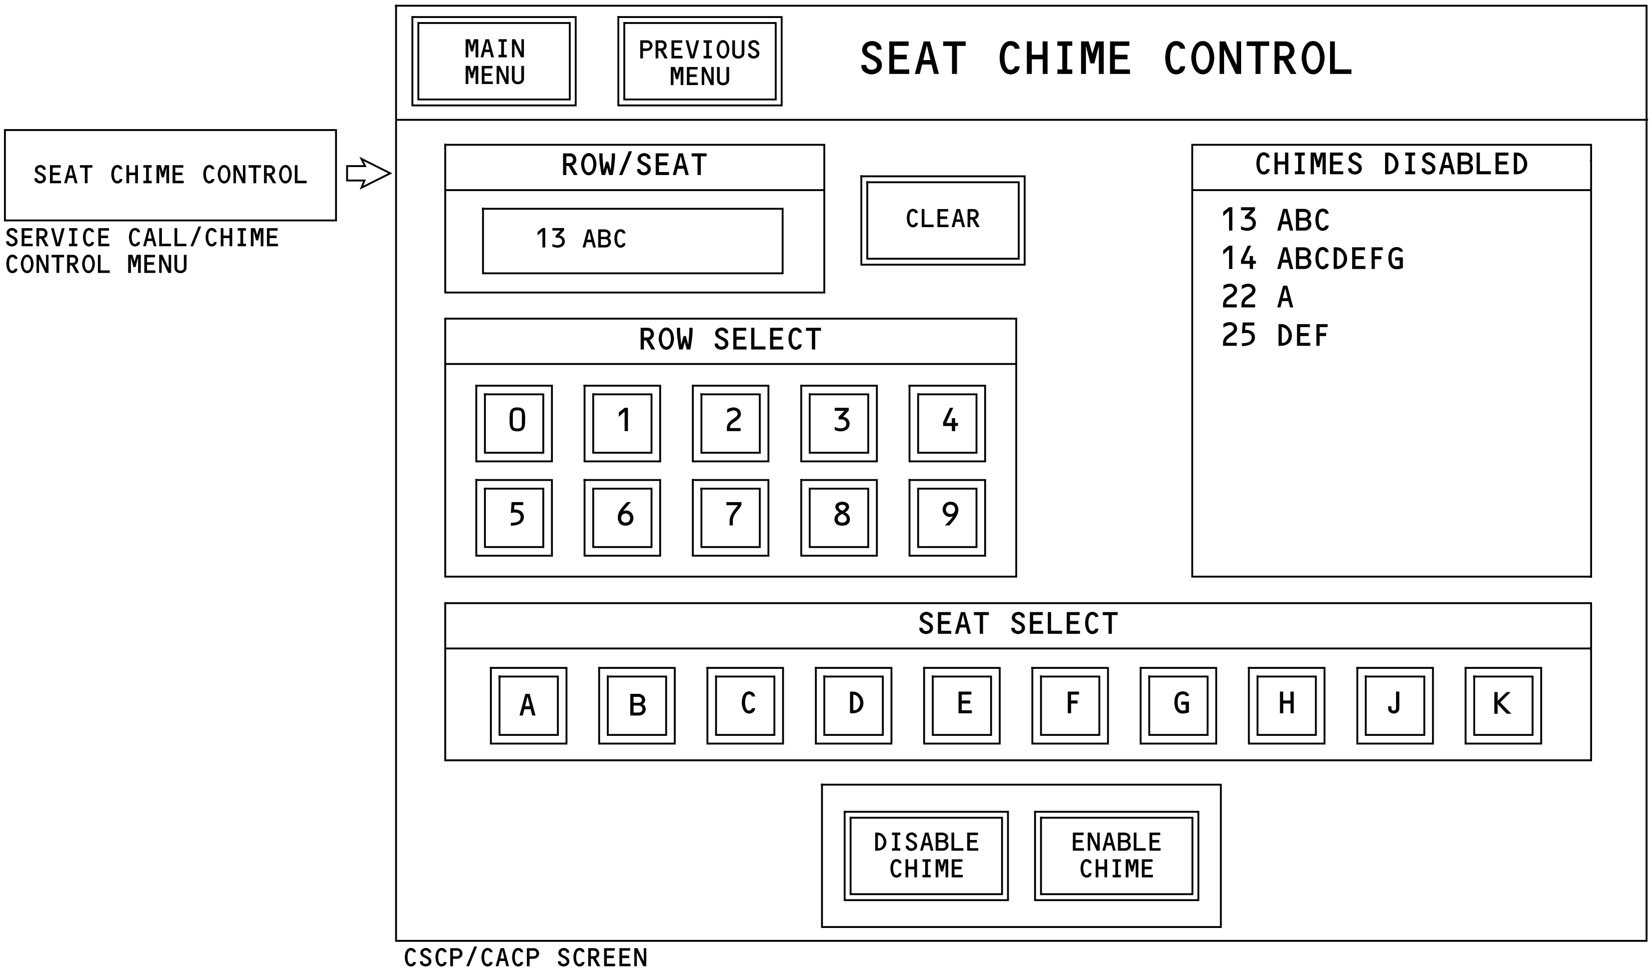
The configuration data base defines the row numbers and seat letters.

Touch the row select numbers and seat select letters to select seats. You must select the row before selecting a seat. If you only select a row and do not select any seats, the chime is enabled or disabled for all seats in the row.

The row/seat window above the numbers shows the selection.

Touch ENABLE CHIME or DISABLE CHIME to enable or disable the passenger-to-attendant call chime for the selected seats. Touch clear to clear the row/seat display.

The chimes disabled window shows all seats that have chimes disabled. Use the up and down arrows to scroll through the data.



23-33-00-026 Rev 1 03/26/96

PSS - OPERATION - SEAT CHIME CONTROL SCREEN

PSS - OPERATION - SMOKING ASSIGNMENTS SCREEN

General

Attendants use the smoking assignments screen to make changes to the smoking areas.

Access

Touch SMOKING ASSIGNMENTS on the cabin controls main menu to show this screen.

Controls and Indications

Use the left and right arrows to select the cabin areas. The space between the arrows shows the selected cabin area description.

Use the smoking row select up and down arrows to select a begin and end seat row. Use the selections in the seat column select area to select columns. If you do not select a column, any changes affect all columns.

Touch SMOKING or NO SMOKING to make the selected seats as smoking or no smoking.

The smoking seats area of this display shows all assigned smoking seats in the selected cabin area. Use the up and down arrows to scroll through the list.

Touch AREA RESET to cancel all changes to the selected area. Smoking seat assignments return to those identified by the configuration database.

PSS - OPERATION - SMOKING ASSIGNMENTS SCREEN

PSS - CABIN TESTS

General

Use the cabin system control panel (CSCP) to do the cabin test for the passenger service system (PSS).

See the cabin services system (CSS) section for more information about tests (AMM PART I 23-39).

Quick Test

Use quick test to quickly find major faults. This test does a check of these PSS components:

- Passenger address/cabin interphone (PA/CI) controller
- Cabin system management unit (CSMU)
- Zone management units (ZMUs)
- Overhead electronics units (OEUs).

This test collects continuous monitor data for as long as 20 seconds. The CSCP shows the failures.

To start a quick test, touch START QUICK TEST.

All Test

Use all test for a more complete test. All test starts a complete BITE of the system. The screen shows all the failures the BITE finds.

To start an all test, touch START ALL TEST.

Engineering Tests

Use engineering tests for more detailed tests.

Touch ENGINEERING TESTS to show the engineering tests menu.

Lamps Test

The lamps test does not test the PSS.

TABLE OF CONTENTS

THIS PAGE INTENTIONALLY LEFT BLANK

General

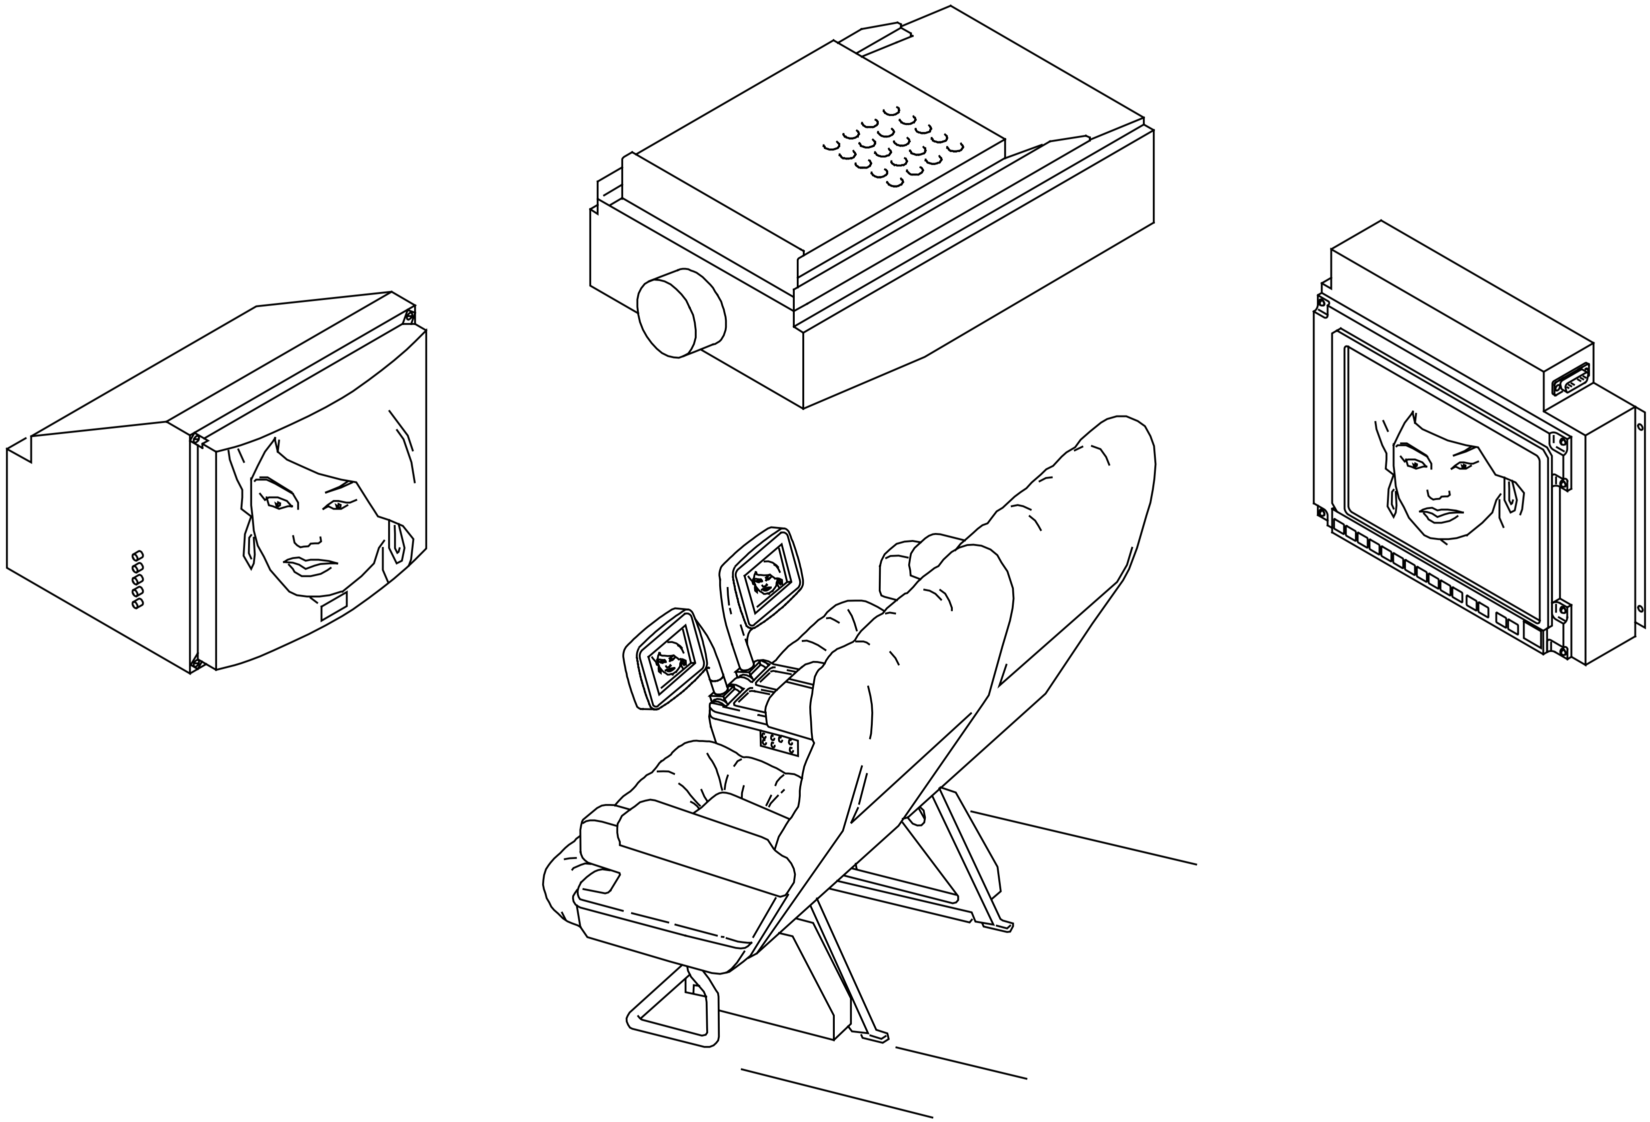
The passenger entertainment system (PES)-video supplies video entertainment to the passengers.

The in-flight entertainment (IFE) system vendor for an airline may use many different types of components to show video to the passengers. These are the types of components they may use:

- CRT and LCD monitors
- Video projectors
- Seat video displays.

Abbreviations and Acronyms

ADB - area distribution box
AIMS - airplane information management system
CCR - credit card reader
CDB - configuration data base
CD ROM - compact disk read only memory
CMEU - cabin management expansion unit
CMT - cabin management terminal
CSCP - cabin system control panel
CSMU - cabin system management unit
CSS - cabin services system
CTU - cabin telecommunications unit
DCMF - data communication management function
EPESC - enhanced passenger entertainment system controller
EVSCU - enhanced video system control unit
FDD - floppy disk drive
IFE - in-flight entertainment
IRS - inertial reference system
kbd - keyboard
LAN - local area network
NVM - non-volatile memory
PA/CI - passenger address/cabin interphone
PAS - passenger address system
pax tel - passenger telephone
PES - passenger entertainment system
PIIC - passenger in-flight information computer
PRAM - prerecorded announcement machine
RAD - random access device
RFCS - RF combiner/splitter
RFDA - RF distribution amplifier
SEB - seat electronics box
SSB - system setup box
SVD - seat video display
VDU - video distribution unit
VEP - video entertainment player
VHS - video helical scan
VMU - video modulator unit
ZIA - zone integration area
ZIU - zone integration unit
ZMU - zone management unit



IN-FLIGHT ENTERTAINMENT SYSTEM/PASSENGER ENTERTAINMENT SYSTEM-VIDEO - INTRODUCTION

IFE/PES-VIDEO - GENERAL DESCRIPTION

General

The passenger entertainment system (PES)-video gets video from many sources. Attendants can select a source and send video to the overhead video components.

For seats that have seat video displays, passengers may select and show one of many video channels on their display. In-flight entertainment (IFE) system software options may also let passengers make selections to play video games and buy duty free items.

Components

These are the types of components the PES-video may have:

- Video sources
- Head-end interface and control
- Zone interface and control
- Overhead video
- Local area network
- File servers for interactive functions
- Seat components.

The IFE connects to these other airplane systems and components:

- AIMS cabinets
- Cabin system management unit (CSMU)
- Passenger address system (PAS)
- Passenger telephone (pax tel) system
- Cabin system control panel (CSCP)
- Zone management unit (ZMU).

Video Sources

These components are the sources for video entertainment:

- Random access device (RAD)
- Passenger in-flight information computer (PIIC)
- Video entertainment players (VEPs).

Each video source sends its video signal to a video modulator unit (VMU). The VMUs put each video input on a different RF channel. Each VMU sends a mixed RF output to an RF combiner/splitter (RFCS). The RFCS combines the inputs and sends them to another RFCS.

The audio from the video sources goes to the enhanced video system control unit (EVSCU). The EVSCU changes the analog audio to digital and puts it on an RF carrier. It sends this RF signal to the enhanced passenger entertainment system controller (EPESC). The EPESC sends the digitized RF to an RFCS.

This RFCS mixes the video inputs with the RF audio from the EPESC and sends its output to another RFCS. The second RFCS sends the mixed RF signal to a seat electronics box (SEB) for the attendants to be able to see video selections on the cabin management terminal (CMT). The RFCS also sends the combined video signal to an RF distribution amplifier (RFDA) for distribution to the seats.

The RFDA amplifies the RF signal and sends it to the area distribution boxes (ADBs). The ADBs split the RF and send it to their related columns of SEBs.

The SEBs get video channel selections from the passengers. When a passenger makes a video channel selection, the SEB demodulates the RF signal and sends the selected video to the seat video display.

Interactive Video

Attendants use screens on the CMT to control the operation of the interactive functions.

The cabin management enhancement units (CMEUs) are the main controllers for interactive video. They are the file servers that store the interactive software. they connect to the LAN hub to provide game data and software storage for items such as in-flight sales data and configuration databases. The LAN hub allows many units to connect to each other on the network.

The EPESC connects to the LAN hub to send and get data to and from the passengers. Passengers use controllers at the seat to make game selections on the seat video display. The request goes from the related SEB to the ADB. The ADB sends the request to the EPESC. The EPESC gets the requested data from a CMEU and sends it back to the SEB through the ADB.

Interface and Control

Attendants may use a CMT to monitor and control all functions of the entertainment system. Maintenance technicians may also use screens on a CMT to test the system and install software. The CMT connects to the LAN hub to send commands and get data from other components in the system.

The system setup box (SSB) permits connection to the network for uploading and downloading data.

The CMT also connects to these components:

- Credit card reader (CCR)
- CD ROM drive
- Printer
- Keyboard (kbd)
- Floppy disk drive (FDD).

The cabin management terminal connects to a CD ROM drive to let you upload data to the system. You can only use the CD ROM on the ground.

The cabin system control panel (CSCP) may send print data to a CMT. The CMT then sends the data to the printer.

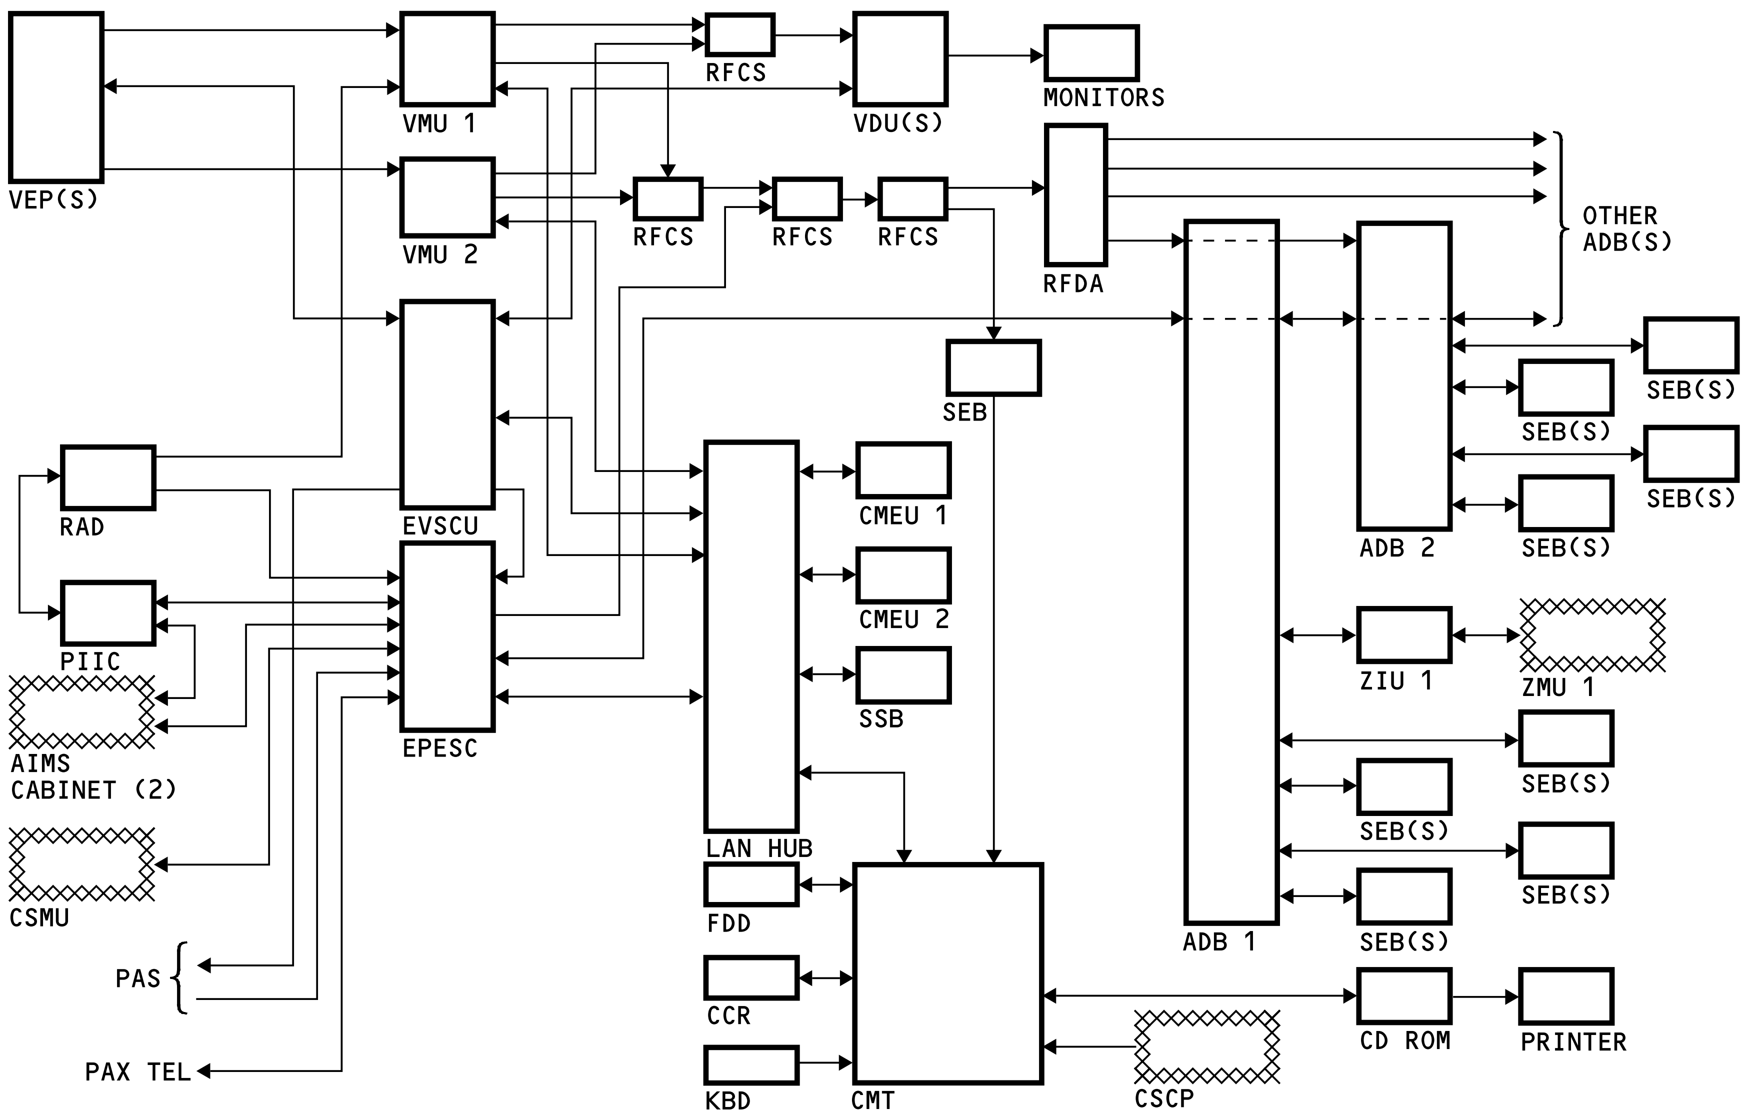
The EPESC connects to these other systems and components for the related functions:

IFE/PES-VIDEO - GENERAL DESCRIPTION

- Airplane information management system (AIMS) cabinets - send reports to the ground using ACARS and get uplink data from the data communication management function (DCMF)
- Cabin system management unit (CSMU) - sends and gets data such as airplane configuration and seating areas to and from the cabin services system (CSS)
- Passenger telephone (pax tel) - sends and gets telephone signals to and from the seat telephones if available
- Passenger address system (PAS) - gets PA override audio and keylines for passenger address announcements to the passenger headphones.

The passenger in-flight information computer (PIIC) connects to AIMS to get airplane data such as airspeed, location, and direction.

The EVSCU connects to the passenger address system to send video audio and related keylines for video announcements.



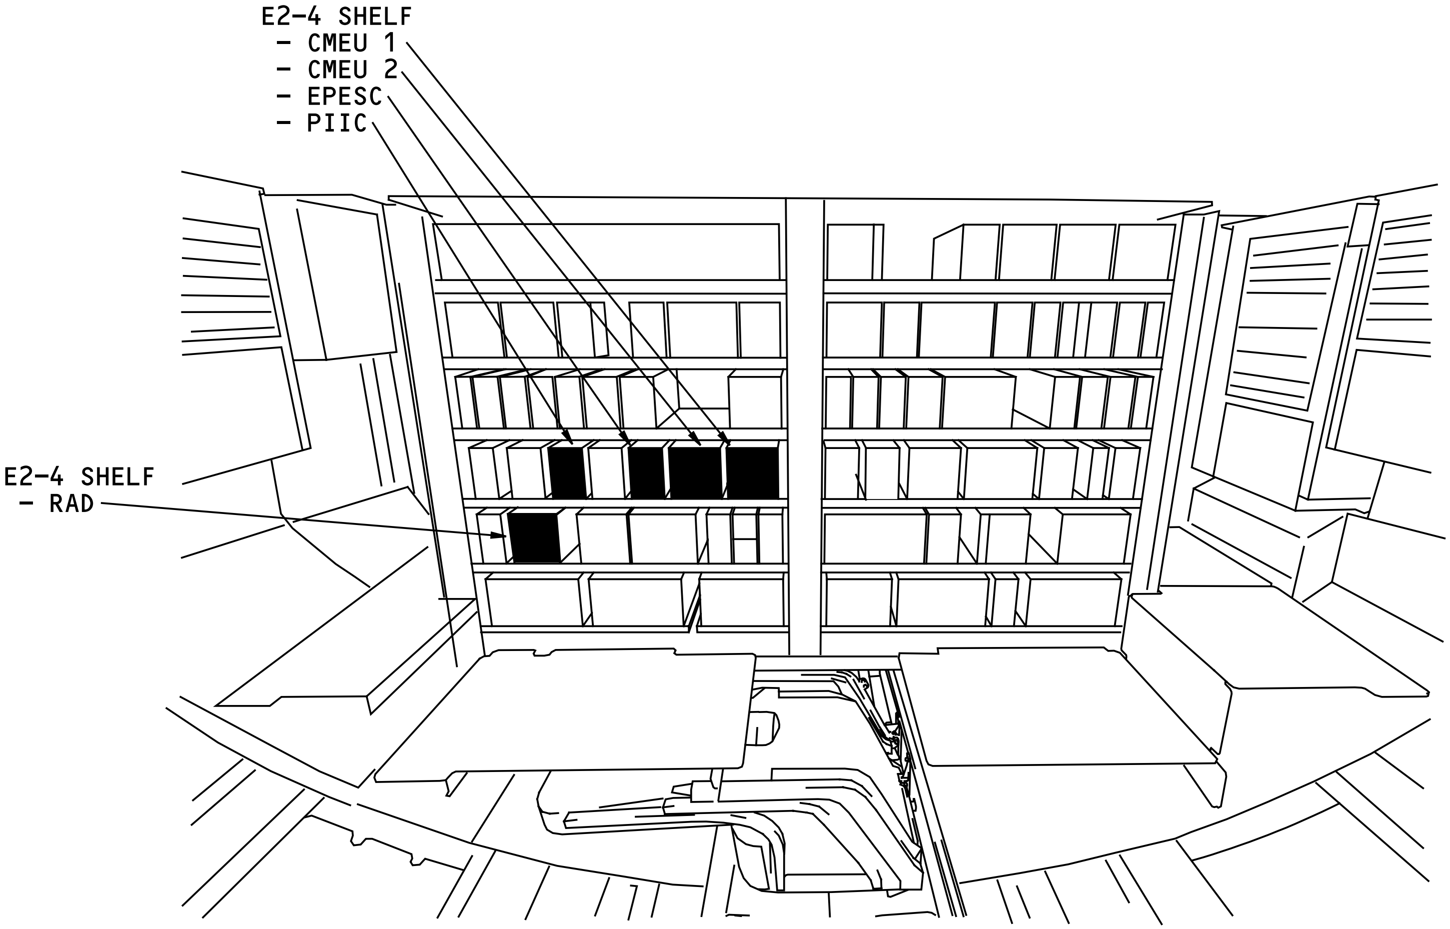
IFE/PES-VIDEO - GENERAL DESCRIPTION

IFE/PES-VIDEO - EQUIPMENT CENTER COMPONENT LOCATIONS

General

These in-flight entertainment components are in the main equipment center:

- Cabin management expansion unit (CMEU) 1 and 2
- Enhanced passenger entertainment system controller (EPESC)
- Random access device (RAD)
- Passenger in-flight information computer (PIIC).



MAIN EQUIPMENT CENTER
(LOOKING AFT)

23-32-00-502 Rev 11 02/24/1998

IFE/PES-VIDEO - EQUIPMENT CENTER COMPONENT LOCATIONS

IFE/PES-VIDEO - CABIN COMPONENT LOCATIONS

General

Many IFE components for PES-video are in the passenger cabin and above the cabin ceiling panels.

Cabin Area Components

The purser station has these IFE components:

- Credit card reader (CCR)
- Compact disk read only memory (CD ROM) drive
- Cabin management terminal (CMT)
- Enhanced video system control unit (EVSCU)
- Floppy disk drive (FDD)
- Keyboard
- Local area network (LAN) hub
- Printer
- RF combiner/splitters (RFCSs)
- RF distribution amplifier (RFDA)
- Seat electronics box (SEB)
- System setup box (SSB)
- Video modulation unit (VMU)
- Video entertainment players (VEPs).

Passenger Seat Components

Seats that have seat video displays (SVDs) also have seat electronics boxes (SEBs) under the passenger seats.

Passengers use controls at the seat to make video channel selections.

Overhead Video Components

Video monitors are on the class dividers and other vertical surfaces and over some doors.

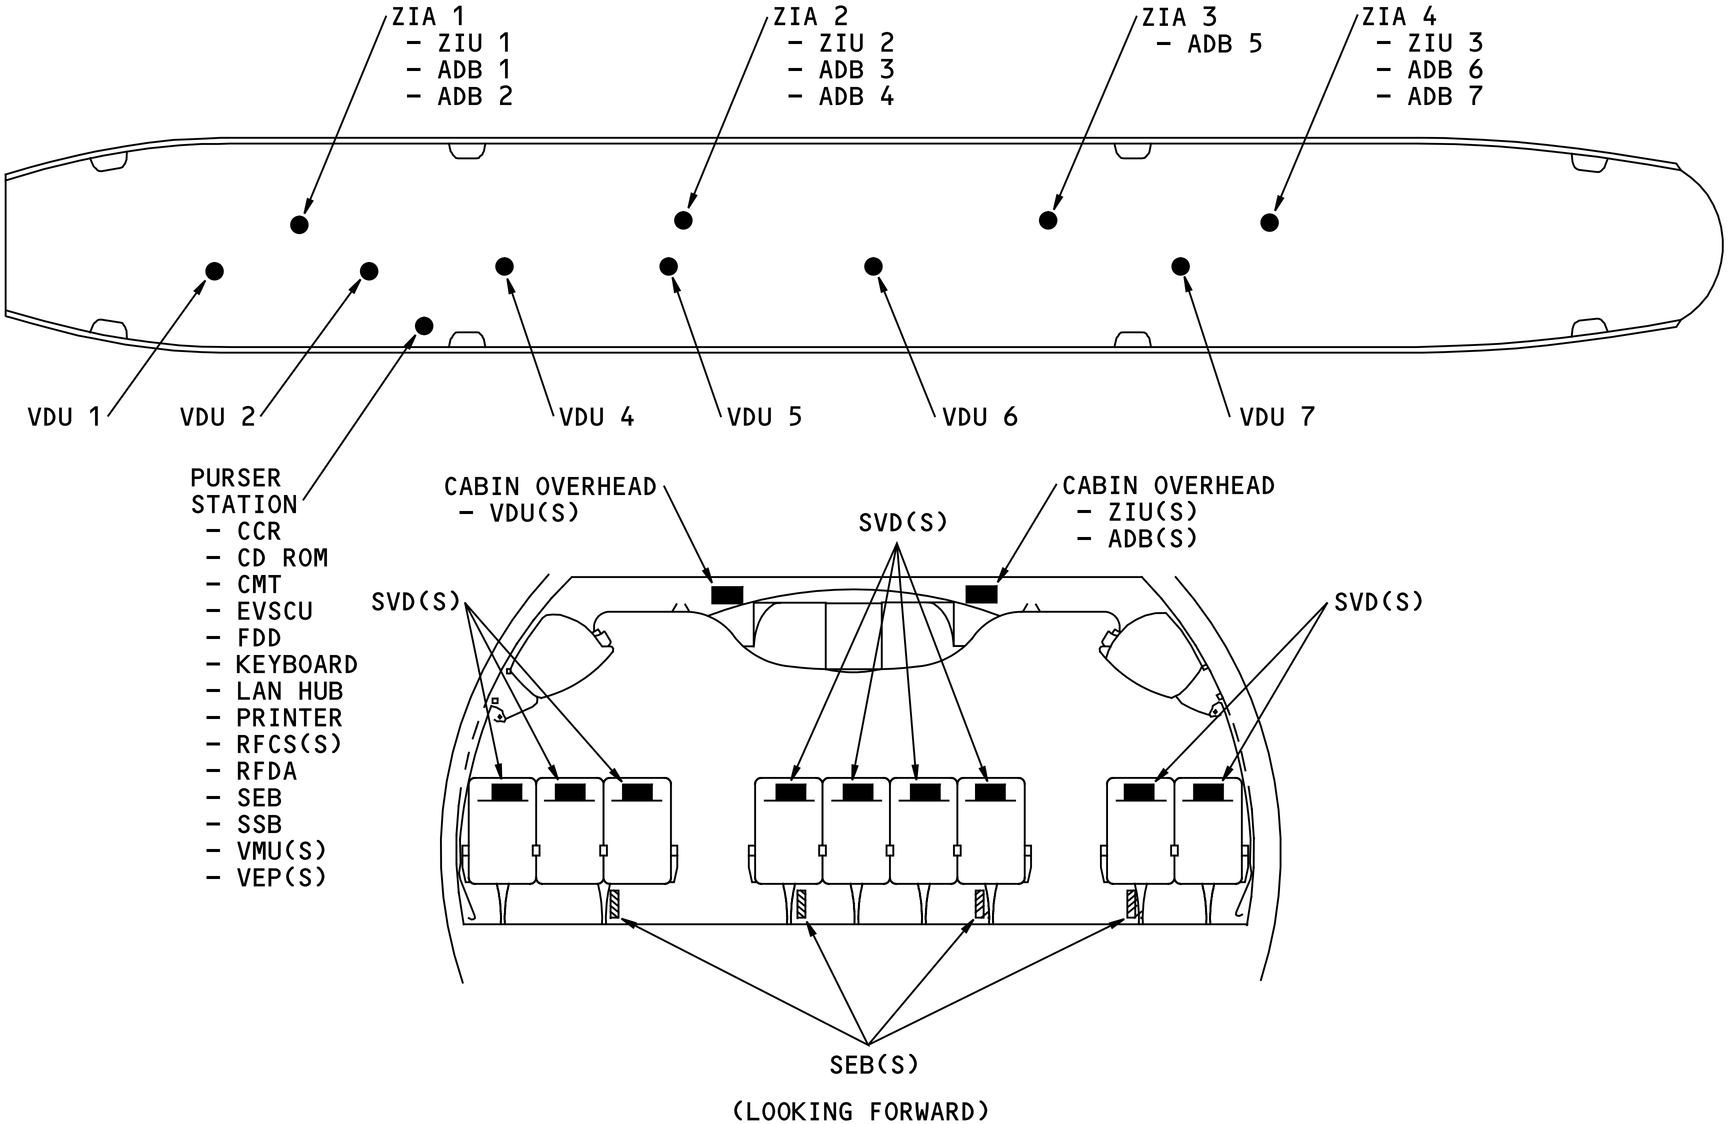
Some areas of the cabin may also have video projectors.

Video distribution units (VDUs) are on the left side of the crown area above the ceiling panels.

Zone Integration Areas

Some IFE components are on the right side of the crown area above the ceiling panels. These components are in locations called zone integration areas (ZIAs). There are four ZIAs.

Zone integration units (ZIUs) and area distribution boxes (ADBs) are in ZIA 1, ZIA 2, and ZIA 4. ZIA 3 has only one ADB.



IFE/PES-VIDEO - CABIN COMPONENT LOCATIONS

THIS PAGE INTENTIONALLY LEFT BLANK

IFE/PES-VIDEO - POWER INTERFACES

General

Power for the PES-video comes through the P110 left power management panel and the P210 right power management panel.

Circuit breakers control power to these PES-video components:

- Enhanced passenger entertainment system controller (EPESC)
- Cabin management expansion units (CMEUs)
- Enhanced video system control unit (EVSCU)
- 8 Passenger entertainment system controller-audio (PESC-A) 1 and 2
- Video entertainment players (VEPs)
- Cabin management terminal (CMT)
- Video modulation units (VMUs)
- Random access device (RAD)
- Passenger in-flight information computer (PIIC)
- Local area network (LAN) hub
- System setup box (SSB)
- RF distribution amplifier (RFDA)
- Compact disk read only memory (CD ROM) drive
- Seat electronics box (SEB)
- Printer
- Video distribution units (VDUs).

P110 Left Power Management Panel

The MULTP AUDIO ENTMT CTRL circuit breaker connects 115v ac through the audio entertainment player (AEP) relay to these LRUs:

- RAD
- EPESC
- CMEU 1 and 2

The ENTMT CTRL L circuit breaker connects 28v dc to the AEP relay. The ELMS electronic unit connects a ground to energize the relay during load shedding. When the relay energizes, it removes power from the components.

The VIDEO DISTR 1 circuit breaker connects 115v ac power to VDU 2.

The VIDEO DISTR 2 circuit breaker connects 115v ac power to VDU 4. VDU 4 connects 115v ac power to VDU 5.

P210 Right Power Management Panel

The VIDEO PGMS & CTRL circuit breaker connects 115v ac through the video programs and control relay to these LRUs:

- EVSCU
- CMT
- CD ROM
- VMU
- LAN hub
- SSB

IFE/PES-VIDEO - POWER INTERFACES

- RFDA
- SEB.

The VIDEO PGMS & CTRL B circuit breaker connects 115v ac through the video programs and control relay and a relay in the purser station to all video entertainment players (VEPs). The EVSCU controls the relay in the purser station. When the EVSCU connects a ground to the relay, it energizes and removes power from all VEPs.

The ENTMT CTRL R circuit breaker connects 28v dc to these components:

- Video programs and control relay
- A relay in the purser station
- RAD
- PIIC.

The ELMS electronic unit connects a ground to energize the video programs and control relay during load shedding. When the relay energizes, it removes power from the components.

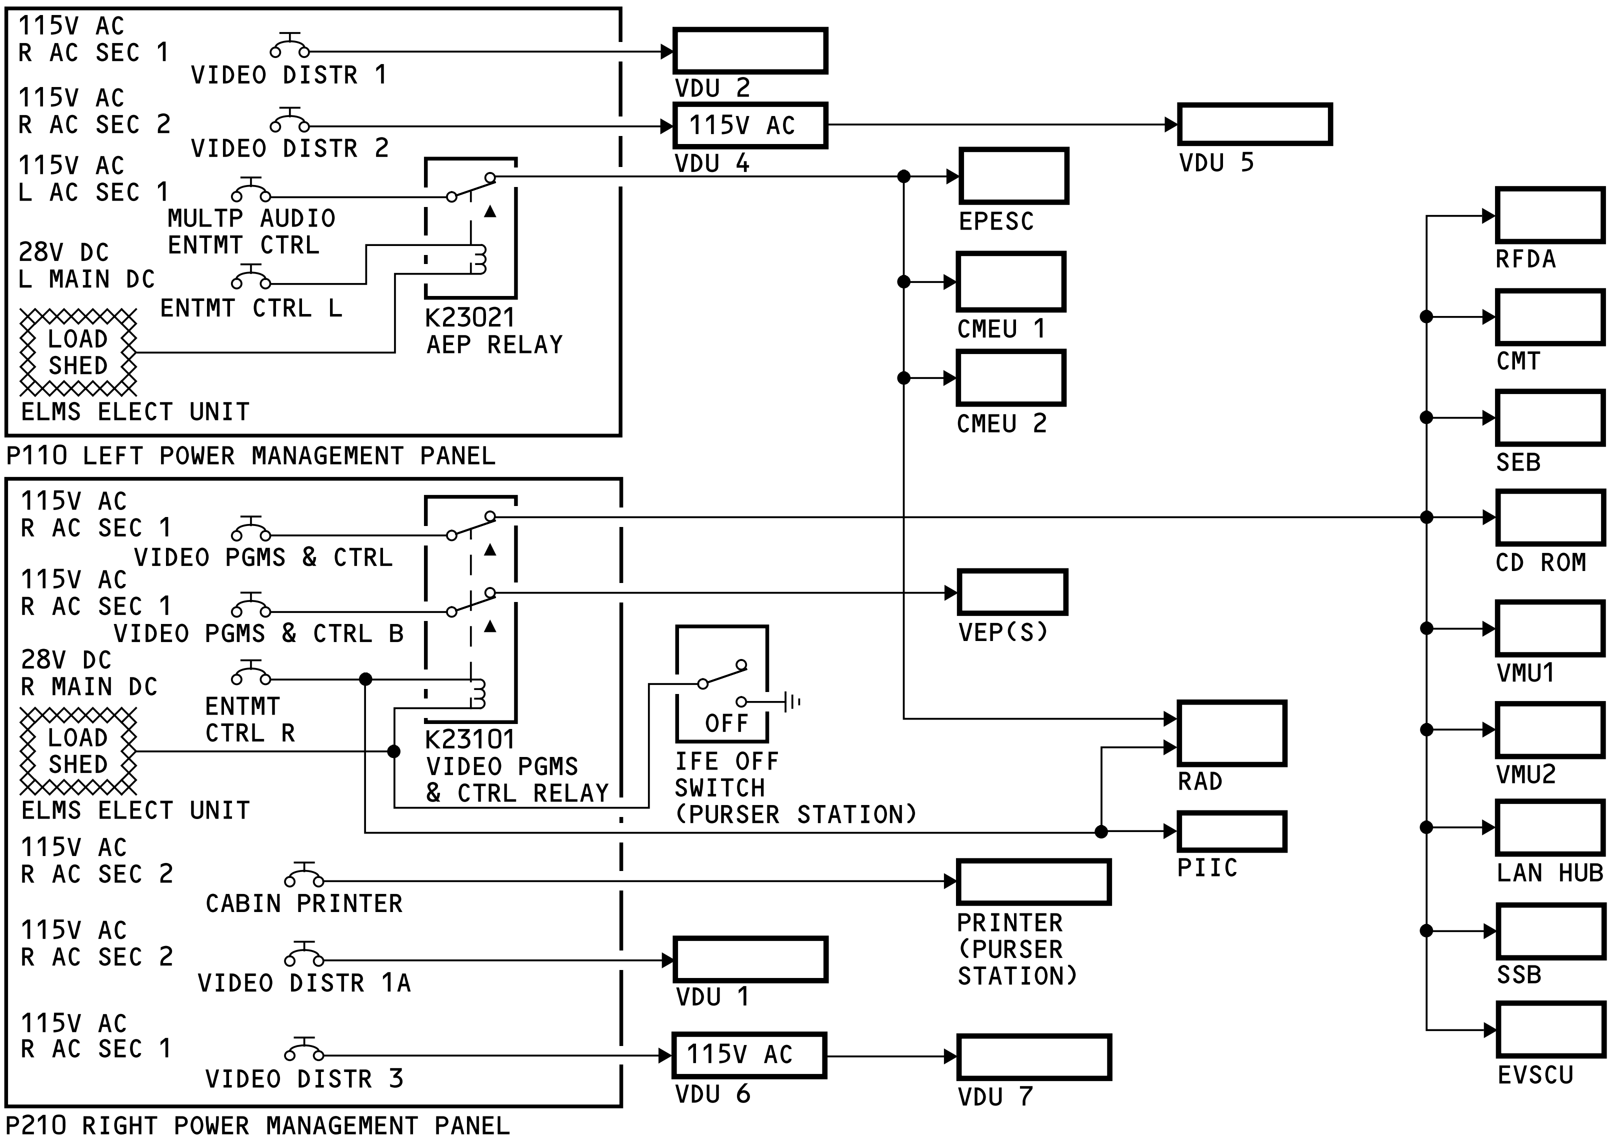
You can also use the IFE off switch in the purser station to remove power from the components. In the OFF position, the switch connects a ground to energize the video programs and control relay.

The CABIN PRINTER circuit breaker connects 115v ac to the printer in the purser station.

The VIDEO DISTR 1A circuit breaker connects 115v ac power to VDU 1.

The VIDEO DISTR 1 circuit breaker connects 115v ac power to VDU 2.

The VIDEO DISTR 2 circuit breaker connects 115v ac power to VDU 4. VDU 4 connects 115v ac power to VDU 5.



IFE/PES-VIDEO - POWER INTERFACES

23-32-00-505 Rev 11 02/24/1998

IFE/PES-VIDEO - ZONE INTEGRATION AREA 1 POWER INTERFACES

General

Circuit breakers and a relay on the P210 right power management panel controls power to the components in zone integration area 1.

Power

The IFE ZIA 1 circuit breaker connects 115v ac, three-phase power to the IFE ZIA 1 relay. The relay connects two phases of the power to the area distribution boxes (ADBs). Each ADB gets power from a different phase.

The ENTMT CTRL R circuit breaker connects 28v dc to the IFE ZIA 1 relay.

Relay Control

The ELMS electronic unit connects a ground to energize the relay during load shedding. When the relay energizes, it removes power from the components in the zone integration area.

You can also use the IFE off switch in the purser station to remove power from the relay. In the OFF position, the switch connects a ground to energize the relay.

IFE/PES-VIDEO - ZONE INTEGRATION AREA 2 POWER INTERFACES

General

Circuit breakers and a relay on the P110 left power management panel controls power to the components in zone integration area 2.

Power

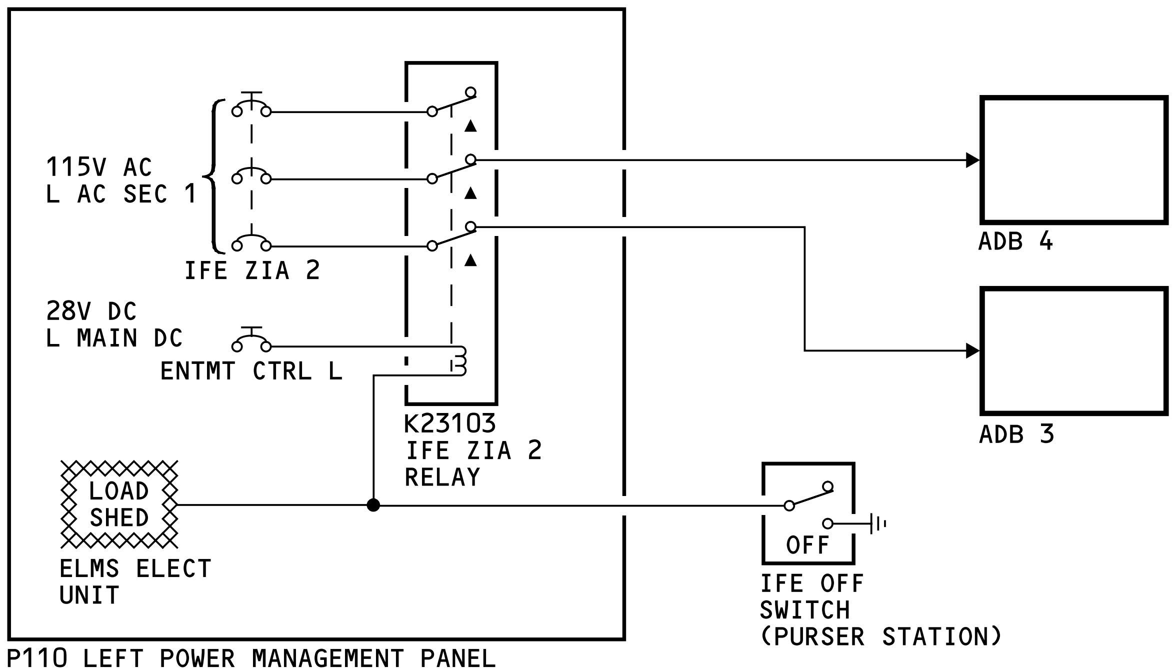
The IFE ZIA 2 circuit breaker connects 115v ac three-phase power to the IFE ZIA 2 relay. The relay connects two phases of the power to the area distribution boxes (ADBs). Each ADB gets power from a different phase.

The ENTMT CTRL L circuit breaker connects 28v dc to the IFE ZIA 2 relay.

Relay Control

The ELMS electronic unit connects a ground to energize the relay during load shedding. When the relay energizes, it removes power from the components in the zone integration area.

You can also use the IFE off switch in the purser station to remove power from the relay. In the OFF position, the switch connects a ground to energize the relay.



23-32-00-507 Rev 8 02/24/1998

IFE/PES-VIDEO - ZONE INTEGRATION AREA 2 POWER INTERFACES

IFE/PES-VIDEO - ZONE INTEGRATION AREA 3 POWER INTERFACES

General

Circuit breakers and a relay on the P110 left power management panel controls power to the components in zone integration area 3.

Power

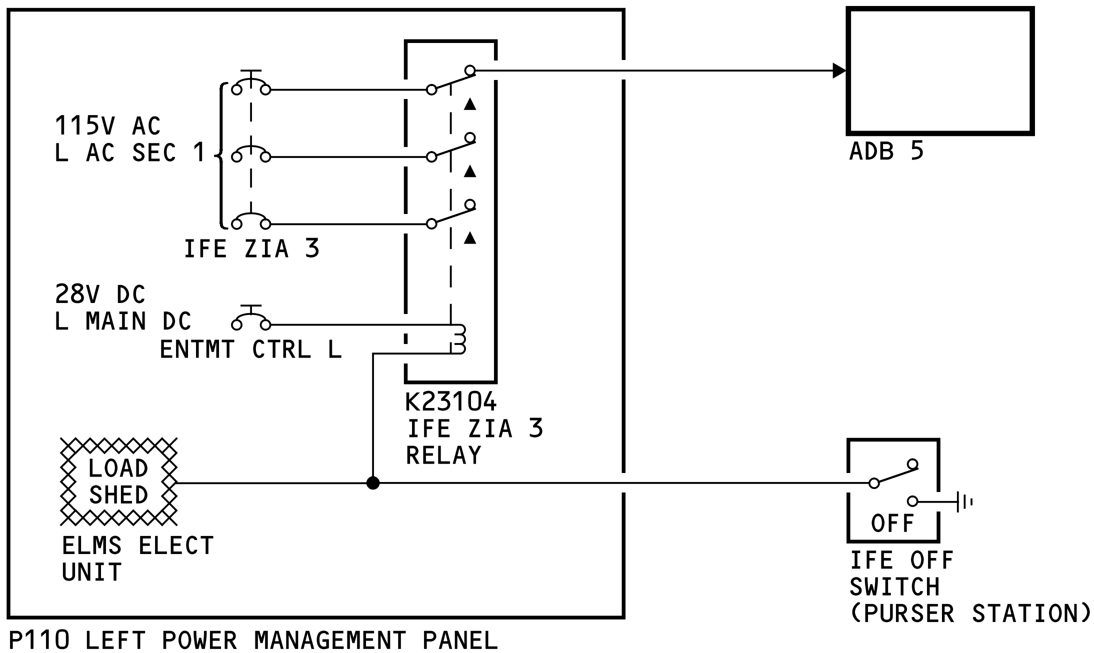
The IFE ZIA 3 circuit breaker connects 115v ac three-phase power to the IFE ZIA 3 relay. The relay connects only one phase of the power to area distribution box (ADB) 5.

The ENTMT CTRL L circuit breaker connects 28v dc to the IFE ZIA 3 relay.

Relay Control

The ELMS electronic unit connects a ground to energize the relay during load shedding. When the relay energizes, it removes power from the components in the zone integration area.

You can also use the IFE off switch in the purser station to remove power from the relay. In the OFF position, the switch connects a ground to energize the relay.



IFE/PES-VIDEO - ZONE INTEGRATION AREA 3 POWER INTERFACES

IFE/PES-VIDEO - ZONE INTEGRATION AREA 4 POWER INTERFACES

General

Circuit breakers and a relay on the P210 right power management panel controls power to the components in zone integration area 4.

Power

The IFE ZIA 4 circuit breaker connects 115v ac three-phase power to the IFE ZIA 4 relay. The relay connects two phases of the power to the area distribution boxes (ADBs). Each ADB gets power from a different phase.

The ENTMT CTRL R circuit breaker connects 28v dc to the IFE ZIA 4 relay.

Relay Control

The ELMS electronic unit connects a ground to energize the relay during load shedding. When the relay energizes, it removes power from the components in the zone integration area.

You can also use the IFE off switch in the purser station to remove power from the relay. In the OFF position, the switch connects a ground to energize the relay.

IFE/PES-VIDEO - ZONE INTEGRATION AREA 4 POWER INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

IFE/PES-VIDEO - AIRPLANE INTERFACES

General

The in-flight entertainment (IFE) equipment connects to these other airplane system components:

- Passenger address/cabin interphone (PA/CI) controller
- Right and left AIMS cabinets
- Cabin system management unit (CSMU)
- Prerecorded announcement machine (PRAM)
- Cabin telecommunications unit (CTU)
- Cabin system control panel (CSCP)
- Zone management unit (ZMU).

Passenger Address Interfaces

The enhanced video system control unit (EVSCU) can send as many as four video audio outputs and related keylines to the PA/CI controller. It also sends a signal through the cabin interphone controller to tell the flight crew when the video system is in use. The EVSCU gets a decompression discrete from the PA/CI controller when necessary.

The PA/CI controller sends as many as six channels of passenger address (PA) audio and related keylines to the enhanced passenger entertainment system controller (EPESC). The different channels relate to passenger address areas in the cabin that the configuration database defines. The IFE sends this audio to the passenger headphones. The PA/CI controller also sends a PA-All keyline for announcements in all areas of the cabin.

The EPESC connects to the PRAM to control automatic announcements and boarding music.

AIMS Interfaces

The right and left AIMS cabinets connect to the passenger in-flight information computer (PIIC) and the EPESC.

The PIIC can get this data from these AIMS buses:

- General purpose bus 1 - universal time, time and distance to destination, and present position
- Inertial reference system (IRS) bus - ground speed, track angle, and wind speed and direction
- General purpose bus 3 - altitude, airspeed, and air temperature.

The PIIC can also send and get cabin ACARS data to and from the EPESC. This data may be messages or other items uplinked from the ground and shown on the video displays.

The EPESC connects to the left and right data communication management function (DCMF) buses to get messages or other data from the ground. The EPESC can send messages to the ground or the PIIC on a cabin ACARS bus.

Other Interfaces

The EPESC connects to the cabin system management unit (CSMU) with an ARINC 628 head end bus. This connection

IFE/PES-VIDEO - AIRPLANE INTERFACES

lets the in-flight entertainment system and the cabin services system send configuration data to each other.

The EPESC also connects to the CTU with a standard CEPT-E1 telephone interface. This connection lets passengers make telephone calls on individual seat telephones if installed.

Each zone integration unit (ZIU) connects to a zone management unit of the cabin services system (CSS) with a zone bus. This connection permits passenger service system functions such as reading light control and passenger to attendant calls.

The cabin system control panel of the CSS can send print data to the cabin management terminal (CMT) on an RS-232 data bus. The CMT sends the data to a cabin printer if installed.

IN-FLIGHT ENTERTAINMENT SYSTEM/PASSENGER ENTERTAINMENT SYSTEM-AUDIO - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

IFE/PES-AUDIO - GENERAL DESCRIPTION

General

The in-flight entertainment (IFE) system gets audio from many sources. The passengers select audio channels to hear the audio in their headphones. During passenger address (PA) announcements, passengers hear the PA audio in their headphones.

Components

These are the types of IFE components that PES-audio may have:

- Audio sources
- Video sources
- Head-end interface and control
- Zone interface and control
- Seat components.

The IFE system connects to these other airplane systems and components:

- Passenger entertainment system (PES)-video
- Passenger address system (PAS)
- Cabin system management unit (CSMU).

Audio Sources

These IFE components are the sources for audio entertainment:

- Audio entertainment players (AEPs)
- Video source components.

The audio sources send audio signals to the enhanced video system control unit (EVSCU).

The EVSCU changes the audio from analog to digital. The EVSCU then compresses and multiplexes it and sends this audio signal to the enhanced passenger entertainment system controller (EPESC).

The EPESC puts this signal on an RF carrier and sends it to an RF combiner/splitter (RFCS). This RFCS combines the audio signal with video RF from the video system.

The RFCS sends the signal to a second RFCS where the signal splits. This RF signal goes to the seat electronics box (SEB) for the attendants to preview the audio selections at the cabin management terminal (CMT).

The other RF signal from the second RFCS goes to an RF distribution amplifier (RFDA). The RFDA increases the RF signal strength and sends it to the area distribution boxes (ADBs). The ADBs split the RF and send it to their related columns of SEBs.

The SEBs at the passenger seats get audio channel selections from the passengers. When a passenger makes an audio channel selection, the SEB demodulates the RF signal and sends the audio to the passenger headphones.

When the EPESC gets a PA announcement, it changes the PA audio from analog to digital. It then puts the signal in the place of the entertainment audio in the

IFE/PES-AUDIO - GENERAL DESCRIPTION

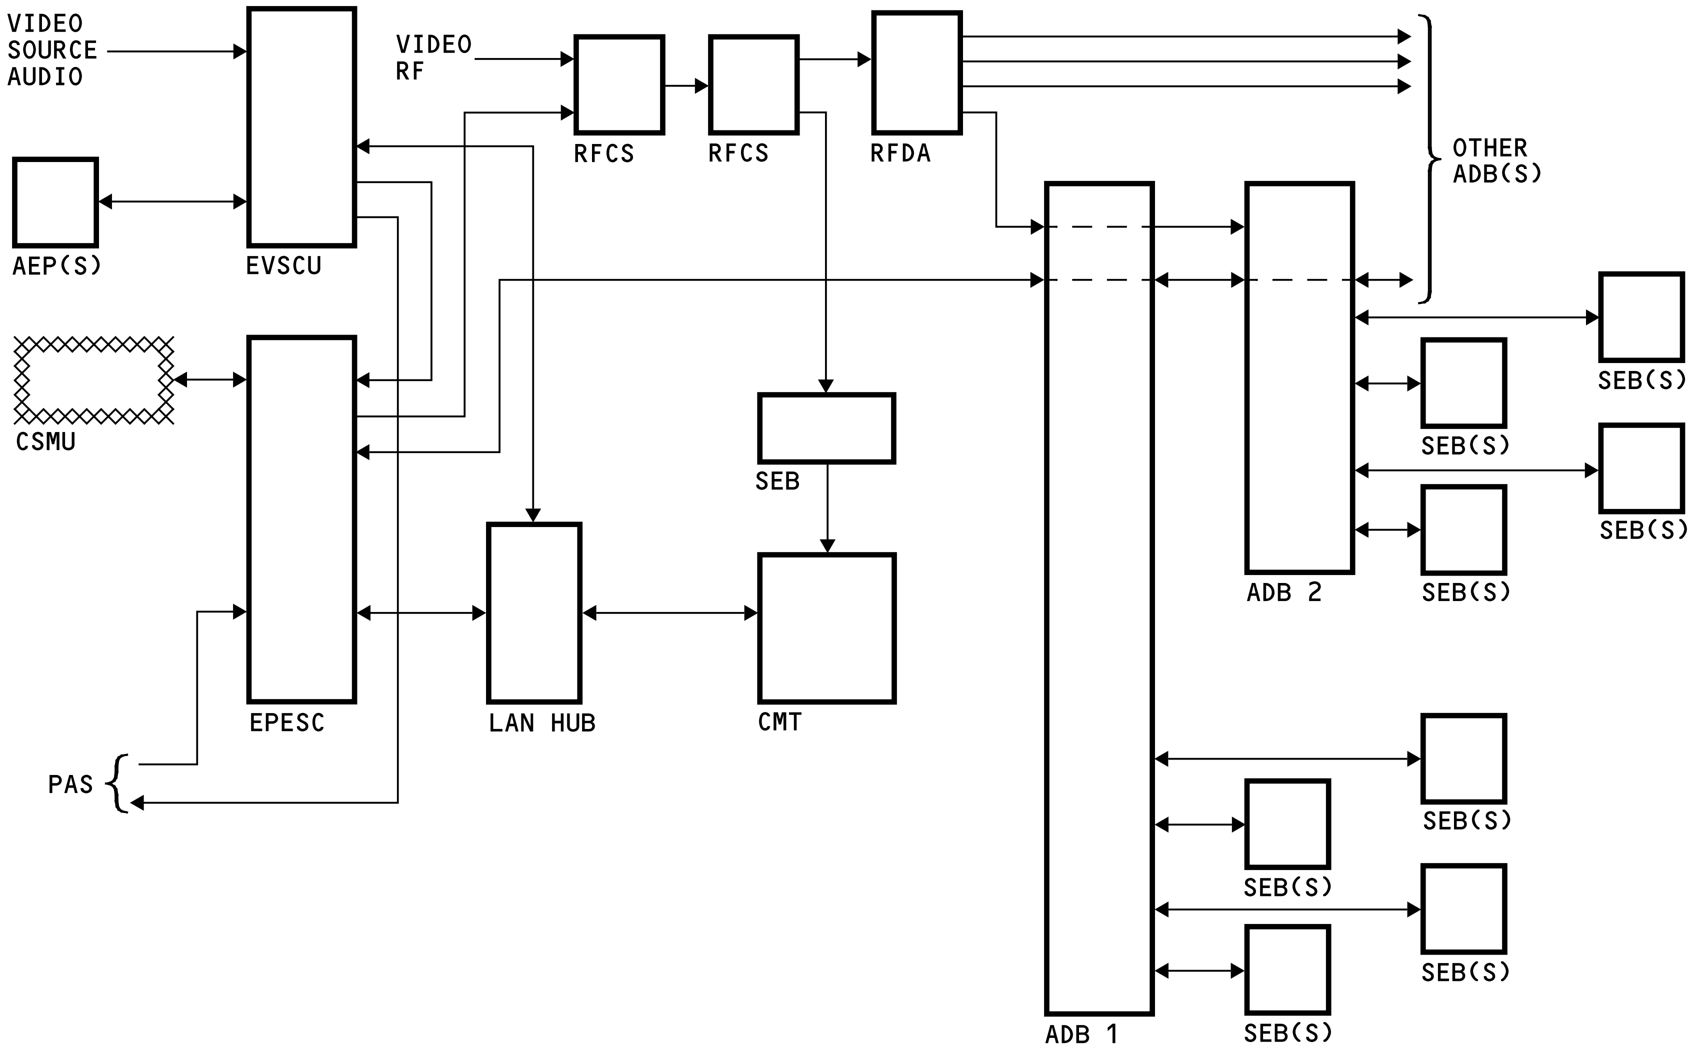
data stream. The EPESC puts this signal on an RF carrier and sends it to the area distribution boxes (ADBs). The EPESC sends data on a digital bus to the ADBs. This data tells the ADBs to demodulate the PA audio signals from the RF signal. The ADBs send this PA audio through the SEBs to the passenger headphones.

Interface and Control

The EPESC connects to these other systems and components for the related functions:

- Cabin system management unit (CSMU) - sends and gets data, such as airplane configuration and seating areas to and from the cabin services system (CSS)
- Passenger address system (PAS) - gets PA override audio and keylines from passenger address announcements to the passenger headphones.

Attendants use the CMT to control the audio entertainment. Control signals from the CMT go through the local area network (LAN) hub to the EVSCU and EPESC.



IFE/PES-AUDIO - GENERAL DESCRIPTION

IFE/PES-AUDIO - CABIN COMPONENT LOCATIONS

General

Many of the IFE components for PES-audio are in the passenger cabin and above the cabin ceiling panels.

Cabin Area Components

The purser station has these IFE components:

- Audio entertainment players (AEPs)
- Cabin management terminal (CMT)
- Enhanced video system control unit (EVSCU)
- Local area network (LAN) hub
- Radio frequency combiner/splitters (RFCSs)
- RF distribution amplifier (RFDA)
- Seat electronics box (SEB).

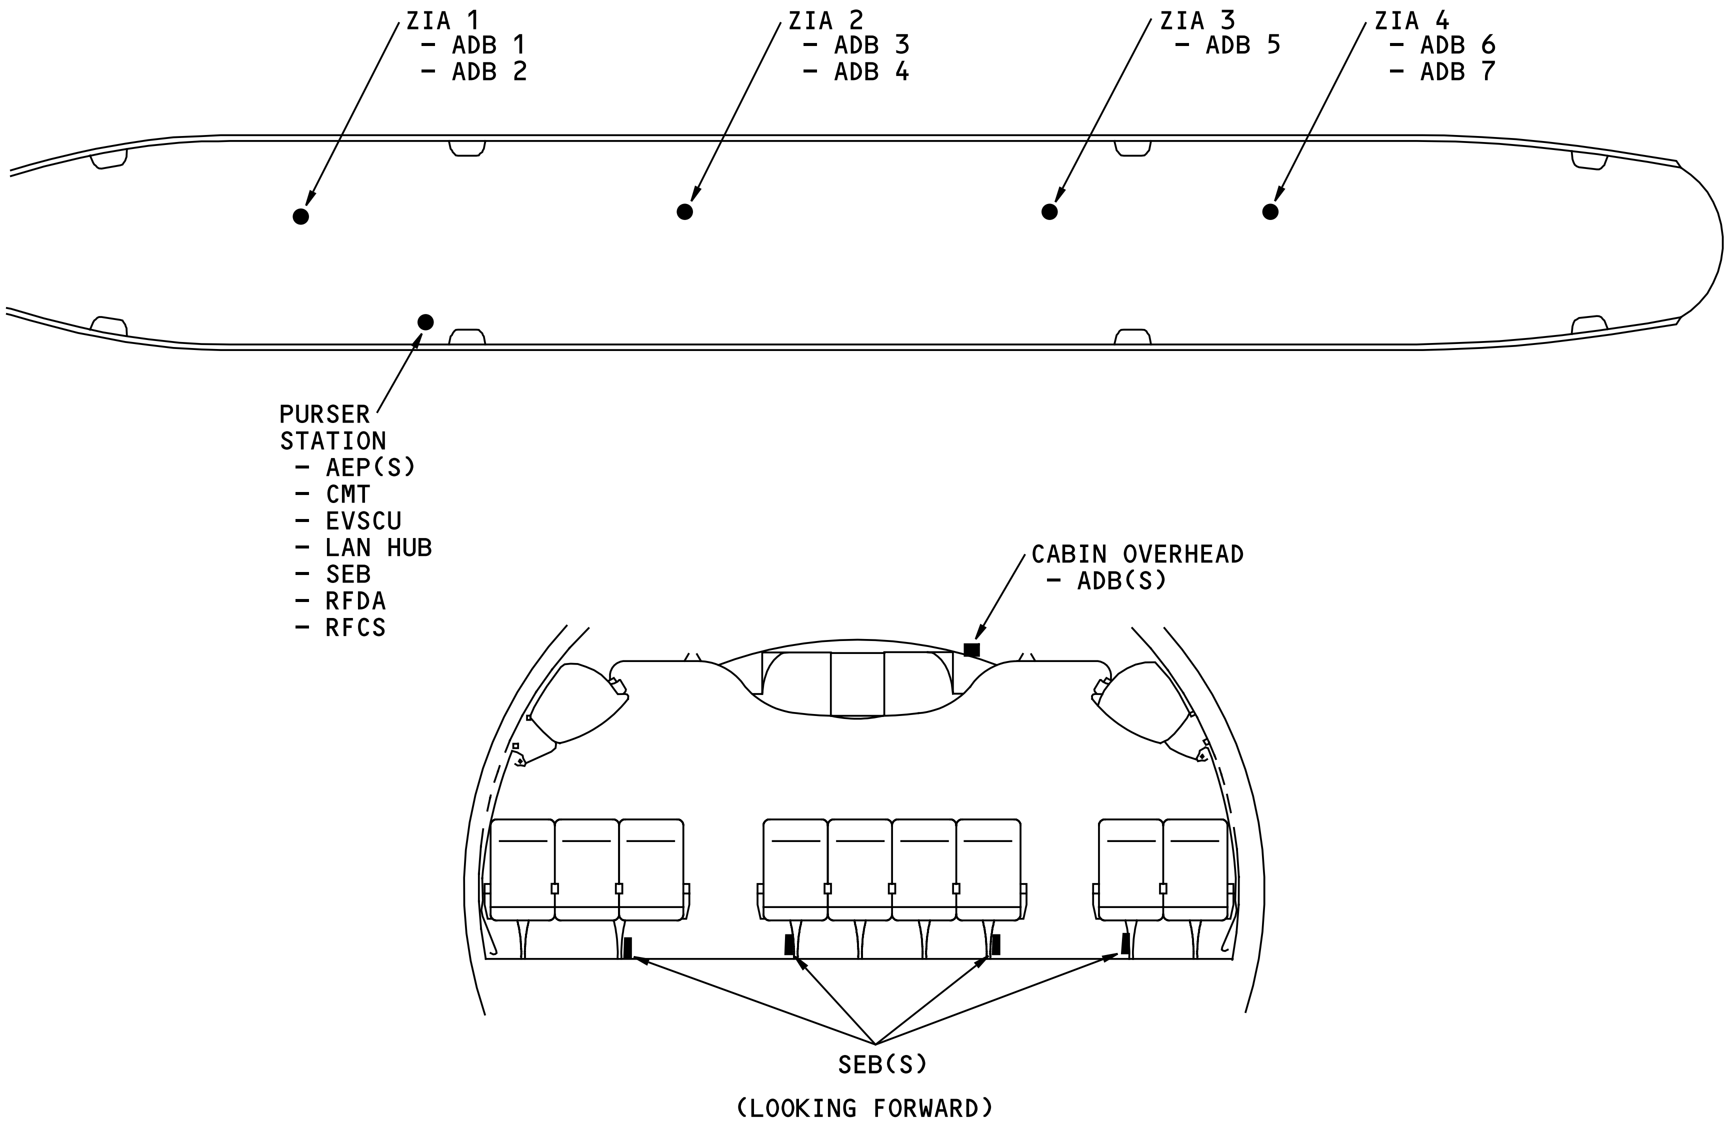
Passenger Seat Components

Passenger seats have seat electronics boxes (SEBs) under the seats. Passengers use controls at the seat to make audio channel selections.

Components Above the Ceiling Panels

Some of the IFE components are above the ceiling panels. The components are in locations called zone integration areas (ZIAs). There are four ZIAs.

The area distribution boxes (ADBs) are in ZIA 1, ZIA 2, ZIA 3 and ZIA 4.



IFE/PES-AUDIO - CABIN COMPONENT LOCATIONS

IFE/PES-AUDIO - MAIN EQUIPMENT CENTER COMPONENT LOCATIONS

General

The enhanced passenger entertainment system controller (EPESC) is in the main equipment center.

IFE/PES-AUDIO - MAIN EQUIPMENT CENTER COMPONENT LOCATIONS

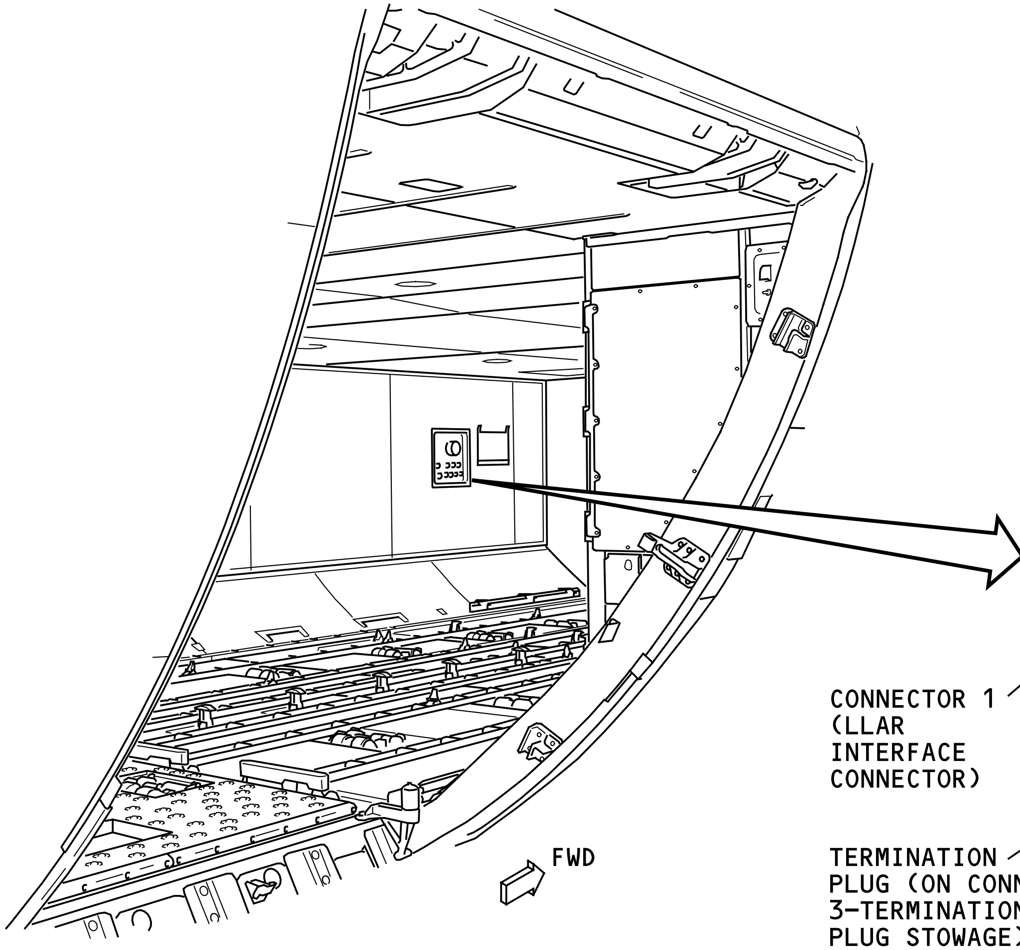
IFE/PES-AUDIO - CARGO COMPARTMENT COMPONENT LOCATIONS

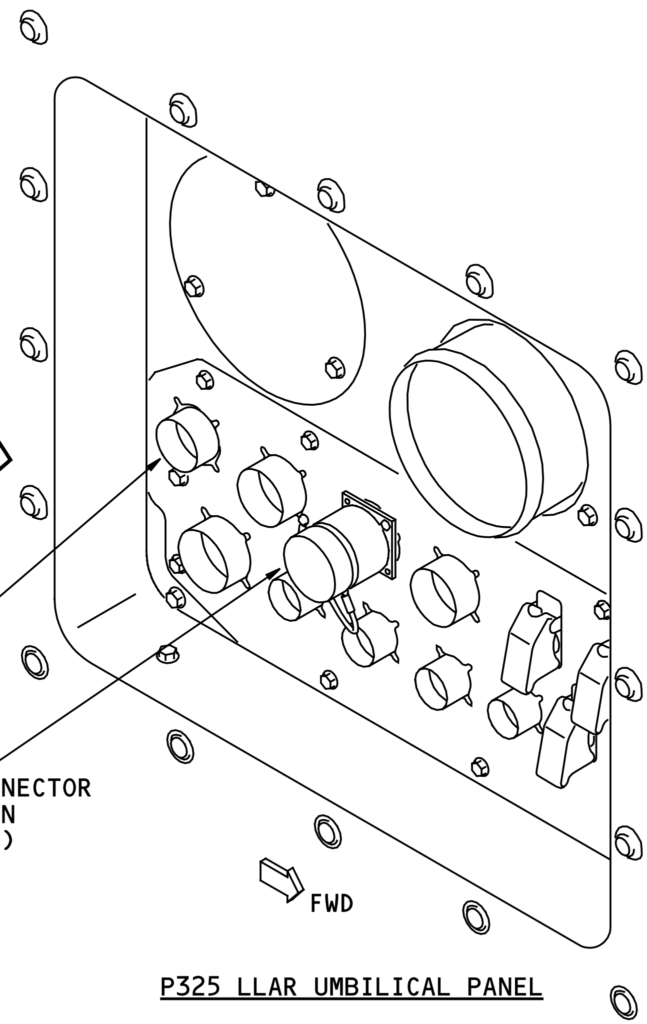
General

The P325 lower lobe attendants rest (LLAR) umbilical panel is on the left sidewall in the aft cargo compartment.

When the LLAR is not in the airplane, you must put a termination plug on connector 1 on the P325 panel.

When you install the LLAR, one of the LLAR cables goes to connector 1 on the P325 panel. Move the termination plug to connector 3 for stowage. Connector 3 has no electrical connections.





IFE/PES-AUDIO - CARGO COMPARTMENT COMPONENT LOCATIONS

IFE/PES-AUDIO - POWER INTERFACES

General

Power for the PES-audio comes through the P110 power management panel and the P210 right power management panel.

Circuit breakers control power to these PES-audio components:

- Audio entertainment players (AEPs)
- Enhanced passenger entertainment system controller (EPESC)
- Enhanced video system control unit (EVSCU)
- Cabin management terminal (CMT)
- RF distribution amplifier (RFDA)
- Local area network (LAN) hub
- Seat electronics box (SEB) in the purser station.

P110 Left Power Management Panel

The MULTP AUDIO ENTMT circuit breakers connects 115v ac through the AEP relay to the EPESC.

The ENTMT CTRL L circuit breaker connects 28v dc to the AEP relay. The ELMS electronic unit connects a ground to energize the relay during load shedding. When the relay energizes, it removes the power from the components.

You can also use the IFE off switch in the purser station to remove power from the components. When you turn the switch off, the switch connects a ground to the relay. The relay energizes and removes power from IFE/PES-audio components.

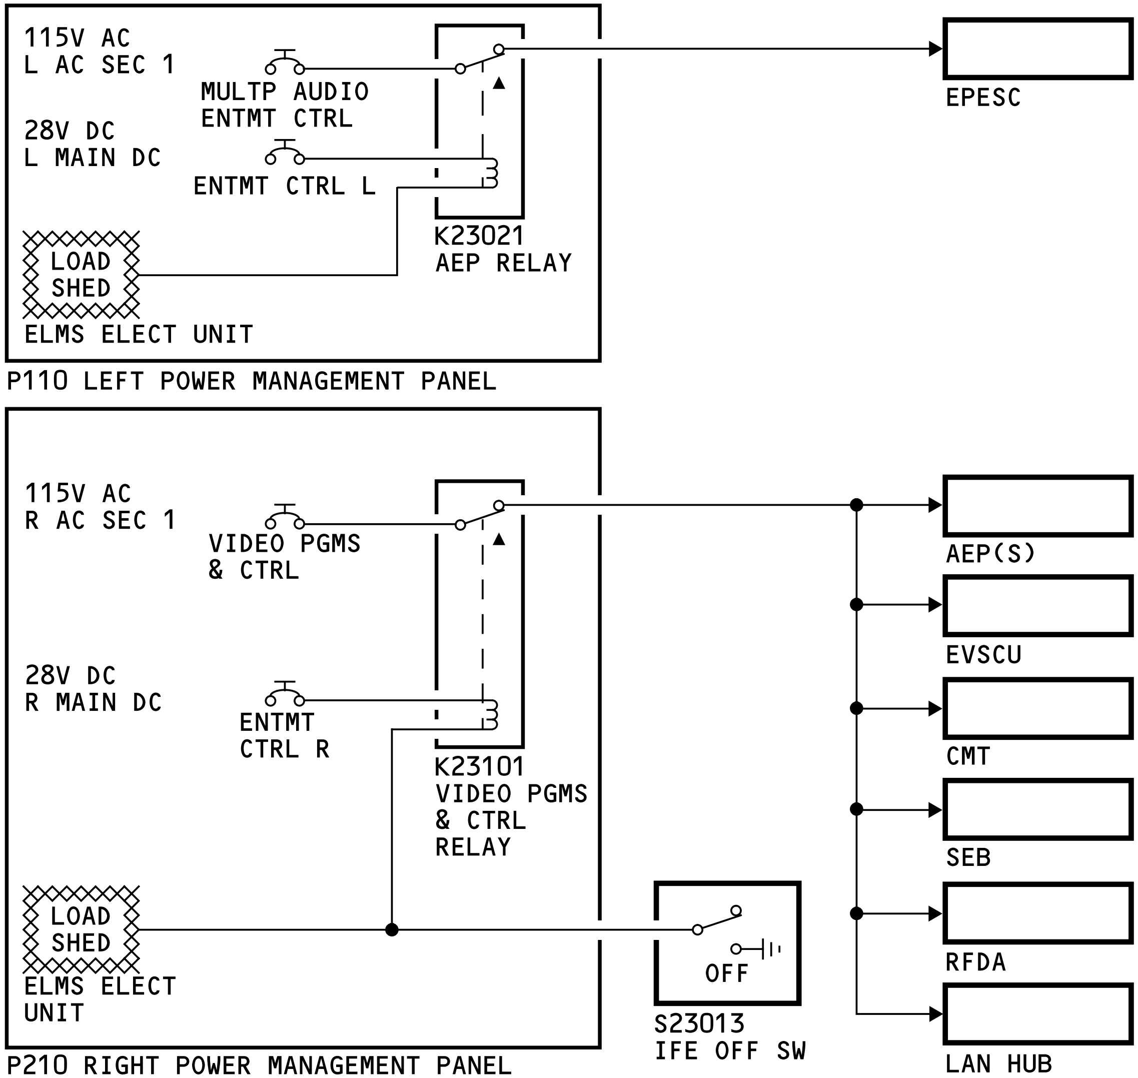
P210 Right Power Management Panel

The VIDEO PGMS & CTRL circuit breaker connects 115v ac through the video program and control relay to these LRUs:

- EVSCU
- CMT
- RFDA
- LAN hub
- SEB.

The ELMS electronic unit connects a ground to energize the relay during load shedding. When the relay energizes, it removes the power from the components.

You can also use the IFE off switch in the purser station to remove power from the components. When you turn the switch off, the switch connects a ground to the relay. The relay energizes and removes power from IFE/PES-audio components.



IFE/PES-AUDIO - POWER INTERFACES

IFE/PES-AUDIO - ZONE INTEGRATION AREA 1 POWER INTERFACES

IFE/PES-AUDIO - ZONE INTEGRATION AREA 4 POWER INTERFACES

IFE/PES-AUDIO - AIRPLANE INTERFACES

General

The in-flight entertainment (IFE) system connects to these airplane systems and components:

- Passenger address/cabin interphone (PA/CI) controller
- Prerecorded announcement machine (PRAM)
- Cabin system management unit (7).

Passenger Address Interfaces

The enhanced video system control unit (EVSCU) sends as many as four video audio outputs and related video audio keylines to the PA/CI controller. It also sends a signal to tell the flight crew when the video is in use. The EVSCU gets a decompression signal from the PA/CI controller when necessary.

The PA/CI controller sends as many as six channels of passenger address (PA) audio and related keylines to the enhanced passenger entertainment system controller (EPESC). The different channels relate to the PA areas in the cabin that the configuration database defines. The IFE sends this audio to the passenger headphones. The PA/CI controller also sends a PA-All keyline for announcements in all areas of the cabin. This replaces PES-audio with the PA announcement. The PA audio then goes to the passenger headphones.

The EPESC connects to the PRAM to control the prerecorded announcements and boarding music.

The CSMU connects to the IFE system with an ARINC 628 head-end interface. It sends airplane data and cabin services system (CSS) configuration data to the IFE system.

AERONAUTICAL TELECOMMUNICATION SYSTEM/PASSENGER TELEPHONE SYSTEM - INTRODUCTION

ATS/PASSENGER TELEPHONE SYSTEM - GENERAL DESCRIPTION

General

Passengers use handsets to make telephone calls. Outgoing calls go to the cabin telecommunications unit (CTU). The CTU sends the calls to the satellite communication (SATCOM) system.

Components

The main component of the passenger telephone system is the cabin telecommunications unit (CTU).

The passenger telephone system connects with these airplane systems and components:

- In-flight entertainment (IFE) system. The IFE system has handsets that the passengers use to make telephone calls
- Satellite communication (SATCOM) system
- Airplane information management system (AIMS).

In-Flight Entertainment System

Passengers use a handset at the seat to make a telephone call. The call signals from the handset go through the IFE components to the CTU.

The CTU connects telephone calls to a ground station through the SATCOM system.

To make a facsimile (FAX) or modulator/demodulator (modem) call, the passenger starts the call the same as for a voice call. The passenger then connects a FAX machine or a modem to the FAX/modem connector on the handset or in the seat arm.

System Maintenance

The IFE system sends test commands and program data to the CTU. The results of a test or software installation, go to the IFE system for display.

23-18-00-505 Rev 8 02/19/1998

ATS/PASSENGER TELEPHONE SYSTEM - POWER INTERFACE

ATS/PASSENGER TELEPHONE SYSTEM - AIRPLANE INTERFACES

General

The main component of the passenger telephone system is the cabin telecommunications unit (CTU). The CTU receives telephone signals on the Conference Europeenne des Administrations des Postes et des Telecommunications (CEPT)-E1 bus and sends these signals to the correct LRU.

These airplane systems have an interface with the passenger telephone system:

- In-flight entertainment system
- Satellite communications system (SATCOM)
- Airplane information management system (AIMS).

In-Flight Entertainment System Interface

The enhanced passenger entertainment system controller (EPESC) is part of the IFE system. The IFE system sends the passenger telephone system:

- Passenger telephone calls
- Digital data
- Facsimile (FAX)/modulator/demodulator (modem) data.

Passengers use passenger handsets to make telephone calls. The telephone signals go to the EPESC which sends the signals to the CTU on the CEPT-E1 bus. The EPESC may also send digital data, such as inventory information, from the in-flight entertainment system to the CTU.

A connector on the passenger handset allows passengers to connect a personal computer with FAX/modem capabilities. The passenger handset sends these signals the same as outgoing telephone calls.

SATCOM System Interface

The CTU sends outgoing telephone signals to the satellite data unit (SDU). SATCOM transmits the signals through a satellite to the ground stations.

AIMS Interface

The right and left AIMS cabinets connect to the cabin telecommunications unit (CTU).

The CTU gets ICAO and weight on wheels (WOW) data from general purpose bus 1. It also gets time and date from the CMC-C bus. The CTU sends BITE status to the left and right AIMS cabinets on the cabin communication system (CCS) bus.

FLIGHT INTERPHONE SYSTEM - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

FLIGHT INTERPHONE SYSTEM - GENERAL DESCRIPTION

General

The audio management unit (AMU) controls the routing of audio signals to and from the flight crew.

Flight Crew Interfaces

This system description shows the captain's system. Interfaces and components for other flight crew stations are almost the same.

The flight crew uses microphone (mic) switches on these components to send audio to the AMU:

- Glareshield
- Control column
- Hand microphone
- Audio control panel (ACP).

A microphone on these components lets the flight crew speak on the flight interphone system:

- Hand mic
- Oxygen mask
- Headset (through the boom mic/headphone panel).

The flight crew uses ACPs for these functions:

- Audio signal selection and monitoring
- Connect to other communication systems.

The AMU sends audio signals to the headsets and to the flight interphone speakers.

The observer audio selector controls a backup mode when the captain's or first officer's audio system has a failure.

Ground Crew Interfaces

The ground crew uses jacks in the main equipment center (MEC) and on the service and APU shutdown panel to connect to the flight interphone system.

Other Component and System Interfaces

The AMU connects to these other components for the related function:

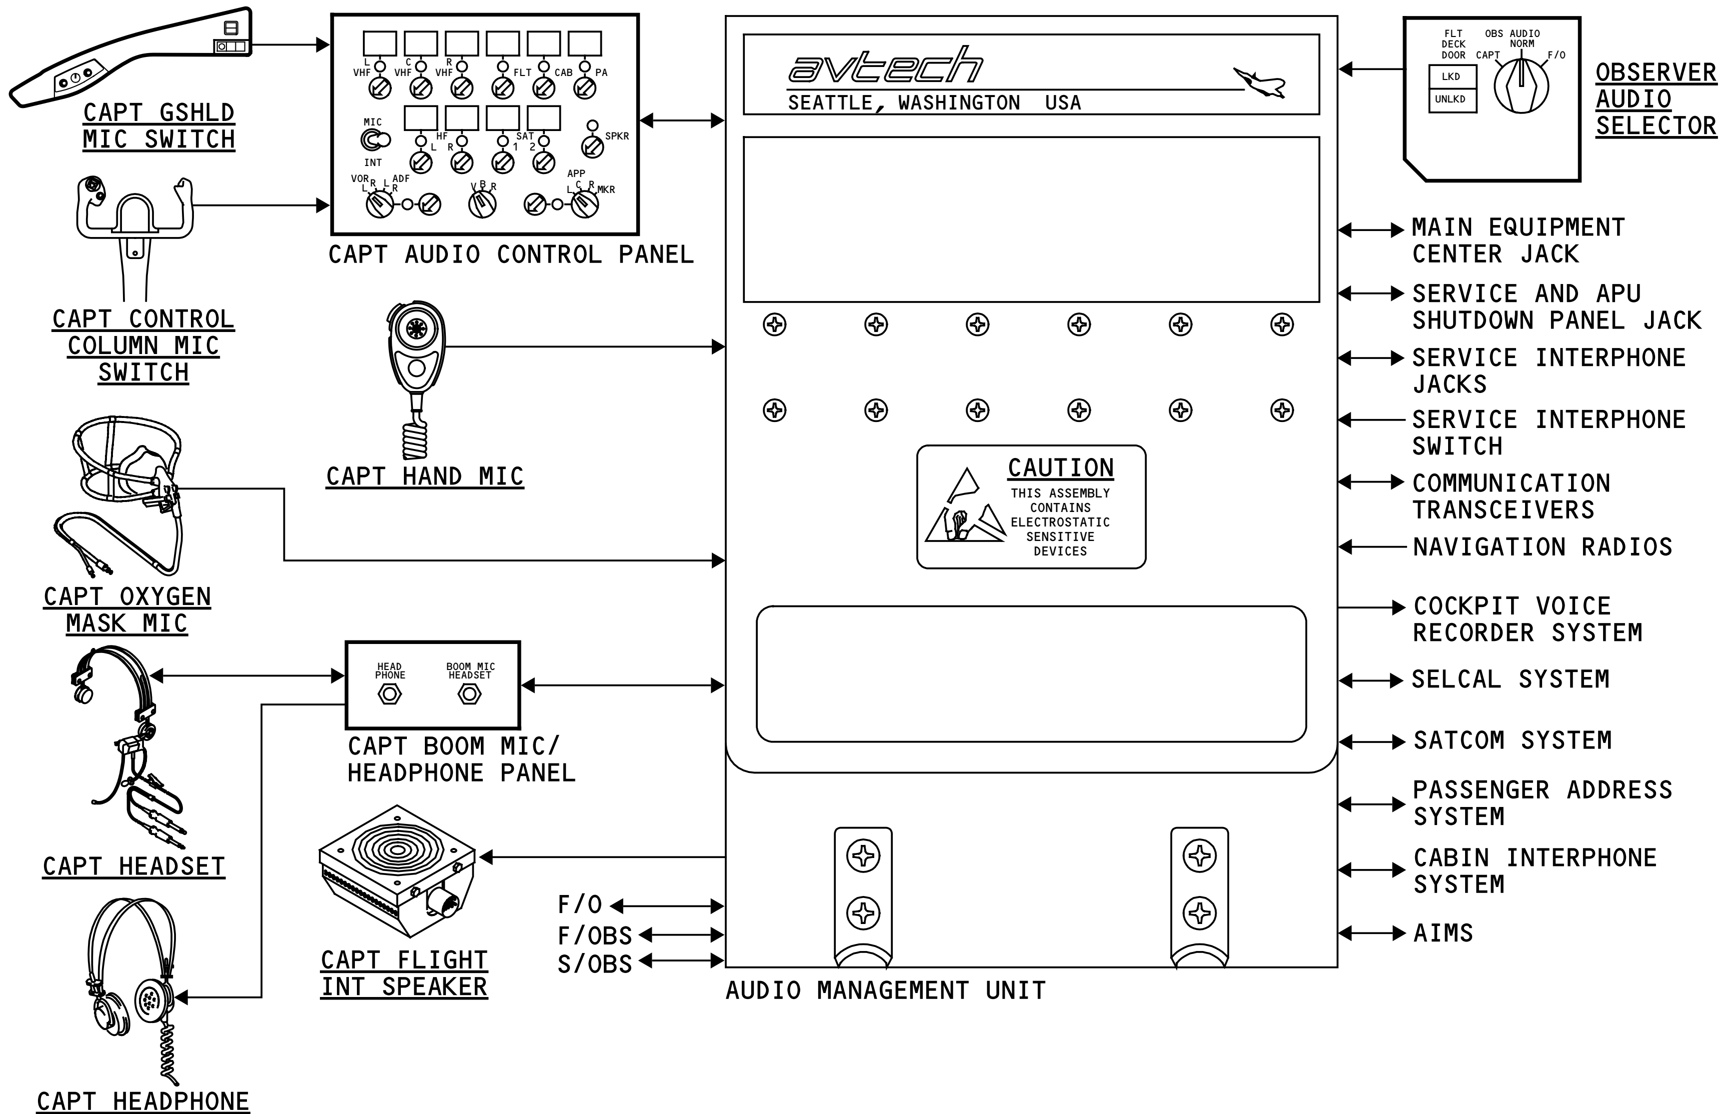
- Service interphone jacks - to send and get audio from the service interphone system
- Service interphone switch - connects the service interphone system with the flight interphone system
- Communications transceivers - the AMU sends push-to-talk (PTT) and microphone audio to the transceivers and gets audio back from them
- Navigation radios - the AMU gets voice and Morse code identification tones.

The flight interphone system also has an interface with these other systems:

- Cockpit voice recorder system - to record the flight crew microphone and receive audio

FLIGHT INTERPHONE SYSTEM - GENERAL DESCRIPTION

- SELCAL system - the AMU gets discretes to control call lights on the ACP and sends resets to the SELCAL decoder
- SATCOM system - permits the flight crew to speak with ground stations
- Passenger address system - this connection lets the flight crew make announcements to passengers
- Cabin interphone system - lets the flight crew speak with attendants
- AIMS - the AMU sends BITE data to AIMS and receives DME pairing data from AIMS over an ARINC 629 systems bus.



FLIGHT INTERPHONE SYSTEM - GENERAL DESCRIPTION

FLIGHT INTERPHONE SYSTEM - FLIGHT DECK COMPONENT LOCATIONS

Flight Deck Component Locations

These are the captain's flight interphone system components:

- Boom mic/headphone panel
- Control column mic switch
- Flight interphone speaker
- Hand mic jack
- Glareshield mic switch
- Audio control panel (ACP) on the P8 aft aisle stand panel.

The other flight crew stations have the same components except that the first and second observers do not have a glareshield mic switch or a control column mic switch.

The second observer does not have an audio control panel or a hand mic jack.

The observer audio selector is on the P8 aft aisle stand panel.

Other Systems Component Locations

The captain, first officer and first observer each have an oxygen mask with a microphone in a stowage box adjacent to the station.

FLIGHT INTERPHONE SYSTEM - POWER INTERFACE

General

Power for the flight interphone system comes through circuit breakers in the overhead circuit breaker panel.

The audio management unit (AMU) has a connector board and three station cards, one for each of the flight crew stations. Each station card has a power supply for its circuits.

INTERPHONE-CAPT Circuit Breaker

The INTERPHONE-CAPT circuit breaker connects 28v dc to these components:

- Captain's flight interphone speaker
- Captain's card
- Captain's audio control panel (ACP) through the AMU.

INTERPHONE-F/O Circuit Breaker

The INTERPHONE-F/O circuit breaker connects 28v dc to these components:

- First officer's flight interphone speaker
- First officer's card
- First officer's ACP through the AMU.

A different source of power for these components is through the INTERPHONE-F/O STBY PWR circuit breaker.

INTERPHONE-OBS Circuit Breaker

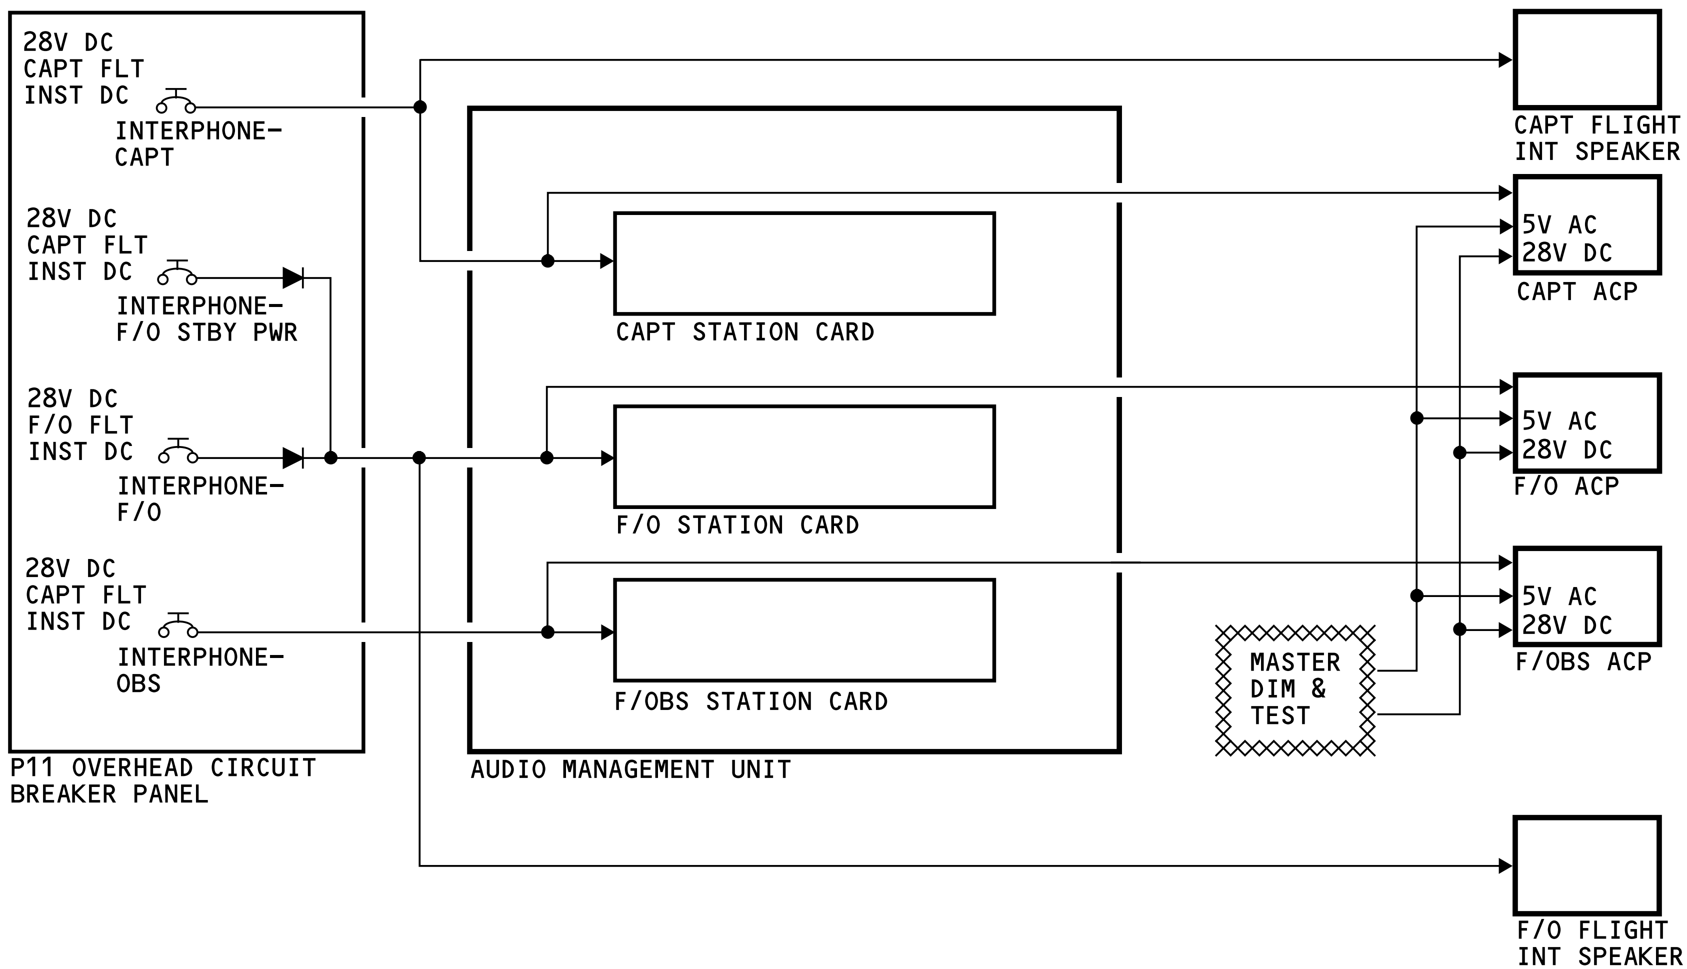
The INTERPHONE-OBS circuit breaker connects 28v dc to these components:

- First observer's card
- First observer's ACP through the AMU.

Master Dim and Test

Each ACP gets 5v ac and 28v dc from the master dim and test (MD&T) system. The ACP uses 5v ac for the panel lights and 28v dc for:

- Call lights
- Mic lights
- Receive LEDs.



23-51-00-005 Rev 5 01/16/95

FLIGHT INTERPHONE SYSTEM - POWER INTERFACE

FLIGHT INTERPHONE SYSTEM - FLIGHT DECK INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

FLIGHT INTERPHONE SYSTEM - FLIGHT DECK INTERFACES

General

The flight interphone system has these four flight deck stations:

- Captain
- First officer
- First observer
- Second observer.

The captain's, first officer's and first observer's stations connect to a related circuit card in the audio management unit (AMU) for these functions:

- Receive inputs from the stations
- Supply audio signal routing
- Give selection indications to the audio control panels (ACPs).

Captain and First Officer Stations

The captain's and first officer's stations have these control signal and audio interfaces:

- Glareshield microphone (mic) switches
- Control wheel mic switches
- ACP
- Hand microphone
- Oxygen mask microphone and door switch (mask mic on/off)
- Headset
- Headphone
- Flight interphone speaker.

The glareshield and control wheel microphone switches connect to the station's ACP. The ACP sends a microphone or interphone (INT) PTT signal to the AMU. You use a mic/interphone switch on the ACP to send the related PTT signal to the AMU.

The hand microphone sends a PTT signal and audio through a jack panel to the AMU.

A door switch in the oxygen mask stowage box sends a mic on/off signal to the AMU. A microphone in the mask sends audio.

The AMU gets audio from a boom microphone on a headset.

The AMU sends audio to the headset, headphones, and flight interphone speaker.

First and Second Observer Stations

The first observer station has the same controls and interfaces as the captain and first officer except that it does not have these components:

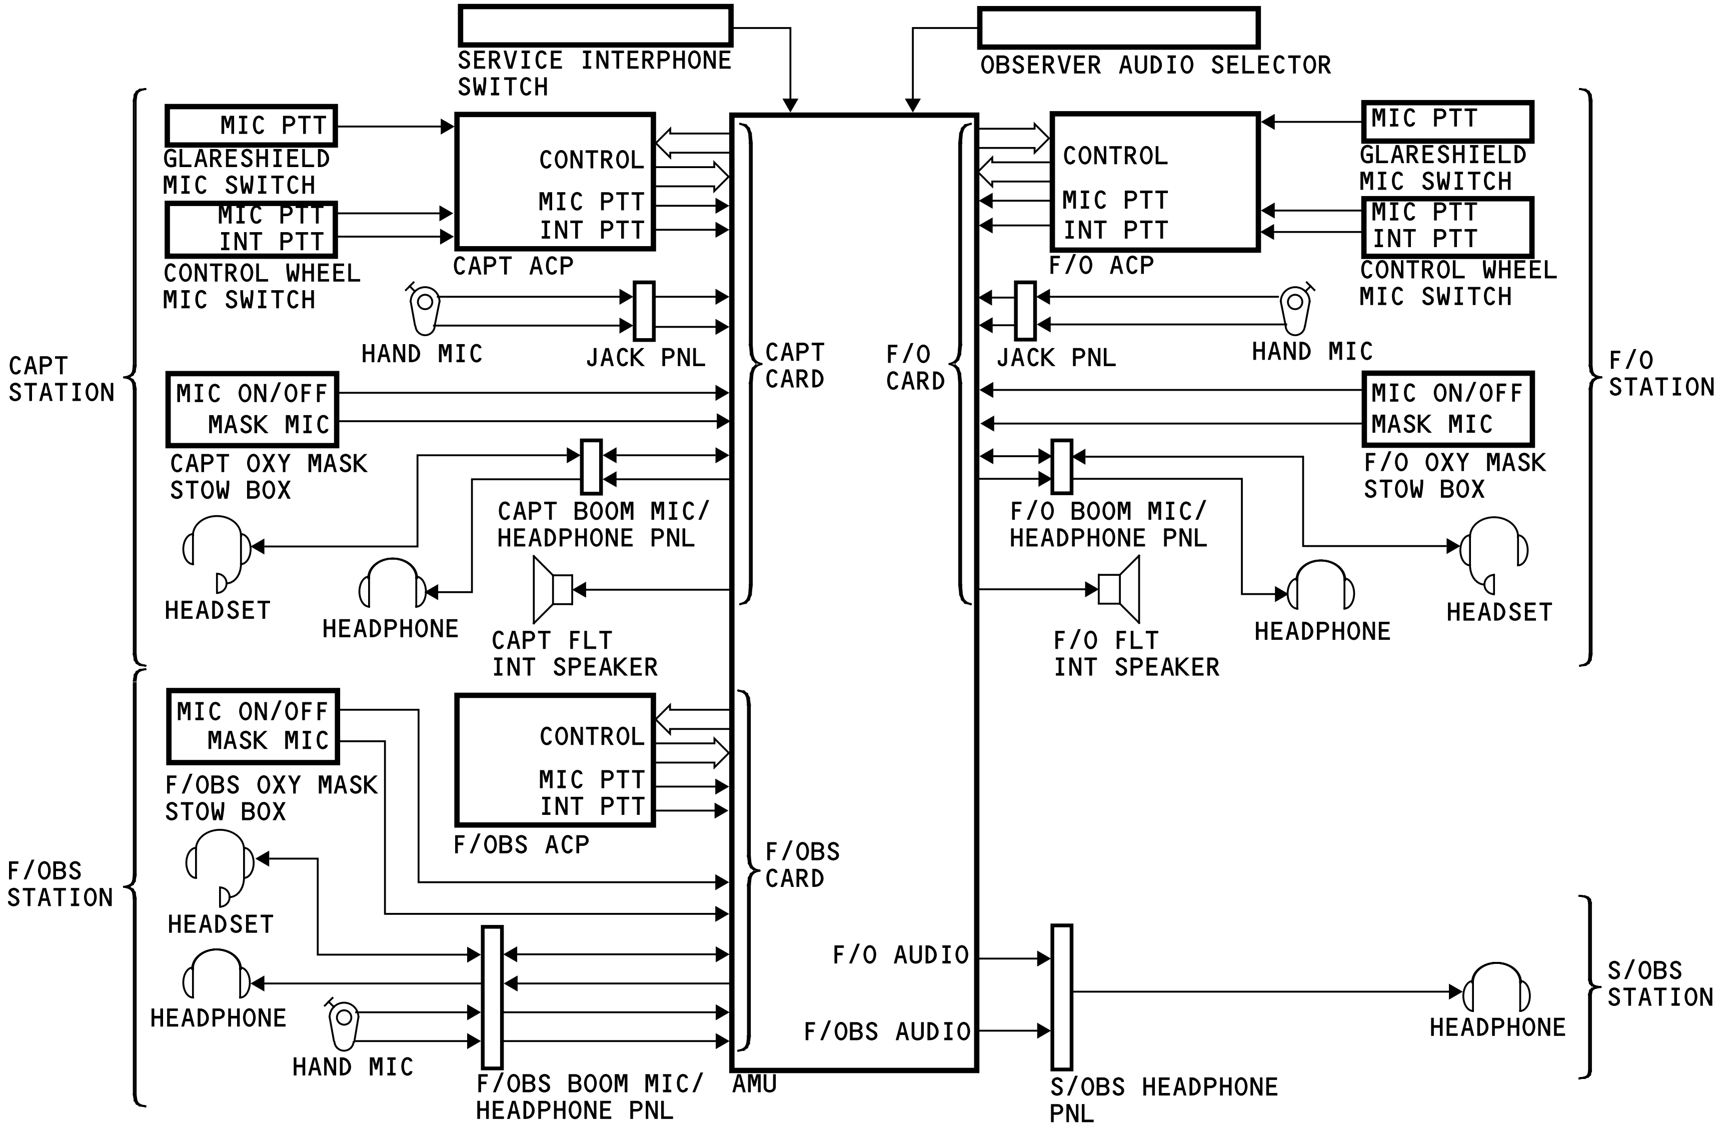
- Flight interphone speaker
- Control wheel mic switches
- Glareshield mic switches.

The second observer station has a jack panel that allows the second observer to monitor the first officer or the first observer audio.

FLIGHT INTERPHONE SYSTEM - FLIGHT DECK INTERFACES

Other Flight Deck Interfaces

The service interphone switch and observer audio selector connect to the AMU to control audio modes and selections.



FLIGHT INTERPHONE SYSTEM - FLIGHT DECK INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

FLIGHT INTERPHONE SYSTEM - COMMUNICATION SYSTEM INTERFACES

General

The audio management unit (AMU) controls the routing of audio in the flight interphone system.

The AMU gets control and PTT signals from the audio control panels (ACPs). The AMU sends data to the ACPs to control lights.

Satellite Data Unit

The AMU gets call light and audio signals from the satellite data unit (SDU). The AMU turns on an associated call light on the ACPs. The flight crew makes selections on the ACP to reset the SATCOM call chime, turn on a microphone signal, and send audio to the SDU.

Communication Transceivers

The communication transceivers send audio outputs to the AMU. The transceivers get microphone audio and PTT discretes from the AMU.

The HF antenna couplers use the PTT signal to tune to a frequency.

SELCAL Decoder

The SELCAL decoder sends call set discretes to the AMU. The AMU uses them to control ACP call lights. The AMU sends call reset discretes to the SELCAL decoder to cancel the call discrete and turn off the call lights.

Passenger Address/Cabin Interphone (PA/CI) Controller

The AMU sends audio and PTT signals to the PA/CI controller. It receives audio from the PA/CI controller.

When the AMU receives a cabin call from the PA/CI controller, the ACP CALL lights come on. When the flight crew selects CAB on the ACP, the AMU sends a cabin call answer signal to the PA/CI controller. The PA/CI controller sends the cabin reset signal to the AMU. This causes the ACP CALL lights to go off.

The flight crew selects PA on the ACP to talk to passengers. The AMU sends a PTT signal and audio to the PA/CI controller. The PA/CI controller sends a sidetone audio back to the AMU.

When the ground crew calls the flight deck from the nose gear electrical service panel, the PA/CI controller sends a flight deck call signal to the AMU. This causes the ACP CALL lights to come on. When the flight crew selects FLT on any ACP, the AMU sends a flight reset signal to the PA/CI controller.

Cockpit Voice Recorder

The AMU sends audio from the captain, first officer, and first observer to the cockpit voice recorder.

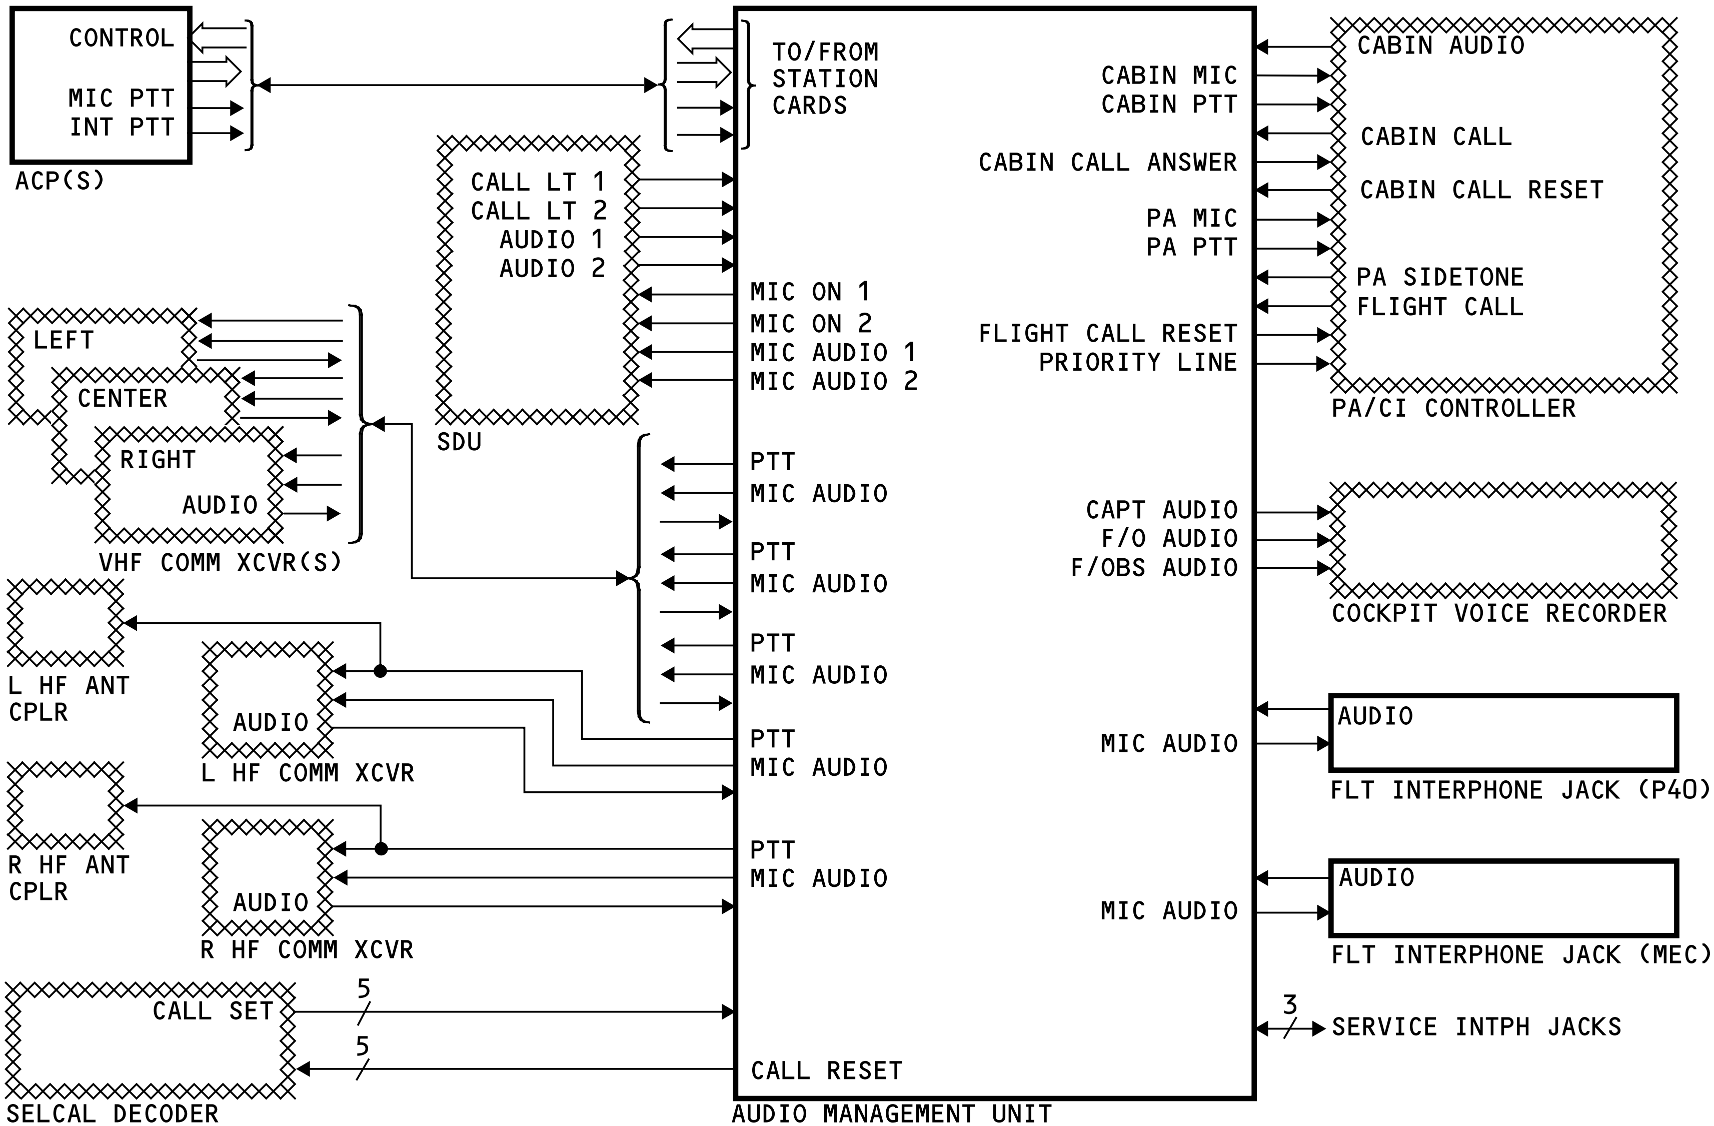
FLIGHT INTERPHONE SYSTEM - COMMUNICATION SYSTEM INTERFACES

Flight Interphone Jacks

The ground crew use the flight interphone jacks at the service and APU shutdown panel and in the main equipment center to talk to the flight crew.

Service Interphone Jacks

The AMU has three outputs that connect to many service interphone jacks on the airplane.



FLIGHT INTERPHONE SYSTEM - COMMUNICATION SYSTEM INTERFACES

23-51-00-007 Rev 6 11/10/1997

FLIGHT INTERPHONE SYSTEM - NAVIGATION AND AIMS INTERFACES

Navigation Interfaces

These four navigation radio systems send audio signals to the audio management unit (AMU):

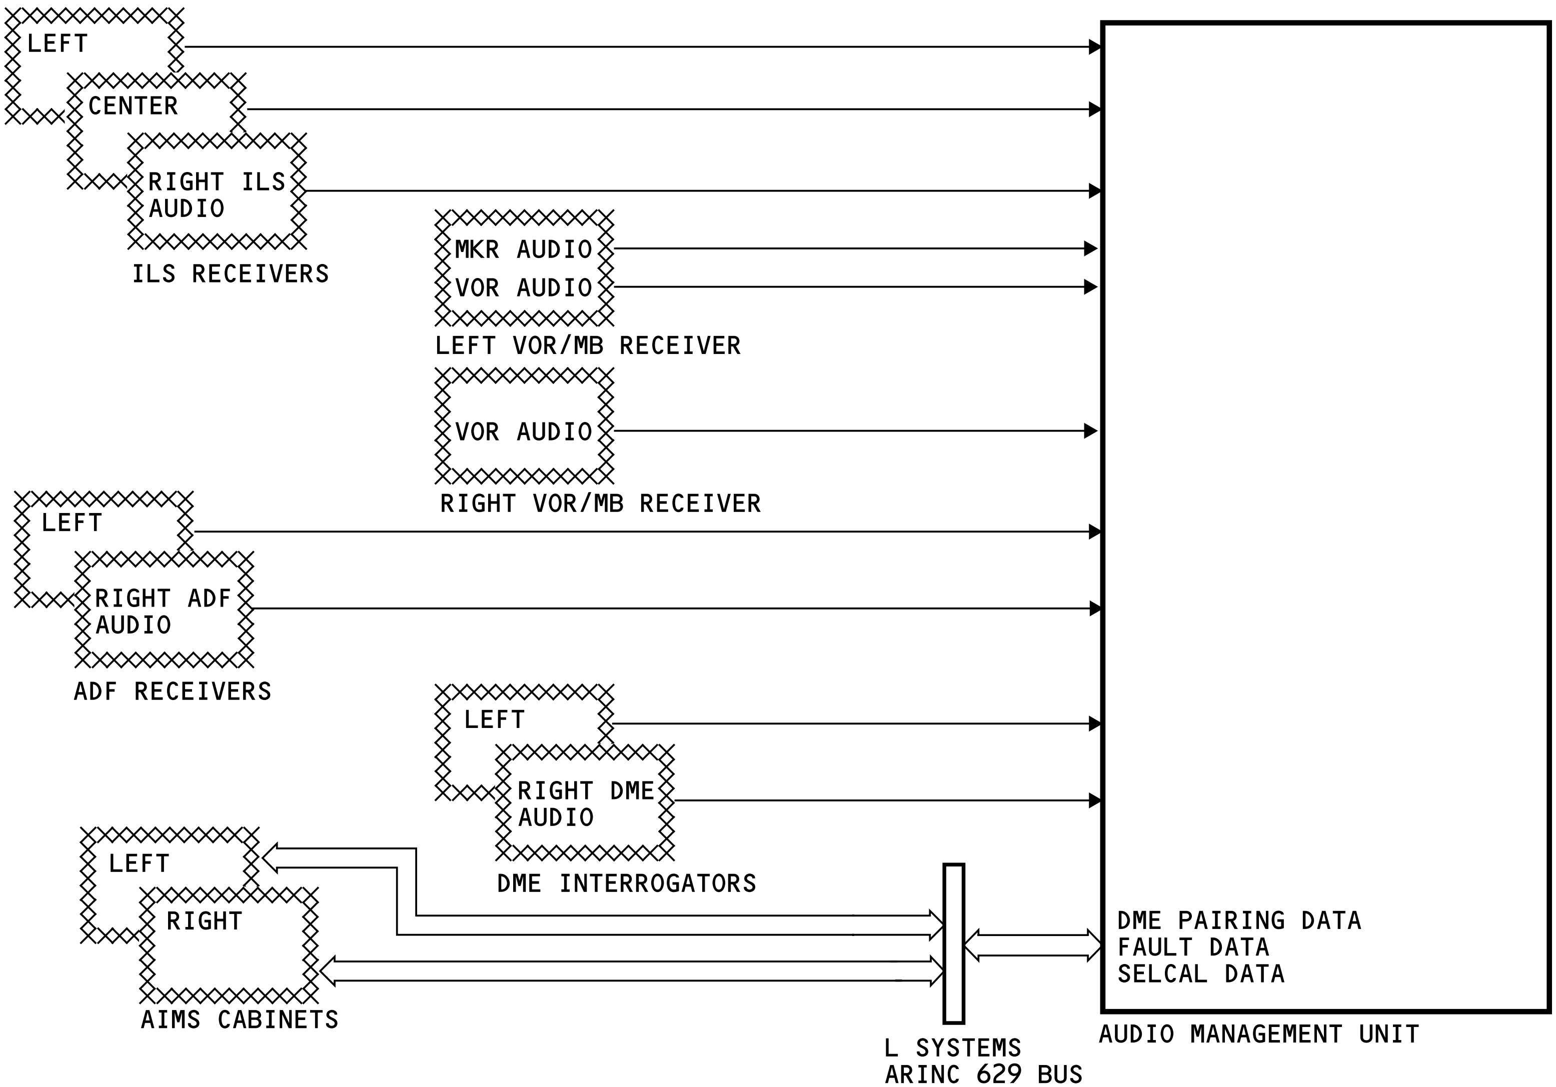
- Instrument landing system (ILS) receivers
- VHF omnidirectional range (VOR)/marker beacon receivers
- Automatic direction finder (ADF) receivers
- Distance measuring equipment (DME) interrogators.

AIMS Interface

The AIMS cabinets send DME pairing data to the AMU. This data tells the AMU to place DME audio on the VOR or ILS audio channel.

The AMU sends failure data to the AIMS cabinets.

The AMU also sends SELCAL set/reset data to the AIMS cabinets. The AIMS cabinets use this data to alert the flight crew.



23-51-00-008 Rev 1

FLIGHT INTERPHONE SYSTEM - NAVIGATION AND AIMS INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

FLIGHT INTERPHONE SYSTEM - AUDIO CONTROL PANEL

Purpose

The flight crew uses the audio control panels (ACPs) to control audio for the communication and navigation radio systems. Each ACP controls one station.

Controls

These are the controls on the ACP:

- Transmitter select switches
- Receiver volume controls
- Speaker volume control
- Approach receiver selector
- NAV filter selector
- VOR/ADF receiver selector
- Mic/interphone switch.

Lights

These are the three kinds of lights on the ACP:

- Call lights
- Mic lights
- Receiver lights.

Transmit Operation

To connect a microphone (boom, oxygen mask, or handheld) to a communication radio or system, push the related transmitter select switch. You can select only one system at a time. When you push a transmitter select switch, this is what happens:

- The MIC light on the upper half of the switch comes on
- The receive audio of the selected system comes on at the volume set by the receiver volume control.

A call goes to an attendant station when you push the cabin interphone (CAB) transmitter select switch twice in one second. The cabin management system (CMS) identifies the attendant station.

When the ACP first gets power, all transmitter select switches are off.

Receive Operation

The lower half of a transmitter select switch is a CALL light. This light comes on when the related system calls the flight crew.

The call light goes off when you push the transmitter select switch. If the MIC light for that transmitter select switch is on, push any mic switch to reset the call light. The flight interphone call light also goes out when you select the INT position of the mic/int switch on the ACP or on the control column.

The call lights for the SATCOM system do not go off when you push the transmitter select switch. You make selections on a control display unit (CDU) to turn off the SATCOM call lights.

The SELCAL inputs to the audio management unit (AMU) control the HF and VHF call lights. The passenger address/cabin interphone controller input controls the CAB call light. The flight deck call switch on the P40 service and APU shutdown panel controls the FLT call light.

To listen to communication or navigation system audio, push the receiver volume control (push-on, push-off) and turn it to adjust the volume. You can monitor any combination of systems at any time. The receiver light comes on to show that the related receiver control is on.

Mic/Interphone Switch

This switch is a three-position switch that is spring loaded to center. In the MIC position, a PTT signal causes the selected system to transmit. The flight crew member talks on the oxygen mask microphone or the boom microphone.

In the INT position, a PTT signal to the AMU connects the flight crew together through the flight interphone system. It is not necessary to select any transmit switch to use the flight interphone. The flight crew member talks on either the oxygen mask microphone or the boom microphone.

Speaker Volume Control

This control is functional only on the audio control panels in the captain and first officer positions. The speaker volume control turns on or off the flight deck speaker at the related station and adjusts its volume.

VOR/ADF Selector

Use the VOR/ADF selector to select a VOR or ADF receiver.

Filter Selector

The filter selector tells the AMU how to process VOR, ADF, and ILS audio. In the V (voice) position, the AMU passes only voice frequencies through the filter and filters out the 1020 Hz range frequency.

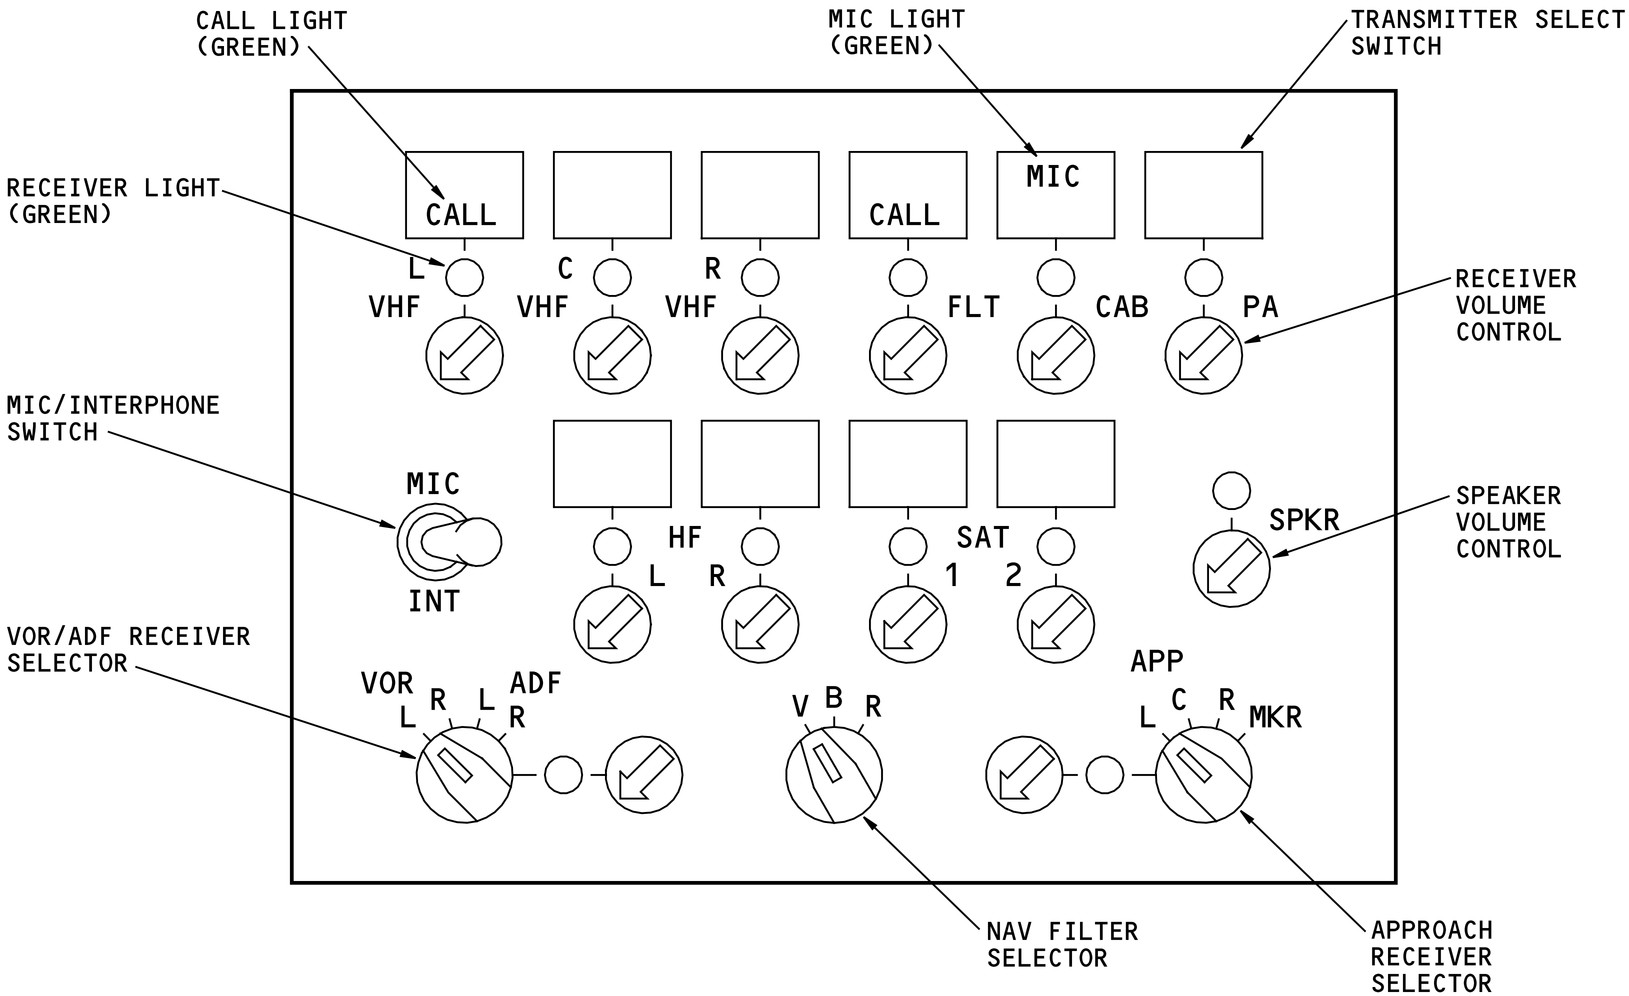
In the B (both) position, the AMU permits voice and range (coded station identification) frequencies through the filter to the audio output.

In the R (range) position, the AMU passes only the range frequency through the filter and filters out the voice frequencies.

Approach Receiver Selector

The approach receiver selector controls selection of these navigation radios:

- Left instrument landing system (ILS) receiver
- Center ILS receiver
- Right ILS receiver
- Marker beacon receiver.



FLIGHT INTERPHONE SYSTEM - AUDIO CONTROL PANEL

FLIGHT INTERPHONE SYSTEM - OBSERVER AUDIO SELECTOR

Purpose

The observer audio selector controls the inputs and outputs of the first observer's station card in the audio management unit (AMU).

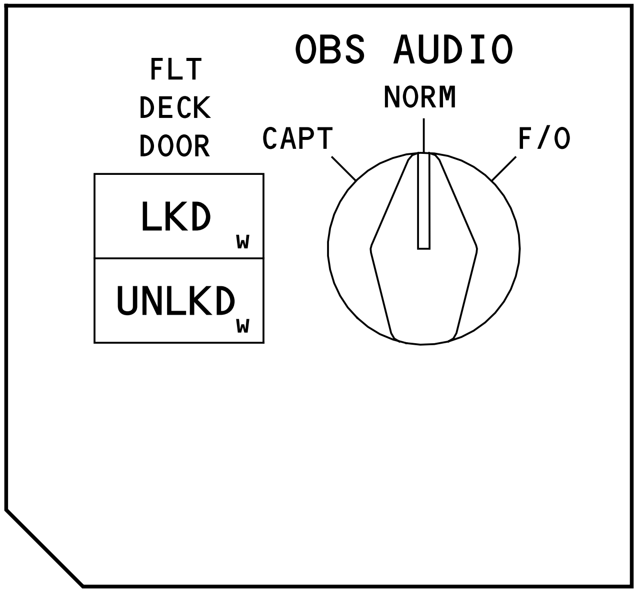
The switch lets the captain or first officer use the first observer's audio control panel (ACP) if their AMU audio station card or ACP has a failure.

Selector Positions

When you select CAPT, the captain's inputs and outputs connect to the first observer's station card.

When you select NORM, the first observer's inputs and outputs connect to the first observer's station card.

When you select F/O, the first officer's inputs and outputs connect to the first observer's station card.



OBSERVER AUDIO PANEL

FLIGHT INTERPHONE SYSTEM - JACK PANELS

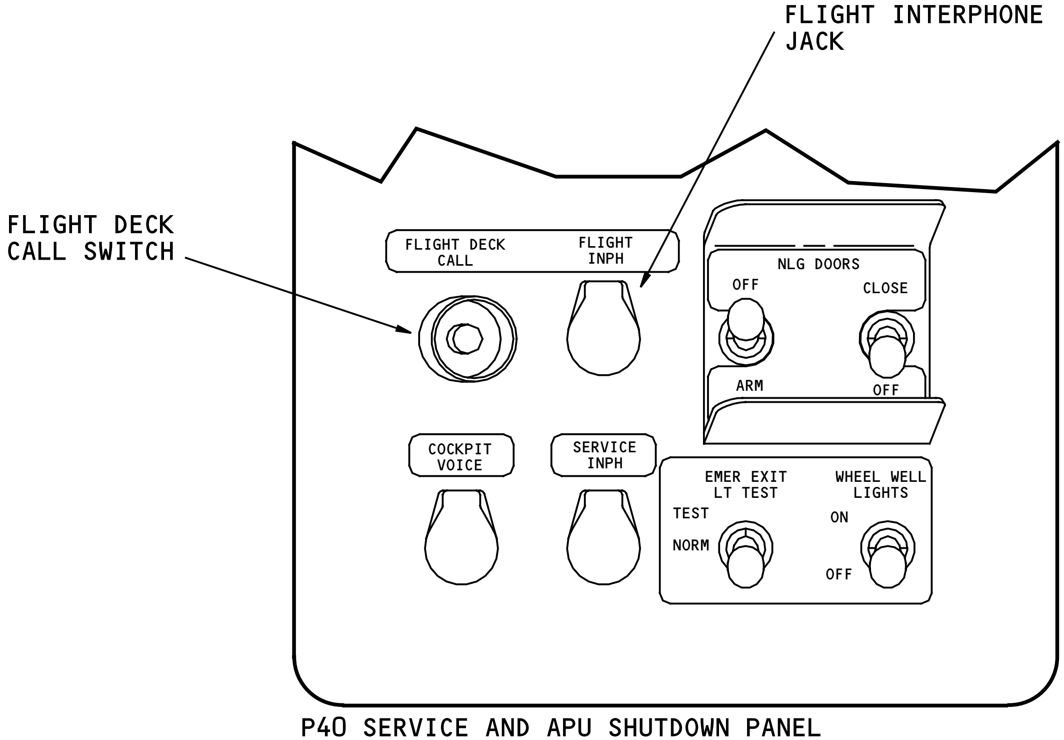
FLIGHT INTERPHONE SYSTEM - FLIGHT INTERPHONE JACK

Purpose

The ground crew talks to the flight crew on the flight interphone system. A ground crew headset connects to the flight interphone jack on the service and APU shutdown panel.

When you push the flight deck call switch, the flight interphone CALL lights on all audio control panels (ACPs) come on.



23-51-00-013 Rev 1

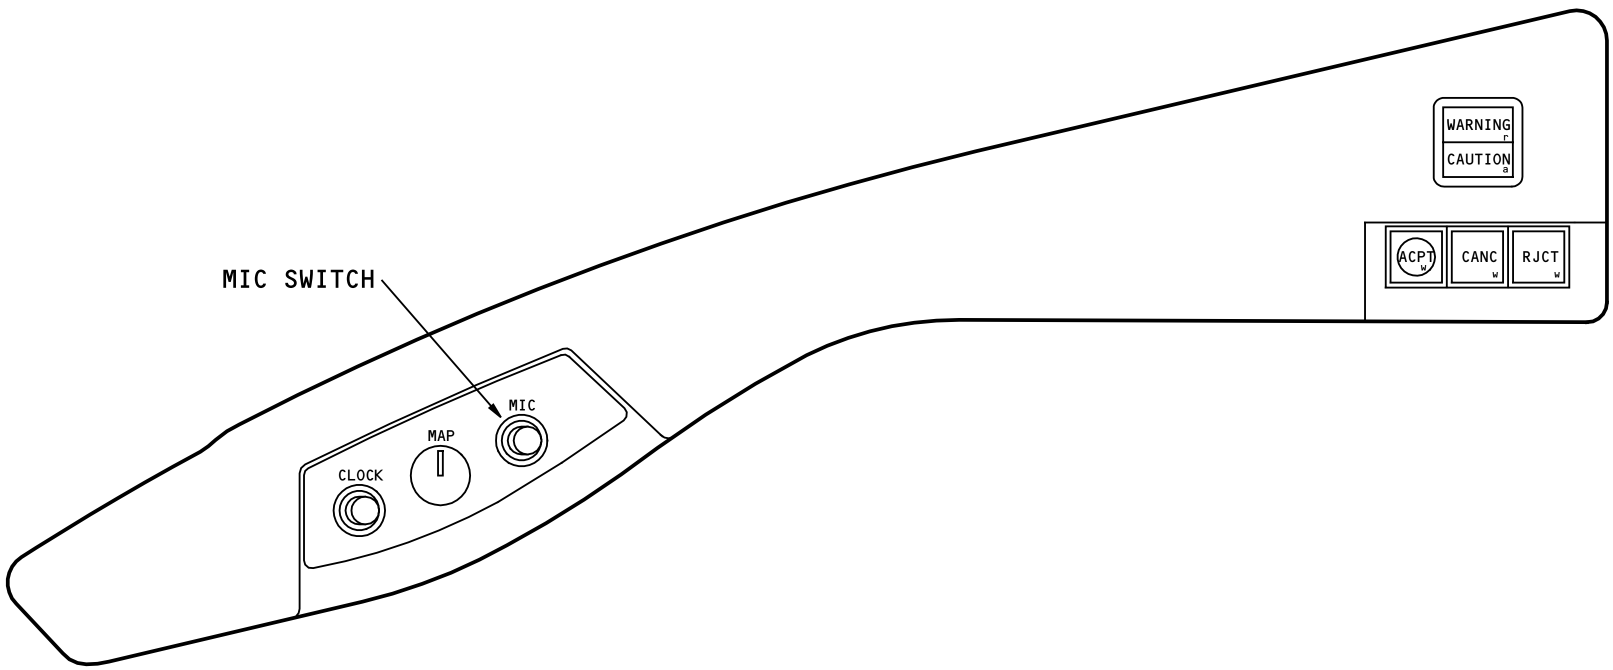
FLIGHT INTERPHONE SYSTEM - FLIGHT INTERPHONE JACK

FLIGHT INTERPHONE SYSTEM - GLARESHIELD MIC SWITCH

General

The glareshield microphone (mic) switch gives PTT inputs to the audio management unit (AMU) for the headset or oxygen mask microphones.

When you push the mic switch, microphone audio and the PTT signal go to the selected communication system.



CAPT GLARESHIELD

23-51-00-025 Rev 1 09/16/96

FLIGHT INTERPHONE SYSTEM - GLARESHIELD MIC SWITCH

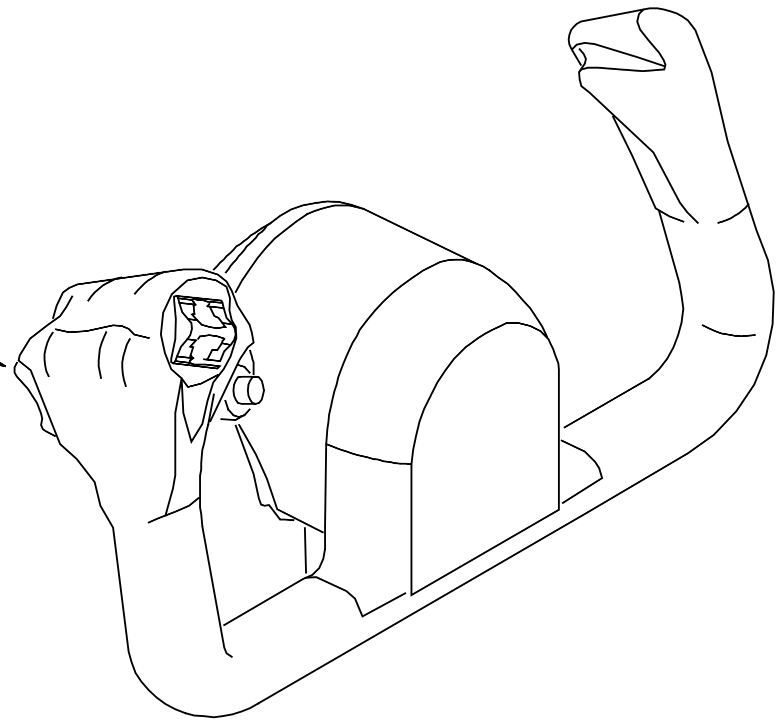
FLIGHT INTERPHONE SYSTEM - CONTROL WHEEL MIC SWITCH

Purpose

The control wheel microphone (mic) switch gives PTT inputs to the audio management unit (AMU) for the headset or oxygen mask microphones.

Locations and Functions

The switch is a three-position switch and is on the outboard horn of each control wheel. In the MIC position, the microphone audio goes to the selected communication system. In the INT position, the microphone audio goes directly to the flight interphone system without selecting the FLT transmit switch on the audio control panel.



CAPT CONTROL WHEEL

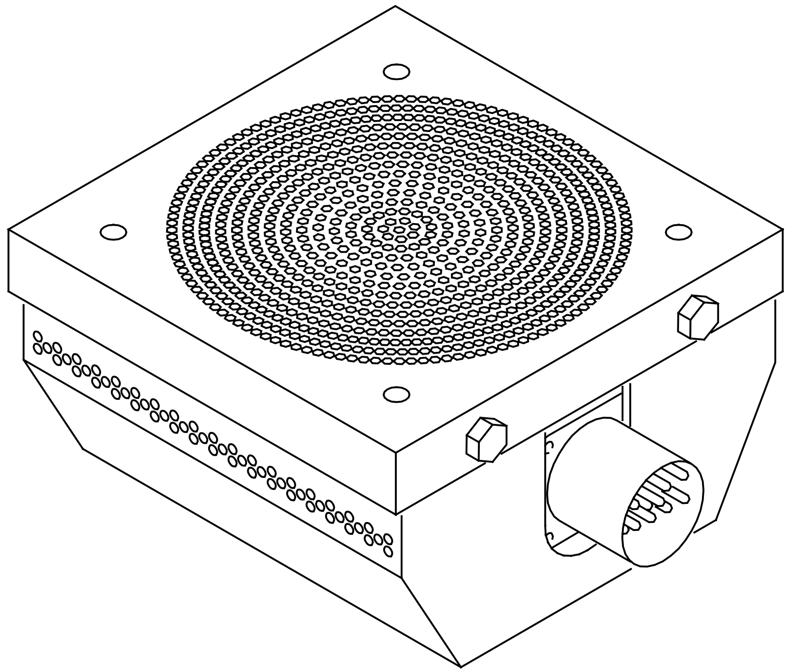
23-51-00-015 Rev 4 03/31/1997

FLIGHT INTERPHONE SYSTEM - CONTROL WHEEL MIC SWITCH

FLIGHT INTERPHONE SYSTEM - FLIGHT INTERPHONE SPEAKER

Function

The captain's and first officer's flight interphone speakers receive audio from the audio management unit (AMU). You use the speaker volume control on the audio control panel (ACP) to select and adjust the volume of the related speaker.



23-51-00-016 Rev 1 05/29/1996

FLIGHT INTERPHONE SYSTEM - FLIGHT INTERPHONE SPEAKER

FLIGHT INTERPHONE SYSTEM - OBSERVER AUDIO SYSTEM SWITCHING

General

The observer audio selector controls connections to the first observer's station card in the audio management unit (AMU). The AMU has many switches that connect the first observer to a flight crew station. The observer audio selector has these three positions:

- CAPT
- NORM
- F/O.

CAPT Position

When you select the CAPT position, the switch connects a ground to the AMU. The AMU disconnects the first observer and connects the captain's audio and PTT interfaces to the first observer's card. This includes the microphone and interphone PTTs from the captain's ACP. The captain makes all other selections with the first observer's audio control panel (ACP).

NORM Position

When you select NORM, the first observer's AMU inputs and outputs connect to the first observer's card.

F/O Position

When the observer audio selector is in the F/O position, it sends a ground to the AMU. The AMU disconnects the first observer and connects the first officer's audio and PTT interfaces to the first observer's card. This includes the microphone and interphone PTTs from the first officer's ACP. The first officer makes all other selections with the first observer's ACP.

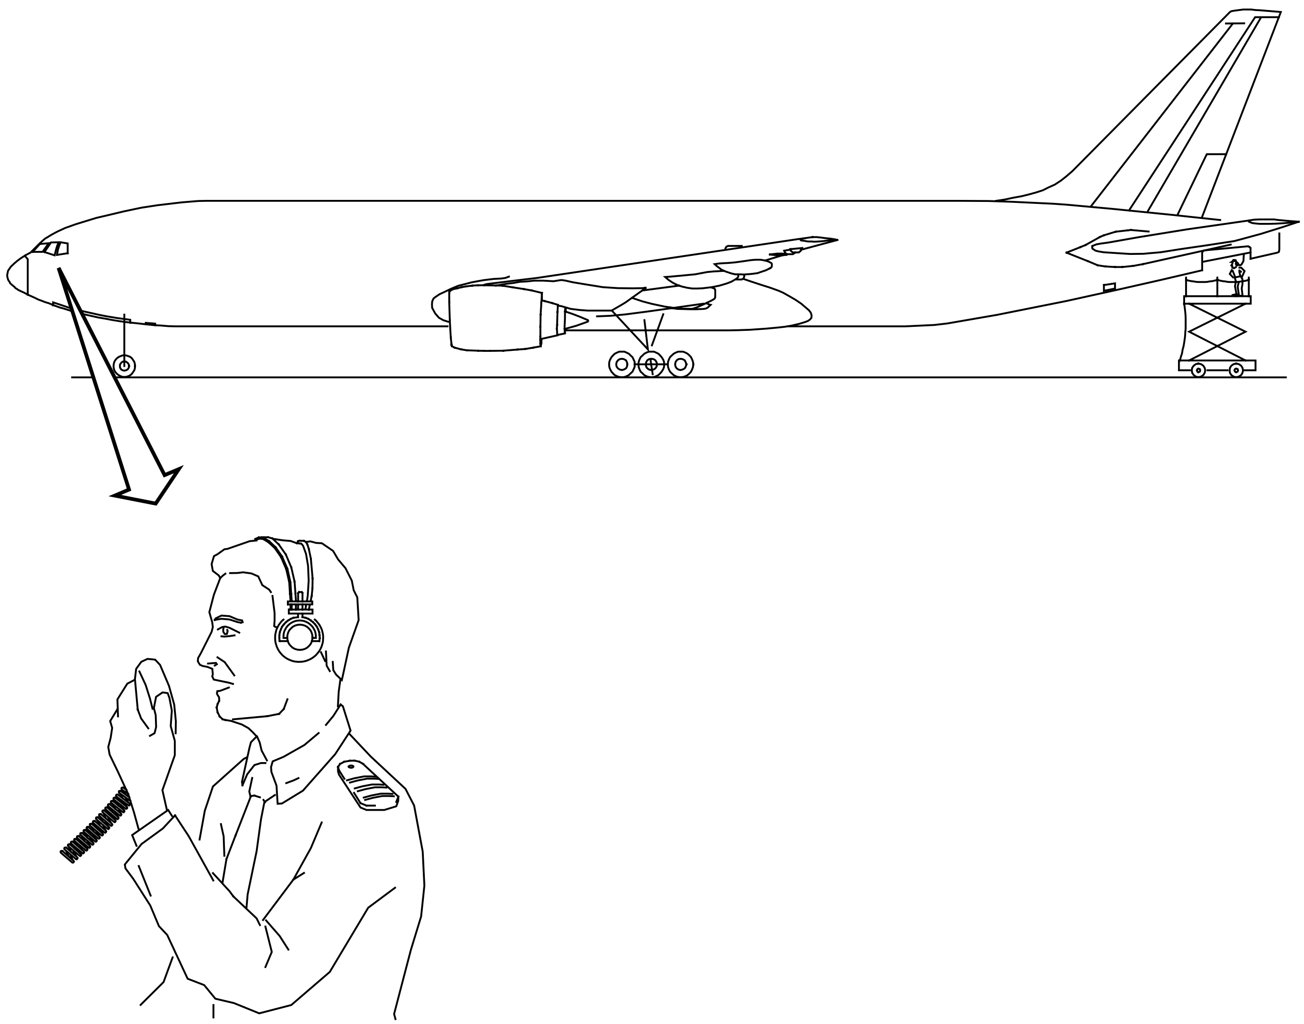
xcvr	- transceiver



SERVICE INTERPHONE SYSTEM - INTRODUCTION

SERVICE INTERPHONE SYSTEM - GENERAL DESCRIPTION

General

The service interphone jacks are in three groups:

- Service interphone 1
- Service interphone 2
- Service interphone 3.

Each group sends a single audio input to the audio management unit (AMU).

The AMU mixes the audio from all three groups. It sends this mixed audio back to the headsets in all groups.

The AMU mixes the service interphone audio with the flight interphone audio if the service interphone switch is in the ON position.

The AMU sends fault data to AIMS over an ARINC 629 bus.

SERVICE INTERPHONE SYSTEM - TEST

SERVICE INTERPHONE SYSTEM - FUNCTIONAL DESCRIPTION

General

The audio management unit (AMU) controls all service and flight interphone audio signals. The service interphone circuits are on the connector board of the audio management unit (AMU). Service interphone circuits have amplifiers for output audio. The AMU uses the service interphone switch position to send signals through either or both interphone systems.

Operation

The connector board mixes the three service interphone microphone inputs. This audio signal goes to switches S1 and S2. If the service interphone switch is OFF, the audio goes through switch S1 to the service interphone jacks.

If the service interphone switch is ON, the audio goes through switch S2 and connects with these audio signals:

- Flight interphone ground crew mic
- Flight interphone main equipment center mic
- Flight interphone station cards mic.

This audio then goes to:

- The flight interphone station cards
- The flight interphone main equipment center audio jack
- The flight interphone ground crew audio jack
- Switch S3.

Switch S3 sends the audio to the service interphone jacks.

Ground Crew Call System

WB371

TABLE OF CONTENTS

THIS PAGE INTENTIONALLY LEFT BLANK

GROUND CREW CALL SYSTEM - INTRODUCTION

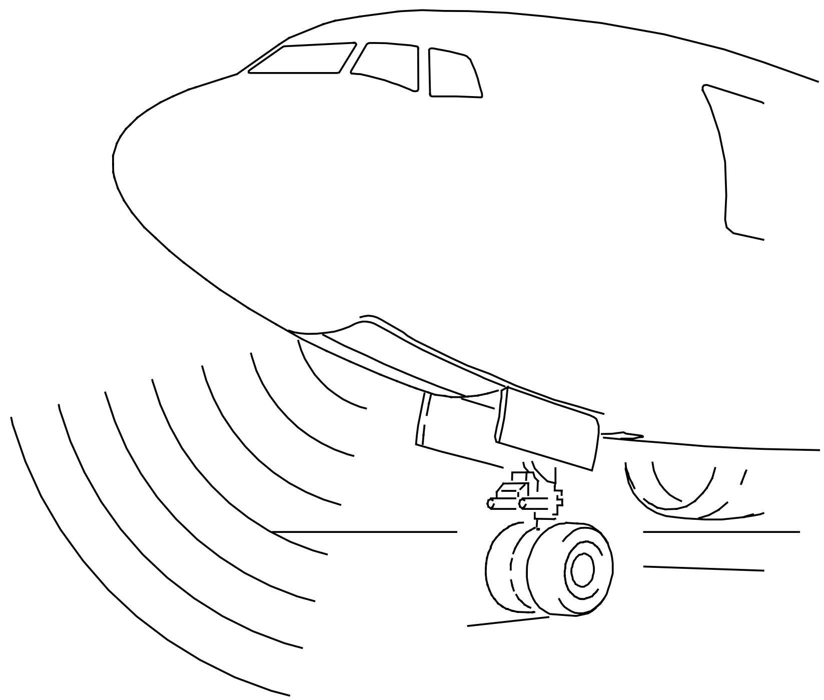
Purpose

The ground crew call system has these three functions:

- It tells flight deck personnel that there is a call from the ground
- It tells ground personnel that there is a call from the flight deck
- It tells ground personnel that the air data inertial reference unit (ADIRU) is on battery power or that there is an equipment cooling failure.

Abbreviations and Acronyms

ACP	- audio control panel
ADIRS	- air data inertial reference system
ADIRU	- air data inertial reference unit
AIMS	- airplane information management system
AMU	- audio management unit
CDU	- control display unit
ECS	- environmental control system
EICAS	- engine indication and crew alerting system
ELMS	- electrical load management system
flt	- flight
gnd	- ground
LSK	- line select key
PA/CI	- passenger address/cabin interphone



GROUND CREW CALL SYSTEM - INTRODUCTION

GROUND CREW CALL SYSTEM - GENERAL DESCRIPTION

General

The flight crew and the ground crew use the ground crew call system to tell each other to answer a call on the flight interphone system. The system supplies aural and visual signals in the flight deck and in the nose wheel well area.

Flight Deck Call

To call the flight deck, the ground crew pushes the flight deck call switch. This causes these flight deck indications:

- A light comes on the audio control panel (ACP)
- A chime comes on in the flight deck
- A message shows on EICAS.

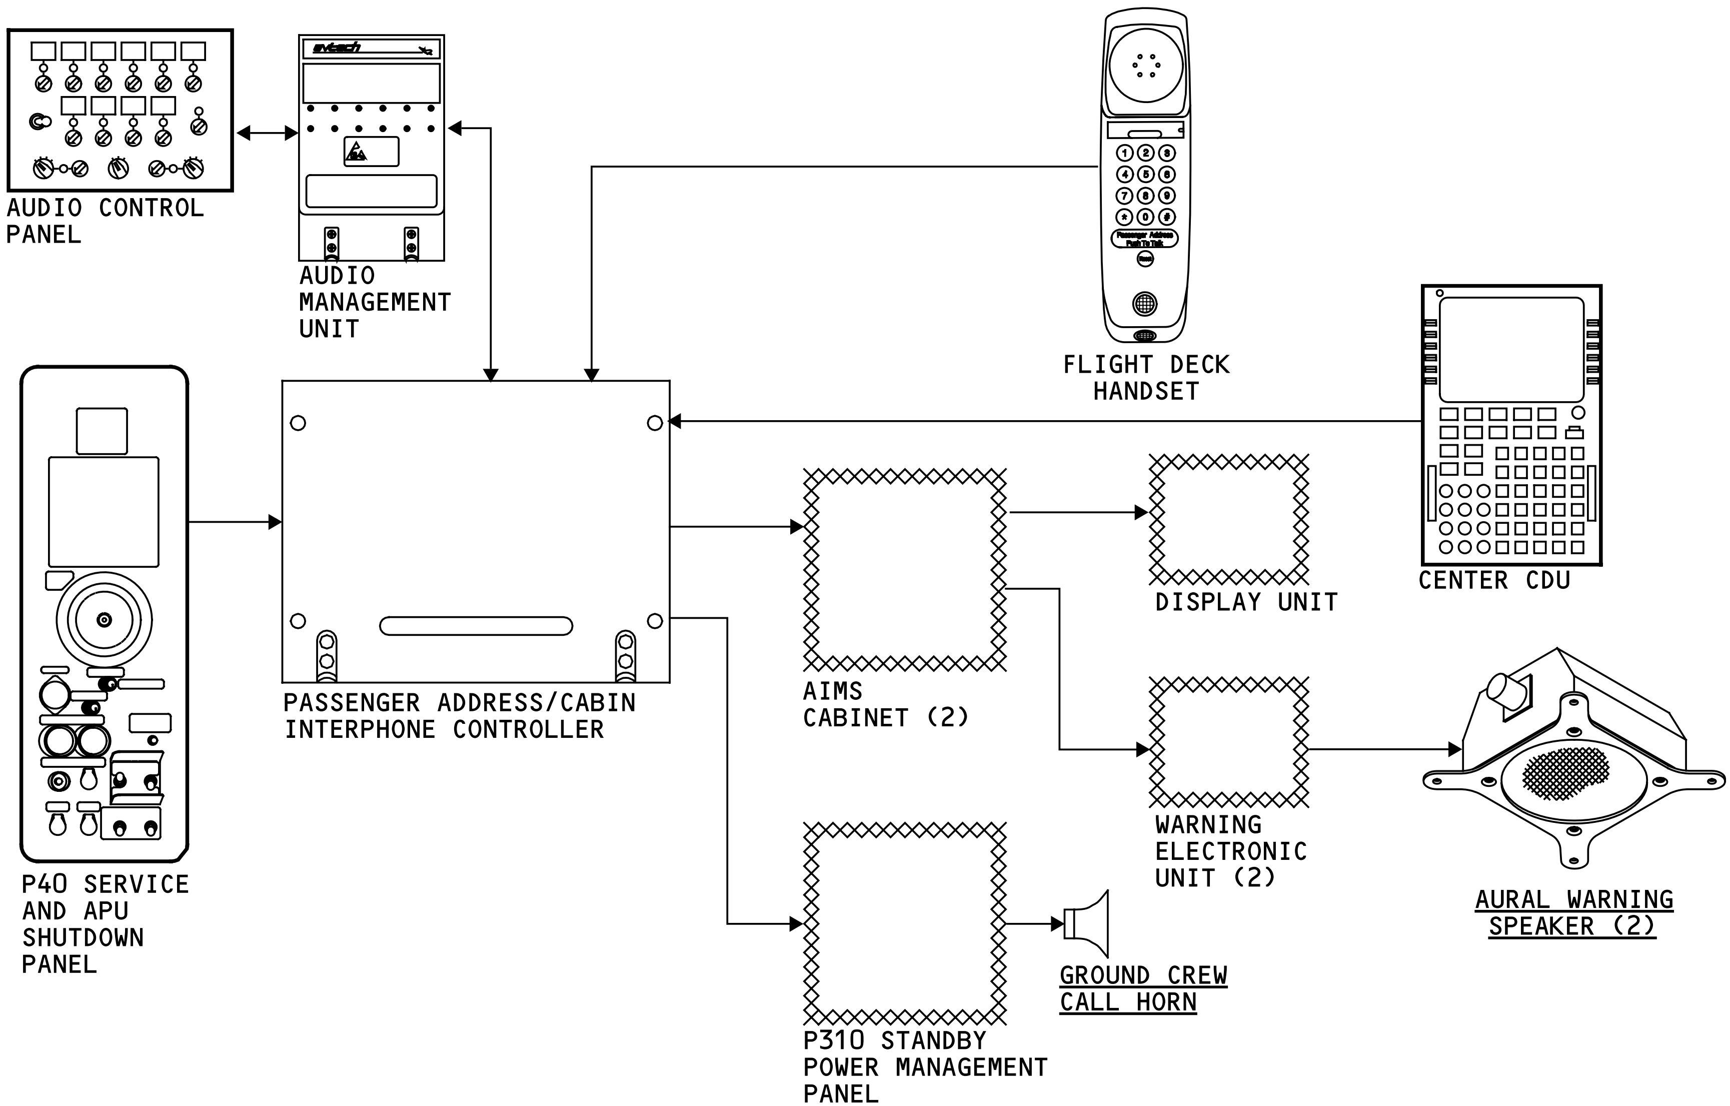
Ground Crew Call

To call the ground crew, the flight crew selects GND CREW on the center CDU cabin interphone menu or uses the flight deck handset. This causes the ground crew call horn to come on.

Power or Equipment Cooling Failures

The ground crew call horn also comes on when the airplane is on the ground and one of these occurs:

- There is an equipment cooling failure
- The air data inertial reference unit (ADIRU) is on and there is no ac power on the airplane.



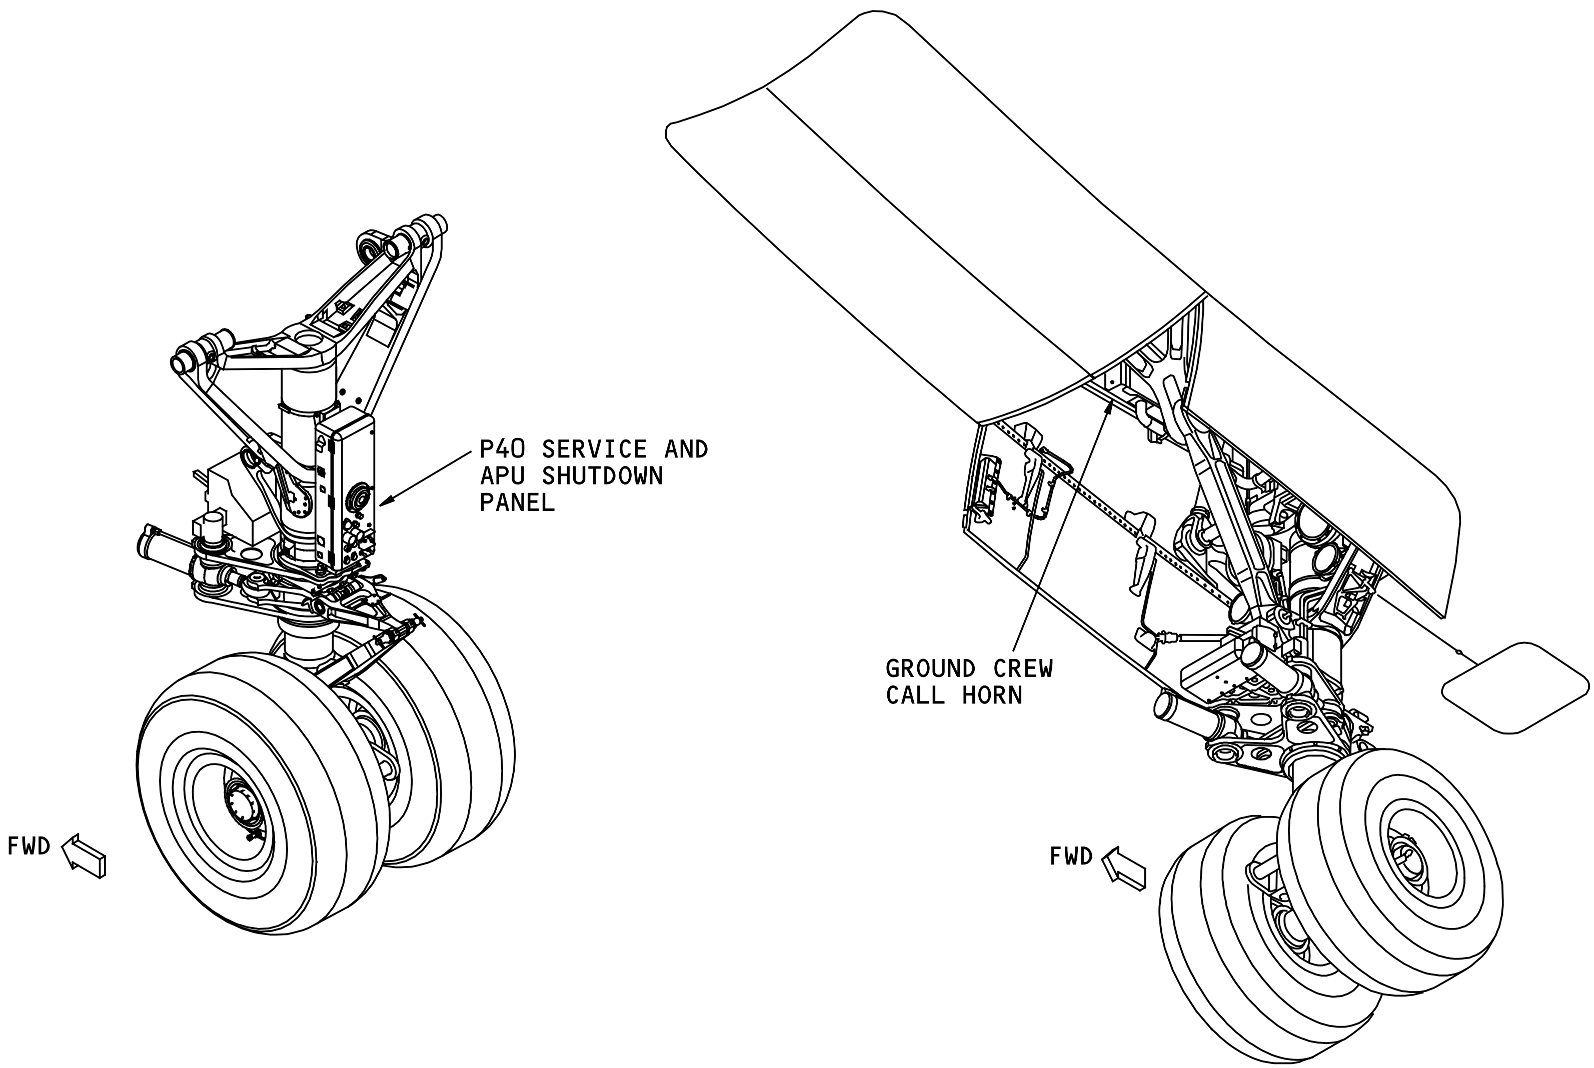
23-43-00-002 Rev 2 10/25/95

GROUND CREW CALL SYSTEM - GENERAL DESCRIPTION

GROUND CREW CALL SYSTEM - NOSE WHEEL WELL COMPONENT LOCATIONS

Ground Crew Call System Component Locations

The ground crew call horn and the service and APU shutdown panel are in the nose wheel well area.



GROUND CREW CALL SYSTEM - NOSE WHEEL WELL COMPONENT LOCATIONS

GROUND CREW CALL SYSTEM - INTERFACES

General

The ground crew call system uses the passenger address/ cabin interphone (PA/CI) controller to send signals between the flight crew and the ground crew.

PA/CI Controller

The standby power management panel has two circuit breakers that connect power to the PA/CI controller. One supplies power to the normal cabin interphone controller. The other supplies power to the secondary cabin interphone controller.

The nose gear electrical service panel sends a flight deck call discrete to the PA/CI controller.

The PA/CI controller sends a flight call discrete to the audio management unit (AMU) and gets a flight call reset signal from the AMU.

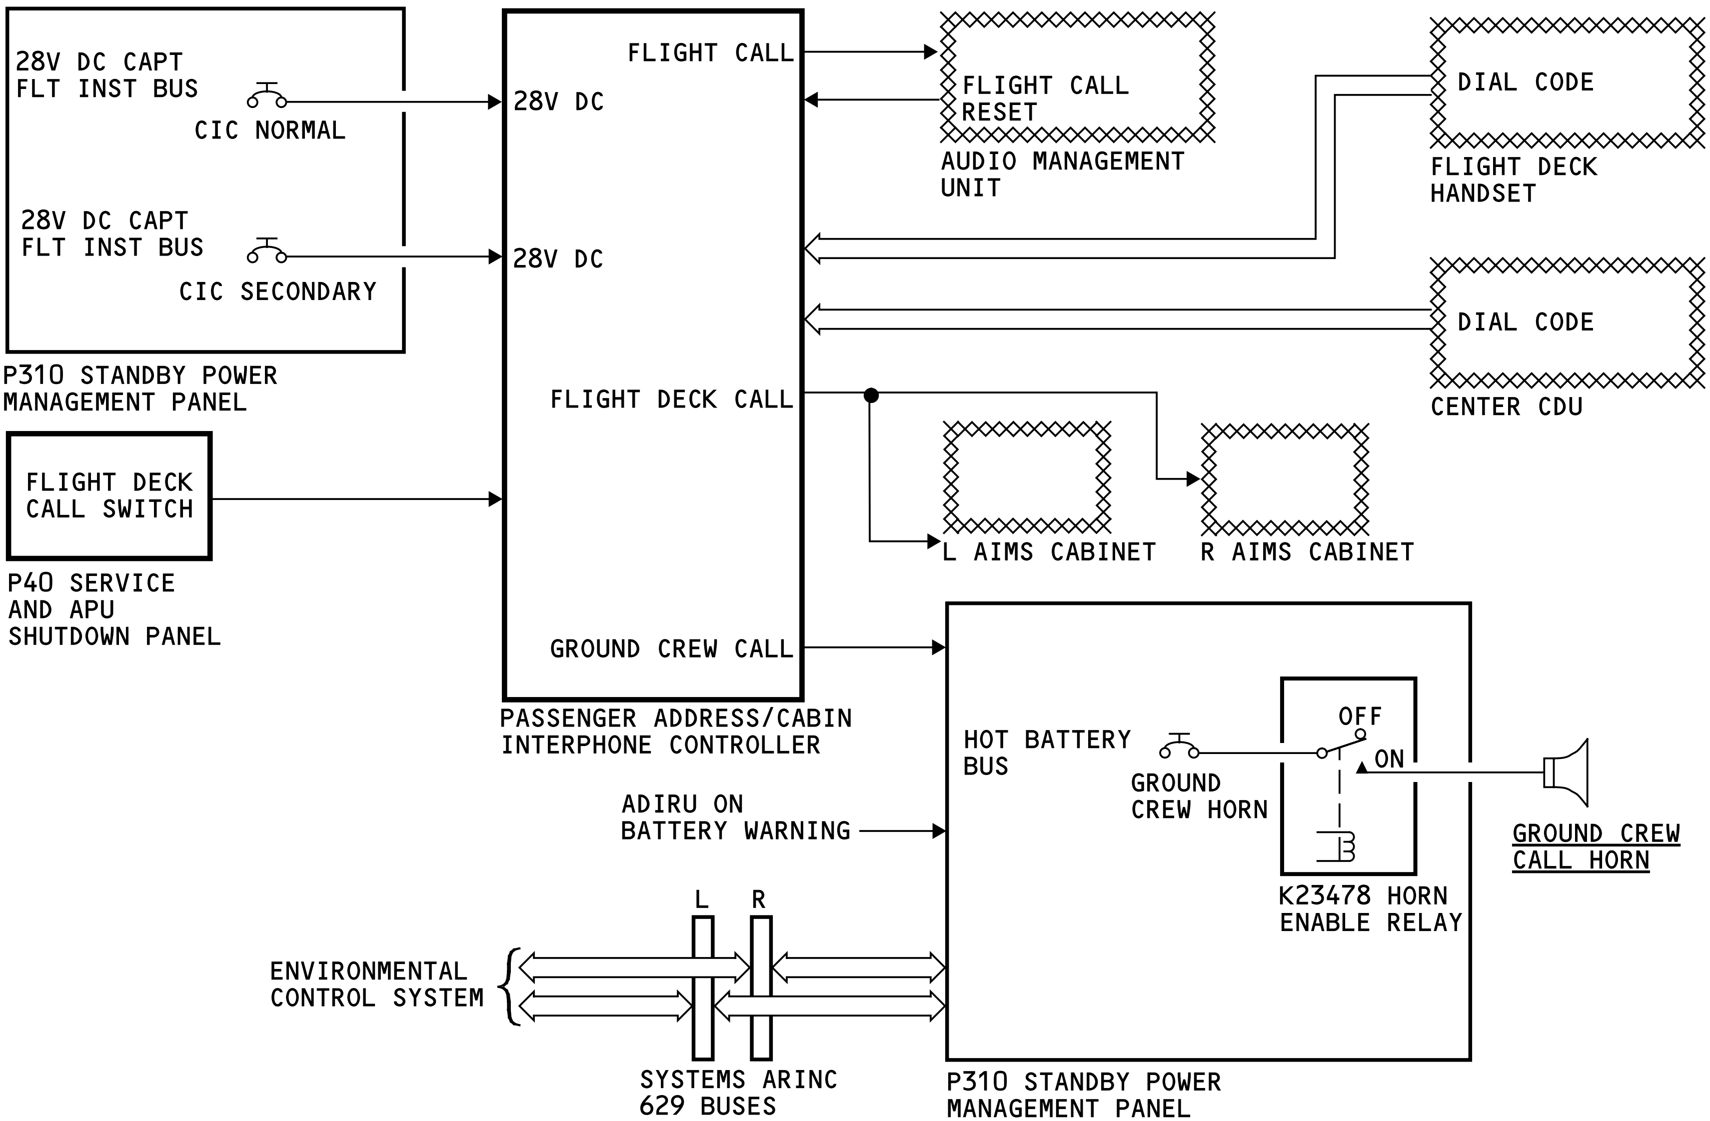
The center control display unit (CDU) or flight deck handset (FDH) sends dial code information to the PA/CI controller.

The PA/CI controller sends a flight deck call discrete to the AIMS cabinets to make a chime come on and show a message on EICAS.

Standby Power Management Panel

The PA/CI controller sends a discrete to the standby power management panel. The standby power management panel also gets signals from the environmental control system (ECS) and from the air data inertial reference system (ADIRS).

These signals cause the ground crew call horn to come on.



GROUND CREW CALL SYSTEM - INTERFACES

23-43-00-004 Rev 2 10/25/95

GROUND CREW CALL SYSTEM - GROUND CREW CALL HORN

Purpose

The ground crew call horn comes on for 3 seconds when there is a call from the flight deck. The horn comes on continuously when the air data inertial reference unit (ADIRU) is on battery power, or there is an equipment cooling failure.

GROUND CREW CALL SYSTEM - AUDIO CONTROL PANEL

GROUND CREW CALL SYSTEM - CENTER CDU

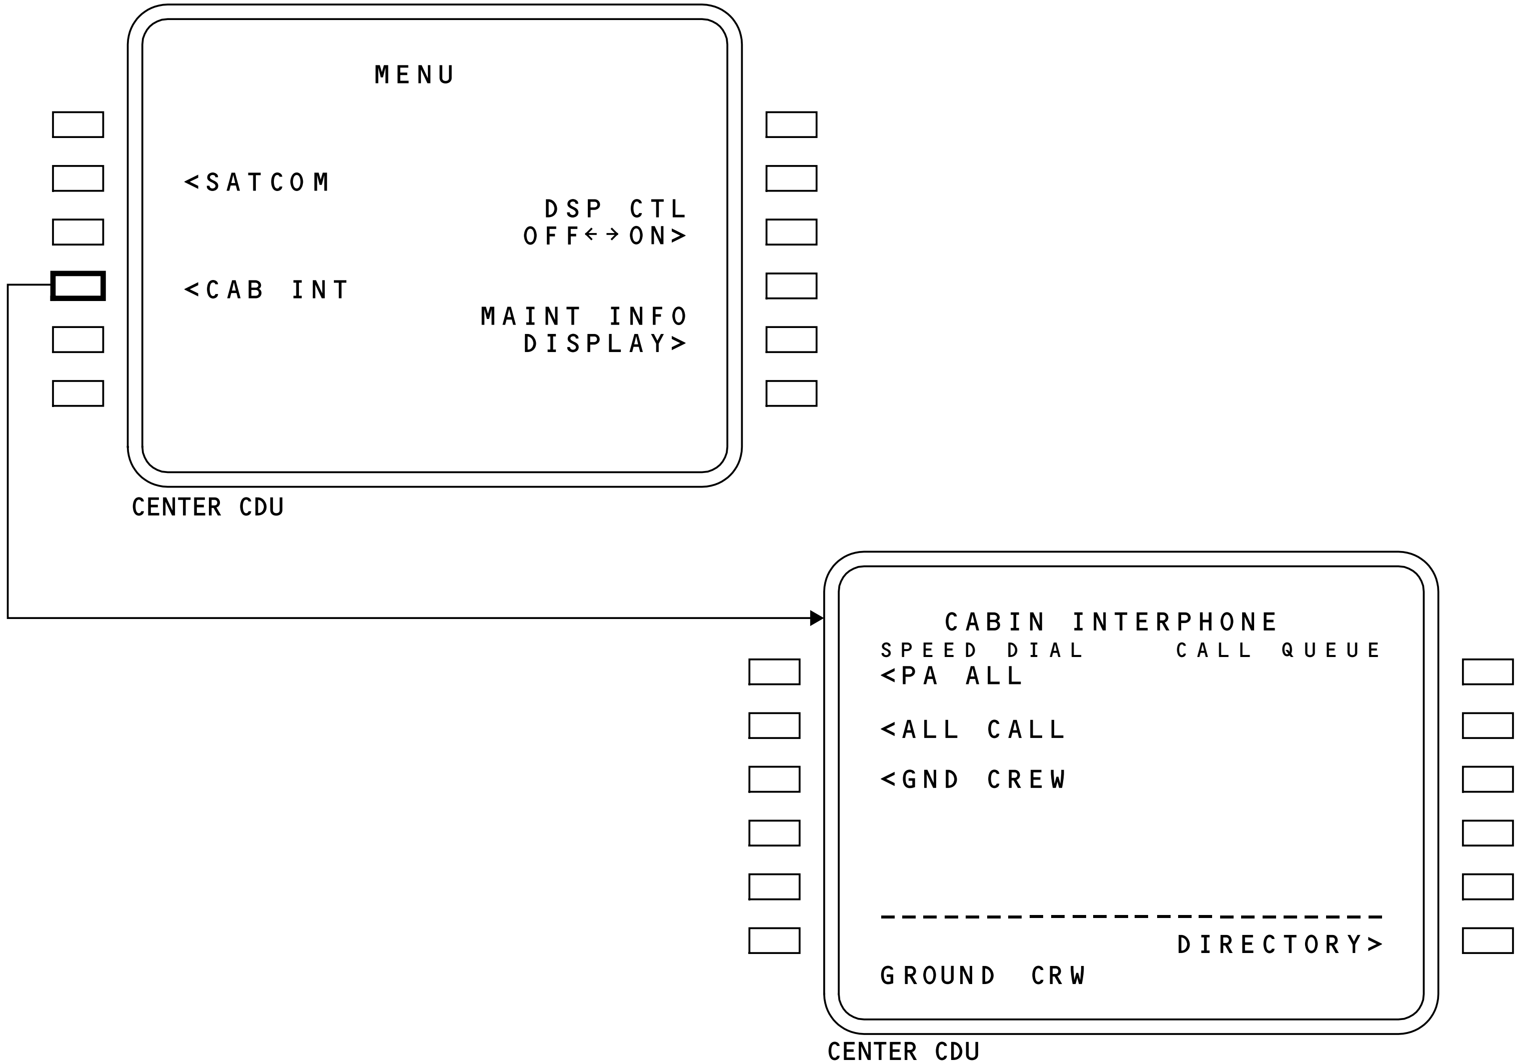
Purpose

The flight crew uses the center control display unit (CDU) or enters the applicable dial code on the flight deck handset to start a ground crew call.

Cabin Interphone Menu

The flight crew uses the cabin interphone menu to call the ground crew. To show the cabin interphone menu, push the line select key (LSK) next to <CAB INT on the CDU menu.

Push the LSK next to the <GND CREW selection or enter the applicable dial code on the CDU keypad, and push LSK 6L to call the ground crew.



23-43-00-008 Rev 2

GROUND CREW CALL SYSTEM - CENTER CDU

GROUND CREW CALL SYSTEM - FUNCTIONAL DESCRIPTION

General

The passenger address/cabin interphone (PA/CI) controller gets flight deck and ground crew call signals. It sends signals to cause different indications in the flight deck and at the nose wheel well.

Flight Deck Call Operation

When you push the flight deck call switch, a ground goes to the PA/CI controller. This causes the microprocessor to send messages to the:

- Audio management unit (AMU)
- AIMS cabinets.

The AMU causes the CALL light on the flight interphone transmit switch on each audio control panel (ACP) to come on.

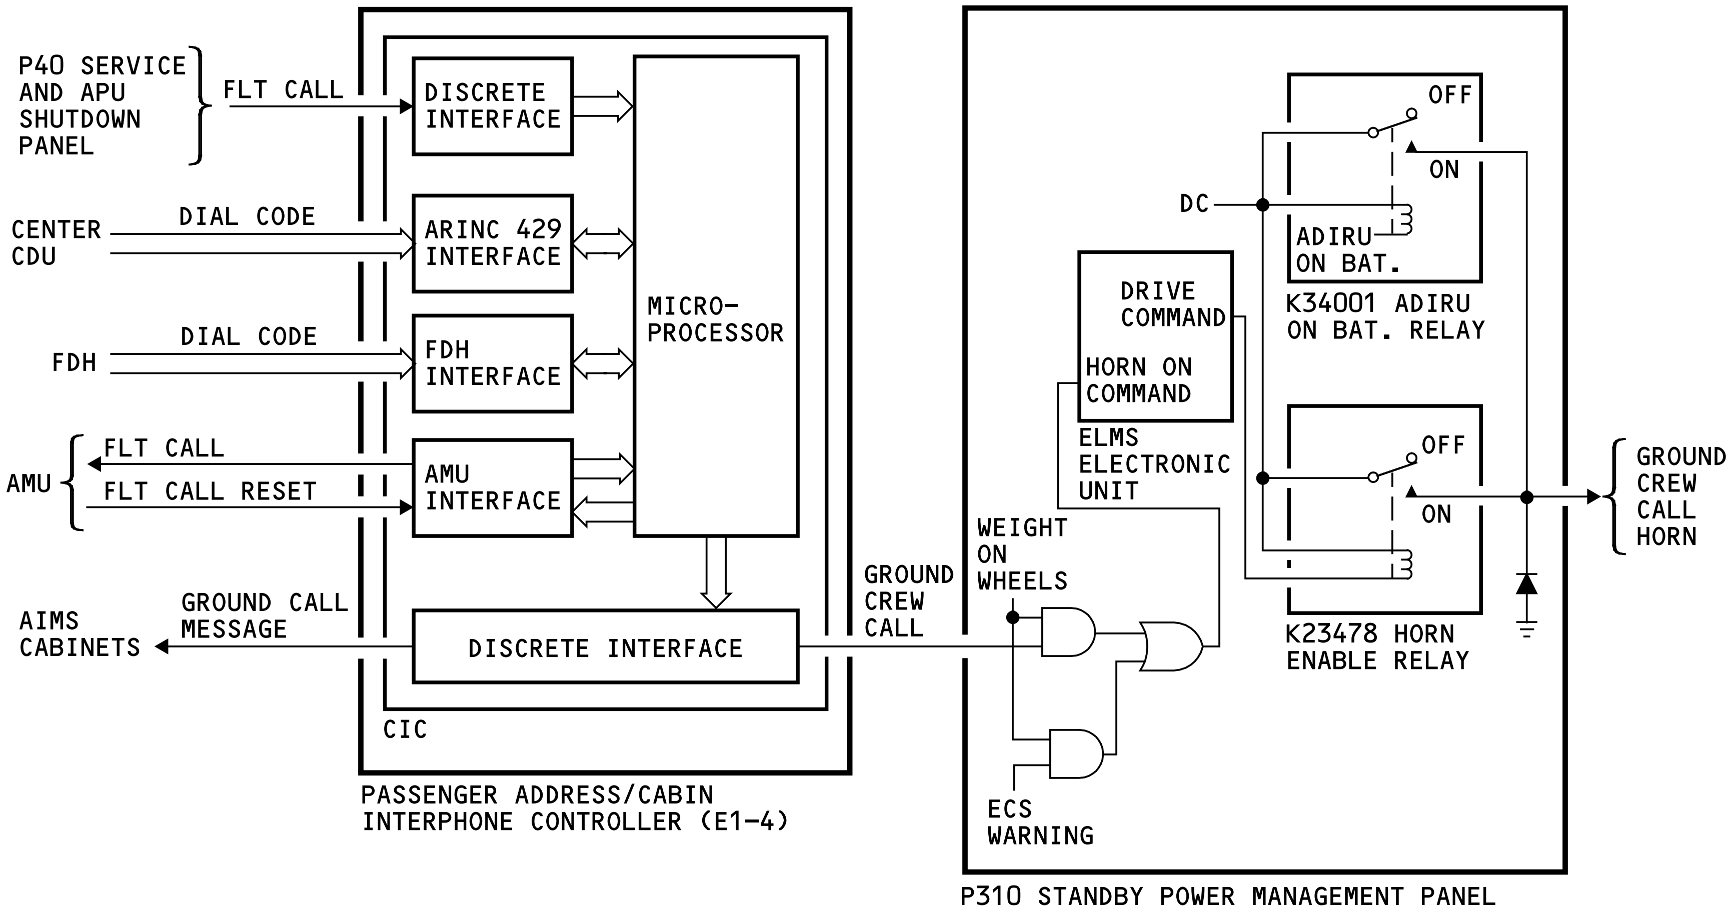
The AIMS cabinets send signals for a high-low chime through the aural warning speakers and a message on EICAS.

Horn Operation

When you select GND CREW on the center CDU cabin interphone menu or enter the applicable diale code on the flight deck handset, the microprocessor sends a signal to the standby power management panel. The electrical load management system (ELMS) electronic unit on the standby power management panel energizes the horn enable relay when the airplane is on the ground.

When there is an equipment cooling failure, the horn enable relay also energizes.

When the ADIRU is on without ac power, the ADIRU on-battery relay energizes and causes the horn to come on. This signal does not go through the horn enable relay.



GROUND CREW CALL SYSTEM - FUNCTIONAL DESCRIPTION

Very High Frequency Communications System

WB371

TABLE OF CONTENTS

THIS PAGE INTENTIONALLY LEFT BLANK

VERY HIGH FREQUENCY COMMUNICATION SYSTEM - INTRODUCTION

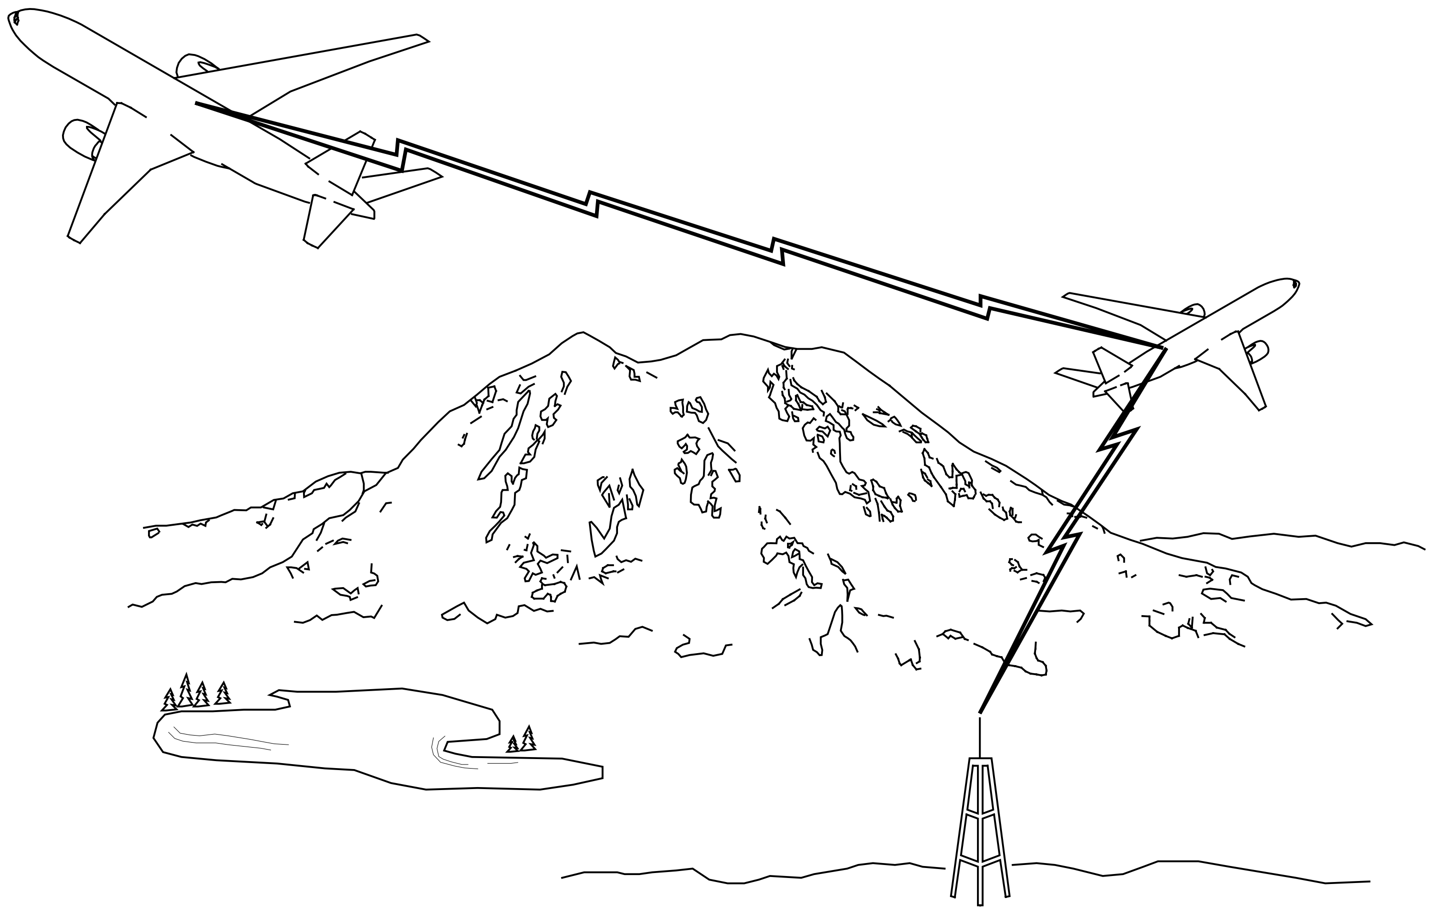
General

The very high frequency (VHF) communication system permits voice and data communication over line-of-sight distances. It permits communication between airplanes or between ground stations and airplanes.

The VHF system operates in the VHF aeronautical frequency range of 118.000 MHz to 136.975 MHz.

Abbreviations and Acronyms

ACP	- audio control panel
AIMS	- airplane information management system
AM	- amplitude modulation
AMU	- audio management unit
capt	- captain
CMCF	- central maintenance computing function
DCGF	- data conversion gateway function
DCMF	- data communication management function
DFDAF	- digital flight data acquisition function
ELMS	- electrical load management system
F/O	- first officer
F/OBS	- first observer
HF	- high frequency
MAT	- maintenance access terminal
pnl	- panel
PTT	- push to talk
RF	- radio frequency
RTP	- radio tuning panel
SSB	- single side band
VHF	- very high frequency
VSWR	- voltage standing wave ratio



VERY HIGH FREQUENCY COMMUNICATION SYSTEM - INTRODUCTION

VHF SYSTEM - GENERAL DESCRIPTION

General

The VHF communication system uses three VHF systems. Each VHF system has:

- A VHF antenna
- A VHF communication transceiver.

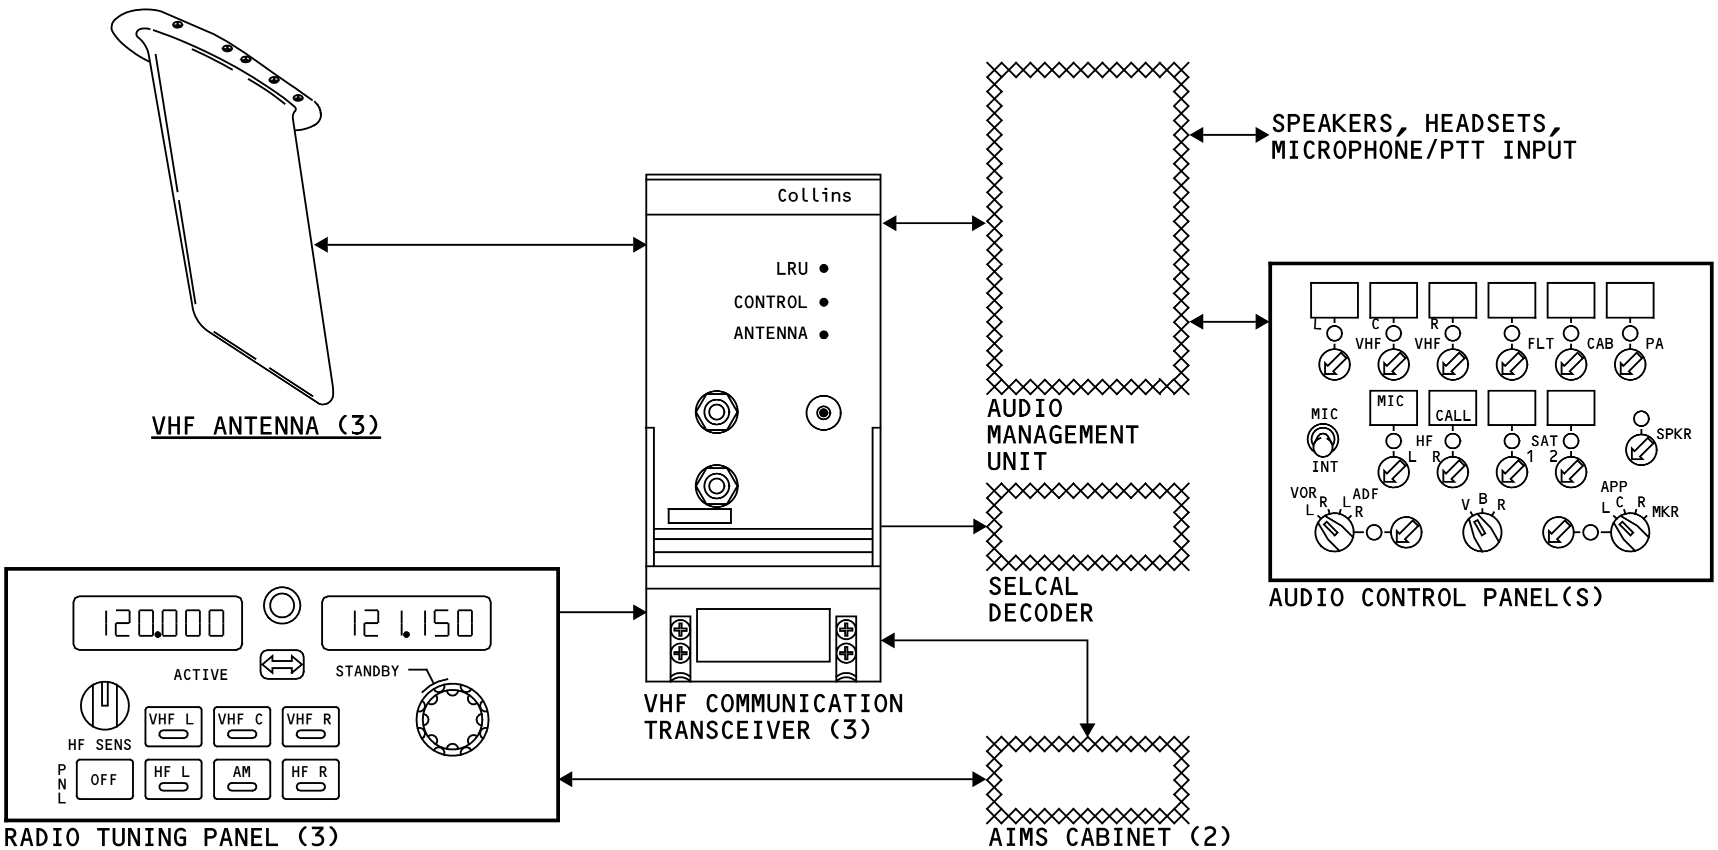
General Description

The VHF communication system connects with:

- Three radio tuning panels (RTPs). The RTPs send tuning data to the VHF communication transceiver.
- The audio management unit (AMU). Microphone audio and mic switch discretes go to the VHF transceiver through the AMU. Receiver audio goes from the VHF communication transceiver to the speakers and headsets through the AMU.
- The SELCAL decoder. The SELCAL decoder starts an alert when a call comes in for that airplane.

The VHF communication system also connects with the airplane information management system (AIMS) for these functions:

- Digital flight data acquisition function (DFDAF). The DFDAF in the AIMS cabinet receives the mic switch signals for input to the flight data recorder.
- Central maintenance computing function (CMCF). The CMCF gets fault reports from the VHF system and records this information in a fault history. This shows the maintenance crew the faulty component or function.
- Data conversion gateway function (DCGF). The VHF transceiver gets air/ground discretes from DCGF and uses its air/ground logic to define flight legs for its internal fault memory.
- Data communication management function (DCMF). The DCMF supplies data communications control and services for airplane air/ground datalink on the VHF system.



23-12-00-002 Rev 5 02/19/96

VHF SYSTEM - GENERAL DESCRIPTION

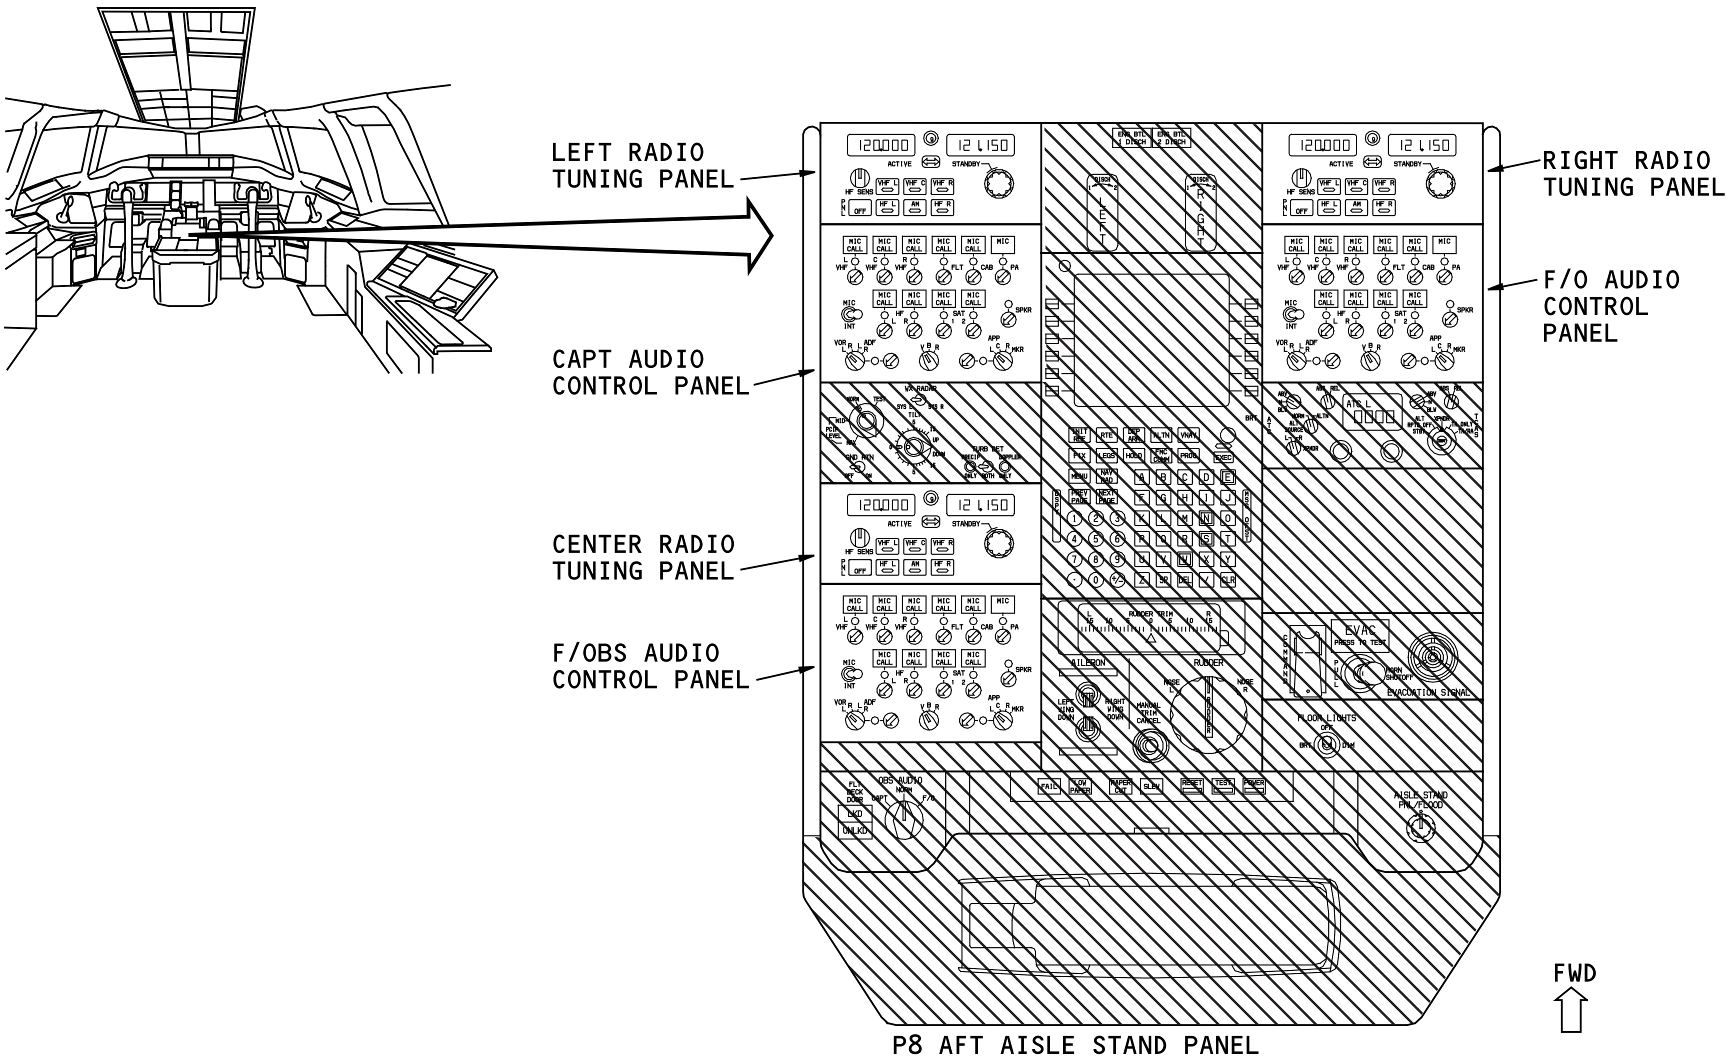
VHF SYSTEM - FLIGHT DECK COMPONENT LOCATIONS

VHF System Component Locations

The radio tuning panels (RTPs) are in the aft aisle stand panel.

Other Systems Component Locations

The audio control panels (ACPs) are part of the flight interphone system. They have an interface with the VHF communication system.



VHF SYSTEM - FLIGHT DECK COMPONENT LOCATIONS

VHF SYSTEM - MAIN EQUIPMENT CENTER COMPONENT LOCATIONS

VHF Component Locations

The VHF communication transceivers are in the main equipment center.

VHF SYSTEM - EXTERNAL COMPONENT LOCATIONS

VHF SYSTEM - POWER INTERFACE

General

The captain's flight instrument bus sends 28 VDC to:

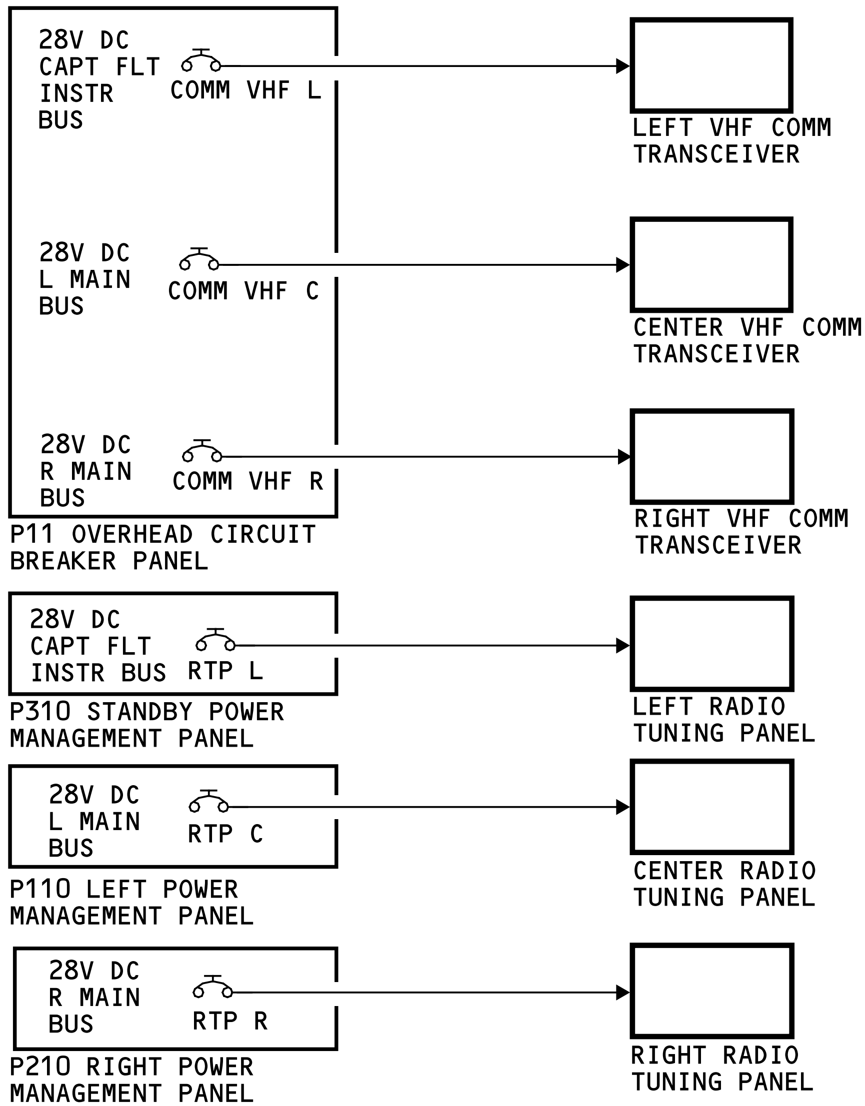
- The left VHF communication transceiver
- The left radio tuning panel (RTP).

The left main dc bus sends 28 VDC to:

- The center VHF communication transceiver
- The center RTP.

The right main dc bus sends 28 VDC to:

- The right VHF communication transceiver
- The right RTP.



23-12-00-006 Rev 0

VHF SYSTEM - POWER INTERFACE

VHF SYSTEM - TUNING INTERFACE

General

The VHF communication system uses data buses to share tuning information between the radio tuning panels (RTPs), the VHF communication transceivers, and the airplane information management system (AIMS) cabinets.

Tuning Buses

The RTPs send tuning data to the VHF communication transceivers. Any RTP can tune any transceiver.

Each RTP has these two ARINC 429 output buses:

- Tuning bus
- Crosstalk bus.

Both the left and right RTPs send tuning data to all three transceivers and to the left and right AIMS cabinets.

The center RTP sends tuning data to the left and right RTPs and to the left and right AIMS cabinets.

Both the left and right AIMS cabinets send auto-tune data to all three RTPs.

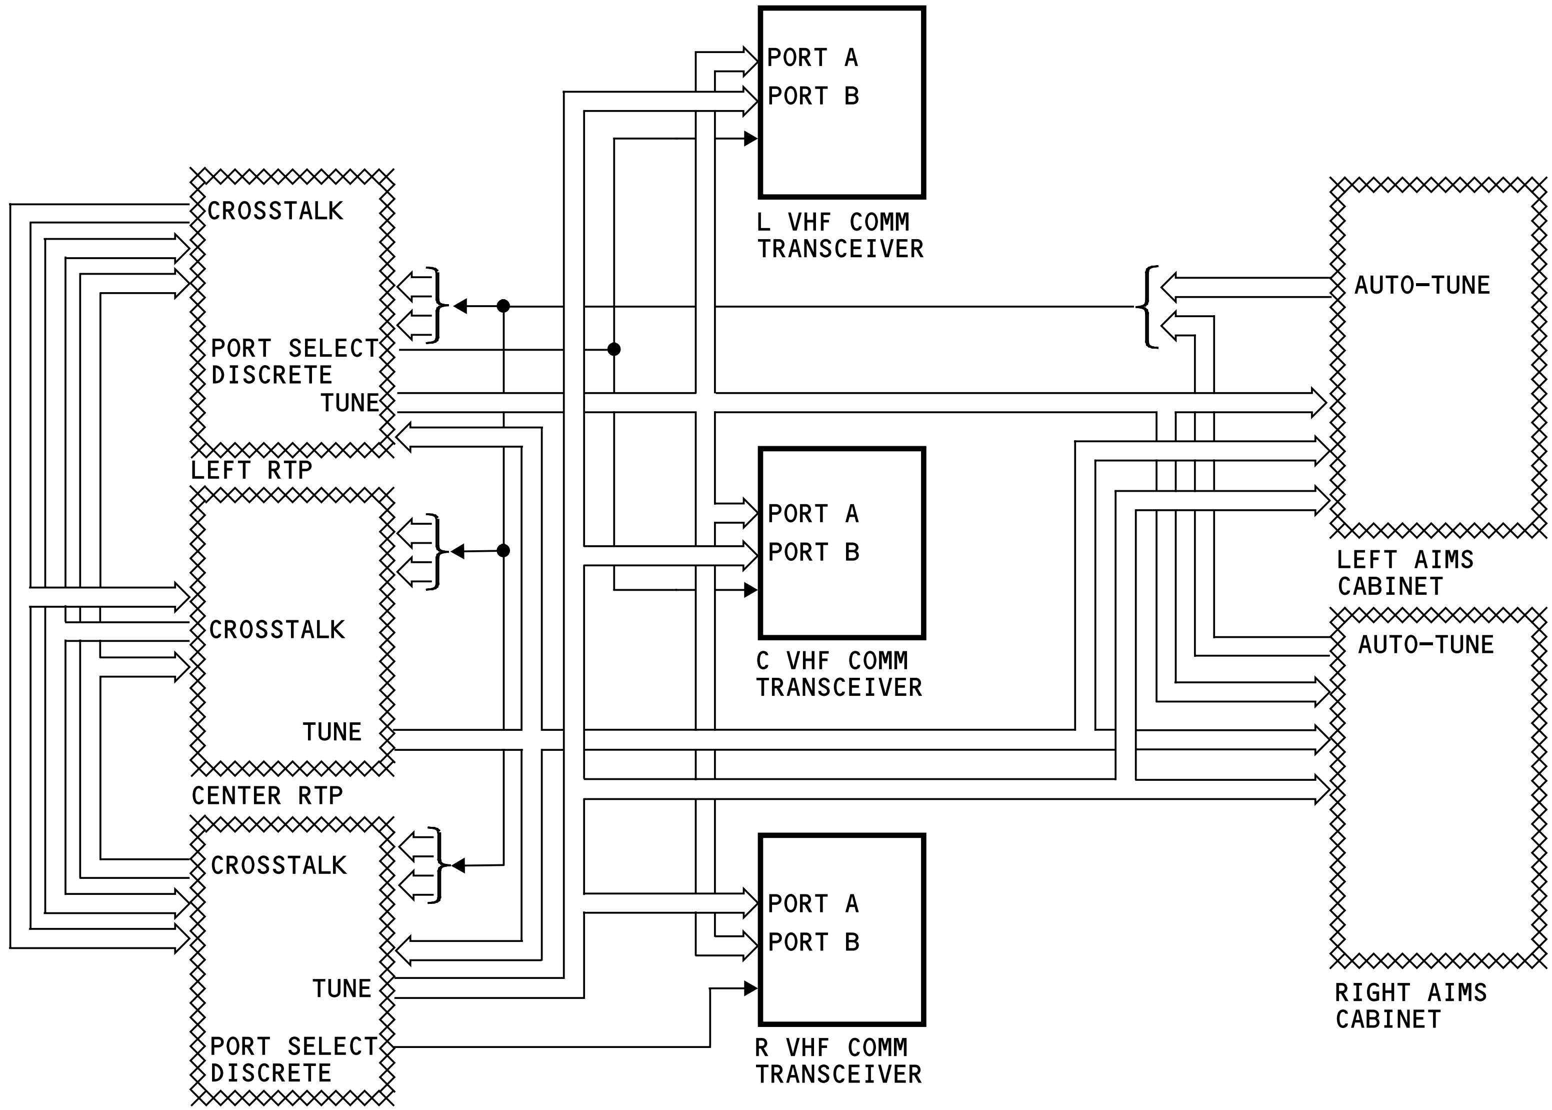
Port Select Discrete

The left RTP sends a port select discrete to the left and center transceivers. The right RTP sends a port select discrete to the right transceiver.

Each transceiver has two tuning data input ports; port A and port B. The transceiver uses the port select discrete to select its input port. A grounded port select discrete causes the transceiver to use port A. An open port select discrete causes the transceiver to use port B.

Crosstalk Buses

Each RTP sends tuning data to the other RTPs on crosstalk buses. This keeps the RTP tuning data synchronized and permits any RTP to tune any transceiver.



23-12-00-007 Rev 1

VHF SYSTEM - TUNING INTERFACE

VHF SYSTEM - VOICE RECEIVE/TRANSMIT INTERFACES

General

You use an audio control panel (ACP) to select a VHF communication transceiver for voice communication. You also use a radio tuning panel (RTP) to select a frequency for the transceiver. Any push to talk (PTT) signal activates the selected transceiver.

Signal Flow - Receive

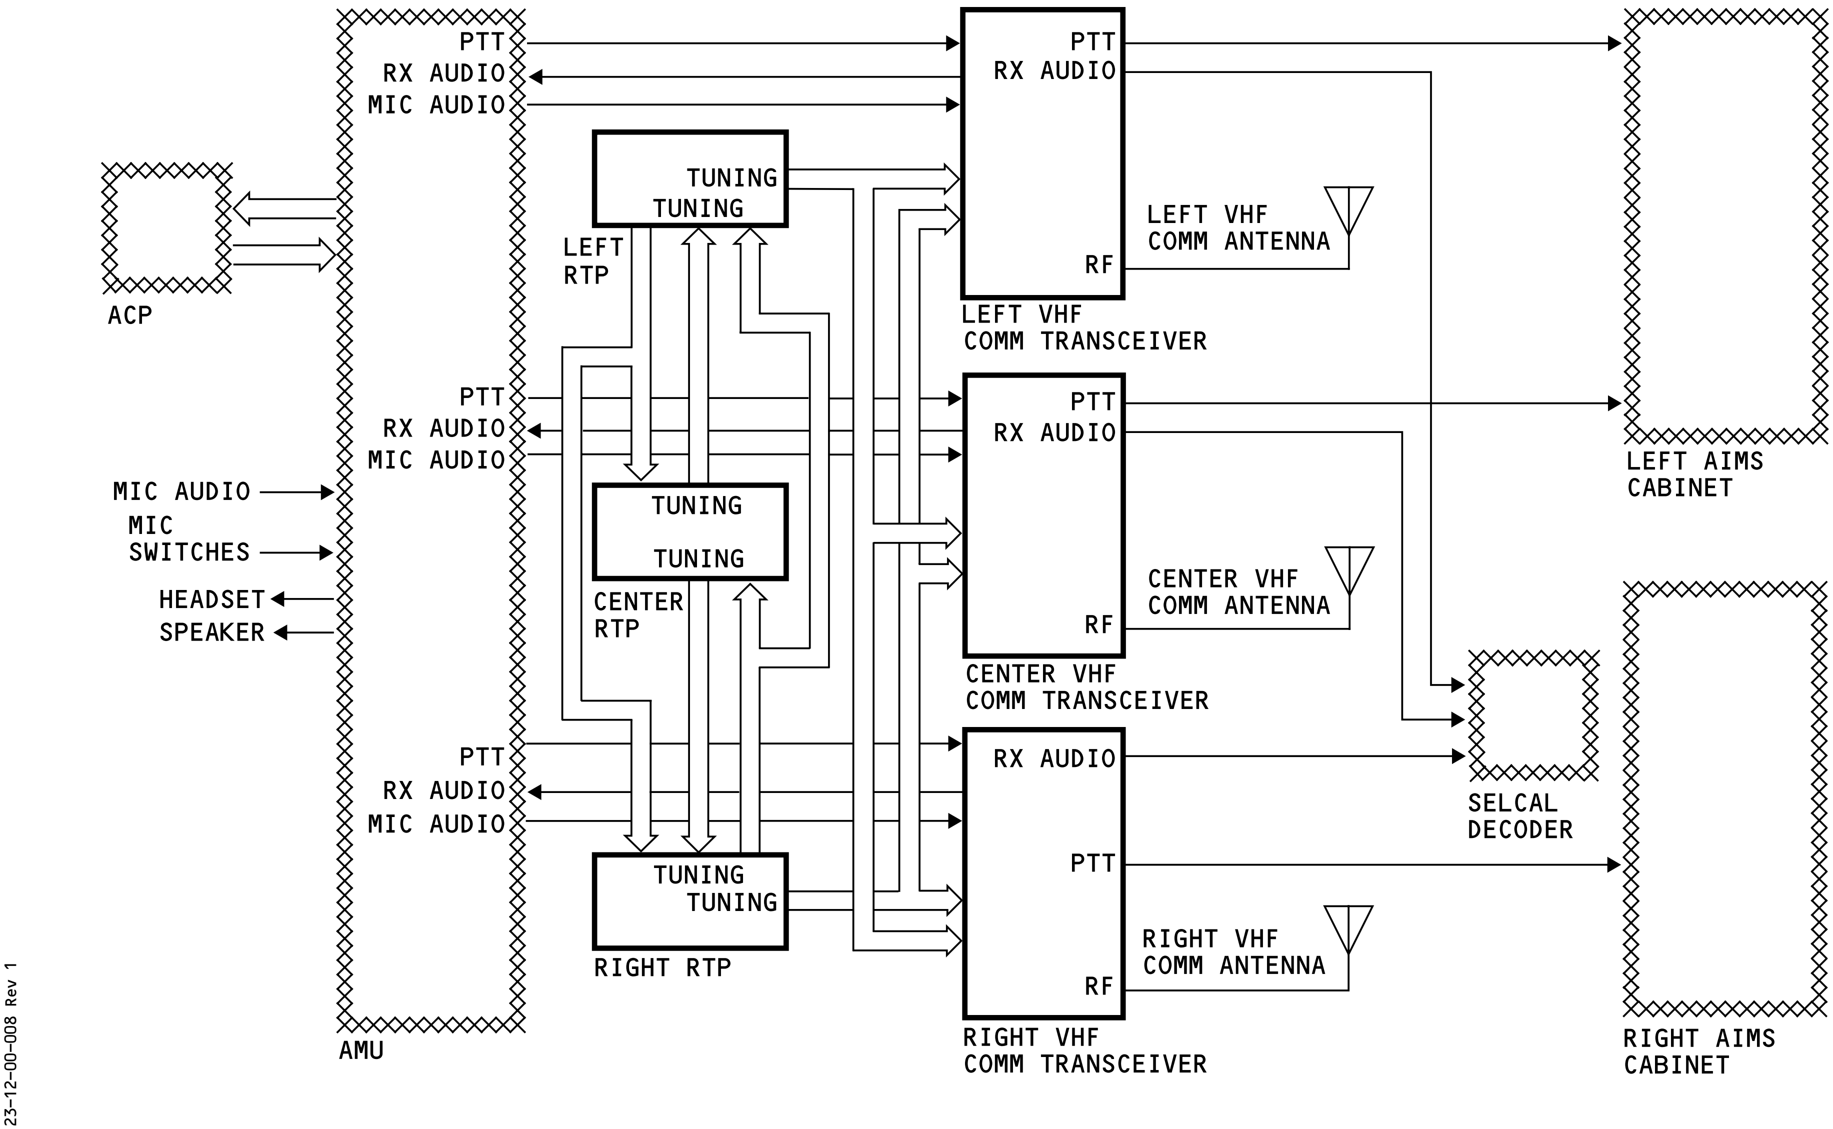
The VHF communication antennas receive RF signals and send them to the transceivers. The transceivers change the RF signals to audio signals and send them to the audio management unit (AMU). The AMU sends the audio signals to the headsets and speakers.

The transceiver sends received audio to the SELCAL decoder to monitor for selective call tones.

Signal Flow - Transmit

The AMU sends the mic audio and the mic switches signal to the selected transceiver. The transceiver changes the mic audio to an RF signal and sends it to the VHF antenna. The VHF antenna transmits the RF signal.

The transceiver sends key event (PTT) to the AIMS digital flight data acquisition function (DFDAF).



VHF SYSTEM - VOICE RECEIVE/TRANSMIT INTERFACES

VHF SYSTEM - DATA RECEIVE/TRANSMIT INTERFACES

General

To receive and transmit data, the VHF communication system uses the three radio tuning panels (RTPs) and only two VHF communication transceivers. These components continuously communicate with the airplane information management system (AIMS) during data communication.

Discrete Interfaces

The transceivers get a voice/data select signal from AIMS. The voice/data signal selects the voice or data transmission mode of the transceiver.

The selected transceiver receives a data keyline signal from AIMS. The data keyline signal starts the data transmission.

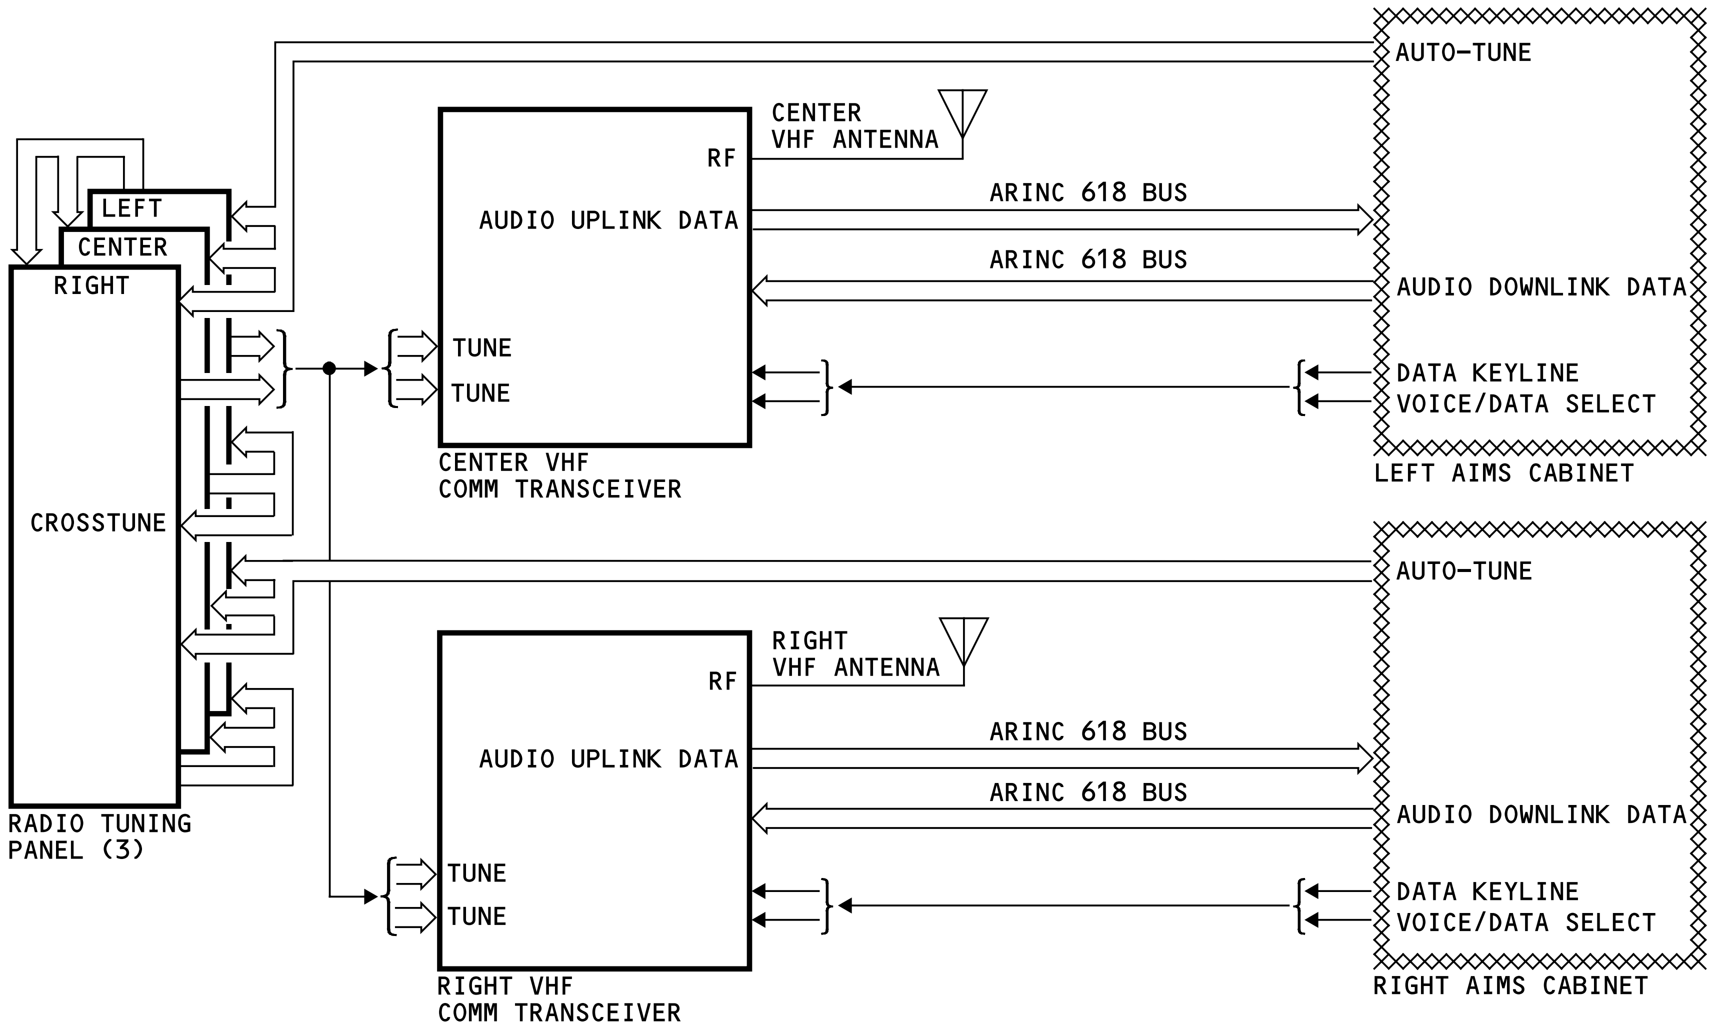
Tuning Interfaces

AIMS uses ARINC 429 buses to send auto-tuning frequencies to the left, right, and center RTPs. The RTPs send the tuning frequencies to the center transceiver or to the right transceiver.

Data Interface

The transceivers get audio uplink data from ground stations and send it to AIMS on ARINC 618 buses.

The AIMS data communication management function (DCMF) sends the audio downlink data to the transceivers on ARINC 618 buses. The transceivers send this data to the ground communication stations.



23-12-00-009 Rev 2 06/01/95

VHF SYSTEM - DATA RECEIVE/TRANSMIT INTERFACES

VHF SYSTEM - AIMS FAULT REPORTING AND TESTING INTERFACES

General

The VHF communication system sends fault information to the airplane information management system (AIMS) from the VHF transceivers and the radio tuning panels (RTPs).

VHF Communication Transceiver Interfaces

The transceivers send real time fault and status information to the AIMS cabinets.

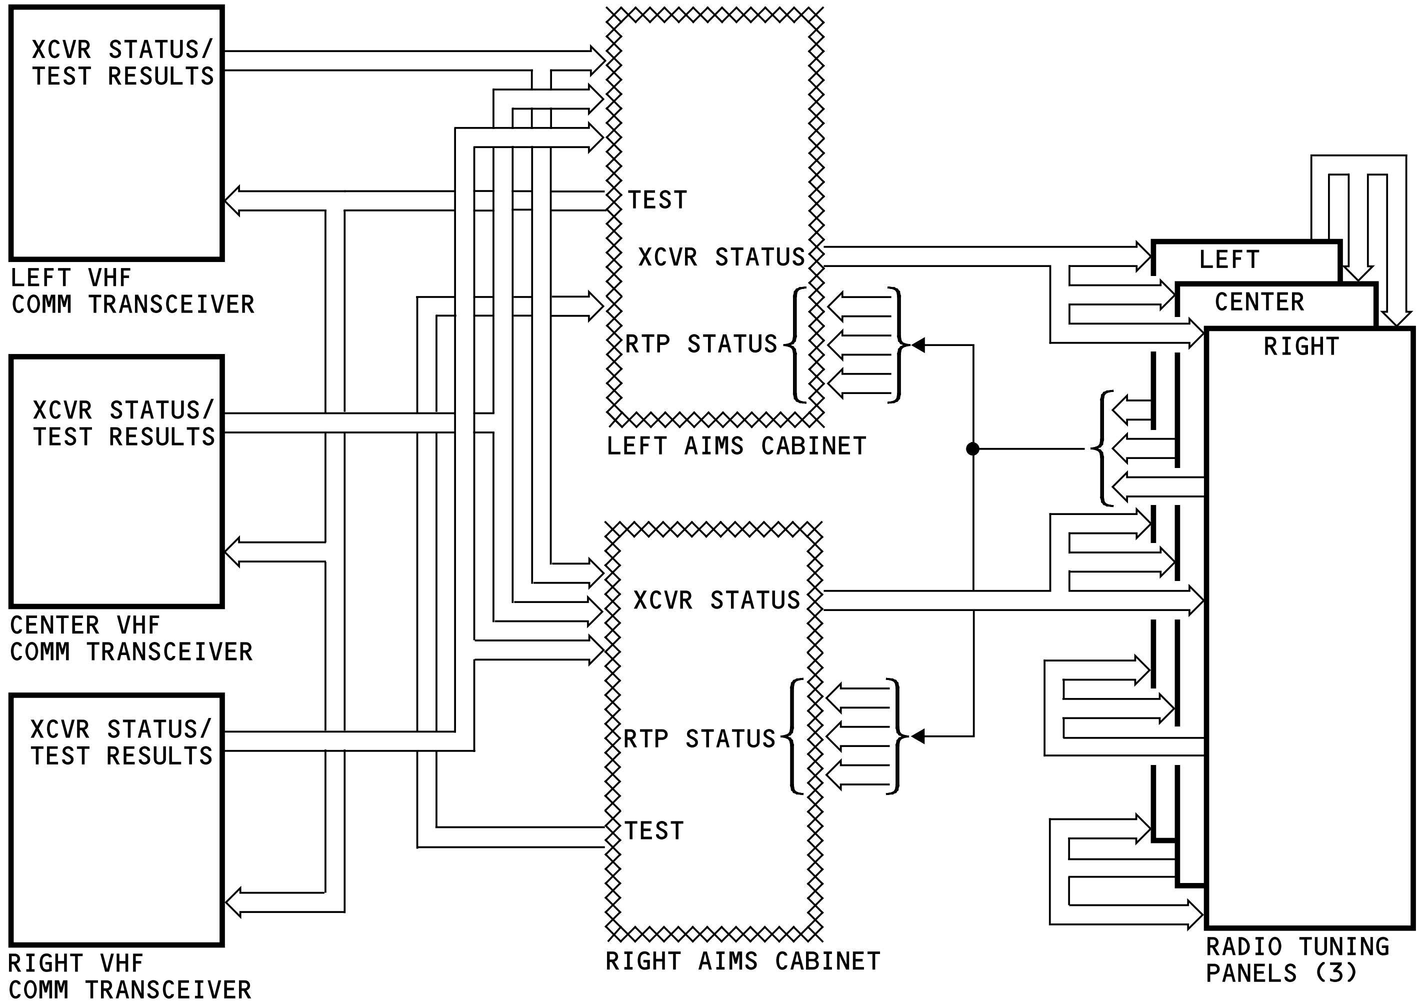
AIMS data conversion gateway function (DCGF) sends air/ground information to the transceiver.

The transceivers use the AIMS central maintenance computing function (CMCF) for on ground maintenance tests. The right AIMS cabinet CMCF sends ground maintenance test requests to the left AIMS cabinet. The left AIMS cabinet CMCF sends all test requests to the VHF transceivers. The transceivers return the test requests to the CMCF.

RTP Interfaces

The AIMS central maintenance computing function (CMCF) sends transceiver status to the RTPs.

The RTPs send fault status information to the AIMS cabinets.



23-12-00-010 Rev 1 06/01/95

VHF SYSTEM - AIMS FAULT REPORTING AND TESTING INTERFACES

VHF SYSTEM - VHF COMMUNICATION TRANSCEIVER

Purpose

The VHF communication transceiver changes RF signals to audio signals during receive and changes audio signals to RF signals during transmit.

General Description

The transceiver has:

- 8.33 KHz frequency spacing
- 118 MHz to 136.975 MHz frequency range
- 25 watts minimum output power.

Controls and Indications

The LED indicators show the status of the VHF system after you do a self-test from the front panel. These are the LED indicators on the front panel:

- LRU, shows a failure of the transceiver
- CONTROL, shows a failure of the ARINC 429 input
- ANTENNA, shows a failure of the antenna.

The TEST switch starts a 100 msec system self test. This includes these tests:

- Transceiver self-test
- Input serial tuning word test
- Antenna VSWR test.

All LEDs turn red for about two seconds. Then the LRU LED turns green and all other LEDs remain red for about 2 seconds. All LEDs turn off for about 2 seconds. Then the LRU LED comes on green for about 30 seconds and the CONTROL and ANTENNA LEDs turn off.

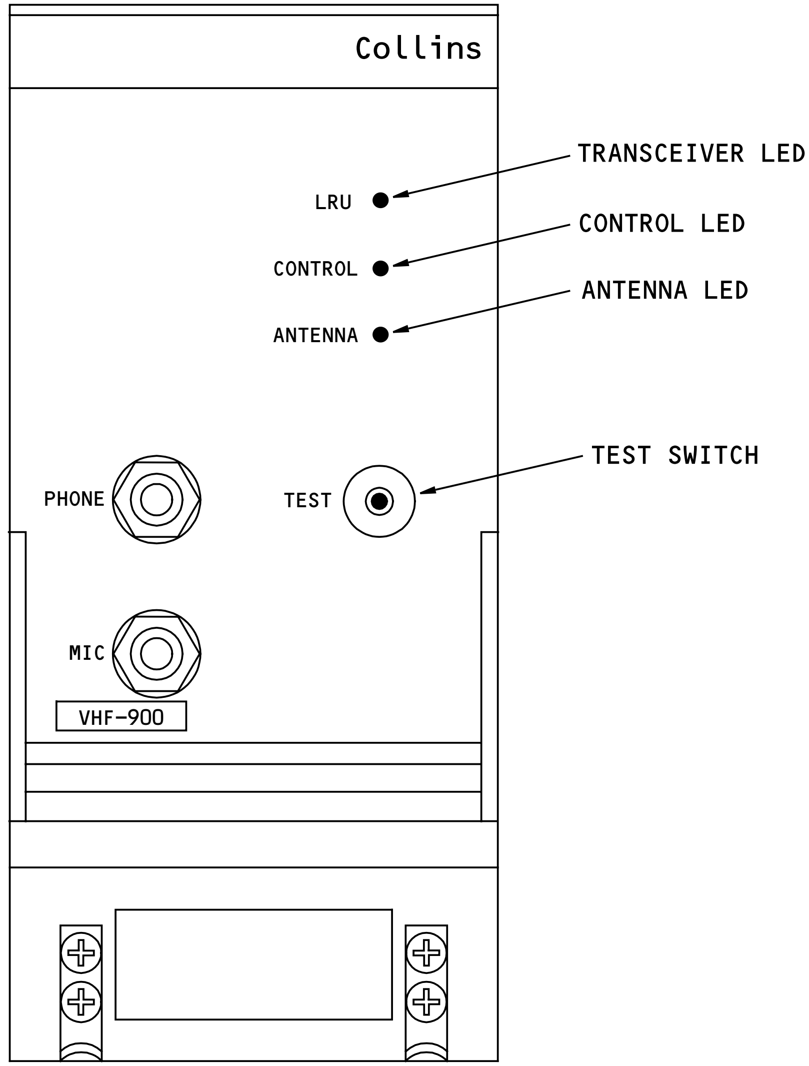
The LRU LED turns red after the self-test shows a failure.

The other LEDs come on red after the self-test to show a failure.

The self-test done from the MAT does the same tests but does not show the LED indications.

Phone and Mic Jacks

Phone and mic jacks give connection points for headphones and microphone.



23-12-00-011 Rev 5 06/02/95

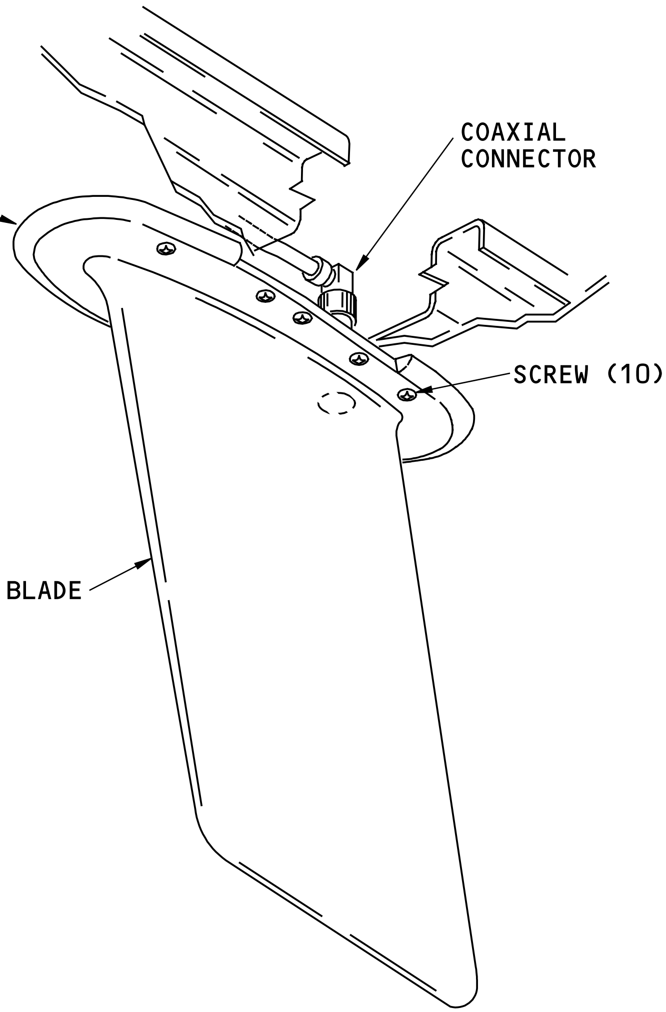
VHF SYSTEM - VHF COMMUNICATION TRANSCEIVER

VHF SYSTEM - VHF COMMUNICATION ANTENNA

General Description

The VHF communication antenna receives and transmits RF signals in the VHF frequency range.

The antenna attaches with 10 screws. There is an aerodynamic smoother around the antenna base. An o-ring seals the coaxial connector.



23-12-00-012 Rev 0

VHF SYSTEM - VHF COMMUNICATION ANTENNA

VHF SYSTEM - RADIO TUNING PANEL

THIS PAGE INTENTIONALLY LEFT BLANK

VHF SYSTEM - RADIO TUNING PANEL

Purpose

The radio tuning panel (RTP) selects the modes of operation, and selects the active and standby frequencies for each communication radio. Each RTP sends tuning and mode information to:

- Communication radios
- Other two RTPs
- Airplane information management system (AIMS) cabinets.

Description

Each RTP has these features:

- Active and standby frequency windows
- Frequency transfer switch
- Offside tuning light
- Frequency selectors
- Radio switches
- AM switch
- RTP off (OFF) switch
- HF sensitivity (HF SENS) control.

The frequency windows show this additional information:

- Messages from selected radio systems
- Transfer frequencies from the AIMS data communication management function (DCMF).

Operation

When the RTP is off, the white PNL OFF light comes on. Push the RTP OFF switch to turn the RTP on. When the RTP is on, the white PNL OFF light goes off.

The active frequency window shows the current frequency of the selected radio. The standby frequency window shows the frequency that the flight crew selects with the frequency selectors. The standby frequency window also shows autotune frequency information from the AIMS cabinets during a voice uplink.

The flight crew sets the standby frequency with the frequency selectors. The first digit is always 1. The outer knob adjusts the second two digits (10 MHz and 1 MHz) in 1 MHz steps. The inner knob adjusts the fourth, fifth and sixth digits (100 KHz, 10 kHz, and 1 kHz) in 8.33 kHz steps. The RTP automatically selects 25 kHz spacing for 121.425 to 121.575 for the 121.5 MHz emergency frequency.

The frequency transfer switch causes the active and standby frequencies to change windows. The active frequency goes to the standby frequency window, and the standby frequency goes to the active frequency window.

You use the radio switches to select a radio. You select only one radio at a time. The white light in the selected radio switch comes on.

When the flight crew selects an off-side radio, two offside tuning lights come on. One light is on the RTP that the flight crew uses to make the selection. The other light is on the onside RTP of the selected radio.

The HF SENS control sets the RF sensitivity level of the onside HF transceiver. The left RTP sets the left HF sensitivity. The right RTP sets the right HF sensitivity. The center RTP HF SENS control does not connect to any transceiver.

Use the AM switch to select between AM and SSB modulation modes for the selected HF transceiver. When you select AM mode, the white light comes on in the AM mode switch on its onside RTP if any of these conditions exist:

- Flight crew selects any VHF communication transceiver while in the AM mode
- Flight crew selects the onside HF transceiver while in the AM mode.

The AM mode light bar goes off when the flight crew selects SSB mode.

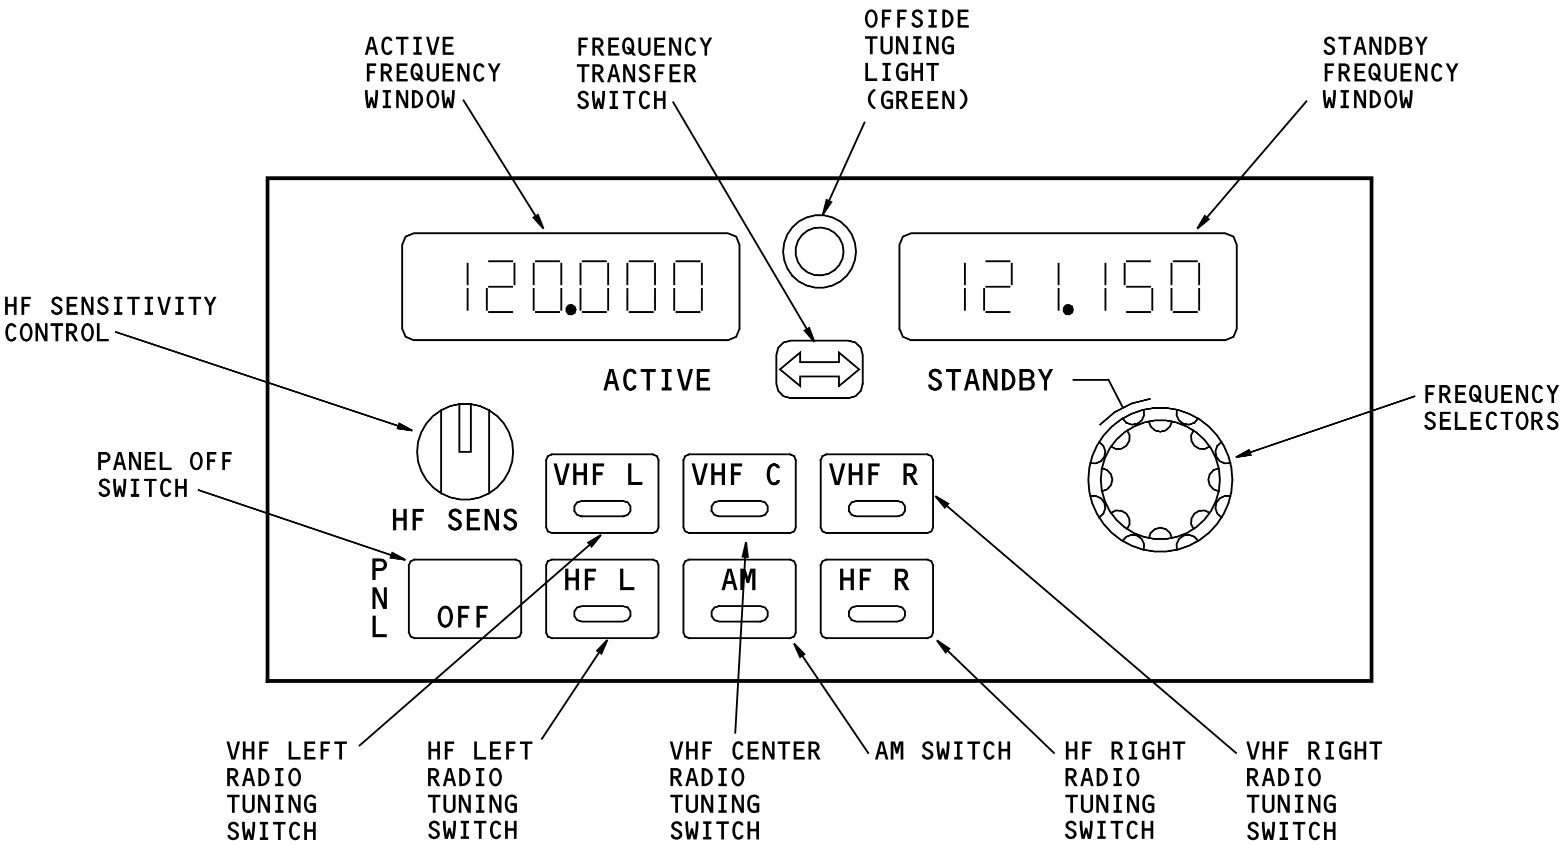
Push the PNL OFF switch to stop the operation of the RTP. When the RTP is off, the white PNL OFF light comes on and all functions stop except these:

- Displays continue to show any current fault
- RTP continues to receive 28v dc
- RTP continues to send BITE information to the AIMS central maintenance computer function (CMCF).

BITE

The RTP does a test of itself continuously. The RTP shows PANEL FAIL in the two frequency display windows when the RTP has an internal failure or there is a system failure.

The two frequency windows show all dashes if the flight crew selects a failed radio.



23-12-00-013 Rev 3 08/21/1997

VHF SYSTEM - RADIO TUNING PANEL

VHF SYSTEM - AUDIO CONTROL PANEL

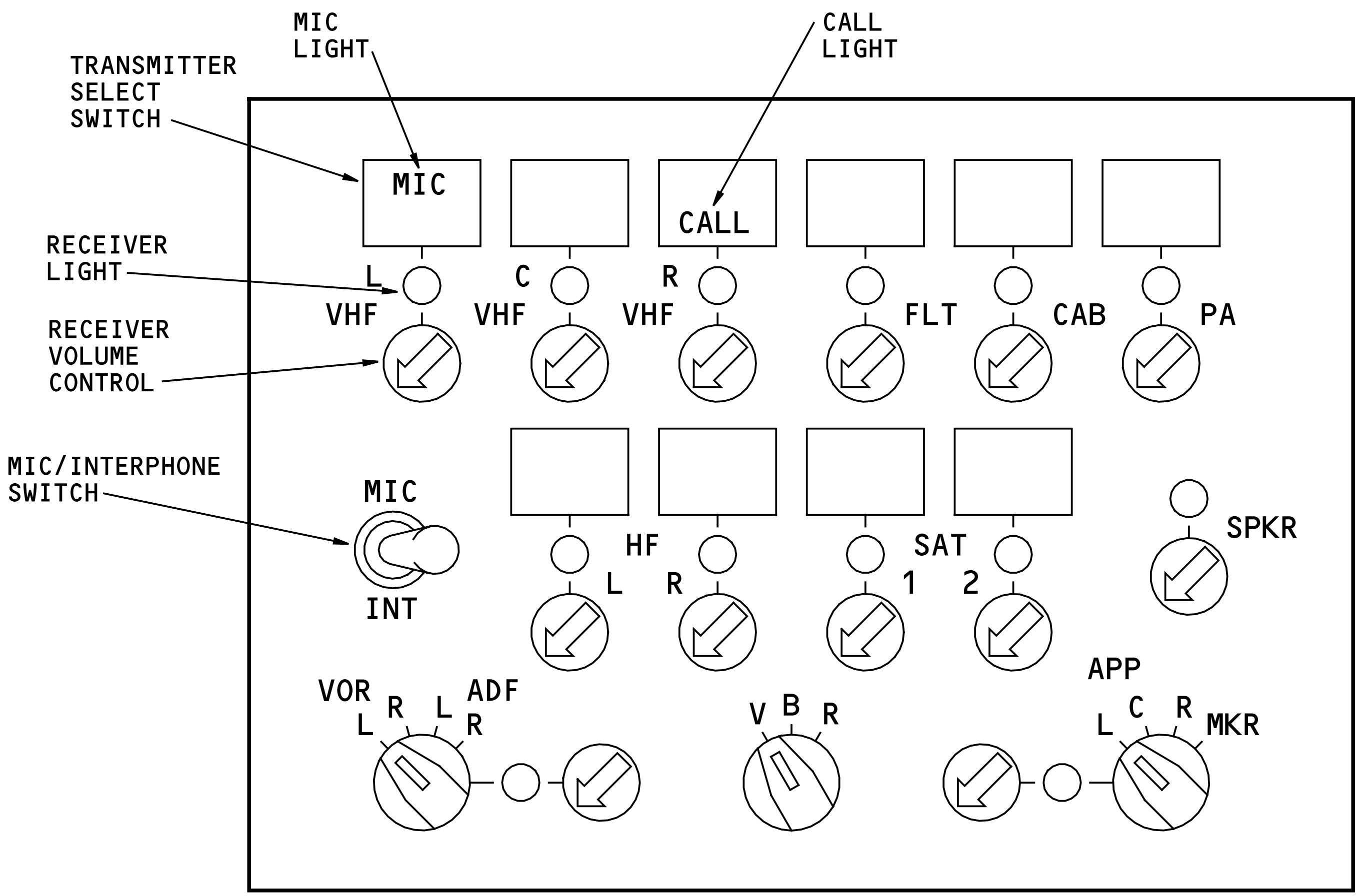
General Description

The audio control panel (ACP) supplies transmitter selection, receiver selection and volume control for the left, center, or right VHF communication transceiver. The VHF controls are on the upper half of the ACP.

Control and Indications

Push a VHF receiver volume control to listen to a VHF receiver. Rotate the receiver volume control for volume control. The receiver light above the control shows green with the receiver control on.

Push a transmitter select switch to select a transceiver for transmission. The mic light shows green for the selected system. Push the mic/interphone switch to connect the microphone to the transceiver and key the transceiver.



VHF SYSTEM - AUDIO CONTROL PANEL

23-12-00-014 Rev 1 11/08/1995

VHF SYSTEM - RECEIVE MODE

General

The VHF antenna receives RF signals and sends them to the VHF communication transceiver through the coaxial cable. The transceiver processes the RF signal and sends the audio to the audio management unit (AMU), the airplane information management system (AIMS), and SELCAL decoder.

The three VHF communication systems operate in a similar way. The right VHF system is an example.

Receive Operation

The microprocessor sends the receive frequency to the frequency synthesizer. The frequency synthesizer sets the frequency of the AM receiver.

The microprocessor also sends a logic 1 to the transfer switch when the transceiver is in the receive mode. This closes the transfer switch and sends the received RF signal from the antenna to the AM receiver.

The AM receiver demodulates the RF input and detects the audio signal.

The audio output from the AM receiver goes to:

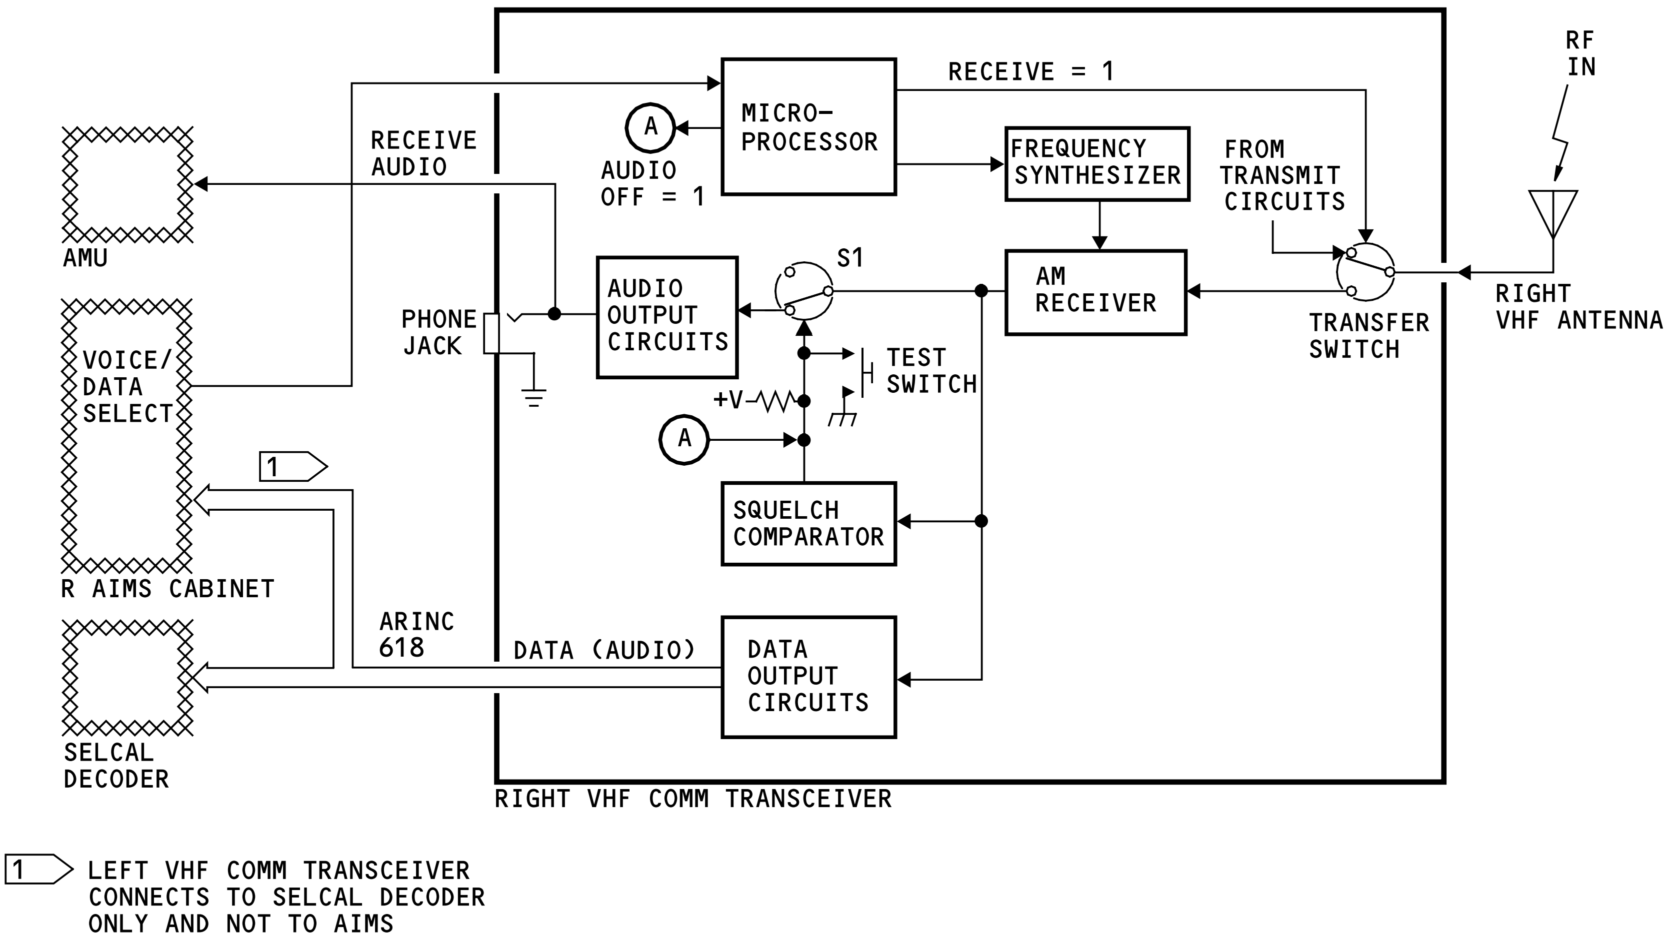
- Switch S1
- The squelch comparator
- The data output circuits.

The audio output circuits send the audio signal to the AMU and to the headphone jack. Push the TEST switch to close switch S1 and send the received audio to the audio output circuits.

The squelch comparator circuit compares the detected audio with a threshold value. If the level of the detected audio is greater than the threshold, the squelch circuits sends a ground to switch S1. Switch S1 closes and sends the audio to the audio output circuits.

The microprocessor changes the audio off signal to a logic 1 when the transceiver is in the data mode. This causes switch S1 to open and disable the audio output and the squelch comparator.

The data output circuits send unsquelched audio to the SELCAL decoder and to the right airplane information management system (AIMS) cabinets on an ARINC 618 bus.



VHF SYSTEM - RECEIVE MODE

VHF SYSTEM - TRANSMIT MODE

General

Audio signals from the audio management unit (AMU) and data (audio) from the airplane information management system (AIMS) go to the selected VHF transceiver. The transceiver processes the signals and sends them to the selected antenna for transmission.

The three VHF communication systems operate in a similar way. The right VHF system is an example.

Transmit Operation

During transmission, the microprocessor receives a push to talk (PTT) signal from the audio management unit (AMU) or a data key signal from AIMS. This causes the microprocessor to send a logic 0 to the transfer switch. The transfer switch connects the output of the transmit circuits to the VHF antenna.

The voice/data select discrete from AIMS determines the operation mode of the transceiver. A ground input sets the transceiver to the data mode. An open input sets the transceiver to the voice mode.

In the data mode, the microprocessor sets the audio off signal to a logic 1 to disable the sidetone.

Mic audio from the AMU or the data audio from AIMS go to the transmit circuits in the transceiver. The AIMS cabinet uses an ARINC 618 bus to send the data to the transceiver. The transmit circuits modulate the transmit frequency with the mic audio or the data audio. This makes an amplitude modulated RF signal. The signal goes to the directional coupler and transfer switch. The RF signal goes through the closed transfer switch and to the antenna. The antenna transmits the RF signal.

The RF output from the directional coupler also goes to the power monitor. The power monitor sends a logic 1 when the output power is greater than 15 watts.

The sidetone switch closes when the output power is greater than 15 watts and the transceiver is in the voice mode.

The sidetone switch closes and the mic audio goes to the AMU for the flight crew.

The PTT signal goes to the AIMS cabinet for the digital flight data acquisition function (DFDAF).

HIGH FREQUENCY COMMUNICATION SYSTEM - INTRODUCTION

General

The high frequency (HF) communication system permits voice communication over greater distances than line-of-sight radio systems. The HF system is for communication with ground stations or with other airplanes during long over-water flights. The HF system operates in the HF aeronautical communication band between 2.000 MHz and 29.999 MHz.

Long Range Communication

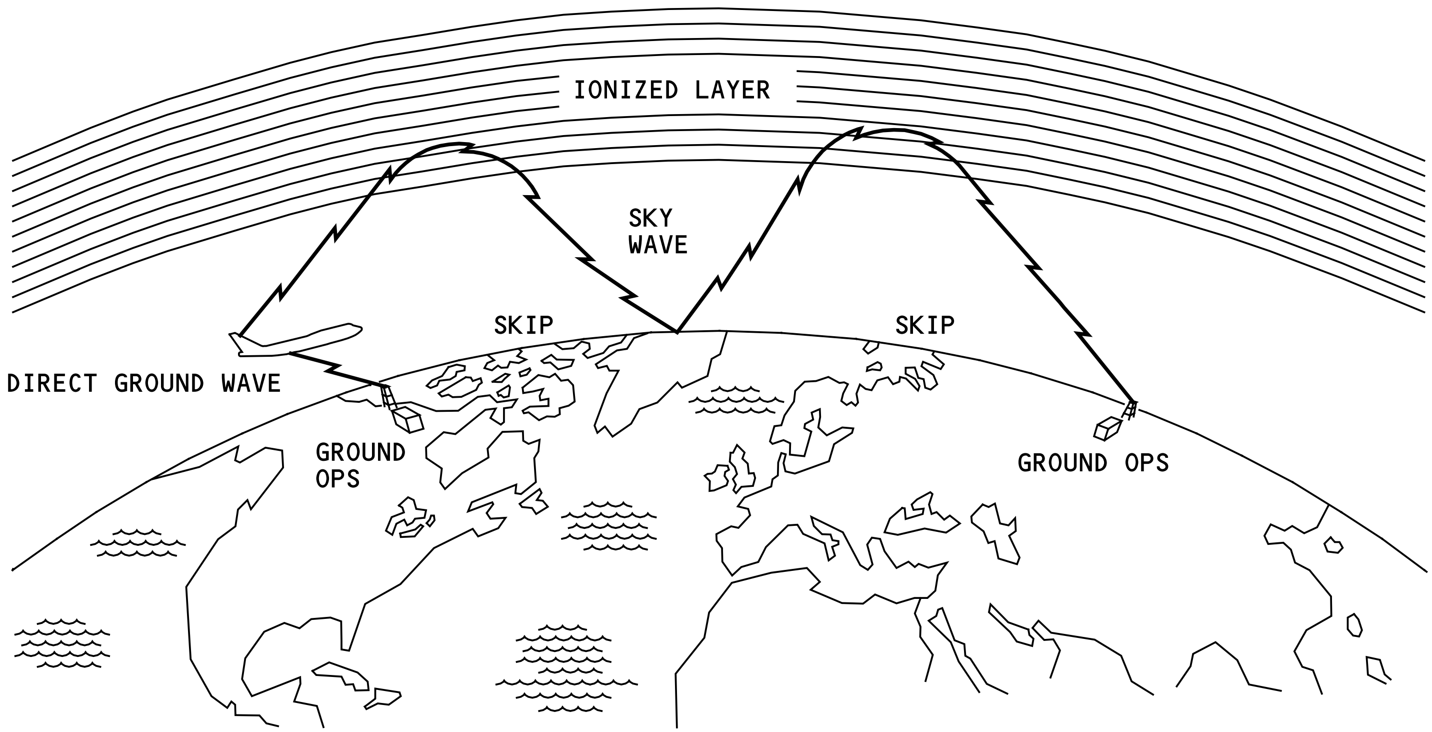
The HF system uses sky waves for long range communication. The HF signals pass into the ionized layers of the atmosphere. The ionized layers refract the signals toward the earth. The earth reflects the signals back toward the ionized layers. Sky wave distances depend upon frequency, time of day and airplane altitude. Skips are the areas between sky waves reflections.

Short Range Communication

HF signals also go directly to ground stations and other airplanes.

Abbreviations and Acronyms

ACP	- audio control panel
AM	- amplitude modulation
AMU	- audio management unit
CAPT	- captain
CMCF	- central maintenance computing function
CMCS	- central maintenance computing system
DFDAF	- digital flight data acquisition function
F/O	- first officer
F/OBS	- first observer
PSIGA	- pounds per square inch gage absolute
RTP	- radio tuning panel
sens	- sensitivity
seq	- sequence
USB	- upper side band



23-11-00-001 Rev 2

HIGH FREQUENCY COMMUNICATION SYSTEM - INTRODUCTION

HF SYSTEM - GENERAL DESCRIPTION

General

The HF communication system uses two HF systems. Each system has these components:

- A common HF antenna. The antenna transmits and receives RF signals in the HF range
- An HF antenna coupler. The antenna coupler matches the impedance of the antenna and transmission line to the output of the transceiver at the selected frequency
- An HF communication transceiver. The transceiver operates in the AM or upper side band (USB) mode.

WARNING: DO NOT TRANSMIT WITH THE HF COMMUNICATION SYSTEM WHILE THE AIRPLANE IS REFUELED OR DEFUELED. AN EXPLOSION CAN CAUSE INJURIES TO PERSONNEL AND DAMAGE TO THE AIRPLANE.

WARNING: MAKE SURE PERSONNEL STAY A MINIMUM OF 6 FEET AWAY FROM THE VERTICAL STABILIZER WHEN THE HF SYSTEM TRANSMITS. RF ENERGY FROM THE HF COMMUNICATION ANTENNA CAN CAUSE INJURIES TO PERSONNEL.

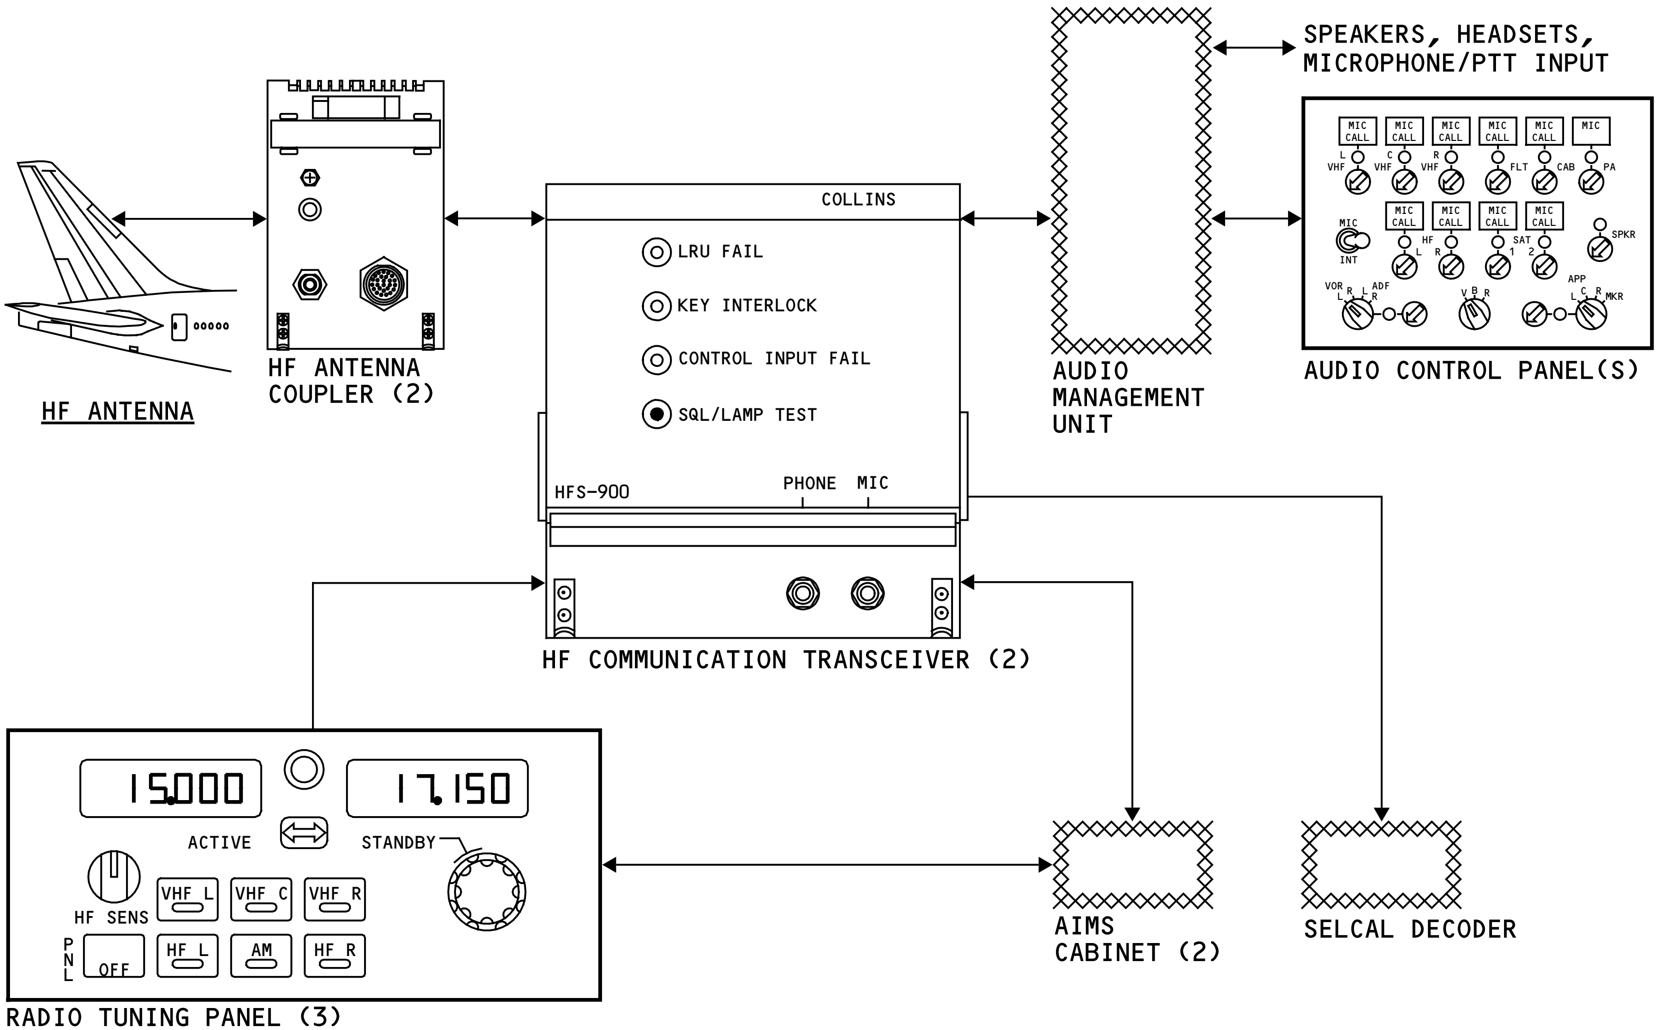
HF System Connections

The HF communication system connects with these components:

- Three radio tuning panels (RTPs). The RTPs send tuning data and mode information to the HF transceivers
- The audio management unit (AMU). Microphone audio and push-to-talk (PTT) discretes go to the transceiver through the AMU. Received audio goes from the transceiver to the speakers and headsets through the AMU
- The SELCAL decoder. The SELCAL decoder alerts the flight crew when the airplane receives a call.

The HF communication system also connects with the airplane information management system (AIMS) for these functions:

- Digital flight data acquisition function (DFDAF). The DFDAF in the AIMS cabinet receives the microphone PTT signal for input to the flight recorder
- Central maintenance computing function (CMCF). The CMCF gets fault reports from the HF system and records this information in a fault history. This shows the maintenance crew the faulty component or function.



HF SYSTEM - GENERAL DESCRIPTION

HF SYSTEM - FLIGHT DECK COMPONENT LOCATIONS

HF Interface Component Locations

These are the components in the flight deck that have an interface with the HF communication system:

HF SYSTEM - VERTICAL STABILIZER COMPONENT LOCATION

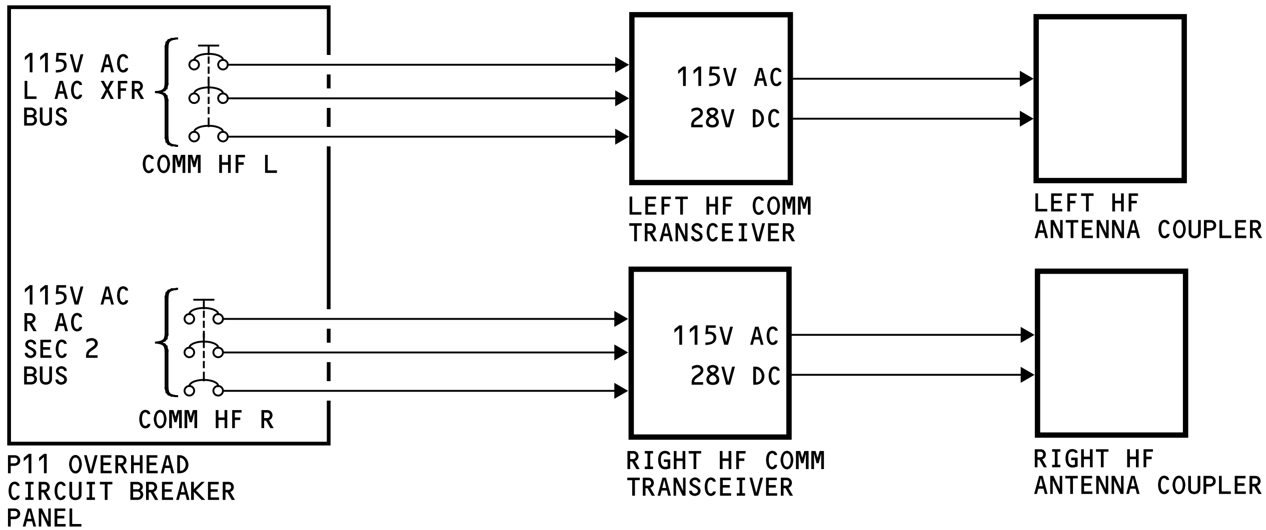
HF SYSTEM - POWER INTERFACE

General

The left transfer bus sends 115v ac three-phase power to the left HF communication transceiver.

The left HF communication transceiver supplies 115v ac single phase to the left HF antenna coupler for operational power. It also supplies 28v dc for the key interlock function.

The right HF communication system is the same as the left, except that it uses power from the right ac sec 2 bus.



23-11-00-006 Rev 1 03/07/96

HF SYSTEM - POWER INTERFACE

HF SYSTEM - TUNING INTERFACE

General

The HF communication system uses data buses to share tuning information between these:

- Radio tuning panels (RTPs)
- HF communication transceivers
- airplane information management system (AIMS) cabinets.

Tuning Buses

The RTPs send tuning data to the HF communication transceivers. Any RTP can tune any transceiver.

Each RTP has these two ARINC 429 output buses:

- Tuning bus
- Crosstalk bus.

Both the left and right RTPs send tuning data to both HF communication transceivers and to the left and right AIMS cabinets.

The center RTP sends its tuning bus output to the left and right RTPs in case of failure.

AIMS sends auto-tune data to all three RTPs.

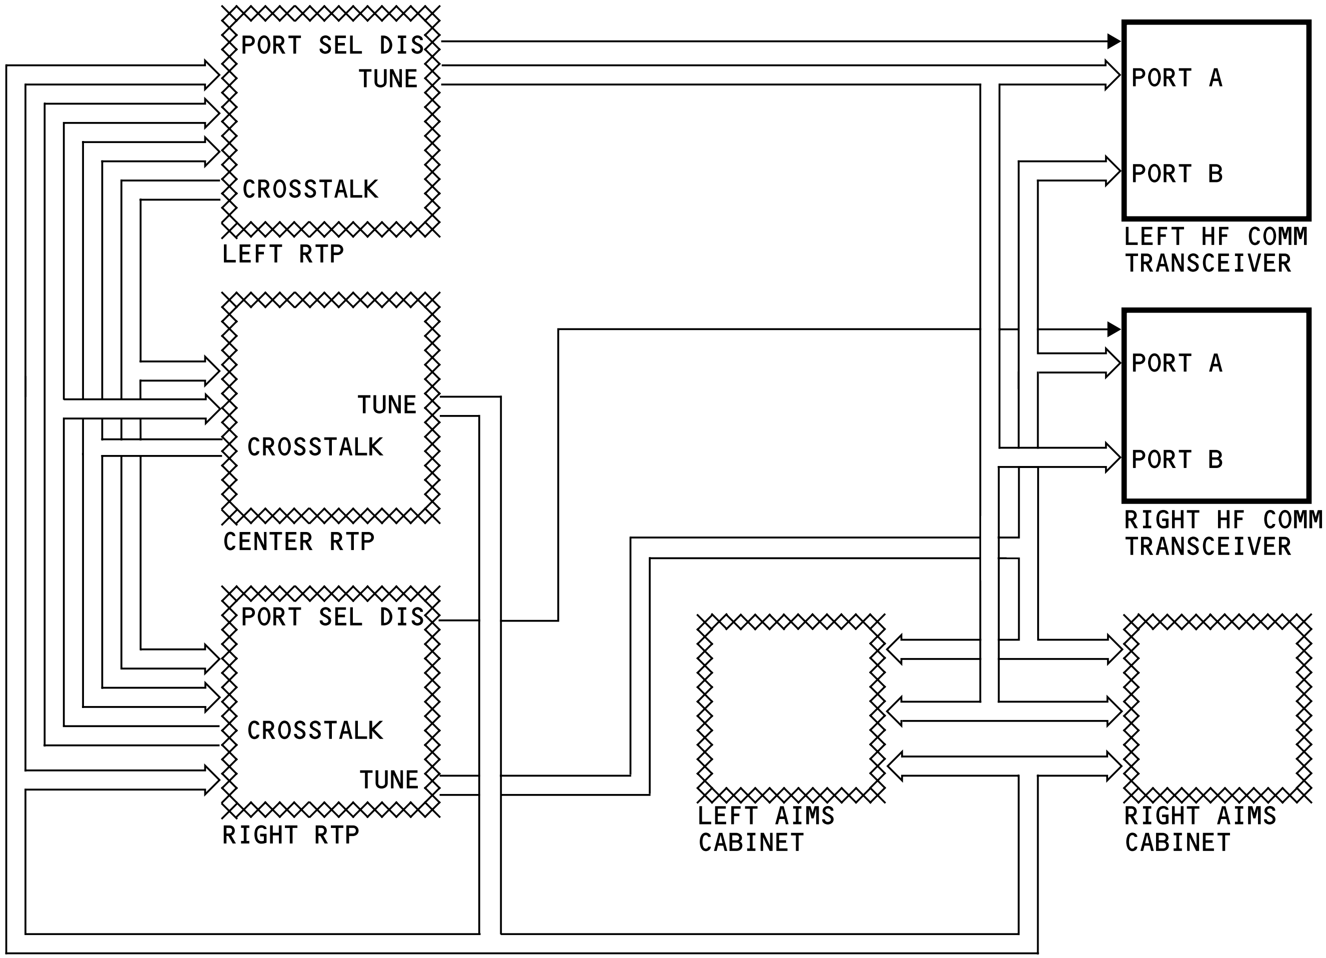
Port Select Discrete

Each HF communication transceiver has two tuning data input ports: port A and port B. The transceiver uses the port select discrete to select its input port. A grounded port select discrete causes the transceiver to use port A. An open port select discrete causes the transceiver to use port B.

The port select discrete for the left HF communication transceiver comes from the left RTP. The port select discrete for the right HF transceiver comes from the right RTP.

Crosstalk Buses

Each RTP sends tuning data to the other RTPs on crosstalk buses. Synchronized tuning data allows any RTP to tune any transceiver.



23-11-00-007 Rev 3 03/28/96

HF SYSTEM - TUNING INTERFACE

HF SYSTEM - RECEIVE/TRANSMIT INTERFACES

General

You use an audio control panel (ACP) to select an HF communication transceiver for voice communication. You use a radio tuning panel (RTP) to select a frequency or adjust HF sensitivity of the transceiver. A push-to-talk (PTT) signal from any mic switch activates the selected transceiver.

Signal Flow - Transmit

You select a transmit switch on any ACP and push a mic switch to transmit. The audio management unit (AMU) sends the mic audio and the PTT signal to the selected HF transceiver. The transceiver changes the mic audio to an RF signal. The transceiver sends the RF signal to the antenna coupler. Only one antenna coupler can transmit at a time. The antenna coupler sends the RF signal to the HF antenna. The HF antenna transmits the signal.

WARNING: DO NOT TRANSMIT WITH THE HF COMMUNICATION SYSTEM WHILE THE AIRPLANE IS REFUELED OR DEFUELED. AN EXPLOSION CAN CAUSE INJURIES TO PERSONNEL AND DAMAGE TO THE AIRPLANE.

WARNING: MAKE SURE PERSONNEL STAY A MINIMUM OF 6 FEET AWAY FROM THE VERTICAL STABILIZER WHEN THE HF SYSTEM TRANSMITS. RF ENERGY FROM THE HF COMMUNICATION ANTENNA CAN CAUSE INJURIES TO PERSONNEL.

The antenna coupler tunes itself to match the output impedance of the transceiver to the impedance of the transmission line at the selected frequency.

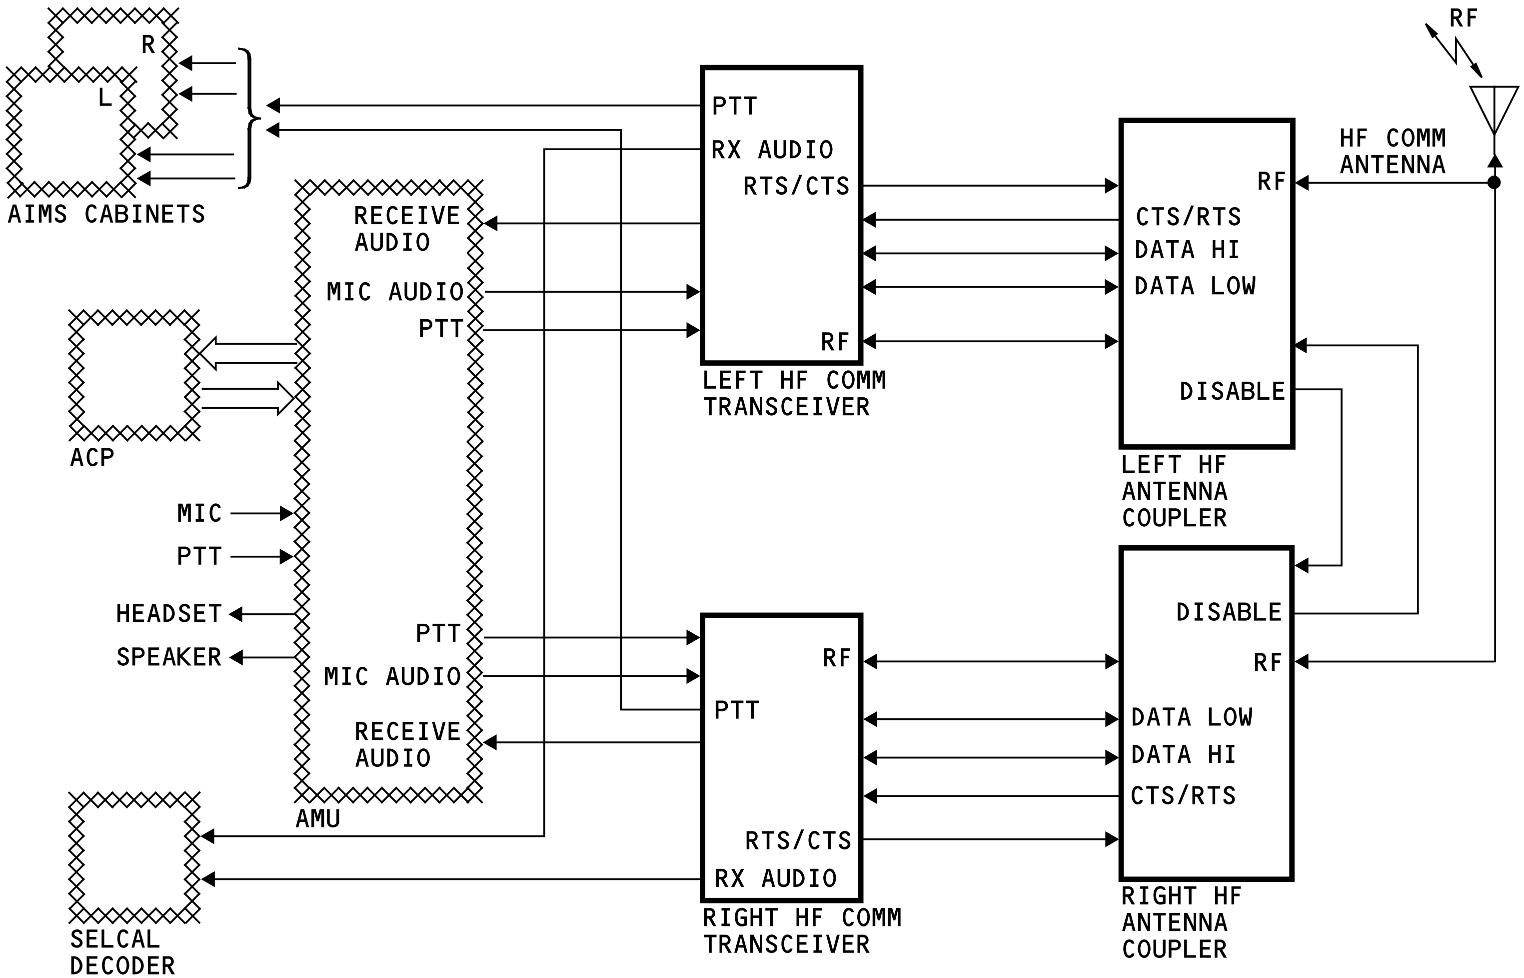
The PTT signal goes to the airplane information management system (AIMS) digital flight data acquisition function (DFDAF).

Signal Flow - Receive

The HF antenna receives RF signals and sends them to both HF antenna couplers. The antenna couplers send the RF signals to the HF communication transceivers. The transceivers change the RF signals to audio signals. The transceivers send the audio signals to the audio management unit (AMU).

The flight crew selects a receiver control switch on their ACP. The AMU sends the received audio to the flight crew stations.

The transceivers send received audio to the SELCAL decoder. The SELCAL decoder monitors the audio for an incoming call. It alerts the flight crew when the airplane receives a call.



23-11-00-008 Rev 3 07/17/1997

HF SYSTEM - RECEIVE/TRANSMIT INTERFACES

HF SYSTEM - AIMS FAULT REPORTING AND TESTING INTERFACES

General

The HF system sends fault information to the AIMS cabinets from three sources:

- HF communication transceivers
- HF antenna couplers
- Radio tuning panels (RTPs).

Transceiver and Antenna Coupler Interfaces

The HF communication transceivers send real time fault and status information to the AIMS cabinets. The fault information includes faults generated by the antenna couplers and the transceivers.

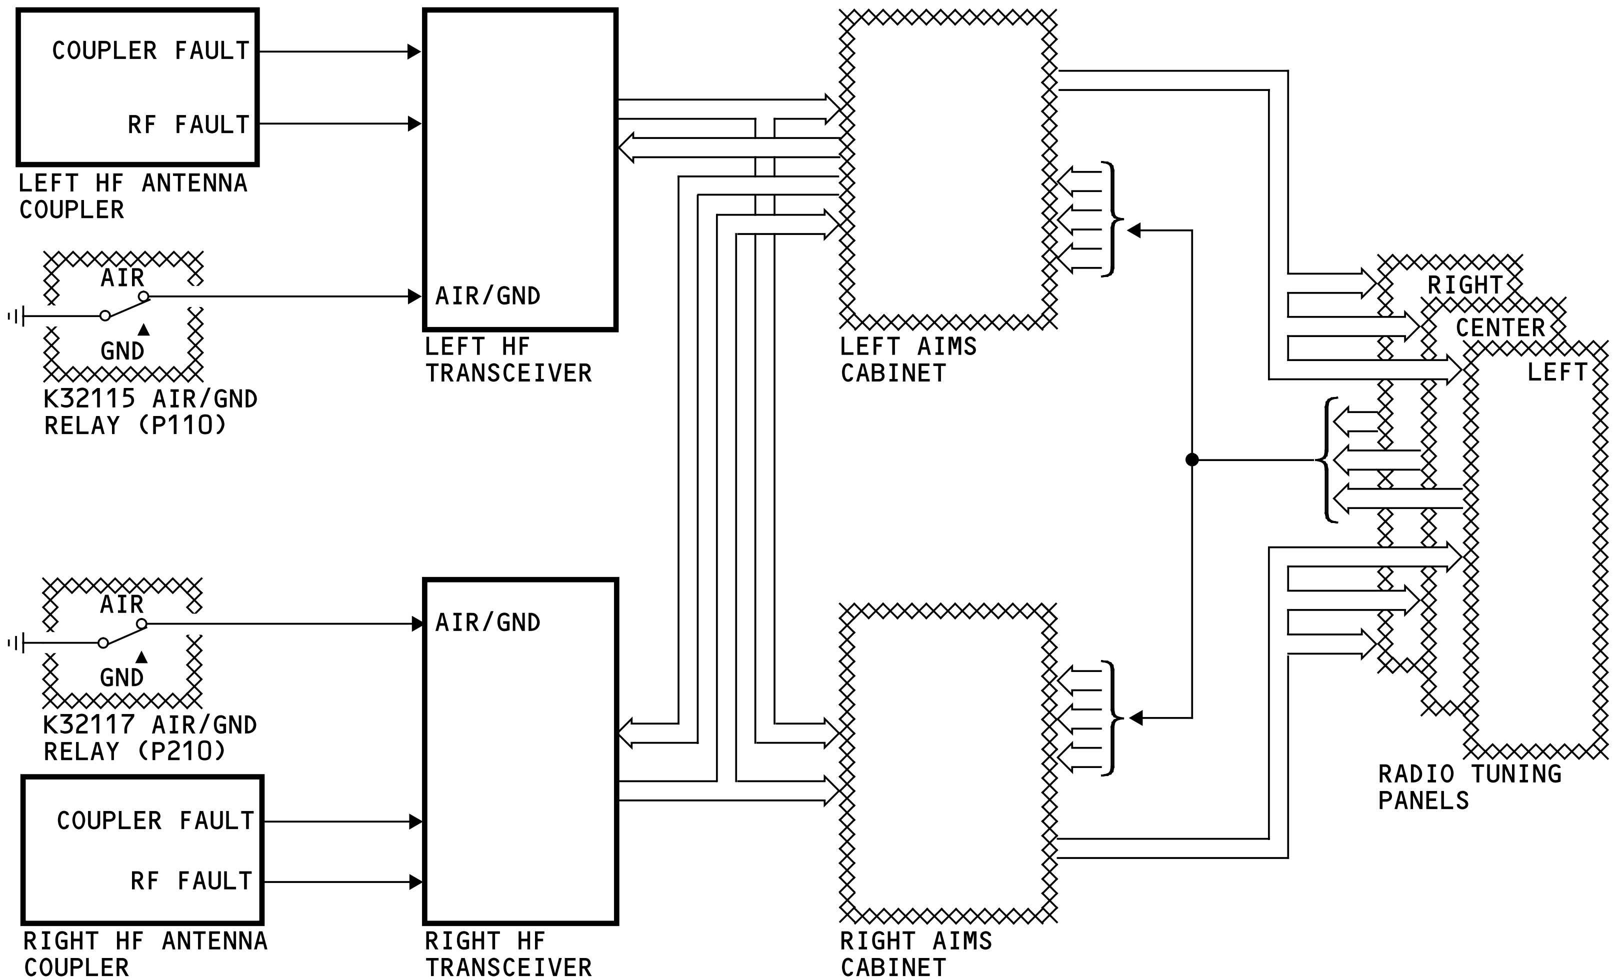
The air/ground relays send air/ground signals to the transceivers. The tranceivers use these signals to keep flight leg faults in memory.

The left AIMS central maintenance computing function (CMCF) tests the HF transceivers during ground tests. The CMCF sends test requests to the HF transceivers. The HF transceivers give the test results to the CMCF. The right AIMS cabinet gives test information, if the left AIMS cabinet fails.

Radio Tuning Panel (RTP) Interfaces

Each RTP sends HF system fault/status information to both AIMS cabinets.

AIMS sends HF system fault/status to the RTPs.



23-11-00-009 Rev 3 03/28/96

HF SYSTEM - AIMS FAULT REPORTING AND TESTING INTERFACES

HF SYSTEM - HF COMMUNICATION TRANSCEIVER

Purpose

The HF communication transceiver changes RF signals to audio signals during receive operation, and changes audio signals to RF signals during transmit operation. The transceiver amplifies RF transmit signals.

Physical Description

The HF transceiver has these features:

- One KHz channel spacing
- A frequency range of 2.000 MHz to 29.999 MHz
- Maximum RF output power of 400 watts peak envelope power (USB), 125 watts (AM).

Operation - Controls and Indications

There are three LED indicators and one push-button on the transceiver front panel:

- LRU FAIL indicator - comes on for a transceiver fault
- KEY INTERLOCK indicator - comes on for an antenna coupler fault
- CONTROL INPUT FAIL indicator - comes on for an RTP tuning fault
- SQL/LAMP TEST switch - HF system squelch disables and all LEDs come on.

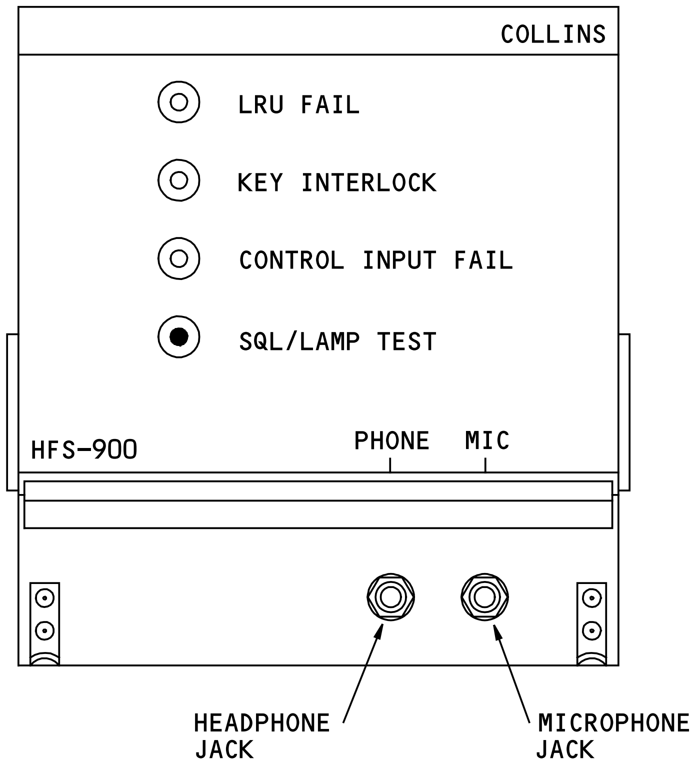
The LED indicators come on to show failures.

The headphone and microphone jacks permit operation of the HF transceiver from the E6 rack in the aft cargo compartment.

Functional Description

The HF communication transceiver operates as a receiver/transmitter in the amplitude modulation (AM) or upper side band (USB) modes. The transceiver detects the voice audio from the carrier frequency during reception, and modulates the voice audio during transmission.

An internal blower cools the transmitter.



23-11-00-010 Rev 3 04/18/1997

HF SYSTEM - HF COMMUNICATION TRANSCEIVER

HF SYSTEM - HF ANTENNA COUPLER

Purpose

The HF antenna coupler matches the impedance of the antenna and feedline with the output impedance of the transceiver at the selected frequency. This results in a voltage standing wave ratio (VSWR) of less than 1.3:1.

General Description

The antenna coupler is a sealed, pressurized unit that weighs 15.5 pounds. A feedline connects each coupler to the antenna. A coaxial cable connects each coupler to its transceiver.

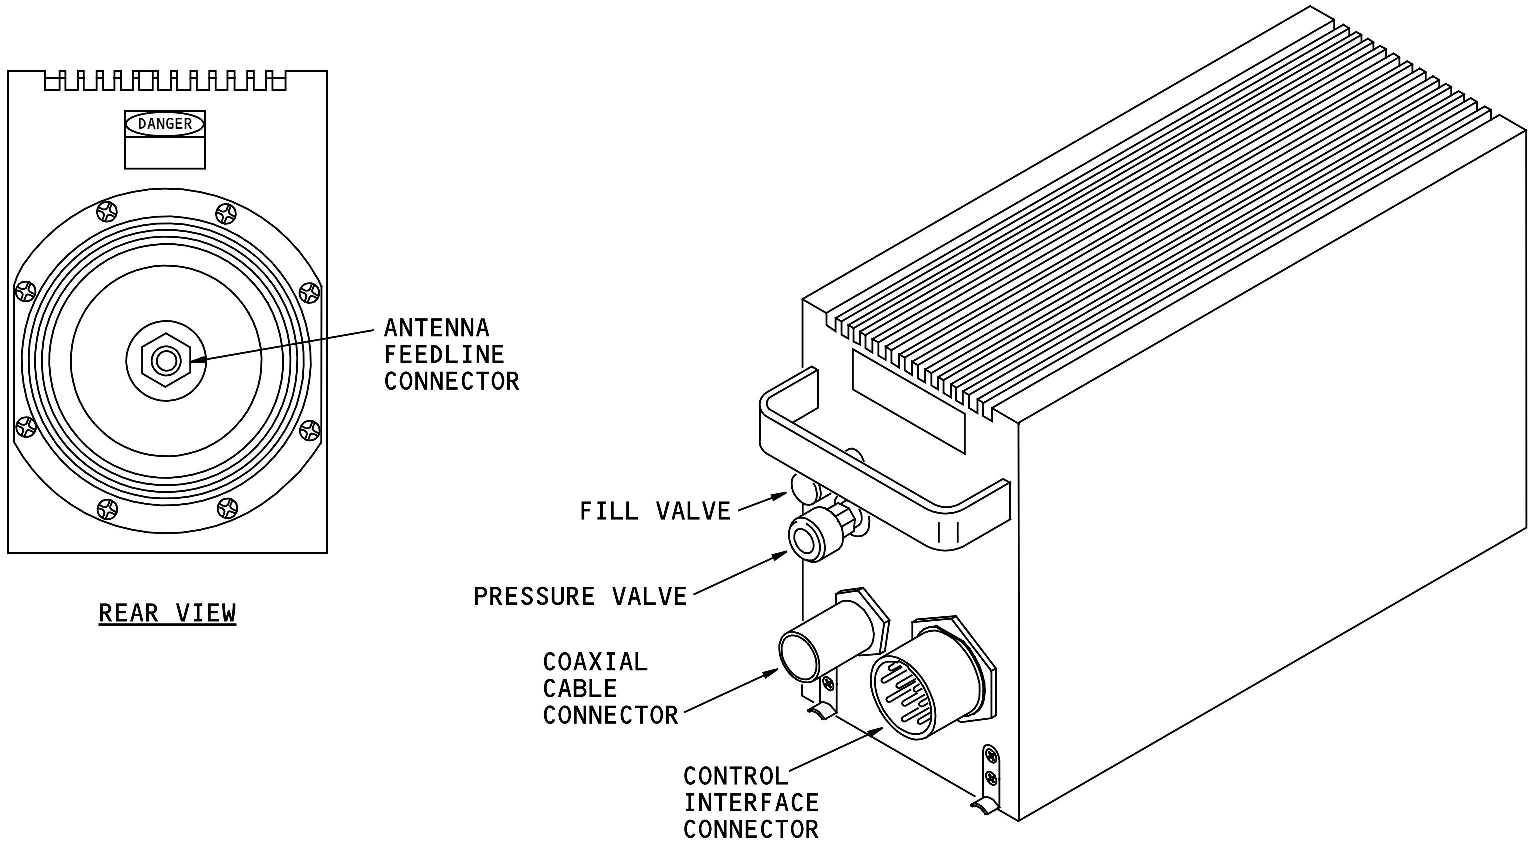
There are two connectors on the coupler:

- Control interface
- Coaxial cable.

Dry air or nitrogen pressurizes the antenna coupler at five to seven PSIGA. Pressurization is through the pressure valve on the front of the coupler.

Functional Description

The coupler has tuning elements and control circuits. The coupler constantly monitors the RF transmissions to automatically adjust the tuning elements. Typical tuning time is two to four seconds.



23-11-00-011 Rev 3 02/25/1997

HF SYSTEM - HF ANTENNA COUPLER

HF SYSTEM - HF ANTENNA COUPLER ACCESS AND INSTALLATION

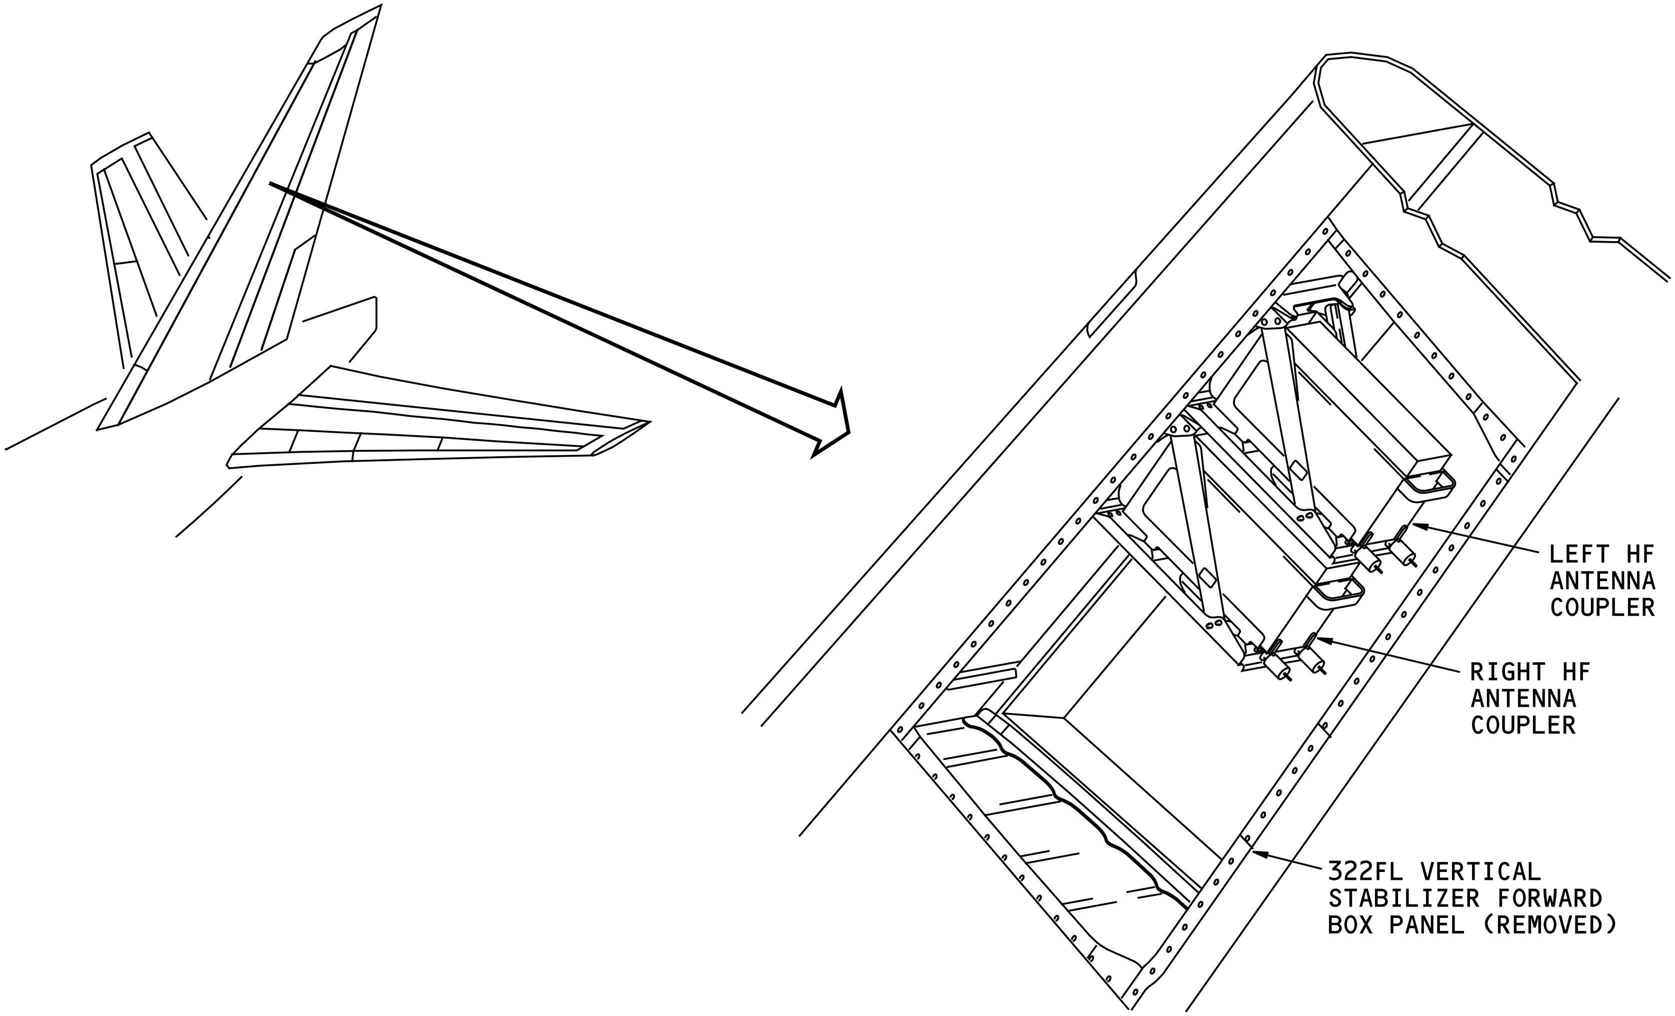
Installation

The two HF antenna couplers are in the vertical stabilizer at the top of the HF communication antenna. Each coupler is on a shelf. A coaxial cable and control interface cable connect to the coupler front panel.

CAUTION: YOU MUST PREPARE EACH HF ANTENNA COUPLER FOR THE REMOVAL, YOU CAN EASILY CAUSE DAMAGE TO INTERNAL PARTS OF THE HF ANTENNA COUPLER.

Access

A panel on the left side of the vertical stabilizer allows access to the antenna couplers.



23-11-00-012 Rev 5 04/28/1997

HF SYSTEM - HF ANTENNA COUPLER ACCESS AND INSTALLATION

HF SYSTEM - HF COMMUNICATION ANTENNA

Purpose

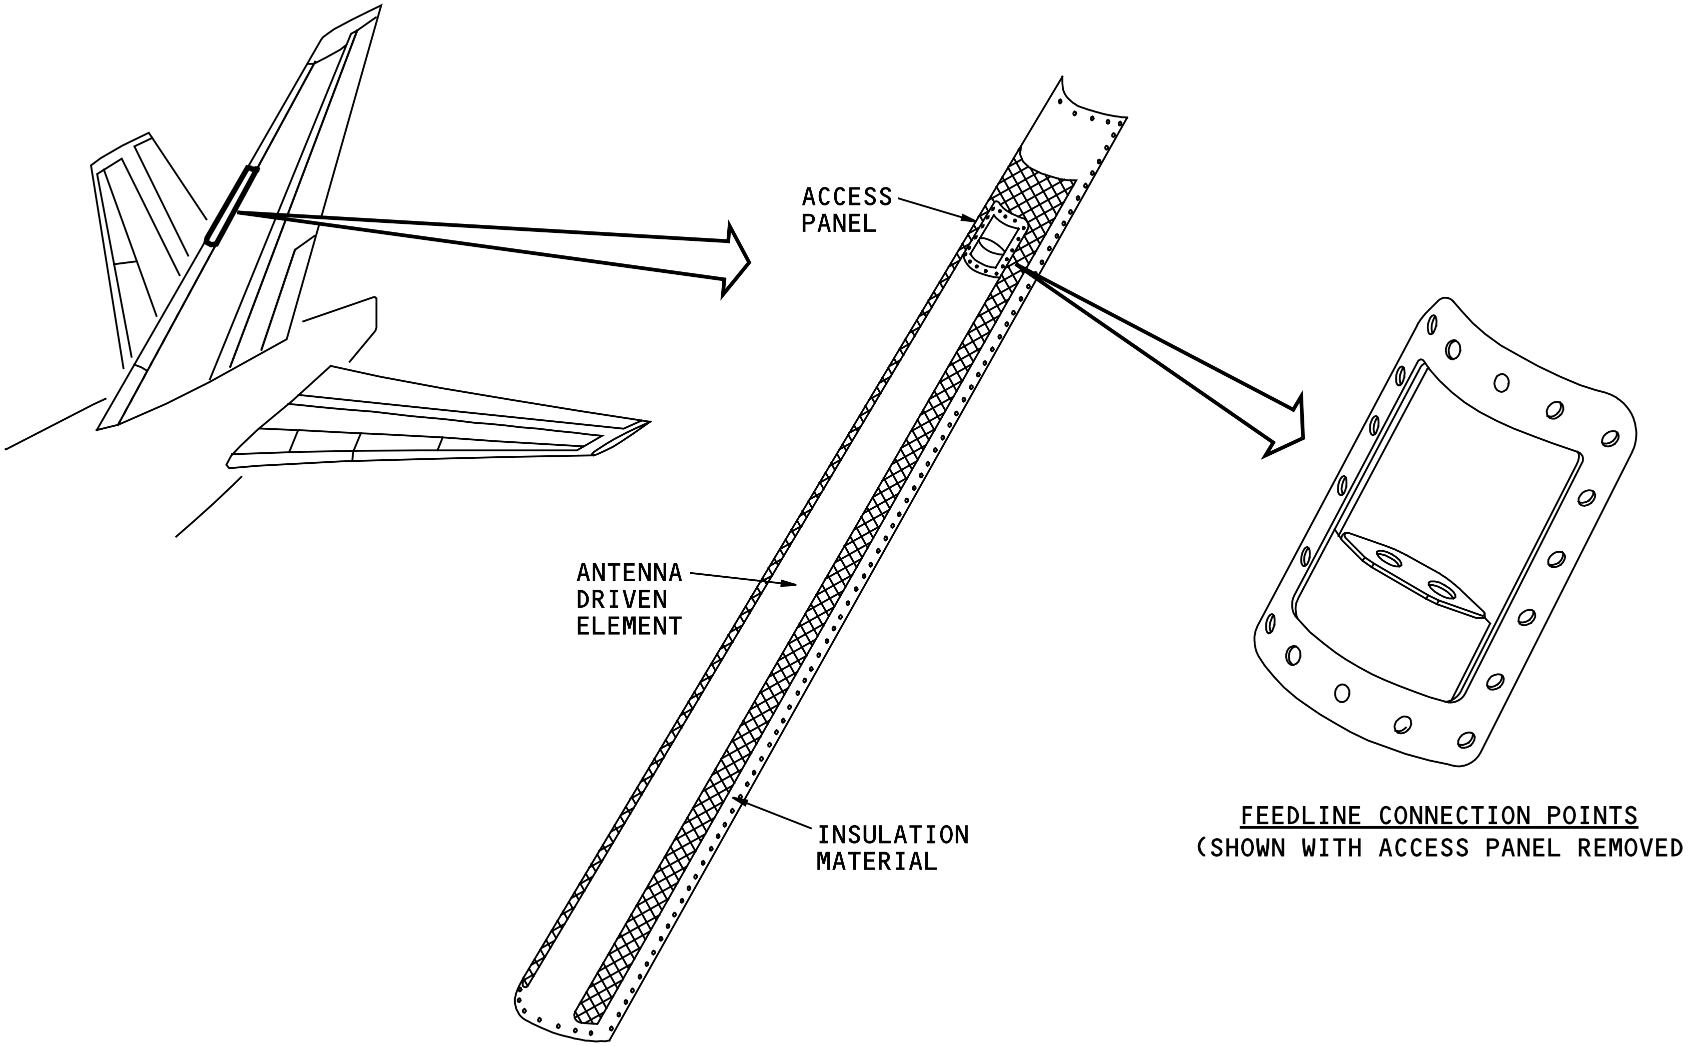
The HF communication antenna transmits and receives RF signals in the HF frequency range.

General Description

The antenna is a flush-mounted, slot-type antenna, approximately nine feet long. An inverted U-shaped insulation material on the leading edge of the vertical stabilizer surrounds the antenna driven element. The antenna insulation is composite material.

Location and Access

The HF antenna is a part of the leading edge of the vertical stabilizer. An access panel at the top of the antenna covers the connections to the antenna couplers.



23-11-00-013 Rev 1

HF SYSTEM - HF COMMUNICATION ANTENNA

THIS PAGE INTENTIONALLY LEFT BLANK

HF SYSTEM - RADIO TUNING PANEL

Purpose

Use the radio tuning panel (RTP) to select the modes of operation, and to select the active and standby frequencies for each communication radio. Each RTP sends tuning and mode information to these components:

- The communication radios
- The other two RTPs
- The airplane information management system (AIMS) cabinets.

Description

Each RTP has these features:

- Active and standby frequency windows
- A frequency transfer switch
- An offside tuning light
- Frequency selectors
- Radio tuning switches
- An AM switch
- A radio tuning panel off switch
- An HF sensitivity control.

Momentary switches have a white light in them that comes on when the function is selected.

Controls and Indications

Push the radio tuning panel off switch to turn the RTP on. When the panel is on, the white radio tuning panel off light goes off. When the RTP is off, the radio tuning panel off light comes on.

The active frequency window shows the frequency of the selected radio. The standby frequency window shows the frequency selected by the flight crew with the frequency selectors. The standby frequency window also shows auto-tune frequency information supplied by the AIMS cabinets during a data uplink.

You set the standby frequency with the frequency selectors. The outer knob adjusts the first three digits (10 MHz, 1 MHz and 100 KHz) in 100 KHz steps. The inner knob adjusts the fourth and fifth digits (10 KHz and 1 KHz) in 1 KHz steps.

The frequency transfer switch causes the active frequency to go to the standby frequency window, and the standby frequency to go to the active frequency window.

You use the radio tuning switches to select a radio. You select only one radio at a time. The white light in the selected radio tuning switch comes on.

When you select an offside radio, two offside tuning lights come on. One light is on the RTP that the flight crew uses to make the selection. The other light is on the onside RTP of the selected radio.

The HF sensitivity control sets the RF sensitivity level of the onside HF transceiver. The left RTP sets the left HF sensitivity. The right RTP sets the right

HF SYSTEM - RADIO TUNING PANEL

HF sensitivity. The center RTP HF sensitivity control does not connect to any transceiver.

Use the AM switch to operate the selected transceiver in the amplitude modulation (AM) mode. In the AM mode, the white light in the AM switch comes on if the onside HF transceiver is selected or if any VHF transceiver is selected. If the AM switch is not selected, the HF communication transceiver operates in the upper side band (USB) mode.

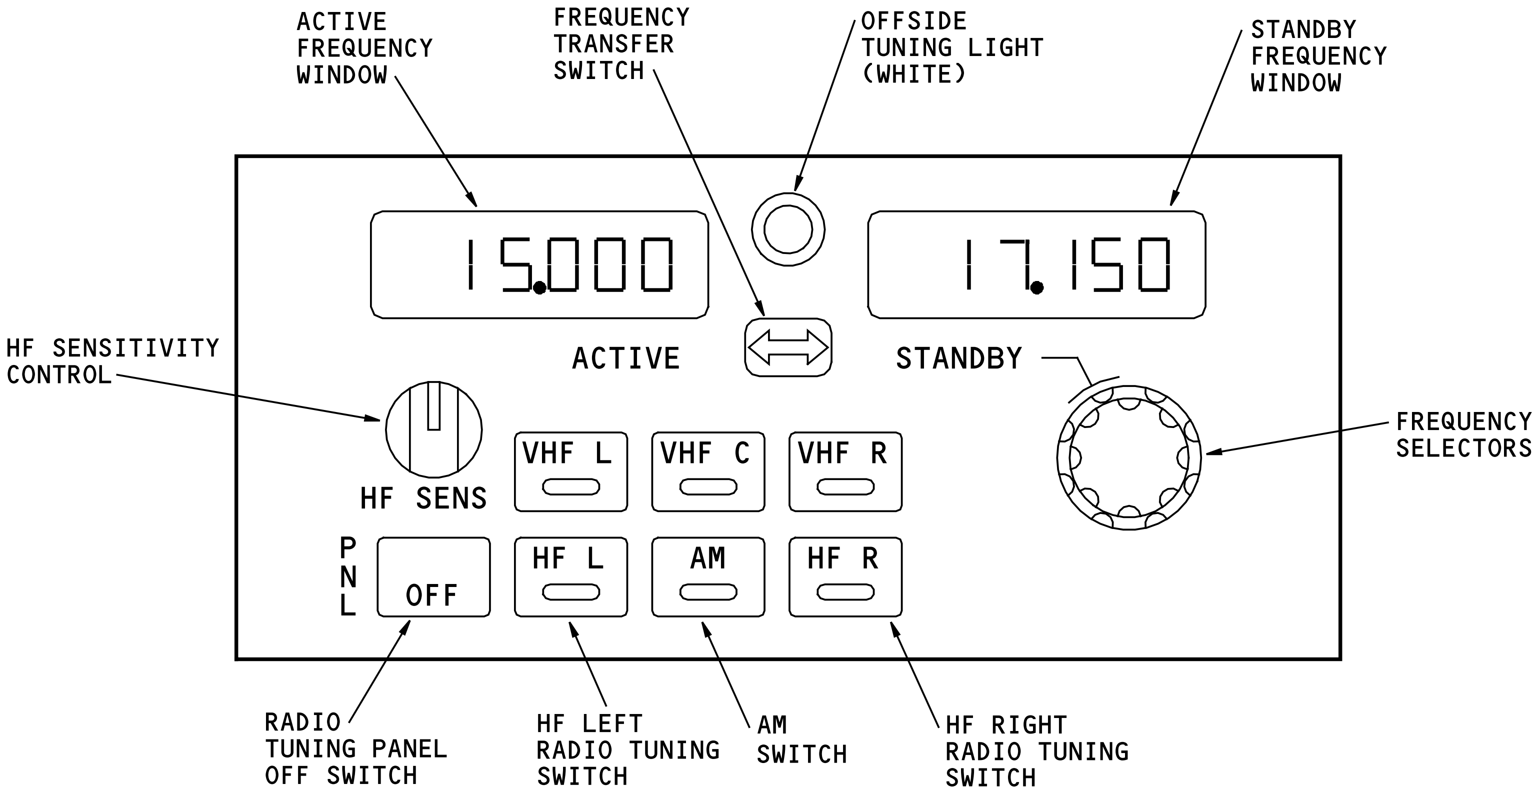
Push the radio tuning panel off switch to stop the operation of the RTP. When the RTP is off, the white radio tuning panel off light comes on and all functions stop except these three:

- The frequency windows continue to show any current fault
- The RTP continues to receive 28v dc
- The RTP continues to send BITE information to the AIMS central maintenance computer function (CMCF).

<u>BITE</u>

The RTP tests itself continuously. The RTP shows PANEL FAIL in the two frequency windows if the RTP has an internal failure or if there is a system failure.

The two frequency display windows show all dashes if the flight crew selects a failed radio.



23-11-00-014 Rev 2 03/18/96

HF SYSTEM - RADIO TUNING PANEL

HF SYSTEM - AUDIO CONTROL PANEL

General

The audio control panel (ACP) supplies transmitter selection, receiver selection and volume control for the left and right HF transceivers.

The operator transmits on only one HF system at a time. The ACP permits the operator to listen to one or both HF systems at the same time.

Control and Indications

Push an HF receiver volume control to listen to an HF receiver. Rotate the receiver volume control for volume control. The receive light above the control shows green when a receiver volume control is on. Push both HF receiver volume controls to listen to both HF radios at the same time.

Push an HF transmitter select switch to select an HF transceiver for transmission. The mic light shows green to show the selected system. Push the mic/interphone switch to connect the microphone to the transceiver and to key the transceiver.

The call light comes on when the SELCAL system detects a call for the system.

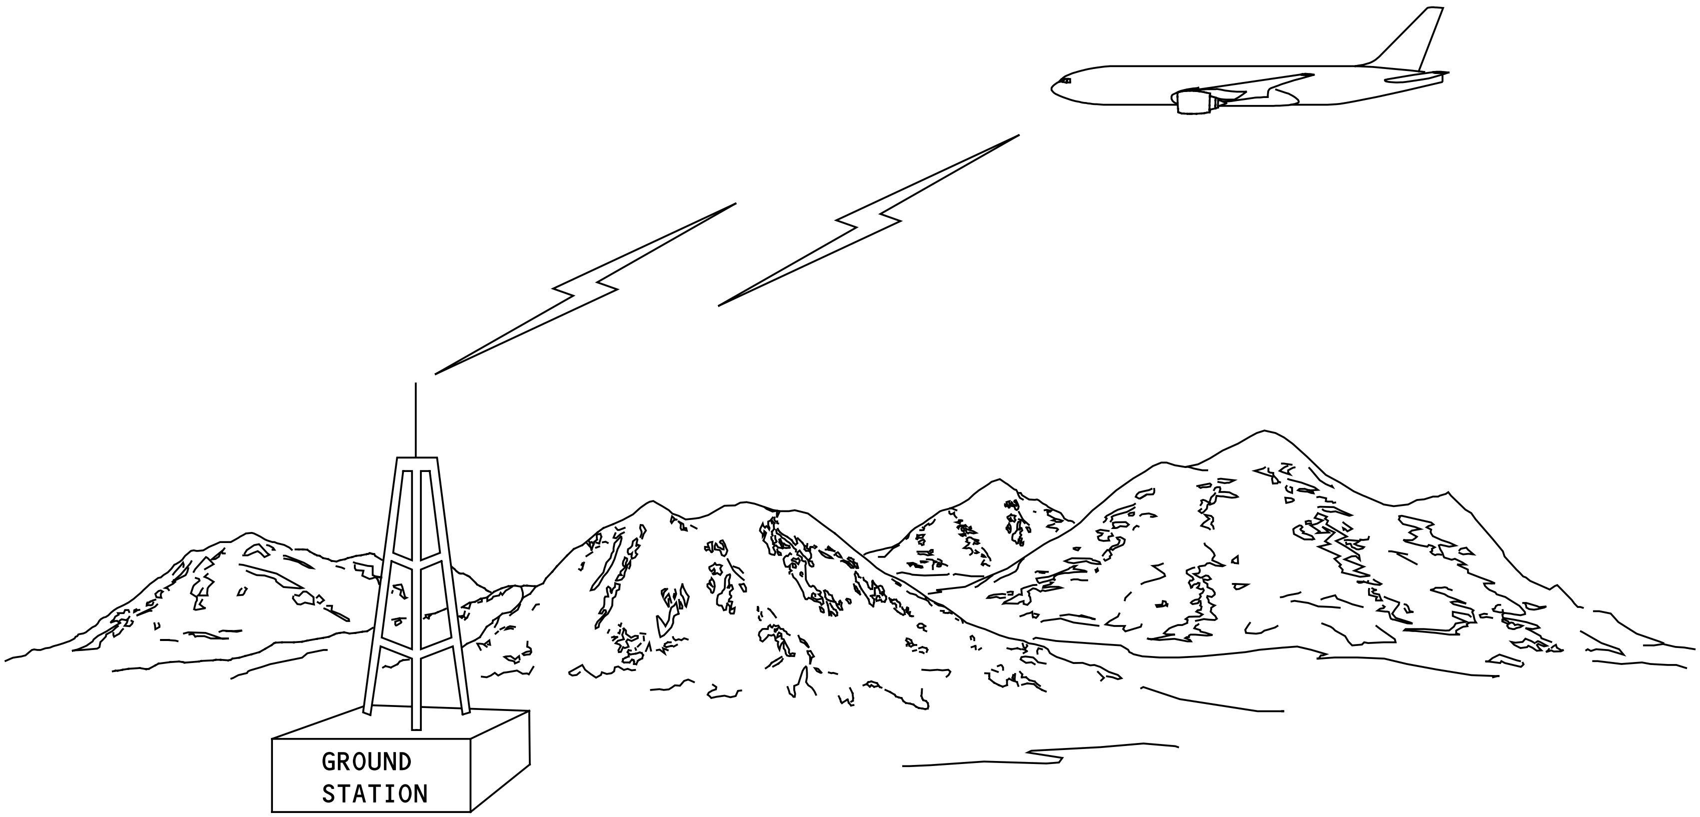
SELCAL	- selective calling
VHF	- very high frequency
WEU	- warning electronic unit
WES	- warning electronic system



23-21-00-001 Rev 1

SELCAL - INTRODUCTION

SELCAL - GENERAL DESCRIPTION

General

Each airplane has a different SELCAL code. A ground station transmits this code with a signal to contact an airplane. When the airplane receives its SELCAL code, several flight deck indications come on to alert the flight crew.

HF and VHF Transceivers

The communication transceivers send received audio to the SELCAL decoder.

SELCAL Decoder

A SELCAL coding switch connects to the SELCAL decoder and gives each airplane its SELCAL code.

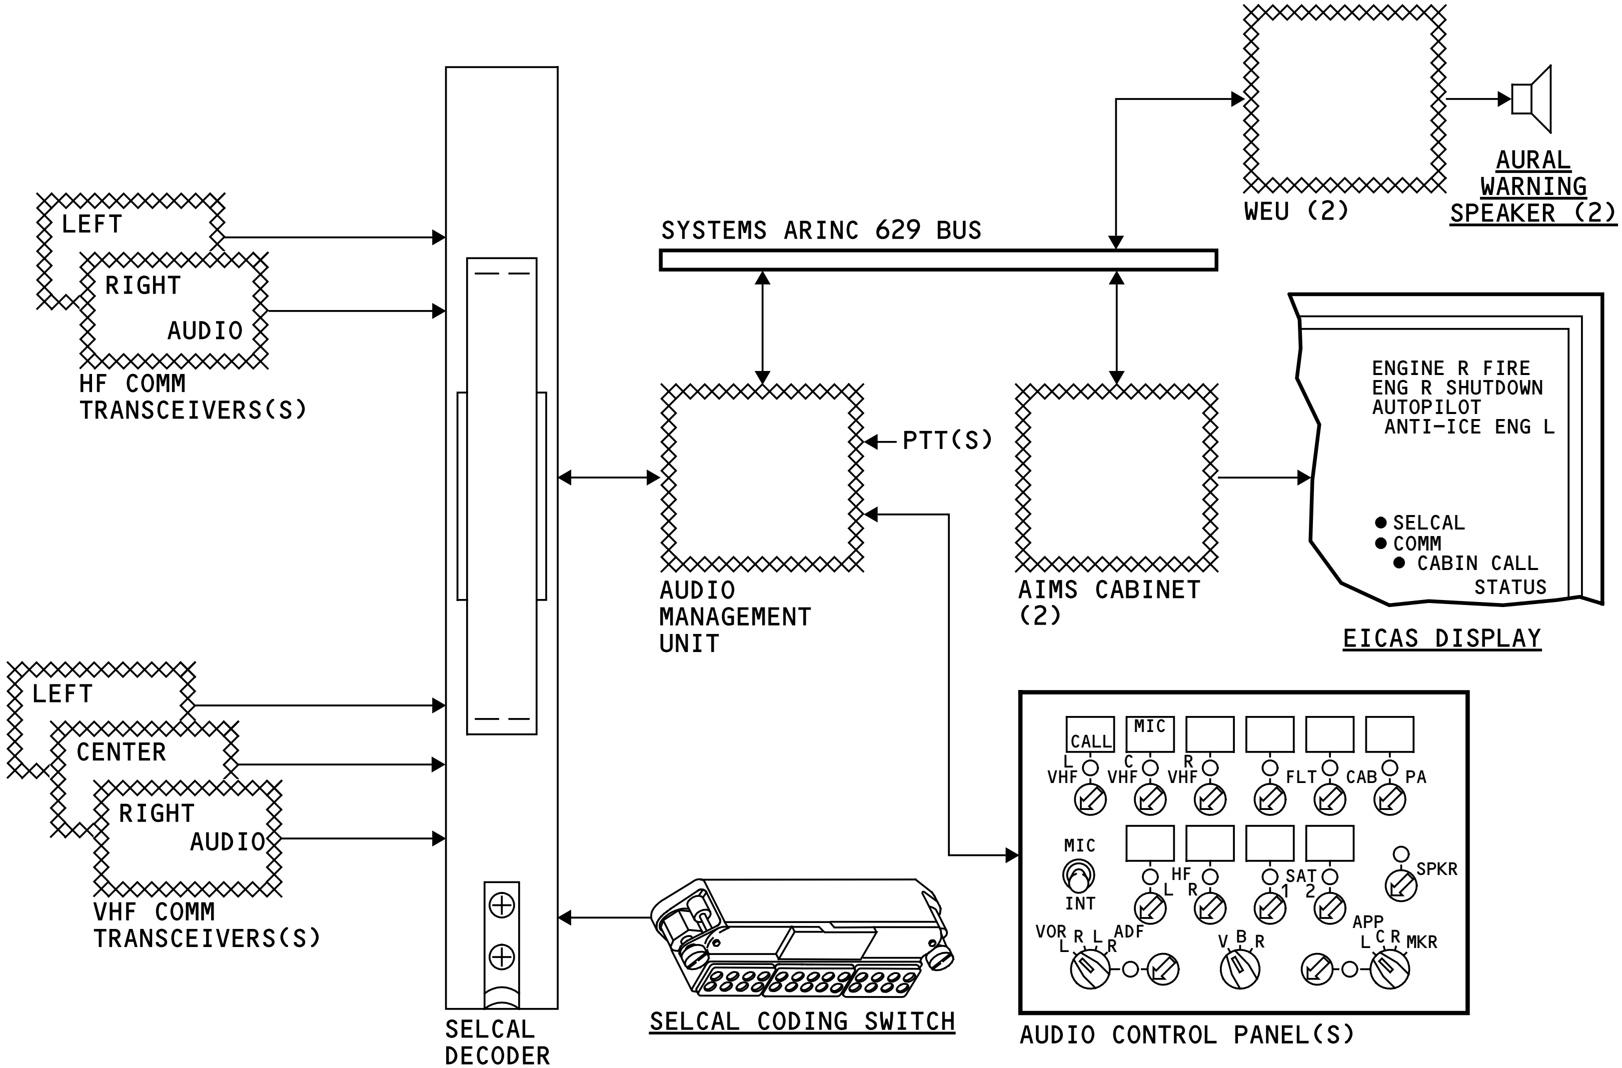
The SELCAL decoder monitors for audio tones. If the tones are the same as the code, the decoder sends a signal to the audio management unit.

Indications

The audio management unit (AMU) sends a signal to the AIMS cabinets. The AIMS primary display function (PDF) then makes a COMM medium message, SELCAL. The AIMS cabinets also send a chime request to the warning electronic units (WEUs). The WEUs make a chime signal and send it to the aural warning speakers.

The AMU also sends a signal to the audio control panels (ACPs). The ACPs turn on the call light for the transceiver that received the SELCAL code.

To reset the indications, push the CALL light on the audio control panel or push the mic switch for the related radio.

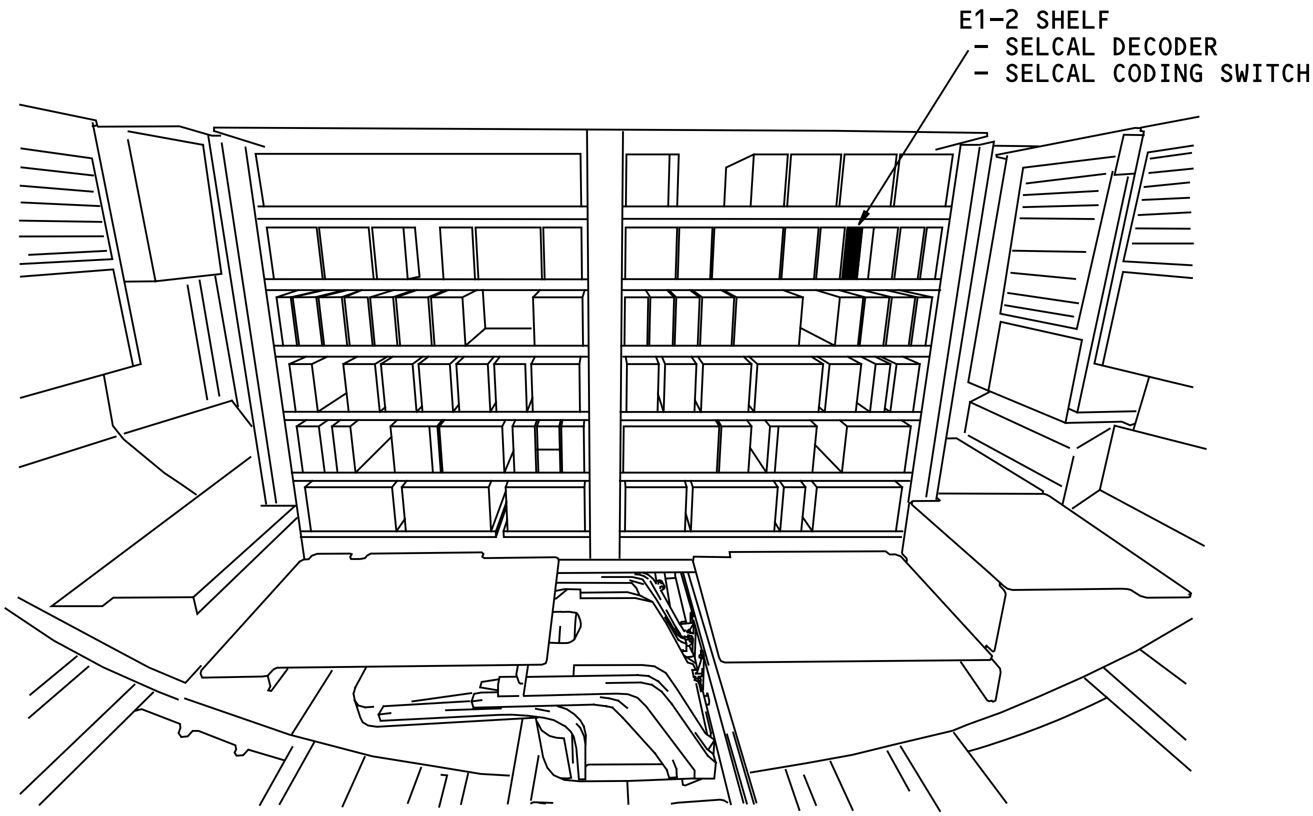


SELCAL - GENERAL DESCRIPTION

SELCAL - COMPONENT LOCATION

Main Equipment Center

The SELCAL decoder is in the main equipment center on the E1-2 rack. The SELCAL coding switch is on the rack behind the decoder.



MAIN EQUIPMENT CENTER
(LOOKING AFT)

23-21-00-003 Rev 1 10/20/1997

SELCAL - COMPONENT LOCATION

SELCAL - INTERFACES

Power

The left main DC bus sends 28v dc power to the SELCAL decoder power supply.

Audio

The SELCAL decoder gets audio from the communication transceivers.

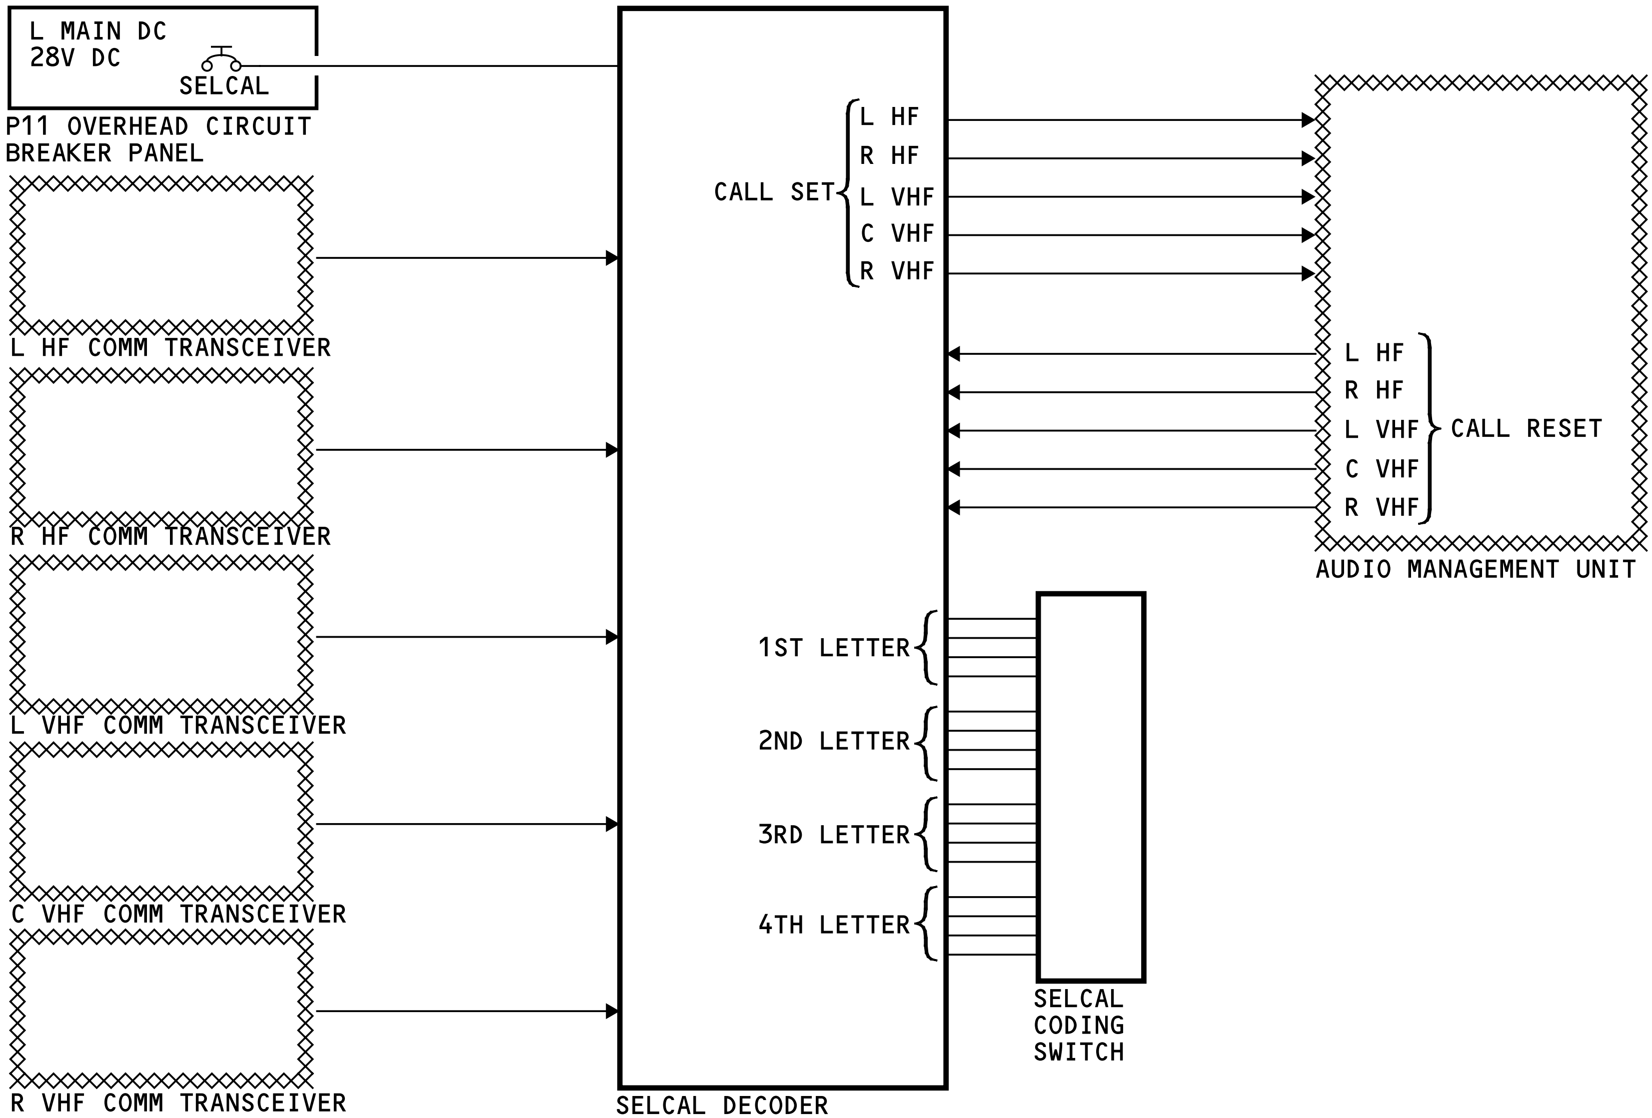
Discretes

The SELCAL decoder sends call set discretes to the audio management unit. There is a different discrete for each transceiver.

The audio management unit sends call reset discretes to the SELCAL decoder. There is a different discrete for each transceiver.

SELCAL Coding Switch

The SELCAL coding switch on the back of the decoder has 16 switches in groups of four. There are four letters in the SELCAL code. The positions of the switches in each group identify one of the four SELCAL code letters.



SELCAL - INTERFACES

23-21-00-004 Rev 2 05/16/96

SELCAL - SELCAL DECODER

Purpose

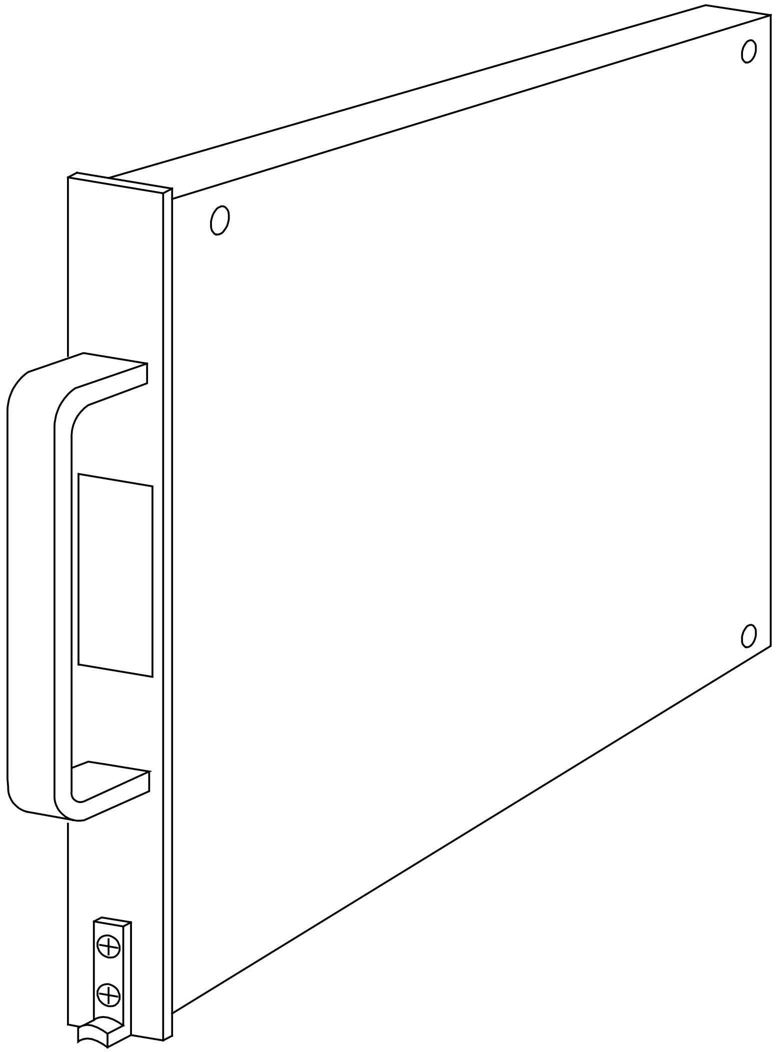
The SELCAL decoder has these functions:

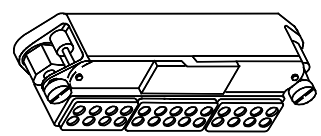
- Monitors audio from the communication transceivers
- Identifies the SELCAL signal that is the same as its code
- Causes flight deck indications for a call.

There are no lights or test switches on the SELCAL decoder front panel.

SELCAL Coding Switch

Switches inside of the SELCAL coding switch set the airplane's SELCAL code.





SELCAL CODING SWITCH

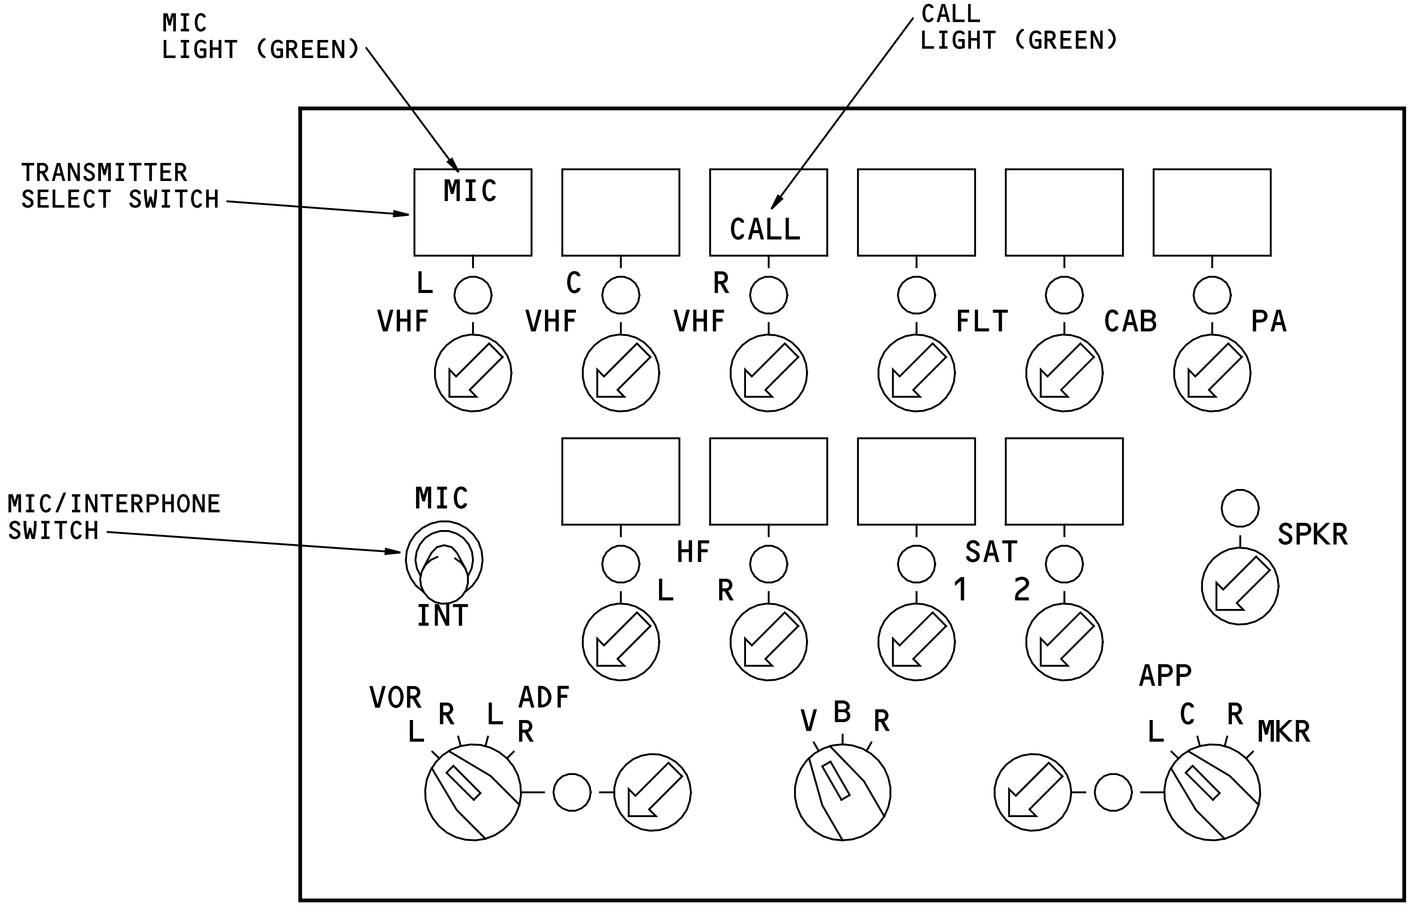
SELCAL - SELCAL DECODER

SELCAL - ACP CALL LIGHTS AND RESET SWITCHES

Control and Indications

On the audio control panel, a transmitter select switch CALL light comes on when the SELCAL decoder gets a SELCAL signal.

To make the CALL light go off, push the transmitter select switch. If the MIC light for that transmitter select switch is on, push any mic switch or that transmitter select switch to reset the call light.



SELCAL - ACP CALL LIGHTS AND RESET SWITCHES

SELCAL - ALERT MESSAGE AND AURAL

Indications

An alert message shows when the SELCAL decoder gets a SELCAL signal. The alert message, SELCAL, is a comm medium message. With the comm medium message there is a high/low chime from the aural warning speakers.

Training Information Point

The same comm medium message, SELCAL, also shows when the SATCOM system receives a call.

SATELLITE COMMUNICATIONS SYSTEM - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

SATCOM SYSTEM - GENERAL DESCRIPTION

General

The satellite communications (SATCOM) system uses a satellite network, ground stations and airplane satellite communication equipment to transmit and receive data and voice messages.

Satellites

Satellites act as relay stations between the ground stations and the airplane.

Ground Station

The ground station connects the SATCOM system to the ground-based aircraft communications addressing and reporting system (ACARS) and public telephone networks.

Airplane SATCOM Equipment

These are the components of a SATCOM system:

- Radio frequency unit (RFU)
- Radio frequency attenuator (RF ATTN)
- Radio frequency splitter (RFS)
- Class C high power amplifier (HPA)
- Class A high power amplifier (HPA)
- Low noise amplifier/diplexer (LNA/DIP)
- Low gain antenna (LGA)
- Beam steering unit (BSU)
- Top mounted high gain antenna (HGA)
- Radio frequency combiner (RFC)
- Satellite data unit (SDU).

SATCOM System Connections

The airplane SATCOM equipment connects with:

- The control display units (CDUs). The SATCOM control and status pages on the CDU give flight crew control of the SATCOM system. These pages also give system status data.
- The audio management unit (AMU). Microphone audio and push-to-talk discretes go to the SDU through the AMU. Receive audio goes from the SDU to the speakers and headsets through the AMU.
- The cabin telecommunications unit (CTU). Passengers use the SATCOM system through the CTU.

AIMS Connections

The SATCOM system also connects with the airplane information management system (AIMS) for these functions:

- Data communication management function (DCMF). The DCMF supplies data communications control for airplane air/ground datalink over the SATCOM system.
- Central maintenance computing function (CMCF). The CMCF gets SATCOM system fault reports and writes this data in a fault history. This shows the maintenance crew the defective component or function. The maintenance access terminal (MAT) gives access to the CMCF for loading and updating SATCOM configuration data.

- Data conversion gateway function (DCGF). The DCGF changes inertial reference system data into ARINC 429 data for high gain antenna (HGA) beam steering. The DCGF also supplies international civil aviation organization (ICAO) addresses.

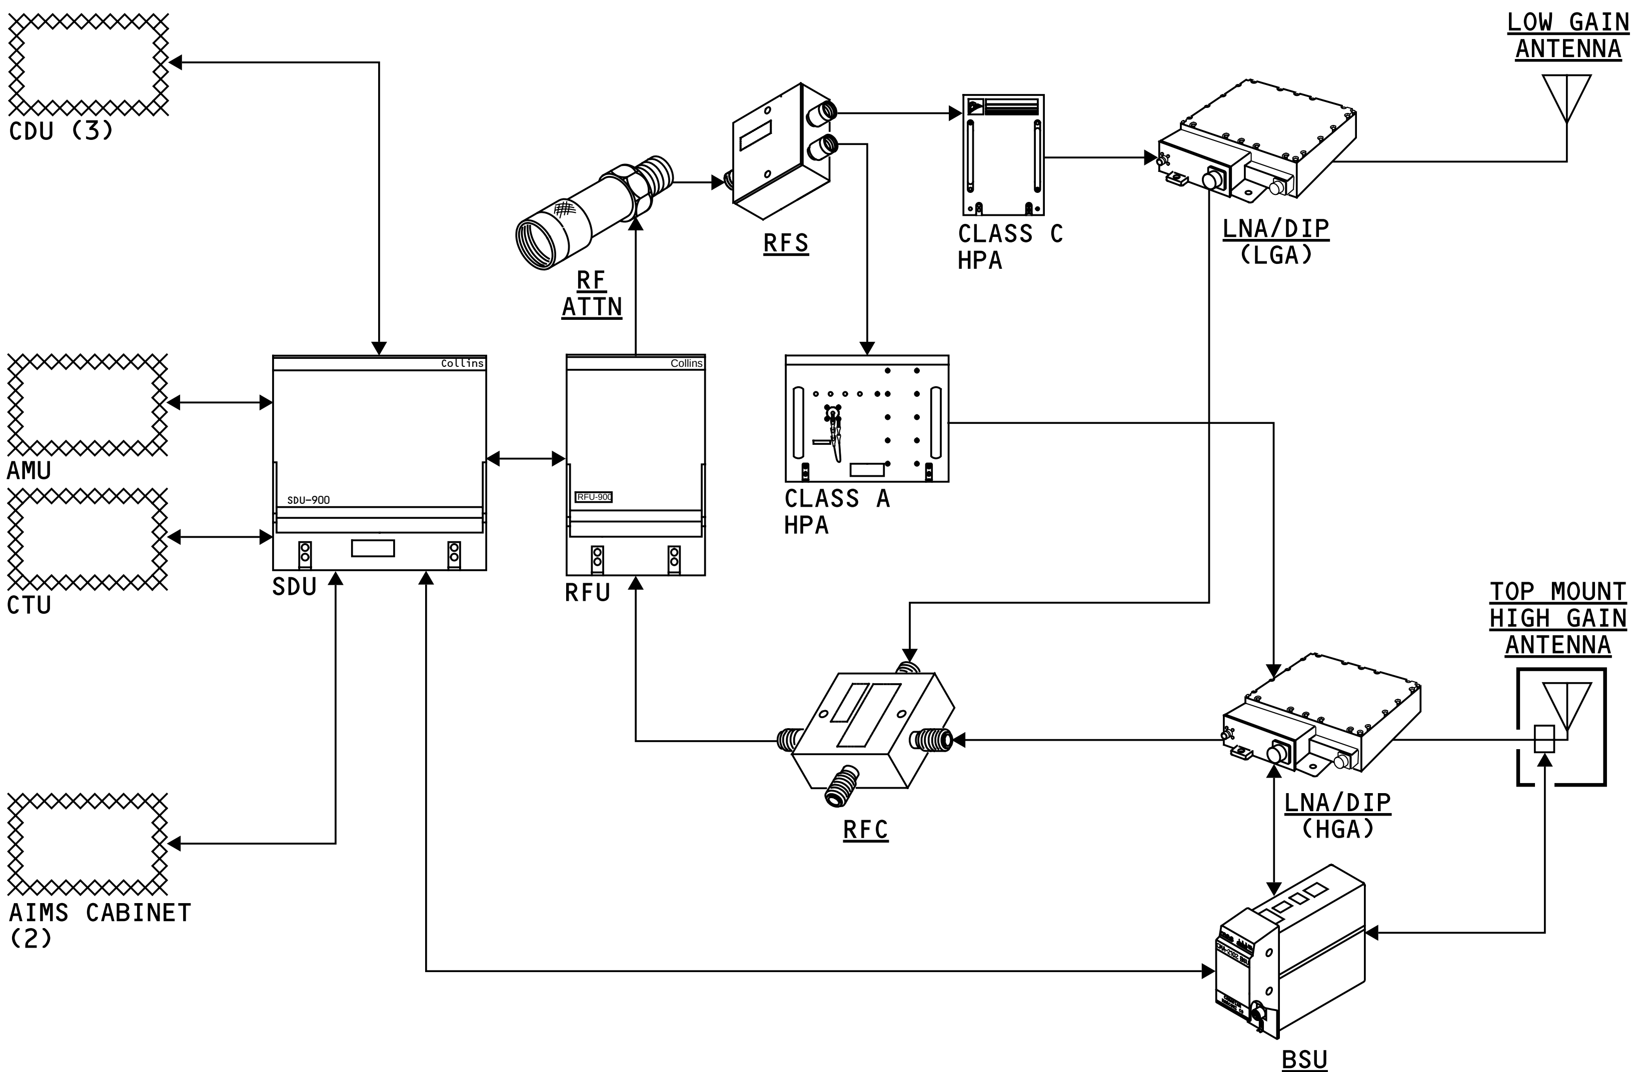
High Gain Antenna System

The high gain antenna system receives and transmits voice and data signals. A high power amplifier (HPA) sends transmit signals to the high gain antenna system. The antenna system sends receive signals to the radio frequency unit (RFU). The antenna system has these components:

- High gain antenna
- Beam steering unit
- Low noise amplifier/diplexer (LNA/DIP).

Low Gain Antenna System

The low gain antenna system receives and transmits data signals. This system operates only when a high gain antenna system fails or class A high power amplifier fails. The low gain antenna system has a low gain antenna (LGA) and a low noise amplifier/diplexer (LNA/DIP).



SATCOM SYSTEM - GENERAL DESCRIPTION

SATCOM SYSTEM - COMPONENT LOCATIONS - 1

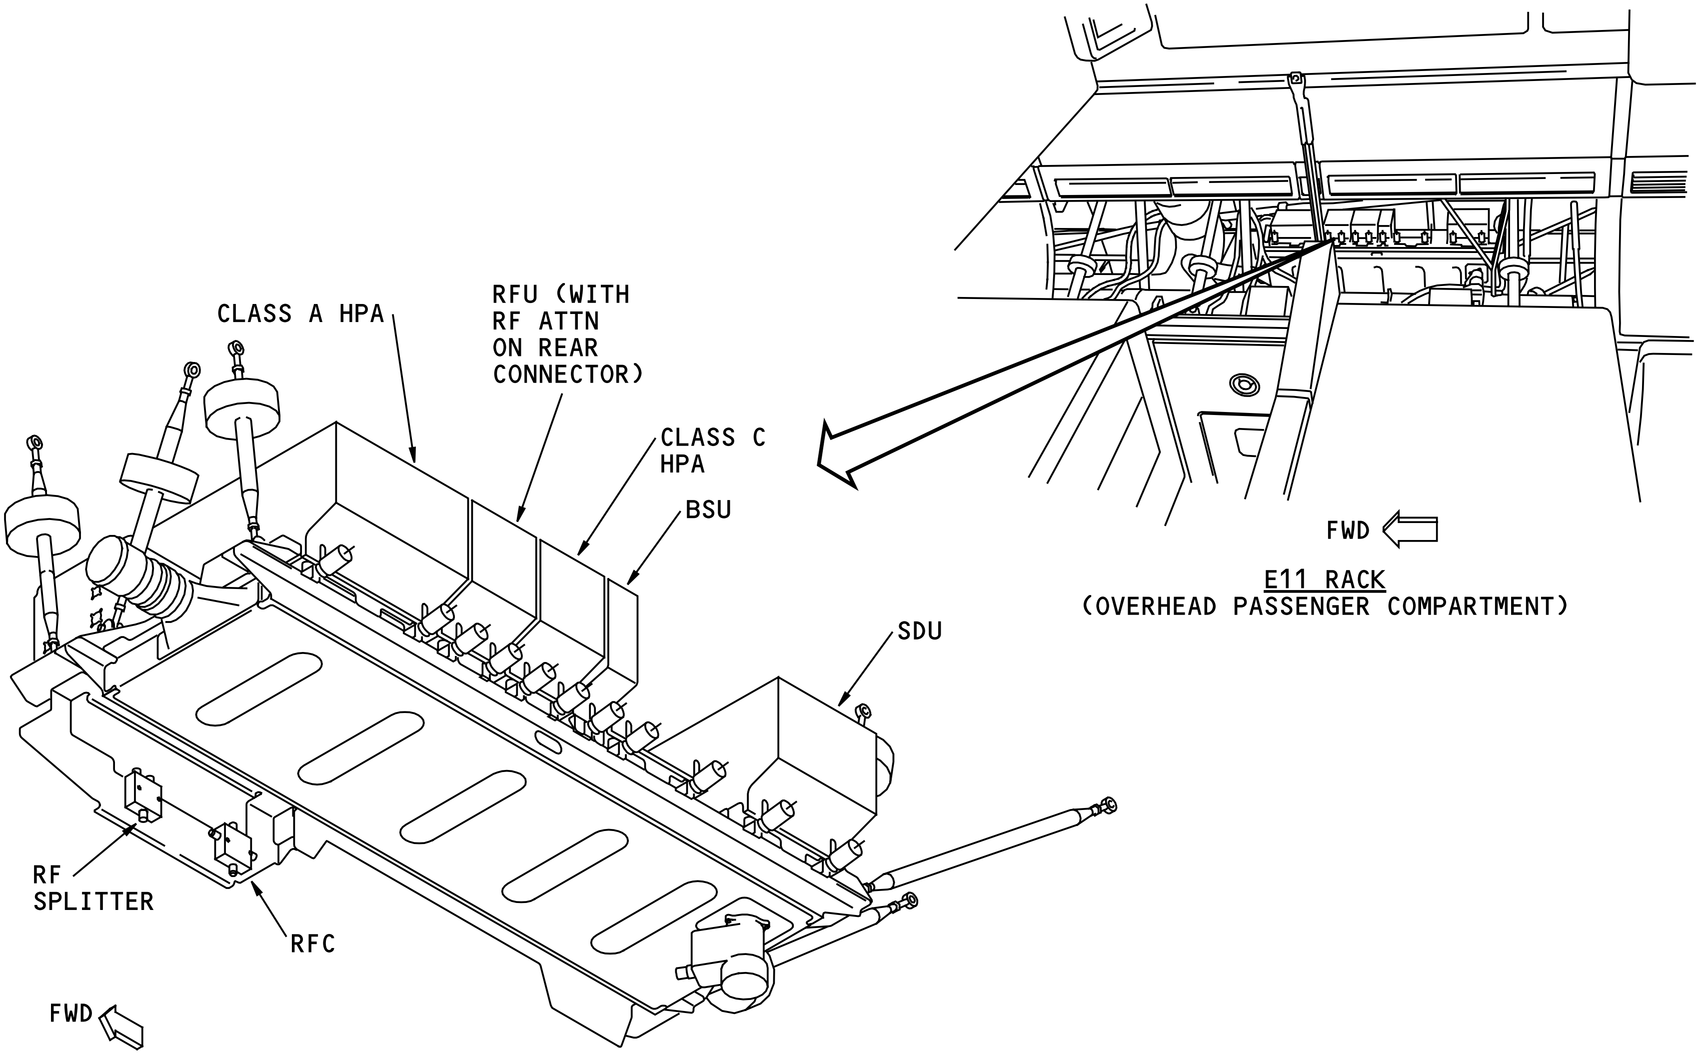
Cabin Overhead Area

This equipment is on the E11 rack:

- Radio frequency splitter (RFS)
- Radio frequency attenuator (RF ATTN)
- Radio frequency combiner (RFC)
- Satellite data unit (SDU)
- Class C high power amplifier (HPA)
- Radio frequency unit (RFU)
- Beam steering unit (BSU)
- Class A high power amplifier (HPA).

Access

Access to the E11 rack is through a ceiling panel on the left side of the door 3 cross aisle area.



SATCOM SYSTEM - COMPONENT LOCATIONS - 1

SATCOM SYSTEM - COMPONENT LOCATIONS - 2

High Gain Antenna System

The SATCOM system has a top mounted high gain antenna system. The high gain antenna system has these components:

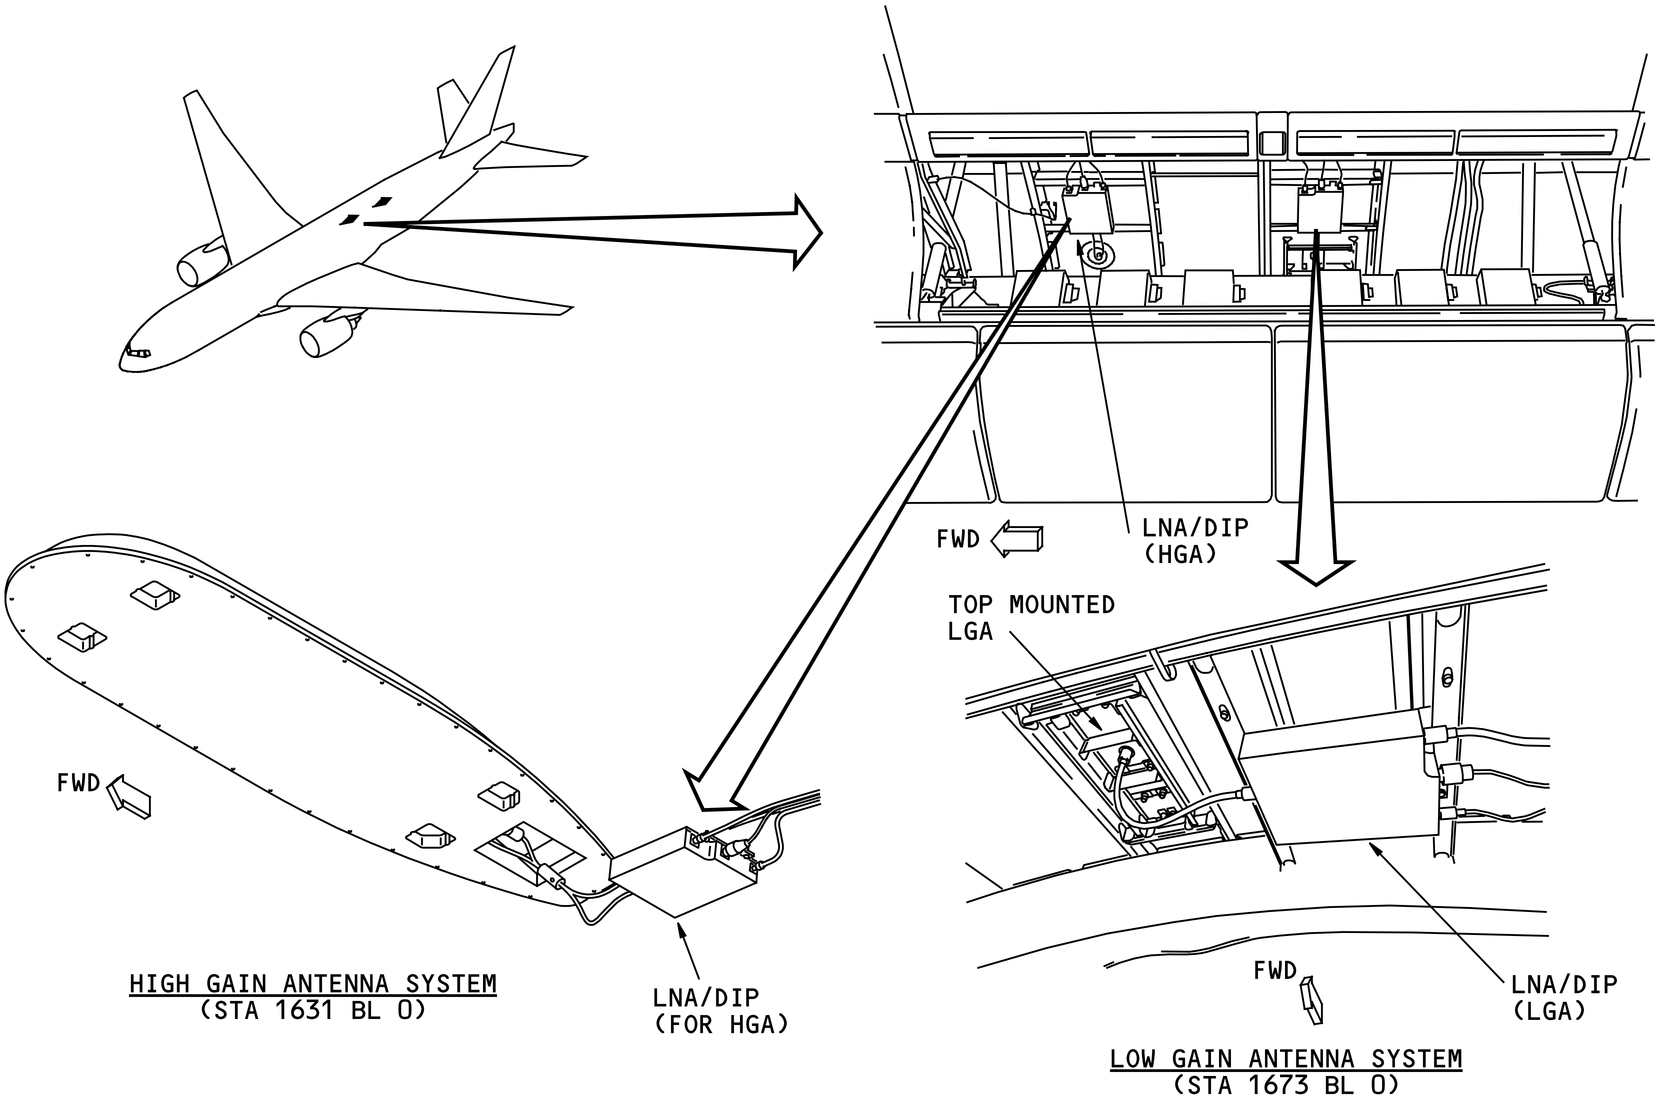
- High gain antenna (HGA)
- Beam steering unit (BSU)
- Low noise amplifier/diplexer (LNA/DIP).

Low Gain Antenna System

The low gain antenna system has a low gain antenna (LGA) and a low noise amplifier/diplexer (LNA/DIP) (top).

Access

Access to the antenna systems is through overhead panels in the passenger cabin.



SATCOM SYSTEM - COMPONENT LOCATIONS - 2

SATCOM SYSTEM - FLIGHT DECK INTERFACE COMPONENT LOCATIONS

Flight Deck Interface Components

These components in the flight deck have interfaces with the SATCOM system:

- left, center, and right control display units (CDUs)
- Captain (CAPT), first officer (F/O), and first observer (F/OBS) audio control panels (ACPs).

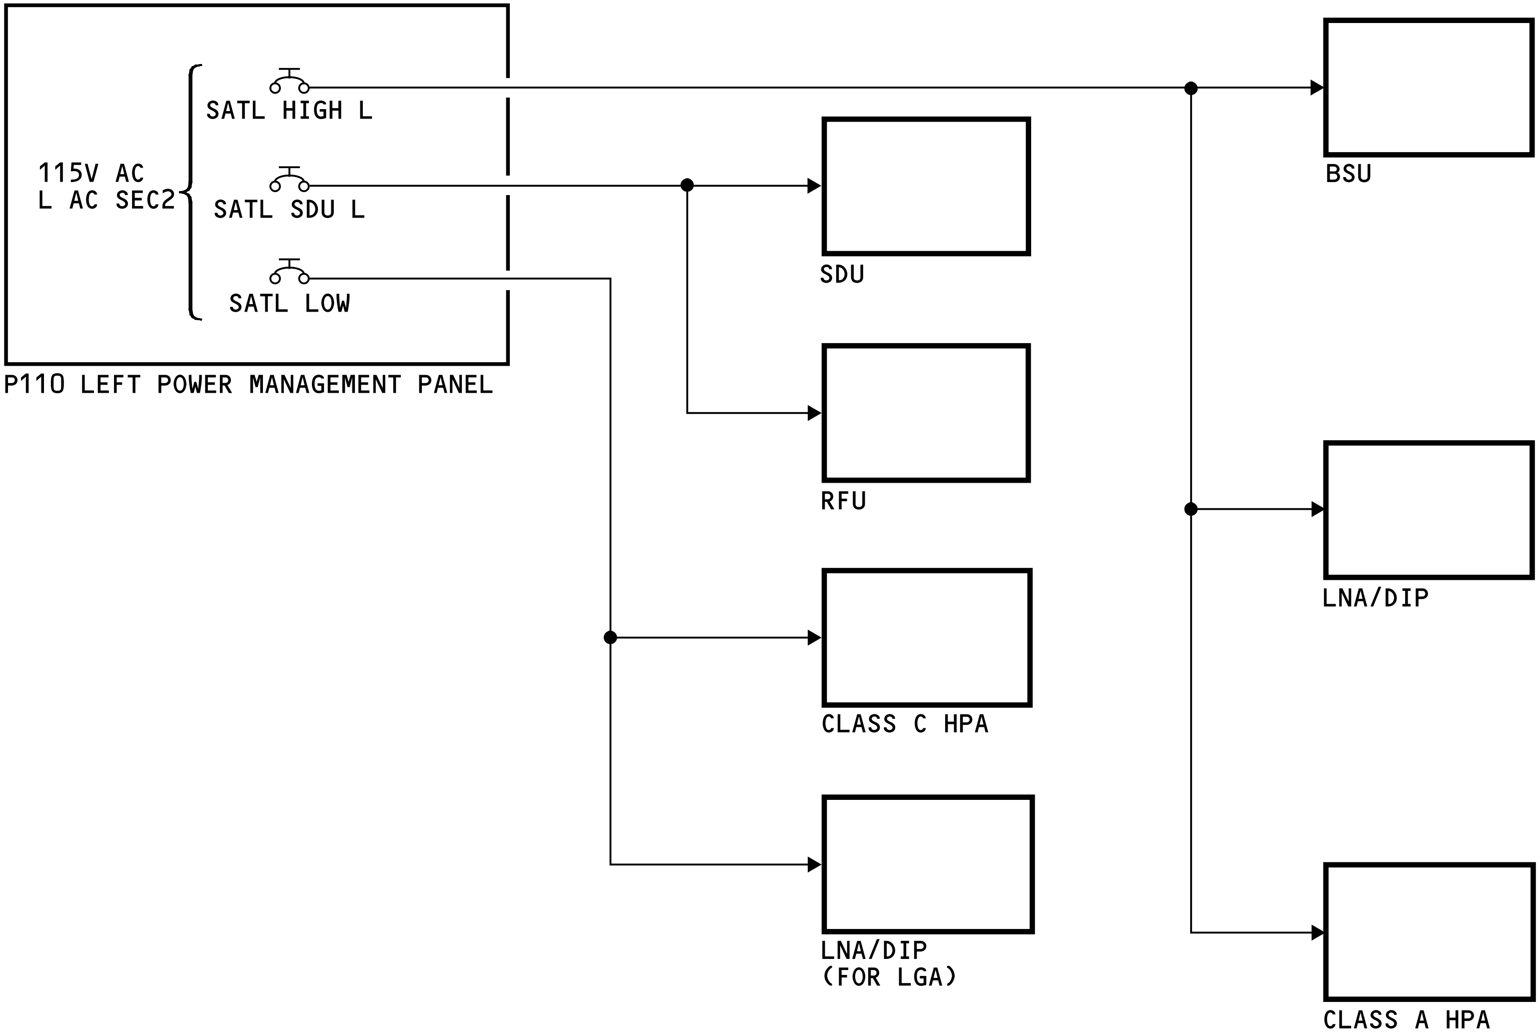
SATCOM SYSTEM - FLIGHT DECK INTERFACE COMPONENT LOCATIONS

SATCOM SYSTEM - POWER INTERFACE

Left Power Management Panel

The left main ac bus sends 115v ac to these units:

- Beam steering unit
- Low noise amplifier/diplexer (LNA/DIP)
- Class A high power amplifier (HPA)
- Class C HPA
- Satellite data unit (SDU)
- Radio frequency unit (RFU).



SATCOM SYSTEM - POWER INTERFACE

THIS PAGE INTENTIONALLY LEFT BLANK

SATCOM SYSTEM - VOICE AND DATA TRANSMIT/RECEIVE INTERFACES

General

The SATCOM system provides a total of five voice channels and one data channel.

The control display units (CDUs) connect with the satellite data unit (SDU). The flight crew use the CDUs to control the SATCOM system.

Voice Operation

Audio control panels (ACPs) connect to the audio management unit (AMU) to control the voice signals from the flight deck to the SATCOM system.

The AMU connects with the SDU to send and receive audio signals for the flight crew.

The cabin telecommunication unit (CTU) connects with the SDU to send and receive voice signals.

Data Operation

The airplane information management system (AIMS) connects with the SDU to send and receive data signals.

The CTU connects with the SDU to receive and transmit data signals.

Signal Flow - Receive

The high gain antenna (HGA) receives radio frequency (RF) signals. It sends them to the LNA/Diplexer (LNA/DIP).

The LNA/DIP increases the power level of the received signals. The LNA/DIP sends the amplified RF signals to the radio frequency unit (RFU).

The RFU receives the amplified signals and changes the RF signals to intermediate frequency (IF) signals for the satellite data unit (SDU).

The SDU demodulates the received IF signals and sends them to the AMU, the AIMS cabinets, or the CTU.

Signal Flow - Transmit

The AMU, AIMS, or the CTU sends transmit signals to the SDU. The SDU modulates the signals and sends them to the RFU.

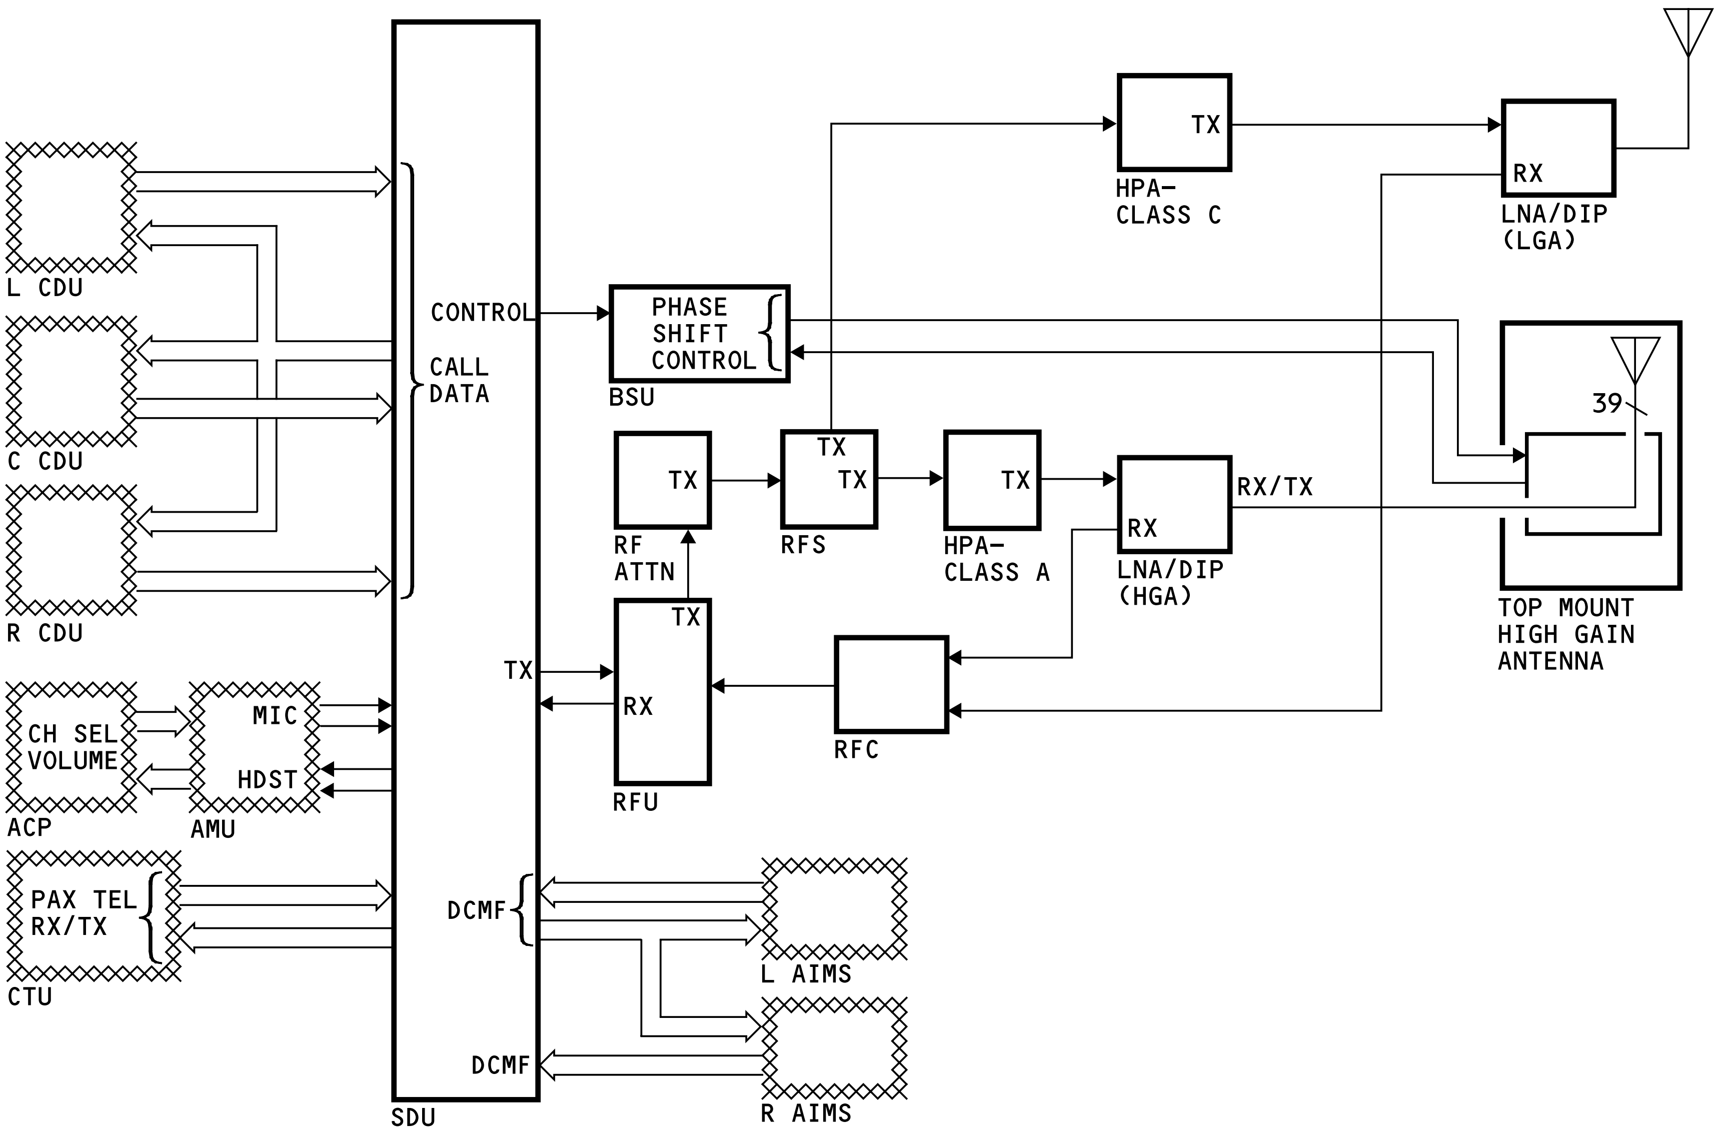
The RFU sends the RF signals through the radio frequency attenuator and the radio frequency splitter (RFS) to the high power amplifier (HPA).

The HPA increases signal strength and sends the signal to the low noise amplifier/diplexer (LNA/DIP).

The LNA/DIP sends the RF signal to the top mounted high gain antenna (HGA). The HGA receives beam steering information from the beam steering unit (BSU). The HGA splits the RF into thirty nine identical signals. The HGA electronically steers the RF signals to the satellite by sending them through the antenna arrays in an aligned beam.

Low Gain Antenna

The low gain antenna system is for data only. It operates if a high gain antenna system fails or the class A high power amplifier fails.



SATCOM SYSTEM - VOICE AND DATA TRANSMIT/RECEIVE INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

SATCOM SYSTEM - CONTROL AND STATUS INTERFACES

General

The satellite data unit (SDU) supplies control and failure data for the SATCOM system.

These components have an interface with the SDU for control and status data:

- High power amplifiers (HPAs)
- Low noise amplifier/diplexers (LNA/DIPs)
- Beam steering unit (BSU)
- Airplane information management system (AIMS)
- Control display units (CDUs)
- Radio frequency unit (RFU).

High Power Amplifiers

The high power amplifiers (HPAs) receive control signals from the SDU. The HPAs receive the control signals to adjust the output of their transmit signals. The HPAs send BITE data to the SDU. The class A HPA receives a mute signal from the BSUs to shut down the HPA when the system switches outputs from one antenna to the other.

Low Noise Amplifier/Diplexer

The low noise amplifier/diplexer (LNA/DIP) for the low gain antenna (LGA) receives on/off signals from the SDU. The LNA/DIP sends BITE data to the SDU. The LNA/DIPs for the high gain antennas send BITE data to the beam steering units (BSUs).

The LNA/DIP for the high gain antenna (HGA) receives on/off control from the beam steering unit. The LNA/DIP for the HGA sends BITE data to the beam steering unit (BSU).

Beam Steering Unit

The BSU receives direction signals from the SDU. The BSU sends BITE data to the SDU. The BSU sends on/off signals to the LNA/DIP. The BSU sends beam steering data to the high gain antenna (HGA). The BSU receives BITE data from the HGA.

Airplane Information Management System (AIMS)

The central maintenance computing function (CMCF) in the airplane information management system (AIMS) receives SATCOM system BITE data from the SDU.

AIMS sends this data to the SDU:

- International Civil Aviation Organization (ICAO) address
- Inertial reference data
- Software for system configuration
- Data load enable
- BITE commands.

Radio Frequency Unit

The radio frequency unit (RFU) receives frequency selection data from the SDU. Each satellite operates on

SATCOM SYSTEM - CONTROL AND STATUS INTERFACES

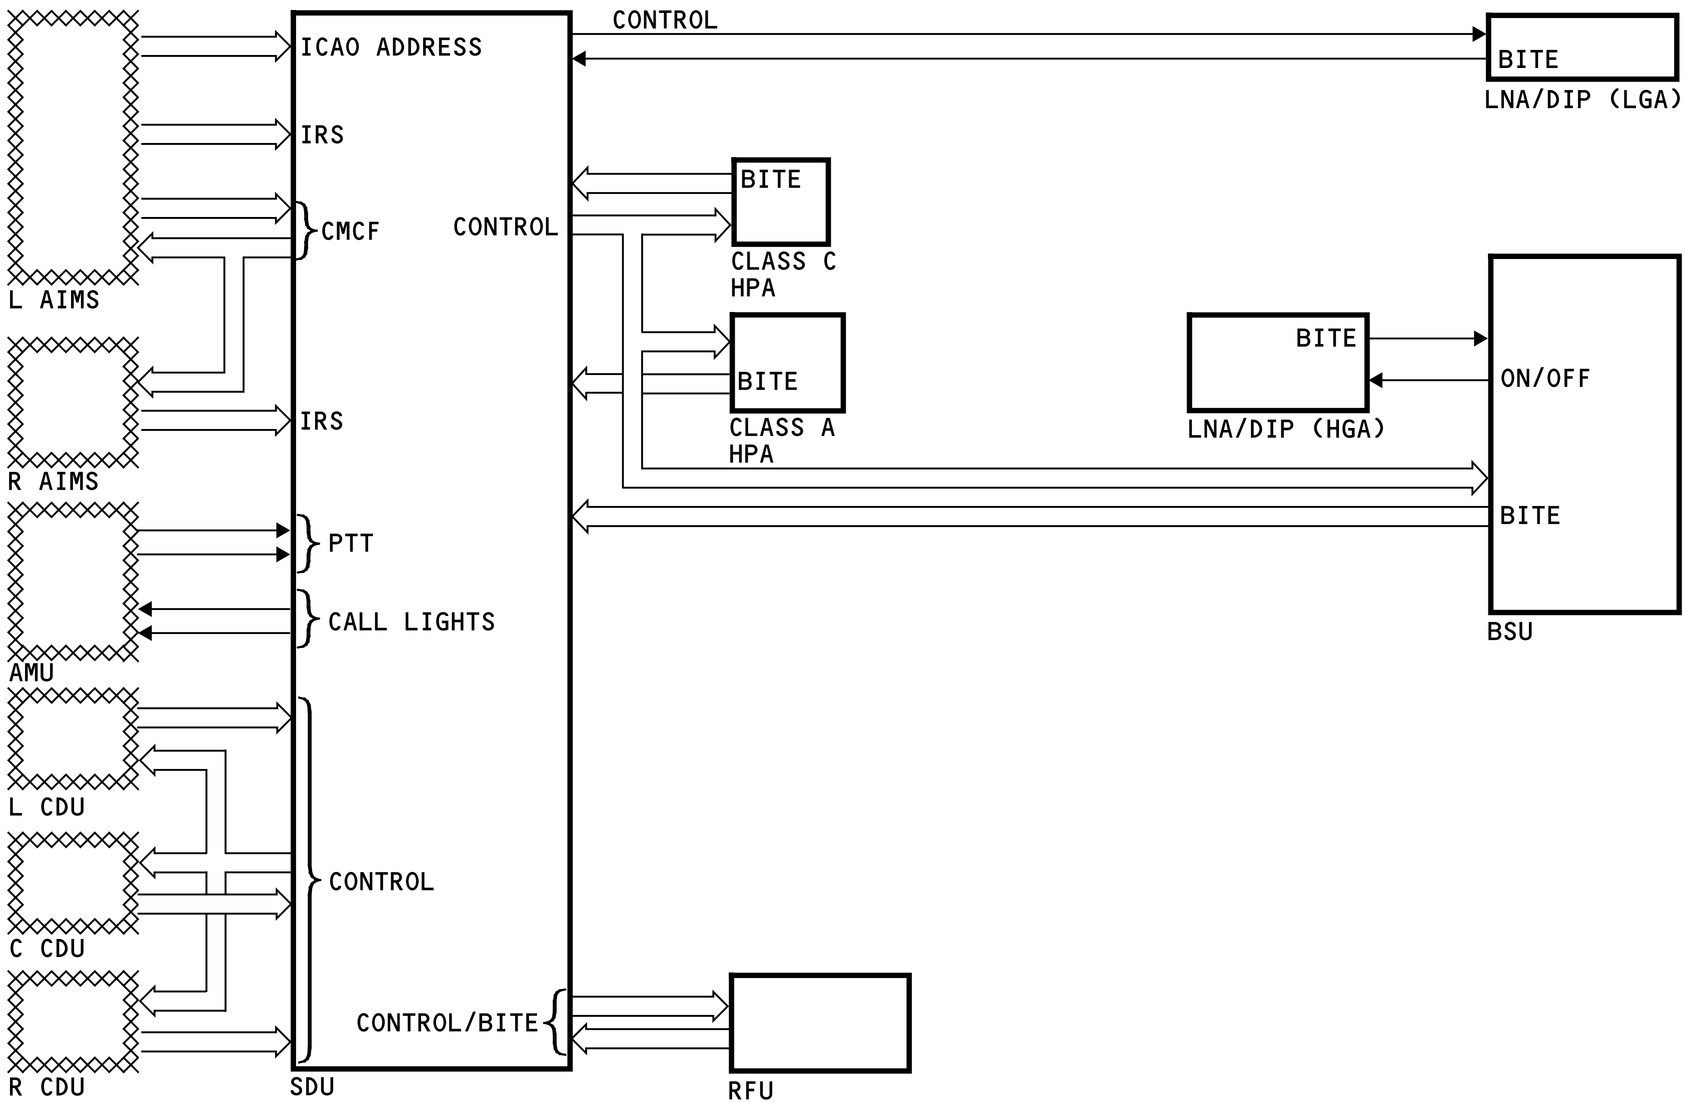
a different frequency to decrease interference from other satellite signals.

Audio Management Unit

The audio management unit (AMU) sends PTT signals to the SDU. The SDU sends call light signals to the AMU.

Control Display Units

The flight crew uses the control display units (CDUs) to send control signals to the SDU for SATCOM system operation.



SATCOM SYSTEM - CONTROL AND STATUS INTERFACES

SATCOM SYSTEM - HIGH GAIN ANTENNA

Purpose

The top mount high gain antenna (HGA) transmits and receives signals.

Functional Description

The HGA transmits signals from the low noise amplifier/diplexer (LNA/DIP). As the signal enters the antenna it goes through power divider/combiners. The signal divides into 39 identical signals. Each signal goes to an individual phase shift element. Each element phase shifts the signal. The phase shift aligns the signals in the antenna elements into a thin beam aimed at the satellite.

The beam steering unit provides beam alignment information to the HGA.

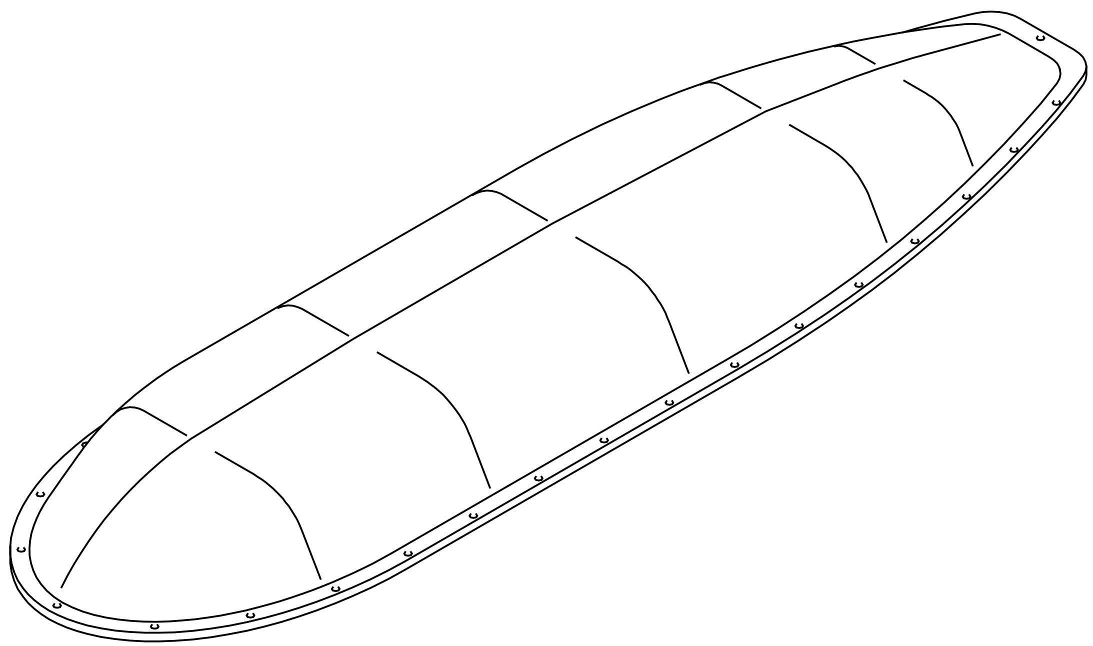
The HGA receives satellite signals through the 39 element array. The received signals go to the LNA/DIP.

Physical Description

The HGA has an array of 39 elements in an aerodynamic dome that is longer in the forward and aft directions.

The HGA has these properties:

- Length - 66 inches
- Height - 5 inches
- Width - 18 inches
- Weight - 65 pounds.



23-15-00-018 Rev 2 11/25/1996

SATCOM SYSTEM - HIGH GAIN ANTENNA

SATCOM SYSTEM - LOW GAIN ANTENNA

Purpose

The low gain antenna (LGA) transmits and receives radio frequency signals for low speed data link. The low gain antenna operates only if the high gain antenna (HGA) system fails.

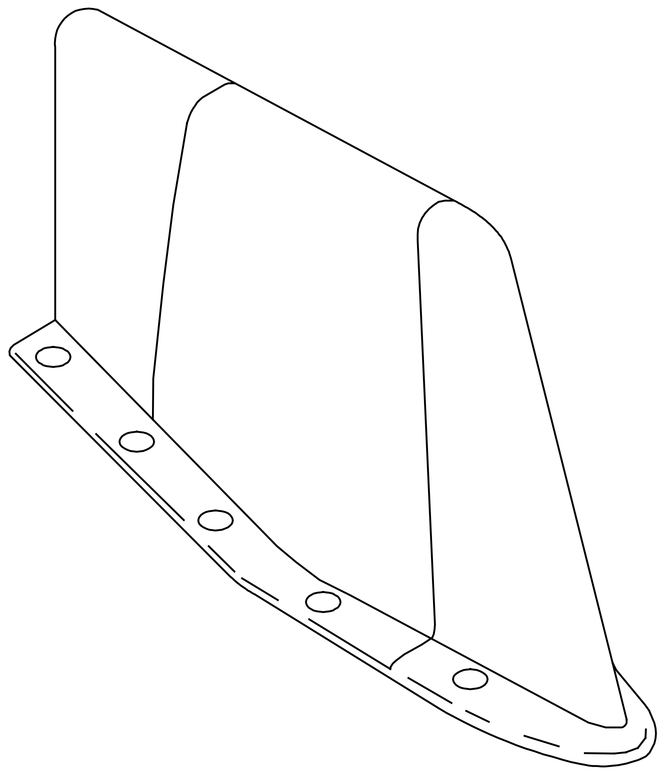
Physical Description

The LGA contains a single antenna element. A blade-shaped aerodynamic radome protects the element.

The LGA has these properties:

- Base length - 15 inches
- Base width -3.75 inches
- Height - 6 inches
- Weight - 2 pounds.

CAUTION: BE CAREFUL WHEN YOU REMOVE THE AERODYNAMIC SEAL WITH THE SEALANT REMOVAL TOOL. DAMAGE TO THE AIRPLANE SKIN CAN OCCUR.



23-15-00-019 Rev 2

SATCOM SYSTEM - LOW GAIN ANTENNA

SATCOM SYSTEM - CONTROL AND STATUS PAGES

General

The control display unit (CDU) has SATCOM pages that give control and status of the SATCOM system.

Satcom Main Menu

The SATCOM main menu shows:

- The name selected for call on channel 1 or 2.
- Call controls
- SATCOM directory access
- Log-on menu access
- BITE menu access and present BITE status.

For each channel, SATCOM shows these items:

- Channel status
- Call connection commands
- Call disconnect commands
- The call destination name chosen from the directory.

SATCOM Directory

The SATCOM directory pages show the labels for each phone number in the directory.

SATCOM Log Page

This page shows selections for control of system log on. The log-on status is on this page also.

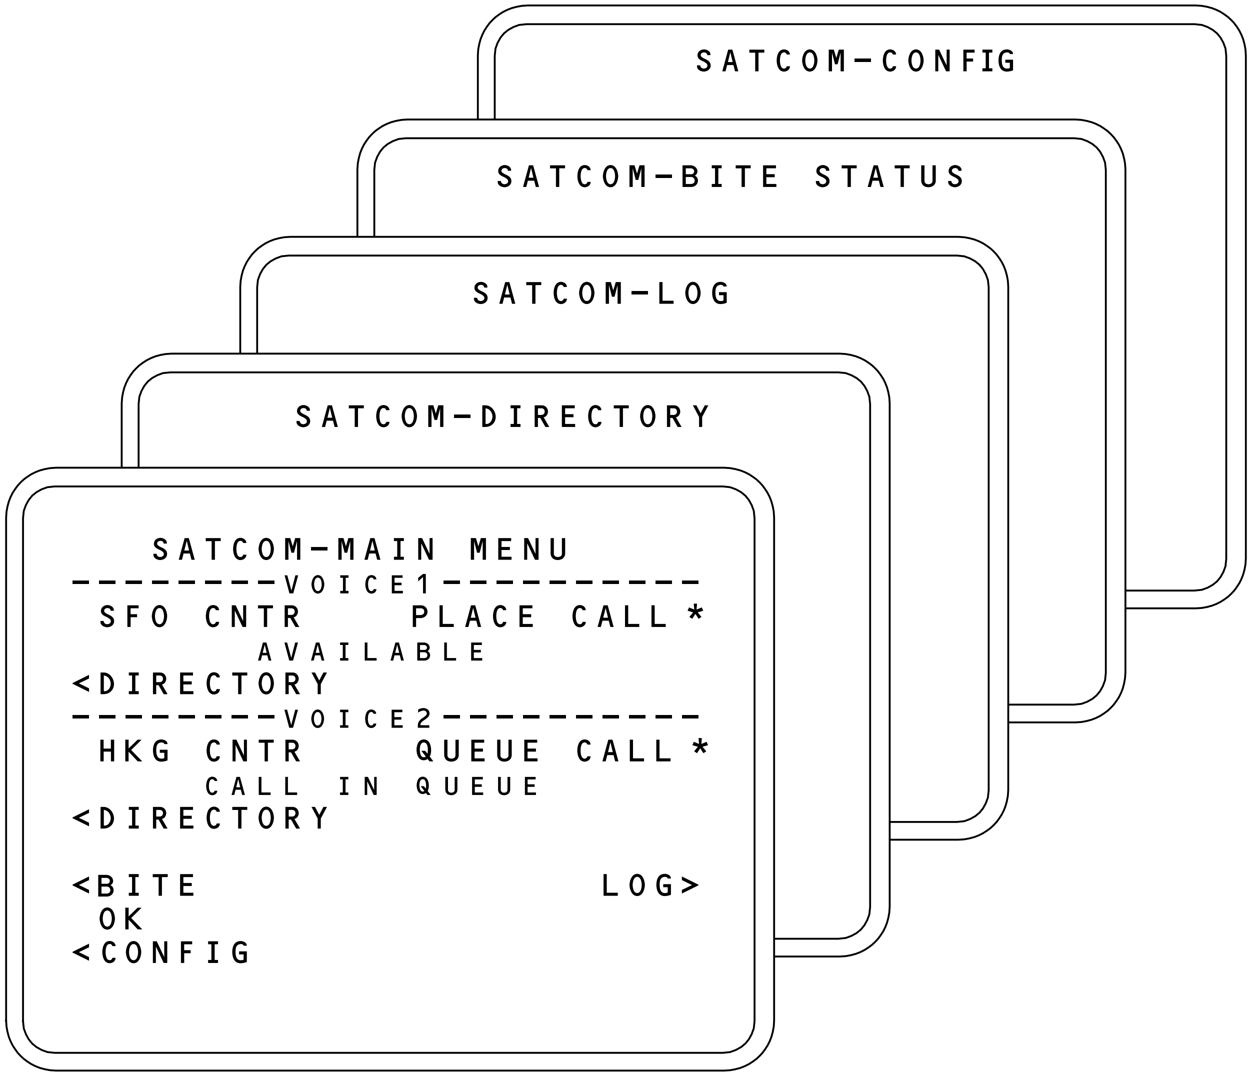
SATCOM BITE Status Page

The BITE status page shows:

- The status of the SATCOM system components
- The SATCOM system bus page. This page shows the status of systems that interface with SATCOM as OK or INACTIVE.

SATCOM CONFIG Page

This page shows the part number for the SDU and the airline database number.



23-15-00-028 Rev 3 01/24/95

SATCOM SYSTEM - CONTROL AND STATUS PAGES

SATCOM SYSTEM - LOG ON

General

To use the SATCOM system, the airplane must log-on to a communication service company.

Automatic Log-On

An automatic log-on occurs when the system powers up. The SATCOM system uses satellite frequencies in memory to find a satellite transmit signal. When the SATCOM system finds an active frequency from the satellite, it locks on to it. The system then uses the satellite as a relay to log-on to a ground station.

After the airplane logs on, the log-on data goes to all ground station networks so that any of the ground stations can locate a specified airplane SATCOM system.

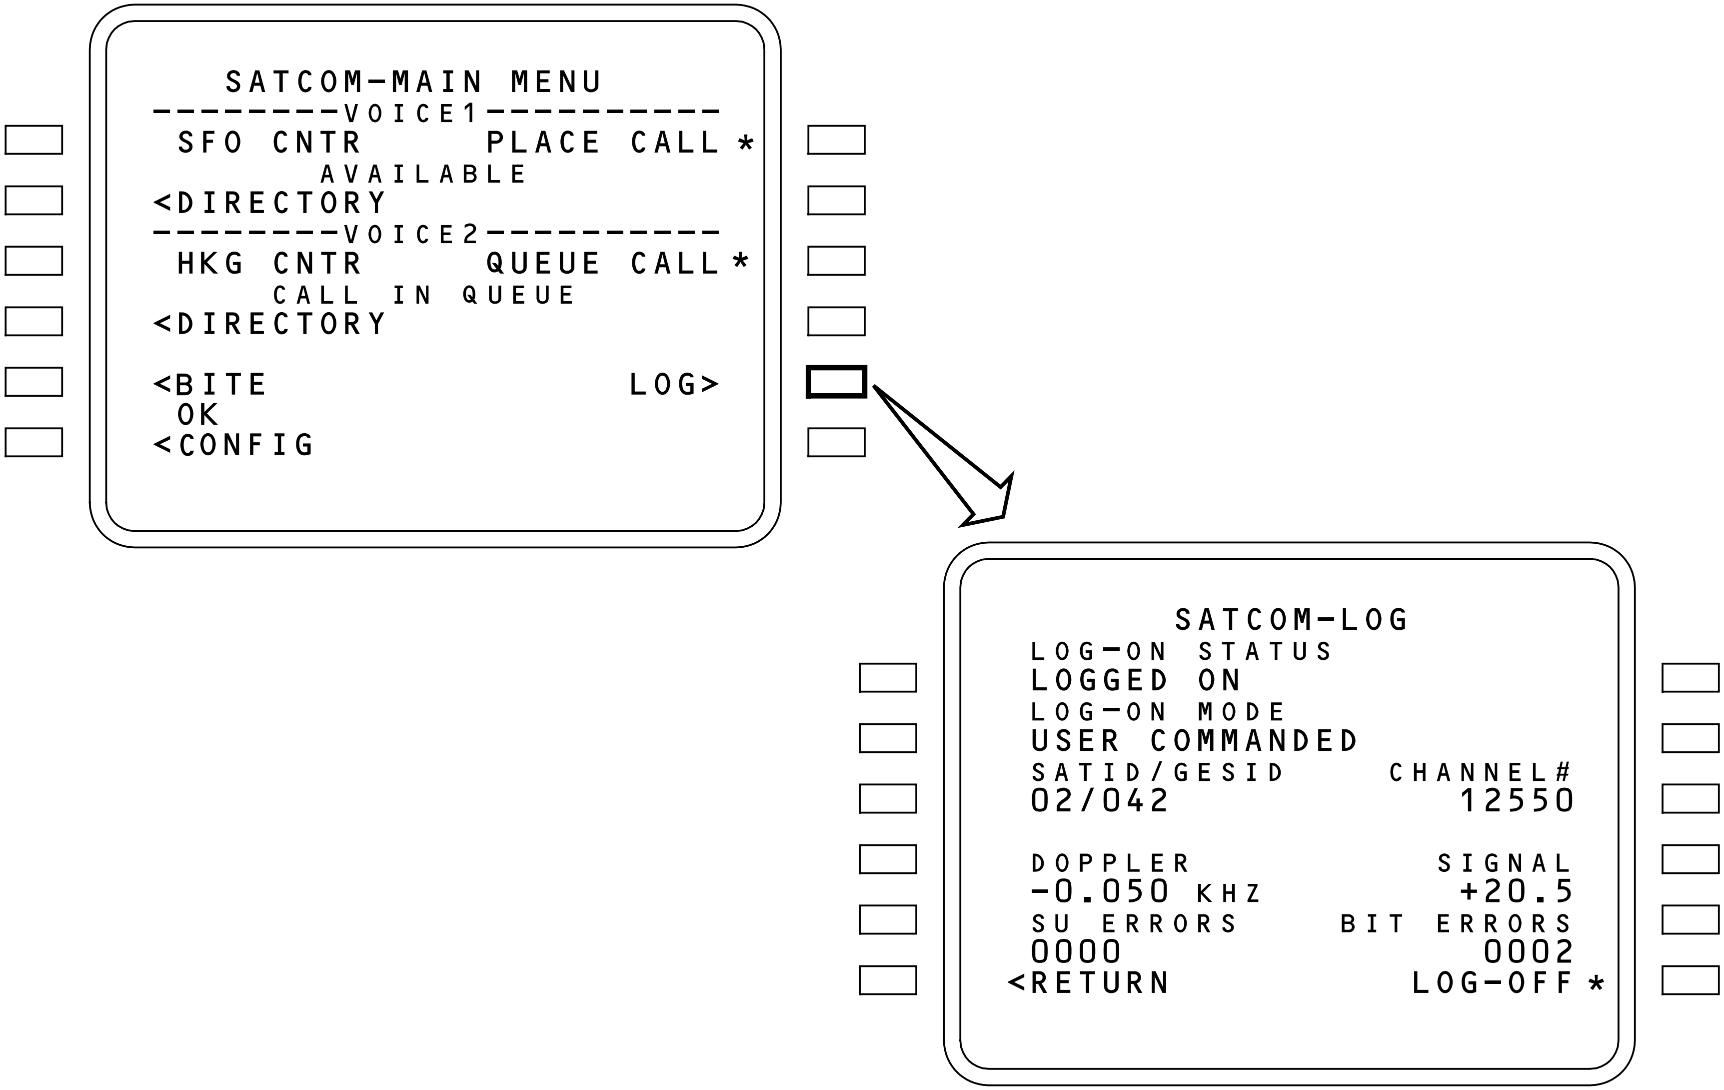
Manual Log-On

Use the control display unit (CDU) to see the SATCOM-main menu. Push the line select key (LSK) adjacent to LOG for the SATCOM-log page. The SATCOM-log page gives selection and control of the manual log-on process. Enter the satellite and ground station identification numbers and push the LSK 3 left. This starts manual log-on. The title field at LSK 1 left shows log-on status.

If the system is logged off, select the LSK adjacent to *AUTO LOG-ON to make the system automatically log-on to a satellite and GES. You may also push the LSK adjacent to GES-SEL to show a list of ground earth stations. From this screen, you may select a GES and log-on.

An airplane can only log-on to one ground station at a time. However, the airplane does not have to get all communication services from that ground station. The airplane may use other links with other ground stations. A typical multi-ground station operation permits an airplane to do these functions:

- Keep data links with the airline operations base
- Talk to an air traffic control (ATC) center through the log-on ground station
- Operate passenger communications through a different ground station.



23-15-00-029 Rev 4 01/05/95

SATCOM SYSTEM - LOG ON

SATCOM SYSTEM - VOICE OPERATIONS

General

The flight crew uses the control display units (CDUs) and audio control panels (ACPs) to control the voice mode of the SATCOM system.

Outgoing Calls

Push a SATCOM transmitter select switch on the ACP. Adjust the volume with the related SAT receiver control.

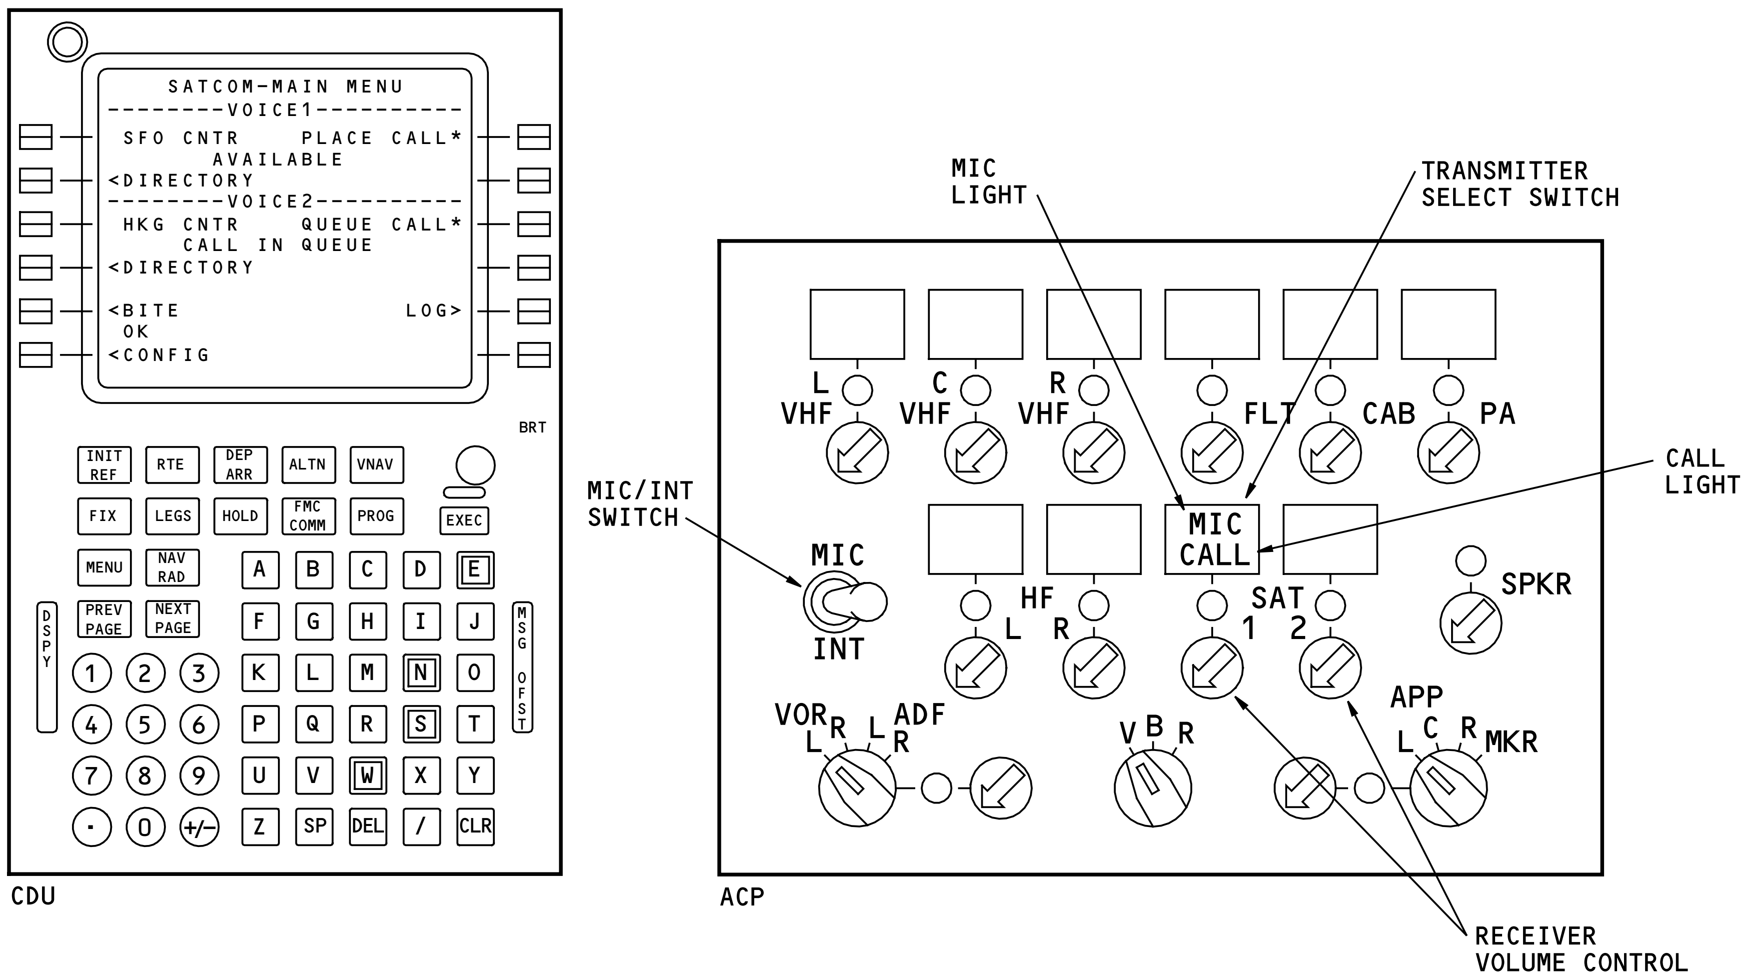
Push the MENU key on the CDU and then push the line select key (LSK) adjacent to <SAT. The SATCOM-MAIN MENU shows on the CDU.

Push the LSK adjacent to DIRECTORY for voice channel 1 or 2. Push the LSK next to the name you want to call.

Push the LSK adjacent to RETURN to go back to the SATCOM-MAIN MENU. Check that the name selected in the directory shows at LSK 1L if you use voice channel 1 or LSK 3L if you use voice channel 2.

Push the LSK adjacent to PLACE CALL. The airplane SATCOM system now makes the call. When the call is connected to the called station, the related SAT CALL light comes on, the SELCAL message shows on EICAS, and you hear the ringback tone in the headset.

When the called party answers, you can push any MIC/interphone switch and speak into the microphone. You do not need to release the MIC/interphone switch to listen. When you finish the call, push the LSK adjacent to END CALL from the SATCOM-MAIN MENU.



SATCOM SYSTEM - VOICE OPERATIONS

SATCOM SYSTEM - DATA OPERATIONS

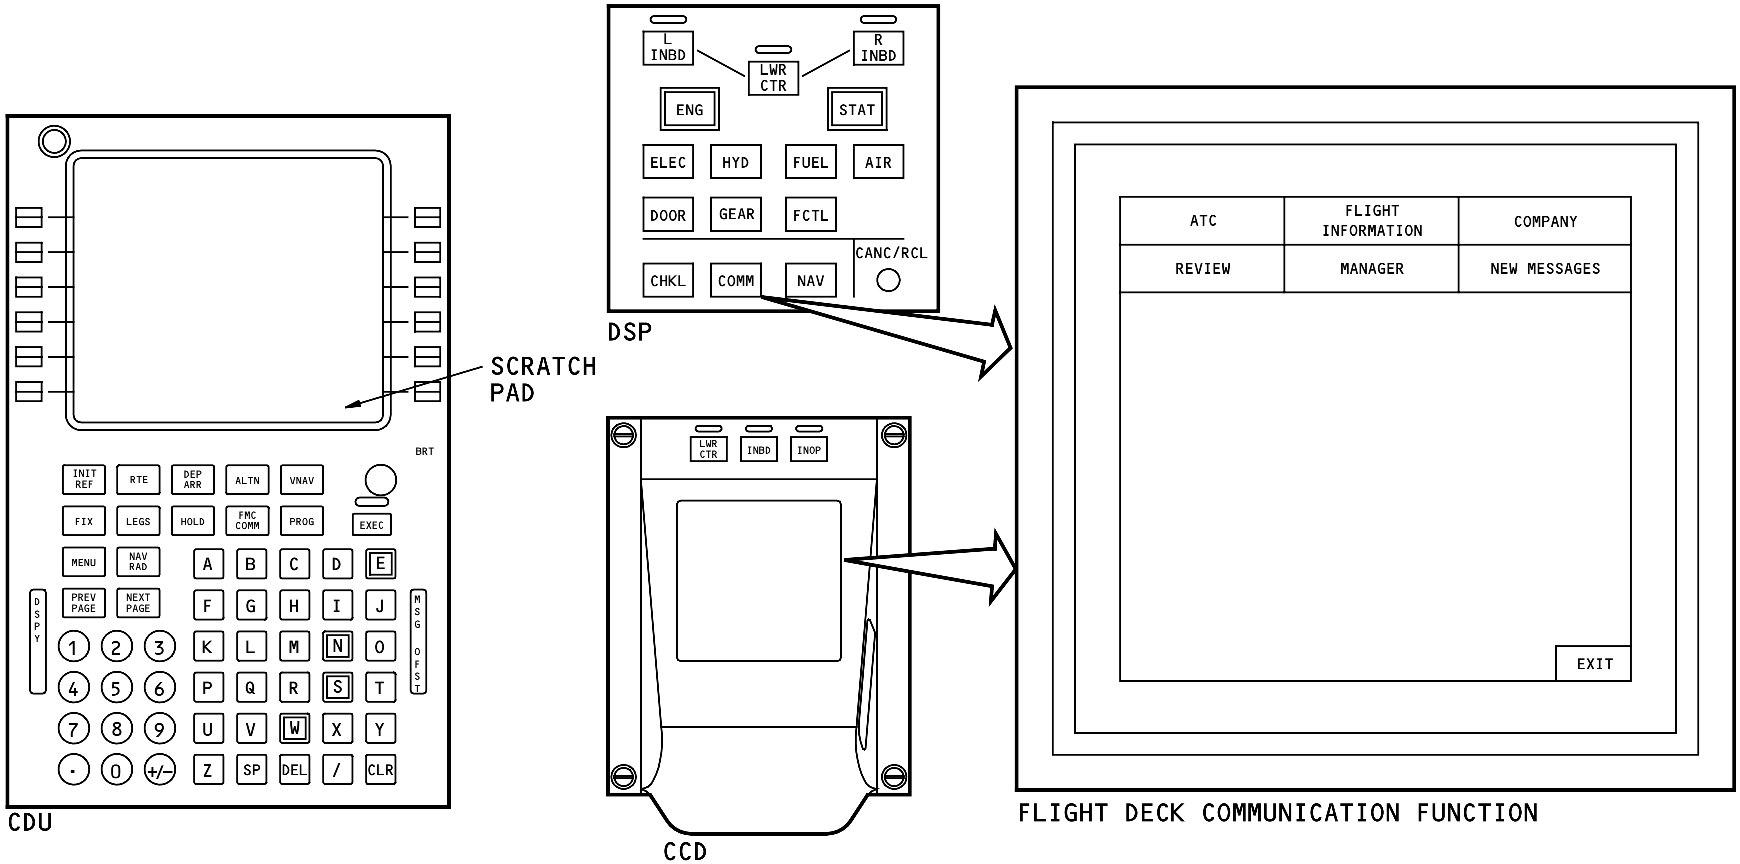
Outbound Datalink

Push the COMM button on the display select panel (DSP) to access the flight deck communication function (FDCF). The communication page shows on the selected display unit.

Use the cursor control device (CCD) to select the MANAGER menu from the main menu. Select the ACARS menu. Use the ACARS menu to select SATCOM for downlink. Use the control display unit (CDU) keyboard and the FDCF COMPANY menu to send a free text message.

Inbound Data link

When the airplane receives a data message through SATCOM, a chime sounds and a COMM or PRINTER message shows on the EICAS display. The COMM EICAS message tells you to read the message on the communication page under the NEW MESSAGES menu. The PRINTER message tells you the message is on the flight deck printer.



23-15-00-031 Rev 3 02/25/1997

SATCOM SYSTEM - DATA OPERATIONS

SATCOM SYSTEM - BITE

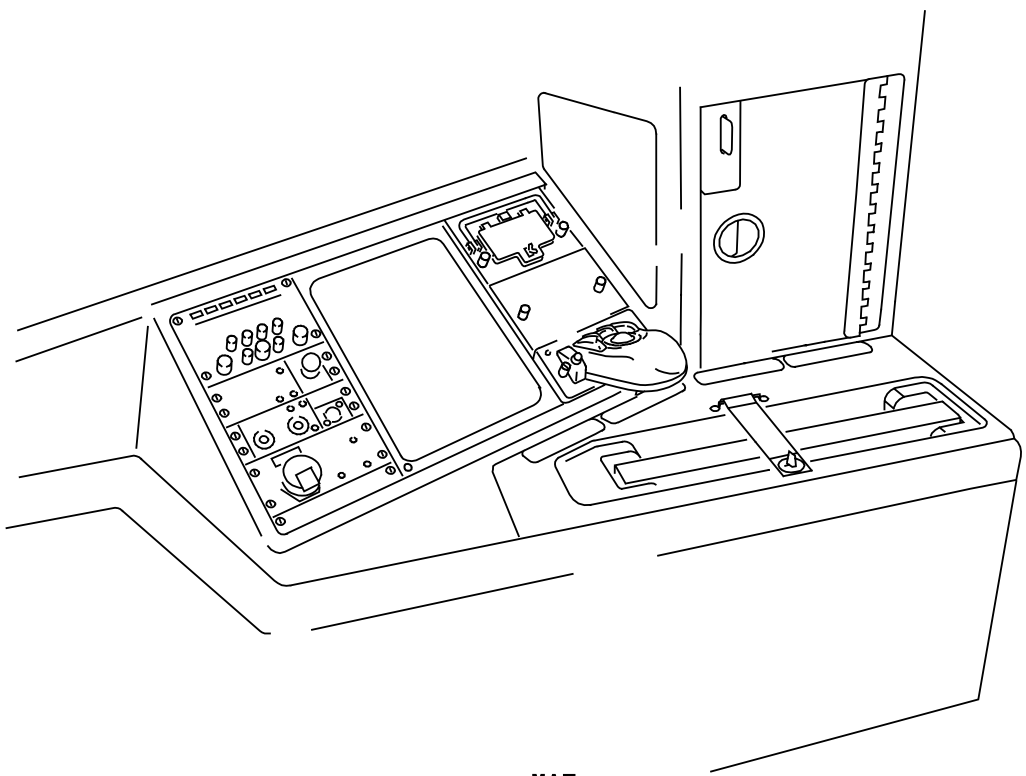
General

The SATCOM system has interfaces with the central maintenance computer system (CMCS) through the airplane information management system (AIMS). Use the maintenance access terminal (MAT) to do a test of the SATCOM system. You can see the test results on the MAT or on the SATCOM MAIN-MENU on the control display unit (CDU).

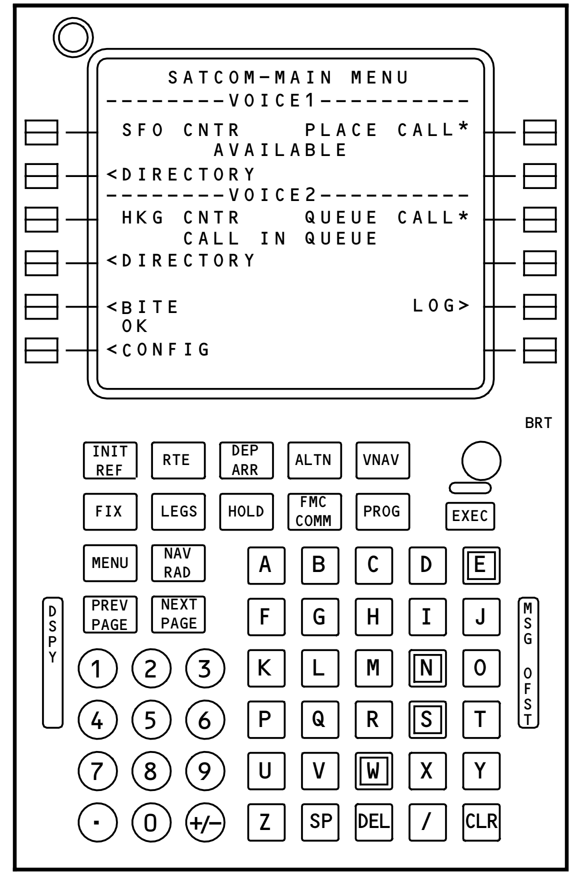
Built-In Test Equipment (BITE)

The SATCOM system has BITE to monitor line replaceable units (LRUs). At power-up, BITE automatically does a test of the system components. Use the MAT to start a manual BITE test.

SATCOM reports all BITE-detected faults to the on-board maintenance system (OMS). Use the MAT to get access to the OMS to get fault data. Use the CDU to get access to BITE-detected faults and system failures in the satellite data unit (SDU).



MAT



CDU

23-15-00-032 Rev 5 02/25/1997

SATCOM SYSTEM - BITE

SATCOM SYSTEM - SYSTEM TESTS

General

Use a maintenance access terminal to do the SATCOM system tests. To do a complete system test, you also need to make a call.

SATCOM System Test

The test does a check of the SATCOM system equipment and the data bus inputs to the system. The test takes between 2 and 5 minutes to complete. To run the test, select CONTINUE.

WARNING: MAKE SURE PERSONS STAY A MINIMUM OF 10 FEET AWAY FROM THE SIDE-MOUNTED HIGH GAIN ANTENNAS DURING THE INSTALLATION TEST. MAKE SURE THE PASSENGER ENTRY DOORS NEAR THE ANTENNAS ARE CLOSED. RF ENERGY CAN CAUSE INJURIES TO PERSONS.

NOTE: All SATCOM communications stop during this test. If SATCOM communications are in progress, they are disconnected when you do this test.

VOICE RECORDER SYSTEM - INTRODUCTION

VOICE RECORDER SYSTEM - GENERAL DESCRIPTION

General

The cockpit voice recorder (CVR) receives audio from the audio management unit (AMU) and CVR microphone. The cockpit voice recorder panel connects the cockpit voice recorder microphone and the CVR.

Components

The voice recorder system has these components:

- Cockpit voice recorder microphone
- Cockpit voice recorder panel.

Functional Description

The voice recorder system records inputs from these two sources:

- Cockpit voice recorder microphone
- AMU.

The cockpit voice recorder microphone collects flight compartment sounds, such as voices and aural warnings. The audio goes through the cockpit voice recorder panel to the CVR.

The AMU sends these three channels of audio to the CVR:

- Captain
- First officer (F/O)
- First observer (F/OBS).

You monitor recorded audio with phone jacks at these locations:

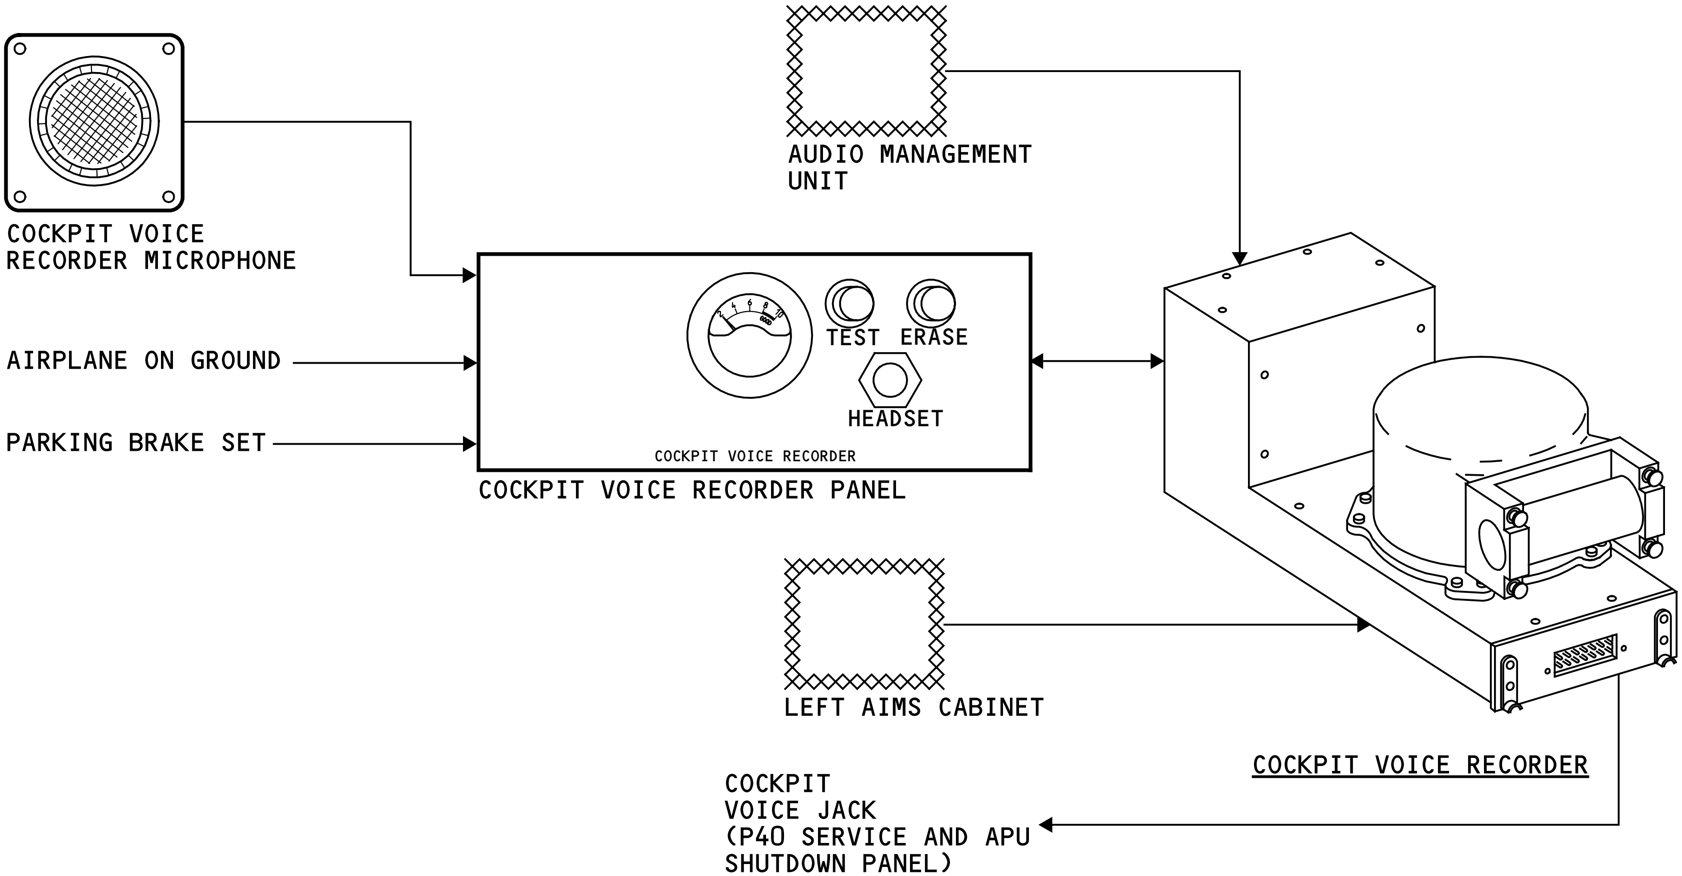
- Cockpit voice recorder panel
- P40 service and APU shutdown panel.

An erase switch on the cockpit voice recorder panel erases the recorded audio when the airplane is on the ground and the parking brake is set.

A test switch on the cockpit voice recorder panel starts a test of the voice recorder system. The cockpit voice recorder panel shows the results of the test.

An underwater locator beacon is on the front panel of the CVR. It operates underwater.

The CVR gets the universal coordinated time constant (UTC) from the left AIMS cabinet.

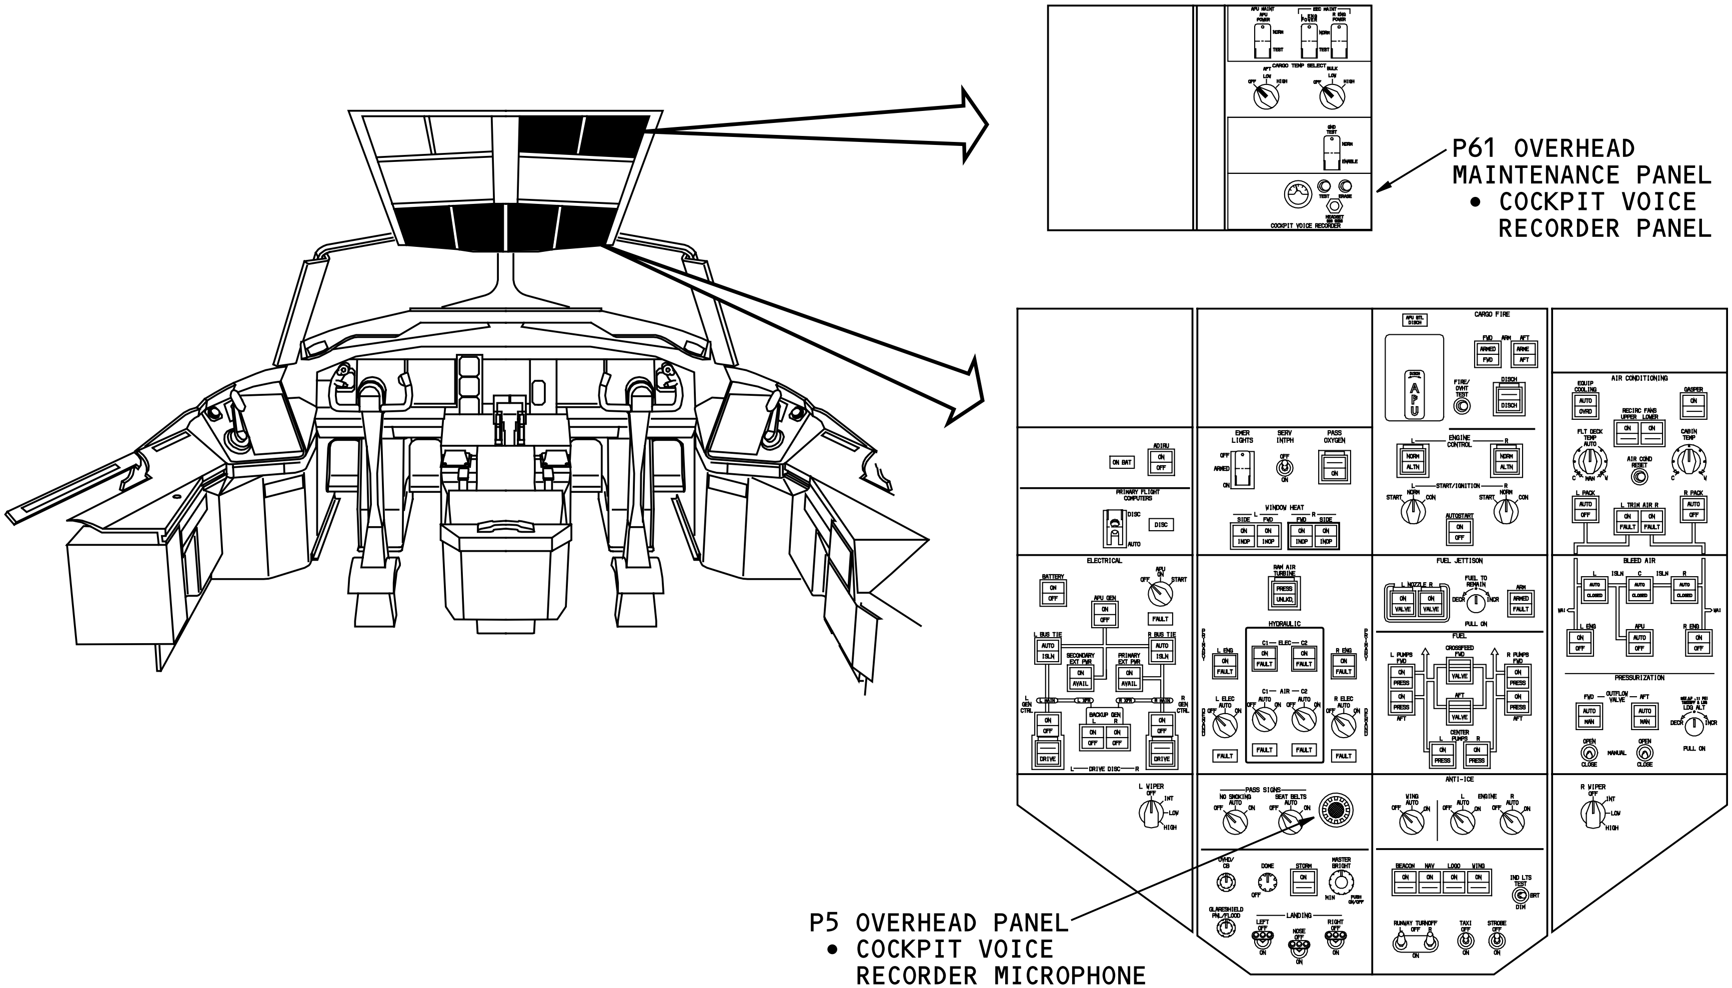


VOICE RECORDER SYSTEM - GENERAL DESCRIPTION

VOICE RECORDER SYSTEM - COMPONENT LOCATIONS 1

General

The cockpit voice recorder panel and cockpit voice recorder microphone are in the flight deck.

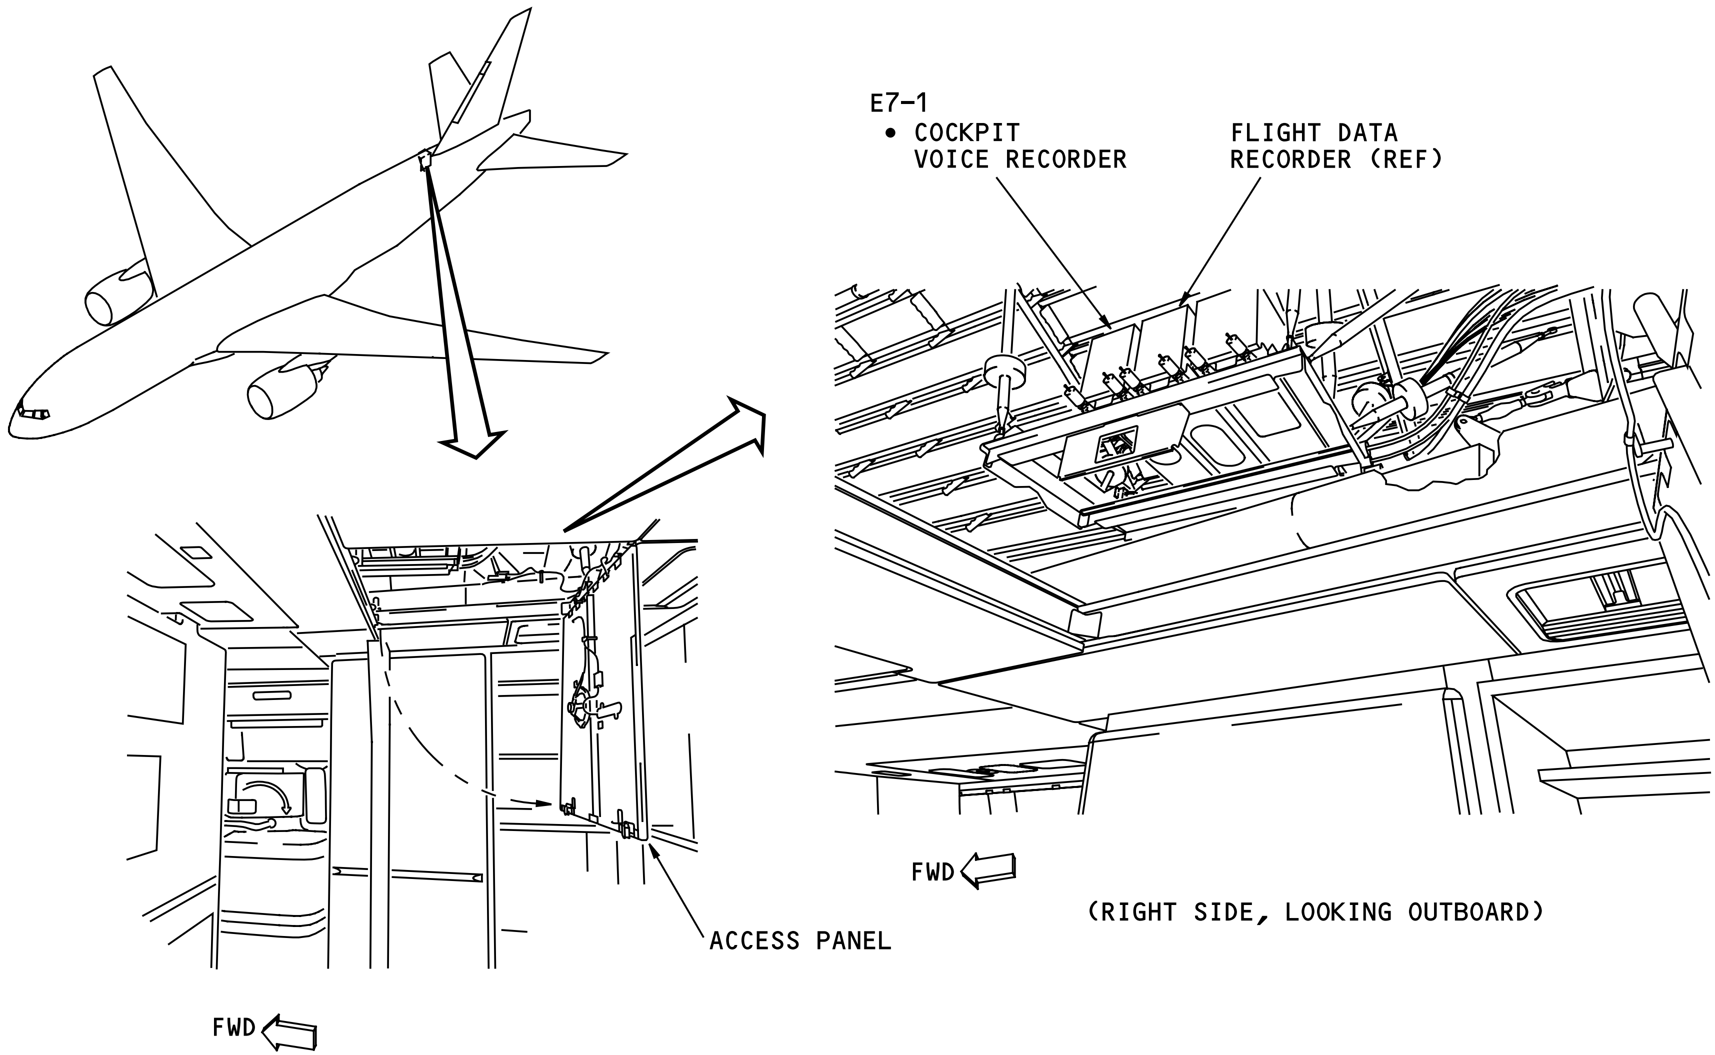


VOICE RECORDER SYSTEM - COMPONENT LOCATIONS 1

VOICE RECORDER SYSTEM - COMPONENT LOCATIONS 2

General

The cockpit voice recorder is overhead in the E7-1 rack in the aft cabin.



VOICE RECORDER SYSTEM - COMPONENT LOCATIONS 2

VOICE RECORDER SYSTEM - INTERFACE

Power

The cockpit voice recorder (CVR) gets 115v ac from the VOX RCDR circuit breaker. The CVR supplies 18v dc to the audio amplifier in the cockpit voice recorder panel.

Relays

The K32001 parking brake relay gets 30v dc from the CVR. When the parking brake is on, the relay closes. The relay sends 30v dc to the K32216 ground mode relay.

The K32216 ground mode relay gets 30v dc from the closed K32001 parking brake relay. When the airplane is on the ground, K32216 closes. The relay sends 30v dc to the cockpit voice recorder panel. This 30v dc goes to the erase switch.

Cockpit Voice Recorder Microphone

The cockpit voice recorder microphone sends area audio to the cockpit voice recorder panel.

Cockpit Voice Recorder Panel

The cockpit voice recorder panel sends these signals:

- Area audio to the channel 4 input of the CVR
- Test discrete to the CVR
- Erase discrete to the CVR.

Audio Management Unit

The audio management unit (AMU) sends these signals:

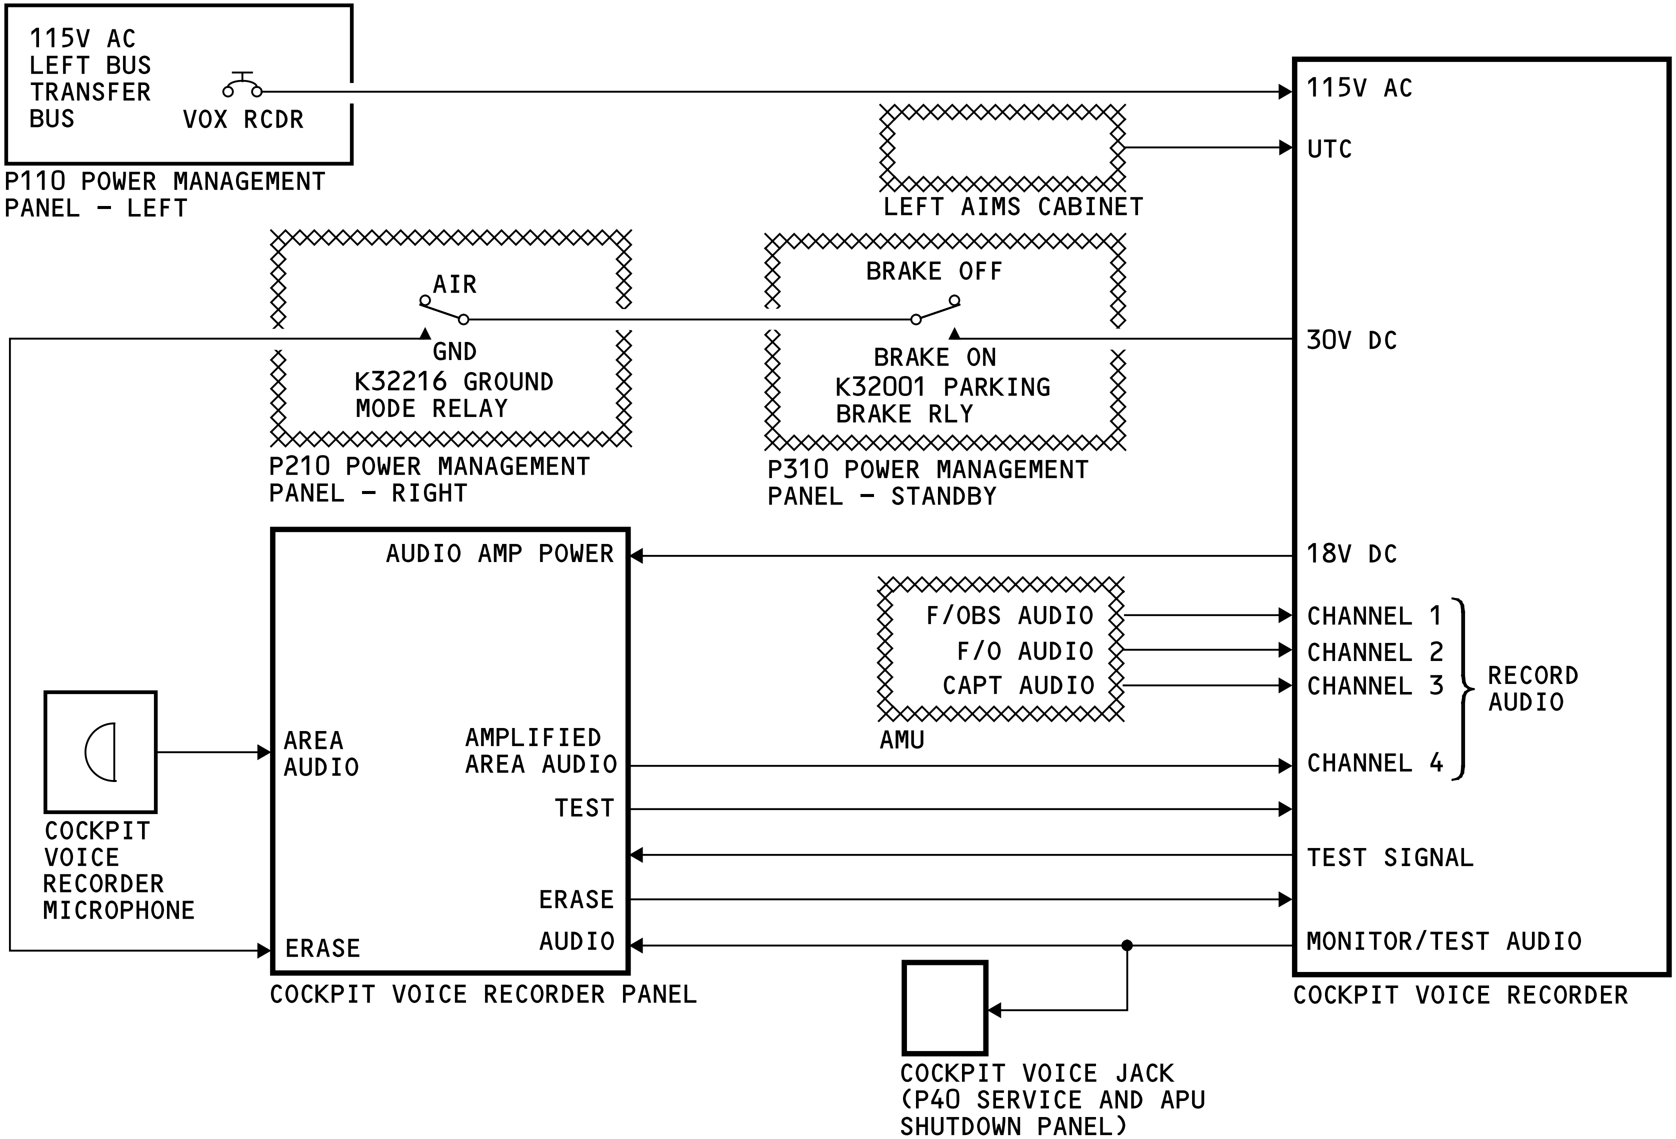
- First observer (F/OBS) audio to the channel 1 input of CVR
- First officer (F/O) audio to the channel 2 input of the CVR
- Captain (CAPT) audio to the channel 3 input of CVR.

Cockpit Voice Recorder

The CVR sends these signals:

- 30v dc to the parking brake relay
- Test results to the cockpit voice recorder panel
- Audio to the cockpit voice jack on the P40 service and APU shutdown panel
- Audio to the cockpit voice recorder panel.

The CVR gets these signals universal coordinated time (UTC) from the left AIMs cabinet



23-71-00-005 Rev 6 12/22/1997

VOICE RECORDER SYSTEM - INTERFACE

VOICE RECORDER SYSTEM - COCKPIT VOICE RECORDER

Purpose

When activated manually or automatically,the cockpit voice recorder (CVR) continuously records these flight deck sounds:

- Flight crew communications
- Conversations
- Aural warnings.

The recorder keeps the last 30 minutes of audio.

Physical Description

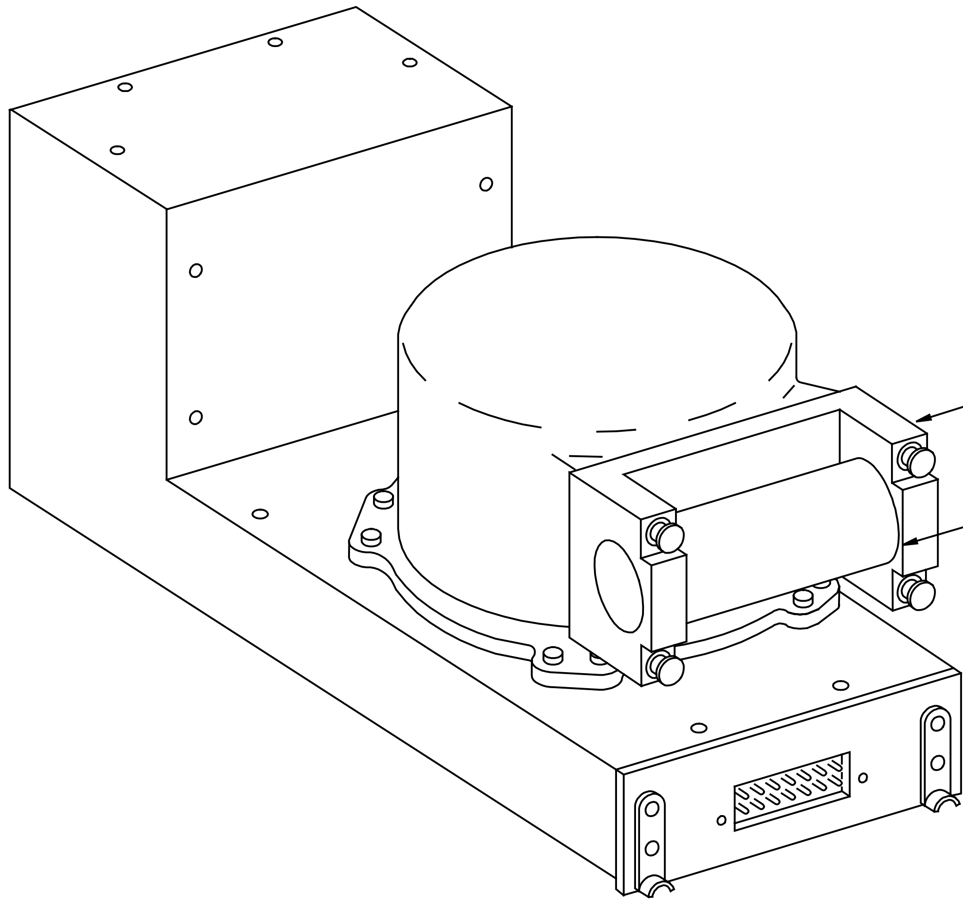
The CVR uses a solid-state memory as the record medium. The case of the CVR is watertight, shock resistant, and heat resistant.

The CVR has these physical characteristics:

- Height - 7.5 inches
- Width - 5.0 inches
- Depth - 12.5 inches
- Weight - 24 pounds maximum.
- Weight - 10.2 pounds maximum.

The CVR is bright orange with reflective stripes.

An underwater locator beacon (ULB) is on the CVR front panel. The ULB helps locate the CVR in water.



23-71-00-006 Rev 4 12/22/1997

VOICE RECORDER SYSTEM - COCKPIT VOICE RECORDER

VOICE RECORDER SYSTEM - COCKPIT VOICE RECORDER PANEL

Purpose

Use the cockpit voice recorder panel for these purposes:

- Monitor the recorded audio
- Erase the recorded audio
- Test the voice recorder system.

Controls and Indications

The cockpit voice recorder panel has these controls and indicators:

- Test meter
- TEST switch
- ERASE switch
- 600 Ohm headset jack.

The ERASE switch starts the erase operation. This erases the recorded audio if the airplane is on the ground with the parking brake set.

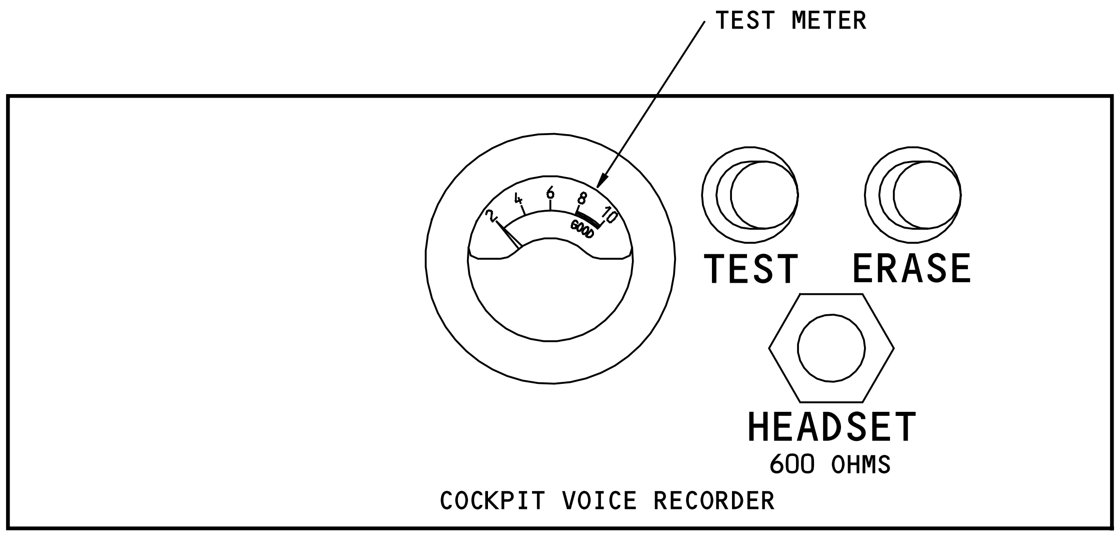
The headset jack permits you to monitor the mixed audio of the four channels during record operation.

Test

The operation test of the voice recorder system does a check of the audio circuits of the cockpit voice recorder (CVR).

To do the test, connect a headset to the headset jack on the cockpit voice recorder panel. Push and hold the TEST switch for a minimum of five seconds. These are the results of a good test:

- The needle on the test meter of the cockpit voice recorder panel goes to the green area and stays
- You hear a 620 Hz tone on the headset.



23-71-00-007 Rev 5 02/10/1997

VOICE RECORDER SYSTEM - COCKPIT VOICE RECORDER PANEL

VOICE RECORDER SYSTEM - COCKPIT VOICE RECORDER MICROPHONE

Purpose

The cockpit voice recorder microphone collects flight deck area audio for input to the CVR.

VOICE RECORDER SYSTEM - COCKPIT VOICE RECORDER MICROPHONE

VOICE RECORDER SYSTEM - FUNCTIONAL DESCRIPTION

General

The voice recorder system receives flight deck sounds and flight crew communications. It keeps this audio in a solid state memory. The voice recorder system has these modes of operation:

- Normal operation
- Erase
- Test.

Normal Operation

With power on the airplane and the cockpit voice recorder (CVR) circuit breaker closed, the CVR operates continuously.

Four audio channels go to the CVR. Channel 1, 2, and 3 audio is from the audio management unit (AMU). Each channel carries audio from one crew member's flight interphone audio. The audio on each channel is the sum of these signals:

- Hot mic audio (microphone audio when there is no PTT)
- Received audio as selected on the crew member's audio control panel (ACP)
- Sidetone audio to the crew member.

Channel 4 audio is from the cockpit voice recorder microphone. The cockpit voice recorder microphone sends flight deck area audio to the CVR. The CVR panel gets 18v dc for the preamplifier from the CVR. The preamplifier in the panel increases the strength of the channel 4 audio and sends it to the CVR.

30v dc bias signal is a record enable signal from the airplane interface through an external jumper back to the airplane interface.

All audio goes to the CVR airplane interface. The airplane interface has these functions:

- Monitors power in the CVR
- Changes the format of input and output signals
- Controls the audio record process.

When CVR power is not in tolerance, the airplane interface sends a low power discrete to turn off other CVR circuits.

The airplane interface changes the input audio signals in the A/D-D/A circuits for use by the audio processor.

The airplane interface sends a record discrete to the audio processor and store processor to start the record process.

The audio processor samples the flight deck audio signals 8,000 times per second and the cockpit voice recorder microphone audio signals 12,000 times per second. It changes the analog signals to digital signals. These signals go to the store processor on the digital audio bus.

VOICE RECORDER SYSTEM - FUNCTIONAL DESCRIPTION

The audio processor also mixes the four digital signals and sends them to the airplane interface. The airplane interface sends these signals to headphone jacks in these locations:

- Cockpit voice recorder panel
- P40 service and APU shutdown panel.

The store processor uses signals on the control bus to control the functions of the flash memory. The store processor sends address signals to the flash store on the address bus. The addresses tell the flash memory where to keep the digital data. The data goes to the flash memory on the data bus.

The flash memory keeps the digital data in a first-in, first-out solid state memory.

The CVR gets universal coordinated time (UTC) data from the left AIMs cabinet. UTC data is sent to both the CVR and the flight data recorder (FDR). CVR and FDR events are synchronized using UTC data.

Test

Push and hold the TEST switch on the cockpit voice recorder panel to start a CVR self test. Hold the switch for a minimum of five seconds. The cockpit voice recorder panel sends a ground discrete to the airplane interface circuits in the CVR. The airplane interface sends this test discrete to the audio processor and to the store processor.

In the audio processor, the test discrete enables a tone generator. The tone generator sends a 620 Hz. tone to A/D-D/A circuits. They change the tone to a digital signal. The audio processor connects the digital tone in sequence to each of the four audio inputs of the store processor.

In the store processor, the test discrete enables the flash memory to store the digital test tones for each channel. It also enables the store processor to playback the test tones from the flash memory. The store processor sends the digital playback signals back to the audio processor.

The audio processor changes the digital signals to analog signals. It mixes the four signals into one audio signal and sends it to these locations:

- Test meter
- Cockpit voice recorder panel headset jack
- P40 service and APU shutdown panel.

The test meter reads the strength of the audio signal and shows it on the meter dial on the cockpit voice recorder panel. The meter needle moves to the green area of the meter dial for a normal test. The needle stays in the green area while you hold the TEST switch.

The store processor monitors for faults. When it finds one, it sends a fault signal to the airplane interface. When it detects the fault signal, the airplane interface keeps the audio signal from the meter.

VOICE RECORDER SYSTEM - FUNCTIONAL DESCRIPTION

You monitor the 620 Hz test tone at any of the headset jacks.

Erase

When the airplane is on the ground with the parking brake on, you push and hold the ERASE switch on the cockpit voice recorder panel to erase the CVR.

The airplane interface in the CVR sends 30v dc to K32001 parking brake relay. When the parking brake is on, the relay closes.

The 30v dc goes through the K32001 relay to K32216 ground mode relay. When the airplane is on the ground, the relay closes. The 30v dc goes through the K32216 relay to the ERASE switch in the cockpit voice recorder panel.

When you push the ERASE switch, the 30v dc goes to the airplane interface in the CVR. The airplane interface sends this erase discrete to the audio processor and the store processor.

In the audio processor, the erase discrete disables the A/D-D/A circuits. The store processor sends the erase discrete to the flash memory. The flash memory erases all data in the memory.

Underwater Locator Beacon Functions

The underwater locator beacon (ULB) sends a sound signal when in water. It uses a battery for power. The battery sends power to the oscillator when the ULB is in water. The oscillator operates at 37.5 kHz. The transducer changes electrical signal to a sound signal and transmits the signal once per second.

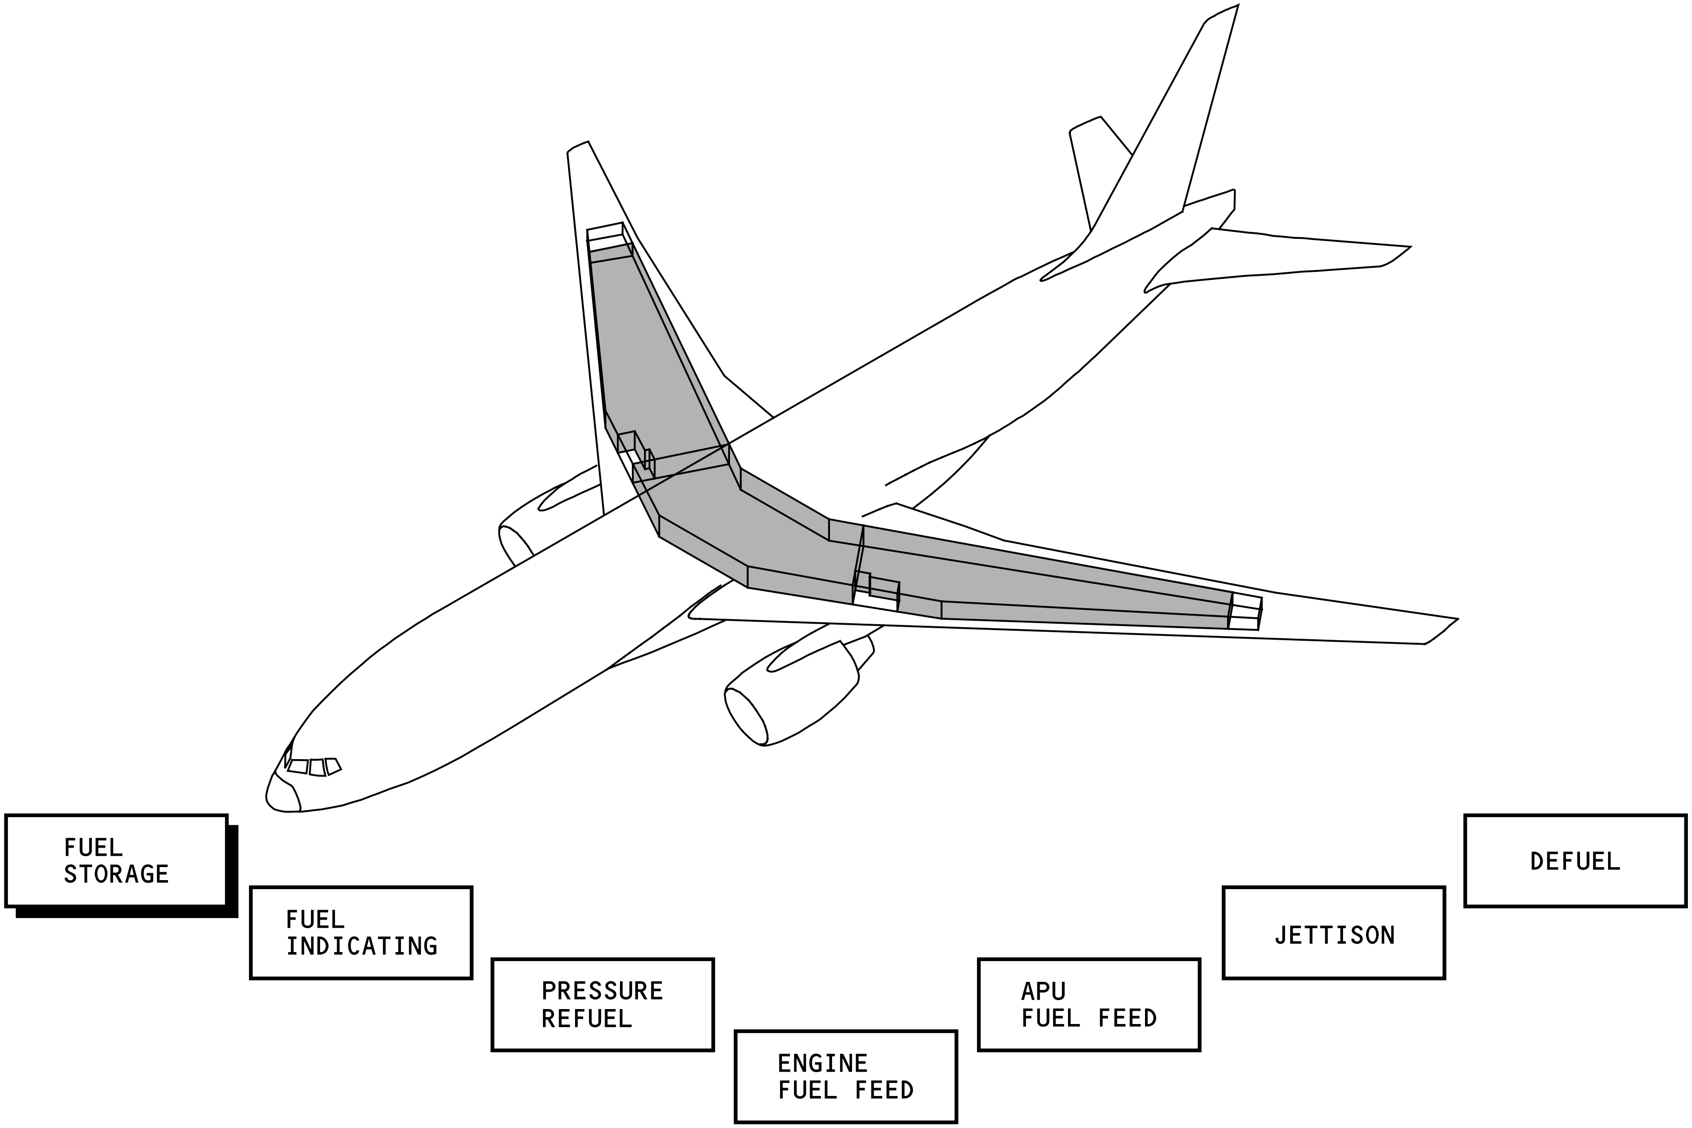
FUEL STORAGE - INTRODUCTION

General

The fuel storage system holds the fuel necessary for engine and APU operation.

The fuel storage system also does these functions:

- Gives maintenance access
- Prevents large pressure differences
- Helps drain the fuel tanks.



FUEL STORAGE - INTRODUCTION

FUEL STORAGE - GENERAL DESCRIPTION - TANK ARRANGEMENT

Fuel Tank Arrangement

These are the three fuel storage tanks:

- Left main tank
- Center tank
- Right main tank.

Surge tanks collect fuel overflow. The fuel overflow drains into the main tanks. Each main tank has a dry bay that does not hold fuel.

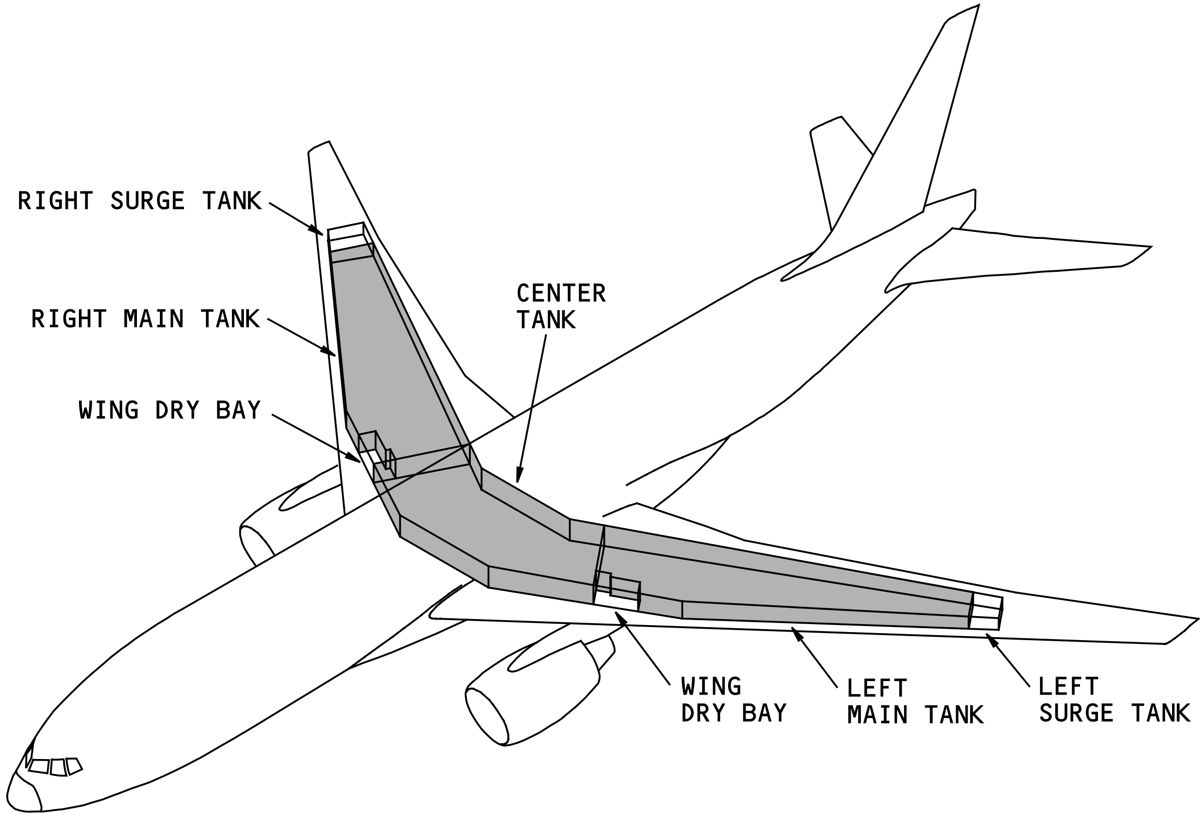
Component Locations

The left main tank is in the wing box of the left wing. The right main tank is in the wing box of the right wing. An adjacent surge tank is outboard of each main wing. An adjacent surge tank is outboard of each main tank. The wing dry bays are above each engine strut.

The center tank is in the center wing section and in the inboard wing box of the left and right wings.

Capacity

The capacity of each main tank is approximately 64,640 lb (29 320 kg) of fuel. The capacity of the center tank is approximately 176,440 lb (79 720 kg)



777 FUEL TANK CAPACITIES				
	GALS	LITERS	LB *	KG *
MAIN TANKS	9,560 EA	36 200 EA	64,626 EA	29 322 EA
CENTER TANK	26,100	98 800	176,436	80 028
TOTALS	45,220	171 200	305,687	138 672

* DENSITY = 6.76 LB/GAL (.81 KG/L)

FUEL STORAGE - GENERAL DESCRIPTION - TANK STRUCTURE AND ACCESS - 1

THIS PAGE INTENTIONALLY LEFT BLANK

FUEL STORAGE - GENERAL DESCRIPTION - TANK STRUCTURE AND ACCESS - 1

General

The fuel tanks are sealed parts of the wing structure. These are the parts of the fuel tanks:

- Upper wing skin
- Lower wing skin
- Front spar
- Rear spar
- Wing ribs.

Wing ribs divide the fuel tanks into bays, and reduce the movement of fuel during airplane maneuvers. Access doors and cutouts are entrances into the airplane fuel tanks for inspection or component repair.

Fuel Tank Locations

The center fuel tank is between rib 8 of the left wing and rib 8 of the right wing. Wing ribs divide each side of the center tank into seven fuel bays. The center wing section between the left and right side-of-body ribs (rib 1) is also a part of the center fuel tank. Three spanwise beams between the left and right side-of-body ribs divide the center wing section into four fuel bays. A purge door for the fuel bays in the center wing section is on the rear spar.

The main tanks are between rib 8 and rib 32 in each wing. Wing ribs divide each main tank into 24 fuel bays. The forward parts of the bays between rib 8 and rib 11 are dry. These wing dry bays prevent a fuel spill on the engine if an engine burst occurs.

The surge tanks are between rib 32 and rib 34 in each wing. A wing rib divides each surge tank into two fuel bays.

Wing Ribs

Standard wing ribs have upper and lower openings between the stringers that let fuel and air flow through them.

Tank-end ribs close the ends of each fuel tank. Tank-end ribs are sealed. No fuel can flow through them.

Rib 18 is a baffle rib. The rib is sealed, but has check valves between each lower stringer. The check valves let fuel flow inboard at a slow rate. One hole at the bottom of the rib lets fuel flow outboard. This keeps the fuel level on the two sides of the rib the same. Two large holes and six smaller holes at the top of the rib let air through it.

Rib 10 is a fuel dam rib. The lower section is the same as the baffle rib, but the upper section is the same as a standard rib. The fuel dams of rib 10 prevent fuel from flowing away from the fuel pump inlets.

Fuel Tank Access Doors

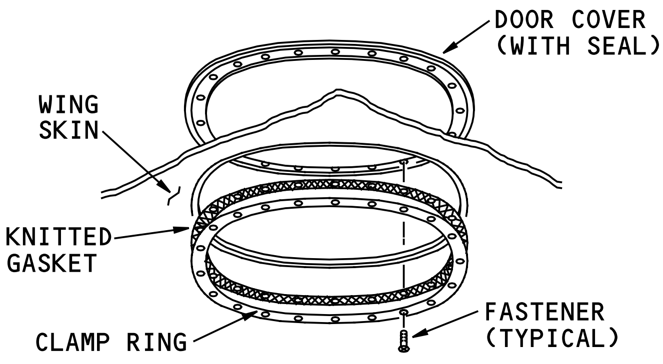
The access doors fit in fuel bays over openings in the airplane skin. A clamp ring and knitted aluminum gasket bolt to the access door from outside the airplane to hold the access door in its position. Thus, no bolt holes are in the skin. The gasket makes an electrical bond between the access door and the airplane skin. A rubber seal in the access door prevents fuel leaks around the access door.

Six of the access doors in each main fuel tank have fuel quantity measuring stick assemblies. The eleven inboard access doors of each wing have impact-resistant access doors.

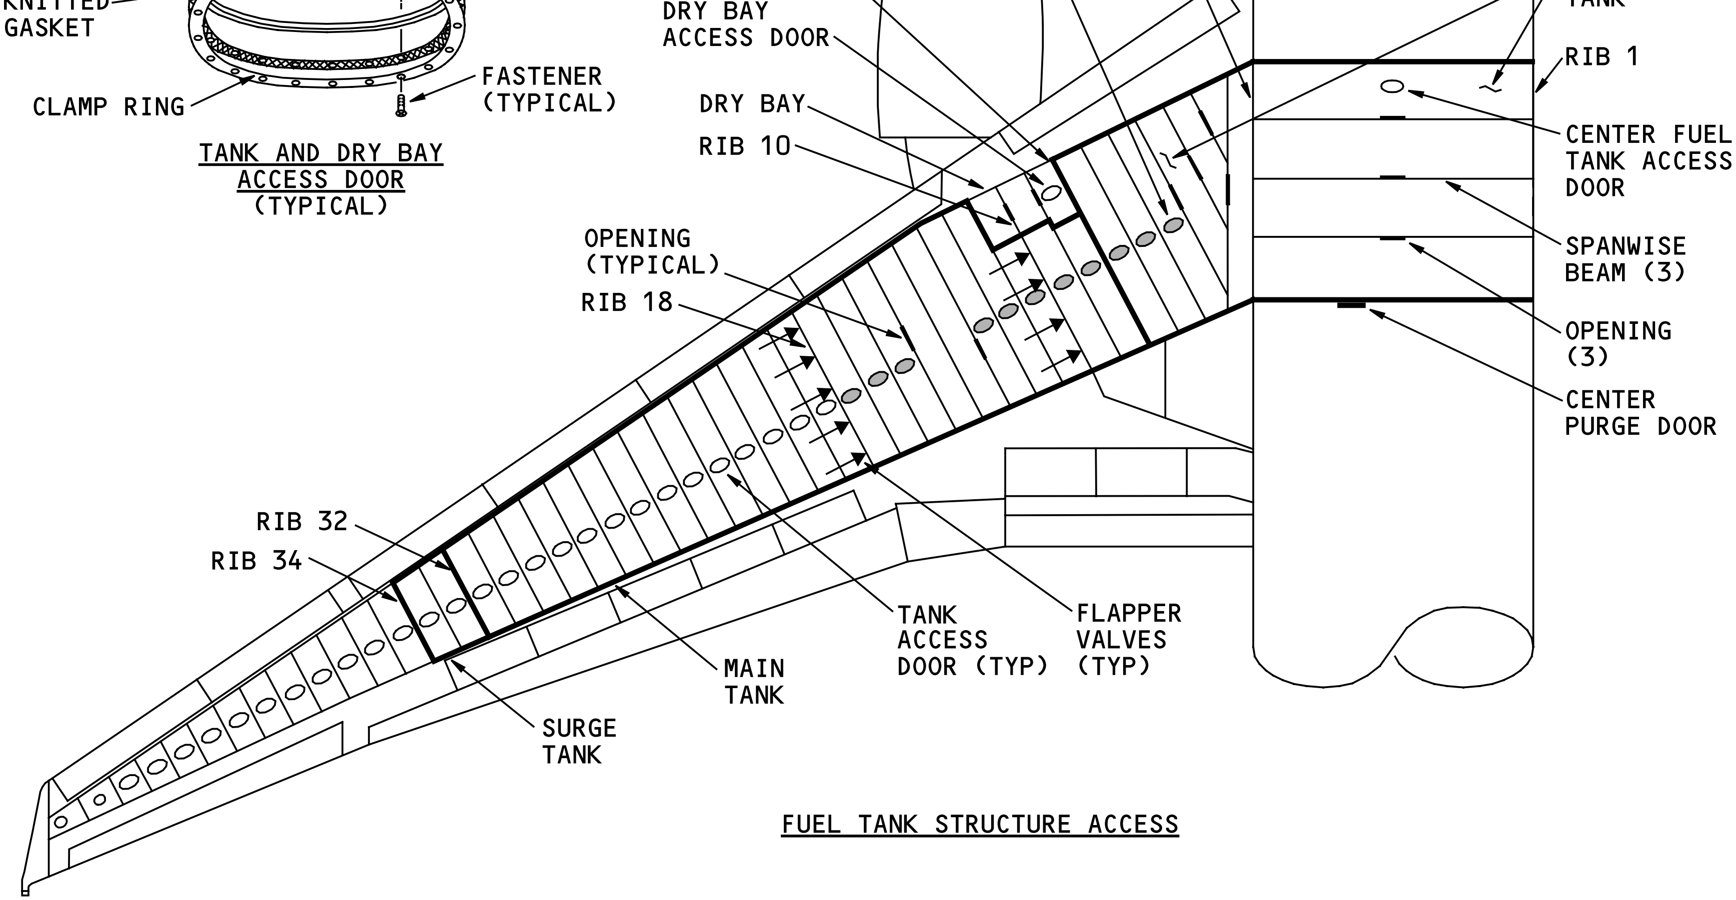
Rib and Spanwise Beam Cutouts

Some of the bays do not have an access door. You can get access to these bays from adjacent bays. Access openings in wing ribs and spanwise beams let you go in from an adjacent bay.

The purge door is in the left main wheel well. It supplies an opening for airflow when you purge the fuel bays in the center wing section.



TANK AND DRY BAY
ACCESS DOOR
(TYPICAL)



FUEL TANK STRUCTURE ACCESS

28-10-00-003 Rev 6 03/26/96

FUEL STORAGE - GENERAL DESCRIPTION - TANK STRUCTURE AND ACCESS - 1

FUEL STORAGE - GENERAL DESCRIPTION - TANK STRUCTURE AND ACCESS - 2

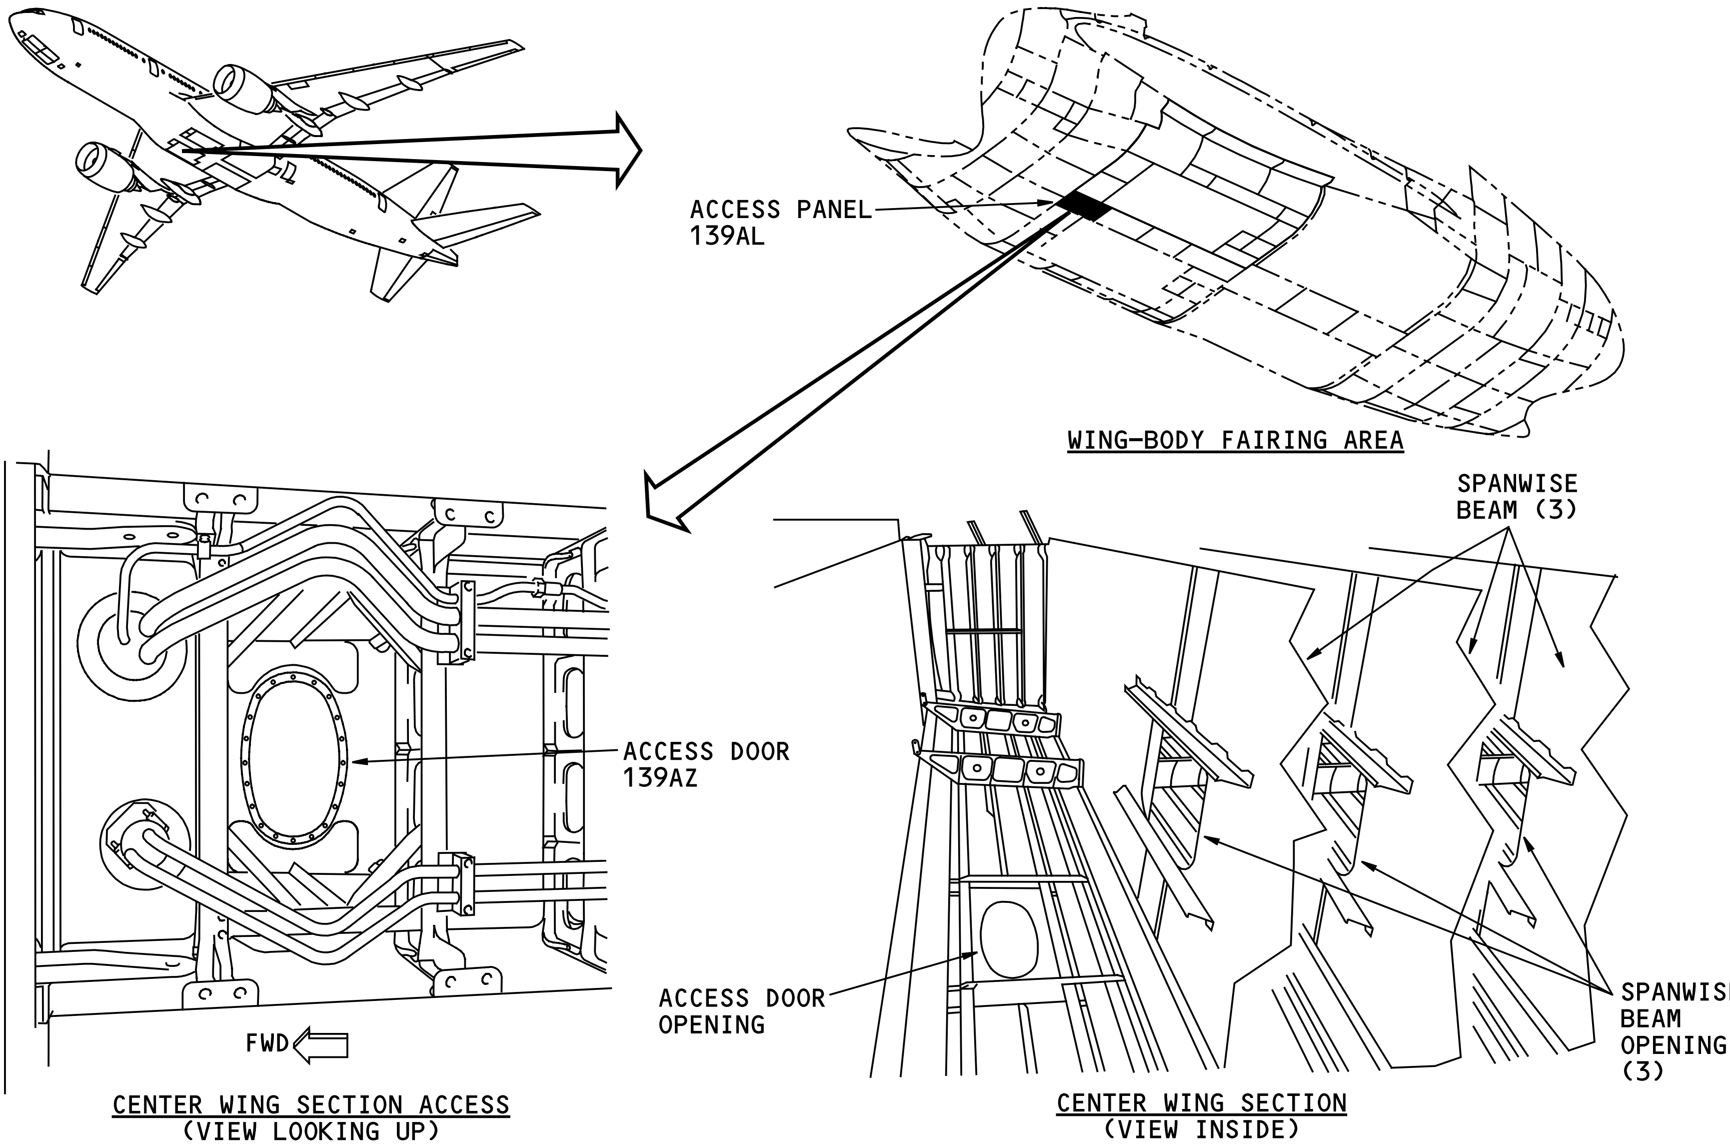
General

You remove access doors on the bottom of the tanks and dry bays to get access inside the tanks.

Center Wing Section Access

You get access into the center wing section fuel bays through a single access door. The access door (139AZ) is on the forward, center, lower skin of the center wing section. You must open panel 139AL on the wing-body fairing to get to access door 139AZ.

Spanwise beams in the center wing section have access openings. You get access to each bay through the spanwise beam openings.



FUEL STORAGE - GENERAL DESCRIPTION - TANK STRUCTURE AND ACCESS - 2

THIS PAGE INTENTIONALLY LEFT BLANK

FUEL STORAGE - SUMP DRAIN VALVES

General

Sump drain valves are at the low point of each fuel tank.

You use the sump drain valves to these functions:

- Get fuel samples
- Remove water and contaminants from the fuel tanks
- Drain all the fuel that remains after the defuel procedure
- Check for fuel in a surge tank before you open an access door.

Component Locations

The center tank has two sump drain valves. The valves are at the low points of the center wing section next to the side of body ribs. You get access to each valve through an access door in the wing-to-body fairing. A flexible hose connects the valve to a drain hole in the fairing.

Each main tank has one sump drain valve. The sump drain valve is in the lower wing skin near the fourth access door from the fuselage (between rib 8 and rib 9).

A sump drain valve for each surge tank is between rib 32 and rib 33 (26 access doors away from the fuselage).

Functional Description

Each sump drain valve in the main tank and the surge tank has a primary poppet and a secondary poppet (not shown). The secondary poppet lets you remove the primary poppet without defueling.

The sump drain valve in the center tank has a poppet valve in the valve body. A flapper valve lets you remove the valve body without defueling.

Operation

To drain fluid from the center tank, push up on the flexible hose connection on the sump drain valve. This opens the valve and lets the fuel sample drain through the hose. Use a container to collect the sample at the drain hole in the wing-to-body fairing. You must hold the valve in the open position.

To drain fluid from a main tank or to check for fuel in a surge tank, turn and push up on the primary poppet with a fuel sampling tool. You must hold the poppet in the open position.

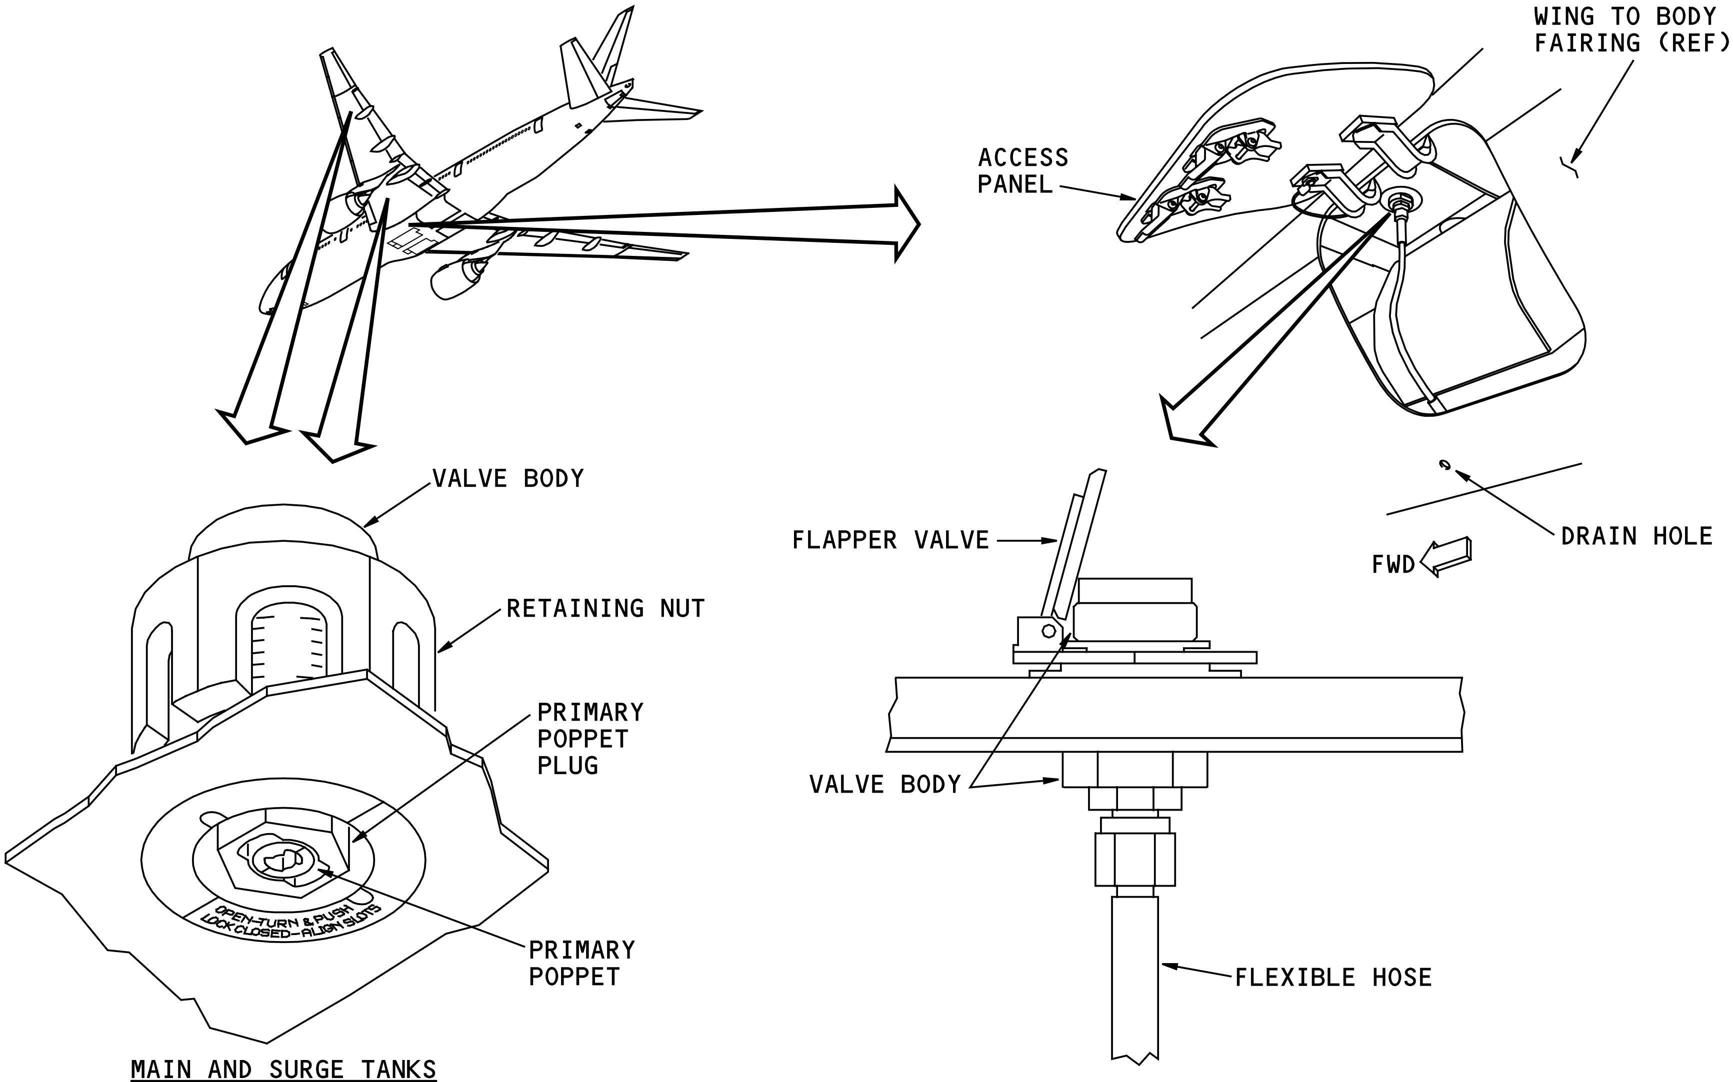
To drain the fuel that remains after you do the defuel procedure, you can remove the primary poppet plug and primary poppet. Then install the sump drain fitting/tool to hold the secondary poppet open. This lets all the fuel drain through the sump drain/fitting tool.

FUEL STORAGE - SUMP DRAIN VALVES

Training Information Point

You should get a fuel sample from the sump drain valves before and after you do the refuel procedure. A large quantity of water in a fuel sample that you drain from a tank before refueling is an indication of a blocked water scavenge jet pump.

Cold weather can freeze the water in the fuel tanks. This can prevent the drain valves from opening.



MAIN AND SURGE TANKS SUMP DRAIN VALVE (TYPICAL)

CENTER TANK SUMP DRAIN VALVE (TYPICAL)

FUEL STORAGE - SUMP DRAIN VALVES

THIS PAGE INTENTIONALLY LEFT BLANK

FUEL STORAGE - TANK VENT SYSTEM

General

The fuel vent system keeps the pressure of the fuel tanks near the pressure of the outside atmosphere. A large pressure difference can damage the wing structure.

Drains let fuel in the vent system return to the fuel tanks so the engines or APU can use it.

Flame arrestors make sure that a flame does not come inside the fuel tanks through the vent system. If a flame arrestor becomes blocked, pressure relief valves in the surge tank open to make a vent.

Component Locations

Hat-section upper stringers and the upper wing skin make vent channels. A vent tube that has a drain valve at the low point attaches to each vent channel.

Each main tank has a forward and an aft vent channel. A fuel vent float valve attaches to the outboard end of each forward vent channel.

The center tank has three vent channels. Two float actuated drain valves attach to the low points on each vent channel.

There is a vent scoop access door in each surge tank. Each vent scoop contains a flame arrestor.

There is a pressure relief valve in the inboard access door of each surge tank.

A check valve in the inboard rib of each surge tank lets any fuel in the surge tank drain back into the main tank.

Functional Description

Vent channels and vent tubes keep the pressure of all the fuel tanks near the pressure in the surge tanks. The surge tanks are open to outside air through the vent scoops. The shape of the vent scoops keep positive pressure inside the surge tanks during flight.

Vent tube drain valves let fuel in the vent tubes drain back into the tank when the fuel level is below the level of the valve.

Fuel in the center tank vent channels drains through the float-actuated drain valves when the drain valves are not covered by fuel. Float-actuated drain valves close when the fuel level is above them. Thus, fuel does not get into the vent channels through the drain valves.

When the fuel level is higher than the outboard end of the main tank vent channels, the fuel vent float valves close to keep fuel out of the vent channels. When the fuel level is below these valves, the floats open them.

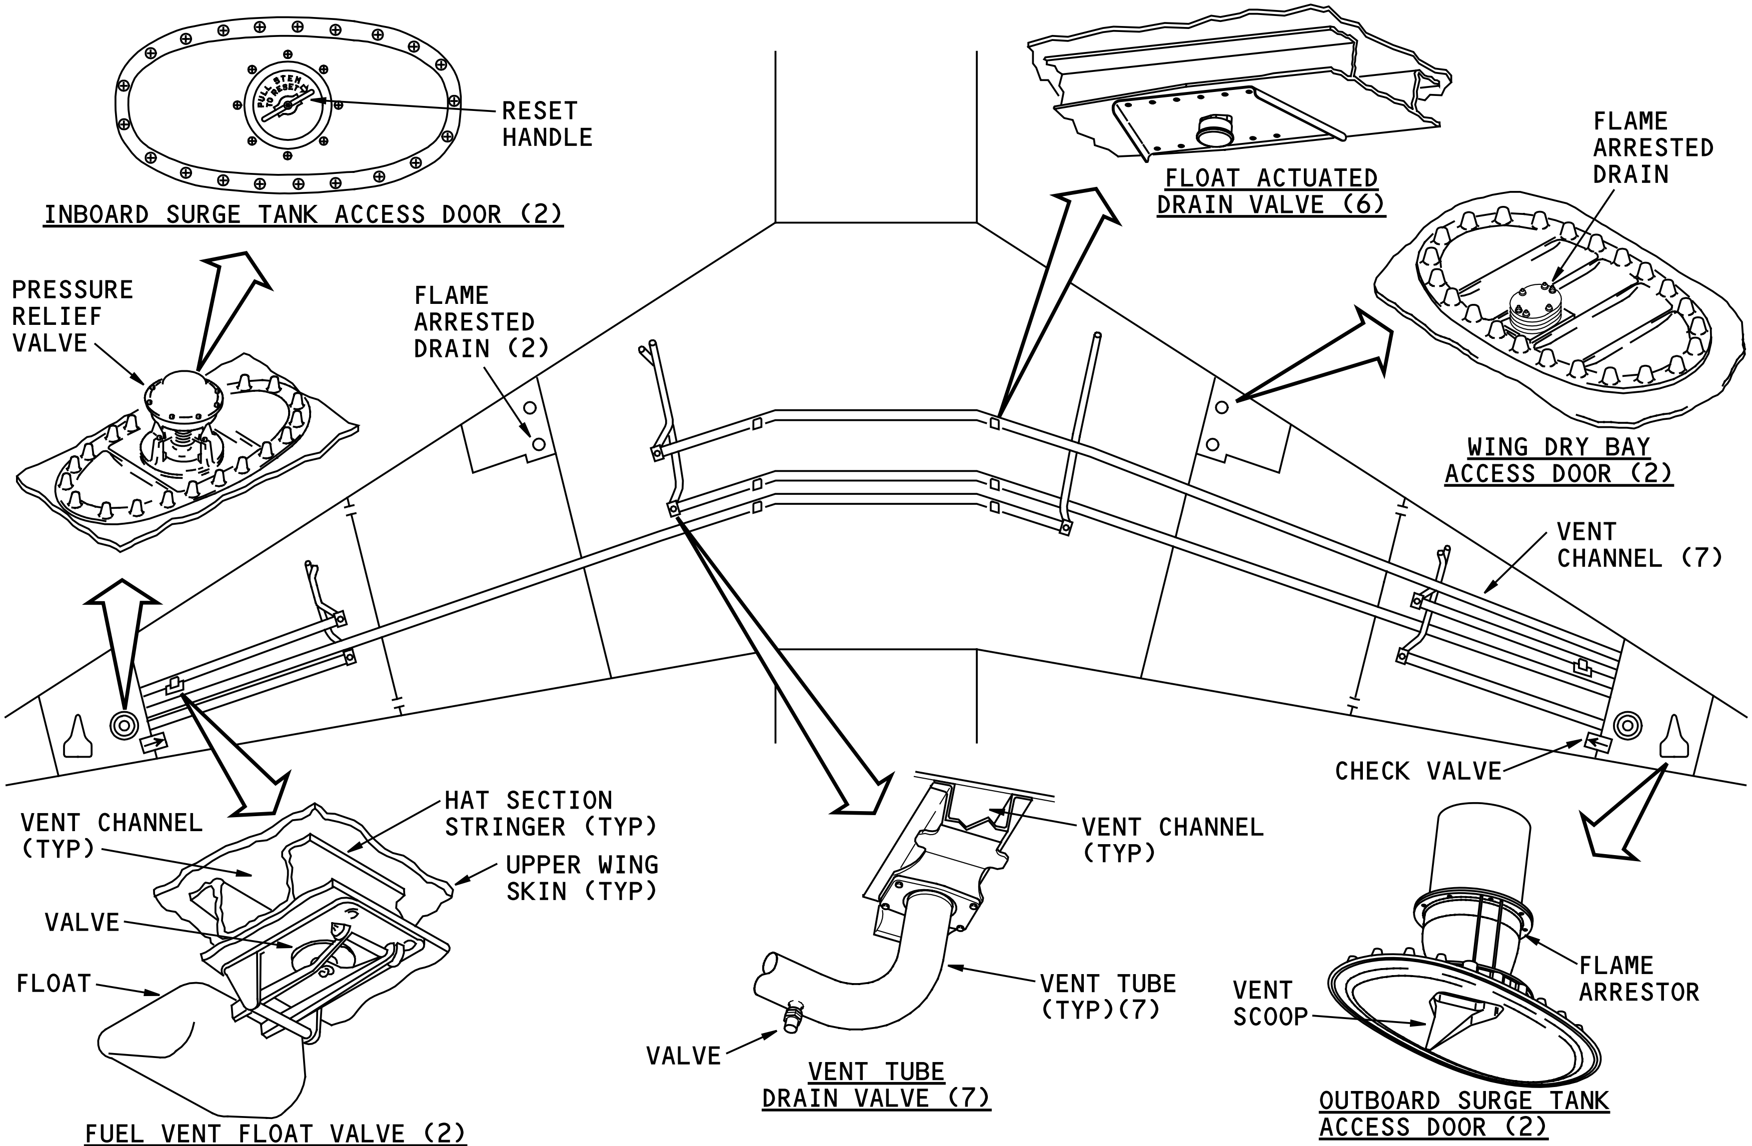
The pressure relief valve is normally closed. When it is closed, the valve is in line with the bottom of the

FUEL STORAGE - TANK VENT SYSTEM

wing. If a pressure difference opens the valve, it moves up as it opens. A spring holds the valve open until you close it. Pull the reset handle to move the valve back to the closed position.

Training Information Point

When you do an inspection, you must look at the pressure relief valves. Make sure they are closed. An open pressure relief valve is a symptom of a blocked vent scoop or flame arrestor. The pressure relief valve can also open to relieve air or fuel pressure if there is too much pressure during refueling.



FUEL STORAGE - TANK VENT SYSTEM

FUEL STORAGE - TANK ENTRY - TRAINING INFORMATION POINTS

Fuel Tank Entry

The fumes from fuel in a fuel tank are explosive and poisonous.

Before you go into a fuel tank, you must defuel the fuel tank and decrease the fuel fumes to a safe level. You do the purging and fuel tank entry procedure to remove fuel fumes.

A spark in the fuel tank can cause an explosion. When you are in a fuel tank you must do these things to prevent sparks:

- Put on approved clothing
- Obey the fuel fume concentration limits
- Have good air flow through the tank
- Obey instructions for use of tools.

Clothing

You must put on approved clothing, and rubber gloves. Nylon, rayon, silk, or wool clothing can cause sparks and are not approved.

Fuel Fume Concentration

The air in the fuel tank must be fire-safe or, health-safe. The limits for the fire-safe condition and the health-safe condition are in the purging and fuel tank entry procedure.

A fuel tank in the fire-safe condition is safe to work in if you use respirator equipment. A fuel tank in the health-safe condition is safe to work in without respirator equipment.

You use a combustible gas indicator to measure the fuel fume concentration in a fuel tank.

Air Flow

The fuel tank must have a good flow of air to keep it fire-safe or health-safe.

Install an air mover in an access door at one end of the tank. Remove an access door at the opposite end of the tank, so the air mover can pull a good flow of air through the fuel tank.

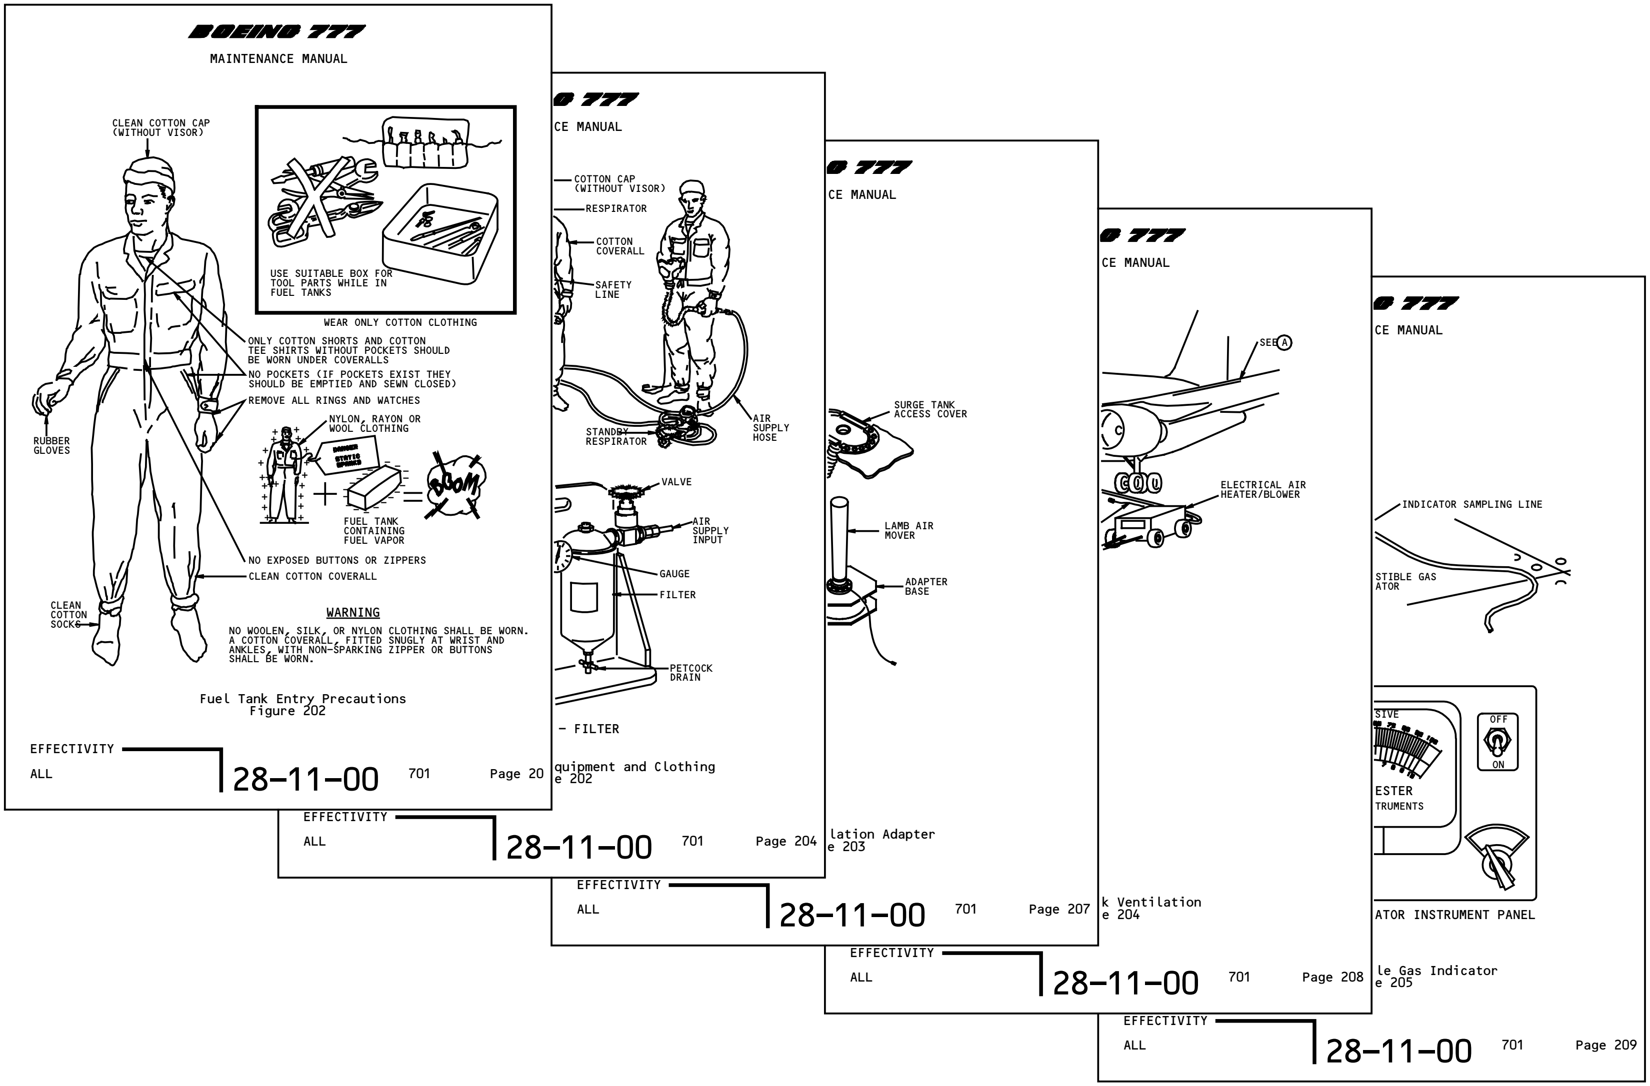
In the main tanks, make sure that the air mover pulls the air inboard. This lets a good flow of air go through the baffle rib.

Tools

Keep tools in non-static containers that have rounded corners while you do not use them.

Use only explosion-proof electrical equipment.

Make sure to remove all the equipment you bring into the fuel tank.



28-10-00-007 Rev 1

FUEL STORAGE - TANK ENTRY - TRAINING INFORMATION POINTS

FUEL INDICATING - INTRODUCTION

General

The fuel indicating system has these subsystems:

- Fuel quantity indicating system
- Fuel measuring sticks
- Fuel temperature indicating
- Fuel pressure indicating.

Fuel Quantity Indicating System (FQIS)

The FQIS measures fuel quantity in the tanks. The primary display system (PDS) and the IRP indicators show fuel quantity.

Fuel Measuring Sticks

The fuel measuring sticks permit you to manually measure fuel quantity in each tank.

Fuel Temperature Indicating System

The fuel temperature indicating system measures the fuel temperature in the left main tank. The PDS shows the temperature.

Fuel Pressure Indicating System

The fuel pressure indicating system shows low pressure at the fuel pump outlets. See the engine fuel feed section for more information about fuel pressure indicating (AMM PART I 28-22).

DEFUEL

FUEL INDICATING - INTRODUCTION

FUEL INDICATING - FQIS - GENERAL DESCRIPTION

General

The fuel quantity indicating system (FQIS) does these functions:

- Measures the fuel volume
- Calculates the fuel quantity
- Controls refuel operations
- Shows when there is water in the tanks.

These are the FQIS components:

- Tank units
- Densitometers
- Water detectors
- Fuel temperature sensor
- Wiring harnesses
- Fuel quantity processor unit (FQPU).

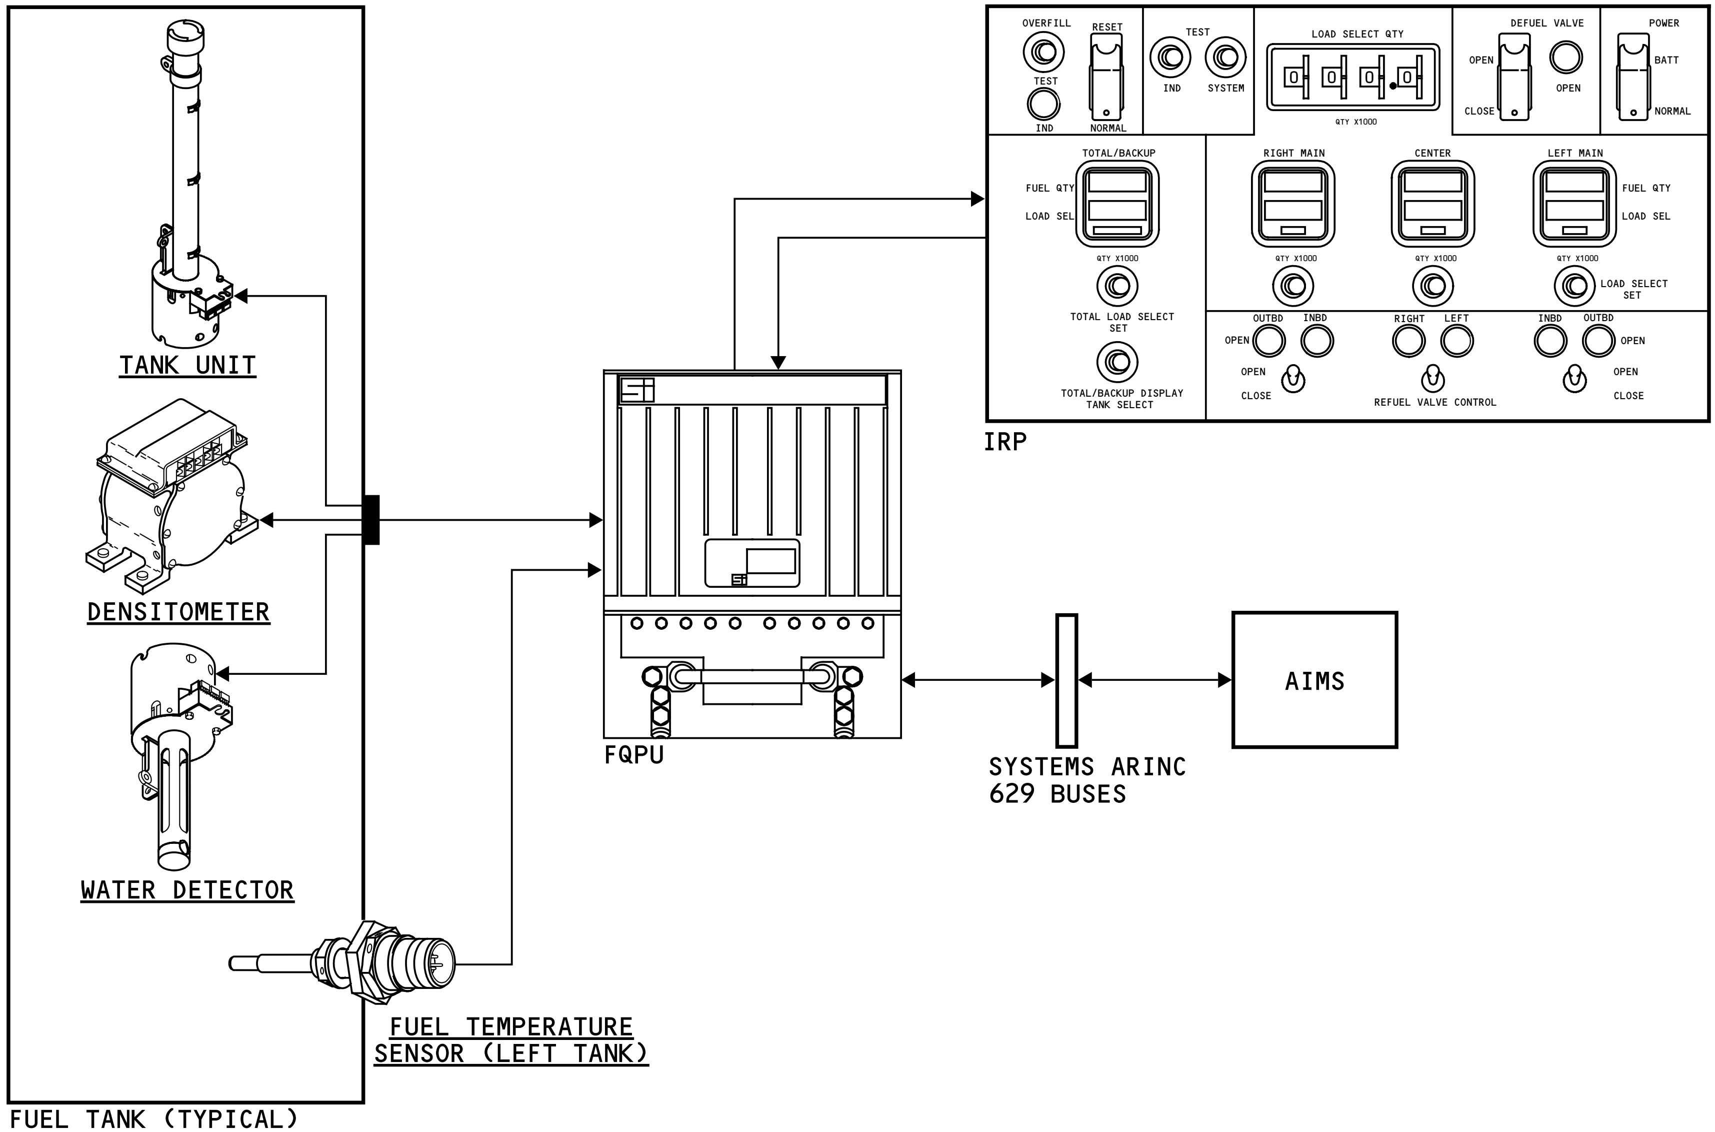
Operation

The FQPU sends signals to and gets signals from the fuel tank sensors. The FQPU uses the signals to calculate these data:

- Fuel height
- Fuel quantity in each tank
- Total fuel quantity.

The FQPU shows fuel quantity data on the EICAS display and on the integrated refuel panel (IRP) indicators.

Fuel weights go to the IRP on ARINC 429. Fuel weights, and FQIS data and fault information go to the AIMS on the systems ARINC 629 buses.



FUEL INDICATING - FQIS - GENERAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

FUEL INDICATING - FQIS - FUEL TANK SENSORS

General

These are the sensors in the fuel tanks:

- Tank units
- Densitometers
- Water detectors
- Temperature sensor.

Tank Units

The tank units measure fuel height. There are 60 tank units in the three tanks: 20 in each main tank and 20 in the center tank.

Each tank unit position has a number. In the main tanks, tank unit 1 is at the inboard end of the tank. Tank unit 20 is at the outboard end of the tank. In the center tank, the left and right side tank unit numbers are from 1 to 10. The left tank unit 1 is at the left outboard end of the center tank. The right tank unit 1 is at the right outboard end of the center tank.

Each tank unit has an ultrasonic transmitter/receiver and a stillwell. Ten of the tank units also have calibration targets.

The fuel quantity processor unit (FQPU) sends a signal to the ultrasonic transmitter/receiver. This causes a sonic pulse to go through the fuel in the stillwell to the fuel surface, and back to the receiver. The FQPU measures the travel time of the pulse and uses it to find the fuel height.

The sonic pulse also reflects from the targets back to the receiver. The FQPU uses these pulses to measure the velocity of sound (VOS)in the fuel.

Densitometers

Each fuel tank has one densitometer. Densitometers use a vibrating cylinder transducer to measure the fuel density in each tank. The frequency of the vibrations is proportional to the fuel density. The densitometers are energized and monitored by the FQPU.

Water Detectors

Water detectors are at the low point in each fuel tank in the tank sump area. The FQPU uses water detector signals to see if there is water in the tank sump area. Each fuel tank has one water detector. The fuel quantity maintenance page shows a message when there is water in the fuel tank.

The water detectors are ultrasonic devices like the tank units. The FQPU sends a signal to the water detectors. The water detectors send a pulse to the bottom of the tank. If there is water in the bottom of the tank, the pulse reflects off the interface between the water and fuel.

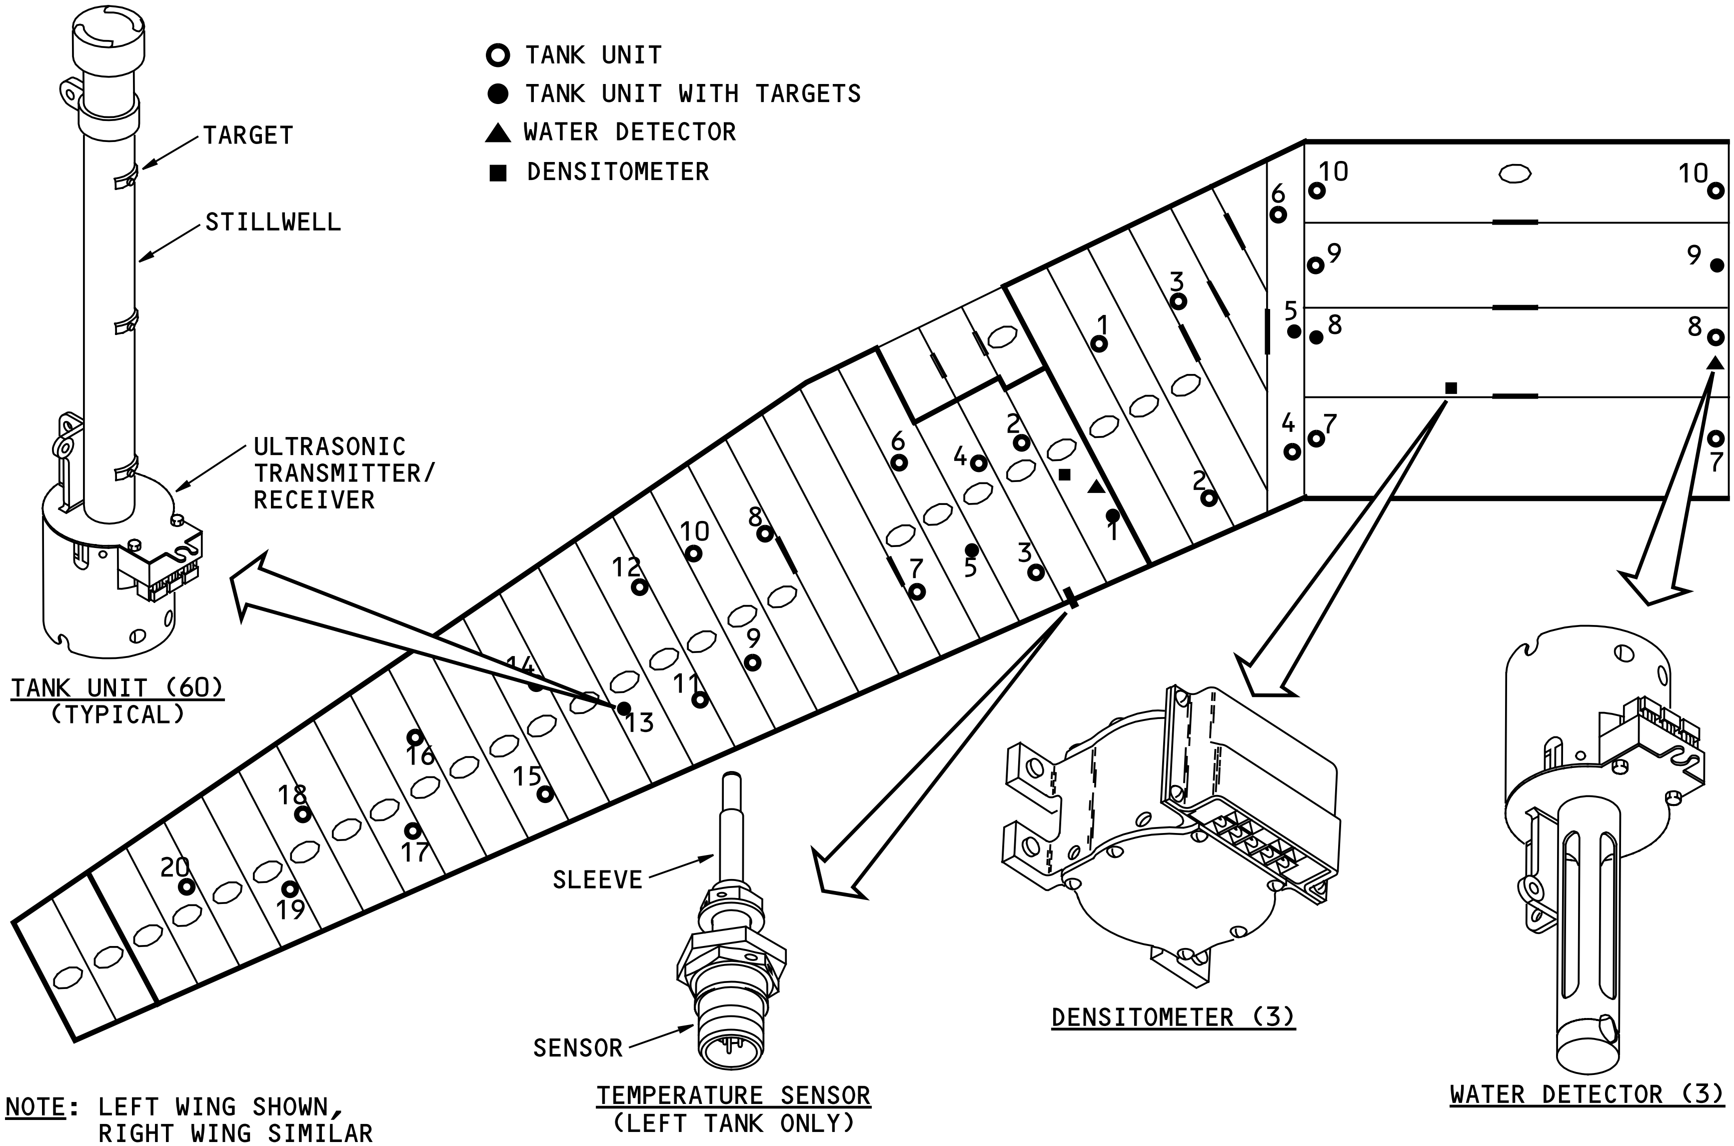
Temperature Sensor

There is only one fuel temperature sensor. It measures the fuel temperature in the left main tank. The

FUEL INDICATING - FQIS - FUEL TANK SENSORS

temperature sensor is a resistance-type sensor that fits inside a sleeve.

The sleeve is on the rear spar of the left wing, aft of the fifth fuel tank access door (between ribs 9 and 10).



FUEL INDICATING - FQIS - FUEL TANK SENSORS

FUEL INDICATING - FQIS - WIRING HARNESS

General

Tank wiring includes internal harnesses, external harnesses, and connectors. Internal harnesses connect the fuel tank sensors to connectors on the spars. External harnesses go from the spar connectors to the FQPU.

Internal Harness

Each main tank has two internal harnesses. The inboard harness connects eight tank units, one densitometer, and one water detector to one connector on the rear spar. The inboard harness connector is aft of the fifth fuel tank access door (between ribs 9 and 10). The outboard harness (not shown) connects twelve tank units to another connector on the rear spar. The outboard harness connector is aft of the sixth fuel tank access door (between ribs 10 and 11).

The center tank has two internal harnesses. The left center tank harness connects ten tank units and the densitometer to a connector on the left front spar. The right center tank harness connects ten tank units and the water detector to a connector on the right front spar. The connectors are between ribs 2 and 3.

The internal wire harnesses connect to fuel tank sensors with Faston connectors. The Faston connectors have a terminal and insulator on the wire, and a tab on the sensor. The insulator is around the terminal.

External Harness

There are two external harnesses for each tank. The main tank external harnesses go from the connectors on the rear spar to the FQPU.

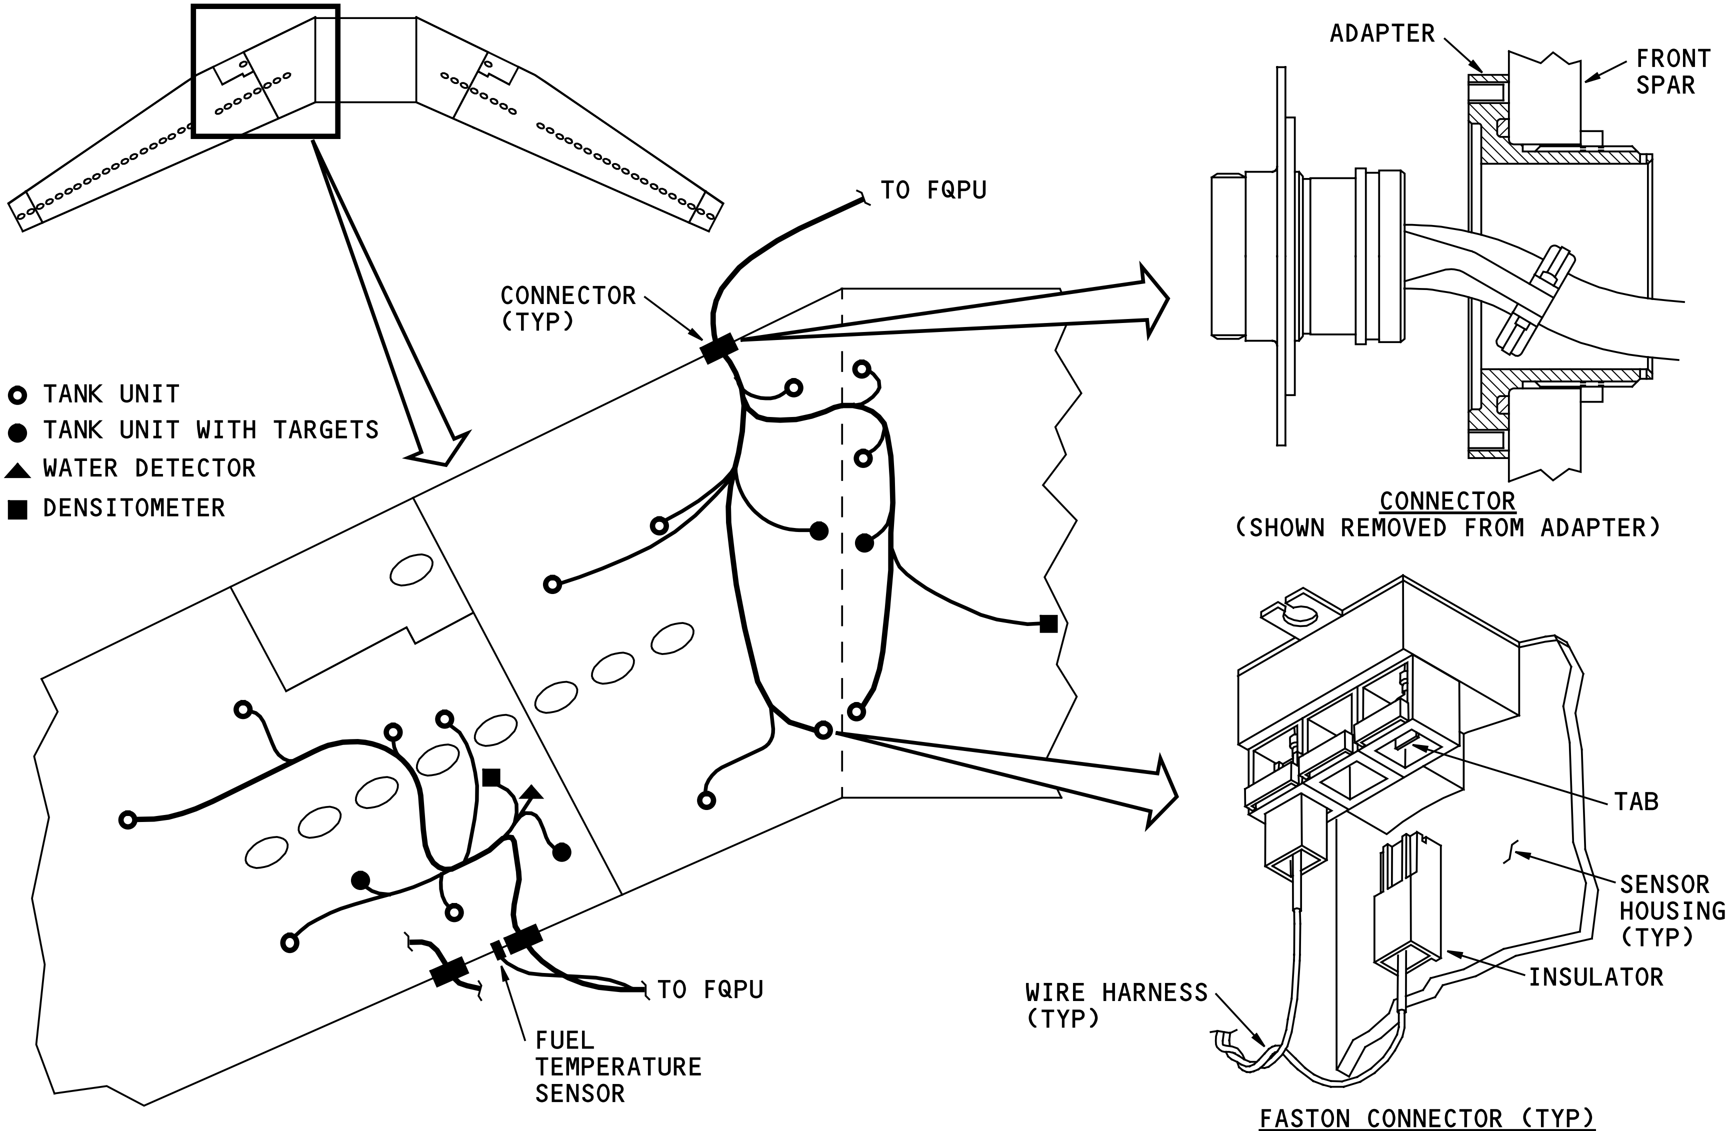
The center tank harnesses go from the connectors on the front spar to the FQPU.

Each connector attaches to the spar with an adapter. You can remove and repair the connectors without entering the tank.

Training Information Point

Each fuel tank sensor has a separate twisted wire pair. Thus, a single wire failure does not affect the whole tank. You cannot make splices in the wire harnesses.

You pull the insulator to disconnect the Faston connector. You push the insulator onto the tab to install the Faston connector. The shape of the insulator does not let you put a wire on the wrong tab.



FUEL INDICATING - FQIS - WIRING HARNESS

FUEL INDICATING - FQIS - COMPONENT LOCATIONS - WINGS

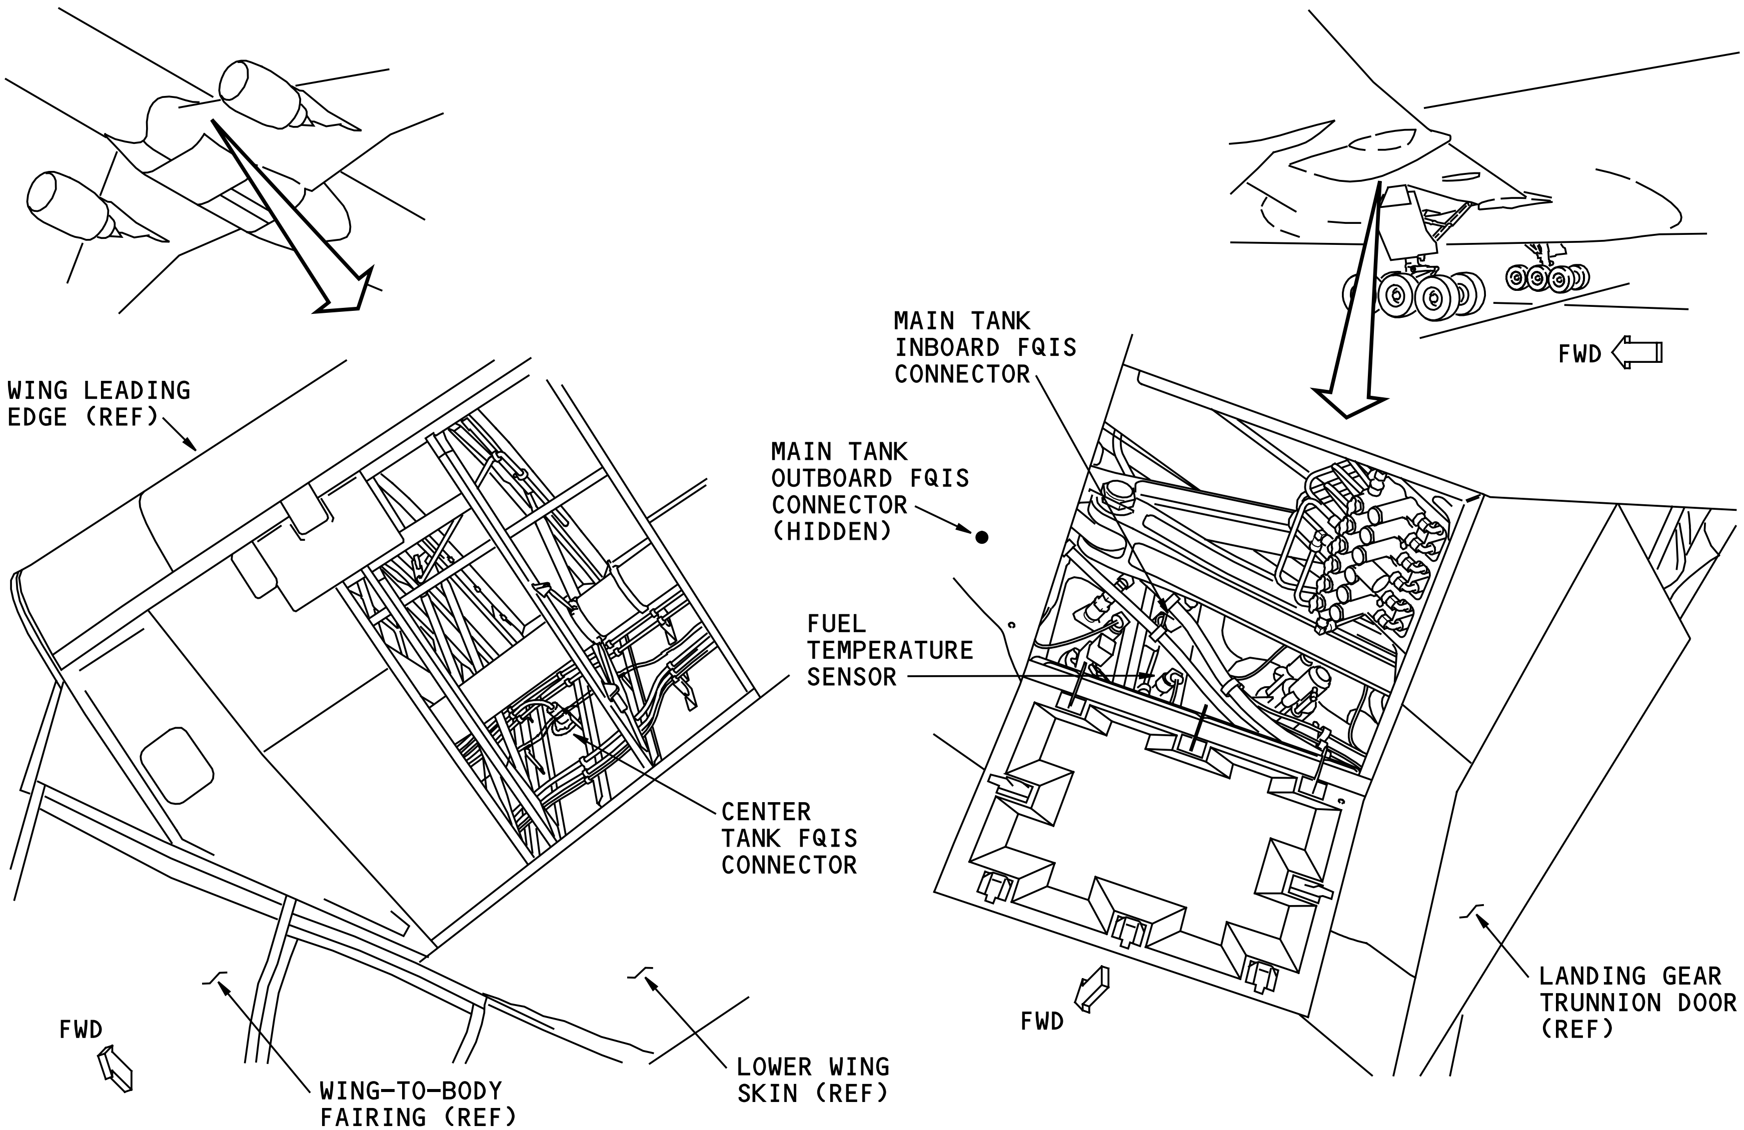
FQIS Connectors

Each half of the center tank has one FQIS connector. It is on the front wing spar near the wing-to-body fairing.

Each main tank has two FQIS connectors. They are on the rear wing spar, outboard of the main landing gear shock strut, near the landing gear trunnion door.

Fuel Temperature Sensor

There is one fuel temperature sensor in the left main tank. It attaches to the rear spar of the left wing, below the main tank inboard FQIS connector.



28-40-00-011 Rev 1

FUEL INDICATING - FQIS - COMPONENT LOCATIONS - WINGS

FUEL INDICATING - FQIS - FUEL QUANTITY PROCESSOR UNIT

Purpose

The fuel quantity processor unit (FQPU) does these functions:

- Calculates the fuel weight for each tank
- Calculates the total fuel weight
- Shows the weights on the IRP indicators
- Sends the weights to the AIMS
- Causes the refuel valves to close
- Monitors the FQIS for faults
- Sends fault data to the CMCS.

Location

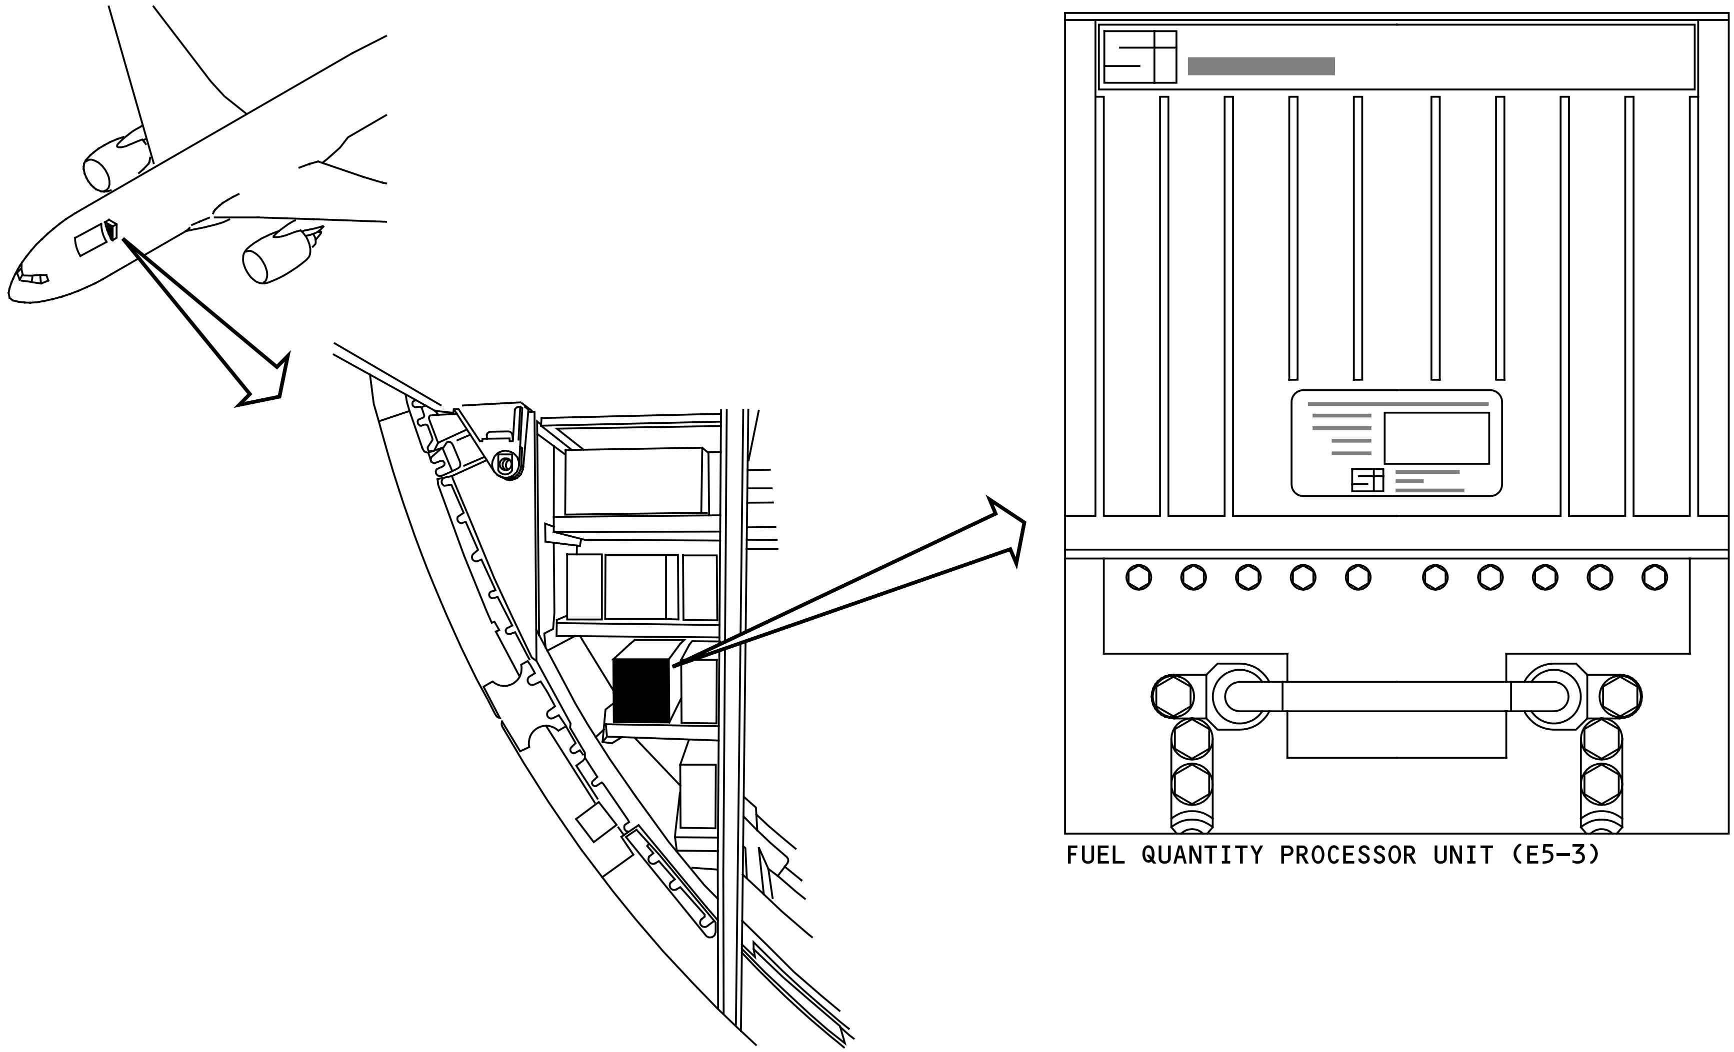
The FQPU is on the E5-3 shelf.

Physical Description

The FQPU is in a 5 MCU ARINC 600 container. The container has twelve printed circuit boards. The FQPU connects to airplane wiring.

Training Information Point

The FQPU has software that is data-loadable.



28-40-00-005 Rev 2

FUEL INDICATING - FQIS - FUEL QUANTITY PROCESSOR UNIT

FUEL INDICATING - FQIS - POWER

General

The FQPU connects to two isolated 28v dc power sources at one time. The FQPU operates when one or both of the sources have power.

Power Sources

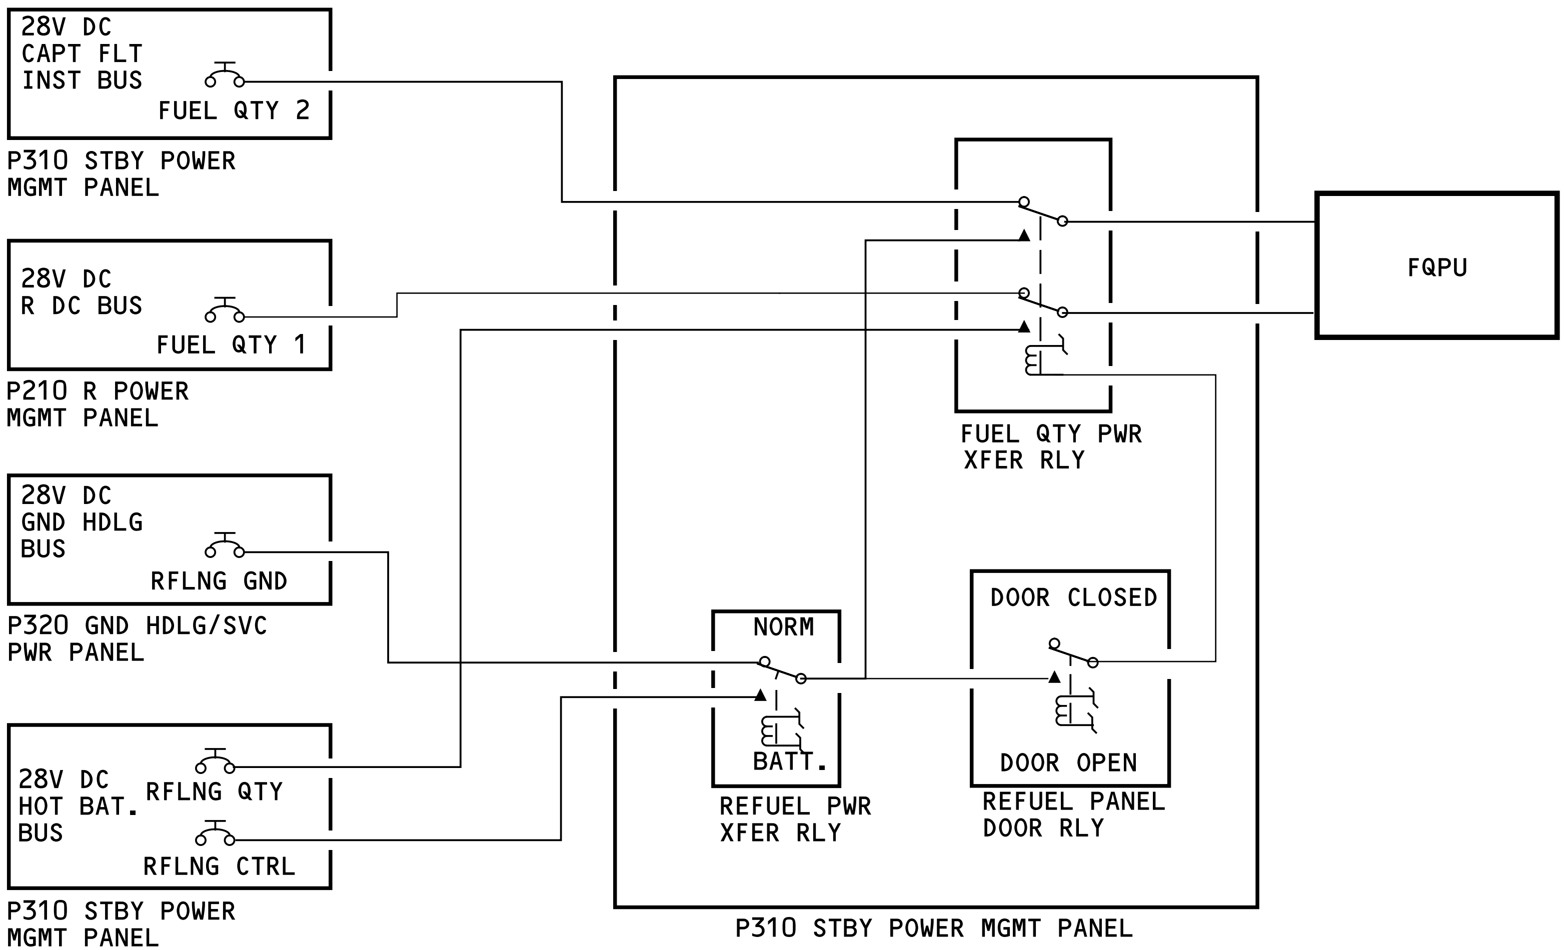
The FQPU gets power from four different sources:

- Captain's flight instrument bus
- Right dc bus
- Ground handling bus
- Hot battery bus.

During normal operation, the refuel station door is closed. The FQPU gets power from the captain's flight instrument bus and the right dc bus. The two power sources are connected together inside the FQPU. Whichever has the higher voltage supplies power to the two FQPU channels.

When the refuel station door is open and the ground handling bus has power, the fuel quantity power transfer relay energizes. This causes the FQPU to get power from different sources. The FQPU gets power from the ground handling bus and the hot battery bus.

If ground handling power is not available, you put the refuel station power switch in the battery position (BATT). This causes the hot battery bus to energize the refuel power transfer relay and the fuel quantity power transfer relay. When the two relays energize, the FQPU gets power from the hot battery bus only.



28-40-00-006 Rev 6 01/15/1997

FUEL INDICATING - FQIS - POWER

FUEL INDICATING - FQIS - INDICATIONS

General

The EICAS display shows total fuel quantity and fuel temperature in the lower right corner of the EICAS display.

The fuel synoptic display shows individual tank quantities and the total fuel quantity. It also shows the fuel temperature and the minimum fuel temperature. The minimum temperature is 3C more than the freeze temperature.

Non-Normal EICAS Displays

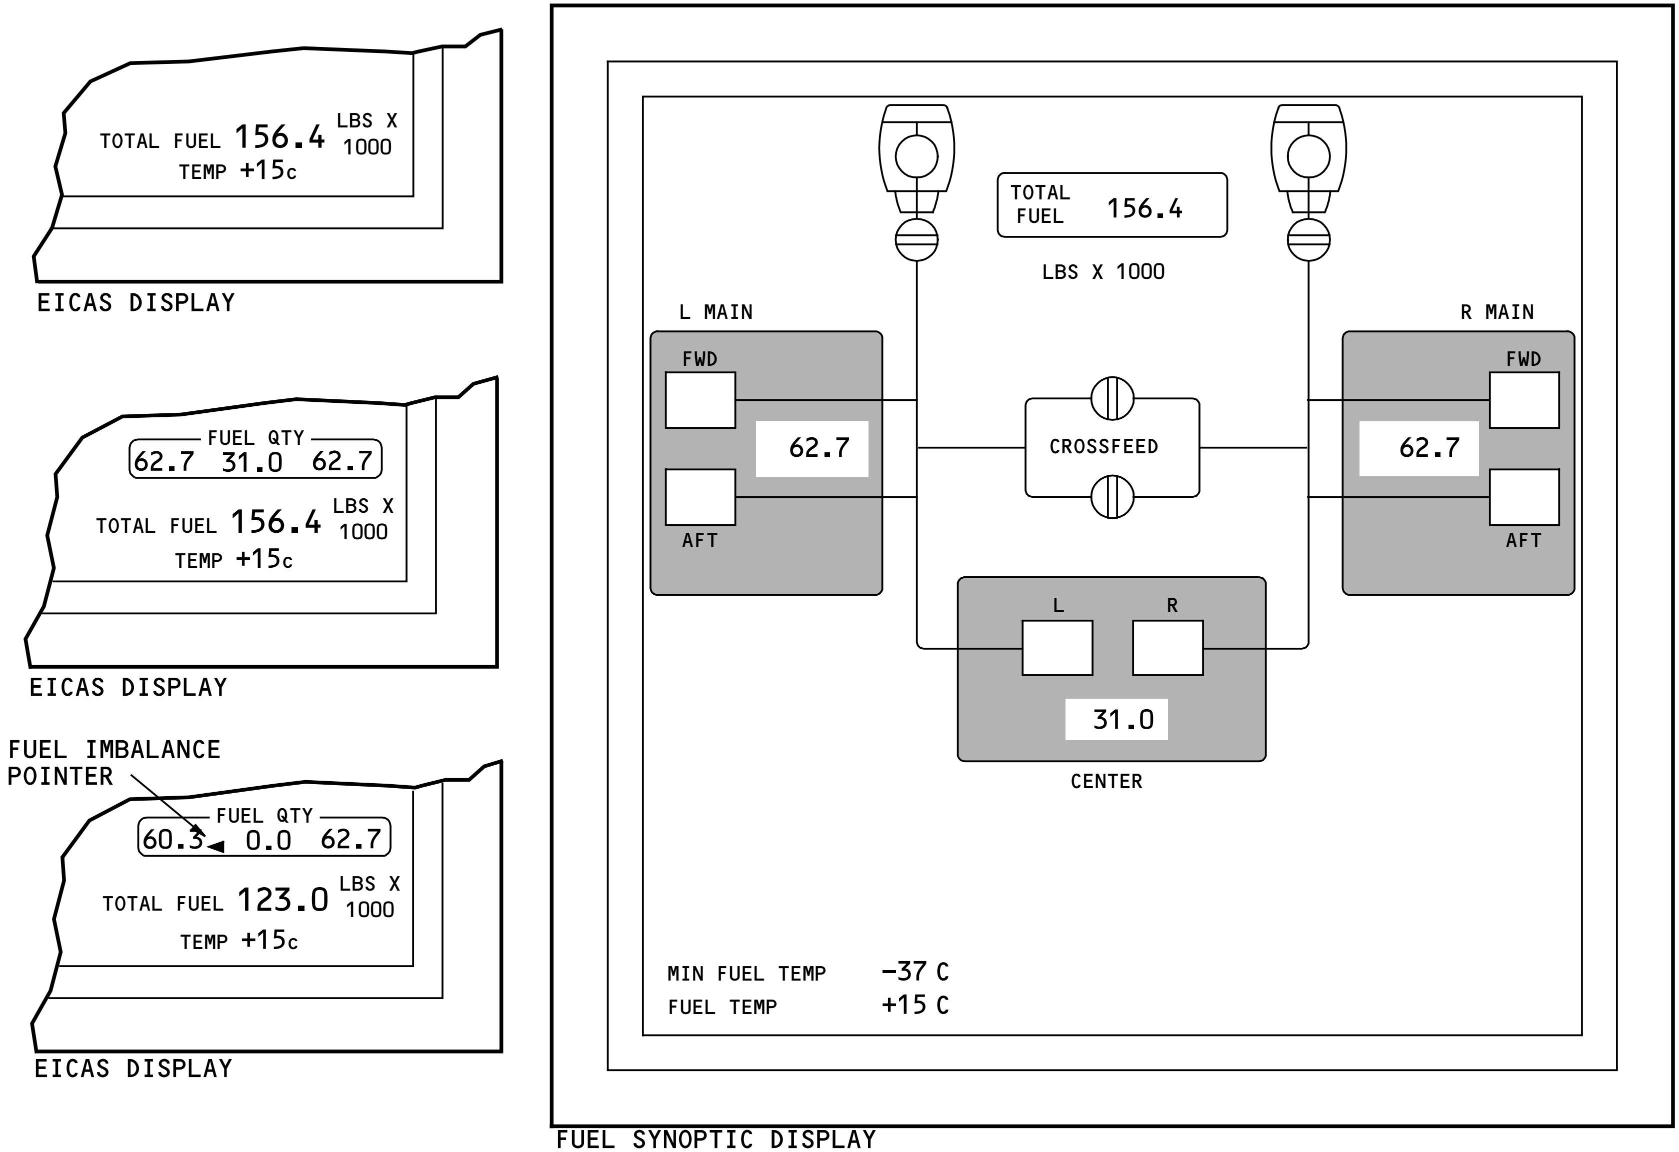
The EICAS display also shows the fuel quantity for each tank when these non-normal conditions exist:

- Low fuel in the main tanks
- Fuel is in the center tank and the center tank pumps are off
- Forward or aft crossfeed valve is open
- You select the fuel synoptic display and the MFD does not work
- Fuel imbalance between the left and right main tanks.

When a fuel imbalance larger than 1000 lb (454 kg) exists, the EICAS display also shows a fuel imbalance pointer. The pointer points to the main tank that has the least fuel. The pointer stays until the imbalance is less than 200 lb (91 kg). If a crossfeed valve is open, a fuel imbalance larger than 200 lb (91 kg) will cause the pointer to show.

The pointer is normally white. When the FUEL IMBALANCE EICAS advisory message shows, the color of the pointer changes to amber.

The fuel temperature data on the EICAS display and the fuel synoptic display can change from white to amber. This occurs when the fuel temperature equals, or becomes less than the minimum fuel temperature.



FUEL INDICATING - FQIS - INDICATIONS

28-40-00-008 Rev 5 02/11/1997

FUEL INDICATING - FQIS - MAINTENANCE PAGES

General

Fuel quantity data shows on the fuel quantity maintenance pages 1 and 2. Page 1 shows data for the left and right main tanks. Page 2 shows similar data for the center tank.

The maintenance page shows this data:

- Fuel quantities
- Fuel temperature
- Fuel densities
- Height of fuel at each tank unit
- Velocity of sound (VOS) at each tank unit
- Volumetric top-off (VTO) values
- Water detection status.

Uplift Quantity

The uplift quantity is the change in the total quantity from the time that the refuel station door opens to the time that the last refuel valve closes.

Uplift Density

The uplift density is the average density of the fuel added from the time that the refuel station door opens to the time that the last refuel valve closes.

Volumetric Top-Off

The VTO for a tank is the volume of fuel the tank can hold. The FQPU uses VTO values to calculate the load select set values for the main tanks when you do a total load select set for automatic refueling. The FQPU also uses the VTO value to close the refuel valves when the tank is full.

Water Detection Status

If a water detector finds water in a tank, the FQPU causes the water detection message for that tank to show. The main tank water detection messages show at the bottom of maintenance page 1. The center tank water detection messages show at the bottom of maintenance page 2.

Training Information Point

Fuel quantity maintenance page 2 shows airplane pitch and roll data. When you use the fuel measuring sticks to find fuel quantity, you can use the pitch and roll data from the maintenance page.

FUEL INDICATING - FUEL QUANTITY MEASURING STICK ASSEMBLY

General

You can manually measure fuel quantity with the fuel measuring stick assemblies.

Eight measuring stick assemblies install through the bottom of each wing. Six are in each main tank and two are in each section of the center tank. They are numbered from inboard to outboard.

The measuring sticks in the main tanks are installed in the fuel tank access doors. The measuring sticks in the center tank are installed in the lower wing skin.

Physical Description

The fuel measuring stick assemblies have these parts:

- Base
- Housing
- Magnetic float
- Measuring stick.

The base and housing are inside the tank. There is a red retainer in the base. The magnetic float surrounds the housing and moves up and down the housing as the fuel level changes. There is a float stop at the top of the housing to keep the float on the housing when the tanks are full.

The measuring stick is inside the housing. The measuring stick is flexible. It has a latch assembly at the bottom and a steel armature at the top. The stick has graduation marks to show the fuel level. The graduation marks are non-dimensional linear units.

You can remove the fuel measuring sticks from the assembly without defueling the airplane.

Operation

You use airplane attitude (pitch and roll) and fuel height to manually measure fuel quantity. The nose wheel well has inclinometers. The right main wheel well has a leveling scale and plumb bob attachment. You use the inclinometers or the leveling scale to measure airplane pitch and roll.

Use a screwdriver to unlock and release the measuring stick latch. Lower the stick to its fully extended length. Raise the stick slowly until you feel the magnetic float catch the stick. Read the graduation mark at the bottom of the stick to get the fuel level. You do this procedure three times to make sure you accurately read the fuel level.

You use airplane attitude, fuel density, and the fuel level from the sticks to find the fuel quantity in the fuel measuring stick conversion tables. The fuel measuring stick conversion tables are in the servicing section of part II of the airplane maintenance manual (AMM).

FUEL INDICATING - FUEL QUANTITY MEASURING STICK ASSEMBLY

Training Information Point

Because it is flexible, move the measuring stick slowly when you stow it.

PRESSURE REFUEL - INTRODUCTION

PRESSURE REFUEL - GENERAL DESCRIPTION

General

The pressure refuel system transfers fuel from the refuel adapters to the airplane tanks. You operate the pressure refuel system with the IRP on the left wing. The FQPU and the ELMS control the system.

Fault information goes to the AIMS.

Control

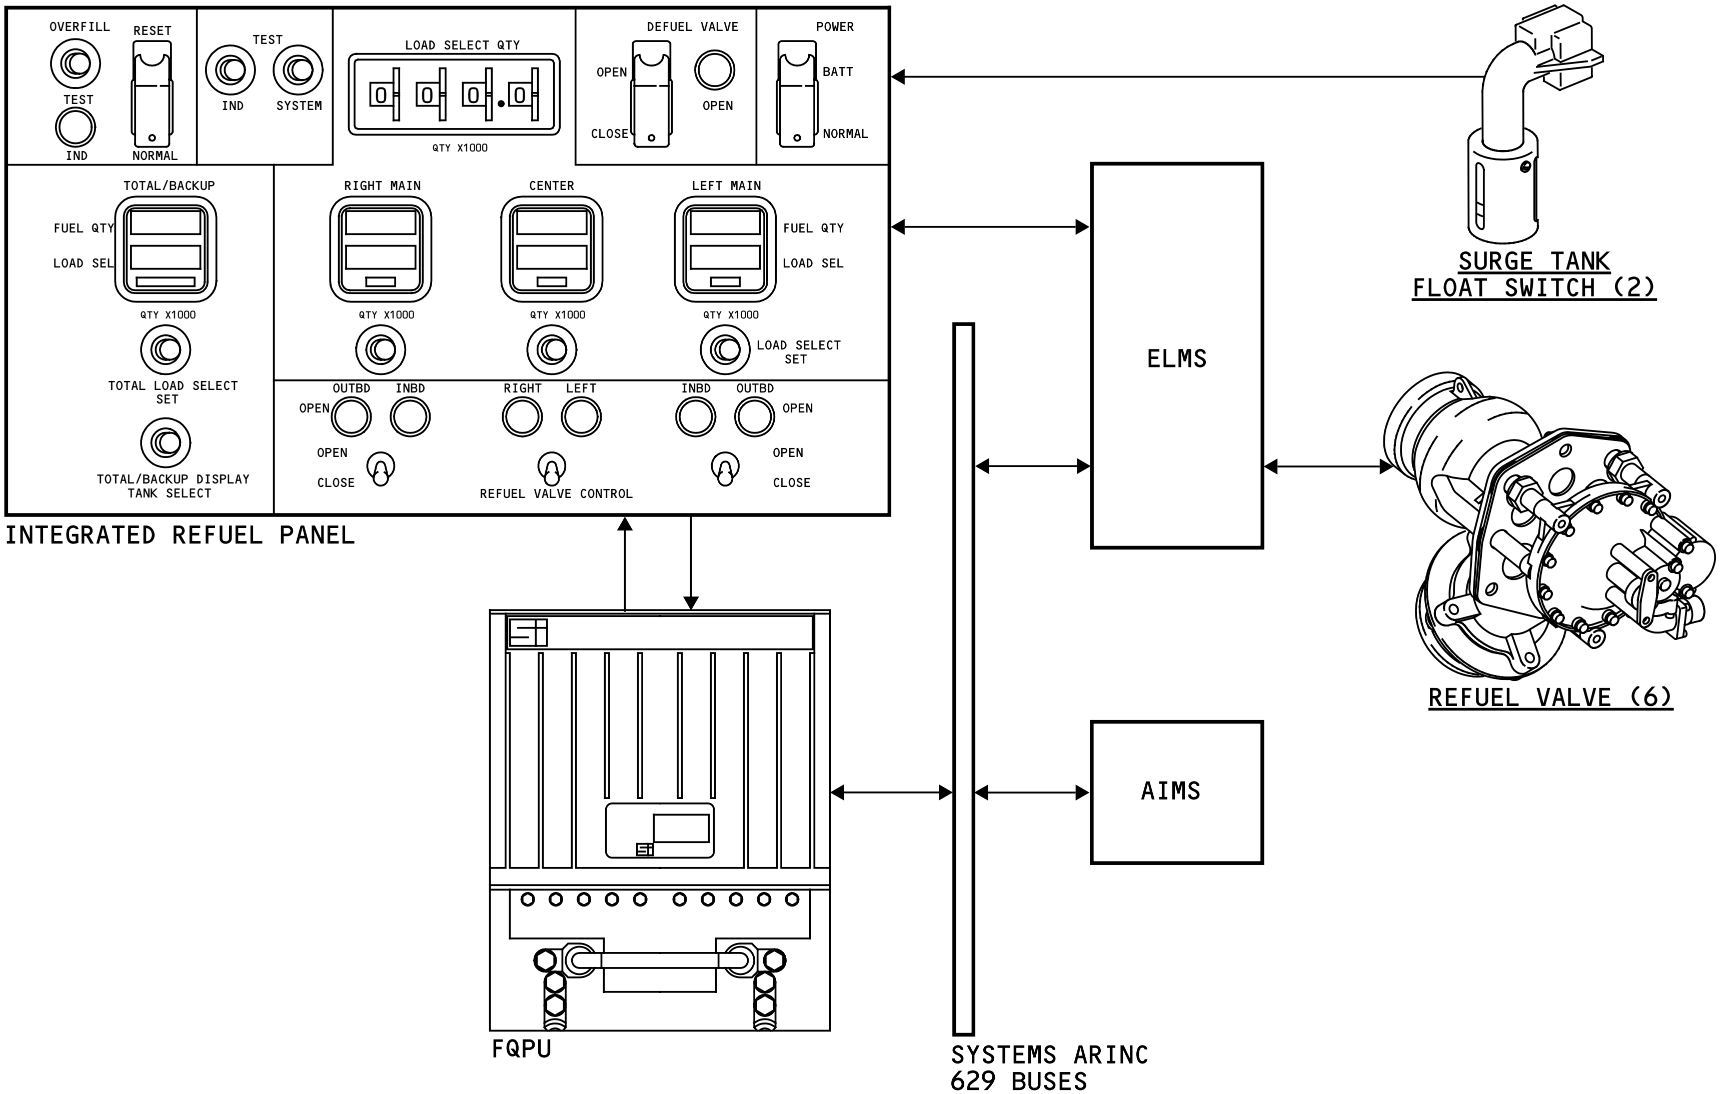
The IRP sends fuel load data and refuel valve switch positions to the FQPU through an ARINC 429 data bus. The processor sends the switch positions to the ELMS through the systems ARINC 629 buses. The ELMS supplies power to open and close the refuel valves.

Indication

The ELMS monitors refuel valve positions. When a refuel valve is open, the ELMS sends a signal to the FQPU on the systems ARINC 629 buses. The FQPU makes the related valve-open light come on.

Overfill Protection

There is a surge tank float switch in each surge tank. If fuel enters the surge tank, the surge tank float switch sends a signal through the IRP to the ELMS. This causes the ELMS to remove power from all the refuel valves so the valves close.



PRESSURE REFUEL - GENERAL DESCRIPTION

PRESSURE REFUEL - COMPONENT LOCATIONS

General

The components for the pressure refuel system are:

- Refuel station
- Refuel valves
- Refuel/jettison manifold
- Refuel/jettison manifold drain valves
- Refuel/jettison manifold vacuum relief valves.

Refuel Station

There is a refuel station on the leading edge of the left wing, outboard of the engine. The refuel station has an access door, two refuel adapters, and an IRP.

Refuel Valves

There are six refuel valves; two in each tank. The valve bodies are on the rear spar, inside the tanks. The valve actuators are on the rear spar, outside the tanks.

The refuel valve in the left side of the center tank is aft of the second fuel tank access door. The refuel valve in the right side of the center tank is in a similar position.

The inboard refuel valve in the left main tank is aft of the fourth fuel tank access door. The outboard refuel valve in the main tank is aft of the eighteenth fuel tank access door. The refuel valves in the right main tank are in similar positions.

Refuel/Jettison Manifold

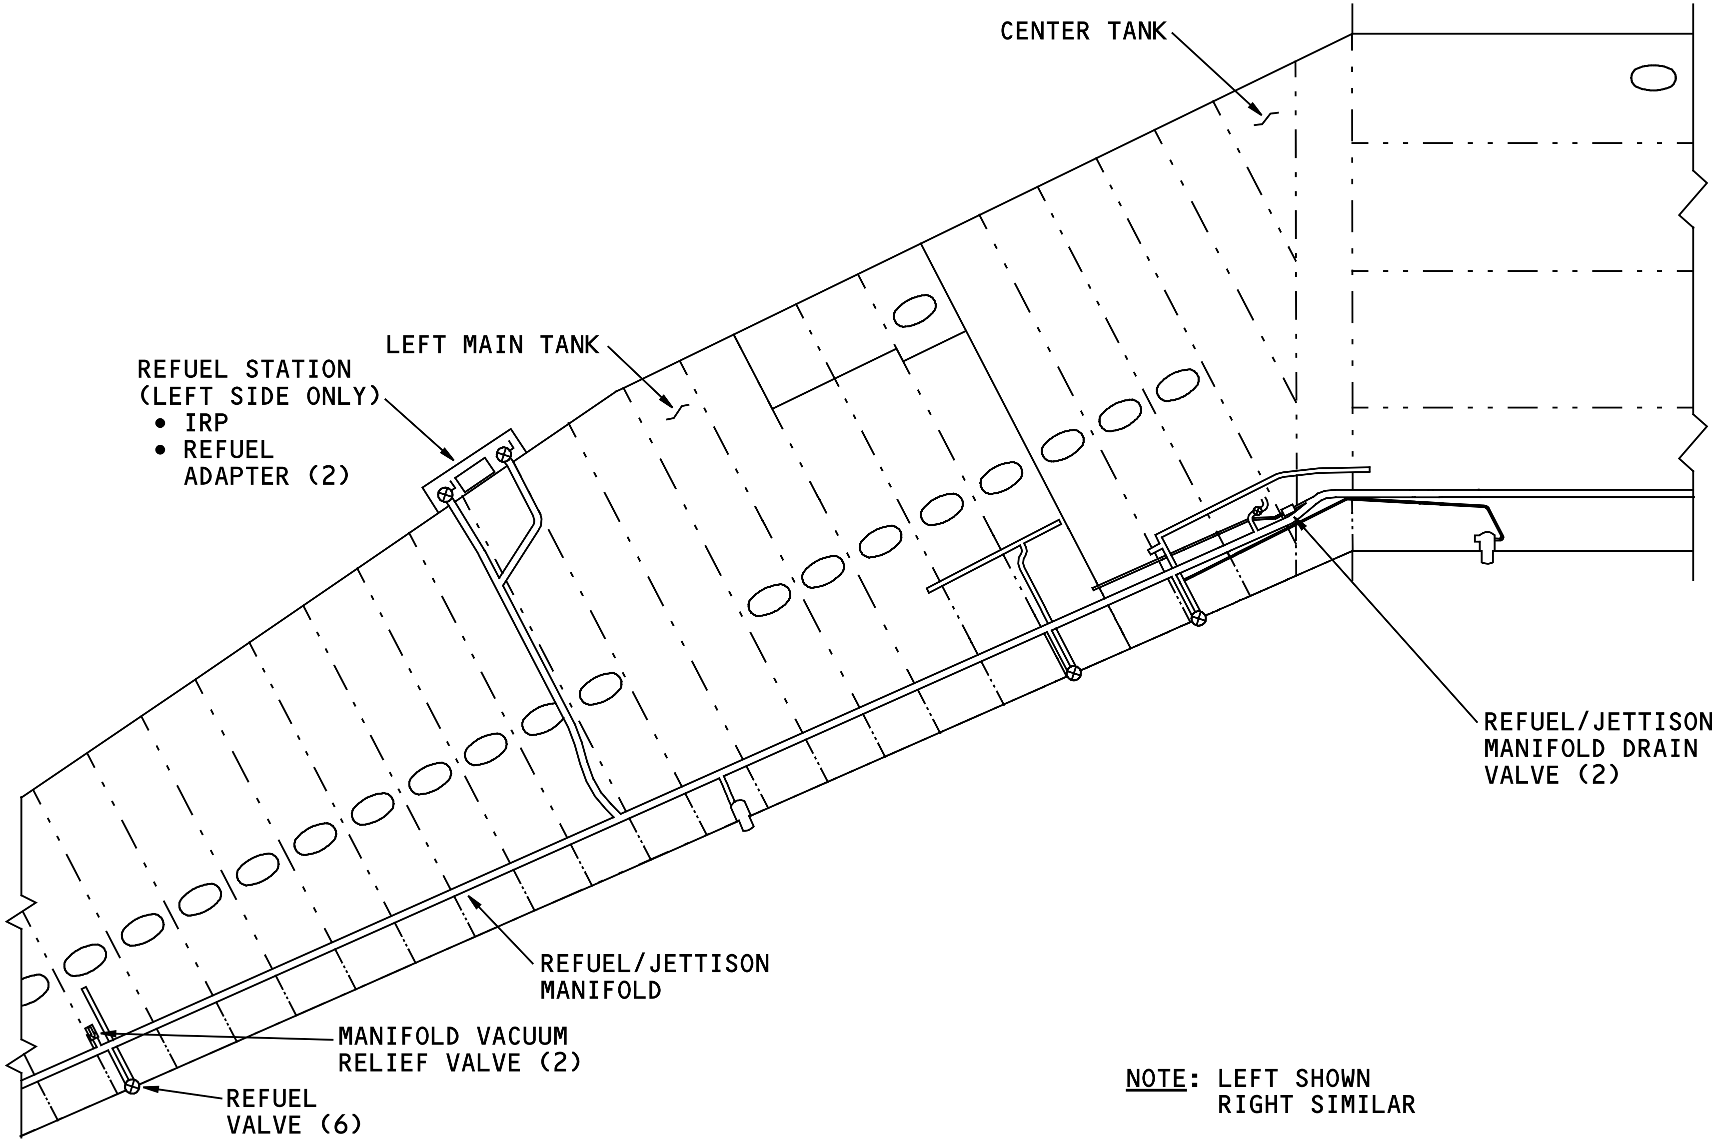
The refuel/jettison manifold connects the refuel station to all the refuel valves. It supplies fuel from the refuel adapters to each tank.

Refuel/Jettison Manifold Drain Valves

There are two refuel/jettison manifold drain valves. One is in each half of the center tank. You get access to them through the first fuel tank access door.

Refuel/Jettison Manifold Vacuum Relief Valves

There are two refuel/jettison manifold vacuum relief valves. They are on the refuel/jettison manifold, near the outboard refuel valve in each main tank. You get access to them through the eighteenth fuel tank access door.



PRESSURE REFUEL - COMPONENT LOCATIONS

PRESSURE REFUEL - REFUEL STATION

General

There is a refuel station on the leading edge of the left wing. The refuel station has these components:

- Access door
- Access door switch
- Refuel adapter (2)
- Bonding point (2)
- IRP.

You use the IRP to control refuel and defuel operations.

Access Door

Two hold-open rods keep the access door in the full-open position. To close the access door, you must move a collar on each hold-open rod. There are four placards on the access door. They tell you about refuel and defuel procedures.

When the access door is open, the access door switch permits power to go to the IRP and the FQIS processor unit. The switch also controls the panel lights.

Integrated Refuel Panel

The IRP has these parts:

- Front panel
- Fuel quantity indicators in an electronics module
- Switches and lights
- Load select module.

The electronics module has two channels.

Refuel Adapters

The refuel adapters connect the fueling nozzles to the refuel system. The two refuel adapters are at the refuel station. The adapters attach to the front spar of the wing.

Each adapter has these parts:

- Break-away flange
- Check valve (not shown)
- Refuel/defuel handle.

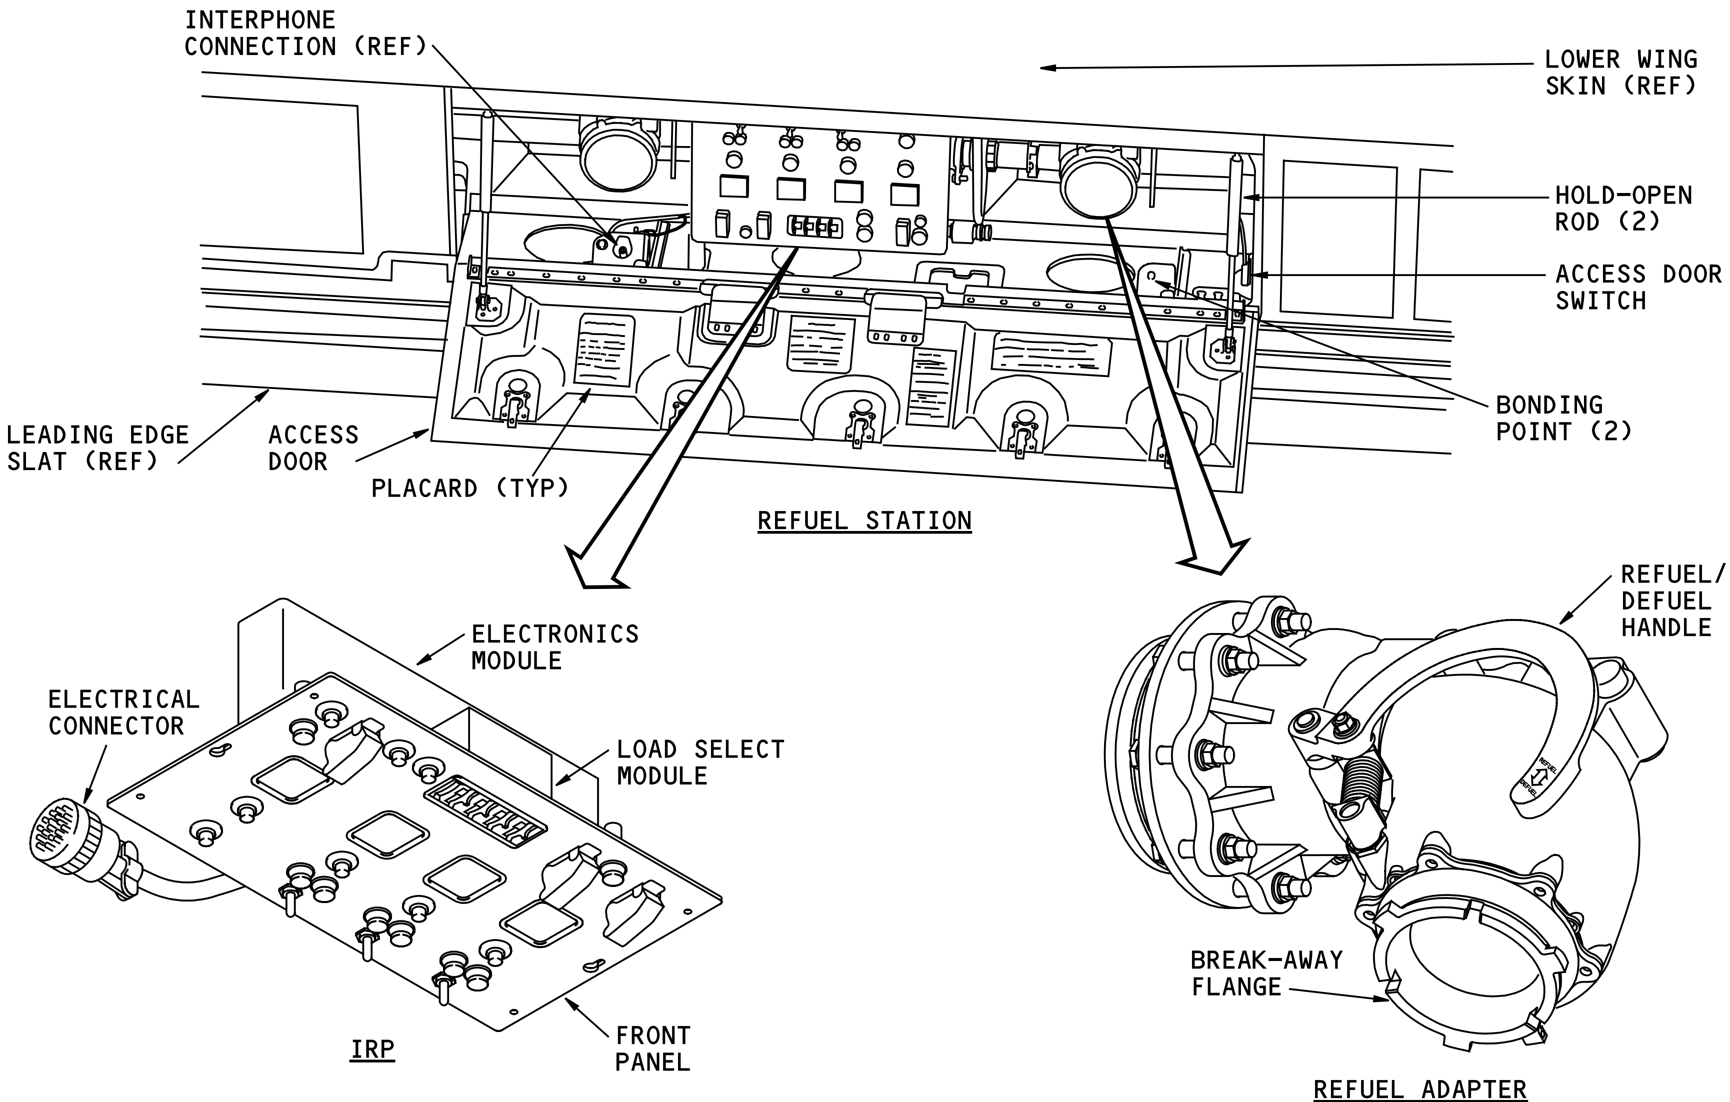
The adapter check valve prevents fuel in the refuel/jettison manifold from flowing back through the adapters.

Training Information Point

The adapter grounds the fueling nozzles to the airplane. If there is electrical continuity between the fueling source and the fueling nozzle, it is not necessary to attach a bonding cable.

Caps are not required on the adapters.

The IRP is an LRU.



PRESSURE REFUEL - REFUEL STATION

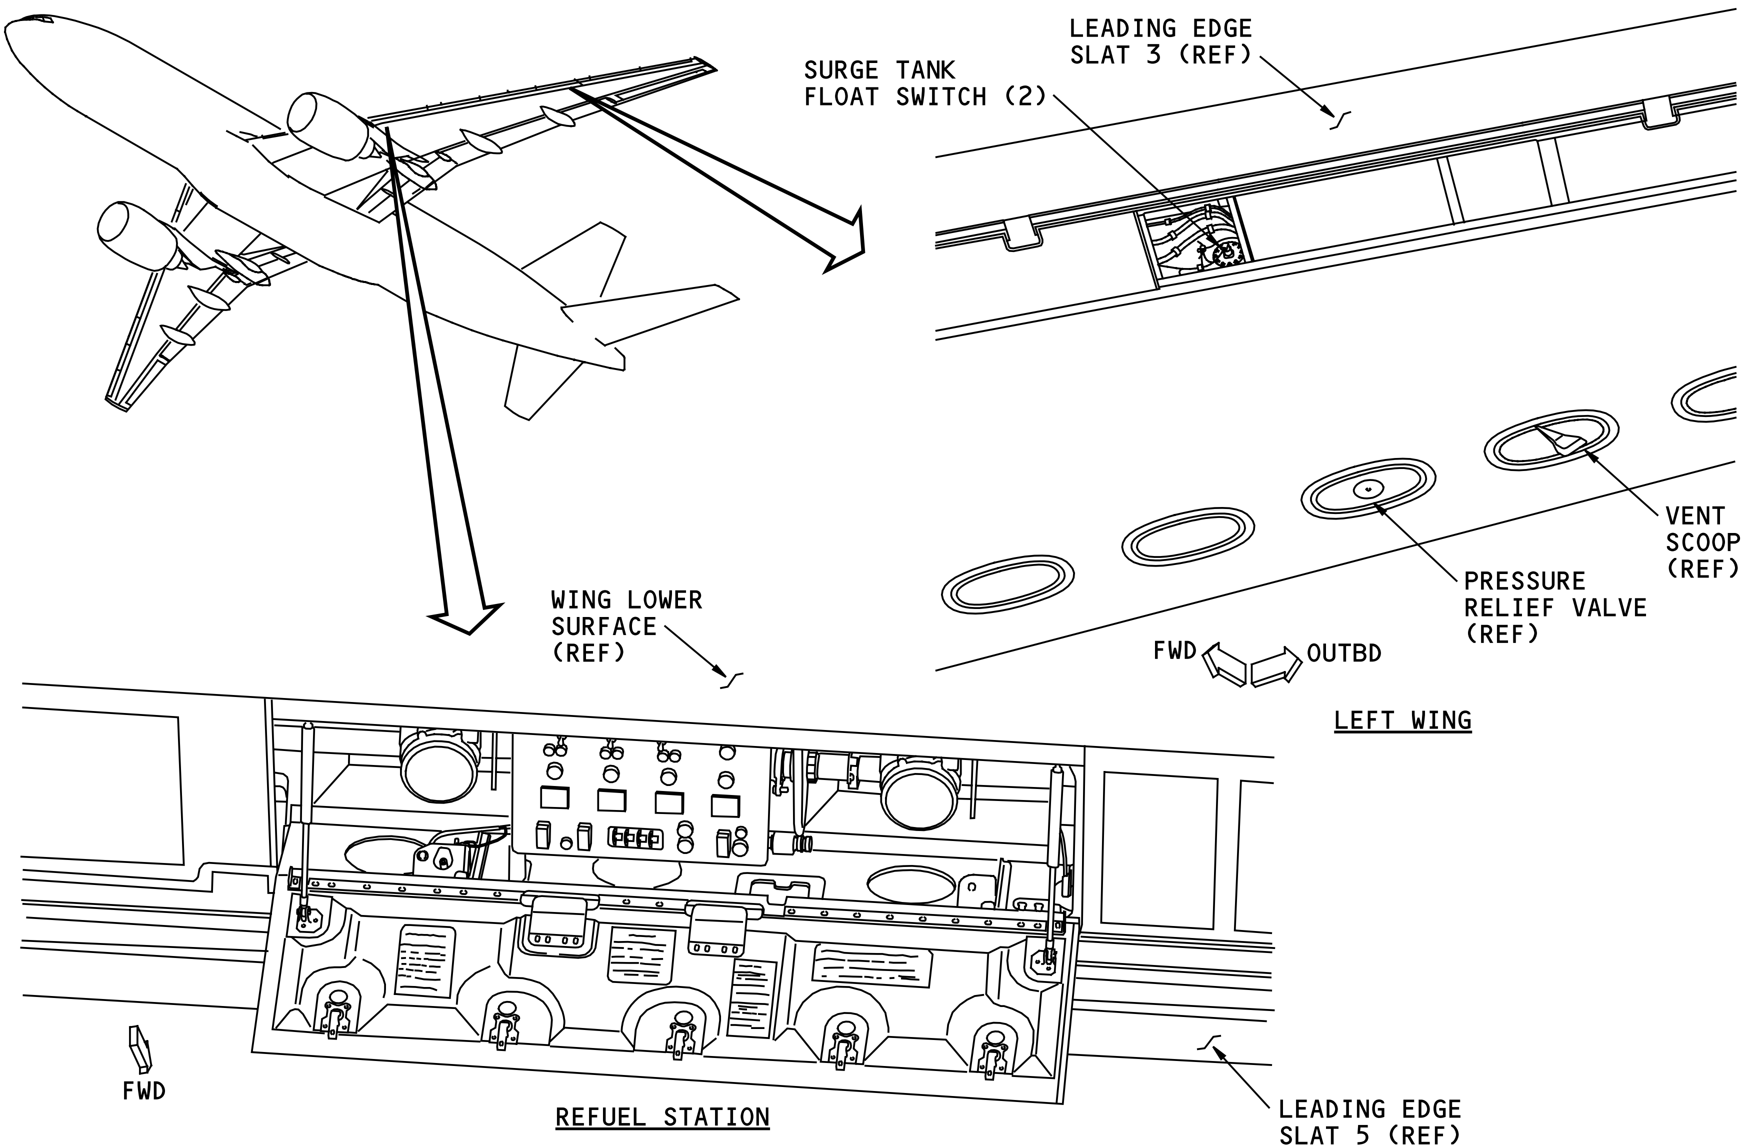
PRESSURE REFUEL - COMPONENT LOCATIONS - FRONT SPAR

Refuel Station

There is a refuel station on the left wing, aft of leading edge slat 5. The refuel station contains two refuel adapters and an IRP.

Surge Tank Float Switches

There is one surge tank float switch on each wing, near the pressure relief valve and vent scoop. The left switch is on the front spar, aft of leading edge slat 3. The right switch is on the front spar, aft of leading edge slat 12.



28-21-00-013 Rev 1 03/06/1996

PRESSURE REFUEL - COMPONENT LOCATIONS - FRONT SPAR

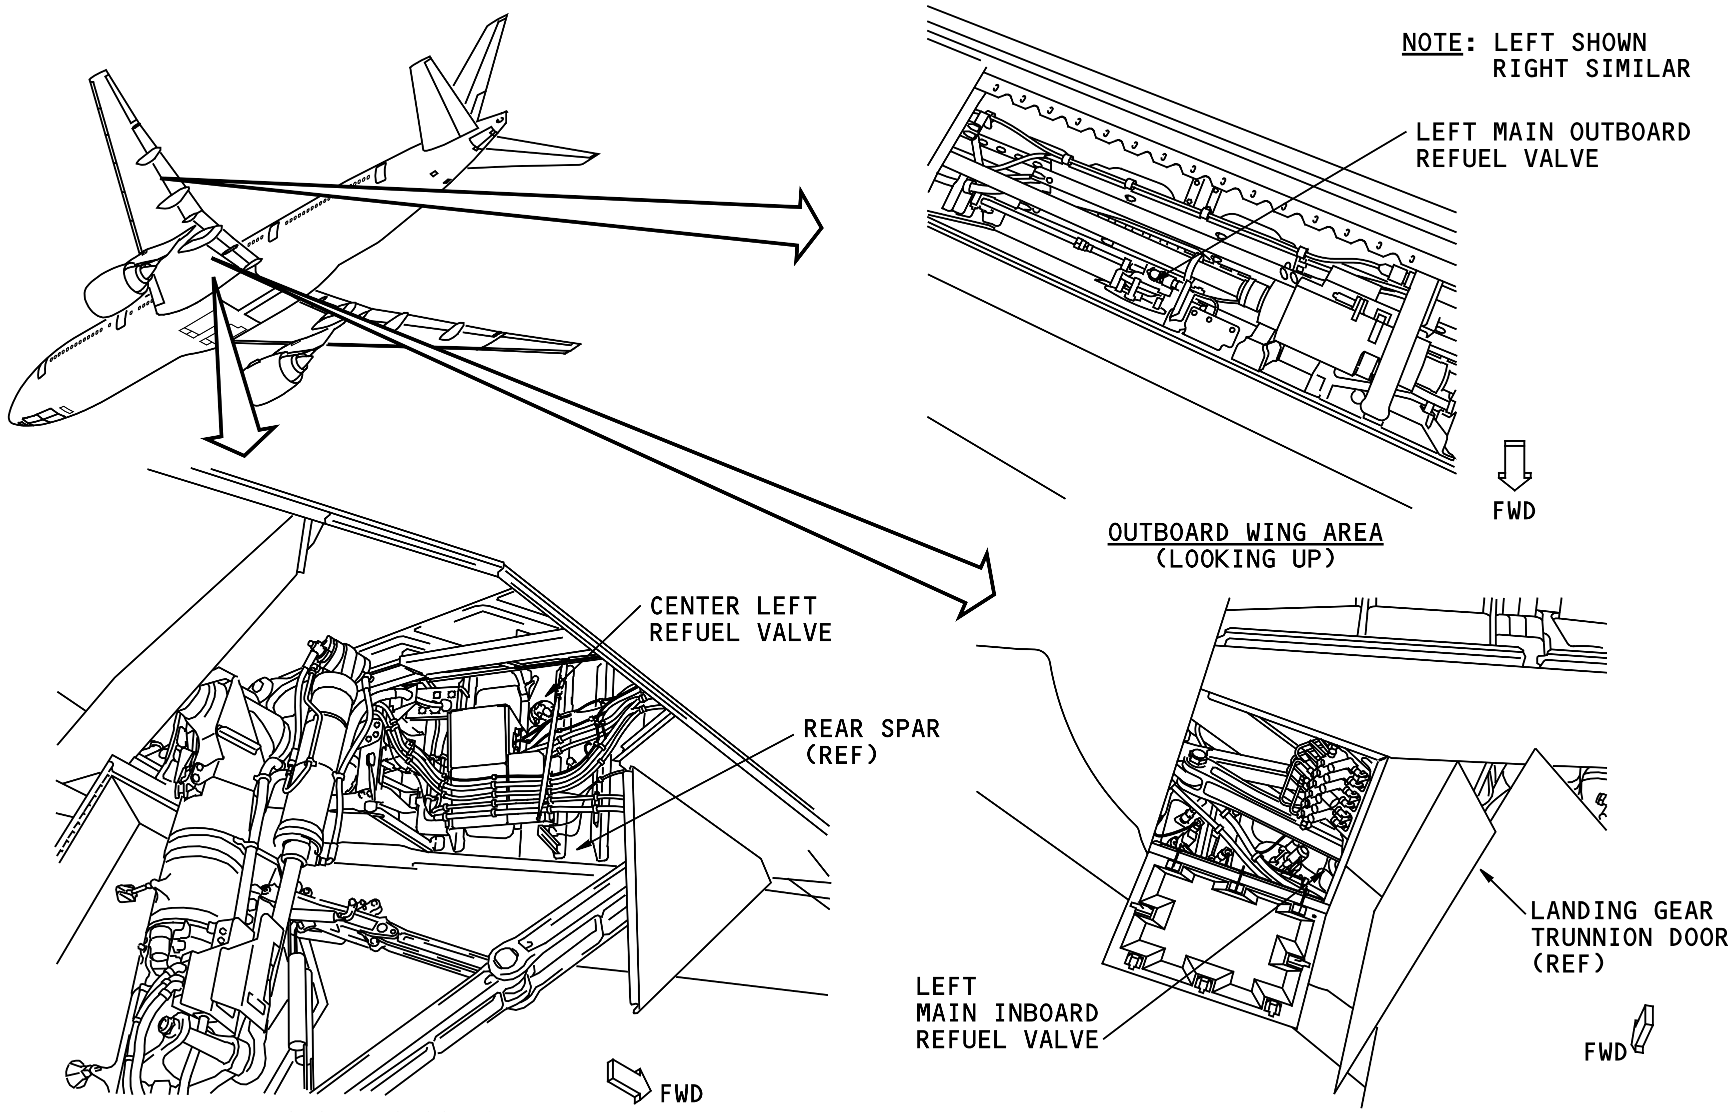
PRESSURE REFUEL - COMPONENT LOCATIONS - REAR SPAR

General

There are two refuel valves in each fuel tank.

In the left main fuel tank, the inboard refuel valve actuator is outboard of the main landing gear shock strut. The outboard refuel valve is between the fairings of the outboard flap. The refuel valve actuators are in similar locations in the right main fuel tank.

In the center tank, the left refuel valve actuator is on the rear spar, inboard of the main landing gear shock strut. The right refuel valve actuator is in a similar location in the right side of the center tank.



PRESSURE REFUEL - COMPONENT LOCATIONS - REAR SPAR

28-21-00-014 Rev 1 03/16/95

THIS PAGE INTENTIONALLY LEFT BLANK

PRESSURE REFUEL - INTEGRATED REFUEL PANEL

Overfill Test Switches

The overfill test switch starts the overfill test. This causes the overfill protection to immediately close all the refuel valves. You do the overfill test during refueling.

The overfill indication light is a red light that comes on when there is fuel in a surge tank, or when you do the overfill test. It stays on until the surge tanks are empty and the overfill reset switch is in the RESET position.

The overfill reset switch disables the overfill protection. It has two positions: NORMAL and RESET. The NORMAL position arms the overfill protection. The RESET position turns off the overfill protection.

Indicator Test Switch

The indicator test switch does a test of these indicators:

- Fuel quantity indicators
- Refuel valve position indication lights
- Defuel valve position indication light.

During the test, a test pattern shows in the fuel quantity indicators, and the valve position indication lights come on. If a fuel quantity indicator fails the test, all of its LEDs go off.

The IRP also does the indicator test when it initially gets power.

System Test Switch

You push the system test switch during refueling to do a test of the refuel system. During the test all the refuel valves close, two at a time, and the refuel valve position indication lights go off. Then, the valves automatically open, two at a time, and the lights come on again.

Load Select Quantity Selectors

The load select quantity selectors permit you to select fuel load quantity. There are four selectors. Each selector has a thumbwheel and shows a number. You turn the thumbwheel to set the related number of the fuel load quantity.

Defuel Valve Switch and Light

The defuel valve switch opens and closes the defuel valve.

The defuel valve open light is a blue light that shows the position of the defuel valve. It comes on when the defuel valve opens.

Power Switch

The power switch permits you to refuel the airplane when the ground handling bus does not have power. When

PRESSURE REFUEL - INTEGRATED REFUEL PANEL

you move the power switch to the battery (BATT) position, it causes the hot battery bus to send power to the refuel system.

Fuel Quantity Indicators

There are four fuel quantity indicators:

- Total/backup
- Right main
- Center
- Left main.

The fuel quantity indicators have two LED displays. The upper display shows actual fuel quantity. The lower display shows load select quantity.

The total fuel quantity indicator can show indications for one of the other tanks if its indicator fails.

Load Select Set Switches

There are four load select switches, one below each fuel quantity indicator. Load select set switches move the load select quantity from the selector to the related load select display. These switches permit you to set the total fuel load or the fuel load for each tank.

Refuel Valve Switches and Lights

Refuel valve control switches send command signals to the FQPU to control the refuel valves.

Each refuel valve open light is a blue light that shows the position of the related refuel valve. The light comes on when the valve opens.

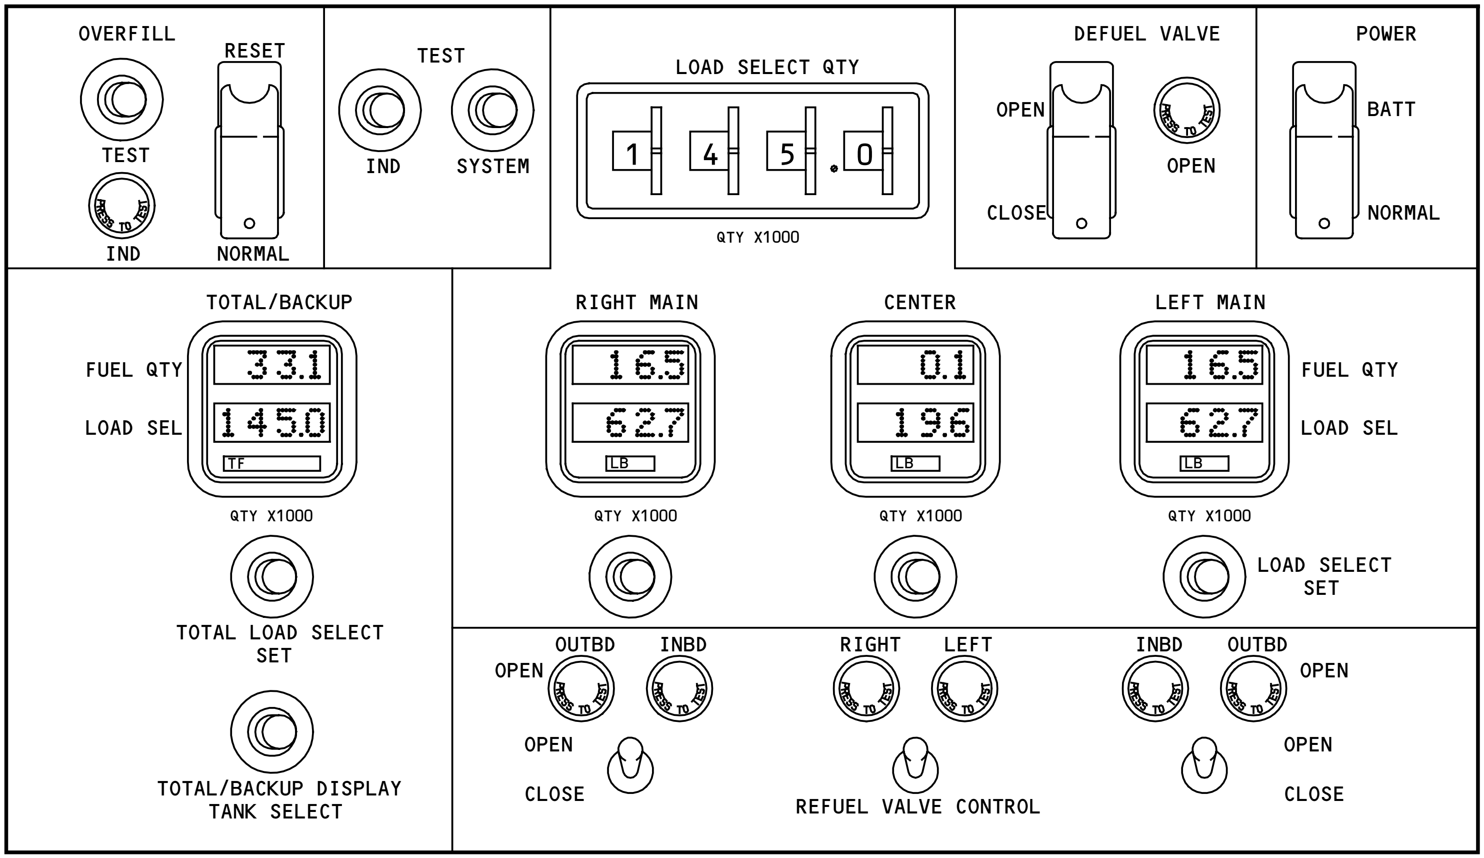
Total/Backup Display Tank Select Switch

The display tank select switch permits you to use the total fuel quantity indicator as a backup for the left, right, or center tank indicator. Each time you push the switch, a different tank quantity and identifier show on the total/backup display. This is the sequence of the identifiers:

- TF - total fuel quantity
- RM - right main tank quantity
- CT - center tank quantity
- LM - left main tank quantity.

Training Information Point

The IRP also does the indicator test when it initially gets power.



28-21-00-005 Rev 5

PRESSURE REFUEL - INTEGRATED REFUEL PANEL

PRESSURE REFUEL - REFUEL VALVE

General

The refuel valves permit fuel to flow from the refuel/ jettison manifold into the fuel tanks. Each valve has a valve body and a control unit.

Valve Body

The valve body has a poppet-type valve. The valve body is on the rear spar, inside the fuel tank.

Control Unit

The control unit opens and closes the valve. The control unit is on the rear spar, outside the fuel tank. It has these parts:

- Solenoid
- Actuator
- Manual override knob
- Position switch.

When the solenoid energizes, it supplies pressurized fuel into the actuator. This causes the valve to open.

If the valve does not open, you can use the manual override knob to manually open and close it.

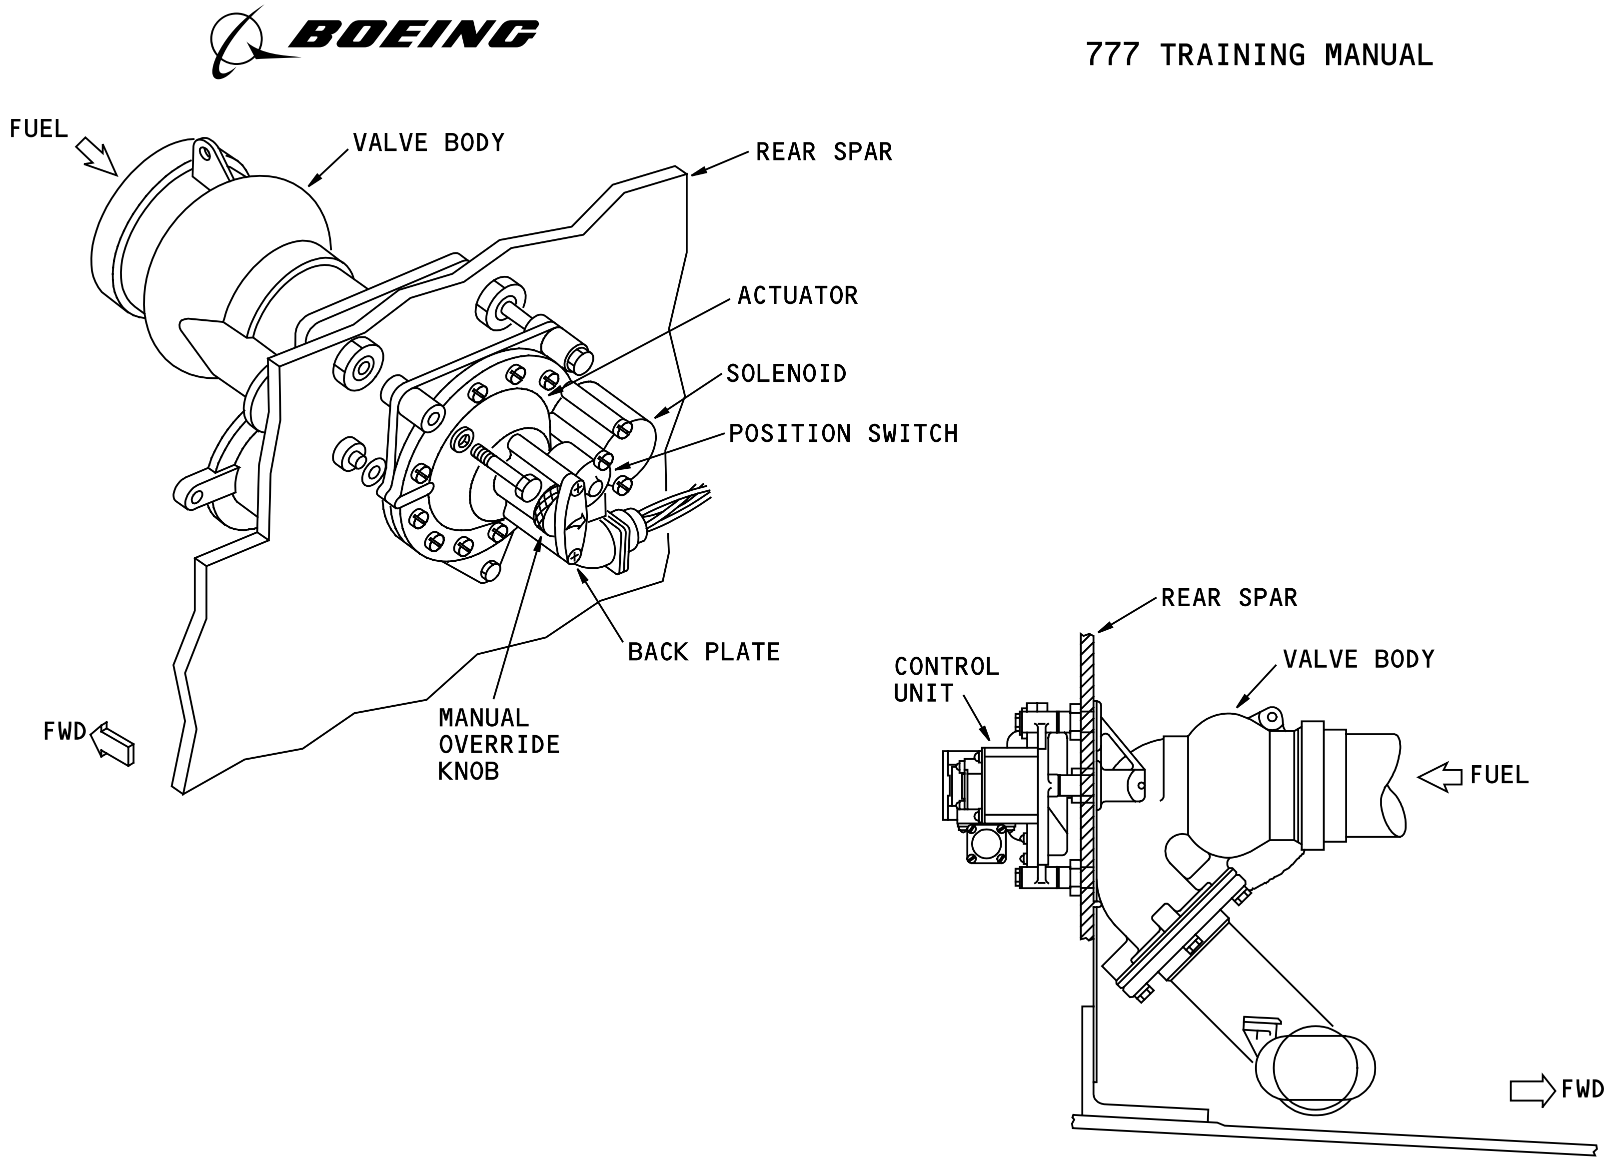
The valve position switch sends a signal to the ELMS when the valve is open. This causes the valve position light on the IRP to come on.

You can remove the control unit without defueling. A removal check valve in the valve body prevents fuel from coming out.

Do not remove or loosen the back plate when you open the valve manually.

Training Information Point

Keep manual operation of the valve to a minimum. Damage to an O-ring inside the valve can occur if you manually operate the valve many times.



28-21-00-006 Rev 3

PRESSURE REFUEL - REFUEL VALVE

PRESSURE REFUEL - SURGE TANK FLOAT SWITCH

Purpose

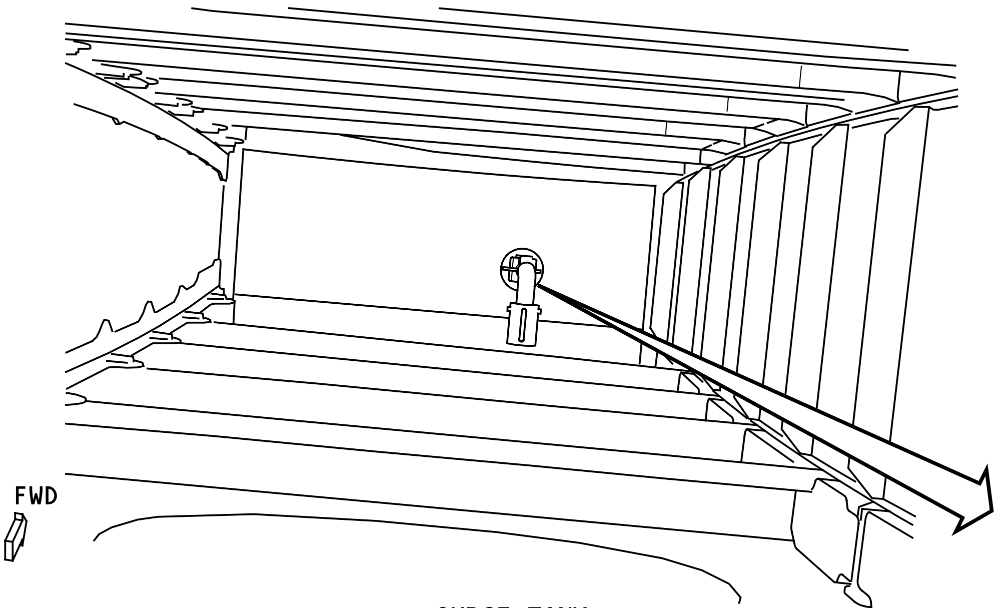
The surge tank float switch sends a signal to close all the refuel valves if there is fuel in the surge tank.

Location

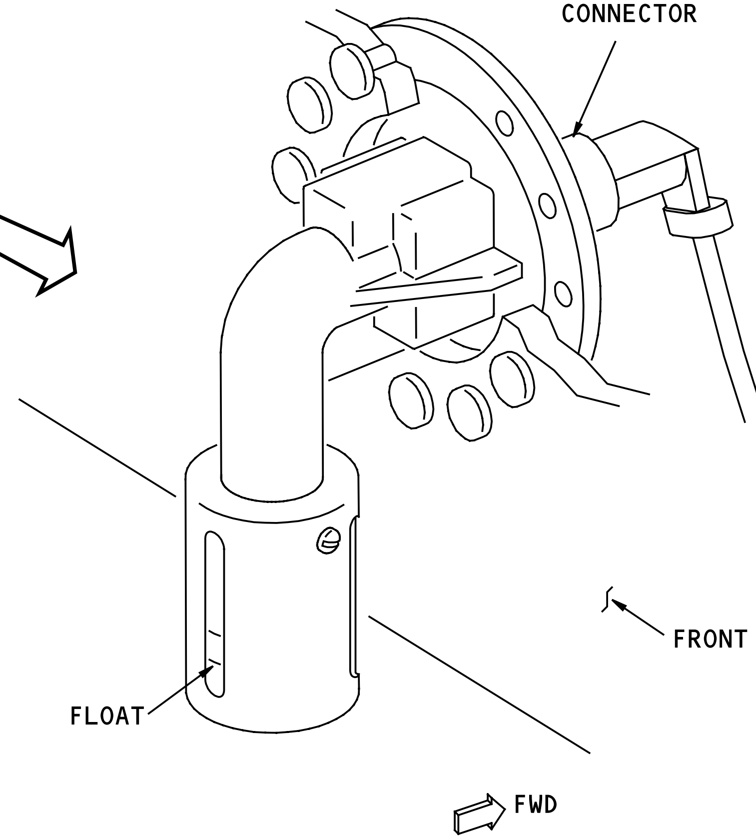
One surge tank float switch is on the front spar in each surge tank.

Functional Description

Each surge tank float switch contains a magnetic reed float switch. The switch closes when fuel in the surge tank gets above a specified level.



SURGE TANK



SURGE TANK FLOAT SWITCH

28-21-00-007 Rev 2

PRESSURE REFUEL - SURGE TANK FLOAT SWITCH

PRESSURE REFUEL - REFUEL MANIFOLD VALVES

Purpose

There are two types of refuel manifold valves: refuel manifold drain valves and refuel manifold vacuum relief valves.

The refuel manifold drain valves drain fuel from the refuel/jettison manifold into the main tanks. This increases the amount of fuel that the airplane can use.

The refuel manifold vacuum relief valves prevent a vacuum in the manifold, so fuel can drain.

Location

One refuel manifold drain valve is in each refuel manifold drain line. You get access to the drain valve through the first fuel tank access door.

One manifold vacuum relief valve is on the refuel manifold near the outboard refuel valve in each main tank. You get access to the drain valve through the eighteenth fuel tank access door (between ribs 24 and 25).

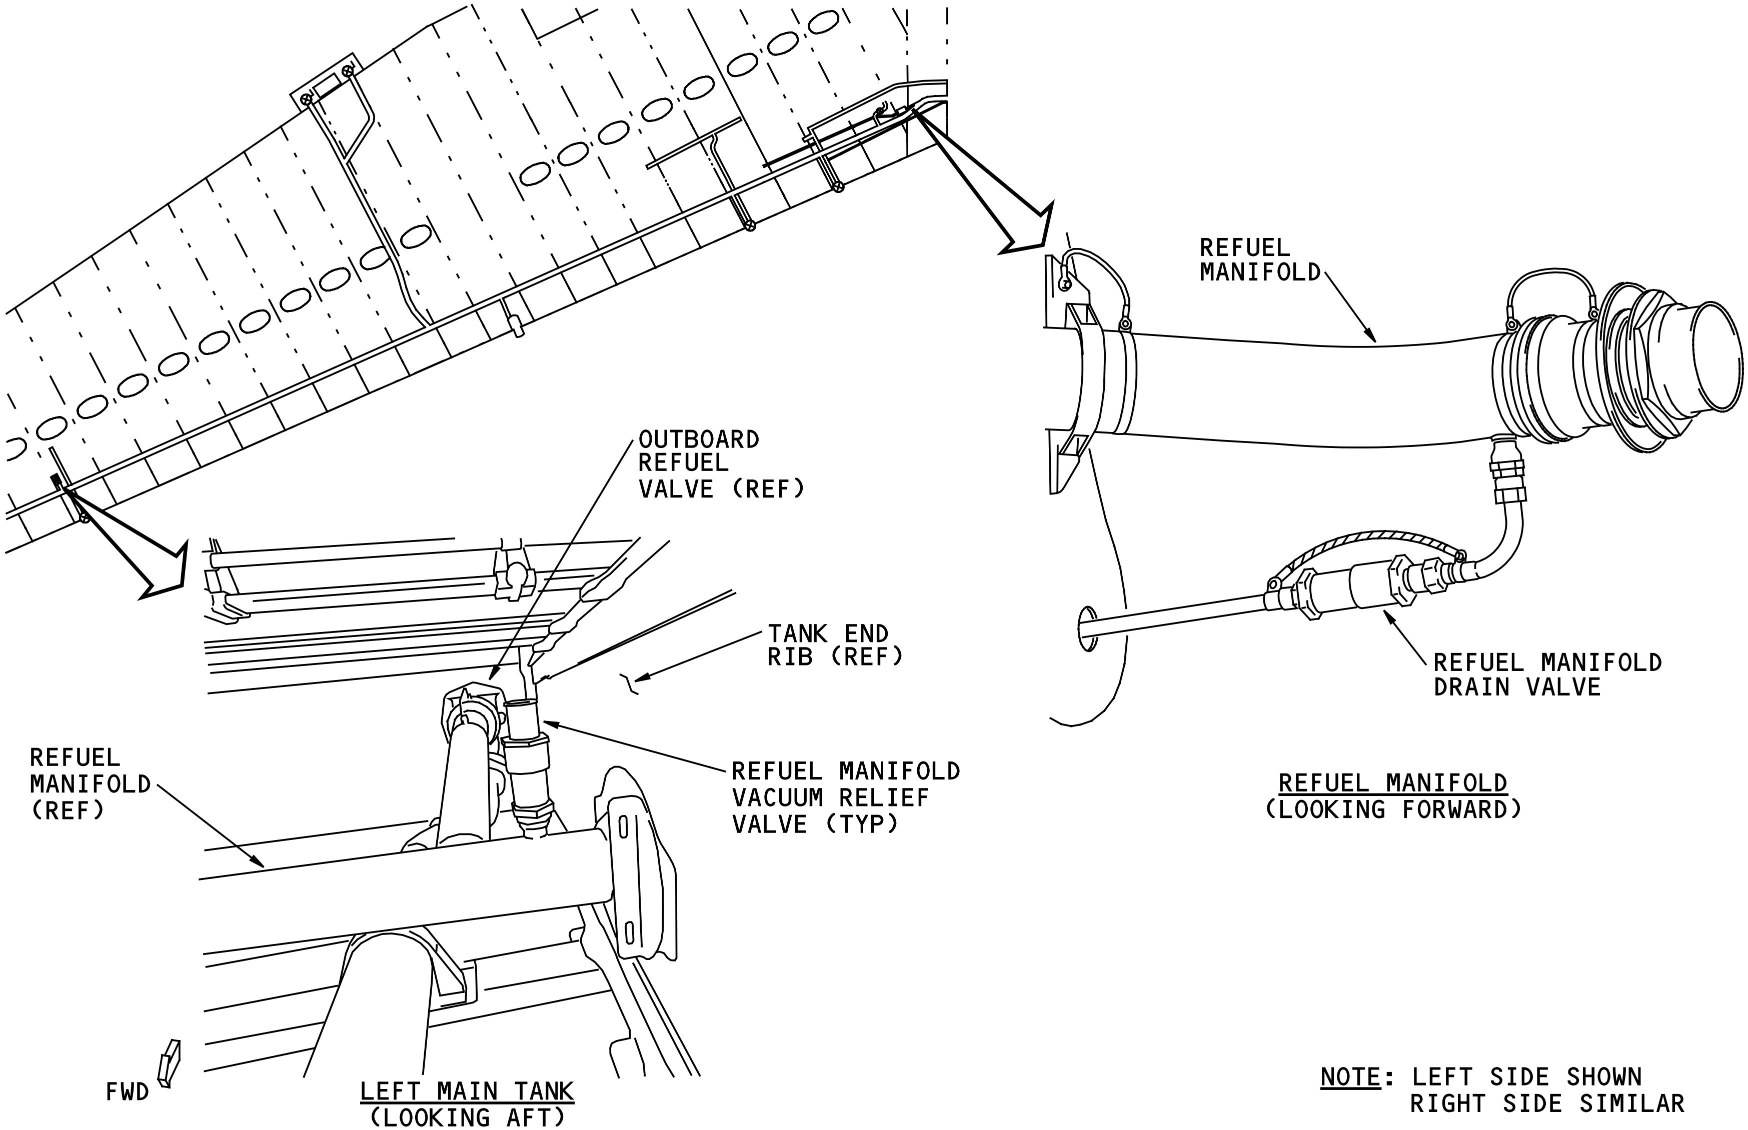
Refuel Manifold Drain Valve - Functional Description

When the manifold has pressure, the valve prevents fuel from flowing into the main tanks.

When the main tank is full, the drain valve prevents fuel from flowing from the tank into the manifold. When the main tank is not full, fuel drains from the refuel/jettison manifold into the main tank.

Refuel Manifold Vacuum Relief Valve - Functional Description

When fuel drains through a refuel manifold drain valve, the pressure in the refuel manifold becomes less than the pressure inside the fuel tank. This causes the refuel manifold vacuum relief valve(s) to open. The open valve permits air to enter the refuel manifold and increase the pressure. Then fuel can continue to drain from the refuel manifold.



28-21-00-008 Rev 4 03/18/96

PRESSURE REFUEL - REFUEL MANIFOLD VALVES

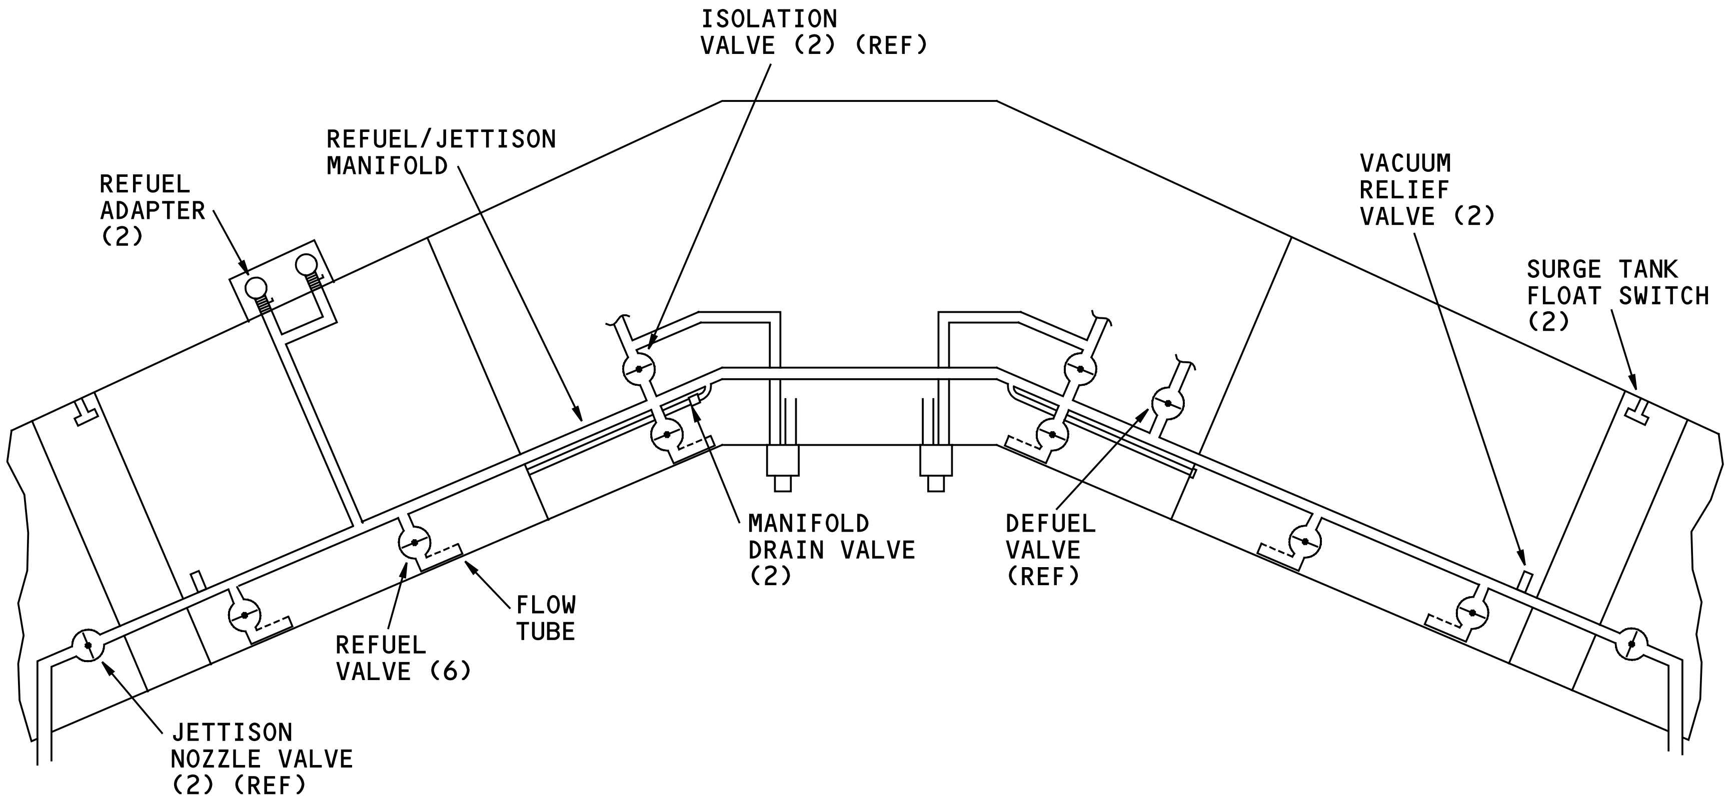
PRESSURE REFUEL - FUNCTIONAL DESCRIPTION - FUEL FLOW

General

Fuel flows from the refuel adapters into the refuel/jettison manifold. When the refuel valves open, fuel flows from the manifold into the fuel tanks. A flow tube at the end of each refuel valve decreases the exit force of the fuel. The flow tube also puts the fuel in different parts of the tank.

The refuel valves close to stop fuel flow. Fuel that is left in the refuel/jettison manifold goes through the manifold drain valves and into the main tanks. The manifold has two vacuum relief valves. These valves permit air to go into the manifold when the fuel goes out of the manifold drain valves.

If a refuel system failure prevents the refuel valves from closing, fuel goes into the surge tanks. If the fuel gets to the level of the surge tank float switches, the switches close. When one of the two switches close, the ELMS closes all refuel valves.



28-21-00-009 Rev 5 03/18/96

PRESSURE REFUEL - FUNCTIONAL DESCRIPTION - FUEL FLOW

PRESSURE REFUEL - FUNCTIONAL DESCRIPTION - POWER

General

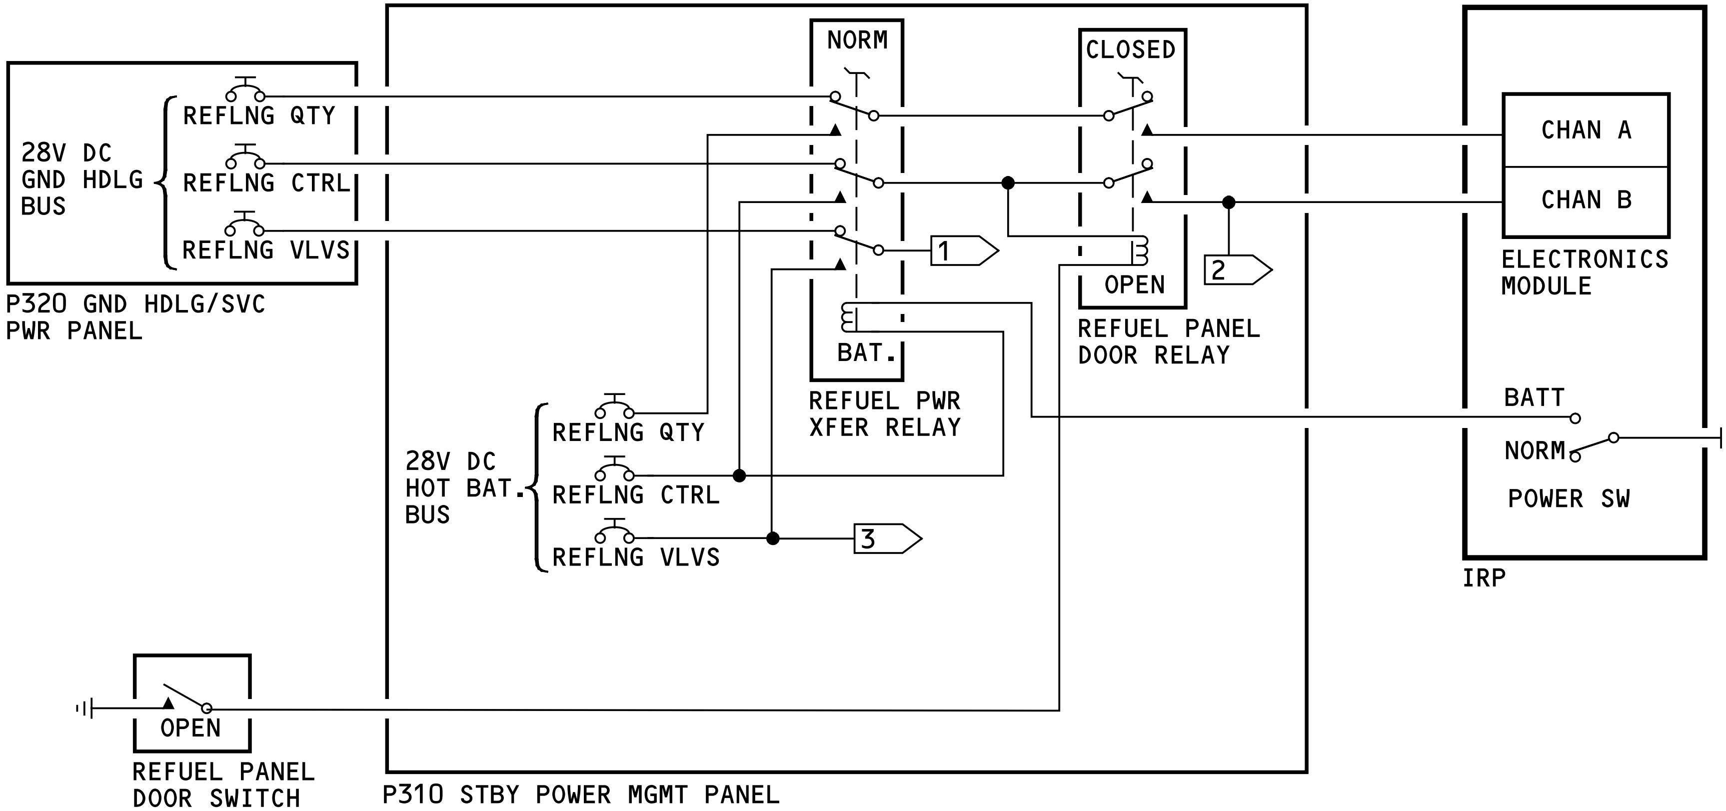
Power for the refuel system comes from the ground handling bus or the hot battery bus. Power control relays for the refuel system are in the standby power management panel.

Ground Handling Power

When the refuel panel door opens, the refuel panel door relay energizes. This permits power to go from the ground handling bus to the IRP.

Battery Bus Power

If the ground handling bus has no power, you close the refuel power (POWER) switch. This energizes the refuel power transfer relay and permits power to go from the hot battery bus to the IRP and the overfill control relay.



1 OVERFILL CONTROL RELAY

2 OVERFILL CONTROL RELAY COIL

3 REFUEL VALVE CONTROL RELAYS (6)

28-21-00-010 Rev 3 03/02/95

PRESSURE REFUEL - FUNCTIONAL DESCRIPTION - POWER

THIS PAGE INTENTIONALLY LEFT BLANK

PRESSURE REFUEL - FUNCTIONAL DESCRIPTION - CONTROL

General

During automatic refueling, you use the IRP to set the fuel load and to open the refuel valves. The FQPU closes the refuel valves.

During manual refueling, you use refuel valve control switches on the IRP to open and close the refuel valves

Refuel Valve Open Control

The refuel valves open when they get a refuel-valve-open command from the FQPU. The IRP sends refuel valve switch position signals to the FQPU on an ARINC 429 data bus. The FQPU sends refuel-valve-open commands on the systems ARINC 629 buses to the EEU in the P310 standby power management panel. The EEU supplies a ground to close each refuel valve control relay. This permits power to go to the related refuel valve solenoid. Fuel pressure opens the refuel valve.

Refuel Valve Close Control

Each refuel valve closes when the FQPU removes the related refuel-valve-open command.

When you put the refuel valve control switches in the close position, the FQPU removes the refuel-valve-open commands.

The FQPU automatically removes the refuel-valve-open commands for these conditions:

- Tank quantity reaches the load select value
- Tank quantity reaches the volumetric top-off (VTO) value
- System test switch is in (test position).

You set the load select value at the IRP. The refueling operation section describes this.

The FQPU memory has the VTO values for each tank. When a tank quantity equals the VTO value, the tank is full. The FQPU removes the refuel-valve-open commands for that tank.

Refuel Valve Indication

The refuel valve position switch closes when the valve opens. This sends a signal to the EEU. The EEU sends an ARINC 629 signal to the FQPU. The FQPU sends an ARINC 429 signal to the IRP. The IRP turns on the valve open light (not shown).

Overfill Protection

If fuel flows into a surge tank, the related surge tank float switch closes. This supplies a ground to energize the overfill control relay. The relay removes power from all the refuel valves. Immediately, all the refuel valves close at the same time.

The overfill control relay has a latching ground. After the fuel in the surge tank drains out, the relay stays energized. You must operate the overfill reset switch to remove the latching ground.

PRESSURE REFUEL - FUNCTIONAL DESCRIPTION - CONTROL

The overfill reset switch disables the overfill protection. When the overfill reset switch is in the reset position, the surge tank float switches and the overfill test switch can not energize the overfill control relay.

Overfill Test

You use the overfill test switch to do a test of the overfill protection. The switch supplies a ground, similar to a closed surge tank float switch, to energize the overfill control relay. Immediately, all the refuel valves close at the same time.

Overfill Indication

The overfill indication light on the IRP comes on for these conditions:

- A surge tank float switch is closed
- The overfill control relay is energized
- The overfill test switch is in (test position).

Training Information Point

When you set the total fuel load, the FQPU calculates the fuel load quantities for each tank two times. It calculates when you set the total fuel load, and when the main tanks are almost full. When the main tanks are almost full, the FQPU usually opens the center tank refuel valves again.

ENGINE FUEL FEED - INTRODUCTION

ENGINE FUEL FEED - GENERAL DESCRIPTION

General

The engine fuel feed system controls and supplies fuel to the engines. It uses these inputs:

- Fuel panel
- Fuel control switches
- Engine fire switches
- The ELMS.

The engine fuel feed system uses these components to supply fuel to the engines:

- Fuel pumps
- Fuel pump pressure switches
- Crossfeed valves
- Spar valves

The engine fuel feed system uses power from the ELMS and the engine fuel spar valve battery.

Fuel Pump Control

Each fuel pump has a switch on the fuel panel. The switches control relays in the ELMS to supply power to the pumps.

Fuel Pump Pressure Switches

Pump pressure switches send low pressure signals to the ELMS. The ELMS sends the signals through OPAS to turn on the low pressure lights on the pump switches.

Crossfeed Valves Control

The crossfeed valve switches on the fuel panel directly control the crossfeed valves. The ELMS supplies the power that opens or closes the valves.

Spar Valve Control

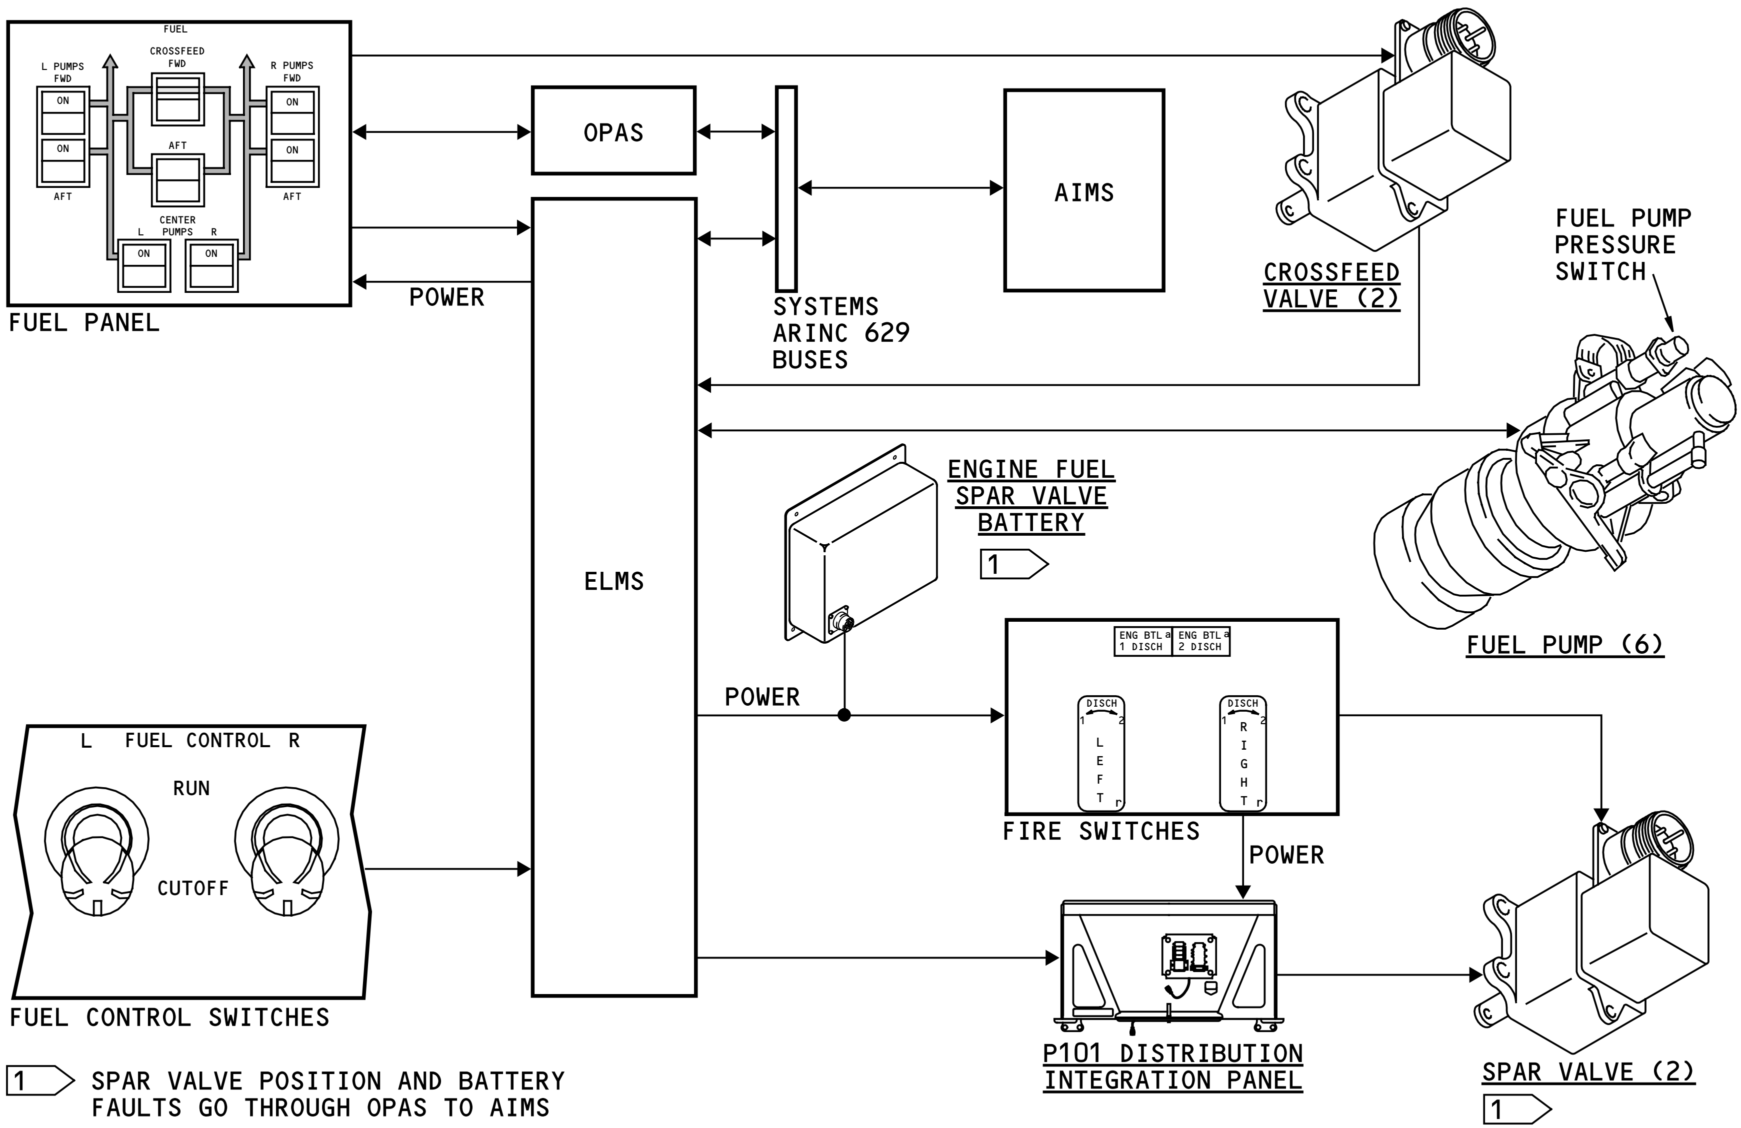
The fuel control switches control relays to open and close the spar valves. The engine fire switch must be down to permit the power to get through the relays to the spar valve.

The fire switch also has a direct circuit to the spar valve. This closes the valve when you pull the fire switch.

The hot battery bus (ELMS) or the engine fuel spar valve battery supply the power to open or close the spar valve.

Fault Indication

The ELMS compares fuel panel switch positions with crossfeed valve and fuel pump relay positions to look for disagreements. The ELMS receives switch positions on the systems ARINC 629 buses. The OPAS reports faults of the spar valves and the engine fuel spar valve battery. Faults go to the AIMS for indication.



ENGINE FUEL FEED - GENERAL DESCRIPTION

ENGINE FUEL FEED - COMPONENT LOCATIONS - TANKS

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE FUEL FEED - COMPONENT LOCATIONS - TANKS

General

The engine fuel feed system has these components:

- Fuel suction bypass valve (2)
- Outlet float-operated shutoff valve (2)
- Crossfeed valve (2)
- Engine feed manifold
- Override/jettison pump (2)
- Scavenge jet pump (6)
- Inlet float-operated shutoff valve (2)
- Boost Pump (4)
- Spar valve (2).

Main Tank Fuel Suction Bypass Valves

There is one fuel suction bypass valve in each main tank. It attaches to the engine feed manifold. You get access to the bypass valve through the fourth fuel tank access door.

Fuel Crossfeed Valves

The forward and aft crossfeed valves isolate the left and right sides of the engine feed manifold. Both valve bodies are in the left side of the center tank. You get access to the valve bodies through the first fuel tank access door in the left wing. The valve actuators are on the rear spar aft of the first fuel tank access door.

Engine Feed Manifold

The engine feed manifold connects the output of the fuel pumps to the engine fuel main supply line. Sections of the manifold are in the center tank and the main tanks.

Center Fuel Tank Override/Jettison Pumps

There are two override/jettison pumps that attach to the rear spar of the center tank. You get access to the pumps in the main wheel wells.

Scavenge Jet Pumps

There are four water scavenge jet pumps and two center tank fuel scavenge jet pumps. Each main tank has one water scavenge jet pump on the rear spar aft of the Fourth fuel tank access door.

Each side of the center tank has a water scavenge jet pump and a fuel scavenge jet pump. The water scavenge jet pumps are on the rear spar of the center fuel tank. The fuel scavenge jet pumps are on the rear spars of the wings.

Float-Operated Shutoff valves

Each center tank fuel scavenge jet pump has an inlet and an outlet float-operated shutoff valve. You get access to the inlet valve through the first fuel tank access door. You get access to the outlet valve through the seventh fuel tank access door.

ENGINE FUEL FEED - COMPONENT LOCATIONS - TANKS

Main Fuel Tank Fuel Boost Pumps

Each main tank has a forward and an aft boost pump. The boost pumps are on the rear spar. The left forward boost pump is aft of the fourth fuel tank access door. The left aft boost pump is aft of the third fuel tank access door. The right tank boost pumps are in a similar position on the right rear spar.

Engine Fuel Spar Valves

There is one spar valve in each main tank. You get access to the valve bodies through the fifth fuel tank access doors. The valve actuators are on the rear spar aft of the fifth fuel tank access doors.

ENGINE FUEL FEED - OVERRIDE/JETTISON PUMP

General

The override/jettison pumps supply fuel from the center tank to the engine feed manifold. They also supply fuel to the refuel/jettison manifold during fuel jettison.

The override/jettison pumps can supply fuel at a pressure of 36 psi and a flow rate of 70,000 pounds (31,750 kgs) per hour. Each pump assembly has a motor-impeller and a housing.

Location

There is one override/jettison pump in each main landing gear wheel well, at the rear spar. The housings are inside the center wing section, on the rear spar. The motor-impellers install in the housings.

Pump Housing

The housing contains the motor-impeller and these valves:

- Discharge check valve
- Motive flow check valve
- Vapor vent valve
- Inlet valve.

The discharge check valve prevents engine feed manifold fuel from flowing back through the pump.

The motive flow check valve prevents fuel from the scavenge pumps from flowing back through the pump.

The vapor vent valve permits fuel vapor to go into the tank, but does not permit fuel to enter the pump.

The inlet valve is a gate valve that closes when you remove the pump. This permits you to remove the pump when the tanks have fuel in them.

Motor-Impeller

The motor-impeller uses 115v ac power. Each pump has these parts:

- Electrical connector
- Pressure switch
- Drain plug
- Extraction lever.

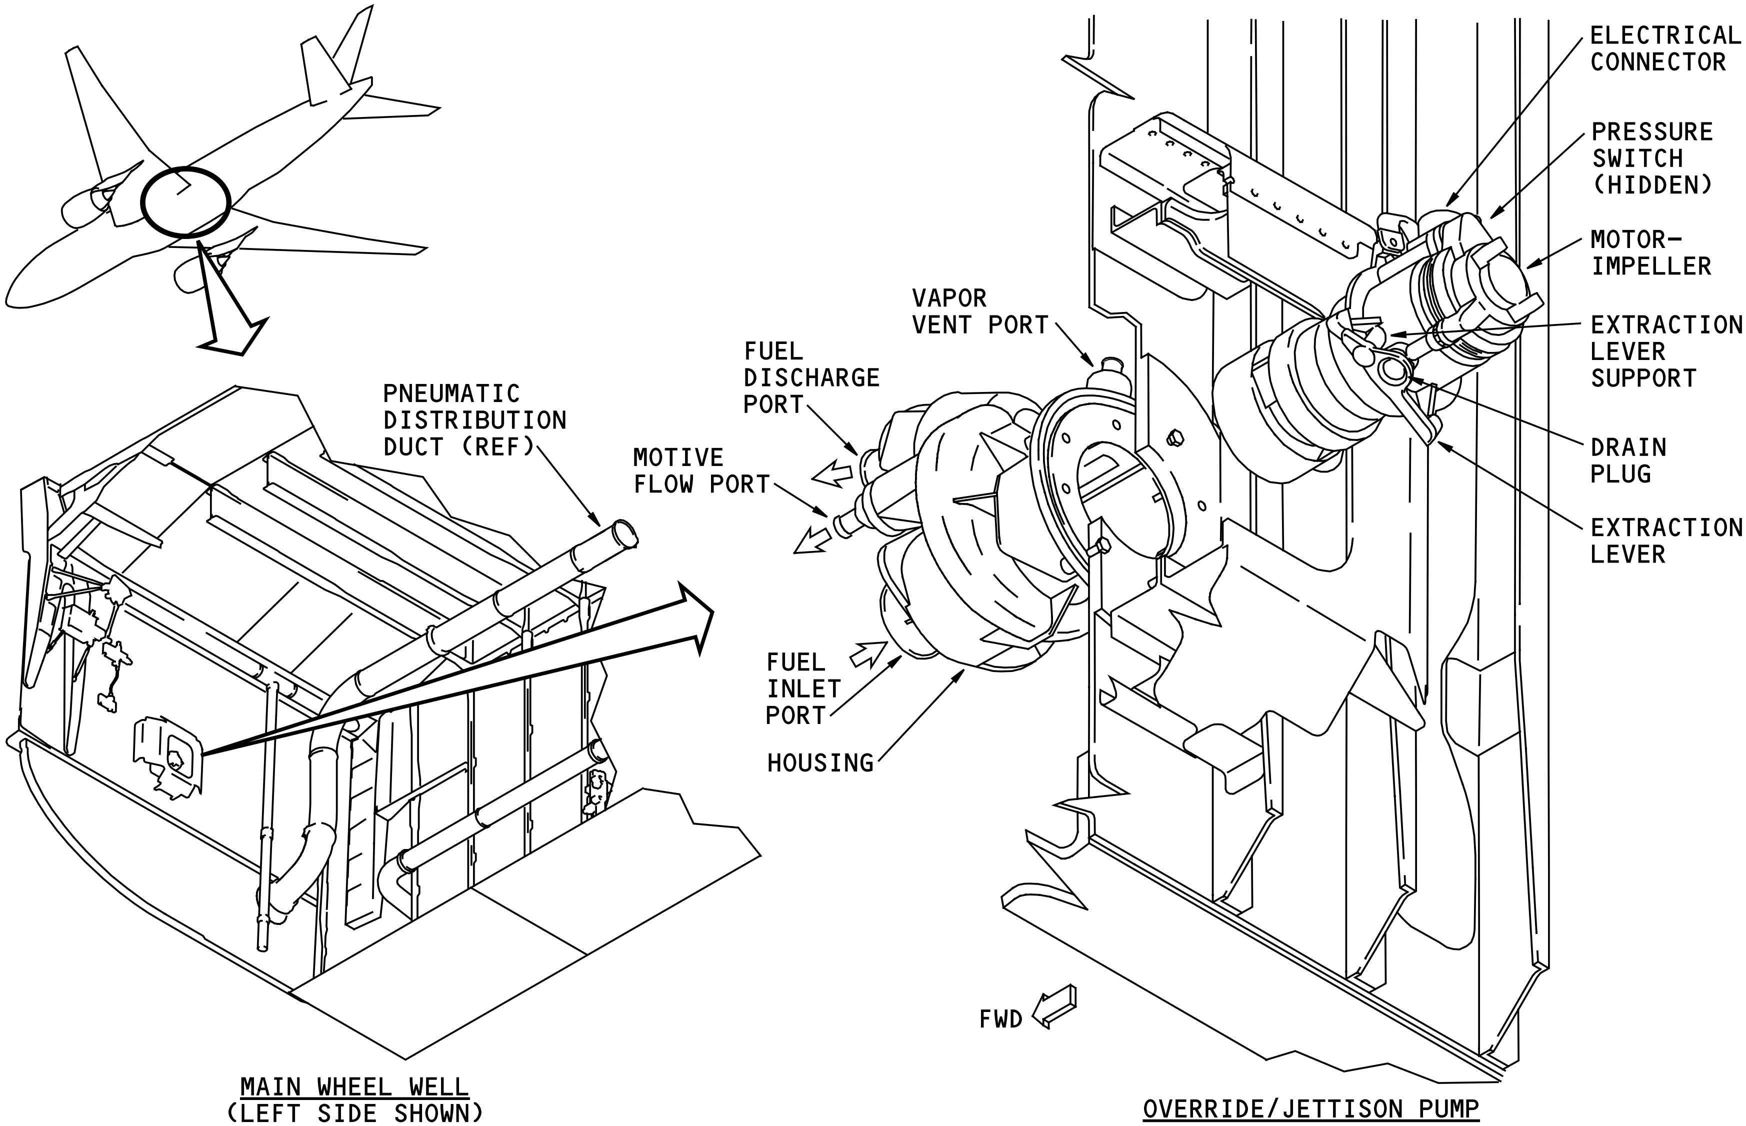
Training Information Point

The override/jettison pump motor-impellers are interchangeable with the jettison pump motor-impellers.

To remove the motor-impeller, you rotate it 35 degrees CCW to close the inlet valve. Then you remove the drain plug to remove residual fuel. You use the extraction lever to move the motor-impeller out of the housing.

To install the motor-impeller, you must align pins in the housing to slots on the motor-impeller.

You can remove the discharge, motive flow, and vapor vent valves through the housing from outside the tank.



28-22-00-004 Rev 4

ENGINE FUEL FEED - OVERRIDE/JETTISON PUMP

ENGINE FUEL FEED - CENTER TANK FUEL SCAVENGE JET PUMP

Purpose

The fuel scavenge jet pumps take fuel from the low points in the center tank and send it to the main tanks. This increases the amount of usable fuel in the center tank. Float-operated shutoff valves prevent fuel scavenge when the main tanks are full.

Location

There is one fuel scavenge jet pump in each side of the center tank. They are in the left and right wheel wells on the rear spar.

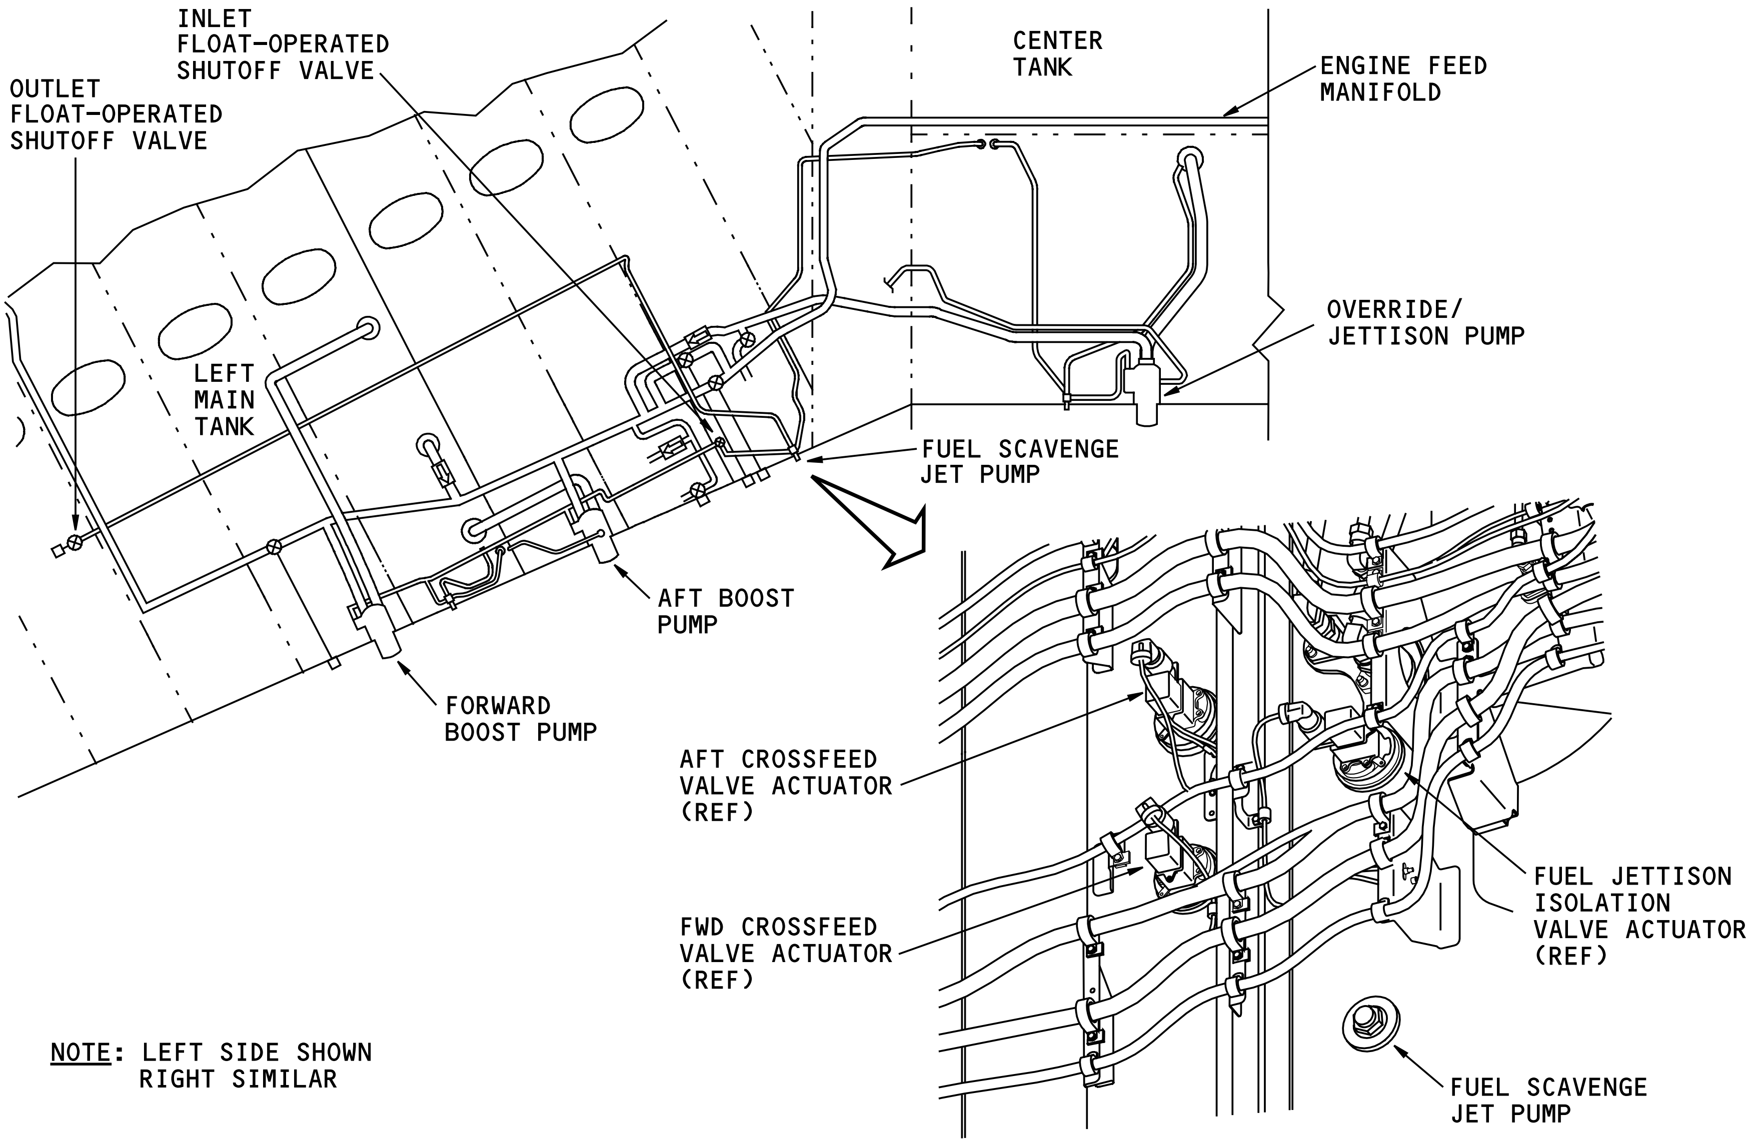
There is an outlet float-operated shutoff valve in each main tank. You get access to these valves through the seventh fuel tank access door.

There is an inlet float-operated shutoff valve in each side of the center tank. You get access to these valves through the first fuel tank access door.

Functional Description

The jet pumps operate automatically when the boost pumps are on. They use fuel from the boost pumps as motive fuel. The flow of the motive fuel through the jet pump causes suction that takes fuel from the center tanks. The fuel goes through the jet pump discharge lines to the main tanks. When the main tanks are full, the outlet float-operated shutoff valve closes to stop fuel flow through the discharge line.

The inlet float-operated shutoff valve prevents motive flow to the jet pump until the center tank is almost empty. This prevents the fuel from flowing into the main tank too early if the outlet float-operated shutoff valve fails. A check valve in the jet pump prevents fuel movement from the main tank to the center tank.



28-22-00-005 Rev 5 03/18/96

ENGINE FUEL FEED - CENTER TANK FUEL SCAVENGE JET PUMP

ENGINE FUEL FEED - BOOST PUMP

General

The boost pumps supply main tank fuel to the engine feed manifold.

The boost pumps can supply fuel at a pressure of 12 psi and a flow rate of 35,200 pounds (16,000 kgs) per hour. Each pump assembly has a motor-impeller and a housing.

Location

There are two boost pumps in each main tank. The forward boost pumps are on the rear spar, outboard of each main landing gear shock strut. The aft boost pumps are on the rear spar, inboard of each main landing gear shock strut. The housings are inside the tanks, on the rear spar. The motor/impellers install in the housings.

Pump Housing

The housing contains the motor-impeller and these valves:

- Discharge check valve
- Motive flow check valve
- Vapor vent valve
- Inlet valve.

The discharge check valve prevents engine feed manifold fuel from flowing back through the pump.

The motive flow check valve prevents fuel from the scavenge pumps from flowing back through the pump.

The vapor vent valve permits fuel vapor to go into the tank, but does not permit fuel to enter the pump.

The inlet valve is a gate valve that closes when you remove the pump. This permits you to remove the pump when the tanks are full.

Motor-Impeller Unit

The motor-impeller uses 115v ac power. Each pump has these parts:

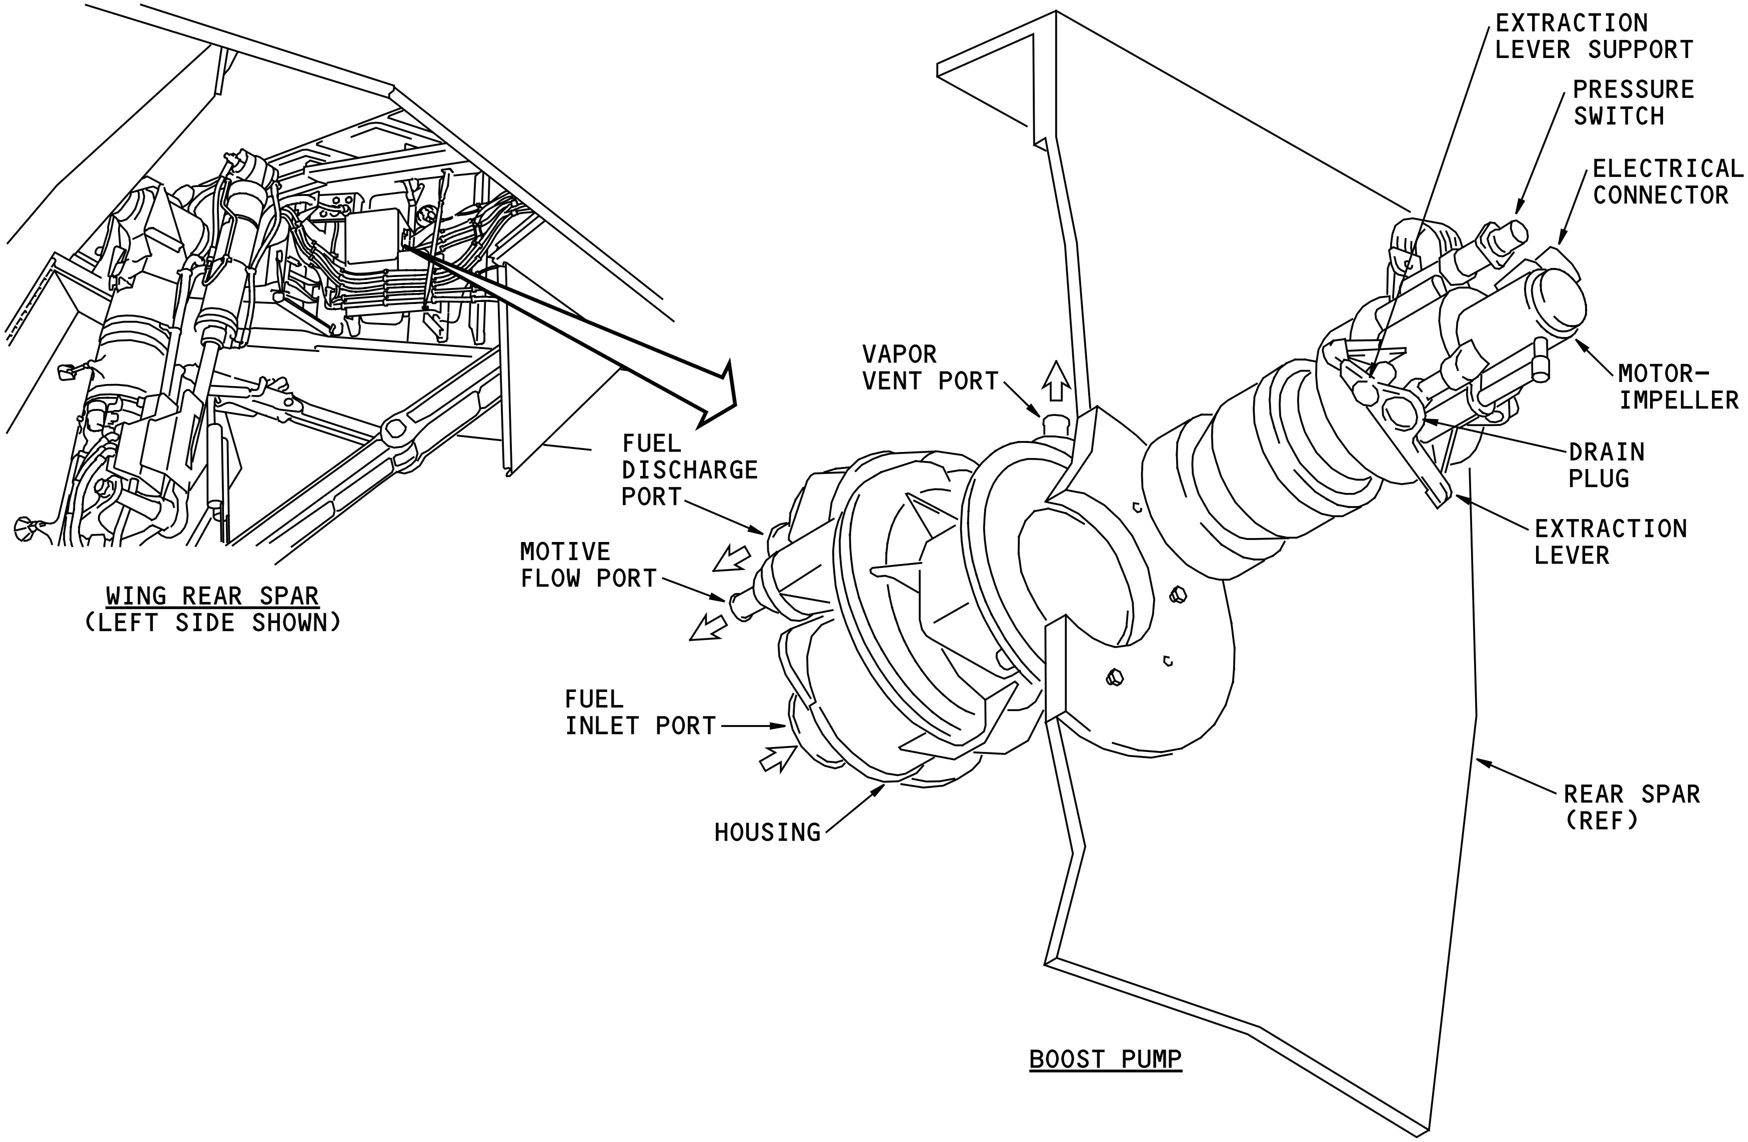
- Electrical connector
- Pressure switch
- Drain plug
- Extraction lever.

Training Information Point

To remove the motor-impeller, you turn it 35 degrees CCW to close the inlet valve. Then you remove the drain plug to remove residual fuel. You use the extraction lever to move the motor-impeller out of the housing.

To install the motor-impeller, you must align pins in the housing to slots on the motor-impeller.

You can remove the discharge, motive flow, and vapor vent valves through the housing from outside the tank.



ENGINE FUEL FEED - BOOST PUMP

ENGINE FUEL FEED - WATER SCAVENGE JET PUMP

General

The water scavenge jet pumps take fluid from the low points in the tanks and send it to the pump inlets. This prevents water from collecting in the bottom of the tanks.

Location

The water scavenge jet pumps are on the rear spar. There is one jet pump in each side of the center tank and one in each main tank.

Functional Description

The jet pumps operate automatically when the fuel pumps are on. They use fuel from the fuel pumps as motive fuel. The flow of the motive fuel through the jet pump causes suction that takes fluid from the low points in the tanks.

28-22-00-007 Rev 3 03/18/96

ENGINE FUEL FEED - WATER SCAVENGE JET PUMP

ENGINE FUEL FEED - MOTOR-ACTUATED VALVES

General

The fuel system has 11 motor-actuated valves. These seven valves have a valve body, an adapter/shaft and an actuator:

- Engine fuel spar valves (2)
- Fuel crossfeed valves (2)
- Fuel jettison isolation valves (2)
- Defuel valve.

These four valves have the same actuator, a different valve body, but no adapter/shaft:

- APU fuel shutoff valve
- APU fuel isolation valve
- Fuel jettison nozzle valves (2).

Valve Body

The valve body connects two fuel lines. It has these parts:

- Butterfly valve (not shown)
- Operating shaft
- Thermal relief valve.

There are no hard stops for the valve body. You look at alignment marks to find out if the valve is closed.

Adapter

The adapter/shaft mounts through the rear spar. It has these parts:

- Mount plate
- Index plate
- Adapter shaft.

The adapter shaft connects the adapter to the operating shaft on the valve body.

The index plate attaches to the mount plate with three screws. You loosen these screws to rotate the index plate when you align the valve. You must get access to the valve body to check the valve position when you align it.

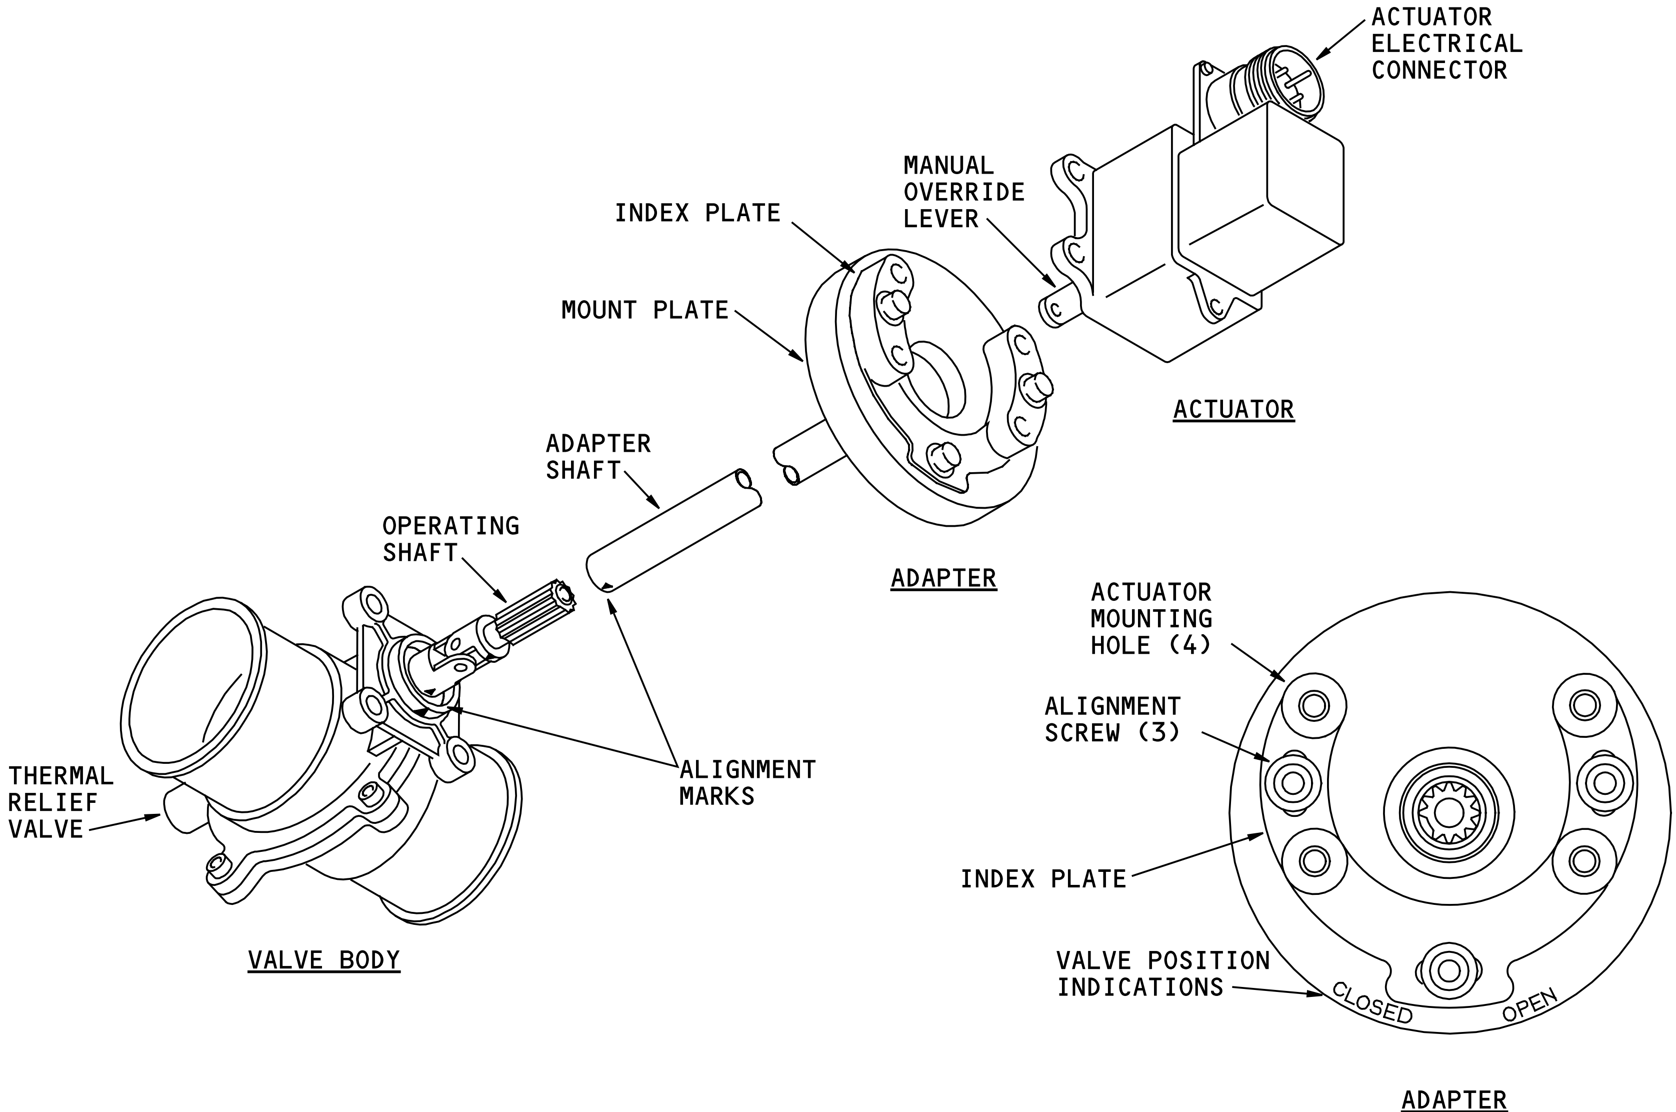
Actuator

The actuator is a 28v dc motor. It has a manual override lever that permits you to operate the actuator without electrical power. The lever aligns with marks on the adapter. This shows you the valve position.

You can remove the actuator without defueling the airplane.

Training Information Point

The valves use interchangeable actuators.



ENGINE FUEL FEED - MOTOR-ACTUATED VALVES

ENGINE FUEL FEED - SPAR VALVE BATTERY

Purpose

The engine fuel spar valve battery makes sure that the fuel system always has power to close these shutoff valves:

- Engine fuel spar valves
- APU fuel shutoff valve.

Components

The engine fuel spar valve battery has these components:

- Aluminum case
- Battery pack
- Printed circuit board assembly
- Electrical connector.

Battery Assembly

The battery pack contains rechargeable nickel-cadmium batteries. They supply 28v dc power to the valve actuators.

Printed Circuit Board Assembly

The printed circuit board assembly has these functions:

- Switching
- Charging
- Testing.

The switch circuit monitors the voltage of the hot battery bus. If the voltage becomes less than 22v, the switch circuit supplies power from the spar valve battery to the valve actuator circuits.

The charge circuit uses power from the right main dc bus to charge the batteries.

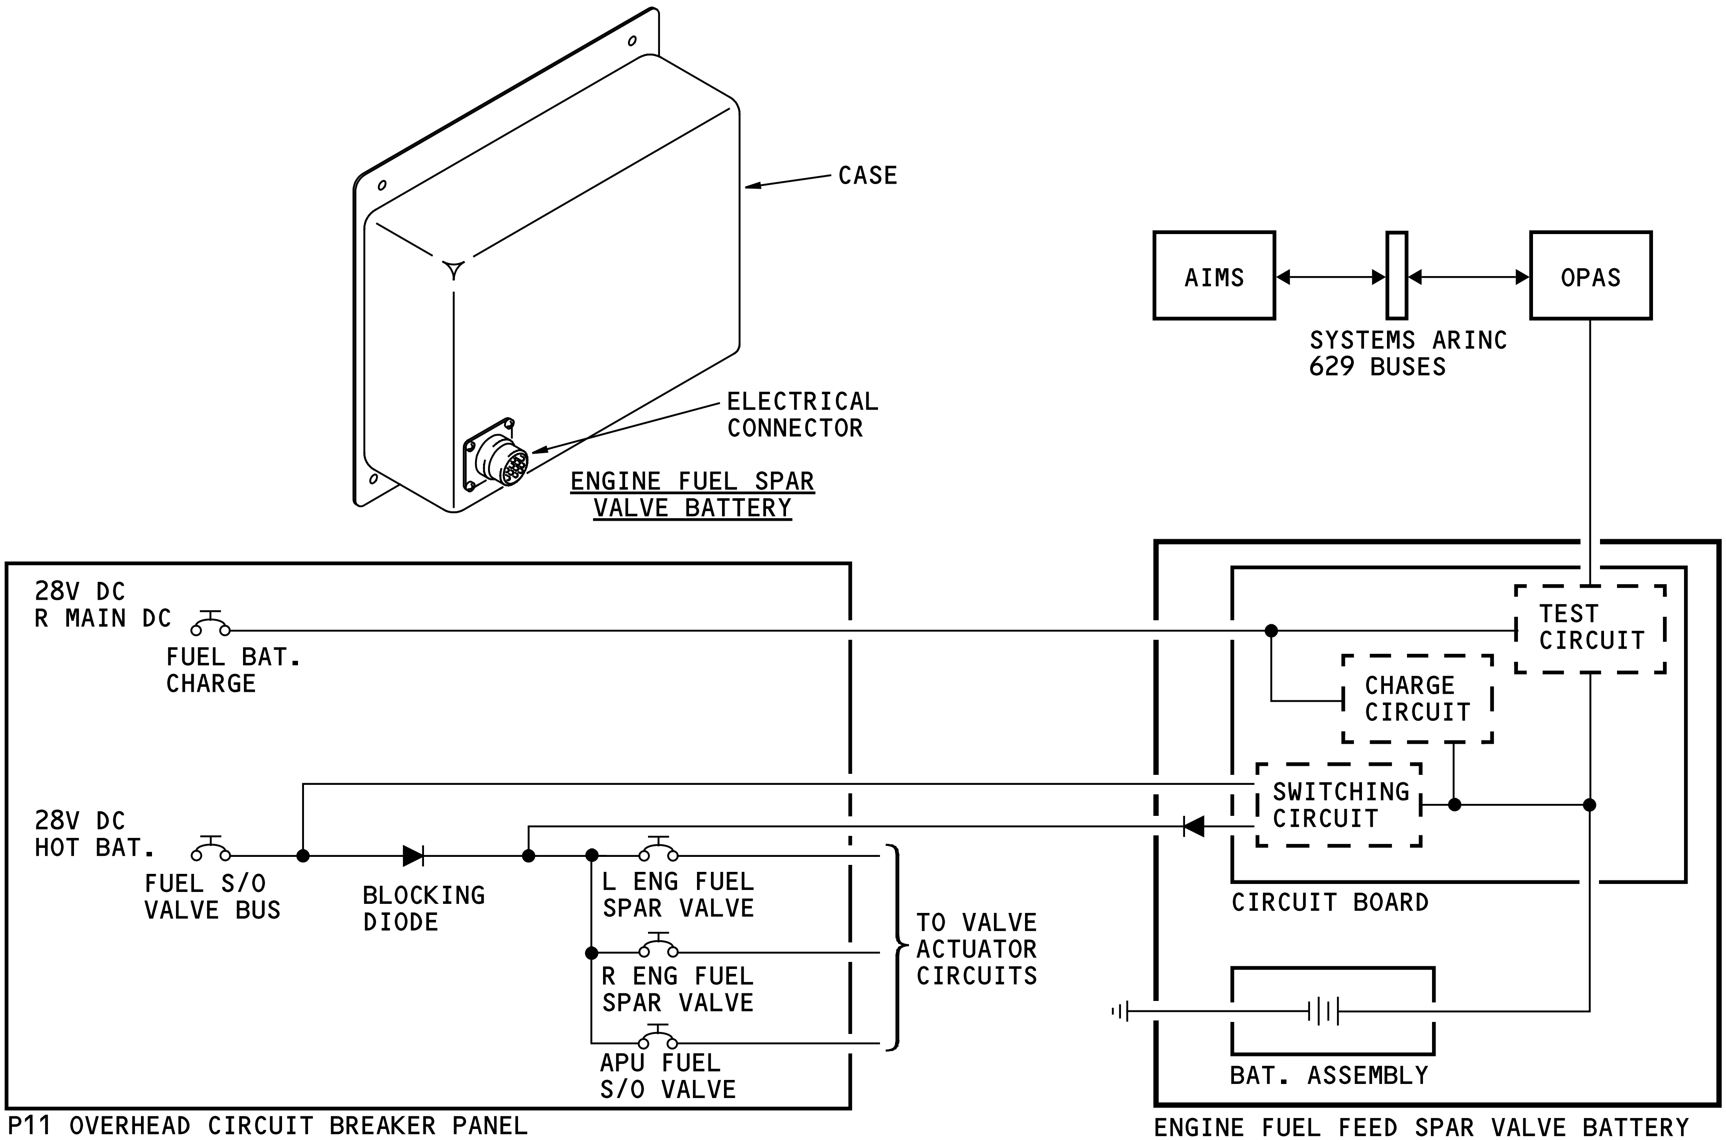
The test circuit does automatic tests of the spar valve battery. It also continuously monitors the battery for these faults:

- Voltage
- Shorted cell
- Open cell
- One battery section has lower voltage than the other battery section.

The test circuit sends a status signal to OPAS that tells the AIMS if the batteries have sufficient capacity. It sends a health signal to OPAS that tells the AIMS if a fault is found. The AIMS shows the EICAS status message FUEL SOV BATTERY when there is a fault.

Training Information Point

There is a airplane maintenance manual (AMM) test of the blocking diode for the fuel shutoff valve bus. The blocking diode is in the P11 panel.



ENGINE FUEL FEED - SPAR VALVE BATTERY

ENGINE FUEL FEED - FUNCTIONAL DESCRIPTION - FUEL FLOW

General

The normal procedure for engine fuel feed operation is to supply fuel from the center tank first. When the center tank is empty, you supply fuel from the main tanks.

If you open a crossfeed valve, you can feed an engine from the opposite main tank to correct a fuel imbalance between the main tanks.

The engines can also use suction feed from a main tank.

Center Tank Engine Feed

When the override/jettison pumps are on and there is fuel in the center tank, fuel goes from the center tank into the engine feed manifold. When the spar valves open, fuel goes from the engine feed manifold to the engines.

Main Tank Engine Feed

When the center tank is empty and the boost pumps are on, fuel goes from the main tanks into the engine feed manifold.

Cross Feed

The crossfeed valves isolate the left and right sides of the engine feed manifold. If a crossfeed valve is open, an engine can receive fuel from the fuel pumps on the opposite side.

Suction Feed

Suction (gravity) feed occurs when all the pumps on one side are off and the crossfeed valves are closed. During suction feed, the engine gets fuel through the suction bypass valve. The engines can only suction feed from the main tanks.

ENGINE FUEL FEED - FUNCTIONAL DESCRIPTION - FUEL FLOW

ENGINE FUEL FEED - FUNCTIONAL DESCRIPTION - LEFT FORWARD BOOST PUMP CONTROL

General

The left forward boost pump receives 115v ac power from two sources: the ground service bus or the left transfer bus.

The boost pump control switch controls power to the pump. A light on the switch shows when there is low pressure at the pump outlet.

Ground Service Bus Power

The usual power source for the boost pump is the ground service bus. Power goes through the boost pump switching and control relays to the pump.

Power from the ground service bus automatically closes the boost pump switching relay.

Left Transfer Bus Power

The left transfer bus is an alternative power source for the left forward boost pump. The left aft boost pump switch must be off for the forward boost pump to receive power from the left transfer bus. This prevents both boost pumps from operating when the backup generator is the power source.

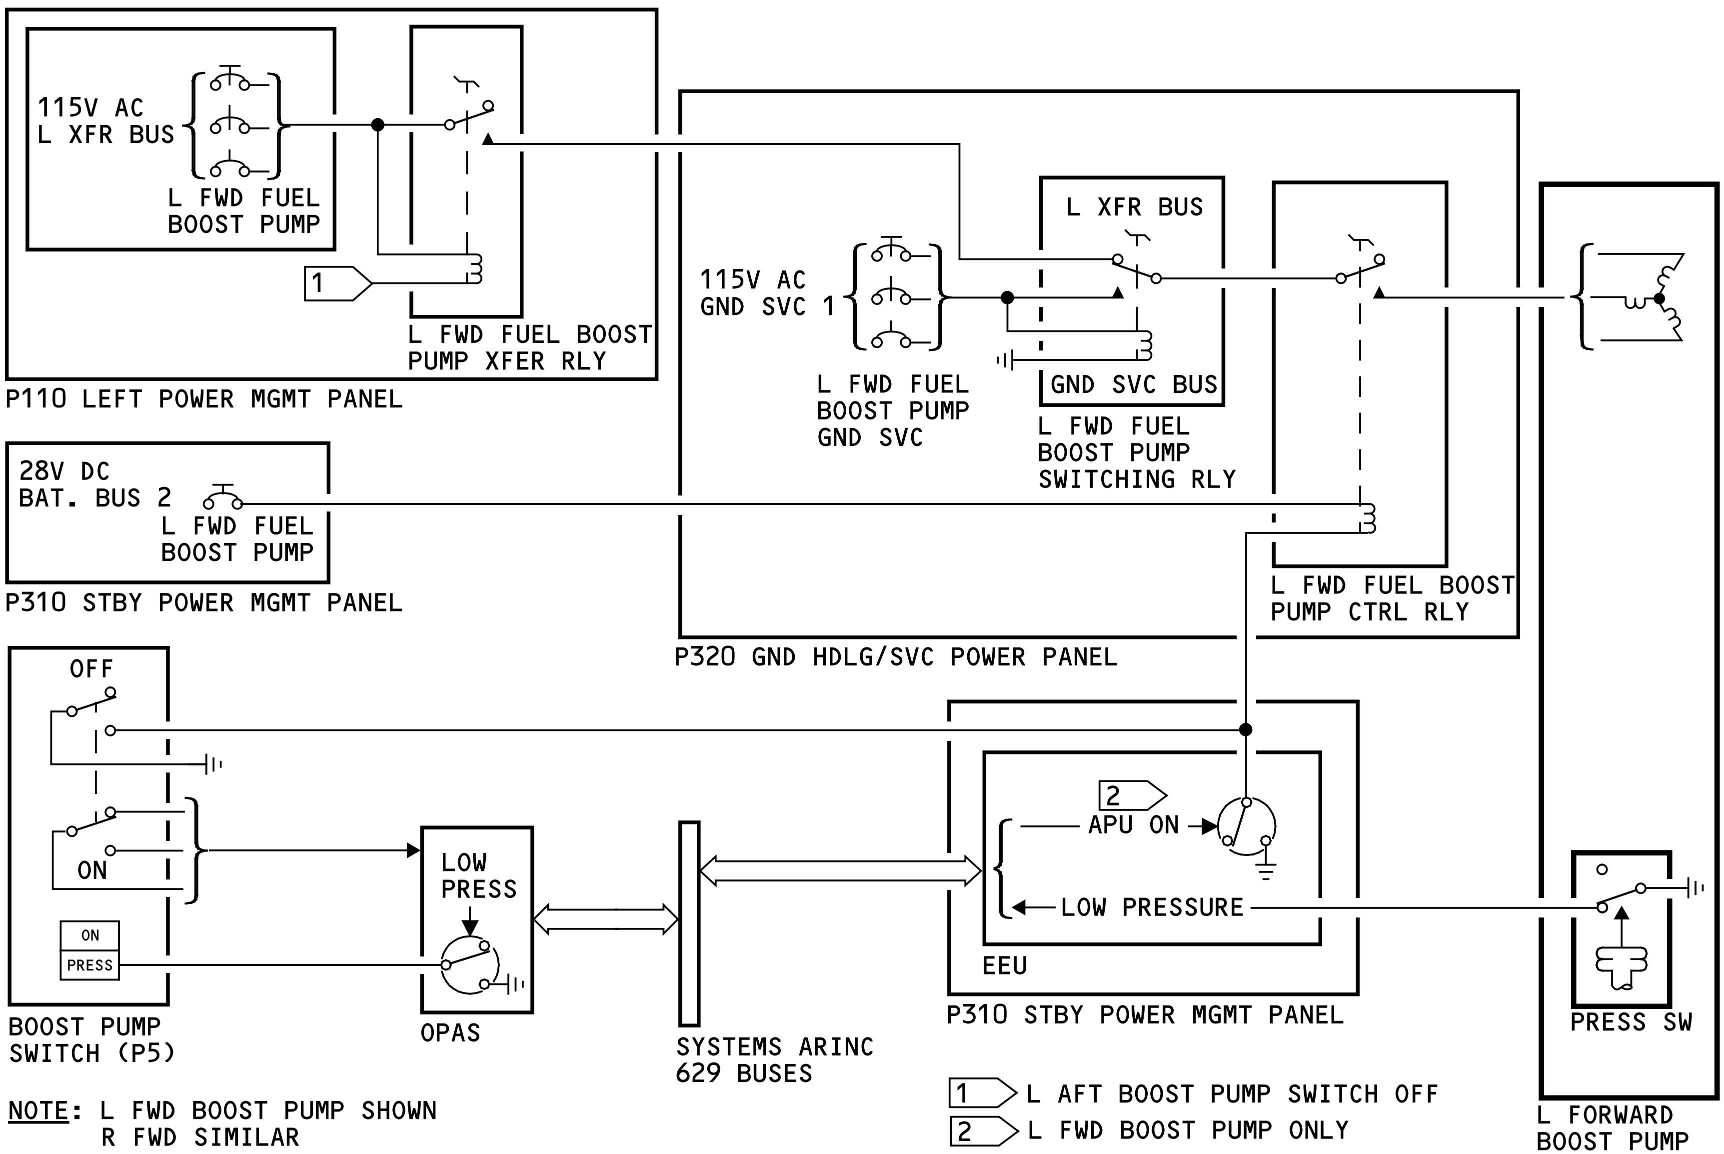
Boost Pump Power Control

The boost pump control switch supplies a ground to close the boost pump control relay.

The ELMS logic can also supply a ground to close the boost pump control relay. It does this when the airplane is on the ground and the APU selector is on or the APU is running. This permits the APU to get fuel when the boost pump switches are off.

Pressure Indication

The pressure light on the boost pump control switch shows low pump pressure. The boost pump pressure switch closes when there is low pressure at the pump outlet. The ELMS electronics unit sends a signal through OPAS to turn on the low pressure light.



NOTE: L FWD BOOST PUMP SHOWN
R FWD SIMILAR

ENGINE FUEL FEED - FUNCTIONAL DESCRIPTION - LEFT FORWARD BOOST PUMP CONTROL

ENGINE FUEL FEED - FUNCTIONAL DESCRIPTION - LEFT AFT BOOST PUMP CONTROL

General

This page shows control for the left aft boost pump. Control of the right aft boost pump is almost the same.

The left aft boost pump receives 115v ac power from the left transfer bus.

Left Aft Boost Pump Control

The boost pump control switch closes the boost pump control relay in the left power management panel. This permits power to go from the left transfer bus to the boost pump.

Pressure Indication

The boost pump control switch has a light to show when there is low pressure at the pump outlet. The boost pump pressure switch closes when there is low pressure. The ELMS logic sends a signal through OPAS to turn on the low pressure light in the switch.

1 TO L FWD FUEL BOOST PUMP XFER RELAY

ENGINE FUEL FEED - FUNCTIONAL DESCRIPTION - LEFT AFT BOOST PUMP CONTROL

ENGINE FUEL FEED - FUNCTIONAL DESCRIPTION - LEFT CENTER OVERRIDE/JETTISON PUMP CONTROL

General

The left center override/jettison pump receives 115v ac power from the left main bus. Control of the right center override/jettison pump is almost the same.

Left Center Override/Jettison Pump Control

The center left fuel pump switch supplies a ground to an electrical load control unit (ELCU) in the left power panel. The ELCU uses a control relay to close an internal contactor. This permits power to go from the left main bus to the pump.

The ELCU receives power from the left main dc bus. When the airplane is on the ground and has only one external power source, the ELMS removes the dc power to the ELCU. The right override/jettison pump operates the same. This inhibits the pump and prevents an electrical power overload. During the inhibit no EICAS message shows.

If the APU generator is the single power source, you can operate the left override/jettison pump. You cannot operate the right override/jettison pump if the APU generator is the only power source.

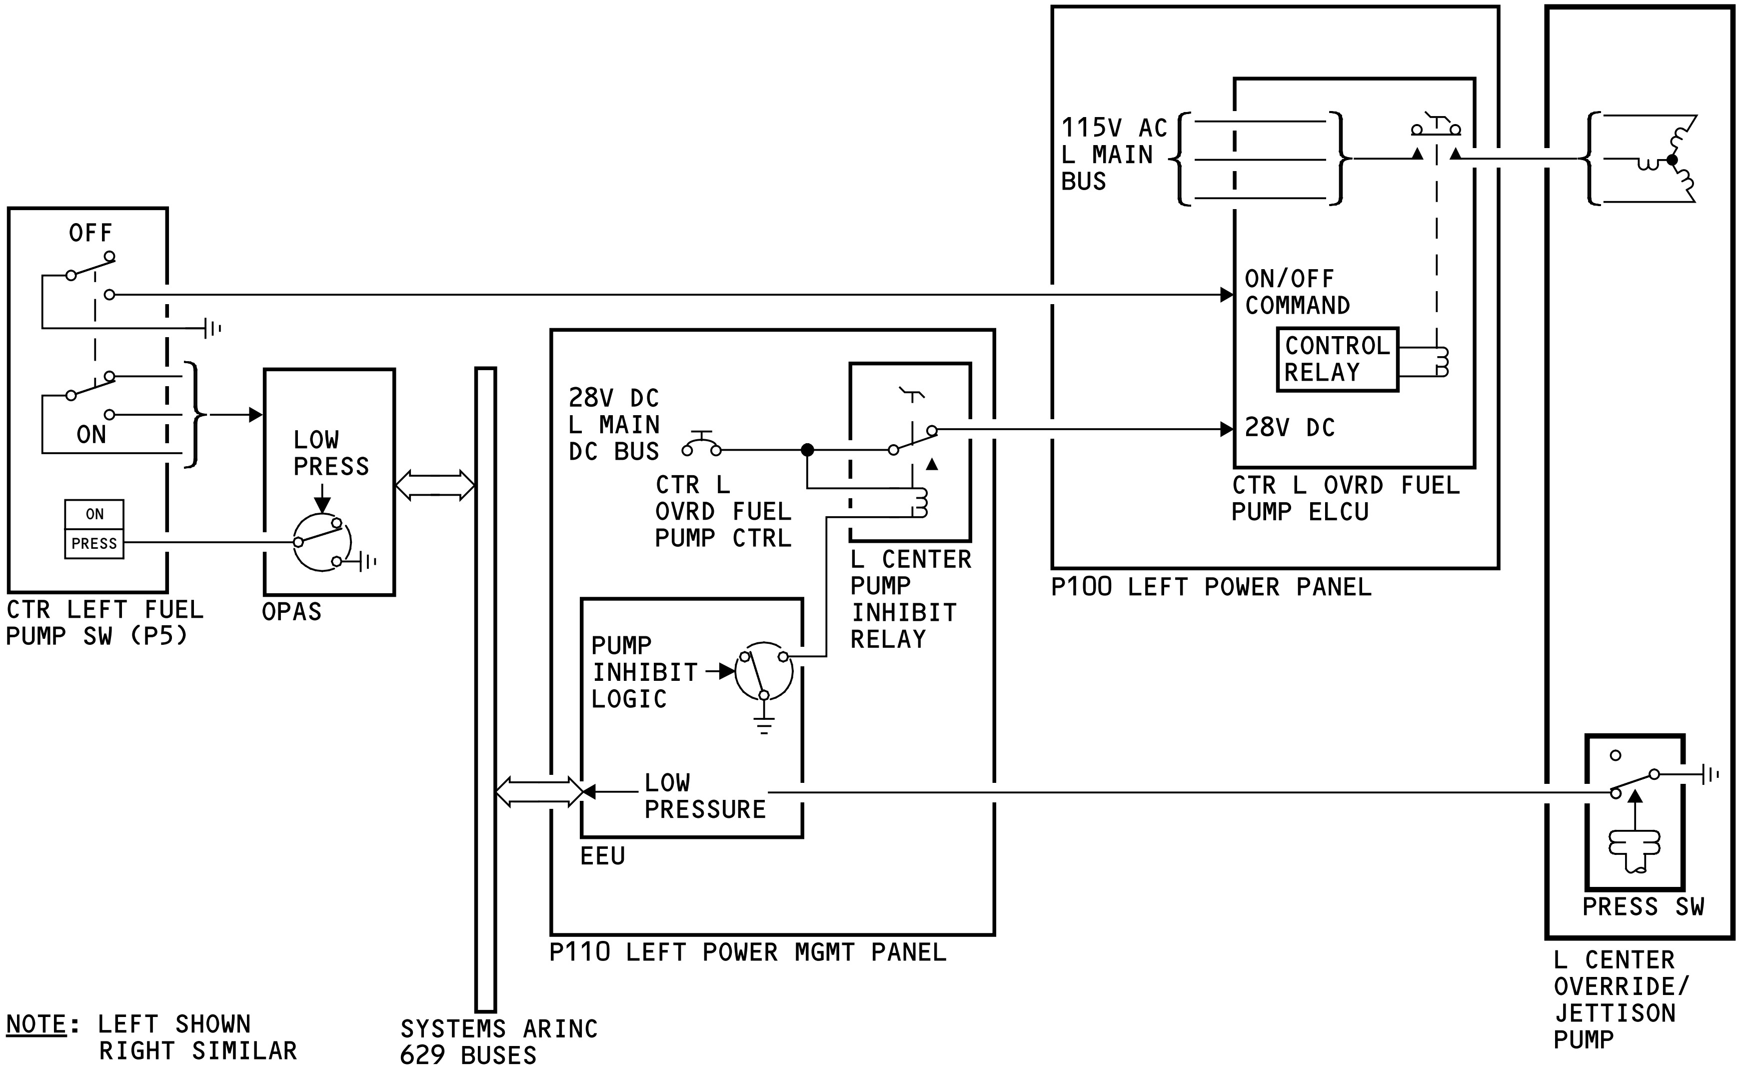
If an IDG is the single power source, you can operate the related override/jettison pump.

The pump inhibit logic does not operate during these conditions:

- The air/ground system is set to air mode
- A refuel panel door is open
- The fuel jettison arm switch is in the armed position.

Pressure Indication

The pressure light on the switch shows low pump pressure. The override/jettison pump pressure switch closes when there is low pressure at the pump outlet. The EEU sends a signal through the OPAS to turn on the pressure light on the switch. The pressure light will come on only when the pump is commanded on.



NOTE: LEFT SHOWN

28-22-00-012 Rev 5 03/31/95

ENGINE FUEL FEED - FUNCTIONAL DESCRIPTION - LEFT CENTER OVERRIDE/JETTISON PUMP CONTROL

ENGINE FUEL FEED - FUNCTIONAL DESCRIPTION - ENGINE FUEL SPAR VALVE

General

The engine fuel spar valves get power to operate from the hot battery bus or the spar valve battery. The fuel control switches control relays to operate the spar valves. The engine fire switch must be down to permit the spar valve to open.

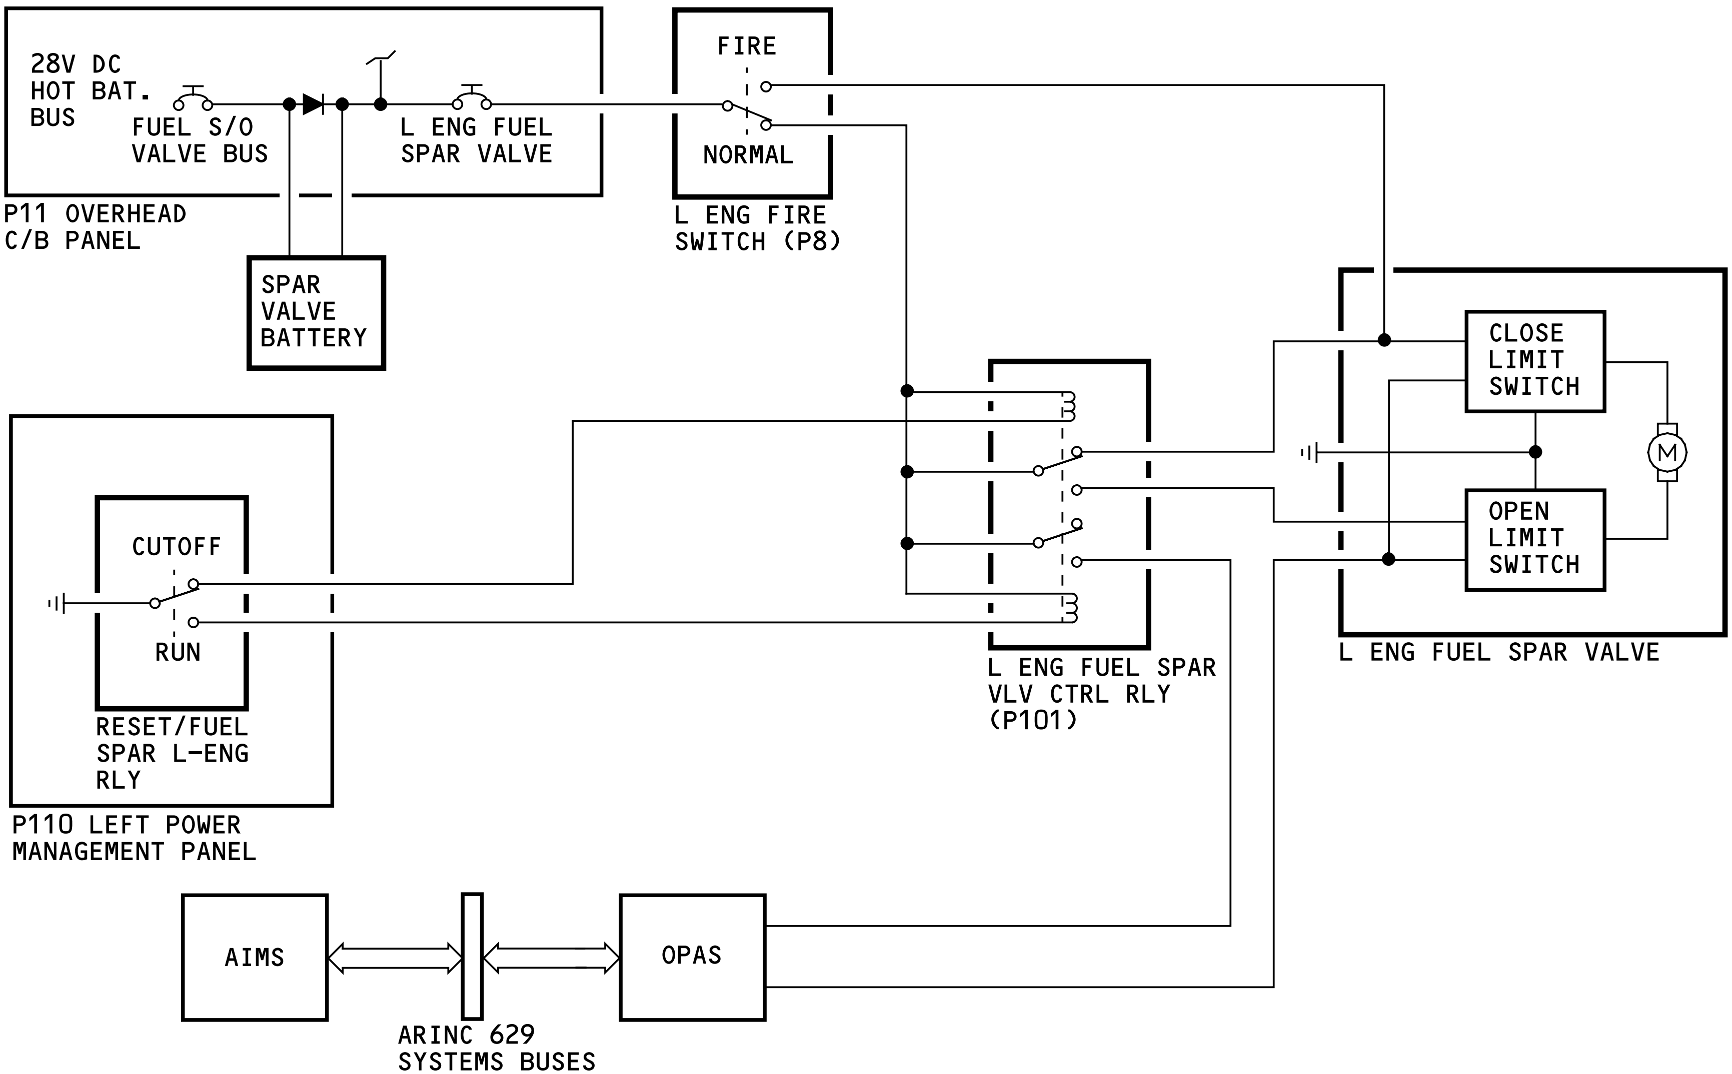
Control

Power goes through engine fuel spar valve control relay to the spar valve. The fuel control switch controls the reset/fuel spar relay to move the control relay. When the fuel control switch is in the RUN position, the open coil in the control relay energizes. This sends power to open the spar valve. When the fuel control switch is in the CUTOFF position, the close coil in the control relay energizes. This sends power to close the valve.

Power to operate the valve goes through limit switches to the actuator. The actuator moves the valve to the commanded position. When the valve is in the commanded position, the limit switches remove power from the actuator.

Fault Indications

The OPAS monitors the spar valve control relay position and the spar valve position. If there is a disagreement between the relay position and valve position, the OPAS sends a fault message to the AIMS. The fault messages cause an EICAS status message.



NOTE: LEFT SHOWN, RIGHT SIMILAR

ENGINE FUEL FEED - FUNCTIONAL DESCRIPTION - ENGINE FUEL SPAR VALVE

ENGINE FUEL FEED - FUNCTIONAL DESCRIPTION - CROSSFEED VALVE CONTROL

Control

The crossfeed valve switches on the P5 directly control the crossfeed valves. A 28v dc bus supplies power to the crossfeed valve actuator. When you push the switch, you supply power through the limit switches to the actuator. The actuator moves the valve to the commanded position. When the valve is in the commanded position, the limit switches remove power from the actuator and send power to the ELMS valve agree status logic.

Fault Indications

The VALVE light comes on to show the related valve is in transit, or a valve disagree fault exists. The light comes on when the valve position disagrees with the switch position. The ELMS controls the light. An EEU sends a valve disagree message to the OPAS to cause the OPAS to turn on the light.

If the valve disagree condition exists for more than 10 seconds, the ELMS sends a fault signal to the AIMS. The AIMS shows the related EICAS advisory and status messages.

ENGINE FUEL FEED - INDICATIONS

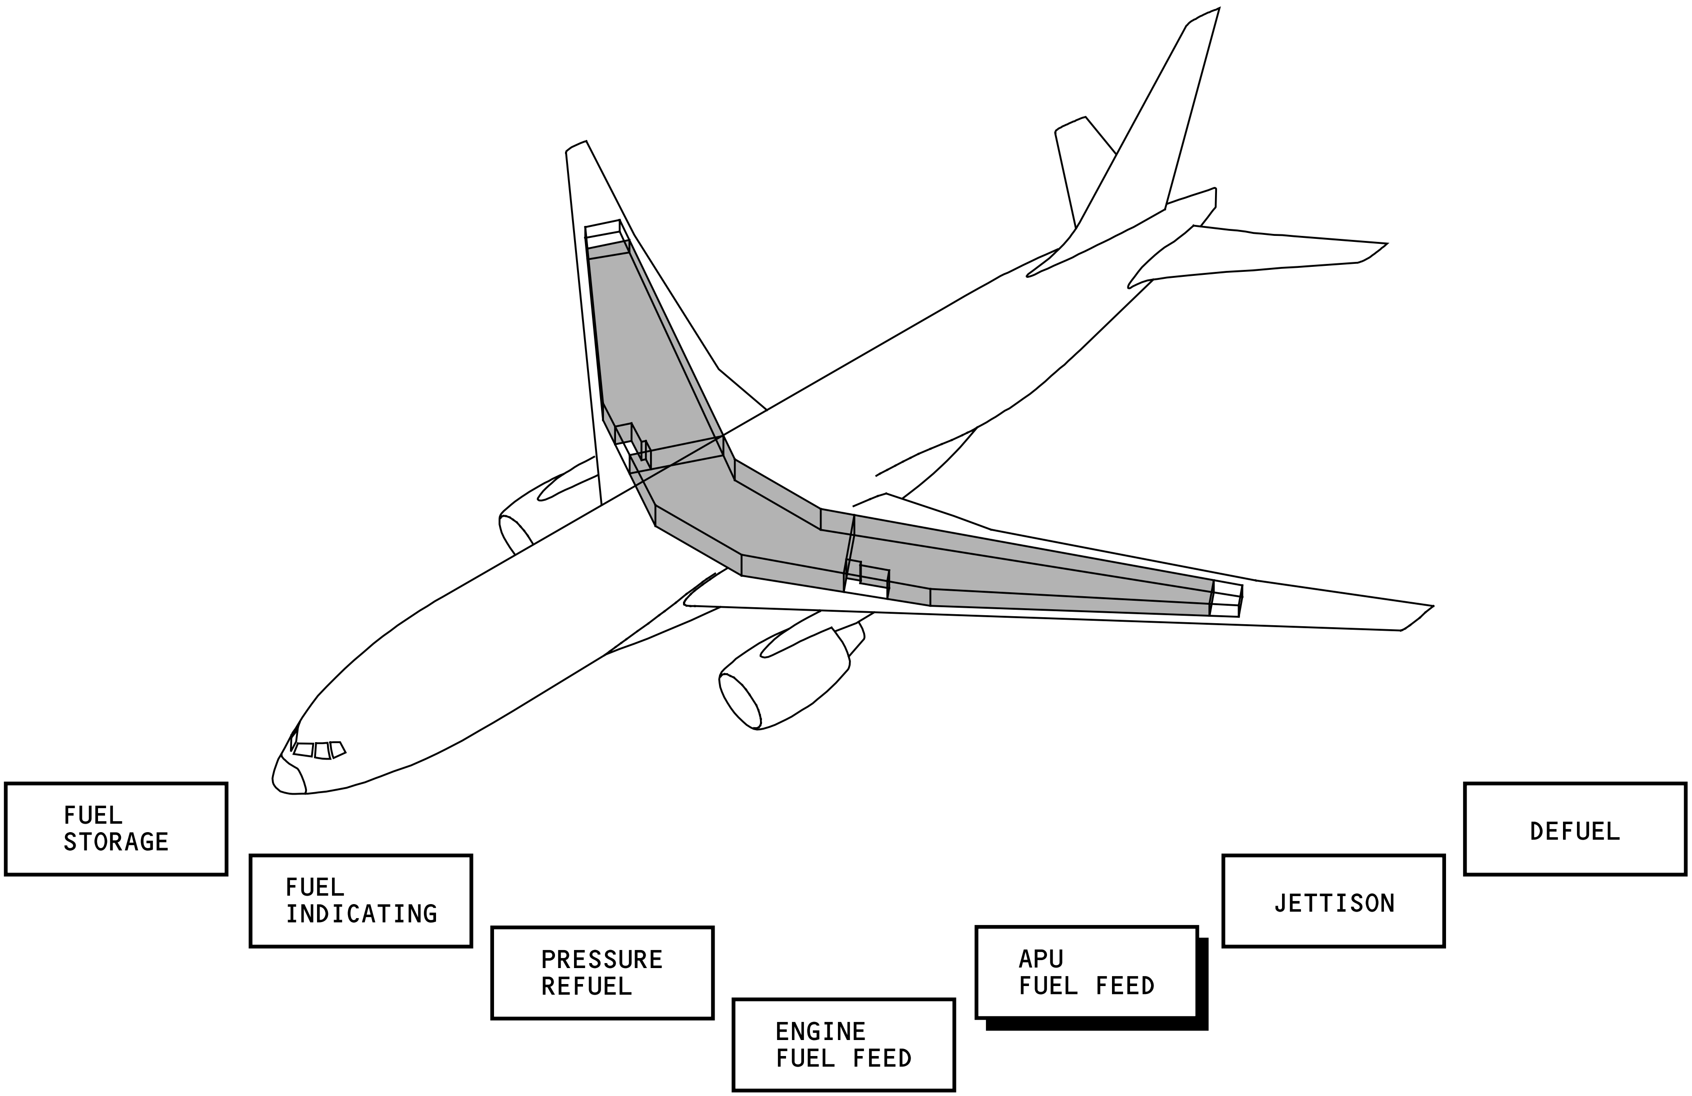
APU FUEL FEED - INTRODUCTION

Purpose

The APU fuel feed system normally supplies fuel to the APU. It can also supply fuel to the left engine when there is no pressure in the left engine feed manifold and the left engine is not operating.



APU FUEL FEED - INTRODUCTION

28-25-00-001 Rev 2 03/26/96

APU FUEL FEED - GENERAL DESCRIPTION

General

The APU fuel feed system supplies fuel to the APU during APU operation. Fuel comes from the fuel pumps (not shown) or the APU dc fuel pump. Power and control come from the ELMS.

APU Feed

The ELMS supplies power to the APU dc fuel pump and APU fuel shutoff valve. The pump operates automatically when the APU selector is in the ON position and there is no pressure in the left engine feed manifold. When there is pressure in the left engine feed manifold, the pump does not operate.

The ELMS uses crossfeed valve position and pump pressure switch signals to find if there is pressure in the manifold. The ELMS uses the dc pump pressure switch to monitor pump operation.

The APU fuel shutoff valve opens to permit fuel to go to the APU. In normal operation, the ELMS controls the valve through the a relay in the P101 panel. The ELMS opens the APU fuel shutoff valve when the APU selector is in the ON position or when the APU is running. The APU controller tells the ELMS when the APU is running.

The hot battery bus or the engine fuel spar valve battery supplies the power to open or close the APU fuel shutoff valve. The APU fire switch must be down to open the valve.

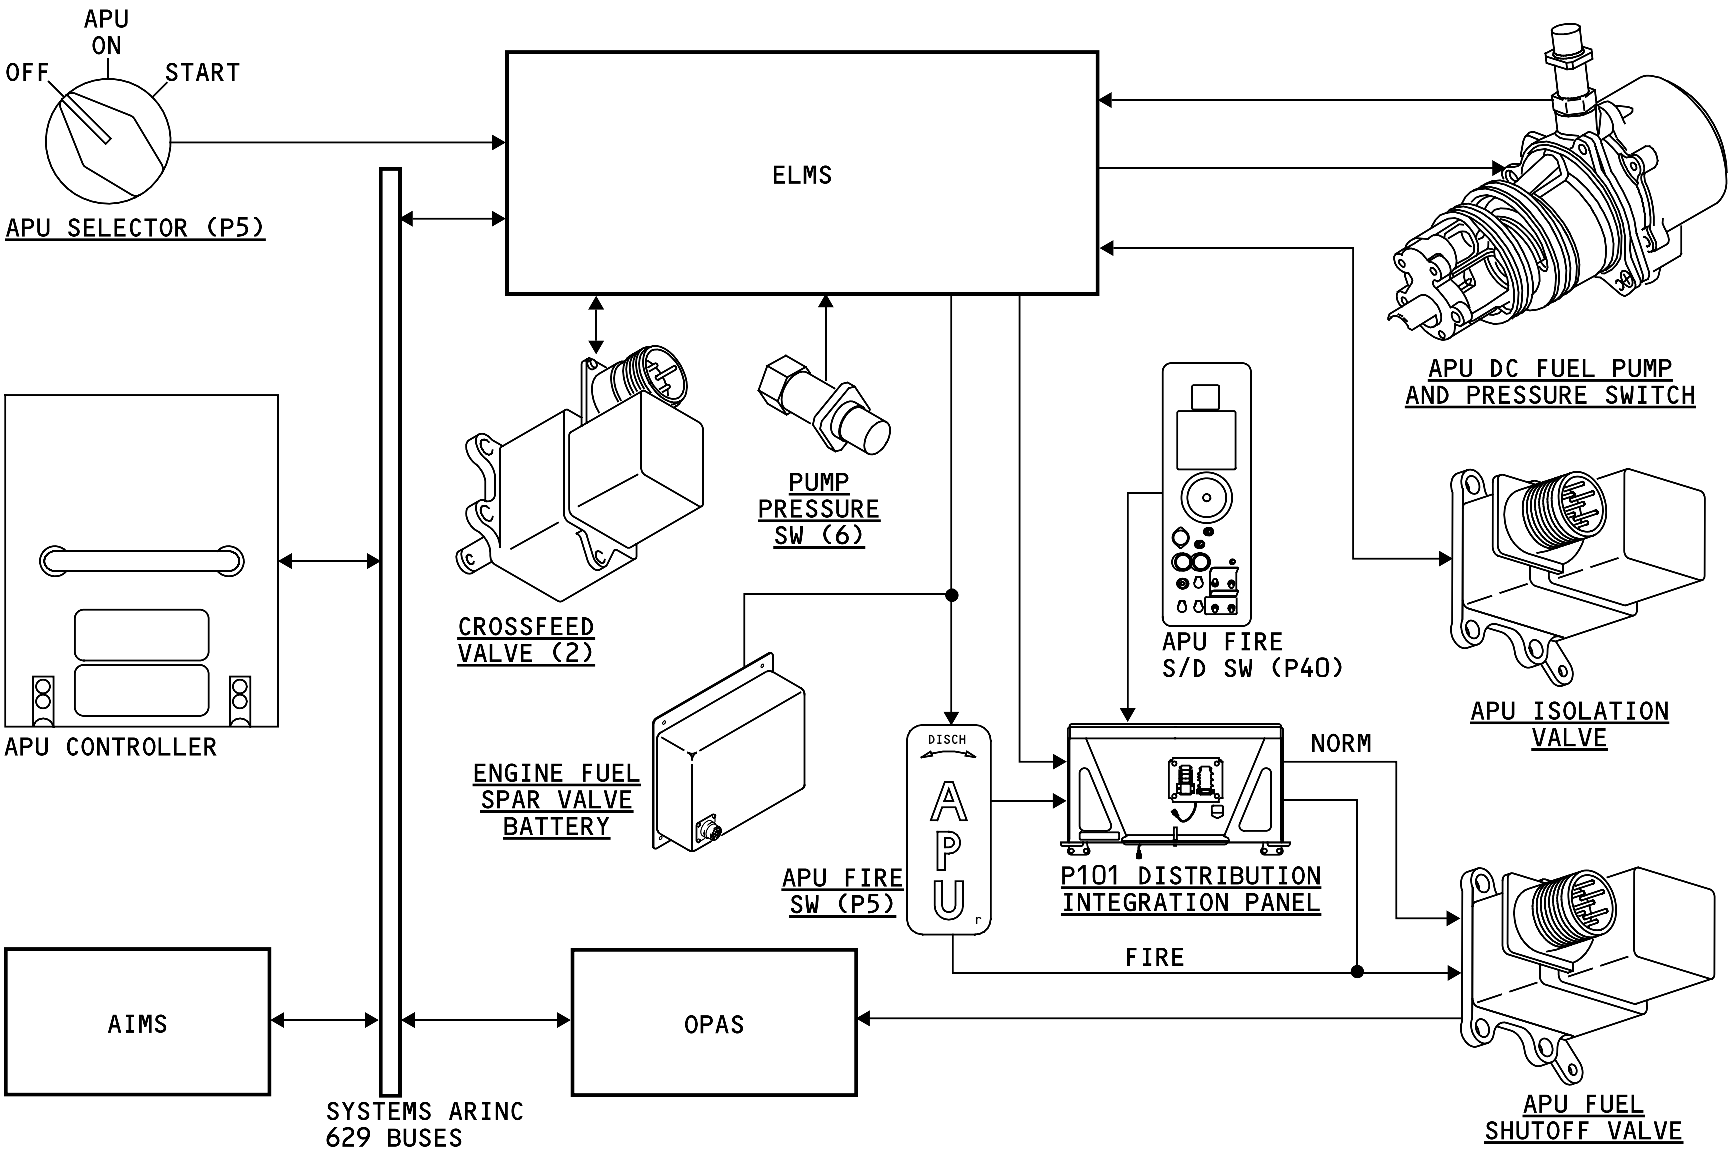
The APU fire switch and the APU fire shutdown switch close the APU fuel shutoff valve. The APU fire switch has a direct circuit to the valve. The APU fire shutdown switch controls a relay in the P101 panel to close the valve.

Engine Feed

The APU fuel feed system can supply fuel to the left engine in the air when there is no pressure in the left engine feed manifold and the left engine is not operating. The ELMS opens the APU isolation valve and turns on the APU dc fuel pump to permit this.

Fault and Indicating Information

APU fuel feed faults and indication information goes to the AIMS on the systems ARINC 629 buses.



APU FUEL FEED - GENERAL DESCRIPTION

28-25-00-002 Rev 5 07/27/95

APU FUEL FEED - COMPONENT LOCATIONS - FUEL TANKS

General

The APU fuel feed system has these components:

- APU DC fuel pump
- APU isolation valve
- APU fuel shutoff valve
- APU isolation check valve.

The APU fuel supply line goes through the center tank, then aft to the APU. The fuel supply line has a shroud around it. The shroud has a drain line that goes to the APU shroud drain mast on the bottom of the airplane.

APU DC Fuel Pump

The APU dc fuel pump is on the rear spar of the left wing, aft of the second fuel tank access door. The pump housing is inside the center tank. The pump inlet is in the left main tank.

APU Fuel Shutoff Valve

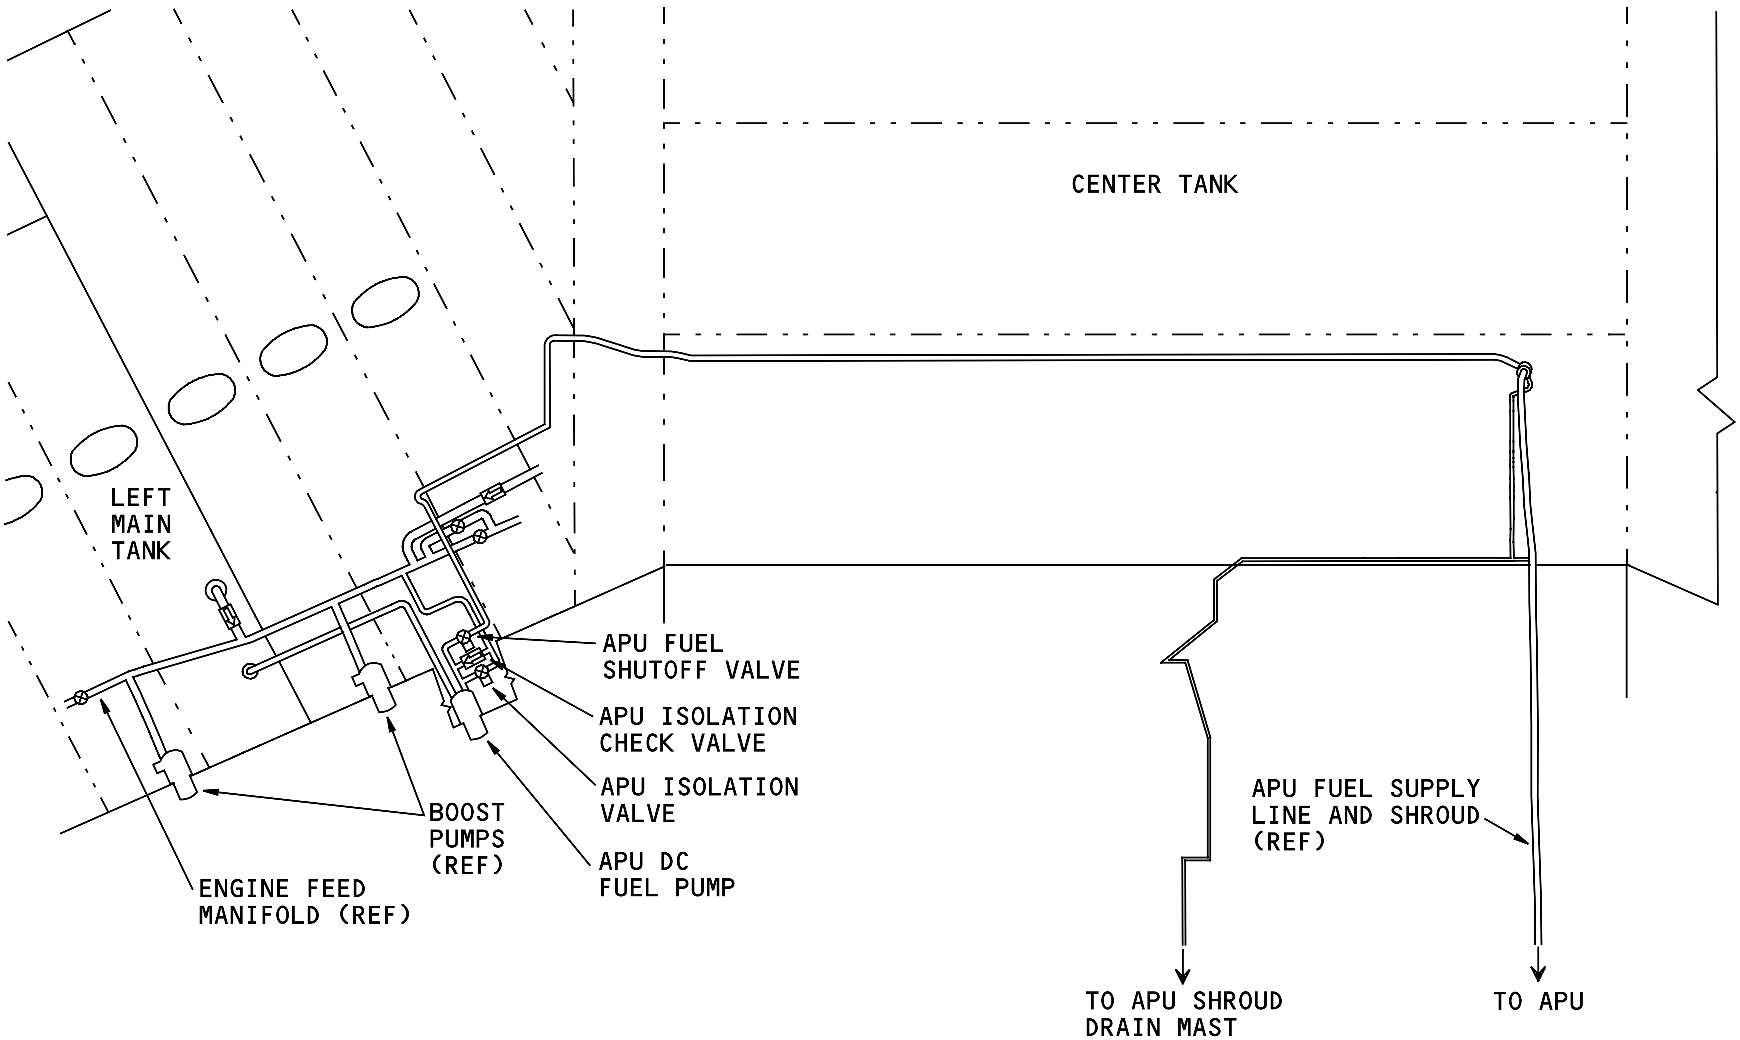
The APU fuel shutoff valve body is high in the left side of the center tank, above the APU isolation valve. You get access to the fuel shutoff valve through the second fuel tank access door. The valve actuator is on the rear spar of the left wing, inboard of the dc fuel pump.

APU Isolation Valve

The APU isolation valve body is in the left side of the center tank, below the APU fuel shutoff valve. You get access to the isolation valve through the second fuel tank access door. The valve actuator is on the rear spar of the left wing, inboard of the dc fuel pump.

APU Isolation Check Valve

The APU isolation check valve is in the left side of the center tank, between the APU fuel shutoff valve and isolation valve. You get access to the isolation check valve through the second fuel tank access door.



28-25-00-003 Rev 2 03/18/96

APU FUEL FEED - COMPONENT LOCATIONS - FUEL TANKS

APU FUEL FEED - COMPONENTS

APU DC Fuel Pump

The APU dc fuel pump supplies fuel to the APU and to the engine feed manifold. It uses 28v dc power. It supplies fuel at a pressure of 24 psi and a flow rate of 3150 pounds per hour (1430 kilograms per hour).

The pump has a pressure switch that sends a signal to the ELMS when the pump is operating.

APU Fuel Shutoff Valve

The APU fuel shutoff valve opens to permit fuel to flow to the APU. Fuel comes from the left engine feed manifold, or from the dc pump.

The APU fuel shutoff valve actuator is the same as the other 28v dc motor actuators on other fuel system valves. See the engine fuel feed section for more information about motor actuated fuel valves (AMM PART I 28-22).

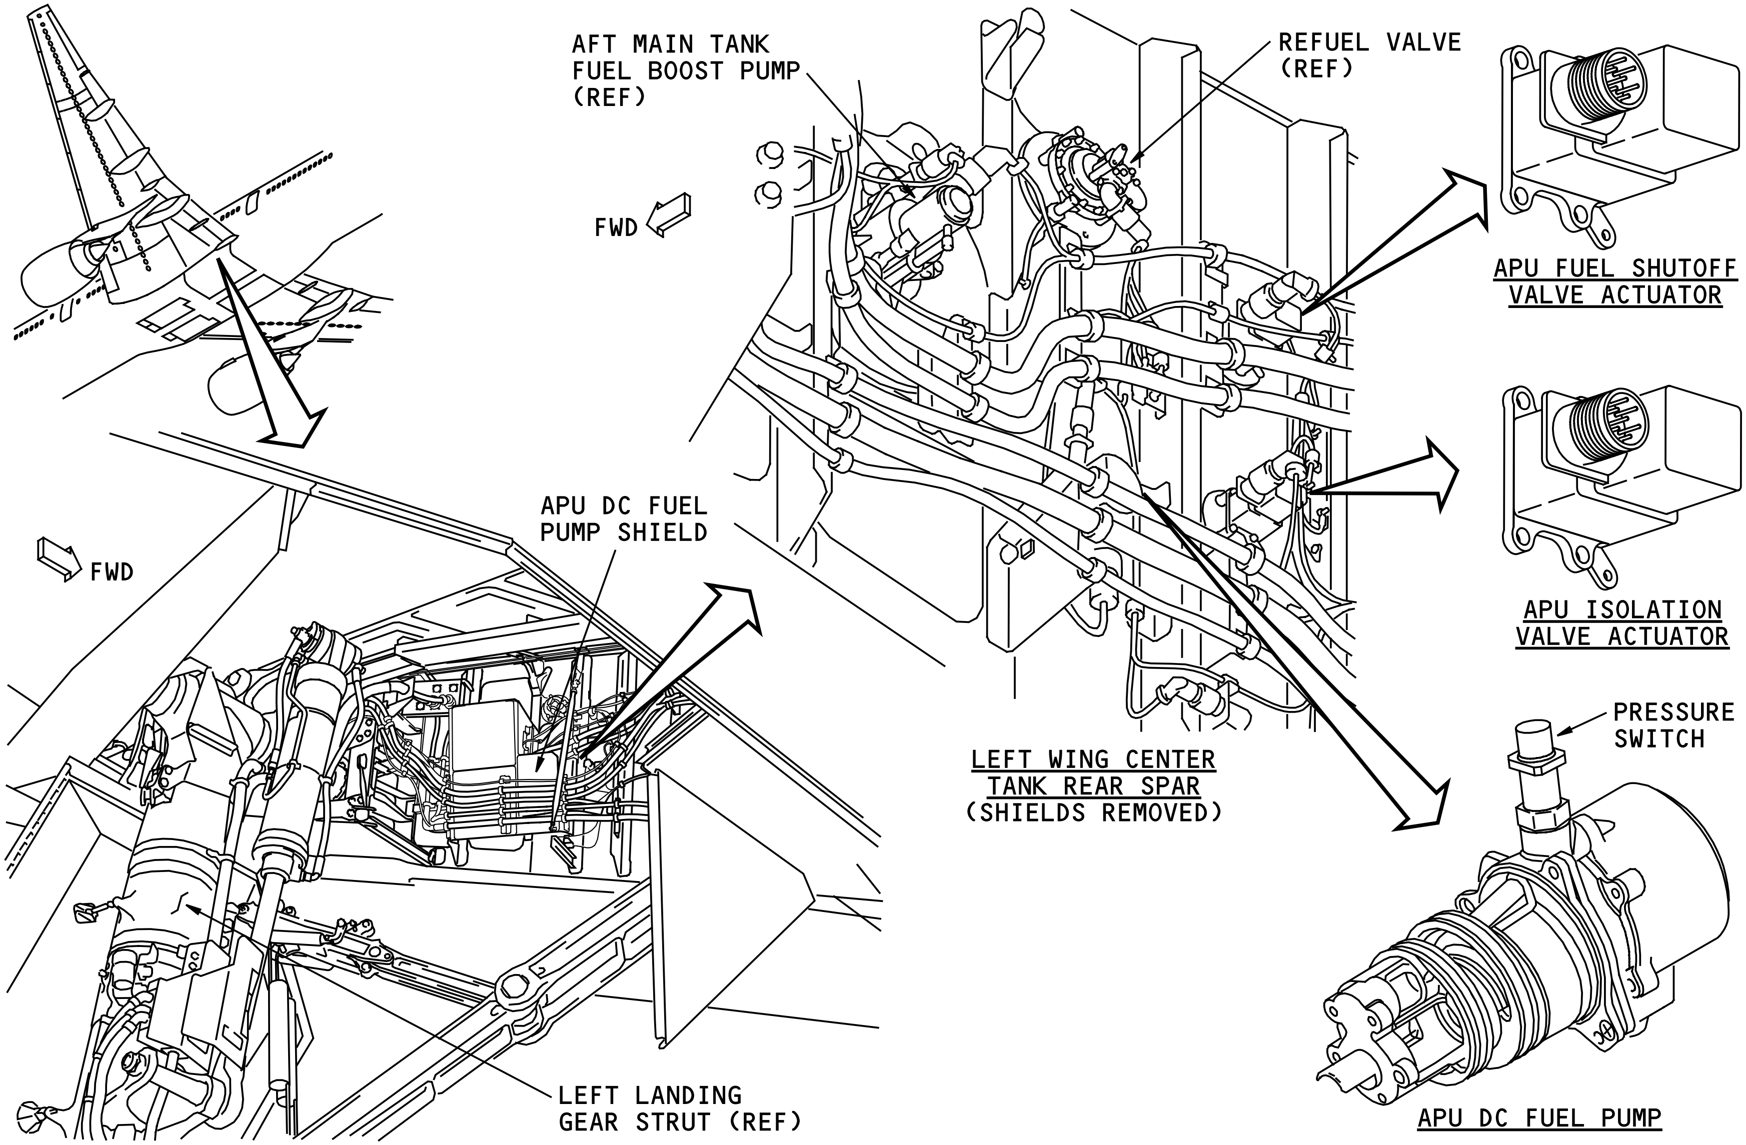
APU Isolation Valve

The APU isolation valve opens to let fuel flow from the APU dc fuel pump to the engine feed manifold. The isolation valve is normally closed. The valve operates automatically in flight when there is no engine fuel feed pressure and the engine has a flameout.

The APU isolation valve actuator is the same as the other 28v dc motor actuators on other fuel system valves. See the engine fuel feed section for more information about motor actuated fuel valves (AMM PART I 28-22).

Training Information Point

The APU dc fuel pump has a shield that protects it from thrown tire treads. You must remove the shield to get access to the pump.



APU FUEL FEED - COMPONENTS

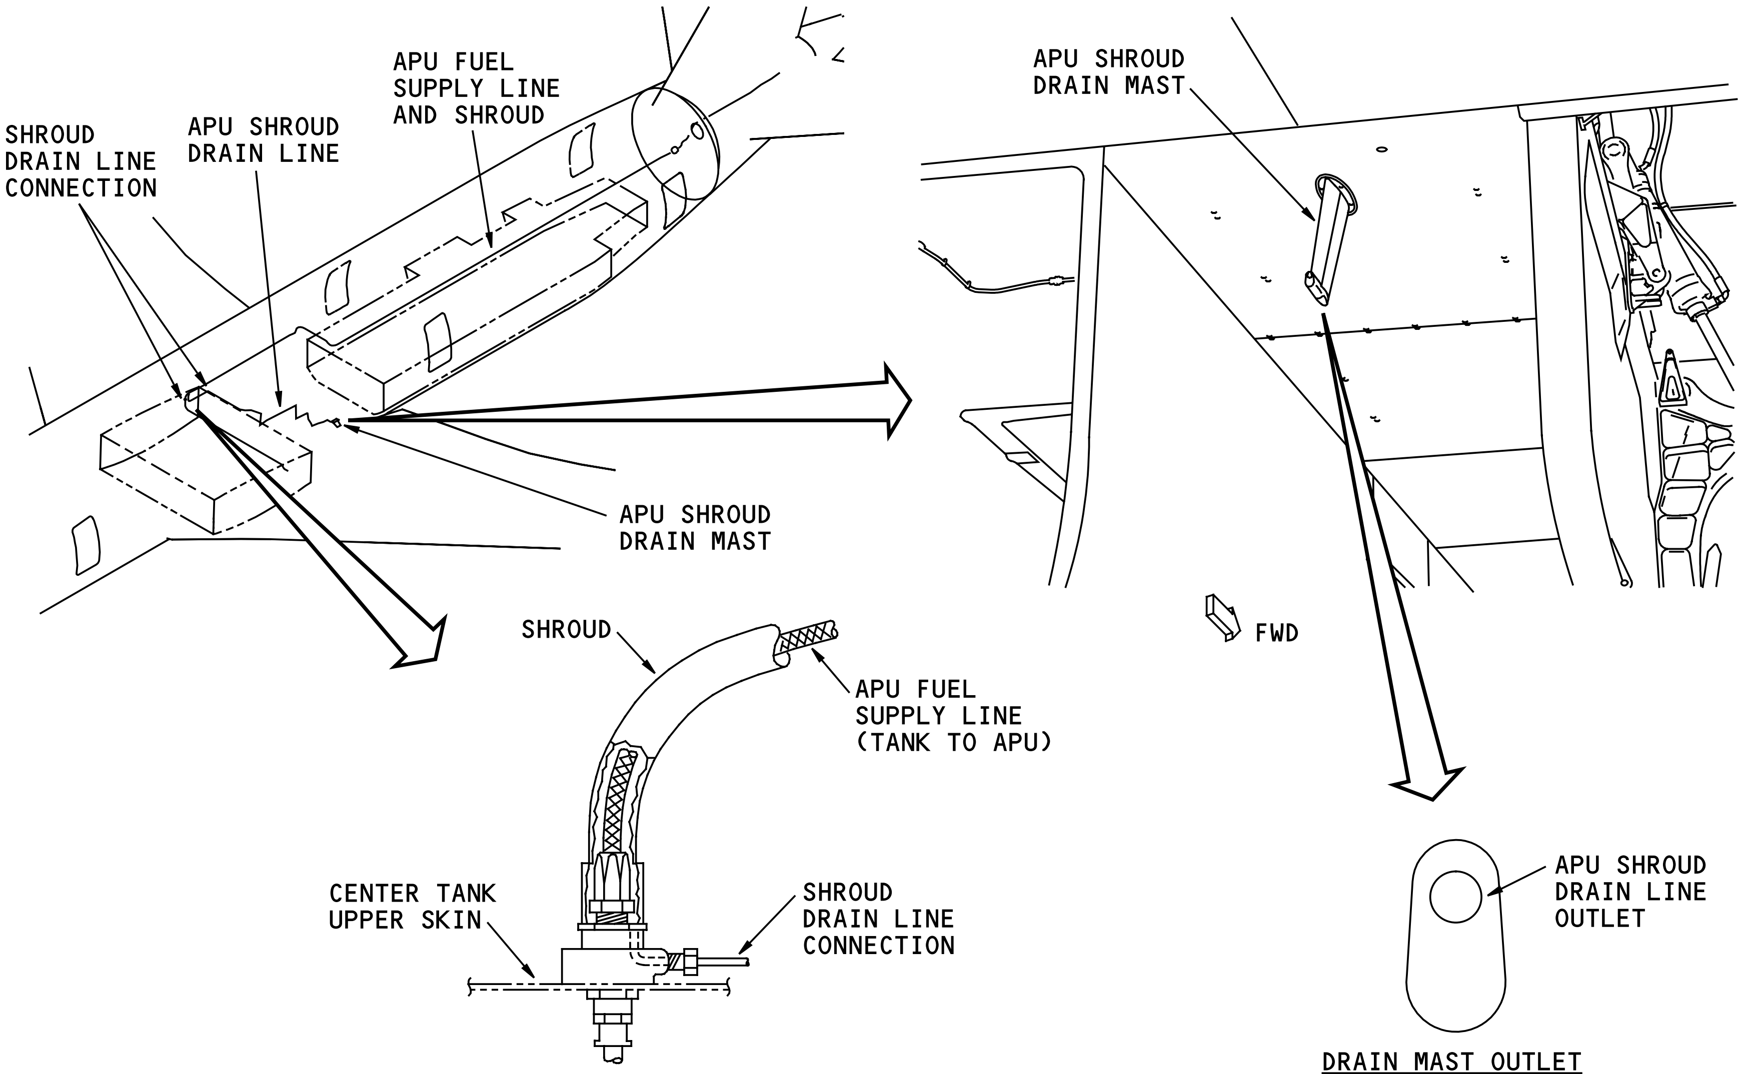
APU FUEL FEED - FUEL SUPPLY LINE AND SHROUD

APU Fuel Supply Line and Shroud

The APU fuel supply line is flexible rubber and kevlar. It has an aluminum shroud. The fuel supply line exits from the center fuel tank. It passes through the right wheel well, and goes under the floor to the APU.

Shroud Drain Line

The shroud drain line connects the fuel line shroud to the APU shroud drain mast. If there is a leak in the fuel supply line, the fuel is contained by the shroud and flows overboard through the drain mast.



APU FUEL SUPPLY LINE CONNECTION

DRAIN MAST OUTLET
(LOOKING FORWARD)

APU FUEL FEED - FUEL SUPPLY LINE AND SHROUD

28-25-00-005 Rev 2 03/18/96

APU FUEL FEED - FUNCTIONAL DESCRIPTION - FUEL FLOW

General

The APU fuel feed system uses the main pumps or the DC pump to supply fuel to the APU. The system can also supply fuel to the left engine feed manifold.

APU Fuel Feed From Main Pumps

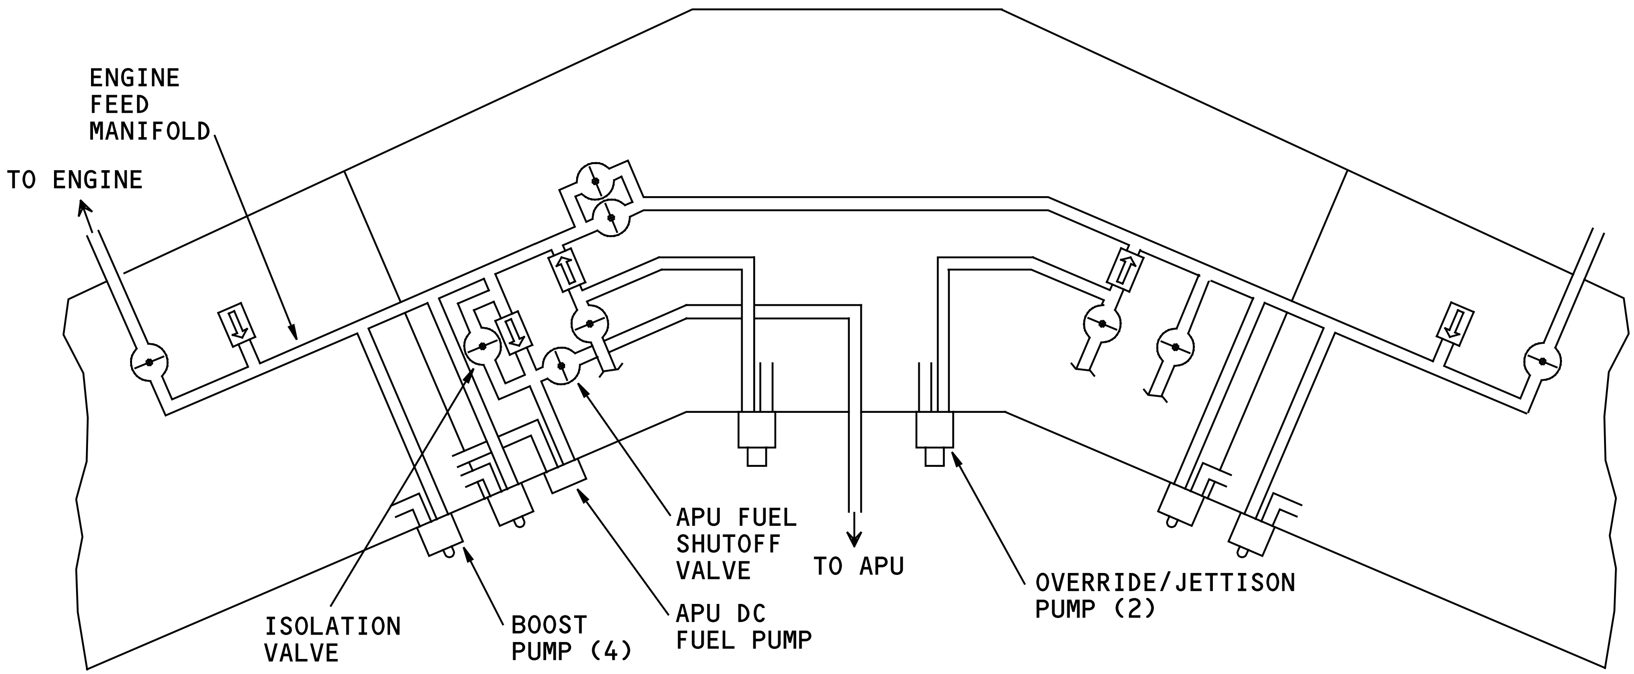
The APU normally receives fuel from the left engine feed manifold. The engine feed manifold receives fuel from any of the main or center tank fuel pumps. The fuel flows through a check valve and the APU fuel shutoff valve to the APU fuel line.

APU Fuel Feed From DC Fuel Pump

During APU starts and operation, if there is no fuel pressure in the left engine feed manifold, the APU dc fuel pump automatically turns on. This supplies fuel through the APU fuel valve to the APU fuel line.

Main Engine Feed From DC Fuel Pump

The APU dc fuel pump also turns on to feed the left engine during an in-flight flameout. Fuel flows through the APU isolation valve into the left engine feed manifold.



APU FUEL FEED - FUNCTIONAL DESCRIPTION - FUEL FLOW

THIS PAGE INTENTIONALLY LEFT BLANK

APU FUEL FEED - FUNCTIONAL DESCRIPTION - APU DC FUEL PUMP & ISOLATION VALVE

General

The ELMS automatically controls the APU dc fuel pump and the APU isolation valve. When you start the APU on the ground and ac power is not available, the ELMS starts the APU dc fuel pump. During flight, if there is an engine flameout, the ELMS can start the APU dc fuel pump and open the APU isolation valve. This lets the dc fuel pump supply fuel to the left engine when the ac boost pumps do not operate.

APU DC Fuel Pump

The APU dc fuel pump gets power from battery bus #2. The P310 EEU sends a signal to turn on the pump. This energizes the APU dc pump control relay to supply power to the pump.

Isolation Valve

The APU isolation valve gets power to open or close from the captain's flight instrument bus. The P310 EEU sends a signal to open the valve. This energizes the APU isolation valve relay to supply power to open the valve.

Power to operate the valve goes through limit switches to the actuator. The actuator moves the valve to the commanded position. When the valve is in the commanded position, the limit switches remove power from the actuator and send power to the ELMS valve agree status logic.

Control

For APU fuel feed, the P310 EEU sends the dc pump command signal when these conditions occur:

- No pressure in the left engine feed manifold
- APU running, or APU selector in START or ON position.

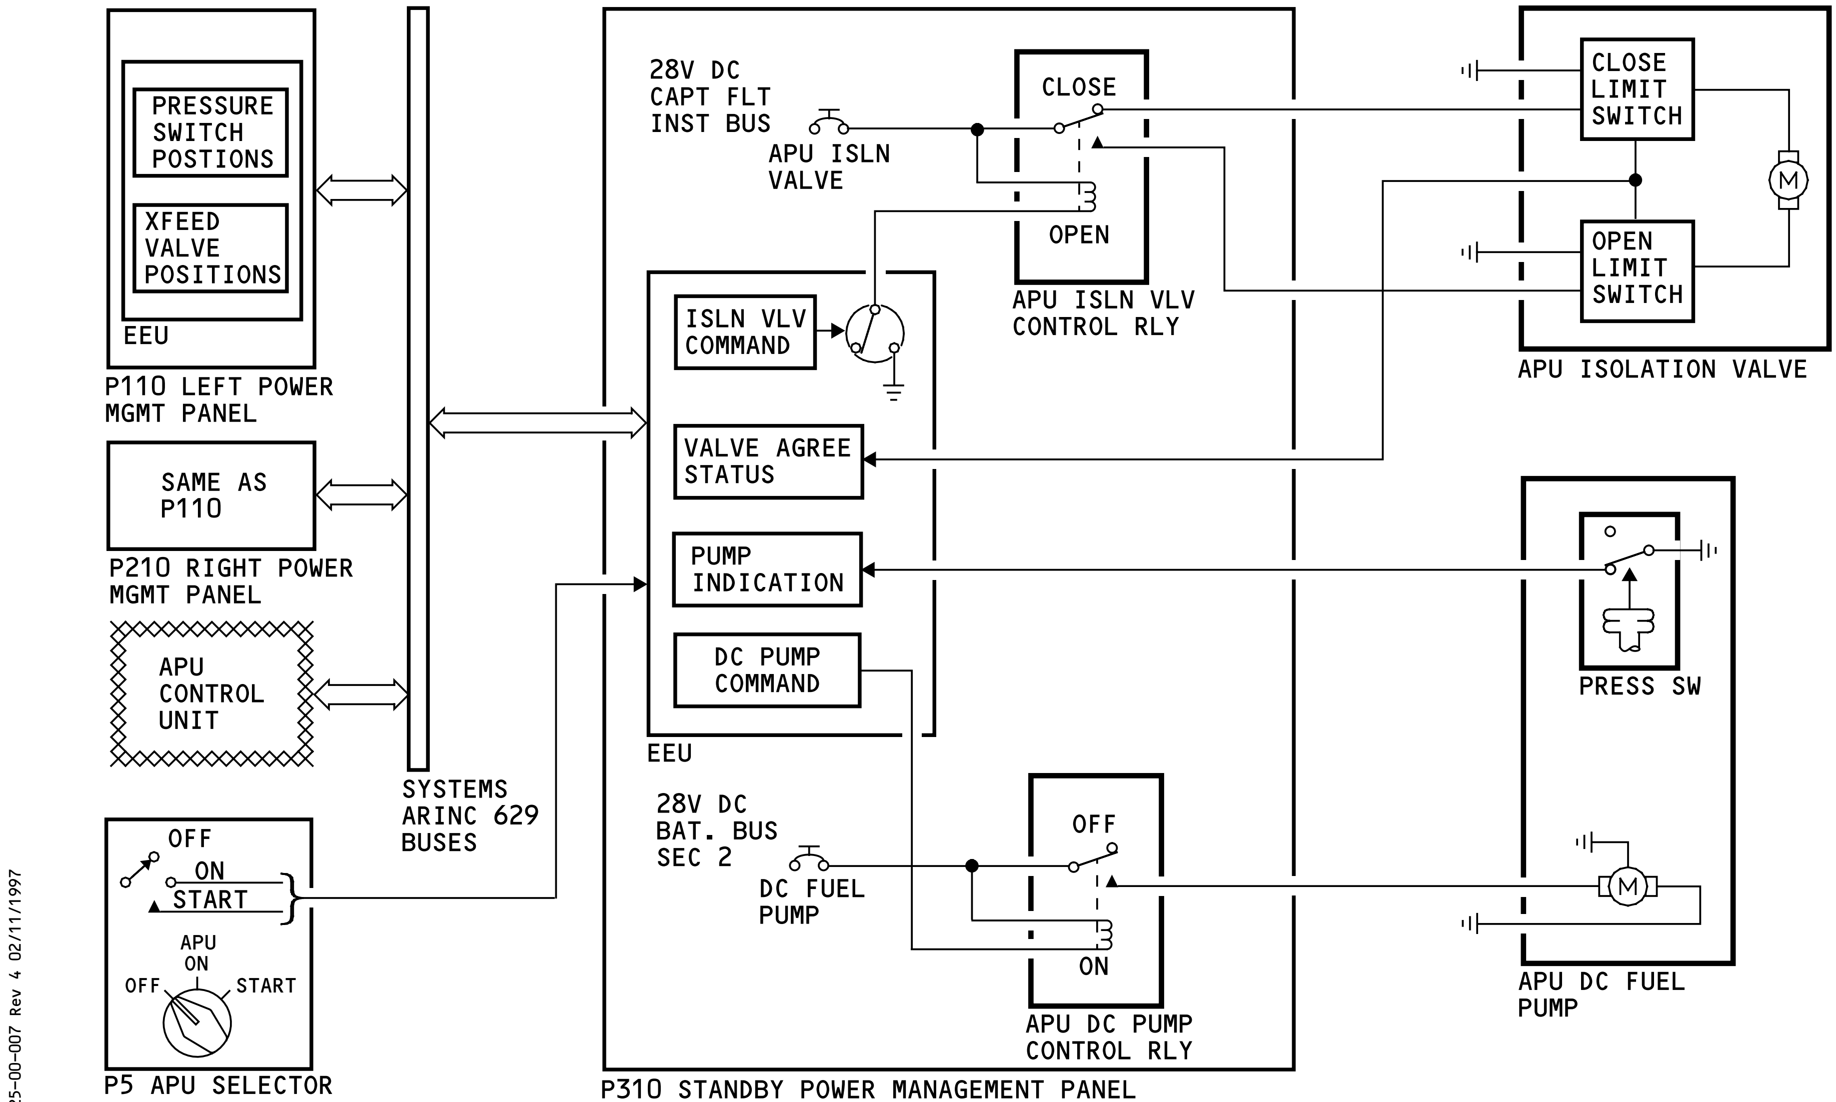
For left engine fuel feed, the P310 EEU sends the dc pump command signal and the isolation valve command signal when these conditions occur:

- No pressure in the left engine feed manifold
- left engine N2 is less than the engine run speed
- Left engine fuel control switch is in the RUN position
- The airplane is in the air.

The ELMS uses signals from the ac fuel pump pressure switches and the crossfeed valves to find if there is pressure in the left engine feed manifold. The P110 and P210 EEUs send the signals on the systems ARINC 629 buses to the P310 EEU. The APU signals come from the APU control unit and the APU selector.

Fault Indications

The P310 EEU monitors the status of the APU dc pump pressure switch and the APU isolation valve position. If the pressure switch does not agree with the dc pump command status, the EEU sends a fault message to the systems ARINC 629 buses. If the APU isolation valve position does not agree with the isolation valve command status, the EEU sends a fault message to the systems ARINC 629 buses. The fault messages cause EICAS advisory and status messages.



APU FUEL FEED - FUNCTIONAL DESCRIPTION - APU DC FUEL PUMP & ISOLATION VALVE

APU FUEL FEED - FUNCTIONAL DESCRIPTION - APU FUEL SHUTOFF VALVE

General

The ELMS automatically controls the APU fuel shutoff valve. The EEU in the P310 panel uses inputs from the APU controller and the APU selector to control the valve.

Control

The P310 EEU sends a valve open command when any of these conditions occur:

- APU is running
- APU selector is in the ON or START position.

It sends a valve close command when any of these conditions occur:

- APU is not running
- APU fire switch closes
- APU fire shutdown switch closes
- APU fire.

The APU running signal comes from the APU controller.

Power

The APU fuel shutoff valve gets power to open or close from the fuel shutoff valve bus. The P310 EEU sends a command to operate the valve. This energizes the open or close coil of the APU fuel shutoff valve control relay and permits power to go to the valve.

Power to operate the valve goes through limit switches to the actuator. The actuator moves the valve to the commanded position. When the valve is in the commanded position, the limit switches remove power from the actuator.

If you pull the APU fire switch or push the APU fire shutdown switch, power goes directly to the APU fuel shutoff valve to close it. Pushing the APU fire shutdown switch energizes the APU remote shutdown relay. APU fire control circuits keep it energized.

Fault Indications

The P310 EEU monitors the positions of the APU fuel shutoff valve control relay and the APU remote shutdown relay. The EEU gets the APU fuel shutoff valve position from the OPAS on the systems ARINC 629 buses. If there is a disagreement between the valve position and the relay positions, the EEU sends a fault message to the AIMS. The fault message causes EICAS advisory and status messages.

APU FUEL FEED - INDICATIONS

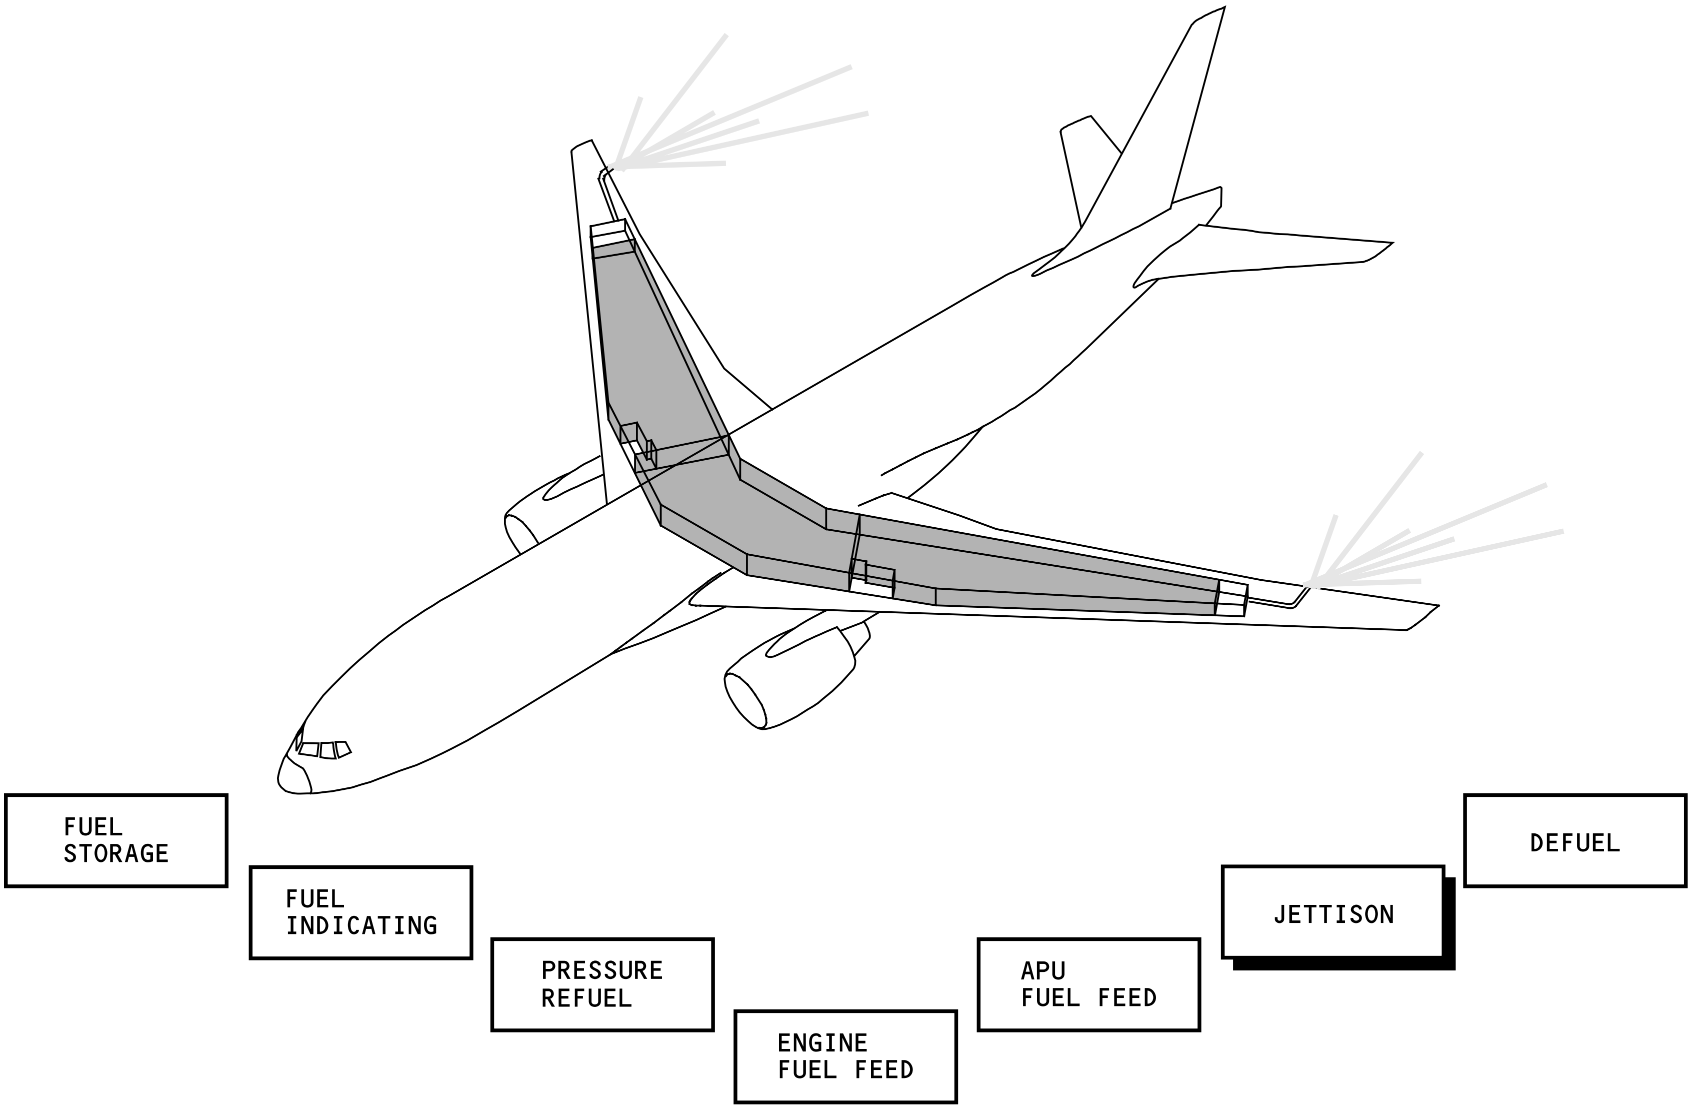
FUEL JETTISON - INTRODUCTION

Purpose

The fuel jettison system dumps fuel overboard to reduce the landing weight. You operate the jettison system from the fuel panel on the P5 overhead panel.



FUEL JETTISON - INTRODUCTION

FUEL JETTISON - GENERAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

FUEL JETTISON - GENERAL DESCRIPTION

General

The fuel jettison system dumps fuel overboard to reduce the landing weight. You operate the jettison system from the fuel jettison panel (P5). The ELMS controls the fuel jettison system.

Jettison Pumps

There are two override/jettison pumps in the center tank and one fuel jettison pump in each main tank.

Each pump has a pressure switch that sends a signal through the ELMS to the systems ARINC 629 buses. The signal goes to the jettison panel and the AIMS for fault indication.

Jettison Isolation Valves

These valves let the override/jettison pumps put fuel into the refuel/jettison manifold (not shown). A signal goes to the AIMS for valve fault indication.

Jettison Nozzle Valves

In the air, the nozzle valves let fuel in the refuel/ jettison manifold go overboard. This reduces the landing weight.

On the ground, you cannot open the nozzle valves. The power to close the valves goes directly from the ELMS to the nozzle valve actuators.

A signal for valve fault indication goes to the fuel jettison panel and the AIMS.

General Operation

In the air, you push the arm switch to operate the fuel jettison system. The arm switch sends a signal through the systems ARINC 629 buses to the ELMS.

The jettison system has two operating modes:

- Maximum landing weight (MLW) mode
- Manual (MAN) mode.

When you arm the jettison system, it is in the MLW mode. The ELMS calculates the quantity of fuel to remain after it jettisons fuel to the MLW. The ELMS subtracts zero fuel weight (ZFW) from MLW to get the fuel to remain. It gets the MLW and ZFW from the AIMS. The quantity of fuel to remain in the airplane shows on the EICAS display.

The ELMS gets actual fuel quantity from the FQPU. It uses this information to calculate the time to jettison.

When you pull out the fuel-to-remain selector, the jettison system is in the MAN mode. You can use the fuel-to-remain selector to increase or decrease the quantity of fuel to remain.

In the air, the jettison nozzle valve switches cause the ELMS to open the nozzle valves. Each switch also

FUEL JETTISON - GENERAL DESCRIPTION

causes the ELMS to open the isolation valves and start the fuel jettison pumps. You must use the center tank pump switches to start the override/jettison pumps.

Fuel jettison can cause the airplane center of gravity to be forward of the center of gravity limit. If the ELMS calculates that this will happen, it stops the main tank jettison pumps for 7.5 minutes.

On the ground, the arm switch causes the ELMS to open the two jettison isolation valves and start the fuel jettison pumps.

FUEL JETTISON - GENERAL DESCRIPTION

FUEL JETTISON - COMPONENT LOCATIONS - FUEL TANKS

General

The jettison system has these components:

- Override/jettison pumps
- Jettison pumps
- Jettison isolation valves
- Isolation check valves
- Refuel/jettison manifold
- Jettison nozzle valves.

Override/Jettison Pumps

There are two override/jettison pumps in the center tank. They are in the left and right wheel wells on the rear spar. The engine feed section describes these pumps.

Fuel Jettison Pumps

There is one fuel jettison pump in each main tank. They are on the rear spar forward of the flaperons. These pumps are interchangeable with the override/jettison pumps.

Fuel Jettison Isolation Valves

There is one fuel jettison isolation valve in each section of the center tank. The valve actuators are on the rear spar just outboard from the fuselage.

These are the same kind of valve as the other motor-actuated valves in the fuel system.

Jettison Isolation Check Valve

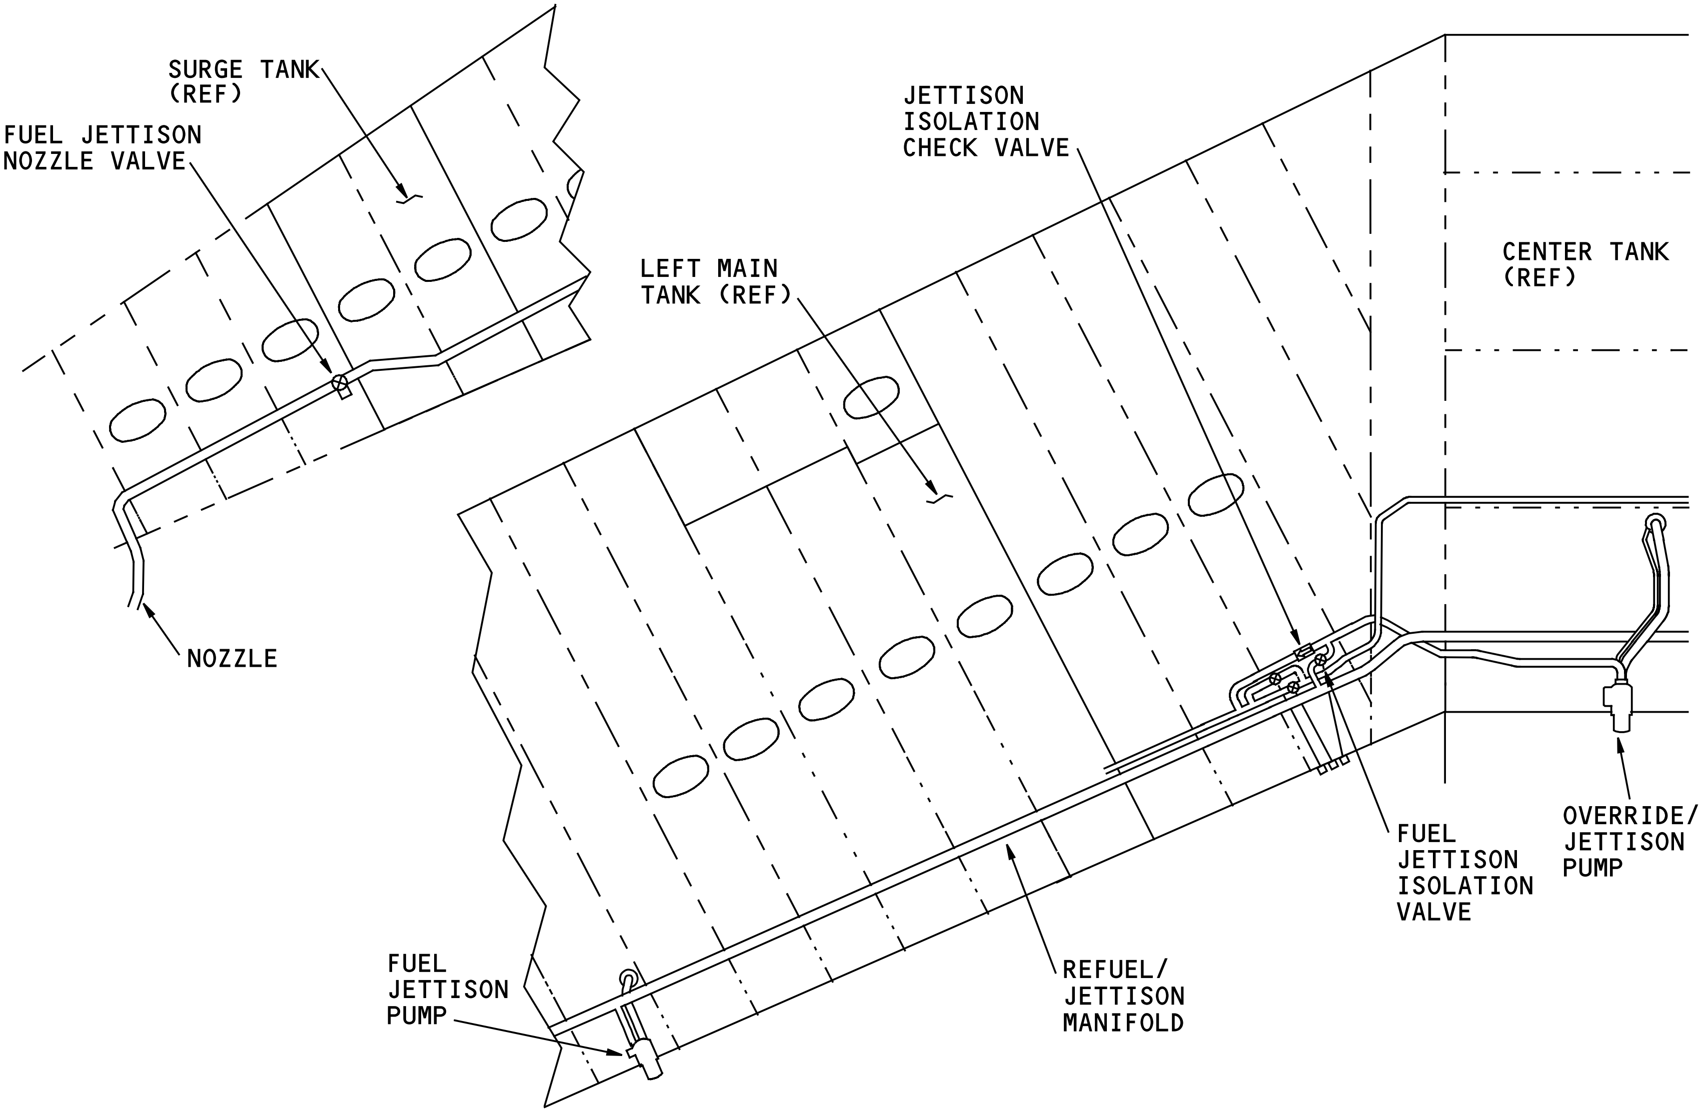
There is a jettison isolation check valve in each section of the center tank. The valve prevents fuel jettison by the left and right main tank fuel boost pumps.

Refuel/Jettison Manifold

The refuel/jettison manifold is in both wings and goes through the end of the main tank and surge tank. The end of the refuel/jettison manifold has a nozzle. The nozzle comes out of the trailing edge of each wing between the outboard flap and the aileron.

Fuel Jettison Nozzle Valves

There is one jettison nozzle valve near each end of the refuel/jettison manifold. They attach to the refuel/jettison manifold.



FUEL JETTISON - COMPONENT LOCATIONS - FUEL TANKS

FUEL JETTISON - COMPONENT LOCATIONS - REAR SPAR

General

The fuel jettison pumps are on the rear spar, aft of each engine.

There are two fuel jettison isolation valves. The valve actuators are on the rear spar. There is an actuator in each main landing gear wheel well.

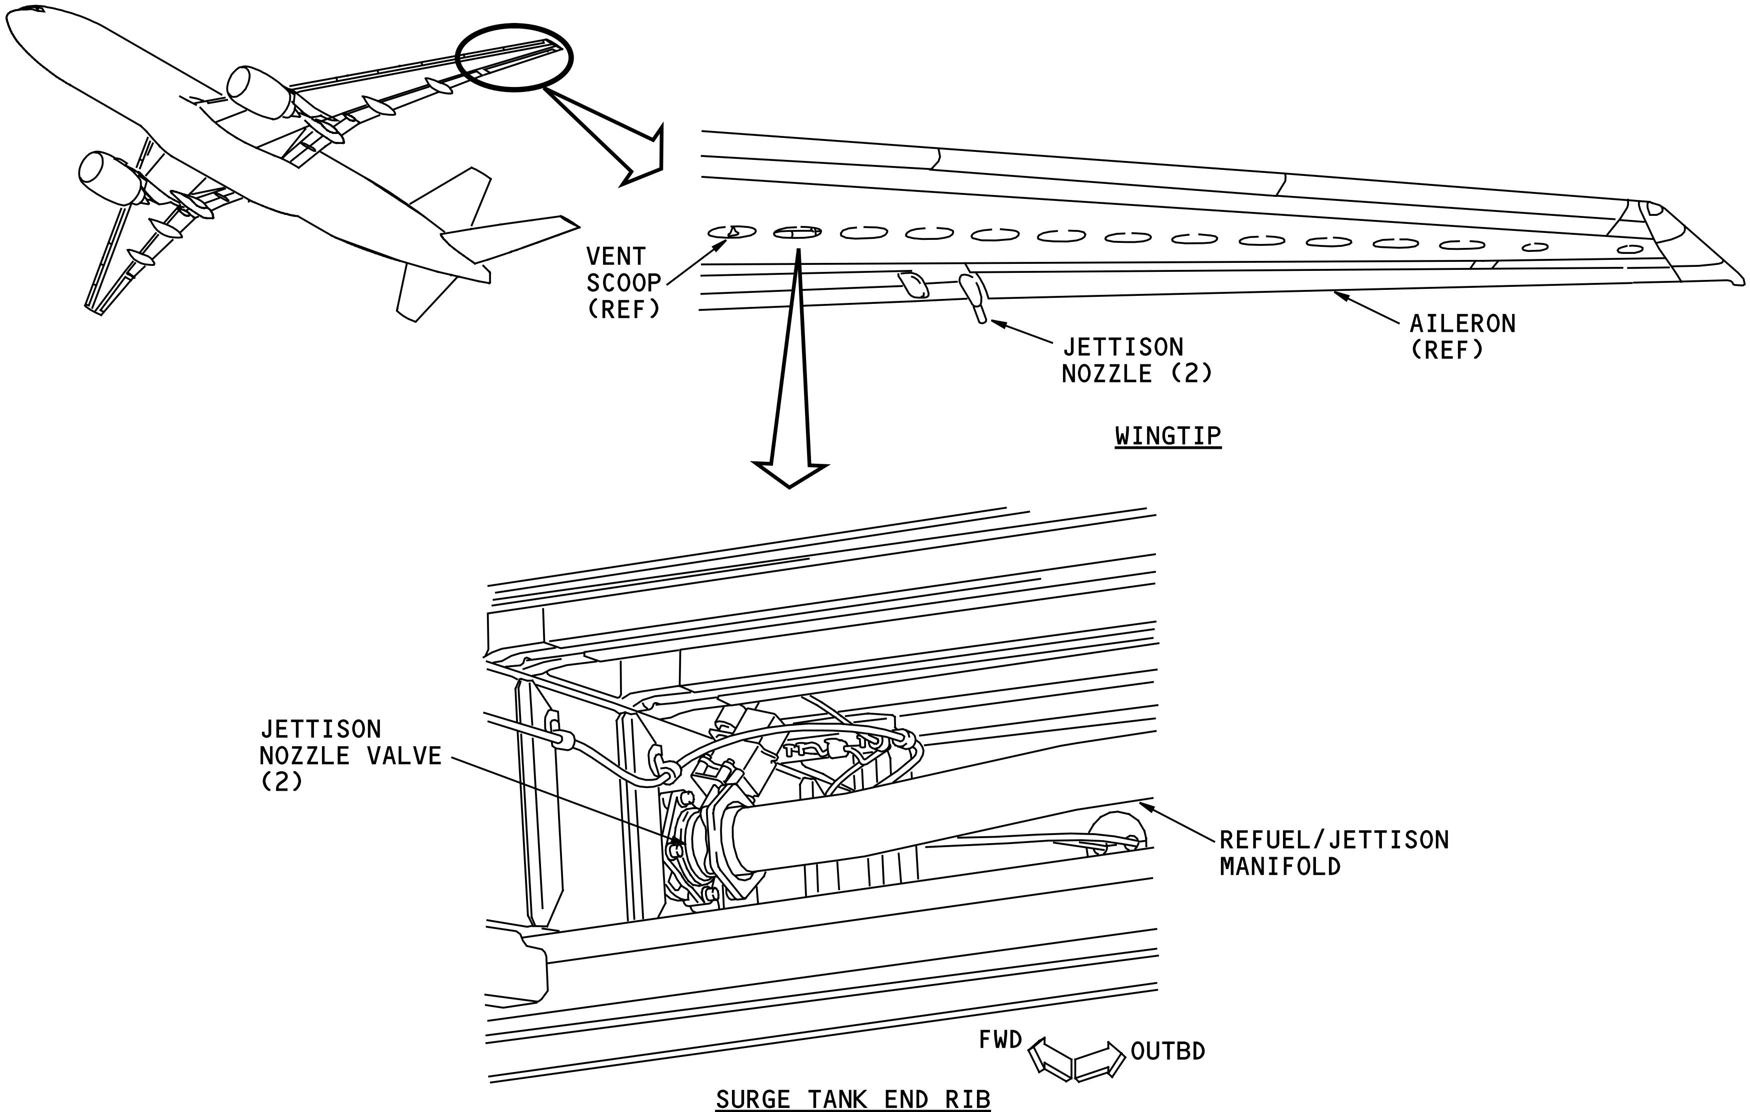
There is a jettison nozzle valve and actuator on each wing. Each nozzle valve is in the dry bays near the surge tanks. The valve attaches to the refuel/jettison manifold.



28-31-00-012 Rev 0

FUEL JETTISON - COMPONENT LOCATIONS - WINGS

FUEL JETTISON - FUEL JETTISON PUMP

General

The jettison pumps supply fuel from the main tank to the refuel/jettison manifold during fuel jettison.

The jettison pumps can supply fuel at a pressure of 36 psi and a flow rate of 70,000 pounds (31750 kg) per hour. Each pump assembly has a motor-impeller and a housing.

Location

There is one jettison pump in each main tank. They are on the rear spar, aft of the engine strut. The housings are inside the tanks, on the rear spar. The motor-impellers install in the housings.

Pump Housing

The housing contains the motor-impeller and these valves:

- Discharge check valve
- Vapor vent valve
- Inlet valve.

The discharge check valve prevents engine feed manifold fuel from flowing back through the pump.

The vapor vent valve permits fuel vapor to go into the tank, but does not permit fuel to enter the pump.

The inlet valve is a gate valve that closes when you remove the pump. This permits you to remove the pump when the tanks have fuel in them.

Motor-Impeller

The motor-impeller uses 115v ac power. Each pump has these parts:

- Electrical connector
- Pressure switch
- Drain plug
- Extraction lever.

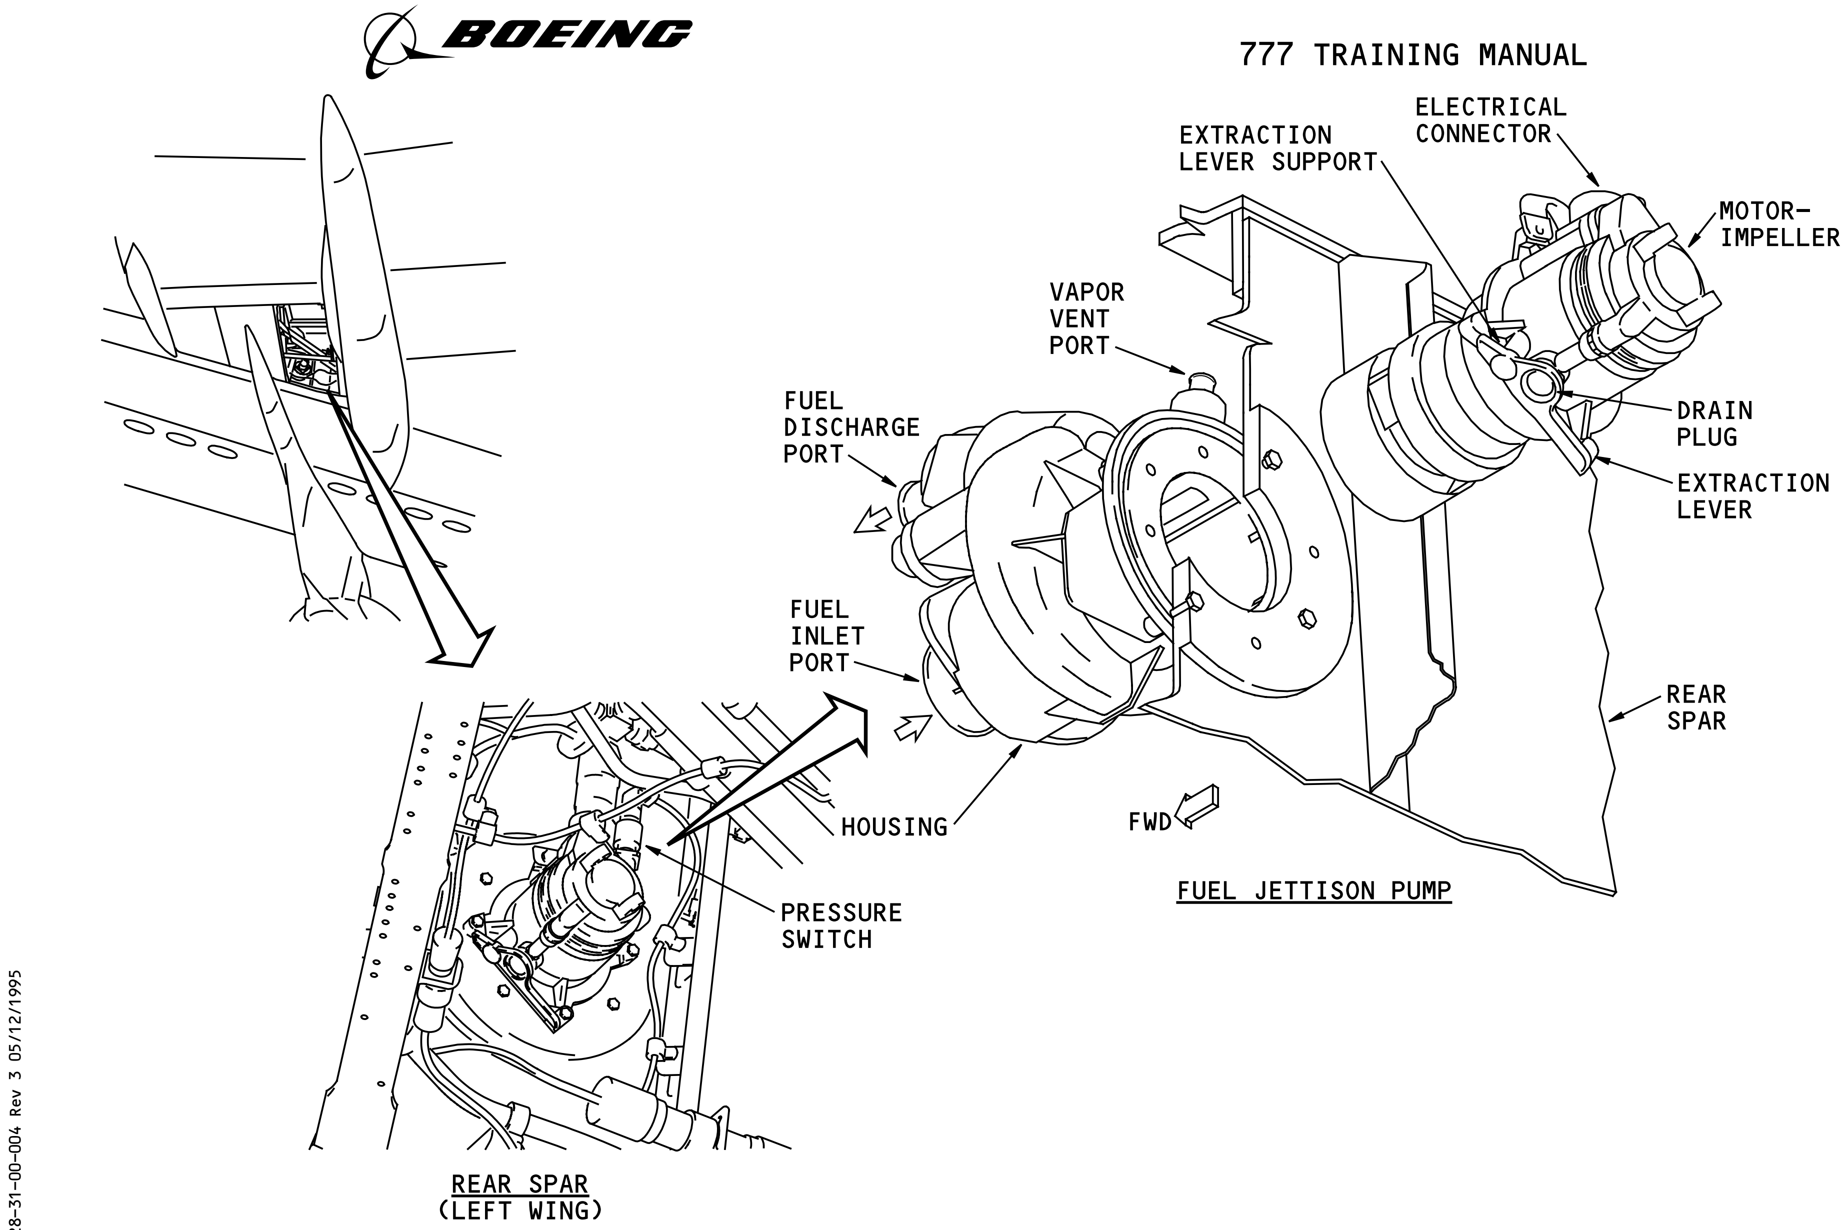
Training Information Point

The jettison pump motor-impellers are interchangeable with the override/jettison pump motor-impellers.

To remove the motor-impeller, you rotate it 35 degrees CCW to close the inlet valve. Then you remove the drain plug to remove residual fuel. You use the extraction lever to move the motor-impeller out of the housing.

To install the motor-impeller, you must align pins in the housing to slots on the motor-impeller.

You can remove the discharge and vapor vent valves through the housing from outside the tank.



FUEL JETTISON - FUEL JETTISON PUMP

FUEL JETTISON - ISOLATION VALVE

Purpose

The fuel jettison isolation valves open during fuel jettison operation. The open isolation valve lets override/jettison pump fuel go to the refuel/jettison manifold.

Location

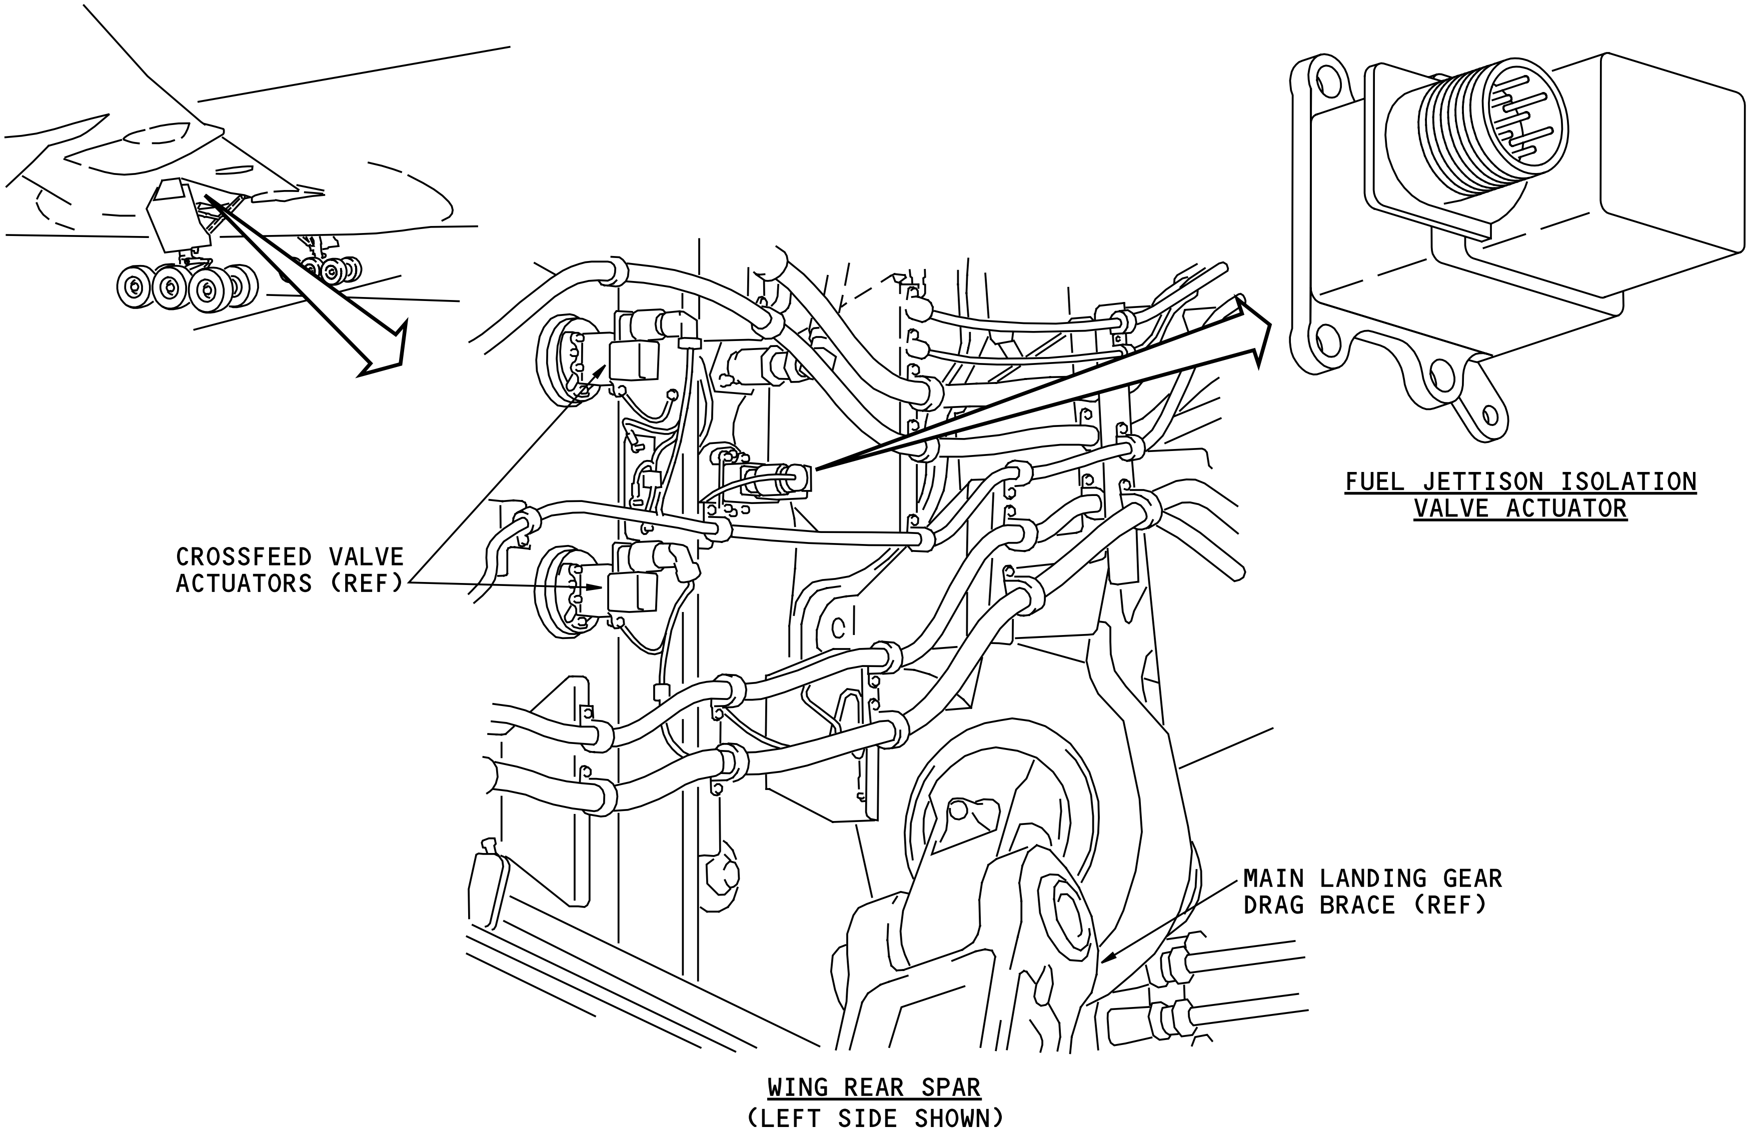
There is one fuel jettison isolation valve in each section of the center tank. The valve actuators are on the rear spar in the wheel wells.

Isolation Valve Description

The fuel jettison isolation valve is the same type of valve as the other motor-actuated valves in the fuel system.

Actuator

The actuator is a 28v dc motor. It has a manual override lever so you can operate the actuator without electrical power. The lever also shows valve position.



FUEL JETTISON - ISOLATION VALVE

28-31-00-005 Rev 2 05/12/1995

FUEL JETTISON - JETTISON NOZZLE VALVE

Purpose

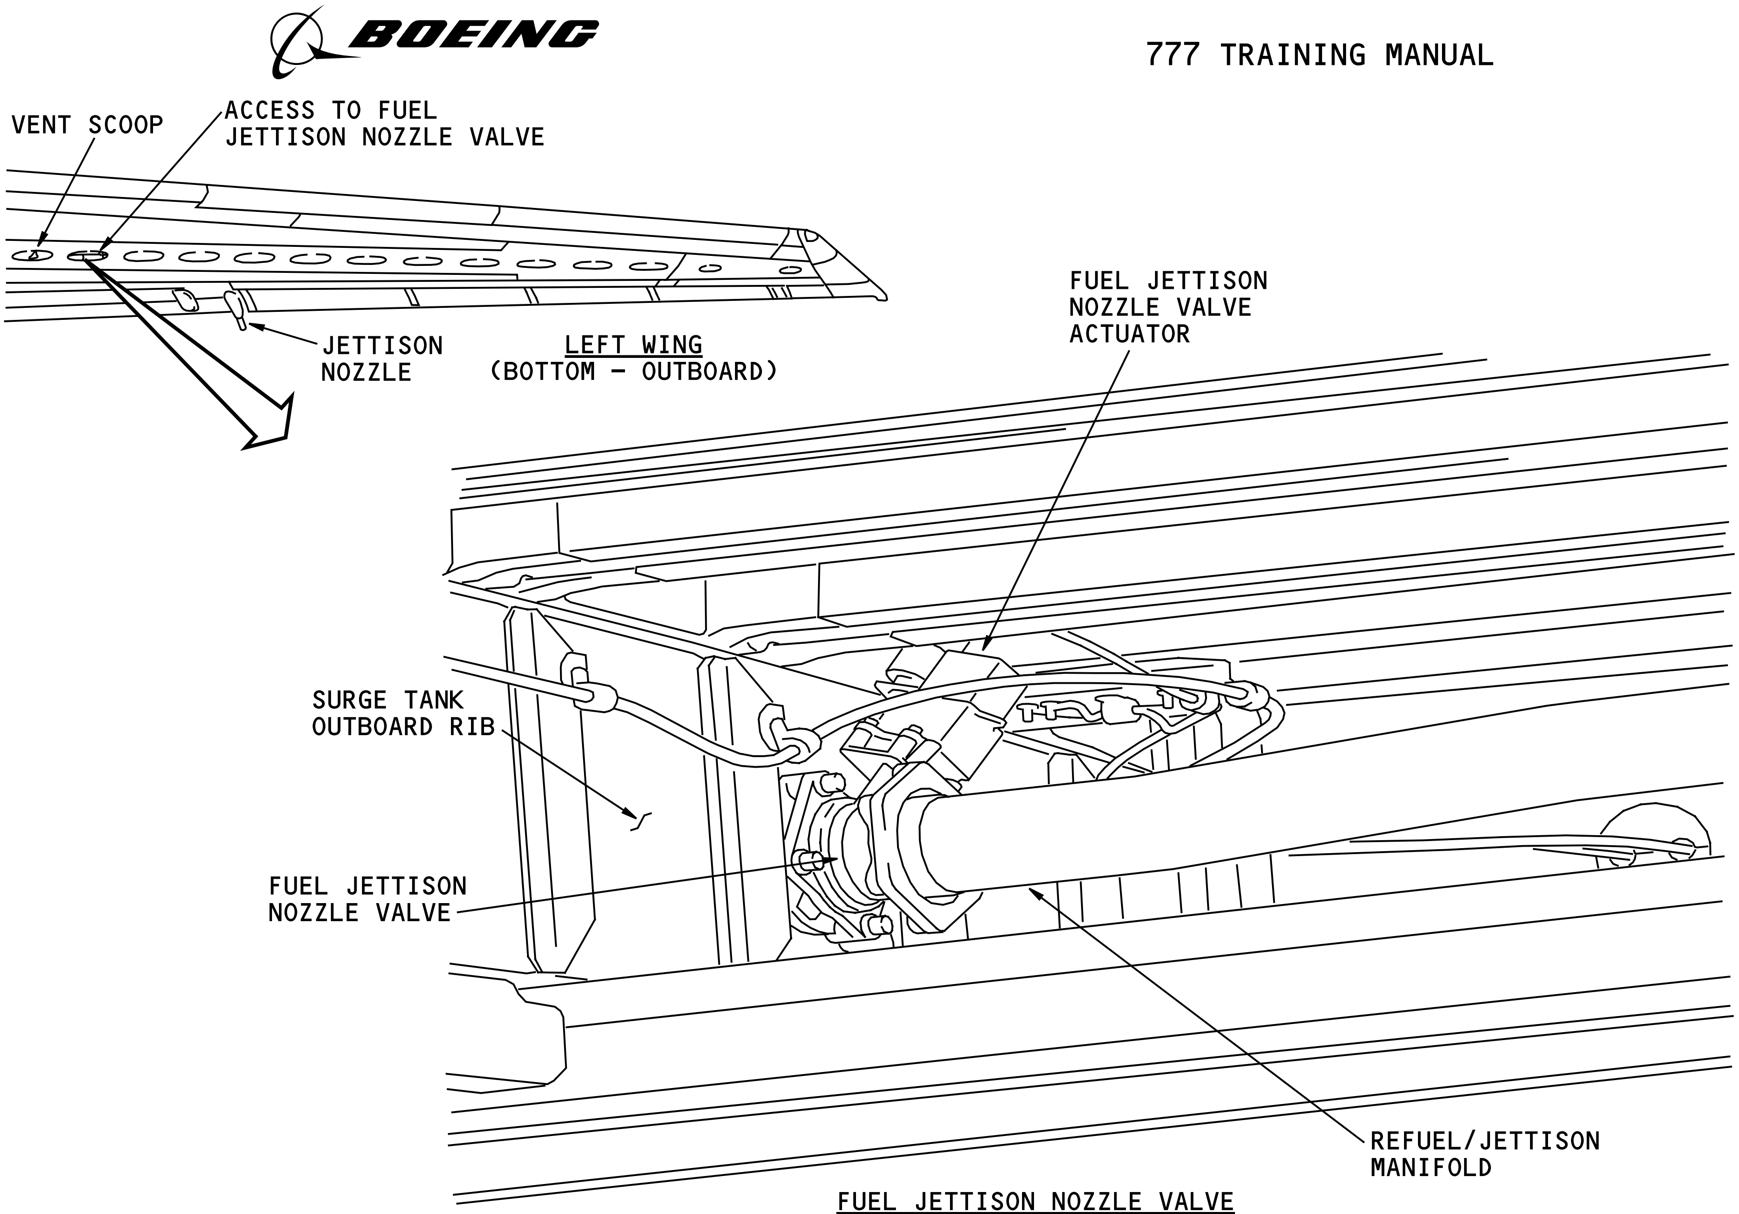
The fuel jettison nozzle valves open during fuel jettison operation. When the valve opens, fuel goes out of the jettison nozzle near the wing tip.

Location

There is one fuel jettison nozzle valve at each end of the refuel/jettison manifold. They are outboard of the surge tank (outboard of rib 34).

Jettison Valve Description

The fuel jettison nozzle valves are the same type of valve as the other motor-actuated valves in the fuel system.



FUEL JETTISON - JETTISON NOZZLE VALVE

28-31-00-006 Rev 3 05/12/1995

FUEL JETTISON - FUNCTIONAL DESCRIPTION - FUEL FLOW

General

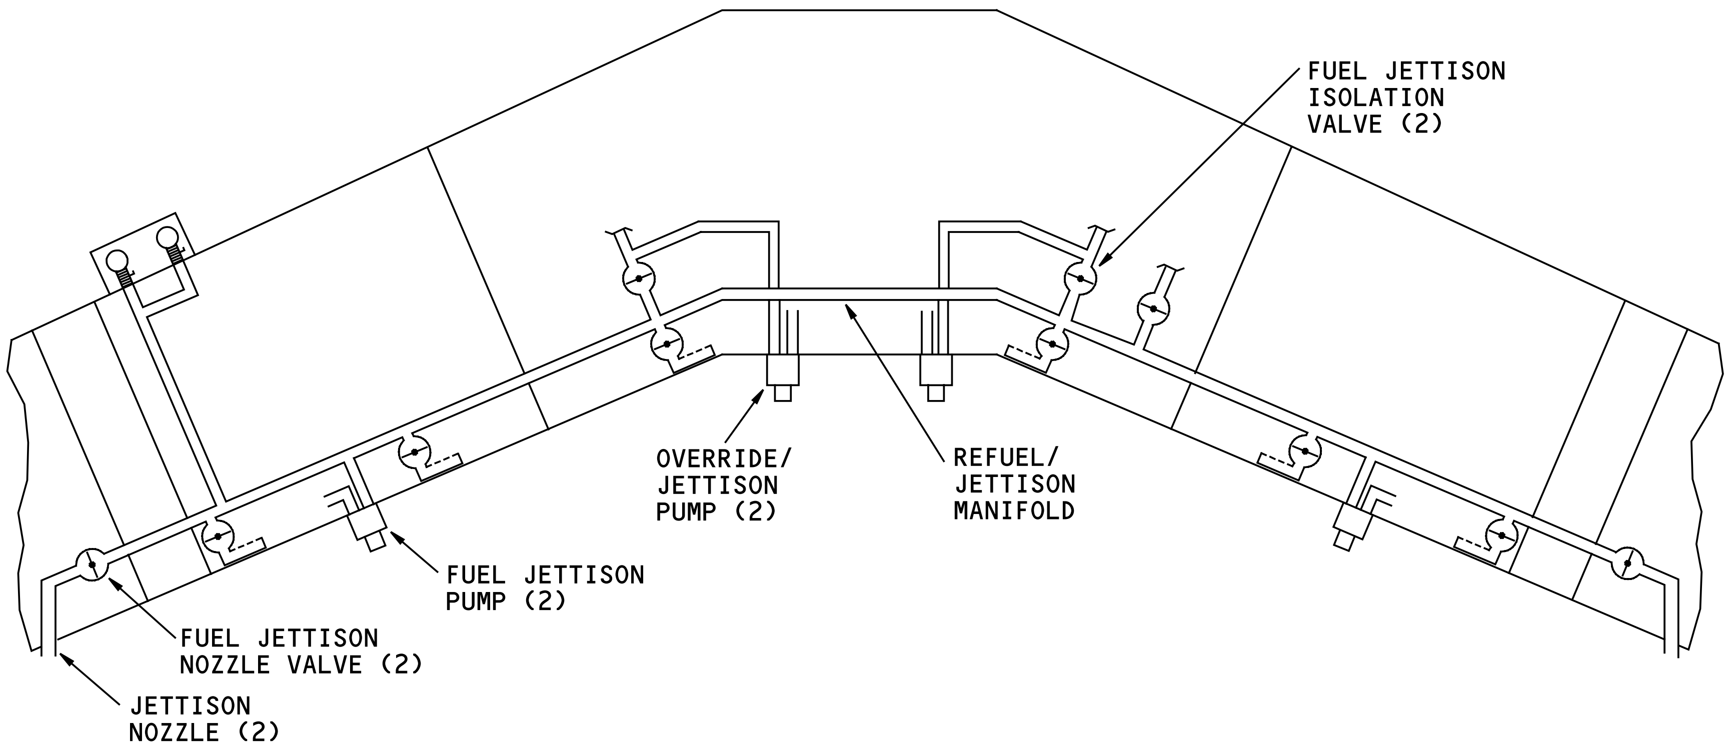
Jettison can occur from the center tank or the main tanks. Fuel from the tank flows through the refuel/ jettison manifold.

Center Tank Jettison

The center tank uses the override/jettison pumps as engine feed pumps and jettison pumps. When the jettison system operates, the pumps put fuel through the fuel jettison isolation valves into the refuel/jettison manifold. The fuel goes out of the manifold through the fuel jettison nozzle valves and jettison nozzles.

Main Tank Jettison

The main tanks have pumps that operate only during fuel jettison. These pumps deliver fuel directly into the refuel/jettison manifold. This fuel also leaves the manifold through the fuel jettison nozzle valves and jettison nozzles.



28-31-00-007 Rev 4 03/11/96

FUEL JETTISON - FUNCTIONAL DESCRIPTION - FUEL FLOW

FUEL JETTISON - FUNCTIONAL DESCRIPTION - POWER & CONTROL

Power

The left fuel jettison pump receives 115v ac power from the left main bus.

Jettison Pump Control - Ground

When the airplane is on the ground, the ELMS electronics unit turns on the fuel jettison pumps when you put the jettison ARM switch in the ARM position.

The jettison arm switch sends a signal on the systems ARINC 629 buses to the ELMS electronics unit in the left power management panel. Pump logic in the ELMS electronics unit sends a command to an ELCU in the left power panel to turn on the left fuel jettison pump. The pump logic also sends a signal to turn on the right fuel jettison pump. The ELCU closes a contactor to permit power to go from the left main bus to the pump. The ELCU receives power from the left main dc bus.

The pump control logic in the P210 panel can also turn on the left fuel jettison pump.

Jettison Pump Control - Air

When the airplane is in the air, the ELMS electronics unit turns on the fuel jettison pumps, when all of these conditions occur:

- Jettison arm switch is in the ARM position
- Left or right jettison nozzle valve is open
- Fuel quantity is more than the fuel-to-remain value.

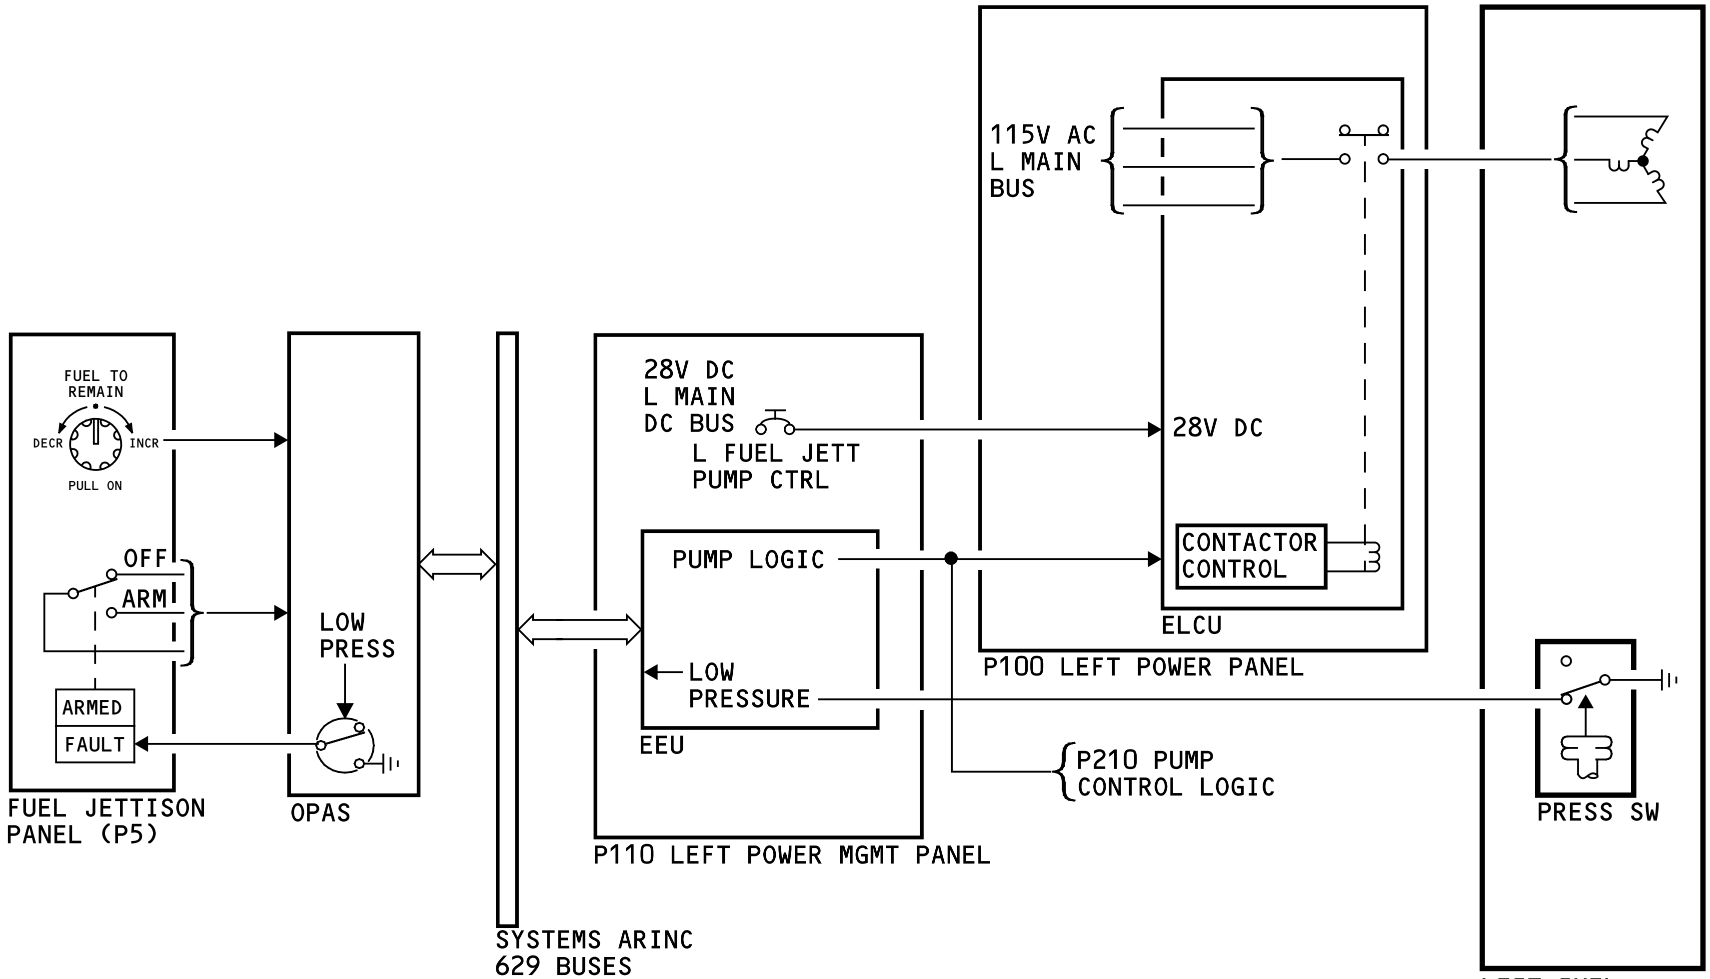
Fuel jettison can cause the airplane center of gravity to be forward of the center of gravity limit. If the ELMS calculates that this will happen, it stops the main tank jettison pumps for 7.5 minutes. The ELMS monitors these parameters to see if it is necessary to stop the main tank jettison pumps:

- Airplane center of gravity
- Airplane gross weight
- Center tank fuel weight.

Fault Indication

The jettison pump has a pressure switch to check for low pressure at the pump outlet. The jettison pump pressure switch closes when there is low pressure. The ELMS logic sends a signal through OPAS to turn on the fault light in the arm switch. The fault light comes on only when the system is armed.

An EICAS status message tells you which pump is defective.



NOTE: LEFT SHOWN
RIGHT SIMILAR

28-31-00-008 Rev 4 05/12/95

FUEL JETTISON - FUNCTIONAL DESCRIPTION - POWER & CONTROL

FUEL JETTISON - FUNCTIONAL DESCRIPTION - ISOLATION AND NOZZLE VALVE CONTROL

Fuel Jettison Isolation Valve

The left main dc bus supplies power to open and close the left fuel jettison isolation valve. Valve logic in two ELMS electronics units (P110 or P210) controls the left and right jettison isolation valve control relays. The relay energizes to open the isolation valve.

When the airplane is on the ground, the ELMS electronics units open the isolation valves when the jettison arm switch is on.

The ELMS electronics units open the isolation valves in the air when these conditions are met:

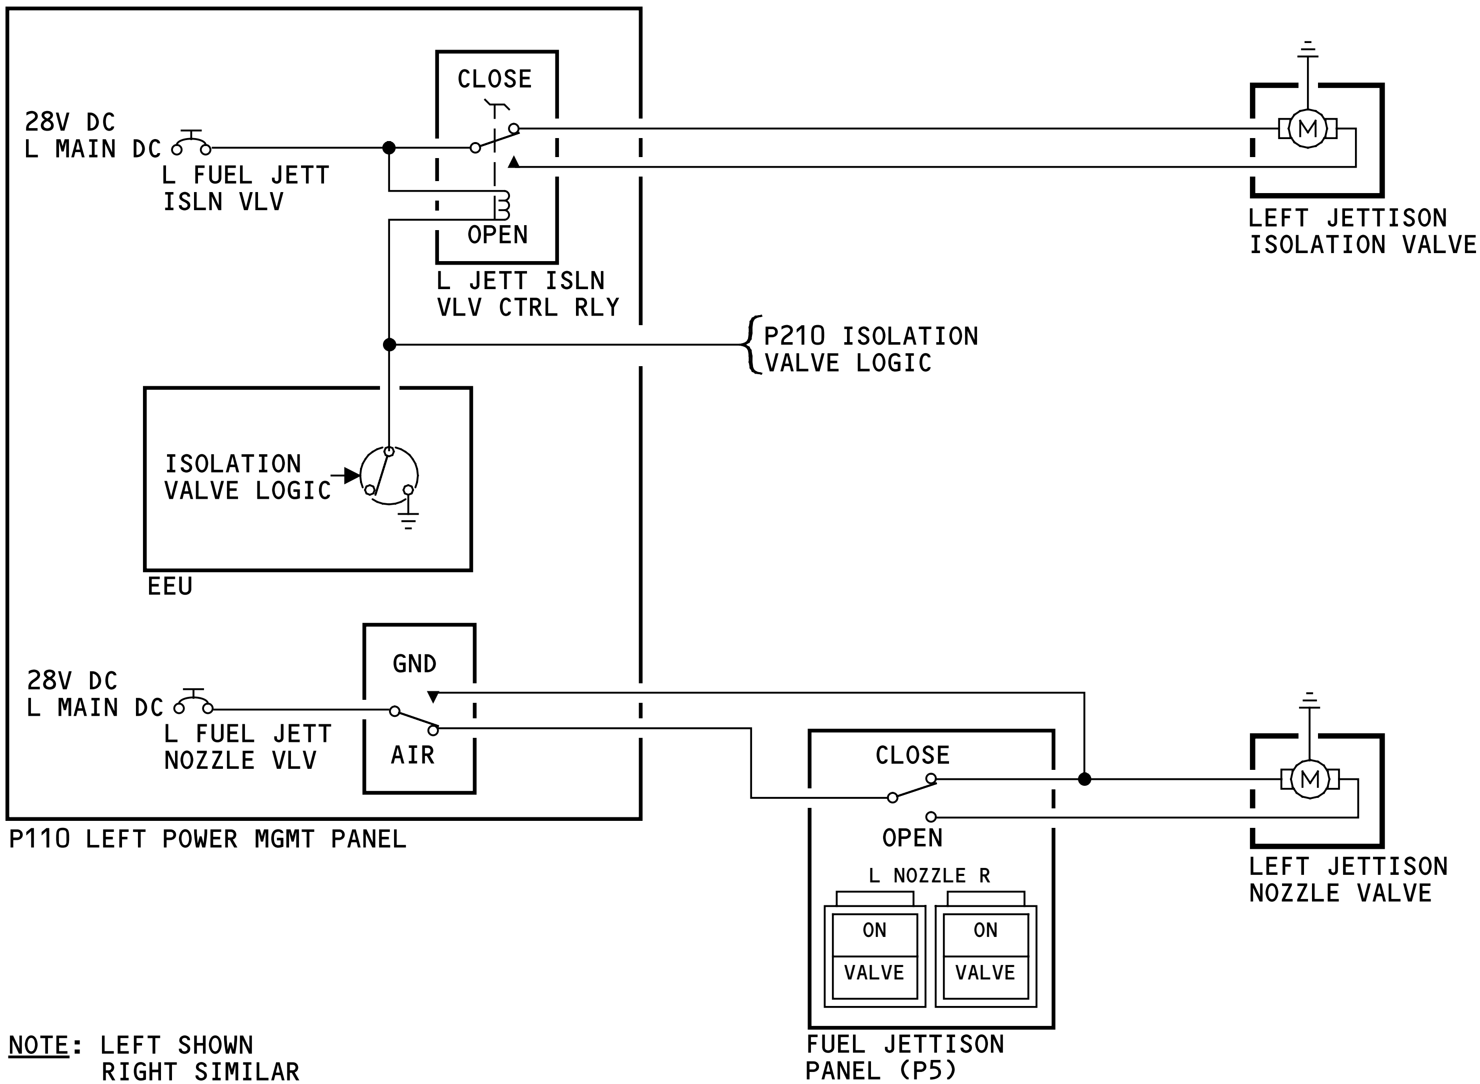
- Jettison arm switch is on
- Left or right jettison nozzle valve is open
- Fuel quantity is greater than fuel-to-remain.

Fuel Jettison Nozzle Valve

The left main dc bus supplies power to open and close the nozzle valve. Power goes through an air/ground relay.

The nozzle valve does not open when the airplane is on the ground.

When the airplane is in the air, the nozzle valve opens when the jettison system is armed and you push the nozzle switch.



28-31-00-009 Rev 2

FUEL JETTISON - FUNCTIONAL DESCRIPTION - ISOLATION AND NOZZLE VALVE CONTROL

THIS PAGE INTENTIONALLY LEFT BLANK

FUEL JETTISON - OPERATION

General

You can use the jettison system in the air to dump fuel overboard. The airplane must be in air mode for the jettison nozzle valves to open. If the airplane is in ground mode when you arm the jettison system, the main tank fuel jettison pumps and the jettison isolation valves operate immediately.

Jettison

This is a brief description of jettison system operation when the airplane is in the air mode:

- Push the ARM switch
- Increase or decrease the fuel-to-remain with the FUEL TO REMAIN selector
- Push the NOZZLE switches to open the jettison nozzle valves, start the jettison pumps, and open the jettison isolation valves
- Turn off the NOZZLE switches when the EICAS display shows the jettison complete advisory message
- Turn off the ARM switch.

When you arm the jettison system, it is in the maximum-landing-weight mode. In this mode, the jettison system automatically sets the fuel-to-remain quantity that will make the airplane weight equal to the maximum landing weight.

If you pull the FUEL TO REMAIN selector, the jettison system changes to the manual mode. Then you turn the FUEL TO REMAIN selector to change the fuel-to-remain quantity. Turn the selector left to decrease or right to increase the fuel-to-remain quantity.

You use the override/jettison pump switches to control the center tank override/jettison pumps. The jettison system does not control the override/jettison pumps.

The fuel jettison rate with one nozzle valve open is 2700 lbs/hr (1224 kg/hr) with the operation of the jettison pumps only, and 3500 lbs/hr (1587 kg/hr) with the jettison and the override/jettison pumps.

The fuel jettison rate with two nozzle valves open is 3100 lbs/hr (1406 kg/hr) with the operation of the jettison pumps only, and 5400 lbs/hr (2449 kg/hr) with the jettison and the override/jettison pumps.

Indications

The EICAS display shows these jettison system indications:

- Total fuel quantity
- Fuel-to-remain
- Jettison mode.

The jettison mode shows adjacent to the fuel-to-remain quantity. MLW shows if the jettison system is in the maximum-landing-weight mode. MAN shows if the jettison system is in the manual mode.

FUEL JETTISON - OPERATION

The fuel synoptic display shows these jettison system indications:

- Override/jettison pump operation
- Jettison isolation valve position
- Jettison pump operation
- Jettison nozzle valve position
- Fuel-to-remain
- Jettison mode
- Time until jettison complete.

DEFUEL

28-26-00-001 Rev 3 03/26/96

DEFUEL - INTRODUCTION

DEFUEL - GENERAL DESCRIPTION

General

The defuel system moves fuel from the airplane tanks to refuel station. It also moves fuel from one airplane tank into another (tank-to-tank transfer). There are two ways to get fuel out of the tanks:

- Use the airplane fuel pumps (pressure-defuel)
- Use ground pumps (suction-defuel).

You must open the defuel valve to move fuel to the refuel station. Refuel hoses transfer fuel to ground tanks or a defuel truck.

You do these things for a tank-to-tank transfer:

- Open the defuel valve
- Open the applicable refuel valves
- Operate the applicable fuel pumps.

You must open a crossfeed valve to remove fuel from the left main tank through the engine feed manifold.

Control and Indication

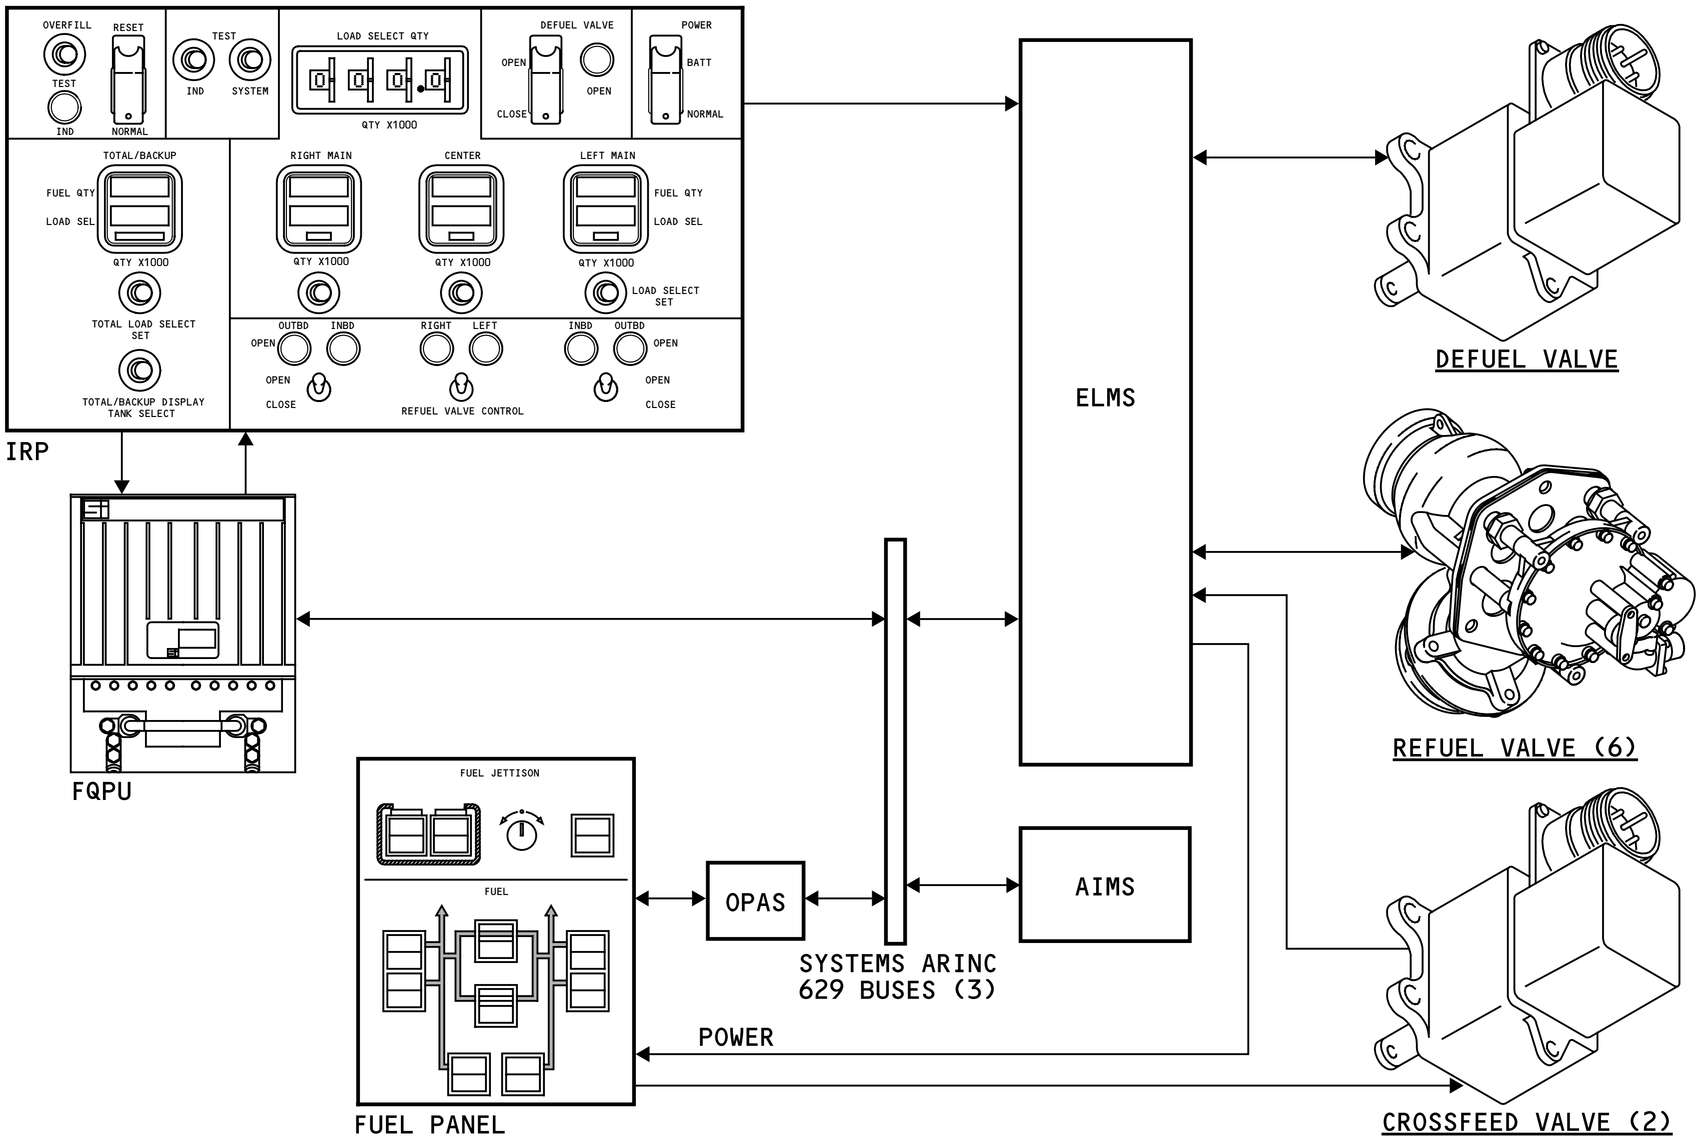
You use the IRP to open and close the defuel valve and refuel valves. The ELMS supplies power to open and close the valves.

The defuel valve switch controls relays in the ELMS to open and close the defuel valve. The refuel valve switches send valve position signals to the FQPU. The FQPU controls relays in the ELMS to open and close the refuel valves. The FQPU controls the refuel and defuel valve position lights on the IRP.

The FQPU supplies fuel quantity data to the IRP.

You use the fuel panel switches on the P5 panel to operate the fuel pumps.

The refuel section describes the refuel valves. The engine fuel feed section describes the fuel pumps and the crossfeed valves.



DEFUEL - GENERAL DESCRIPTION

DEFUEL - COMPONENT LOCATIONS - CENTER FUEL TANK

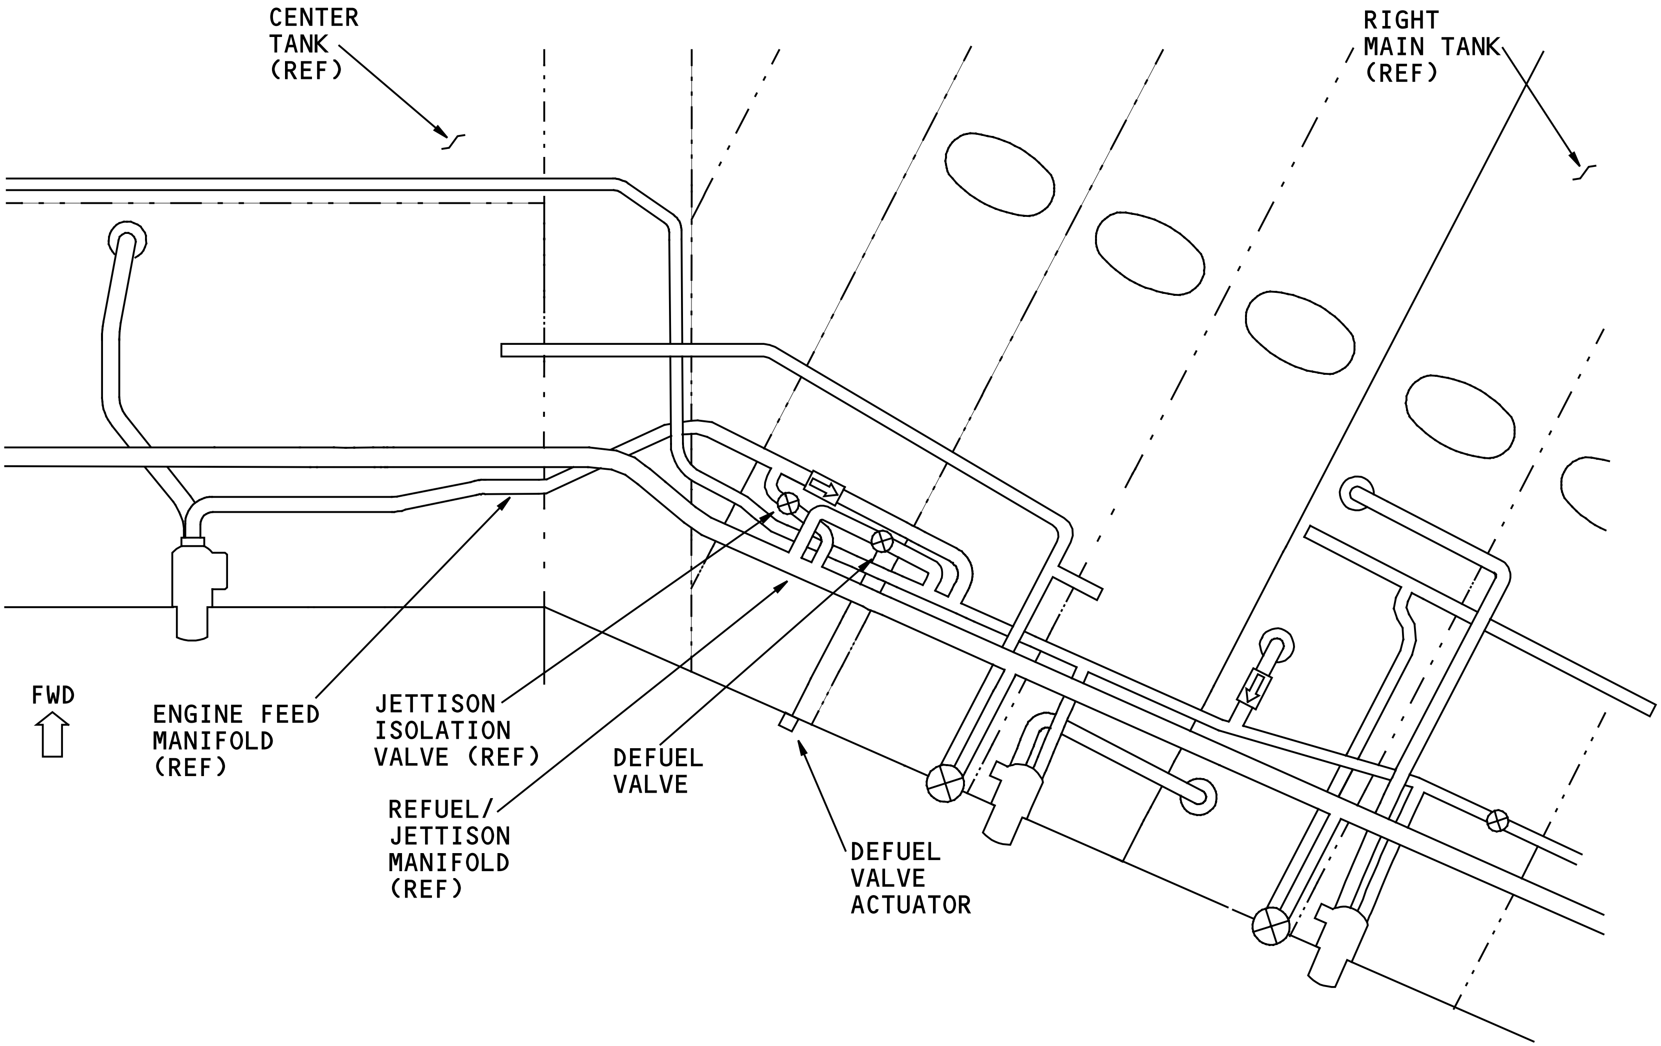
Purpose

The defuel valve connects the engine feed manifold to the refuel/jettison manifold.

Location

There is one defuel valve. It is in the right side of the center tank. You get access to the defuel valve though the first fuel tank access door in the right wing.

The defuel valve actuator is on the rear spar. It is aft of the first fuel tank access door in the right wing.



28-26-00-003 Rev 3 03/18/96

DEFUEL - COMPONENT LOCATIONS - CENTER FUEL TANK

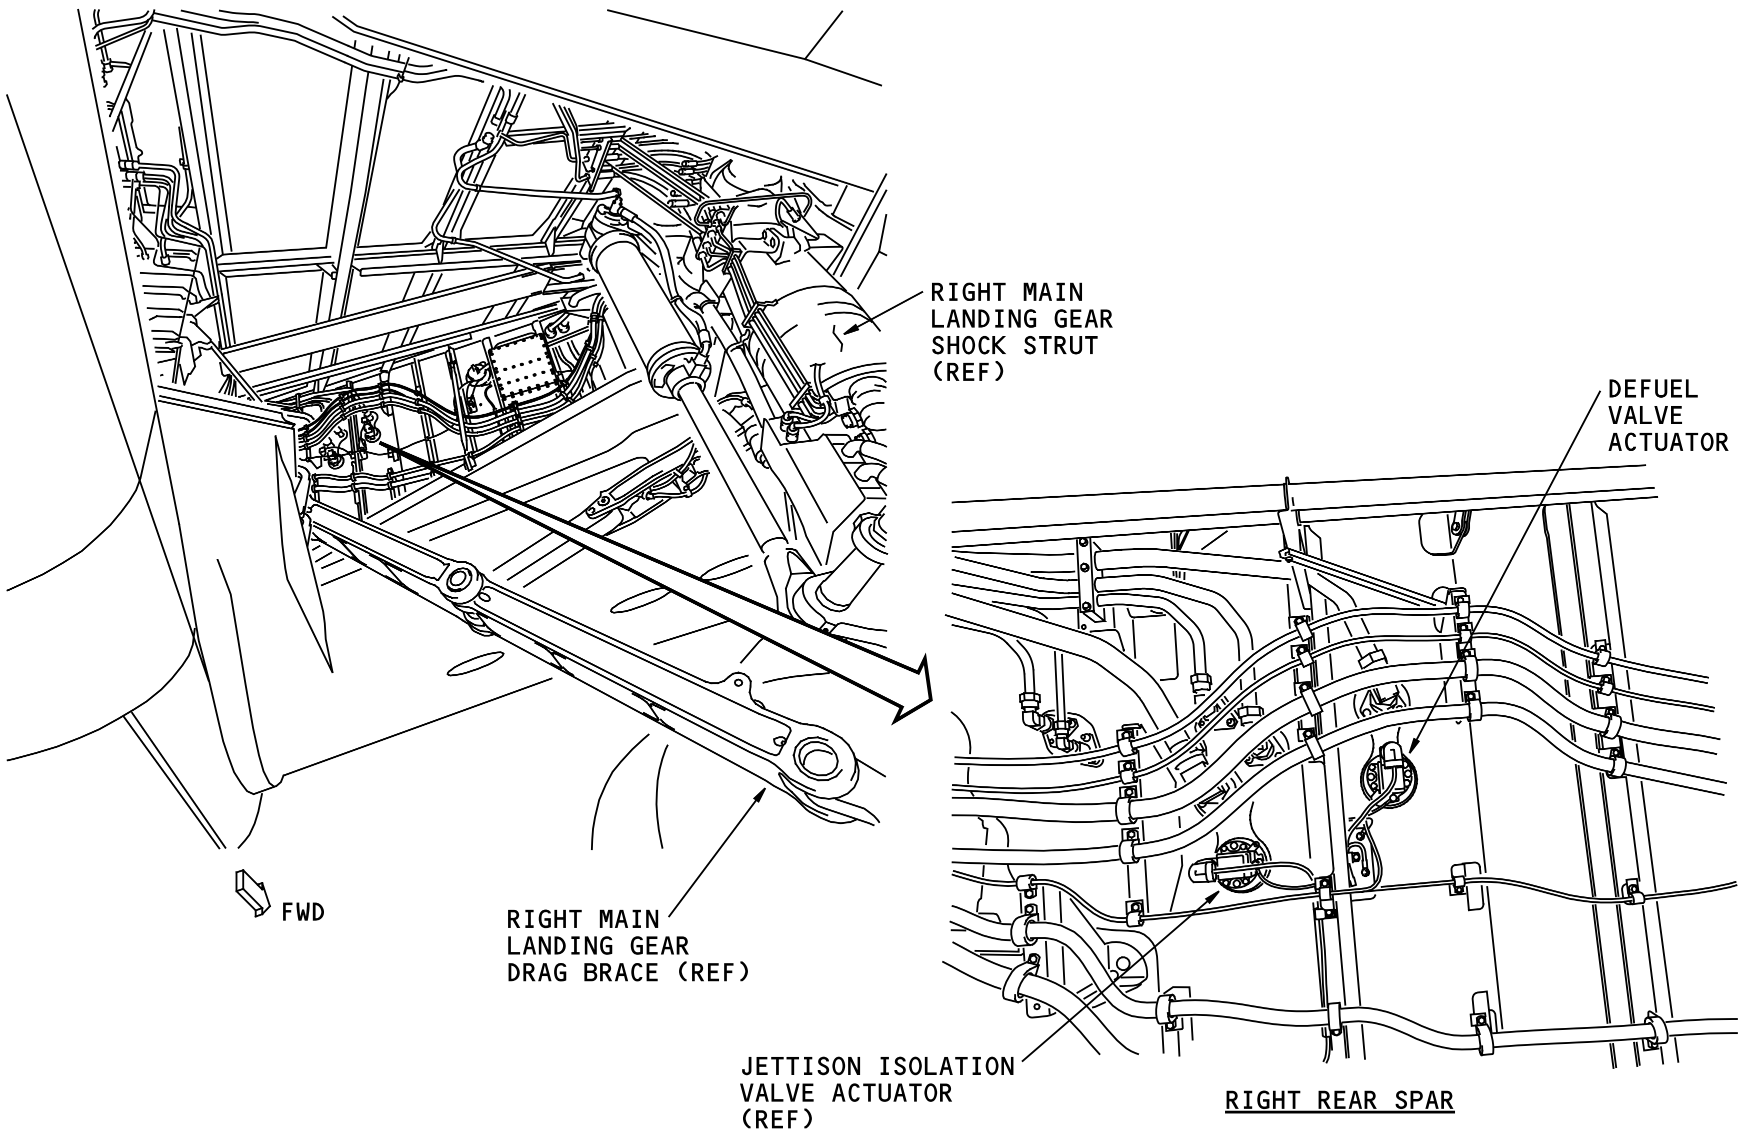
DEFUEL - DEFUEL VALVE

Purpose

The defuel valve connects the engine feed manifold to the refuel/jettison manifold so you can remove fuel from the fuel tanks.

Description

The defuel valve is a motor-actuated valve. The valve body is in tubing in the right side of the center tank. The tubing connects to the right engine feed manifold and the refuel/jettison manifold. The valve actuator is on the right rear spar. See the engine fuel feed section for more information about motor-actuated fuel valves (AMM PART I 28-22).



DEFUEL - DEFUEL VALVE

DEFUEL - FUNCTIONAL DESCRIPTION - FUEL FLOW

General

You can pressure-defuel the fuel tanks with the engine feed system. You can also suction defuel the main tanks through the bypass valve.

Pressure-Defueling With Engine Feed System

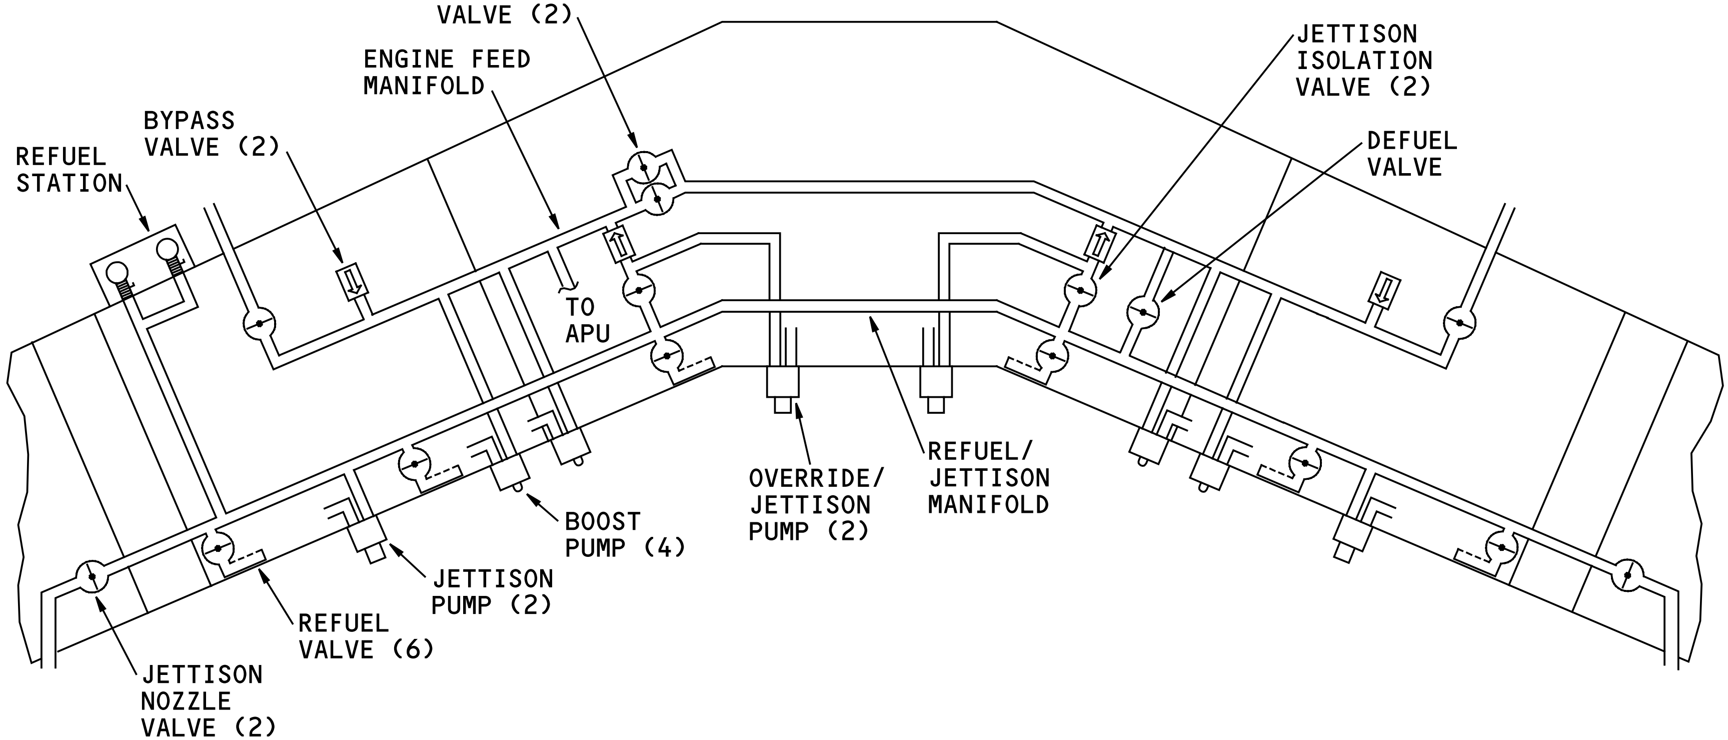
When you use the boost pumps to pressure-defuel the airplane, the pumps put fuel into the engine feed manifold. When you open the defuel valve the fuel goes into the refuel/jettison manifold and out the refuel station adapters. One of the crossfeed valves must be open for fuel from the left side to get to the defuel valve.

Suction-Defueling

You suction-defuel the main tanks through the bypass valves. You must open the defuel valve to get fuel from the engine feed manifold into the refuel/jettison manifold. Suction-defuel will remove fuel until the fuel level is below one of the two bypass valves. Then you must use another method to defuel the tanks.

Tank-to-Tank Transfer

You can also defuel a tank by moving fuel into another tank. In this case, instead of removing fuel through the refuel adapters at the refuel station, you open the refuel valves for the tank in which you want to put the fuel.



28-26-00-004 Rev 5 03/18/96

DEFUEL - FUNCTIONAL DESCRIPTION - FUEL FLOW

DEFUEL - FUNCTIONAL DESCRIPTION - ELECTRICAL

General

The hot battery bus supplies power to the defuel valves. Power goes through the refuel panel door relay and defuel valve control relay in the P310 standby power management panel.

Defuel Valve Control

Power to operate the valve goes through limit switches to the actuator. The actuator moves the valve to the commanded position. When the valve is in the commanded position, the limit switches remove power from the actuator and send power to the ELMS valve disagree logic.

The defuel valve control relay energizes when you put the defuel valve switch in the open position.

You can open the defuel valve only when the refuel panel door is open. When the refuel panel door closes, the defuel valve automatically closes. When the door closes, it also moves the defuel valve switch to the closed position.

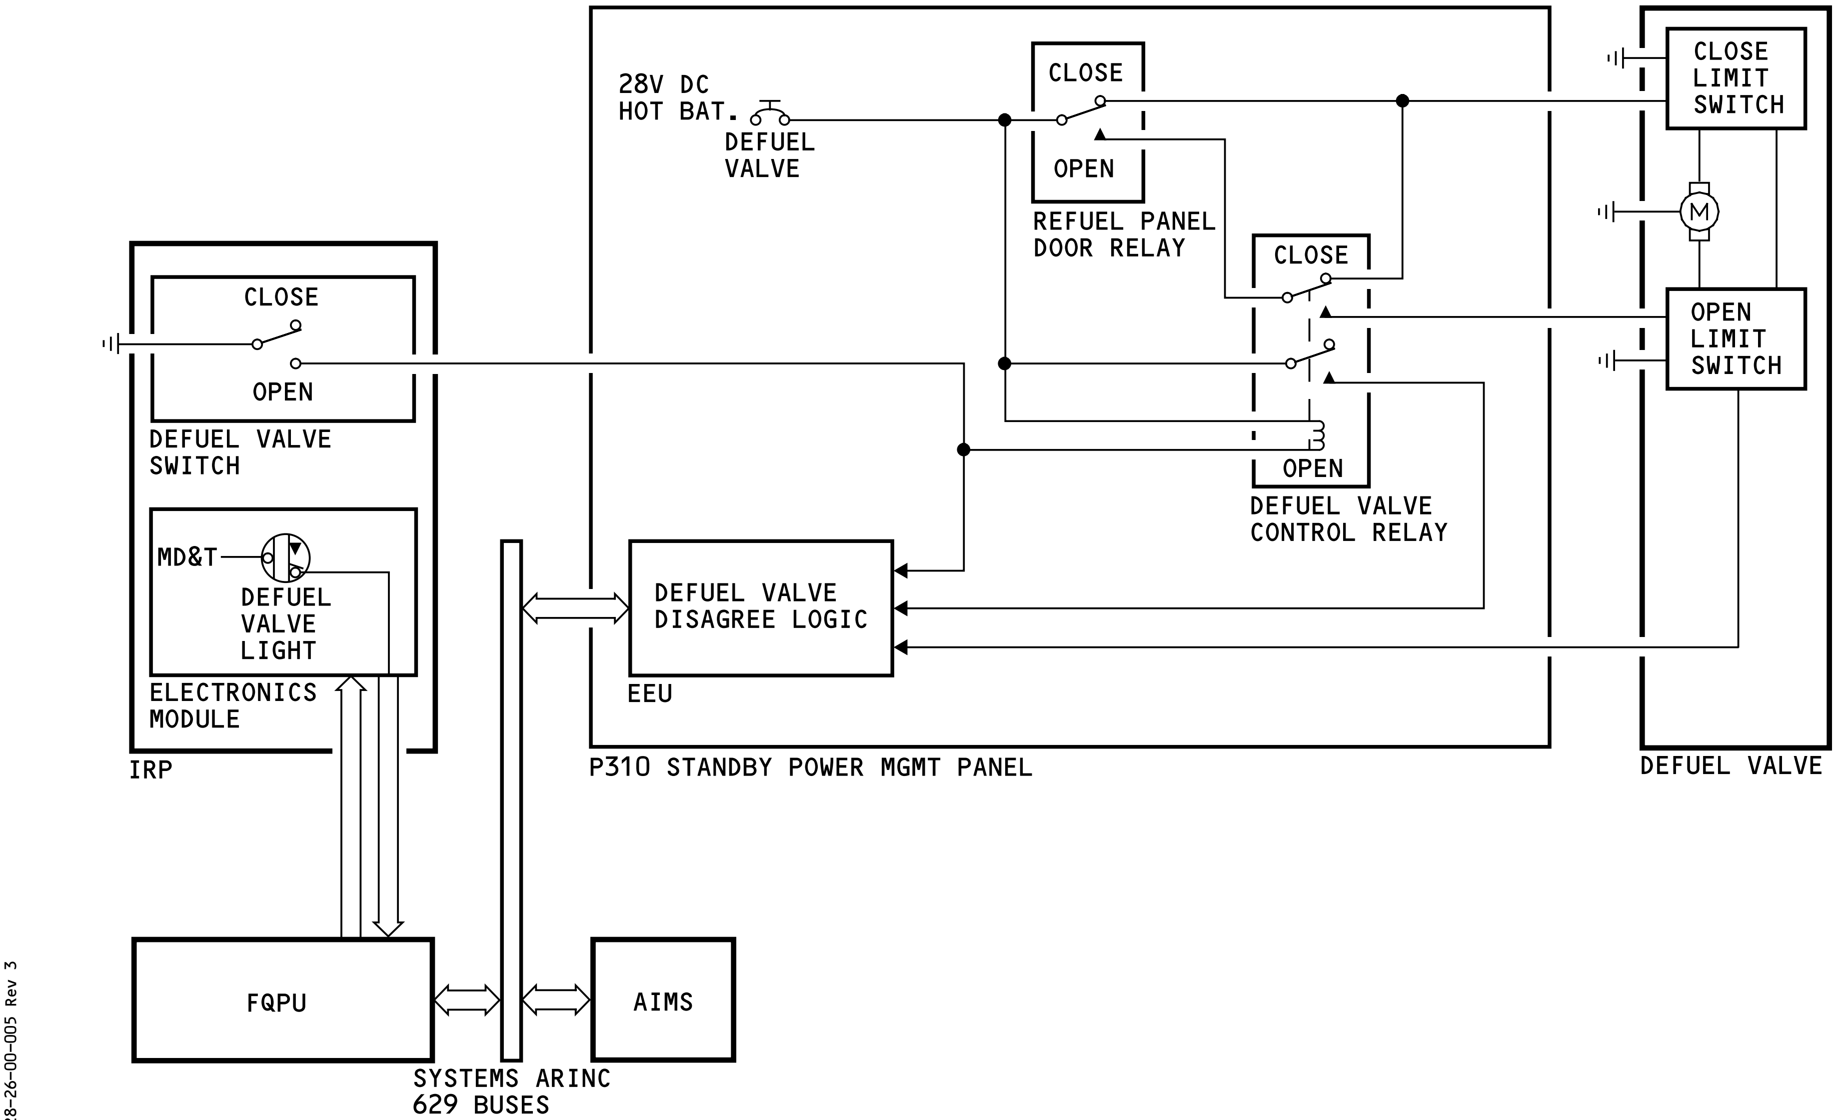
Indication

The P310 EEU monitors the position of these components:

- Defuel valve switch
- Defuel valve control relay
- Defuel valve.

The EEU sends the position signals to the FQIS processor unit (FQPU) on the ARINC 629 system buses. When the valve is open, the FQPU turns on the blue defuel valve light. You push the defuel valve light to do a test of it.

If there is a disagreement between the switch position and the defuel valve control relay, the FQPU sends a fault signal to the AIMS.



DEFUEL - FUNCTIONAL DESCRIPTION - ELECTRICAL

DEFUEL - OPERATION

General

The defuel procedure is on a placard on the refuel station door. The procedure is also in the maintenance manual.

Defuel Procedure

This is a brief summary of the pressure-defuel procedure:

- Connect the fueling nozzles
- Move the defuel lever on refuel adapter to the defuel position
- Move the defuel valve switch to OPEN
- Turn on the fuel pumps in each tank that you want to defuel
- Open crossfeed valve if necessary
- Move the defuel valve switch to CLOSE when the tanks are empty
- Turn off the fuel pumps
- Move the defuel lever on the refuel adapter to the refuel position
- Remove the fueling nozzles
- Do a test of the defuel valve open light.

The suction-defuel procedure is the same as the pressure-defuel procedure except you do not turn on the fuel pumps. Suction defueling stops when one of the bypass valve inlets is uncovered. Thus, if the tanks do not become empty at the same time, there may be fuel remaining in one of the tanks.

Tank-to-Tank Transfer

To move fuel from one tank to another you must use the engine feed, defuel, and refuel systems. These steps are necessary for tank-to-tank transfer:

- Do a test of the indicators and defuel valve open light
- Move the defuel valve switch to OPEN
- Turn on the fuel pumps in the tank you want to defuel
- Open crossfeed valve if necessary
- Move the refuel valve switches to OPEN in the tank you want to put the fuel into.

If you want to defuel the tank, let the pump operate until the tank is empty. If you want to move only part of the fuel, use the refuel valve control switches to stop the fuel flow.

POWER PLANT - INTRODUCTION

POWER PLANT - ENGINE HAZARDS

General

It is dangerous to work around engines. Use the engine entry corridors to go near an engine in operation.You must stay out of the inlet and exhaust hazard areas when the engine is running.

The hazards around jet engines in operation include:

- Inlet suction
- Heat
- Exhaust
- Noise.

Engine Entry Corridors

Engine entry corridors are between the inlet hazard areas and the exhaust hazard areas. You should go near an engine in operation only when:

- The engine is at idle (forward thrust only)
- You can speak with the flight deck.

Inlet Suction

Suction at the inlet of an engine can pull objects, including a person, into the engine. At idle power, the hazard area is an 12 ft (3.7 m) radius around the inlet. At takeoff thrust, the hazard area is a 28.5 ft (8.8 m) radius around the inlet.

WARNING: IF SURFACE WIND IS GREATER THAN 25 KNOTS, INCREASE THE INLET HAZARD AREA BY 20%.

Engine damage can result when rags, eyeglasses, hats, or other loose objects go into the inlet cowl. You must attach or remove any loose objects before you work around the engine.

Heat

The engine exhaust temperature can remain high for a long distance behind the engine.

Exhaust

The engine fan and thrust reverser develop high speed exhaust gases that can cause injury. The exhaust gases move forward when the thrust reverser deploys.

Noise

Engine noise can cause temporary and permanent hearing loss. You must wear cup-type ear protection near an engine in operation.

WARNING: LONG EXPOSURES TO JET ENGINE NOISE CAN CAUSE HEARING DAMAGE EVEN WHEN YOU WEAR EAR PROTECTION.

POWER PLANT - ENGINE HAZARDS

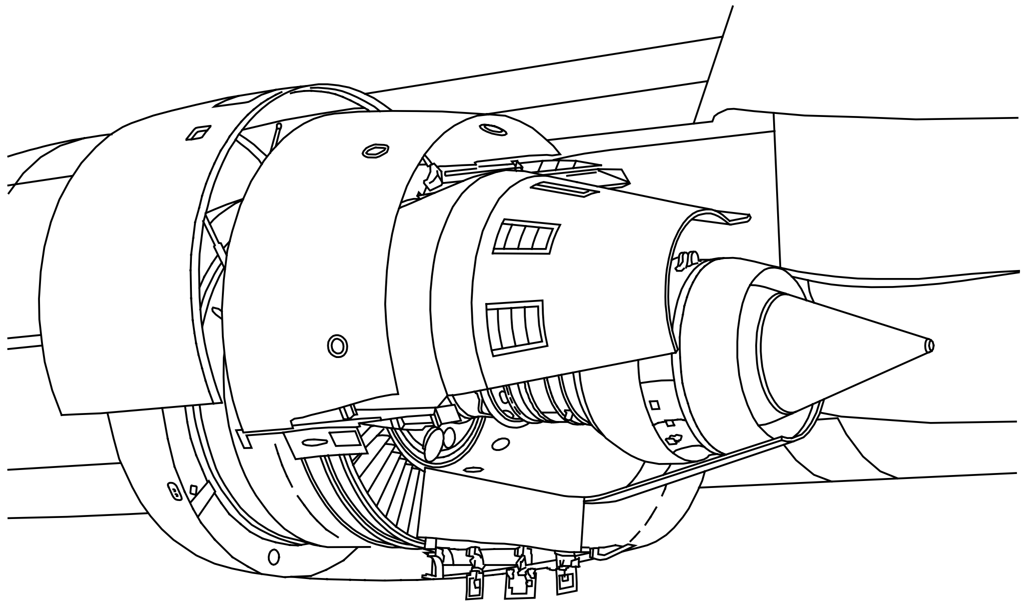
ENGINE COWLING - INTRODUCTION

General

The cowl contains and protects the engine components. The cowl also controls the airflow through and around the engine. Some of the engine cowl opens for maintenance access.

The engine cowl has four parts:

- Inlet cowl
- Fan cowl
- Thrust reverser
- Turbine exhaust system.



POWER PLANT

ENGINE COWLING | PDOS | TRAINING INFORMATION POINTS

ENGINE COWLING - INTRODUCTION

ENGINE COWLING - GENERAL DESCRIPTION

General

The engine cowling is a cover that contains and gives protection to the engine components. The cowling also controls the airflow through and around the engine. Some parts of the engine cowling open for maintenance access.

The engine cowling has four parts:

- Inlet cowl
- Fan cowl
- Thrust reverser
- Turbine exhaust.

Inlet Cowl

The inlet cowl supplies a smooth airflow into the engine. The inlet cowl weighs approximately 690 lb (315 kg).

Fan Cowl

The fan cowl is aft of the inlet cowl. The fan cowl attaches to the fan cowl support beam on the engine. The fan cowls open for maintenance. Each fan cowl panel weighs approximately 310 lb (140 kg).

Thrust Reverser

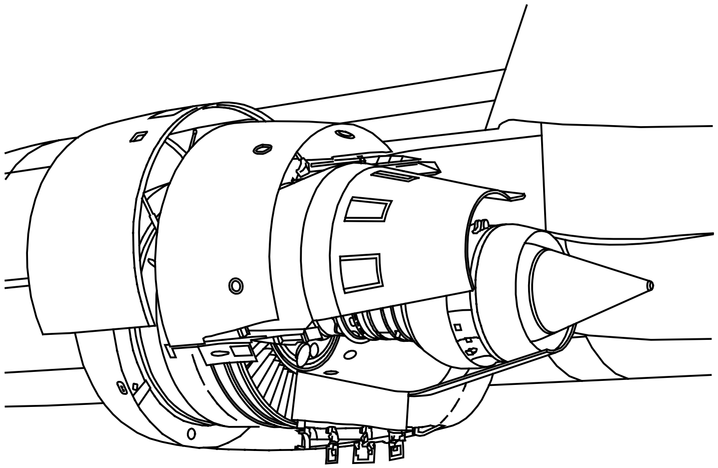
The thrust reverser is aft of the fan cowl. The thrust reverser attaches to the strut and opens for maintenance. Each thrust reverser half weighs approximately 1760 lb (800 kg).

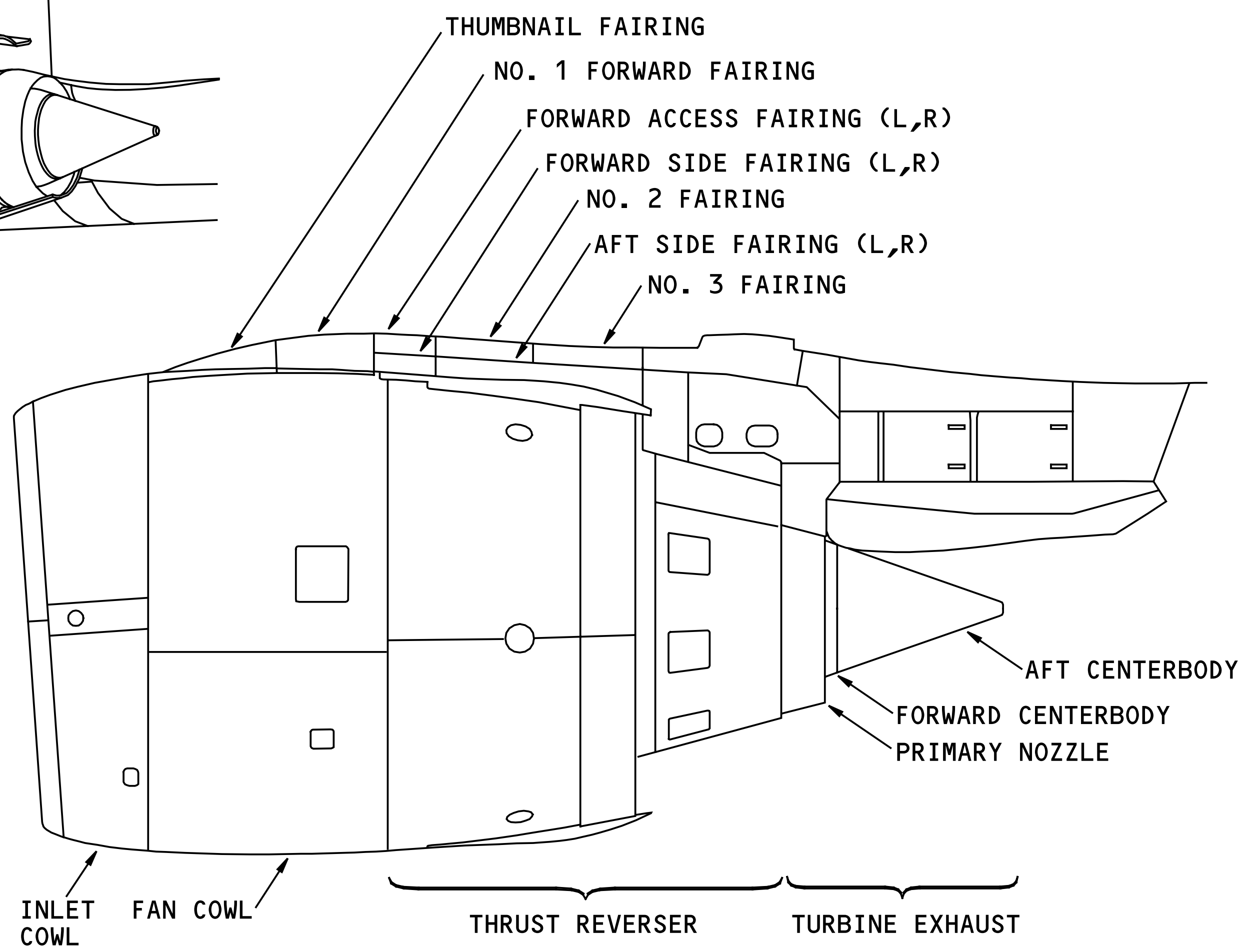
Turbine Exhaust

The turbine exhaust system is aft of the thrust reverser. The system has three parts:

- Primary nozzle
- Forward centerbody
- Aft centerbody.

The primary nozzle weighs approximately 70 lb (30 kg). The forward and aft centerbodies weigh approximately 80 lb (35 kg) together.





ENGINE COWLING - GENERAL DESCRIPTION

71-11-00-101 Rev 3 02/08/1997

ENGINE COWLING - INLET COWL

General

The inlet cowl controls the airflow into the engine fan. The inlet cowl is a single assembly with an upper and a lower half. The inlet cowls for the left and the right engines are interchangeable. The cowl includes these components:

- T12 sensor
- Engine anti-ice (EAI) system
- Powered door opening system (PDOS) actuation and control switches
- Hoist points.

EAI System

The EAI supply duct is at the 11:00 position on the inlet cowl. It gives anti-ice air to the inlet cowl.

The EAI exhaust duct is at the 9:00 position on the inlet cowl. The exhaust duct permits EAI air to flow overboard.

The EAI duct inside the inlet cowl has a shroud. It sends EAI air into the fan compartment if the duct breaks open.

Electrical Connections

There are two electrical connections on the aft bulkhead of the inlet cowl. They are at the 12:30 and the 3:00 positions. The connections are for the T12 sensor and the PDOS switches.

The T12 sensor measures engine inlet temperature and sends it to the EEC.

PDOS Actuation and Control Switches

The PDOS opens the fan cowls and the thrust reverser halves. Two PDOS switches are on each side of the inlet cowl. The fan cowl switches are at the 4:00 and the 8:00 positions on the outside of the inlet cowl. The thrust reverser switches are at the 4:00 and the 8:00 positions on the aft bulkhead of the inlet cowl.

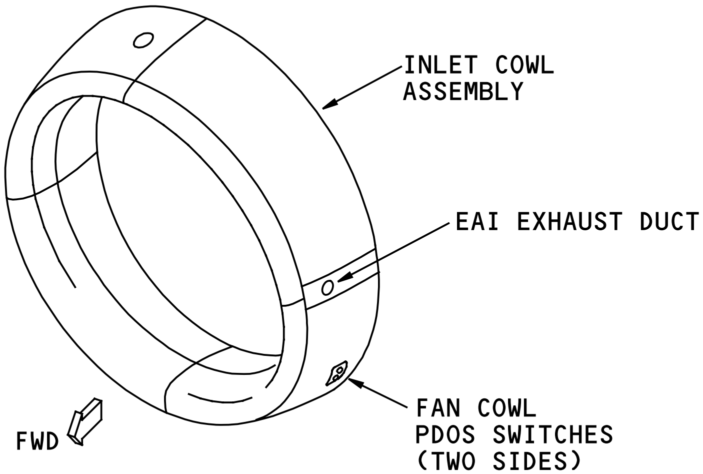
See the powered door opening system section for more information (AMM PART I 71-12).

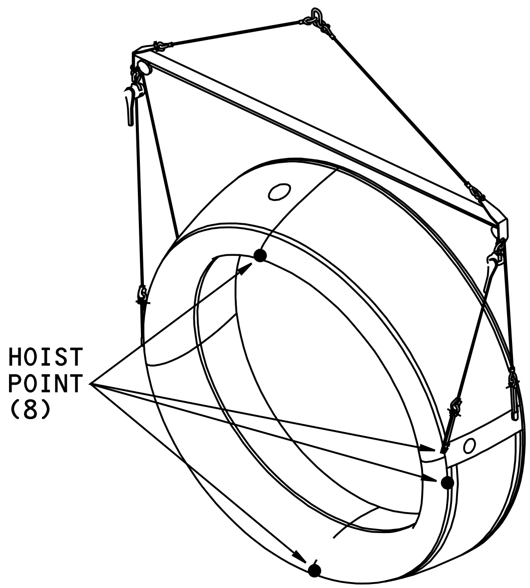
Hoist Points

The inlet cowl has eight hoist points. There are five hoist points on the upper inlet assembly and three on the lower inlet assembly.

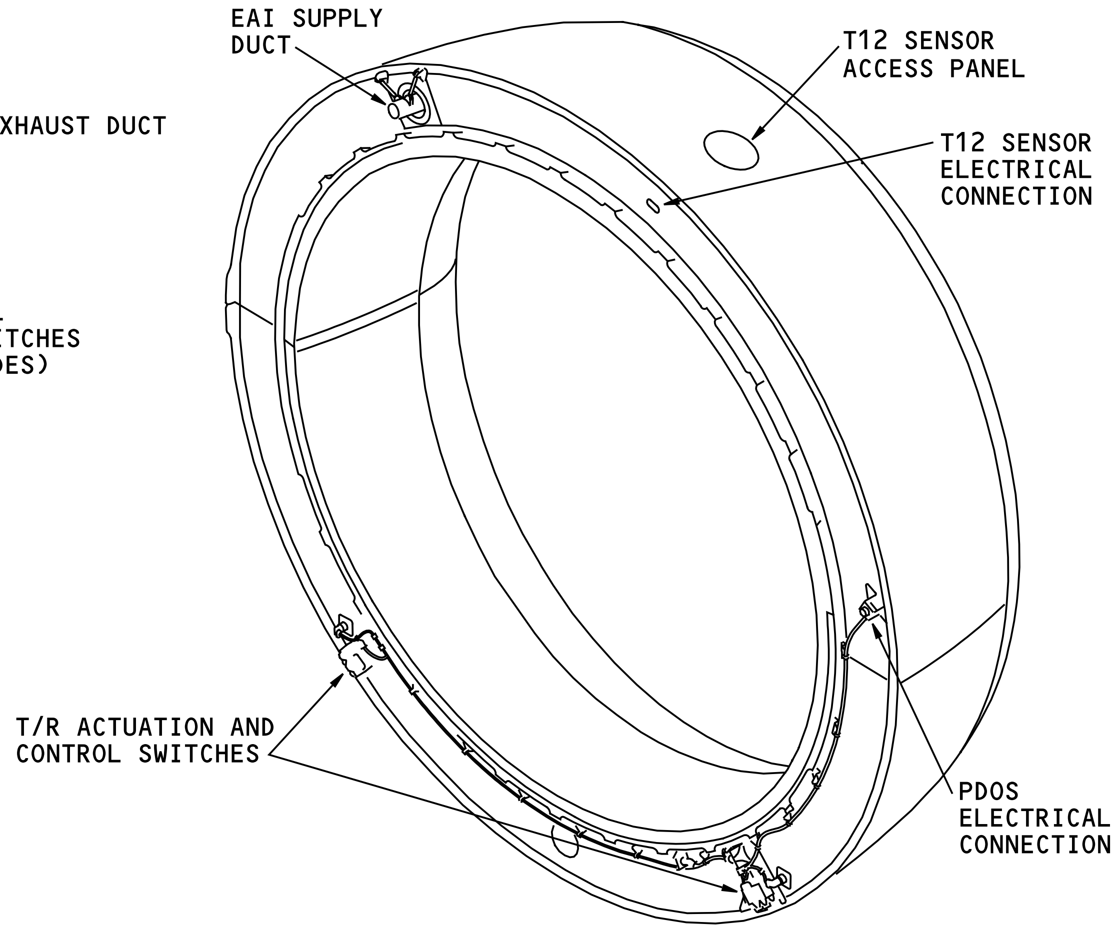
Training Information Point

You can separate the upper and the lower halves of the inlet cowl to move it. The upper and the lower halves are matched sets. They are not interchangeable with other inlet cowl halves.





SLING ATTACHMENT



INLET COWL ASSEMBLY

71-11-00-102 Rev 5 02/08/1997

ENGINE COWLING - INLET COWL

ENGINE COWLING - FAN COWL

General

Each engine has two fan cowls. The fan cowls let the air flow smoothly around the engine. The fan cowls open for maintenance.

Physical Description

The fan cowls are graphite-epoxy structures. Each fan cowl has four hinges. Each hinge attaches to the fan cowl support beam on the fan case. Each hinge has a quick release pin.

The inboard fan cowl on each engine has a chine at the 10:00 position. The fan cowl chine controls the airflow direction over part of the wing.

The left fan cowl has an oil tank access door and a pressure relief door. You service the engine oil tank through the oil tank access door.

You can remove each fan cowl panel with a sling that attaches at three hoist points.

Hold-Open Rods

Each fan cowl has a forward and an aft hold-open rod. The rods are telescopic. One end of the hold-open rod attaches to a bracket on the fan case. The other end attaches to fittings on the fan cowl.

Each hold-open rod has a locking collar. The collar locks the hold-open rod in place. When you can see a yellow stripe next to the collar, it is locked.

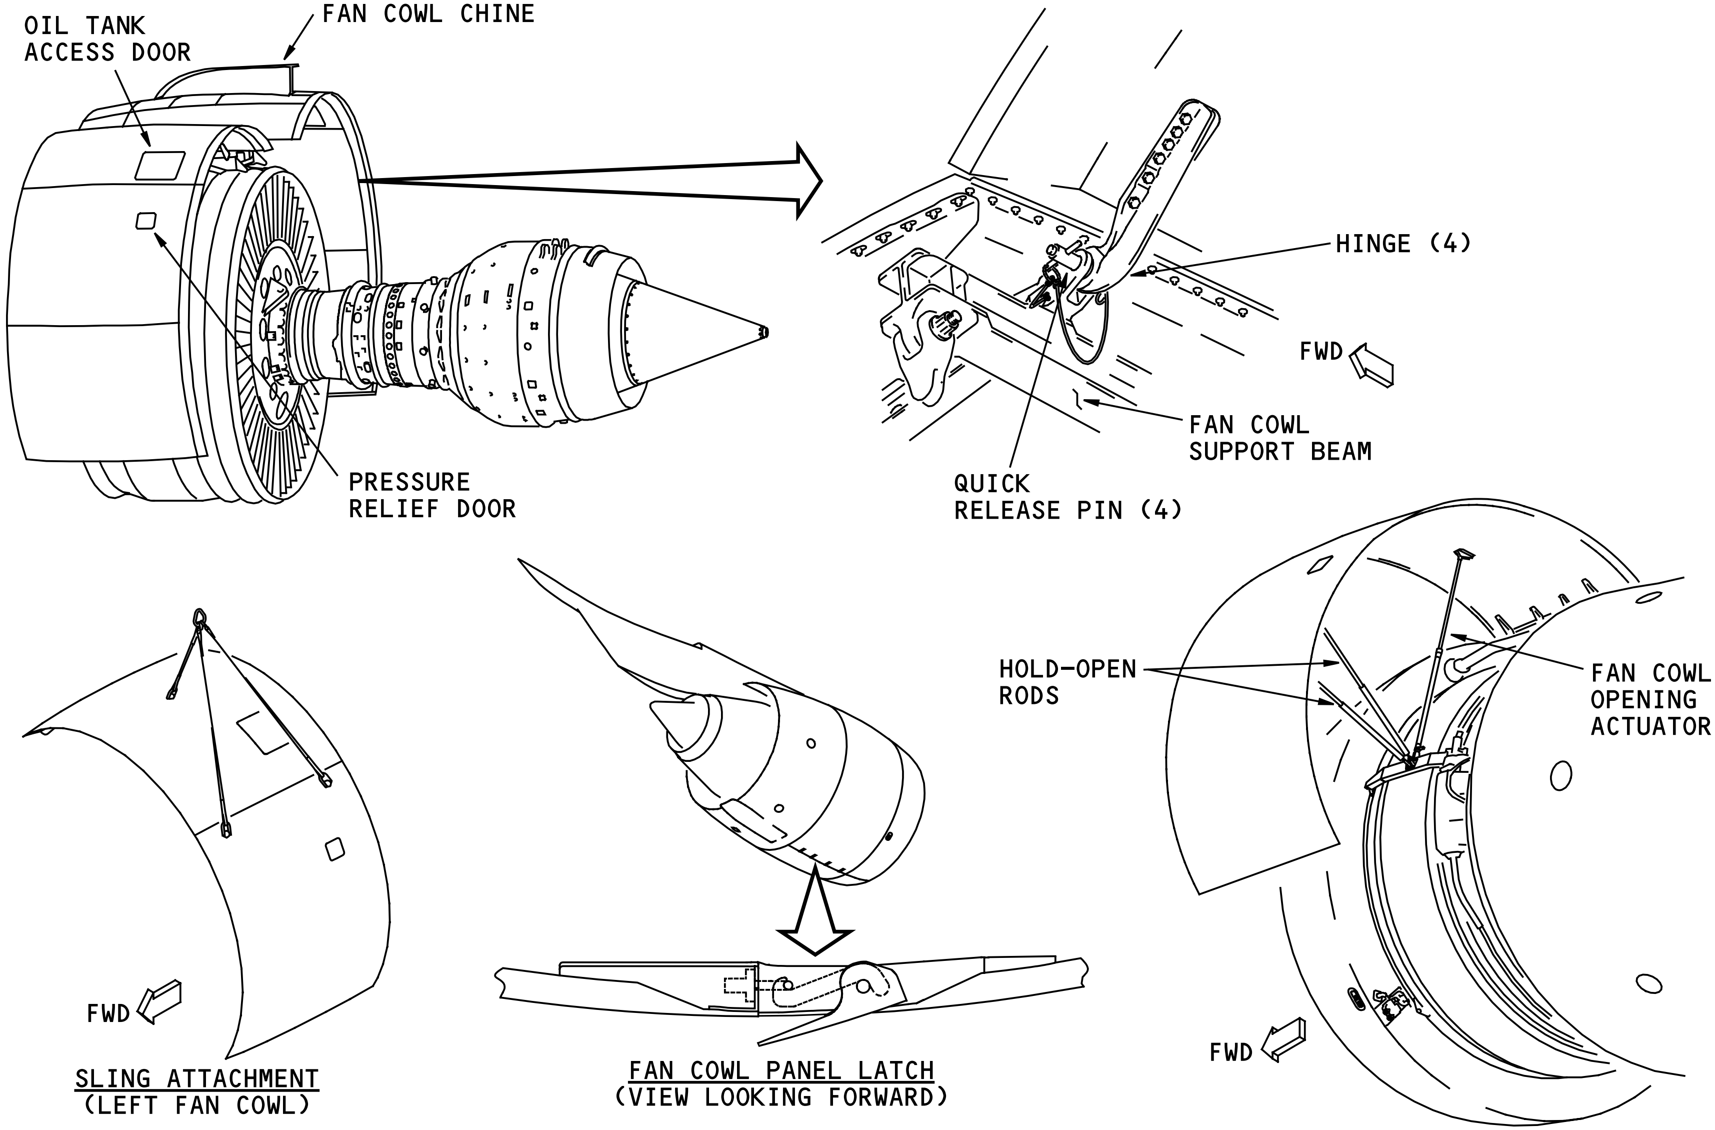
See the powered door opening system section for more information (AMM PART I 71-12).

Fan Cowl Opening Actuators

You use the PDOS to open and close the fan cowls. Each fan cowl has a fan cowl opening actuator. The actuator attaches to a bracket on the fan cowl and to the fan case. The fan cowl opening actuators open and close the fan cowls with hydraulic power.

Fan Cowl Panel Latches

There are four adjustable fan cowl panel latches at the bottom of the cowls. The latches hold the left and right fan cowl panels together.



ENGINE COWLING - FAN COWL

ENGINE COWLING - FAN COWL HOLD-OPEN RODS

General

The fan cowl hold-open rods keep the fan cowls open for maintenance. The hold-open rods are also a safety device. They protect persons at work on the engine or at work on the fan cowl from injury. They prevent the accidental closure of the fan cowl.

Fan Cowl Hold-Open Rods

Each fan cowl has a forward and an aft hold-open rod. The rods are telescopic. The rods stay attached to the fan case and fan cowl when you open and close the fan cowl

Each hold-open rod has a locking collar. The locking collars lock the hold-open rods. When you can see the red stripe next to the collar, the hold-open rod is not locked. When you can see the yellow stripe next to the collar, the hold-open rod is locked.

Fan Cowl Opening

This is a summary of how you open the fan cowl:

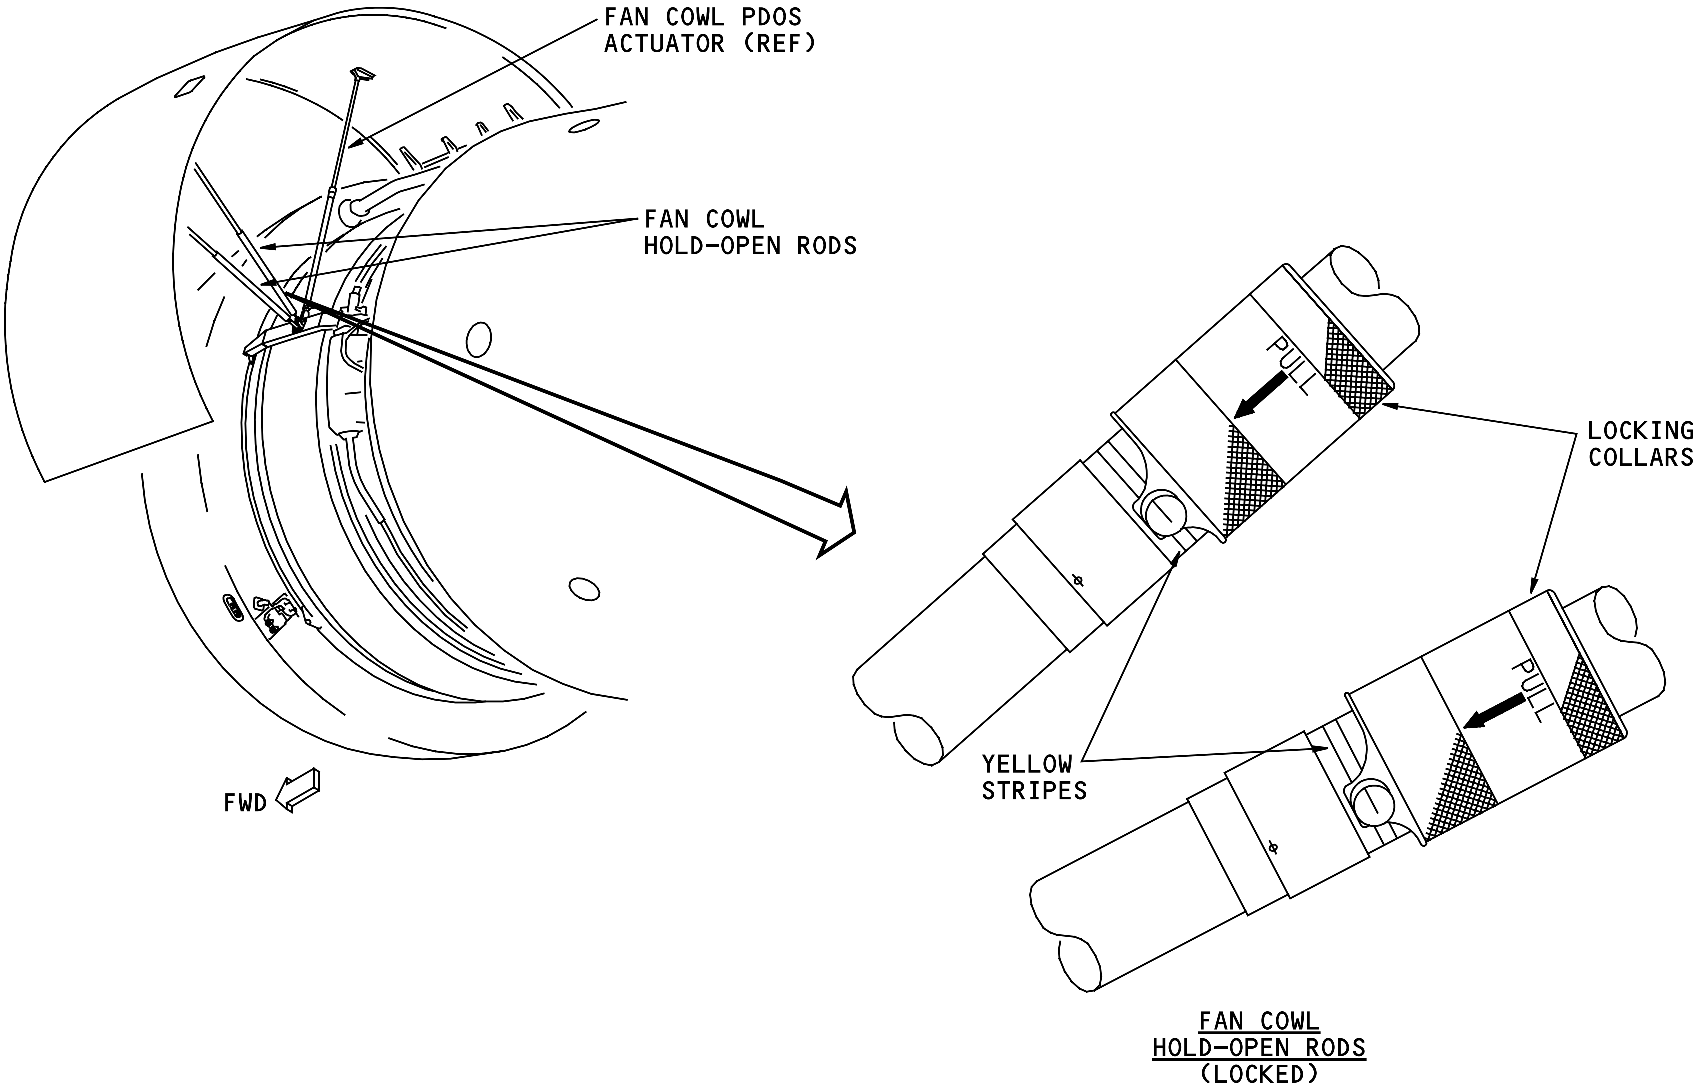
- Open the fan cowl panel latches from aft to forward
- Use the PDOS to open the fan cowl
- The hold-open rods automatically extend and lock.

Make sure the hold-open rod collars are locked (yellow stripes visible) before you go under the fan cowl.

Fan Cowl Closing

This is a summary of how you close the fan cowl:

- Unlock the hold-open rods
- Use the PDOS to close the fan cowl
- Close the fan cowl panel latches from forward to aft.



71-11-00-111 Rev 1 07/11/1997

ENGINE COWLING - FAN COWL HOLD-OPEN RODS

ENGINE COWLING - THRUST REVERSER

Purpose

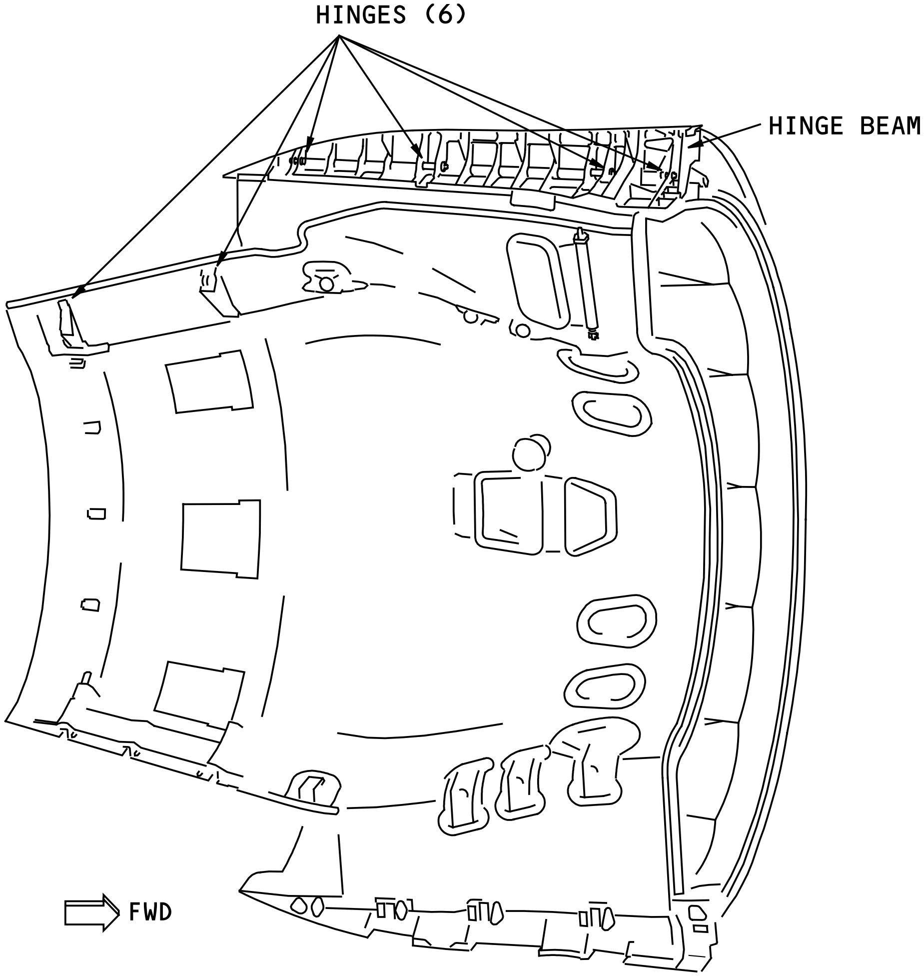
The thrust reverser controls the direction of the fan exhaust. It makes forward or reverse thrust. Reverse thrust can decrease the speed of the airplane during landing rollout or rejected take-off. The surface of the thrust reverser lets air flow smoothly around the engine. The thrust reverser halves open for maintenance.

Physical Description

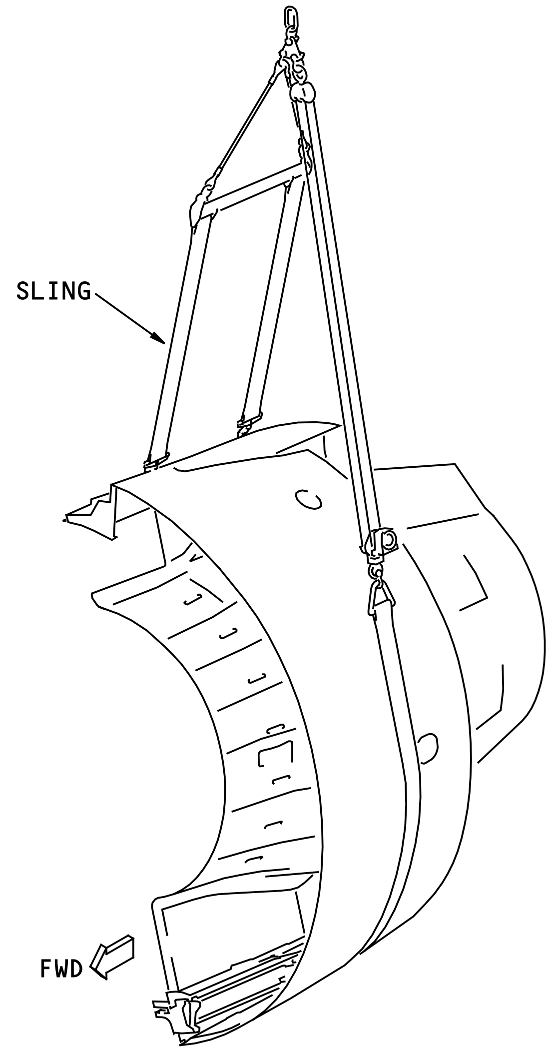
Each thrust reverser has a left and a right half. Each thrust reverser half has a hinge beam with six hinges. Four hinges attach the thrust reverser halves to the strut. The two aft hinges attach to cross-tie rods (not shown).

Sling Attach Points

Sling attach points for the thrust reverser are on the hinge beam and the latch beam of each thrust reverser half.You install attach fittings on the hinge beam and latch beam to attach a sling.



THRUST REVERSER HALF (LEFT SIDE)



LEFT THRUST REVERSER HALF

ENGINE COWLING - THRUST REVERSER

ENGINE COWLING - THRUST REVERSER LATCHES

General

The thrust reverser (T/R) latches hold the T/R halves together. There are four groups of latches:

- Deflection limiter (4)
- Aft cowl (3)
- Thrust reverser (5)
- V-band (1).

Deflection Limiter Latches

There are four deflection limiter latches. These latches attach to two straps that go around the aft part of the T/R. You open the deflection limiter latches first.

CAUTION: FAILURE TO OPEN THE DEFLECTION LIMITER LATCHES BEFORE YOU OPEN THE THRUST REVERSER CAN CAUSE DAMAGE TO THE THRUST REVERSER.

Aft Cowl Latches

There are three aft cowl latches. These latches hold the aft part of the T/R together. You open the aft cowl latches after you open the deflection limiter latches.

T/R Latches

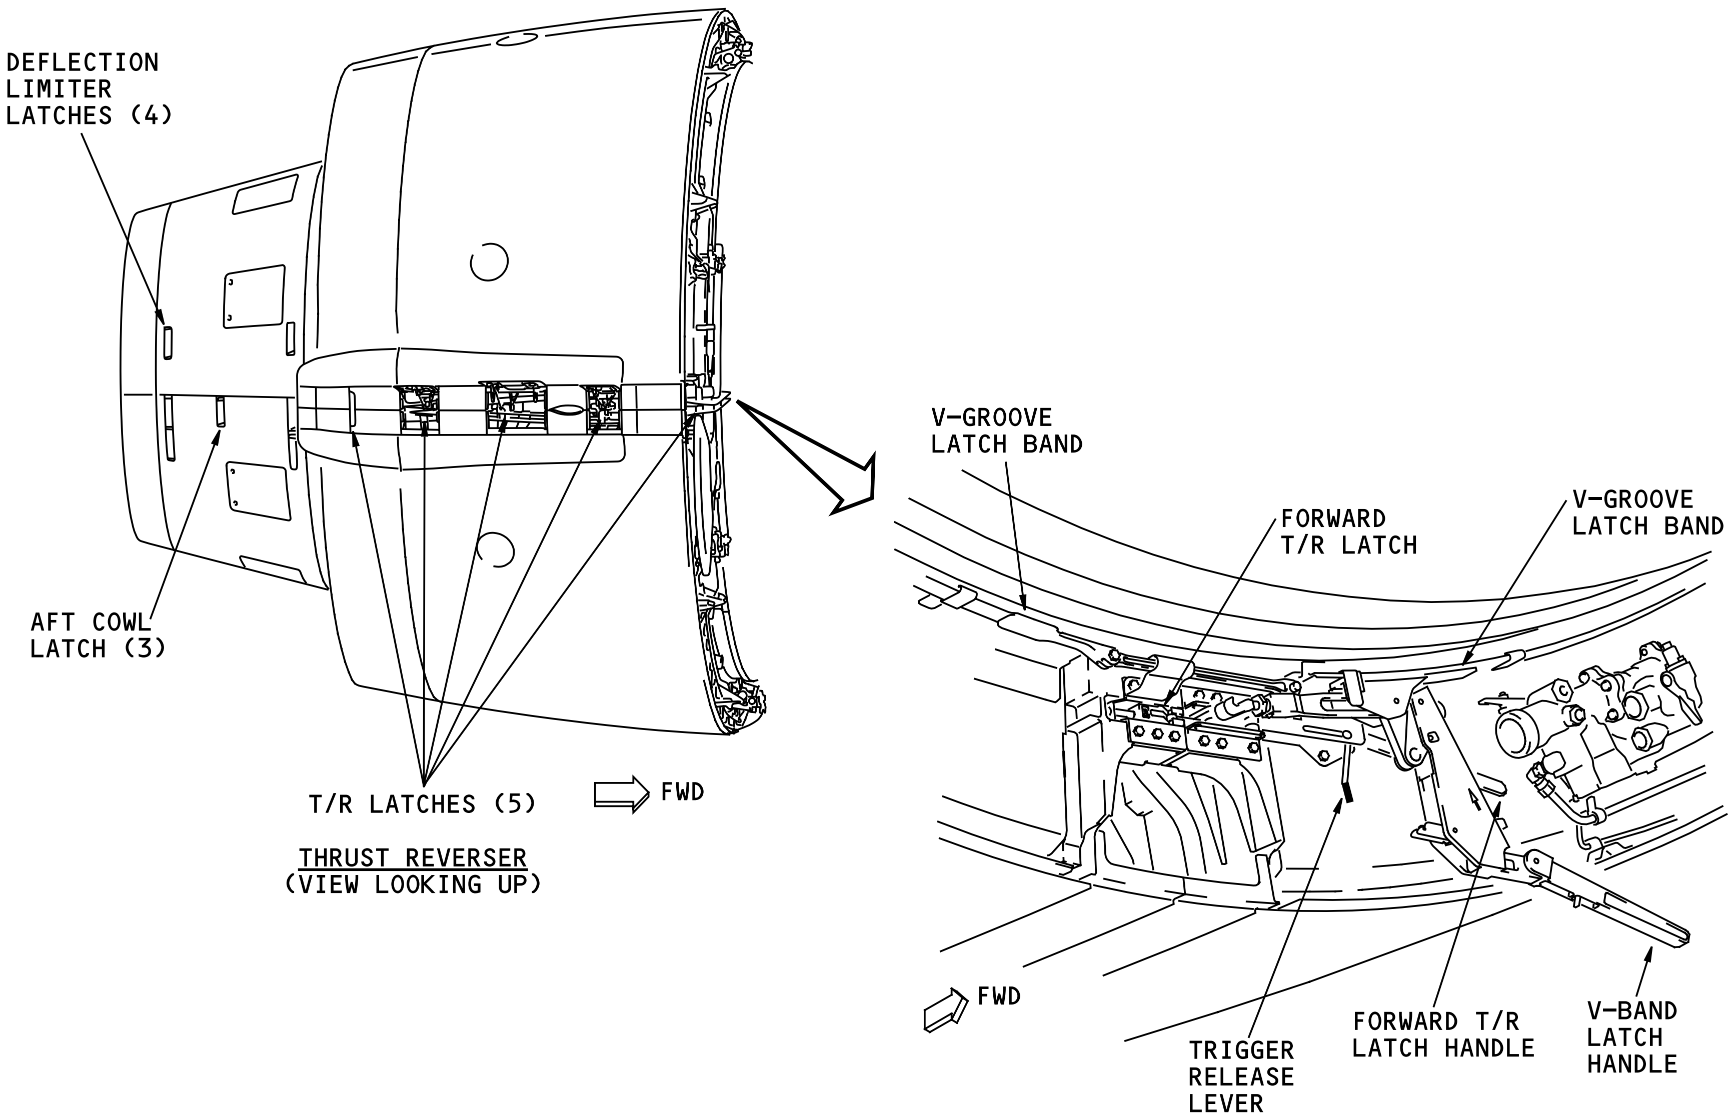
There are five T/R latches. These latches hold the forward part of the T/R together. You must open latch access doors to get access to the three middle T/R latches.

The forward latch is next to the V-band latch handle on the T/R torque box. There is a trigger release lever on the forward latch. You must move the trigger release lever to the left (looking aft) before you can open the forward latch.

You open the T/R latches after you open the aft cowl latches.

V-band Latch

The v-band latch supplies tension around the forward part of the T/R. This tension holds the T/R to the fan case. The v-band latch has a handle that loosens the v-groove latch band. You open the v-band latch last.



ENGINE COWLING - THRUST REVERSER LATCHES

ENGINE COWLING - THRUST REVERSER HOLD-OPEN ROD

General

The thrust reverser (T/R) hold-open rods keep the T/R halves open for maintenance. The hold-open rods are also a safety device. They protect persons at work on the engine or the T/R from injury. They prevent the accidental closure of the T/R.

Thrust Reverser Hold-Open Rod

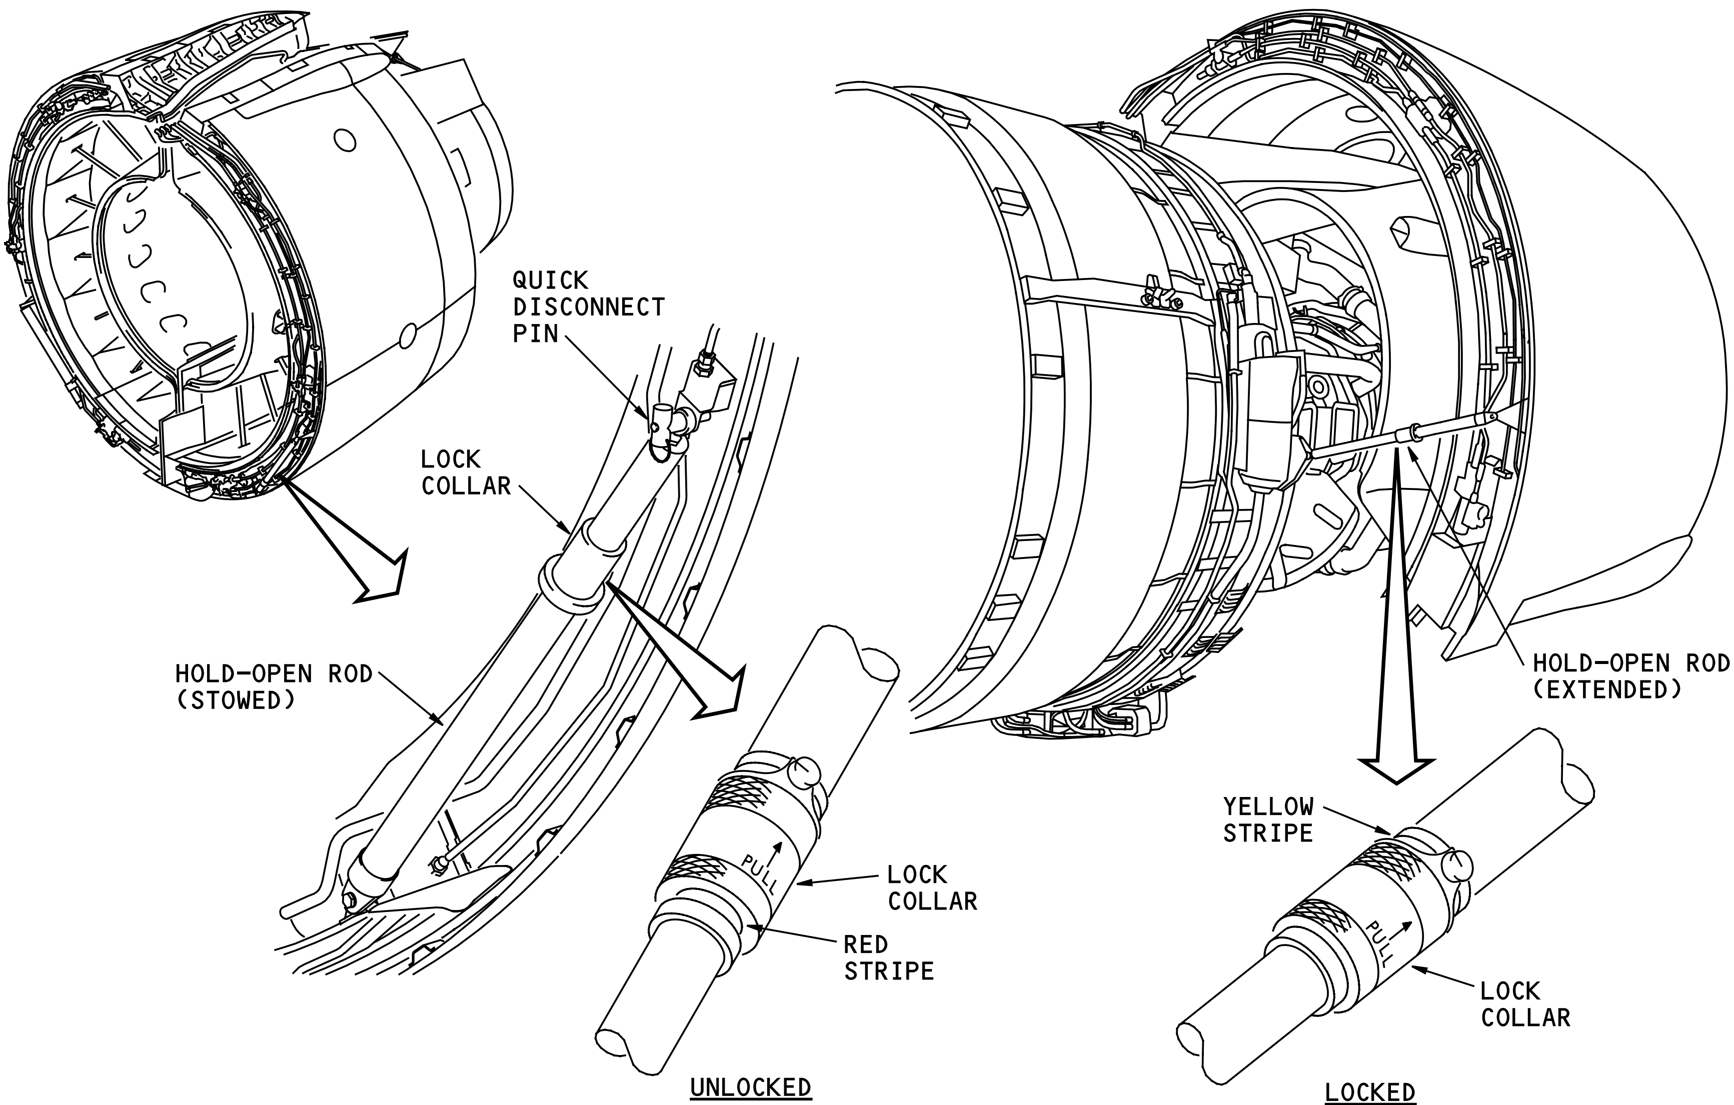
Each T/R half has one hold-open rod on the torque box of the T/R half. The rod is telescopic. There is a quick disconnect pin on the upper end of the hold-open rod.

Each hold-open rod has a lock collar. The collar locks the hold-open rod in place. When the hold open rod locks, you can see the yellow stripe next to the collar. When you can see the red stripe next to the collar, the hold-open rod is not locked.

WARNING: NEVER STAND UNDER THE THRUST REVERSER HALVES WHEN YOU OPEN OR CLOSE THE THRUST REVERSER.

Training Information Point

Before you remove the engine or thrust reverser you must stow the hold-open rod on the thrust reverser. First, remove the quick disconnect pin to disconnect the hold-open rod from the engine. Then attach the hold-open rod to the thrust reverser with the same quick disconnect pin.



ENGINE COWLING - THRUST REVERSER HOLD-OPEN ROD

ENGINE COWLING - TURBINE EXHAUST

Purpose

The turbine exhaust system makes the airflow smooth as it exits the engine. This increases engine efficiency and reduces noise.

Primary Nozzle

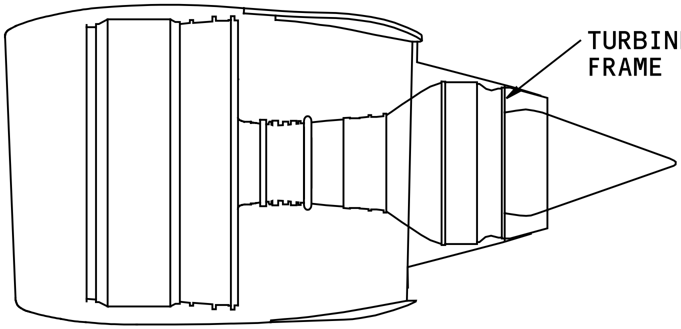
The primary nozzle is aft of the thrust reverser. The primary nozzle attaches to the turbine rear frame.

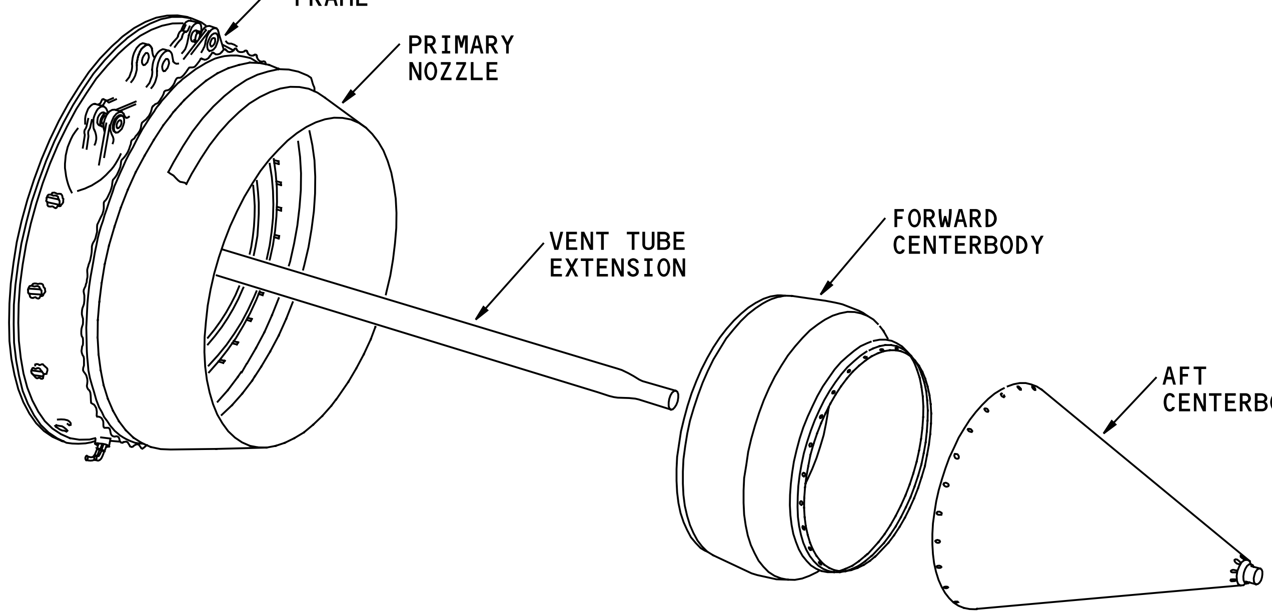
Centerbody

The centerbody is inside the primary nozzle. The centerbody has two parts. The forward centerbody attaches to the turbine rear frame. The aft centerbody attaches to the forward centerbody.

Vent Tube Extension

The vent tube extension supplies a path for the oil system vent air to go overboard. The vent tube extension fits inside the centerbody. It attaches to the no. 5 bearing sump cover.





TURBINE EXHAUST SYSTEM

71-11-00-107 Rev 2 09/11/96

ENGINE COWLING - TURBINE EXHAUST

ENGINE COWLING - FAN COWL LATCH ADJUSTMENT - TIP

General

The correct adjustment of fan cowl panel latches supplies a smooth airflow over the engine cowling. A latch with the correct adjustment closes with a loud pop noise.

You adjust the thrust reverser latches before you adjust the fan cowl panel latches. You adjust the fan cowl panel latches with the thrust reverser halves closed and latched. You adjust the fan cowl panel latches when you replace any of these components:

- Engine
- Fan cowl panel
- Fan cowl panel latches
- Thrust reverser.

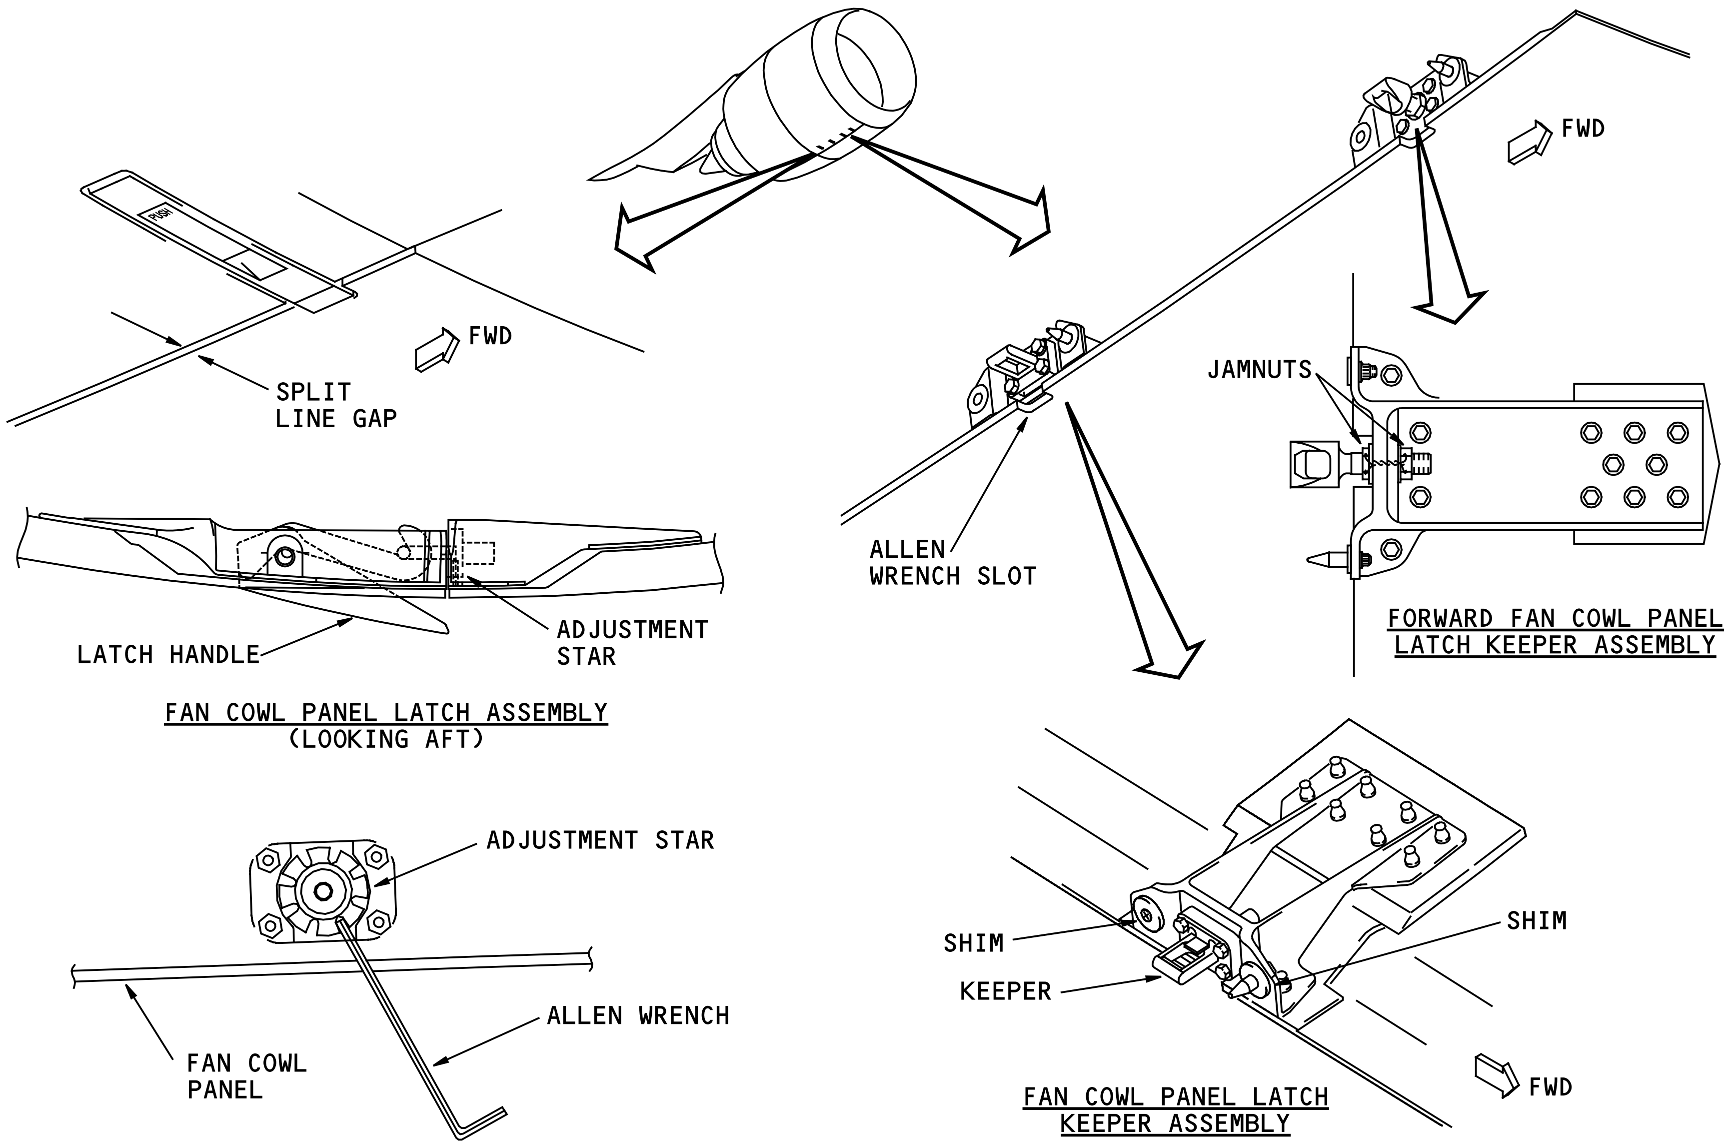
Fan Cowl Panel Latch Adjustment

CAUTION: DO NOT USE MORE THAN 100 POUNDS OF FORCE ON THE LATCH HANDLE. TOO MUCH FORCE CAN CAUSE DAMAGE TO THE LATCH, THE KEEPER, OR THE FAN COWL PANEL.

You adjust the fan cowl panel latches when you find the split line gap or the closing force of the latches is incorrect. The shims set the width of the split line gap between the fan cowl panels.

You adjust the closing force of the latches by changing the position of the keeper. Adjust the latches from forward to aft.

You change the position of the forward latch keeper with the two jamnuts that hold it in place. You change the position of the other three latch keepers by turning the adjustment star. Use an allen wrench to turn the adjustment star. The allen wrench goes through a slot in the fan cowl panel.



ENGINE COWLING - FAN COWL LATCH ADJUSTMENT - TIP

71-11-00-108 Rev 3 02/08/1997

ENGINE COWLING - THRUST REVERSER LATCH ADJUSTMENT - TIP

General

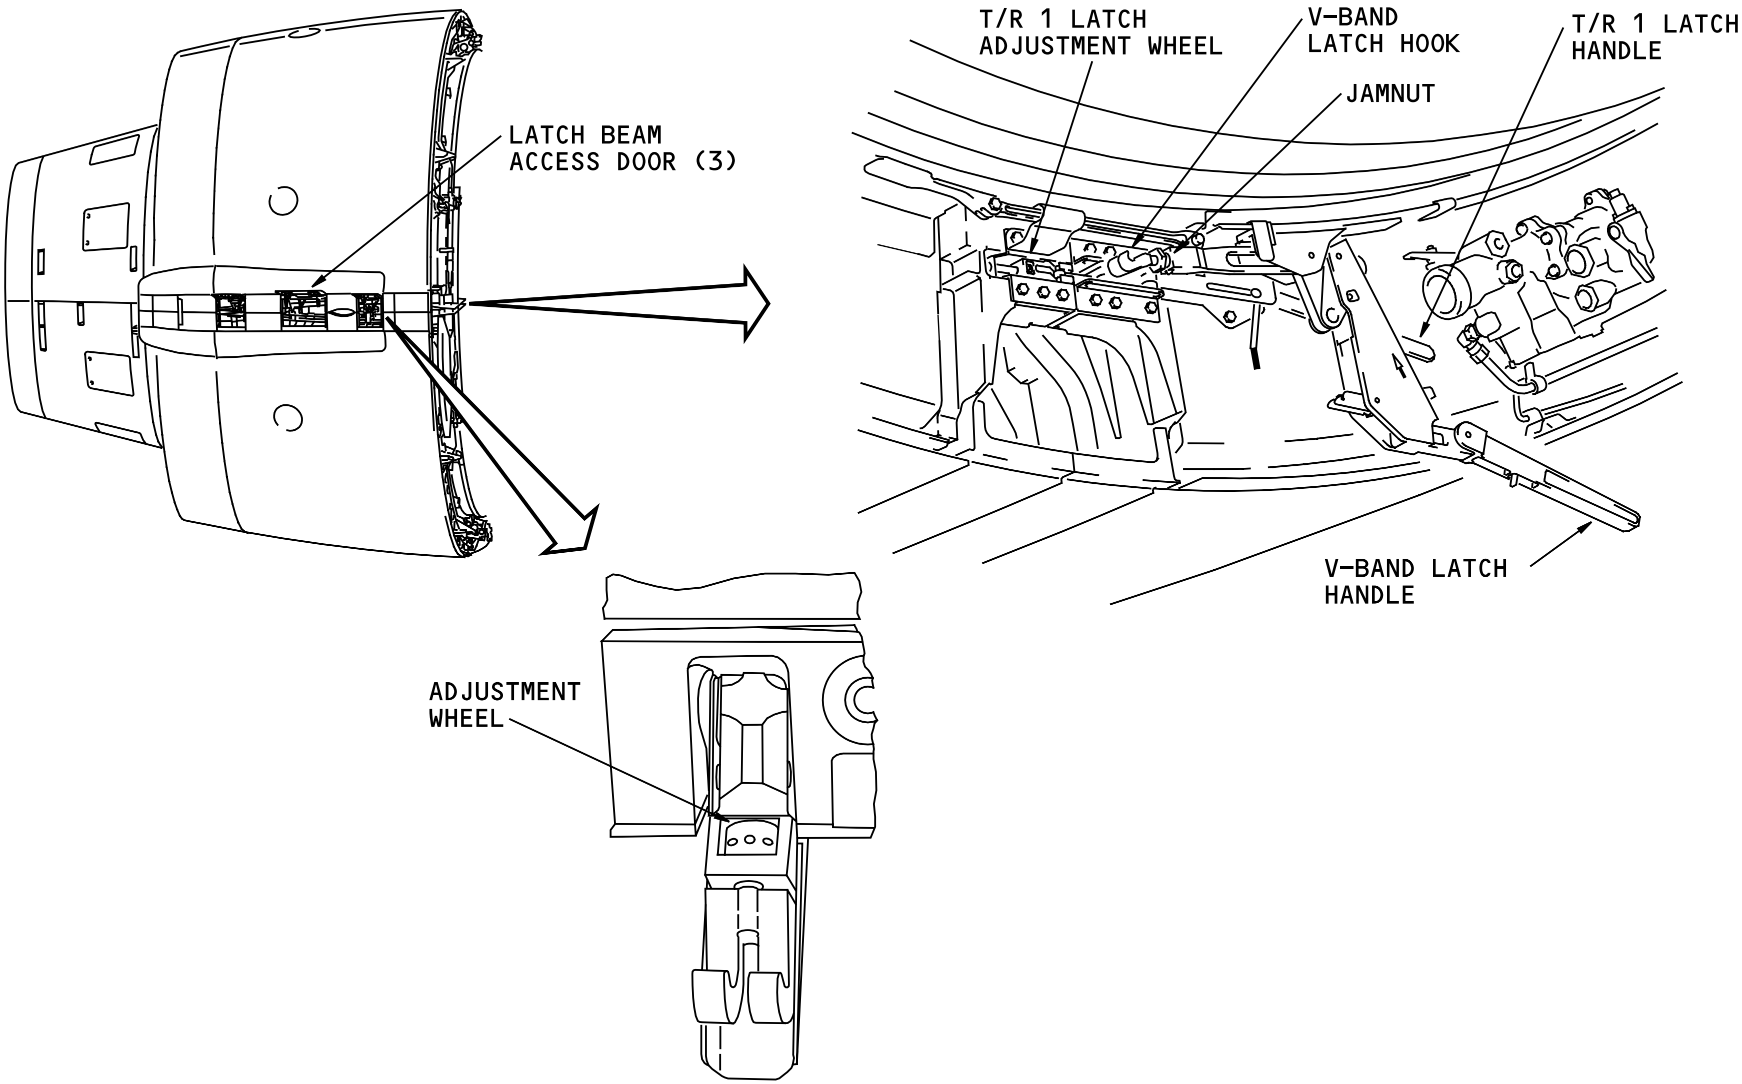
There are 13 latches which hold the thrust reverser (T/R) together. You adjust the tension of the v-band latch first. Then adjust the remaining latches from forward to aft with the v-band latch closed.

V-band Latch Adjustment

You adjust the v-band latch first. All of the other T/R latches must be open. You measure the force necessary to close the v-band latch with a spring scale. If the force is not within limits, adjust the v-band latch hook position with the jamnut until the closing force is within limits.

T/R Latch Adjustment

You measure the force necessary to close the T/R latches with a spring scale. If the force is not within limits, turn the adjustment wheel until the closing force is within limits.



71-11-00-109 Rev 5 07/11/1997

ENGINE COWLING - THRUST REVERSER LATCH ADJUSTMENT - TIP

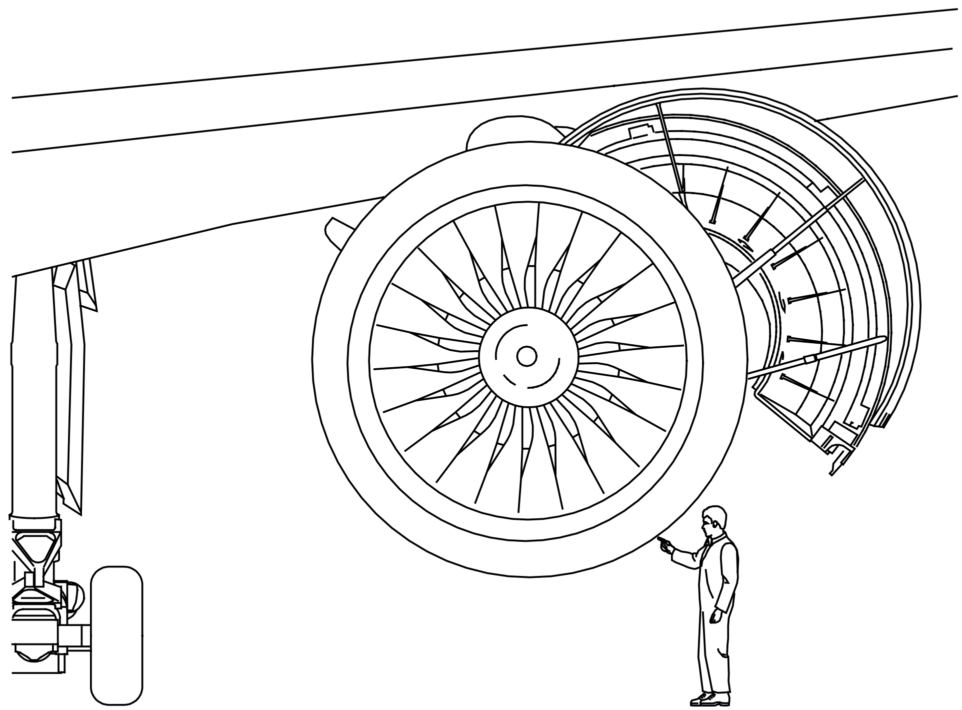
POWERED DOOR OPENING SYSTEM (PDOS) - INTRODUCTION

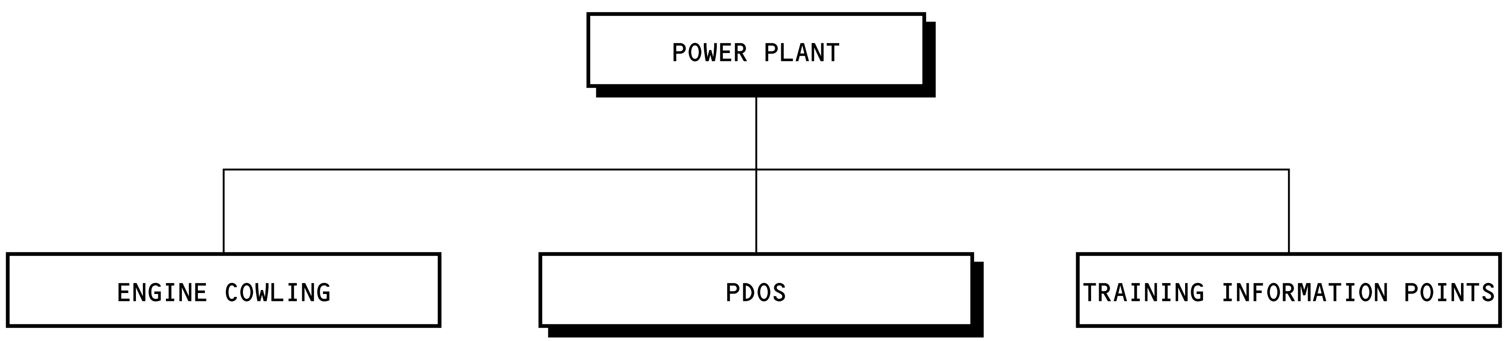
General

The powered door opening system (PDOS) opens and closes the fan cowls and the thrust reversers. You can also use the PDOS to manually open and close the fan cowls and the thrust reversers.

The PDOS uses hydraulic power to open the fan cowls and the thrust reversers. Gravity closes the fan cowls and the thrust reversers.

You operate the PDOS with the actuation and control switches. Each fan cowl and each thrust reverser half has an actuation and control switch.





POWERED DOOR OPENING SYSTEM (PDOS) - INTRODUCTION

PDOS - GENERAL DESCRIPTION

General

The powered door opening system (PDOS) uses hydraulic power to open the fan cowls and thrust reversers (T/R). It uses gravity to close them.

The PDOS has these components:

- Actuation and control switches
- Pump/power pack
- Actuators.

Actuation And Control Switches

Each fan cowl and each T/R half has an actuation and control switch. Each switch has an up and a down button. The up button opens the cowl and the down button closes the cowl. The switches permit 28v dc power to go to the pump/power pack solenoids.

Pump/Power Pack

The pump/power pack supplies hydraulic pressure to the actuators. It has a hydraulic reservoir and an electric hydraulic pump. The pump/power pack gets 115v ac power from the ground handling bus. The hydraulic fluid goes to an actuator when the related solenoid(s) energizes.

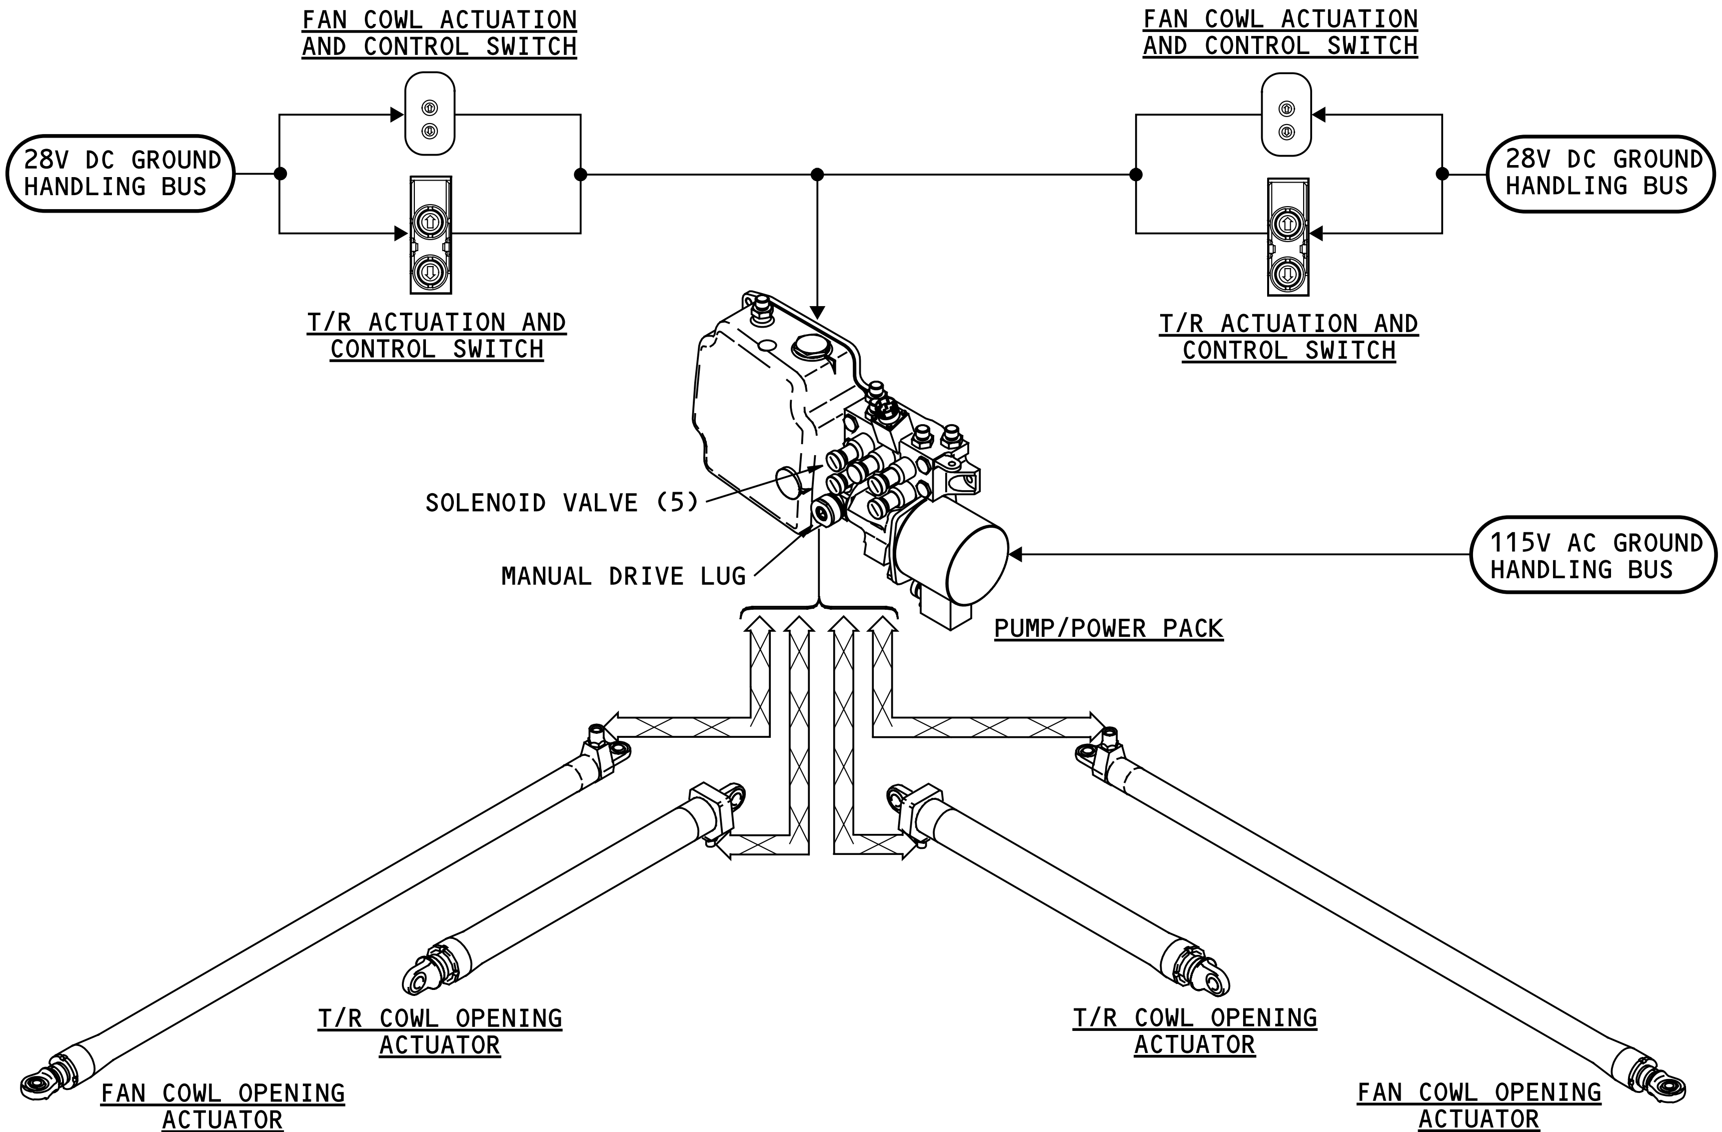
Actuators

There are four actuators on each engine. Each fan cowl and each T/R half has an actuator. When the actuators receive hydraulic pressure, they extend to open the cowls. When hydraulic pressure is removed, the actuators retract to close the cowls.

The actuators are also safety devices. Flow control valves in the actuators limit the flow of hydraulic fluid in the closing direction. This prevents the fan cowls and T/Rs from closing quickly.

Manual Operation

The PDOS pump/power pack has a manual drive lug. When there is no airplane power, you can manually operate the solenoid valves and the manual drive lug to open the fan cowls and T/Rs. You operate only the solenoid valves to permit gravity to close the fan cowls and T/Rs.



PDOS - GENERAL DESCRIPTION

PDOS - COMPONENT LOCATIONS

General

The PDOS has these components:

- Pump/power pack
- Cowl opening actuators
- Hydraulic cowl opening flex hoses
- Actuation and control switches.

Pump/Power Pack

Each engine has one pump/power pack. The pump/power pack is under forward fairing 1.

Fan Cowl Opening Actuators

The fan cowl opening actuators are under the fan cowls. The top of each actuator attaches to an actuator bracket on the fan cowl. The bottom of each actuator attaches to the engine fan case.

The thrust reverser (T/R) cowl opening actuators are under the T/Rs. The top of each actuator attaches to the engine strut. The bottom of each the actuator attaches to the inner wall of the T/R.

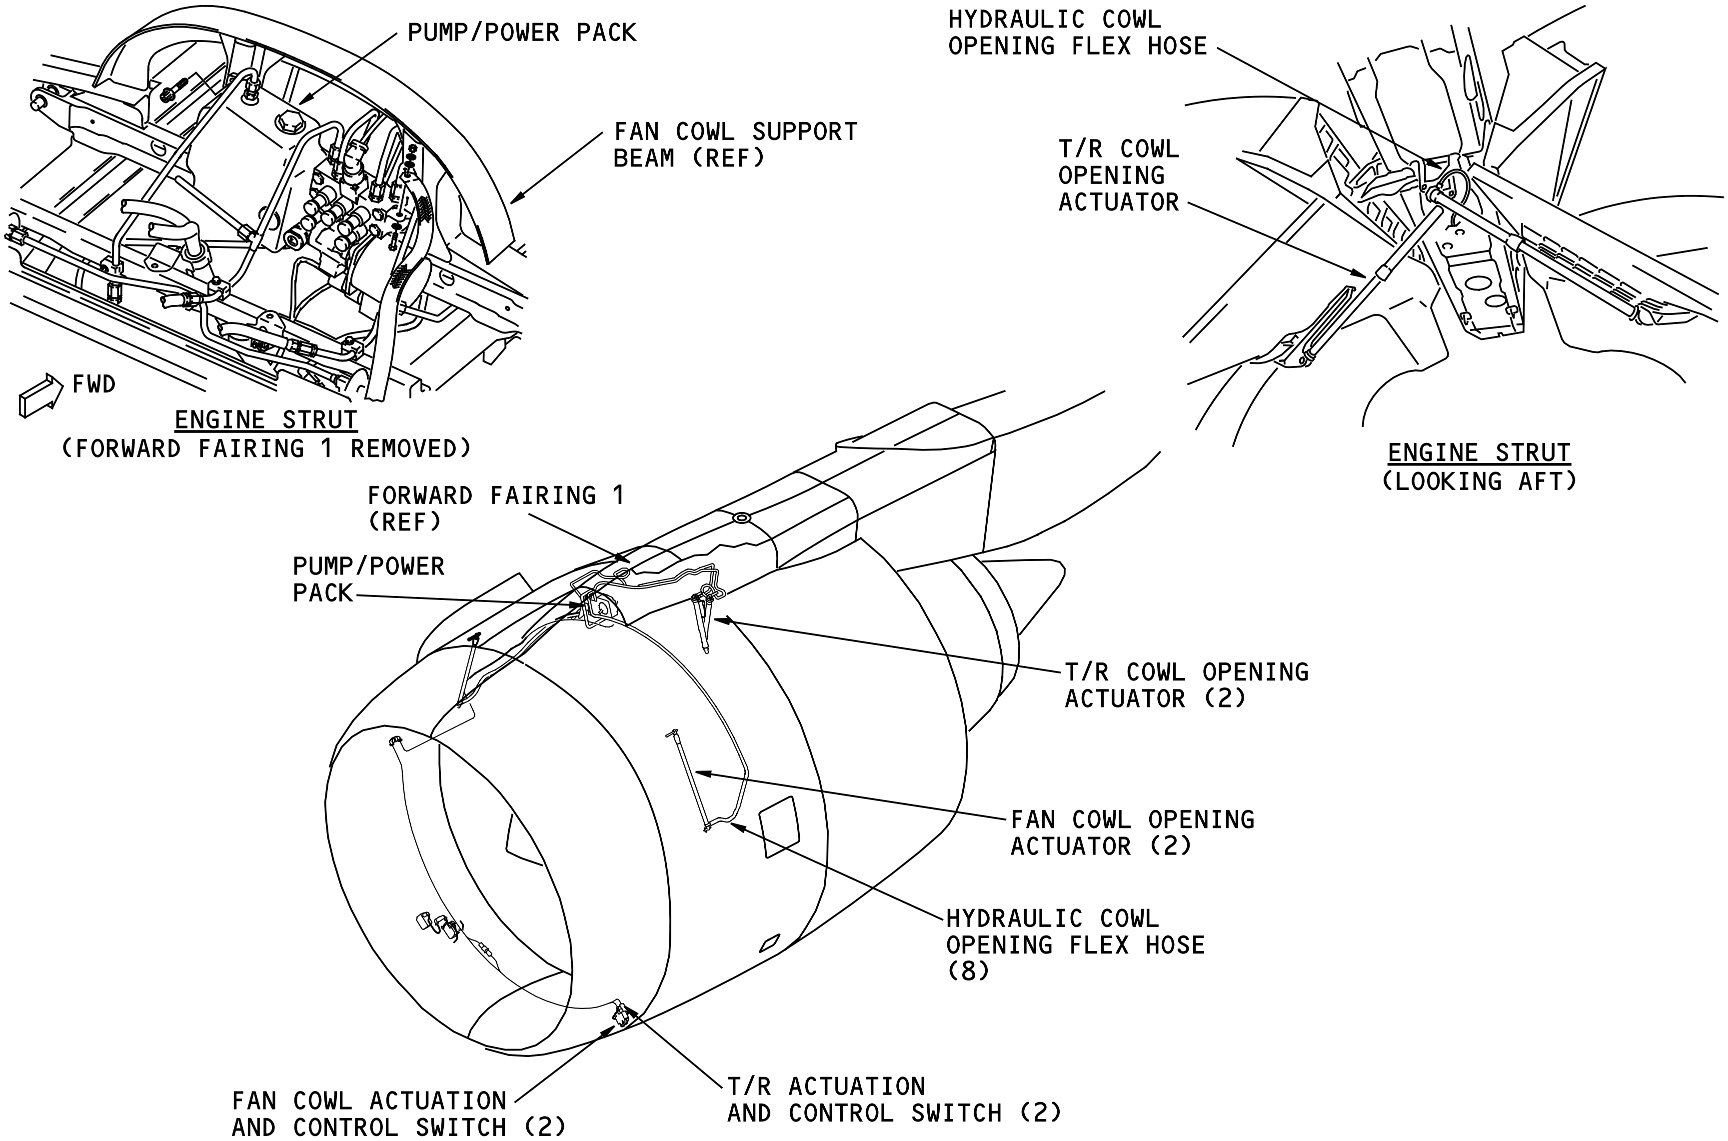
Hydraulic Cowl Opening Flex Hoses

The hydraulic cowl opening flex hoses permit the necessary movement of the PDOS hydraulic supply lines. The fan cowl flex hoses connect the PDOS hydraulic tubes on the fan case to the actuators and to the strut. The T/R flex hoses connect the PDOS hydraulic tubes in the strut to the actuators.

Actuation and Control Switches

The fan cowl actuation and control switches are on the inlet cowl at the 4:00 and 8:00 positions.

The T/R actuation and control switches are on the aft bulkhead of the inlet cowl near the fan cowl switches.



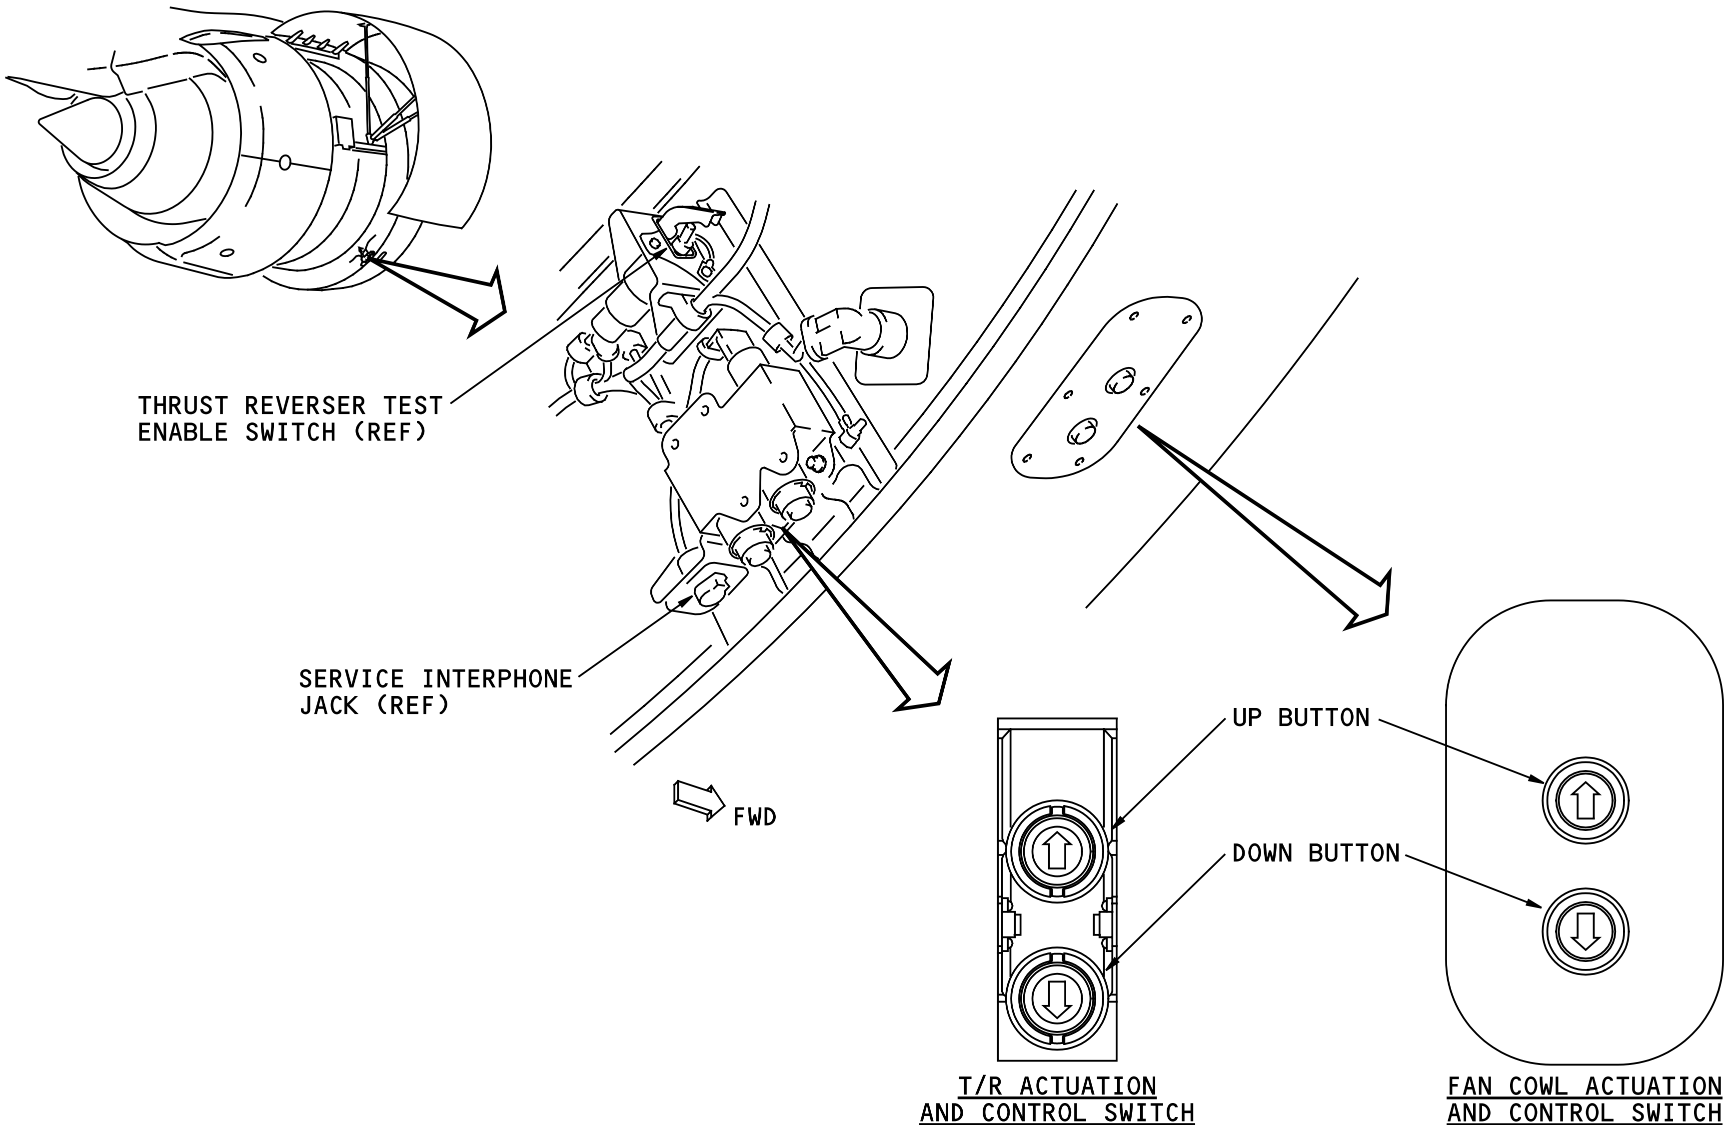
PDOS - COMPONENT LOCATIONS

71-12-00-103 Rev 5 07/11/1997

PDOS - ACTUATION AND CONTROL SWITCHES

Actuation And Control Switches

The actuation and control switches are on each side of the inlet cowl. Each actuation and control switch has an UP button and a DOWN button. The buttons are momentary-action type.



PDOS - ACTUATION AND CONTROL SWITCHES

71-12-00-104 Rev 4 02/08/1997

PDOS - PUMP/POWER PACK

General

The pump/power pack supplies hydraulic power to the cowl opening actuators. The actuators open and close the fan cowls and thrust reverser halves.

These are the parts of the pump/power pack:

- Housing
- Reservoir
- Solenoid valve (5)
- Electric motor
- Manual drive.

Housing

The pump/power pack parts attach to the housing. The housing contains the pump drive shaft and the pump filter element. The filter element is under the high pressure filter plug.

There are four connectors for hydraulic supply lines to the cowl opening actuators. There is one connector for the solenoid valves.

Reservoir

The reservoir attaches to the housing. The reservoir has a vent and an oil filler cap with a dipstick on it.

Solenoid Valves

Five solenoid valves attach to the housing. The solenoids get power from the 28v dc ground handling bus when you push the actuation and control switches.

Electric Motor

The electric motor turns the hydraulic pump. It gets power from the 115v ac ground handling bus.

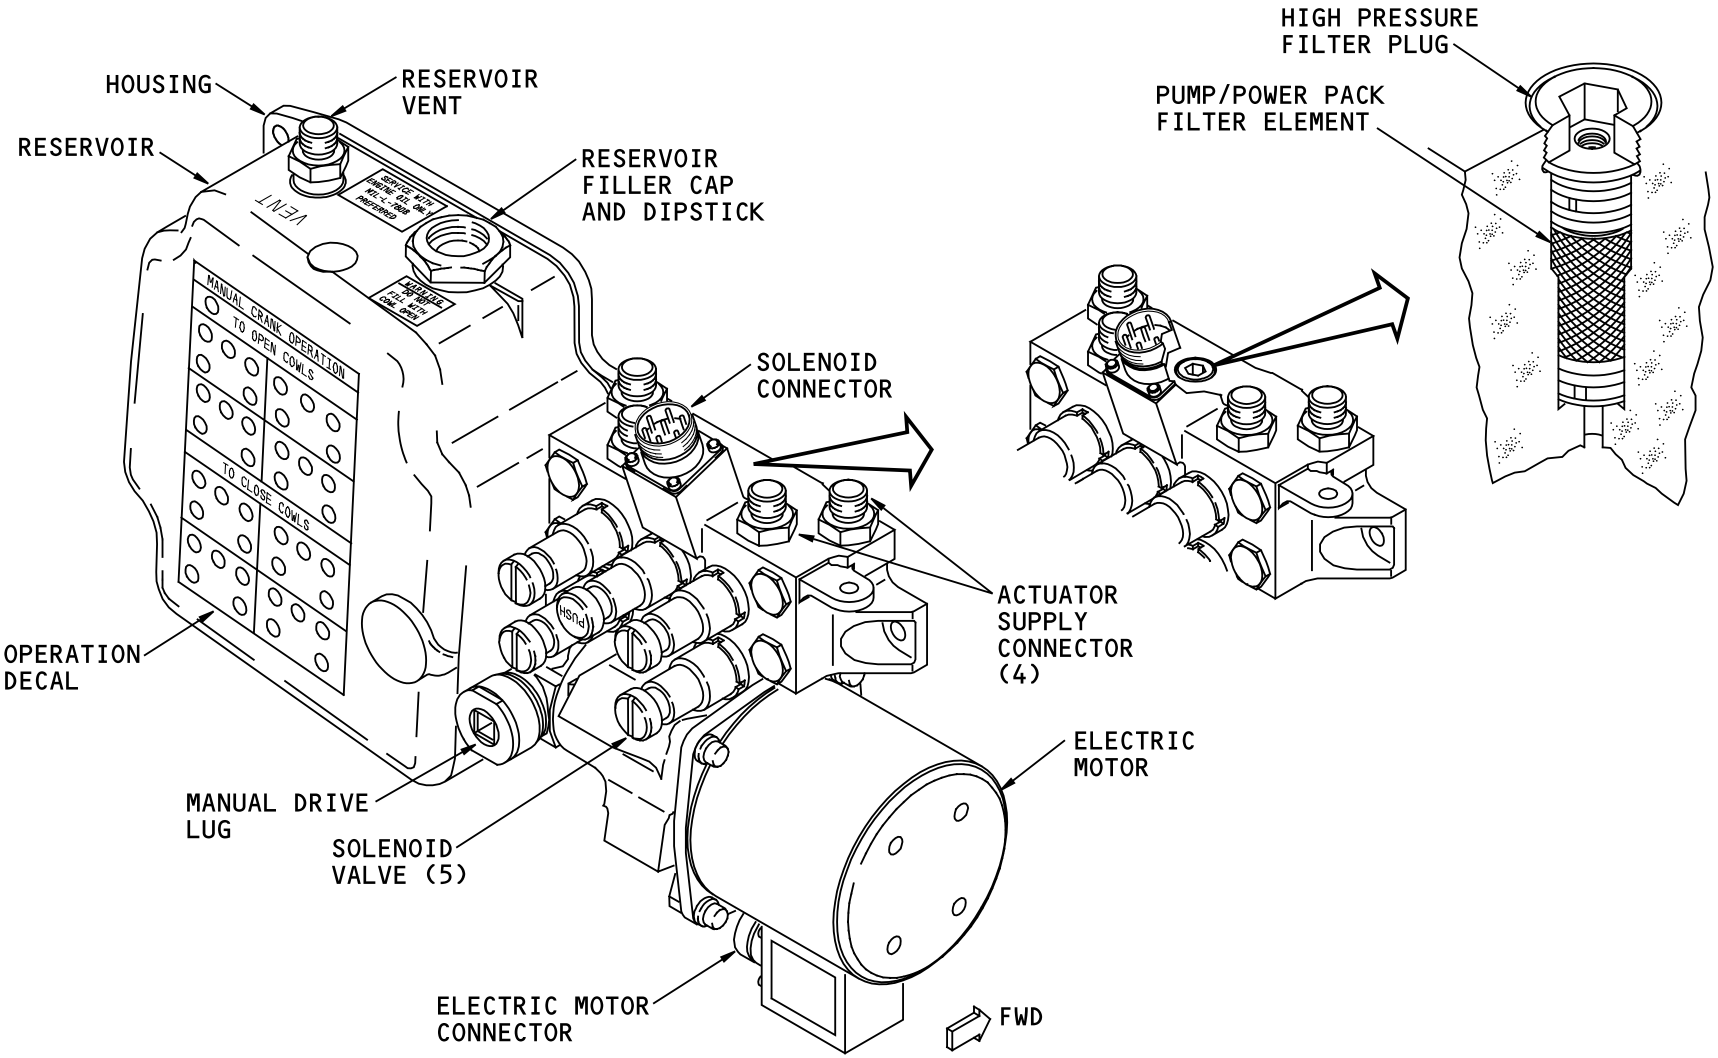
Manual Drive Lug

The manual drive lug is on the housing and connects to the pump drive shaft. You use a 3/8 inch square drive to turn the manual drive. A decal on the reservoir shows you how to manually operate the pump/power pack.

Training Information Point

You service the PDOS pump/power pack with engine oil.

The PDOS pump/power pack filter is an LRU.



PDOS - PUMP/POWER PACK

PDOS - OPERATION - FAN COWL

General

When you work on engine components under the fan cowl, you open the fan cowl only. If you must repair engine components under the thrust reverser (T/R), you open the fan cowl first, and then you open the T/R. You must have electric power before you use the PDOS.

Open the Fan Cowl

CAUTION: RETRACT THE LEADING EDGE SLATS AND DO THE DEACTIVATION PROCEDURE BEFORE YOU OPEN THE FAN COWL PANELS. IF THE LEADING EDGE SLATS ARE NOT RETRACTED, THE FAN COWL PANELS WILL HIT THEM AND CAUSE DAMAGE.

Here is a summary of how you open the fan cowl:

- Make sure the area around the engine is clear
- Open the four fan cowl latches
- Push the UP button until the cowl stops moving and you hear the collars lock
- Make sure the collars on the hold-open rods are locked (yellow stripes will be visible)
- Push the DOWN button momentarily to put the fan cowl weight on the hold-open rods.

WARNING: MAKE SURE THE FAN COWL HOLD-OPEN RODS ARE FULLY EXTENDED AND LOCKED WHEN THE FAN COWL PANEL IS OPEN. THE RODS ARE NOT LOCKED WHEN YOU CAN SEE THE RED STRIPE WITH THE WORD 'UNLOCKED' ON THE LOCK COLLAR. IF THE RODS ARE NOT LOCKED, THEY COULD RETRACT AND CAUSE INJURY TO PERSONS OR DAMAGE TO EQUIPMENT.

Close the Fan Cowl

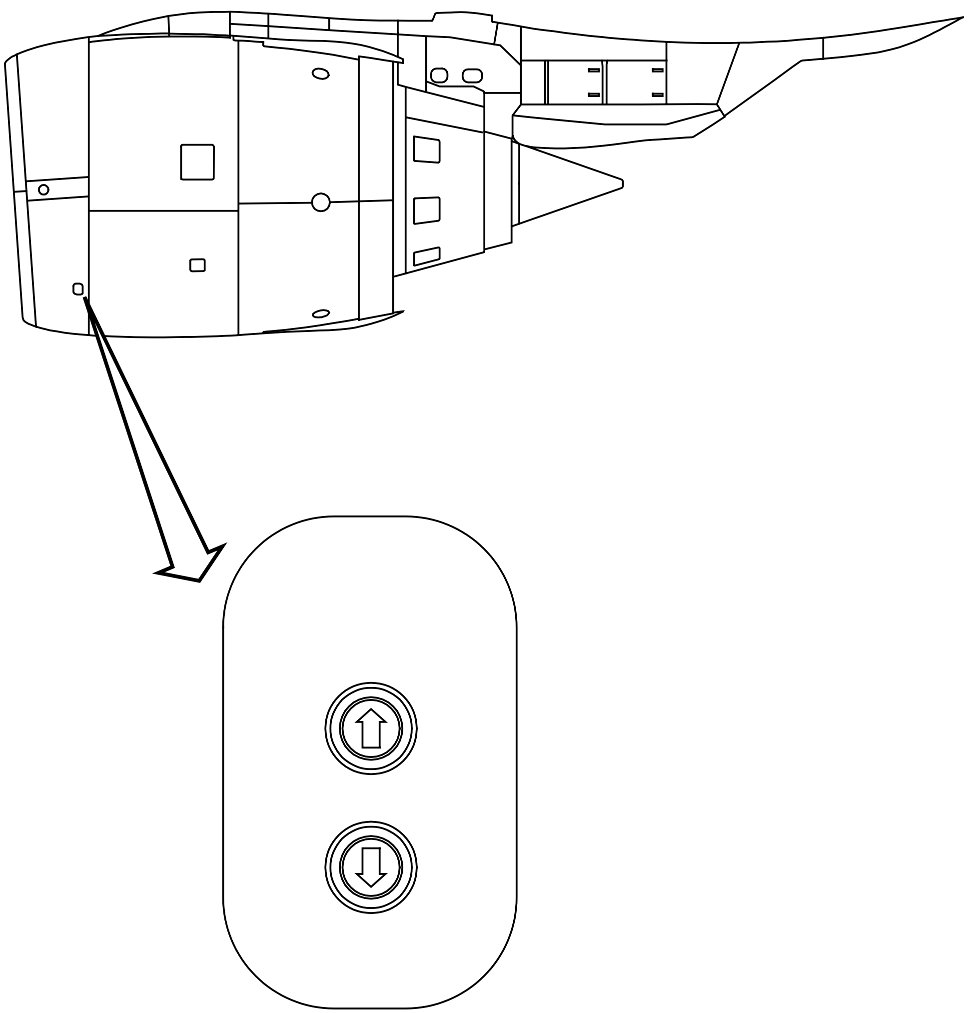
Here is a summary of how you close the fan cowl:

- Push the UP button to take the fan cowl weight off the hold-open rods
- Unlock the collars on the hold-open rods (red stripes will be visible)
- Push the DOWN button until the fan cowl closes
- Close the fan cowl latches.

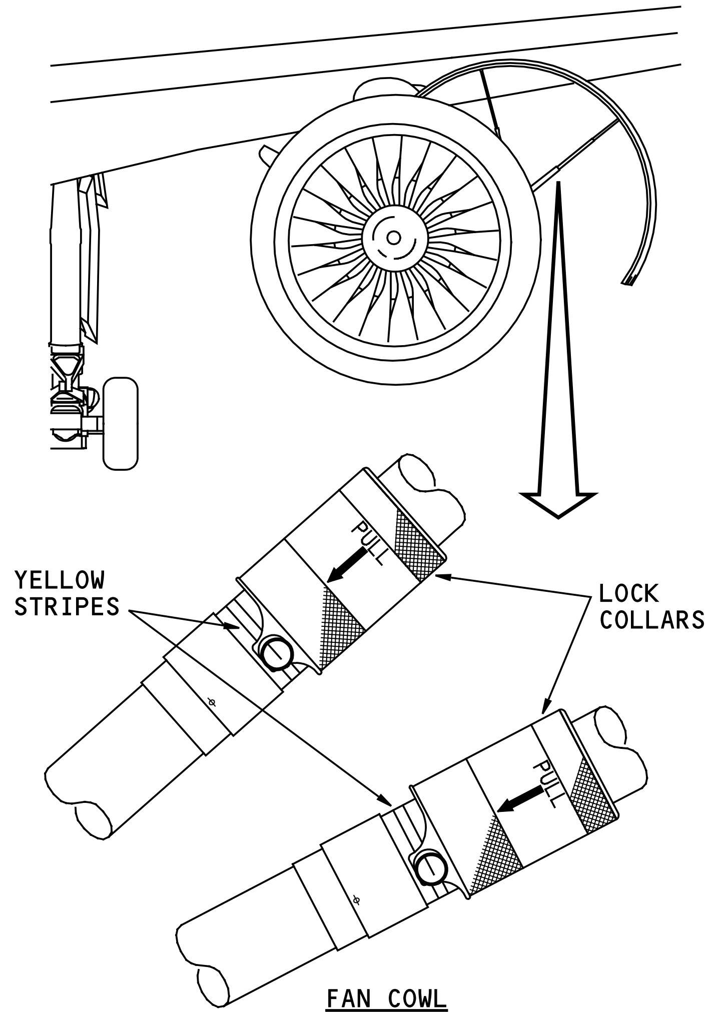
Training Information Point

The fan cowl opens in approximately 20 seconds. When you open the two fan cowls at the same time, it takes approximately 50 seconds.

You can close only one fan cowl at a time. The fan cowl closes in approximately 25 seconds.



FAN COWL ACTUATION
AND CONTROL SWITCH



FAN COWL
HOLD-OPEN RODS
(LOCKED)

PDOS - OPERATION - FAN COWL

71-12-00-107 Rev 5 02/08/1997

PDOS - OPERATION - THRUST REVERSER

General

Before you open a thrust reverser (T/R) half, you must open the necessary fan cowl(s). You must also make sure you do these three tasks:

- Retract the leading edge slats
- Deactivate the leading edge slats
- Deactivate the T/R for ground maintenance.

WARNING: DO NOT MOVE BETWEEN THE ENGINE AND THE OPEN THRUST REVERSER UNTIL YOU LOCK THE HOLD-OPEN ROD. THE THRUST REVERSER IS HEAVY AND CAN CLOSE QUICKLY IF THE PDOS HAS A FAILURE. THIS CAN CAUSE INJURIES TO PERSONS AND DAMAGE TO EQUIPMENT.

Open the Thrust Reverser

This is a summary of the procedure to open a T/R half:

- Open the T/R latches
- Push the UP button until the collar on the hold-open rod locks (a yellow stripe will be visible)
- Push the DOWN button to put the weight of the T/R on the hold-open rod.

Close the Thrust Reverser

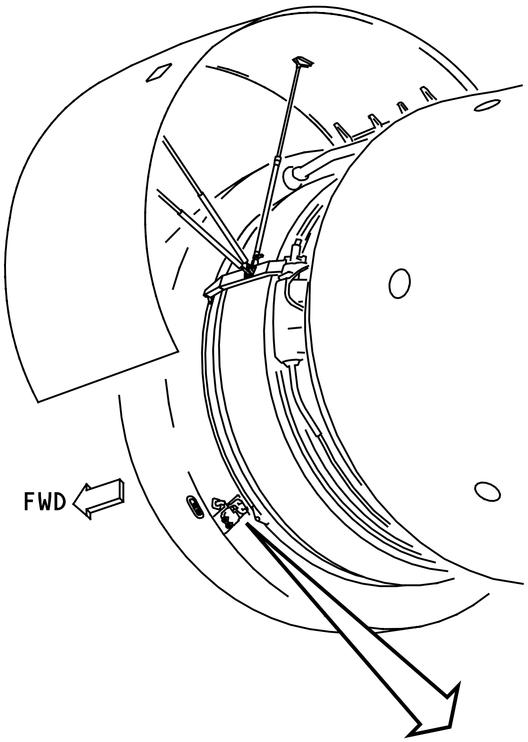
This is a summary of the procedure to close a T/R half:

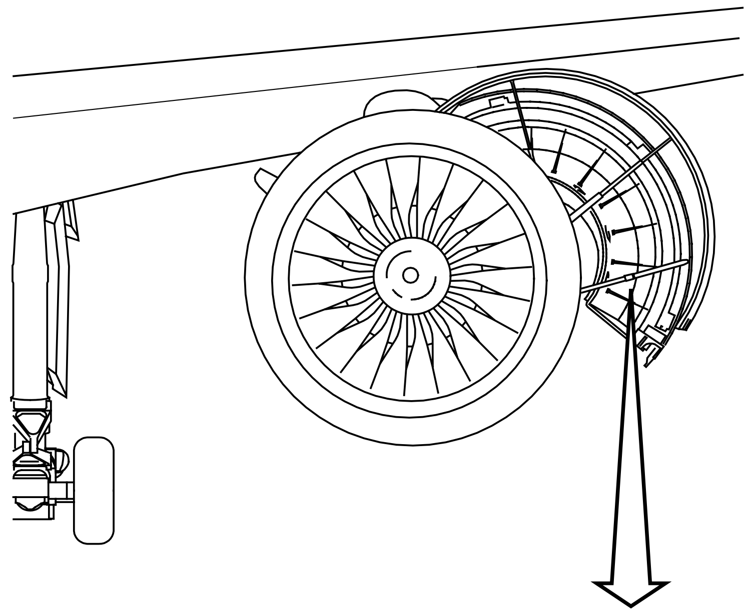
- Push the UP button to take the weight of the T/R off the hold-open rod
- Unlock the collar on the hold-open rod (a red stripe will be visible)
- Push the DOWN button until the T/R closes
- Close the T/R latches.

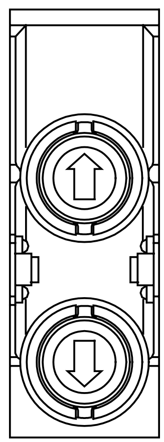
Training Information Point

A T/R half opens in approximately 40 seconds. When you open the two T/R halves at the same time, it takes approximately 100 seconds. A T/R half closes in approximately 25 seconds. You can close only one T/R half at a time.

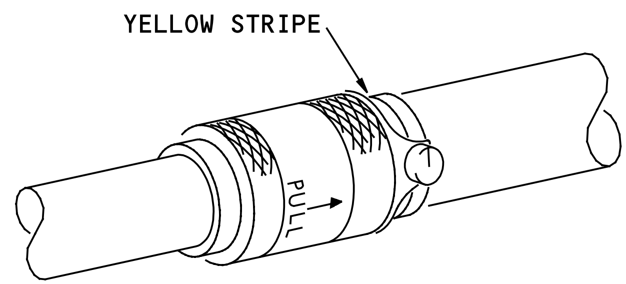
When you open the right T/R half you must open the left and right fan cowls. This is because the v-band latch handle will hit the left fan cowl panel if it is not open.







T/R ACTUATION
AND CONTROL SWITCH



HOLD-OPEN ROD
(LOCKED)

PDOS - OPERATION - THRUST REVERSER

71-12-00-108 Rev 4 09/11/96

PDOS - MANUAL OPERATION

General

When there is no airplane power you use the manual drive lug and the solenoid valves on the PDOS pump/power pack to open and close the fan cowls and the thrust reverser (T/R) halves. A decal on the pump/power pack shows the manual operation procedures.

The manual drive lug uses a 3/8 inch square drive.

Open the Fan Cowl and Thrust Reverser

This is a summary of the procedure to open a fan cowl or T/R half:

- Use a flat blade screwdriver to set the solenoid valves to the positions to open the related cowl
- Turn the manual drive lug
- When the cowl is open and the hold-open rods are locked, set the solenoid valves to the positions to close the related cowl
- Push and hold the V5 solenoid valve to put the weight of the cowl on the hold-open rods
- Put the solenoid valves back to their initial positions.

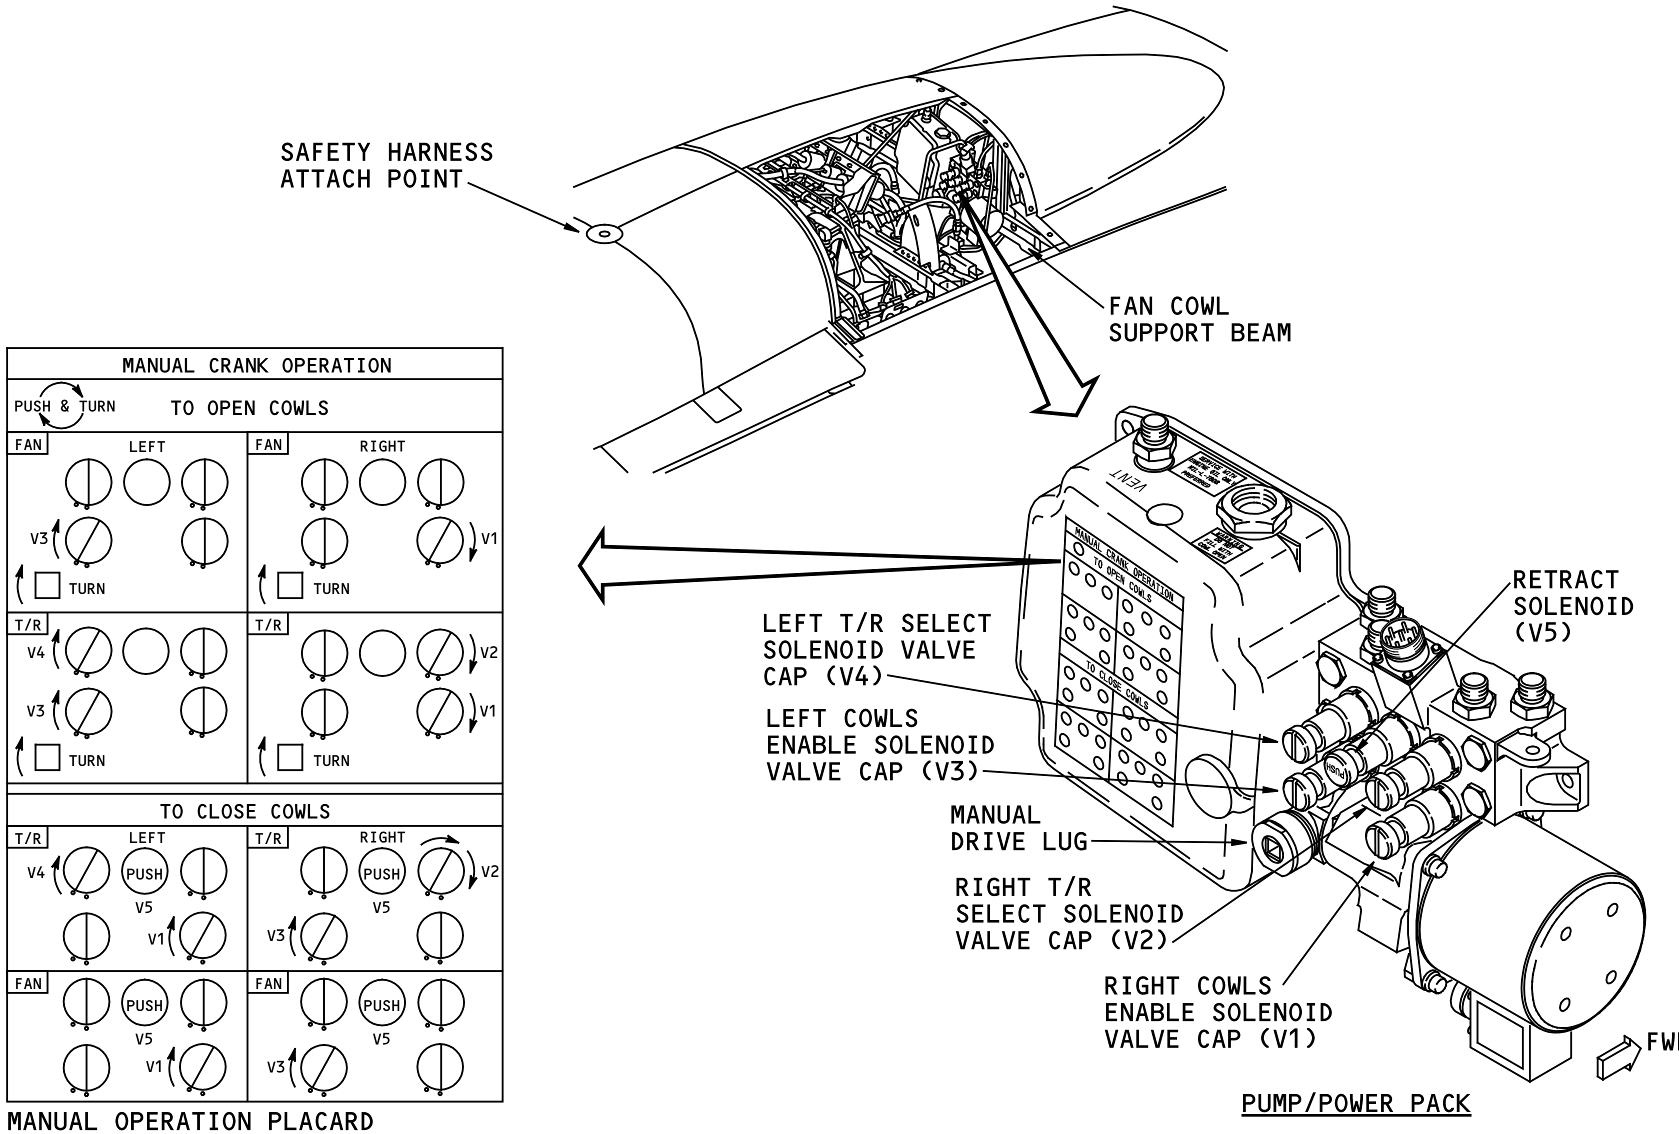
Close the Fan Cowl and Thrust Reverser

This is a summary of the procedure to close a fan cowl or T/R half:

- Use a flat-blade screwdriver to set the solenoid valves to the positions to open the related cowl
- Turn the manual drive lug to move the cowl up and then unlock the hold-open rods
- Set the solenoid valves to the positions to close the related cowl
- Push and hold the V5 solenoid valve to close the cowl
- Put the solenoid valves back to their initial positions.

Training Information Point

The pump/power pack is approximately 14 ft. (4.3 m) from the ground. There is a safety harness attach point with a receptacle for a safety harness. The safety harness attach point is aft of the forward access fairing. Attach the safety harness to the attach point when you operate the pump/power pack.



71-12-00-109 Rev 5 02/11/1997

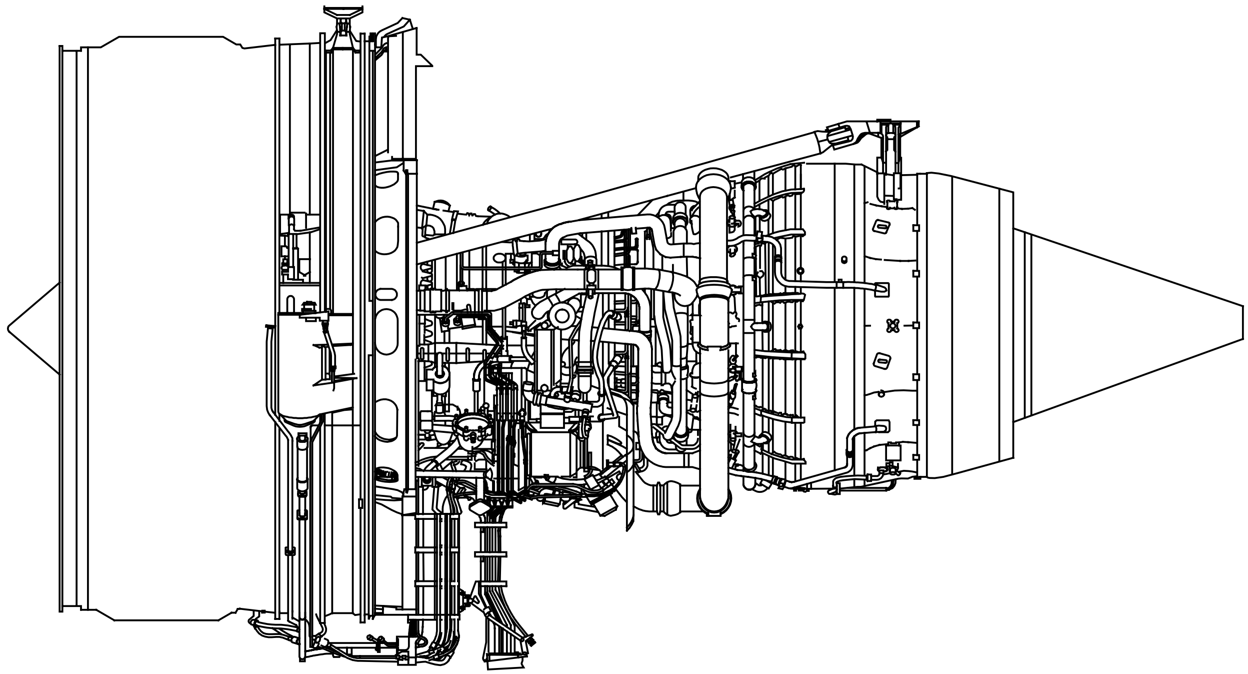
PDOS - MANUAL OPERATION

TRAINING INFORMATION POINT (TIP) - INTRODUCTION

General

The power plant has many LRUs. But, the power plant itself is an LRU. There are several procedures with related equipment that apply to the power plant as an LRU. These are the items in this training information points (TIP) section:

- Engine handling
- Thrust reverser hold-open equipment (engine removed)
- Engine disconnects
- Bootstrap equipment
- Engine mounts
- Engine drains
- System tests.



POWER PLANT

ENGINE COWLING

PDOS

TRAINING INFORMATION POINTS

TRAINING INFORMATION POINT (TIP) - INTRODUCTION

TIP - ENGINE HANDLING

General

The removal and installation of a power plant is a long task. Many special tools and equipment are necessary.

This is a summary of the tasks necessary to change an engine:

- Prepare the airplane for an engine change by doing all the necessary safety and disconnect tasks
- Install the engine ground handling adapters
- Install the bootstrap equipment
- Raise the engine cradle and attach it to the ground handling adapters
- Disconnect the engine mounts
- Lower the engine to the transportation stand.

To install the engine you reverse the procedures.

Preparation

Many procedures must be done to make it safe to remove and install the power plant. This is a summary of the procedures:

- Electrically ground the airplane
- Level the airplane
- Close the engine fuel valve and engine fuel spar valve
- Depressurize the hydraulic system
- Close the engine driven pump supply shutoff valve
- Depressurize the pneumatic system
- Retract the leading edge slats
- Deactivate the leading edge slats
- Deactivate the thrust reverser.

You must remove the fan cowls before you remove the engine. They attach to the fan cowl support beam which attaches to the engine.

Remove the inlet cowl before you remove the engine if you intend to install the same inlet cowl on the replacement engine.

You must open the thrust reverser halves before you remove the engine. You do not remove them for an engine change. The thrust reverser halves attach to the strut. Special hold-open equipment is necessary to keep the reverser halves open.

Apply tape over the bleed air deflector panels to prevent small parts from falling into the engine.

With the thrust reverser hold-open equipment installed, you disconnect all of these types of connections:

- Electrical
- Hydraulic
- Pneumatic
- Mechanical
- Fuel.

Ground Handling Adapters

There are four places on the engine to attach the ground handling adapters. You remove the adapters from the cradle and install them on the engine. The forward ground handling adapters attach to the fan case. A bracket on each side of the low pressure turbine case is where you attach the aft ground handling adapters.

NOTE: The forward ground handling adapters on some engine cradles attach to the fan hub frame. You must remove two blank-off panels to install these adapters. This type of engine cradle is required when you separate the fan stator module assembly from the core of the engine.

Bootstrap Equipment

The bootstrap equipment has the forward and aft bootstrap assemblies. The assemblies attach to fittings under the strut.

The forward bootstrap assembly uses only one dynamometer. It is part of the forward inboard cradle attach assembly.

Engine Cradle

The bootstrap assembly hoists attach to the engine cradle. You must be careful to attach the hoists to the proper lug holes on the cradle.

NOTE: Attach the outboard hoists to the inner hole and the inboard hoists to the outer hole.

You initially raise the cradle and transportation stand together to let gravity align them with the engine. You then lower them and disconnect the cradle from the stand. You raise the cradle and attach it to the ground handling adapters.

WARNING: MONITOR THE DYNAMOMETERS ON THE FORWARD AND THE AFT HOISTS. MAKE SURE THE LOADS ARE LESS THAN THESE LOAD LIMITS: 10,000 LB (4545 KG) ON THE FORWARD DYNAMOMETER, 3000 LB (1363 KG) ON AN AFT INBOARD DYNAMOMETER, AND 4000 LB (1818 KG) ON AN AFT OUTBOARD DYNAMOMETER. IF THE LOADS ARE MORE THAN THE LOAD LIMITS GIVEN, THE ENGINE CAN FALL AND CAUSE INJURIES TO PERSONS AND DAMAGE TO EQUIPMENT.

Engine Mounts

There are two engine mounts: forward and aft. The upper part of each mount is part of the strut. The lower part of each mount attaches to the engine. When the bootstrap loads are within limits, you remove the tension bolts that hold the upper and lower mounts together.

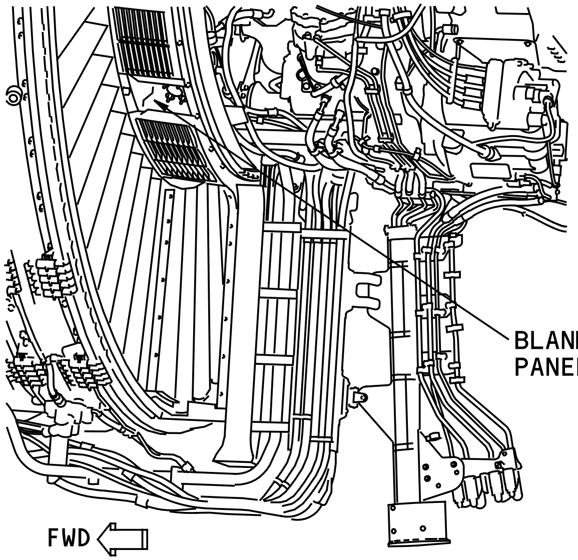
Transportation Stand

You lower the engine and cradle down to the transportation stand. Use the aft bootstrap assembly to change the roll angle of the engine to align it with the stand.

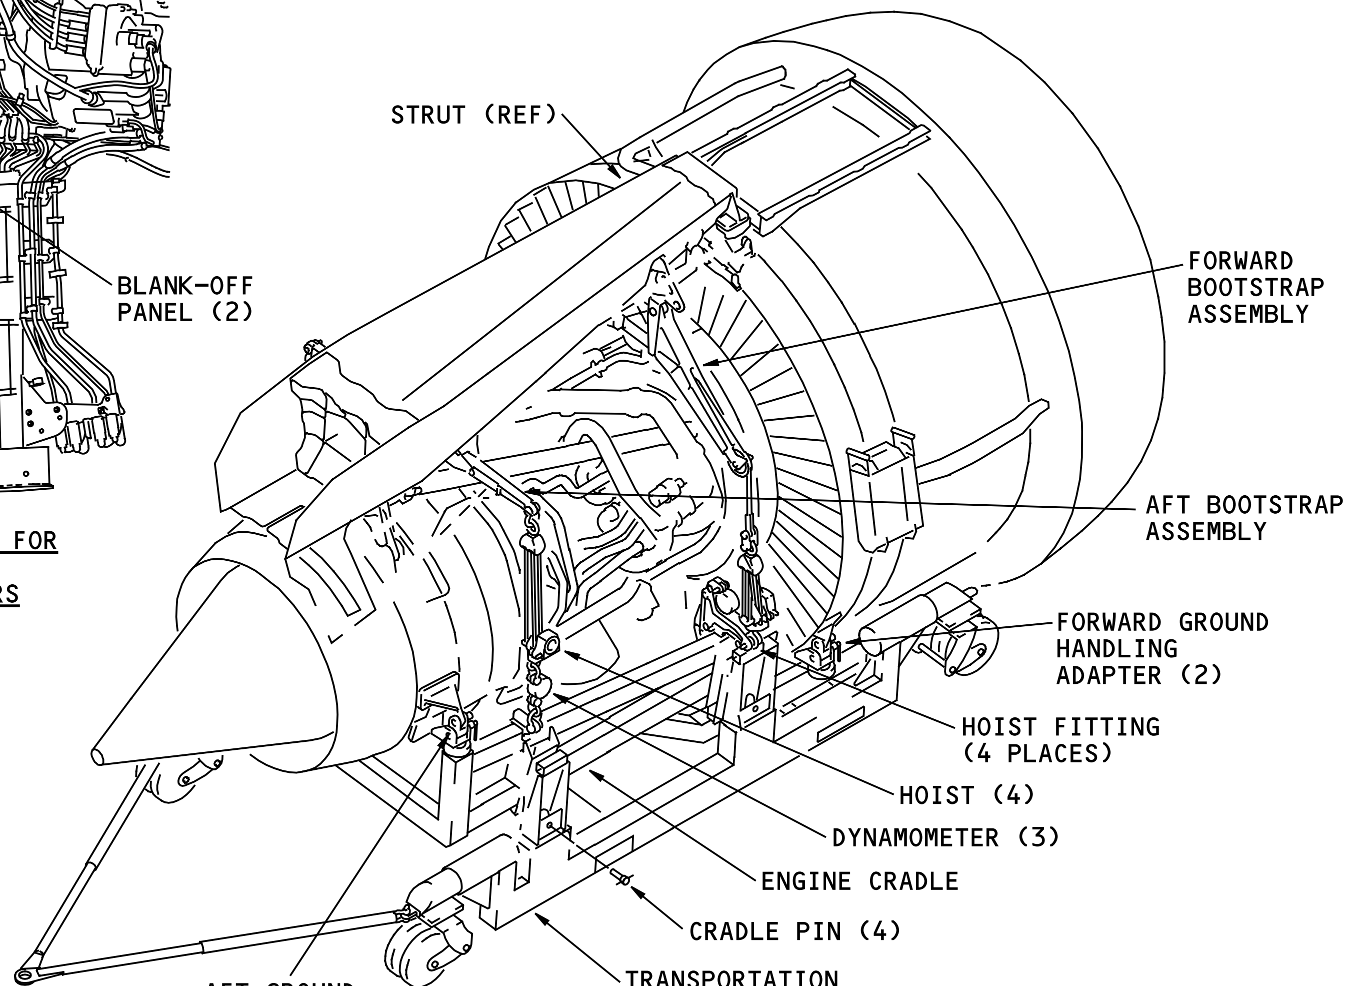
TIP - ENGINE HANDLING

Power Plant Installation

The procedures for installing the engine are basically the reverse of the removal procedures.



ALTERNATE LOCATION FOR
FORWARD GROUND
HANDLING ADAPTERS



TIP - ENGINE HANDLING

TIP - THRUST REVERSER HOLD-OPEN EQUIPMENT

General

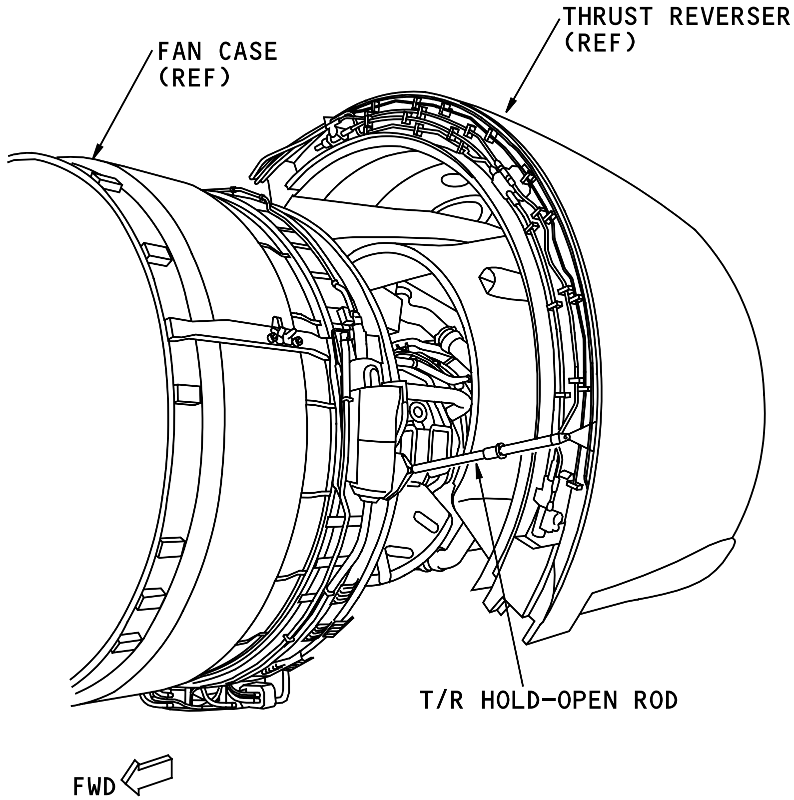
Normally when you open the thrust reverser (T/R) halves, hold-open rods that attach to the engine hold the T/R halves open. When you change an engine, you must attach special T/R hold-open equipment to the T/R PDOS actuators to hold the T/R halves open.

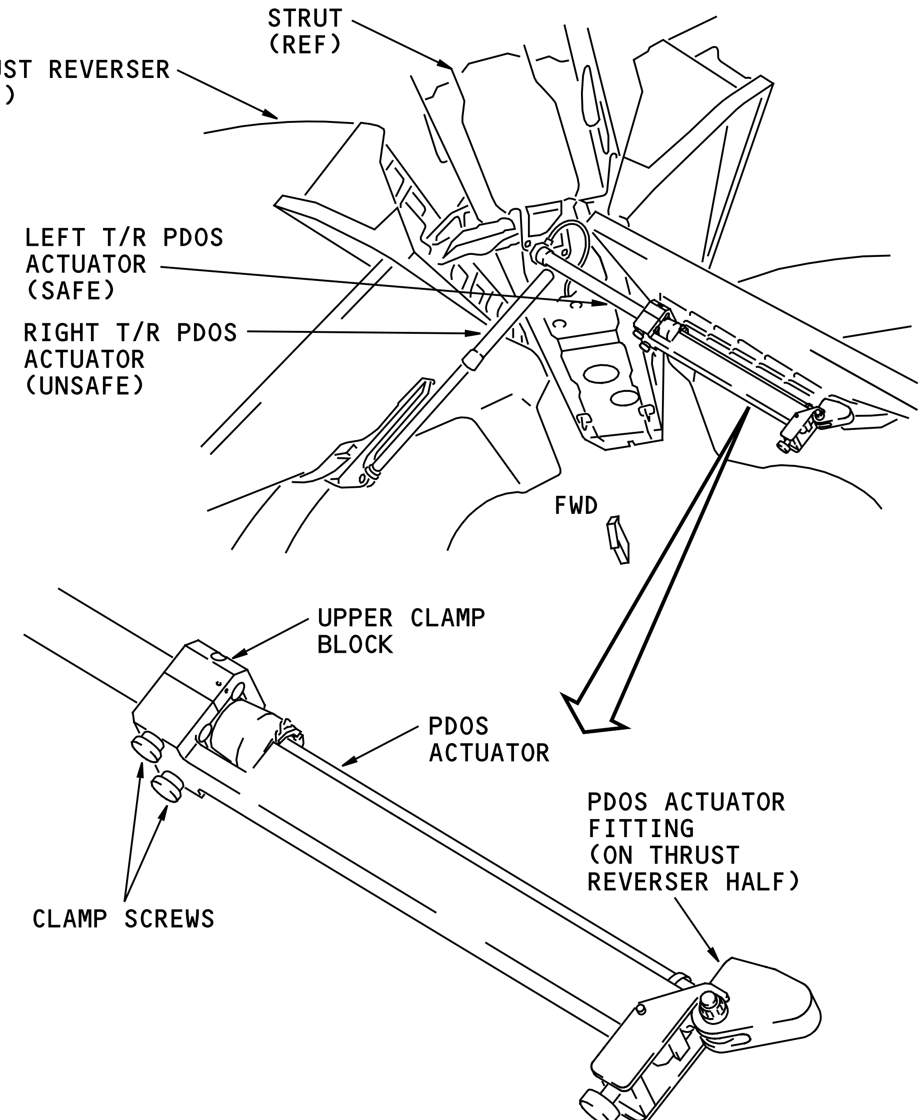
Thrust Reverser Hold-Open Tool

The T/R hold-open tools let the strut hold the weight of the T/R halves. There is one tool for each T/R half.

Operation

With the T/R held open by the hold-open rods, you install the T/R hold-open tools on the T/R PDOS actuators. This makes sure the T/R does not close when you disconnect the hold open rods.





THRUST REVERSER HOLD-OPEN TOOL

TIP - THRUST REVERSER HOLD-OPEN EQUIPMENT

TIP - ENGINE DISCONNECTS LEFT

General

When you change an engine you must disconnect many things. You make the disconnects above the fan case and above the engine core just below the strut.

Fan Disconnects

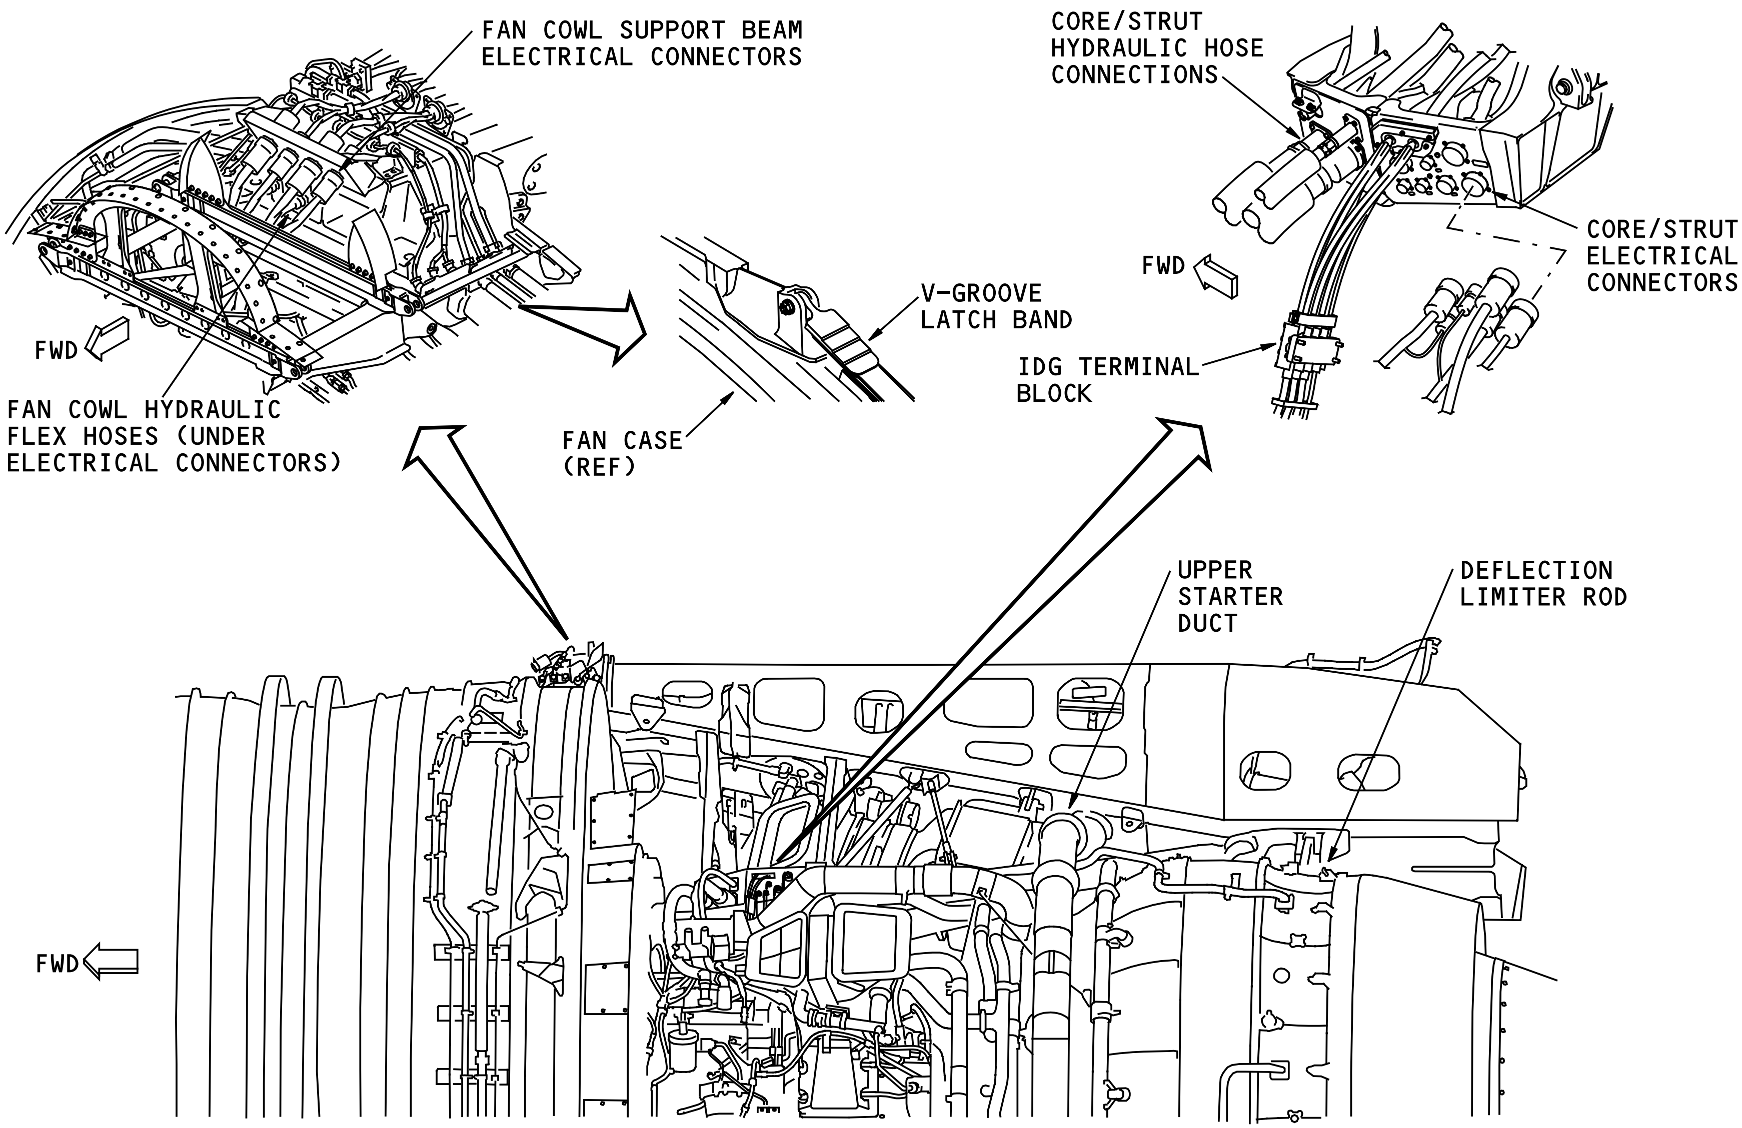
There is a fan/strut disconnect panel above the fan case on the forward end of the strut. The panel contains four electrical connectors and the fan cowl PDOS hydraulic tubes.

When you change an engine, you must also disconnect the left T/R v-groove latch band.

Core Disconnects

There is a core/strut disconnect panel on the left side of the engine that attaches to the bottom of the strut. This panel has seven electrical connections and three hydraulic hose connections. Just below the panel is the IDG terminal block. This is where you disconnect the IDG feeder cables.

When you change an engine, you must also disconnect the upper starter duct and the left end of the deflection limiter rod.



TIP - ENGINE DISCONNECTS LEFT

TIP - ENGINE DISCONNECTS (RIGHT)

General

When you change an engine you must disconnect many things. You make the disconnects above the fan case and above the engine core.

Fan Disconnects

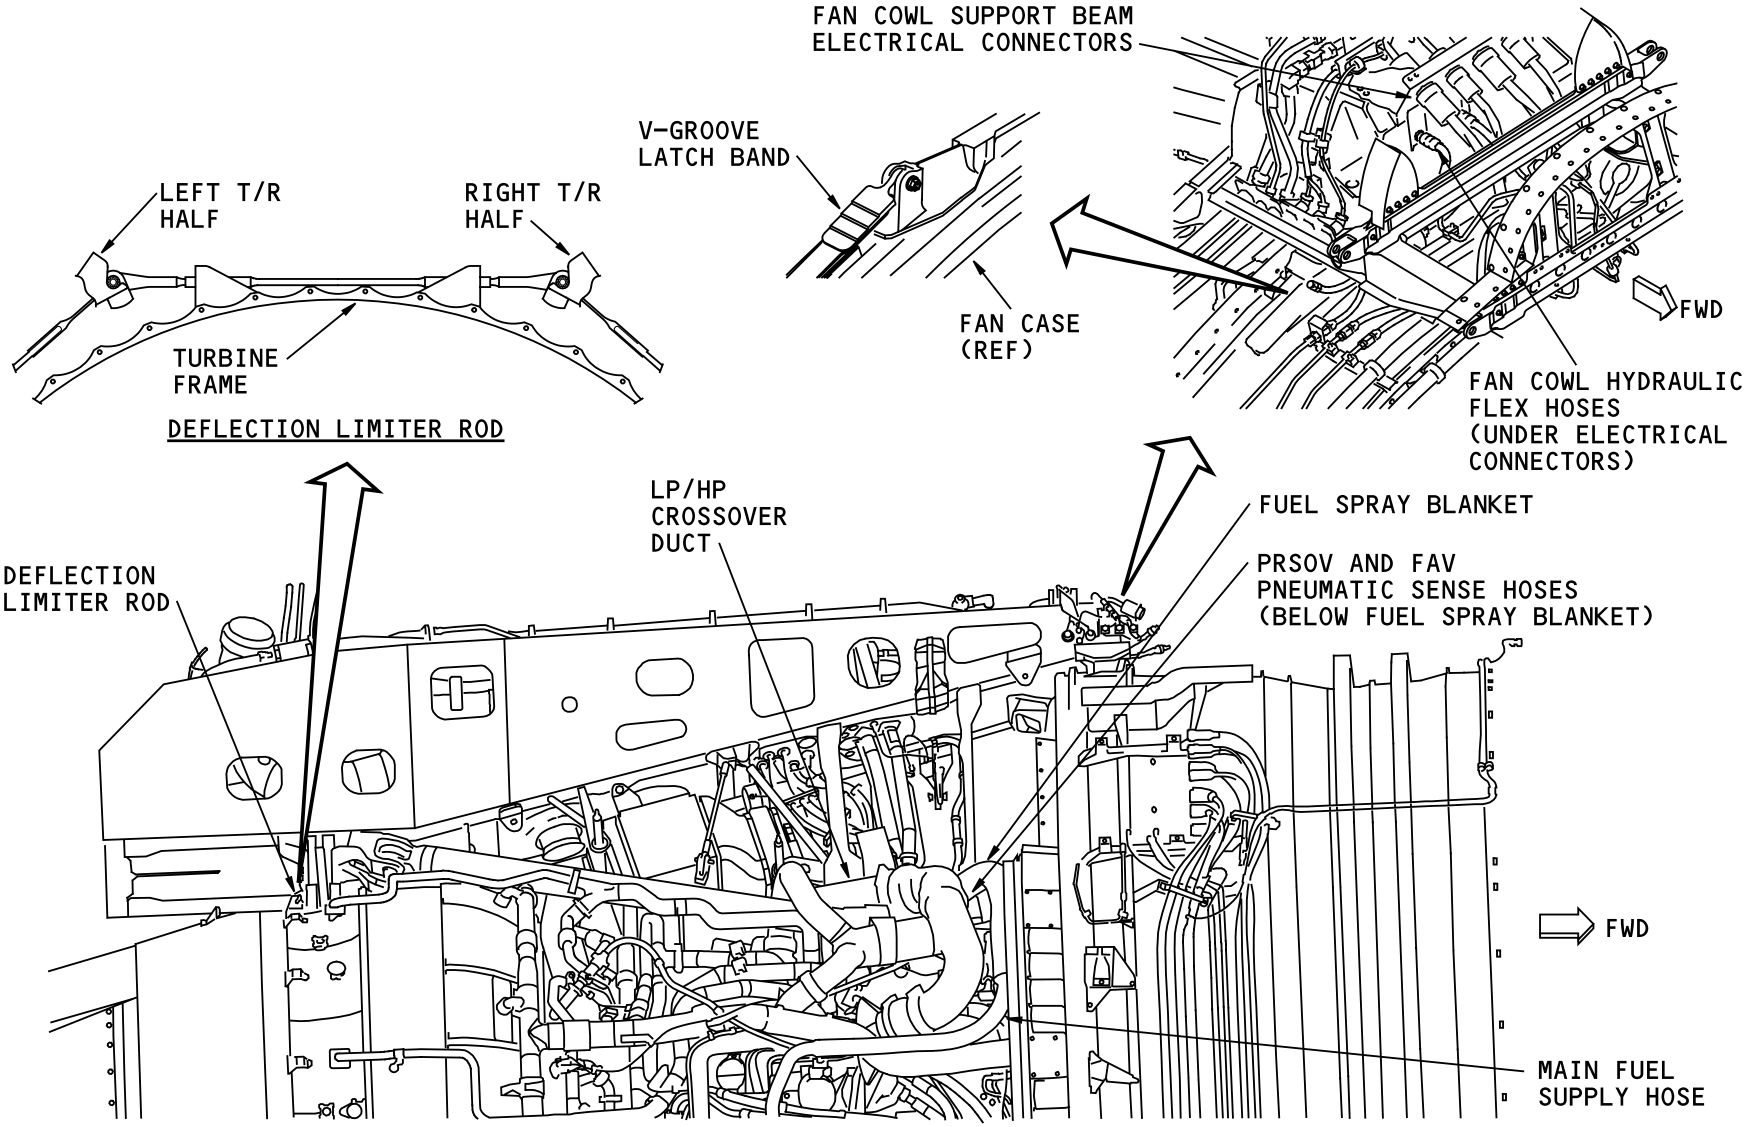
There is a fan/strut disconnect panel above the fan case on the forward end of the strut. The panel contains four electrical connectors and the fan cowl PDOS hydraulic tubes.

When you change an engine, you must also disconnect the right T/R v-groove latch band.

Core Disconnects

When you change an engine, you must disconnect these five mechanical connections:

- Right end of the deflection limiter rod
- LP/HP crossover duct
- PRSOV pneumatic sense hose
- FAV pneumatic sense hose
- Main fuel supply hose.



71-00-00-111 Rev 0 02/11/1997

TIP - ENGINE DISCONNECTS (RIGHT)

TIP - BOOTSTRAP EQUIPMENT

General

When you change an engine, you lift and lower it with bootstrap equipment. The bootstrap equipment includes these assemblies:

- Forward bootstrap
- Aft bootstrap
- Hoist.

Forward Bootstrap Assembly

The forward bootstrap assembly attaches to the bottom, forward end of the strut. The assembly has these seven structural components:

- Forward arm (2)
- Forward upper attach fitting (2)
- Forward center plate assembly 1
- Forward center plate assembly 2
- Upper forward center beam.

Aft Bootstrap Assembly

The aft bootstrap assembly attaches to the bottom, aft end of the strut. The assembly has these three structural components:

- Aft inboard arm (short)
- Center beam
- Aft outboard arm (long).

Hoist Assemblies

The hoist assemblies connect the bootstrap assemblies to the engine cradle. These are the three hoist assemblies:

- Forward inboard
- Forward outboard
- Aft.

The forward inboard hoist assembly includes these components:

- Hoist
- Forward inboard cradle attach assembly
- Dyno link assembly.

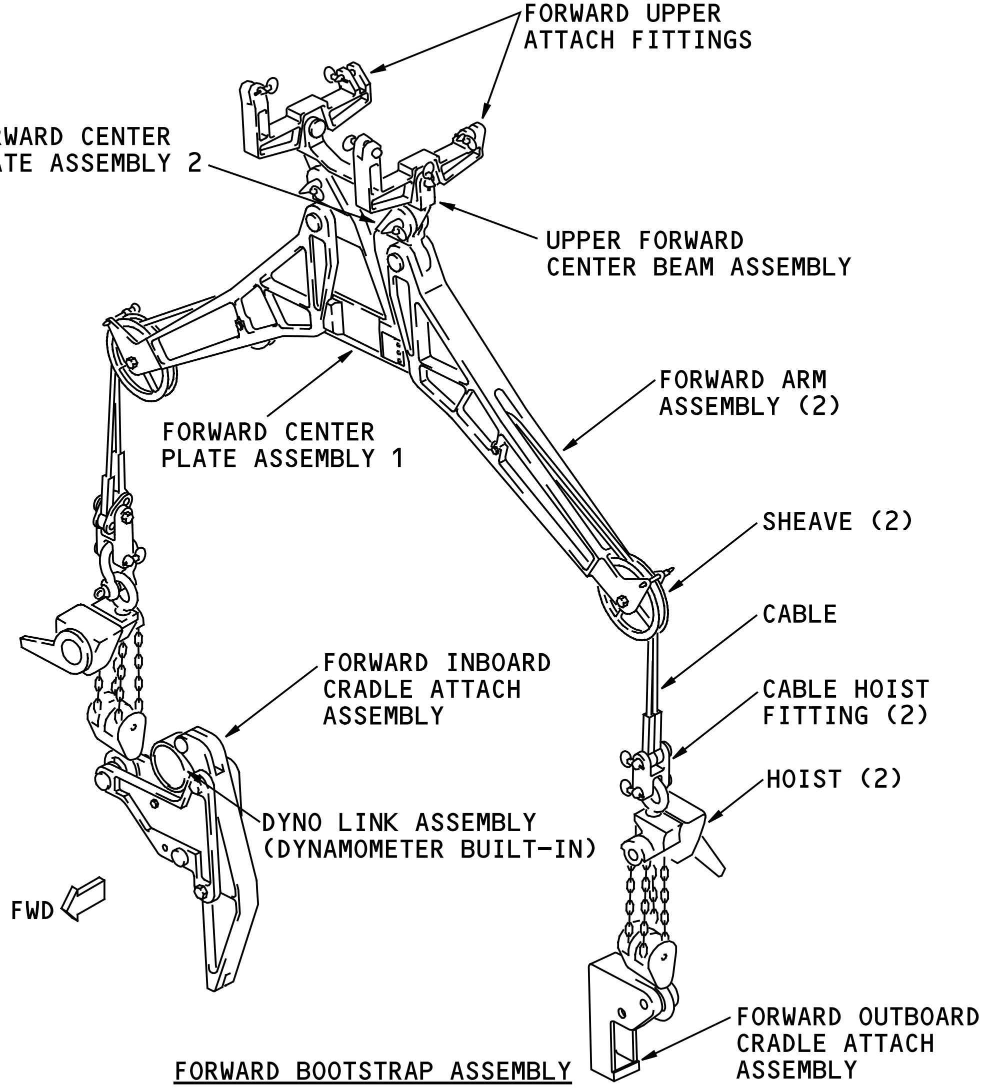
The forward outboard hoist assembly includes these components:

- Hoist
- Forward outboard cradle attach assembly.

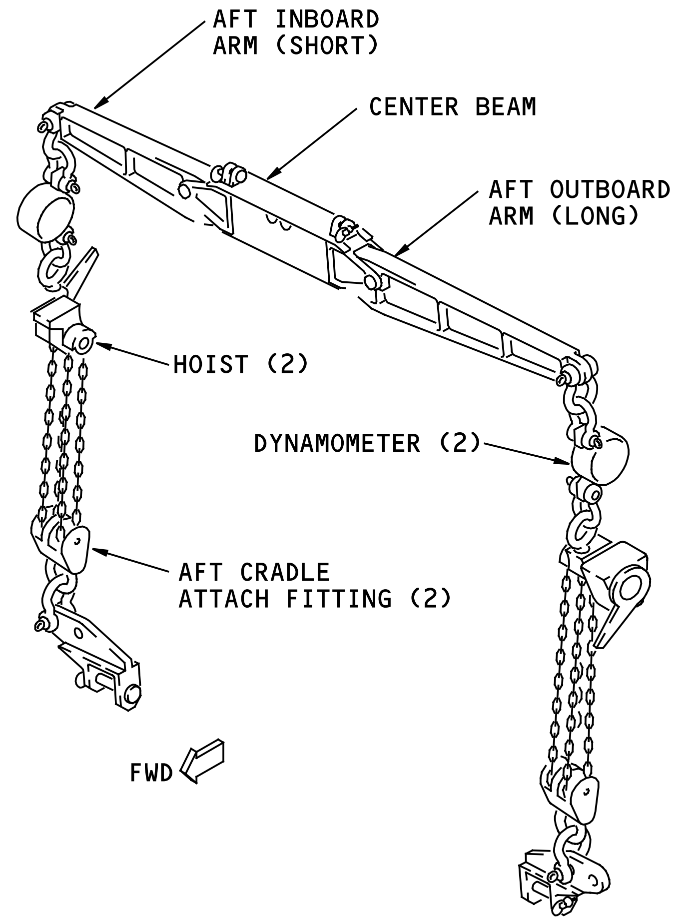
The aft hoist assembly includes these components:

- Hoists
- Dynamometers
- Aft cradle attach fittings.

You use the aft hoist assembly to change the roll of the engine.



FORWARD BOOTSTRAP ASSEMBLY



AFT BOOTSTRAP ASSEMBLY

NOTE: LEFT ENGINE INSTALLATION SHOWN

TIP - BOOTSTRAP EQUIPMENT

TIP - ENGINE DRAINS

Purpose

The engine drains system removes fluid from the engine cowls, components, and strut. This prevents fluid leakage on to the engine.

Drains

The drain system collects fuel, oil, and hydraulic fluid from leaking components and sends it overboard. The fluids go overboard through the drain mast.

The drain mast is at the 6:00 position on the thrust reverser aft of the forward latch beam access door. Eight drain tubes go from engine components to the drain mast.

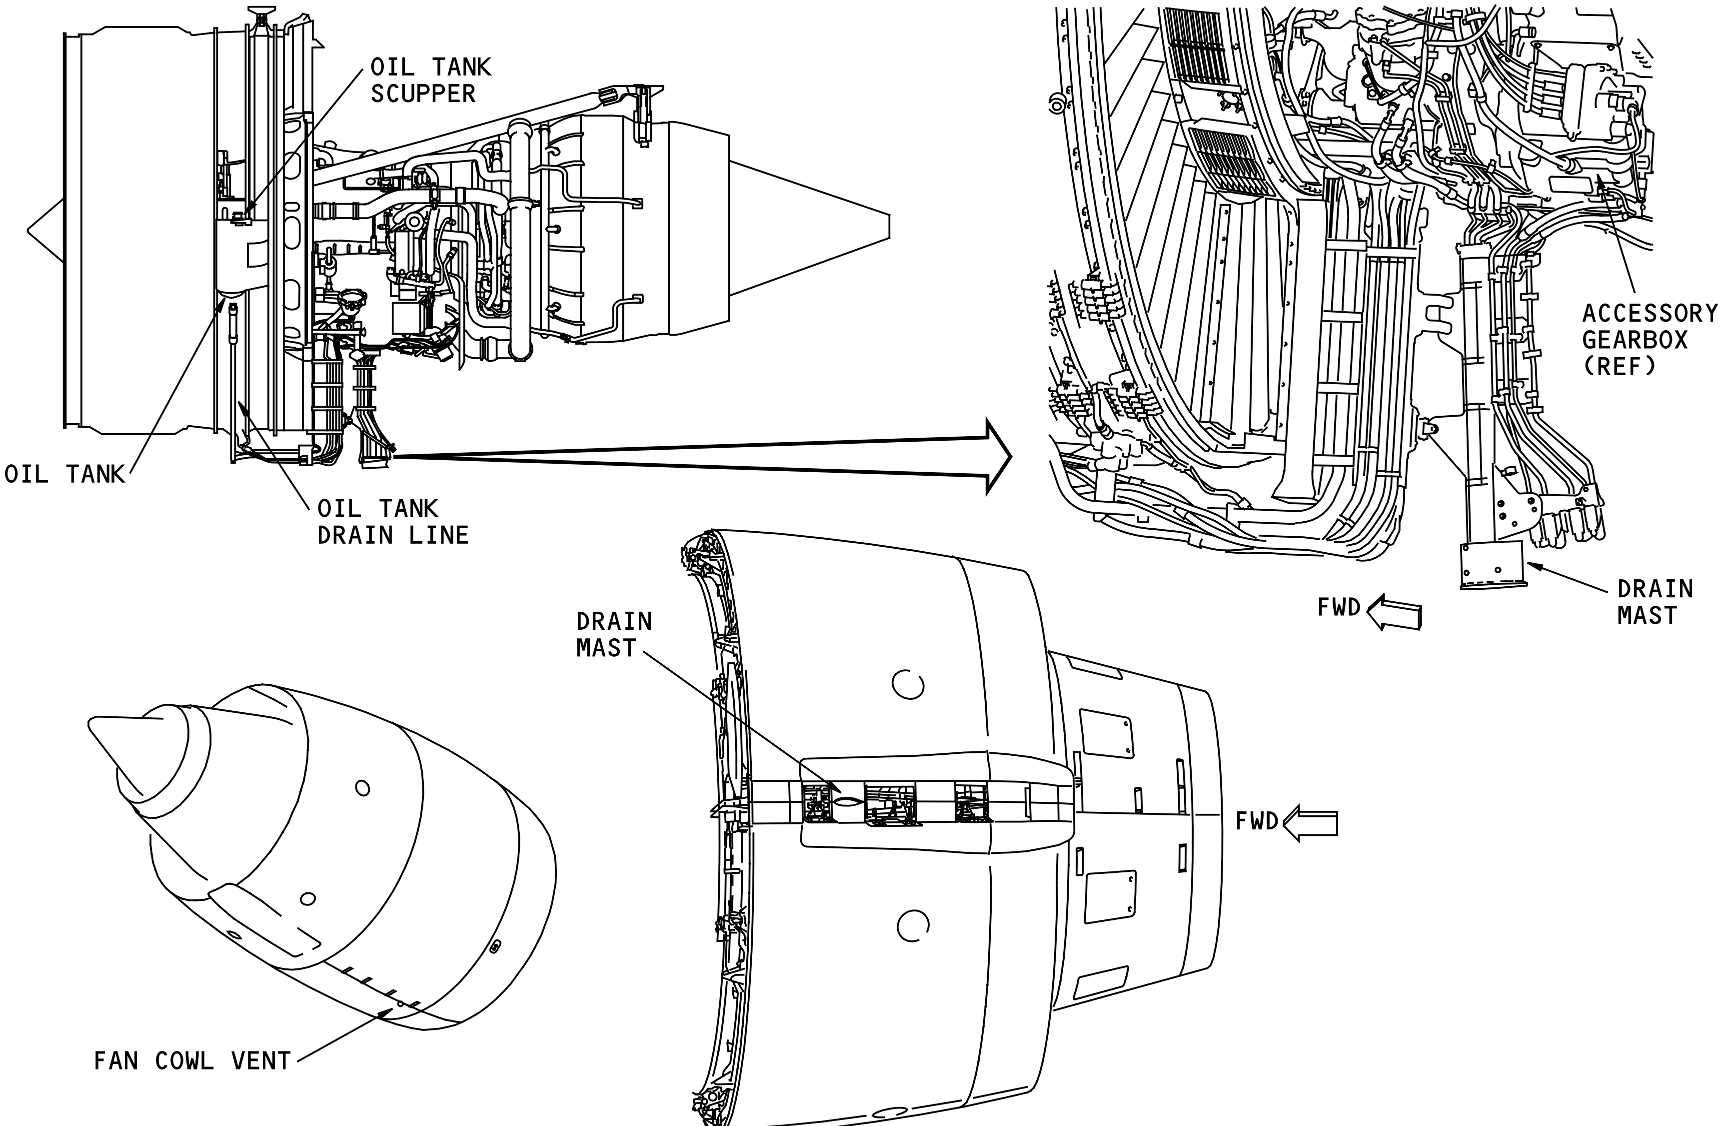
These are the engine components that drain through the eight drain tubes:

- VBV/VSV actuators
- HPT ACC and STB valve actuators
- Main fuel pump drive pad
- HMU drive pad
- Backup generator seal and drive pad
- Hydraulic pump seal
- Hydraulic pump drive pad
- IDG drive pad.

The components that mount to the accessory gearbox have drains that connect to their adapter drive pads.

Some of the fuel driven actuators have drain lines that combine into a single line before they get to the drain mast. These components have drain cans (not shown) which also collect leakage. You look in the drain cans to isolate the leakage to a specific component.

The oil tank scupper has a drain line that goes down to the fan cowl vent. The oil tank scupper collects leakage from oil tank servicing and drains it overboard through the fan cowl vent.



TIP - ENGINE DRAINS

71-00-00-106 Rev 3 02/08/1997

TIP - SYSTEM TESTS

General

There are four system tests and two special function tests for each engine. You use the maintenance access terminal (MAT) to do the tests. The left and right engine tests are the same except for the titles.

These are the system tests:

- Fuel Driven Actuator
- Air Driven Actuator
- Ignition System
- Reverse Thrust Lever Interlock Actuator.

This is the special function test:

- VSV Opening for Maintenance.

Fuel Driven Actuator Test

As you dry motor the engine, this test opens and closes the actuators for these components:

- Fuel metering valve (in HMU)
- Staging valve (in HMU)
- Variable stator vanes
- Variable bypass valves
- HPT active clearance control valve
- Start transient bleed valve.

Air Driven Actuator Test

With the engine at approach idle, this test opens and closes the actuators for these components:

- Core compartment cooling valve
- LPT active clearance control valve.

Ignition System Test

This test makes the EEC supply power to the igniters.

Reverse Thrust Lever Interlock Actuator Test

This test makes the EEC open and close the interlock actuator.

VSV Opening for Maintenance Test

As you dry motor the engine, this test opens the variable stator vanes (VSV). When you stop the dry motor the VSVs stay open so you can do maintenance. The VSVs reset the next time the engine is started or motored.

TABLE OF CONTENTS

ENGINE - INTRODUCTION

General

This chapter gives general information about the modules and internal components of the GE90-90B engine.

The bypass ratio is a ratio of the mass of air going through the fan duct to the mass of air going through the engine core.

The engine weight includes the engine build up (EBU) equipment that Boeing installs. The engine driven hydraulic pump (EDP), the integrated drive generator (IDG), and the inlet cowl are examples of EBU equipment.

Data Plate

The engine data plate is on the aft face of the fan hub frame at the 9:00 position. It is below the configuration box. The data plate shows this information about the engine.

- Type certificate number
- Model number
- Serial number
- Engine configuration
- Take off (TO) thrust
- Maximum continuous thrust
- Service bulletin number that sets engine configuration
- Date of manufacture
- Emissions compliance
- Manufacturing location.

Type certificate is issued by the applicable regulatory agency. The certificate shows that the agency approves the engine as airworthy.

The production certificate number is issued by the applicable regulatory agency. The space shows the current Production Certificate number, PC - 108.

The CONFIG field shows engine rating and configuration information. TO THRUST is the takeoff thrust (in pounds) at the specified rating. The TO thrust is the approved maximum thrust level at which the engine can operate. The TO thrust on the data plate is different than the TO thrust that Boeing uses, called Boeing equivalent thrust (BET). The thrust on the data plate is measured on a test stand and is equivalent to the static thrust at sea level. Boeing equivalent thrust (BET) is a calculated number. It is equivalent to the thrust at 165 knots at sea level. BET is defined so that engines with the same BET will have approximately the same TO performance at sea level.

MAX CONT is the maximum continuous thrust (in pounds) at specified rating. Maximum continuous thrust is measured on a test stand. It is the approved maximum thrust level at which the engine can operate with no time limit.

The SERV BUL field shows the service bulletin number that goes with a change in the engine configuration. You install different EEC rating and configuration plugs to change the engine configuration.

ENGINE - INTRODUCTION

The emissions field shows that the engine complies with emissions standards.

ENGINE - INTRODUCTION

ENGINE - GENERAL DESCRIPTION - 1

General

The GE90 is a high-bypass, two shaft, turbofan engine. It has a low pressure (LP) rotor system (N1) and a high pressure (HP) rotor system (N2).

The engine has station numbers to identify locations along its axis.

Airflow

The engine has primary (core) airflow and secondary (bypass) airflow. The bypass ratio of this engine is 8.4:1. This means that 8.4 times more secondary air goes through the engine than primary air.

The primary airflow goes through the compressors, combustion section, and turbines. The combustion section also gets fuel from the fuel nozzles. This mixture of air and fuel burns to make high pressure exhaust gas. The exhaust gas goes out of the combustion section to turn the turbines. The exhaust gas from the primary airflow makes approximately 20 percent of the forward thrust.

The secondary airflow goes around (bypasses) the core of the engine. The secondary airflow makes approximately 80 percent of the forward thrust. The thrust reverser system also uses secondary airflow for reverse thrust.

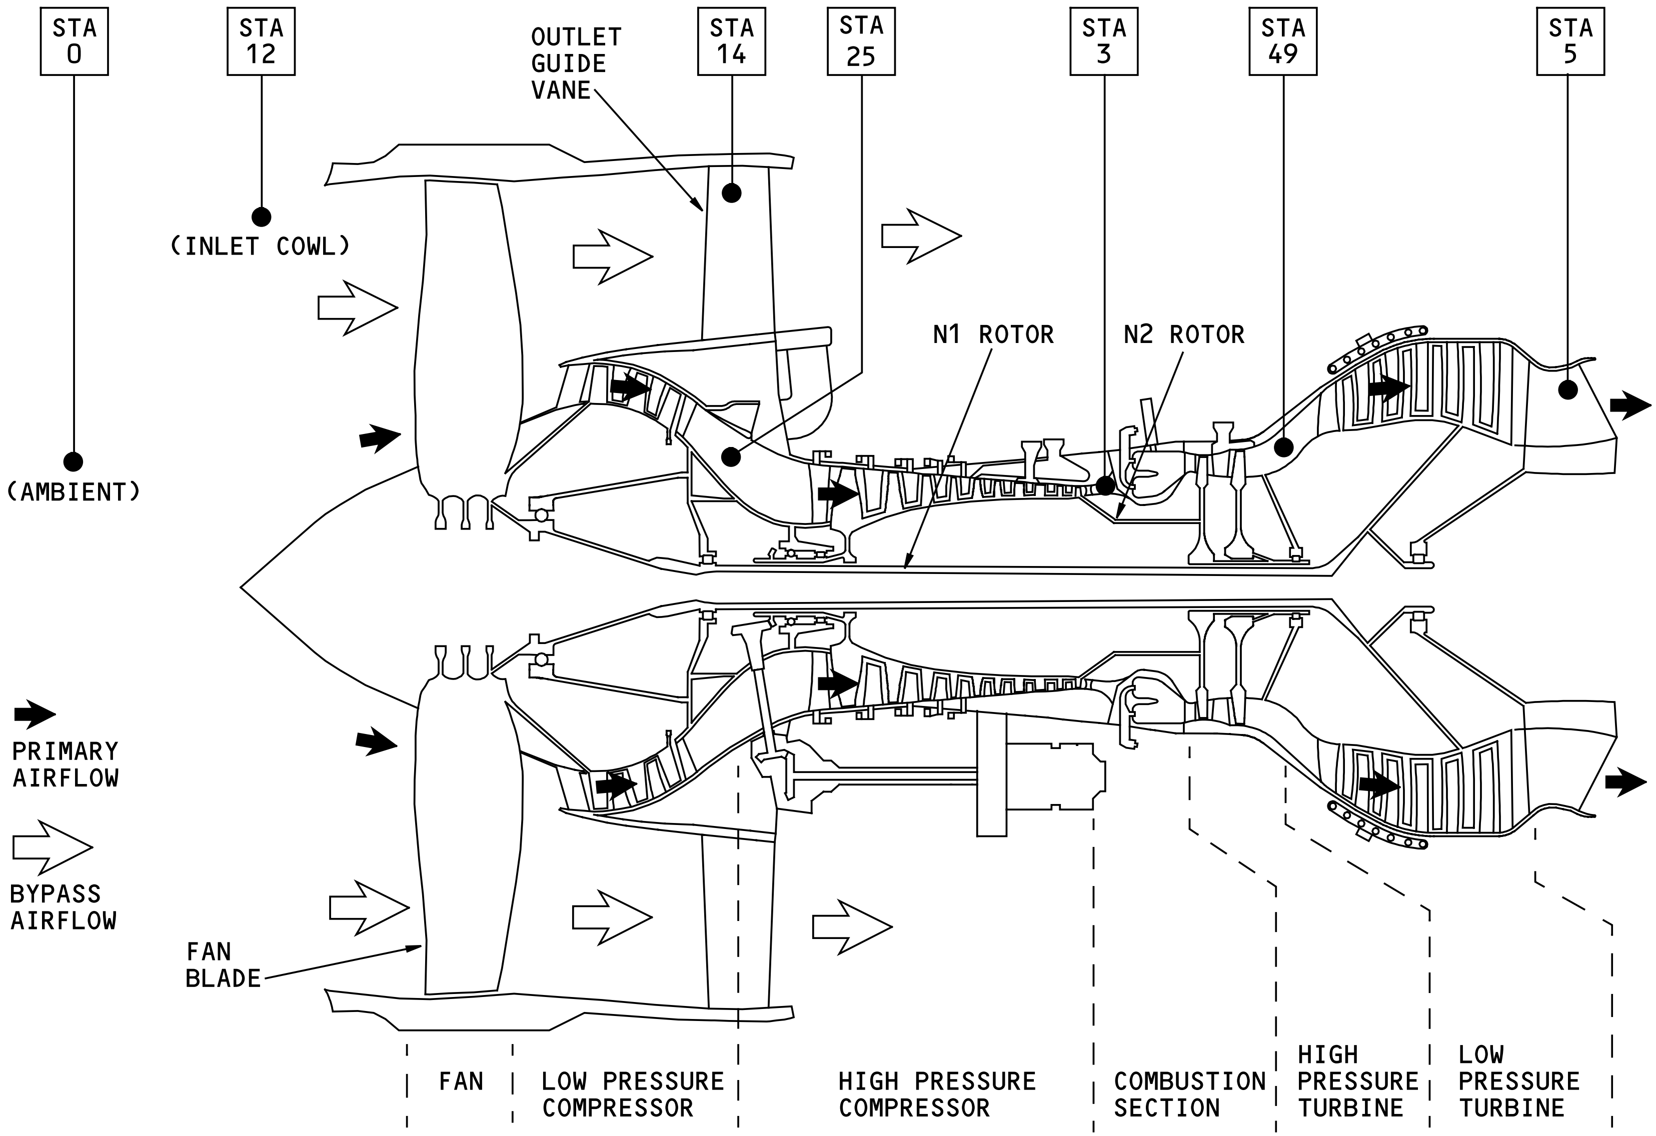
Low Pressure Rotor System (N1)

The LP rotor system includes the fan and a three-stage low pressure compressor (LPC) connected to a six-stage low pressure turbine (LPT). A coupling connects the LPT drive shaft to the LPC.

High Pressure System

The HP rotor system is an ten-stage high pressure compressor (HPC) connected to a two-stage high pressure turbine (HPT). A coupling connects the HPT drive shaft to the HPC.

The HPC has variable stator vanes in the first four stages.



ENGINE - GENERAL DESCRIPTION - 1

ENGINE - GENERAL DESCRIPTION - 2

Main Engine Bearings

Six main engine bearings hold the N1 shaft and the N2 shaft. Numbers identify the engine bearings. The main engine bearings are in three dry-sump cavities. The letters A, B, and C identify the sumps. The lube and scavenge pump supplies lubricating oil to the bearings and draws oil out of the bearing sumps.

The number 1 and number 2 bearings hold the front of the N1 shaft. The number 1 bearing is a ball bearing. It is the thrust bearing for the N1 shaft. The number 2 bearing is a roller bearing and holds only radial loads.

There are two number 3 bearings. One is a ball bearing and one is a roller bearing. The two of them hold the front of the N2 shaft. The ball bearing is the thrust bearing for N2 shaft. The roller bearing holds only radial loads.

The number 1, 2, and 3 bearings are in the A sump.

The number 4 roller bearing holds the rear of the N2 shaft. The number 4 roller bearing is in the B sump.

The number 5 roller bearing holds the rear of the N1 shaft. The number 5 roller bearing is in the C sump.

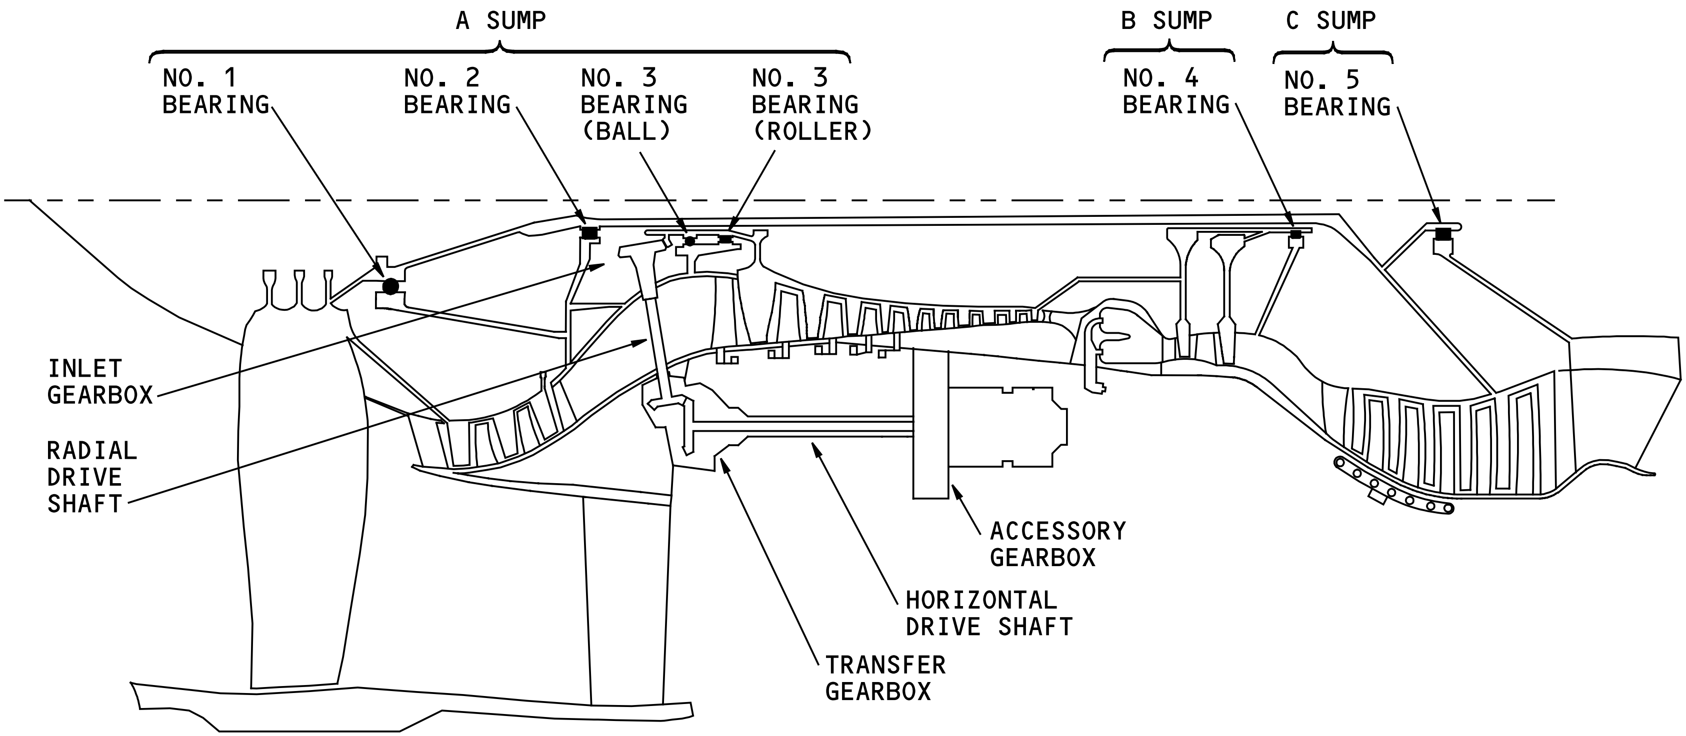
Accessory Drives

There are three gearboxes on the engine:

- Inlet gearbox
- Transfer gearbox
- Accessory gearbox.

The inlet and transfer gearboxes transfer energy from the N2 shaft to the accessory gearbox. The accessory gearbox holds and turns the engine accessories.

The N2 shaft turns the radial drive shaft through the inlet gearbox. The radial drive shaft turns the horizontal drive shaft through the transfer gearbox. The horizontal drive shaft turns the accessory gearbox.



72-00-00-103 Rev 4 02/12/96

ENGINE - GENERAL DESCRIPTION - 2

ENGINE - COMPONENT LOCATIONS

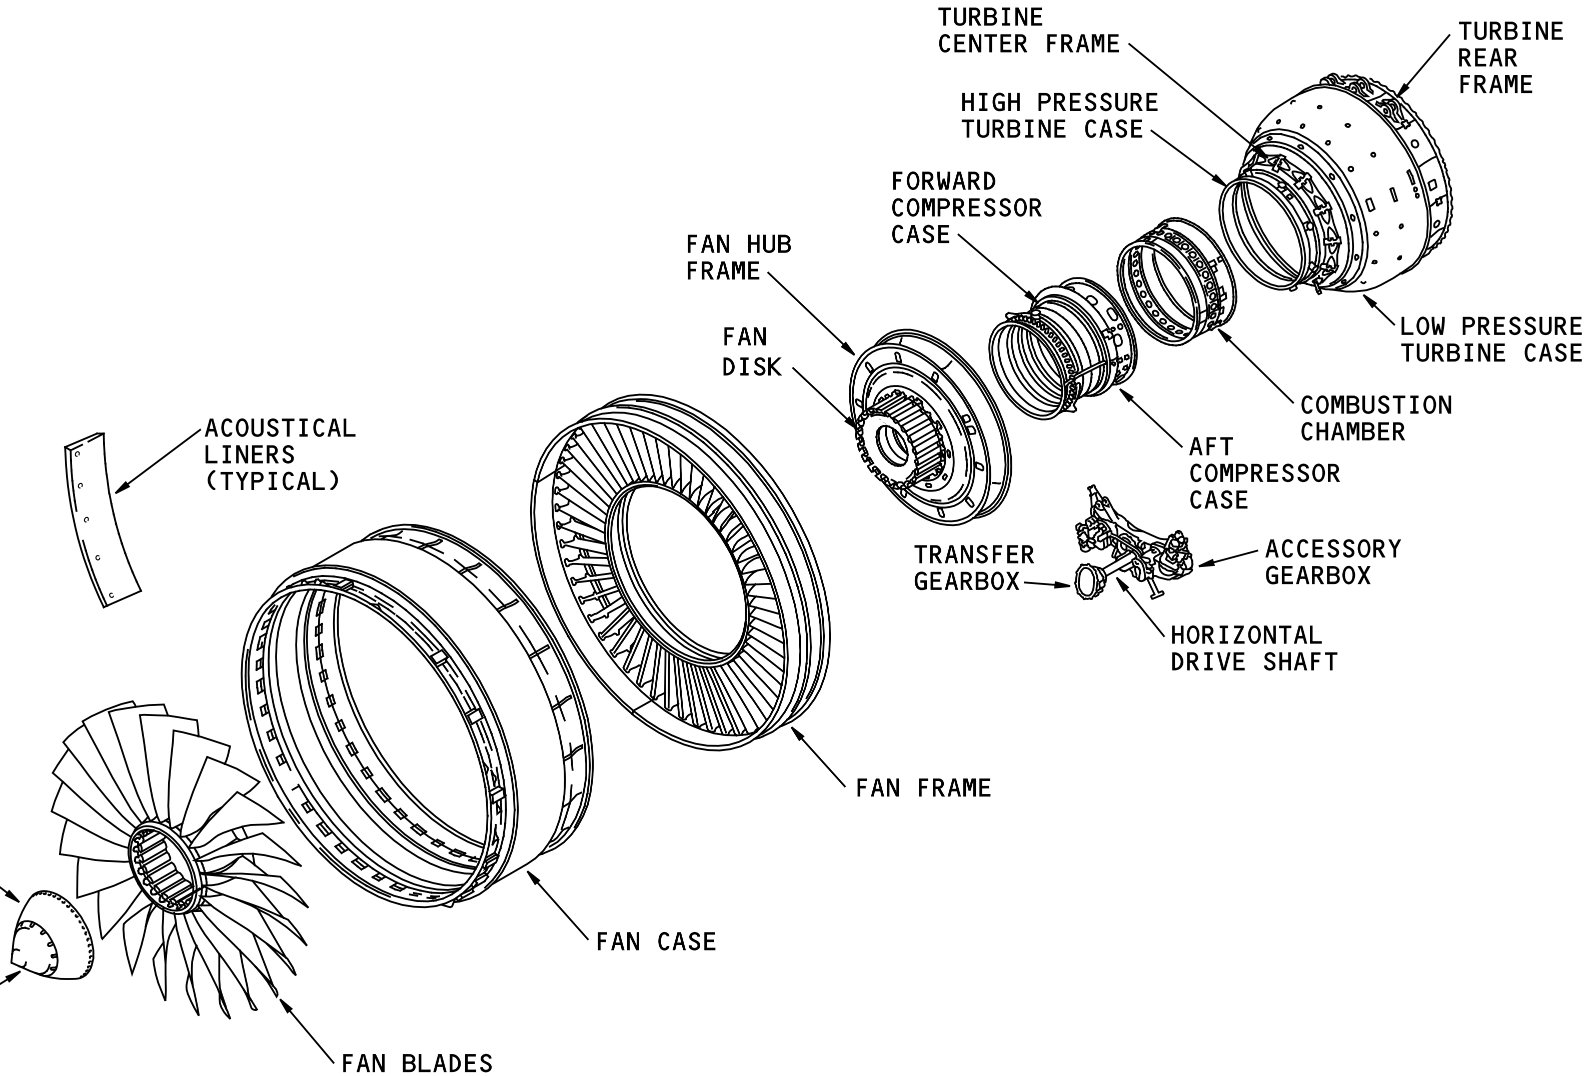
General

The GE90 engine has these primary engine modules and components:

- Forward and aft spinners
- Fan blades
- Fan disk
- Fan case
- Fan frame
- Fan hub frame
- Forward compressor case
- Aft compressor case
- Combustion chamber
- HPT case
- Turbine center frame
- LPT case
- Turbine rear frame
- Accessory drives.

Acoustical liners attach to the inside of the fan case to absorb the sound of the fan blades. There are eight forward and eight aft acoustical liners.

The accessory drives are below the HPC at the 6:00 position.



72-00-00-104 Rev 5 02/12/96

ENGINE - COMPONENT LOCATIONS

ENGINE - SPINNERS AND FAN BLADES

Spinners

The one piece spinner is an aerodynamic fairings that directs inlet airflow. The spinner attaches to the fan disk with 22 attach screws.

Fan Blades

There are 22 wide-chord fan blades on the engine. The fan blades are carbon fiber and resin with a titanium leading and trailing edge. The fan blades are line replaceable units.

The fan blades fit into dovetail slots in the fan disk. The dovetail slots hold the fan blades in place radially. There are fan blade platforms between the fan blades. They make an aerodynamic surface for the air flow. The spinner, fan disk, and forward face of the fan hub frame hold the fan blade platforms in place.

Fan blade spacers and dovetail keys fit at the base of the fan blade in the dovetail slot. These help the fan blade fit tight in the dovetail slot.

Fan Blade Removal

You remove each fan blade independently. To prepare for fan blade removal, first put the fan blade you will remove in the 6:00 position. Turn the fan blades counterclockwise to move the fan blades. To remove a fan blade, remove the components in this order:

- Forward and aft spinner
- Fan blade platform
- Retainer bolt
- Fan blade spacer
- Dovetail key
- Retainer
- Fan blade.

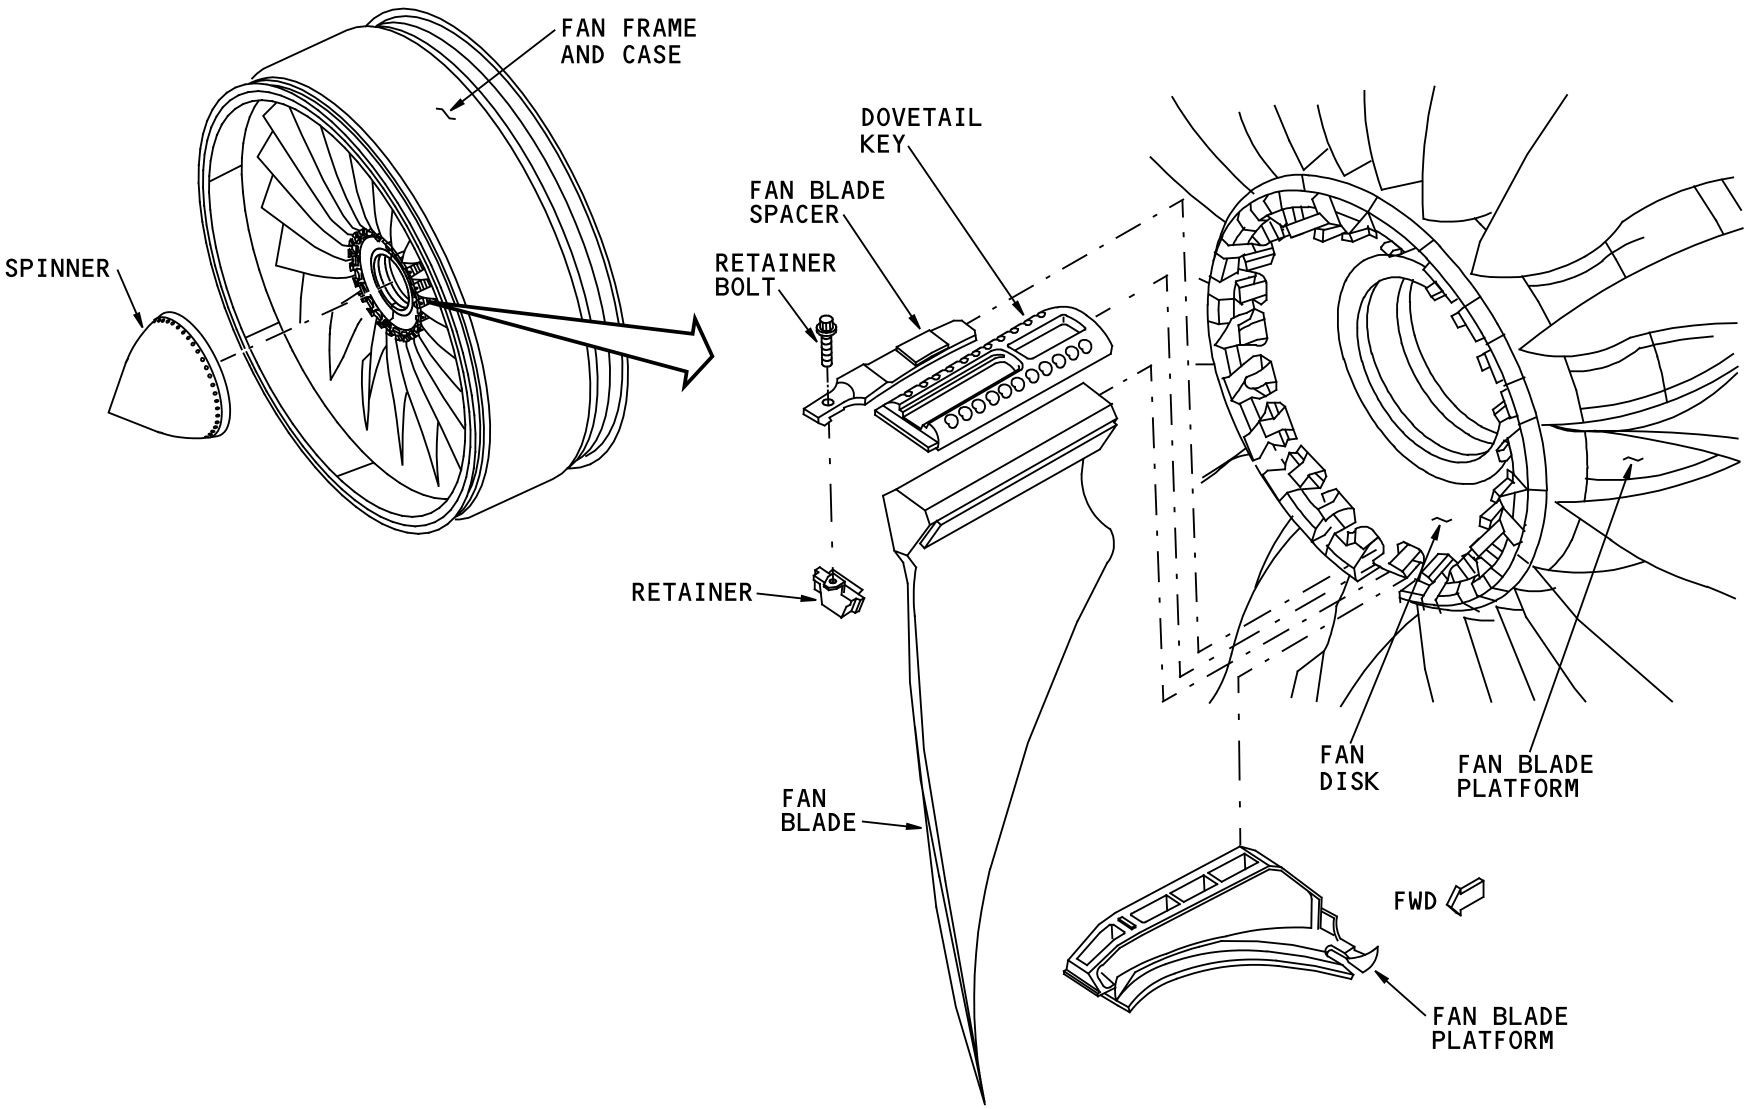
You use a slide hammer to remove the fan blade spacers. You use a plastic hammer to install the fan blade spacers.

Training Information Point

The dovetail slots for fan blade numbers 1 and 5 are marked. The numbers are on the fan disk.

You must apply dry teflon spray lubricant to the dovetail end of the fan blade and to the fan blade spacer before you install them.

CAUTION: MAKE SURE YOU PUT A MAT IN THE INLET COWL. THIS WILL PREVENT DAMAGE TO THE INLET COWL OR ENGINE BY TOOLS, PARTS, OR UNWANTED MATERIALS THAT FALL ON THE INLET COWL SURFACE.



ENGINE - SPINNERS AND FAN BLADES

ENGINE - ENGINE SEPARATION

General

You can remove the fan case and frame from the core engine. This divides the engine into two parts. There are two advantages to this:

- The engine is easier to move
- When you replace the engine, you only need to replace the engine core.

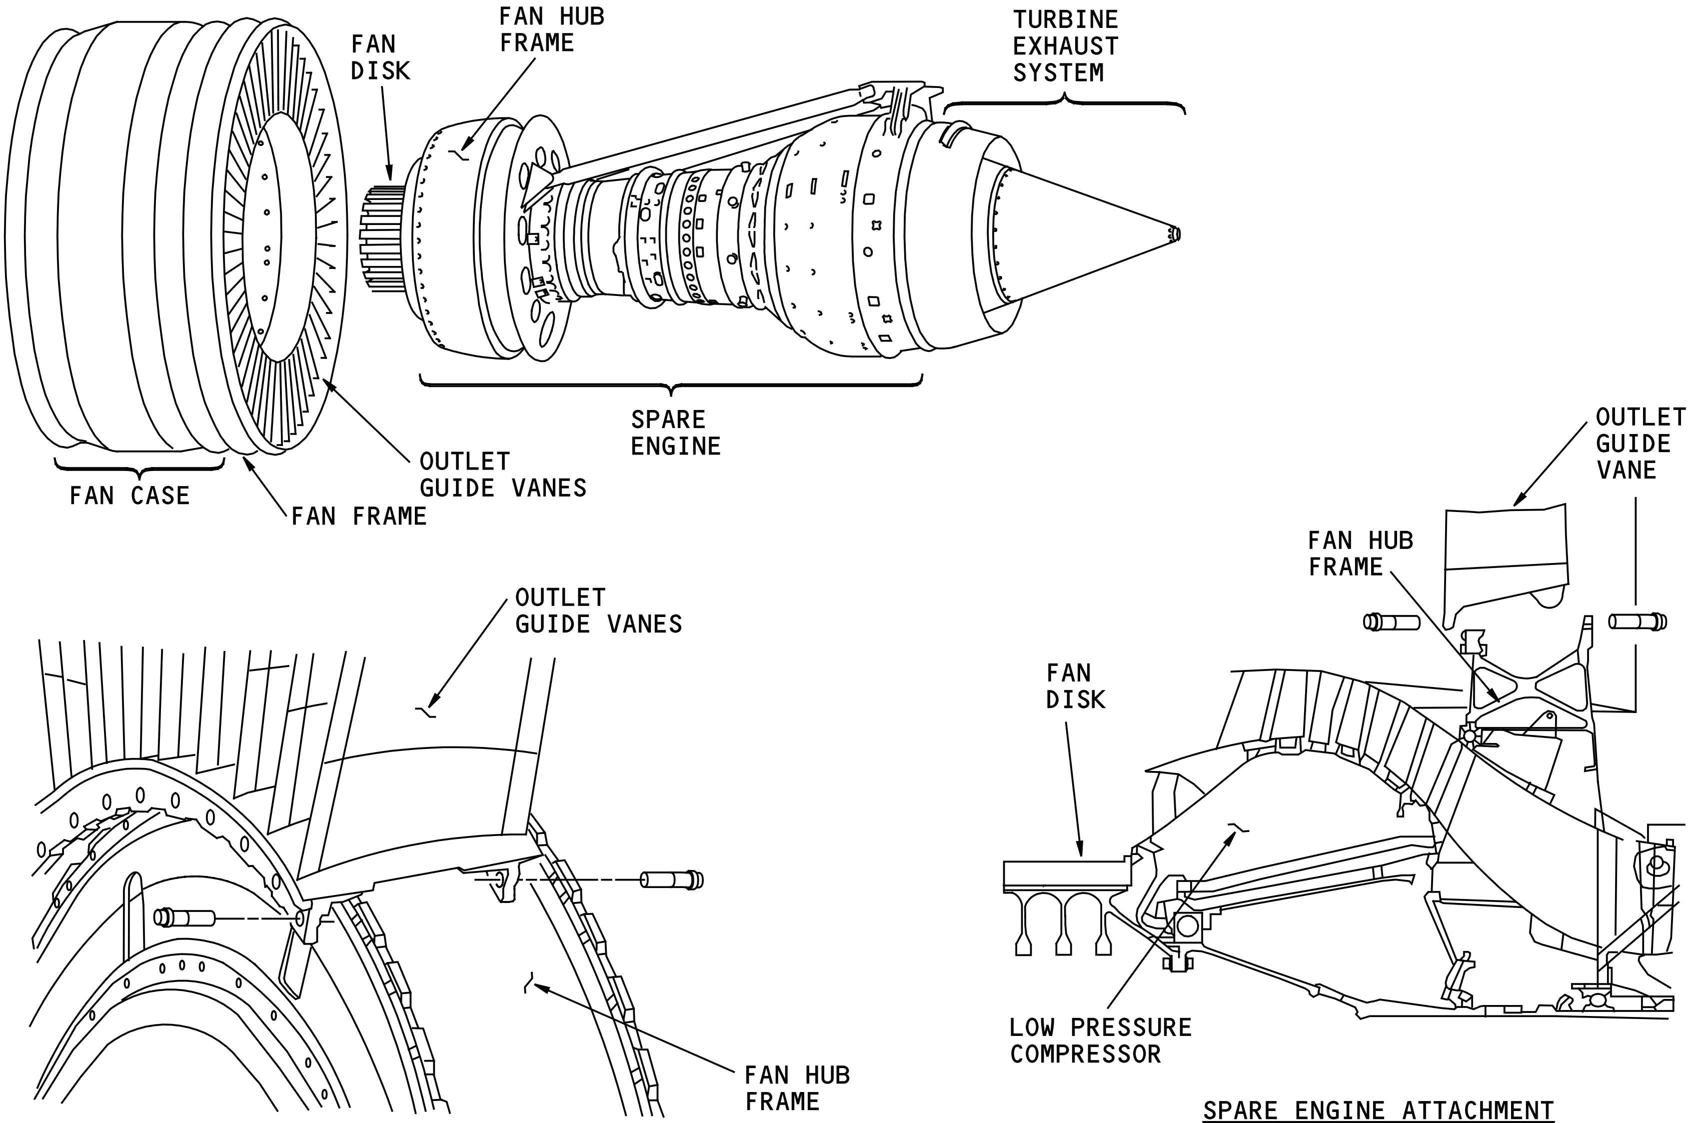
When you move the engine over long distances, it is necessary to divide it into two parts because it is so big.

Most engine work is done on the core engine. Very little work is done on the fan case and frame. Since you can remove the fan case and frame from the core engine, you do not have to include those parts with a spare engine. You can install the same fan case and frame on the new engine.

The spare engine attaches to the rear of the fan case and frame. The forward flange of the fan hub frame attaches to the inner diameter of the outlet guide vanes (OGVs) on the aft fan case.

Training Information Point

You remove the turbine exhaust system and put a cover on the fan disk when you move the engine.



ENGINE - ENGINE SEPARATION

72-00-00-106 Rev 3

ENGINE - BALANCE WEIGHTS

General

You can balance the fan section and the low pressure turbine on the GE90 engine. See the airborne vibration monitoring section for more information on the engine balance procedure (AMM PART I 77-31).

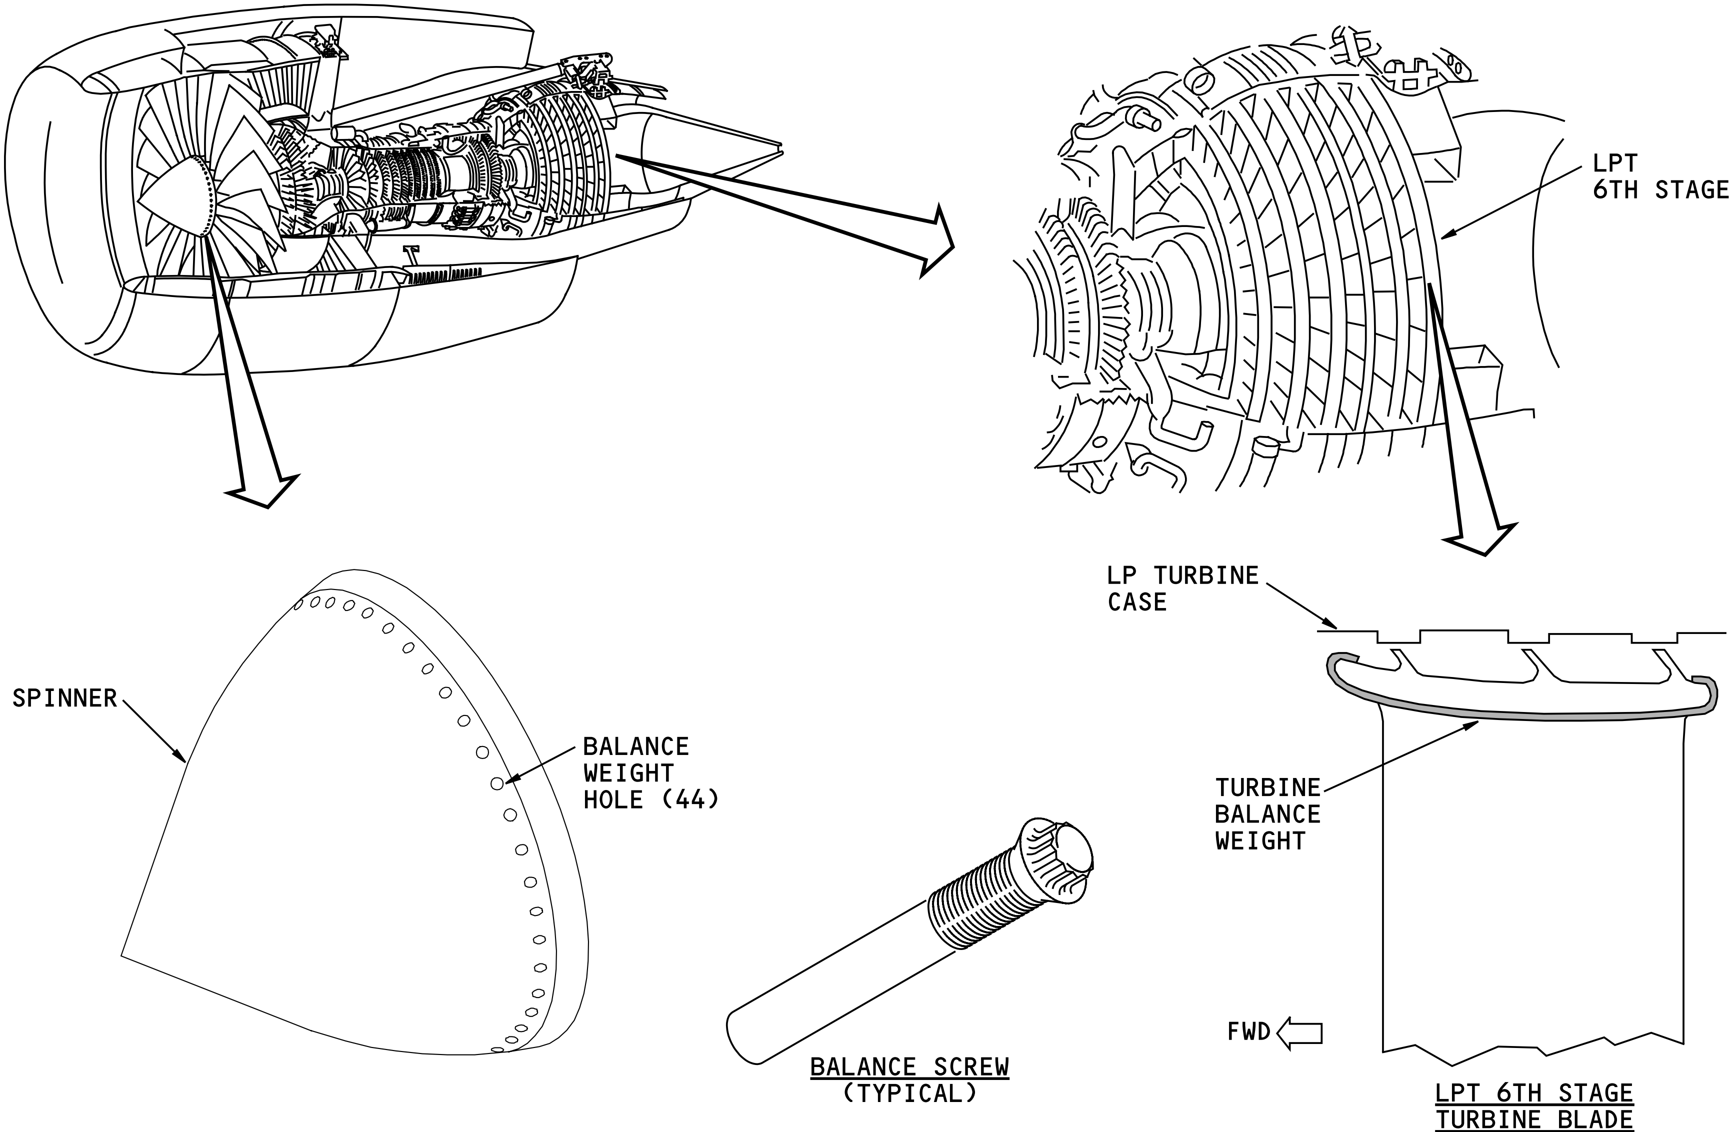
Fan Balance

To balance the fan, you change balance screws in the spinner. There are 44 balance weights on the aft edge of the spinner between the spinner attach screws.

LP Turbine Balance

You balance the LPT with sheet metal clip-on weights. The weights attach at the tip shroud of the LPT stage 6 blades.

You use a special tool to attach the LPT clip-on balance weights. The tool bends (crimps) the aft end of the balance weight to hold it in place.



ENGINE - BALANCE WEIGHTS

72-00-00-107 Rev 6 03/18/1998

ENGINE - ACCESSORY DRIVES - COMPONENT LOCATIONS - FORWARD

Accessory Gearbox

The accessory gear box (AGB) turns the engine accessories. The AGB gets torque from the N2 shaft through the horizontal drive shaft. It sends the torque through spur gears to turn the components on the gearbox. You get access to the accessory gearbox (AGB) with the thrust reverser halves open. The AGB is below the high pressure compressor.

Heat Shield

A titanium heatshield is between the core engine and the AGB. The heatshield protects the components on the gearbox from engine heat. It also prevents the spray of combustible fluids from the components on the hot engine case.

Accessory Gearbox Components

These components are on the front of the accessory gearbox:

- IDG fuel/oil heat exchanger
- Hydraulic pump
- Backup generator
- Borescope cranking pad
- Horizontal drive shaft
- Control alternator
- Lube and scavenge pump.

Training Information Point

The borescope cranking pad is on the front of the AGB on the left side. Engine components do not cause a blockage of access to the borescope cranking pad. Use a CF6-80C2 core motoring device to turn the borescope cranking pad.

ENGINE - BORESCOPE ACCESS PORTS

General

There are 19 borescope ports on the GE90 engine. There are 17 ports on the left side of the engine. Two borescope ports are on the right side of the combustion chamber.

You use the borescope cranking pad to turn the horizontal drive shaft when you make borescope inspections.

Borescope Access Port Identification

These are the borescope access ports on the engine:

- Booster acoustical panel - LPC stage 3 (no plug)
- Fan hub frame - IGV
- Forward HPC case - HPC stages 1-4
- Aft HPC case - HPC stages 5-8
- Combustion chamber - 2 ports on the left side and 2 on the right side (not shown)
- HPT case - HPT stages 1 and 2
- LPT case - LPT stages 2 and 6.

Training Information Point

The GE90 borescope plugs are self-locking and do not use seals. You remove the plugs with a standard 3/8 inch square drive.

The aft HPC has an inner and outer case which cover the five aft stages of the HPC. For this reason, the borescope plugs in the HPC ports at stator stages 5, 6 and 8 have double plugs which seal in the inner case and the outer case. You remove and install each double plug as a single assembly.

When you do a borescope inspection, use a 30 inch probe for the HPC inlet guide vanes (IGVs) borescope port. Use a 20 inch probe for all other borescope ports.

ENGINE FUEL AND CONTROL - INTRODUCTION

General

The engine fuel and control system supplies airplane fuel to the engine at the correct pressure and rate. The system has these subsystems:

- Distribution
- Control
- Indicating.

Abbreviations and Acronyms

ACC	- active clearance control
ACMS	- airplane condition monitoring system
AIMS	- airplane information management system
ARINC	- Aeronautical Radio, Inc.
ASCPC	- air supply and cabin pressure controller
BPV	- bypass valve
CCC	- core compartment cooling
CDU	- control display unit
CH	- channel
DP	- differential pressure
DRV	- driver
EDIU	- engine data interface unit
EEC	- electronic engine control
EGT	- exhaust gas temperature
EHSV	- electro-hydraulic servo valve
EICAS	- engine indication and crew alerting system
ELMS	- electrical load management system
ENG	- engine
F/O HX	- fuel/oil heat exchanger
FMV	- fuel metering valve
FSEU	- flap/slat electronics unit
GSE	- ground support equipment
HMU	- hydromechanical unit
HPC	- high pressure compressor
HPT	- high pressure turbine
ID	- identification
IDG	- integrated drive generator
LPC	- low pressure compressor
LPT	- low pressure turbine
MFD	- multi-functional display
OPAS	- overhead panel ARINC system
OSG	- overspeed governor
PDS	- primary display system
PHS	- pressure of heated servo
RVDT	- rotary variable differential transducer
SOV	- shutoff valve
STB	- start/transient bleed
SV	- staging valve
TLA	- thrust lever angle
T/R	- thrust reverser
VBV	- variable bypass valve
VSV	- variable stator vane

ENGINE FUEL AND CONTROL - INTRODUCTION

ENGINE FUEL AND CONTROL - INTERFACES

General

The engine fuel and control system has interfaces with many systems and components. The interfaces with other engine systems are primarily analog. The interfaces with airplane systems and components are primarily on the ARINC 629 buses.

Analog Interfaces

These analog engine fuel and control system interfaces supply control and feedback:

- Engine ignition - exciter power
- Engine air - actuator positions
- Engine controls - resolver excitation
- Engine indicating - engine parameter data
- Engine exhaust - thrust reverser operation
- Engine oil - indication
- Engine starting - starter pneumatic supply
- Electrical power - airplane power application.

ARINC 629 Interfaces

These ARINC 629 engine fuel and control system interfaces supply and receive control and indication data:

- AIMS - indication, air data, and flight management control
- Flight deck controls - switch position and indication
- FSEU - flap position
- ASCPC - pneumatic supply status
- Card file - air driven pump and anti-ice status.

ENGINE FUEL DISTRIBUTION - INTRODUCTION

ENGINE FUEL DISTRIBUTION - GENERAL DESCRIPTION

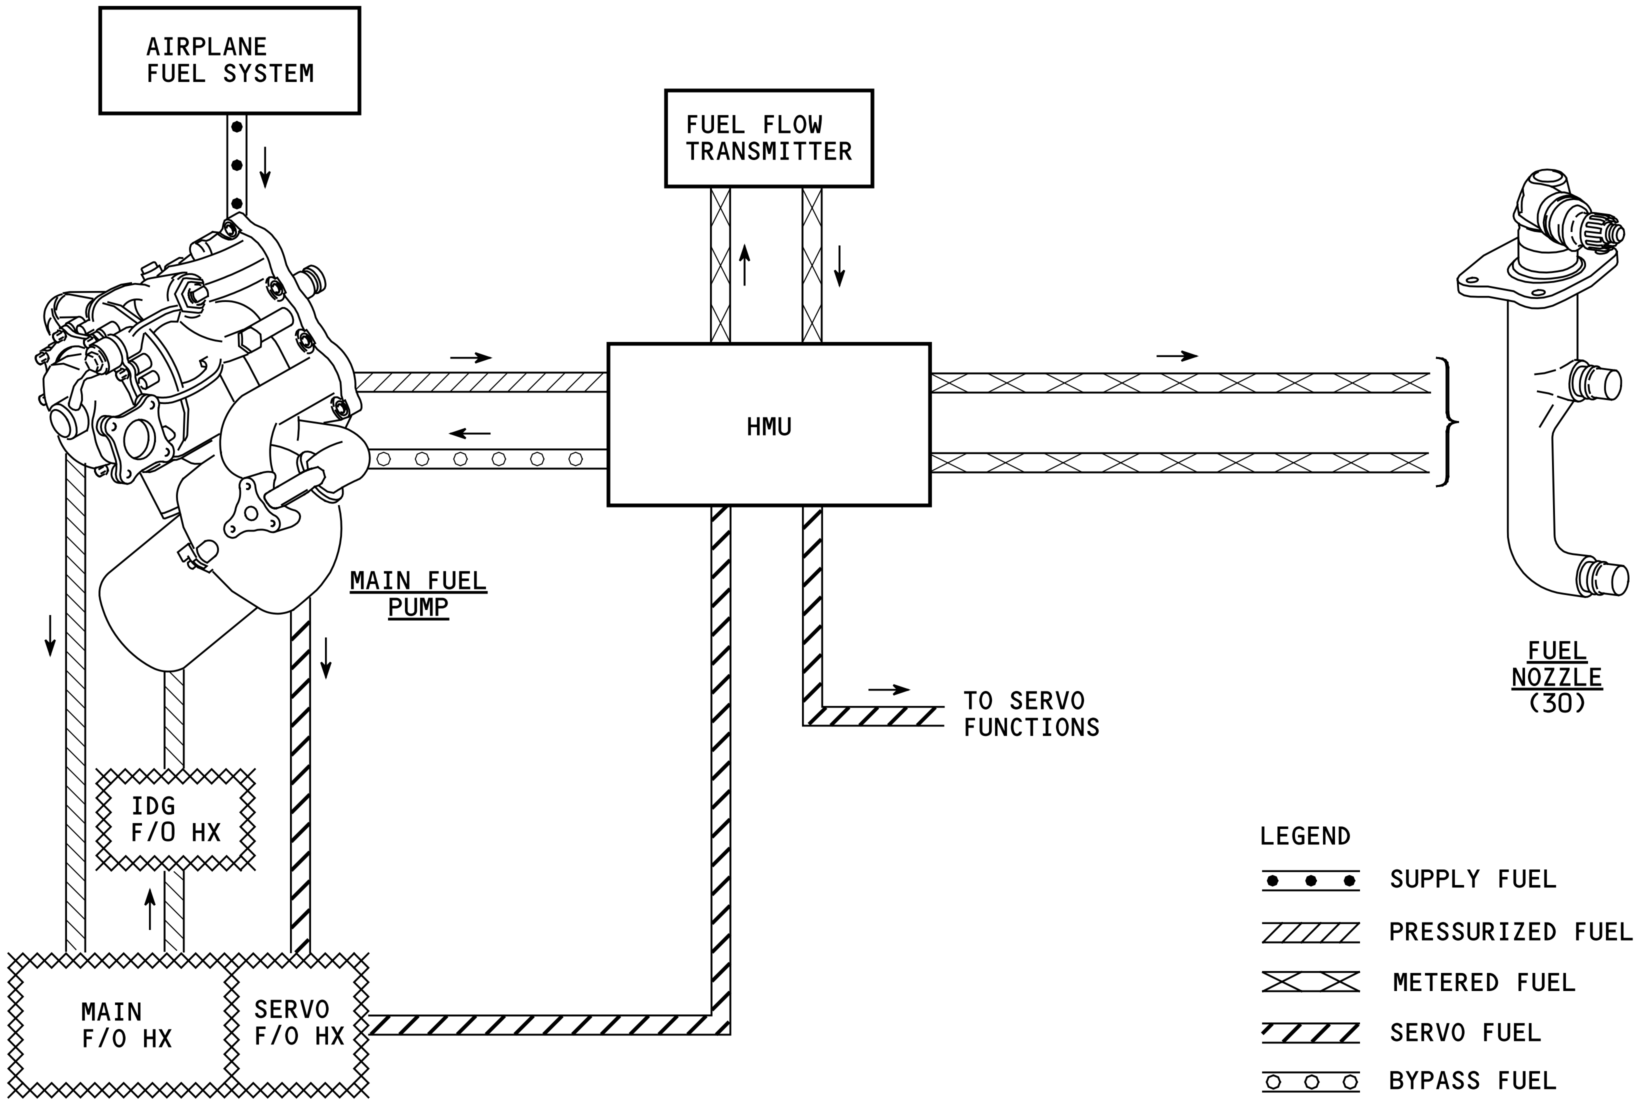
General

The main fuel pump gets fuel from the airplane fuel system. The pump pressurizes the fuel and sends it through the main and IDG fuel/oil heat exchangers. After the fuel goes through the heat exchangers, it flows back to the pump where it goes through the fuel filter element.

After the fuel goes through the fuel filter element, it goes to the hydromechanical unit (HMU). The HMU meters the fuel. The fuel goes from the HMU, through the fuel flow transmitter, then back into the HMU. The HMU distributes the fuel into two fuel supply manifolds. The supply manifolds send the fuel to 30 fuel nozzles.

The HMU gets more fuel from the pump than the engine needs. The fuel that the HMU does not use goes back to the main fuel pump. This fuel is called bypass fuel.

Downstream from the fuel filter, a small amount of fuel also goes to the servo fuel/oil heat exchanger then to the HMU. The servo fuel/oil heat exchanger increases the temperature of the servo fuel before it goes to the HMU. The HMU uses servo fuel pressure to move internal valves and engine air system components (not shown).



73-11-00-102 Rev 2 08/21/1997

ENGINE FUEL DISTRIBUTION - GENERAL DESCRIPTION

ENGINE FUEL DISTRIBUTION - COMPONENT LOCATIONS

General

These are the fuel distribution system components:

- Main fuel supply hose
- Main fuel pump
- Fuel filter element
- Fuel supply manifolds
- Fuel nozzles.

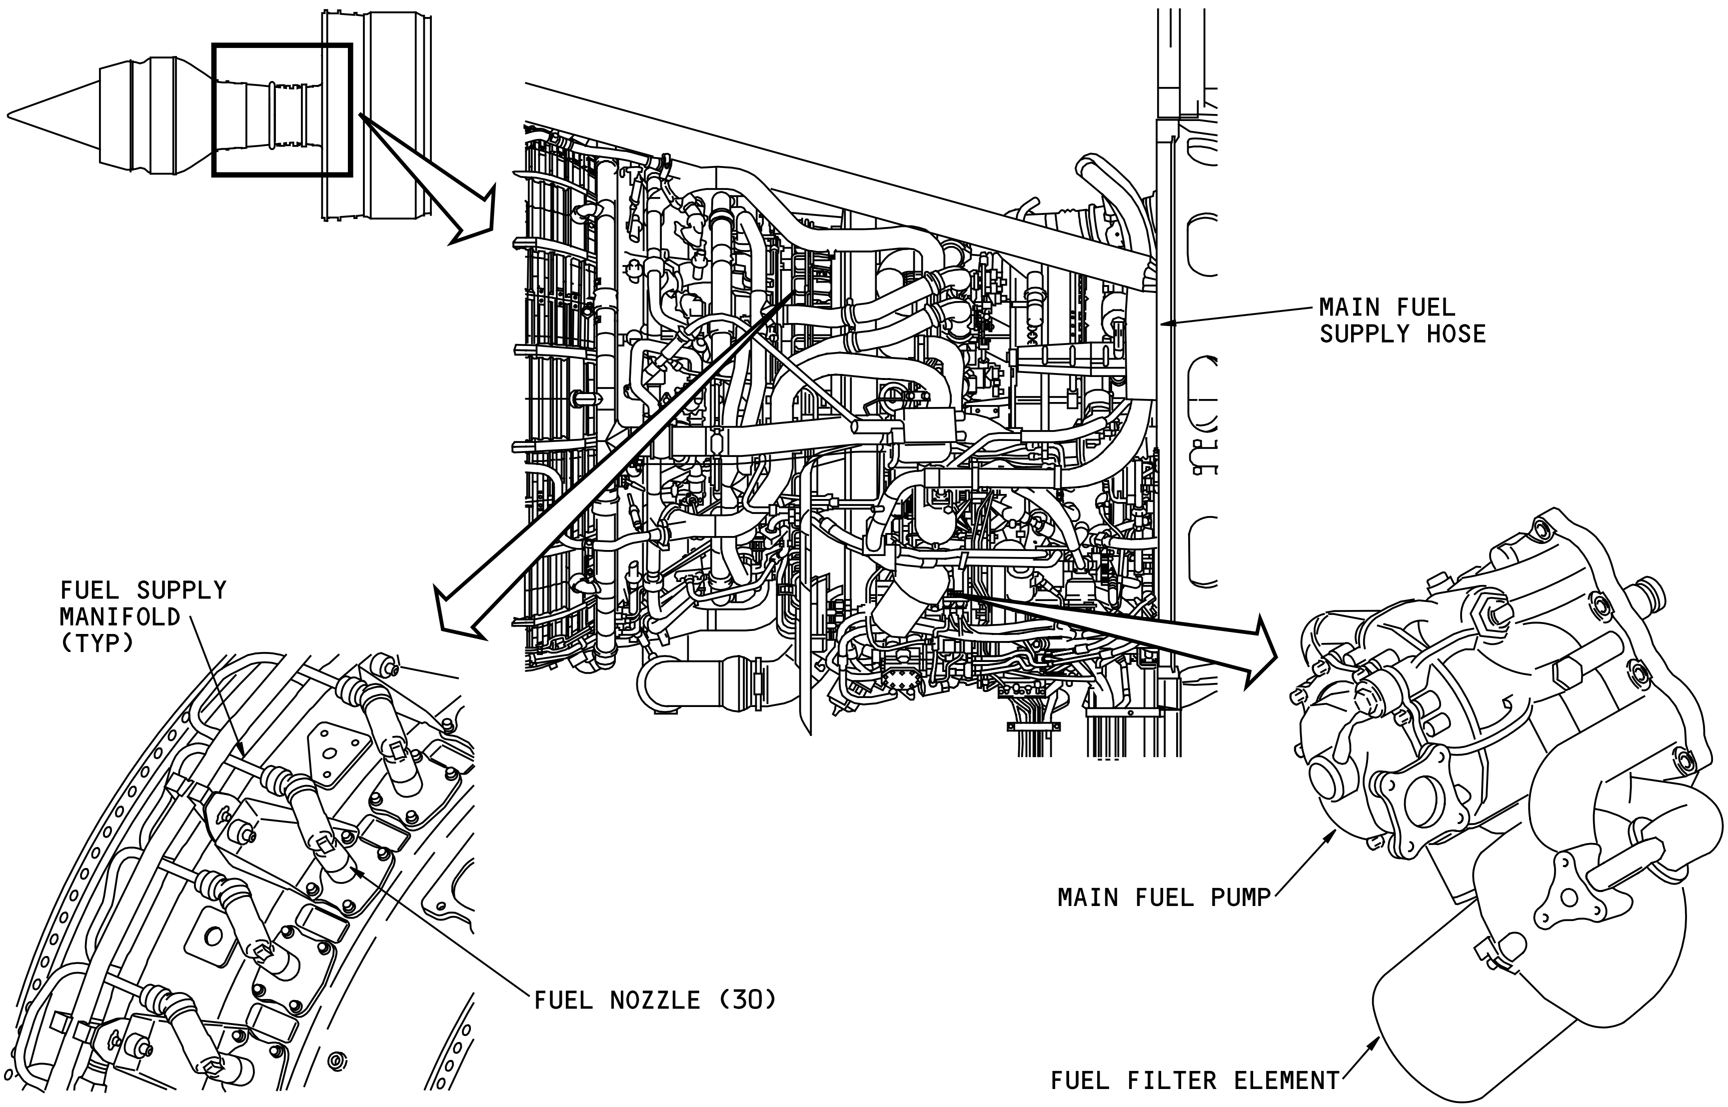
Component Locations

The main fuel supply hose is on the right side of the engine core. It goes from the forward engine strut to the main fuel pump.

The main fuel pump attaches to the aft, right face of the main gearbox. The fuel filter element attaches to the main fuel pump.

The two fuel supply manifolds attach to the compressor rear frame around the engine.

The 30 fuel nozzles attach to the combustor diffuser nozzle case around the engine.



ENGINE FUEL DISTRIBUTION - COMPONENT LOCATIONS

ENGINE FUEL DISTRIBUTION - MAIN FUEL PUMP

General

The main fuel pump pressurizes and cleans fuel from the airplane fuel system. It is on the aft face of the gearbox. The pump has external and internal connections for fuel flow.

The main fuel pump has a pump and a filter assembly element.

Fuel Pump

The fuel pump is a two-stage pump. The main gearbox turns the pump. The pump has an external connection for fuel from the airplane tanks. The other fuel flow into and out of the pump is through the fuel adapter on the gearbox (not shown).

The pump has an inlet drain plug. You remove this plug to get access to the strainer between the two pump stages and to drain fuel from the pump.

Fuel Filter Assembly

The fuel filter assembly has these parts:

- Housing
- Filter element
- Bypass valve.

You remove the filter housing to change or inspect the filter element. The filter housing has a ratchet lock. To remove the housing, you must push the ratchet lock while you turn the housing. You drain the fuel from the housing with the drain plug before you remove the housing.

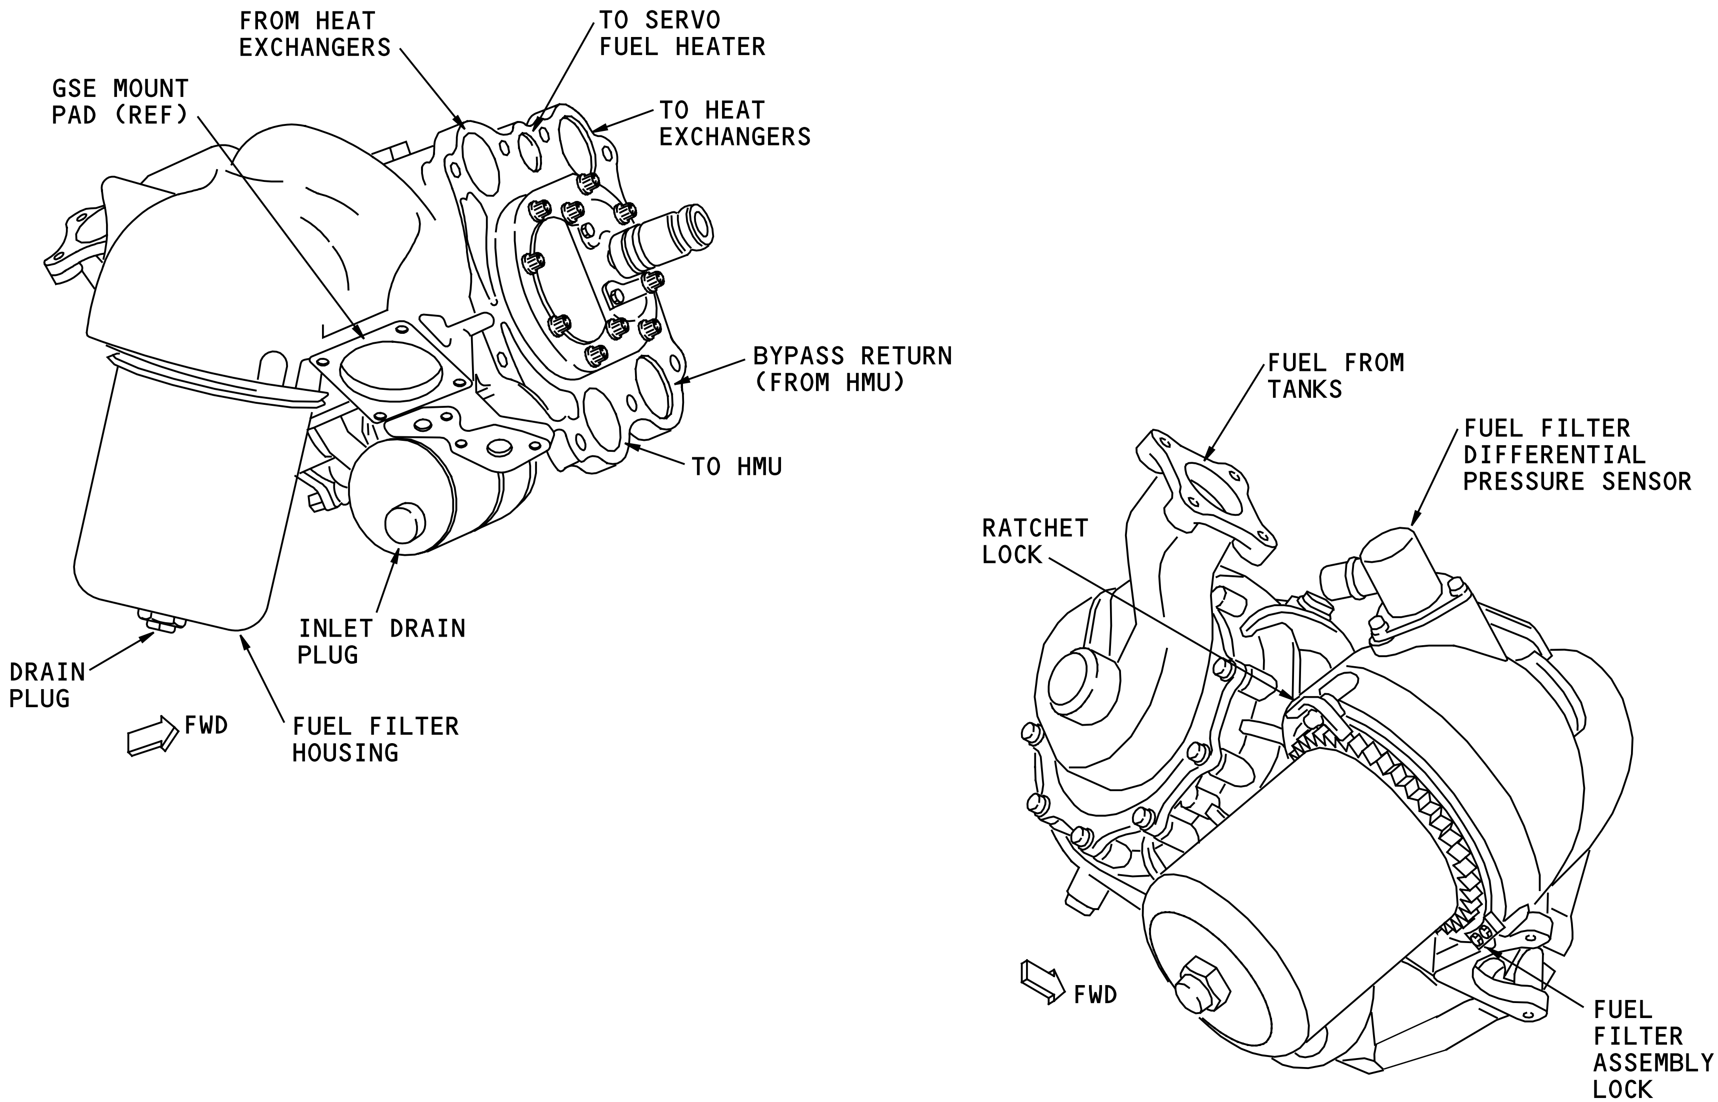
You can remove the filter assembly as a unit. You must remove the filter assembly lock and use a special tool to remove the filter assembly.

Pressure Sensors

The fuel manifold pressure sensor mounts to the forward side of the HMU. This sensor provides the fuel pressure in the HMU manifold 2. The EEC uses this information for fuel system fault monitoring.

The fuel pump has a fuel filter differential pressure sensor on the aft end of the MFP just above the filter bowl.

See the fuel control system section for more information on these sensors (AMM PART I 73-21).



ENGINE FUEL DISTRIBUTION - MAIN FUEL PUMP

ENGINE FUEL DISTRIBUTION - FUEL SUPPLY MANIFOLDS AND NOZZLES

General

Fuel goes through the fuel supply manifolds to 30 fuel nozzles. The fuel nozzles spray fuel into the combustion chamber.

Fuel Supply Manifolds

There is one dual fuel supply manifold which includes these:

- Manifold 1
- Manifold 2.

The fuel supply manifold has two halves to make it easy to remove and install it.

Fuel Nozzles

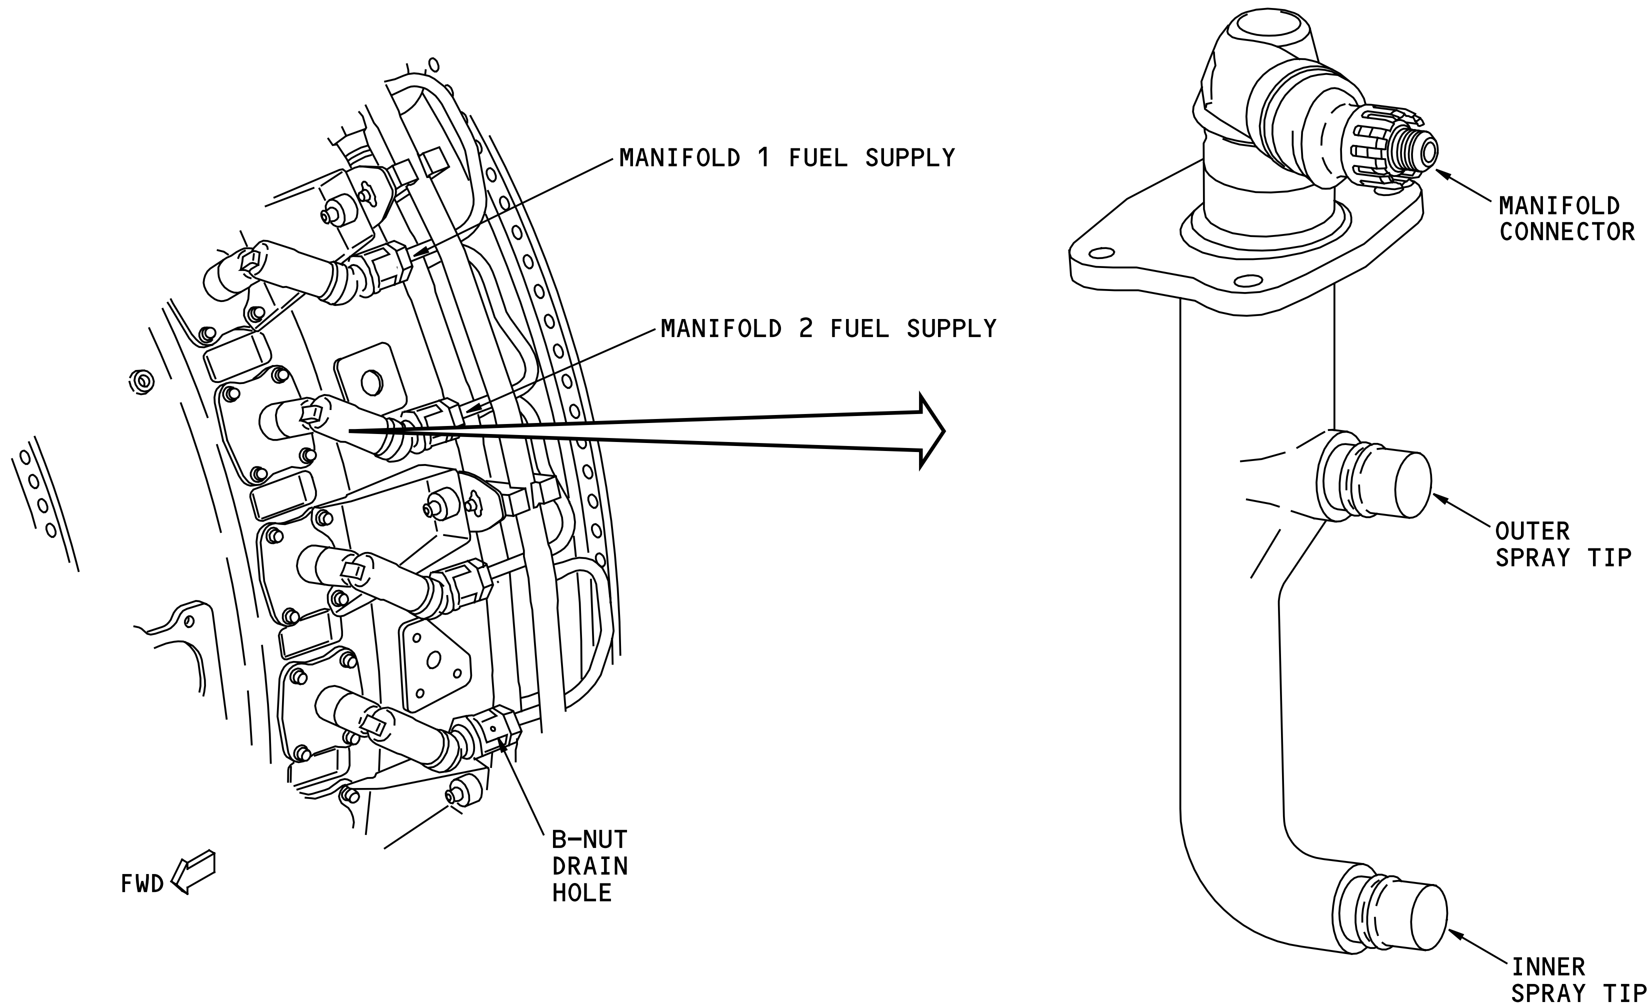
There is one kind of fuel nozzle. Each fuel nozzle has one connector and two spray tips. Twenty fuel nozzles use fuel from manifold 1. Manifold 2 supplies fuel to the other ten fuel nozzles. There are two nozzles with fuel from manifold 1 between each nozzle with fuel from manifold 2.

Fuel comes out of all 60 tips except for these conditions when 40 tips, connected to manifold 1, supply fuel:

- Decel (transient condition)
- Cold day decent idle.

Training Information Point

The fuel manifold connects to the nozzle with a B-nut. There are two seals (not shown) at the connection. If the first seal leaks, the fuel comes out of a small drain hole in the B-nut. You do a check for leaks from the B-nut drain hole after you replace a fuel nozzle.



73-11-00-105 Rev 5 03/12/1998

ENGINE FUEL DISTRIBUTION - FUEL SUPPLY MANIFOLDS AND NOZZLES

ENGINE FUEL DISTRIBUTION - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE FUEL DISTRIBUTION - FUNCTIONAL DESCRIPTION

General

The main fuel pump pressurizes and cleans fuel from the airplane fuel tanks. The pump supplies the fuel to the HMU and the servo fuel heater. The HMU sends metered fuel to the fuel flow transmitter, then to the fuel supply manifolds. The manifolds connect to the fuel nozzles. The fuel nozzles spray the fuel into the engine for combustion.

Main Fuel Pump

The main fuel pump has two pump stages and a fuel filter element. The boost stage is a centrifugal-type pump. The main stage is a gear-type pump. Fuel goes through both stages of the pump, then to the main and IDG fuel/oil heat exchangers. Fuel then goes back into the pump and through the filter.

After the filter, fuel goes to the HMU. A small amount of fuel also goes through the servo fuel/oil heat exchanger to the HMU. This fuel supplies servo pressure to move HMU valves and engine air system actuators.

The main fuel pump has one sensor, the Fuel filter differential pressure sensor. It sends signals to the EEC.

HMU

The HMU has these valves to control and distribute the fuel:

- Fuel metering valve (FMV)
- Bypass valve (BPV)
- Engine fuel shutoff valve (SOV)
- Staging valve (SV).

The fuel metering valve controls the amount of fuel that goes to the engine for combustion.

The HMU sends fuel that is not necessary for combustion (bypass fuel) through the bypass valve, back to the gear stage inlet.

The engine fuel shutoff valve opens to permit fuel to go to the engine for combustion. After the engine fuel shutoff valve, the fuel goes through the fuel flow transmitter.

See the fuel control system section for more information on the HMU (AMM PART I 73-21).

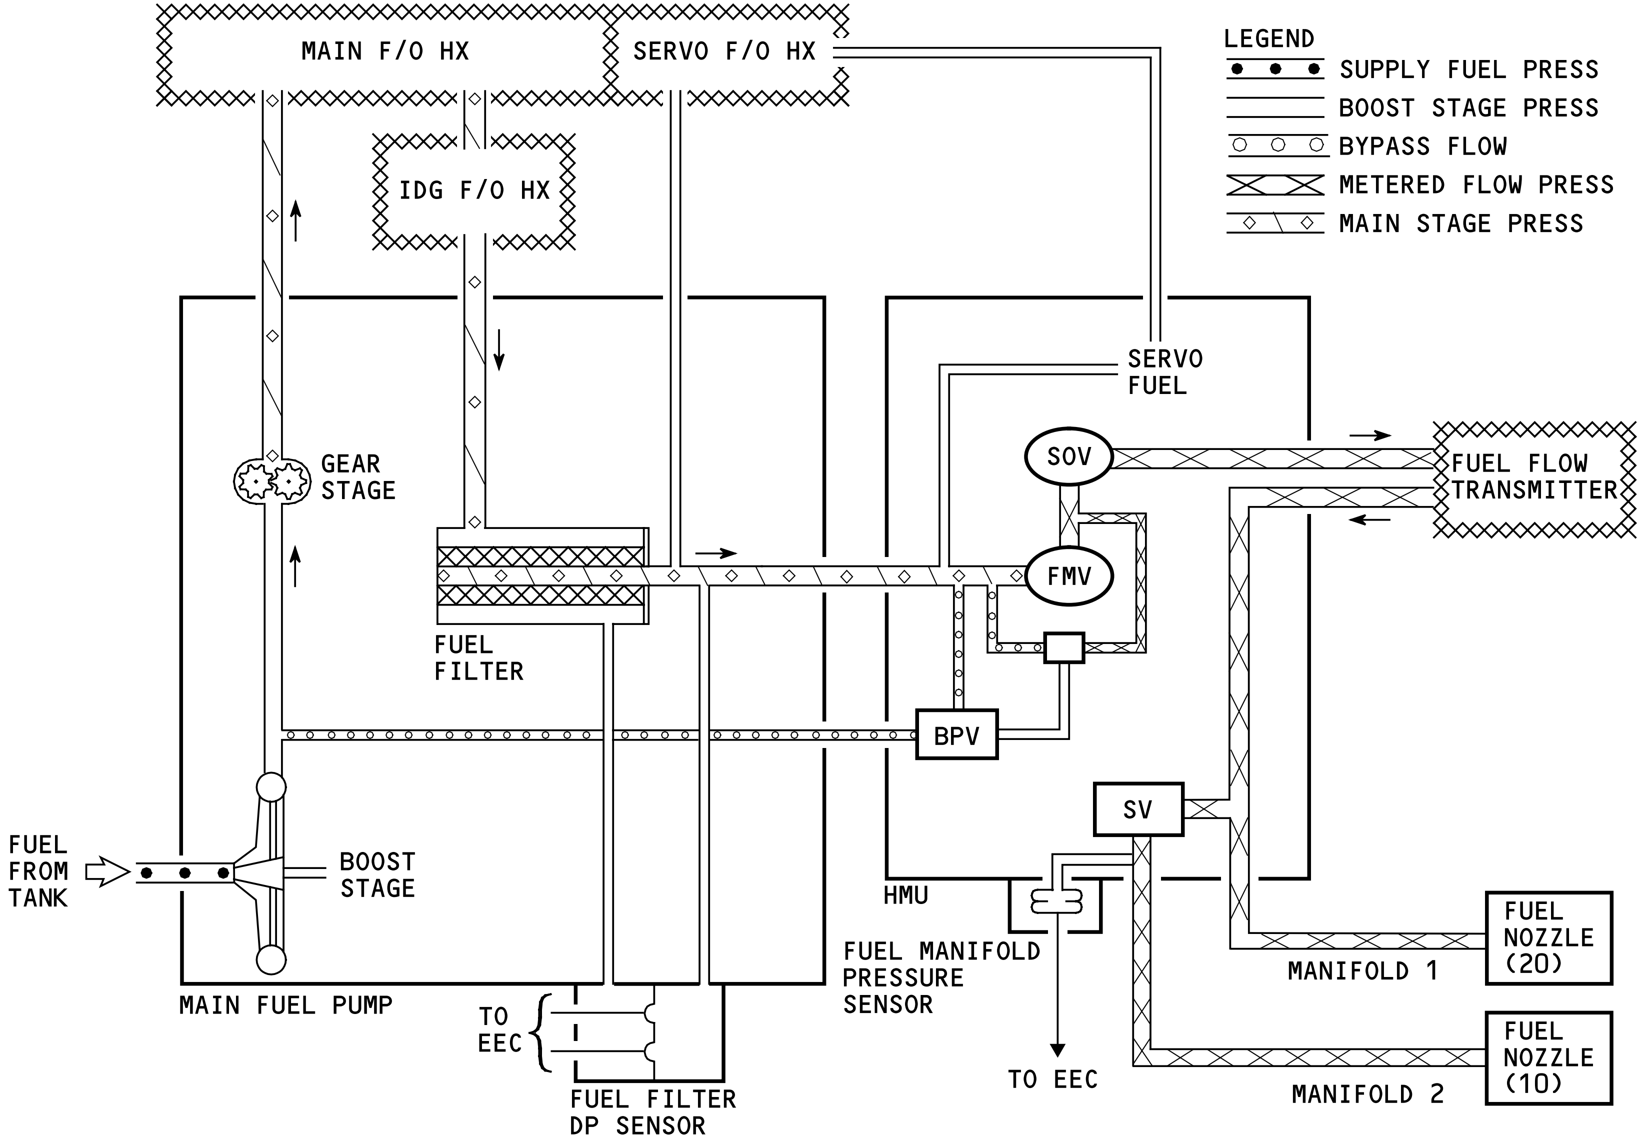
Fuel Flow

Fuel returns to the HMU from the fuel flow transmitter. The HMU distributes the fuel to the two manifolds. Fuel flow to manifold 2 is controlled by the staging valve (SV).

The manifolds distribute fuel to 30 nozzles. Fuel in manifold 1 goes to 20 fuel nozzles. Fuel in manifold 2 goes to the other ten fuel nozzles.

ENGINE FUEL DISTRIBUTION - FUNCTIONAL DESCRIPTION

When the engine is at idle and above, fuel goes to both manifolds. The staging valve closes during cold day descent idle and transient rapid decel operations.



ENGINE FUEL DISTRIBUTION - FUNCTIONAL DESCRIPTION

ENGINE FUEL CONTROL - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE FUEL CONTROL - GENERAL DESCRIPTION

General

The EEC is the primary component of the engine fuel control system. The EEC uses data from engine sensors and airplane systems to control the engine operation.

POWER

The EEC gets power from two sources, the airplane or the engine. When the engine is not running, the electrical load management system (ELMS) supplies airplane power to the EEC. The ELMS supplies power to the EEC when any of these conditions occur:

- Fuel control switch is in the RUN position
- Start/ignition selector is in the START position
- EEC maintenance switch is in the TEST position.

When the engine is running, the control alternator supplies power to the EEC. If the control alternator has a failure, the ELMS supplies power to the EEC.

EEC

The EEC is a two channel computer that controls the operation of the engine. Each channel can completely control the operation of the engine.

The EEC uses N1 to calculate thrust. The EEC controls thrust in three different modes:

- Normal
- Soft reversionary
- Hard reversionary (alternate).

When the EEC is in the soft or hard reversionary mode, the thrust calculations are less accurate. The EEC goes into soft reversionary mode automatically. You push the EEC mode switch to put the EEC in hard reversionary mode.

The EEC also controls many components in other engine subsystems and gets feedback of their status.

The EEC monitors engine sensors to get data. It is also the interface for some sensors with thier systems.

When you move the fuel control switch from RUN to CUTOFF, the EEC resets. When the EEC resets, it writes all fault data in its non-volatile memory (NVM). The reset also sets the engine start logic to run from the start of the program.

HMU

The EEC controls valves in the HMU to supply metered fuel flow to the engine and to distribute fuel to the fuel nozzles. The EEC also controls torque motors in the HMU to supply servo fuel to engine air system actuators (not shown). The HMU gives the EEC feedback about valve and torque motor positions.

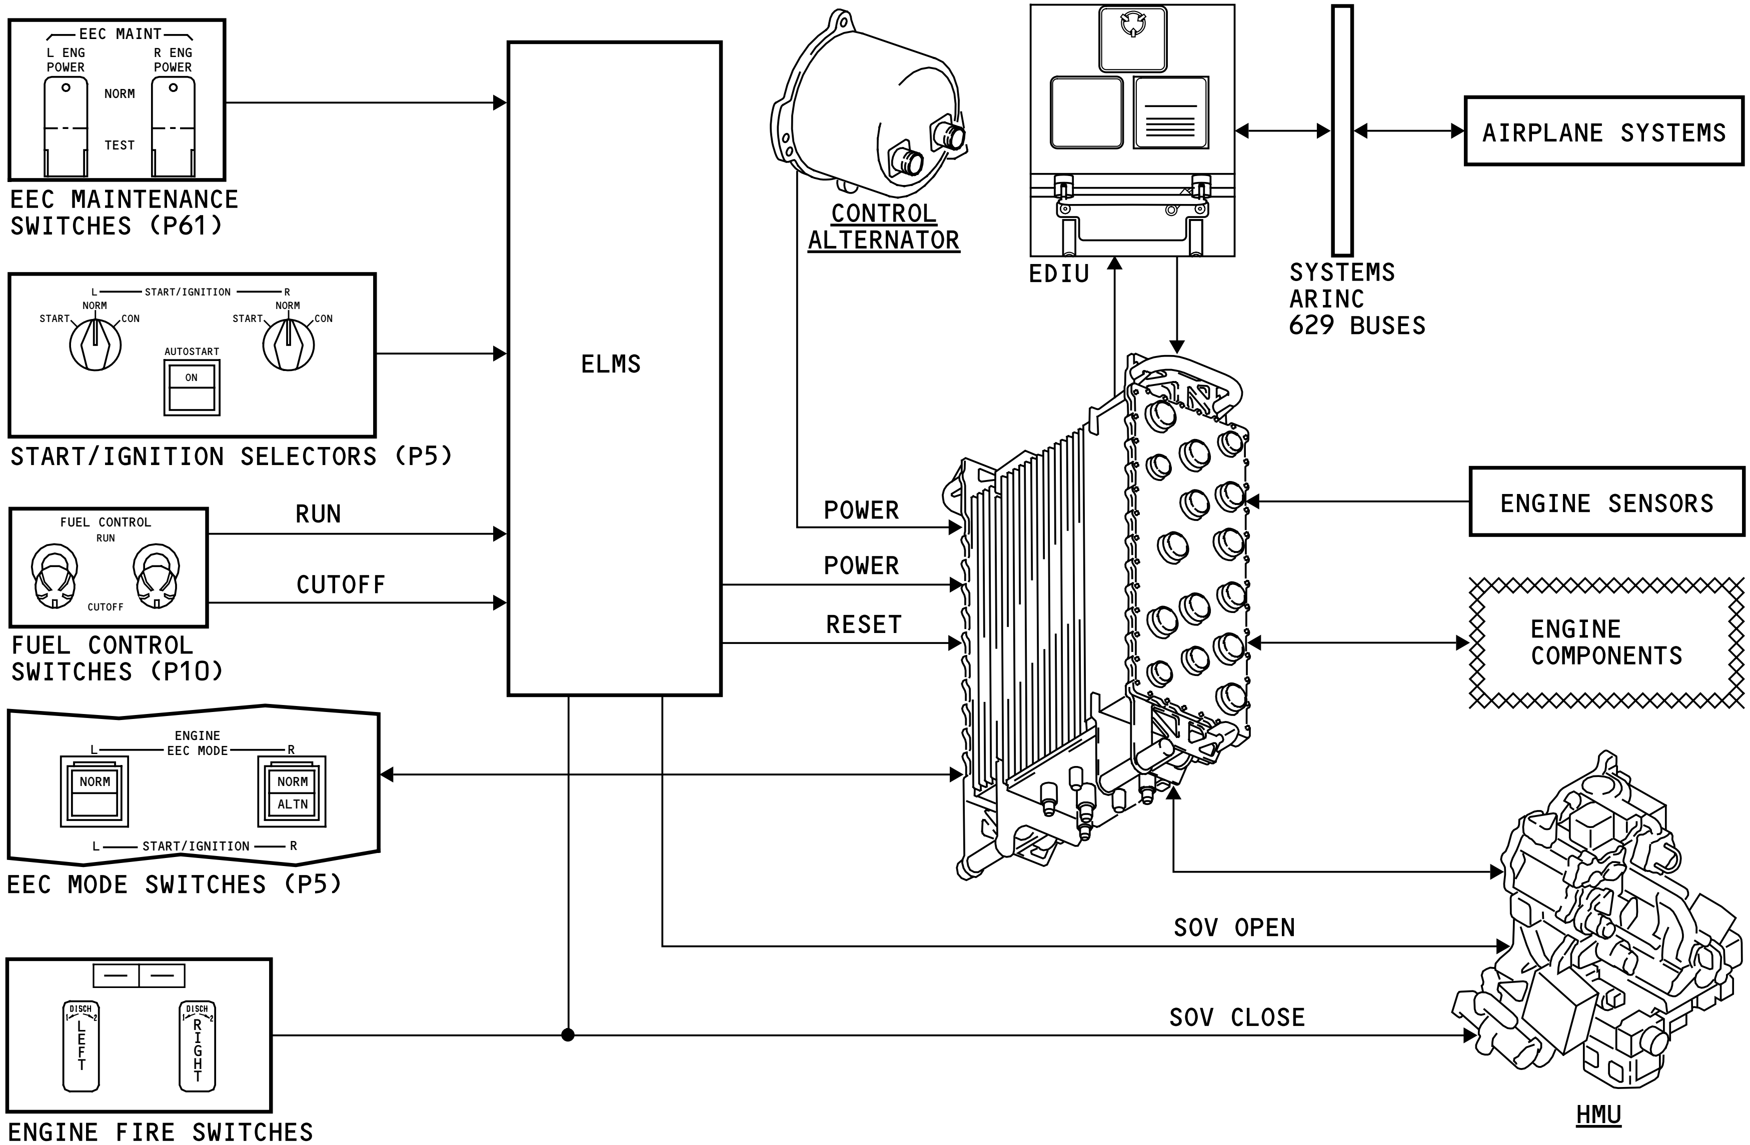
The fuel control switch controls the engine fuel shutoff valve (SOV) in the HMU to start and stop fuel flow to the engine. When you move the fuel control switch to the RUN position, the ELMS sends power to

ENGINE FUEL CONTROL - GENERAL DESCRIPTION

open the valve. When you move the fuel control switch to the CUTOFF position, the ELMS sends power to close the valve. The valve also closes when you pull up on the engine fire switch.

EDIU

The engine data interface unit (EDIU) changes the ARINC 429 formatted data of the EEC to ARINC 629. It also changes ARINC 629 data to ARINC 429. This permits the EEC to transmit data to and receive data from airplane systems.



ENGINE FUEL CONTROL - GENERAL DESCRIPTION

ENGINE FUEL CONTROL - ENGINE COMPONENT LOCATIONS - 1

Component Locations - Engine Right Side

Most of the engine fuel control components are on the right side of the engine. These are the components:

- EEC
- Engine rating plug

ENGINE FUEL CONTROL - AIRPLANE INTERFACES

General

The engine fuel control system has many interfaces with airplane components and systems. Most of the interfaces are digital, but some are analog. The interfaces are with the EEC and EDIU. The EDIU permits digital interfaces with the EEC.

Analog Interfaces

These components have analog interfaces with the engine fuel control system:

- EEC mode switch
- Thrust lever angle (TLA) resolver
- Thrust reverser interlock actuator
- Fuel control switch
- EEC maintenance switch
- Start/ignition selector
- ELMS.

EEC Mode Switch

The EEC mode switch sends a signal to the EEC to put it into the normal or alternate mode of control. The EEC turns on the ALTN light in the mode switch to tell you to put the switch into the alternate position.

Thrust Lever Angle Resolver

The TLA resolver supplies the EEC with a signal in proportion to the thrust lever position. The EEC supplies power to the resolvers.

Thrust Reverser Interlock Actuator

The EEC energizes the thrust reverser (T/R) interlock actuator during reverser operation when the reverser extends. The EEC supplies a ground through the ELMS to energize the actuator.

Fuel Control Switch

When you move the fuel control switch to the RUN position, a signal permits the ELMS to supply ac power to the EEC. When you move the fuel control switch from RUN to CUTOFF, the ELMS sends a reset signal to each EEC channel. The reset signal stops the programs of the EEC and sets them to run from the start (boots the computer).

EEC Maintenance Switch

The EEC maintenance switch permits the ELMS to supply ac power to the EEC during maintenance operations.

Start/Ignition Selector

The start/ignition selector sends a start signal to the EEC and permits the ELMS to supply ac power to the EEC. The selector is held in the START position by a ground in the AIMS.

ENGINE FUEL CONTROL - AIRPLANE INTERFACES

AIMS

The AIMS transmits and receives a large amount of data to and from the EEC. This is a summary of that data and its function:

- Bleed status - EEC thrust limit calculations
- Air data - EEC thrust limit calculations
- Engine data - system data requirements
- Autothrottle trim - thrust balancing
- Condition monitoring - performance tracking
- Maintenance data - fault isolation
- EICAS data - indication.

FSEU

The FSEU supplies the EEC with flap position data for idle and ignition logic.

Card File

The card file supplies the EEC anti-ice bleed status and air driven pump status for idle logic.

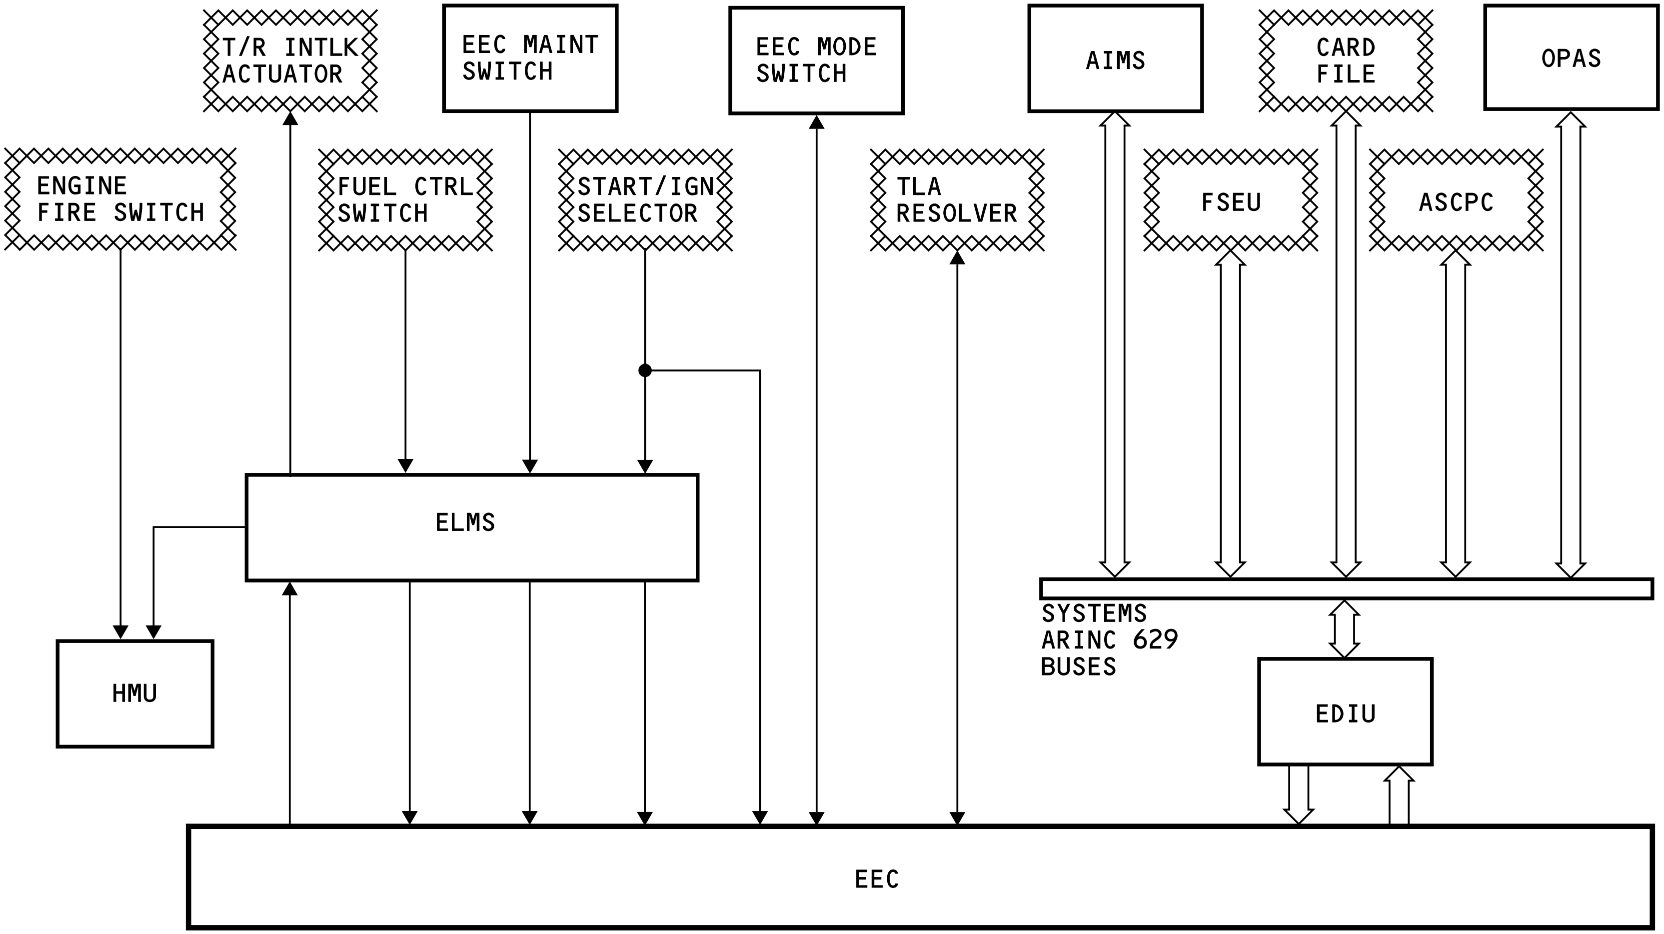
ASCPC

The ASCPC supplies the EEC with duct pressure, and pressure regulating and shutoff valve status. The EEC uses this information for thrust calculations, start control, and idle speed control.

OPAS

The OPAS sends a digital signal of these switch positions to the EEC:

- Autostart switch
- EEC maintenance switch
- Start/ignition selector.



ENGINE FUEL CONTROL - AIRPLANE INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE FUEL CONTROL - ENGINE INTERFACES

General

The EEC controls most engine components and receives feedback from them. Many components send data to the EEC for engine operation.

The EEC uses torque motor drivers to move multiple-position actuators. It uses solenoid drivers to move two-position open/close valves.

Engine Rating Plug

The engine rating plug selects the software in the EEC that corresponds to the thrust rating of the engine. It connects to the EEC.

Configuration Box

The configuration box supplies data on the correct version of the engine hardware to the EEC.

Engine Identification Box

The engine identification (ID) box supplies the EEC with the engine serial number. This input is only connected the first time the EEC gets power.

Control Alternator

The control alternator supplies the EEC with dedicated electrical power.

HMU

The EEC controls these valves in the HMU:

- Fuel metering valve
- Burner staging valve
- Main staging valve.

The EEC also controls torque motors in the HMU that send servo fuel to operate these engine air system components:

- VSVs
- VBVs
- STB valve
- HPT ACC valve.

All these valves and components send position feedback signals to the EEC.

Starter Air Valve

The EEC energizes the starter air valve solenoid to open the valve. The EEC receives feedback of the valve position from the starter air pressure sensor.

Ignition Exciters

The EEC sends 115v ac power to the ignition exciters.

CCC Valve

The EEC energizes the core compartment cooling (CCC) valve solenoid to close the valve. The EEC receives feedback of the valve position from a switch.

LPT ACC Valve

The EEC energizes the LPT active clearance control (ACC) valve solenoid to open the valve. The EEC receives feedback of the valve position from a switch.

T/R Test Enable Switch

The T/R test enable switch puts the EEC into a maintenance mode. This permits the thrust reverser to be extended or retracted without running the engine.

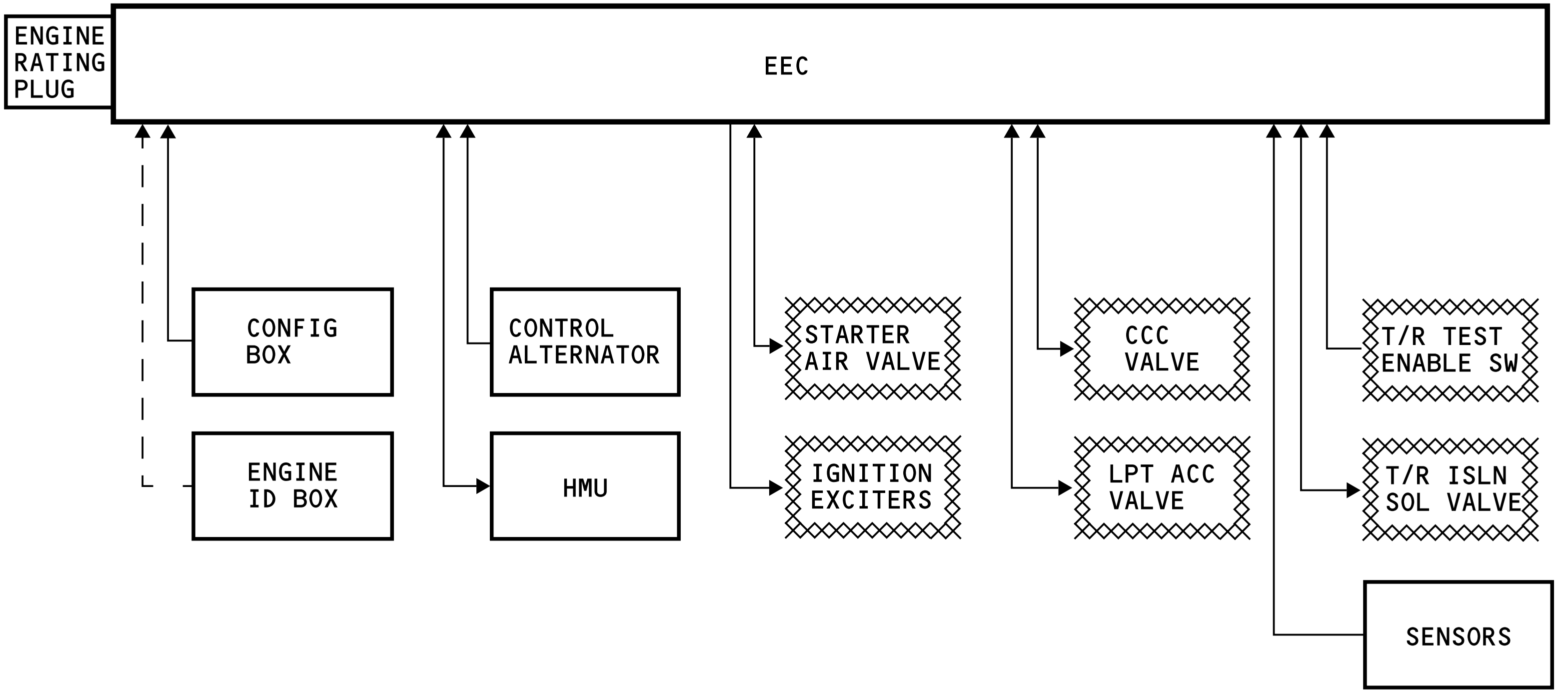
T/R Isolation Valve

The EEC energizes the T/R isolation solenoid valve to open the valve. The EEC receives feedback of the valve position from a pressure switch.

Sensors

Many engine sensors supply this information to the EEC:

- Rotor speeds
- Pressures
- Temperatures
- Valve and actuator positions
- Oil data
- Fuel data.



73-21-00-107 Rev 3 08/24/95

ENGINE FUEL CONTROL - ENGINE INTERFACES

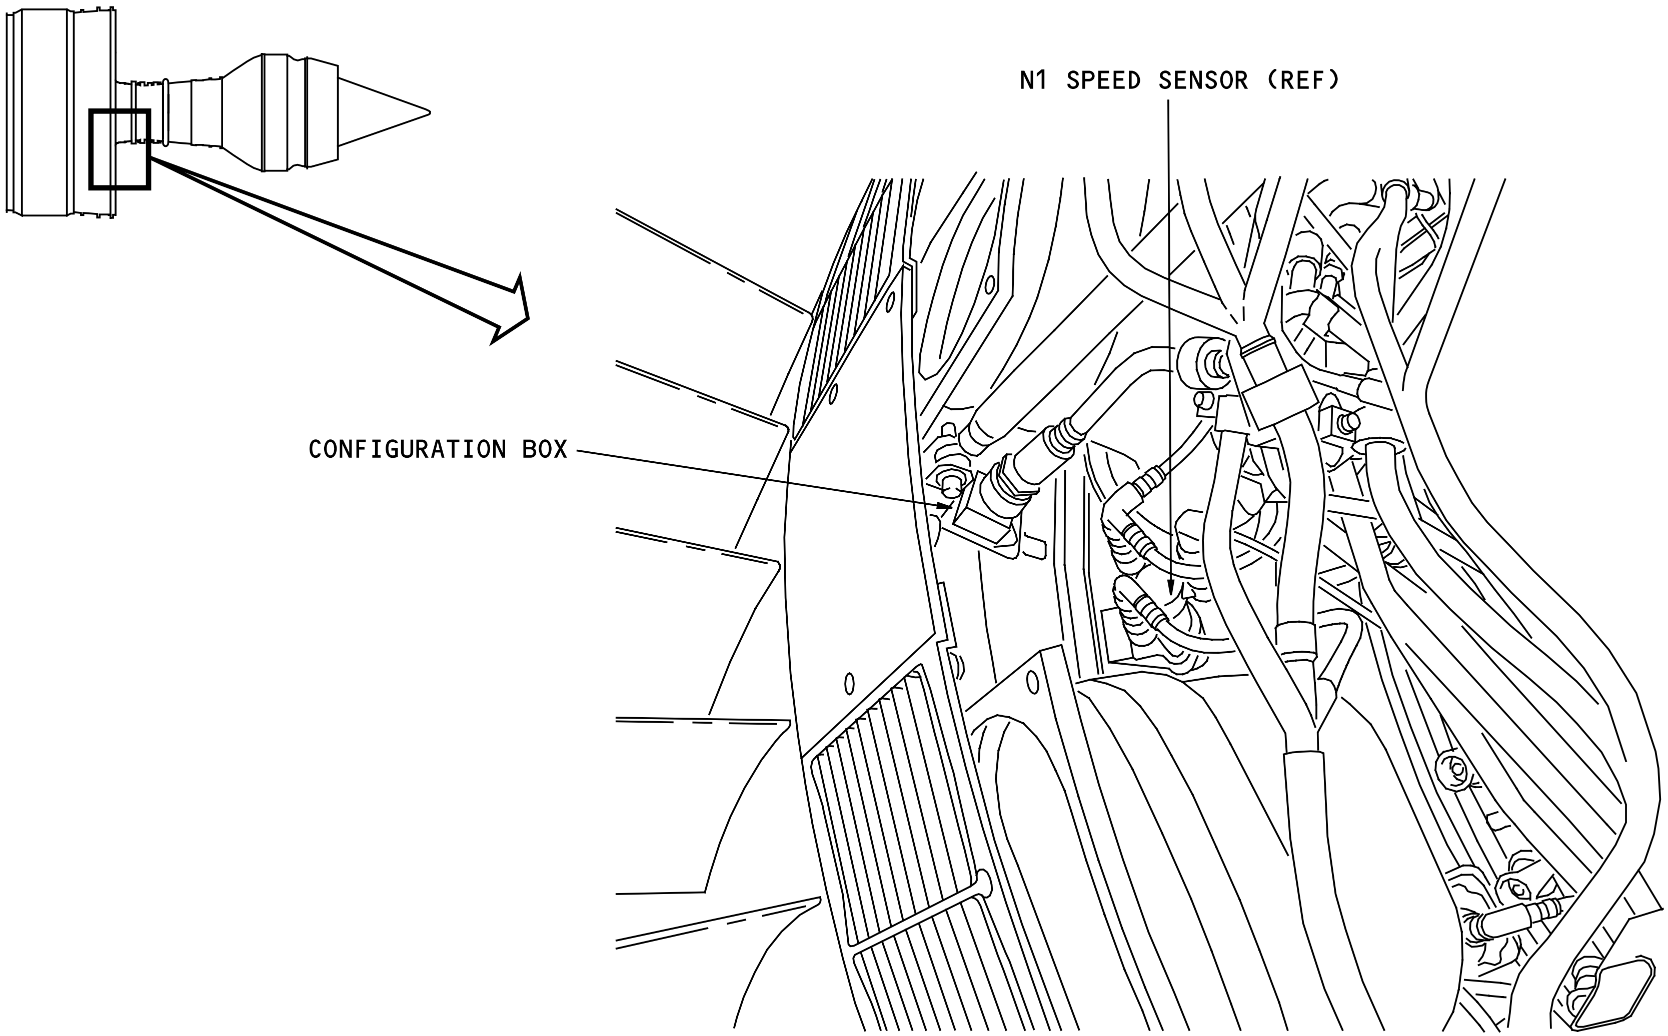
ENGINE FUEL CONTROL - CONFIGURATION / IDENTIFICATION

General

The configuration box is on the left side of the engine on the fan hub frame. The engine serial number (ESN) is input into the EEC through the Special Functions page on the MAT.

Configuration Box

The configuration box supplies data on the correct version of the engine hardware to the EEC. An electrical connector on the box attaches it to the EEC.



ENGINE FUEL CONTROL - CONFIGURATION / IDENTIFICATION

ENGINE FUEL CONTROL - EEC - INTRODUCTION

General

The EEC is a computer that controls the operation of the engine. It attaches to the upper-right fan case with shock mounts. It is cooled by convection.

Electrical Connections

The EEC has fifteen electrical connections labeled J1-J15. J1-J4 connect the EEC to airplane systems. J5-14 are engine inputs to the EEC. The odd numbered connections go to channel A. The even numbered connections go to channel B. Each channel A connection has a colored outline around its base. Each channel B connection has a colored outline with a white stripe around it.

J15 is the engine rating plug connection. The engine rating plug selects the software in the EEC that corresponds to the thrust rating of the engine. The plug attaches to the engine fan case with a lanyard. When you remove the EEC, the plug stays with the engine fan case.

Pneumatic Connections

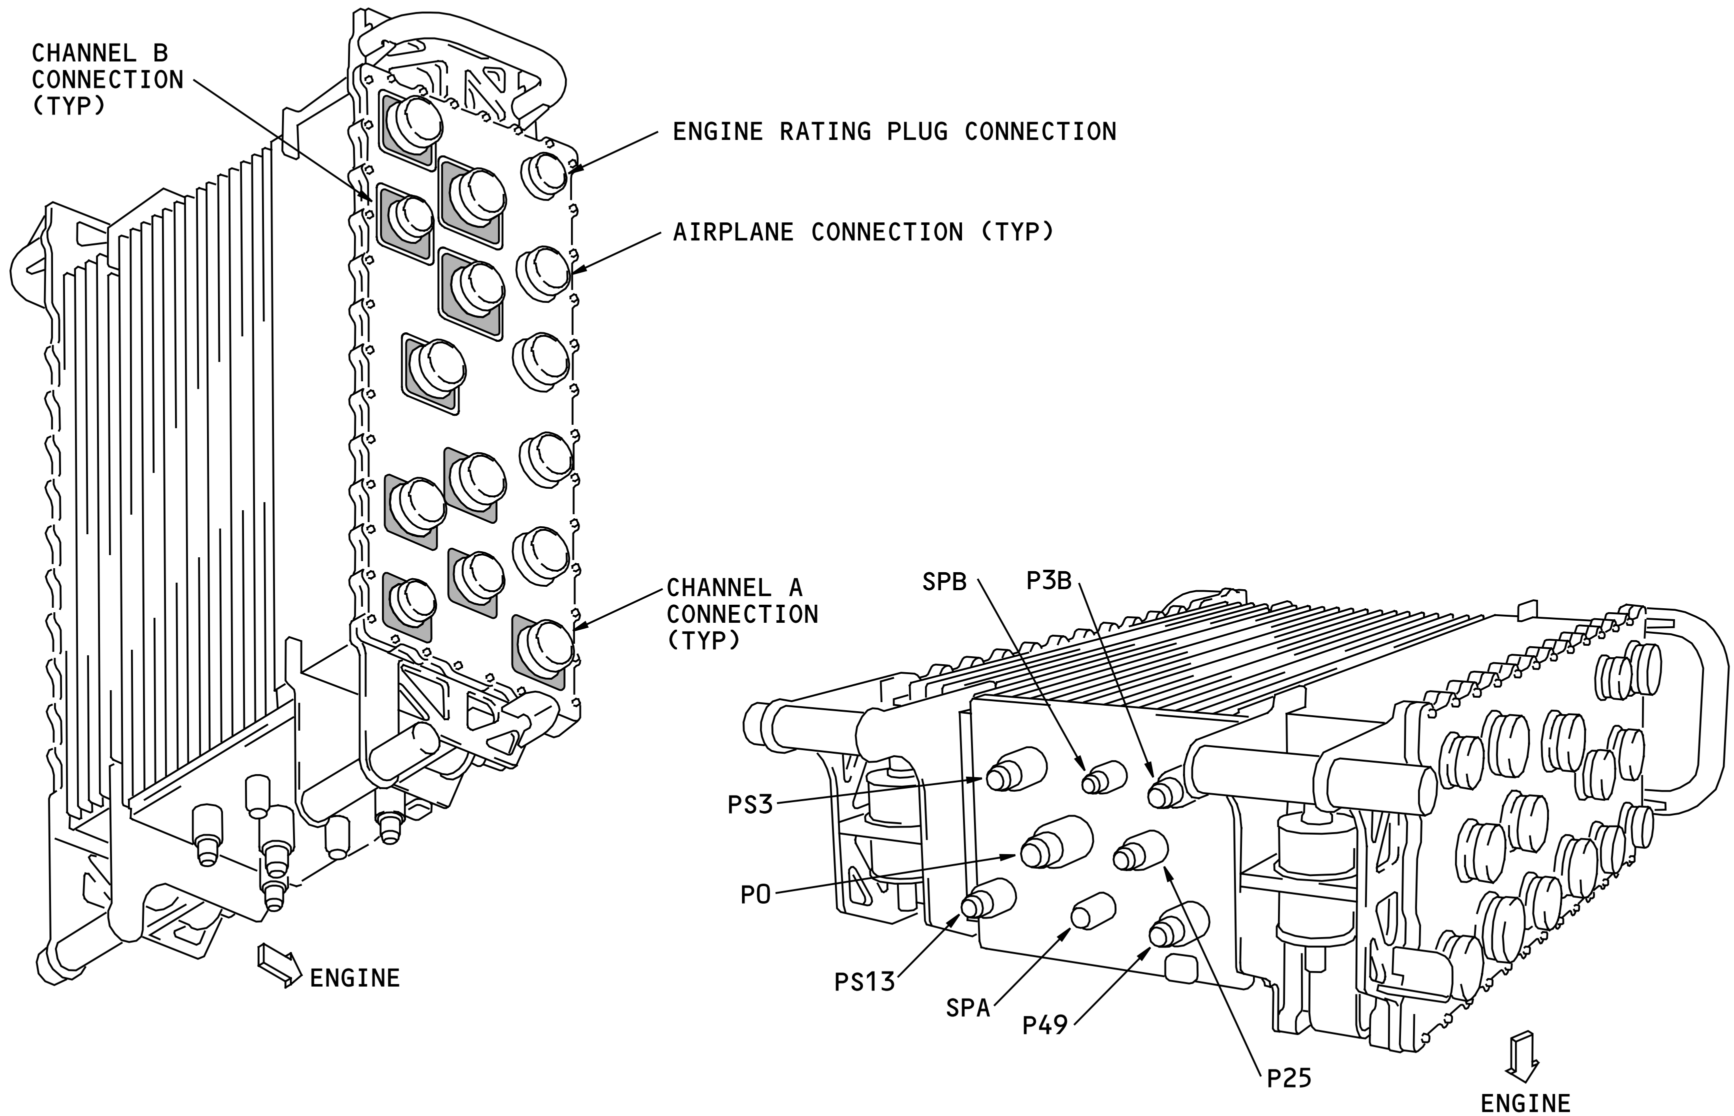
There are eight pneumatic connections on the bottom of the EEC. Transducers inside the EEC change the pneumatic signals to electrical signals. These are the pneumatic connections:

- PS3 (combustion inlet static pressure)
- P3B (HP bleed duct pressure)
- P25 (LPC exit pressure)
- P49 (LPT inlet pressure)
- PS13 (fan exit static pressure)
- P0 (ambient pressure).

SPA and SPB connections are spare pneumatic connections.

Training Information Point

The EEC mount (not shown) has hooks that permit you to hang the EEC on the engine. The hooks support the weight of the EEC while you install the mount bolts.



ENGINE FUEL CONTROL - EEC - INTRODUCTION

73-21-00-109 Rev 3 02/08/1997

ENGINE FUEL CONTROL - EEC - FUNCTIONAL DESCRIPTION

General

The EEC is a two-channel computer that controls the operation of the engine. It has two channels, but only one is in control at a time (active channel). The active channel changes each time you start the engine.

Power

Each channel of the EEC gets power from two sources: airplane and engine. The EEC gets power from the airplane when one or more of these conditions occur:

- Fuel control switch in RUN
- Start/ignition selector in START
- EEC maintenance switch in TEST.

Engine power for the EEC comes from the control alternator. The control alternator has a separate winding for each channel of the EEC. The control alternator starts to supply power at approximately 7 percent N2. The control alternator has priority over airplane power.

Computer

The EEC has two channels with these main sections:

- Processor
- Cross-talk logic
- Input/Output (I/O)
- Memory
- Pressure transducers.

The processor does all of the control calculations. It supplies all the data for the I/O section and control signals to the drivers.

For some inputs, the cross-talk logic compares the signals to channels A and B. If both channels get a good signal, the EEC uses the average of the two signals. If one channel does not get a good signal, the EEC uses only the other channel signal. If both channels get good a signal but they do not agree, the EEC uses a calculated value.

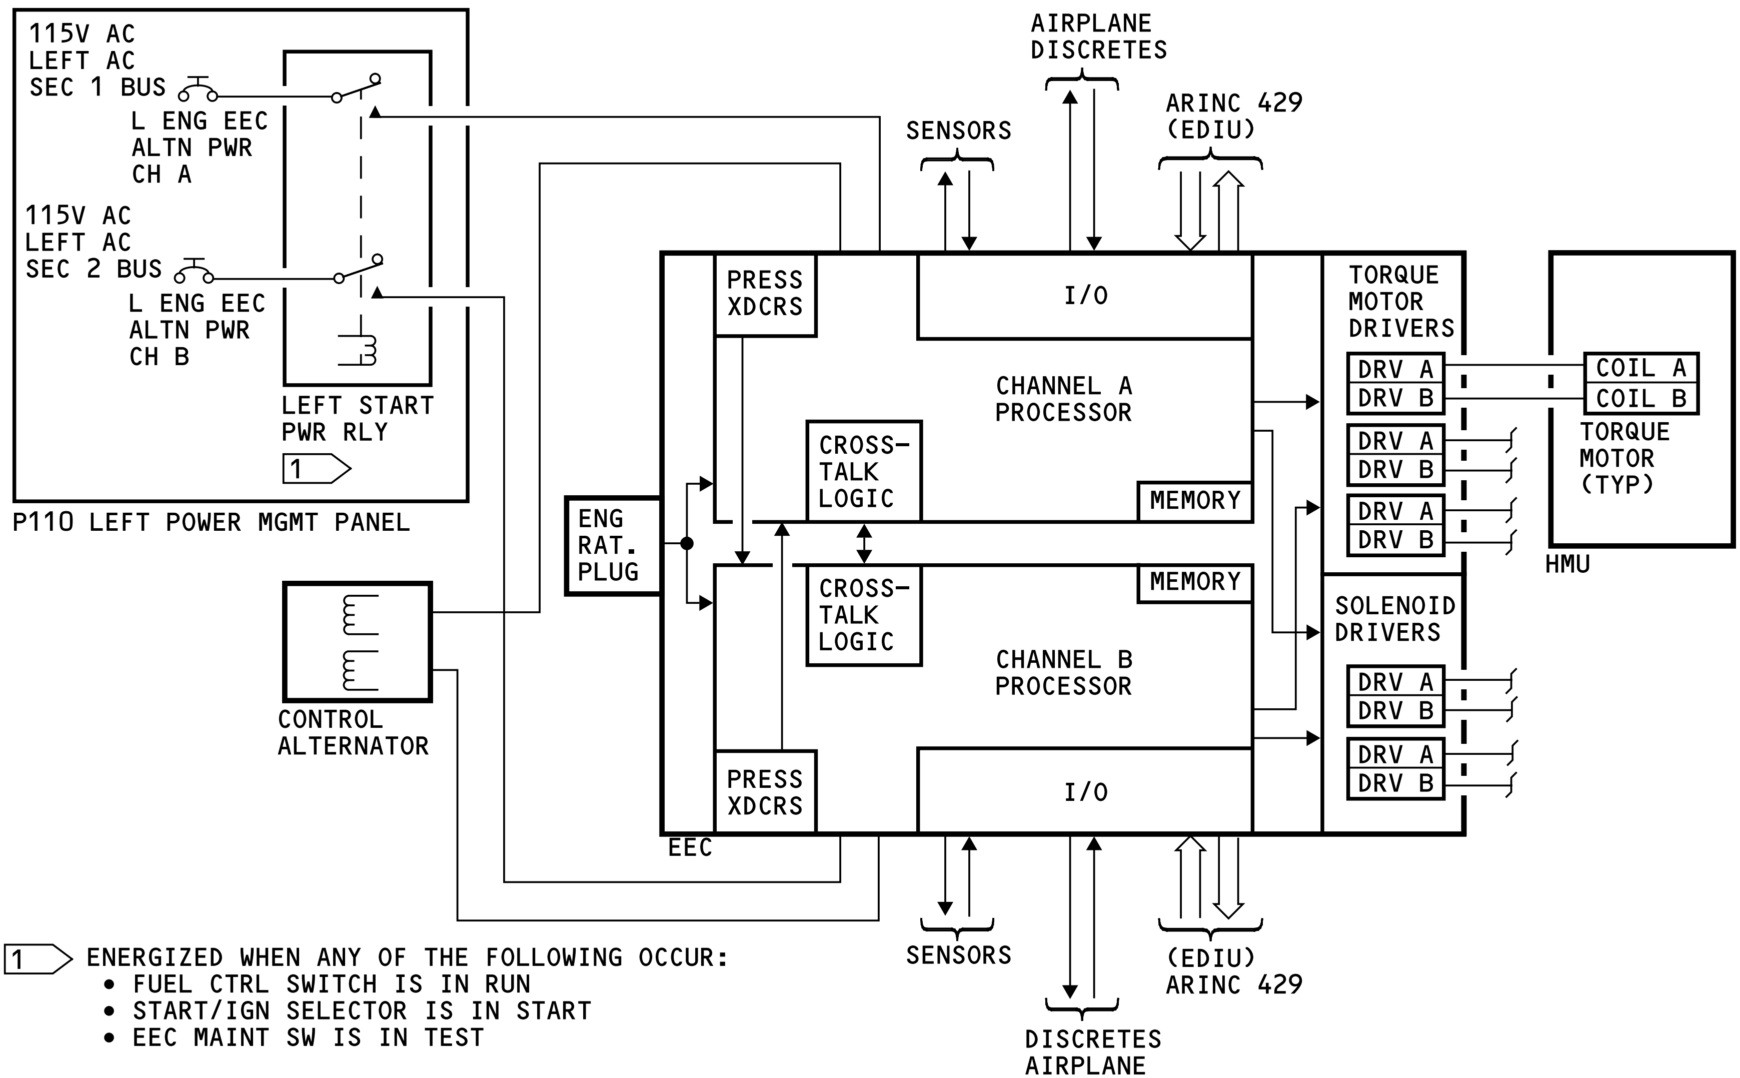
The I/O section receives and transmits digital and analog data.

The EEC has both non-volatile and volatile memory to keep performance and maintenance data.

Each channel has four pressure transducers. They send signals in proportion to the pressure in the lines connected to the EEC. The transducers also send the signals to the other channel. One transducer in each channel is not used.

Output Drivers

The EEC has output drivers that send the control signals to engine components. The active channel of the EEC sends control signals to the drivers. There are torque motor drivers and solenoid drivers.



1 ENERGIZED WHEN ANY OF THE FOLLOWING OCCUR:
- FUEL CTRL SWITCH IS IN RUN
- START/IGN SELECTOR IS IN START
- EEC MAINT SW IS IN TEST

NOTE: LEFT ENGINE SHOWN
RIGHT SIMILAR

ENGINE FUEL CONTROL - EEC - FUNCTIONAL DESCRIPTION

ENGINE FUEL CONTROL - CONTROL ALTERNATOR

General

The control alternator supplies power to the EEC. It attaches to the front of the main gearbox.

Physical Description

The control alternator has a rotor and a stator. The rotor attaches to a shaft on the main gearbox. The stator goes over the rotor and attaches to the gearbox housing.

Engine oil cools the control alternator.

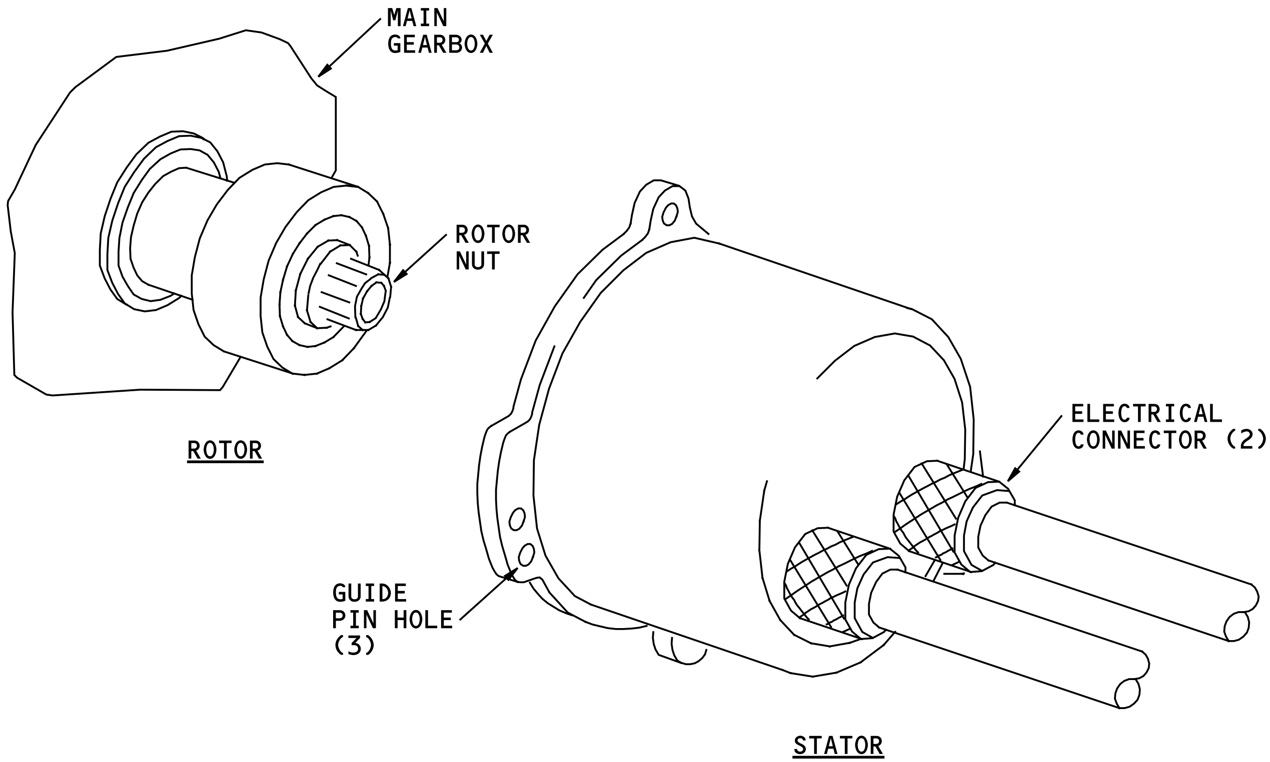
Functional Description

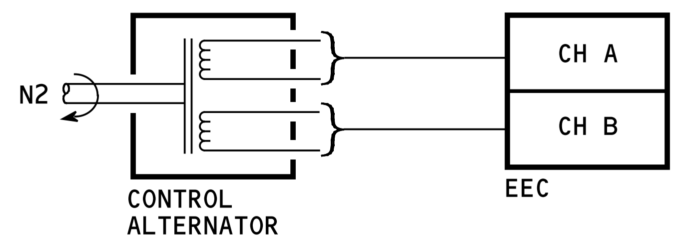
The control alternator makes electrical power when the gearbox turns the rotor inside the stator. The stator has two coils. Each EEC channel gets power from one of the coils when the engine reaches approximately 7 percent N2.

Training Information Point

You use guide pins when you remove or install the stator. The guide pins prevent the stator windings from hitting the rotor. The guide pins install in two places.

A nut holds the rotor on the gearbox shaft. You use a special tool to prevent the rotor drive shaft from turning when you turn the nut.





73-21-00-111 Rev 3

ENGINE FUEL CONTROL - CONTROL ALTERNATOR

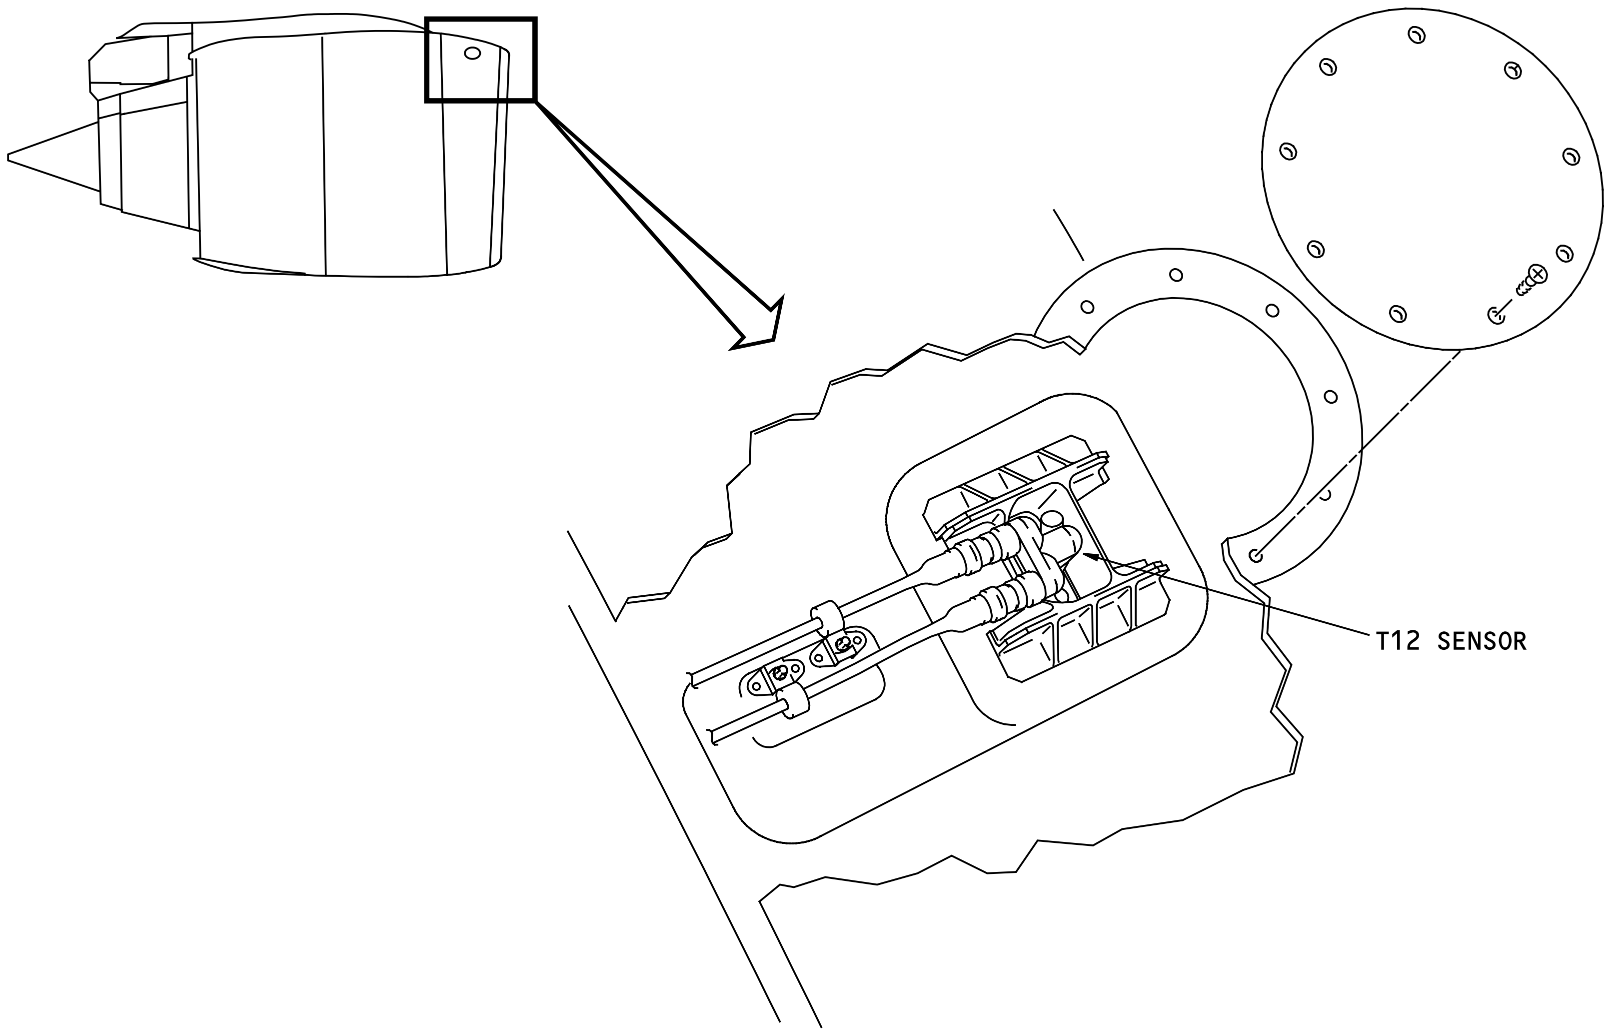
ENGINE FUEL CONTROL - T12 SENSOR

General

The T12 sensor sends the fan inlet air temperature to the EEC. The EEC uses T12 as an input to control fuel flow.

The T12 sensor is on the inlet cowl at the 12:30 position. You get access to the sensor through a panel on top of the inlet cowl.

The T12 sensor has two outputs, one to each channel of the EEC. It is a resistive thermal sensor. The EEC monitors the T12 sensor for faults.



ENGINE FUEL CONTROL - T12 SENSOR

ENGINE FUEL CONTROL - PT25 SENSOR

General

The PT25 sensor supplies HPC inlet pressure and temperature to the EEC. The EEC uses T25 as one of the inputs to control the variable bypass valves (VBV) and variable stator vanes (VSV). The EEC sends P25 to the AIMS as part of the airplane condition monitoring system (ACMS).

The EEC monitors the PT25 sensor for faults.

Location

The PT25 sensor is on the fan hub frame at the 7:00 position.

Temperature Sensing

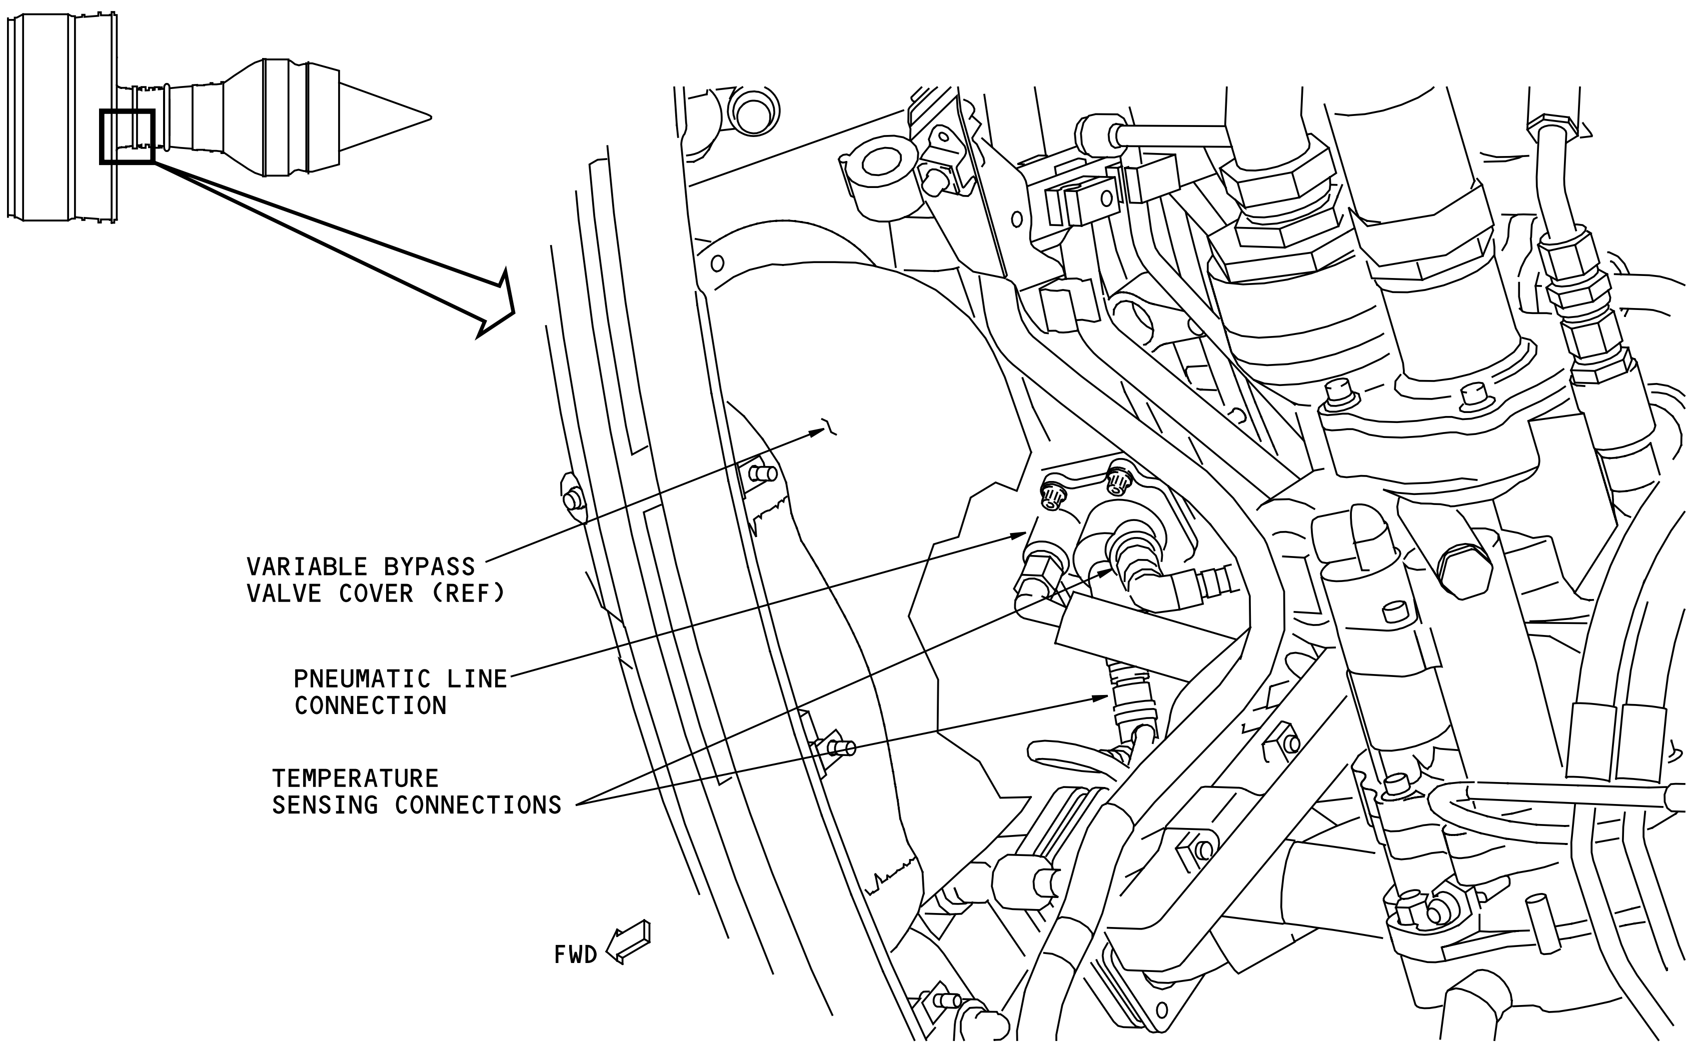
The PT25 sensor has two resistive thermal sensors. There are two outputs, one to each channel of the EEC.

Pressure Sensing

The PT25 sensor has a pneumatic line that goes to a pressure transducer in the EEC. The transducer sends an electrical signal to each channel of the EEC. The electrical signal is proportional to P25.

Training Information Point

You must remove the oil/oil heat exchanger before you can remove the PT25 sensor.



73-21-00-113 Rev 3 03/30/95

ENGINE FUEL CONTROL - PT25 SENSOR

ENGINE FUEL CONTROL - T3 SENSOR

General

The T3 sensor supplies combustion inlet (HPC exit) temperature to the EEC. The EEC uses T3 in some of its calculations.

It is on the combustor diffuser nozzle case at the 3:30 position

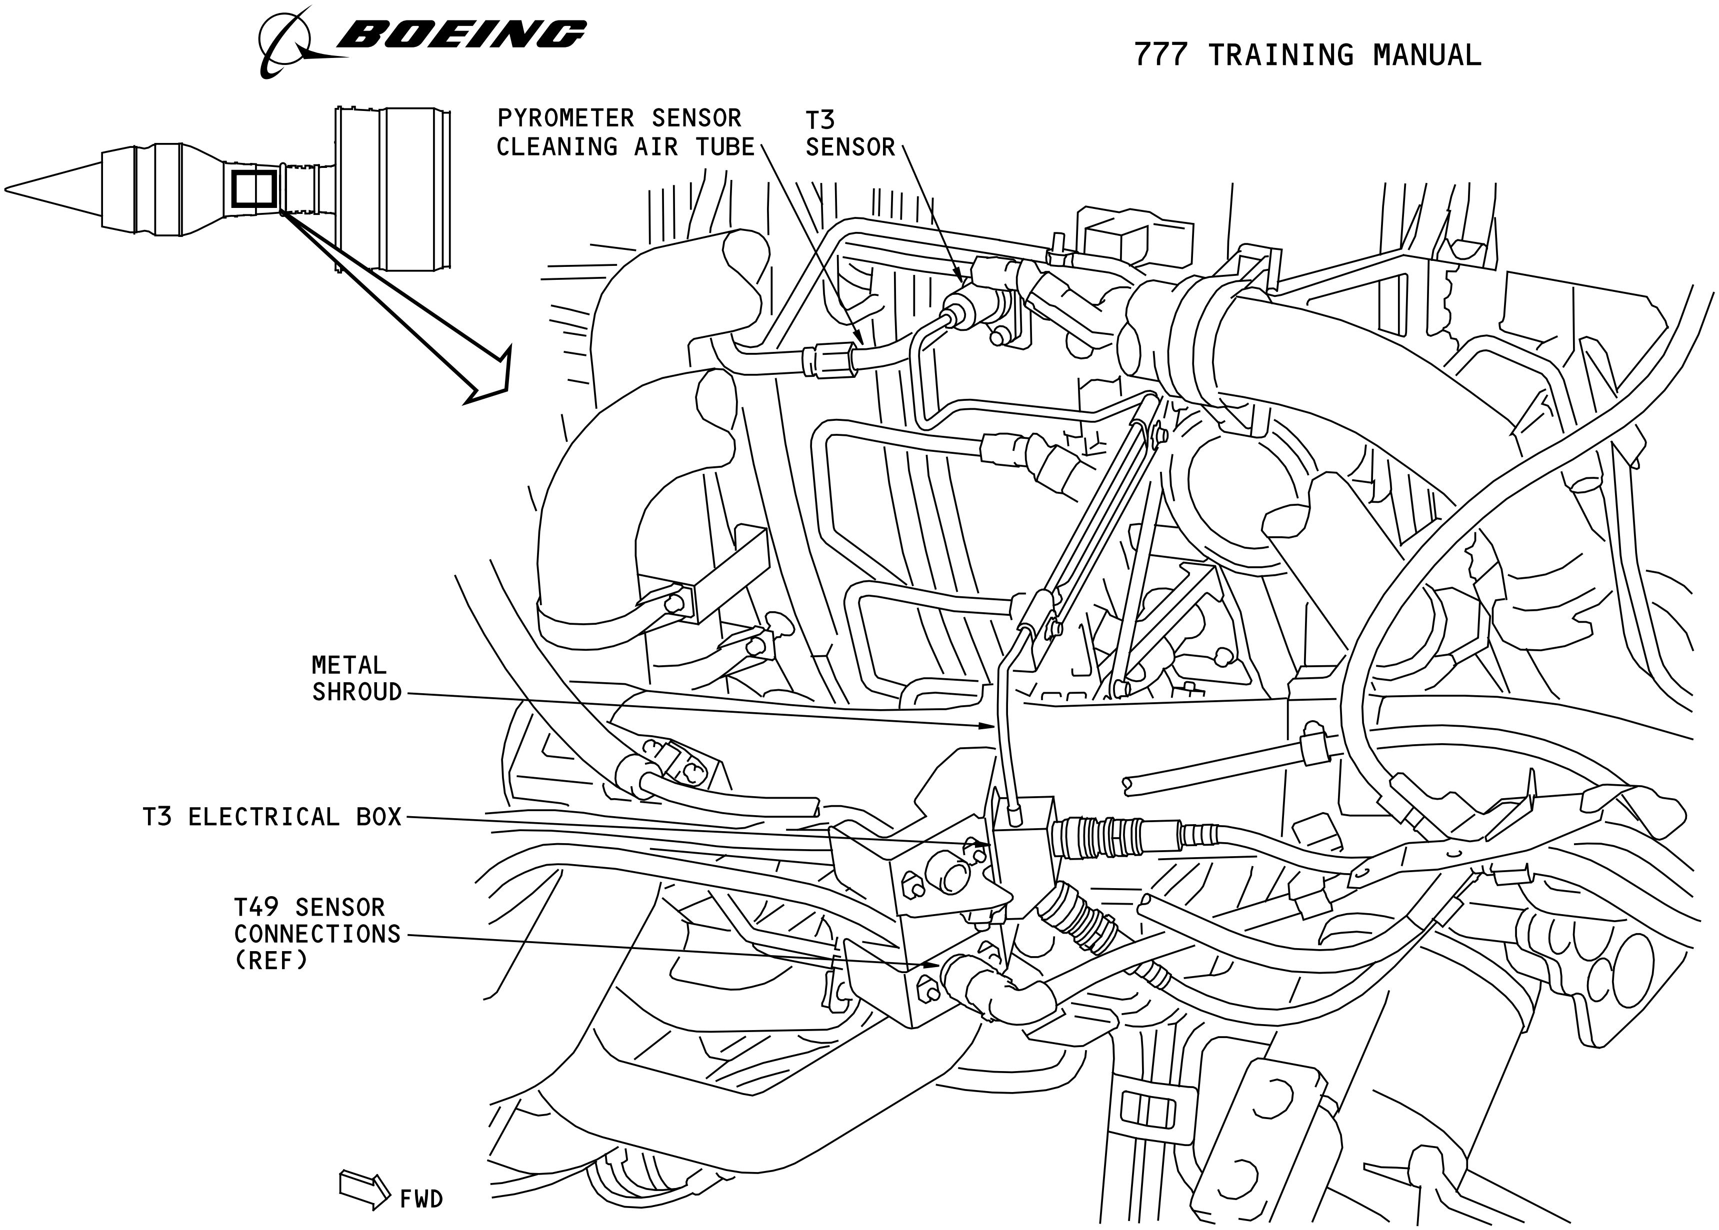
Physical Description

The T3 sensor has two thermocouples. One thermocouple goes to each channel of the EEC. The wires go from the sensor, through a metal shroud, to the electrical box. The electrical box is part of the T3 sensor.

Functional Description

Air from the combustion inlet flows into the T3 sensor and over the thermocouples. The air then goes through a cooling air tube to the pyrometer and flows over the pyrometer lens (not shown). This keeps the lens clean.

The EEC monitors the T3 sensor for faults.



ENGINE FUEL CONTROL - T3 SENSOR

73-21-00-114 Rev 6 08/21/1997

ENGINE FUEL CONTROL - BLEED BIAS FLOW SENSOR

General

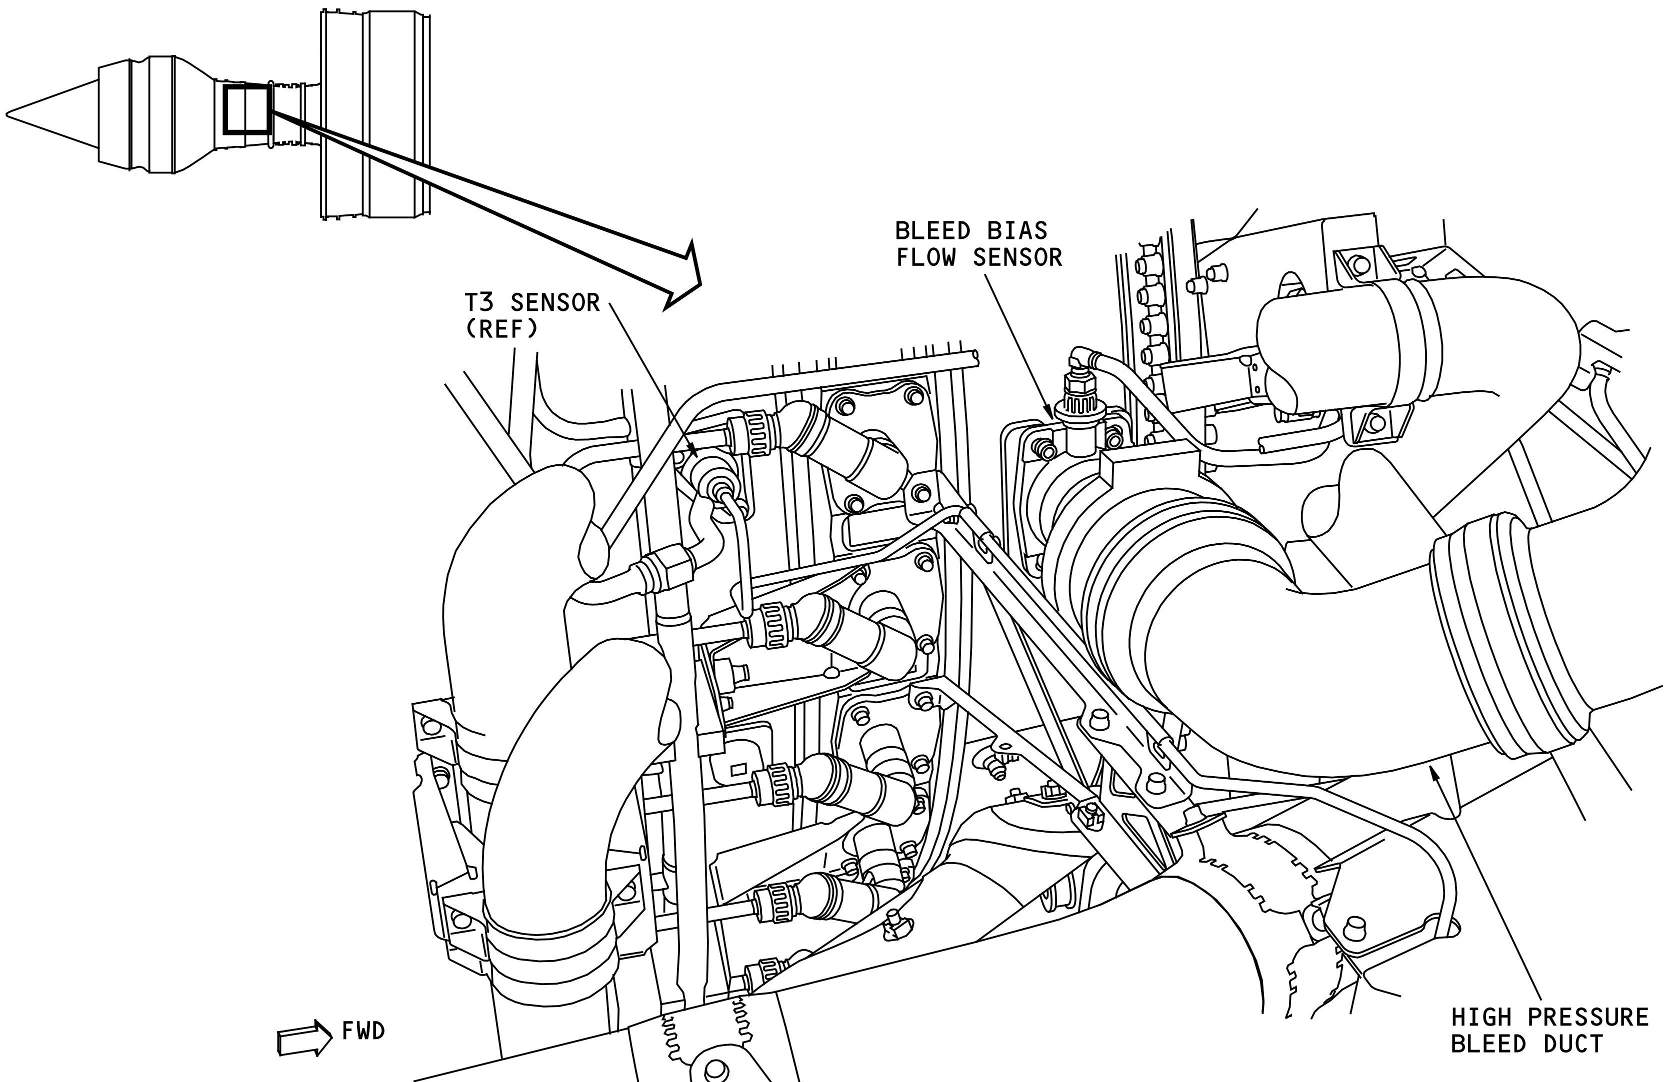
The bleed bias flow sensor has a venturi in the high pressure bleed duct. It supplies the EEC with the static pressure at the throat of the venturi. This pressure is called P3B.

The EEC uses P3B and PS3 (not shown) to calculate the high stage bleed flow rate. The EEC also uses P3B to make adjustments to improve engine acceleration.

It is on the combustor diffuser nozzle case at the 3:30 position. It attaches between the case and the lower high pressure bleed duct.

The bleed bias flow sensor has a pneumatic line that goes to a pressure transducer in the EEC.

The EEC monitors the bleed bias flow sensor for faults.



ENGINE FUEL CONTROL - BLEED BIAS FLOW SENSOR

73-21-00-115 Rev 5 08/21/1997

ENGINE FUEL CONTROL - ACMS SENSORS

Airplane Condition Monitoring System (ACMS)

The ACMS sensors supply specific pressures and temperatures to the EEC. The ACMS monitors the engine condition to look for engine degradation.

PS13 Pressure Probe

The PS13 pressure probe supplies fan exit static pressure to the EEC. It is on the aft fan case at the 2:00 position. The probe connects to a pneumatic line that goes to a pressure transducer in the EEC.

See the engine mounted sensors section for more information about the PS13 sensor (AMM PART I 77-34).

P49 Pressure Probe

The P49 pressure probe supplies LPT inlet total pressure to the EEC. It is on the turbine center frame at the 4:00 position. The probe connects to a pneumatic line that goes to a pressure transducer in the EEC.

See the engine mounted sensors section for more information about the P49 sensor (AMM PART I 77-34).

T5 Sensor

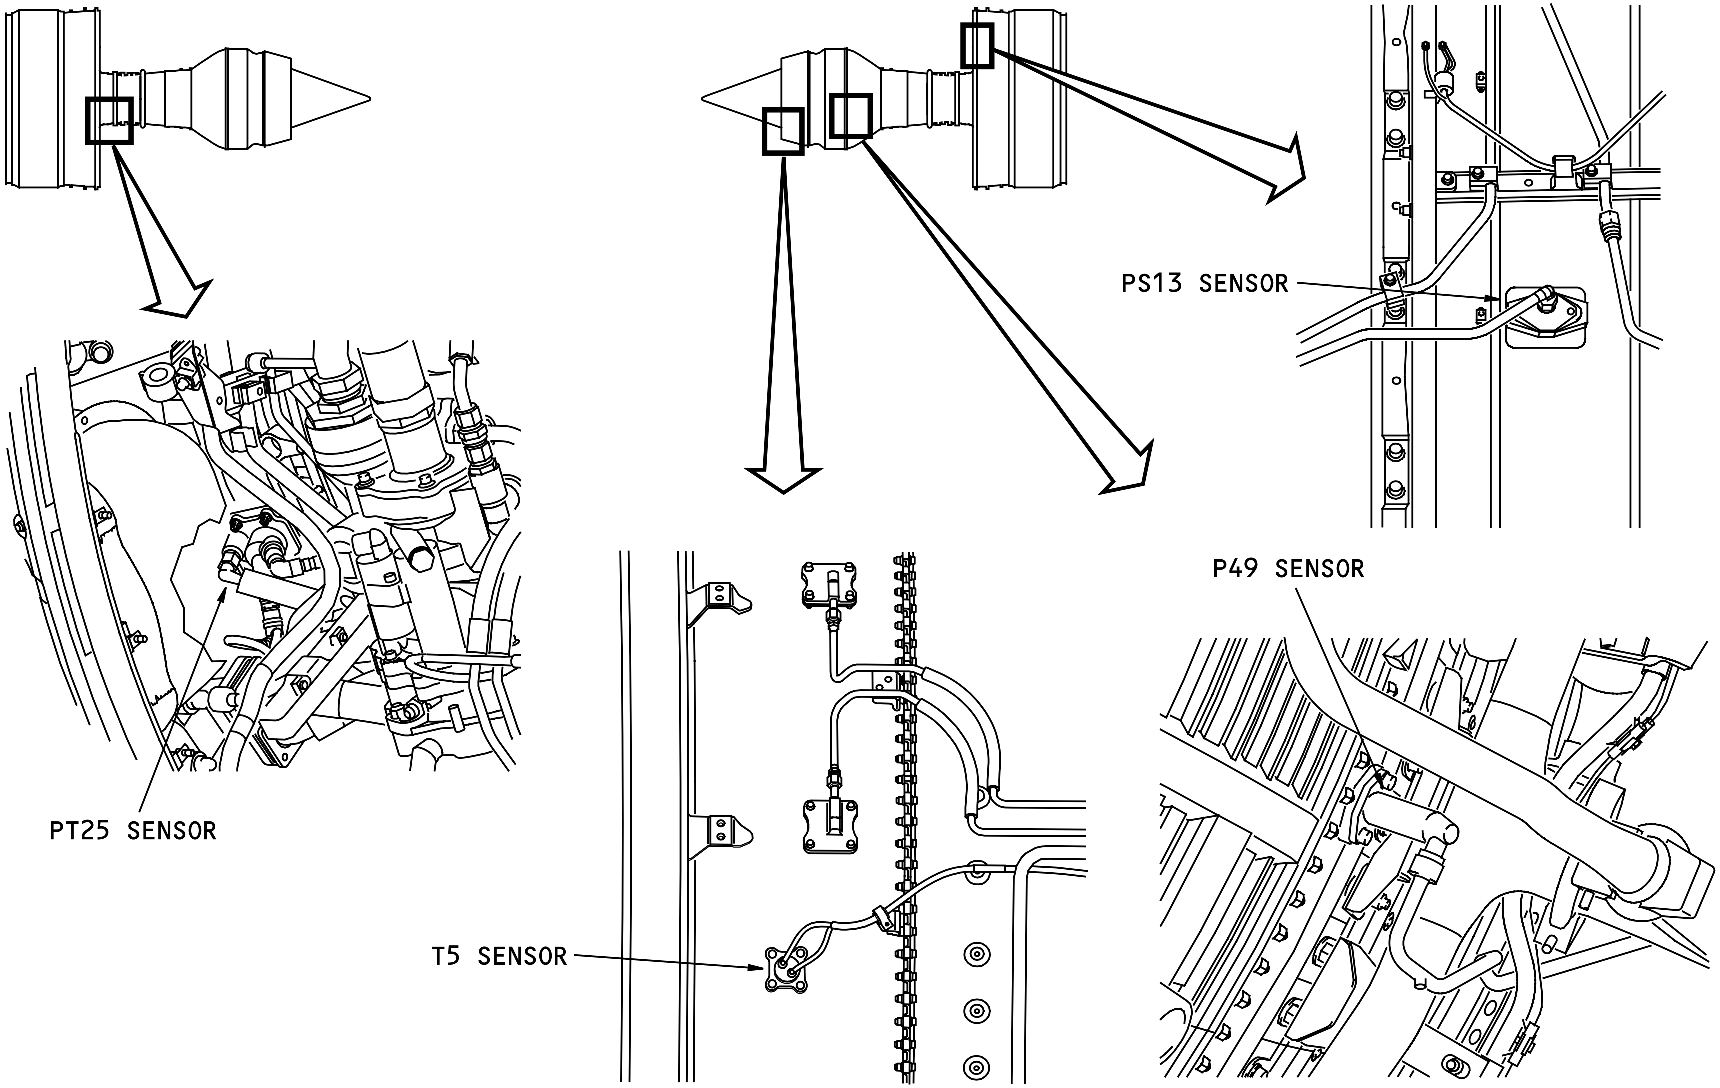
The T5 sensor supplies LPT exit temperature to the EEC. It is on the turbine rear frame at the 5:30 position. The sensor has two thermocouples that go to different depths at the LPT exit. The average of the two thermocouples goes to the EEC.

See the engine mounted sensors section for more information about the T5 sensor (AMM PART I 77-34).

PT25 Sensor

The PT25 sensor supplies HPC inlet pressure and temperature to the EEC. It is on the fan hub frame at the 7:00 position.

The PT25 sensor has a pneumatic line that goes to a pressure transducer in the EEC. The EEC measures the pressure.



ENGINE FUEL CONTROL - ACMS SENSORS

ENGINE FUEL CONTROL - FUEL PRESSURE SENSORS

General

The fuel control system has two pressure sensors. One on the main fuel pump and one on the hydromechanical unit (HMU). Signals from the pressure sensors go to the EEC. The EEC uses the information to monitor the fuel filter, fuel pump and HMU for faults.

These are the pressure sensors:

- Fuel filter differential pressure
- Fuel manifold pressure sensor.

Each sensor has two sensing elements, one for each channel of the EEC. The EEC monitors the sensors for faults.

Fuel Filter Differential Pressure Sensor

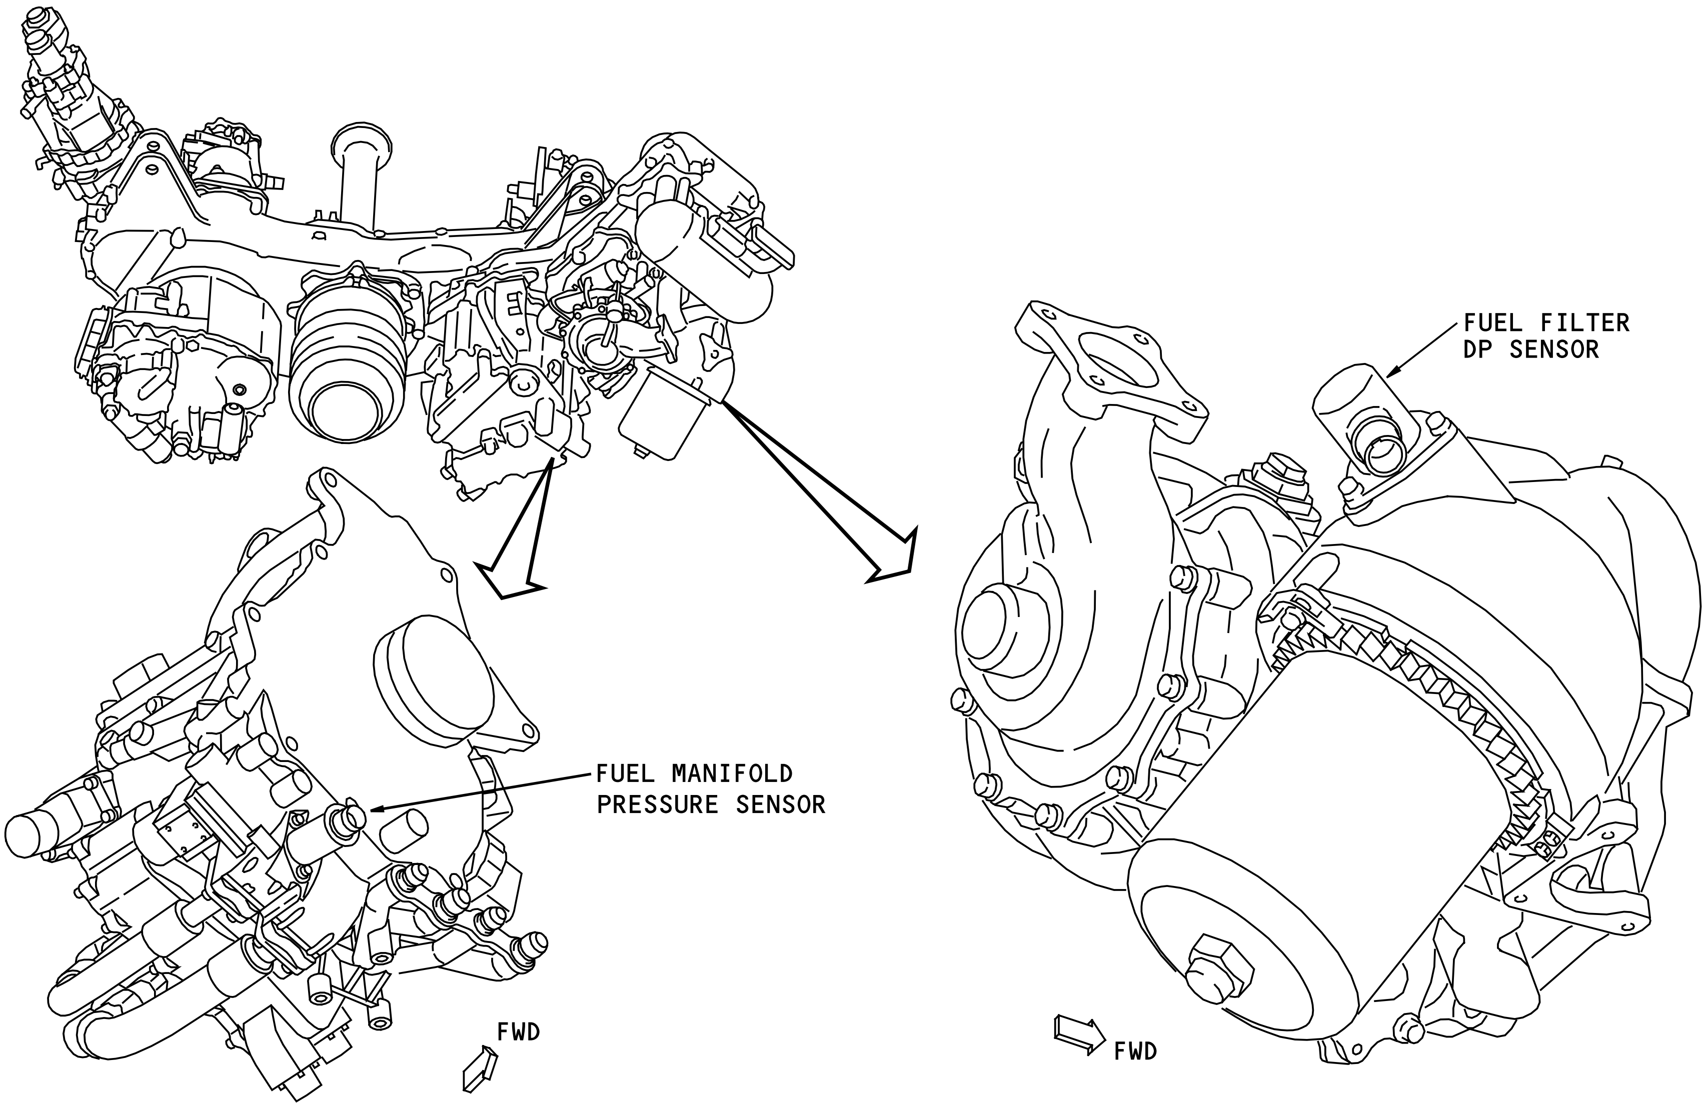
The fuel filter differential pressure sensor measures the fuel pressure on each side of the filter. The EEC sends a signal to the AIMS when the filter begins to clog. The fuel filter will bypass fuel if it becomes clogged.

It is on the aft side of the fuel pump, just above the filter.

Fuel Manifold Pressure Sensor

The fuel manifold pressure sensor (FMPS) measures the fuel pressure in the HMU output to manifold 2. The pressure signal provides the staging valve and pressurizing and shutoff valve position feedback to the EEC. The EEC sends a signal to the AIMS when the sensor has a fault.

It is on the aft side of the hydromechanical unit, just above the fuel feeder hoses.



73-21-00-117 Rev 4 08/21/1997

ENGINE FUEL CONTROL - FUEL PRESSURE SENSORS

ENGINE FUEL CONTROL - HMU - INTRODUCTION

Purpose

The hydromechanical unit (HMU) meters and distributes the proper amount of fuel needed for combustion. It also supplies servo fuel to move actuators and valves of the engine air system.

Location

The HMU is on the aft face of the main gearbox.

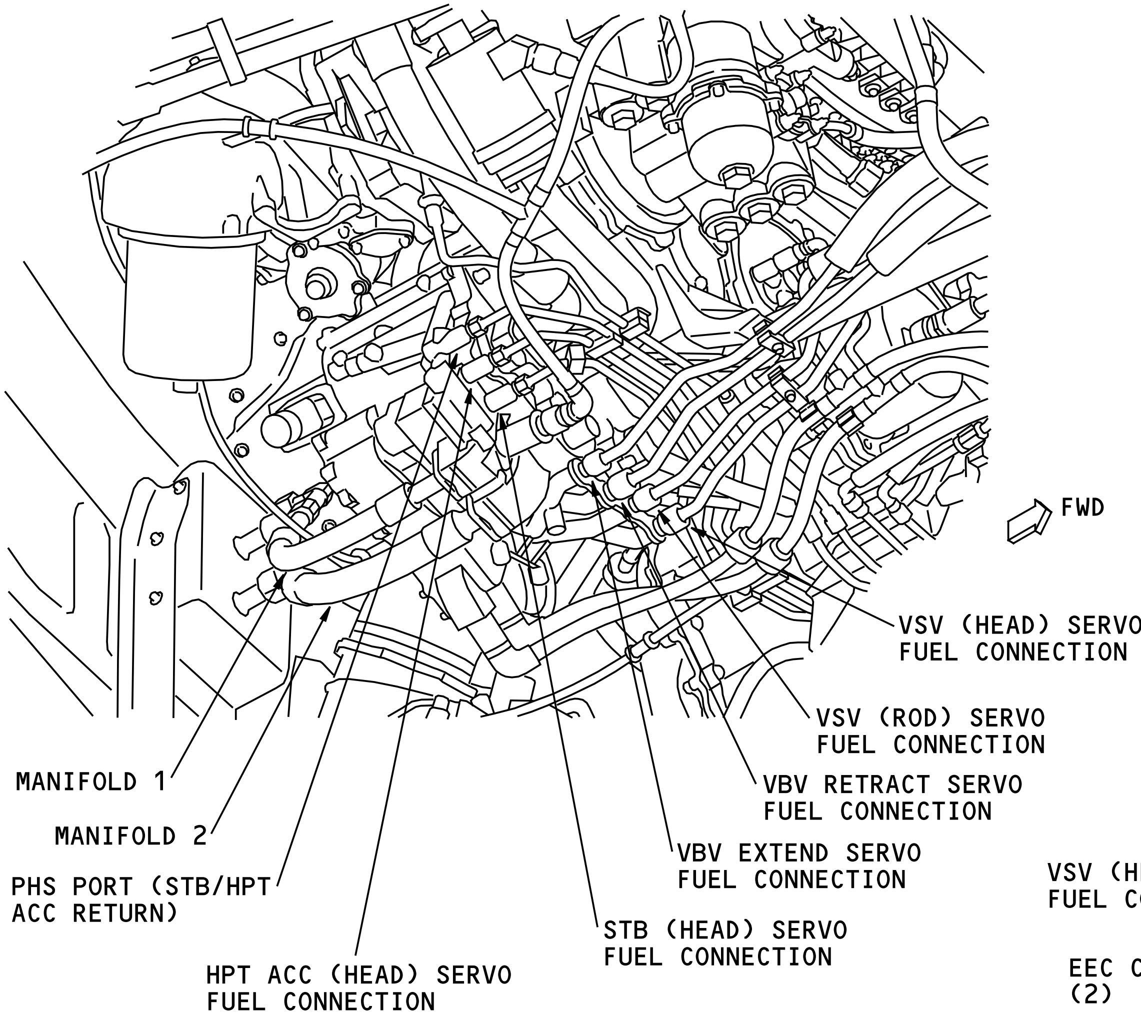
Physical Description

These electrical connections are on the left side of the HMU:

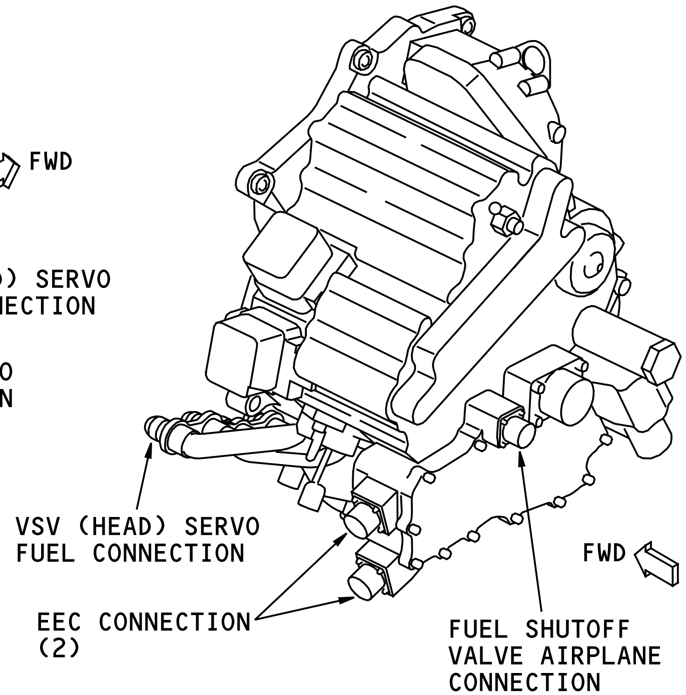
- EEC Connections (2)
- Fuel shutoff valve.

These servo fuel tube and fuel manifold connections are on the bottom of the HMU:

- Manifold 1
- Manifold 2
- PHS port (STB/HPT ACC return)
- HPT active clearance control (ACC)
- Start/transient bleed (STB) valve
- Variable bypass valve (VBV) (2)
- Variable stator vane (VSV) (2).



HMU BOTTOM



HMU LEFT SIDE

73-21-00-118 Rev 1 08/21/1997

ENGINE FUEL CONTROL - HMU - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE FUEL CONTROL - HMU FUNCTIONAL DESCRIPTION

General

The HMU has these functions:

- Permits only the correct amount of fuel to flow to the engine for combustion
- Turns fuel flow to the engine on or off
- Distributes fuel to the manifolds
- Supplies servo fuel to actuators and valves of other engine systems.

Metered Fuel Flow Control

Fuel flows into the HMU from the fuel pump. The fuel metering valve (FMV) controls how much fuel goes to the engine (metered fuel). Fuel not used for combustion (bypass fuel) returns to the fuel pump through the bypass valve (BPV).

The EEC controls a torque motor in the HMU (not shown) to control the FMV position. The torque motor controls servo fuel pressure to the FMV. The EEC gets FMV position feedback.

An overspeed governor (OSG) mechanically connects the differential pressure regulator to the main gearbox. If the engine overspeeds, the OSG causes the differential pressure regulator to open the bypass valve to send most of the fuel back to the fuel pump.

Run/Cutoff Control

The engine fuel shutoff valve (SOV) turns fuel flow to the engine on or off. The ELMS energizes the run and cutoff solenoids (not shown) to open or close the SOV. The cutoff solenoid also energizes when you pull the fire switch.

When the run solenoid energizes, fuel pressure opens the SOV. The valve stays open until the ELMS energizes the cutoff solenoid. This permits fuel pressure to close the SOV.

Fuel Distribution

After fuel goes through the fuel flow transmitter, it goes to manifold 1 and to the staging valve (SV).

Fuel to manifold 2 goes through the SV. The EEC controls the SV. The fuel manifold pressure sensor (FMPS) provides feedback to the EEC about the positions of the SV and the SOV.

Servo Fuel

The HMU supplies servo fuel pressure to move these engine air system actuators:

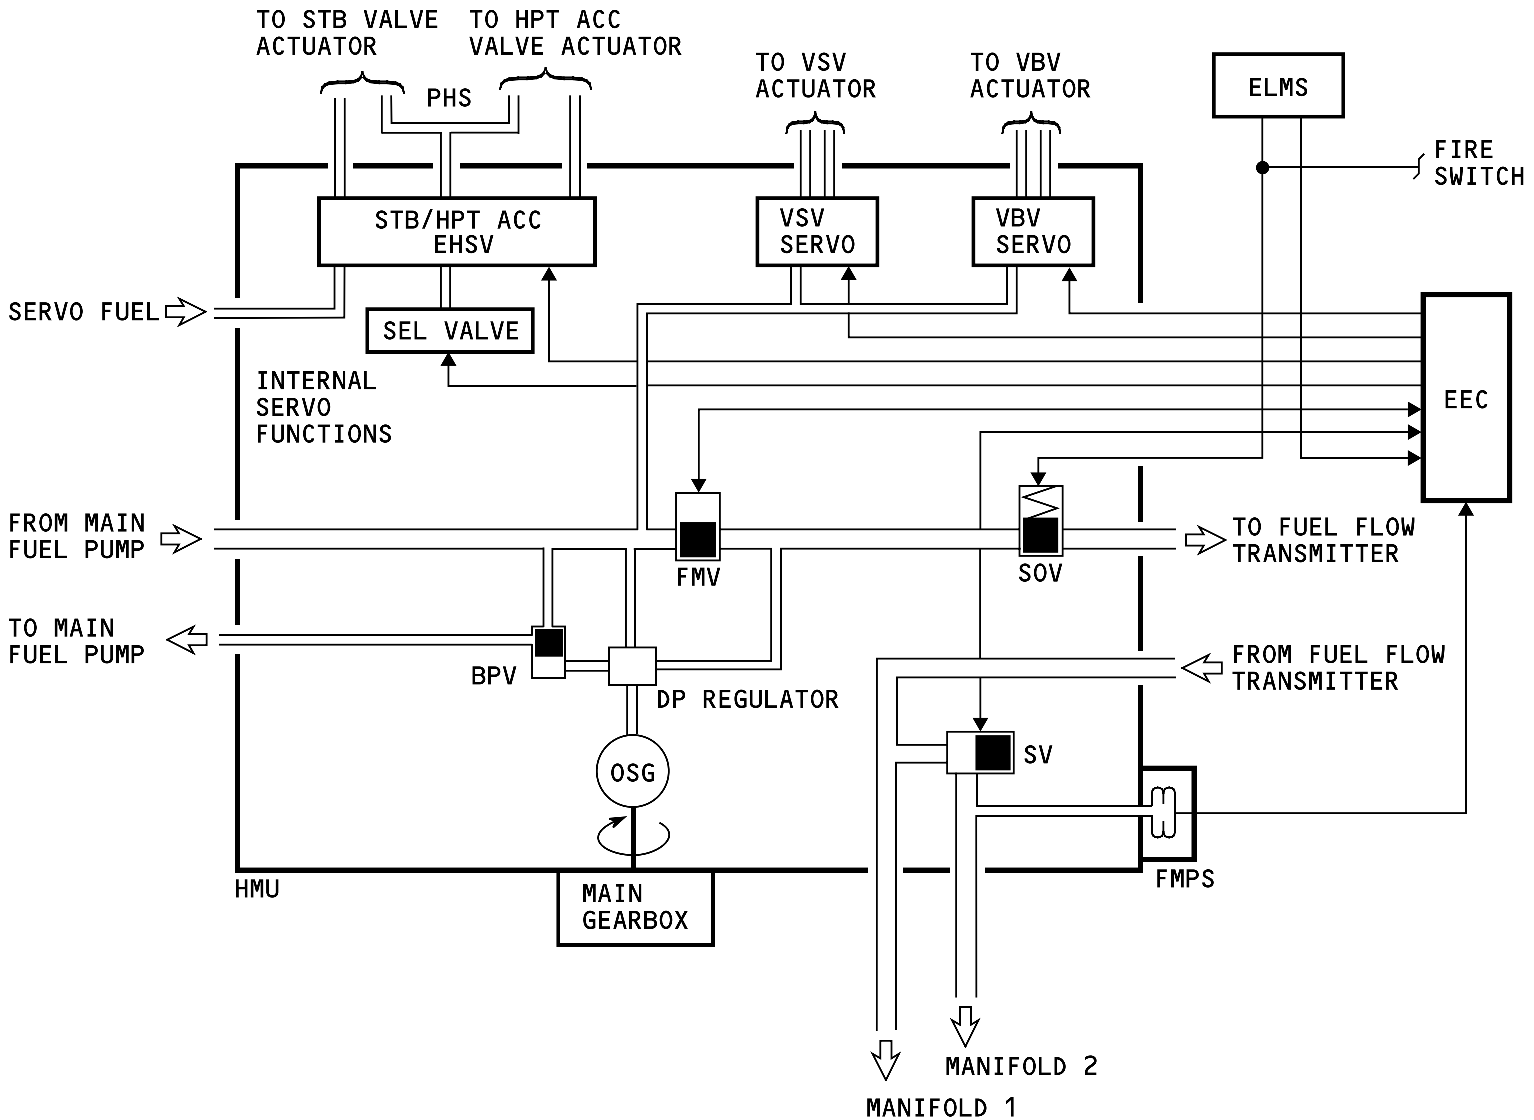
- Start transient bleed (STB) valve
- HPT ACC valve
- Variable stator vanes (VSV)
- Variable bypass valves (VBV).

ENGINE FUEL CONTROL - HMU FUNCTIONAL DESCRIPTION

The EEC controls torque motors and an electro-hydraulic servo valve (EHSV) to let servo fuel pressure go to the actuators.

The STB/HPT ACC EHSV can operate either the STB or the HPT ACC valve but not both at the same time. The EEC controls the selector valve and moves the STB/HPT ACC EHSV in either the STB or HPT ACC operating range. The PHS (pressure heated servo) port supplies a reference pressure of heated servo fuel. There is a port for HPT ACC head pressure and a port for STB head pressure. The HPT ACC and STB valves make the head pressure greater than or less than the PHS reference pressure.

The HMU also uses servo fuel pressure to move internal HMU valves.

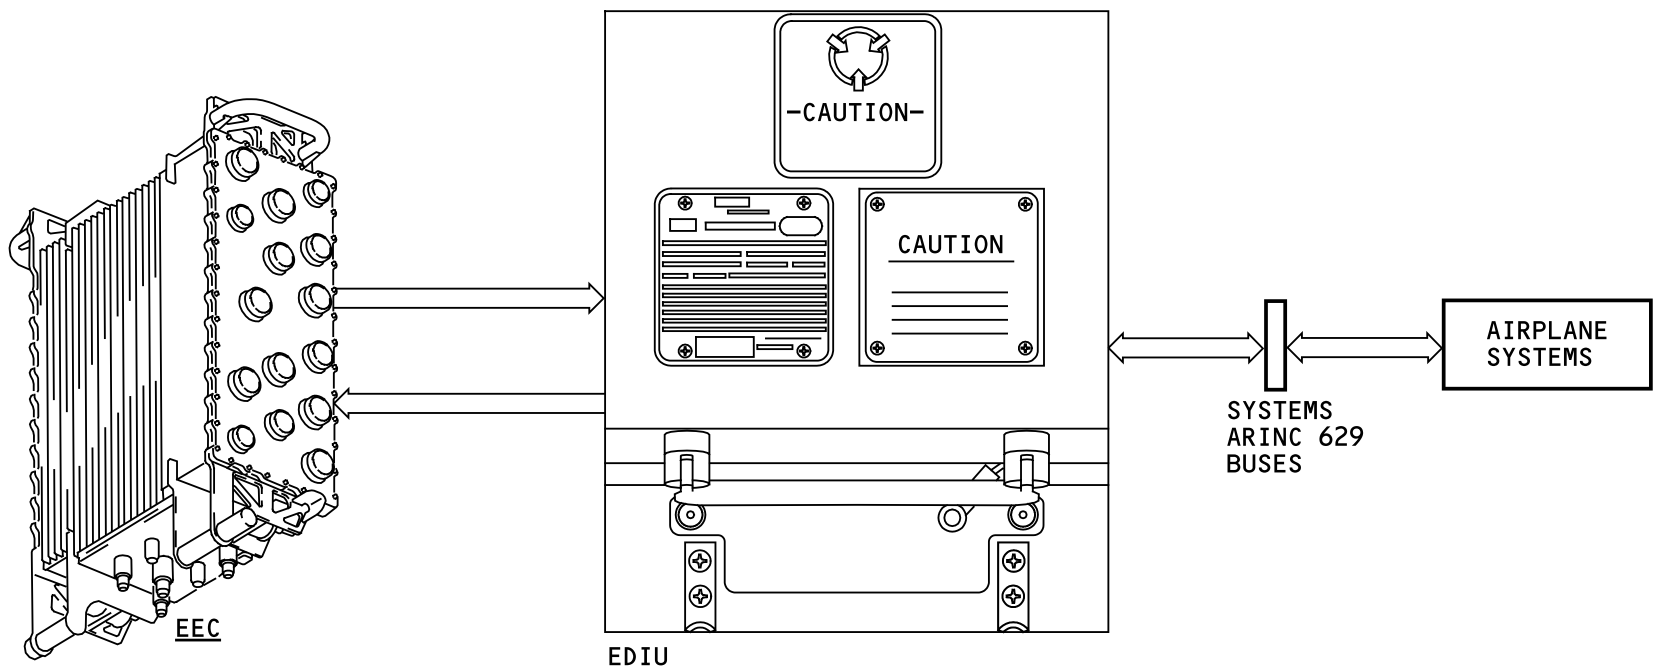


ENGINE FUEL CONTROL - HMU FUNCTIONAL DESCRIPTION

ENGINE FUEL CONTROL - EDIU

General

The EDIU changes the ARINC 429 formatted data to ARINC 629. The EDIU also changes ARINC 629 data to ARINC 429. This permits the EEC to transmit and receive data to and from airplane systems. Each engine has its own EDIU.



73-21-00-120 Rev 0

ENGINE FUEL CONTROL - EDIU

ENGINE FUEL CONTROL - CONTROL - EEC POWER MANAGEMENT - FUNCTIONAL DESCRIPTION

General

The EECs get airplane power when one of these conditions occur:

- Fuel control switch is in RUN position
- Start/ignition selector is in START position
- EEC maintenance switch is in TEST position.

The left EEC gets power from the left ac bus. The right EEC gets power from the right ac bus. Each channel of the EEC has a separate source. Channel A gets power from section 1 of the ac bus. Channel B gets power from section 2.

The EEC gets airplane power when the start power relay in the P110 left power management panel energizes. The start power relay coil gets power from the captain's flight instrument bus. The switches control the ground for the start power relay coil.

The control alternator supplies each channel of the EEC with power at approximately 7 percent N2.

Fuel Control Switch

The fuel control switch energizes the ignition/fire detection relay when it is in the RUN position. The ignition/fire detection relay supplies a ground for the start power relay. This permits the EEC to get airplane power during engine operation when there is a control alternator failure. The control alternator (not shown) is the normal power source when the engine is running.

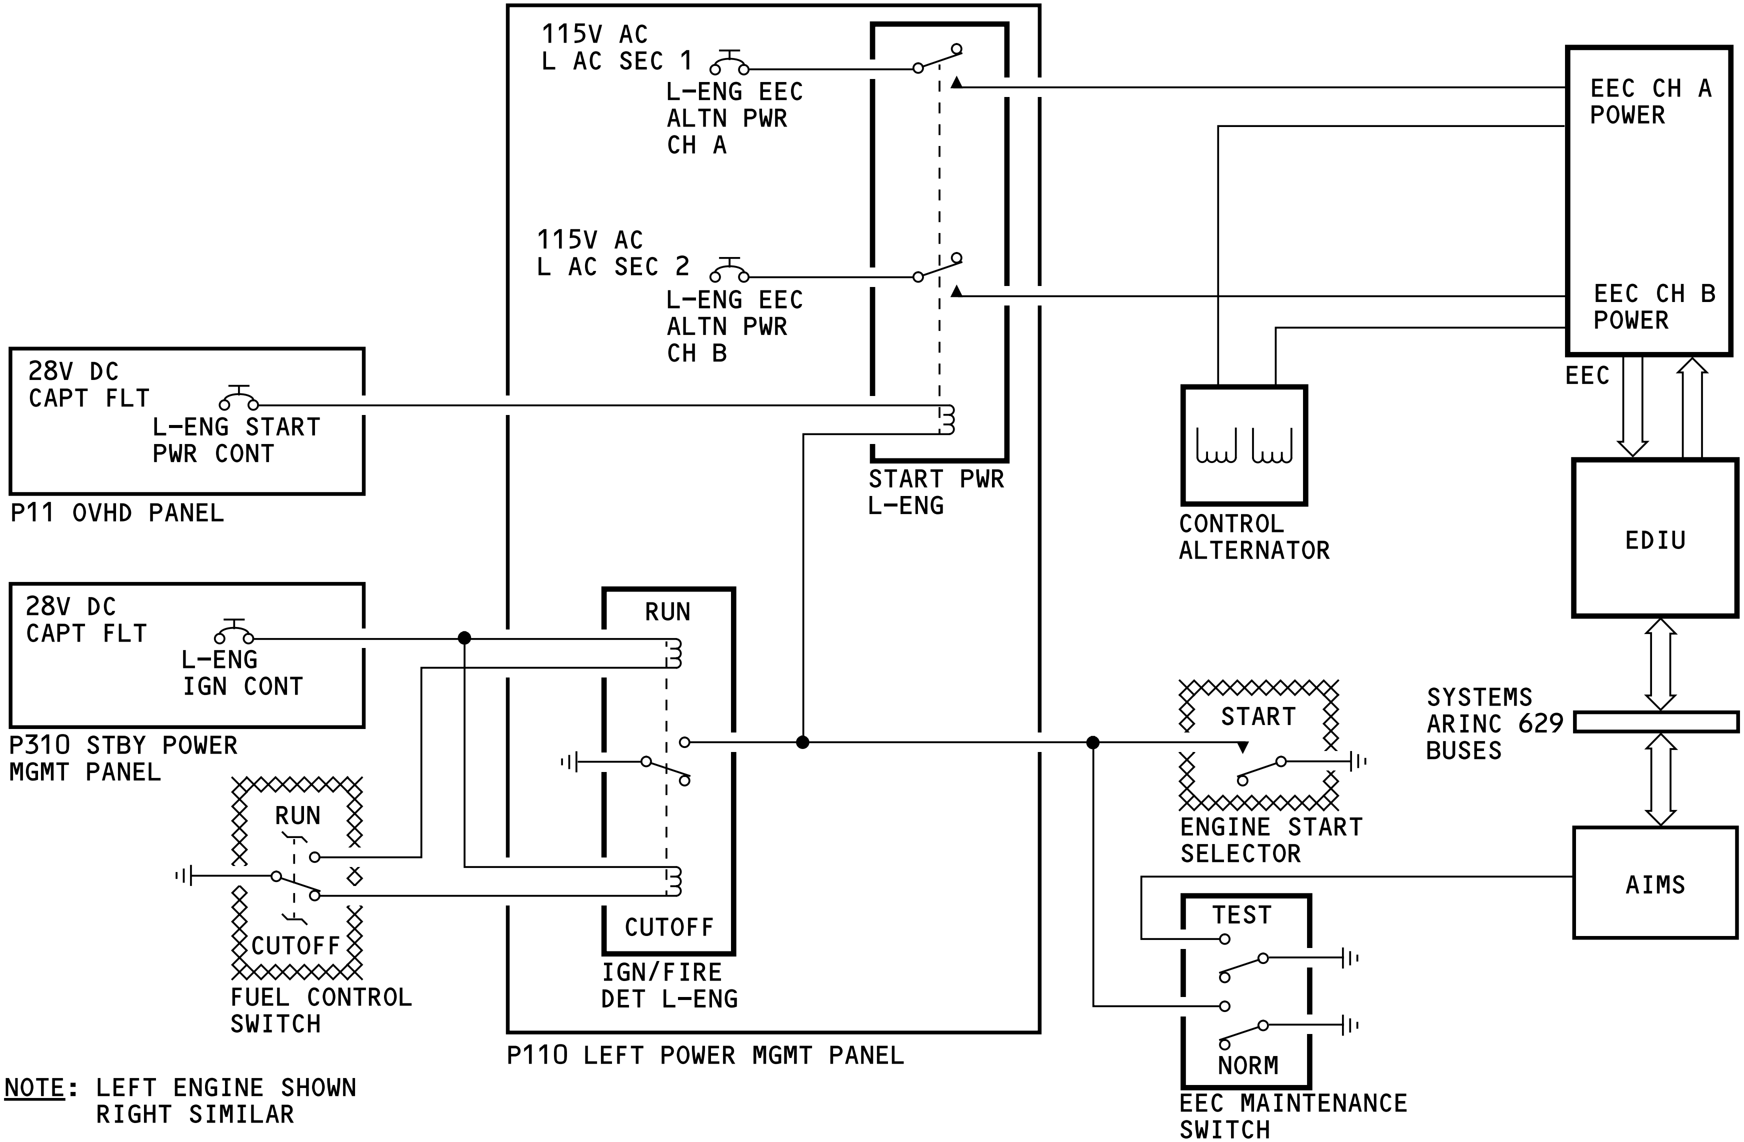
Engine Start/Ignition Selector

The engine start/ignition selector supplies a ground for the start power relay when it is in the START position. This gives the EEC power during engine starts.

EEC Maintenance Switch

The EEC maintenance switch supplies a ground for the start power relay when it is in the TEST position. This gives the EEC power during tests and maintenance operations.

The AIMS sends the position of the switch to the EEC.



NOTE: LEFT ENGINE SHOWN

ENGINE FUEL CONTROL - CONTROL - EEC POWER MANAGEMENT - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE FUEL CONTROL - OPERATION

Controls

You operate the engine fuel and control system with these flight deck controls:

- EEC maintenance switch
- EEC mode switch
- Thrust lever
- Fuel control switch
- Fire switch.

EEC Maintenance Switch

The EEC maintenance switch is on the P61 overhead maintenance panel. The switch is a two-position, guarded, toggle switch.

When the switch is in the NORM position, it permits power to go from normal operating power sources to the EEC. When the switch is in the TEST position, it connects airplane ac power to the EEC without starting any EEC control logic. It also sends a ground test discrete signal to the AIMS.

EEC Mode Switch

The EEC mode switch is on the engine start/ignition panel on the P5 overhead panel. The switch is a two-position, guarded, alternate-action switch.

The switch permits the pilots to set the EEC control mode. You should always operate the engines in the same control mode.

CAUTION: DO NOT MOVE THE EEC MODE SWITCH FROM NORM TO ALTN WHEN THE ENGINE IS OPERATING AT HIGH POWER. THE ENGINE MAY OVERBOOST IF YOU DO.

Normal Mode (N1)

The normal position of the EEC mode switch is in. When the switch is in, the EEC is in normal mode (NORM). In normal mode, the EEC uses N1 corrected for inlet temperature as the main thrust parameter.

You can put the thrust levers at specified positions to set thrust ratings. When the thrust levers are all the way forward, the engine is at takeoff thrust or maximum continuous thrust. The maximum climb and cruise thrust ratings are set at thrust lever positions less than all the way forward.

Alternate Mode (N1)

The non-normal position of the EEC mode switch is out. When the switch is out, the EEC is in alternate mode (ALTN). In alternate mode, the EEC uses N1 and a TLA schedule to control the engine thrust.

In alternate mode with the thrust levers at a specific position, the thrust changes as the flight condition changes. This requires adjustment of the thrust levers as the airplane flies in order to keep the correct thrust.

The EEC turns on the ALTN light on the EEC mode switch if it does not get the aircraft total pressure signal.

ENGINE FUEL CONTROL - OPERATION

Then, you must put the switch in the ALTN position to put the EEC in alternate mode.

Thrust Lever

The thrust levers move the TLA resolvers. The resolver sends the EEC a position signal to permit it to set the proper thrust.

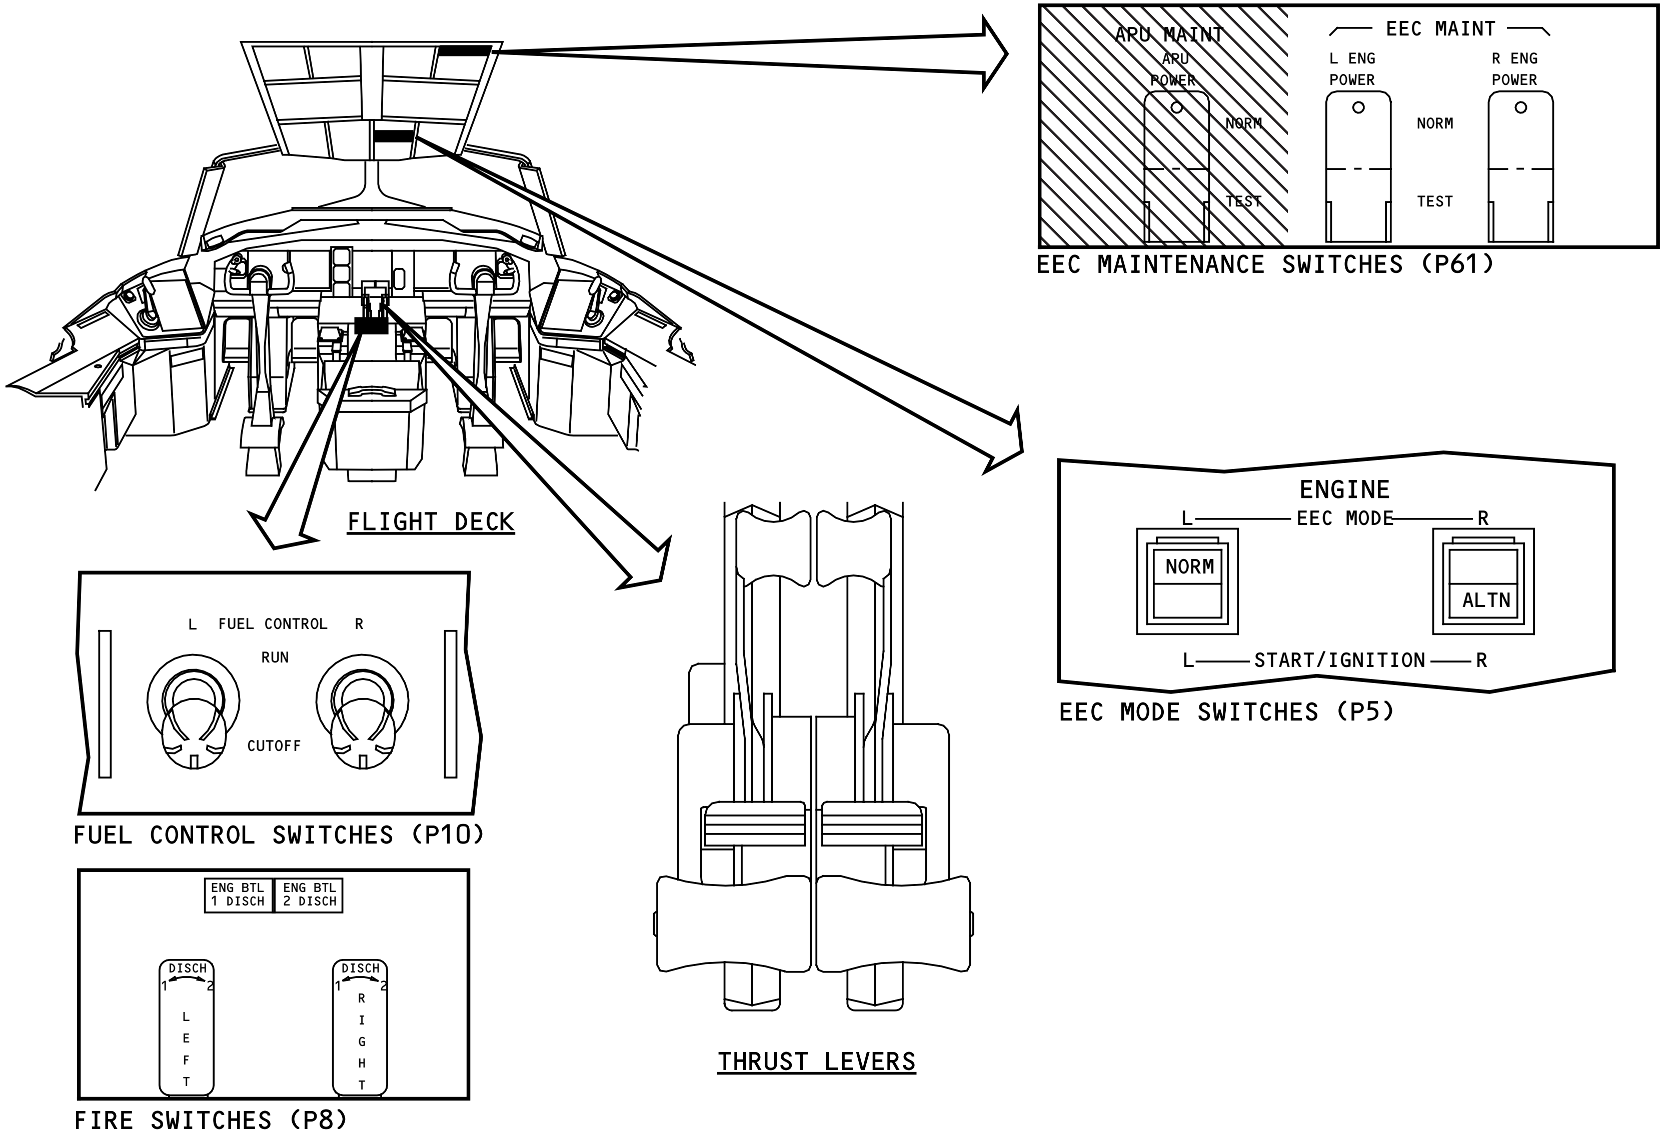
Fuel Control Switch

The fuel control switches have two positions: RUN and CUTOFF. The switches control the shutoff valve in the HMU to control fuel flow to the engine.

In addition, when you move the fuel control switch from RUN to CUTOFF, the EEC resets. This stops the EEC programs and sets them to run from the start.

Fire Switch

The fire switch permits power to go to the shutoff valve relays when the switch is in. When the switch is in the out position, power connects directly to the HMU cutoff solenoid to stop fuel flow to the engine.



ENGINE FUEL CONTROL - OPERATION

73-21-00-123 Rev 5 02/08/1997

ENGINE FUEL CONTROL - CONTROL - EEC RESET/ENGINE FUEL SHUTOFF VALVE CONTROL

General

The EEC gets a reset signal when you move the fuel control switch from the RUN to the CUTOFF position. When the EEC resets, it writes all fault data in its non-volatile memory (NVM). It also sets the engine start logic to run from the start of the program.

The fuel control switch controls relays in the P110 to open or close the engine fuel shutoff valve (SOV). The SOV gets power to open or to close. Power to operate the SOV comes from the captain's flight instrument bus.

EEC Reset Control

Each channel of the EEC gets a reset signal from a relay in the P110. When you put the fuel control switch in the CUTOFF position, the two EEC reset relays energize after a short time dalay. This energizes the cutoff coils in the reset/fuel spar relay and the EEC reset/IDG disconnect relay. The relay contacts close a circuit to the EEC, which causes the EEC to reset.

Engine Fuel Shutoff Valve Control

When the fuel control switch is in the RUN position, power goes through the generator control/ignition relay to open the SOV. When the fuel control switch is in the CUTOFF position, the generator control/ignition relay energizes to the cutoff position and then, after a short time delay, the fuel control T/D relay energizes and power goes to close the SOV.

The fire switch must be in the NORMAL position to permit power to go through the P110 to operate the SOV. When the fire switch is in the FIRE position, power to close the SOV goes directly to the SOV. It does not go through the P110.

ENGINE FUEL FLOW INDICATING - INTRODUCTION

ENGINE FUEL FLOW INDICATING - GENERAL DESCRIPTION

Purpose

The fuel flow indicating system measures the engine fuel flow rate. It also supplies the airplane with the information for indication and flight management.

Fuel Flow Transmitter

The fuel flow transmitter is on the right side of the engine at approximately the 5:00 position. Fuel flows from the HMU to the transmitter, then back to the HMU.

The transmitter does not have a motor. It sends analog pulse signals to the EEC that are in proportion to the fuel mass flow rate.

Functional Description

The EEC uses the signals from the fuel flow transmitter to calculate the fuel mass flow rate. The EEC sends this data to the AIMS.

The AIMS shows the fuel flow rate in thousands of pounds per hour, on the secondary engine display and performance maintenance page.

The flight management function of the AIMS uses the data to calculate fuel-used data. The control display unit (CDU) shows the fuel used on the CDU progress page 2.

ENGINE CONTROLS - INTRODUCTION

General

The engine controls system supplies most of the control signals the engine needs to operate. It also controls inputs to other airplane systems that require engine control status.

The engine controls system includes these components:

- Thrust levers
- Fuel control switches
- Autothrottle servo motors
- Thrust lever switches
- Microswitch pack
- Thrust lever angle (TLA) resolvers.

Abbreviations and Acronyms

AIMS	- airplane information management system
ASM	- autothrottle servo motor
ATA	- air transport association
A/T	- autothrottle
EDIU	- engine data interface unit

ENGINE CONTROLS - INTRODUCTION

ENGINE CONTROLS - GENERAL DESCRIPTION

General

The engine controls system supplies manual and automatic control inputs to operate the engine. You use the thrust levers and fuel control switches to supply the manual inputs. The AIMS supplies the automatic inputs.

Thrust Control

The thrust levers supply thrust command signals to the electronic engine controls (EEC) through the TLA resolvers. Each thrust lever mechanically connects to a TLA resolver. When the thrust lever moves, it turns the TLA resolver. The EEC supplies power to excite the TLA resolver and reads the position of the resolver.

The thrust management function of the AIMS supplies automatic thrust command signals to the EEC with the TLA resolver. To do this, it turns the TLA resolver (and thrust lever) with the autothrottle servo motor (ASM). The ASM turns a brake that connects to the thrust lever and TLA resolver. See the autoflight chapter for more information on the ASM control (AMM PART I 22).

Fuel Control Switches

The fuel control switches control relays in the electrical load management system (ELMS). The relays control the start and stop functions of the engine.

Thrust Lever Switches

These are the thrust lever switches:

- Takeoff/Go-around (TO/GA)
- Autothrottle (A/T) disconnect
- Thrust reverser (T/R) sync lock control valve.

See the autoflight chapter for more information on the TO/GA and A/T disconnect switches (AMM PART I 22).

See the engine exhaust chapter for more information on the T/R sync lock control valve switch (AMM PART I 78).

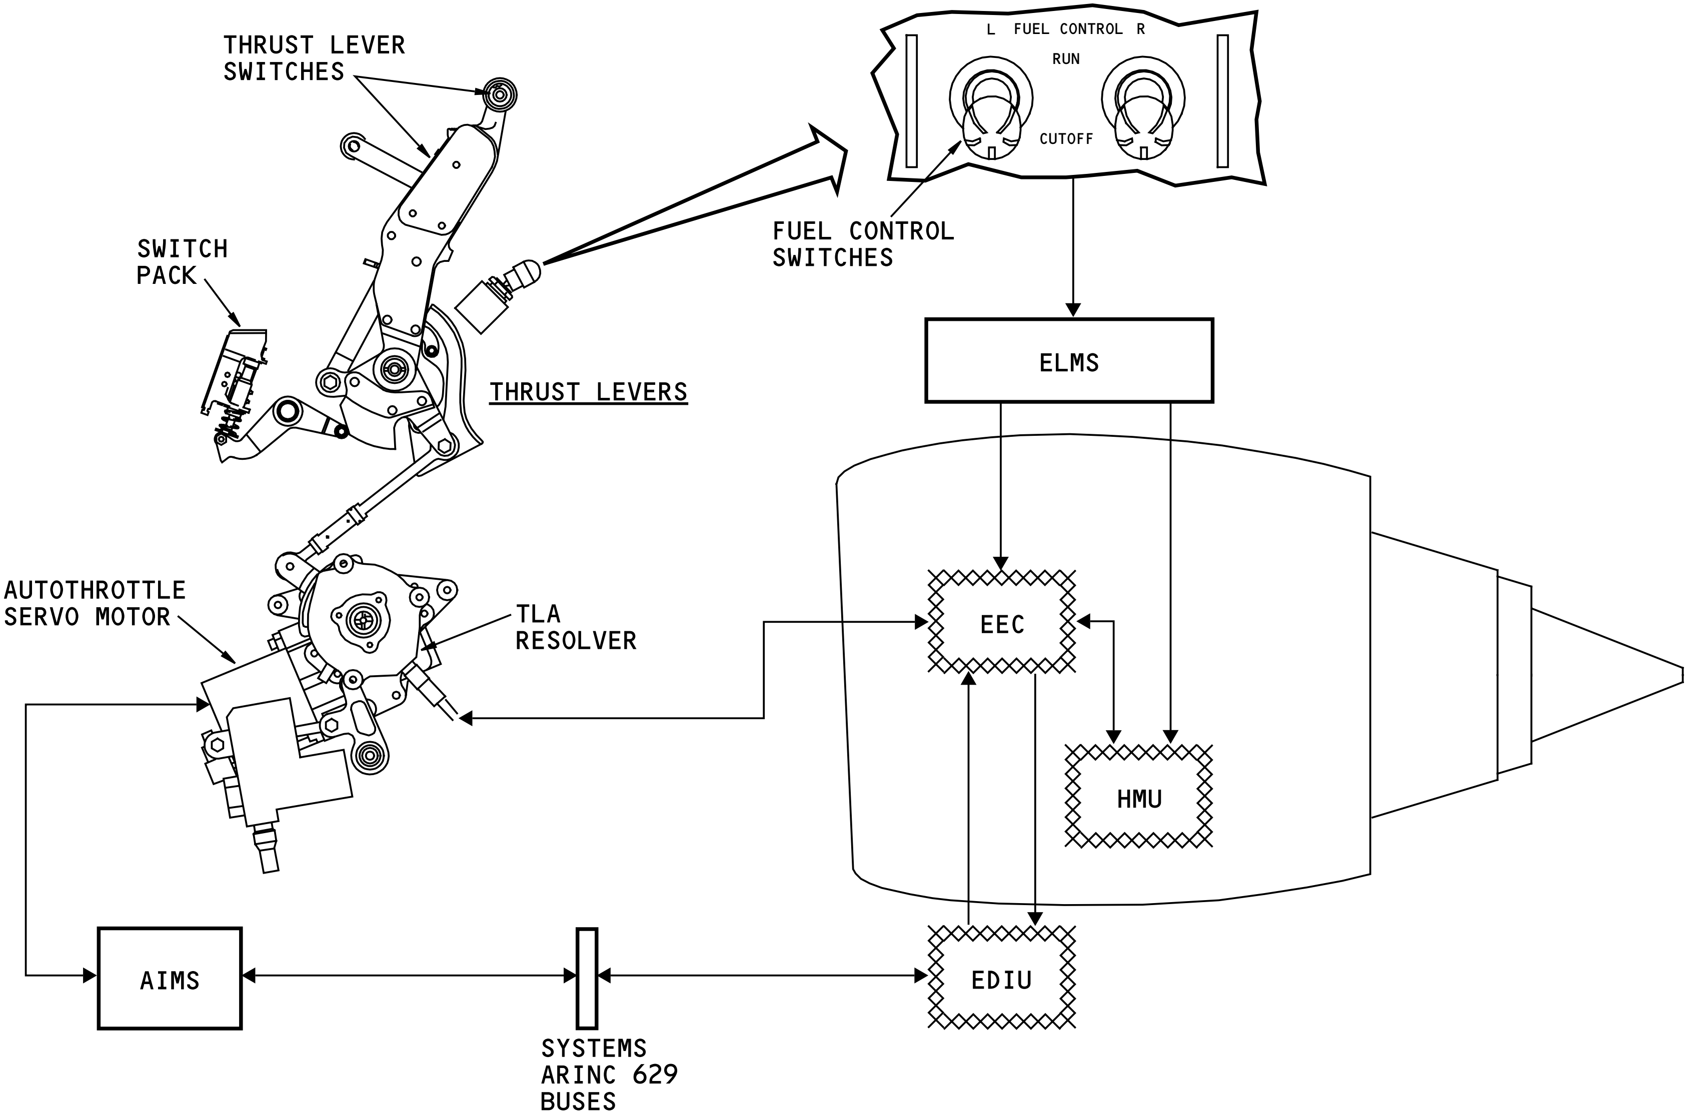
Switch Pack Switches

These are the switch pack switches:

- T/R directional control valve
- Autobrake inhibit.

See the engine exhaust chapter for more information on the T/R directional control valve pack switch (AMM PART I 78).

See the landing gear chapter for more information on the autobrake inhibit pack switch (AMM PART I 32).



ENGINE CONTROLS - GENERAL DESCRIPTION

76-00-00-102 Rev 3

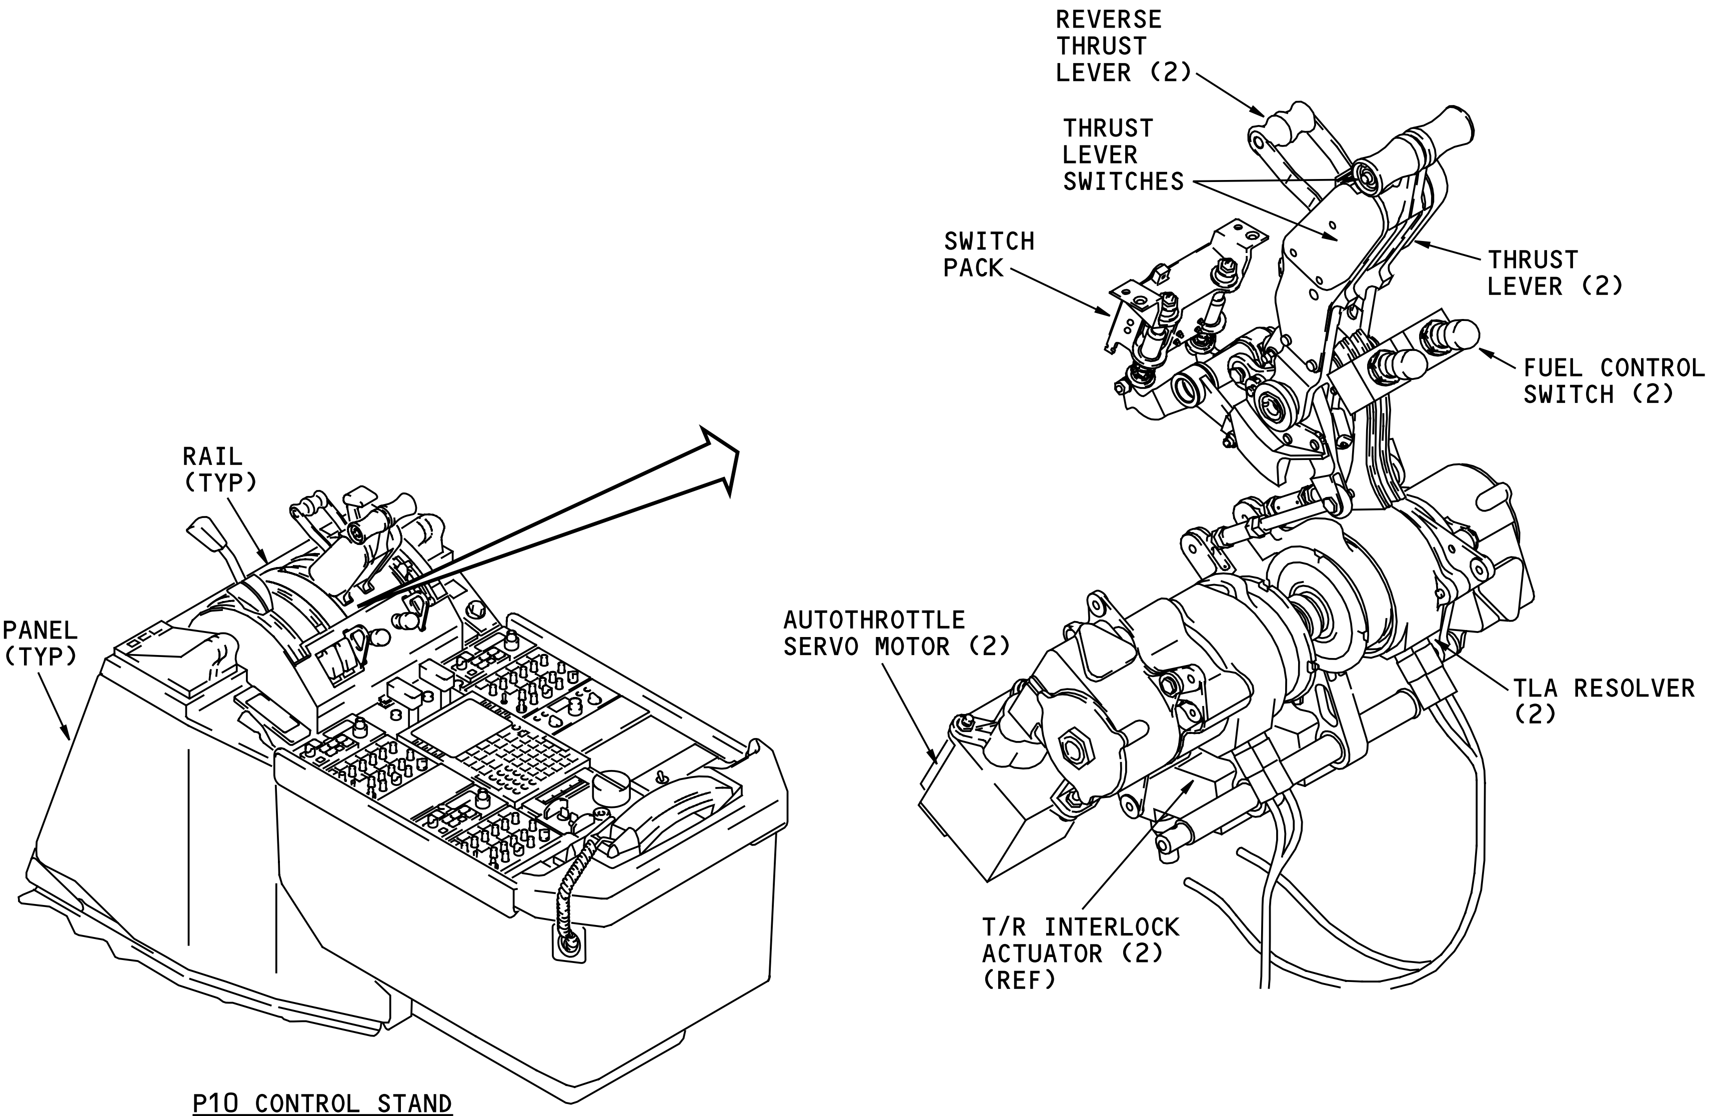
ENGINE CONTROLS - COMPONENT LOCATIONS

General

All of the engine controls components are at the P10 control stand in the flight deck. You get access to the components by removing panels, rails, or covers. These are the components:

- Switch pack
- Thrust lever switches
- Thrust levers
- Fuel control switches
- TLA resolvers
- Autothrottle servo motors.

See the autoflight chapter for more information on the autothrottle servo motors (AMM PART I 22).



76-00-00-103 Rev 1

ENGINE CONTROLS - COMPONENT LOCATIONS

ENGINE CONTROLS - SWITCHES - COMPONENT LOCATIONS

General

The thrust levers contain removable control switches. You remove covers to get access to the switches.

Thrust Lever Switches

Four switches attach to the sides of each thrust lever. The TO/GA switches are on the outboard side. The T/R sync lock switch is on the inboard side. The TO/GA trigger moves the TO/GA switches. The reverse thrust lever moves the T/R sync lock switch.

The A/T disconnect switch is in the handle of the forward thrust lever.

Microswitch Pack

The microswitch pack is in the forward part of the control stand. It contains six switches. Each thrust lever moves a plunger in the switchpack to operate three of the switches. You can remove and install the pack as an assembly or replace an individual switch. You must use a soldering iron to replace an individual switch. These are the switches:

- S1 - autobrake inhibit left 1
- S2 - autobrake inhibit left 2
- S3 - autobrake inhibit right 1
- S4 - autobrake inhibit right 2
- S5 - T/R directional control solenoid valve left
- S6 - T/R directional control solenoid valve right.

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE CONTROLS - THRUST LEVER & AUTOTHROTTLE ASSEMBLY - FUNCTIONAL DESCRIPTION

General

The thrust lever and autothrottle assembly work together to supply thrust commands to the EEC. You use the thrust levers to make manual inputs. The autothrottle servo motor (ASM) makes automatic inputs.

Thrust Lever

The thrust lever is one assembly with many pieces. These pieces mechanically transmit the thrust lever commands to the autothrottle assembly:

- Reverse thrust lever
- Forward thrust lever
- Thrust lever crank
- Lever latch
- Control rod.

When you move the forward thrust lever, the force goes through the reverse thrust lever down to the thrust lever crank. The forward thrust lever and crank turn on the same shaft, but only connect together with the reverse thrust lever. The crank connects to the ASM brake with the control rod. The ASM brake turns the rotor of the TLA resolver. The resolver sends a thrust resolver angle (TRA) signal to the EEC.

When the forward thrust lever is not at idle, the lever latch holds the reverse thrust lever down. When the forward thrust lever is at idle, you can raise the reverse thrust lever. When the reverse thrust lever is up, the latch holds the forward thrust lever at idle.

Autothrottle Assembly

These are the four components of the autothrottle (A/T) assembly:

- ASM
- ASM gearbox
- TLA resolver
- ASM brake.

The ASM turns a shaft in the A/T assembly through the ASM gearbox. When the shaft turns, it turns the ASM brake. The ASM brake turns the rotor of the TLA resolver and, at the same time moves the thrust lever.

ASM Brake

The ASM brake is a spring-loaded clutch assembly. These are its functions:

- Mechanical connection to the thrust lever
- Friction source for the thrust lever
- Mechanical connection to the TLA resolver
- Mechanical connection to the A/T assembly shaft
- T/R control interface.

The ASM brake connects to the A/T assembly shaft with a clutch. This permits you to manually override ASM inputs.

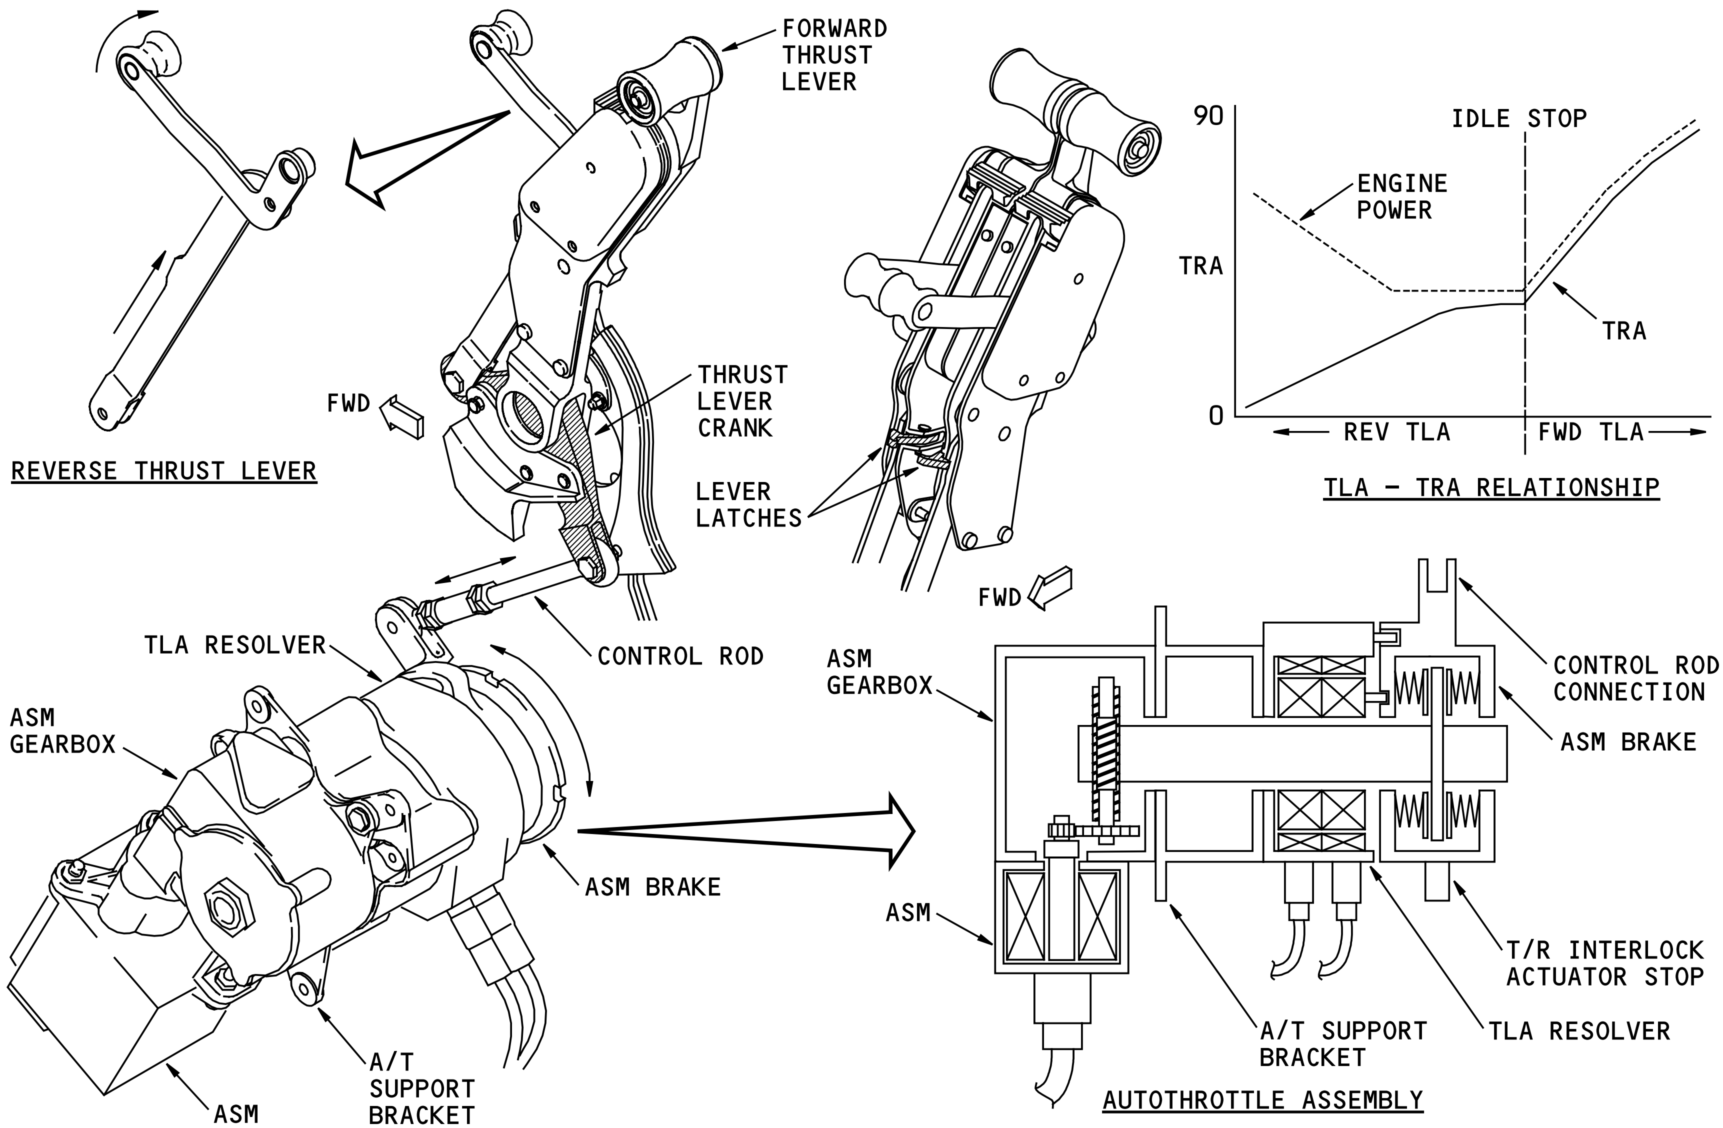
The T/R interlock actuator (not shown) keeps the ASM brake from turning beyond reverse idle until the thrust reverser deploys.

TLA-TRA Relationship

When the thrust lever is at idle, the TRA is approximately 34 degrees. As you move the thrust lever forward, the forward TLA increases. At full forward TLA, the TRA is approximately 85 degrees.

When you raise the reverse thrust lever, the reverse TLA increases. At full reverse TLA, the TRA is approximately 5 degrees. The flat spot in the reverse TRA curve is where the reverse thrust lever closes reverser control switches without increasing engine power.

Engine power increases between approximately 34 and 85 degrees TRA in forward thrust. Engine power increases between approximately 24 and 5 degrees TRA in reverse thrust.



ENGINE CONTROLS - THRUST LEVER & AUTOTHROTTLE ASSEMBLY - FUNCTIONAL DESCRIPTION

ENGINE CONTROLS - TLA RESOLVER

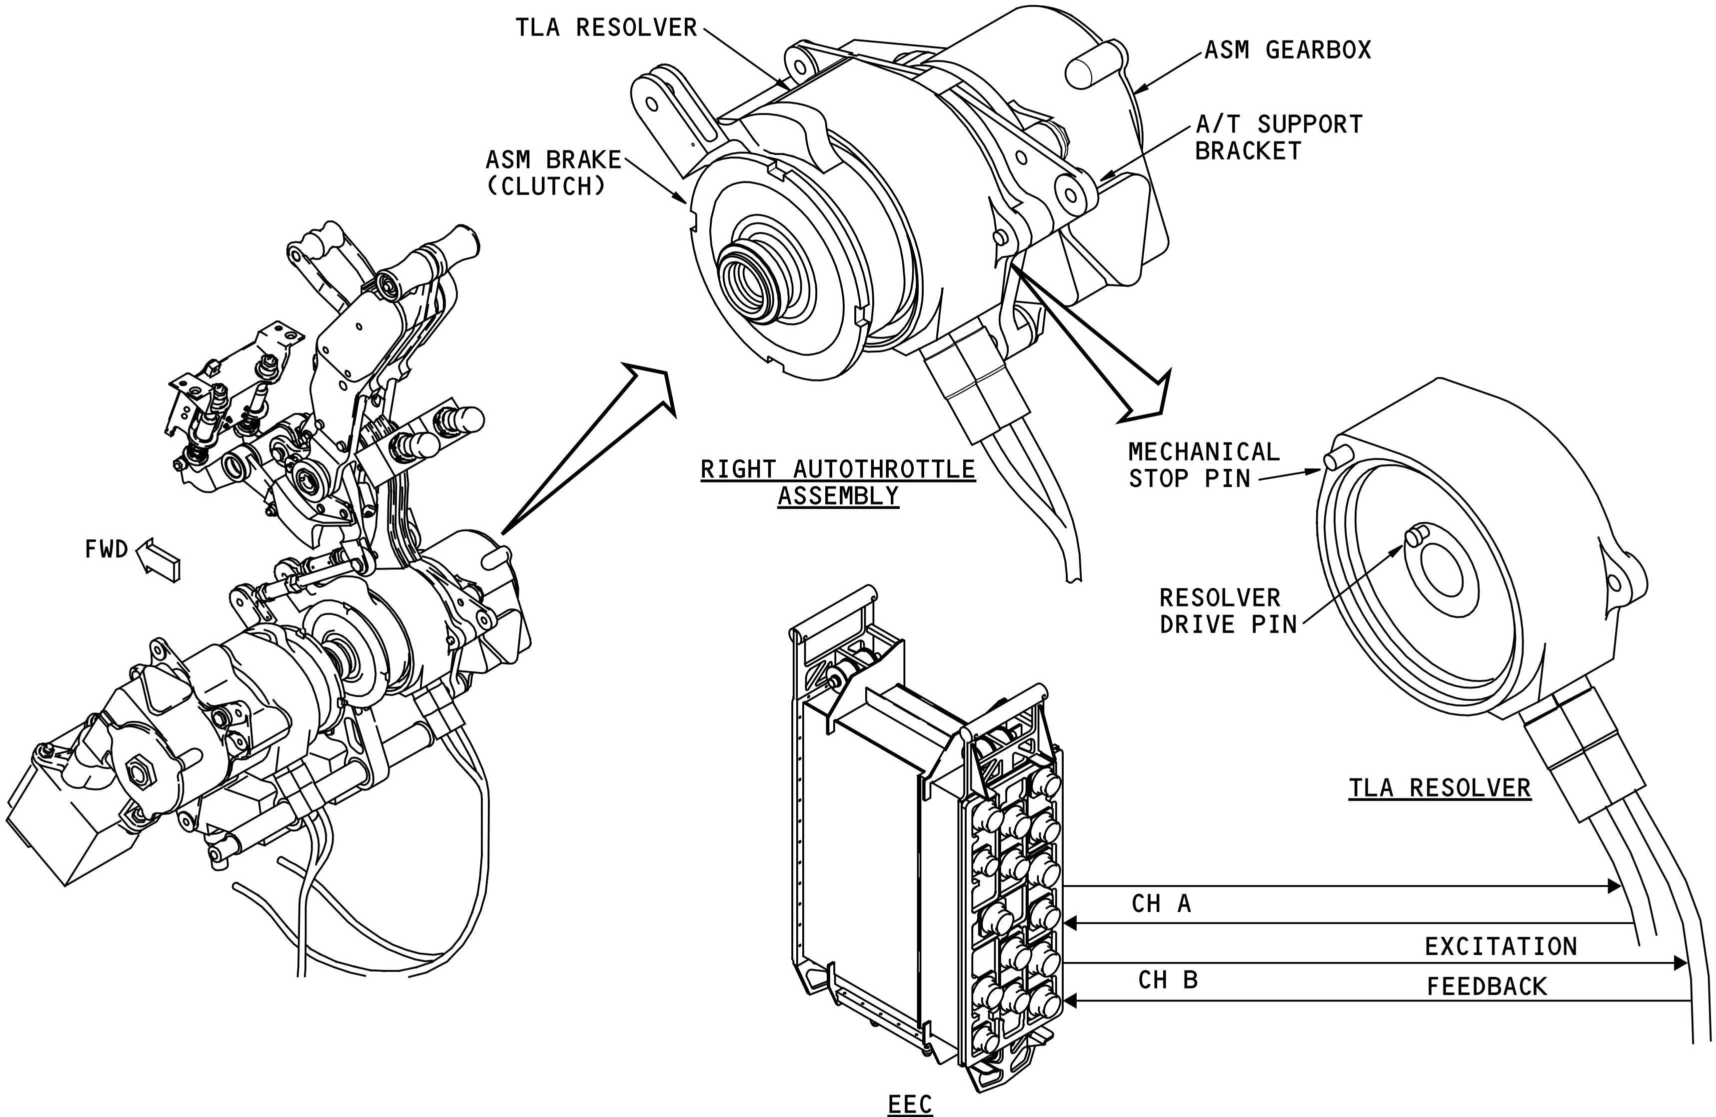
General

There is one TLA resolver for each engine. The resolver supplies the EEC with an electrical signal in proportion to the thrust lever angular position.

Functional Description

The TLA resolver has two elements. Each channel of the EEC supplies a low-voltage, ac excitation signal to one element of the resolver. The feedback signal from the resolver to the EEC is in proportion to the thrust lever angular position.

The ASM brake turns the resolver with the resolver drive pin. The mechanical stop pin prevents too much ASM brake movement that can damage the resolver.



76-00-00-106 Rev 2

ENGINE CONTROLS - TLA RESOLVER

ENGINE CONTROLS - FUEL CONTROL SWITCHES - FUNCTIONAL DESCRIPTION

General

Each fuel control switch controls a set of four relays in the ELMS. The relays control many functions. These are the relays:

- A: reset/fuel spar
- B: ignition/fire detection
- C: generator control/ignition
- D: EEC reset/IDG disconnect.

One electrical source supplies power to both coils of each relay. Each position of the fuel control switch supplies a ground for one coil of each relay.

A: Reset/Fuel Spar Relay

The reset/fuel spar relay controls these functions:

- Fuel control switch position signal to the AIMS
- EEC channel A reset signal
- Fuel control switch position signal to the ELMS
- Fuel spar valve control.

B: Ignition/Fire Detection Relay

The ignition/fire detection relay controls these functions:

- EEC power control
- Fuel control switch position signal to the engine data interface unit (EDIU)
- Ignition 1 power
- Fire switch lockout control.

C: Generator Control/Ignition Relay

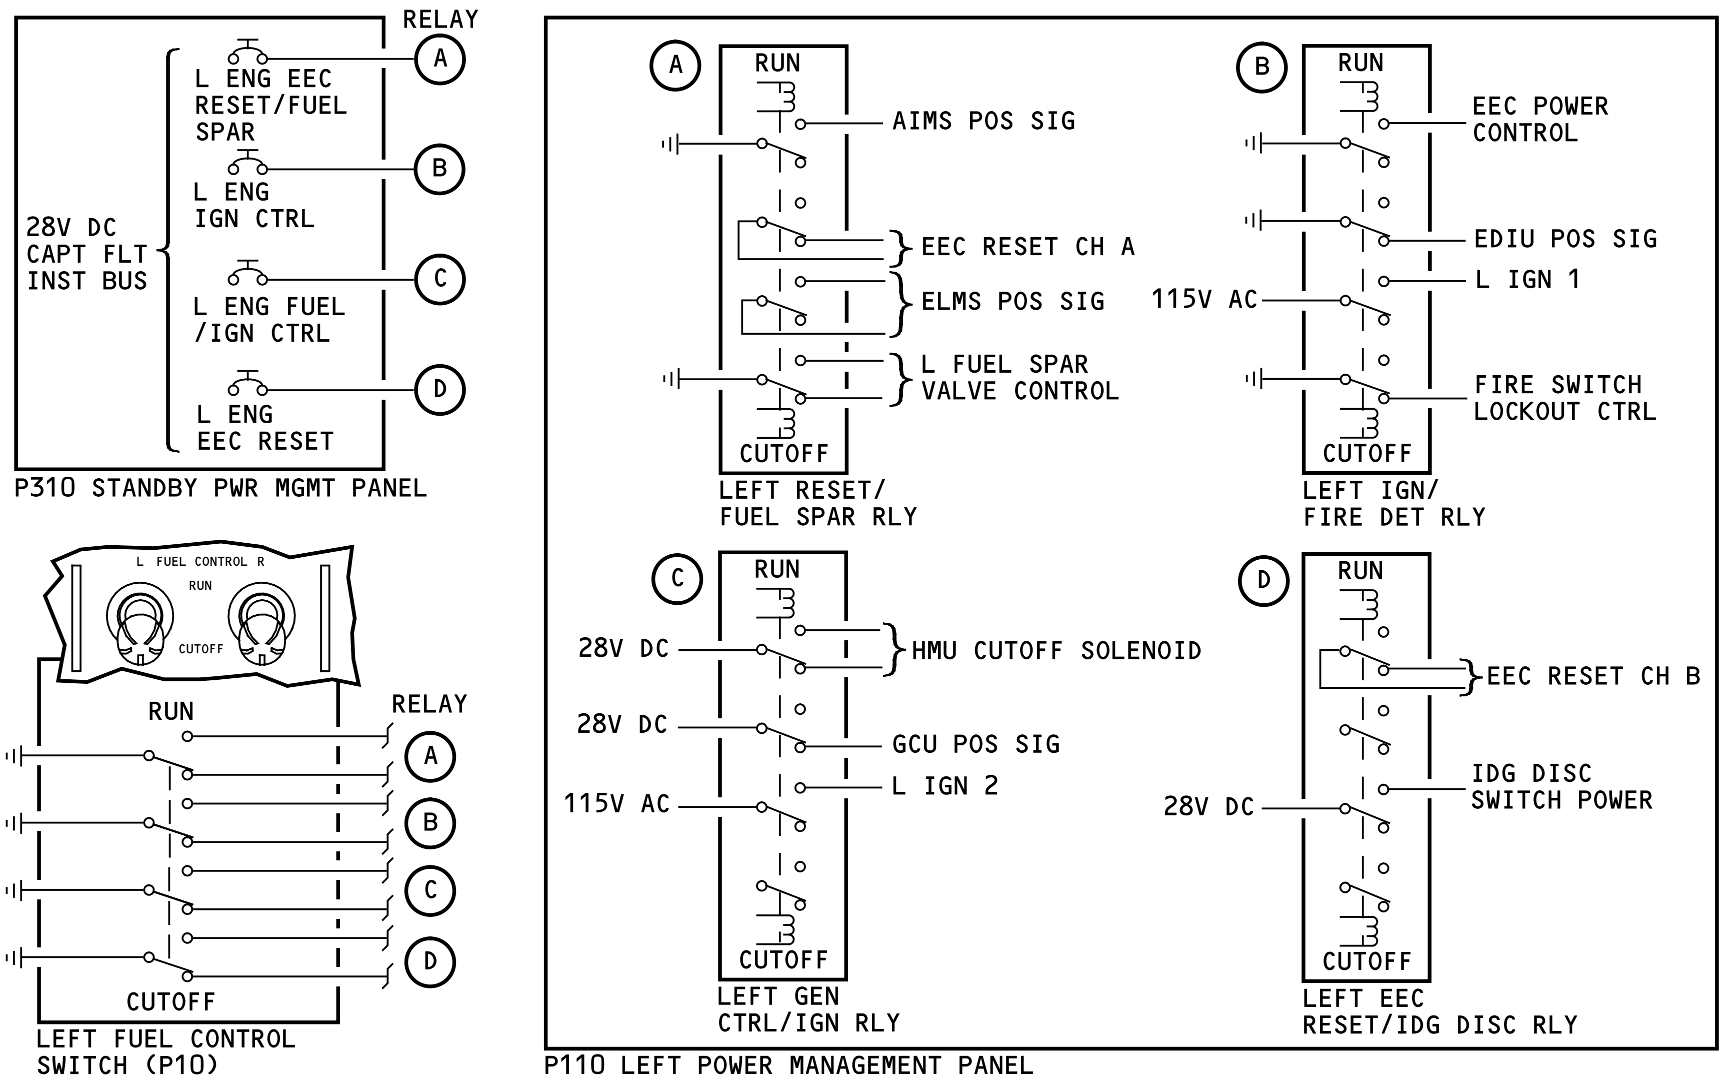
The generator control/ignition relay controls these functions:

- Hydromechanical unit (HMU) cutoff solenoid power
- Fuel control switch position signal to the generator control unit (GCU)
- Ignition 2 power.

D: EEC Reset/IDG Disconnect Relay

The EEC reset/IDG disconnect relay controls these functions:

- EEC channel B reset signal
- IDG disconnect switch power.



NOTE: LEFT SYSTEM SHOWN,

ENGINE CONTROLS - FUEL CONTROL SWITCHES - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE CONTROLS - OPERATION

Controls

You use many flight deck controls and displays with the engine controls system to operate the engine. These are the controls and displays and the ATA chapters where you find the details on them:

- Thrust levers (76)
- Fuel control switches (76)
- EEC maintenance switches (73)
- EEC mode switches (73)
- Start/Ignition switches (74,80)
- Autostart switch (80)
- Fire switches (26)
- EICAS display (77)
- Multi-function display (MFD) (73,75,76,77,78,79,80).

Thrust Lever (76)

Each thrust lever mechanically moves its TLA resolver. The resolver sends the EEC a signal in proportion to the angular position of the thrust lever. This permits the EEC to set the proper thrust.

Fuel Control Switch (76)

Each fuel control switch has two positions; RUN and CUTOFF. In RUN, the switch controls the HMU to open the engine fuel shutoff valve. In CUTOFF, the switch controls the HMU to close the valve.

In addition, when you move the fuel control switch from RUN to CUTOFF, the EEC resets. This stops the software programs in the EEC and sets them to run from the start.

EEC Maintenance Switch (73)

Each EEC maintenance switch has two positions; NORM and TEST. In NORM, the switch lets EEC power come from normal operating power sources. In TEST, the switch connects airplane ac power to the EEC without starting any EEC control logic.

EEC Mode Switch (73)

Each EEC mode switch lets the pilots set the EEC control mode: normal or alternate. You should always operate both engines in the same control mode.

Start/Ignition Switches (74,80)

You use the start/ignition switch to begin the start of the engine. It also lets you select continuous ignition on the engine.

Autostart Switch (80)

The autostart switch permits the EEC to automatically control engine starts.

ENGINE CONTROLS - OPERATION

Fire Switch (26)

The fire switch permits fuel control power to go to the hydromechanical unit (HMU) when the switch is in its normal position (in). If the switch is pulled out, power connects directly to the HMU cutoff solenoid to stop fuel flow to the engine.

EICAS Display (77)

The EICAS display shows the primary engine indications. These are N1 and EGT.

Multi-Function Display (MFD) (73,75,76,77,78,79,80)

Many different MFDs show data that relates to engine controls. These are those MFDs:

ENGINE CONTROLS - OPERATION

Thrust Lever Check

You measure the force to move the thrust levers to make sure they are within limits. To move the reverse thrust lever, you must disconnect the T/R interlock actuator rod end from the thrust lever assembly.

TLA Resolver Adjustment

Each thrust lever connects to an ASM brake with an adjustable control rod. The ASM brake turns the TLA resolver. You adjust the length of the control rod to change the relationship between the thrust lever position and the resolver position. You make the adjustment with either portable ground support equipment (GSE) or with onboard equipment.

Adjustment - GSE

The most accurate method of adjustment for the TLA resolver is to use special GSE to:

- Measure the thrust lever position
- Excite the resolver
- Read the resolver angle.

With the thrust lever at idle, you turn the turnbarrel to change the length of the control rod to get the correct resolver angle. Jam nuts and safety wire hold the turnbarrel in position.

To make sure the adjustment is correct, you move the thrust lever to its full-forward position and back to idle. Read the resolver angle again. It should agree with the first number. You also check the resolver angle at the thrust lever positions of full-forward and full-reverse.

Adjustment - Onboard

You can adjust the resolver using airplane equipment. You supply the EEC with airplane power and read the TLA resolver angle (thrust resolver angle - TRA) on the electronic propulsion control system (EPCS) maintenance page 1.

ENGINE INDICATING - COMPONENT LOCATIONS - LEFT SIDE

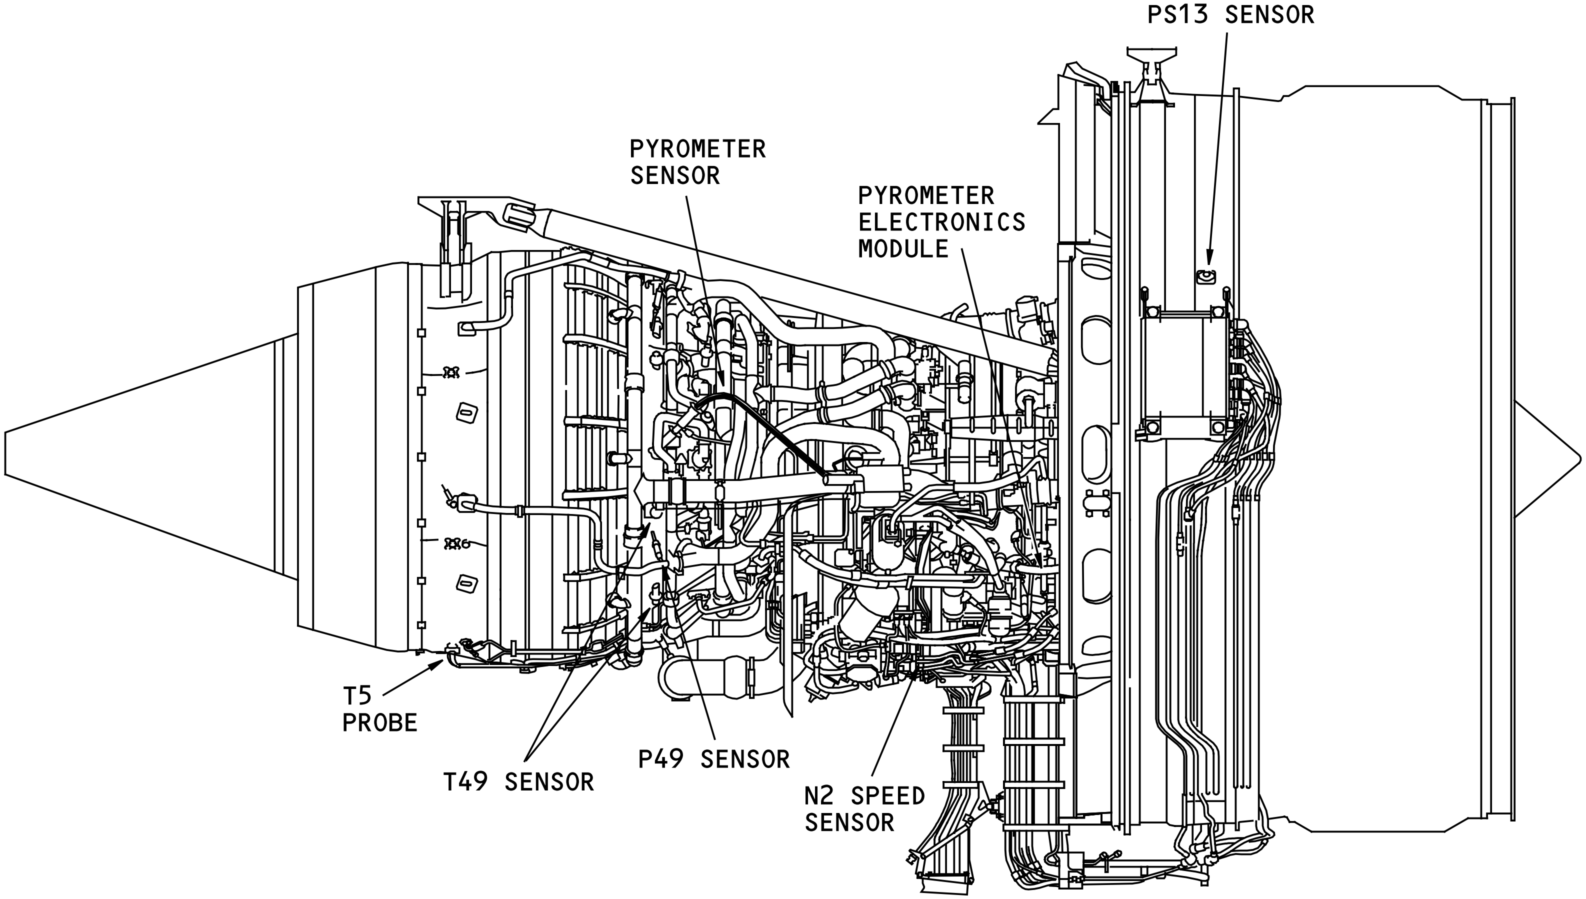
ENGINE INDICATING - COMPONENT LOCATIONS - RIGHT SIDE

General

These engine indicating components are on the right side of the engine:

- Pyrometer (sensor and electronics module)
- PS13 sensor
- N2 speed sensor
- P49 sensor
- T49 sensor
- T5 probe.



ENGINE - RIGHT SIDE

ENGINE INDICATING - COMPONENT LOCATIONS - RIGHT SIDE

ENGINE INDICATING - ENGINE TACHOMETER - GENERAL DESCRIPTION

Purpose

The engine tachometer system supplies N1 and N2 signals to engine and airplane systems. The engine and airplane systems use N1 and N2 for control, indication, and monitoring.

General Description

The N1 and N2 speed sensors each send three analog speed signals. Two signals from each sensor go to the EEC channels A and B.

The EEC changes the analog speed data into ARINC 429 digital data. The EDIU receives the digital data and sends ARINC 629 data to the AIMS.

The N1 speed sensor also sends analog signals to the AIMS, the AVM signal conditioner, and the EDIU. The N2 speed sensor sends analog signals to the AIMS and the AVM signal conditioner.

The AIMS uses the analog speed signals when there is no digital engine speed data.

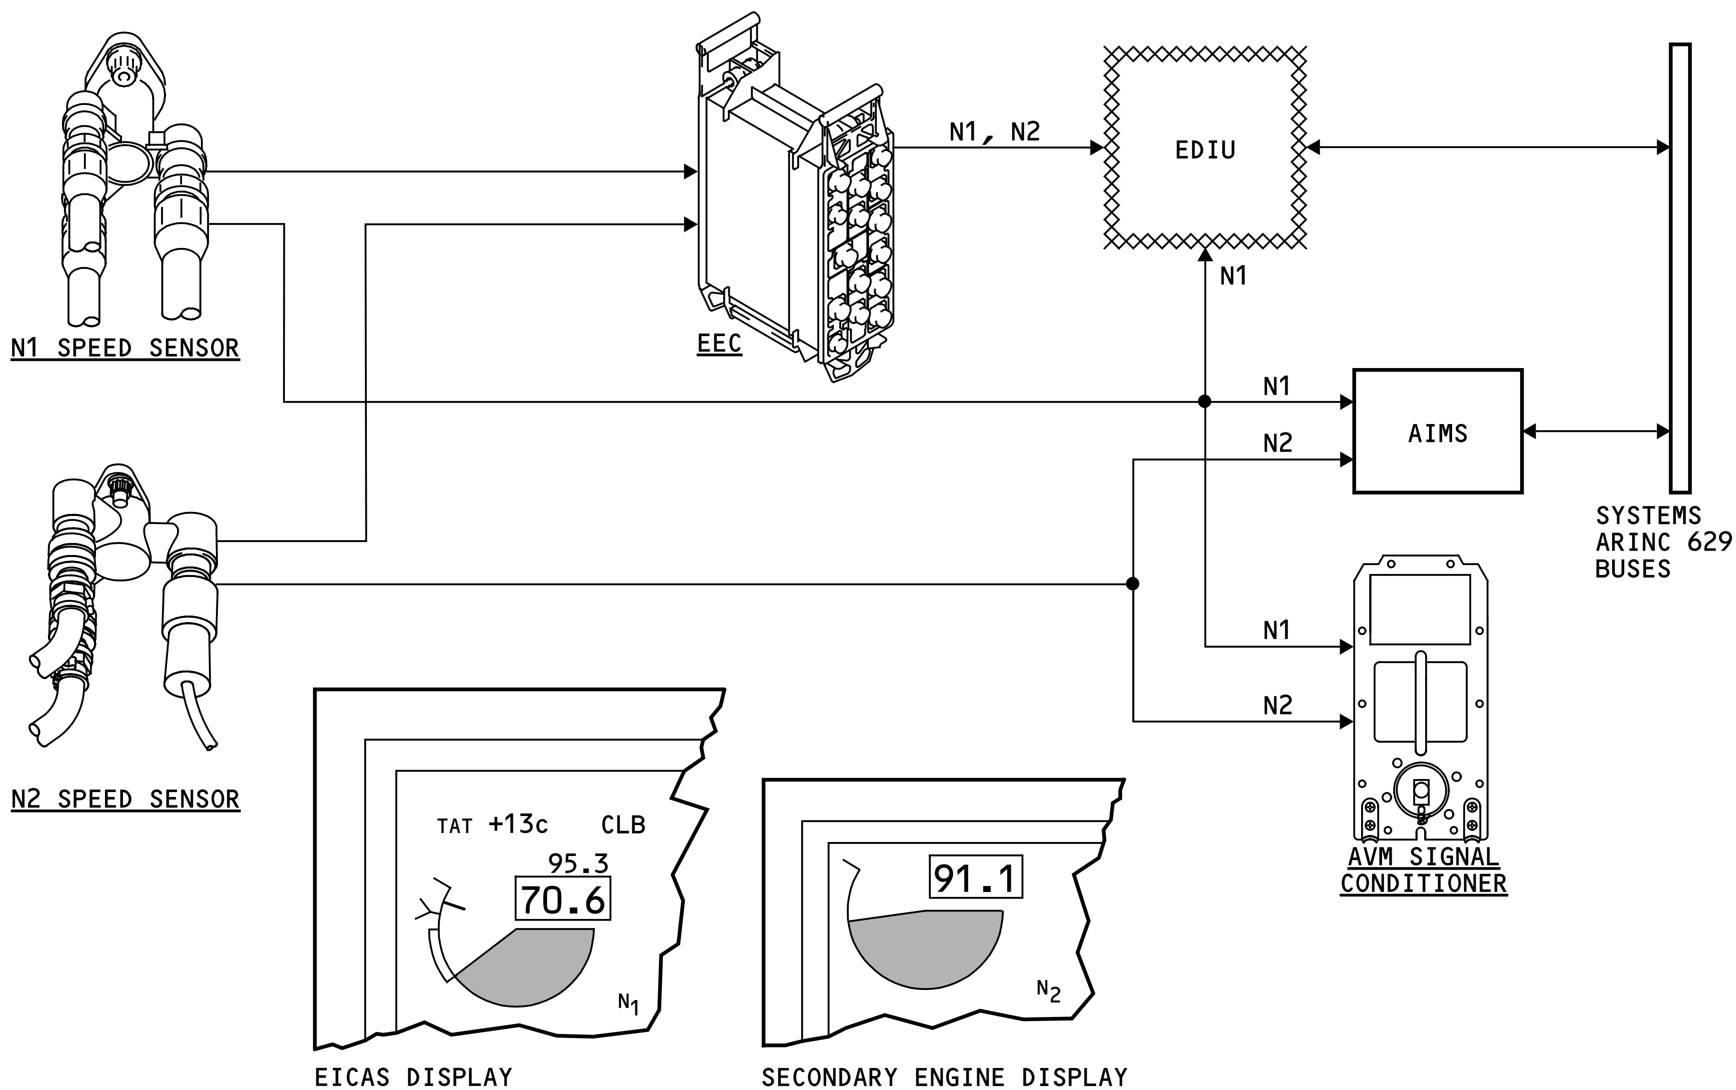
The AVM signal conditioner uses the analog speed signals in its vibration calculations.

The EDIU uses the analog N1 signal for thrust asymmetry compensation (TAC).

See the rudder control section for more information on the TAC (AMM PART I 27-21).

Indication

The EICAS display and the secondary engine display show N1 and N2 data. The data also shows on the performance maintenance page. Percent rpm are the units for the data.



ENGINE INDICATING - ENGINE TACHOMETER - GENERAL DESCRIPTION

ENGINE INDICATING - ENGINE TACHOMETER - N1 SPEED SENSOR

General

The N1 speed sensor uses signal pulses to measure N1 rotor speed.

The N1 sensor is at the 8:30 position on the fan hub frame aft side. You get access to the sensor with the left T/R half open.

Physical Description

The N1 sensor has a rigid probe that goes inside the fan hub frame. The outer end of the probe has three electrical connectors. Two bolts hold the sensor on the fan hub frame.

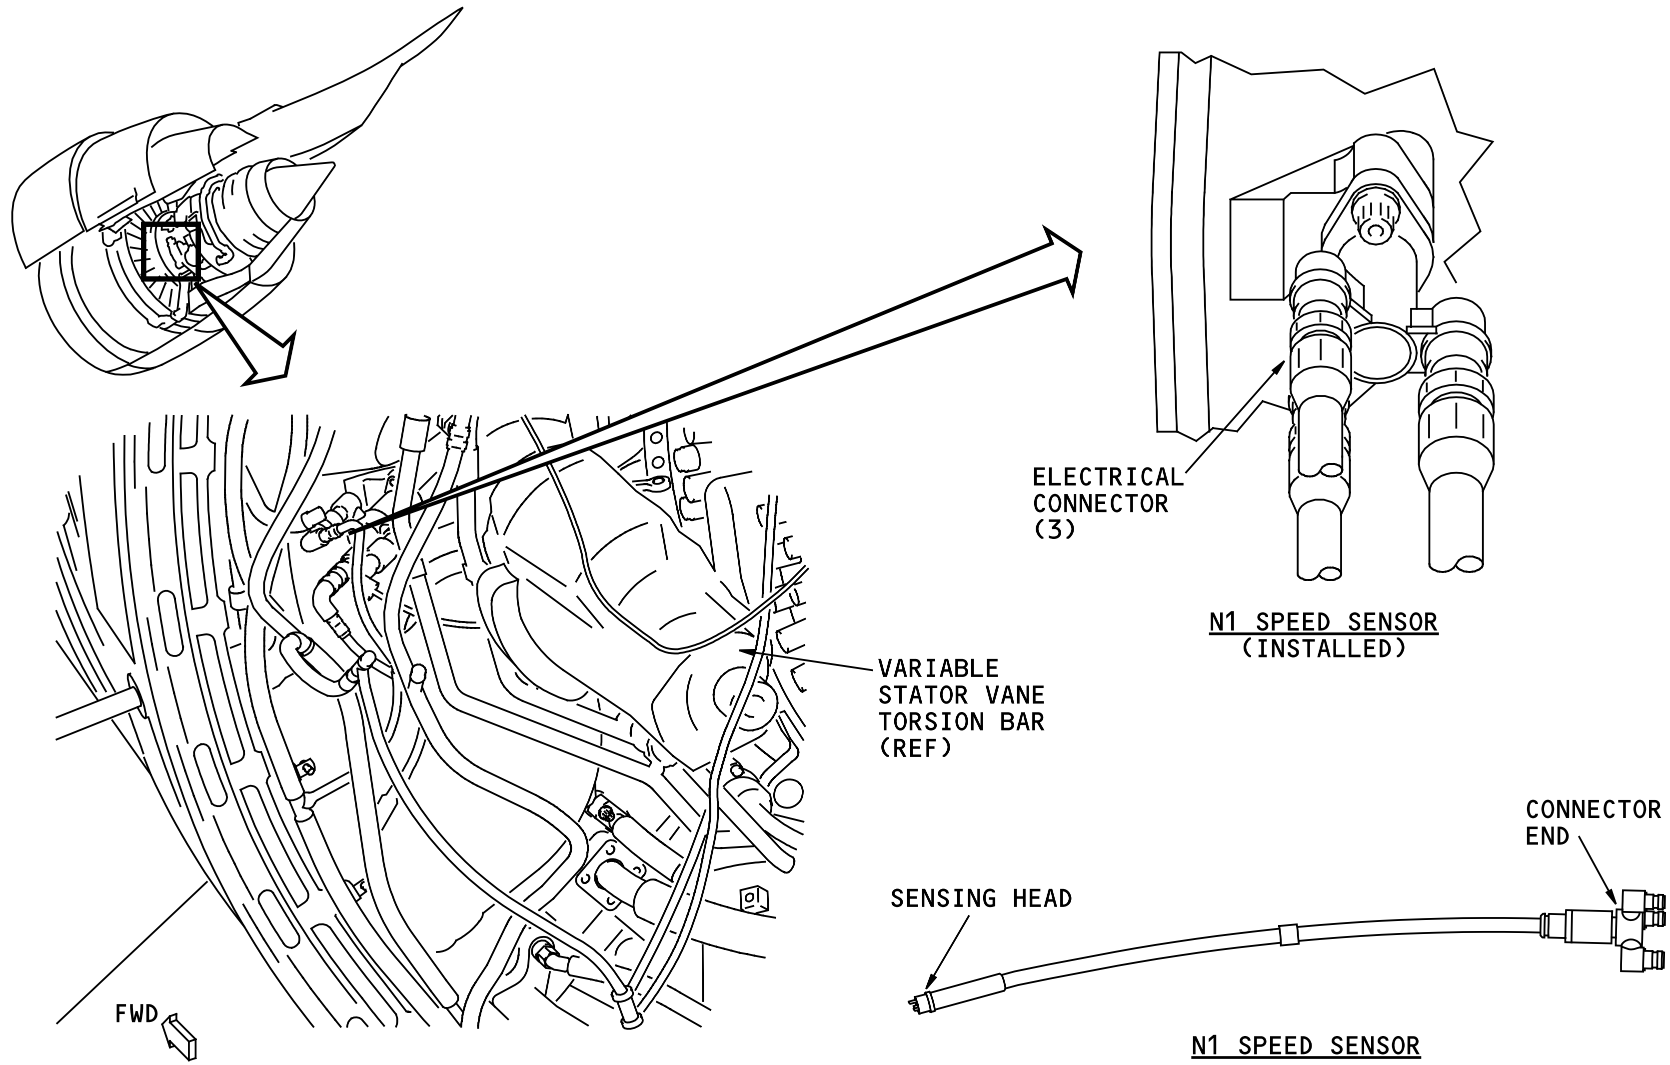
Functional Description

A sensing head on the inner end of the probe is near a wheel with teeth on the N1 shaft. The speed sensor receives electromagnetic pulses from the teeth as they go by the sensing head.

Training Information Point

The N1 speed sensor is about 2 feet (600 mm) long. You should be careful when you remove or install the sensor.

When you remove the N1 speed sensor, approximately one cup of oil comes out.



77-12-00-102 Rev 3 12/19/95

ENGINE INDICATING - ENGINE TACHOMETER - N1 SPEED SENSOR

ENGINE INDICATING - ENGINE TACHOMETER - N2 SPEED SENSOR

General

The N2 speed sensor uses signal pulses to measure N2 rotor speed.

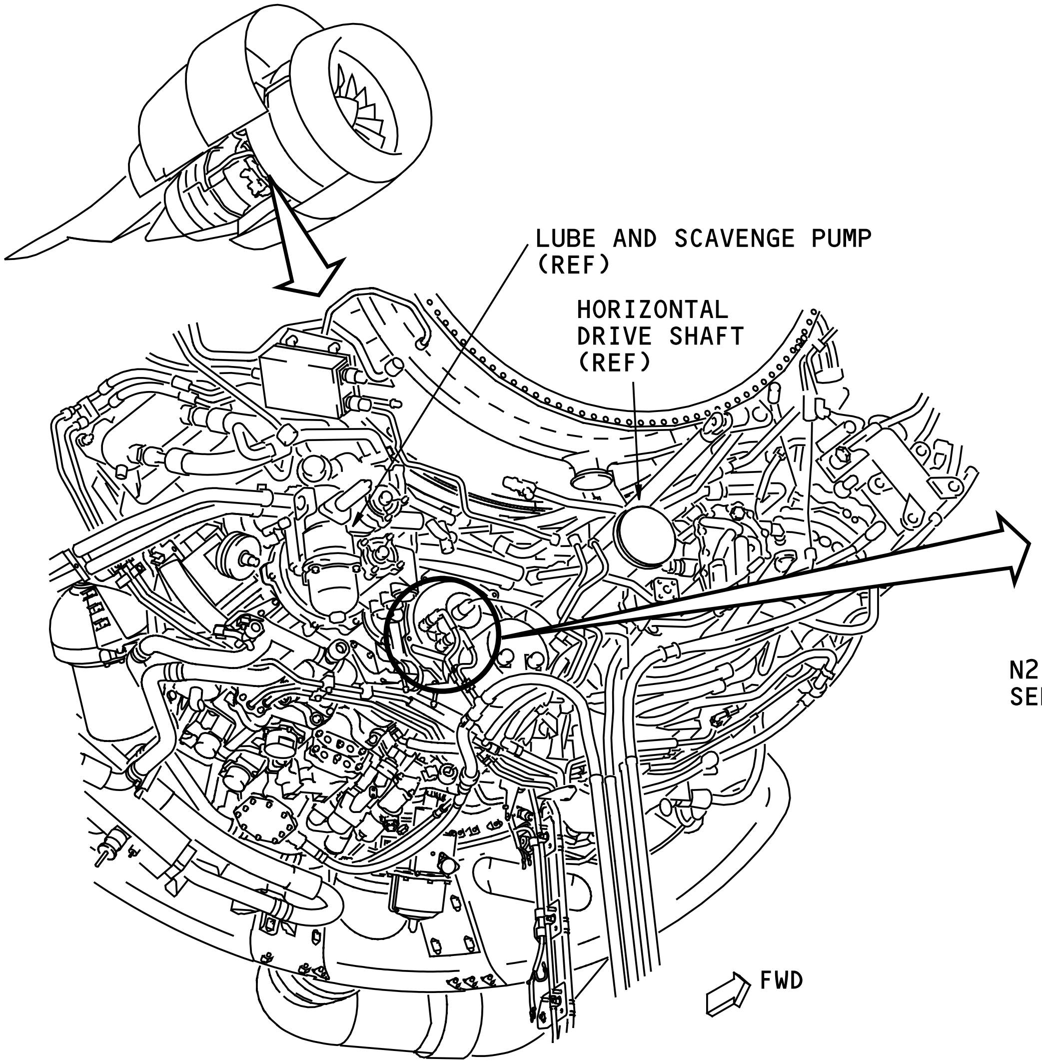
The N2 sensor is at the 5:30 position on the front of the accessory gearbox. You get access to the sensor with the right T/R half open.

Physical Description

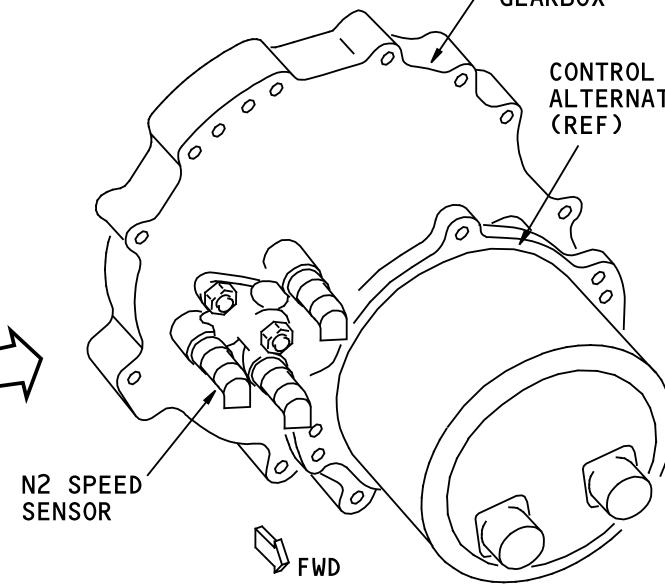
The N2 sensor has a short probe that fits into the accessory gearbox. The outer end has three electrical connectors. Two nuts hold the sensor on the gearbox.

Functional Description

A sensing head on the inner end of the N2 sensor probe is near a gear in the accessory gearbox. The speed sensor gets electromagnetic pulses as the gear teeth go by sensing head.



ENGINE ACCESSORY GEARBOX
(LOOKING AFT)



N2 SPEED SENSOR INSTALLATION

77-12-00-103 Rev 2 11/28/95

ENGINE INDICATING - ENGINE TACHOMETER - N2 SPEED SENSOR

ENGINE INDICATING - ENGINE TACHOMETER - INDICATIONS

N1

The EEC uses N1 to set engine thrust. These N1 indications show on the EICAS display:

- N1 redline
- Maximum N1
- Reference/target N1
- N1 command sector
- Actual N1.

N1 redline is the maximum speed limit for the N1 rotor.

Maximum N1 is the highest rotor speed that will not cause the engine to exceed maximum rated thrust. The EEC calculates maximum N1.

Reference/target N1 is the best N1 for the selected thrust reference mode. The flight management computing function of the AIMS supplies the reference/target N1.

N1 command sector is a function of thrust lever position, air data, and altitude. The EEC calculates N1 command. A command sector shows the difference between N1 command and actual N1.

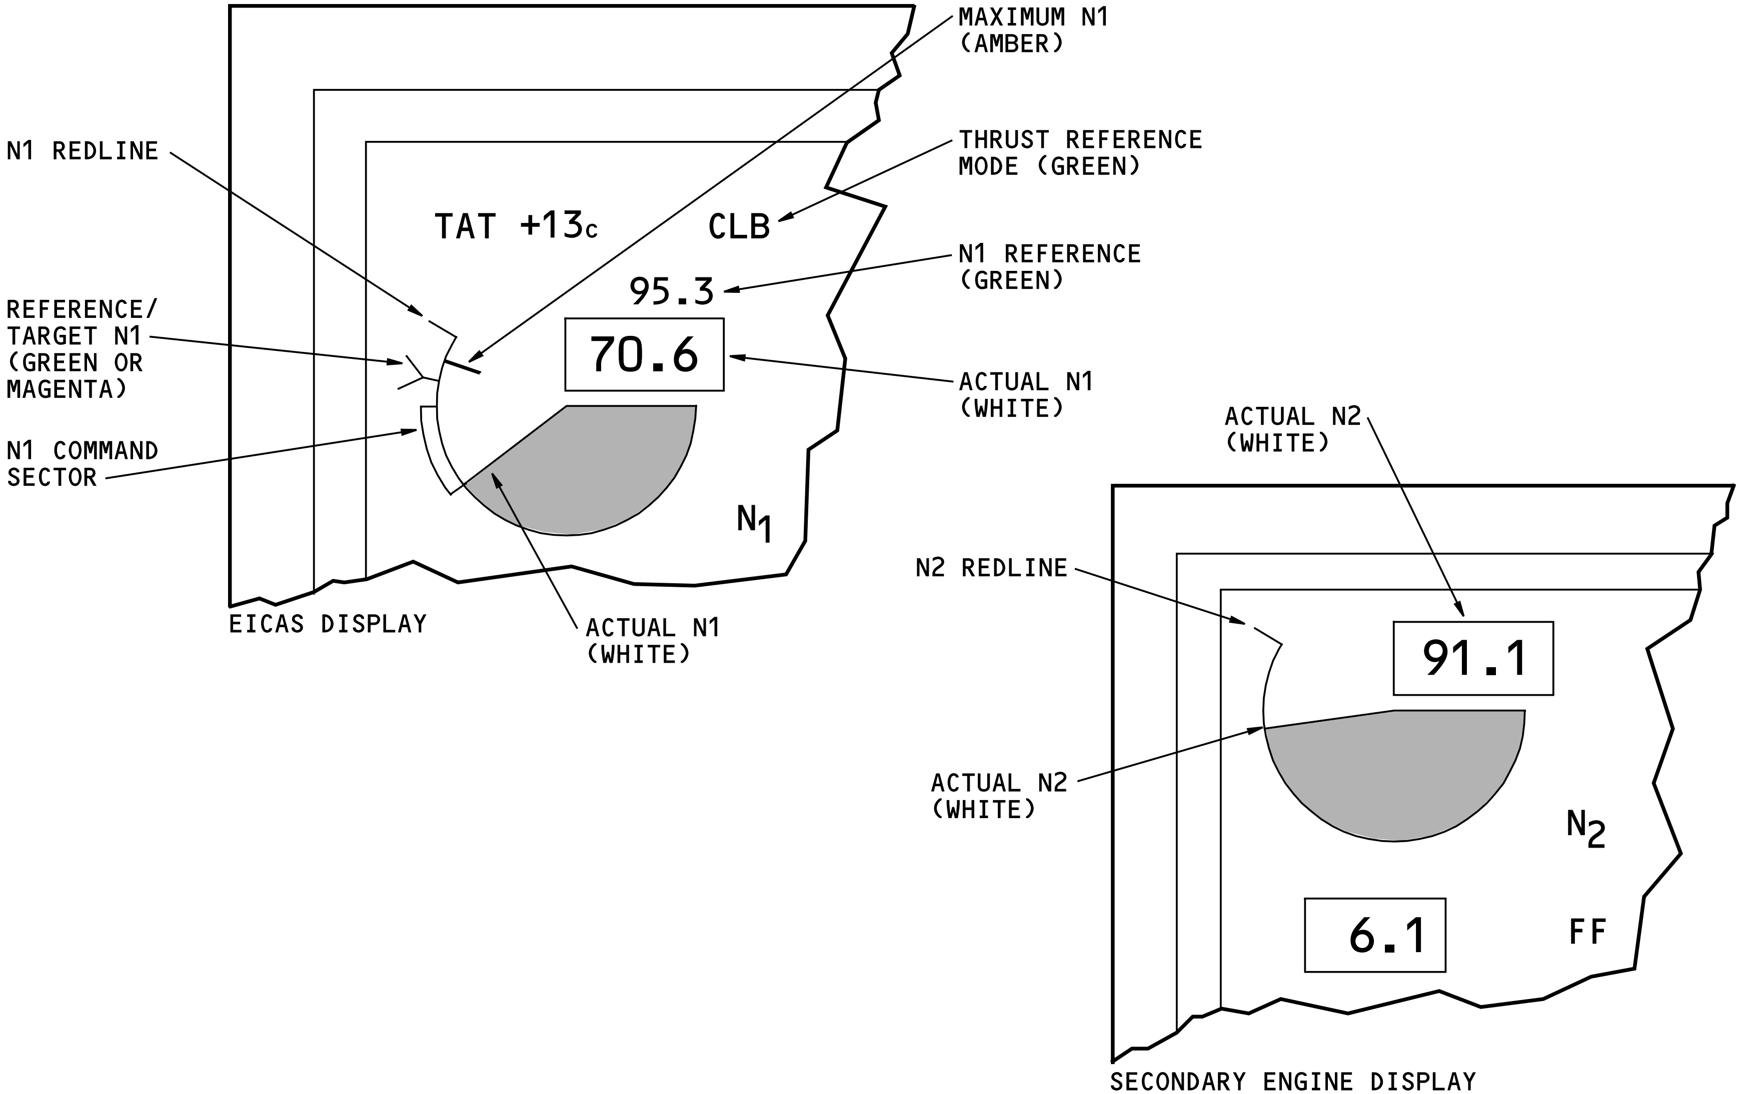
N2

You use N2 during engine start and to monitor HPC rotor speed when the engine operates. The engine secondary display shows actual N2 and N2 redline.

N2 redline is the maximum speed limit for the N2 rotor.

N1 or N2 Exceedance

If N1 or N2 goes above the redline the display turns red. When N1 or N2 goes back to a value below the limit, the display turns to the normal color. The box around the readout, however, stays the exceedance color until you push the CANCEL/RECALL switch on the display select panel (DSP).



77-12-00-104 Rev 5 11/28/95

ENGINE INDICATING - ENGINE TACHOMETER - INDICATIONS

ENGINE INDICATING - AVM - GENERAL DESCRIPTION

Purpose General

The airborne vibration monitoring (AVM) system monitors and records the engine vibration levels.

General Description

There is one AVM system for each engine. Each AVM system has these components:

- No. 1 bearing accelerometer
- Turbine accelerometer
- Remote charge converter (RCC)
- AVM signal conditioner unit.

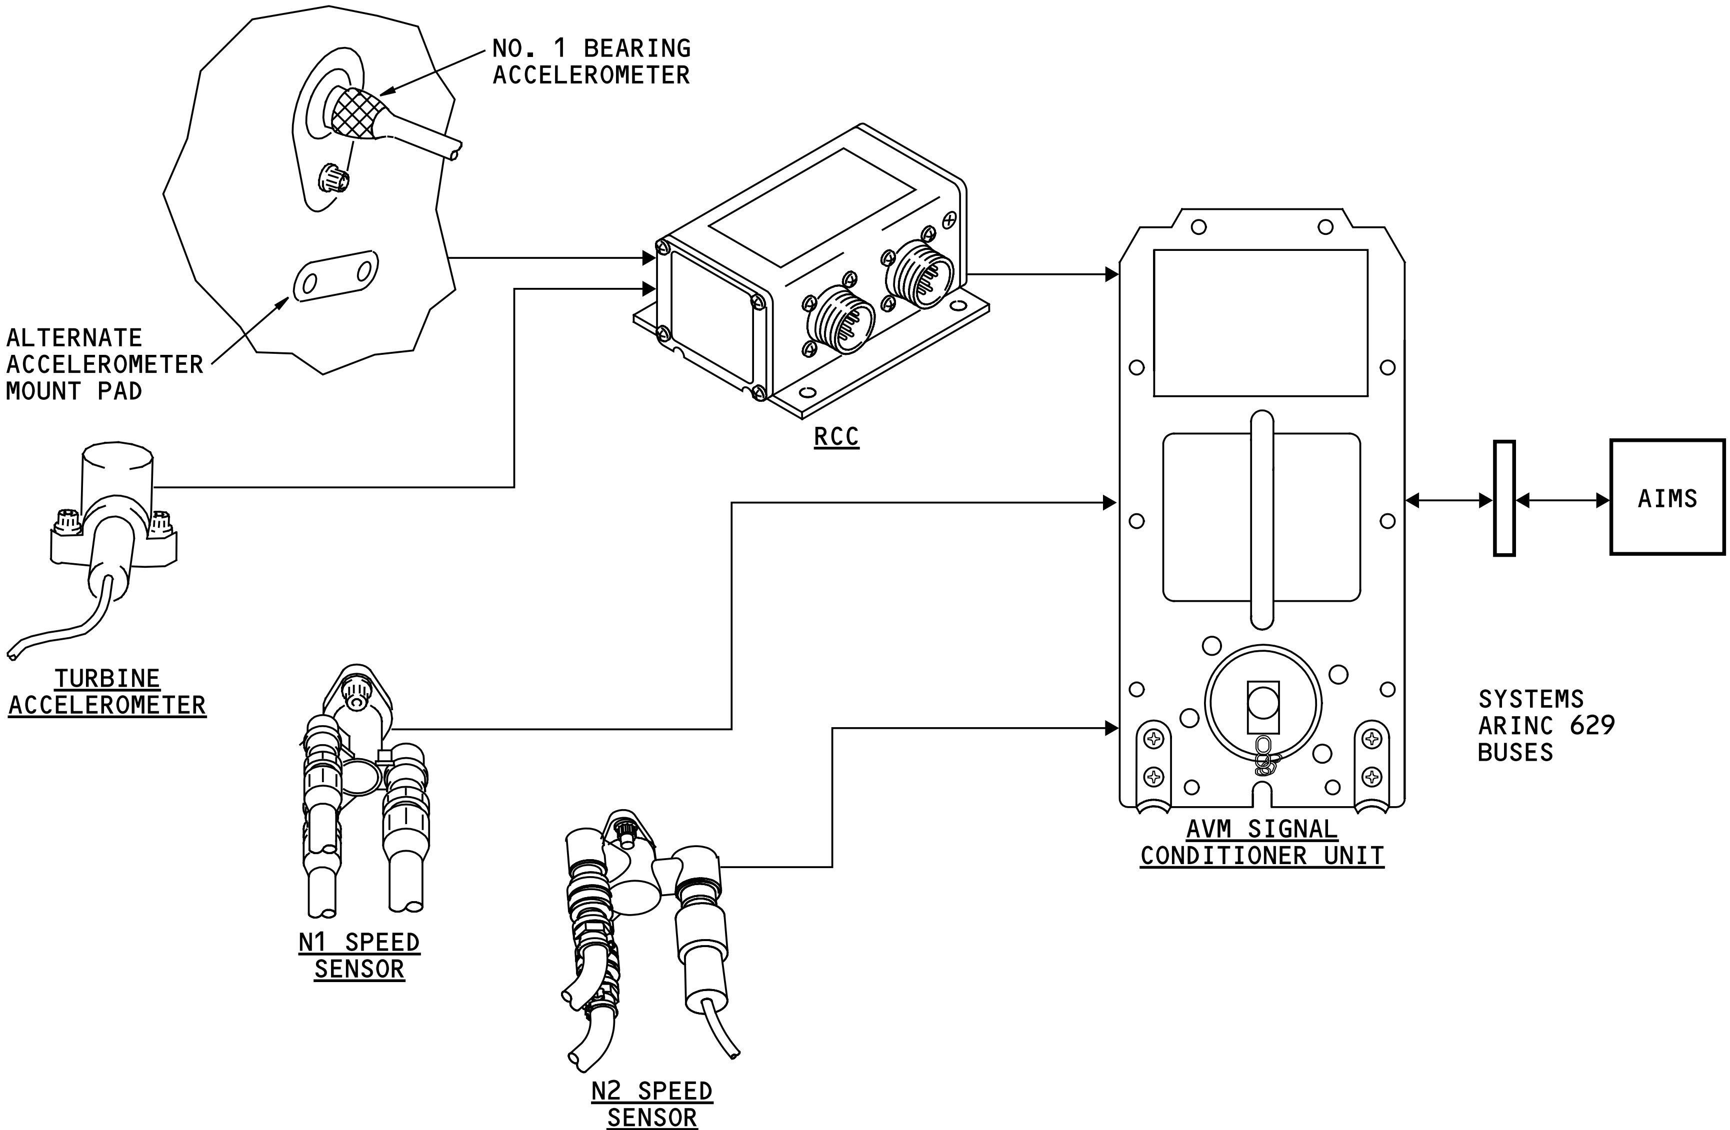
The accelerometers send signals that are proportional to the engine vibration. Each accelerometer signal goes to the RCC for signal conversion and amplification. The RCC sends amplified vibration signals to the AVM signal conditioner unit.

An alternate accelerometer can replace a failed No. 1 bearing accelerometer.

The signal conditioner unit uses the accelerometer signals and N1 and N2 speed signals to calculate the engine vibration levels for each rotor. The AVM signal conditioner unit sends the vibration data to the AIMS. The AIMS shows the vibration data on the primary display system.

The signal conditioner unit also stores the vibration data for use with the engine balancing system (EBS).

The EBS is a function of the signal conditioner unit and the AIMS. You get access to it through the MAT.



ENGINE INDICATING - AVM - GENERAL DESCRIPTION

ENGINE INDICATING - AVM - ACCELEROMETERS AND REMOTE CHARGE CONVERTER

Accelerometers

The accelerometers use piezoelectric crystals to get input for engine vibration and send it to the remote charge converter (RCC).

The No. 1 bearing accelerometer connector is on the fan frame hub at the 7:00 position. The No. 1 bearing accelerometer is inside the engine on the No. 1 bearing housing. If the No. 1 bearing accelerometer fails, you can attach an alternate accelerometer to the mounting pad on the fan hub frame.

The turbine accelerometer is on the turbine center frame at the 11:30 position.

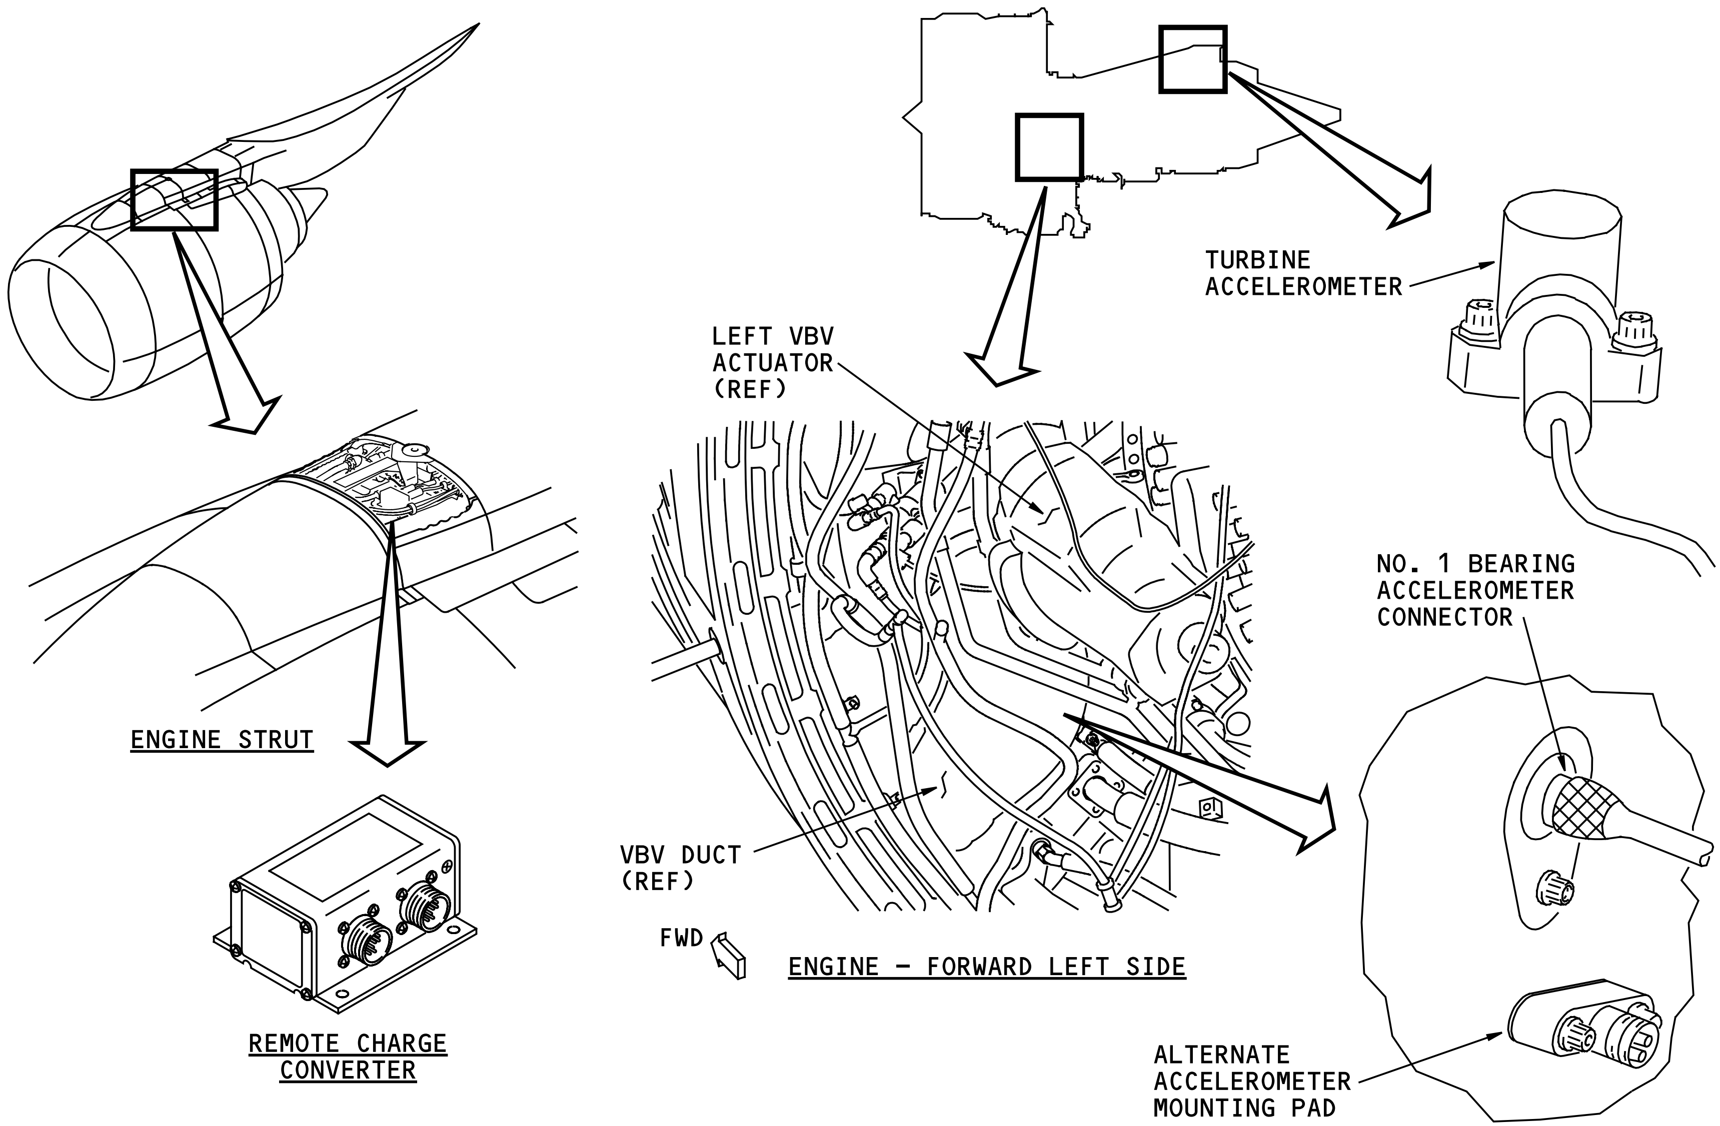
The accelerometers make electrical charge signals that change in proportion to the engine vibration level. The signals go to the RCC.

Remote Charge Converter

The RCC amplifies accelerometer charge signals and changes the signals into voltage signals. It sends the voltage signals to the AVM signal conditioner unit.

The RCC is in the engine strut. You get access to it through the forward access fairing.

The RCC has self-test circuits to continually monitor vibration amplitude and phase accuracy.



77-31-00-102 Rev 5 02/12/96

ENGINE INDICATING - AVM - ACCELEROMETERS AND REMOTE CHARGE CONVERTER

ENGINE INDICATING - AVM - SIGNAL CONDITIONER UNIT

General

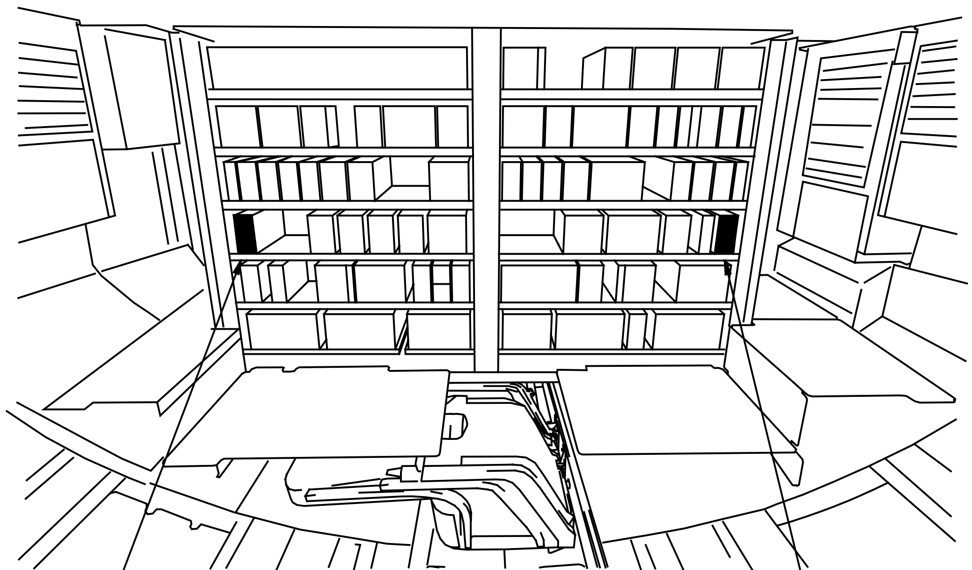
The AVM signal conditioner unit uses vibration and speed signals from engine sensors to calculate engine vibration levels. The signal conditioner unit also does these functions:

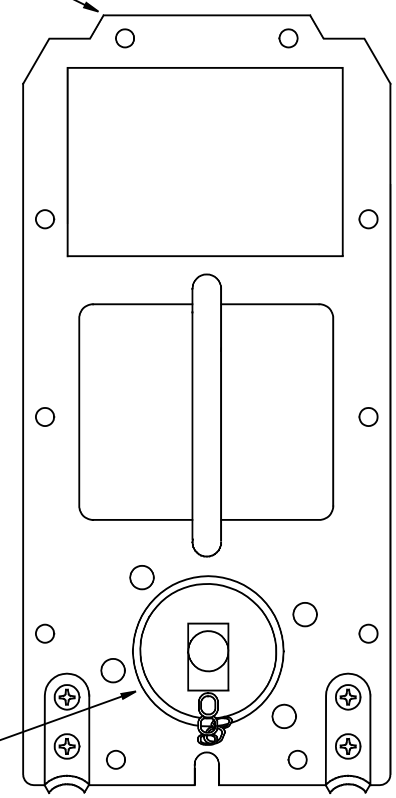
- Compares the N1 and N2 vibration levels to find which is highest
- Keeps in memory the vibration data for the last six flight legs
- Calculates engine balance solutions
- Self-test.

Each engine has one AVM signal conditioner unit. The signal conditioner units are in the main equipment center.

Maintenance Connector

The AVM signal conditioner unit has a maintenance connector on the front. The maintenance connector supplies alternative access for the engine balancing system (EBS) and for data loading. Normal access for these functions is on the MAT.





77-31-00-103 Rev 4 12/19/95

ENGINE INDICATING - AVM - SIGNAL CONDITIONER UNIT

ENGINE INDICATING - AVM - INDICATION

Secondary Engine Display

The secondary engine display shows the highest vibration level for each engine. The rotor identification is below the vibration data. If the N1 or N2 speed signal fails, the rotor identification shows broadband (BB) vibration.

If the vibration level is equal to or more than 4.0 scalar units, the vibration display automatically shows on the secondary engine display. Also, the digital display will show in reverse video format (black numbers on a white background).

When an engine is shut down, the related vibration data does not show.

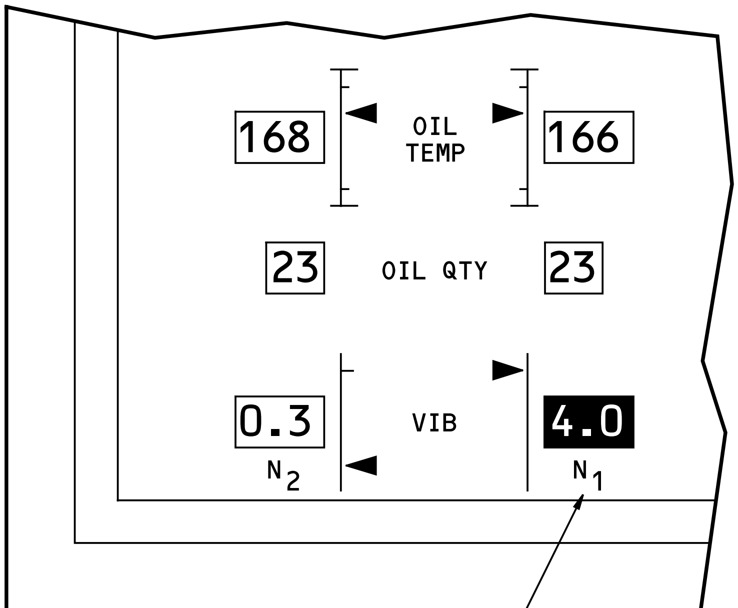
Performance Maintenance Page

The performance maintenance page shows all the engine vibration data. N1 fan vibration shows under channel B for the AVM signal conditioner unit. The other vibration data shows under channel A.

If the N1 or N2 speed signal fails, only the broadband vibration data shows.

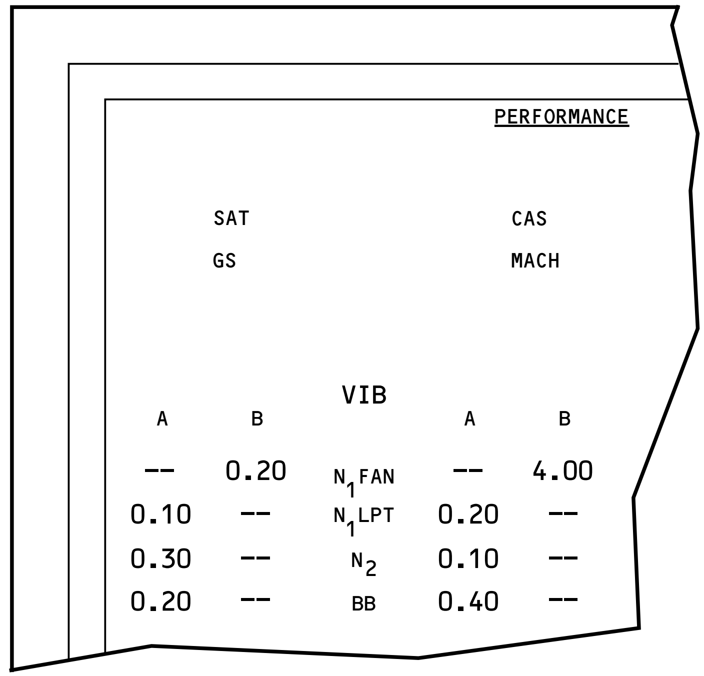
Training Information Point

At low engine speeds, the N1 FAN and N1 LPT data change to dashes. This is because the broadband vibration is too large in proportion to the N1 vibration.



SECONDARY ENGINE DISPLAY

ROTOR IDENTIFICATION



PERFORMANCE MAINTENANCE PAGE

ENGINE INDICATING - AVM - INDICATION

ENGINE INDICATING - AVM - ENGINE BALANCING SYSTEM (EBS)

General

The engine balancing system (EBS) permits you to select which balance weights on the engine to change to decrease engine vibration.The AVM signal conditioning unit for each engine and the AIMS central maintenance computing function (CMCF) make up the EBS.

The AVM signal conditioner unit supplies the data for the engine balancing displays. You use the MAT to operate the EBS.

Engine Balancing Main Menu

You use the MAT to select the OTHER FUNCTIONS menu. The ENGINE BALANCING function shows on the OTHER FUNCTIONS menu.

The HELP selection is active if there is help text in the airline data base.

To start the engine balancing process you must choose these selections:

- ENGINE 1 or ENGINE 2
- PERFORM BALANCE or CALCULATE SPECIFIC BALANCE COEFFICIENTS/GROUND RUN
- CONTINUE.

Perform Balance

The PERFORM BALANCE selection of the EBS calculates a balance solution that corrects high engine vibration.

The solution identifies the balance weights that you should remove and install in the aft spinner or on the LPT blades.

Calculate Specific Balance Coefficients/Ground Run

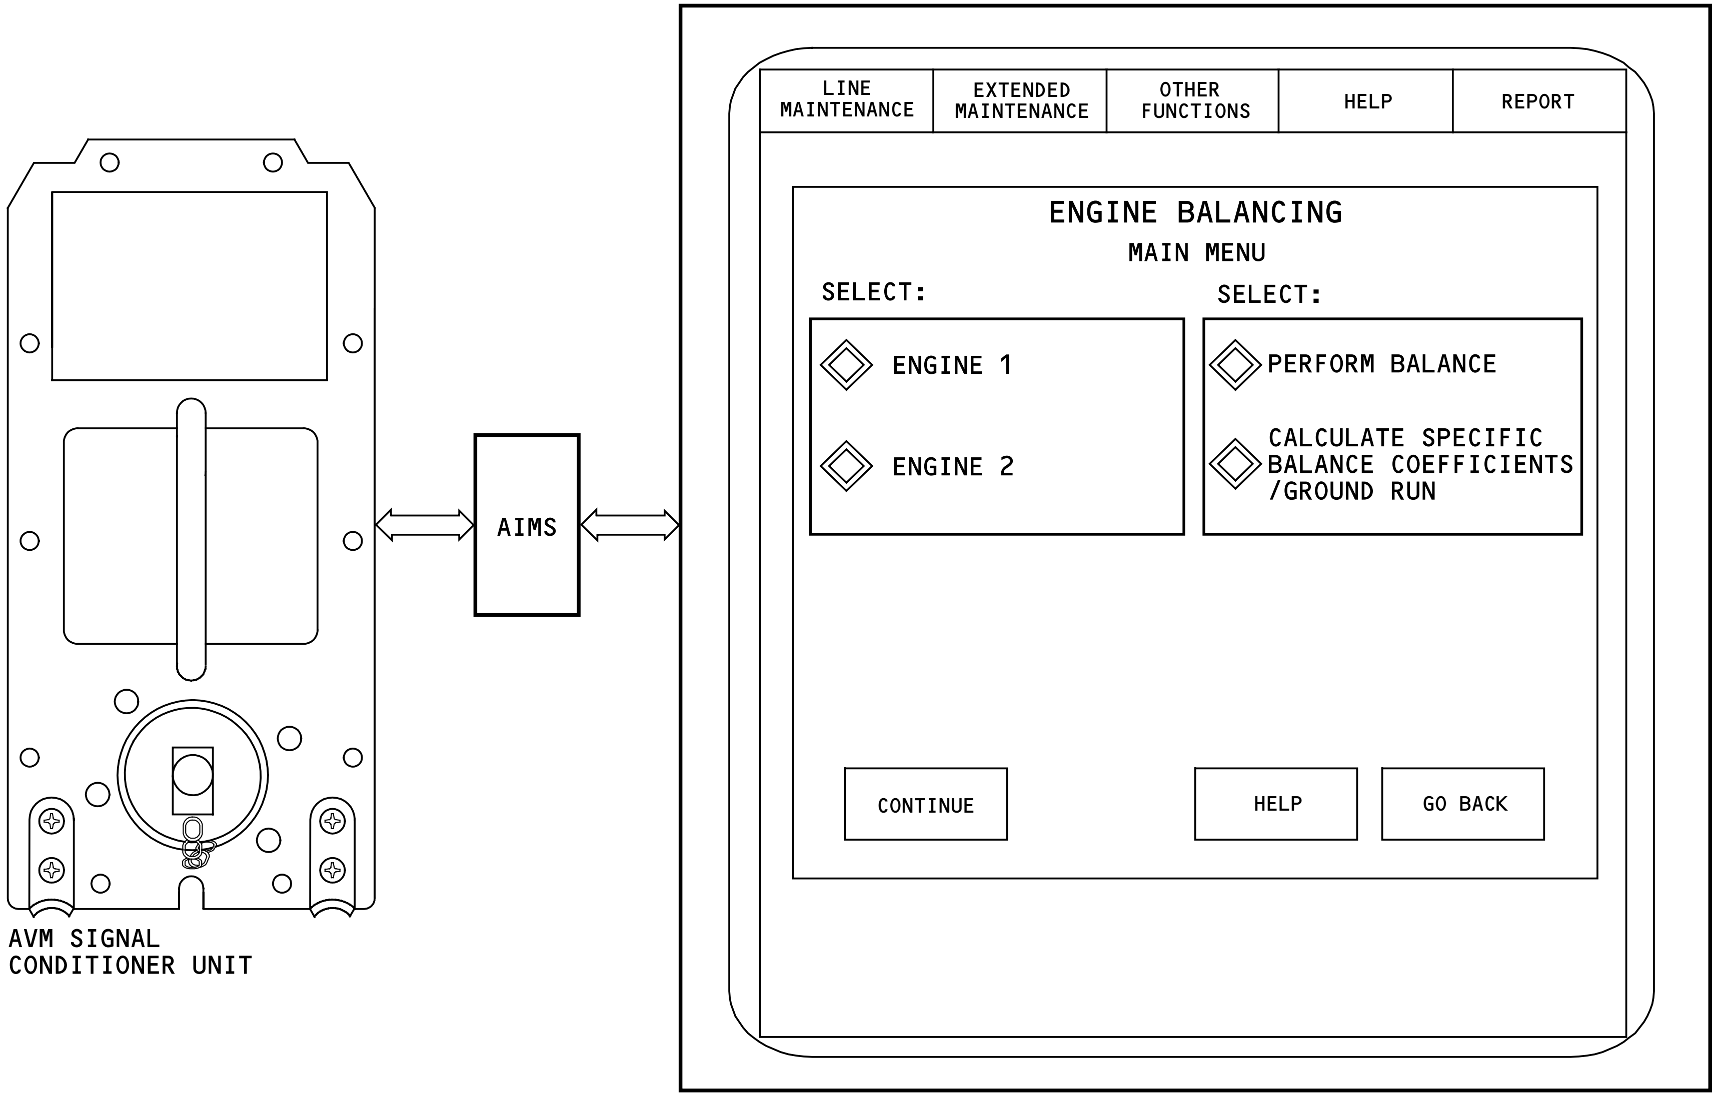
The CALCULATE SPECIFIC BALANCE COEFFICIENTS/GROUND RUN selection of the EBS lets you do these functions:

- Calculate new specific balance coefficients
- Record ground run data for the EBS to use.

When you calculate specific balance coefficients, the EBS replaces the existing balance coefficients. The AVM signal conditioner unit can use ground run data, or both flight data and ground run data, to calculate the new coefficients.

Continue

When you select CONTINUE, the MAT shows the EXISTING BALANCE WEIGHTS display. The CONTINUE selection becomes active after you make the first two selections.



ENGINE INDICATING - AVM - ENGINE BALANCING SYSTEM (EBS)

ENGINE INDICATING - AVM - EBS - PERFORM BALANCE - 1

THIS PAGE INTENTIONALLY LEFT BLANK

Existing Balance Weights Display

The EXISTING BALANCE WEIGHTS display shows the part number and location of the fan and LPT balance weights. The data is in the AVM signal conditioner unit memory.

NOTE: The holes in the aft spinner that do not have balance weights contain a standard weight. The EBS part number for this weight is P01. The EXISTING BALANCE WEIGHTS display does not show P01 weights.

You use this data to make sure the balance weight data in the AVM signal conditioner unit memory matches the weights on the engine. This is necessary for the AVM signal conditioner unit to calculate a correct balance solution. If the balance weight data is not correct, you must change the data. When you select the data or a blank text field, an edit dialog box shows.

On the EXISTING BALANCE WEIGHTS display, you can make two selections:

- CONTINUE
- FLIGHT HISTORY.

When you select CONTINUE, the AVM signal conditioner unit calculates a balance solution and the MAT shows the SOLUTION SUMMARY display.

When you select FLIGHT HISTORY, the MAT shows the N1 VIBRATION FLIGHT HISTORY display.

N1 Vibration Flight History Display

The N1 VIBRATION FLIGHT HISTORY display shows the fan (Front) and LPT (Rear) vibration data and phase angle for six flight legs. The data shows for different N1 speeds. Vibration data shows in reverse video format (black numbers on a white background) when the vibration level is more than the recommended vibration guideline.

You select AVERAGE to cause the AVM signal conditioner unit to use that data to calculate a solution for engine balancing. You may also select a specific flight leg to cause the AVM signal conditioner unit to use that data.

You select GO BACK to return to the EXISTING BALANCE WEIGHTS display.

You select N2 FLIGHT HISTORY to show the N2 VIBRATION FLIGHT HISTORY display (not shown). The N2 VIBRATION FLIGHT HISTORY display shows the N2 rotor vibration data for six flight legs. You use the N2 vibration data to make sure N2 vibration is less than the recommended vibration guideline. You cannot balance the N2 rotor with the EBS.

Training Information Point

When the AVM signal conditioner unit calculates the leg average it uses only the legs or ground runs with the same weight configuration as the present leg (LG 0). When you do a PERFORM BALANCE, the EBS will not let you

ENGINE INDICATING - AVM - EBS - PERFORM BALANCE - 1

select legs with weights that are different from the present leg (LG 0).

Some legs may not have data for one or more engine speeds. This occurs if the engine does not operate at that speed for 30 seconds or more. The AVM signal conditioner unit must have vibration data for a minimum of four speeds to calculate the balance solution.

The N1 VIBRATION FLIGHT HISTORY display shows N1 vibration data in mils S.A. (single amplitude). These are different than the scalar units for N1 vibration on the secondary engine display and the performance maintenance page.

The N2 VIBRATION FLIGHT HISTORY display shows N2 vibration data in scalar units.

ENGINE INDICATING - AVM - EBS - PERFORM BALANCE - 1

Solution Summary Display

The SOLUTION SUMMARY display lets you select a one-plane or two-plane solution.

When you select ONE PLANE, the AVM signal conditioner unit finds the weights you must change in the front balance plane (FAN) to correct high N1 vibration. The SOLUTION SUMMARY display shows the part numbers and locations of the fan balance weights you must remove and install. The display also shows the predicted overall vibration reduction.

When you select TWO PLANE, the AVM signal conditioner unit finds the weights you must change in the front and rear balance planes (FAN and LPT) to correct high N1 vibration. In this case the SOLUTION SUMMARY display also shows the part numbers and locations of the LPT weights you must remove and install.

A message shows at the bottom of the SOLUTION SUMMARY display. This message tells you when:

- An engine check run is not necessary
- A low power engine check run is recommended
- A high power engine check run is recommended
- No solution is available

After you select ONE PLANE or TWO PLANE, you must select CONTINUE or SOLUTION PREDICTION.

When you select CONTINUE, the MAT shows the NEW BALANCE WEIGHTS display.

When you select SOLUTION PREDICTION, the MAT shows the N1 VIBRATION PREDICTION display.

N1 Vibration Prediction Display

The N1 VIBRATION PREDICTION display shows the front and rear vibration at different N1 speeds. It shows the actual and the predicted vibration levels.

The actual vibration comes from the leg average or the specific flight leg you selected on the N1 VIBRATION FLIGHT HISTORY display.

The predicted vibration shows what the vibration will be if you make the balance solution weight changes.

You select GO BACK to return to the SOLUTION SUMMARY display.

Training Information Point

The N1 VIBRATION PREDICTION display shows N1 vibration data in mils S.A. (single amplitude). These are different than the scalar units for N1 vibration on the secondary engine display and the performance maintenance page.

The N1 VIBRATION PREDICTION display shows predicted vibration that is higher than the recommended vibration guideline in reverse video format (black letters on a white background). The display does not show actual vibration in reverse video format.

ENGINE INDICATING - AVM - EBS - PERFORM BALANCE - 3

ENGINE INDICATING - ENGINE MOUNTED SENSORS - GENERAL DESCRIPTION

General

The engine mounted sensors supply data, through the EEC, to the airplane condition monitoring system (ACMS) in the AIMS. You use the ACMS to get reports of engine sensor data for ground-based engine condition monitoring. The EEC does not use these sensors for engine control.

Other engine sensors also supply data for the ACMS. See the engine fuel control section for more information on the other engine sensors (AMM PART I 73-21).

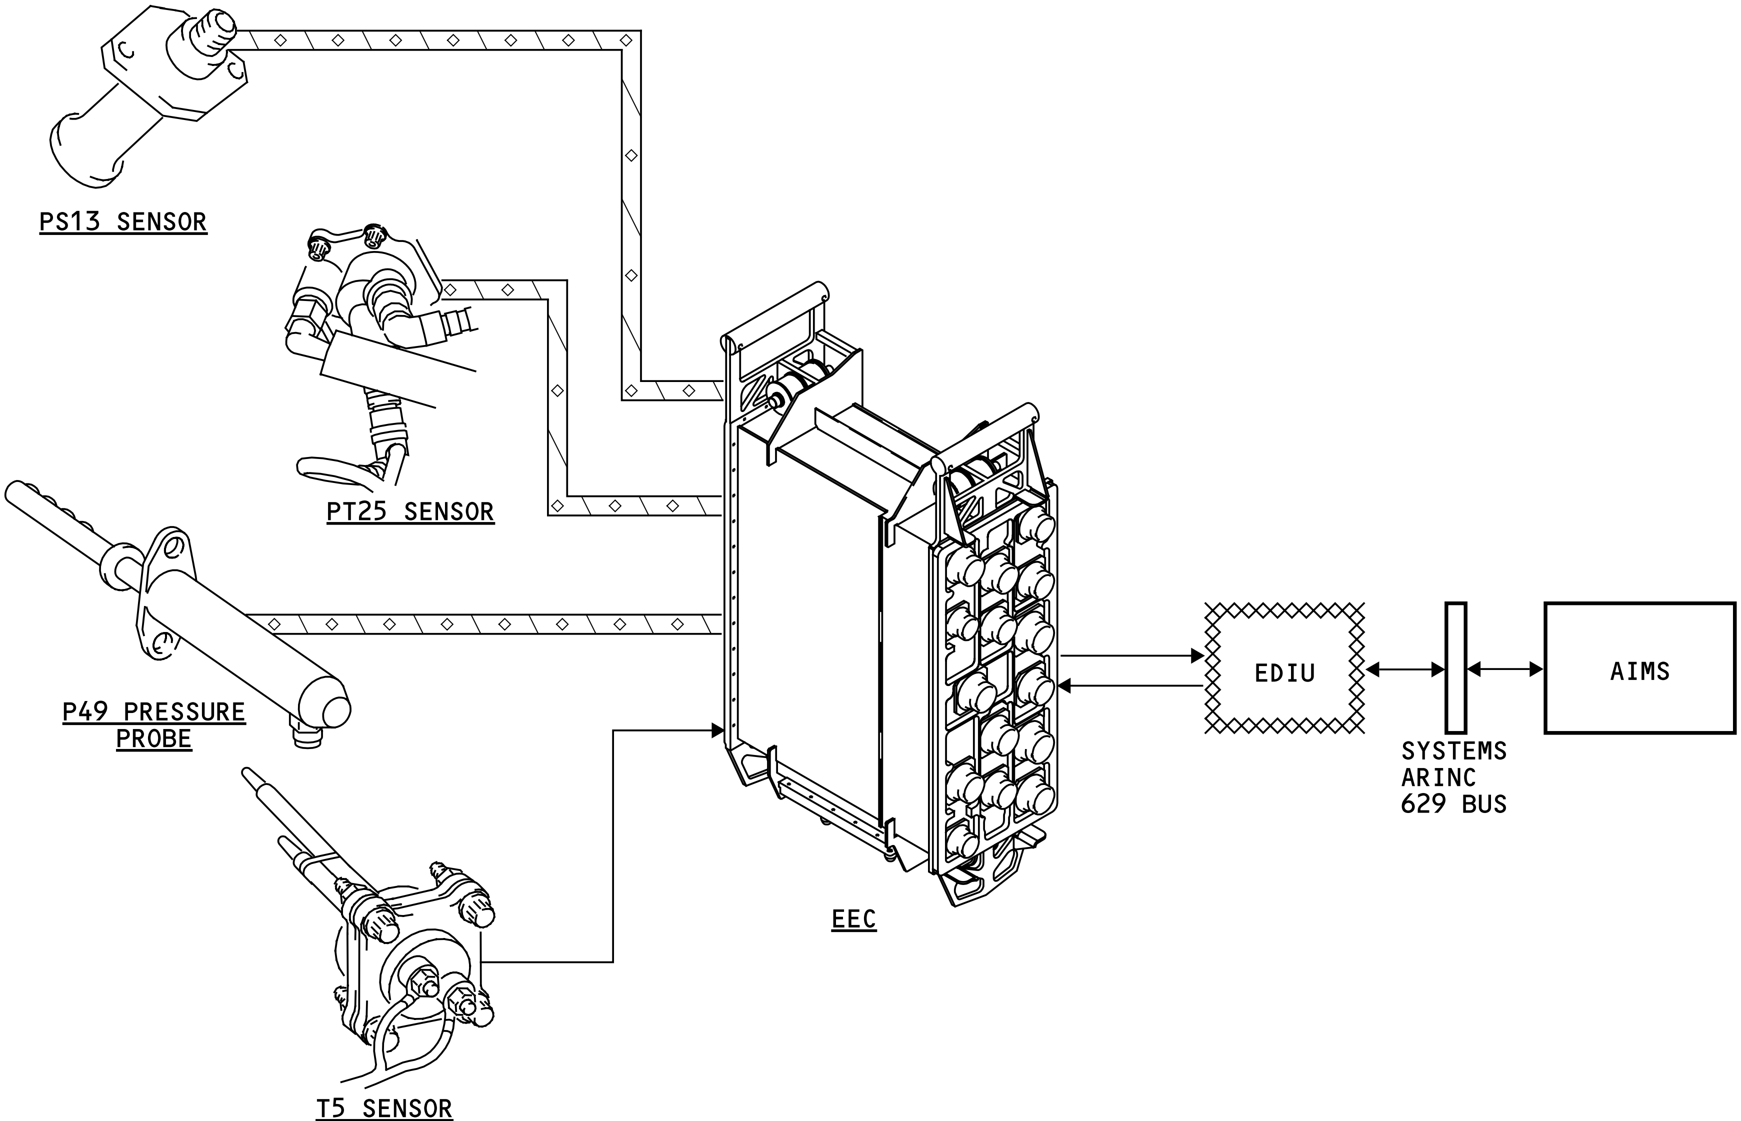
These are the sensors and the data they monitor:

- PS13: fan flow static pressure
- P25: LPC exit pressure
- P49: total pressure between the HPT and LPT
- T5: temperature at the LPT exit.

The EEC gets P25 from the PT25 sensor.

Indications

The engine mounted sensor data does not show in the flight deck.



ENGINE INDICATING - ENGINE MOUNTED SENSORS - GENERAL DESCRIPTION

ENGINE INDICATING - ENGINE MOUNTED SENSORS - T5, P49, AND PS13 SENSORS

PS13 Sensor

The PS13 sensor measures the static air pressure in the fan bypass flow. The pressure data goes to channel A of the EEC.

The PS13 sensor is on the fan case above the EEC at the 2:00 position. Two bolts hold the PS13 sensor on the fan case. A single, pressure-sensing line connects the sensor to the EEC.

You open the right fan cowl to get access to the sensor.

P49 Pressure Sensor

The P49 pressure sensor measures the total air pressure between the HPT and LPT. The pressure data goes to channel A of the EEC.

The P49 pressure sensor is on the turbine center frame (TCF) at the 4:00 position. Two bolts hold the P49 sensor on the TCF. A single, pressure-sensing line connects the sensor to the EEC.

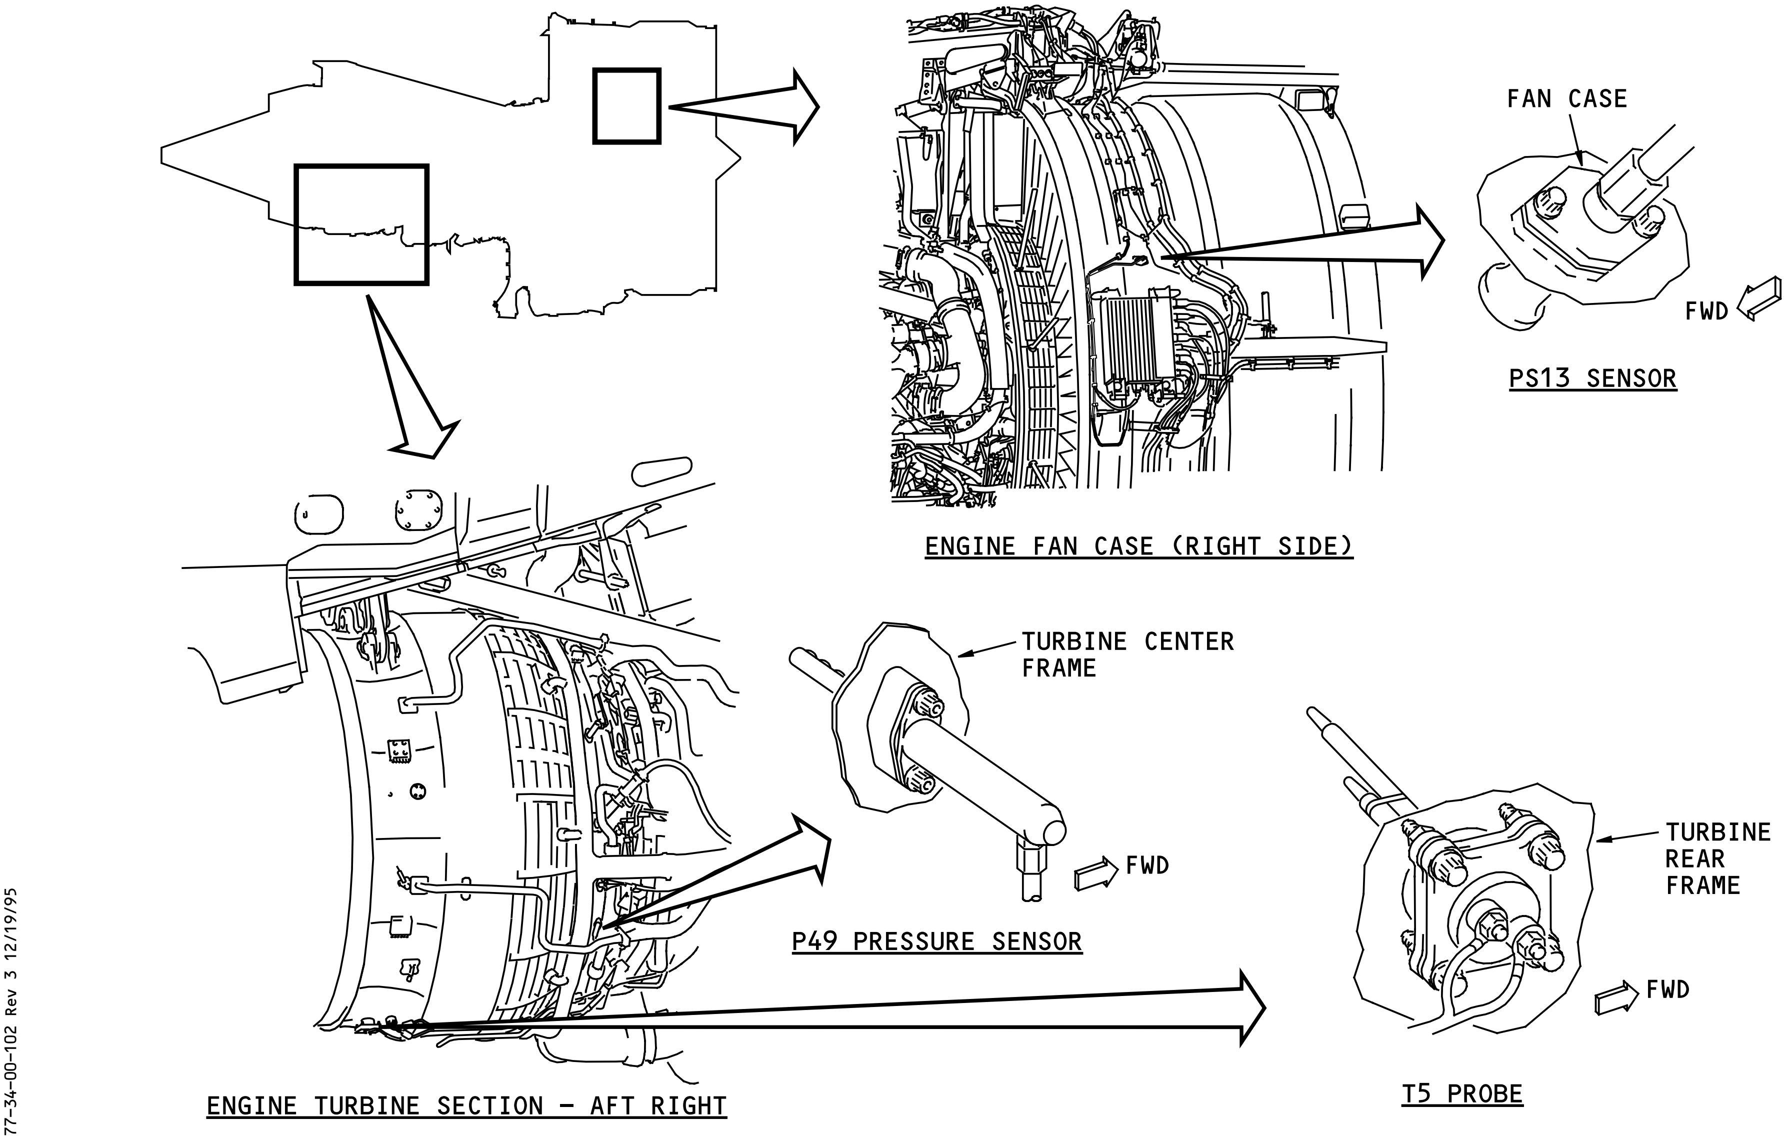
You open the right T/R half to get access to the sensor.

T5 Probe

The T5 probe measures the LPT outlet temperature. The temperature data goes to channel A of the EEC.

The T5 probe is on the turbine rear frame (TRF) at the 5:30 position. Four bolts hold the T5 probe on the TRF. Captured nuts hold chromel and alumel leads on the probe connections.

You open the right T/R half to get access to the T5 probe.



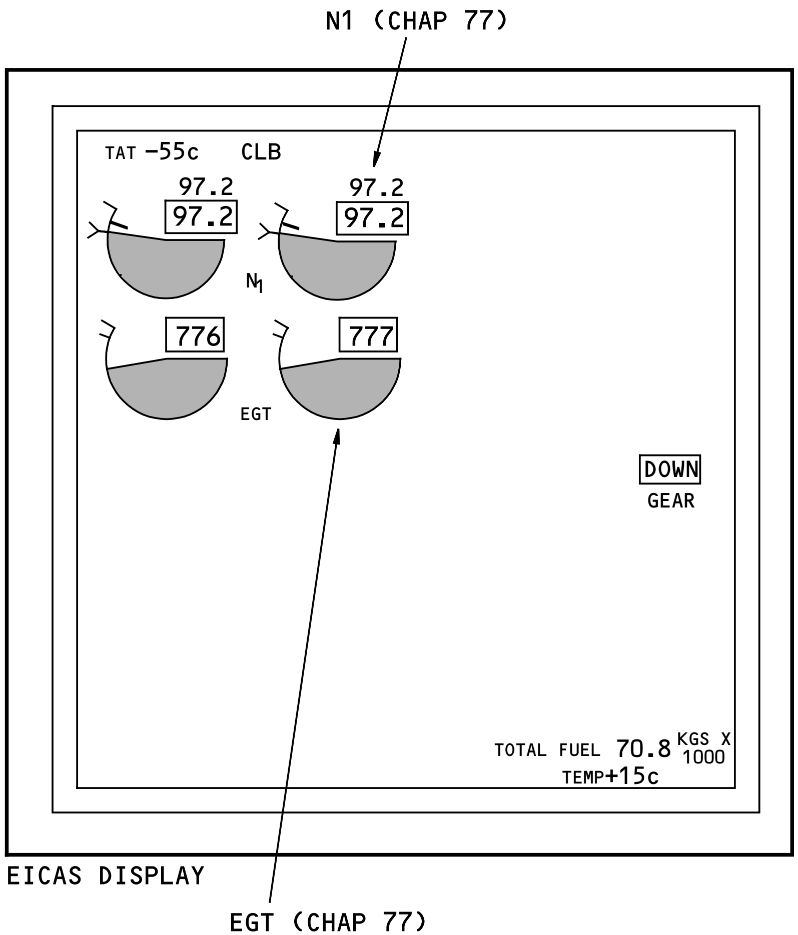
ENGINE INDICATING - ENGINE MOUNTED SENSORS - T5, P49, AND PS13 SENSORS

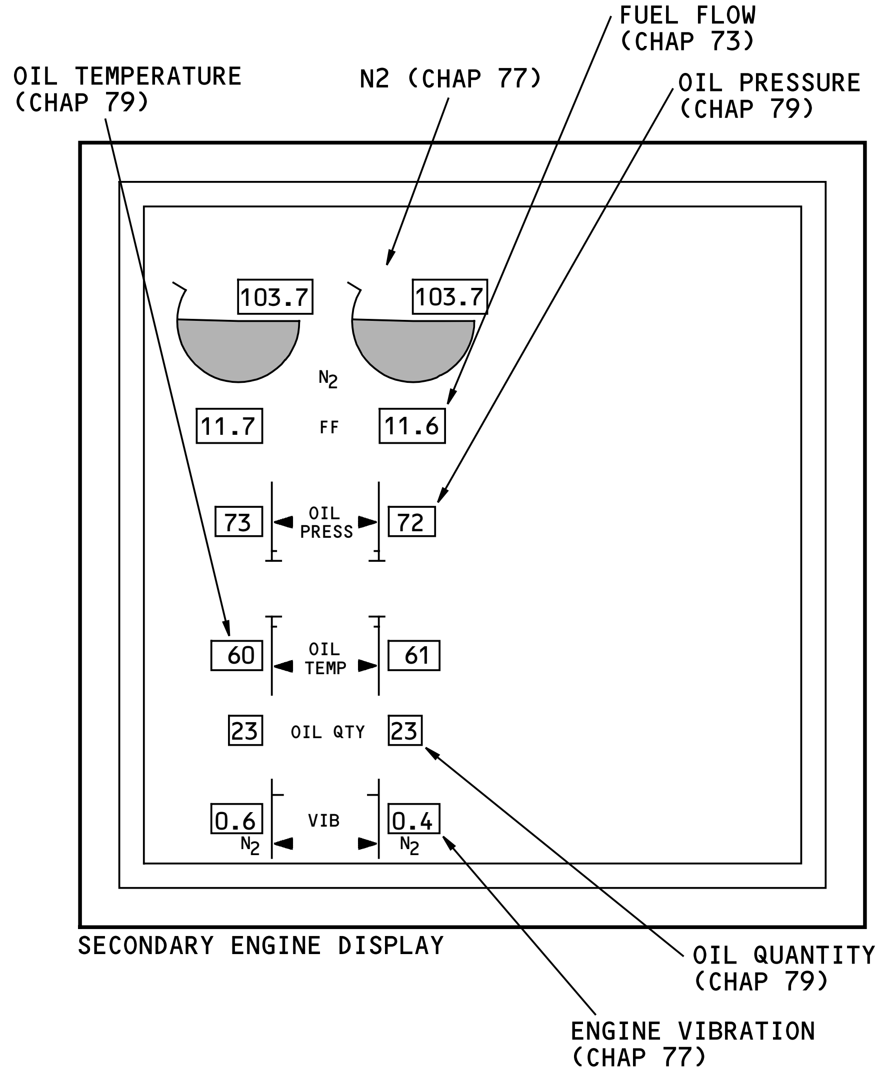
Indications

The EICAS display and the secondary engine display show these engine parameters:

- N1, LPC rotor speed
- EGT, exhaust gas temperature
- N2, HPC rotor speed
- FF, fuel flow
- OIL PRESS
- OIL TEMP
- OIL QTY
- VIB, engine vibration.

Refer to the related ATA chapter for more information about these indications.





77-00-00-105 Rev 4 05/12/95

ENGINE INDICATING - EICAS & SECONDARY ENGINE DISPLAYS

ENGINE INDICATING - PERFORMANCE & ENGINE EXCEEDANCE MAINTENANCE PAGES

Performance Maintenance Page

The top part of the performance maintenance page shows some general airplane and environment data. GROSS WT is the gross weight of the airplane that the dispatch agent puts in. SAT is the static air temperature and TAT is the total air temperature. Both show in degrees Celsius. GS is the ground speed and CAS is the calibrated air speed. Both show in knots. ALT is the altitude in thousands of feet.

The bottom part of the performance maintenance page shows the same engine parameters as the EICAS display and the secondary engine display. These indications are described in their related sections.

The performance maintenance page also shows the value for these indications:

- PS3
- P-BLEED
- DUCT PRESS.

PS3 is the static pressure from the HPC exit. The EEC gets PS3 from the PS3 sensor. The units are in psi.

P-BLEED is the flow rate of the air in the high stage bleed duct. The EEC uses the pressure from the bleed bias sensor to calculate P-BLEED. The units are in percent of core air flow.

DUCT PRESS is the manifold duct pressure. It comes from the air system cabin pressure controller (ASCPC). The units are in psi.

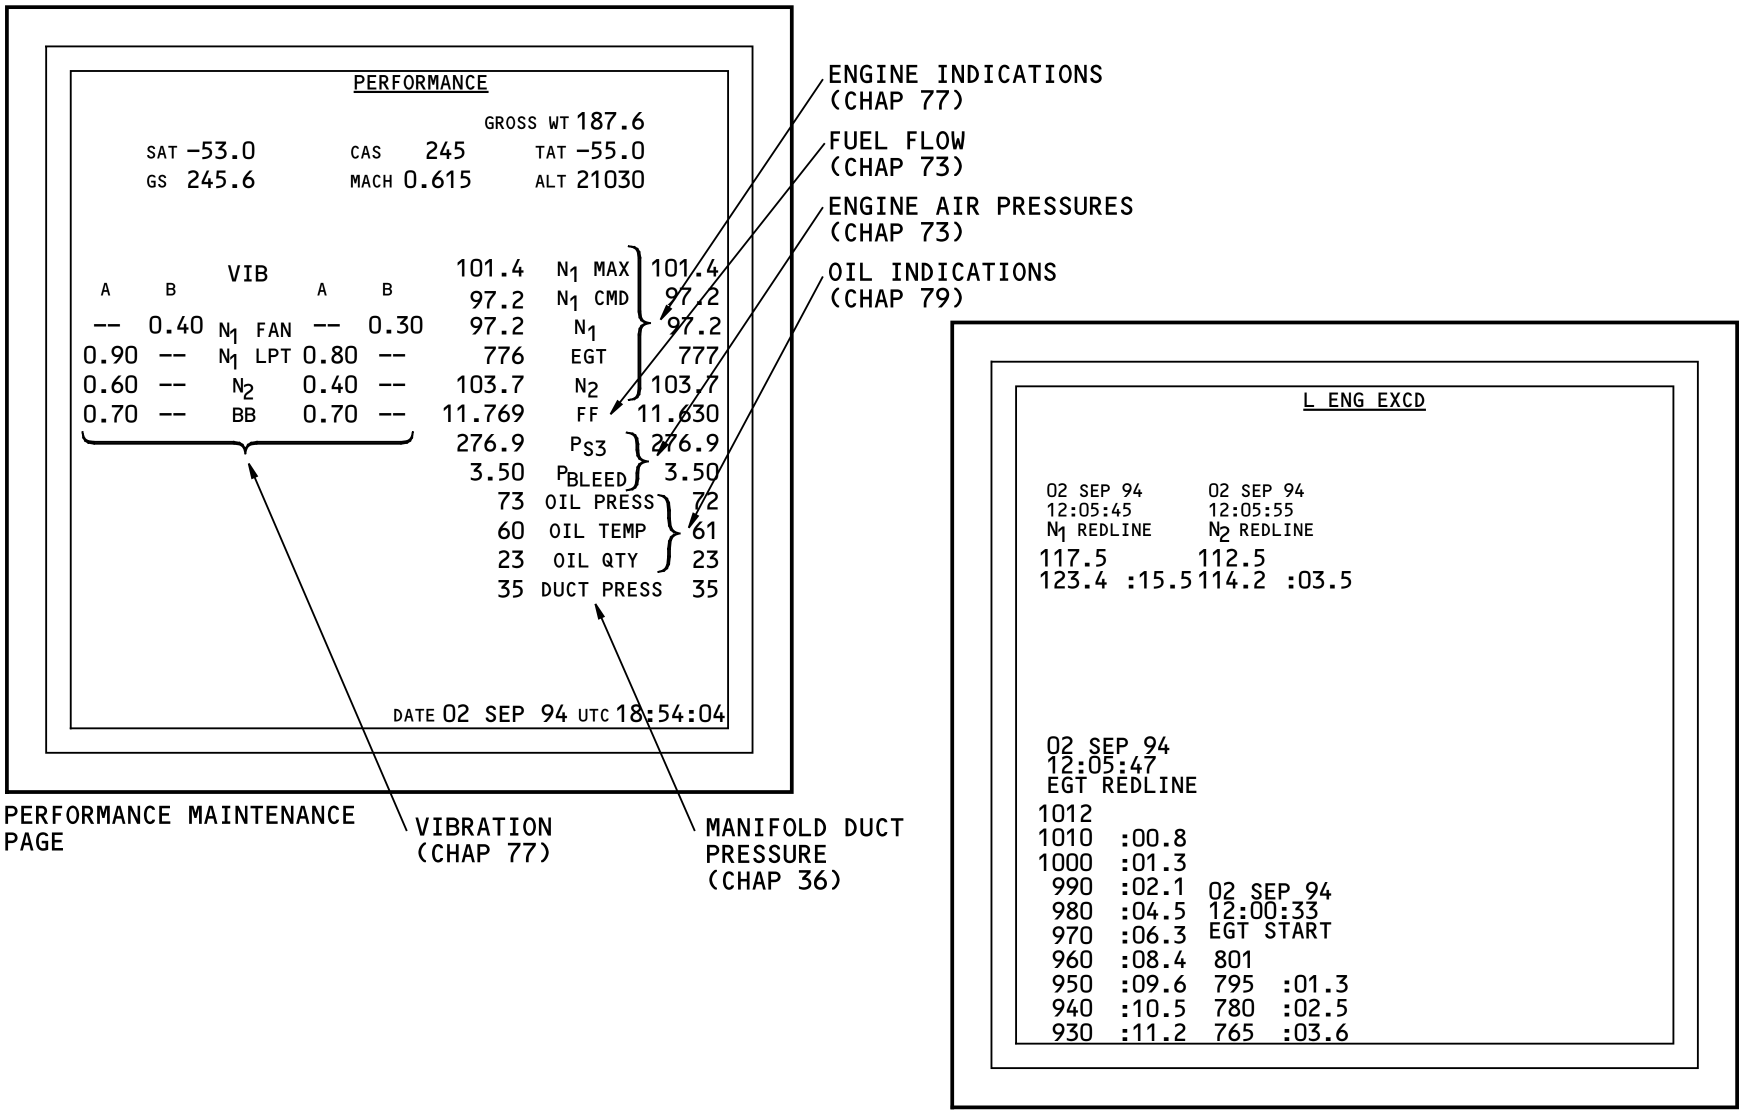
Engine Exceedance Maintenance Page

The N1 and N2 exceedance displays show the redline for the LP and HP rotors. If a rotor speed goes higher than the redline, the exceedance display shows the maximum actual rotor speed, and the time that the rotor speed was above the redline.

The EGT exceedance display shows an EGT profile if the EGT goes above the redline. This display can show as many as four EGT profiles. The most recent profile is on the left. The oldest profile is on the right. If a new EGT exceedance occurs, the profile shows on the left and the oldest profile goes out of view.

There are two separate profiles for each engine. One profile is for the engine run redline. The other profile is for the engine start redline. If the EGT exceeds the redline while the engine is running, the profile shows the EGT in increments up to the maximum actual EGT. It also shows the time that the EGT was more than each increment.

If the EGT exceeds the redline during an engine start, the profile shows the EGT in increments up to the maximum actual EGT. It also shows the time that the EGT was above each increment.



ENGINE EXCEEDANCE MAINTENANCE PAGE

ENGINE INDICATING - PERFORMANCE & ENGINE EXCEEDANCE MAINTENANCE PAGES

77-00-00-106 Rev 4 05/24/95

Indications

The EPCS maintenance pages show engine parameters from many engine sensors. The parameters show for channels A and B of the EEC. There is a box around the channel that the EEC is using to control the engine.

These are the parameters that show on the EPCS maintenance page 1:

- N1: LPC rotor speed (percent)
- N2: HPC rotor speed (percent)
- TRA: thrust resolver angle (degrees)
- T/R: left and right thrust reverser position (percent deployed)
- PAMB: ambient pressure (psi)
- PS3: compressor discharge pressure (psi)
- T12: fan inlet temperature (degrees Celsius)
- T25: core engine inlet temperature (degrees Celsius)
- T3: compressor discharge temperature (degrees Celsius)
- VBV: variable bypass valve position (percent open)
- VSV: variable stator vane position (percent open)
- STB: start/transient bleed valve position (percent open)

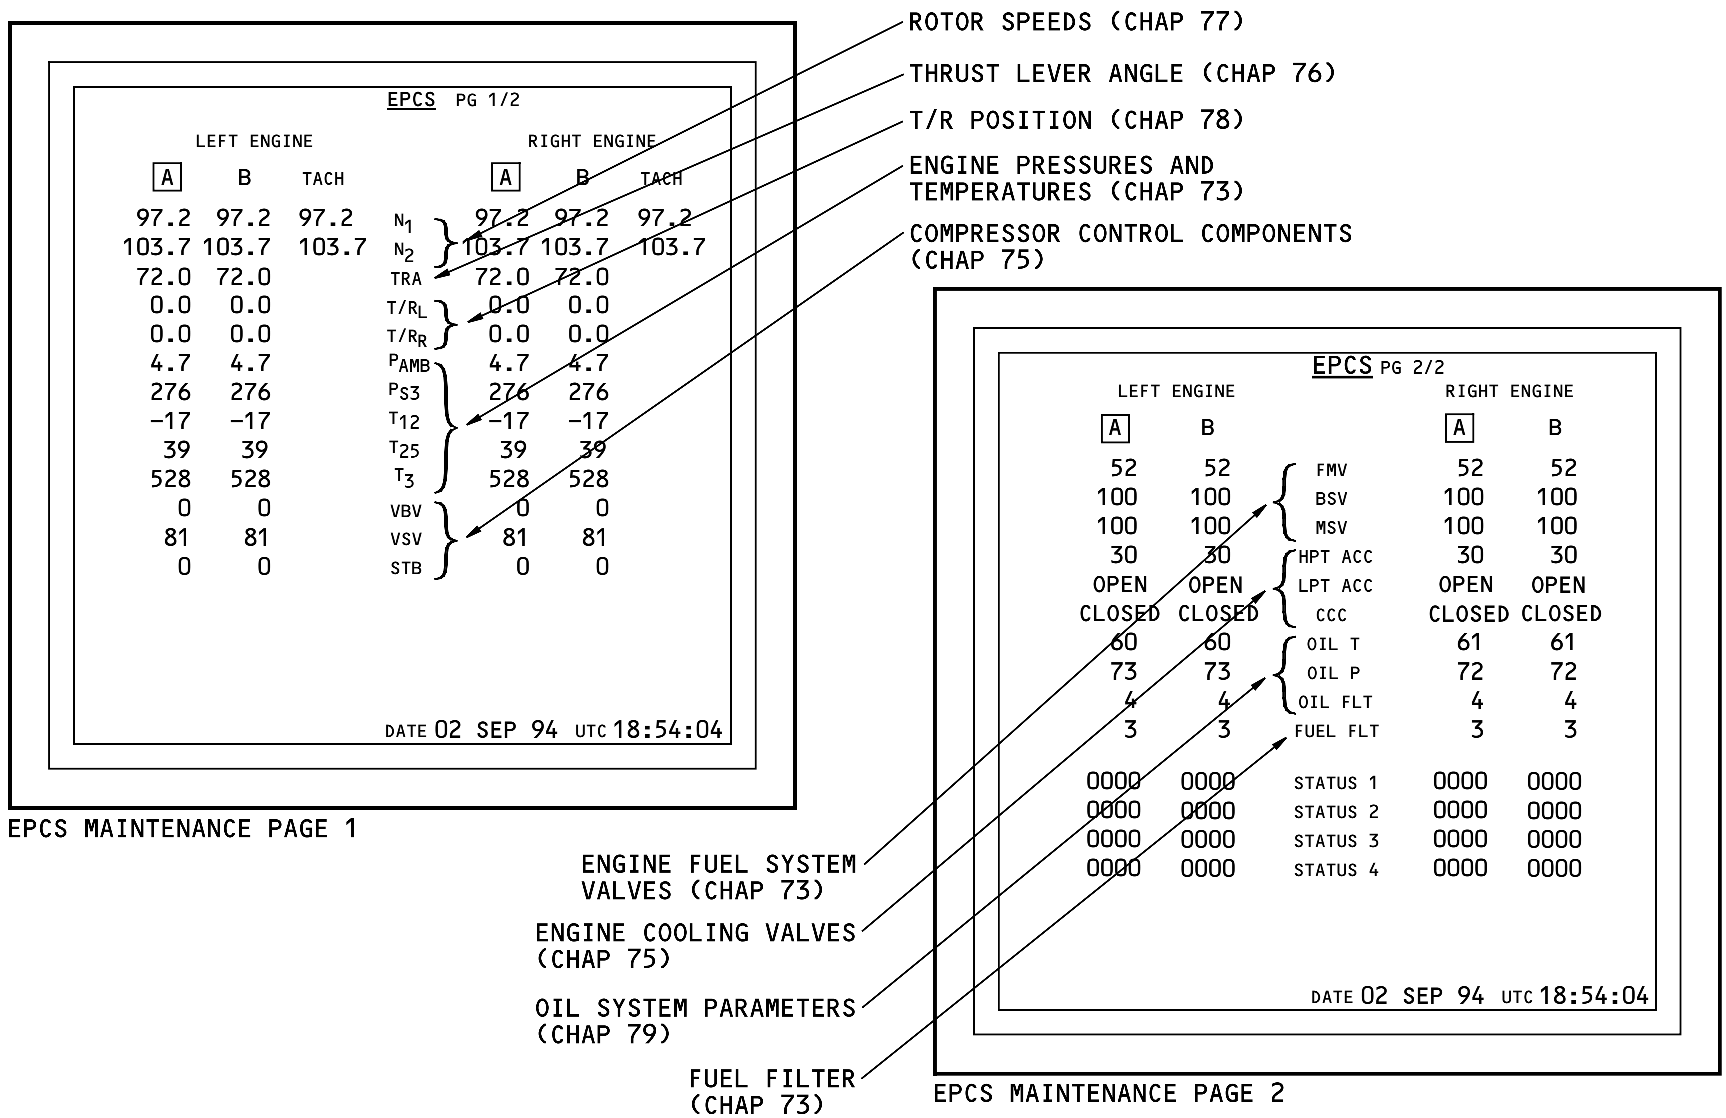
These are the parameters that show on the EPCS maintenance page 2:

- FMV: fuel metering valve position (percent open)
- BSV: burner staging valve position (percent open)
- MSV: main staging valve position (percent open)
- HPT ACC: HPT active clearance control valve position (percent open)
- LPT ACC: LPT active clearance control valve position (OPEN or CLOSED)
- CCC: core compartment cooling valve position (OPEN or CLOSED)
- OIL T: oil temperature (degrees Celsius)
- OIL P: oil pressure (psi)
- OIL FLT: oil filter differential pressure (psi)
- FUEL FLT: fuel filter differential pressure (psi).

Refer to the related ATA chapter for more information about these indications.

Status Words

The status words at the bottom of the page show data about the EEC. Each word is a four character hexadecimal number. When decoded, each word shows 16 different parameters.



ENGINE INDICATING - EPCS MAINTENANCE PAGES

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE INDICATING - PROPULSION DATA LIMITS MAINTENANCE PAGES

Propulsion Data Limits - Page 1

The propulsion data limits maintenance page 1 shows data limits for these engine parameters:

- Rotor speeds
- EGT
- Oil pressure
- Oil temperature.

Propulsion Data Limits - Page 2

The propulsion data limits maintenance page 2 shows these limits:

- Exceedance profiles
- Takeoff thrust
- Minimum idle
- Oil quantity
- Vibration
- In-flight relight
- Cross-bleed start.

The exceedance profile display shows the limits for the EGT profiles. The EGT profiles show on the engine exceedance maintenance page (not shown). EGT OPER ORIGIN is the temperature at which the EGT exceedance profile starts when the engine is running. EGT START ORIGIN is the temperature at which the EGT exceedance profile starts during an engine start. DELTA is the temperature increment for the related exceedance profile.

TAKEOFF THRUST is the N1 value at which the AIMS sets the takeoff thrust discrete. The AIMS shows a takeoff warning if the takeoff thrust discrete is set and the airplane is not in the correct takeoff configuration.

The MINIMUM IDLE and DELAY display show data that the AIMS uses to find if the engine is running. MINIMUM IDLE is an N2 reference value. DELAY is a time delay in seconds. The AIMS usually gets an engine run discrete signal from the EEC. If that signal is invalid, it uses N2. If N2 is above minimum idle for more than the time delay shown, then AIMS sets the engine run discrete.

The OIL QTY: LOW display shows the low limit, in quarts, for engine oil quantity. When the quantity gets below the low limit, the oil quantity display on the secondary engine page (not shown) shows in reverse video (black letters on a white background). The letters LO also show next to the oil quantity display.

The VIB: WHITE display shows the vibration level that causes the vibration display on the secondary engine page (not shown) to show in reverse video (black letters on a white background). This vibration level also causes the secondary engine page to show automatically.

In-Flight Relight Data

The IN-FLIGHT RELIGHT display shows data points that the AIMS uses to make the in-flight relight envelope (not shown). The in-flight relight envelope shows on the EICAS display.

ENGINE INDICATING - PROPULSION DATA LIMITS MAINTENANCE PAGES

Cross-Bleed Start Data

The CROSS-BLEED START display shows data points that define the cross-bleed start envelope. If the airplane is in the cross-bleed start envelope, the cross-bleed start annunciation (not shown) shows with the relight start envelope on the EICAS display.

APU Data Limits

The APU display shows data limits for these APU parameters:

- RPM
- EGT
- Oil pressure
- Oil temperature
- Oil quantity.

ENGINE INDICATING - PROPULSION DATA LIMITS MAINTENANCE PAGES

ENGINE INDICATING - FUNCTIONAL DESCRIPTION

General

The engine indicating system supplies engine data to the EEC. The EEC monitors the engine parameters and sends them to the AIMS and the AVM signal conditioner unit. The AIMS shows the engine parameters on the EICAS and secondary engine displays.

These are the engine parameters that engine indicating system monitors:

- N1 (LPC rotor speed)
- N2 (HPC rotor speed)
- EGT (T49)
- Engine vibration
- Fan exit pressure (PS13)
- HPC inlet pressure (P25)
- HPT exit pressure (P49)
- LPT exit temperature (T5).

Engine Tachometer System

The engine tachometer system monitors N1 and N2. The system has an N1 and an N2 speed sensor. The N1 sensor sends signals to the EEC, EDIU, AVM signal conditioner, and the AIMS. The N2 sensor sends signals to the EEC, AVM signal conditioner and the AIMS.

Temperature Sensing System

The EEC uses T49 sensors and a pyrometer to monitor EGT. The T49 sensors are thermocouples. They measure the temperature between the LPT and HPT. The pyrometer is an infrared sensor system. It measures the blade heat energy of the first stage LPT blades.

Airborne Vibration Monitoring (AVM) System

The AVM system measures engine vibration. The two engine accelerometers send electrical charges to the remote charge converter (RCC). The RCC changes the accelerometer electrical charges to voltage signals and sends them to the AVM signal conditioner. The signal conditioner uses the voltage signals and engine speed signals to calculate engine vibration.

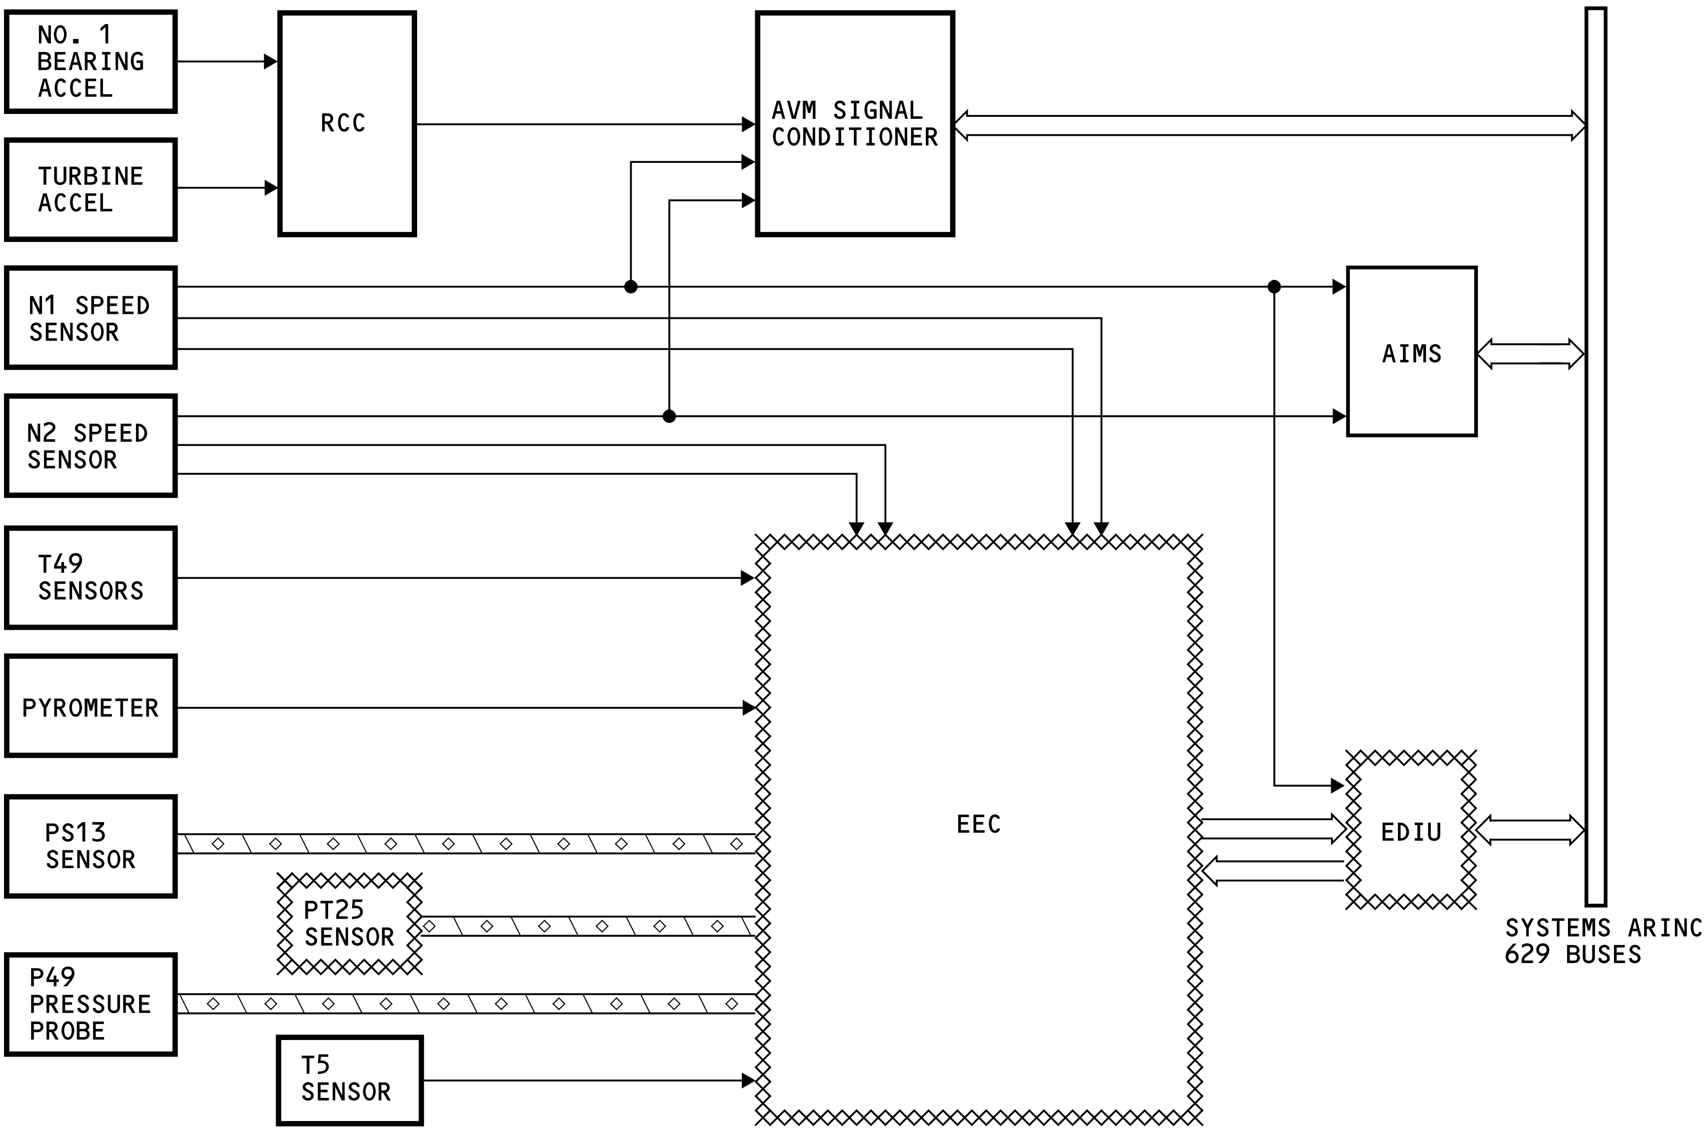
The AVM signal conditioner unit also contains engine balancing system (EBS) functions. It uses speed and vibration signals to calculate a balance solution. You use the EBS to correct high engine vibration caused by the fan or the LPT. The signal conditioner sends the EBS data to the AIMS.

Engine Mounted Sensors

The engine mounted sensors supply this data to the EEC:

- PS13
- P25
- P49
- T5.

This data goes to the ACMS function in the AIMS. You can get reports from the ACMS for engine condition monitoring.



ENGINE INDICATING - FUNCTIONAL DESCRIPTION

Engine Oil

WB371

TABLE OF CONTENTS

THIS PAGE INTENTIONALLY LEFT BLANK

OIL - INTRODUCTION

Purpose

The engine oil system does these functions:

- Supplies oil to lubricate, cool, and clean the engine bearings and gearboxes
- Supplies oil to decrease vibration at the engine bearings (oil damping)
- Gives heat to the engine fuel to prevent ice formation in the fuel.

The oil system has these subsystems:

- Storage
- Distribution
- Indicating.

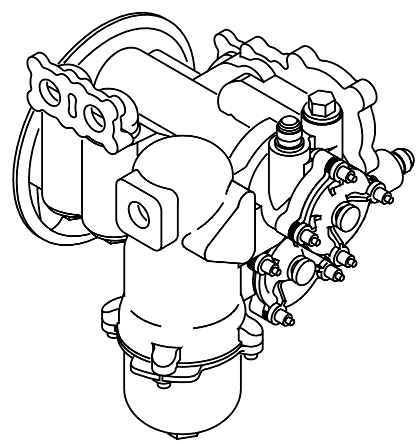
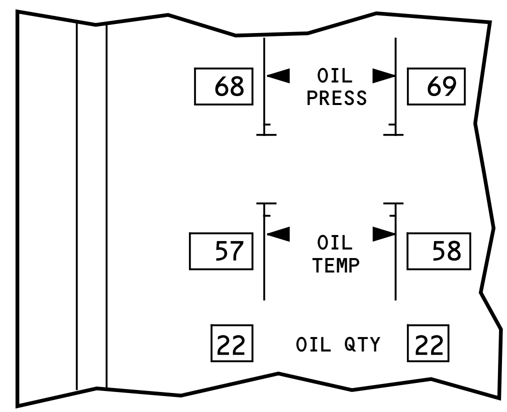
OIL TANK



LUBE & SCAVENGE PUMP



SECONDARY ENGINE DISPLAY

79-00-00-101 Rev 3 04/03/95

OIL - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

OIL - GENERAL DESCRIPTION

Storage

The engine oil tank is the reservoir for the engine oil system. You fill the oil tank through the manual gravity filling cap assembly.

Distribution

The engine oil distribution subsystem has these parts:

- Pressure
- Scavenge
- Breather.

Oil flows from the engine oil tank to the lube and scavenge pump. The lube pump elements pressurize the oil for output. The lube pump does not control the oil output pressure. When the engine speed changes, the oil pressure changes.

The pressurized oil flows through the oil filter element. The oil filter differential pressure sensor and the EEC monitor the condition of the filter.

The oil flows through the main fuel/oil heat exchanger. The heat exchanger gives the heat of the engine oil to the fuel. The fuel/oil heat exchanger is the primary source of engine oil cooling. The oil/oil heat exchanger uses engine oil to cool the backup generator oil. The oil then flows to the engine bearings and gears.

See the generator drive section for more information (AMM PART I 24-10).

Downstream of the main fuel/oil heat exchanger, some pressurized oil returns to the lube pump boost element. The engine uses this boost oil at the bearings to decrease engine vibration.

The scavenge oil flows through the scavenge oil inlet screens inside to the lube and scavenge oil pump. The scavenge pump elements remove oil and contaminants from the bearing compartments and gearboxes. The scavenge oil returns to the engine oil tank.

The scavenge oil enters the oil tank through the debris monitoring system (DMS). The DMS has an air/oil separator, sensor, and conditioner that monitor ferrous particles in the scavenge oil.

The DMS air/oil separator removes air from the scavenge oil. This air pressurizes the oil tank and then goes overboard through the center vent tube extension in the turbine exhaust plug.

Indication

The engine oil indication subsystem uses these sensors and the EEC to monitor the oil system:

- Oil pressure sensor
- Oil temperature sensor
- Oil filter differential pressure sensor.

OIL - GENERAL DESCRIPTION

The AIMS uses the oil level sensor to monitor the oil quantity.

The primary display system (PDS) shows oil pressure, temperature, and quantity.

The PDS also shows advisory and status messages to indicate oil system fault conditions.

Additional oil system data is available at the maintenance access terminal (MAT).

Training Information Point

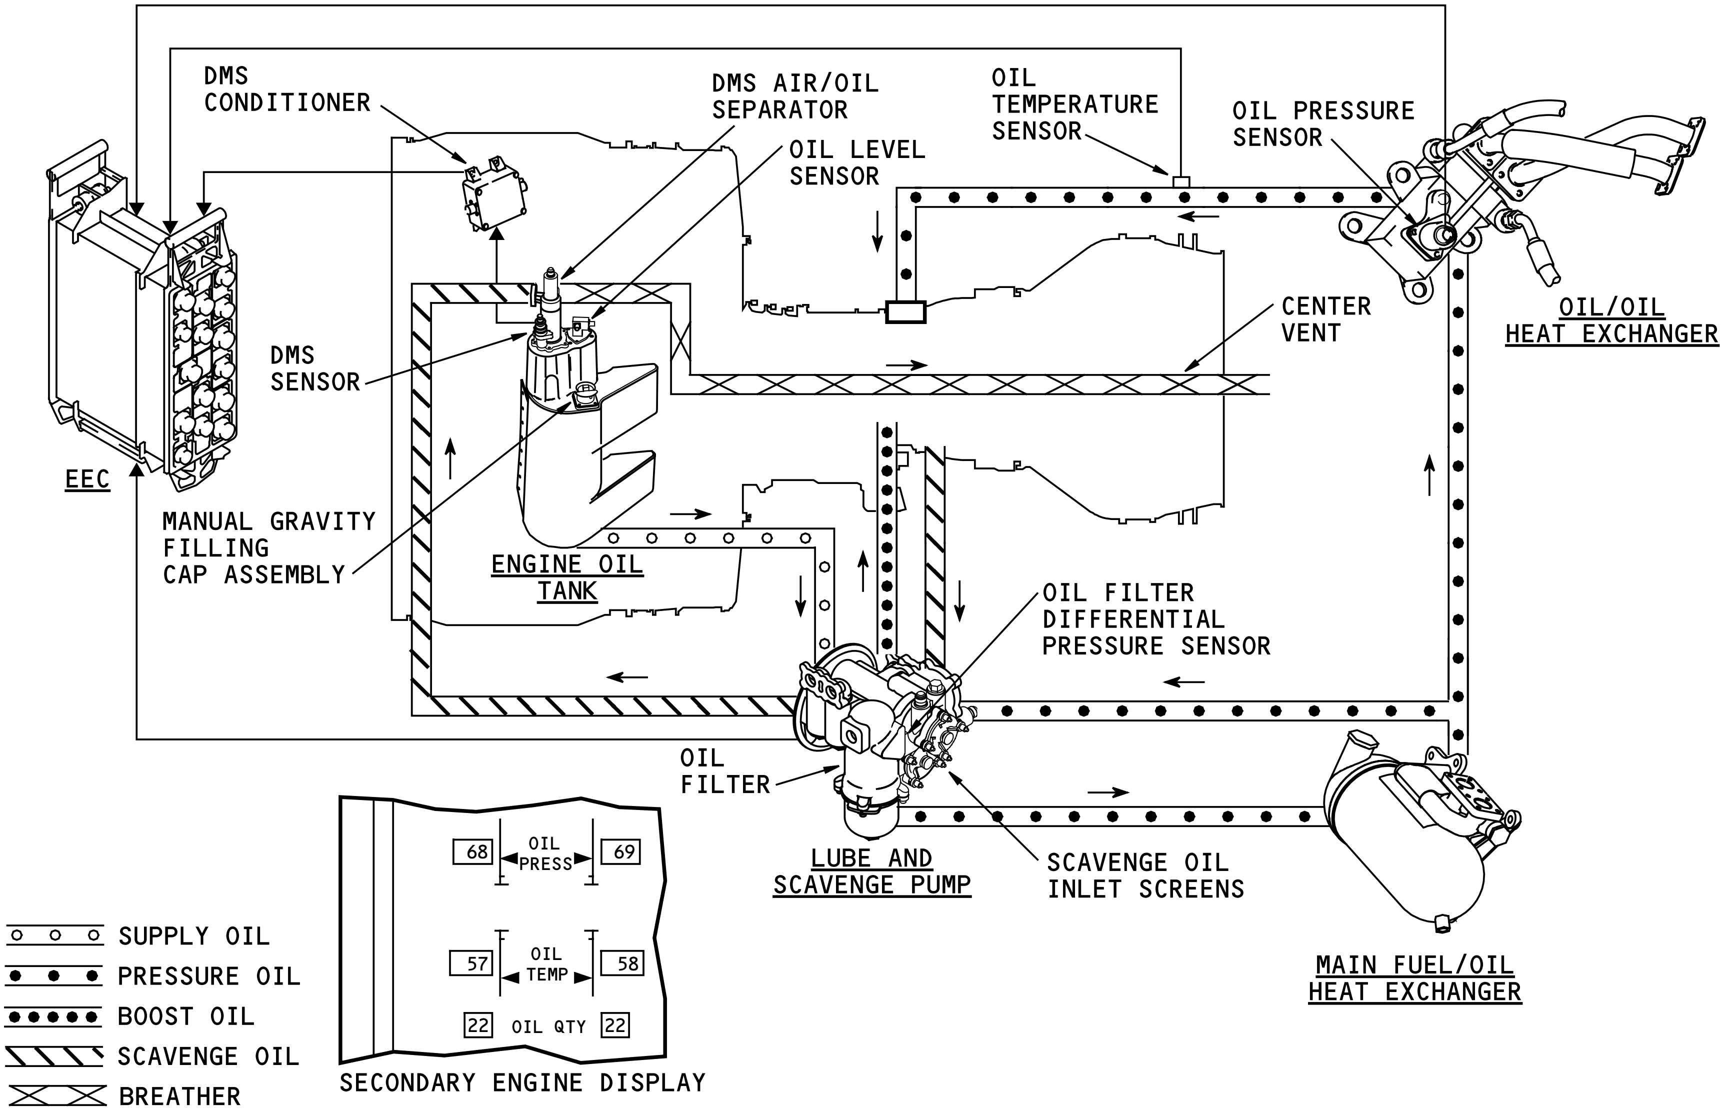
Obey these WARNINGS and CAUTIONS when you do maintenance on the engine oil system:

WARNING: DO NOT TOUCH THE COMPONENTS OF THE OIL SYSTEM IF THE ENGINE IS HOT. THESE COMPONENTS STAY HOTTER THAN OTHER COMPONENTS. HOT COMPONENTS CAN BURN YOU.

WARNING: DO NOT OPEN THE OIL SYSTEM UNTIL THE PRESSURE GOES TO ZERO. THE PRESSURE GOES TO ZERO APPROXIMATELY 5 MINUTES AFTER AN ENGINE SHUTDOWN. A PRESSURIZED OIL SYSTEM CAN RELEASE A SPRAY OF HOT OIL THAT CAN BURN YOU.

WARNING: DO NOT LET THE OIL STAY ON YOUR SKIN. YOU CAN ABSORB POISONOUS MATERIALS FROM THE OIL THROUGH YOUR SKIN.

CAUTION: DO NOT LET OIL GET ON THE ENGINE OR OTHER COMPONENTS. IMMEDIATELY CLEAN THE OIL WHEN IT FALLS ON THEM. OIL CAN CAUSE DAMAGE TO PAINT AND RUBBER.



79-00-00-102 Rev 6

OIL - GENERAL DESCRIPTION

OIL - STORAGE - GENERAL DESCRIPTION

Purpose

The engine oil tank contains the engine oil. It supplies oil to the lube pump elements and gets scavenge oil from the scavenge pump elements.

Location

The engine oil tank attaches to the fan case at the 9:00 position.

Physical Description

The engine oil tank is an aluminum structure. It has a maximum capacity of 28 quarts (26.5 liters).

The oil tank has these line replaceable units (LRU):

- Oil level sensor
- Manual gravity filling cap assembly
- DMS sensor
- DMS air/oil separator.

Functional Description

The oil level sensor sends oil quantity data to the AIMS for display.

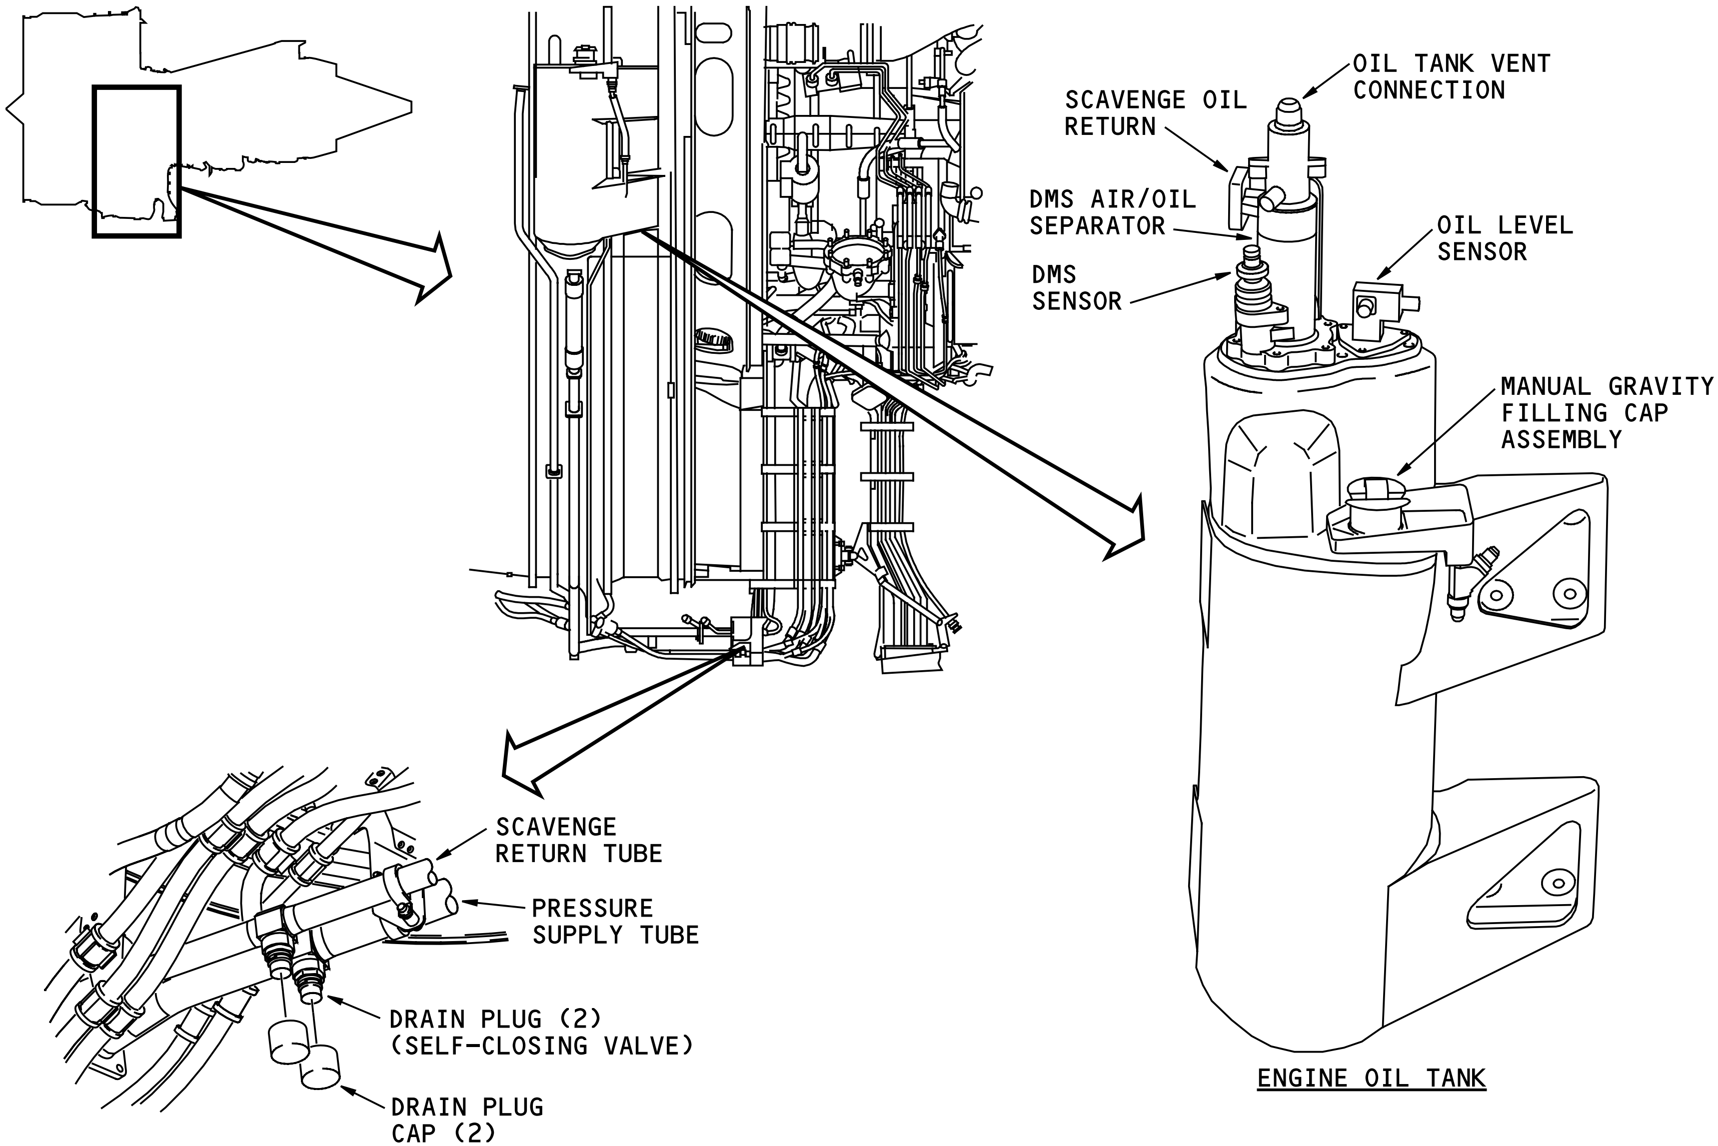
You fill the oil tank through the manual gravity filling cap assembly.

The DMS sensor finds ferrous particles in the scavenge oil.

The DMS air/oil separator removes the air from the scavenge oil.

Training Information Point

You use the drain plugs in the oil pump supply tube and oil tank supply tube to drain the engine oil tank.



79-10-00-101 Rev 4 04/03/95

OIL - STORAGE - GENERAL DESCRIPTION

OIL - STORAGE - TRAINING INFORMATION POINTS - SERVICING

General

You use gravity to fill the engine oil tank for any of these conditions:

- Normal servicing
- After replacement of an oil system component
- An engine oil change.

The oil tank access door is on the left fan cowl. You get access to the engine oil tank filler cap through this door.

Engine Oil Level

Examine the engine oil level in the engine oil tank in 30 minutes or less after you stop the engine.

WARNING: DO NOT OPEN THE OIL SYSTEM UNTIL THE PRESSURE GOES TO ZERO. THE PRESSURE GOES TO ZERO APPROXIMATELY 5 MINUTES AFTER AN ENGINE SHUTDOWN. A PRESSURIZED OIL SYSTEM CAN RELEASE A SPRAY OF HOT OIL THAT CAN BURN YOU.

When you open the engine oil filler cap, do a check for fuel in the oil. A smell check at the engine oil tank fill port can find the odor of fuel.

CAUTION: DO NOT MIX OILS OF DIFFERENT TYPES OR BRAND NAMES. SOME OILS WILL CHEMICALLY CHANGE WHEN YOU MIX THEM. THIS CAN CAUSE DAMAGE TO THE ENGINE.

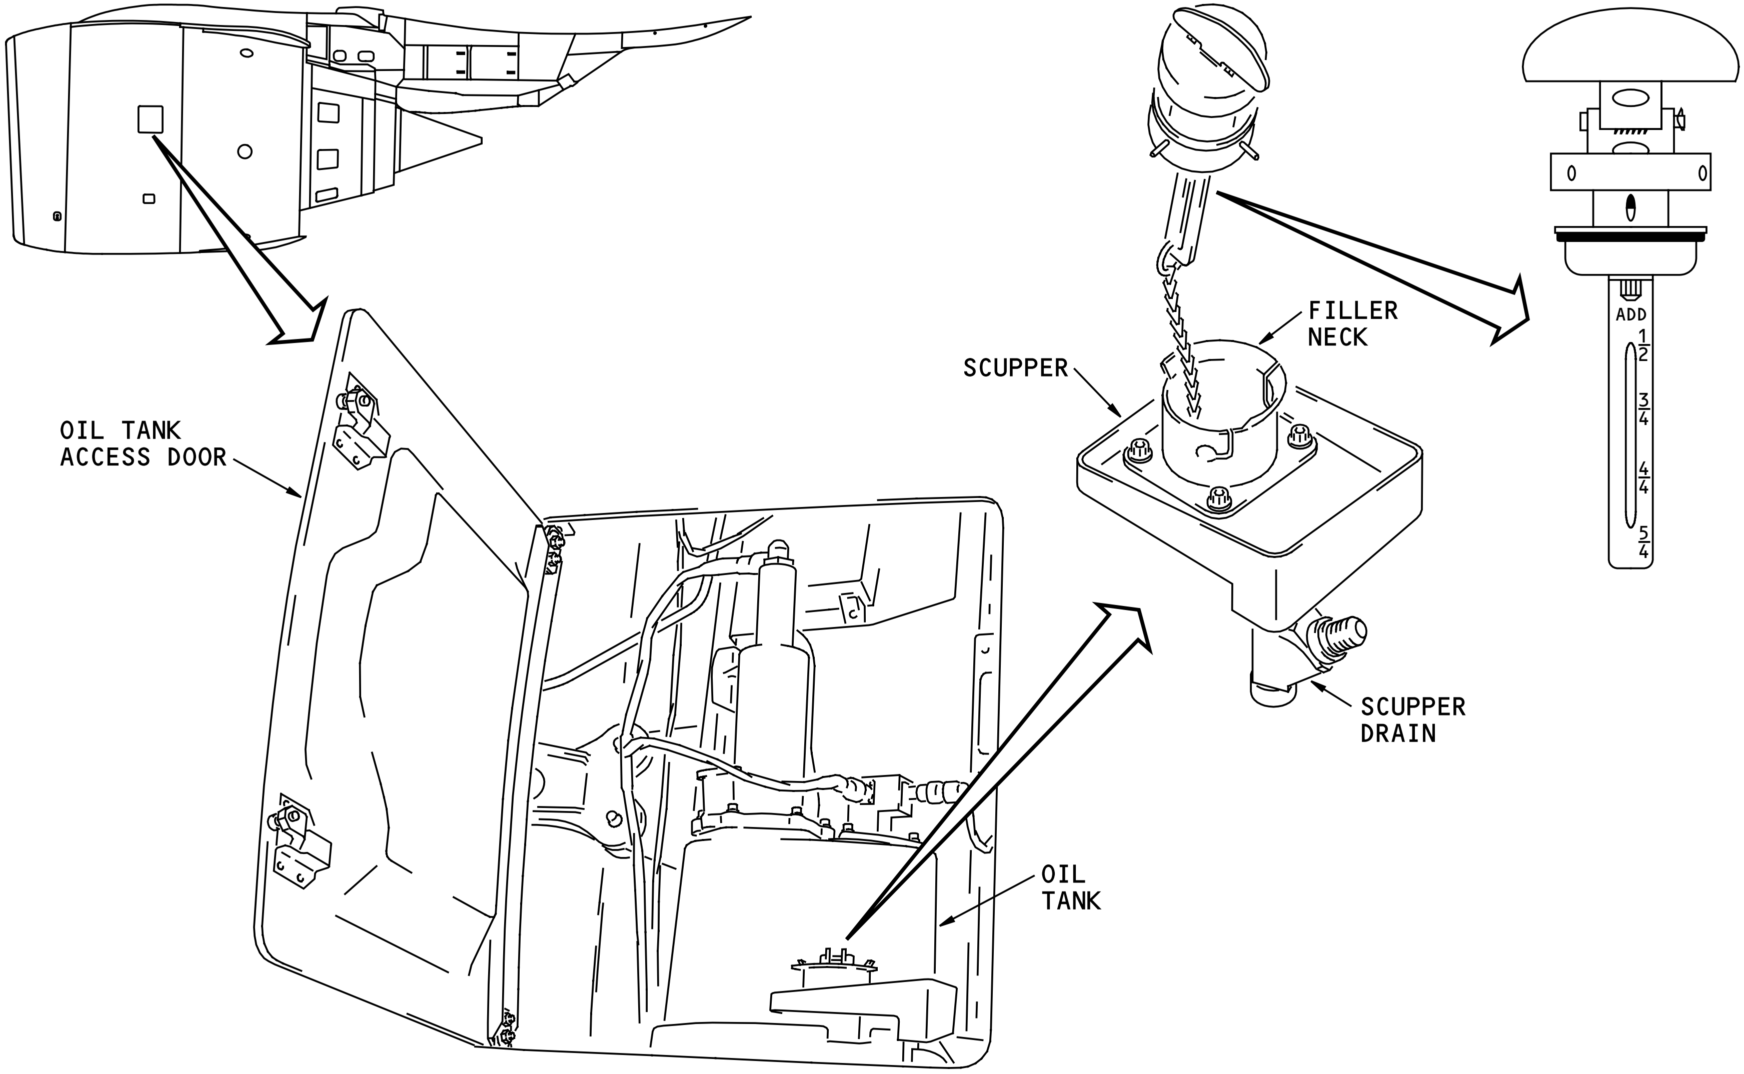
CAUTION: IF YOU ACCIDENTALLY SERVICE THE ENGINE OIL TANK WITH A DIFFERENT TYPE OR NAME BRAND OIL, DO NOT OPERATE THE ENGINE UNTIL A COMPREHENSIVE EVALUATION OF THE EFFECTS ON THE OIL SYSTEM AND ENGINE IS DONE AND A CORRECTIVE ACTION IS COMPLETED.

You measure the oil quantity with the dipstick. The markings on the dipstick show the amount of oil, in fractions of a gallon, that you must add.

NOTE: When you add engine oil to the engine oil tank, make sure you add the oil slowly. If you fill the engine oil tank too quickly, it can cause an overflow at the fill port or cause oil spillage.

The scupper catches the oil overflow and the scupper drain hose removes the overflow to the fan cowl vent.

Close the engine oil filler cap and the oil tank access door.



OIL TANK ACCESS DOOR

- Oil filter element
- Anti-leak valve.

OIL - DISTRIBUTION - RIGHT SIDE COMPONENT LOCATIONS

79-20-00-103 Rev 2

OIL - DISTRIBUTION - OIL FILTER ELEMENT

Purpose

The oil filter element cleans the engine oil.

Location

The oil filter element is in the filter housing. The filter housing is part of the lube and scavenge pump.

There is a shutoff valve and bypass valve in the filter housing.

Physical Description

The oil filter element is a disposable element. One end of the filter element has a mechanical interface that opens the shutoff valve when the element is in the filter housing. The other end of the element has threads and a locating pin.

The drain plug, the filter bowl, and the bolts keep the filter element in the filter housing. You use the drain plug to drain the filter bowl when you do maintenance on the oil filter element.

Functional Description

If the oil filter element becomes blocked, an internal bypass valve opens and lets the oil go around the filter element.

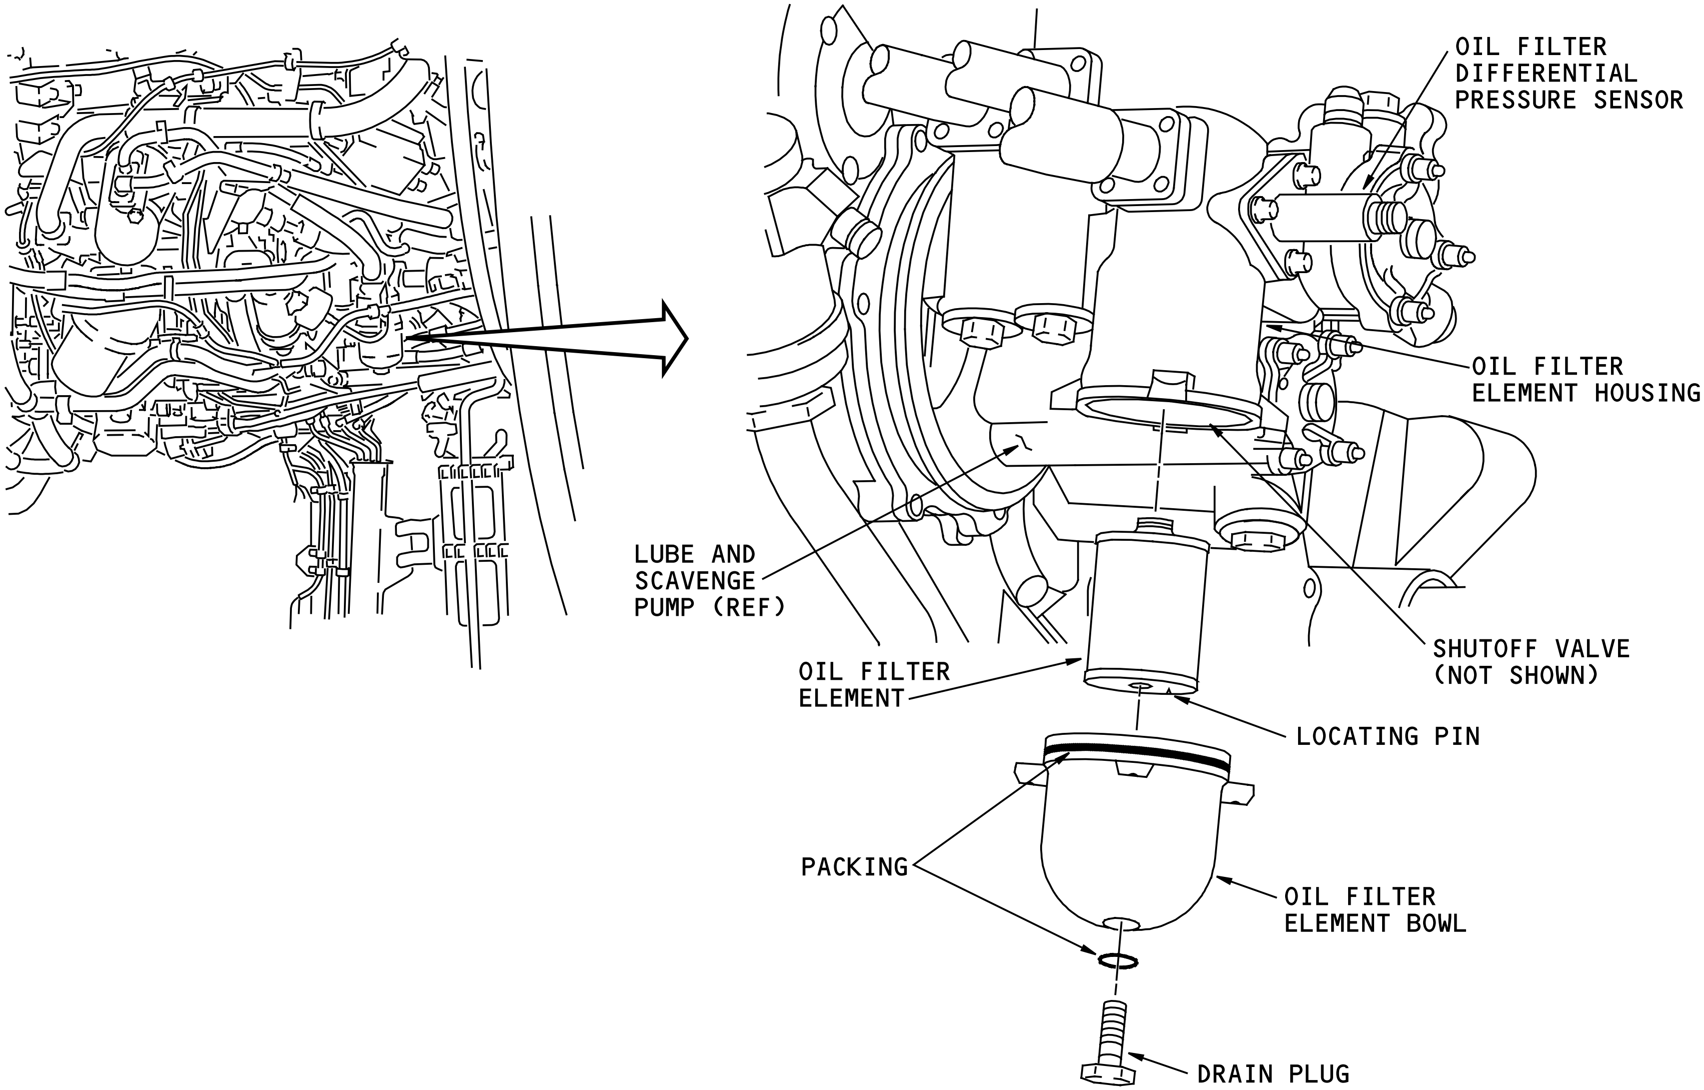
When you remove the oil filter element, an internal shutoff valve (not shown) closes. This prevents the loss of oil.

See the oil filter differential pressure sensor section for more information (AMM PART I 79-30).

Training Information Point

The locating pin aligns the filter element with a hole inside the filter bowl. It prevents the filter element from turning when you remove and install the drain plug.

NOTE: Make sure the locating pin on the filter element is in the hole in the filter bowl.



79-20-00-106 Rev 4 04/03/95

OIL - DISTRIBUTION - OIL FILTER ELEMENT

OIL - DISTRIBUTION - SCAVENGE OIL INLET SCREENS

Purpose

The scavenge oil inlet screens catch particle contamination in the scavenge oil.

Location

Five scavenge oil inlet screens are in the bottom of the lube and scavenge pump. Marks on the pump housing identify the scavenge oil source and the inlet screen location.

Physical Description

The scavenge oil inlet screens are made of metal and have a magnetic plug inside. They use threads for installation. Each screen has a preformed packing and a back up seal. You can clean the scavenge oil inlet screens.

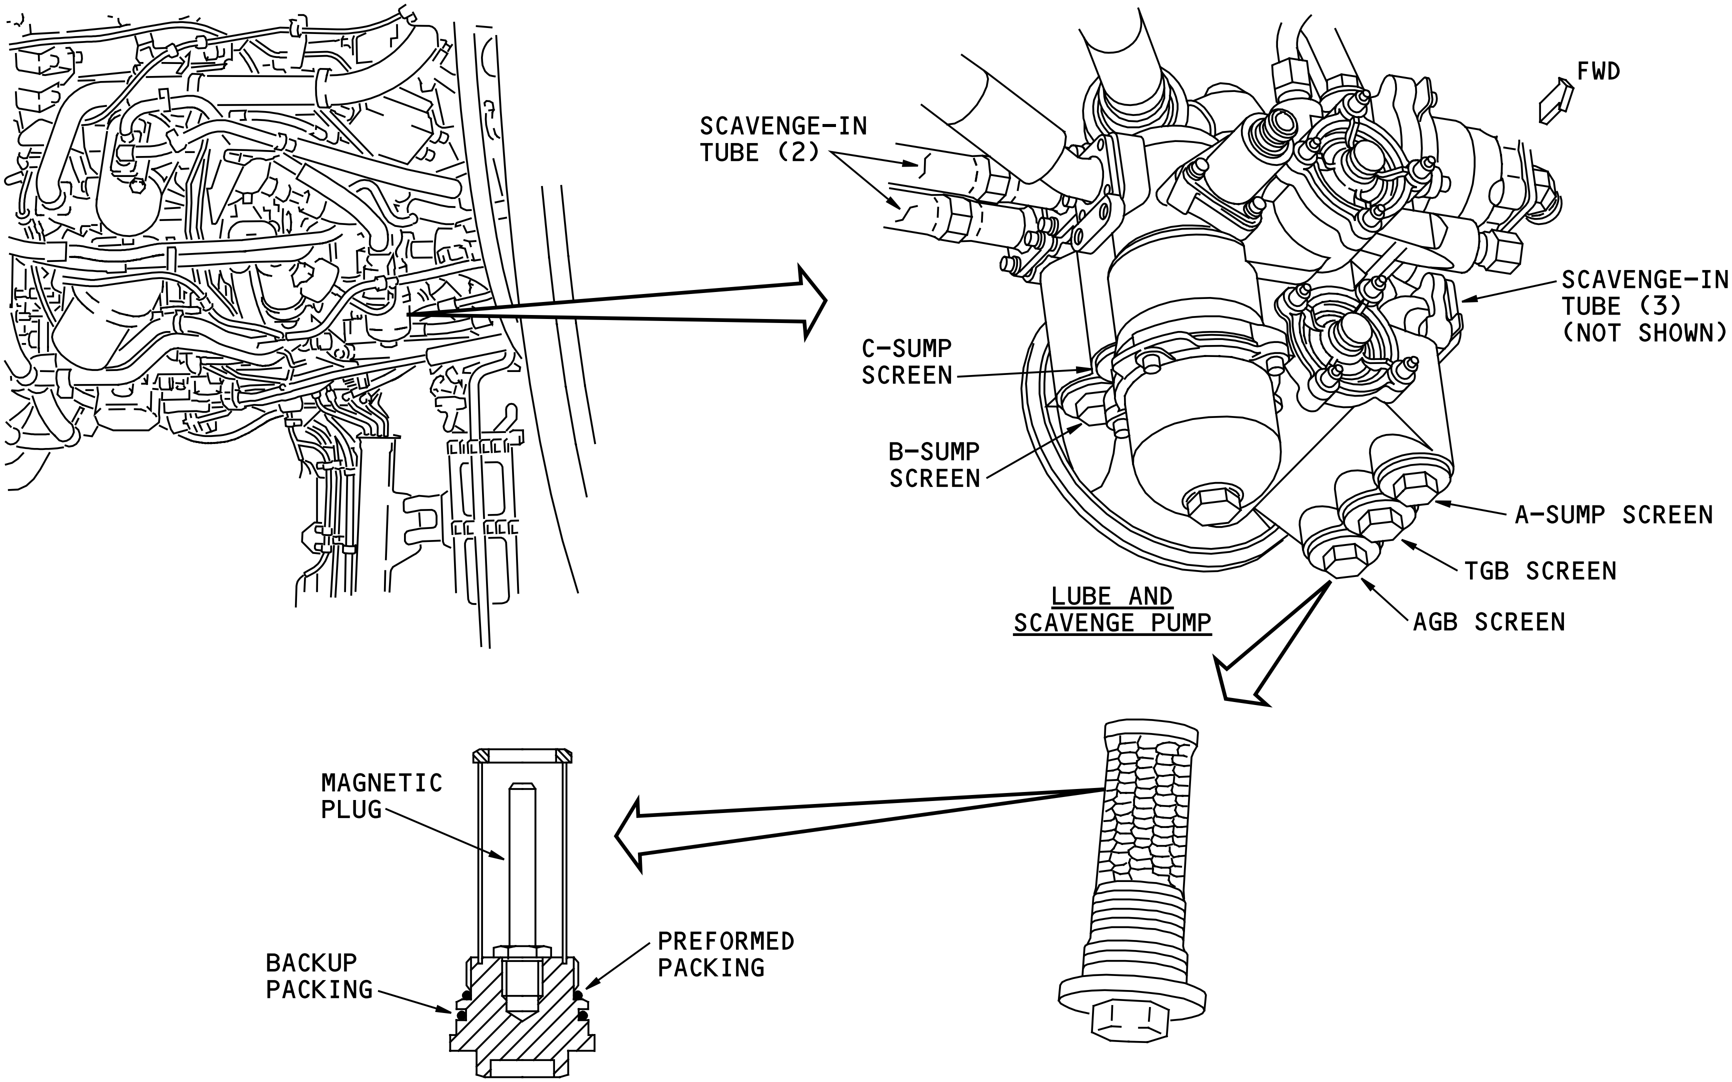
Functional Description

These are the scavenge oil inlet sources:

- A-sump
- TGB
- AGB
- B-sump
- C-sump.

When the scavenge oil returns to the scavenge pump elements, the screens catch the larger particles of contamination. This prevents damage to the pump elements.

You do a check of the magnetic plugs in the scavenge oil inlet screens if the debris monitoring system (DMS) finds ferrous contamination in the scavenge oil. The magnetic plugs catch the ferrous material and let you determine the source(s) of the contamination.



79-20-00-108 Rev 4 04/29/95

OIL - DISTRIBUTION - SCAVENGE OIL INLET SCREENS

OIL - DISTRIBUTION - DEBRIS MONITORING SYSTEM (DMS)

Purpose

The debris monitoring system (DMS) does these functions:

- Removes the air from the engine scavenge oil/air mixture
- Controls the breather air pressure in the engine oil tank
- Catches scavenge oil particle contamination
- Tells the EEC of ferrous contamination in the scavenge oil.

Location

The DMS has these LRU components:

- DMS air/oil separator
- DMS sensor
- DMS conditioner.

The air/oil separator and sensor are on the top of the engine oil tank. The conditioner is on the left side of the fan case above the engine oil tank.

Physical Description

The DMS air/oil separator is a single assembly that has these internal parts:

- Deaerator
- Particle separator.

The DMS sensor has a sensor probe and an adapter. The sensor has a threaded collar that attaches to the adapter. The adapter attaches to the air/oil separator. The sensor has one electrical connector.

The DMS conditioner is an electronic unit that has two electrical connectors. It attaches to the DMS mount adapter on the fan case.

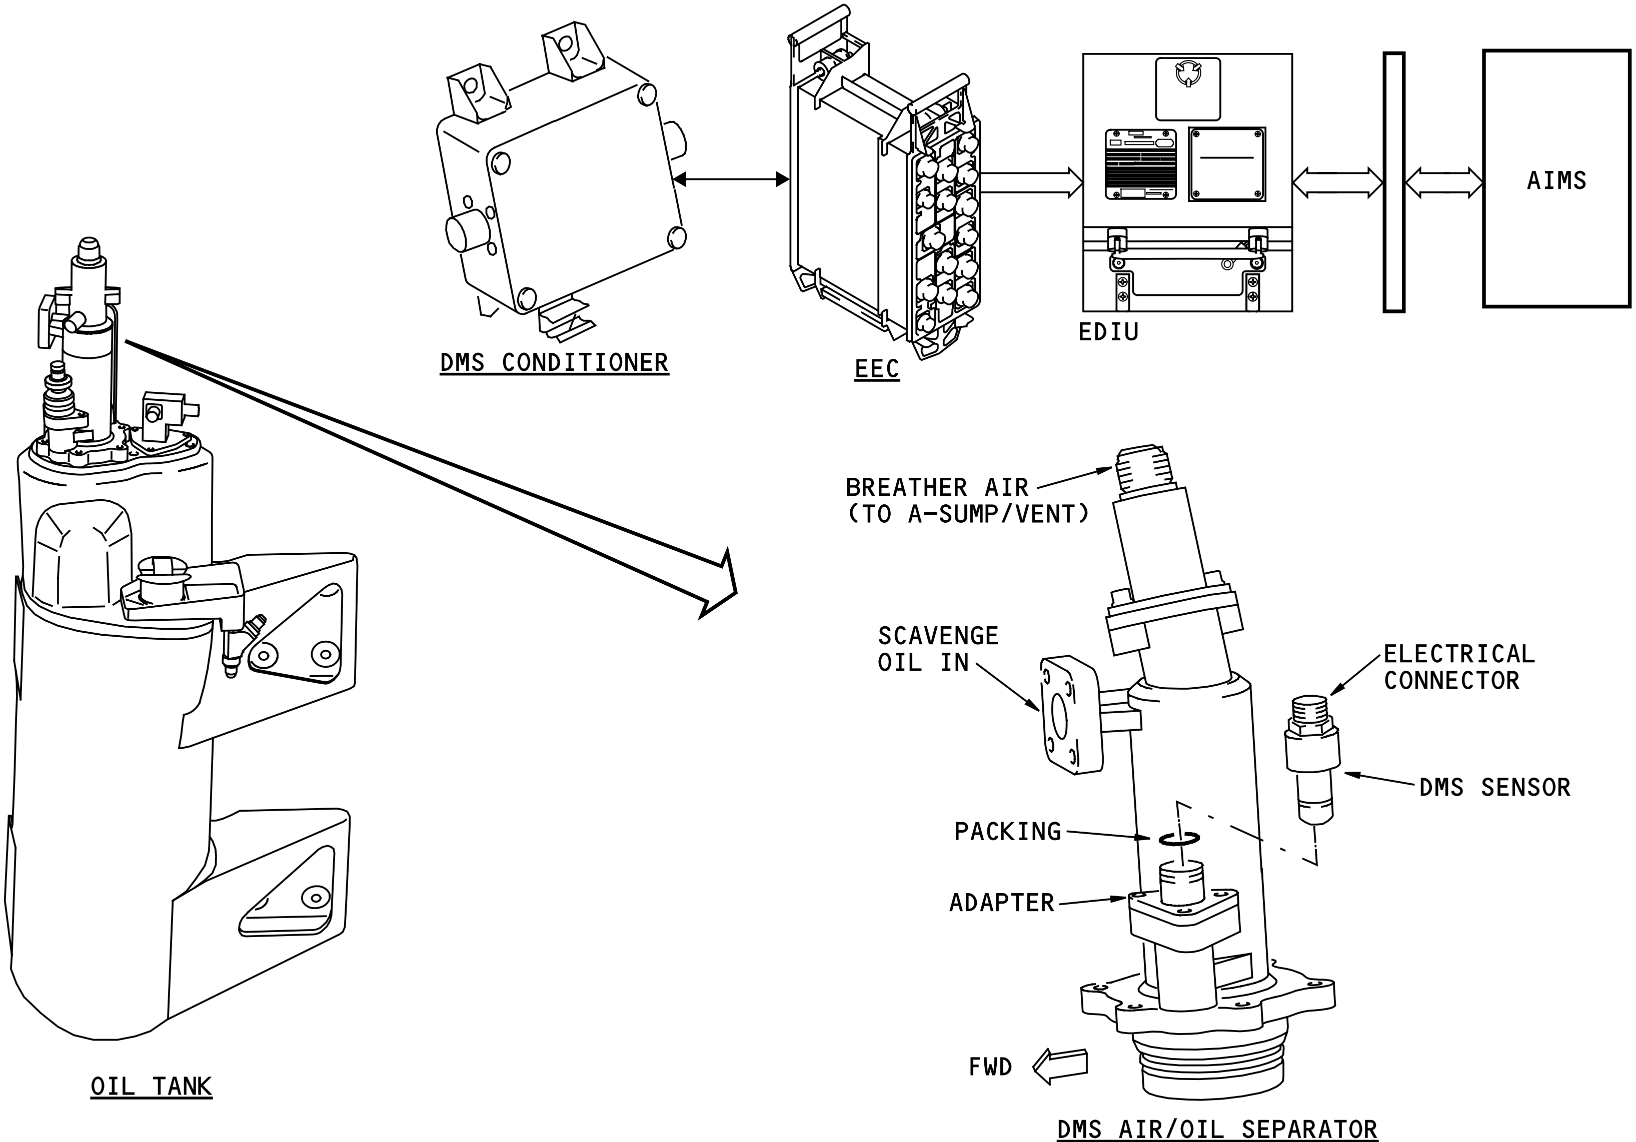
Functional Description

The DMS air/oil separator gets the scavenge oil/air mixture from the lube and scavenge pump. The deaerator removes the air from the mixture. Breather air pressure from the tank goes to A-sump and then to the overboard vent. The particle separator collects particle contamination at the DMS sensor.

The DMS sensor finds ferrous particles in the contamination. It sends a contamination data signal to the DMS conditioner.

The DMS conditioner changes the sensor signal and sends it to the EEC.

A CMCS maintenance message shows if the sensor finds ferrous contamination. The MAT can also tell you if the DMS is defective.



79-20-00-109 Rev 3 04/29/95

OIL - DISTRIBUTION - DEBRIS MONITORING SYSTEM (DMS)

THIS PAGE INTENTIONALLY LEFT BLANK

OIL - DISTRIBUTION - FUNCTIONAL DESCRIPTION

Storage

The engine oil tank contains the engine oil. It supplies oil to the pressure system and gets oil from the scavenge system. Air from the scavenge air/oil mixture pressurizes the oil tank. This prevents cavitation at the lube pump.

You fill the oil tank through the manual gravity filling cap assembly.

Pressure

The oil from the tank flows through the anti-leak valve to the lube pump. The anti-leak valve prevents the flow of oil from the oil tank to the lube and scavenge pump and the AGB when the engine is shutdown.

The lube pump uses two gerotor-type pump elements to pressurize the oil for distribution to the bearings and gearboxes.

The oil filter element cleans the oil before it enters the engine. An internal bypass valve allows unfiltered oil to not go through the filter element if there is a blockage of the element.

The main fuel/oil heat exchanger removes the heat from the engine oil. It also gives heat to the main fuel and servo fuel paths. This prevents ice in the fuel.

Pressure oil from the fuel/oil heat exchanger flows to these items:

- Lube pump
- Oil/oil heat exchanger.

The oil that returns to the lube pump gets more pressure from a single gerotor pump element. This is boost oil and it flows to these bearings for damping:

- Number 3 roller bearing
- Number 5 roller bearing.

The engine oil that flows to the oil/oil heat exchanger gets more cooling. It then goes to lubricate, clean, and cool the individual bearings and gearboxes.

Scavenge

The scavenge pump uses seven gerotor-type pump elements to remove the scavenge air/oil mixture from these engine locations:

- A-sump
- B-sump
- C-sump
- TGB
- AGB.

The scavenge oil inlet screens catch any large particle contamination before the air/oil mixture flows into the pump elements. This prevents damage to the pump.

The DMS receives the scavenge air/oil mixture from the scavenge pump and does these functions:

OIL - DISTRIBUTION - FUNCTIONAL DESCRIPTION

- Removes the air from the mixture
- Controls the air pressure in the tank
- Catches small particle contamination
- Tells the EEC of ferrous contamination in the scavenge oil.

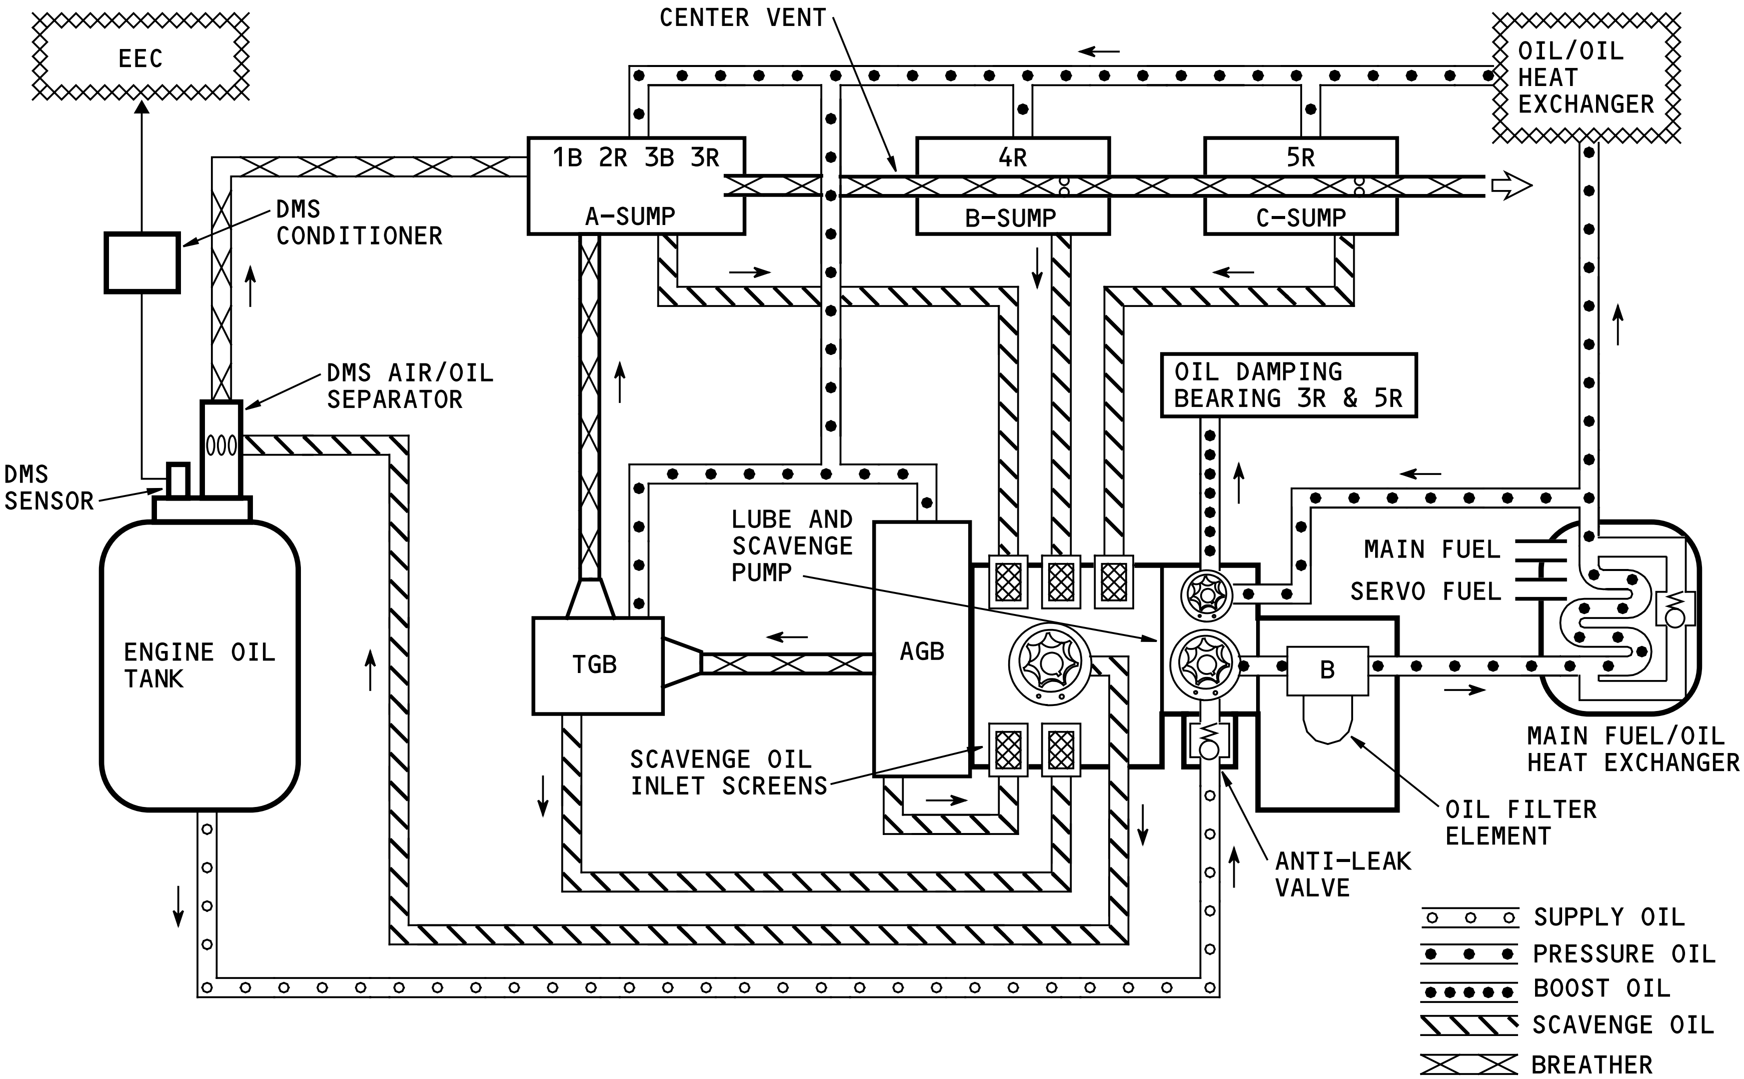
You do a check of the magnetic plugs in the scavenge oil inlet screens if the DMS finds ferrous contamination. The plugs catch the ferrous contamination at the screen location and permit you to identify the source of the contamination.

Breather

The breather system lets the air pressure in the sumps, the gearboxes, and the excess air pressure in the oil tank go to ambient.

The AGB and TGB breather pressure goes to the A-sump. The excess breather pressure from the DMS air/oil separator also goes to the A-sump.

The center vent permits the A, B, and C-sumps breather pressure to go to ambient through the vent tube extension in the aft exhaust plug.



79-20-00-110 Rev 3 09/21/1995

OIL - DISTRIBUTION - FUNCTIONAL DESCRIPTION

OIL - INDICATING - GENERAL DESCRIPTION

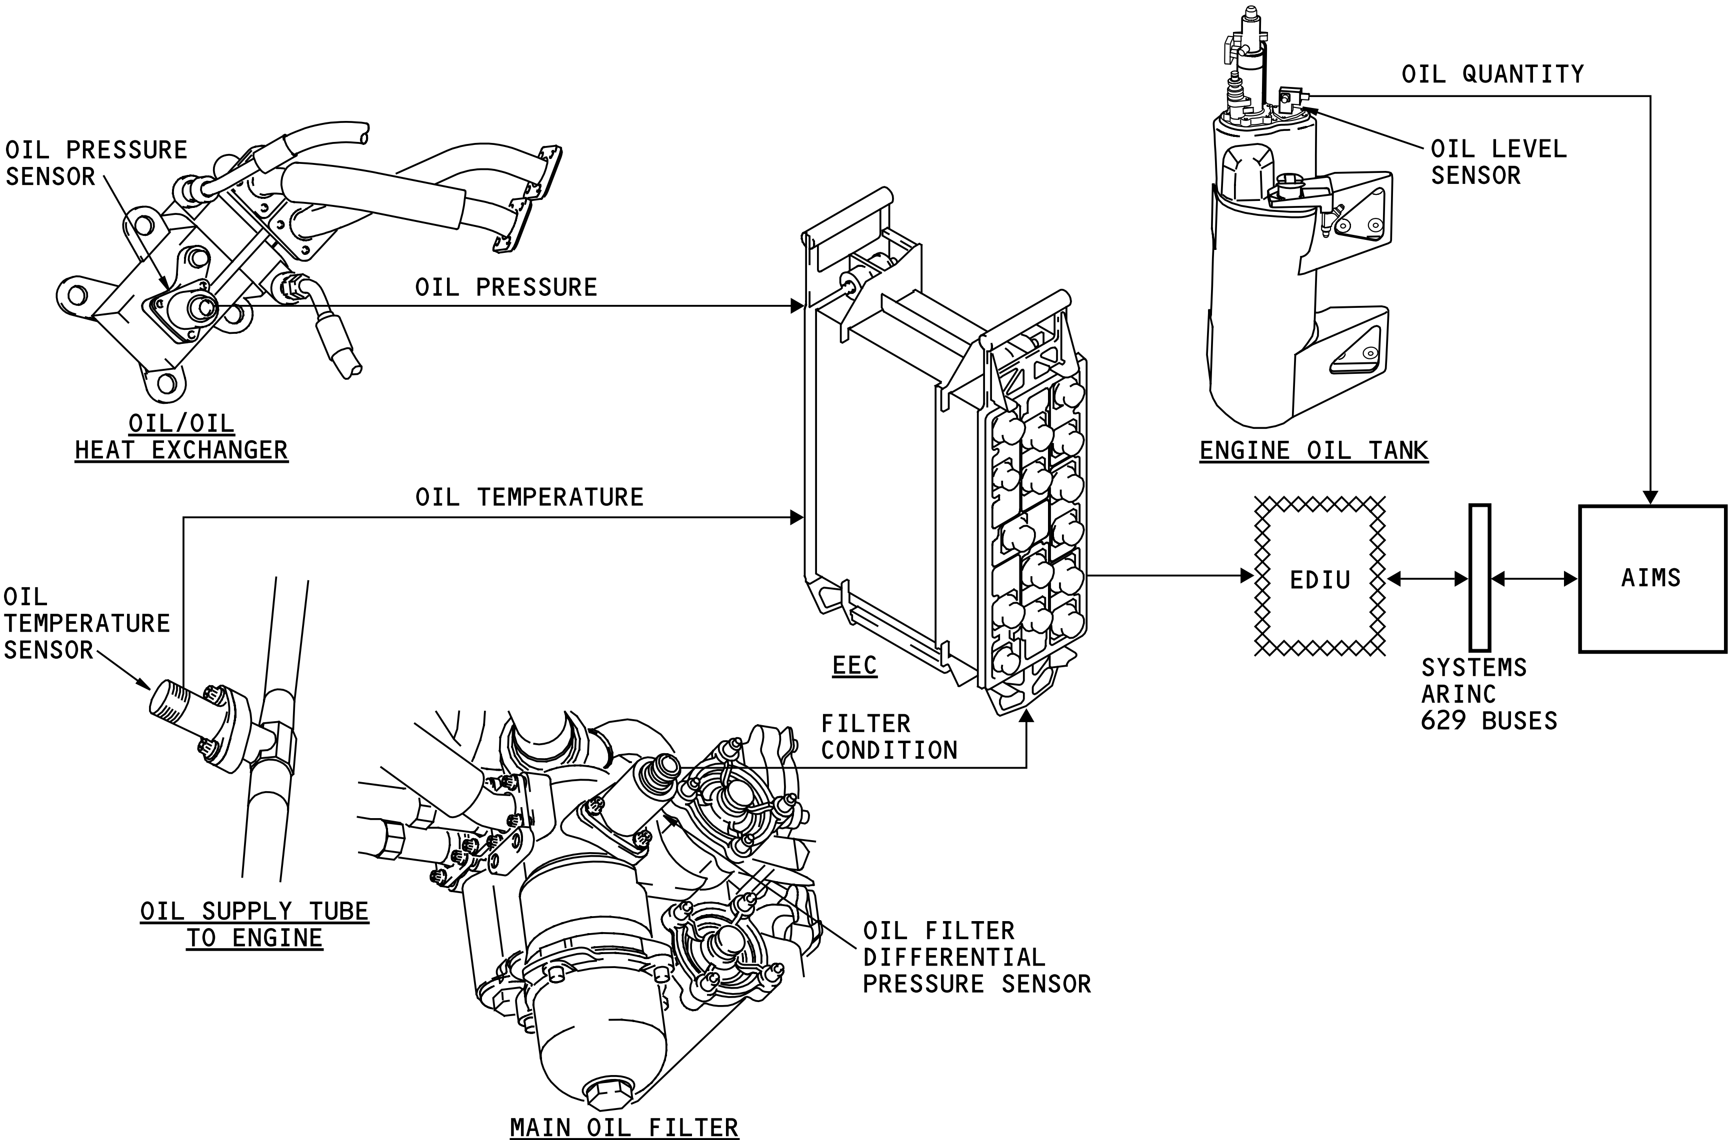
General

The oil indicating subsystem supplies engine oil data to the AIMS for display.

These components monitor the engine oil system:

- Oil level sensor
- Oil pressure sensor
- Oil temperature sensor
- Oil filter differential pressure sensor.

The EEC sends oil pressure, oil temperature, and oil filter element condition to the AIMS. The oil level sensor sends oil quantity data directly to AIMS.



OIL - INDICATING - GENERAL DESCRIPTION

OIL - INDICATING - COMPONENT LOCATIONS

Component Locations

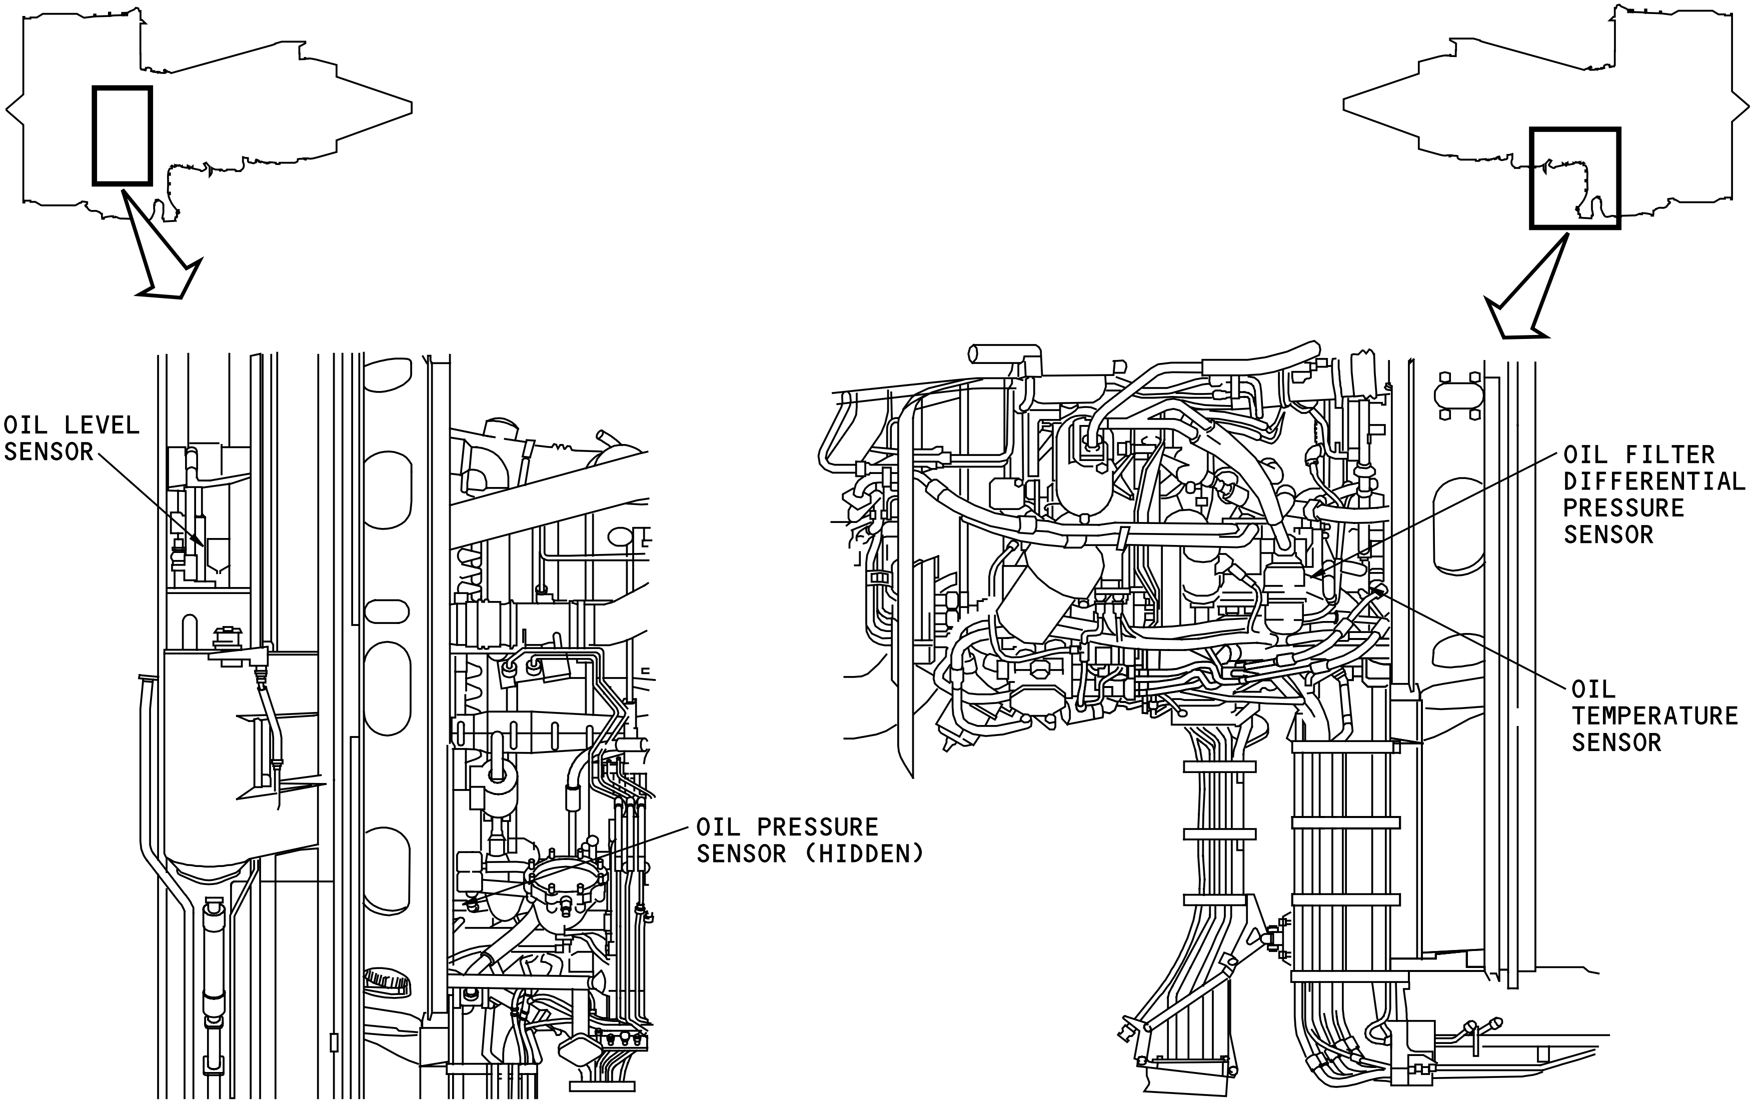
These are the oil indicating components on the left side of the engine:

- Oil level sensor
- Oil pressure sensor.

Component Locations

These are the oil indicating components on the right side of the engine:

- Oil filter differential pressure sensor
- Oil temperature sensor.



79-30-00-102 Rev 2 04/03/95

OIL - INDICATING - COMPONENT LOCATIONS

OIL - INDICATING - OIL QUANTITY INDICATING SYSTEM

Purpose

The oil quantity indicating system sends data about the quantity of oil in the engine oil tank to the AIMS for display. It uses an oil level sensor.

Location

The oil level sensor is on the top of the oil tank and extends into the tank.

Physical Description

The oil level sensor is a magnetic float-reed switch device. It has one sensing circuit that use resistors and one electrical connector.

Functional Description

The AIMS supplies an excitation signal to the sensing circuit of the oil level sensor. As the magnetic float moves up and down with the oil level, the reed switches open and close different resistor circuits. A feedback signal in proportion to the oil level goes to the AIMS. The AIMS changes its feedback signal to oil quantity for display on the secondary engine display.

When the AIMS does not get a satisfactory feedback signal, a status message shows.

Indication

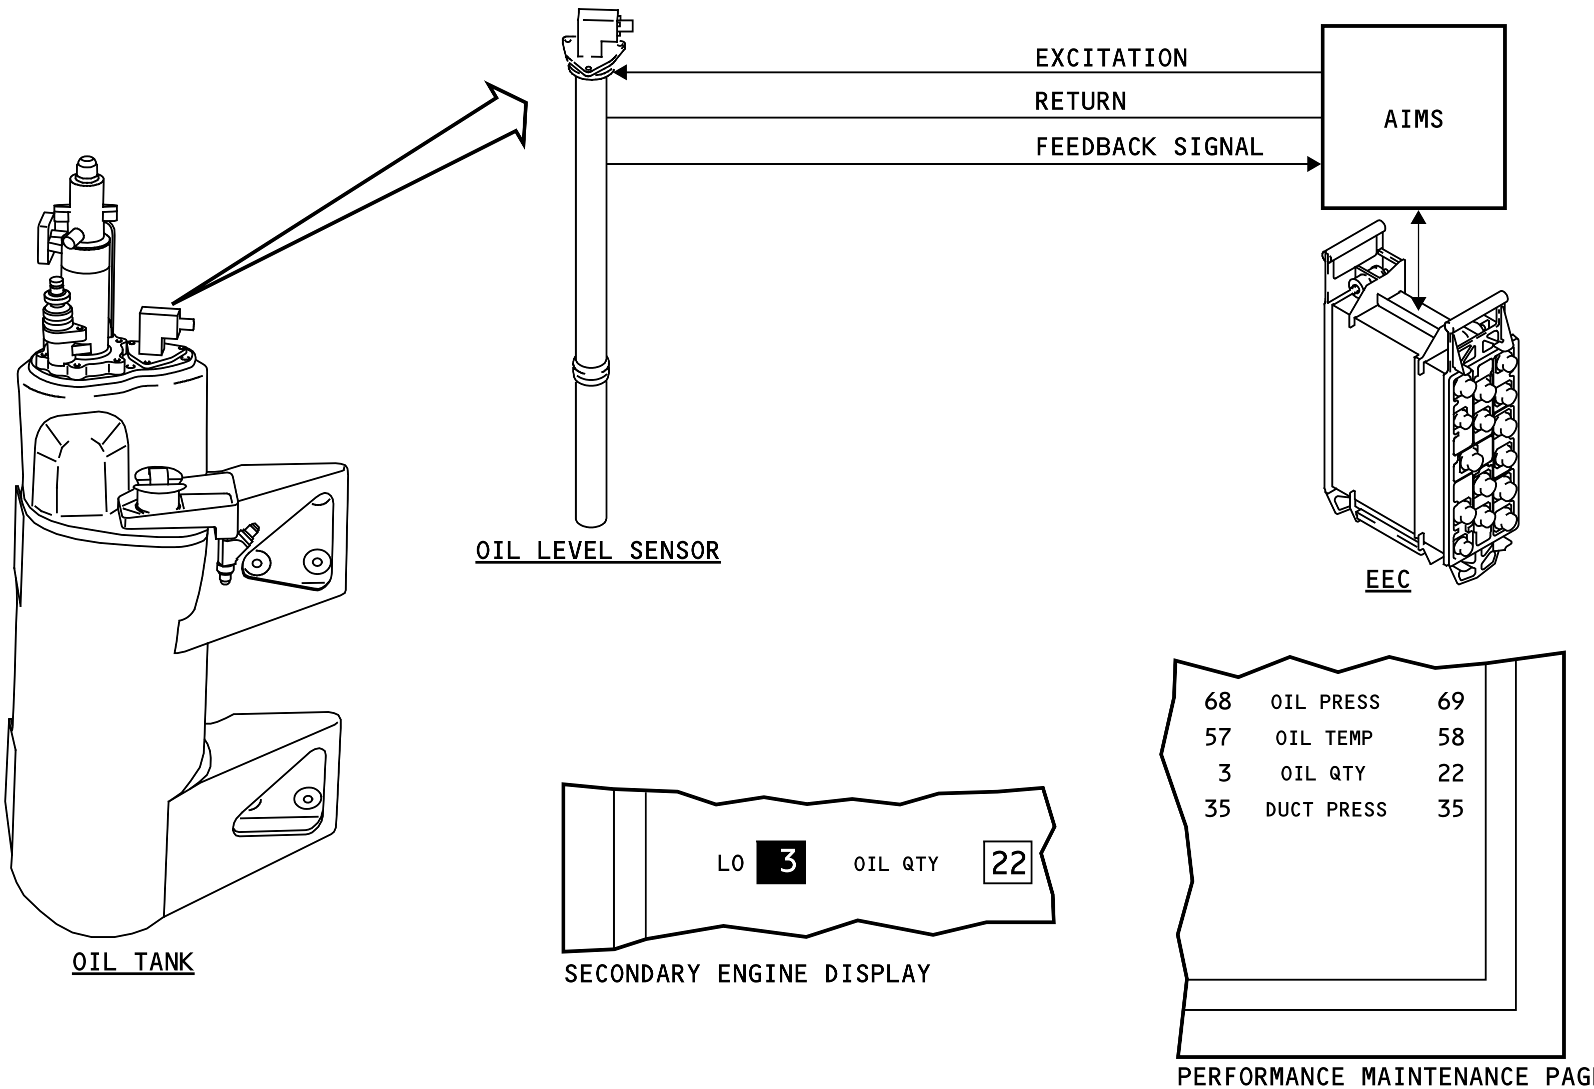
Oil quantity shows in quarts (liters).

Oil quantity shows on the secondary engine display and the performance maintenance page. The propulsion data limits maintenance page (not shown) shows the oil quantity low limit.

The oil quantity low limit is 4 quarts (3.8 liters). When the oil level is below the limit, the oil quantity readout on the secondary engine display changes to reverse video (black numbers on a white background). Also, the letters LO show next to the oil quantity display.

Training Information Point

Put the EEC Maintenance Test Switch to TEST position to read the Oil Quantity on the Secondary Engine page.



79-30-00-104 Rev 4 03/17/1998

OIL - INDICATING - OIL QUANTITY INDICATING SYSTEM

OIL - INDICATING - OIL PRESSURE INDICATING SYSTEM

Purpose

The oil pressure indicating system sends the engine oil pressure data to the AIMS for display. It uses an oil pressure sensor.

Location

The oil pressure sensor attaches to the oil/oil heat exchanger at the 7:30 position on the fan hub frame.

Physical Description

The oil pressure sensor is a piezoresistive device that contains two sensing elements. The sensor has one electrical connector.

Functional Description

The oil pressure sensor gets oil pressure data after the oil flows through the oil/oil heat exchanger.

Each EEC channel supplies an excitation signal to one sensing element. Each element measures the difference between the engine oil pressure and the bearing sump air pressure. Each element sends an oil pressure signal to its EEC channel.

When both signals from an oil pressure sensor are unsatisfactory, the status display shows a status message.

Indication

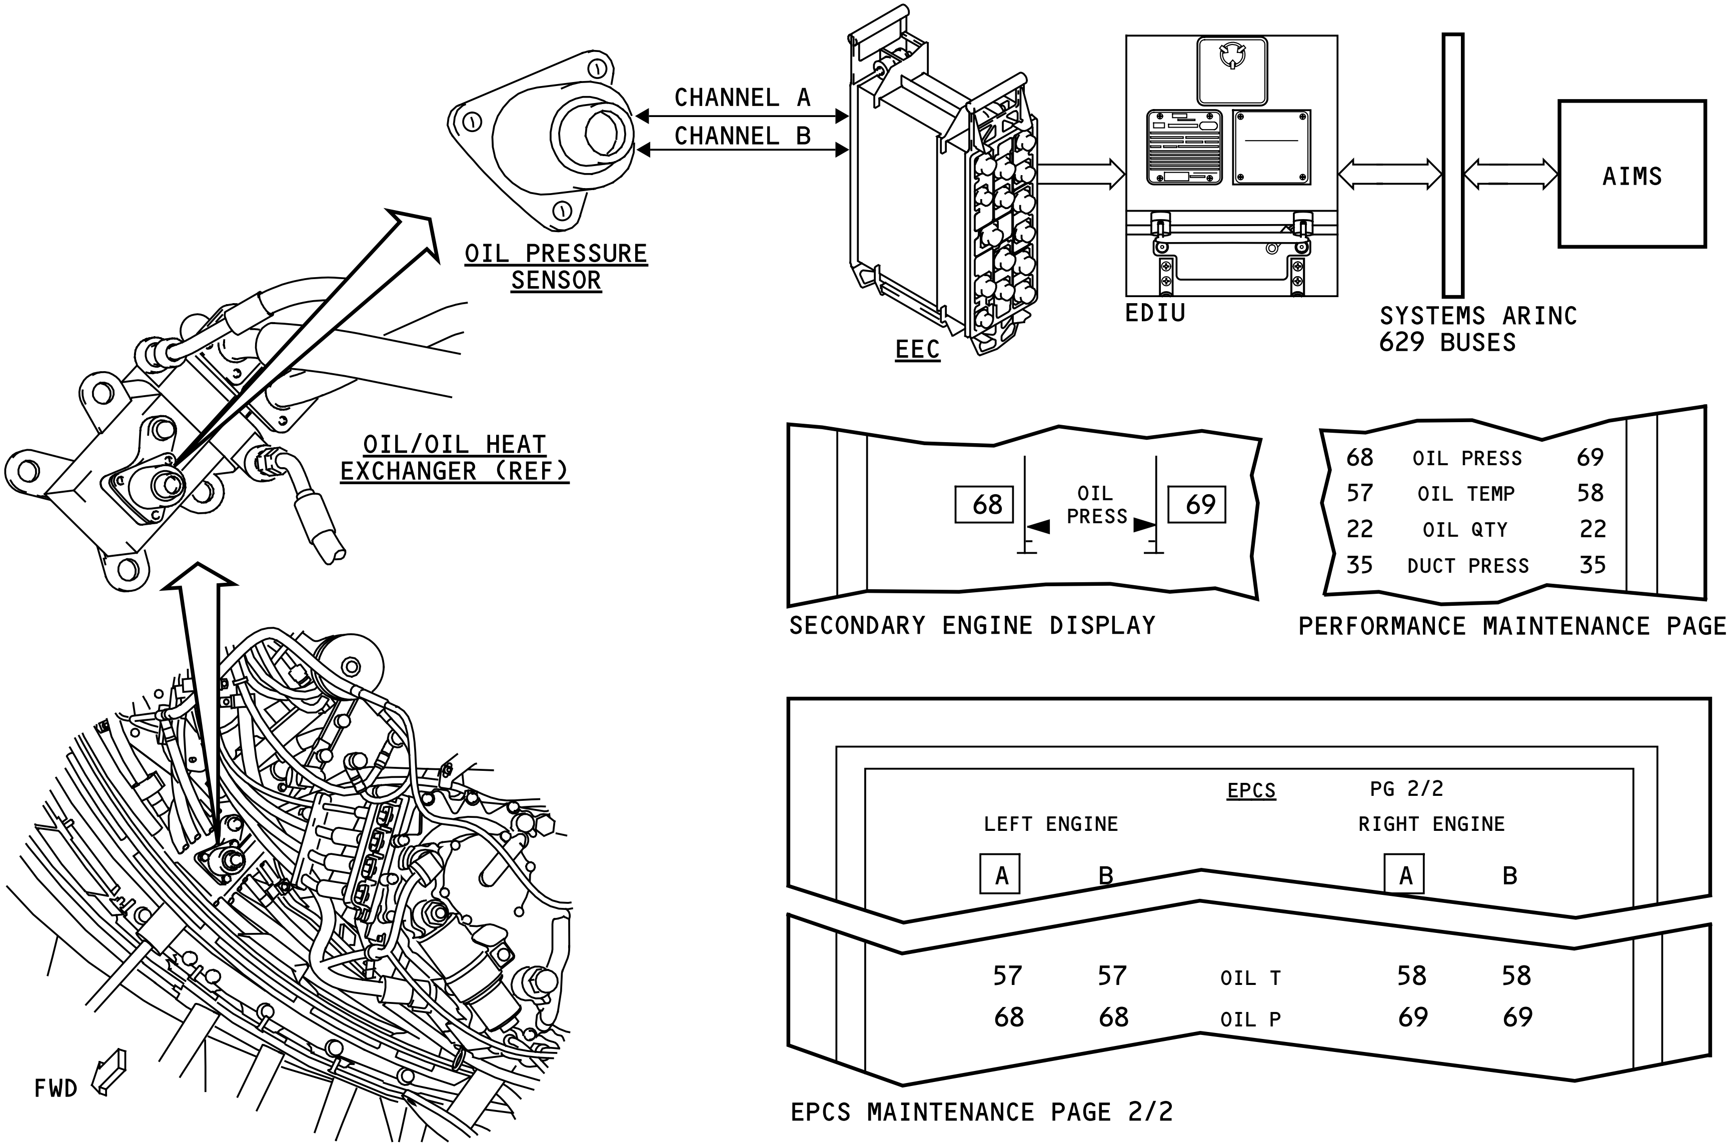
Oil pressure shows in psi.

Oil pressure shows on these formats:

- Secondary engine display
- Performance maintenance page
- EPCS maintenance page 2.

The propulsion data limits maintenance page format shows the oil pressure limits. See the propulsion data limits maintenance page section for more information (AMM PART I 77-00).

When the engine oil pressure is at or below the red line limit, the ENG OIL PRESS L or R caution message shows. An engine shutdown prevents the message.



79-30-00-105 Rev 5 04/29/95

OIL - INDICATING - OIL PRESSURE INDICATING SYSTEM

OIL - INDICATING - OIL TEMPERATURE INDICATING SYSTEM

Purpose

The oil temperature indicating system sends the engine oil temperature data to the AIMS for display. It uses an oil temperature sensor.

Location

The oil temperature sensor installs in an adapter in the engine oil supply tube downstream from the oil/oil heat exchanger. It is at the 5:30 position of the HPC immediately aft of the fan hub frame.

Physical Description

The oil temperature sensor is a variable resistance device. It has two platinum elements and one electrical connector.

Functional Description

The oil temperature sensor gets oil temperature data as the oil flows from the oil/oil heat exchanger to the engine.

Each EEC channel supplies an excitation signal to one element. The resistance value of the element changes as the oil temperature changes. This changes the oil temperature signal to each EEC channel.

When both signals from an oil temperature sensor are unsatisfactory, a status message shows.

Indication

Oil temperature shows in degrees Celsius.

The MFD shows the oil temperature on these pages:

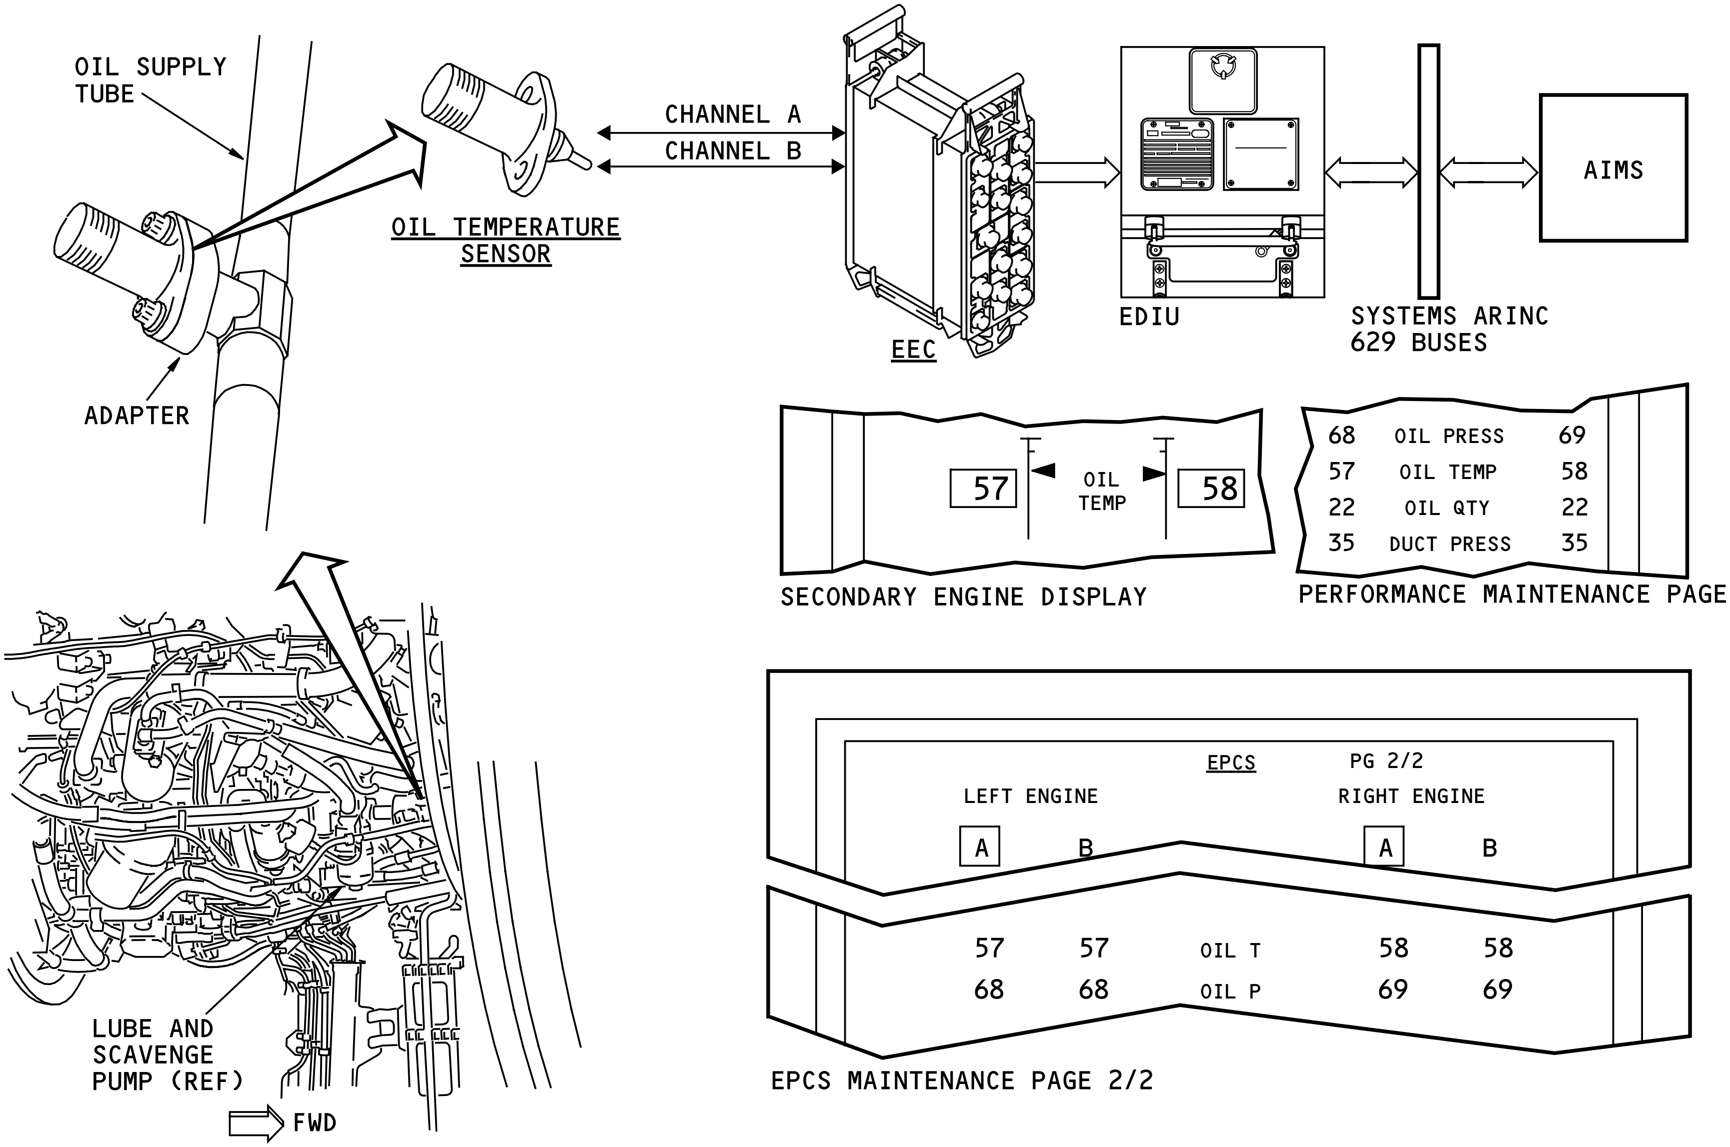
- Secondary engine display
- Performance maintenance page
- EPCS maintenance page 2.

The oil temperature display on the secondary engine display has these limit indications:

- High red line limit
- High amber limit.

The propulsion data limits maintenance page shows the oil temperature limits. See the engine indicating chapter for more information on the propulsion data limits page (AMM PART I 77).

When the engine oil temperature is at or above the amber limit, the ENG OIL TEMP L or R advisory message shows.



OIL - INDICATING - OIL TEMPERATURE INDICATING SYSTEM

OIL - INDICATING - OIL FILTER BYPASS WARNING SYSTEM

Purpose

The oil filter bypass warning system sends engine oil filter differential pressure data to the EEC. This permits the EEC to monitor the condition of the oil filter element. The system uses an oil filter differential pressure sensor.

Location

The sensor is on the forward end of the lube and scavenge pump.

Physical Description

The oil filter differential pressure sensor is a piezoresistive device. It has two sensing elements and one electrical connector.

Functional Description

Each EEC channel supplies an excitation signal to one sensing element. Each element gets an oil pressure input before and after the oil filter. Each element sends an oil pressure signal to its EEC channel.

When both signals from an oil filter differential pressure sensor are unsatisfactory, a the ENG OIL FILT SNSR L or R status message shows.

Indication

The MFD shows the oil filter differential oil pressure in psi on the EPCS maintenance page 2/2.

The EEC determines the filter condition and sends signals to AIMS to show advisory and status messages.

When the engine oil filter differential oil pressure goes near the filter bypass condition, the status page display shows the ENG OIL FILTER L or R status message.

When the engine oil filter differential oil pressure is at or above the filter bypass condition, the ENG OIL FILTER L or R advisory message shows.

ENGINE AIR - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE AIR - GENERAL DESCRIPTION

General

The engine air system has two subsystems:

- Engine air cooling
- Engine compressor control.

The electronic engine control (EEC) controls the engine air system components. The engine air system component positions and faults show on the primary display system (PDS).

Engine Air Cooling

These are the engine air cooling subsystems:

- Engine accessory cooling
- Turbine cooling system.

Engine accessory cooling uses fan or LPC air to keep core components cool. The EEC controls the core compartment cooling (CCC) valve. Seventh stage servo air operates the CCC valve.

The turbine cooling system uses fan air to cool the turbine cases. This makes the turbine case smaller and decreases the clearance between the turbine blade tips and the turbine case. The smaller clearance increases engine efficiency.

The low pressure turbine active clearance control (ACC) valve permits fan air blow on the LPT case. The EEC controls the LPT ACC valve. Seventh stage servo air operates the valve.

The high pressure turbine (HPT) active clearance control (ACC) valve permits fan air blow on the HPT case. The EEC controls a torque motor in the HMU to operate the HPT ACC valve. The torque motor sends servo fuel pressure to the valve actuator.

Compressor Control System

The compressor control system matches low pressure compressor (LPC) and high pressure compressor (HPC) airflows for all power conditions. This helps to prevent an engine stall.

These are the compressor control subsystems:

- Variable bypass valve system
- Variable stator vane system
- Start transient bleed system.

The variable bypass valve (VBV) system sends air from the LPC exit into the fan stream. This decreases the amount of air going into the HPC. The EEC controls a torque motor in the HMU to operate the VBVs. The torque motor sends servo fuel pressure to two VBV actuators. The actuators move 10 bypass valves

The variable stator vane (VSV) system moves HPC stator vanes to control HPC airflow. The EEC controls a torque motor in the HMU to operate the VSVs. The torque motor sends servo fuel pressure to two VSV actuators. The VSV

ENGINE AIR - GENERAL DESCRIPTION

actuators operate the HPC inlet guide vanes (IGV) and the stage 1 through 4 stator vanes.

The start/transient bleed (STB) system sends 7th stage HPC air to the fan stream. The STB valve only operates during engine starts to unload the HPC. The EEC controls a torque motor in the HMU to operate the STB valve. The torque motor sends servo fuel pressure to the STB actuator.

Indication and Control

The valves and actuators send feedback data to the EEC. The EEC uses the feedback data for control and indication. The AIMS receives position data from the EEC to show on the PDS.

ENGINE AIR - COMPONENT LOCATIONS - RIGHT

ENGINE AIR - ENGINE ACCESSORIES COOLING - GENERAL DESCRIPTION

General

The engine accessories cooling system uses air from the LPC or the fan stream to cool the core compartment. When the VBVs are open, LPC air cools the core compartment. When the VBVs close, fan air cools the core compartment. The cooling air goes through the CCC valve.

The EEC sends engine accessory cooling faults to the AIMS.

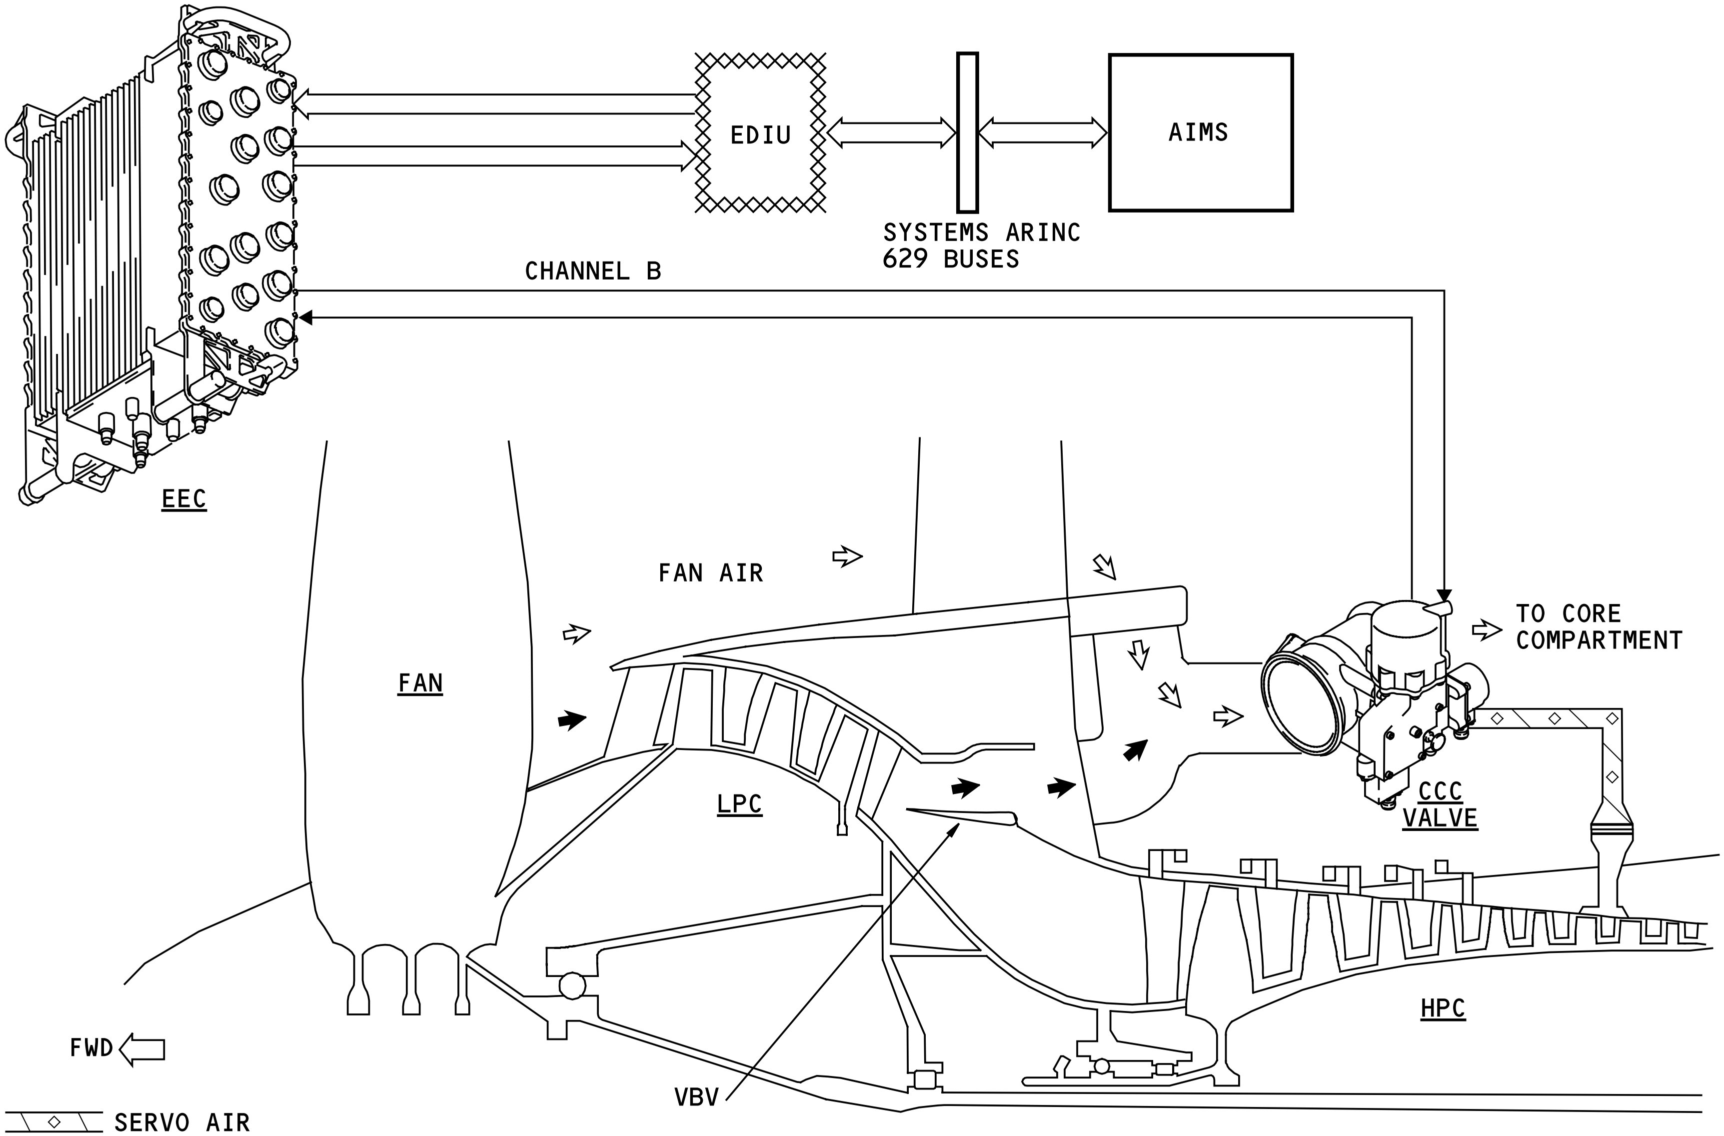
CCC Control

Channel B of the EEC controls a solenoid on the CCC valve to operate the valve. When the solenoid energizes, 7th stage servo air goes to the valve actuator to close the valve.

When the airplane is at cruise, the valve closes to increase engine efficiency. At all other times the valve is open. The EEC uses altitude and N1 to find when the airplane is at cruise. The CCC valve permits low air flow when it is closed.

Position Feedback

A feedback switch on the CCC valve sends a valve position signal to each channel of the EEC. You can see CCC valve position on the EPCS maintenance page (not shown). The position shows OPEN or CLOSED.



ENGINE AIR - ENGINE ACCESSORIES COOLING - GENERAL DESCRIPTION

ENGINE AIR - ENGINE ACCESSORIES COOLING - CORE COMPARTMENT COOLING VALVE

Purpose

The CCC valve controls the cooling air to the engine core compartment and the aft face of accessory gearbox.

Location

The CCC valve is on the forward engine core at the 1:00 position. You must open the right thrust reverser (T/R) to get access to the CCC valve.

Physical Description

The CCC valve has solenoid control and pneumatic actuation. The valve has two positions: open or closed. The CCC valve has these parts:

- Solenoid
- Lockout control
- Servo air connector
- Valve position indicator
- Feedback switch.

The CCC valve feedback switch is line replaceable.

Functional Description

The CCC valve inlet connects to the VBV duct. The CCC valve outlet connects to the CCC air distributor duct.

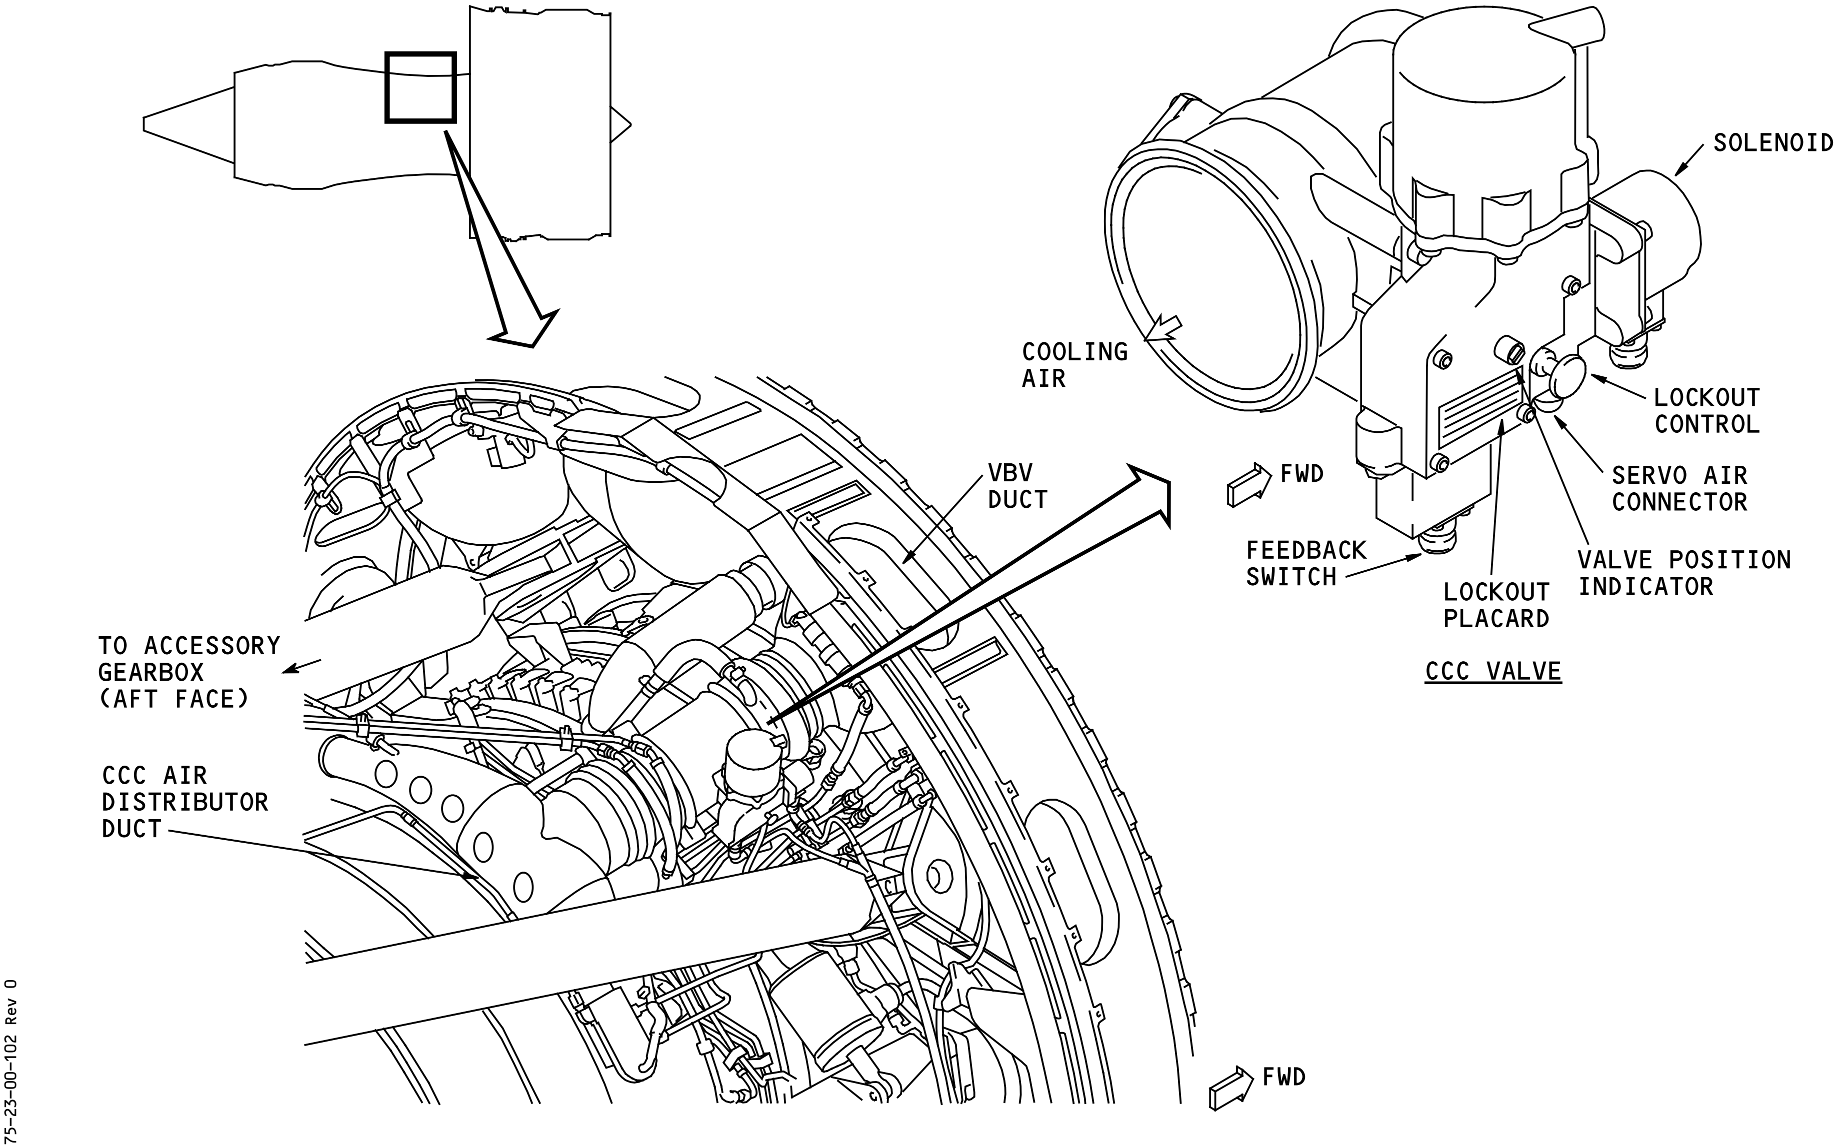
The cooling air flows out of the CCC air distributor duct into the core compartment. A connecting duct also sends cooling air to the aft face of the accessory gearbox. The cooling air goes overboard through vents in the cowling.

Training Information Point

A placard on the CCC valve tells you how to lock the valve open. You use a tool in a slot in the valve position indicator to move the valve. You turn the lockout control on the valve to lock it open.

The servo air line attaches to the CCC valve actuator with a B-nut. Observe this note when you tighten the B-nut:

NOTE: Use the wrench arc method to tighten the B-nut (AMM 70-51-00/201).



ENGINE AIR - ENGINE ACCESSORIES COOLING - CORE COMPARTMENT COOLING VALVE

ENGINE AIR - TURBINE COOLING - GENERAL DESCRIPTION

General

The turbine cooling system uses fan air to cool the LPT and HPT turbine cases. This makes the turbine cases smaller and decreases the clearance between the turbine blade tips and the turbine case. The smaller clearance increases engine efficiency.

The turbine cooling system has two subsystems:

- LPT ACC system
- HPT ACC system.

Each system has a valve that permits fan air to go through a duct to the turbine case. The duct puts the air into a manifold that goes around the turbine case. The inside of the manifold has holes that blow air onto the turbine case.

The EEC sends turbine cooling system faults to the AIMS.

LPT ACC System

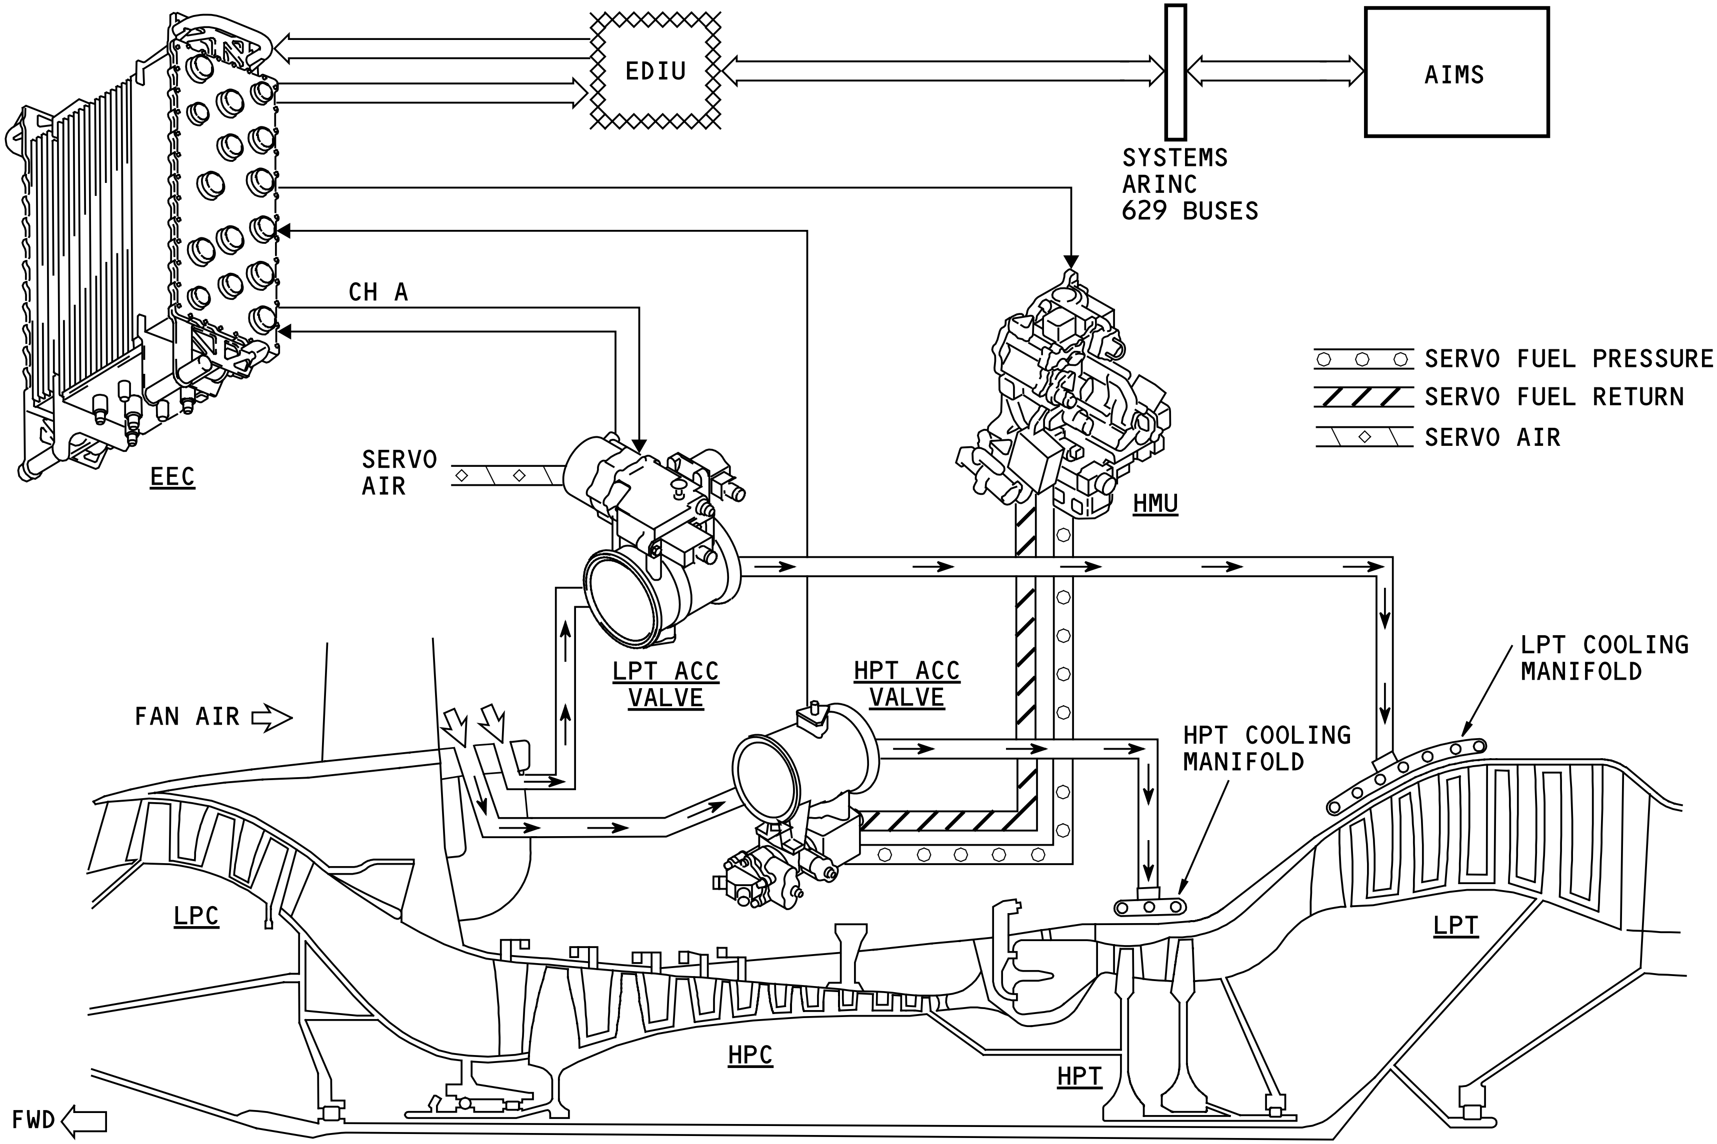
The EEC only uses channel A to control the LPT ACC valve. When the EEC energizes the LPT ACC valve solenoid, 7th stage servo air opens the valve. The valve permits full flow when it opens, and low flow when it closes. The EEC uses N1 and altitude to control the valve. The valve opens when the engine goes to takeoff thrust, and stays open through the climb and cruise flight phases.

A feedback switch on the LPT ACC valve sends a valve position signal to each channel of the EEC. You can see the valve position on the EPCS maintenance page (not shown). Valve position shows OPEN or CLOSED.

HPT ACC System Functional Description

The EEC controls a torque motor in the HMU to modulate the HPT ACC valve. The EEC controls the torque motor based on inlet temperature, N1, and N2. The torque motor sends servo fuel pressure to the HPT ACC valve actuator to move the valve. When the valve opens, fan air blows on the HPT case. The valve opens for a short time after the engine goes to takeoff thrust. The valve modulates during engine operation. The valve permits low flow when it closes.

An dual LVDT on the valve sends a valve position to each channel of the EEC. You can see the valve position on the EPCS maintenance page (not shown). Valve position shows in percent open.



ENGINE AIR - TURBINE COOLING - GENERAL DESCRIPTION

75-24-00-101 Rev 1 04/03/95

ENGINE AIR - TURBINE COOLING - LPT ACTIVE CLEARANCE CONTROL VALVE

Purpose

The LPT ACC valve controls fan air flow to cool the LPT case.

Location

The LPT ACC valve is at the 3:00 position on the engine core. You must open the right T/R to get access to the LPT ACC valve.

Physical Description

The LPT ACC valve has solenoid control and pneumatic actuation. The valve has two positions: open or closed. The LPT ACC valve has these parts:

- Valve position indicator
- Lockout control
- Servo air connection
- Solenoid
- Feedback switch.

A feedback switch sends a valve position signal to the EEC. The feedback switch is an LRU.

Functional Description

When the LPT ACC valve is open, full cooling flow goes to the LPT case. When the valve closes, a small amount of cooling flow goes to the LPT case.

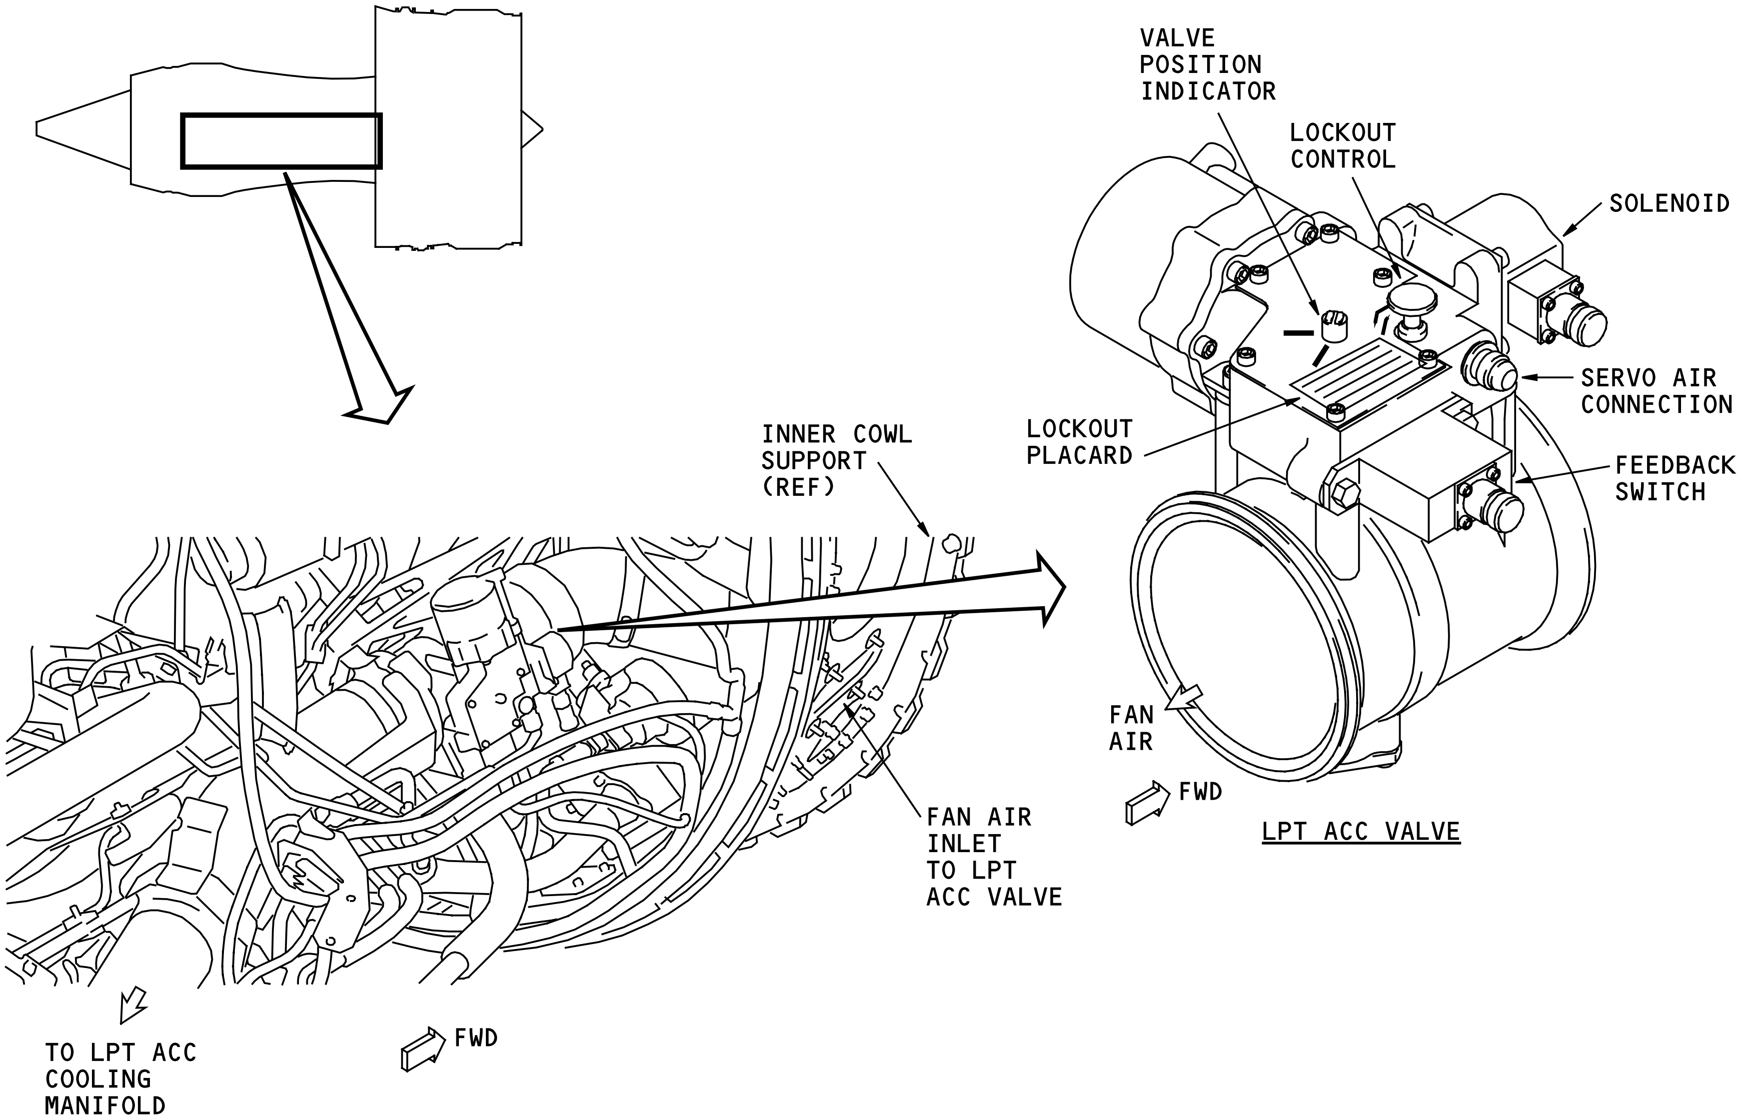
The EEC controls the LPT ACC valve solenoid to move the valve. When the solenoid is not energized, a spring closes the valve. The valve is fail-safe to the closed position. When the solenoid energizes, seventh stage servo air moves the valve open.

Training Information Point

You can lock the LPT ACC valve closed. A placard on the valve tells you how to lock the valve. You use a tool in a slot in the valve position indicator to move the valve. You turn the lockout control on the valve to lock it closed.

The servo air line attaches to the actuator with a B-nut. Observe this note when you tighten the B-nut:

NOTE: Use the wrench arc method to tighten the B-nut (AMM 70-51-00/201).



75-24-00-102 Rev 1 08/28/1995

ENGINE AIR - TURBINE COOLING - LPT ACTIVE CLEARANCE CONTROL VALVE

ENGINE AIR - TURBINE COOLING - HPT ACTIVE CLEARANCE CONTROL VALVE

Purpose

The HPT ACC valve controls fan air flow to cool the HPT case.

Location

The HPT ACC valve is on the forward engine core at the 9:00 position. You must open the left T/R to get access to the HPT ACC valve.

Physical Description

The HPT ACC valve is a modulating valve. It uses servo fuel pressure for actuation. The HPT ACC valve has these parts:

- Valve position indicator
- Servo fuel connection (2)
- Drain can (2)
- Lockout pin
- LVDT.

Each servo fuel connection has a drain line and a drain can. The drain lines combine into one drain line that goes to the drain mast. The drain can collects fuel leakage. You do a check of the drain cans if you see a leak at the drain mast. This permits you to identify which connection has leakage. Observe the following caution:

CAUTION: DO NOT REMOVE THE CAPTIVE BOLTS FROM THE DRAIN CAN. DAMAGE CAN OCCUR TO THE DRAIN CAN OR THE CAPTIVE BOLTS.

An LVDT sends HPT ACC valve position to the EEC. It has two connections, one for each channel of the EEC.

Functional Description

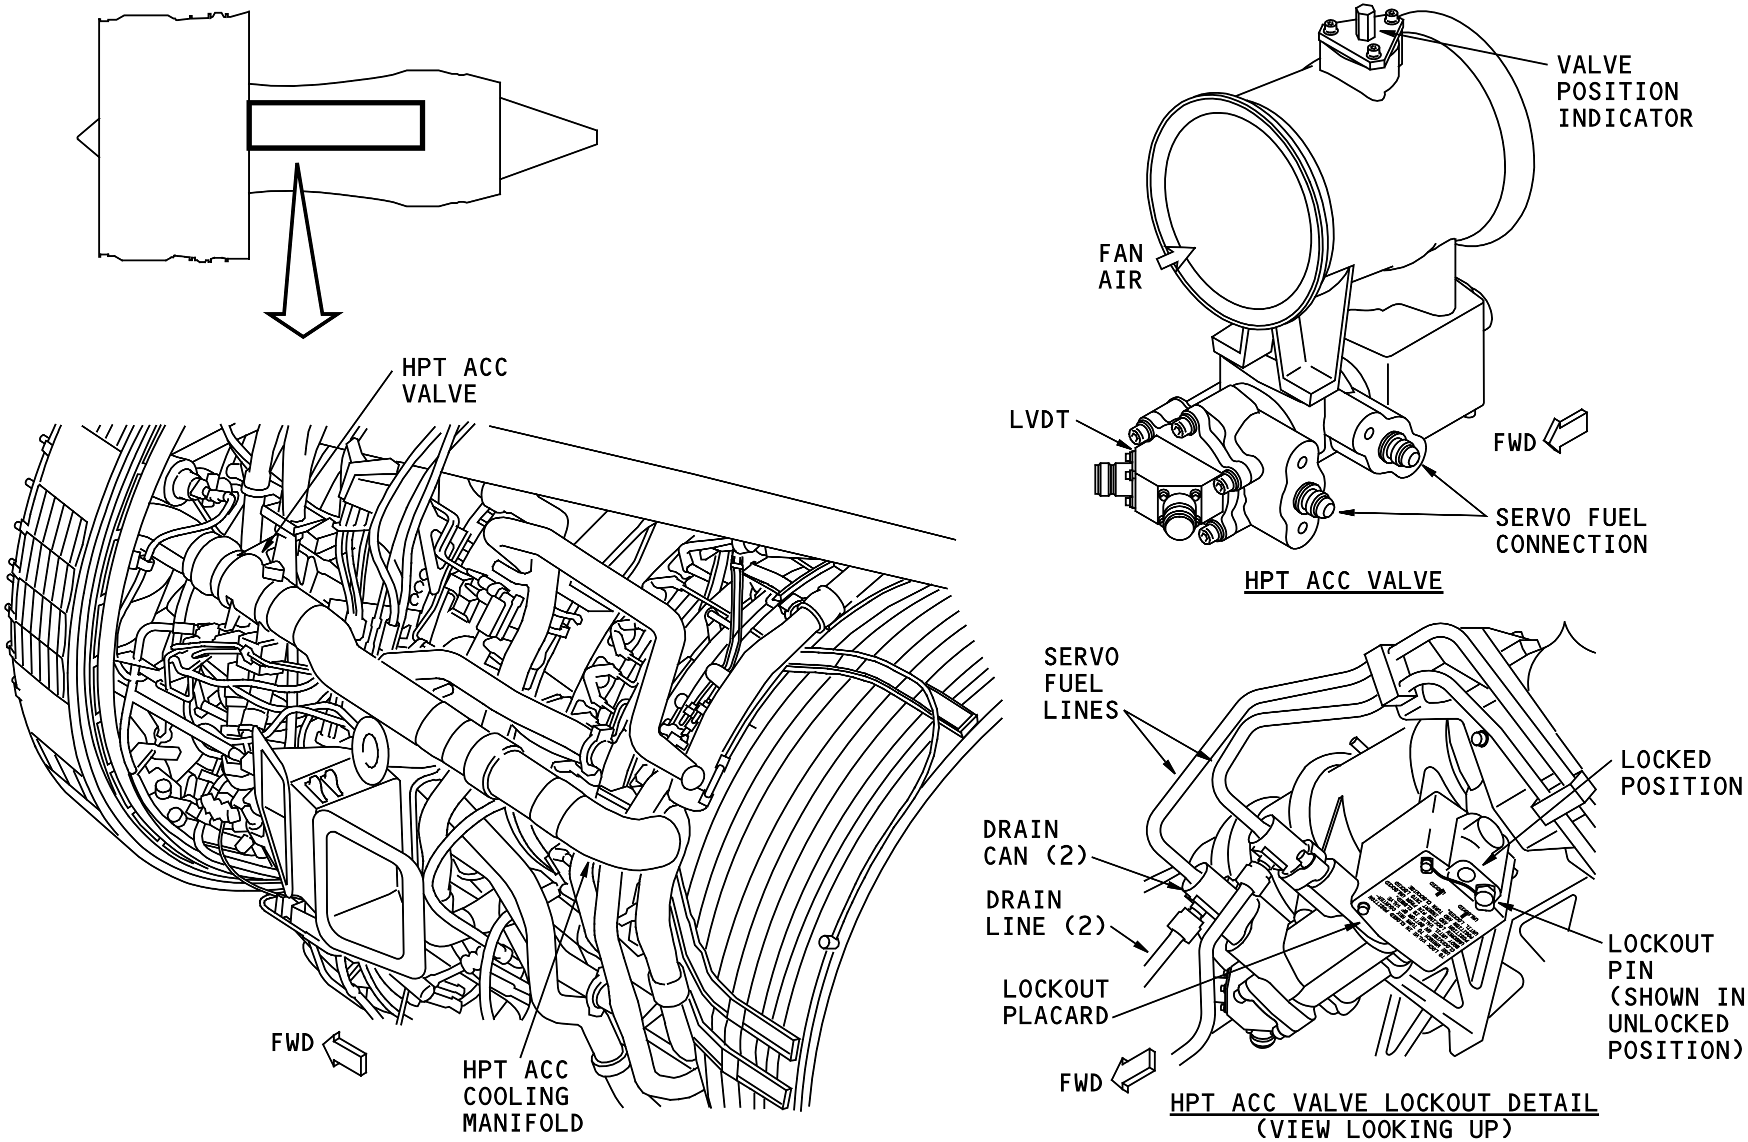
The EEC controls a torque motor in the HMU to control servo fuel pressure to the valve. There are two servo fuel lines to the valve. Pressure in one line moves the valve more open. Pressure in the other line moves the valve more closed.

Training Information Point

You can lock the HPT ACC valve closed. A placard on the valve tells you how to lock the valve. You put a tool on the hexagonal valve position indicator shaft to move the valve. You move the lockout pin from the UNLOCKED to the LOCKED position to keep the valve closed.

The servo fuel lines attach to the HPT ACC valve actuator with B-nuts. Observe this note when you tighten the B-nuts:

NOTE: Use the wrench arc method to tighten the B-nut (AMM 70-51-00/201).



75-24-00-103 Rev 1 08/28/1995

ENGINE AIR - TURBINE COOLING - HPT ACTIVE CLEARANCE CONTROL VALVE

ENGINE AIR - VSV SYSTEM - GENERAL DESCRIPTION

General

The VSV system moves the HPC inlet guide vanes (IGV) and the 1st through 4th stage stator vanes. The system operates automatically at all power settings to control airflow through the HPC. The VSVs move from full closed at idle to full open at takeoff.

There are two VSV actuators. One actuator is on the left side of the engine and one actuator is on the right side.

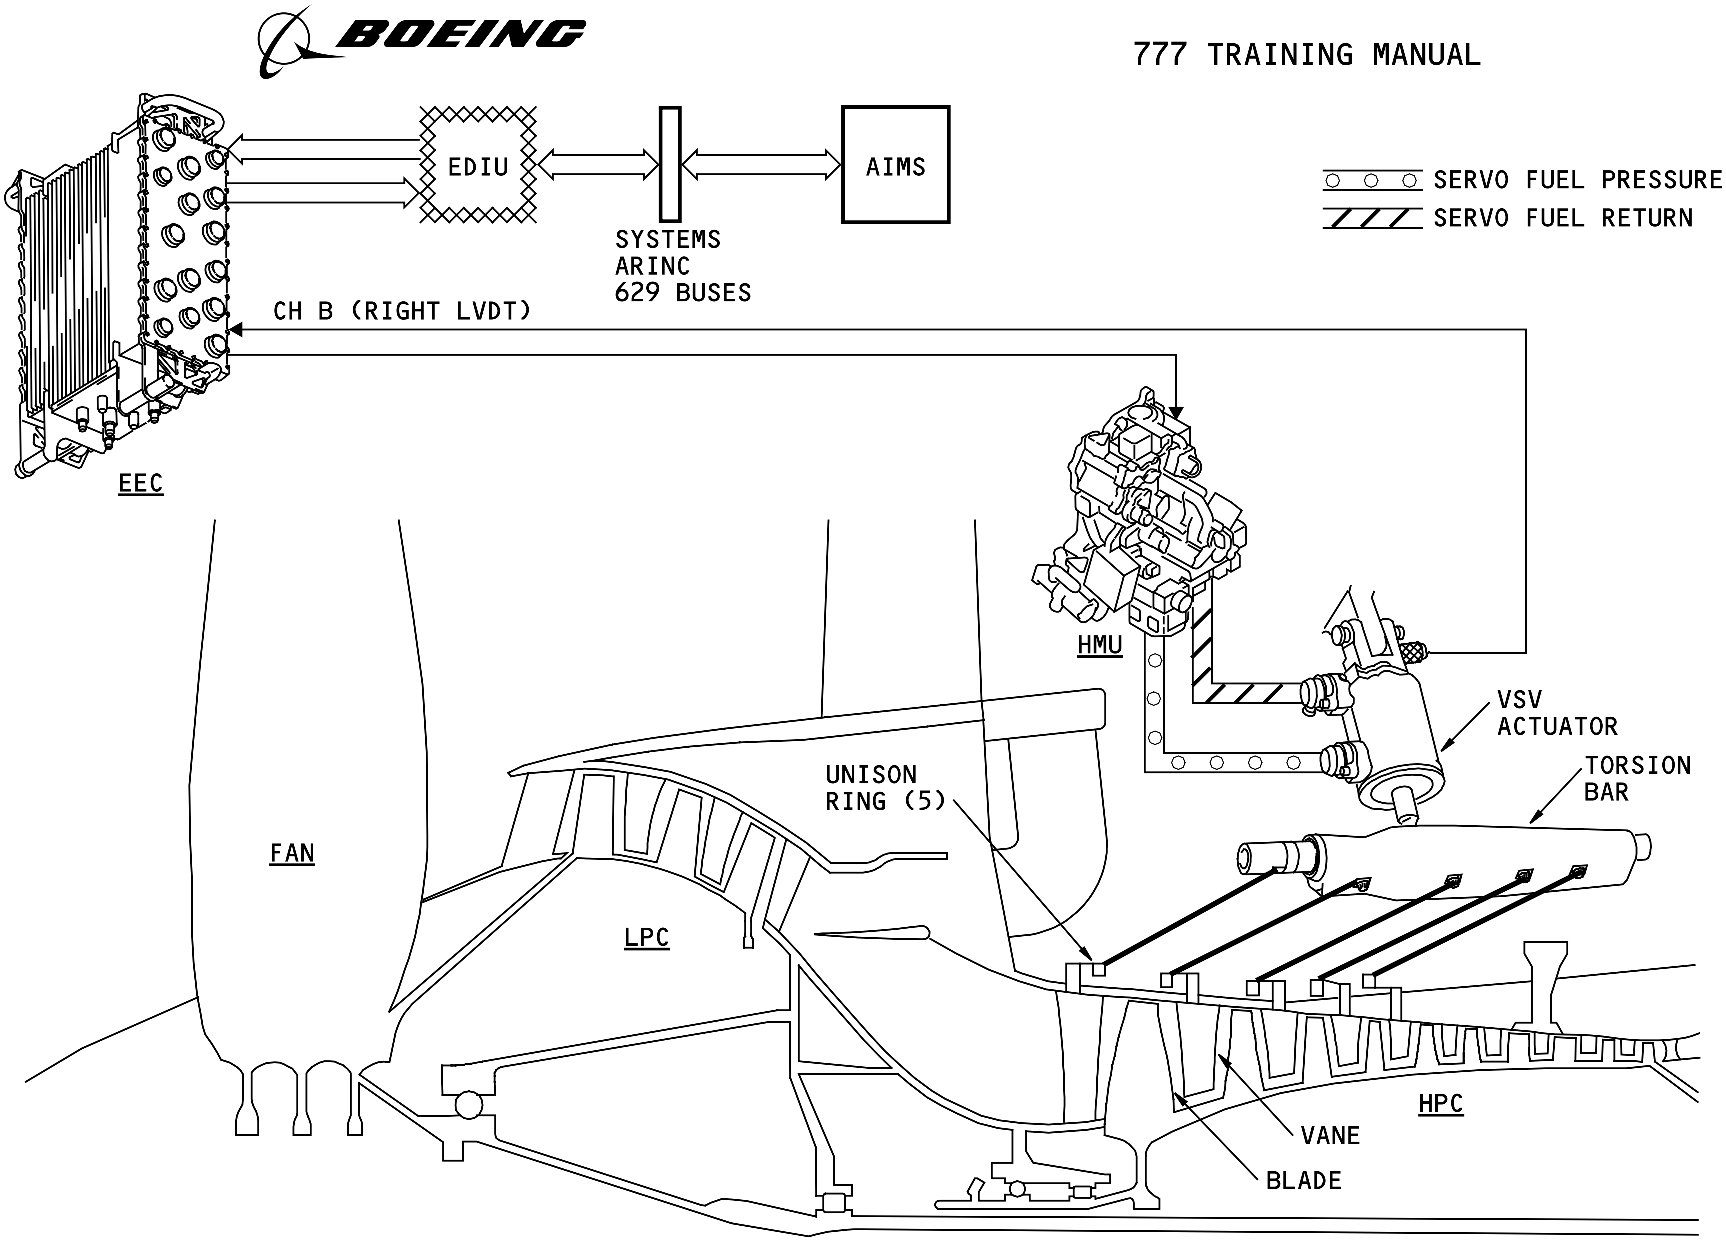
You find VSV system faults on the MAT.

VSV Control

The EEC controls a torque motor in the HMU to operate the VSVs. The EEC uses N2 and T25 to control the torque motor. The torque motor sends fuel pressure to the VSV actuators to turn the torsion bars. The torsion bars move unison rings on the HPC. The unison rings connect to the stator vanes. When the unison rings move, the stator vane angles change.

Position Feedback

An LVDT in each actuator sends a position signal to the EEC. The left actuator LVDT sends a signal to EEC channel A. The right actuator LVDT sends a signal to EEC channel B. You can see VSV position on the EPCS maintenance page (not shown). The VSV position shows in percent open.



ENGINE AIR - VSV SYSTEM - GENERAL DESCRIPTION

ENGINE AIR - VSV SYSTEM - VSV ACTUATOR

Purpose

The VSV actuators move the variable stator vanes in the HPC.

Location

The VSV actuators are on the HPC case at the 2:30 and 8:30 positions. Each actuator attaches to the HPC case with a pin.

Physical Description

Each actuator has these parts:

- Servo fuel connection (2)
- Drain can (2)
- Actuator rod
- LVDT.

Each servo fuel connection has a drain line and a drain can. The drain lines combine into one drain line that goes to the drain mast. The drain can collects fuel leakage. You check the drain cans if you see a leak at the drain mast. This permits you to identify which connection has leakage. Observe the following caution:

CAUTION: DO NOT REMOVE THE CAPTIVE BOLTS FROM THE DRAIN CAN. DAMAGE CAN OCCUR TO THE DRAIN CAN OR THE CAPTIVE BOLTS.

The actuator has a rod that attaches to the torsion bar. When the actuator rod moves, the torsion bar turns.

A single channel LVDT in each actuator sends actuator position to one channel of the EEC. The left actuator LVDT connects to channel A and the right actuator connects to channel B.

Functional Description

Servo fuel pressure moves each VSV actuator at the same time. Each actuator rod turns a torsion bar. The torsion bars attach to 5 unison rings (not shown). The unison rings attach to the HPC inlet guide vanes (IGV), and the 1st through 4th stage stator vanes. When the unison rings move, the IGVs and stator vanes move.

Training Information Point

The servo fuel lines attach to the VSV actuators with B-nuts. Observe this note when you tighten the VSV actuator B-nuts:

NOTE: Use the wrench arc method to tighten the B-nut (AMM 70-51-00/201).

ENGINE AIR - VSV SYSTEM - VSV ACTUATOR

ENGINE AIR - VBV SYSTEM - GENERAL DESCRIPTION

General

The VBVs open to let air go out of the engine core, through the VBV ducts, and into the fan stream. The VBV ducts open to the fan stream just aft of the LPC exit. This decreases the amount of air that goes into the HPC. The system operates automatically at all power settings. The VBVs move from full open at idle to full closed at takeoff.

There are two VBV actuators and ten VBVs. One actuator is on the left side of the engine and one actuator is on the right side.

You find VBV system faults on the MAT.

VBV Control

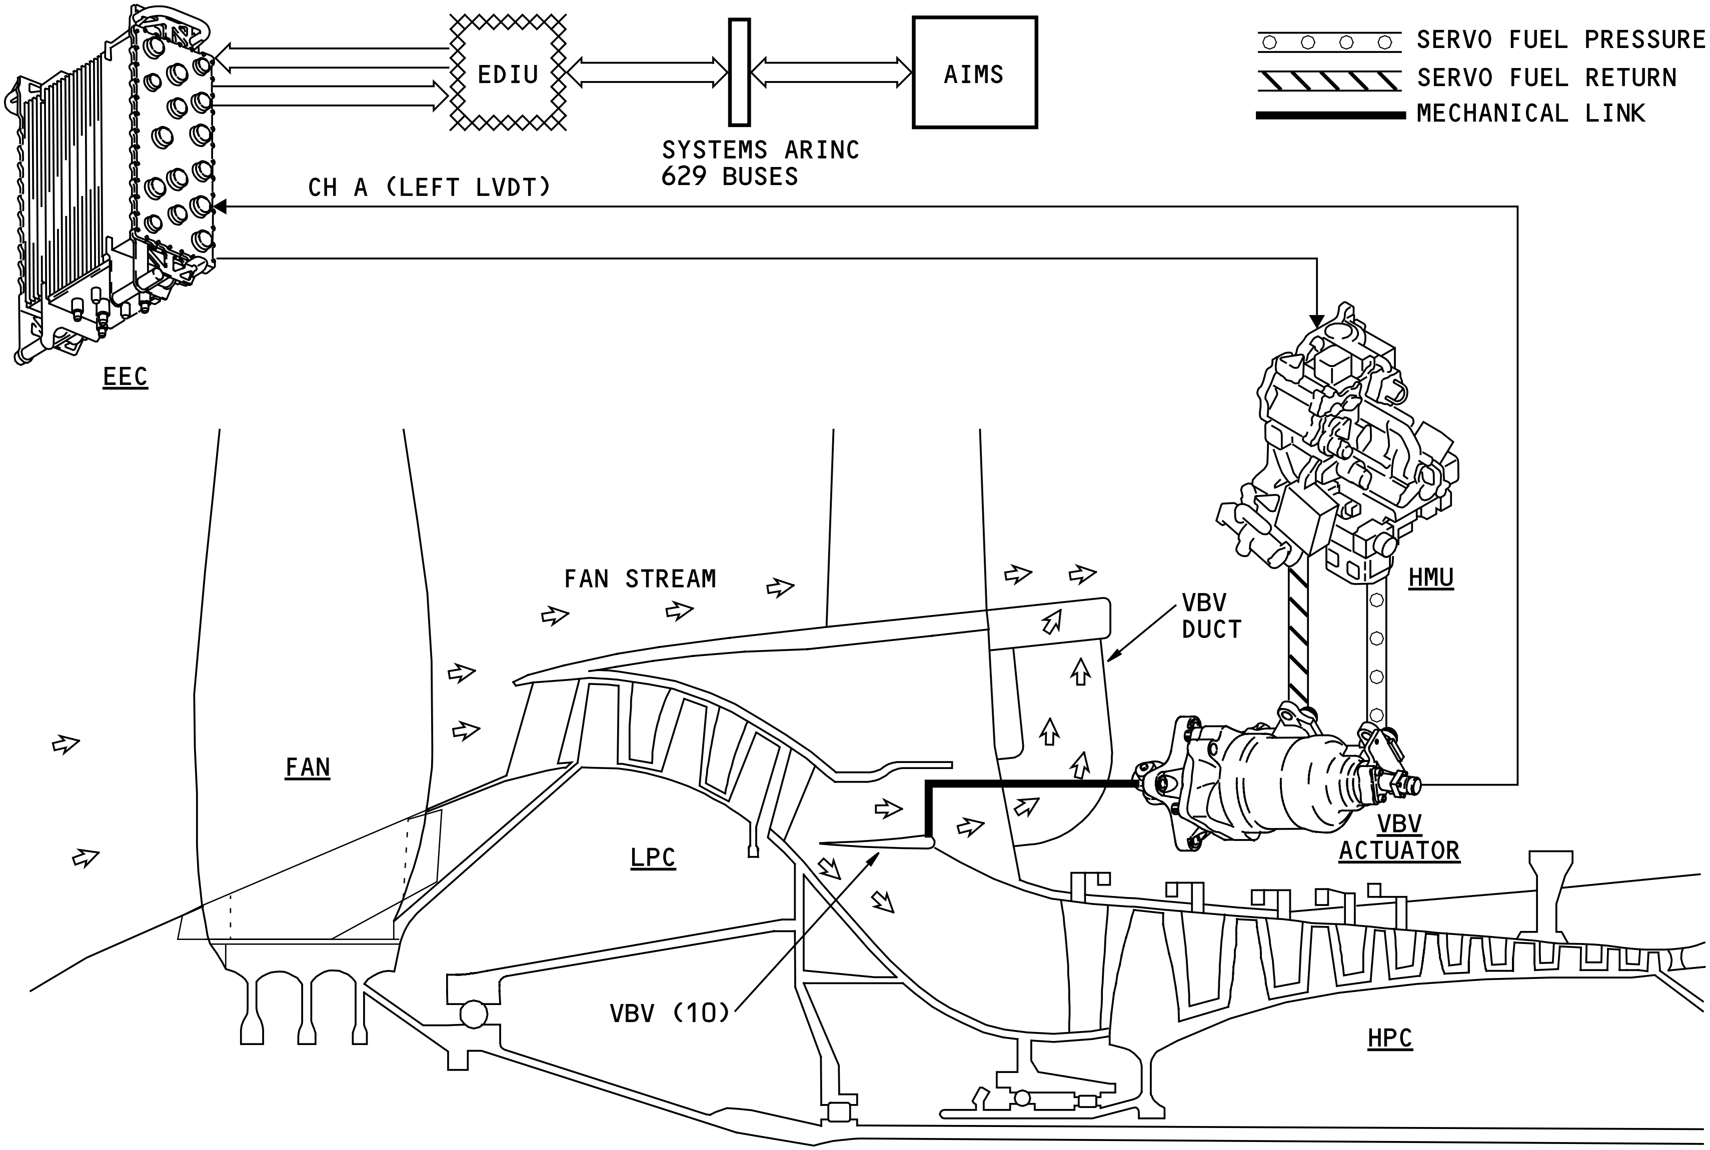
The EEC controls a torque motor in the HMU to operate the VBVs. These are the main inputs the EEC uses to control VBV operation:

- N1
- N2
- T12
- T25.

The EEC sends a signal to a torque motor in the HMU. The torque motor sends fuel pressure to the VBV actuators to open or close the VBVs.

Position Feedback

An LVDT in each actuator sends a position signal to the EEC. The left actuator LVDT sends a signal to EEC channel A. The right actuator LVDT sends a signal to EEC channel B. You can see VBV position on the EPCS maintenance page (not shown). The VBV indication shows in percent open.



ENGINE AIR - VBV SYSTEM - GENERAL DESCRIPTION

ENGINE AIR - VBV SYSTEM - VBV ACTUATOR AND VBV

General

The VBV system has two actuators and ten valves. A unison ring and bellcrank linkages connect the actuators to the valves. The actuators turn the unison ring to move the VBVs.

Location

The actuators are on the forward engine core at the 3:30 and 9:30 positions. The VBV actuators attach to the fan hub frame with bolts.

The VBVs are forward of the actuators inside the fan hub frame. They are equally spaced around the engine.

VBV Actuators

Each actuator has these parts:

- Servo fuel connection (2)
- Drain can (not shown) (2)
- Rod
- LVDT.

Each servo fuel connection has a drain line (not shown) and a drain can. The drain lines combine into one drain line that goes to the drain mast. The drain can collects fuel leakage. You do a check of the drain cans if you see a leak at the drain mast. This permits you to identify which connection has leakage. Observe the following caution:

CAUTION: DO NOT REMOVE THE CAPTIVE BOLTS FROM THE DRAIN CAN. DAMAGE CAN OCCUR TO THE DRAIN CAN OR THE CAPTIVE BOLTS.

Each VBV actuator has a rod that attaches to one end of a bellcrank linkage. The other end of the bellcrank linkage attaches to the unison ring. When the actuator rod moves, the unison ring turns.

A single channel LVDT in each actuator sends actuator position to the EEC. The left actuator LVDT connects to channel A and the right LVDT connects to channel B.

Functional Description

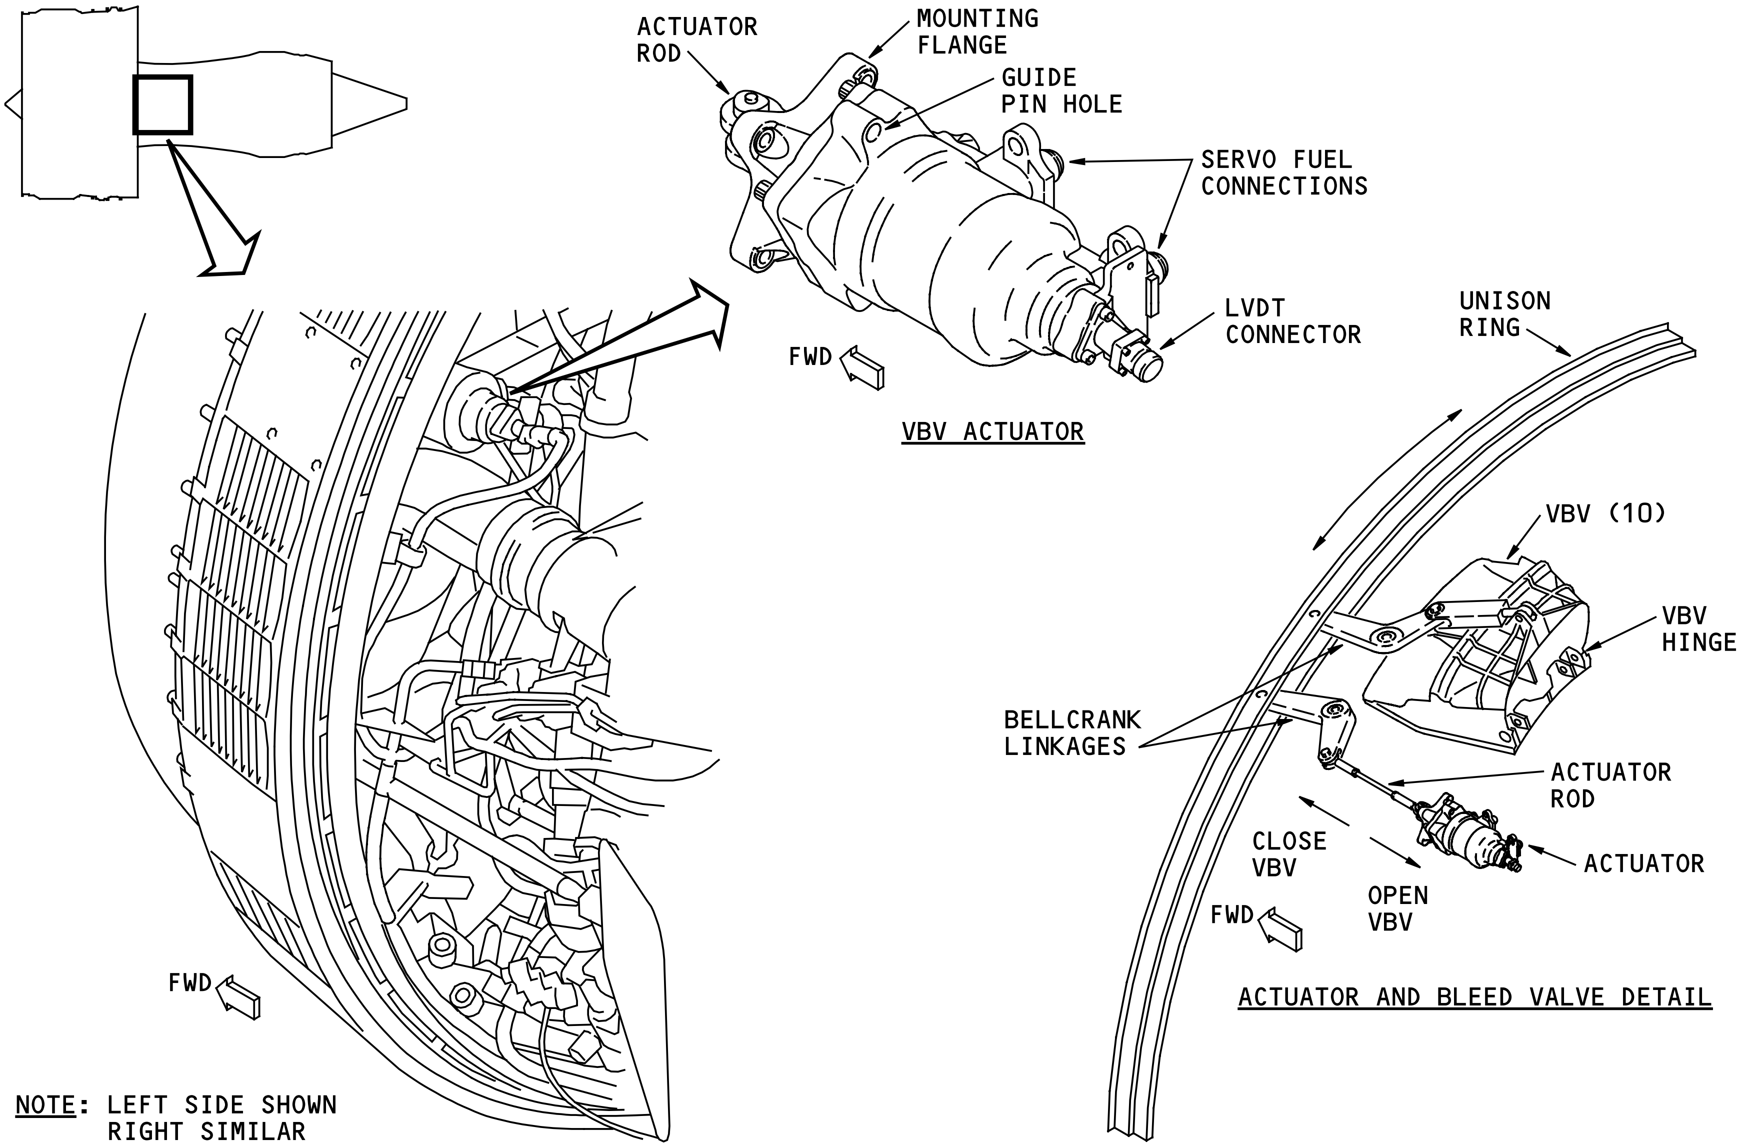
Servo fuel pressure moves the actuator rods forward and aft. The actuators move together to modulate the VBVs. When the rod moves forward, the unison ring turns clockwise. This causes the VBVs to move towards the closed position.

Training Information Point

You use a guide pin to install or remove the VBV actuator. The pin goes through a hole in the mounting flange and attaches to the fan hub frame. The pin supports and guides the actuator.

The servo fuel lines attach to the VBV actuators with B-nuts. Observe this note when you tighten the B-nuts:

NOTE: Use the wrench arc method to tighten the B-nut (AMM 70-51-00/201).



ENGINE AIR - VBV SYSTEM - VBV ACTUATOR AND VBV

ENGINE AIR - STB SYSTEM - GENERAL DESCRIPTION

General

The start/transient bleed (STB) valve opens during engine starts to remove the load on the HPC. When the valve opens, 7th stage HPC air goes to the fan stream. The STB valve has only two positions, open and closed.

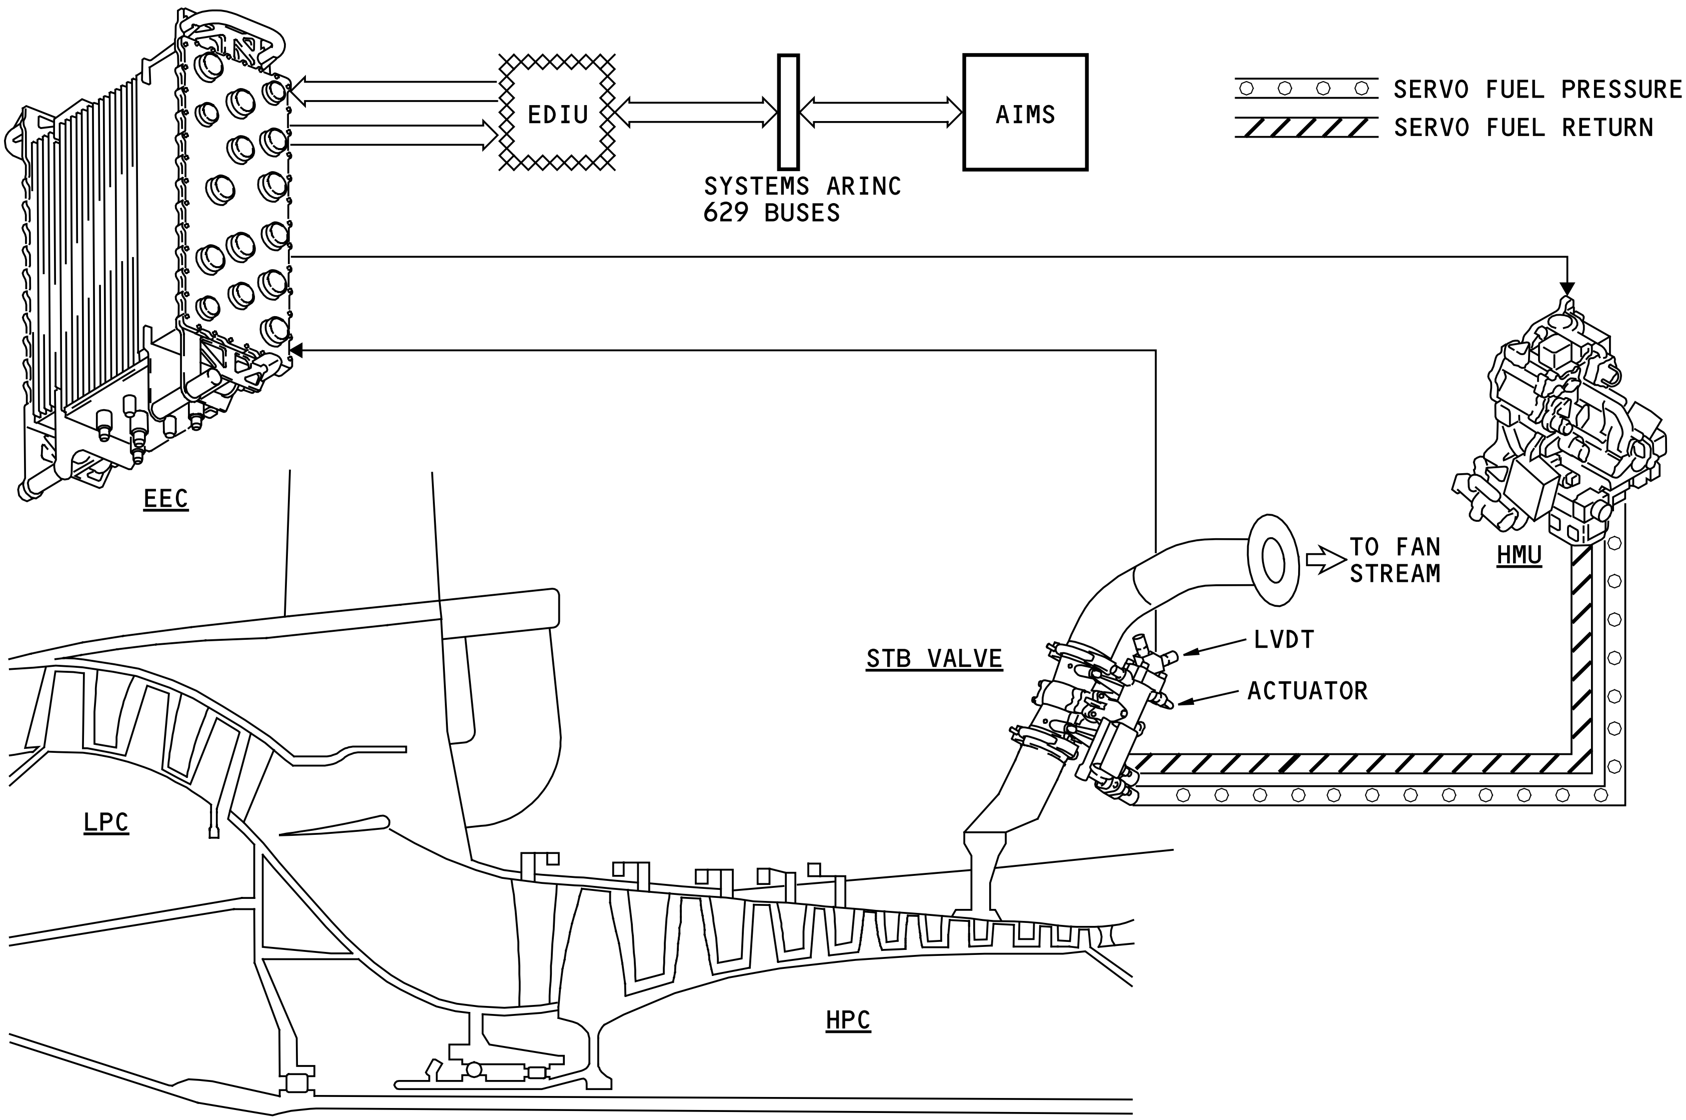
You find STB system faults on the MAT.

STB Valve Control

The EEC controls a torque motor in the HMU to operate the STB valve. The torque motor sends servo fuel pressure to the STB valve actuator. The actuator opens the valve.

Position Feedback

A dual LVDT in the STB valve sends valve position to each channel of the EEC. You can see STB valve position on the EPCS maintenance page (not shown). STB valve position shows in percent open.



ENGINE AIR - STB SYSTEM - GENERAL DESCRIPTION

ENGINE AIR - STB SYSTEM - STB VALVE

Purpose

The start/transient bleed (STB) valve opens to send HPC 7th stage air to the fan stream. The valve operates with servo fuel pressure.

Location

The STB valve is at the 10:30 position on the left side of the HPC.

Physical Description

The STB valve is in the 7th stage bleed duct. An actuator is part of the valve assembly. The actuator uses servo fuel pressure to open the valve. The STB valve has these components:

- Servo fuel connection (2)
- Drain line
- LVDT
- LVDT cooling line
- Lockout knob and valve position indicator.

A fuel drain line goes from the STB valve to the drain mast.

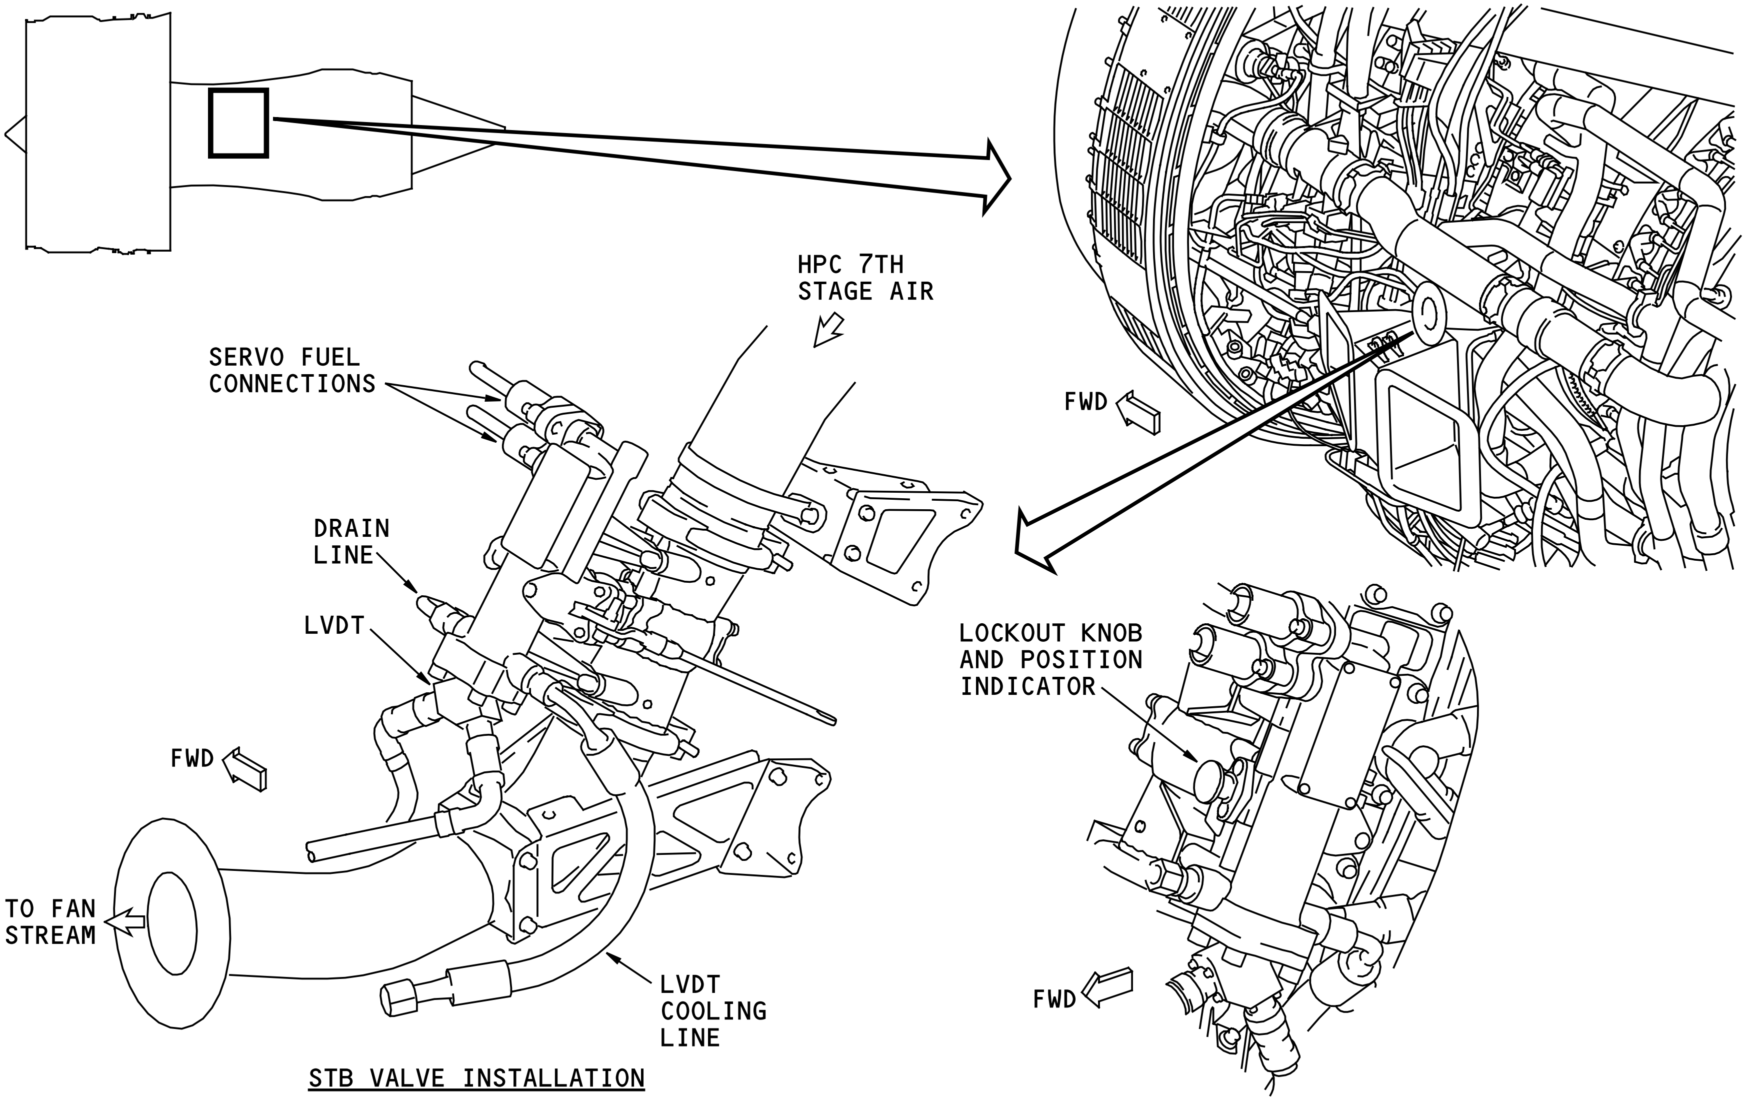
A dual channel LVDT sends valve position to the EEC. One signal goes to each channel of the EEC. Fan air cools the LVDT.

Training Information Point

The lockout instructions are on the lockout knob. You can use the valve position indicator to manually operate the valve. You push and turn the lockout knob 180 degrees to lock the valve.

The servo fuel lines attach to the VBV actuators with B-nuts. Observe this note when you tighten the VSV actuator B-nuts:

NOTE: Use the wrench arc method to tighten the B-nut (AMM 70-51-00/201).



STB VALVE INSTALLATION

STB VALVE LOCKOUT DETAIL

ENGINE AIR - STB SYSTEM - STB VALVE

ENGINE AIR - FUNCTIONAL DESCRIPTION

General

The EEC automatically controls the engine air system to cool engine components and to improve compressor operation.

Valves control fan bypass air for cooling. Bleed valves and variable stator vanes control the compressor.

The EEC uses engine and airplane data to control the air system. The EEC also sends valve and stator vane position and system faults through the EDIU to the AIMS.

Cooling

These valves control engine cooling air:

- CCC valve
- LPT ACC valve
- HPT ACC valve.

Cooling air goes through the CCC valve to cool the area between the engine core and the thrust reverser cowl. The valve closes during cruise to improve engine efficiency. Channel B of the EEC controls the valve. Servo air operates the valve.

Fan air goes through the LPT ACC and HPT ACC valves to cool the LP and HP turbine cases. Channel A of the EEC controls the LPT ACC valve. Servo air actuates the valve. The EEC controls a torque motor in the HMU to operate the HPT ACC valve. Servo fuel actuates the valve.

Compressor Control

These components control airflow through the compressor:

- VBVs
- VSVs
- STB valve.

The EEC controls torque motors in the HMU to operate the VBVs, VSVs and the STB valve. Servo fuel actuates the components.

The VBVs open to bleed air from the LPC to the fan duct. The VBVs open at low power and move closed at high power.

The VSVs control airflow through the HPC with variable stators. The VSVs are closed at low power and move to open at high power.

The STB valve bleeds 7th stage HPC air to increase stall margin for engine starts.

Feedback switches or LVDTs on the valves and actuators send valve and actuator position signals to the EEC.

TABLE OF CONTENTS

ENGINE STARTING - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE STARTING - INTRODUCTION

General

The engine starting system uses pneumatic power to turn the N2 shaft during an engine start. You also use the system to motor the engine.

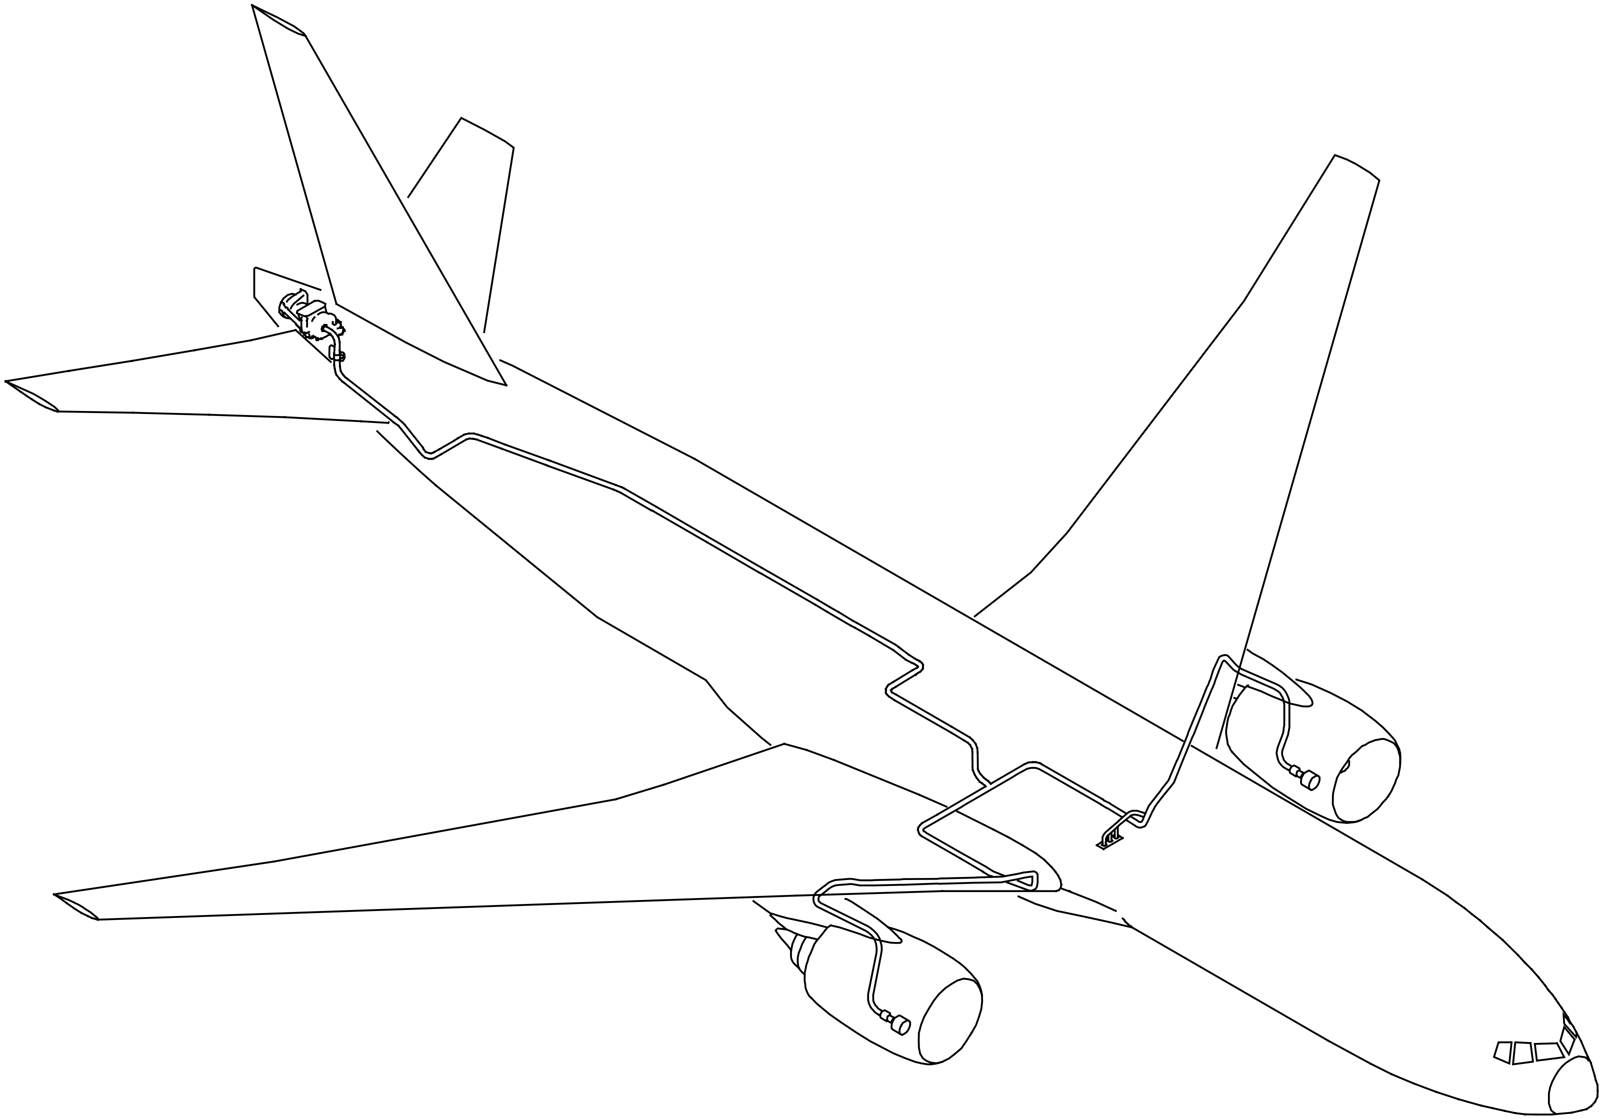
The engine starting system operates on the ground and in the air. Flight deck switches and the EEC control the system.

The engine starting system uses these pneumatic power sources:

- Auxiliary power unit (APU)
- Ground power unit (GPU)
- Opposite operating engine.

Abbreviations and Acronyms

AIMS	- airplane information management system
APU	- auxiliary power unit
ASCPC	- air supply cabin pressure controller
capt	- captain
EEC	- electronic engine control
EDIU	- engine data interface unit
EICAS	- engine indication and crew alerting system
ELMS	- electrical load management system
flt	- flight
GPU	- ground power unit
inst	- instrument
LRU	- line replaceable unit
max	- maximum
mgmt	- management
OPAS	- overhead panel ARINC system
PRSOV	- pressure regulating and shutoff valve
QAD	- quick attach detach
SAV	- starter air valve
stby	- standby
typ	- typical
vlv	- valve



ENGINE STARTING - INTRODUCTION

General

The EEC controls the engine starting system using these inputs:

- Flight deck controls
- Electrical power
- Pneumatic power.

Start Selection

You can start the engines manually or automatically, but you normally do automatic starts. You control the type of start with the autostart switch.

The autostart switch sends a signal to the EEC on the systems ARINC 629 buses. When the autostart switch is in the ON position, the EEC controls fuel and ignition, and monitors the engine parameters. The fuel control switch (not shown) must be in the RUN position for the EEC to do an autostart.

When the autostart switch is in the OFF position, you manually control and monitor the engine start.

Engine Starting

When you put the start/ignition selector to the START position it does these functions:

- Energizes a relay in the ELMS to supply 115v ac power to the EEC
- Energizes a relay in the ELMS to supply 28v dc power to the EEC to open the SAV
- Sends analog and digital start signals to the EEC
- Sends a discrete signal to the air supply cabin pressure controller (ASCPC).

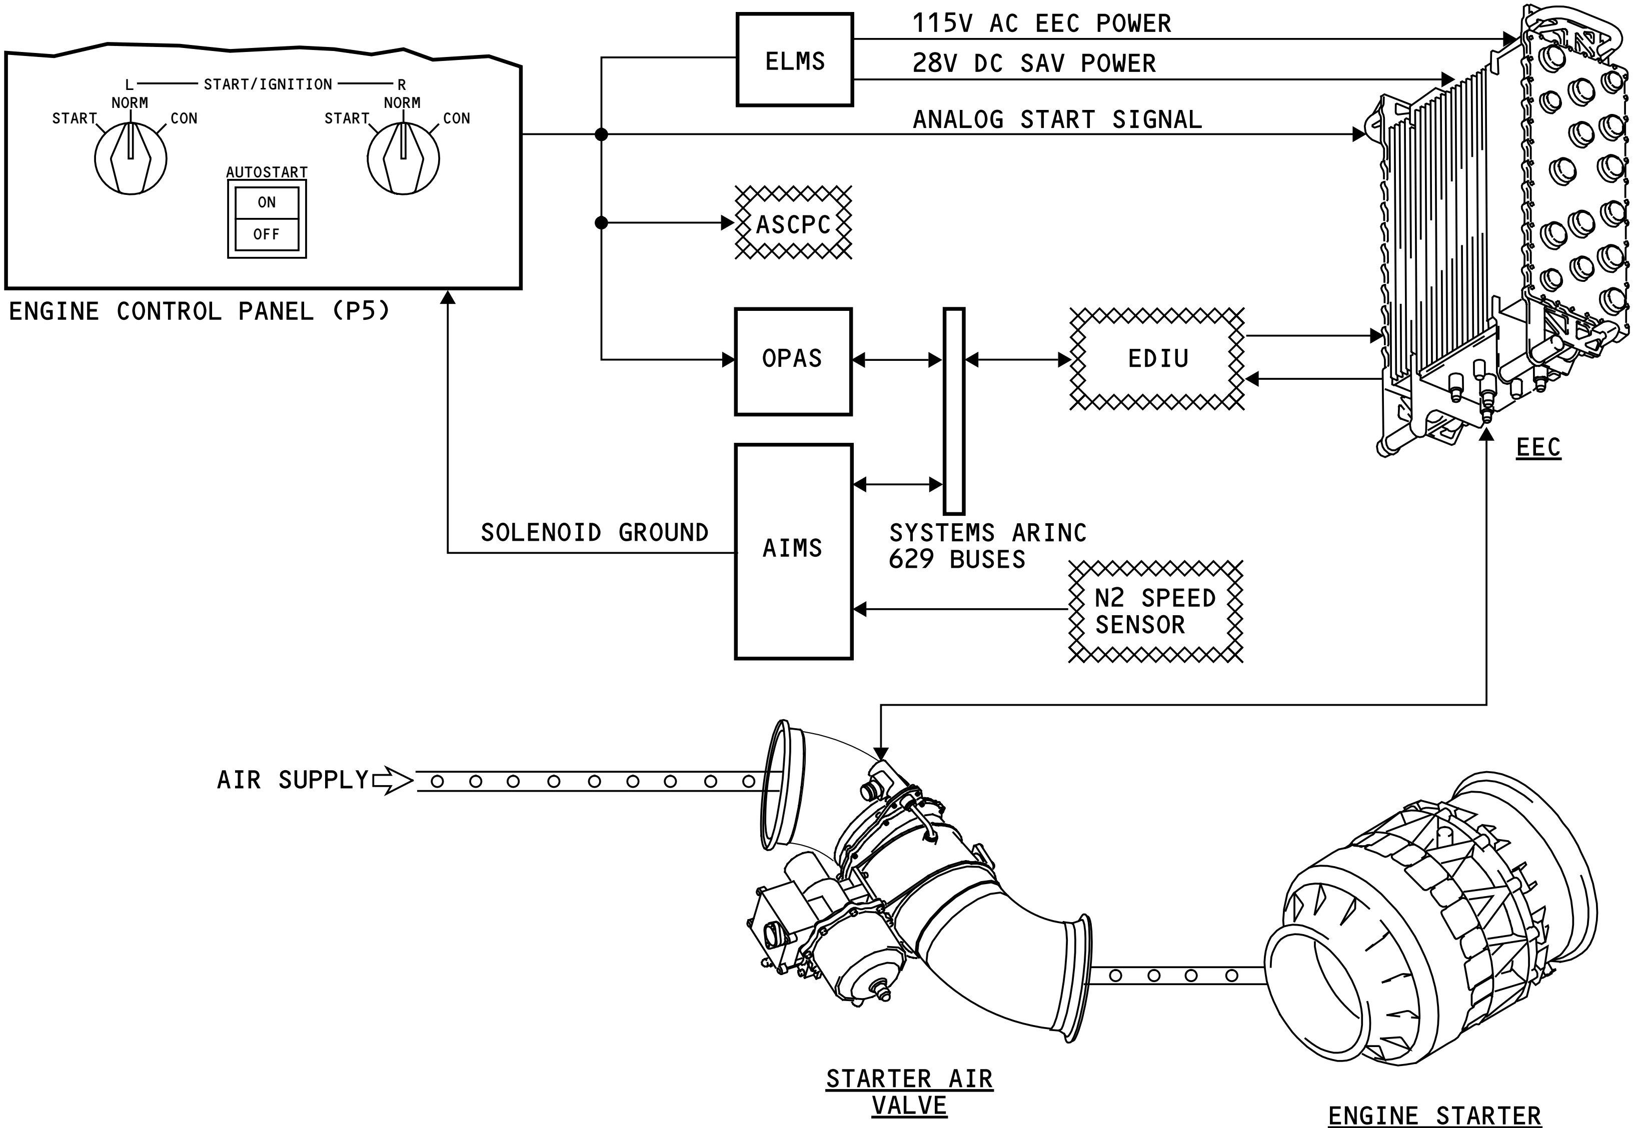
The AIMS supplies a ground for a solenoid that holds the engine start/ignition selector in the START position. The EEC sends a digital signal to tell the AIMS when to release the selector. If the AIMS does not receive the signal from the EEC, it uses N2 to decide when to release the selector.

See the engine air supply section for more information about the ASCPC (AMM PART I 36-11).

Starter Air Valve and Engine Starter

The EEC controls the starter air valve (SAV). When the valve is open, pneumatic power from the airplane air supply goes to the engine starter. This causes the engine starter to turn the N2 rotor.

The starter air valve has a pressure sensor that measures the pressure downstream of the valve. The sensor sends a signal to the EEC. The EEC uses this to find the valve position.



ENGINE STARTING - GENERAL DESCRIPTION

ENGINE STARTING - COMPONENT LOCATIONS - ENGINE

General

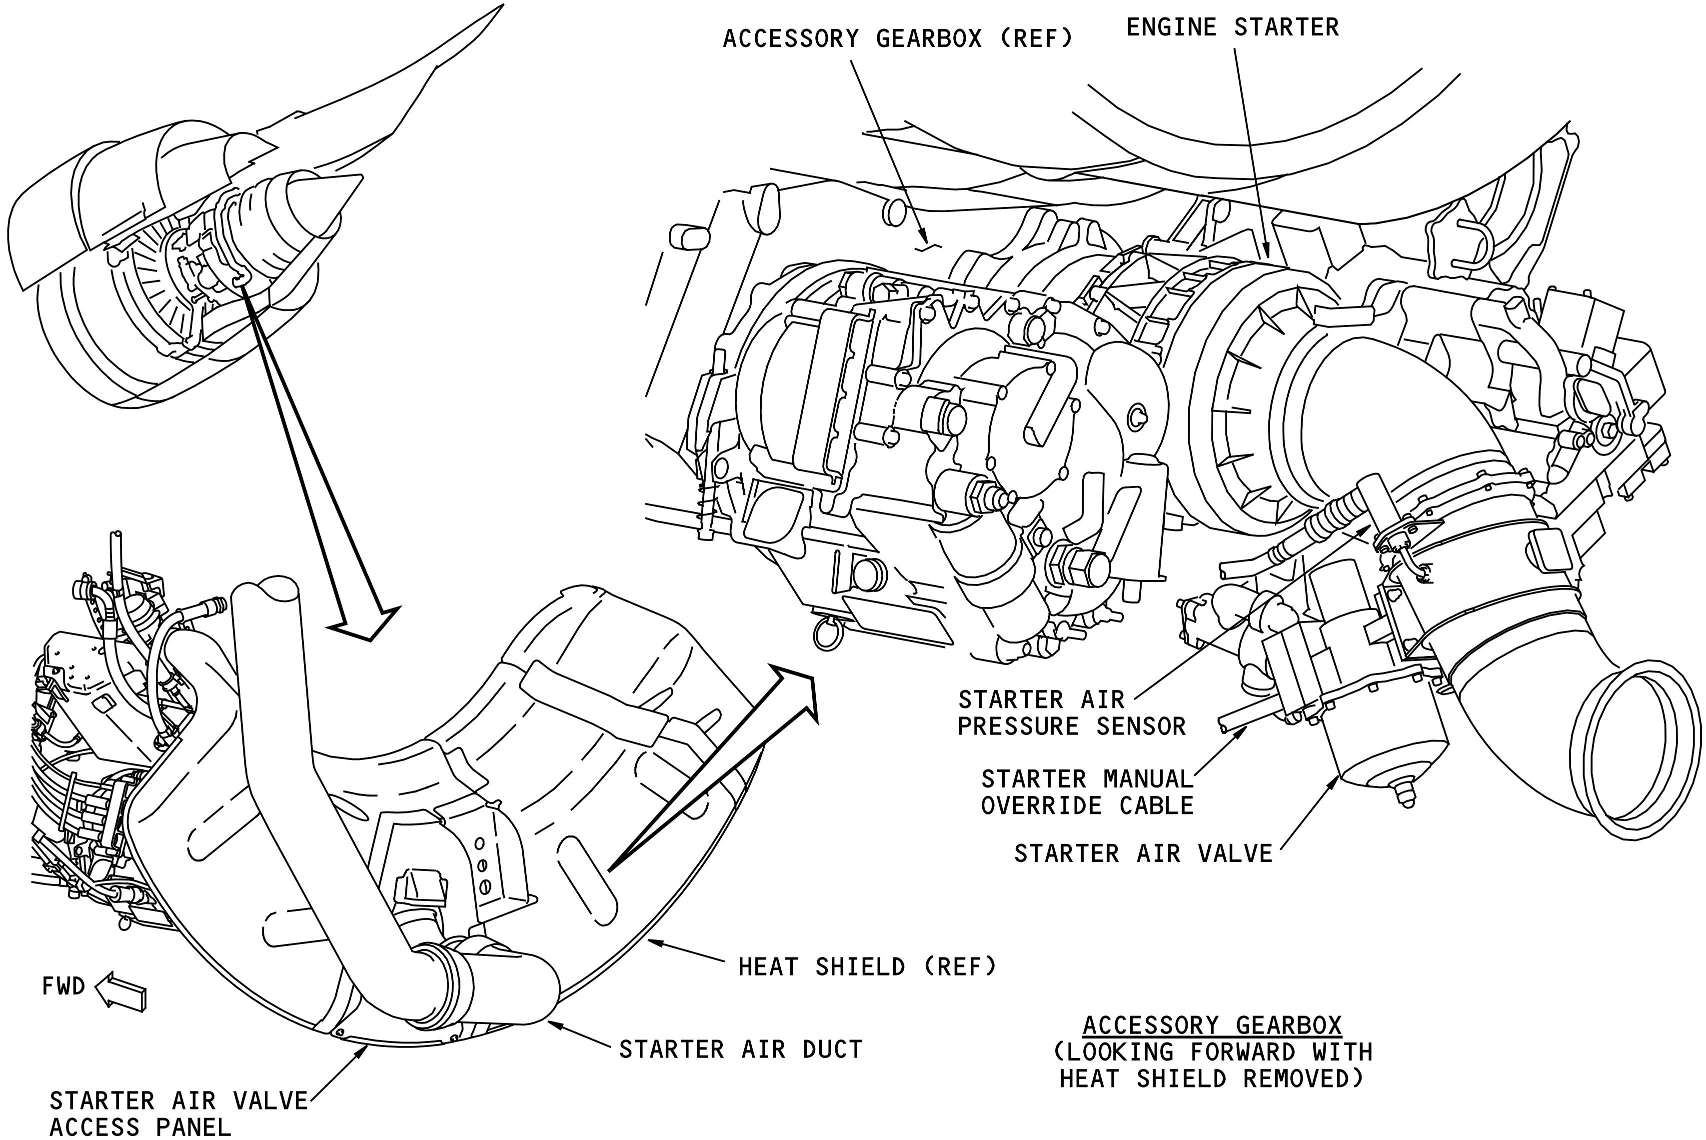
You open the fan cowls and thrust reversers to get access to these engine starting system components:

- Starter air duct
- Starter air valve
- Starter manual override cable
- Starter air pressure sensor
- Engine starter.

All of the engine starting system components are just aft of the accessory gearbox.

Training Information Point

To remove the starter air valve, you must first remove the starter air valve access panel which is part of the heat shield.



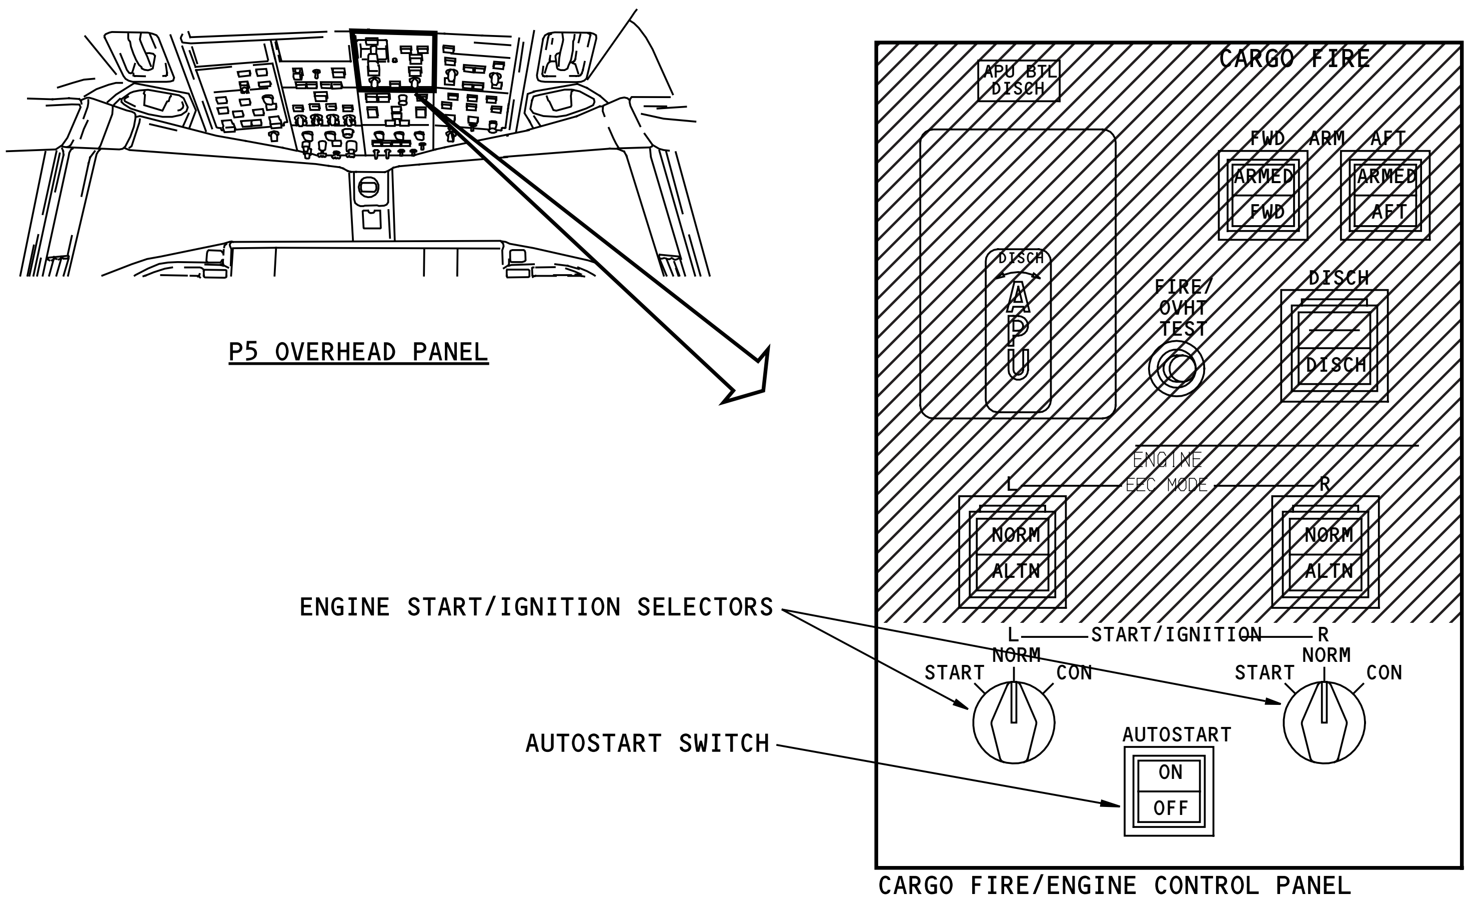
80-00-00-103 Rev 2 02/28/96

ENGINE STARTING - COMPONENT LOCATIONS - ENGINE

ENGINE STARTING - COMPONENT LOCATIONS - FLIGHT DECK

Engine Start Controls

The engine start/ignition selectors and the autostart switch are on the cargo fire/engine control panel on the P5 overhead panel.



ENGINE STARTING - COMPONENT LOCATIONS - FLIGHT DECK

ENGINE STARTING - STARTER AIR VALVE - MANUAL OVERRIDE

General

If the starter air valve (SAV) does not open automatically, you can manually open the valve.

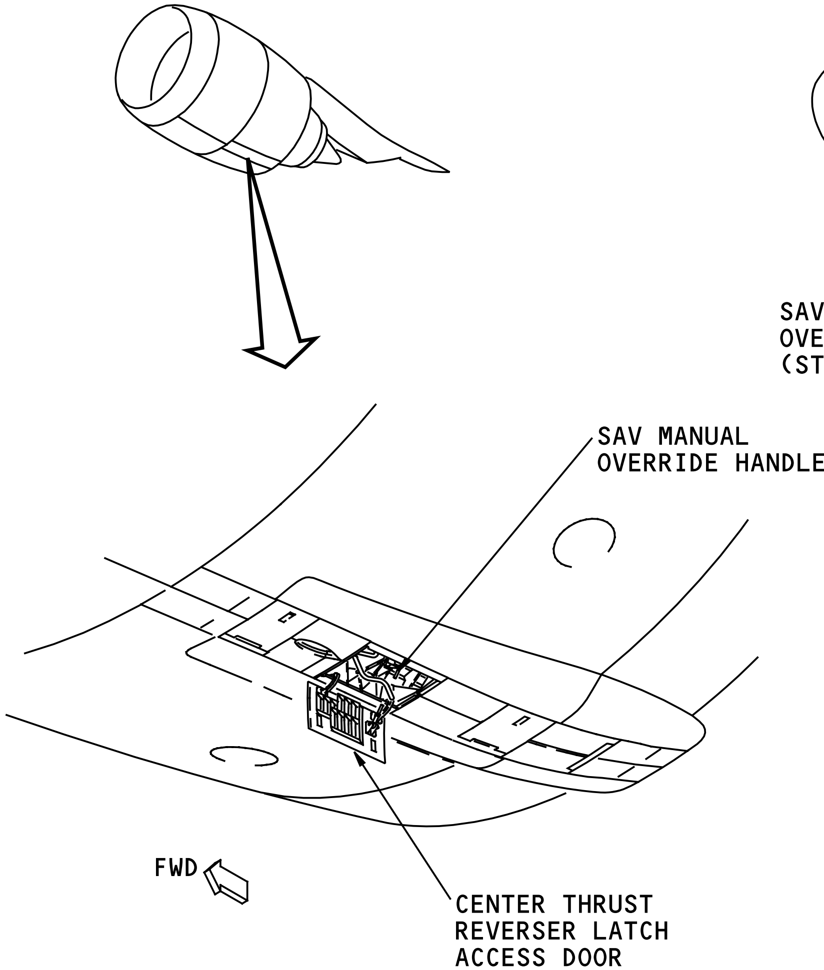
Location

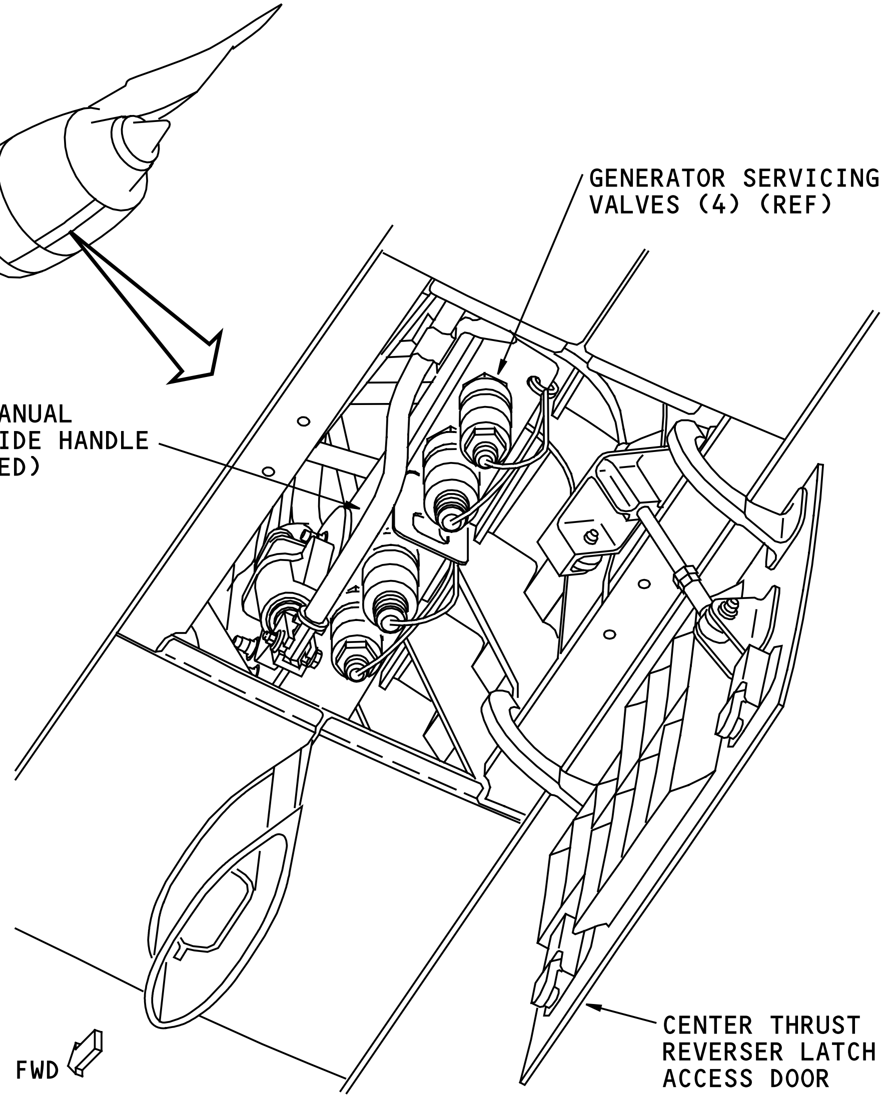
You open the center thrust reverser latch access door to get access to the starter air valve manual override handle. The handle folds down and extends out through the access opening.

Operation

Rotate the handle down, then push the handle up to engage it with the manual override flex cable. Turn the handle to open the valve (counter-clockwise as seen looking up at the bottom of the engine). The valve has a spring that closes it, so you must hold the handle to keep the valve open. When you release the handle, the valve closes.

CAUTION: MAKE SURE THERE IS AIR PRESSURE IN THE STARTER AIR DUCT. IF YOU DO NOT HAVE AIR PRESSURE, DAMAGE TO THE STARTER AIR VALVE CAN OCCUR.





80-00-00-106 Rev 3 11/25/1996

ENGINE STARTING - STARTER AIR VALVE - MANUAL OVERRIDE

ENGINE STARTING - ENGINE STARTER

Purpose

The engine starter turns the accessory gearbox for starting or motoring the engine. The accessory gearbox turns the high pressure compressor (N2) shaft.

Physical Description

The engine starter is a single stage, axial flow, turbine air motor. It attaches to the aft face of the accessory gearbox with a v-band clamp.

The starter has an oil sight glass and an oil fill and drain plug on the bottom. The plug has a magnetic chip detector for oil inspection. You remove the oil fill and drain plug by hand (push and turn). A check valve in the fill and drain port prevents oil from coming out.

Functional Description

Pneumatic power from the starter air duct turns the turbine air motor. The turbine air exhaust then goes out through the exhaust deflector baffles.

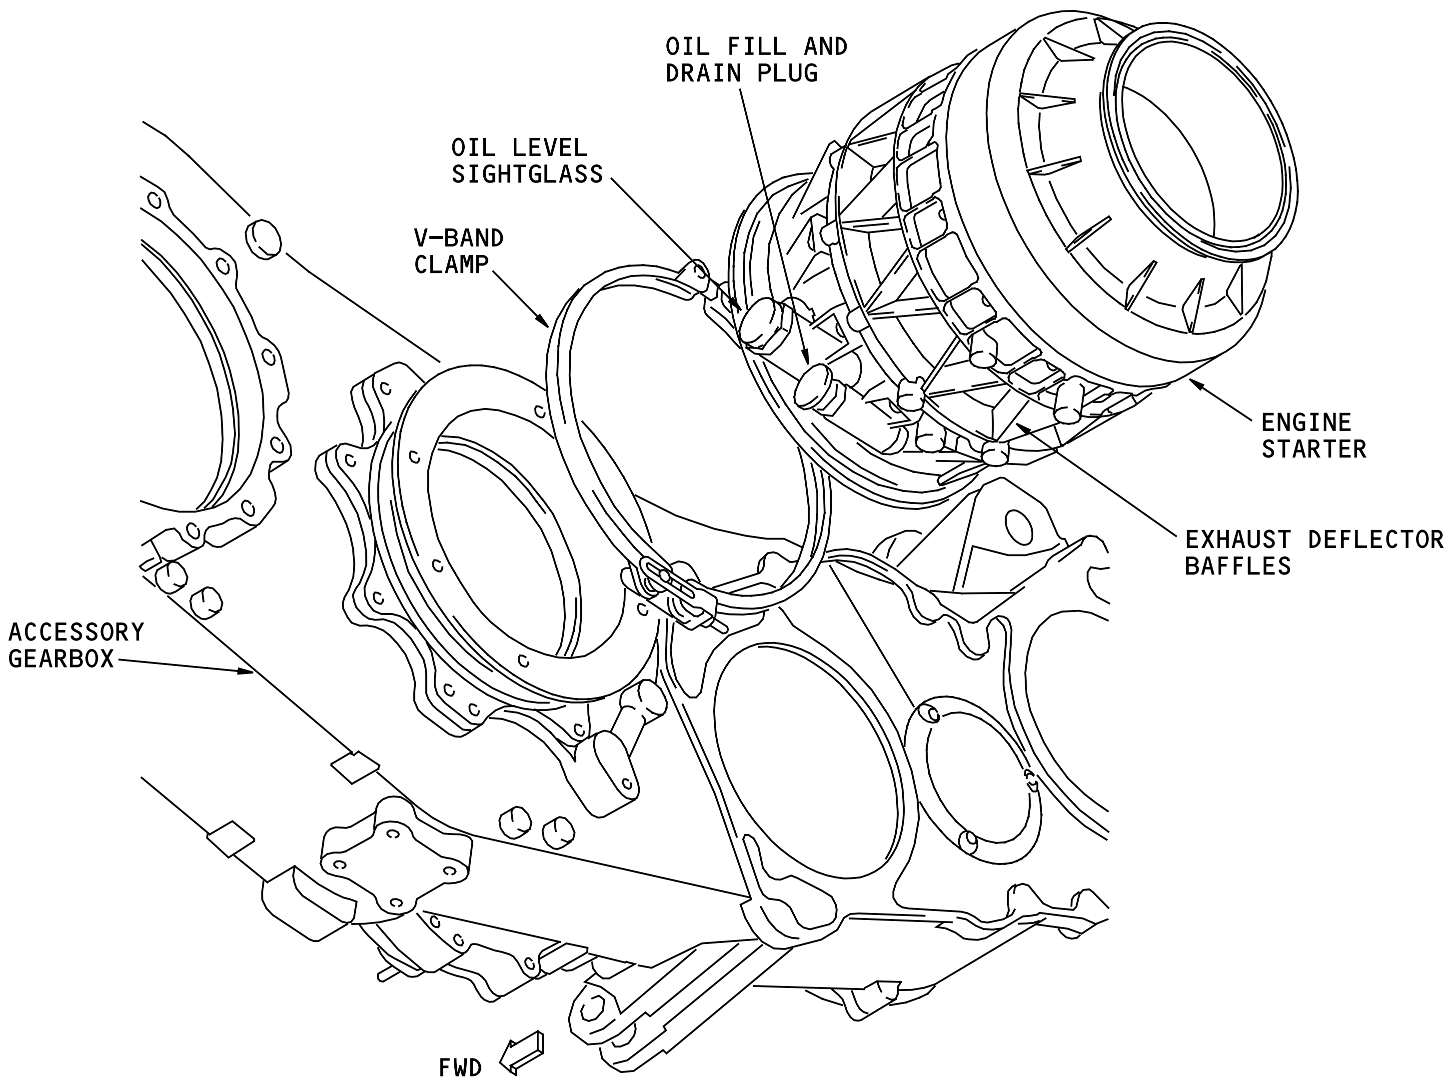
The starter uses reduction gears and a clutch mechanism to turn the output shaft. The clutch mechanism has a primary and a secondary clutch that prevent crash engagements.

Training Information Point

The engine starter uses engine oil for lubrication and cooling.

When you install a new starter, you must fill it with oil. After that, it is not necessary to add oil to the starter because it is automatically kept full with oil from the engine oil system.

You use a tool in the oil fill and drain plug port to drain and fill the starter. Do not use the oil level sightglass to get the correct oil level.



80-00-00-107 Rev 3 02/28/96

ENGINE STARTING - ENGINE STARTER

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE STARTING - FUNCTIONAL DESCRIPTION

General

You control the engine starting system with the autostart switch and the start/ignition selector. The EEC automatically controls the starter air valve (SAV).

Autostart Switch

The position of the autostart switch goes to the EEC digitally. When the switch is in the ON position, it arms the EEC to do an autostart operation.

Start/Ignition Selector

When you put the start/ignition selector in the START position, it sends signals to these systems and components:

- ELMS
- ASCPC
- EEC
- AIMS.

ELMS Power

The ELMS supplies 28v dc power from the captain's flight instrument bus to energize the engine start control relay. This lets 28v dc power go through the EEC to energize the SAV solenoid.

ASCPC

The ASCPC uses the start signal to control the pressure regulating and shutoff valve (PRSOV) and the isolation valves in the pneumatic system. During an engine start, the ASCPC closes the related PRSOV and opens the applicable isolation valve(s). See the engine air supply section for more information about the ASCPC (AMM PART I 36-11).

EEC

The EEC gets an analog start signal directly from the start/ignition selector. It also gets a digital start signal through the EDIU. These signals tell the EEC that there is a command to open the SAV.

When you put the start/ignition selector in the START position, 28v dc power goes through the EEC to energize the SAV solenoid.

The SAV logic in the EEC removes the 28v dc power from the SAV solenoid at the starter cutout speed (approximately 64 percent N2). This causes the SAV to close.

The SAV logic does not let 28v dc power energize the SAV solenoid if the N2 is more than the maximum starter engagement limit.

When the start/ignition selector moves to the NORM position, the engine start control relay de-energizes. This removes 28v dc power to the EEC.

ENGINE STARTING - FUNCTIONAL DESCRIPTION

Both channel A and channel B of the EEC get a signal of the duct pressure downstream of the SAV. The EEC uses these signals to find the SAV position.

AIMS

The AIMS controls the latching solenoid that keeps the start/ignition selector in the START position. The solenoid cannot move the selector. It only holds it in the momentary START position.

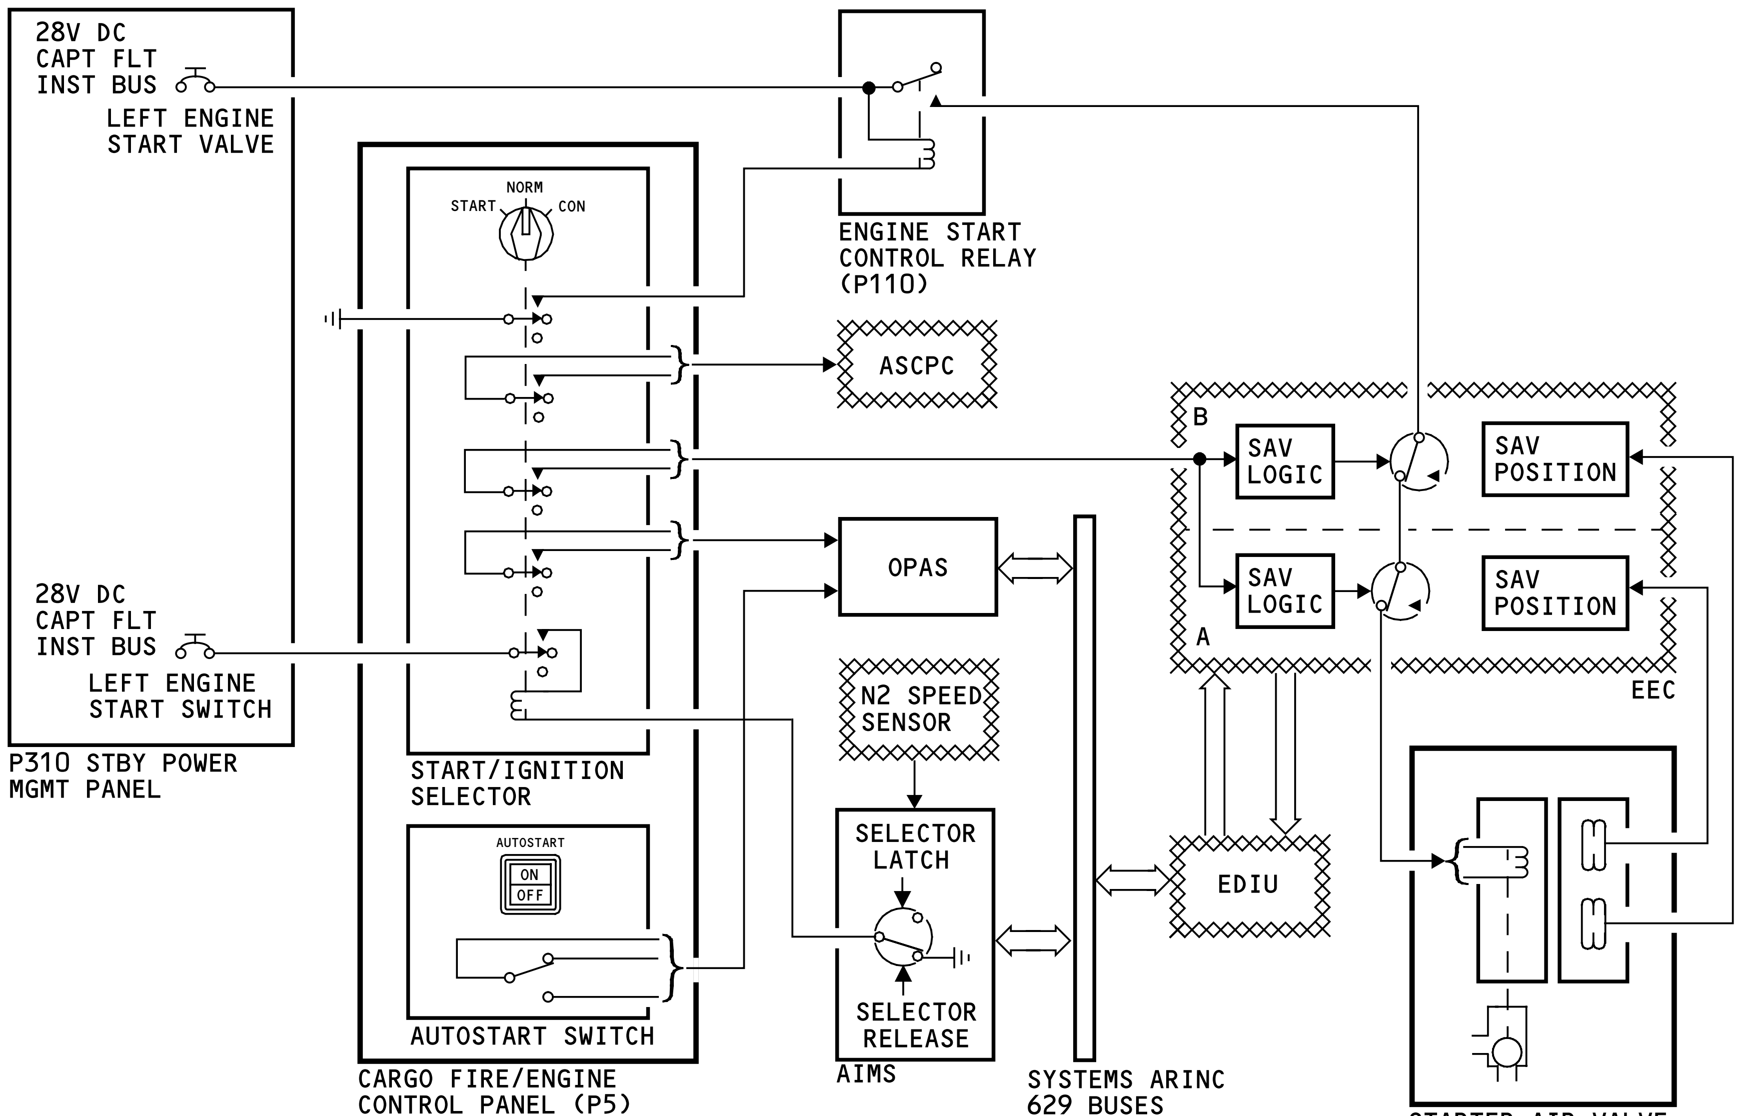
The EEC sends a digital engine start signal to the AIMS. This signal is set true when the engine start begins. When the engine start signal is true, the AIMS latches the selector by energizing the solenoid.

The EEC sets the engine start signal false when any of these conditions occur:

- The EEC aborts an autostart process
- The engine gets to the starter cutout speed (approximately 64 percent N2)

When the engine start signal is false, the AIMS releases the selector by de-energizing the solenoid. The selector automatically moves to the NORM position when the solenoid de-energizes.

If the digital engine start signal is not valid or is not available, the AIMS uses the analog N2 signal from the N2 speed sensor to control the latching solenoid. Less than 60 percent N2, the solenoid energizes. More than 60 percent N2, the solenoid de-energizes.



ENGINE STARTING - FUNCTIONAL DESCRIPTION

80-00-00-108 Rev 4 03/21/96

THIS PAGE INTENTIONALLY LEFT BLANK

Normal Autostart

When you enable an autostart, the EEC automatically starts the engine. You enable an autostart by doing these steps:

- Push the autostart switch to ON
- Turn the start selector to START
- Move the fuel control switch to RUN.

The EEC opens the starter air valve (SAV), which causes N2 to rotate.

At 16 percent N2 the EEC energizes one igniter. At 22 percent N2 the EEC opens the shutoff valve in the HMU to let fuel flow to the engine.

When the engine speed reaches approximately 56 percent N2, the EEC de-energizes the igniter. At approximately 64 percent N2, the EEC closes the SAV.

At idle, the EEC sets the AIMS engine start signal to false. This causes the AIMS to de-energize the start/ ignition selector latching solenoid. The selector returns to the NORM position.

Abnormal Autostart

If the EEC finds a problem during an autostart try, it will do another autostart try. The EEC can do three autostart tries.

Before the EEC does a second or third autostart try, it motors the engine to cool it and remove any fuel.

If an autostart problem occurs after the SAV closes, the EEC waits until the engine speed gets to the maximum starter re-engagement speed before it re-opens the SAV.

The EEC uses two igniters after the first autostart try.

Manual Start

When you do a manual start, the EEC only controls some of the start sequence. It does not monitor or control starting faults. You enable a manual start by doing these steps:

- Push the autostart switch to OFF
- Turn the start selector to START.

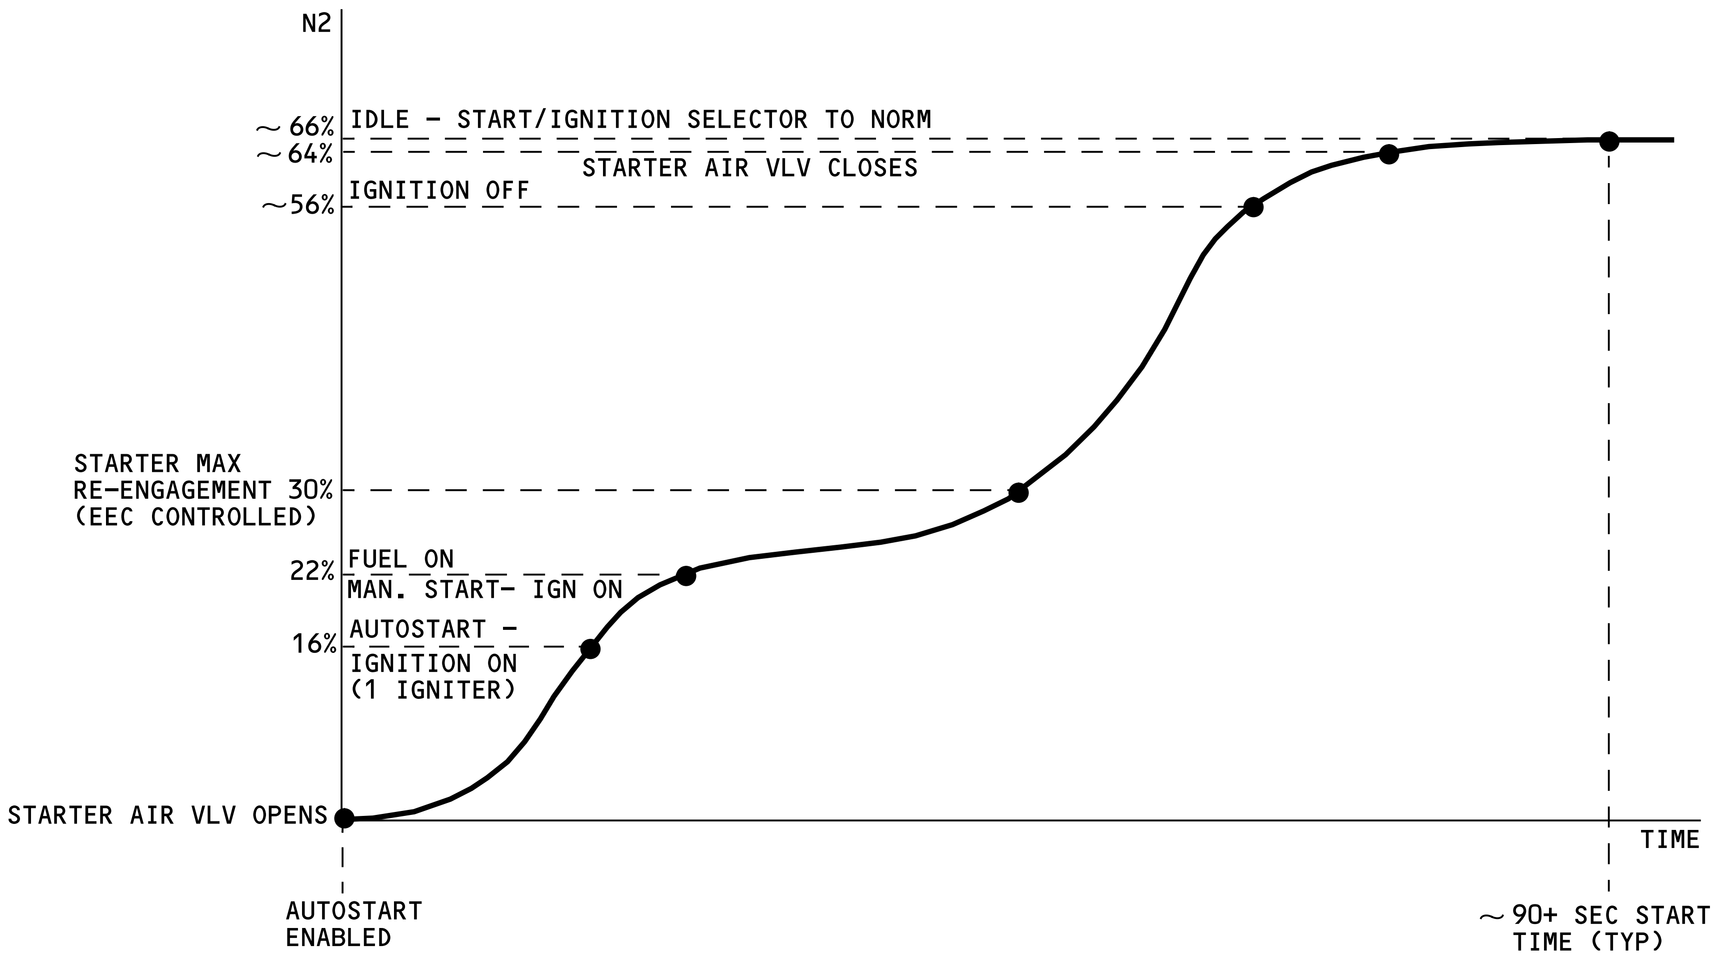
The EEC opens the SAV, which causes N2 to rotate.

At 22 percent N2 or higher, you put the fuel control switch in the RUN position. When the fuel control switch is in the RUN position, the EEC opens the shutoff valve in the HMU and energizes one igniter.

When the engine speed reaches approximately 56 percent N2, the EEC de-energizes the igniter. At approximately 64 percent N2, the EEC closes the SAV.

ENGINE STARTING - FUNCTIONAL DESCRIPTION - START PROFILE

At idle, the EEC sets the AIMS engine start signal to false. This causes the AIMS to de-energize the start/ignition selector latching solenoid. The selector goes back to the NORM position.



80-00-00-110 Rev 0 03/21/96

ENGINE STARTING - FUNCTIONAL DESCRIPTION - START PROFILE

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE STARTING - OPERATION

General

The engine starting system has these modes of operation:

- Autostart
- Manual start.

These are the flight deck controls you use for an engine start operation:

- Start/ignition selectors
- Autostart switch
- Fuel control switches.

It is important to monitor the engine parameters to find or prevent these fault conditions:

- Low starter air pressure
- No light-up
- Locked rotor(s)
- Hung start
- Hot start
- Starter shaft breakage
- Starter duty cycle exceedance.

Autostart Operation

This is a brief summary of the autostart operation procedure:

- Put the autostart switch in ON
- Put the engine start/ignition selector in START
- Put the fuel control switch in RUN.

The EEC automatically controls and monitors the autostart operation. It will stop the operation for a fault condition. If the autostart try fails, the EEC automatically does another start operation.

On the ground, the EEC permits only three tries to start the engine. If the third try fails, then the autostart operation stops.

The start/ignition selector moves to the NORM position when one of these conditions occur:

- The N2 speed gets to approximately 66 percent
- The EEC stops the autostart operation.

In the air, the autostart operation continues until the engine starts or you move the start/ignition selector to NORM.

Manual Start Operation

This is a brief summary of the manual start operation procedures:

- Put the autostart switch in OFF
- Put the engine start/ignition selector in START
- Monitor the engine parameters for the correct indications
- Put the fuel control switch in RUN at 22 percent N2.

ENGINE STARTING - OPERATION

You must monitor the manual start operation and stop the operation for a fault condition.

Starter Cutout

The EEC closes the starter air valve when the engine gets to approximately 64 percent N2. The valve position is shown on the air synoptic display.

Training Information Point

The EEC does not use oil pressure as a input to find a starting fault.

For a manual start, if the fuel control switch is put into the RUN position below 18 percent N2, the advisory message ENG AUTOSTART shows to tell you the start procedure is incorrect.

IGNITION - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

IGNITION - INTRODUCTION

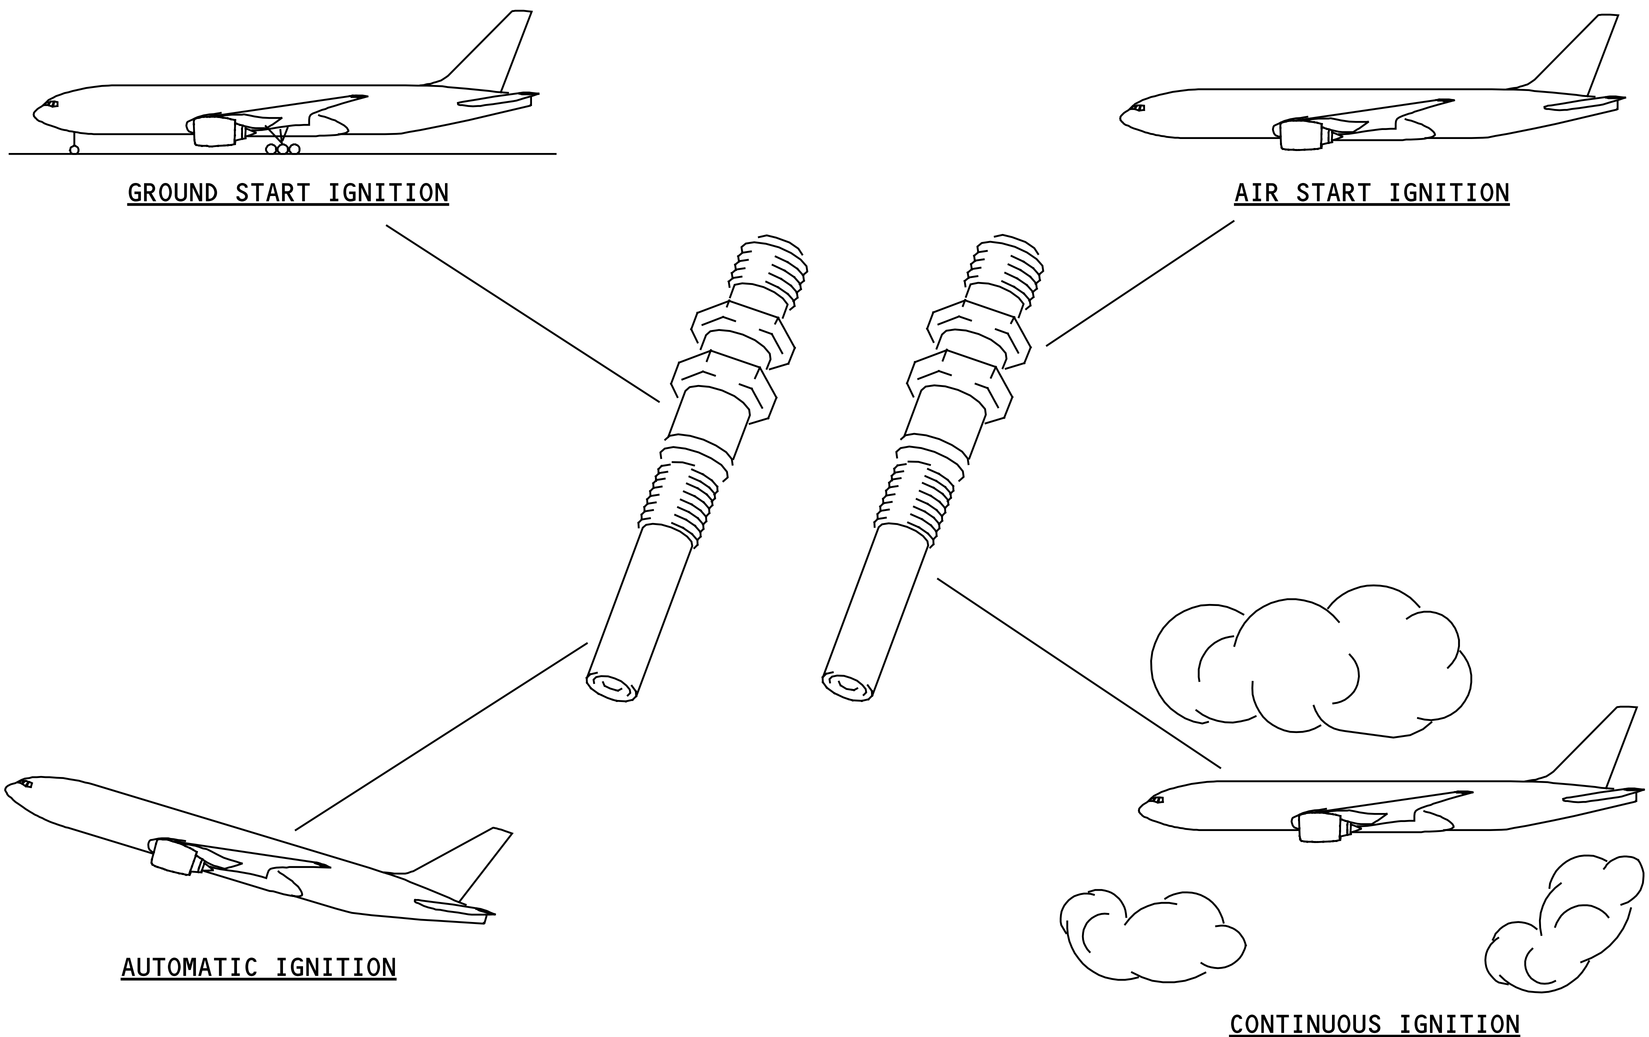
Purpose

Each engine has two ignition systems that operate independently. They supply electrical sparks in the combustion chamber to start combustion or make sure combustion continues.

The ignition system has automatic and manual operation modes on the ground and in flight.

Abbreviations and Acronyms

ACIPS	- airfoil and cowl ice protection system
AIMS	- airplane information management system
CON	- continuous
EAI	- engine anti-ice
EDIU	- engine data interface unit
EEC	- electronic engine control
ELMS	- electrical load management system
FSEU	- flap slat electronics unit
HPC	- high pressure compressor
NORM	- normal
OPAS	- overhead panel ARINC 629 system



IGNITION - INTRODUCTION

IGNITION - GENERAL DESCRIPTION

General

The ignition system for each engine contains these components:

- Ignition exciter (2)
- Ignition lead (2)
- Igniter (2).

These components control the operation of the ignition system:

- Start/ignition selector
- Fuel control switch
- EEC
- Airfoil and cowl ice protection system (ACIPS)
- Flap slat electronics unit (FSEU).

Power

The ignition system gets 115v ac power from the electrical load management system (ELMS). The fuel control switch must be in the RUN position to let the ELMS supply ignition power to the EEC. The EEC controls the power to the ignition exciters.

Autostart or Manual Start Ignition

For the first automatic or manual engine start on the ground, the EEC supplies power to one ignition exciter only. During the second attempt, the EEC selects the other ignition system. If a third attempt is necessary, the EEC selects both ignition systems.

When an autostart occurs, the EEC supplies ignition power at 16 percent N2. For a manual start, the EEC supplies power when the fuel control switch is put in the RUN position.

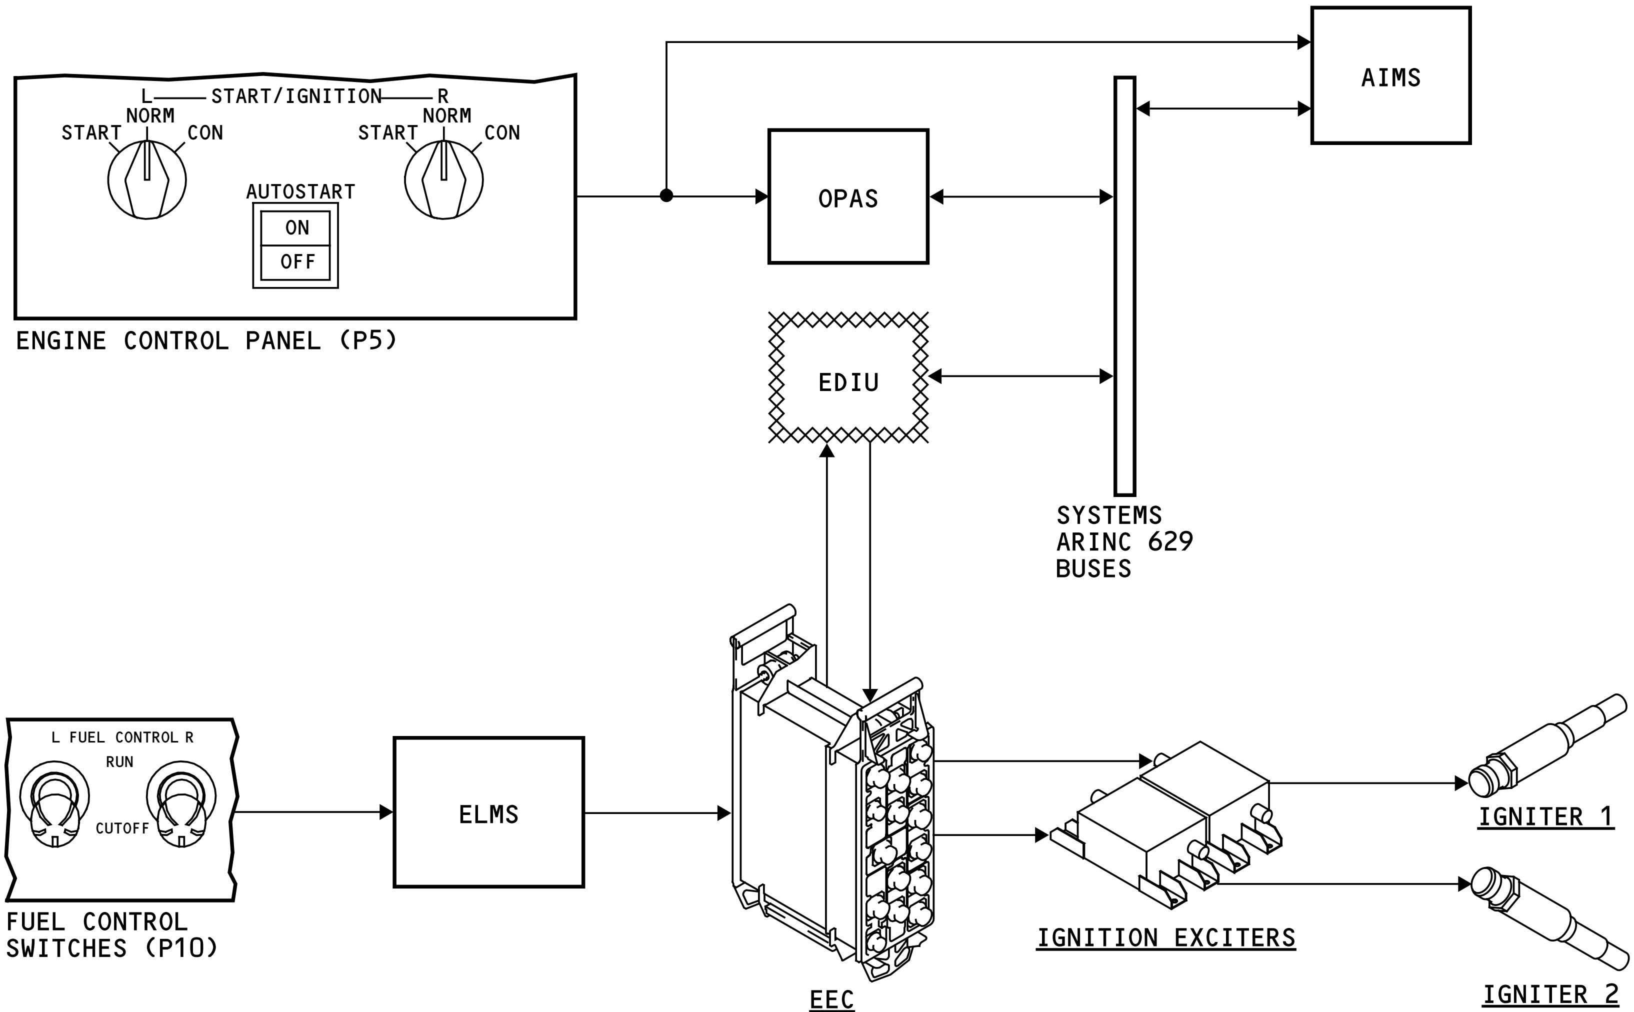
During a ground or in-flight engine start, the EEC removes power to the ignition system at approximately 56 percent N2. The start/ignition selector moves to the NORM position just before the engine gets to idle speed.

Automatic Ignition

When the start/ignition selector is in the NORM position, the EEC controls the two ignition exciters.

Continuous Ignition

When the start/ignition selector is in the CON position, the EEC controls the power to the exciters. The ignitors will fire when the EEC finds it is nesessary.



IGNITION - GENERAL DESCRIPTION

IGNITION - ENGINE COMPONENT LOCATIONS

General

The ignition system components are on the left side of the engine. You open the left thrust reverser half to get access to these components:

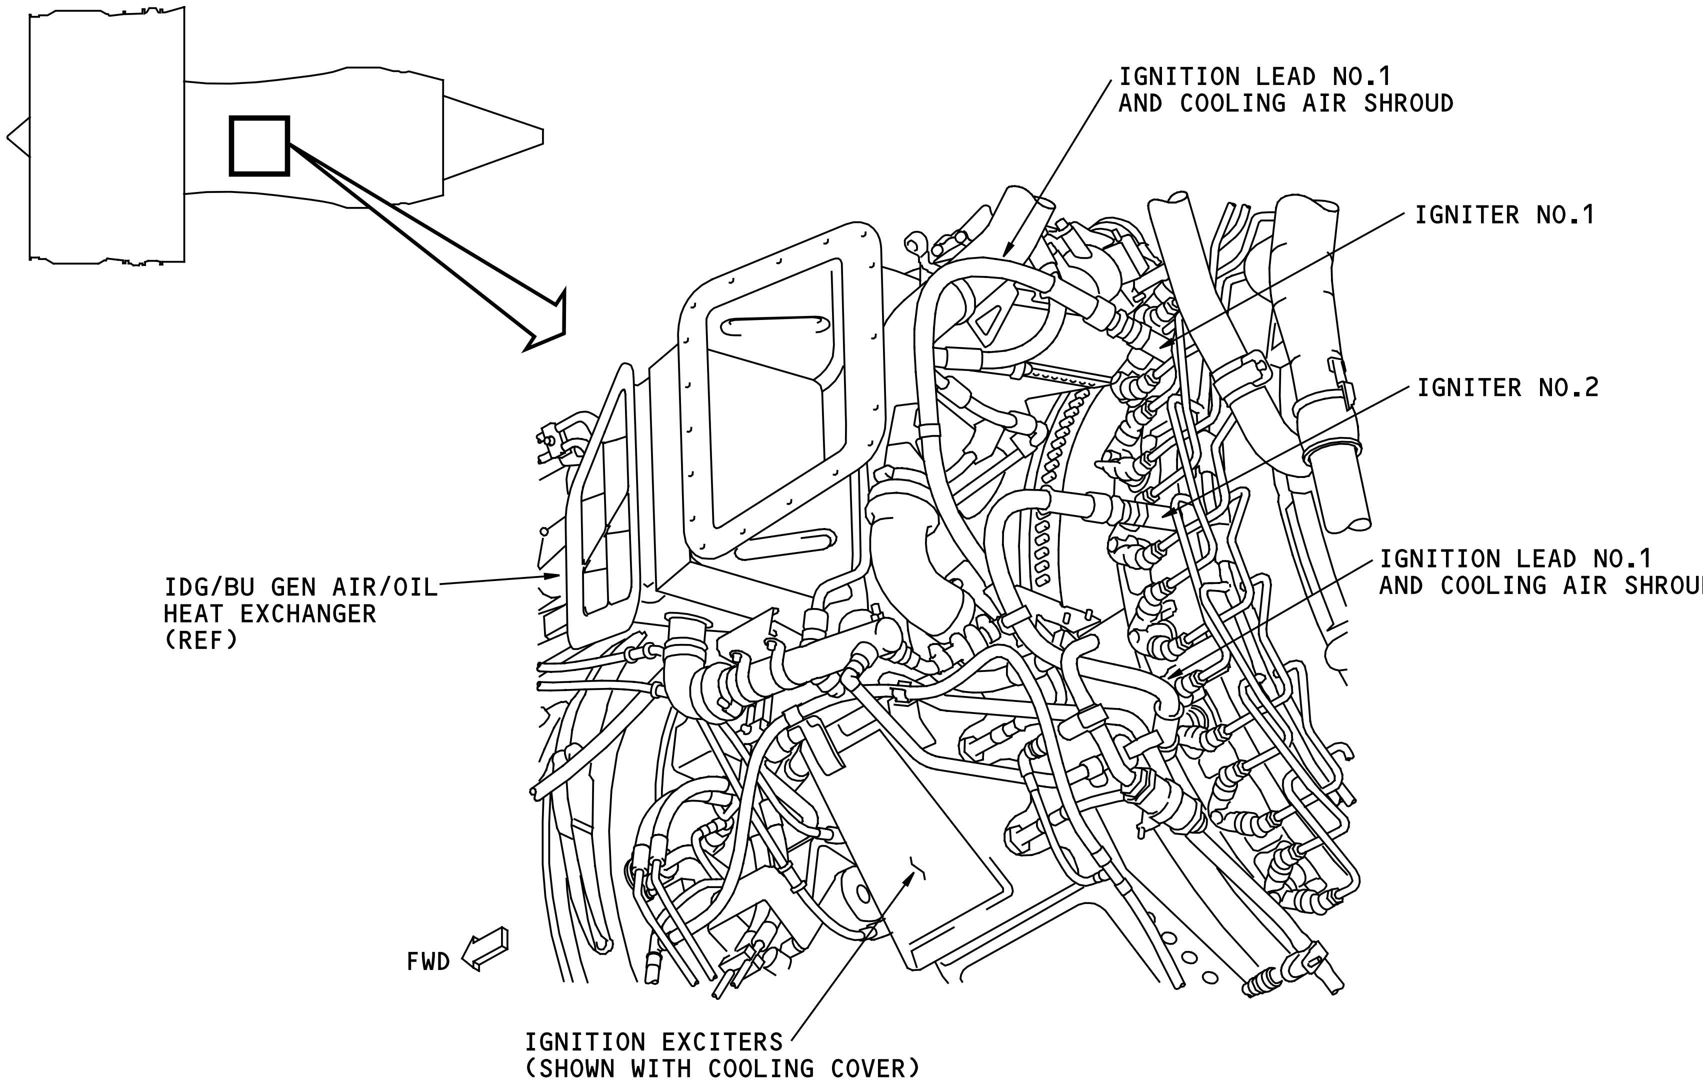
- Ignition exciter (2)
- Ignition lead (2)
- Igniter (2).

The two ignition exciters are on the left side of the high pressure compressor (HPC), above the accessory gearbox.

The upper ignition lead goes to the upper igniter at the 9:30 position. The lower ignition lead goes to the lower igniter at the 8:00 position.

Training Information Point

WARNING: MAKE SURE THAT THE IGNITION SYSTEM DOES NOT OPERATE FOR FIVE MINUTES BEFORE YOU REMOVE THE COMPONENT. IGNITION VOLTAGE IS DANGEROUSLY HIGH AND CAN CAUSE INJURY TO PERSONS.



74-00-00-104 Rev 2 06/17/96

IGNITION - ENGINE COMPONENT LOCATIONS

IGNITION - IGNITION EXCITER

General

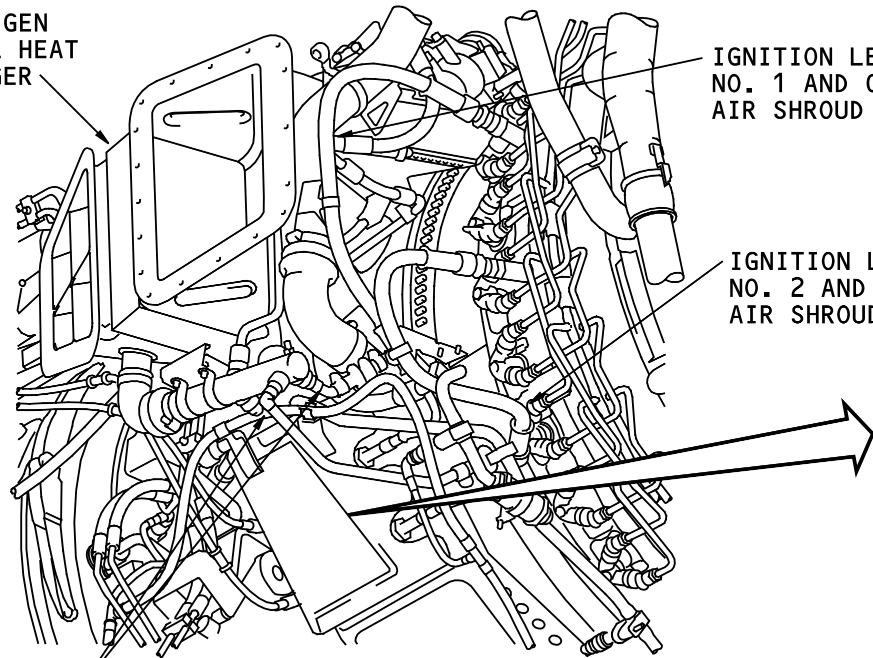
The ignition exciter changes 115v ac input power to pulsing high voltage output power. The high voltage power operates the igniter.

The exciter is a sealed unit. The input lead connects to the front of the exciter. It supplies 115v ac power to the exciter. The output lead connects to the rear of the exciter. It supplies high voltage pulses to the igniter.

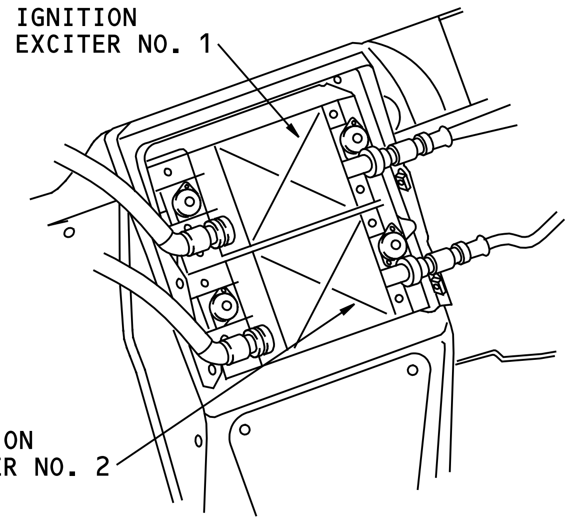
Fan air cools the ignition exciters, leads and igniters.

Functional Description

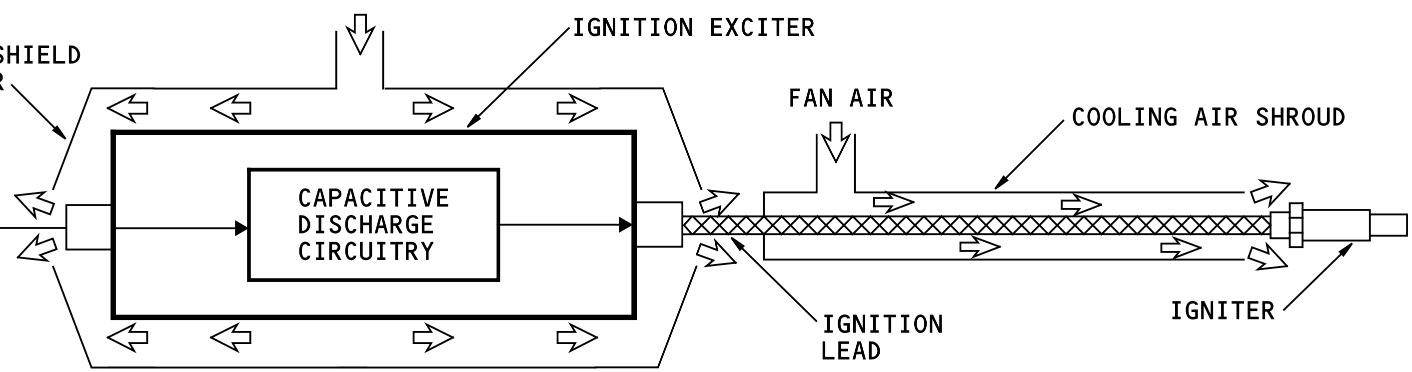
The exciter uses capacitive discharge to make high voltage output pulses. The output pulses go through the ignition lead to the igniter tip.



ENGINE HPC - LEFT SIDE



IGNITION EXCITERS
(HEATSHIELD COVER REMOVED)



IGNITION - IGNITION EXCITER

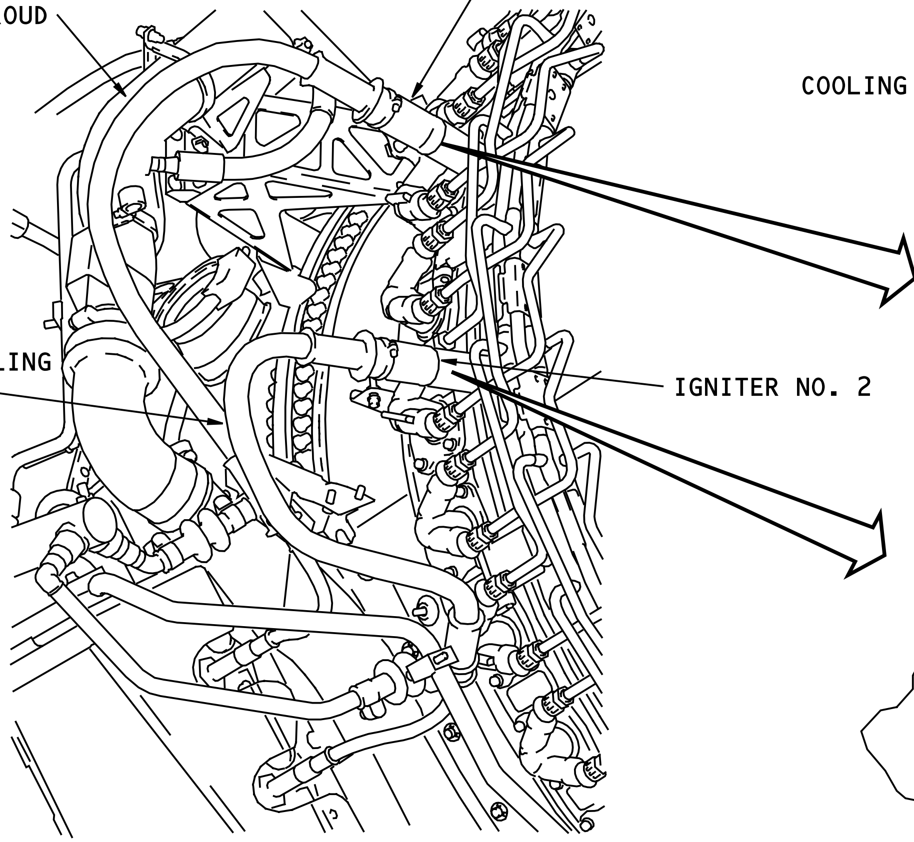
IGNITION - IGNITERS

General

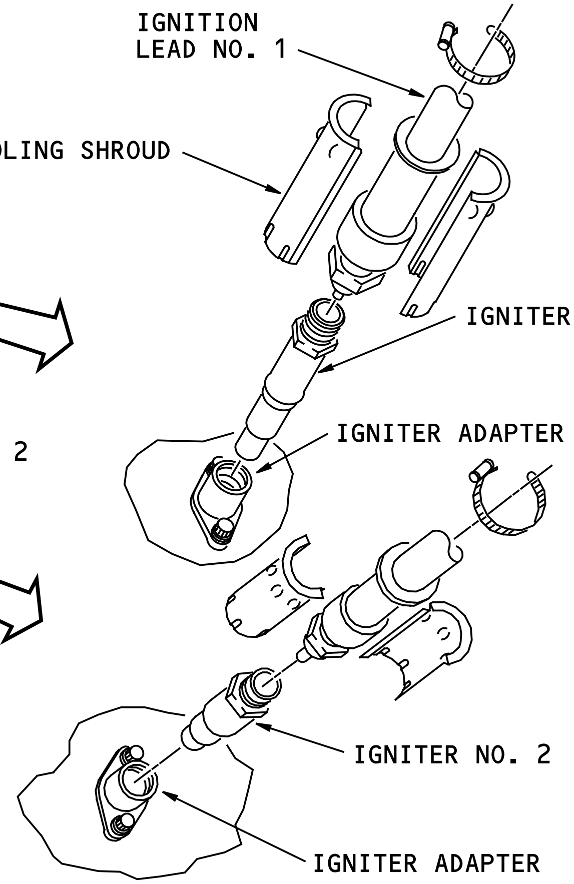
The igniters fit into threaded adapters on the combustor/diffuser assembly. The fan air that cools the ignition lead goes out through the cooling shroud. This keeps the igniter cool.

Training Information Point

To remove an igniter, you must disconnect the cooling shroud halves and the ignition lead. Do not remove the igniter adapter.



ENGINE HPC - LEFT SIDE



IGNITER PLUG INSTALLATION

74-00-00-106 Rev 1

IGNITION - IGNITERS

IGNITION - FUNCTION DESCRIPTION

General

The EEC uses 28v dc and 115v ac to control and supply power to the ignition system.

Power Sources

The normal supply of power to energize the ignition exciters is 115v ac from the left and right main ac buses. The 115v ac standby bus is the alternate power supply to energize the ignition units.

Relays in the P110 left power management panel automatically select the supply for the ignition units.

Control

When the fuel control switch is in the RUN position, the ignition/fire detection relay and the generator control/ignition relay send power to the EEC.

The EEC uses airplane and engine conditions to control power to the ignition exciters. Each channel of the EEC can control power to one or two ignition exciters. Each ignition exciter can get power through one of two EEC switches. Channel A of the EEC commands one switch and channel B commands the other switch.

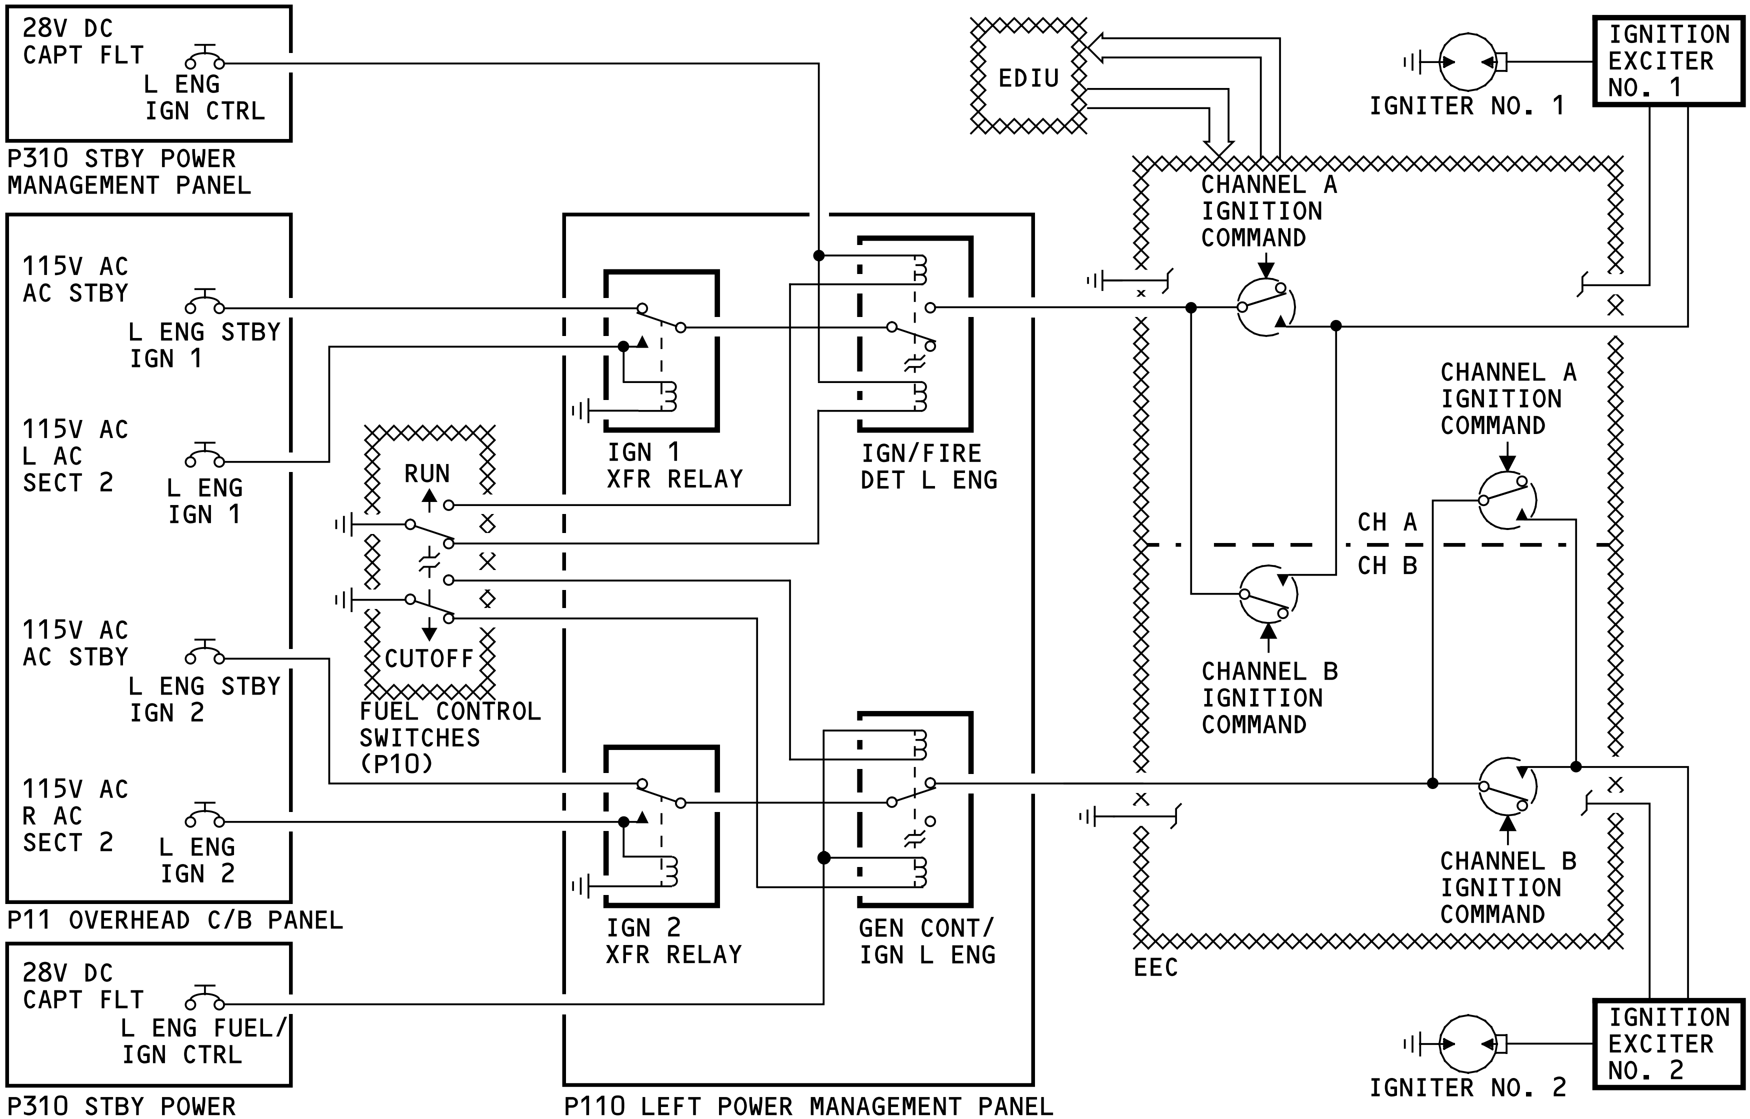
The EEC monitors the position of each switch. A failure of one switch causes the EEC channel in command to operate the switch in the other EEC channel.

For an autostart or a manual start on the ground, the EEC lets only one ignition exciter get power. The choice of the ignition exciter changes for each ground start. If the engine fails to start, the EEC supplies power to the two ignition exciters on the second try.

During a normal in-flight start, the EEC selects the two ignition exciters to get power.

When the start/ignition selector is in the NORM position, the two ignition exciters operate when the engine anti-ice is on, or the flaps are not retracted. The ACIPS supplies the engine anti-ice signal and the FSEU supplies flap position. The EDIU gets the data from the ARINC 629 systems buses and sends it to the EEC. The EEC automatically supplies power to the two ignition exciters.

When the start/ignition selector is in the CON position, the EDIU gets the switch position signal from the ARINC 629 system busses. This signal causes the EEC to operate the two ignition exciters continuously.



IGNITION - FUNCTION DESCRIPTION

74-00-00-107 Rev 2 02/08/1997

IGNITION - OPERATION

General

The EEC controls the operation of the ignition system. The EEC gets the start/ignition selector position to set these modes of operation for the ignition system:

- Engine start ignition
- Automatic ignition
- Continuous ignition.

The fuel control switch must be in the RUN position for the ignition system to operate.

Engine Start Ignition

When you do an autostart or manual start of the engine, the EEC can use one or two igniters.

On the first ground start (autostart or manual), the EEC uses one igniter. If the engine fails to start, the EEC selects the other ignition system. If the second start attempt fails, the EEC selects both ignition systems during the third attempt.

For all in-flight restarts, the EEC powers both igniter systems.

During an autostart, the EEC operates the ignition system at 16 percent N2. For a manual start, the ignition system operates when you put the fuel control switch in the RUN position.

The EEC removes power to the igniter(s) at approximatly 56% N2.

Automatic Ignition

When the start/ignition selector is in the NORM position, the EEC uses the two igniters. The EEC supplies power to the igniters when any of these conditions occur:

- Rejected take off (RTO)
- PS3 is less than 175 psig
- Rapid decel to Idle at altitude
- Engine flameout.

When the engine is shut down, automatic operation of the ignition system stops.

Continuous Ignition

The EEC has full control of the exciter power when you put the start/ignition selector in the CON position. When the engine is shut down, the operation of continuous ignition stops.

ENGINE EXHAUST SYSTEM - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE EXHAUST SYSTEM - GENERAL DESCRIPTION

General

The engine exhaust system controls the direction of the fan exhaust and turbine exhaust gases that make forward thrust and reverse thrust.

To make reverse thrust, you use the reverse thrust levers in the flight deck to control the direction of the fan exhaust gases. The pilot uses reverse thrust to help slow the airplane after landing or during a rejected takeoff (RTO).

Turbine Exhaust System

The turbine exhaust system uses the primary sleeve and forward and aft centerbodies to make an exit duct for the turbine exhaust gases. This system makes forward thrust only.

Thrust Reverser (T/R) System

The T/R system uses these components to control the direction of the fan exhaust:

- Sleeves
- Cascade segments
- Blocker doors
- Drag links.

This system makes forward and reverse thrust.

When the sleeves are forward (retracted), the fan exhaust makes forward thrust.

When the sleeves are aft (extended), the blocker doors and cascade segments turn the fan exhaust. This makes reverse thrust.

Thrust Reverser Actuation System (TRAS)

The TRAS moves the T/R sleeves. It uses hydraulic power for operation and electrical power for control.

The TRAS uses solenoids to control hydraulic power with these valves:

- Sync lock valve (SLV)
- Directional control valve (DCV)
- Isolation valve (IV)

Control stand switches energize the sync lock (SL) solenoid valve and the directional control solenoid valve. The sync lock valve supplies hydraulic power to release the sync lock. The DCV controls the direction of the hydraulic flow.

The EEC uses a thrust resolver angle (TRA) and other EEC inputs to control the isolation valve (IV). The IV supplies hydraulic pressure to the actuators.

The hydraulic actuators move the T/R sleeves to the extended or retracted position. The sync shafts keep the movement of the hydraulic actuators together. The sync lock/manual drive unit locks the sync shafts when the sleeves are in the retracted position.

ENGINE EXHAUST SYSTEM - GENERAL DESCRIPTION

The EEC monitors the T/R sleeve position with a rotary variable differential transformer (RVDT) to control the thrust lever interlock actuator and to schedule thrust. The thrust lever interlock actuator prevents the full movement of the reverse thrust lever until the T/R sleeves are in the correct position.

The test enable switch permits the operation of the TRAS for maintenance when the engine is not in operation.

The electrical load management system (ELMS) contains the TRAS relays.

Thrust Reverser Indicating and Fault Detection System

The T/R indicating and fault detection system uses the proximity sensor system and the EEC to monitor the TRAS.

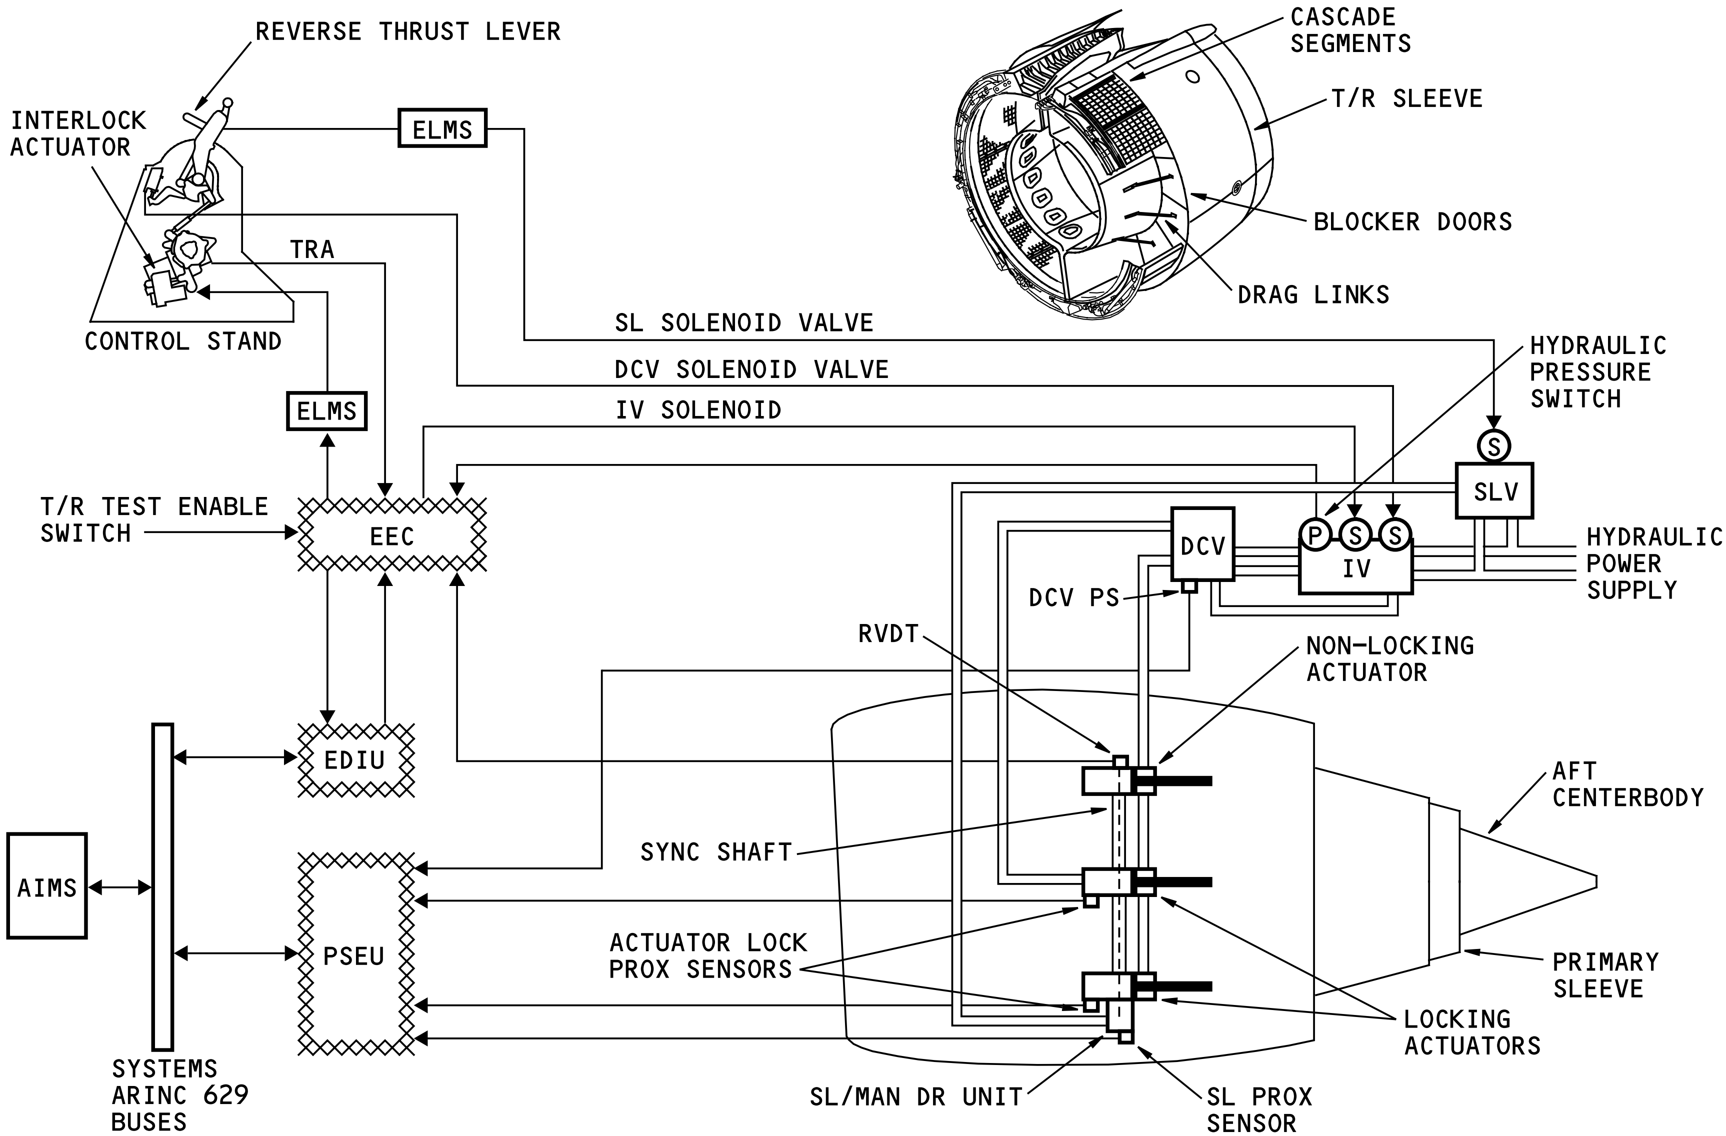
The proximity sensor electronics unit (PSEU) receives position signals from proximity sensors for these components:

- Actuator locks
- Sync locks
- DCV.

The EEC receives position signals from these components:

- RVDTs (T/R sleeve positions)
- Hydraulic pressure switch (on IV).

The EEC sends the positions of the components to the AIMS.



ENGINE EXHAUST SYSTEM - GENERAL DESCRIPTION

TURBINE EXHAUST SYSTEM - INTRODUCTION

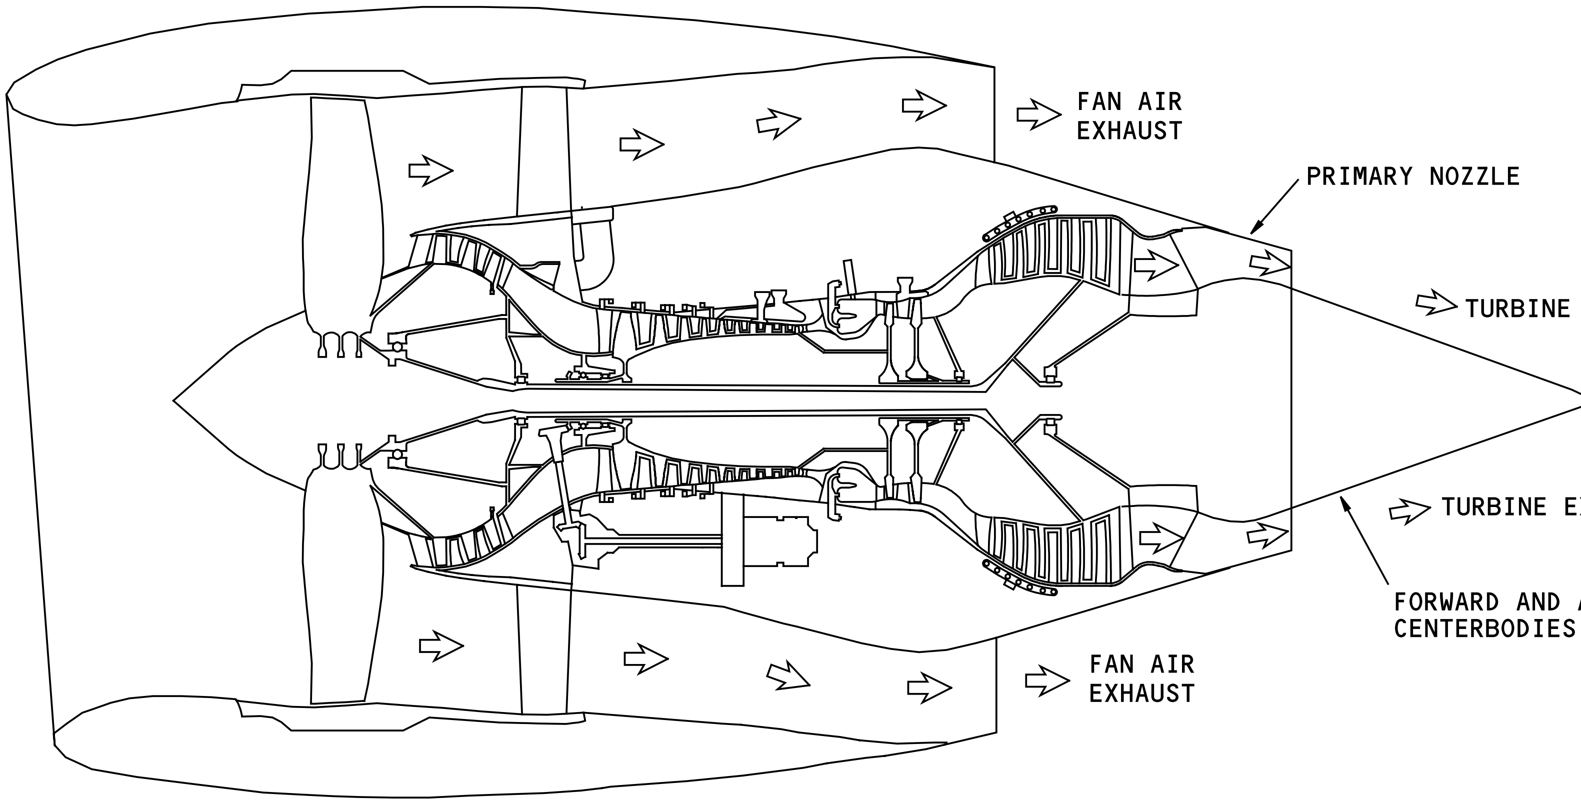
TURBINE EXHAUST SYSTEM - GENERAL DESCRIPTION

General

The turbine exhaust system controls the direction of the turbine exhaust and makes maximum thrust from the exhaust.

Physical Description

The primary nozzle makes the outer contour for the turbine exhaust. The centerbodies make the inner contour for the turbine exhaust.



78-11-00-102 Rev 0

TURBINE EXHAUST SYSTEM - GENERAL DESCRIPTION

TURBINE EXHAUST SYSTEM - COMPONENTS

General

These are the turbine exhaust system components:

- Primary nozzle
- Forward centerbody.
- Aft centerbody
- Vent tube extension (not shown).

Primary Nozzle

The primary nozzle makes the outer contour for the turbine exhaust.

The primary nozzle is aft of the thrust reverser. It attaches to the turbine rear frame with 56 bolts.

Forward and Aft Centerbodies

The forward and aft centerbodies make the inner contour of the turbine exhaust.

The forward center body is aft of the thrust reverser. It attaches to the turbine rear frame with 28 nuts.

The aft center body attaches to the forward center body with 24 bolts.

Vent Tube Extension

The vent tube extension sends the oil sump vent air overboard.

The vent tube extension attaches to the number 5 bearing sump cover with six bolts.

THRUST REVERSER SYSTEM - INTRODUCTION

78-31-00-101 Rev 0

THRUST REVERSER SYSTEM - GENERAL DESCRIPTION

General

The T/R system controls the direction of the fan exhaust. It makes forward thrust or reverse thrust.

The T/R system has left and right T/R halves that attach to the engine strut. Each T/R half has these parts:

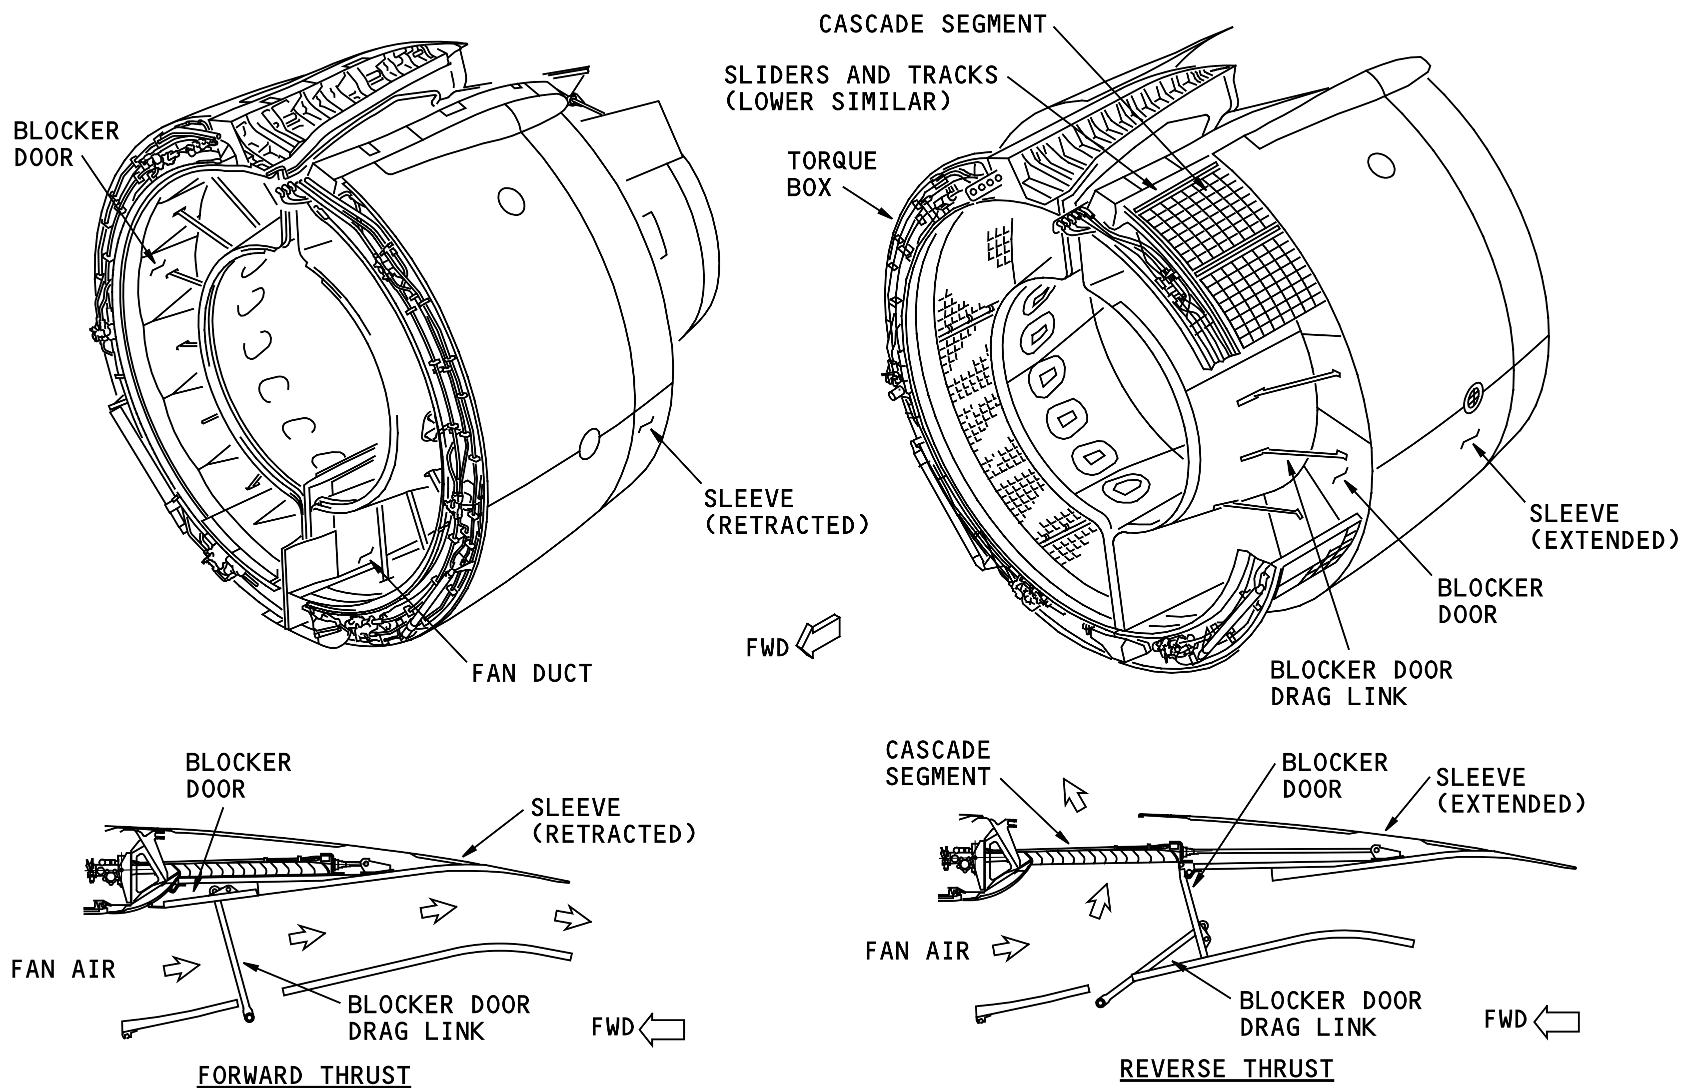
- Torque box
- Sliders and tracks
- Cascade segments
- Sleeve
- Blocker doors
- Blocker door drag links

The sleeve is part of the fan duct. It uses sliders to move forward and aft in the tracks.

Functional Description

When the T/R sleeves are in the forward (retracted) position, the fan air goes through the fan duct and comes out at the rear of the fan duct. This makes forward thrust.

When the T/R sleeves move to the aft (extended) position, the blocker door drag links move the blocker doors into the fan duct. This makes the fan air flow through the cascade segments. The segments turn the fan air and cause it to come out the sides of the T/R in a forward direction. This makes reverse thrust.



THRUST REVERSER SYSTEM - GENERAL DESCRIPTION

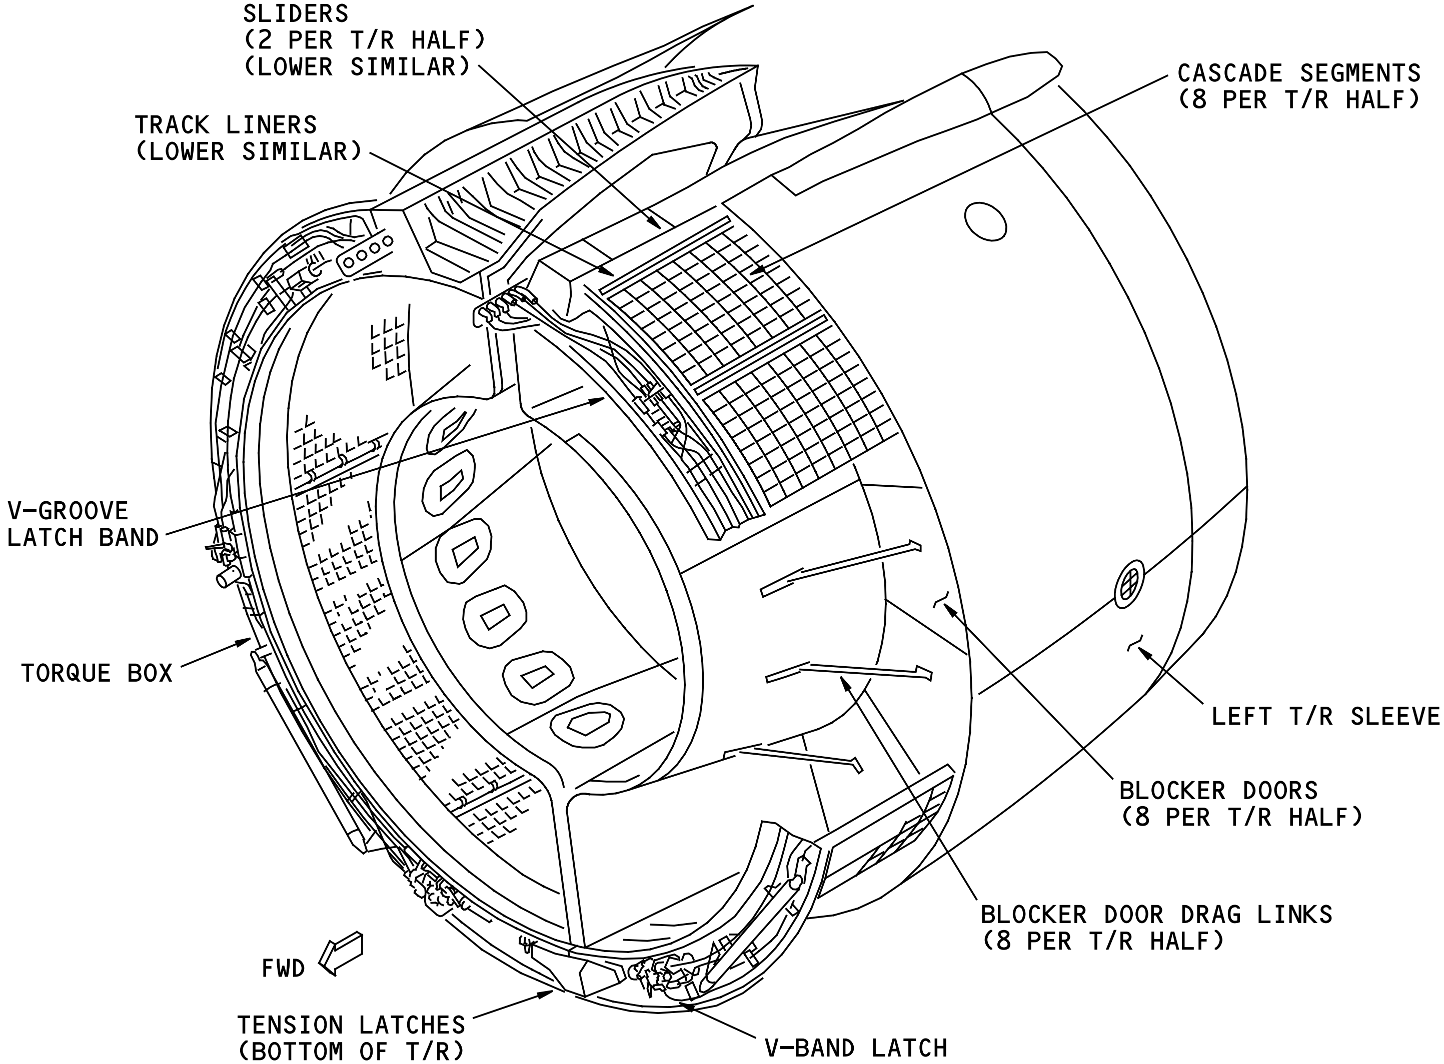
78-31-00-102 Rev 0

THRUST REVERSER SYSTEM - COMPONENT LOCATIONS

General

The T/R system has two T/R halves on each engine. The T/R system has the these components:

- Cascade segments
- Sleeve
- Blocker doors
- Blocker door drag links
- V-band latch
- Tension latches
- Torque box
- V-groove latch band
- Track liners
- Sliders.



78-31-00-103 Rev 1 08/28/95

THRUST REVERSER SYSTEM - COMPONENT LOCATIONS

THRUST REVERSER SYSTEM - TENSION LATCHES

General

The thrust reverser (T/R) latches hold the T/R halves together. There are four groups of latches:

- Deflection limiter (4)
- Aft cowl (3)
- T/R latch (5)
- V-groove latch band.

You open the latches from aft to forward. You close the latches from forward to aft.

Deflection Limiter Latches

There are four deflection limiter latches. These latches attach to two straps that go around the aft part of the T/R. You open the deflection limiter latches first.

CAUTION: FAILURE TO OPEN THE DEFLECTION LIMITER LATCHES BEFORE YOU OPEN THE THRUST REVERSER CAN CAUSE DAMAGE TO THE THRUST REVERSER.

Aft Cowl Latches

There are three aft cowl latches. These latches hold the aft part of the T/R together. You open the aft cowl latches after you open the deflection limiter latches.

T/R Latches

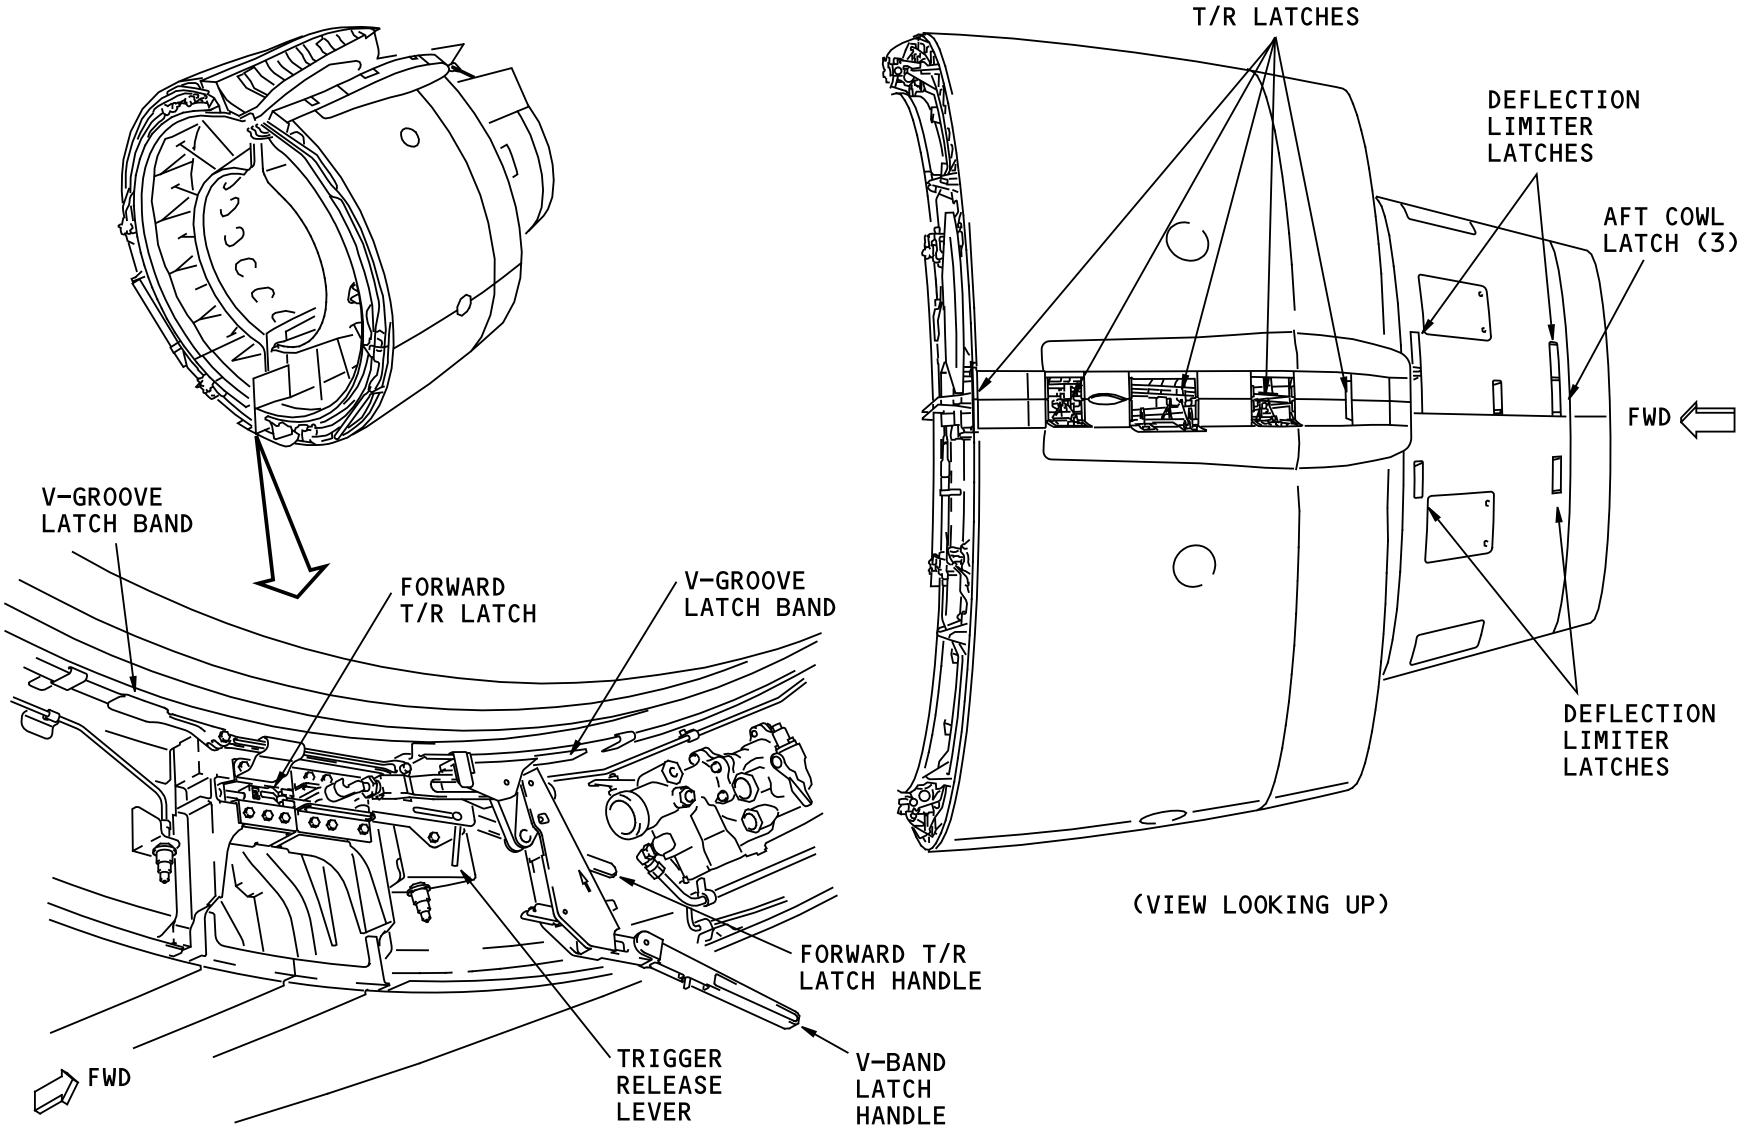
There are five T/R latches. These latches hold the forward part of the T/R together. You must open latch access doors to get access to the three middle T/R latches.

The forward latch is next to the V-band latch handle on the torque box. There is a trigger release lever on the forward latch. You move the trigger release lever to the left before you open the forward latch.

You open the T/R latches after you open the aft cowl latches.

V-groove Latch Band

The v-groove latch band supplies tension around the forward part of the T/R. This tension holds the T/R to the fan case. The v-band latch has a handle that loosens the v-groove latch band. You open the v-band latch last.



THRUST REVERSER SYSTEM - TENSION LATCHES

THRUST REVERSER SYSTEM - V-GROOVE LATCH BANDS

Purpose

The V-groove latch bands supply the tension that holds the T/R halves to the fan case. This transmits the reverse thrust loads to the fan case.

Location

The V-groove latch bands are on the forward part of the T/R halves. They are installed from the top of the T/R to the bottom of the T/R.

Physical Description

The V-groove latch bands attach to the top of the T/R with a bolt. The latch bands come together at the bottom of the T/R.

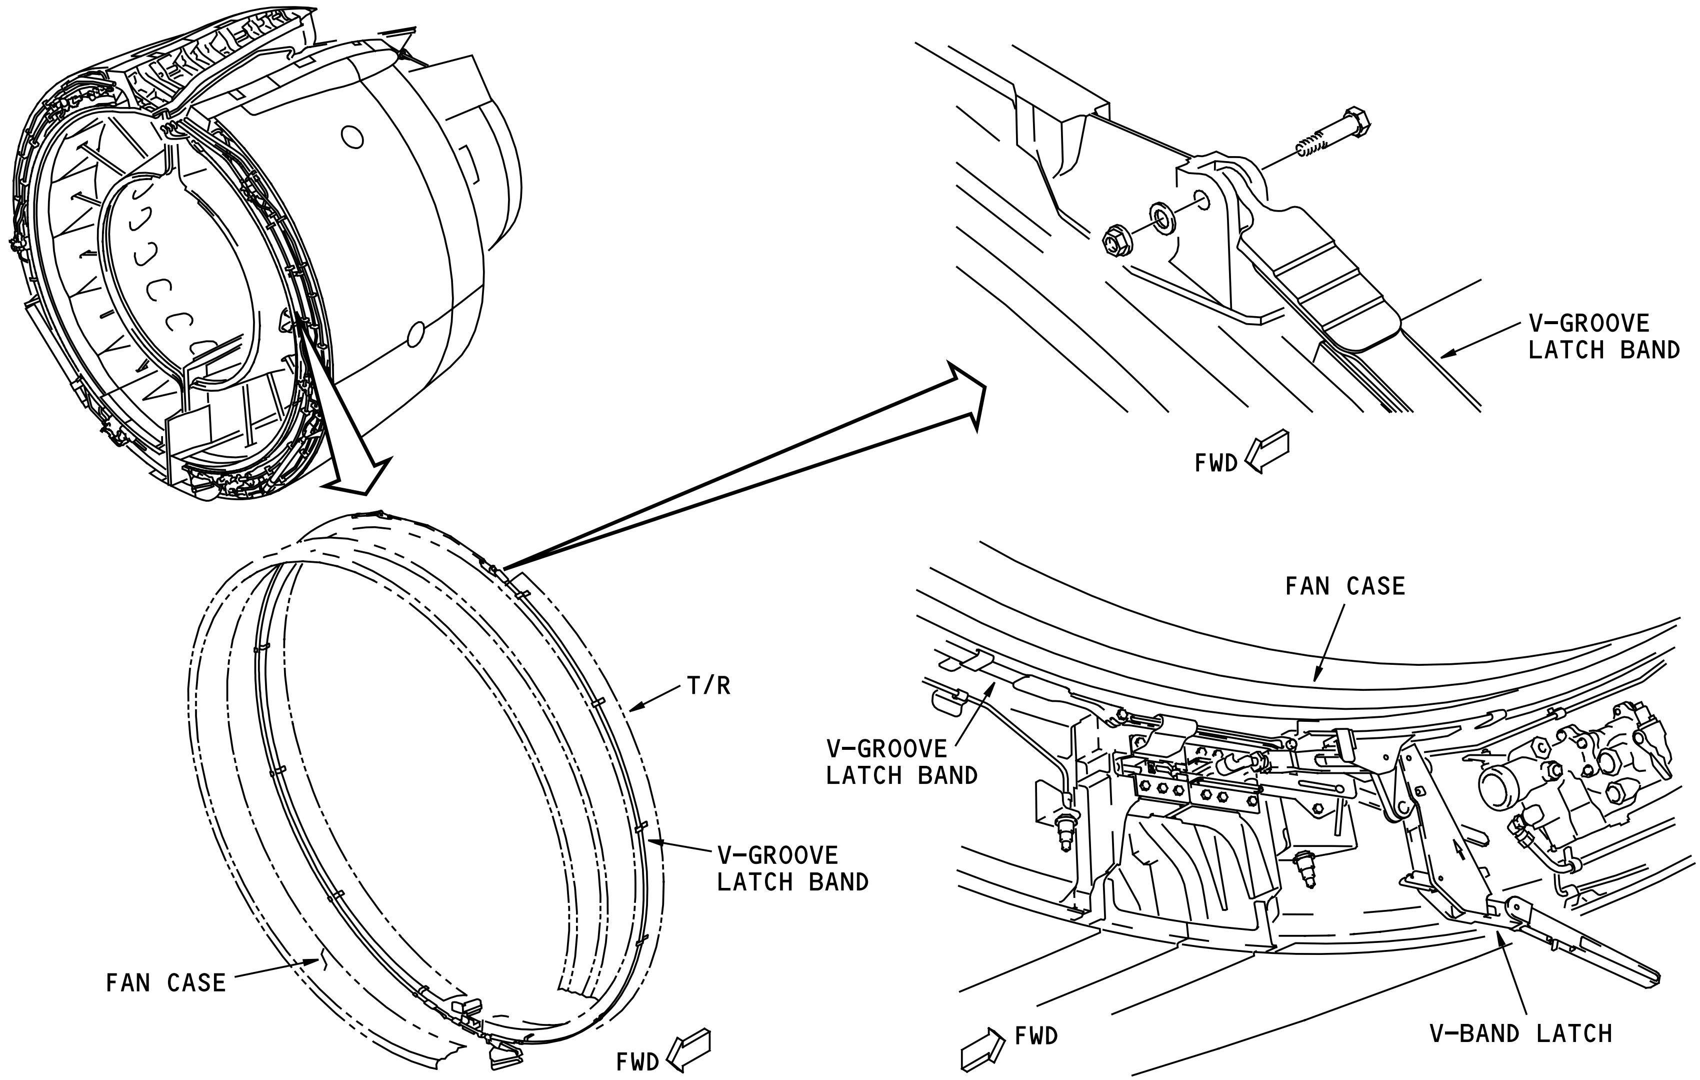
Functional Description

You use the V-band latch to connect the V-groove latch bands together. This puts the tension on the T/R halves.

Training Information Point

Chapter 71 tells you how to operate the latch assembly.

WARNING: DO THE DEACTIVATION PROCEDURE FOR THE THRUST REVERSER TO PREVENT THE OPERATION OF THE THRUST REVERSER. THE ACCIDENTAL OPERATION OF THE THRUST REVERSER CAN CAUSE INJURIES TO PERSONS OR DAMAGE TO EQUIPMENT.



V-GROOVE LATCH BANDS

78-31-00-105 Rev 1

THRUST REVERSER SYSTEM - V-GROOVE LATCH BANDS

THRUST REVERSER SYSTEM - T/R SLEEVE

Purpose

The T/R sleeve makes two different routings for the fan air:

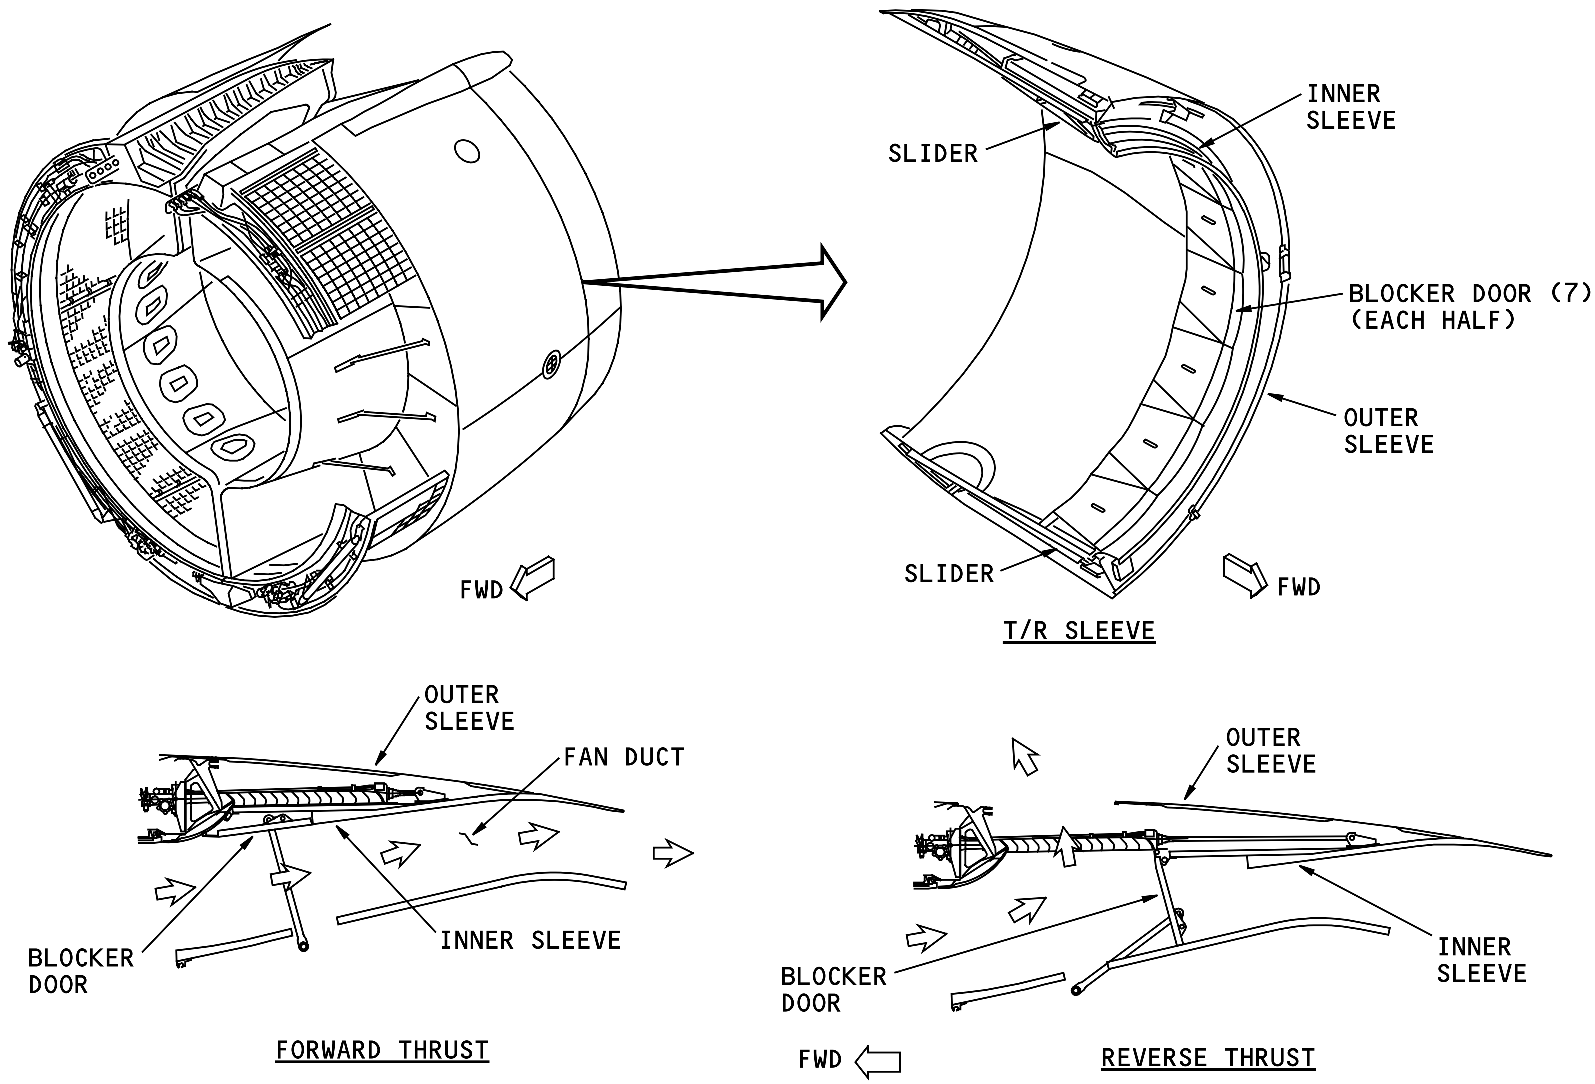
- Forward
- Reverse.

Location

The T/R sleeve is aft of the fan cowl. Sliders and tracks attach the sleeve to the structure.

Physical Description

The T/R sleeve is a composite assembly with an outer sleeve and an inner sleeve. The outer sleeve makes the exterior contour of the T/R. The inner sleeve makes the outer wall of the fan duct. Also, the inner sleeve holds the T/R blocker doors. The inner and outer sleeves come together at the aft end.



78-31-00-106 Rev 0

THRUST REVERSER SYSTEM - T/R SLEEVE

THRUST REVERSER SYSTEM - T/R SLIDERS

Purpose

The T/R sliders permit the sleeves to move forward and aft in the tracks.

location

The main and auxiliary sliders are on the top and the bottom of each sleeve.

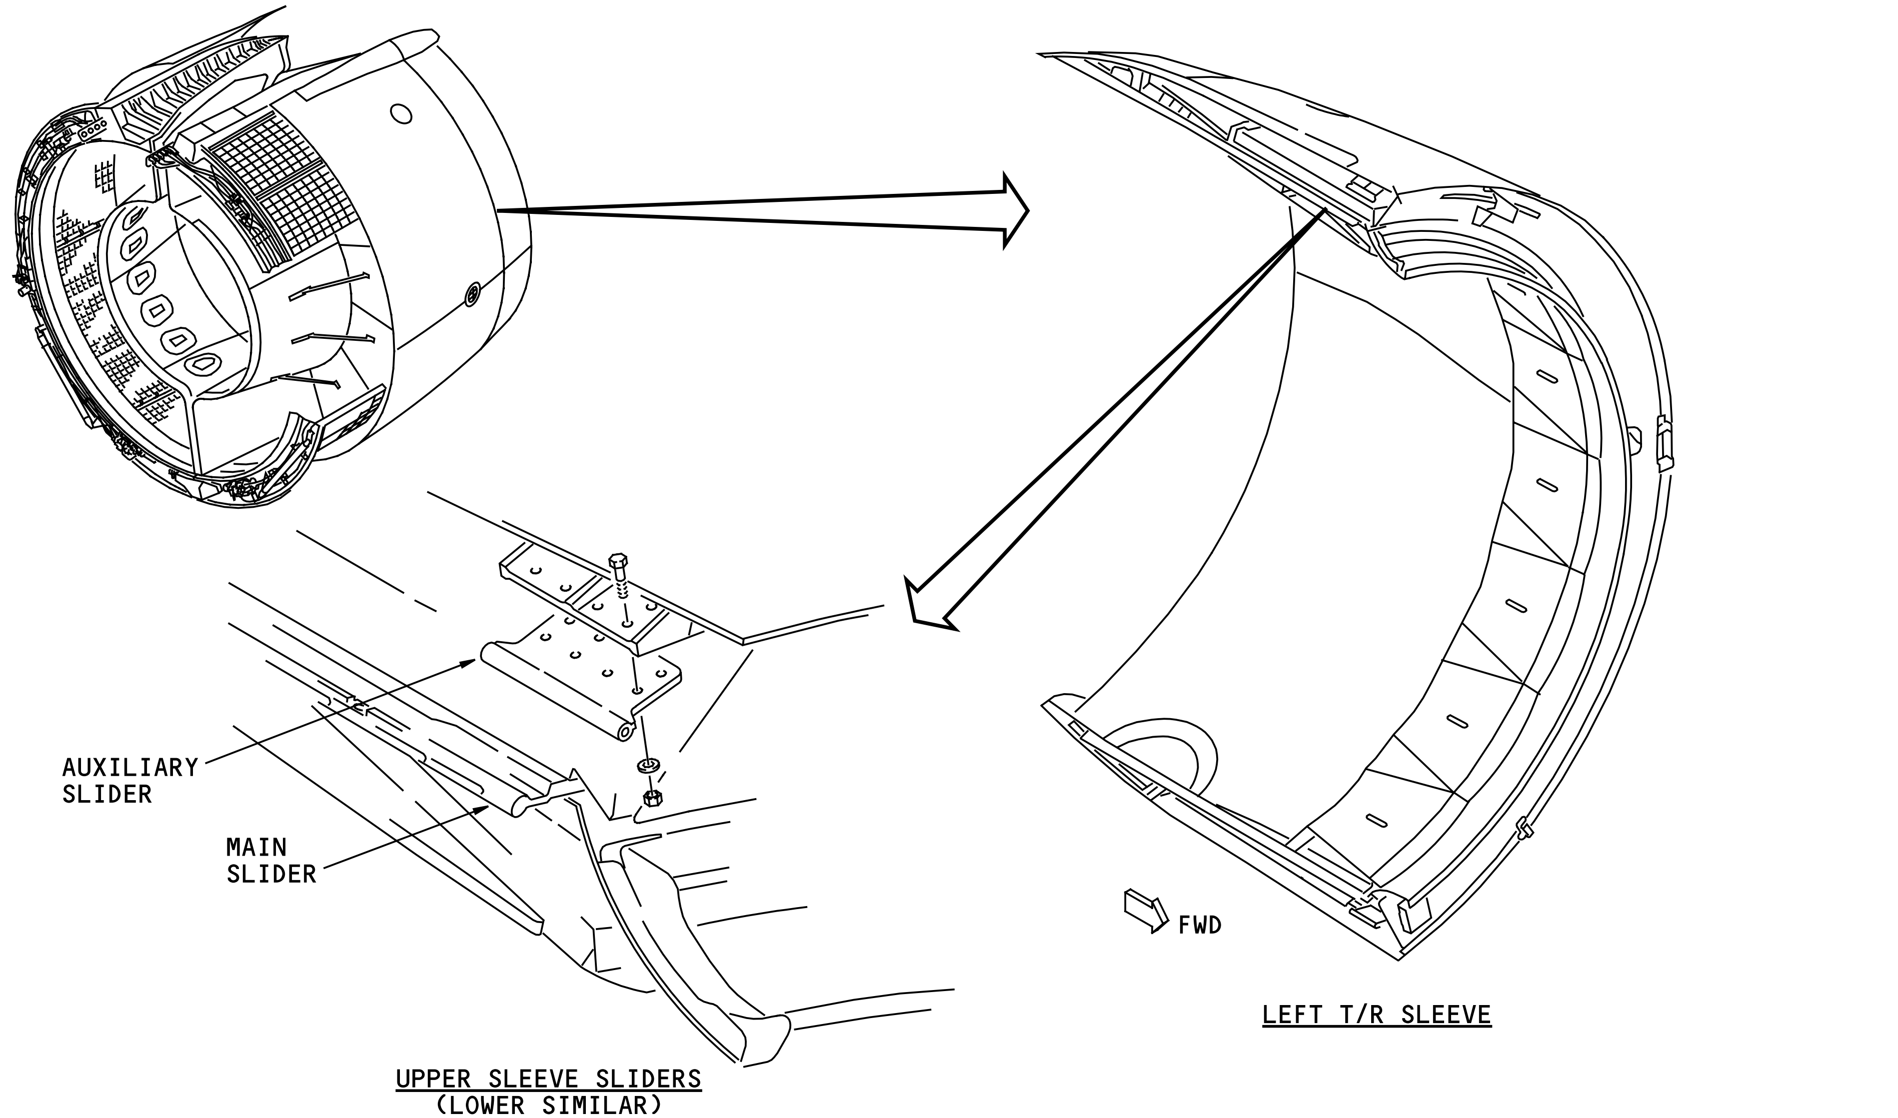
Physical Description

The sliders have a wear surface that reduces the friction between the sliders and the track liners.

Training Information Point

You must remove the sleeve to do a complete inspection of the sliders. You must also remove the sleeve to replace the sliders or the wear surfaces.

WARNING: DO THE DEACTIVATION PROCEDURE FOR THE THRUST REVERSER TO PREVENT THE OPERATION OF THE THRUST REVERSER. THE ACCIDENTAL OPERATION OF THE THRUST REVERSER CAN CAUSE INJURIES TO PERSONS OR DAMAGE TO EQUIPMENT.



78-31-00-107 Rev 0

THRUST REVERSER SYSTEM - T/R SLIDERS

THRUST REVERSER SYSTEM - T/R TRACKS AND TRACK LINERS

Purpose

The T/R tracks and track liners hold the sliders and permit the sleeve to move forward and aft.

Location

The main and auxiliary tracks are on the upper and lower hinge beams of each T/R half.

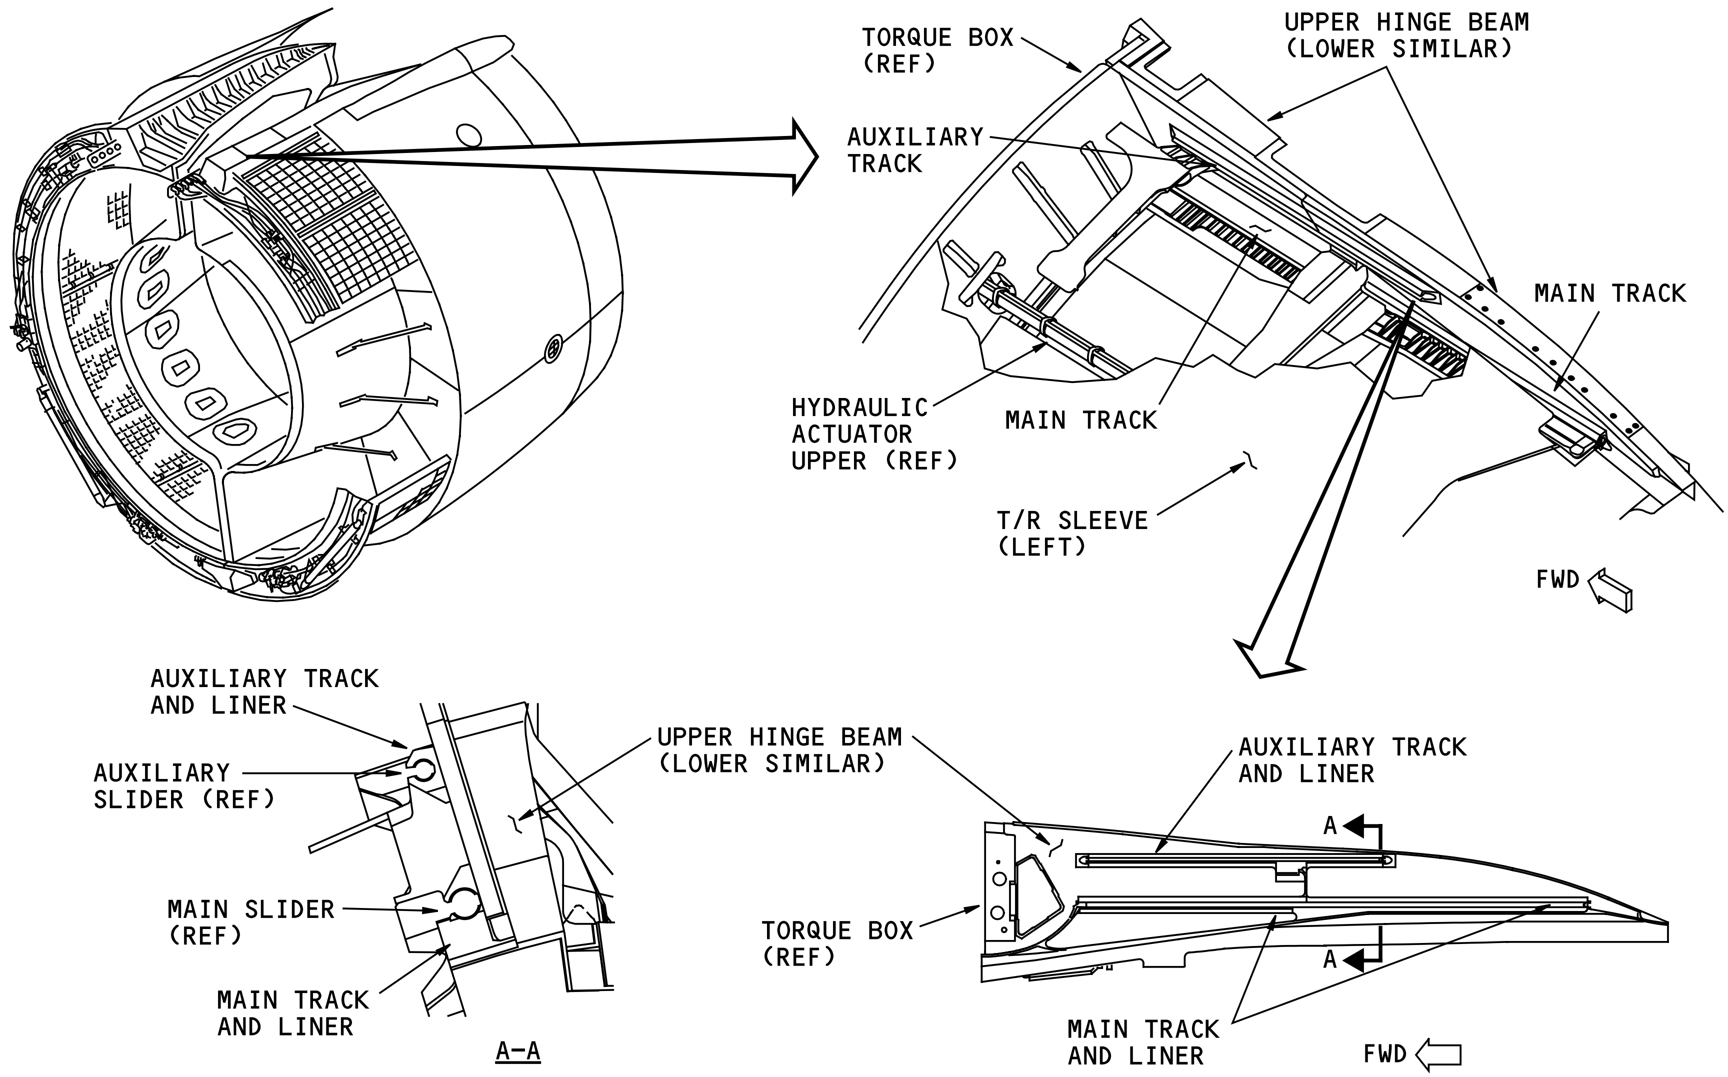
Physical Description

Each track has a track liner that holds the slider. The track liners are steel and protect the aluminum tracks.

Training Information Point

You must remove the sleeve to do a complete inspection of the track liners. You must also remove the sleeve to replace the track liners.

WARNING: DO THE DEACTIVATION PROCEDURE FOR THE THRUST REVERSER TO PREVENT THE OPERATION OF THE THRUST REVERSER. THE ACCIDENTAL OPERATION OF THE THRUST REVERSER CAN CAUSE INJURIES TO PERSONS OR DAMAGE TO EQUIPMENT.



78-31-00-108 Rev 0

THRUST REVERSER SYSTEM - T/R TRACKS AND TRACK LINERS

THRUST REVERSER SYSTEM - T/R BLOCKER DOORS AND BLOCKER DOOR DRAG LINKS

Purpose

The T/R blocker doors and the blocker door drag links make a blockage in the fan duct to change the direction of the fan air.

Location

The blocker doors connect to the forward end of the inner T/R sleeve. The blocker door drag links connect the blocker doors to the fan duct inner wall.

Physical Description

Each sleeve has eight epoxy-graphite blocker doors.

Functional Description

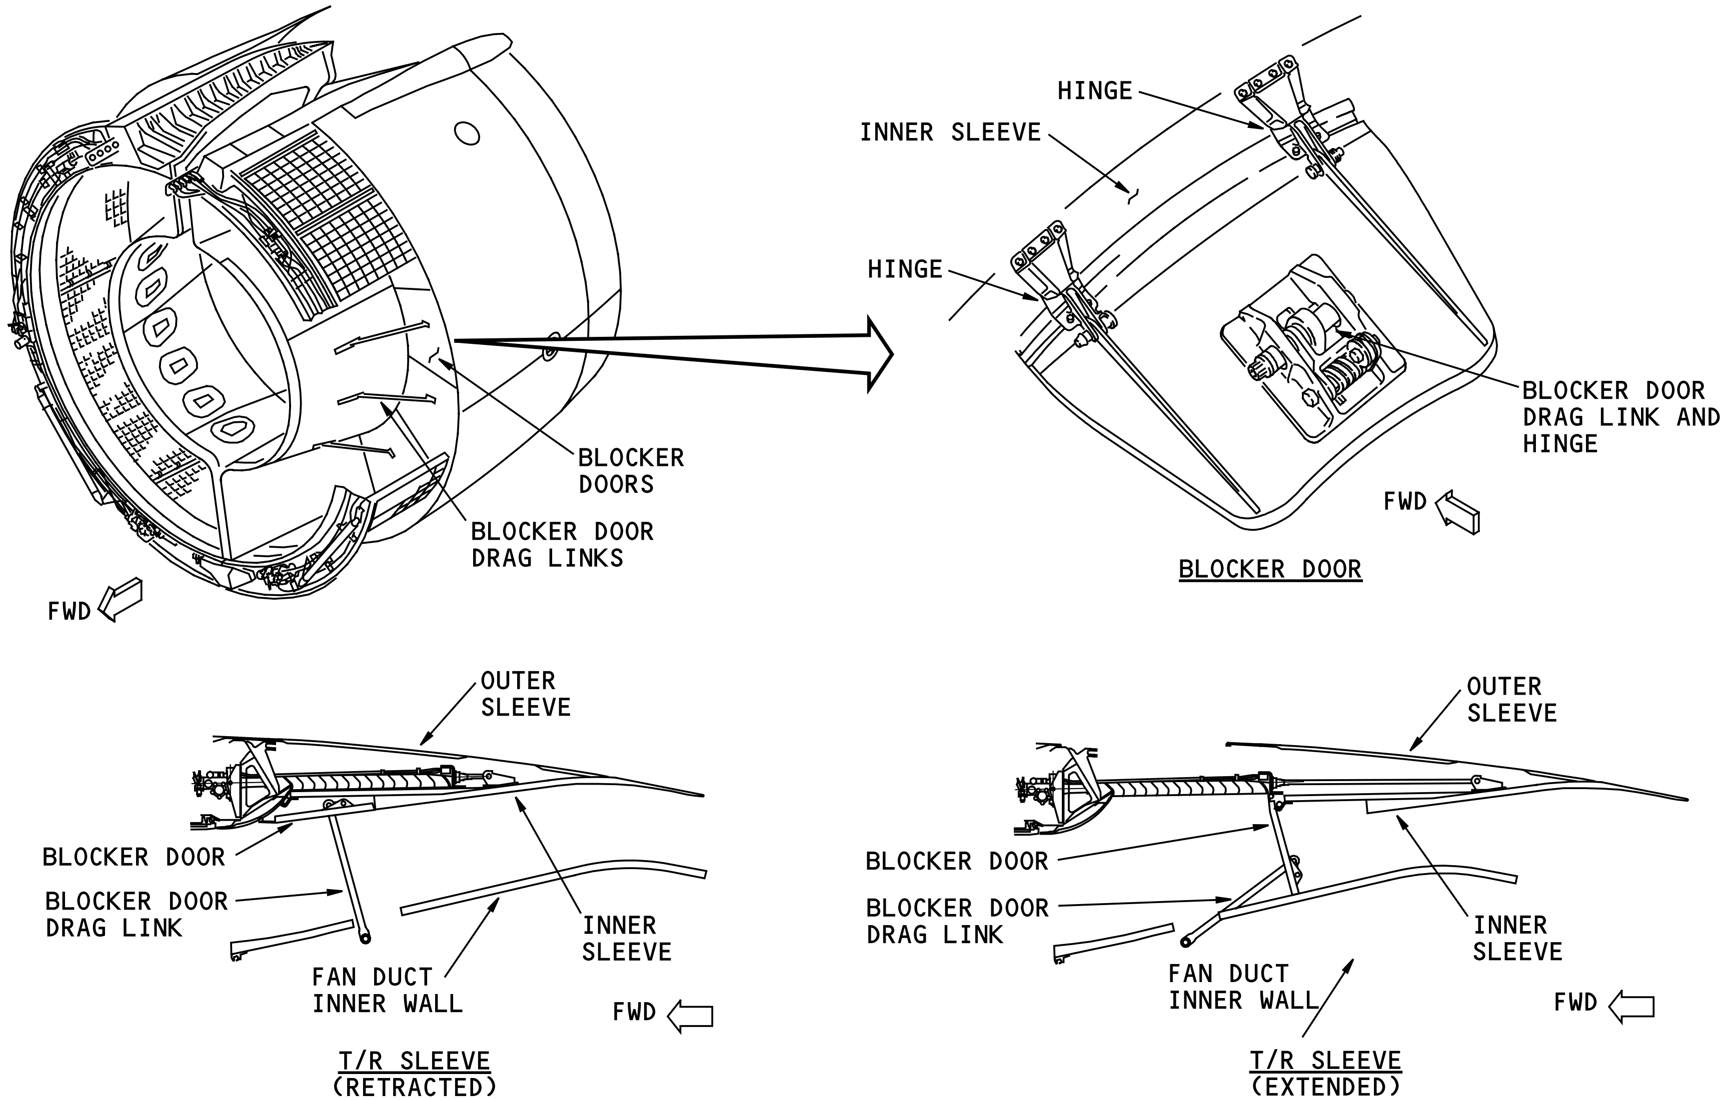
When the sleeve is in the forward (retracted) position, the blocker doors make part of the fan duct outer wall.

When the sleeve is in the aft (extended) position, the blocker door drag links move the blocker doors into the fan duct.

Training Information Point

You must extend the sleeve to inspect, remove, or install the blocker doors and blocker door drag links. Also, you must open the T/R to inspect, remove, or install the blocker door drag links at the fan duct inner wall.

WARNING: DO THE DEACTIVATION PROCEDURE FOR THE THRUST REVERSER TO PREVENT THE OPERATION OF THE THRUST REVERSER. THE ACCIDENTAL OPERATION OF THE THRUST REVERSER CAN CAUSE INJURIES TO PERSONS OR DAMAGE TO EQUIPMENT.



78-31-00-109 Rev 1

THRUST REVERSER SYSTEM - T/R BLOCKER DOORS AND BLOCKER DOOR DRAG LINKS

THRUST REVERSER SYSTEM - T/R CASCADE SEGMENTS

Purpose

The cascade segments control the direction of the fan air when the sleeves are in the aft (extended) position and the blocker doors are in the fan duct. The cascade segments also give structural strength to the T/R.

Location

The cascade segments attach to the torque box and the cascade segment attach ring.

The T/R on each engine has 16 cascade segments. The T/R system uses the numbers 1 through 16 to identify the cascade segment locations on the engine.

Physical Description

The T/R cascade segments are graphite-epoxy assemblies.

There are ten different types of cascade segments. Each type causes the fan airflow to go out in a different direction.

Training Information Point

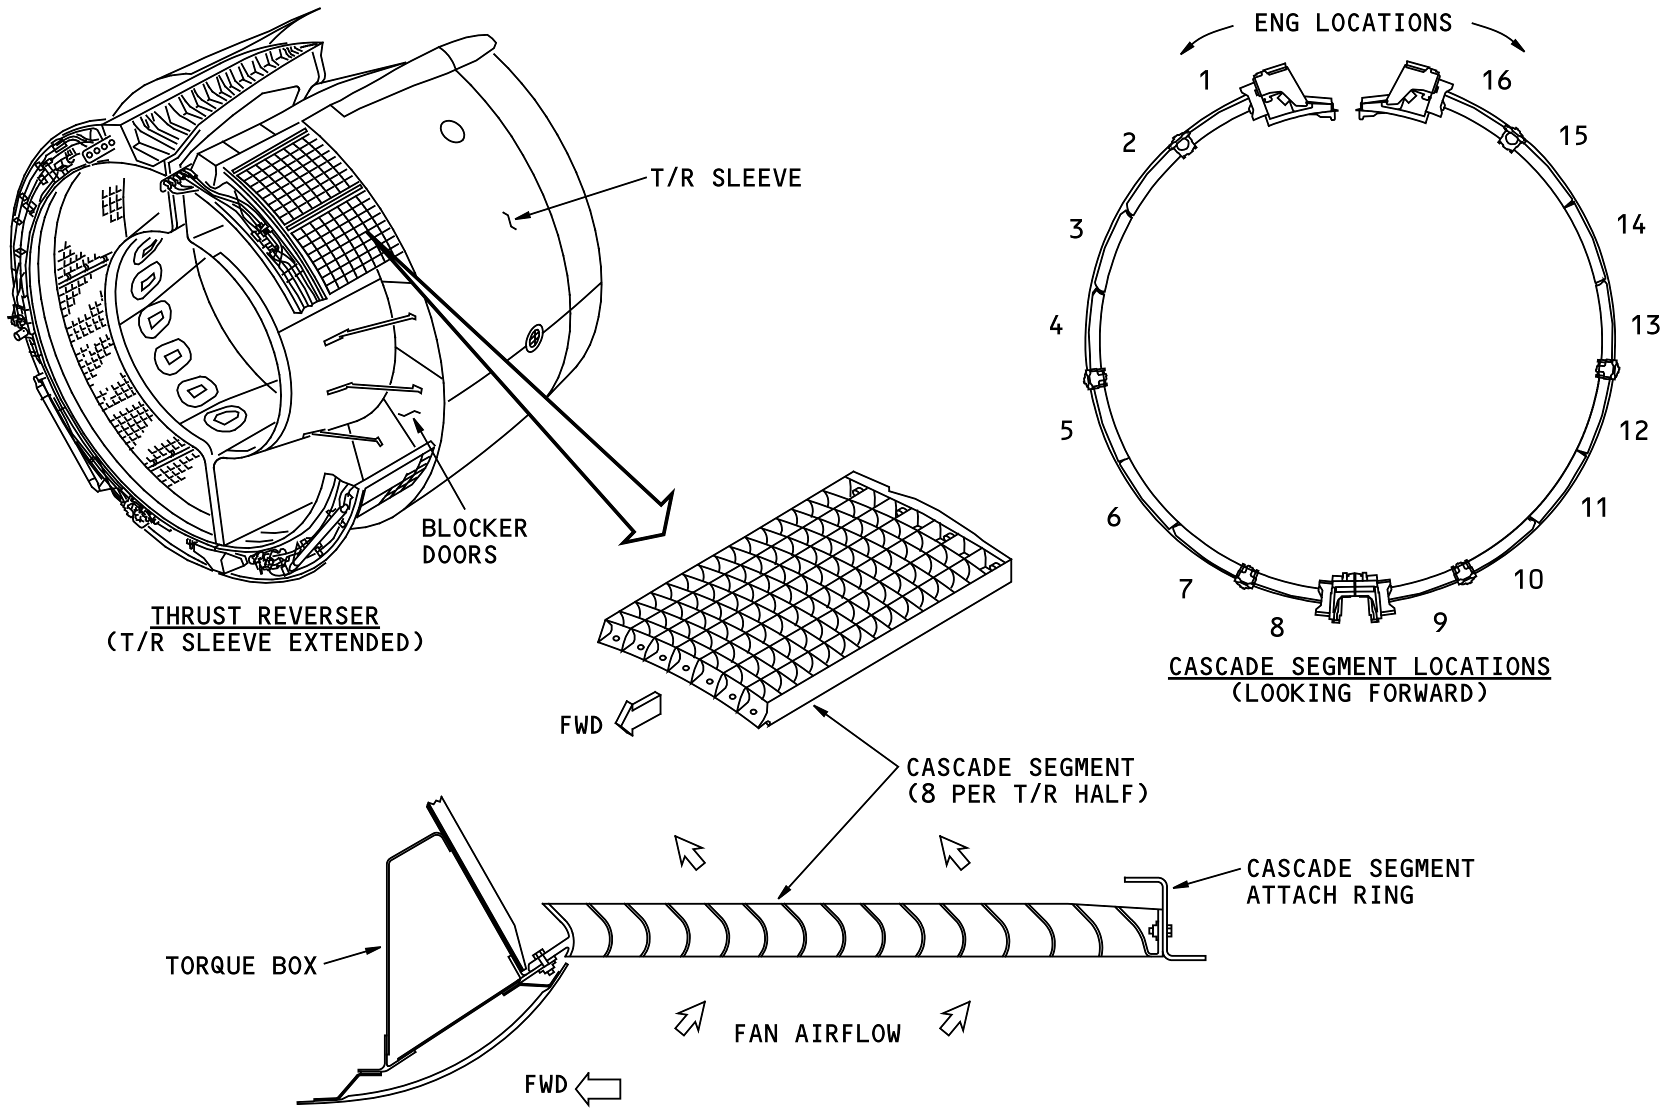
You must extend the T/R sleeve to inspect, remove, or install the T/R cascade segments.

You must install the cascade segment in its correct location.

CAUTION: MAKE SURE YOU CORRECTLY INSTALL THE CASCADE SEGMENTS ON THE THRUST REVERSER. IF YOU DO NOT DO THIS, YOU CAN CAUSE DAMAGE TO THE ENGINE.

WARNING: DO THE DEACTIVATION PROCEDURE FOR THE THRUST REVERSER TO PREVENT THE OPERATION OF THE THRUST REVERSER. THE ACCIDENTAL OPERATION OF THE THRUST REVERSER CAN CAUSE INJURIES TO PERSONS OR DAMAGE TO EQUIPMENT.

WARNING: DO NOT LIFT OR MOVE THE THRUST REVERSER WITH LESS THAN THREE CASCADE SEGMENTS INSTALLED. MAKE SURE THERE IS NO MORE THAN TWO OPEN SPACES BETWEEN EACH CASCADE SEGMENT. IF YOU DO NOT HAVE A MINIMUM OF THREE CASCADE SEGMENTS INSTALLED WHEN YOU MOVE THE THRUST REVERSER, YOU CAN CAUSE DAMAGE TO THE THRUST REVERSER.



THRUST REVERSER SYSTEM - T/R CASCADE SEGMENTS

78-34-00-101 Rev 0

THRUST REVERSER ACTUATION SYSTEM (TRAS) - INTRODUCTION

TRAS - GENERAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

TRAS - GENERAL DESCRIPTION

General

The TRAS moves the thrust reverser (T/R) sleeves. It operates on the ground only. The TRAS uses hydraulic pressure for operation and electrical power for control.

The TRAS uses these valves to control hydraulic pressure to the hydraulic actuators:

- Sync lock valve (SLV)
- Directional control valve (DCV)
- Isolation valve.

The hydraulic actuators move the T/R sleeves.

The sync shafts keep the movement of the actuators together. They also permit manual operation of the T/R sleeves for maintenance.

The sync lock/manual drive units lock the sync shafts in the retracted position.

The T/R interlock actuator prevents the maximum reverse thrust command until the T/R sleeves get near the extended position. The EEC uses T/R sleeve position data from the RVDTs to control the interlock actuator.

The T/R test enable switch permits the operation of the TRAS when the engine is not in operation. You use this switch for T/R maintenance.

Extend

To extend the T/R sleeves you put the reverse thrust lever in the reverse thrust interlock position. This causes three control signals to go to the TRAS. These are the effects of the control signals:

- The SLV opens and supplies hydraulic control pressure to release the sync locks.
- The directional control solenoid valve opens and supplies hydraulic control pressure to the DCV. This moves the DCV to permit hydraulic power to go to the extend and retract sides of the actuators.
- The isolation valve opens and supplies hydraulic pressure through the DCV to the actuators.

Hydraulic pressure to the actuators releases the locking actuators and moves the sleeves to the aft (extended) position.

Retract

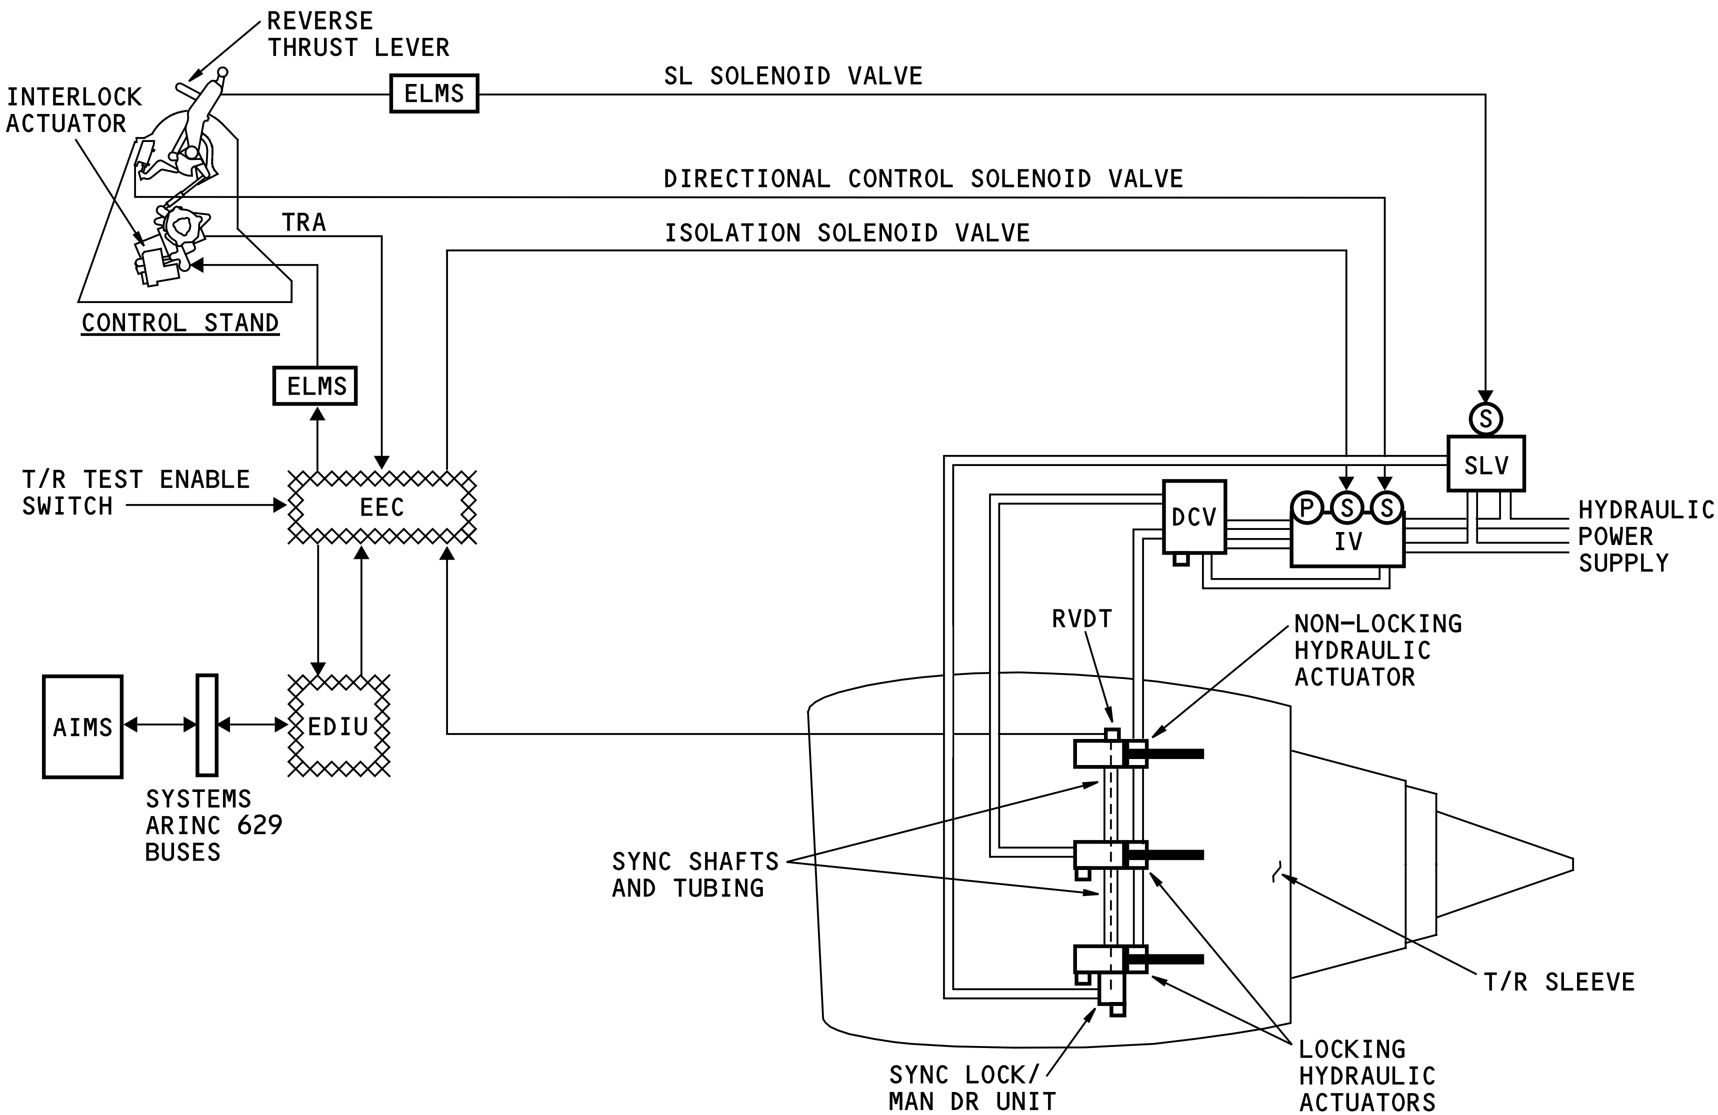
To retract the T/R sleeves you put the reverse thrust levers in the forward thrust position. This causes two control signals to go to the TRAS. These are the effects of the control signals:

- The signal to open the SLV is removed. A time delay circuit in the ELMS keeps the sync lock solenoid valve energized. This keeps the SLV open and the sync lock unlocked. The sync locks stay unlocked until the time delay is complete.

TRAS - GENERAL DESCRIPTION

- The directional control solenoid valve closes and removes the hydraulic control pressure to the DCV. This moves the DCV to permit hydraulic power to go to the retract side of the actuators.
- The EEC begins a time delay before closing the isolation valve. The isolation valve stays open and supplies hydraulic power through the DCV to the actuators. The isolation valve closes when the time delay is complete

Hydraulic power to the retract side of the actuators moves the T/R sleeves to the forward (retracted) position.



TRAS - GENERAL DESCRIPTION

TRAS - ENGINE COMPONENT LOCATIONS

General

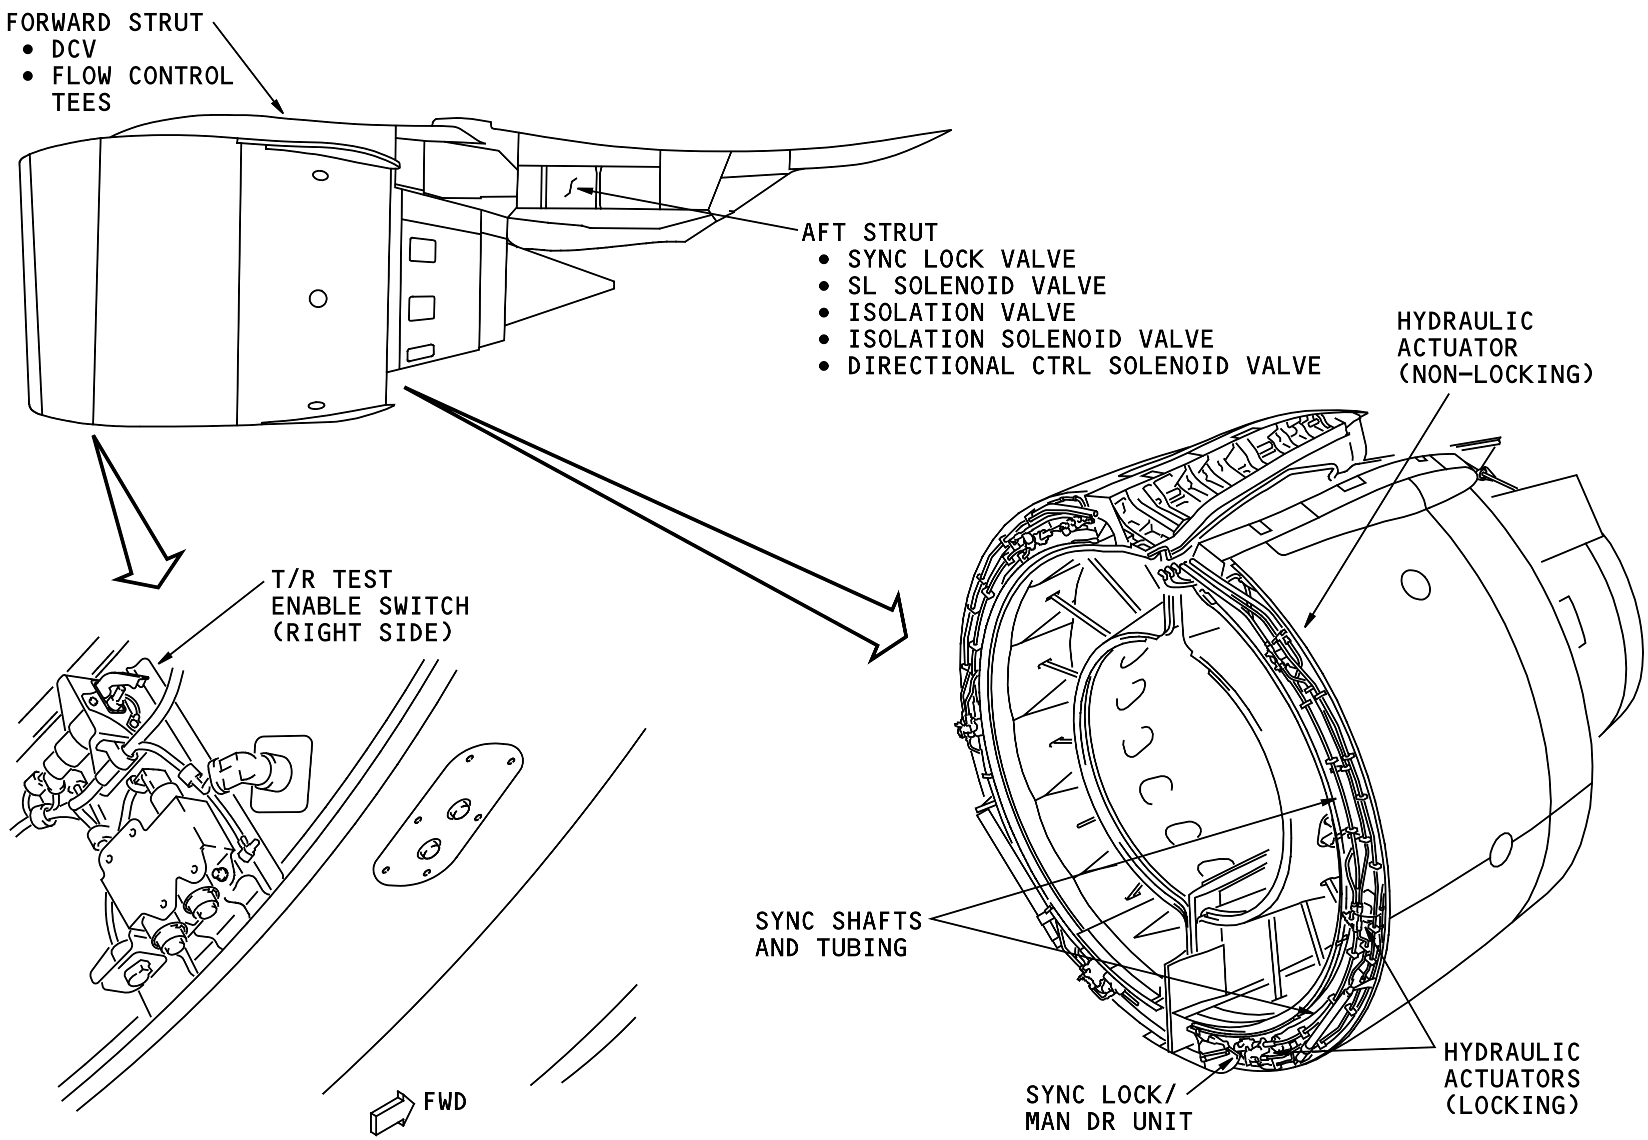
These are the TRAS components on the strut:

- DCV
- Flow control tees
- Sync lock valve
- SL solenoid valve
- Isolation valve
- Isolation solenoid valve
- Directional control solenoid valve.

These are the TRAS components on the thrust reverser (T/R):

- Hydraulic actuator (non-locking)
- Hydraulic actuator (locking)
- Sync lock/manual drive unit
- Sync shafts and tubing.

The T/R test enable switch is on the inlet cowl bulkhead.



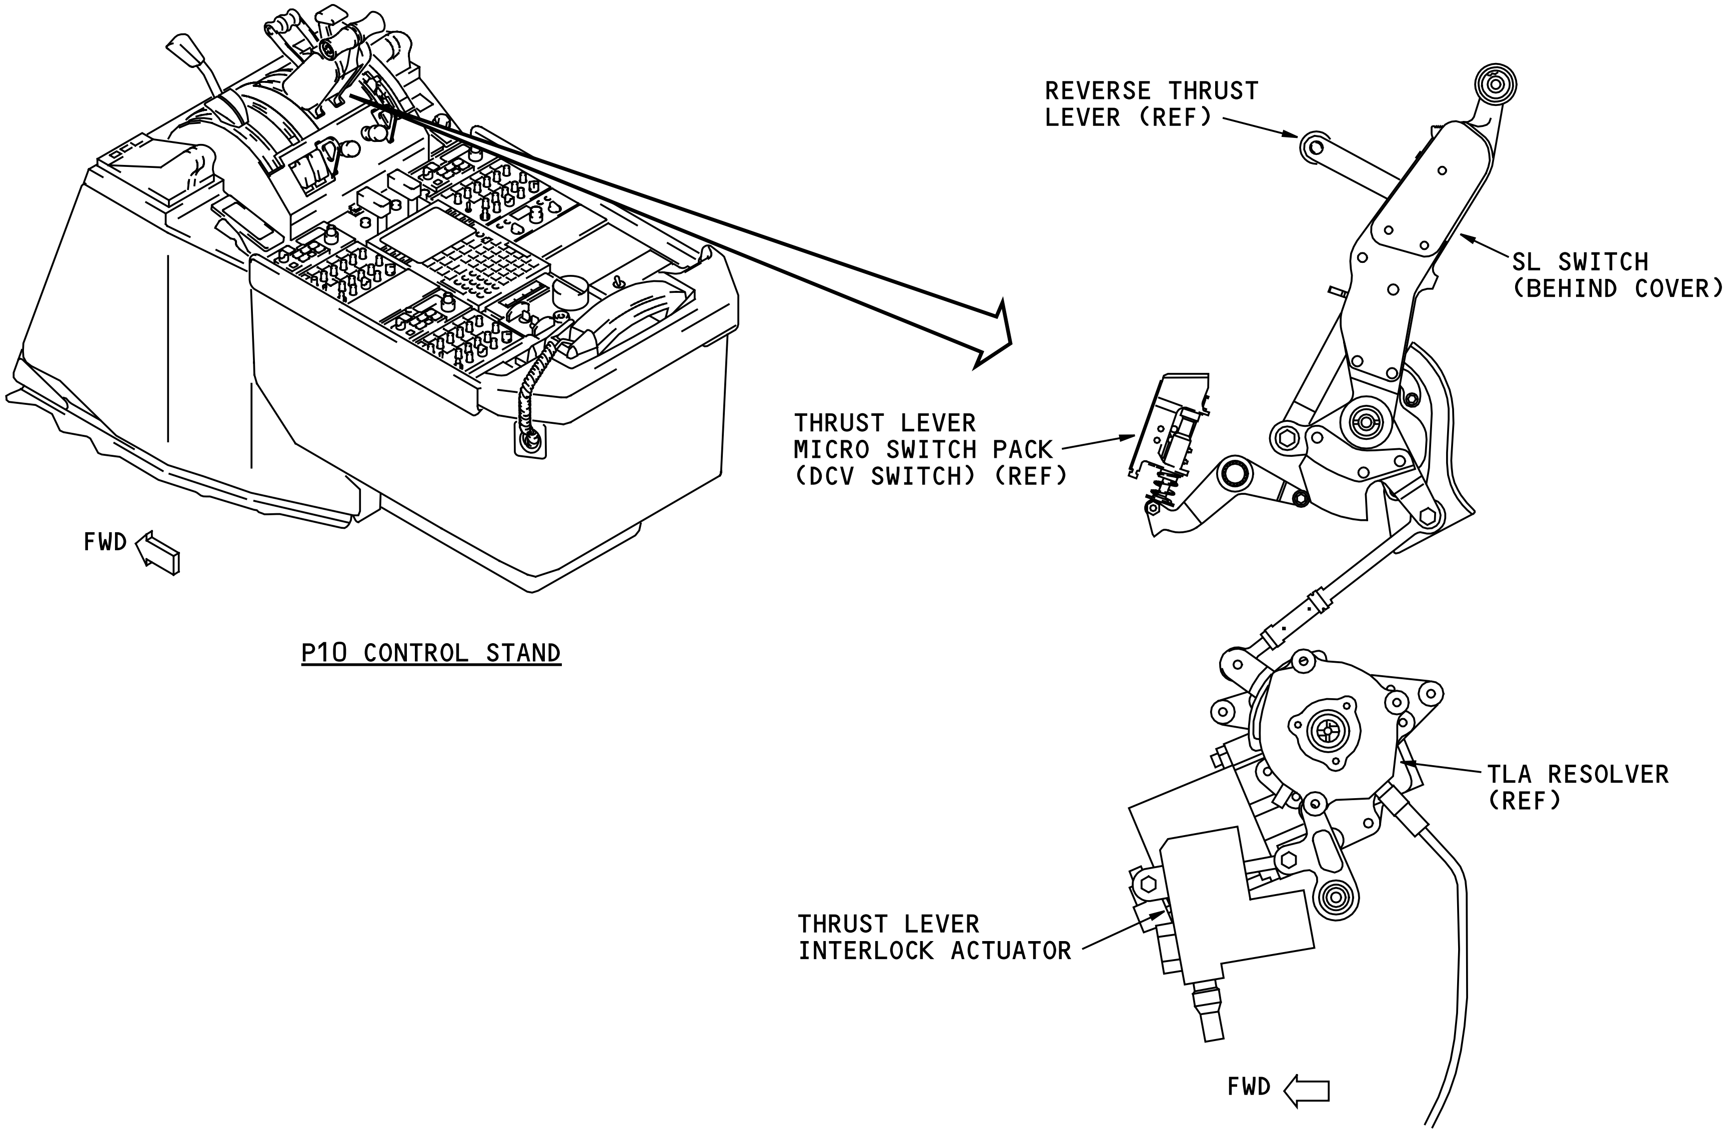
TRAS - ENGINE COMPONENT LOCATIONS

TRAS - FLIGHT DECK COMPONENT LOCATIONS

General

These are the TRAS components in the P10 control stand:

- SL switch
- Thrust lever interlock actuator.



78-34-00-104 Rev 0

TRAS - FLIGHT DECK COMPONENT LOCATIONS

TRAS - SYNC LOCK SWITCH

Purpose

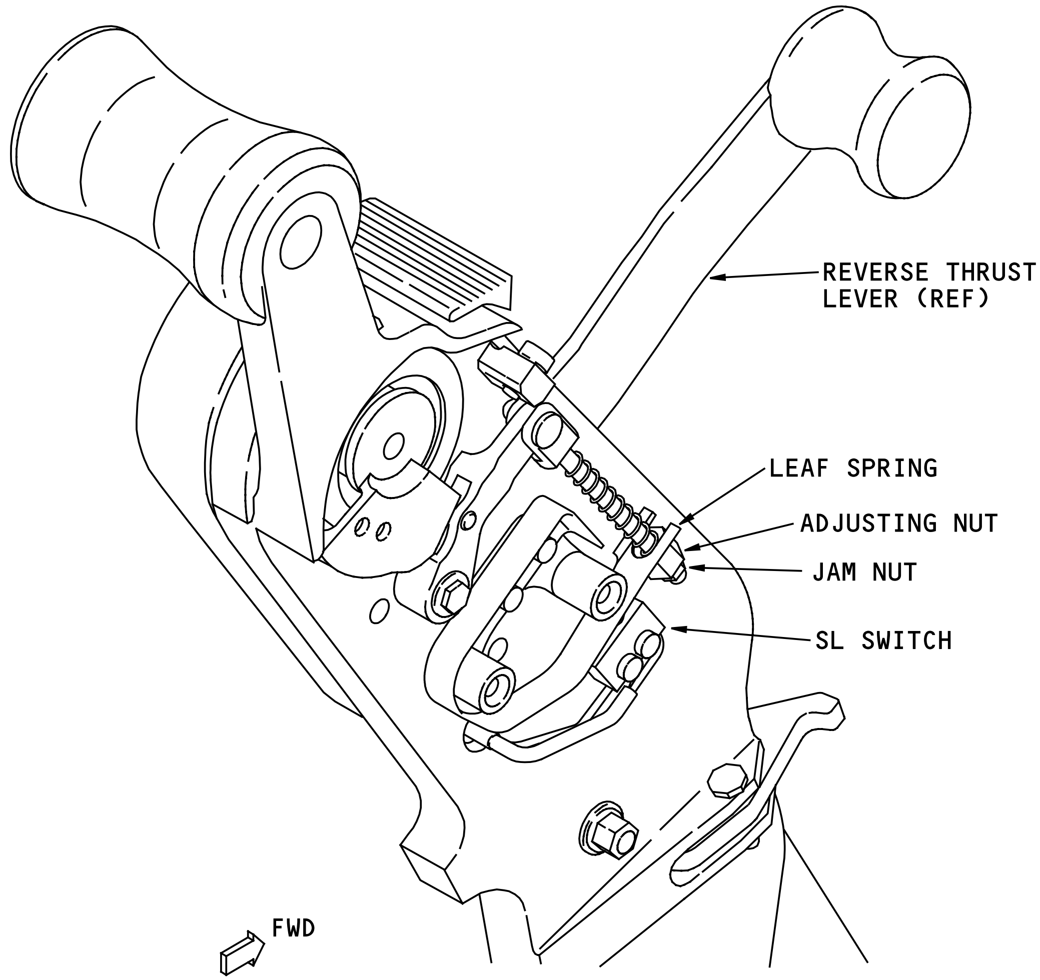
The SL switch sends the signal that causes the SL solenoid valve to energize.

Location

The SL switch is in the thrust lever. You remove the cover on the side of the thrust lever to get access to the switch.

Training Information Point

You use a protractor on the reverse thrust lever to adjust the SL switch. The SL switch is set at a specified reverse thrust lever angle. You turn the adjusting nut to make the leaf spring touch the SL switch at the specified angle.



LEFT THRUST LEVER
(SIDE COVER REMOVED - RIGHT SIMILAR)

TRAS - SYNC LOCK SWITCH

TRAS - SYNC LOCK VALVE

Purpose

The SLV supplies hydraulic control pressure to release the sync lock/manual drive unit.

Location

The SLV is in the aft strut. You must open the left access panel on the aft strut fairing to get access to the SLV.

Physical Description

The SLV has these electrical parts:

- SL solenoid valve
- Electrical connector.

The SLV has these hydraulic connections:

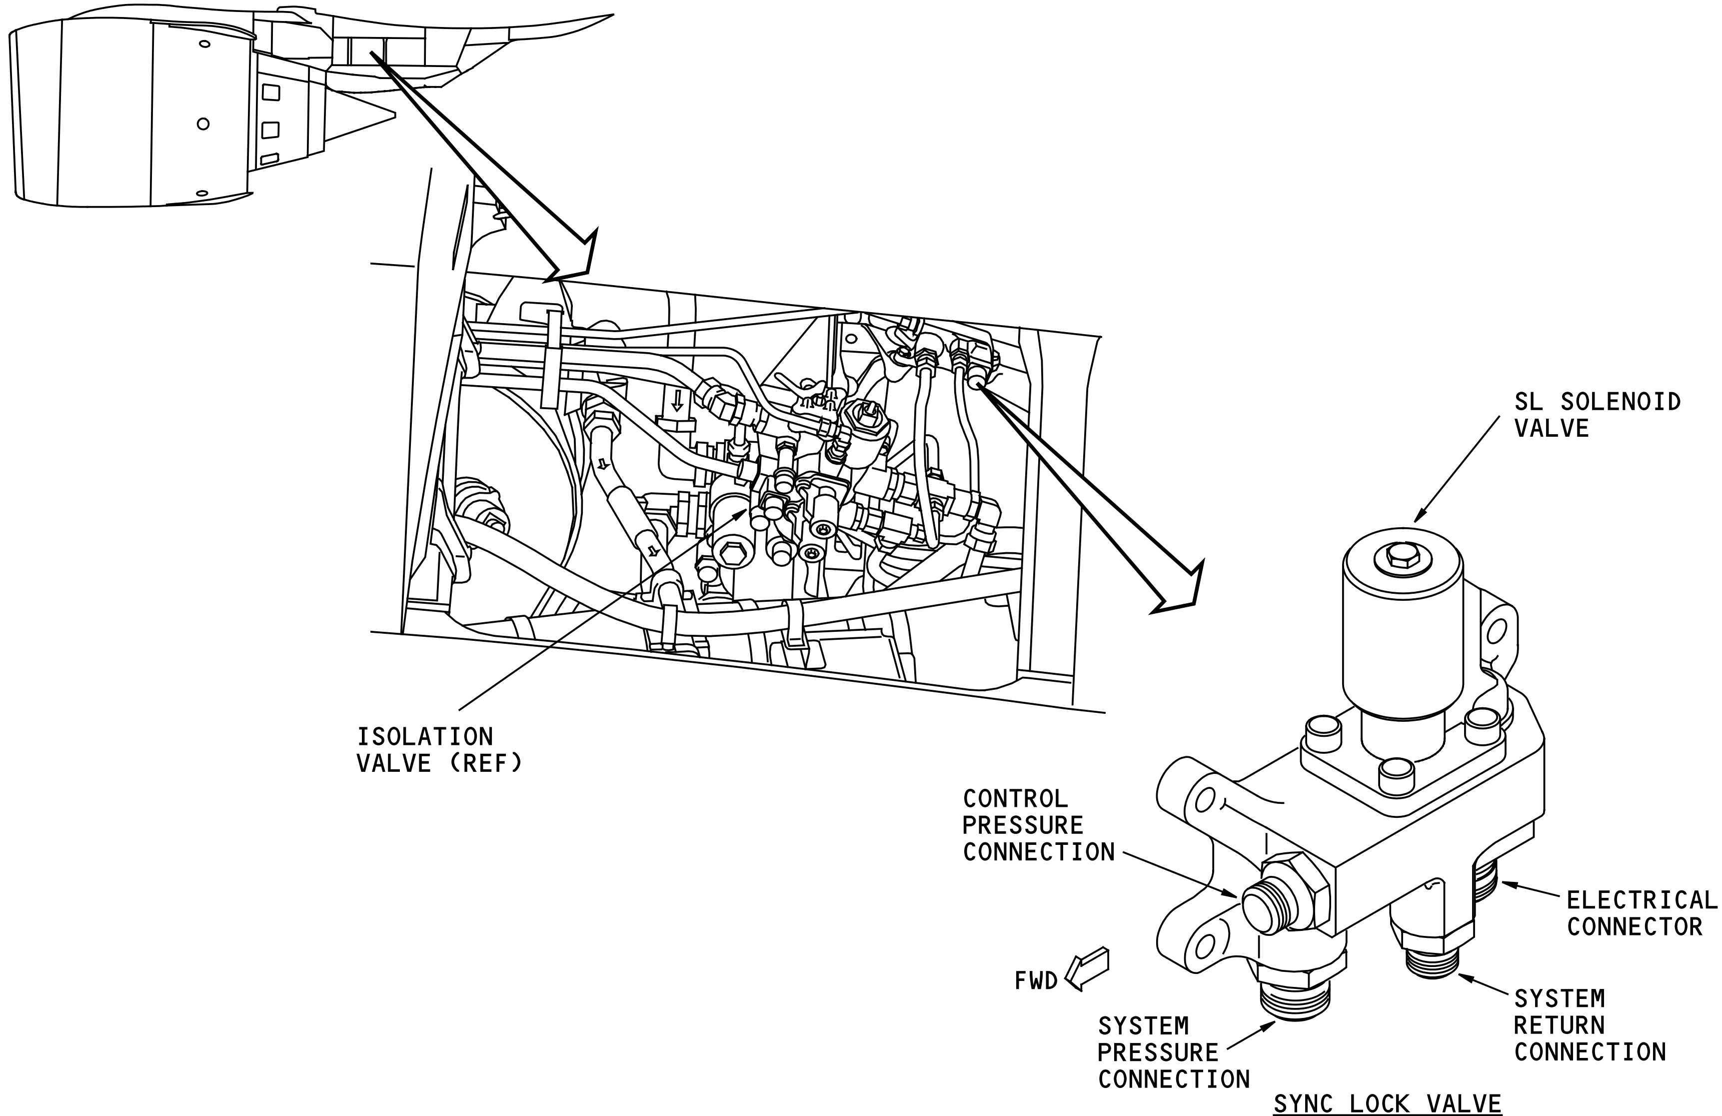
- System return
- System pressure
- Control pressure.

The SLV and the SL solenoid valve are LRUs.

SL Solenoid Valve

The SL solenoid valve attaches to the SLV. It energizes when there is a reverse thrust command. This permits system pressure to go to the control pressure port.

Control pressure from the SLV goes to the sync lock/manual drive unit and releases the lock. When there is no reverse thrust command, control pressure goes to the system return port.



78-34-00-106 Rev 1 12/19/1995

TRAS - SYNC LOCK VALVE

TRAS - SYNC LOCK/MANUAL DRIVE UNIT

Purpose

The sync lock/manual drive unit does these mechanical functions:

- Locks the sync shafts
- Moves the sync shafts during manual operation.

The sync lock/manual manual drive units prevent the movement of the sync shafts when there is no reverse thrust command. This keeps the actuators and sleeves in the forward (retracted) position.

Location

A unit attaches to the lower hydraulic actuator on each T/R half.

Physical Description

These are the parts on the sync lock/manual drive unit:

- Lock pin
- Lock release lever
- Control pressure connection
- Manual drive unit
- Proximity sensor
- Target

Lock Release lever and Lock Pin

You use the lock release lever to manually release the sync lock. The lock pin holds the lever in the not locked position.

Control Pressure Connection

The control pressure connection gets hydraulic control pressure from the SLV. This releases the sync lock when there is a reverse thrust command.

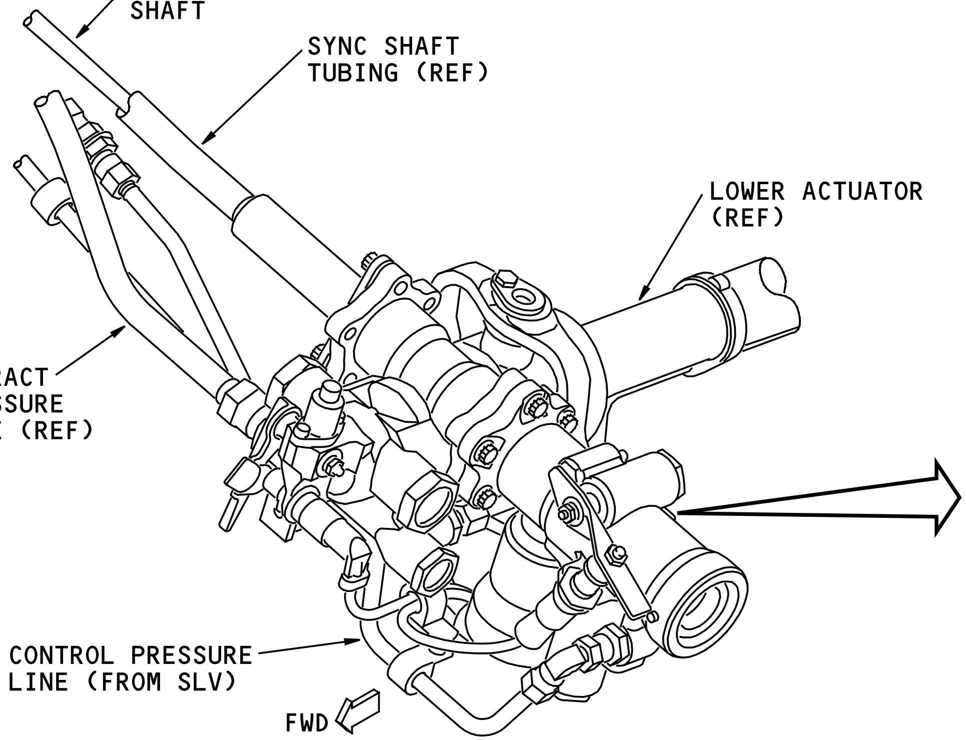
Manual Drive Unit

A 3/8 inch manual drive permits you to manually extend the T/R sleeve for maintenance.

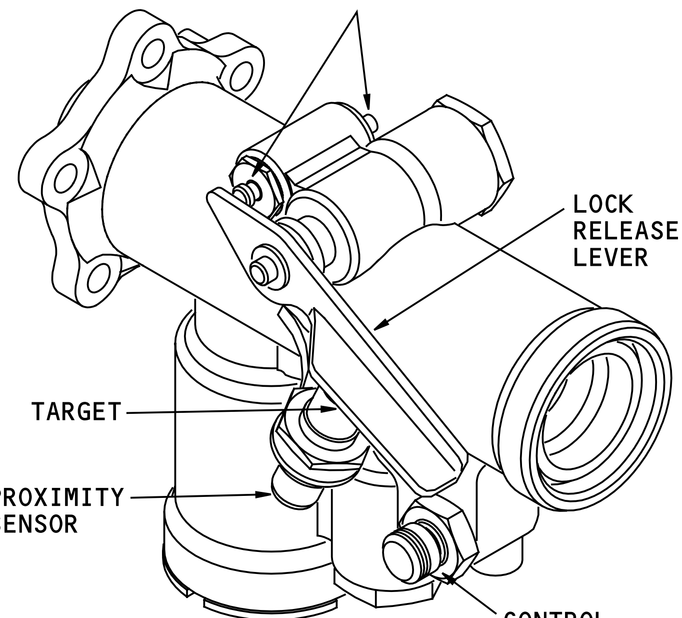
Proximity Sensor and Target

The proximity sensor uses a target on the lock release lever to send sync lock position data to the T/R indicating and fault detection system.

See section 78-36 for more information.



RIGHT T/R HALF INSTALLATION
(LEFT SIMILAR)



SYNC LOCK/MANUAL DRIVE UNIT

78-34-00-107 Rev 2 11/28/95

TRAS - SYNC LOCK/MANUAL DRIVE UNIT

TRAS - ISOLATION VALVE

Purpose

The isolation valve isolates the airplane hydraulic system from the TRAS. It also permits hydraulic power to go to the TRAS to move the T/R sleeves.

Physical Description

The isolation valve has these components:

- Hydraulic pressure switch
- Bypass valve
- Isolation shutoff valve
- Directional control solenoid valve
- Isolation solenoid valve.

The isolation valve has these hydraulic connections:

- Hydraulic system return
- Hydraulic system pressure
- Control pressure
- TRAS pressure
- TRAS return.

Hydraulic Pressure Switch

The hydraulic pressure switch sends the isolation shutoff valve position to the T/R indicating and fault detection system.

Bypass Valve

The bypass valve prevents a hydraulic lock in the TRAS when you manually extend or retract the T/R sleeve.

Isolation Shutoff Valve

The isolation shutoff valve isolates the airplane hydraulic system pressure from the TRAS.

Directional Control Solenoid Valve

The directional control solenoid valve supplies external hydraulic control pressure to operate the DCV.

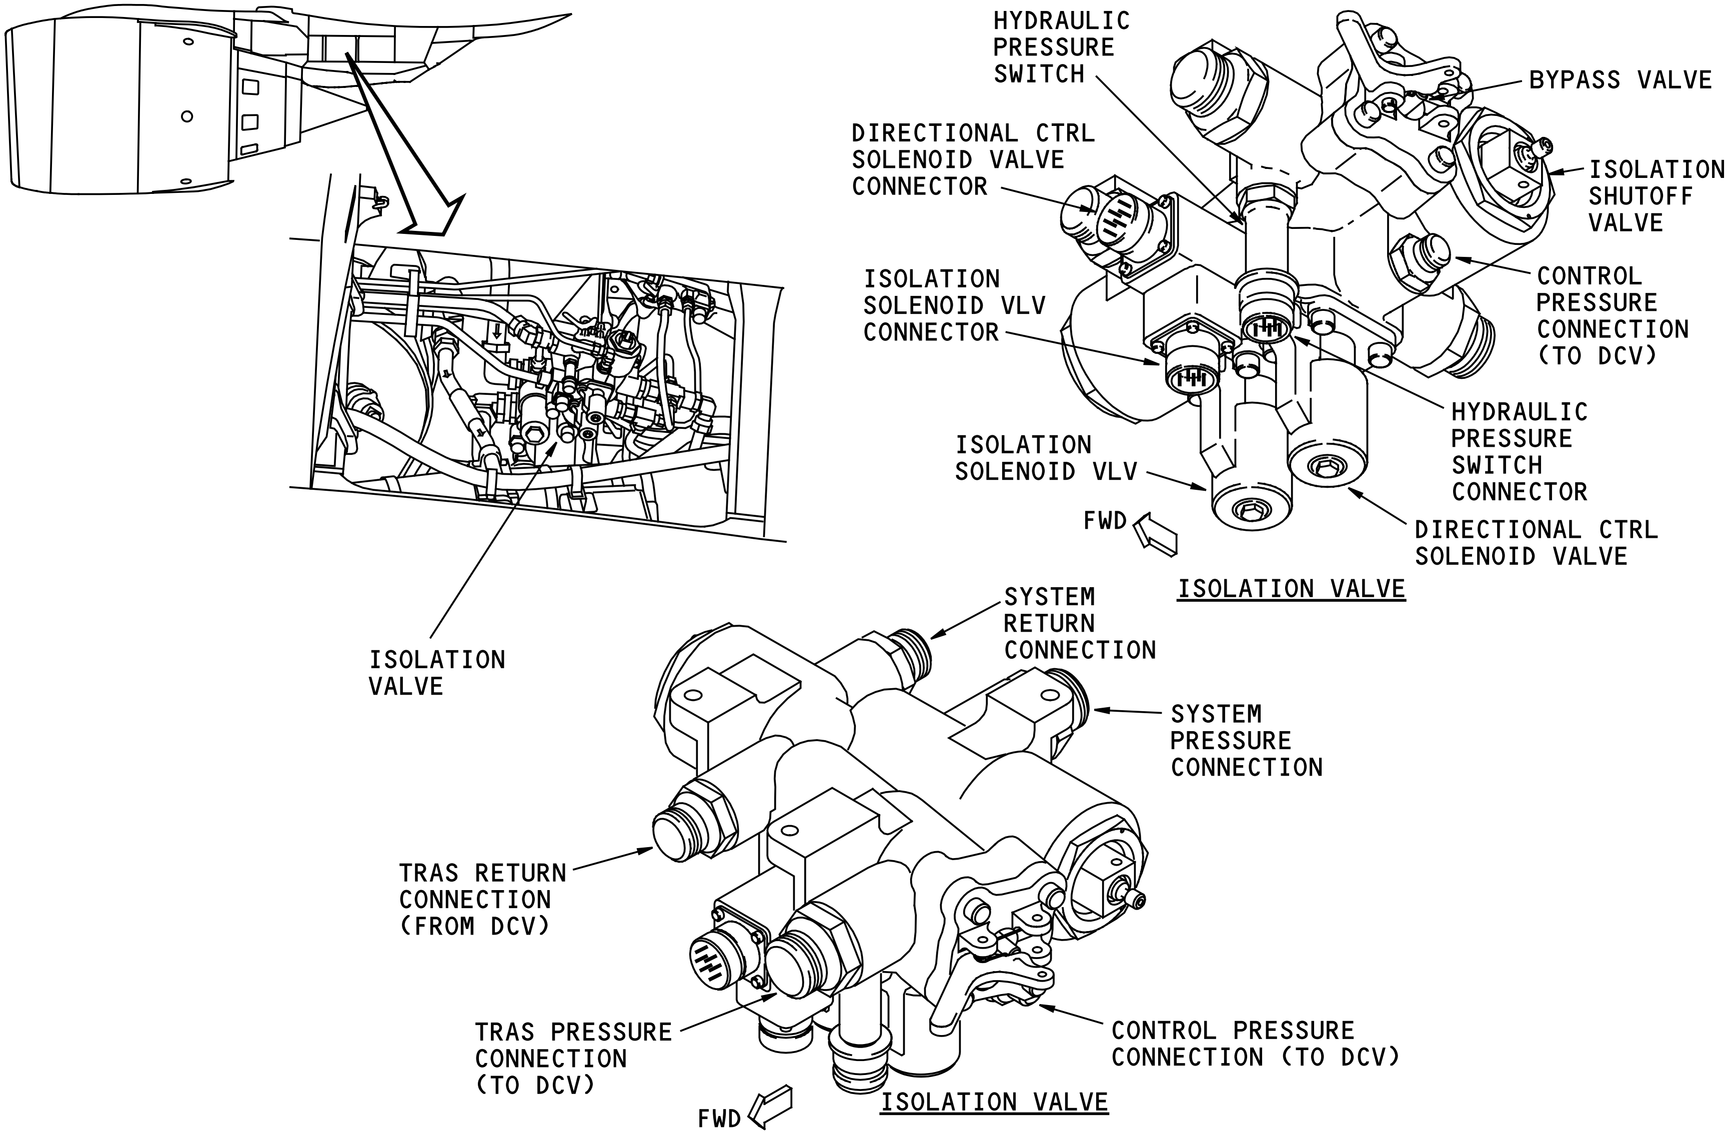
Isolation Solenoid Valve

The isolation solenoid valve supplies internal hydraulic control pressure to move the isolation shutoff valve.

Training Information Point

You use the bypass valve for ground maintenance. You use a pin to mechanically lock the isolation shutoff valve in the closed position when you do the T/R deactivation procedure. The isolation valve is an LRU. These isolation valve components are also LRUs:

- Directional control solenoid valve
- Isolation solenoid valve
- Hydraulic pressure switch.



TRAS - ISOLATION VALVE

TRAS - DIRECTIONAL CONTROL VALVE

Purpose

The DCV supplies hydraulic pressure to extend or retract the T/R actuators.

Physical Description

The DCV has a DCV proximity sensor and these hydraulic connections:

- TRAS return
- TRAS pressure
- Control pressure
- Retract pressure
- Extend pressure.

The DCV and DCV proximity sensor are LRUs.

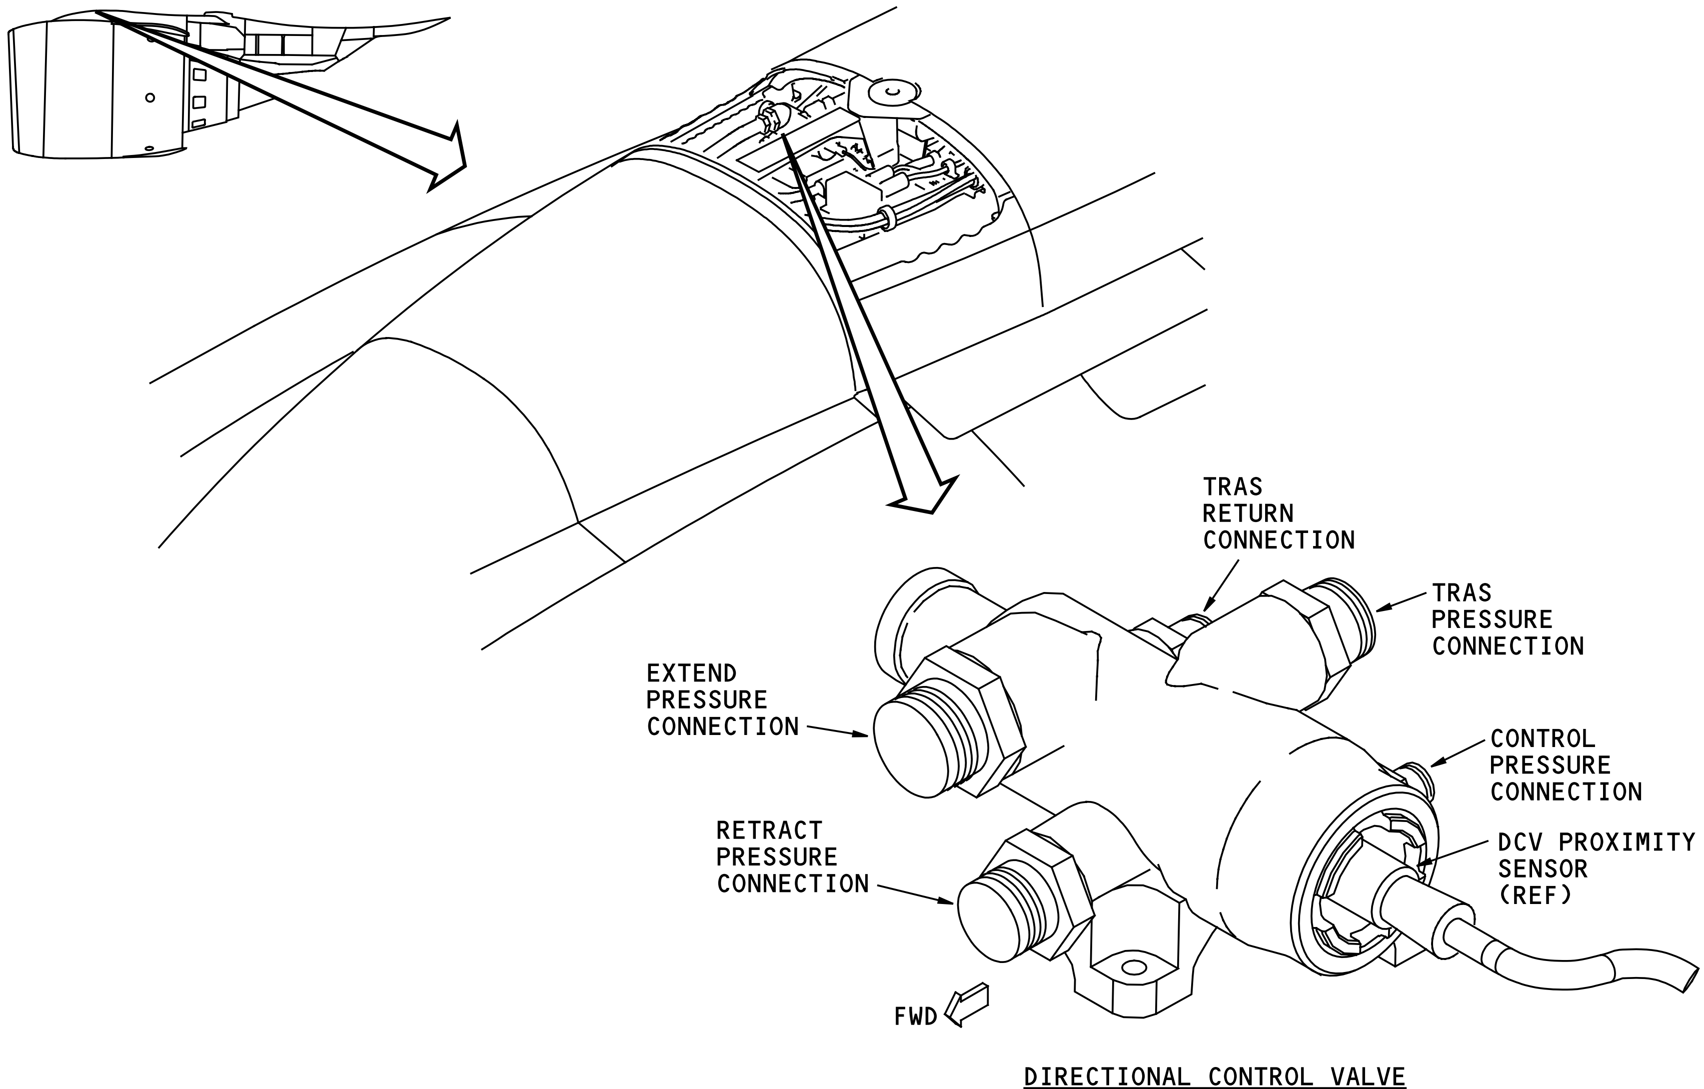
Functional Description

When there is control pressure, the DCV permits TRAS pressure to go to the extend and retract lines to the actuators.

When there is no control pressure, the DCV permits TRAS pressure to go to the retract line to the actuators. Hydraulic fluid in the extend line goes to TRAS return.

DCV Proximity Sensor

The DCV proximity sensor sends DCV position data to the T/R indicating and fault detection system.



78-34-00-109 Rev 2

TRAS - DIRECTIONAL CONTROL VALVE

TRAS - HYDRAULIC ACTUATORS, SYNC SHAFTS AND TUBING - INTRODUCTION

General

The TRAS uses six hydraulic actuators to extend and retract the T/R sleeves.

The sync shafts make sure the actuators on each sleeve move together.

Hydraulic Actuators

The actuators are linear movement actuators and attach to the torque box and the T/R sleeves. They get hydraulic power from the DCV.

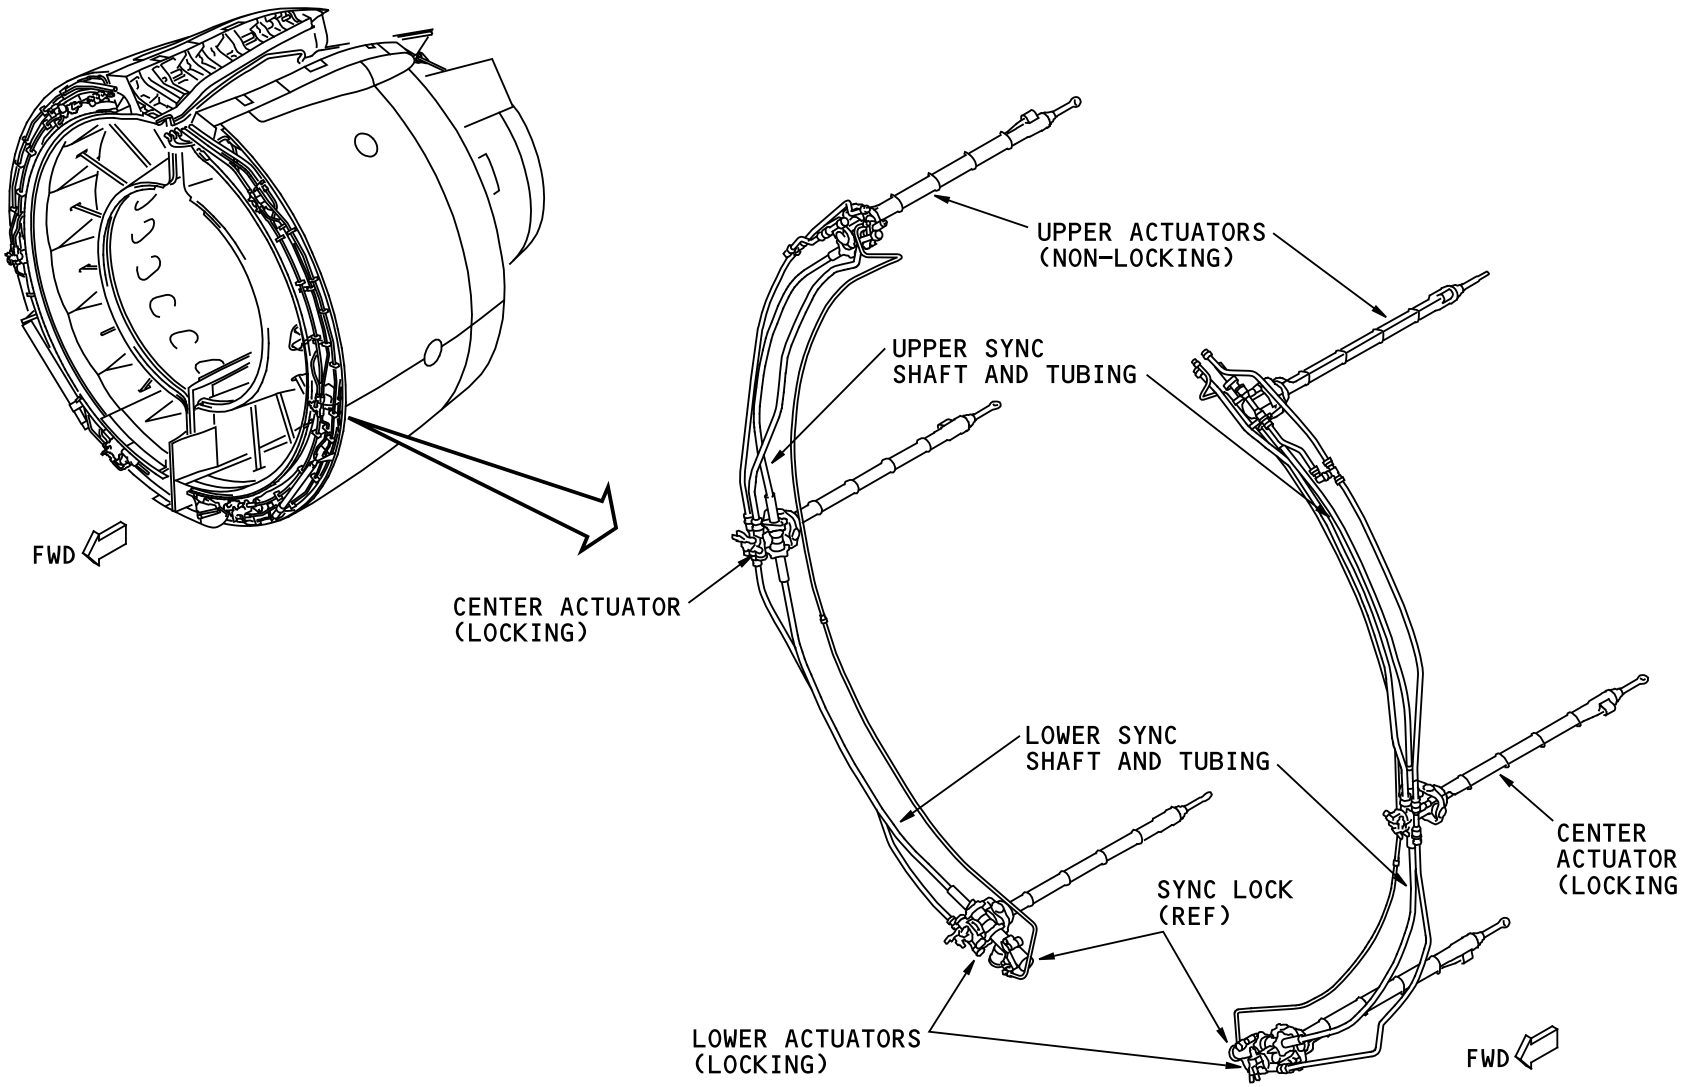
Each T/R half has two locking actuators and one non-locking actuator.

Sync Shafts and Tubing

There is an upper and lower sync shaft and tubing on each T/R half.

The sync shaft tubing contains the sync shaft. The tubing also makes a routing for the TRAS extend pressure to go from the center actuator to the upper and lower actuators.

The sync shafts connect the drive mechanisms of the actuators together. The sync shafts on the left T/R half operate independently of sync shafts on the right T/R half.



78-34-00-110 Rev 0

TRAS - HYDRAULIC ACTUATORS, SYNC SHAFTS AND TUBING - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

TRAS - LOCKING HYDRAULIC ACTUATORS

Purpose

The locking hydraulic actuators do these functions:

- Extend the T/R sleeves
- Retract the T/R sleeves
- Lock the T/R sleeves in the retracted position.

Location

Each T/R half has a center and lower locking actuator. They attach to the T/R torque box and the T/R sleeve.

You get access to the end that attaches to the sleeve through the access panels on the side of the T/R sleeve.

Physical Description

The locking actuators have these parts and connections:

- Extend pressure connections
- Retract pressure connections
- Sync shaft and tubing connections
- Gimbal assembly
- Lock release lever and lever lock pin
- Actuator lock proximity sensor.

Extend Pressure Connections

The extend pressure connection on the center actuator gets extend pressure from the DCV.

The extend pressure connection on the lower actuator has a cap. The lower actuator does not use the extend pressure connection. It gets extend pressure from the center actuator through the sync shaft tube.

Retract Pressure Connections

The upper retract pressure connection on the center actuator gets TRAS retract pressure from the upper actuator. The lower actuator gets retract pressure from the center actuator.

Sync Shaft and Tubing Connections

The sync shaft connects the drive mechanisms of the actuators together. There are connections on both the top and bottom of each actuator. The sync lock/manual drive unit connects to the sync shaft connection on the bottom of the lower actuator. The tubing makes a routing for the TRAS extend pressure.

Gimbal Assembly

A gimbal assembly attaches the head end of the actuator to the forward side of the T/R torque box. You must open the fan cowl to get access to the gimbal assembly.

Lock Release Lever and Lever Lock Pin

The lock release lever releases the locking mechanism in the actuator. The lever lock pin holds the lever in the not locked position. This permits the manual movement of the T/R sleeve.

TRAS - LOCKING HYDRAULIC ACTUATORS

Actuator Lock Proximity Sensor

The actuator lock proximity sensor sends lock position data to the T/R indicating and fault detection system.

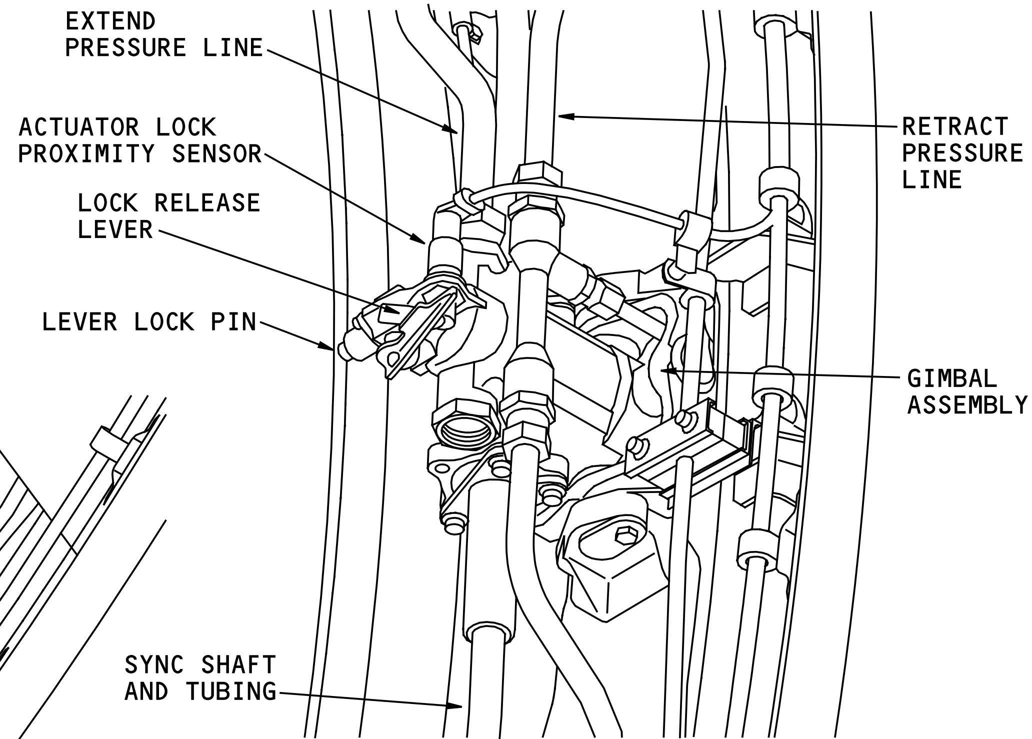
Functional Description

When there is no reverse thrust command, an internal lock mechanism locks the actuators in the retracted position.

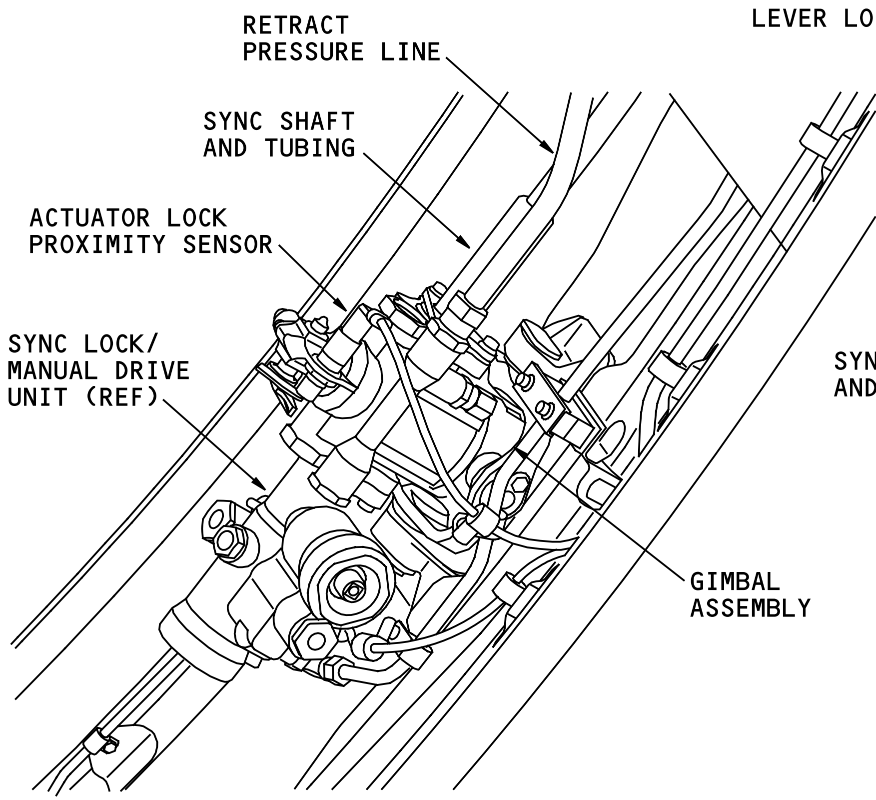
When there is a reverse thrust command, TRAS extend pressure releases the actuator lock mechanism. This permits the actuators to move the T/R sleeve to the extended position.

Training Information Point

The locking actuators are interchangeable.



CENTER ACTUATOR



LOWER ACTUATOR

78-34-00-111 Rev 3 10/23/95

TRAS - LOCKING HYDRAULIC ACTUATORS

TRAS - NON-LOCKING HYDRAULIC ACTUATORS

Purpose

The non-locking hydraulic actuators do these functions:

- Extend the T/R sleeves
- Retract the T/R sleeves
- Turn the RVDTs.

Location

Each T/R half has one non-locking actuator on the upper part of the T/R. It attaches to the torque box and the T/R sleeve.

You get access to the end that attaches to the sleeve through the access panels on the side of the T/R sleeve (not shown).

Physical Description

The non-locking actuators have these parts and connections:

- Retract pressure connections
- Sync shaft and tubing connections
- Gimbal assembly
- RVDT.

Retract Pressure Connections

The upper retract pressure connection gets TRAS retract pressure from the DCV. The lower retract pressure connection sends retract pressure to the center actuator.

Sync Shaft and Tubing Connections

The sync shaft connects the drive mechanisms of the actuators together. There are connections on both the top and bottom of each actuator. The tubing makes a routing for the TRAS extend pressure. The center actuator sends extend pressure to the upper actuator through the sync shaft tubing.

Gimbal Assembly

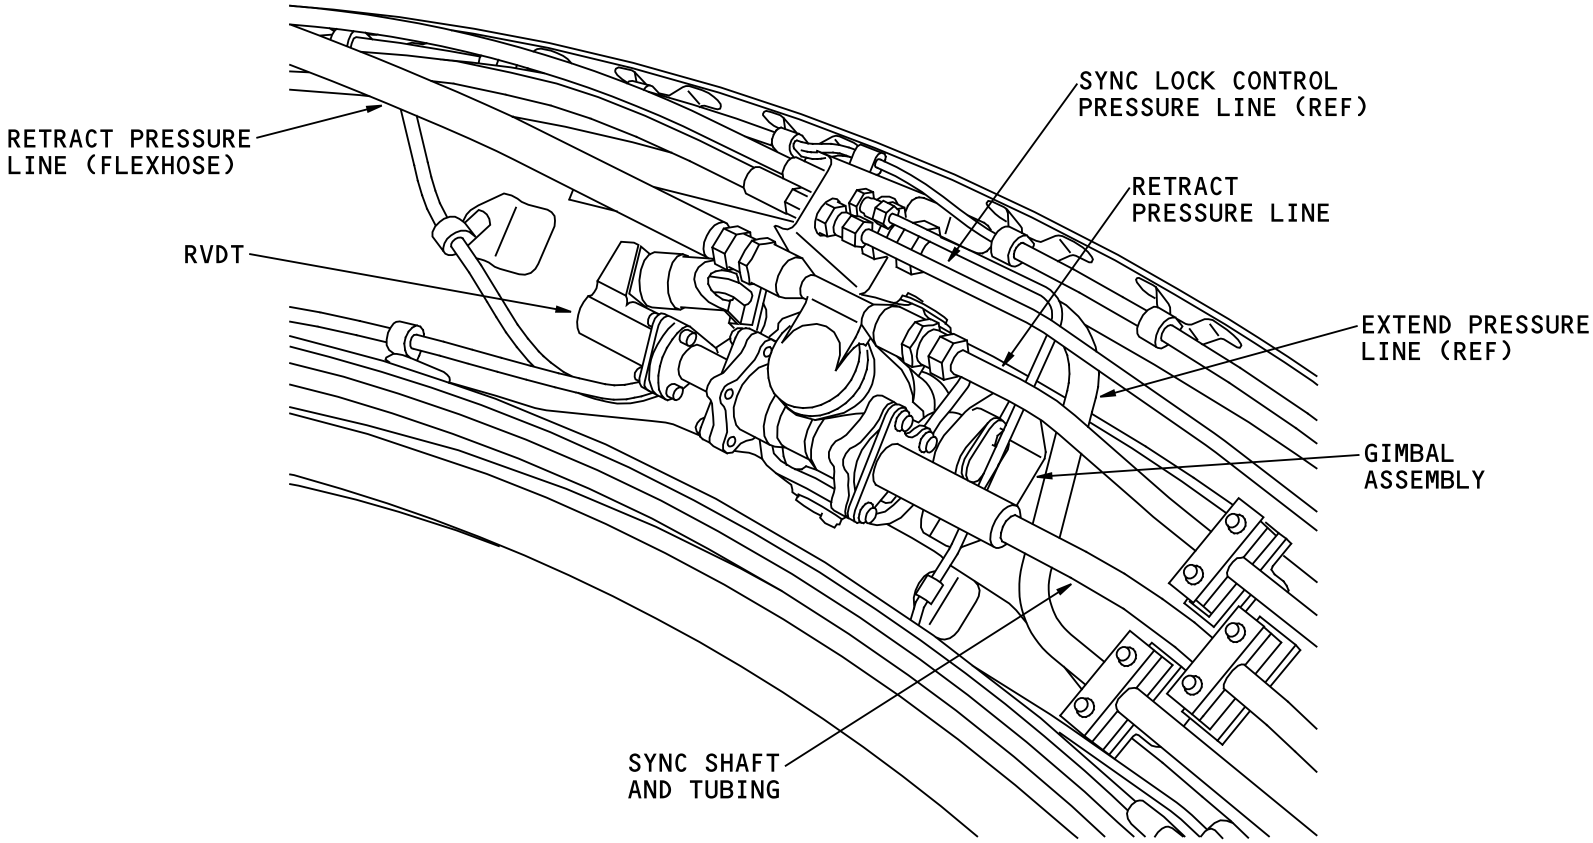
A gimbal assembly attaches the head end of the actuator to the forward side of the T/R torque box. You must open the fan cowl to get access to the gimbal assembly.

RVDT

The RVDT attaches to the upper sync shaft and tubing connection. The drive mechanism in the upper actuator turns the RVDT. The RVDT sends T/R sleeve position data to the EEC for control and indication functions.

Training Information Point

The non-Locking actuators are interchangeable.



LEFT UPPER ACTUATOR

78-34-00-112 Rev 3 10/23/95

TRAS - NON-LOCKING HYDRAULIC ACTUATORS

TRAS - THRUST LEVER INTERLOCK ACTUATOR

Purpose

The thrust lever interlock actuator keeps the movement of the reverse thrust lever to a limit when you command reverse thrust. This keeps the engine thrust command at idle until the T/R sleeves get near the extended position.

Physical Description

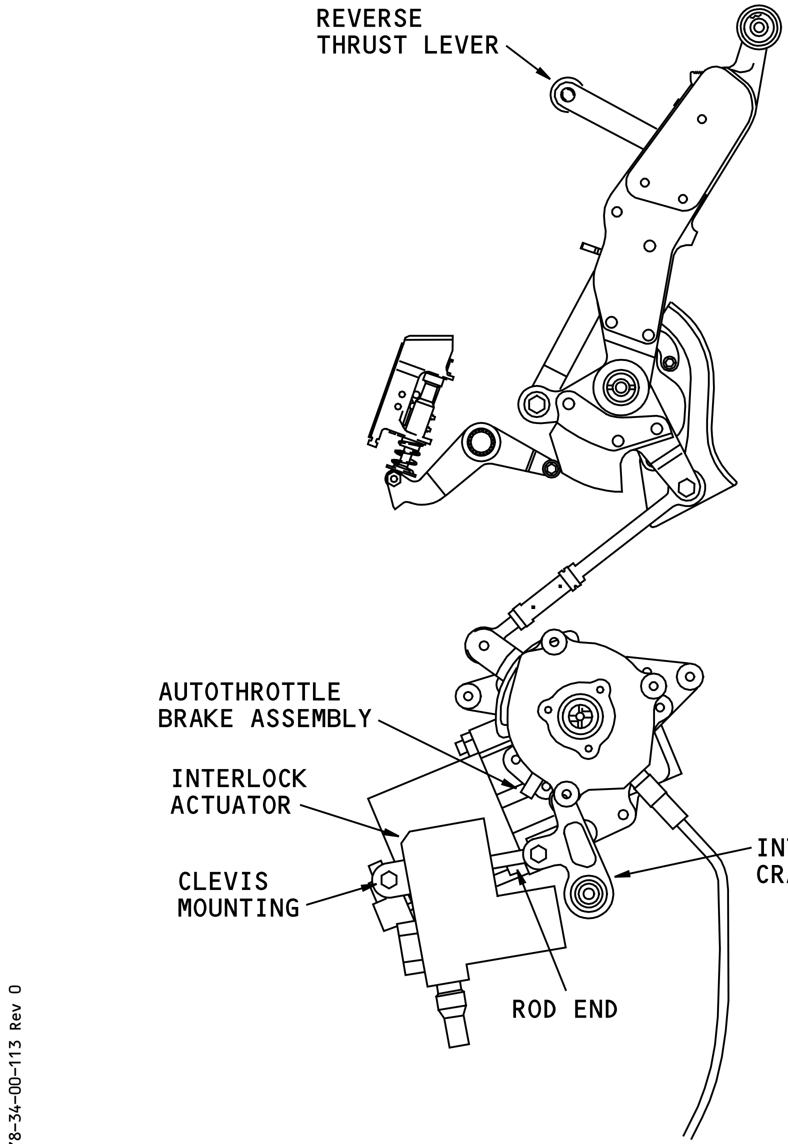
The actuator is a 28v dc linear type. It has a clevis mounting that attaches the actuator to the control stand structure. It has a rod that attaches to the interlock crank assembly.

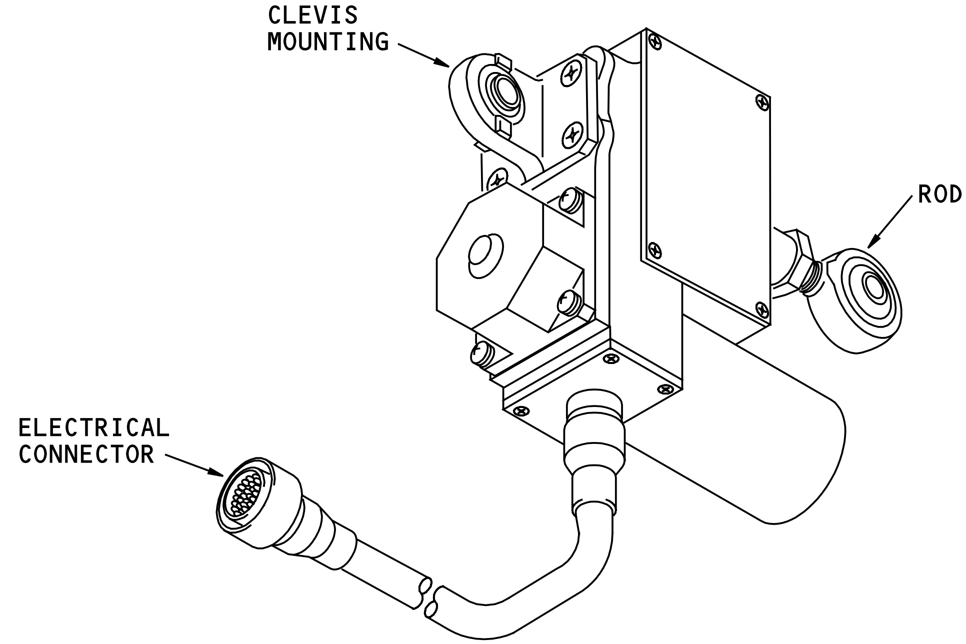
Functional Description

When you command reverse thrust, the reverse thrust lever causes the autothrottle brake assembly to turn into the interlock crank assembly. The crank assembly prevents any more movement of the autothrottle brake assembly in the reverse thrust direction. It stops the assembly at the reverse thrust interlock position.

When the T/R sleeves get near the extended position, the EEC energizes the interlock actuator to extend the rod end. This moves the interlock crank assembly and permits the autothrottle brake assembly to turn to the maximum reverse thrust position.

There is no interlock actuator limit when you command forward thrust.





INTERLOCK ACTUATOR

TRAS - THRUST LEVER INTERLOCK ACTUATOR

TRAS - FUNCTIONAL DESCRIPTION - CONTROL

THIS PAGE INTENTIONALLY LEFT BLANK

TRAS - FUNCTIONAL DESCRIPTION - CONTROL

General

When the engine fire switch is in the NORM position, the TRAS uses electrical power from the main dc bus to control the extension and retraction of the T/R sleeves.

These components must get control signals before the thrust reversers can move:

- SL solenoid valve
- Directional control solenoid valve
- Isolation solenoid valve.

These components send the control signals:

- SL switch through the SL relay
- DCV switch
- EEC.

Extend

When you move the reverse thrust lever to the reverse idle position, the SL and DCV switches move to the extend position. The SL switch sends a control signal to the SL relay. When the SL relay energizes, power goes to the SL solenoid valve. The SL solenoid valve energizes so that hydraulic control pressure can release the sync lock.

The DCV switch energizes the directional control solenoid valve. This permits hydraulic control pressure to operate the DCV. The DCV moves to the extend position.

The EEC must have these inputs to energize the isolation solenoid valve:

- TRA less than 30 degrees
- Airplane on ground
- Engine operating.

If the EEC finds the inputs to be in the proper configuration to extend the thrust reverser, the EEC energizes the isolation solenoid valve. This pressurizes the T/R system and extends the sleeves. The EEC uses data from the hydraulic pressure switch to make sure the isolation valve is in the correct position.

Retract

When you move the reverse thrust lever to the forward idle position, the isolation valve stays open. The EEC starts a 20 second time delay. The time delay keeps the isolation valve open to make sure retraction is complete. After the time delay, the EEC de-energizes the isolation valve solenoid.

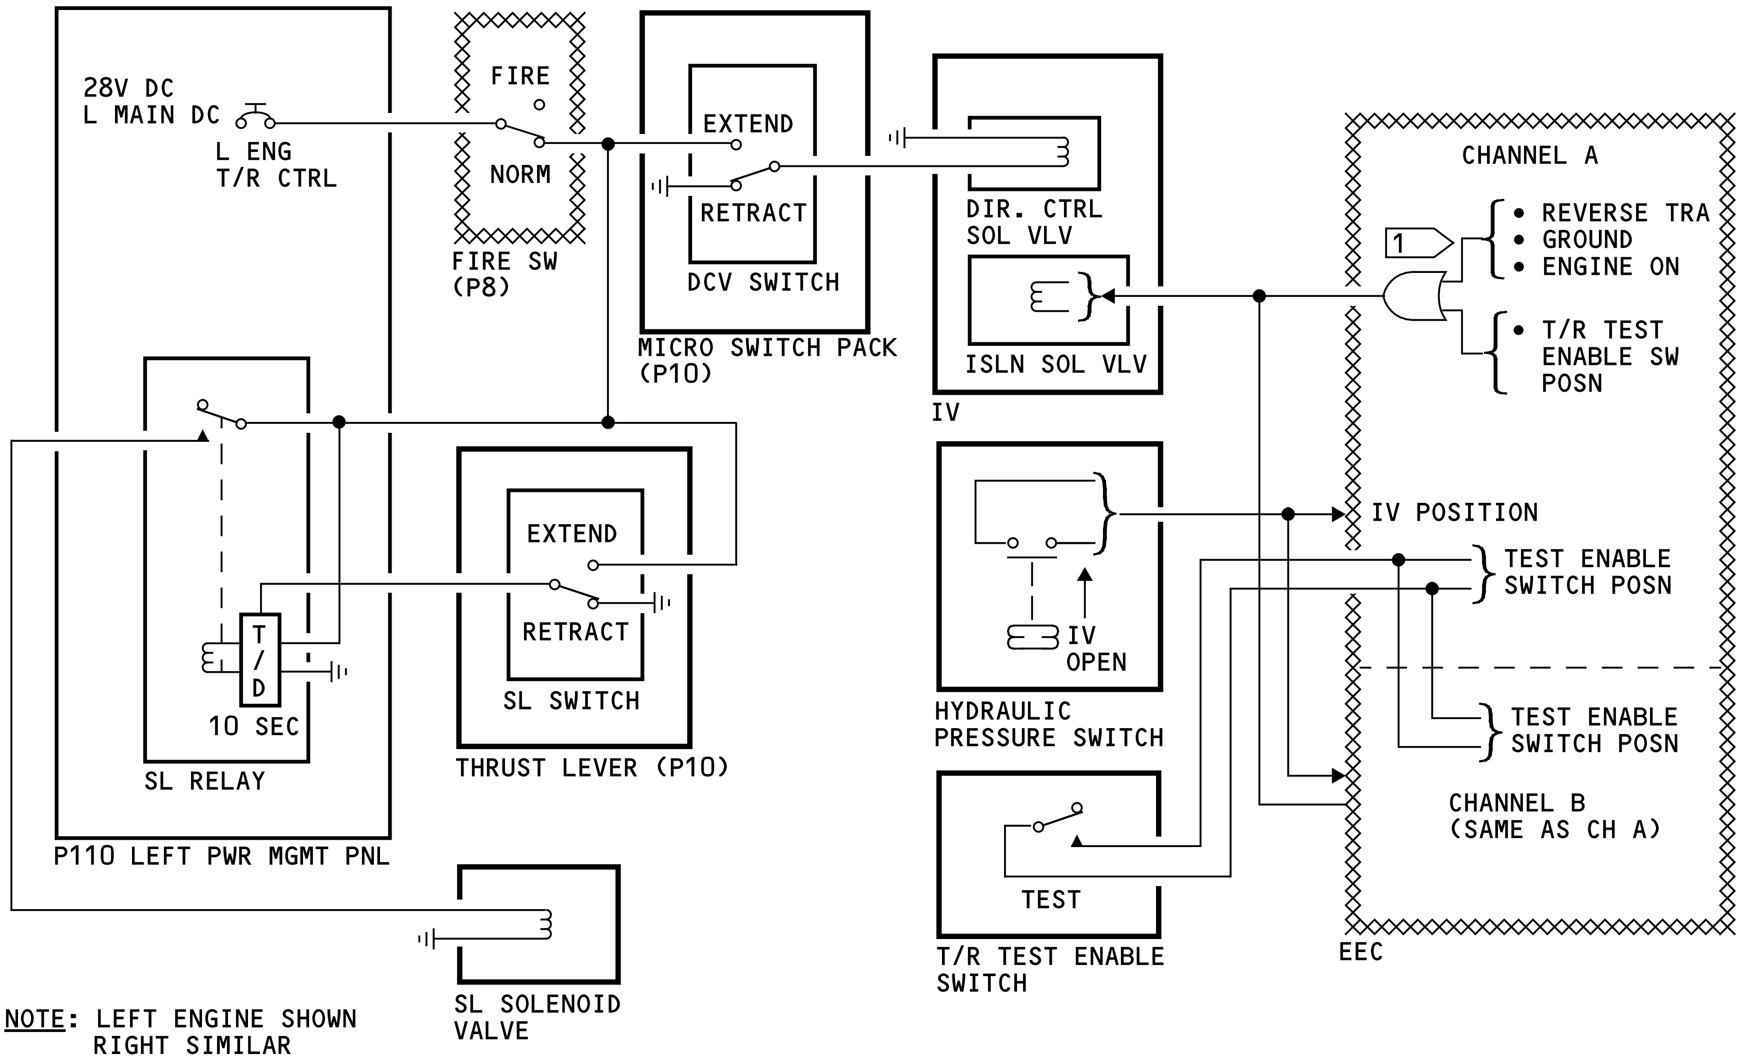
The DCV switch moves to the retract position and de-energizes the directional control solenoid valve. The DCV moves to the retract position. This permits hydraulic power to retract the hydraulic actuators.

TRAS - FUNCTIONAL DESCRIPTION - CONTROL

The SL switch moves to the retract position and de-energizes the SL relay. A 10 second time delay keeps the SL relay energized to make sure retraction is complete. When SL relay de-energizes, the SL solenoid valve closes. This locks the sync lock/manual drive unit.

Manual Operation

You use the T/R test enable switch to extend the T/R sleeves to do maintenance. You push and hold the switch with the reverse thrust levers up. This permits the EEC to energize the isolation solenoid valve when the engine is not running.



NOTE: LEFT ENGINE SHOWN

TRAS - FUNCTIONAL DESCRIPTION - CONTROL

TRAS - FUNCTIONAL DESCRIPTION - ACTUATION

THIS PAGE INTENTIONALLY LEFT BLANK

TRAS - FUNCTIONAL DESCRIPTION - ACTUATION

General

To extend or retract the T/R sleeves, hydraulic pressure must release the sync locks and move the hydraulic actuators.

To release the sync locks, hydraulic pressure goes through the SLV to the sync locks.

To move the T/R sleeves, hydraulic pressure goes to the actuators in this sequence:

- IV
- DCV
- Hydraulic actuators.

Flow tees hydraulically connect the components of the two T/R halves to the control components in the strut. The flow tees in the lines from the DCV also contain orifices to hydraulically synchronize the T/R halves.

Extend

This sequence occurs when there is a command to extend the T/R sleeves:

- The SL switch in the thrust lever sends a signal through a relay in the ELMS to energize the SL solenoid valve. The SL solenoid valve opens and supplies hydraulic control pressure through the SLV to the sync locks. The hydraulic control pressure moves the lock mechanisms in the sync locks to release the sync shafts.
- The DCV switch in the switch pack sends a signal to energize the directional control solenoid valve. The directional control solenoid valve opens and supplies hydraulic control pressure to the DCV. This moves an internal spool valve to the extend position.
- The EEC energizes the isolation solenoid valve. This supplies internal hydraulic control pressure to move the isolation shutoff valve to the open position. The open shutoff valve supplies hydraulic system pressure through the bypass valve to the TRAS pressure port of the isolation valve.

TRAS pressure from the isolation valve goes through DCV to the head (extend) and rod (retract) ends of the hydraulic actuators.

The TRAS extend pressure releases the lock mechanisms in the locking actuators. It also applies a force to the head (extend) end of the actuator pistons. The TRAS retract pressure applies a force on the rod (retract) end of the actuator pistons.

Because the work area of the piston head (extend) ends is larger than the rod (retract) ends, the TRAS pressure moves the actuator to the extended position.

The EEC gets sleeve position data from the RVDTs. When both sleeves are more than 60 percent extended, the EEC energizes the thrust lever interlock actuator. This permits reverse thrust greater than idle.

TRAS - FUNCTIONAL DESCRIPTION - ACTUATION

Retract

This sequence occurs when there is a command to retract the T/R sleeves:

- The SL solenoid valve stays open and supplies hydraulic control pressure through the SLV to the sync locks. The hydraulic control pressure keeps the sync locks and sync shafts released.
- The directional control solenoid valve closes. This removes hydraulic control pressure to the DCV. A spring force moves the internal spool valve to the retract position. This permits TRAS pressure to go only to the retract port of the DCV.
- The isolation solenoid valve stays energized. The internal hydraulic control pressure keeps the isolation shutoff valve open. It supplies hydraulic system pressure through the bypass valve to the TRAS pressure port of the isolation valve.

TRAS pressure from the isolation valve goes through DCV to the rod (retract) end of the hydraulic actuators. This moves the actuators to the retracted position. The head (extend) hydraulic fluid goes to TRAS return.

Time delay circuits in the EEC and the ELMS cause the SLV and isolation valve to stay open. When the time delays are complete, the valves close. This removes hydraulic pressure from the TRAS and causes the sync locks to lock the sync shafts.

When both sleeves are less than 40 percent extended, the EEC energizes the thrust lever interlock actuator. This sets the thrust lever interlock.

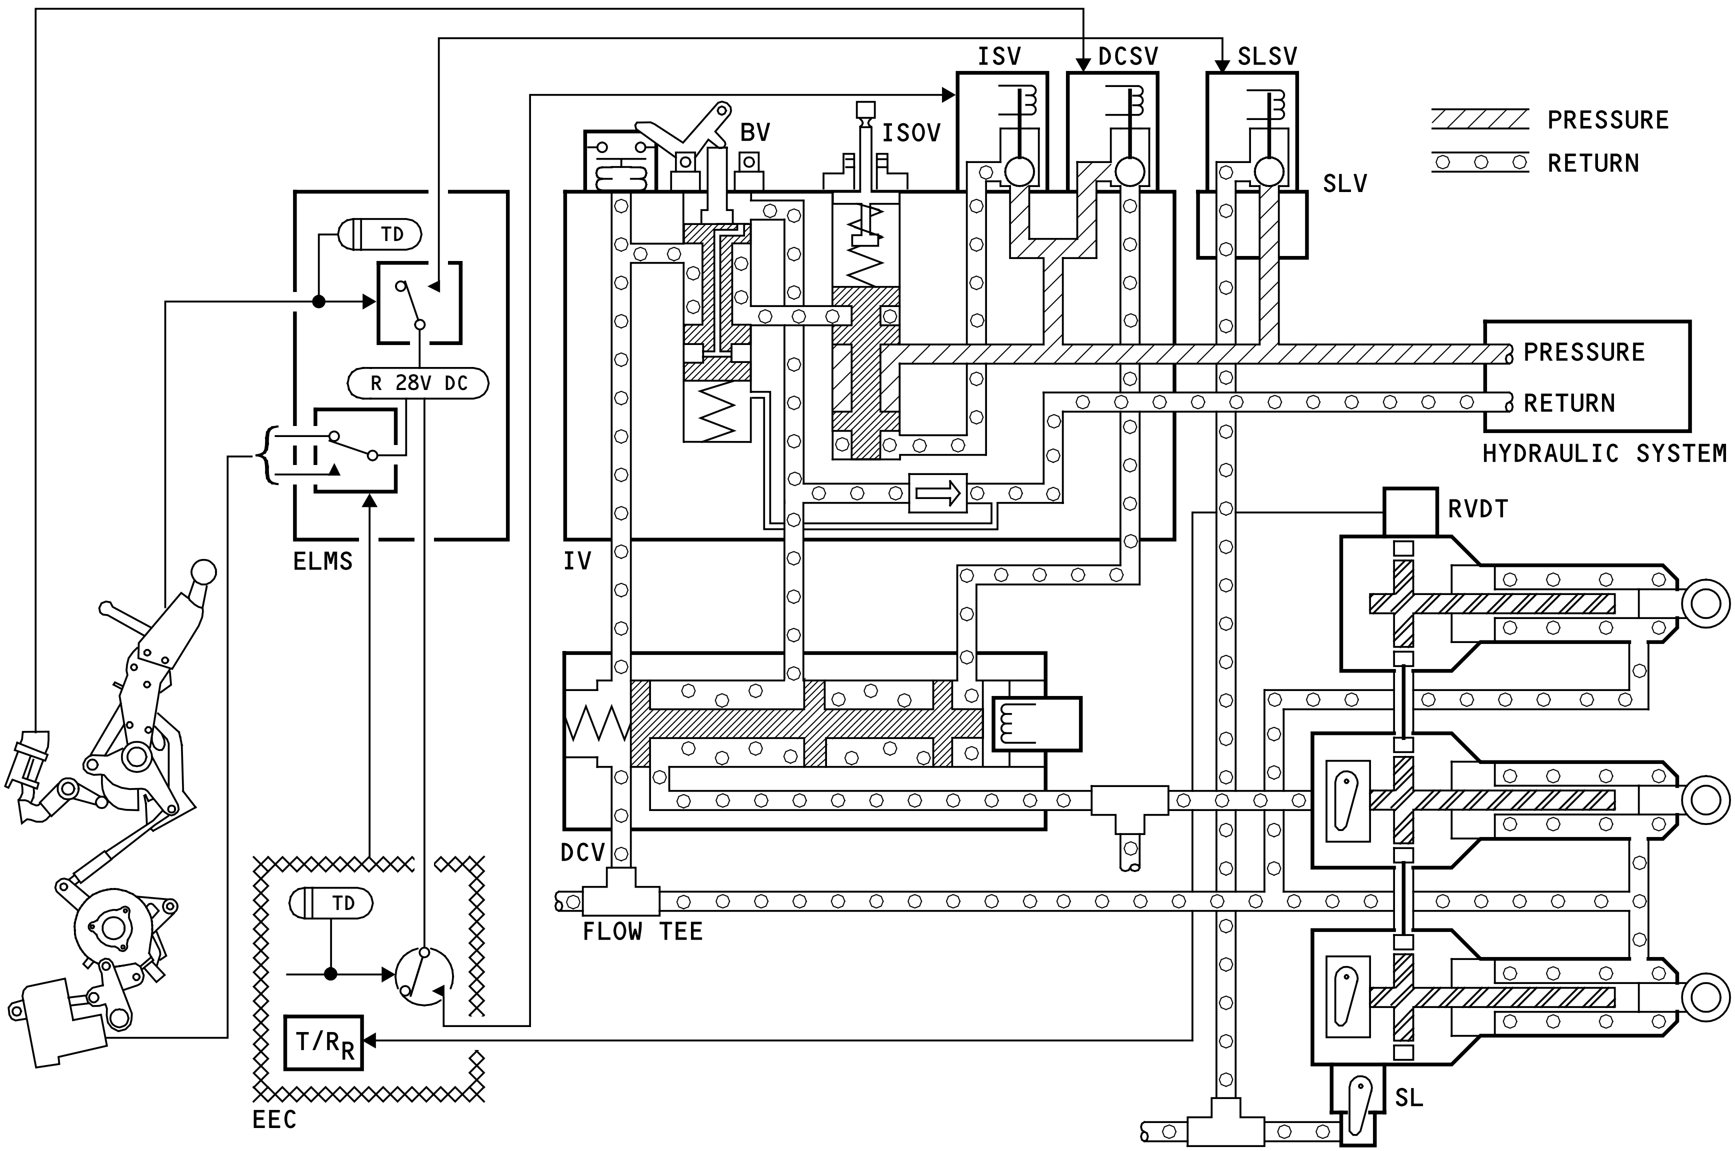
Deactivation

To deactivate the T/R for maintenance, you pull circuit breakers to keep power from the solenoid valves. You must also push the isolation shutoff valve plunger and install pin to hold it in place. This keeps the shutoff valve closed which prevents hydraulic system pressure from going into the T/R actuation system.

Manual Operation

To manually operate the T/R you must deactivate the T/R for maintenance. Then, push the bypass valve handle and install a pin to hold it in place. The bypass valve now connects the extend and retract pressure lines of the TRAS together. This permits hydraulic fluid to flow between them. You use the manual drive unit of the sync locks to extend and retract the T/R.

A small bypass line in the isolation valve body and the bypass valve lets some return pressure fluid into the system. This is needed to prevent a hydraulic lock, because the volume of fluid on the extend side of the actuators is greater than on the retract side.



78-34-00-115 Rev 2 02/14/1997

TRAS - FUNCTIONAL DESCRIPTION - ACTUATION

TRAS - FUNCTIONAL DESCRIPTION - THRUST LEVER INTERLOCK

General

Each thrust lever interlock actuator has two positions:

- Clear (no interlock)
- Set (interlock).

When the interlock actuator is in the set position, you cannot move the reverse thrust lever beyond idle. When the interlock actuator is in the clear position, you can move the reverse thrust lever beyond idle to maximum reverse.

The left main dc bus supplies power to move the interlock actuator.

Clear (No Interlock)

The EEC controls the interlock actuator through the T/R interlock relay in the left power management panel. When the EEC supplies a ground to energize the relay, power goes to the actuator motor. This moves the interlock actuator to the clear position. These conditions must be met for the EEC to energize the relay:

- Both T/R sleeves are more than 60 percent extended
- The TRA is less than 30 degrees.

After the actuator moves to the clear position, limit switches open to remove power to the motor.

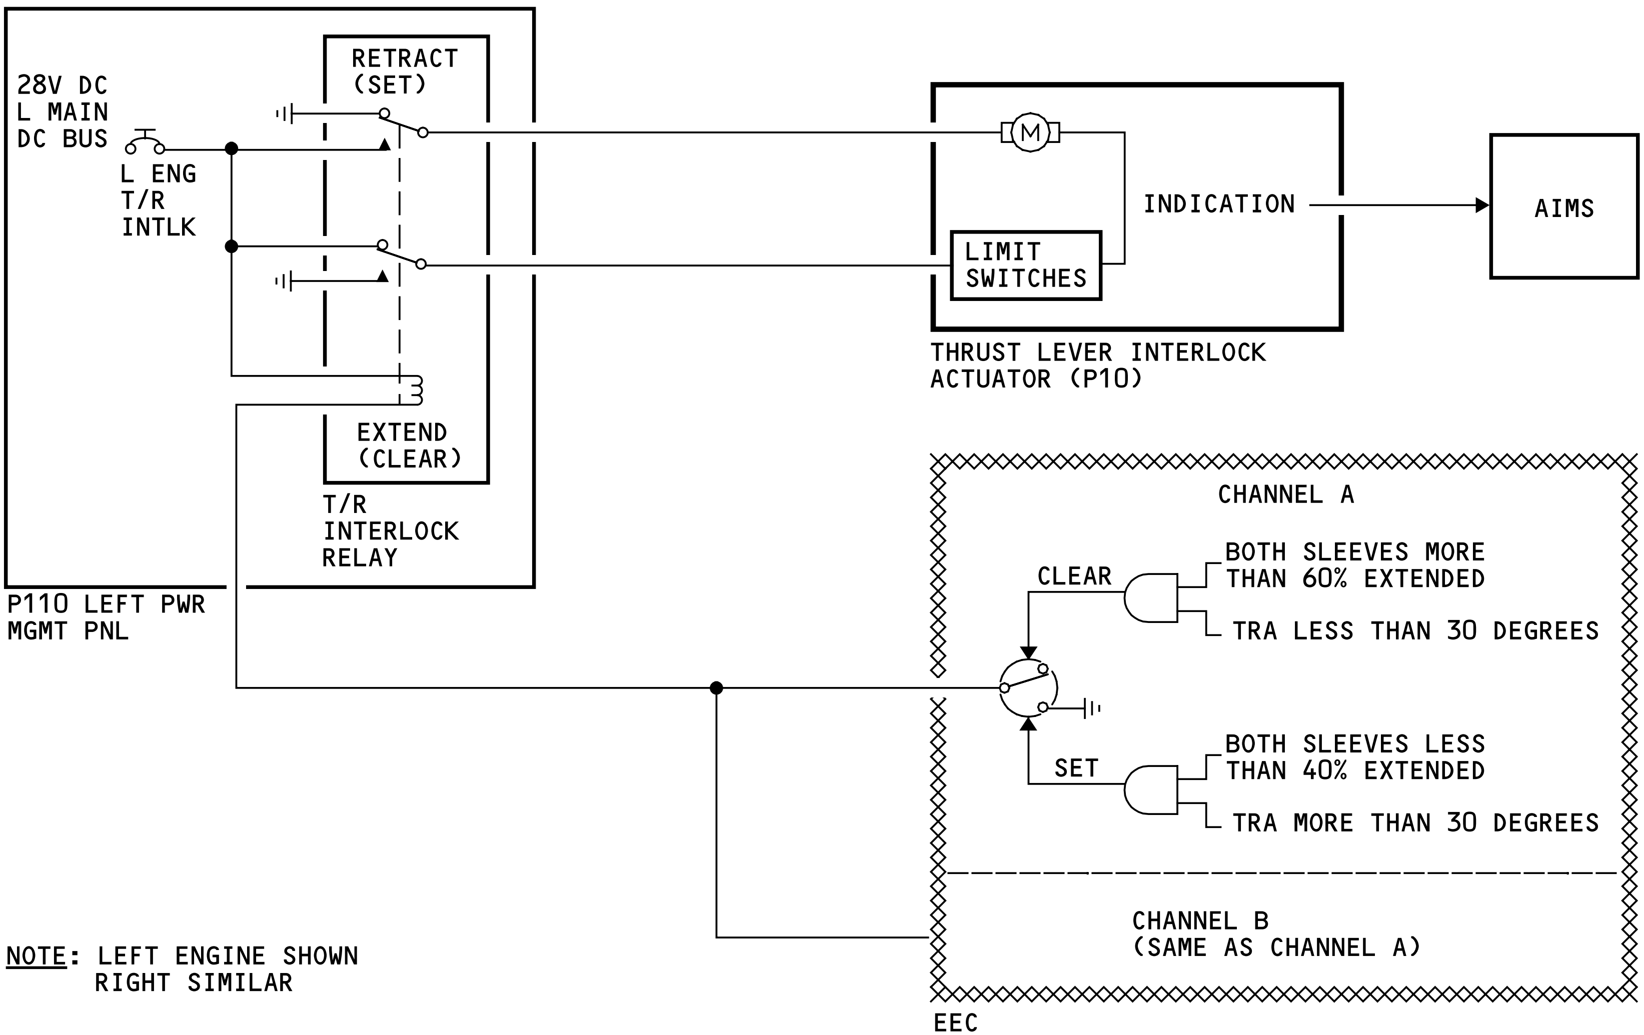
Set (Interlock)

When the EEC removes the ground to the T/R interlock relay, power goes to the actuator motor. This moves the interlock actuator to the set position. These conditions must be met for the EEC to remove the ground:

- Both T/R sleeves are less than 40 percent extended
- The TRA is more than 30 degrees.

After the actuator moves to the set position, limit switches open to remove power to the motor.

If neither of the conditions to clear or set the interlock actuator occur, the EEC does not change the position of the interlock actuator.



78-34-00-116 Rev 1

TRAS - FUNCTIONAL DESCRIPTION - THRUST LEVER INTERLOCK

TRAS - POWER EXTENSION/RETRACTION - TRAINING INFORMATION POINTS

General

To do maintenance on the T/R, you can extend or retract the T/R sleeves without operating the engines. To do this, you supply electrical and hydraulic power. Then you use the EEC maintenance switch and the T/R test enable switch.

Extend

WARNING: DO THE DEACTIVATION PROCEDURE FOR THE SPOILERS. THE SPOILERS CAN EXTEND QUICKLY AND CAUSE INJURY TO PERSONS AND DAMAGE TO EQUIPMENT.

WARNING: MAKE SURE ALL PERSONS AND EQUIPMENT ARE CLEAR OF THE AREA AFT OF THE APPLICABLE THRUST REVERSER. IF YOU DO NOT OBEY THIS INSTRUCTION, INJURIES TO PERSONS OR DAMAGE TO EQUIPMENT CAN OCCUR WHEN THE THRUST REVERSER EXTENDS.

This is an overview of the procedure to extend the T/R sleeves:

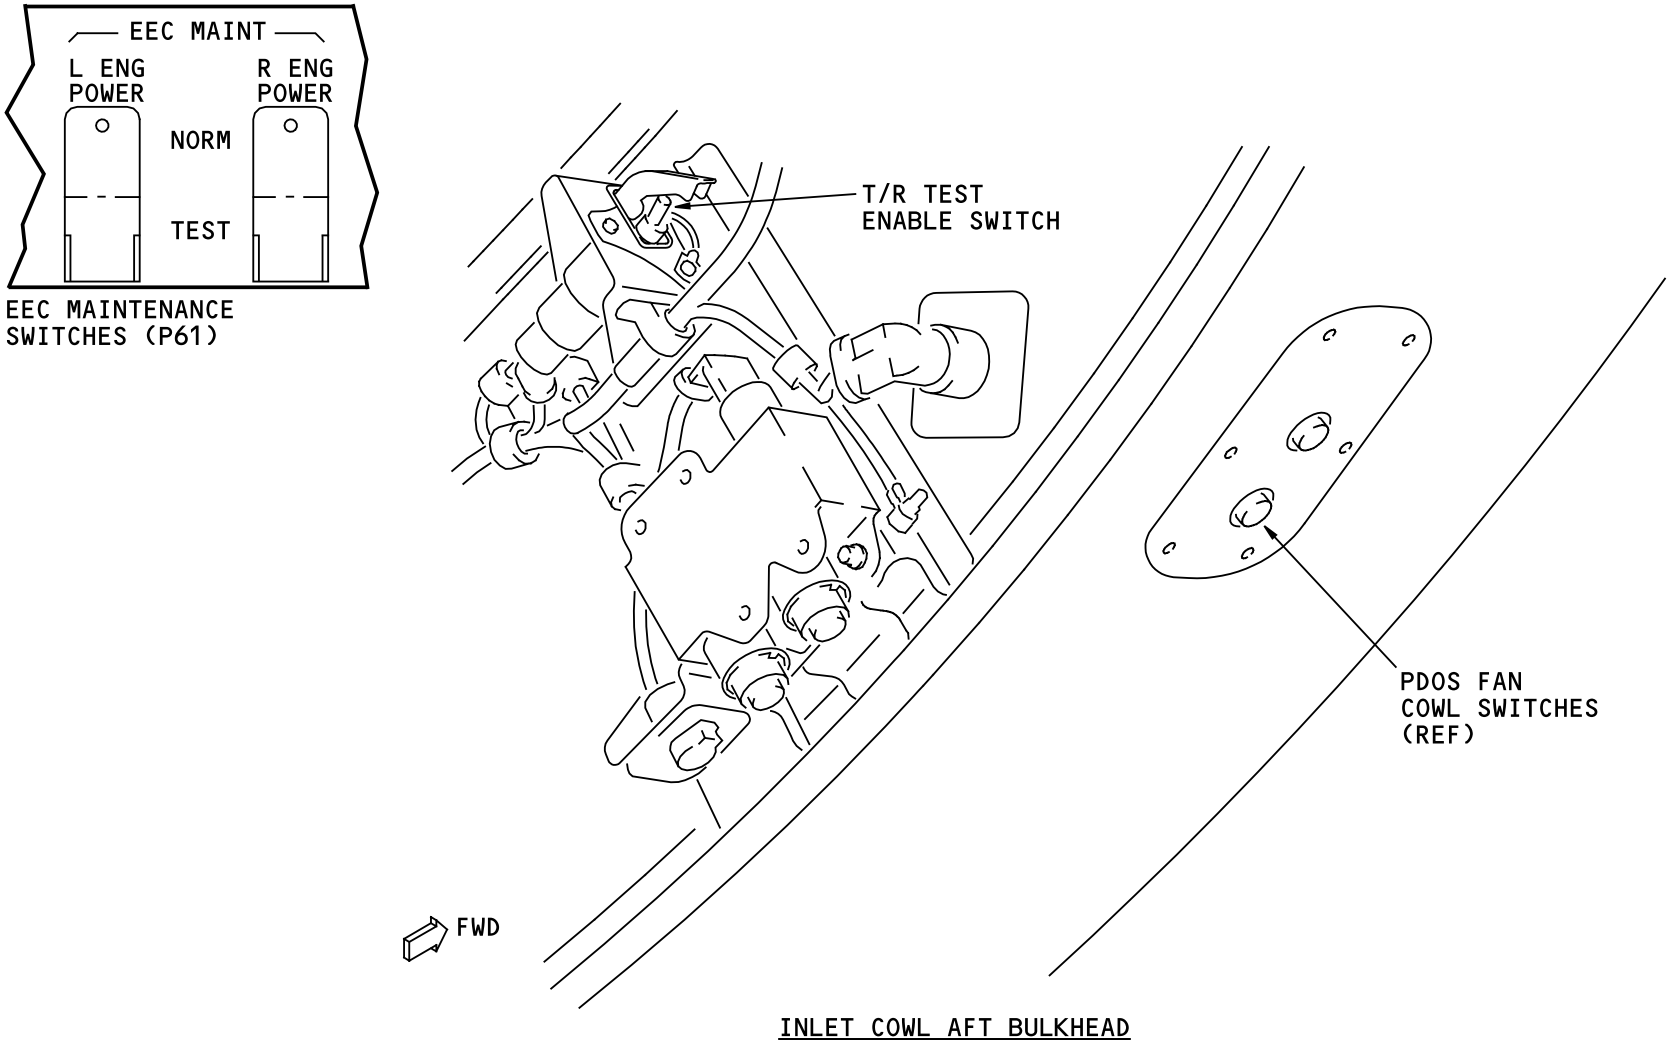
- After you supply electrical and hydraulic power, make sure the fuel control switch is in cutoff.
- Move the applicable EEC maintenance switch to the TEST position. This switch permits power to go to the EEC.
- Move the reverse thrust levers to the interlock (reverse idle) position.
- To extend the sleeve, push and hold the T/R test enable switch. This switch permits the EEC to open the IV when the engine is not running).

When the sleeve is in the fully extended position, you must deactivate the IV before you do maintenance.

Retract

You must use two people to retract the T/R sleeves. This is an overview of the procedure:

- Push and hold the T/R test enable switch.
- Move the reverse thrust levers to the forward idle position.
- When the sleeves are fully retracted, do not hold the T/R test enable switch for more than 20 seconds. If you do, EICAS and CMCS messages will show.



78-34-00-117 Rev 2

TRAS - POWER EXTENSION/RETRACTION - TRAINING INFORMATION POINTS

TRAS - DEACTIVATION - TRAINING INFORMATION POINTS

General

To deactivate the thrust reverser (T/R), you must do these two tasks:

- Make sure that hydraulic power does not go to the T/R system
- Mechanically prevent the movement of each T/R sleeve.

WARNING: DO ALL OF THE SPECIFIED TASKS IN THE CORRECT SEQUENCE TO DEACTIVATE THE THRUST REVERSER. IF YOU DO NOT OBEY THIS INSTRUCTION, INJURIES TO PERSONS AND DAMAGE TO EQUIPMENT CAN OCCUR.

Hydraulic Deactivation

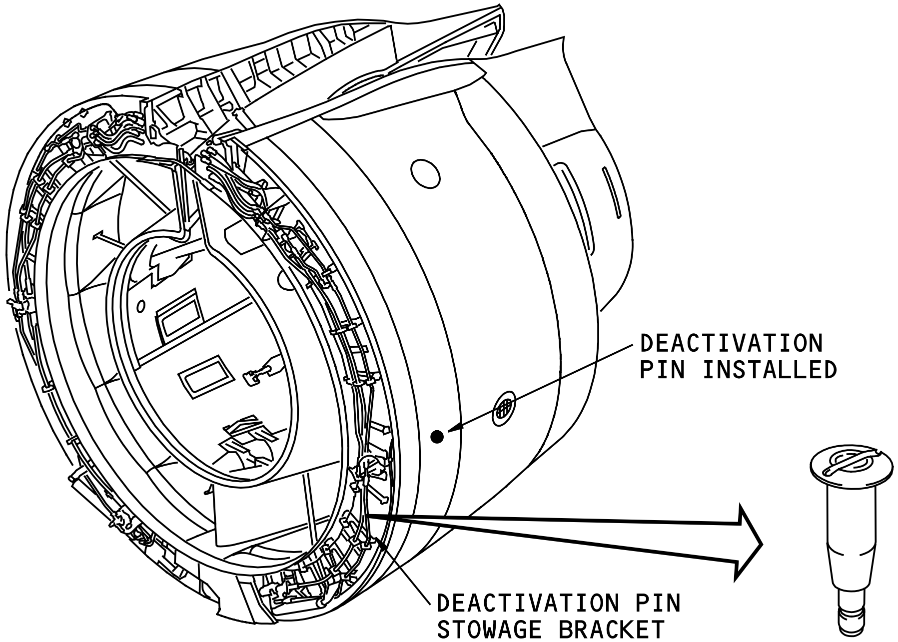
To make sure that hydraulic power does not go to the T/R system, you must put a pin in the isolation shutoff valve spool on the IV. Because the spool is spring-loaded to the out position, you push the spool in and lock it with a pin. This keeps hydraulic power away from the DCV and the hydraulic actuators.

Mechanical Deactivation

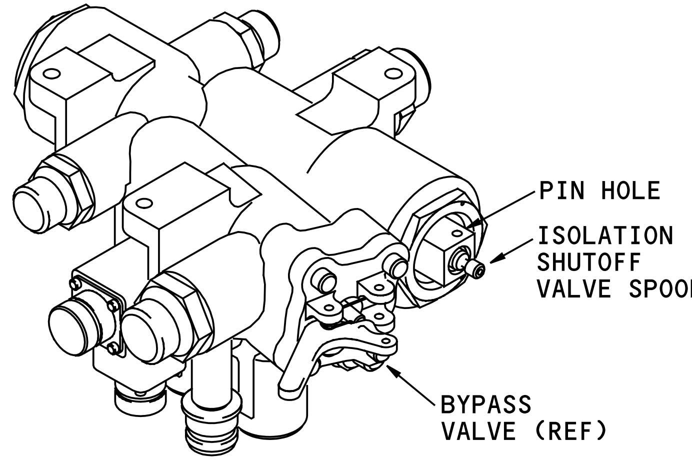
To mechanically prevent the movement of each T/R sleeve, the sleeves must be in the fully retracted position. Then, you remove the plug that is in each outer sleeve and replace it with a deactivation pin. The pins are in a bracket on the T/R torque box between the center and lower actuators of each sleeve. The pin screws in.

Activation

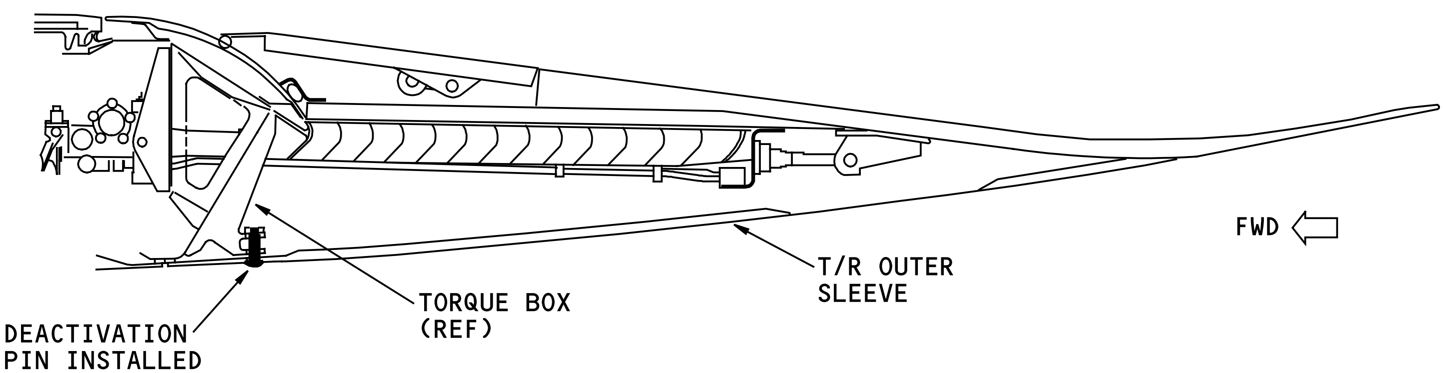
To activate the T/R system, do the deactivation procedure in the reverse order.



DEACTIVATION
PIN



ISOLATION VALVE



VIEW LOOKING DOWN

TRAS - DEACTIVATION - TRAINING INFORMATION POINTS

78-34-00-118 Rev 2 10/23/95

TRAS - MANUAL EXTENSION/RETRACTION - TRAINING INFORMATION POINTS

General

Manual operation permits you to move one sleeve at a time. To move each sleeve manually, you must unlock the related two locking actuators and the related sync lock. You also operate the bypass valve in the isolation valve.

Extend/Retract

This is an overview of the procedure to manually extend the T/R sleeves:

- Deactivate the IV. (See the section on T/R deactivation for more information.)
- Move the bypass valve handle on the IV so it aligns with the clevis. Install a pin. This keeps the bypass valve open.
- Release the locks on the center actuator, lower actuator, and SL. Push the lock pins in to keep the locks released.
- Use a 3/8 inch square drive on the manual drive unit to extend the sleeve.

NOTE: The bypass valve must be open before you manually extend or retract the T/R sleeve. This will prevent a hydraulic lock, which can prevent movement of the T/R sleeve. But, you must close the bypass valve if you remove T/R components or hydraulic tubing. If you do not close the bypass valve, leakage of the hydraulic fluid from the reservoir will occur when you remove the components or tubing.

NOTE: You must push and hold the 3/8 inch drive in while you turn the manual drive unit. A clutch in the manual drive unit prevents damage to the sync shaft system.

To manually retract the sleeve, do the procedure in the reverse order.

78-36-00-101 Rev 0

THRUST REVERSER (T/R) INDICATING AND FAULT DETECTION - INTRODUCTION

T/R INDICATING AND FAULT DETECTION - GENERAL DESCRIPTION

General

The T/R indicating and fault detection system monitors the TRAS. It sends T/R sleeve, lock, and valve position data to the EEC and the proximity sensor electronics unit (PSEU).

EEC Data

The T/R indicating and fault detection system sends this data to the EEC:

- T/R isolation valve (IV) position with the hydraulic pressure switch
- T/R sleeve position with the RVDT.

The EEC uses the pressure switch data to monitor the position of the IV. The EEC uses the RVDT data to make sure the T/R sleeves are in the correct position before you can increase thrust.

The EEC sends data to the AIMS for these indications:

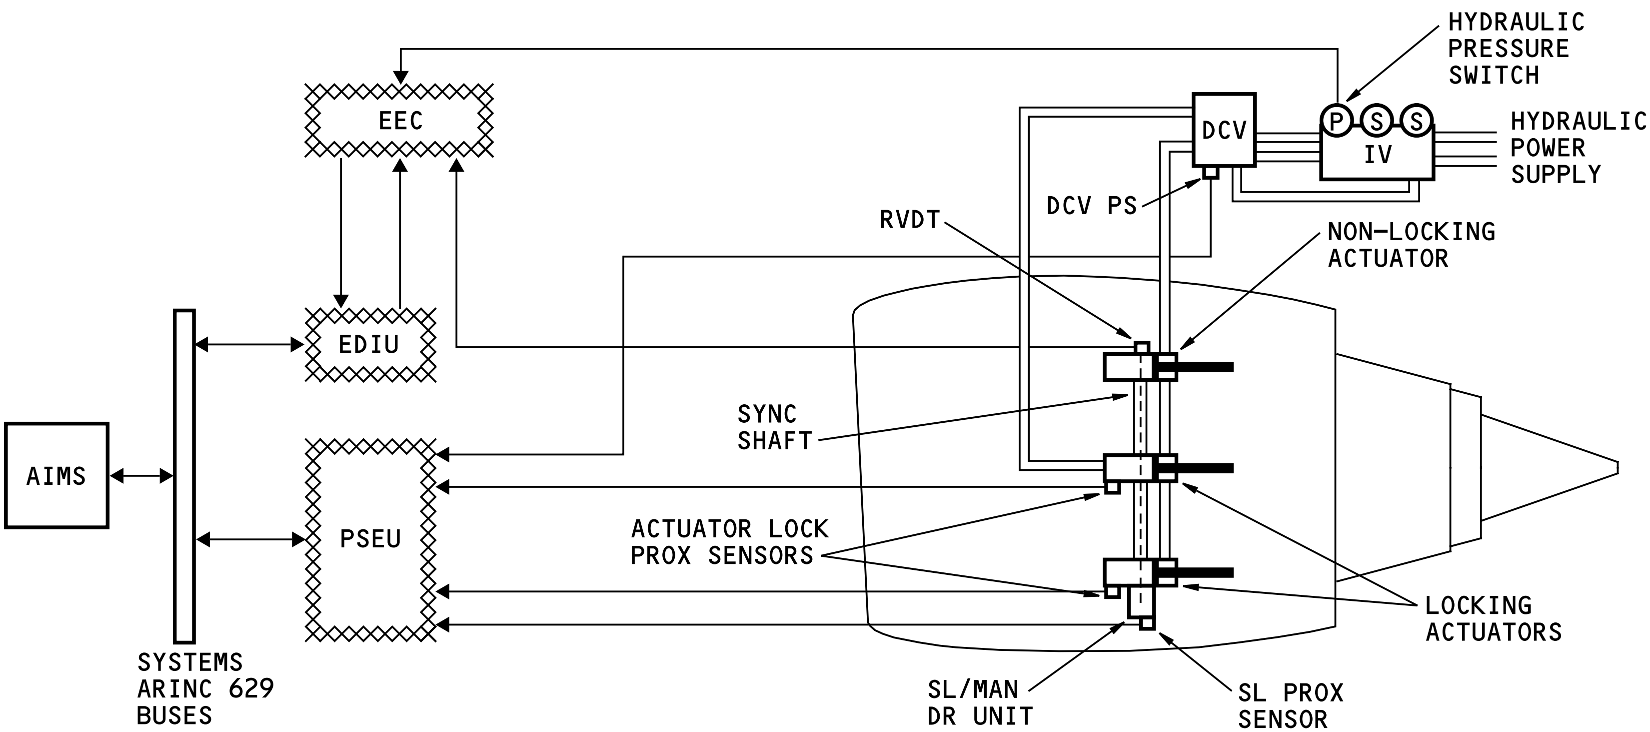
- Normal extend and retract indication
- Alert, status, and maintenance messages if the position of the isolation valve or the T/R sleeve is not correct.

PSEU Data

The T/R on each engine has seven proximity sensors. They send this data to the PSEU:

- DCV position
- Locking hydraulic actuator positions (locked or not locked)
- Sync lock positions (locked or not locked).

The PSEU sends the data to the AIMS to make alert, status, and maintenance messages for non-normal conditions.



78-36-00-102 Rev 1 09/11/1995

T/R INDICATING AND FAULT DETECTION - GENERAL DESCRIPTION

T/R INDICATING AND FAULT DETECTION - ENGINE COMPONENT LOCATIONS

General

All components on the engine are on the forward torque box of the thrust reverser. You open the fan cowl to get access to these components.

Component Locations

There is one RVDT on the non-locking (upper) hydraulic actuator of each thrust reverser half. The RVDT is opposite the sync shaft connection to the actuator.

The actuator lock proximity sensor is on the forward part of each locking hydraulic actuator. The sensor uses a proximity sensor and a target.

The sync lock proximity sensor is on the thrust reverser sync lock/manual drive unit. The sync lock/manual drive unit attaches to the locking (lower) hydraulic actuator on each thrust reverser. The sensor uses a proximity sensor and a target.

T/R INDICATING AND FAULT DETECTION - ENGINE COMPONENT LOCATIONS

T/R INDICATING AND FAULT DETECTION - HYDRAULIC PRESSURE SWITCH AND DCV PROXIMITY SENSOR

Hydraulic Pressure Switch

The hydraulic pressure switch monitors the pressure out of the isolation shutoff valve. It sends a signal to the EEC when the isolation valve is open. If the isolation valve is open when there is no command to extend or retract the reverser, the EEC sends a signal to the AIMS to show an alert or status message.

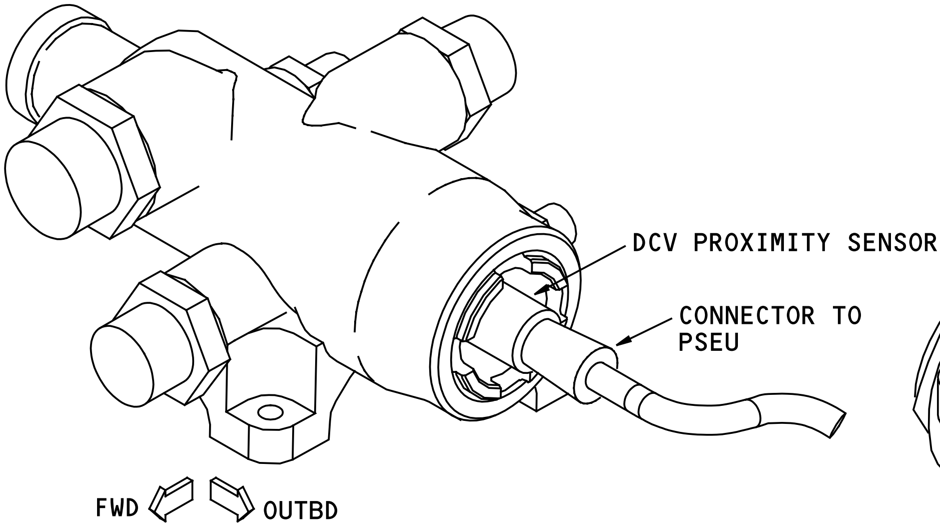
The hydraulic pressure switch is on the forward, left side of the isolation valve. It is near the hydraulic tube that connects to the DCV.

DCV Proximity Sensor

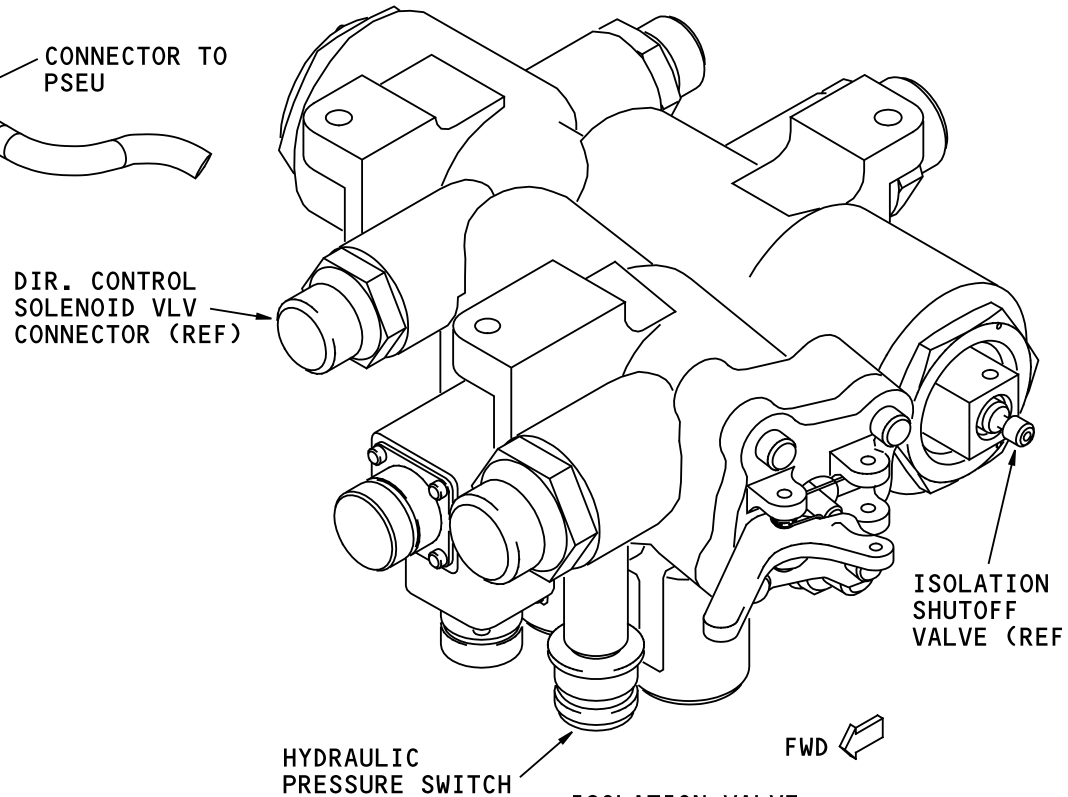
The DCV sensor monitors the position of the directional control valve. The position data goes to the PSEU. If the DCV is in the extend position when there is a retract command, the PSEU sends a signal to the AIMS for fault indication on the flight deck.

The DCV sensor is on the left side of the DCV.

The sensor monitors the position of the spool valve in the DCV (not shown). When the DCV is in the extend position, the spool valve is away from the sensor. When the DCV is in the retract position, the spool valve is near the sensor.



DIRECTIONAL CONTROL VALVE



ISOLATION VALVE

78-36-00-104 Rev 1

T/R INDICATING AND FAULT DETECTION - HYDRAULIC PRESSURE SWITCH AND DCV PROXIMITY SENSOR

T/R INDICATING AND FAULT DETECTION - ACTUATOR LOCK PROXIMITY SENSOR

General

The actuator lock sensor monitors the position of the locking sleeve in each locking hydraulic actuator. It sends the position data to the PSEU.

Each thrust reverser sleeve has two actuator lock sensors. Thus, there are four actuator lock sensors on each engine.

Location

The actuator lock sensors are on the forward end of each locking actuator. You open the fan cowls to get access to the sensors.

Physical Description

Each sensor has two parts: a proximity sensor and a target. The target is part of the lever that connects to the locking sleeve (not shown) in the actuator. The lever is also the lock release lever for the actuator.

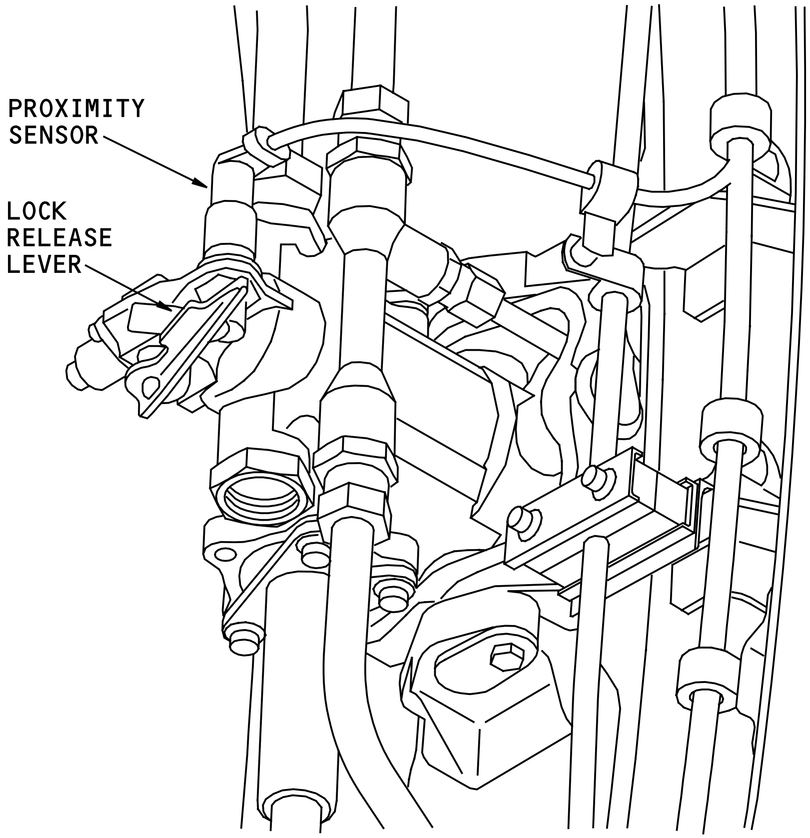
Functional Description

When the actuators get hydraulic pressure, the locking sleeve moves. The target moves away from the sensor. This sends a signal to the PSEU that the actuator is not locked.

If the locking sleeve is not locked when the thrust reverser is in the retracted position, fault indication shows on the flight deck.

Training Information Point

It is not necessary to rig the actuator lock sensors.



LOCKING ACTUATOR

T/R INDICATING AND FAULT DETECTION - ACTUATOR LOCK PROXIMITY SENSOR

T/R INDICATING AND FAULT DETECTION - SYNC LOCK PROXIMITY SENSOR

General

The sync lock proximity sensor monitors the position of the sync lock which attaches to each lower locking hydraulic actuator. It sends the position data to the PSEU.

Each T/R sleeve has one sync lock sensor.

Location

One sensor is on the aft side of the sync lock on the left T/R sleeve. The other sensor is on the forward side of the sync lock on the right T/R sleeve. You open the fan cowls to get access to the sensors.

Physical Description

The sync lock proximity sensor has these parts: a proximity sensor and a target. The target attaches to a lever that connects to the lock mechanism in the sync lock. The lever is also the lock release lever for the sync lock.

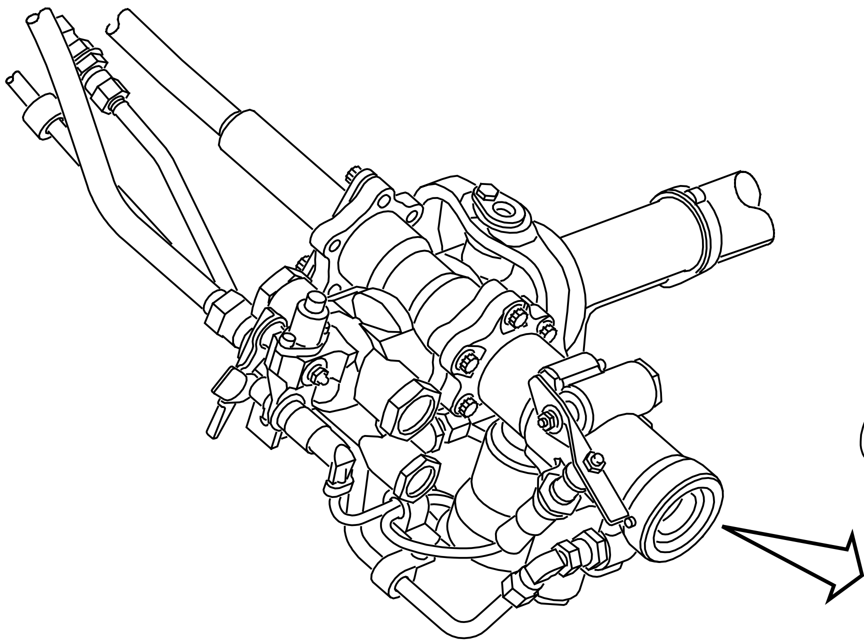
Functional Description

When the sync lock gets hydraulic power, the lock mechanism moves to the released position. Hydraulic pressure and an internal pin keep the lock mechanism in the released position. The target moves away from the sensor. This sends a signal to the PSEU that the actuator is not locked.

If the sync shaft is not locked when the thrust reverser is in the retracted position, fault indication shows on the flight deck.

Training Information Point

When you install a new proximity sensor, you must do a check of the gap between the proximity sensor and the target. There is a nut on the lock release lever so you can adjust the gap.



LOCKING ACTUATOR

T/R INDICATING AND FAULT DETECTION - SYNC LOCK PROXIMITY SENSOR

T/R INDICATING AND FAULT DETECTION - T/R POSITION TRANSDUCER (RVDT)

General

The RVDT sends T/R sleeve position data to the EEC. The EEC will not permit more than idle thrust if the sleeves are less than 60 percent of full extension. The EEC also uses the data to supply flight deck indication of when the sleeve is not in the fully retracted position, and when the sleeve is fully extended.

There is one RVDT on the non-locking (upper) hydraulic actuator of each sleeve. Thus, each engine has two RVDTs.

Location

The RVDT attaches to the upper end of each non-locking actuator. You open the fan cowls to get access to the RVDTs.

Functional Description

Each RVDT has two sets of windings and two output signals. One signal goes to each channel of the EEC.

The RVDT attaches to an extension of the sync shaft through a drive gearbox. When the shaft turns, the RVDT makes a voltage that changes linearly in proportion to the sync shaft position.

Training Information Point

If you replace the RVDT and the drive gearbox together, do not turn the gearbox drive spline.

T/R INDICATING AND FAULT DETECTION - T/R POSITION TRANSDUCER (RVDT)

T/R INDICATING AND FAULT DETECTION - INDICATIONS

General

Flight deck indication of the thrust reverser (T/R) position shows on the EICAS display, status display, and EPCS maintenance page 1. Any system failure that reduces the level of safety of the system shows on both the EICAS display and the status display. There are no alert messages that show in flight. Thus, no crew action is necessary for T/R system faults.

For system faults, the CMCS has maintenance messages to aid in fault isolation.

EICAS Display

T/R position shows above the N1 data on the EICAS display.

When one T/R sleeve extension is 5 percent or more, the amber REV shows on the EICAS display. This tells the flight crew that the T/R is released and in transit.

When both sleeves are 90 percent extended, the amber REV changes to green. This tells the flight crew that the T/R is fully extended.

If the airspeed is less than 80 kts, a system failure that reduces the level of safety causes the ENG REVERSER L(R) advisory message to show.

Status Display

The ENG REVERSER L(R) status message shows for any failures that may reduce the system level of safety.

The ENG REVERSER SNSR L(R) status message shows for sensor or sensor circuit faults. This message does not show if the ENG REVERSER L(R) message shows.

EPCS Maintenance Page

T/R sleeve position shows on the EPCS maintenance page 1. For each EEC channel, the data shows for both the left and right sleeves. The range is from zero percent (fully retracted) to 100 percent (fully extended).

T/R INDICATING AND FAULT DETECTION - INDICATIONS

T/R INDICATING AND FAULT DETECTION - FUNCTIONAL DESCRIPTION - EEC INPUTS

General

The EEC gets data from thrust reverser (T/R) sensors to make sure these conditions occur:

- The isolation valve sends pressure to the hydraulic actuators only during T/R extend and retract operation
- The engine operates above idle thrust only when the T/R is in the fully extended position
- The flight deck gets proper indication of normal and non-normal T/R operation.

This data comes from the hydraulic pressure switch on the isolation valve and the RVDTs.

Hydraulic Pressure Switch

The hydraulic pressure switch signal goes to both channels of the EEC. The switch closes when the isolation valve is open. If the switch shows that the valve is open without an open command, the EEC sends a signal to the AIMS to show advisory and status messages.

If the isolation valve does not open when it gets an EEC command to open, the EEC sends a signal to the AIMS for central maintenance computing system (CMCS) maintenance messages.

T/R Position Transducer (RVDT)

Each EEC channel gets data from the RVDT on each non-locking (upper) hydraulic actuator. The EEC uses this data to:

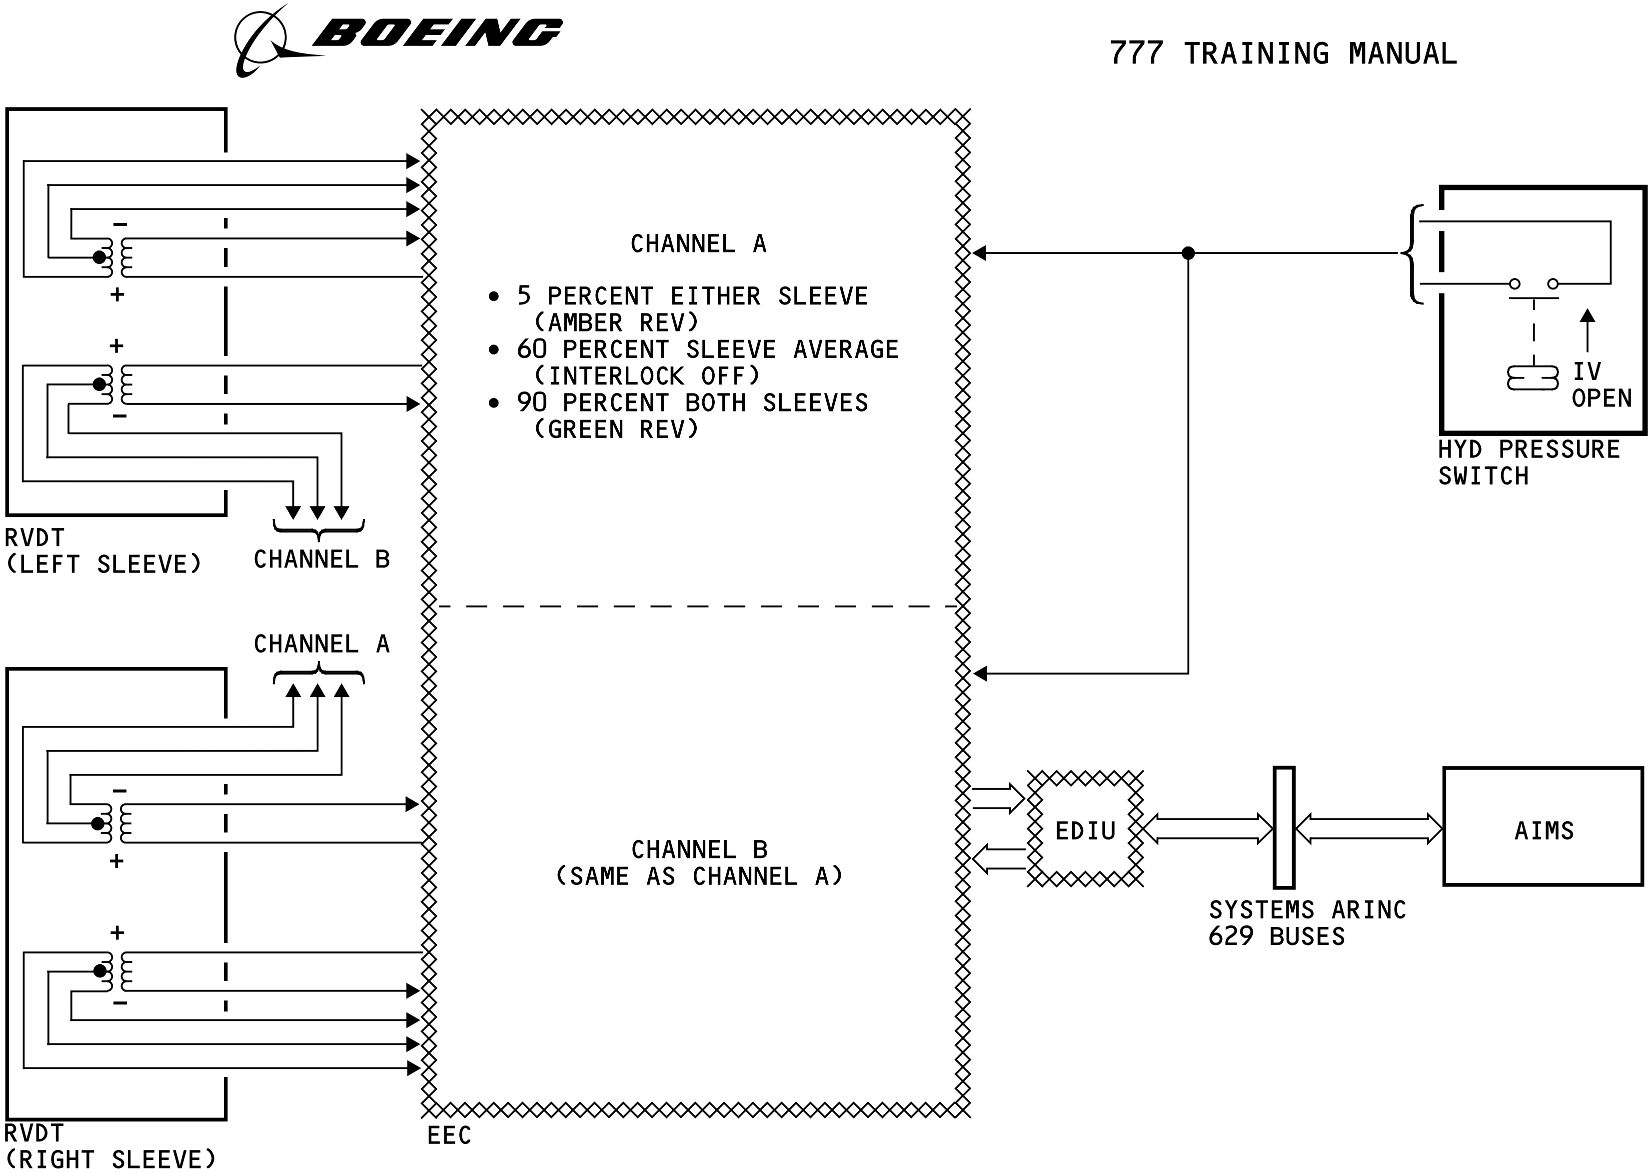
- Operate the thrust lever interlock actuator
- Send indication data to the AIMS
- Schedule reverse thrust.

When either T/R sleeve extension is 5 percent, the EEC sends a signal to the AIMS to show the amber REV on the EICAS display. This tells the flight crew that the T/R is released and in transit.

When the average of the sleeve extensions is 60 percent, the EEC sends a signal to the ELMS to operate the thrust lever interlock actuator. This permits the flight crew to command more than reverse idle thrust.

When both T/R sleeves are 90 percent extended, the EEC sends a signal to the AIMS to change the amber REV to green. This tells the flight crew that the T/R is fully extended. The EEC will permit maximum thrust based on the command from the flight crew.

The EEC does a rate and range check on the position data to make sure the RVDT data is valid.



NOTE: LEFT ENGINE SHOWN, RIGHT SIMILAR

T/R INDICATING AND FAULT DETECTION - FUNCTIONAL DESCRIPTION - EEC INPUTS

78-36-00-109 Rev 3

T/R INDICATING AND FAULT DETECTION - FUNCTIONAL DESCRIPTION - PSEU INPUTS

General

The PSEU gets data from these sensors to make sure the actuators and valves are in the correct positions:

- DCV sensor
- Actuator lock sensor
- Sync lock sensor.

The PSEU sends signals to the AIMS through the systems ARINC 629 buses.

Sensors Show Not Locked

If any of the locks are not locked and the sleeve is in the retracted position, the AIMS shows advisory and status messages.

If the DCV is in the extended position without an extend command, the AIMS shows advisory and status messages.

Sensor Failure

If there is a single failure in a sensor, or in a sensor circuit, the AIMS shows the ENG REVERSER SNSR L(R) status message. The AIMS also makes a CMCS maintenance message.

AUXILIARY POWER SYSTEM - INTRODUCTION

Purpose

The AlliedSignal Engines 331-500 gas turbine APU supplies the auxiliary power system with electric and pneumatic power. This permits airplane systems to operate independently of ground external power sources or the main engines. Auxiliary power is also available in the air.

Operating Limits

The APU generator supplies 120 KVA electrical power at any altitude. Pneumatic pressure is available up to an altitude of 22,000 feet (6700 m).

Specifications

The dimensions and weights shown do not include the air inlet duct, the exhaust duct, and the APU generator.

Abbreviations and Acronyms

ADIRU - air data inertial reference unit
ADP - air-driven pump
AIMS - airplane information management system
APU - auxiliary power unit
APUC - auxiliary power unit controller
ARINC - aeronautical radio, inc.
ASCPC - air supply and cabin pressure controller
ATS - air turbine starter
ATSCV - air turbine starter control valve
BPCU - bus power control unit
CTC - cabin temperature controller
DLODS - duct leak and overheat detection system
DMM - data memory module
dr - door
ECS - environmental control system
EDIU - engine data interface unit
EGT - exhaust gas temperature
EHSV - electrohydraulic servo valve
ELMS - electrical load management system
FODC - fire overheat detection card
GCU - generator control unit
HYDIM - hydraulic interface module
IGV - inlet guide vanes
LVDT - linear variable differential transformer
LRU - line replaceable unit
MFD - multi-function display
OPAS - overhead panel ARINC system
PPM - pounds per minute
PSI - pounds per square inch
PSIA - pounds per square inch absolute
PSID - pounds per square inch differential
PSIG - pounds per square inch gage
RPM - revolutions per minute
RVDT - rotary variable differential transformer
SCV - surge control valve
SHP - shaft horsepower
S/O - shutoff
temp - temperature
WOW - weight on wheels

AUXILIARY POWER SYSTEM - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

AUXILIARY POWER SYSTEM - GENERAL DESCRIPTION

General

The APU system contains these subsystems:

- APU control system (49-60)
- APU power plant (49-10)
- APU engine (49-21)
- APU and generator lubrication system (49-27)
- APU oil indicating system (49-94).
- APU engine fuel system (49-30)
- APU ignition/starting system (49-40)
- APU air (49-50)
- APU indicating system (49-70)
- APU exhaust system (49-80).

APU Control System

An APU controller controls APU system functions and is an interface with other airplane systems.

APU Power Plant

The APU is a single shaft gas turbine engine which drives an electric generator and a load compressor. A gearbox on the front of the APU supplies power to APU accessories.

The power plant has these systems and components:

- Auxiliary power unit
- APU mounts
- APU wire harness
- APU air inlet
- APU drains.

APU Engine

The APU engine has a two stage centrifugal flow compressor, a reverse flow annular combustion chamber, and a three stage axial flow turbine.

APU and Generator Lubrication System

The APU and generator lubrication system lubricates and cools the APU bearings, the gearbox, and the electric generator.

APU Oil Indication System

The oil indication system supplies APU oil temperature, pressure, and quantity for flight deck display.

APU Engine Fuel System

The APU engine fuel system supplies pressurized and metered fuel to the APU combustion chamber. It also supplies pressurized fuel to operate the inlet guide vanes and the surge control valve.

APU Ignition/Starting System

During engine start, the ignition/starting system turns the APU and supplies ignition.

AUXILIARY POWER SYSTEM - GENERAL DESCRIPTION

APU Air System

The APU air system supplies pressurized air to the airplane pneumatic system. Inlet guide vanes control the amount of air supplied to the load compressor. A surge control valve releases excess bleed air overboard. An eductor removes APU compartment air by suction through the oil cooler to cool engine oil.

APU Indicating System

The APU indicating system supplies APU EGT data for flight deck display. A data memory module keeps APU operation data.

APU Exhaust System

The APU exhaust system sends the APU exhaust gasses out of the left side of the tailcone.

AUXILIARY POWER SYSTEM - GENERAL DESCRIPTION

AUXILIARY POWER SYSTEM - INTERFACES

General

The APUC gets airplane system data and sends APU data to airplane systems through the left and right system ARINC 629 data buses. The APUC also sends and receives some data through other connections.

ARINC 629 Interfaces

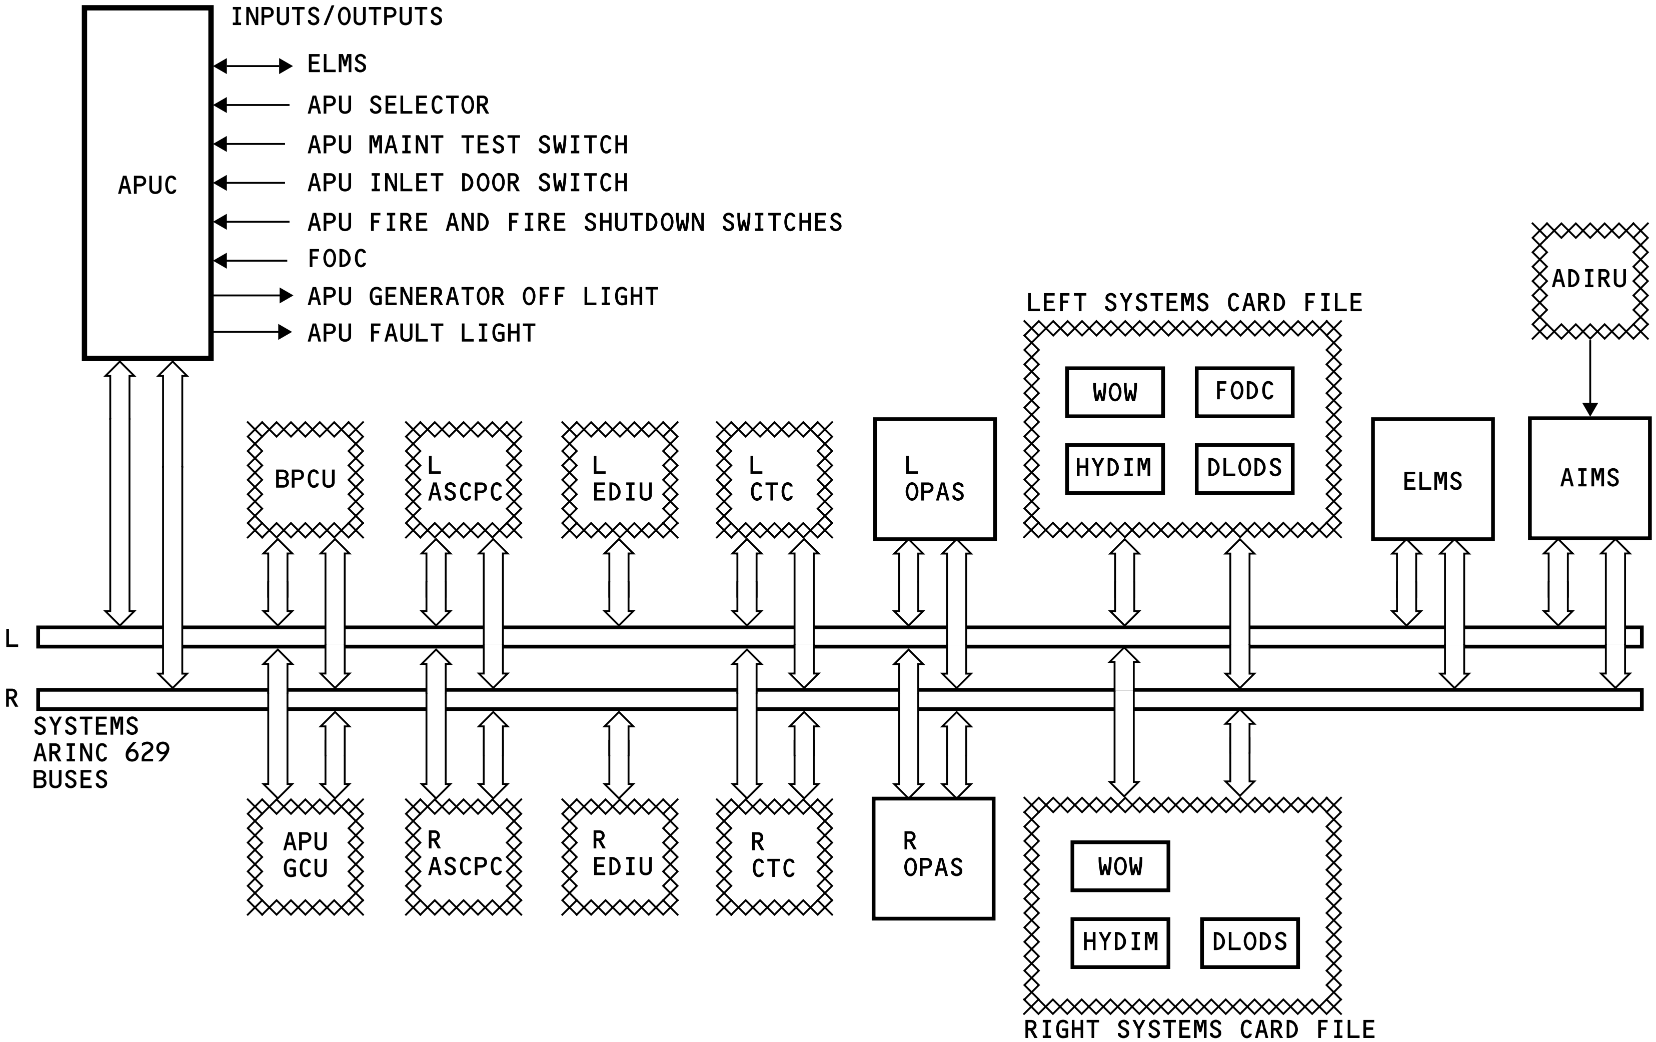
These systems have interfaces with the APUC through systems ARINC 629 buses:

- Bus power control unit (BPCU) - generator trim frequency
- APU generator control unit (GCU) - generator load
- Left and right air supply cabin pressure controller (ASCPC) - pneumatic valve positions, pack operation, and pneumatic duct pressure
- Left and right engine data interface unit (EDIU) - engine data
- Left and right cabin temperature controller (CTC) - pneumatic valve position and ECS data
- Left and right overhead panel ARINC 629 system (OPAS) - overhead panel switch/selector positions
- Left and right weight on wheels (WOW) cards - air/ ground condition
- Hydraulic interface module (HYDIM) cards - ADP operation data
- Fire overheat detection card (FODC) - APU fire
- Left, right, and center duct leak and overheat detection system (DLODS) - wing/body duct overheat
- Electrical load management system (ELMS) - start control, shutdown control, autostart, attended/ unattended mode
- Airplane information management system (AIMS) engine running status, air data (from ADIRU), airplane data, fault reporting, indications.

Other Interfaces

The APUC also has interfaces with these systems and components without ARINC 629:

- Electrical load management system (ELMS)
- The APU selector
- The APU maintenance switch
- The APU inlet door switch
- APU fire switch and fire shutdown switch
- Fire overheat detection card (FODC)
- APU generator OFF light
- APU fault light.



AUXILIARY POWER SYSTEM - INTERFACES

AUXILIARY POWER SYSTEM - COMPONENT LOCATIONS

General

The APU is in the tailcone at a 10 degree nose down attitude in relation to the tail of the airplane. A titanium firewall isolates the APU compartment from the rest of the airplane.

Ducts

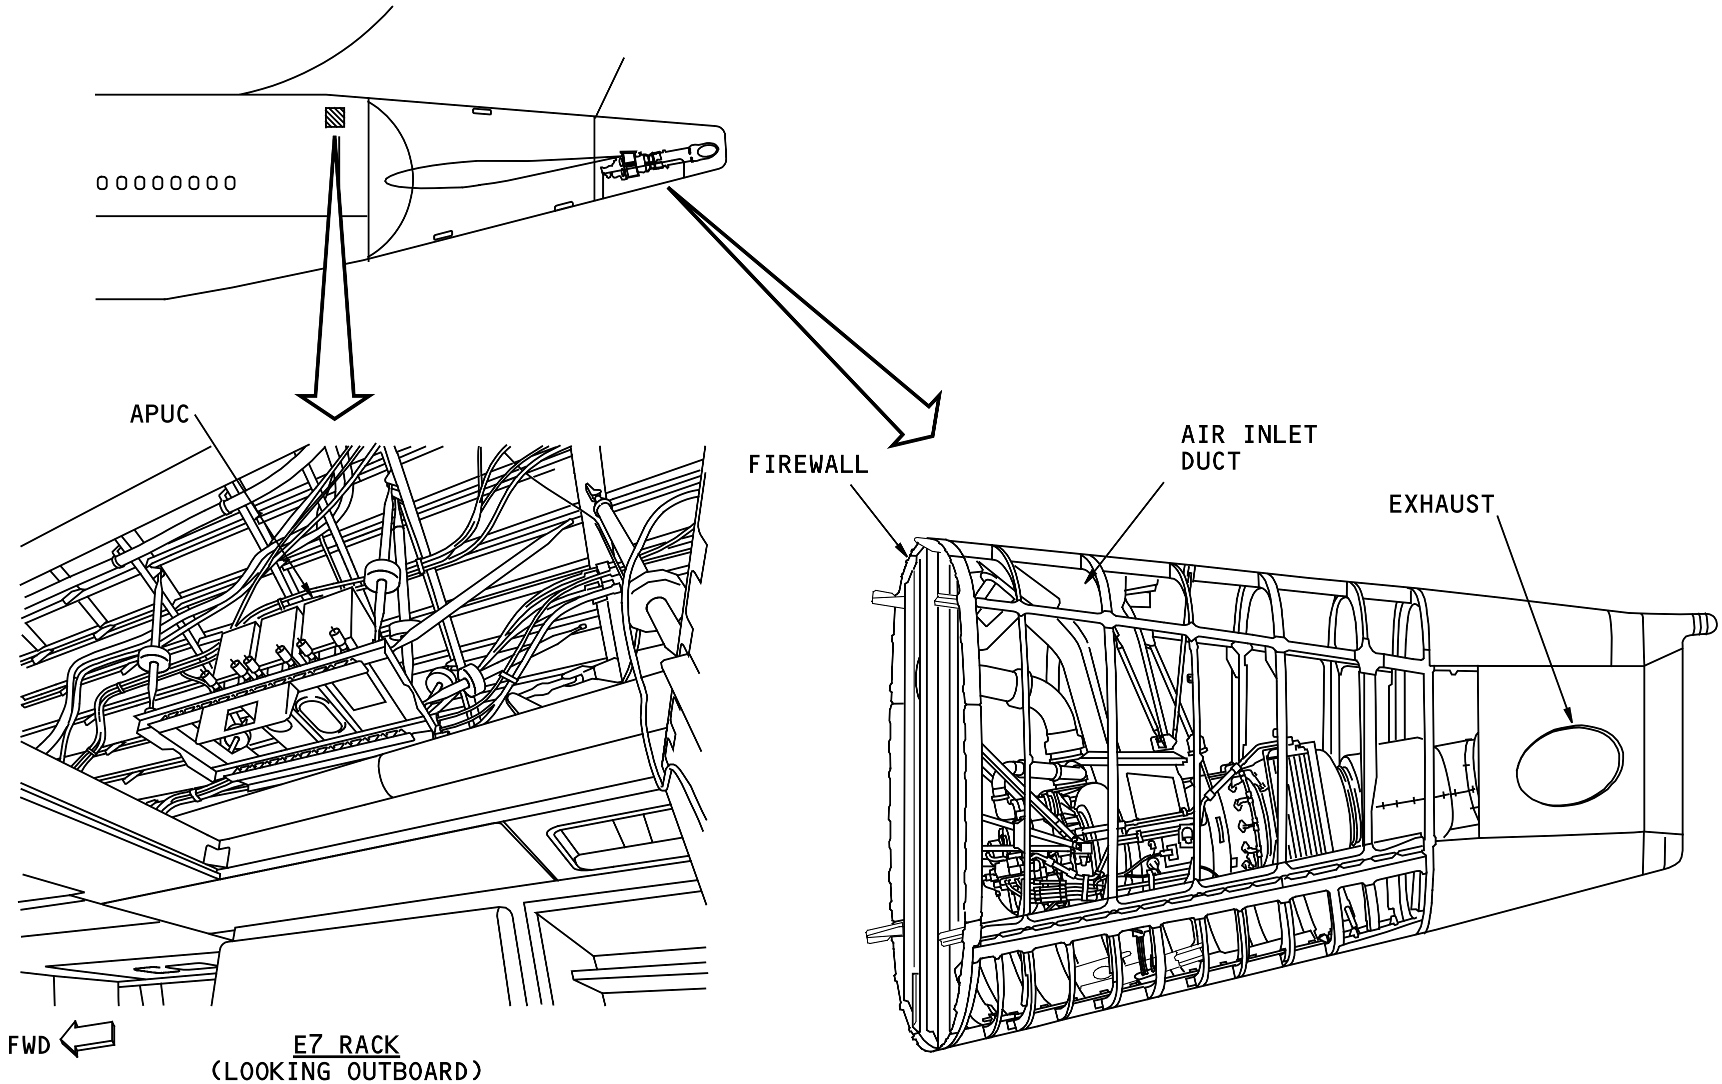
The air inlet is on the top, right side of the fuselage behind the rudder. The APU exhaust gases exit on the left side of the tail fairing.

Doors

Two APU access doors on the bottom of the APU compartment permit service and maintenance access.

APU Controller

The APU controller (APUC) is in the E7 rack in the ceiling of the aft cabin.



49-00-00-003 Rev 2 12/19/95

AUXILIARY POWER SYSTEM - COMPONENT LOCATIONS

AUXILIARY POWER SYSTEM - APU GENERATOR

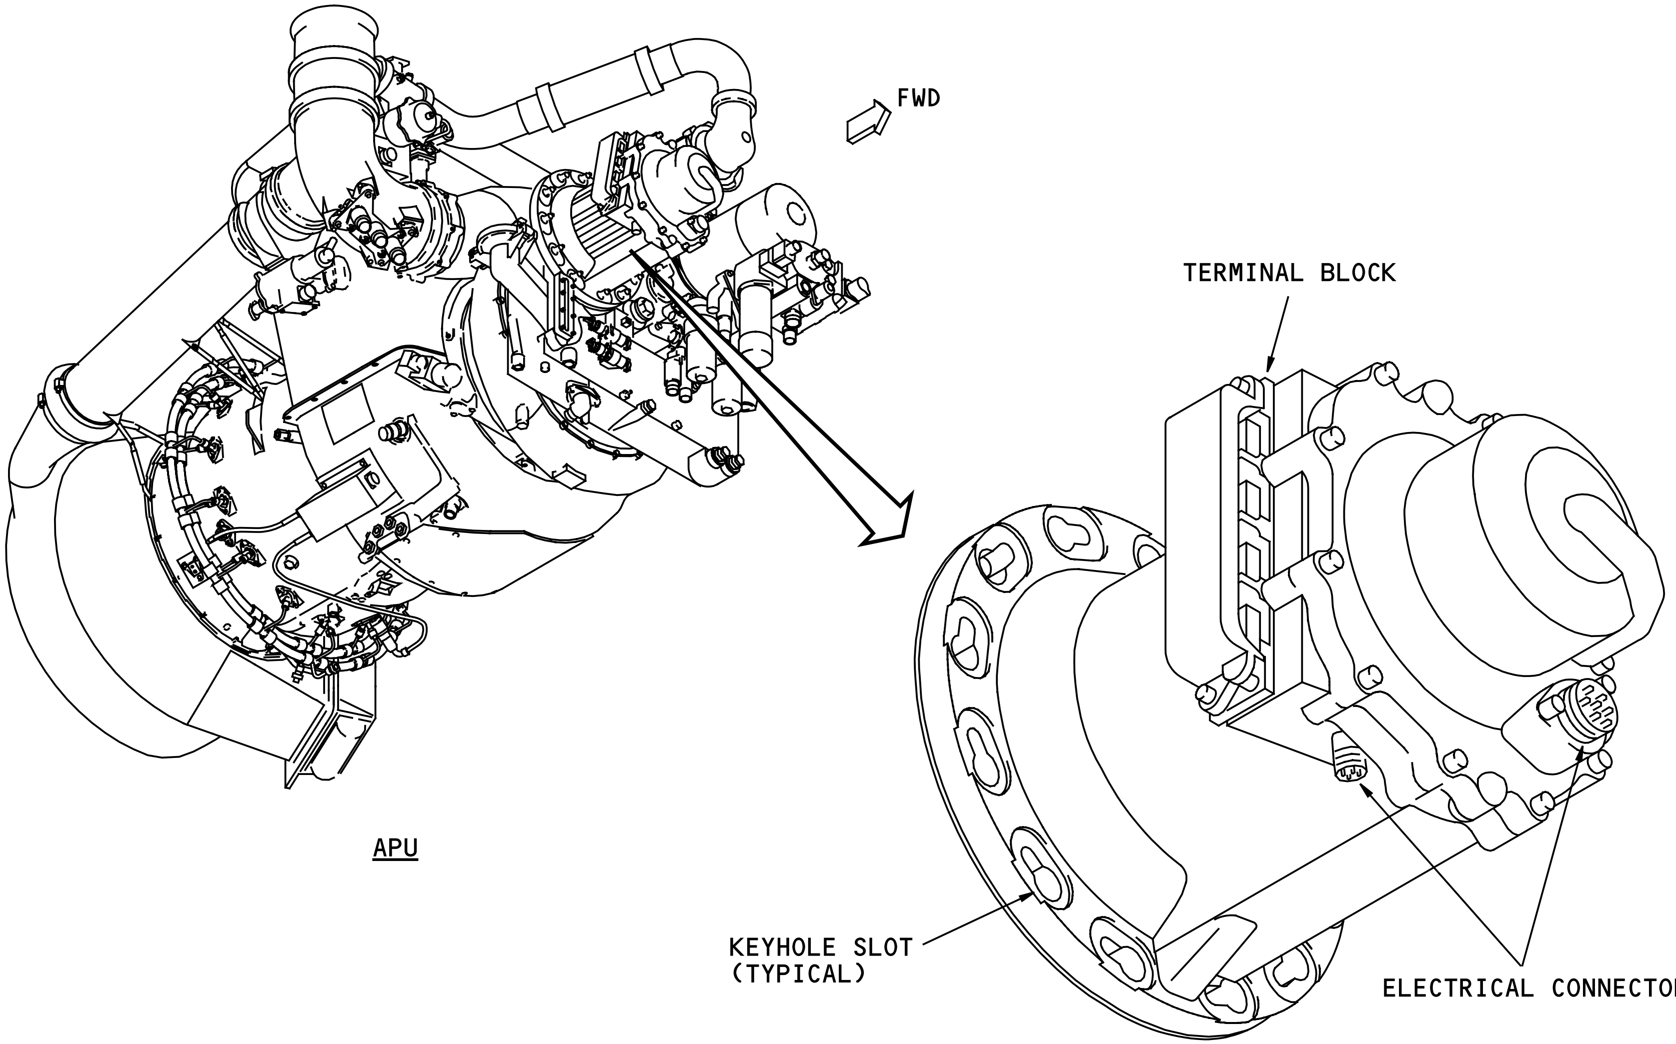
General

The APU generator is a secondary source of electrical power for airplane systems. It can supply 120 kva of ac electrical power when the airplane is on the ground or during flight. See chapter 24 for more information on the electrical system.

The APU generator attaches to the accessory pad of the APU gearbox.There is a seal plate between the APU generator and the APU gearbox.

The APU generator has a terminal block and two electrical connectors.

The APU gearbox turns the APU generator. The APU oil system lubricates the APU generator and keeps it cool.



AUXILIARY POWER SYSTEM - APU GENERATOR

AUXILIARY POWER SYSTEM - CONTROLS

APU Flight Deck Controls

These control the APU from the flight deck:

- The APU selector
- The APU maintenance switch
- The APU fire switch.

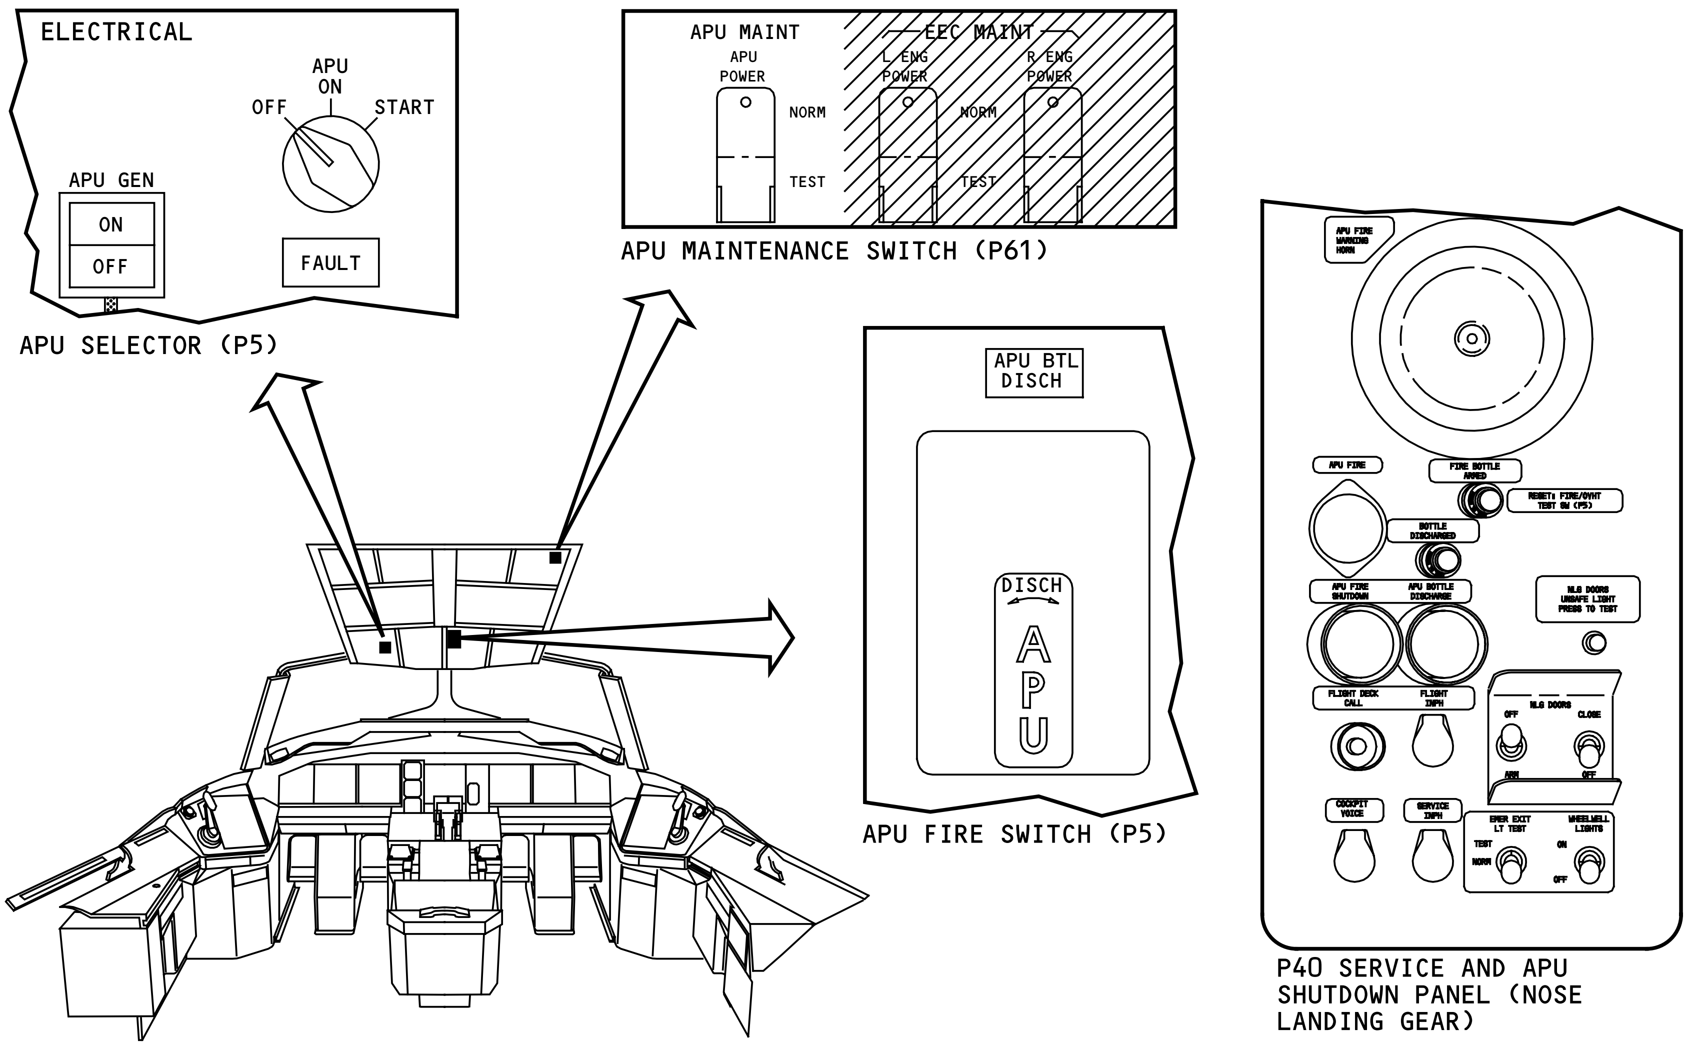
You use the APU selector on the electrical panel (P5) to start and shut down the APU.

You use the APU maintenance switch on the P61 overhead maintenance panel to supply power to the APUC when the APU selector is OFF. This permits the APUC to show APU indications on the status and maintenance page formats.

You can shutdown the APU with the APU fire switch on the cargo fire/engine control panel (P5).

Auxiliary Shutdown Control Switch

You can shutdown the APU from outside the airplane with the APU fire shutdown switch. This switch is on the P40 service and APU shutdown panel on the nose landing gear strut.



49-00-00-005 Rev 2 07/27/1995

AUXILIARY POWER SYSTEM - CONTROLS

APU CONTROL SYSTEM - INTRODUCTION

Purpose

The APU control system uses an APU controller to control these APU functions:

- Starting and ignition
- Fuel metering
- Surge control
- Inlet guide vane (IGV) control
- Data Storage
- Protective shutdown
- BITE/fault reporting
- APU indication.

System Components

The other control system components are:

- The speed sensor (2)
- The inlet temperature sensor.

These sensors supply data to the APUC for control functions.

Location

The APUC is on the E7 rack above the aft galley. The two APU speed sensors and the inlet temperature sensor are on the sides of the APU.

APU CONTROL SYSTEM - INTRODUCTION

APU CONTROL SYSTEM - APU CONTROLLER - INTRODUCTION

Purpose

The APUC controls APU functions. The APUC also contains circuits for fault detection and isolation.

APUC Modes

The APUC operates in one of these eight operating modes:

- Test mode - APUC doing power-up test
- Idle mode - APUC powered and APU is not on.
- Start - air mode - APU is doing an air start
- Start - electric mode - APU is doing an electric start
- Onspeed mode - APU RPM is more than 95 percent
- Cooldown mode - APU is in the cooldown mode
- Shutdown mode - APU RPM is less than 15 percent during APU shutdown
- Auto-shutdown mode - the APUC is doing an APU protective shutdown.

Location

The APUC is on the E7 rack above the aft galley.

Training Information Point

The APUC is an LRU. The circuit cards in the APUC are not LRUs.

You must remove a ceiling panel above the aft galley to get access to the APUC.

CAUTION: DO NOT REMOVE THE APUC AND THE DATA MEMORY MODULE AT THE SAME TIME. IF YOU REMOVE THE APUC AND THE DATA MEMORY MODULE AT THE SAME TIME, YOU WILL LOSE THE DATA FOR THE APU.

APU CONTROL SYSTEM - APU CONTROLLER - INTRODUCTION

APU CONTROL SYSTEM - APU CONTROLLER - INPUTS

General

The APUC gets inputs from both airplane systems and the APU.

The APUC receives 28v dc power from both the 28v dc battery bus and the 28v dc APU battery bus.

Airplane Systems ARINC 629 Inputs

The APUC receives these airplane system inputs through the left and right ARINC 629 system buses:

- Pneumatic duct pressure
- APU fuel shutoff valve position
- ECS data
- Main engine start/run
- Air driven pumps (ADPs) ON
- Electrical system demand
- Air/ground indication
- Date/time
- Air data
- APU bleed valve position.

Airplane Systems Discrete Inputs

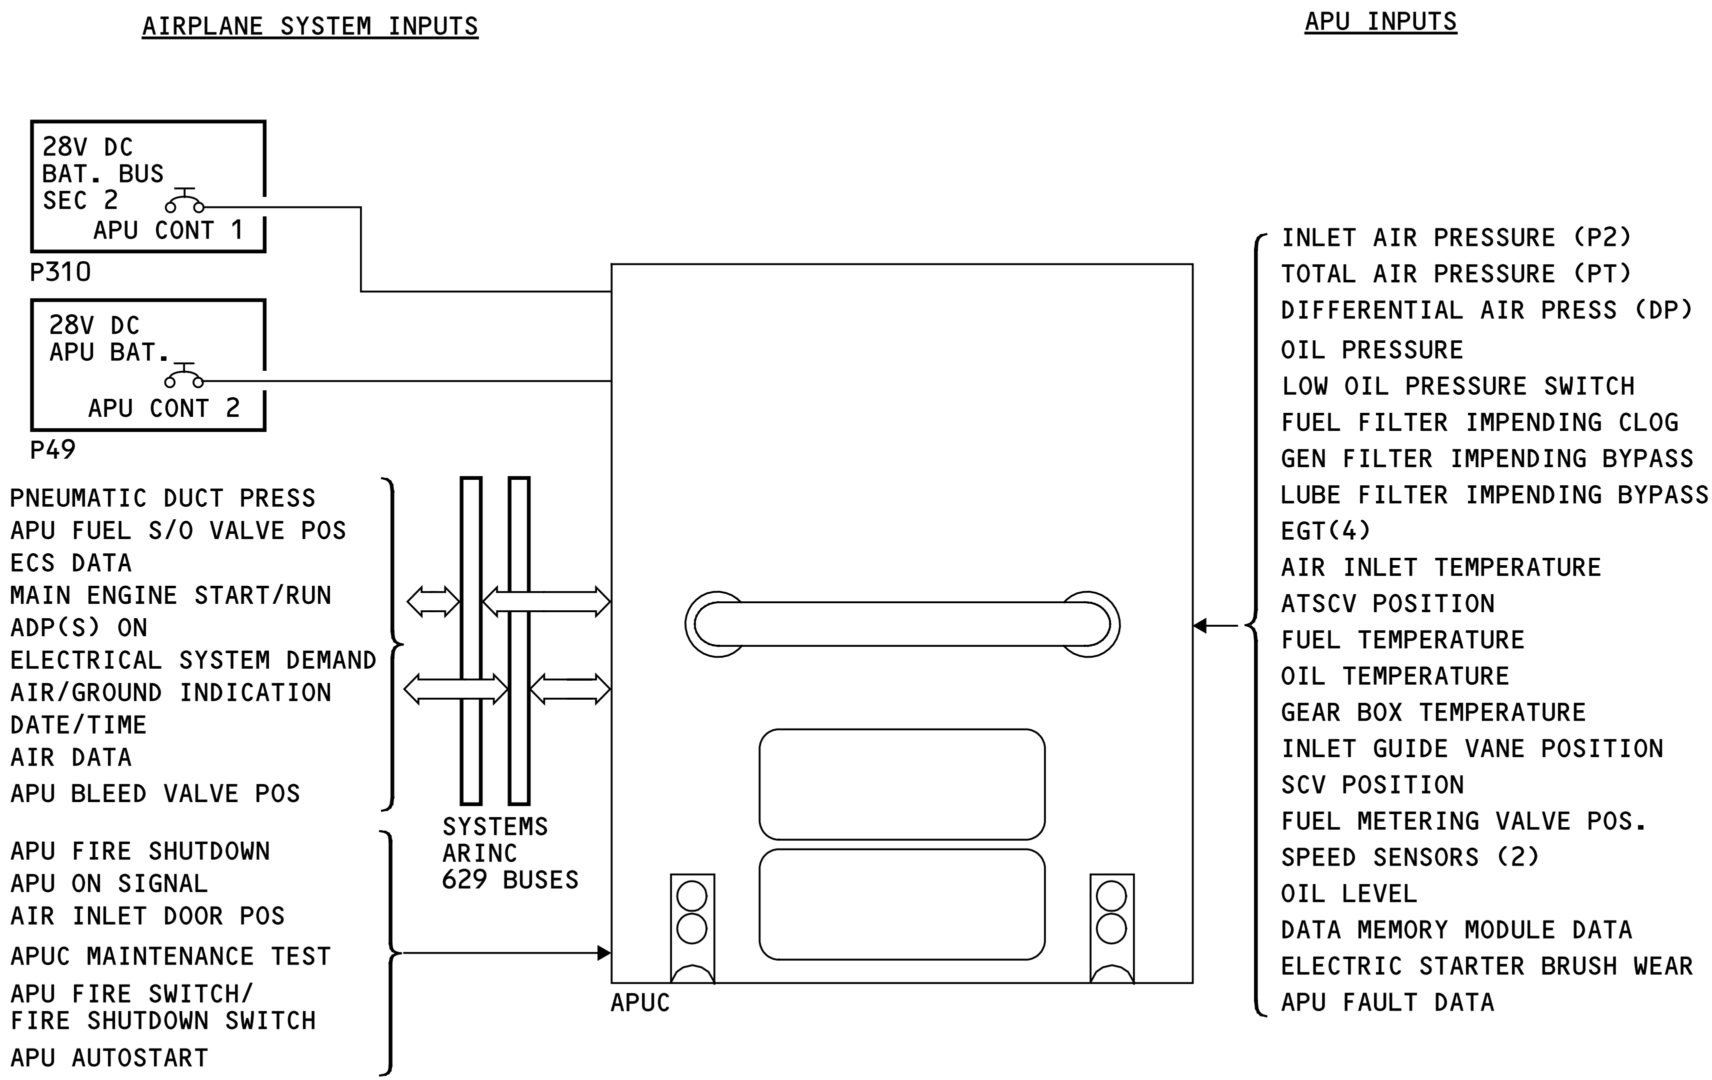
The APUC also receives other airplane systems inputs. These inputs include:

- APU fire shutdown
- APU ON signal
- Air inlet door position
- APUC maintenance test
- APU fire switch/fire shutdown switches
- APU autostart.

APU Inputs

Inputs from the APU to the APUC are:

- Inlet air pressure (P2)
- Total air pressure (PT)
- Differential air pressure (DP)
- Oil pressure
- Low oil pressure switch
- Fuel filter impending clog
- Generator filter impending bypass
- Lube filter impending bypass
- EGT (4)
- Air inlet temperature
- Fuel temperature
- Oil temperature
- Gear box temperature
- IGV position
- SCV position
- Fuel metering servo valve position
- ATSCV position
- Speed sensors (2)
- Oil level
- Data memory module data
- Electric starter motor brush wear
- APU fault data.



49-60-00-004 Rev 2

APU CONTROL SYSTEM - APU CONTROLLER - INPUTS

APU CONTROL SYSTEM - APU CONTROLLER - OUTPUTS

General

The APUC supplies APU data to airplane systems and controls some APU functions.

APUC ARINC 629 Outputs

The APUC supplies this APU data to the airplane through the left and right systems ARINC 629 buses:

- EGT
- Air inlet temperature
- APU speed
- Oil quantity
- Oil pressure
- Gearbox temperature
- Fuel temperature
- Generator load available
- APU fault data
- APU shutdown data
- IGV angle
- SCV angle
- Pressure sensor data
- Ignitor ON/OFF
- Fuel shutoff solenoid ON/OFF
- Filter clog sensor status (3)
- Low oil pressure status
- Electric starter brush wear
- Maintenance test status.

Other APUC Airplane System Outputs

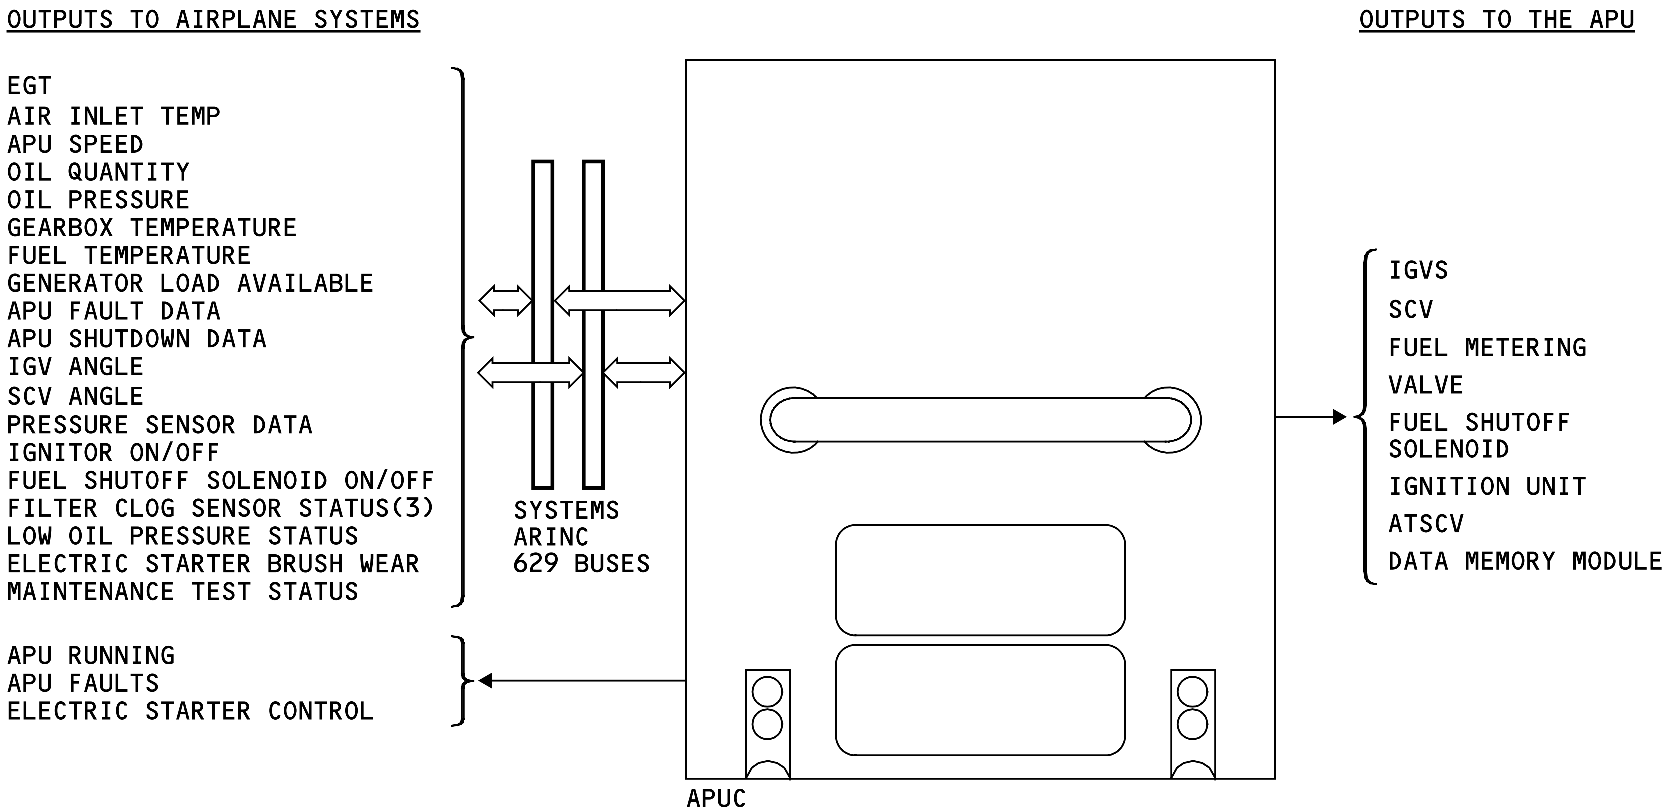
The APUC also sends these signals on non-ARINC 629 connections:

- APU running status
- APU fault indication
- APU starter control.

APUC Outputs to the APU

The APUC sends signals to control these APU components:

- IGVs
- SCV
- Fuel metering valve
- Fuel shutoff solenoid
- Ignition unit
- Air turbine starter control valve
- Data memory module.



49-60-00-005 Rev 3

APU CONTROL SYSTEM - APU CONTROLLER - OUTPUTS

APU CONTROL SYSTEM - APU CONTROLLER - FAULT MONITORING

General

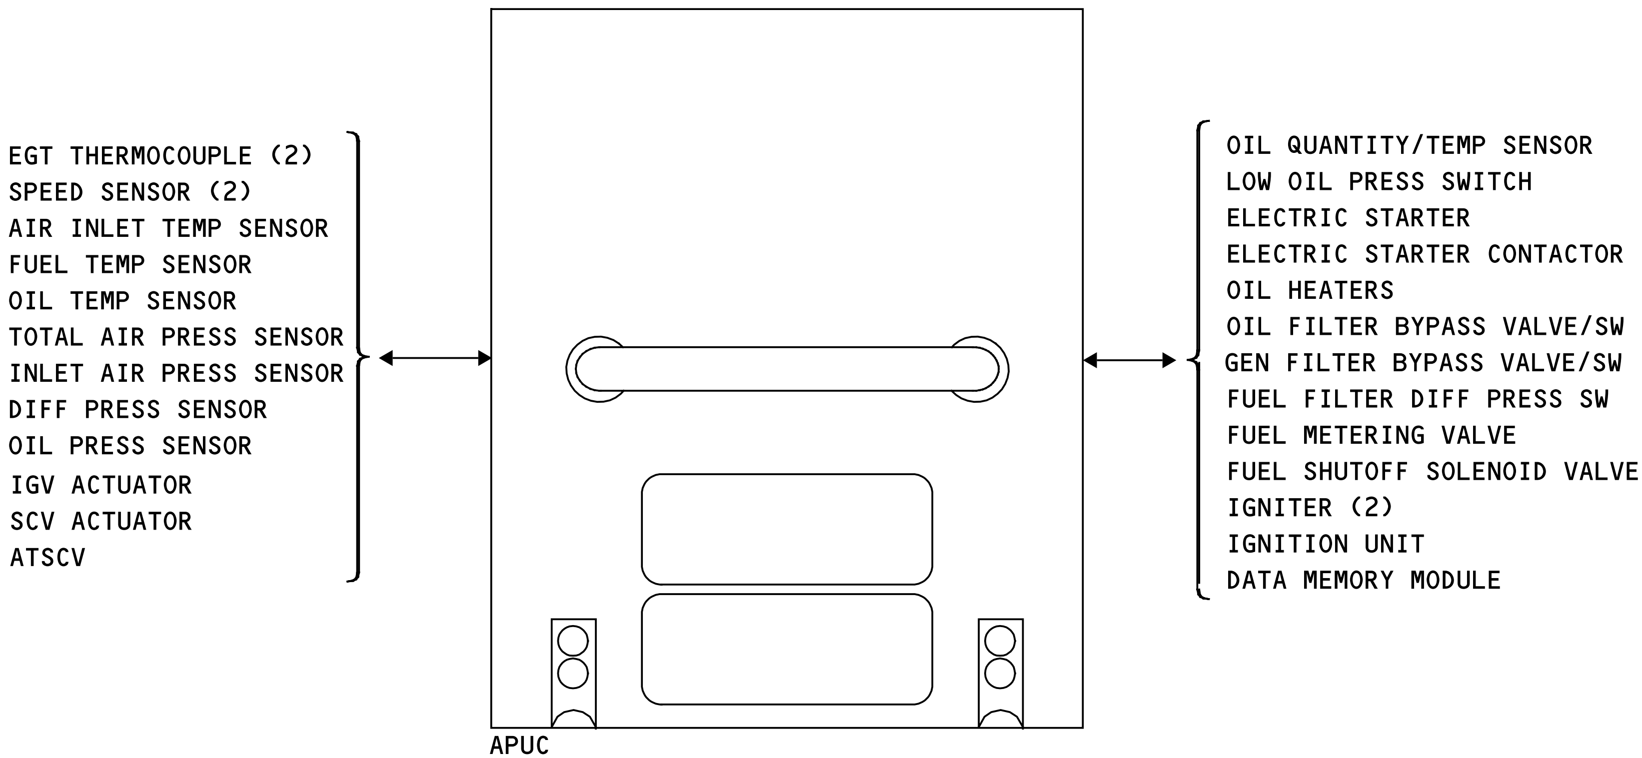
The APUC does tests of APU components and the internal functions of itself. The APUC tests some components continuously and others only when the APU is in a specific mode (power-up, power-down, shutdown).

The APUC memory holds 256 faults. When the memory is full, new faults record over the oldest faults.

APU Faults

The APUC monitors these APU components:

- EGT thermocouple (2)
- Speed sensor (2)
- Air inlet temperature sensor
- Fuel temperature sensor
- Oil temperature sensor
- Total air pressure sensor
- Inlet air pressure sensor
- Differential pressure sensor
- Oil pressure sensor
- IGV actuator
- Surge control valve actuator
- ATSCV
- Oil quantity/temperature probe
- Low oil pressure switch
- Electric starter (brush wear)
- Electric starter contactor
- APU oil heater assembly
- Oil filter bypass valve/switch
- Generator filter bypass valve/switch
- Fuel filter differential pressure switch
- Fuel metering valve
- Fuel shutoff solenoid valve
- Igniter (2)
- Ignition unit
- Data memory module.



49-60-00-006 Rev 0

APU CONTROL SYSTEM - APU CONTROLLER - FAULT MONITORING

APU CONTROL SYSTEM - SPEED SENSORS

Purpose

Two speed sensors measure APU shaft speed and supply the data to the APUC for control and display functions.

Location

The speed sensors are on each side of the compressor section.

Functional Description

The speed sensors are variable reluctance motion sensors. Each speed sensor sends a signal with a frequency in proportion to engine RPM. The APUC selects the higher of the two signals for control and display functions.

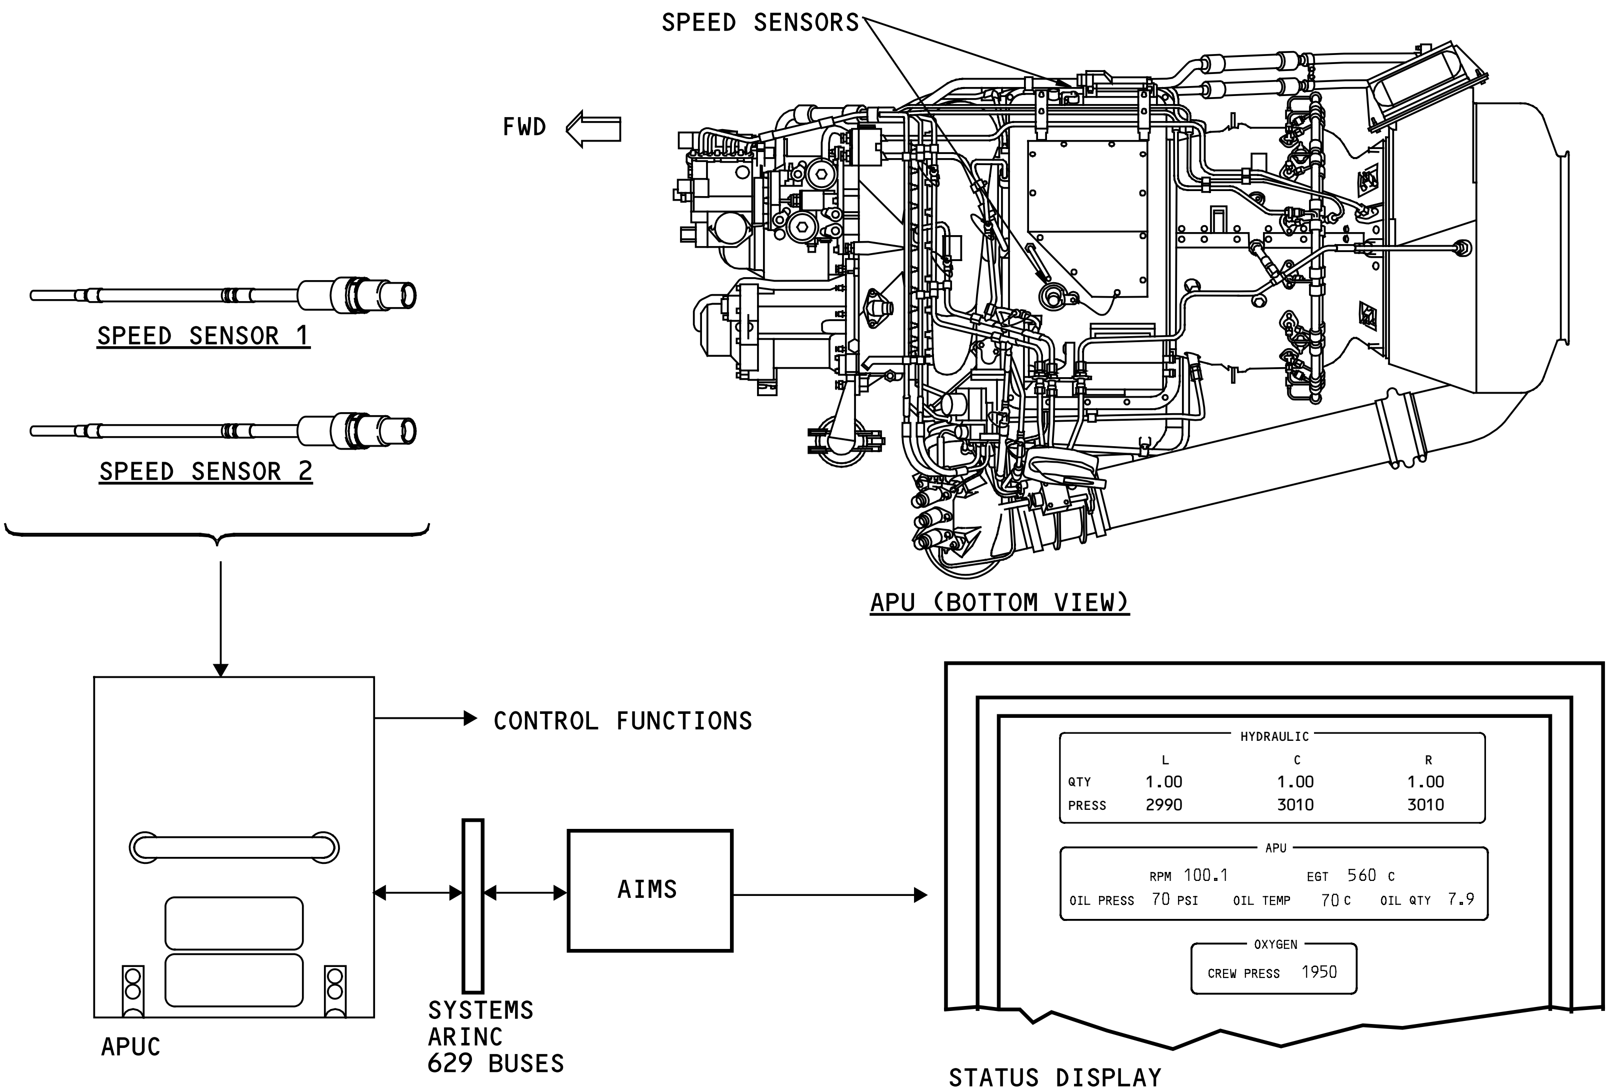
Control

The APUC uses engine speed to control these functions:

- Ignition system control
- Starter system control
- Fuel system control
- Engine speed control
- Overspeed automatic shutdown protection
- No-acceleration automatic shutdown protection.

Indications

APU engine RPM shows on the status display and the maintenance page.



49-60-00-007 Rev 2

APU CONTROL SYSTEM - SPEED SENSORS

APU CONTROL SYSTEM - INLET TEMPERATURE SENSOR

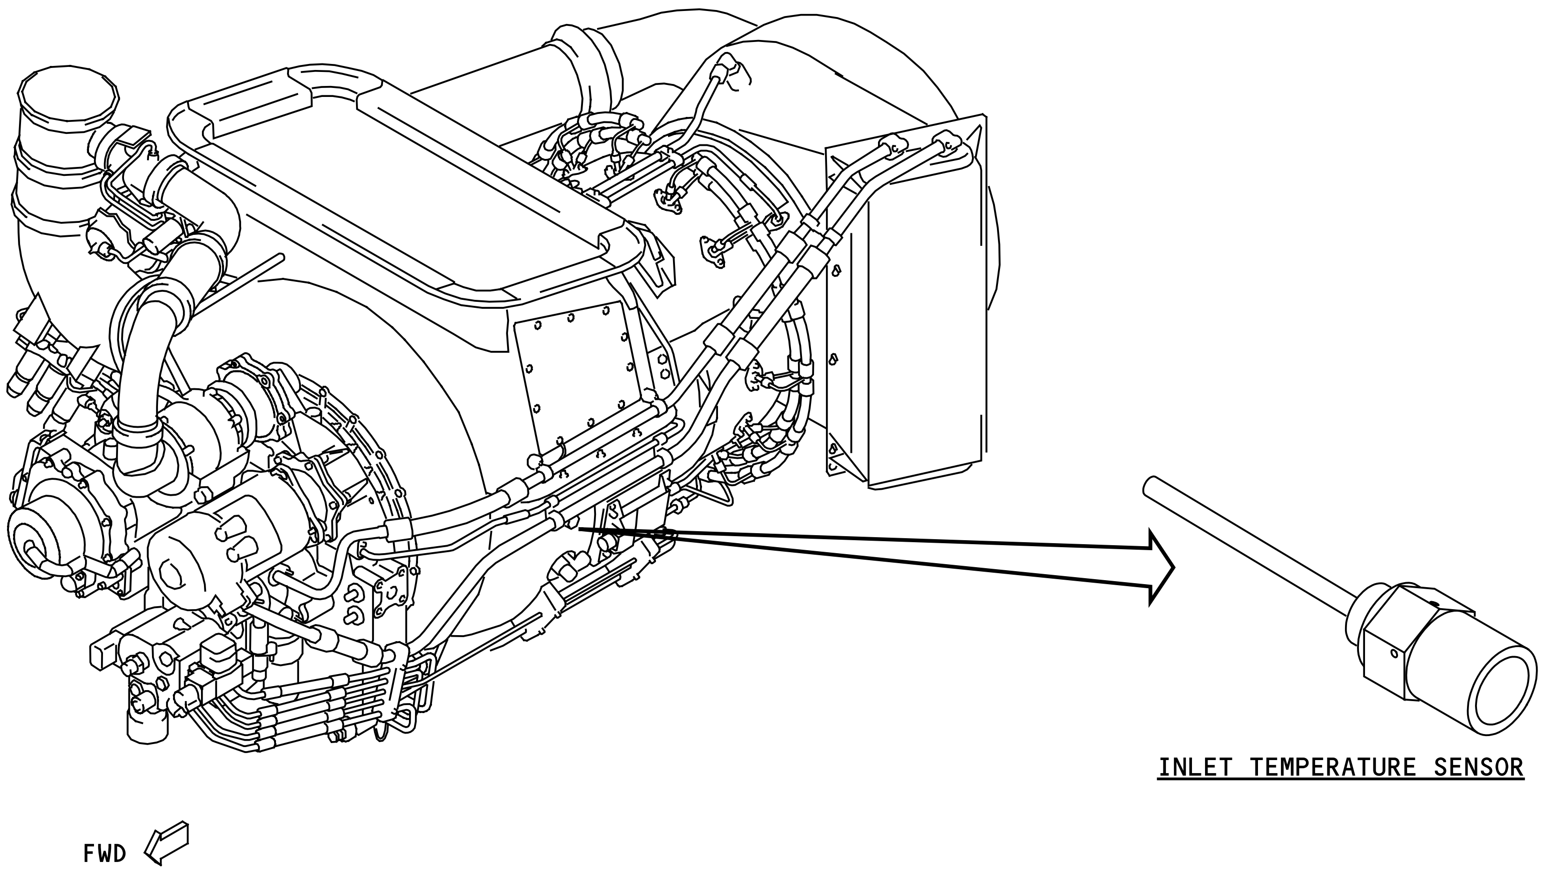
Inlet Temperature Sensor

The inlet temperature sensor supplies inlet air temperature data (T2). The APUC uses this data for these functions:

- Fuel control
- IGV control
- SCV control
- Turbine inlet temperature calculation.

The inlet temperature sensor is an RTD (resistance temperature detector) type sensor.

This sensor is on the left side of the APU.



49-60-00-008 Rev 2

APU CONTROL SYSTEM - INLET TEMPERATURE SENSOR

APU POWER PLANT - INTRODUCTION

General

The power plant has these systems and components:

- Auxiliary power unit
- APU mounts
- APU wire harness
- APU air inlet
- APU drains.

Auxiliary Power Unit

The auxiliary power unit contains these major sections:

- Accessory gearbox
- Pneumatic load compressor
- Gas turbine engine.

APU Mounts

The APU mounts hold the APU in the APU compartment and isolate the structure from APU vibration.

APU Wire Harness

The APU wire harness contains all the electrical wiring for the APU.

APU Air Inlet

The APU air inlet supplies the air for the APU engine and APU load compressor operation.

APU Drains

The APU drains permit flammable fluid to drain from the APU.

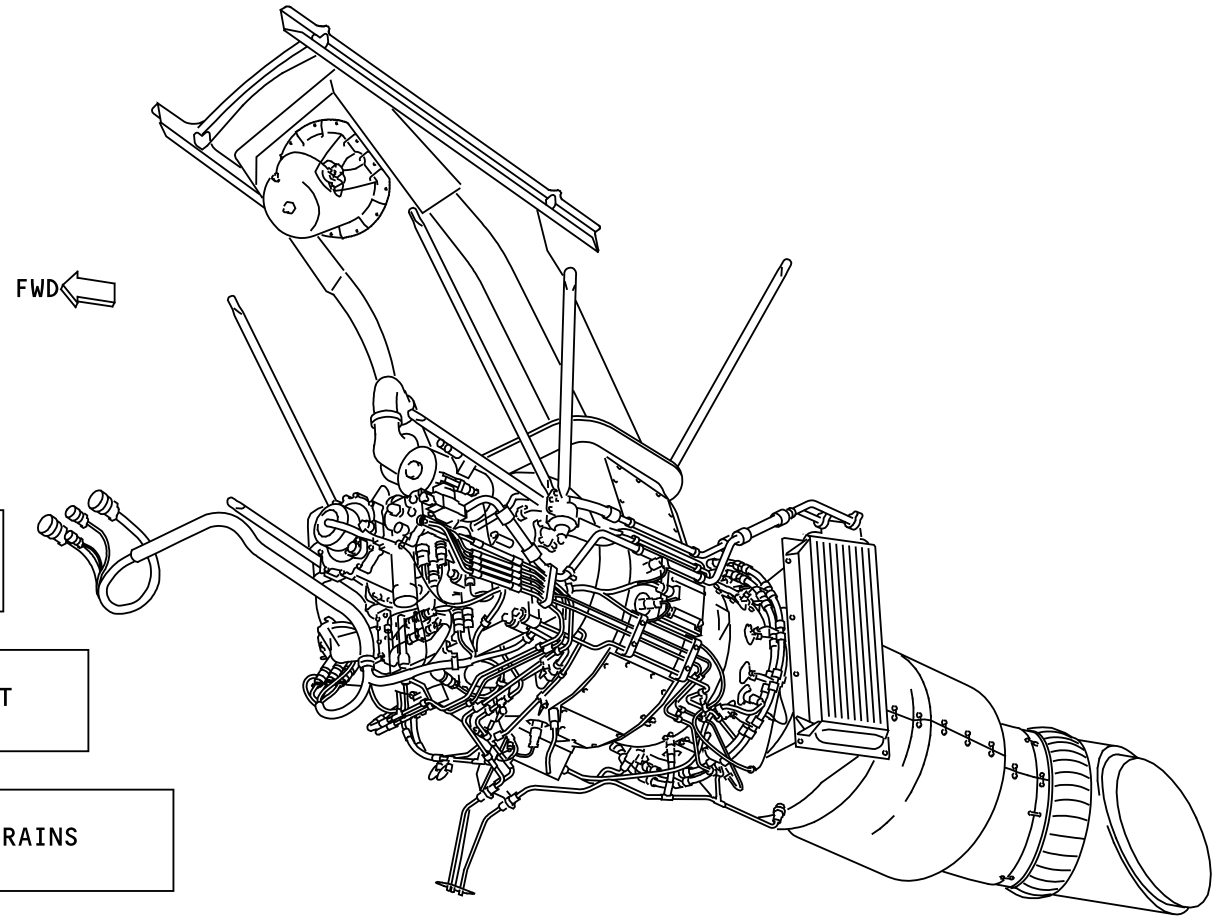
AUXILIARY POWER UNIT

APU MOUNTS

APU WIRE HARNESS

APU AIR INLET

APU DRAINS



APU POWER PLANT - INTRODUCTION

APU POWER PLANT - AUXILIARY POWER UNIT

Clustered Components

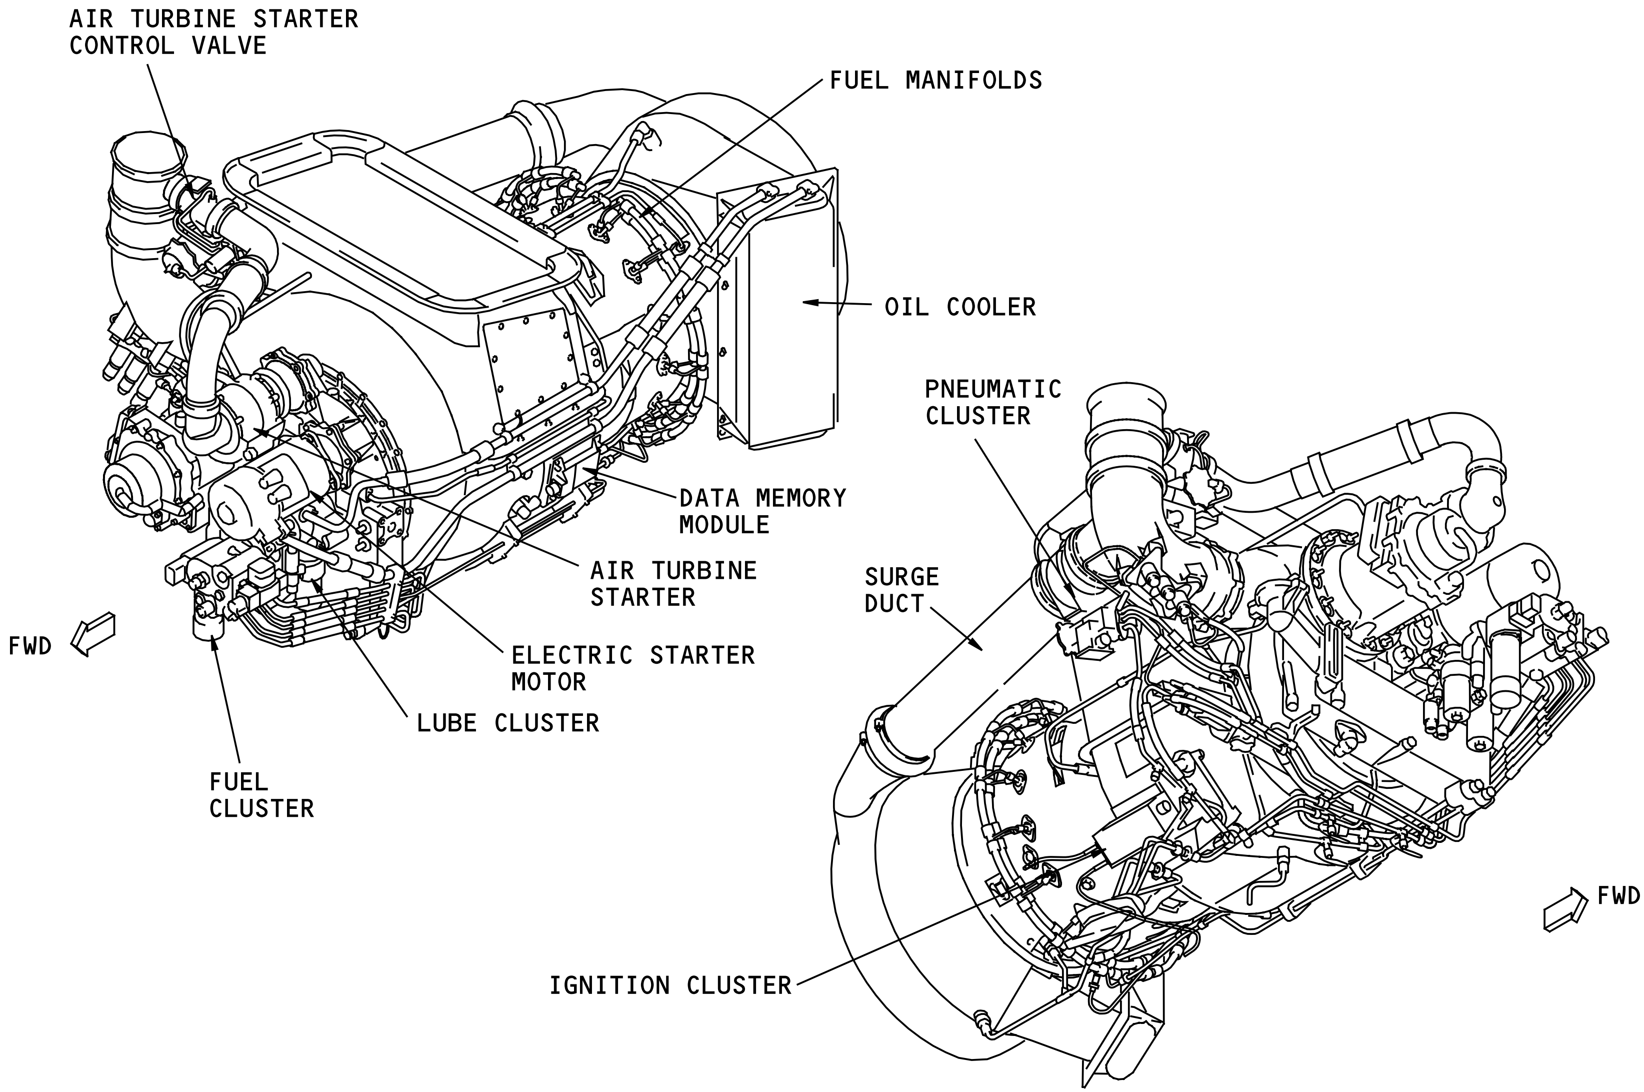
Some APU components are in functional clusters to make maintenance easier. These clusters include:

- Lube cluster
- Fuel cluster
- Pneumatic cluster
- Ignition cluster.

Other Components

These are the other main APU components:

- Air turbine starter control valve (ATSCV)
- Fuel manifolds
- Oil cooler
- Data memory module (DMM)
- Air turbine starter (ATS)
- Electric starter motor
- Surge duct.



49-10-00-002 Rev 1

APU POWER PLANT - AUXILIARY POWER UNIT

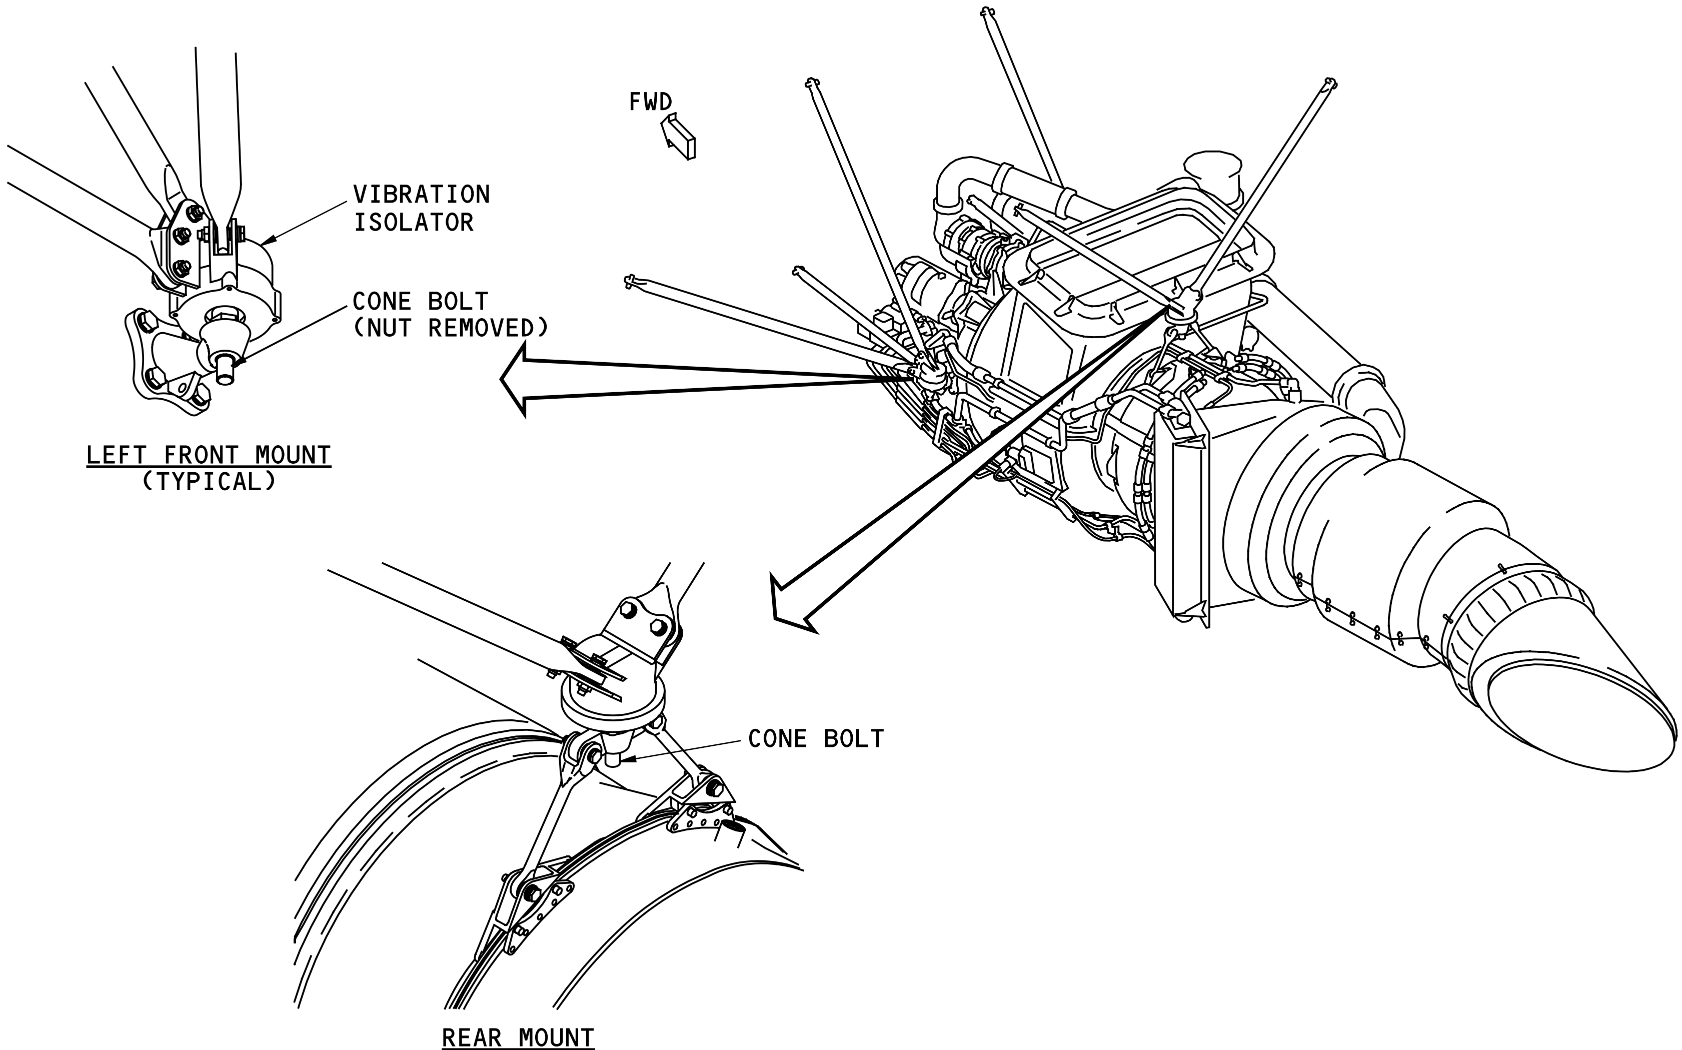
APU POWER PLANT - APU MOUNTS

Purpose

Three APU mounts hold the APU in its compartment. The mounts also isolate the structure from APU vibration.

Location

The two forward mounts attach to the APU firewall. The aft APU mount hangs from the upper tailcone structure.



APU POWER PLANT - APU MOUNTS

APU POWER PLANT - APU WIRE HARNESS

Purpose

The APU wire harness holds all the electrical wires in one assembly.

Location

The APU wire harness extends from the firewall connector to the front of the APU. From the front of the APU it goes in different directions around the APU to connect all electrical components.

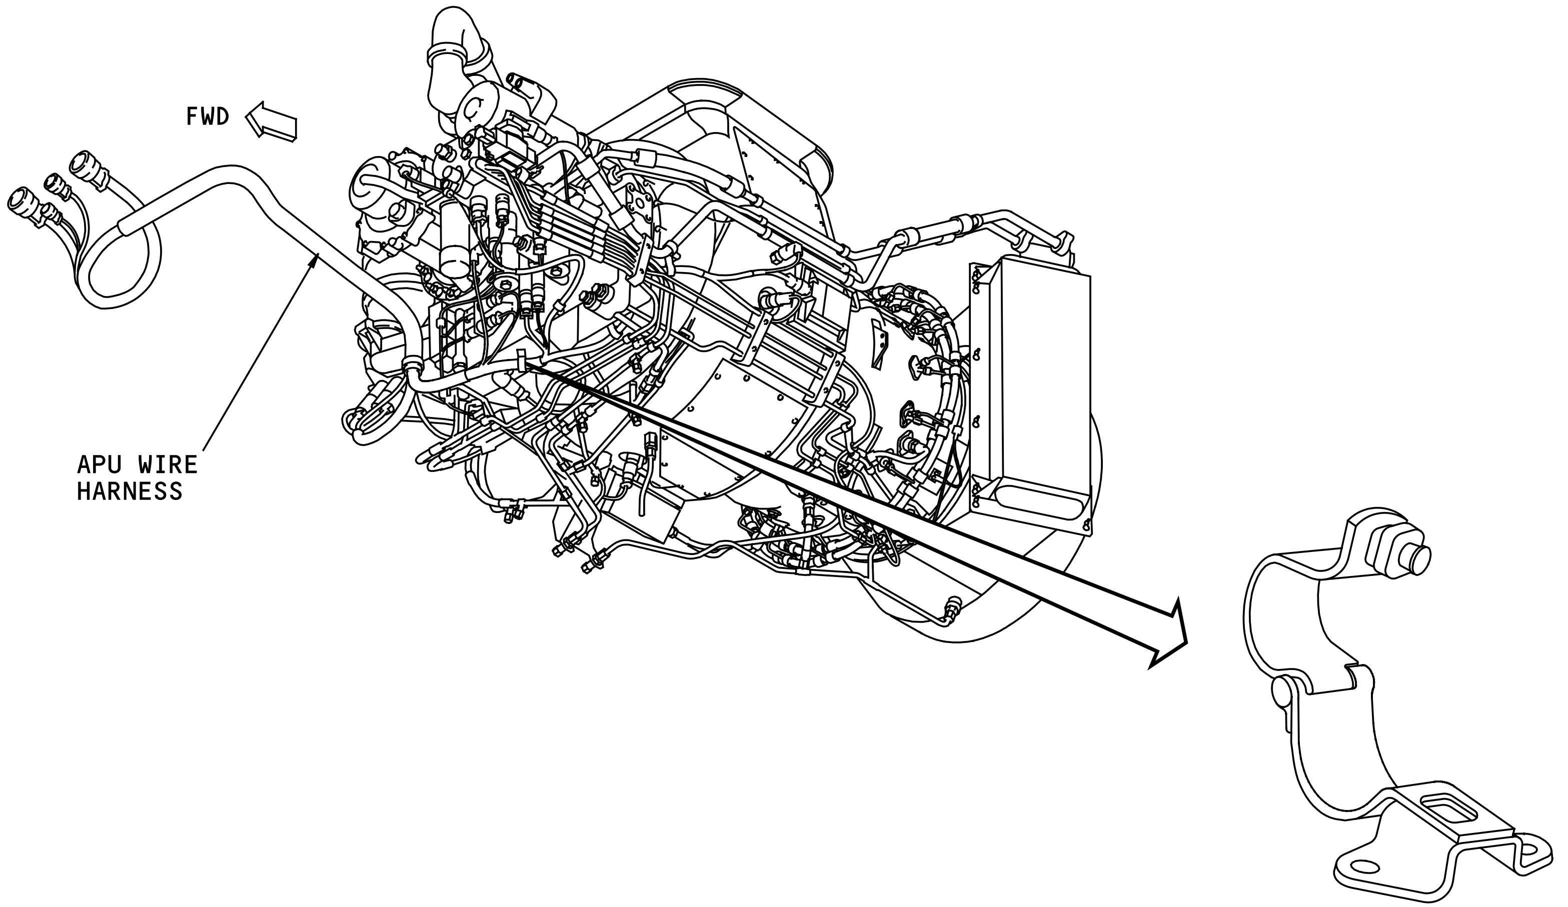
Physical Description

Shielded, twisted pair conductors keep electromagnetic interference on circuits to a minimum. APU harness connectors are threaded, stainless steel, and self-locking.

Training Information Point

Wiring routing tags on the harness show pin to pin electrical continuity.

Quick release fastener cable clamps attach the APU harness to the APU.



49-10-00-004 Rev 1

APU POWER PLANT - APU WIRE HARNESS

APU POWER PLANT - AIR INLET - INTRODUCTION

Purpose

The APU air inlet supplies air to the APU for APU engine and load compressor operation, and for oil and APU compartment cooling. These are the APU air inlet components:

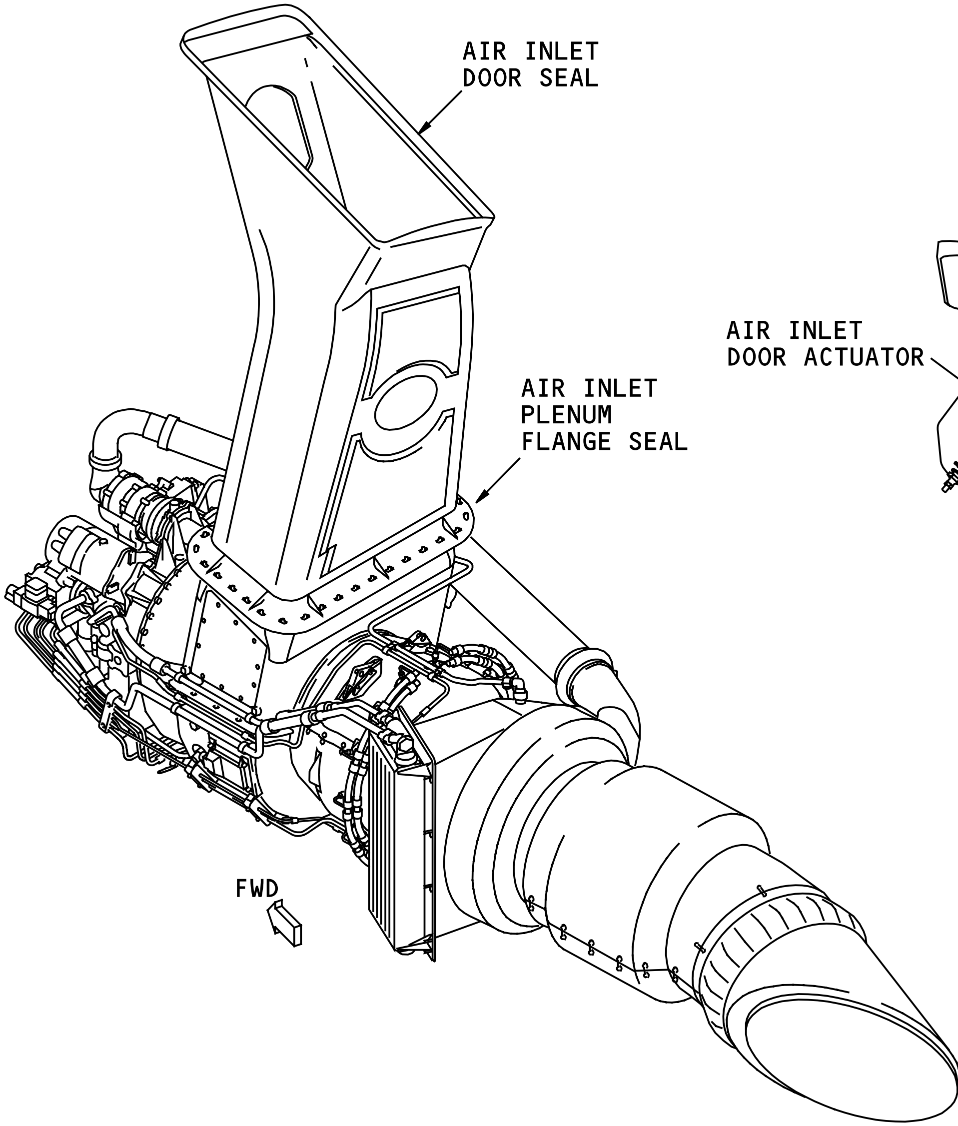
- Air inlet duct
- Air inlet plenum flange seal
- Air inlet door
- Air inlet door actuator
- Air inlet door position switch
- Air inlet door seal.

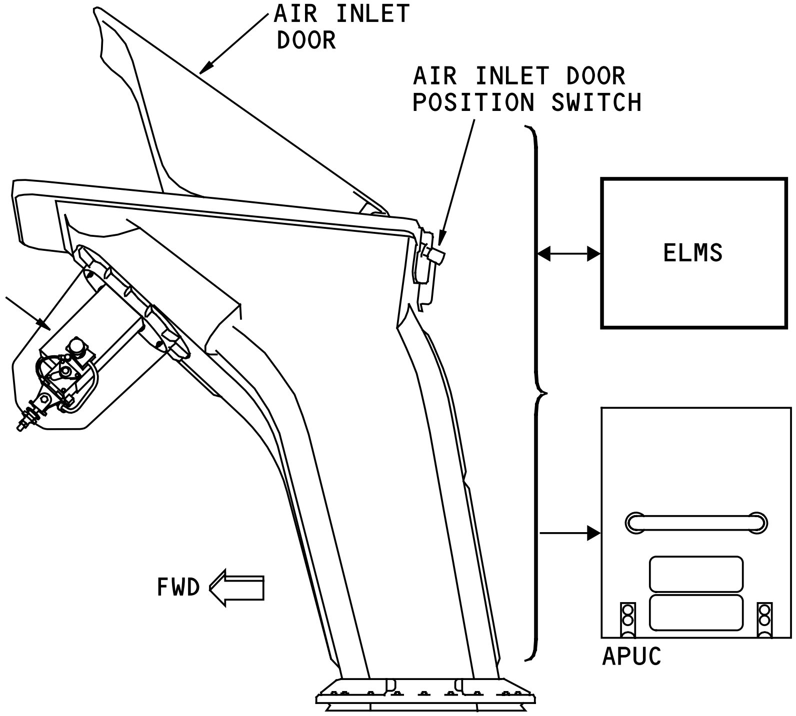
Location

The air inlet components are above the APU. The air inlet door is on the upper right side of the tailcone.

Interface

The electrical load management system (ELMS) controls the air inlet door. The APUC receives door position data for control and fault indications.





APU AIR INLET DUCT

49-10-00-005 Rev 2 12/19/95

APU POWER PLANT - AIR INLET - INTRODUCTION

APU POWER PLANT - AIR INLET - AIR INLET DUCT AND PLENUM FLANGE SEAL

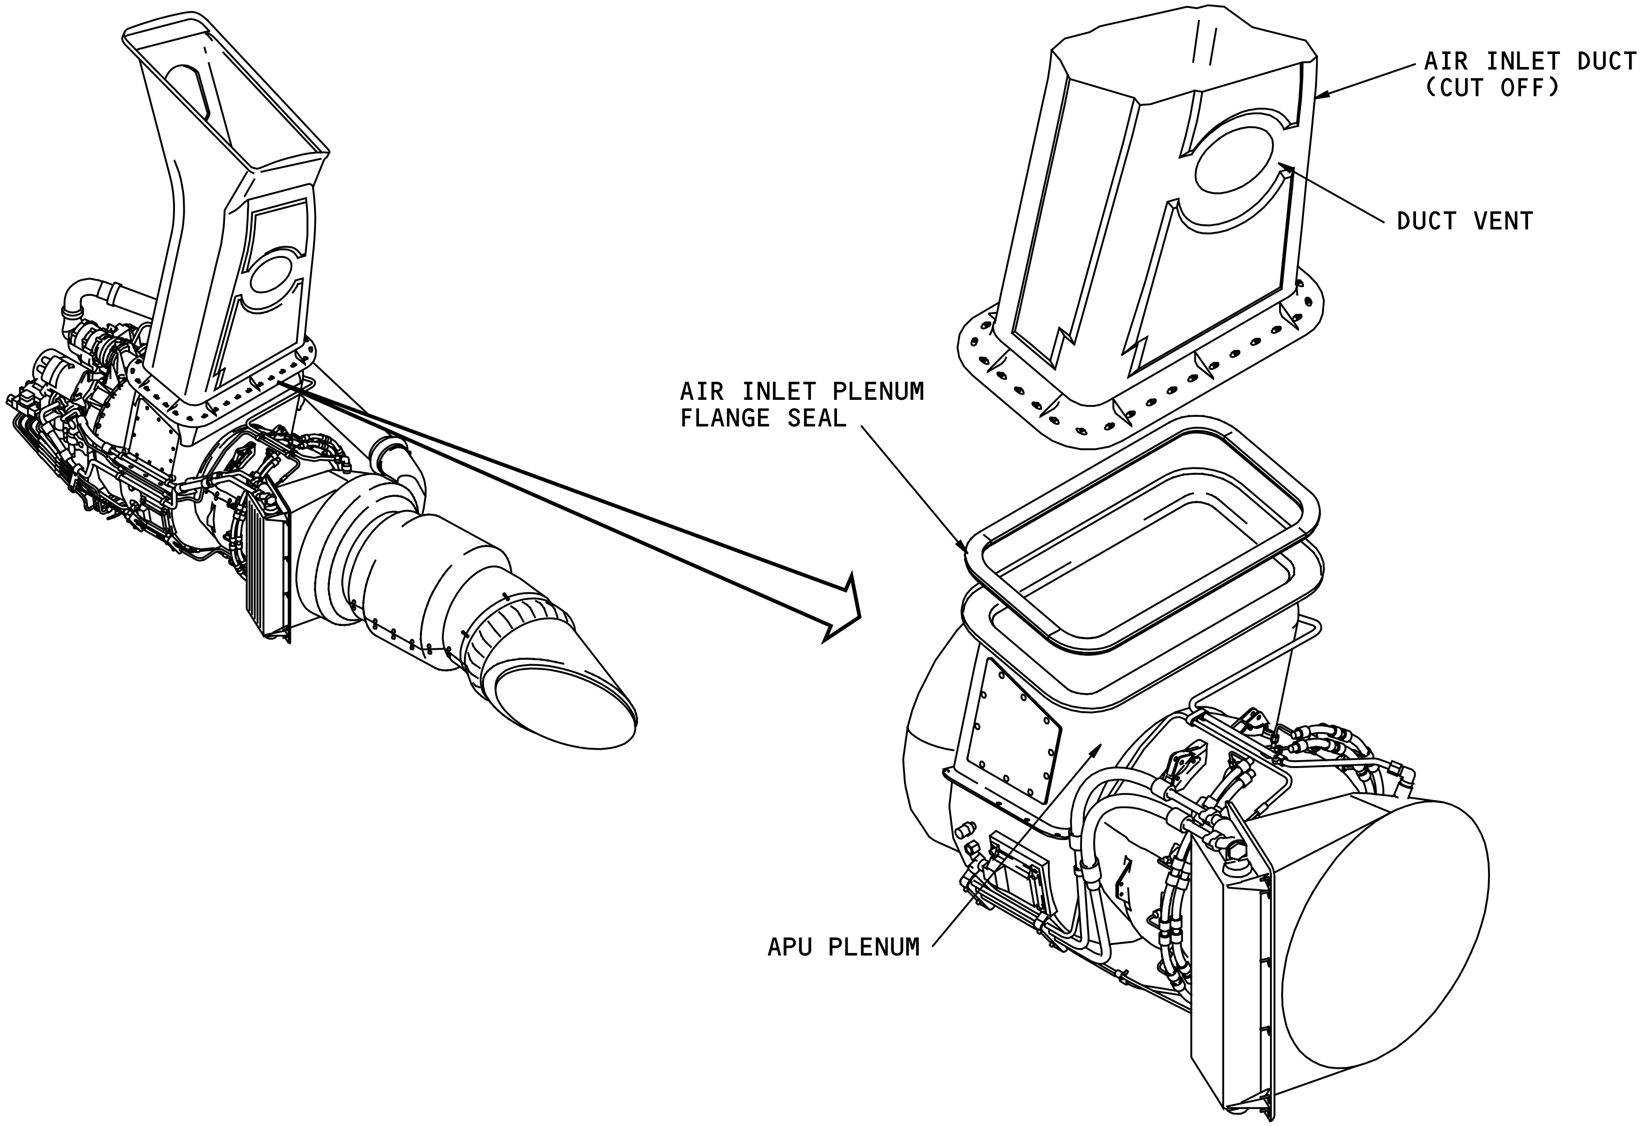
Air Inlet Duct

The air inlet duct connects the APU door to the APU plenum. The duct supplies air to the APU by the shortest, most direct path. The duct is made of composite material.

The duct vent supplies air to the APU compartment for compartment and oil cooling.

APU Air Inlet Plenum Flange Seal

The air inlet plenum flange seal closes and seals the air inlet duct where it connects with the APU plenum. The flange seal is made of a flexible fiberglass/NOMEX/ silicone material. The seal also helps to isolate APU vibration from the duct.



APU POWER PLANT - AIR INLET - AIR INLET DUCT AND PLENUM FLANGE SEAL

49-10-00-006 Rev 2 12/19/95

APU POWER PLANT - APU AIR INLET - AIR INLET DOOR COMPONENTS

Air Inlet Door

The air inlet door opens to let air into the engine and load compressor plenum.

The air inlet door is on the right, upper surface of the tail cone immediately aft of the rudder trailing edge. This position decreases the possibility of water or slush ingestion during ground and flight operations.

Air Inlet Door Seal

The air inlet door seal keeps fluids and contaminants out of the inlet duct when the door is closed. The seal is a bulb-type seal made of silicone rubber.

Air Inlet Door Actuator

The air inlet door actuator is an electric actuator that opens and closes the air inlet door.

The inlet door actuator is in a cannister assembly on the upper forward section of the air inlet duct. The cannister assembly supports the actuator and seals the operating rod slot in the duct.

Air Inlet Door Position Switch

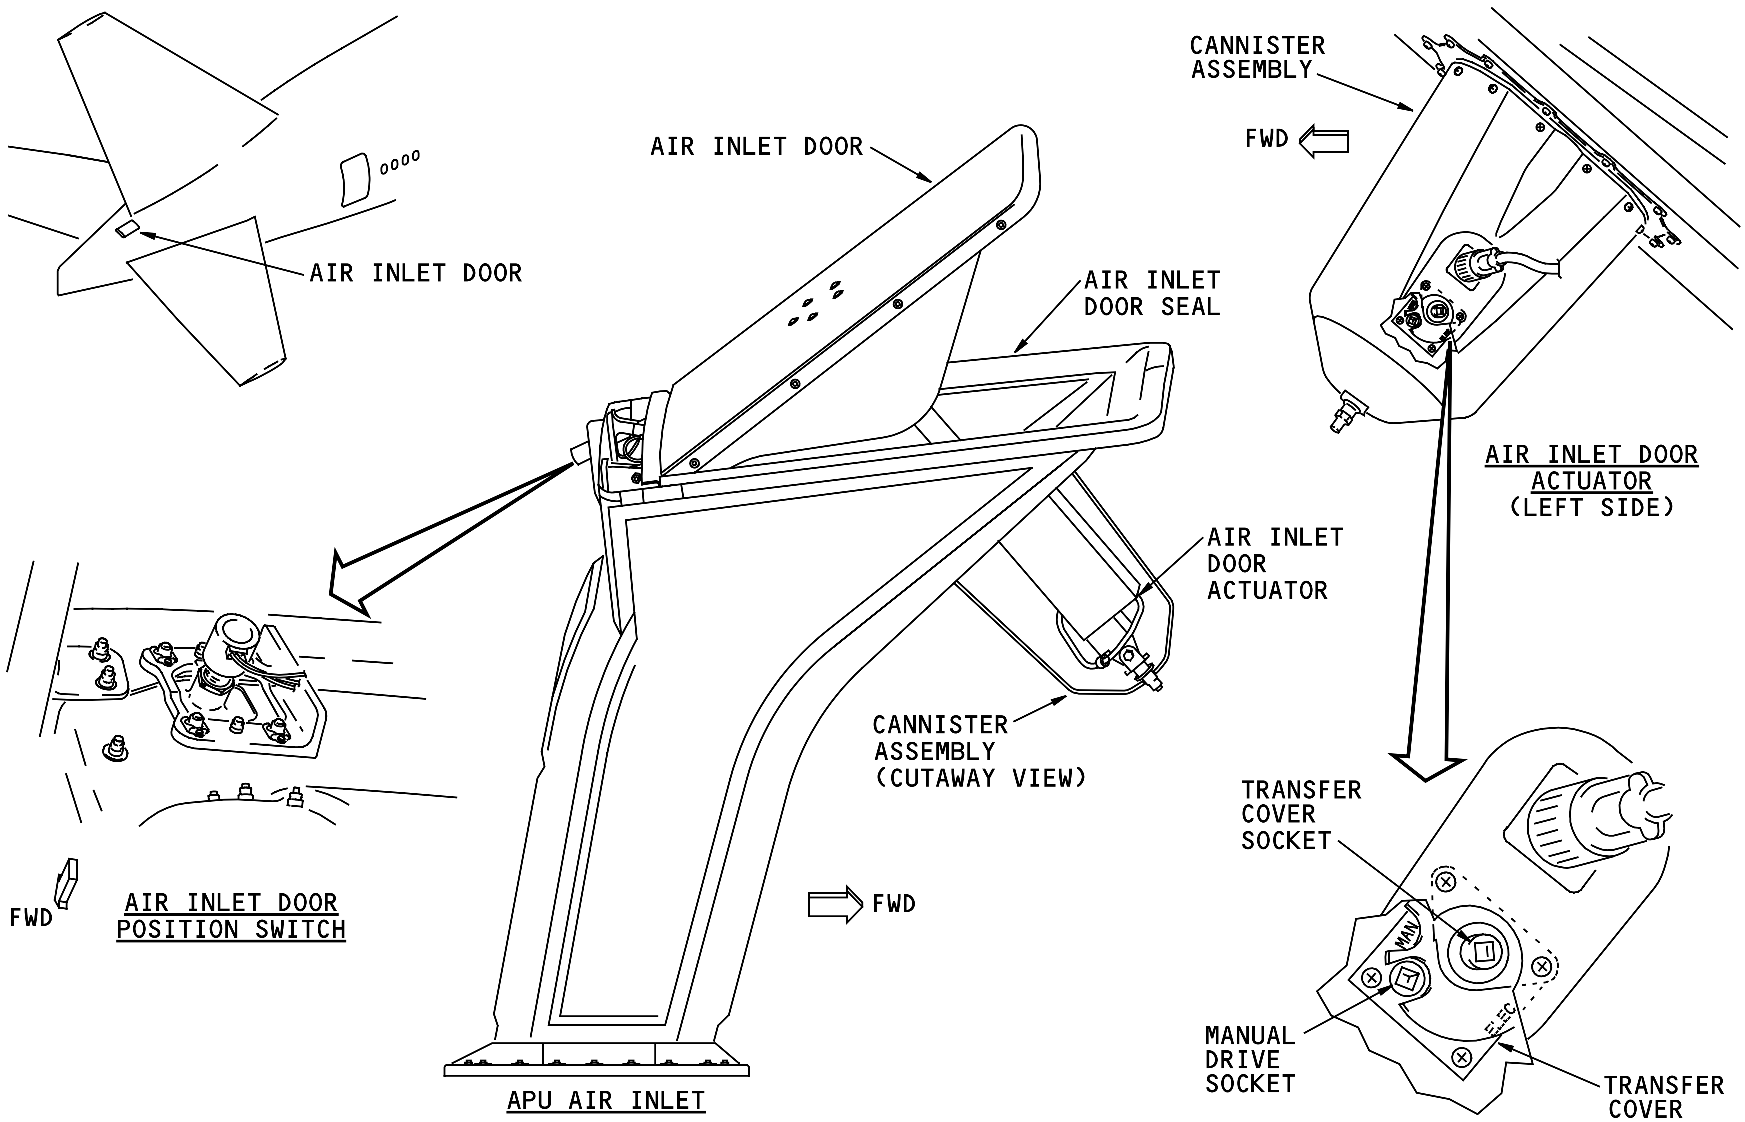
The air inlet door position switch supplies a door open or door not open signal to the ELMS and to the APUC. The switch is on the aft side of the air inlet duct.

Training Information Point

You can manually operate the air inlet door with the manual drive socket on the inlet door actuator assembly.

You must remove a cover (not shown) on the cannister assembly to get access to the transfer cover and the manual drive sockets.

You turn the transfer cover socket to select the manual mode. This uncovers the manual drive socket and disconnects the actuator electrically.



APU POWER PLANT - APU AIR INLET - AIR INLET DOOR COMPONENTS

APU POWER PLANT - APU AIR INLET - FUNCTIONAL DESCRIPTION

General

The APU air inlet door opens for APU start and run operation and closes when the APU is not running. The ELMS contains the control logic for the APU air inlet door.

APU Start

When the APU is OFF, the air inlet door is closed and sealed. When the APU selector is in the ON or START position, the ELMS energizes the control relay to open the air inlet door.

The air inlet door position switch sends a signal to the APUC and to the ELMS when the air inlet door gets to the open position. The door takes 30-40 seconds to open fully.

Normal Operation

During normal operation, an APU running signal from the APUC to the ELMS keeps the door open.

APU Shutdown

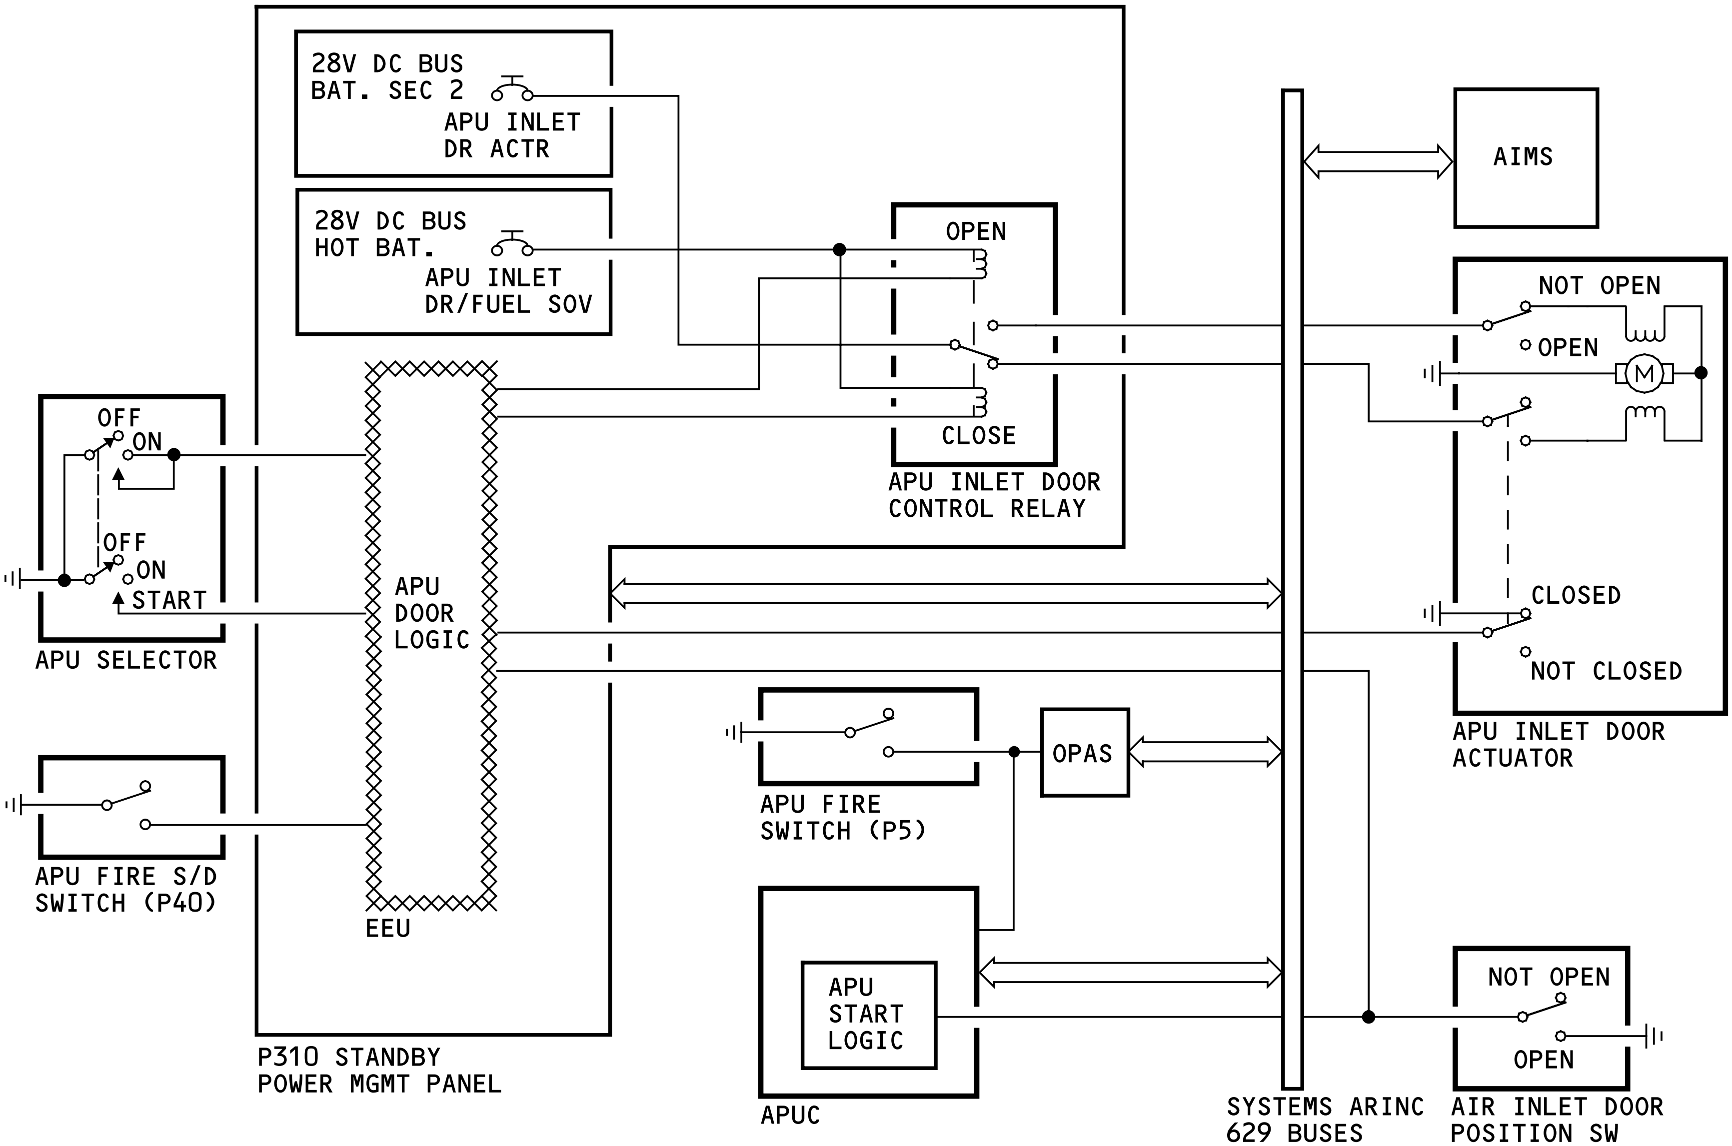
On shutdown, the ELMS energizes the control relay to close the air inlet door when the speed of the APU engine goes below 15 percent RPM. The door takes 30-40 seconds to close fully.

The APU fire switch (P5) or fire shutdown switch (P40) operation cause the air inlet door to close immediately.

Door Position Disagreement

If door position disagrees with the commanded position, the ELMS sends a signal to the AIMS to show the APU DOOR status message.

An air inlet door failure causes an automatic APU shutdown when the APU is in the unattended mode. See the auxiliary power system section for more information on the protective shutdowns (AMM PART I 49-00).



APU POWER PLANT - APU AIR INLET - FUNCTIONAL DESCRIPTION

APU POWER PLANT - APU DRAINS - INTRODUCTION

General

APU flammable fluids drain overboard through drains connected to a drain mast. These drains remove fuel or oil that leaks through seals. These drains also remove fuel that does not burn from the combustion chamber and tailpipe.

APU non-flammable fluids drain overboard through drain holes in the APU compartment doors. These drains remove fluids that go into the APU air inlet plenum from the APU air inlet. These fluids go from the APU air inlet plenum into the APU compartment through the APU plenum drain.

Flammable Fluid Drains

Flammable fluid drains through three separate tubes. The drains attach together at the bottom of the APU. They connect with a drain mast on the right APU access door when the door is closed.

Fuel that does not burn during APU start or operation goes through the APU combustor drain valve. The APU combustor drain valve is at the bottom of the combustion chamber. The drain line from the combustion chamber connects to the combustor drain valve. APU combustion chamber pressure closes the combustor drain valve when the APU operates. The valve is open when the APU is off.

Non-Flammable Fluid Drains

The APU plenum drain is at the bottom of the air inlet plenum.

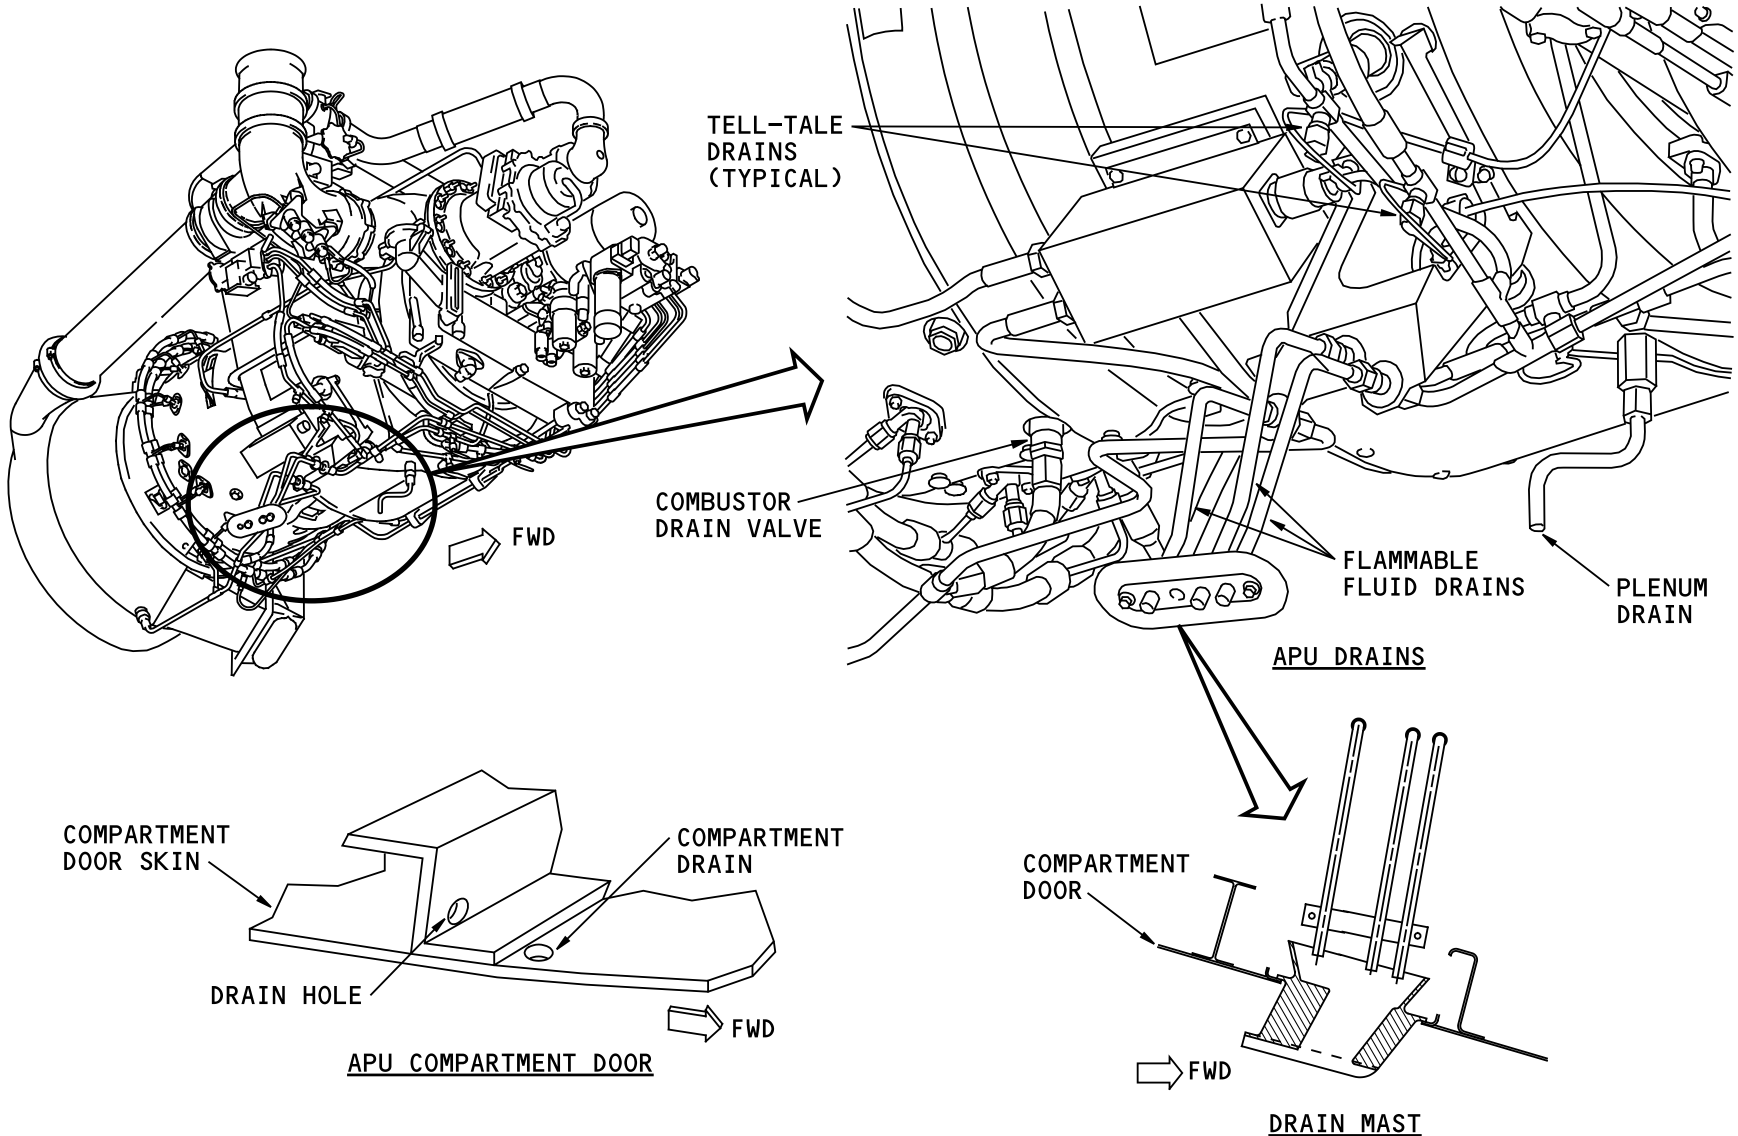
Compartment drains are along the bottom skin of the APU compartment access doors. The APU access doors and compartment structure have drain holes to permit the fluid to flow to the compartment drains.

Training Information Point

Tell-tale drains help find fuel seal failures. Three tell-tale drains are on the APU.

If fuel goes through a drain tube with a tell-tale drain, then the tell-tale drain fills with fuel. You remove the cap of the tell-tale drain to do a check for fluid. If fluid is in the tell-tale drain, the APU component that connects to the drain tube is leaking fuel.

The APU combustor drain valve is an LRU.



APU POWER PLANT - APU DRAINS - INTRODUCTION

49-10-00-009 Rev 3 03/19/1997

APU POWER PLANT - APU DRAINS - FUNCTIONAL DESCRIPTION

General

These APU drains send fuel and oil to the drain mast on the right APU access door:

- Combustion chamber fuel drain
- Eductor/Tailpipe fuel drain
- Surge control valve (SCV) actuator seal drain
- Inlet guide vane (IGV) actuator seal drain
- Forward mid-bearing seal drain
- Aft mid-bearing seal drain
- Load compressor bearing seal drain
- Fuel cluster seal drain.

Drains

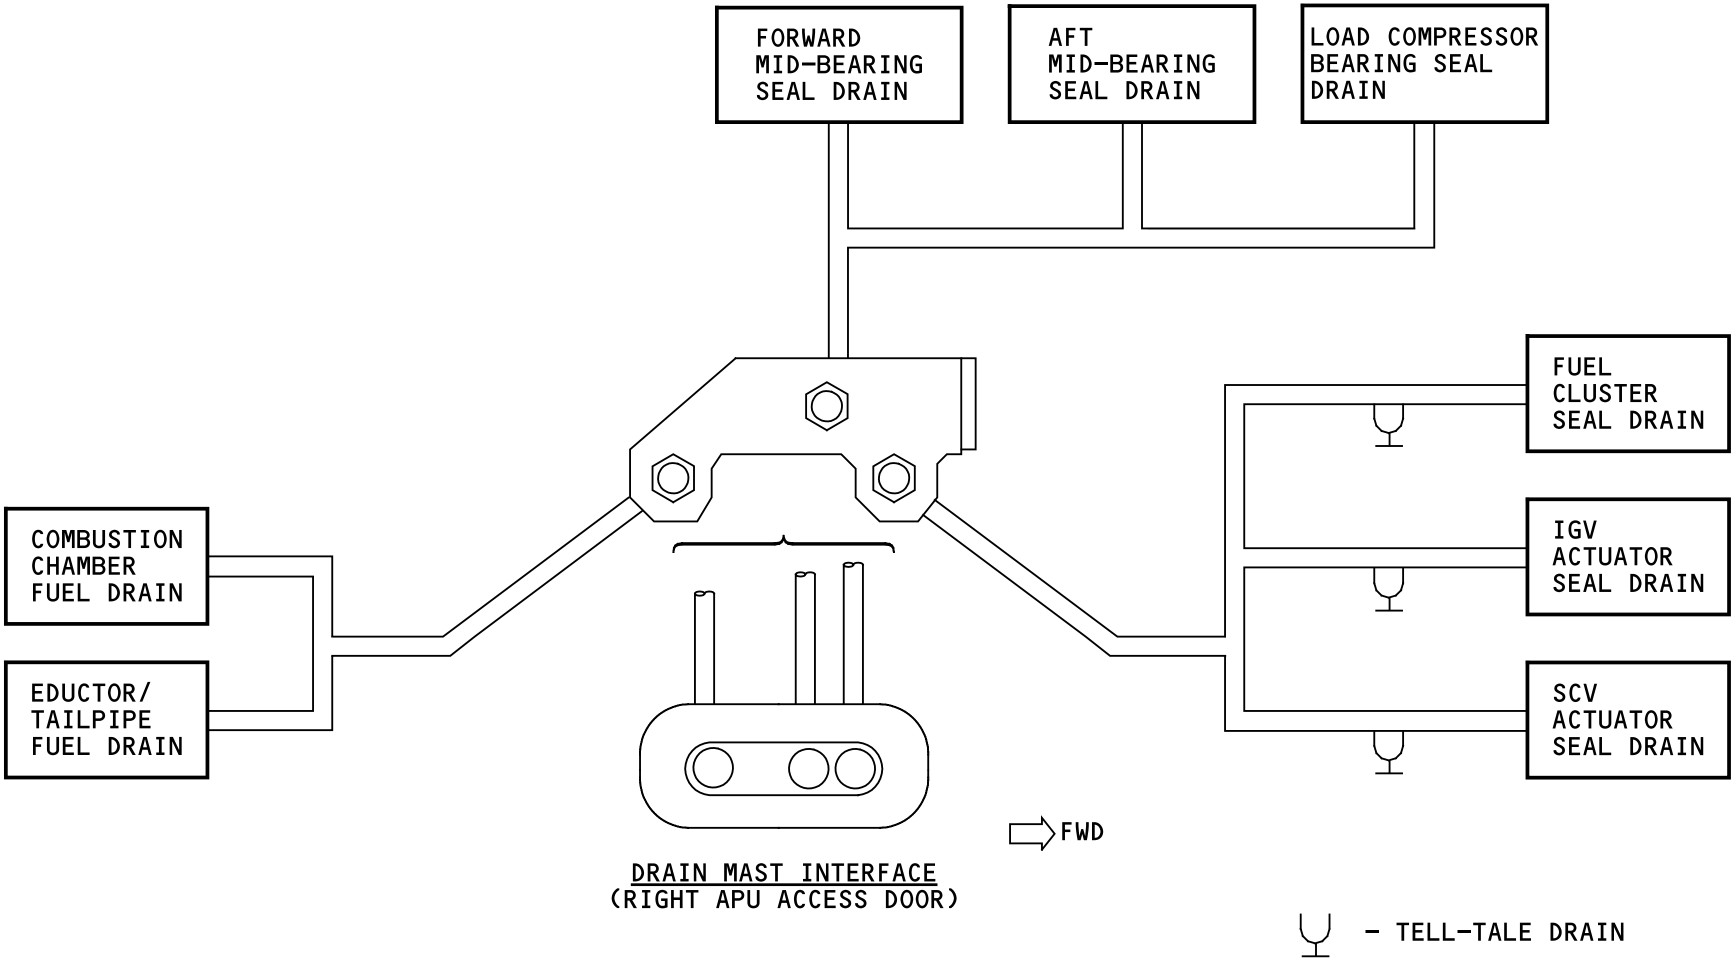
The APU drains connect directly to the drain mast.

The combustion chamber fuel drain and the eductor/tail pipe fuel drain connect together at the bottom of the APU.

The surge control valve seal drain, the IGV actuator seal drain, and the fuel cluster seal drain connect at the bottom of the APU.

The two mid-bearing seal drains and the load compressor bearing seal drain connect at the bottom of the APU.

The drain lines from the SCV actuator seal drain, the IGV actuator seal drain, and the fuel cluster seal drain have tell-tale drains. These tell-tale drains let you find the source of fluid in these drain lines and do a check of the leakage rate.



49-10-00-010 Rev 4 07/18/1997

APU POWER PLANT - APU DRAINS - FUNCTIONAL DESCRIPTION

APU ENGINE - INTRODUCTION

Purpose

The APU engine supplies power to operate the load compressor and the APU generator.

General Description

The APU gas turbine engine has these main components:

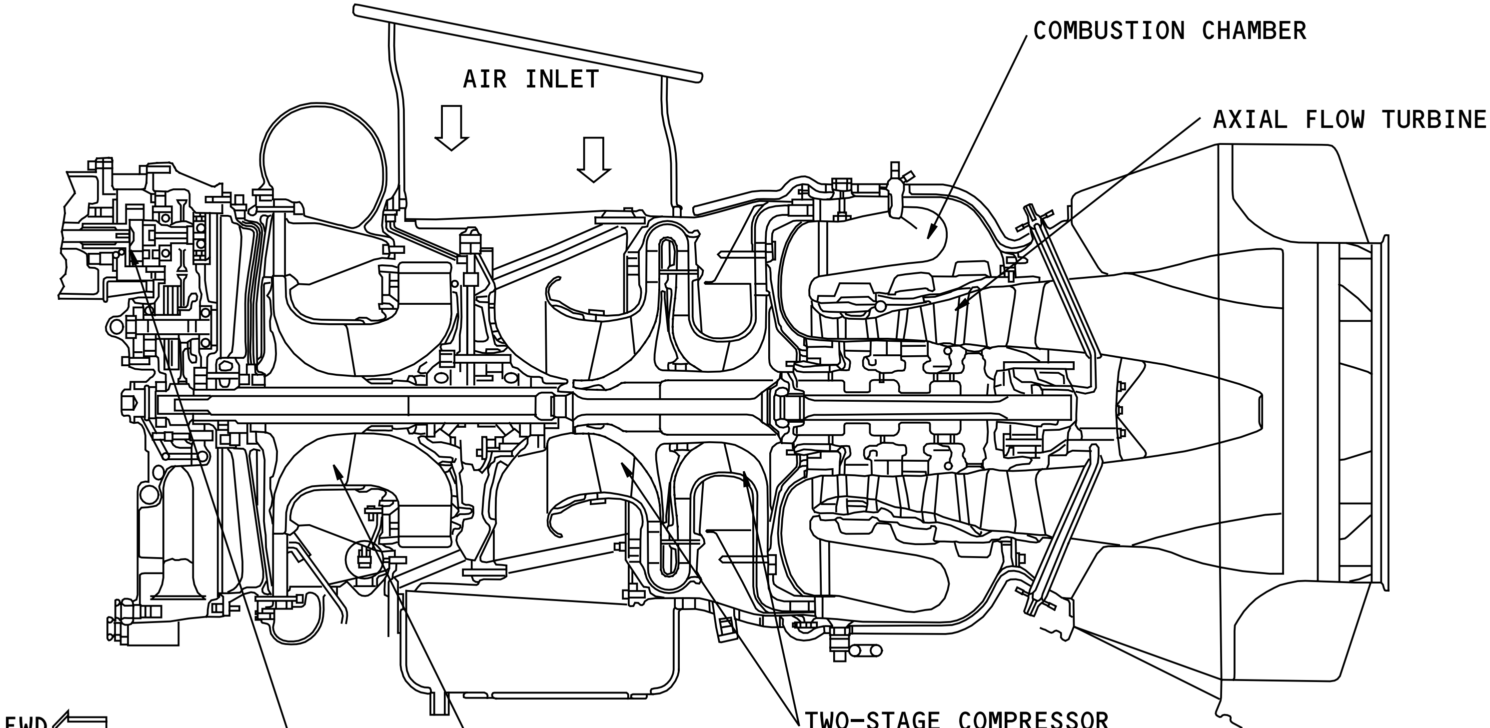
- Two-stage centrifugal compressor
- Reverse flow annular combustion chamber
- Three stage axial flow turbine.

All rotating components in the engine are on a common shaft.

The shaft turns the accessory gearbox and the load compressor. The accessory gearbox turns the APU generator and other APU components.

The engine uses air that flows through the air inlet duct.

The engine operates at a constant speed to permit a 400 hertz generator output frequency. The APU adjusts fuel flow to the engine to keep a constant speed when electrical and pneumatic loads change.



APU ENGINE

APU AND GENERATOR LUBRICATION SYSTEM - INTRODUCTION

Purpose

The APU lubrication system lubricates and cools these components:

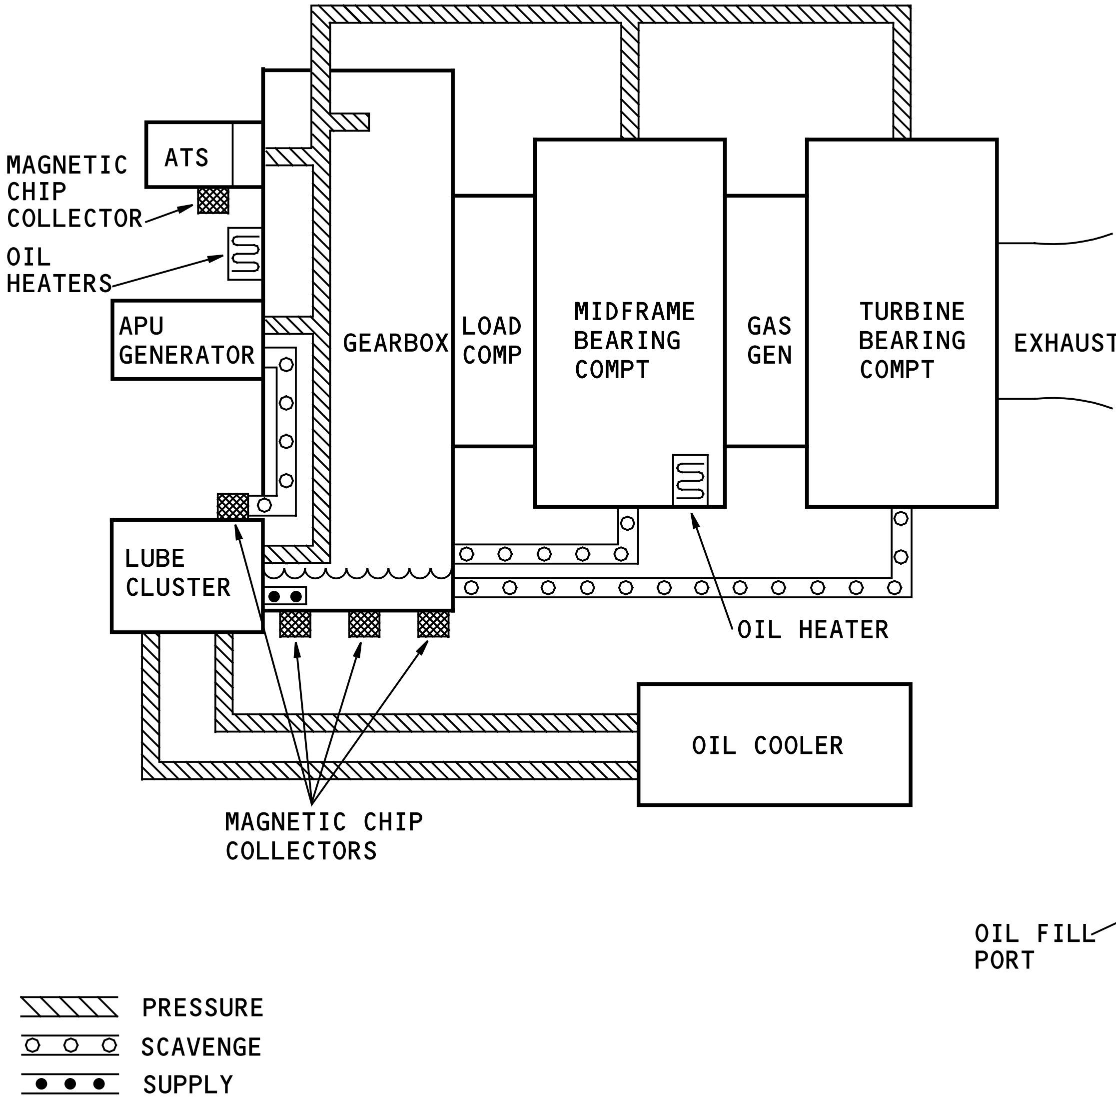
- APU generator
- Air turbine starter (ATS)
- APU bearings
- APU gearbox.

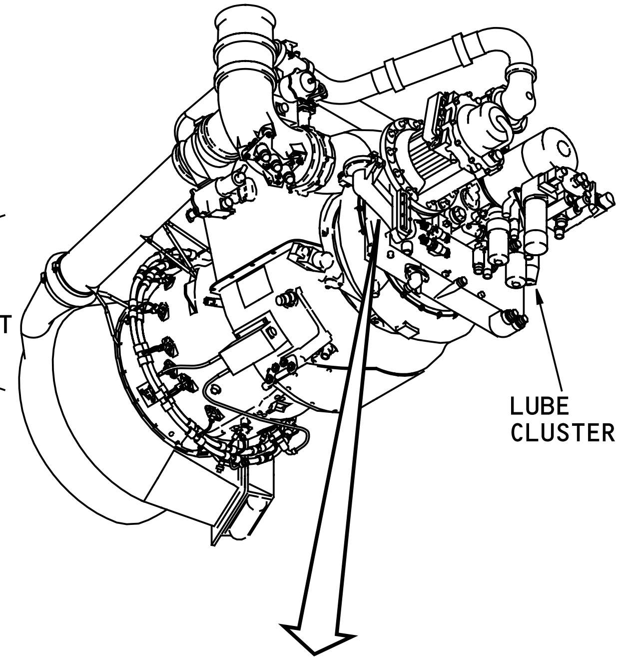
Components

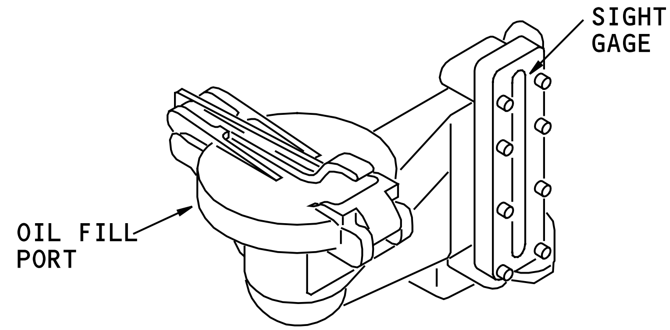
Some lubrication system components are on a common cluster on the front of the APU. These lubrication system components are not on the cluster:

- Magnetic chip collectors
- APU oil heater system components
- Oil cooler.

An 8.2 quart (7.8 liter) oil tank is inside the load gearbox. A sight gage shows the oil level. An oil fill port is adjacent to the gage.







OIL FILL PORT AND SIGHT GAGE

APU AND GENERATOR LUBRICATION SYSTEM - INTRODUCTION

49-27-00-001 Rev 3 01/09/95

APU AND GENERATOR LUBRICATION SYSTEM - LUBE CLUSTER - INTRODUCTION

General

The lube cluster contains many of the lubrication system components. It is on the gearbox on the front of the APU.

Components

The lube cluster contains lube and scavenge pump elements internally. A shaft from the gearbox turns the pumps. A pressure regulating/relief valve is also internal to the lube cluster.

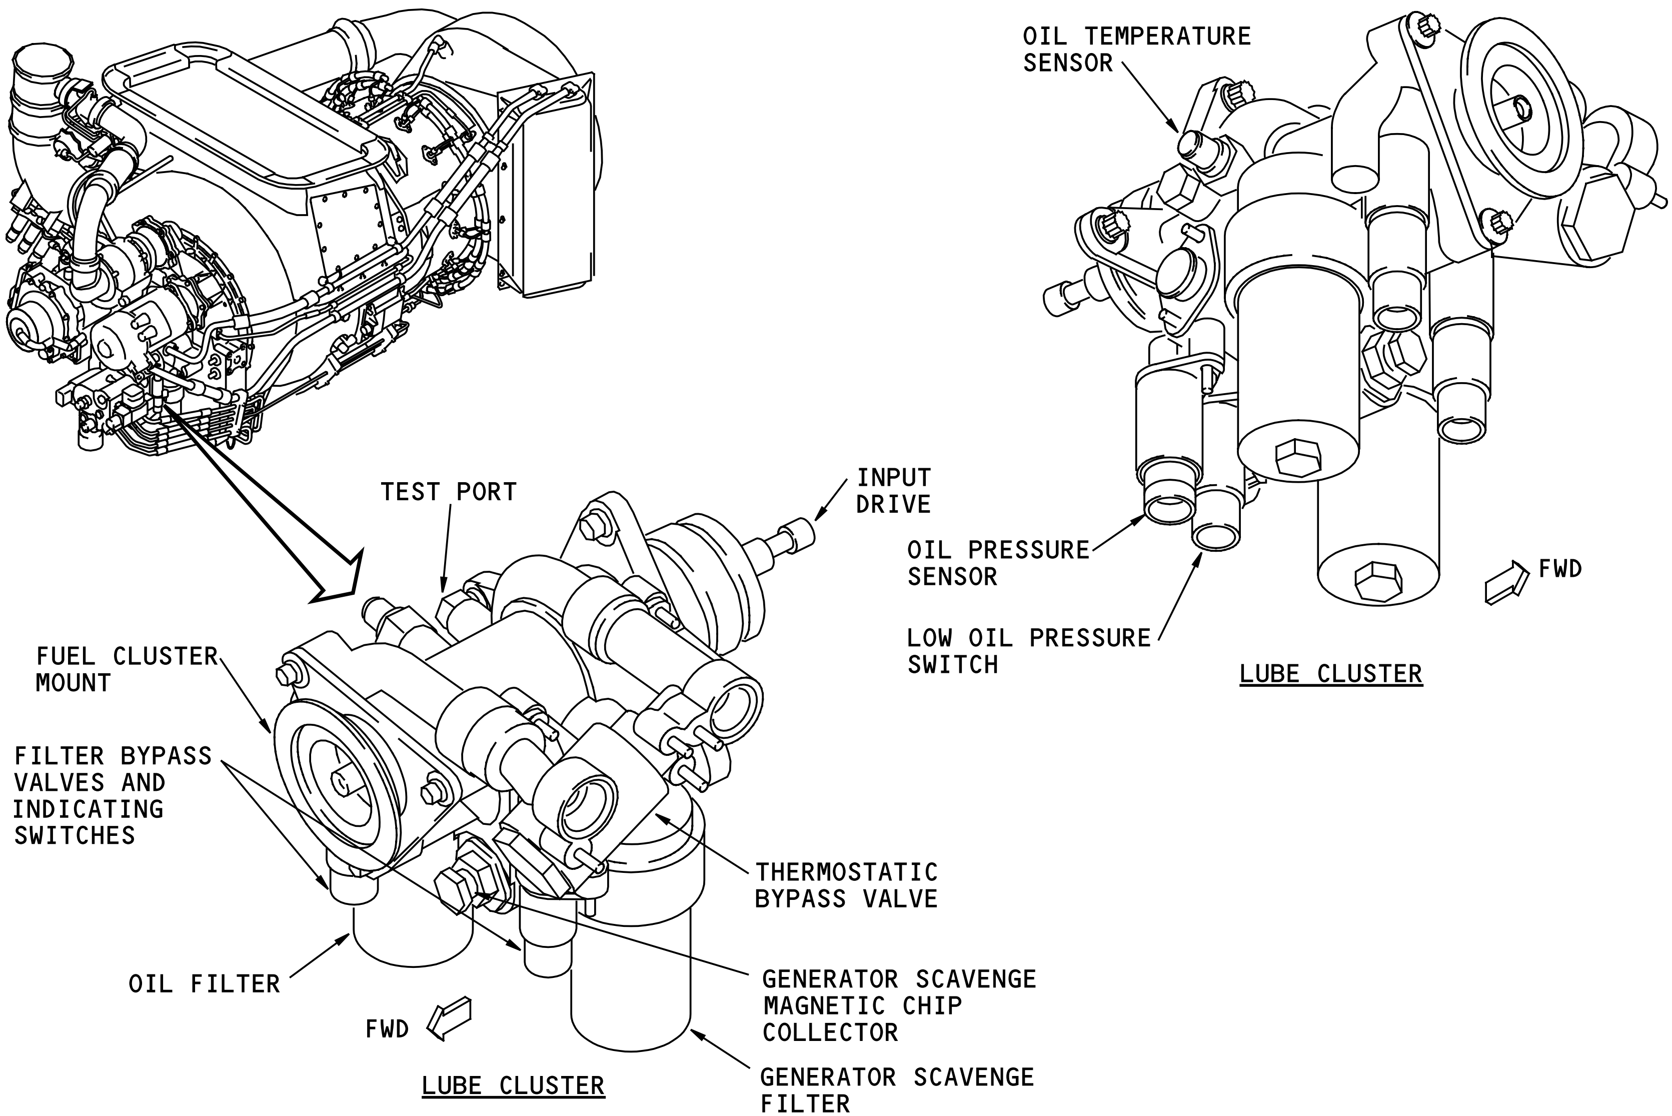
These components are on the outside of the lube cluster and are LRUs:

- Generator scavenge magnetic chip collector
- Filter bypass valve and indicating switches
- Oil and generator scavenge filters
- Low oil pressure switch
- Oil pressure sensor
- Oil temperature sensor
- Thermostatic bypass valve.

A test port permits you to attach a pressure gage to the lube cluster to do a check of the output pressure.

Training Information Point

The fuel cluster mounts to the lube cluster. To remove the lube cluster, you must first remove the fuel cluster.



APU AND GENERATOR LUBRICATION SYSTEM - LUBE CLUSTER - INTRODUCTION

49-27-00-002 Rev 3 07/20/95

APU AND GENERATOR LUBRICATION SYSTEM - MAGNETIC CHIP COLLECTORS

Purpose

Magnetic chip collectors collect metallic particles in the engine oil. This permits you to do an inspection of the APU for damage.

Location

These are the five chip collectors on the APU:

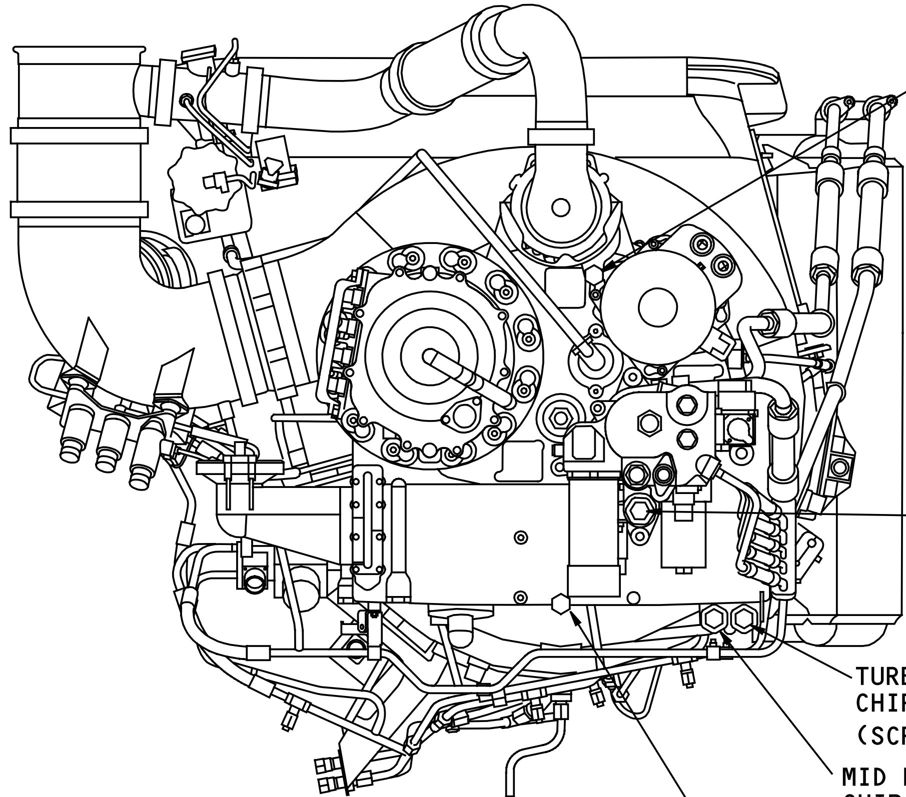
- ATS chip collector - on the lower side of the air turbine starter
- Generator scavenge chip collector - on the lube cluster
- Turbine bearing chip collector - on the left forward side of the load gearbox
- Mid-bearings chip collector - on the left forward side of the load gearbox inboard of the turbine bearing chip collector
- Sump drain chip collector - on the forward side of the load gearbox in the center.

Physical Description

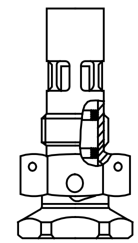
The magnetic chip collectors have magnets inside them to collect the metal chips.

All the chip collectors are the same. They are in adapters which are also removal check valves. The check valves close to prevent oil loss when you remove the chip collector.

Some removal check valves are inside screens. The screens stop large metal particle movement through the lubrication system.



APU (FRONT VIEW)



MAGNETIC CHIP COLLECTOR AND ADAPTER

APU AND GENERATOR LUBRICATION SYSTEM - MAGNETIC CHIP COLLECTORS

APU AND GENERATOR LUBRICATION SYSTEM - OIL COOLER

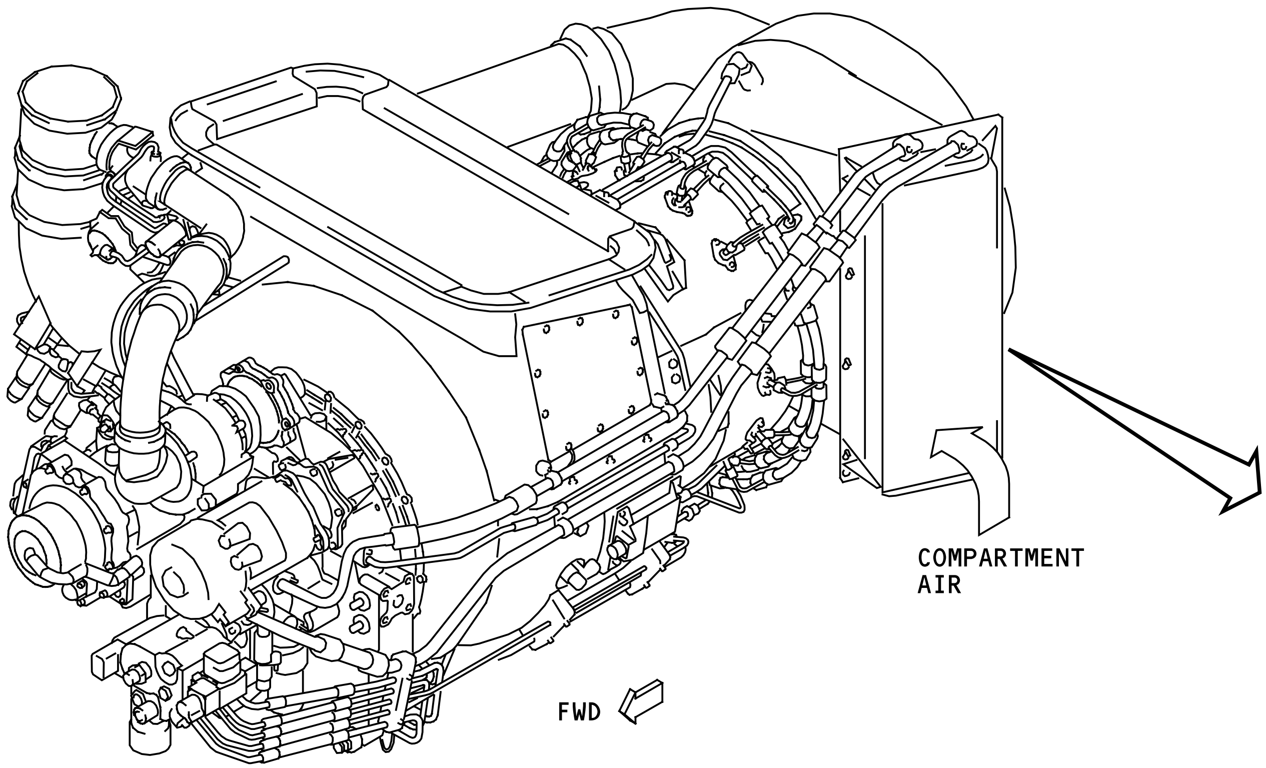
General

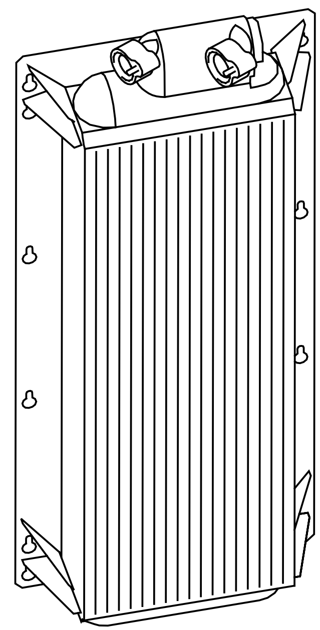
The oil cooler is a stainless steel air/oil heat exchanger. Compartment air cools the pressurized oil after the oil leaves the oil pump.

The oil cooler is on the left side of the APU turbine case. It is part of the exhaust eductor cooling system.

Functional Description

The APU exhaust causes a suction of air. This causes APU compartment air to move through the oil cooler to cool the APU oil. The cooling air then flows overboard through the exhaust duct.





OIL COOLER

49-27-00-005 Rev 1

APU AND GENERATOR LUBRICATION SYSTEM - OIL COOLER

APU AND GENERATOR LUBRICATION SYSTEM - FUNCTIONAL DESCRIPTION

General

The APU and generator lubrication system supplies pressurized oil to cool and lubricate APU components and the APU generator. A scavenge system returns the oil to the reservoir in the gearbox.

Supply

Oil pump elements in the lube cluster pump oil from the reservoir in the gearbox. Pressurized oil from the lube cluster goes to the oil cooler and then returns to the lube cluster.

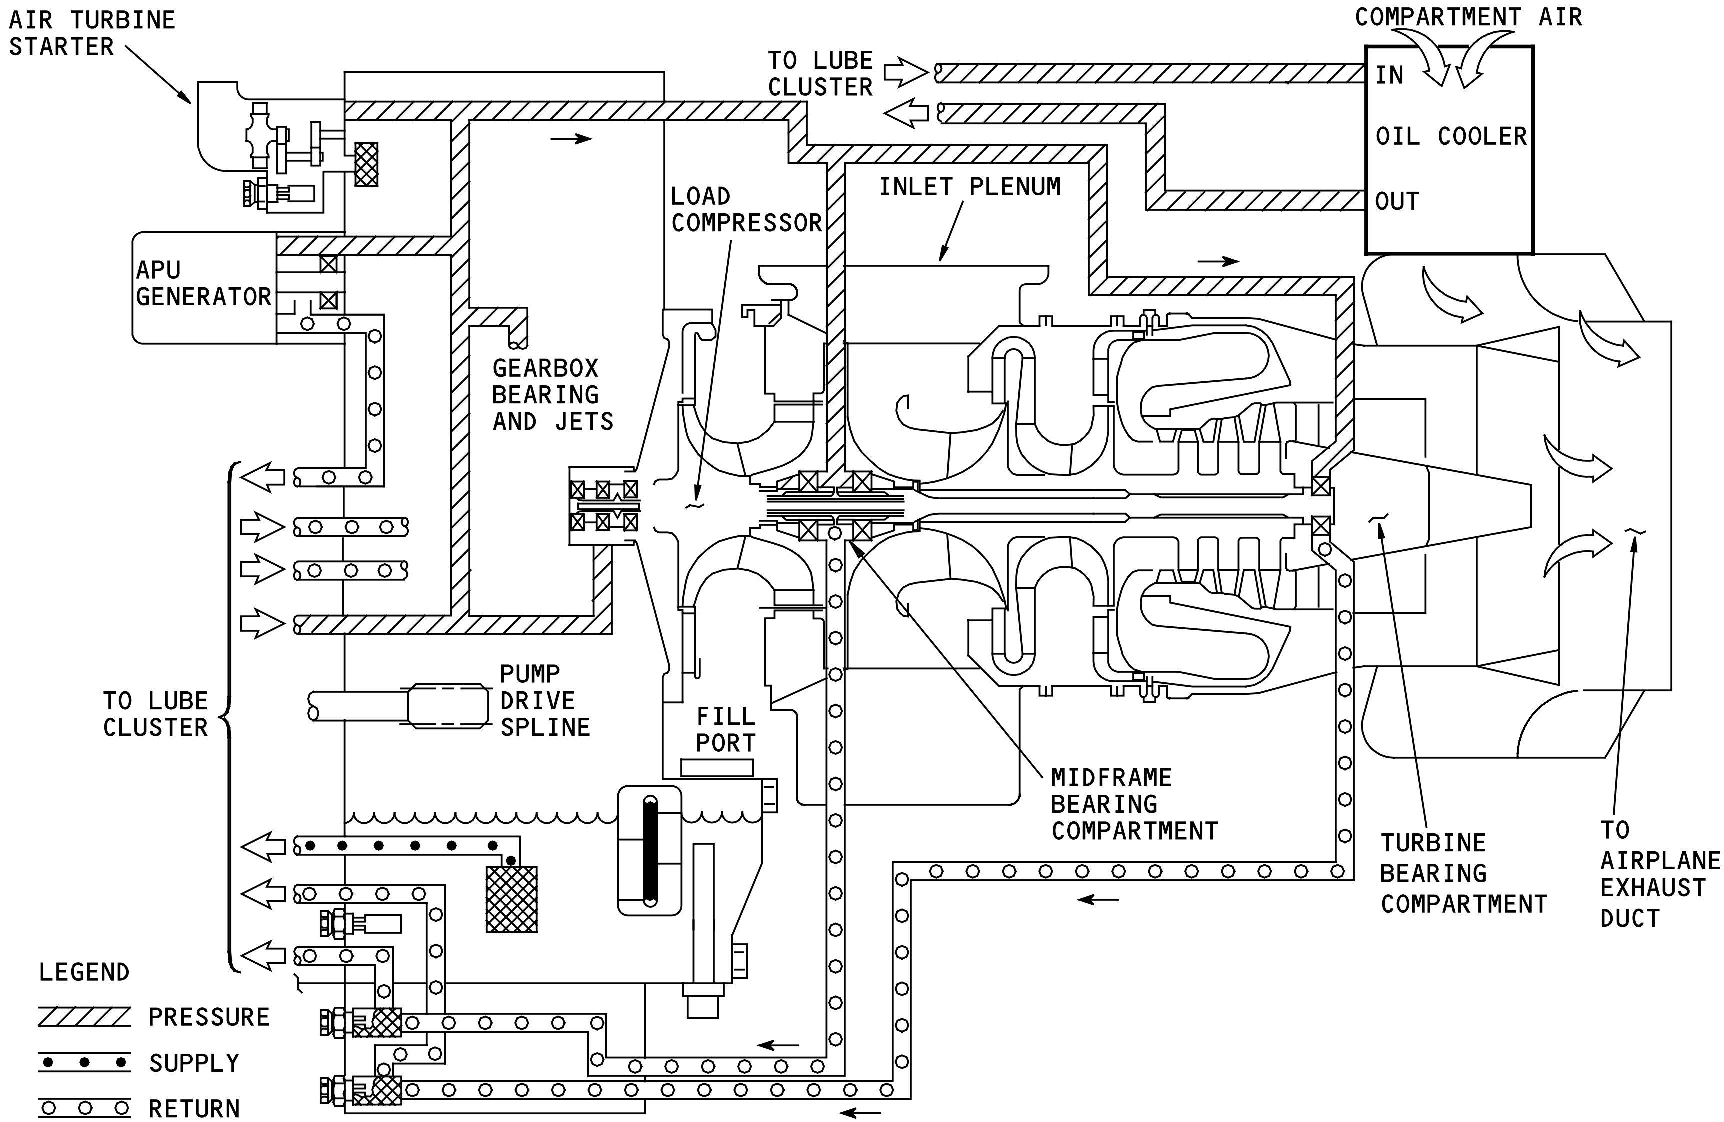
The lube cluster cleans the oil and regulates the oil pressure. Oil pressure and temperature sensors supply data to the APUC.

The oil then goes to the:

- APU generator
- Air turbine starter (ATS)
- Gearbox bearings and jets
- Load compressor bearings
- Midframe bearing compartment
- Turbine bearing compartment.

Scavenge

Scavenge pump elements in the lube cluster send the oil from the midframe and turbine bearing compartments back to the reservoir. Other scavenge pump elements send the scavenge oil from the APU generator through the scavenge filter and back to the gearbox reservoir.



49-27-00-006 Rev 2

APU AND GENERATOR LUBRICATION SYSTEM - FUNCTIONAL DESCRIPTION

APU OIL HEATER SYSTEM

Purpose

The APU oil heater system uses 115v ac electric-resistive heaters to heat the gearbox and midframe bearings. The heaters reduce bearing oil drag on start which increases starting reliability when the APU has been cold-soaked.

Location

There are three gearbox heater pads on the front face of the APU gearbox. A midframe heater probe is in a well on the bottom of the APU air inlet plenum.

Functional Description

The oil heater system operates continuously when the ground service bus has power.

The gearbox heater pads are made of aluminum. They heat the gearbox and gearbox bearings. The gearbox heater pads are self-regulating and can be as hot as 450F (232C). There are insulation pads (not shown) on the gearbox heater pads.

A probe-type stainless steel heater heats the midframe bearings.

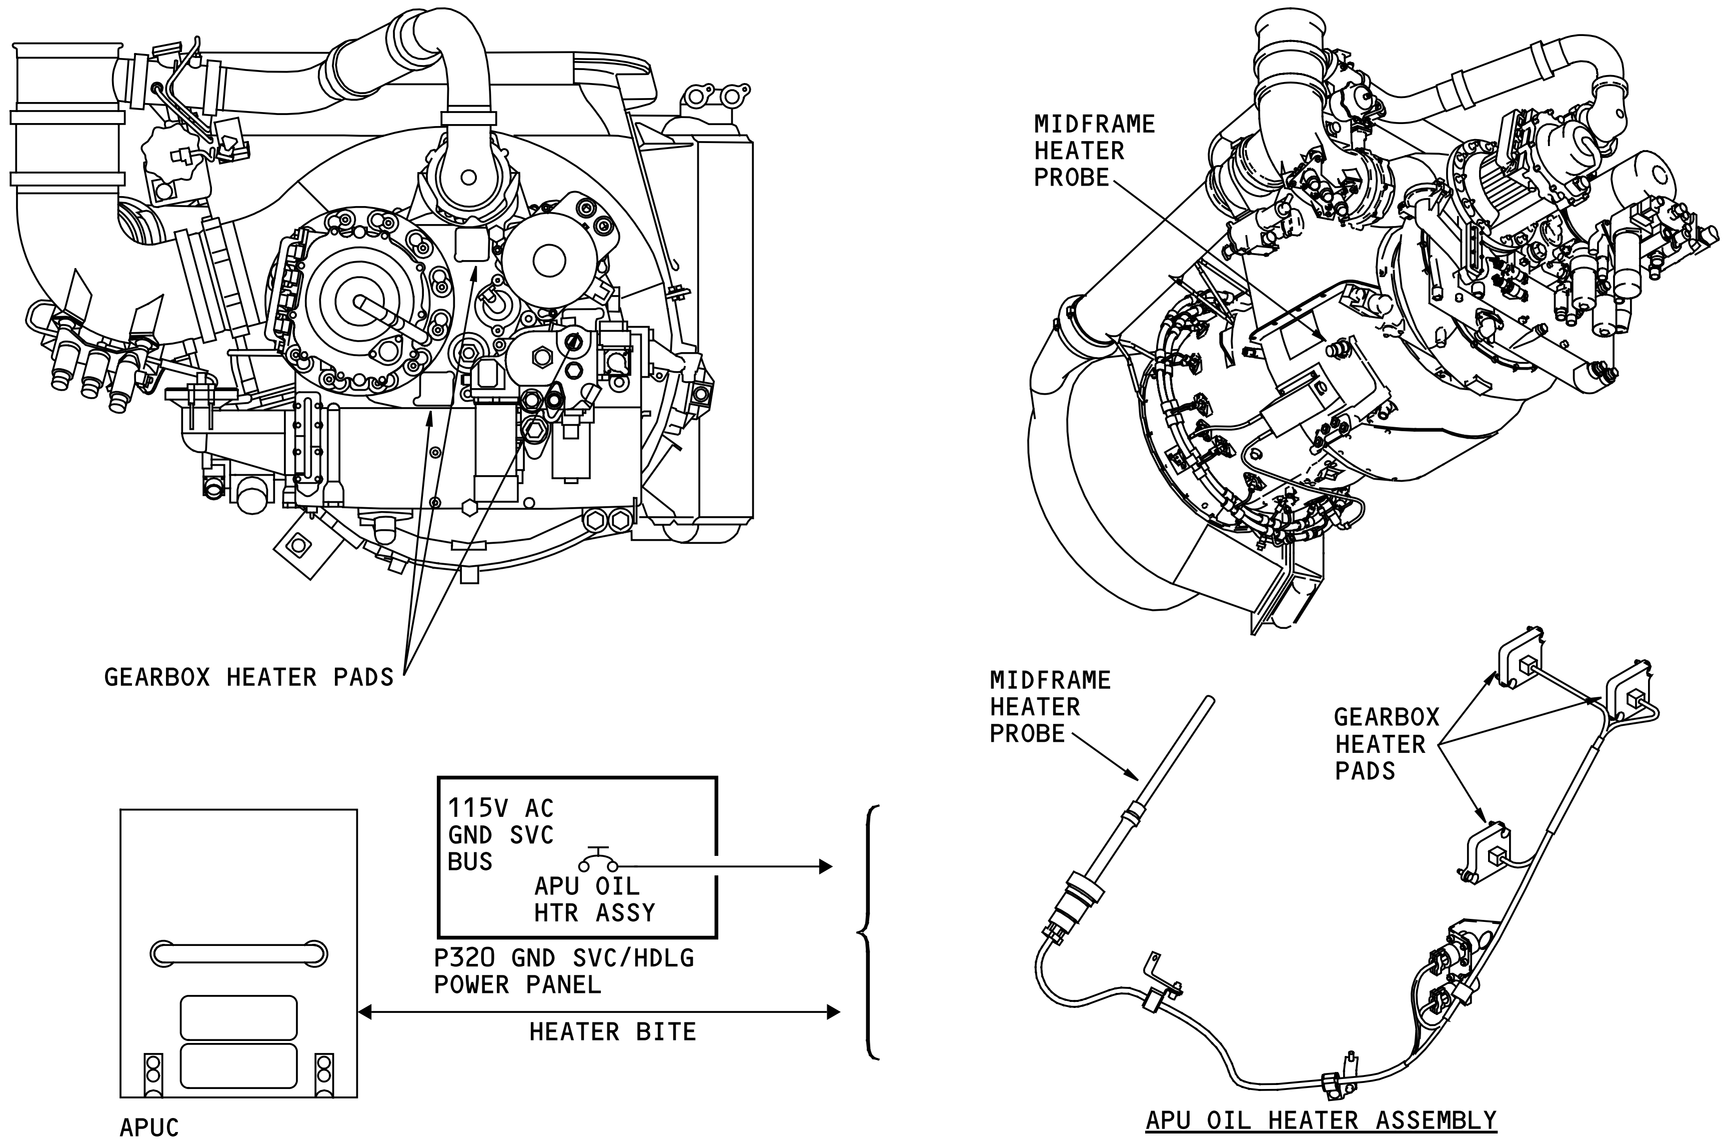
The APUC monitors the heaters for faults.

Training Information Point

The APU oil heater assembly is an LRU.

The APU CONTROL status message shows is there is an APU oil heater fault.

WARNING: DO NOT TOUCH THE APU OIL HEATER ASSEMBLY. THE GEARBOX HEATERS STAY HOT WHEN THE AIRPLANE HAS AC POWER.



APU OIL HEATER SYSTEM

APU OIL INDICATING SYSTEM - INTRODUCTION

Purpose

The APU oil indicating system supplies APU oil temperature, pressure, and quantity data for APU flight deck display and APU control functions.

Components

These are the oil indicating system components:

- Oil pressure sensor
- Low oil pressure switch
- Oil temperature sensor
- Oil quantity/sump temperature sensor.

An oil level sight gage on the gearbox shows oil level.

Location

The oil pressure sensor, the low oil pressure switch, and the oil temperature sensor are on the lube cluster. The oil quantity/sump temperature sensor and the oil level sight gage are on the APU gearbox.

General Description

The APUC receives oil indicating system inputs and supplies this data to the AIMS to show on the MFD.

Oil indicating system data shows on the status display and on the APU maintenance page.

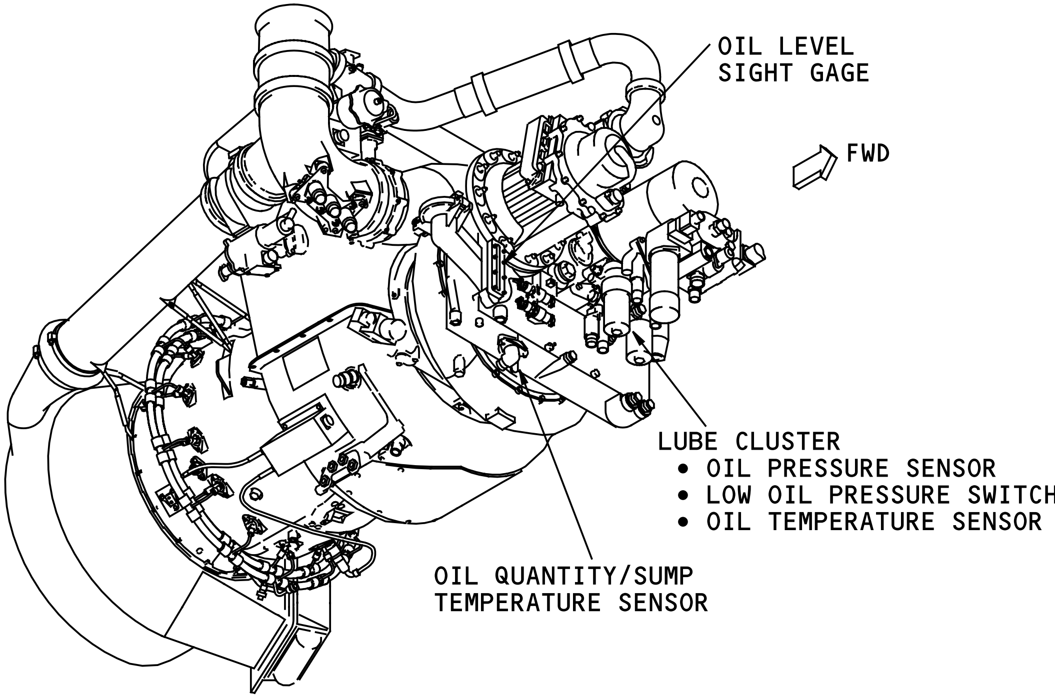
Protective Shutdowns

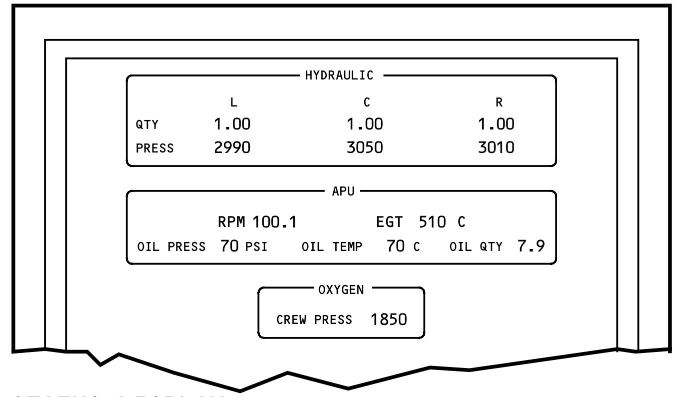
Low oil pressure, loss of oil pressure input, or high oil temperature will cause the APUC to do a protective shutdown when the APU is in the unattended mode.

Non-Normal Indications

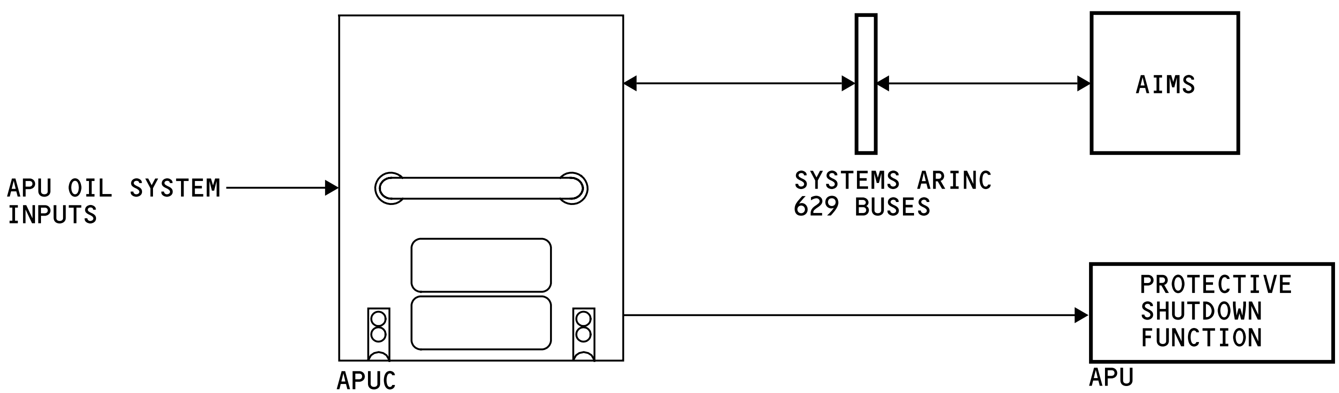
The APU OIL QTY status message shows when the APU oil quantity is 3.8 quarts (3.5 liters) or less. This message also shows for an oil quantity/sump temperature sensor failure.

The APU status message shows for an oil temperature sensor failure.





STATUS DISPLAY



APU OIL INDICATING SYSTEM - INTRODUCTION

APU OIL INDICATING SYSTEM - COMPONENTS

Oil Quantity/Sump Temperature Sensor

The oil quantity/temperature sensor is a capacitance-type sensor and is in the sump of the oil reservoir on the bottom of the APU gearbox. The sensor sends both oil quantity and oil temperature data to the APUC.

Oil Pressure Sensor

The oil pressure sensor sends oil system pressure data to the APUC. This sensor is on the lube cluster.

Low Oil Pressure Switch

The low oil pressure switch sends a low oil pressure signal to the APUC when APU oil pressure is below 30 to 40 psi. This switch is on the lube cluster.

Oil Temperature Sensor

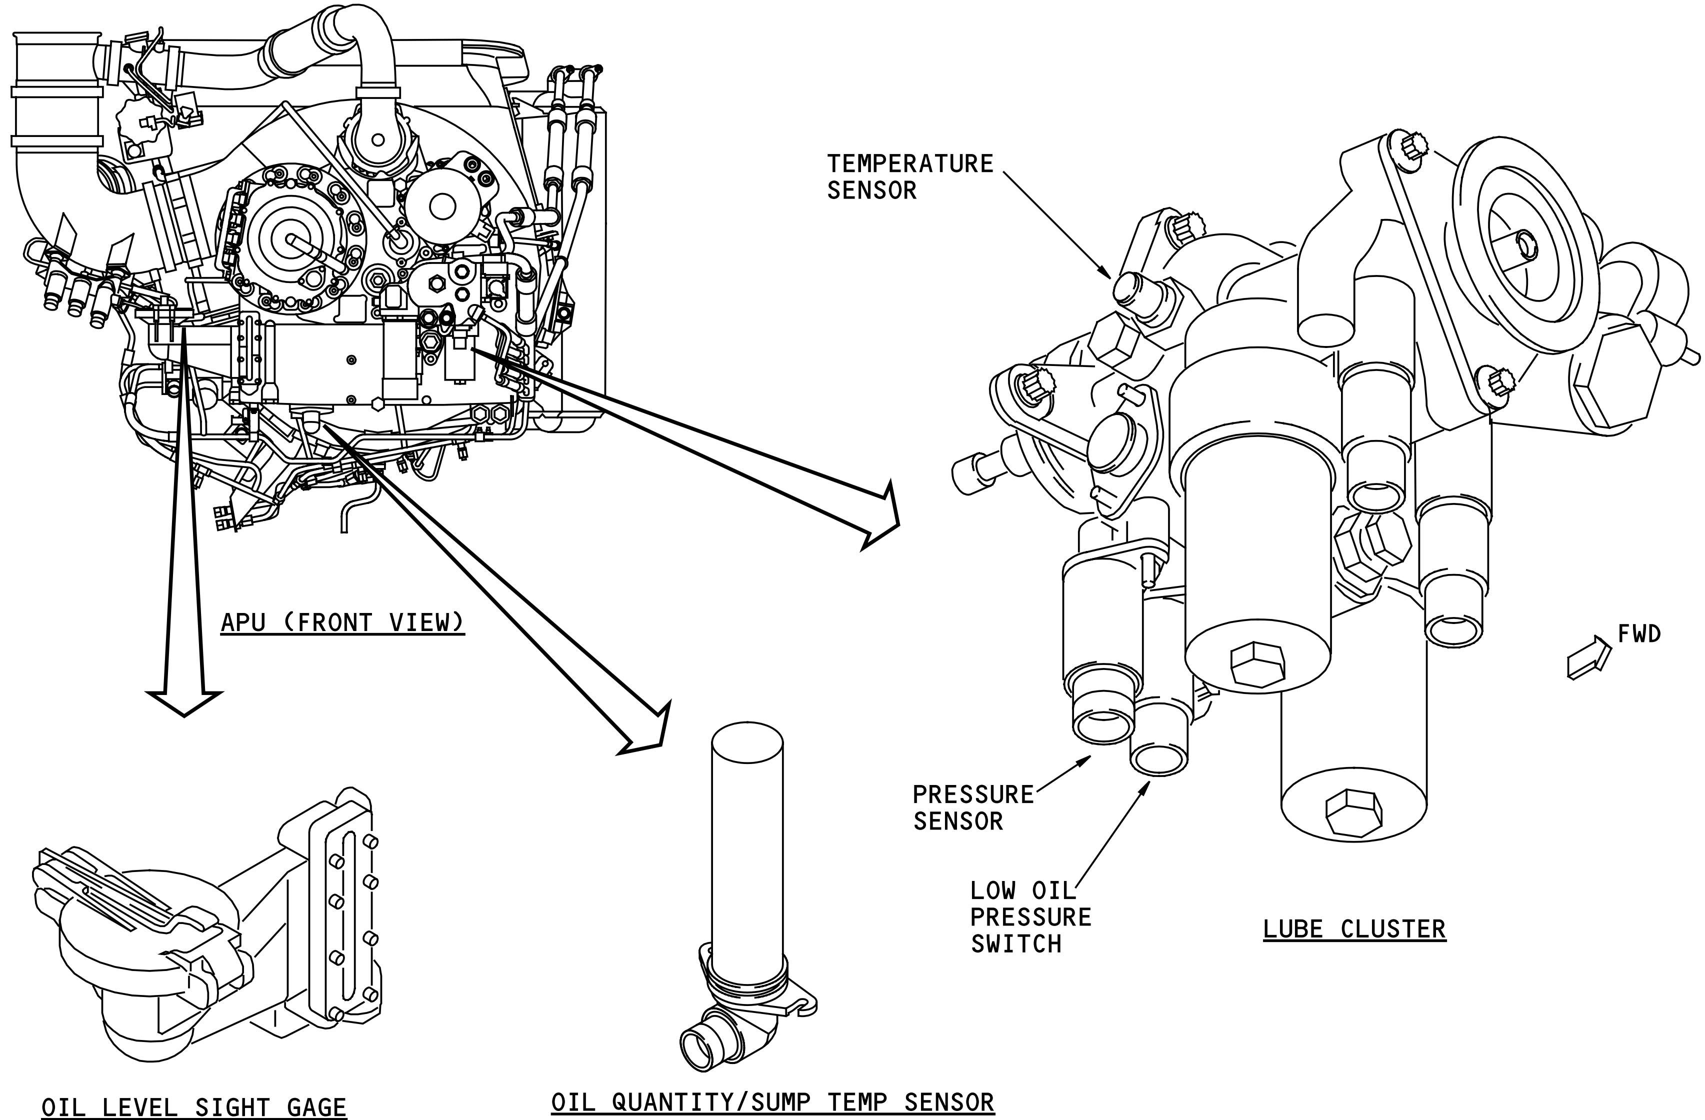
The oil temperature sensor is a resistive type sensor. It sends oil temperature data to the APUC and is on the Lube cluster.

Oil Level Sight Gage

The oil level sight gage is on the right, front of the gearbox. The sight gage is part of the oil fill port.

Training Information Point

All APU oil sensors are LRUs. The sight gage and fill port are a single LRU.



APU OIL INDICATING SYSTEM - COMPONENTS

APU FUEL SYSTEM - INTRODUCTION

Purpose

The APU fuel system supplies pressurized and metered fuel to the APU combustion chamber. It also supplies pressurized fuel to actuators for the inlet guide vanes and the surge control valve.

Interfaces

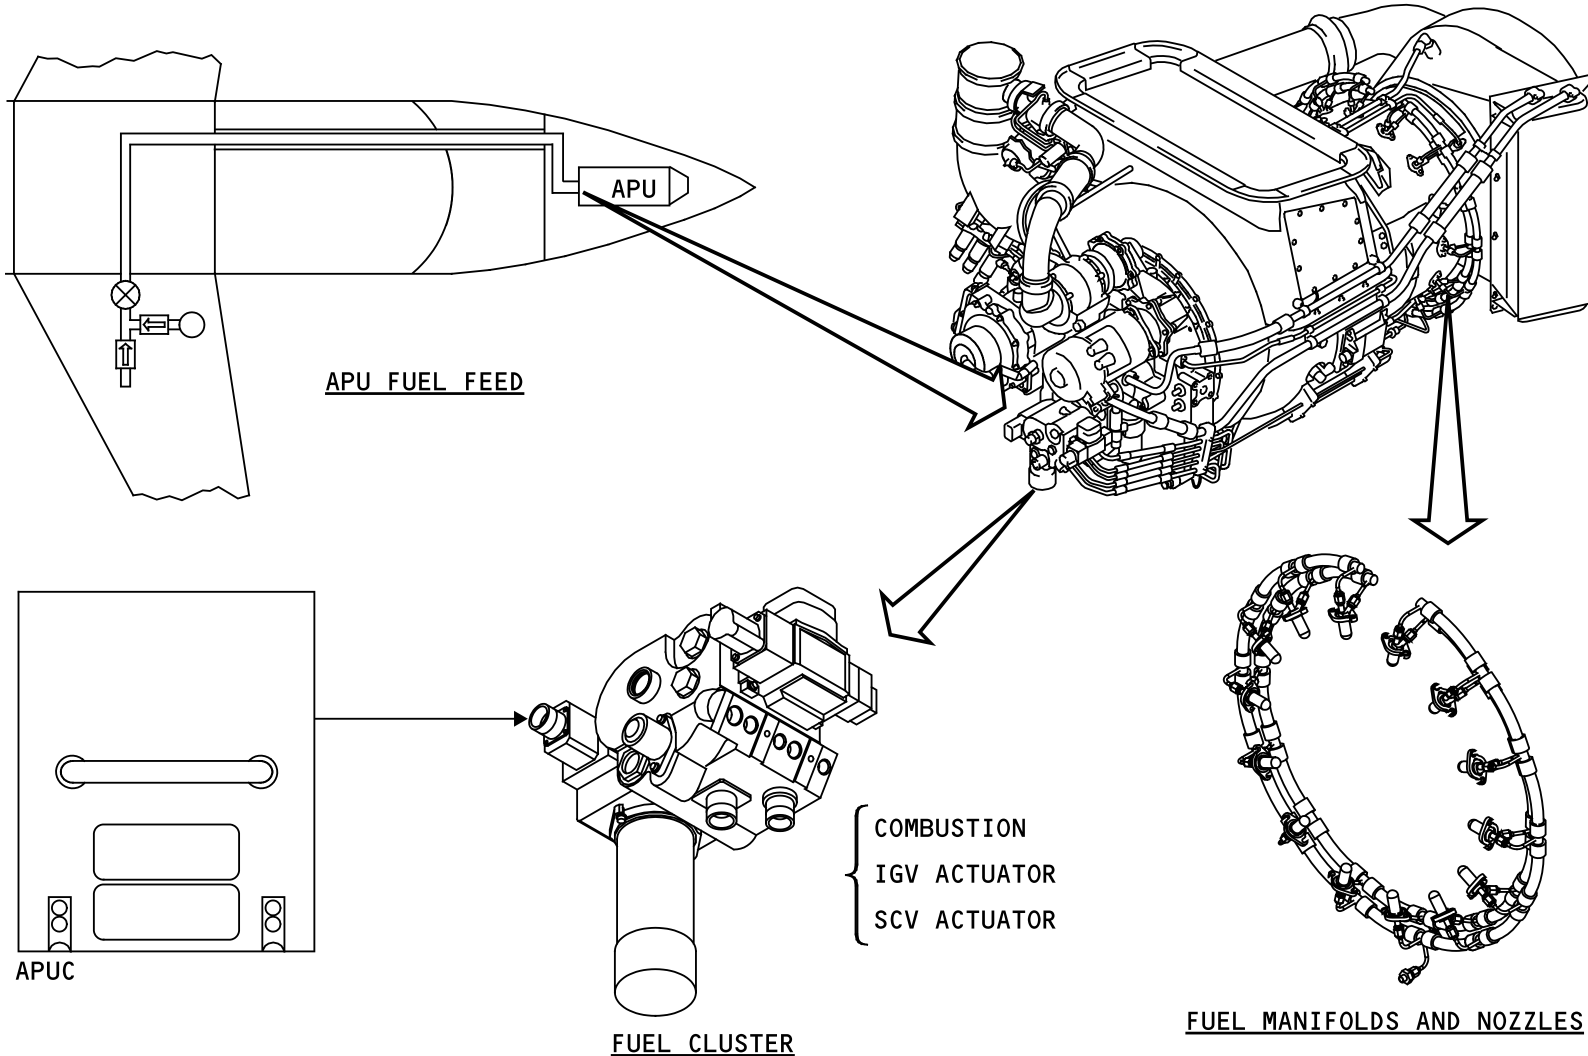
Fuel system ac boost pumps or the APU dc fuel pump in the wing supply fuel from the airplane fuel system for APU operation.

The APU controller (APUC) controls the APU fuel system.

Components

Most fuel system components are on a common fuel cluster on the forward side of the APU gearbox.

Other fuel system components are the fuel manifolds and the fuel nozzles.



APU FUEL SYSTEM - INTRODUCTION

APU FUEL SYSTEM - FUEL CLUSTER - INTRODUCTION

General

The fuel cluster contains the APU fuel control and other fuel system components. The fuel cluster is attached to the lube cluster which turns the fuel system pumps.

Training Information Point

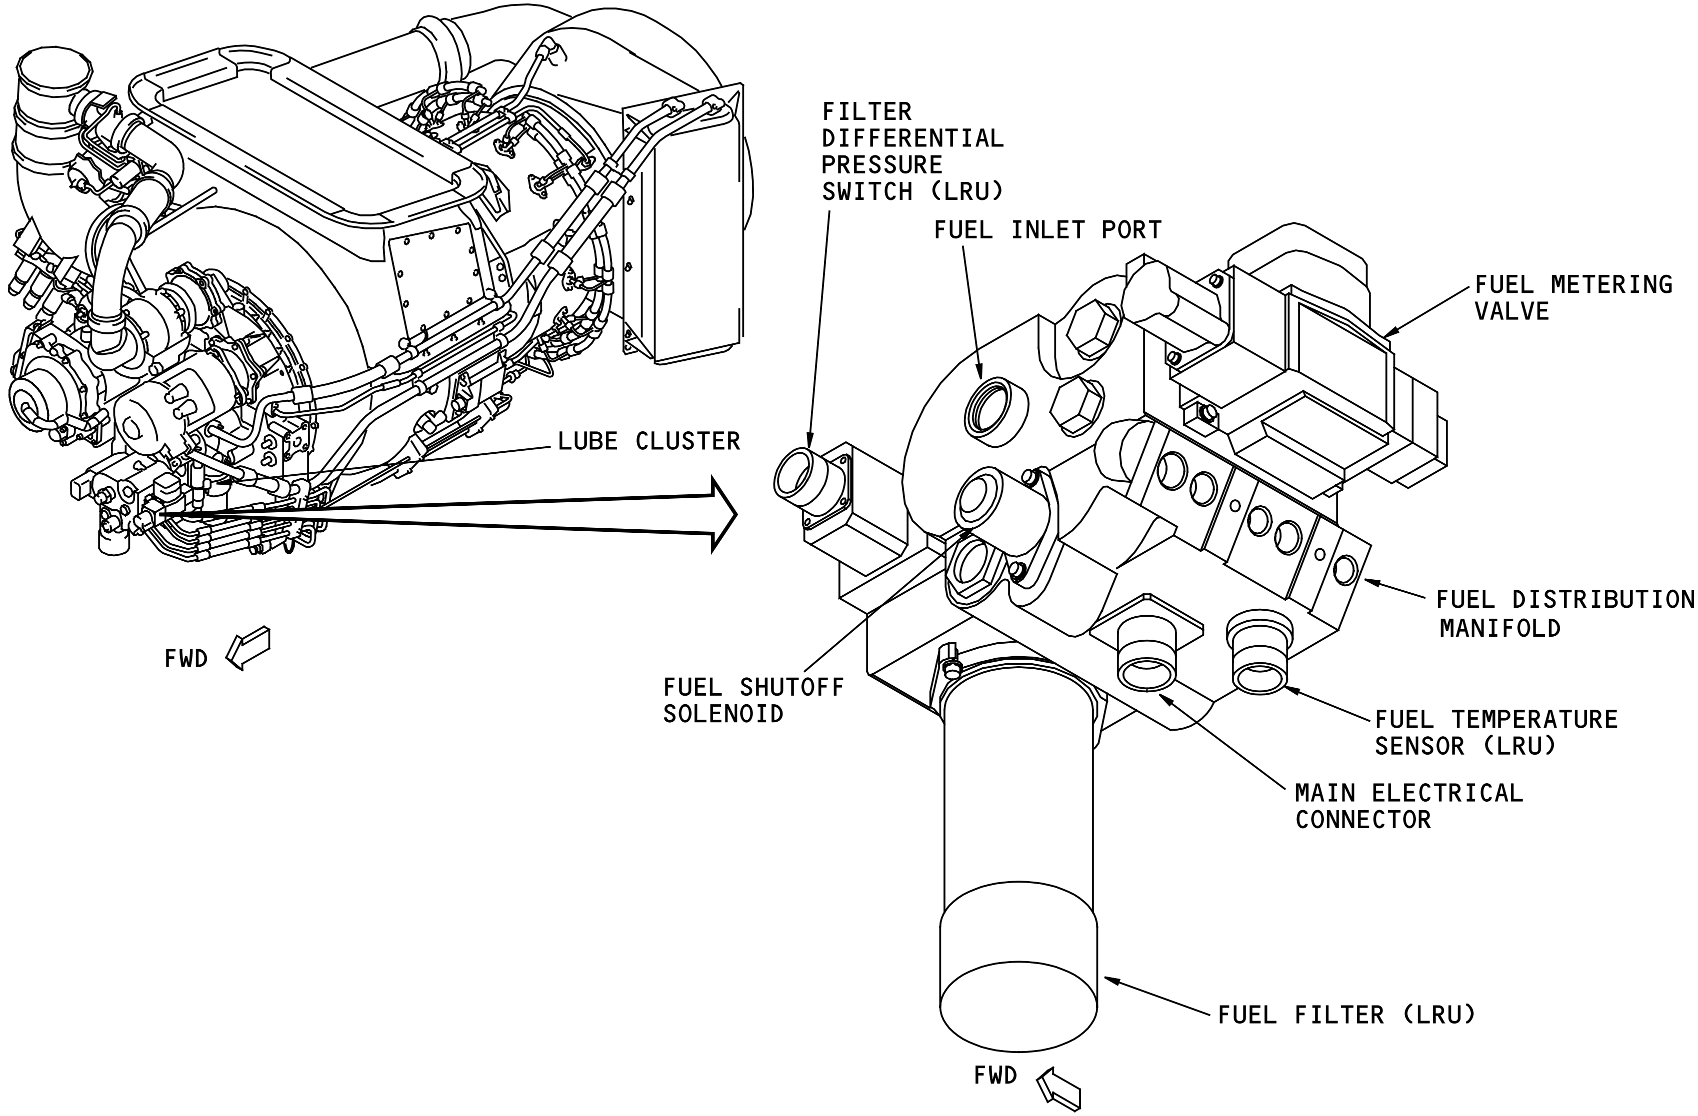
The entire fuel cluster is an LRU. These components are also LRUs:

- Fuel filter
- Fuel filter differential pressure switch
- Fuel temperature sensor.

These fuel cluster components are not LRUs:

- Fuel shutoff solenoid
- Fuel metering valve
- Fuel distribution manifold.

The fuel cluster also contains the fuel pumps and some internal pressure regulating valves.



49-30-00-002 Rev 1

APU FUEL SYSTEM - FUEL CLUSTER - INTRODUCTION

APU FUEL SYSTEM - MANIFOLDS AND NOZZLES

Fuel Manifolds

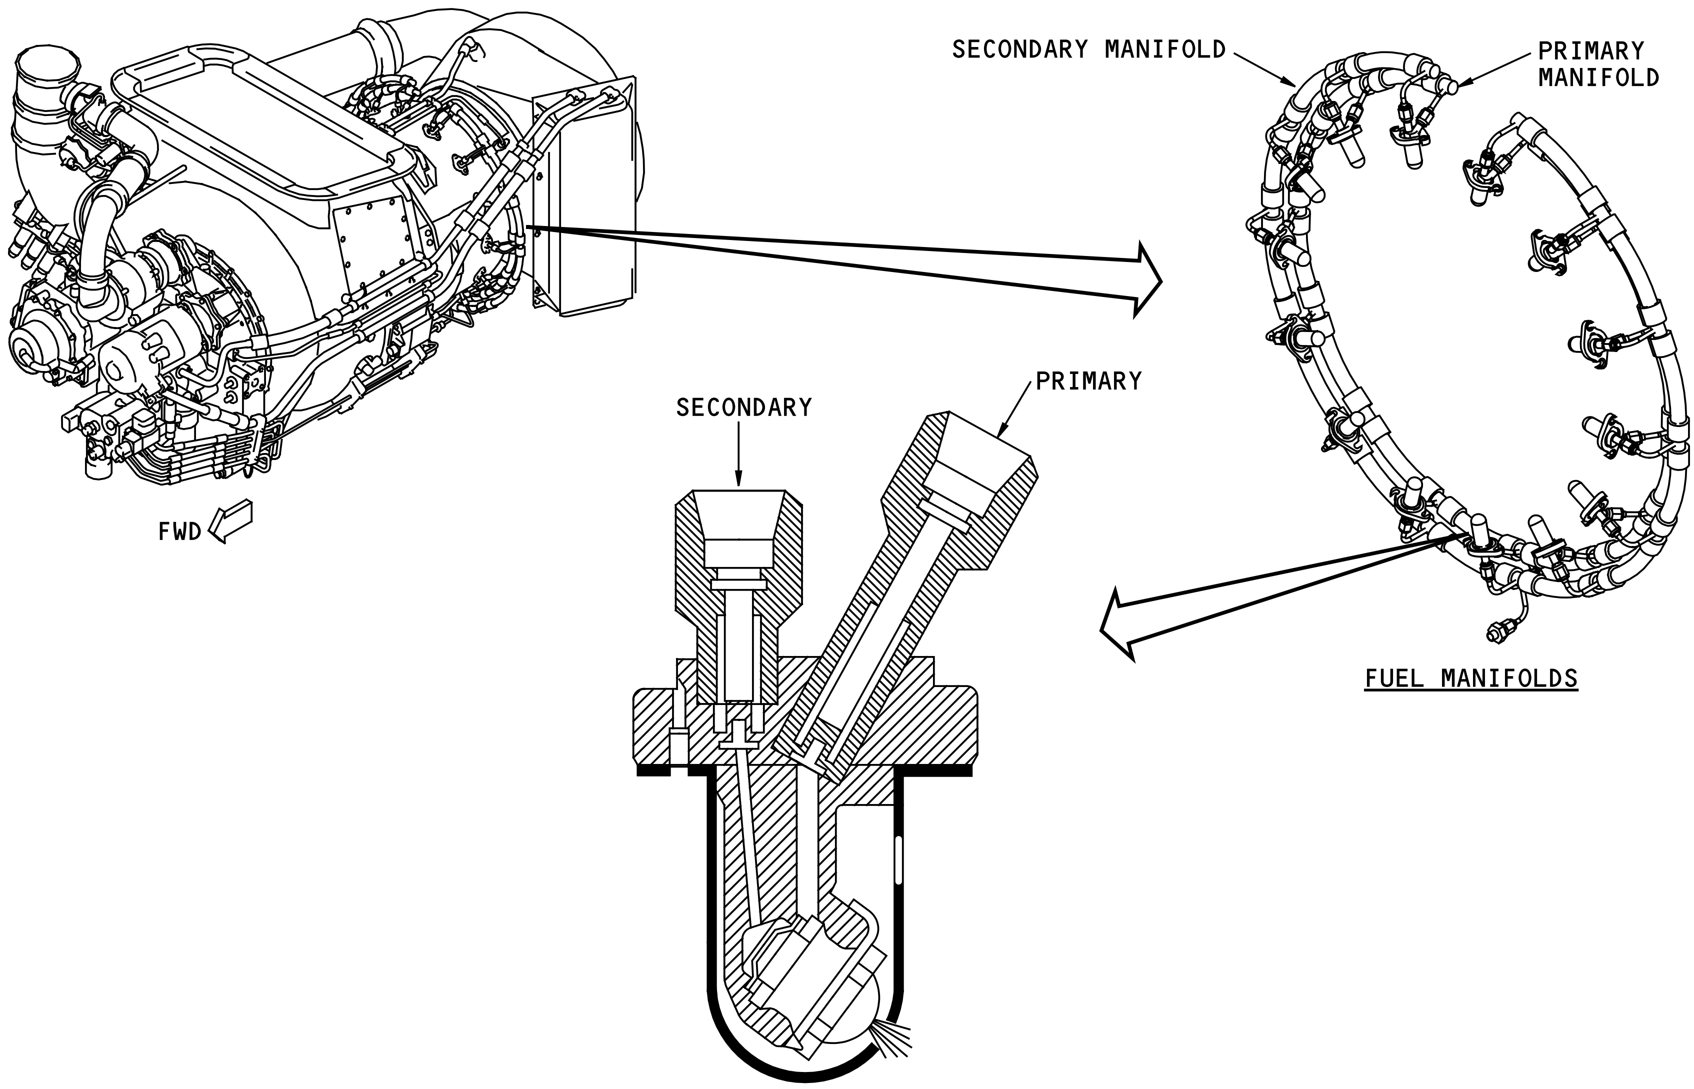
A primary fuel manifold and a secondary fuel manifold supply fuel from the fuel cluster to the fuel nozzles.

The manifolds are insulated flexible lines and are on the combustion section.

Both manifolds supply fuel when the APU is running. Only the primary manifold supplies fuel during the first part of APU start at low RPM.

Fuel Nozzles

Fourteen fuel nozzles atomize and inject fuel into the engine combustion section. The fuel nozzles are equally spaced around the combustion section.



APU FUEL SYSTEM - MANIFOLDS AND NOZZLES

THIS PAGE INTENTIONALLY LEFT BLANK

APU FUEL SYSTEM - FUNCTIONAL DESCRIPTION

General

The APU controller automatically controls the APU fuel system. The APU fuel system supplies fuel for combustion and is a pressure source for the IGV and SCV actuators.

Fuel Supply

Fuel system ac boost pumps or the APU dc fuel pump supplies fuel through the APU fuel shutoff valve. The shutoff valve opens when the APU selector is ON. The dc pump operates when ac power is not available. When ac power becomes available, the left forward boost pump turns on and the dc pump turns off.

Fuel Cluster

The fuel cluster gets the fuel from the airplane fuel system and does these functions:

- Pressurizes the fuel (fuel pump)
- Cleans the fuel (filter)
- Controls the fuel pressure (pressure regulator)
- Controls fuel flow (fuel metering valve and fuel shutoff solenoid valve)
- Divides the fuel flow (fuel flow divider)
- Monitors the fuel temperature (fuel temperature sensor).

APUC Control

The APUC has the logic to control the fuel solenoid valve and the fuel metering valve.

During APU start, the APUC energizes the fuel shutoff solenoid valve when the APU engine RPM is more than 7 percent. The APUC also controls the fuel metering valve when the RPM is more than 7 percent.

The APUC uses start-up control logic to control the fuel metering valve when the RPM is less than 95 percent. This logic schedules fuel flow to start the APU quickly and to keep the maximum EGT low. Start-up fuel flow logic uses these inputs:

- APU RPM (N)
- Inlet pressure (P2)
- Inlet temperature (T2)
- Turbine inlet temperature (T4)
- Exhaust gas temperature (EGT)
- ATS command
- Fuel temperature.

The APUC uses on-speed control logic to control the fuel metering valve when the RPM is more than 95 percent. This logic schedules fuel flow to keep APU speed at 100 percent RPM or at the correct speed for no-break power transfers. During no-break-power-transfers between the APU generator and external power, the APUC adjusts the APU speed between 96.25 percent and 104.5 percent.

APU FUEL SYSTEM - FUNCTIONAL DESCRIPTION

The on-speed control logic uses these inputs:

- APU RPM
- Fuel temperature
- Frequency trim.

Fuel Manifolds

The fuel cluster supplies metered fuel to the primary and secondary fuel manifolds for combustion.

Only the primary manifold gets fuel at low engine speeds during engine start. Both manifolds get fuel when the engine speed is more than approximately 50 percent RPM.

Servo Fuel

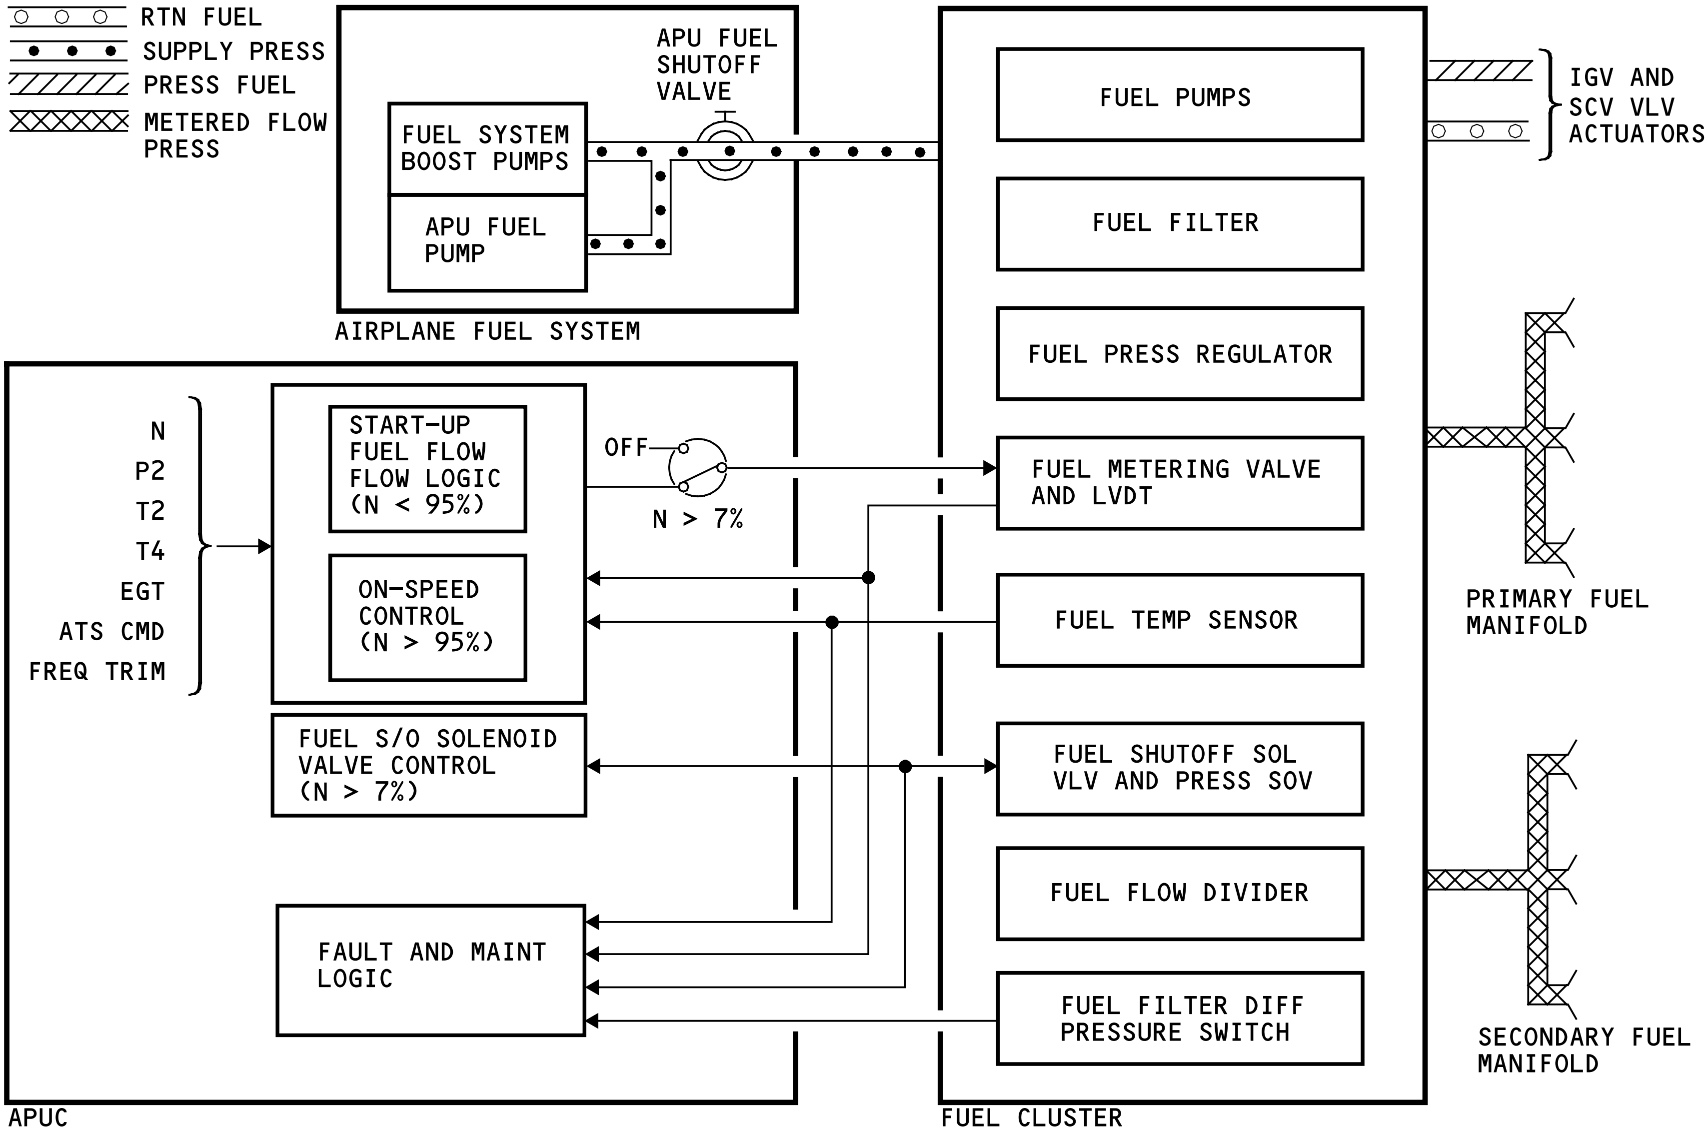
The fuel cluster also supplies pressurized fuel to operate the inlet guide vane and surge control valve actuators.

Return fuel from these actuators goes back to the pump in the fuel cluster.

APUC Monitoring

The APUC monitors these APU fuel system components:

- Fuel temperature sensor
- Fuel filter differential pressure switch
- Fuel metering valve
- Fuel shutoff valve.



APU FUEL SYSTEM - FUNCTIONAL DESCRIPTION

49-30-00-005 Rev 3

APU IGNITION/STARTING - INTRODUCTION

General

The APU ignition/starting system has these systems:

- Ignition system
- Air turbine starter system
- Electric starter system.

Ignition System

The ignition system starts the APU combustion during APU start. These components are part of the ignition cluster on the right side of the APU:

- Ignition unit
- Ignition lead (2)
- Igniter plug (2).

The APUC controls the ignition system.

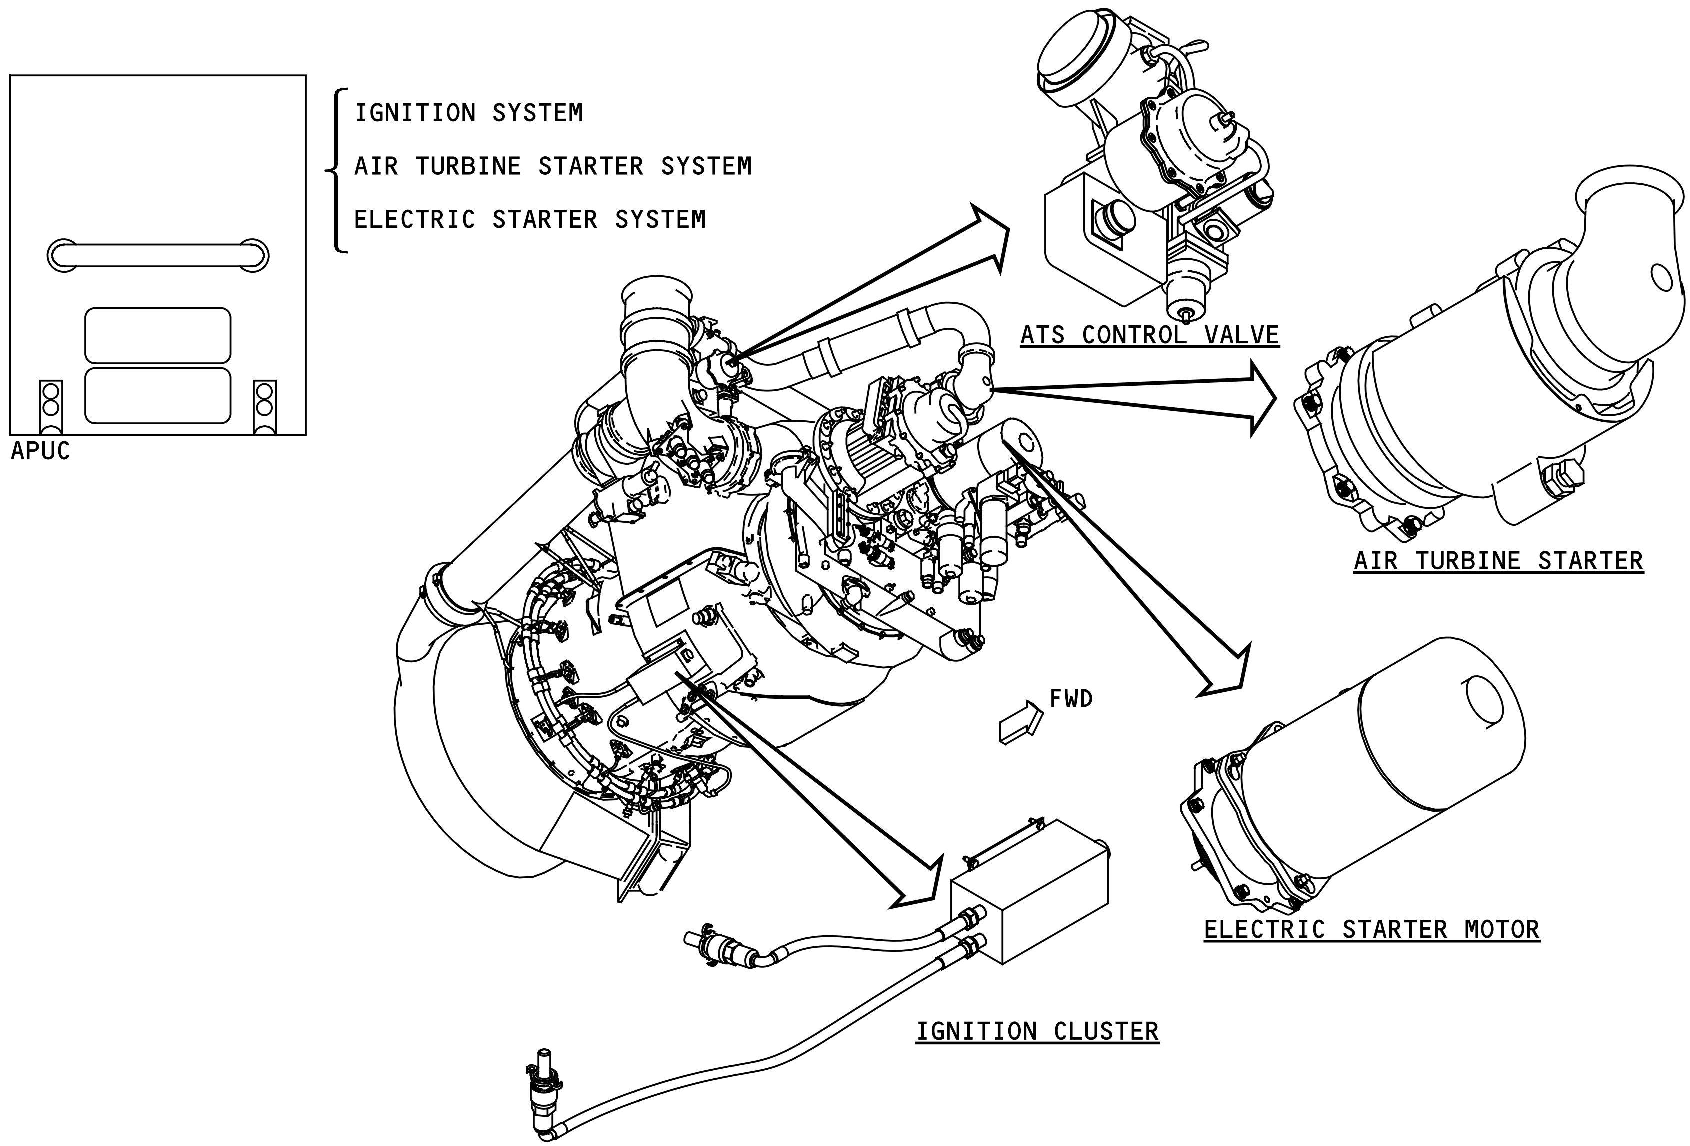
Start Systems

There are two starter motors: one pneumatic and one electric. They are on the front of the APU.

The air turbine starter system starts the APU when pneumatic pressure is available. The air turbine starter system uses an air turbine starter control valve (ATSCV) to control pneumatic flow to the air turbine starter.

The electric starter system starts the APU only when the pneumatic system is not pressurized or if there is a failure in the air turbine starter system.

The APUC controls both start systems and automatically selects between the starters.



APU IGNITION/STARTING - INTRODUCTION

49-40-00-001 Rev 1

APU IGNITION/STARTING - APU IGNITION SYSTEM - GENERAL DESCRIPTION

General

The ignition system starts the combustion of the fuel-air mixture during engine start. The APU controller controls the ignition system.

The ignition system components are part of a common cluster and are on the right side of the engine.

Ignition Unit

The ignition unit changes 28v dc power to high voltage pulsed current that goes to the ignitor plugs. The ignition unit has two channels: one for each igniter plug. Four bolts hold the ignition unit to the APU.

Ignition Leads

Ignition leads connect the ignition unit to the igniter plugs. The leads are insulated to protect against radio interference. There are connectors at each end of the ignition leads.

Igniter Plugs

Two igniter plugs supply the high energy spark for fuel/air ignition. One is on the right side and the other is on the bottom of the APU combustion section. The ignition lead connectors hold the plugs in the boss.

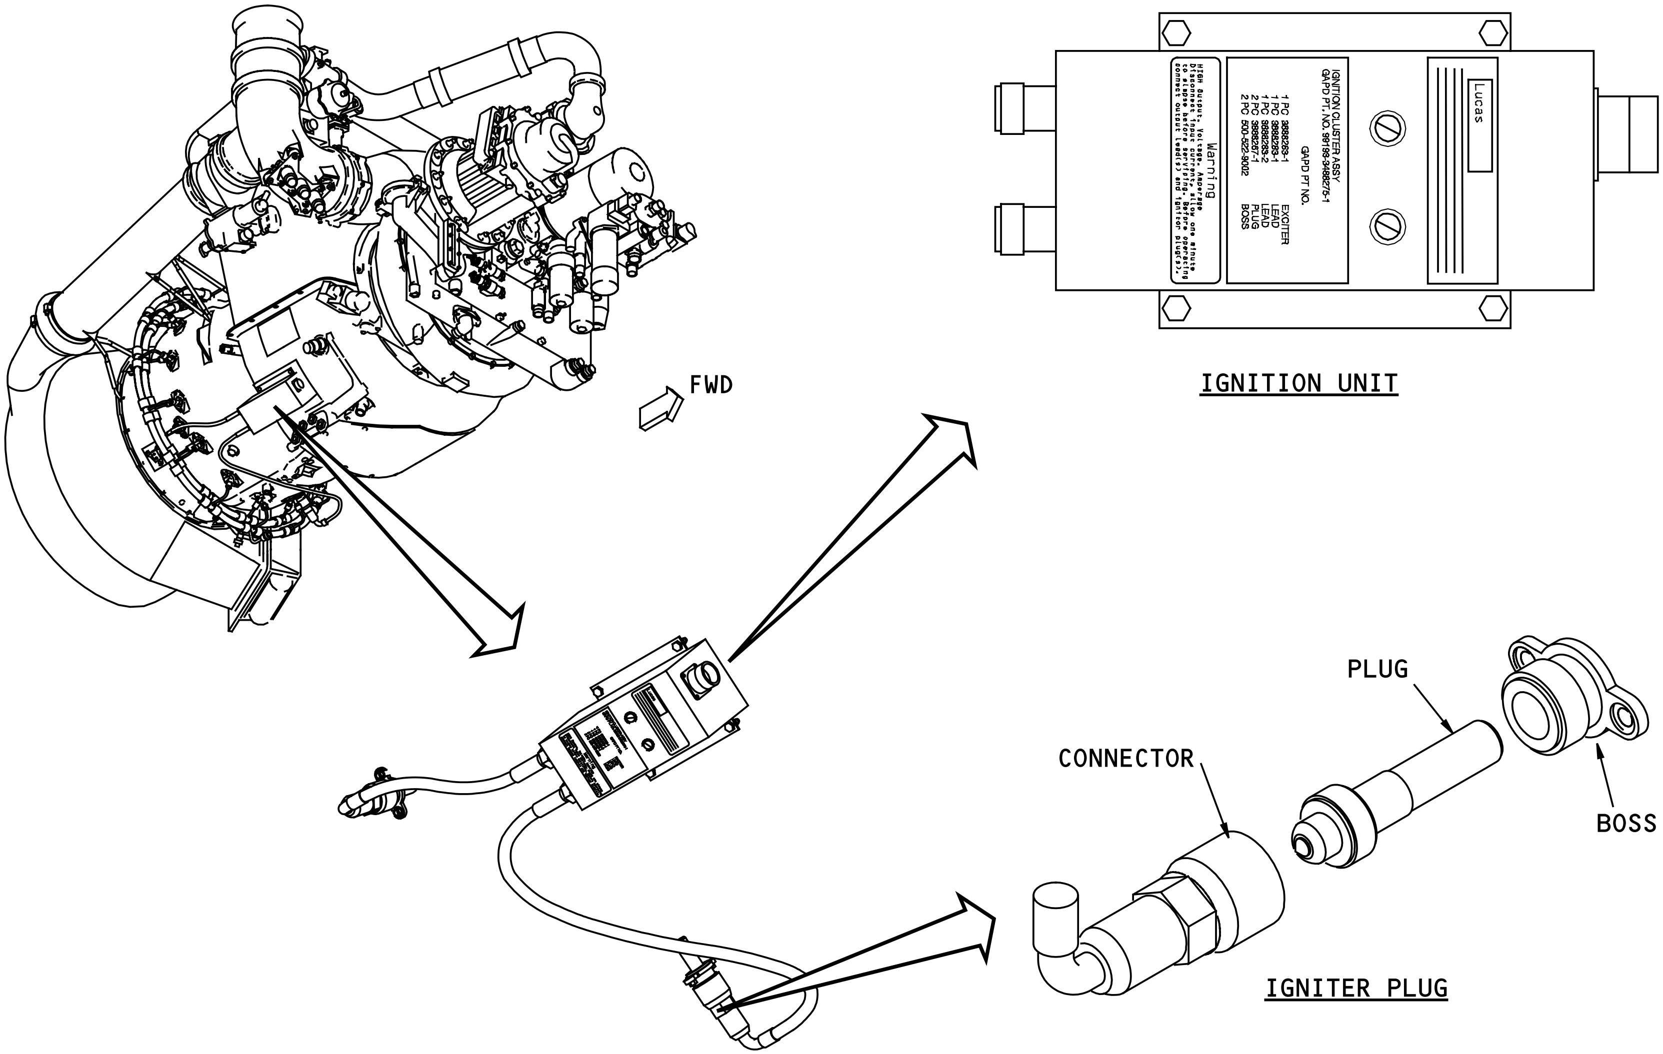
Functional Description

The APUC turns on the igniter plugs at 7 percent APU engine RPM during APU start. The APUC turns the plugs off at 50 percent RPM.

The APUC also turns the igniter plugs on if the APU engine RPM goes below 95 percent RPM during APU operation (speed droop).

Training Information Point

WARNING: DO NOT TOUCH THE IGNITION COMPONENTS UNTIL YOU RELEASE THE HIGH VOLTAGE FROM THE IGNITION UNIT. IF YOU DO NOT OBEY THIS PROCEDURE, INJURY TO PERSONS CAN OCCUR.



49-40-00-002 Rev 2

APU IGNITION/STARTING - APU IGNITION SYSTEM - GENERAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

APU IGNITION/STARTING - APU ELECTRIC STARTER SYSTEM - GENERAL DESCRIPTION

General

The electric starter system has these components:

- The electric starter motor
- The electric starter clutch.

The electric starter system starts the APU when pneumatic power is not available or if the air turbine starter system has a failure. The APUC controls the electric starter system.

Physical Description

The electric starter motor is a 28v dc series-wound motor. Four bolts hold the motor to the gearbox adapter on the front of the APU. A ratchet on the electric starter motor shaft connects the starter motor to the electric starter clutch. The starter motor weighs 38 pounds (17 kg).

The electric starter clutch is a pawl and ratchet type mechanism which transmits the starter motor torque to the APU gearbox. The pawls turn with the APU and the ratchet wheel turns with the starter motor. Pawl springs hold the pawls against the ratchet wheel at low speeds. The pawls disengage by centrifugal force after the starter turns off. A single bolt attaches the clutch to the starter drive gear shaft. The clutch is inside the gearbox adapter.

Functional Description

During an electric start, the starter motor turns the ratchet wheel and the electric starter clutch through the three pawls. The clutch turns the APU engine through the APU gearbox.

The electric starter motor turns off at 49 percent engine RPM for low altitude starts and 55 percent engine RPM for starts above 22,000 feet (5800m). The pawls then move outward against the pawl springs by centrifugal force. This disengages the clutch from the starter motor.

During an air turbine start, the electric starter clutch turns with the APU engine. The electric starter motor and the ratchet wheel do not turn. The pawls move up the sloped edge of the ratchet teeth to permit rotation between the ratchet wheel and the clutch. At approximately 17 percent APU engine RPM, the pawls lift off of the ratchet by centrifugal force to disengage the clutch from the starter motor.

Training Information Point

A lifting lug on the top of the electric starter permits attachment of a fishpole hoist for removal and installation.

A hand crank access on the electric starter motor permits you to manually crank the engine through the starter motor.

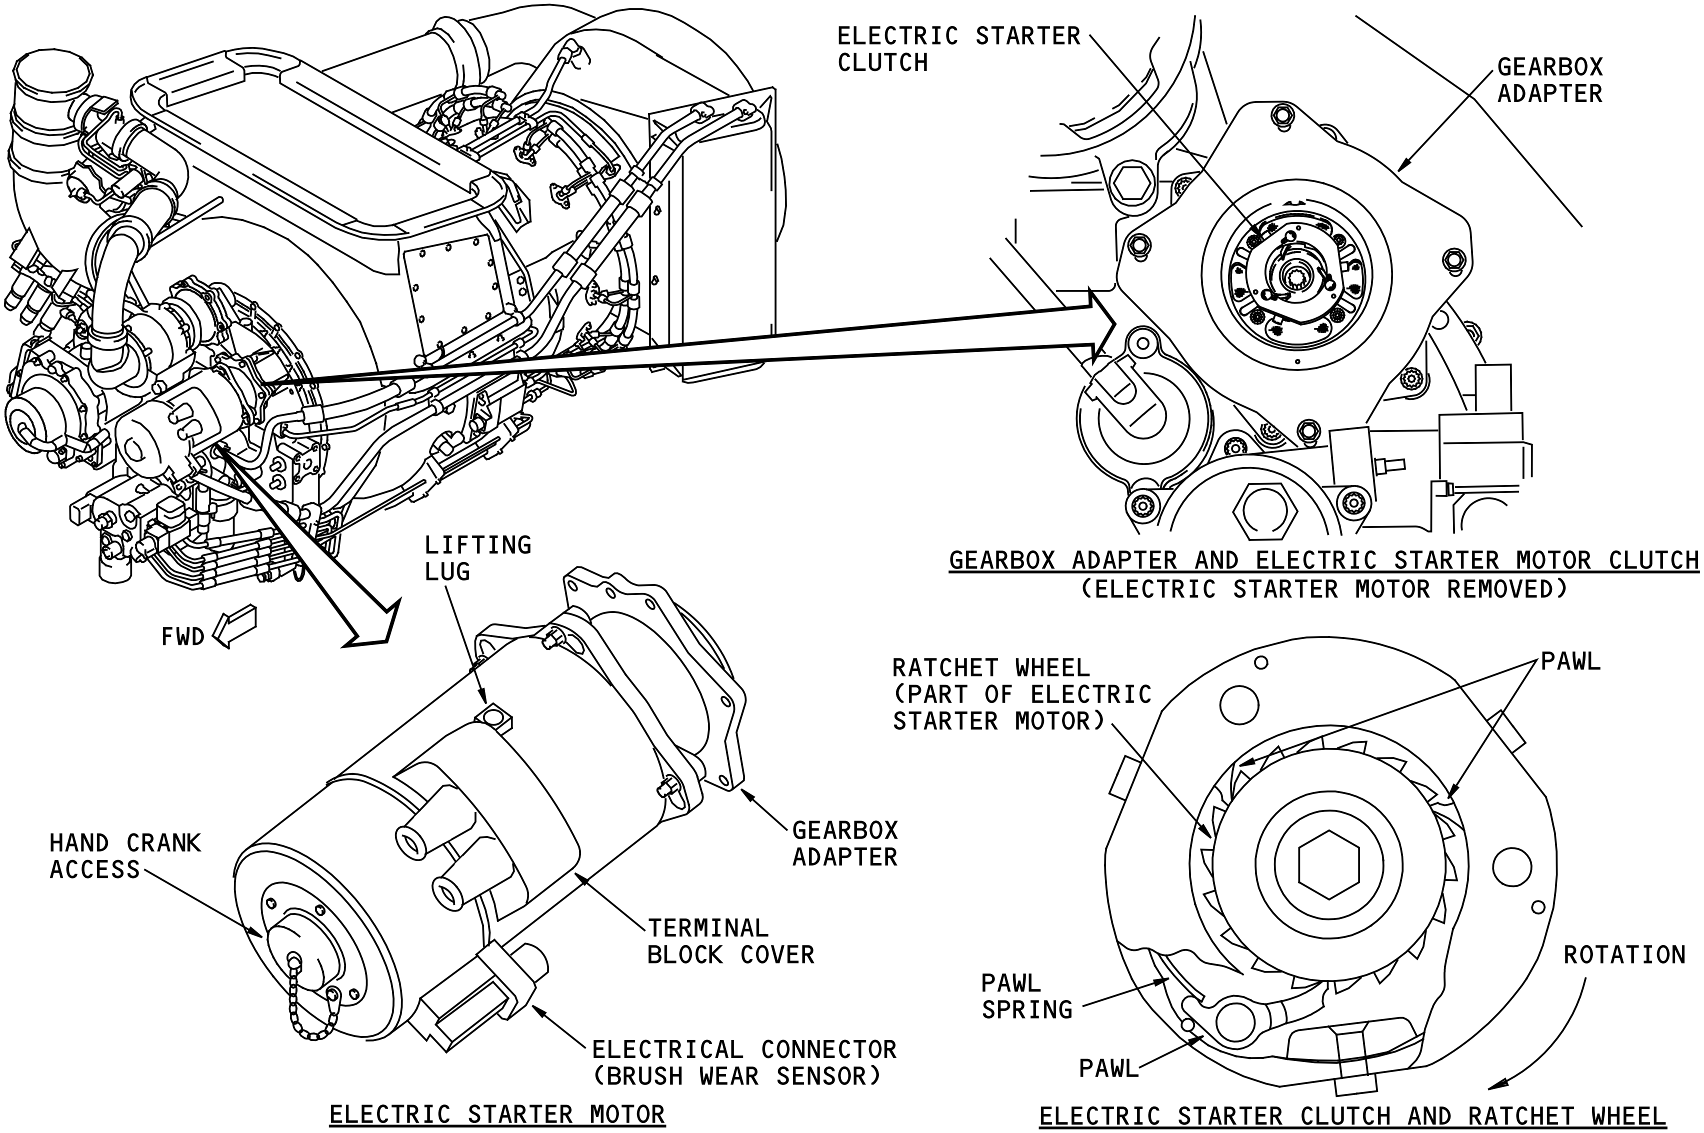
APU IGNITION/STARTING - APU ELECTRIC STARTER SYSTEM - GENERAL DESCRIPTION

You can try three APU starts in a 60 minute period with the electric starter motor.

A brush wear sensor inside the starter motor sends a signal to the APUC when the motor needs to be replaced. The APU CONTROL status message shows for this condition.

Both the electric starter motor and the electric starter clutch are LRUs.

The ATS clutch and electric starter clutch are not interchangeable.



49-40-00-003 Rev 3 10/21/1996

APU IGNITION/STARTING - APU ELECTRIC STARTER SYSTEM - GENERAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

APU IGNITION/STARTING - AIR TURBINE STARTER SYSTEM - GENERAL DESCRIPTION

General

These are the air turbine starter system components:

- Air turbine starter
- Air turbine starter clutch
- Air turbine starter control valve (ATSCV).

The air turbine starter system starts the APU when pneumatic pressure is available.

A magnetic chip collector on the air turbine starter collects metallic particles in the oil.

Physical Description

The air turbine starter is an axial flow turbine. The starter attaches with a V-band clamp to the gearbox adapter which is on the APU gearbox. A ratchet wheel on the air turbine starter shaft connects the starter to the clutch. The APU lubrication system supplies the air turbine starter with oil for cooling and lubrication. The air turbine starter weighs 9.5 pounds (4.3 kg).

The air turbine starter clutch is a pawl and ratchet type mechanism which transmits the starter motor torque to the APU gearbox. Pawl springs hold the pawl in the ratchet wheel at low speeds. The pawls disengage by centrifugal force after the ATSCV closes and the starter speed decreases. A single bolt attaches the clutch to the starter drive gear shaft. The clutch is inside the gearbox adapter.

The ATSCV is a pneumatically actuated, solenoid-controlled butterfly valve. It is spring-loaded closed. The ATSCV is above the air turbine starter. The ATSCV weighs 6.5 lbs (2.9 kg).

Functional Description

The air turbine starter clutch is functionally equivalent to the electric starter clutch. During an air turbine start, the ATSCV opens to permit air from the pneumatic system to go to the air turbine starter. The air turbine starter turns the ratchet wheel. The ratchet wheel turns the air turbine starter clutch through the three pawls. The clutch turns the APU engine through the APU gearbox.

At 55 percent APU engine RPM, the ATSCV closes to stop the air supply to the air turbine starter. The pawls then move outward against the pawl springs by centrifugal force. This disengages the clutch from the air turbine starter motor.

During an electric start, the air turbine starter clutch turns with the APU engine. The air turbine starter and the ratchet wheel do not turn. The pawls move up the sloped edge of the ratchet teeth to permit rotation between the ratchet wheel and the clutch. At approximately 17 percent APU engine RPM, the pawls lift off of the ratchet wheel by centrifugal force to disengage the clutch from the air turbine starter.

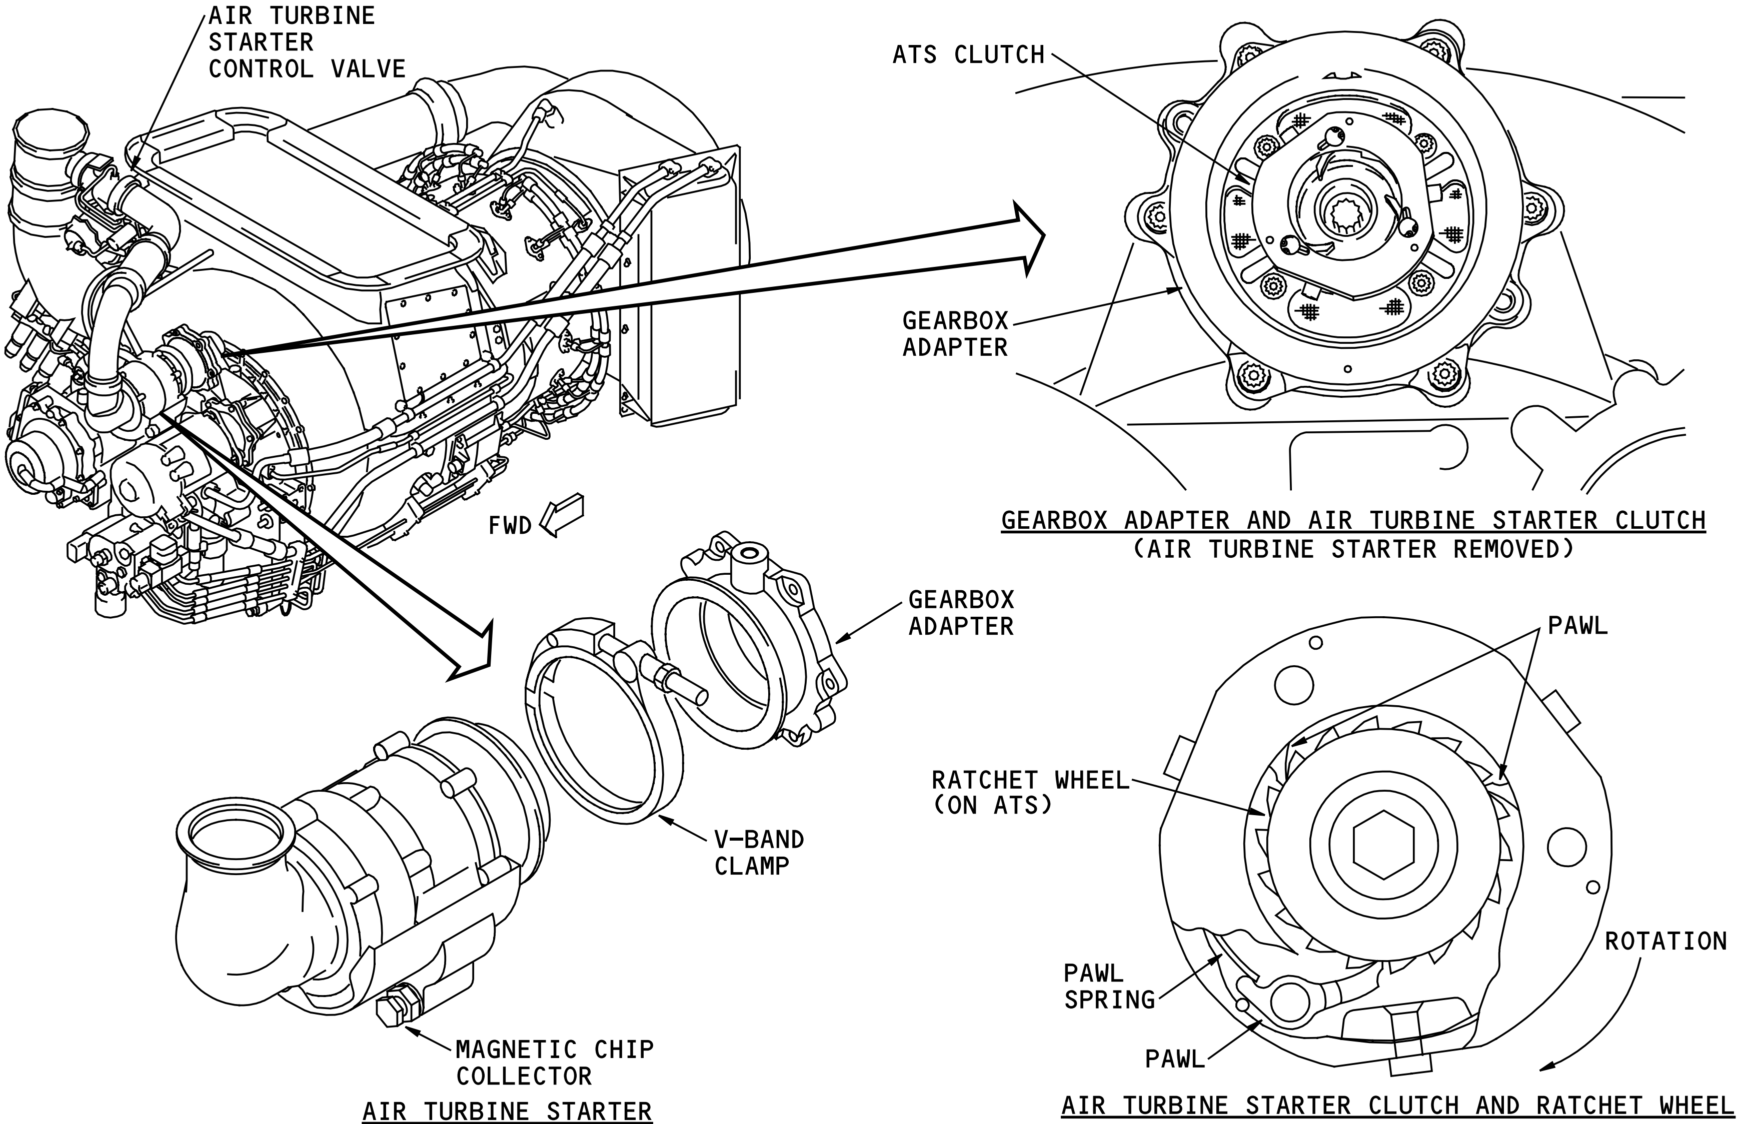
APU IGNITION/STARTING - AIR TURBINE STARTER SYSTEM - GENERAL DESCRIPTION

Training Information Point

The air turbine starter, the air turbine starter clutch, and the ATSCV are LRUs.

The air turbine starter clutch and the electric starter clutch are not interchangeable.

There is no limit to the number of APU starts you may try with the air turbine starter.



49-40-00-004 Rev 5 10/15/96

APU IGNITION/STARTING - AIR TURBINE STARTER SYSTEM - GENERAL DESCRIPTION

APU IGNITION/STARTING - AIR TURBINE STARTER SYSTEM - AIR TURBINE STARTER CONTROL VALVE

Purpose

The ATSCV controls pneumatic pressure to the air turbine starter during APU start.

Physical Description

The ATSCV is a pneumatically-actuated, solenoid-controlled, butterfly valve. It is spring-loaded closed. The ATSCV is above the air turbine starter.

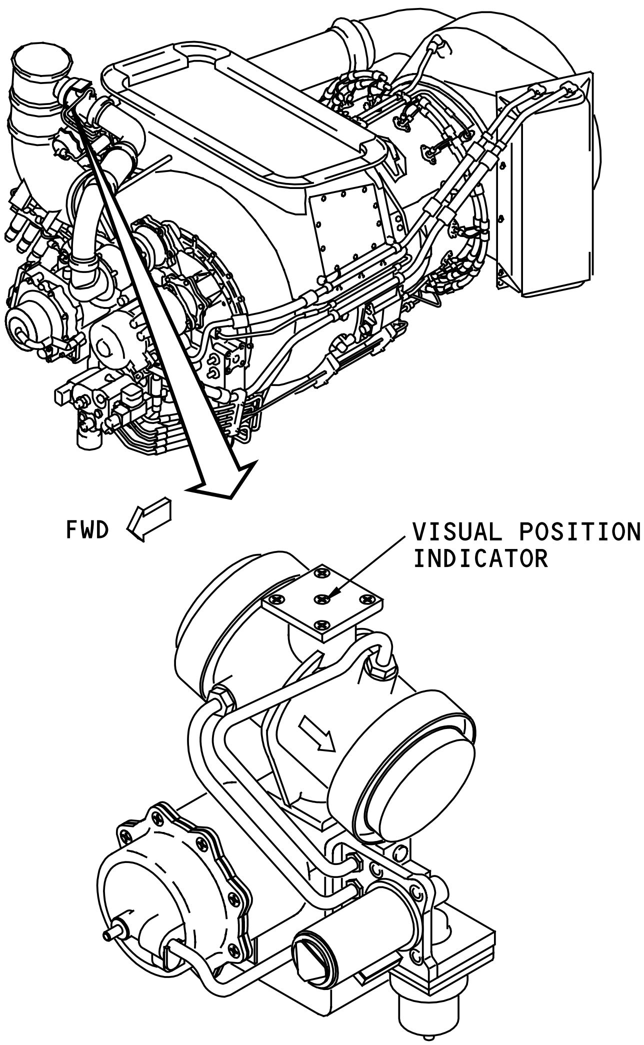
Functional Description

To start the APU air turbine starter operation, the APUC opens the solenoid valve. This permits bleed air to flow to the reference pressure regulator. The reference pressure regulator controls air pressure to chamber A of the spring and pressure balanced butterfly valve. This opens the butterfly valve. Duct pressure downstream of the butterfly valve pressurizes chamber B to balance the butterfly valve. Air output of the starter control valve is 18 to 22 psig.

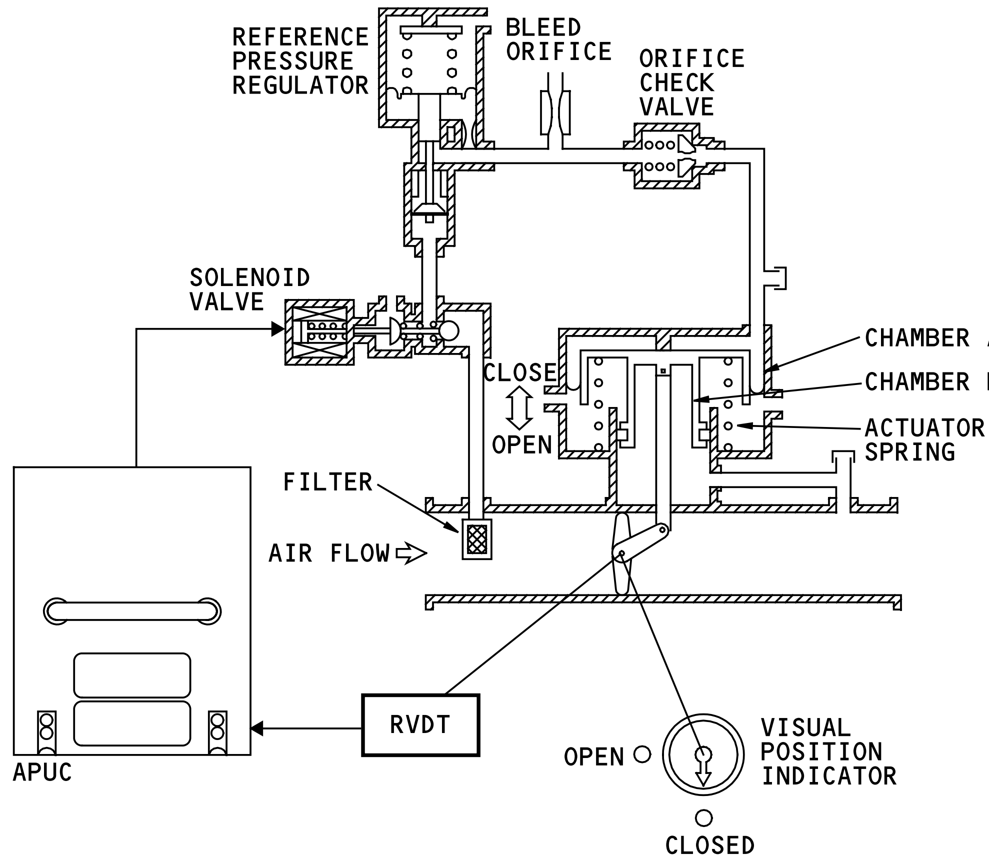
An RVDT sends butterfly valve position to the APUC for feedback.

Training Information Point

A visual position indicator shows butterfly valve position.



AIR TURBINE STARTER CONTROL VALVE



49-40-00-005 Rev 2

APU IGNITION/STARTING - AIR TURBINE STARTER SYSTEM - AIR TURBINE STARTER CONTROL VALVE

THIS PAGE INTENTIONALLY LEFT BLANK

APU IGNITION/STARTING - FUNCTIONAL DESCRIPTION

General

To start the APU, turn the APU switch to START and then release it to ON. This signals the APUC through the ELMS to start the APU.

Pneumatic Start

The APUC gets pneumatic system pressure signals through ARINC 629. If pressure is available, the APUC energizes the solenoid valve on the ATSCV. This opens the starter control valve and pressure regulated air flows to the air starter and turns the APU engine.

At approximately seven percent engine RPM, the APUC energizes the ignition unit. The ignition unit supplies the ignition power to energize the igniter plugs. The ignition turns off at approximately 50 percent engine RPM.

At approximately 55 percent engine RPM, the APUC removes power from the ATSCV solenoid valve to shut off the air turbine starter. The APU continues to increase the speed of rotation to its operating RPM (100 percent).

Electric Start

If pneumatic pressure is not available, the APUC energizes the APU crank contact relay. This supplies 28v dc power from the APU battery to the electric starter which turns the APU. At about 49 percent engine RPM, the APUC removes power from the electric starter and the APU continues to increase the speed of rotation to its operating RPM.

The ignition system operates the same during both types of starts.

Autostart

The APU will automatically start for these conditions:

- Airplane is in the air
- Power removed from the left and right transfer buses.

The ELMS contains the APU autostart logic and sends the start signal to the APUC.

To shutdown the APU after an autostart, you must first move the APU selector to ON and then back to OFF.

The ram air turbine will automatically extend during an APU autostart.

Start Failure

These conditions cause an APU start failure:

- No acceleration (no RPM increase after ignition or start command failure)
- No ignition (no EGT increase above 7 percent RPM).

These are the indications of a start failure:

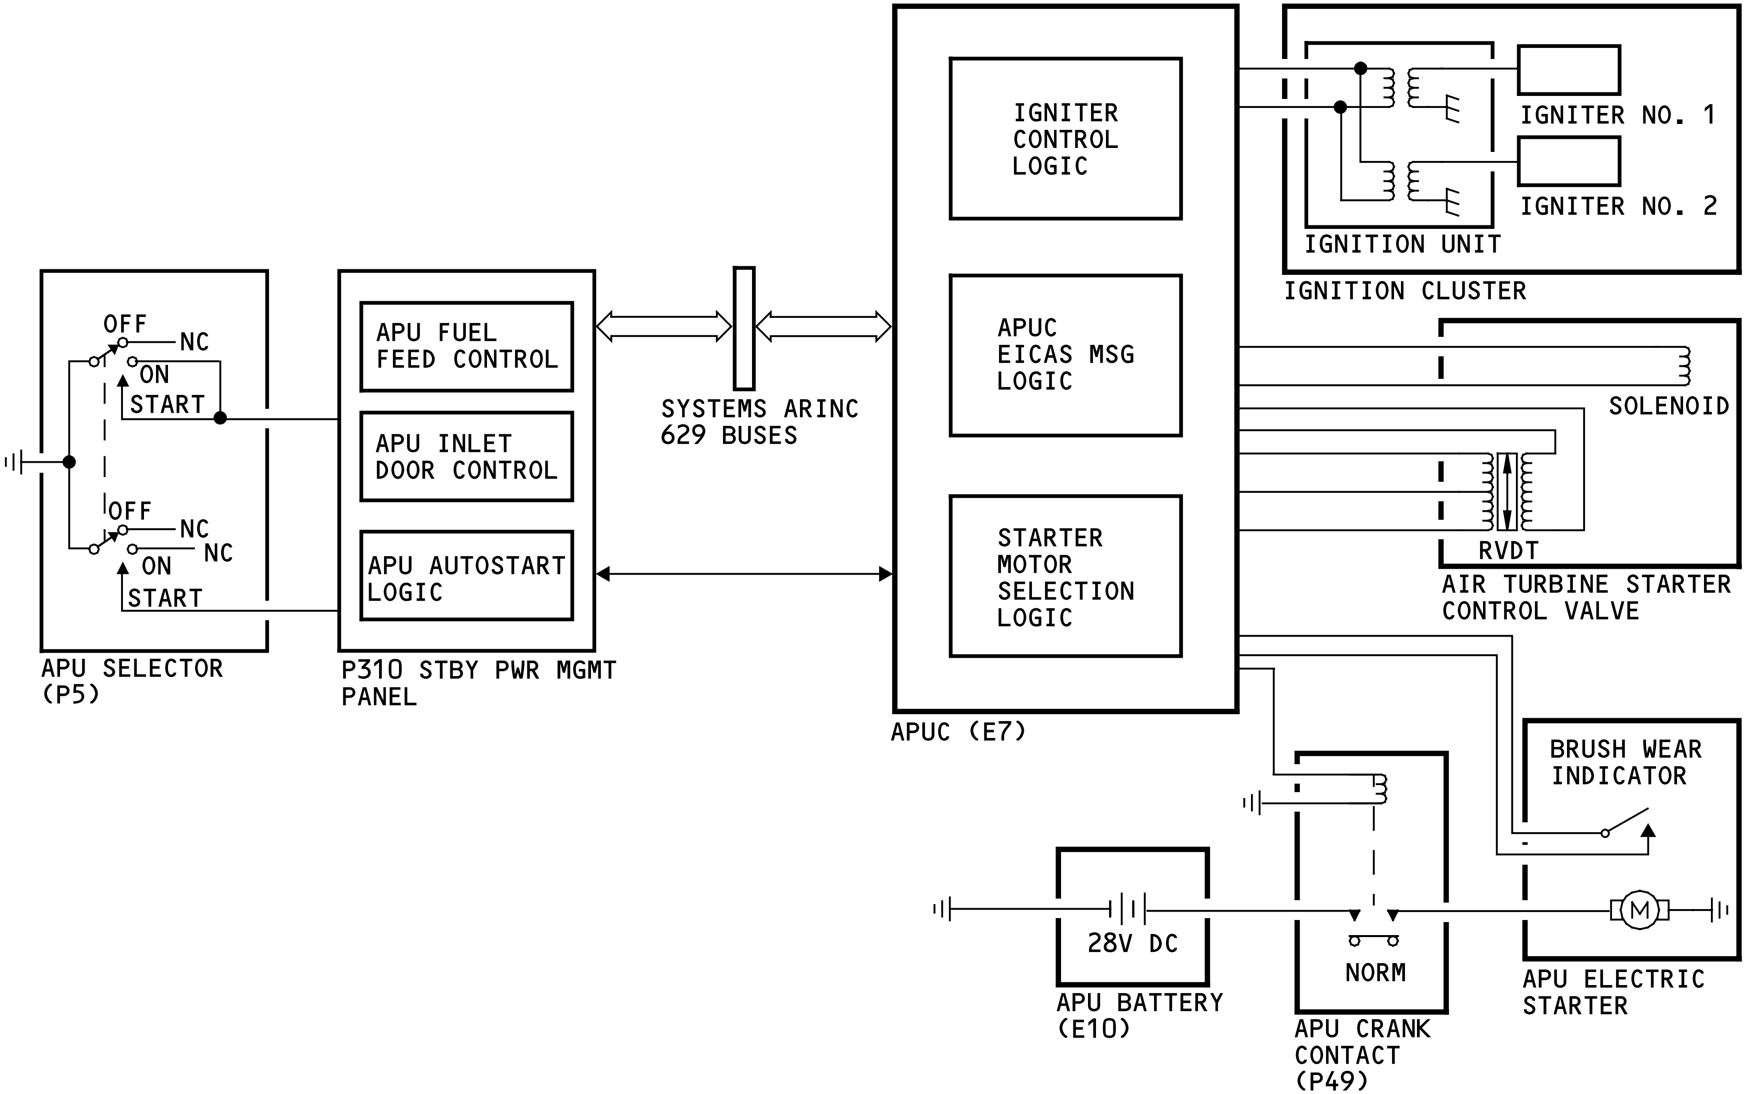
APU IGNITION/STARTING - FUNCTIONAL DESCRIPTION

- APU SHUTDOWN advisory message
- APU status message
- APU fault light.

Training Information Point

If you lift the airplane on jacks, the APU may do an autostart. To prevent this, you need to pull some circuit breakers.

See the applicable section in part two of the airplane maintenance manual for the full procedure.



APU IGNITION/STARTING - FUNCTIONAL DESCRIPTION

APU AIR - INTRODUCTION

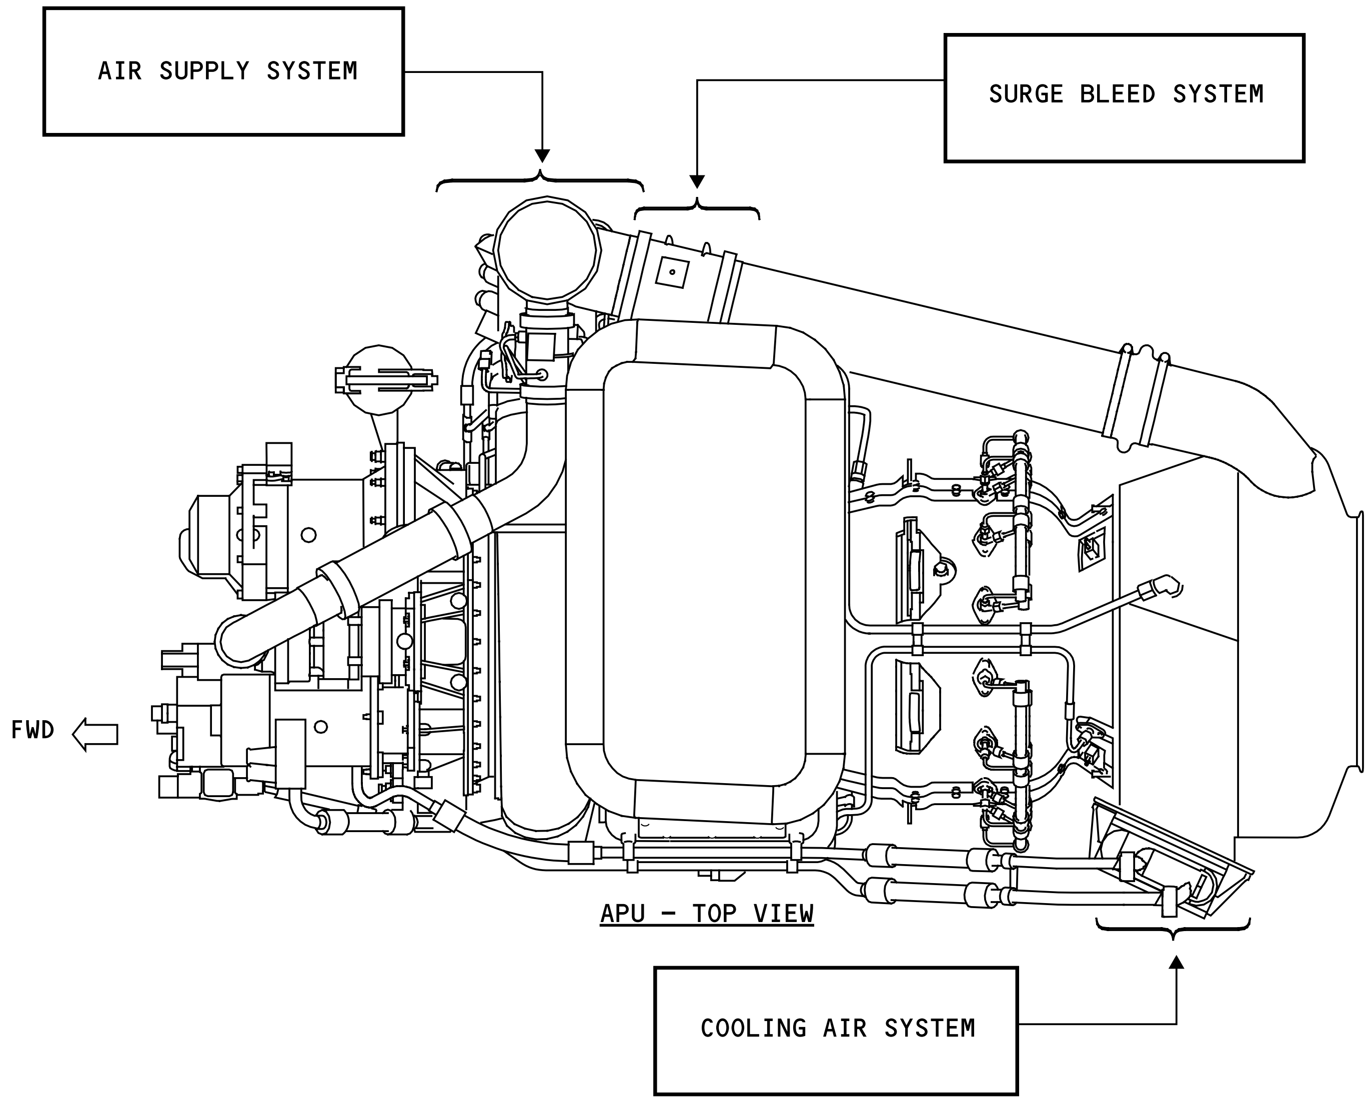
Purpose

These subsystems make up the APU Air System:

- APU cooling air system
- APU air supply system
- APU surge bleed system.

The APU air system does these functions:

- Cools the APU compartment and the APU engine oil
- Supplies compressed air to the airplane pneumatic system
- Releases excess load compressor output (surge control).



APU AIR - INTRODUCTION

APU AIR - APU COOLING AIR SYSTEM - GENERAL DESCRIPTION

General

The APU Cooling Air System cools the APU compartment and the APU engine oil. There are no moving parts in this system.

Compartment Cooling

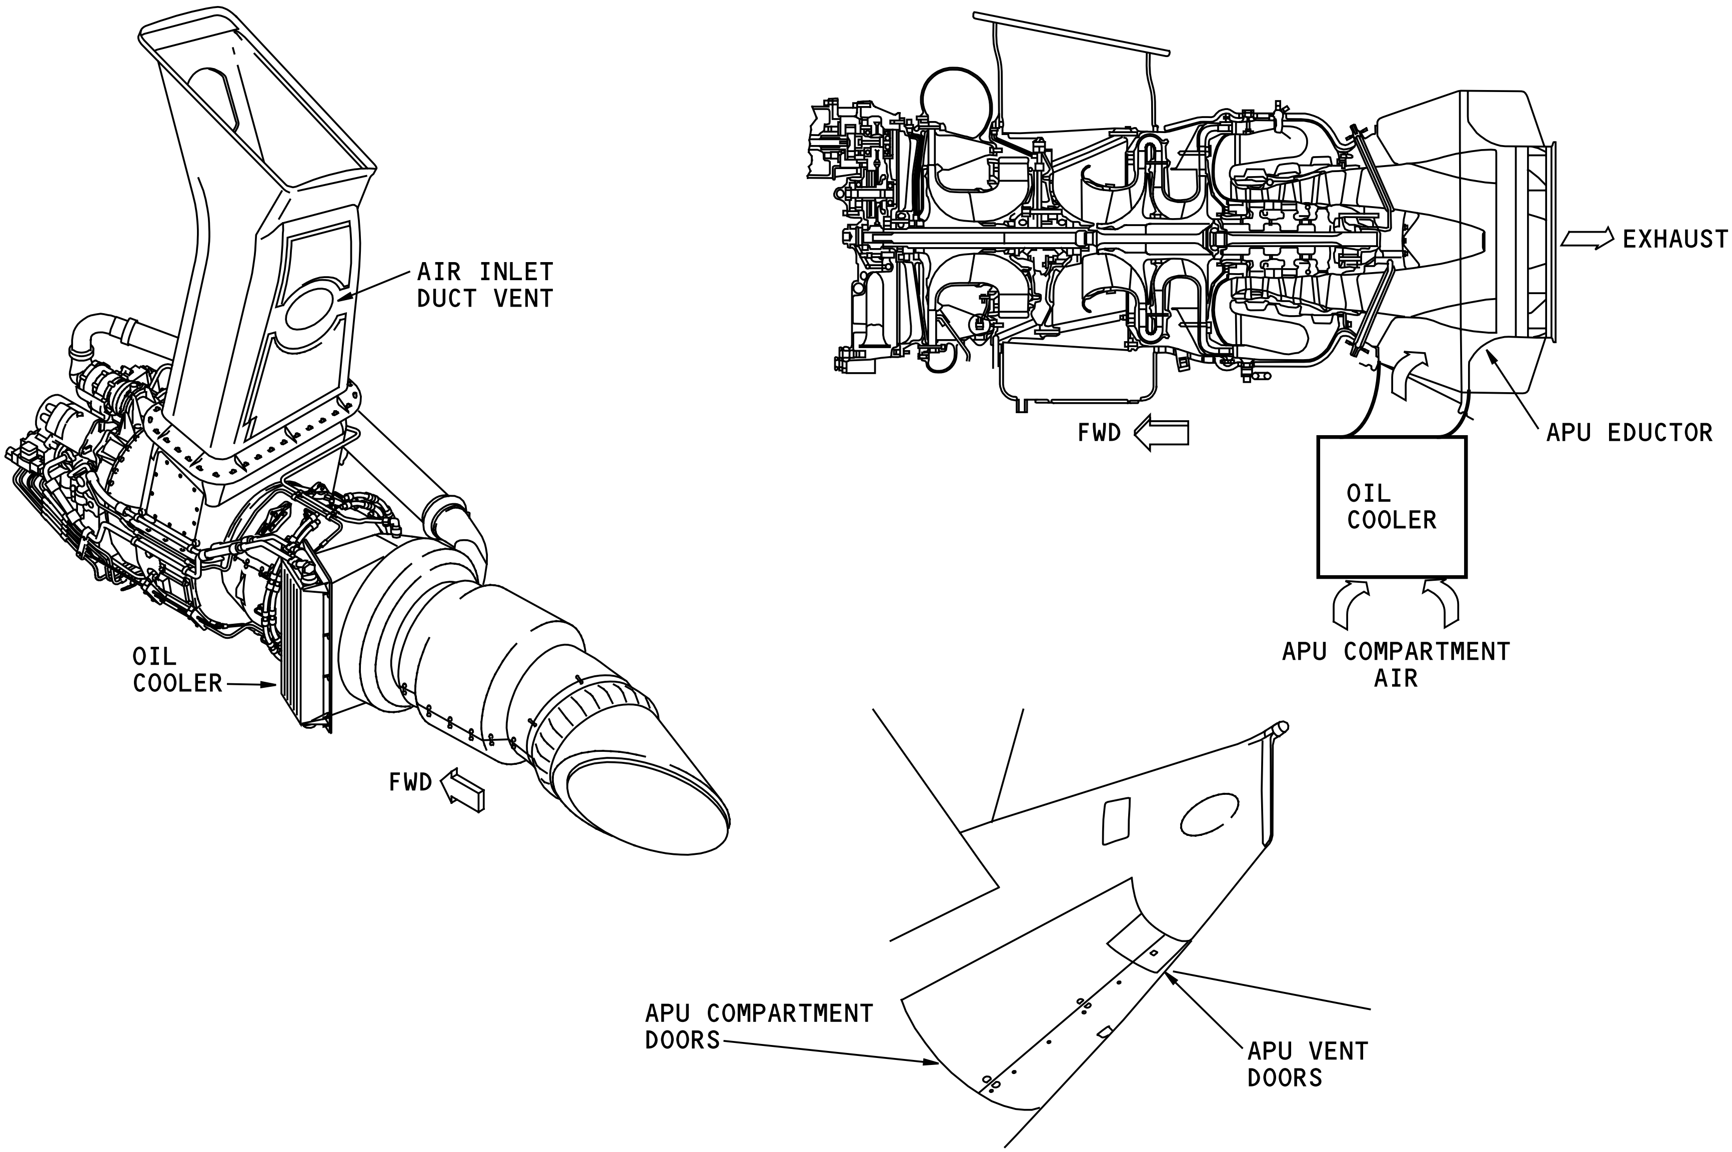
A cooling eductor behind the APU engine turbine uses high speed exhaust flow to form low pressure suction. This suction pulls a continuous cooling air flow from the compartment through the oil cooler and out through the exhaust duct.

See the APU and generator lubrication section for more information about the oil cooler (AMM PART I 49-27).

Outside air goes into the APU compartment through an opening in the back of the air inlet duct.

Training Information Point

There is a small negative pressure in the APU compartment when the APU is running. APU vent doors on the APU compartment doors permit you to equalize pressure before you open the doors.



APU AIR - APU COOLING AIR SYSTEM - GENERAL DESCRIPTION

APU AIR - APU AIR SUPPLY SYSTEM - INTRODUCTION

Purpose

The APU air supply system supplies compressed air to the airplane pneumatic system for:

- Main engine start
- Air conditioning and pressurization
- Air-driven hydraulic pump operation
- Other pneumatic system functions.

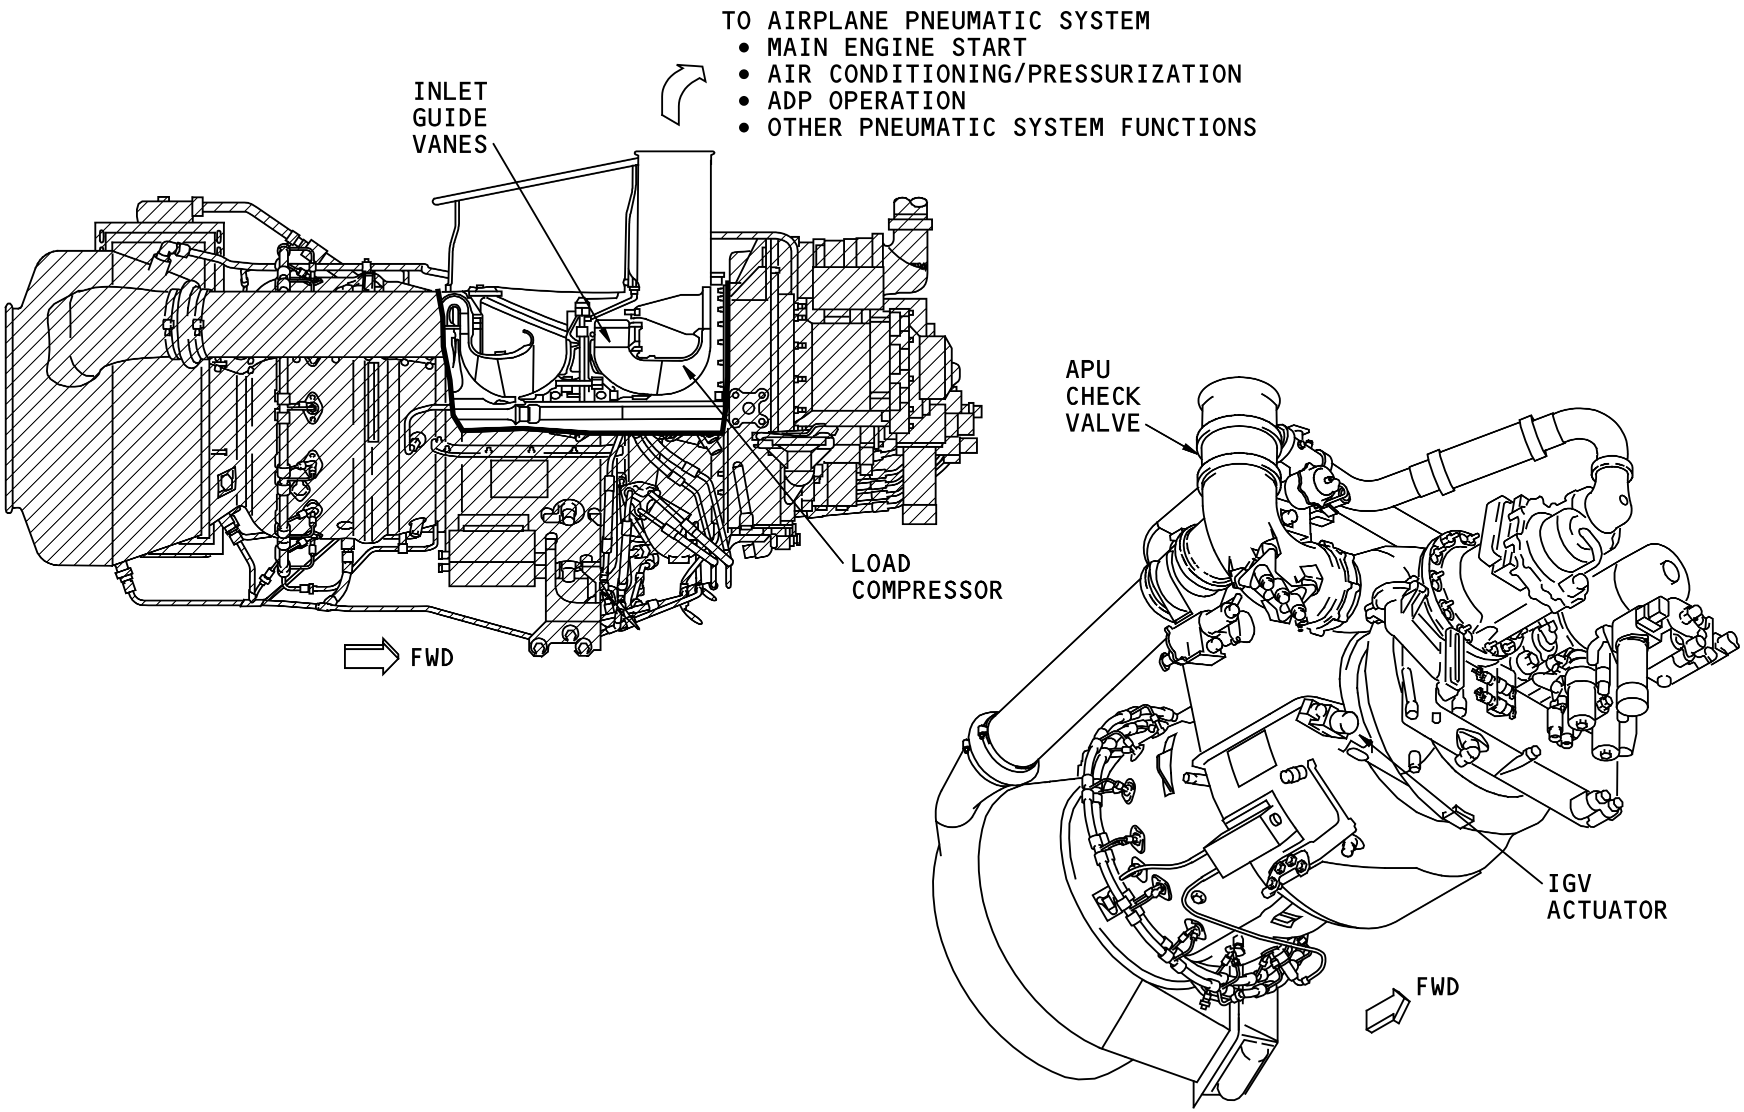
Components

Air supply components include:

- Inlet guide vanes (IGVs)
- Inlet guide vane actuator
- APU check valve.

Control

The APUC sends signals to the IGV actuator to control the IGV angle position. This controls the output of the air supply system.



APU AIR - APU AIR SUPPLY SYSTEM - INTRODUCTION

APU AIR - APU AIR SUPPLY SYSTEM - INLET GUIDE VANES

Purpose

The inlet guide vanes control the air flow to the load compressor and thus control APU air output.

Physical Description

Twenty eight inlet guide vanes (IGVs) are inside the APU around the load compressor inlet.

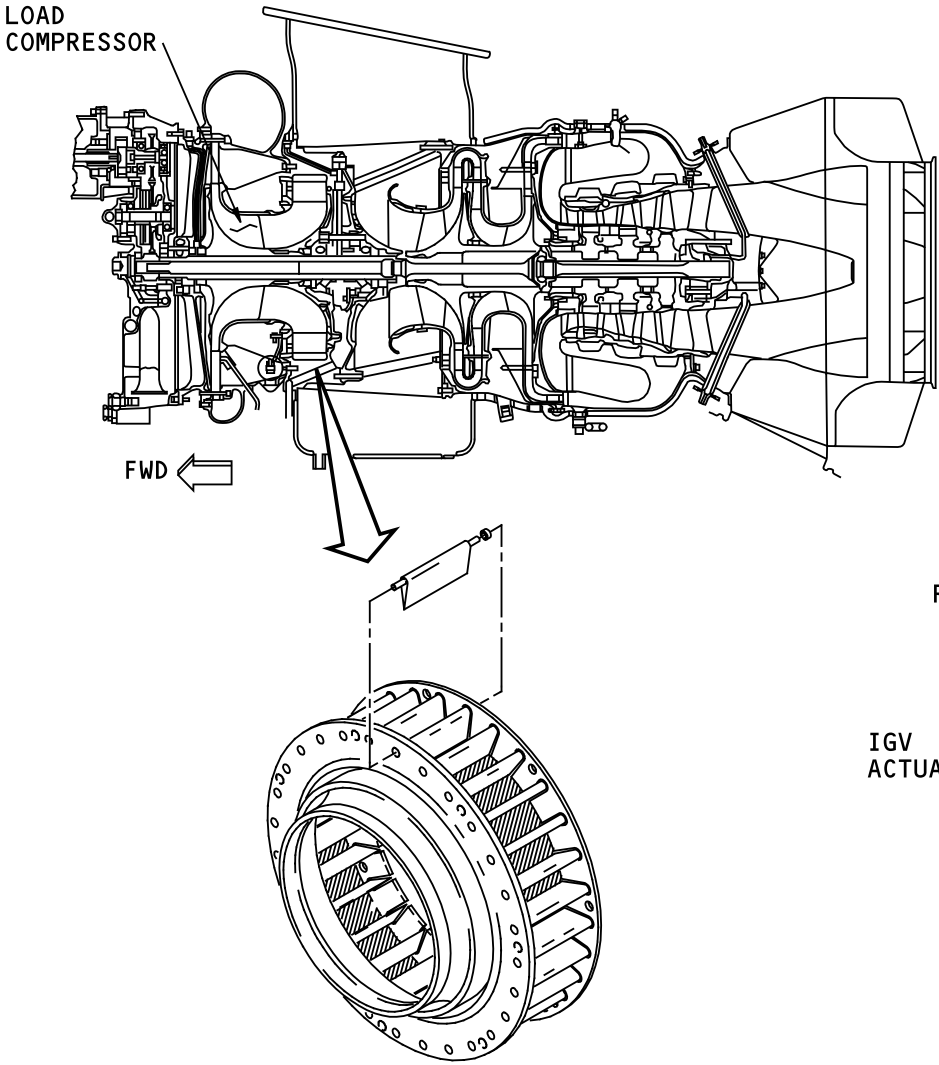
Functional Description

The guide vanes rotate between 76.2 degrees (fully closed) and -10 degrees (fully open). This angle is in relation to the airflow.

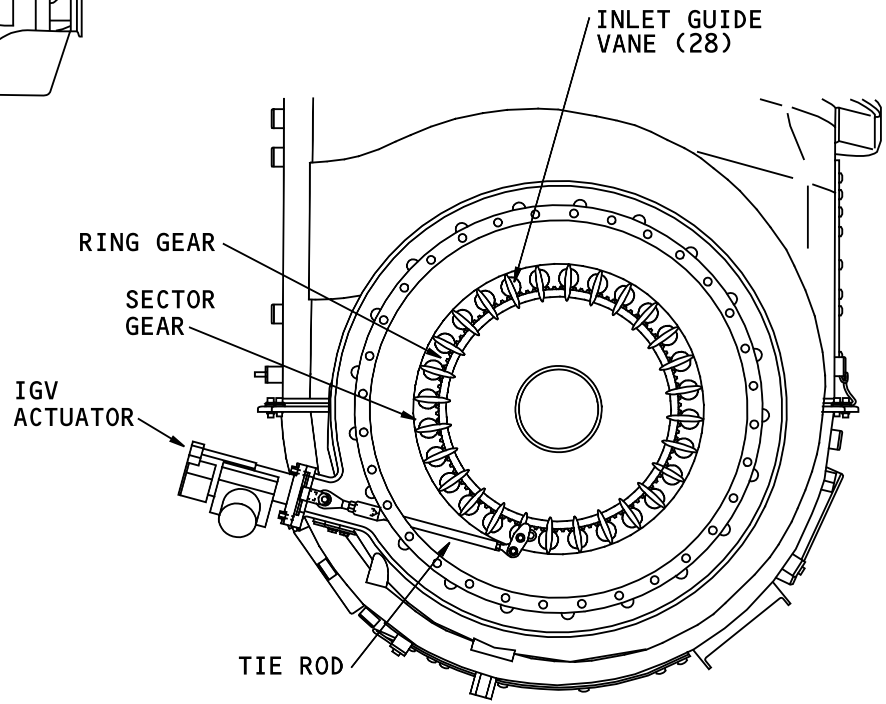
Sector gears connect each IGV to a ring gear. The IGV actuator connects to the ring gear by the tie rod.

Training Information Point

The IGV position shows on the APU maintenance page.



INLET GUIDE VANES



IGV MECHANISM - LOOKING AFT

49-50-00-004 Rev 3

APU AIR - APU AIR SUPPLY SYSTEM - INLET GUIDE VANES

APU AIR - APU AIR SUPPLY SYSTEM - IGV ACTUATOR AND CHECK VALVE

Inlet Guide Vanes Actuator

The IGV actuator uses high pressure fuel to operate the inlet guide vanes.

The APUC controls a torque motor on a two-stage servo-valve to move the actuator. An internal LVDT sends actuator position to the APUC for position feedback.

The IGV actuator connects to the IGVs through a tie rod, ring gear, and sector gears (not shown).

The IGV actuator is on the right side of the APU below the pneumatic cluster.

APU Check Valve

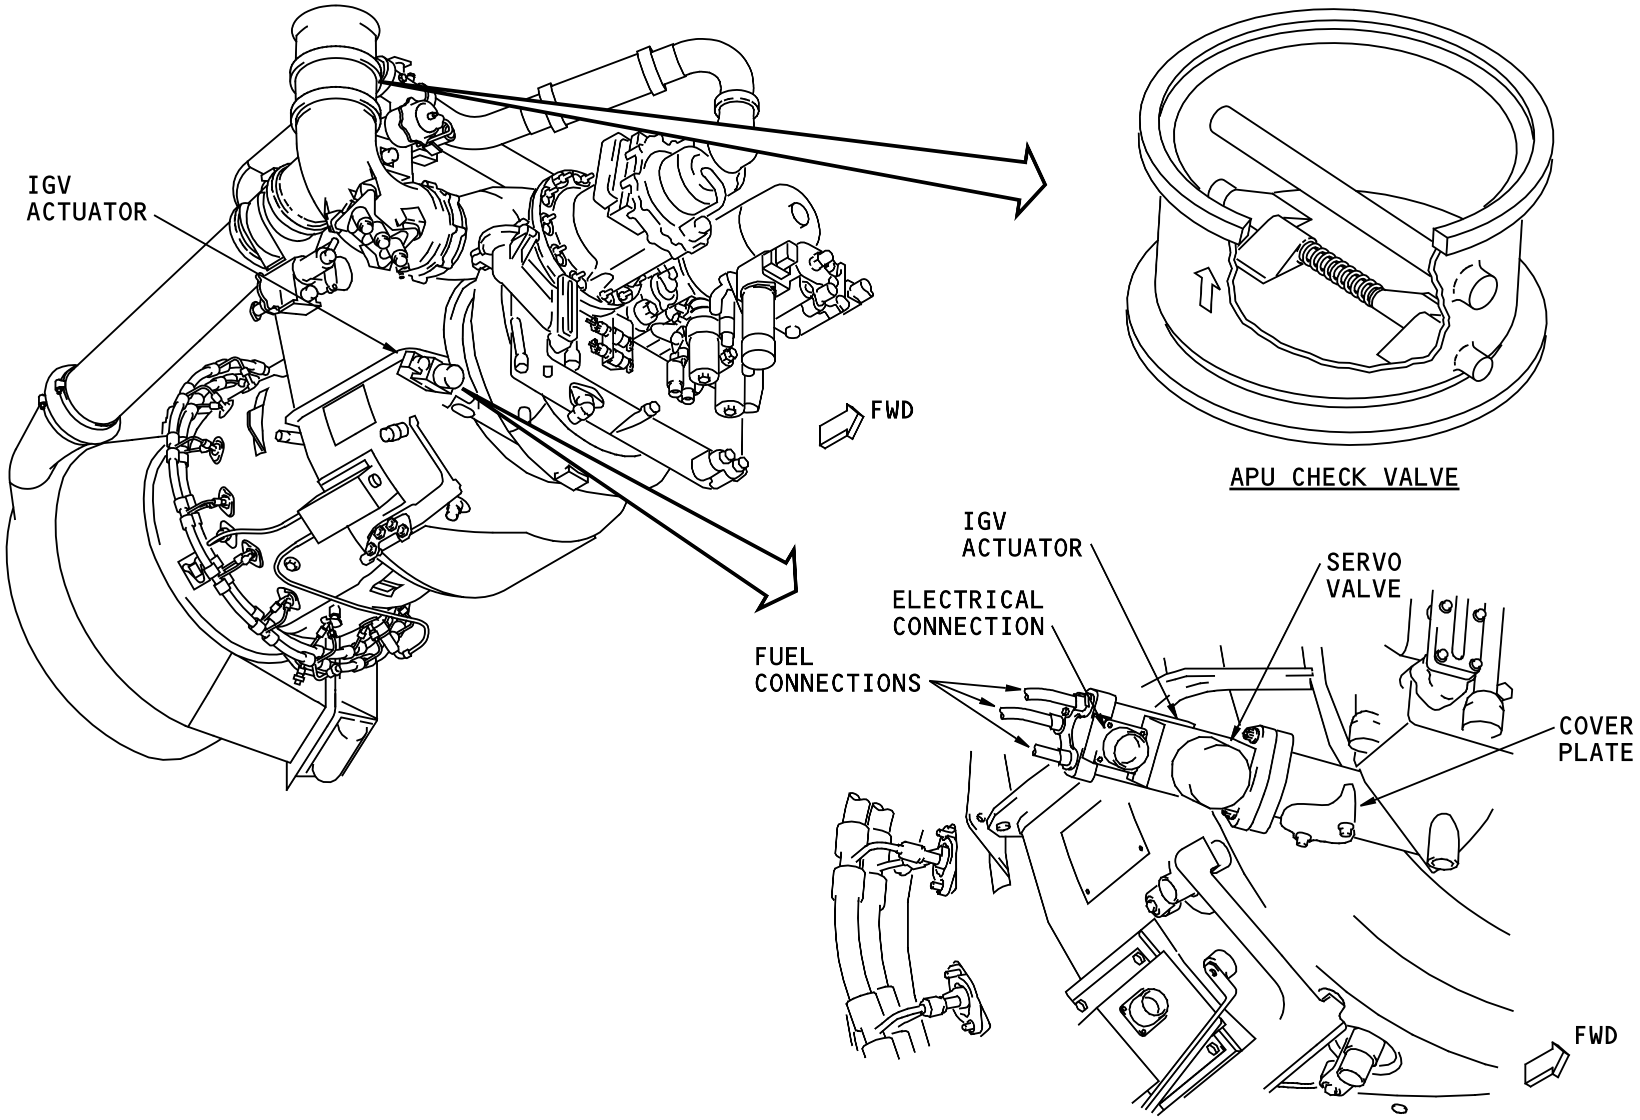
The APU check valve prevents pneumatic system flow from turning the APU load compressor in reverse.

The valve is in the pneumatic duct between the load compressor and the air turbine starter control valve (ATSCV).

The check valve is spring-loaded closed and opened by airflow from the load compressor.

Training Information Point

A cover plate supplies access to a captive bolt that connects the IGV actuator to the tie rod. You loosen this captive bolt when you remove the IGV actuator.



APU AIR - APU AIR SUPPLY SYSTEM - IGV ACTUATOR AND CHECK VALVE

THIS PAGE INTENTIONALLY LEFT BLANK

APU AIR - APU AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION

General

The APUC contains pneumatic mode selection logic and IGV control logic to control the inlet guide vanes. The APUC monitors pneumatic system demands and selects a pneumatic mode. The IGV control logic sends signals to the electro-hydraulic servo valve (EHSV) to change the IGV position. A linear variable differential transformer (LVDT) sends actuator position feedback signals to the APUC.

The APUC also calculates a turbine inlet temperature (T4). If T4 is too high, the APUC starts to close the IGVs to reduce the pneumatic loading. This permits electrical power output of the APU to have the highest priority.

Pneumatic Modes

The APUC uses these inputs to select a pneumatic mode:

- APU shutoff valve position
- Main engine start
- ADP operation
- A/C pack operation
- Air inlet pressure (P2).

These are the pneumatic modes:

- Idle
- Duct Pressurization
- Main Engine Start
- Air Driven Pump (ADP)
- ECS
- ADP/ECS.

The APUC selects the idle mode when the APU shutoff valve is closed and there is no pneumatic system demand. The IGVs are closed in this mode. The APUC also selects this mode any time the airplane is above 22,000 feet (6700 meters).

The APUC selects the duct pressurization mode when the APU shutoff valve is open and there is no pneumatic system demand. The IGVs open enough to pressurize the pneumatic ducts.

During a main engine start, the APUC selects the main engine start mode. The IGVs open to meet airflow requirements for a main engine start. This mode has priority over all other modes.

The APUC selects the ADP mode when one or two of the ADPs operate. The IGVs open to supply enough airflow to operate the air driven hydraulic pumps.

When one or two air conditioning packs operate, the APUC selects the ECS mode. The IGVs open the amount necessary to supply air to the airplane environmental control system.

When the ADPs and the air conditioning packs operate, the APUC selects the ADP/ECS mode and opens the IGVs the amount necessary to supply both of these systems.

APU AIR - APU AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION

Inlet Guide Vane Control Logic

After pneumatic mode selection, the APUC uses inlet temperature and inlet pressure data to adjust the IGV angle for the correct airflow. For the ECS and ADP/ECS modes, the APUC also uses ECS inputs and APU total operating hours to control the IGV position.

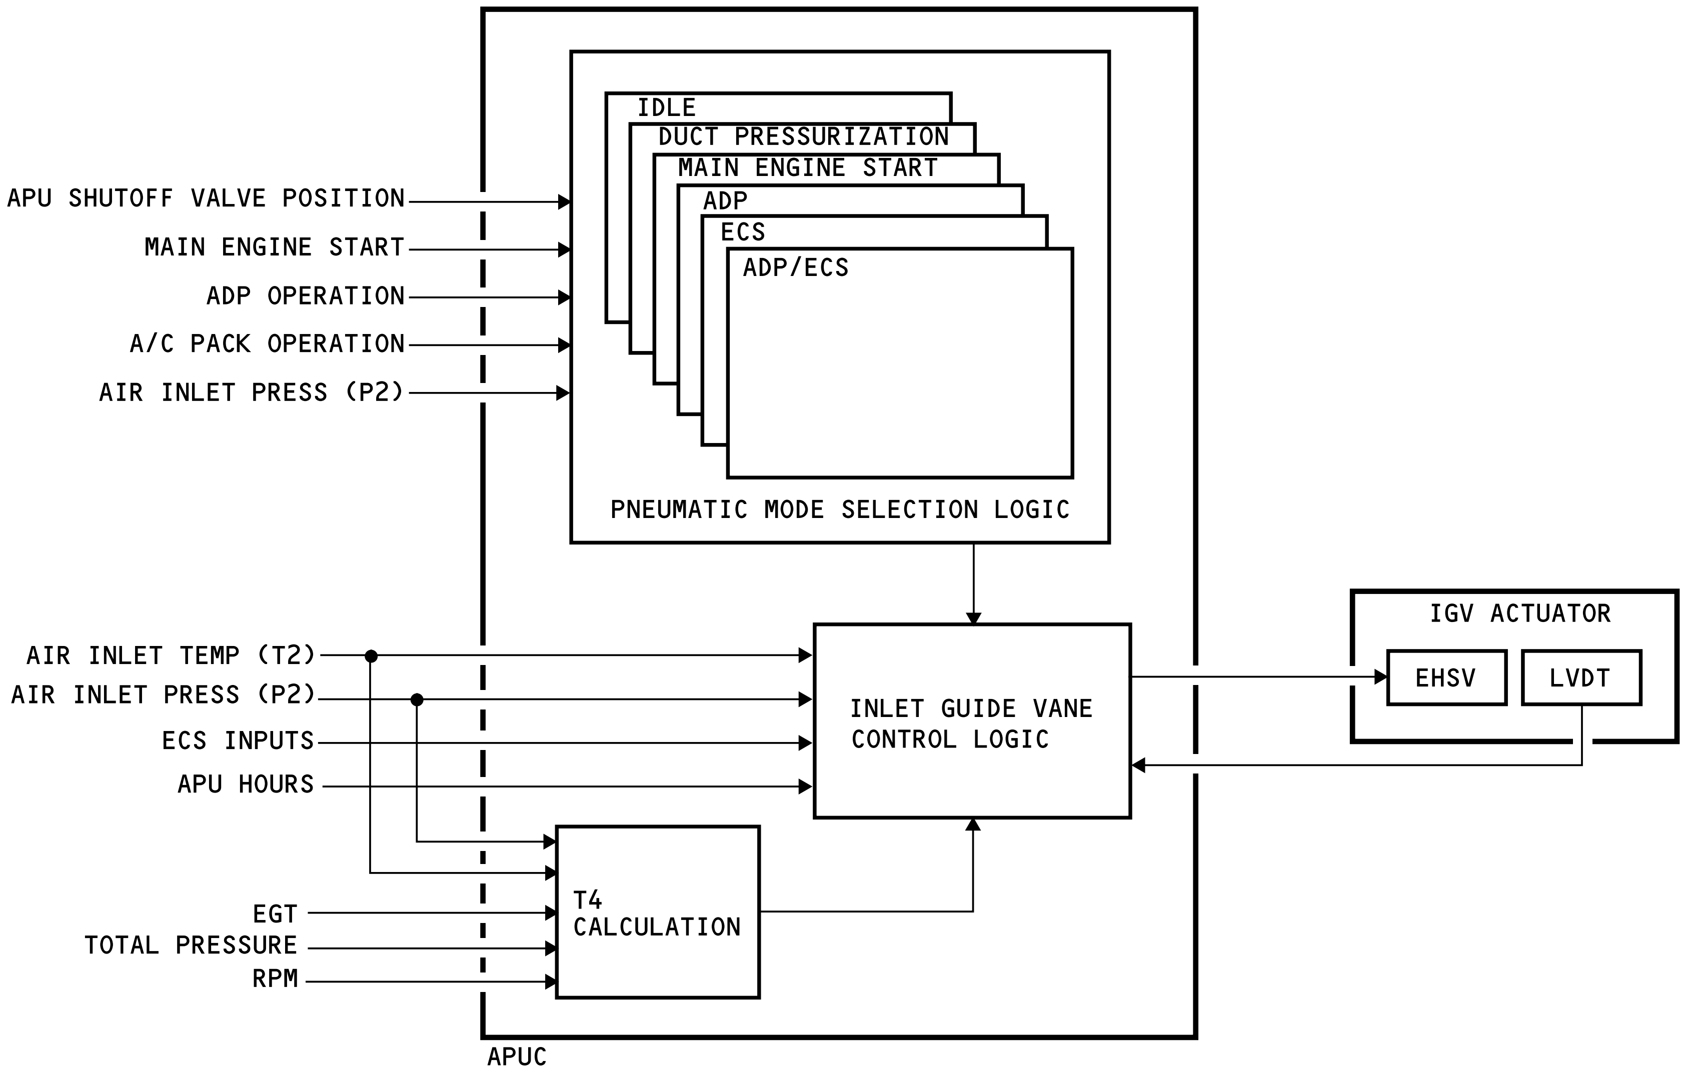
During APU start, the APUC closes the IGVs to keep APU loading to a minimum. At 95 percent RPM, the IGVs can open to supply pneumatic airflow.

Turbine Inlet Temperature Calculation

The APUC calculates turbine inlet temperature (T4) from these inputs:

- Air inlet temperature (T2).
- Air inlet pressure (P2)
- Exhaust gas temperature (EGT)
- Total pressure
- RPM.

If a heavy APU load causes a T4 increase, the APUC starts to close the IGVs. If T4 continues to increase, the APUC can close the IGVs completely. This gives APU output priority to electrical power generation.



49-50-00-006 Rev 3 10/28/1996

APU AIR - APU AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION

APU AIR - APU SURGE BLEED SYSTEM - INTRODUCTION

Purpose

The APU surge bleed system releases load compressor air that the aircraft pneumatic system does not use. This air flows outboard through the APU exhaust.

The APUC controls the surge bleed system.

Components

Surge bleed system components are on a common pneumatic cluster. These are the components:

- Surge control valve and actuator
- Inlet pressure sensor
- Total pressure sensor
- Differential pressure sensor.

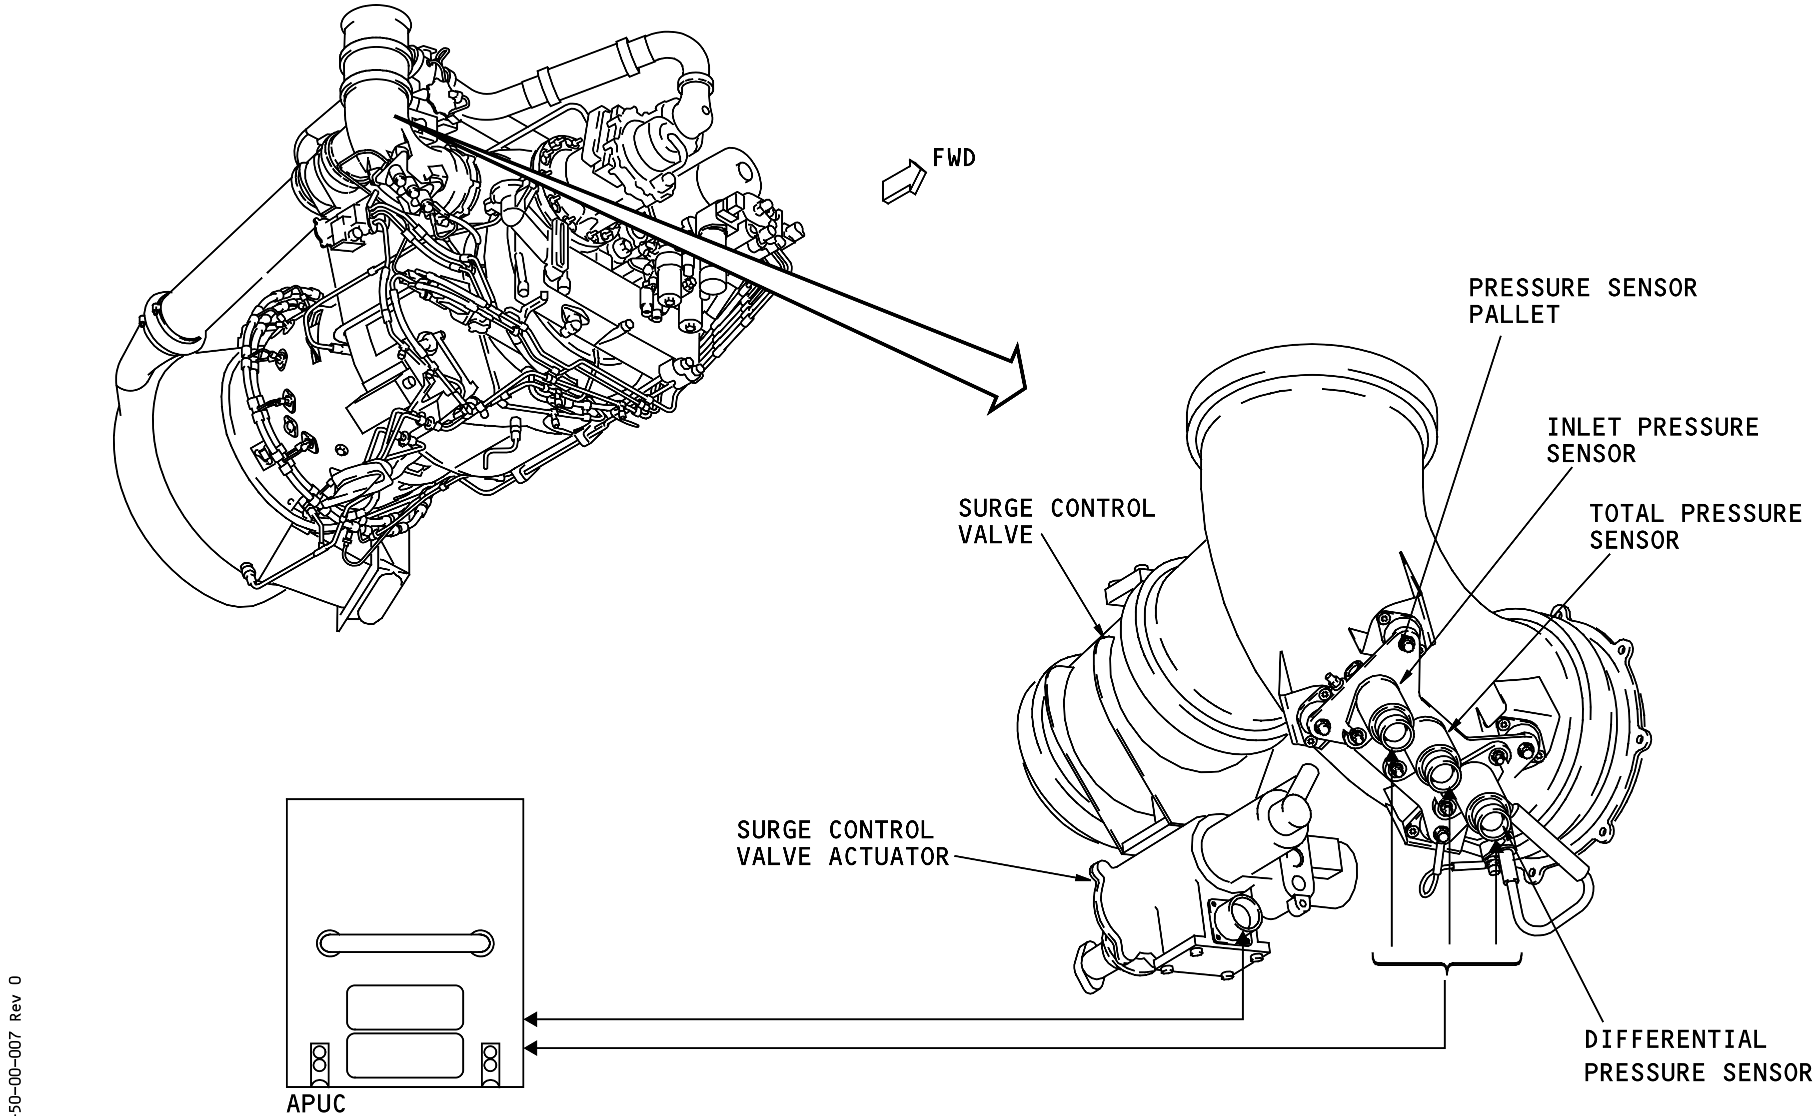
Control

The APUC controls the surge bleed system.

Training Information Point

These are the surge bleed system LRUs:

- Pneumatic cluster
- Surge control valve
- Pressure sensor pallet
- Each pressure sensor.



APU AIR - APU SURGE BLEED SYSTEM - INTRODUCTION

APU INDICATING SYSTEM - EGT INDICATING SYSTEM

Purpose

The APU EGT indicating system supplies APU exhaust gas temperature data for flight deck indication and APU control.

Component Locations

Four chromel/alumel thermocouple probes, grouped in two rakes, are on the exhaust section 90 degrees apart. The thermocouple housing is stainless steel. Each probe has two temperature sensing junctions.

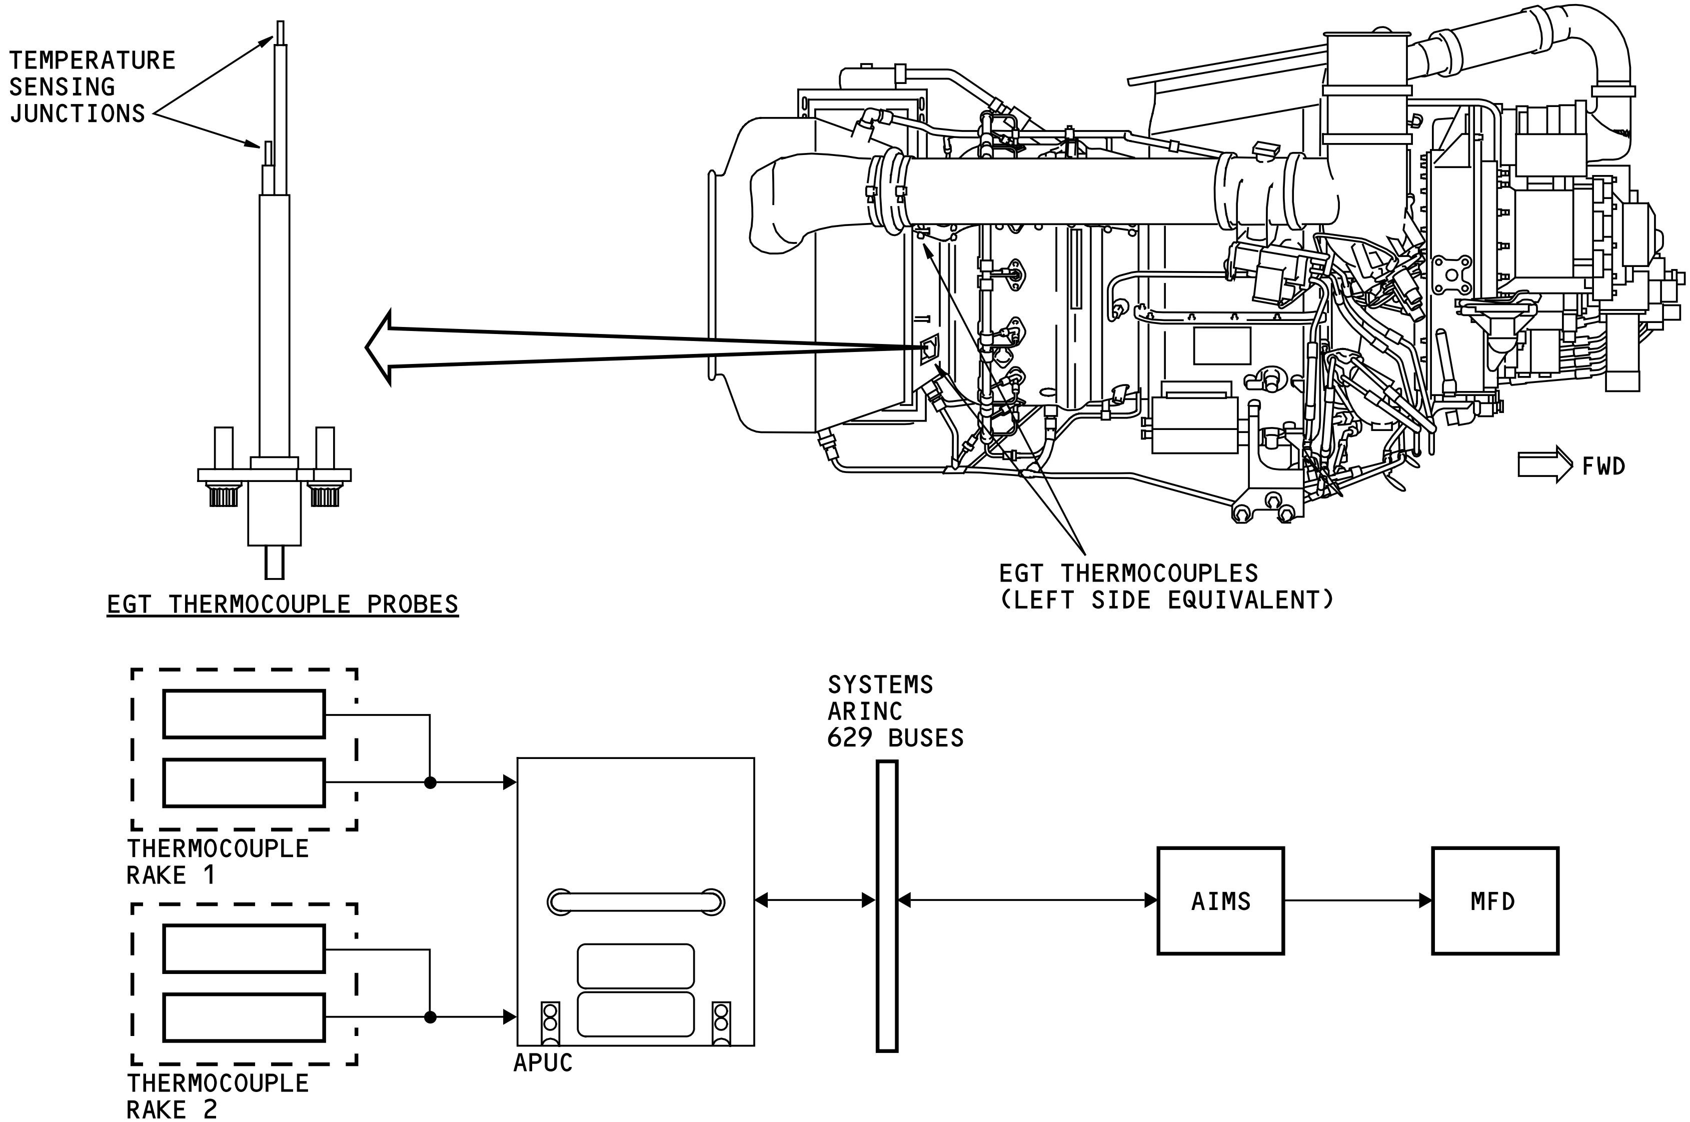
Functional Description

The APUC receives temperature inputs from the two thermocouple rakes. The APUC uses the strongest signal output (highest temperature) for indication and control.

Training Information Point

Loss of input from one rake does not cause the loss of EGT indication. Loss of EGT input from both rakes causes loss of indication. EGT overtemperature or loss of EGT from both rakes causes an APU protective shutdown in the unattended mode.

APU EGT shows on the MFD status display and the APU maintenance page.



49-70-00-001 Rev 1

APU INDICATING SYSTEM - EGT INDICATING SYSTEM

APU INDICATING SYSTEM - DATA MEMORY MODULE

Purpose

The data memory module(DMM) keeps this APU data in non-volatile memory:

- APU serial number
- APU operating hours
- Number of APU starts
- Start data
- Shutdown data
- Pneumatic system operating mode
- APU turbine life used.
- APU health data.

The DMM keeps this APU data so that APUC replacement will not cause loss of APU operation data.

General Description

The APUC controls the data flow into the DMM. The APUC reads the DMM memory during the APU start sequence and transmits updated information to the DMM during APU shutdown.

Location

The DMM is on the left side of the APU.

Training Information Point

You can read DMM data with special test equipment.

Replacement of the APUC does not cause the loss of the data stored in the DMM.

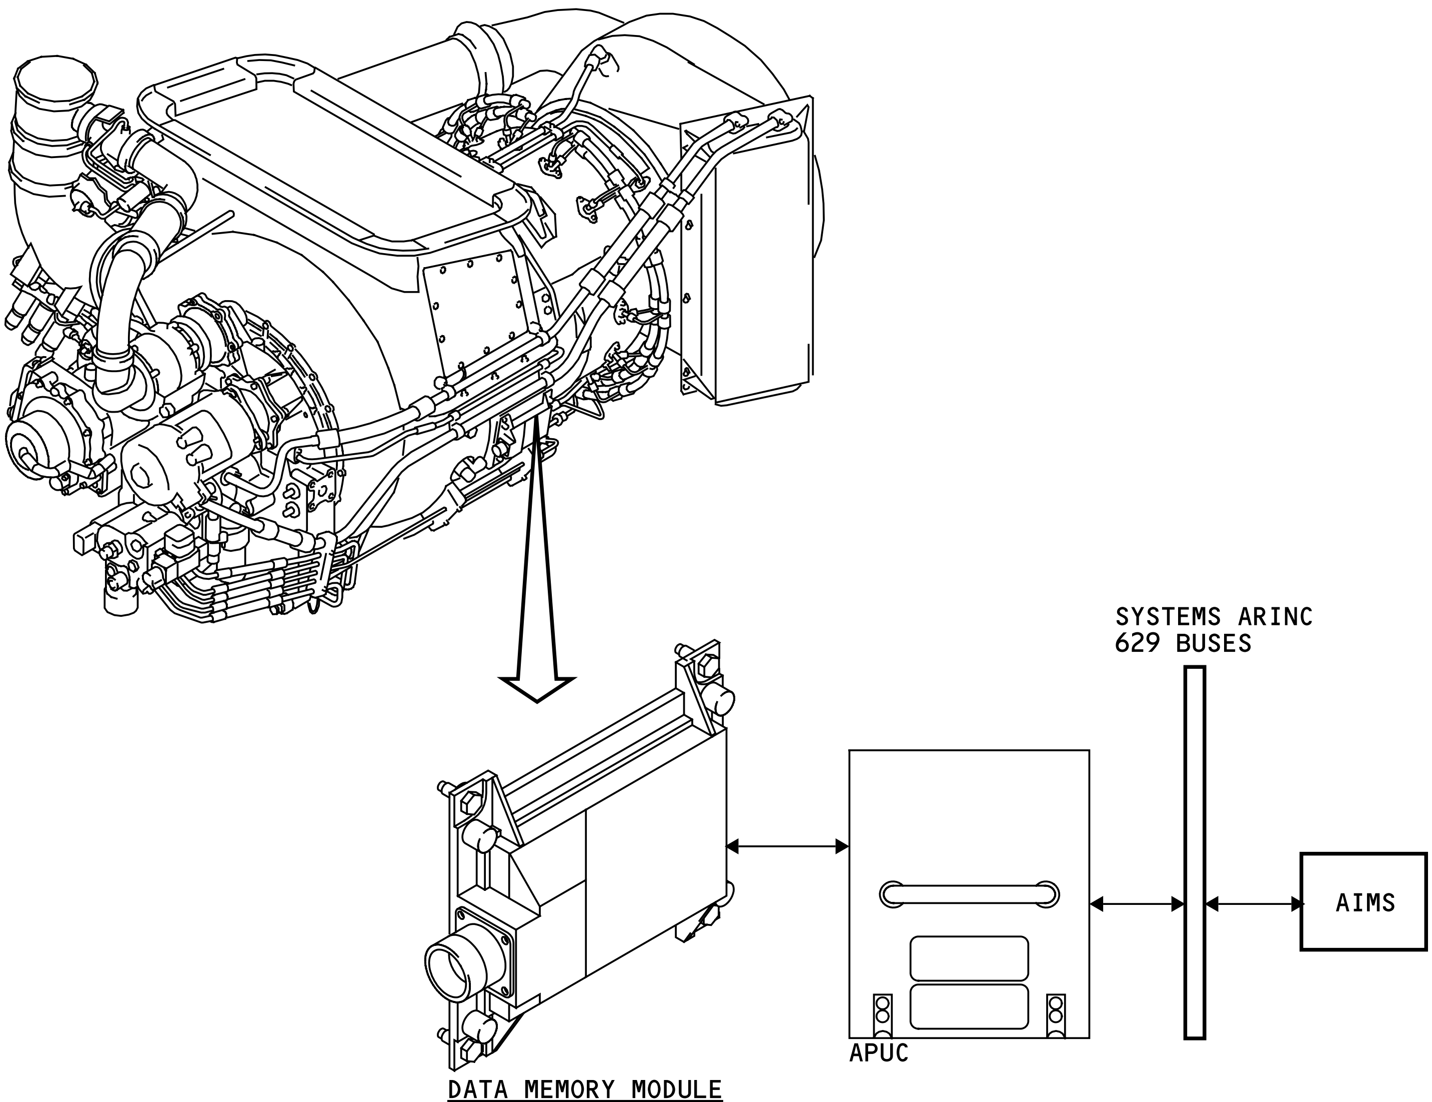
CAUTION: DO NOT REMOVE THE APUC AND THE DATA MEMORY MODULE AT THE SAME TIME. IF YOU REMOVE THE APUC AND THE DATA MEMORY MODULE AT THE SAME TIME, YOU WILL LOSE THE DATA FOR THE APU.

If you replace the DMM, make sure you obey the precaution given below.

CAUTION: YOU MUST USE A BLANK DATA MEMORY MODULE. IF YOU DO NOT USE A BLANK DATA MEMORY MODULE, LOSS OF DATA OR INCORRECT DATA CAN OCCUR.

If you replace both the APUC and the DMM, make sure you obey the precaution given below.

CAUTION: YOU MUST DO THE APU CONTROLLER INSTALLATION TEST BEFORE YOU REMOVE THE DATA MEMORY MODULE. IF YOU DO NOT DO THE INSTALLATION TEST FOR THE APU CONTROLLER BEFORE YOU REMOVE THE DATA MEMORY MODULE, YOU WILL LOSE THE DATA FOR THE APU.



APU INDICATING SYSTEM - DATA MEMORY MODULE

APU EXHAUST SYSTEM

Purpose

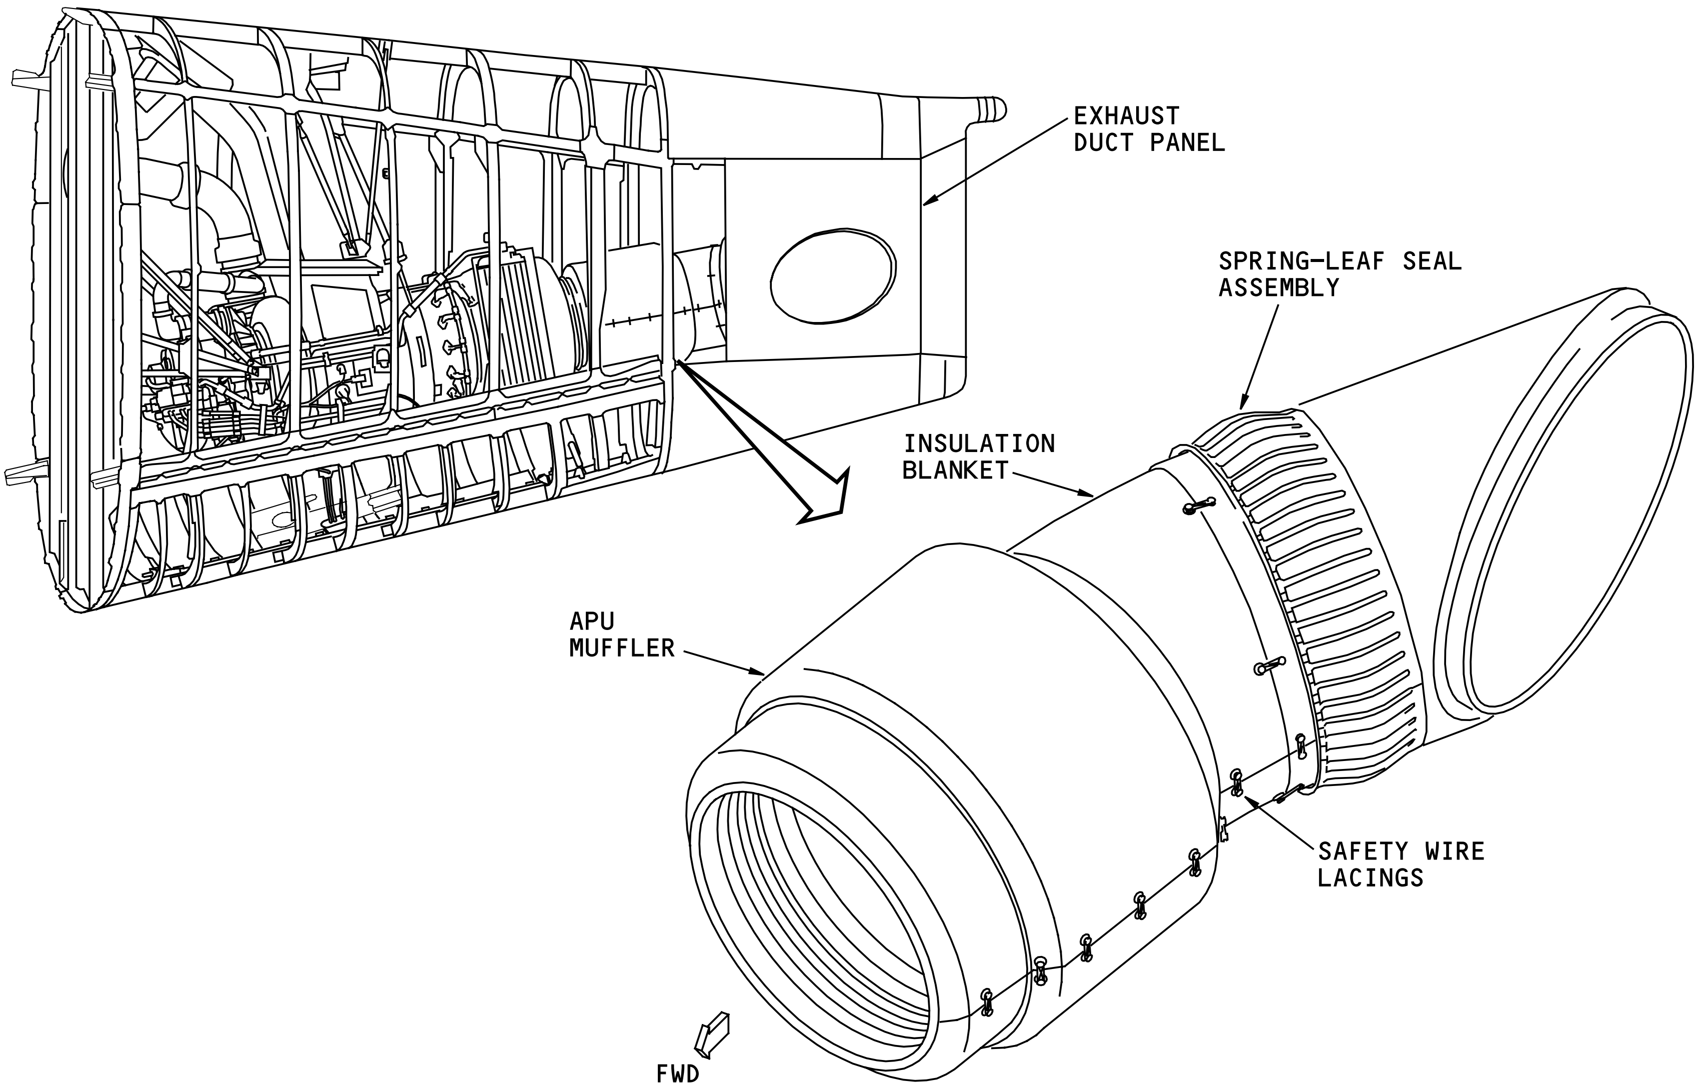
The APU exhaust system sends the APU exhaust overboard through the exhaust duct. The exhaust system prevents APU compartment damage from high exhaust gas temperatures and decreases exhaust noise levels.

Components

The stainless steel APU exhaust duct attaches to the APU turbine section with a V-Band clamp. A spring-leaf seal assembly holds the exit end of the exhaust duct in the exhaust duct panel. The 13 degree exhaust duct angle sends the exhaust out the left side of the aircraft.

An insulation blanket goes around the exhaust duct. Safety wire lacings hold the blanket together.

A muffler and acoustic assemblies in the exhaust duct decrease exhaust noise.



APU EXHAUST SYSTEM

THIS PAGE INTENTIONALLY LEFT BLANK

AUXILIARY POWER SYSTEM - OPERATION

Pre-Start

The left main fuel tank must contain a minimum of 950 pounds (430 kg) of fuel to start and operate the APU for one hour.

The battery switch on the electrical panel (P5) must be in the ON position before you can start the APU.

The APU GEN switch on the electrical panel should be in the ON position before you start the APU.

If electrical power is available, you should do a test of the fire detection system before you start the APU. You do this test with the fire/OVHT test switch on the cargo fire panel (P5).

If electrical power is available, you should also do a check of the APU oil quantity. You can see the APU oil quantity on the status display or on the APU maintenance page.

Start

You can start the APU with the electric starter motor or the air turbine starter. If pneumatic power is available, the APUC will normally select the air turbine starter to start the APU.

The APU BLEED switch on the bleed air/pressurization Panel (P5) must be in the AUTO position to do a pneumatic start.

You move the APU selector from OFF to START to start the APU. The selector moves to ON after you release it. The start is automatic.

The APU FAULT light below the APU selector will flash one time during APU start. The APU RUNNING memo message shows on the EICAS engine primary format when the APU speed is greater than 95 percent RPM.

Normal Operation

The APU operates at 100 percent RPM. The status page shows EGT, RPM, and oil system data.

Normal Shutdown

You move the APU selector to OFF to shutdown the APU. The APU stays at 100 percent RPM for 15 seconds after you move the selector. The APU then decreases speed to 70 percent RPM and stays at this speed for 80 seconds. The memo message APU COOLDOWN shows during this period. After the cooldown, the APU shuts down. The APU FAULT light flashes one time during APU shutdown.

Non-Normal Shutdown

You can also shutdown the APU with the APU fire switch on the P5 overhead panel. From outside the airplane you can shut down the APU with the APU fire shutdown switch on the P40 panel.

The APU shuts down immediately when you use the APU fire switch or the APU fire shutdown switch.

AUXILIARY POWER SYSTEM - OPERATION

The APU shuts down automatically for non-normal conditions.

APU Maintenance Switch

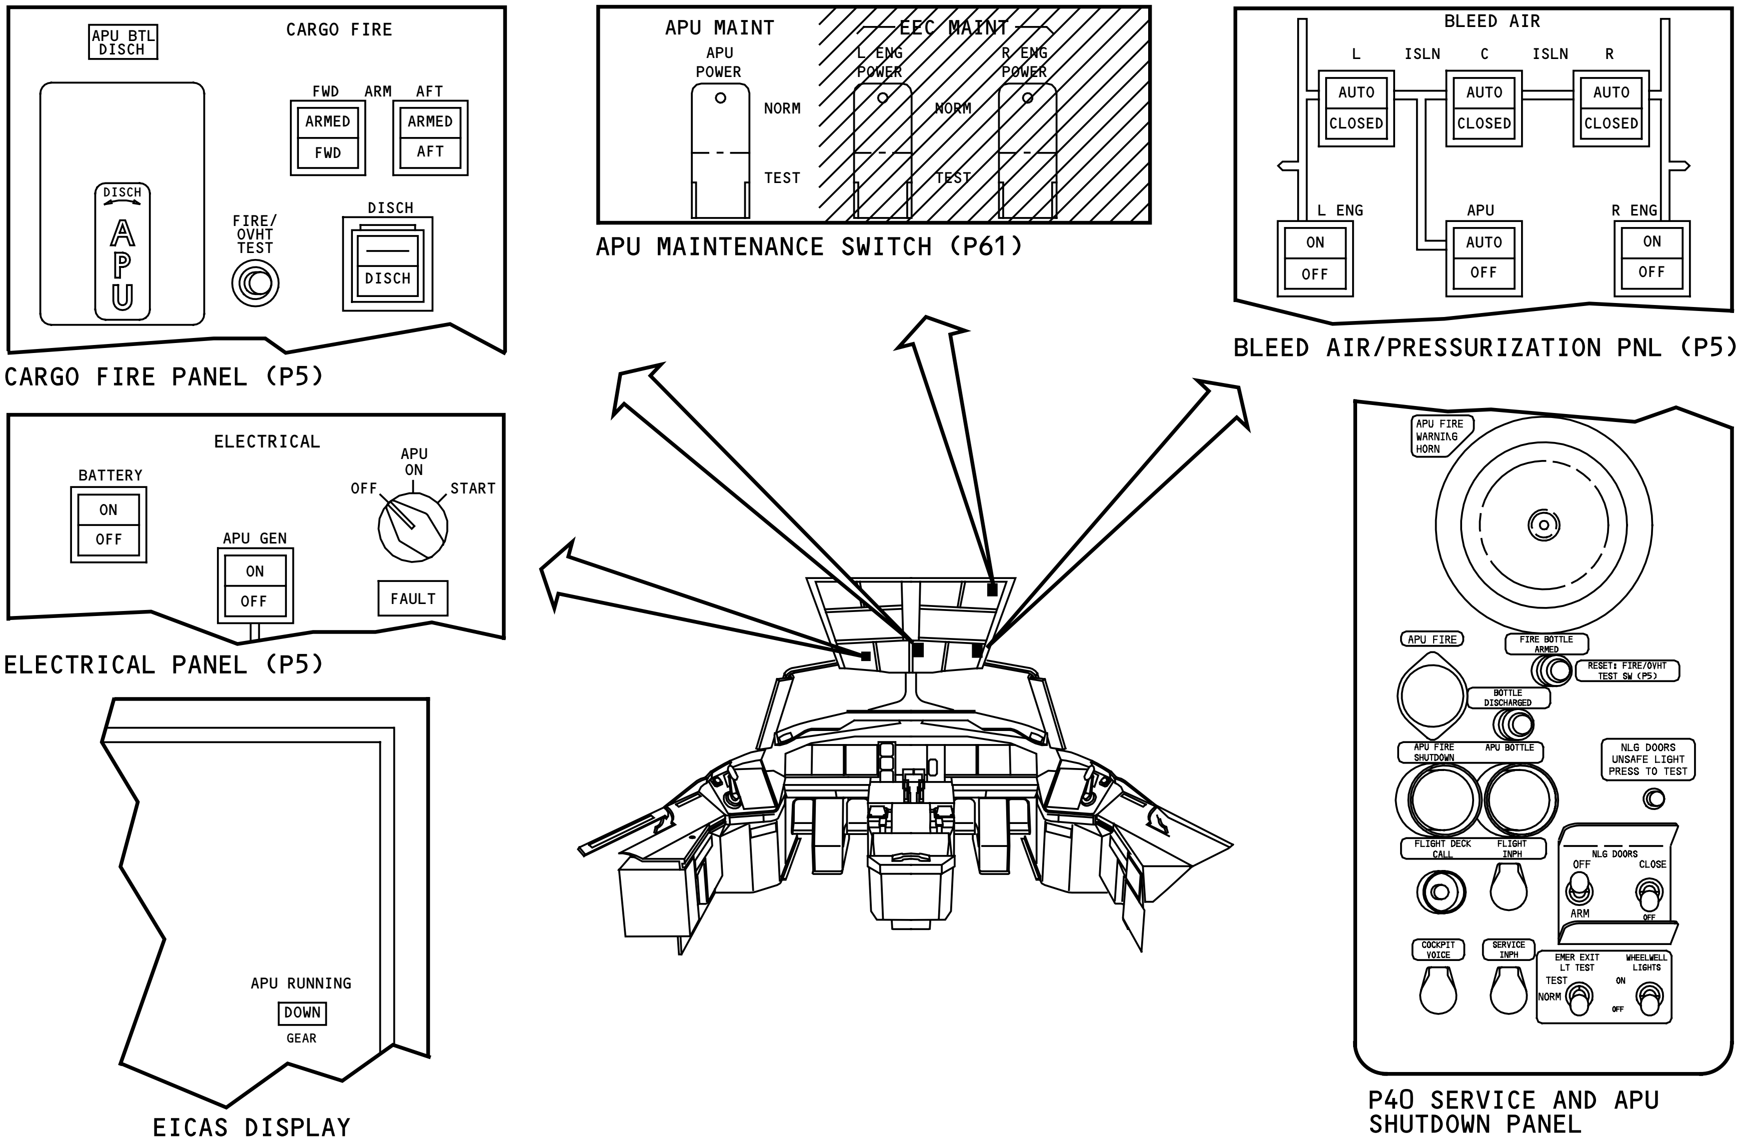
The APU maintenance switch (P61) in the TEST position supplies power to the APUC when the APU control selector is OFF. This permits the APU data to show on the status and maintenance page formats.

Training Information Point

After an emergency shutdown from the APU fire shutdown switch (P40), push the fire and overheat test switch to reset the start system.

After an APU fire switch (P5) shutdown, push the fire switch back in to reset the system.

The APU uses 675 lb (306 kg) of fuel for each hour of APU operation after the first hour.



AUXILIARY POWER SYSTEM - OPERATION

AUXILIARY POWER SYSTEM - STARTING

General

The APU can be started at any altitude.

The APU selector makes inputs to the P310 standby power management panel in the ELMS. The ELMS sends signals to the APUC.

The APUC controls the APU fuel, ignition, and starter systems during APU start.

APU Selector - ON

When you move the APU selector to ON, the APU shutoff valve and the APU air inlet door open. The APU dc fuel pump also turns on if ac power is not available. If ac power is available, fuel system boost pumps supply fuel to the APU and the APU dc pump stays OFF.

When you move the selector to START and release it, the selector moves back to ON. The APUC then selects the air turbine starter system or the electric starter system.

The APUC selects the air turbine starter system if pneumatic pressure is available. The APUC selects the electric starter system if pneumatic pressure is not available or if the air turbine start fails.

APU engine RPM must be less than 12 percent RPM and the air inlet door must be fully open before the start sequence starts.

As the APU speeds up, the pressurizing shutoff valve in the fuel cluster opens at 7 percent RPM. The igniter plugs energize immediately after the pressurizing shutoff valve opens.

During a low altitude electric start (below than 22,000 feet, (6700 meters)), the starter motor turns off at approximately 49 percent RPM. For a high altitude electric start (above 22,000 feet, 6700 meters), the starter motor turns off at 55 percent RPM.

During a pneumatic start, the ATSCV closes at 55 percent RPM.

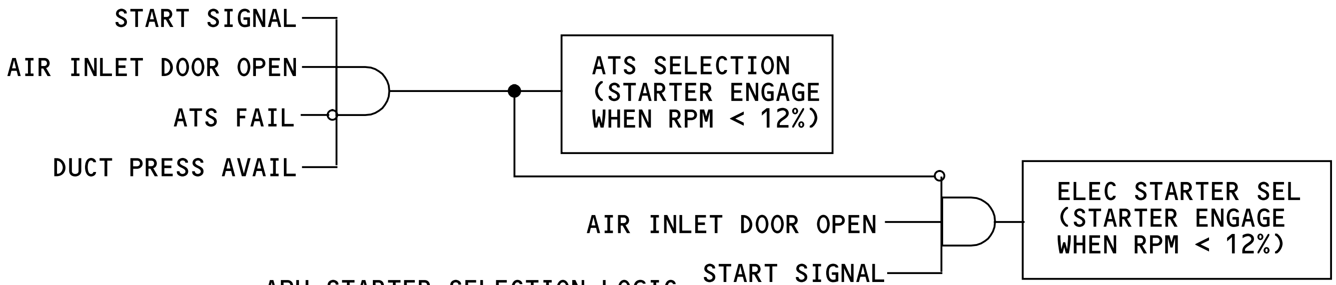
The APUC turns off the igniter plugs at 50 percent RPM.

The APU continues to speed-up. Two seconds after the APU reaches 95 percent RPM, pneumatic and electric loading become available.

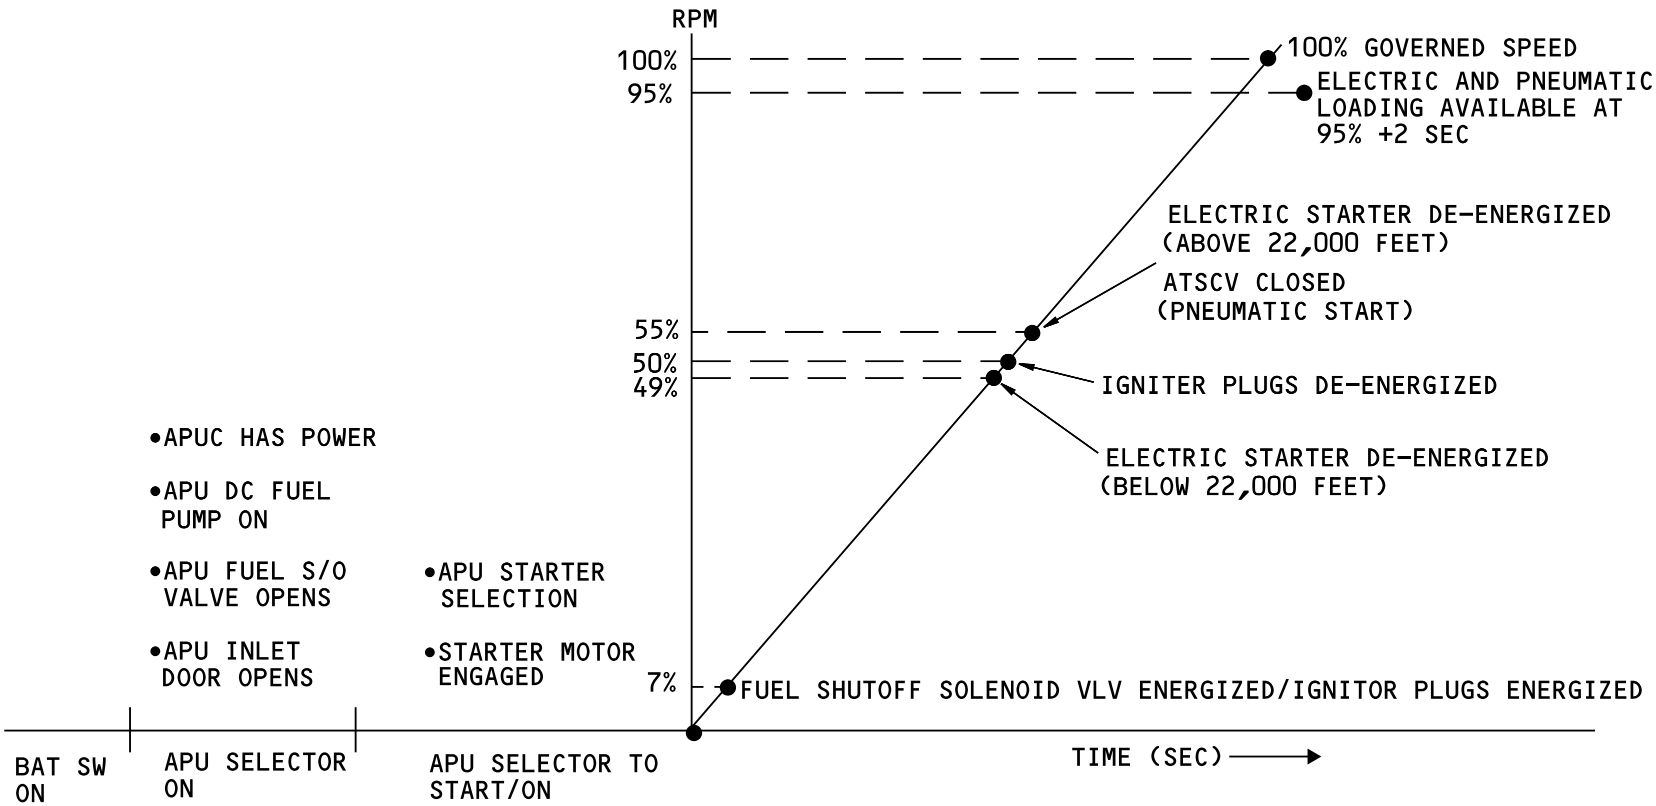
The APU speeds up to its normal operating speed of 100 percent (39,044) RPM.

Training Information Point

During an APU start, if the APU stops its acceleration for more than seven seconds, the APUC shuts down the APU.



APU STARTER SELECTION LOGIC



AUXILIARY POWER SYSTEM - STARTING

AUXILIARY POWER SYSTEM - NORMAL SHUTDOWN

General

The APUC controls the APU shutdown sequence. APU shutdown is not immediate. The APU goes through a cool-down period before shutdown.

There are different cooldown schedules for when the airplane is above 22,000 feet (6700 m) and below 22,000 feet (6700 m).

APU Selector to OFF

When you turn the APU control selector to OFF, the APUC sends a signal to the ASCPCs to close the APU shutoff valve. The APUC also closes the IGVs and opens the SCV to pneumatically unload the APU.

Thirteen seconds after you move the selector to OFF, the APUC sends a signal to the APU generator control unit (GCU) to unload the APU generator.

Above 22,000 Ft Cooldown

When the airplane is above 22,000 feet (6700 m), the APU cools down at 100 percent RPM for 105 seconds after you move the selector to OFF.

Below 22,000 Ft Cooldown

When the airplane is below 22,000 feet (6700 m), the APU stays at 100 percent RPM for 15 seconds. The APU then starts a 10 second controlled deceleration to 70 percent RPM. APU RPM stays at this speed for 80 seconds for additional cooldown.

Shutdown

After cooldown, the APUC does a test of the overspeed shutdown circuits to shut down the engine. The APUC sends a signal to the fuel shutoff solenoid valve and to the torque motor on the fuel metering valve to stop fuel flow. The APU speed then starts to decrease.

At 15 percent RPM, the air inlet door begins to close and the APU fuel shutoff valve in the left wing tank closes.

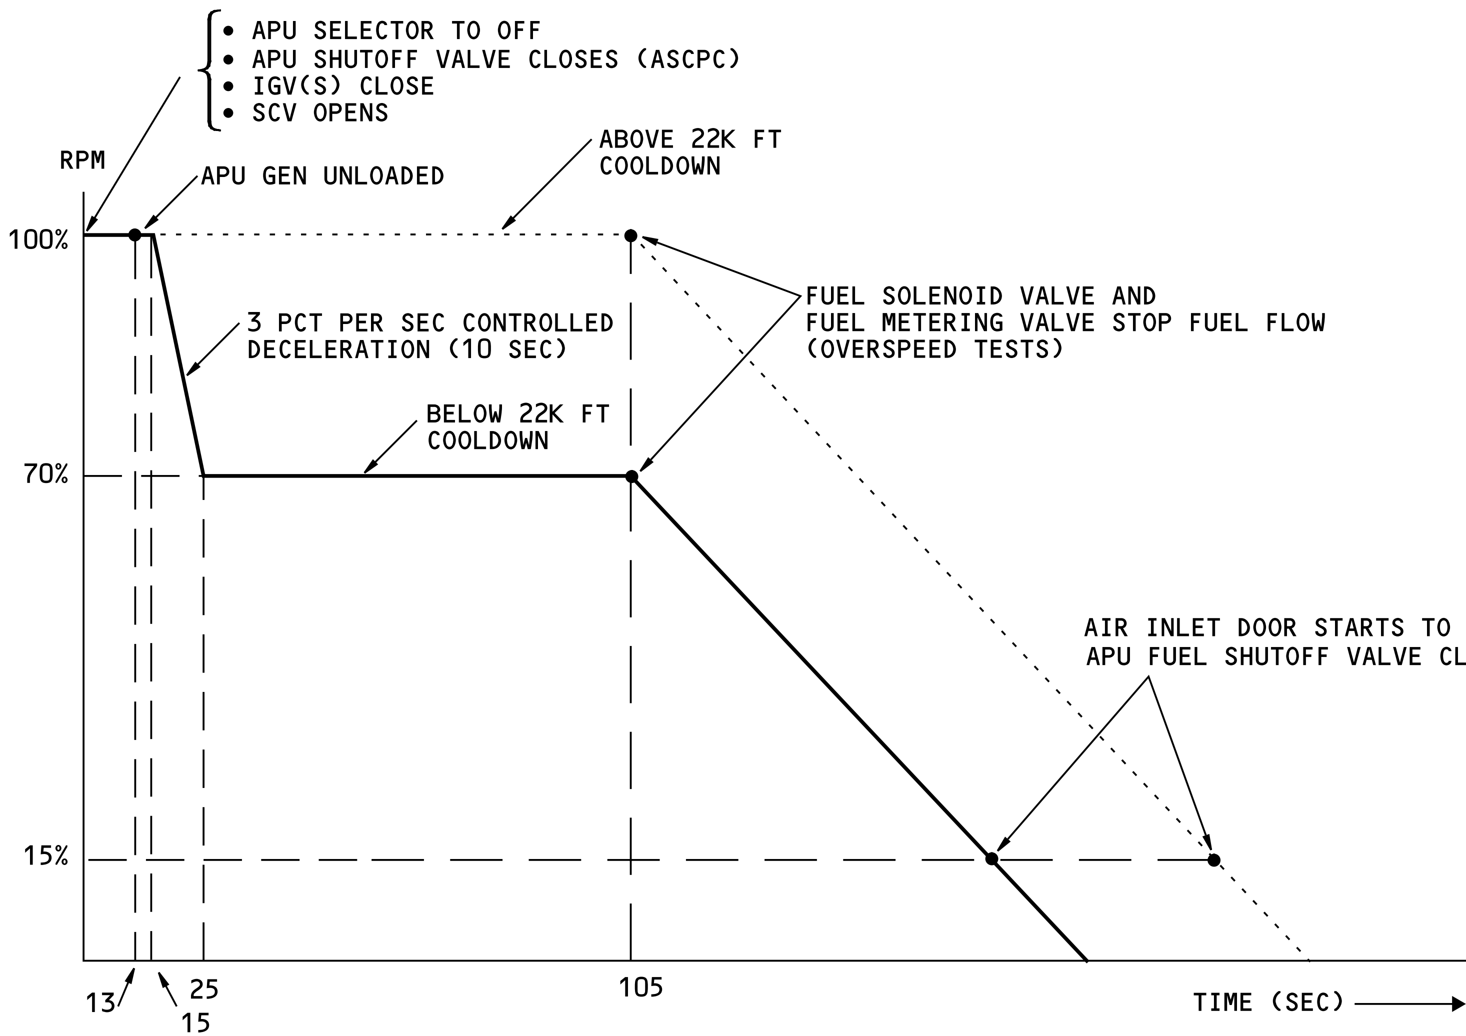
The APU speed decreases to zero.

Training Information Point

15 seconds after you move the APU selector to the OFF position, the APU COOLDOWN memo message shows. This message goes out of view after 80 seconds.

If you move the APU selector to the ON position during APU cooldown (less than 105 seconds after the selector is moved to OFF), the APU will accelerate to 100 percent and continue to operate.

If you move the APU selector to the ON position after the cooldown period has ended (more than 105 seconds after the selector is moved to OFF), the APU shutdown will continue.



AUXILIARY POWER SYSTEM - NORMAL SHUTDOWN

49-00-00-008 Rev 3 01/08/1997

THIS PAGE INTENTIONALLY LEFT BLANK

AUXILIARY POWER SYSTEM - PROTECTIVE SHUTDOWNS

General

The APUC controls the automatic protective shutdown of the APU. If the APUC finds some APU conditions or faults, it will send a protective shutdown signal.

There are two modes of APU automatic shutdown protection: the unattended mode and the attended mode.

Unattended Protective Shutdown

The unattended mode operates when the main engines are not running and the airplane is on the ground. This mode supplies protection against more types of failures than the attended mode. Any of these conditions will cause a shutdown in this mode:

- APU overspeed (more than 106 percent RPM)
- Loss of overspeed protection (loss of the two overspeed protection circuits)
- APU compartment fire
- APU inlet fire/load compressor reverse flow (T2 > 177C or low load compressor flow sensed by the total pressure sensor)
- APU speed droop (RPM less than 88 percent and no acceleration for 10 seconds)
- APUC failure
- Air inlet door failure
- Low oil pressure (less than 35 psi)
- Loss of oil pressure signal (from both the pressure sensor and the low oil pressure switch)
- High EGT (Calculated turbine inlet temperature is high. This occurs at approximately 710C EGT.)
- Loss of EGT signal (from both thermocouple rakes)
- High oil temperature (more than 156C).

Attended Protective Shutdown

The attended mode operates when at least one engine is running or if the aircraft is in the air. Only these conditions will cause a protective shutdown in the attended mode:

- APU overspeed
- Loss of overspeed protection
- APU compartment fire
- APU inlet fire/load compressor reverse flow
- APU speed droop
- APUC failure.

Indication

All protective shutdowns cause the APU SHUTDOWN advisory message to show and turn on the APU fault light on the P5 overhead panel. The APU status message also shows when there is a protective shutdown. In the attended mode, these conditions cause the APU LIMIT caution message to show:

- Low oil pressure
- High EGT
- High oil temperature.

AUXILIARY POWER SYSTEM - PROTECTIVE SHUTDOWNS

Training Information Point

You can attempt to restart the APU after you move the APU selector to OFF to unlatch the protective shutdown.

UNATTENDED MODE

- APU OVERSPEED
- LOSS OF OVERSPEED PROTECTION
- APU COMPARTMENT FIRE
- AIR INLET FIRE/LOAD COMPRESSOR REVERSE FLOW
- APU SPEED DROOP
- APUC FAILURE
- AIR INLET DOOR FAILURE
- LOW OIL PRESSURE
- LOSS OF OIL PRESSURE SIGNAL
- HIGH EGT
- LOSS OF EGT SIGNAL
- HIGH OIL TEMP

ATTENDED MODE

- APU OVERSPEED
- LOSS OF OVERSPEED PROTECTION
- APU COMPARTMENT FIRE
- AIR INLET FIRE/LOAD COMPRESSOR REVERSE FLOW
- APU SPEED DROOP
- APUC FAILURE

AUXILIARY POWER SYSTEM - INDICATIONS

General

The status display and maintenance page show APU system data.

Status Display

The status display shows these data:

- APU RPM
- APU EGT in degrees C
- APU oil pressure in psi
- APU oil temperature in degrees C
- APU oil quantity in quarts.

Maintenance Page

The APU maintenance page shows the status of many APU systems and the outputs of the APU sensors. The data shown includes:

- APU pneumatic mode
- APUC mode
- Speed sensor input in percent RPM. A box shows for the highest value
- Exhaust gas temperatures corrected to standard sea level conditions in degrees C
- Exhaust gas temperatures from each of the two rakes in degrees C
- Oil pressure in psi
- Oil temperature in degrees C
- Oil quantity in quarts (LO shows when the quantity is less than 3.75)
- Inlet static pressure (P2) in psia
- Load compressor total pressure (exit pressure from the load compressor) in psia
- Load compressor differential pressure (DP) in psi (difference between the load compressor total pressure and the static pressure downstream of the load compressor)
- Compressor inlet temperature (T2) in degrees C
- Oil sump temperature in degrees C
- Surge control valve position from 90 degrees (fully closed) to 10 degrees (fully open)
- Inlet guide vane actuator position from 76 degrees (fully closed) to -10 degrees (fully open)
- Fuel metering unit fuel temperature in degrees C
- Fuel cluster fuel metering valve position from 0 percent (fully closed) to 100 percent (fully open)
- Air inlet door command - OPEN or CLOSED (from ELMS)
- Air inlet door position - OPEN or CLOSED
- Bleed corrected flow in pounds of air per minute from the load compressor
- Bleed corrected flow setpoint in pounds of air per minute (calculated by the APUC). This is the surge margin set point
- APU battery DC voltage and amperage (charging or discharging)
- APU generator AC voltage, frequency, and load in percentage of maximum load.

APU fuel feed data also shows on the maintenance page. This data includes:

- APU fuel shutoff valve data

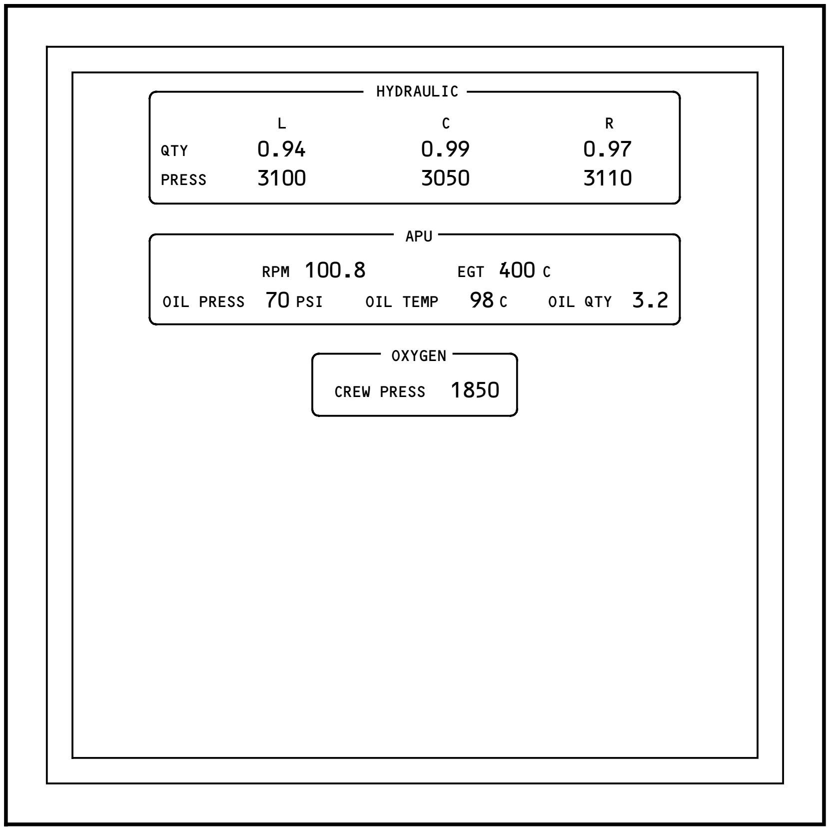
- DC fuel pump data
- AC fuel pump data.

The status codes show in digital format (1 or 0) the status of some of the APU inputs and outputs. Refer to section 49-70 in Part II of the airplane maintenance manual (AMM) for more information on the status codes.

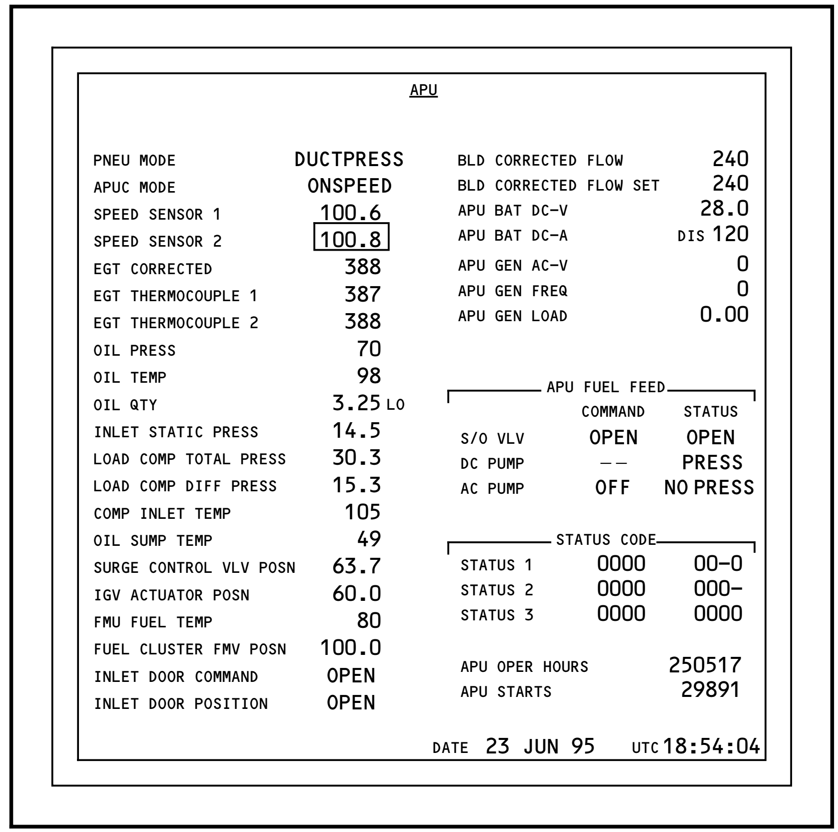
APU operating hours and the number of APU starts also shows on the maintenance page.

Training Information Point

You can use the APU maintenance switch to power the APUC when the APU selector is OFF. This permits you to read APU oil system indications on the status display without turning the APU selector to ON.



STATUS DISPLAY



APU MAINTENANCE PAGE

49-00-00-010 Rev 6 05/16/1997

AUXILIARY POWER SYSTEM - INDICATIONS

APU Access

You get access to the APU compartment through the APU doors.

You open the APU vent doors first to permit air to go into the APU compartment. This makes the pressure equal in the APU compartment and permits you to open the main APU doors when the APU is on.

Each main APU door has a latch on the forward edge of the door. You must release the latches to permit the main APU doors to open. Hold-open rods keep the doors in the open position.

APU Oil Servicing

You add oil to the APU at the oil fill port. The oil level sight gage shows full on the APU OFF side when the oil quantity is at the correct level.

The status display shows the APU oil quantity in quarts. The APU maintenance page (not shown) also shows the APU oil quantity.

This is a summary of the procedure to add oil to the APU:

- Make sure the APU selector on the P5 overhead panel is OFF and attach a DO-NOT OPERATE tag
- Open the APU access doors
- Open the oil fill cap
- Slowly add oil until the oil level is at the FULL mark on the APU OFF side of the oil level sight gage
- Close the oil fill cap
- Put the airplane back in its usual condition.

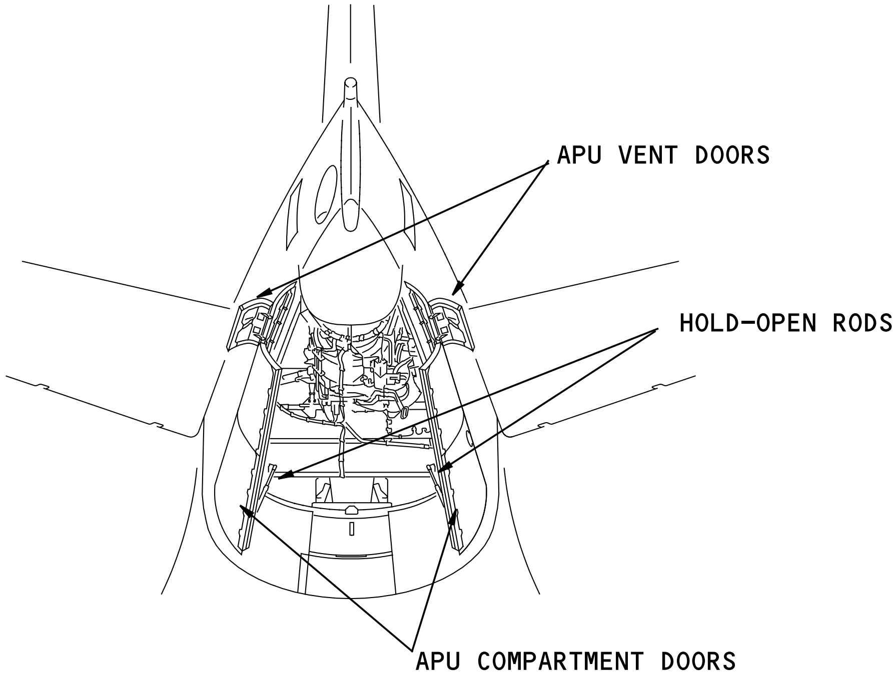
WARNING: DO NOT TOUCH THE APU GEARBOX HEATERS. THE GEARBOX HEATERS STAY HOT WHEN THE AIRPLANE HAS AC POWER. DO NOT TOUCH THE COMPONENTS OF THE OIL SYSTEM IF THE APU IS HOT. THESE COMPONENTS STAY HOTTER THAN OTHER COMPONENTS. HOT COMPONENTS CAN BURN YOU.

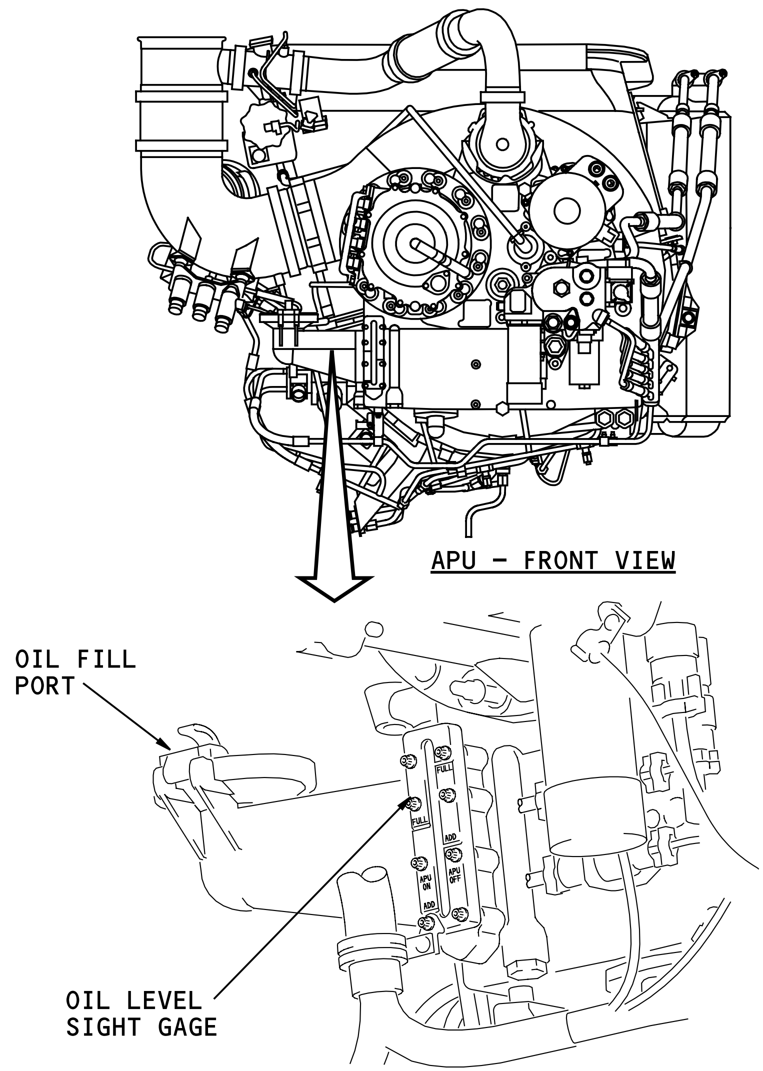
WARNING: DO NOT LET HOT OIL GET ON YOU. PUT ON PROTECTIVE CLOTHES, GOGGLES, AND EQUIPMENT, OR LET THE APU BECOME COOL. HOT OIL CAN BURN YOU.

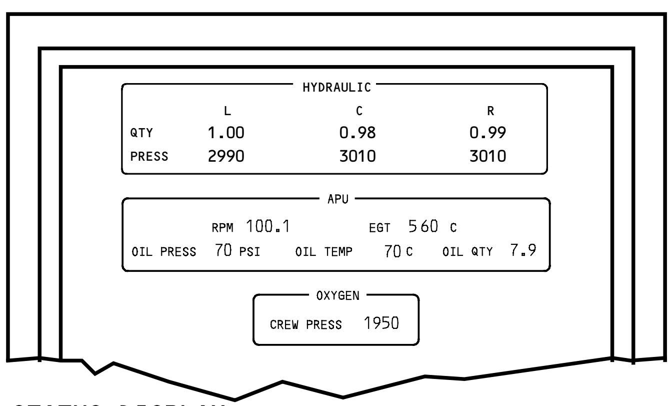
WARNING: DO NOT LET THE OIL STAY ON YOUR SKIN. YOU CAN ABSORB POISONOUS MATERIALS FROM THE OIL THROUGH YOUR SKIN.

CAUTION: DO NOT LET OIL GET ON THE APU OR OTHER COMPONENTS. IMMEDIATELY CLEAN THE OIL WHEN IT FALLS ON THEM. OIL CAN CAUSE DAMAGE TO PAINT AND RUBBER.

CAUTION: DO NOT MIX TYPES OR BRANDS OF OIL WHEN YOU ADD OR REPLACE THE OIL IN THE APU. INCORRECT OILS CAN CAUSE DAMAGE TO THE APU.







STATUS DISPLAY

AUXILIARY POWER SYSTEM - APU ACCESS AND SERVICING

AUXILIARY POWER SYSTEM - INTERFACES

General

The APUC gets airplane system data and sends APU data to airplane systems through the left and right system ARINC 629 data buses. The APUC also sends and receives some data through other connections.

ARINC 629 Interfaces

These systems have interfaces with the APUC through systems ARINC 629 buses:

- Bus power control unit (BPCU) - generator trim frequency
- APU generator control unit (GCU) - generator load
- Left and right air supply cabin pressure controller (ASCPC) - pneumatic valve positions, pack operation, and pneumatic duct pressure
- Left and right engine data interface unit (EDIU) - engine data
- Left and right cabin temperature controller (CTC) - pneumatic valve position and ECS data
- Left and right overhead panel ARINC 629 system (OPAS) - overhead panel switch/selector positions
- Left and right weight on wheels (WOW) cards - air/ground condition
- Hydraulic interface module (HYDIM) cards - ADP operation data
- Fire overheat detection card (FODC) - APU fire
- Left, right, and center duct leak and overheat detection system (DLODS) - wing/body duct overheat
- Electrical load management system (ELMS) - start control, shutdown control, autostart, attended/unattended mode
- Airplane information management system (AIMS) engine running status, air data (from ADIRU), airplane data, fault reporting, indications.

Other Interfaces

The APUC also has interfaces with these systems and components without ARINC 629:

- Electrical load management system (ELMS)
- The APU selector
- The APU maintenance switch
- The APU inlet door switch
- APU fire switch and fire shutdown switch
- Fire overheat detection card (FODC)
- APU generator OFF light
- APU fault light.

TABLE OF CONTENTS

TABLE OF CONTENTS

HYDRAULIC POWER - INTRODUCTION

General

Three hydraulic systems supply pressurized hydraulic fluid to supply power to these airplane systems:

- Flight controls
- Landing gear actuation
- Main gear brakes
- Main and nose landing gear steering
- Leading edge slats
- Trailing edge flaps
- Thrust reversers.

These systems make up the hydraulic power system:

- Main hydraulic systems
- Ram air turbine (RAT) system
- Hydraulic indicating systems
- Ground servicing system.

Main Hydraulic Systems

The three hydraulic systems are Left, Center, and Right. The names give the location of their main components.

Ram Air Turbine System

The ram air turbine supplies an emergency source of hydraulic power to operate the flight controls. The RAT also supplies emergency electrical power.

Hydraulic Indicating System

The hydraulic indicating system shows these hydraulic system indications on the flight deck:

- System pressure
- Pump pressure
- Reservoir pressure
- Pump temperature
- Reservoir temperature
- Hydraulic reservoir quantity
- Valve positions.

Ground Servicing System

A central servicing bay permits you to fill the three hydraulic reservoirs from a single location.

HYDRAULIC POWER - INTRODUCTION

HYDRAULIC POWER - COMPONENT LOCATIONS

General

Hydraulic system components are in these locations:

- Left and right engine aft strut fairings
- Right wheel well
- Aft wing to body fairings
- Main equipment center
- Stabilizer compartment.

Left and Right Hydraulic Systems

The left and right hydraulic system components are almost the same. Most left system components are in the left engine aft strut fairing. Most right system components are in the right engine aft strut fairing.

The components in each engine aft strut fairing include:

- A hydraulic reservoir
- An alternating current motor pump (ACMP)
- Filter modules (3)
- A reservoir pressurization module.

The left system engine-driven pump (EDP) is on the left engine. The right system EDP is on the right engine.

The system pressure transducers are in the wing structure behind each engine.

Center Hydraulic System

Most center hydraulic system components are in the right wheel well. These components include:

- A hydraulic reservoir
- ACMPs (2)
- Filter modules (3)
- A reservoir pressurization module
- A system pressure transducer
- Isolation valves.

Two air-driven pumps (ADPs) are in the left aft wing to body fairing behind the left wheel well.

The ram air turbine (RAT) is in the right aft wing to body fairing behind the right wheel well.

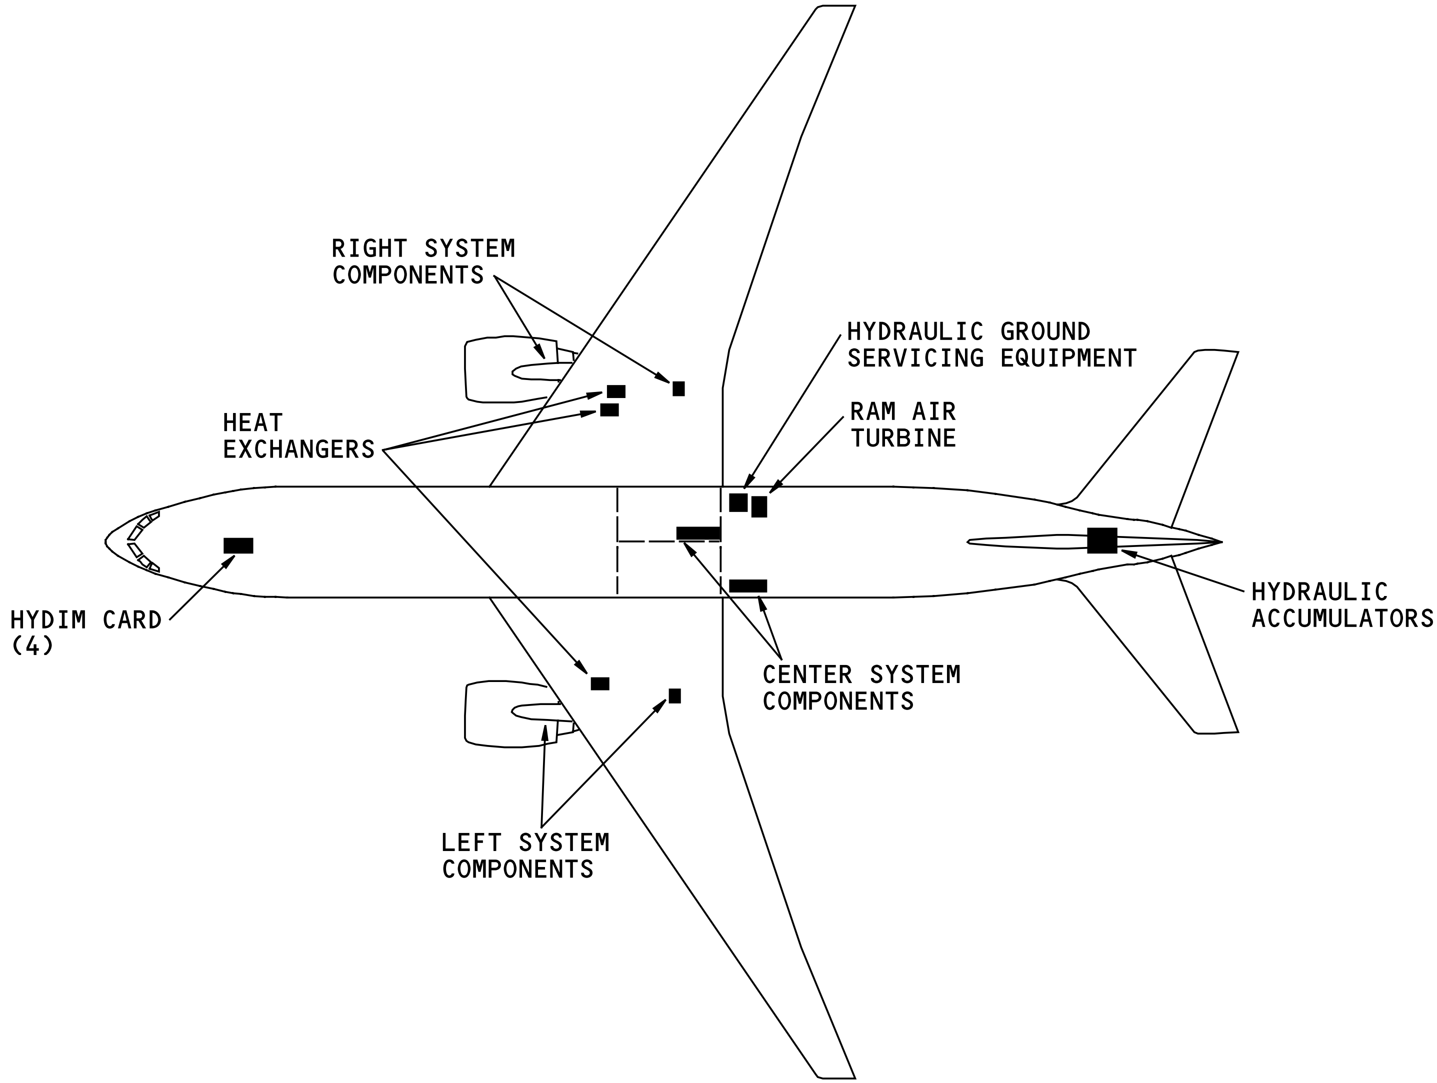
Other Hydraulic System Components

Four hydraulic interface module (HYDIM) cards are in the cardfiles in the main equipment center.

Heat exchangers are in the left and right main fuel tanks.

Hydraulic ground servicing equipment is in the ground servicing bay. The ground servicing bay is in the right aft wing to body fairing.

Hydraulic accumulators are in the stabilizer compartment.



29-00-00-002 Rev 3 02/22/95

HYDRAULIC POWER - COMPONENT LOCATIONS

MAIN HYDRAULIC SYSTEMS - INTRODUCTION

General

The left, center, and right hydraulic systems operate independently to supply hydraulic power to the airplane systems. All three systems operate at 3000 psi nominal pressure.

The hydraulic systems use BMS 3-11 hydraulic fluid.

The components and hydraulic tubing of the three systems are color coded. The left system is red, the center system is blue, and the right system is green.

Each hydraulic system has one or more primary and demand pumps. Primary pumps normally operate continuously. Demand pumps operate only when additional power is necessary.

Left and Right System

The left and right hydraulic systems are similar. These systems each have an engine-driven pump (EDP) as the primary pump and an alternating current motor pump (ACMP) as the demand pump.

The left hydraulic system supplies power for these systems:

- Primary flight control system (PFCS)
- Left thrust reverser.

The right system supplies power for these systems:

- PFCS
- Right thrust reverser
- Normal brake system.

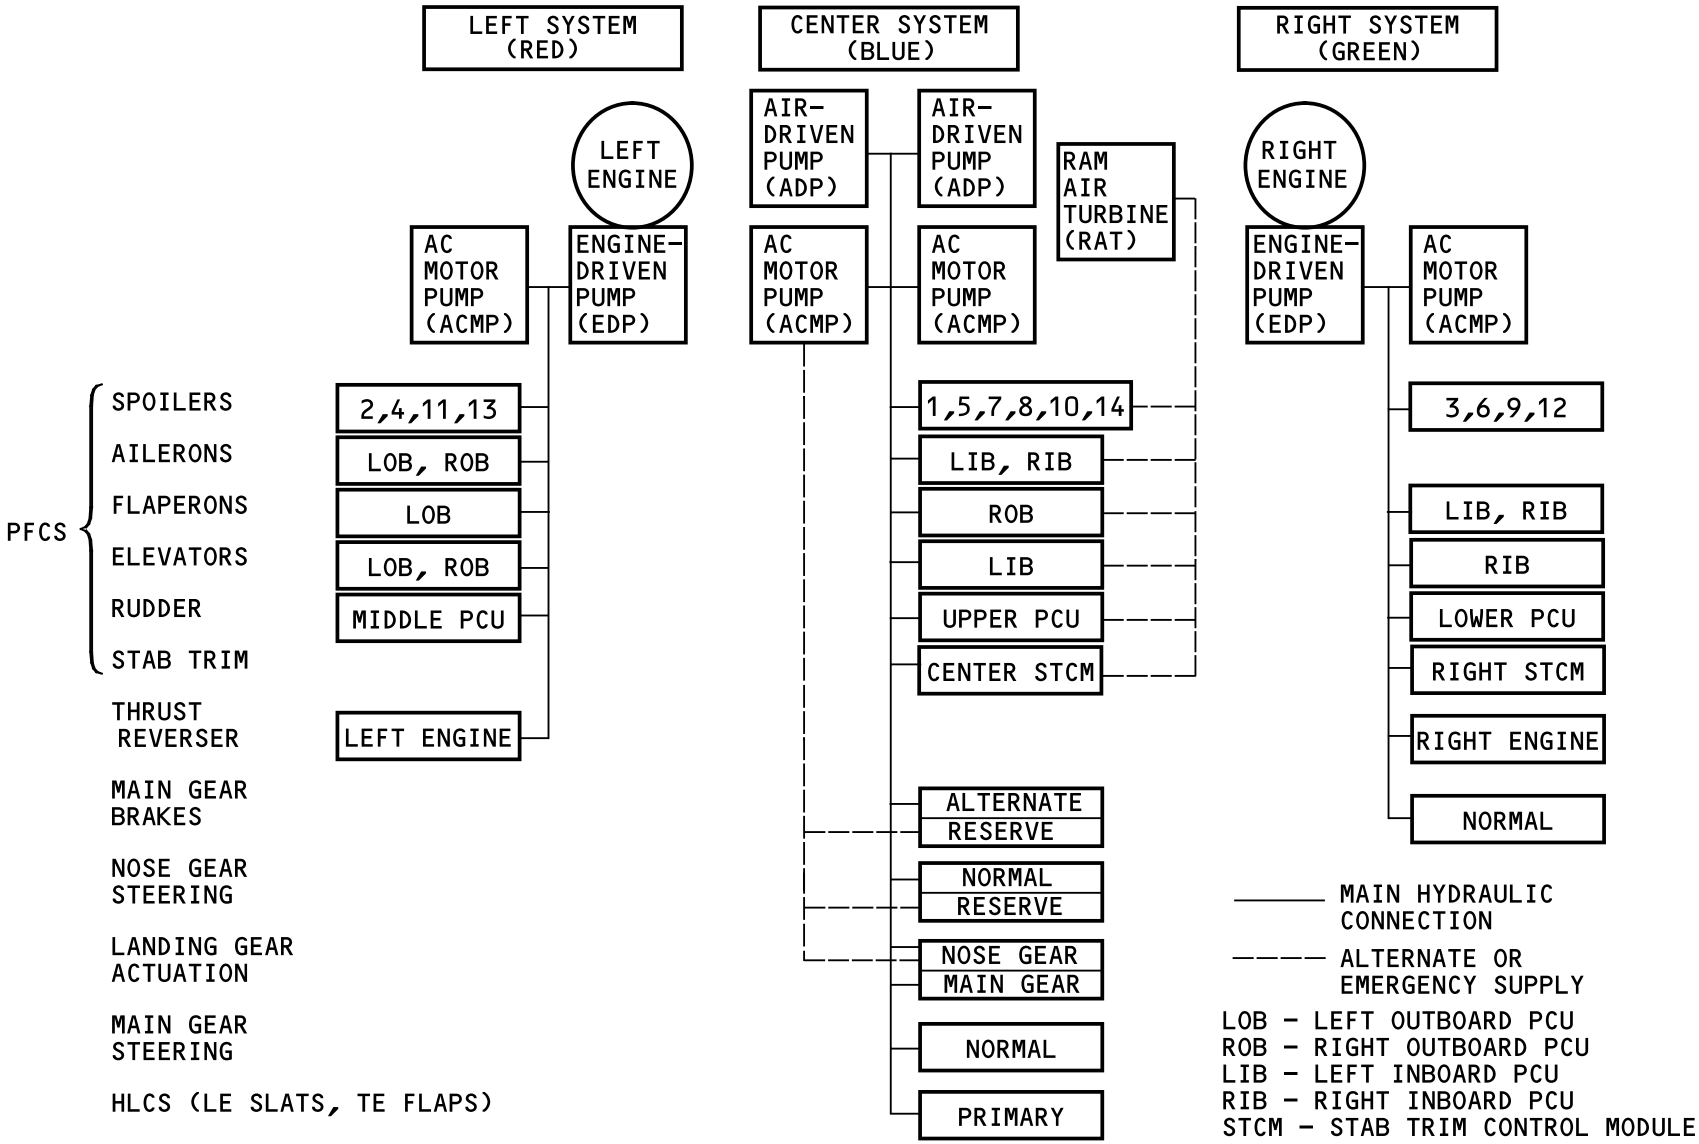
Center System

The center hydraulic system has two ACMPs as the primary pumps. Two air-driven pumps (ADPs) are the center system demand pumps. A ram air turbine (RAT) supplies an emergency source of hydraulic power to the flight controls in the center hydraulic system.

The center system also includes a center hydraulic isolation system (CHIS) for reserve brake and steering operation.

The center system supplies hydraulic power for these systems:

- PFCS
- Alternate and reserve brakes
- Normal and reserve nose gear steering
- Landing gear actuation
- Main gear steering
- High lift control system (HLCS)(LE slats, TE flaps).



29-10-00-001 Rev 5

MAIN HYDRAULIC SYSTEMS - INTRODUCTION

MAIN HYDRAULIC SYSTEMS - INTERFACES

General

Four hydraulic interface module (HYDIM) cards are the interface between the hydraulic systems and other airplane systems.

The HYDIM cards receive and transmit data through the ASG cards and the systems ARINC 629 buses. The HYDIM cards also send and get signals through hard-wires.

ARINC 629 Interfaces

The HYDIM cards have these interfaces through the left and right systems ARINC 629 buses:

- Proximity sensor electronic unit (PSEU) (2)
- Flap/slat electronic unit (FSEU) (2)
- Overhead panel ARINC 629 system (OPAS)
- Electrical load management system (ELMS) power management panels (P110, P210, and P310)
- APU controller (APUC)
- Air supply and cabin pressure controller (ASCPC) (2)
- Cabin temperature controller (CTC) (2)
- Engine data interface unit (EDIU) (2)
- Autopilot flight director computer (AFDC) (3)
- Airplane information management system (AIMS).

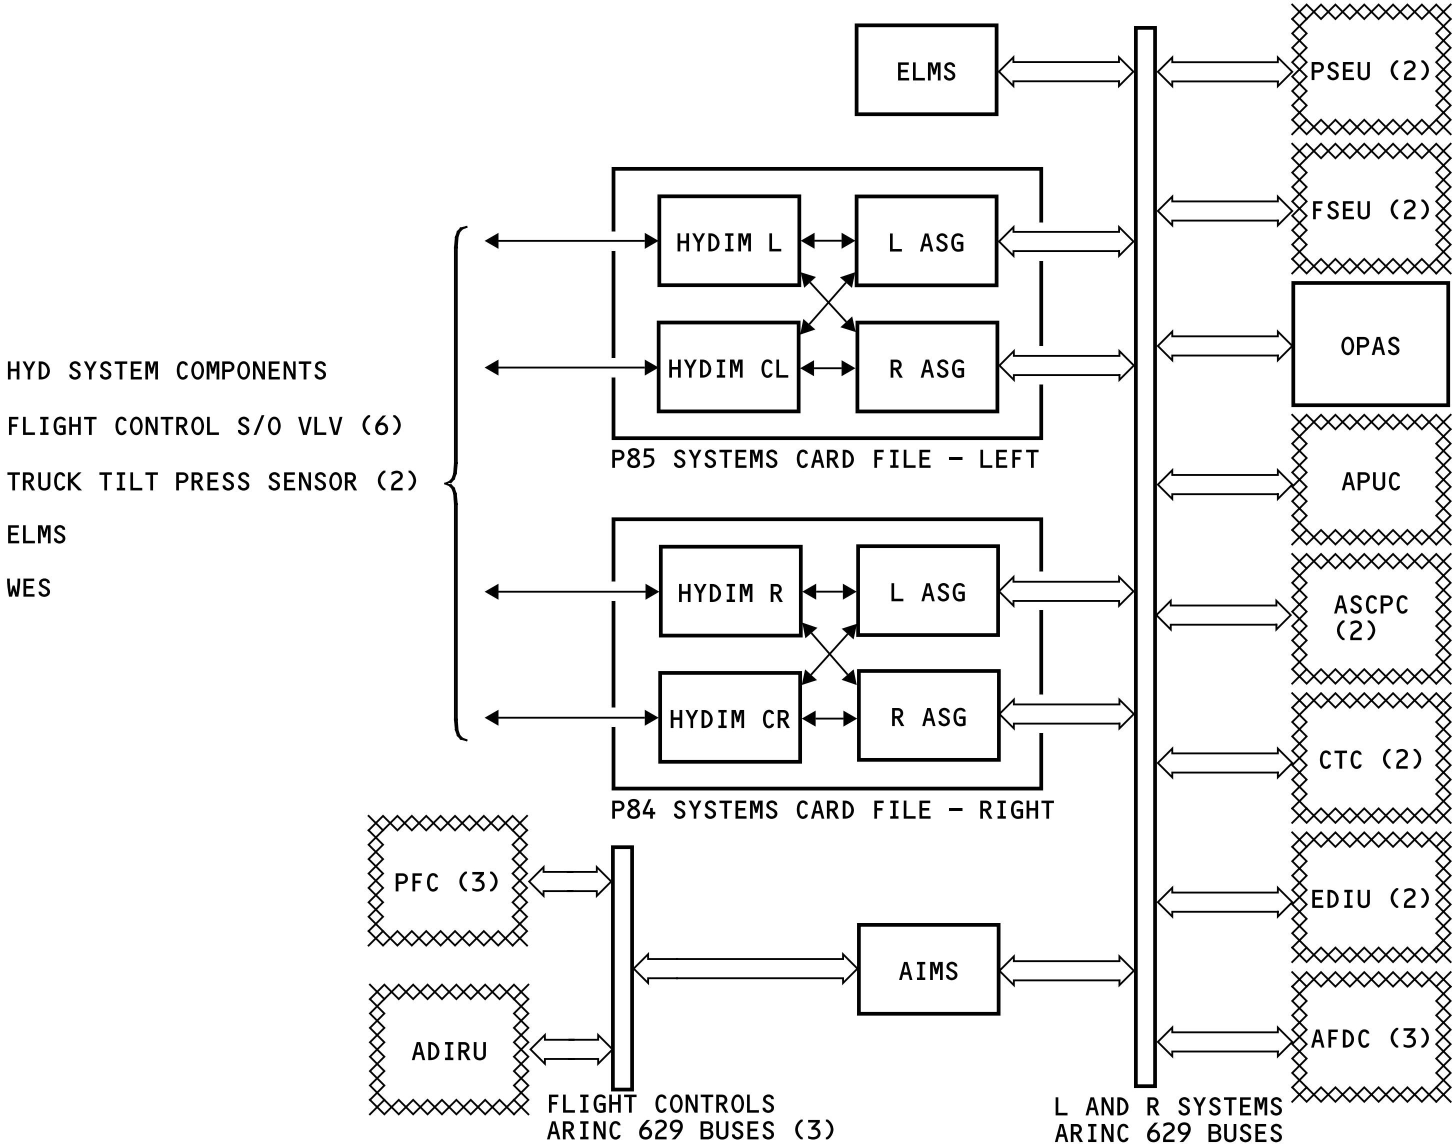
The HYDIM cards also send and receive data through AIMS and the flight controls ARINC 629 buses for these components:

- Primary Flight Computers (3)
- Air Data Inertial Reference Unit (ADIRU).

Hard-wire Interfaces

The HYDIM cards also have these interfaces through hard-wires:

- Hydraulic system components
- Flight control shutoff valve (6)
- Truck tilt pressure sensors
- ELMS
- Warning electronic system (WES).



MAIN HYDRAULIC SYSTEMS - INTERFACES

MAIN HYDRAULIC SYSTEMS - CONTROLS

General

The controls for the hydraulic system pumps and the RAT manual deployment are on the hydraulic/RAT panel. This panel is on the P5 overhead panel.

The engine fire switches on the P8 aisle stand panel also control EDP operation.

Primary and Demand Pump Controls

Each primary pump has an alternate action switch. You select the pump OFF or ON.

Each demand pump has a rotary selector. You select the pump OFF, AUTO, or ON. When you select AUTO, the pump is in the demand mode and the HYDIM cards control the operation. When you select ON, the pump operates continuously.

Fault lights for each pump turn on if there is a pump overheat or pump low pressure condition.

Rat Deploy Switch

A RAT deploy switch at the top of the panel permits manual deployment of the ram air turbine. The RAT deploy switch is a momentary switch and is guarded.

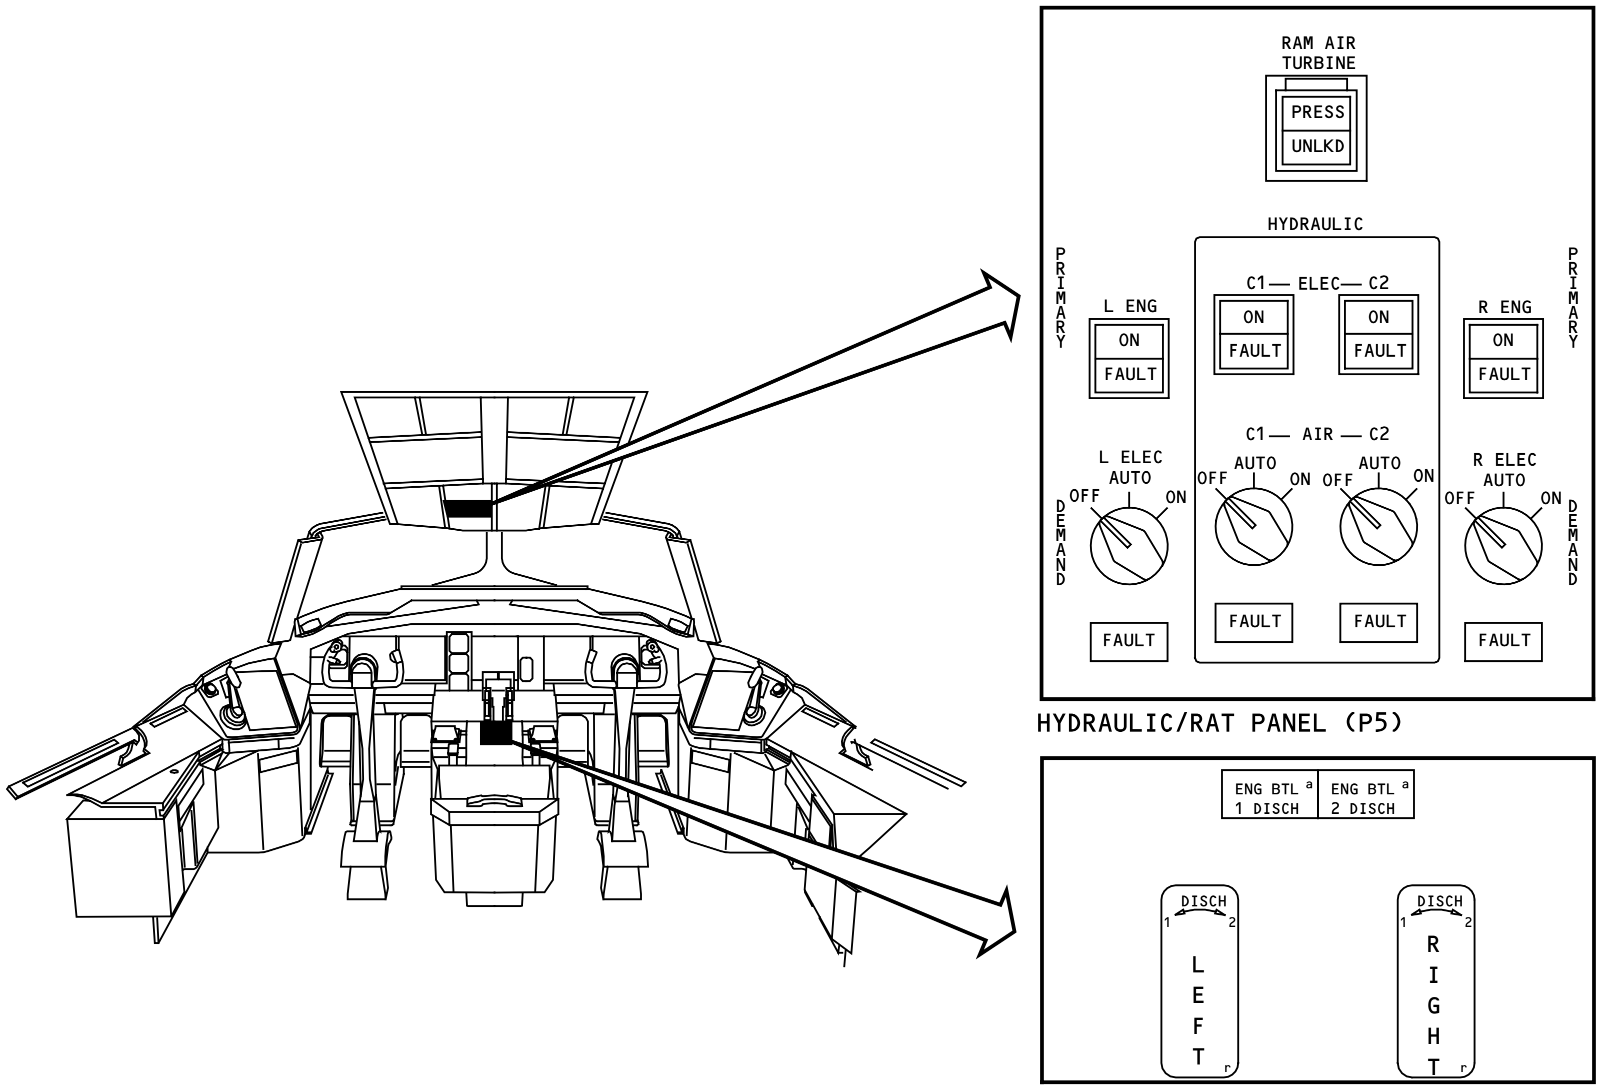
This switch also has an unlocked light and a pressure light. The unlocked light turns on when the RAT is not up and locked. The pressure light turns on when the RAT supplies hydraulic pressure.

Engine Fire Switches

The engine fire switches isolate the engine if there is an engine fire. When you operate one of the fire switches, the hydraulic fluid supply to the related pump shuts off and the pump depressurizes.

Training Information Point

Because the EDP depressurization valve gets electrical power when the EDP control switch is OFF, keep the switch in the ON position. If the switch is in the OFF position for a long period, you should open the circuit breaker for the EDP solenoid.



HYDRAULIC/RAT PANEL (P5)

ENGINE FIRE SWITCHES (P8)

MAIN HYDRAULIC SYSTEMS - CONTROLS

MAIN HYDRAULIC SYSTEMS - HYDRAULIC INTERFACE MODULE CARDS

General

Four hydraulic interface module (HYDIM) cards supply control, indication, and other functions to the hydraulic system. The HYDIM cards have these names:

- HYDIM left (L)
- HYDIM right (R)
- HYDIM center left (CL)
- HYDIM center right (CR).

HYDIM L controls the functions for the left system. HYDIM R controls the functions for the right system. HYDIM CL and CR control the functions for the center system.

The HYDIM cards are interchangeable. Card position in the card file determines the function of the card.

HYDIM sends and receives some signals directly through hard wires.

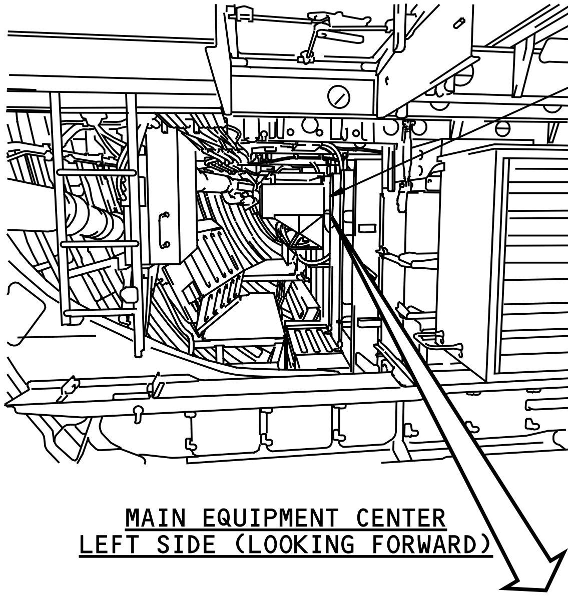
HYDIM also sends and receives signals through the left and right systems ARINC 629 buses through the ARINC signal gateway (ASG) cards.

Location

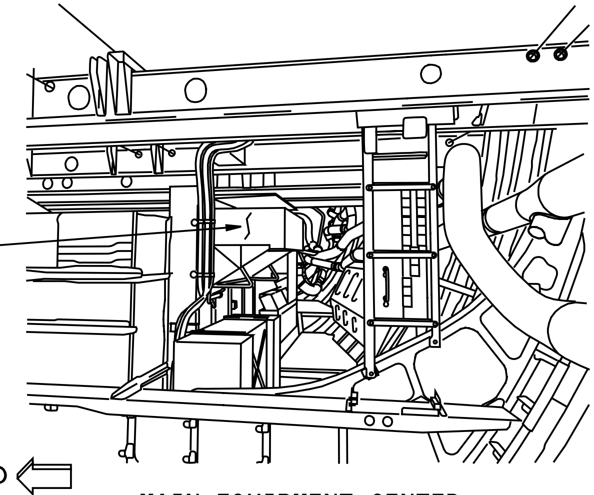
The HYDIM cards are in the P85 left systems card file and the P84 right systems card file.

Training Information Point

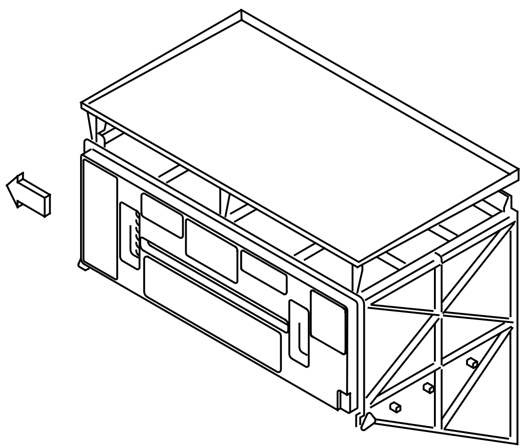
The HYDIM cards are software loadable. See the CMCS section for more information about the data load (AMM PART I 45-10).



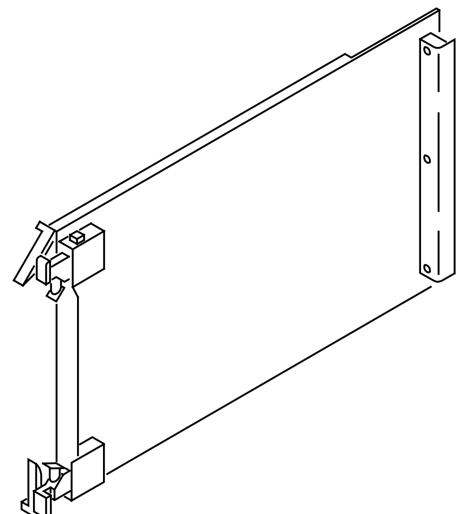
MAIN EQUIPMENT CENTER
LEFT SIDE (LOOKING FORWARD)



MAIN EQUIPMENT CENTER
RIGHT SIDE (LOOKING FORWARD)



P85 LEFT SYSTEMS CARDFILE
(P84 RIGHT SYSTEMS CARDFILE SIMILAR)



HYDIM CARD (TYPICAL)

MAIN HYDRAULIC SYSTEMS - HYDRAULIC INTERFACE MODULE CARDS

MAIN HYDRAULIC SYSTEMS - HYDRAULIC INTERFACE MODULE CARDS - FUNCTIONAL DESCRIPTION

General

Four HYDIM cards in the system card files monitor and control the hydraulic system and do other functions.

The HYDIM cards send and receive some data through ARINC 429 buses to the ARINC signal gateway (ASG) cards. The ASG cards send and receive data through the systems ARINC 629 buses.

The HYDIM cards also send and receive data through hard wires.

Control Functions

The HYDIM cards control these functions:

- Demand pump (L, R ACMP; ADP C1, C2) AUTO operation
- Reserve and NG isolation valve operation
- Landing gear auto-off (MLG and NLG selector/bypass valves)
- RAT auto deploy.

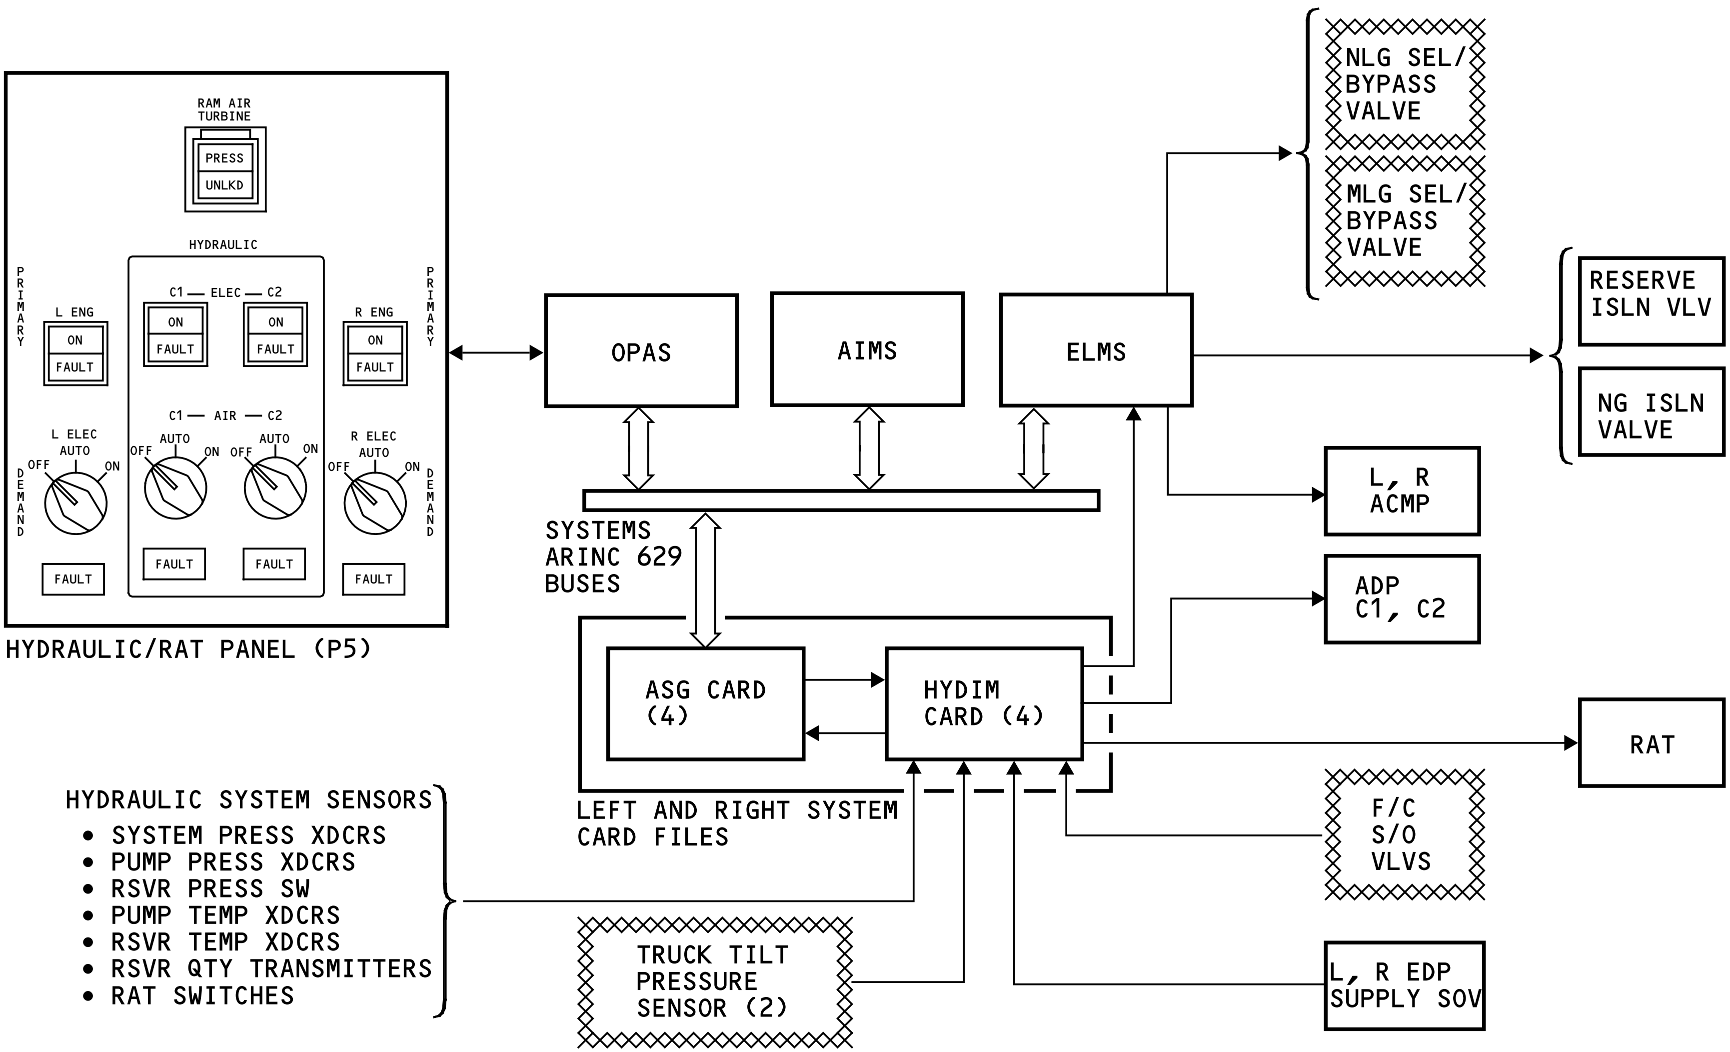
Indications

HYDIM supplies these hydraulic system indications through AIMS:

- System pressures
- Pump pressures
- Reservoir pressures
- Pump temperatures
- Reservoir fluid temperatures
- Reservoir quantities
- RAT locked status
- Valve positions.

HYDIM also does these functions:

- Hydraulic system fault detection
- Monitor EDP supply shutoff valve positions
- Monitor truck tilt pressures
- Monitor flight control shutoff valve positions.



MAIN HYDRAULIC SYSTEMS - HYDRAULIC INTERFACE MODULE CARDS - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

MAIN HYDRAULIC SYSTEMS - HYDRAULIC SYSTEM RESERVOIRS

Purpose

The hydraulic reservoirs supply hydraulic fluid under pressure to the hydraulic pumps. The reservoirs also get the return hydraulic fluid from the airplane systems that use hydraulic power.

Physical Description

The left and right system reservoirs are the same. Each has a total volume of 12.6 gallons (47.8 liters) and normally contains 7.4 (28 liters) gallons of hydraulic fluid.

The center system reservoir has a total volume of 25.6 gallons (97 liters) and normally contains 11 gallons (41.7 liters) of hydraulic fluid.

Each reservoir has these components:

- Reservoir pressure relief valve
- Sight glasses (low and overfull)
- Reservoir sample valve
- Reservoir drain valve
- Reservoir temperature transducer
- Reservoir quantity transmitter.

Location

The left hydraulic system reservoir is in the left engine aft strut fairing.

The right hydraulic system reservoir is in the right engine aft strut fairing.

The center system reservoir is in the aft part of the right wheel well.

Functional Description

The reservoirs are pressurized by the bleed air system for positive supply to the pumps.

The reservoirs have an internal trap to make sure fluid goes to the pumps during negative-G conditions.

Each reservoir also has a standpipe. For the left and right reservoirs there are 2 gallons (7.6 liters) of fluid below the standpipe. The EDPs get a fluid supply from the standpipe. A port at the bottom of the reservoir supplies fluid to the ACMPs.

For the center hydraulic system, there are 1.2 gallons (4.5 liters) below the standpipe. The standpipe supplies the fluid to ACMP 2, to both ADPs, and to the RAT. ACMP 1 gets fluid from the bottom of the reservoir.

The reservoir pressure relief valve opens between 85 and 90 psi to protect the reservoir against over-pressurization.

MAIN HYDRAULIC SYSTEMS - HYDRAULIC SYSTEM RESERVOIRS

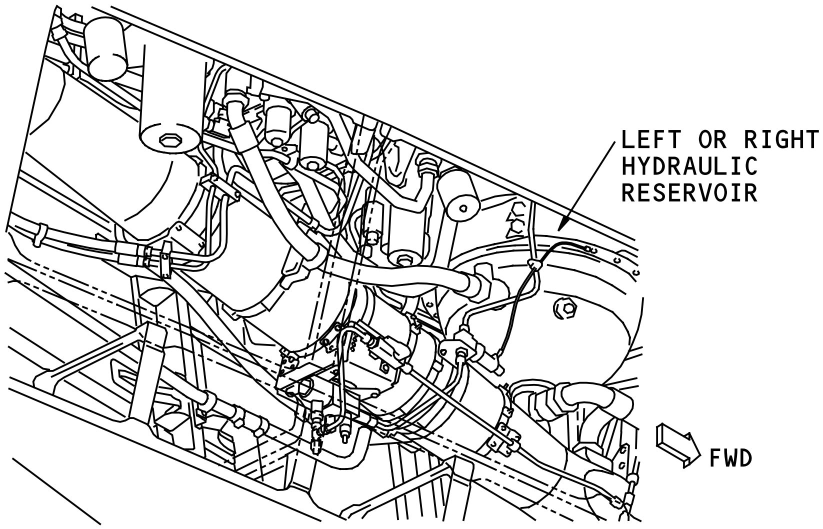
Training Information Point

You get access to the left and right reservoirs through the aft strut fairing doors on both sides of the aft engine struts.

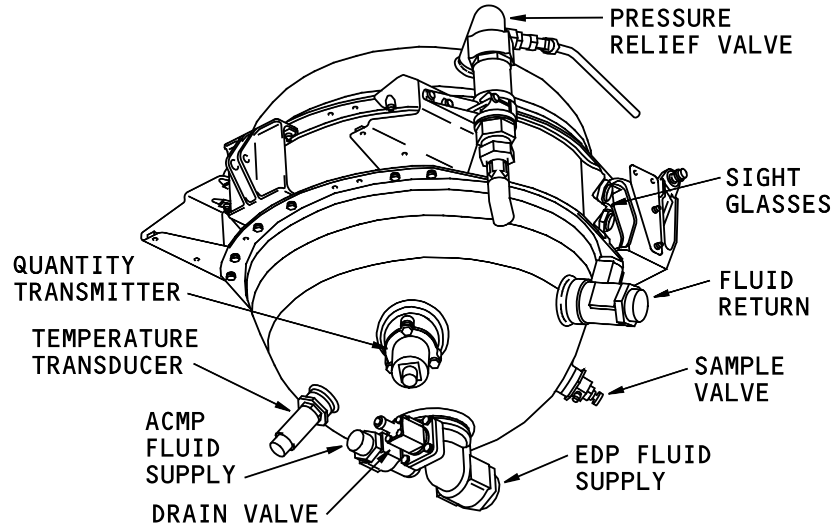
When filled to the correct level, the top sight glass shows red and the bottom sight glass shows black.

When the reservoir is in an overfull condition, both sight glasses show black.

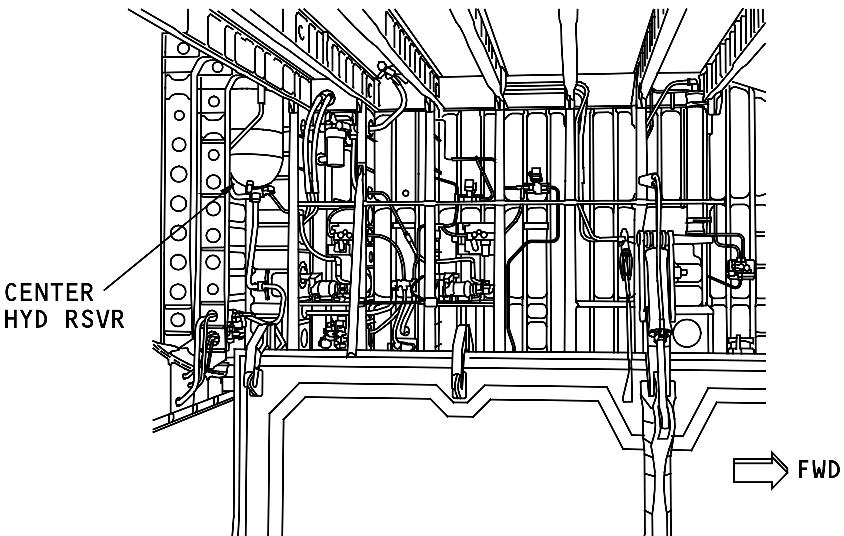
When the reservoir needs to be filled, both sight glasses show red.



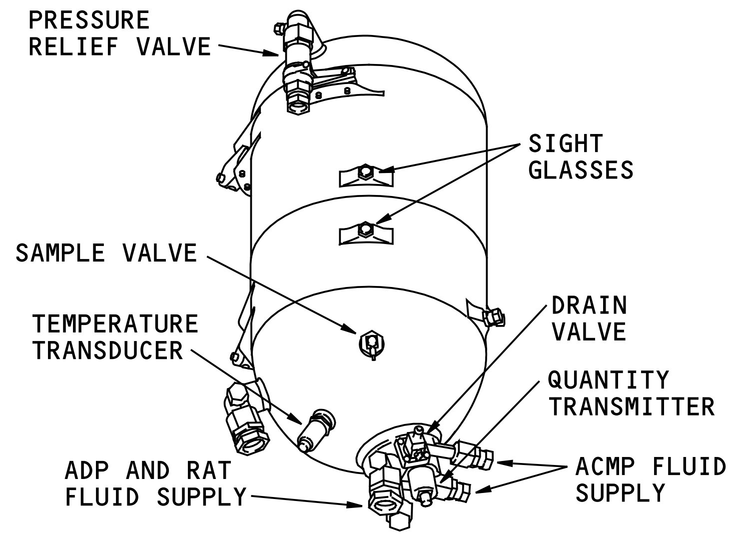
ENGINE STRUT



LEFT AND RIGHT HYDRAULIC RESERVOIR



RIGHT WHEEL WELL



CENTER HYDRAULIC RESERVOIR

MAIN HYDRAULIC SYSTEMS - HYDRAULIC SYSTEM RESERVOIRS

MAIN HYDRAULIC SYSTEMS - RESERVOIR PRESSURIZATION MODULE AND SHUTOFF VALVE

General

The reservoir pressurization modules supply airplane bleed air to the reservoirs.

The reservoir pressurization shutoff valves are manually operated valves which permit the shutoff of air pressure to the reservoir.

Each hydraulic system has a reservoir pressurization module, and a reservoir pressurization shutoff valve.

Physical Description

Each reservoir pressurization module has these components:

- Filter (2)
- Check valve (2)
- Test port
- Manual bleed valve
- Gage port.

The reservoir pressurization shutoff valves are simple manual shutoff valves. These shutoff valves are before the pressurization module in the pneumatic line to the reservoir.

Location

The modules for the left and right systems are in the engine aft struts below their reservoir.

The center system module is on the aft bulkhead in the right wheel well.

The shutoff valves are near the pressurization modules.

Operation

To depressurize a reservoir, first turn the shutoff valve to the closed position. Install the lock pin to hold the valve in the closed position.

You depressurize the reservoir with the manual bleed valve on the reservoir pressurization module.

CAUTION: PUT A RAG AROUND THE AIR BLEED VALVE ON THE RESERVOIR PRESSURIZATION MODULE TO CATCH HYDRAULIC FLUID SPRAY. HYDRAULIC FLUID SPRAY CAN CAUSE INJURIES TO PERSONS.

Training Information Point

A reservoir pressure switch near each of the reservoirs send reservoir pressure low or reservoir pressure not-low signals to the HYDIM cards.

See the hydraulic indicating section for more information about the reservoir sensors (AMM PART I 29-30).

RESERVOIR PRESSURIZATION MODULE

MAIN HYDRAULIC SYSTEMS - RESERVOIR PRESSURIZATION MODULE AND SHUTOFF VALVE

29-10-00-007 Rev 5

MAIN HYDRAULIC SYSTEMS - ENGINE DRIVEN PUMP

Purpose

The engine driven pump (EDP) is the primary pump for the left and right hydraulic systems.

Physical Description

The EDP is an axial-piston, variable displacement, hydraulic pump assembly.

An internal pressure compensator controls the output pressure of the pump to approximately 3000 psi.

A depressurization solenoid valve blocks the pump output flow when you turn off the pump.

Case drain hydraulic flow cools and lubricates the engine driven pump.

A ripple damper smooths the pump pressure output.

The pump is rated at 48 gpm at 2850 psi and 3900 rpm.

The dry weight of the pump is 36 pounds (16 kg).

Location

The EDP is on the front face of the engine main gearbox on the left side of each engine.

Functional Description

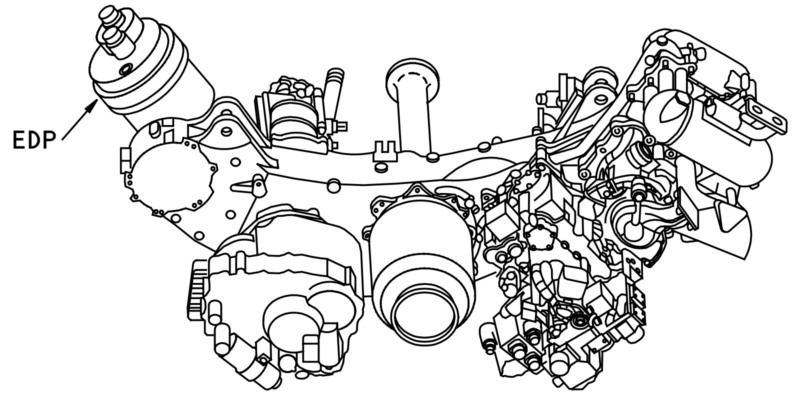
The engine main gearbox turns the EDP when the engine turns. When the depressurization solenoid valve is not energized, pump pressure output goes to the hydraulic system.

When you turn off the pump, the depressurization solenoid valve gets electrical power. This permits pressurized hydraulic fluid from the pump output line to move the blocking valve. This causes a blockage and removes the pressure from the EDP.

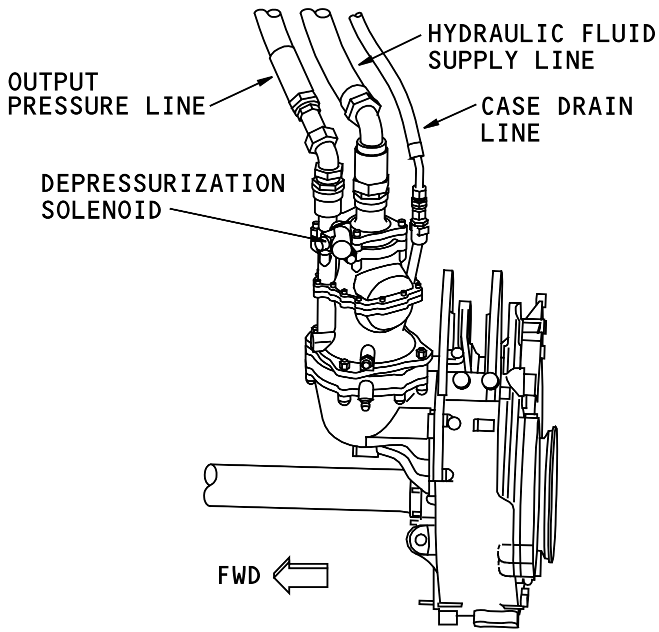
Training Information Point

You get access to the EDPs through the left thrust reverser half.

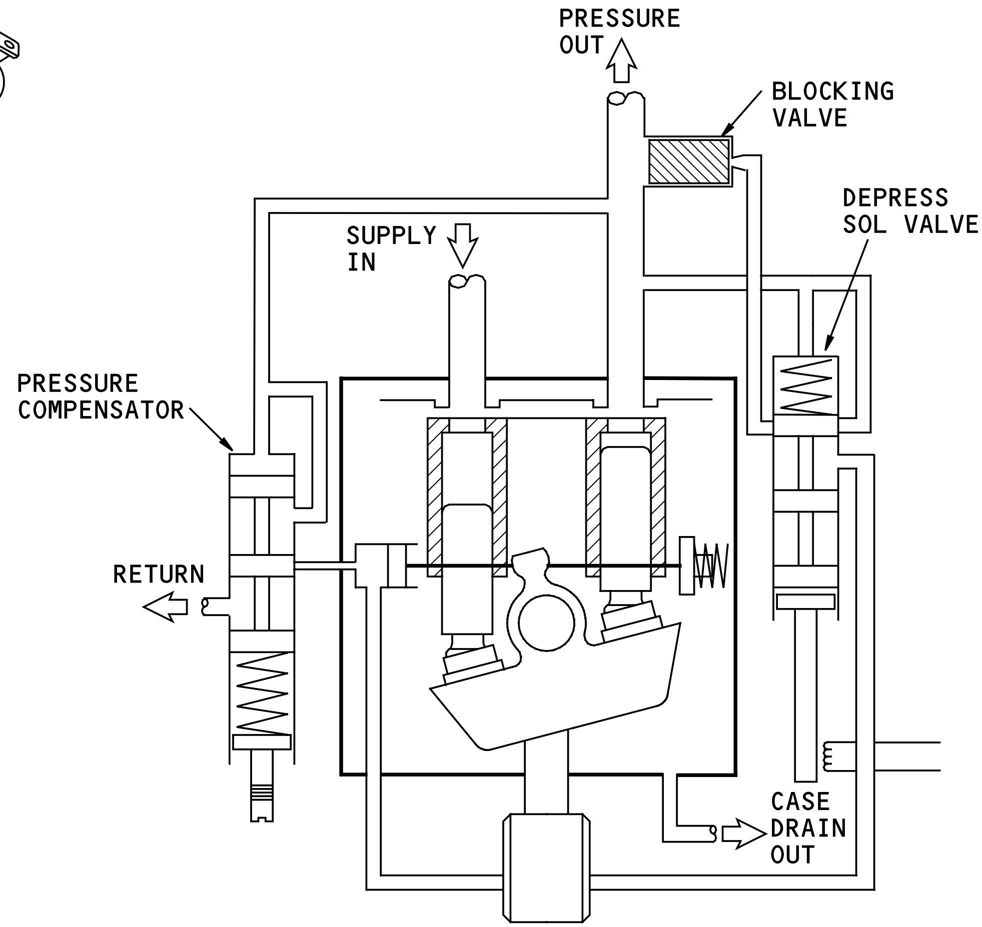
CAUTION: MAKE SURE YOU INSTALL THE O-RING IN THE SPLINE GROOVE ON THE DRIVE SHAFT OF THE ENGINE DRIVEN PUMP. THE O-RING PREVENTS LEAKAGE OF OIL FROM THE ENGINE GEARBOX.



ENGINE MAIN GEARBOX (LOOKING FORWARD)



ENGINE DRIVEN PUMP



EDP - SCHEMATIC

29-10-00-008 Rev 3

MAIN HYDRAULIC SYSTEMS - ENGINE DRIVEN PUMP

MAIN HYDRAULIC SYSTEMS - ENGINE DRIVEN PUMP - SUPPLY SHUTOFF VALVE

Purpose

The EDP supply shutoff valve stops hydraulic supply from the reservoir to the EDP when the engine fire switch is in the up position.

Physical Description

The supply shutoff valve is a two-position valve operated by a 28v dc motor. A position indicator shows the position of the valve.

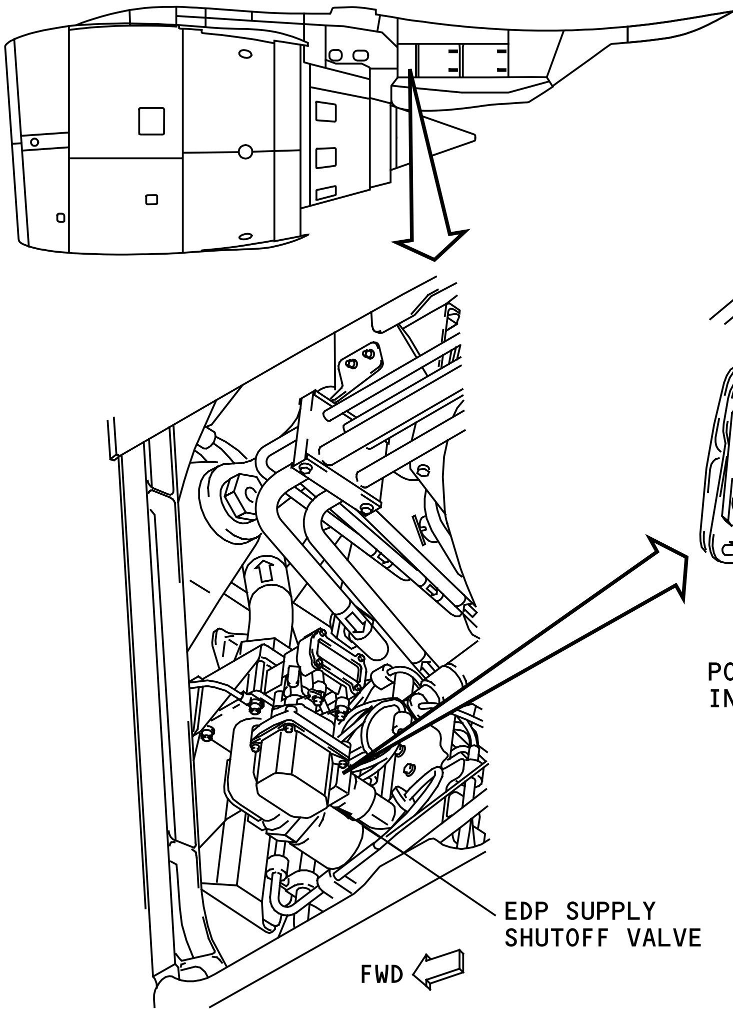
Location

There is a supply shutoff valve in the left side of each engine aft strut fairing near the hydraulic reservoir.

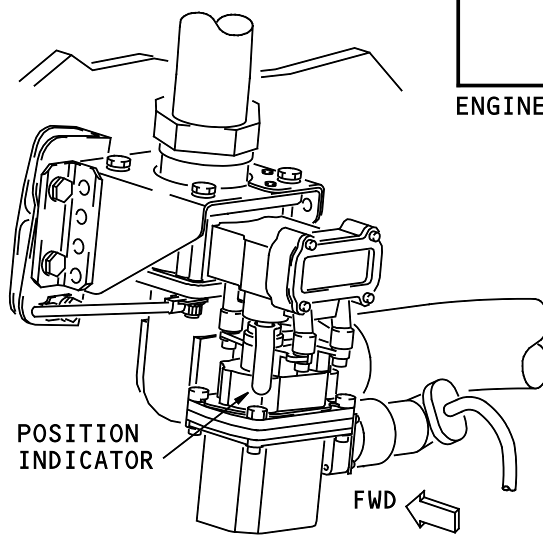
Training Information Point

Because the supply of hydraulic fluid to the pump stops when the fire switch is up, there is no pump case drain flow.

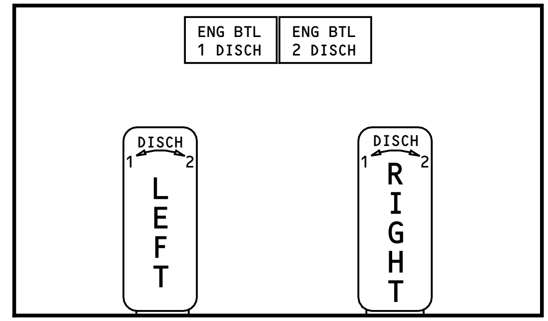
If the engine continues to turn (windmill) with the valve in the OFF position, the EDP may be damaged. You must do an inspection of the EDP filter module.



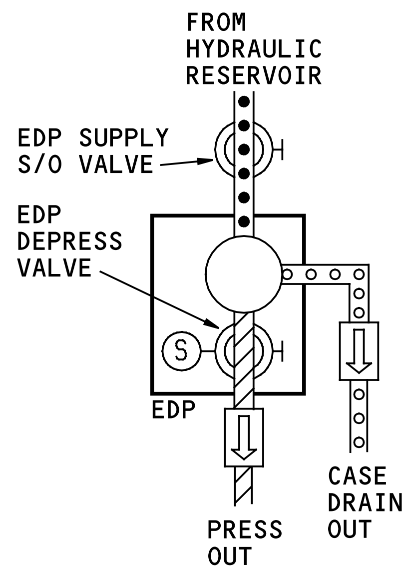
ENGINE AFT STRUT FAIRING



EDP SUPPLY SHUTOFF VALVE



ENGINE FIRE SWITCHES (P8)



29-10-00-009 Rev 6 10/21/96

MAIN HYDRAULIC SYSTEMS - ENGINE DRIVEN PUMP - SUPPLY SHUTOFF VALVE

MAIN HYDRAULIC SYSTEMS - ALTERNATING CURRENT MOTOR PUMP

Purpose

The ACMPs are the primary pumps in the center hydraulic system and the demand pumps in the left and right hydraulic systems.

Physical Description

The ACMP has an electric motor that mechanically connects to a hydraulic pump. The motor operates with three-phase, 400 Hz, 115/200v ac power. The pump is a nine piston variable-displacement hydraulic pump.

Case drain flow cools the electric motor and cools and lubricates the pump.

A ripple damper smooths the pump pressure output.

The ACMPs are rated at 6 gpm at 2850 psi.

All ACMPs are the same and weigh 27 pounds (12.3 Kg).

Location

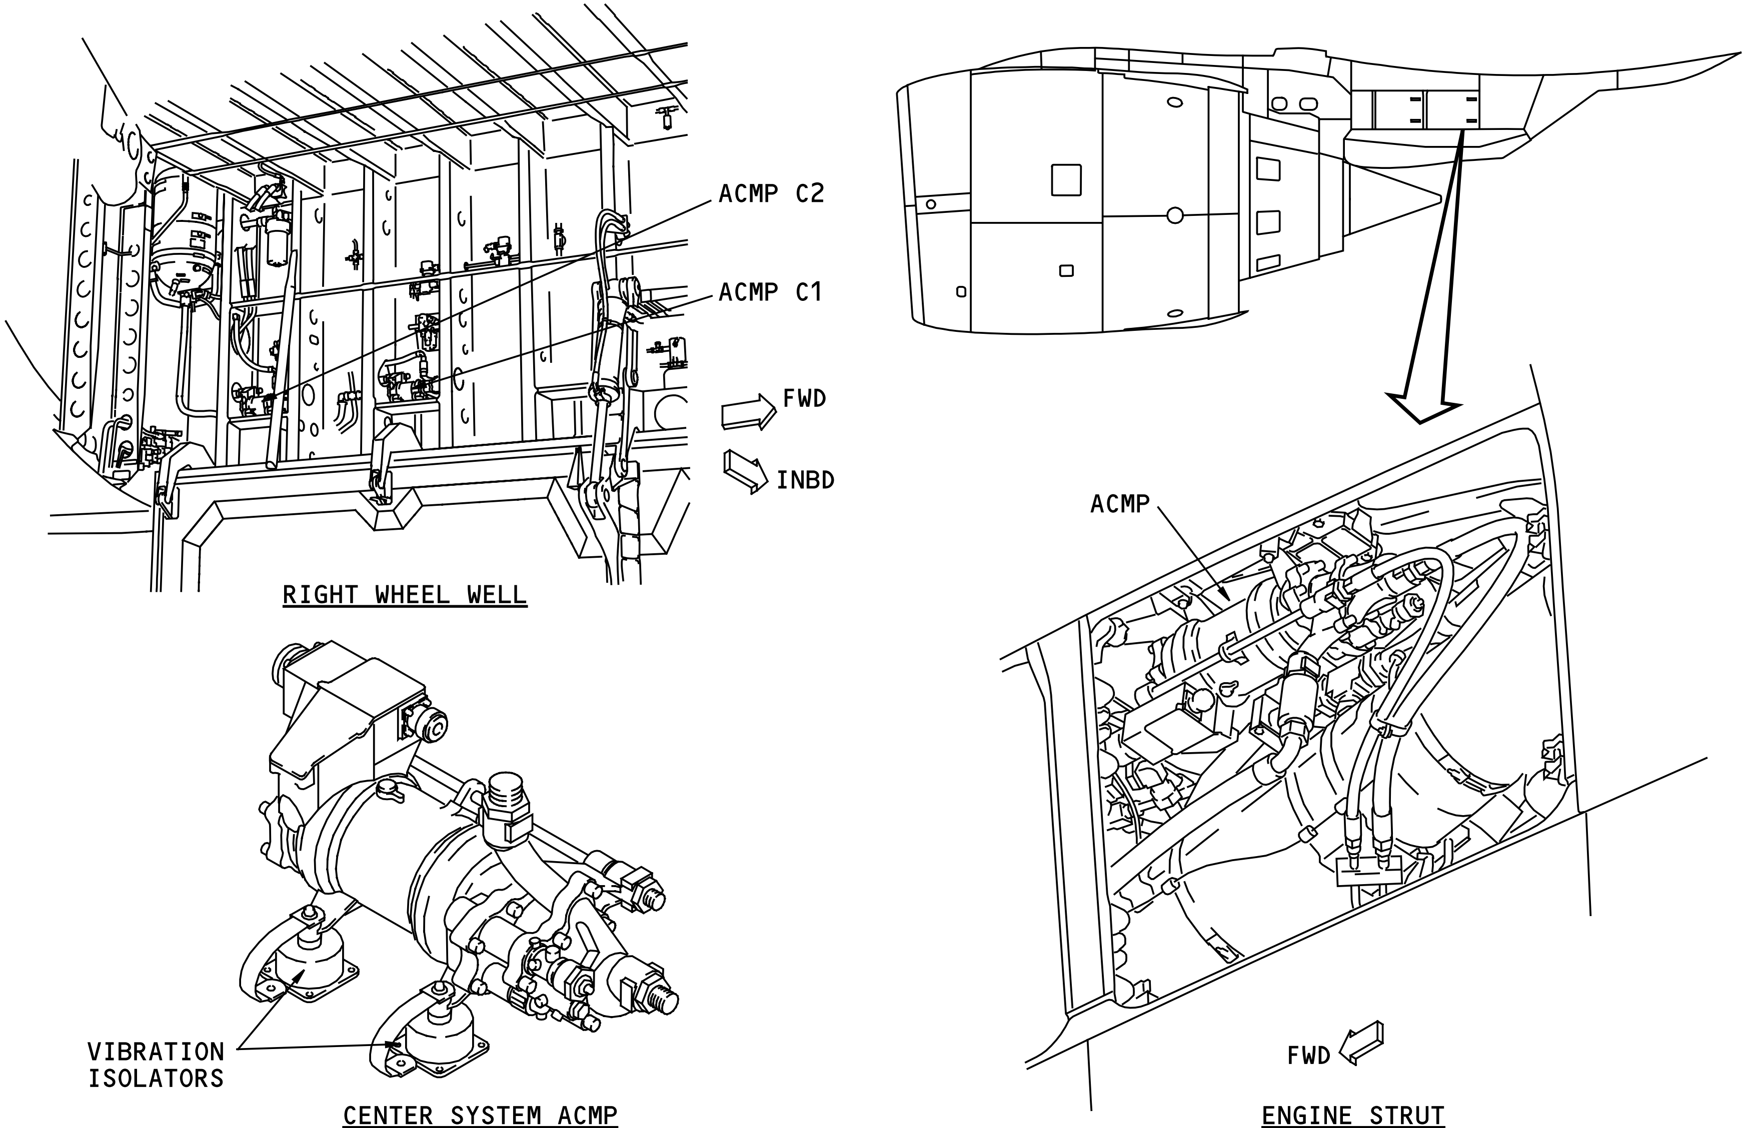
The ACMPs for the left and right hydraulic systems are in the engine struts aft of the reservoirs.

The center system ACMPs are on the keel beam in the right wheel well.

Training Information Point

The center system ACMPs attach to airplane structure through four vibration isolators.

The left and right ACMPs attach to a mounting bracket (not shown) before installation.



MAIN HYDRAULIC SYSTEMS - ALTERNATING CURRENT MOTOR PUMP

MAIN HYDRAULIC SYSTEMS - ADP ASSEMBLY - INTRODUCTION

Purpose

Two air driven pump (ADP) pumps are the demand pumps for the center hydraulic system.

General Description

Each ADP pump is part of an ADP assembly. The ADP assembly also has an air drive unit (ADU). The ADU contains these components:

- Turbine gearbox assembly (TGA)
- Modulating shutoff valve (MSOV)
- Air drive unit (ADU) heater.

A mount truss assembly attaches each ADP assembly to the airplane structure. The mount truss assembly for ADP assembly C1 is not the same as the one for ADP assembly C2.

The ADP assemblies use airplane pneumatic power to operate. An inlet duct supplies air pressure to each ADU. The MSOVs let air flow to the turbine of the TGAs. The gearbox of TGAs reduces the turbine speed and operates the pump. ADU heaters are on the ADUs to prevent ice formation. The pumps connect directly to the TGAs. The airflow from the TGAs exits the airplane through two exhaust ducts and two exhaust vents directly aft of the ADP assemblies.

The two TGAs have the same components. The turbine housing of ADP assembly C1 is different than the turbine housing for ADP assembly C2 to permit the exhaust ducts to be near each other.

Two ADP logic speed control units (LSCU), one for each ADP assembly, control the pump operation. The LSCUs supply speed control and overspeed protection to the TGAs. The LSCUs are circuit card assemblies and are LRUs.

A wiring harness for each ADP assembly connects the LSCU to the MSOV and the TGA.

The ADP pumps are the same as the engine driven pumps.

The ADP pump is rated at 53 gpm at 4315 rpm. A reserve mode permits the pump to supply 63 gpm at 5160 rpm. The pumps are LRUs.

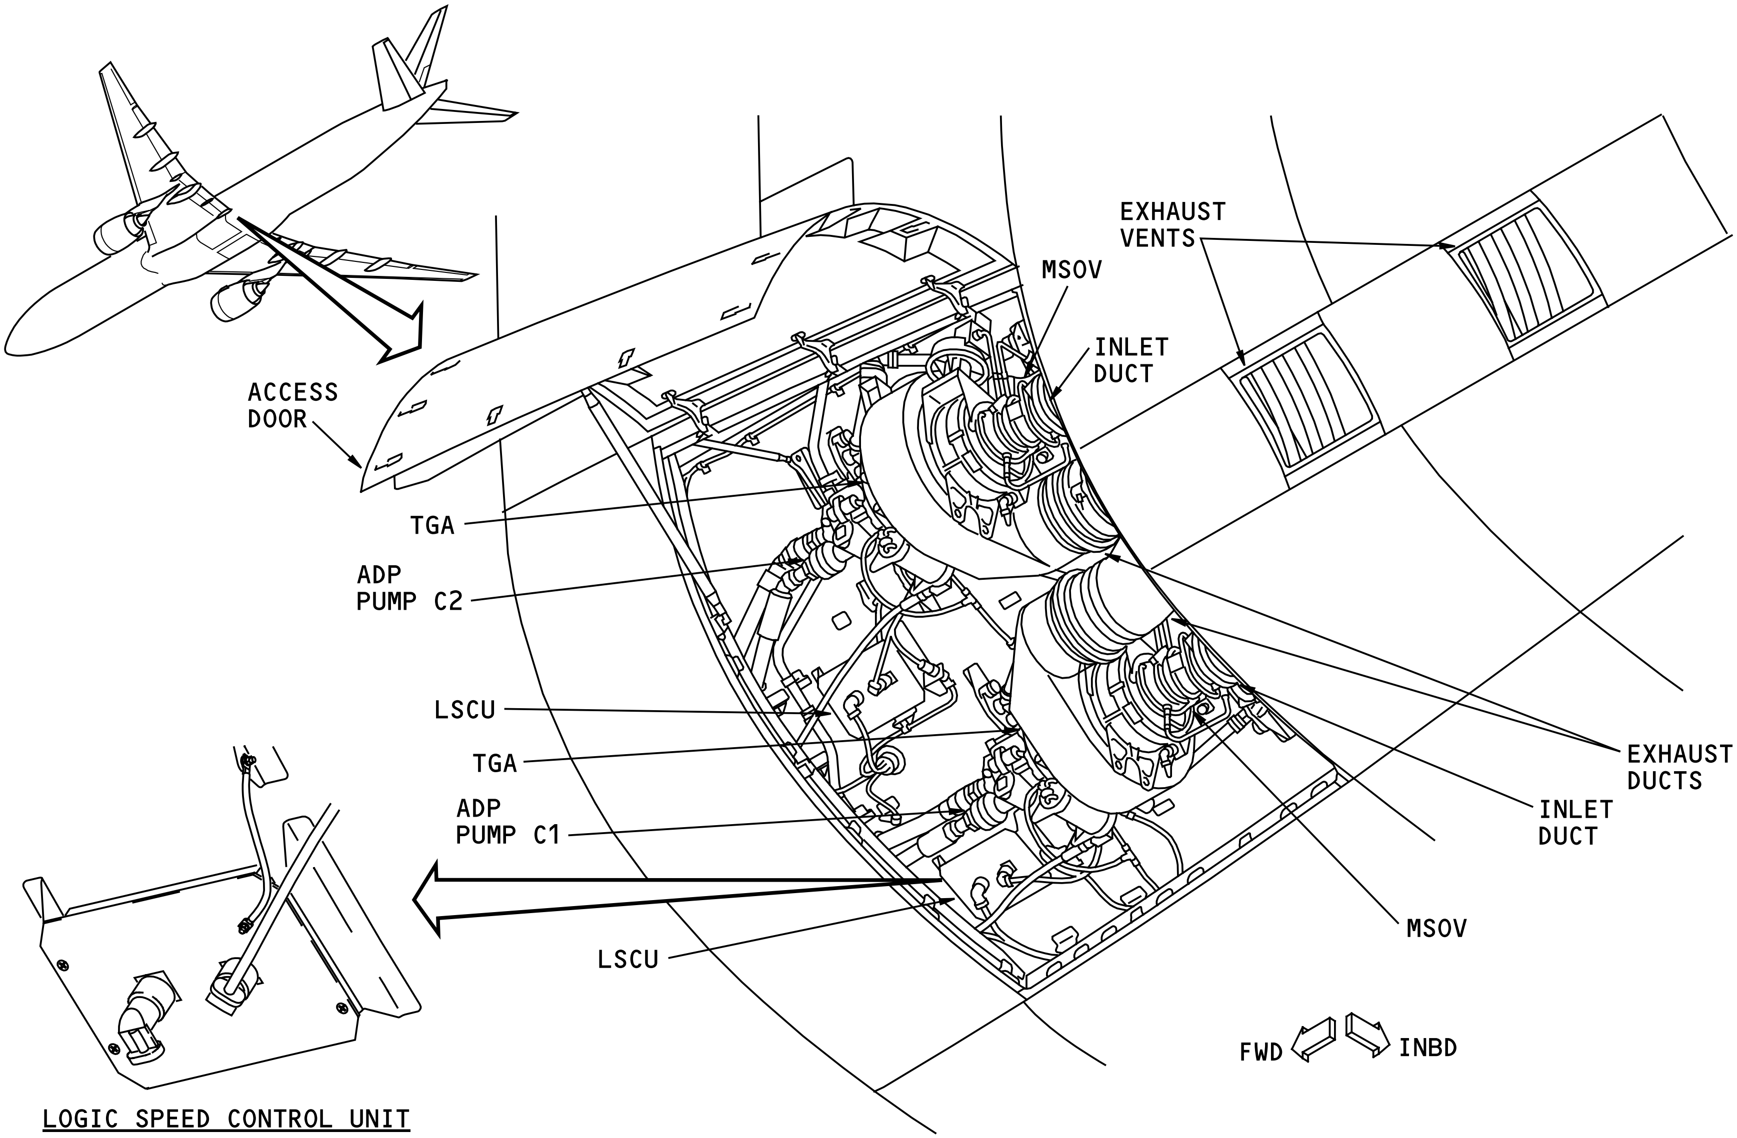
Location

The two ADP assemblies are in the left wing-to-body fairing behind the left wheel well. The LSCUs are also in this compartment.

Training Information Point

The EDPs and the ADP pumps are interchangeable. When the pump operates as an ADP pump, the depressurization solenoid does not operate.

CAUTION: MAKE SURE THE ADP ACCESS DOOR IS FULLY OPEN OR FULLY CLOSED WHEN OPERATING THE TRAILING EDGE FLAPS.



MAIN HYDRAULIC SYSTEMS - ADP ASSEMBLY - INTRODUCTION

MAIN HYDRAULIC SYSTEMS - ADP ASSEMBLY- AIR DRIVE UNIT

General

Each ADU has these components:

- Modulating shutoff valve (MSOV)
- Turbine gearbox assembly (TGA)
- ADU heater (not shown).

Modulating Shutoff Valve

The MSOV is a pneumatically-operated butterfly valve that controls airflow to the TGA. A pneumatic actuator moves the butterfly valve.

The MSOV normally operates as a two position valve, either full open or full closed. When the MSOV is open, it supplies the airflow to the turbine.

The MSOV pneumatic actuator modulates the butterfly valve position during secondary speed control.

A position indicator on the MSOV shows the position of the butterfly valve.

The MSOV attaches to the TGA with a V-band clamp. The MSOV also attaches with a V-band clamp to the inlet isolator. The inlet isolator decreases the vibration and noise from the ADP assembly. The inlet duct attaches to the inlet isolator with a V-band clamp.

Turbine Gearbox Assembly

Pneumatic power goes through the MSOV to the TGA.

The turbine in the TGA turns the gearbox. The gearbox has a planetary gearset to reduce turbine speed to operate the ADP pump.

A pneumatic actuator moves the variable inlet guide vanes (VIGVs) in the TGA assembly. The VIGVs open and close to control the airflow to the turbine. During primary speed control, the VIGVs control the turbine speed.

A position indicator shows the VIGV position.

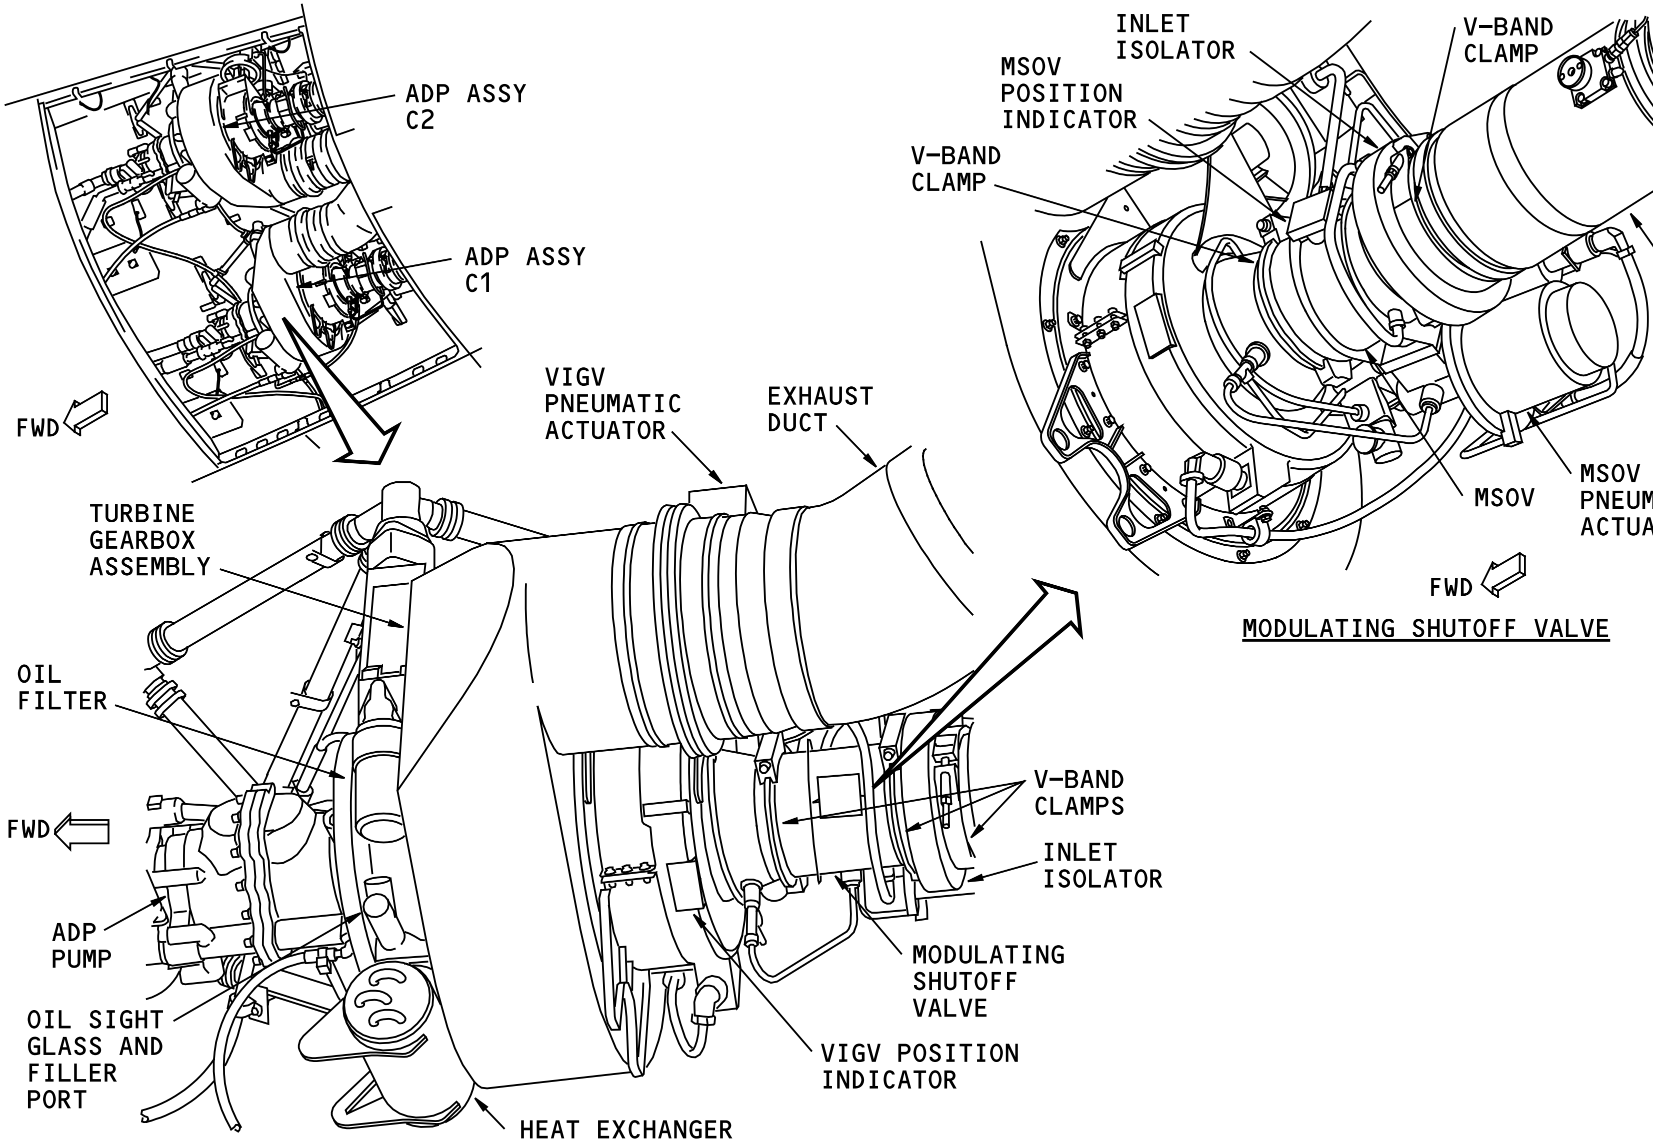
A TGA lubrication system cools and lubricates the TGA gears, bearings, and seals. An oil filter cleans the TGA oil. The oil filter has a differential pressure indicator to show the condition of the filter.

The heat exchanger on the TGA uses case drain fluid from the ADP pump to cool the TGA oil.

There is an oil sight glass and filler port on the front of the TGA.

ADU Heater

The ADU heater keeps the temperature of parts of the MSOV and the TGA higher than freezing. This prevents ADU ice formation. The ADU heater is on the ADU and is an LRU.



MAIN HYDRAULIC SYSTEMS - ADP ASSEMBLY- AIR DRIVE UNIT

THIS PAGE INTENTIONALLY LEFT BLANK

MAIN HYDRAULIC SYSTEMS - ADP ASSEMBLY - FUNCTIONAL DESCRIPTION

General

The ADP assembly gets pressurized air from the airplane pneumatic system.

Air flows through the modulating shutoff valve (MSOV) to the turbine gearbox assembly (TGA). The TGA turns the ADP hydraulic pump. The LSCU supplies primary speed control and overspeed protection.

The MSOV has these components:

- Butterfly valve
- Dual coil solenoid (auto and continuous run coils)
- Pneumatic actuator.

The TGA has these components:

- Variable inlet guide vanes (VIGVs)
- Unison ring
- Pneumatic actuator
- Electro-pneumatic servo-valve
- LVDT
- Turbine wheel
- Gearbox
- Monopole speed sensor (2)
- Pneumatic speed sensor
- Primary reserve solenoid
- Secondary speed control fluidic circuit.

Normal Operation

The signal to operate the ADP assembly comes from the HYDIM cards when the selector is in the AUTO position or from the ADP selector when the selector is in the ON position. These signals go to the LSCU.

The LSCU energizes either the auto run or continuous run coil in the MSOV. This permits air to go to the MSOV pneumatic actuator.

The actuator opens the butterfly valve and air goes through the open VIGVs to turn the turbine.

Speed Control

The ADP assembly has primary and secondary speed control circuits.

The LSCU contains the primary speed control. A monopole speed sensor on the gearbox sends ADP speed signals to the LSCU. The primary speed control circuits control the pneumatic actuator for the VIGVs. The actuator moves the VIGVs through the unison ring. This keeps the turbine within 2.5 percent of the normal operating speed. Normal turbine speed is approximately 32,000 RPM. Normal pump speed is 4315 RPM.

An LVDT supplies actuator position feedback to the LSCU.

The secondary speed control controls the position of the MSOV butterfly valve. The pneumatic speed sensor on the TGA sends a pulsed pneumatic signal in proportion to turbine speed. This signal goes to the secondary speed control fluidic circuit. This pneumatic circuit controls the MSOV pneumatic actuator.

The secondary speed control tries to keep the pump speed approximately 700 RPM higher than the primary speed control. When the system operates on the primary speed control, the secondary speed control gets an underspeed input and keeps the MSOV fully open.

If the primary speed control fails and the speed starts to increase, the MSOV starts to close to keep the pump speed at approximately 5000 RPM.

Reserve Mode

A reserve mode lets the turbine turn at a higher speed to operate the pump at 5160 RPM. This increases pump output for autoslat operation when only one ADP can operate. The HYDIM card commands reserve mode operation for 8 seconds.

For reserve mode operation, the LSCU resets the primary speed control circuit to operate the turbine at the higher RPM. The primary speed control uses the monopole speed sensor input to control the VIGVs. To operate at this higher speed, the secondary speed control must be stopped. The LSCU sends a signal to energize the solenoid in the primary reserve solenoid valve. The valve closes and blocks the pulsed pneumatic signal from the pneumatic speed sensor. Without a speed input, the secondary speed control fluidic circuit does not operate and the butterfly valve in the MSOV fully opens.

Overspeed Protection

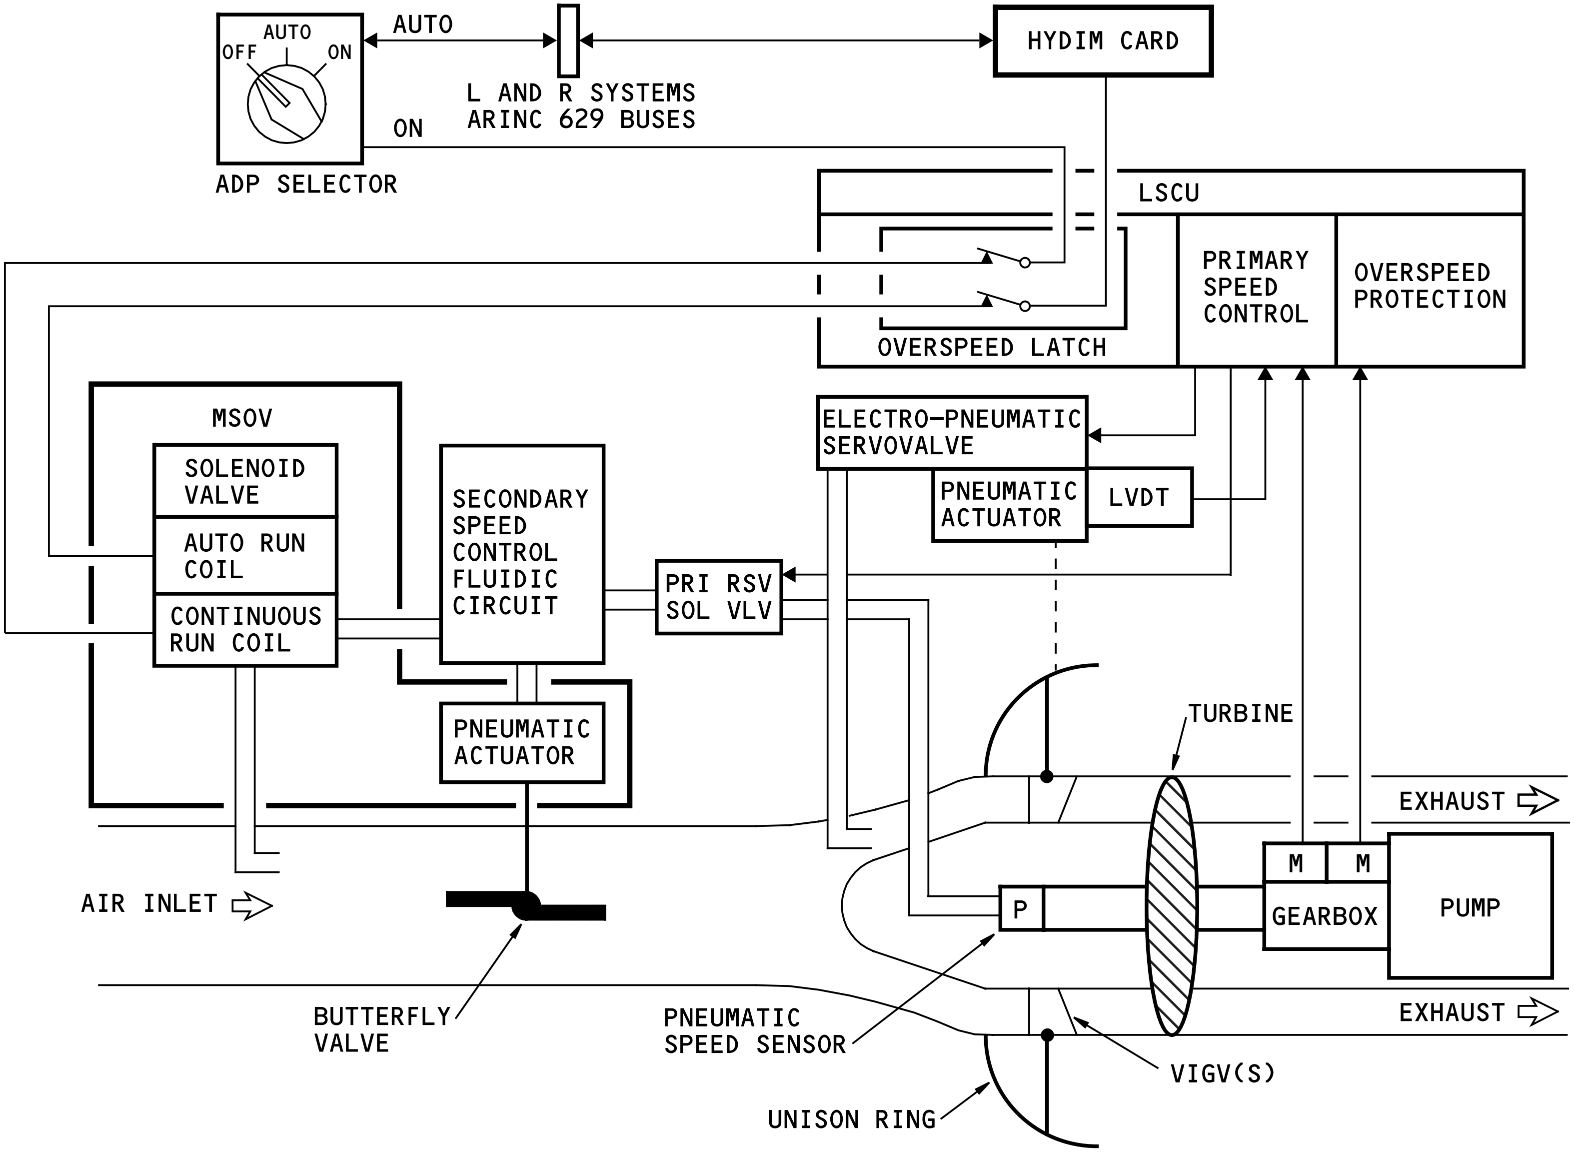
Overspeed protection keeps the ADP assembly from turning too fast.

A second monopole speed sensor on the gearbox supplies a speed signal to the LSCU. If the pump speed is more than 6590 RPM, the LSCU opens the control circuits through the overspeed latch. This removes the power from the solenoid in the MSOV and closes the butterfly valve.

Training Information Point

A containment ring protects the airplane from a turbine failure.

The overspeed shutdown system has a latching function that keeps the ADP off until it is reset by a MAT test.



MAIN HYDRAULIC SYSTEMS - ADP ASSEMBLY - FUNCTIONAL DESCRIPTION

29-10-00-013 Rev 4 10/18/96

MAIN HYDRAULIC SYSTEMS - ADU HEATERS

Purpose

The air drive unit (ADU) heaters keep the speed control components of the ADU warm to prevent icing. This increases the ADP reliability after being cold-soaked. The ADU is made of the turbine gearbox assembly (TGA) and the modulating shutoff valve (MSOV).

Physical Description

Each ADU has an electric heater assembly. Each heater assembly has four heater elements. The heater elements warm these parts of the ADU:

- MSOV pneumatic actuator
- VIGV electro-pneumatic servo valve
- Secondary speed control assembly
- MSOV solenoid.

The four heater elements are wired in series.

Location

You get access to the ADUs through the ADP access door. The ADU heaters are on the aft part of the ADP assemblies.

Indications

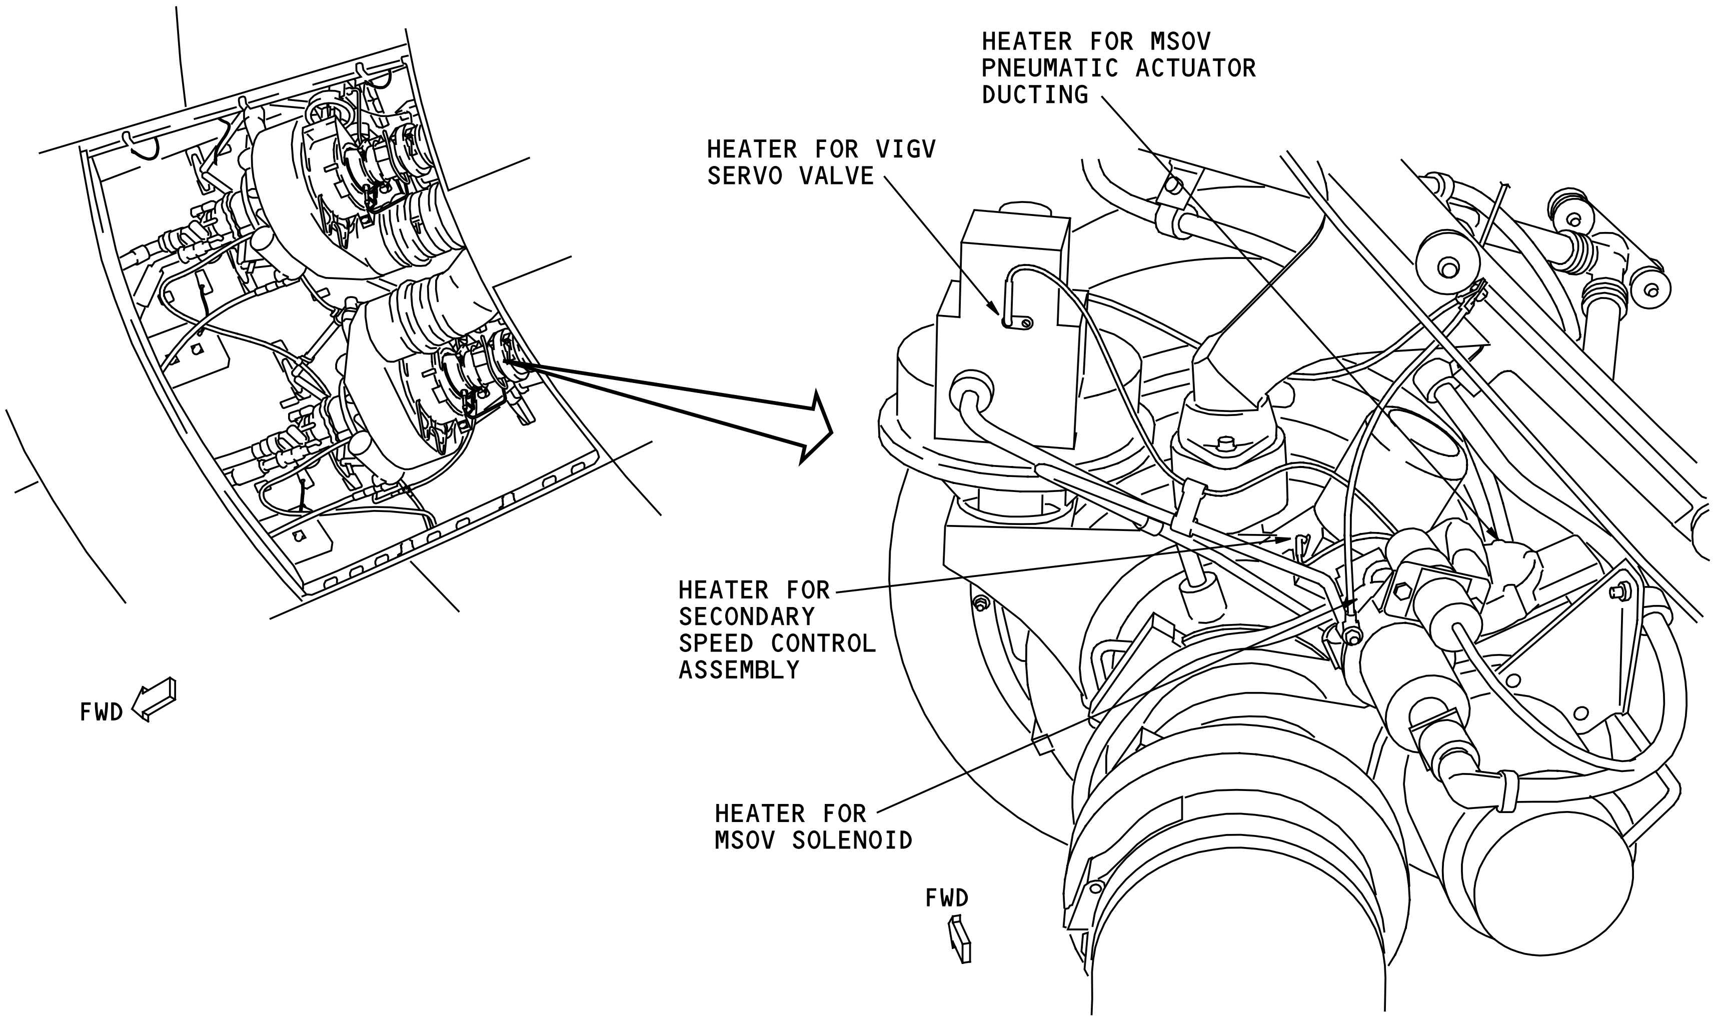
There is no indication that the ADU heaters are on.

The AIMS shows the status message HYD PUMP DEM C1 or HYD PUMP DEM C2 if there is a failure in an ADU heater element.

Training Information Point

Each ADU heater assembly is an LRU.

You can do a test of the two ADU heaters with the HEATERS operational test. You can also do a test of each of the heaters with the ADP C1 or ADP C2 operational tests.



ADP ASSEMBLY - LOOKING FORWARD

29-10-00-028 Rev 0

MAIN HYDRAULIC SYSTEMS - ADU HEATERS

MAIN HYDRAULIC SYSTEMS - ADU HEATERS - FUNCTIONAL DESCRIPTION

General

The air drive unit (ADU) heaters operate automatically to keep the temperature of the ADU speed control components higher than freezing. This prevents icing in the ADU.

The HYDIM CL card controls the heaters for both ADUs. The P210 right power management panel supplies the electrical power to operate the heaters.

Functional Description

The HYDIM CL card sends a signal to the ELMS to operate the ADU heaters for any of these conditions:

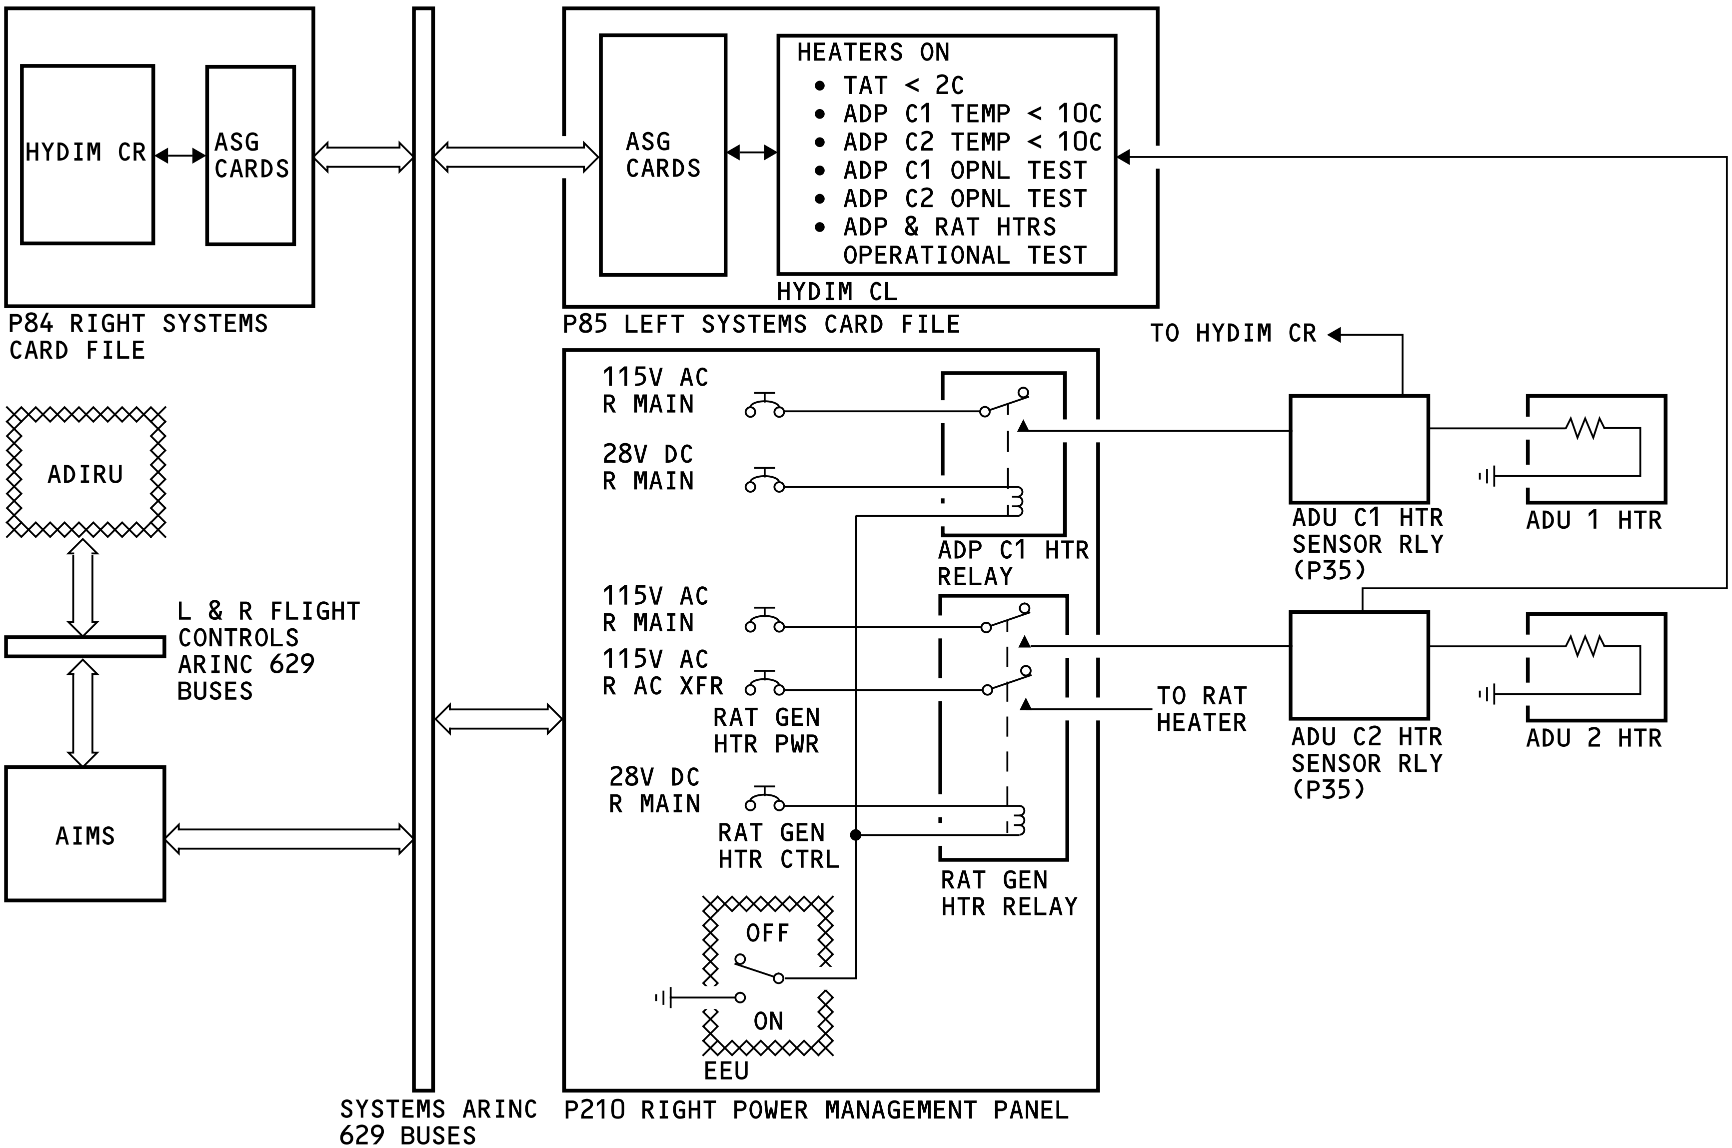
- Total air temperature is less than 2C (ADIRU input through the AIMS)
- ADP C1 case drain temperature is less than 10C
- ADP C2 case drain temperature is less than 10C
- ADP C1 operational test (MAT test)
- ADP C2 operational test (MAT test)
- Heaters operational test (MAT test).

The ON signal goes to the ELMS electronics unit (EEU) in the P210 right power management panel. The EEU energizes heater relays to supply power to the ADU heaters and also to the RAT heater.

The heaters go off 30 minutes after the total air temperature goes above 2C and both ADP case drain temperatures are more than 10C. The heaters also go off 5 seconds after a RAT deployment.

ADU heater sensor relays send the ADU heater on/off condition to the HYDIM cards. The HYDIM cards use this to monitor for correct heater operation.

The ADU heater elements connect in series. A failure of a single element causes the failure of all the elements in the assembly.



MAIN HYDRAULIC SYSTEMS – ADU HEATERS – FUNCTIONAL DESCRIPTION

29-10-00-027 Rev 3 08/07/96

MAIN HYDRAULIC SYSTEMS - AC MOTOR PUMP (ACMP) PRESSURE AND CASE DRAIN FILTER MODULE

Purpose

The ACMP pressure and case drain filter module removes particles from the hydraulic fluid after the fluid leaves the ACMP. Transducers on or near the filter module send pressure and temperature signals to the HYDIM cards.

Physical Description

Each of the four ACMPs has its own pressure and case drain filter module. All of these modules are interchangeable.

Each filter module has these components:

- Case drain filter
- Pressure filter
- Automatic filter bowl removal shutoff valve (not shown) (2)
- Differential pressure indicators (red pop-up indicator)(2)
- Check valves (2)
- Pressure transducer (center system filter modules)
- Temperature transducer.

Location

The filter module for the left hydraulic system is in the left aft engine strut fairing. The filter module for the right hydraulic system is in the right engine strut. You get access to these filter modules through the aft strut fairing doors on the right side of each engine strut.

The filter modules for the two center system ACMPs are in the right wheel well on the keelbeam.

Functional Description

Hydraulic pressure and case drain flow goes through the filters in the filter modules.

A temperature transducer in the case drain line sends temperature signals to the HYDIM cards. A pressure transducer in the pressure line sends pressure signals to the HYDIM cards.

Check valves prevent hydraulic backflow through the filter module.

Training Information Point

You can not clean the filters and use them again.

The red differential pressure indicator extends to show a clogged filter. Replace the filter and manually reset the indicator.

MAIN HYDRAULIC SYSTEMS - ADP AND EDP PRESSURE AND CASE DRAIN FILTER MODULES

Purpose

The pressure and case drain filter modules for the EDPs and the ADPs remove the particles from the hydraulic fluid after the fluid leaves the pumps. A pressure relief valve in the modules supplies system protection if pressure gets too high.

Transducers on the filter modules send pressure and temperature signals to the HYDIM cards.

Physical Description

The ADP filter module and the EDP filter module are interchangeable.

Each module has these components:

- Pressure filter
- Case drain filter
- Automatic filter bowl removal shutoff valve (2)
- Differential pressure indicator (red pop-up indicator) (2)
- Check valve (3)
- Pressure transducer
- Temperature transducer
- Relief valve.

The EDP filter modules and the filter module for ADP C2 also have a ground service disconnect.

Location

The filter module for the left system EDP is in the left engine aft strut fairing. The filter module for the right system EDP is in the right engine aft strut fairing.

You get access to these filter modules through the aft strut fairing doors on the left and right sides of each engine strut.

The ADP filter modules are in the left wing to body fairing forward of the ADPs. An access panel permits you to get access to the filter modules.

Functional Description

Hydraulic pressure and case drain flow go through the filters in the filter modules.

A temperature transducer in the case drain line sends temperature signals to the HYDIM cards. A pressure transducer in the pressure line sends pressure signals to the HYDIM cards.

The check valves prevent hydraulic backflow. The check valve in the pressure line also isolates the pressure transducer from system pressure.

The relief valve starts to open at 3400 psid to protect the system from over-pressure. Full flow occurs at 4100 psi. The relief valve sends the hydraulic fluid back to the reservoir through the system return lines.

MAIN HYDRAULIC SYSTEMS - ADP AND EDP PRESSURE AND CASE DRAIN FILTER MODULES

Training Information Point

You can not clean the filters and use them again.

The red differential pressure indicator extends to show a clogged filter. Replace the filter and manually reset the indicator.

You can pressurize the hydraulic system with a ground pressure source through the ground service disconnect.

MAIN HYDRAULIC SYSTEMS - RETURN FILTER MODULES

Purpose

The return filter modules remove particles from the hydraulic fluid before the fluid returns to the reservoirs.

Physical Description

The left and right return filter modules are the same. The center return filter module is different than the left and right modules.

Each module has these components:

- Replaceable filter
- Automatic filter bowl removal shutoff valve
- Differential pressure indicator (red pop-up indicator)
- Check valve (2) (left and right modules only)
- Bypass relief valve with indicator
- Ground service disconnect (Left and right modules only).

Location

The return filter module for the left system is in the left engine aft strut fairing. The return filter module for the right system is in the right engine aft strut fairing. You get access to these filter modules through the aft strut fairing doors on the right side of each engine strut.

The center system return filter module is on the keelbeam in the right wheel well.

Functional Description

Return fluid from airplane hydraulic systems and the heat exchangers goes through the return filter modules before it goes into the hydraulic reservoirs again.

The left and right return filter modules have a negative pressure loop.

The negative pressure loop and the check valves permit backwards flow of fluid from the reservoir to the system without backflush of the filter.

The center hydraulic system has a negative pressure loop outside the return filter module.

Bypass relief valves open to permit continued hydraulic flow if the filter clogs. The relief valve starts to open at approximately 165 psid.

Training Information Point

You can not clean the filters and use them again.

The red differential pressure indicator extends if the pressure difference across the filter is 48 - 62 psi. This shows a clogged filter. Replace the filter and manually reset the indicator.

MAIN HYDRAULIC SYSTEMS - RETURN FILTER MODULES

A red indicator on the bypass relief valve extends to show the bypass valve is open.

You use the ground service disconnect as the return port during ground hydraulic pressure cart operation. The center system ground service disconnect is not on the return filter module. A hydraulic tube connects the disconnect to the module.

MAIN HYDRAULIC SYSTEMS - RETURN FILTER MODULES

MAIN HYDRAULIC SYSTEMS - HEAT EXCHANGERS

Purpose

A heat exchanger in each hydraulic system cools the case drain hydraulic fluid from the EDPs and the ACMPs. This extends the service life of the fluid and the hydraulic pumps.

Physical Description

The heat exchangers use aluminum finned tubes to transfer heat from the fluid to the fuel. Fuel in the left and right main tanks cools the hydraulic fluid.

Location

The heat exchanger for the left hydraulic system is in the left main fuel tank between ribs 10 and 11.

The heat exchangers for the right hydraulic system is in the right main fuel tank between ribs 10 and 11.

The heat exchangers for the center hydraulic system is in the right main fuel tank between ribs 11 and 12.

Training Information Point

NOTE: The heat exchangers in the hydraulic system use the fuel to remove heat from the hydraulic system.

Approximately 709 gallons (2688 liters) (4794 pounds) (2175 kg) of fuel in the left and right main fuel tanks is necessary to cool the case drain flow from the left and right hydraulic systems.

Approximately 1080 gallons (4095 liters) (7303 pounds) (3313 kg) of fuel in the right main tank is necessary to cool the case drain flow from the center hydraulic system.

You can operate the hydraulic pumps if fuel goes below these levels if you obey the CAUTION below.

CAUTION: DO NOT OPERATE THE HYDRAULIC PUMPS AFTER THE HYDRAULIC TEMPERATURE INDICATION IS MORE THAN 100C (212F) OR AFTER THE PUMP FAULT LIGHT COMES ON. IF YOU CONTINUE TO OPERATE THE PUMPS, THE HYDRAULIC FLUID CAN BECOME TOO HOT.

MAIN HYDRAULIC SYSTEMS - HEAT EXCHANGERS

MAIN HYDRAULIC SYSTEMS - RESERVE ISOLATION VALVE AND NOSE GEAR ISOLATION VALVE

General

The reserve isolation valve and the nose gear isolation valve supply engine burst protection to the center hydraulic system to prevent complete loss of center system fluid.

These valves permit a reserve brake and nose gear steering operation if there is a leak in the PFCS or MLG hydraulic lines. The valves also permit PFCS and MLG operation if there is a leak in the NLG or LE slat hydraulic lines.

The reserve isolation valve and the nose gear isolation valve are part of the center hydraulic isolation system (CHIS).

The reserve isolation valve isolates brakes and steering from the center hydraulic system.

The nose gear isolation valve controls ACMP C1 output to nose gear steering.

Physical Description

The reserve isolation valve and nose gear isolation valves are the same.

They are 28v dc motor-powered, two-position valves. They each have a position indication lever which permits you to manually operate the valve.

Location

Both valves are in the right wheel well on the keelbeam.

MAIN HYDRAULIC SYSTEMS - RESERVE ISOLATION VALVE AND NOSE GEAR ISOLATION VALVE

MAIN HYDRAULIC SYSTEMS - CENTER SYSTEM RETURN MANIFOLD AND PRESSURE RELIEF VALVE

Return Manifold

The center system return manifold collects the return hydraulic flows from center hydraulic system components.

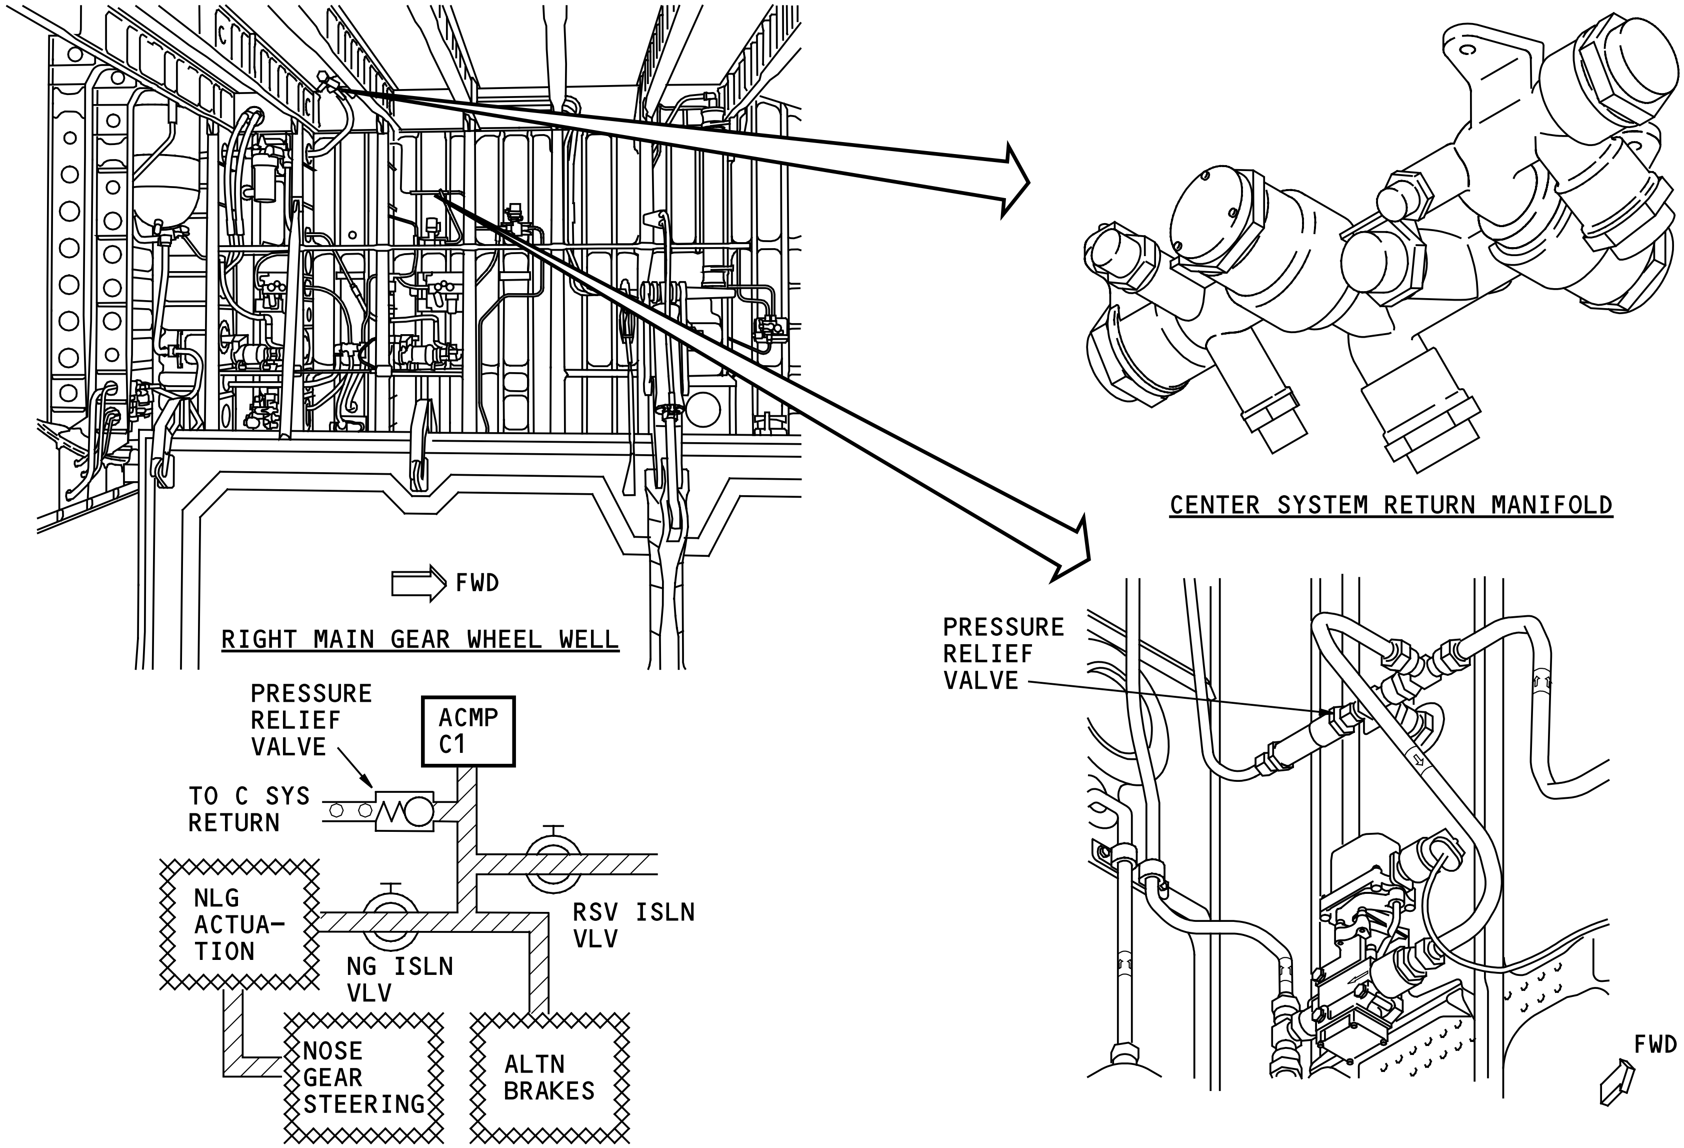
The manifold is on the ceiling in the right wheel well near the keelbeam.

Pressure Relief Valve

A center system pressure relief valve supplies overpressure protection to the part of the center system that may be isolated by the CHIS.

The relief valve is on the keelbeam in the right wheel well.

The relief valve starts to open at a pressure of 3700 - 3900 psid.



MAIN HYDRAULIC SYSTEMS - CENTER SYSTEM RETURN MANIFOLD AND PRESSURE RELIEF VALVE

MAIN HYDRAULIC SYSTEMS - HYDRAULIC ACCUMULATORS

Purpose

Four hydraulic accumulators absorb pressure changes caused by tail flight control PCU operation. This increases the life of the hydraulic system components.

Physical Description

The right and center hydraulic systems each have a single hydraulic accumulator in the pressure lines to the tail flight controls. The left hydraulic system uses two accumulators that connect in the tail flight control pressure lines. All accumulators are the same and have a volume of 50 cubic inches.

The accumulators have a hydraulic fluid side and a gas side. A fluid port connects the fluid side to the hydraulic line. You service the gas side of the accumulator with nitrogen.

Location

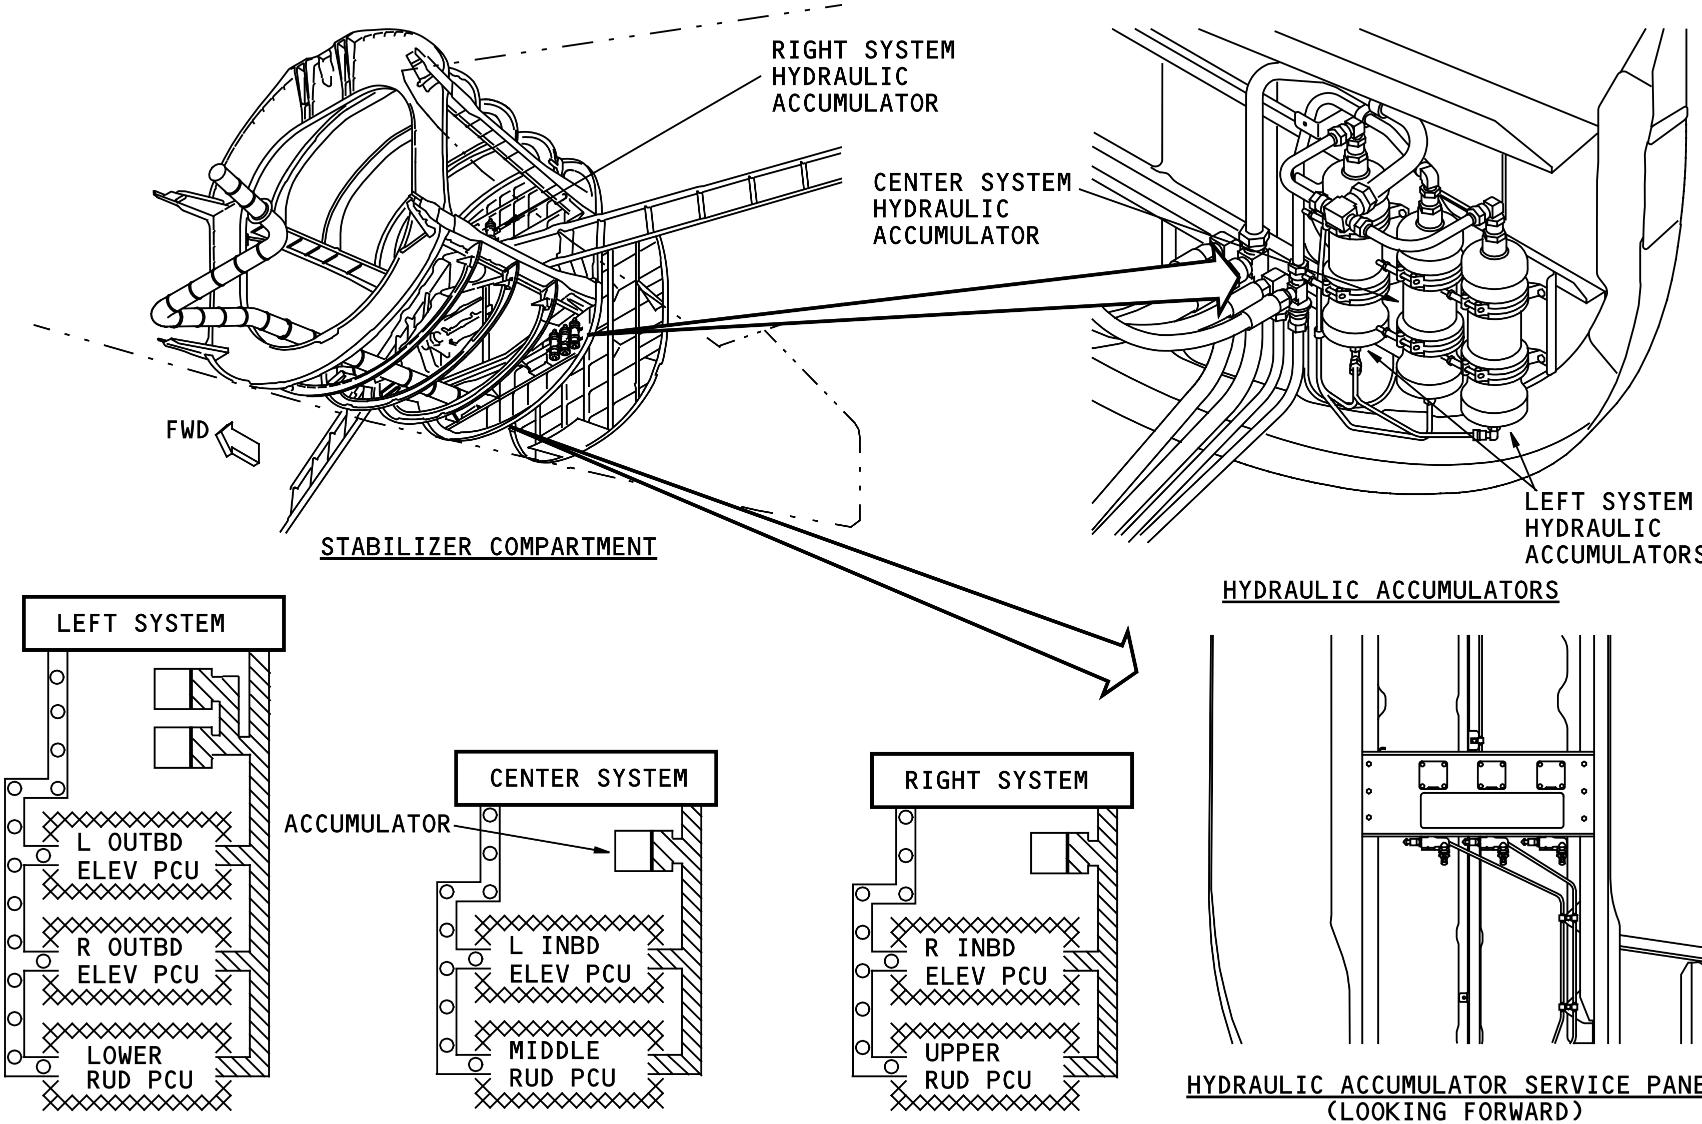
The hydraulic accumulators are on the forward side of the aft bulkhead of the stabilizer compartment. The hydraulic accumulator service panel is on the aft side of the stabilizer compartment aft bulkhead.

Training Information Point

You get access to the hydraulic accumulator service panel through the controls bay access door which is immediately forward of the APU compartment. A decal on the service panel shows servicing instructions.

WARNING: YOU MUST PREVENT ALL POSSIBLE OPERATION OF THE HORIZONTAL STABILIZER WHEN YOU WORK ON OR NEAR IT. THE HORIZONTAL STABILIZER MOVES QUICKLY AND WITH FORCE. IF THE STABILIZER MOVES WHEN PERSONS ARE IN THE TORSION BOX COMPARTMENT OR NEAR THE STABILIZER, IT CAN CAUSE INJURY TO THEM.

WARNING: DO NOT ENTER THE COMPARTMENT WITHOUT FORCED AIR VENTILATION WHEN YOU SERVICE THE HYDRAULIC ACCUMULATORS. DO NOT RELEASE NITROGEN INTO THE COMPARTMENT WHEN SERVICING THE ACCUMULATORS. NITROGEN WILL DISPLACE AIR AND REDUCE THE OXYGEN LEVEL IN THE COMPARTMENT. LACK OF OXYGEN CAN RESULT IN UNCONSCIOUSNESS OR DEATH. A SECOND MECHANIC WHO CAN OBSERVE THE WORK MUST BE LOCATED OUTSIDE THE COMPARTMENT WHEN NITROGEN IS BEING SERVICED IN A CLOSED COMPARTMENT.



29-10-00-026 Rev 2 03/07/96

MAIN HYDRAULIC SYSTEMS - HYDRAULIC ACCUMULATORS

MAIN HYDRAULIC SYSTEMS - FUNCTIONAL DESCRIPTION - ENGINE DRIVEN PUMP

General

The EDPs operate when the related engine turns.

The EDPs can be depressurized by the EDP switch or by the engine fire switch.

HYDIM L monitors the operation of the left EDP. HYDIM R monitors the operation of the right EDP.

EDP Switch Operation

When the EDP switch is in the ON position, the depressurization solenoid valve is not energized. This permits the pressure output of the EDP to go to the hydraulic system.

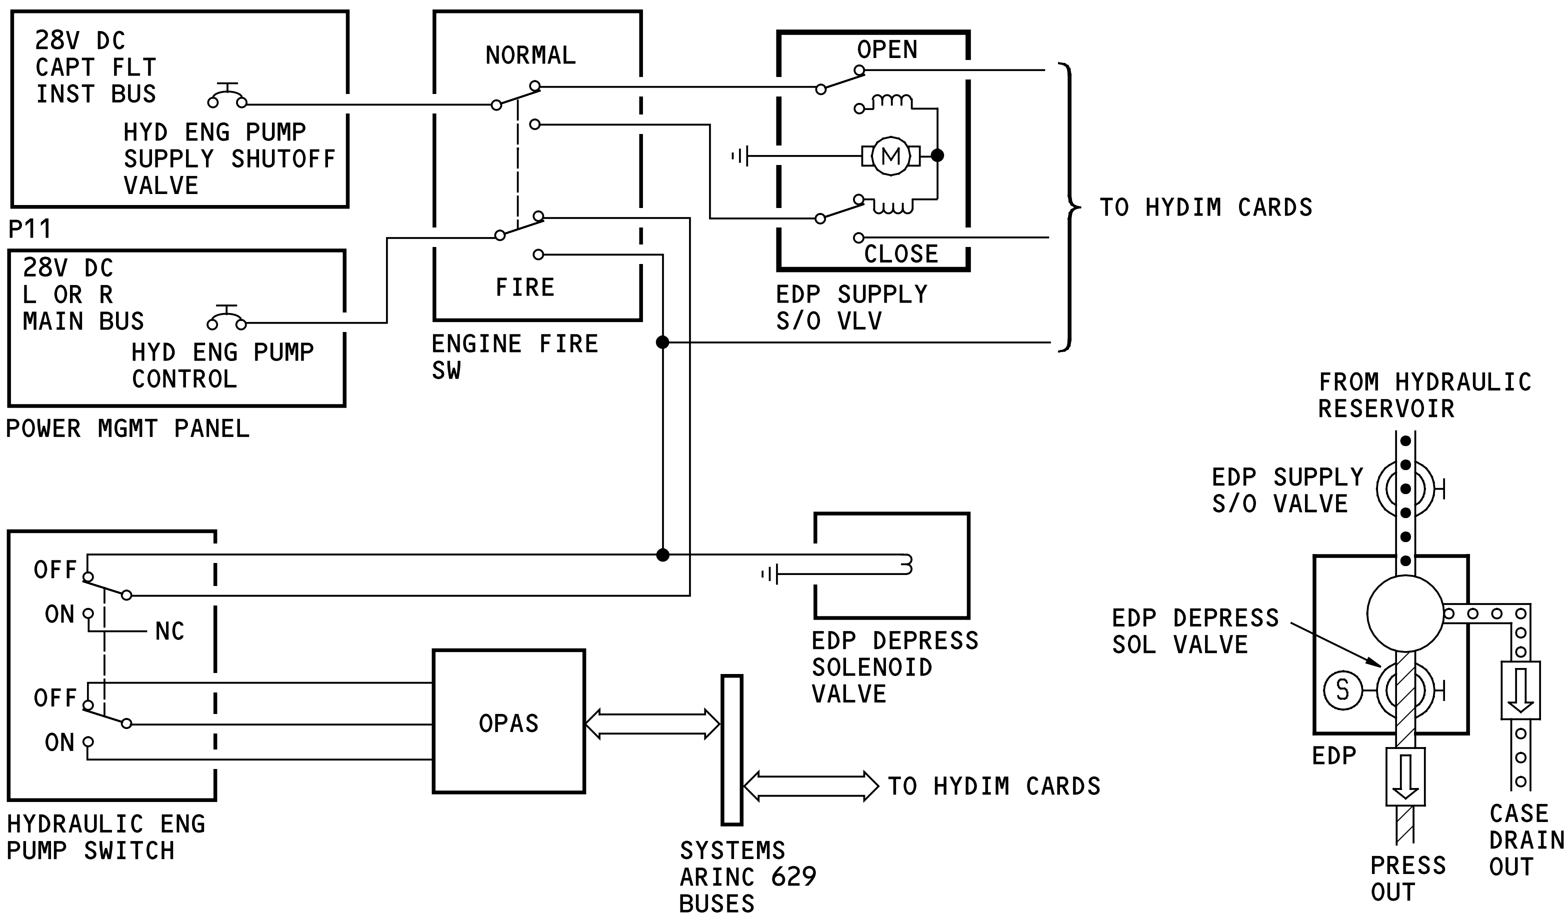
When the EDP switch is in the OFF position, power from the left 28v dc main bus (left engine) or the right 28v dc main bus (right engine) goes to EDP solenoid valve. This closes the valve to stop the pump output and depressurize the pump.

The case drain flow continues when the switch is in the OFF position.

Supply Shutoff Valve Operation

When you pull the engine fire switch, the supply shutoff valve moves to the CLOSED position. This stops the supply of hydraulic fluid to the EDP. The engine fire switch also energizes the depressurization solenoid valve to remove pressure from the EDP. There is no case drain flow in this condition.

The supply shutoff valve moves to the OPEN position when you move the engine fire switch to the stowed position.



29-10-00-020 Rev 0

MAIN HYDRAULIC SYSTEMS - FUNCTIONAL DESCRIPTION - ENGINE DRIVEN PUMP

THIS PAGE INTENTIONALLY LEFT BLANK

MAIN HYDRAULIC SYSTEMS - FUNCTIONAL DESCRIPTION - AIR DRIVEN PUMP

General

The pneumatic system supplies the pressurized air to operate the air driven pumps.

The ADP selectors are on the hydraulic/RAT panel.

The ADP selectors send pump control signals to the overhead panel ARINC 629 system (OPAS). The OPAS sends these control signals through the systems ARINC 629 buses to the HYDIM cards. The HYDIM cards use these signals to operate the pumps in the demand mode. HYDIM CR controls ADP C1 in the demand mode. HYDIM CL controls ADP C2 in the demand mode. The control circuits on each card are equivalent.

The HYDIM cards do not control the ADPs in the continuous run (ON) mode. The ADP selectors send electrical signals directly to the LSCU to operate the pump in the continuous run mode.

An LSCU for each ADP gets the input signals to open the MSOV to permit the ADP to operate.

Demand Mode

With the two ADP selectors in AUTO, the HYDIM cards start one or both of the ADPs when the center hydraulic system must supply a large hydraulic flow rate.

The HYDIM cards get the ADP selector input signal from the ARINC 629 systems buses. The HYDIM cards must also get a hardwire electrical signal from the AUTO position of the ADP selector.

The HYDIM cards prevent or stop demand mode ADP operation during main engine start on the ground.

One ADP operates during any of these conditions:

- Landing gear extension
- Flap/slat operation
- Low pressure (less than 2400 psi) in the center system or in both center system ACMPs
- Touchdown (airspeed more than 80 kts and altitude less than 30 feet)
- Air mode, flaps and slats not up, and one ADP selected OFF or does not operate (in case of autoslat demand)
- Failure of the ADU heaters on both ADPs and groundspeed is more than 80 knots (turns on ADP C1).

When an ADP turns on for low pressure, the pump turns off 15 seconds after the pressure goes above 2700 psi.

The ADP turns on during the touchdown conditions to supply pressure to operate the auto speedbrakes. The pump turns off 5 seconds after the speedbrake lever moves to the stowed position.

The HYDIM cards CL and CR make a selection of one of the two ADPs during single pump operation. They use the other ADP the next time they turn on a single pump. This equalizes the pump wear.

MAIN HYDRAULIC SYSTEMS - FUNCTIONAL DESCRIPTION - AIR DRIVEN PUMP

Both ADPs operate for these conditions:

- Autoslat operation
- Landing gear retraction
- Takeoff roll (ground mode, airspeed is more than 80 kts, and the flaps are in the takeoff position).

Both ADPs turn on during the takeoff roll to make sure that at least one of them operates if there is an engine loss. This makes sure that there is sufficient hydraulic flow to operate the rudder for the thrust asymmetry compensation function. The ADPs turn off 10 seconds after the airplane takes off.

Reserve Mode

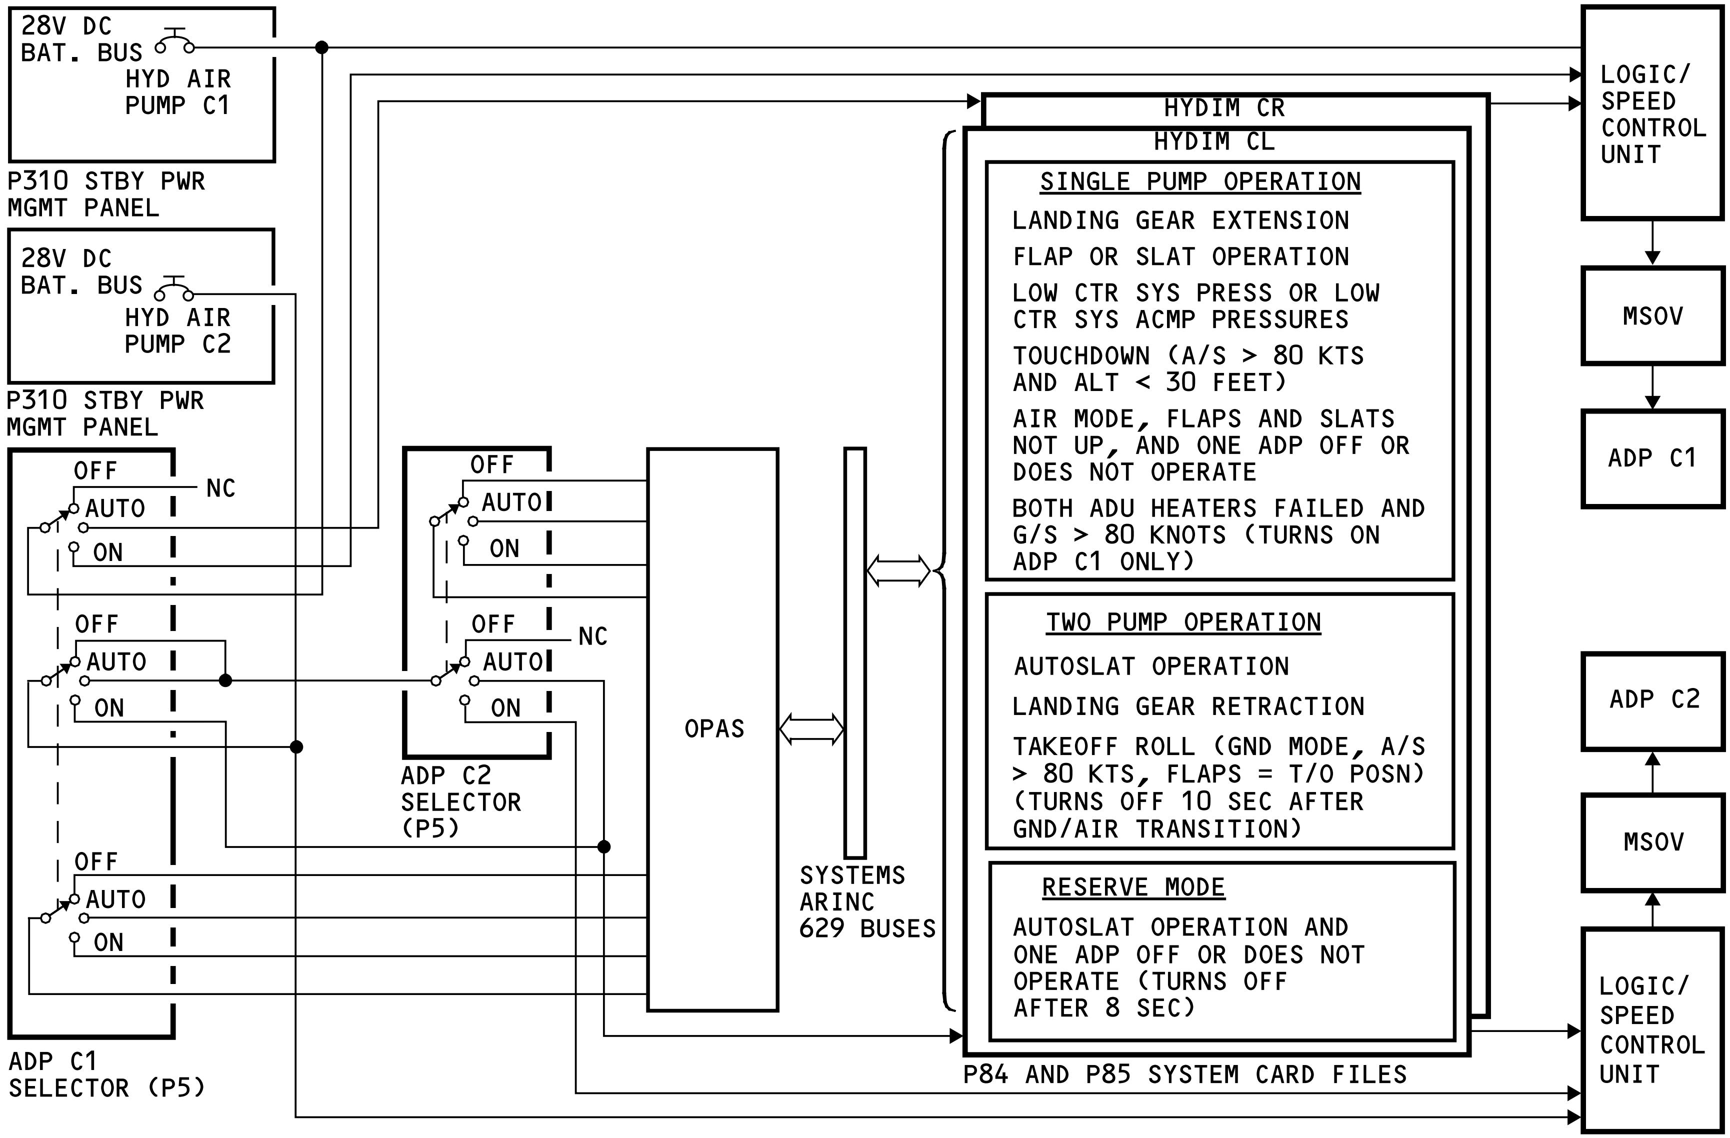
If one of the two ADPs does not operate and there is an autoslat signal, the HYDIM cards will operate the remaining ADP in the reserve mode. This permits the ADP to operate at a higher speed to make sure sufficient hydraulic flow goes to the leading edge slats. The reserve mode turns off after 8 seconds. The reserve mode operates when the selector is in AUTO or ON.

Continuous Operation

An ADP selector in the ON position sends a signal directly to the related LSCU. The LSCU then opens the MSOV to operate the ADP continuously.

Training Information Point

The ADP C1 selector must be in the OFF or AUTO position for ADP C2 to run continuously. If both ADP selectors are in the ON positions, only ADP C1 will operate.



MAIN HYDRAULIC SYSTEMS - FUNCTIONAL DESCRIPTION - AIR DRIVEN PUMP

THIS PAGE INTENTIONALLY LEFT BLANK

MAIN HYDRAULIC SYSTEMS - FUNCTIONAL DESCRIPTION - ALTERNATING CURRENT MOTOR PUMP

General

The control switches and selectors on the hydraulic control panel send pump control signals to the overhead panel ARINC 629 system (OPAS). The OPAS sends these control signals through the left and right systems ARINC 629 buses to the ELMS.

The ELMS contains the logic and electrical relays that controls the ACMPs.

Power management panels and the power panels in the ELMS control electrical power to the ACMPs.

The wiring between the power management panels and the power panels goes through the control switches and selectors. This makes sure that pumps cannot operate when their switch or selector is in the OFF position.

Primary Pump Operation

Signals from the primary pump switches for the center system ACMPs go directly to the ELMS. The HYDIM cards do not control primary pump operation.

Demand Pump Operation

Signals from the demand pump selectors for the left and right system ACMPs go to the HYDIM cards and to the ELMS.

When a demand pump selector is in the ON position, the signal goes directly to the ELMS.

When a demand pump selector is in the AUTO position, HYDIM cards control the pump operation signal to the ELMS.

When the left demand pump switch is in AUTO, the left HYDIM card turns on the left ACMP for any of these conditions:

- Left engine not running
- Touchdown - CAS is more than 60 kts and altitude is less than 30 feet (to prepare for auto speedbrake operation)
- Left EDP pressure less than 2400 psi (pump turns off 15 seconds after EDP pressure is more than 2800 psi).

When the right demand pump switch is in AUTO, the right HYDIM card turns on the right ACMP for any of these conditions:

- Right engine not running
- Altitude is less than 30 feet (prepares for wheel brake and auto speedbrake operation)
- Right EDP pressure less than 2400 psi (pump turns off 15 seconds after EDP pressure is more than 2800 psi).

ELMS Operation

The ELMS electronics unit (EEU) in the power management panel gets the pump control signal from the pump switches or HYDIM cards. The electronics unit then sends a signal to the electrical load control unit

(ELCU) in the power panel. If the switch or selector is in the OFF position, the ELCU does not get the signal. If the selector is in AUTO or ON or if the switch is in ON, the ELCU gets the signal and energizes a relay to supply electrical power to the ACMP.

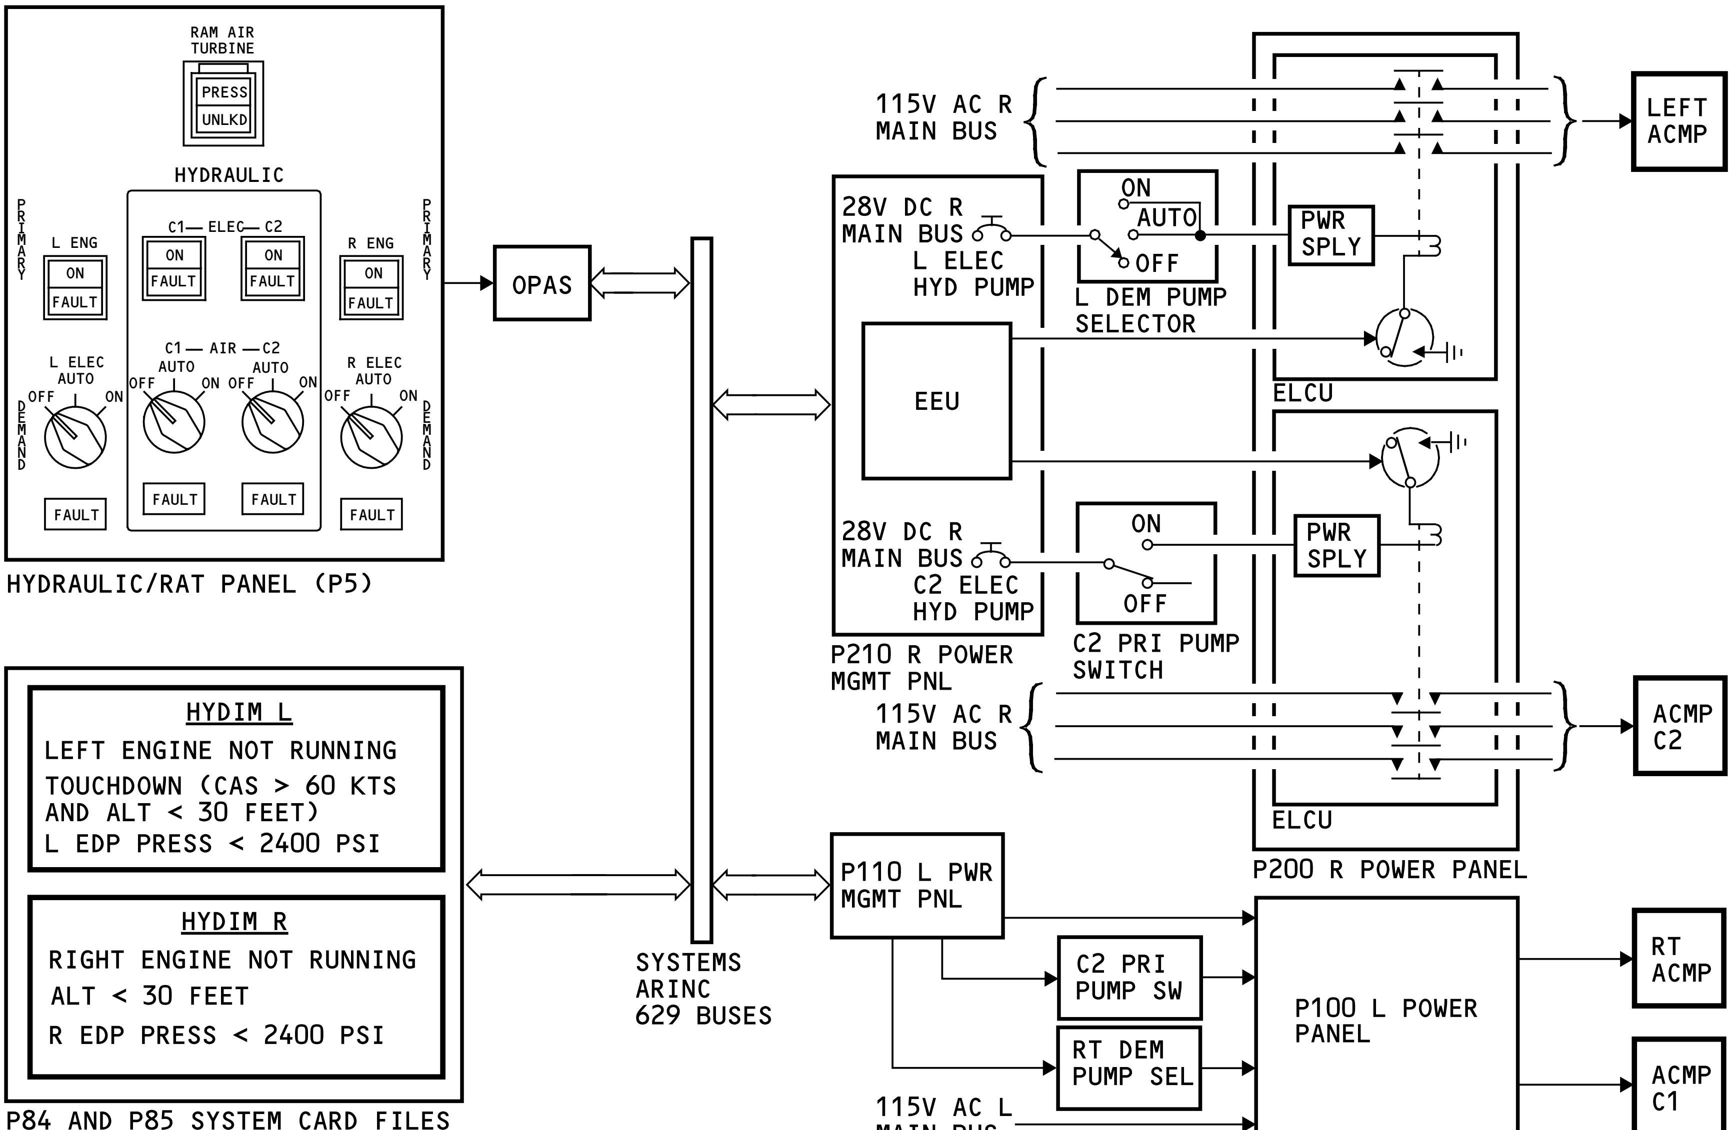
The ELMS uses time delays of approximately 1.125 seconds between ACMP starts to protect the electrical system from overload.

ELMS Load Shed

The ELMS sheds one or two of the ACMPs during some conditions.

On a single 90 kVA ground power source, the ELMS may shed ACMP C2. For this condition, the ELMS also may shed the left ACMP during engine start.

On a single 120 kVA airplane power source, the ELMS may shed ACMP C2 during fuel jettison when all ACMPs are ON.



MAIN HYDRAULIC SYSTEMS - FUNCTIONAL DESCRIPTION - ALTERNATING CURRENT MOTOR PUMP

THIS PAGE INTENTIONALLY LEFT BLANK

MAIN HYDRAULIC SYSTEMS - LEFT AND RIGHT SYSTEMS - FUNCTIONAL DESCRIPTION

General

The left and right hydraulic systems are functionally the same.

The left hydraulic system supplies pressurized hydraulic fluid to operate the left thrust reverser and the PFCS. The right hydraulic system supplies pressurized hydraulic fluid to operate the right thrust reverser, the PFCS, and the normal brake system.

Fluid Supply

The hydraulic system reservoirs contain the hydraulic fluid supply for the hydraulic pumps.

A reservoir pressurization module supplies pressurized air from the pneumatic system to pressurize the reservoir.

The reservoir supplies fluid to the EDP through a standpipe. The ACMP gets fluid from the bottom of the reservoir.

Pressurization

The EDPs are the primary pumps for the left and right hydraulic systems. The EDPs get reservoir fluid through the EDP supply shutoff valves.

The EDPs operates whenever the engines operate. A solenoid valve in each EDP controls the pressurization and depressurization of the pump.

The ACMPs are the demand pumps for the left and right hydraulic systems. The ACMPs normally operate only when there is high hydraulic system demand.

Filtration

Pressure and case drain filter modules clean the pressure flows and the case drain flows of the hydraulic pumps.

A return filter module cleans the return flow of hydraulic fluid from the user systems. The module can be bypassed if the filter clogs.

The heat exchanger cools the hydraulic fluid from ACMP and EDP case drain lines before the fluid goes back to the reservoir.

Hydraulic System Sensors

The hydraulic system sensors send pressure, temperature, and quantity signals to the HYDIM cards.

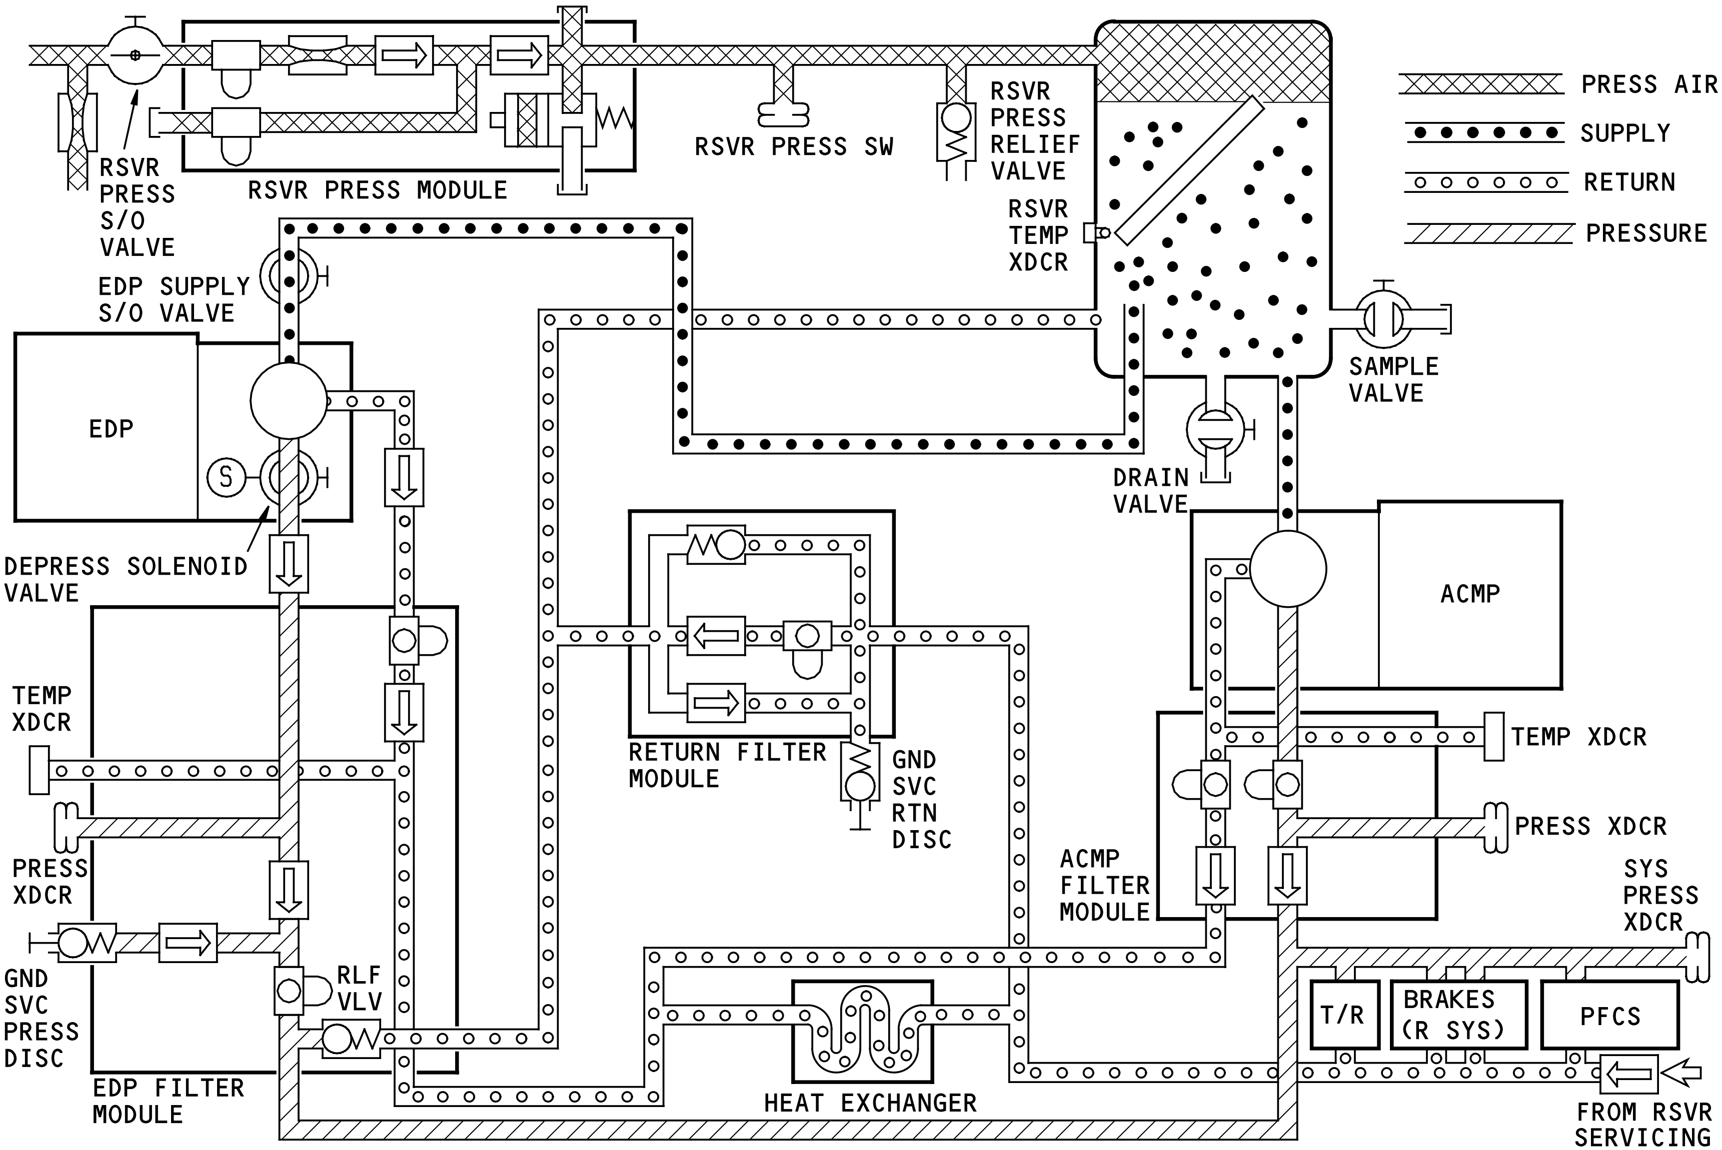
A reservoir quantity transmitter and temperature transducer are on each of the reservoirs. A hydraulic reservoir pressure switch is on the pneumatic line between the reservoir pressurization module and the reservoir.

The ACMP and EDP filter modules each have a pressure transducer to measure pump output pressure. A temperature transducer is in the case drain line of each filter module measures pump case drain fluid temperature.

A system pressure transducer measures hydraulic system pressure.

Pressure Relief

A pressure relief valve on the EDP filter module protects the system against overpressurization.



MAIN HYDRAULIC SYSTEMS - LEFT AND RIGHT SYSTEMS - FUNCTIONAL DESCRIPTION

29-10-00-023 Rev 3

THIS PAGE INTENTIONALLY LEFT BLANK

MAIN HYDRAULIC SYSTEMS - CENTER SYSTEM - FUNCTIONAL DESCRIPTION

General

The center hydraulic system supplies pressurized hydraulic fluid to operate these systems:

- Nose landing gear actuation
- Nose landing gear steering
- Alternate brakes
- Main landing gear actuation
- Main landing gear steering
- Trailing edge flaps
- Leading edge slats
- PFCS.

Fluid Supply

The center system reservoir contains the hydraulic fluid supply for the center system hydraulic pumps.

A reservoir pressurization module supplies pressurized air from the pneumatic system to pressurize the reservoir.

The reservoir supplies fluid to the ADPs, the RAT, and one of the ACMPs through a standpipe. The other ACMP gets fluid from the bottom of the reservoir.

The reservoir also supplies hydraulic fluid to the landing gear alternate extension system.

Pressurization

The ACMPs are the primary pumps in the center hydraulic system and are normally on.

The ADPs are the demand pumps in the center system. They normally operate only when the center system needs more hydraulic flow capacity.

The ram air turbine system supplies an emergency source of hydraulic power to the center hydraulic system flight controls.

Filtration

Filter modules clean the pressure and case drain output of the hydraulic pumps.

A return filter module cleans the return flow of hydraulic fluid from the user systems. The module can be bypassed.

The heat exchanger cools the hydraulic fluid from the ACMP case drains before the fluid goes back to the reservoir. ADP case drain fluid does not go through the heat exchangers.

Hydraulic System Sensors

A reservoir quantity transmitter and temperature transducer are on the reservoir. A hydraulic reservoir pressure switch is on the pneumatic line between the reservoir and the reservoir pressurization module.

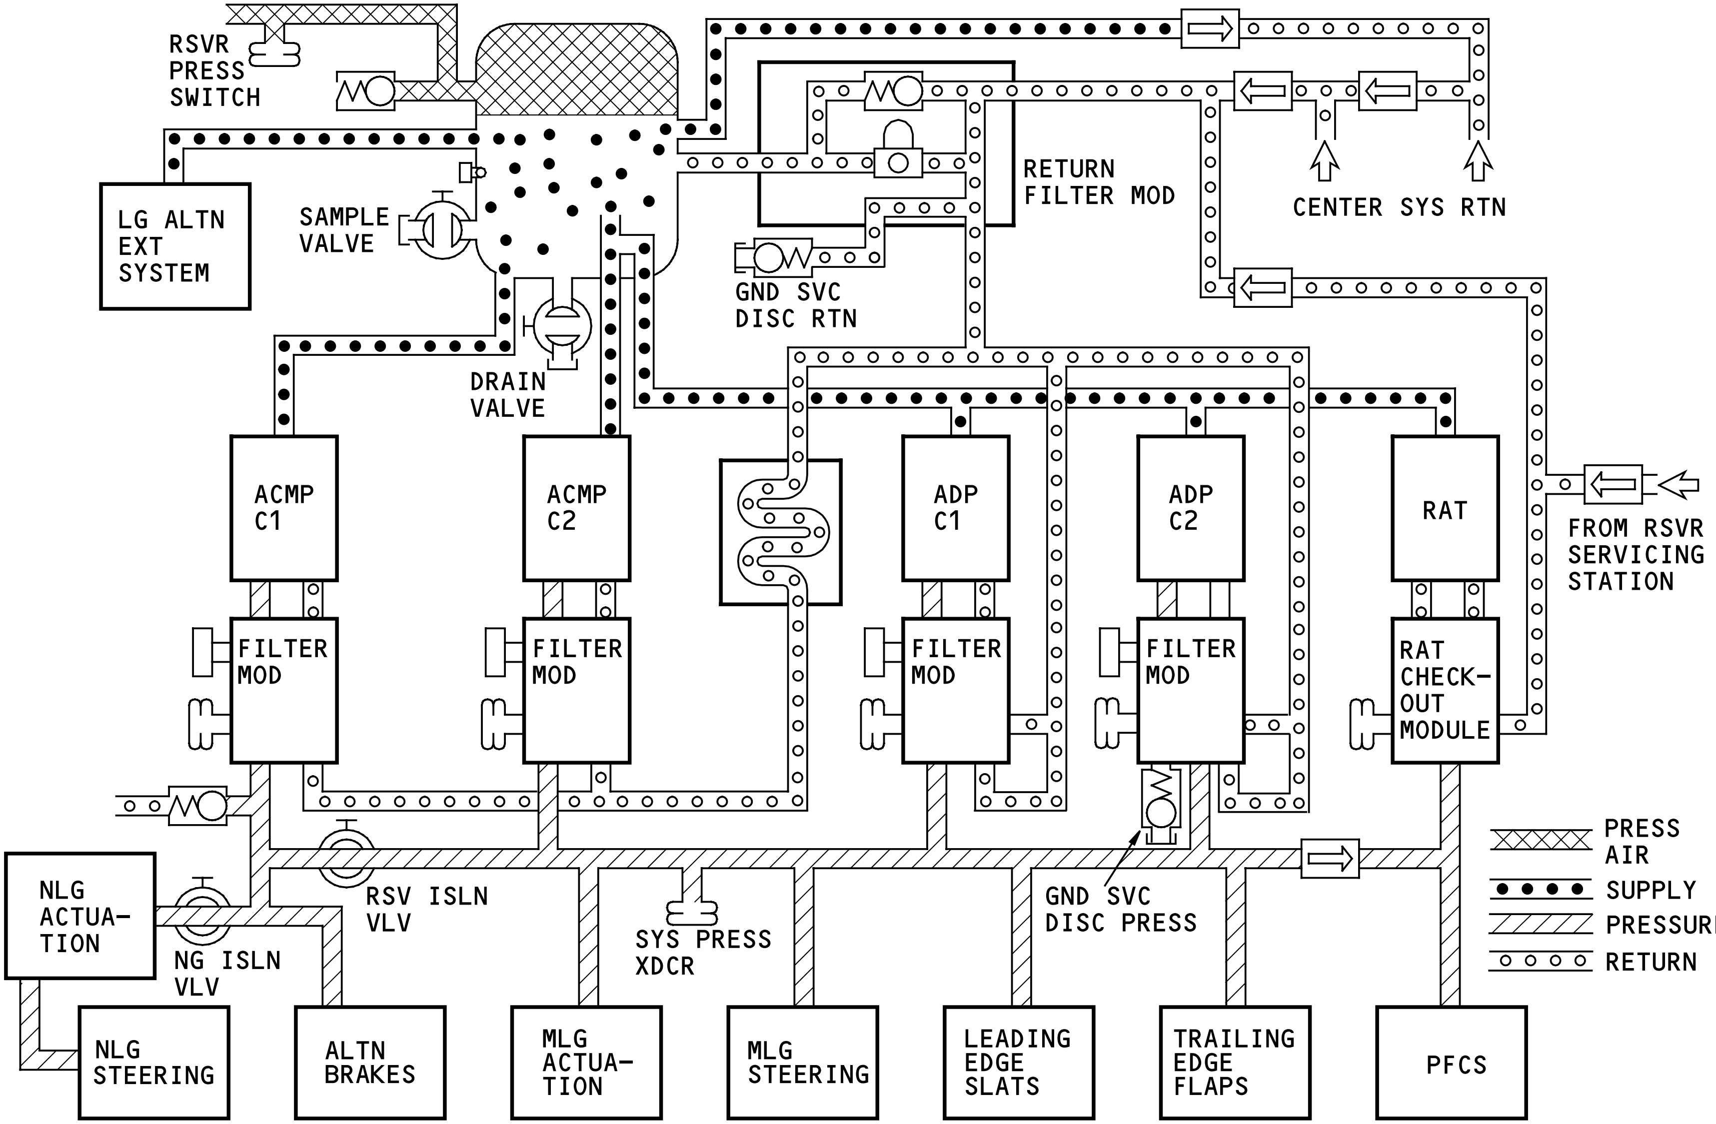
MAIN HYDRAULIC SYSTEMS - CENTER SYSTEM - FUNCTIONAL DESCRIPTION

The ACMP and ADP filter modules each have a pressure transducer to measure pump output pressure. A temperature transducer in each filter module measures pump case drain temperature.

A system pressure transducer measures hydraulic system pressure.

Pressure Relief

Pressure relief valves in each ADP filter module prevent system overpressurization. A pressure relief valve near ACMP C1 supplies overpressure protection for the CHIS.



MAIN HYDRAULIC SYSTEMS - CENTER SYSTEM - FUNCTIONAL DESCRIPTION

29-10-00-024 Rev 2 01/19/95

THIS PAGE INTENTIONALLY LEFT BLANK

MAIN HYDRAULIC SYSTEMS - CENTER HYDRAULIC ISOLATION SYSTEM - FUNCTIONAL DESCRIPTION

General

The center hydraulic isolation system (CHIS) supplies engine burst protection and a reserve brakes and steering function.

The HYDIM CL card, in the left systems card file, automatically controls CHIS operation through relays in the ELMS. The relays control the electric motors in the reserve and nose gear isolation valves.

HYDIM CL also sends a signal to the FSEUs to prevent hydraulic operation of the leading edge slats.

Hydraulic Supply

ACMP C1 gets hydraulic fluid from the bottom of the center system reservoir. All other hydraulic pumps in the center system get fluid through a standpipe in the reservoir. This gives ACMP C1 a 1.2 gallon (4.5 liter) reserve supply of hydraulic fluid.

Isolation

The reserve and nose gear isolation valves are normally open.

Both valves close if the quantity in the center system reservoir is low (less than 0.40) and the airspeed is more than 60 knots for more than one second. The HYDIM CL card also sends a signal to the FSEUs. The FSEUs do not send commands to the leading edge slats primary control valve (PCV) for this condition. This prevents hydraulic operation of the slats.

When CHIS is active, this divides the center hydraulic system into different parts. The NLG actuation and steering, and the leading edge slat hydraulic lines are isolated from center system pressure.

The output of ACMP C1 goes only to the alternate brake system.

The output of the other center hydraulic system pumps goes to the trailing edge flaps, the MLG actuation and steering and the PFCS.

If there is a leak in the NLG actuation and steering or LE slat lines, there is no further loss of hydraulic fluid. The alternate brakes, the trailing edge flaps, the MLG actuation and steering, and the PFCS continue to operate normally.

If there is a leak in the trailing edge flaps, the MLG actuation and steering, or the PFCS lines, the reservoir loses fluid down to the standpipe level (0.00 indication). This causes a loss of these systems. But, the alternate brake system continues to get hydraulic power from ACMP C1.

If there is a leak in the lines between ACMP C1 and the alternate brake system, all center hydraulic system fluid is lost.

Nose Gear Isolation Valve

The HYDIM CL reopens the nose gear isolation valve for any of these conditions:

- Airspeed is less than 60 knots
- Pump pressures for ACMP C2, ADP C1, ADP C2, and the RAT is less than 1200 psi for 30 seconds
- Left and right engine RPM is above idle, left and right EDP pressure is more than 2400 psi, and (the NLG is not up, the NLG doors are not closed, or the landing gear lever is not up) for 30 seconds.

The first condition permits the flight crew to operate the NLG steering when airspeed is less than 60 kts (decreased rudder control authority during taxi).

The second condition permits operation of the NLG actuation and steering if the hydraulic leak is in the part of the center hydraulic system isolated by the reserve isolation valve.

The third condition permits operation of the NLG actuation and steering if there has not been an engine burst and the other hydraulic systems are pressurized. The nose gear isolation valve opens when pressure is necessary at the NLG. If the NLG is not fully retracted or the NLG doors are not closed, the nose gear isolation valve opens to let the NLG complete the retraction. When the landing gear lever is moved to the DOWN position, the nose gear isolation valve opens to let the NLG extend with center system pressure.

CHIS Reset

Both valves open again automatically when the center system quantity is more than 0.70 and airspeed is less than 60 knots for five seconds.

Both valves also reset when the center system quantity is more than 0.70 and both engines and both engine driven pumps operate normally for 30 seconds.

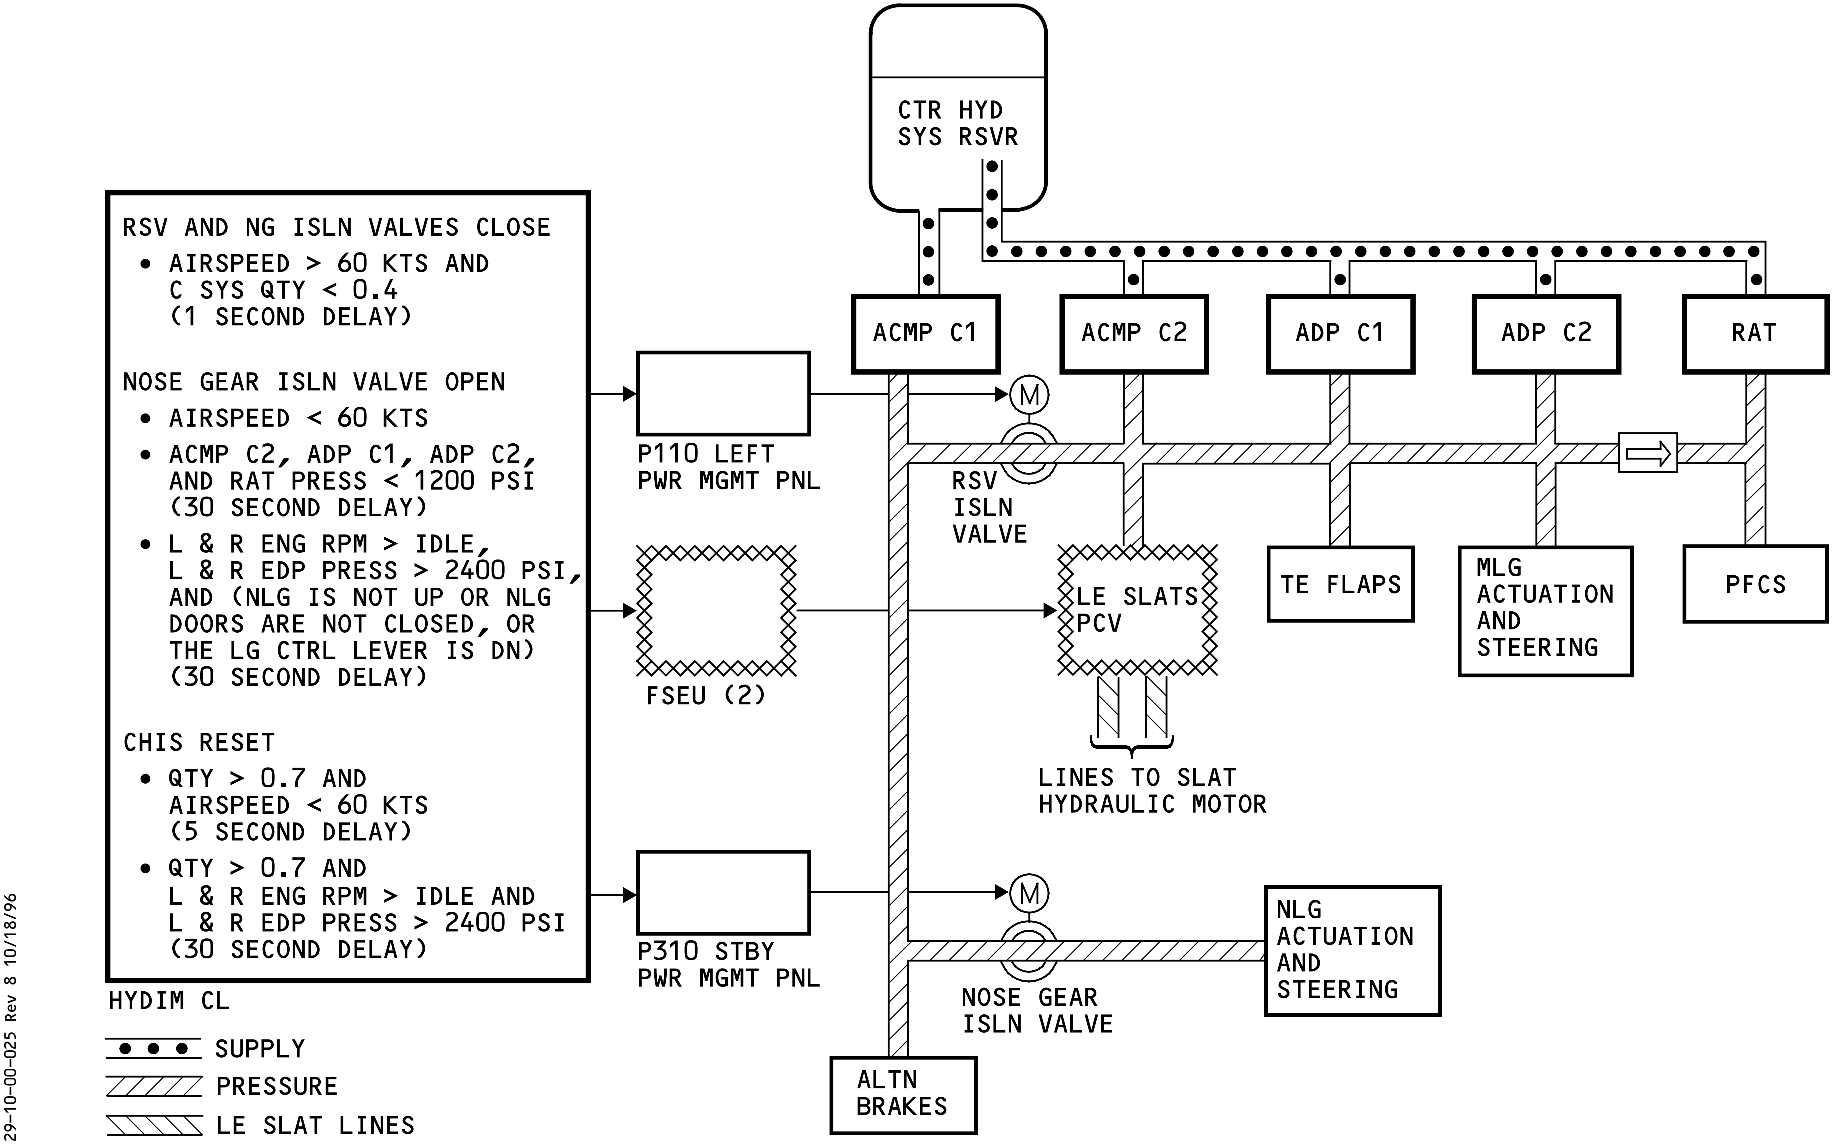
Indications

The positions of the nose gear isolation valve and the reserve isolation valve show on the hydraulic synoptic display and the hydraulic maintenance page.

The RESERVE BRAKES/STRG advisory message tells the flight crew that brakes or steering may not be available. This message shows for any of these conditions:

- The center system is isolated and ACMP C1 pressure is less than 1200 psi
- The center system is isolated and the center system pressure is more than 1200 psi
- The reserve isolation valve is not open and ACMP C1 pressure is less than 1200 psi
- The nose gear isolation valve is not open and there is no command to isolate the center system.

The HYD ISLN VALVE status message shows if one or two isolation valves are not in the commanded position.



MAIN HYDRAULIC SYSTEMS - CENTER HYDRAULIC ISOLATION SYSTEM - FUNCTIONAL DESCRIPTION

RAM AIR TURBINE SYSTEM - INTRODUCTION

General

The ram air turbine (RAT) supplies an emergency source of hydraulic power to operate the flight controls. The RAT also is an emergency source of electrical power.

The RAT extends automatically in flight with a loss of hydraulic pressure in the three hydraulic systems. You can manually extend the RAT from the flight deck.

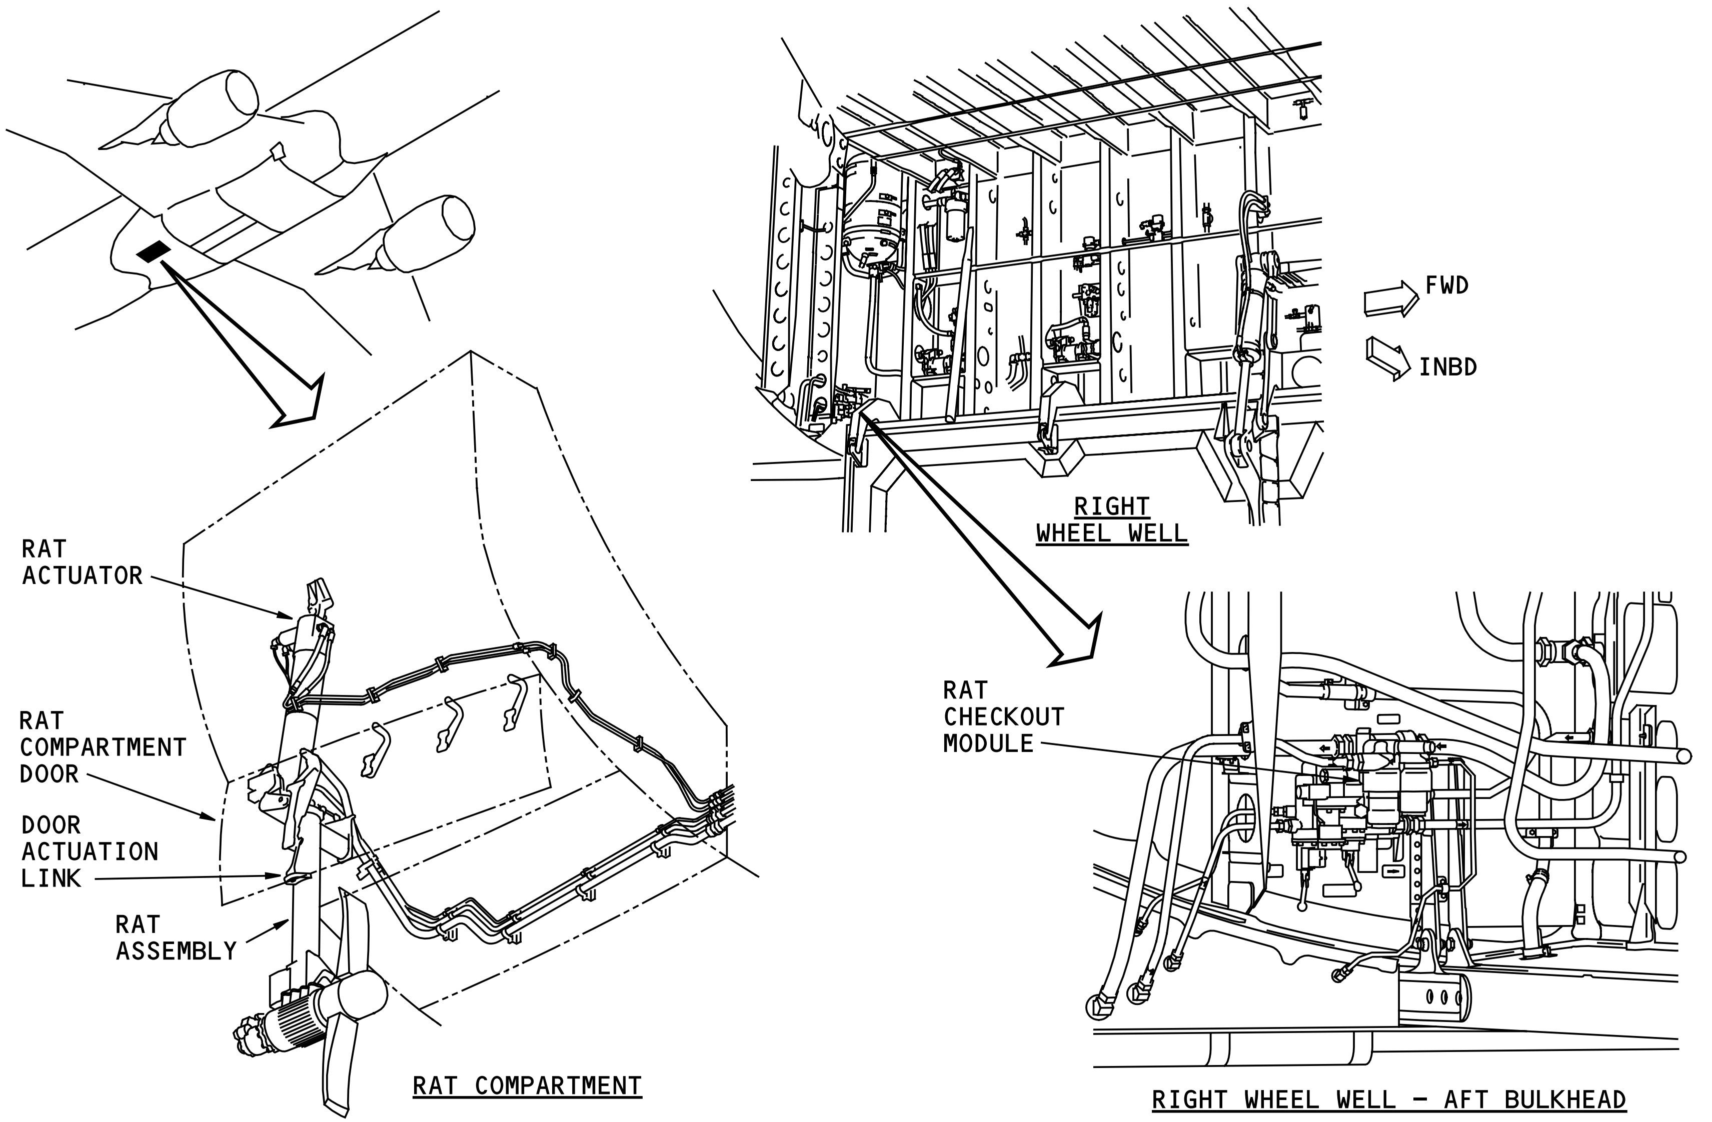
Control of RAT retraction is from the right wheel well.

Components

These are the components of the ram air turbine system:

- RAT assembly
- RAT actuator
- RAT compartment door and actuation link
- RAT stowed switch (not shown)
- RAT checkout module.

Most RAT components are in the RAT compartment behind the right wheel well. The RAT checkout module is in the right wheel well.



29-20-00-001 Rev 1

RAM AIR TURBINE SYSTEM - INTRODUCTION

RAM AIR TURBINE SYSTEM - GENERAL DESCRIPTION

General

The HYDIM cards or the ELMS control the automatic operation of the RAT.

The RAT manual switch permits manual RAT extension. Indication lights on the RAT manual switch show RAT pressure indication and RAT unlocked condition.

HYDIM Control

The two center HYDIM cards get these inputs to control automatic RAT extension:

- Airspeed (ADIRU through the AIMS)
- Groundspeed (ADIRU through the AIMS)
- Air/ground condition (WOW cards)
- Engines above idle (EDIUs)
- Hydraulic system pressures (HYDIM).

RAT Power Output

The RAT hydraulic pump supplies hydraulic power for some of the center hydraulic system flight controls.

The RAT generator supplies electrical power to the P310 standby power management panel in the ELMS. See the standby power section for more information about the RAT generator (AMM PART I 24-33).

Indications

The AIMS gets RAT position and pressure data for flight deck indication and fault detection.

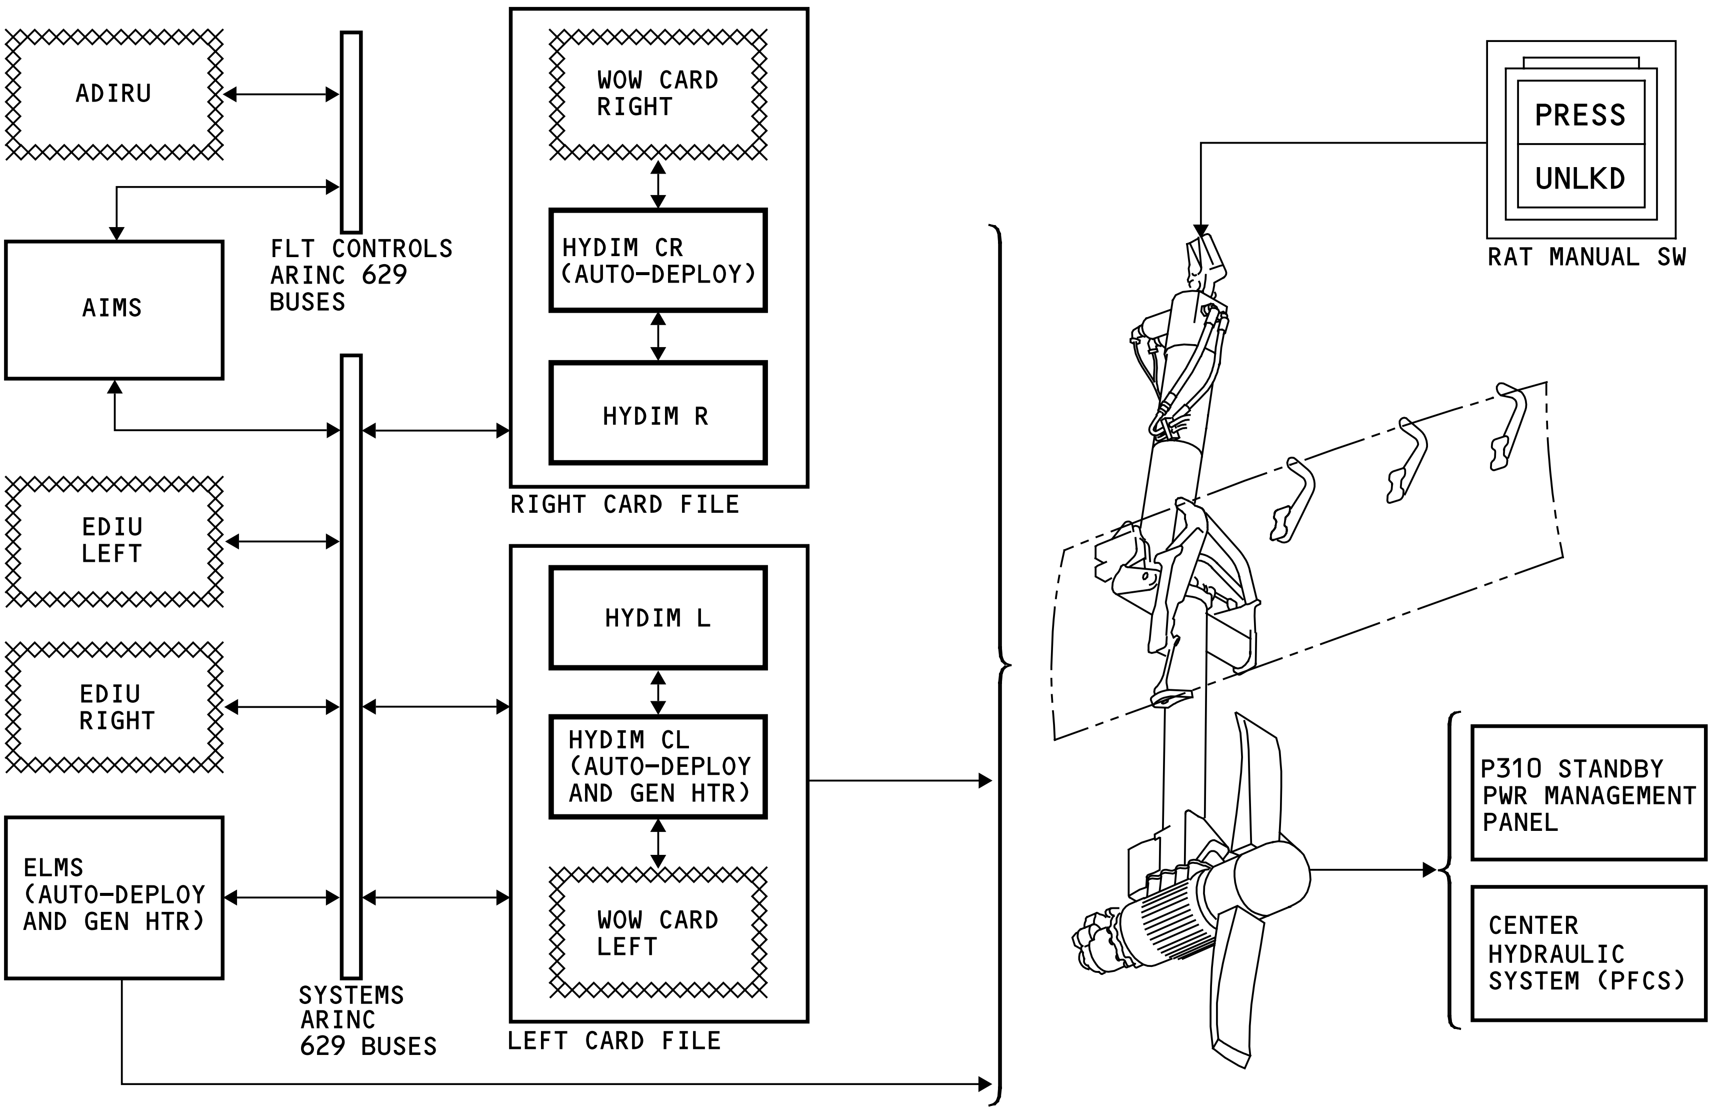
RAT pressure indication shows on the hydraulic synoptic display, the hydraulic maintenance page, and the pressure light on the RAT manual switch.

The ELMS calculates RAT speed from the RAT generator frequency. RAT speed shows on the hydraulic maintenance page.

RAT Generator Heater System

A RAT generator heater system keeps moisture from freezing inside the RAT generator. Ice inside the generator could stop RAT spin-up if the RAT is deployed at low airspeeds.

HYDIM controls the RAT generator heater system. The ELMS supplies the electrical power to operate the heaters.



RAM AIR TURBINE SYSTEM - GENERAL DESCRIPTION

29-20-00-002 Rev 6 03/16/95

THIS PAGE INTENTIONALLY LEFT BLANK

RAM AIR TURBINE SYSTEM - RAT ASSEMBLY

General

These components are part of the RAT assembly:

- RAT governor-generator assembly
- RAT hydraulic pump
- RAT strut
- RAT blade lock pin
- RAT blade locked switch
- RAT strut angle switch.

RAT Governor-Generator Assembly

The RAT governor-generator assembly has these components:

- Turbine
- Flyweight governor
- Electric generator.

A two-bladed variable pitch turbine turns the shaft of the generator and the pump. Turbine blade diameter is approximately 41.5 inches (105 cm).

The flyweight governor is inside the turbine hub. It controls turbine blade pitch to control turbine speed. Governed speed is approximately 4510 rpm.

The generator is a 115v ac, 3-phase generator rated at 7.5 KVA. A RAT generator heater system keeps ice out of the generator. See the standby power section for more information about the RAT generator (AMM PART I 24-33).

RAT Hydraulic Pump

The RAT hydraulic pump is a two-stage pressure-compensated pump. It attaches to the aft face of the governor-generator assembly.

The pump flow rate is 10 gpm at 2850 psi.

RAT Strut

The trunnion mounted strut assembly attaches the governor-generator and hydraulic pump to the airplane. Electric and hydraulic lines are in the strut.

RAT Blade Lock Pin and Blade Locked Switch

The RAT blade lock pin behind the turbine locks the turbine blades in a vertical position when the RAT is more than 9 degrees from the extended position. This keeps the blades from turning until they are clear of the structure of the airplane. It also keeps the blades from causing damage to the airplane during retraction.

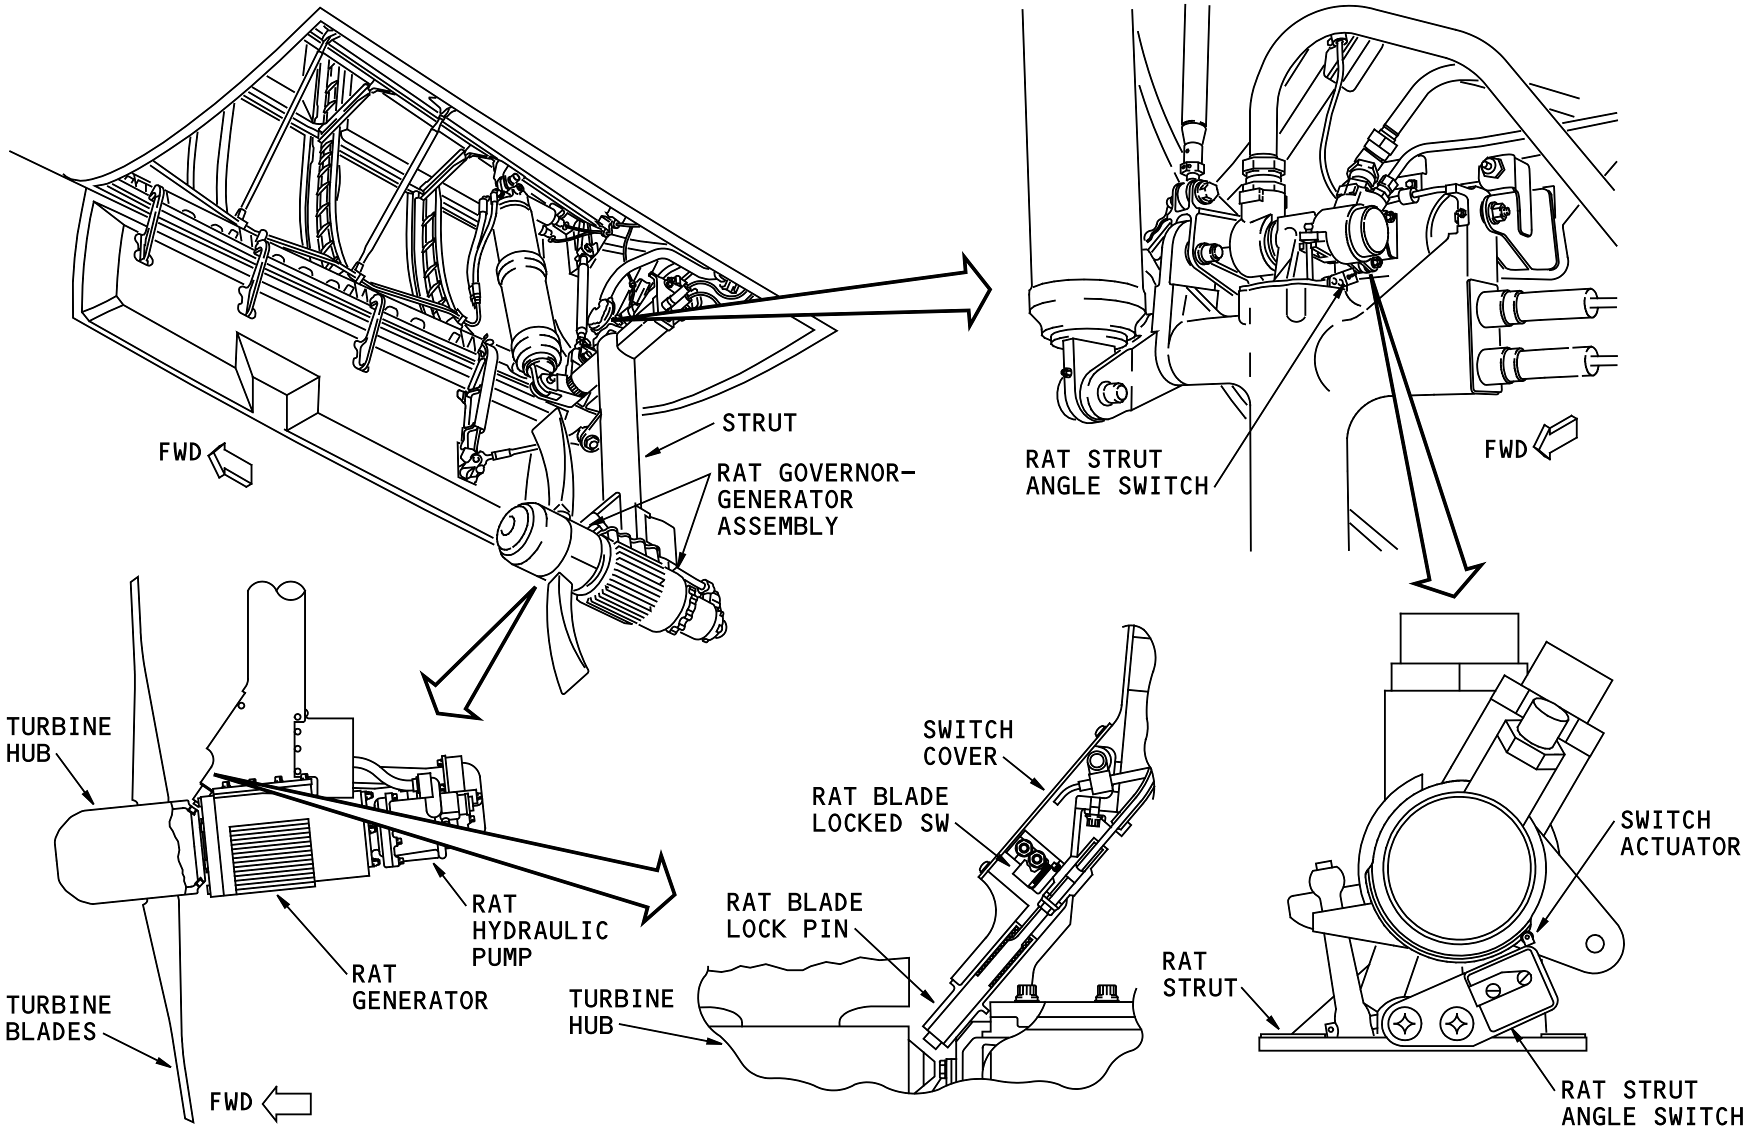
The RAT blade locked switch closes when the blade lock pin locks the turbine. This switch keeps the RAT from retracting more than 15 degrees unless the blades are locked by the blade index pin.

RAT Strut Angle Switch

The RAT strut angle switch at the top of the RAT strut permits initial RAT retraction. The switch is closed between 0 and 15 degrees of the RAT extended position.

RAM AIR TURBINE SYSTEM - RAT ASSEMBLY

It opens when the RAT is 15 degrees from the extended position to change retraction control to the RAT blade locked switch.



RAM AIR TURBINE SYSTEM - RAT ASSEMBLY

RAM AIR TURBINE SYSTEM - RAT ACTUATOR AND STOWED SWITCH

Purpose

The RAT actuator extends and retracts the ram air turbine assembly.

The RAT stowed switch gets RAT stowed position input for flight deck indication.

Physical Description

The RAT actuator is a spring-loaded hydraulic actuator. An internal spring extends the RAT. Hydraulic pressure retracts the RAT.

An internal mechanical lock keeps the actuator in the retracted position.

Two solenoids on the actuator unlock the actuator to extend the RAT.

Location

The RAT actuator and RAT stowed switch are in the RAT compartment aft of the right wheel well.

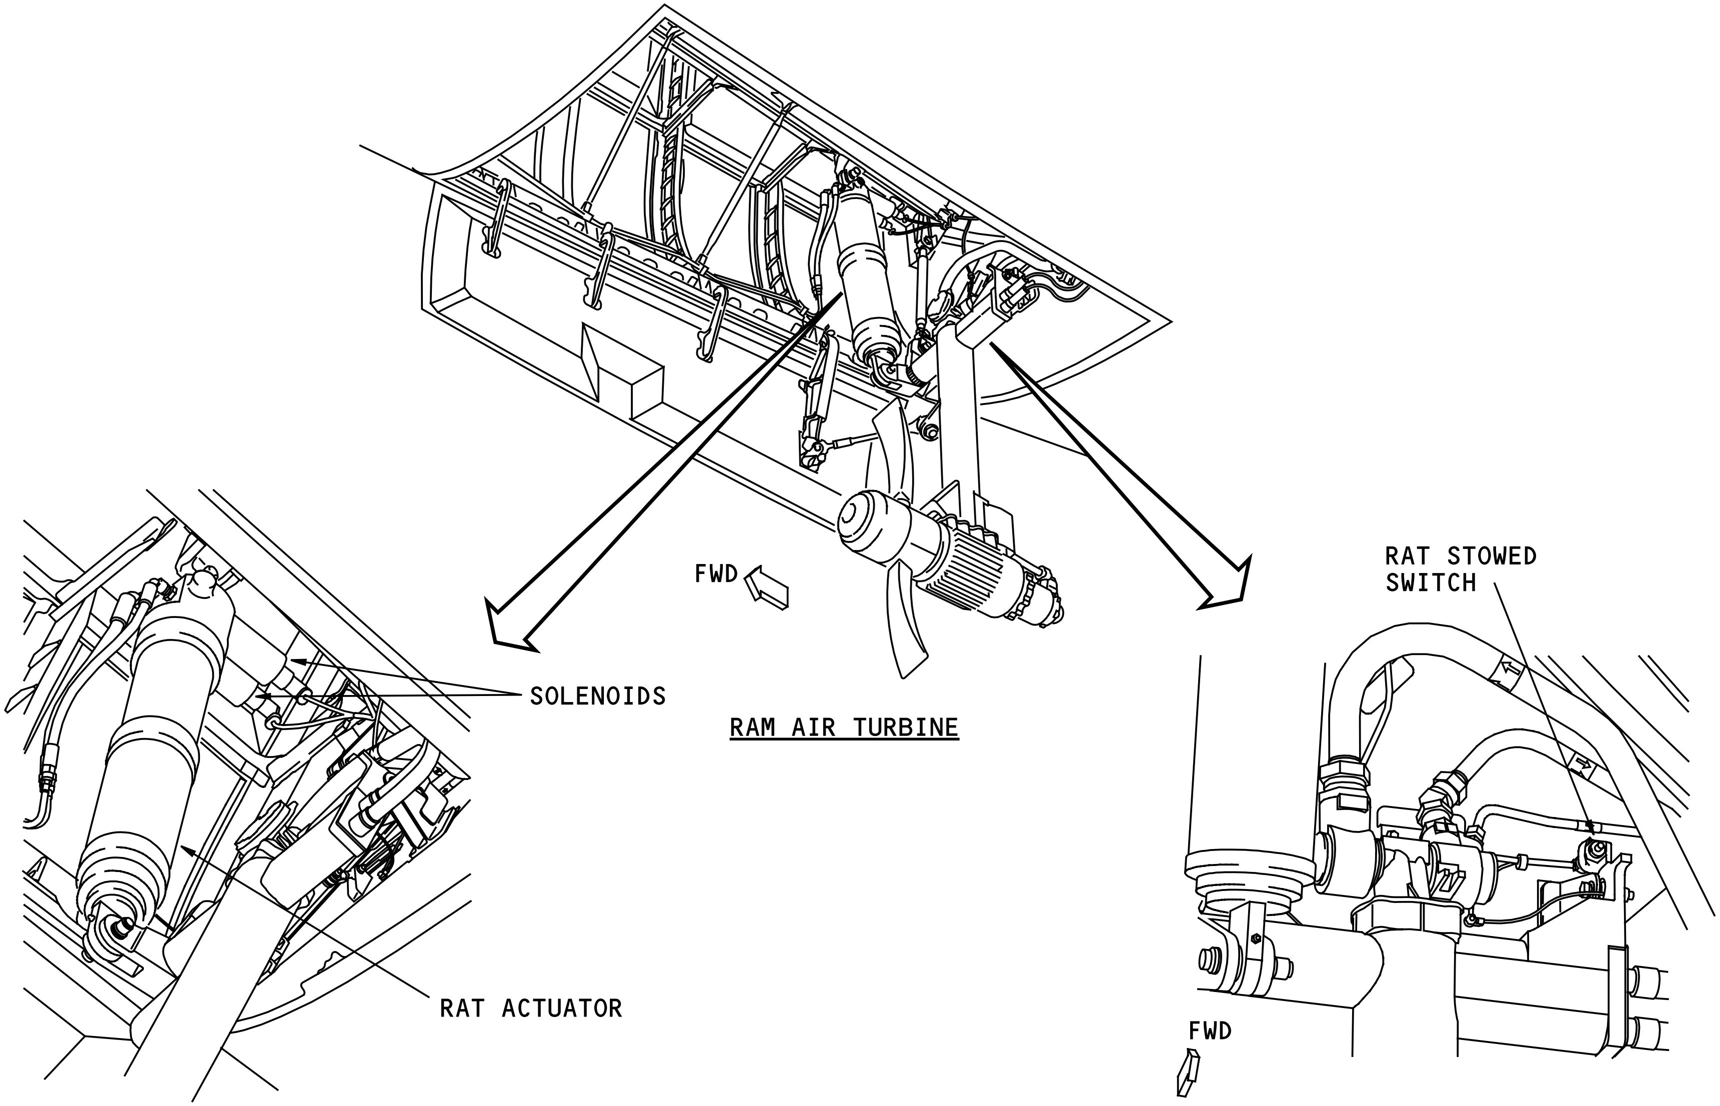
Functional Description

To extend the RAT, one or both solenoids are energized by a signal from any of these:

- HYDIM cards
- ELMS
- RAT manual switch.

This unlocks the actuator and the internal spring extends the RAT.

To retract the RAT, center system hydraulic pressure goes to the retract side of the RAT actuator. The RAT retracts and the internal lock keeps the actuator in the retracted position.



29-20-00-004 Rev 2

RAM AIR TURBINE SYSTEM - RAT ACTUATOR AND STOWED SWITCH

MAIN HYDRAULIC SYSTEMS - ADP ASSEMBLY - INTRODUCTION

Purpose

Two air driven pump (ADP) pumps are the demand pumps for the center hydraulic system.

General Description

Each ADP pump is part of an ADP assembly. The ADP assembly also has an air drive unit (ADU). The ADU contains these components:

- Turbine gearbox assembly (TGA)
- Modulating shutoff valve (MSOV)
- Air drive unit (ADU) heater.

A mount truss assembly attaches each ADP assembly to the airplane structure. The mount truss assembly for ADP assembly C1 is not the same as the one for ADP assembly C2.

The ADP assemblies use airplane pneumatic power to operate. An inlet duct supplies air pressure to each ADU. The MSOVs let air flow to the turbine of the TGAs. The gearbox of TGAs reduces the turbine speed and operates the pump. ADU heaters are on the ADUs to prevent ice formation. The pumps connect directly to the TGAs. The airflow from the TGAs exits the airplane through two exhaust ducts and two exhaust vents directly aft of the ADP assemblies.

The two TGAs have the same components. The turbine housing of ADP assembly C1 is different than the turbine housing for ADP assembly C2 to permit the exhaust ducts to be near each other.

Two ADP logic speed control units (LSCU), one for each ADP assembly, control the pump operation. The LSCUs supply speed control and overspeed protection to the TGAs. The LSCUs are circuit card assemblies and are LRUs.

A wiring harness for each ADP assembly connects the LSCU to the MSOV and the TGA.

The ADP pumps are the same as the engine driven pumps.

The ADP pump is rated at 53 gpm at 4315 rpm. A reserve mode permits the pump to supply 63 gpm at 5160 rpm. The pumps are LRUs.

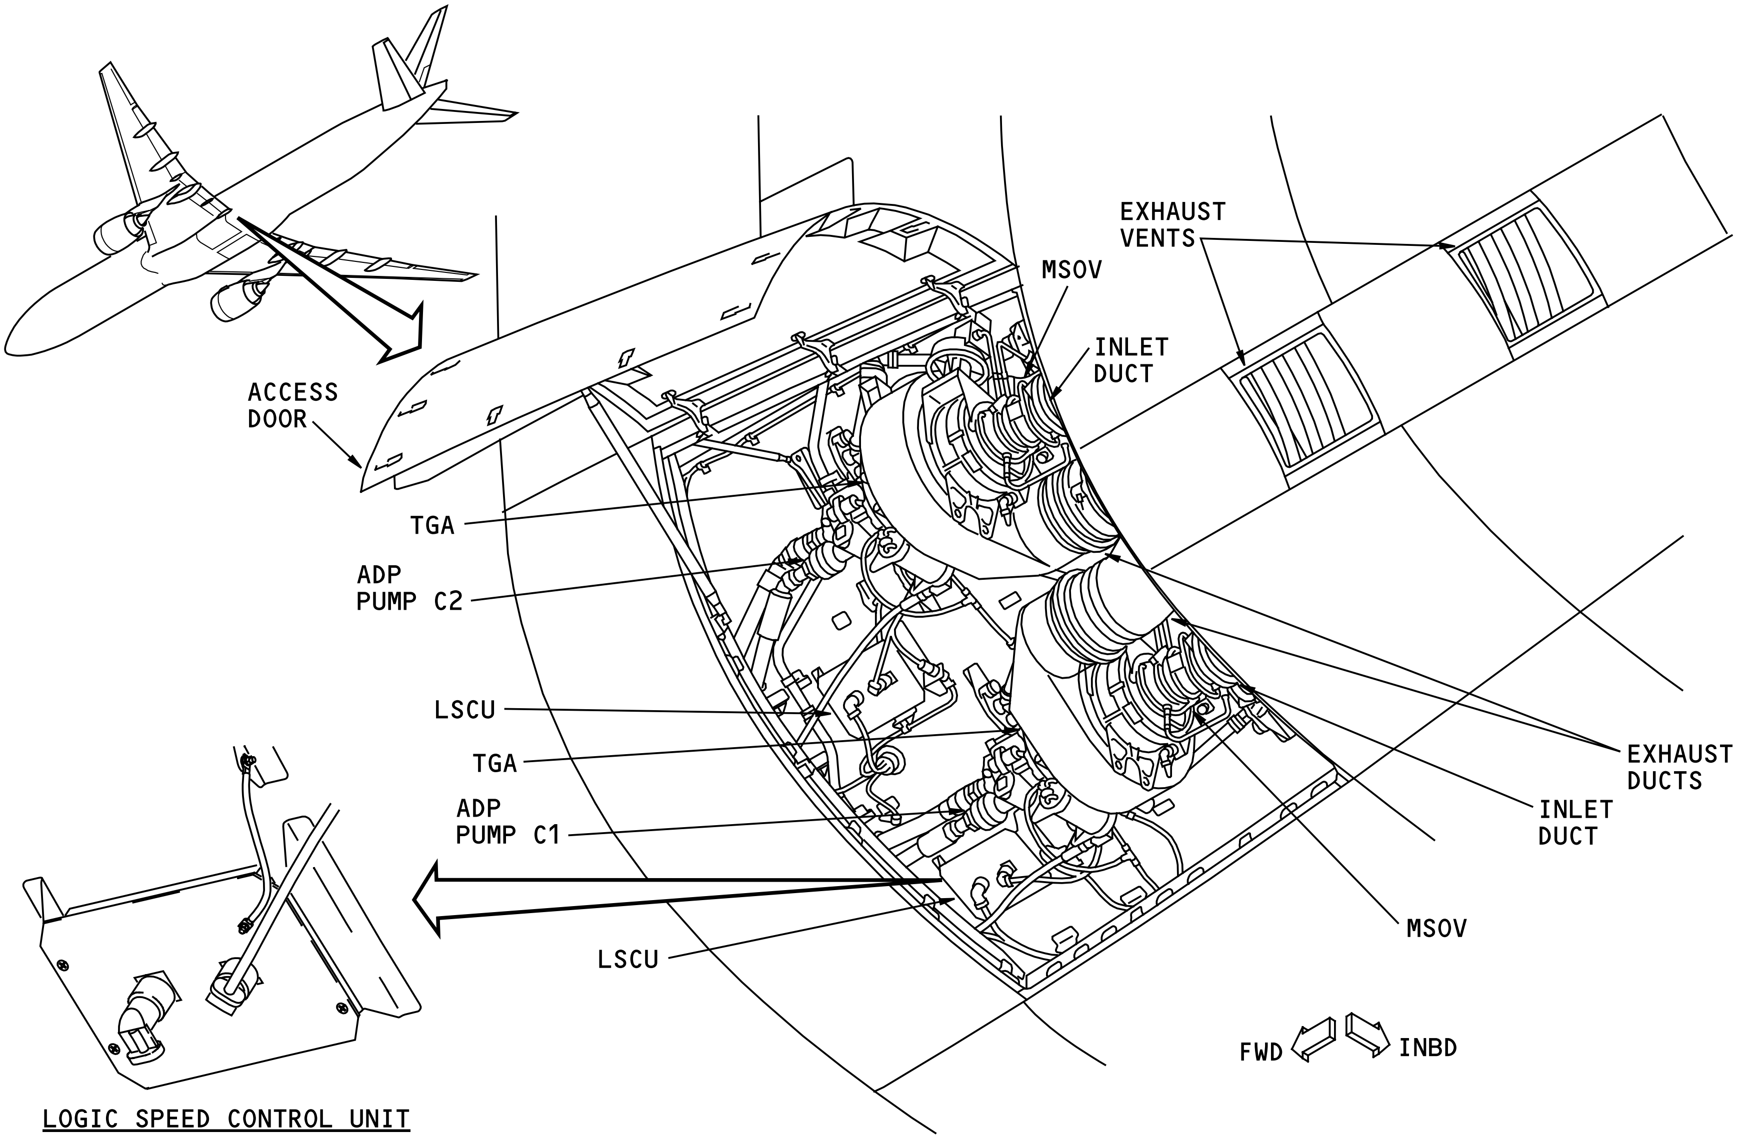
Location

The two ADP assemblies are in the left wing-to-body fairing behind the left wheel well. The LSCUs are also in this compartment.

Training Information Point

The EDPs and the ADP pumps are interchangeable. When the pump operates as an ADP pump, the depressurization solenoid does not operate.

CAUTION: MAKE SURE THE ADP ACCESS DOOR IS FULLY OPEN OR FULLY CLOSED WHEN OPERATING THE TRAILING EDGE FLAPS.



29-10-00-011 Rev 5 07/03/1997

MAIN HYDRAULIC SYSTEMS - ADP ASSEMBLY - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

RAM AIR TURBINE SYSTEM - EXTENSION - FUNCTIONAL DESCRIPTION

General

A switch on the P5 overhead panel permits manual RAT extension. The HYDIM cards or the ELMS can automatically extend the RAT.

The extend signal supplies power to either or both of the solenoids on the RAT actuator. This unlocks the RAT and permits the spring in the actuator to extend the RAT.

As the RAT gets near the fully extended position, the blade lock pin releases the turbine. The airstream turns the RAT.

Power Sources

These sources can energize the RAT actuator solenoids:

- APU battery bus
- Hot battery bus
- Captain's flight instrument bus.

HYDIM Auto-Extension

The HYDIM cards CL and CR independently control the automatic RAT extension.

CR extends the RAT for these conditions:

- Airplane is in the air mode
- Airspeed or ground speed is more than 80 knots
- Both engines are below idle rpm and center hydraulic system pressure is low or (L,C, and R hydraulic system pressures are low).

CL automatic extension conditions are almost the same as CR. CL extends the RAT for these conditions:

- Airplane is in the air mode
- Airspeed or ground speed is more than 80 knots
- Both engines are below idle rpm and center hydraulic system pump pressures are low or (left and right systems and center system pump pressures are low).

Both CL and CR energize one of the solenoids to unlock the RAT actuator.

ELMS Auto-Extension

The ELMS energizes the other solenoid on the RAT actuator to extend the RAT for these conditions:

- Airplane in the air mode
- Airplane not in the ground mode
- Left and right transfer buses have lost electrical power for 15 seconds.

Manual Extension

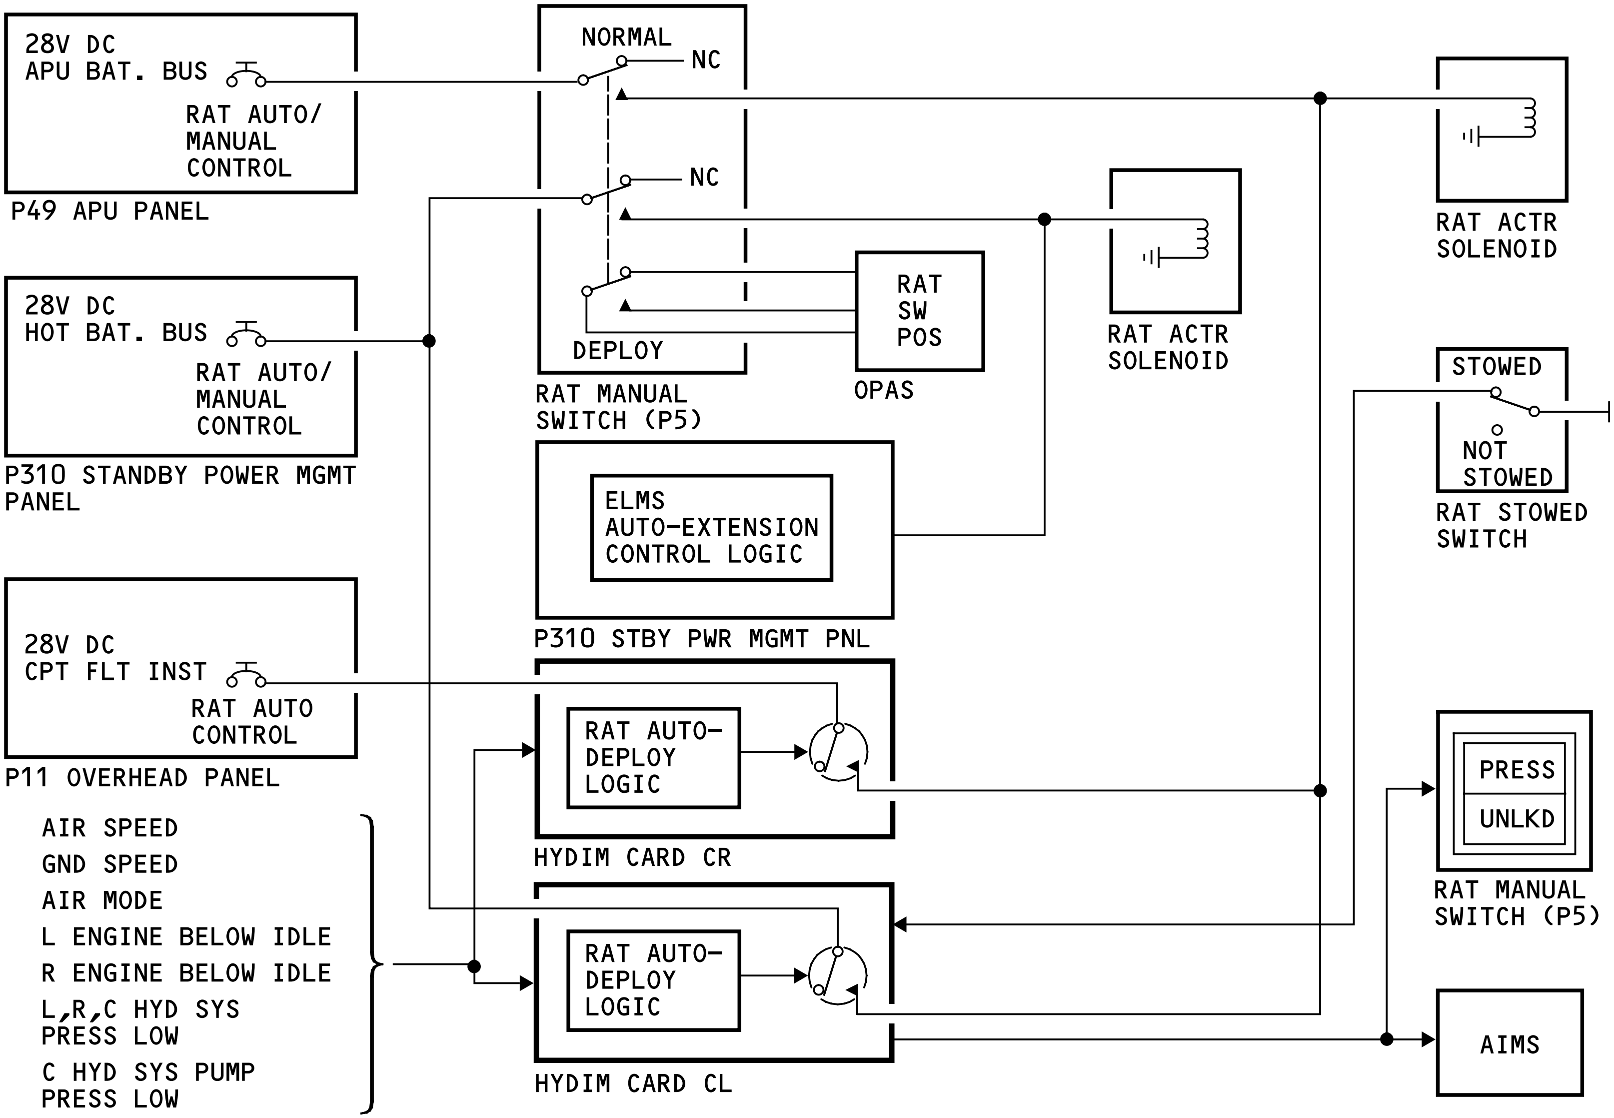
The RAT manual switch on the hydraulic/RAT panel energizes both the solenoids on the RAT actuator to extend the RAT.

RAM AIR TURBINE SYSTEM - EXTENSION - FUNCTIONAL DESCRIPTION

Indication

The RAT stowed switch in the RAT compartment sends a not-stowed signal to HYDIM CL when the RAT is not in the stowed position.

HYDIM CL turns on the RAT switch UNLKD light and sends a signal to the AIMS to show the RAT UNLOCKED advisory message.



RAM AIR TURBINE SYSTEM - EXTENSION - FUNCTIONAL DESCRIPTION

MAIN HYDRAULIC SYSTEMS - ALTERNATING CURRENT MOTOR PUMP

Purpose

The ACMPs are the primary pumps in the center hydraulic system and the demand pumps in the left and right hydraulic systems.

Physical Description

The ACMP has an electric motor that mechanically connects to a hydraulic pump. The motor operates with three-phase, 400 Hz, 115/200v ac power. The pump is a nine piston variable-displacement hydraulic pump.

Case drain flow cools the electric motor and cools and lubricates the pump.

A ripple damper smooths the pump pressure output.

The ACMPs are rated at 6 gpm at 2850 psi.

All ACMPs are the same and weigh 27 pounds (12.3 Kg).

Location

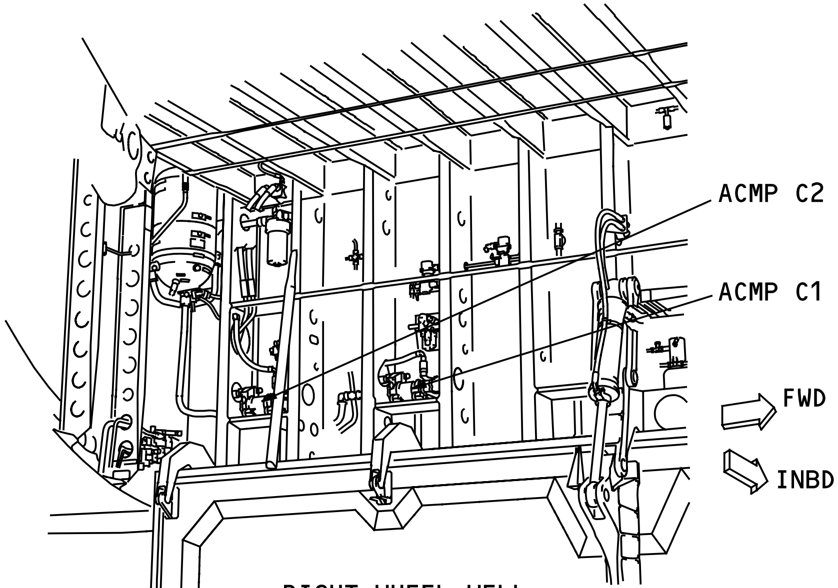
The ACMPs for the left and right hydraulic systems are in the engine struts aft of the reservoirs.

The center system ACMPs are on the keel beam in the right wheel well.

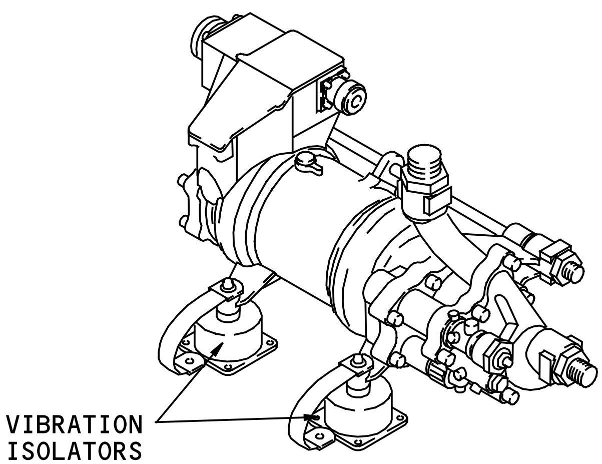
Training Information Point

The center system ACMPs attach to airplane structure through four vibration isolators.

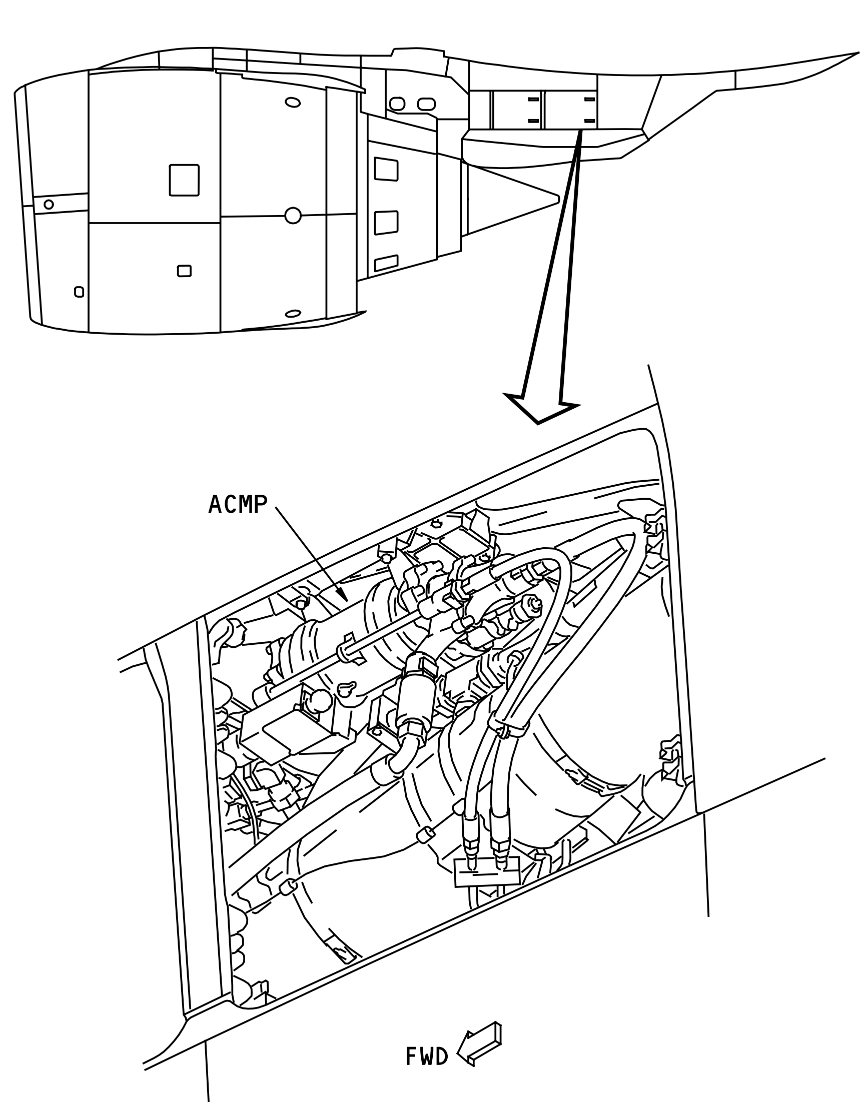
The left and right ACMPs attach to a mounting bracket (not shown) before installation.



RIGHT WHEEL WELL



CENTER SYSTEM ACMP



ENGINE STRUT

MAIN HYDRAULIC SYSTEMS - ALTERNATING CURRENT MOTOR PUMP

HYDRAULIC INDICATING SYSTEM - INTRODUCTION

General

The hydraulic indicating system monitors these values:

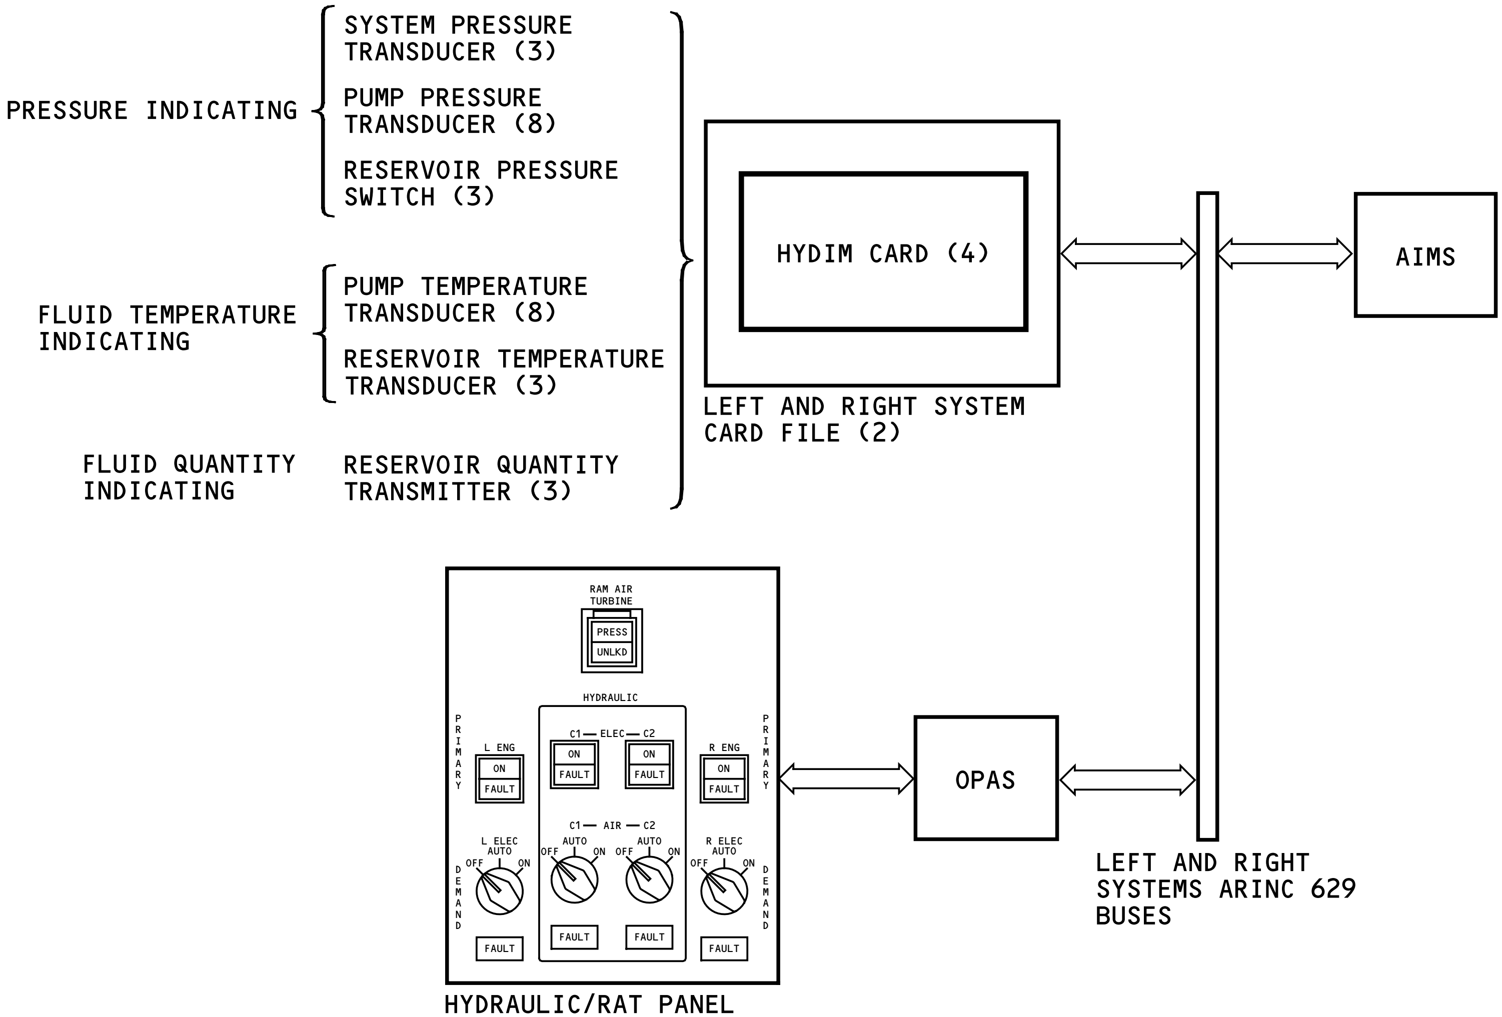
- Fluid and reservoir pressures
- Fluid temperature
- Fluid quantity.

The indicating systems get inputs from these sensors:

- Hydraulic pump pressure transducer (8)
- Hydraulic system pressure transducer (3)
- Hydraulic reservoir pressure switch (3)
- Hydraulic pump temperature transducer (8)
- Hydraulic reservoir temperature transducer (3)
- Hydraulic reservoir quantity transmitter (3).

Interface

The indicating systems sensors send data to the HYDIM cards. The HYDIM cards send the data to the AIMS for flight deck indication. The HYDIM cards also control the fault lights and the RAT indication lights on the hydraulic/RAT panel.



29-30-00-001 Rev 1

HYDRAULIC INDICATING SYSTEM - INTRODUCTION

HYDRAULIC INDICATING SYSTEM - HYDRAULIC SYSTEM PRESSURE TRANSDUCER - COMPONENT LOCATIONS

General

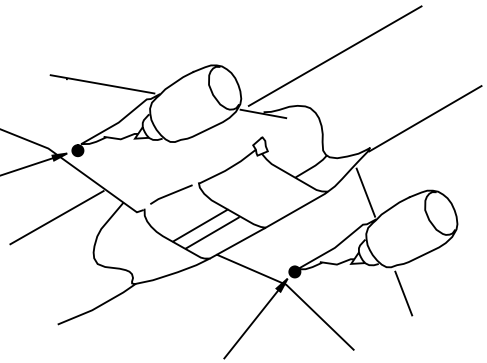
The left and right hydraulic system pressure transducers are on the rear wing spar of the left and right wings.

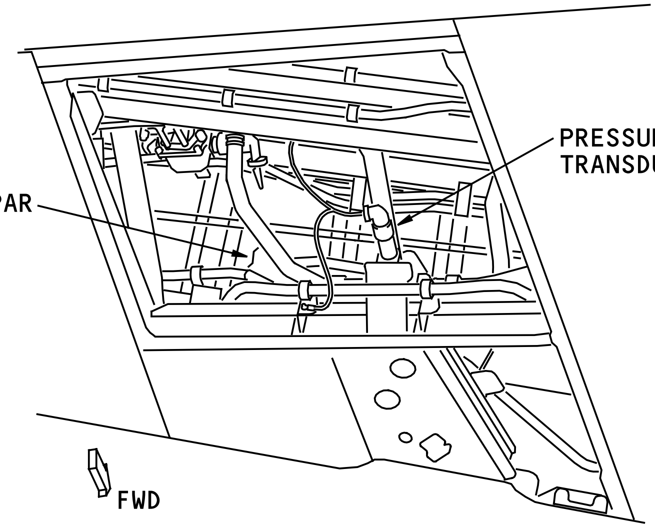
The center system pressure transducer is near the keelbeam in the right wheel well.

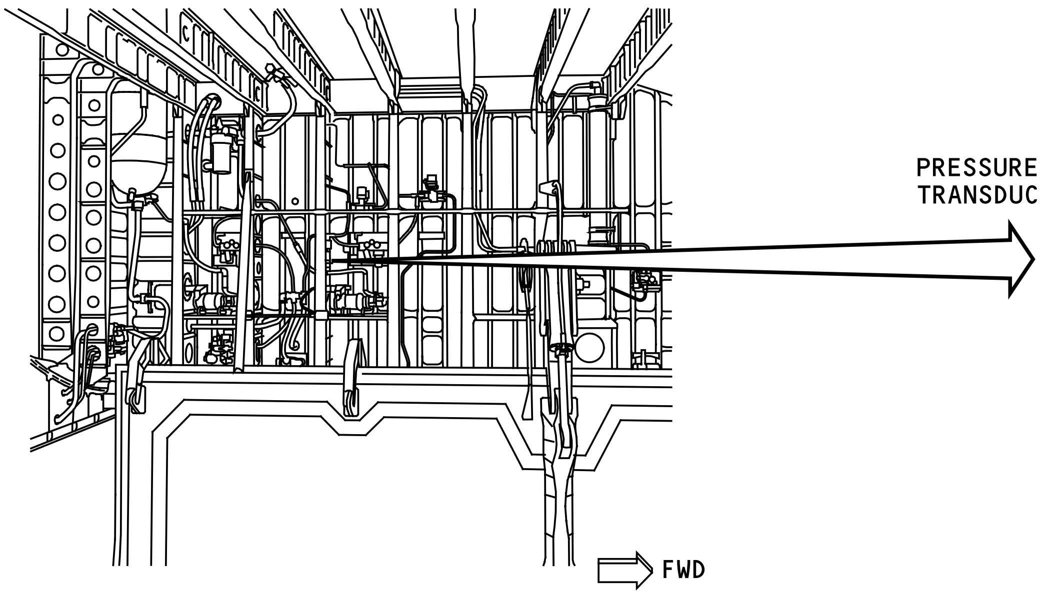
Training Information Point

The hydraulic system pressure transducers are interchangeable with the pump pressure transducers.

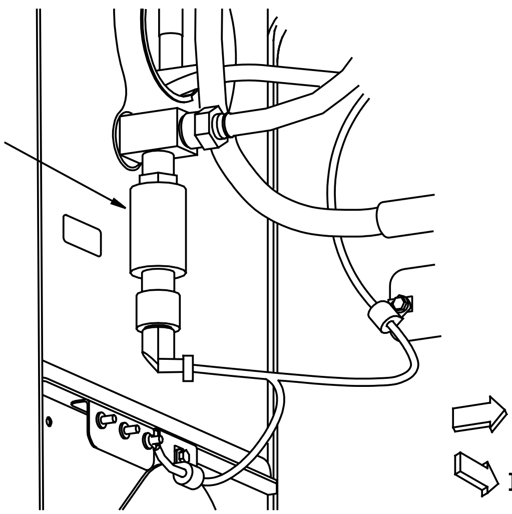
Access panels (552LB - left system, 652LB - right system) on the bottom of the wings give access to the pressure transducers.







RIGHT WHEEL WELL



CENTER SYSTEM PRESSURE TRANSDUCER

HYDRAULIC INDICATING SYSTEM - HYDRAULIC SYSTEM PRESSURE TRANSDUCER - COMPONENT LOCATIONS

THIS PAGE INTENTIONALLY LEFT BLANK

HYDRAULIC INDICATING SYSTEM - PRESSURE INDICATING

General

These sensors in the hydraulic systems send hydraulic pressure data to the HYDIM cards:

- System pressure transducer (3)
- Pump pressure transducer (8)
- Reservoir pressure switches (3).

The HYDIM cards control the pressure indications.

Functional Description

The pressure transducers send signals in proportion to pressure between 0 and 4000 psi. The transducers make allowance for temperature changes.

The reservoir pressure switches send a reservoir low pressure signal when the reservoir pressure is 21 psia or less. They send a reservoir not low signal when reservoir pressure is 25 psia or more.

Hydraulic System Pressure Indications

Hydraulic system pressure shows on these displays:

- The status display
- The hydraulic synoptic display
- The hydraulic maintenance page.

These caution messages show if hydraulic system pressure is below 1200 psi:

- HYD PRESS SYS L
- HYD PRESS SYS C
- HYD PRESS SYS R
- HYD PRESS SYS L+C
- HYD PRESS SYS R+C
- HYD PRESS SYS L+R
- HYD PRESS SYS L+C+R.

Hydraulic Pump Pressure Indications

The maintenance page shows hydraulic pump pressure in psi.

Advisory messages show if hydraulic pump pressure is less than 1200 psi for ACMPs or 1800 psi for ADPs and EDPs. These are the advisory messages:

- HYD PRESS PRI L
- HYD PRESS PRI C1
- HYD PRESS PRI C2
- HYD PRESS PRI R
- HYD PRESS DEM L
- HYD PRESS DEM C1
- HYD PRESS DEM C2
- HYD PRESS DEM R.

These advisory messages do not show for a demand pump when the demand pump selector is in AUTO and there is no control signal from HYDIM to operate the pump.

Also, these advisory messages do not show if the system pressure is low.

HYDRAULIC INDICATING SYSTEM - PRESSURE INDICATING

Status messages show if there is a signal for a pump to operate and the pump pressure is less than 1200 psi for ACMPs or 1800 psi for ADPs and EDPs. These are the status messages:

- HYD PUMP PRI L
- HYD PUMP PRI C1
- HYD PUMP PRI C2
- HYD PUMP PRI R
- HYD PUMP DEM L
- HYD PUMP DEM C1
- HYD PUMP DEM C2
- HYD PUMP DEM R.

These status messages also show if there is a pump overheat condition.

The status and advisory low pressure messages for the EDPs do not show if the related engine speed for the EDP is less than idle.

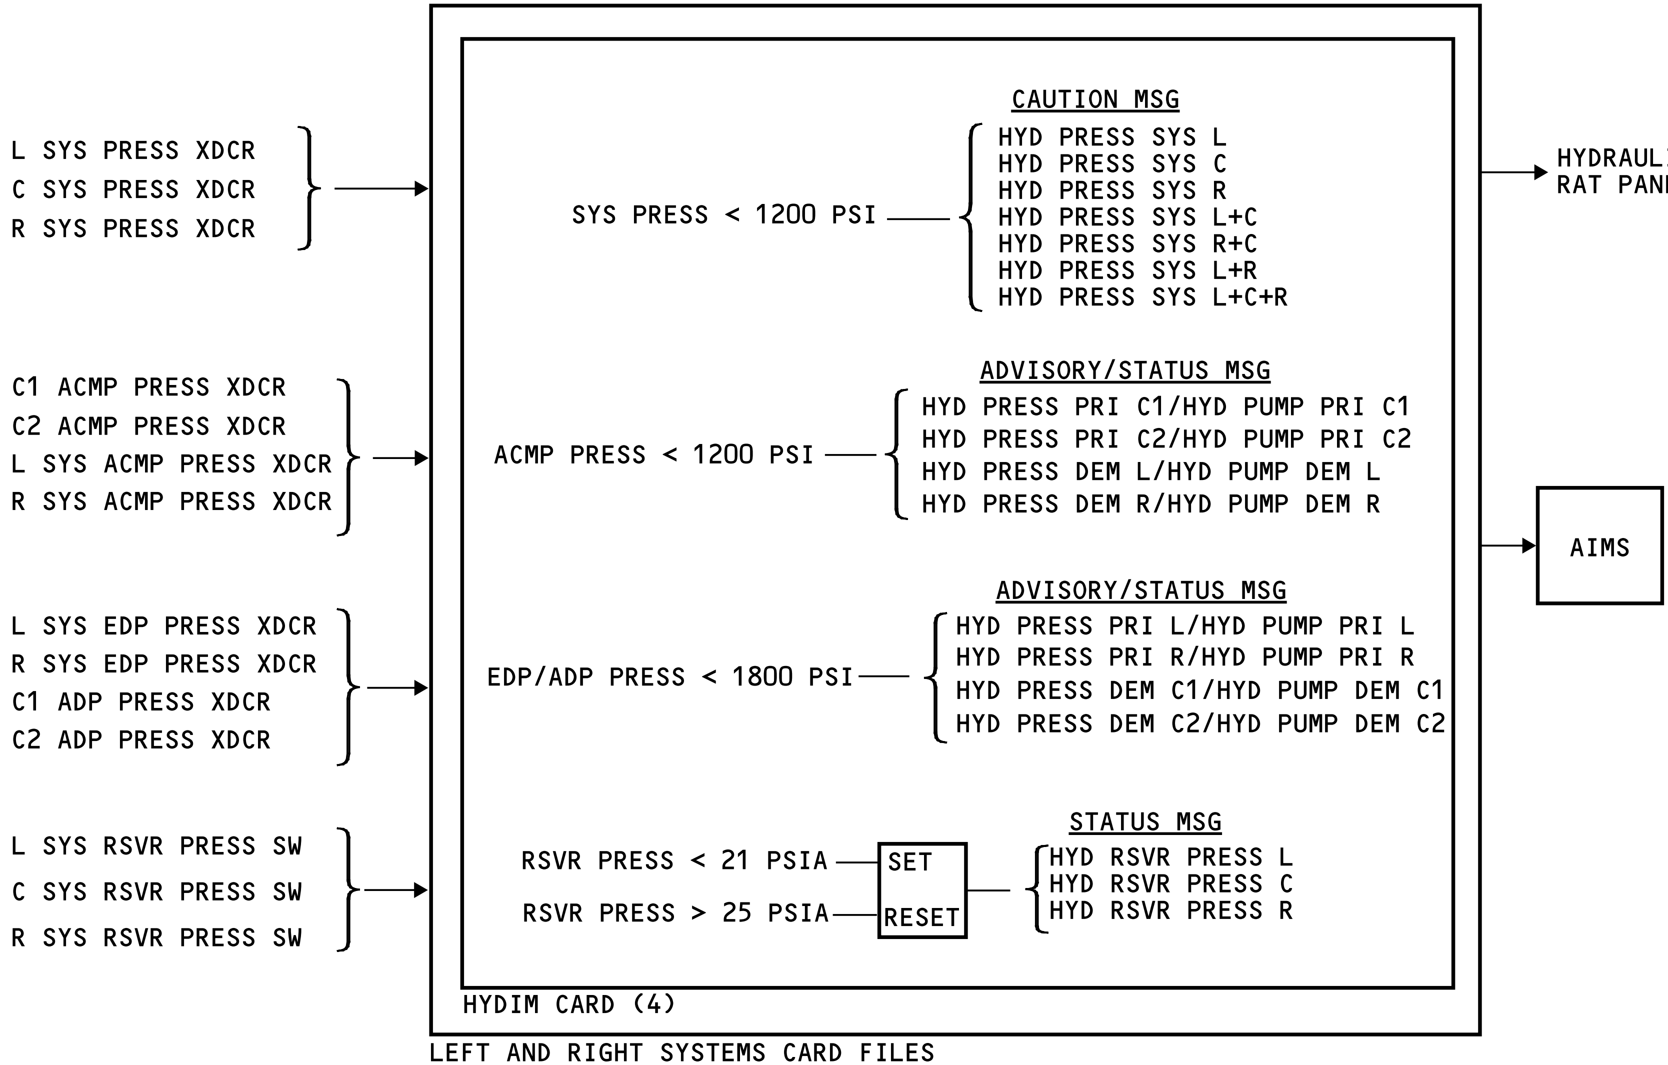
Low pump pressure also makes the pump fault light on the hydraulic control panel come on. The pump fault light does not come on for a demand pump when the demand pump selector is in AUTO and there is no control signal from HYDIM to operate the pump.

Reservoir Pressure Indications

Hydraulic reservoir pressure (LO or NORM) shows on the hydraulic maintenance page. LO shows when the pressure is 21 psia or less. NORM shows when the pressure is 25 psia or more.

These status messages show if the hydraulic reservoir pressure is low:

- HYD RSVR PRESS L
- HYD RSVR PRESS C
- HYD RSVR PRESS R.



29-30-00-004 Rev 6 11/25/1996

HYDRAULIC INDICATING SYSTEM - PRESSURE INDICATING

HYDRAULIC INDICATING SYSTEM - TEMPERATURE INDICATING

General

Temperature transducers for each hydraulic reservoir and each hydraulic pump send temperature data to the HYDIM cards. The HYDIM cards control temperature indication.

Sensor Functional Description

The temperature transducers are RTD (resistance temperature detector) type transducers. The transducer signal is from 4 to 20 milliamperes for temperatures between -54C and 149C (-63.6F to 300F).

Hydraulic Pump Temperature Indication

Hydraulic pump temperatures in degrees C show on the hydraulic maintenance page.

These advisory messages show if pump temperature is more than 105C:

- HYD OVERHEAT PRI L
- HYD OVERHEAT PRI C1
- HYD OVERHEAT PRI C2
- HYD OVERHEAT PRI R
- HYD OVERHEAT DEM L
- HYD OVERHEAT DEM C1
- HYD OVERHEAT DEM C2
- HYD OVERHEAT DEM R

These messages go away when the pump temperature is less than 75C.

These status messages show for a pump overheat condition:

- HYD PUMP PRI L
- HYD PUMP PRI C1
- HYD PUMP PRI C2
- HYD PUMP PRI R
- HYD PUMP DEM L
- HYD PUMP DEM C1
- HYD PUMP DEM C2
- HYD PUMP DEM R

These messages go away when the pump temperature is less than 100C with normal pump pressure for 10 seconds (for the EDPs) or 60 seconds (for the ACMPs and ADPs).

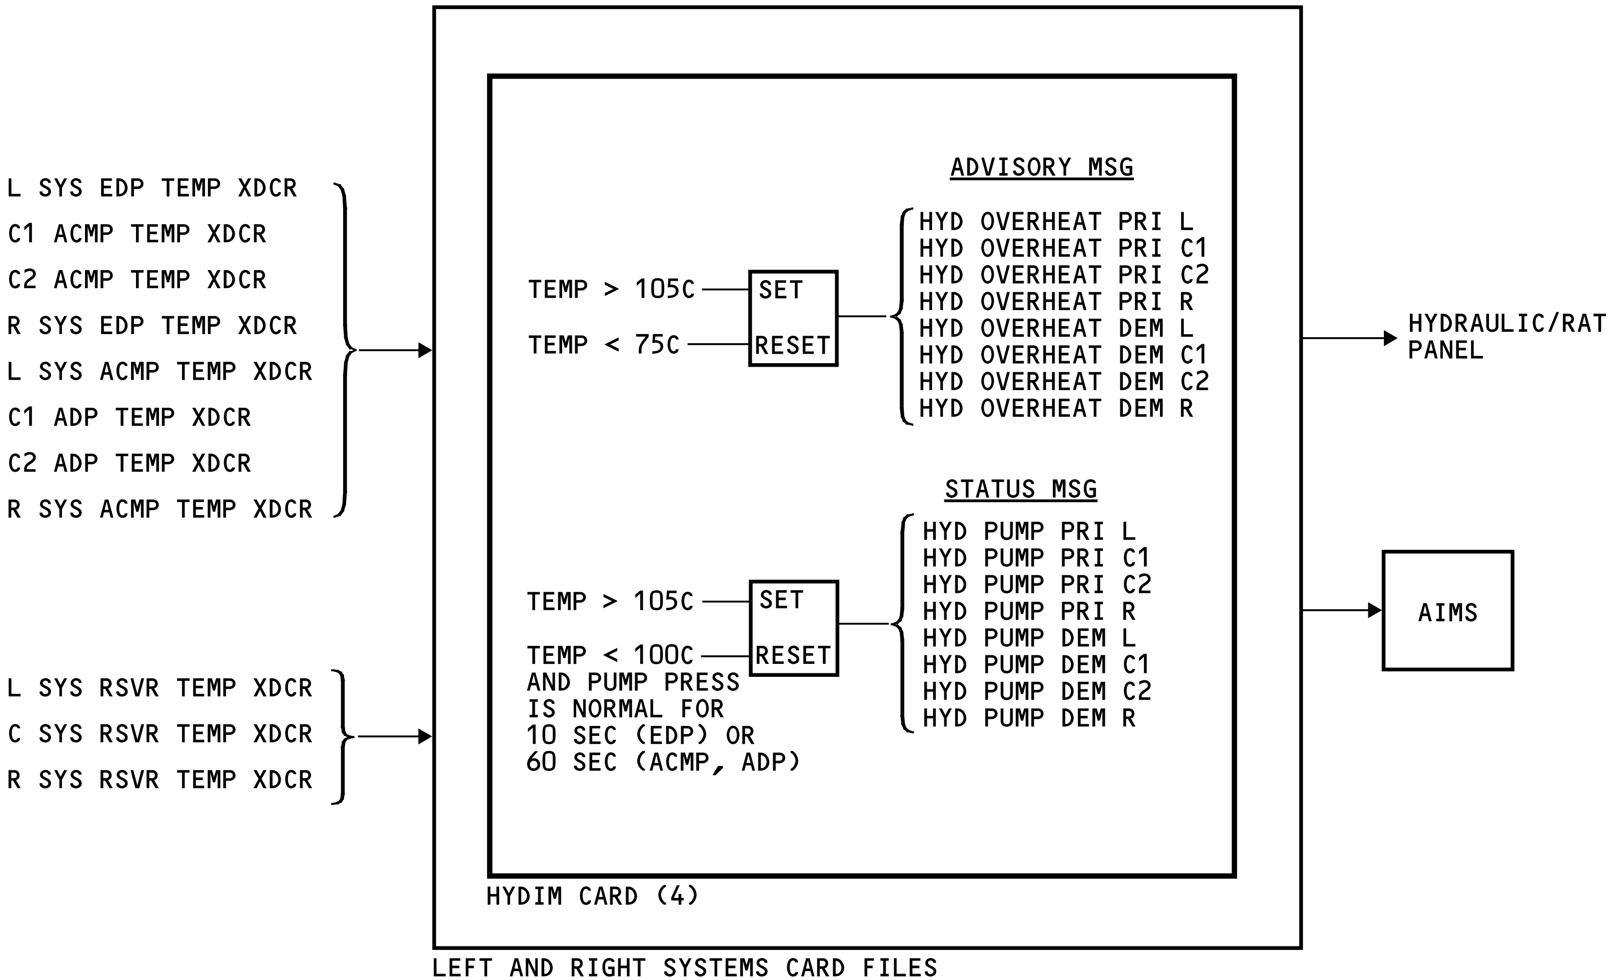
These indications also show for a pump overheat:

- Fault light on P5 hydraulic/RAT panel
- OVHT next to the pump symbol on the hydraulic synoptic display.

Hydraulic Reservoir Temperature Indication

Reservoir temperature in degrees C shows on the hydraulic maintenance page. There are no reservoir overheat indications.

CAUTION: DO NOT OPERATE THE HYDRAULIC PUMPS AFTER THE TEMPERATURE INDICATION ON EICAS IS MORE THAN 100C (212F) OR AFTER THE PUMP FAULT LIGHT COMES ON. IF YOU CONTINUE TO OPERATE THE PUMPS, THE HYDRAULIC FLUID CAN BECOME TOO HOT.



29-30-00-005 Rev 5 11/25/1996

HYDRAULIC INDICATING SYSTEM - TEMPERATURE INDICATING

HYDRAULIC INDICATING SYSTEM - FLUID QUANTITY INDICATING

General

A quantity transmitter in each of the hydraulic reservoirs measures fluid quantity. Reservoir quantity data goes to the HYDIM cards.

Functional Description

The reservoir quantity transmitters are capacitance-type transmitters. They send a signal to the HYDIM cards in proportion to reservoir fluid quantity. The HYDIM cards send reservoir quantity signals to the AIMS and to the reservoir quantity gage in the hydraulic service bay.

The reservoir quantity indication makes allowance for temperature changes to prevent nuisance refill and overfill indications.

Indication

Reservoir quantities show on these MFD formats:

- Status display
- Hydraulic synoptic display
- Maintenance page.

Quantity indication shows as a decimal number. The reservoir full level shows as 1.00.

If the reservoir quantity is 1.20 or more, an OF (overfill) shows next to the quantity indication on the status display, the hydraulic synoptic display and the hydraulic maintenance page. The OF shows only when the airplane is on the ground.

If reservoir quantity is 0.75 or less, an RF (refill) shows next to the quantity indication on the status display, the hydraulic synoptic display, and the hydraulic maintenance page. The RF shows only when the airplane is on the ground.

If reservoir quantity is 0.40 or less, a LO shows next to the quantity indication on the status display, the hydraulic synoptic display, and the hydraulic maintenance page.

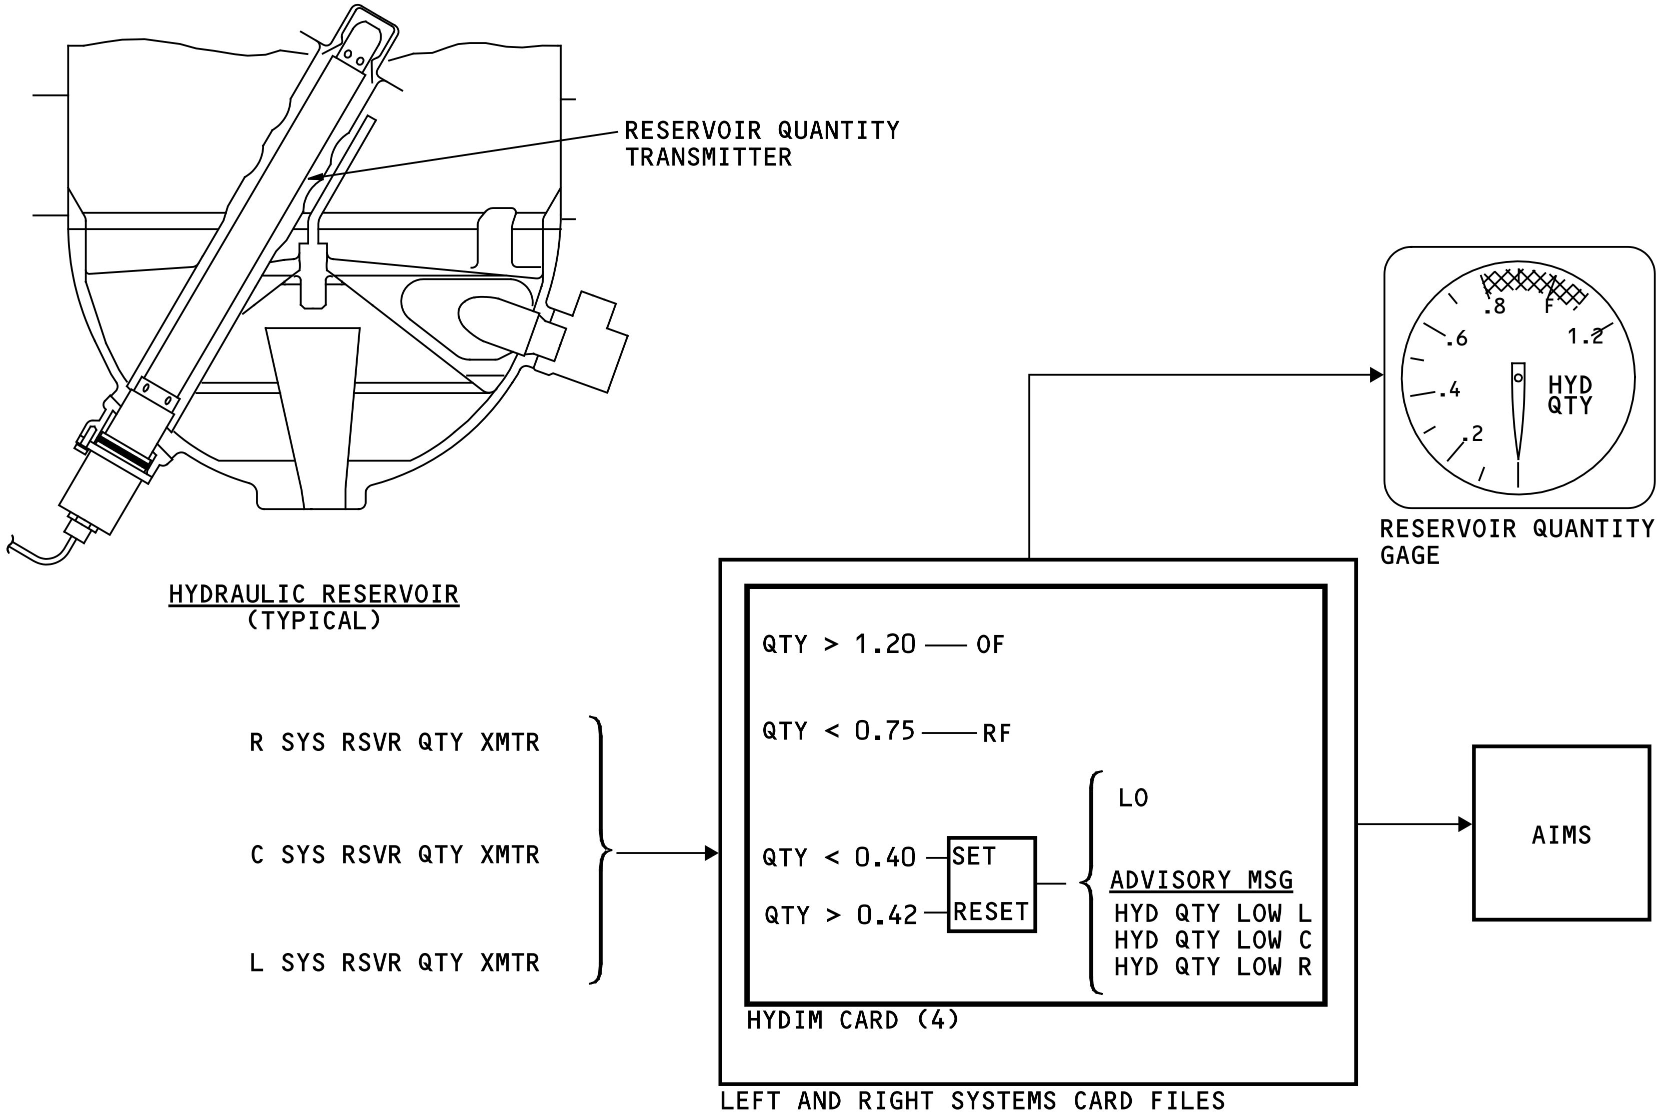
These advisory messages show if reservoir quantity is 0.40 or less:

- HYD QTY LOW L
- HYD QTY LOW C
- HYD QTY LOW R.

The advisory messages and the LO indication reset when the quantity is more than 0.42.

Training Information Point

If the reservoir fluid level is at the top of the standpipe, the quantity indication shows 0.00.



29-30-00-006 Rev 2

HYDRAULIC INDICATING SYSTEM - FLUID QUANTITY INDICATING

THIS PAGE INTENTIONALLY LEFT BLANK

MAIN HYDRAULIC SYSTEMS - TRAINING INFORMATION POINTS - GROUND SERVICING SYSTEM

General

A central fill station in the ground service bay permits you to fill the three hydraulic reservoirs from a single location.

Components

Hydraulic servicing components include:

- Manual pump handle
- Manual pump suction hose
- Pressure fill connection
- Reservoir fill manual pump
- Reservoir fill filter
- Reservoir fill quantity gage
- Reservoir fill selector valve
- Instruction placard.

You set the four-position fill selector valve to send hydraulic fluid to one of the three hydraulic systems. The valve is set to OFF after servicing.

The reservoir fill quantity gage shows the reservoir quantity of the selected hydraulic system.

The reservoir fill filter cleans the fluid that goes into the hydraulic systems.

The reservoir fill manual pump permits you to fill the hydraulic systems manually.

The pressure fill connection permits the connection of a ground service cart to fill the hydraulic systems. A cap covers the connection when not in use.

You use the manual pump suction hose during manual fill operation. One end of the hose connects to the manual pump. The other end of the hose goes in the hydraulic fluid container. When not in use, you put the end of the suction hose in a protective cover.

You use the manual pump handle to operate the manual pump. You put the pump handle next to the suction hose when not in use.

Training Information Point

To get the correct results when you do a check of the hydraulic fluid quantities or fill the reservoirs, the airplane should be in this condition:

- Spoilers retracted
- Landing gear down
- Landing gear doors closed
- Thrust reversers retracted
- Parking brake accumulator pressure at least 2500 psi.

WARNING: DO NOT GET HYDRAULIC FLUID IN YOUR EYES OR ON YOUR SKIN. THE HYDRAULIC FLUID CAN CAUSE INJURY TO PERSONS. IF YOU GET THE HYDRAULIC FLUID ON YOUR SKIN, FLUSH YOUR SKIN WITH

WATER. IF YOU GET THE HYDRAULIC FLUID IN YOUR EYES, FLUSH YOUR EYES WITH WATER AND GET MEDICAL AID. IF YOU GET THE HYDRAULIC FLUID IN YOUR MOUTH, GET MEDICAL AID.

CAUTION: USE CLEAN HYDRAULIC FLUID AND CLEAN EQUIPMENT TO FILL THE HYDRAULIC SYSTEM RESERVOIR. IF YOU DO NOT DO THIS YOU CAN CAUSE CONTAMINATION OF THE HYDRAULIC SYSTEM.

CAUTION: DO NOT FILL THE RESERVOIR TO MORE THAN THE FULL LEVEL. IF YOU PUT TOO MUCH FLUID IN THE RESERVOIR AND THERE IS A CHECK VALVE FAILURE, THE FLUID CAN GO INTO THE DUCTS OF THE PNEUMATIC SYSTEM AND THE AIR CONDITIONING PACKS. IF CONTAMINATION OF THE PNEUMATIC SYSTEM OCCURS MANY TIMES, IT CAN CAUSE DAMAGE TO THE TITANIUM DUCTS. IF YOU PUT TOO MUCH FLUID IN THE RESERVOIR, THE FLUID CAN FLOW OUT OF THE RESERVOIR VENT TUBE, THROUGH THE PRESSURE RELIEF VALVE.

MAIN HYDRAULIC SYSTEMS - TRAINING INFORMATION POINTS - GROUND SERVICING SYSTEM

THIS PAGE INTENTIONALLY LEFT BLANK

HYDRAULIC POWER - OPERATION

General

You can pressurize the hydraulic systems with a ground service cart or with the hydraulic pumps.

Ground Service Cart Pressurization

The ground pressurization connections for the left system are in the left engine strut.

The ground pressurization connections for the right system are in the right engine strut.

You get access to these connections through the aft strut fairing doors on the right side of each engine strut.

The ground pressurization connections for the center hydraulic system are in the left wing to body fairing behind the left wheel well.

You get access to these connections through the ADP filter module access door.

Hydraulic Pump Pressurization

You use the Hydraulic/RAT panel on the P5 overhead panel to turn on the hydraulic pumps.

Training Information Point

If you pressurize the hydraulic systems with the hydraulic pumps, make sure there is sufficient fuel in the main fuel tanks to cool the heat exchangers. Approximately 709 gallons (2688 liters) (4794 pounds) (2175 kg) of fuel in the left and right main fuel tanks is necessary to cool the heat exchangers in the left and right hydraulic systems. Approximately 1080 gallons (4095 liters) (7303 pounds) (3313 kg) of fuel in the right main tank is necessary to cool the center system heat exchanger.

To pressurize a hydraulic system with a ground service cart, you first need to remove the pressure from the hydraulic reservoir.

The sequence in which you pressurize or remove the pressure from the hydraulic systems can cause fluid to move between the center and right systems. This can cause a high fluid level in one system and a low fluid level in the other system.

If you set the parking brake in one of these conditions:

- The right and center system pressurized
- Only the right pressurized
- No hydraulic system pressurized

and then release the brake with only the center system pressurized, the fluid can move to the center system.

If you set the parking brake with only the center system pressurized, and then release the brake in one of these conditions:

HYDRAULIC POWER - OPERATION

- The right and center system depressurized
- Only the right system pressurized
- No hydraulic system pressurized

the fluid can move to the right system.

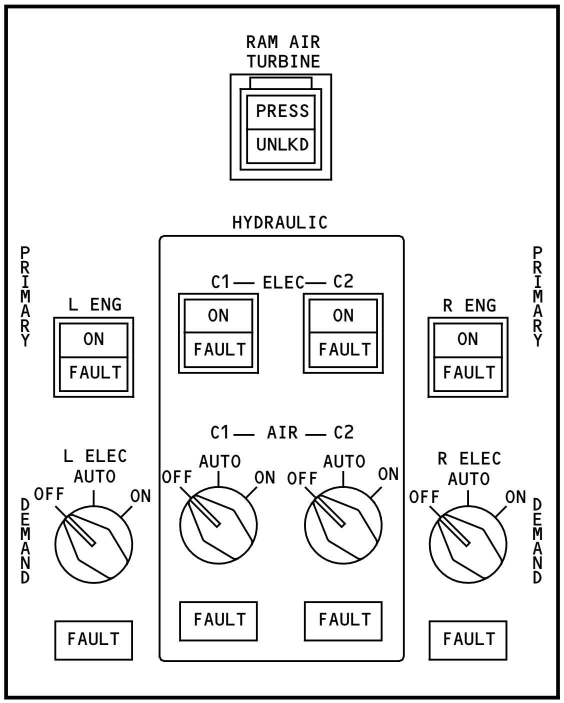
To keep the movement of fluid between the right and center hydraulic systems to a minimum, do these steps:

- Pressurize the right hydraulic system first
- Remove the pressure from the right hydraulic system last.

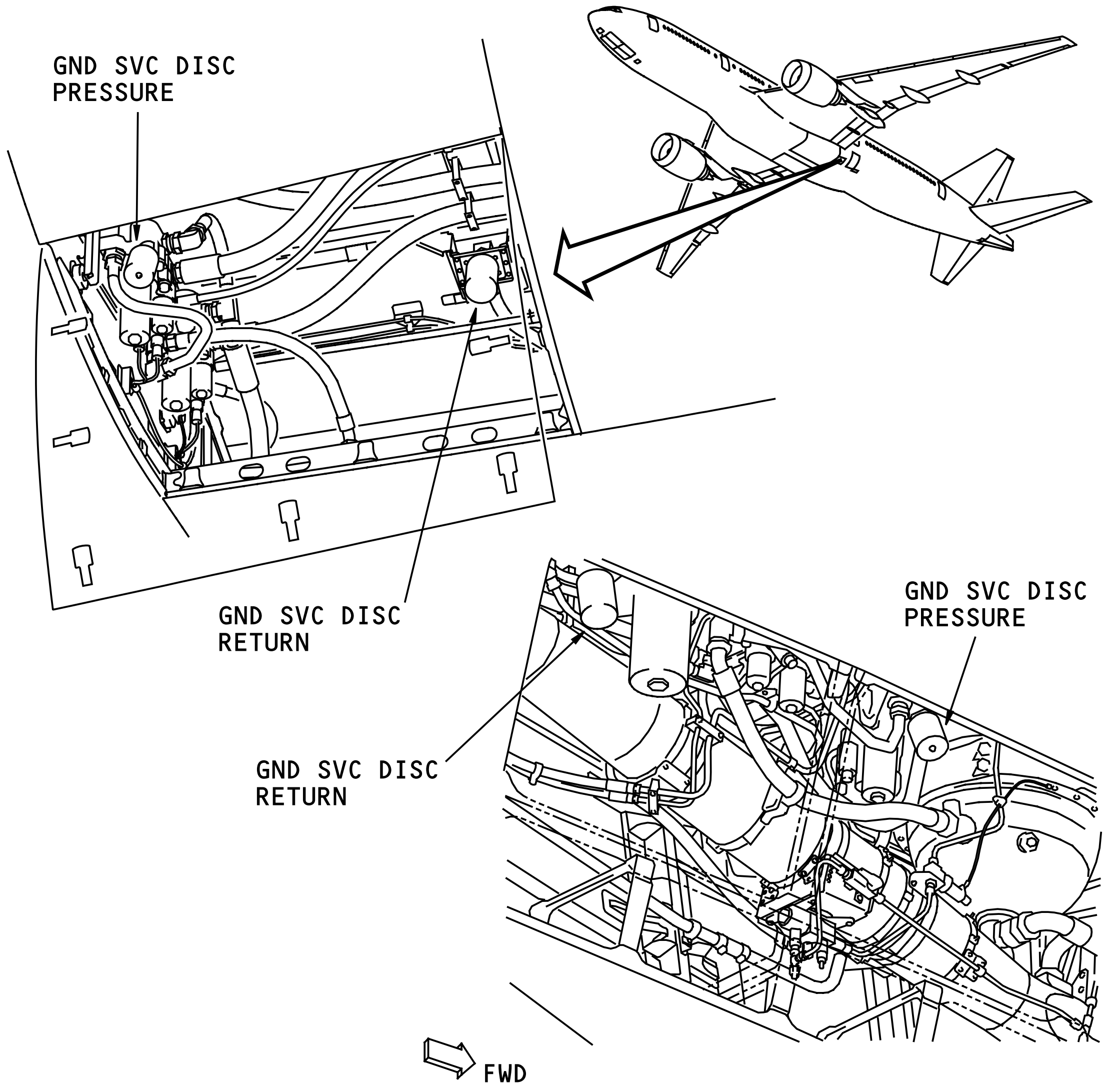
WARNING: KEEP PERSONS AND EQUIPMENT CLEAR OF THE FLIGHT CONTROL SURFACES, THE THRUST REVERSERS, THE LANDING GEAR, AND THE DOORS FOR THE MAIN LANDING GEAR. THESE COMPONENTS CAN MOVE SUDDENLY WHEN YOU SUPPLY HYDRAULIC POWER. THIS CAN CAUSE INJURIES TO PERSONS AND DAMAGE TO EQUIPMENT.

CAUTION: WHEN YOU PRESSURIZE THE MAIN HYDRAULIC SYSTEMS, CAREFULLY MONITOR THE HYDRAULIC INDICATING SYSTEMS IN THE FLIGHT COMPARTMENT TO MAKE SURE THE SYSTEMS OPERATE SATISFACTORILY. IF THE HYDRAULIC FLUID BECOMES TOO HOT, STOP OPERATION OF THE SYSTEM.

CAUTION: DO NOT OPERATE THE HYDRAULIC PUMPS AFTER THE HYDRAULIC TEMPERATURE INDICATION IS MORE THAN 100C (212F) OR AFTER THE PUMP FAULT LIGHT COMES ON. IF YOU CONTINUE TO OPERATE THE PUMPS, THE HYDRAULIC FLUID CAN BECOME TOO HOT.



HYDRAULIC/RAT PANEL (P5)



ENGINE STRUT - RIGHT SIDE

HYDRAULIC POWER - OPERATION

HYDRAULIC POWER - INDICATIONS

General

Hydraulic system data shows on these displays:

- Status display
- Hydraulic synoptic display
- Hydraulic maintenance page.

Status Display

The status display shows the pressure (psi) and the hydraulic reservoir fluid quantity (percent) for each hydraulic system.

Hydraulic Synoptic

The hydraulic synoptic display shows a real time picture of the conditions in the three hydraulic systems.

The hydraulic synoptic display shows these data for normal hydraulic system operation:

- Hydraulic system pressures (psi)
- Hydraulic reservoir fluid quantities (percent)
- Hydraulic pump status (green symbol - pump pressurized, white symbol - pump not pressurized)
- Hydraulic system valve positions (open - green, closed - white).

Green flow lines go from the reservoir symbols through the pump symbols when the pumps operate.

The synoptic display also shows these non-normal conditions:

- Pump failure (amber symbol)
- Valve failure (amber symbol)
- Pump overheat condition (amber OVHT).

Hydraulic Maintenance Page

The hydraulic maintenance page shows for each system:

- Hydraulic system pressures (psi)
- Hydraulic primary and demand pump data (pressure in psi, temperature in degrees C, selector position, and run status)
- RAT pump data (pressure in psi, speed in RPM, and position)
- Hydraulic system reservoir data (quantity in percent, pressure in psi, temperature in degrees C)
- Flight control shutoff valve positions
- Reserve and nose gear isolation valve positions.

Training Information Point

When the hydraulic pumps are off, the system pressure indication shows the pressure in the hydraulic reservoirs.

HYDRAULIC POWER - OPERATIONAL TESTS

General

These are the operational tests for the hydraulic system:

- Air Driven Pump (ADP) (C1)
- Air Driven Pump (ADP) (C2)
- Center hydraulic isolation system (CHIS) test
- Heaters test
- Landing gear auto-off relay A test
- Landing gear auto-off relay B test.

Air Driven Pump Tests

The ADP tests are interactive tests to test the operation of each ADP. These functions are tested during these tests:

- Overspeed protection
- Secondary speed control
- Reserve power
- Auto/On control
- ADP heater operation
- Pressure and temperature indication.

These tests also reset an ADP after an overspeed shutdown.

Center Hydraulic Isolation System (CHIS) Test

This test makes sure CHIS control and indications operate normally. Both isolation valves close and open during this test.

Heaters Test

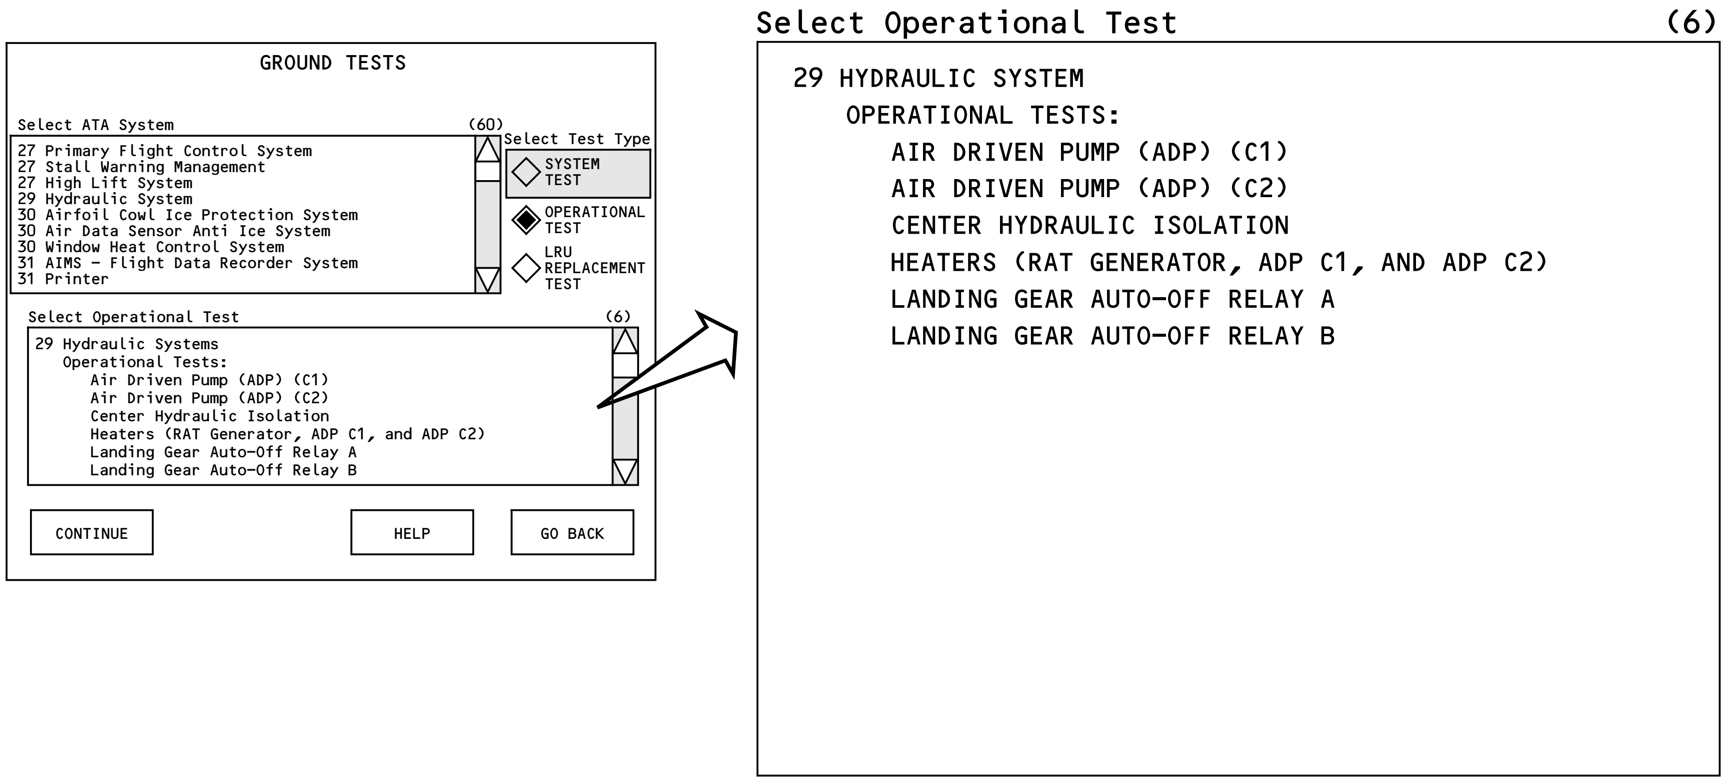
The heaters test makes sure that the RAT heater and the ADP heaters operate normally. This test starts the heaters, then stops them again.

Landing Gear Auto-Off Relay Tests

These tests make sure the landing gear auto-off relays operate correctly. The relays are energized and de-energized during the tests.

Training Information Point

Pneumatic power is necessary to do the air driven pump test.



29-00-00-006 Rev 2 01/10/96

HYDRAULIC POWER - OPERATIONAL TESTS

HYDRAULIC POWER - LRU REPLACEMENT TESTS

General

These are the LRU replacement tests for the hydraulic systems:

- HYDIM CL LRU replacement test
- HYDIM CR LRU replacement test
- HYDIM L LRU replacement test
- HYDIM R LRU replacement test.

HYDIM LRU Replacement Tests

A HYDIM LRU replacement test for each of the four HYDIM cards does a test of the HYDIM cards.

HYDRAULIC POWER - LRU REPLACEMENT TESTS

THIS PAGE INTENTIONALLY LEFT BLANK

MAIN HYDRAULIC SYSTEMS - HYDRAULIC SYSTEM SUMMARY

General

Three independent hydraulic systems supply hydraulic power to airplane systems.

Left Hydraulic System

An EDP is the primary pump for the left hydraulic system. An ACMP is the demand pump for the left hydraulic system.

The left hydraulic system supplies hydraulic power to these systems:

- Flight controls
- Left thrust reverser.

Right Hydraulic System

An EDP is the primary pump for the right hydraulic system. An ACMP is the demand pump for the right hydraulic system.

The right hydraulic system supplies hydraulic power to these systems:

- Flight controls
- Right thrust reverser
- Normal brake system.

Center Hydraulic System

Two ACMPs are the primary pumps for the center hydraulic system. Two ADPs are the demand pumps for the center hydraulic system. A ram air turbine is an emergency source of hydraulic pressure for the center system primary flight controls.

The center hydraulic system supplies hydraulic power to these systems:

- Flight controls
- Leading edge slats
- Trailing edge flaps
- Landing gear actuation
- Alternate and reserve brakes system
- Normal and reserve nose landing gear steering
- Main landing gear steering.

Hydraulic System Servicing

A service bay permits you to fill the three hydraulic systems from a single location.

Hydraulic System Indications

Pressure, temperature, and quantity sensors supply this hydraulic system data:

- System pressures
- Pump pressures
- Reservoir pressures
- Pump temperatures

- Reservoir temperatures
- Reservoir quantities.

LANDING GEAR - INTRODUCTION

32-00-00-001 Rev 2 07/20/1995

LANDING GEAR - GENERAL - INTRODUCTION

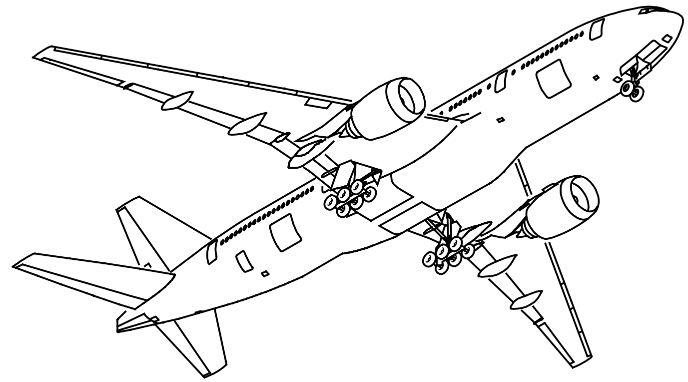
Purpose

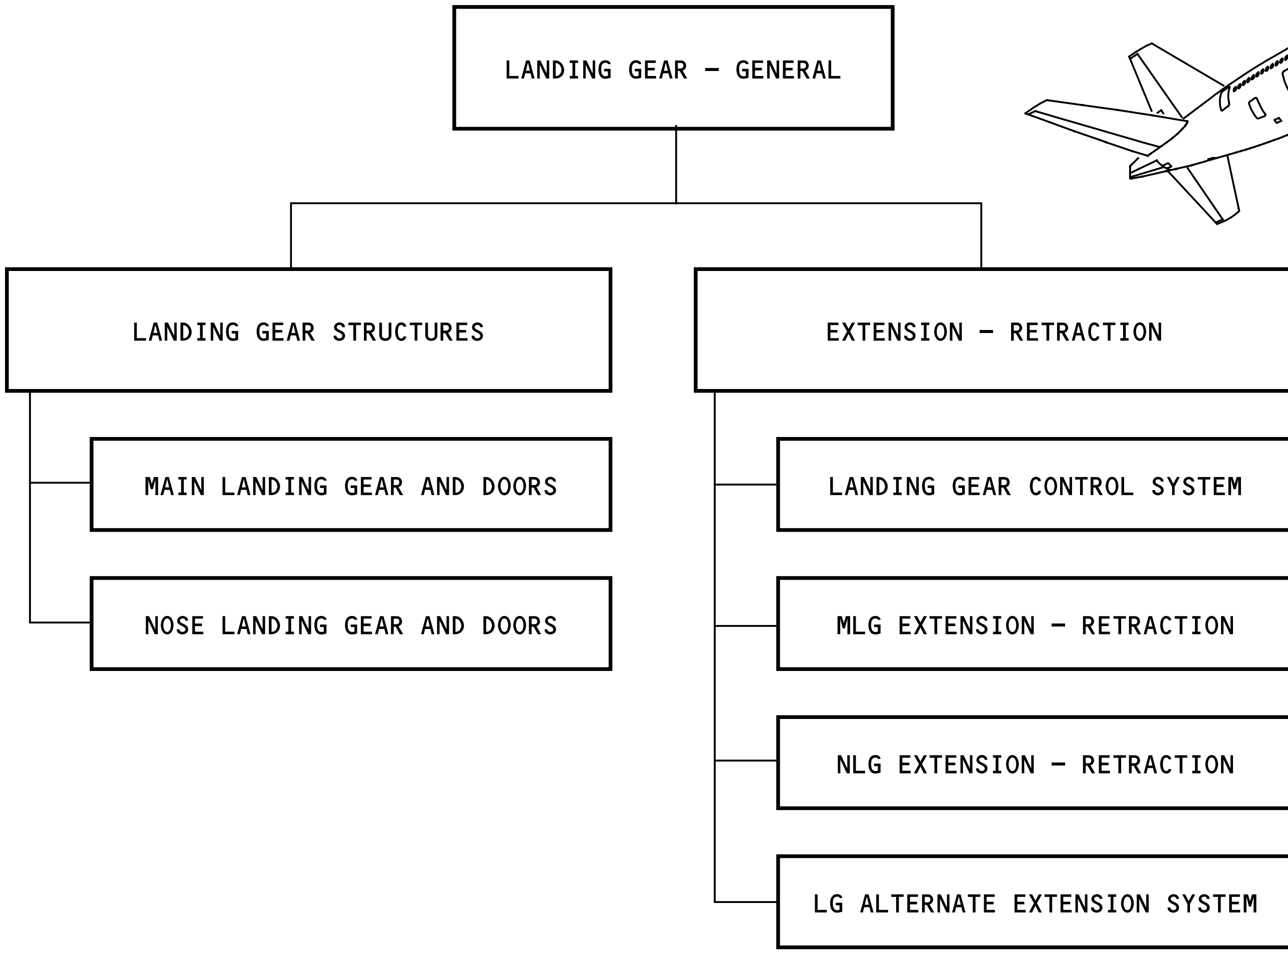
Landing gear structural components hold the weight of the airplane while the airplane is on the ground. These are the landing gear structural systems:

- The main landing gear (MLG) and doors (section 32-10)
- The nose landing gear (NLG) and doors (32-20).

Landing gear extension-retraction systems extends and retracts the landing gear to reduce airplane drag in flight. These are the landing gear extension-retraction systems:

- The landing gear control system (32-31)
- The main landing gear extension and retraction (32-32)
- The nose landing gear extension and retraction (32-34)
- The landing gear alternate extension system (32-35).





32-00-00-002 Rev 0

LANDING GEAR - GENERAL - INTRODUCTION

MAIN LANDING GEAR AND DOORS - INTRODUCTION

General

The two main landing gear absorb landing forces and hold most of the airplane weight when the airplane is on the ground.

The main landing gear doors open to permit MLG operation. The doors close to aerodynamically seal the MLG wheel wells.

Main Landing Gear

Each main landing gear has a six-wheel truck. A drag brace and a side brace hold each gear in the extended position. Lock links hold the drag brace and side brace in the extended position. Over-center toggles, on the lock links, lock the gear in the extended position.

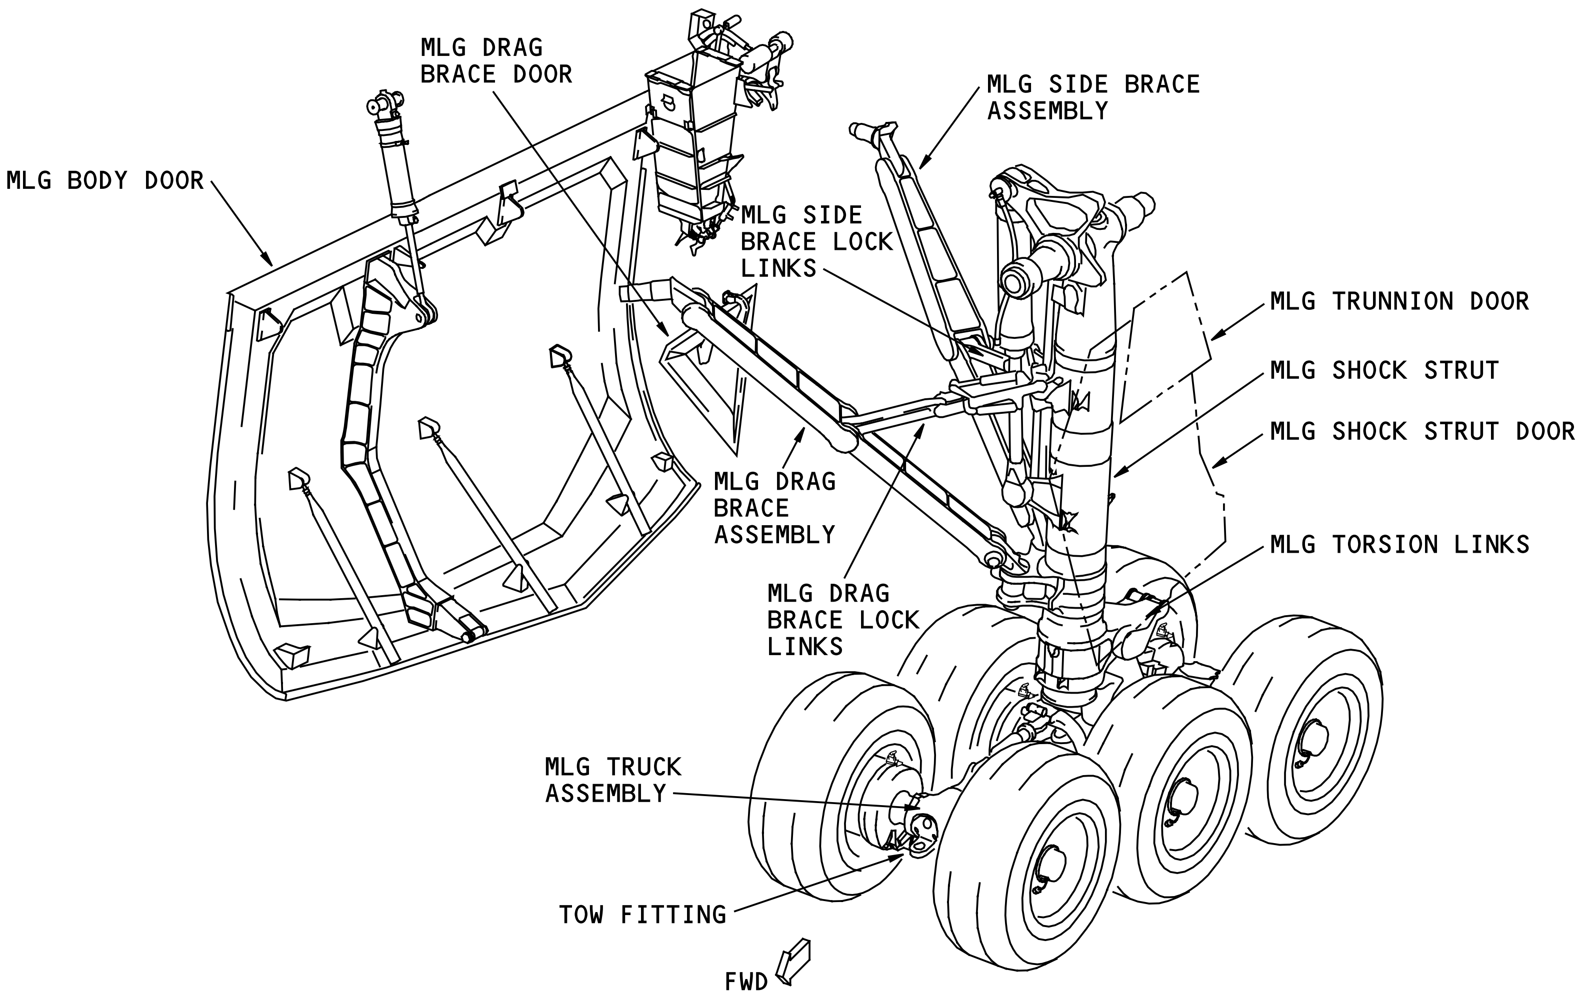
Each main landing gear has these components:

- MLG drag brace assembly
- MLG side brace assembly
- MLG side brace lock links
- MLG drag brace lock links
- MLG torsion links
- MLG truck assembly
- MLG shock strut.

Main Landing Gear Doors

These are the four doors for each main landing gear:

- MLG body door
- MLG drag brace door
- MLG shock strut door
- MLG trunnion door.



<u>LEFT MAIN LANDING GEAR AND DOORS</u>

32-10-00-001 Rev 2 03/28/96

MAIN LANDING GEAR AND DOORS - INTRODUCTION

MAIN LANDING GEAR AND DOORS - SIDE BRACE ASSEMBLY, DRAG BRACE ASSEMBLY, AND LOCK LINKS

General

The MLG side brace assembly and the MLG drag brace assembly hold the main landing gear in the extended position. They also supply lateral support to the main landing gear.

Lock links hold the braces in the down position. Toggles on the lock links hold the lock links in the locked position.

MLG Drag Brace Assembly

The MLG drag brace assembly is on the forward side of each main landing gear. The upper and lower drag braces connect by a hinge.

A spindle on the upper drag brace pivots around a fitting in the forward part of the main gear wheel well.

A spindle on the lower drag brace pivots around a fitting on the main gear shock strut.

MLG Drag Brace Lock Links

The MLG drag brace lock links hold the MLG drag brace when the gear is in the extended position. Upper and lower toggles connect to the upper and lower lock links. These toggles move to an over-center locked position when the gear is down. Two springs hold the toggles in the over-center locked position.

MLG Side Brace Assembly

The MLG side brace assembly is on the aft side of the main landing gear. Upper and lower side braces connect by a hinge.

A spindle on the upper side brace pivots around a fitting in the inboard end of the main landing gear beam.

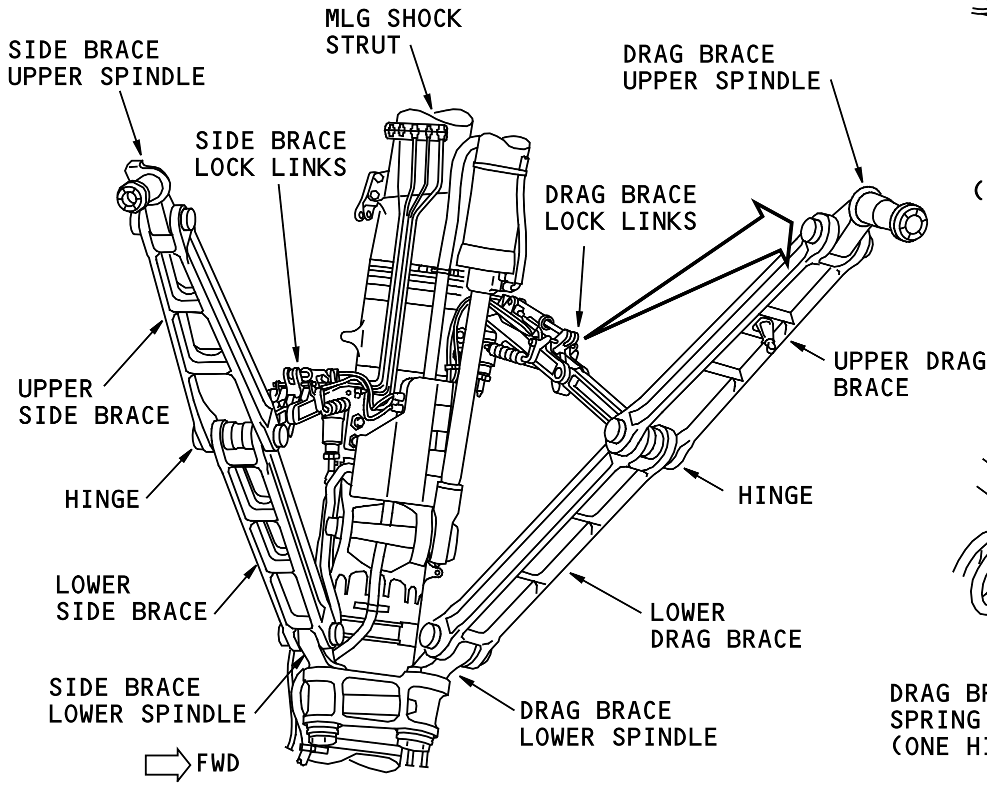
A spindle on the lower side brace pivots around a fitting on the main gear shock strut.

MLG Side Brace Lock Links

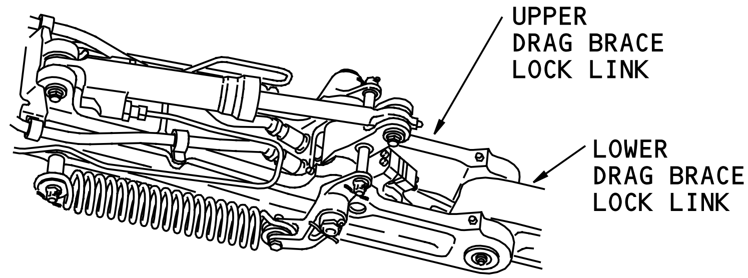
The MLG side brace lock links hold the MLG side brace when the gear is in the extended position. Upper and lower toggles connect to the upper and lower lock links. These toggles move to an over-center locked position when the gear is down. Two springs hold the toggles in the over-center locked position.

Training Information Point

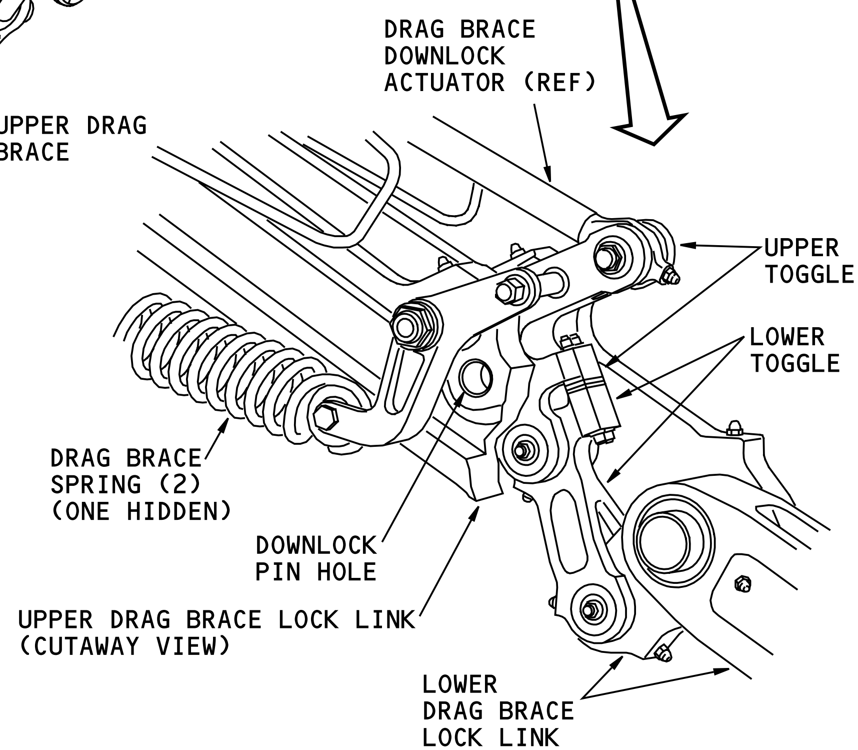
You install downlock pins in the upper side brace lock link and the upper drag brace lock link. Each pin holds the upper toggle and the upper lock link together. The pins prevent MLG retraction.



LEFT MAIN LANDING GEAR
DRAG BRACE AND SIDE BRACE



MLG DRAG BRACE LOCK LINKS
(SIDE BRACE LOCK LINKS SIMILAR)



MAIN LANDING GEAR AND DOORS - SIDE BRACE ASSEMBLY, DRAG BRACE ASSEMBLY, AND LOCK LINKS

MAIN LANDING GEAR AND DOORS - TRUCK ASSEMBLY

General

Each main landing gear truck has these components:

- Axles
- Tow fittings
- Brake rods
- Wheels and tires
- Brakes
- Truck positioner actuator
- Main gear steering components.

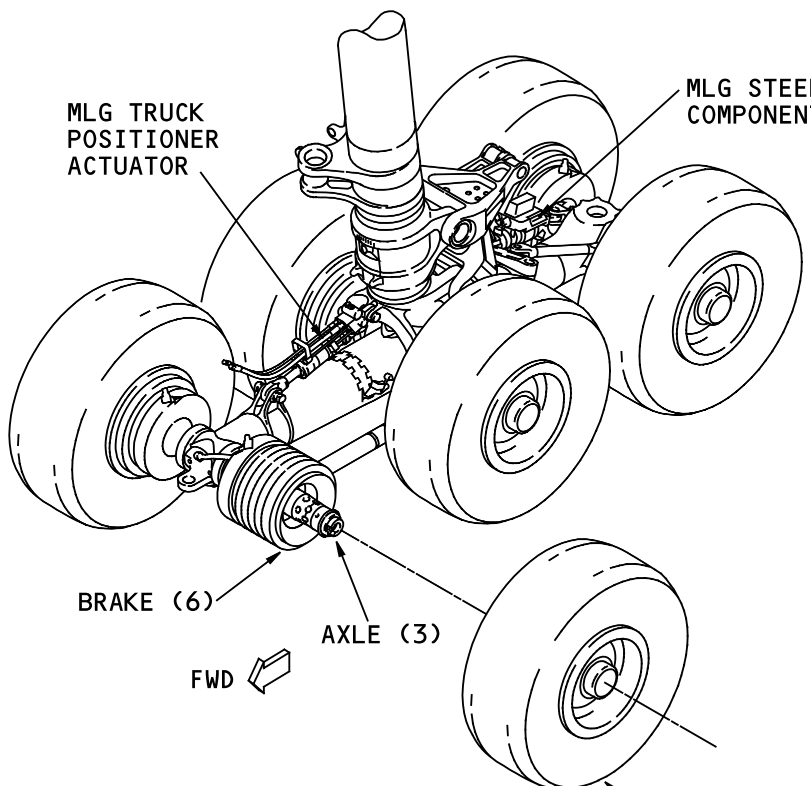
There are three axles on each MLG truck. A jacking point is under the center of the forward and aft axles.

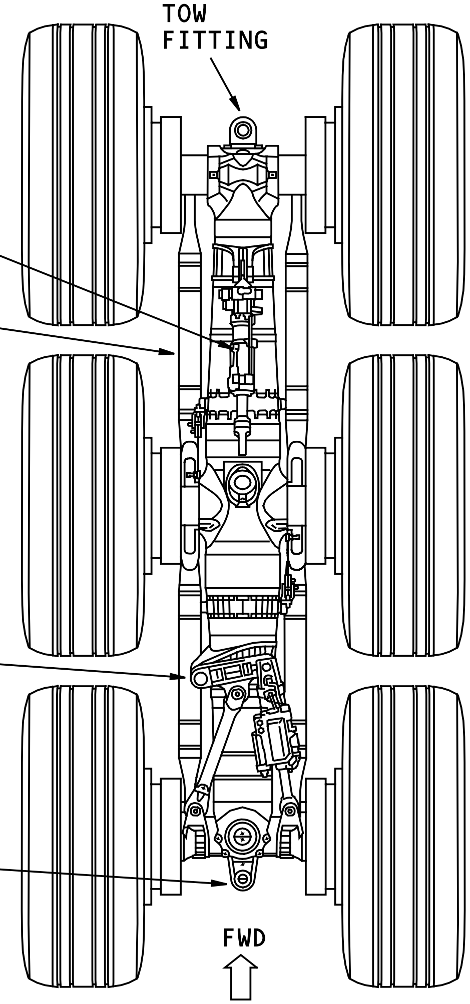
A tow fitting is on the forward part of the MLG truck. There is also a tow fitting/jackpoint on the aft part of the MLG truck.

Brake rods attach the brakes to the MLG shock strut to prevent rotation.

The truck positioner actuator tilts the MLG truck up and down when the airplane is in the air. See the MLG extension-retraction section for more information on the truck positioner actuator (AMM PART I 32-32).

The main landing gear steering components steer the aft axle eight degrees left or right. See the main gear steering section for more information (AMM PART I 32-53).





MAIN LANDING GEAR TRUCK
(TOP VIEW)

32-10-00-003 Rev 4 08/03/95

MAIN LANDING GEAR AND DOORS - TRUCK ASSEMBLY

MAIN LANDING GEAR AND DOORS - SHOCK STRUT

Purpose

The main landing gear shock struts absorb landing forces and transmit vertical loads to the airplane structure.

Physical Description

The shock struts are standard forged steel air-oil shock absorbers. They have an inner cylinder which moves inside an outer cylinder.

Compressed dry nitrogen is in the upper part of the shock strut. BMS3-32 hydraulic fluid is in the lower part of the shock strut.

Torsion links on the aft part of the shock strut connect the inner and outer cylinders.

Shock Strut Seals

A static seal and a dynamic seal keep the nitrogen and the hydraulic fluid in the shock strut. The static seal is between the lower bearing and the outer cylinder. The dynamic seal is between the lower bearing and the inner cylinder.

There are two spare static seals in the shock strut. There are also two spare dynamic seals and dynamic seal backup rings in the shock strut. The spare dynamic seals and backup rings are on the spare seal carrier. These permit change of faulty seals without removal of the inner cylinder.

Training Information Point

The dynamic seal is not the same as the spare dynamic seals. The spare dynamic seals are more flexible. This permits installation of the spare dynamic seals on to the larger diameter of the spare seal carrier.

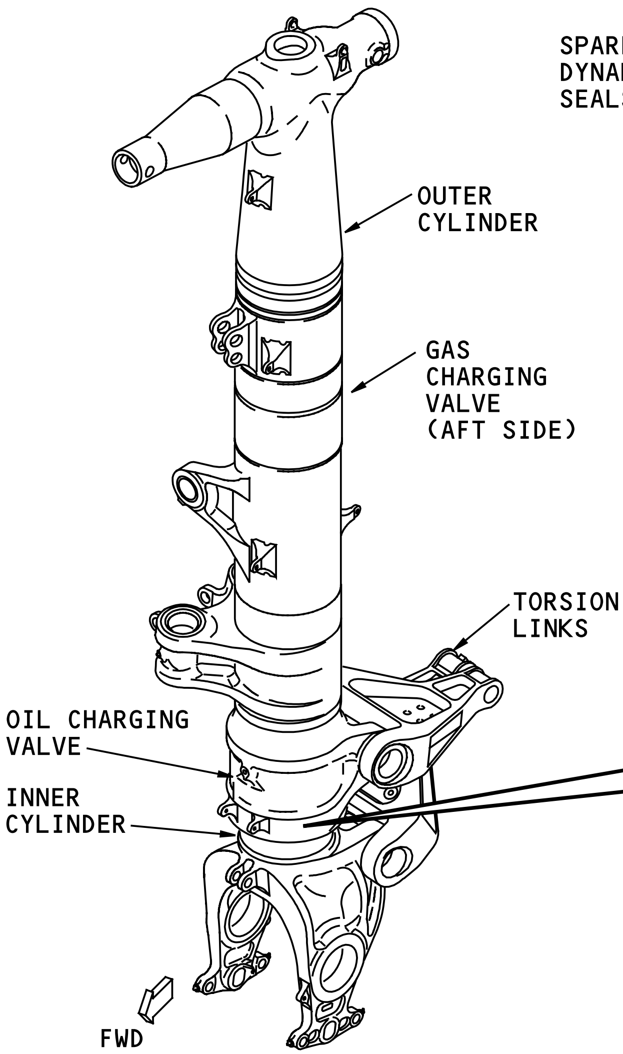
A gas charging valve (not shown) is on the aft side of the MLG shock strut near the side brace lock links.

The oil charging valve is on the front of the shock strut forward of the upper torsion link.

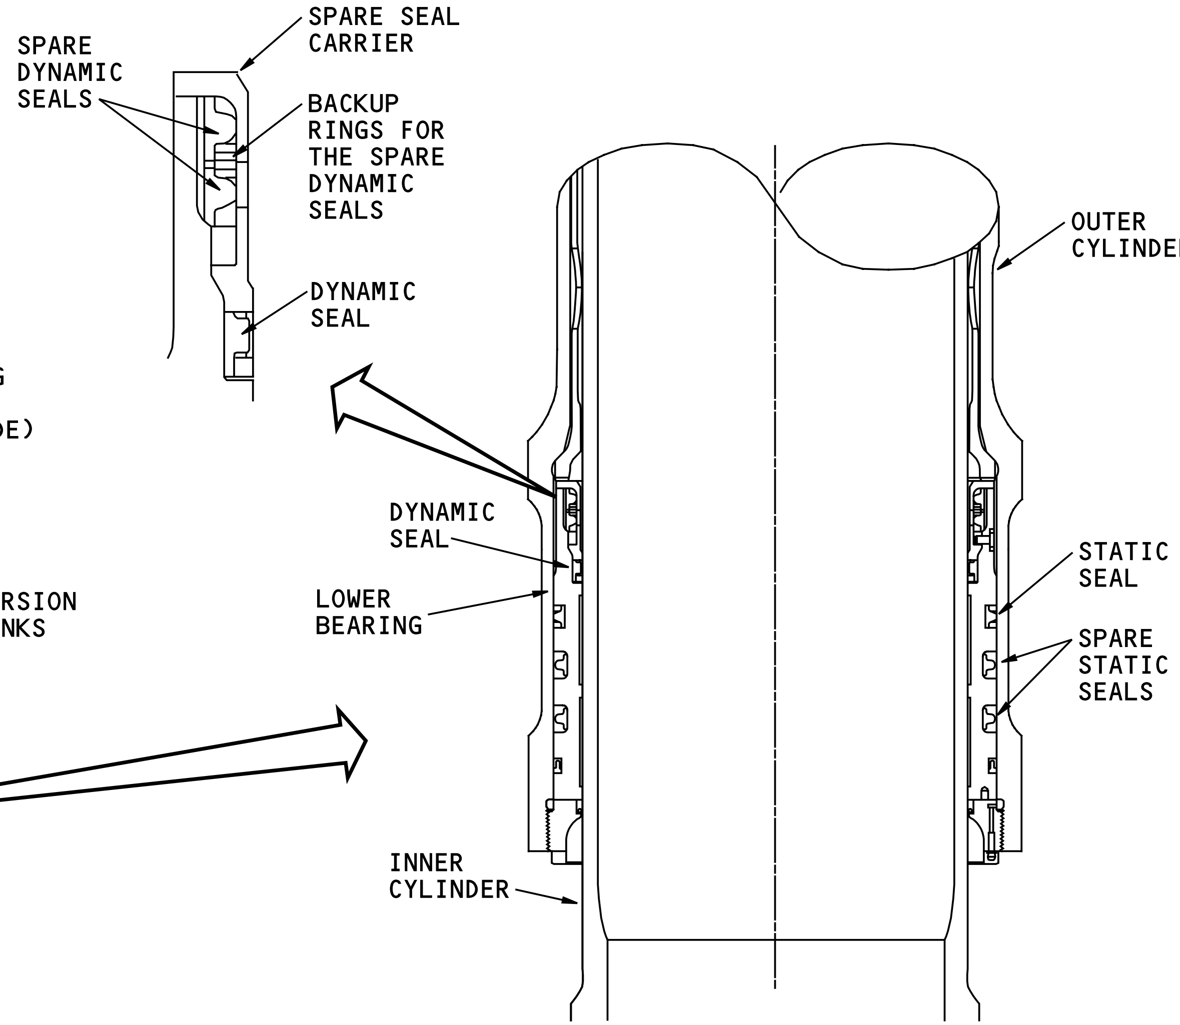
A servicing chart (not shown) is on the main landing gear shock strut door.

CAUTION: WHEN SERVICING THE SHOCK STRUT WITH FLUID, USE ONLY THE FLUID SPECIFIED ON THE NAMEPLATE. FLUIDS WHICH ARE NOT COMPATIBLE OR OF THE WRONG TYPE WILL CAUSE THE SEALS TO DETERIORATE AND RESULT IN LEAKS.

WARNING: DO NOT REMOVE THE AIR VALVE BODY UNTIL THE SHOCK STRUT HAS BEEN DEFLATED. INTERNAL PRESSURE CAN BLOW THE VALVE OUT, CAUSING INJURY TO PERSONNEL.



MAIN GEAR SHOCK STRUT



MAIN GEAR SHOCK STRUT SEALS

32-10-00-004 Rev 3 03/17/1997

MAIN LANDING GEAR AND DOORS - SHOCK STRUT

NOSE LANDING GEAR AND DOORS - INTRODUCTION

General

The nose landing gear absorbs landing forces and holds the forward part of the airplane weight when the airplane is on the ground. The nose gear also steers the airplane on the ground.

The nose landing gear doors open to permit gear operation and close to aerodynamically seal the NLG wheel well.

Nose Landing Gear

The nose landing gear is a conventional two wheel gear. A drag strut assembly holds the nose gear in the extended or retracted position. A lock link assembly moves to the over-center position to lock the drag strut in either position.

These are the nose landing gear components:

- NLG drag strut assembly
- NLG lock link assembly
- NLG torsion links
- NLG shock strut.

Nose Landing Gear Doors

Two forward and two aft doors aerodynamically seal the nose gear wheel well to reduce drag.

The forward doors attach to the outer edge of the NLG wheel well. A hydraulic actuator opens and closes the forward doors.

The aft doors attach to the outer edge of the wheel well. They connect to the shock strut and move mechanically with the gear during extension and retraction.

Training Information Point

There is a tow fitting forward of the shock strut between the nose landing gear tires.

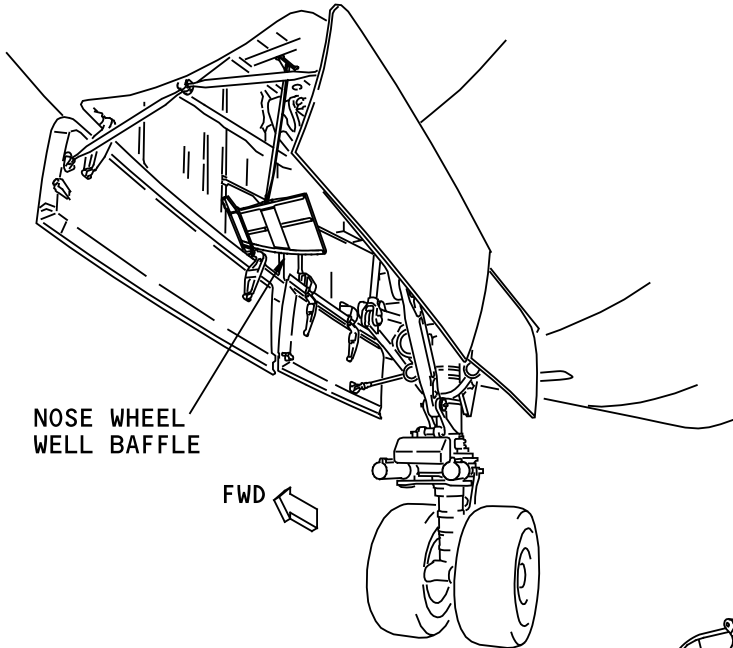
You can disconnect the torsion links to permit the nose landing gear to move greater than the normal steering limits (70 degrees).

The nose landing gear doors are made of composite materials.

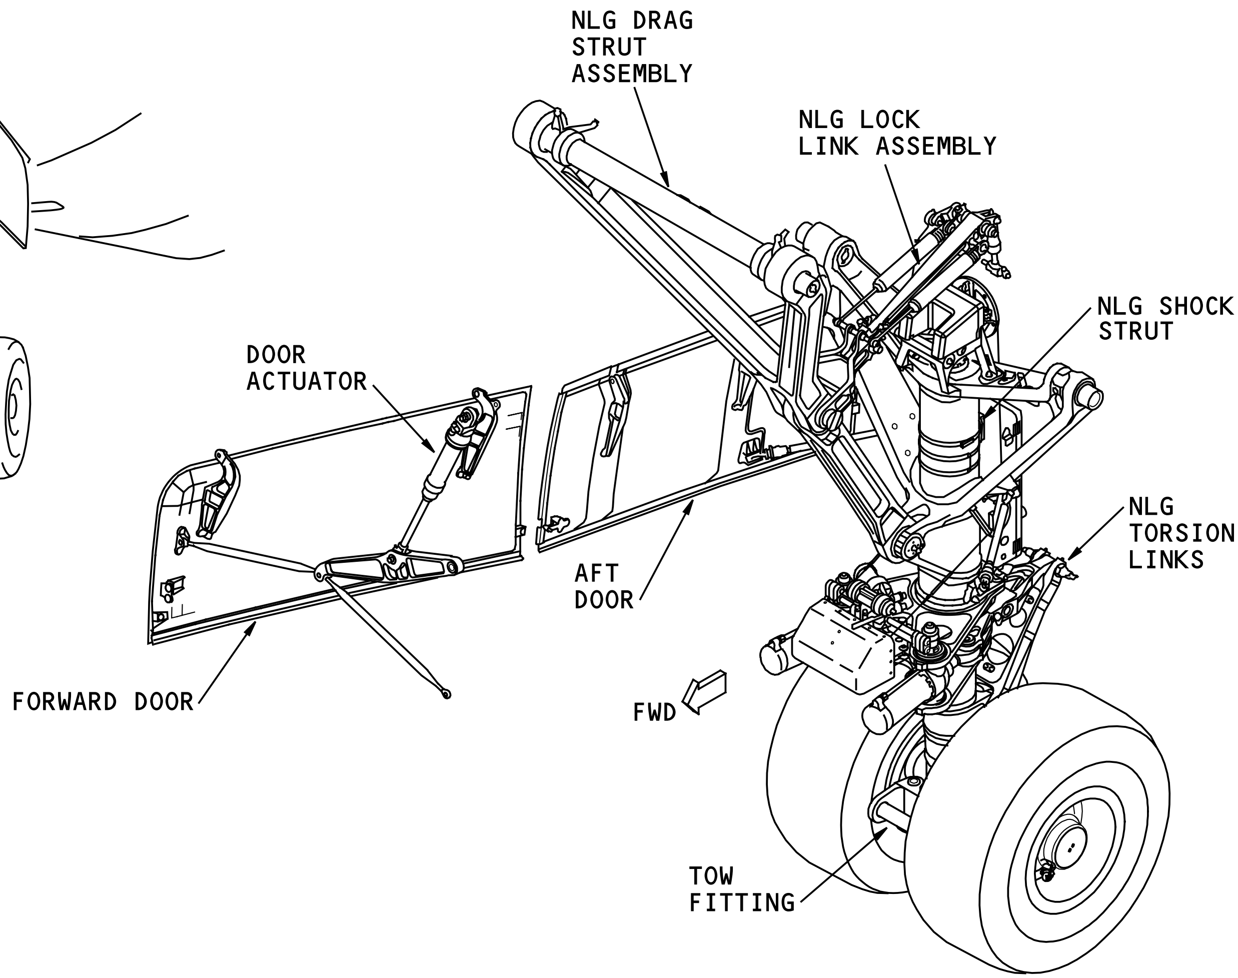
You use the alternate extension system to operate the forward NLG doors on the ground.

See the alternate extension system section for more information on the NLG door operation (AMM PART I 32-35).

Nose wheel well baffles on the left and right sides of the wheel well decreases landing gear door vibrations during gear operation.



NOSE LANDING GEAR



32-20-00-001 Rev 5 03/17/1997

NOSE LANDING GEAR AND DOORS - INTRODUCTION

NOSE LANDING GEAR AND DOORS - SHOCK STRUT

Purpose

The nose landing gear shock strut absorbs airplane landing forces and transmits vertical loads to the airplane structure.

Physical Description

The nose landing gear shock strut is a standard forged steel air-oil shock strut. It has an inner and an outer cylinder.

Compressed dry nitrogen is in the upper part of the shock strut. BMS3-32 hydraulic fluid is in the lower part of the shock strut.

Torsion links on the aft part of the shock strut connect the inner and outer cylinders.

Centering cams inside the shock strut center the nose wheels when the shock strut extends.

Shock Strut Seals

A static seal and a dynamic seal keep the nitrogen and the hydraulic fluid in the shock strut. The static seal is between the lower bearing and the outer cylinder. The dynamic seal is between the lower bearing and the inner cylinder.

There are two spare static seals, one spare dynamic seal, and backup rings for the spare dynamic seal in the shock strut. The spare seals permit change of faulty seals without removal of the inner cylinder.

Training Information Point

The dynamic seal is not the same as the spare dynamic seal. The spare dynamic seal is more flexible. This permits installation of the spare dynamic seal on to the larger diameter of the spare seal carrier.

A gas charging valve is on the top of the nose landing gear shock strut.

The oil charging valve is on the left side of the shock strut.

A servicing chart (not shown) is on the right aft nose landing gear door.

CAUTION: WHEN SERVICING THE SHOCK STRUT WITH FLUID, USE ONLY THE FLUID SPECIFIED ON THE NAMEPLATE. FLUIDS WHICH ARE NOT COMPATIBLE OR OF THE WRONG TYPE WILL CAUSE THE SEALS TO DETERIORATE AND RESULT IN LEAKS.

WARNING: DO NOT REMOVE THE AIR VALVE BODY UNTIL THE SHOCK STRUT HAS BEEN DEFLATED. INTERNAL PRESSURE CAN BLOW THE VALVE OUT, CAUSING INJURY TO PERSONNEL.

NOSE LANDING GEAR AND DOORS - SHOCK STRUT

NOSE LANDING GEAR AND DOORS - DRAG STRUT AND LOCK LINK ASSEMBLIES

General

Drag strut and lock link assemblies hold the nose landing gear in the extended and retracted positions.

Drag Strut Assembly

The drag strut assembly has upper and lower struts which attach by a hinge in the center.

The upper drag strut is trunnion-mounted to the side walls in the nose wheel well.

The lower drag strut attaches to a hinge on the shock strut.

Lock Link Assembly

The lock link assembly has forward and aft lock links and two lock springs.

The forward and aft lock links attach by a hinge.

The lock springs help keep the lock link in the locked position.

Training Information Point

A lock pin hole in the lock link assembly permits you to install a down lock pin. Use this pin to keep the nose gear in the down and locked position.

EXTENSION-RETRACTION - INTRODUCTION

General

Extension and retraction lowers and raises the landing gear.

These are part of extension and retraction:

- The landing gear control system (32-31)
- The main landing gear extension and retraction (32-32)
- The nose landing gear extension and retraction (32-34)
- The landing gear alternate extension system (32-35).

EXTENSION–RETRACTION

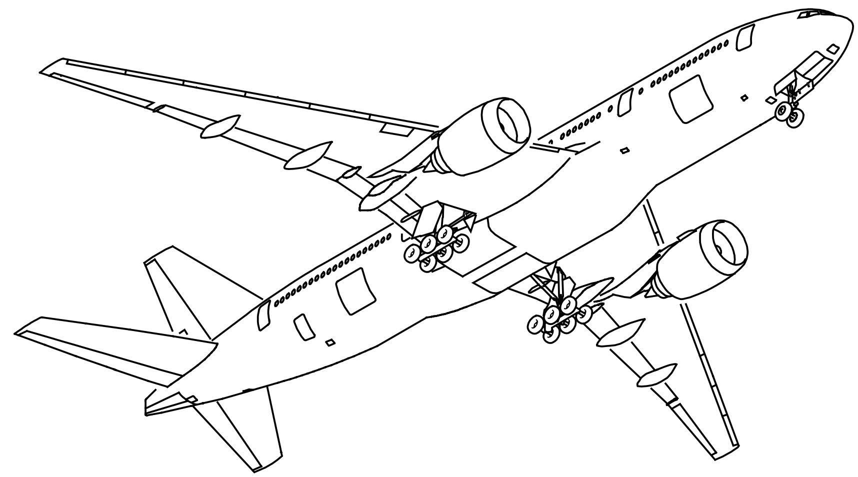
- LANDING GEAR ALTERNATE EXTENSION SYSTEM



32-30-00-001 Rev 2

EXTENSION–RETRACTION – INTRODUCTION

LANDING GEAR CONTROL SYSTEM - INTRODUCTION

Purpose

The landing gear control system controls the extension and retraction of the main and nose landing gears.

Components

Landing gear control system components are:

- The landing gear control lever module
- The NLG selector/bypass valve
- The MLG selector/bypass valve.

Location

The landing gear control lever is on the P2 center instrument panel.

The NLG selector/bypass valve is in the NLG wheel well.

The MLG selector bypass valve is the right MLG wheel well.

General Description

Landing gear control is electrical. A two-position (UP and DOWN) landing gear control lever controls the extension and retraction.

When the airplane is on the ground, a landing gear lever lock solenoid locks the landing gear lever in the DOWN position. A solenoid releases the lock when the airplane is in the air.

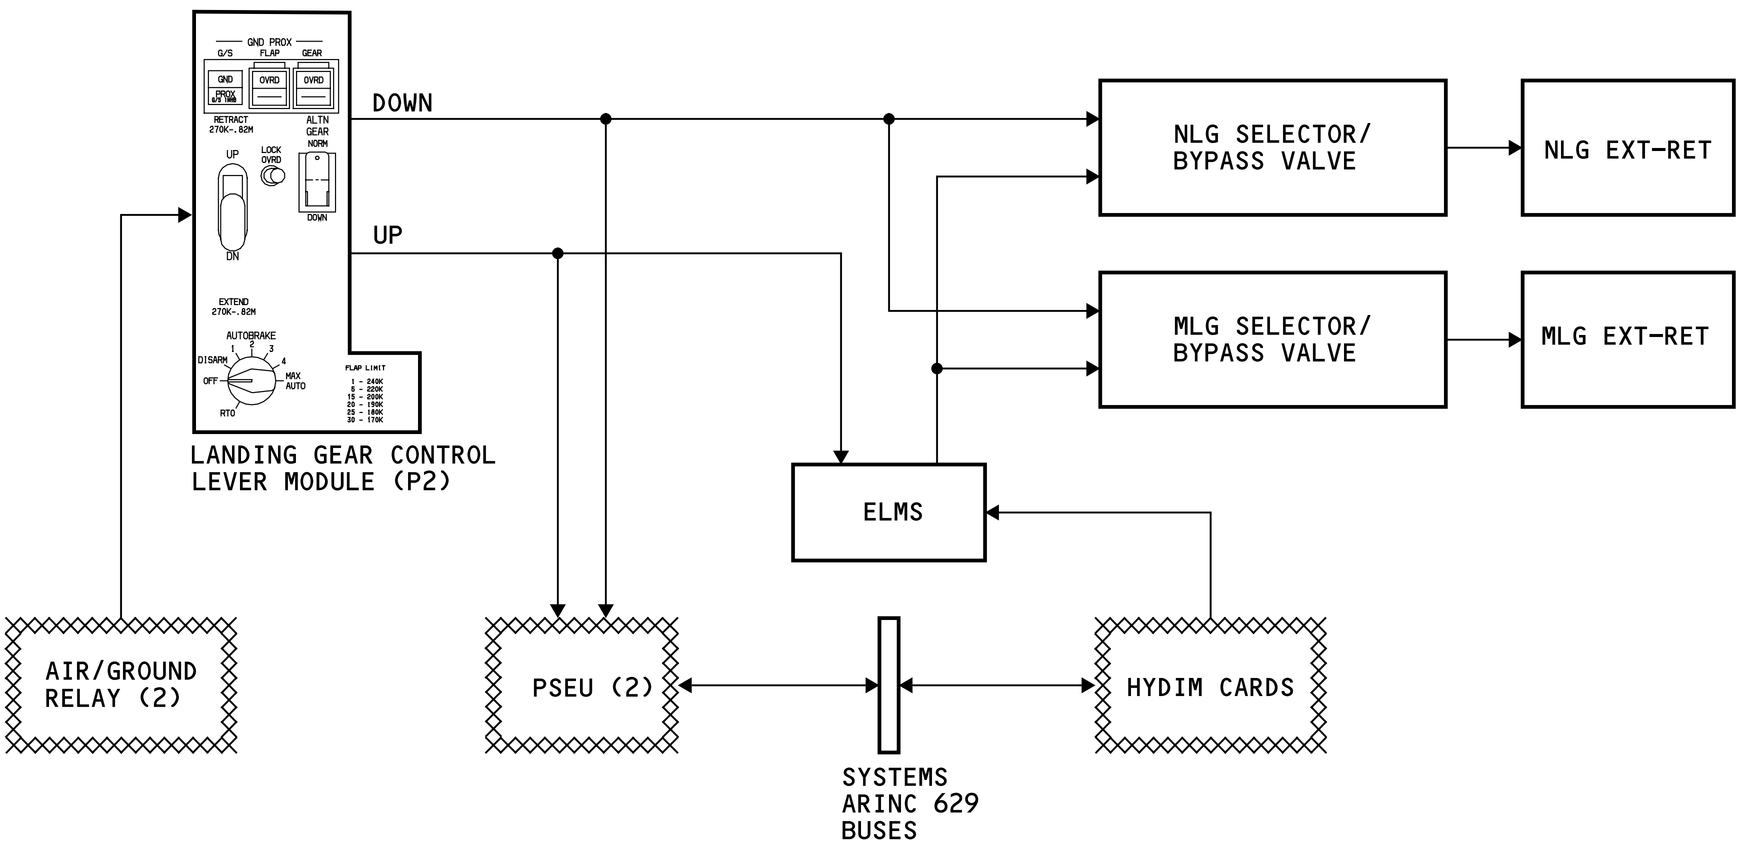
Auto-off relays in ELMS remove the gear-up signal ten seconds after the landing gear retracts. This removes the pressure from the landing gear components.

Interfaces

The proximity sensor electronics unit (PSEUs) get landing gear lever position. The PSEUs also supply landing gear position data to the HYDIM cards.

The HYDIM cards control the auto-off relays in ELMS.

Air/ground relays control the landing gear lever lock solenoid.



32-31-00-001 Rev 0

LANDING GEAR CONTROL SYSTEM - INTRODUCTION

LANDING GEAR CONTROL SYSTEM - LANDING GEAR CONTROL LEVER MODULE

Purpose

The landing gear control lever module sends signals to the landing gear selector/bypass valves to extend and retract the landing gear.

Physical Description

The module has these components:

- Lever
- Switches
- Lock mechanism.

Location

The landing gear lever is on the P2 center forward panel.

Functional Description

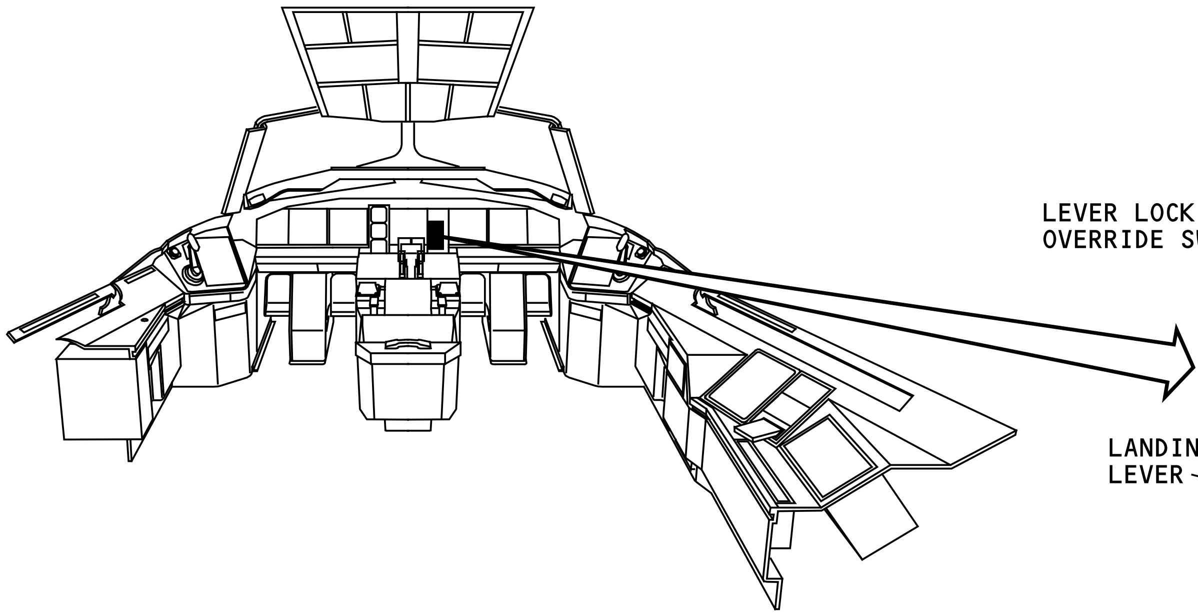
The lever has two positions with detents: UP and DN. You must first pull the lever out before you can raise or lower the lever.

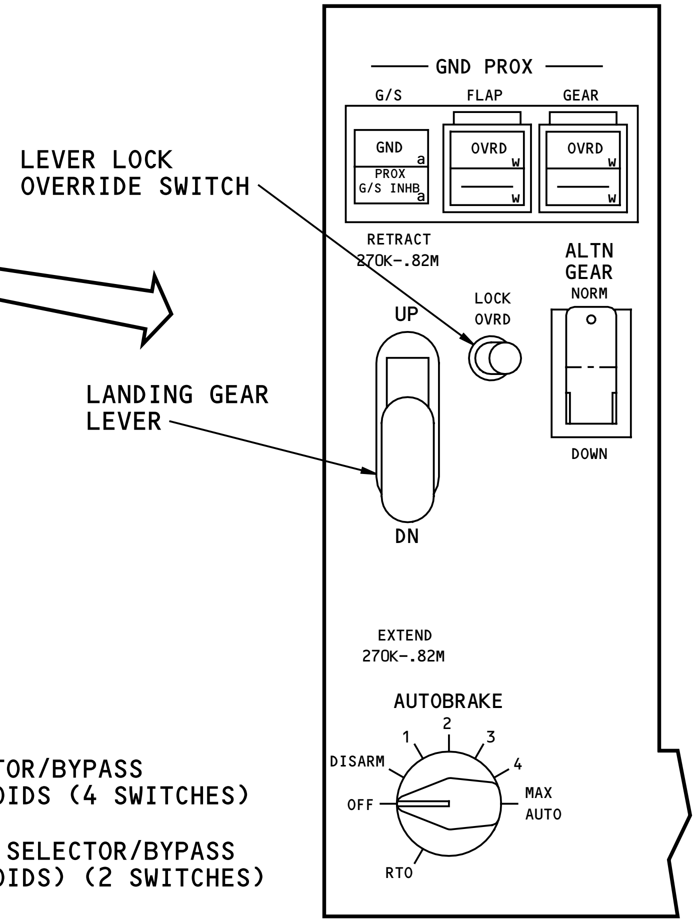
The lever has seven internal switches. Four of these switches control power and ground to the down solenoids in the NLG and MLG selector/bypass valves. Two switches go to the ELMS to control power to the up solenoids in the NLG and MLG selector/bypass valves. One switch resets the gear door release/safety valve modules after an alternate gear extension or ground door operation.

The module also has a solenoid controlled lever lock mechanism. The lever lock prevents accidental movement of the control lever from DN to UP when the airplane is on the ground. When the aircraft takes off, the solenoid gets electrical power and releases the lever lock.

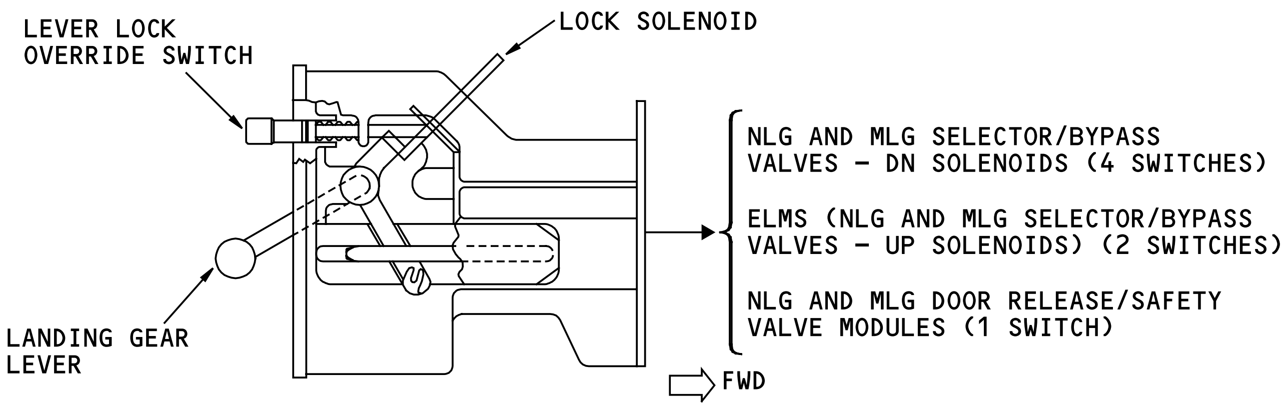
Training Information Point

You can mechanically release the landing gear lever lock with the lever lock override switch.





LANDING GEAR PANEL (P2)



LANDING GEAR CONTROL LEVER MODULE

LANDING GEAR CONTROL SYSTEM - LANDING GEAR CONTROL LEVER MODULE

LANDING GEAR CONTROL SYSTEM - LANDING GEAR SELECTOR/BYPASS VALVES - INTRODUCTION

Purpose

The NLG selector/bypass valve controls extend and retract pressure to NLG extension and retraction components.

The MLG selector/bypass valve controls extend and retract pressure to the left and the right MLG extension and retraction components.

The NLG and MLG selector/bypass valves operate the same way. The MLG selector/bypass valve is larger to permit higher hydraulic flow.

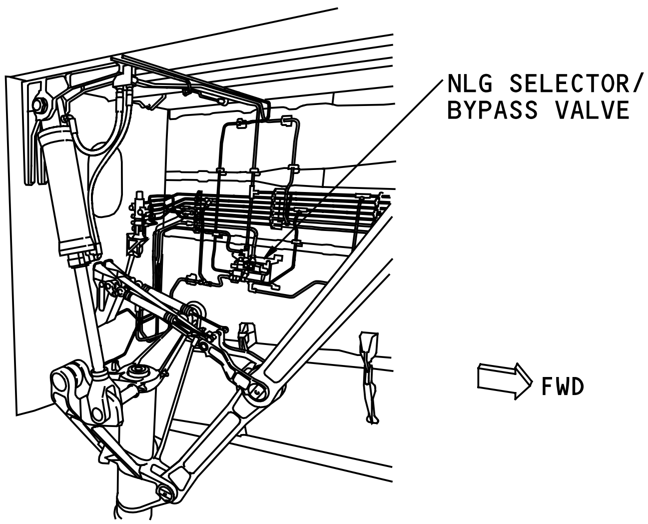
Location

The NLG selector/bypass valve is on the left bulkhead in the NLG wheel well.

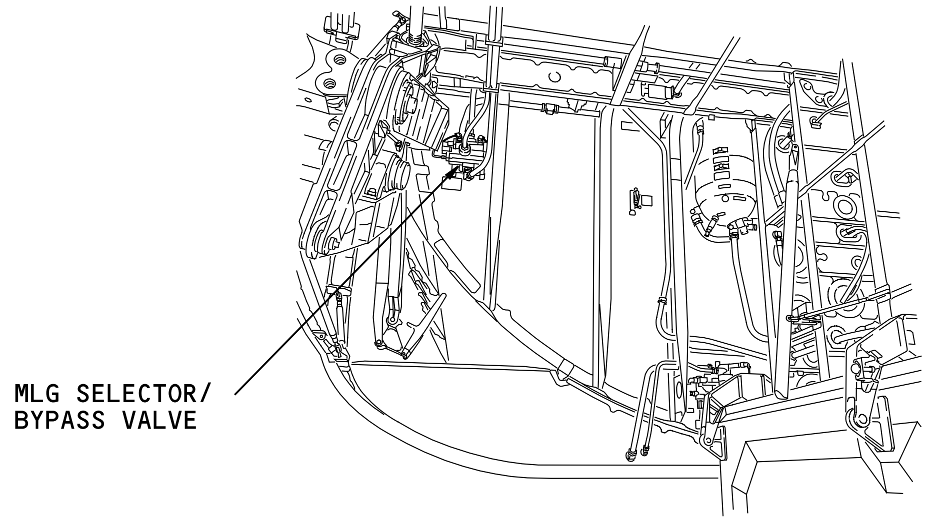
The MLG selector/bypass valve is on the aft bulkhead in the right MLG wheel well.

Training Information Point

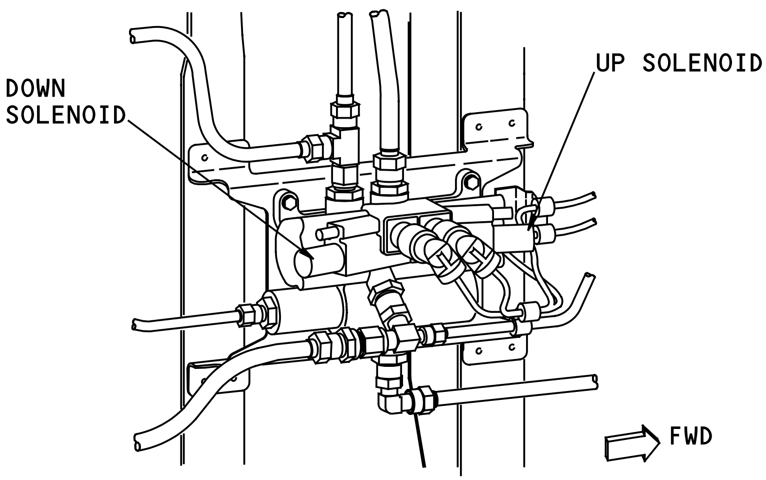
The solenoids on the selector/bypass valves are LRUs.



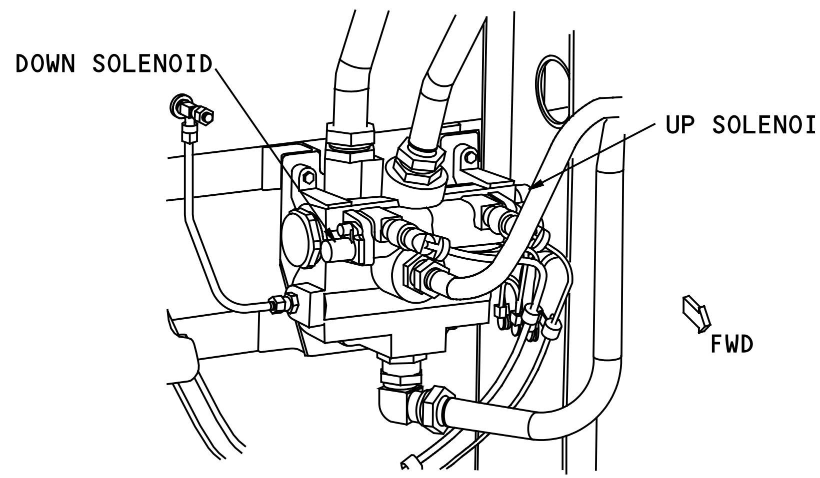
NLG WHEEL WELL



RIGHT MLG WHEEL WELL - AFT BULKHEAD



NLG SELECTOR/BYPASS VALVE



MLG SELECTOR/BYPASS VALVE

LANDING GEAR CONTROL SYSTEM - LANDING GEAR SELECTOR/BYPASS VALVES - INTRODUCTION

LANDING GEAR CONTROL SYSTEM - FUNCTIONAL DESCRIPTION

General

The landing gear control system controls landing gear extension and retraction.

Lever Lock

When the airplane is in the air, two air/ground relays in the ELMS supply a ground to energize the lever lock solenoid. This releases the lock on the landing gear control lever and permits you to move the control lever UP.

Retraction

When you put the landing gear control lever UP, two switches in the landing gear control lever module supply power to auto-off relays in ELMS. The auto-off relays supply the power to UP solenoid in each of the landing gear selector/bypass valves.

Hydraulic pressure then goes through the selector/ bypass valves to the UP lines for gear retraction.

Another switch in the landing gear control lever module resets the alternate extension system MLG and NLG door release/safety valve modules.

Auto-Off

After gear retraction, the PSEUs send signals to the HYDIM cards L and R. After a ten second delay, the HYDIM cards energize the auto-off relays in the ELMS.

This removes electrical power from the UP solenoid and the selector valve moves to OFF to remove pressure from the landing gear.

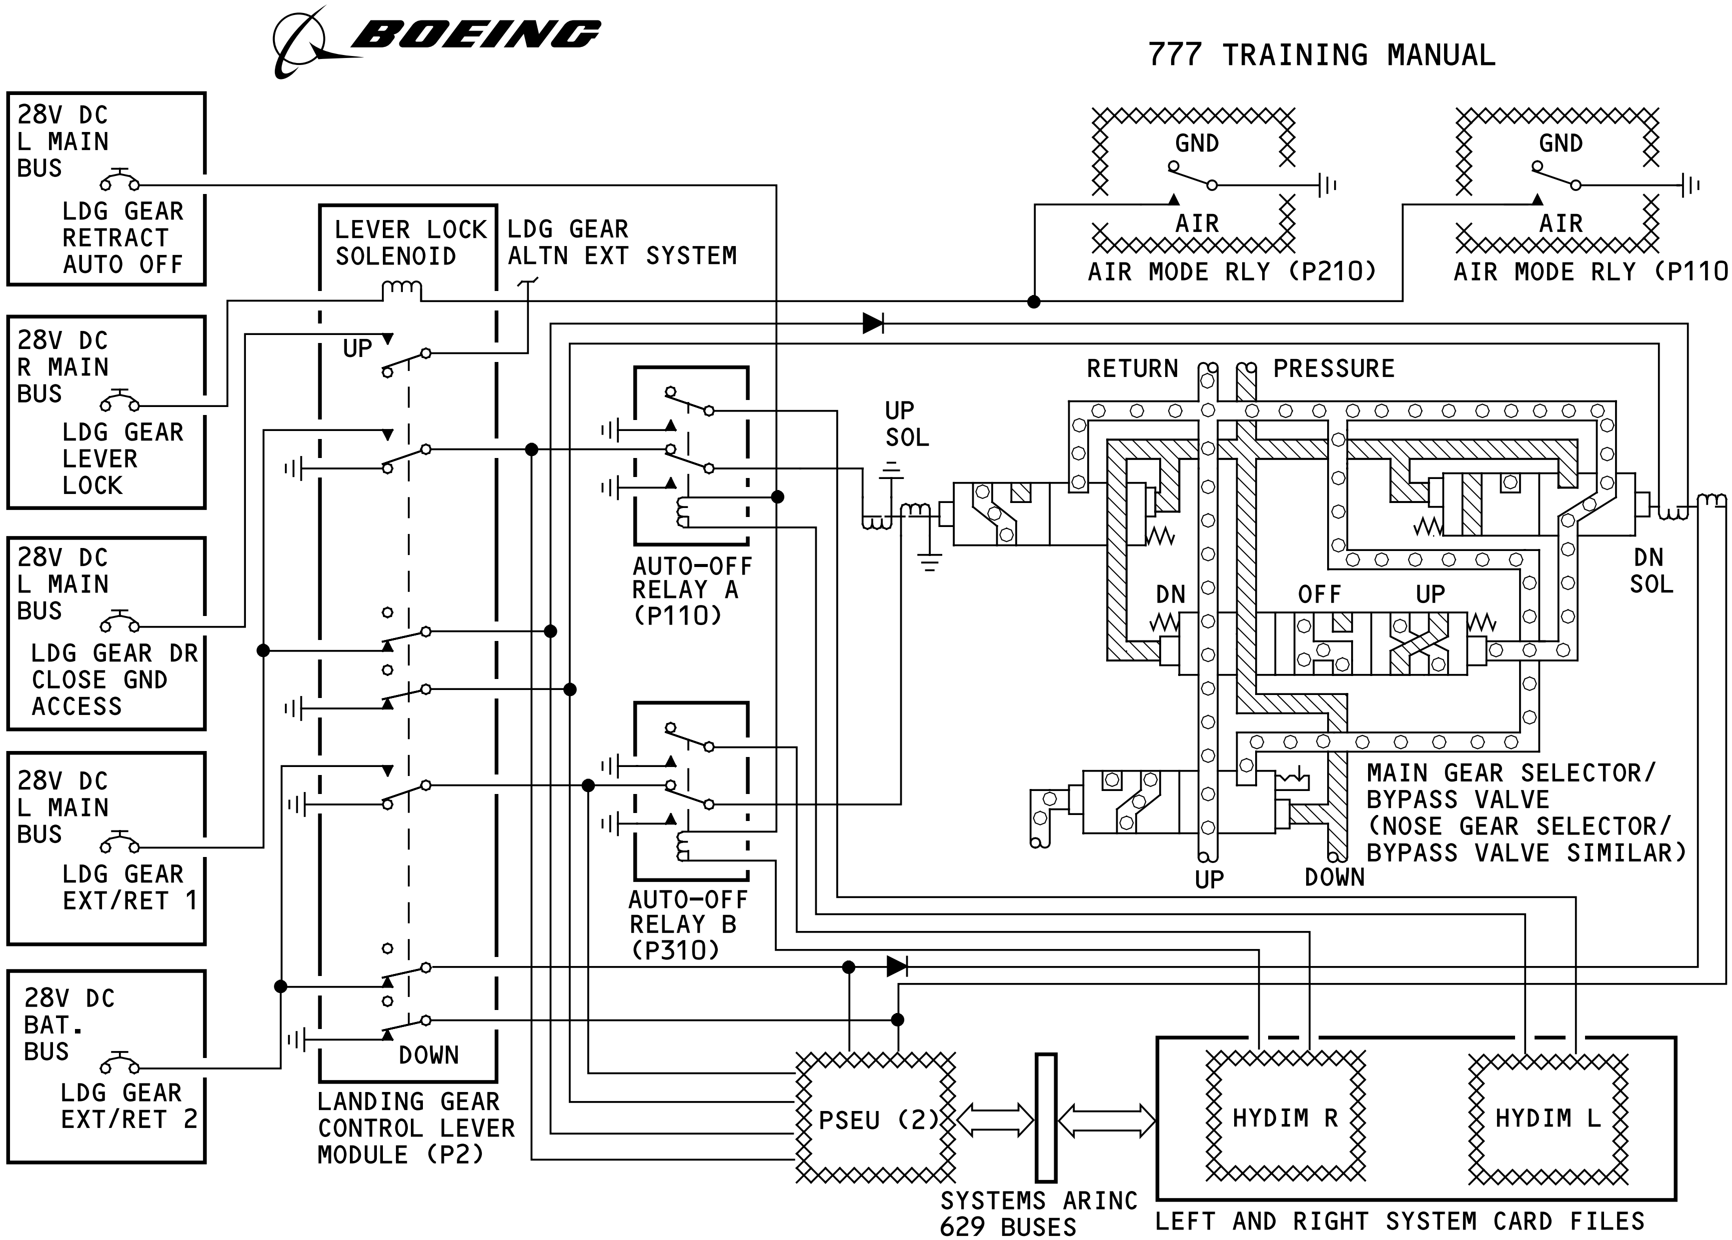
Extension

When you put the landing gear lever DOWN, four switches in the landing gear lever module close. These switches control the electrical power and the ground to the DOWN solenoid in each of the landing gear selector valves.

Hydraulic pressure goes through the landing gear selector/bypass valves to the DOWN lines for gear extension.

Down pressure stays on as long as the landing gear lever is DOWN and the center hydraulic system is pressurized.

Normal system gear extend pressure resets the bypass valves to NORMAL.



LANDING GEAR CONTROL SYSTEM - FUNCTIONAL DESCRIPTION

MLG EXTENSION-RETRACTION - INTRODUCTION

Purpose

The MLG extension and retraction system extends and retracts the main landing gear and opens and closes the main landing gear doors.

The extension and retraction system also tilts the MLG truck forward wheels up when the gear is in the extended position in flight. It tilts the MLG truck forward wheels down during gear retraction.

Components

Each MLG has these extension and retraction components:

- MLG door-operated sequence valve
- MLG uplock assembly and actuator
- MLG retract actuator
- MLG drag brace-operated sequence valve
- MLG uplock-operated sequence valve
- MLG truck positioner actuator fuses
- MLG truck positioner actuator
- MLG door priority/relief valve
- MLG door actuator
- MLG door uplock hook and door lock actuator
- MLG side brace downlock actuator
- MLG drag brace downlock actuator.

General Description

The center hydraulic system supplies pressure through the autoslat priority valve and the MLG selector/bypass valve to operate the main landing gear. See the leading edge slats section for more information about the autoslat priority valve (AMM PART I 27-81).

The door-operated sequence valve controls hydraulic pressure to the MLG uplock actuator and the MLG retract actuator.

The MLG drag brace-operated sequence valve and the MLG uplock-operated sequence valve together control hydraulic pressure to these actuators:

- MLG truck positioner actuator
- MLG door actuator
- MLG door lock actuator
- MLG side brace downlock actuator
- MLG drag brace downlock actuator.

MLG EXTENSION-RETRACTION - MLG RETRACT ACTUATOR

Purpose

The MLG retract actuator supplies the force to retract the main landing gear.

Physical Description

The retract actuator is a hydraulic piston-type actuator. The actuator retracts to raise the gear and extends when the gear extends. The actuator is not pressurized during gear extension.

A flow restrictor in the retract port union controls the gear extension rate.

Snubbers on the rod end and the head end of the actuator control actuator speed at the ends of the actuator stroke.

The dry weight of the retract actuator is approximately 240 pounds (109 kilograms).

Location

The retract actuator is inboard of the main landing gear shock strut. The rod end attaches to the inboard side of the shock strut. The head end attaches to the retract fitting mounted on the trunnion. Two reaction links connect the retract fitting to the wing rear spar.

Training Information Point

A removable wing panel permits access to the head end of the actuator from above.

MLG RETRACT ACTUATOR
(WING PANEL REMOVED)

MLG EXTENSION-RETRACTION - MLG RETRACT ACTUATOR

MLG EXTENSION-RETRACTION - MLG SIDE BRACE AND DRAG BRACE DOWNLOCK ACTUATORS

Purpose

The side brace downlock actuator locks and unlocks the over-center toggles between the side brace lock links during extension and retraction.

The drag brace downlock actuator locks and unlocks the over-center toggles between the drag brace lock links during extension and retraction.

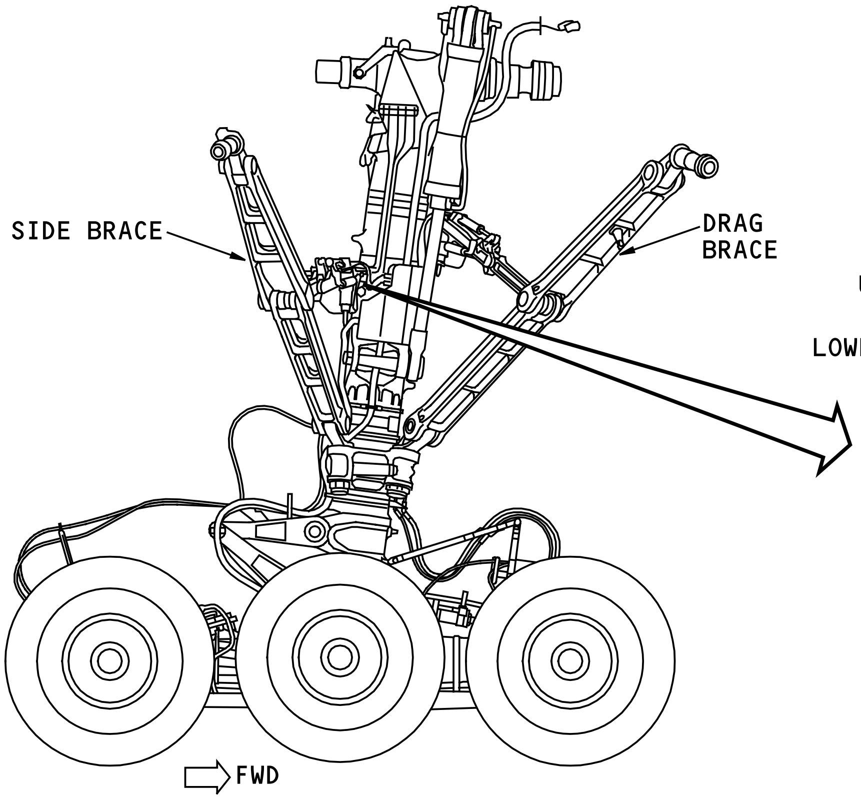
The MLG side brace downlock actuator and the MLG drag brace downlock actuator are identical and interchangeable.

Physical Description

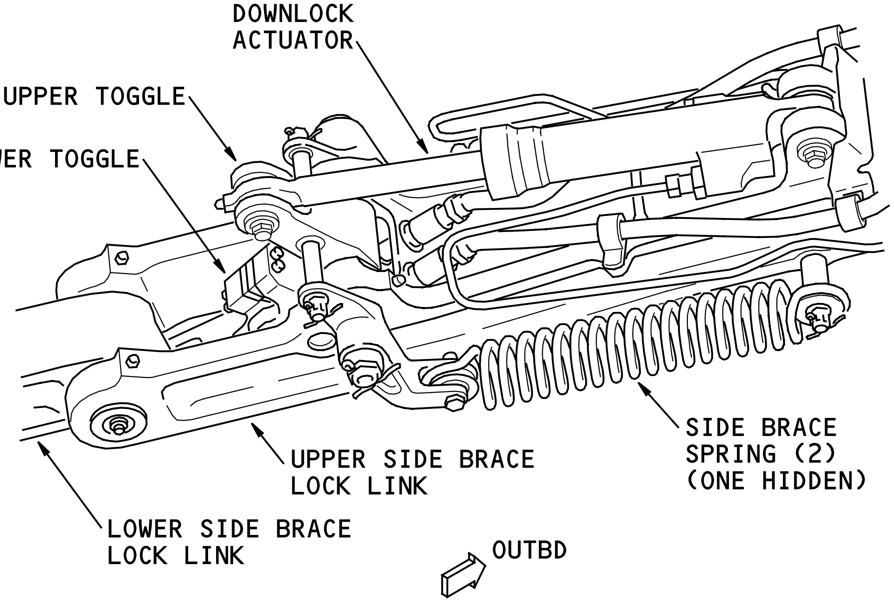
The actuators are hydraulic cylinders. They extend to lock the toggles during gear extension. They retract to unlock the toggles during gear retraction.

Location

The head ends of the actuators attach to the upper lock links. The rod ends attach to the upper toggles.



LEFT MAIN LANDING GEAR



MLG SIDE BRACE DOWNLOCK ACTUATOR

MLG EXTENSION-RETRACTION - MLG SIDE BRACE AND DRAG BRACE DOWNLOCK ACTUATORS

MLG EXTENSION-RETRACTION - MLG DOOR ACTUATOR AND MLG DOOR-OPERATED SEQUENCE VALVE

Purpose

The MLG door actuator opens and closes the main gear door during gear extension and retraction.

The MLG door-operated sequence valve controls hydraulic flow to the main gear uplock actuator and to the MLG retract actuator.

Physical Description

The MLG door actuator is a hydraulic piston-type actuator. The actuator extends to open the main gear door and retracts to close the MLG door. Flow restrictors in the extend and retract port unions control the rate of door operation. Snubbers in the rod end and head end of the actuator control actuator speed at the ends of the actuator travel. The dry weight of the MLG door actuator is approximately 72 pounds (32.7 kg).

The MLG door-operated sequence valve is a two-position valve - DOOR OPEN and DOOR NOT OPEN. A mechanical linkage from the main landing gear door operates the sequence valve. The mechanical linkage includes these components:

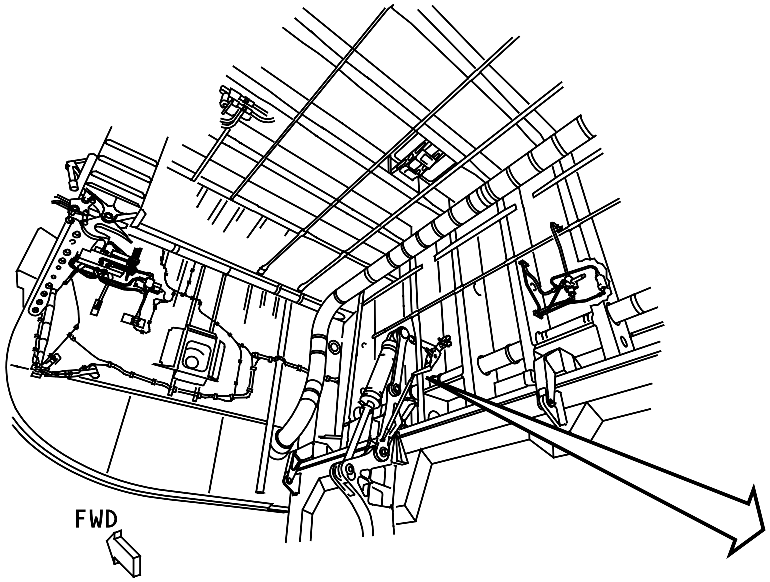
- Control rod
- Input crank
- Input link
- Intermediate crank
- Valve link (not shown).

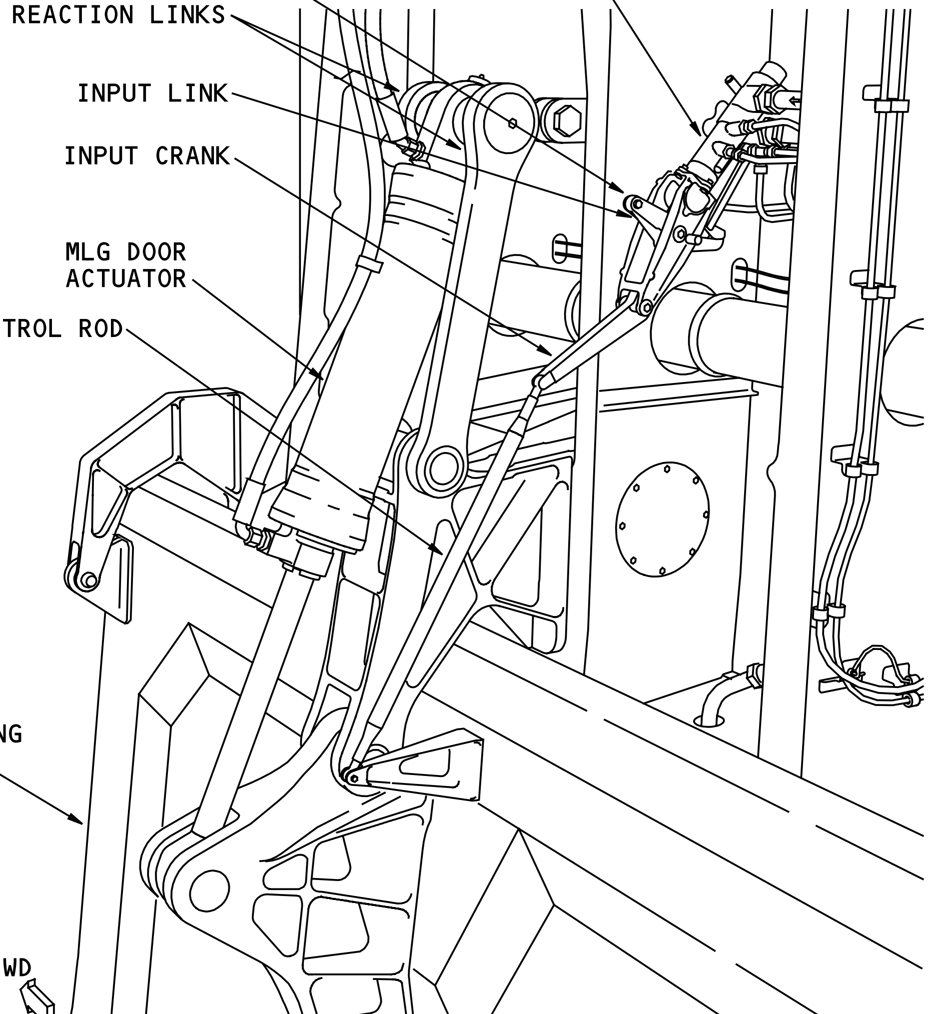
The MLG door-operated sequence valve weighs 4.6 pounds (2.1 kg).

Location

The head end of the MLG door actuator attaches to reaction links which attach to the keel beam. The rod end attaches to the landing gear door.

The MLG door-operated sequence valve is on the keel beam aft of the MLG door actuator.





MLG EXTENSION-RETRACTION - MLG DOOR ACTUATOR AND MLG DOOR-OPERATED SEQUENCE VALVE

MLG EXTENSION - MLG DOOR UPLOCK HOOK AND MLG DOOR LOCK ACTUATOR

Purpose

The MLG door uplock hook and MLG door lock actuator are part of the door uplock assembly.

The door uplock hook holds the main gear door closed.

The door lock actuator locks and unlocks the door uplock hook during landing gear door operation.

Physical Description

The uplock hook uses over-center locking to hold the door closed. Two springs keep the hook in this position.

The door lock actuator is a piston-type actuator. It retracts to unlock the uplock hook and extends to lock the uplock hook.

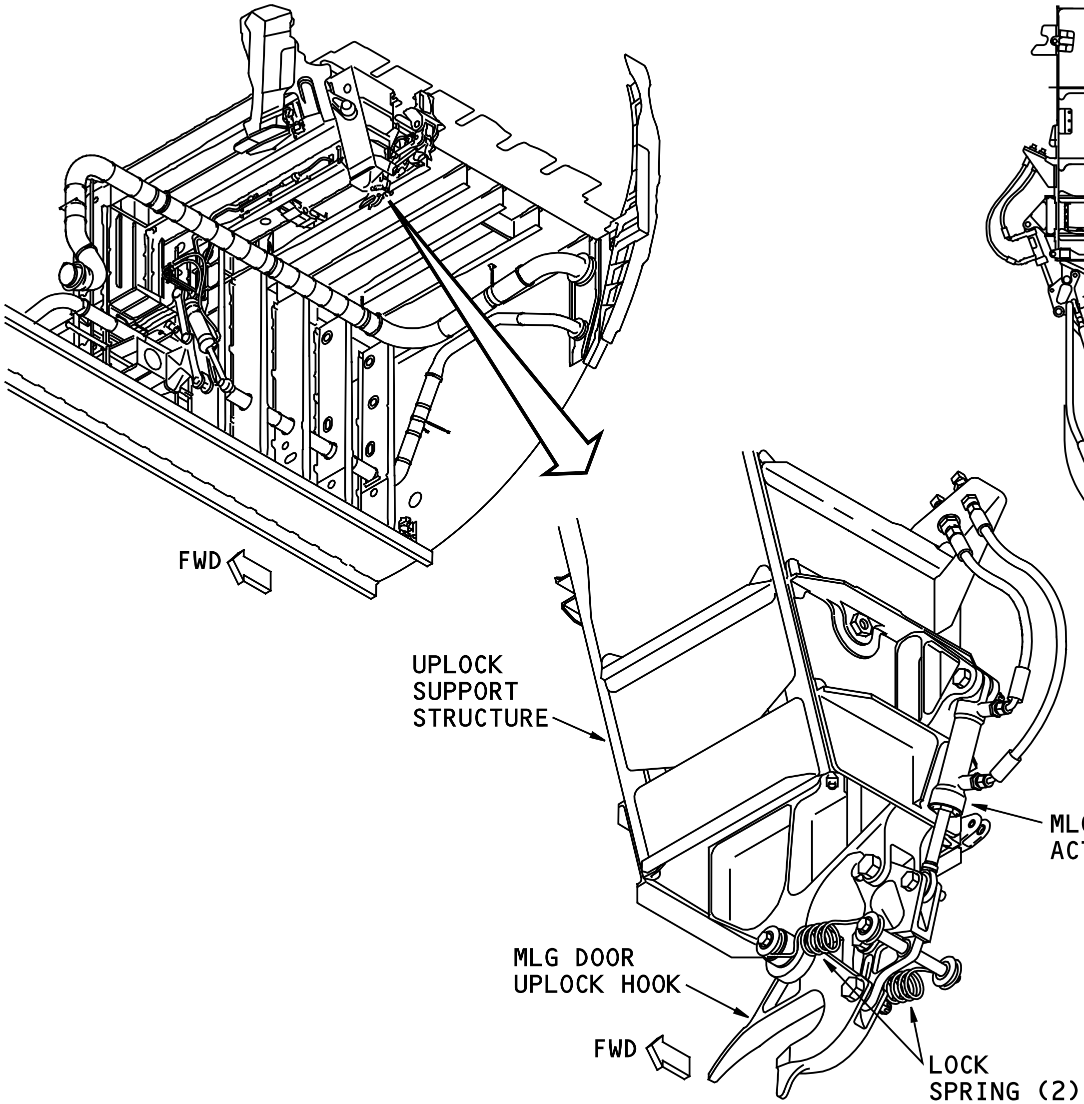
Location

The door uplock assembly is on the uplock support structure. This structure is on the outboard side of the wheel well and attaches to the wheel well ceiling.

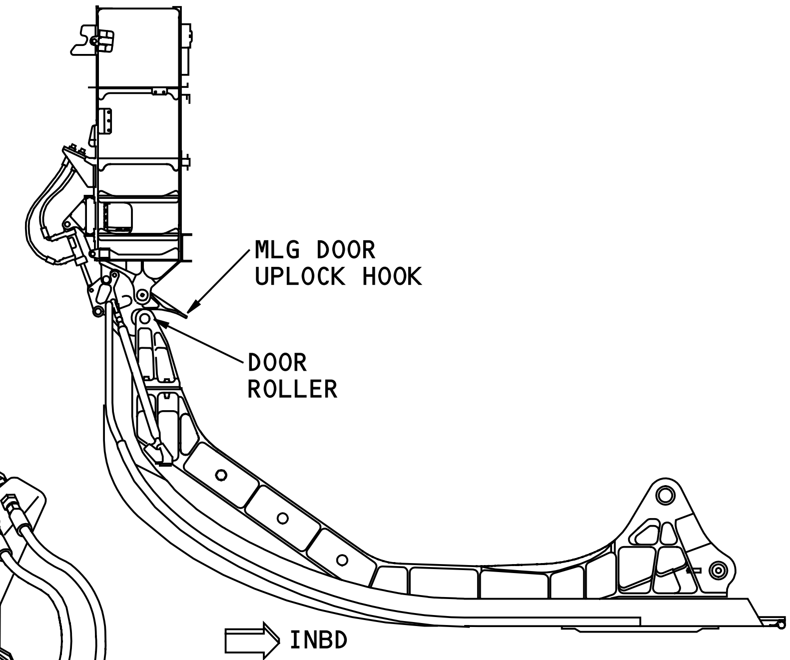
Functional Description

To open the MLG door, the door lock actuator moves the door uplock hook to the unlocked position. This permits the roller on the door to move out of the hook and the door to open.

When the door closes, the roller on the door engages the uplock hook. The motion of the door and pressure in the door lock actuator drive the uplock hook to the overcenter locked position.



DOOR UPLOCK ASSEMBLY



MLG DOOR AND UPLOCK ASSEMBLY
(LOOKING FORWARD)

MLG EXTENSION - MLG DOOR UPLOCK HOOK AND MLG DOOR LOCK ACTUATOR

32-32-00-007 Rev 2 05/28/96

MLG EXTENSION-RETRACTION - MLG UPLOCK ASSY, UPLOCK ACTUATOR, AND UPLOCK-OPERATED SEQUENCE VALVE

Purpose

The MLG uplock assembly holds the main landing gear in the UP position.

The MLG uplock actuator unlocks the main gear uplock assembly during gear extension.

The MLG uplock-operated sequence valve controls main landing gear door close operation.

Physical Description

The MLG uplock assembly uses over-center locking to keep the main landing gear up and locked. Two springs hold the uplock hook in this position.

The MLG uplock actuator is a two-position piston-type actuator. It retracts to unlock the gear and extends during gear uplock operation.

The MLG uplock-operated sequence valve is a two-position sequence valve (LOCKED AND UNLOCKED). A mechanical linkage from the uplock mechanism moves the sequence valve.

Location

The MLG uplock assembly is on the ceiling on the outboard edge of each wheel well. The uplock assembly is aft of the door uplock assembly.

The MLG uplock actuator attaches horizontally above the MLG uplock mechanism.

The MLG uplock-operated sequence valve attaches vertically above the MLG uplock mechanism.

Functional Description

During gear retraction, the roller on the MLG shock strut engages the hook in the uplock assembly. The motion of the gear starts to move the uplock mechanism to the over-center locked position. This also moves the MLG uplock-operated sequence valve to the lock position.

The MLG uplock-operated sequence valve then supplies pressure to the extend side of the MLG uplock actuator. This makes sure the uplock mechanism moves to the over-center locked position.

Lock springs hold the mechanism in this position.

During gear extension, the MLG uplock actuator moves the uplock mechanism to the unlocked position. This releases the gear from the up and locked position.

MLG EXTENSION-RETRACTION - MLG UPLOCK ASSY, UPLOCK ACTUATOR, AND UPLOCK-OPERATED SEQUENCE VALVE

MLG EXTENSION-RETRACTION - MLG DRAG BRACE-OPERATED SEQUENCE VALVE

Purpose

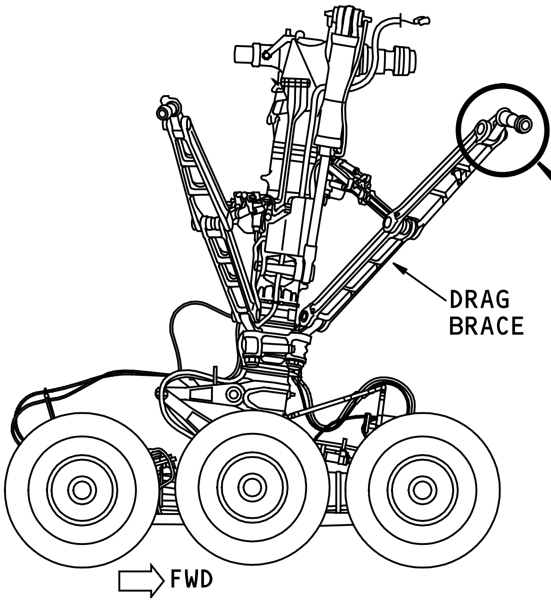
The MLG drag brace-operated sequence valve controls MLG door close operation during landing gear extension.

Physical Description

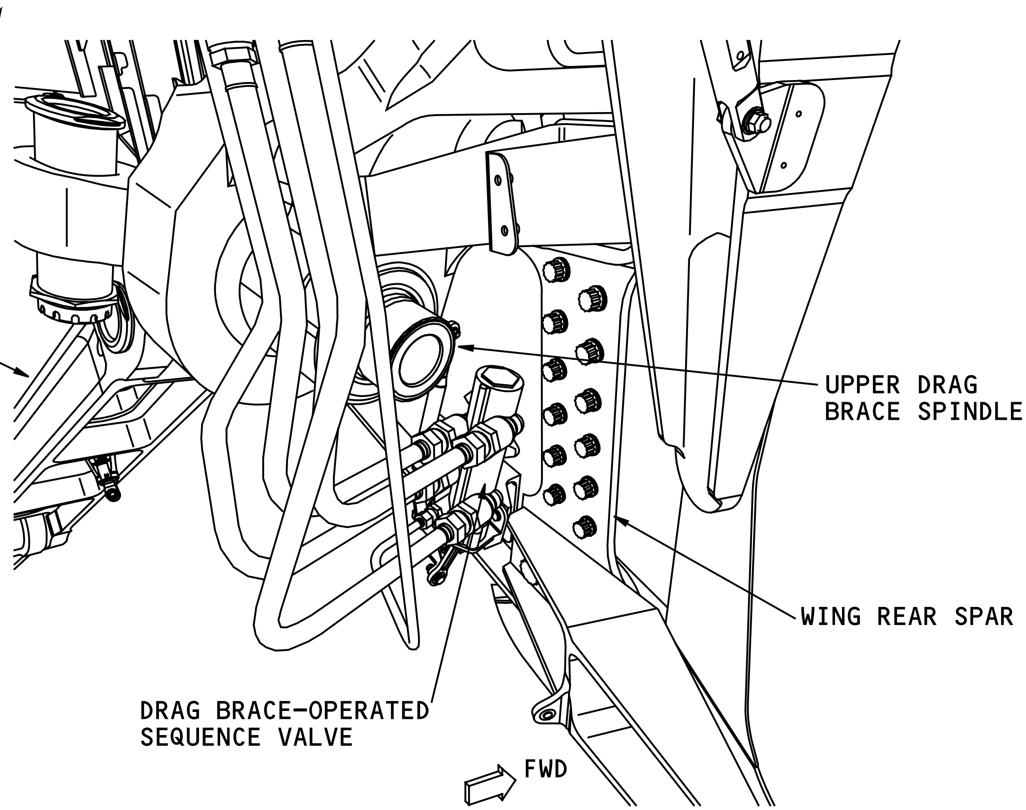
The MLG drag brace-operated sequence valve has two positions: GEAR DOWN and GEAR NOT DOWN. Linkage from the upper drag brace spindle moves the valve.

Location

The MLG drag brace-operated sequence valve is in the MLG wheel well on the wing rear spar.



LEFT MAIN LANDING GEAR



32-32-00-009 Rev 2 03/26/96

MLG EXTENSION-RETRACTION - MLG DRAG BRACE-OPERATED SEQUENCE VALVE

MLG EXTENSION-RETRACTION - MLG TRUCK POSITIONER ACTUATOR - FUNCTIONAL DESCRIPTION

General

The MLG truck positioner actuator retracts to move the MLG truck to the TILT position and extends to move the MLG truck to the STOW position.

Tilt Position

When the landing gear is down and locked, hydraulic pressure goes to both sides of the floating piston and the rod side of the main piston. This retracts the truck positioner actuator which moves the truck to 13 degrees forward wheels up (airplane in the air).

Stow Position

During gear retraction, hydraulic pressure goes between the floating piston and the rod side of the main piston. This makes the pistons move apart until the floating piston touches the rod shoulder.

Since the floating piston has a larger surface area than the main piston, the actuator extends until the floating piston touches the stops on the cylinder rod end. This moves the truck to the 5 degrees forward wheels down position.

After the landing gear is up and locked, the pressure in the truck positioner actuator keeps the gear in the STOW position.

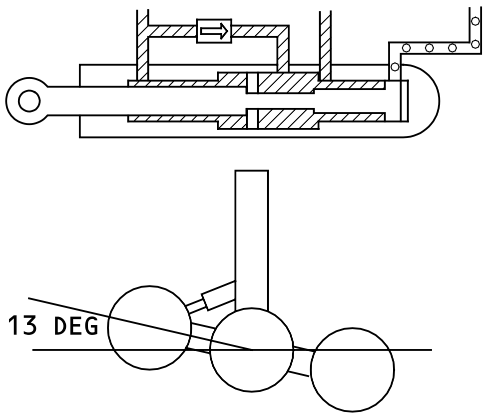
A relief valve opens to release actuator pressure increases caused by thermal expansion and touch down loads.

Training Information Point

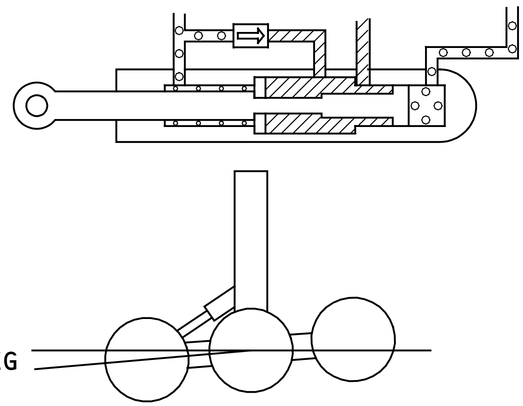
The design of the MLG truck positioner actuator permits the truck to tilt 19 degrees forward wheels down. This tilt may occur after a high rate of sink landing or when you jack the aft axle.

The maximum distance you can lift the forward axles of the MLG trucks on jacks is to a distance of 19.8 inches between the ground and the jacking point.

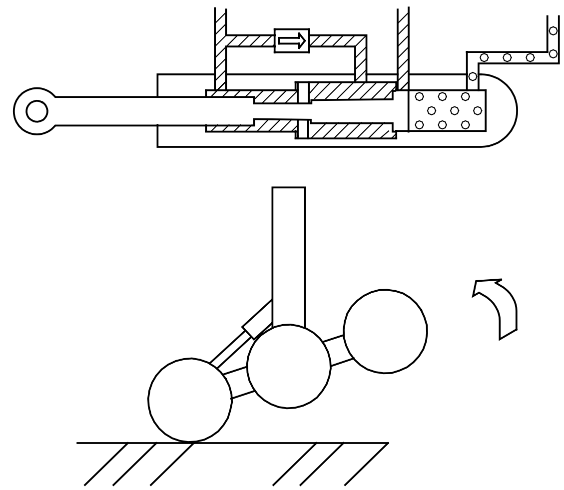
The maximum distance you can lift the aft axles of the MLG trucks on jacks is to a distance of 17.6 inches between the ground and the jacking point.



TILT POSITION



STOW POSITION



19 DEGREE DOWN POSITION

32-32-00-011 Rev 1

MLG EXTENSION-RETRACTION - MLG TRUCK POSITIONER ACTUATOR - FUNCTIONAL DESCRIPTION

MLG EXTENSION-RETRACTION - MLG TRUCK POSITIONER ACTUATOR FUSES

Purpose

The MLG truck positioner actuator fuses prevent loss of center hydraulic system fluid if there is a leak in the hydraulic lines to the MLG truck positioner actuator.

There are fuses in the tilt and stow hydraulic pressure lines that go to each MLG truck positioner actuator.

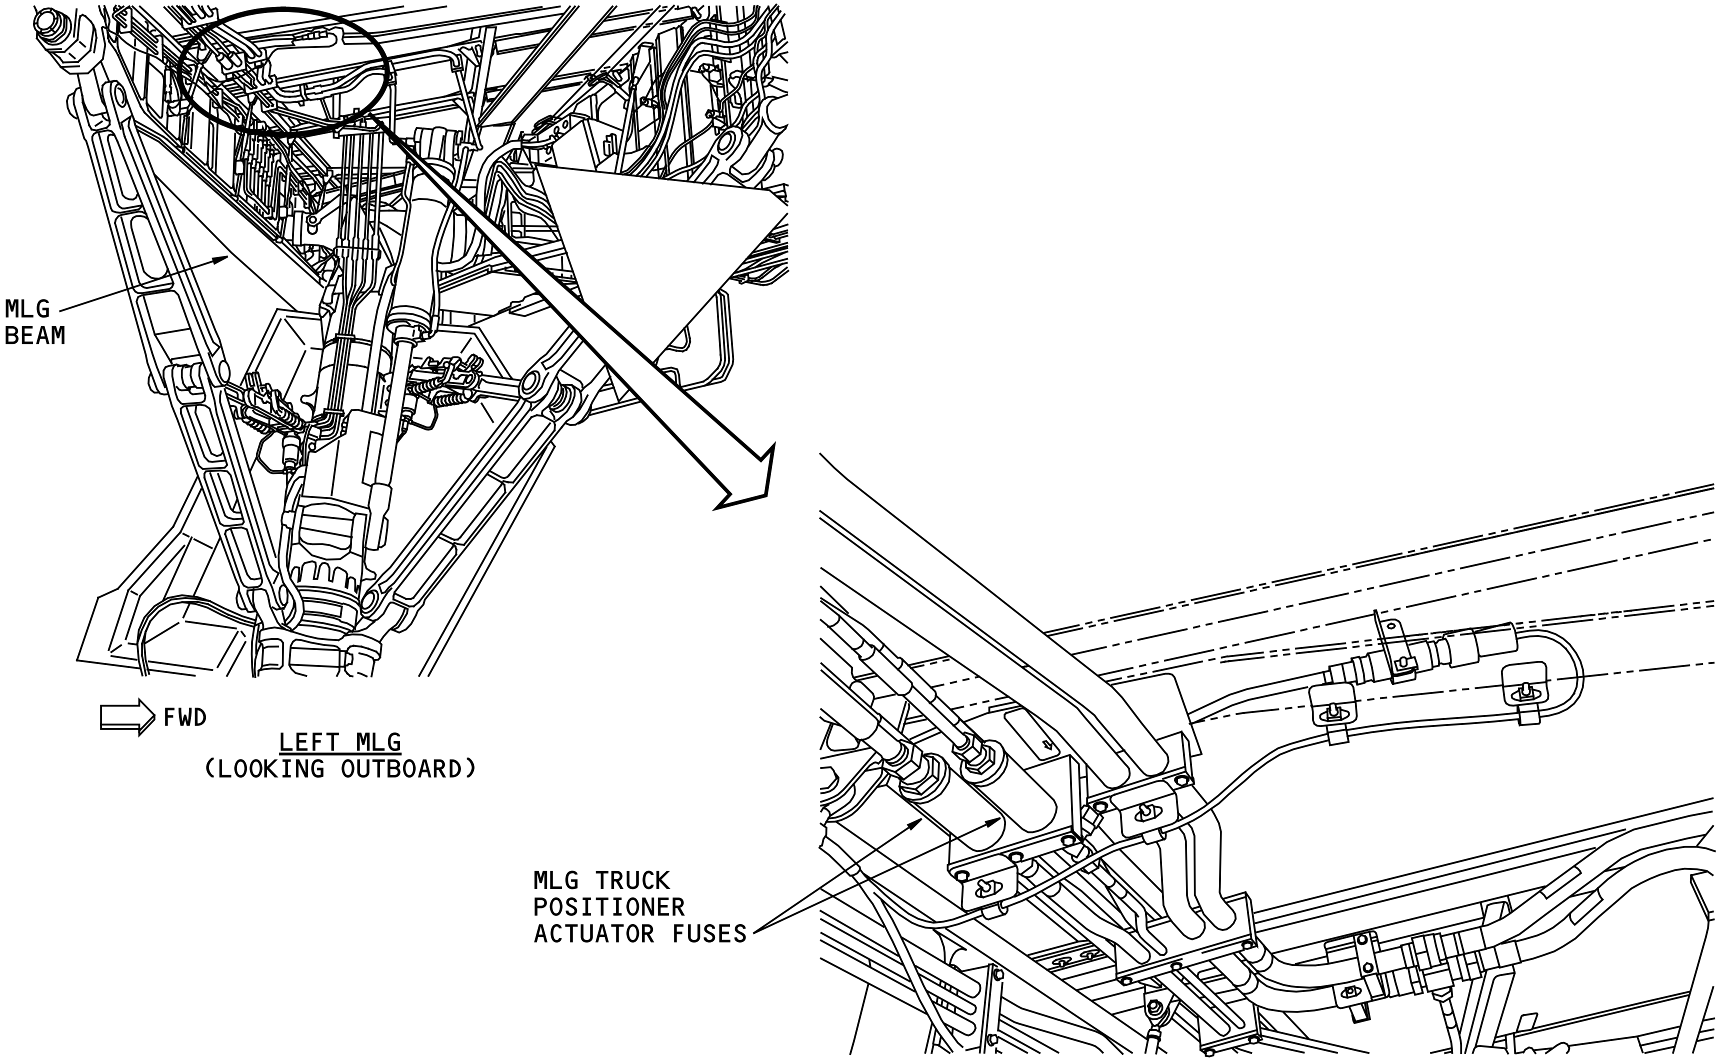
Location

The truck positioner actuator fuses are above the MLG truck near the main landing gear beam.

Training Information Point

The fuses close if 60 - 90 cubic inches of hydraulic fluid go through the fuse at a minimum rate of 0.1 gallons per minute.

The fuses reset automatically when the pressure difference across the fuse is five psi or less.



32-32-00-012 Rev 3 03/26/96

MLG EXTENSION-RETRACTION - MLG TRUCK POSITIONER ACTUATOR FUSES

MLG EXTENSION-RETRACTION - RETRACTION SEQUENCE

THIS PAGE INTENTIONALLY LEFT BLANK

MLG EXTENSION-RETRACTION - RETRACTION SEQUENCE

General

MLG retraction is the same for both left and right main gears.

These are the start positions:

- MLG - DOWN and LOCKED
- MLG door - CLOSED and LOCKED
- MLG truck positioner actuator - TILT
- MLG drag brace-operated sequence valve - DOWN
- MLG uplock-operated sequence valve - UNLOCKED
- MLG door-operated sequence valve - NOT OPEN.

Control

When you move the landing gear lever to the UP position, the MLG selector/bypass valve moves to the UP position. Hydraulic pressure then goes to the retract lines.

Gear Unlock - Truck Tilt

The pressure goes to the MLG drag brace and MLG side brace downlock actuators. These actuators start to retract to unlock the gear downlocks.

Pressure also goes through the MLG drag brace-operated sequence valve and the MLG uplock-operated sequence valve. This pressure extends the MLG truck positioner actuator to the STOW position.

Door Opens

Pressure through the sequence valves also retracts the MLG door lock actuator to unlock the main gear door. The MLG door actuator gets extend pressure through the MLG door priority/relief valve. The MLG door starts to open.

Gear Retracts

When the MLG door is almost all the way open, the MLG door-operated sequence valve moves to OPEN. Pressure then goes to the MLG retract actuator to retract the gear.

When the gear starts to retract, the MLG drag brace-operated sequence valve moves to the NOT DOWN position.

As the MLG goes into the wheel well, a roller on the landing gear strut moves the MLG uplock mechanism to the LOCKED position. This moves MLG uplock-operated sequence valve to the locked position.

This removes pressure from the MLG truck positioner actuator. Pressure trapped in the MLG truck positioner actuator keeps the MLG truck in the STOW position.

Pressure then goes to the MLG uplock actuator to make sure the MLG uplock mechanism locks.

Pressure through the MLG door-operated sequence valve also goes to brake system components for the gear

MLG EXTENSION-RETRACTION - RETRACTION SEQUENCE

retract braking function. See the wheels and brakes section for more information (AMM PART I 32-40).

Door Closes

Pressure also goes to the close side of the MLG door actuator and the lock side of the MLG door lock actuator. The door starts to close.

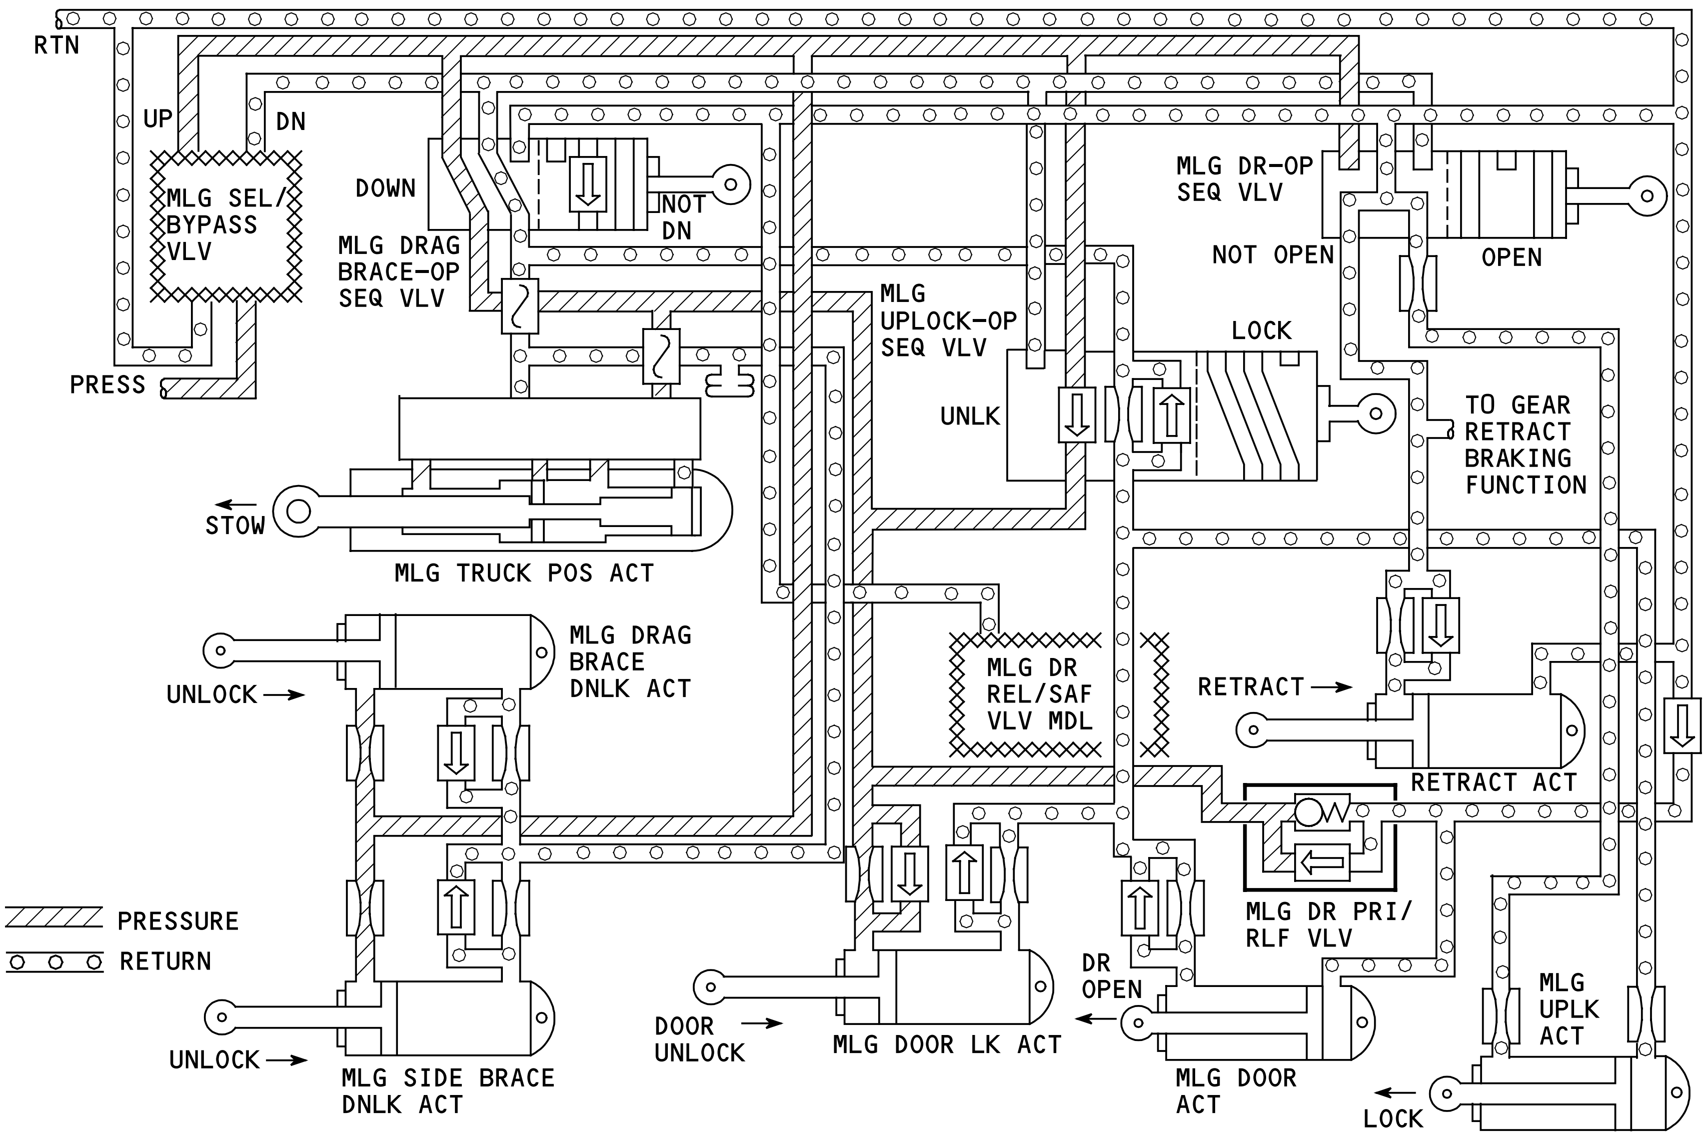
When the door is almost closed, a roller on the door starts to move the MLG door uplock mechanism to the locked position. Pressure in the MLG door lock actuator moves the uplock mechanism over-center to the locked position.

Final Position

Final main gear conditions are:

- MLG - UP and LOCKED
- MLG door - CLOSED and LOCKED
- MLG truck position actuator - STOW
- MLG drag brace-operated sequence valve - NOT DOWN
- MLG uplock-operated sequence valve - LOCKED
- MLG door-operated sequence valve - NOT OPEN.

Pressure stays in the retract lines until the auto-off function moves the MLG selector/bypass valve to OFF.



MLG EXTENSION-RETRACTION - RETRACTION SEQUENCE

THIS PAGE INTENTIONALLY LEFT BLANK

MLG EXTENSION-RETRACTION - EXTENSION SEQUENCE

General

Main gear extension is the same for both left and right main gear.

These are the start conditions:

- MLG - UP and LOCKED
- MLG door - CLOSED and LOCKED
- MLG truck positioner actuator - STOW
- MLG Drag brace-operated sequence valve - NOT DOWN
- MLG uplock-operated sequence valve - LOCKED
- MLG door-operated sequence valve - NOT OPEN

Control

When you select DOWN with the landing gear lever, the MLG selector/bypass valve moves to the down position. This permits hydraulic pressure to go to the extend lines.

Door Opens

Pressure goes through the MLG drag brace-operated sequence valve and the MLG uplock-operated sequence valve. This pressure goes to the MLG truck positioner actuator to hold the MLG truck in the STOW position.

This pressure also goes to the MLG door lock actuator to unlock the MLG door. The MLG door actuator then gets extend pressure through the MLG door priority/relief valve. The MLG door starts to open.

Gear Extends - Truck Tilts

When the MLG door is almost all the way open, the MLG door-operated sequence valve moves to OPEN. Pressure then goes to the MLG uplock actuator to unlock the MLG uplock.

The MLG extends by its own weight and by airloads. It is not pressurized during extension.

When the main landing gear is 20 degrees from fully extended, the MLG drag brace-operated sequence valve moves to DOWN.

Hydraulic pressure then retracts the MLG truck positioner actuator which moves the MLG truck to the TILT position.

Hydraulic pressure also goes to the MLG drag brace and MLG side brace downlock actuators to lock the gear down.

Door Closes

Pressure from the MLG drag brace-operated sequence valve goes through the MLG uplock-operated sequence valve and the MLG door release/safety valve module. This pressure goes to the MLG door actuator and the MLG door lock actuator. The MLG main gear door closes.

When the door is almost closed, a roller on the door starts to move the MLG door uplock mechanism to the locked position. Pressure in the MLG door lock actuator

MLG EXTENSION-RETRACTION - EXTENSION SEQUENCE

moves the uplock mechanism over-center to the locked position.

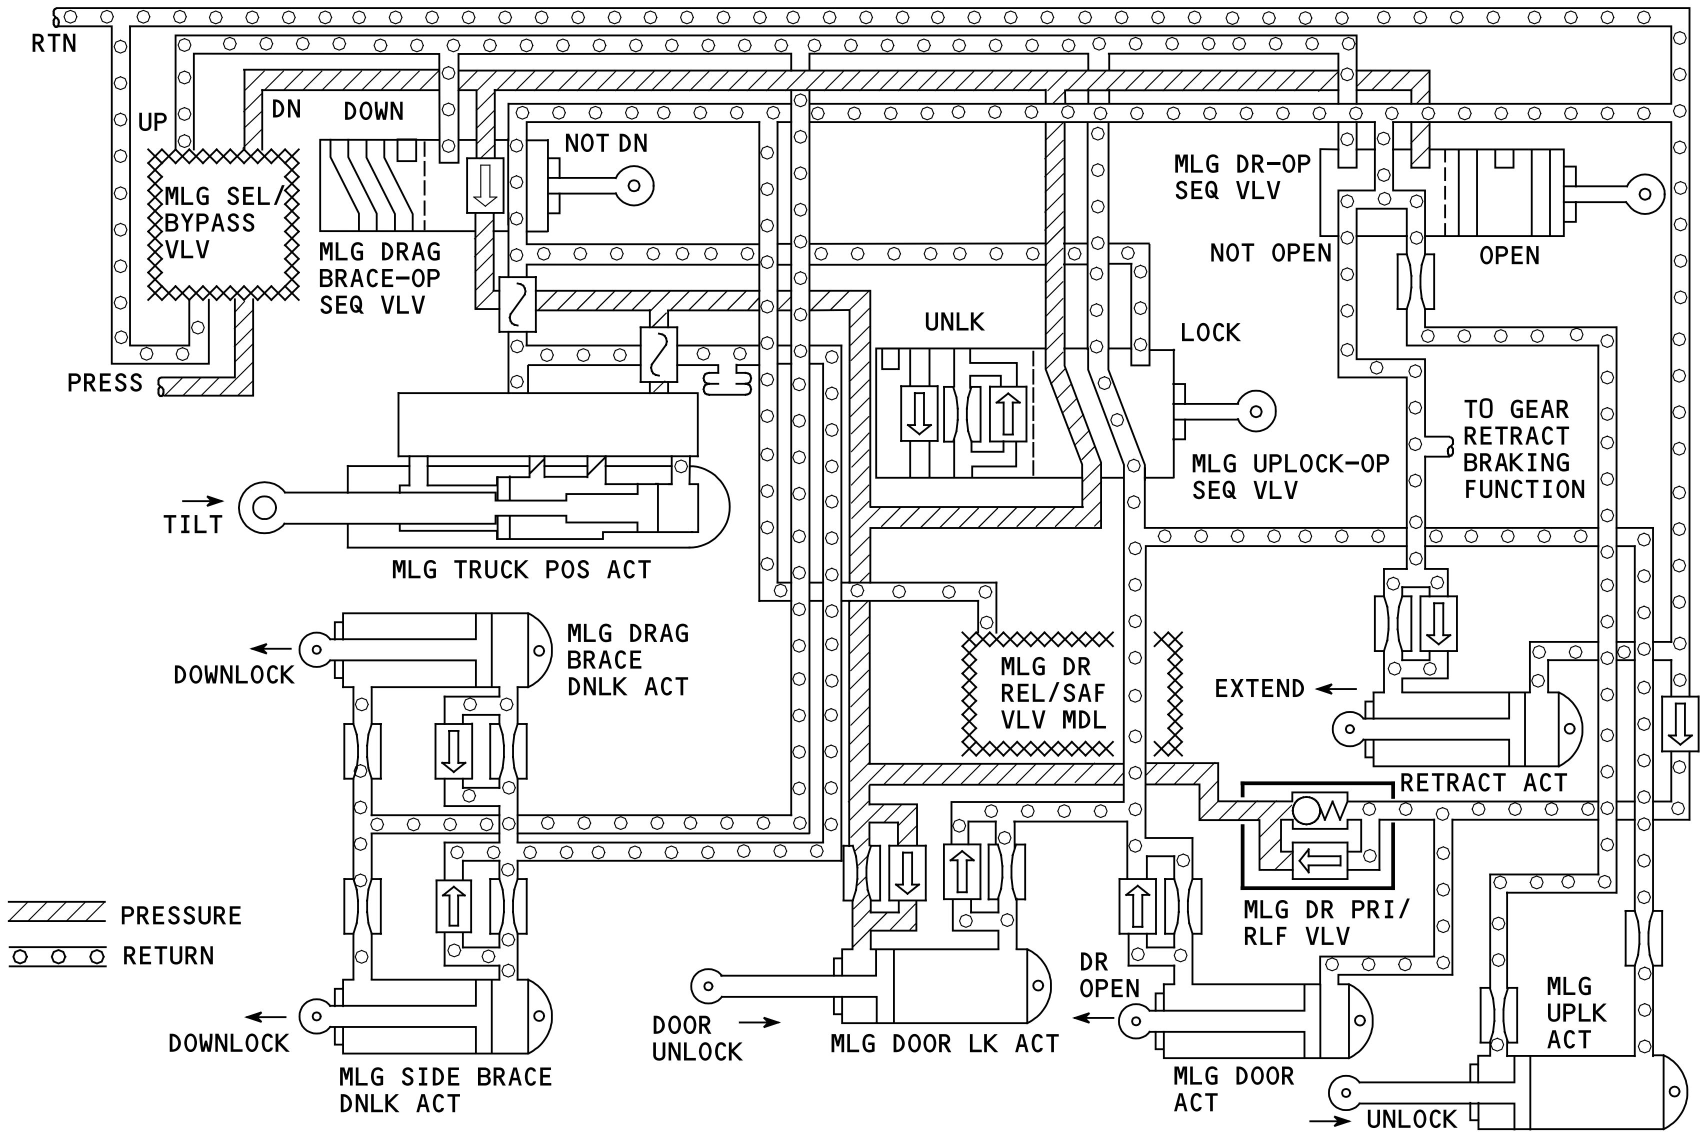
Final Condition

The final condition of the MLG is:

- MLG - DOWN and LOCKED
- MLG door - CLOSED and LOCKED
- MLG truck positioner actuator - TILT
- MLG drag brace-operated sequence valve - DOWN
- MLG uplock-operated sequence valve - UNLOCKED
- MLG door-operated sequence valve - NOT OPEN.

These actuators stay pressurized when the MLG is down and the center hydraulic system is pressurized:

- MLG door actuator
- MLG door lock actuator
- MLG truck positioner actuator
- MLG side brace actuator
- MLG drag brace actuator.



MLG EXTENSION-RETRACTION - EXTENSION SEQUENCE

NLG EXTENSION-RETRACTION - INTRODUCTION

Purpose

The NLG extension-retraction system extends and retracts the nose landing gear and opens and closes the NLG doors.

Components

These are the NLG extension-retraction components:

- NLG-operated sequence valve
- NLG door actuator
- NLG door-operated sequence valve
- NLG retract actuator
- NLG lock actuator
- NLG locking mechanism.

General Description

The center hydraulic system supplies pressure to operate the nose landing gear. The pressure goes through the NLG selector/bypass valve. The NLG door-operated sequence valve controls hydraulic pressure to the NLG retract actuator and the NLG lock actuator.

The NLG-operated sequence valve controls hydraulic pressure to the NLG door actuator.

NLG EXTENSION-RETRACTION - COMPONENT LOCATIONS

NLG EXTENSION-RETRACTION - NLG LOCKING MECHANISM AND NLG LOCK ACTUATOR

Purpose

The NLG locking mechanism holds the NLG in the extended or the retracted position.

The NLG lock actuator unlocks the NLG locking mechanism at the start of an extension or retraction. It also locks the mechanism when the NLG is fully extended or fully retracted.

Physical Description

The NLG locking mechanism uses over-center locking to lock the NLG in either the extended or retracted position. The locking mechanism has a forward and an aft lock link which connect by a hinge. Two lock springs keep the lock links in position.

The NLG lock actuator is a hydraulic piston-type actuator. Flow restrictors control the hydraulic flow rate in both directions of actuator motion.

Location

The nose gear locking mechanism is directly above the nose gear shock strut. The forward lock link attaches to the drag strut hinge. The aft lock link attaches to the NLG wheel well aft bulkhead.

The NLG lock actuator is at the aft end of the NLG locking mechanism. The rod end of the actuator attaches to the NLG wheel well aft bulkhead. The head end attaches to the aft part of the locking mechanism.

NLG EXTENSION-RETRACTION - NLG LOCKING MECHANISM AND NLG LOCK ACTUATOR

NLG EXTENSION-RETRACTION - NLG LOCKING MECHANISM AND NLG LOCK ACTUATOR - FUNCTIONAL DESCRIPTION

Retraction

Before gear retraction, the NLG lock actuator retracts. This unlocks the NLG locking mechanism and permits the NLG to retract.

The hydraulic pressure stays on the retract side of the NLG lock actuator while the gear is in transit.

The NLG lock actuator moves the NLG locking mechanism to the lock position when the NLG is in the retracted position.

Extension

Before gear extension, the NLG lock actuator extends. This unlocks the NLG locking mechanism and permits the NLG to extend.

Hydraulic pressure stays on the extend side of the NLG lock actuator while the gear is in transit.

The NLG lock actuator moves the NLG locking mechanism to the lock position when the NLG is in the extended position.

NLG EXTENSION-RETRACTION - NLG LOCKING MECHANISM AND NLG LOCK ACTUATOR - FUNCTIONAL DESCRIPTION

NLG EXTENSION-RETRACTION - NLG-OPERATED SEQUENCE VALVE

Purpose

The NLG-operated sequence valve makes sure that the doors move only if the NLG is in the retracted or the extended position. It makes sure that the doors do not move if the NLG is in-transit.

Physical Description

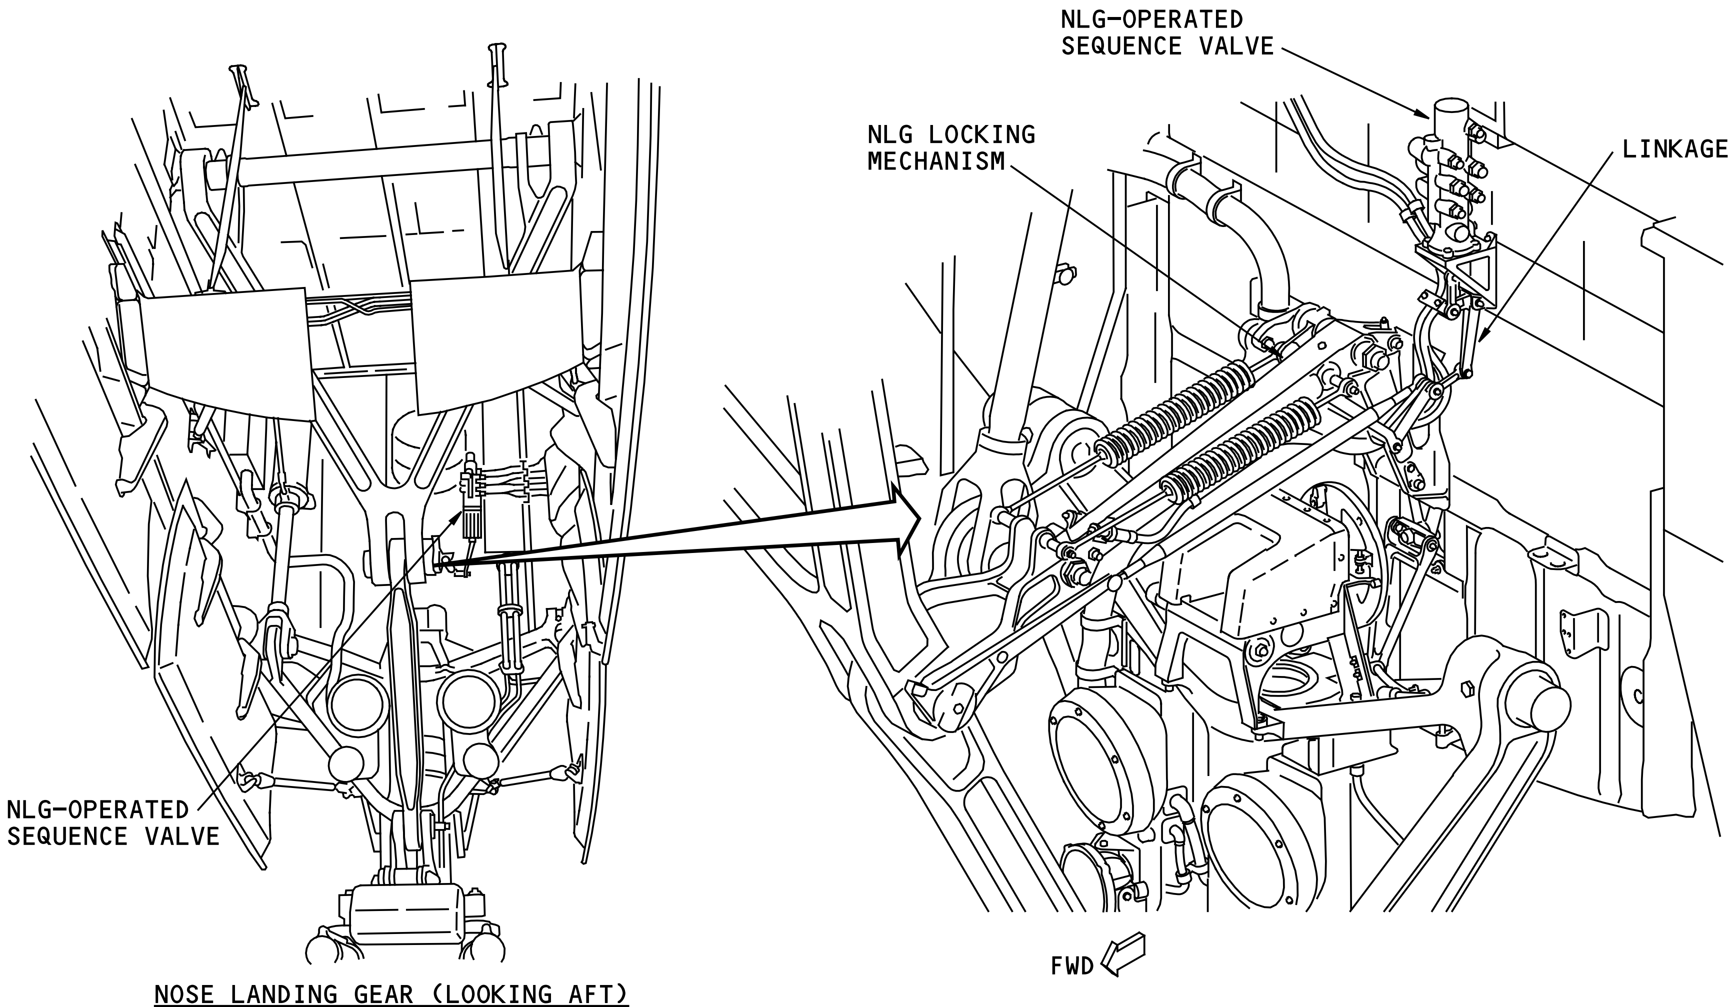
The NLG-operated sequence valve is a three position valve. The positions are:

- Gear up
- Gear in transit
- Gear down.

A linkage from the nose landing gear locking mechanism moves the sequence valve.

Location

The NLG-operated sequence valve is on the aft bulkhead in the nose wheel well.



32-34-00-006 Rev 3 08/07/95

NLG EXTENSION-RETRACTION - NLG-OPERATED SEQUENCE VALVE

NLG EXTENSION-RETRACTION - NLG DOOR ACTUATOR AND NLG DOOR-OPERATED SEQUENCE VALVE

Purpose

The NLG door actuator opens and closes the NLG forward doors. A lock in the actuator holds the doors closed.

The NLG door-operated sequence valve controls the hydraulic flow to the NLG lock and retract actuators. This makes sure the NLG extends or retracts only when the NLG doors are open.

Physical Description

The NLG door actuator is a two-position hydraulic actuator. The actuator extends to open the doors and retracts to close the doors.

Flow restrictors at the head and rod ends of the actuator control actuator speed.

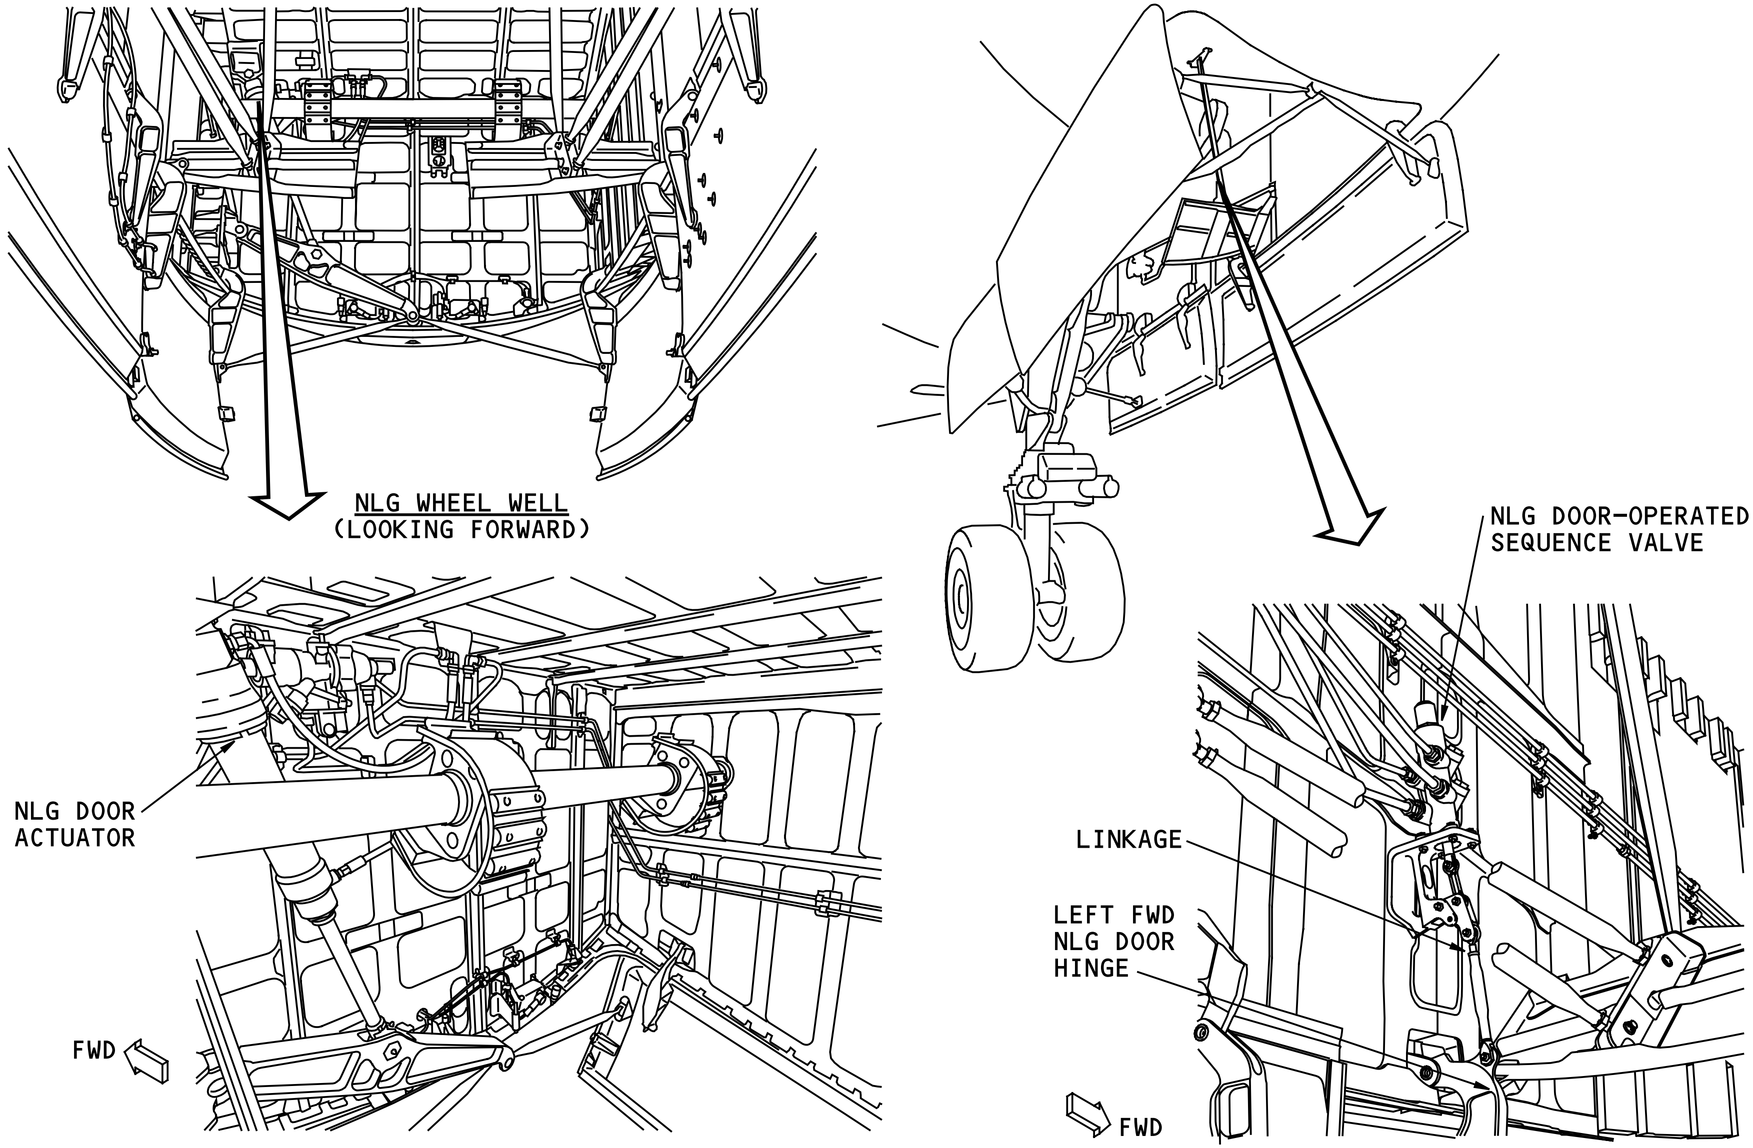
An internal lock engages when the NLG doors close. During normal operation, hydraulic pressure to open the NLG doors unlocks this lock.

The NLG door-operated sequence valve is a two position valve - OPEN and CLOSED. The sequence valve moves to the OPEN position when the doors are four degrees from the fully open position. A linkage from a hinge on the left forward NLG door operates the sequence valve.

Location

The NLG door actuator is in the forward, left side of the nose wheel well. The head end of the actuator attaches to a bracket on the wheel well ceiling. The rod end attaches to a crank. The crank moves both forward doors through rods.

The NLG door-operated sequence valve is on the left NLG wheel well wall.



32-34-00-007 Rev 3 11/13/95

NLG EXTENSION-RETRACTION - NLG DOOR ACTUATOR AND NLG DOOR-OPERATED SEQUENCE VALVE

NLG EXTENSION-RETRACTION - RETRACTION SEQUENCE

Initial Position

These are the initial positions for NLG components:

- NLG - DOWN AND LOCKED
- NLG doors - CLOSED
- NLG-operated sequence valve - GEAR DOWN
- NLG door-operated sequence valve - CLOSED.

Control

When you select UP with the landing gear control lever, the NLG selector/bypass valve moves to the up position. Hydraulic pressure then goes to the retract lines.

Gear Unlocks - Doors Open

Hydraulic pressure goes to the NLG lock actuator. The actuator starts to retract to unlock the downlock.

Pressure also goes through the NLG-operated sequence valve to the NLG door actuator. The actuator extends and opens the forward doors.

Gear Retracts

When the doors are almost fully open, the NLG door-operated sequence valve moves to OPEN. Pressure then goes to the NLG retract actuator and the NLG starts to retract.

After the NLG starts to retract, the NLG-operated sequence valve moves to the GEAR IN TRANSIT position. This keeps pressure on the open side of the door actuator.

Doors Close - Gear Locks

When the NLG is almost all the way up, the NLG-operated sequence valve moves to the UP position. Pressure now goes to the retract side of the NLG door actuator and the NLG doors start to close.

Pressure through the NLG-operated sequence valve also goes to the NLG retract actuator. This keeps the NLG up after the nose gear doors close.

The NLG lock actuator continues to retract and locks the NLG when the gear is fully up.

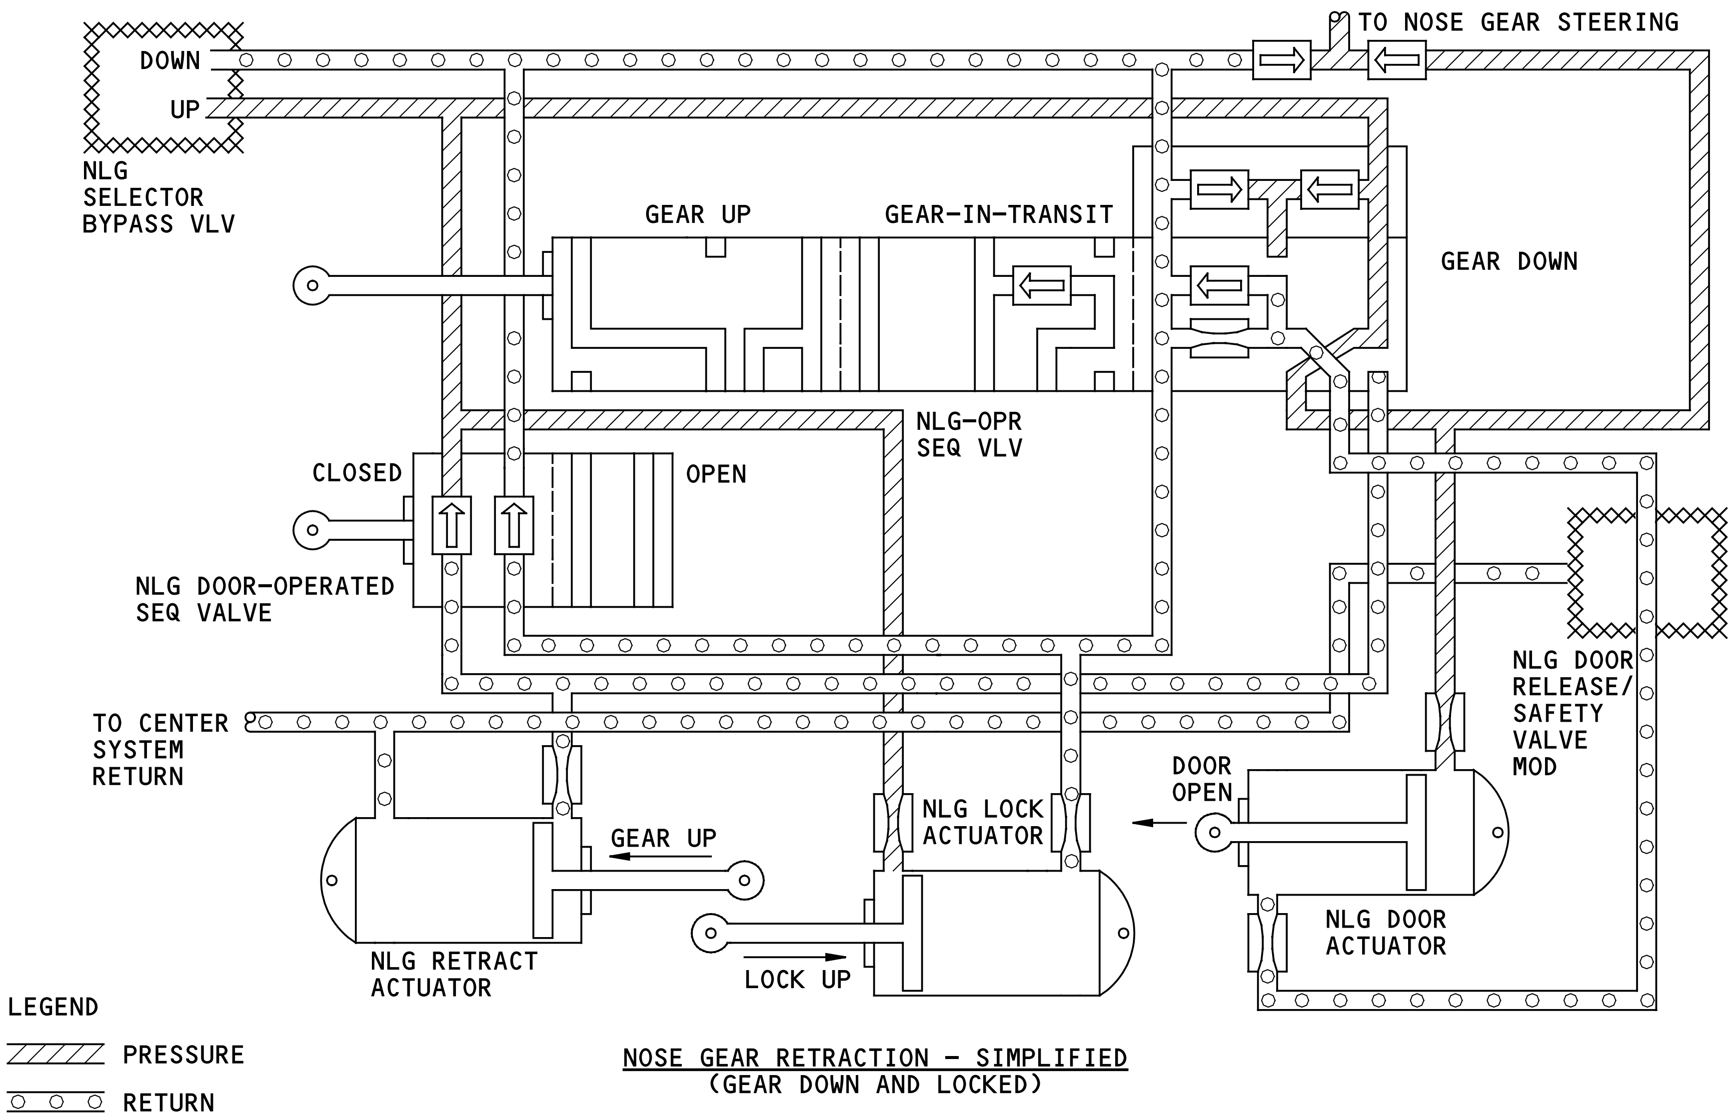
The lock inside the NLG door actuator locks the NLG when the doors are in the CLOSED position.

Final Positions

These are the final positions for nose gear components:

- NLG - UP AND LOCKED
- NLG doors - CLOSED
- NLG gear-operated sequence valve - GEAR UP
- NLG door-operated sequence valve - CLOSED.

The NLG selector/bypass valve automatically removes pressure from the NLG retract lines approximately ten seconds after the gear is up and locked.



NOSE GEAR RETRACTION - SIMPLIFIED
(GEAR DOWN AND LOCKED)

NLG EXTENSION-RETRACTION - RETRACTION SEQUENCE

NLG EXTENSION-RETRACTION - EXTENSION SEQUENCE

Initial Positions

These are the initial positions for the nose gear components:

- NLG - UP AND LOCKED
- NLG doors - CLOSED
- NLG-operated sequence valve - GEAR UP
- NLG door-operated sequence valve - CLOSED.

Control

When you select DOWN with the landing gear control lever, the nose landing gear selector/bypass valve moves to the DOWN position. Hydraulic pressure then goes to the extend lines.

Doors Open

Hydraulic pressure goes through the NLG-operated sequence valve to the NLG door actuator. The pressure unlocks the actuator and opens the forward nose landing gear doors.

Gear Unlocks - Gear Extends

When the nose landing gear doors are almost at the full open position, the NLG door-operated sequence valve moves to OPEN.

Pressure then goes to the extend side of the NLG lock actuator to unlock the uplock.

The NLG extends by the force of its own weight and by airloads. As the NLG starts to extend, the NLG-operated sequence valve moves to the GEAR-IN-TRANSIT position.

Doors Close

When the NLG is almost down, the NLG-operated sequence valve moves to the DOWN position. Pressure now goes to the retract side of the NLG door actuator and the doors start to close.

The NLG lock actuator continues to extend and locks the NLG when the gear is fully down.

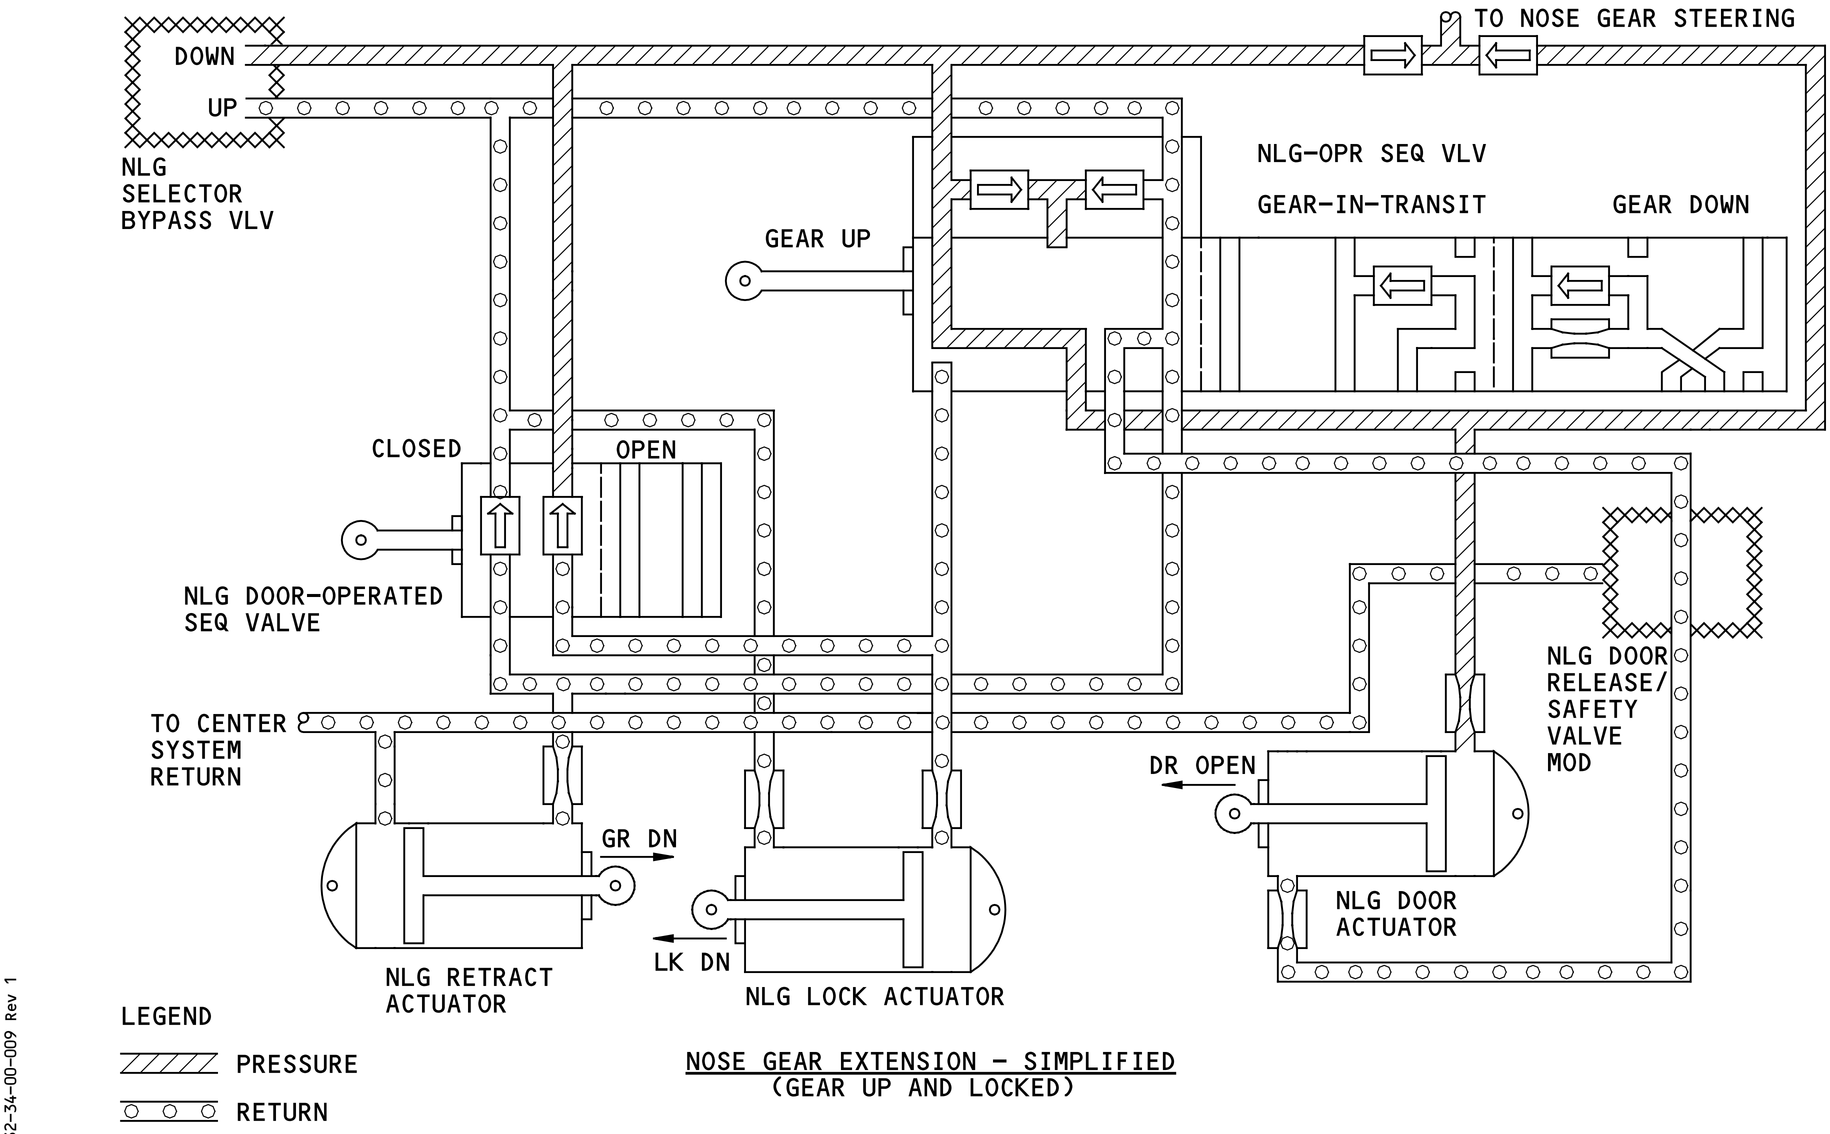
The lock inside the NLG door actuator locks when the doors are in the CLOSED position.

Final Positions

The final positions for NLG components are:

- NLG - DOWN AND LOCKED
- NLG doors - CLOSED
- NLG-operated sequence valve - GEAR DOWN
- NLG door-operated sequence valve - CLOSED.

Pressure stays in the NLG lock actuator and the NLG door actuator when the gear is down and the center hydraulic system is pressurized.



NOSE GEAR EXTENSION - SIMPLIFIED
(GEAR UP AND LOCKED)

NLG EXTENSION-RETRACTION - EXTENSION SEQUENCE

LANDING GEAR ALTERNATE EXTENSION SYSTEM - INTRODUCTION

Purpose

The alternate extension system permits you to extend the landing gear when there is no center hydraulic system pressure or if normal extension fails.

You also use the alternate extension system to open the landing gear doors on the ground.

Components

The alternate extension system components include:

- The alternate extend power pack
- The main landing gear door release/safety valve modules
- The nose landing gear door release/safety valve module
- The main landing gear alternate uplock release actuators
- The nose landing gear alternate uplock release actuator
- The alternate extend hydraulic pressure switch.

General Description

The alternate extension system operates independently of the normal extension and retraction system.

The hot battery bus supplies power to control and operate the alternate extension system. The ELMS contains relays that control the power to the alternate extend power pack.

The alternate extend power pack has a hydraulic pump operated by an electric motor. The alternate extend power pack pressurizes fluid from the center hydraulic system. This fluid then goes to door release/safety valve modules for each landing gear and unlocks the landing gear doors.

Fluid then goes to alternate uplock release actuators for each landing gear and unlocks the uplocks for the landing gear.

The landing gear doors open and the landing gear extend by airloads and their own weight. The landing gear tires may contact the landing gear doors during an alternate extension.

The alternate extend pressure switch stops operation of the power pack after the extend cycle is complete.

These switches are on these two panels:

- P56 wheel well electrical service panel
- P40 service and APU shutdown panel.

Wheel Well Electrical Service Panel Switches

The wheel well electrical service panel is on the bottom of the airplane behind the main landing gear wheel wells.

These two switches on the wheel well electrical service panel control the landing gear doors:

- Arm doors switch
- All doors open/MLG doors close switch.

The arm doors switch is a two-position toggle switch. The two positions are OFF and ARM. The all doors open/MLG doors close switch is a three position switch. The positions are MLG DOOR CLOSE, OFF, and ALL DOORS OPEN. To operate the switches, you must pull them out from the OFF detent. Both switches are spring-loaded to OFF.

You must operate both switches at the same time. You move the arm doors switch to the ARM DOORS position. You move the all doors open/MLG doors close switch to the ALL DOORS OPEN position to open all landing gear doors (MLG and NLG). This operates the LG alternate extension system.

You move the arm doors switch to the ARM DOORS position and the all doors open/MLG doors close switch to the MLG DOORS CLOSE position to close the MLG doors. The doors close with center hydraulic system pressure.

Two control switches make sure that a single electrical failure does not accidentally operate the landing gear doors.

Service and APU Shutdown Panel Switches

The service and APU shutdown panel is on the aft side of the nose landing gear shock strut.

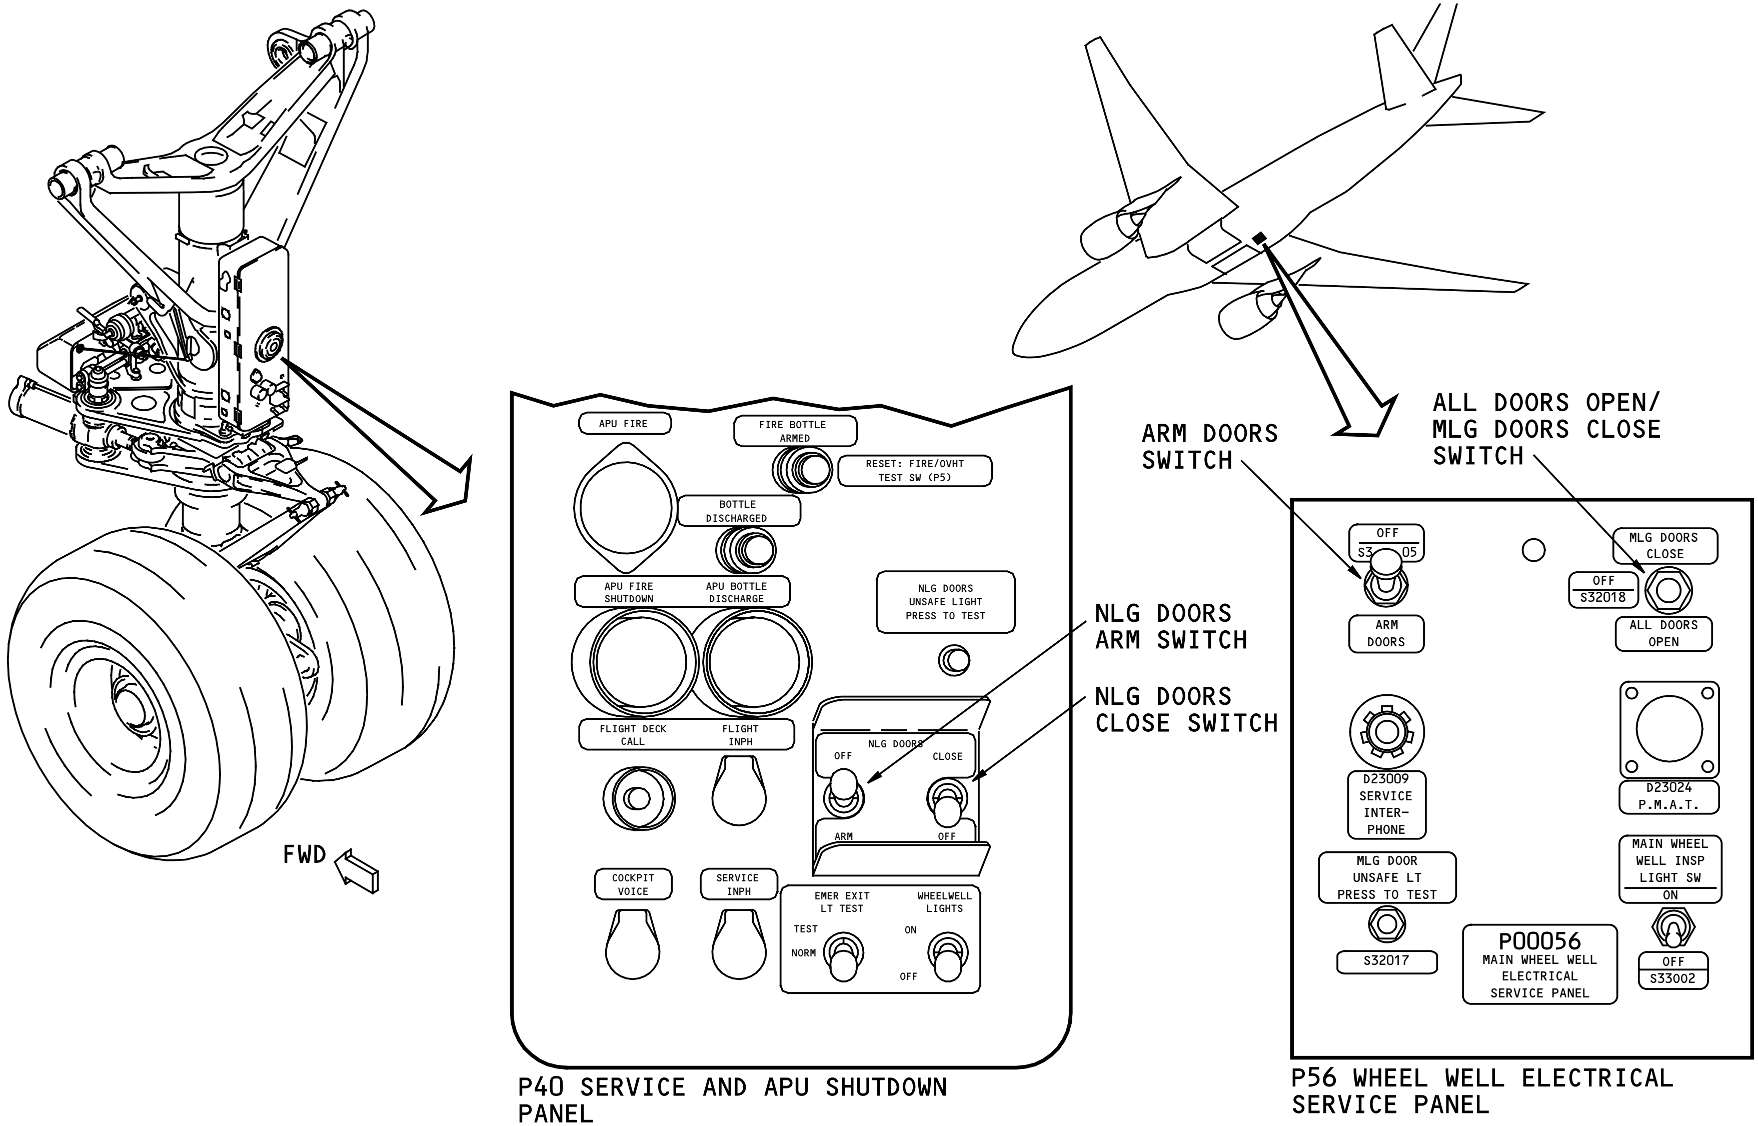
Two switches on the service and APU shutdown panel operate the nose landing gear doors:

- NLG doors arm switch
- NLG doors close switch.

These switches are two-position toggle switches. To operate the switches, you must pull them out from the OFF detent. Both switches are spring-loaded to OFF.

You must operate both switches at the same time. You move the switches to the ARM and CLOSE positions to close the NLG doors. The doors close with center hydraulic system pressure.

LANDING GEAR ALTERNATE EXTENSION SYSTEM - GROUND DOOR OPERATION CONTROLS



LANDING GEAR ALTERNATE EXTENSION SYSTEM - GROUND DOOR OPERATION CONTROLS

LANDING GEAR ALTERNATE EXTENSION SYSTEM - ALTERNATE EXTEND POWER PACK

Purpose

The alternate extend power pack supplies hydraulic pressure to the alternate extension system.

Physical Description

The power pack is an electric motor hydraulic pump. The 28v dc hot battery bus supplies power to the motor.

An oversize tube from the center hydraulic system reservoir supplies hydraulic fluid to the hydraulic pump in the power pack.

The power pack has internal hydraulic routing to let hydraulic fluid flow back into the oversize supply tube when the power pack is off.

Location

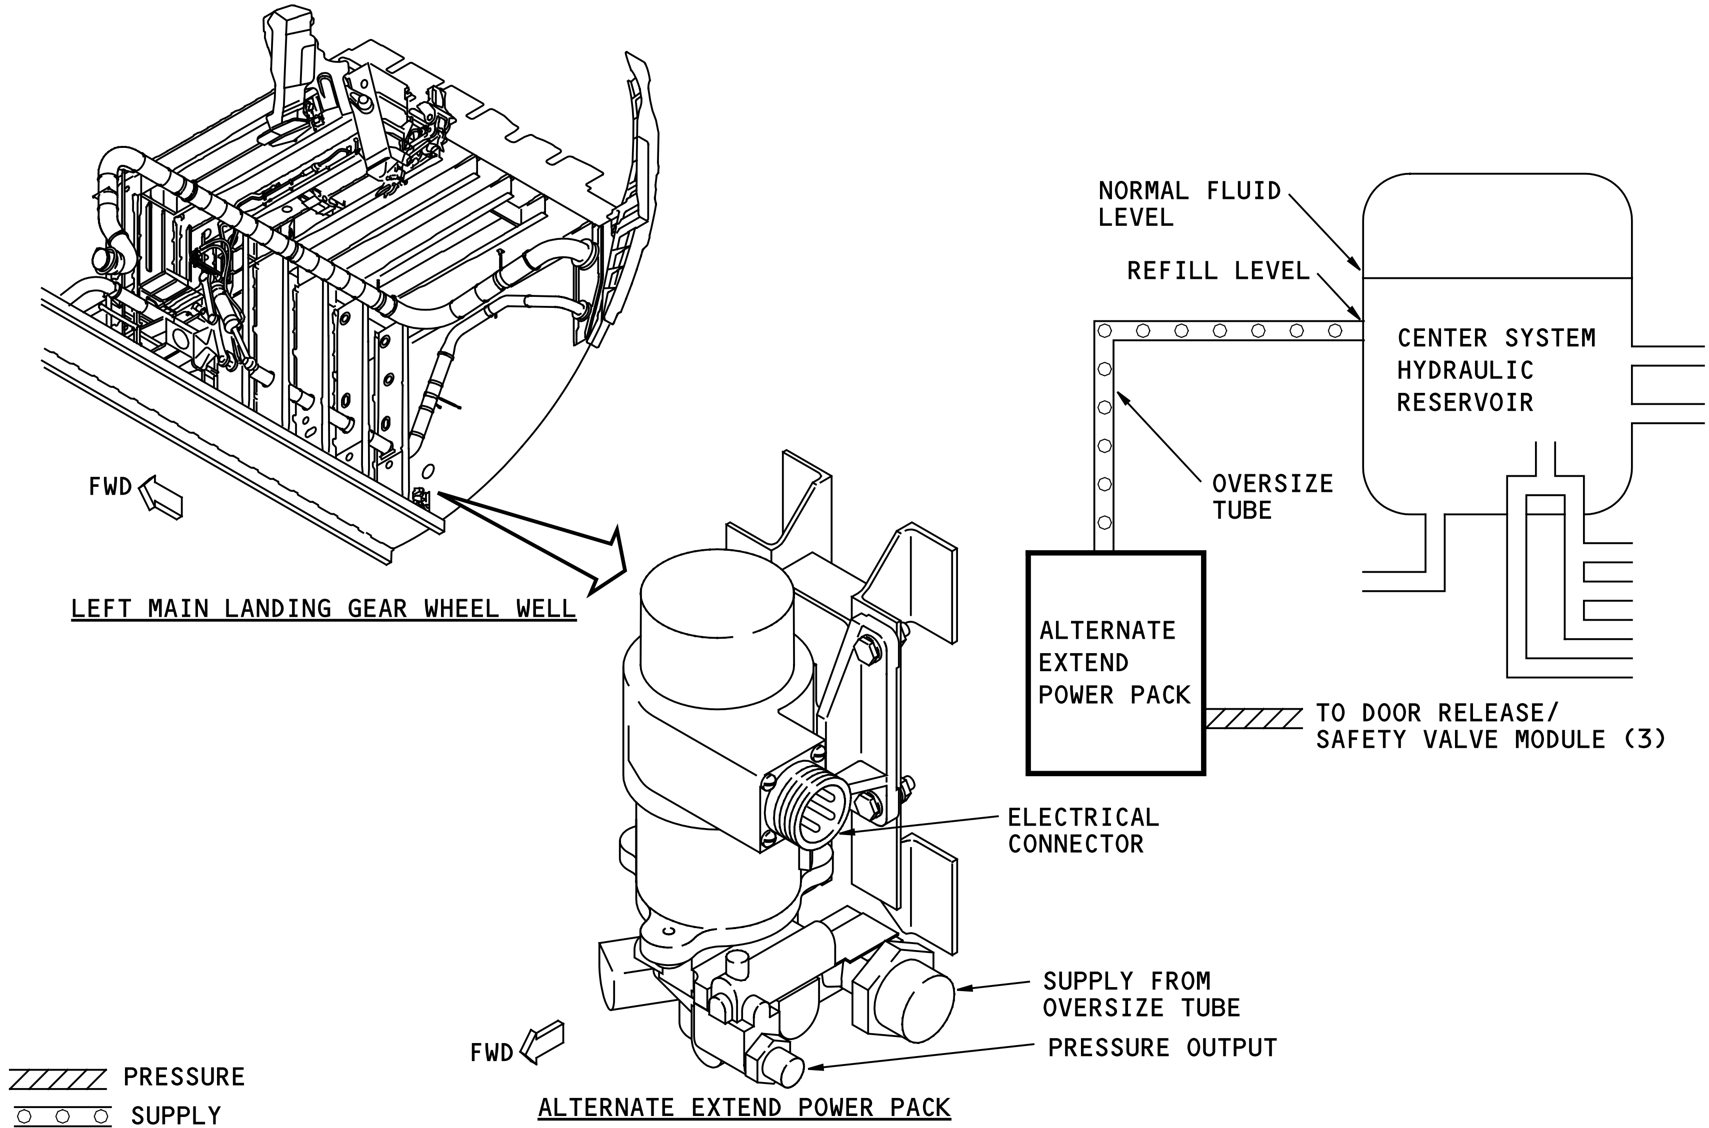
The alternate extend power pack is in the aft-inboard corner of the left main landing gear wheel well.

Training Information Point

The supply tube connects to the side of the reservoir. The connection is slightly below the reservoir refill level (0.75 reservoir fluid level). This makes sure that a hydraulic fluid leak in the alternate extension system is detected by reservoir refill indications. This also makes sure that the supply tube is filled when the reservoir is correctly serviced.

A leak in the alternate extension system does not drain all the fluid from the center hydraulic system reservoir.

The supply tube from the reservoir contains enough hydraulic fluid to do an alternate extension. The alternate extension system does function with an empty center hydraulic system reservoir.



32-35-00-005 Rev 2 10/29/1996

LANDING GEAR ALTERNATE EXTENSION SYSTEM - ALTERNATE EXTEND POWER PACK

LANDING GEAR ALTN EXTENSION SYSTEM - DOOR RELEASE/SAFETY VALVE MODULES - GENERAL DESCRIPTION

Purpose

There is one main landing gear door release/safety valve module for each main landing gear. There is one nose landing gear door release/safety valve module.

When the alternate extension system operates, the door release/safety valve modules do these functions:

- Stop the normal hydraulic system pressure to the close side of each landing gear door actuator
- Connect the close side of each door actuator to return, so the doors can open
- Extend a rod to release the landing gear door locks
- Send pressure to the alternate uplock release actuators to release the landing gear uplocks.

Each MLG door release/safety valve module extends a rod to push the gear door uplock mechanism to release the over-center lock. This permits the MLG doors to open. The NLG door release/safety valve module extends a rod to push a crank on the NLG door actuator. This crank turns to release the lock inside the NLG door actuator. This permits the NLG doors to open.

The door release/safety valve modules also have a reset function to close the doors. You use switches on the P40 and P56 panels to reset the modules. Center hydraulic system pressure closes the landing gear doors.

Location

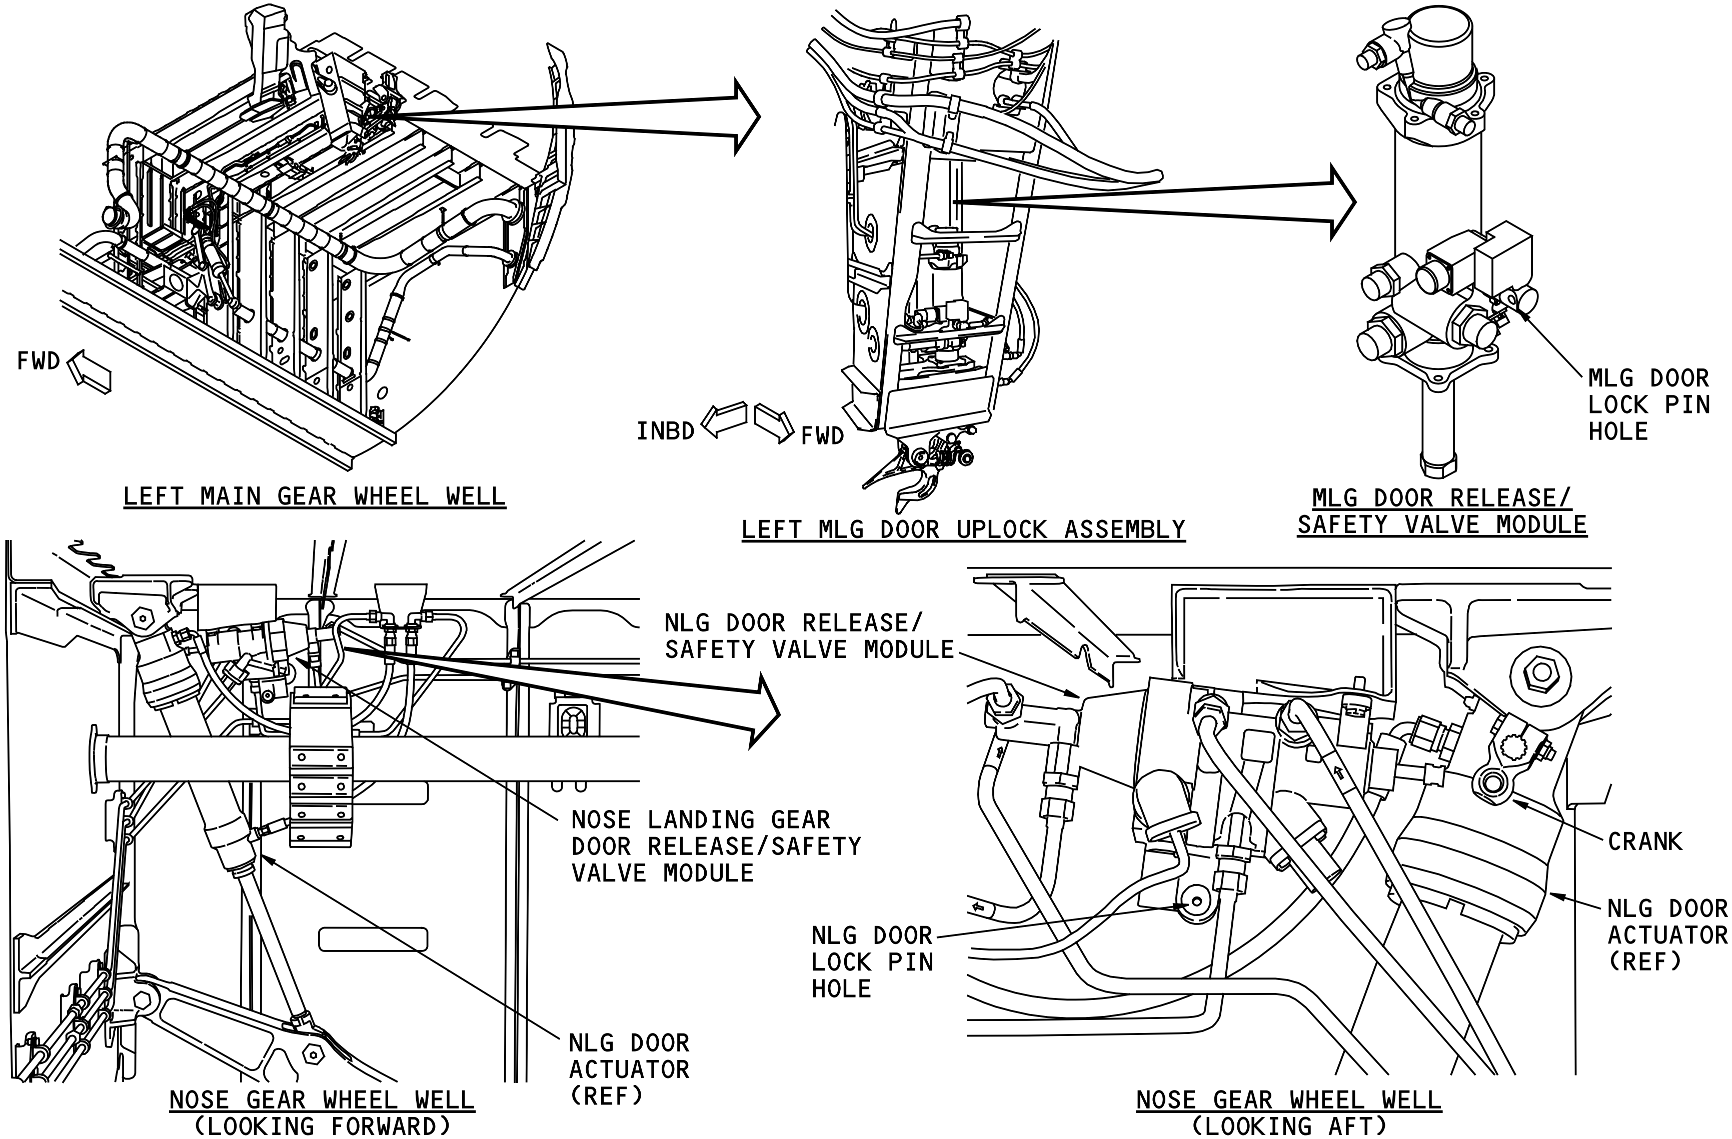
The main landing gear door release/safety valve modules are inside the door uplock assembly. A removable panel permits access to the module.

The nose landing gear door release/safety valve module is on the ceiling in the nose wheel well near the nose landing gear door actuator.

Training Information Point

The nose landing gear door release/safety valve module is not interchangeable with the main landing gear door release/safety valve modules.

You install door lock pins in the door release/safety valve modules for safety. With the pins installed, you cannot reset the modules and the doors cannot close.



32-35-00-006 Rev 3 10/28/1996

LANDING GEAR ALTN EXTENSION SYSTEM - DOOR RELEASE/SAFETY VALVE MODULES - GENERAL DESCRIPTION

LANDING GEAR ALTERNATE EXTENSION SYSTEM - ALTERNATE EXTEND HYDRAULIC PRESSURE SWITCH

Purpose

The alternate extend hydraulic pressure switch stops the alternate extend power pack when the extend cycle is complete.

Location

The alternate extend hydraulic pressure switch is on the ceiling in the NLG wheel well. It is near the NLG alternate uplock release actuator.

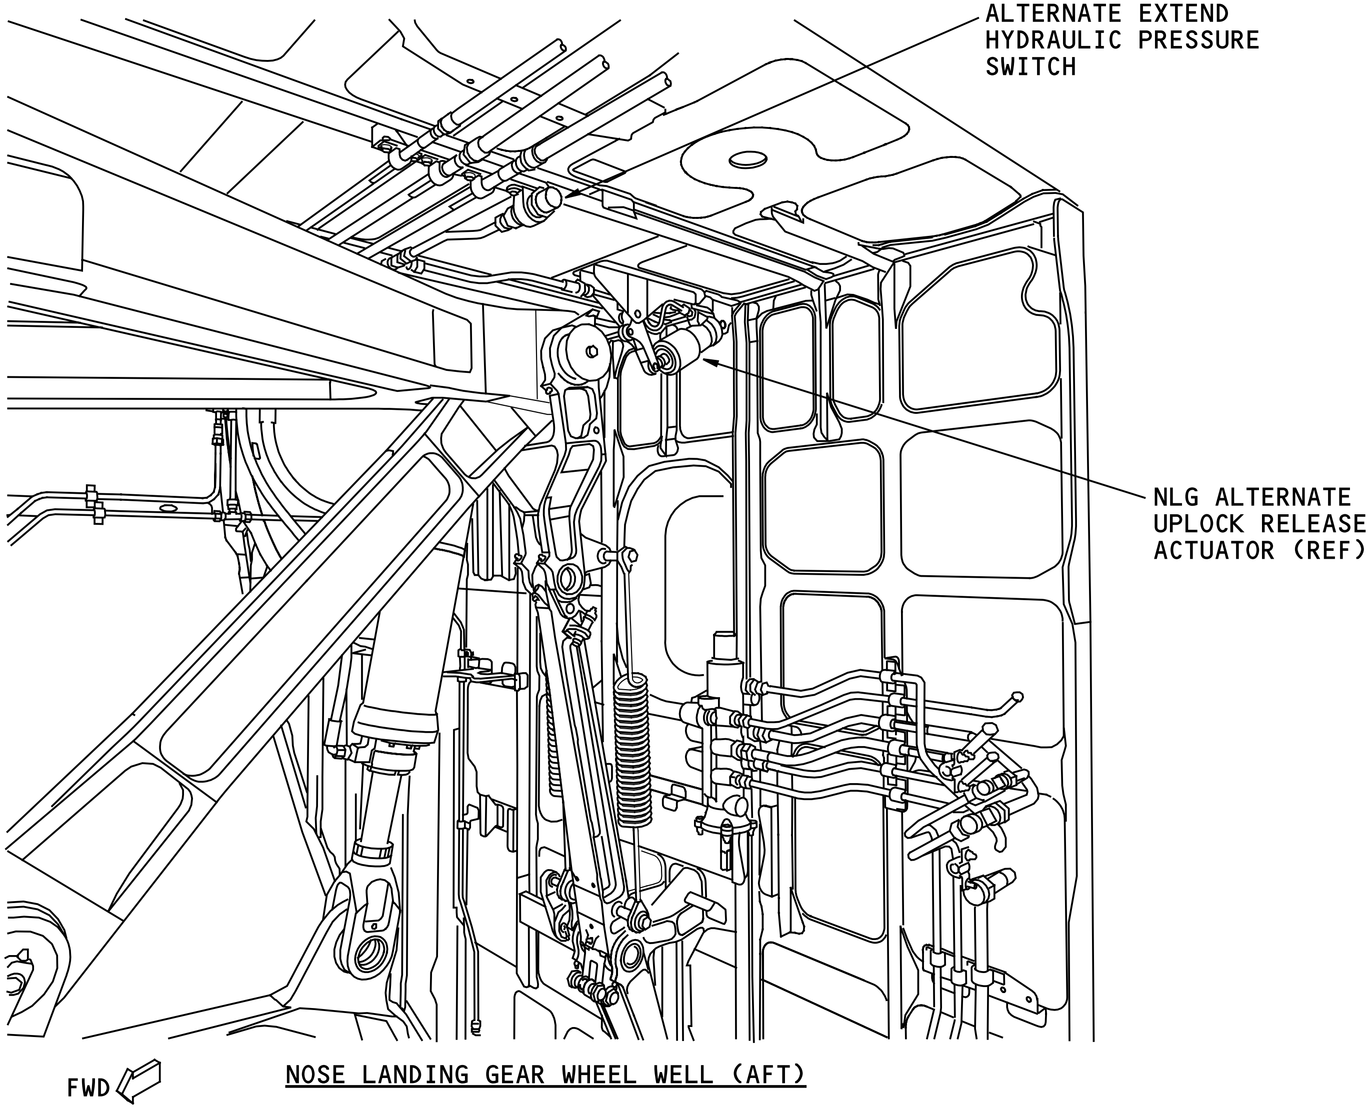
Functional Description

The pressure switch is in the hydraulic line between the NLG door release/safety valve module and the NLG alternate uplock release actuator.

The NLG alternate uplock release actuator is the farthest point in the alternate extension system from the power pack. It is the last component to get hydraulic pressure.

The switch opens when there is 2100 psi in the pressure line. This removes electrical power from the alternate extend power pack and it stops.

When the alternate extend pressure decreases below 1700 psi, the pressure switch closes to reset the alternate extension system.



NOSE LANDING GEAR WHEEL WELL (AFT)

LANDING GEAR ALTERNATE EXTENSION SYSTEM - ALTERNATE EXTEND HYDRAULIC PRESSURE SWITCH

LANDING GEAR ALTERNATE EXTENSION SYSTEM - LANDING GEAR DOOR CLOSED SWITCHES

Purpose

The landing gear door closed switches supply landing gear door position input to control landing gear door unsafe light operation.

Each main landing gear door has a MLG door closed switch. The nose landing gear forward doors have a single NLG door closed switch.

Physical Description

The switches are mechanical plunger-type switches. They operate by direct contact with the landing gear door.

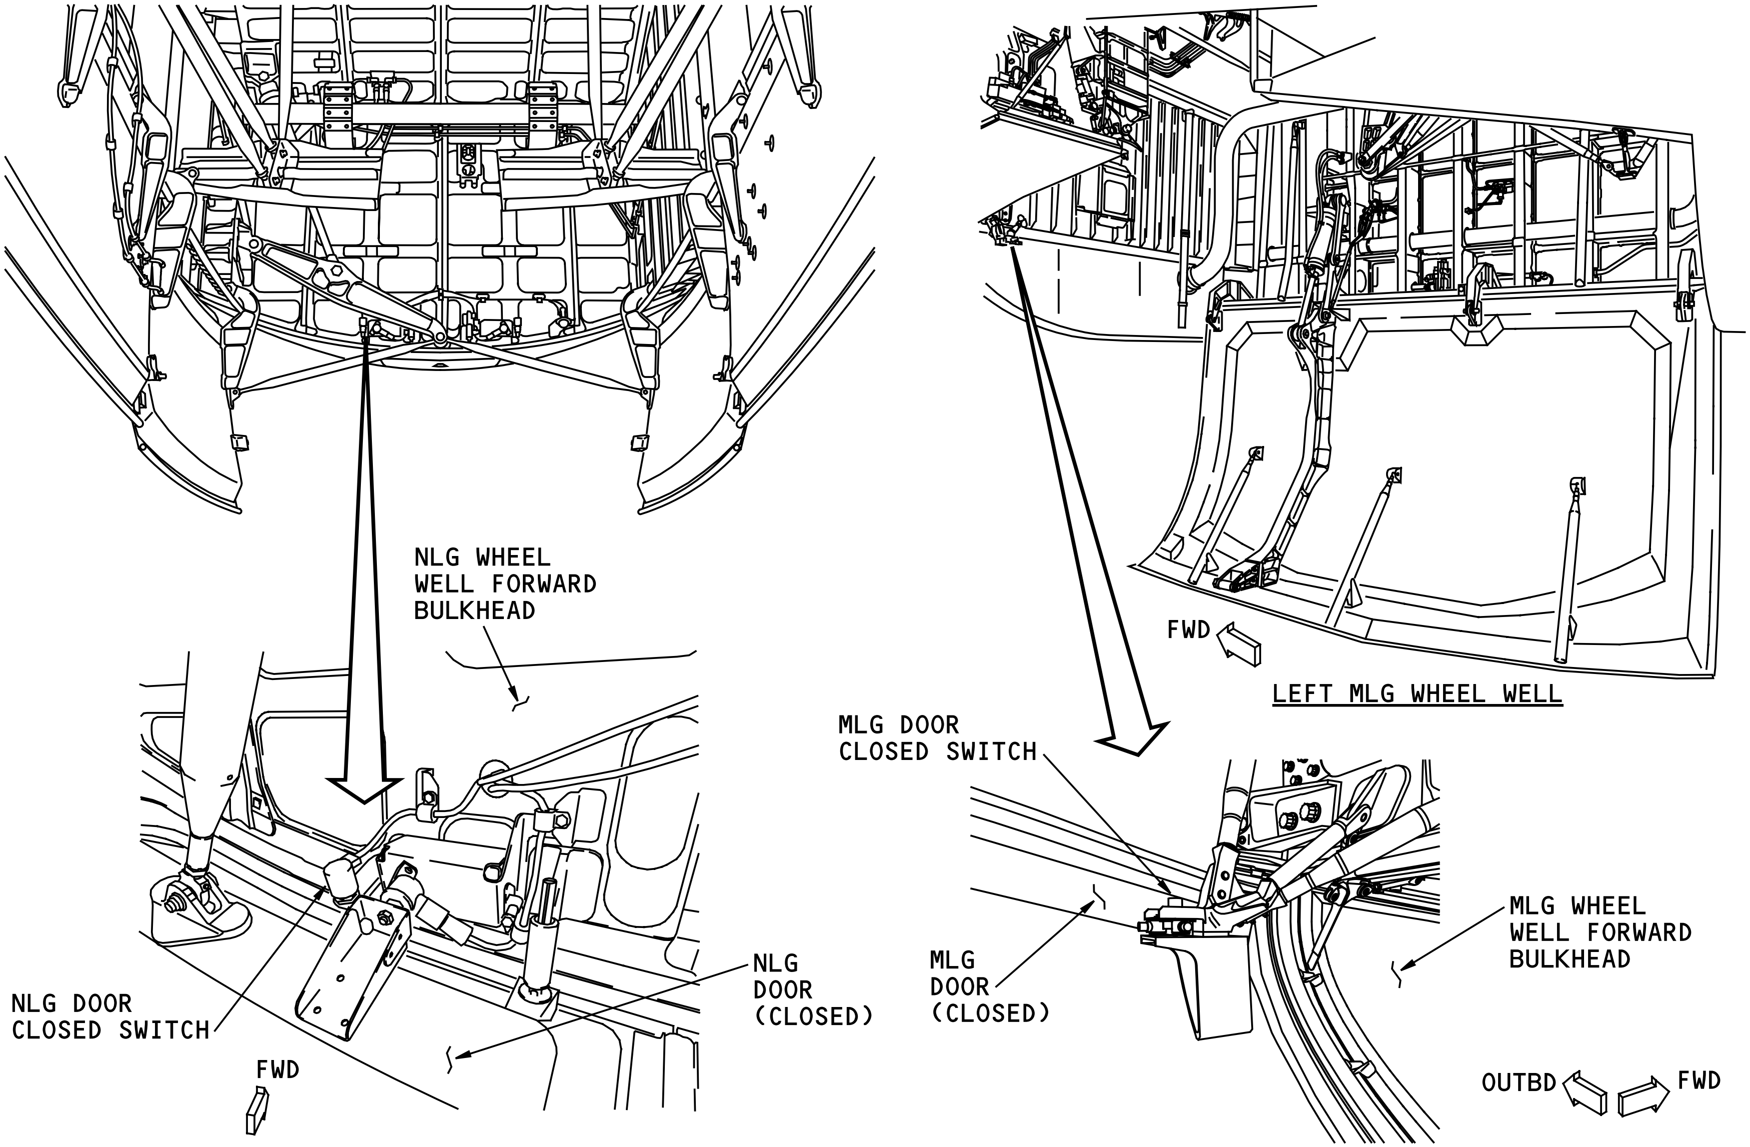
The switches open when the landing gear doors are closed. The door unsafe lights are always off when the LG doors are closed.

The switches close when the LG doors are open.

Location

The NLG door closed switch is on the forward bulkhead of the nose landing gear wheel well.

A MLG door closed switch is in the outboard forward corner of each main landing gear wheel well on the forward door stop.



32-35-00-011 Rev 3 10/28/1996

LANDING GEAR ALTERNATE EXTENSION SYSTEM - LANDING GEAR DOOR CLOSED SWITCHES

LANDING GEAR ALTERNATE EXTENSION SYSTEM - LANDING GEAR DOOR UNSAFE LIGHTS

Purpose

A red landing gear door unsafe light is in each wheel well. Each light turns on when the door is open and the wheel well is not safe to enter. The position of the safety valve in the landing gear door release/safety valve module controls the light.

Location

A main landing gear door unsafe light is on the lower part of the keel beam in each wheel well.

The nose landing gear door unsafe light is on the nose landing gear wheel well forward bulkhead above the right nose landing gear forward door.

Training Information Point

A press-to-test switch on the main wheel well electrical service panel tests the operation of both main landing gear door unsafe lights.

A press-to-test switch on the service and APU shutdown panel tests the operation of the nose landing gear door unsafe light.

WARNING: MAKE SURE THE DOOR UNSAFE LIGHT IN EACH WHEEL WELL FOR THE MAIN LANDING GEAR IS OFF. IF A DOOR UNSAFE LIGHT IS ON, DO NOT GO INTO THE RELATED WHEEL WELL. WHEN A DOOR UNSAFE LIGHT IS ON, THE DOOR FOR THE RELATED MAIN LANDING GEAR IS IN A NOT SAFE CONDITION AND CAN ACCIDENTALLY CLOSE. THE DOORS CLOSE QUICKLY AND CAN CAUSE INJURIES TO PERSONS OR DAMAGE TO EQUIPMENT.

WARNING: MAKE SURE THE DOOR UNSAFE LIGHT IN THE WHEEL WELL FOR THE NOSE LANDING GEAR IS OFF. IF THE DOOR UNSAFE LIGHT IS ON, DO NOT GO INTO THE WHEEL WELL. WHEN THE DOOR UNSAFE LIGHT IS ON, THE DOORS FOR THE NOSE LANDING GEAR ARE IN A NOT SAFE CONDITION AND CAN ACCIDENTALLY CLOSE. THE DOORS CLOSE QUICKLY AND CAN CAUSE INJURIES TO PERSONS OR DAMAGE TO EQUIPMENT.

LANDING GEAR ALTERNATE EXTENSION SYSTEM - LANDING GEAR DOOR UNSAFE LIGHTS

LANDING GEAR ALTERNATE EXTENSION SYSTEM - LG DOOR UNSAFE LIGHTS - FUNCTIONAL DESCRIPTION

General

The landing gear door unsafe lights come on when a landing gear door is open and the safety valve in the landing gear door release/safety valve module is in the NORMAL position.

Inputs

The 28v dc hot battery bus supplies power for operation of the landing gear door unsafe lights.

The safety latch position sensing switch in the door release/safety valve modules supply safety valve position inputs.

The door closed switches supply landing gear door position inputs.

Press-To-Test

The nose landing gear press-to-test switch lets you do a test of the nose landing gear unsafe light when the nose gear door is open and the safety valve is SAFE.

The main landing gear press-to-test switch lets you do a test of both main landing gear unsafe lights when the main landing gear doors are open and the safety valves are SAFE.

Training Information Point

During normal operation of the landing gear extension-retraction system, the safety valves in the door release/safety valve modules are in the NORMAL positions. The LG door unsafe lights turn on while the LG doors are open during normal landing gear extension and retraction.

LANDING GEAR ALTERNATE EXTENSION SYSTEM - LG DOOR UNSAFE LIGHTS - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

LANDING GEAR ALTERNATE EXTENSION SYSTEM - FUNCTIONAL DESCRIPTION - ELECTRICAL

General

A switch on the P2 center instrument panel or switches on the wheel well electrical service panel (P56) start alternate extend power pack operation.

Alternate Extension System Operation

The alternate gear switch is a two position (NORM and DOWN) guarded toggle switch. It is a momentary switch and is spring-loaded to NORM.

When you push the alternate gear switch, the alternate extend control relays in ELMS energize. These relays have a latching circuit which keep them energized after you release the alternate gear switch.

The relays permit power from the hot battery bus to go to the alternate extend power pack.

The alternate extend power pack comes on and supplies hydraulic pressure for alternate extend operation.

After all doors and gear are unlocked, the alternate extend hydraulic pressure increases. At 2100 psi, the alternate extend hydraulic pressure switch opens and removes electrical power in the latching circuits for both alternate extend control relays. This removes electrical power from the alternate extend power pack.

Ground Door Operation

Ground door operation is almost the same as operation with the alternate gear switch.

The only difference is that you use the switches on the P56 panel to power the alternate extend control relays.

Indications

The PSEUs monitor the alternate extend control relays.

When you operate the alternate extend switch or the ground door release switches, the gear display on the EICAS expands to the multi-symbol display. The multi-symbol display shows the position of each gear. The display remains expanded until all landing gear doors are closed.

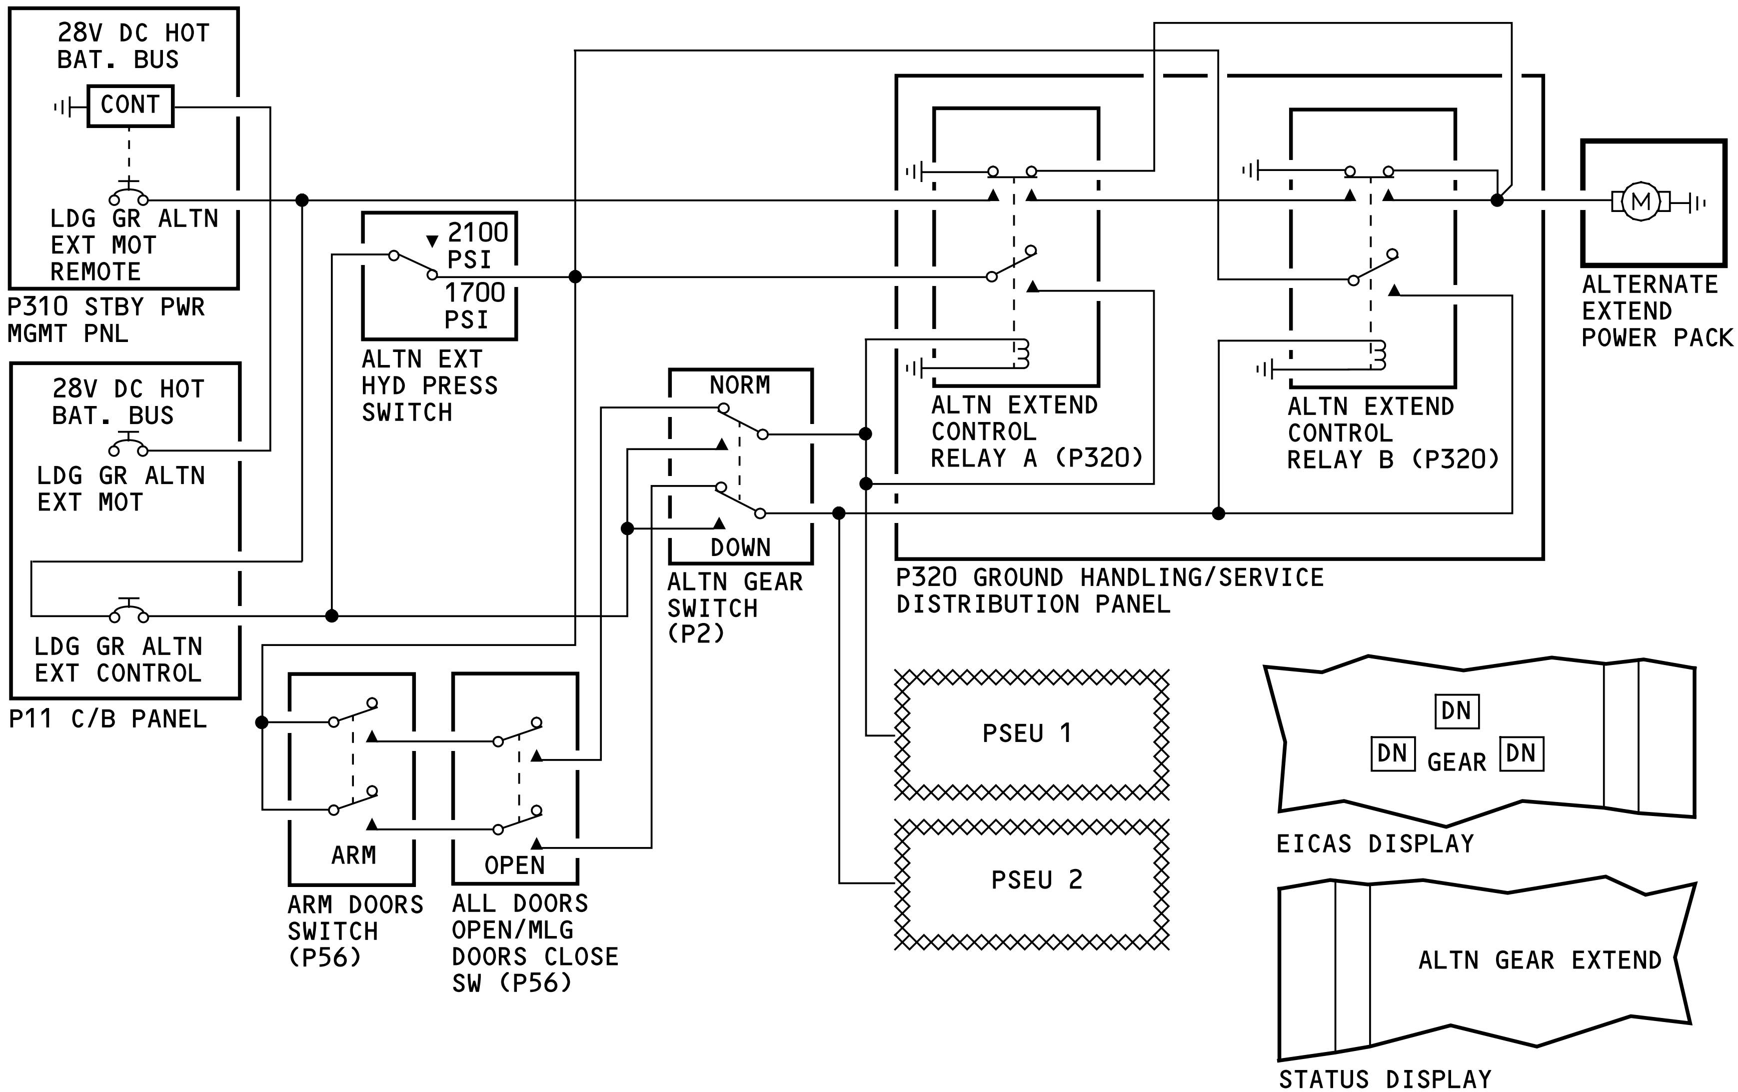
The position of each door shows on the landing gear synoptic display. The GEAR DOOR advisory message shows on the EICAS when the alternate extension system is energized. The GEAR DOOR advisory message stays displayed until all of the doors close.

If either or both relays are energized for more than 60 seconds, the ALTN GEAR EXTEND message shows on the status display. Since the normal alternate extension cycle is less than 60 seconds, this indicates a system fault.

LANDING GEAR ALTERNATE EXTENSION SYSTEM - FUNCTIONAL DESCRIPTION - ELECTRICAL

Training Information Point

To manually remove power from the alternate extension system, you pull the LDG GR ALTN EXT MOT circuit breaker on the P11 panel. This circuit breaker controls the LDG GR ALTN EXT MOT REMOTE circuit breaker on the P310 standby power management panel.



32-35-00-014 Rev 3 10/29/1996

LANDING GEAR ALTERNATE EXTENSION SYSTEM - FUNCTIONAL DESCRIPTION - ELECTRICAL

THIS PAGE INTENTIONALLY LEFT BLANK

LANDING GEAR ALTERNATE EXTENSION SYSTEM - FUNCTIONAL DESCRIPTION - HYDRAULIC

General

The alternate extend power pack pressurizes hydraulic fluid from the center hydraulic system.

Pressure goes to the MLG and the NLG selector/bypass valves. If the selector valve is in the UP or OFF position, the bypass valve moves to the BYPASS position to let the gear extend. See the landing gear control section for more information about the landing gear selector/bypass valves (AMM PART I 32-31).

The MLG and NLG alternate extend components operate the same. Each MLG and the NLG have these components:

- Landing gear door release/safety valve module
- Landing gear alternate uplock release actuator.

There is one alternate extend hydraulic pressure switch located in the NLG wheel well.

Landing Gear Door Release/Safety Valve Module

Alternate extend pressure extends the door release actuator. This actuator releases the landing gear door which then opens by gravity and airloads.

As the door release actuator extends, the safety valve moves to the SAFE position. The safety valve is latched in the SAFE position.

After it extends, the door release actuator sends pressure to the landing gear alternate uplock release actuator.

Landing Gear Alternate Uplock Release Actuator

The landing gear alternate uplock release actuator extends to unlock the landing gear uplock. This permits gravity and airloads to extend the gear. The tires may contact the door during alternate extension.

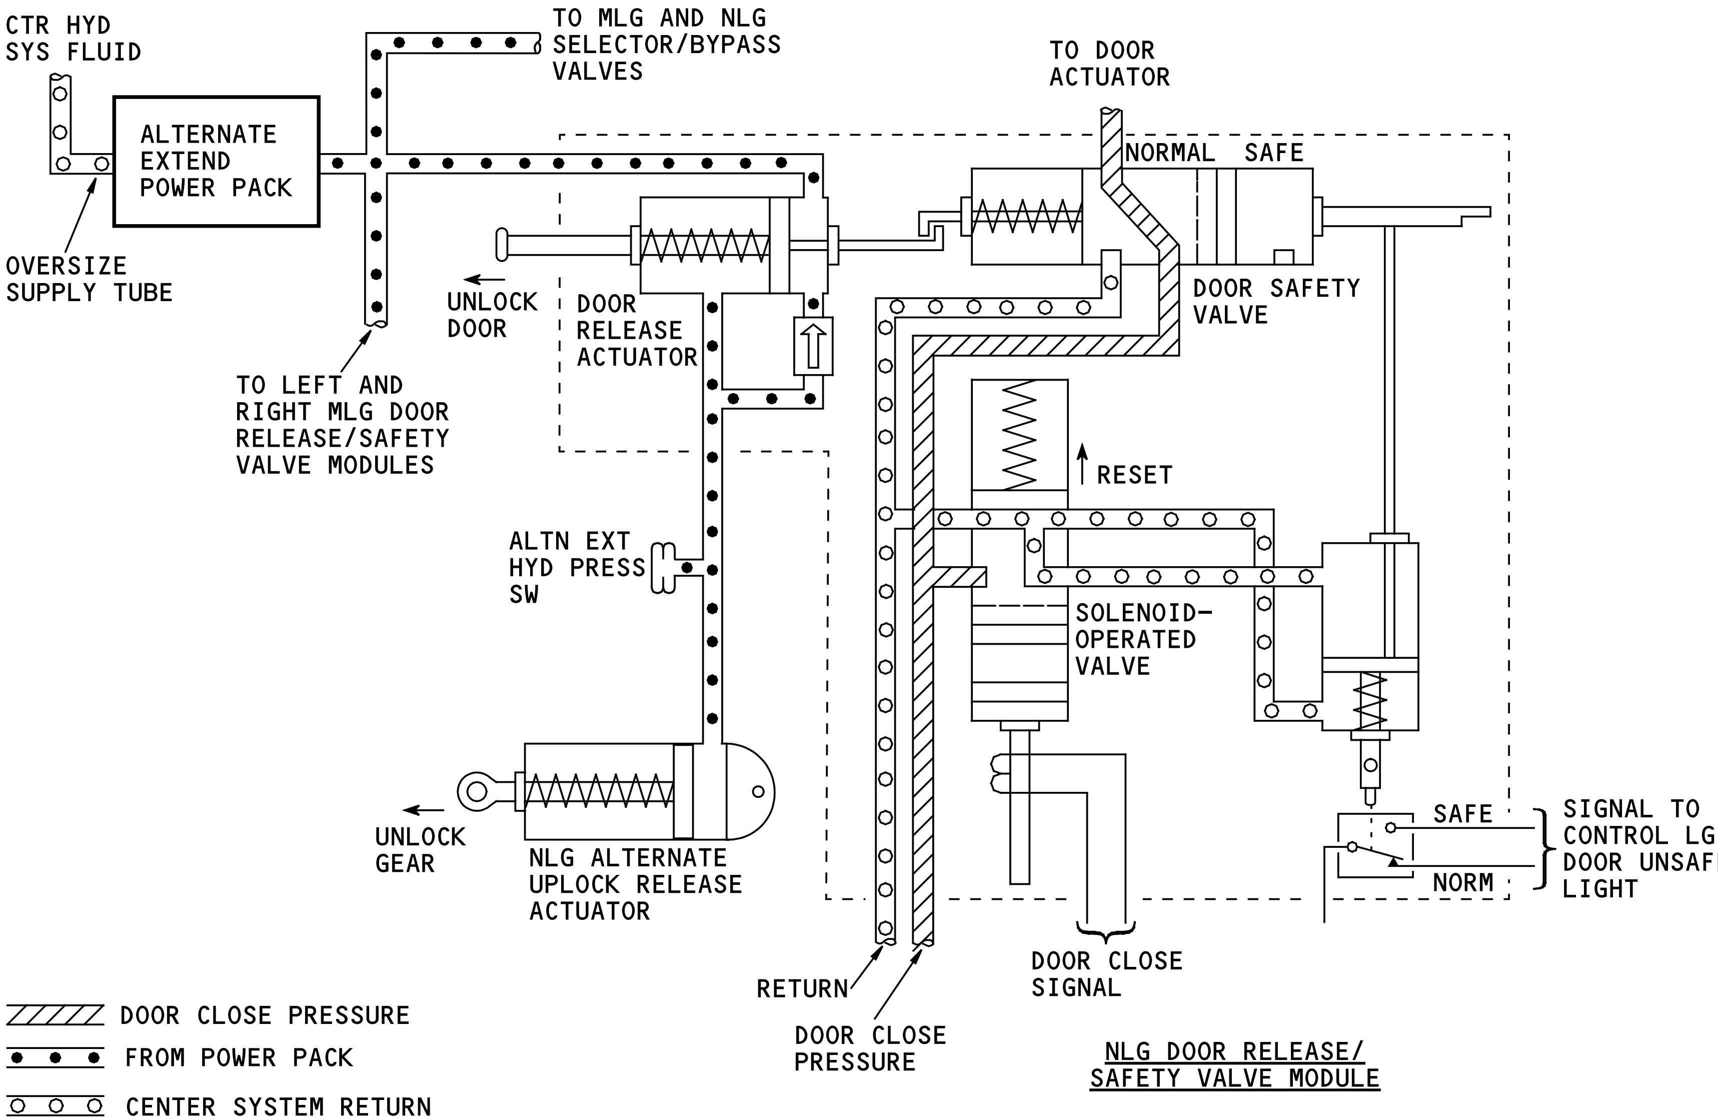
Alternate Extend Hydraulic Pressure Switch

After all doors and gear are unlocked, hydraulic pressure in the alternate extension system increases. When the pressure gets to 2100 psi, the alternate extend hydraulic pressure switch opens. This removes electrical power from the alternate extend control relays. The relays de-energize and remove electrical power from the alternate extend power pack.

Reset

When the alternate extend power pack stops, the alternate uplock release actuator and the door release actuator in the door release/safety valve reset. The springs in the actuators push the hydraulic fluid through the alternate extend power pack and into the oversize supply tube.

The door safety valve in the door release/safety valve module remains in the SAFE position until it is reset. This prevents the door from closing. The door safety valve is reset by an electric signal to the solenoid operated valve. Switches on the P40 and P56 panels, or a switch within the landing gear control lever module provide the reset signal. When the solenoid energizes, the valve permits hydraulic pressure to release the safety valve latch. The reset signal must be made while door close hydraulic pressure is available. When the valve moves to the NORMAL position, the door closes.



LANDING GEAR ALTERNATE EXTENSION SYSTEM - FUNCTIONAL DESCRIPTION - HYDRAULIC

32-35-00-015 Rev 3 10/28/1996

LANDING GEAR ALTERNATE EXTENSION SYSTEM - LANDING GEAR DOOR CLOSE OPERATION

General

You can close the landing gear doors with the door close switches or with the landing gear lever. The center hydraulic system supplies the pressure to close the landing gear doors.

MLG and NLG gear door close operation is almost the same.

Door Close Operation

You close the two main landing gear doors at the same time with switches on the P56 wheel well electrical service panel.

You close the nose landing gear doors with switches on the P40 service and APU shutdown panel.

The landing gear lever closes all the landing gear doors only after the gear have retracted. The landing gear door close signal from the landing gear lever goes through a five second time delay relay in the P320 ground handling/service distribution panel. When you move the landing gear lever to the UP position, the solenoids in the door release/safety valve modules get power five seconds later. This delay gives the selector valves time to move to the UP position. This prevents the safety valve from accidental movement to the NORMAL position before the selector valve has time to move. The delay makes sure the door release/safety valve modules are reset by the lever only after the gear retract.

For any door close signal, power from the 28v dc left main bus goes to the solenoid valves in the landing gear door release/safety valve modules.

To close the doors, the door close signal must be made at the same time door close hydraulic pressure is available.

Training Information Point

When you use the switches on the P56 panel, the main landing gear doors close in approximately 10 seconds.

WARNING: MAKE SURE THE AREA AROUND THE DOORS FOR THE MAIN LANDING GEAR IS CLEAR OF PERSONS AND EQUIPMENT. THE DOORS CLOSE QUICKLY AND CAN CAUSE INJURY TO PERSONS OR DAMAGE TO EQUIPMENT.

When you use the switches on the P40 panel, the nose landing gear doors close in approximately 5 seconds.

WARNING: MAKE SURE THE AREA AROUND THE DOORS FOR THE NOSE LANDING GEAR IS CLEAR OF PERSONS AND EQUIPMENT. THE DOORS CLOSE QUICKLY AND CAN CAUSE INJURY TO PERSONS OR DAMAGE TO EQUIPMENT.

Once the door close operation starts, you can not stop the operation with the switches on the remote panels.

LANDING GEAR ALTERNATE EXTENSION SYSTEM - LANDING GEAR DOOR CLOSE OPERATION

LANDING GEAR ALTERNATE EXTENSION SYSTEM - BLEED VALVES

General

Four bleed valves let you bleed air from the alternate extension system. You need to bleed the alternate extension system when you replace some of the alternate extension system components.

Location

The bleed valves are near these components:

- The NLG selector/bypass valve (NLG wheel well)
- The NLG alternate uplock release actuator (NLG wheel well)
- The left and right MLG alternate uplock release actuators (left and right MLG wheel wells).

Training Information Point

You operate the alternate extend power pack when you bleed the alternate extension system.

NOTE: The alternate extend power pack operates when you command the landing gear doors open with the ground door release system.

NOTE: The EICAS displays indicate non-normal sequencing during this test.

NOTE: The power pack remains ON until the LDG GR ALTN EXT CONTROL circuit breaker is opened. (The pressure switch that usually stops the power pack does not work since you are bleeding the system.)

CAUTION: MAKE SURE YOU DO NOT RUN THE ALTERNATE EXTEND POWER PACK FOR MORE THAN FIVE MINUTES. IF YOU RUN THE POWER PACK FOR MORE THAN FIVE MINUTES, THE POWER PACK CAN GET TOO HOT. THIS CAN CAUSE DAMAGE TO THE EQUIPMENT.

PROXIMITY SENSOR SYSTEM - INTRODUCTION

PROXIMITY SENSOR SYSTEM - GENERAL DESCRIPTION

General

The PSS gets position data for some airplane components and supplies this data to other airplane systems for indication and control functions.

The proximity sensor system components include:

- Two proximity sensor electronics units (PSEUs)
- Proximity sensors.

Inputs

The PSEUS get position data from proximity sensors on these systems/components:

- Landing gear
- Passenger entry doors
- Cargo doors and access doors
- Thrust reversers.

The PSS also gets some discrete hardwire inputs from the tail strike system and other airplane components.

Outputs

The PSEUs supply position data through the systems ARINC 629 buses to these airplane systems:

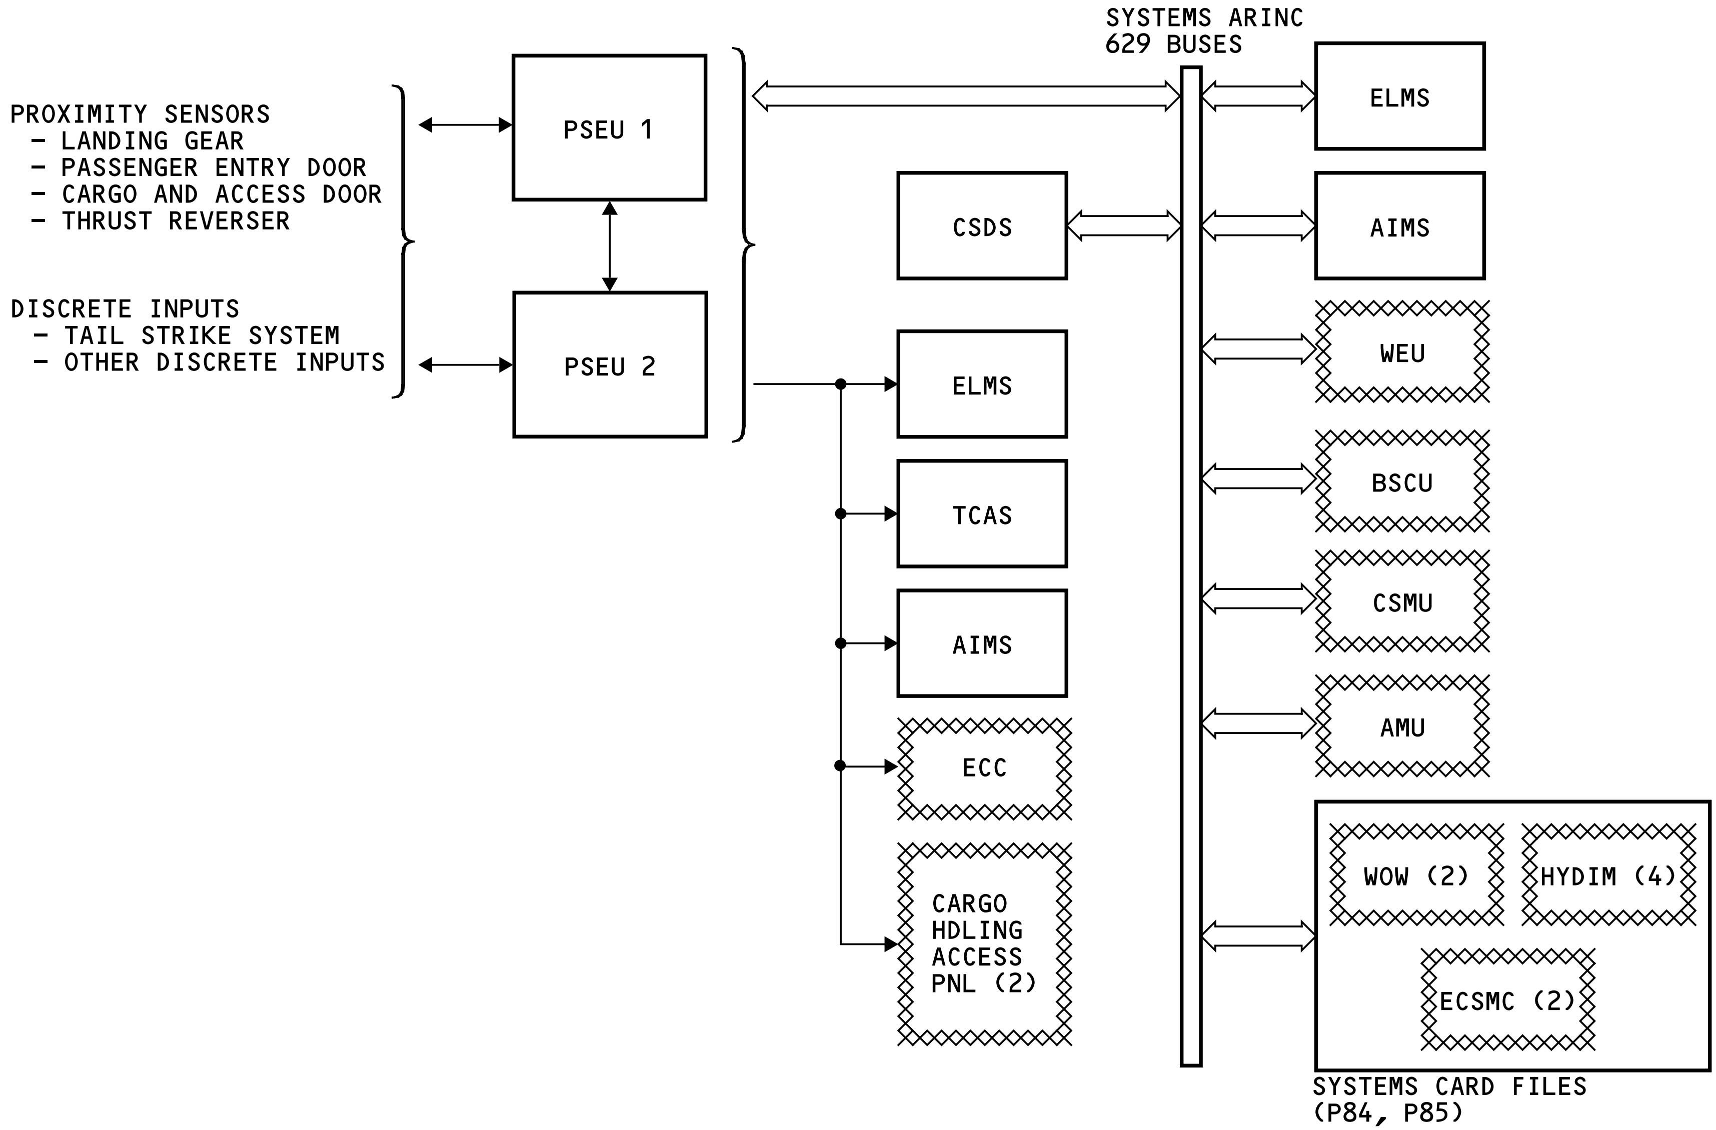
- Airplane information management system (AIMS)
- Electrical load management system (ELMS)
- Brake sytem control unit (BSCU)
- Warning electronic unit (WEU)
- Cabin system management unit (CSMU)
- Audio management unit (AMU)
- Cargo smoke detection system (CSDS).

These components in the left and right system card files get PSEU data through the ARINC signal gateway (ASG) cards:

- Weight on wheels (WOW) cards
- Hydraulic interface module (HYDIM) cards
- Environmental control system miscellaneous cards (ECSMC).

The PSEUs supply data through hardwire discretes to these systems:

- ELMS
- Traffic alert and collision avoidance system (TCAS)
- AIMS
- ECC (equipment cooling controller)
- Cargo handling access panels.



PROXIMITY SENSOR SYSTEM - GENERAL DESCRIPTION

PROXIMITY SENSOR SYSTEM - PROXIMITY SENSORS

Purpose

The proximity sensors get position input of airplane components. They supply this position data to the PSEUs.

Physical Description

There are two types of sensors:

- Flange mount
- Thread mount.

Both types of sensors are inductance-type sensors. There are approximately 96 sensors on the airplane.

Functional Description

The PSEU sends a signal to energize the magnetic core in the sensor. The inductance of the sensor changes when a steel target gets near the sensor.

The flange mount sensors send a near signal when the target is 0.24 inches (6.1 mm) from the sensor (head-on). They send a far signal when the target is 0.3 inches (7.6 mm) from the sensor (head-on).

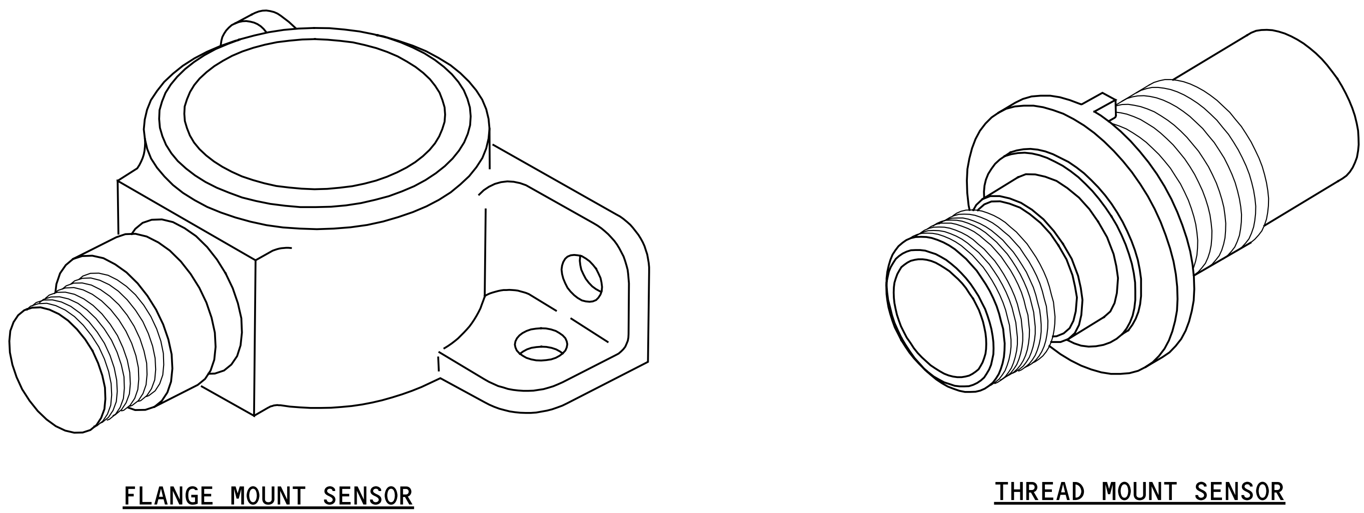
The thread mount sensors send a near signal when the target is 0.085 inches (2.2 mm) from the sensor (head-on). They send a far signal when the target is 0.12 inches (3.1 mm) from the sensor (head-on).

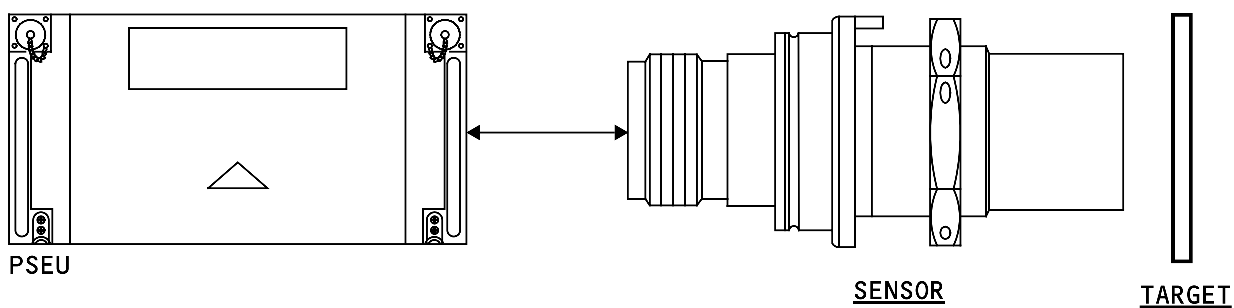
Training Information Point

The targets are made of corrosion-resistant steel. Standard target sizes are 0.05 inches (1.3 mm) thick and either 1.25 inches (31.7 mm) or 0.75 inches (19 mm) in diameter.

Some proximity sensors use non-standard targets. For example, sensors for the cargo doors and passenger entry doors use door structure for the targets.

Correct sensor-target gap is important for correct PSS operation.





32-08-00-003 Rev 1

PROXIMITY SENSOR SYSTEM - PROXIMITY SENSORS

PROXIMITY SENSOR SYSTEM - PSEU - COMPONENT LOCATION

Purpose

The PSEUs are the central components of the proximity sensor system. They get proximity sensor input and other discrete signals. The PSEUs process this data and send control and indication signals to other airplane systems.

Location

The PSEUs are in the main equipment center. PSEU 1 is on the E1-5 shelf. PSEU 2 is on the E4-1 shelf.

Training Information Point

The PSEUs are electrostatic discharge sensitive devices.

CAUTION: DO NOT TOUCH THE PSEU BEFORE YOU DO THE PROCEDURE FOR DEVICES THAT ARE SENSITIVE TO ELECTROSTATIC DISCHARGE. ELECTROSTATIC DISCHARGE CAN CAUSE DAMAGE TO THE PSEU.

PROXIMITY SENSOR SYSTEM - PSEU - COMPONENT LOCATION

PROXIMITY SENSOR SYSTEM - PSEU - CIRCUIT CARDS

General

PSEU 1 contains 13 circuit cards and PSEU 2 contains 11 circuit cards.

These are the five different types of circuit cards:

- Microprocessor cards
- Proximity cards
- Driver cards
- Communication cards
- Power supply cards.

Microprocessor Card

There are two microprocessor cards in each PSEU. These cards control the operation of the PSEU. They also supply BITE functions.

The microprocessor cards are interchangeable.

Proximity Card

Each proximity card has 24 channels. Each channel controls the power to a proximity sensor and calculates the near or far condition. PSEU 1 has three proximity cards and PSEU 2 has four proximity cards.

The proximity cards are interchangeable.

Driver Card

There are three different types of driver cards. Two of these types have 18 channels and one has 10 channels. The driver cards contain the driver outputs of the PSEUs. The driver cards also supply some logic functions. PSEU 1 has three driver cards and PSEU 2 has one driver card.

Communication Card

Two communication cards are in each PSEU. The PSEU needs only one card to operate. The other card is back-up. Each contains an ARINC 629 terminal and a ARINC 429 interface to communicate with airplane systems and with the other PSEU.

The communication cards are interchangeable.

Power Supply Card

Two power supply cards in each PSEU change 28v dc power to other voltages for PSEU operation. These cards are interchangeable.

PSEU 1 has a third power supply card. This card gets power from the ground handling bus for cargo door control. This card is not interchangeable with the other two power supply cards.

1. POWER SUPPLY CARD
2. COMMUNICATION CARD
3. MICROPROCESSOR CARD

PROXIMITY SENSOR SYSTEM - OPERATIONAL TESTS

LG POSITION INDICATING AND WARNING SYSTEM - INTRODUCTION

Purpose

The landing gear position indicating and warning system shows landing gear position on the flight deck displays.

Inputs

The landing gear position indicating and warning system uses these proximity sensors to supply landing gear position data to the PSEUs:

- Left and right MLG up and locked proximity sensor (4)
- Left and right MLG side brace down proximity sensor (4)
- left and right MLG drag brace down proximity sensor (4)
- Left and right MLG door closed proximity sensor (4)
- NLG locked proximity sensor (2)
- NLG up proximity sensor (2)
- NLG down proximity sensor (2)
- Nose gear door closed proximity sensor (2).

Four MLG truck tilt proximity sensors and two NLG not-compressed proximity sensors also supply data to the PSEUs.

The PSEUs also get inputs from the landing gear lever and the alternate extend command.

General Description

The landing gear position indicating and warning system is a dual redundant system. Each PSEU gets position input from a different proximity sensor in each location.

The PSEUs supply the position data through the left and right ARINC 629 buses to the AIMS and to other systems.

LG POSITION INDICATING AND WARNING SYSTEM - MLG UP AND LOCKED PROXIMITY SENSORS

Purpose

Two MLG up and locked sensors on each of the MLG supply uplock input to the PSEUs.

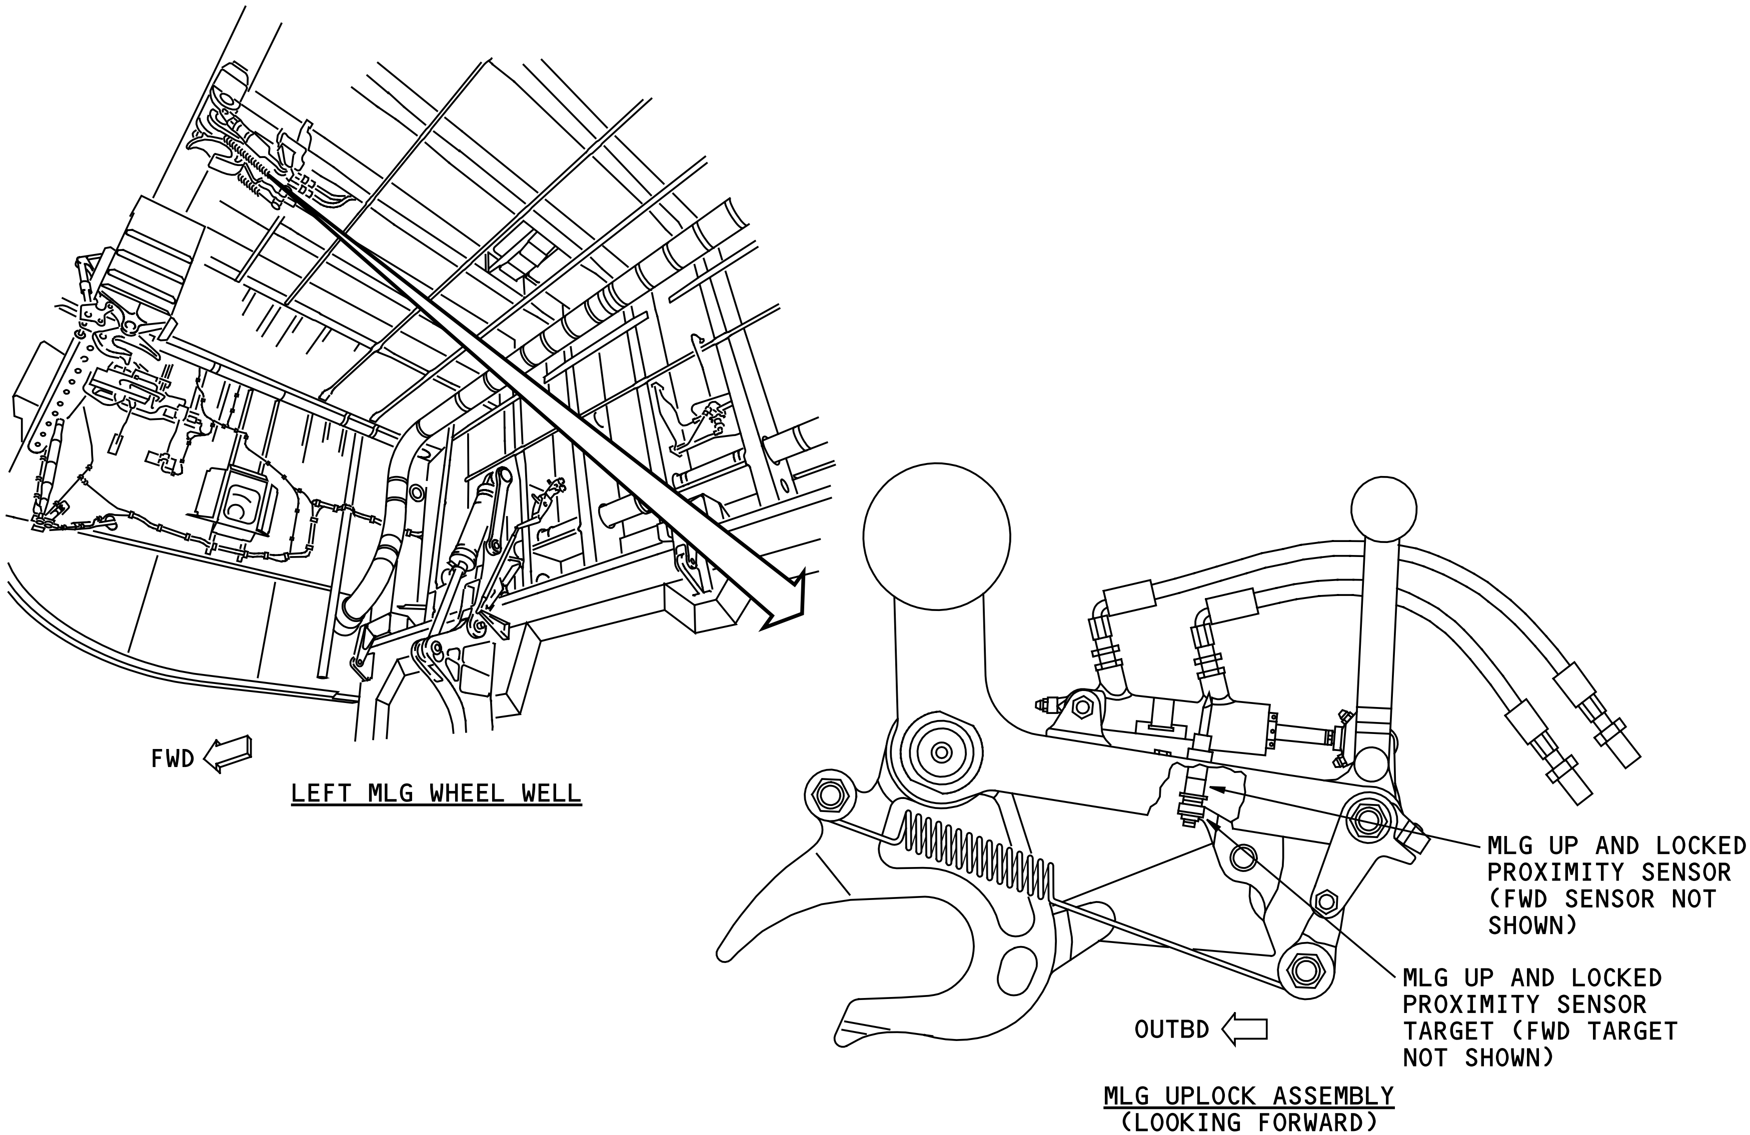
Location

The sensors are on the forward and aft sides of the MLG uplock assembly.

The proximity sensor targets are also on the uplock assembly and move with the uplock hook.

Functional Description

The targets are near the proximity sensors when the uplock assembly is in the uplocked position.



32-61-00-002 Rev 2 05/27/95

LG POSITION INDICATING AND WARNING SYSTEM - MLG UP AND LOCKED PROXIMITY SENSORS

LG POSITION INDICATING AND WARNING SYSTEM - MLG DOWN PROXIMITY SENSORS

Purpose

Main landing gear down proximity sensors supply downlock data to the PSEUs. There are four MLG down proximity sensors for each MLG.

Location

The two MLG drag brace down sensors are on the upper drag brace lock link. The targets (not shown) are on the upper toggle.

The two MLG side brace down sensors are on the upper side brace lock link. The targets (not shown) are on the upper toggle.

Functional Description

For both the drag and the side braces, the targets are near the sensors when the gear is down and the toggles are in the over-center locked position.

LG POSITION INDICATING AND WARNING SYSTEM - MLG DOWN PROXIMITY SENSORS

LG POSITION INDICATING AND WARNING SYSTEM - MLG DOOR CLOSED PROXIMITY SENSORS

Purpose

Two MLG door closed sensors for each main landing gear door supply door position data to the PSEUs.

Location

The sensors are on the outboard forward corner of the wheel wells. The targets are on the main landing gear doors.

Functional Description

The targets are near the sensors when the main landing gear doors are in the closed position.

LG POSITION INDICATING AND WARNING SYSTEM - NLG LOCKED PROXIMITY SENSORS

Purpose

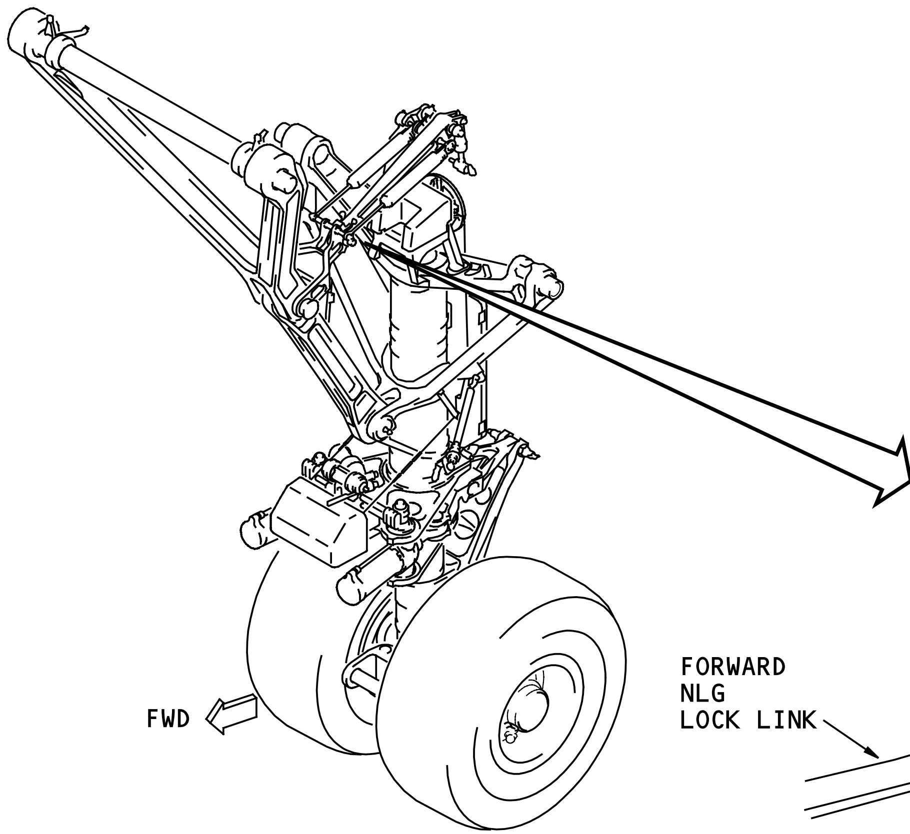
Two NLG locked sensors supply nose landing gear lock link lock position data to the PSEUs.

Location

The sensors are on the aft NLG lock link. The targets are on the forward lock link.

Functional Description

The targets are near the sensors when the NLG lock link is in the locked position.



NOSE LANDING GEAR

32-61-00-005 Rev 1

LG POSITION INDICATING AND WARNING SYSTEM - NLG LOCKED PROXIMITY SENSORS

LG POSITION INDICATING AND WARNING SYSTEM - NLG UP AND NLG DOWN PROXIMITY SENSORS

Purpose

Two NLG up sensors and two NLG down sensors supply nose gear position data to the PSEUs.

Location

All four sensors are on the ceiling of the nose landing gear wheel well above the drag brace trunnions. The NLG down sensors are outboard. The NLG up sensors are inboard.

The targets attach to brackets which are on, and rotate with the drag brace trunnions.

Functional Description

When the NLG is up, the NLG up targets will be near their sensors. The NLG down targets will not be near their sensors.

When the NLG is down, the NLG down targets will be near their sensors. The NLG up targets will not be near their sensors.

LG POSITION INDICATING AND WARNING SYSTEM - NLG DOOR CLOSED PROXIMITY SENSORS

LG POSITION INDICATING AND WARNING SYSTEM - MLG TRUCK TILT PROXIMITY SENSORS

Purpose

Two MLG truck tilt sensors for each main landing gear supply truck tilt position data to the PSEUs.

Physical Description

The MLG truck tilt sensors are on the sensor target bracket assemblies which include the sensor targets.

A rod connects each sensor target bracket assembly to the inner shock strut cylinder. This rod moves the target near and far as the truck tilts.

Location

One sensor target bracket assembly is on the left side of each MLG truck beam forward of the shock strut. The other sensor target bracket assembly is on the right side of each MLG truck aft of the shock strut.

Functional Description

The target is near the sensors when the MLG truck is tilted between 10 and 13 degrees forward wheels up (TILT position). The target is in the far position when the MLG truck is less than 10 degrees forward wheels up (UNTILT position).

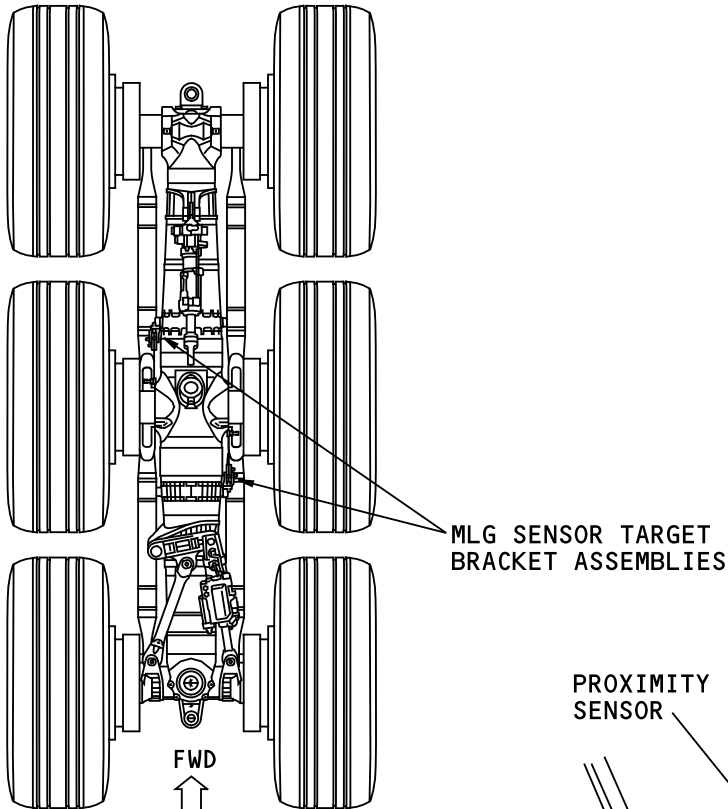
The PSEU supplies a signal that the airplane is on the ground.

Training Information Point

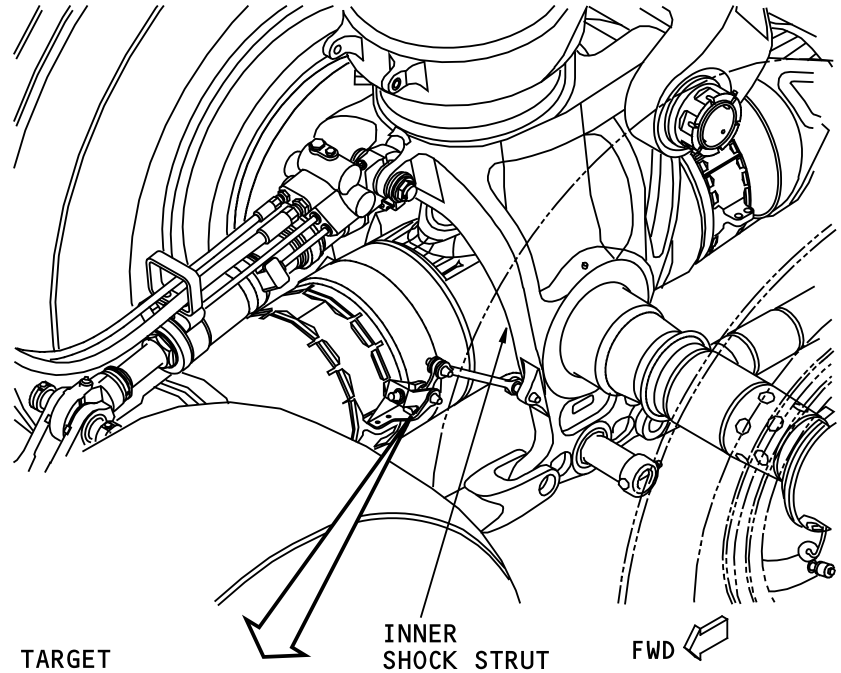
The sensor assemblies on the forward part of the MLG truck are different than the sensor assemblies on the aft part of the truck.

The truck tilt sensors are LRUs. There is no adjustment of the sensors or the target after replacement.

The primary flight computers (PFCs) use the truck position signal to operate the auto speedbrakes. The brake system control unit (BSCU) uses the same signal to operate the autobrakes.



MLG TRUCK
(TOP VIEW)



MLG TRUCK

32-61-00-008 Rev 2 03/05/96

LG POSITION INDICATING AND WARNING SYSTEM - MLG TRUCK TILT PROXIMITY SENSORS

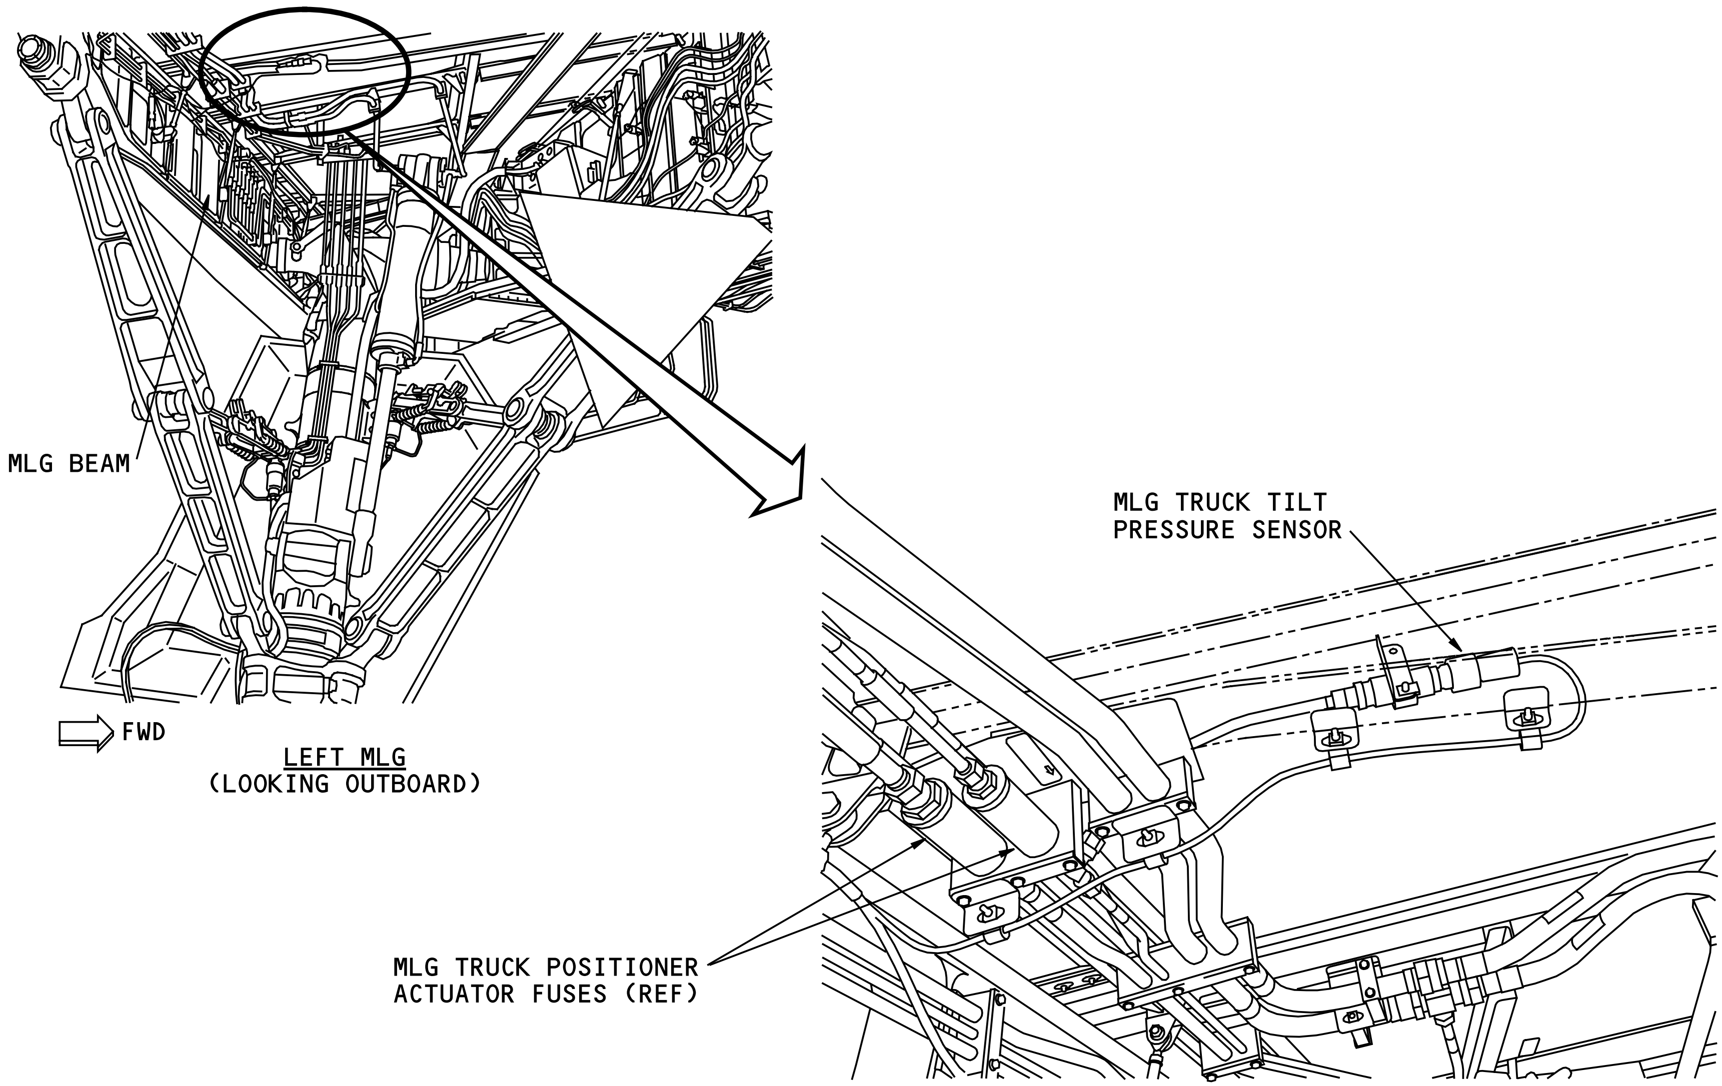
LG POSITION INDICATING AND WARNING SYSTEM - MLG TRUCK TILT PRESSURE SENSORS

Purpose

A truck tilt pressure sensor for each of the MLG truck tilt actuators sends truck tilt pressure data to the HYDIM cards. The HYDIM cards send a high pressure signal to the AIMS when the truck tilt pressure is more than 2500 psi. The HYDIM cards send a low pressure signal when the truck tilt pressure is less than 2400 psi. The AIMS sends these signals to the primary flight control computers (PFCs) to operate the auto-speedbrakes.

Location

The MLG truck tilt pressure sensors are above the MLG truck near the main landing gear beam.



LEFT MLG
(LOOKING OUTBOARD)

32-61-00-009 Rev 3 03/05/96

LG POSITION INDICATING AND WARNING SYSTEM - MLG TRUCK TILT PRESSURE SENSORS

LG POSITION INDICATING AND WARNING SYSTEM - NLG NOT-COMPRESSED PROXIMITY SENSORS

Purpose

Two NLG not-compressed sensors supply NLG shock strut compressed - not compressed data to the PSEUs.

Location

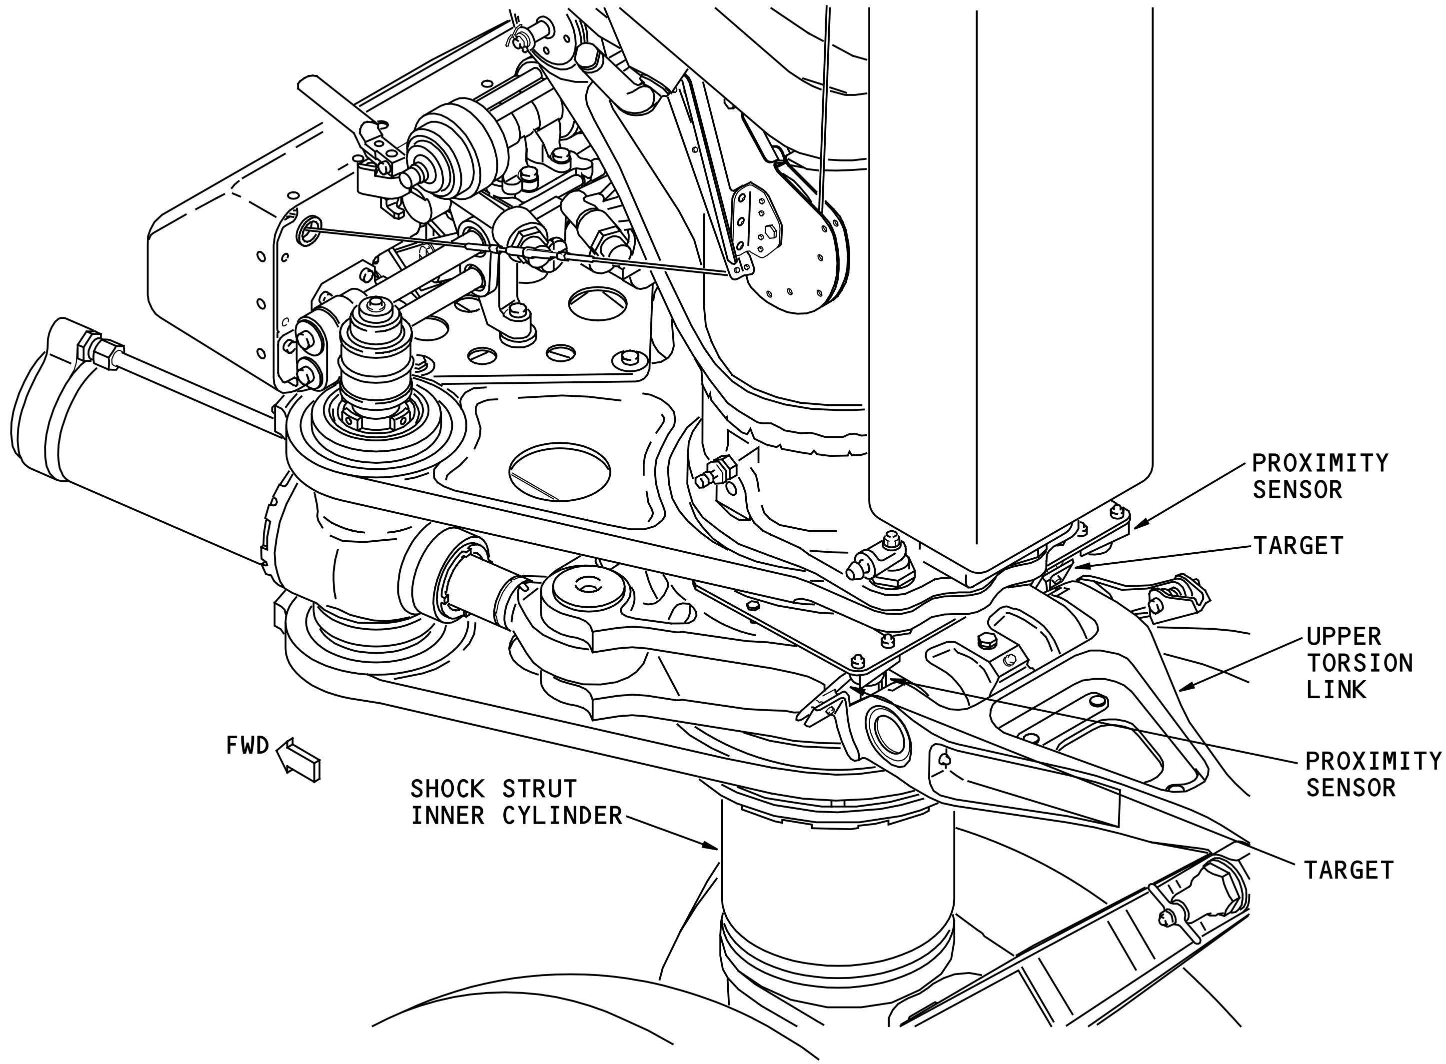
The sensors are on the aft side of the NLG shock strut. The targets attach to the upper torsion link.

Functional Description

When the airplane is on the ground, airplane weight compresses the nose landing gear. The NLG compressed targets are in the far position.

When the airplane is in the air, the inner cylinder of the NLG shock strut extends to move the torsion links to the not-compressed position. This moves the targets near the NLG not-compressed sensors.

The PSEUs supply NLG not-compressed sensor data to the ECS miscellaneous cards and to the equipment cooling controllers to operate the equipment cooling supply fans.



32-61-00-010 Rev 3 06/20/96

LG POSITION INDICATING AND WARNING SYSTEM - NLG NOT-COMPRESSED PROXIMITY SENSORS

LG POSITION INDICATING AND WARNING SYSTEM - INDICATIONS - EICAS DISPLAY

General

In normal operation, the EICAS display shows the position of the three landing gear with a single symbol format.

The format shows individual gear position for non-normal conditions.

Single-Symbol Display

The single symbol display shows the all gears down and locked condition with a green DOWN, in a box.

A white hatched box shows the gear in the in-transit condition.

An empty white box shows the loss of gear position data.

The display shows the all gears up and locked condition with a white UP, in a box. This display goes out of view approximately ten seconds after the gear moves to this position.

Multi-Symbol Display

The landing gear display shows all three gears for these conditions:

- There is a disagreement between the landing gear lever and the landing gear position for more than 40 seconds (normal actuation time is approximately 17 seconds for retraction and 23 seconds for extension)
- The landing gear doors are open (alternate extension or ground operation of the landing gear doors).

The display shows the gear down and locked condition with a green DN, in a box.

The display shows the gear in-transit condition with a white hatched box.

The display shows the gear up and locked condition with a white UP, in a box.

An empty white box shows the loss of position data for the applicable gear.

LG POSITION INDICATING AND WARNING SYSTEM - INDICATIONS - EICAS DISPLAY

LG POSITION INDICATING AND WARNING SYSTEM - INDICATIONS - ALERT AND STATUS MESSAGES

Alert Messages

These alert messages show for non-normal landing gear conditions:

- CONFIG GEAR (Warning) - any landing gear is not down and locked and the airplane is in a landing configuration (the flap lever is in a landing position or a thrust lever is at idle with the radio altitude less than 800 feet)
- GEAR DISAGREE (Caution) - disagreement between the landing gear lever and one or more gear positions 40 seconds after landing gear lever movement
- MAIN GEAR BRACE L (Caution) - one brace on the left gear is unlocked for more than 40 seconds after the landing gear lever is in the down position and the other brace on the left gear is locked
- MAIN GEAR BRACE R (Caution) - one brace on the right gear is unlocked for more than 40 seconds after the landing gear lever is in the down position and the other brace on the right gear is locked
- GEAR DOOR (Advisory) - one or more landing gear doors are not closed 40 seconds after landing gear lever movement. This message also shows after an alternate extension or after ground door operation.

Status Messages

The GEAR INDICATION SYS status message shows for any of these conditions:

- Failure of both up sensors on the same gear
- Failure of both door sensors on the same gear
- Failure of any side brace sensor
- Failure of any drag brace sensor
- Failure of either NLG down sensor
- Failure of either NLG locked sensor
- Failure of any truck tilt sensor
- Failure of either NLG not-compressed sensor
- Invalid PSEU channel.

One or more of these status messages show for landing gear door sensor or gear uplock sensor failures:

- L GEAR DOOR SENSOR
- R GEAR DOOR SENSOR
- NOSE GEAR DOOR SENSOR
- L GEAR UPLOCK SENSOR
- R GEAR UPLOCK SENSOR
- NOSE GEAR UP SENSOR.

LG POSITION INDICATING AND WARNING SYSTEM - INDICATIONS - ALERT AND STATUS MESSAGES

LG POSITION INDICATING AND WARNING SYSTEM - INDICATIONS - MULTI-FUNCTION DISPLAY

General

The multi-function display shows landing gear position data on the landing gear synoptic display. Additional landing gear data and PSEU outputs show on the landing gear actuation/indication maintenance page.

Landing Gear Synoptic Display

The landing gear synoptic display shows the position of the landing gear doors.

The display shows a door closed condition with the word CLOSED in white, in a box.

The display shows a door not closed condition with a white hatched box.

The display shows a loss of input data from both PSEUs with an empty white box.

Landing Gear Actuation/Indication Maintenance Page

The landing gear actuation/indication maintenance page shows the NEAR/FAR position for all the landing gear proximity sensors for both PSEUs.

The display shows the loss of a proximity sensor input or an invalid input as an empty space.

The display also shows the gear lever switch positions and the alternate extension system status.

LG POSITION INDICATING AND WARNING SYSTEM - INDICATIONS - MULTI-FUNCTION DISPLAY

TAIL STRIKE SYSTEM - INTRODUCTION

Purpose

The tail strike system supplies tail strike indication to the flight deck if a tail strike occurs.

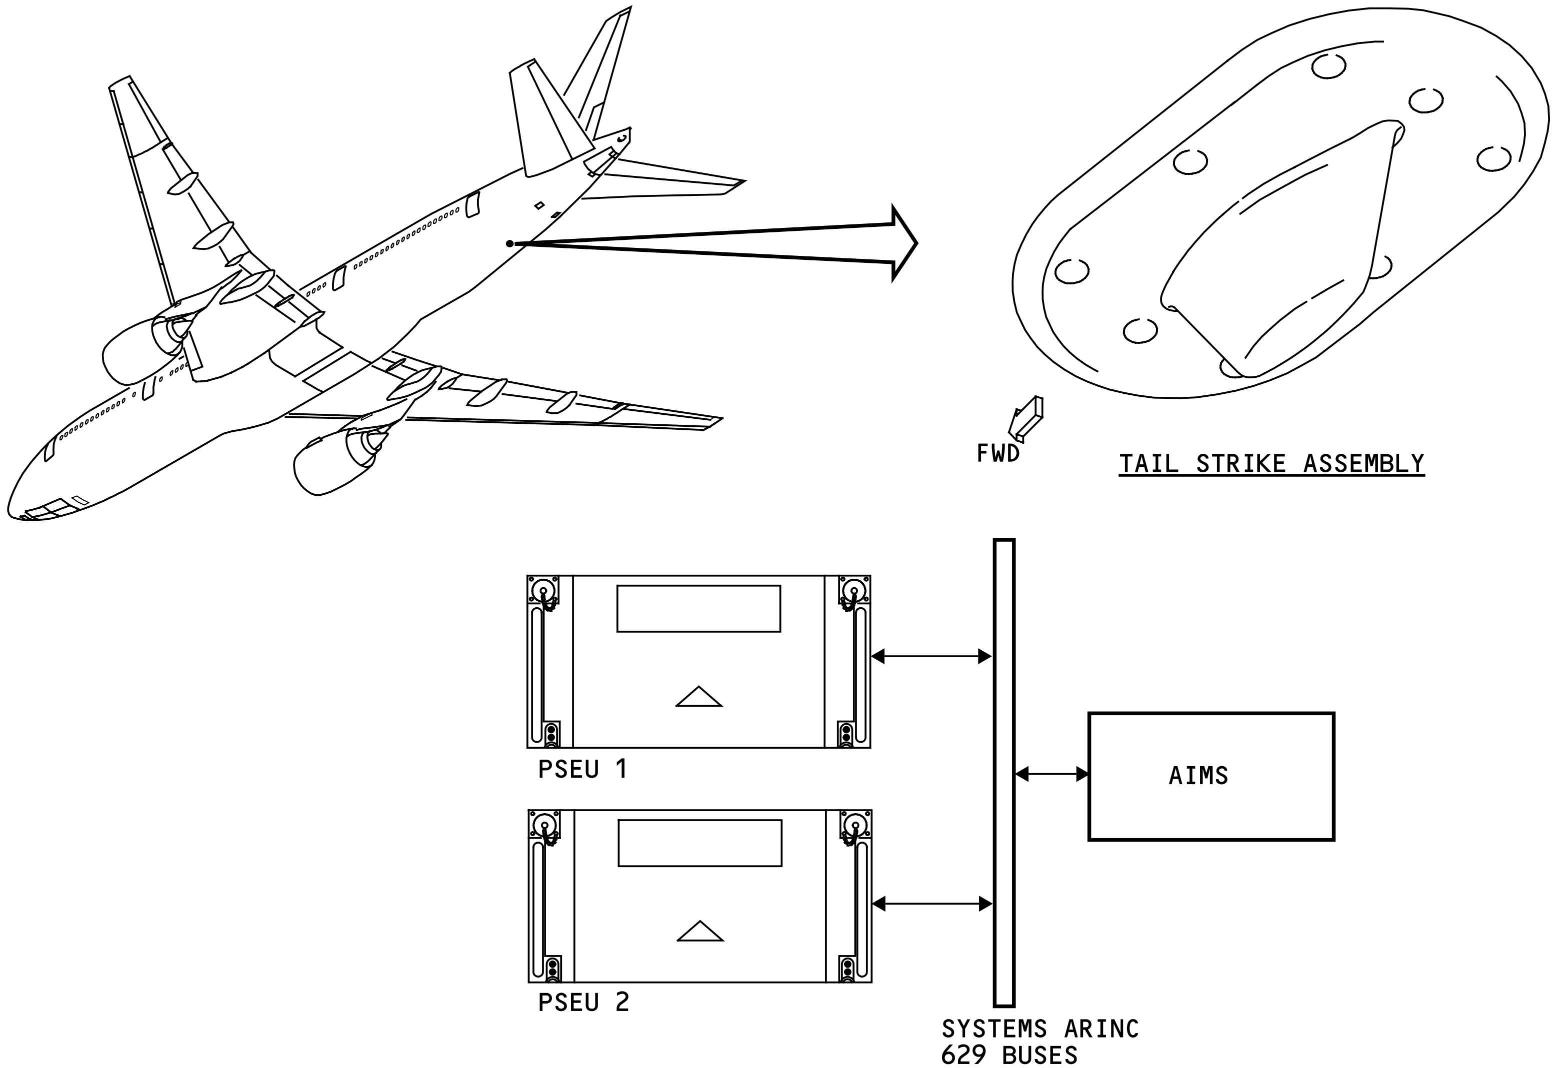
Tail Strike Assembly

The tail strike assembly (TSA) is a blade antenna shaped device. There are two wires in the assembly which are near the outside surface of the TSA.

The TSA is in the airplane tail strike area on the bottom of the aft fuselage at station 2041.75.

Interface

The two wires in the TSA make inputs to the two proximity sensor electronics units (PSEUs). The PSEUs supply tail strike data to the AIMS for flight deck display.



32-71-00-001 Rev 0

TAIL STRIKE SYSTEM - INTRODUCTION

TAIL STRIKE SYSTEM - FUNCTIONAL DESCRIPTION

General

The two wires in the TSA are on separate channels. Both wires get 28v dc power. One wire gets electrical power from the primary power circuit breaker that also supplies primary power to PSEU 1. PSEU 1 monitors this wire. The other wire gets electrical power from the circuit breaker that also supplies primary power to PSEU 2. PSEU 2 monitors this wire. Both channels are normally closed circuits.

Detection

If a tail strike occurs, the TSA contacts the ground and becomes damaged or breaks off the airplane. This damages both wires and causes both PSEUs to get open/short circuit inputs.

Indication

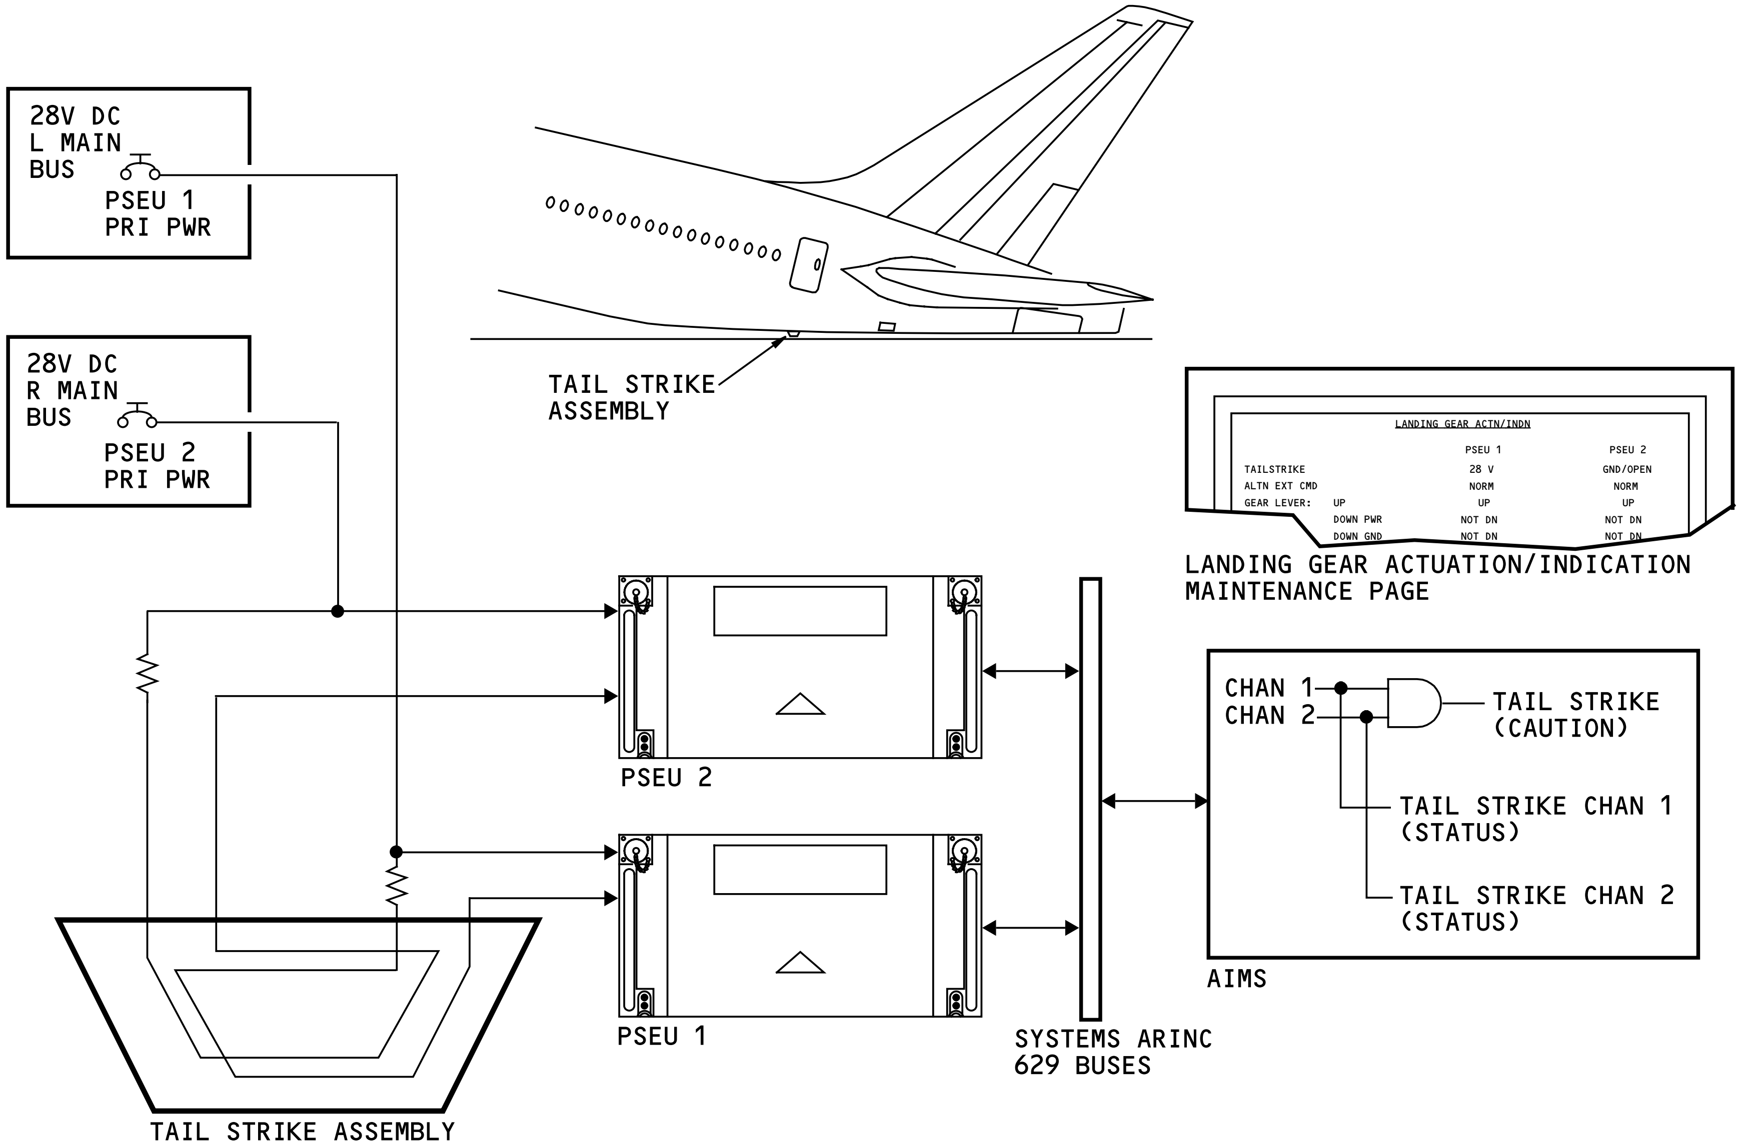
If both PSEUs get open/short circuit inputs, a TAIL STRIKE caution message shows.

The landing Gear actuation/indication maintenance page shows the status of the inputs from the tail strike system.

Training Information Point

If there is a failure (open/short circuit) in a single channel, the TAIL STRIKE CHAN 1 or TAIL STRIKE CHAN 2 status message shows.

Both of these messages also show if there is a tail strike.



TAIL STRIKE SYSTEM - FUNCTIONAL DESCRIPTION

AIR/GROUND SYSTEM - INTRODUCTION

Purpose

The air/ground system (AGS) supplies air mode and ground mode signals to airplane systems.

Components

These are the AGS components:

- Air/Ground load sensors (4)
- Weight-on-wheels (WOW) logic cards (2)
- Air/ground relays.

General Description

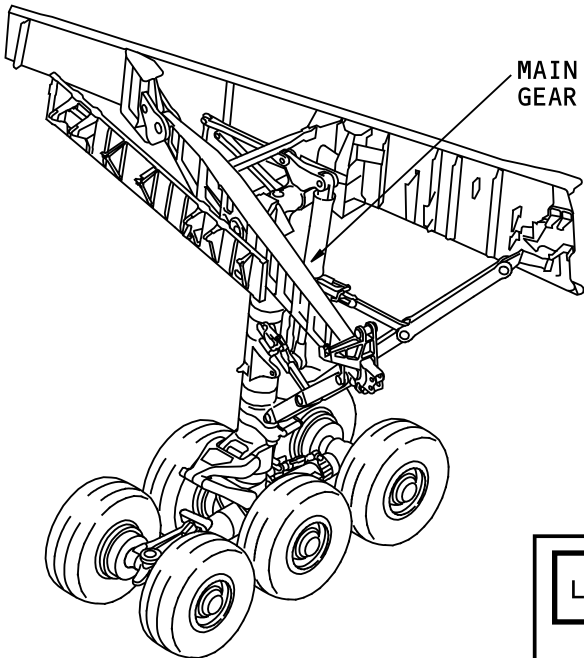
Two load sensors on each main landing gear beam send landing gear load data to the two WOW cards.

The WOW cards control air/ground relays in the ELMS. These relays supply air/ground signals to other airplane systems.

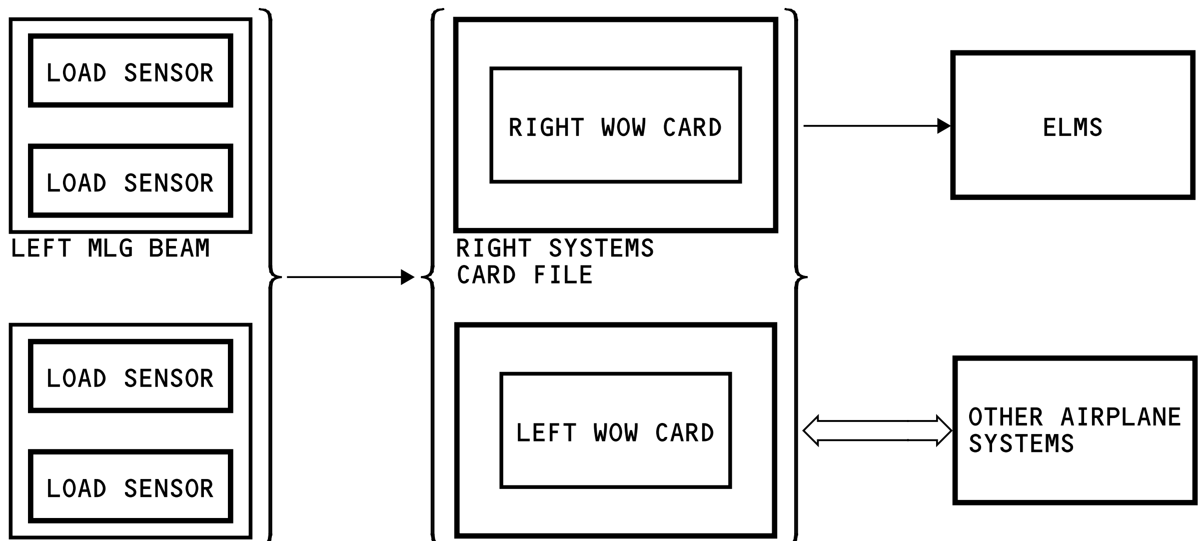
The WOW cards also send digital air/ground data through the systems ARINC 629 buses to airplane systems.

Abbreviations and Acronyms

ADF	- automatic direction finder
ADIRU	- air data inertial reference unit
A/G	- air/ground
AGS	- air/ground system
AIMS	- airplane information management system
APU	- auxiliary power unit
ASCPC	- air supply and cabin pressure controller
ASG	- ARINC signal gateway
ARINC	- Aeronautical Radio, Inc.
ATC	- air traffic control
EEC	- electronic engine control
ELMS	- electrical load management system
gnd	- ground
HF	- high frequency
HYDIM	- hydraulic interface module
ILS	- instrument landing system
MAT	- maintenance access terminal
MLG	- main landing gear
PA/CI	- passenger address/cabin interphone
PSEU	- proximity sensor electronic unit
TCAS	- traffic alert and collision avoidance system
VOR/MB	- VOR/marker beacon
WHCU	- window heat control unit
WOW	- weight-on-wheels
WX	- weather



MAIN LANDING GEAR (2)



32-09-00-001 Rev 2 03/26/96

AIR/GROUND SYSTEM - INTRODUCTION

AIR/GROUND SYSTEM - INTERFACES

General

Two WOW cards supply air/ground signals to other airplane systems through:

- Left and right systems ARINC 629 buses
- ARINC 429 buses
- Air/ground relays in the ELMS.

The WOW cards get inputs from airplane systems through:

- Left and right systems ARINC 629 buses
- ARINC 429 buses
- Hard-wire.

ARINC 629 Interfaces

These systems and components get air/ground signals through the systems ARINC 629 buses:

- Airplane information management system (AIMS)
- Airborne vibration monitor signal conditioner unit (AVMSCU) (2)
- Autopilot flight director computer (AFDC) (3)
- Audio management unit (AMU)
- APU controller (APUC)
- Air supply cabin pressure controller (ASCPC) (2)
- Backup generator converter
- Bus power control unit (BPCU)
- Cabin system management unit (CSMU)
- Cabin temperature controllers (CTC) (2)
- Control display unit (CDU) (3)
- Engine data interface unit (EDIU) (2)
- Electrical load management system (ELMS)
- Fuel quantity indication system (FQIS) processor
- Flap slat electronic unit (FSEU) (2)
- Generator control unit (GCU) (3)
- Overhead panel bus controller (OPBC)
- Passenger address/cabin interphone (PA/CI) controller
- Proximity sensor electronics unit (PSEU) (2)
- Warning electronic unit (WEU) (2).

The AIMS uses the air/ground signals for these functions:

- Central maintenance computing
- Data communications management
- Data conversion gateway
- Flight management computing
- Navigation display
- Primary flight display
- Software data loader
- Thrust management computing function.

These systems get air/ground data through the data conversion gateway function in the AIMS:

- Cabin telecommunications unit
- Flight recorder
- Global positioning system
- Ground proximity warning system
- Primary flight computer (3).

The ELMS supplies air/ground signals for these functions:

AIR/GROUND SYSTEM - INTERFACES

- APU controls
- Cargo fire extinguishing
- DC standby system
- Ground crew call horn
- Fuel jettison
- Fuel management
- Hydraulic pump control
- Passenger oxygen system.

Internal Card File Systems

These cards in the left and right systems card files get air/ground signals through ARINC 429 which go through the ASG cards:

- Airfoil and cowl ice protection system (ACIPS) card (2)
- Cargo smoke detection system (CSDS) card (2)
- Environmental control system miscellaneous card (ECSMC) (2)
- Hydraulics interface modules (HYDIM) card (4).

The duct leak overheat detection system (DLODS) also gets air/ground inputs through the systems card files.

Air/Ground Relay Interfaces

The WOW cards control air/ground relays in the ELMS. The left WOW card controls air/ground relays in the P110 power management panel. The right WOW card controls air/ground relays in the P210 and P310 power management panels.

These systems, components, and functions get air/ground signals through the air/ground relays:

- AIMS
- Air data inertial reference unit (ADIRU) on battery relay
- APU external shutdown
- ATC/TCAS control panel
- Automatic direction finder (ADF) (2)
- Brake status lights
- Brouter
- Captain's side display
- Center system tail and wing flight control shutoff valves
- Cockpit voice recorder control panel
- Distance measuring equipment (DME) interrogator (2)
- Drain line valve (2)
- Drain mast heaters (2)
- First officer's display
- HF communication transceiver (2)
- Instrument landing system (ILS) receiver (3)
- Jettison nozzle valve (2)
- Landing gear lever lock
- Maintenance access terminal (MAT)
- Radio altimeter transceiver (3)
- Traffic alert and collision avoidance system (TCAS) computer
- Voice recorder control panel
- VOR/MB receiver (2)
- Water drain line hose heater thermostat
- Wing root landing light heating
- Window heat control unit (WHCU) (2)

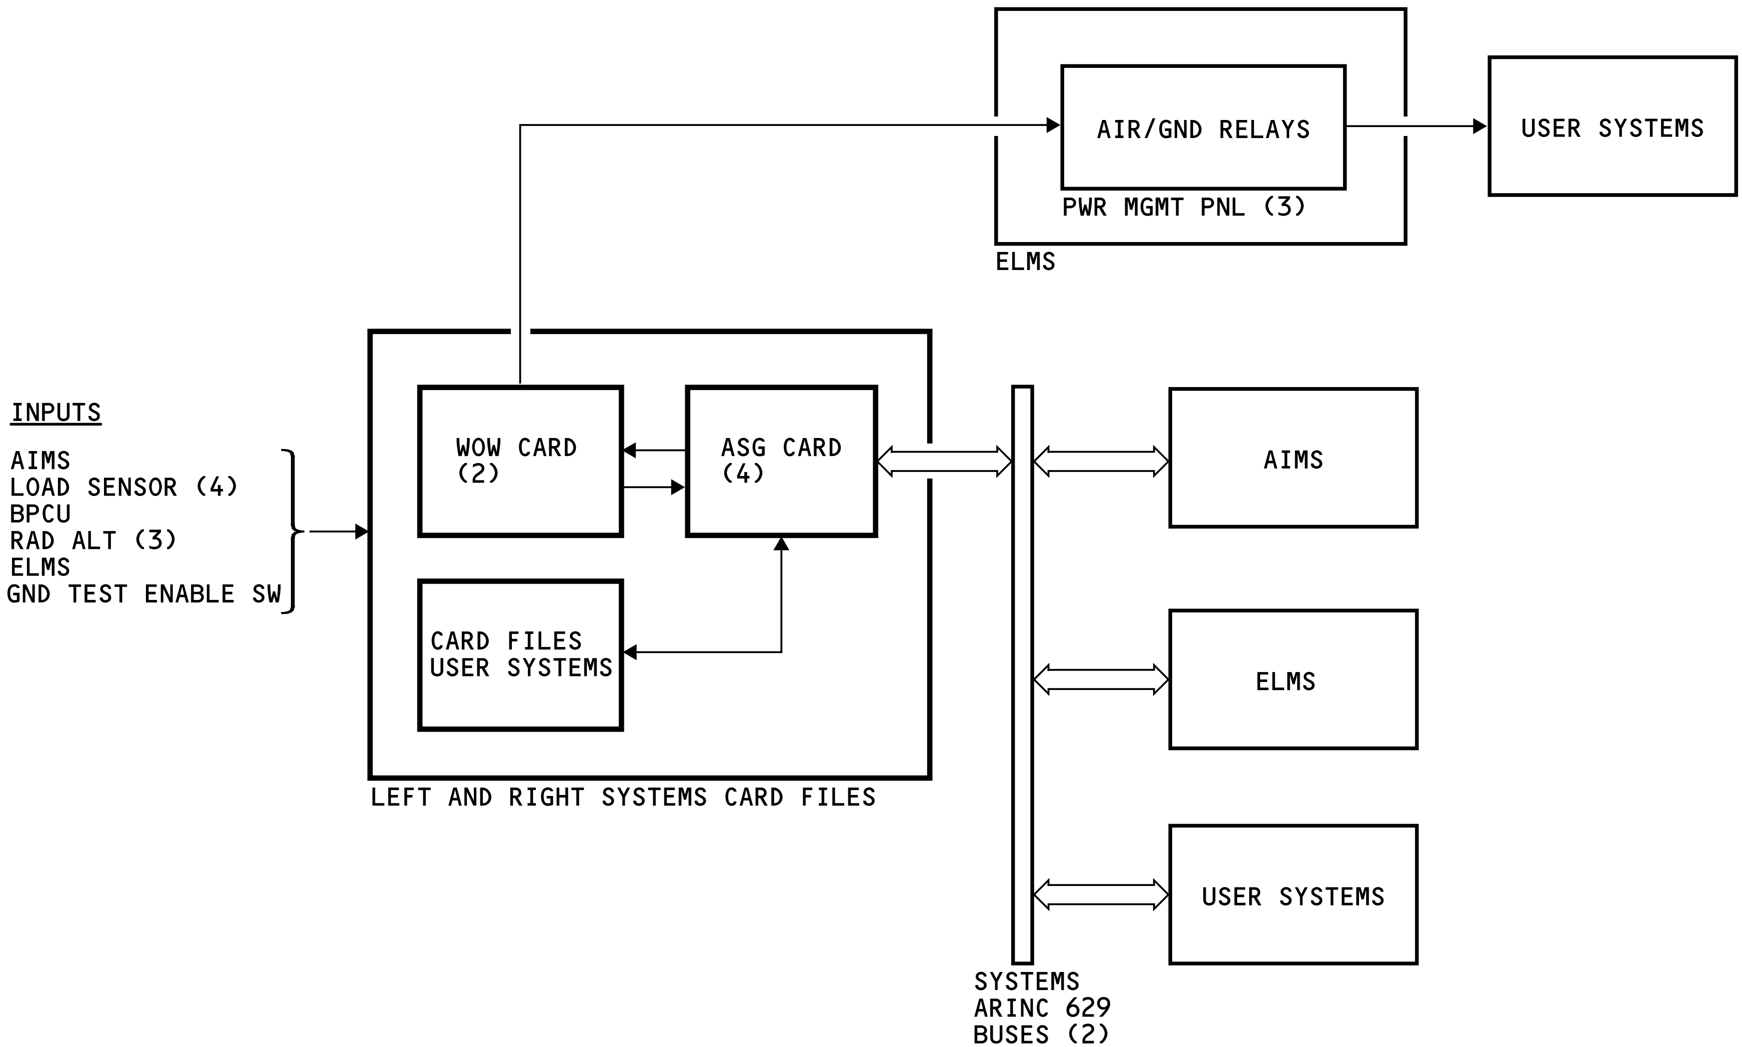
AIR/GROUND SYSTEM - INTERFACES

- WX radar transceiver.

WOW Card Inputs

The WOW cards get inputs from:

- AIMS (time and date, flight phase/leg, airplane registration number, ICAO code)
- Bus power control unit (external power available)
- ELMS (air/ground relay status)
- Ground test enable switch
- Load sensors
- Radio altimeter (3).



32-09-00-002 Rev 2 02/22/95

AIR/GROUND SYSTEM - INTERFACES

AIR/GROUND SYSTEM - WOW LOAD SENSOR

Purpose

The load sensors measure the load on the main landing gear beams to find when the airplane has weight on wheels.

Location

Two load sensors are on each main landing gear (MLG) beam. The load sensors attach to mounting brackets. Covers supply protection to the sensors. These covers attach to the MLG beam.

Functional Description

The load sensor is a variable reluctance strain measurement device.

The sensor has two pieces which attach by mounting brackets to the MLG beam structure in two places. The two pieces move independently as the MLG beam bends.

One piece has a target and the other piece has two coils. The target and coils do not touch each other.

These two pieces connect by a flexible bellows.

In the air mode, the MLG beam is in an unloaded condition and the sensor target is in the in-air position.

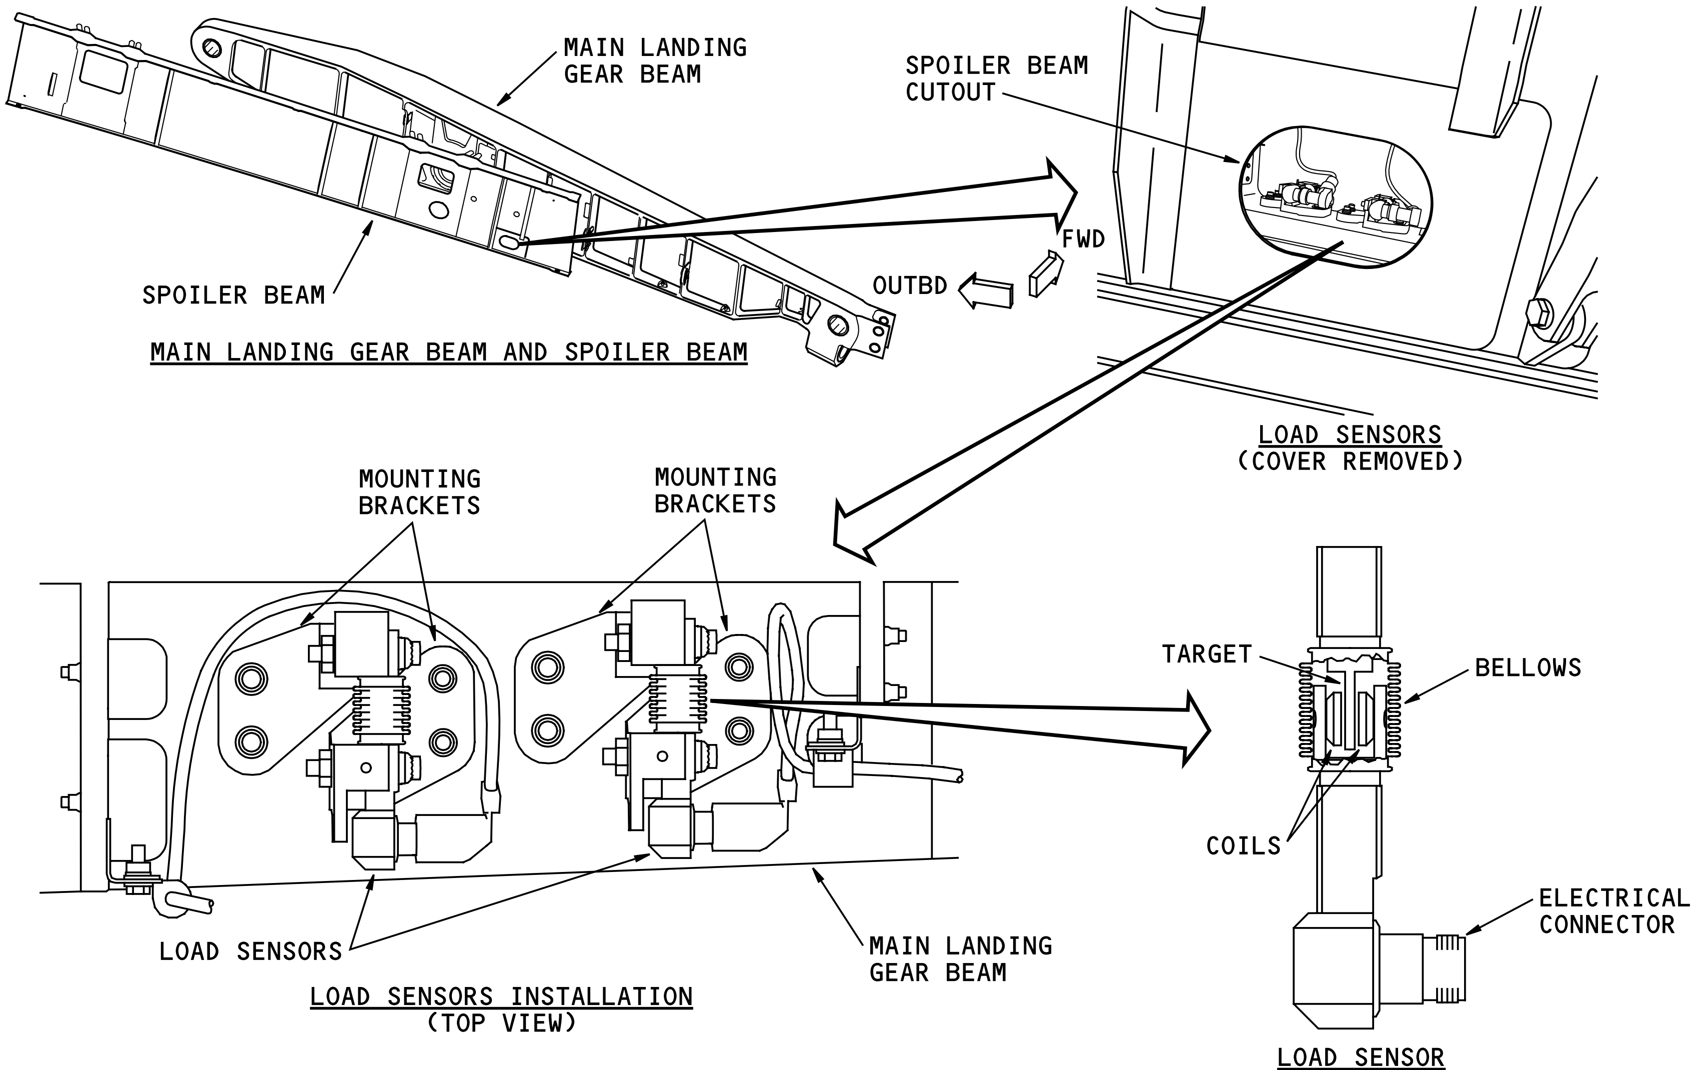
In the ground mode, airplane weight causes the MLG beam to bend. This changes the distance between the target and the coils and causes the target to be in the on-ground position.

The load sensor sends an analog signal to the WOW cards.

Training Information Point

You remove a panel from the bottom of the wing to get access to the load sensors. The panel attaches to the MLG beam and the spoiler beam.

A cutout in the spoiler beam lets you see the load sensors.



32-09-00-003 Rev 2 07/15/96

AIR/GROUND SYSTEM - WOW LOAD SENSOR

AIR/GROUND SYSTEM - WOW CARDS AND AIR/GROUND RELAYS

Purpose

Two WOW cards get the weight-on-wheels signals from the WOW sensors. The WOW cards then send air/ground data to other airplane systems. The WOW cards also control master air/ground relays in ELMS.

Air/ground relays get the signals from the WOW cards and supply air/ground analog signals to other aircraft systems.

Location

The right WOW card is in the P84 systems card file in the main equipment center. The left WOW card is in the P85 systems card file in the main equipment center.

The air/ground relays are in the ELMS P110, P210, and P310 power management panels (not shown) in the main equipment center.

Training Information Point

The WOW cards are electrostatic sensitive.

The WOW cards are software loadable. See chapter 45-10-00 for more information.

AIR/GROUND SYSTEM - INDICATION

AIR/GROUND SYSTEM - SYSTEM TESTS

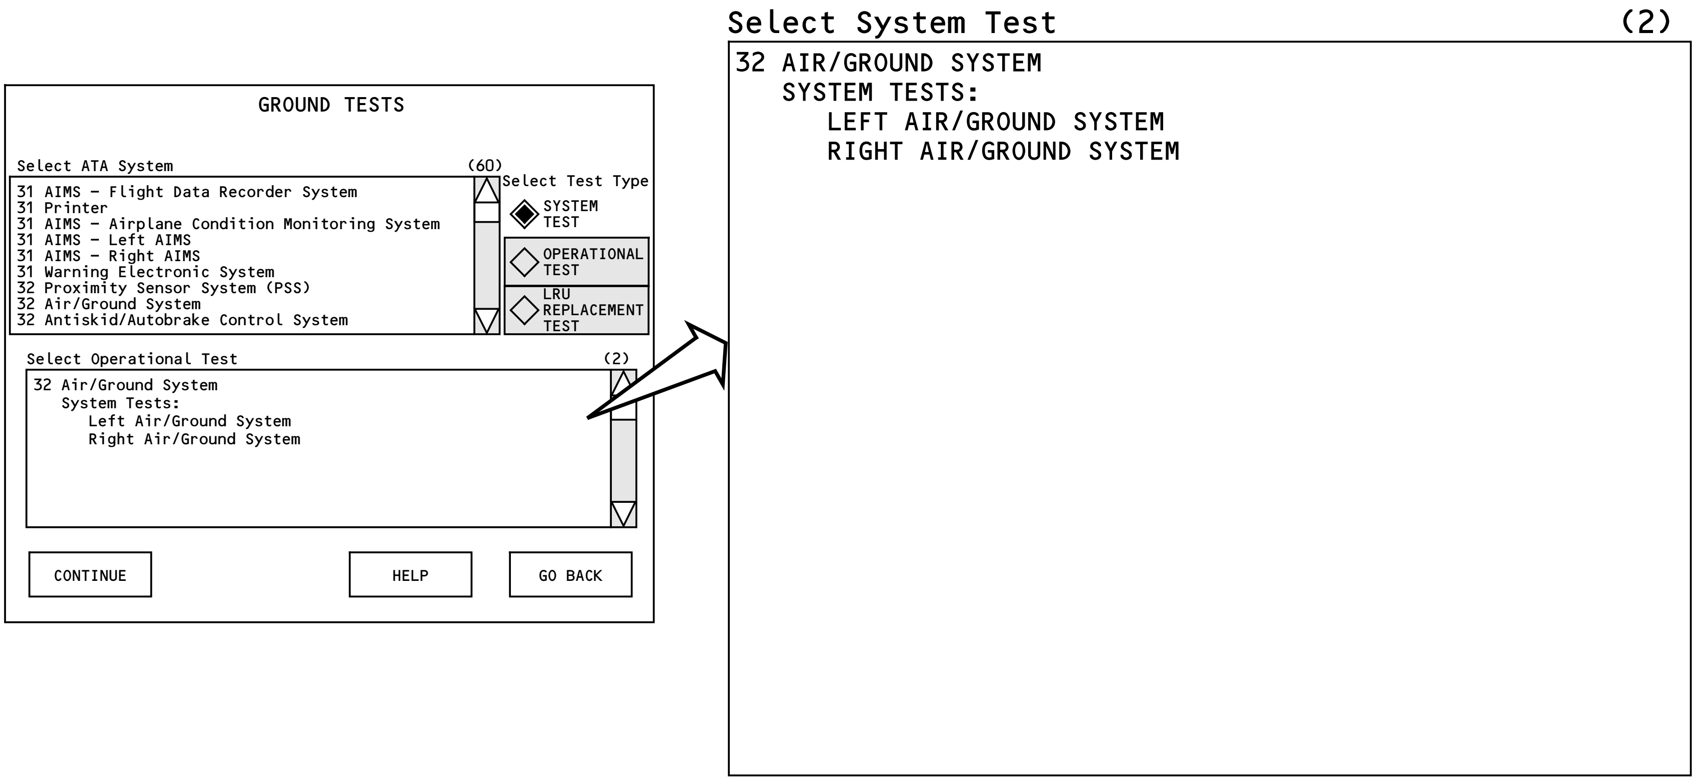
General

These are the air/ground system tests:

- LEFT AIR/GROUND SYSTEM
- RIGHT AIR/GROUND SYSTEM.

Air/Ground System Tests

There is an air/ground test for each of the air/ground systems. These tests do a check of the functions of the air/ground system components.



32-09-00-007 Rev 4 01/11/96

AIR/GROUND SYSTEM - SYSTEM TESTS

AIR/GROUND SYSTEM - SPECIAL FUNCTIONS

General

You can control air mode and ground mode simulation through these six special functions on the MAT:

- Left air simulation
- left ground simulation
- Left stop simulation
- Right air simulation
- Right ground simulation
- Right stop simulation.

The simulation functions make the outputs of the selected WOW cards (left or right) go to the simulated condition.

To simulate air mode when the airplane is on the ground, you use the air simulation function.

To simulate the ground mode if the airplane is on jacks, you use the ground simulation function.

You use the stop simulation function to stop the air or ground simulation.

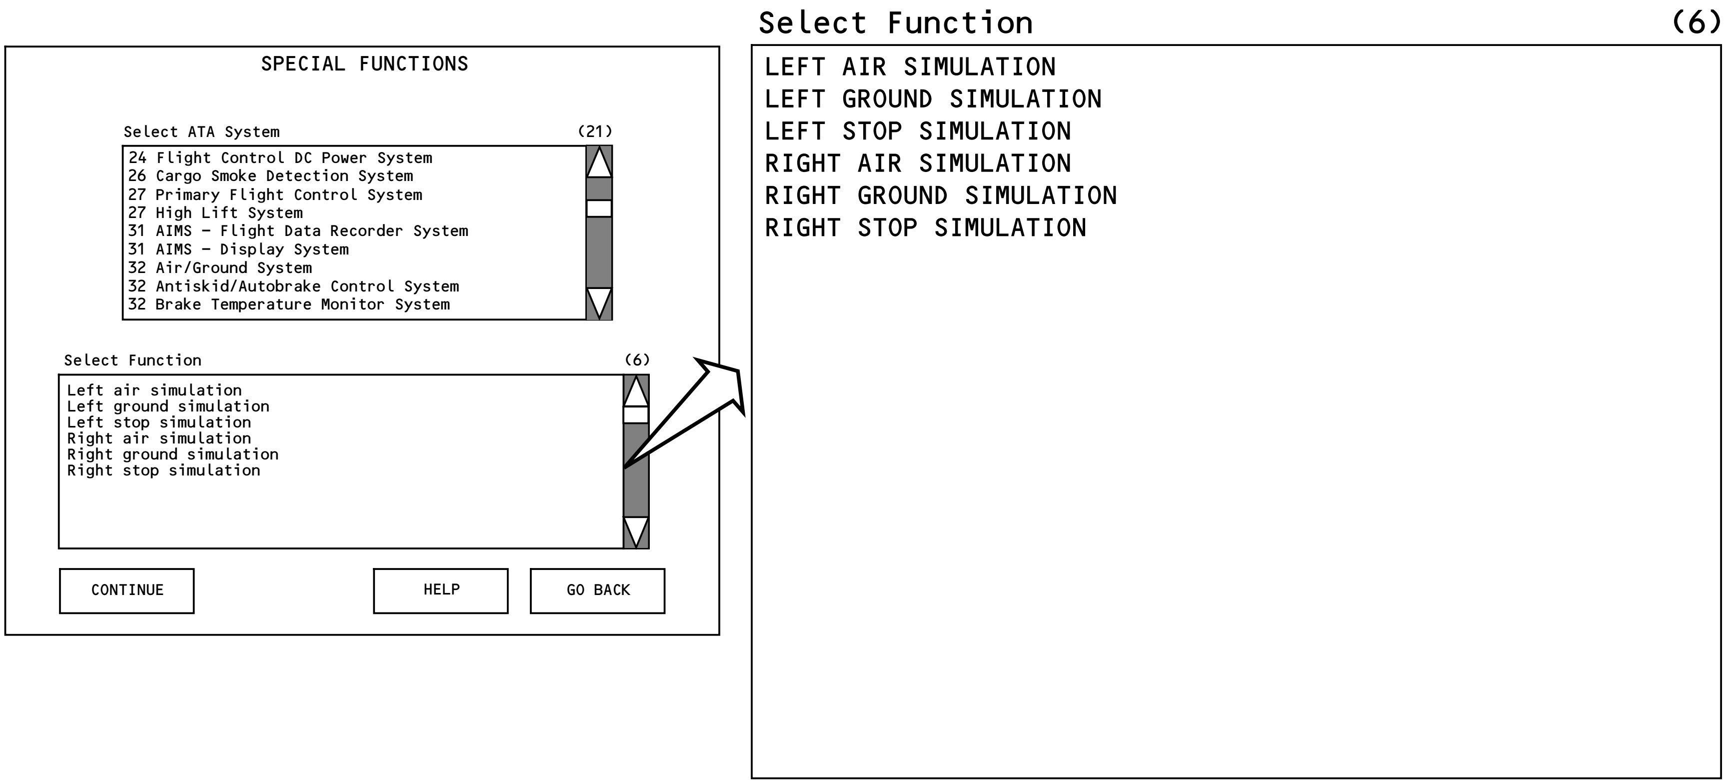
Training Information Point

To do a simulation, you must use the ground test enable switch (P61). Also, one of these two conditions must be true:

- Primary or secondary external electrical power is available
- Radio altitude is less than 2 feet (from any of the three radio altimeters).

To simulate air mode or ground mode to all the airplane systems, you must do the simulation function for the left and the right WOW cards.

WARNING: PREPARE THE SAFETY SYSTEMS FOR THE AIR MODE BEFORE YOU SIMULATE THE AIR MODE. IN THE AIR MODE, AIRPLANE SYSTEMS CAN OPERATE AND CAUSE INJURIES TO PERSONS AND DAMAGE TO EQUIPMENT.



32-09-00-008 Rev 2

AIR/GROUND SYSTEM - SPECIAL FUNCTIONS

AIR/GROUND SYSTEM - AIR/GROUND RIGGING/CALIBRATION

General

After you replace a load sensor, the new sensor must be calibrated to the airplane. You calibrate all four load sensors if you replace the two WOW cards.

You can calibrate each WOW load sensor with the air/ground rigging/calibration function on the MAT. This function is in the PSEU and Air/Ground Rigging function in the Other Functions menu. There is a calibration function for each of the four load sensors.

Calibration

The screen for this function shows a rigging status ruler. The ruler shows the output of the selected load sensor in counts. The count is a measurement of the bending of the main landing gear beam.

This screen also shows the acceptable count ranges for air and ground calibrations and the limits for air and ground rigging. The calibration ranges are wider than the rigging limits.

The sensor reading must be within the rigging limits when you install a new load sensor. You use the calibration range when you replace the WOW cards or if you want to do a check of the sensors. If the sensor is not within the applicable limits, you must adjust the sensor mounting brackets before you calibrate.

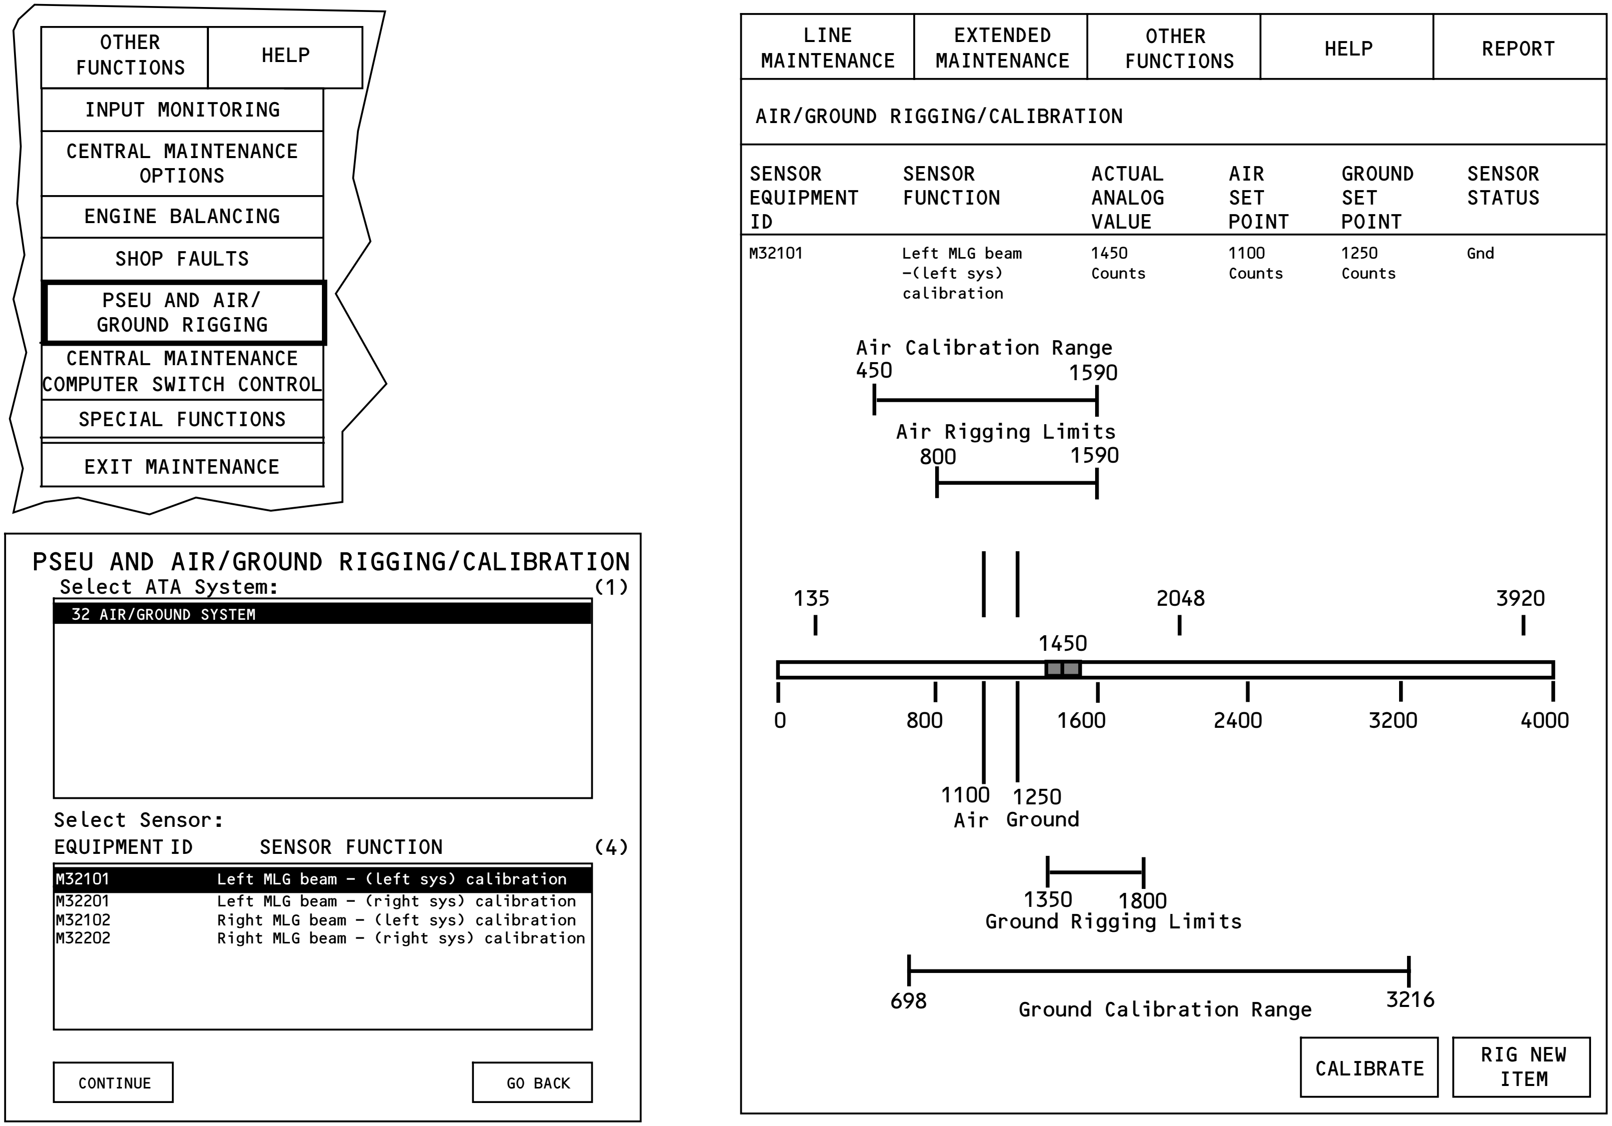
When you select calibrate at the bottom of the screen, ground calibration and air calibration buttons show.

If the airplane weight is on the landing gear, do the ground calibration.

If the airplane is on jacks, do the air calibration.

Training Information Point

The ground test enable switch must be in the ENABLE position to do this function.



AIR/GROUND SYSTEM - AIR/GROUND RIGGING/CALIBRATION

Continental Airlines, Inc

Steering

WB371

TABLE OF CONTENTS

THIS PAGE INTENTIONALLY LEFT BLANK

STEERING - INTRODUCTION

Purpose

The nose gear steering (NGS) system and the main gear steering system (MGSS) supply directional control of the airplane on the ground.

The MGSS also decreases tire scrub and the U-turn radius.

You make steering inputs through two steering tillers and the rudder pedals.

Nose Gear Steering

The nose gear steering system is a hydro-mechanical system that moves the nose landing gear up to 70 degrees left or right.

Main Gear Steering

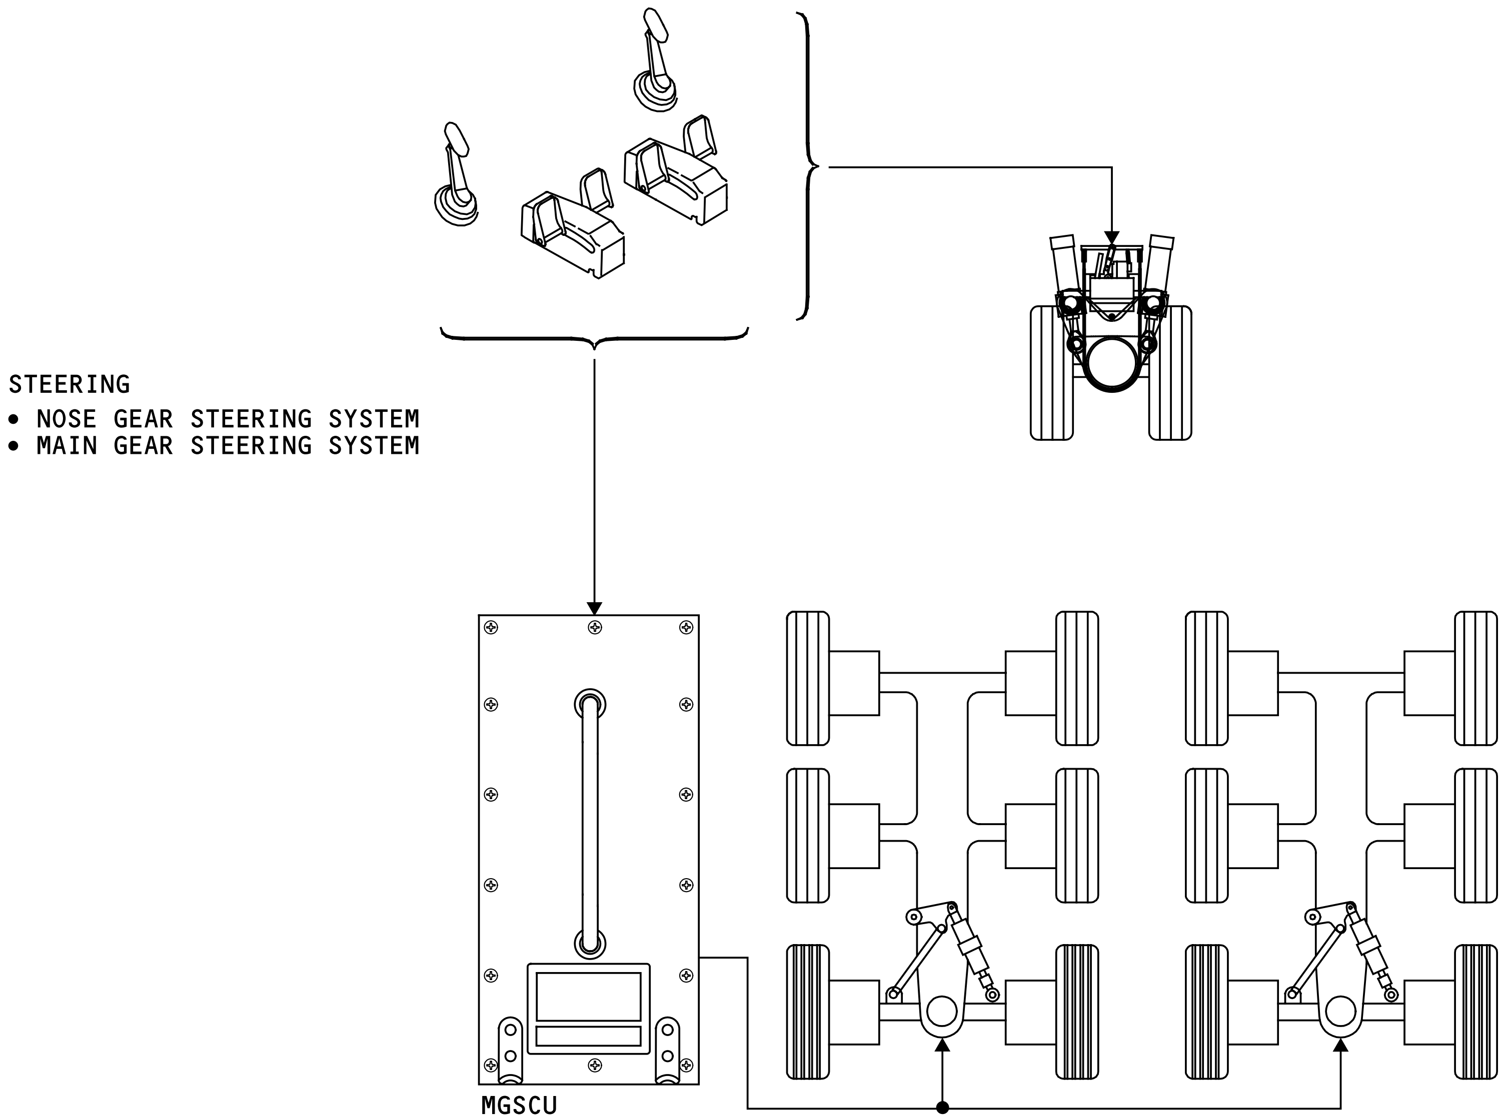
The main gear steering operates when the nose gear turns more than 13 degrees.

The aft axles on each main gear truck move up to 8 degrees in each direction.

The main gear steering system gets position inputs from the NGS. A main gear steering control unit (MGSCU) controls the main gear steering system.

Abbreviations and Acronyms

AIMS - airplane information management system
ARINC - Aeronautical Radio, Inc.
EHSV - electrohydraulic servovalve
F/O - first officer
LVDT - linear variable differential transformer
MGSCU - main gear steering control unit
MGSS - main gear steering system
MLG - main landing gear
MFD - multi-function display
NG - nose gear
NGS - nose gear steering
NLG - nose landing gear
PCA - power control actuator
pos - position
PSI - pounds per square inch
RVDT - rotary variable differential transformer
WES - warning electronic system
xdcr - transducer.



STEERING - INTRODUCTION

32-50-00-001 Rev 1

NOSE GEAR STEERING SYSTEM - INTRODUCTION

Purpose

The nose gear steering system supplies the primary ground directional control of the airplane.

Inputs

Steering inputs are from the steering tillers or the rudder pedals.

Cable Loops

Steering inputs move an upper cable loop. This loop connects to a lower cable loop. The lower cable loop makes inputs to a NLG steering metering valve module.

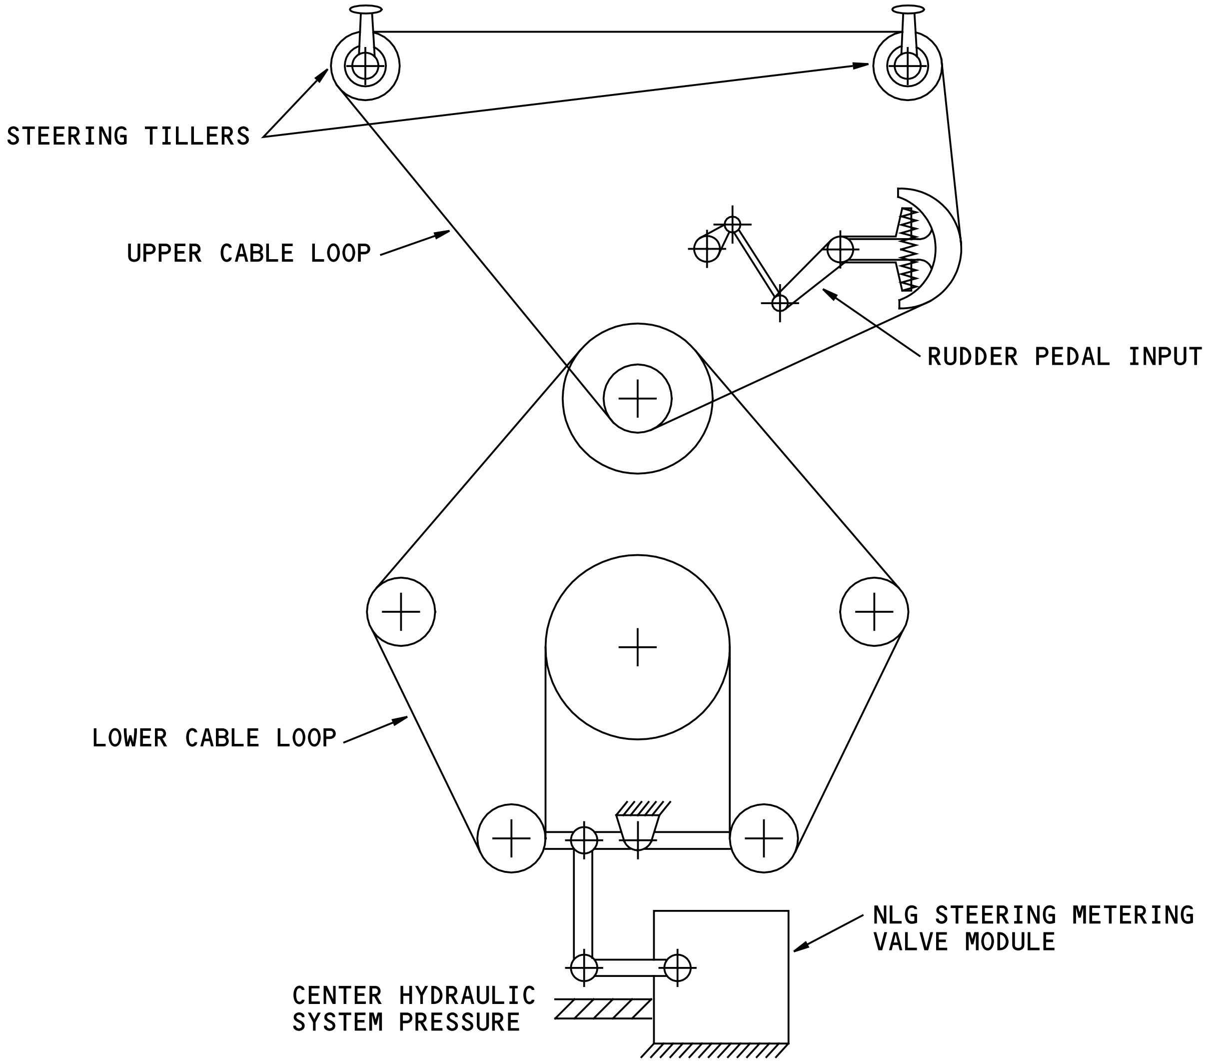
Hydraulic Supply

The center hydraulic system supplies the pressure to operate the nose gear steering system.

Limits

Steering tiller input turns the nose gear up to 70 degrees in each direction.

Rudder pedal input turns the nose gear approximately 7 degrees in each direction.



32-51-00-001 Rev 1

NOSE GEAR STEERING SYSTEM - INTRODUCTION

NOSE GEAR STEERING SYSTEM - COMPONENTS

Upper Cable Loop Components

These are the nose gear steering components on the upper cable loop:

- NLG steering tiller and gearbox (2)
- NLG drum mechanism (2)
- NLG steering centering and rudder interconnect mechanism
- NLG steering broken cable compensator
- NLG steering pivot link.

Lower Cable Loop Components

These are the nose gear steering components on the lower cable loop:

- NLG steering centering mechanism
- NLG steering summing mechanism
- NLG steering metering valve module
- NLG steering actuator (2)
- Nosewheel steering collar.

NOSE GEAR STEERING SYSTEM - COMPONENTS

THIS PAGE INTENTIONALLY LEFT BLANK

NOSE GEAR STEERING SYSTEM - NLG STEERING CENTERING AND RUDDER INTERCONNECT MECHANISM

Purpose

The NLG steering centering and rudder interconnect mechanism connects the rudder pedals to the upper cable loop. It also moves the steering system to the neutral position when there are no inputs.

The NLG steering centering and rudder interconnect mechanism permits the tillers to move the upper cable loop without moving the rudder pedals. It also permits the rudder pedals to move the upper cable loop.

Physical Description

The NLG steering centering and rudder interconnect mechanism has these components:

- Cable quadrant
- Cable quadrant arm
- Rudder pedal arm
- Free arm assembly (2)
- Roller (2)
- Centering spring (4).

The cable quadrant and cable quadrant arm are one assembly. The cable quadrant attaches directly to the upper cable loop.

The rudder pedal arm is directly below the cable quadrant arm and connects through a rod to rudder system forward control components.

A roller attaches to each of the free arm assemblies. The rollers can touch the cable quadrant arm and the rudder pedal arm.

Two centering springs are above and two centering springs are below (not shown) the cable quadrant arm. The springs are connected to the two free arm assemblies.

The cable quadrant and cable quadrant arm, the rudder pedal arm, and the free arm assemblies pivot about the same point.

Location

The NLG steering centering and rudder interconnect mechanism is below the flight deck floor. You get access to the mechanism through the forward equipment center access door.

Neutral Position

When the tillers and the rudder pedals are in the neutral position, the centering springs keep or return the cable quadrant and cable quadrant arm to the centered position. This keeps the upper cable loop and the nose gear steering system in the centered position.

Tiller Inputs

Tiller inputs move the upper cable loop. The upper cable loop directly moves the cable quadrant and cable quadrant arm. The cable quadrant arm pushes on one of the two rollers. This causes one of the free arm assemblies to move and pulls on the centering springs.

The centering springs pull the other free arm assembly and roller against the rudder pedal arm.

The rudder pedal arm does not move because the rudder pedal centering force (from springs in the rudder system forward control components) is greater than the force that pulls on the centering springs. This causes the centering springs to extend.

The result is that the tiller input moves the cable quadrant to make a steering input but the rudder system does not get an input.

Rudder Pedal Inputs

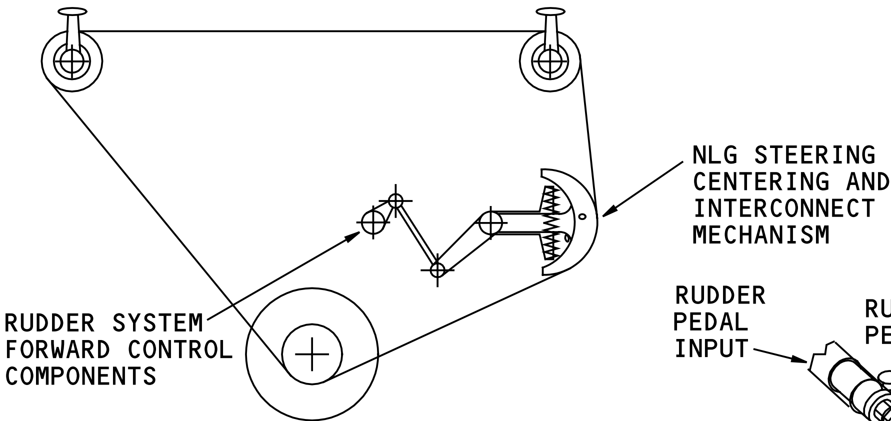
Rudder pedal inputs through the rudder system forward control components move the rudder pedal arm. This arm pushes against one of the two rollers and moves one of the free arm assemblies. The centering springs pull on the other free arm assembly and roller. If the nose landing gear is in the extended position, the roller pushes and moves the cable quadrant arm, the cable quadrant, and the upper cable loop. This results in a nose gear steering input.

The upper cable loop motion moves the steering tillers.

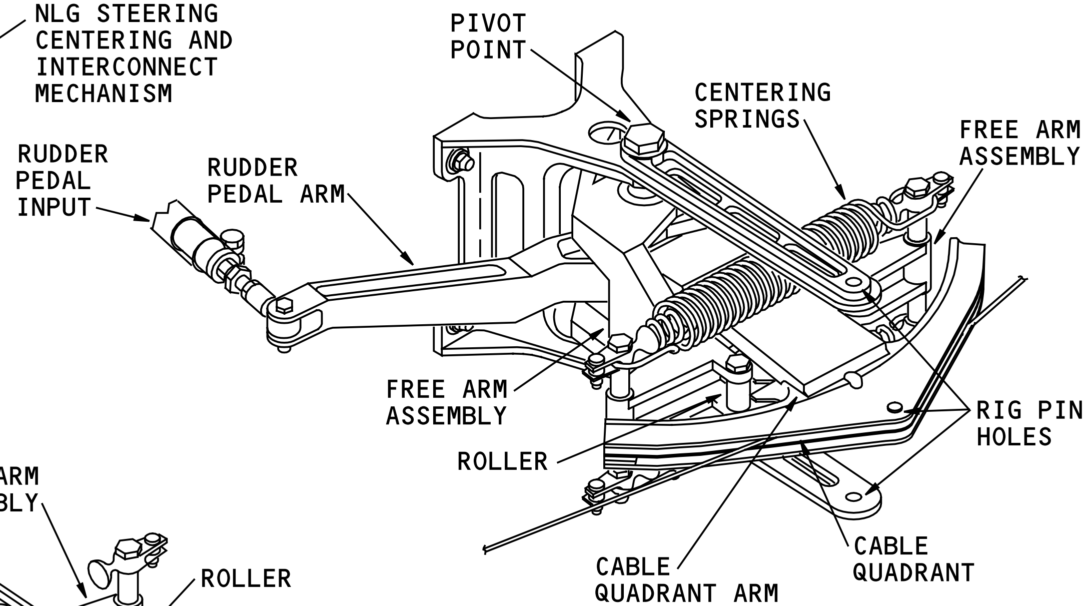
If the nose landing gear is in the retracted position, the upper cable loop is locked. This also locks the cable quadrant and quadrant arm. Rudder pedal inputs will then cause the centering springs to extend.

Training Information Point

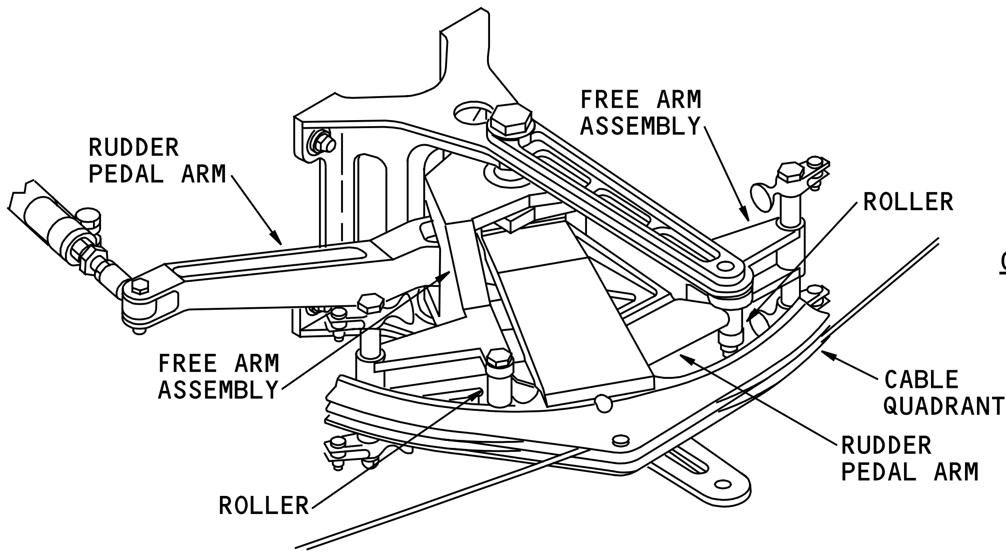
Rig pin holes in the mechanism keep the system in the neutral position during cable rigging.



UPPER CABLE LOOP



CENTERING AND RUDDER INTERCONNECT MECHANISM
(NEUTRAL POSITION)



CENTERING AND RUDDER INTERCONNECT MECHANISM
(TILLER INPUT) (CENTERING SPRINGS REMOVED)

NOSE GEAR STEERING SYSTEM - NLG STEERING CENTERING AND RUDDER INTERCONNECT MECHANISM

NOSE GEAR STEERING SYSTEM - NLG STEERING BROKEN CABLE COMPENSATOR

Purpose

The NLG steering broken cable compensator protects the steering system from inputs caused by a break in the upper cable loop.

Physical Description

These are the NLG steering broken cable compensator components:

- Two pulleys
- Two force links
- A roller
- An output cam and shaft.

The pulleys are bearing-mounted on the output shaft. A roller connects to each of the pulleys by force links. The output cam attaches to the output shaft.

Location

The NLG steering broken cable compensator is on the aft side of the nose gear wheel well rear bulkhead in the main equipment center.

The output shaft of the broken cable compensator goes through the bulkhead into the wheel well.

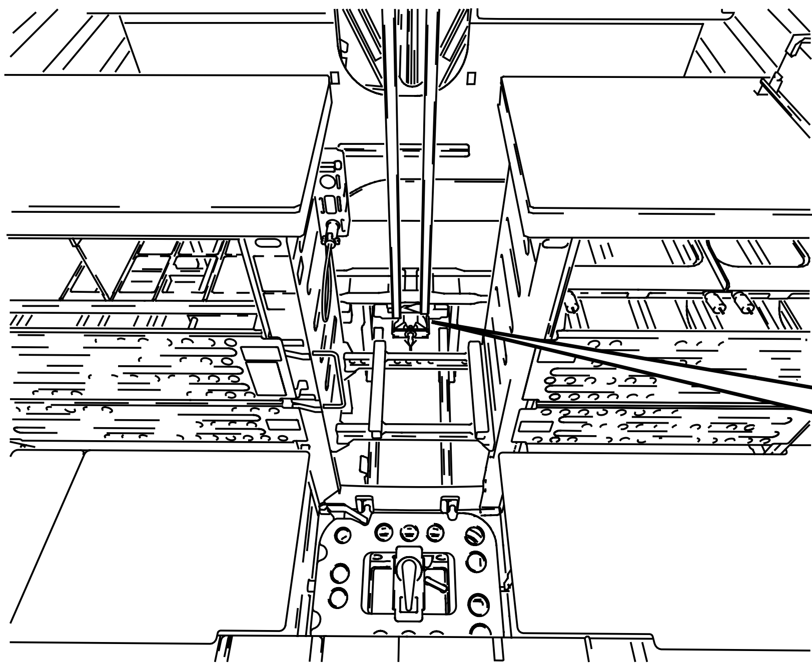
Functional Description

Tension in the upper cable loop pulls on the force links. This keeps the roller in the output cam and permits cable motion to move the output cam.

A break in the upper cable loop causes tension to be lost in one cable. Asymmetric tension moves the roller out of the cam detent. This stops all steering inputs.

Training Information Point

You must remove the main battery to get access to the NLG steering broken cable compensator.



MAIN EQUIPMENT CENTER - LOOKING FORWARD

NOSE GEAR STEERING SYSTEM - NLG STEERING BROKEN CABLE COMPENSATOR

32-51-00-005 Rev 2 05/03/95

NOSE GEAR STEERING SYSTEM - NLG STEERING PIVOT LINK AND NLG STEERING CENTERING MECHANISM

Purpose

The NLG steering pivot link connects the upper cable loop to the lower cable loop.

The NLG steering centering mechanism locks the NGS system in the centered position during gear retraction.

Physical Description

The hinged pivot links connect the output shaft of the NLG steering broken cable compensator to the NLG steering centering mechanism.

The NLG steering centering mechanism has these components:

- Spring cartridge
- Crank and shaft
- Driver
- Guide link
- Cam assembly
- Cam follower
- Drum.

Location

The NLG steering centering mechanism is on top of the nose landing gear.

Functional Description

When the nose gear starts to retract, the movement of the nose gear lock link moves the spring cartridge.

The spring cartridge turns the shaft through the crank. This lifts the driver and cam assembly.

The driver and cam assembly moves the cam follower to the centered position. This moves the upper and lower cable loops to the neutral position.

THIS PAGE INTENTIONALLY LEFT BLANK

NOSE GEAR STEERING SYSTEM - NLG STEERING SUMMING MECHANISM AND METERING VALVE MODULE

General

The NLG steering summing mechanism adds steering tiller input and nose gear position feedback to control the NLG steering metering valve module.

The NLG steering metering valve module controls the flow of hydraulic fluid to the NLG steering actuators.

The summing mechanism is on top of the upper steering plate on the front of the nose gear. A protective cover is on the summing mechanism.

The NLG steering metering valve module is on the upper steering plate on the front of the nose gear shock strut.

NLG Steering Summing Mechanism

The NLG steering summing mechanism contains these components:

- Summing lever
- Pulley (2)
- Input rod.

The pulleys connect to each side of the summing lever. The lower cable loop winds around each pulley.

The summing mechanism pivots about its center. The input rod connects the summing mechanism to the metering valve module.

NLG Steering Metering Valve Module

The NLG steering metering valve module contains these components:

- Metering valve
- Dynamic load damper
- Bypass/relief valve (not shown)
- Compensator
- Towing shutoff valve and lever
- Swivel valve (2).

The metering valve controls hydraulic flow to the steering actuators. The valve is spring-loaded to the centered position.

The dynamic load damper supplies shimmy damping to the nose gear.

The bypass/relief valve protects the steering actuators against high hydraulic pressures. When pressure in an actuator goes above 4000 psi, the bypass/relief valve opens and permits hydraulic fluid to move between the actuators.

The compensator keeps a 250 psi backpressure in the steering metering valve module. This prevents steering actuator cavitation during shimmy damping.

A towing lever on the metering valve module controls a towing shutoff valve. In the tow position, the towing valve shuts off pressure to the nose gear steering system. This permits the nose gear to turn during towing. A towing lever pin holds the towing lever in the TOW position.

The swivel valves control hydraulic flow to the two sides of the steering actuators.

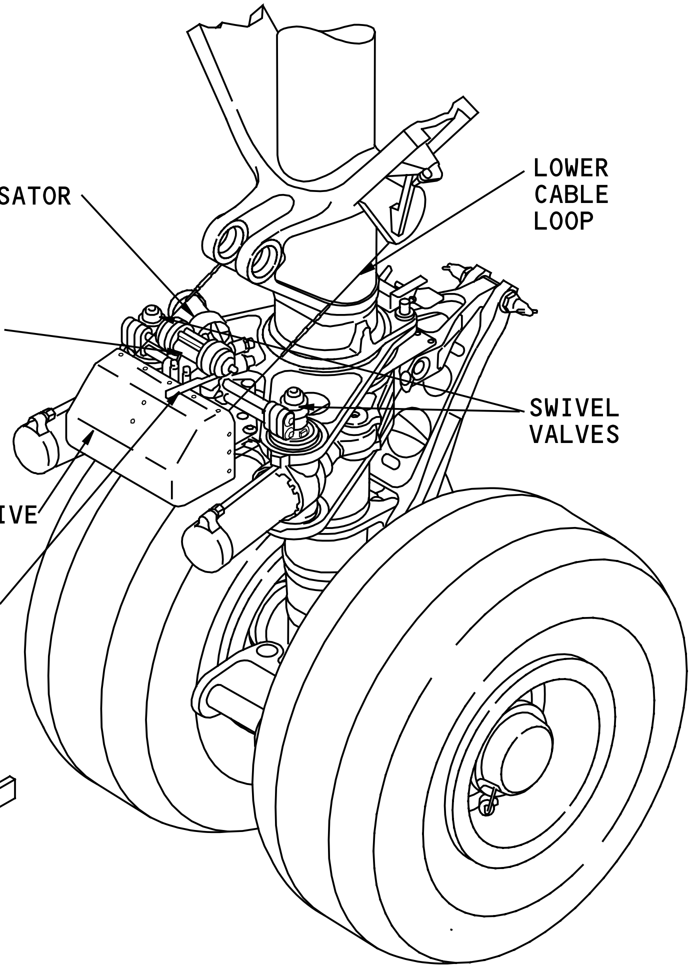
Functional Description

Tiller operation moves the summing mechanism from the neutral position. This makes an input to the metering valve module which sends pressure to the NLG steering actuators. The NLG steering actuators turn the nose gear.

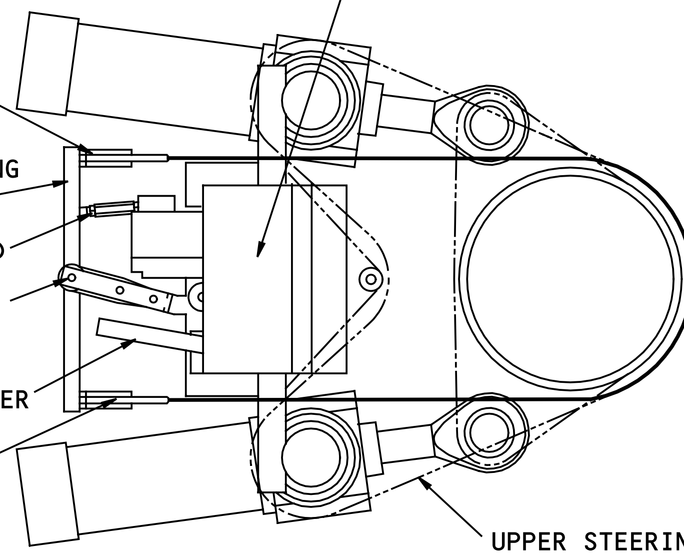
The rotation of the nose gear moves the summing mechanism back towards the neutral position. When the nose gear position agrees with the tiller position, the summing mechanism moves the metering valve to the neutral position. This shuts off the flow to the NLG steering actuators.

Training Information Point

A towing lever permits you to depressurize the nose gear steering system. This permits towing without depressurizing the center hydraulic system.



NOSE LANDING GEAR



NLG STEERING SUMMING MECHANISM - (PROTECTIVE COVER REMOVED) - TOP VIEW

32-51-00-007 Rev 0

NOSE GEAR STEERING SYSTEM - NLG STEERING SUMMING MECHANISM AND METERING VALVE MODULE

NOSE GEAR STEERING SYSTEM - FUNCTIONAL DESCRIPTION

General

The NGS system uses center hydraulic system pressure to turn the nose gear.

Steering inputs move the upper and lower cable loops. This makes an input through the summing mechanism to move the NLG steering metering valve. This permits hydraulic pressure to go through the swivel valves to the steering actuators.

The actuators get pressure on the extend side, the retract side, or both sides to move the nose gear from 0 - 70 degrees.

Rotation: 0 - 27 Degrees

One actuator gets pressure to its head end and the other actuator gets pressure to its rod end. This causes one actuator to extend and the other to retract.

This rotates the nose gear through the torsion links.

Rotation: 27 - 70 Degrees

When the nose gear turns to approximately 27 degrees, the swivel valve for the retracting actuator sends pressure to both sides of that actuator.

Both actuators now extend and permit nose gear rotation to the 70 degree limit.

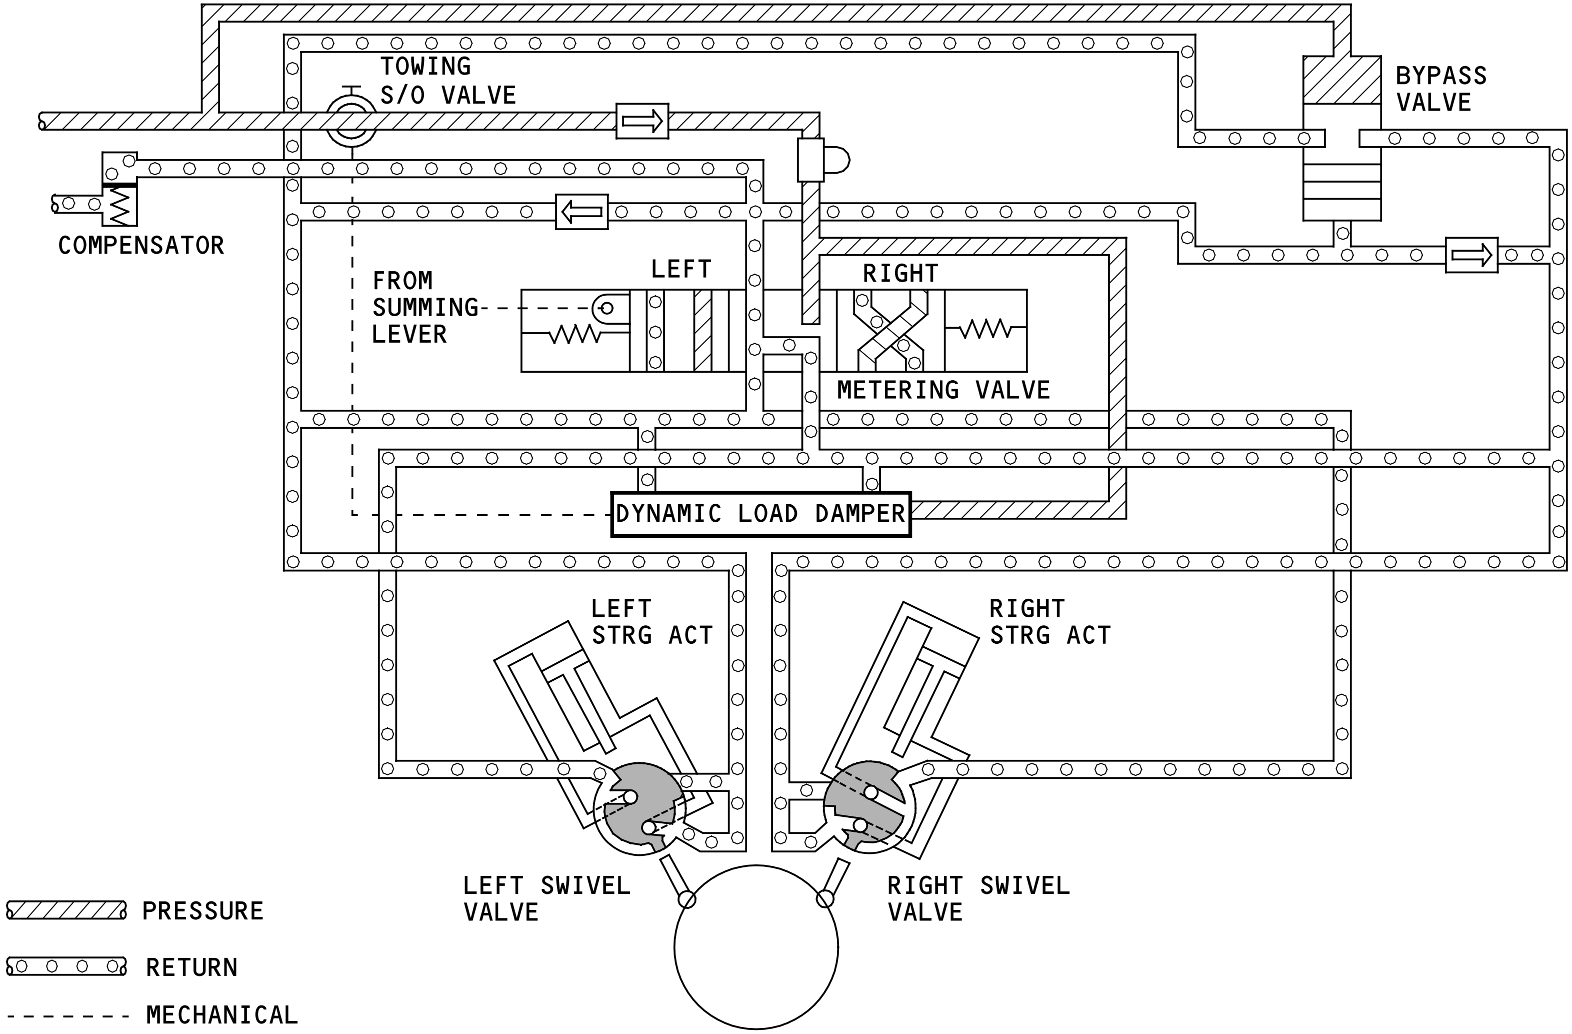
Feedback

When the nose gear gets to the commanded position, the summing mechanism moves the metering valve back to neutral. This stops hydraulic pressure to the actuators and stops nose gear movement.

Training Information Point

To tow the airplane, you move the towing lever on the metering valve module to the tow position. This closes the towing shutoff valve to stop hydraulic pressure to the metering valve module. The towing lever also moves the dynamic load damper to let fluid flow between the steering actuators. This lets an external force move the nose gear wheels.

The bypass/relief valve lets fluid flow between the steering actuators when the pressure in either actuator is approximately 4000 psi. This lets an external force move the nose gear wheels if the tow lever is not in the tow position.



32-51-00-009 Rev 2 08/17/96

NOSE GEAR STEERING SYSTEM - FUNCTIONAL DESCRIPTION

MAIN GEAR STEERING SYSTEM - INTRODUCTION

Purpose

The main gear steering system reduces tire scrub and airplane turn radius.

Main gear steering also decreases the force necessary to turn the airplane.

Components

The main gear steering system components include:

- NLG steering tiller position transducer (2)
- Main gear steering control unit (MGSCU)
- Main gear steering/locking power control actuator (2)
- Main gear steering crank (2)
- Main gear steering reaction link (2).

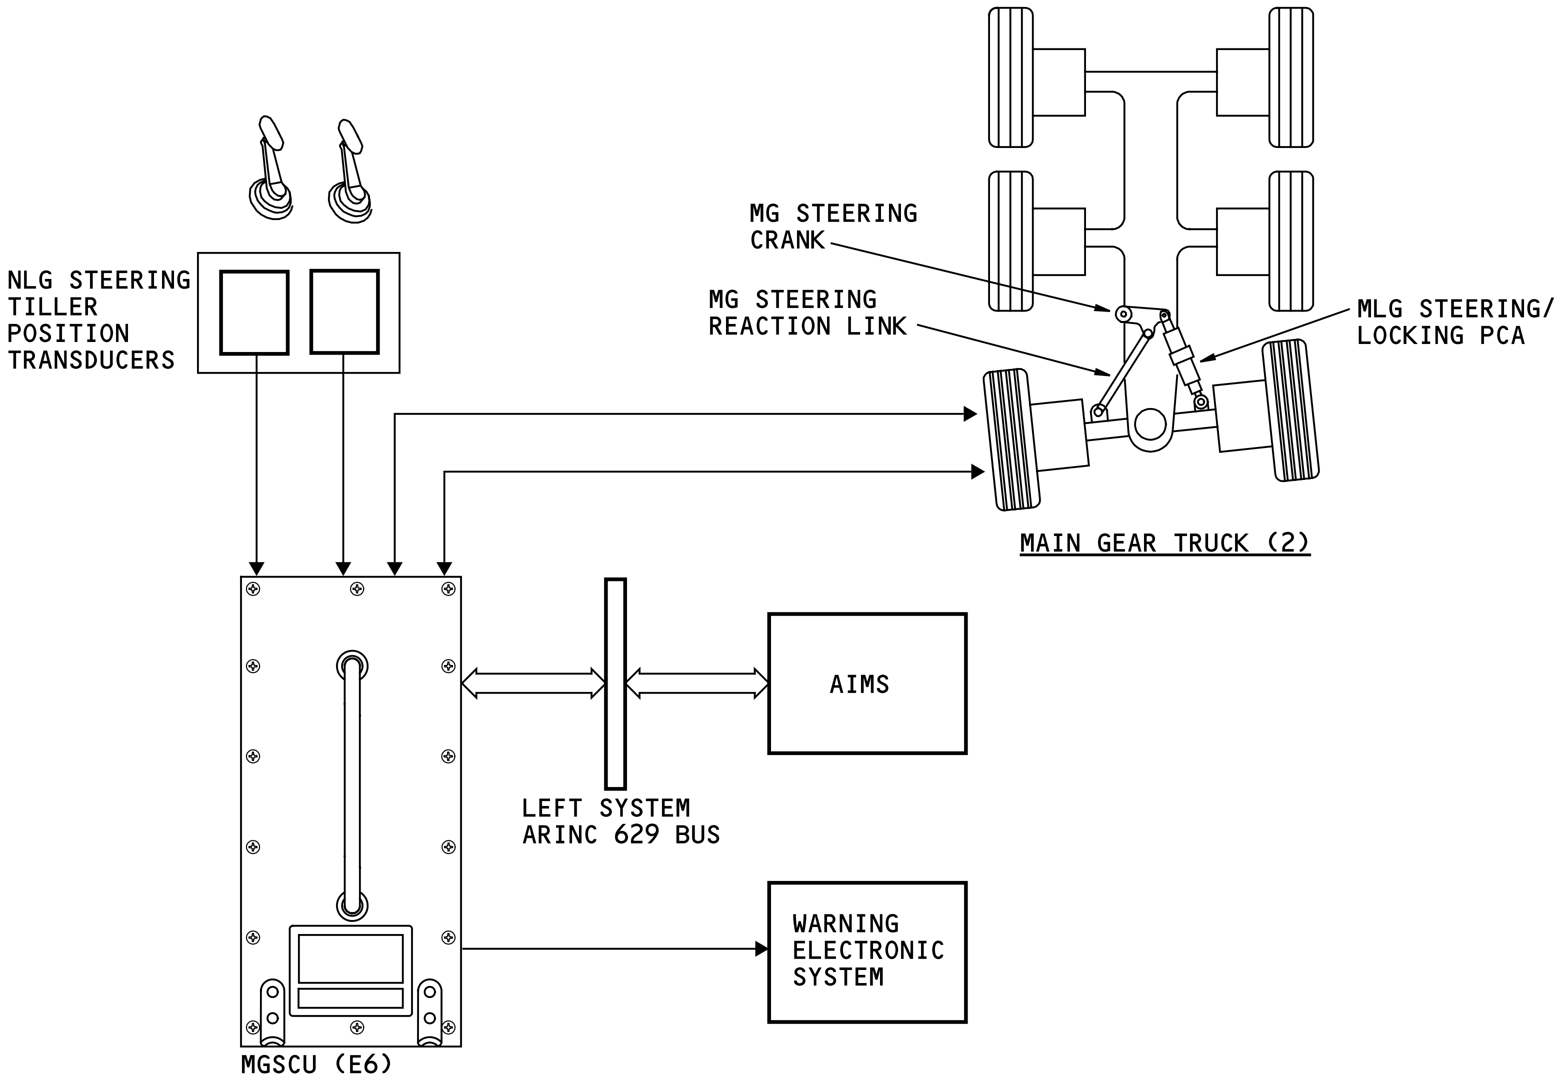
General Description

The NLG steering tiller position transducers supply steering tiller position data to the MGSCU.

The center hydraulic system supplies the hydraulic power for main gear steering operation.

The MGSCU supplies main gear steering position and fault data to the AIMS for flight deck indications.

The MGSCU also supplies aft axle lock status to the warning electronic system (WES). The WES uses this data to calculate the CONFIG GEAR STEERING takeoff configuration warning.



32-53-00-001 Rev 2 11/28/1995

MAIN GEAR STEERING SYSTEM - INTRODUCTION

MAIN GEAR STEERING SYSTEM - NLG STEERING TILLER POSITION TRANSDUCERS

Purpose

Two NLG steering tiller position transducers supply steering tiller data to the MGSCU. The MGSCU uses this data to control the main gear steering.

Physical Description

The two NLG steering tiller position transducers are the same. The transducers are rotary variable differential transformers (RVDTs).

The input shafts of the position transducer turn through a 90 degree arc with the torque shaft from the steering tiller and gearbox.

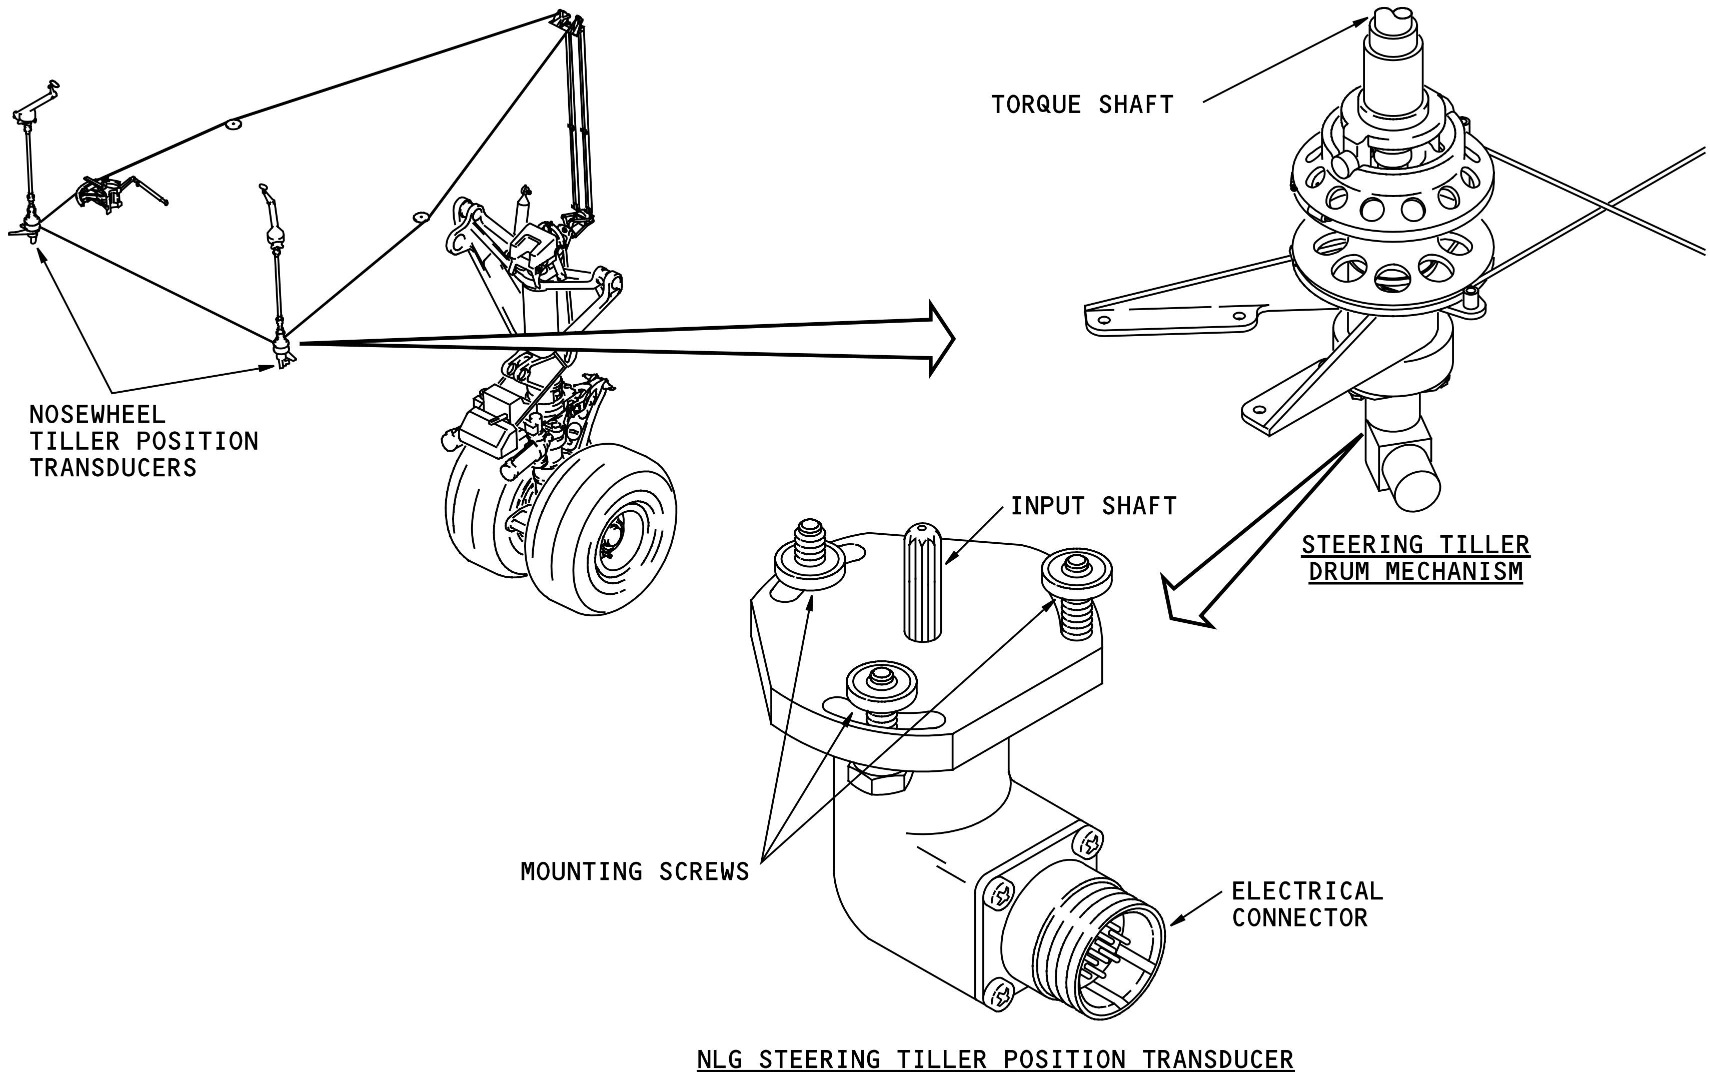
Location

A transducer is on the bottom of each steering tiller drum mechanism in the forward equipment center.

Training Information Point

Before installation, the transducer input shaft is locked in the zero (neutral) position.

The transducer input shaft is unlocked when you install the three captive mounting screws.



32-53-00-002 Rev 1 09/18/1996

MAIN GEAR STEERING SYSTEM - NLG STEERING TILLER POSITION TRANSDUCERS

MAIN GEAR STEERING SYSTEM - MAIN GEAR STEERING CONTROL UNIT

Purpose

The MGSCU gets the steering inputs from the nosegear steering tiller position transducers and controls the main gear steering/locking power control actuators.

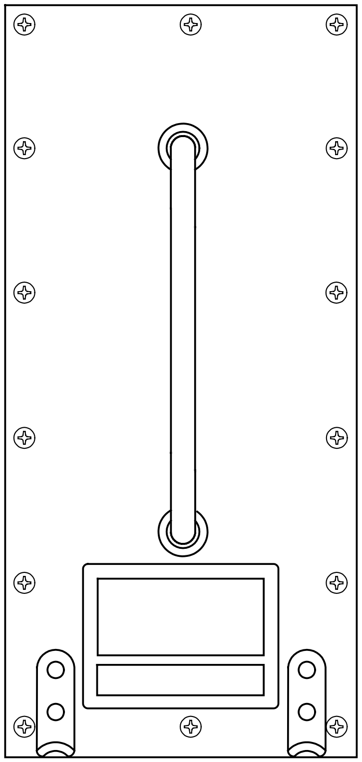
The MGSCU also monitors the main gear steering system for faults.

Location

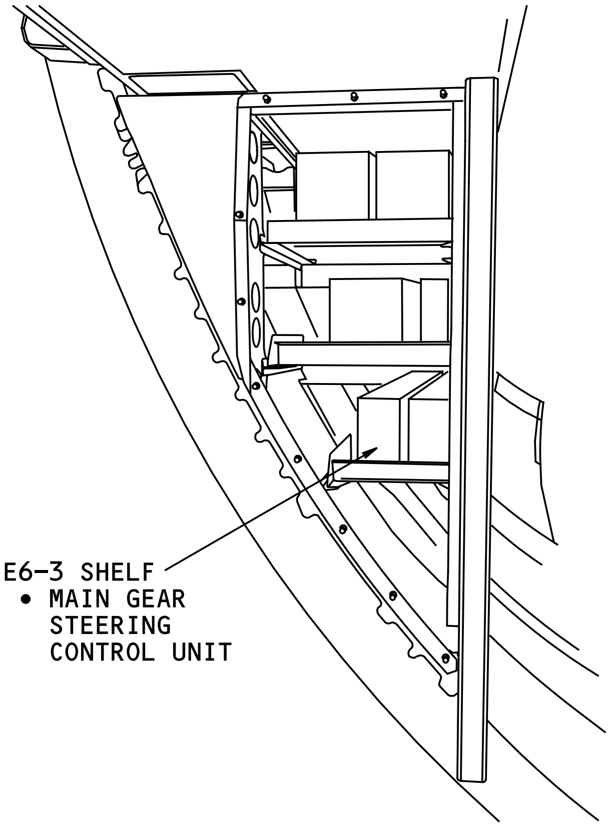
The MGSCU is on the E6-3 shelf in the aft cargo compartment.

Training Information Point

The MGSCU is electrostatic discharge sensitive.



MGSCU



AFT CARGO COMPARTMENT

MAIN GEAR STEERING SYSTEM - MAIN GEAR STEERING CONTROL UNIT

THIS PAGE INTENTIONALLY LEFT BLANK

MAIN GEAR STEERING SYSTEM - MAIN GEAR TRUCK COMPONENTS

General

These components are on the aft part of each main gear truck assembly:

- MLG steering/locking power control actuator (PCA)
- Reaction link
- Steering crank.

Steering/Locking Power Control Actuator

The MLG steering/locking PCA unlocks and turns the aft main gear axle. The PCA locks the aft axle when main gear steering is not used.

The MLG steering/locking PCAs are two-way actuators and have internal locks to keep them in the centered position. An LVDT in the actuator rod supplies position feedback to the MGSCU.

These are the other components in each MLG steering/locking PCA:

- Arming solenoid
- Unlock solenoid
- Electrohydraulic servo valve
- Isolation/power centering valve
- Anti-cavitation check valves
- Compensator
- Manual shutoff valve
- Lock position linear variable differential transformer (LVDT).

Reaction Link

A reaction link transmits steering forces back to the steering crank. This link connects the left side of the aft axle to the steering crank.

Steering Crank

The steering crank transmits actuator and the reaction link loads to the truck beam.

Training Information Point

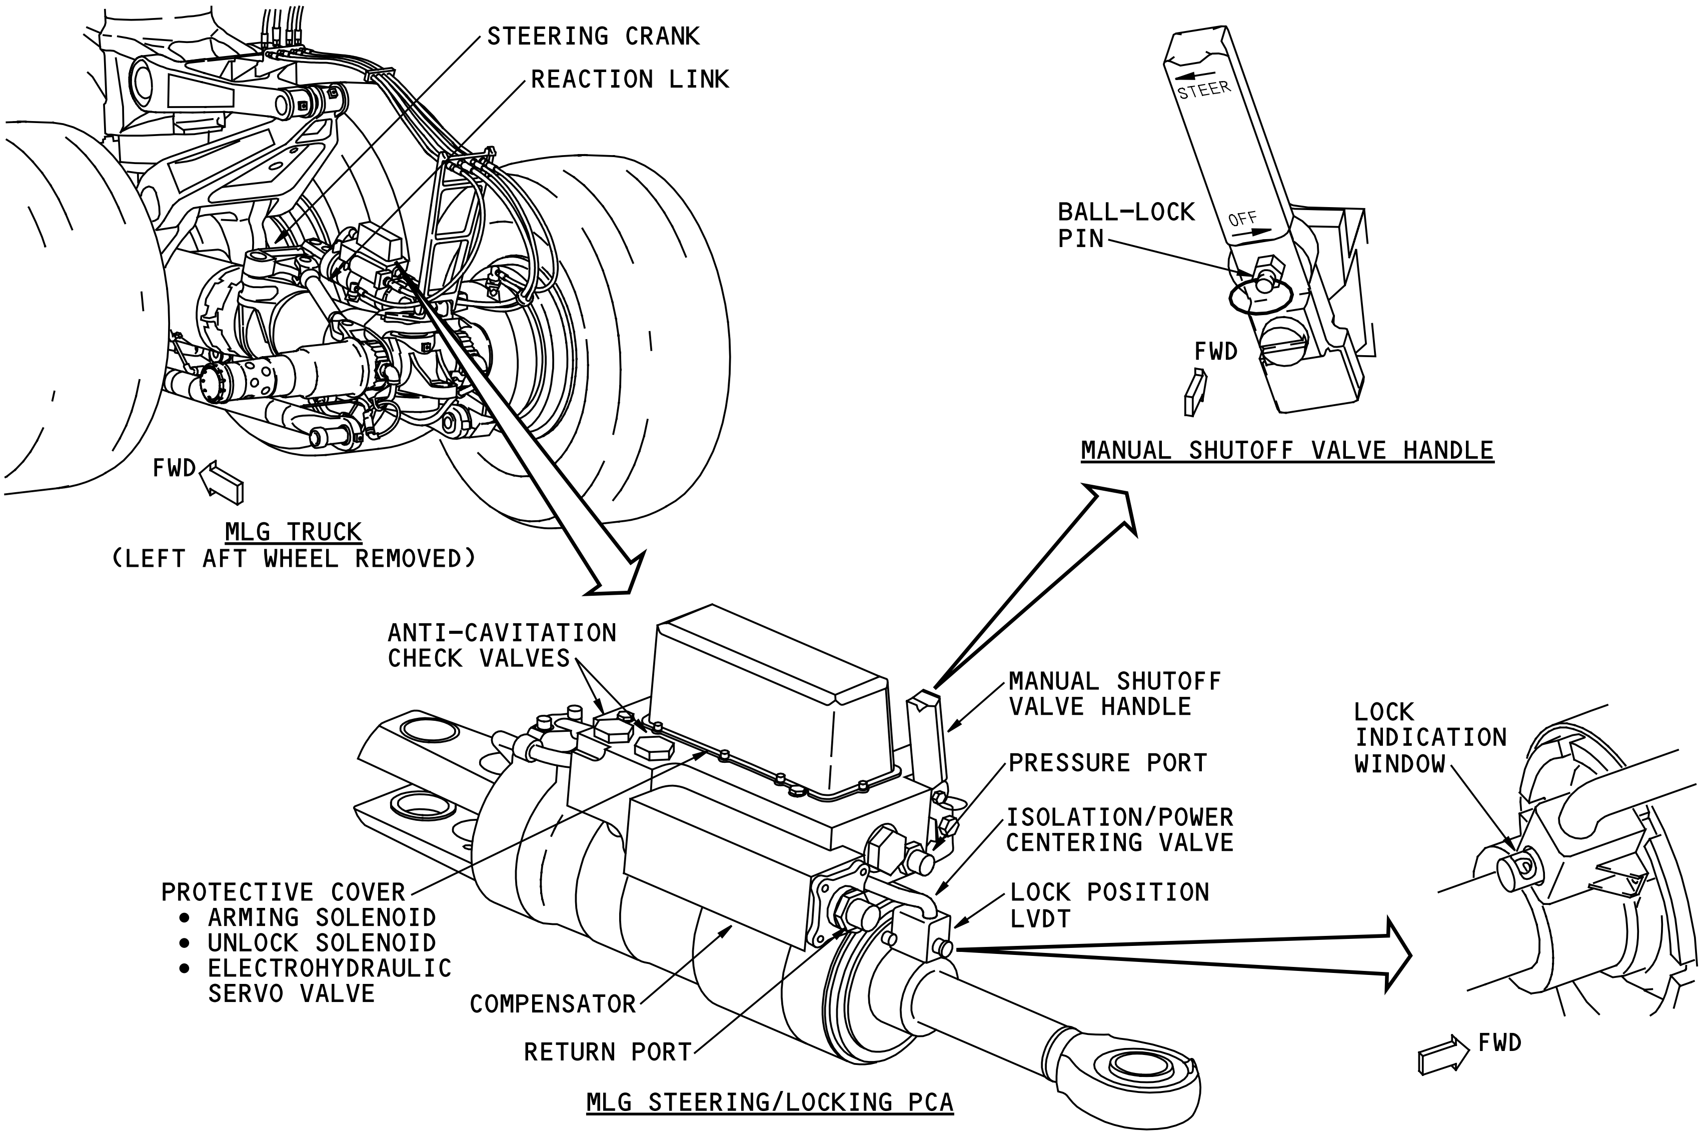
A manual shutoff valve permits you to stop the hydraulic flow to the steering locking PCA to disable the main gear steering. You operate the valve with the manual shutoff valve handle. A ball-lock pin keeps the shutoff valve in the selected position.

A valve position sensor sends shutoff valve position data to the MGSCU. The MAIN GEAR STEERING status message show when the handle is in the OFF position.

A silver indicator in the lock indication window on the unlock LVDT shows the lock/unlock condition of the PCA. If you can see the indicator, the PCA is unlocked. If you can not see the indicator, the PCA is locked.

MAIN GEAR STEERING SYSTEM - MAIN GEAR TRUCK COMPONENTS

WARNING: MAKE SURE THE MAIN LANDING GEAR STEERING SYSTEM IS ISOLATED FROM HYDRAULIC POWER BEFORE YOU DO WORK NEAR THE TIRES, WHEELS, OR BRAKES. IF YOU DO NOT DO THIS, THE AFT AXLES CAN AUTOMATICALLY TURN. THIS CAN CAUSE INJURIES TO PERSONS AND DAMAGE TO EQUIPMENT.



MAIN GEAR STEERING SYSTEM - MAIN GEAR TRUCK COMPONENTS

MAIN GEAR STEERING SYSTEM - HYDRAULIC FUNCTIONAL DESCRIPTION

General

The MGSCU gets input from the two NLG steering tiller position transducers and sends signals to the steering/locking PCAs. LVDTs on the PCAs send signals back to the MGSCU.

PCA Initial Condition

Each steering/locking PCA is centered and locked. Center system hydraulic pressure is on both sides of the PCA piston. The lock collar is in the locked position.

Arm - Unlock

When steering tiller input is more than 13 degrees of NLG steering angle, the MGSCU sends a signal to energize the unlock solenoid. This moves the unlock solenoid valve to the unlock position.

The MGSCU then sends a signal to energize the arm solenoid. Hydraulic pressure now goes through the unlock solenoid valve to unlock the lock collar on the actuator. The unlock LVDT sends an actuator unlock feedback signal to the MGSCU.

Pressure through the arm solenoid also moves the isolation/power centering valve to the ON position. This permits pressure to go to the electrohydraulic servo valve (EHSV).

Main gear steering is now armed and unlocked.

Control

The MGSCU sends signals to the EHSV to extend or retract the actuator. The aft axles turn in proportion to tiller position.

Maximum aft axle angle of eight degrees occurs at a nose gear angle of 70 degrees.

The actuator position LVDT sends actuator position data to the MGSCU.

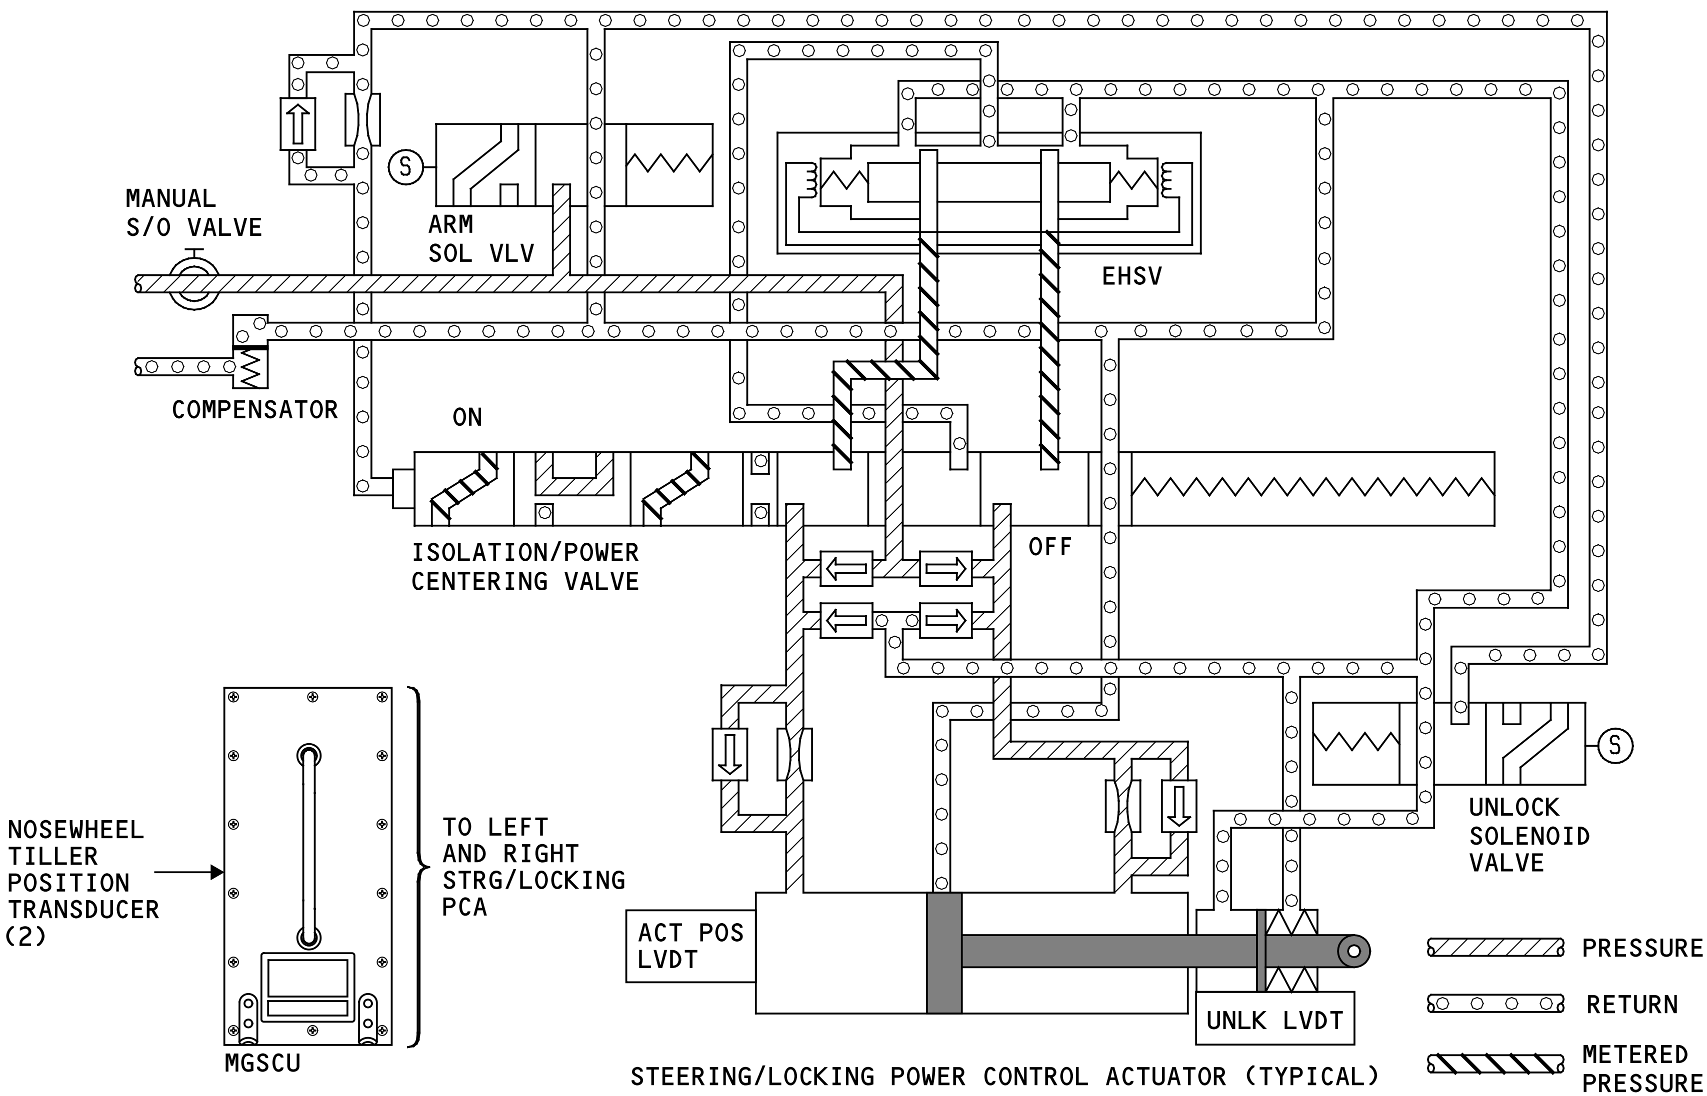
Disarm

When tiller angle is less than 9 degrees, the MGSCU removes power from the arm solenoid and the unlock solenoid. This stops hydraulic pressure to the lock collar and to the isolation/power centering valve.

A spring moves the isolation/power centering valve to the OFF position. This removes power from the EHSV and supplies pressure to both sides of the actuator. A return port in the center of the actuator (hole-in-the-wall) reduces pressure in the side of the actuator that is opposite to the actuator position. This moves and keeps the actuator in the centered position.

The spring-loaded lock collar locks the actuator after the pressure unlock solenoid removes the hydraulic pressure.

System faults will also disarm the main gear steering system.



MAIN GEAR STEERING SYSTEM - HYDRAULIC FUNCTIONAL DESCRIPTION

MAIN GEAR STEERING SYSTEM - INDICATIONS

Alert and Status Messages

The CONFIG GEAR STEERING warning message shows when a steering/locking PCA is not locked during takeoff.

The MAIN GEAR STEERING advisory message shows if a main gear steering/locking PCA is commanded locked and is not locked.

The MAIN GEAR STEERING status message shows if there is a failure in a component in the main gear steering system or if a steering/locking PCA is disabled.

Maintenance Page Indications

The multi-function display (MFD) shows steering tiller position on the landing gear brake and steering maintenance page. The angle of the main gear aft axles and locked/unlocked status also show on this display.

The page also shows failure or disable (manual shutoff valve closed) conditions below the aft axle angle display.

WHEELS AND BRAKES - INTRODUCTION

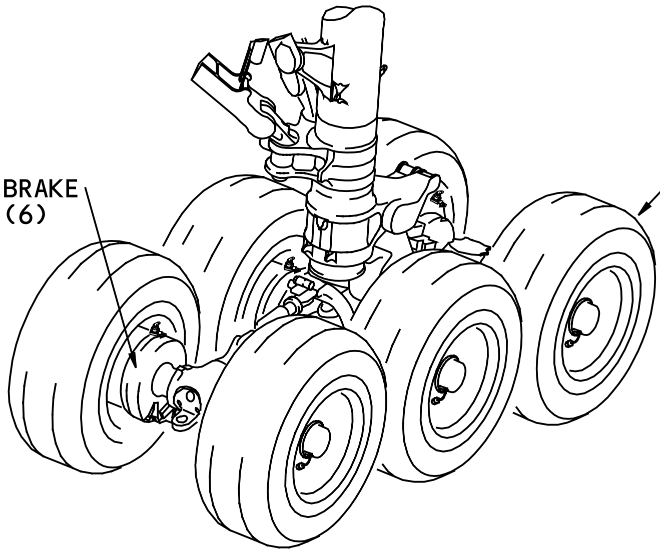
WHEELS, BRAKES, AND TIRES - INTRODUCTION

Main Landing Gear

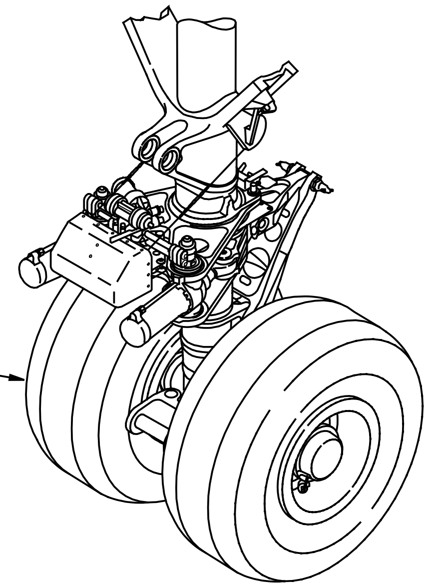
Each main landing gear has a six wheel truck. A brake assembly is in each of the 12 main landing gear wheel and tire assemblies.

Nose Landing Gear

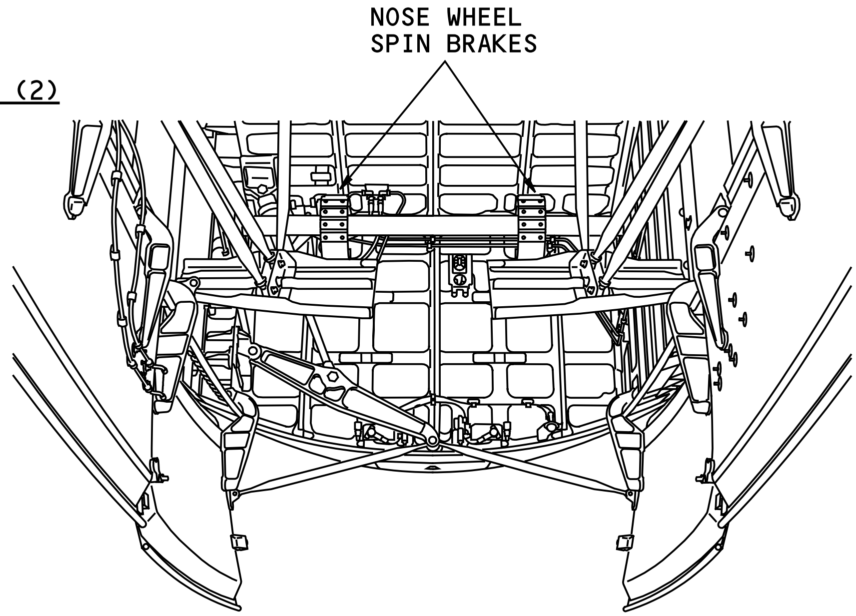
The nose landing gear has two wheel and tire assemblies. There are no hydraulic brakes for these wheels. Nose wheel spin brakes stop nose wheel rotation during retraction when the nose wheels enter the wheel well.



MAIN LANDING GEAR TRUCK (2)



NOSE LANDING GEAR



NOSE LANDING GEAR WHEEL WELL
(LOOKING FORWARD)

WHEELS, BRAKES, AND TIRES - INTRODUCTION

32-45-00-001 Rev 1 11/09/95

WHEELS, BRAKES, AND TIRES - MAIN LANDING GEAR WHEEL AND TIRE

Main Landing Gear Wheels

The main wheels are radial tire wheels. They have forged inner and outer halves. Tie bolts hold the two halves together. Brake rotor drive keys and heat shields are in the inner half of each wheel.

Each wheel also has these components:

- Tire inflation valve
- Over-pressure relief valve
- Tire pressure sensor
- Thermal fuse plug (3).

Tire Inflation Valve

A tire inflation valve is in the outer wheel half.

Over-Pressure Relief Valve

An over-pressure relief valve is in the outer wheel half. The relief valve releases tire pressure above 375-450 psig.

Tire Pressure Sensor

A tire pressure sensor is in the outer wheel half. This sensor sends tire pressure data to the tire pressure indication system.

Thermal Fuse Plugs

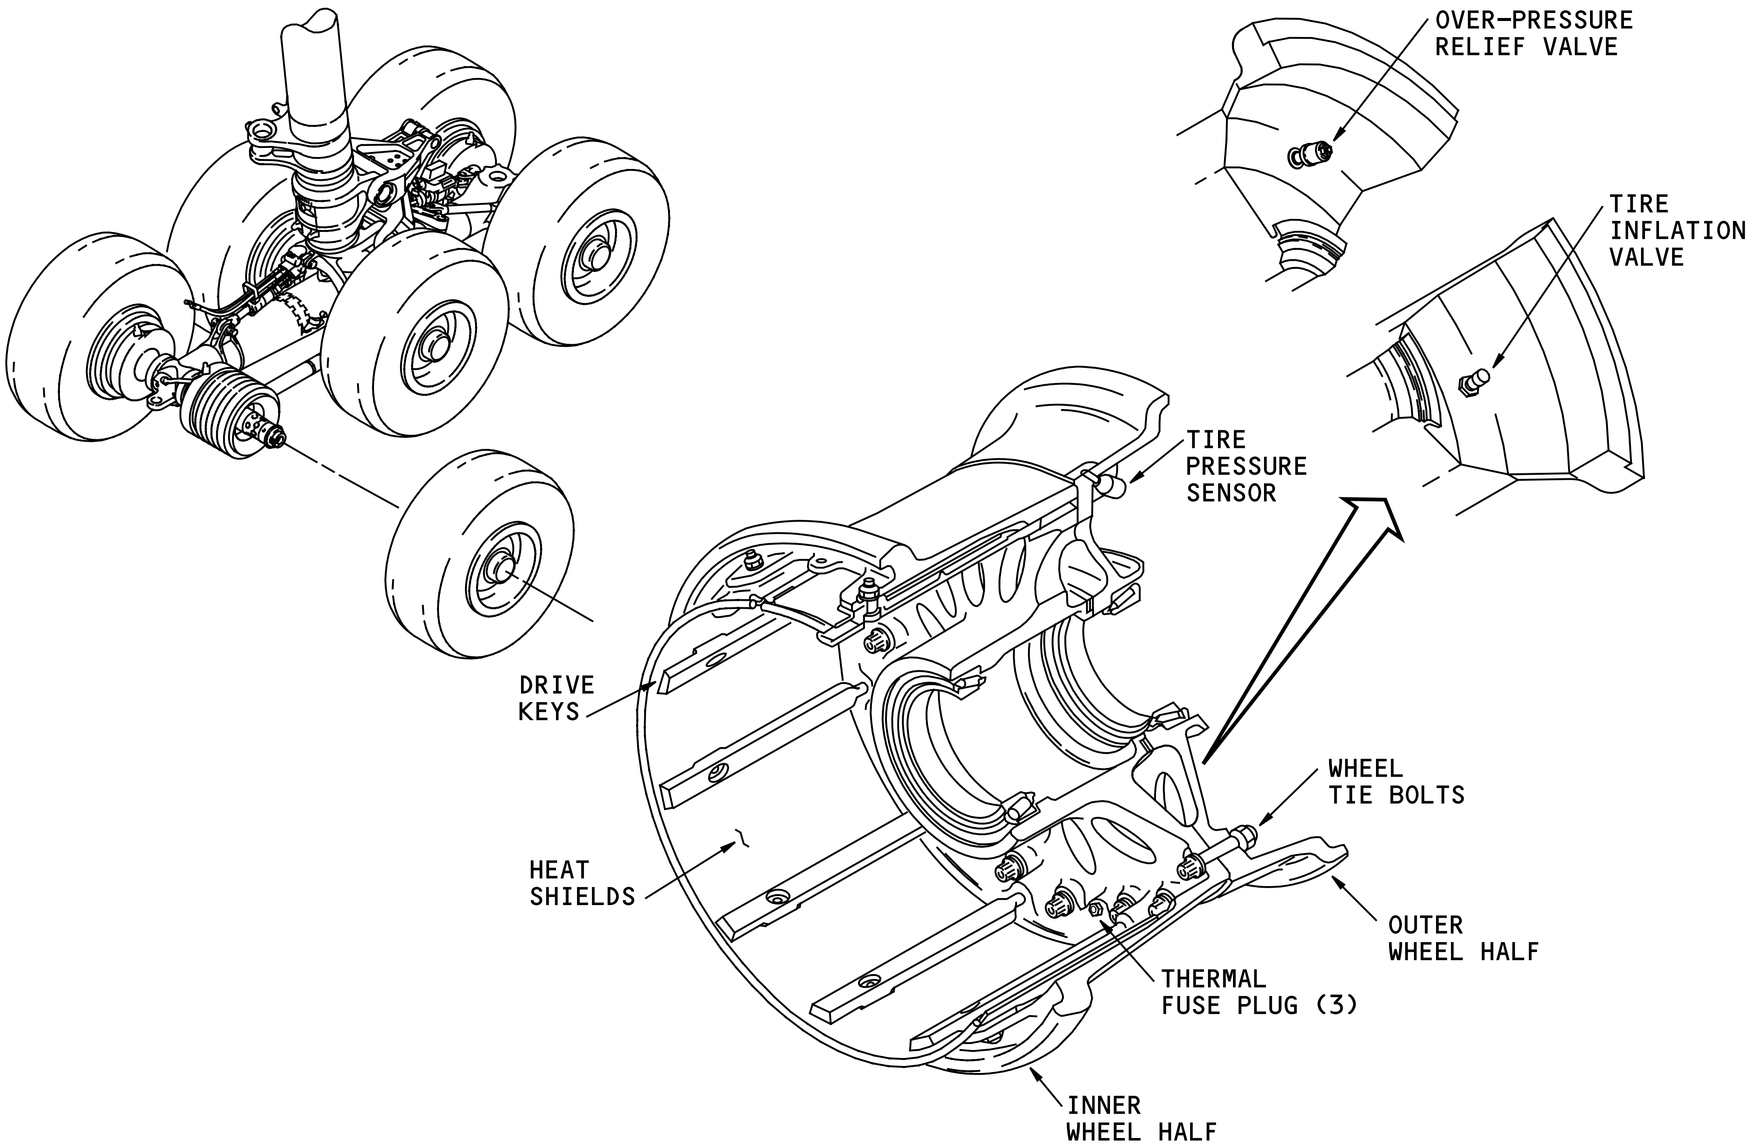
Three thermal fuse plugs in the inner wheel half prevent tire explosion caused by hot brakes. The plugs melt to release tire pressure when their temperature is approximately 360F (182C).

Training Information Point

Radial tires install only on radial tire wheels. The radial tire wheel width between the flanges is larger than bias ply tire wheels of the same size.

You must jack both ends of the main landing gear wheel truck to remove the center wheel and tire assemblies.

The main landing gear wheels can operate with one wheel tie bolt broken or missing.



32-45-00-004 Rev 3

WHEELS, BRAKES, AND TIRES - MAIN LANDING GEAR WHEEL AND TIRE

WHEELS, BRAKES, AND TIRES - MAIN LANDING GEAR WHEEL BRAKES

General

The main landing gear wheel brakes use hydraulic pressure to slow or stop the airplane during landing and taxi.

Each main landing gear wheel brake components include:

- Stators and rotors
- End plate assembly
- Pressure plate
- Self-adjusting piston (7)
- Axle bushing (2)
- Wear indicator pin (2)
- Brake disconnect (not shown)
- Hydraulic bleed port (not shown).

Physical Description

The brake assembly is a rotor-stator unit that operates using hydraulic pressure. The assembly uses carbon discs as rotors and stators.

The rotors and stators are compressed between the pressure plate and the end plate assembly to slow or stop the airplane.

Self-adjusting pistons apply brake system hydraulic pressure to the pressure plate. The pistons automatically adjust for brake wear.

Two indicator pins on the inboard side of the brake housing show brake wear.

The brake units mount on bushings which ride on replaceable landing gear axle sleeves.

The center brake attachment points connect directly to the lower strut at the same place the brake rods attach. The forward and aft brake attachment points connect to the brake rods.

The brake rods transmit brake torque to the strut. They also allow brake rotation as the truck position changes.

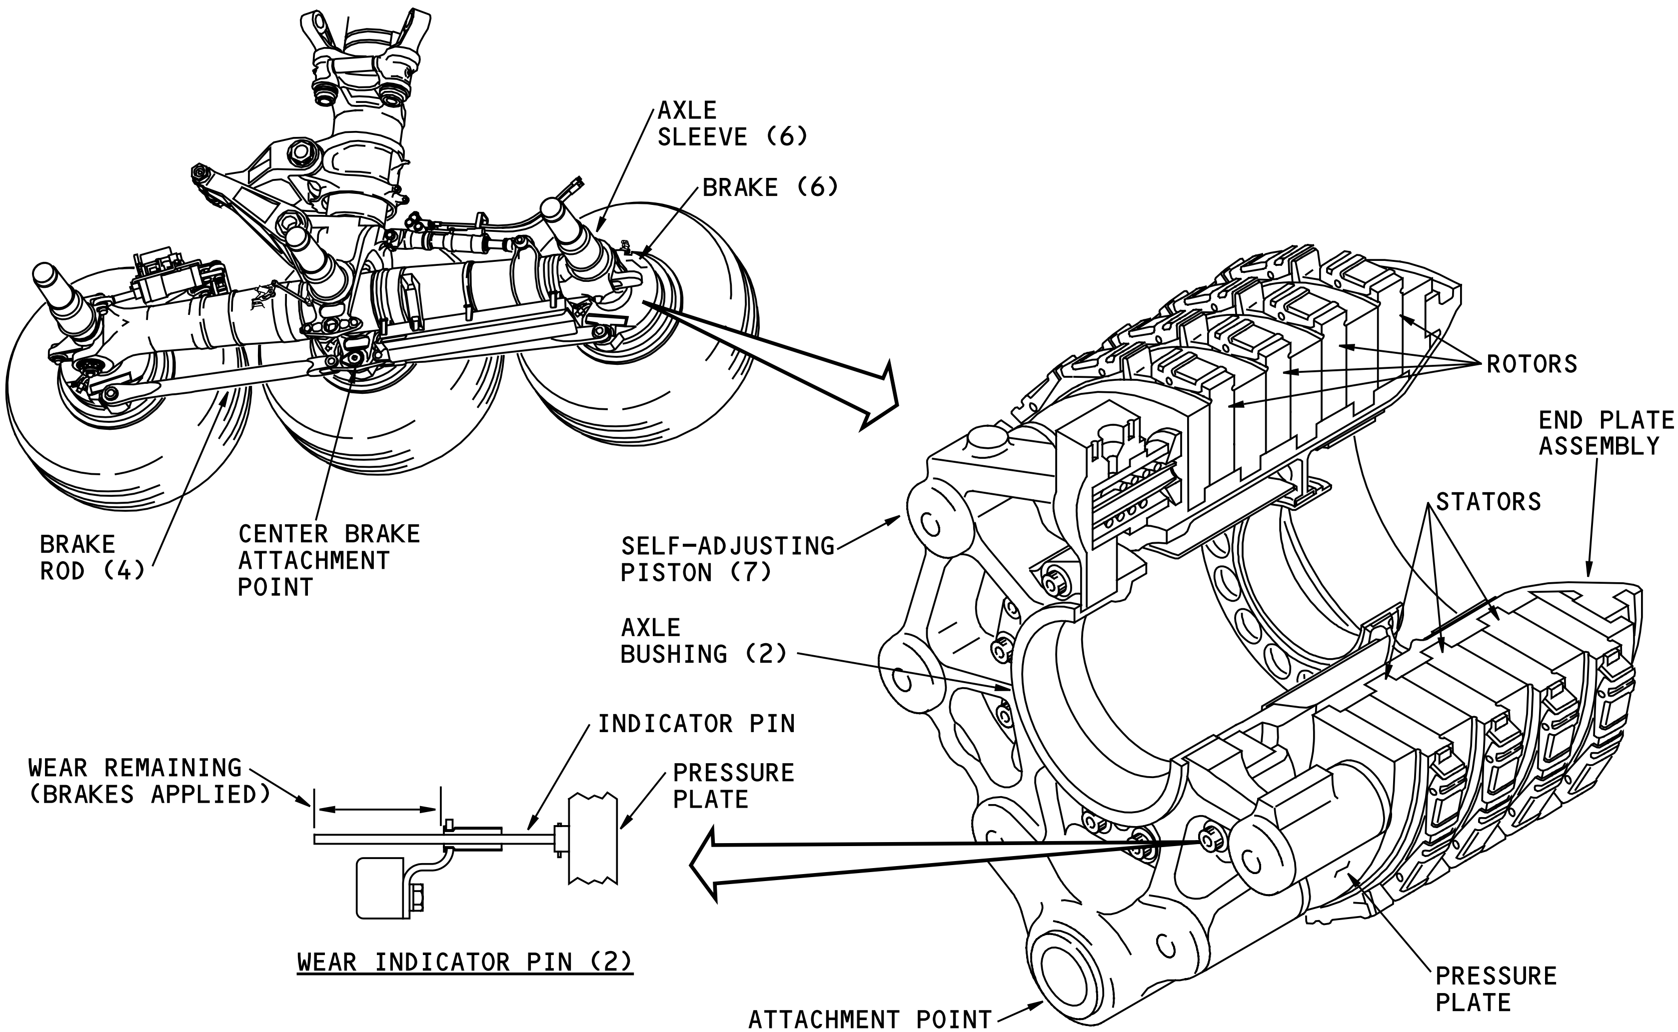
Training Information Point

You must apply the brakes to do a check of the wear indicator pins.

The brake system can operate with one brake on each six wheel truck deactivated. Brakes may be deactivated by three methods:

- Install a flight dispatch disconnect tool in the brake position on the related antiskid shuttle valve module (This deactivates normal braking only. Alternate braking is still available.)
- Disconnect the brake line
- Remove the brake.

If the brake is removed or the brake line is disconnected, the gear must remain down for two minutes before retraction.



32-45-00-005 Rev 3

WHEELS, BRAKES, AND TIRES - MAIN LANDING GEAR WHEEL BRAKES

BRAKE HYDRO-MECHANICAL CONTROL - INTRODUCTION

Purpose

The brake hydro-mechanical system supplies manual control of the main landing gear brakes.

Brake hydraulic source selection uses two valves to automatically control different pressure sources to supply these brake functions:

- Normal brakes
- Alternate brakes
- Reserve brakes
- Accumulator brakes
- Gear retract braking.

The brake pedals control the normal and the alternate brake systems.

Normal Brakes

When all the pressure sources are available, the normal brake system uses right hydraulic system pressure to operate the brakes.

Alternate Brakes

The alternate brake system uses center hydraulic system pressure to operate the brakes when right hydraulic system pressure is low.

Reserve Brakes

Reserve brakes use isolated center system pressure to pressurize the alternate brake system.

When the center hydraulic system reservoir is low, hydraulic system control isolates the output of the C1 ACMP for reserve brakes and nose wheel steering. This pump uses reserve fluid in the reservoir and pressurizes the alternate brake system.

Accumulator Brakes

When the normal, alternate, and reserve brake pressures are low, the accumulator pressurizes the normal brake system. The parking brake uses accumulator pressure when no other pressure sources are available.

Gear Retract Braking

The alternate brake system uses landing gear retract pressure to stop main gear wheel rotation during gear retraction.

BRAKE HYDRO-MECHANICAL CONTROL - INTRODUCTION

BRAKE HYDRO-MECHANICAL CONTROL - FLIGHT DECK COMPONENTS

Flight Deck Components

The hydro-mechanical control system includes these components on or near the flight deck:

- Brake pedal bus mechanism
- Brake cables
- Brake accumulator pressure gage
- Brake source light.

Brake Pedal Bus Mechanism

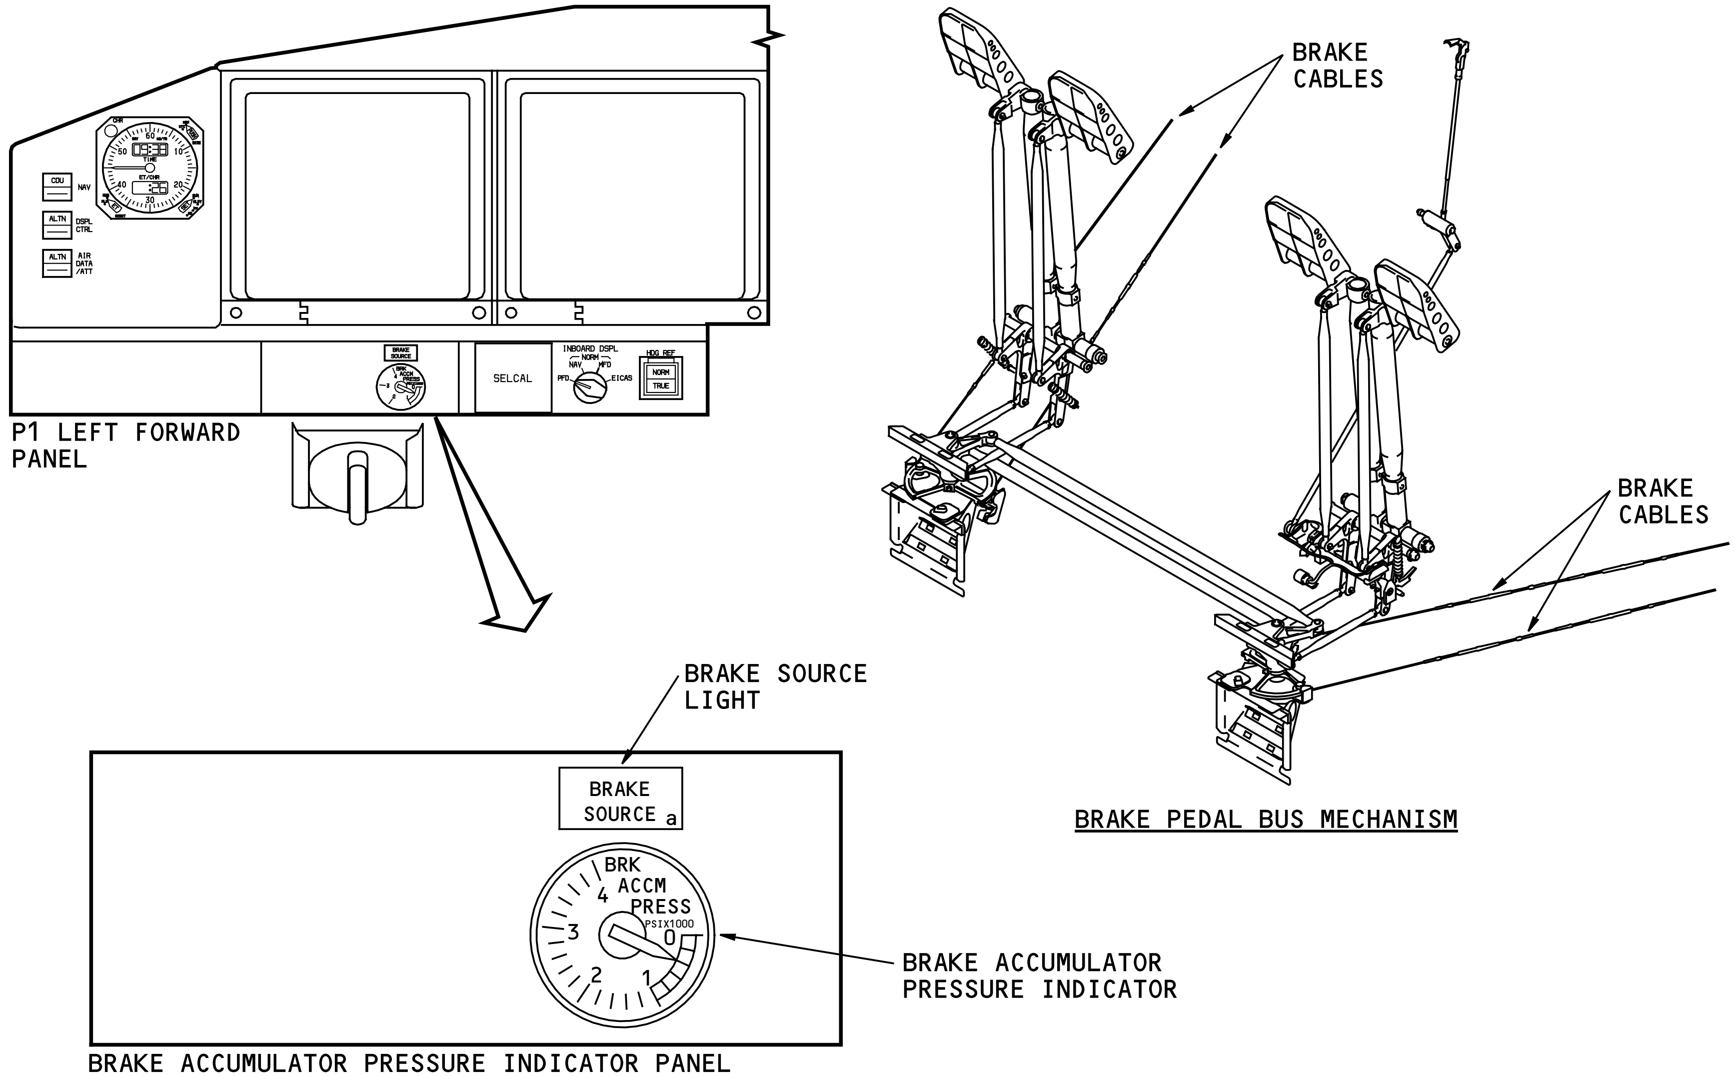
Most of the brake pedal bus mechanism components are below the flight deck floor. You get access to these components through the forward equipment center.

Brake Cables

Brake cables connect the brake pedal bus mechanism to the brake metering valves in the main landing gear wheel wells.

Brake Accumulator Pressure Gage and Brake Source Light

The brake accumulator pressure indicator and brake source light are on the P1 left forward panel.



32-41-00-002 Rev 0

BRAKE HYDRO-MECHANICAL CONTROL - FLIGHT DECK COMPONENTS

THIS PAGE INTENTIONALLY LEFT BLANK

BRAKE HYDRO-MECHANICAL CONTROL - MAIN LANDING GEAR WHEEL WELL COMPONENTS

Main Landing Gear Wheel Well Components

The hydro-mechanical control system includes these components in or near the left and right main landing gear wheel wells:

- Brake metering valves (2)
- Brake alternate source selector valve (ASSV)
- Brake accumulator isolation valve (AIV)
- Brake accumulator
- Brake accumulator servicing components
- Brake source pressure switch (2)
- Antiskid surge accumulator
- Antiskid surge accumulator servicing components.

Brake Metering Valves

The left and right brake metering valves are in the forward section of the main landing gear wheel wells.

Brake Alternate Source Selector Valve

The alternate source selector valve is in the left main landing gear wheel well inboard on the keel beam.

Brake Accumulator Isolation Valve

The accumulator isolation valve is in the right main landing gear wheel well inboard on the keel beam below the brake accumulator.

Brake Accumulator

The brake accumulator is on the keel beam in the right main landing gear wheel well.

Brake Accumulator Servicing Components

Brake accumulator servicing components are on the keel beam below and forward of the brake accumulator in the right main landing gear wheel well.

Brake Source Pressure Switch

There are two brake source pressure switches.

The normal brake hydraulic system pressure switch is in the right main landing gear wheel well on the keel beam inboard of the brake accumulator.

The alternate brake hydraulic system pressure switch is in the left main landing gear wheel well on the alternate source selector valve.

Antiskid Surge Accumulator

The antiskid surge accumulator is on the left main landing gear beam outboard of the landing gear trunnion.

BRAKE HYDRO-MECHANICAL CONTROL - MAIN LANDING GEAR WHEEL WELL COMPONENTS

Antiskid Surge Accumulator Servicing Components

Antiskid surge accumulator servicing components are on the left main landing gear beam outboard of the antiskid surge accumulator.

BRAKE HYDRO-MECHANICAL CONTROL - MAIN LANDING GEAR WHEEL WELL COMPONENTS

BRAKE HYDRO-MECHANICAL CONTROL - BRAKE PEDAL BUS MECHANISM

Purpose

The brake pedal bus mechanism sends brake pedal inputs to manually control brake system pressure.

Components

These are the brake pedal bus mechanism components:

- Captain's and first officer's rudder pedals
- Vertical control rods (4)
- Lower bellcranks (4)
- Fore-aft control rods (4)
- Brake pedal bus crank assemblies (2)
- Cable quadrants (2)
- Transverse control rods (2)
- Brake cables (4).

Location

The rudder pedals are above the flight deck floor. The vertical control rods extend through the floor into the forward equipment center.

The brake cables attach to the brake pedal bus mechanism cable quadrants with a routing through the fuselage sides to the main landing gear wheel wells.

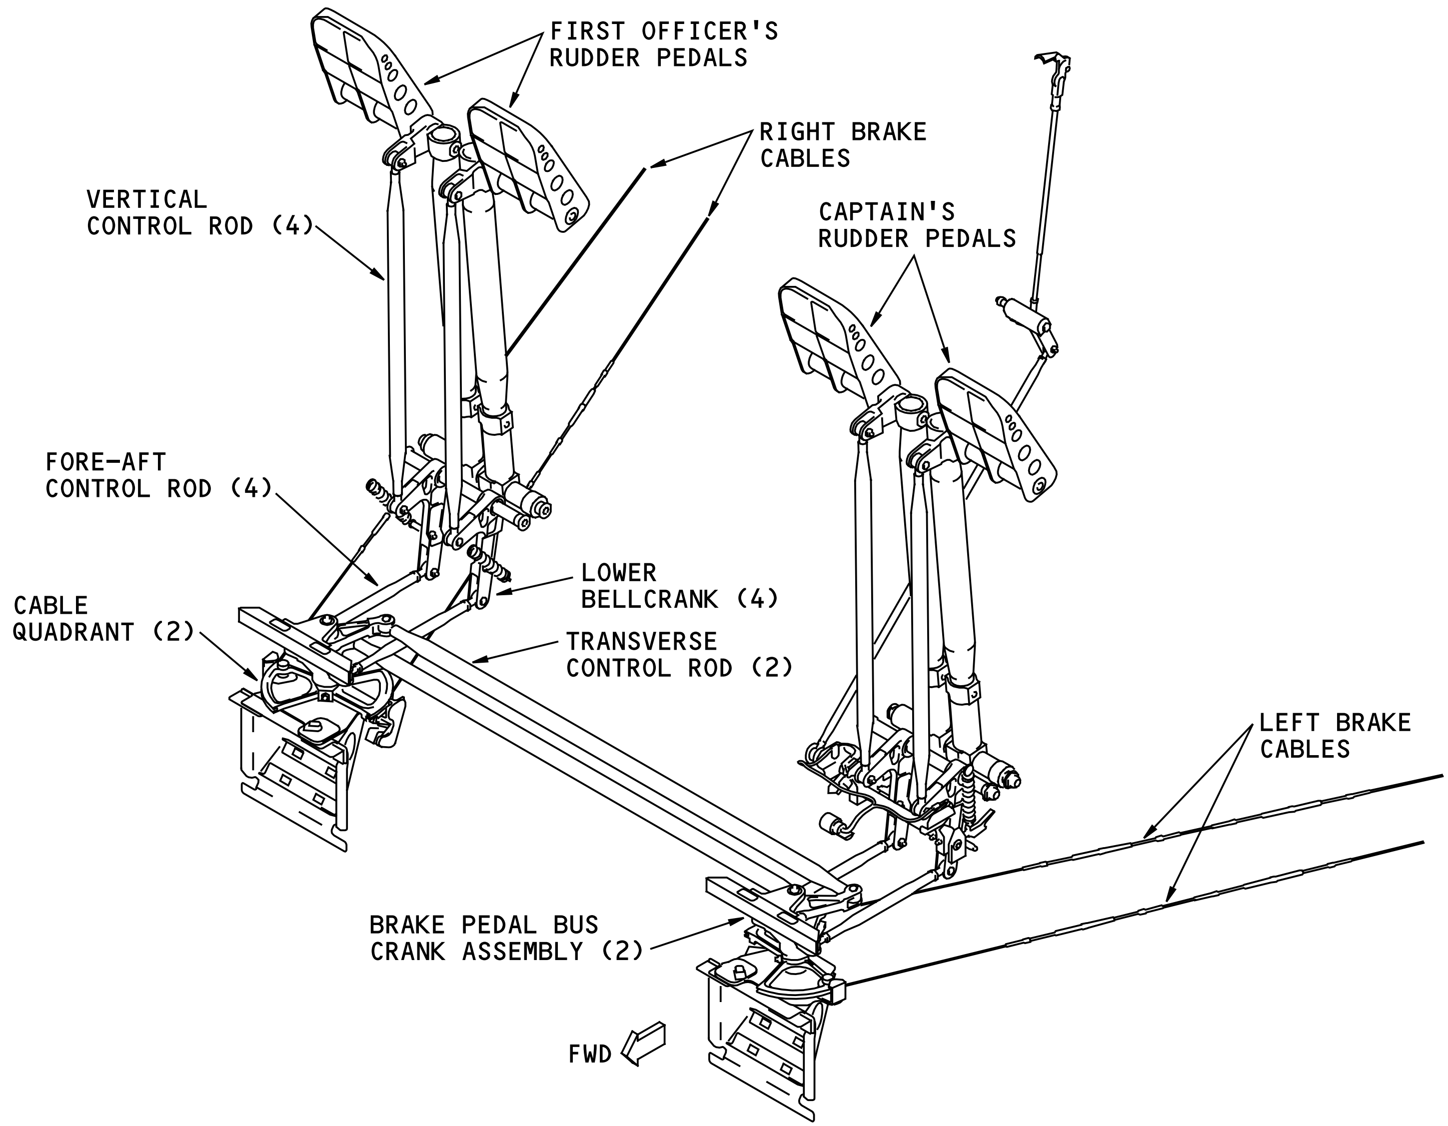
Functional Description

Two sets of brake pedals operate the brake pedal bus mechanism.

Pedal operation goes through vertical control rods to the lower bellcranks. These bellcranks connect to brake pedal bus crank assemblies and cable quadrants with fore-aft control rods.

Input to the left cable quadrant controls the left brakes with brake cables on the left side of the airplane. The right cable quadrant and cables are on the right side of the airplane and operate the same way as the left.

Transverse control rods connect the left and right brake pedal bus crank assemblies. This permits control of the left and right brakes with the captain's or the first officer's pedals.



BRAKE HYDRO-MECHANICAL CONTROL - BRAKE PEDAL BUS MECHANISM

BRAKE HYDRO-MECHANICAL CONTROL - BRAKE METERING VALVE ASSEMBLY - GENERAL DESCRIPTION

Purpose

The brake metering valve assemblies get brake pedal input and control brake pressure.

Components

Each brake metering valve assembly includes these components:

- Brake metering valve actuation/support assembly
- Normal brake metering valve
- Alternate brake metering valve.

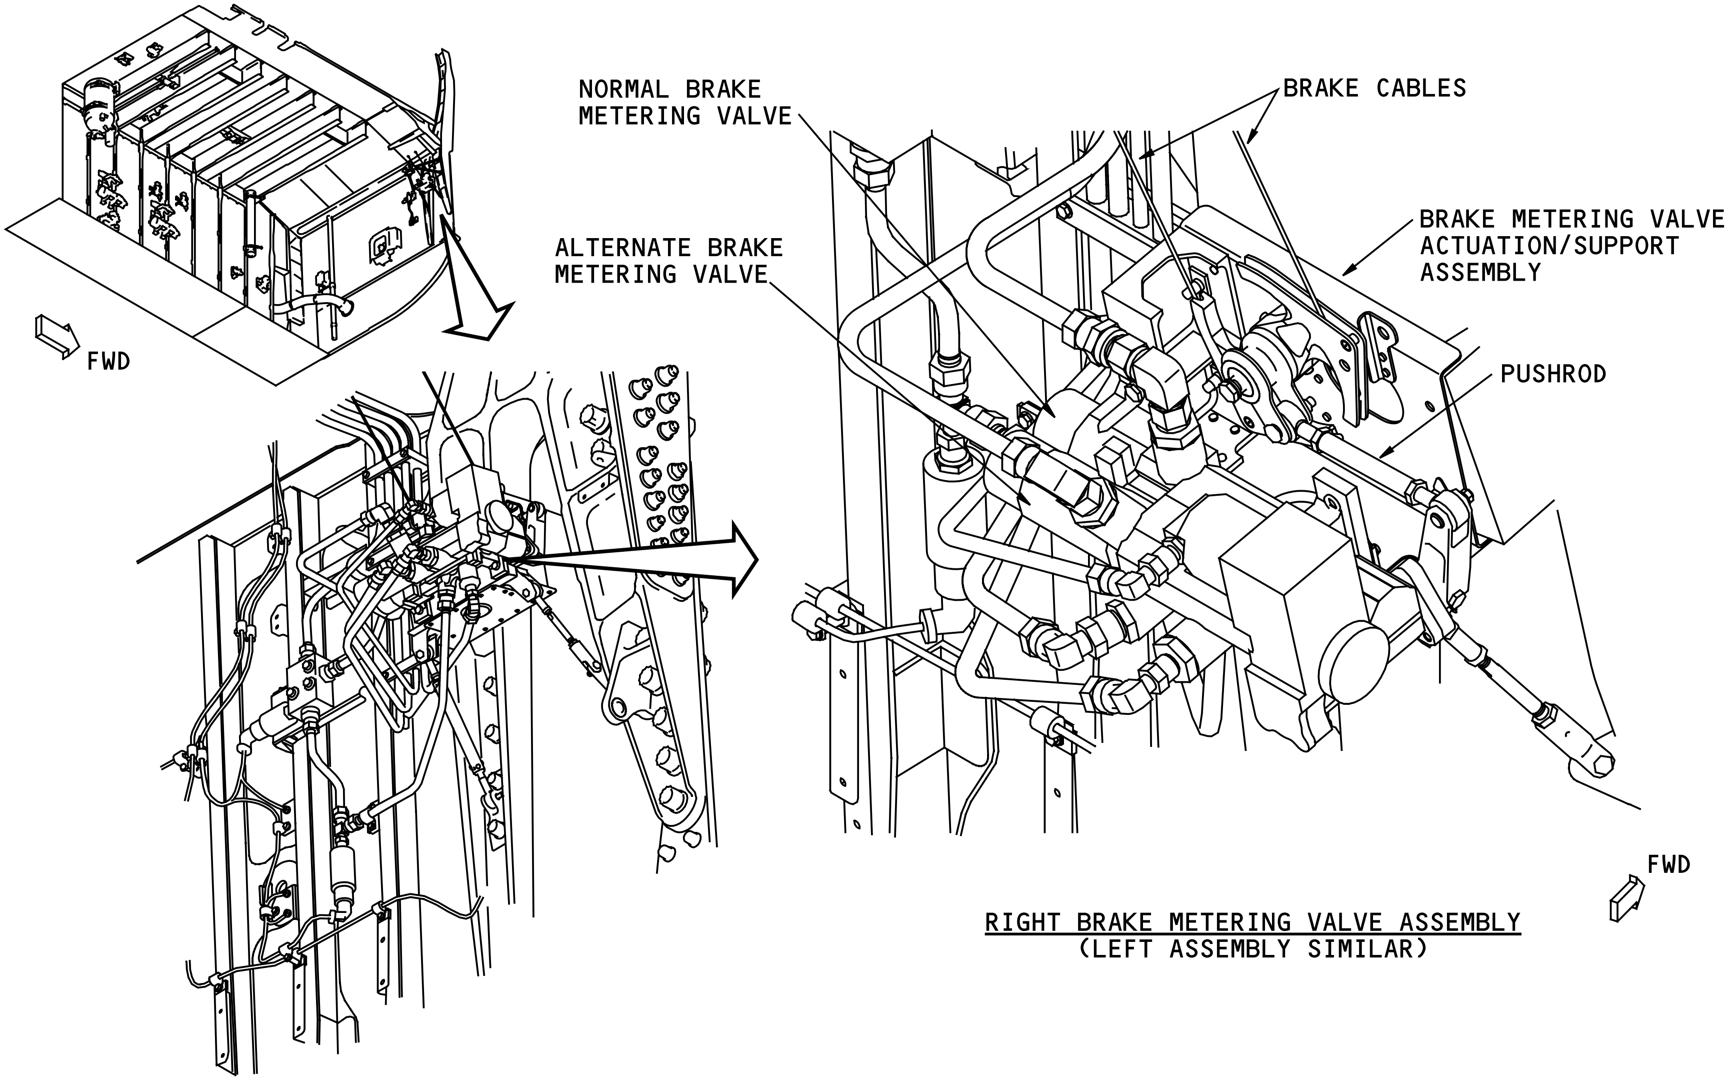
Location

Normal and alternate brake metering valves attach to each other to make the brake metering valve assembly. There is a brake metering valve in each main landing gear wheel well. Each attaches to a brake metering valve actuation/support assembly.

These brake metering valve assemblies attach to the wing rear spar side of body fitting in the forward section of each wheel well.

Training Information Point

You can replace the brake metering valve as a unit with no change in brake cable rigging. To do this, you remove the brake metering valve from the actuation/support assembly. After installation of the new valve, you can make minor adjustments with the pushrod in the actuation/support assembly.



RIGHT MAIN LANDING GEAR WHEEL WELL

RIGHT BRAKE METERING VALVE ASSEMBLY
(LEFT ASSEMBLY SIMILAR)

32-41-00-005 Rev 1

BRAKE HYDRO-MECHANICAL CONTROL - BRAKE METERING VALVE ASSEMBLY - GENERAL DESCRIPTION

BRAKE HYDRO-MECHANICAL CONTROL - BRAKE ACCUMULATOR AND SERVICING COMPONENTS

Purpose

The brake accumulator supplies brake pressure to the normal brake hydraulic system if there are no other brake sources available. It is also the pressure source for the parking brake system when the center and right hydraulic systems are off.

Components

Brake accumulator and servicing components include:

- Brake accumulator
- Charging valve
- Pressure transducer
- Pressure indicator (flight deck)
- Pressure gage (wheel well).

Location

The brake accumulator and servicing components are on the keel beam in the right main wheel well.

The brake accumulator pressure indicator is on the brake accumulator pressure indicator panel on the P1 left forward panel below the brake source light.

Physical Description

The accumulator is a gas charged unit with a floating piston that separates the gas and the fluid sides. It has a precharge of 1000 psi and a volume of 600 cubic inches. The right hydraulic system pressurizes the accumulator.

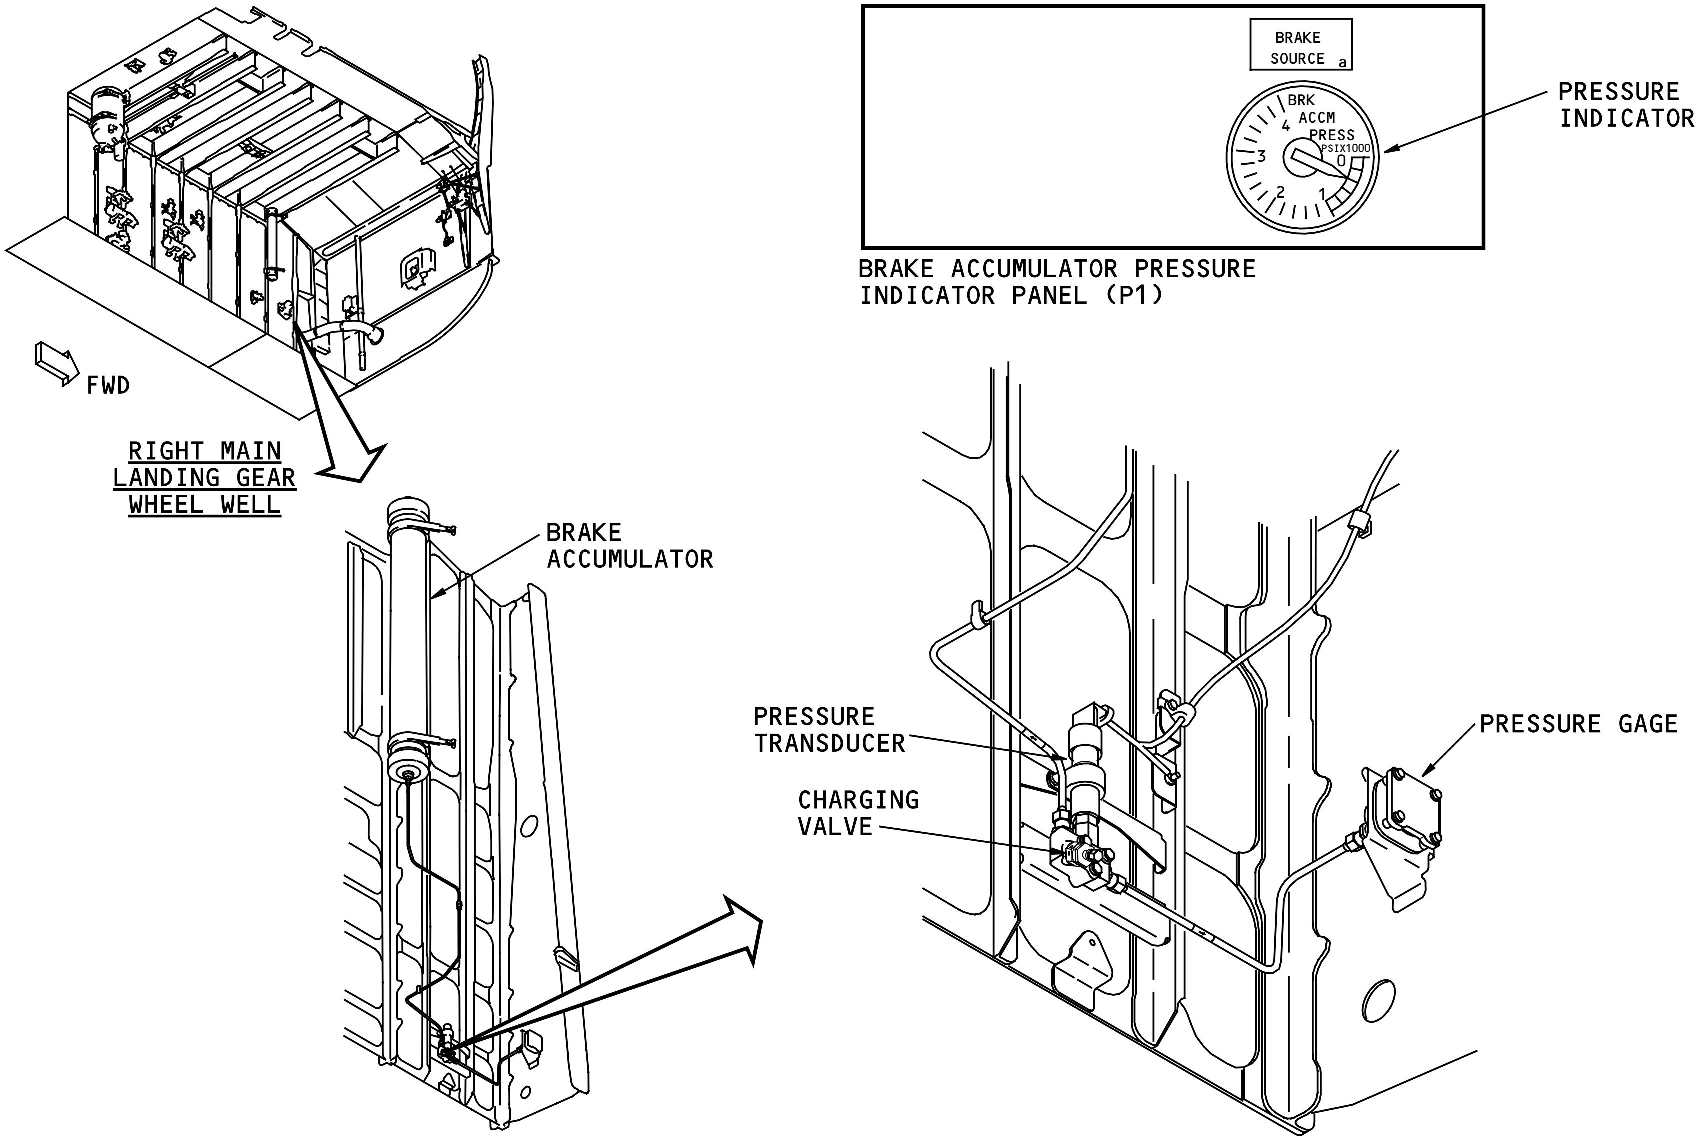
The brake accumulator pressure transducer sends the pressure signal to the pressure indicator on the flight deck.

The pressure gage in the main landing gear wheel well is a direct reading gage used for inspection and servicing.

Charging instructions are on a placard by the charging valve and transducer.

Training Information Point

With a fully charged accumulator, the brake accumulator system supplies enough pressure for six full brake applications or keeps the parking brake pressurized for eight hours.



32-41-00-007 Rev 2

BRAKE HYDRO-MECHANICAL CONTROL - BRAKE ACCUMULATOR AND SERVICING COMPONENTS

BRAKE HYDRO-MECHANICAL CONTROL - ANTISKID SURGE ACCUMULATOR AND SERVICING COMPONENTS

Purpose

The anti-skid surge accumulator absorbs brake release surges from the left normal anti-skid valve module.

Components

The anti-skid surge accumulator and servicing components include:

- Antiskid surge accumulator
- Charging valve
- Pressure gage assembly.

Location

The antiskid surge accumulator and servicing components are on the left main landing beam. They are outboard and aft of the left normal antiskid valve module.

You open an access panel outboard of the left MLG to access the antiskid surge accumulator.

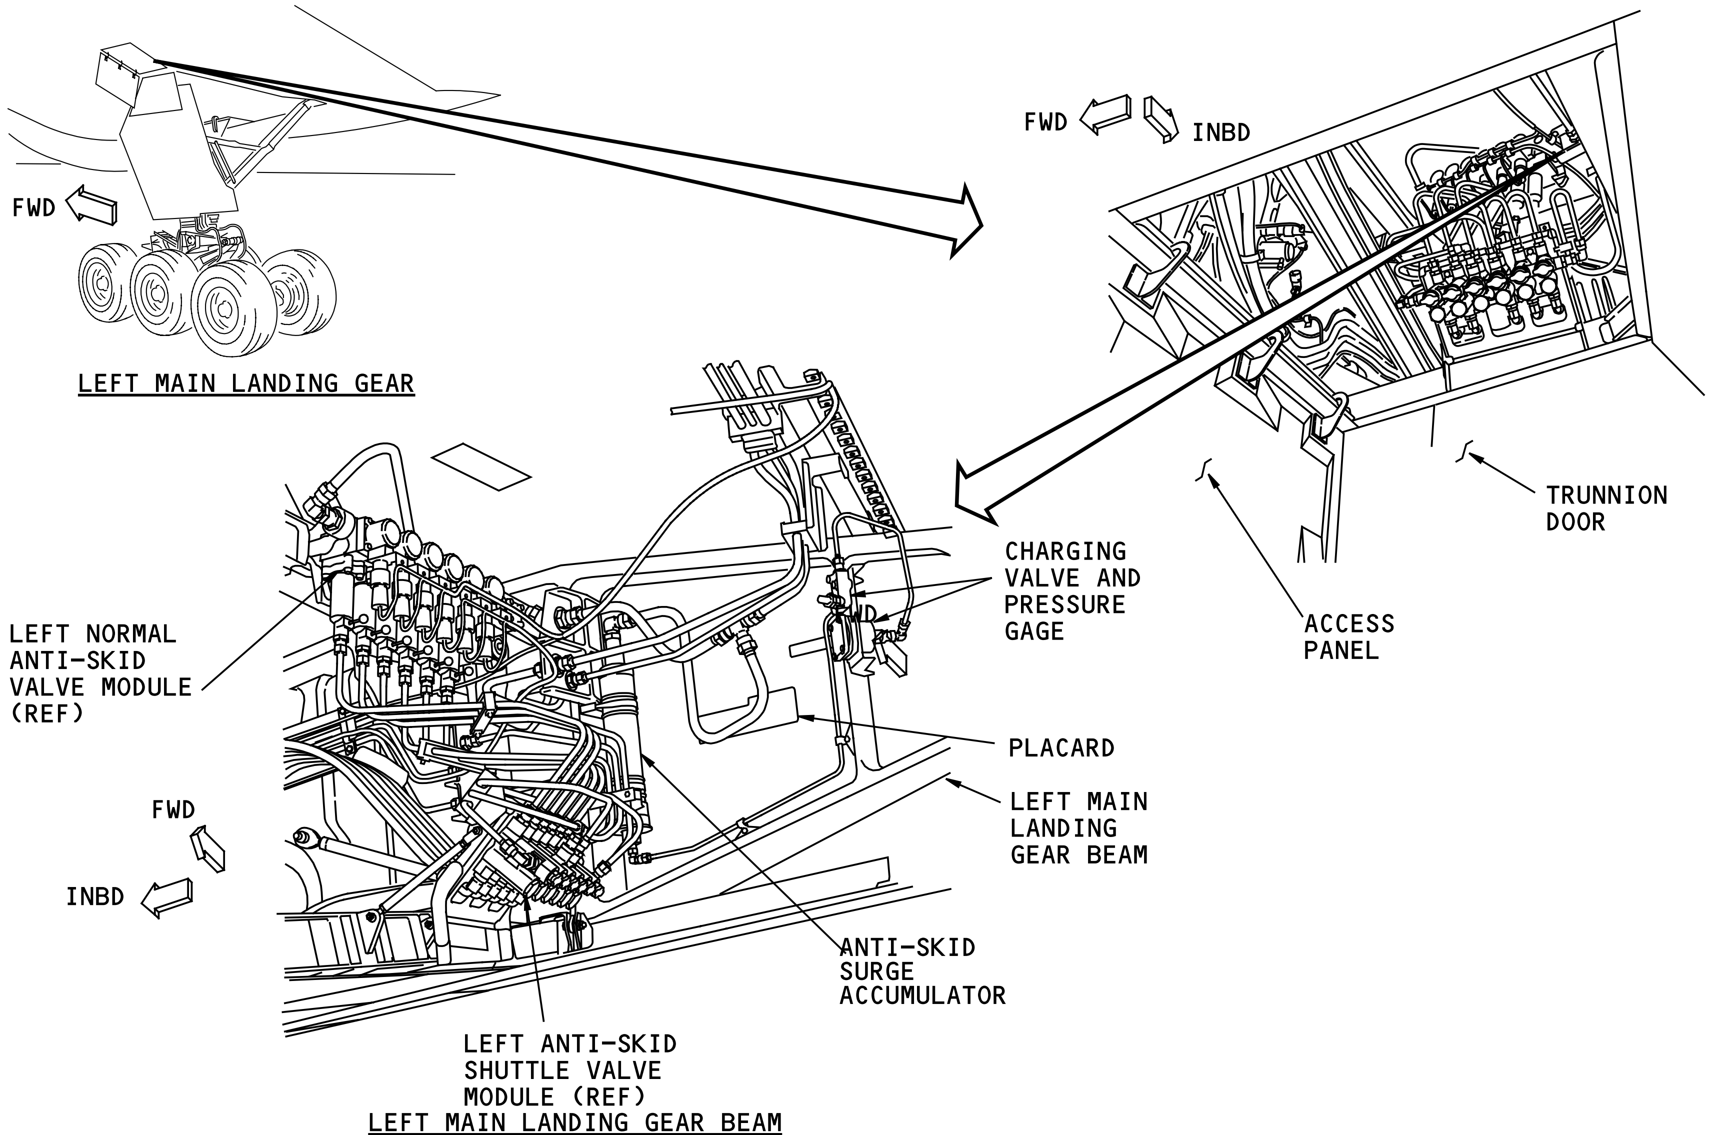
Physical Description

The accumulator is a gas charged unit with a floating piston that separates the gas and the fluid sides. It has a precharge of 150 psi and a volume of 25 cubic inches.

Charging instructions are on a placard by the charging valve and gage.

Training Information Point

The right normal antiskid valve module does not need an antiskid surge accumulator because the right hydraulic system reservoir is very near to the right normal antiskid valve module.



BRAKE HYDRO-MECHANICAL CONTROL - ANTISKID SURGE ACCUMULATOR AND SERVICING COMPONENTS

32-41-00-008 Rev 1 07/26/1995

BRAKE HYDRO-MECHANICAL CONTROL - ALTERNATE SOURCE SELECTOR AND ACCUMULATOR ISOLATION VALVES

Purpose

These two hydro-mechanical valves select and send pressure to the normal or the alternate brake hydraulic systems:

- Brake alternate source selector valve (ASSV)
- Brake accumulator isolation valve (AIV).

Location

The ASSV is on the keel beam in the left main landing gear wheel well.

The AIV is on the keel beam below the brake accumulator in the right main landing gear wheel well.

Physical Description

Both valves are the same and are interchangeable.

Each valve gets pressure from two sources. The pressures push on pistons in the valves that have different areas. This moves the valves to select the brake source.

The alternate source selector valve has the alternate brake hydraulic system pressure switch on the valve.

BRAKE HYDRO-MECHANICAL CONTROL - BRAKE SOURCE PRESSURE SWITCHES

Purpose

These two brake source pressure switches control the brake source light and send pressure signals to the BSCU and AIMS for brake control and indication:

- The normal brake hydraulic system pressure switch
- The alternate brake hydraulic system pressure switch.

The brake source light comes on when there is low right hydraulic system pressure and there is low alternate brake system pressure.

Location

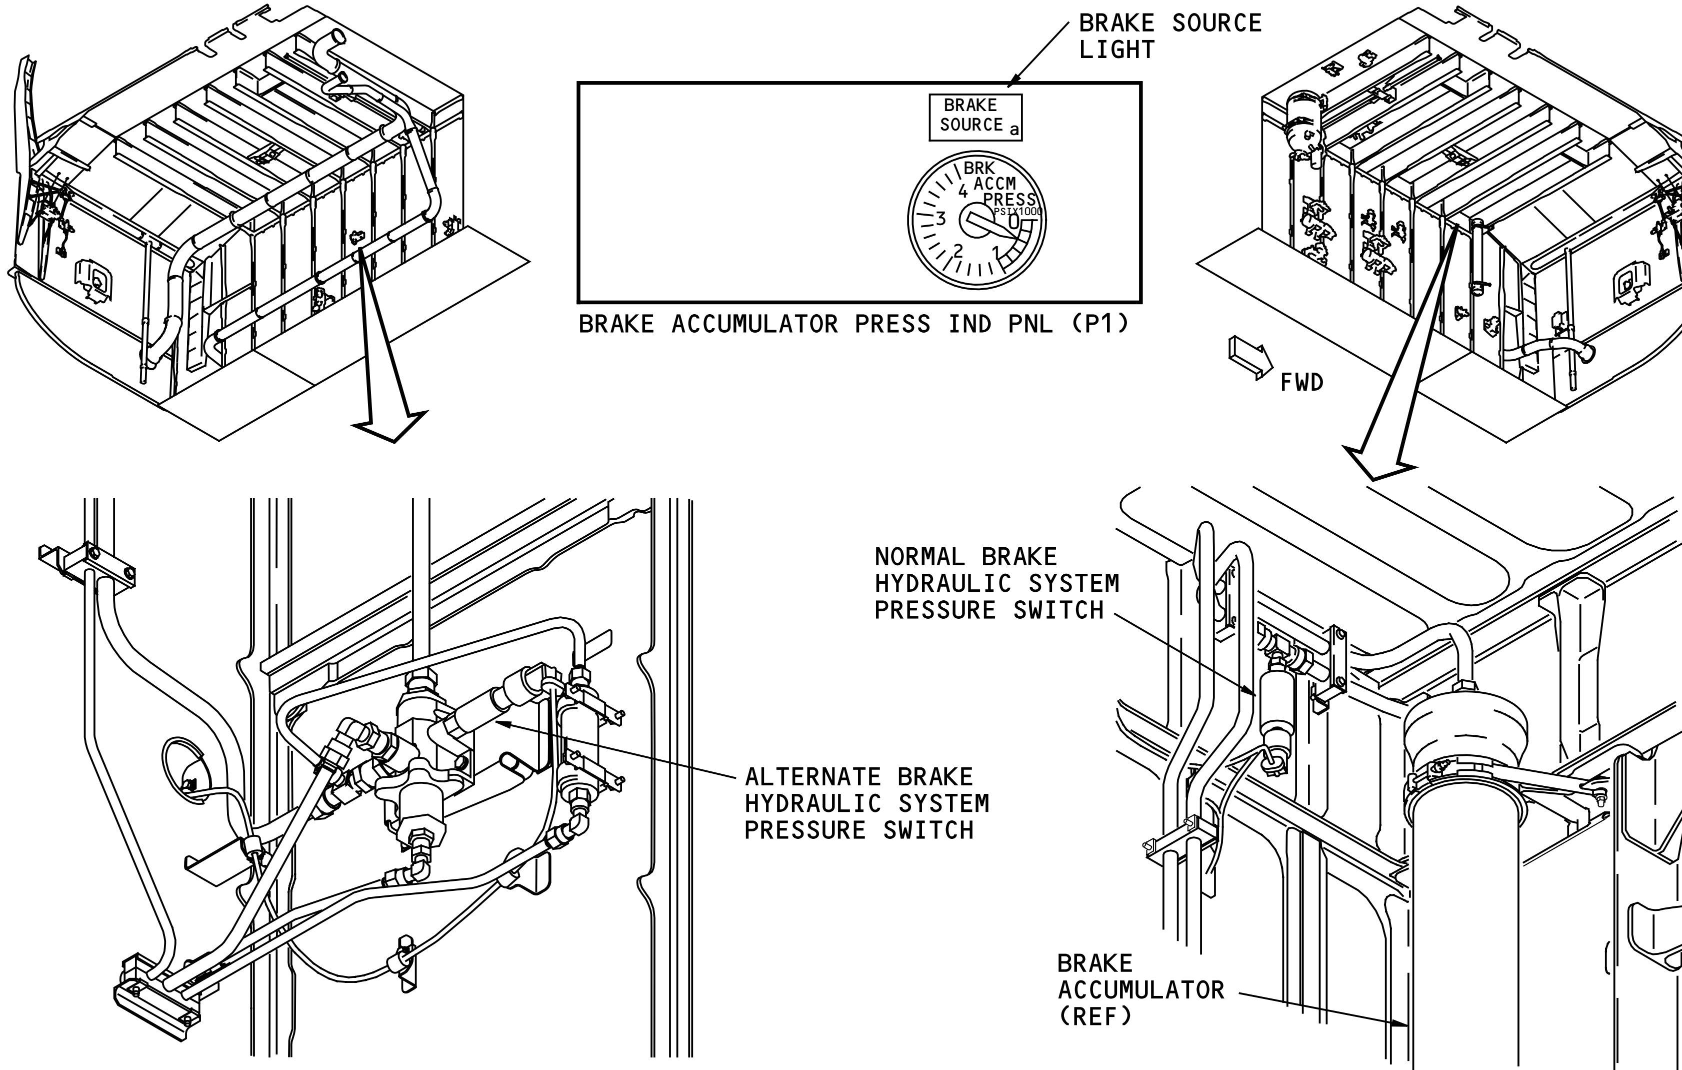
The brake source light is on the P1 left forward panel above the brake accumulator pressure gage on the flight deck.

The normal brake hydraulic system pressure switch is on the keel beam in the right main landing gear wheel well inboard and aft of the brake accumulator.

The alternate brake hydraulic system pressure switch is on the alternate source selector valve in the left main landing gear wheel well.

Physical Description

These switches are interchangeable pressure-operated switches that open at 1700 psi and close at 1200 psi.



ALTERNATE SOURCE SELECTOR VALVE
(LEFT MAIN LANDING GEAR WHEEL WELL)

RIGHT MAIN LANDING GEAR WHEEL WELL

BRAKE HYDRO-MECHANICAL CONTROL - BRAKE SOURCE PRESSURE SWITCHES

THIS PAGE INTENTIONALLY LEFT BLANK

BRAKE HYDRO-MECHANICAL CONTROL - FUNCTIONAL DESCRIPTION

General

The source selection operation supplies pressure for:

- Normal brakes
- Alternate brakes
- Reserve brakes
- Accumulator brakes
- Gear retract braking.

When the pressure in one hydraulic brake source decreases, the ASSV and AIV valves automatically change position to select the next available source and send the pressure to the brake metering valves.

Brake pedal input transmits through the brake pedal bus mechanism and cables to the left and right brake metering valves. These metering valves use this mechanical input to control the selected pressure source and pressurize the brakes.

Normal Brakes

When the right hydraulic system pressurizes, the ASSV operates to depressurize the alternate brake system. The brakes can then get metered right system hydraulic pressure from the normal brake metering valves.

The right hydraulic system pressure also charges the brake accumulator and operates the AIV.

Alternate Brakes

When right hydraulic system pressure is low, center hydraulic system pressure operates the ASSV. The ASSV sends center hydraulic system pressure to the alternate brake system. The brakes can then get metered center system hydraulic pressure from the alternate brake metering valves.

Pressure in the alternate brake system operates the AIV to isolate accumulator pressure.

Reserve Brakes

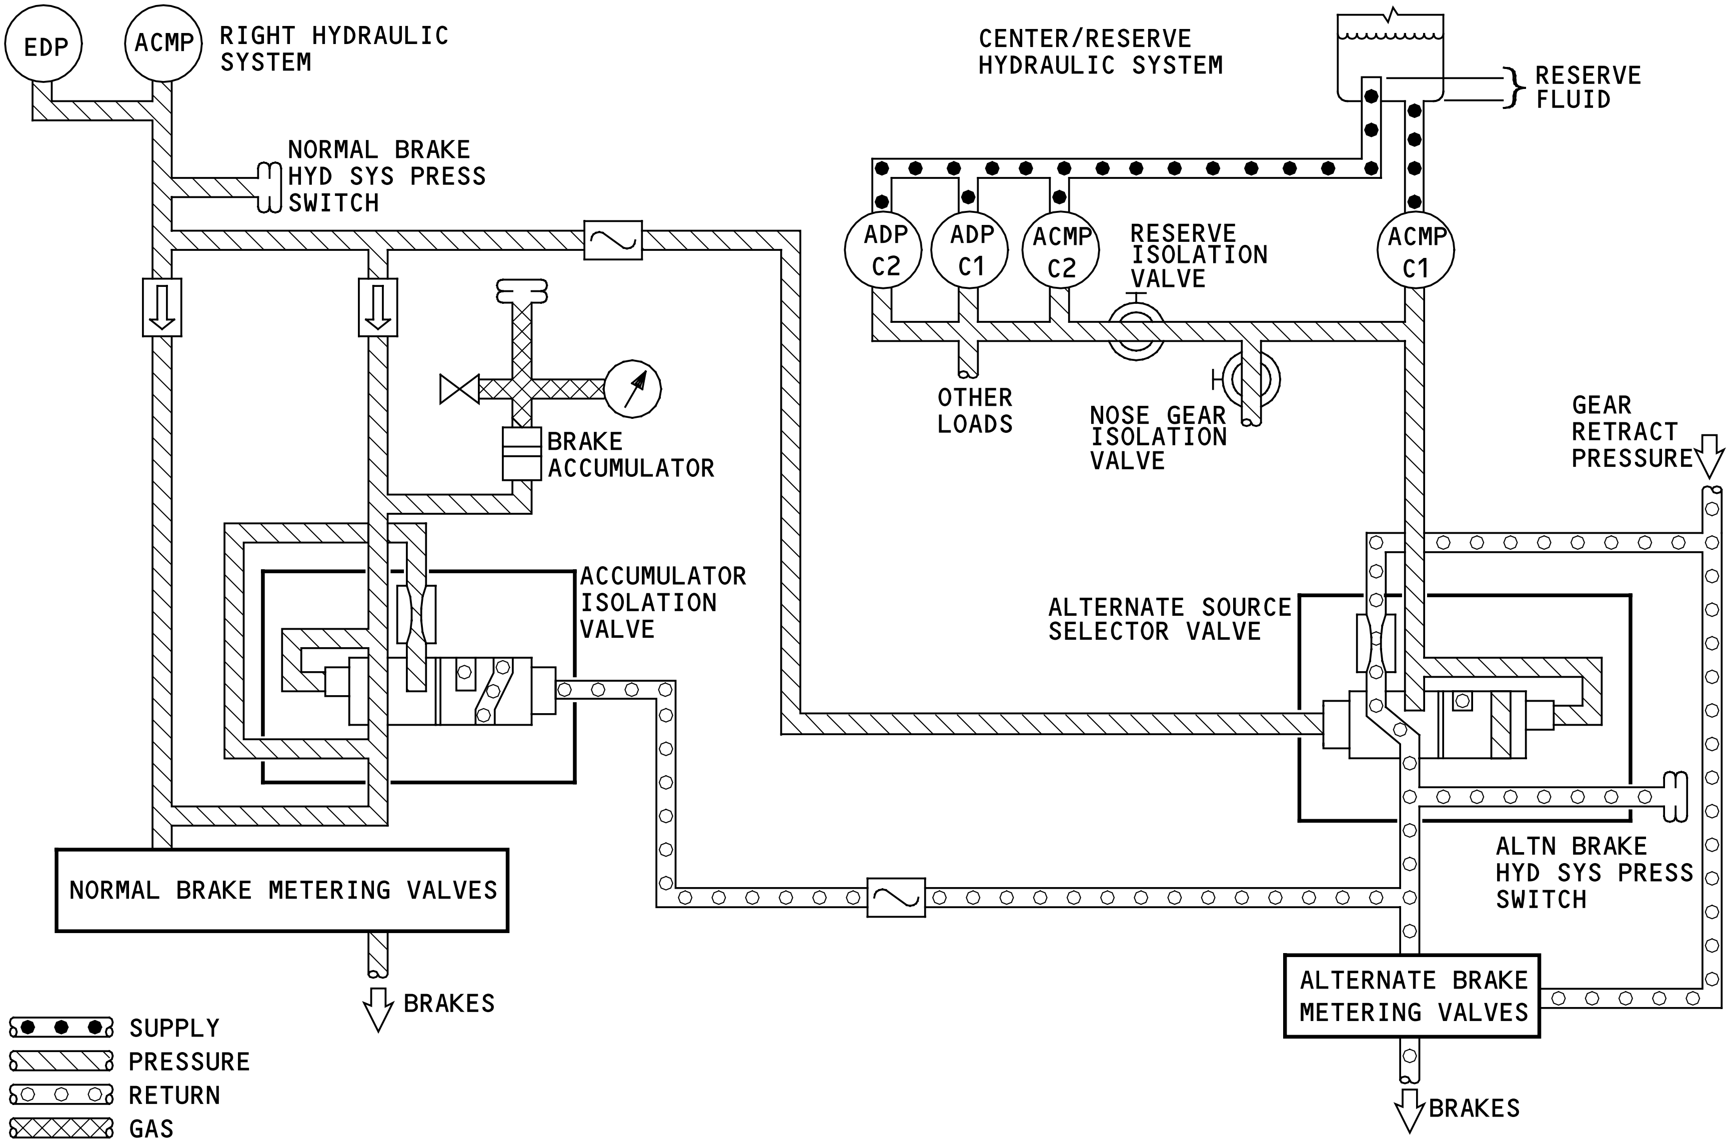
The ASSV and AIV positions and operation are the same as for alternate brakes. The only difference is that the center hydraulic system uses reserve fluid and the C1 ACMP for alternate brake system pressure.

Accumulator Brakes

When both the right and center hydraulic system pressures are low, accumulator pressure opens the AIV. The brakes then get brake accumulator pressure from the normal brake metering valves.

Gear Retract Braking

During landing gear retraction when the normal brake system has pressure, the ASSV sends main landing gear retract pressure to the alternate brake system. The gear retract pressure also operates the gear retract braking actuators on the alternate brake metering valves to pressurize the brakes.



32-41-00-012 Rev 2 10/15/1996

BRAKE HYDRO-MECHANICAL CONTROL - FUNCTIONAL DESCRIPTION

BRAKE HYDRO-MECHANICAL CONTROL - INDICATION

General

The brake source light and advisory message show when the normal and the alternate brake system pressures are low. These two switches control these indications:

- The normal brake hydraulic system pressure switch
- The alternate brake hydraulic pressure switch.

The brake accumulator pressure indicator shows brake accumulator pressure.

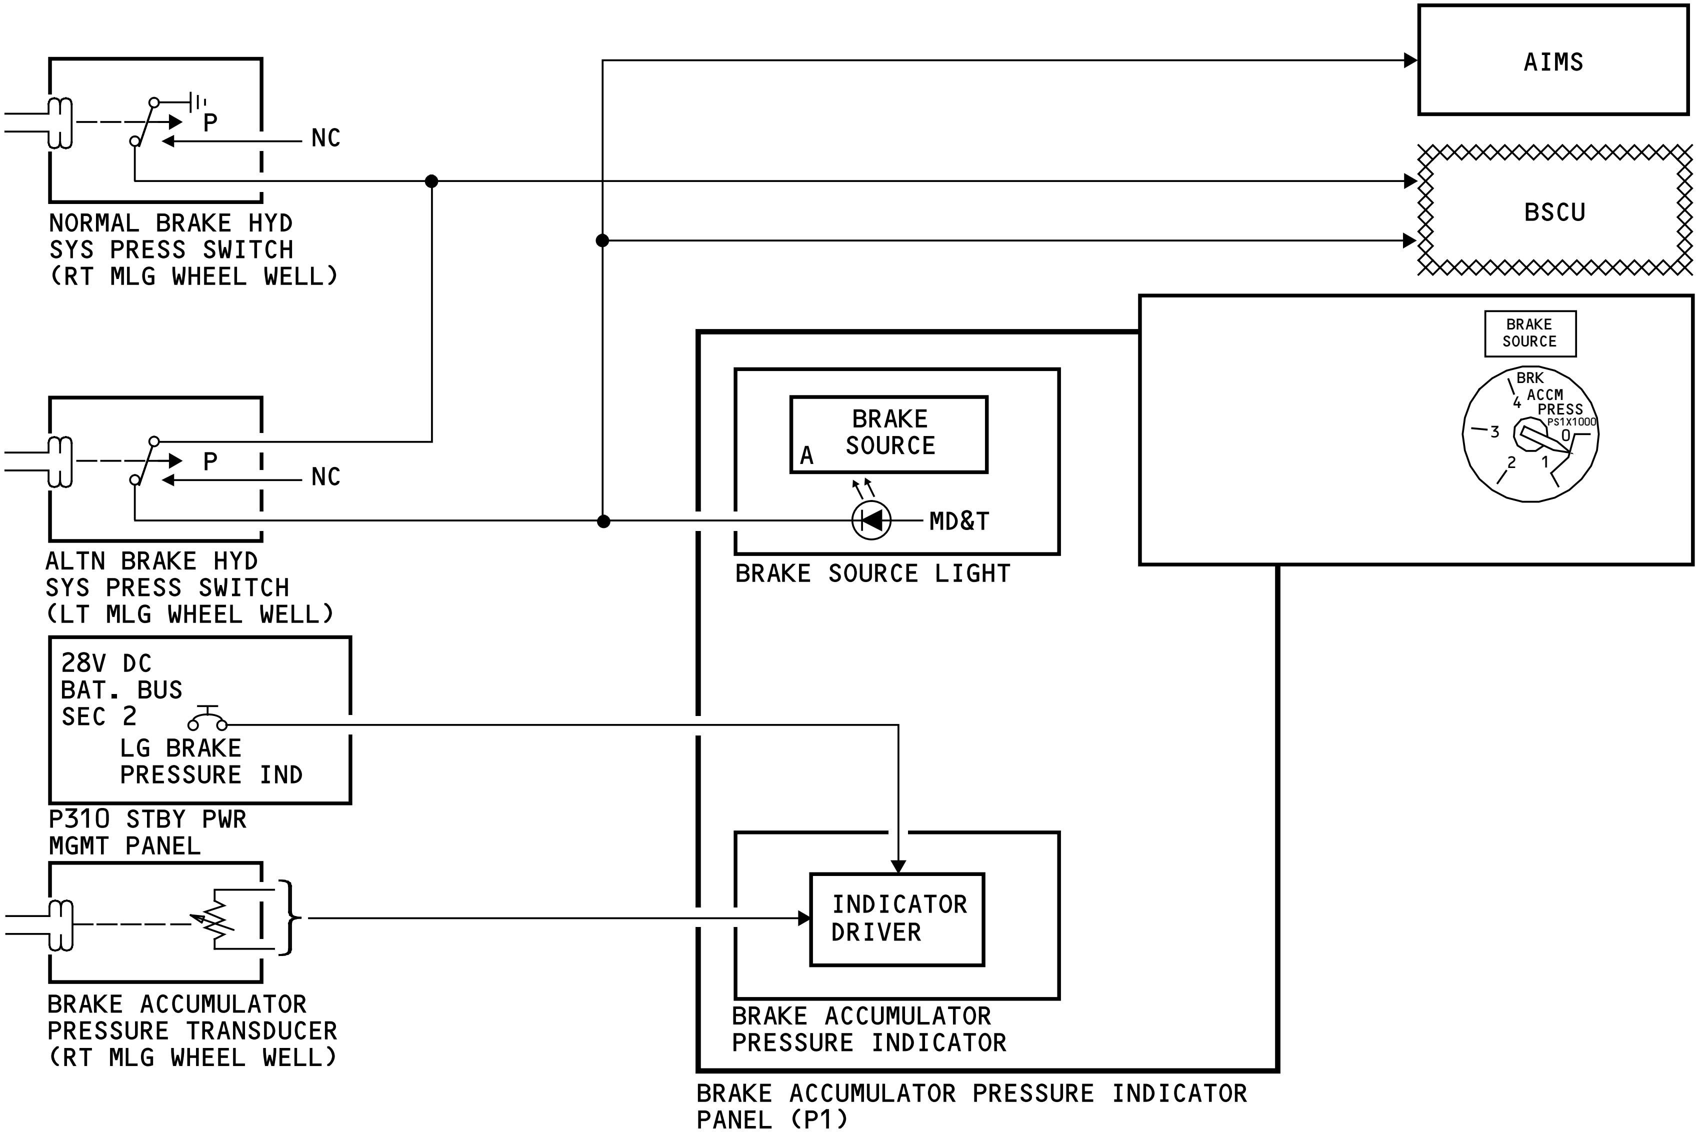
Functional Description

There is no flight deck effect when normal brake system pressure is low and the alternate brake system has pressure. The BSCU uses the normal system low pressure input for control of the antiskid and autobrake systems.

When normal and alternate brake system pressures are low, the brake source light comes on and AIMS shows the BRAKE SOURCE advisory message. The BSCU also uses these inputs for control of the antiskid and autobrake systems.

Brake accumulator pressure is the only pressure source when the brake source light is on.

The indicator driver for the brake accumulator pressure indicator uses accumulator pressure transducer input to show pressure.



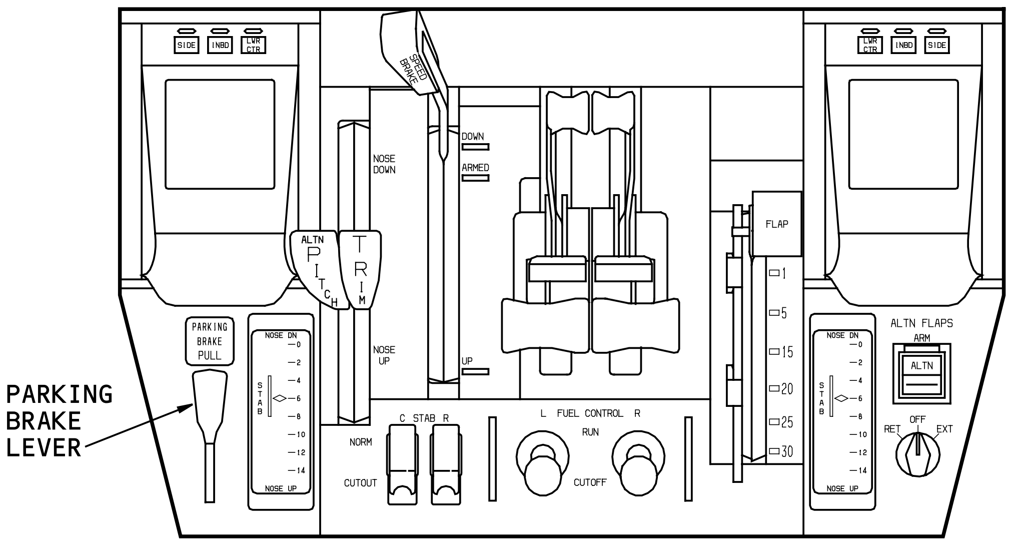
BRAKE HYDRO-MECHANICAL CONTROL - INDICATION

PARKING BRAKE SYSTEM - INTRODUCTION

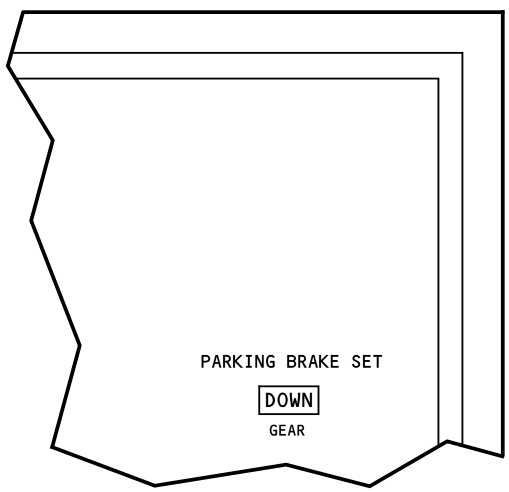
Purpose

The parking brake system uses the available brake pressure to keep the main landing gear brakes applied when the airplane is parked.

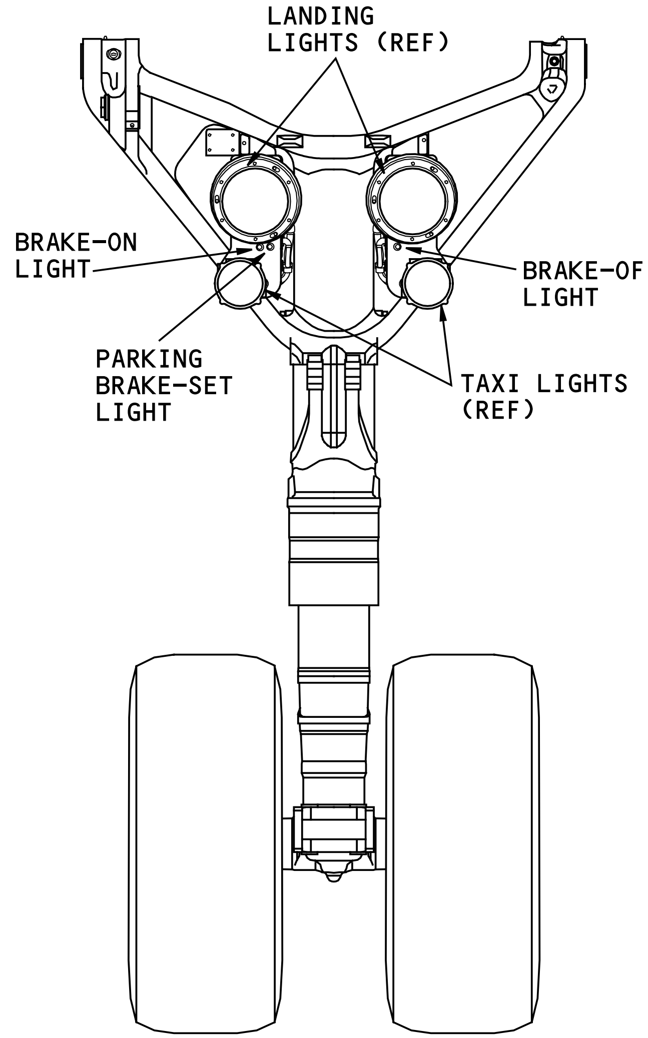
Brake status lights on the nose landing gear and the PARKING BRAKE SET memo message show the condition of the parking brake system.



P10 CONTROL STAND



EICAS DISPLAY



NOSE LANDING GEAR

PARKING BRAKE SYSTEM - INTRODUCTION

PARKING BRAKE SYSTEM - GENERAL DESCRIPTION

Components

These are the parking brake system components:

- Parking brake lever
- Parking brake latch mechanism
- Parking brake latch switch (2)
- Parking brake valve
- Pedal position switch (2)
- Brake metered pressure switch (2)
- Brake status indication light (3).

General Description

When you push the brake pedals and pull the parking brake lever, the latch mechanism latches the brake pedals in the brakes-applied position.

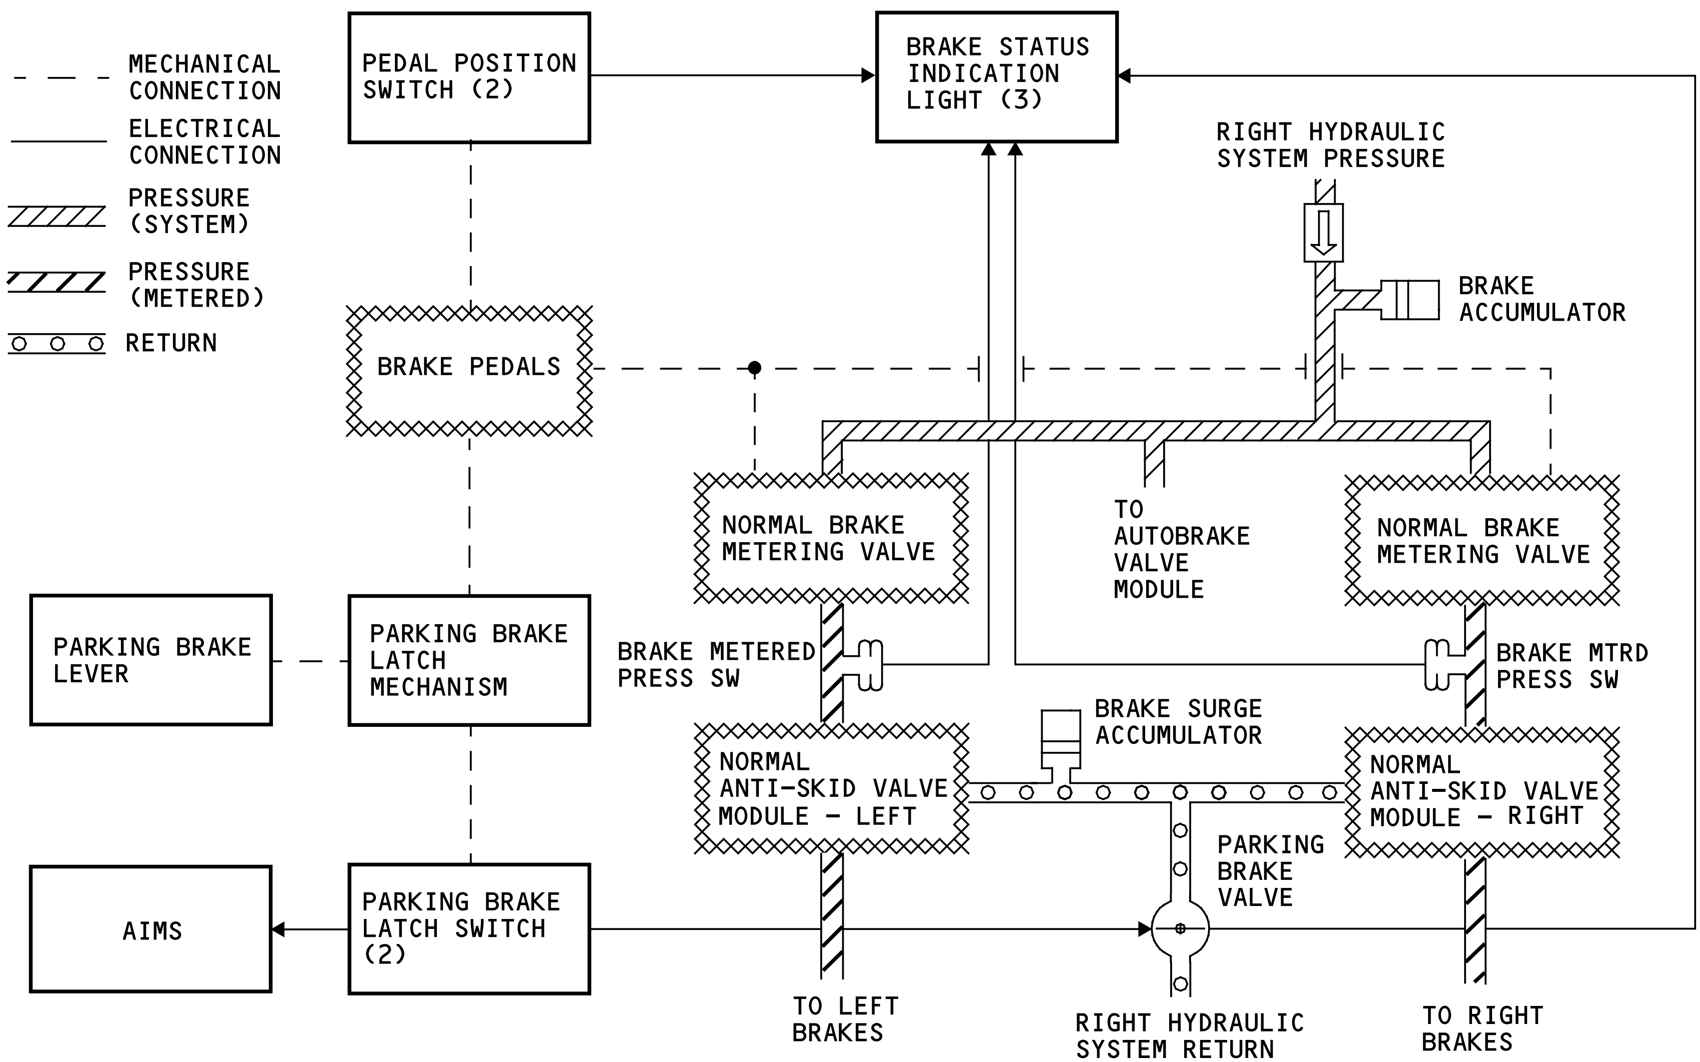
The parking brake latch switches send a signal to close the parking brake valve. They also send a signal to AIMS for flight deck indication.

The parking brake valve prevents brake pressure leakage through the normal antiskid valves.

Pedal position switches and brake metered pressure switches send signals to the brake status indication lights on the nose landing gear. These lights show people on the ground the brake system status.

Training Information Point

A fully charged (3000 psig) brake accumulator will keep the brakes pressurized at least eight hours.



32-44-00-002 Rev 2

PARKING BRAKE SYSTEM - GENERAL DESCRIPTION

PARKING BRAKE SYSTEM - PARKING BRAKE LATCH MECHANISM AND LATCH AND PEDAL POSITION SWITCHES

Purpose

The parking brake latch mechanism mechanically locks the brake pedals in the applied position.

These are the parking brake latch mechanism components:

- Latching pawls (2)
- Pawl stops (2)
- Latch spring.

Two parking brake latch switches control the parking brake valve and parking brake indications.

Two pedal position switches control the brake-off light.

Location

The parking brake latch mechanism is in the forward equipment center below the captain's rudder pedals.

The parking brake latch switches are on both sides of the latch mechanism.

The pedal position switches are on the captain's and the first officer's brake pedal cable quadrants.

Functional Description

When you push on the brake pedals and pull the parking brake lever up, the latching pawls hold the brakes in the applied position. The pawls engage stops on the captain's left and right brake lower bellcranks.

The parking brake latch switches send signals to close the parking brake valve. They also send lever position data to AIMS and to the brake system control unit (BSCU) for control and indication.

The latch spring pulls the pawls up and releases the parking brake latch when you push the pedals forward.

When you release the brake pedals, the parking brake latch switches send signals to open the parking brake valve.

The pedal position switches turn on the brake-off light when both brake pedals are in the not-applied position.

PARKING BRAKE SYSTEM - PARKING BRAKE LATCH MECHANISM AND LATCH AND PEDAL POSITION SWITCHES

PARKING BRAKE - FUNCTIONAL DESCRIPTION - CONTROL AND PARKING BRAKE-SET LIGHT INDICATION

General

When the parking brake lever is set, one parking brake latch switch sends hot battery bus power to close the parking brake valve. The BSCU also monitors lever position through this switch.

Both parking brake latch switches send signals to the AIMS. The AIMS uses this data to monitor parking brake lever position for the warning electronics system and memo message display.

When the parking brake valve is fully closed, an internal switch uses hot battery bus power to energize the parking brake close relay.

Indication

The parking brake close relay tells the AIMS to show the PARKING BRAKE SET memo message on the EICAS display. The close relay also turns on the parking brake set light on the nose gear when the airplane is on the ground.

Training Information Point

You can push-to-test the parking brake-set light.

If the parking brake valve is not fully open with the parking brake lever released, these messages will show:

- ANTISKID advisory message
- ANTISKID status message.

PARKING BRAKE SYSTEM - FUNCTIONAL DESCRIPTION - BRAKE-OFF AND BRAKE-ON LIGHT INDICATION

ANTISKID/AUTOBRAKE SYSTEM - INTRODUCTION

Purpose

The antiskid/autobrake system automatically controls brake metered pressure.

Antiskid System

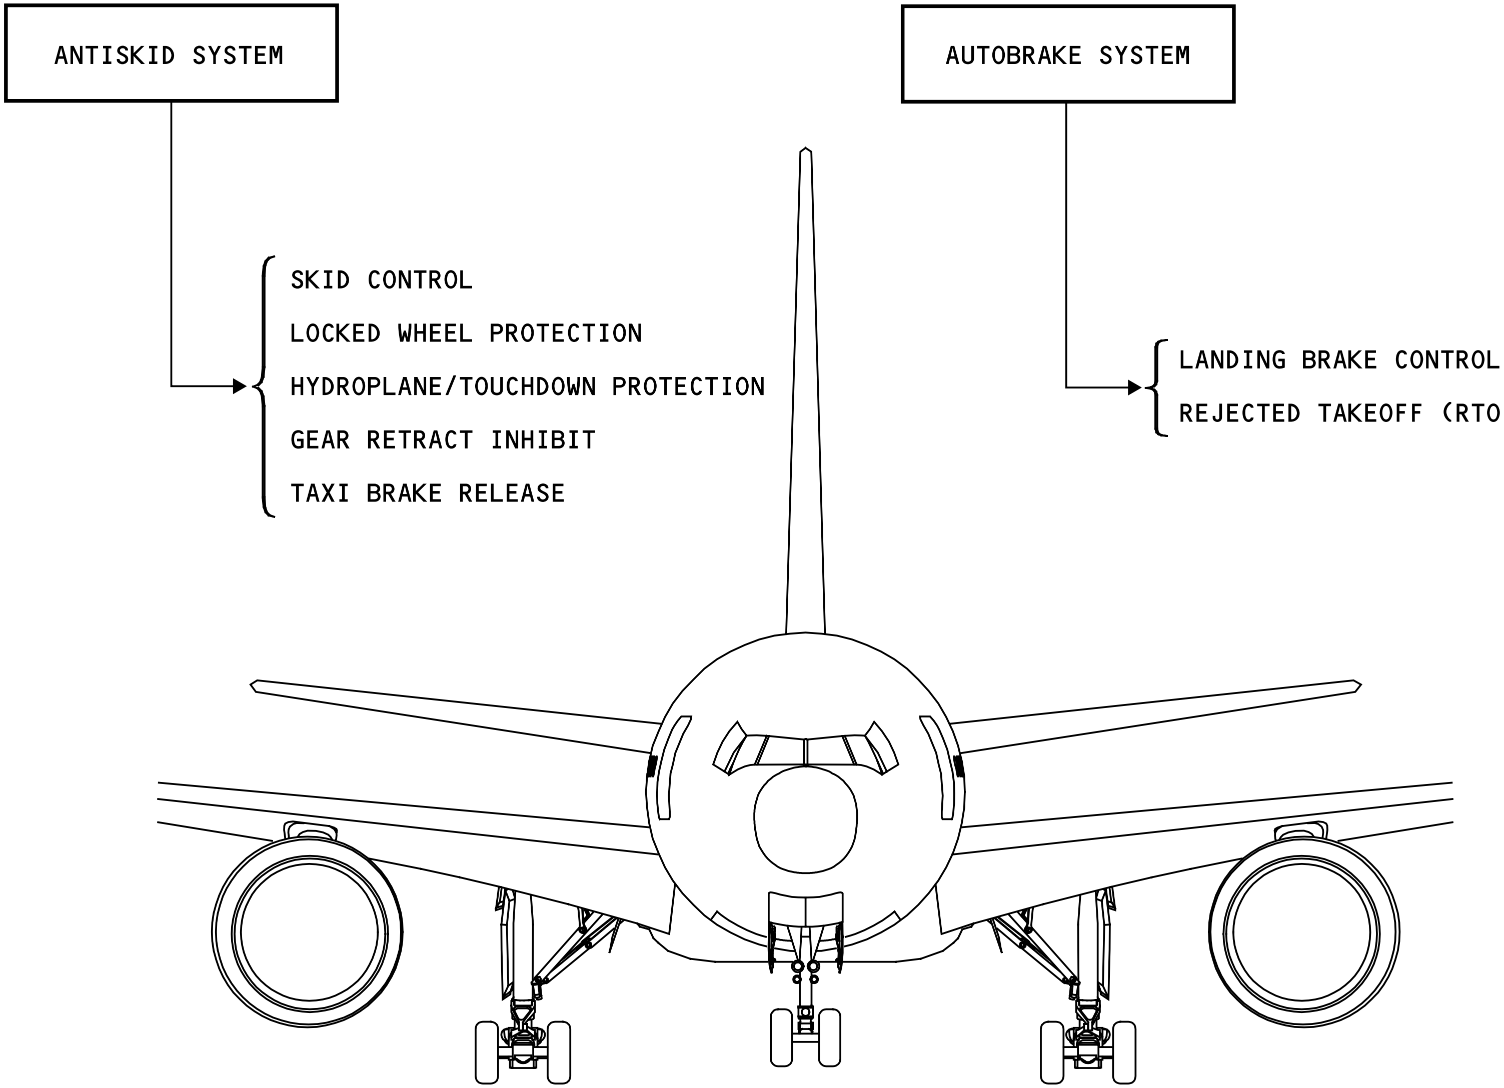
The antiskid system monitors wheel speed deceleration and controls brake pressure to prevent skid conditions. It also releases one third of the brakes during taxi to extend the brake service life.

Antiskid functions include:

- Skid control
- Locked wheel protection
- Hydroplane/touchdown protection
- Gear retract inhibit
- Taxi brake release.

Autobrake System

The autobrake system automatically supplies metered brake pressure to stop the airplane during landing or during a rejected takeoff (RTO).



32-42-00-001 Rev 0

ANTISKID/AUTOBRAKE SYSTEM - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

ANTISKID/AUTOBRAKE SYSTEM - GENERAL DESCRIPTION

General

The antiskid system limits metered brake pressure from the hydro-mechanical or the autobrake systems to prevent wheel skid. This permits maximum braking effectiveness with any runway condition.

Antiskid components for each MLG include:

- Antiskid transducer (6)
- Antiskid shuttle valve module (1)
- Normal antiskid valve module (1)
- Alternate antiskid valve module (1).

The autobrake system automatically applies the brakes to stop the airplane during landing or a rejected takeoff.

Autobrake components for the airplane include:

- Autobrake selector (1)
- Normal brake metered pressure transducer (2)
- Alternate brake metered pressure transducer (2)
- Autobrake valve module (1)
- Autobrake shuttle valve (2).

The brake system control unit (BSCU) controls antiskid and autobrake operation.

Inputs

The BSCU uses these inputs to control antiskid and autobrake operation:

- Truck tilt (PSEUs)
- Landing gear lever position (PSEUs)
- Air and inertial data (ADIRU)
- Speedbrake lever position (PFCs)
- Thrust lever position
- Parking brake valve position
- Parking brake lever position
- Right hydraulic system pressure
- Alternate brake system pressure
- Normal and alternate metered brake pressure
- Wheel speed
- Autobrake selector position.

Normal Antiskid Operation

The normal brake metering valves send metered pressure from the right hydraulic system or the accumulator through the autobrake shuttle valves to the normal antiskid valve modules. The BSCU sends signals to the normal antiskid valve modules to control the metered pressure to each brake. The metered pressure goes through the antiskid shuttle valve modules to the brakes.

An antiskid surge accumulator absorbs pressure surges in the return lines from the left normal antiskid valve module. The pressure surges can occur during antiskid operation. It is not necessary for the right normal antiskid valve to have a surge accumulator since it is near the right system reservoir.

ANTISKID/AUTOBRAKE SYSTEM - GENERAL DESCRIPTION

Alternate Antiskid Operation

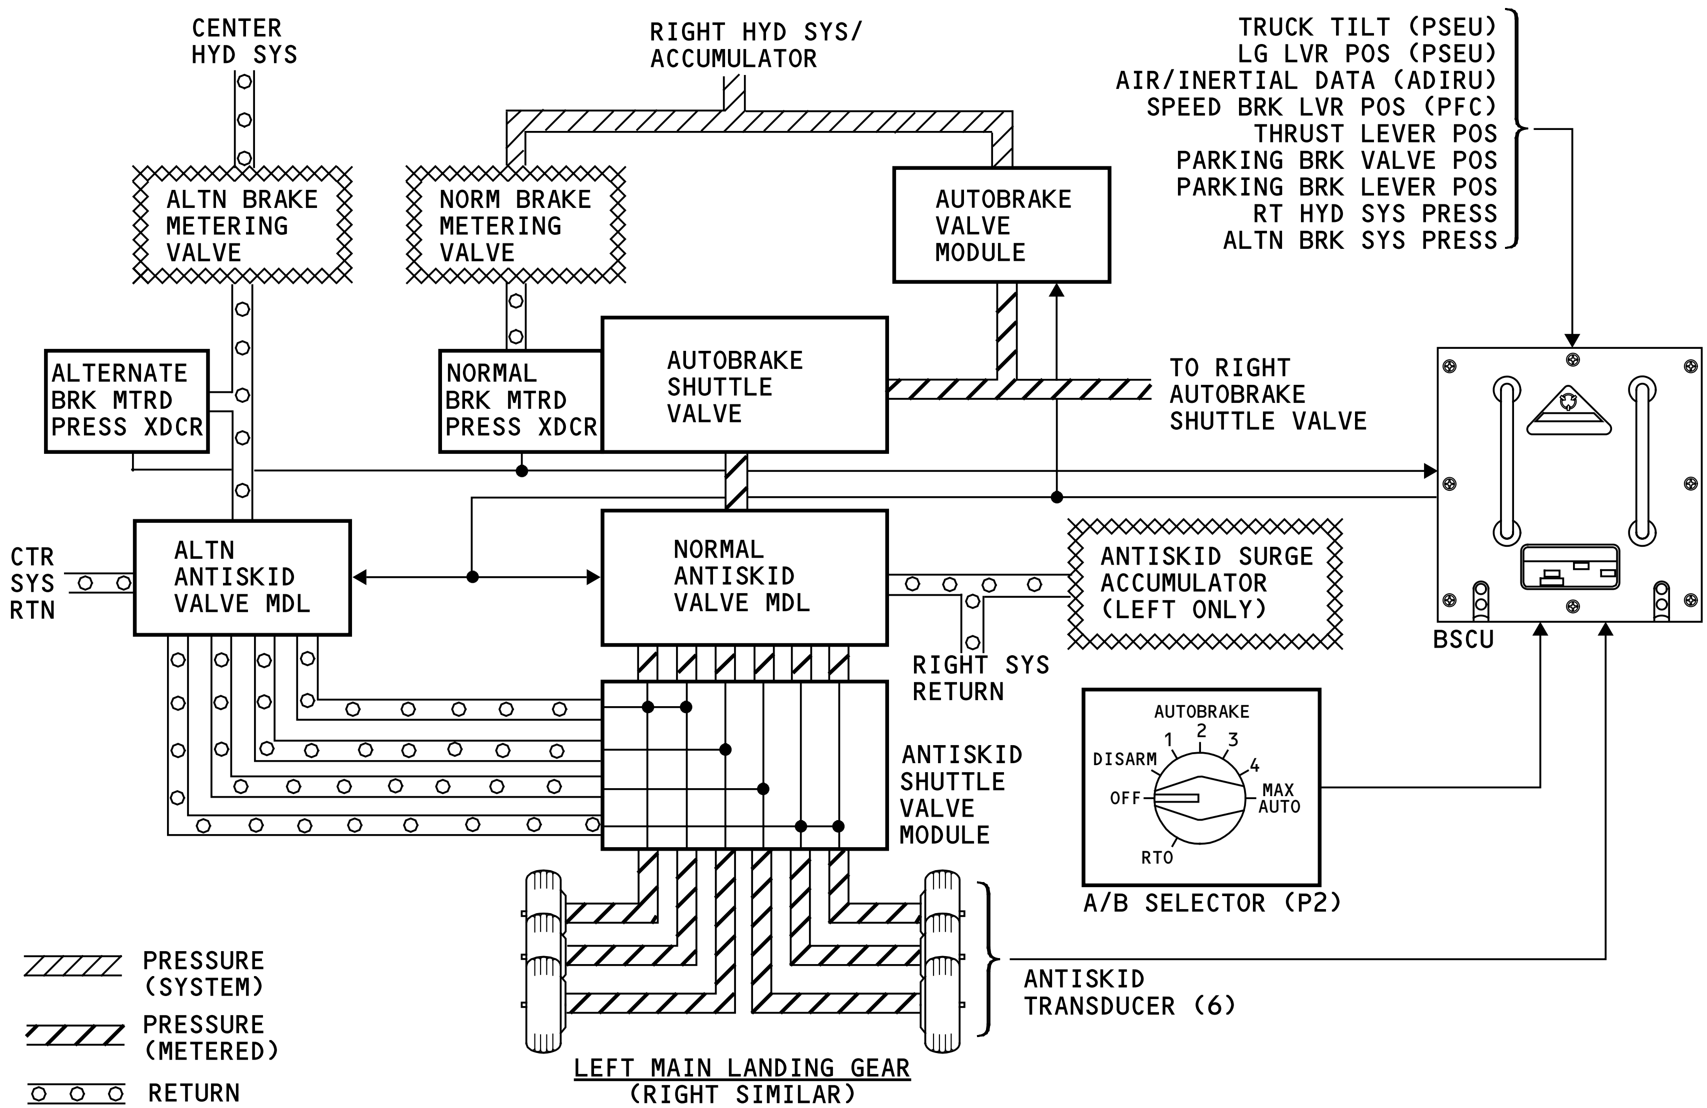
The alternate brake metering valves send metered pressure from the center hydraulic system to the alternate antiskid valve modules. The BSCU sends signals to the alternate antiskid valve modules to control the metered pressure to each aft brake and to forward-middle brake pairs. The metered pressure goes through the antiskid shuttle valve modules to the brakes.

Autobrake Operation

The BSCU sends signals to the autobrake valve module to control autobrake pressure to the normal brake system.

The autobrake valve module meters right hydraulic system pressure to the brakes. The autobrake pressure goes through the autobrake shuttle valves, the normal antiskid valves, and the antiskid shuttle valves.

The normal antiskid operates during autobrake operation.



ANTISKID/AUTOBRAKE SYSTEM - GENERAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

ANTISKID/AUTOBRAKE SYSTEM - AUTOBRAKE - GENERAL DESCRIPTION

Purpose

The autobrake system automatically applies the brakes to stop the airplane during landing or a rejected takeoff.

The BSCU controls autobrake operation. Other autobrake components include:

- The autobrake selector
- Normal brake metered pressure transducer (2)
- Alternate brake metered pressure transducer (2)
- The autobrake valve module
- The autobrake shuttle valve (2) (Not shown).

Autobrake Selector

The autobrake selector permits the pilot to select a rate of deceleration to the BSCU for landing autobrake or rejected takeoff operation.

Brake System Control Unit (BSCU) Inputs

The BSCU gets the following inputs from the left and right ARINC 629 system buses:

- PFC speed brake lever position
- PSEU truck tilt
- ADIRU groundspeed
- ADIRU deceleration
- AIMS test request.

Other inputs the BSCU gets from outside the autobrake system are:

- Wheelspeed
- Thrust lever position
- Normal/alternate brake pressure
- Antiskid faults.

Brake Metered Pressure Transducers

Two brake metered pressure transducers in the normal brake system and two in the alternate brake system send metered brake pressure data to the BSCU.

Autobrake Valve Module

The autobrake valve module sends metered right hydraulic system pressure to the autobrake shuttle valve for the normal brake system.

Autobrake Shuttle Valve (Not Shown)

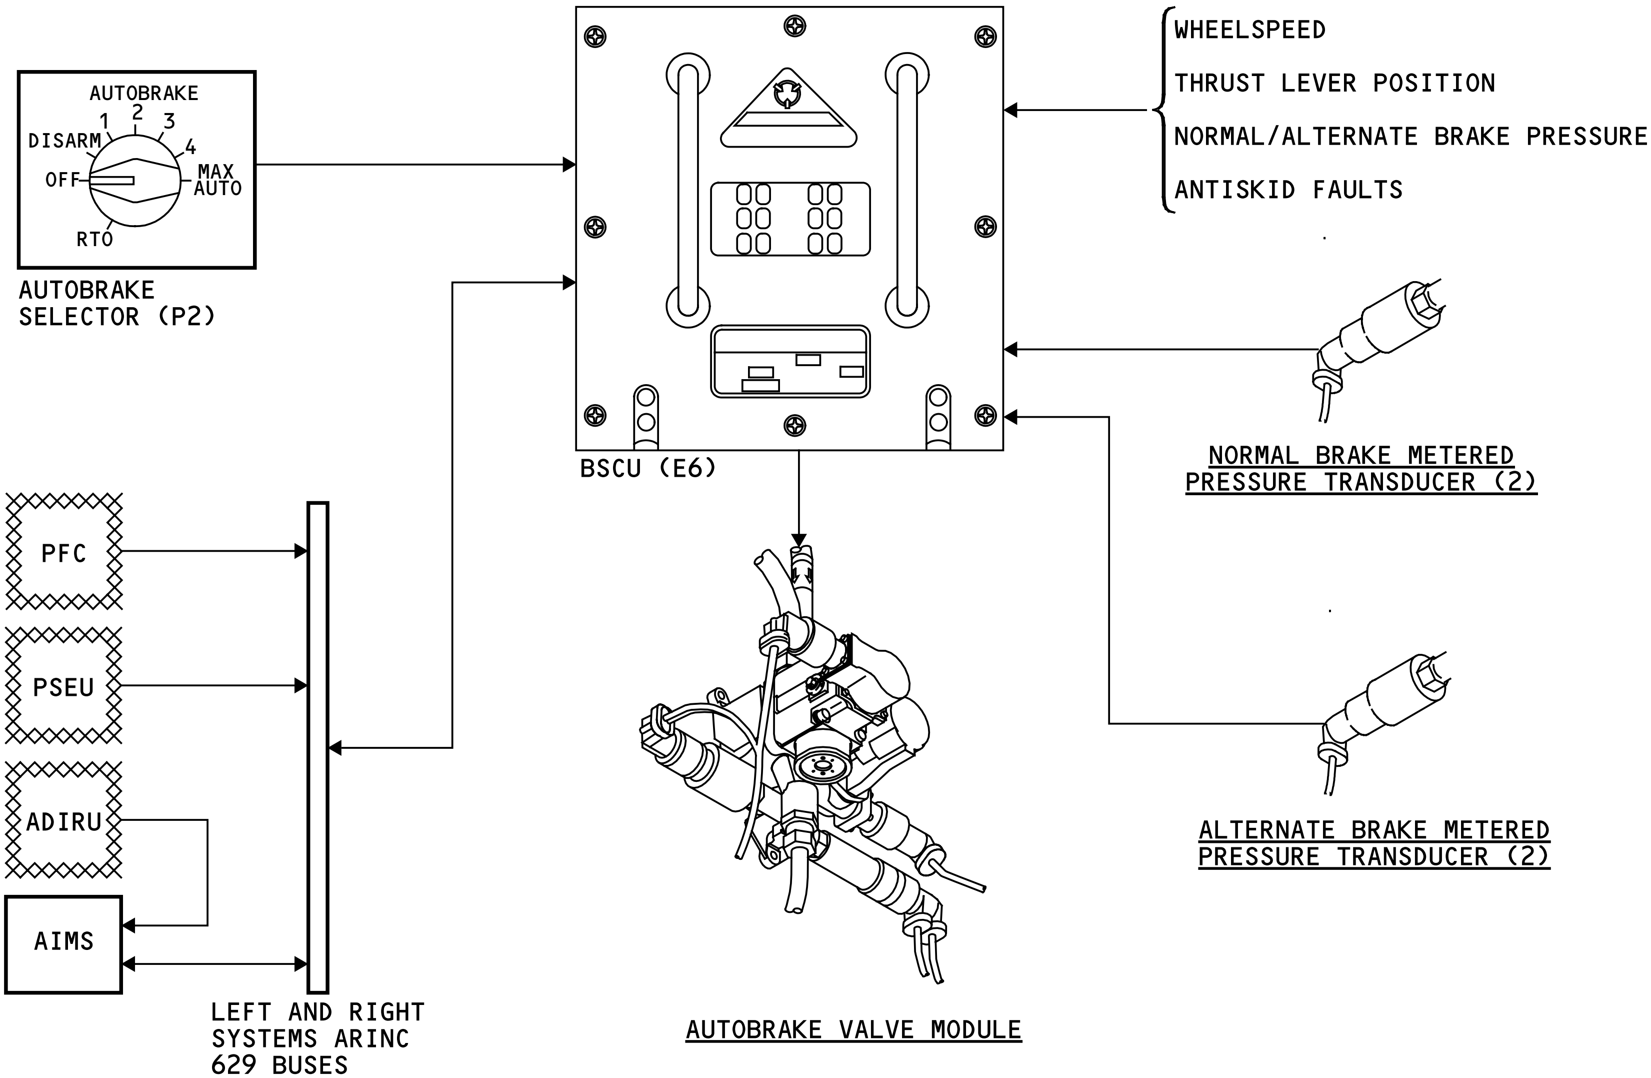
The autobrake shuttle valve sends autobrake valve module metered pressure to the normal brake system. It does this when normal brake metering valve pressure is lower than autobrake pressure.

General Description

You select an autobrake landing rate of deceleration or RTO with the autobrake selector.

ANTISKID/AUTOBRAKE SYSTEM - AUTOBRAKE - GENERAL DESCRIPTION

When all conditions for arming and application are met, the BSCU controls the autobrake valve module. The autobrake valve module sends right system hydraulic pressure to the brakes through the normal brake system.



32-42-00-003 Rev 1

ANTISKID/AUTOBRAKE SYSTEM - AUTOBRAKE - GENERAL DESCRIPTION

ANTISKID/AUTOBRAKE SYSTEM - COMPONENT LOCATIONS

THIS PAGE INTENTIONALLY LEFT BLANK

ANTISKID/AUTOBRAKE SYSTEM - COMPONENT LOCATIONS

General

These are the antiskid/autobrake system components:

- Autobrake selector
- Antiskid transducer (12)
- Brake system control unit (BSCU)
- Normal brake metered pressure transducer (2)
- Autobrake shuttle valve (2)
- Autobrake valve module
- Antiskid shuttle valve module (2)
- Normal antiskid module (2)
- Alternate antiskid module (2)
- Alternate brake metered pressure transducer (2).

Autobrake Selector

The autobrake selector is on the P2 center forward panel below the landing gear control lever.

Antiskid Transducer

There is an antiskid transducer for each main landing gear wheel in the each axle.

Brake System Control Unit (BSCU)

The BSCU is on the E6 rack in the aft cargo compartment.

Normal Brake Metered Pressure Transducer

The normal brake metered pressure transducers are on the autobrake shuttle valves in the left and right main wheel wells.

Autobrake Shuttle Valve

Autobrake shuttle valves are in the left and the right main gear wheel wells on the forward walls inboard of the brake metering valves.

Autobrake Valve Module

The autobrake valve module is on the keel beam in the forward section of the right main wheel well.

Antiskid Shuttle Valve Module

Antiskid shuttle valve modules are outboard of the main landing gear trunnions. They are below the normal antiskid modules.

Normal Antiskid Module

Normal antiskid modules are forward of the left and the right main landing gear beams outboard of the main landing gear trunnions.

Alternate Antiskid Module

Alternate antiskid modules are on the main landing gear beams inboard of the main landing gear trunnions.

ANTISKID/AUTOBRAKE SYSTEM - COMPONENT LOCATIONS

ANTISKID/AUTOBRAKE SYSTEM - COMPONENT LOCATIONS

ANTISKID/AUTOBRAKE SYSTEM - AUTOBRAKE SELECTOR

Purpose

The autobrake selector permits selection of a landing autobrake deceleration rate or the rejected takeoff function.

Location

The autobrake selector is on the P2 center forward panel below the landing gear handle.

Functional Description

The autobrake selector is an eight-position selector. A latch solenoid holds the selector in all positions except OFF and DISARM. The BSCU controls the latch solenoid. If a disarm condition occurs when the selector is in 1 through MAX AUTO, the latch solenoid releases the selector to DISARM.

To move the selector from OFF to DISARM or from DISARM to OFF, push the selector when you turn it. To move the selector to the RTO position, pull the selector when you turn it.

Positions 1 through MAX AUTO set the rate of deceleration for autobrake operation after landing. For each level of deceleration, the BSCU controls the autobrake pressure to a maximum limit. The BSCU uses a 0.1 second time delay before landing autobrake application.

The RTO position commands maximum brake pressure for a rejected takeoff. There is no time delay before RTO autobrake application.

The latch solenoid releases the selector from the RTO position to the OFF position when the airplane goes in the air.

Training Information Point

One of these memo messages shows when the autobrake selector is in a landing autobrake position or in the RTO position:

- AUTOBRAKE 1
- AUTOBRAKE 2
- AUTOBRAKE 3
- AUTOBRAKE 4
- AUTOBRAKE MAX
- AUTOBRAKE RTO.

32-42-00-005 Rev 4 10/15/96

ANTISKID/AUTOBRAKE SYSTEM - AUTOBRAKE SELECTOR

ANTISKID/AUTOBRAKE SYSTEM - ANTISKID TRANSDUCER

Purpose

Antiskid transducers supply wheel speed data to the BSCU to get wheel deceleration input. These data also goes to the BSCU for autobrake operation.

Location

There are twelve antiskid transducers. The antiskid transducer is in a support in each main landing gear axle.

Functional Description

Antiskid transducers are permanent magnetic devices with an internal rotor and stator.

An antiskid transducer cup attaches to the hubcap through a flexible bellows assembly. This bellows assembly makes installation adjustment allowances when it compresses. The hubcap turns with the MLG wheel. The cup connects to the antiskid transducer drive dog which turns the rotor in the antiskid transducer.

Training Information Point

The transducer is an LRU.

The antiskid transducer is part of an in-axle assembly. These components make up the in-axle assembly:

- Wheel interface unit
- Antiskid transducer
- Support.

You remove the in-axle assembly from the axle as a unit to get access to the antiskid transducer.

The system can operate with one unserviceable transducer on each six wheel truck if no other brake on that truck is deactivated.

ANTISKID/AUTOBRAKE SYSTEM - BRAKE SYSTEM CONTROL UNIT (BSCU) - INTRODUCTION

ANTISKID/AUTOBRAKE SYSTEM - ANTISKID MODULES - INTRODUCTION

Purpose

There are two normal antiskid modules and two alternate antiskid modules in the antiskid system.

These modules release brake pressure to prevent wheel skids.

Location

The normal antiskid modules are near the main landing gear beams outboard of the main landing gear trunnions. An access panel permits you to get access to the normal antiskid valve modules.

The alternate antiskid modules are on the main landing gear beams inboard of the main landing gear trunnions.

Normal Antiskid Modules

There are two normal antiskid modules: one for each main landing gear. The modules are the same. Each module has six valves.

The modules are LRUs and each module contains these LRUs:

- Inlet filter (2)
- System pressure shutoff valve
- Antiskid valve (6)
- Hydraulic fuse (6).

Alternate Antiskid Modules

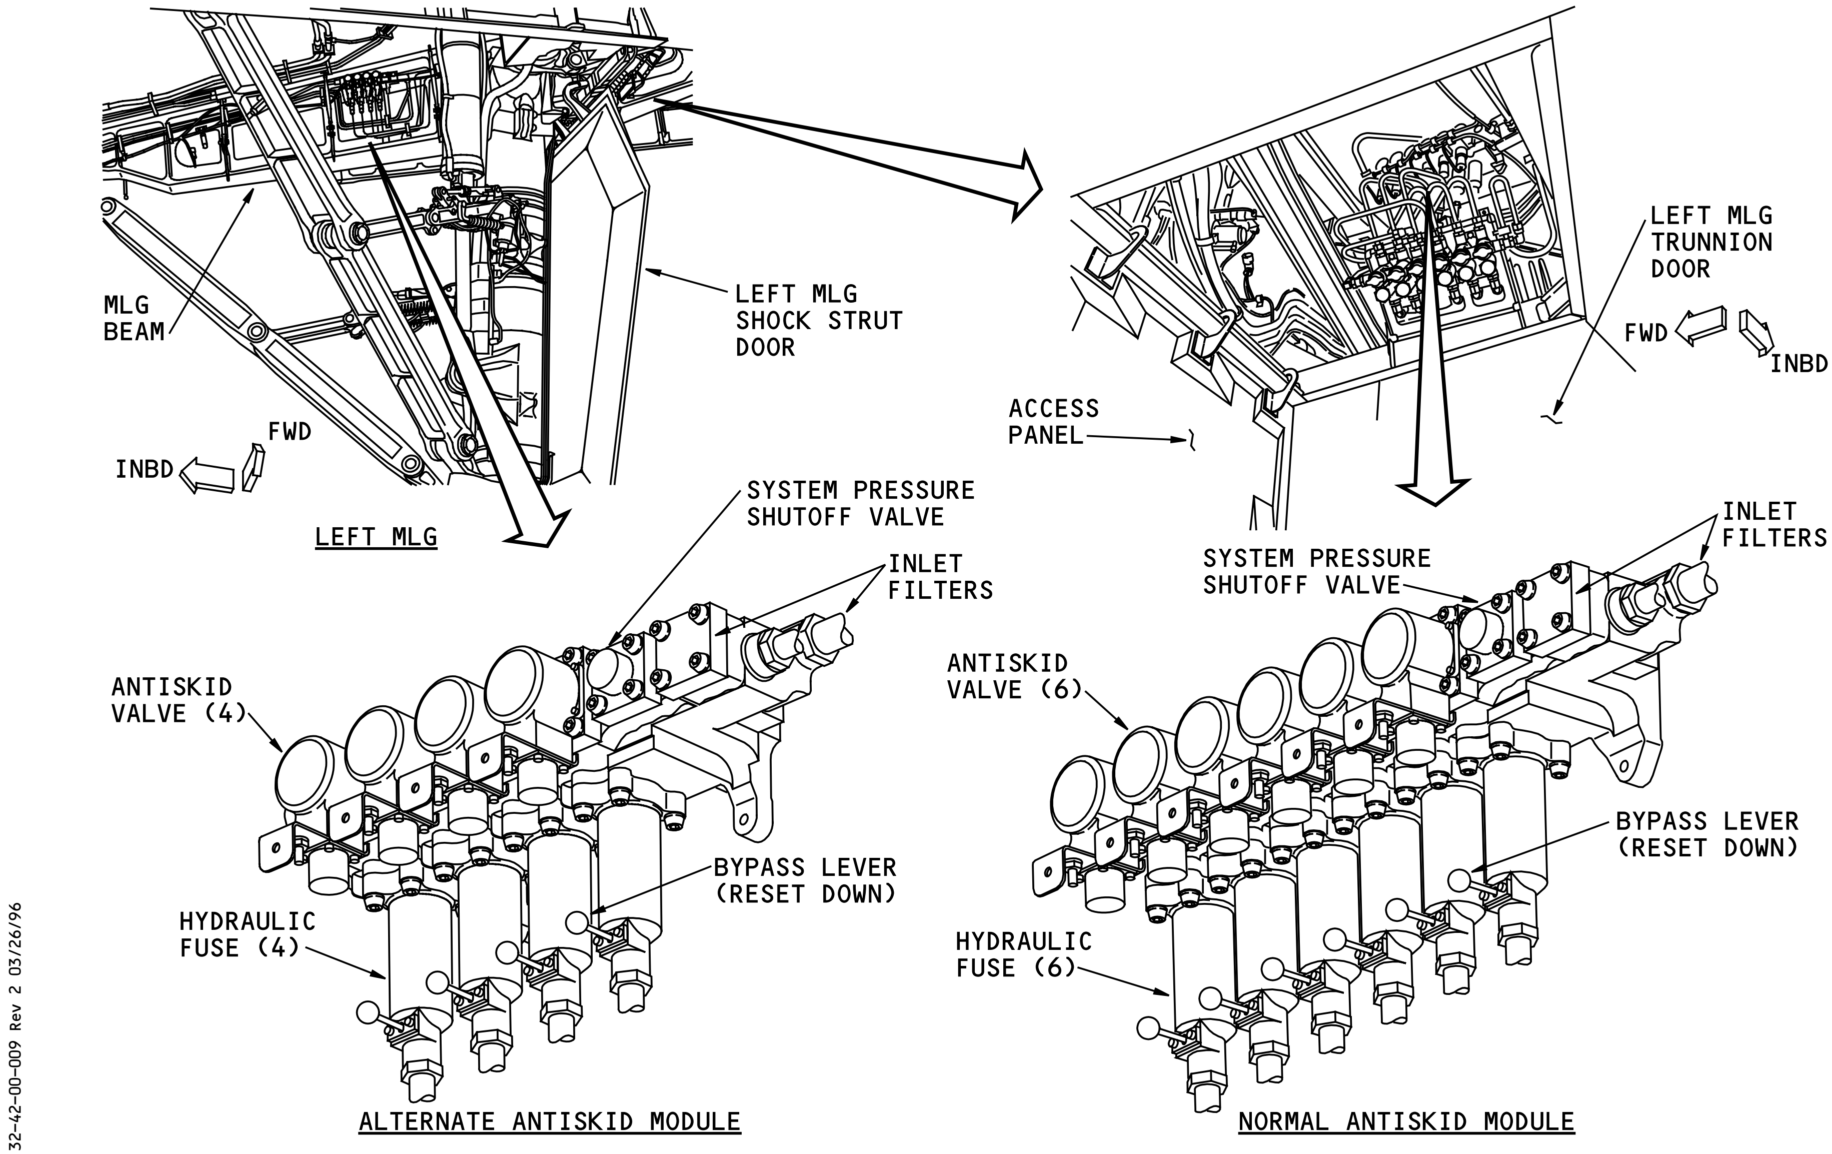
There are two alternate antiskid modules: one for each main landing gear. The modules are the same. Each module has four valves.

The modules are LRUs and each module contains these LRUs:

- Inlet filter (2)
- System pressure shutoff valve
- Antiskid valve (4)
- Hydraulic fuse (4).

Training Information Point

The system can operate with one unserviceable normal antiskid valve for each six wheel truck. You must deactivate the related brake.



ANTISKID/AUTOBRAKE SYSTEM - ANTISKID MODULES - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

ANTISKID/AUTOBRAKE SYSTEM - ANTISKID MODULES - FUNCTIONAL DESCRIPTION

General

The operation of normal and alternate antiskid modules is the same. The number of antiskid valves and hydraulic fuses is the only difference in the two modules.

The normal antiskid module controls brake pressure for six wheels independently. The alternate antiskid module controls two wheels independently and two sets of paired wheels with the other two antiskid valves.

Inlet Filters

An in-line filter screen removes contamination from brake metered pressure fluid as it enters the antiskid module.

System pressure fluid also goes through a filter as it enters the antiskid module.

System Pressure Shutoff Valve

When brake metered pressure is above 225 psig, the system pressure shutoff valve supplies system pressure, if available, to the first stage of each antiskid valve. This provides a constant 3000 psi pressure level for pressure control.

When brake metered pressure is less than 225 psig, system pressure closes the shutoff valve. This prevents wear of first stage components by constant application of system pressure. When the shutoff valve is closed, it uses metered pressure to control the first stage.

Antiskid Valve

Each antiskid valve is a three-way, unigain control valve. The valves have two stages of control:

- The first stage controls pressure in proportion to input current from the BSCU
- The second stage keeps pressure to the brakes equal to the first stage controlled pressure.

The first stage uses a current controlled flapper between two nozzles to adjust first stage pressure. One nozzle connects to system pressure and the other connects to return.

When no current goes to the valve, the flapper moves against the return nozzle. In this position, control pressure is the same as system pressure.

When full current goes to the valve, the flapper moves against the pressure nozzle. In this position, control pressure is the same as return pressure.

For each intermediate value of input current, the flapper moves between the two nozzles to adjust the control pressure (shown).

The second stage uses a spool valve that moves with first stage control pressure and a spring on one end and metered brake pressure on the other end.

When there is no metered brake pressure, the spring holds the spool in position to send initial brake metered pressure to fill the brakes before the shutoff valve opens.

When control pressure is more than metered brake pressure, the spool moves to send metered brake pressure to the brakes.

During antiskid operation, the spool operates to control brake pressure equal to first stage control pressure. It sends excess brake pressure to system return. A flow restrictor slows spool movement.

Hydraulic Fuse

Brake line fuses prevent fluid loss caused by external leakage downstream of the antiskid modules.

If 60 to 95 cubic inches of fluid pass through the fuse, it closes. When the pressure differential across the fuse is between 18 to 30 psi, the fuse automatically resets.

A bypass lever permits manual reset of the fuse. To reset manually, move the lever down to operate a bypass valve that equalizes pressure on each side of the fuse.

There is no indication that a fuse is set.

Return Check Valve

If the return line is blocked and metered pressure is less than return pressure, the return check valve releases brake pressure to metered pressure.

ANTISKID/AUTOBRAKE SYSTEM - ANTISKID MODULES - FUNCTIONAL DESCRIPTION

ANTISKID/AUTOBRAKE SYSTEM - ANTISKID SHUTTLE VALVE MODULE

Purpose

Two shuttle valve modules automatically select the highest metered pressure source and send it to the brakes.

Components

The shuttle valve modules are the same for the left and the right. Each module is an LRU and contains these LRUs:

- Cartridge valves (6)
- Filters (6)
- A flight dispatch disconnect.

Location

The modules are forward of the left and right main landing gear beams. They are outboard of the main landing gear below the normal antiskid modules.

You get access to the modules through an access panel outboard of each main landing gear.

Functional Description

Each shuttle valve moves to a detented position to connect the input line with the higher metered pressure to the related brake line. The line with the lower pressure is blocked.

Fluid to each brake is put through a filter before it goes out of the module.

You use the shuttle valve to deactivate a brake in the normal brake system. To lock the related shuttle valve in the ALTERNATE position, you remove the end cover and install the flight dispatch disconnect. This permits gear retract pressure to the related brake with the normal brake deactivated.

Training Information Point

The system can operate with one brake on each six wheel truck deactivated.

32-42-00-011 Rev 2 11/09/1995

ANTISKID/AUTOBRAKE SYSTEM - AUTOBRAKE VALVE MODULE

Purpose

The autobrake valve module gets BSCU electrical signals to send right hydraulic system pressure to the normal brake system during autobrake operation.

Components

The autobrake valve module is an LRU and contains these LRUs:

- Solenoid valve
- Solenoid valve pressure switch
- Control valve
- Control valve pressure transducer.

There is also a shutoff valve inside the module.

Location

The autobrake valve module is on the keel beam in the right main landing gear wheel well.

Functional Description

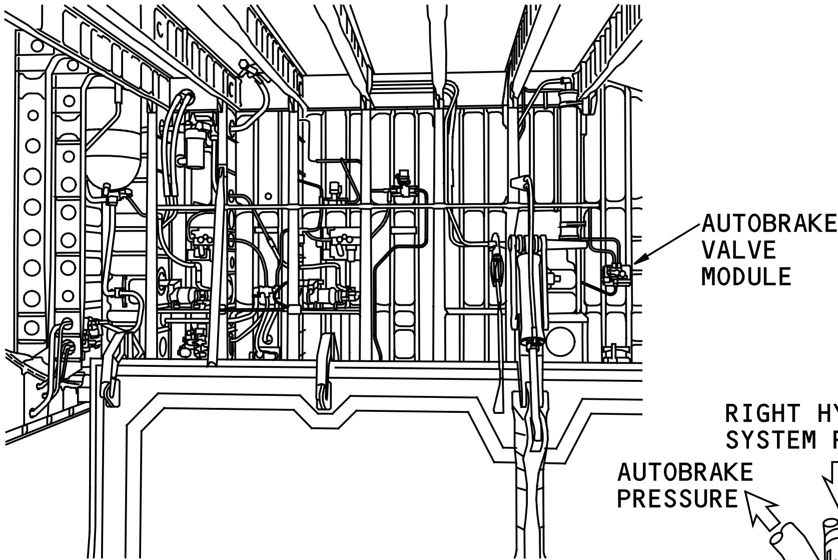
When the autobrake function does not operate, the solenoid valve is not energized. This stops hydraulic pressure downstream of the solenoid valve. During autobrake operation, the BSCU energizes the solenoid valve. This causes the solenoid valve to send right hydraulic system pressure to the shutoff valve.

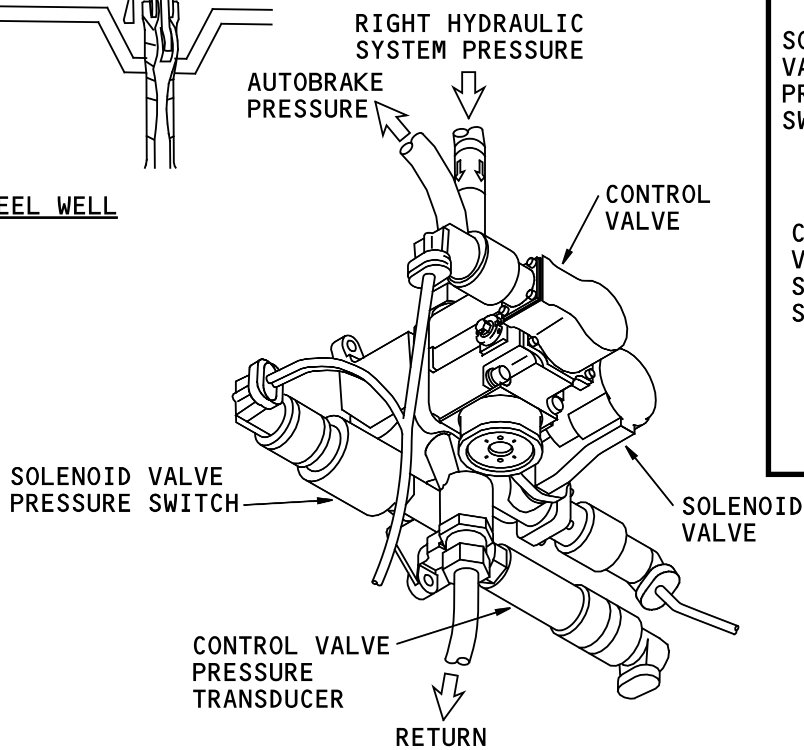
This pressure causes the shutoff valve to open and permits the system pressure to go to the control valve.

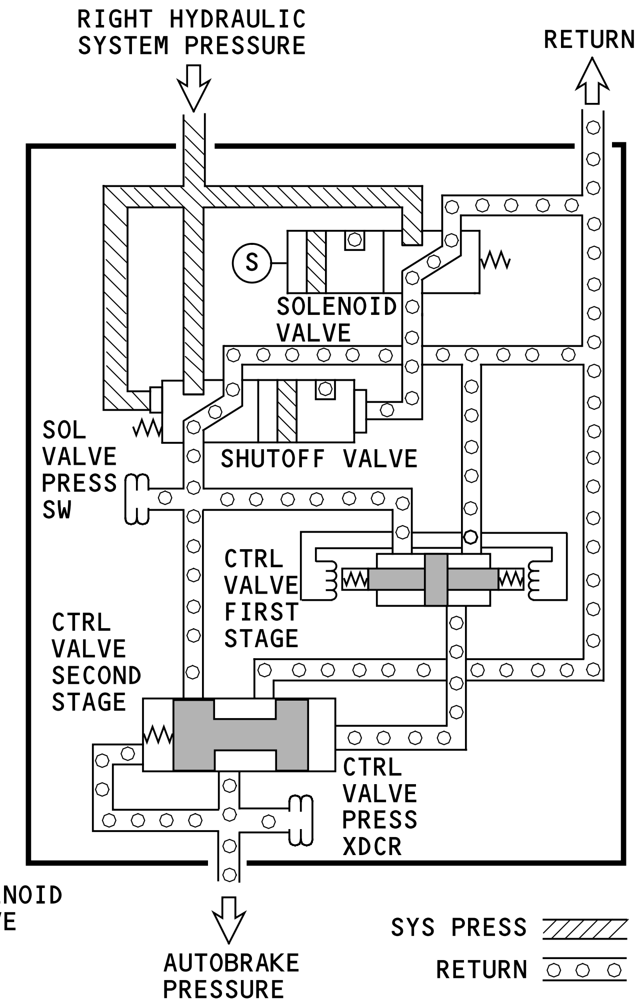
The solenoid valve pressure switch sends a signal to the BSCU when the pressure downstream of the shutoff valve is more than 750 psi. The BSCU uses this signal to find solenoid valve faults.

The control valve is a two-stage servo-operated valve. The BSCU controls this valve to let the necessary hydraulic pressure to go to the brakes.

The control valve pressure transducer sends autobrake pressure output signals to the BSCU for feedback.







ANTISKID/AUTOBRAKE SYSTEM - AUTOBRAKE VALVE MODULE

ANTISKID/AUTOBRAKE SYSTEM - AUTOBRAKE SHUTTLE VALVE

Purpose

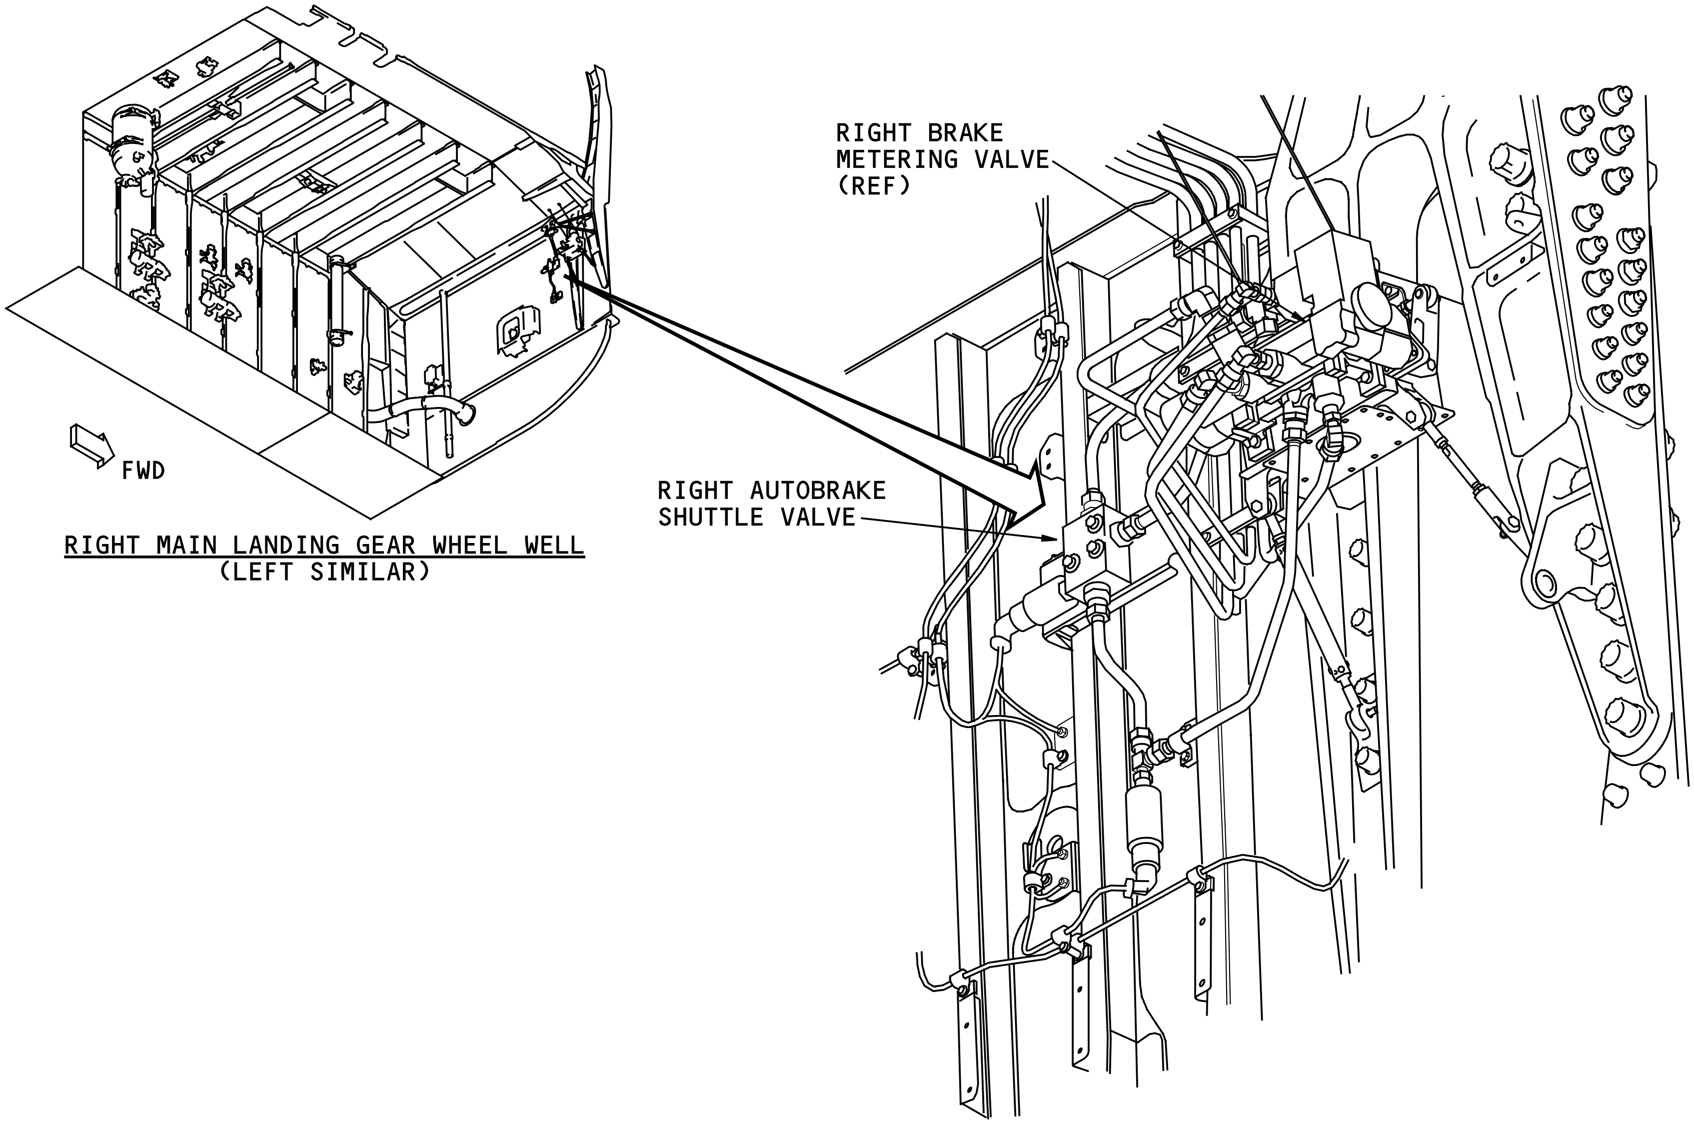
Two autobrake shuttle valves select the highest of autobrake or normal brake metered pressures and send it to the brakes.

Location

The autobrake shuttle valves are on the forward wall in the left and right main landing gear wheel wells. They are inboard of the brake metering valves.

Physical Description

The valves are un-biased shuttle valves with detents and are interchangeable.



32-42-00-013 Rev 0

ANTISKID/AUTOBRAKE SYSTEM - AUTOBRAKE SHUTTLE VALVE

ANTISKID/AUTOBRAKE SYSTEM - BRAKE METERED PRESSURE TRANSDUCERS

Purpose

Four brake metered pressure transducers send normal and alternate metered pressure information to the BSCU for anti-skid and autobrake control.

Location

The two normal brake metered pressure transducers are on the left and right autobrake shuttle valves in the main landing gear wheel wells.

The two alternate brake metered pressure transducers are on the landing gear beams inboard of the left and right alternate antiskid modules.

Functional Description

The BSCU uses inputs from the normal brake metered pressure transducers for autobrake disarm logic and for the taxi brake release function.

All four transducers supply the BSCU with metered pressure data to send to the AIMS. The data shows on the landing gear brakes/steering maintenance page.

The BSCU also sends the pressure data to the flight data recorder.

ANTISKID/AUTOBRAKE SYSTEM - BRAKE METERED PRESSURE TRANSDUCERS

ANTISKID/AUTOBRAKE SYSTEM - ANTISKID FUNCTIONAL DESCRIPTION - CONTROLLERS

General

The antiskid cards use primary and secondary controllers to supply these functions:

- Skid control
- Locked wheel protection
- Hydroplane/touchdown protection
- Gear retract inhibit
- Taxi brake release.

Each controller uses these inputs for control:

- Wheel speed from a fwd-mid-aft wheel group
- Groundspeed
- Landing gear lever position
- Taxi brake release request from the Autobrake/BITE/Comm card.

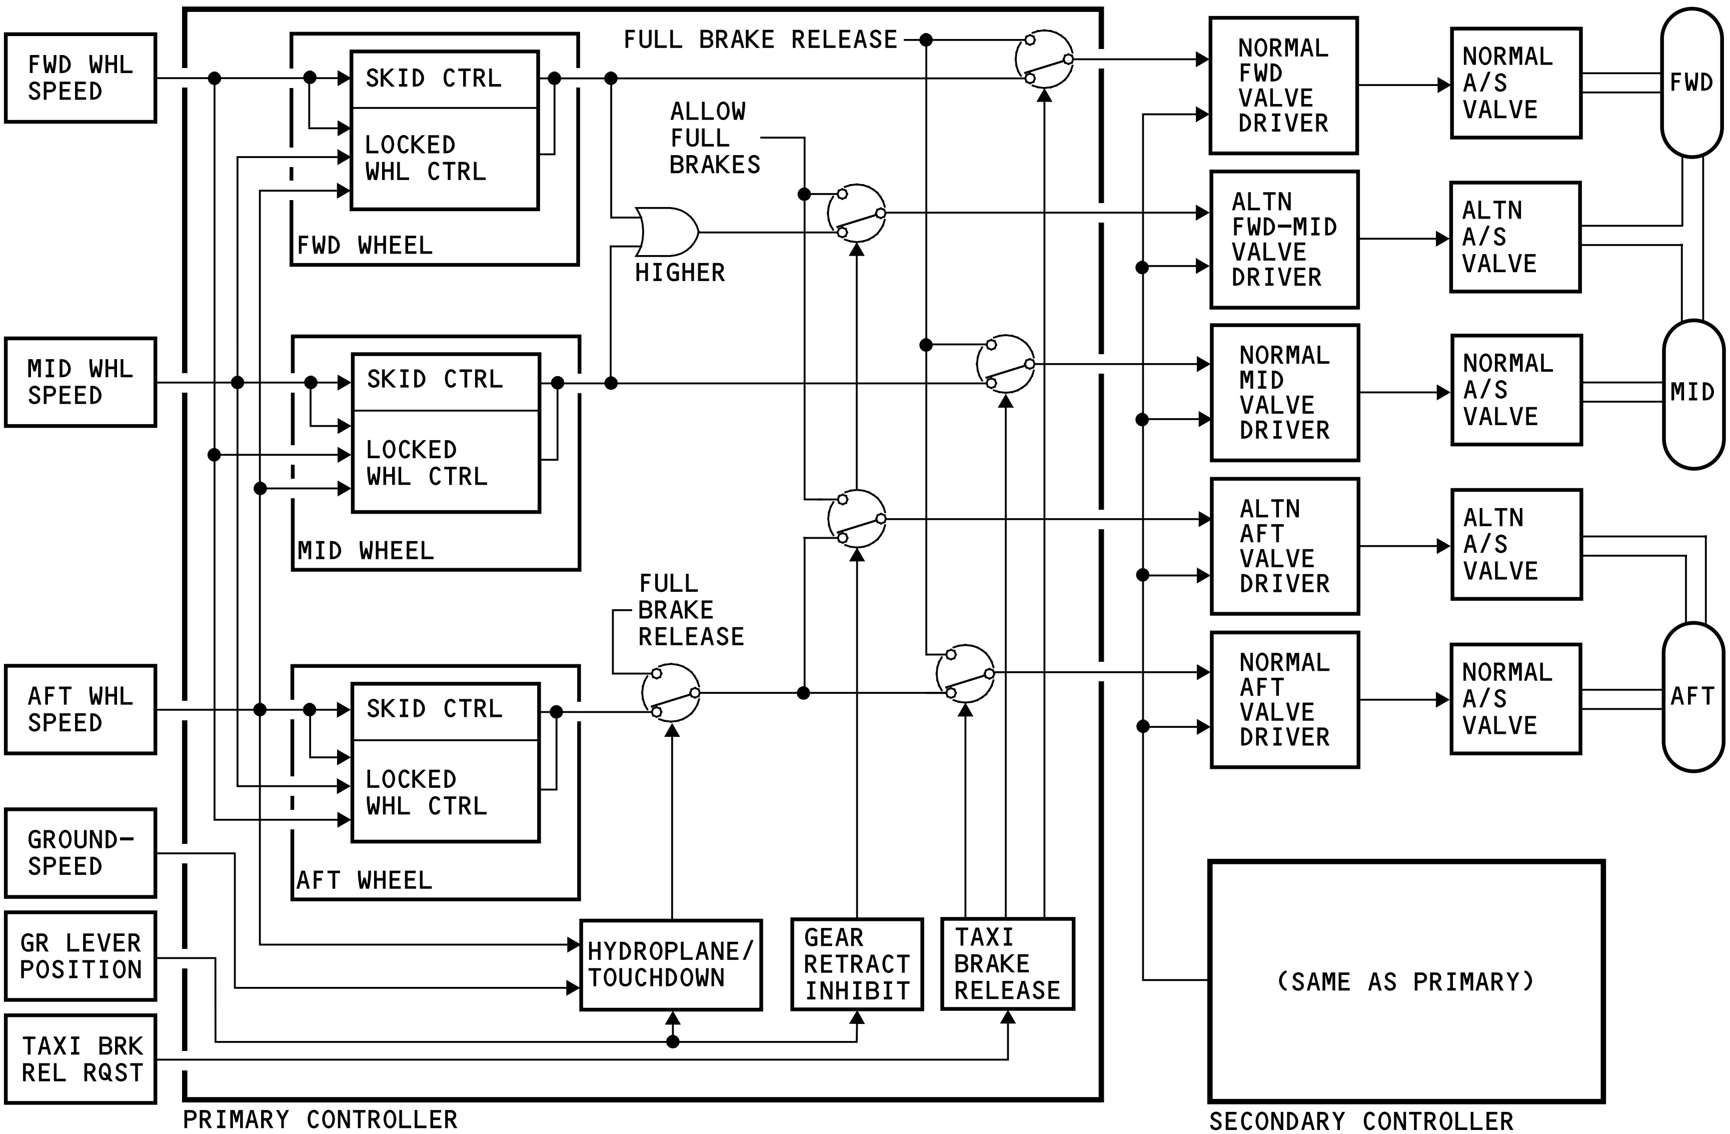
Each controller controls power output to three normal and two alternate antiskid valves with 0-55 milliampere current drivers.

The primary controller on each card uses current drivers on that same card. These drivers also get inputs from the secondary controller on the paired card.

Brake Test and Fault Monitoring (not shown)

When the controllers get a brake release test request, they use the drivers to release all pressure to the requested brake.

The Autobrake/BITE/Comm cards monitor the controllers for antiskid fault data. They send this information to the AIMS for flight deck display.



ANTISKID/AUTOBRAKE SYSTEM - ANTISKID FUNCTIONAL DESCRIPTION - CONTROLLERS

ANTISKID/AUTOBRAKE SYSTEM - INDICATIONS

General

The primary and secondary bite cards in the BSCU send antiskid and autobrake fault data to AIMS for flight deck display.

There is one ANTISKID advisory message. It shows when there is a fault that causes loss of skid protection.

There is one AUTOBRAKE advisory message. It shows when the autobrake system is disarmed, inoperative, or RTO starts but the brakes do not apply. It also shows when the autobrake switch is OFF and the pressure in the autobrake valve module is not shutoff.

Autobrake memo messages show autobrake selector position.

Landing Gear Synoptic Display

The antiskid system shows fault and disabled data for each wheel on the landing gear synoptic display.

ASKID shows next to the applicable wheel when an antiskid fault is active and the ANTISKID advisory or status message shows. If the BSCU loses communication with the flight deck, the AIMS shows ASKID next to each wheel.

When you disable fault indications for a brake, BRAKE shows next to the applicable brake. This makes the ANTISKID advisory message go out of view. You can only disable one brake for each truck.

Landing Gear Brks/Strg Maintenance Page

When a fault and a CMC maintenance message for a wheel are active, one of these labels, shown in decreasing importance, will show next to the applicable wheel:

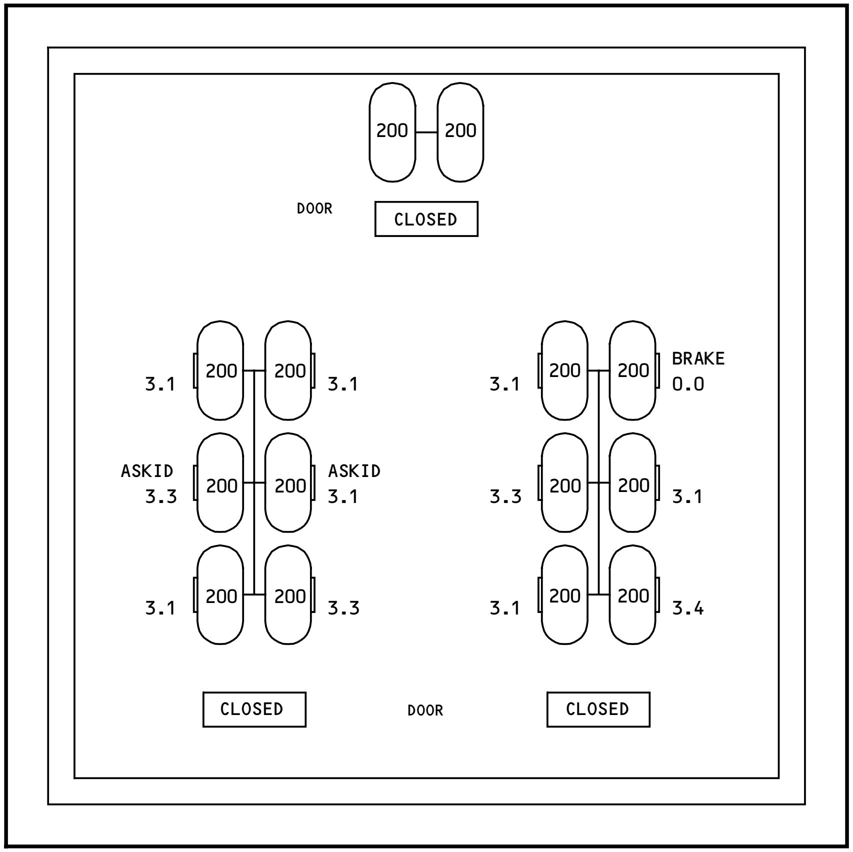
- BRAKE DEACT - brake deactivated
- ASKID PWR - power to the wheel failed
- ASKID CARD - BSCU card failed
- ASKID VALVE - normal valve and/or wiring failed
- ASKID XDCR - transducer and/or wiring failed
- ASKID ALTN - alternate valve and/or wiring failed.

Only the most important label shows for a wheel when more than one fault is active.

If the BSCU loses communication with the flight deck, the AIMS shows ASKID CARD next to each wheel.

Brake metered pressures for the normal and alternate brake systems show on the lower part of the page.

Autobrake pressure indication is between the brake metered pressure indications.



LANDING GEAR SYNOPTIC DISPLAY

ANTISKID/AUTOBRAKE SYSTEM - INDICATIONS

ANTISKID/AUTOBRAKE SYSTEM - SYSTEM TESTS

General

These are the system tests for the antiskid and autobrake systems:

- System Interface
- Antiskid Brake Release
- Autobrake Application
- Wheelspeed Transducer Spin.

System Interface

You use the system interface test to do a test of the BSCU and of the wiring to some of the LRUs in the antiskid and autobrake systems. During the test, the brakes apply and release to check the operation of the autobrake and antiskid systems. This test also does a check of the correct operation of the sensor inputs to the BSCU.

Antiskid Brake Release

The brake release test releases the brake pressure for a selected brake through its antiskid valve. You must visually make sure the brake pressure releases. To do this, monitor the movement of the wear indicator pins.

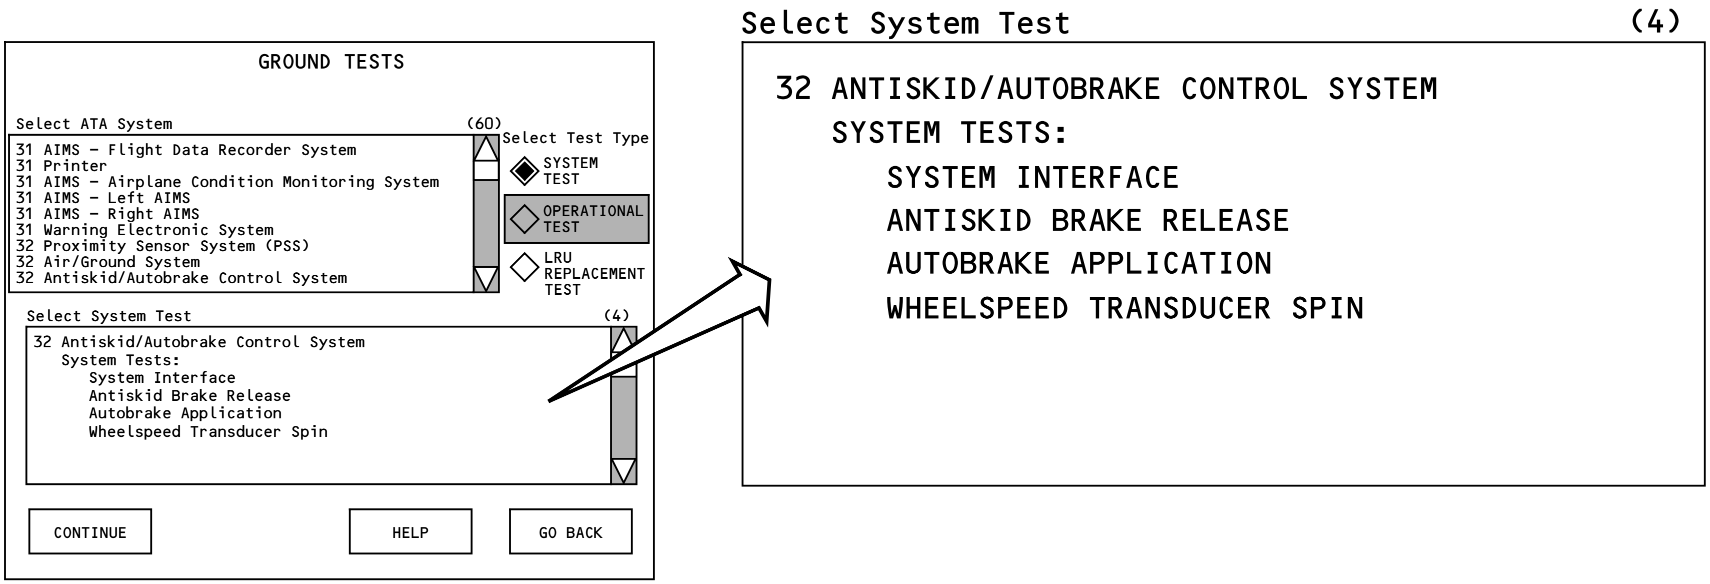
Autobrake Application

The autobrake application test does a check of the autobrake system. The test applies and releases brake pressure to all the brakes.

Wheelspeed Transducer Spin

The wheelspeed transducer spin test lets you do a test of the antiskid transducers and their wiring. You manually turn the selected antiskid transducer during this test. You must turn the transducer at 20 rpm or more during the test.

You remove the hubcap to get access to the antiskid transducer.



32-42-00-028 Rev 4 02/13/1997

ANTISKID/AUTOBRAKE SYSTEM - SYSTEM TESTS

ANTISKID/AUTOBRAKE SYSTEM - LRU REPLACEMENT TESTS

General

These are the LRU replacement tests for the antiskid and autobrake systems:

- Brake System Control Unit
- Antiskid Valve
- Autobrake Valve Module
- Wheelspeed Transducer.

Brake System Control Unit

The brake system control unit replacement test does a check of the BSCU and of the wiring to some of the LRUs in the antiskid and autobrake systems. During the test, the brakes apply and release to check the operation of the autobrake and antiskid systems.

This test is almost the same as the system interface test in the system test menu.

Antiskid Valve

The antiskid valve replacement test lets you do a test of a selected antiskid valve. The test releases the brake pressure for the selected brake. You must visually make sure the brake pressure releases.

This test is the same as the antiskid brake release test in the system test menu.

Autobrake Valve Module

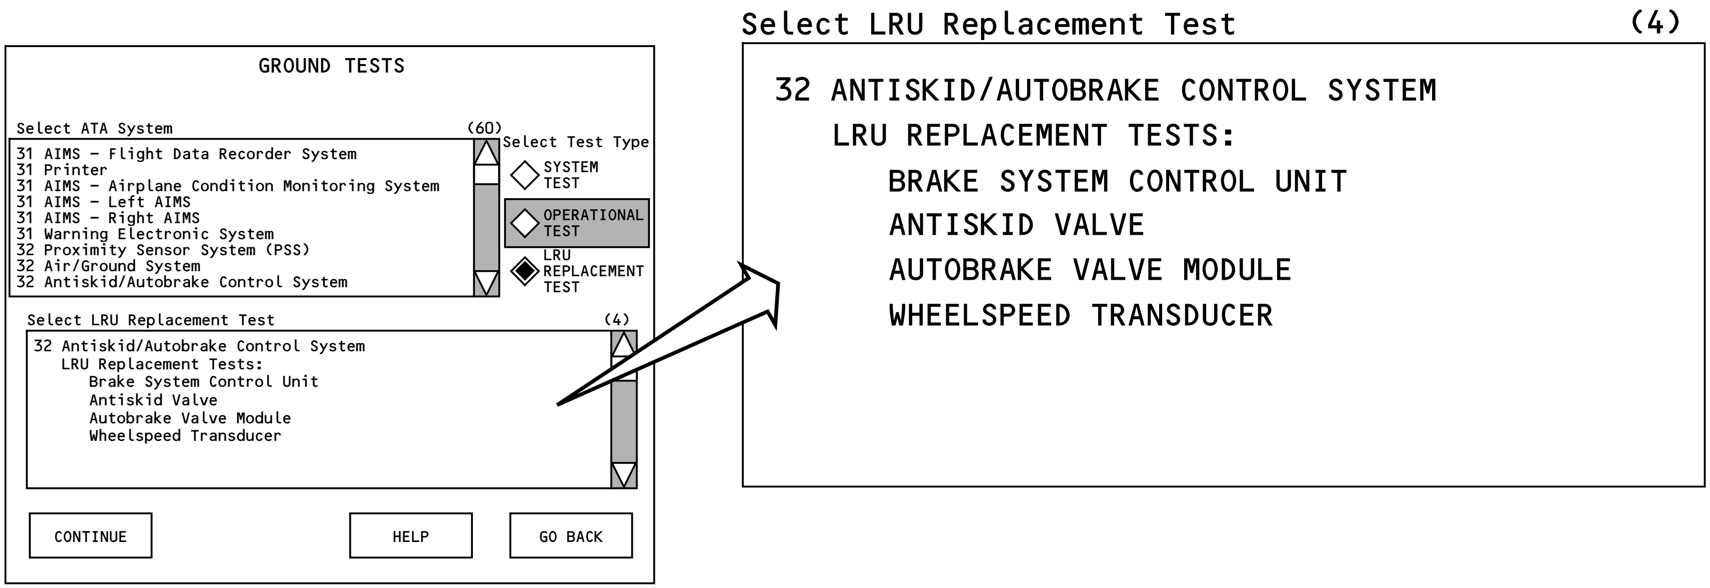
The autobrake valve module replacement test does a check of the autobrake system. The test applies and releases brake pressure to all of the brakes.

This test is the same as the autobrake application test in the system test menu.

Wheelspeed Transducer

The wheelspeed transducer replacement test lets you do a test of a selected antiskid transducer and its wiring. You manually turn the selected antiskid transducer during this test. You must turn the transducer at 20 rpm or more during the test.

This test is the same as the wheelspeed transducer spin test in the system test menu.



32-42-00-029 Rev 3 02/13/1997

ANTISKID/AUTOBRAKE SYSTEM - LRU REPLACEMENT TESTS

ANTISKID/AUTOBRAKE SYSTEM - SPECIAL FUNCTIONS

General

You use the antiskid indication disable function after you deactivate a brake. Brakes may be deactivated by three methods:

- Install a flight dispatch disconnect tool in the brake position on the related antiskid shuttle valve module (This deactivates normal braking only. Alternate braking is still available.)
- Disconnect the brake line
- Remove the brake.

You use the antiskid indication disable function to disable (remove) the ANTISKID advisory message for one MLG wheel on each MLG truck. This makes sure that the advisory message for antiskid failures on the selected wheel or wheels does not show.

The related ANTISKID status message can not be disabled.

This function also lets you operate the autobrake system with an antiskid failure.

Indication

When you use the indication disable function, a BRAKE message shows on the landing gear synoptic display next to the wheel selected. A BRAKE DEACT message also shows on the brake and steering maintenance page.

Training Information Point

This special function removes the ANTISKID advisory message only for the selected brake (one per truck). If an additional brake failure occurs, the ANTISKID advisory shows again. The advisory message can not be disabled (removed) with two brakes on the same truck failed or deactivated.

ANTISKID/AUTOBRAKE SYSTEM - SPECIAL FUNCTIONS

BRAKE TEMPERATURE MONITORING SYSTEM - INTRODUCTION

Purpose

The brake temperature monitoring system (BTMS) gets brake temperature inputs from the twelve main gear brakes and supplies this data for flight deck indication.

Components

These are the brake temperature monitoring system components:

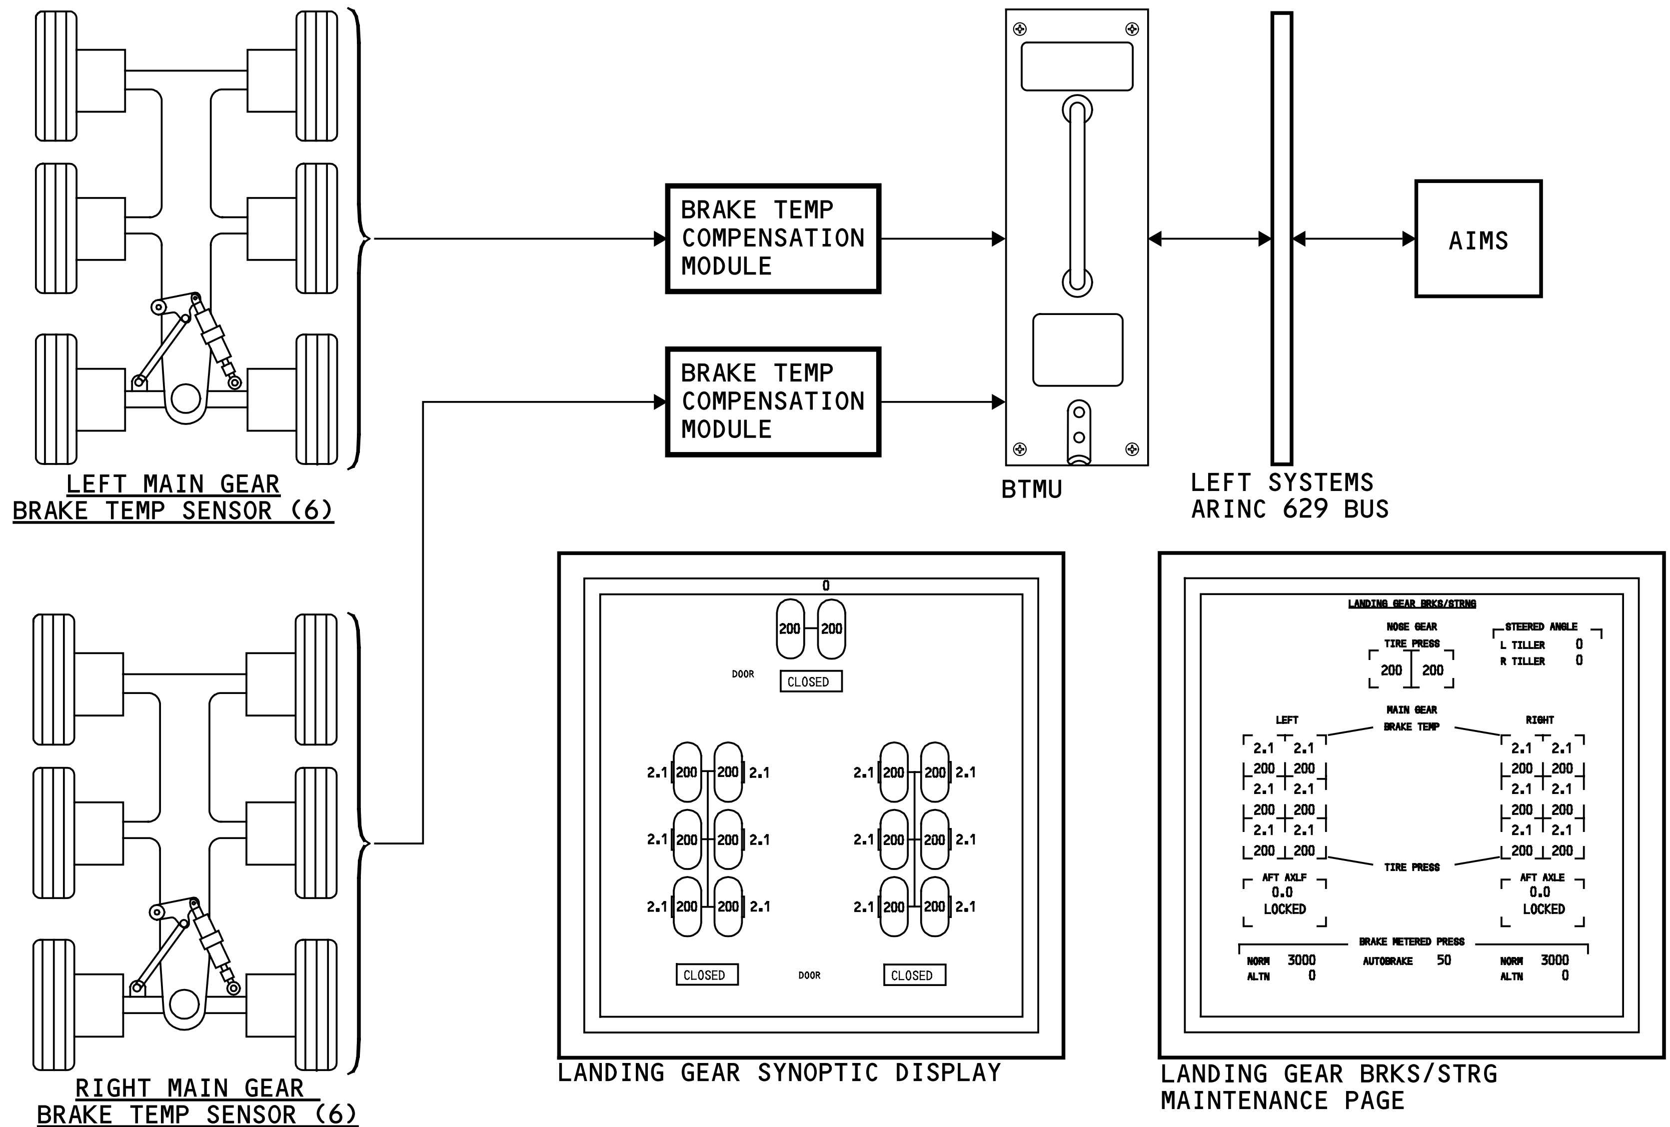
- Brake temperature sensor (12)
- Brake temperature compensation module (2)
- Brake temperature monitor unit (BTMU).

General Description

Brake temperature sensors send brake temperature data through the brake temperature compensation modules to the BTMU. The compensation modules supply a reference ambient temperature.

The BTMU sends brake temperature data to the AIMS through the left ARINC 629 system bus.

The multi-function display (MFD) shows brake temperature data on the landing gear synoptic display and on the landing gear brakes/steering maintenance page.



BRAKE TEMPERATURE MONITORING SYSTEM - INTRODUCTION

BRAKE TEMPERATURE MONITORING SYSTEM - SENSOR AND COMPENSATION MODULE

Brake Temperature Sensor

The brake temperature sensor is a thermocouple. It sends a brake temperature signal through the brake temperature compensation module to the BTMU.

A brake temperature sensor is near the bottom of the brake in each of the main gear brake assemblies.

Brake Temperature Compensation Module

The brake temperature compensation modules connect the thermocouple wire to the aircraft wiring.

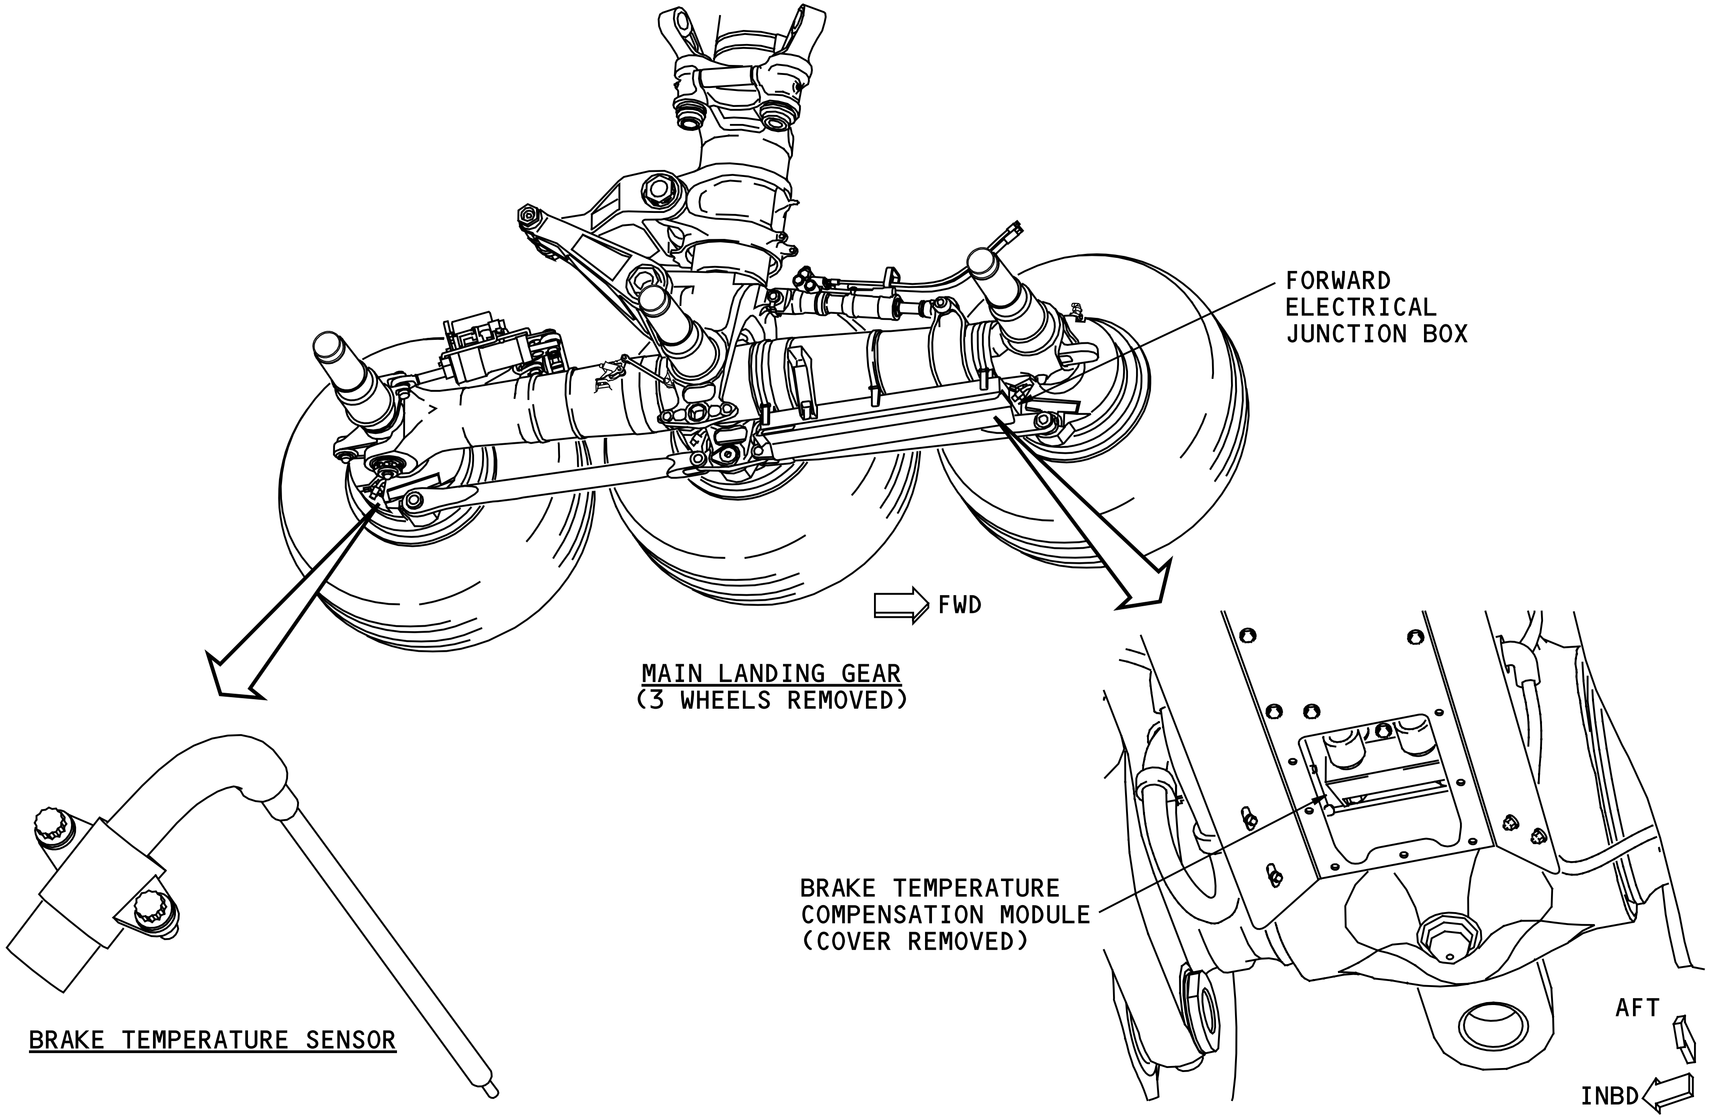
Two reference temperature sensors in each brake temperature compensation module supply reference ambient temperature signals to the BTMU. The BTMU uses this reference temperature to correct the brake temperature signals from the brake temperature sensors.

A brake temperature compensation module is in the forward electrical junction box on the bottom of each wheel truck.

Training Information Point

The brake temperature sensors are LRUs. The brake temperature compensation modules are also LRUs.

A cover on the forward electrical junction box permits easy access to the brake temperature compensation module.



32-46-00-002 Rev 3

BRAKE TEMPERATURE MONITORING SYSTEM - SENSOR AND COMPENSATION MODULE

BRAKE TEMPERATURE MONITORING SYSTEM - BRAKE TEMPERATURE MONITORING UNIT

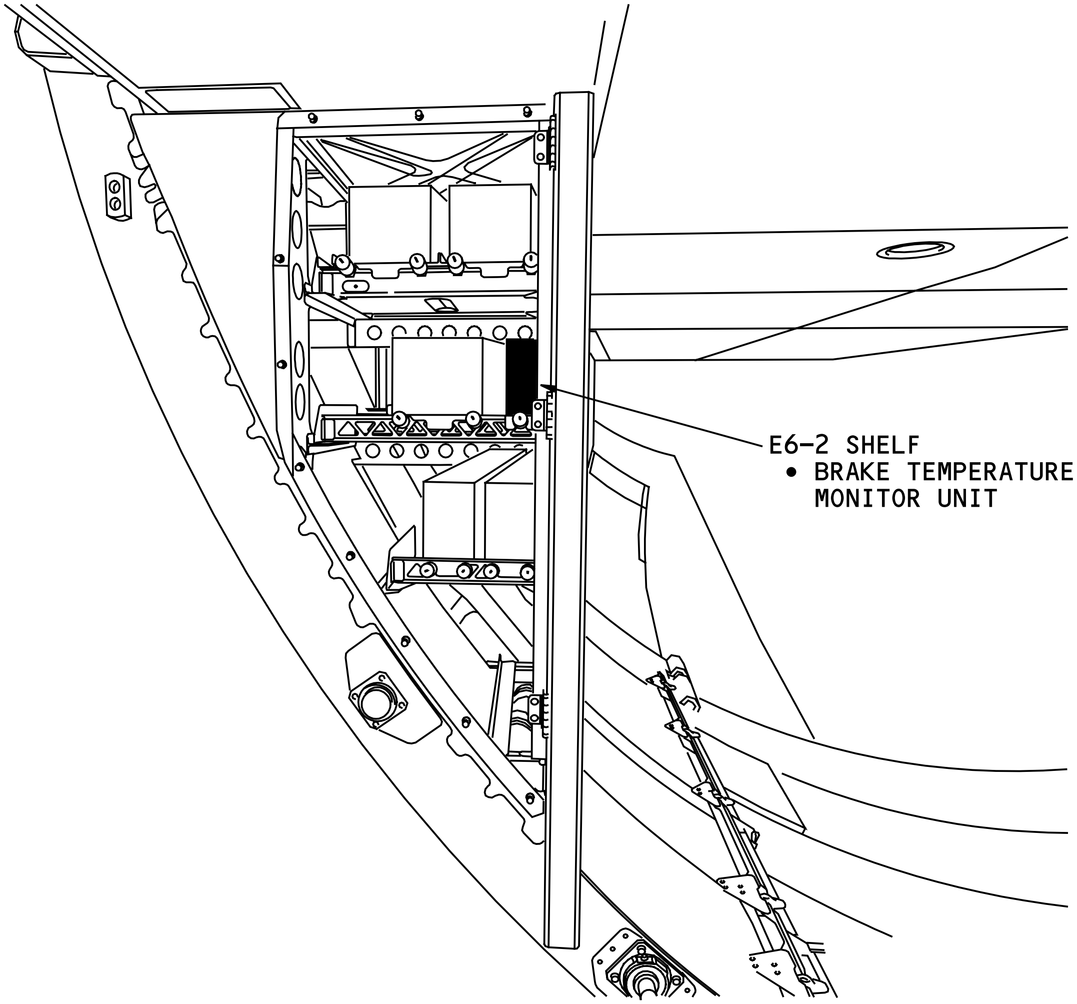
Purpose

The brake temperature monitor unit (BTMU) gets the brake temperature signals from the brake temperature sensors (through the brake temperature compensation modules) and supplies this data to the AIMS.

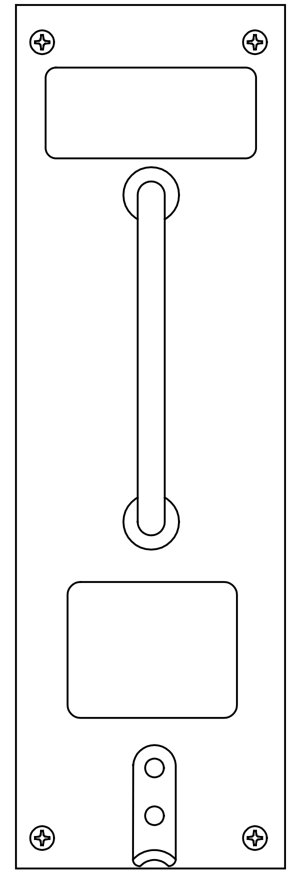
The BTMU also monitors the brake temperature monitoring system for faults.

Location

The BTMU is on the E6-2 shelf in the aft cargo compartment.



AFT CARGO COMPARTMENT
(LOOKING AFT)



BTMU

32-46-00-003 Rev 2

BRAKE TEMPERATURE MONITORING SYSTEM - BRAKE TEMPERATURE MONITORING UNIT

BRAKE TEMPERATURE MONITORING SYSTEM - FUNCTIONAL DESCRIPTION

General

The left 28v dc bus supplies the electrical power for the brake temperature monitoring system.

Brake Temperature Inputs

The brake temperature sensors in each of the wheel brakes send temperature signals to the brake temperature compensation modules.

The compensation modules supply ambient reference temperature signals.

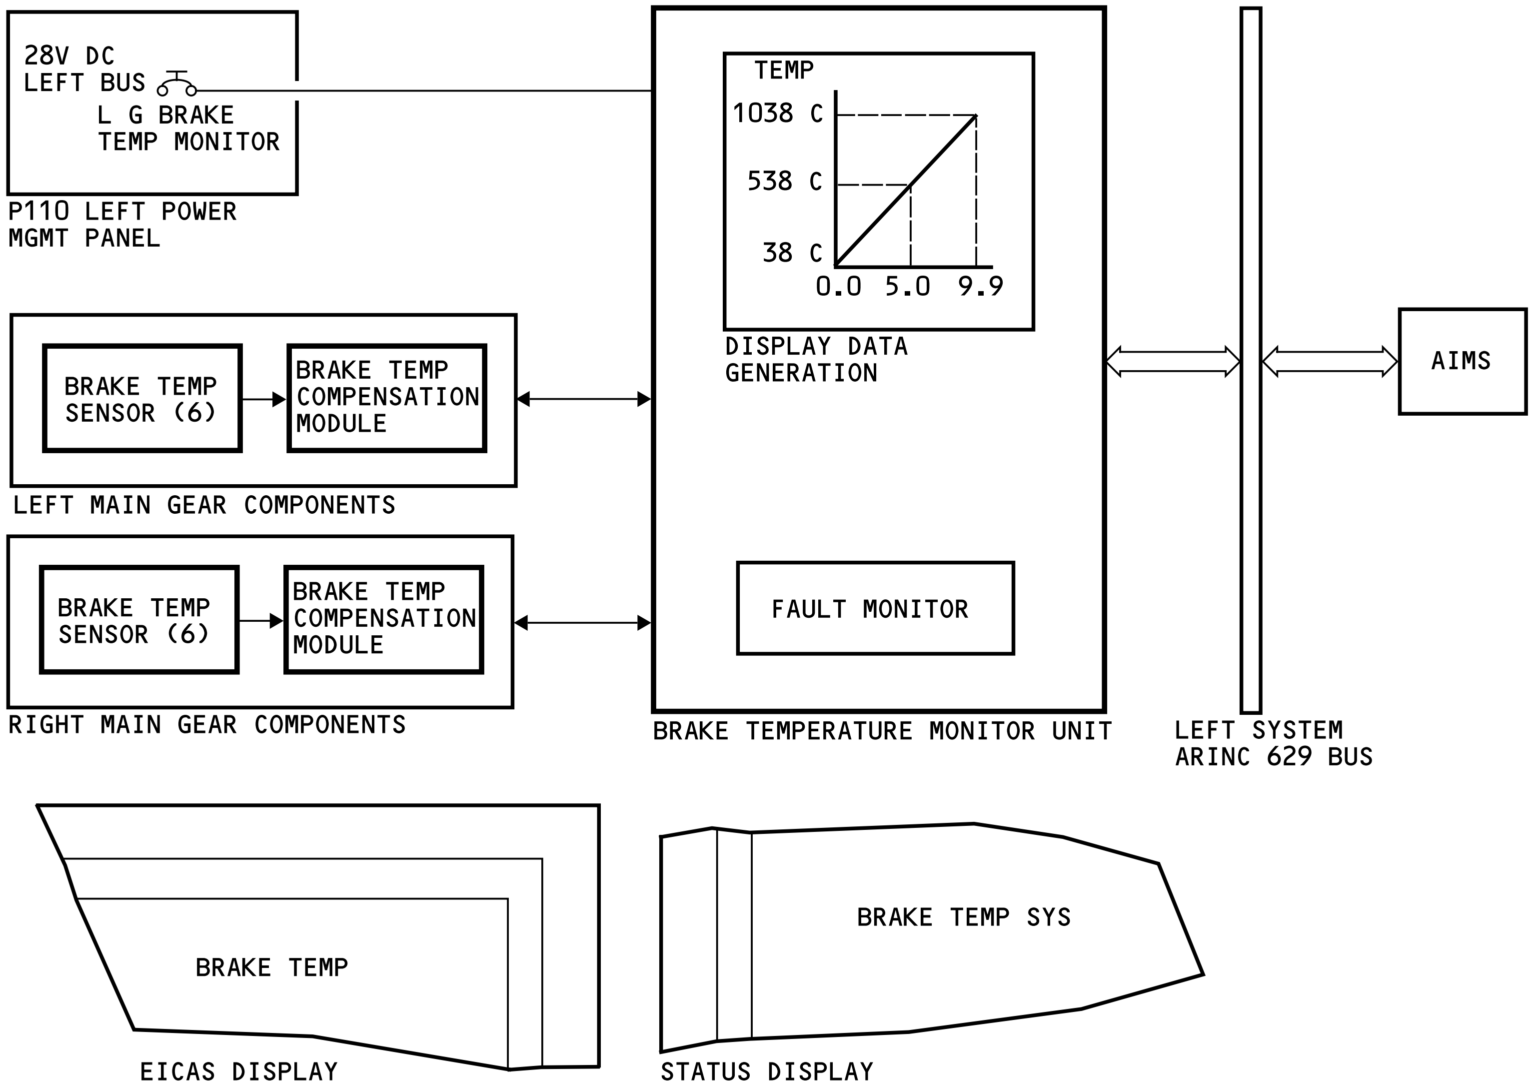
These inputs go to the brake temperature monitor unit.

BTMU Operation

The BTMU gets the brake temperature input and changes this data to a value between 0.0 and 9.9. This value goes to AIMS for flight deck display.

The BTMU also compares the brake temperature to specific advisory condition limits. The BRAKE TEMP advisory message shows when brake temperature is more than these limits.

A fault monitor in the BTMU monitors the BTMS components for faults. The status message BRAKE TEMP SYS shows when there is a loss of brake temperature indication function.



32-46-00-004 Rev 3

BRAKE TEMPERATURE MONITORING SYSTEM - FUNCTIONAL DESCRIPTION

BRAKE TEMPERATURE MONITORING SYSTEM - INDICATION

General

Brake temperature indication shows on the landing gear synoptic display and the brake and steering maintenance page.

Brake Temperature Indication

Brake temperature between approximately 38C (100F) and 1038C (1900F)shows as a number on a linear scale between 0.0 and 9.9.

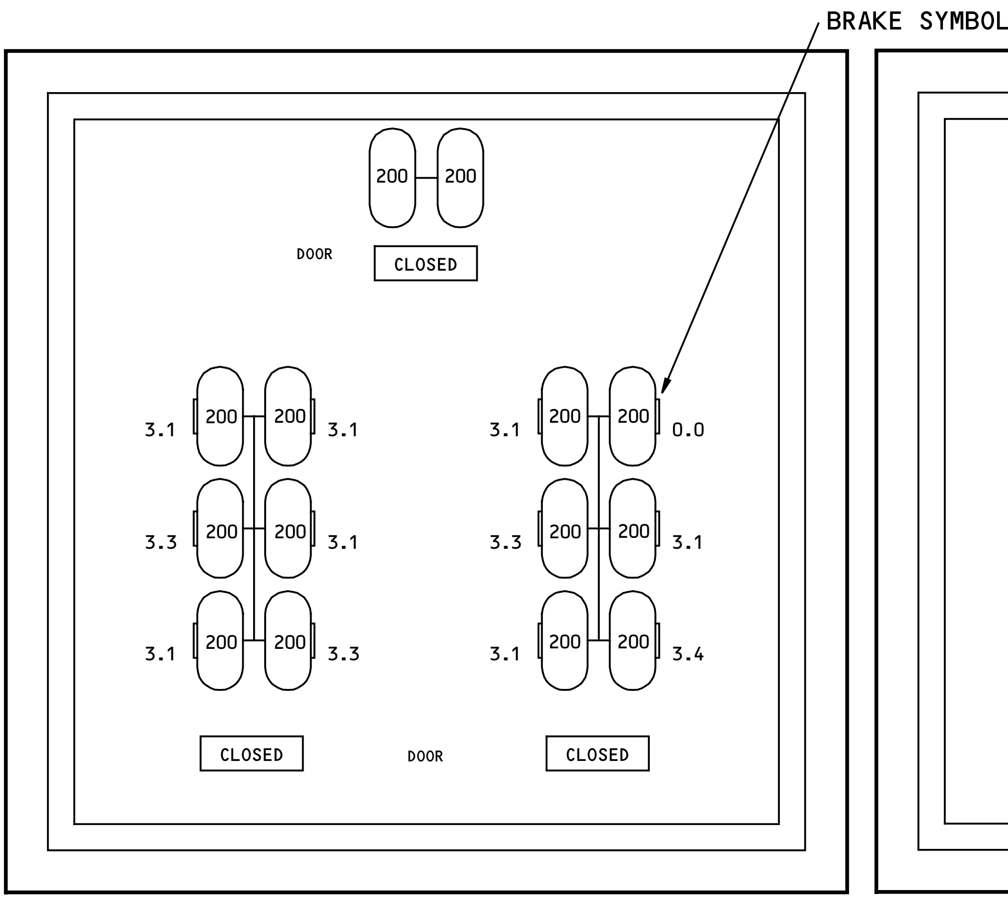
On the landing gear synoptic display, the values less than 5.0 show in white. A solid white brake symbol shows the hottest brake on each main gear truck between 3.0 and 4.9. If two brakes on one truck are the same temperature, the solid white brake symbol shows the brake that first went to that temperature.

When the brake temperature is 5.0 or more, the number changes to amber and the brake symbol changes to a solid amber. All brake temperatures above 5.0 will show this indication. The amber indication stays on until the brake temperature decreases to less than 4.0.

A BRAKE TEMP message shows on the EICAS display if there is an amber temperature indication.

Training Information Point

If the brake temperatures are more than 5.0, the wheel thermal fuse plugs may melt.



LANDING GEAR SYNOPTIC DISPLAY

BRAKE TEMPERATURE MONITORING SYSTEM - INDICATION

TIRE PRESSURE INDICATION SYSTEM - INTRODUCTION

Purpose

The tire pressure indication system measures the tire pressures for the two nose gear and 12 main gear tires.

Components

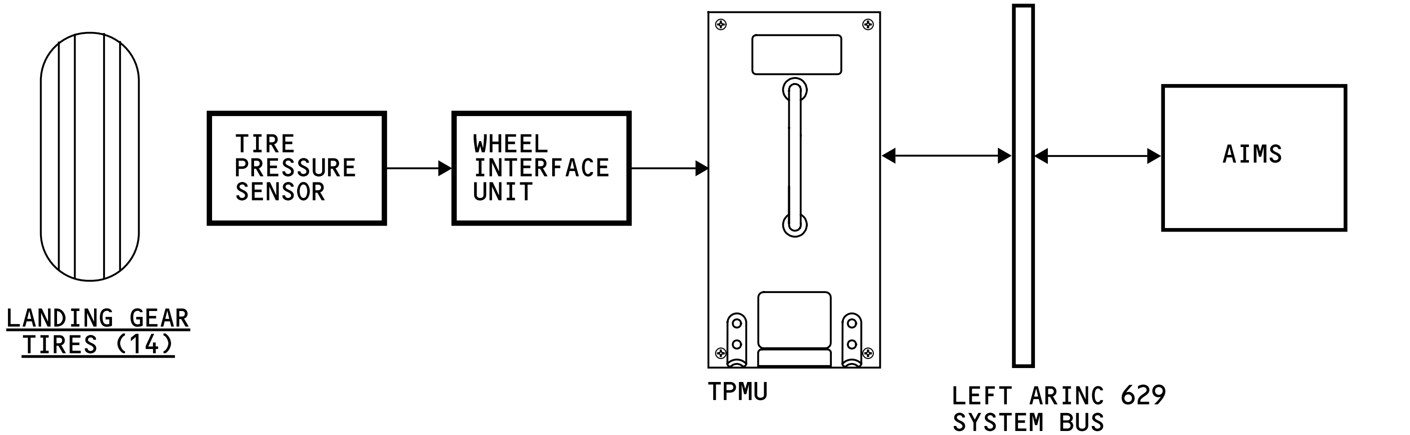
These are the tire pressure indicating system components:

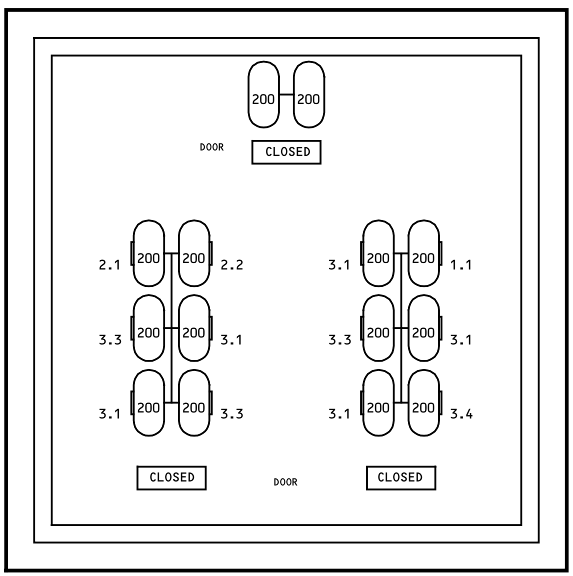
- Tire pressure sensor (14)
- Wheel interface unit (WIU) (14)
- Tire pressure monitor unit (TPMU).

General Description

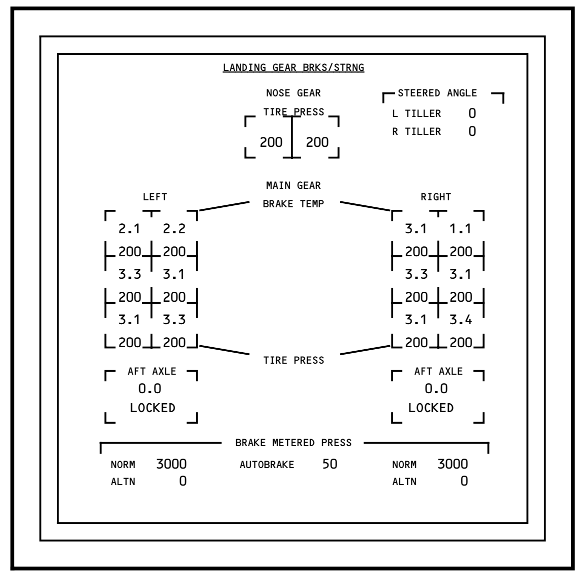
The TPMU sends tire pressure data to AIMS through the left ARINC 629 bus.

The MFD shows tire pressure data on the landing gear synoptic display and brake and steering maintenance page.





LANDING GEAR SYNOPTIC DISPLAY



BRAKE AND STEERING MAINTENANCE PAGE

TIRE PRESSURE INDICATION SYSTEM - INTRODUCTION

TIRE PRESSURE INDICATION SYSTEM - TIRE PRESSURE MONITOR UNIT

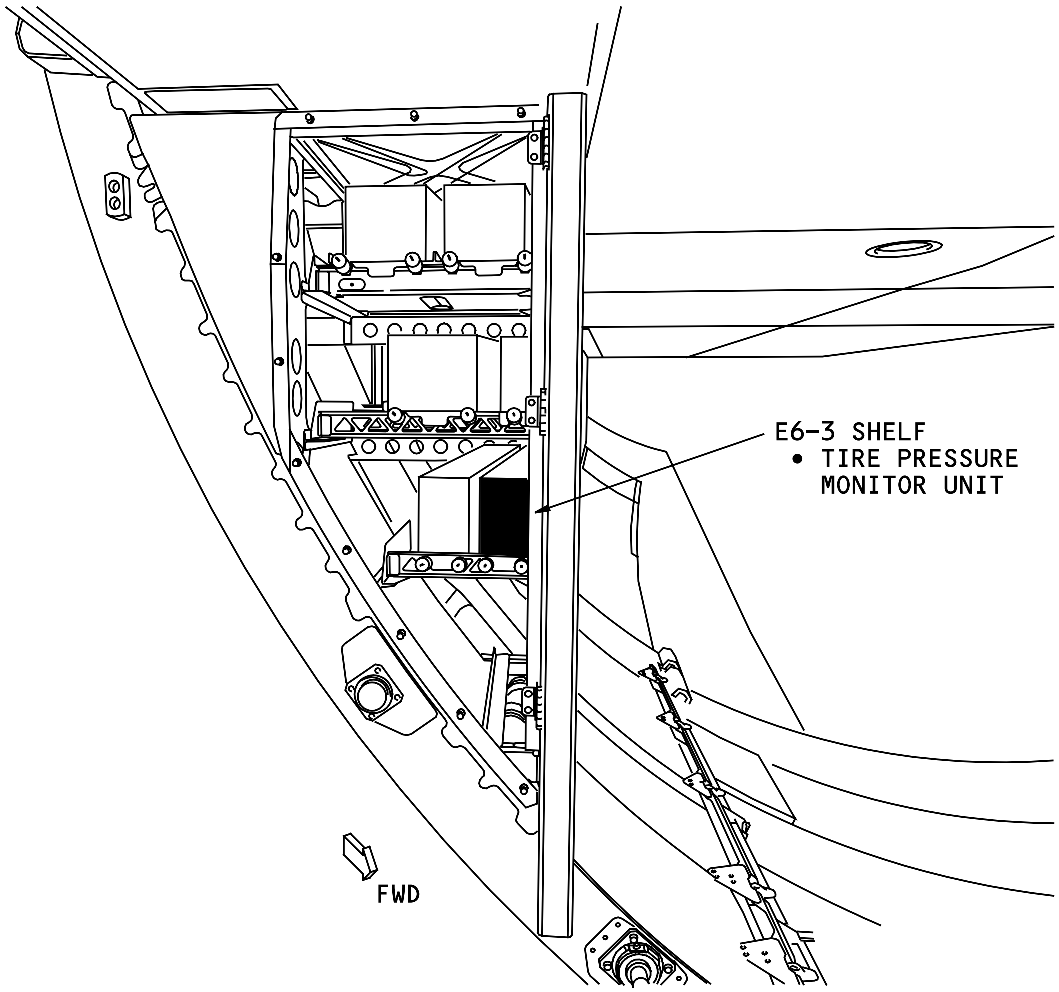
Purpose

The TPMU supplies power to the WIUs and the tire pressure sensors. It gets the tire pressure inputs and sends this data to the AIMS.

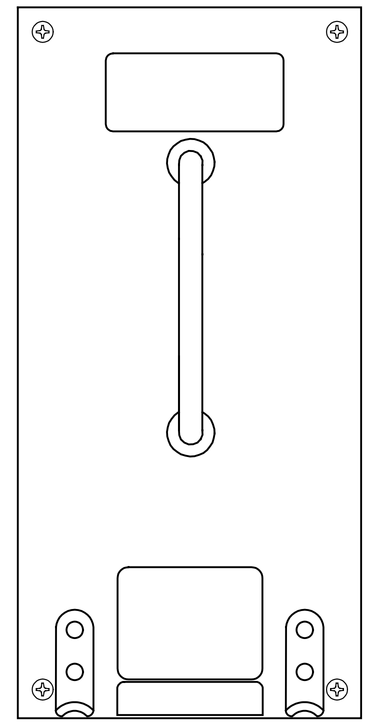
The TPMU also monitors the tire pressure indication system components for faults.

Location

The TPMU is on the E6-3 shelf in the aft cargo compartment.



AFT CARGO COMPARTMENT
(LOOKING AFT)



TPMU

32-49-00-003 Rev 1

TIRE PRESSURE INDICATION SYSTEM - TIRE PRESSURE MONITOR UNIT

TIRE PRESSURE INDICATION SYSTEM - FUNCTIONAL DESCRIPTION

Power Supply

The left 28 v dc MAIN bus supplies the electrical power to operate the tire pressure indication system.

TPMU - Tire Pressure Sensor

The TPMU supplies an excitation signal to each of the 14 wheel interface units.

The wheel interface unit sends the signal across the rotating interface of the wheel to the tire pressure sensor.

Tire Pressure Sensor - TPMU Signal

The tire pressure sensor sends a dc voltage signal that is in proportion to the tire pressure.

The wheel interface unit transmits the signal across the rotating interface of the wheel back to TPMU.

TPMU Operation

The TPMU gets the tire pressure signals and sends them to AIMS for flight deck display.

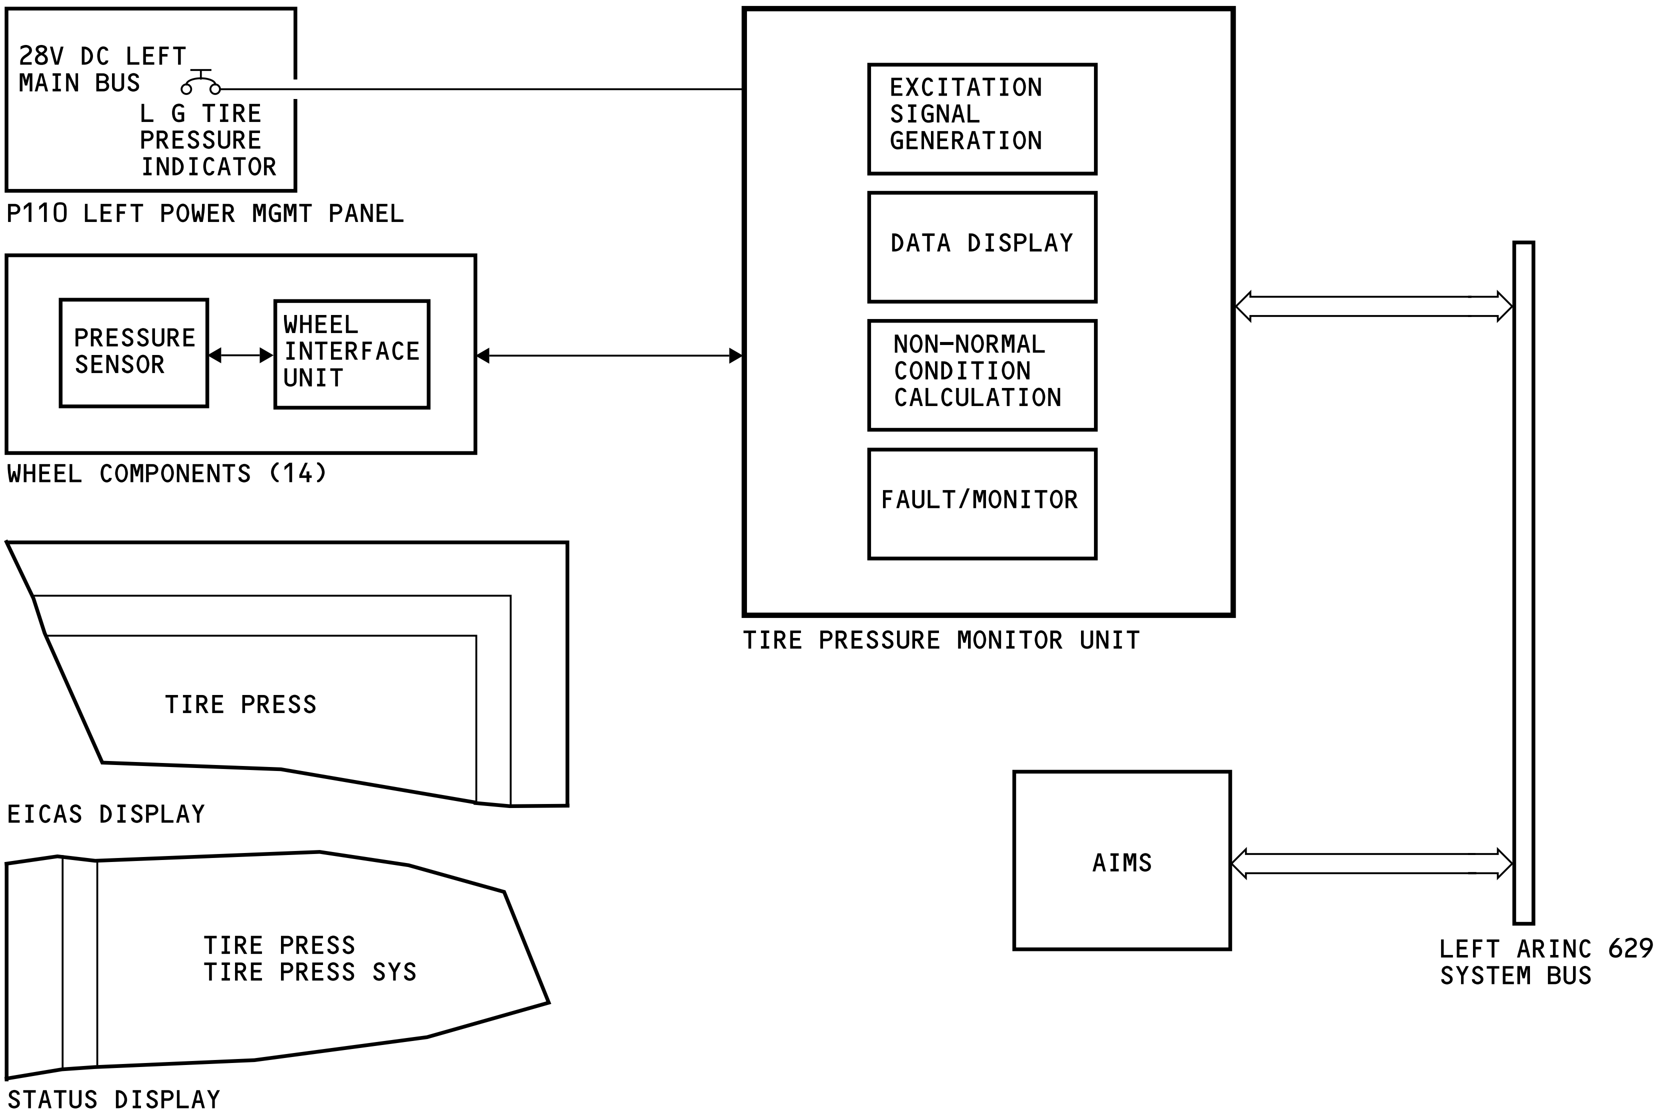
The TPMU also calculates non-normal tire pressure conditions and shows these EICAS messages:

- TIRE PRESS (Advisory) - non-normal tire pressure conditions
- TIRE PRESS (Status) - non-normal tire pressure conditions.

Non-normal tire pressure conditions include:

- Tire pressure below 100 psi
- Main gear tire pressure different from average tire pressure by 18 percent (the TPMU calculates average tire pressure by discarding the three highest and the three lowest tire pressures and averaging the middle six tire pressures)
- More than 25 percent difference in pressure between main gear tires on the same axle
- More than 12 percent difference between the nose gear tire pressures.

A fault monitor in the TPMU monitors TPIS components and interfaces for faults. The status message TIRE PRESS SYS shows if there is a fault.



32-49-00-004 Rev 1

TIRE PRESSURE INDICATION SYSTEM - FUNCTIONAL DESCRIPTION

TIRE PRESSURE INDICATION SYSTEM - INDICATIONS

General

Tire pressure indication, shows in psi on the landing gear synoptic display and the brake and steering maintenance page.

Tire Pressure Indication

The landing gear synoptic display and the brake and steering maintenance page show normal tire pressure in white.

The tire pressure display changes to amber to show non-normal pressure conditions.

Non-normal conditions also cause a message to show on the EICAS display.

The tire display will go out of view if there is a Loss of pressure data or if the pressure data is invalid.

LANDING GEAR - GENERAL - INTRODUCTION

Purpose

Landing gear structural components hold the weight of the airplane while the airplane is on the ground. These are the landing gear structural systems:

- The main landing gear (MLG) and doors (section 32-10)
- The nose landing gear (NLG) and doors (32-20).

Landing gear extension-retraction systems extends and retracts the landing gear to reduce airplane drag in flight. These are the landing gear extension-retraction systems:

- The landing gear control system (32-31)
- The main landing gear extension and retraction (32-32)
- The nose landing gear extension and retraction (32-34)
- The landing gear alternate extension system (32-35).

FLIGHT CONTROLS - INTRODUCTION

General

The flight controls keep the airplane at the desired attitude during flight. They consist of movable surfaces on the wing and the empennage. The flight controls change the lift of the wing and the empennage.

There are two types of flight controls: the primary flight control system and the high lift control system.

Primary Flight Control System

The primary flight control system (PFCS) uses a fly-by-wire control system with digital and analog electronic equipment. It receives commands from the flight crew and the autopilot and causes the control surfaces to move.

The PFCS controls the attitude of the airplane during flight. The control surfaces operated by the PFCS are:

- One aileron on each wing
- One flaperon on each wing
- Seven spoilers on each wing
- One horizontal stabilizer
- One elevator on each side of the horizontal stabilizer
- One tabbed rudder.

High Lift Control System

The high lift control system (HLCS) uses a fly-by-wire control system with digital electronic equipment. It receives commands from the flight crew and causes the flaps and slats to move.

Operation of the HLCS increases the wing lift so the airplane can takeoff and land at lower speed and higher weight. The high lift devices operated by the HLCS are:

- Seven leading edge slats on each wing
- One Krueger flap on each wing
- One single slotted outboard flap on each wing
- One double slotted inboard flap on each wing.

Operation of the HLCS also causes the ailerons and the flaperons to move. They droop on both wings when the high lift devices extend.

Benefits of the Fly-By-Wire System

The fly-by-wire design of the flight controls permits:

- A more efficient structure design
- Increased fuel economy
- A smaller vertical fin
- A smaller horizontal stabilizer
- Reduced weight
- Improved controls and protections.

Abbreviations and Acronyms

ACE - actuator control electronics
ACMS - airplane condition monitoring system
ADIRS - air data inertial reference system
ADIRU - air data inertial reference unit

FLIGHT CONTROLS - INTRODUCTION

PRIMARY FLIGHT CONTROL SYSTEM - INTRODUCTION

Purpose

The primary flight control system (PFCS) controls the airplane flight attitude in relation to the three basic axes:

- Longitudinal
- Lateral
- Vertical.

Roll Control

The roll control uses the ailerons, flaperons, and spoilers to control the airplane attitude about the longitudinal axis. During a bank of the airplane, the aileron and flaperon on one wing move in an opposite direction from the aileron and flaperon on the other wing. The spoilers move up only on the down wing and do not move on the up wing.

Pitch Control

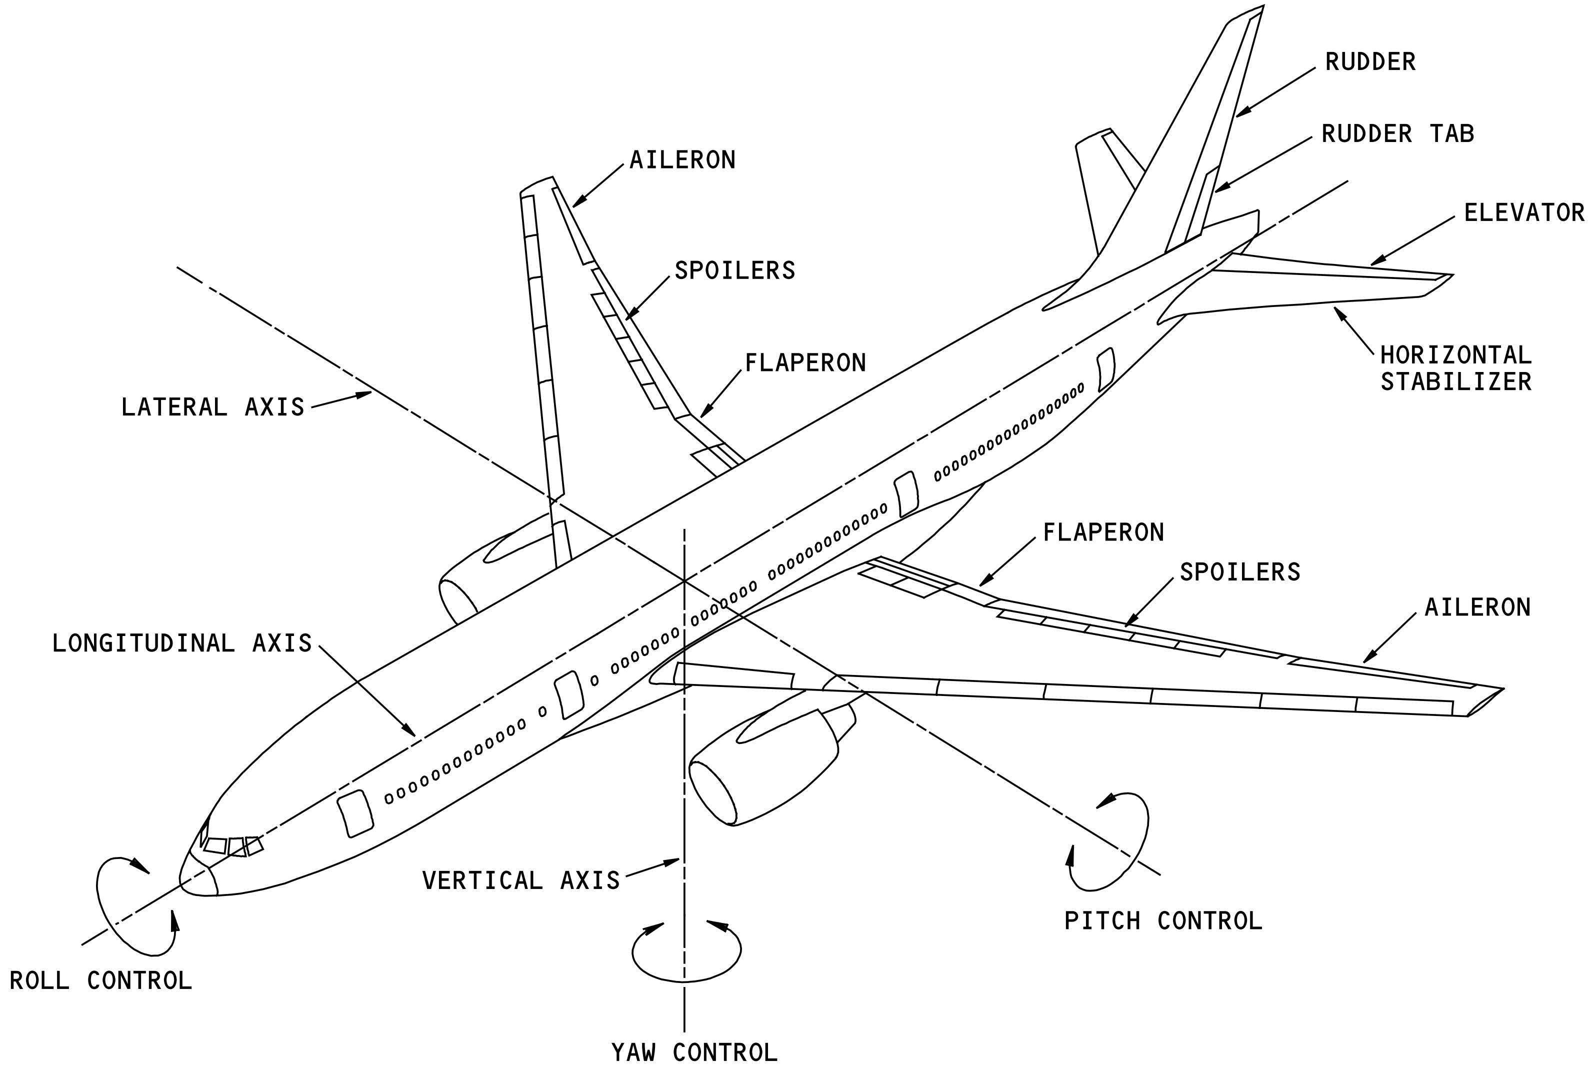
The pitch control uses the horizontal stabilizer and the elevator to control the airplane attitude about the lateral axis. The stabilizer controls long term pitch changes. The elevator supplies short term pitch control.

Yaw Control

The yaw control uses the rudder to control the airplane attitude about the vertical axis. The rudder has a tab which moves to increase the effectiveness of the rudder.

Speedbrakes

The PFCS also includes the speedbrakes. In addition to roll control, the spoilers also act as speedbrakes in the air and on the ground. They deploy on both wings to increase drag and to decrease the amount of lift the wings supply.



27-02-00-001 Rev 0

PRIMARY FLIGHT CONTROL SYSTEM - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

PFCS - GENERAL DESCRIPTION

General

The pilots or the autopilot commands control the PFCS. The pilots can override the autopilot.

Manual Operation

Position transducers change the pilots' manual commands of the control wheel, the control columns, the rudder pedals, and the speedbrake lever to analog electrical signals. These signals go to the four actuator control electronics (ACEs). The ACEs change the signals to digital format and send them to the three primary flight computers (PFCs).

The PFCs have interfaces with the airplane systems through the three flight controls ARINC 629 buses. In addition to command signals from the ACEs, the PFCs also receive data from:

- The airplane information management system (AIMS)
- The air data inertial reference unit (ADIRU)
- The secondary attitude air data reference unit (SAARU).

The PFCs calculate the flight control commands based on control laws and flight envelope protection functions. The control laws supply stability augmentation in the pitch and yaw axes and flight envelope protections in all three axes. The digital command signals from the PFCs go to the ACEs.

The ACEs change these command signals to analog format and send them to the power control units (PCUs) and the stabilizer trim control modules (STCMs). The ACEs and the PCUs form control loops which control the surfaces based on the PFCs commands.

One, two or three PCUs operate each control surface. One PCU controls each spoiler, two PCUs control each aileron, flaperon, and elevator, and three PCUs control the rudder. The PCUs contain a hydraulic actuator, an electrohydraulic servo valve, and a position feedback transducer.

When commanded, the servo valve causes the hydraulic actuator to move the control surface. The position transducer sends a position feedback signal to the ACEs. The ACEs then stop the PCU command when the position feedback signal equals the commanded position.

Two STCMs control hydraulic power to the motors and brakes of the horizontal stabilizer.

Autopilot Operation

The PFCs receive autopilot commands from all three autopilot flight director computers (AFDCs). The PFCs use the autopilot commands in the same manner as the pilots' manual commands. In addition, the PFCs supply the backdrive signals to the backdrive actuators through the AFDCs. The backdrive actuators move the control wheels, control columns, and rudder pedals in synchronization with the autopilot commands. The movement of the flight deck controls supplies visual indications to the flight crew.

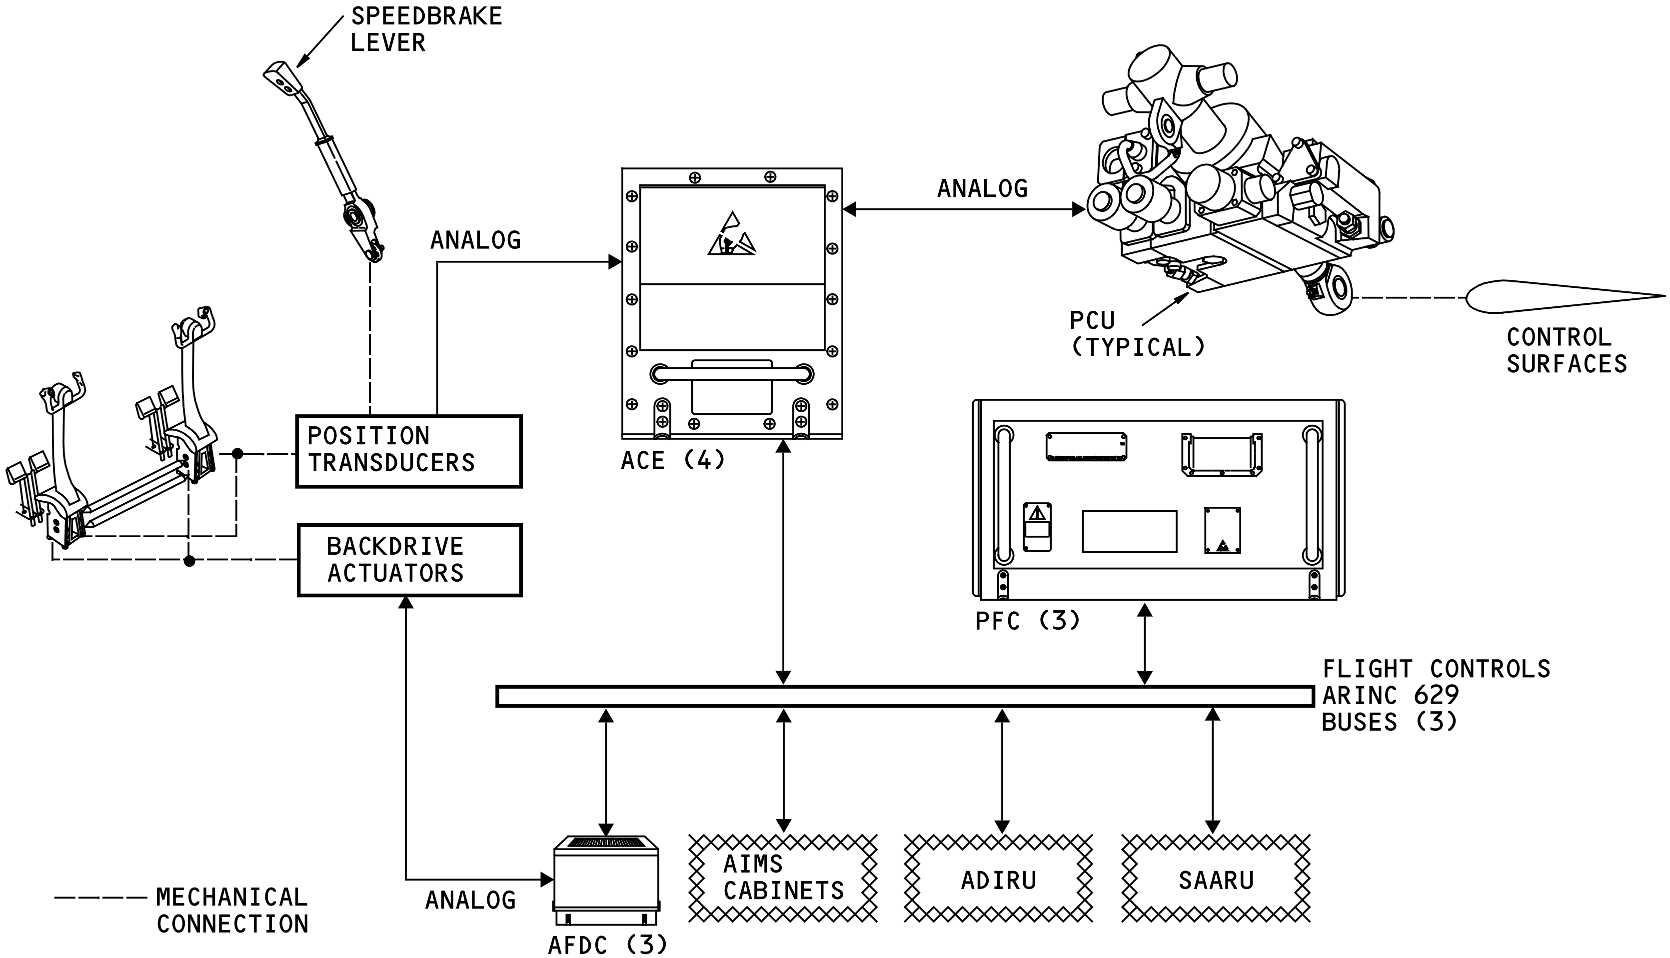
PFCS Modes of Operation

The PFCS has three modes of operation: normal, secondary, and direct.

Normal mode operates when the necessary data are available for the PFCs and the ACEs. All the control laws, protection functions, and the AFDCs operate.

When the PFCS detects the loss of important air and attitude data, the PFCS operation changes to secondary mode. The PFCs and the ACEs operate but the PFC control laws and protection functions downgrade. The autopilot cannot operate in secondary mode.

In direct mode, the PFCs are not used. The ACEs set the position of the control surfaces in direct response to analog pilot control inputs.



27-02-00-002 Rev 4

PFCS - GENERAL DESCRIPTION

PFCS - COMPONENT LOCATION

Flight Deck Controls

The control wheel, control column, and rudder pedal position transducers are below the flight deck floor in the forward equipment center. The speedbrake lever position transducers are in the control stand. The location of these transducers is shown in other sections.

Main Equipment Center

The E1, E2, and E3 racks contain most of the electronic equipment of the PFCS.

The E1 rack contains:

- The left PFC
- The L1 ACE
- The L2 ACE.

The E2 rack contains:

- The center PFC
- The center ACE
- The SAARU.

The E3 rack contains the ADIRU.

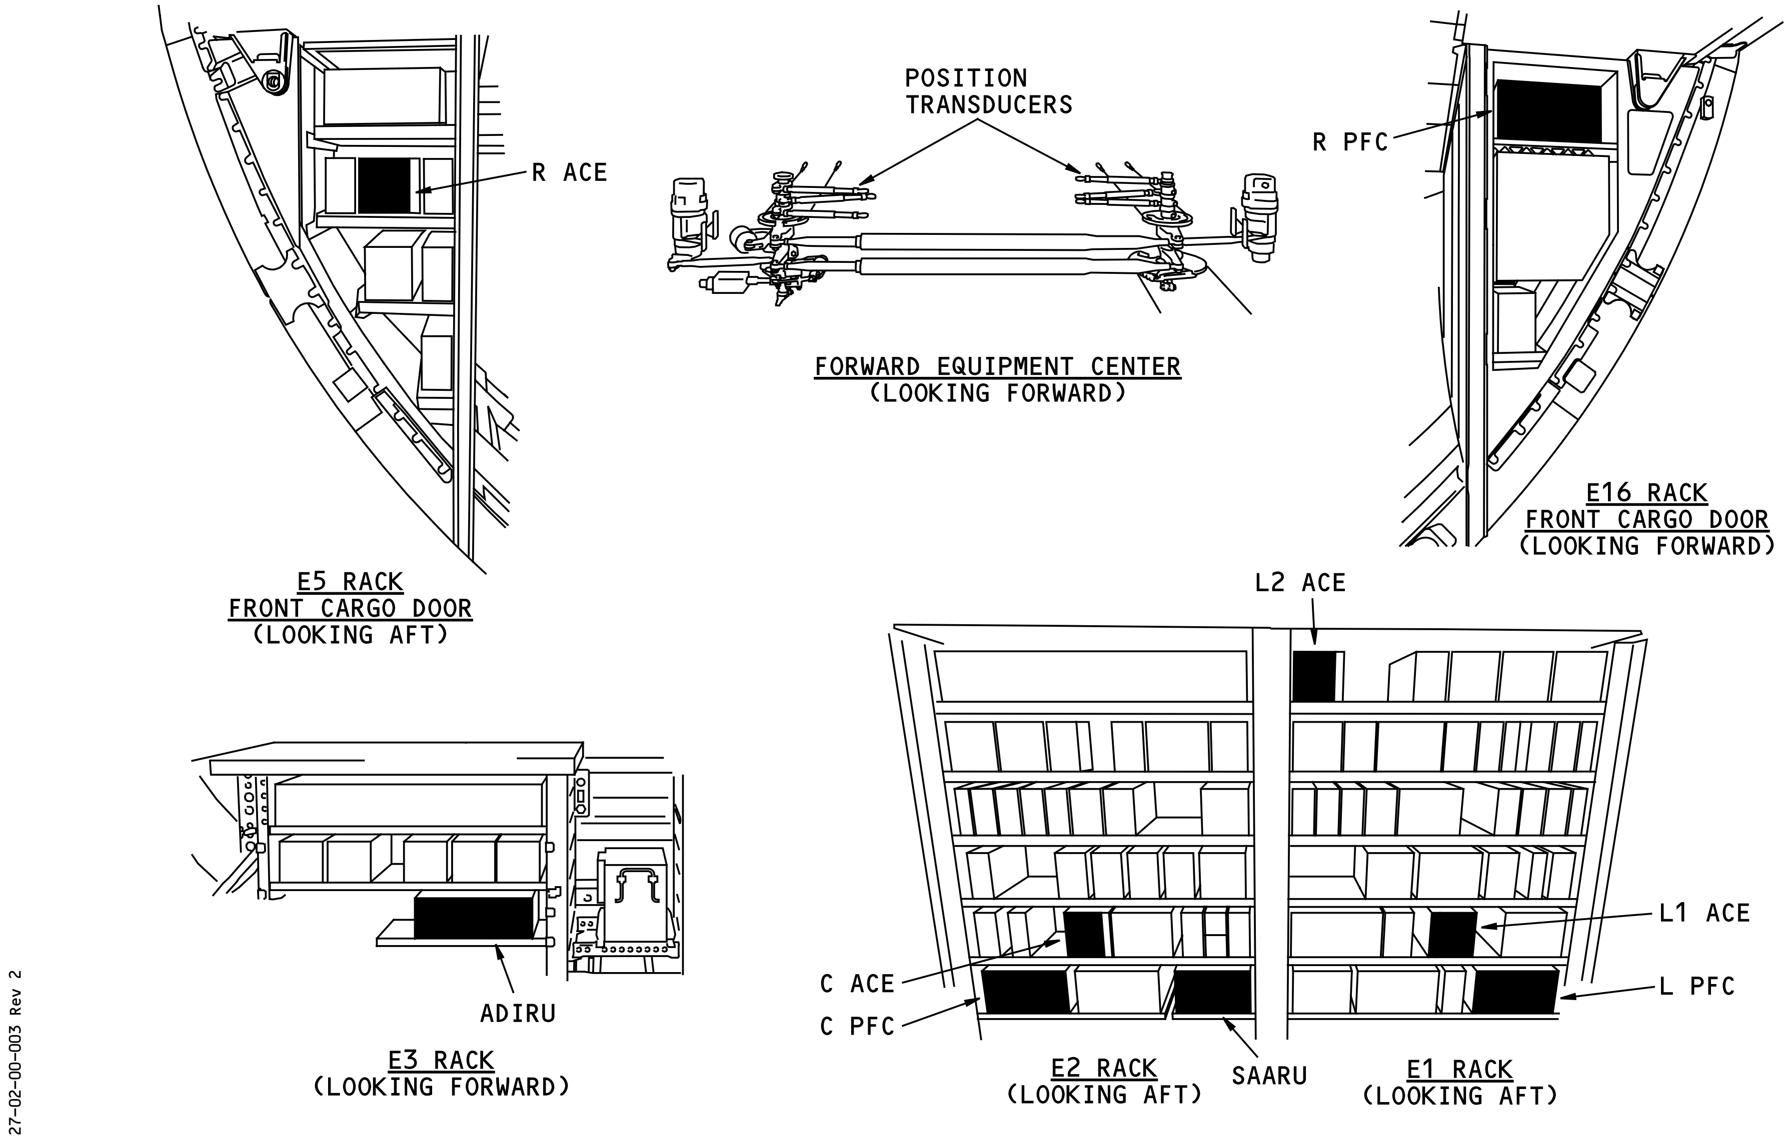
Forward Cargo Compartment

The E16 rack, forward of the forward cargo door, contains the right PFC.

The E5 rack, aft of the forward cargo door, contains the right ACE.

Control Surfaces

Each PCU connects directly to its related control surface on the wing and the empennage. The ballscrew actuator of the horizontal stabilizer is in the stabilizer compartment. The location of the PCUs and the ballscrew actuator is shown in their specified sections.



PFCS - COMPONENT LOCATION

THIS PAGE INTENTIONALLY LEFT BLANK

PFCS - FLIGHT CONTROLS ARINC 629 BUS INTERFACES

General

ARINC 629 digital data buses supply the principal means of communication among airplane systems. Three dedicated flight controls ARINC 629 buses connect the PFCS to:

- The three autopilot flight director computers (AFDC)
- The two airplane information management system (AIMS) cabinets
- The air data inertial reference unit (ADIRU)
- The secondary attitude air data reference unit (SAARU).

Physical separation of the buses, and redundant LRUs, protects against multiple failures due to one event.

PFCS Interface

The three primary flight computers (PFCs) and the four actuator control electronics (ACEs) have interfaces with the flight controls data buses.

The L PFC, C PFC and R PFC receive data from all three flight controls data buses but transmit data only on their on-side data bus. (On-side means that the relationship is with equipment of the same side. For example, the left bus is the on-side bus for the left PFC.)

Each ACE receives data from all three PFCs through the three flight controls data buses. Each ACE processes control data from its on-side PFC. If this data is not valid, the ACE processes data from an alternate PFC. The ACEs process some data from the other PFCs at all times. For example, this occurs during data validation and voted commands. The ACEs transmit only on their on-side bus.

AFDS Interface

The autopilot flight director system (AFDS) interfaces with the PFCS through the autopilot flight director computers (AFDCs). Each AFDC transmits to its on-side flight controls data bus, but receives data from all three buses. The AFDCs receive backdrive commands, engagement status, and other data from the PFCs. The AFDCs transmit pitch, roll and yaw commands and engage requests to the PFCs.

AIMS Interface

The two AIMS cabinets receive data from all three flight controls data buses, but normally transmit only to their on-side bus. During tests on the ground, the AIMS cabinets transmit also to the center bus.

The PFCS supplies information to the AIMS for:

- The primary display system (PDS), (flight, synoptic, and EICAS displays)
- The central maintenance computing system (CMCS)
- The airplane condition monitoring system (ACMS)
- The flight management computing system (FMCS)

PFCS - FLIGHT CONTROLS ARINC 629 BUS INTERFACES

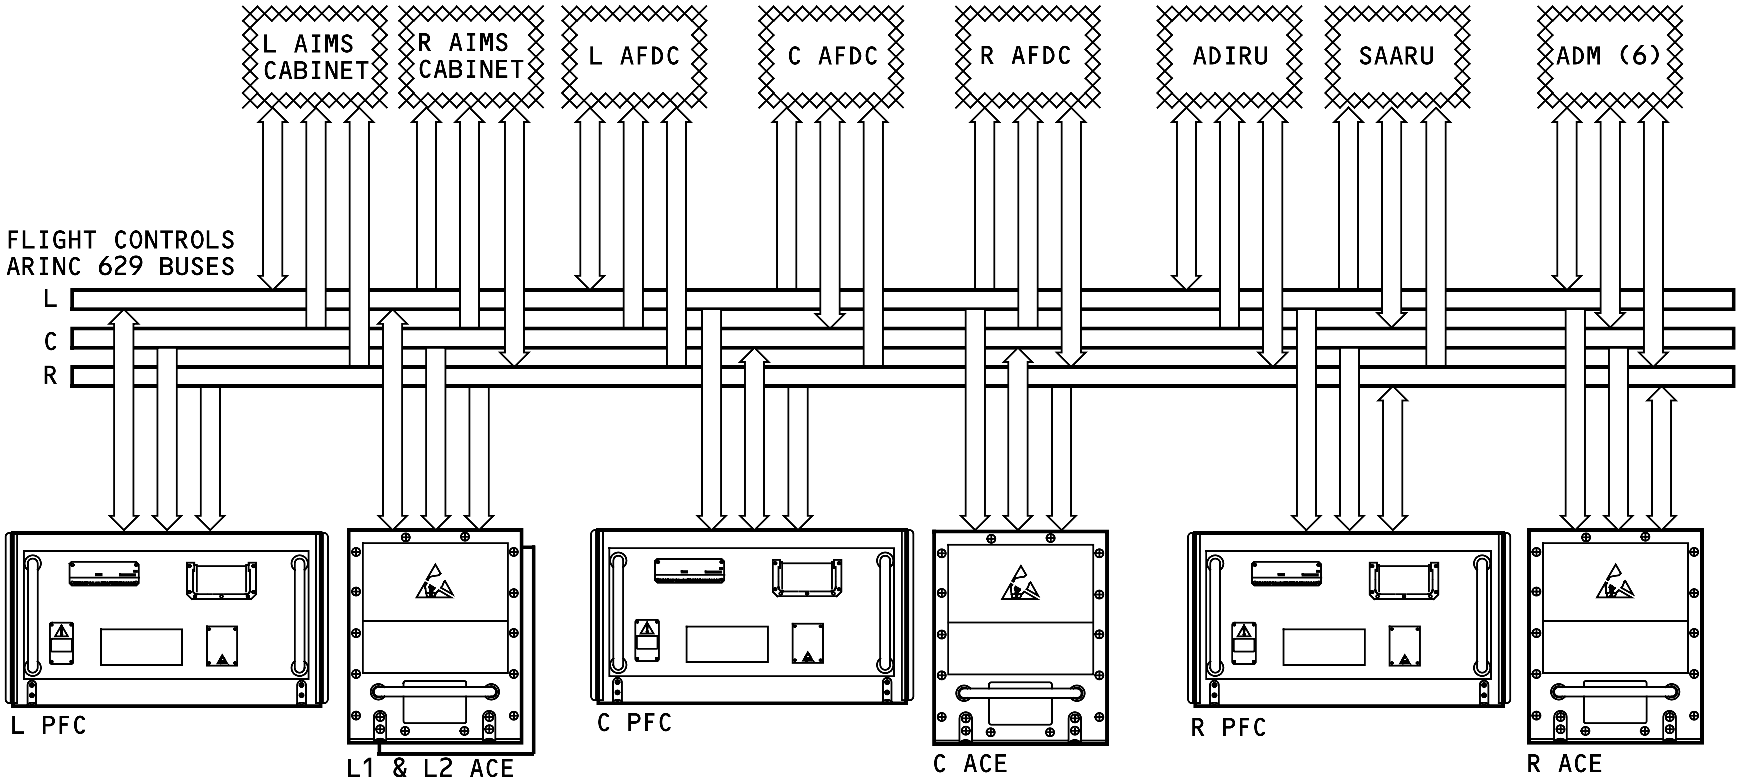
ADIRS Interface

The air data inertial reference system (ADIRS) consists of the air data inertial reference unit (ADIRU) and the secondary attitude air data reference unit (SAARU).

The ADIRU and SAARU supply air data variables and inertial data to the PFCs. The ADIRU receives data from all three buses and transmits data to the left and right flight controls data buses. The SAARU also receives data on all three buses, but transmits data only to the center flight controls data bus.

Air Data Modules

Six air data modules (ADMs) supply pitot and static air data to the ADIRU and the SAARU. The ADMs transmit these data through the flight controls ARINC 629 buses.



27-02-00-004 Rev 3

PFCS - FLIGHT CONTROLS ARINC 629 BUS INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

PFCS - SYSTEMS ARINC 629 BUS INTERFACES

General

Many components of the PFCS transmit to and receive information from other airplane systems. Data on the systems ARINC 629 buses goes through the AIMS data conversion gateway function and then to the flight control ARINC 629 buses. The PFCS uses information from:

- The flap/slat electronics units (FSEUs)
- The proximity sensor electronics units (PSEUs)
- The left and right systems card files.

The PFCS transmits information to the left and right warning electronic units (WEUs).

The PFCS also uses radio altimeter data supplied through AIMS.

FSEU Interface

The FSEUs supply flaps and slats signals to the PFCs for the gain functions of the control laws. These signals show the retracted or not retracted condition of the flaps and the slats. The FSEUs also supply a signal to the ACEs.

PSEU Interface

The PSEUs supply truck tilt signals and associated fault messages to the PFCS. The truck tilt signals are used together with the weight on wheels and radio altimeter functions to operate the auto speedbrake.

Systems Card Files Interface

The two systems card files supply signals from the hydraulic interface module (HYDIM) cards and the weight on wheels (WOW) cards to the PFCS.

The HYDIM cards supply hydraulic systems condition signals to the PFCS. They also supply data about the truck tilt pressure sensors.

The WOW cards supply air/ground signals to the PFCS. These signals supply air/ground information to the PFCS.

WEU Interface

The PFCS sends stabilizer and rudder trim position signals to the WEUs. The WEUs supply a takeoff warning if the stabilizer is out of green band or the rudder trim is out of normal limits.

The PFCs receive stall data from the WEUs for stall protection.

Engine Data Interface Units

The left and right engine data interface units (EDIUs) receive the N1 speed and calculate the thrust for each engine. The EDIUs supply these data to the AIMS and to the PFCS for the thrust asymmetry compensation (TAC) function.

PFCS - SYSTEMS ARINC 629 BUS INTERFACES

Radio Altimeter Interface

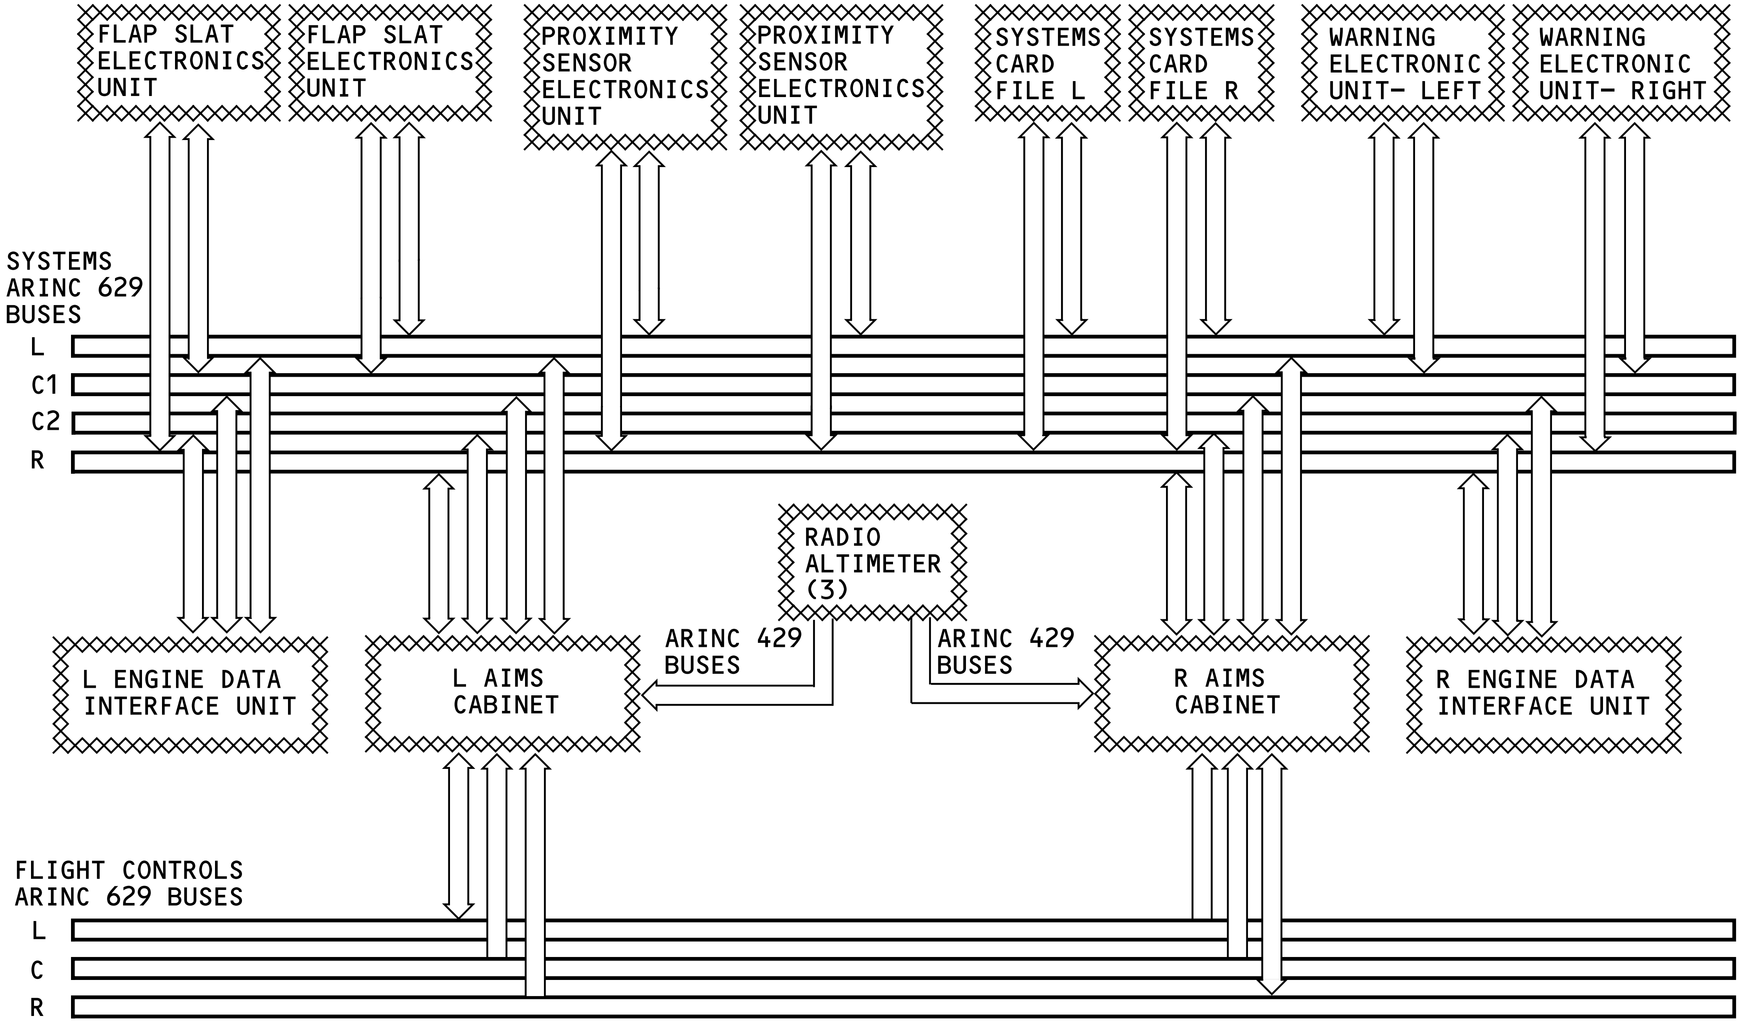
The three radio altimeters supply information to AIMS for use by the PFCS for the flare function during manual landing. The PFCS inhibits the radio altimeter test when ground speed is more than 40 knots and during flight.

Indications

The status message PFCS INTERFACE shows because of one of these faults:

- There is a disagreement with the flap discrete signals in two or more ACEs
- Only two of the four FSEU channels are available
- Only two of the four digital WES channels are available
- Only one of the two truck tilt pressure data sources is available
- Thrust data from one of the left or right EDIU channels does not agree with the others
- Data from the two WOW cards does not agree.

These conditions cause the message to show in normal, secondary, and direct modes.



PFCS - SYSTEMS ARINC 629 BUS INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

PFCS - ANALOG INTERFACES

General

All analog interfaces with the PFCS go to the ACE. The primary inputs/outputs are:

- Rudder trim selector
- Manual trim cancel switch
- Pitch trim switches
- Flight control position transducers
- Flight control force transducers
- FSEUs
- Primary flight computers DISC/AUTO switch
- Thrust asymmetry compensation switch
- AIMS cabinets
- PCUs.

Rudder Trim Selector and Manual Trim Cancel Switch

The rudder trim selector and the manual trim cancel switch supply signals to the ACEs. These signals show the pilot commands for rudder trim.

Pitch Trim Switches

The pitch trim switches supply signals to the ACEs to show the pilot pitch trim commands.

Flight Control Position Transducers

The flight control position transducers supply electrical inputs to the ACEs. They show the position of the:

- Control wheel
- Control column
- Rudder pedals
- Speedbrake lever.

Flight Control Force Transducers

The pitch and roll force transducers supply signals to the ACEs. The signals show when the pilot applies a force to the control wheel or control column.

FSEUs

The FSEUs supply a signal to each ACE showing that the flaps and slats are retracted or not retracted.

Primary Flight Computers DISC/AUTO switch

The primary flight computers DISC/AUTO switch supplies a signal to each ACE that shows the switch position. Switch positions are AUTO or DISC.

Thrust Asymmetry Compensation Switch

The thrust asymmetry compensation (TAC) switch supplies a signal to the C ACE that shows the switch position. The switch positions are AUTO or OFF.

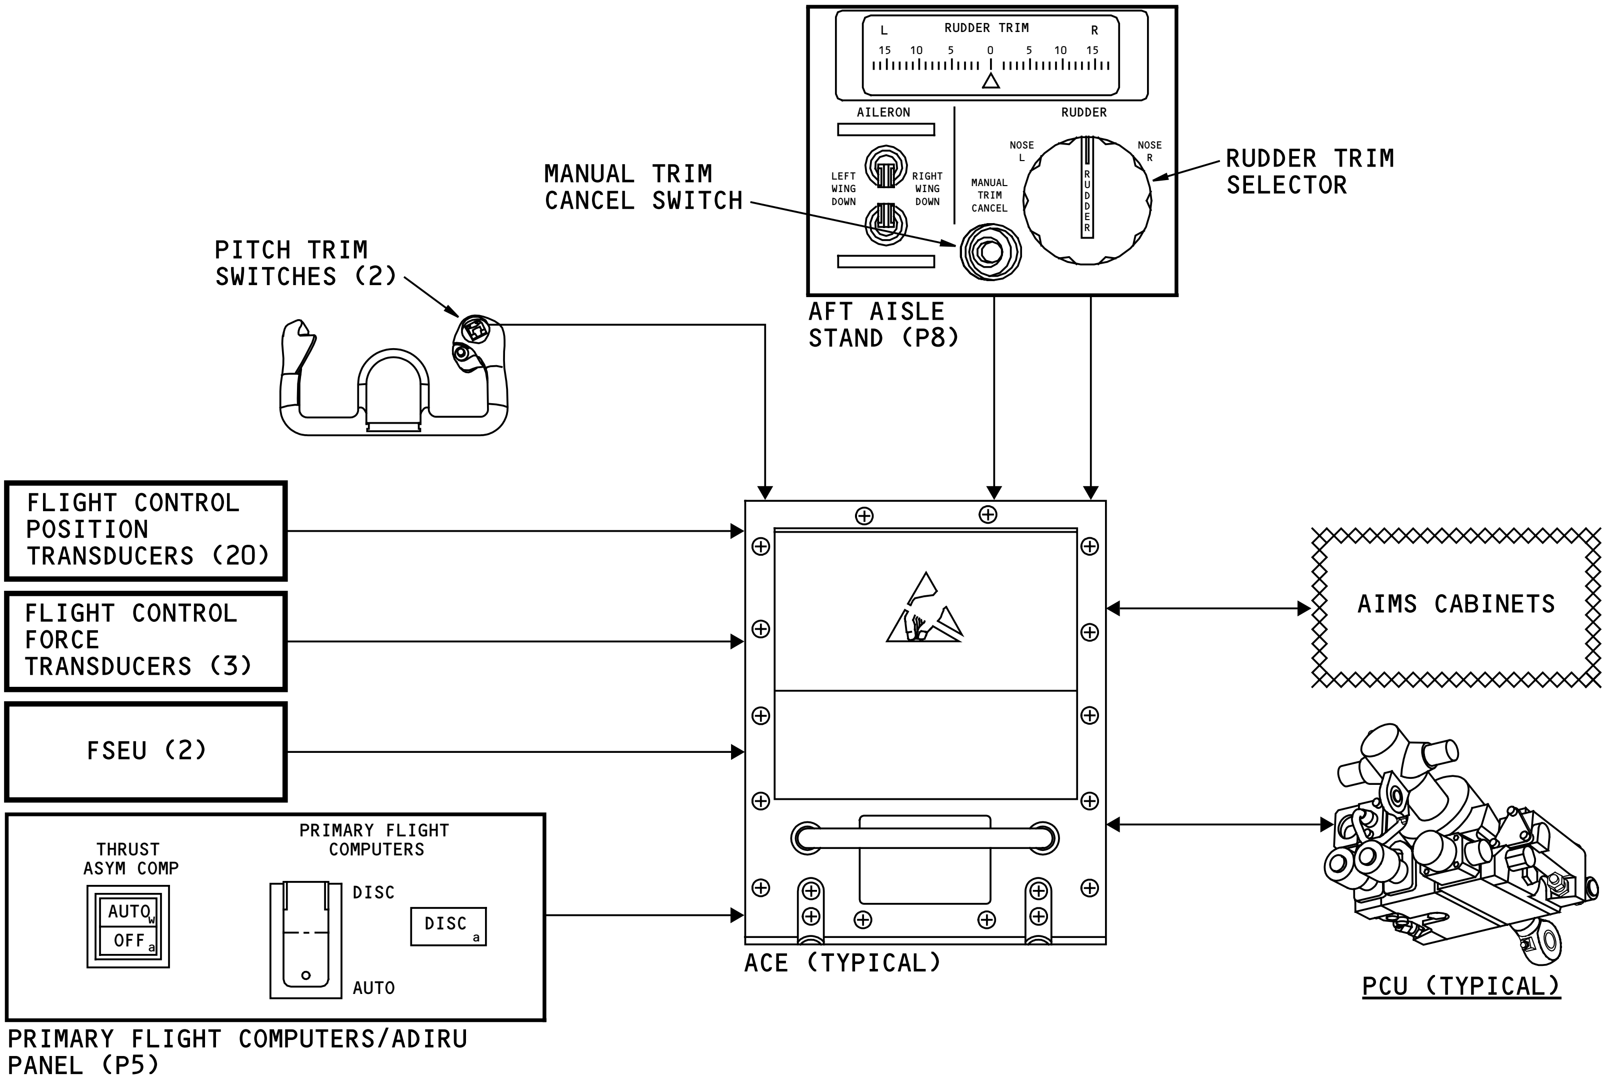
AIMS Cabinets

Each ACE supplies two signals to both AIMS cabinets. The signals show that the ACE is in the direct mode and the ACE power supply is correct.

PFCS - ANALOG INTERFACES

PCUs

The ACEs supply command signals to the PCUs. The PCUs supply position feedback signals to the ACE.



27-02-00-006 Rev 6 04/29/95

PFCS - ANALOG INTERFACES

PFCS - ELECTRICAL POWER DISTRIBUTION

General

Because the electrical power supply to the PFCS is very critical, a high level of redundant power is available.

Power Supply Assembly

Three identical power supply assemblies (PSAs) supply 28v dc to the components of their on-side portion of the PFCS. The PSAs supply electrical power to the ACEs, the PFCs, the PCUs and the STCMs. In addition, the PSAs supply power for the rudder trim, the auto speedbrake, the ADMs and the SAARU.

See the flight controls dc power section for more information (AMM PART I 24-35).

PSA Power Sources

During flight, the left PSA normally receives primary power from one permanent magnet generator (PMG) on the left engine. The right PSA receives primary power from one PMG on the right engine. The center PSA receives primary power from two PMGs, one on each engine. The PSAs change the ac variable electrical power from the PMGs to 28v dc.

If the primary power is not available or not within specified limits, the left and right PSAs change to secondary power from the left and right 28v dc buses. Secondary power to the center PSA is from the captain's flight instrument bus.

When the airplane is on the ground and no engines are running, the PSAs normally change to secondary power.

If primary and secondary power is not available or not within specified limits, the PSA changes to backup power. The left and center PSAs receive backup power from the hot battery bus. The right PSA has no backup power.

Each PSA has a dedicated flight control dc battery (FCDC BATT). It supplies the flight control components with power for one minute during PSA switching.

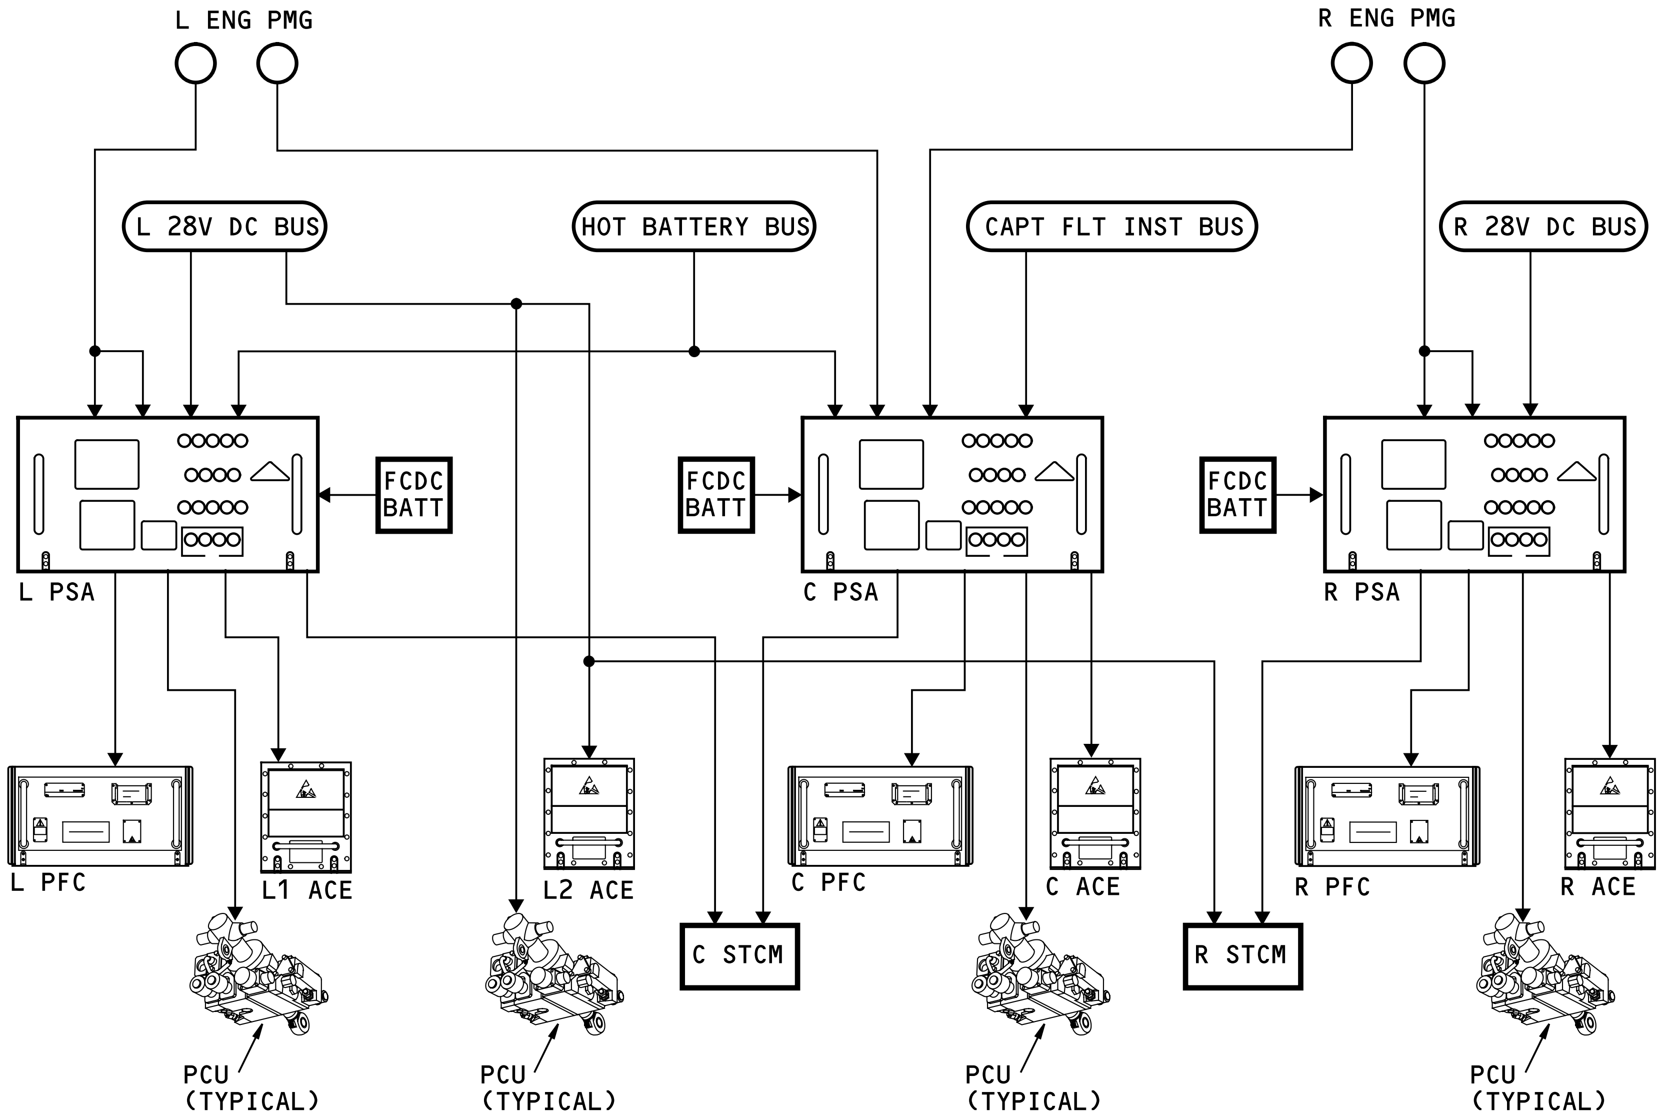
Power to L2 ACE

The L2 ACE and its related PCUs have only one power supply from the left 28v dc bus in the P110 left power management panel. In addition, the left 28v dc bus supplies power for the stabilizer commands, the elevator feel and the aileron/rudder trim module.

Training Information Point

There are circuit breakers on the front of the PSAs and the P110 left power management panel. They control power to the components of the PFCS.

If electrical power is shutdown with a PFC deactivated or removed, the FCDC battery discharges. To prevent FCDC battery discharge, open the applicable circuit breakers on the PSA. When electrical power is available, close the circuit breakers.



PFCS - ELECTRICAL POWER DISTRIBUTION

PFCS - HYDRAULIC POWER AND ACE DISTRIBUTION

Hydraulic Power Distribution

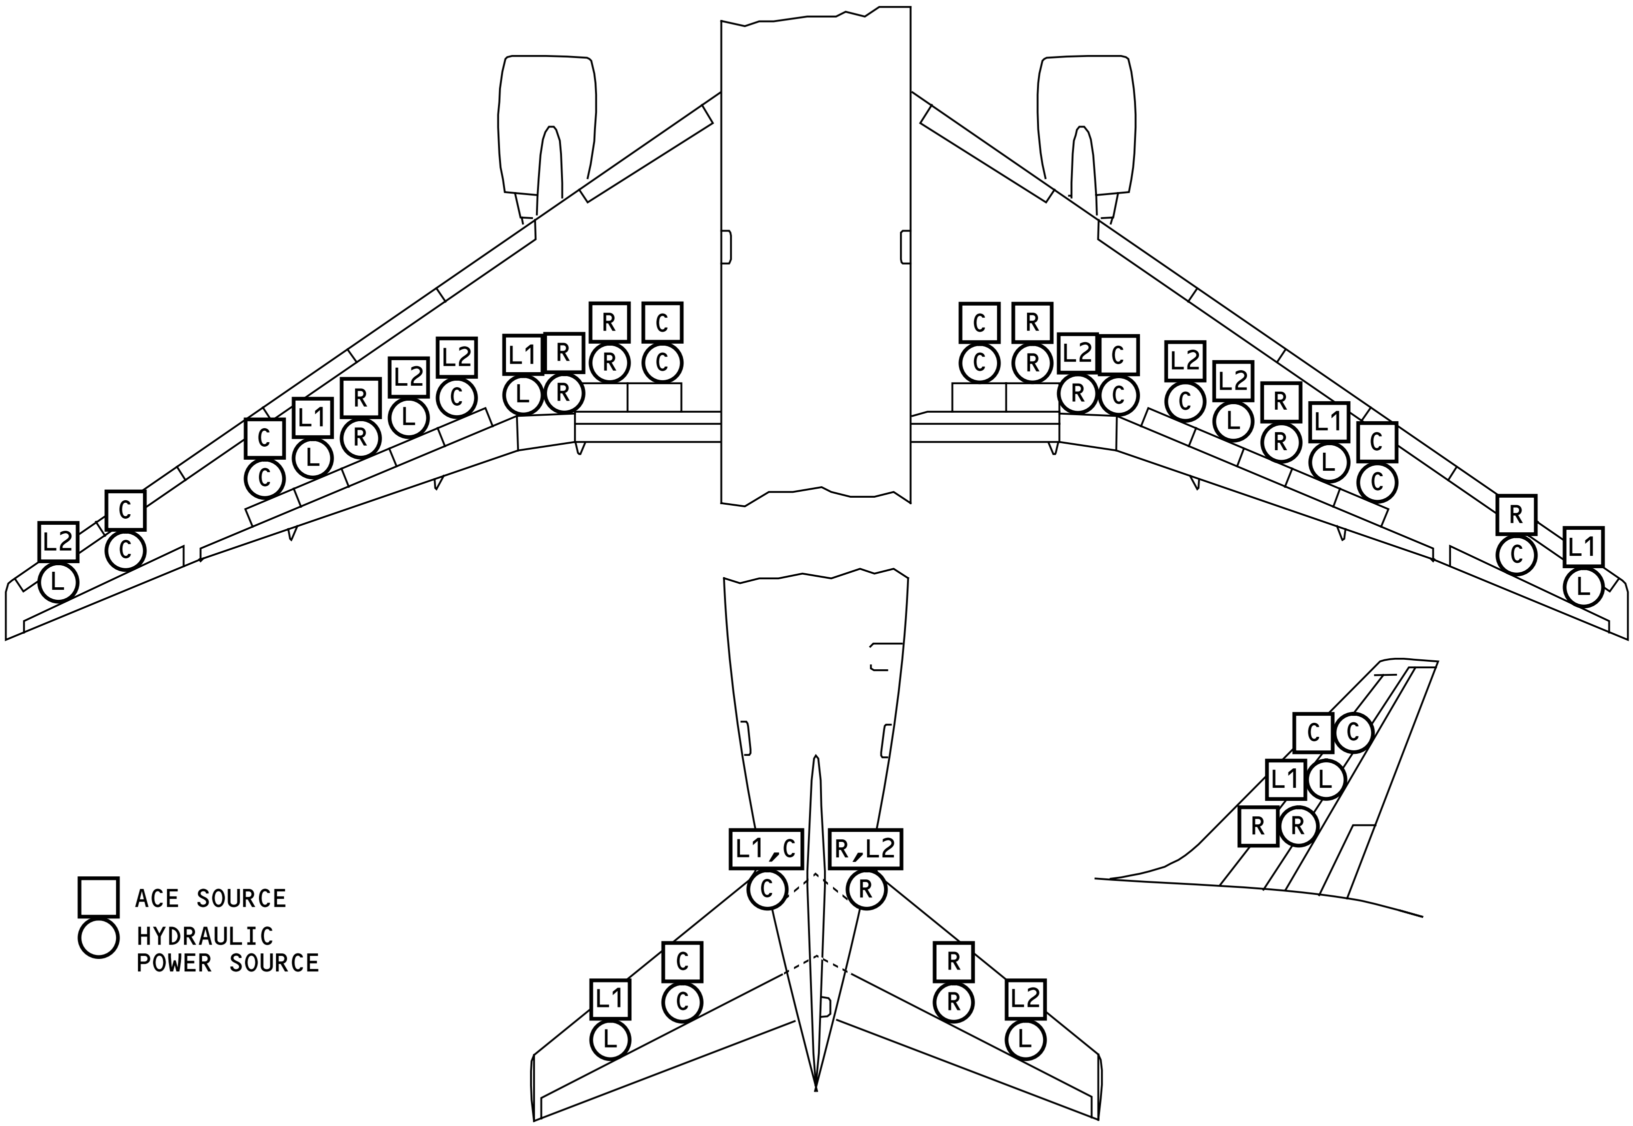
All three hydraulic systems supply power to operate the PCUs of the primary flight controls. The hydraulic distribution is:

- The left aileron: L and C
- Spoiler 1: C
- Spoiler 2: L
- Spoiler 3: R
- Spoiler 4: L
- Spoiler 5: C
- The left flaperon: L and R
- Spoiler 6: R
- Spoiler 7: C
- Spoiler 8: C
- Spoiler 9: R
- The right flaperon: R and C
- Spoiler 10: C
- Spoiler 11: L
- Spoiler 12: R
- Spoiler 13: L
- Spoiler 14: C
- The right aileron: C and L
- The left elevator: L and C
- The right elevator: R and L
- The rudder: L, C and R
- The stabilizer actuator: C and R.

ACE Distribution

The distribution of the four ACEs among the PCUs is in a manner that each PCU for a surface receives commands from a different ACE. The distribution is:

- The left aileron: L2 and C
- Spoiler 1: C
- Spoiler 2: L1
- Spoiler 3: R
- Spoiler 4: L2
- Spoiler 5: L2
- The left flaperon: L1 and R
- Spoiler 6: R
- Spoiler 7: C
- Spoiler 8: C
- Spoiler 9: R
- The right flaperon: L2 and C
- Spoiler 10: L2
- Spoiler 11: L2
- Spoiler 12: R
- Spoiler 13: L1
- Spoiler 14: C
- The right aileron: R and L1
- The left elevator: L1 and C
- The right elevator: R and L2
- The rudder: L1, C and R
- The stabilizer actuator: L1 and C for the left motor/brake, and R and L2 for the right motor/brake.



PFCS - HYDRAULIC POWER AND ACE DISTRIBUTION

27-02-00-008 Rev 0

THIS PAGE INTENTIONALLY LEFT BLANK

PFCS - ACE - FUNCTIONAL DESCRIPTION

General

The ACE is a signal converter and controls the direct mode.

The primary functions of the ACE are:

- A/D converter
- D/A converter
- Direct mode select logic
- Direct mode command calculation
- PCU servo loop control
- Excitation power supply.

The ACE operates in all three PFCS modes. Operation of the ACE in direct mode is different than in normal and secondary mode. In normal and secondary mode, the ACE relays input signals from airplane sensors to the PFC and command output signals from the PFC to the PCUs. In direct mode, the ACE processes the input signals with internal hardware and sends command output signals to the PCUs.

A/D Converter

The analog inputs from the position and force transducers go to the A/D converter which changes them from analog to digital format. The transducers send signals from:

- The control wheels
- The control columns
- The rudder pedals
- The speedbrake lever.

The pitch rate sensor is internal to the ACE. It sends analog input signals to the A/D converter and to the direct mode internal hardware. The ACE supplies the signals to the PFC for secondary mode.

The digital signals then go to the ARINC 629 buses.

D/A Converter

Digital commands from the buses go to the D/A converter which changes them from digital to analog format. They then go to the PCU servo loop to control the surfaces.

Direct Mode Select Logic

The pilots can manually switch the ACE to the direct mode. The PFC disconnect switch commands all ACEs to the direct mode.

The PFC automatically changes the ACE to the direct mode when data is not available from all three flight control buses or when internal monitors find failures. The ACE internal logic executes the command.

Direct Mode Command Calculation

In direct mode, the command calculation uses control laws contained in the ACE hardware. Position transducers, force transducers and the pitch rate sensor supply input signals. The analog command output signals go directly to the PCUs.

PFCS - ACE - FUNCTIONAL DESCRIPTION

PCU Servo Loop Control

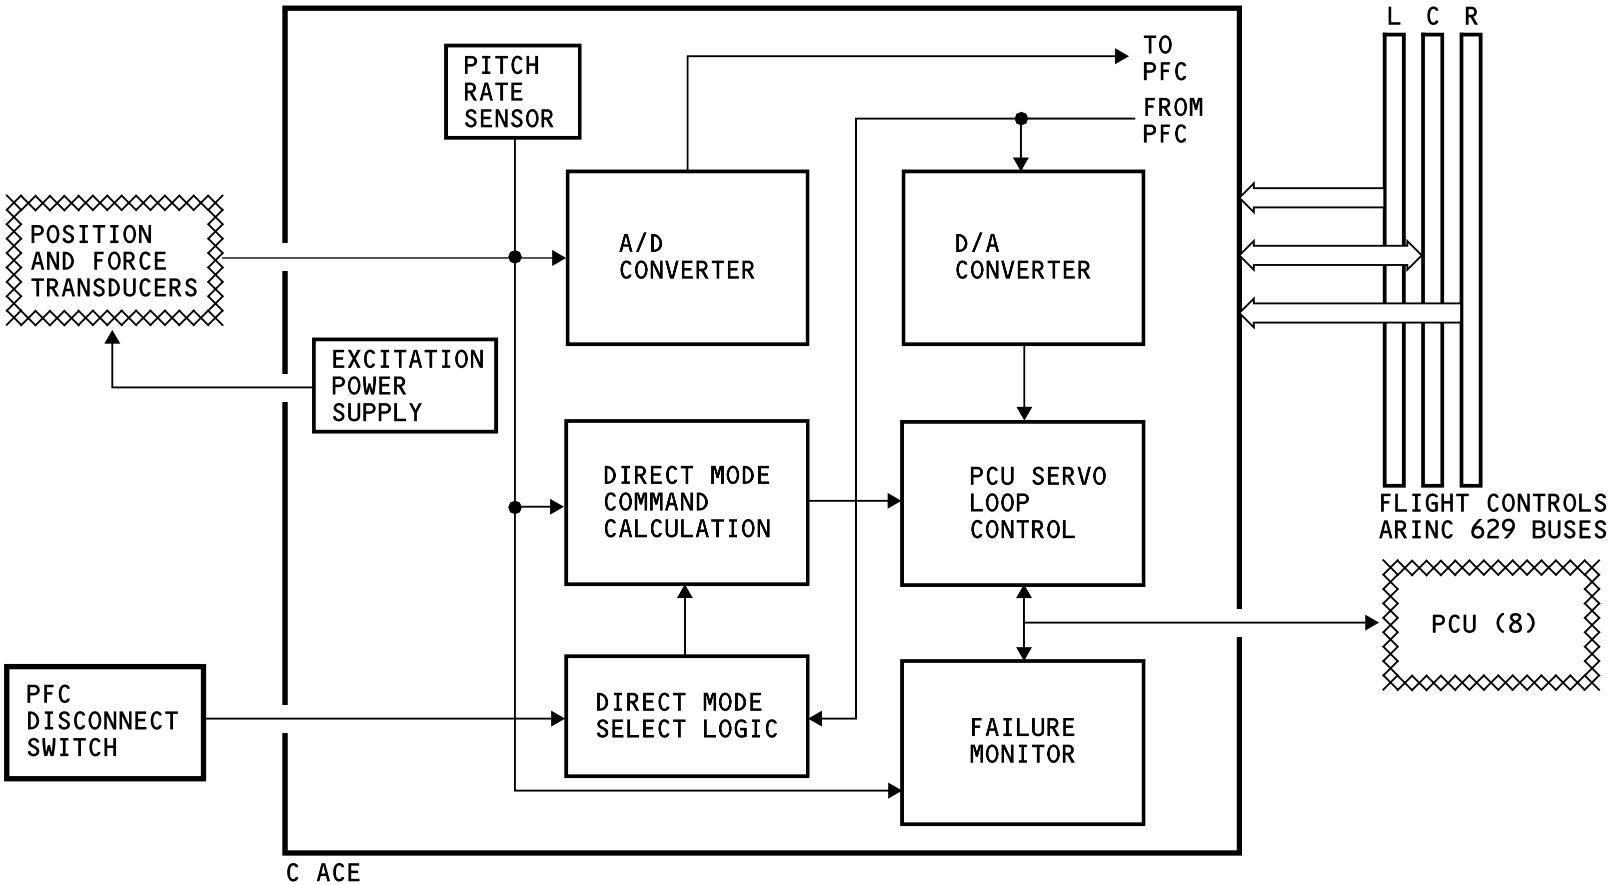
The ACE contains the servo loop control to each PCU. This servo loop operates in all three PFCS modes.

Failure Monitor

The failure monitor controls power to solenoids on the PCUs. When there is a failure, the ACE de-energizes solenoids on the effected PCUs.

Excitation Power Supply

The ACE has power supply circuits that supply 7v AC, 1800 Hz excitation power to the position and force transducers.



NOTE: CENTER ACE SHOWN. OTHERS SIMILAR.

27-02-00-010 Rev 5

PFCS - ACE - FUNCTIONAL DESCRIPTION

PFCS - PFC - COMPONENT LOCATION

Purpose

The primary flight computers (PFC) calculate surface commands for the ailerons, flaperons, speedbrakes, spoilers, elevators, rudder and stabilizer.

These are the functions of the PFC:

- Calculate control surface commands using pilot and autopilot inputs
- Calculate commands for variable elevator feel and backdrive actuators
- Supply stability augmentation
- Supply flight envelope protection
- Send signals for flight deck annunciations
- Send signals for maintenance messages.

Physical Description

The PFC weighs approximately 38 pounds (17 kg). The PFC is passively cooled.

There are thirty-two program pins on each PFC. The program pins supply the following information:

- Airplane type
- Airplane model
- Channel Identification (L,C,R)
- Parity (odd).

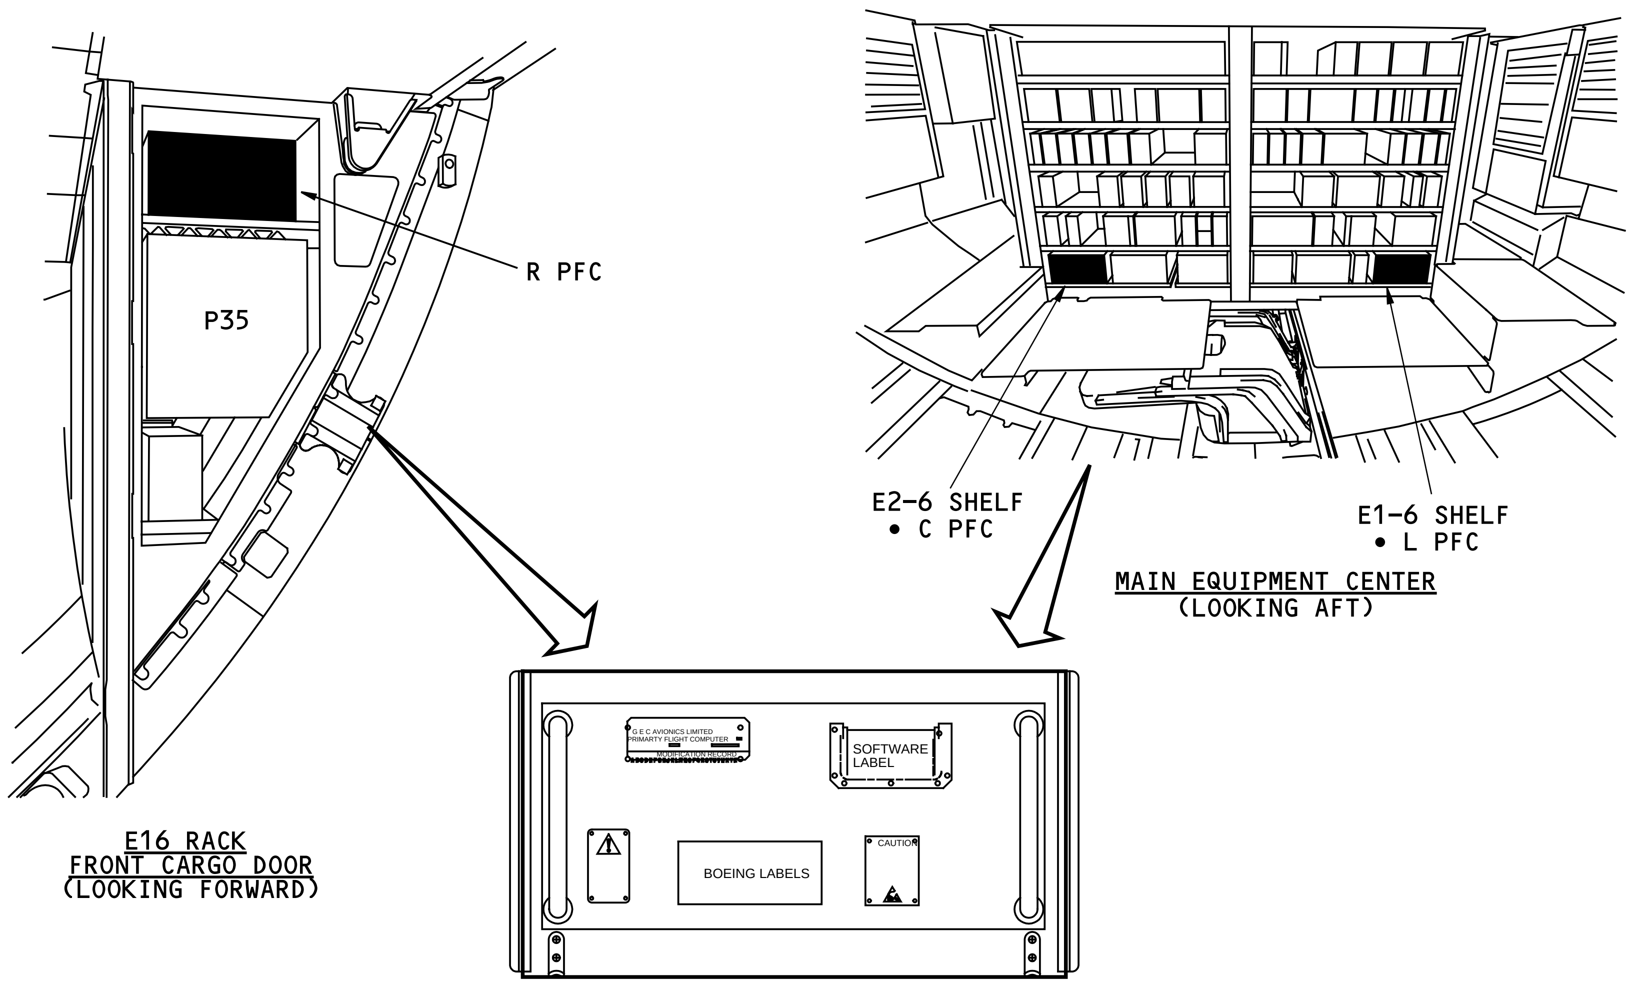
You load the software of the PFC through the maintenance access terminal (MAT). There are no software options.

Location

The three identical and interchangeable PFCs are:

- L PFC (left)
- R PFC (right)
- C PFC (center).

The L and C PFCs are in the main equipment center. The L PFC is on the E1-6 shelf and the C PFC on the E2-6 shelf. The R PFC is in the E16 rack aft of the front cargo door.



E16 RACK
FRONT CARGO DOOR
(LOOKING FORWARD)

MAIN EQUIPMENT CENTER
(LOOKING AFT)

PFC (TYPICAL)

27-02-00-011 Rev 2

PFCS - PFC - COMPONENT LOCATION

PFCS - PFC - FUNCTIONAL DESCRIPTION

General

Each PFC has three independent lanes. The CPU of each lane is of different manufacture and part number. The lanes have identical software and capabilities. This is done to get the necessary redundancy. You use the MAT to load PFC software.

When the airplane initially gets electrical power on the ground, the PFCs do tests between lanes and between PFCs. These tests check the compatibility of software, hardware, airplane type and airplane model. Any lane or PFC that fails the tests is declared a failure.

Each lane has:

- An input signal monitor
- A set of control laws
- A cross-lane monitor
- A PFC output selector.

The PFC operates in two modes: normal and secondary. In normal mode, all the functions of the PFC operate. The PFC selects the secondary mode when there is a loss of important air and attitude sensor data from the ADIRU and SAARU. The secondary mode is a degraded mode in which only specified functions of the PFC operate.

Lane Functions

The three lanes can become any one of these three lanes:

- Command lane
- Standby lane
- Monitor lane.

The command lane transmits its command output signals to the flight controls ARINC 629 buses. The command lane also has a lane monitoring function to find and isolate failures in the standby and monitor lanes.

The standby lane transmits test data only. The standby lane becomes the command lane and transmits its command output signals to the buses when a failure causes the command lane to shut down. The standby lane does monitoring functions to find and isolate failures in the command and monitor lanes.

The monitor lane transmits test data only. The monitor lane command output signals are used internally to find failures in the command and standby lanes. The monitor lane becomes the standby lane when the command lane shuts down.

Lane Selection

When the airplane initially gets electrical power, each PFC starts a lane selection procedure. This procedure automatically sets the function of each lane in each PFC. Each PFC must select a different lane for its command lane.

At the end of each flight, the lane selection in each PFC changes to decrease the exposure time for potentially latent failures.

Input Signal Monitor

Each lane gets input signals from sensors on the captain's and first officer's sides of the flight deck. Dual and triple sensors on each side supply input signals. The input signal monitor of each lane sets which input signal to use by mid-value selection and averaging.

The mid-value selection compares the signal values of each side and selects the signal that has the middle value. The input signal monitor then averages the mid-values from the captain's and the first officer's sides.

This selection causes each independent process software to receive the same input signal. This selection also removes signals that are out of tolerance.

Control Laws

Each lane has a set of control laws to calculate the proposed command output signals. The command lane sends proposed commands to the other two PFCs.

Cross-Lane Monitor

The cross-lane monitor does a check of the validity of the proposed signals generated by all three lanes. If a cross-lane monitor finds a lane fault, it temporarily inhibits the transmission of the lane's data on the flight controls ARINC 629 buses. The monitor lets the faulty lane try to operate as many as four times during a flight. If the lane still cannot operate without failure, then the monitor latches the failed lane so it can no longer operate.

If the command lane fails, the cross-lane monitor shuts it down and causes the standby lane to do the function of the command lane. If a second lane is defective, the PFC shuts down.

PFC Output Selector

Each lane has a PFC output selector to supply a common set of PFC command output signals for use by the ACEs. This function makes sure that all PFC generated command output signals are identical to each other. The PFC output selector operates only in the command lane.

The PFC output selector gets the proposed command output signals from all three PFCs. The PFC output selector compares the three proposed signals and makes a selection by the mid-value process. Only the PFC output selector of the command lane then transmits the selected command output signal to the flight controls ARINC 629 buses and the ACEs.

PFC Self Test

At the end of each flight, the PFCs do an automatic PFC self test to find component failures and confirm failures found in flight.

PFCS - PFC - FUNCTIONAL DESCRIPTION

Lane Availability and Indications

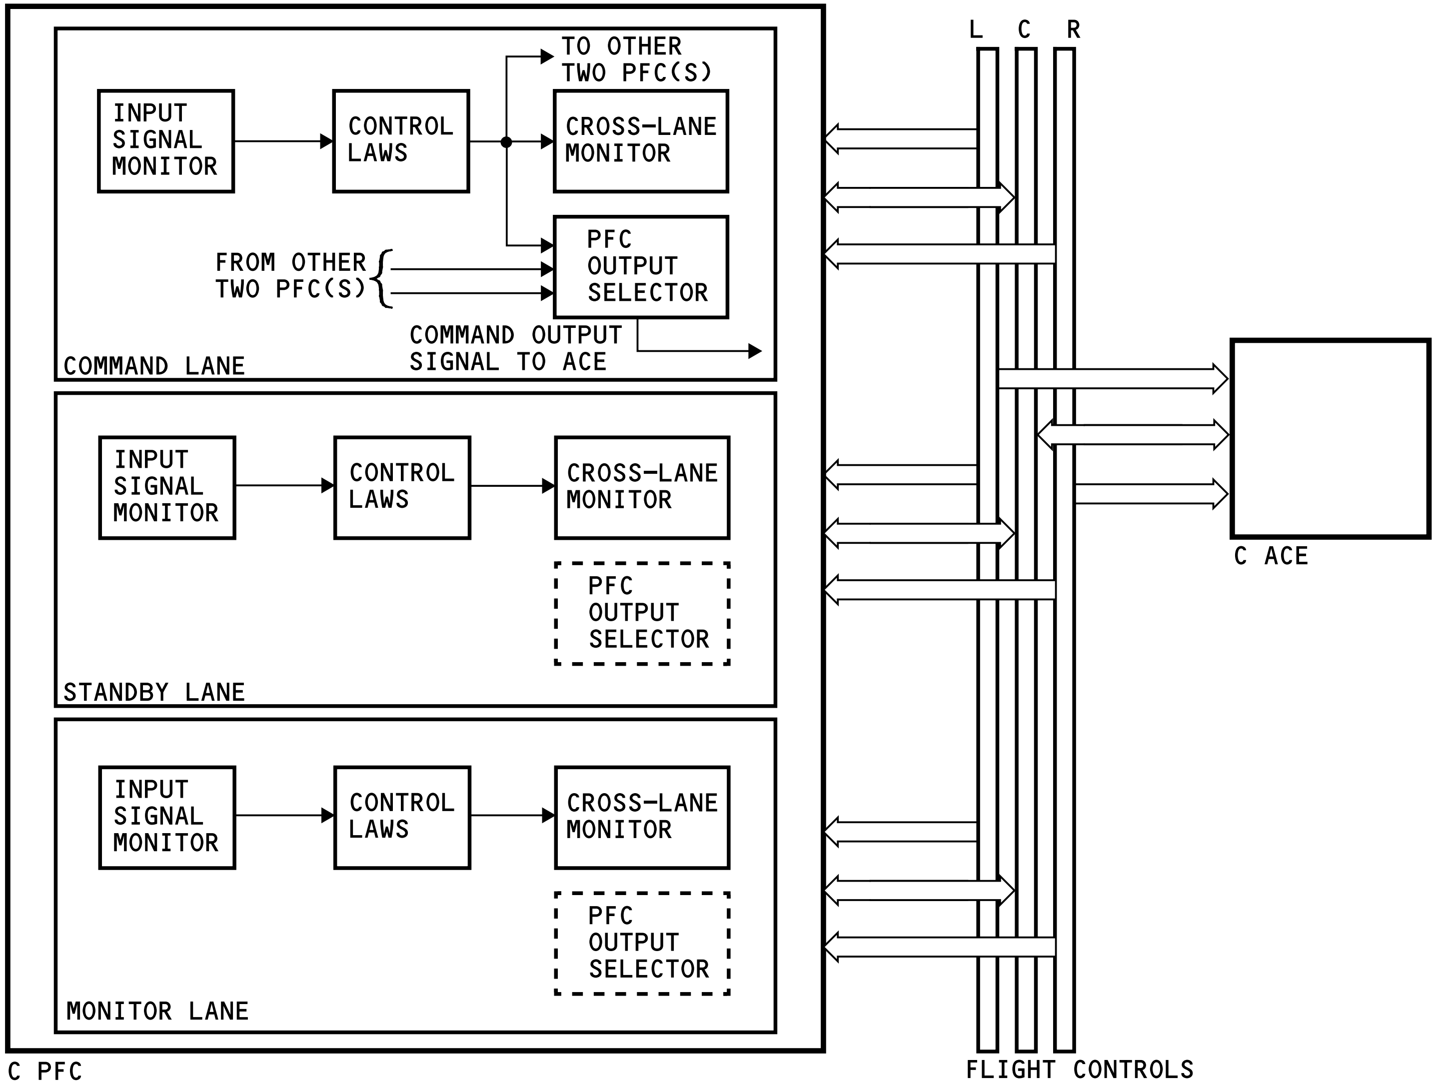
The three PFCs supply a total of nine lanes on the airplane. When there is no failure, the lane availability is referred to as the 3-3-3 lane configuration. If a PFC has a failed lane, the lane availability is 2. The PFC shuts down if there is a second lane failure or if all three lanes fail. In that case, the lane availability is 1 or 0.

The table below shows the indication on the primary display system and the operating mode for each combination of lane availability.

LANE AVAILABILITY	PFCS MODE	MESSAGE	MESSAGE TYPE
3-3-3	NORMAL	NONE	NONE
3-3-2	NORMAL	NONE	NONE
3-2-2	NORMAL	PFC CONTROL LANES	STATUS
3-3-1/0	NORMAL	PFC CHANNEL	STATUS
3-2-1/0	NORMAL	FLIGHT CONTROL SYS	STATUS
3-1/0-1/0	NORMAL	FLIGHT CONTROL SYS	STATUS
2-2-2	NORMAL	FLIGHT CONTROL SYS	STATUS
2-2-1/0	NORMAL	FLIGHT CONTROL SYS	STATUS
2-1/0-1/0	NORMAL	FLIGHT CONTROL SYS	STATUS
1/0-1/0-1/0	DIRECT	PRI FLIGHT COMPUTERS AUTO SPEEDBRAKE THRUST ASYM COMP FLIGHT CONTROL SYS AUTO SPEEDBRAKE THRUST ASYM COMP	CAUTION ADVISORY ADVISORY STATUS STATUS STATUS

The system operates normally with one PFC lane failed, in the 3-3-2 configuration. There is no flight deck indication in this configuration.

The EICAS caution message FLIGHT CONTROL MODE indicates that the PFCS is in secondary mode.



<u>NOTE</u>: CENTER PFC AND ACE RELATIONSHIP SHOWN. OTHERS SIMILAR.

27-02-00-012 Rev 9 07/13/95

PFCS - PFC - FUNCTIONAL DESCRIPTION

PFCS - PFC DISCONNECT SWITCH

Purpose

The PFC disconnect switch lets the pilot select the direct mode of operation.

Physical Description

The PFC disconnect switch is a guarded toggle switch with two positions: AUTO and DISC. The switch is guarded in the AUTO position. An amber PFC disconnect (DISC) light is next to the switch.

Location

The PFC disconnect switch and light are on the P5 panel in the flight deck.

Functional Description

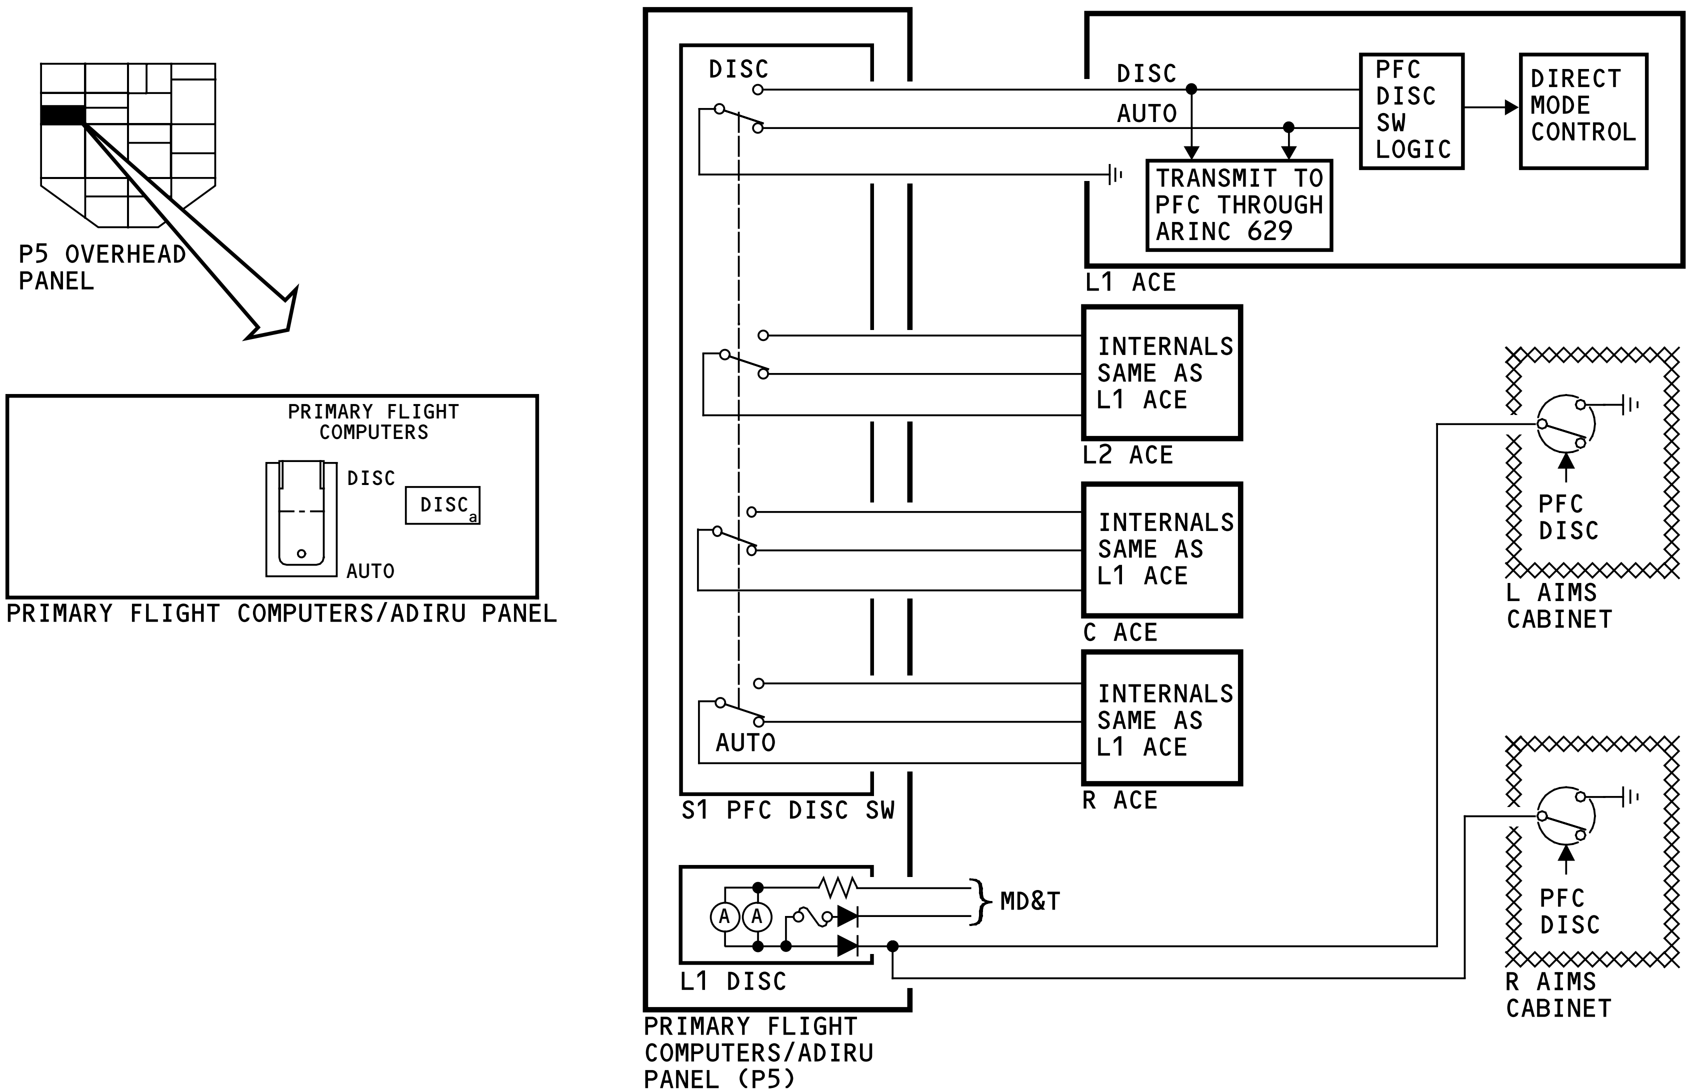
The PFC disconnect switch sends a discrete signal to each ACE. The ACE then transmits this signal to its on-side PFC through the flight controls ARINC 629 buses.

When the PFC disconnect switch is in the AUTO position, PFCS mode selection is automatic. The pilots can set the switch to DISC to select the direct mode of operation.

The amber DISC light shows when the PFCS is in direct mode, regardless of how the direct mode was engaged.

Indications

The EICAS caution message PRI FLIGHT COMPUTERS shows that all the ACEs that have power are in the direct mode and the PFC is not in the hydraulic OFF self-test mode. The message shows when the PFC disconnect switch is in the DISC position.



PFCS - PFC DISCONNECT SWITCH

PFCS - OPERATIONAL MODES - FUNCTIONAL DESCRIPTION

General

These are the three modes of PFCS operation:

- Normal
- Secondary
- Direct.

During the PFCS normal and secondary mode operation, both the PFCs and the ACEs are in operation. In the secondary mode, the PFC's operation downgrades. During the direct mode, only the ACEs operate in response to direct analog inputs.

The PFCS selects the mode of operation. On the ground with ground speed less than 40 knots, the PFCs automatically select the highest mode available based on the inputs from the ADIRU and SAARU. In flight, the pilots cycle the PFC disconnect switch on the P5 panel, or move it back to the AUTO position to cause the selection of the highest mode available.

During PFCS mode changes, there is a smooth change to the new commands.

Normal Mode

The PFCS selects the normal mode when all these conditions are met:

- The PFC disconnect switch, on the P5 panel, is in the AUTO position
- The needed input data is available
- At least one PFC and three ACEs are in normal mode.

All the control laws, the protection functions, and the stability augmentation of the PFCs are active in the normal mode. The autopilot operates only in normal mode.

Secondary Mode

The PFCS selects the secondary mode when it detects the loss of important air and attitude sensor data from both the ADIRU and the SAARU. The PFCS also selects the secondary mode when two ACEs are in direct mode.

A simplified set of control laws operate the PFCS in secondary mode. The protection functions are not available. Gain schedules and limits are a function of flap data discretes from the ACEs. Pitch stability augmentation uses pitch rate data from the ACEs. Yaw damper augmentation uses inertial data from the ADIRU and the SAARU if available.

Direct Mode

The PFCS selects the direct mode when there are failures that make the normal and secondary modes unreliable. If three ACEs are in direct mode, the PFCS switches the last ACE to the direct mode. The PFC disconnect switch also causes the selection of the direct mode.

The PFCs do not control the surfaces in the direct mode. Position transducer signals from the control wheels, columns and pedals go directly to the ACEs which use them to control the PCUs. The protection functions are not available.

When the PFCS is in direct mode, whether automatically or manually, the DISC amber light shows next to the PFC disconnect switch.

Manual Switching

The PFCS goes to the direct mode of operation when the pilots move the PFC disconnect switch to the DISC position.

If the pilots cycle the PFC disconnect switch or move it again to the AUTO position, the PFCS goes from the direct mode to the highest mode available. The PFCS selects the mode based on the validity of available data.

If the PFCS is in the secondary or direct modes and the normal mode becomes available, the PFCS may select the normal mode. To do this in the air, you must cycle the PFC disconnect switch. If the airplane is on the ground and ground speed is less than 40 knots, then the PFCS selects the normal mode automatically.

Indications

The EICAS caution message FLIGHT CONTROL MODE shows when the PFCS is in secondary mode.

The EICAS caution message PRI FLIGHT COMPUTERS shows when all ACEs under power are in direct mode and the PFC is not in the hydraulic OFF self-test mode.

On the status display, the status message FLIGHT CONTROL SYS shows when the PFCS does not operate at minimum dispatch requirement levels. This message shows because of one or more of these faults:

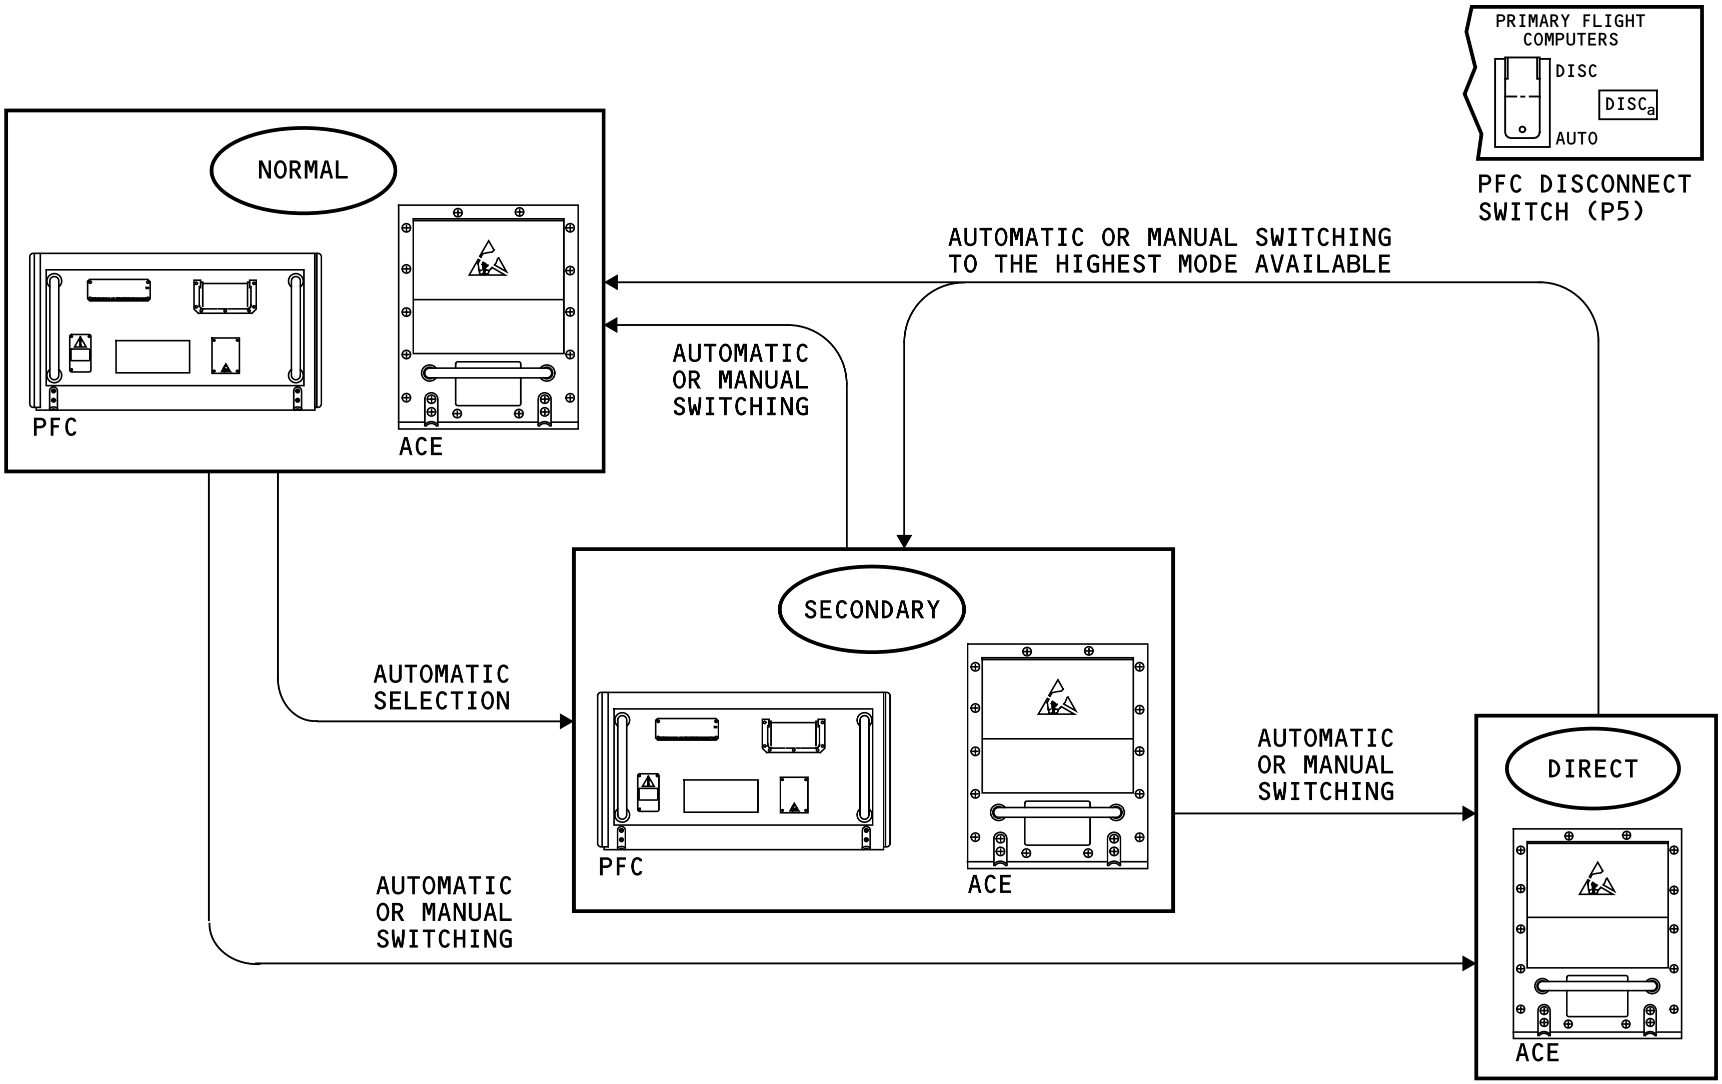
- Failure of a column, wheel, pedal, or speedbrake lever position transducer
- Failure of a rudder, elevator, aileron, flaperon, or spoiler PCU
- Failure of a STCM
- Failure of an elevator feel actuator
- Failure of a PFC and at least one lane in another PFC
- Failure of an ACE or at least one ACE is in direct mode
- Failure of the stabilizer control
- Failure of the actuator confidence test
- Failure of a PSA, a flight controls ARINC 629 bus, or a WES channel.

The EICAS caution message FLIGHT CONTROLS shows when the flight control system has lost substantial capabilities. Any one of these faults causes the message to show:

- The stabilizer is not operative
- Two elevator PCUs and one stabilizer path are not operative

PFCS - OPERATIONAL MODES - FUNCTIONAL DESCRIPTION

- The wheel, column, or pedal position transducers for the captain and first officer disagree by more than 15 percent of full range with the airplane on the ground
- The elevator force fight equalization function is defective.



27-02-00-015 Rev 7 08/18/95

PFCS - OPERATIONAL MODES - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

PFCS - FUNCTIONAL DESCRIPTION

General

The primary flight control system supplies roll, pitch and yaw control to set the desired airplane attitude.

At the end of each flight, the PFCs do internal tests and select the function of each lane.

At the completion of power-up and with the hydraulic systems pressurized, the PFCs command the surfaces to slowly move to agree with the command from the control wheels, control columns and rudder pedals.

On the ground without the engines running, the system receives electrical power from a secondary source. When the engines start, the system automatically switches to the PMGs as its primary power source.

Roll Control

The roll control causes the ailerons, flaperons and spoilers to move. When the pilots move a control wheel, six position transducers send analog signals to the PFCs through the ACEs. The PFCs select the signal to process. The control laws, protection functions and stability augmentation of the PFCs, calculate the command output signals. After selection of one signal among the three supplied by the PFCs, the PFCs send the command output signal to the ACEs. The ACEs then command the control surface PCUs. PCU position transducers send feedback signals to the ACEs.

The PFCs also control:

- The aileron lockout during cruise
- The aileron and flaperon droop when the flaps extend.

Speedbrake Control

When the pilots move the speedbrake lever, four position transducers send analog signals to the PFCs through the ACEs. The PFCs then calculate the command output signals. After selection of one signal, the PFCs send the selected signal to the ACEs. The ACEs then command the spoiler PCUs. PCU position transducers send feedback signals to the ACEs.

Pitch Control

The pitch control causes the elevators and the horizontal stabilizer to move. When the pilots move a control column, six position transducers send analog signals to the PFCs through the ACEs. The PFCs process these signals and command the elevator PCUs in the same manner as the roll control.

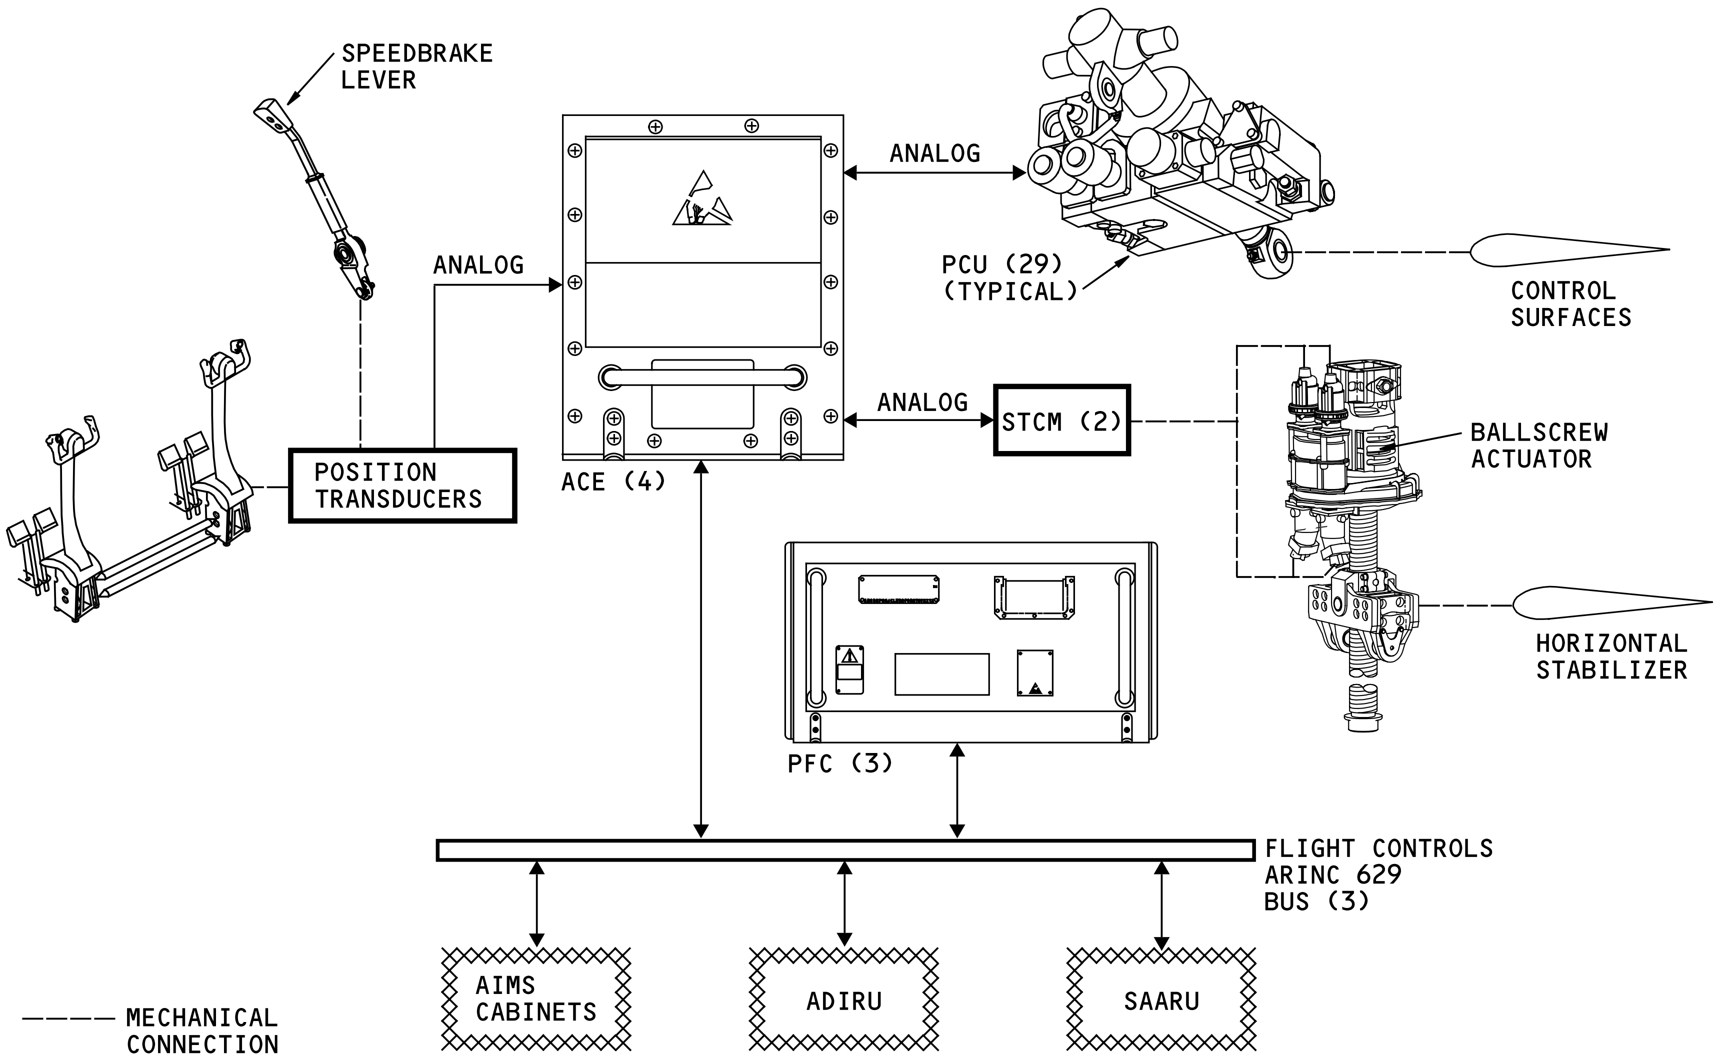
When there is a command to the elevator that lasts longer than a calculated time, the elevator offload function of the PFCs send stabilizer command signals to the ACEs. The ACEs then command the stabilizer trim control modules (STCMs) which hydraulically control the stabilizer ballscrew actuator. The movement of the stabilizer then causes the elevator to fair.

PFCS - FUNCTIONAL DESCRIPTION

Yaw Control

The yaw control causes the rudder to move. When the pilots move the control pedals, four position transducers send analog signals to the PFCs through the ACEs. The PFCs process these signals and command the rudder PCUs in the same manner as the roll control. The PFCs also control changes in the rudder ratio, gust suppression and wheel-rudder cross-tie functions.

The PFCs control the rudder trim when the pilots move the rudder trim selector or the manual trim cancel switch. The thrust asymmetry compensation (TAC) function automatically controls the rudder trim to correct for asymmetrical thrust of the engines.



27-02-00-016 Rev 4

PFCS - FUNCTIONAL DESCRIPTION

PFCS - AUTOPILOT - GENERAL DESCRIPTION

General

With the autopilot engaged, the PFCS receives command inputs from the AFDCs. The PFCS processes these commands in the same manner as manual inputs from the pilots.

The autopilot function of autopilot flight director system (AFDS) supplies automatic control of the:

- Altitude
- Vertical speed
- Flight path angle
- Heading
- Track
- Airspeed
- Approach
- Go-around.

The AFDS does not have servos to move the primary flight control surfaces. The autopilot commands go to the PFCs. The PFCs use these commands to supply surface commands to the ACEs. The PFCs also supply backdrive commands to the AFDCs.

Autopilot Components

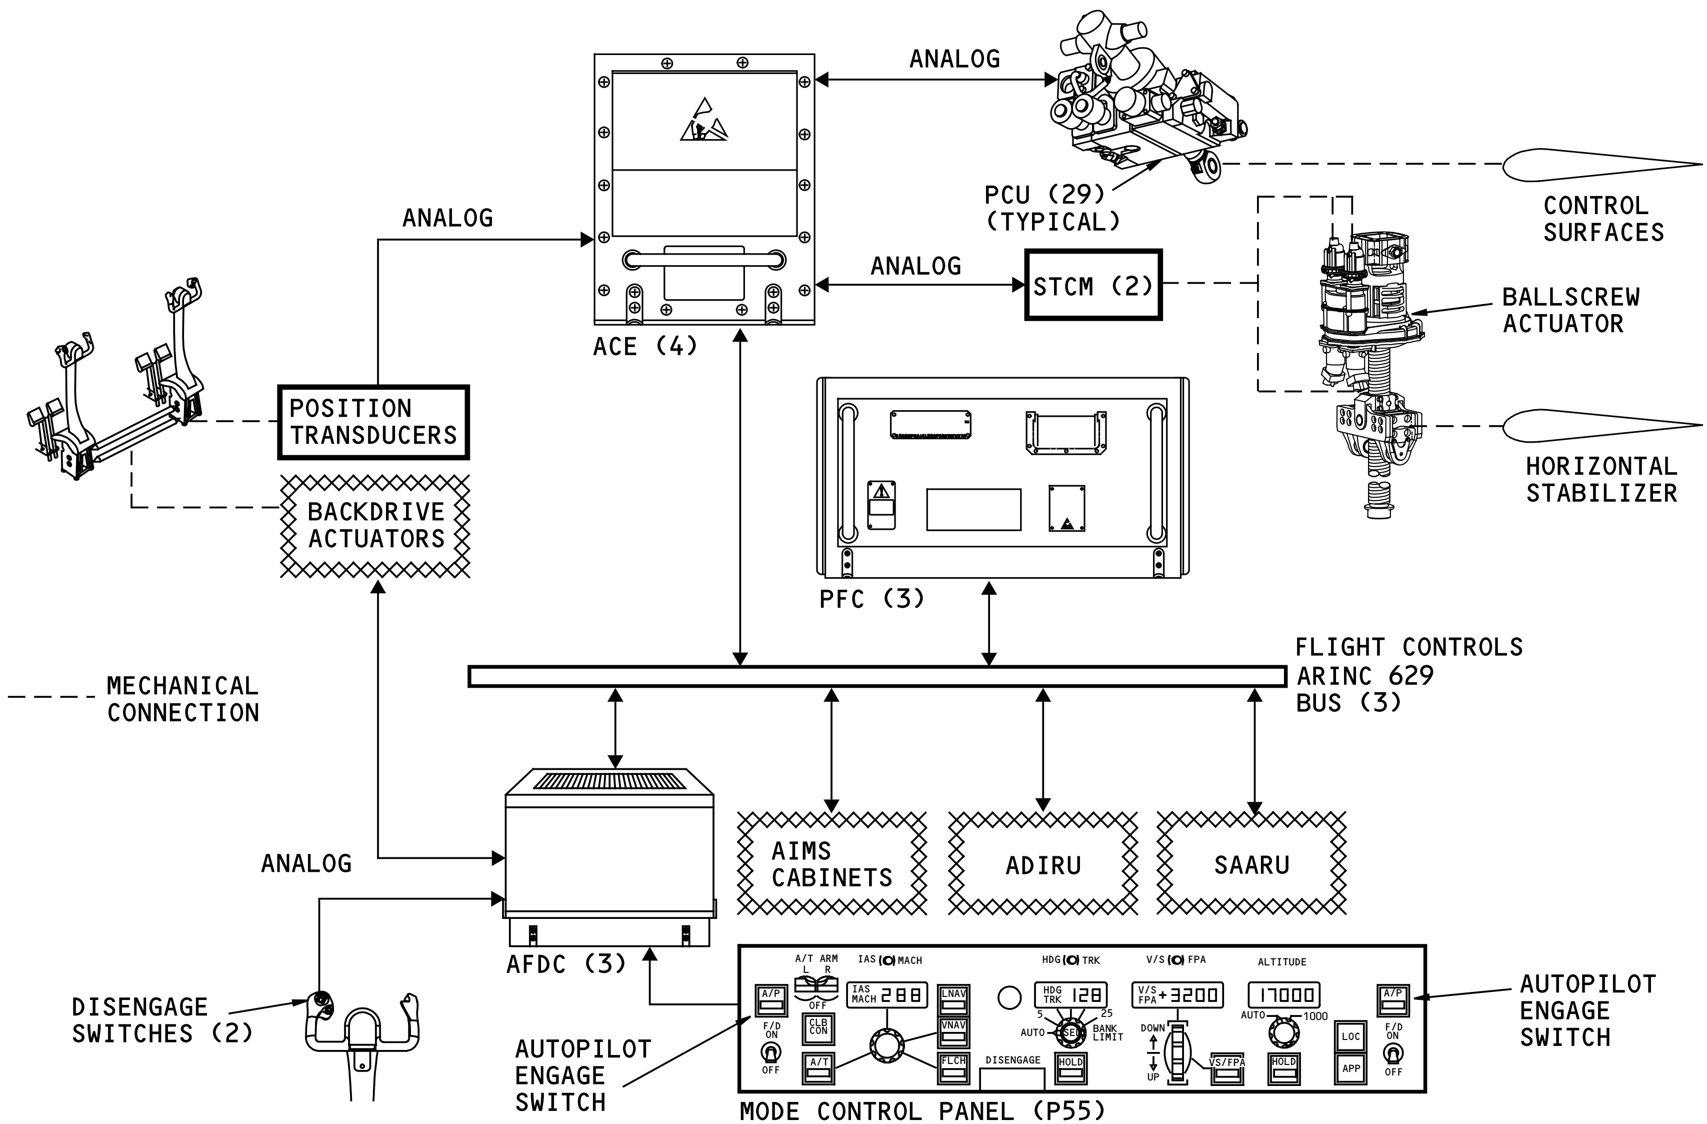
The components of AFDS are:

- One mode control panel (MCP)
- Three autopilot flight director computers (AFDCs)
- Six backdrive actuators
- Two control wheel disengage switches.

Autopilot Engagement

There are two autopilot engage switches on the MCP. When the pilot pushes either momentary action switch, the PFCs receive a request to engage the autopilot function. If conditions are correct, the PFCs permit all the available AFDCs to engage in the pitch and roll axes during cruise.

The autopilot yaw axis engages only during the approach and autoland phase of flight. In yaw, the autopilot can control adverse yaw (engine out) and crab angle.



PFCS - AUTOPILOT - GENERAL DESCRIPTION

PFCS - AUTOPILOT - FUNCTIONAL DESCRIPTION

General

The autopilot flight director computers (AFDCs) calculate roll, pitch and yaw commands to control the airplane automatically. Based on pilot selection, the AFDCs also calculate pitch/roll engage request, yaw engage request and other discrete signals.

Normal Operation

The autopilot commands and discrete engage signals go from the AFDCs to the PFCs through the flight controls ARINC 629 buses. Each PFC receives these inputs from the three AFDCs. The PFC selects a command signal by mid-value selection. This process selects the middle value of the three, not the average value.

The PFC selects the discrete signals by majority selection.

The PFCs filter and limit the autopilot command signals before their use in the control laws. The PFCs process and change the autopilot command signals to surface commands and backdrive commands. The surface commands from the PFCs go to the ACEs to move the flight control surfaces.

Autopilot commands go to the rudder only during automatic approach and landings.

In manual control (no autopilot engaged), the PFCs supply bank angle protection through use of the AFDS wheel backdrive actuators.

Backdrive Operation

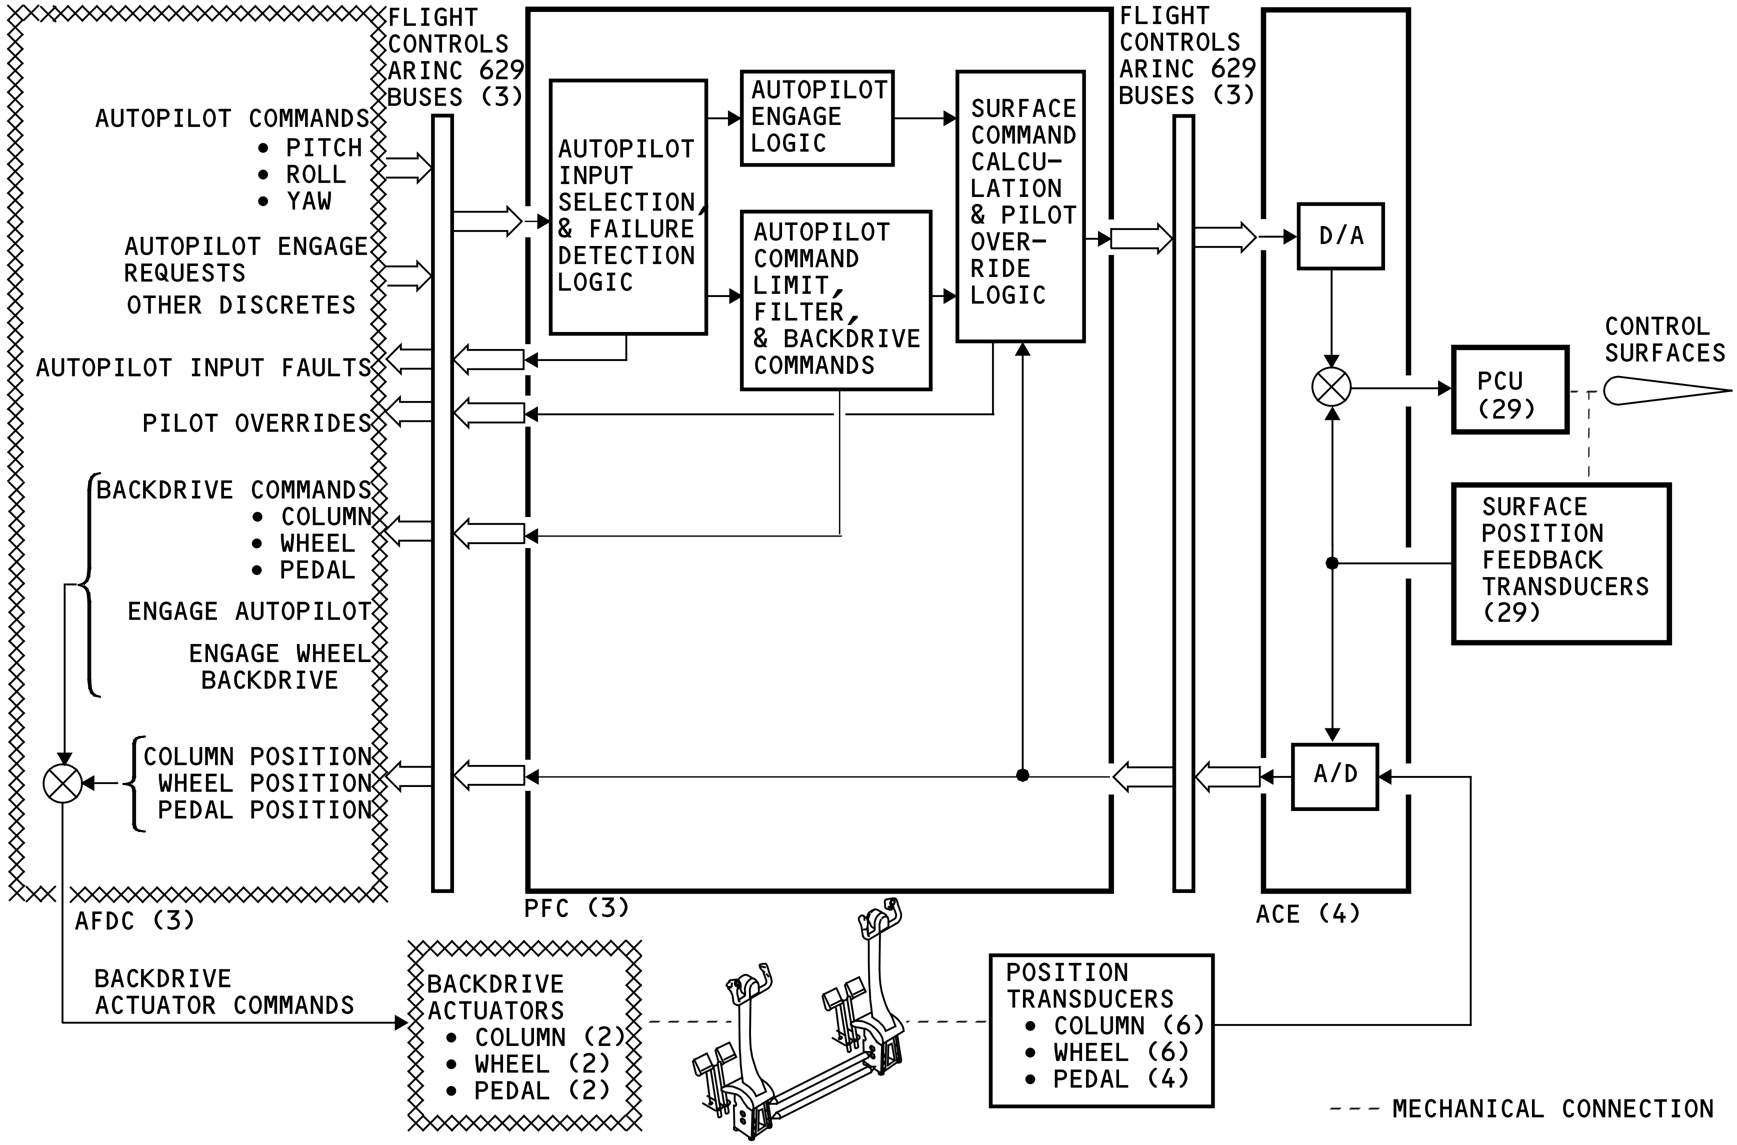
The PFCs send column, wheel and rudder pedal backdrive commands to the AFDCs to operate the backdrive actuators. In cruise, one wheel and one column backdrive actuator operate. Actuator selection alternates at each autopilot engagement. In autoland all backdrive actuators operate. When commanded, the actuators move the control columns, control wheels and rudder pedals to a position that represents the AFDC commands. These movements supply tactile and visual feedback to the pilots.

Position transducers on the columns, control wheels and rudder pedals supply position feedback to the PFCs and AFDCs through the ACEs. The AFDCs use the signal to make sure that the backdrive actuators operate correctly.

Non-normal Operation

For both command and discrete signals, if an input is not valid or failed, the PFC removes it from the calculation. If a second input is not valid, the PFC uses the remaining input. This permits the system to operate with a single AFDC.

When the PFC detects a pilot override in any axis, it disengages all engaged AFDCs.



PFCS - AUTOPILOT - FUNCTIONAL DESCRIPTION

PFCS - FLIGHT CONTROL SHUTOFF VALVES - LOCATION

Purpose

The flight control shutoff valves (SOV) permit the maintenance technicians to stop hydraulic power to the primary flight control actuators.

When 28v dc power is available, the flight control SOVs for the left and right systems can operate in the air or on the ground. The flight control SOVs for the center system can operate only on the ground.

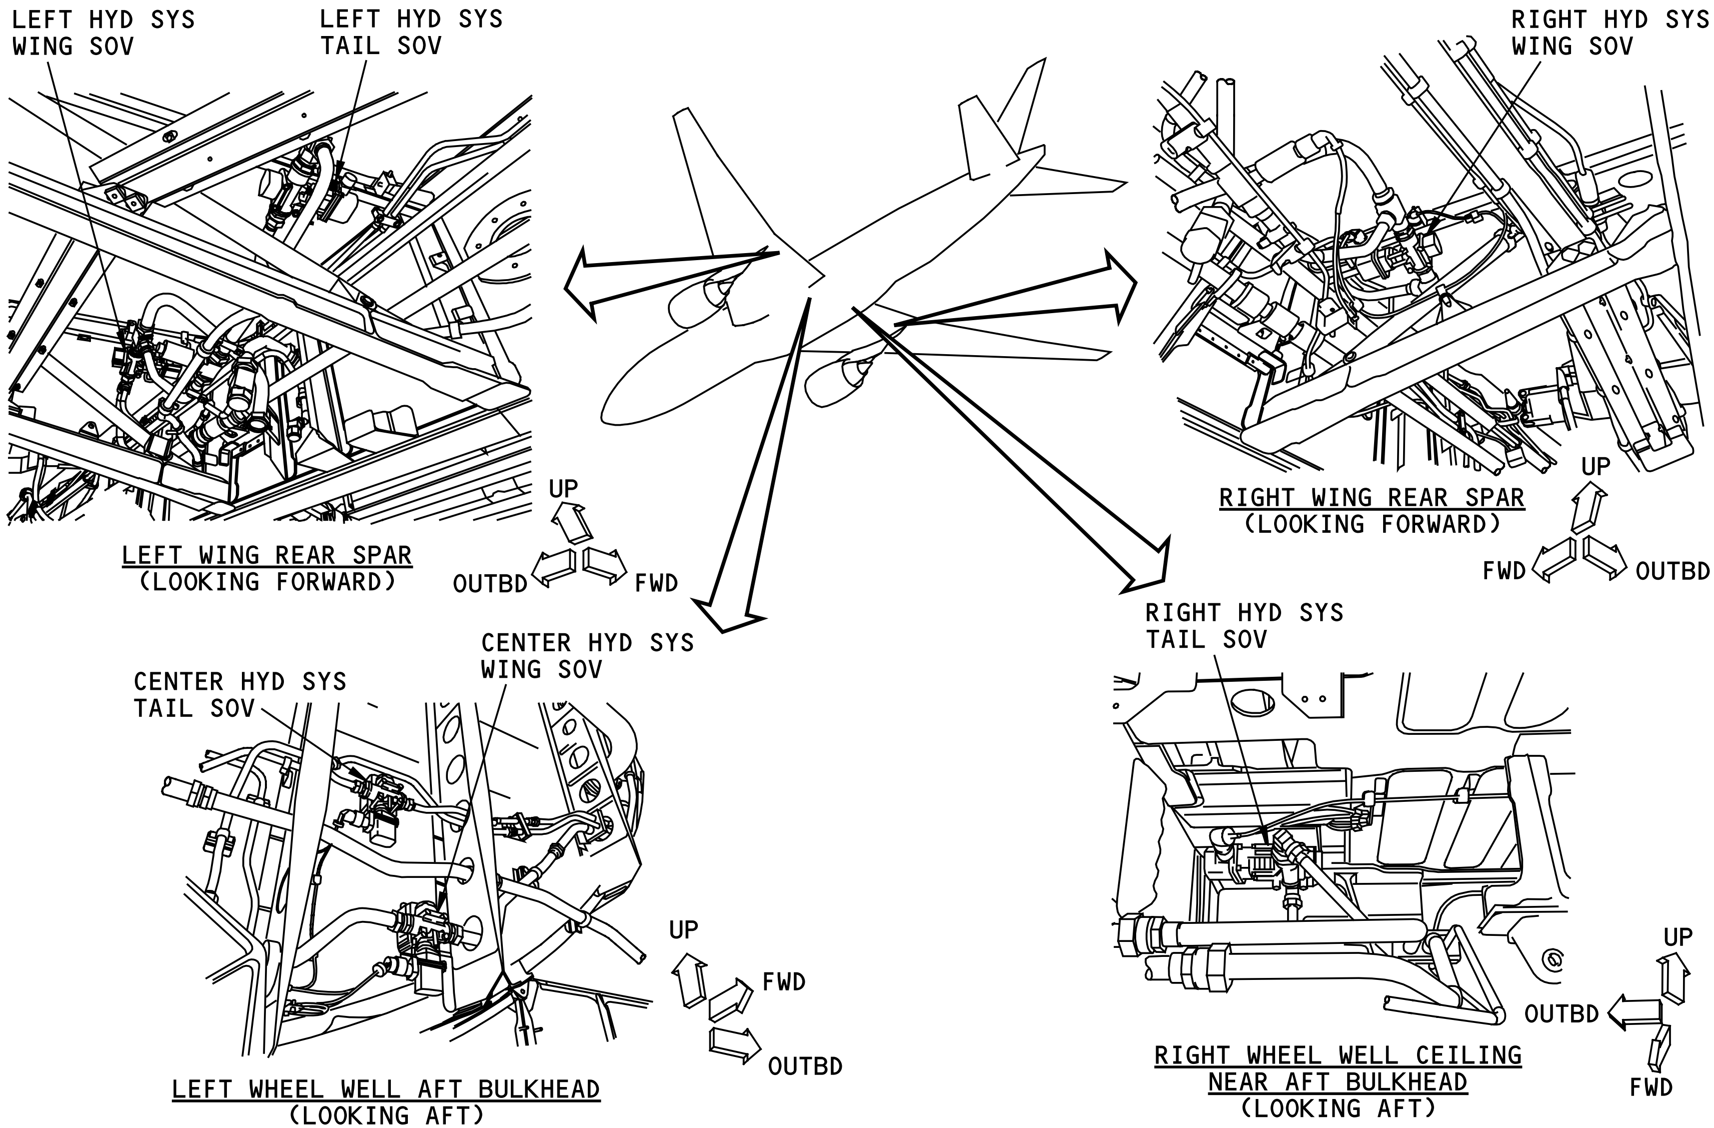
Location

The flight control SOVs for the left hydraulic system are on the left wing, aft of the rear spar, and inboard of the left flaperon. The wing SOV is outboard of the tail SOV.

The flight control SOVs for the center hydraulic system are on the aft bulkhead of the left landing gear wheel well. The tail SOV is the top one, the wing SOV is the bottom one.

The wing shutoff valve for the right hydraulic system is on the right wing, aft of the rear spar, and inboard of the right flaperon.

The tail shutoff valve for the right hydraulic system is on the ceiling of the right landing gear wheel well, near the aft bulkhead.



PFCS - FLIGHT CONTROL SHUTOFF VALVES - LOCATION

PFCS - FLIGHT CONTROL SHUTOFF VALVES - CONTROLS AND DISPLAYS

Controls

The control switches for the flight control SOVs are on the P61 overhead maintenance panel.

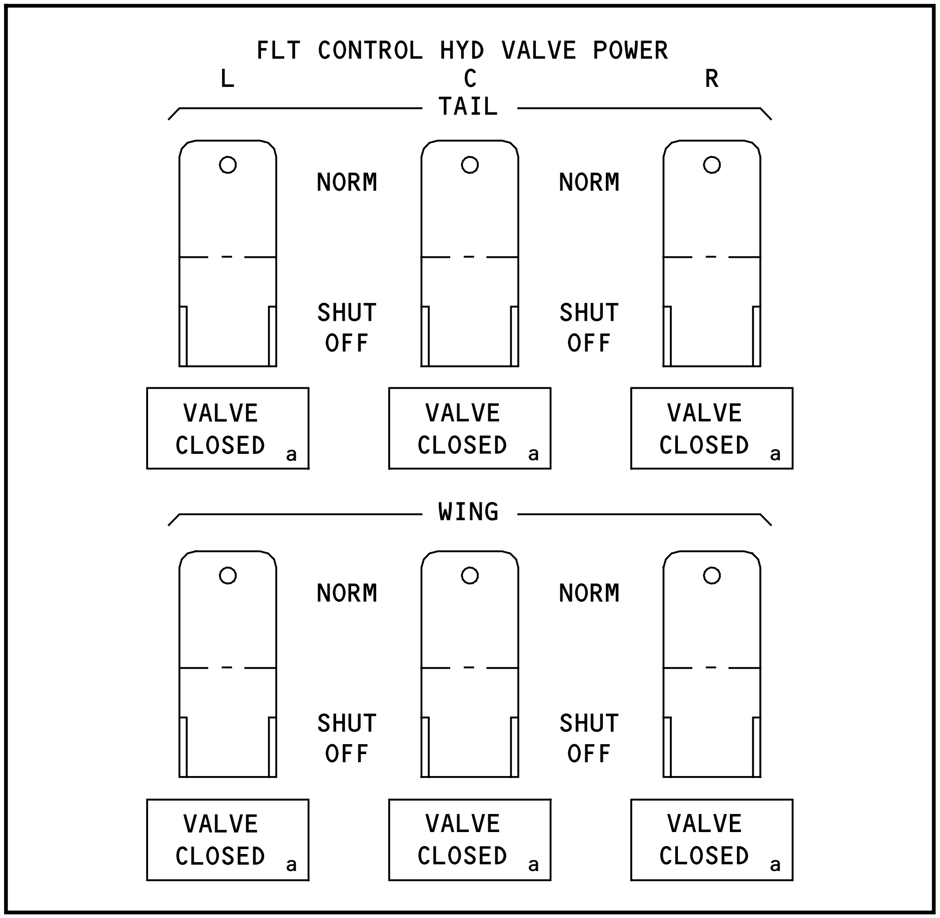
There are six guarded toggle switches. Three are for the tail SOVs and three are for the wing SOVs.

Each toggle switch has two positions: NORM and SHUTOFF. In the NORM position, the switch commands the valve to open. In the SHUTOFF position, the switch commands the valve to close.

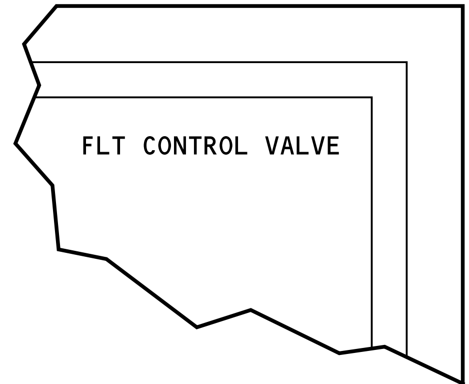
Displays

Below each toggle switch, there is an amber VALVE CLOSED light. The light shows when the valve is not open.

An advisory message FLT CONTROL VALVE shows on the EICAS display when one or more flight control shutoff valves are not open.



FLIGHT CONTROL HYDRAULIC POWER PANEL
(P61)



EICAS DISPLAY

27-02-00-021 Rev 1

PFCS - FLIGHT CONTROL SHUTOFF VALVES - CONTROLS AND DISPLAYS

PFCS - FLIGHT CONTROL SHUTOFF VALVES - FUNCTIONAL DESCRIPTION

General

This description is for the tail flight control SOV for the center system. The other flight control SOVs operate in a similar manner. This does not include the left and right SOVs which do not use air/ground signals.

The 28v dc left and right main buses supply power to the flight control SOVs.

Functional Description

The valve has two positions: open and closed. A 28v dc electric motor opens and closes the valve. Two limit switches stop power to the motor at the end of the valve movement. A position indicating switch sends a signal to the HYDIM cards when the valve leaves the open position. This switch stops the signal to the HYDIM cards when the valve is fully open.

A pair of contacts in one of the air/ground relays controls power to close the valve on the center SOVs.

Operation

When the control switch is in the NORM position, the valve opens. When the valve is fully open, the related amber light VALVE CLOSED does not show. The advisory message FLT CONTROL VALVE does not show on the EICAS display.

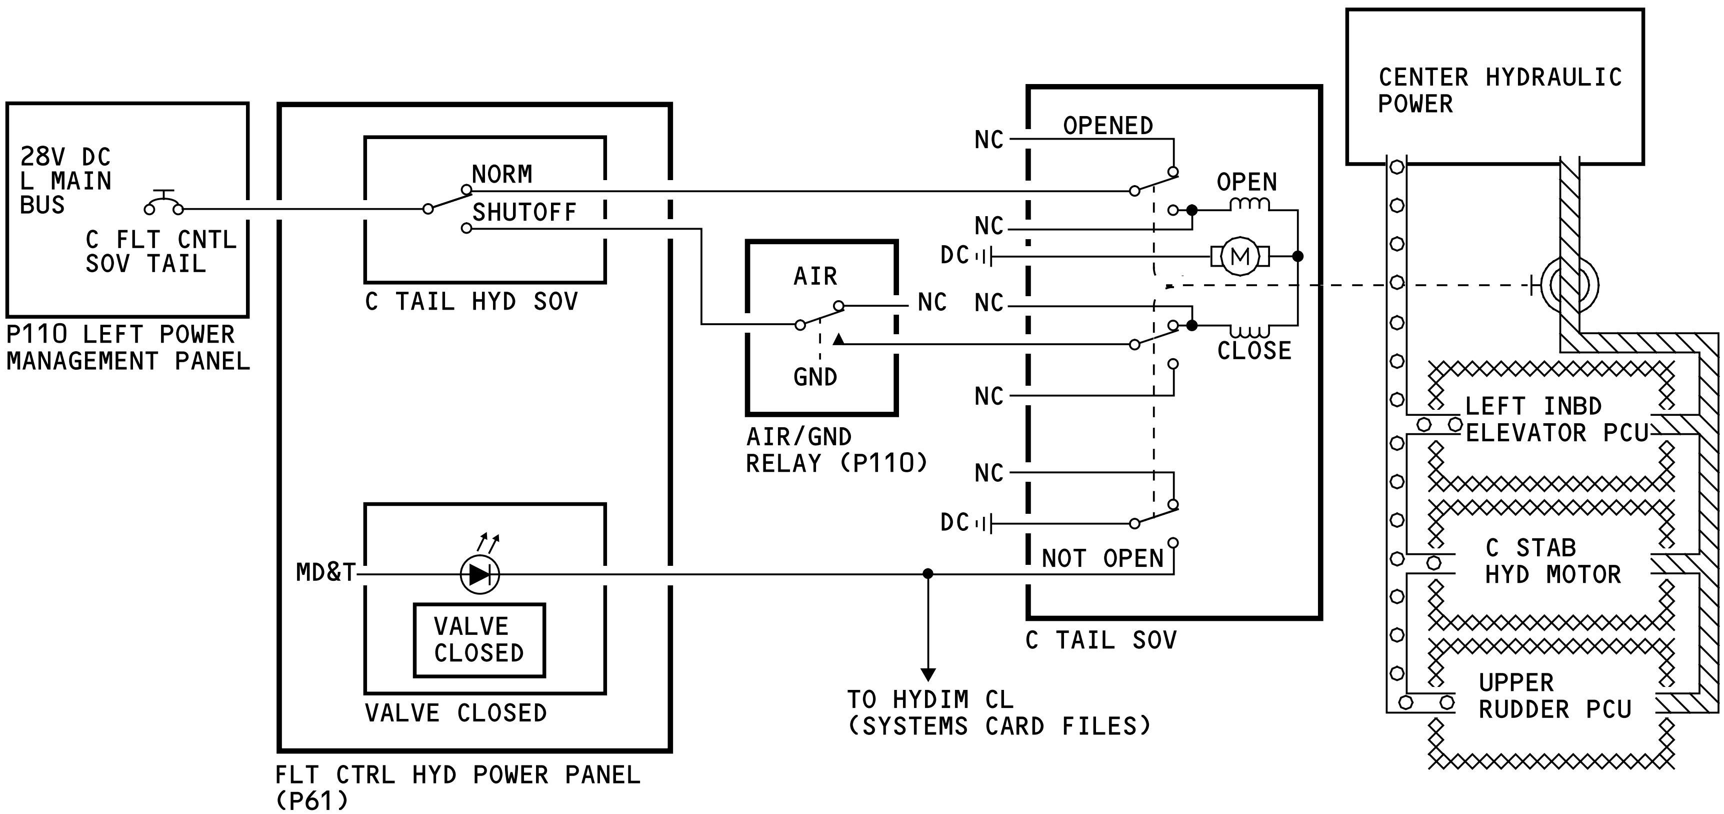
When the control switch is in the SHUTOFF position, the valve closes when the airplane is on the ground. As the valve leaves the open position, the amber VALVE CLOSED light shows on the P61 panel. The advisory message FLT CONTROL VALVE shows on the EICAS display.

Training Information Point

Ground maintenance personnel use the flight control SOVs to isolate certain portions of the flight controls during troubleshooting and other maintenance work.

Only the center flight control SOVs use an air/ground signal. This signal prevents closure of the valves when the airplane is in the air.

The left and right flight control SOVs can be closed in the air or on the ground.



NOTE: TAIL SOV FOR CENTER HYDRAULIC SYSTEM SHOWN.
THIS IS TYPICAL OF THE OTHER SHUTOFF VALVES.
ONLY THE CENTER FLIGHT CONTROL SOV USES THE
AIR/GROUND RELAY.

27-02-00-022 Rev 3

PFCS - FLIGHT CONTROL SHUTOFF VALVES - FUNCTIONAL DESCRIPTION

PFCS - INDICATIONS - FLIGHT CONTROLS SYNOPTIC DISPLAY

General

The flight controls synoptic display gives the flight crew a graphical overview of the flight control system. The display includes individual positions and failures for each flight control surface.

Normal Conditions

Under normal conditions the indications are white. The pointer on the labeled scales shows the position of the control surfaces.

The spoiler position indicators fill white from the bottom up.

The stabilizer and the rudder trim indicators show the stabilizer and rudder position in degrees. The direction of rudder trim is next to the indicator.

Defective Conditions

When a surface does not operate, a defective condition indicator replaces the scale and pointer or the moving band. The color of this indicator is amber.

Unknown Conditions

When the status of a control surface is unknown, the pointer does not show on the scale. In the case of the spoilers, there is no moving band.

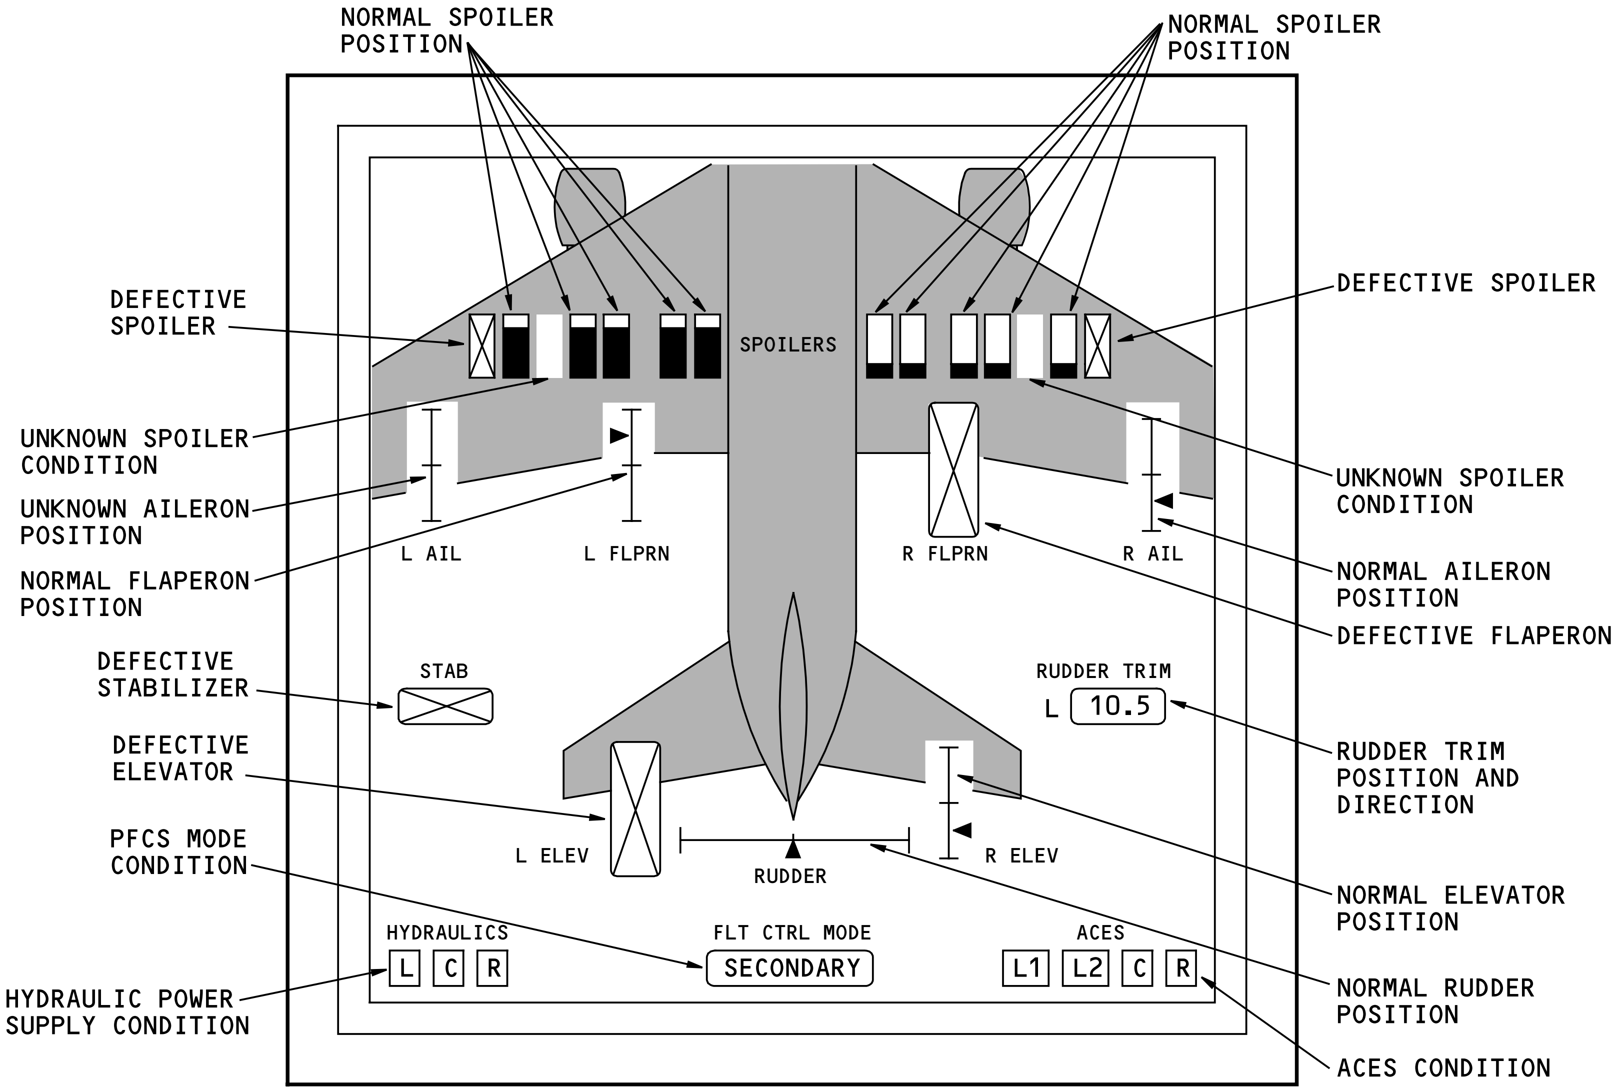
Other System Information

At the bottom of the synoptic display, individual indicators show the condition of:

- The hydraulic power supply systems
- The PFCS mode of operation
- The ACE operation.

The PFCS mode condition shows in green when in normal mode. In secondary or direct mode, the indication shows in amber.

The condition of the hydraulic power supply systems or the ACEs shows only when there is a failure of one of the systems or ACE. The indicator for the failed system or ACE is amber. The others are green.



27-02-00-024 Rev 4 04/19/1997

PFCS - INDICATIONS - FLIGHT CONTROLS SYNOPTIC DISPLAY

PFCS - INDICATIONS - MAINTENANCE PAGE - CONTROLS AND VARIABLES

THIS PAGE INTENTIONALLY LEFT BLANK

PFCS - INDICATIONS - MAINTENANCE PAGE - CONTROLS AND VARIABLES

General

There are three PFCS maintenance pages. Page one contains data for the control inputs and variables.

Maintenance personnel use the maintenance pages to do maintenance functions such as rigging or do a check of the discrete inputs and outputs of the PFCS components.

These are the three different display modes:

- Real time mode
- Manual event mode
- Auto event mode.

The word MANUAL or AUTO at the top of the page identifies the manual event or the auto event page. The message that caused the auto event is at the bottom left of the page. The time of the event is at the bottom right.

Variables and Controls

The top of the page shows:

- Roll rate in degrees per second
- Yaw rate in degrees per second
- Altitude in feet
- Roll angle in degrees
- Angle of attack in degrees
- CAS in knots
- ADIRU pitch rate in degrees per second
- ACE pitch rate in degrees per second for each ACE.

Directly below, the page shows the column, wheel and pedal position for the captain's and the first officer's controls. The position shows the displacement, in inches, of each LVDT.

The page then shows the column and wheel force for the captain's and the first officer's controls. The indication shows the force in lb.

The speedbrake lever position is in degrees of RVDT rotation for each of the four RVDTs.

The rudder trim and elevator feel show the actuator extension in inches. Rudder trim position 1 refers to the rudder trim actuator position RVDT. Position 2 refers to the rudder trim position transducer. Elevator feel position 1 refers to the left feel actuator position. Position 2 refers to the right feel actuator.

The gust suppression differential pressure shows in psid. The modal suppression shows in units of gravitational acceleration (g).

An X shows next to the indication if any of the above position, force or pressure transducer signals is invalid.

The lower part of the page shows the PFCS mode of operation and the autopilot engagement status. Up to three protection mode activity messages can show at the lower right of the page. These messages will only show if they are active and they will show in this priority order:

PFCS - INDICATIONS - MAINTENANCE PAGE - CONTROLS AND VARIABLES

- TAC
- Stall protection
- Bank angle protection
- Overspeed protection
- Flare compensation.

The NORMAL or SECONDARY messages show if the PFC is in the normal or secondary mode. When the PFCS is in direct mode, the PFC mode shows SECONDARY.

Training Information Point

Only the pitch rate measured by the ACE internal pitch rate sensors shows. Because there are no ACE external pitch rate sensors, the external fields show dashes.

PFCS - INDICATIONS - MAINTENANCE PAGE - CONTROLS AND VARIABLES

27-02-00-025 Rev 8 07/10/1997

PFCS - INDICATIONS - MAINTENANCE PAGE - SURFACE POSITION

General

The second PFCS maintenance page contains surface position information and actuator hydraulic data.

The graphic shows the maintenance page in auto event mode caused by a stabilizer fault.

Hydraulic System Pressure

The hydraulic pressure for each of the three systems shows in psi.

If a hydraulic system signal is invalid, the field is blank.

Surface Position

The surface position is in inches of displacement of the LVDT of each PCU. Surface position data shows for:

- Spoilers
- Flaperons
- Ailerons
- Rudder
- Elevators.

The stabilizer position is in degrees of rotation of the RVDT of each stabilizer position module.

Differential Pressure Indication

PCU FORCE shows the flaperons actuator force in pounds. DELTA PRESS shows the differential pressure across the PCU actuator piston. The data shows in psi for the rudder and the elevators.

Failure Indications

When a PCU is shutdown, an amber S shows adjacent to the surface position indication.

If a PCU position signal is invalid, an amber X shows adjacent to the surface position indication or adjacent to the S if the PCU is also shutdown.

When the stabilizer position signal is invalid, an amber X shows adjacent to the stabilizer position.

An amber SR or SC shows adjacent to the stabilizer position indication if there is a shutdown of either the right or center STCM.

PFCS - INDICATIONS - MAINTENANCE PAGE - SURFACE POSITION

PFCS - INDICATIONS - MAINTENANCE PAGE - ANALOG DISCRETES

THIS PAGE INTENTIONALLY LEFT BLANK

PFCS - INDICATIONS - MAINTENANCE PAGE - ANALOG DISCRETES

General

The third PFCS maintenance page contains the status of analog discretes. Normal indications are white. Failure indications are amber.

The graphic shows the maintenance page in auto event mode caused by a stabilizer fault.

ACE Discrete Indications

For each of the four ACEs, the page shows the status of the discrete signals.

The FSEU trailing edge and leading edge retracted signal shows as a YES or NO. If the signal is defective, the field becomes blank.

The PFC disconnect switch position status shows as AUTO or DISC. If the switch signal is invalid, OPEN or CLOSED shows in amber if the contacts are defective in the open or closed position. If the switch is defective and does not supply a signal, the field is blank.

The ACE mode of operation shows as NORMAL or DIRECT. If the ACE mode signal is invalid, the indication shows FAULT in amber.

The indication for the rudder manual trim cancel switch signal is in the L1 column. The indication shows as YES if the switch is pushed or NO if released. If the switch signal is invalid, the indication shows FAULT in amber.

The indication for the rudder trim armed signal is in the R column. The indication shows as YES if armed and NO if not armed. If the armed signal is invalid, the indication shows FAULT in amber.

The rudder trim rate signal is in the R column. The indication shows FAST or SLOW dependent on the condition. If the trim rate signal is invalid, the indication shows FAULT in amber.

The rudder trim direction is in the L1 column. The indication shows LEFT or RIGHT dependent on the rudder direction command. The indication shows NO if there is no rudder trim command. The indication shows L&R in amber if the trim command is for both directions at the same time. The indication shows FAULT in amber if the trim signal is not valid.

The rudder trim brake released indication is in the R column. The indication shows YES when the brake is released or NO when it is not. If the signal is not valid, the field is blank.

The pitch trim arm and control signal indications show in these columns:

- L1 for captain arm
- C for captain control
- L2 for first officer arm
- R for first officer control.

The indication shows UP or DOWN depending on which direction the pilot moves the trim switches. The indication shows NO if the pilot does not move the trim switches. The indication shows UP&DN in amber if the switches signal both up and down commands. If the signal is not valid, the field is blank.

The indication for the STCM brake release pressure is in the C and R columns. The indication shows YES if the brake is released or NO if it is not. If the signal is not valid, the field is blank.

The indication for the STCM hydraulic shutoff relay power is in the C and R columns. The indication shows YES if the relay has power or NO if it does not. If the signal is not valid, the field is blank.

The elevator feel engaged signal is in the L2 and C columns. The indication shows YES or NO depending on the engaged status of the elevator feel actuator. If the signal is not valid, the field is blank.

The auto speedbrake limit switch signal is on the L1 column. The indication shows YES if the auto speedbrake actuator is in the retracted position. It shows NO if the actuator is not retracted. If the signal is not valid, the field is blank.

The TAC switch position signal shows in the C column. The signal can be OFF or AUTO. If the signal is not valid, the field becomes blank.

AIMS Discrete Indications

The AIMS monitors the alternate pitch trim lever arm and control switches for activity and direction. The indication in the ACTIVE columns shows YES when the pilot makes a lever command or NO when there is no command. If the signal is not valid, the indication shows FAULT in amber.

The indication in the DIRECTION column shows UP or DOWN dependent on the direction of the alternate pitch trim command. If the signal is not valid, the indication shows FAULT in amber.

PFCS - SYSTEM TESTS

General

The PFCs control the operation of the MAT tests. There are 54 system tests for the PFCS.

These are the tests:

- Actuator Confidence
- Actuator Control Electronics Monitors
- Air/Ground System to PFC Interface
- Alternate Pitch Trim Levers
- Column Force Transducer
- Column Position
- Elevator Feel System
- Flap/Slat Electronics Unit Interface to ACE
- Flap/Slat Electronics Unit to PFC Interface
- Gust Suppression Pressure Transducers
- Left Aileron Actuator Confidence
- Left Aileron Alignment
- Left Aileron Position
- Left Elevator Actuator Confidence
- Left Elevator Alignment
- Left Elevator Oscillation Monitor
- Left Elevator Position
- Left Flaperon Actuator Confidence
- Left Flaperon Alignment
- Left Flaperon Position
- Modal Suppression Accelerometer
- Pedal Position
- PFC Disconnect Switch
- Primary Flight Computer Reset
- Primary Flight Computer (C) Lane Reset
- Primary Flight Computer (L) Lane Reset
- Primary Flight Computer (R) Lane Reset
- Primary Flight Computer Self Test
- Radio Altimeter Test Inhibit to PFC Interface
- Right Aileron Actuator Confidence
- Right Aileron Alignment
- Right Aileron Position
- Right Elevator Actuator Confidence
- Right Elevator Alignment
- Right Elevator Oscillation Monitor
- Right Elevator Position
- Right Flaperon Actuator Confidence
- Right Flaperon Alignment
- Right Flaperon Position
- Rudder Actuator Confidence
- Rudder Alignment
- Rudder Position
- Rudder Trim System
- Speedbrake System
- Spoiler 1, 7, 8, 14 System
- Spoiler 2, 13 System
- Spoiler 3, 6, 9, 12 System
- Spoiler 4, 11 System
- Spoiler 5, 10 System
- Stabilizer System
- Transmitter Reset Test
- Warning Electronic System to PFC Interface
- Wheel Force Transducer
- Wheel Position.

Actuator Confidence Test

This test checks the proper operation of the power control unit servo valve monitors and for proper operation of the bypass, blocking, and pressure reducing functions of the primary power control units and the motor-operated valve in each of the stabilizer control modules.

Actuator Control Electronics Monitors

This test is to make sure the internal monitors necessary for flight safety in the L1, L2, C and R actuator control electronics operate correctly.

Air/Ground System to PFC Interface

This test does a check of the proper operation of the weight on wheel (WOW) system interface to the primary flight computers (PFCs). The test resets latches associated with the WOW system interface.

Alternate Pitch Trim Levers

This test checks for proper operation of the switches for the alternate pitch trim levers. This test can reset latches for the alternate pitch trim levers.

Column Force Transducer

This test checks for proper operation of the force transducers for the pilot and co-pilot control columns. This test can reset latches for control column force transducers. This test is similar to the wheel force transducer test.

Column Position

This test checks for proper operation of the transducers for the pilot and co-pilot control columns. This test can reset latches for control column transducers. This test is similar to the pedal position test and the wheel position test.

Elevator Feel System

This test checks for proper operation of the elevator feel units. This test can reset latches for the elevator feel units. This test can also set the configuration of either elevator feel unit to 3 different elevator feel settings.

Flap/Slat Electronics Unit Interface to ACE

This test checks for proper operation of the interface between the FSEUs and the ACEs. This test can also set the configuration of either FSEU to its flaps and slats retracted state or its flaps and slats not retracted state for fault isolation purposes. This test can reset latches associated with the analog wiring between the ACEs and the FSEUs.

Flap/Slat Electronics Unit to PFC Interface

This test checks for proper operation of the flap slat electronic units. This test can reset latches for the flap slat electronic units.

PFCS - SYSTEM TESTS

Gust Suppression Pressure Transducers

This test checks the proper operation of the gust suppression transducers. This test can reset latches for the gust suppression transducers.

Left Aileron Actuator Confidence

This test checks the proper operation of the bypass and blocking/damped functions of the left aileron power control units. This test is similar to the actuator confidence tests for the other surfaces.

Left Aileron Alignment

This procedure aligns the power control units for the left aileron. This procedure can also check alignment of the left aileron power control units. This test is similar to the alignment tests for the other surfaces.

Left Aileron Position

This test checks for proper operation of the position transducers for the left aileron. This test can reset latches for left aileron position transducers. This test is similar to the position test for the other surfaces.

Left Elevator Oscillation Monitor

This test checks that the left elevator power control units are operating within the allowable oscillatory force fight tolerances. This test can reset oscillatory force fight latches for the left elevator. This test is similar to the right elevator oscillation monitor test.

Modal Suppression Accelerometer

This test checks for proper operation of the two modal suppression accelerometers. This test can reset latches for the modal suppression accelerometers.

PFC Disconnect Switch

This test checks for proper operation of the PFC DISC switch. This test can reset latches for the PFC DISC switch.

Primary Flight Computer Reset

This test resets a primary flight computer to operational capability after a channel does not operate because the other primary flight computers prevent it.

Primary Flight Computer (C) Lane Reset

This test restores the center primary flight computer to operational capability after a center primary flight computer lane becomes inoperative due to external interface faults or from a maintenance operation. This test is similar to the lane reset tests for the other PFCs.

PFCS - SYSTEM TESTS

Primary Flight Computer Self Test

This test checks internal primary flight computer functions and cross channel functions of the primary flight control computers.

Radio Altimeter Test Inhibit to PFC Interface

This test makes sure that the primary flight computer can put the radio altimeters in test inhibit mode.

Rudder Trim System

This test checks for proper operation of the rudder trim actuator and the rudder trim switch. This test can reset latches for the rudder trim actuator.

Speedbrake System

This test checks for proper operation of the speedbrake lever transducers, the auto speedbrake thrust reverse switch, and the auto speedbrake actuator limit switch. It will reset latches for the speedbrake lever transducers, the auto speedbrake thrust reverse switch, the radio altimeter and the landing gear truck tilt switch.

Spoiler 1,7,8,14 System

This test checks for proper operation of spoiler pairs 1,14 and 7,8. This test can reset latches for spoiler pairs 1,14 and 7,8. This test is similar to the system tests for the other spoiler surfaces.

Stabilizer System

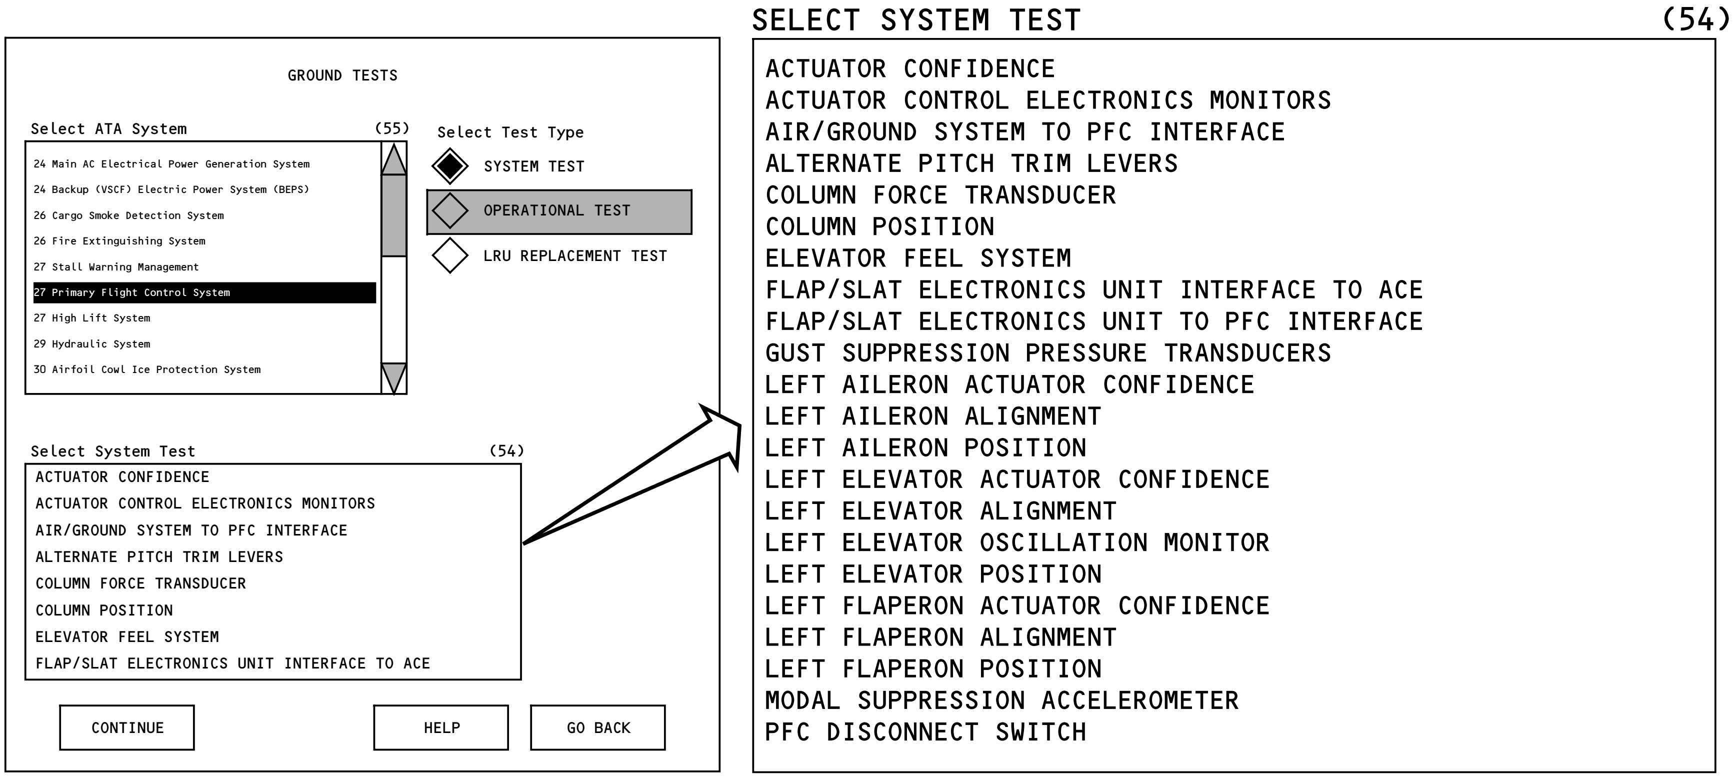
This test checks for proper operation of the stabilizer position transducers, the stabilizer arm and control solenoid operated valves, the stabilizer rate valves, the stabilizer hydraulic shut off valves and the stabilizer brake. This test can reset fault latches for the stabilizer position transducers, it can also reset stabilizer control module disengage latches.

Transmitter Reset Test

This test resets the latches for the primary flight computers ARINC 629 bus transmitters.

Warning Electronic System to PFC Interface

This test resets latches in the primary flight computer caused by the warning electronic system.



27-02-00-028 Rev 3 03/19/96

PFCS - SYSTEM TESTS

PFCS - LRU REPLACEMENT TESTS

General

These are the LRU replacement tests for the PFCSs and the ACEs:

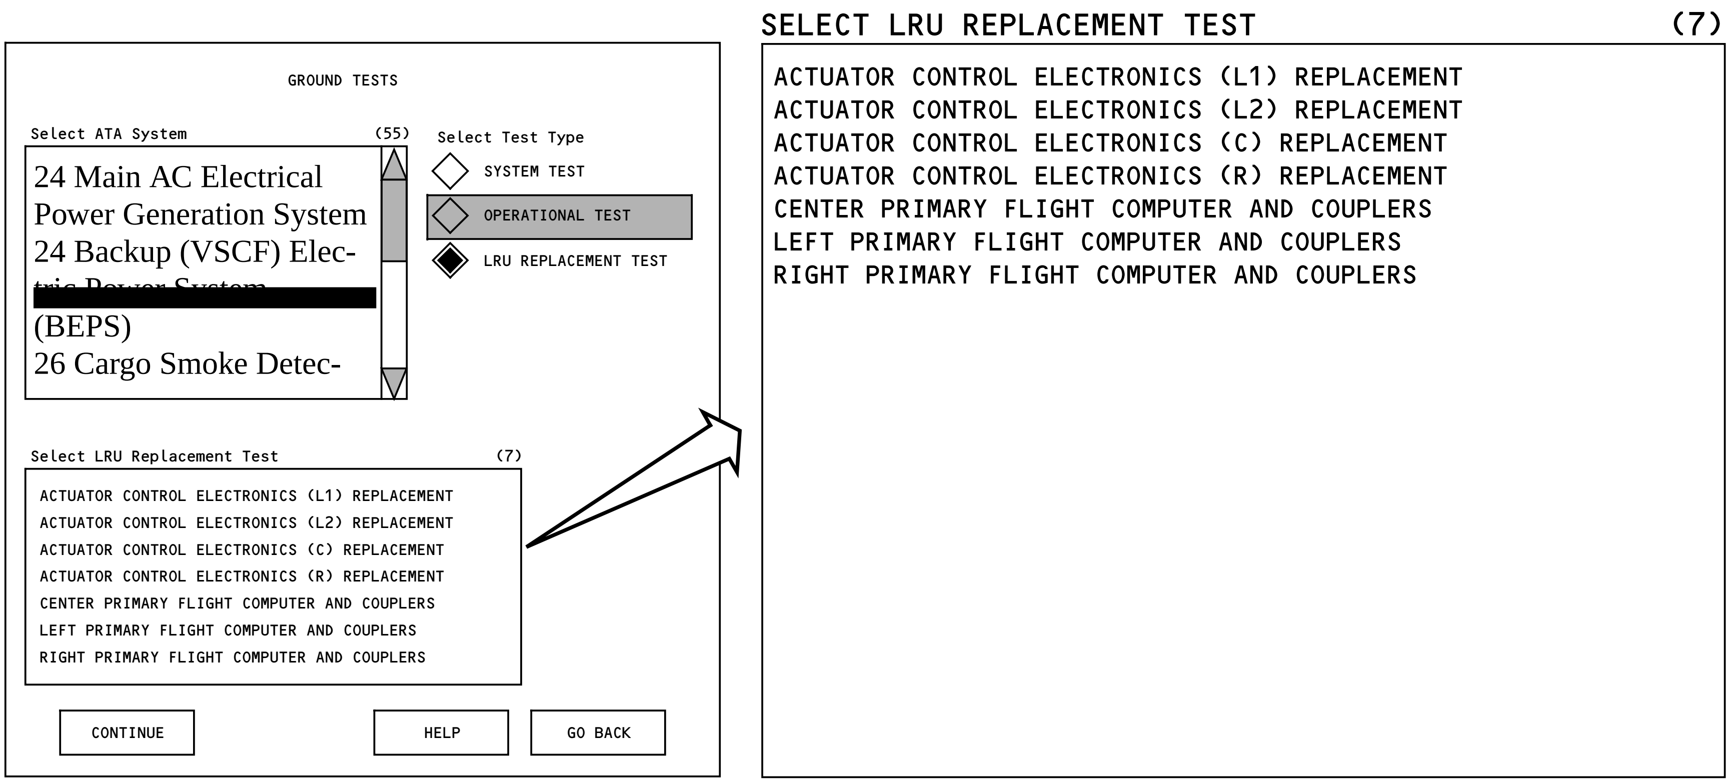
- Actuator Control Electronics (L1) Replacement
- Actuator Control Electronics (L2) Replacement
- Actuator Control Electronics (C) Replacement
- Actuator Control Electronics (R) Replacement
- Center Primary Flight Computers and Couplers
- Left Primary Flight Computers and Couplers
- Right Primary Flight Computers and Couplers.

Actuator Control Electronics (L1) Replacement

This test is to make sure the L1 actuator control electronics has been replaced correctly. This test also resets any fault latches in the primary flight computer caused by the actuator control electronics. This test is similar to the replacement test for the other ACEs.

Center Primary Flight Computer and Couplers Replacement

This test does a check of the proper installation of the center primary flight computer and all associated ARINC 629 couplers. This test is similar to the replacement test for the other PFCs.



27-02-00-029 Rev 1 01/04/96

PFCS - LRU REPLACEMENT TESTS

THIS PAGE INTENTIONALLY LEFT BLANK

AILERON AND FLAPERON CONTROL - INTRODUCTION

General

The ailerons and flaperons control the flight attitude of the airplane about the longitudinal axis. They also increase the wing lift with the high lift system during takeoff, approach and landing.

The ailerons are on the wing outboard trailing edge.

The flaperons are standard inboard ailerons which also operate as flaps. They are between the inboard and the outboard flaps on the wing trailing edge.

Roll Control

During roll control, the aileron and flaperon on one wing move up, and the aileron and flaperon of the other wing move down.

The pilots manually command a roll correction with the rotation of the control wheels. When engaged, the autopilot automatically commands the ailerons and the flaperons. During autopilot operation, actuators backdrive the control wheels.

The spoilers also supply roll control. See the spoiler and speedbrake control section for more information (AMM PART I 27-61).

Aileron Lockout

On the ground and during flight below cruise speed, the ailerons and flaperons are fully operational. At cruise speed, the ailerons fair to the wing surface and lock out. The flaperons supply roll control.

Aileron and Flaperon Droop

During extension of the flaps, the ailerons and flaperons droop to increase the lift of the wing. The ailerons and flaperons of both wings move down. When drooped, the ailerons and flaperons are fully operational for roll control.

Abbreviations and Acronyms

ACE	- actuator control electronics
ACMS	- airplane condition monitoring system
ADIRS	- air data inertial reference system
ADIRU	- air data inertial reference unit
ADM	- air data module
AFDC	- autopilot flight director computer
AFDS	- autopilot flight director system
AIMS	- airplane information management system
ARINC	- Aeronautical Radio, Inc.
BAP	- bank angle protection
B/D	- backdrive
CAS	- calibrated airspeed
CMCS	- central maintenance computing system
CPU	- central processing unit
EHSV	- electrohydraulic servo valve

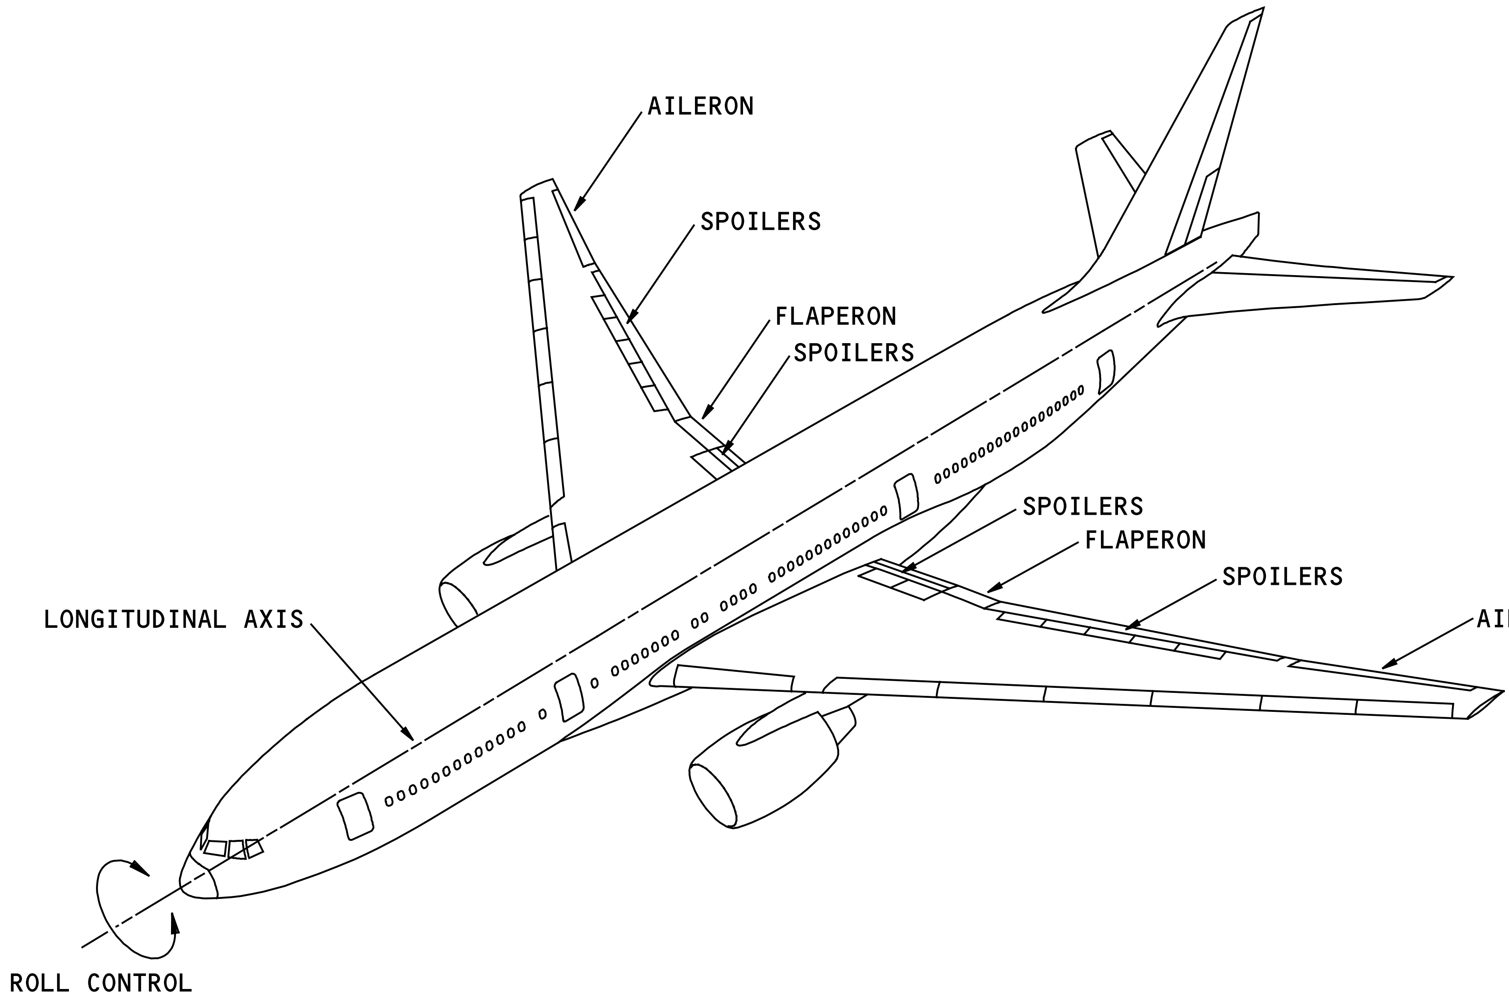
TED - trailing edge down
TEU - trailing edge up
Vdive - maximum design dive speed
Vmo - maximum operating limit speed
WEU - warning electronic unit
WOW - weight-on-wheels



AILERON AND FLAPERON CONTROL - INTRODUCTION

AILERON AND FLAPERON CONTROL - GENERAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

AILERON AND FLAPERON CONTROL - GENERAL DESCRIPTION

General

The pilots manually command the ailerons and flaperons; the autopilot automatically commands them.

Manual Operation - Control Wheels

The flight crew uses two conventional control wheels to control roll. A wheel jam breakout mechanism supplies a mechanical link between the control wheels. If a control wheel jams, the other continues to control.

Six position transducers change the flight crew commands of the control wheel to analog electrical signals. These signals go to the four actuator control electronics (ACEs). The ACEs change the signals to digital format and send them to the three primary flight computers (PFCs) through the flight controls ARINC 629 buses.

The PFCs use the control wheel position data, along with data from the ADIRU and AIMS, to calculate control surface commands. The PFCs send the digital commands to the ACEs, which change them to analog signals. The ACEs send the analog position commands to the power control units (PCUs) which move the control surfaces. The position transducers on the actuator pistons supply position feedback to the ACEs.

Manual Operation - Aileron Trim

The aileron trim switches and the trim actuator permit the flight crew to trim out unwanted control wheel forces. When the pilots move the aileron trim switches on the aisle stand, the switches send a signal to the aileron trim actuator. The trim actuator moves the control wheels and the position transducers through the feel and centering mechanism. This changes the neutral position of the control wheels. The transducers send a signal to the ACEs and PFCs to move the ailerons and flaperons.

When the autopilot is engaged or the bank angle protection (BAP) is active, the aileron trim does not operate.

Autopilot Operation

When engaged, the autopilot flight director computers (AFDCs) control the roll rate and attitude of the airplane. The AFDCs supply roll commands to the PFCs through the flight controls ARINC 629 buses. The PFCs use these inputs to calculate position commands for the ailerons and flaperons in a similar manner as for the manual operation.

The PFCs also calculate wheel backdrive commands. The PFCs send these commands to the AFDCs, which calculate control wheel movement commands for the backdrive actuator. The backdrive actuator moves the wheels the same amount as the pilot would move them manually for the same surface movement. The flight crew can override the autopilot through the use of enough force on the wheel to overcome the backdrive actuator.

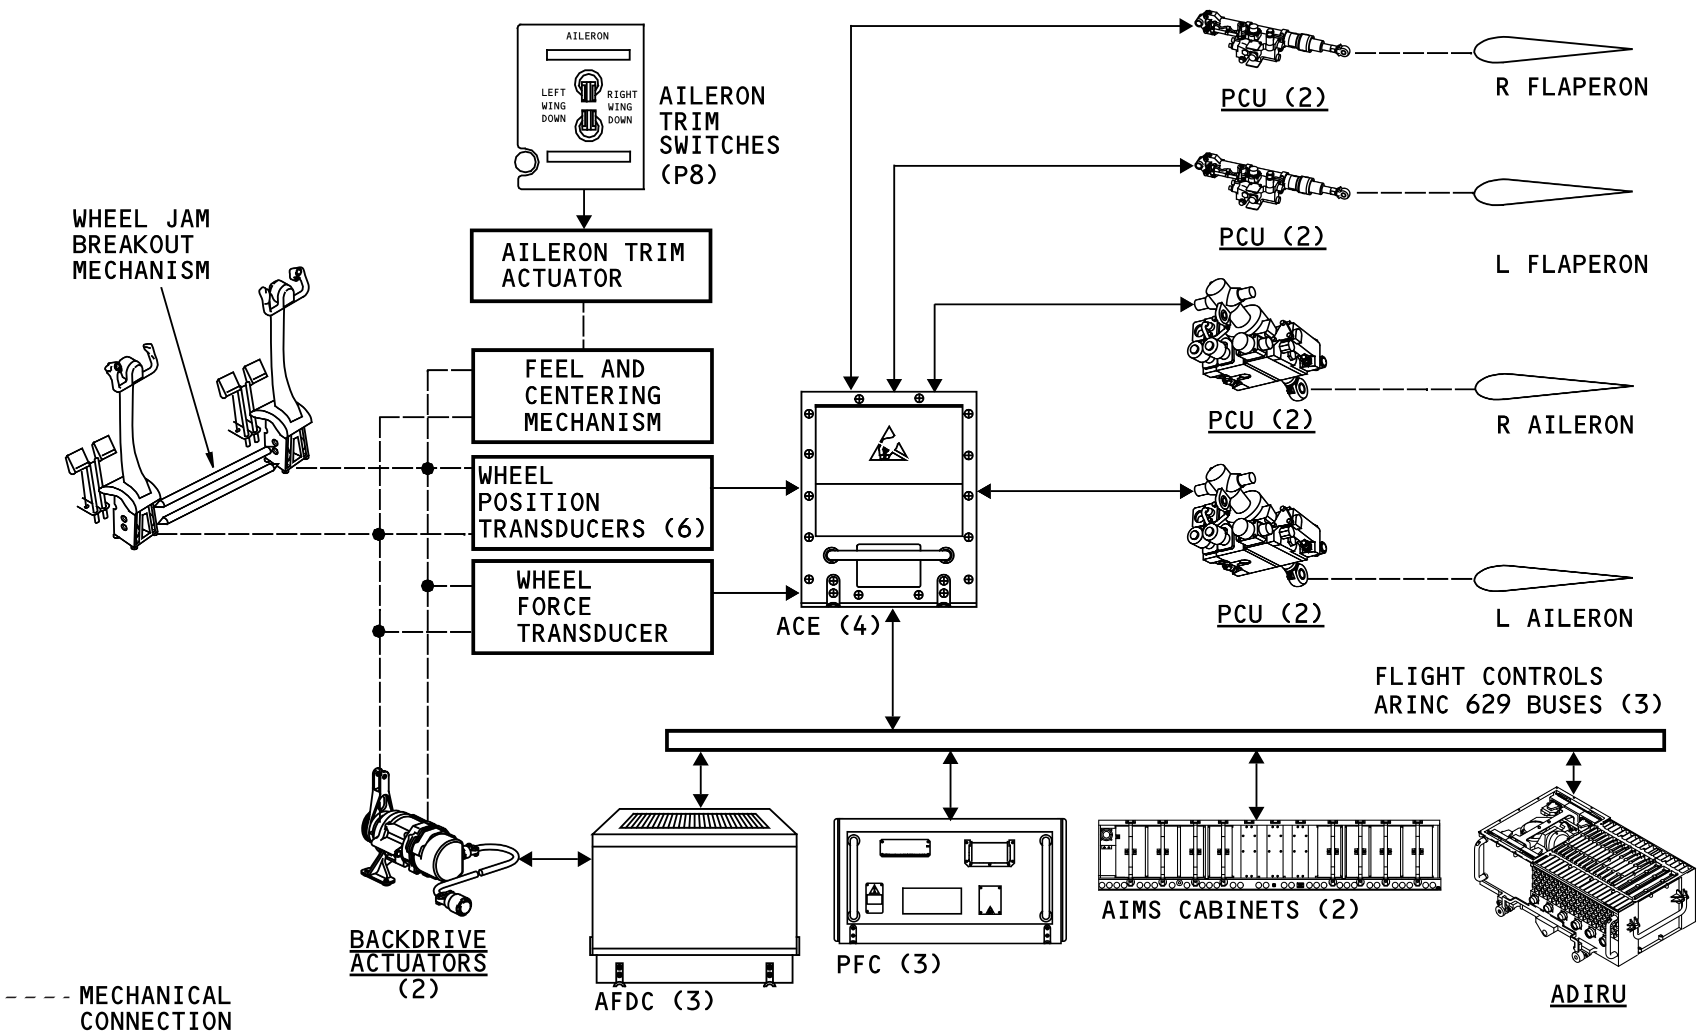
AILERON AND FLAPERON CONTROL - GENERAL DESCRIPTION

The AFDCs prevent the aileron trim operation when the autopilot is engaged.

Bank Angle Protection

A bank angle protection (BAP) function in the PFCs supplies protection in both manual and autopilot operation when the bank angle is more than 35 degrees.

The AFDCs prevent the aileron trim operation when the bank angle protection (BAP) is active.



27-11-00-002 Rev 2

AILERON AND FLAPERON CONTROL - GENERAL DESCRIPTION

AILERON AND FLAPERON CONTROL - COMPONENT LOCATIONS

General

The aileron and flaperon control components are in three areas:

- The wings
- The flight deck
- Below the flight deck floor.

See the primary flight controls section for more information about the location of PFCS electronic components (AMM PART I 27-02).

Wing Components

The aileron and flaperon control surfaces and their PCUs are on the wings. Two PCUs directly connect to each surface. Access to the aileron PCUs is by hinged access panels on the lower wing. Access to the flaperon PCUs is by removable lower skin panels.

Flight Deck Components

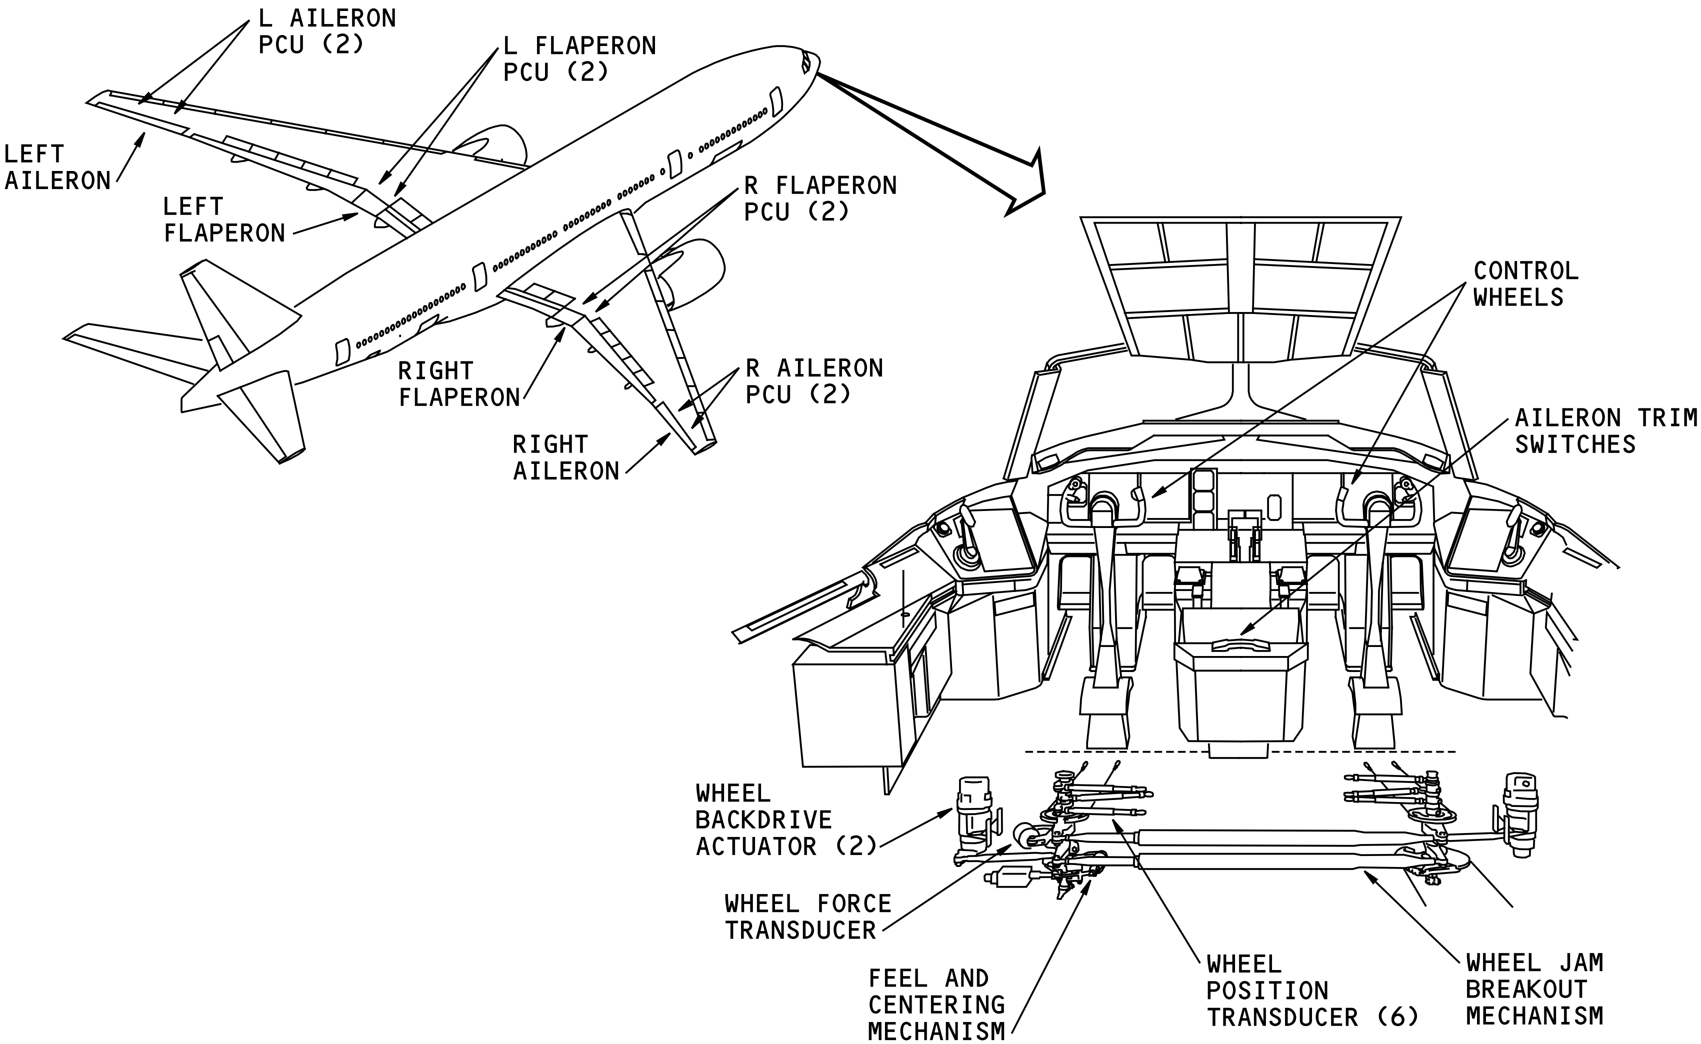
The control wheels and aileron trim switches are in the flight deck. The aileron trim switches are on the P8 aft aisle stand panel.

Components Below the Flight Deck

The rest of the forward controls are below the flight deck floor and above the nose gear wheel well. These are the:

- Wheel position transducers
- Wheel force transducer
- Wheel cable drums
- Feel and centering mechanism
- Wheel jam breakout mechanism
- Wheel backdrive actuators.

Access to these components is through the main equipment center (MEC), and then forward along the nose gear wheel well.



27-11-00-003 Rev 3

AILERON AND FLAPERON CONTROL - COMPONENT LOCATIONS

AILERON AND FLAPERON CONTROL - ANALOG AND DISCRETE INTERFACES

General

All of the aileron and flaperon control electrical interfaces within the PFCS go through the ACEs. Each ACE has interfaces with these components:

- Wheel position transducers
- Wheel force transducer
- Aileron PCUs
- Flaperon PCUs.

The aileron trim switches and trim actuator have mechanical interfaces with the aileron and flaperon control system.

Aileron Trim Switches and Trim Actuator

Two trim switches supply power to the trim actuator. The trim actuator moves the control wheels and the wheel position transducers by rotation of the feel and centering mechanism.

Wheel Position Transducers

There are six position transducers, three for each control wheel. Each transducer is a linear variable differential transformer (LVDT) that sends analog signals to the ACEs. These analog signals represent the control wheel position and its movement.

Wheel Force Transducer

There is one force transducer, with two LVDTs, that sends analog signals to the ACEs. These signals show the amount of force the pilots apply to the control wheels.

Aileron PCUs

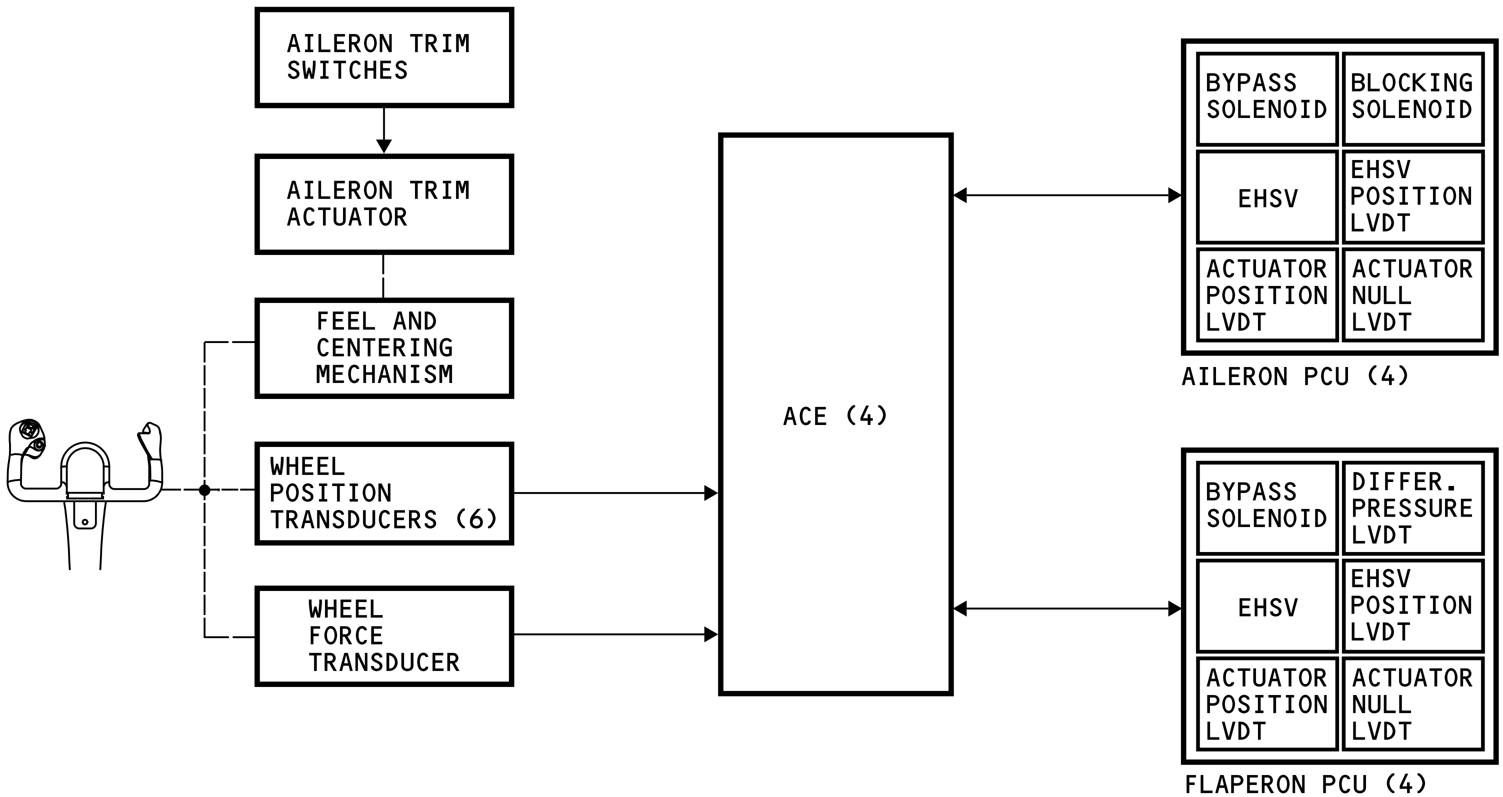
Each of the four aileron PCUs receives analog and discrete electrical signals from the ACEs. The discrete signals are for the bypass and blocking solenoids. The analog signal is for the electrohydraulic servo valve (EHSV).

Each of the four aileron PCUs sends analog feedback signals to the ACEs. These signals are from the EHSV position LVDT, the actuator position LVDT and the null LVDT.

Flaperon PCUs

Each of the four flaperon PCUs receives analog and discrete electrical signals from the ACEs. The discrete signals are for the bypass solenoid. The analog signal is for the EHSV.

Each of the four flaperon PCUs sends analog feedback signals to the ACEs. These signals are from the EHSV position LVDT, the actuator position LVDT and the null LVDT. A differential pressure LVDT sends signals about the difference of pressure between both sides of the PCU piston.



27-11-00-004 Rev 2 06/26/96

AILERON AND FLAPERON CONTROL - ANALOG AND DISCRETE INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

AILERON AND FLAPERON CONTROL - FORWARD CONTROLS

General

The forward controls of the aileron and flaperon control system include:

- Control wheels
- Wheel drums and shaft assemblies
- Wheel jam breakout mechanism
- Wheel position and force transducers
- Wheel backdrive actuators
- Wheel damper
- Feel and centering mechanism
- Travel stops.

The forward controls are below the flight deck.

Control Wheels

Each pilot has a control wheel. The control wheels turn to supply manual input to the aileron and flaperon control.

Wheel Cable Drums and Shaft Assemblies

A pair of control cables connects each control wheel to a cable drum. The left and right cable drums bearing mount on their drive shaft assembly. The cable drums indirectly move the shaft assemblies through the force limiters and the force transducer. There is a lost motion device on each wheel cable drum.

Wheel Jam Breakout Mechanism

The wheel jam breakout mechanism has two identical force limiters and two lost motion devices. If the control wheel jams, the force limiters allow the other control wheel to continue roll control. The upper force limiter connects the two wheel cable drums. The lower force limiter connects the right and left shaft assemblies. The lost motion devices allow the control wheel cable drums to move the left or right shaft assembly in case of failure.

Wheel Position and Force Transducers

Six wheel position transducers, on the airframe structure, connect to cranks at the top of the left and right shaft assemblies.

The wheel force transducer connects the left cable drum to the left crank.

Wheel Backdrive Actuators

Two wheel backdrive actuators connect to the cranks on the left and right shaft assemblies. The backdrive actuators are part of the autopilot system. See the autopilot flight director system section for more information on the backdrive actuators (AMM PART I 22-11).

AILERON AND FLAPERON CONTROL - FORWARD CONTROLS

Wheel Damper

The left shaft assembly connects to a wheel damper. The wheel damper absorbs control wheel vibrations.

Feel and Centering Mechanism

The feel and centering mechanism is at the bottom of the left shaft assembly. The aileron trim actuator connects directly to the feel and centering mechanism.

Travel Stops

Travel stops are at the bottom of the shaft assemblies. They limit the shaft assemblies, cable drums and position transducers movement to 65 degrees of control wheel travel.

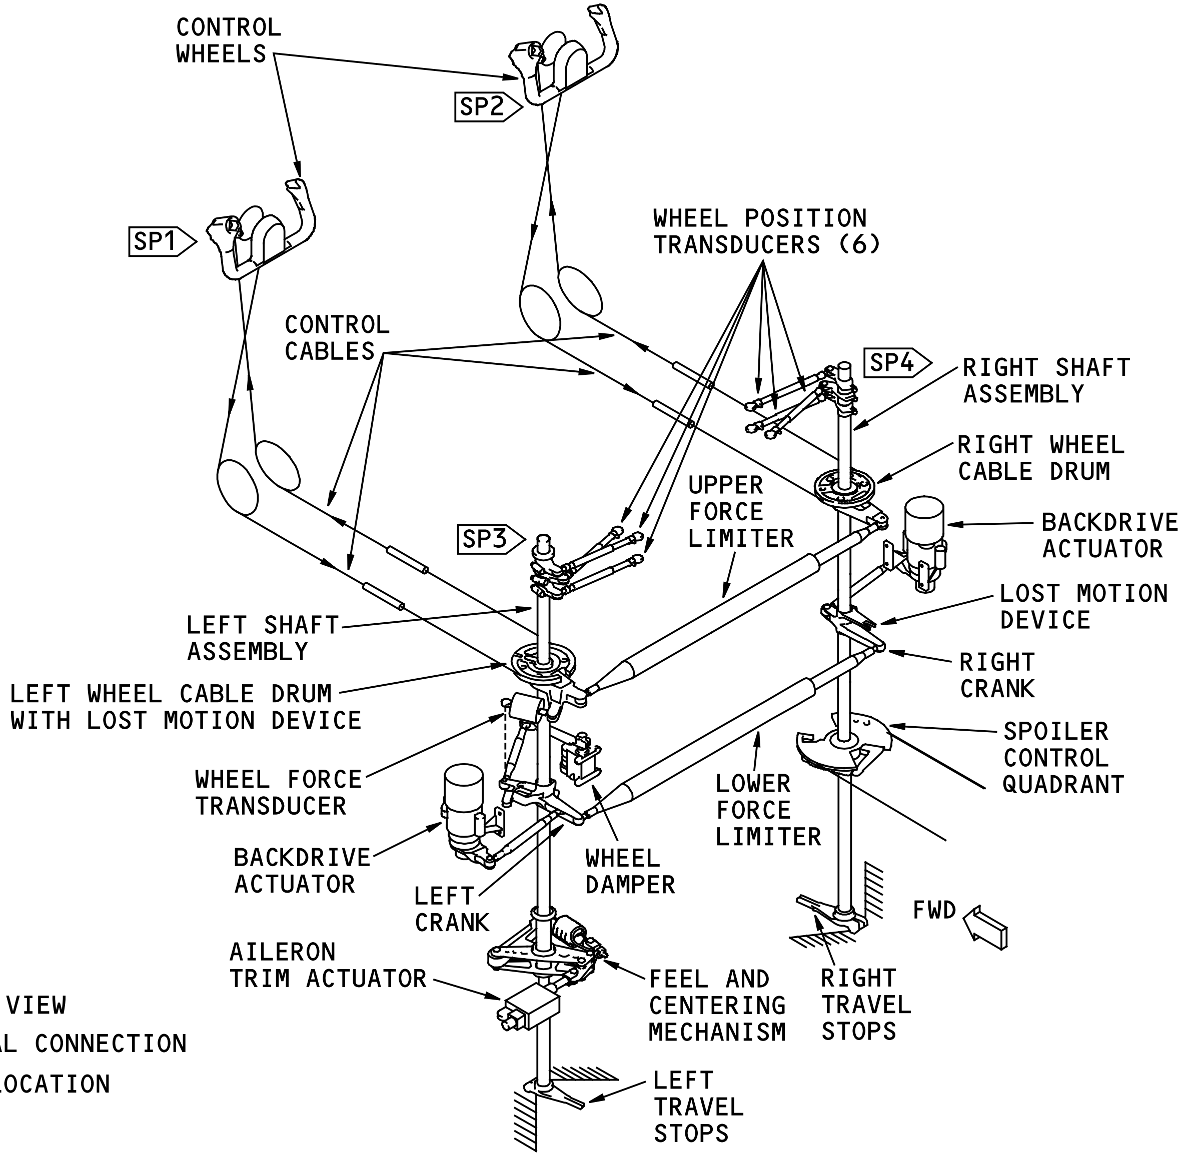
Spoiler Control Quadrant

The spoiler control quadrant is at the bottom of the right shaft assembly. The spoiler control quadrant connects by a pair of cables to the controls of spoilers 4 and 11.

See the spoiler and speedbrake control section for more information (AMM PART I 27-61).

Training Information Point

You use four rig pins to adjust the system.



NOTE: EXPANDED VIEW
------- MECHANICAL CONNECTION
SPX RIG PIN LOCATION

27-11-00-005 Rev 5 03/19/96

AILERON AND FLAPERON CONTROL - FORWARD CONTROLS

AILERON AND FLAPERON CONTROL - WHEEL CABLE DRUM

Purpose

The wheel cable drums transmit the wheel cable motion to the force transducer and upper force limiter.

Physical Description

The wheel cable drums are cast assemblies. The right and left drums are not the same. Both drums have attachment points for the upper force limiter, which is part of the wheel jam breakout mechanism.

The left drum has an additional attachment point for the wheel force transducer. The left drum is bearing mounted on a sleeve which is spline mounted on the left shaft assembly. If there is a failure, the sleeve and left drum can connect through a lost motion device. The lost motion device permits connection after a control wheel rotation of 7.8 degrees in either direction.

The right drum is bearing mounted on the right shaft assembly. The right drum has a peg on the bottom side which is part of the lost motion device. If there is a failure, the lost motion device lets the right drum connect to the right shaft assembly after a control wheel rotation of 2.9 degrees in either direction.

Location

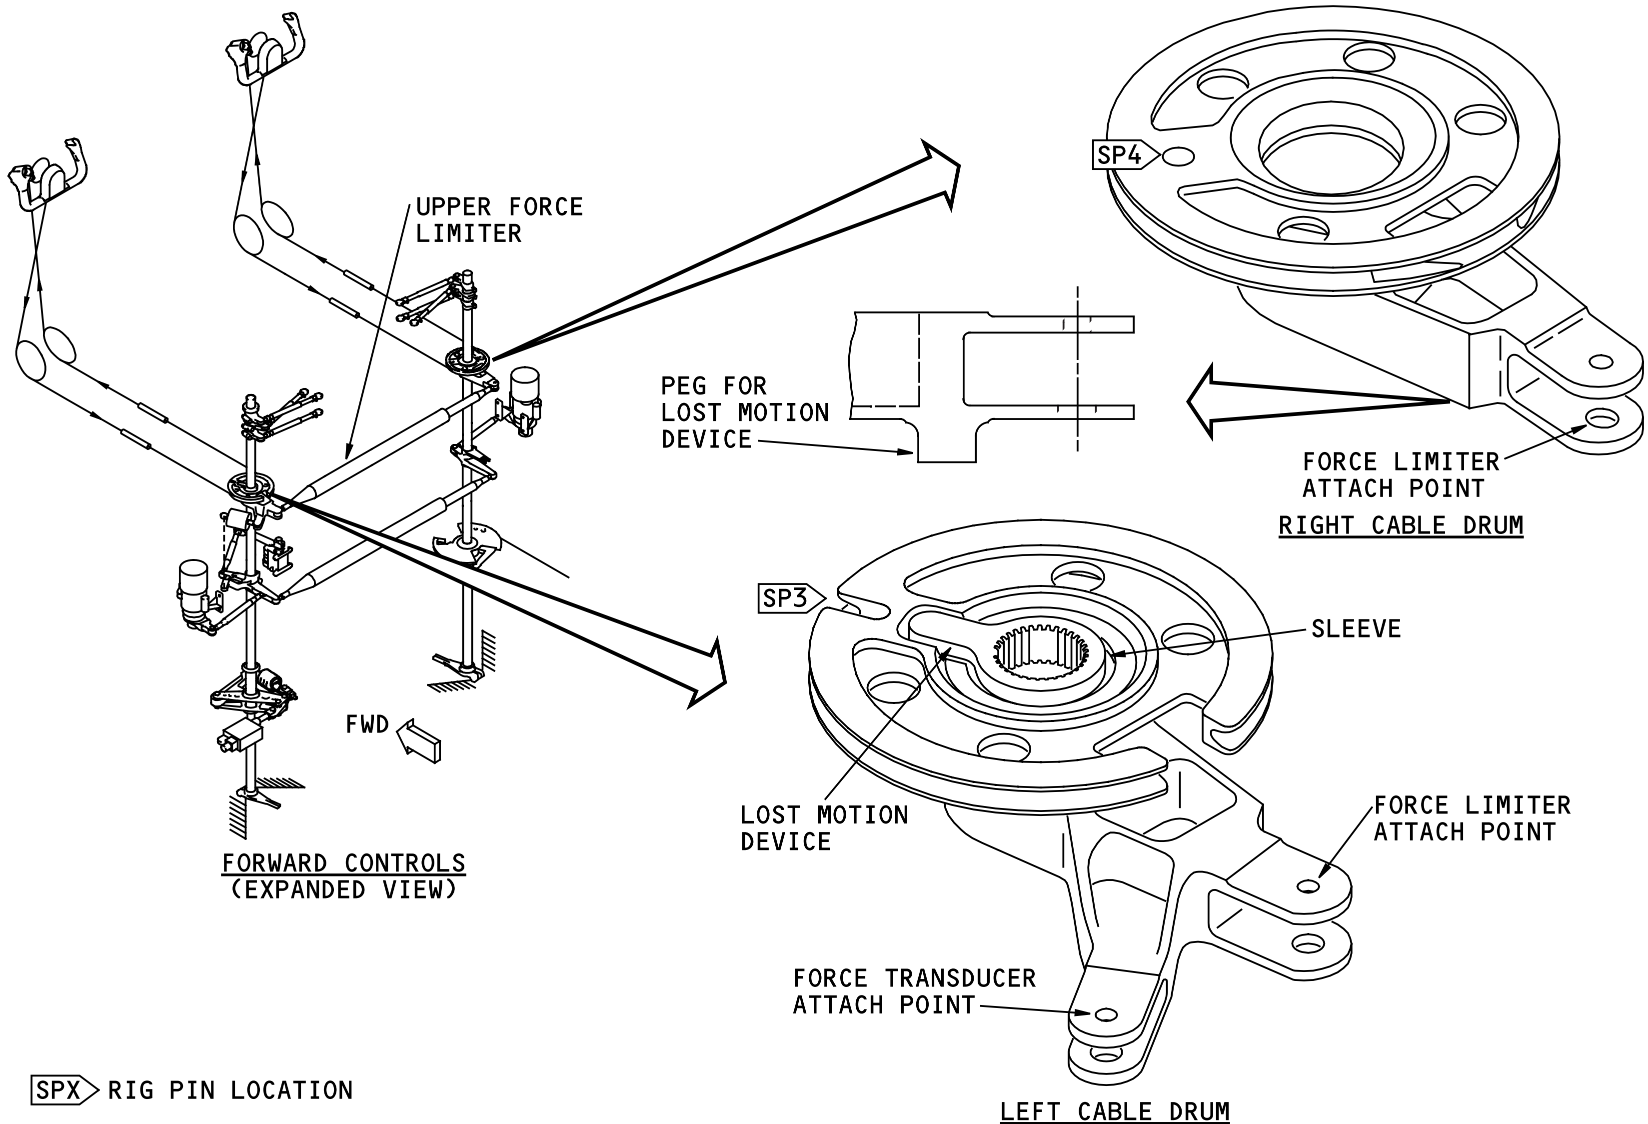
The wheel cable drums are on the shaft assemblies. They are between the flight deck floor and the nose gear well. Access to the drums is through the MEC, along the nose gear wheel well, or through the flight deck floor access panels.

Functional Description

When the pilots move the control wheels, the wheel cables turn the wheel drums.

Training Information Point

Each wheel cable drum has a rig pin hole.



27-11-00-007 Rev 3 03/19/96

AILERON AND FLAPERON CONTROL - WHEEL CABLE DRUM

THIS PAGE INTENTIONALLY LEFT BLANK

AILERON AND FLAPERON CONTROL - WHEEL JAM BREAKOUT MECHANISM

Purpose

The wheel jam breakout mechanism supplies a load path for roll control. In normal operation, the mechanism permits either pilot to make roll control commands. If there is a jam of a control wheel, the breakout mechanism permits the pilot to operate the other control wheel. If the cable or connection breaks, the other control wheel still operates.

Physical Description

The wheel jam breakout mechanism has two identical force limiters and two lost motion devices.

Force Limiter

Each force limiter is a pogo. It contains an inner and outer rod and a spring. It takes a 50 lb (23 kg) force at the control wheel to breakout the force limiters.

The upper force limiter attaches directly to the two wheel cable drums. The lower force limiter attaches to the two cranks on the left and right shaft assemblies.

Lost Motion Devices

There is a lost motion device on the left and right cable drums.

If there is a failure, the left cable drum motion device connects the drum to the left shaft assembly after a control wheel rotation of 7.8 degrees.

The lost motion device on the right drum is a peg and notch type mechanism. The right wheel cable drum has a peg on the bottom surface which inserts in the slot of the right crank, directly below it. If there is a failure, the right lost motion device connects the right wheel cable drum to the right crank after a control wheel rotation of 2.9 degrees.

Location

The wheel jam breakout mechanism is between the flight deck floor and the nose gear wheel well. Access is through the MEC, then along the left side of the nose gear wheel well.

Functional Description - Normal Operation

In normal operation, the two force limiters supply the load path for roll control.

Movement of the left wheel cable drum goes through the upper force limiter to move the right cable drum and the right control wheel. The movement also goes through the force transducer to the left crank. The left crank moves the left shaft assembly. It also moves the right crank and the right shaft assembly through the lower force limiter.

Movement of the right wheel cable drum goes through the upper force limiter to move the left cable drum and the left control wheel. The rotation of the left cable drum moves both shaft assemblies in the same manner as above.

AILERON AND FLAPERON CONTROL - WHEEL JAM BREAKOUT MECHANISM

Functional Description - Failure Mode

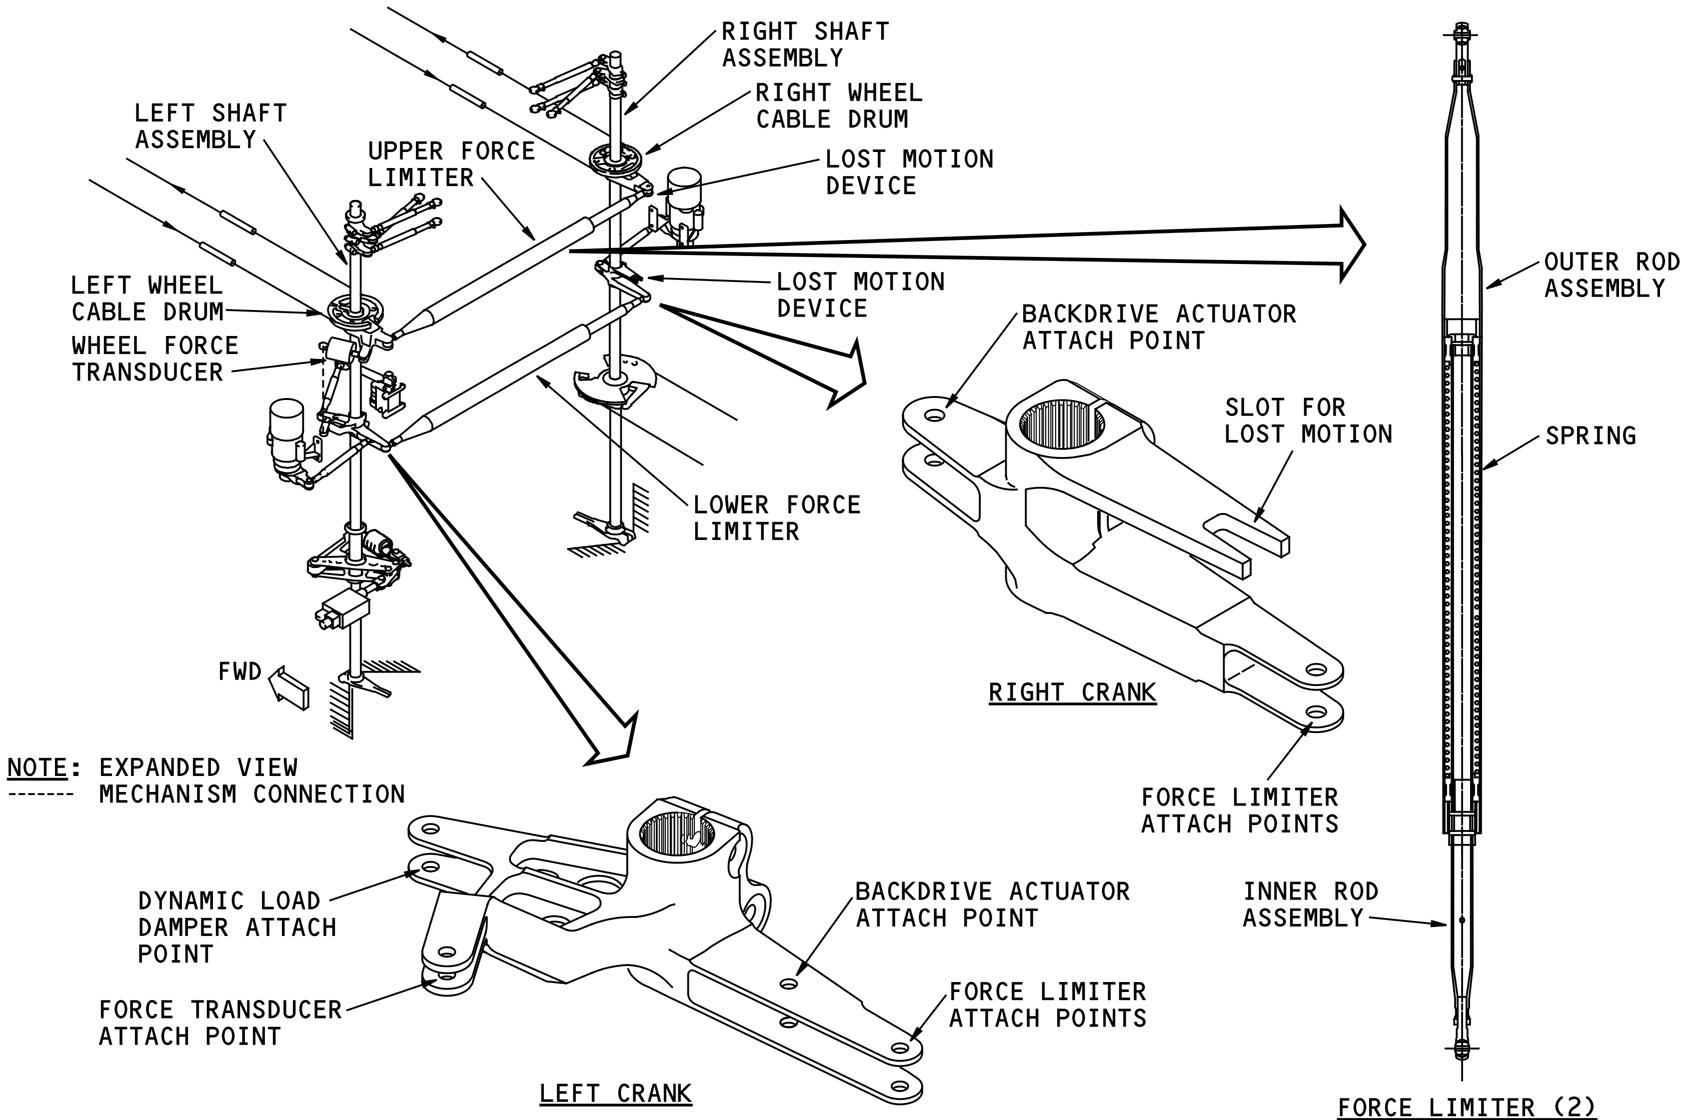
The wheel jam breakout mechanism permits the pilot to continue roll command if either wheel jams or a connection breaks.

If a right control wheel jams, the captain can operate the left wheel after overriding the 50 lb (23 kg) force of the breakout mechanism and the force of the feel and centering mechanism.

If the left control wheel jams, the first officer can operate the right control wheel after overriding only the force of the breakout mechanism. The right lost motion device engages after 2.9 degrees of control wheel movement. The lost motion device then turns the right shaft assembly.

If a control cable breaks between the control wheel and the cable drum, the pilot operates the other control wheel to control roll.

If a connection with the force transducer breaks, control roll through the motion device on the right cable drum. The right lost motion device engages after 2.9 degrees of control wheel movement.



AILERON AND FLAPERON CONTROL - WHEEL JAM BREAKOUT MECHANISM

27-11-00-008 Rev 2 03/19/96

AILERON AND FLAPERON CONTROL - WHEEL DAMPER

Purpose

The wheel damper absorbs control wheel vibrations and brings the wheel control system to rest with minimum oscillation.

Physical Description

The wheel damper is an LRU and weighs approximately 1.6 lb (0.7 kg).

The wheel damper is the same as the pedal damper and the two column dampers. There are four of these dampers on the airplane.

The wheel damper is on the structure of the left shaft assembly mechanism. A damper crank and a control rod connect the damper shaft to the left crank. The control rod is not adjustable.

The wheel damper has an input shaft. The wheel damper uses a fluid to absorb vibrations that go to the shaft. A window on the wheel damper shows the position of the fluid level indicator.

The damper crank, on the damper shaft, has a pair of rivets. These shear out in case of a jam of the wheel damper.

Location

The wheel damper is on the mechanism of the left shaft assembly, between the flight deck floor and the left side of the nose gear wheel well. Access is through the MEC, then along the left side of the nose gear wheel well.

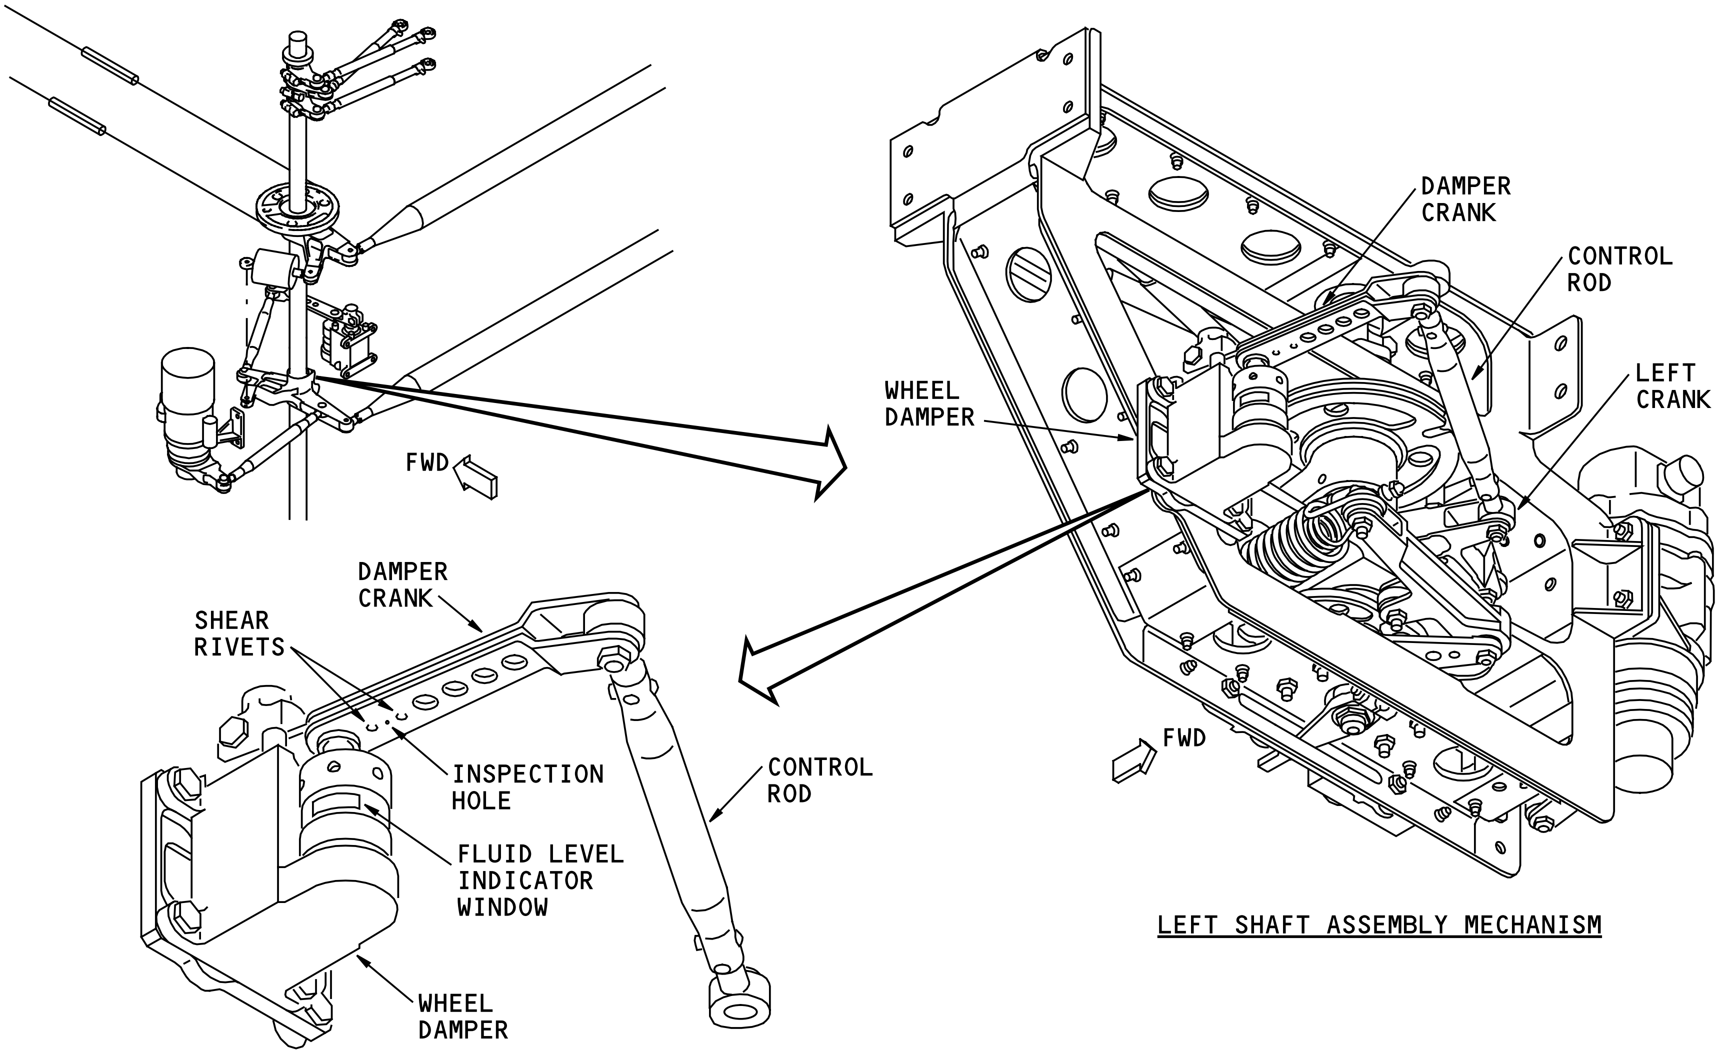
Functional Description

As the left shaft assembly turns, it turns the shaft of the wheel damper which absorbs the vibration of the wheel control system. The wheel damper adds a small force to the wheel control system.

Training Information Point

Put a pin through the inspection hole in the damper crank to check the rivet condition.

If the fluid level indicator shows a green band width of 1/16 inch or less, the fluid level is low. Then it is necessary to replace the wheel damper.



LEFT SHAFT ASSEMBLY MECHANISM

WHEEL DAMPER WITH DAMPER CRANK

27-11-00-030 Rev 3 10/08/96

AILERON AND FLAPERON CONTROL - WHEEL DAMPER

AILERON AND FLAPERON CONTROL - AILERON FEEL AND CENTERING MECHANISM

Purpose

The aileron feel and centering mechanism supplies feel and centering forces to the aileron and flaperon control system. The aileron trim actuator supplies aileron trim control. The aileron trim moves the neutral position of the ailerons, the flaperons and the control wheels.

Physical Description

The aileron feel and centering mechanism consists of a single cam and roller unit. The cam attaches by a spline to the left shaft assembly and turns with it. The follower assembly has a roller which rolls on the cam surface. Two cranks hold the follower assembly. The cranks are bearing mounted on the left shaft assembly. A fitting attaches the two cranks together and to the trim actuator rod end. Two extension springs, between the fitting and the follower assembly, keep the roller on the cam.

The aileron trim actuator is a line replaceable unit (LRU). It is a 28v dc electrical, fixed rate motor which moves a non-reversible acme screw. The actuator attaches to the structure. The rod end of the actuator connects to the fitting of the feel and centering assembly.

Location

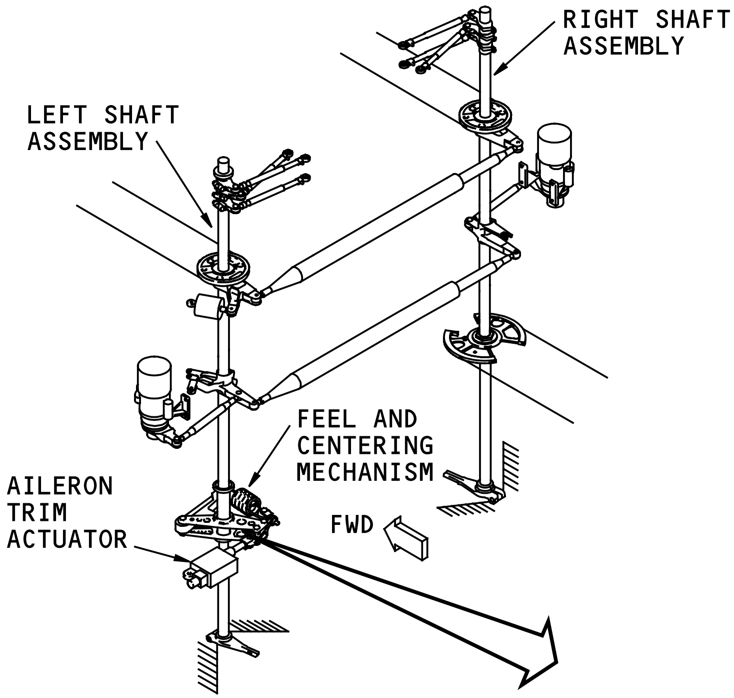
The aileron feel and centering mechanism is at the bottom of the left shaft assembly, between the flight deck floor and the nose gear wheel well. Access is through the MEC, then along the left side of the nose gear wheel well.

Functional Description

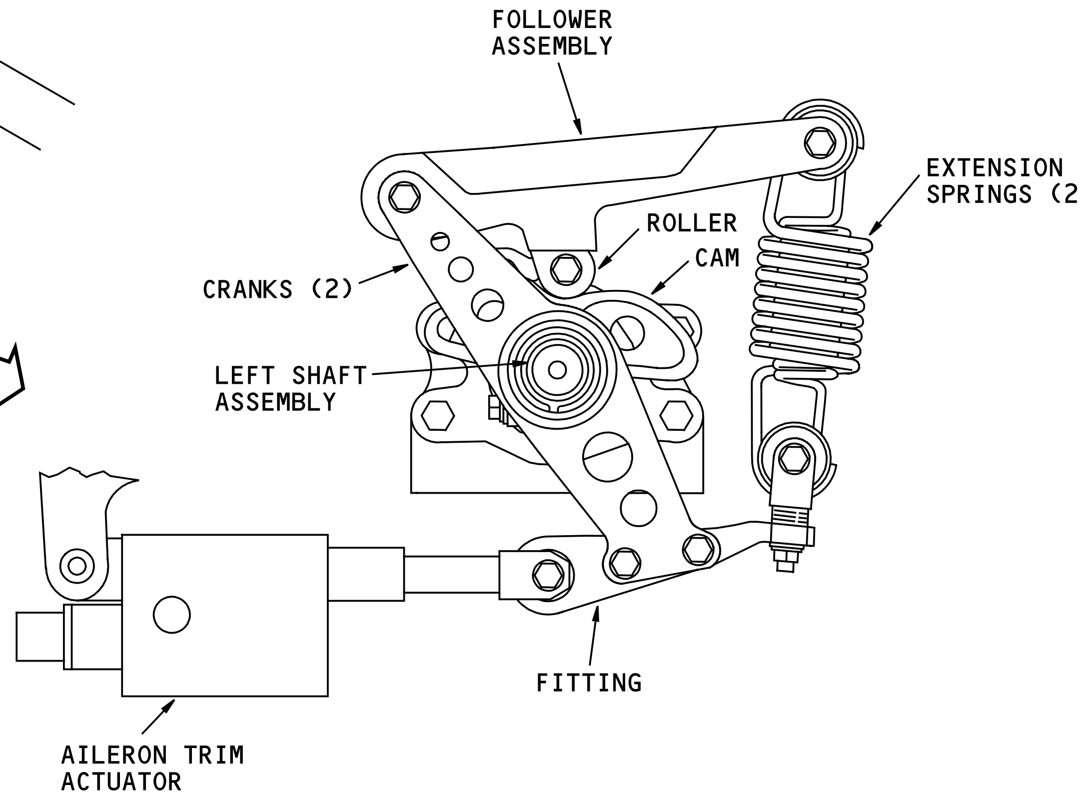
As the left shaft assembly and cam turn, the cam follower moves, which extends the two extension springs. The springs supply a feel force to the control wheels. The feel force varies from 5 lb (2 kg) to a maximum of 14 lb (6 kg) at 65 degrees of control wheel travel.

When the pilots release the control wheels, the springs force the cam follower back to the cam detent. This returns the system to the neutral trimmed position. The neutral, or zero feel force position, changes with trim input.

During trim operation, the aileron trim actuator moves the fitting assembly and cranks, which then move the cam follower assembly. Since the extension springs keep the cam follower in the cam detent, the trim actuator causes the cam and the left shaft assembly to turn. This also turns the right shaft assembly, the control wheels and the control wheel position transducers. The control wheels are backdriven and the ailerons and flaperons move.



NOTE: EXPANDED VIEW



27-11-00-009 Rev 0

AILERON AND FLAPERON CONTROL - AILERON FEEL AND CENTERING MECHANISM

AILERON AND FLAPERON CONTROL - AILERON TRIM

Purpose

The pilots use the aileron trim switches to adjust the trim of the airplane about the longitudinal axis.

Location

Dual aileron trim switches are on the aft end of the P8 aft aisle stand. The aileron trim indicator placards are on top of each control column.

Functional Description

The pilot controls the roll trim with the two aileron trim switches. The switches command the aileron trim actuator. One switch does the arm function and the other does the control function. The pilot must operate both switches at the same time to supply power to the trim actuator.

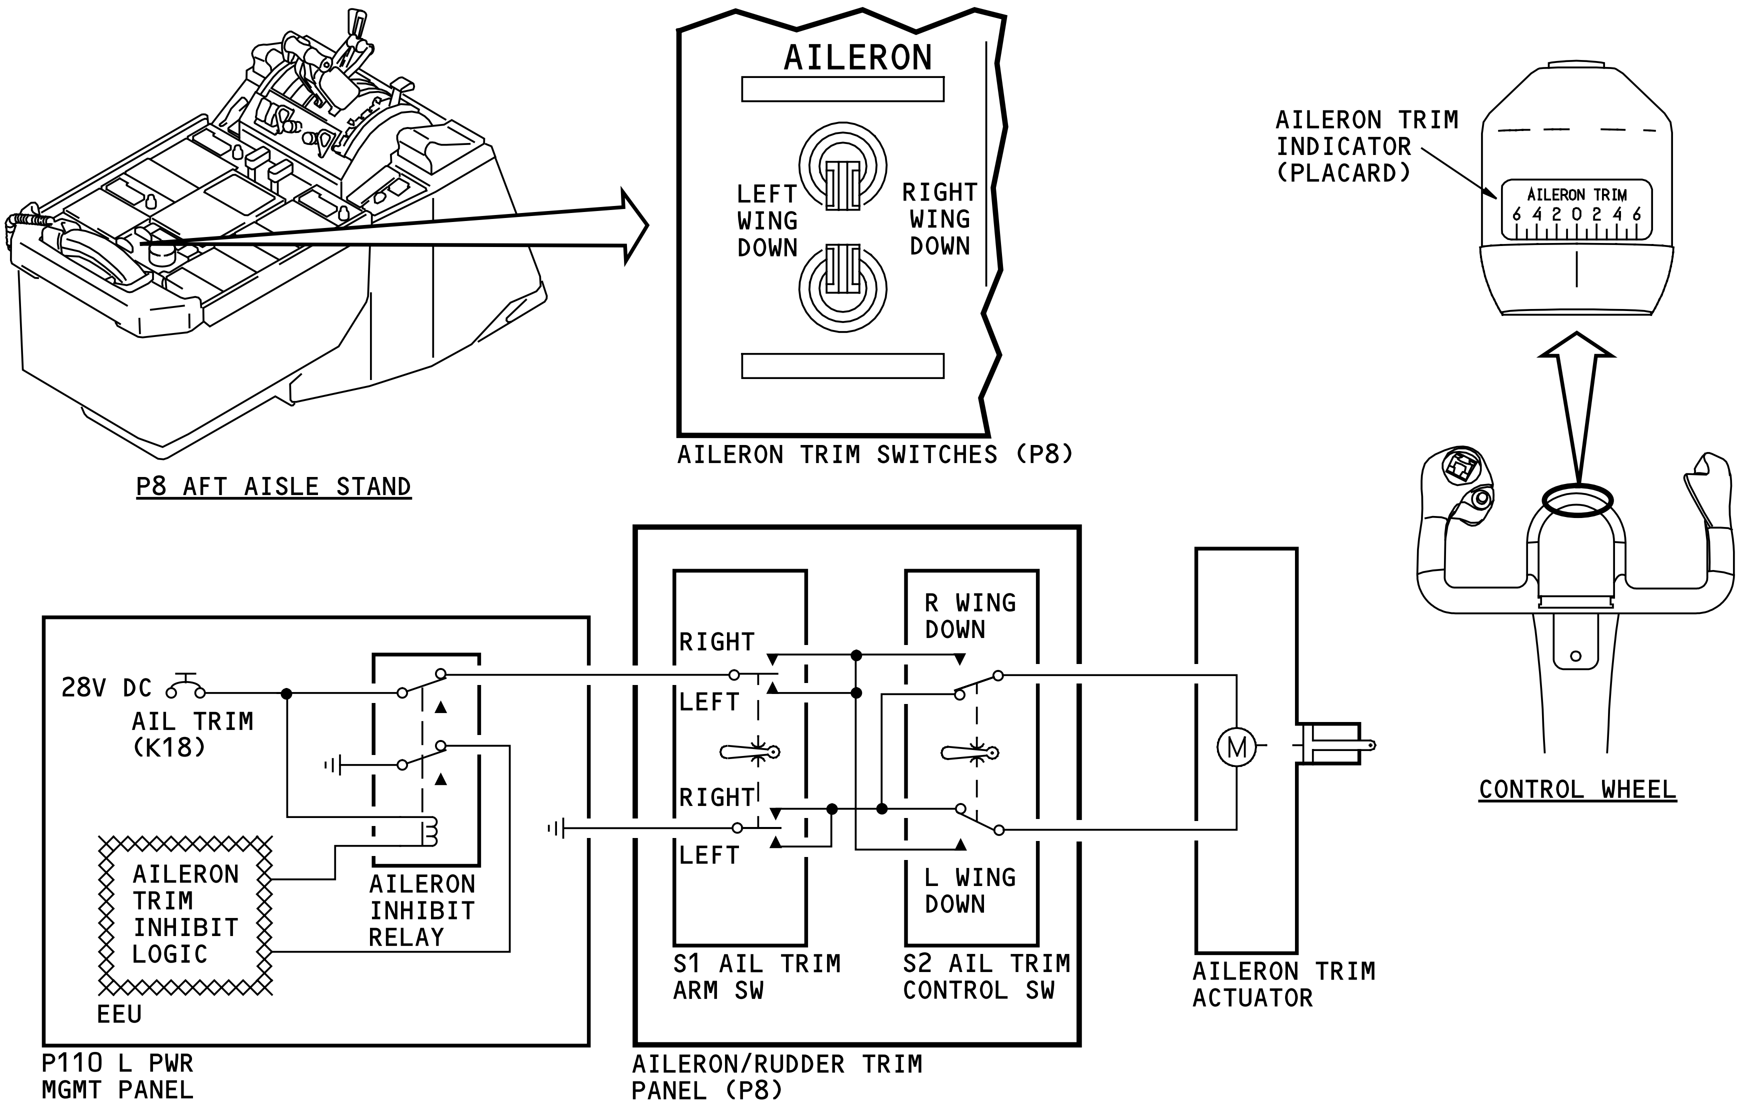
The electrical load management system (ELMS) controls the electrical power to the aileron trim switches through the aileron trim inhibit relay. The ELMS electronic unit (EEU) receives wheel backdrive actuator engagement signals from the AFDCs.

When none of the wheel backdrive actuators is engaged, ELMS keeps the aileron trim inhibit relay deenergized. Electrical power then goes to the aileron trim switches. The arm switch supplies electrical power and motor ground to the control switch which then supplies the direction of the motor rotation.

When one or both wheel backdrive actuator is engaged, the ELMS energizes the aileron trim inhibit relay which stops power to the aileron trim switches. This prevents the operation of the aileron trim during autopilot operation and bank angle protection (BAP) activation.

The aileron trim actuator moves the control wheels at a rate of 2.6 degrees per second. The roll trim authority is 30 degrees of control wheel rotation in both directions.

The aileron trim indicator placards show the amount of trim in units. Each unit indicates 5 degrees of control wheel rotation.



AILERON AND FLAPERON CONTROL - AILERON TRIM

AILERON AND FLAPERON CONTROL - WHEEL POSITION TRANSDUCERS

Purpose

The six control wheel position transducers measure the position of the control wheels. The transducers send analog electrical signals to the ACEs.

Physical Description

Each position transducer is an LVDT. The ACEs supply 7v ac, 1800 Hz excitation power.

The six wheel position transducers are identical to the six column position transducers and the four pedal position transducers. There are 16 of these identical position transducers on the airplane.

Three wheel position transducers are on the right shaft assembly and three are on the left shaft assembly. The position transducers attach at one end to the lateral control support bracket assembly. They attach to the transducer crank at the other end.

Each transducer crank attaches to its shaft assembly with a spline. The spline has a missing tooth to help locate the crank on the shaft. Each transducer crank has two shear rivets to allow override of a jammed position transducer.

Each position transducer has an electrical cable which connects to the ACE connector bracket. This bracket has three receptacles, one for each position transducer. Each receptacle is identified by a placard. The order in which each position transducer connects to the receptacles of the connector bracket determines the transducer-to-ACE relationship.

Location

The six wheel position transducers are between the flight deck floor and the nose gear wheel well. Access is by the access hatch of the MEC, then along the left side of the nose gear wheel well.

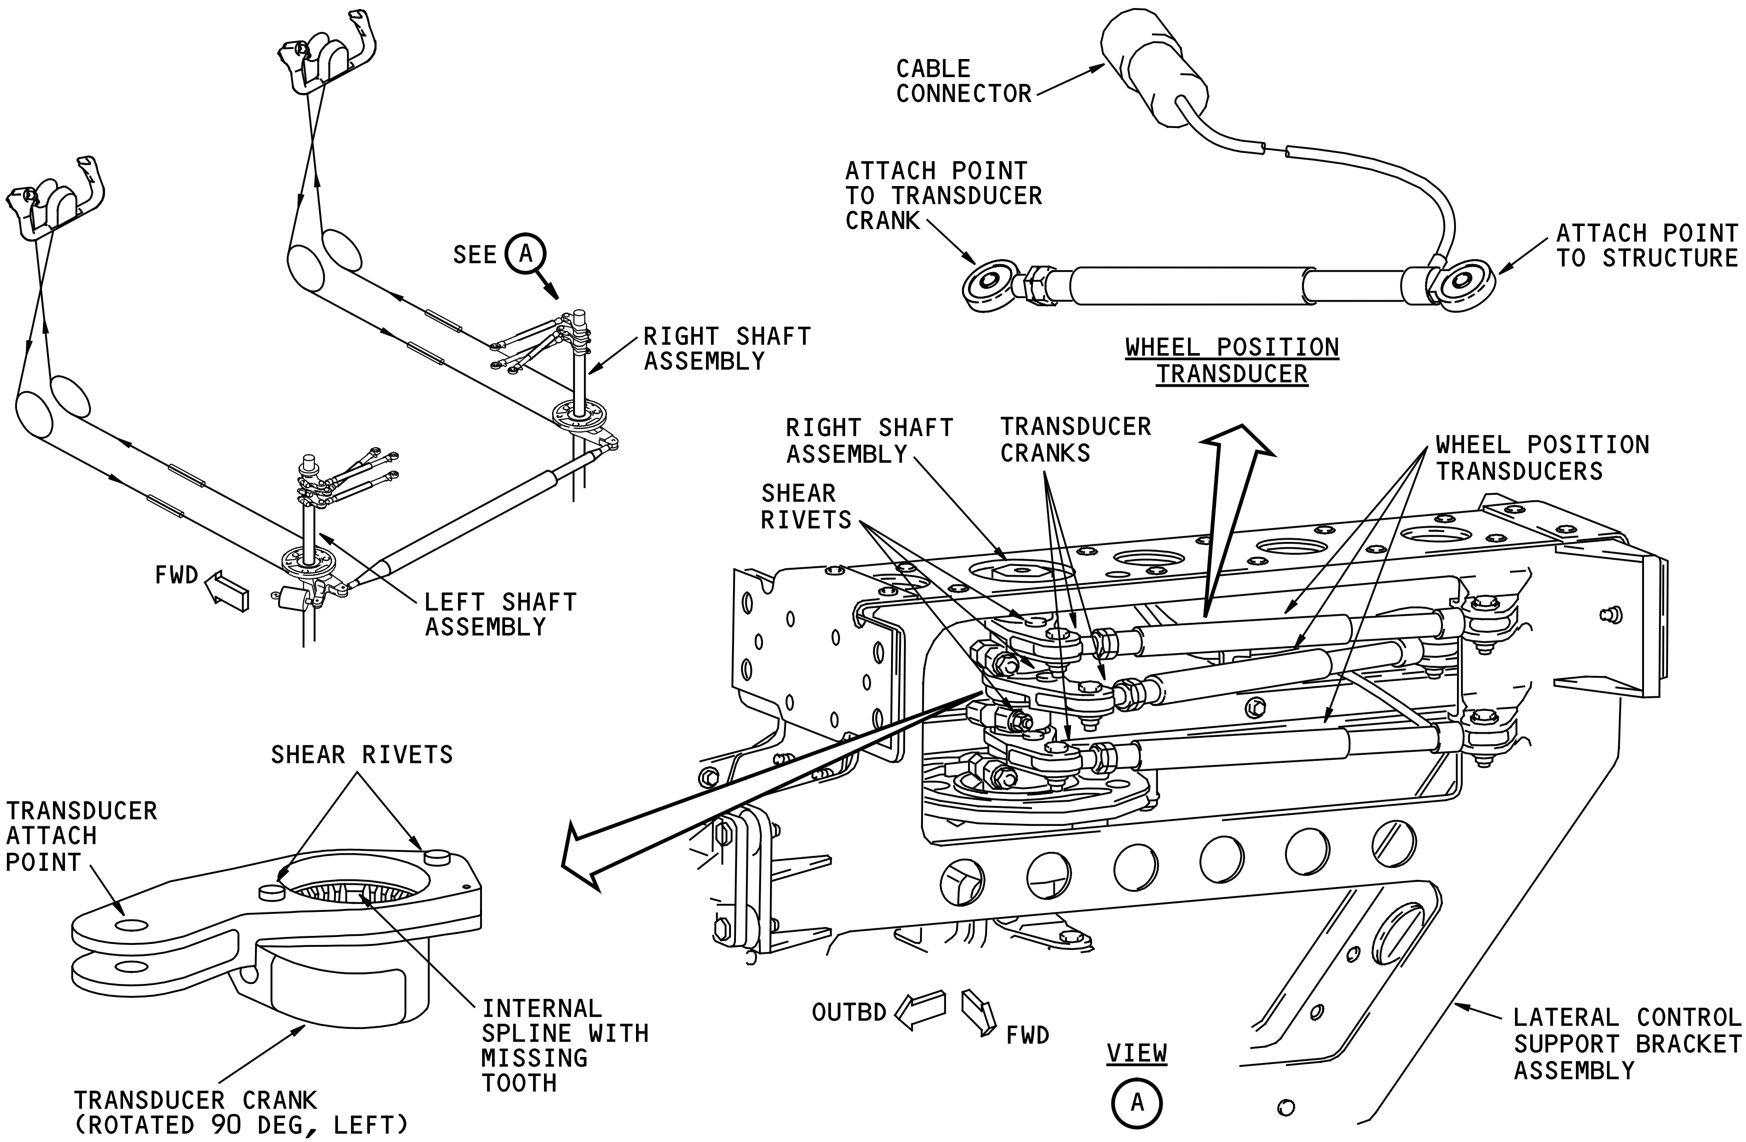
Functional Description

When the right and left shaft assemblies rotate in response to a control wheel command, the control wheel position transducers extend or retract. Each position transducer sends an analog electrical signal to one ACE.

Indications

On the status display, the status message CONTROL WHEEL XDCR indicates that one of the six wheel position transducers is defective.

When two or more wheel position transducers are defective, the status message FLIGHT CONTROL SYS shows.



27-11-00-011 Rev 2 01/19/95

AILERON AND FLAPERON CONTROL - WHEEL POSITION TRANSDUCERS

AILERON AND FLAPERON CONTROL - WHEEL FORCE TRANSDUCER

Purpose

The wheel force transducer measures the total force from the captain and the first officer to the control wheels. The wheel force transducer sends analog electrical signals to the ACEs. The PFCs use these signals for the bank angle protection function.

Physical Description

The wheel force transducer is a spring with two electrically isolated LVDTs inside. The ACEs supply 7v ac, 1800 Hz excitation power.

The wheel force transducer is different from the two elevator force transducers.

The wheel force transducer attaches to the wheel left cable drum and to the left crank of the left shaft assembly.

Each LVDT has a separate cable which connects to the ACE connector bracket. This bracket has two receptacles, one for each LVDT of the force transducer. The order in which each LVDT connects to the connector bracket determines the interface of the LVDT with the ACE.

Location

The wheel force transducer is on the left shaft assembly, between the flight deck floor and the nose gear wheel well. Access is through the MEC, then along the left side of the nose gear wheel well.

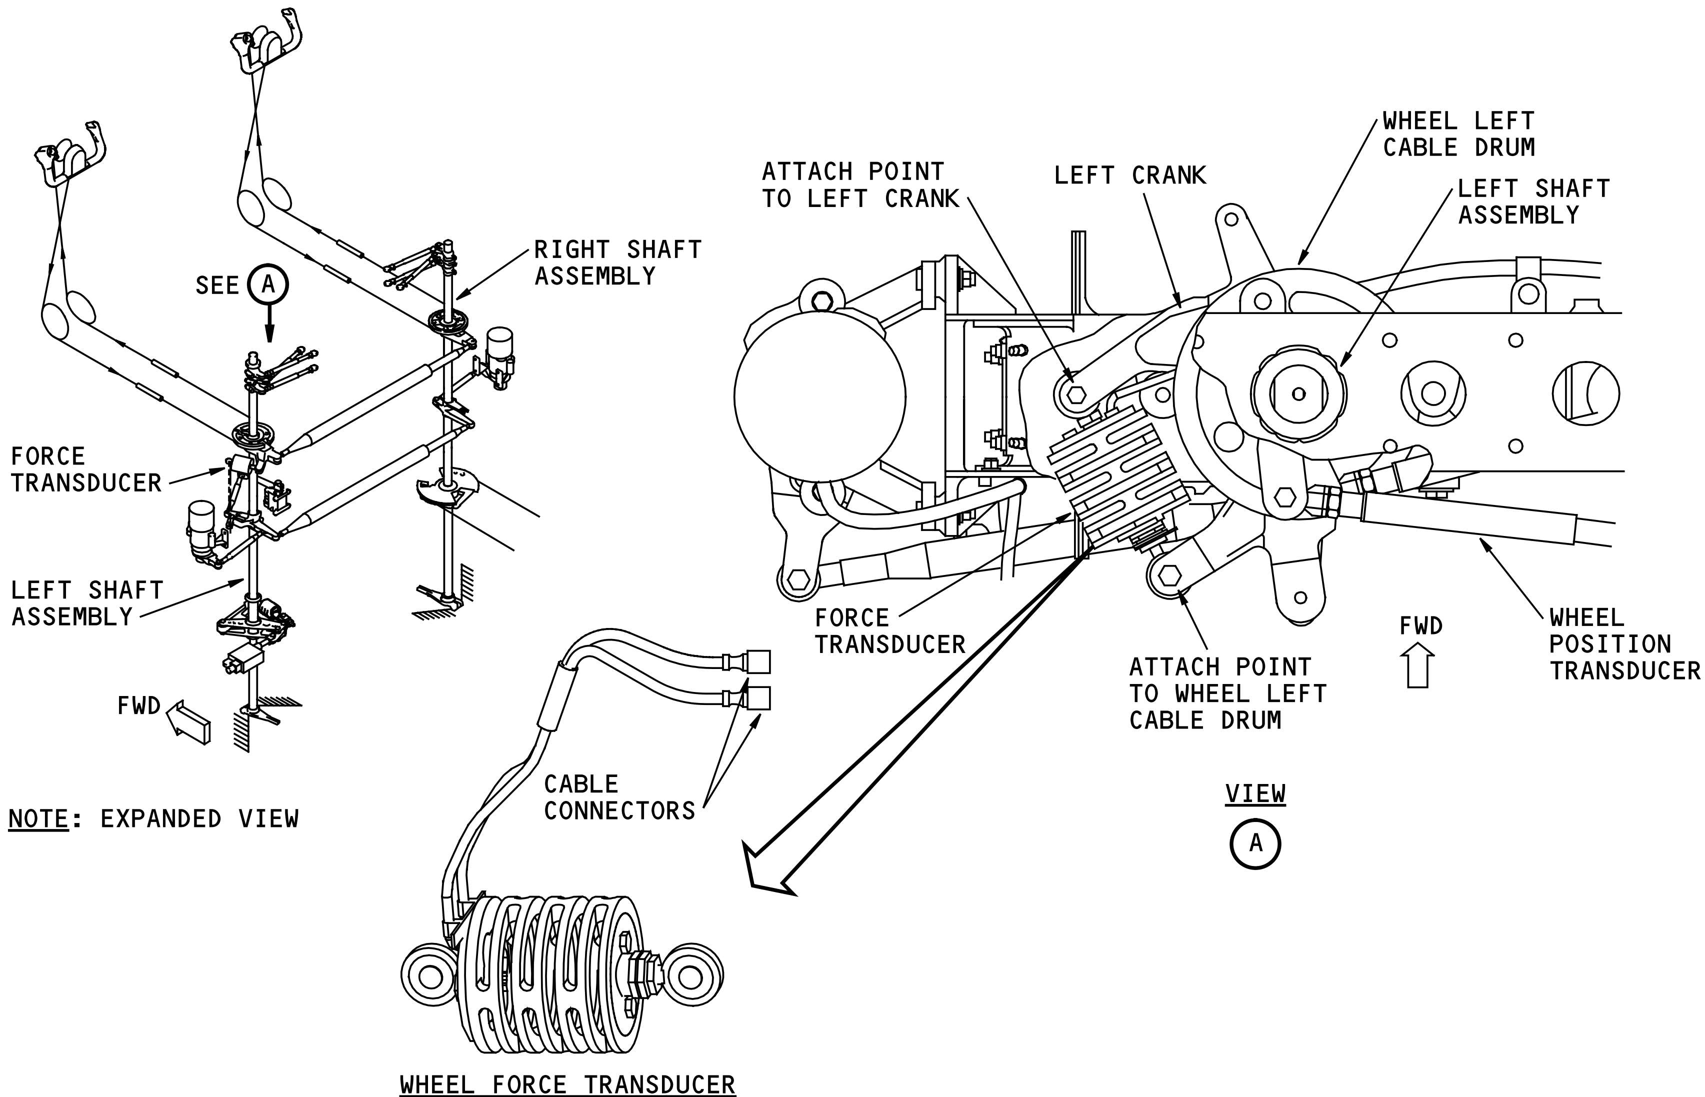
Functional Description

When the pilot applies a force to the control wheel, the wheel force transducer spring extends or compresses. The LVDTs measure the spring movement.

The signal from one LVDT goes to the L2 ACE, and the other to the C ACE.

Indications

When both LVDTs of the wheel force transducer fail, the status message BANK ANGLE PROTECT shows.



27-11-00-012 Rev 2 03/19/96

AILERON AND FLAPERON CONTROL - WHEEL FORCE TRANSDUCER

AILERON AND FLAPERON CONTROL - AILERON PCU - LOCATION

Purpose

The aileron PCUs move the ailerons. Electrical command signals from the ACEs operate the aileron PCUs. Each aileron has two PCUs.

Location

The two PCUs are outboard on the wing rear spar. Access to the PCUs is by two hinged panels on the lower wing.

The kick link connects the PCU to the rear spar fittings. The actuator rod connects to the aileron at the aileron surface attach fitting. The reaction link connects to the aileron at the aileron attach fitting at the hinge line.

Two electrical connectors of different sizes connect to the upper side of the PCU.

Hydraulic tubing connects to ports, one on each side of the PCU. This tubing has fuses and check valves to help prevent the loss of hydraulic fluid if there is damage to the PCUs or hydraulic tubing. The fuses and check valves in the left hydraulic system are inboard of spoilers 1 and 14 in each wing. The fuses and check valves in the center hydraulic system are outboard of spoilers 1 and 14 in each wing.

Training Information Point

Removal and installation of the aileron PCU is in one assembly with the reaction link and the kick link.

To move the actuator for maintenance, depressurize the hydraulic systems. You get access to the manual bypass on the under side of the PCU. Turn the manual bypass to the bypass position while moving the aileron. After release of the manual bypass, it closes.

During installation of the aileron PCU, it is necessary to adjust the actuator null LVDT. Remove the LVDT access cover to adjust the LVDT.

AILERON AND FLAPERON CONTROL - AILERON PCU - LOCATION

THIS PAGE INTENTIONALLY LEFT BLANK

AILERON AND FLAPERON CONTROL - AILERON PCU - FUNCTIONAL DESCRIPTION

General

The aileron PCU operates in three different modes:

- Normal
- Bypass
- Blocking/Damped.

In the normal mode, the ACE energizes both the bypass and blocking solenoids with flight below cruise speed. Above cruise speed, the ACE de-energizes the blocking solenoid.

In the bypass mode, the ACE de-energizes the bypass solenoid.

In the blocking/damped mode, the ACE de-energizes both the bypass and the blocking solenoids.

PCU Operational Matrix

The table below shows the various conditions of the PCU valves in the three modes of operation.

SOLENOID CONDITIONS	PCU MODES OF OPERATION		
	NORMAL	BYPASS	BLOCKING/ DAMPED
BYPASS SOLENOID	E	D	D
BLOCKING SOLENOID	E/D	E	D
LEGEND: E = ENERGIZED D = DE-ENERGIZED			

Normal Mode

During operation below cruise speed, the PCU is in normal mode when the ACE energizes both the bypass and the blocking solenoid valves.

Hydraulic system pressure moves the mode selector valve to the normal position and opens the extension check and relief valve. Under these conditions, an electrical command to the EHSV results in the actuator extension or retraction.

Aileron Lockout

With flight at or above cruise speed, the PFCs command, through the ACEs, the ailerons to fair and to lock out. The ACEs energize the bypass solenoid valve but de-energize the blocking solenoid valve of all the aileron PCUs. The PCUs are in normal mode. The PFC command signals to the EHSV keep the ailerons in the faired position.

Bypass Mode

The PCU is in the bypass mode when the ACE de-energizes the bypass solenoid valve and energizes the blocking solenoid valve. This happens when there is a single hydraulic or electrical failure on the PCU.

The bypass solenoid valve blocks hydraulic pressure to the mode selector valve. However, pressure trapped between the bypass check valves and the thermal relief valve moves the mode selector valve to the bypass position. This pressure also keeps the extension check and relief valve open.

Under these conditions, the mode selector valve blocks control pressure from the EHSV to the actuator cylinder. It also allows free hydraulic flow between both sides of the piston on the failed PCU. The adjacent PCU controls the aileron movement and backdrives the failed PCU.

During rapid backdrive of the failed PCU, the compensator/relief valve supplies fluid to the actuator through the anti-cavitation check valves.

If there is a subsequent failure on the adjacent PCU, its ACE de-energizes its bypass solenoid valve. With both PCUs in the bypass mode, the airloads cause the aileron trailing edge to move up approximately 15 degrees from the faired (neutral) position.

Blocking/Damped Mode

The PCU is in the blocking/damped mode when the ACEs de-energize both the bypass and the blocking solenoid valves. This happens when the PCU has no power or the PCU has a failure at or above cruise speed.

In the blocking/damped mode, there is no hydraulic pressure on the mode selector valve. Its internal spring moves the valve to the blocking/damped position. The mode selector valve blocks control pressure from the EHSV to the actuator cylinder. It also connects both sides of the actuator through a restriction. Also, the extension check and relief valve closes.

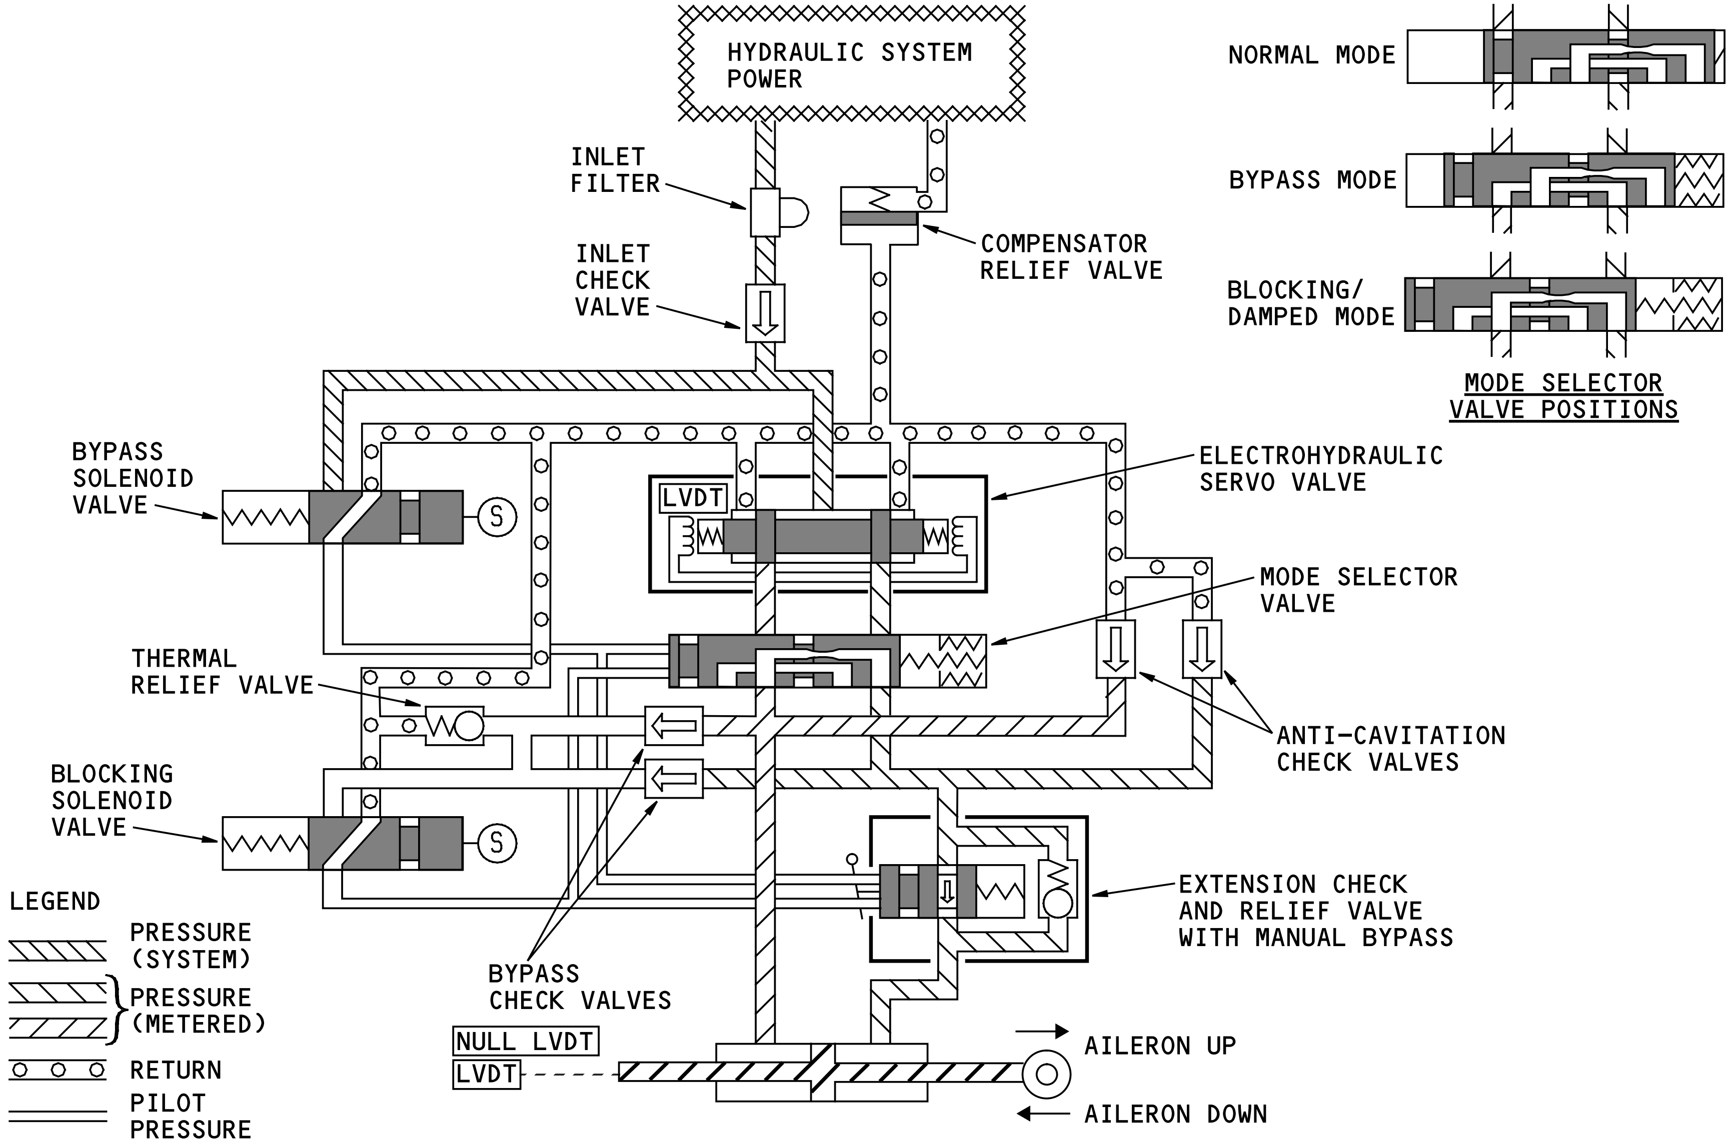
Under these conditions, the actuator cannot extend but can retract very slowly.

During flight at or above cruise speed, when both PCUs of an aileron are in the blocking/damped mode, the closed extension check and relief valve prevents the aileron upward movement caused by aerodynamic lift.

On the ground, with no electrical or hydraulic power on the aileron PCUs, the PCUs are in the blocking/damped mode. The ailerons cannot move up but can move down. Turn the manual bypass to move the ailerons and the PCUs in the up direction.

Indications

The status message FLIGHT CONTROL SYS shows on the status display when one or more aileron actuator is failed or the actuator confidence test has failed.



AILERON AND FLAPERON CONTROL - AILERON PCU - FUNCTIONAL DESCRIPTION

27-11-00-015 Rev 4 06/26/96

AILERON AND FLAPERON CONTROL - FLAPERON PCU - LOCATION

Purpose

The flaperon PCUs move the flaperons. Electrical command signals from the ACEs actuate the flaperon PCUs. Each flaperon has two PCUs.

Location

The two PCUs are on the rear spar of the inboard wing. Access to the PCUs is by a removable lower skin panel below each PCU.

The head end bearing assembly connects the PCU to the rear spar structural fitting. The actuator rod connects to the flaperon surface fitting.

One electrical connector connects to the PCU.

Hydraulic tubing connects to ports near the forward end of the PCU. The hydraulic tubing from these hoses have fuses and check valves to help prevent the loss of hydraulic fluid if there is damage to the PCUs or hydraulic tubing caused by the loss of a flaperon. The hydraulic fuses and check valves for the left and right hydraulic system are near the left flaperon. The fuse and check valve for the center hydraulic system are near the right flaperon.

Training Information Point

The head end bearing assembly stays in place when you remove and install the flaperon PCU.

Installation of the PCUs is with the control modules facing each other. One PCU is up-side-down in relation to its adjacent PCU.

During the adjustment of the flaperon surface, it is necessary to adjust the actuator null LVDT. Remove the LVDT access cover to adjust the LVDT.

AILERON AND FLAPERON CONTROL - FLAPERON PCU - LOCATION

AILERON AND FLAPERON CONTROL - FLAPERON PCU - PHYSICAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

AILERON AND FLAPERON CONTROL - FLAPERON PCU - PHYSICAL DESCRIPTION

Physical Description

All four flaperon PCUs are identical. Each flaperon PCU weighs approximately 43 lb (19 kg).

The flaperon PCU contains a hydraulic actuator with a control module. The control module contains:

- An electrohydraulic servo valve (EHSV)
- A bypass solenoid valve
- A mode selector valve
- A differential pressure sensor
- Two relief valves
- An inlet check valve
- An inlet filter.

Hydraulic Actuator

The actuator piston has an LVDT that sends position feedback signals to the ACE. The actuator piston also has a null LVDT to adjust the null position of the actuator during adjustment of the flaperon surface.

EHSV

The EHSV controls the hydraulic power to the extend and retract sides of the actuator. The EHSV has an LVDT that sends EHSV position feedback signals to the ACE.

Bypass Solenoid Valve

The bypass solenoid valve controls the pilot pressure from the hydraulic system to the mode selector valve.

Mode Selector Valve

Pilot pressure from the bypass solenoid valve commands the mode selector valve in one of two positions:

- Normal
- Bypass.

Differential Pressure Sensor

The differential pressure sensor measures the pressure difference across the actuator piston. The sensor operates an LVDT which sends signals to the ACE.

Relief Valves

The two relief valves protect the actuator from high pressure due to thermal effects or excessive loading conditions.

Inlet Check Valve

The inlet check valves keeps the hydraulic fluid in the actuator when the hydraulic system experiences pressure fluctuations due to system demands.

Inlet Filter

The inlet filter protects the actuator from solids in the hydraulic fluid.

AILERON AND FLAPERON CONTROL - FLAPERON PCU - PHYSICAL DESCRIPTION

Training Information Point

Only the bearing in the actuator rod end, where it attaches to the flaperon, requires lubrication.

All the other bearings are teflon coated. They do not require lubrication.

AILERON AND FLAPERON CONTROL - FLAPERON PCU - PHYSICAL DESCRIPTION

AILERON AND FLAPERON CONTROL - FLAPERON PCU - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

AILERON AND FLAPERON CONTROL - FLAPERON PCU - FUNCTIONAL DESCRIPTION

General

The flaperon PCU operates in two different modes:

- Normal
- Bypass.

In normal mode, the ACE energizes the bypass solenoid valve.

In bypass mode, the ACE de-energizes the bypass solenoid valve.

PCU Operational Matrix

The table below shows the conditions of the PCU bypass valve in the two modes of operation.

VALVE CONDITIONS	PCU MODES OF OPERATION	
	NORMAL	BYPASS
BYPASS SOLENOID	E	D
LEGEND: E = ENERGIZED	D = DE-ENERGIZED	

Normal Mode

The PCU is in normal mode when the ACE energizes the bypass solenoid valve.

Hydraulic system pressure moves the mode selector valve to the normal position. Under these conditions, an electrical command from the ACE to the EHSV results in the actuator extension or retraction.

Bypass Mode

The PCU is in bypass mode when the ACE de-energizes the bypass solenoid. This happens when there is a single hydraulic or electrical failure on the PCU.

The bypass solenoid valve blocks pressure to the mode selector valve which moves to the bypass position.

Under these conditions, the mode selector valve blocks control pressure from the EHSV to the actuator cylinder. It also permits free hydraulic flow between both sides of the failed PCU and the return line. The adjacent PCU controls the flaperon movement and backdrives the failed PCU.

If both PCUs of the same flaperon are in bypass mode, the flaperon can move freely in both directions. In flight, the airloads then cause the flaperon to move up a maximum of 10 degrees.

When the airplane has no power on the ground, the weight of the flaperon causes it to slowly move down to the actuator stop.

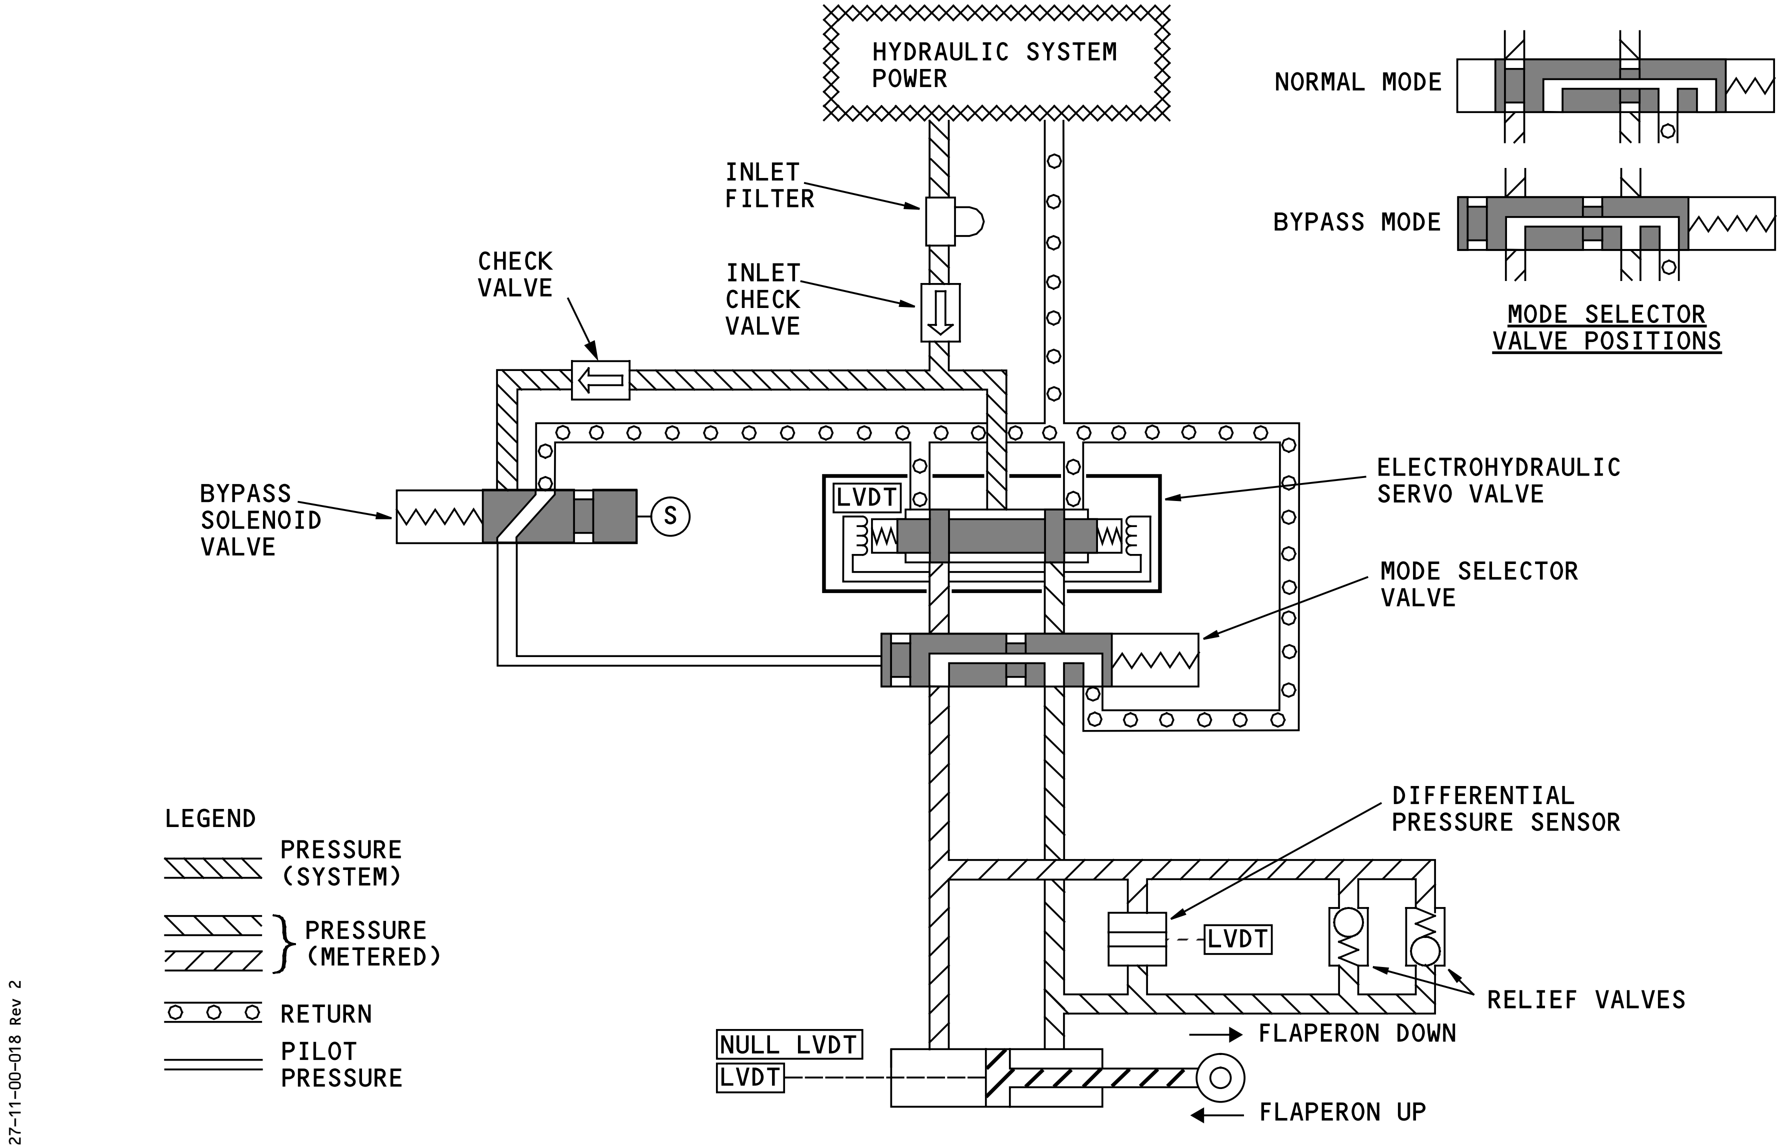
Indications

The EICAS status message ACTUATOR PRESS SNSR shows when the differential pressure sensor on one of the flaperon

AILERON AND FLAPERON CONTROL - FLAPERON PCU - FUNCTIONAL DESCRIPTION

PCUs is defective. The rudder also uses the same message.

The status message FLIGHT CONTROL SYS shows on the status display when one or more flaperon actuator is failed or the actuator confidence test has failed.



AILERON AND FLAPERON CONTROL - FLAPERON PCU - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

AILERON AND FLAPERON CONTROL - AILERON AND FLAPERON PCU - PCU MODES

General

The PFCs and the ACEs control the mode of operation of the aileron PCUs. The ACEs control the bypass solenoid of the PCUs. The PFC sends commands to the ACEs to control the blocking solenoids in all three PFCS modes.

The ACEs control the mode of operation of the flaperon PCUs.

Aileron PCU Modes

The aileron PCU has three modes:

- Normal
- Bypass
- Blocking/Damped.

The aileron PCU is in the normal mode when there is no failure in the PCU and there is no failure in its on-side ACE. In the normal mode, the ACE energizes the bypass and blocking solenoids below cruise speed. At or above cruise speed, the ailerons are locked out. The ACEs keep the bypass solenoid energized but the PFCs send a command to de-energize the blocking solenoid on all the PCUs. The PCUs are still in the normal mode.

The aileron PCU is in the bypass mode when there is an electrical or hydraulic failure with the PCU or its ACE during flight below cruise speed. The ACE then de-energizes the bypass solenoid. The adjacent PCU, still in the normal mode, moves the aileron and backdrives the failed PCU. If both PCUs on the same aileron are in the bypass mode during flight, the aerodynamic lift moves the aileron trailing edge by about 15 degrees up from the faired position.

The aileron PCU is in the blocking/damped mode when there is a failure with the PCU or its ACE during flight at or above cruise speed. The ACE de-energizes the bypass solenoid of the PCU. The aileron lock out function of the PFC causes the ACEs to de-energize the blocking solenoid of all the PCUs. Under these conditions, the failed PCU is in the blocking/damped mode while the other PCUs are locked out in the normal mode. If both PCUs on the same aileron are in the blocking/damped mode, the aerodynamic lift cannot move the aileron up.

If there is a loss of the center and left hydraulic system power during the time the ailerons are locked out, the PFCs send a command signal to the ACEs to keep the blocking solenoids de-energized. All the ailerons PCUs stay in the blocking/damped mode. This prevents the sudden aileron upfloat and undesired roll of the airplane when the ailerons unlock later in the flight.

On the ground, with no electrical or hydraulic power on the aileron PCUs, the PCUs are in the blocking/damped mode. The aileron cannot move up but it can move down with an outside force.

Flaperon PCU Modes

The flaperon PCUs operate in two modes:

- Normal
- Bypass.

The flaperon PCU is in the normal mode when there is no failure in the PCU or its ACE. The ACE then energizes the bypass solenoid.

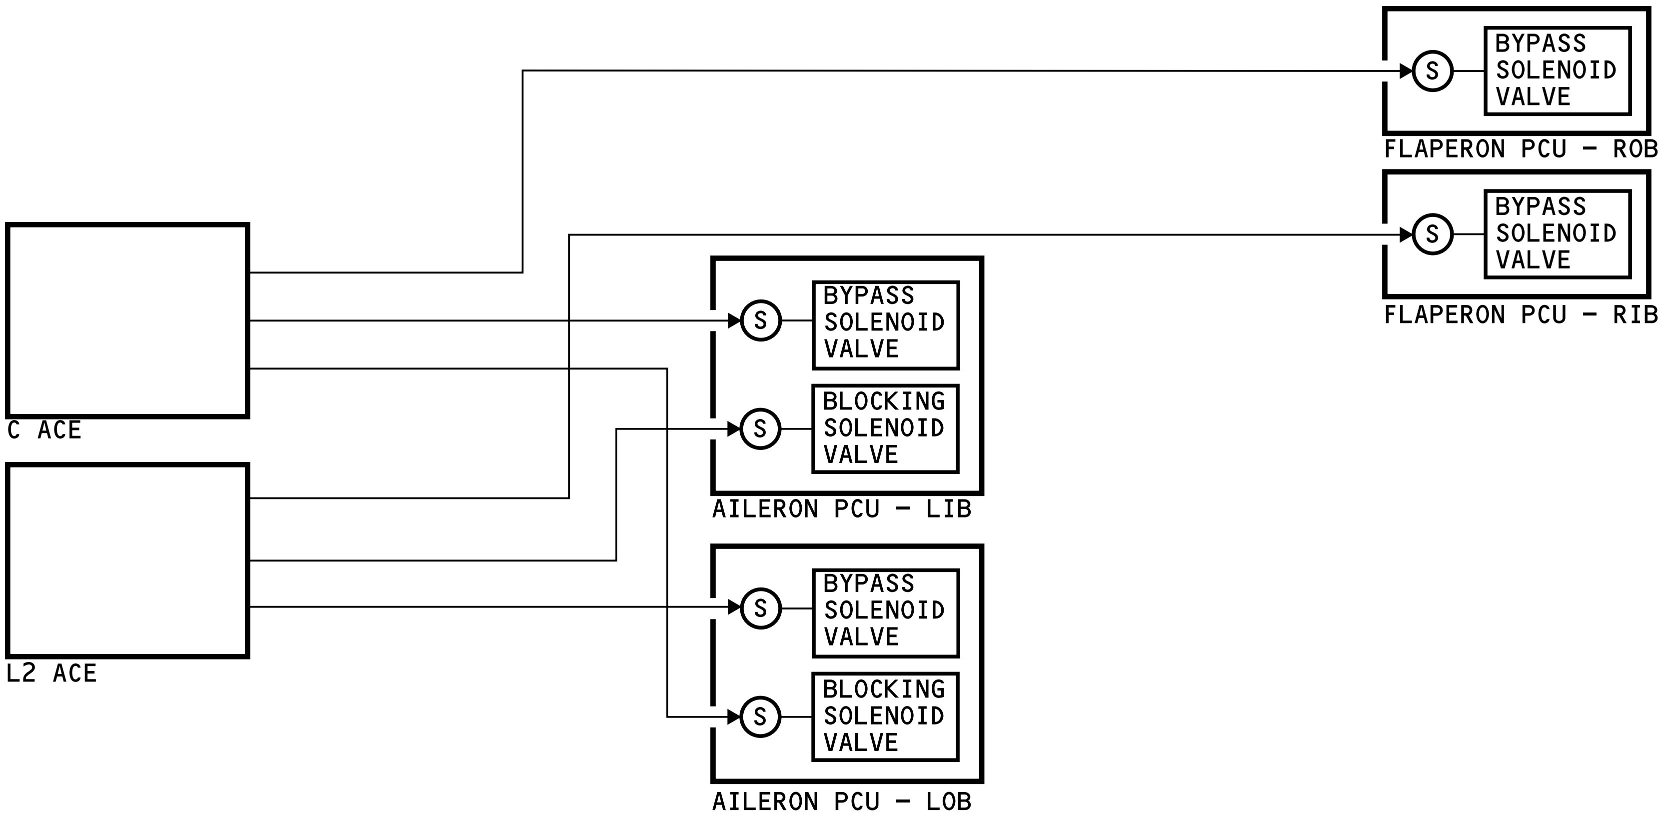
The flaperon PCU is in the bypass mode when there is an electrical or hydraulic failure with the PCU or its ACE. The ACE then de-energizes the bypass solenoid. If both PCUs on a flaperon are in the bypass mode, the flaperon can move freely. In flight, the aerodynamic lift then causes the flaperon to move 10 degrees up from the faired position.

When the airplane is on the ground with airspeed less than 85 knots and at least one engine running near takeoff thrust, the flaperon bypass logic of the PFC normal mode operates. This function sends a command signal to the ACEs to put all the flaperon PCUs in the bypass mode. At low airspeed, the weight of the flaperon causes the flaperons to droop. Also, the flaperons can possibly flutter. As the airspeed increases, the airloads gradually float the flaperons to the neutral position.

When the airspeed is approximately 100 knots, the PFCs send a command signal to the ACEs to put all the flaperon PCUs in the normal mode. The PFCs then send commands to the ACEs to gradually move the flaperons to the drooped position.

<u>Training Information Point</u>

During an engine test run on the ground with thrust near takeoff level, the flaperon behind the engine can possibly flutter. This is a usual condition.



27-11-00-029 Rev 4 06/26/96

AILERON AND FLAPERON CONTROL - AILERON AND FLAPERON PCU - PCU MODES

AILERON AND FLAPERON CONTROL - AILERON SURFACES

Purpose

The ailerons have two purposes. The ailerons supply low speed roll control of the airplane. The flaperons and the flight spoilers help this function. Ailerons also move down (droop) to supplement the high lift system.

Physical Description

The ailerons are light weight composite materials structures. The skin is reinforced graphite/epoxy bonded to a core of Nomex honeycomb. The overall dimensions are approximately 27 in by 259 in (0.7 m x 6.6 m). Each aileron weighs 165 lb (75 kg).

Two adjustable tungsten balance weights prevent flutter if hydraulic power is lost. The aileron attaches to the outboard rear spar with 6 hinges. Jumpers and static dischargers supply electrostatic protection to airplane systems.

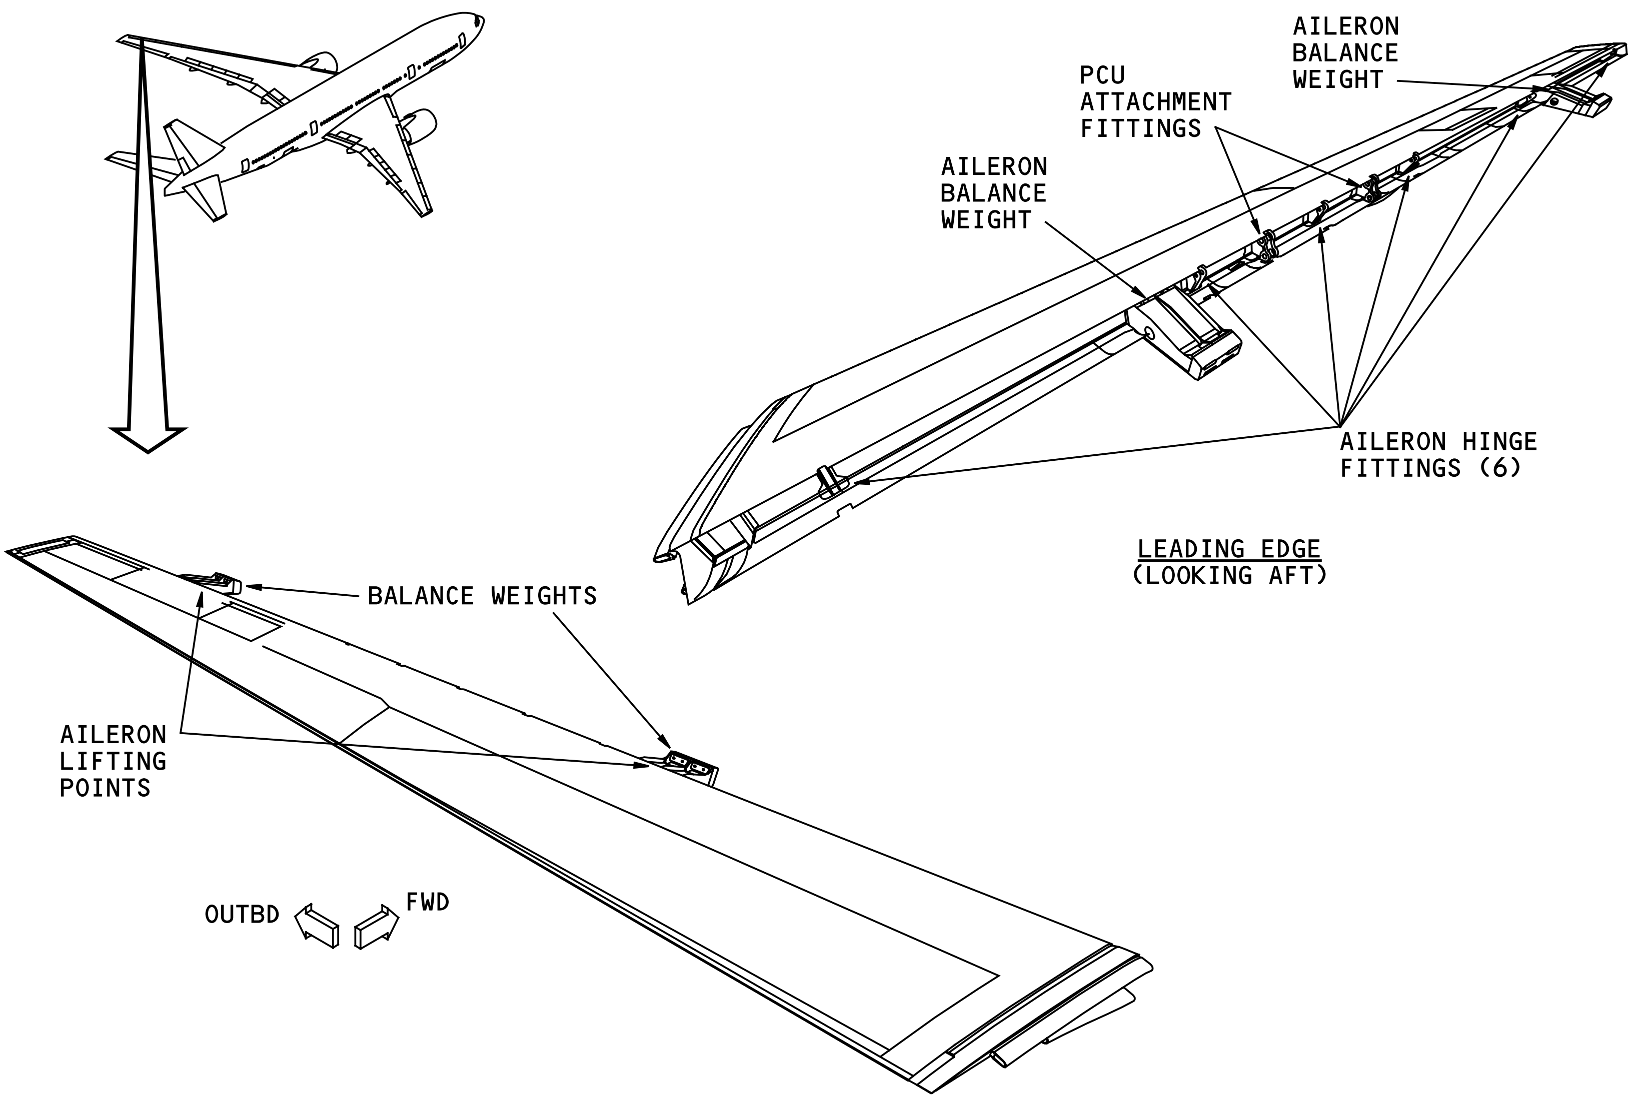
Functional Description

The aileron surface deflection limits are at the PCU internal stops. The ailerons have a maximum movement of 33 degrees trailing edge up (TEU) and 19 degrees trailing edge down (TED) for conditions without loads. You measure the aileron movement in relation to the wing fixed trailing edge.

When there are loads, the maximum PFC and ACE command signals move the ailerons to a nominal position of 30 degrees TEU and 15 degrees TED. Aileron trim authority is 30 degrees of control wheel rotation. You adjust the aileron PCUs on the ground so the aileron control surfaces are about 2 degrees below the wing fixed trailing edge.

Training Information Point

Two hoist attach points are on the upper surface of the aileron front spar for aileron removal and installation.



27-11-00-019 Rev 3

AILERON AND FLAPERON CONTROL - AILERON SURFACES

AILERON AND FLAPERON CONTROL - FLAPERON SURFACES

Purpose

The flaperons have a dual purpose on the 777 airplane. First, flaperons supply roll control of the airplane, assisted by the ailerons and the flight spoilers. Second, flaperons move down (droop) to help the high lift system during takeoff, approach, and landing.

Physical Description

The flaperons are light weight composite materials structures. The skin is carbon fiber reinforced plastic bonded to a core of Nomex honeycomb. The overall dimensions are approximately 62 in by 95 in (1.6 m x 2.4 m). Each flaperon weighs about 110 lb (50 kg).

The flaperon attaches to the airplane structure with 2 hinges. An aluminum strip diverts lightning strikes on the flaperon trailing edge.

A cove lip door at the leading edge of the flaperon supplies a gap when the flaperon is full down to make aerodynamic performance better. The cove lip door attaches to the airplane structure and to the flaperon with two main hinge fittings.

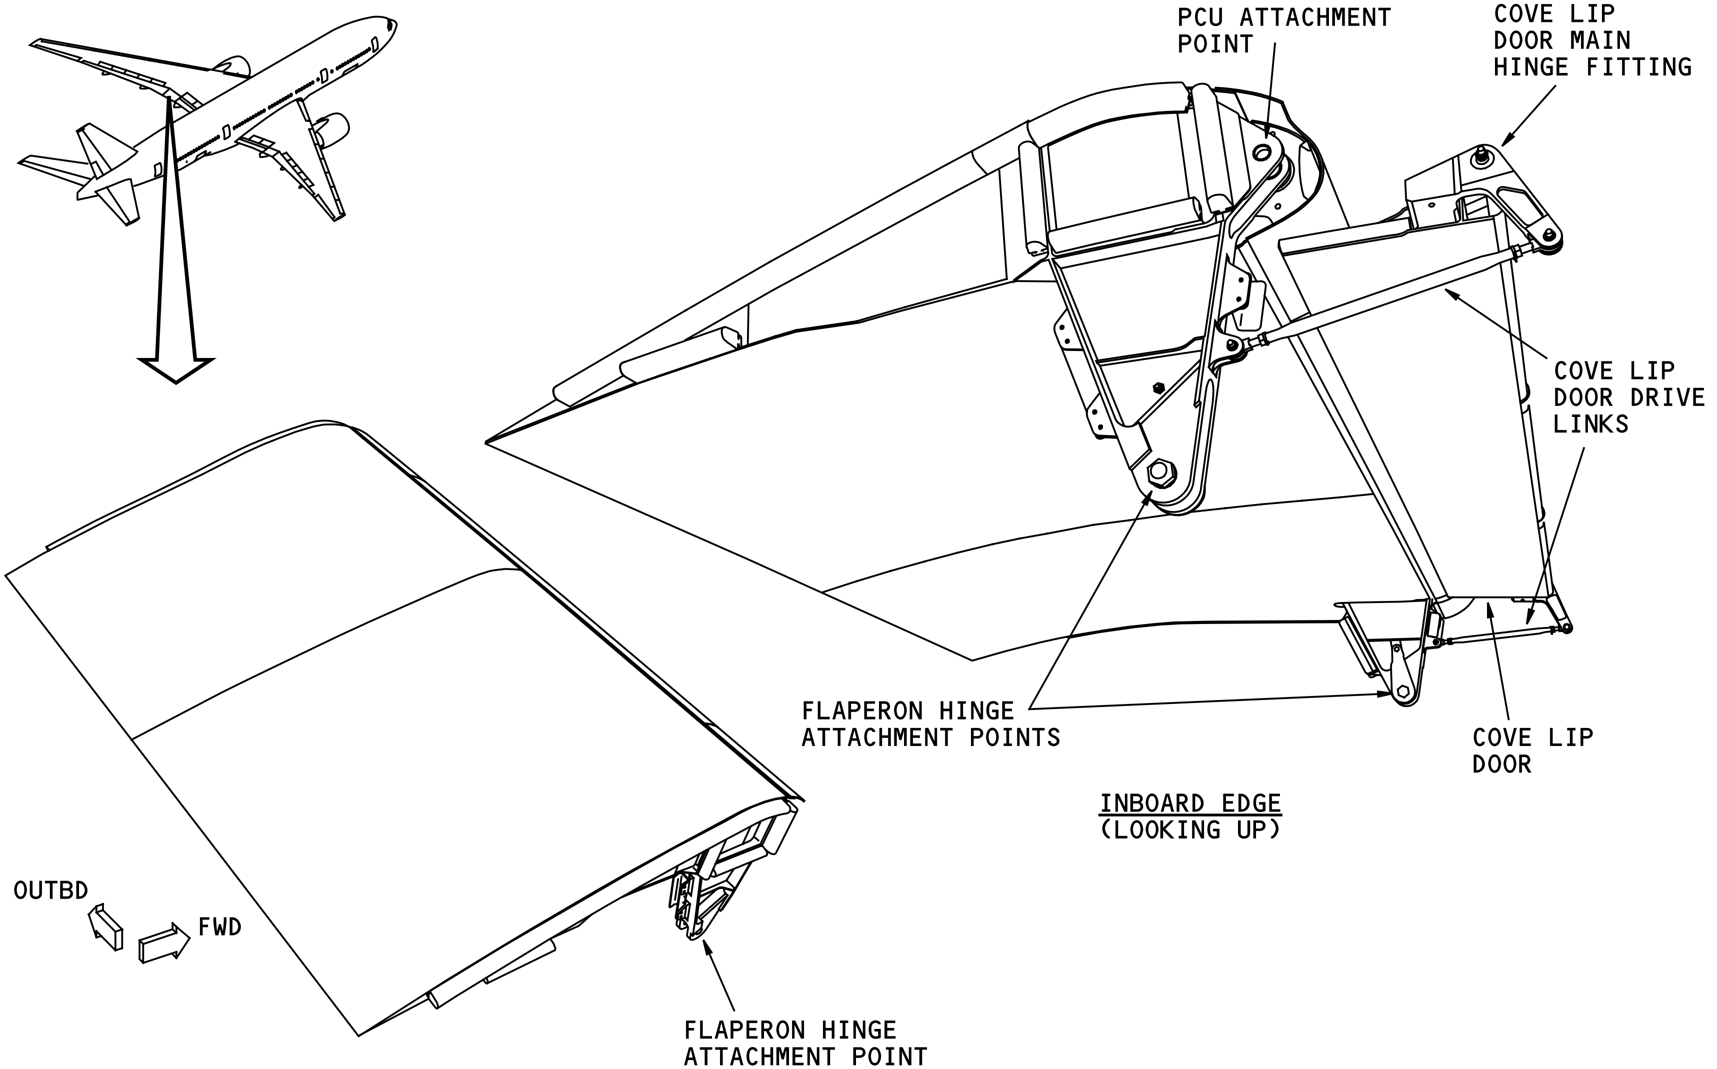
Functional Description

When the flaperon moves down, a mechanical linkage pulls the drive link attachment point of the fitting aft. This rotates the cove lip door up, which supplies a gap along the leading edge of the flaperon.

The flaperon surface deflection limits are at the PCU internal stops. The flaperons have a maximum movement of 11 degrees trailing edge up (TEU) and 37 degrees trailing edge down (TED) for conditions without loads. When there are loads, the maximum PFC and ACE command signals move the flaperons to a nominal position of 10 degrees TEU and 30 degrees TED.

Training Information Point

The flaperon PCU attachment fittings supply lifting points for the flaperons.



27-11-00-020 Rev 2

AILERON AND FLAPERON CONTROL - FLAPERON SURFACES

AILERON AND FLAPERON CONTROL - FUNCTIONAL DESCRIPTION

General

The roll control system for the ailerons and flaperons uses input command signals from the wheel position transducers and the force transducer.

The ACEs receive the input signals and transmit them to the PFCs. The ACEs supply output command signals to the PCUs of the ailerons and the flaperons.

Wheel Position Transducers

The C ACE and R ACE each receive signals from two wheel position transducers. The L1 ACE and L2 ACE each receive signals from one wheel position transducer. After they change the signals to digital format, the ACEs send these signals to the PFCs.

Each PFC receives input signals from all six wheel position transducers. These signals come from the ACEs through the flight controls ARINC 629 buses. Each PFC selects which signal to process by mid-value selection and averaging.

Force Transducers

The two LVDTs of the wheel force transducer send signals to the L2 ACE and the C ACE. The ACEs transmit these signals to their on-side PFCs.

Aileron PCUs

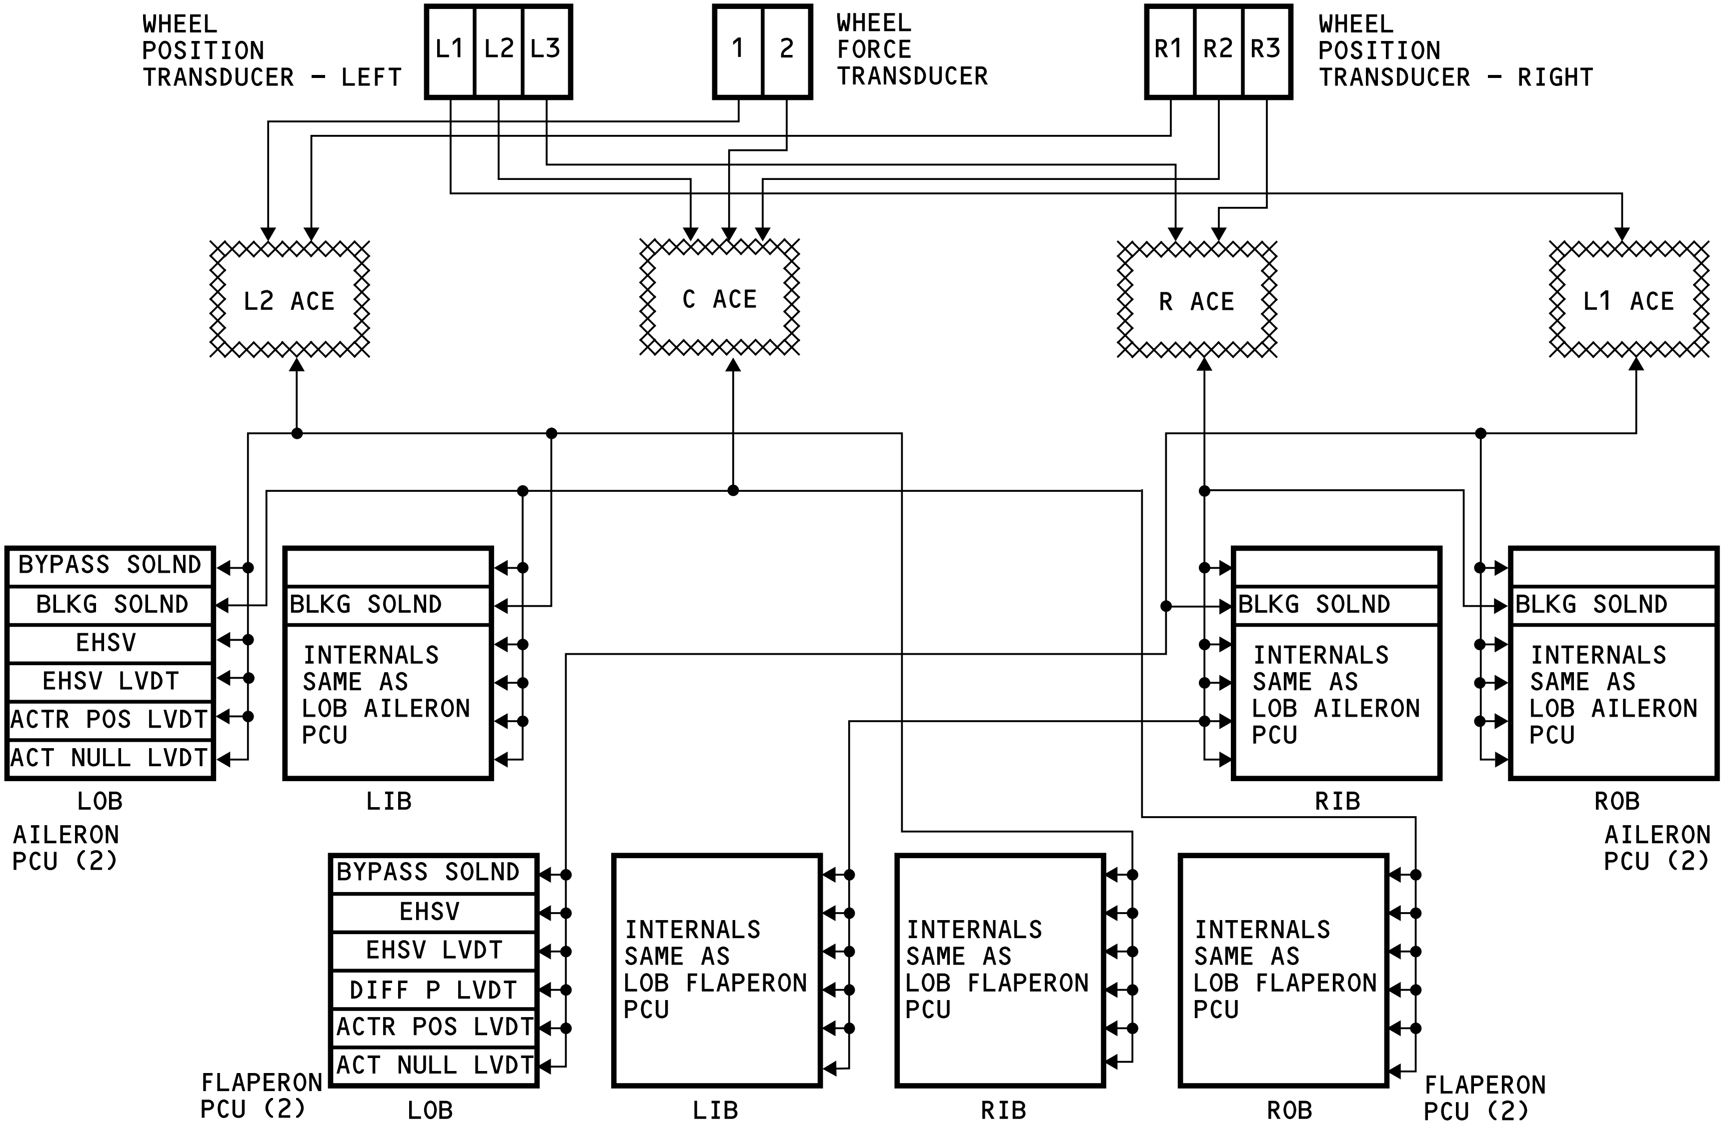
Each ACE sends output command signals to the two PCUs of the same aileron. Two output command signals go to the EHSV and the bypass solenoid of one PCU on the assigned aileron. Another output command signal goes to the blocking solenoid of the adjacent PCU on the same aileron. The PCU sends feedback signals to its assigned ACE from:

- The EHSV position LVDT
- The actuator piston position LVDT
- The actuator null LVDT.

Flaperon PCUs

Each ACE sends output command signals to one flaperon PCU. The output command signals go to the EHSV and the bypass solenoid. The PCU sends feedback signals to its assigned ACE from:

- The EHSV position LVDT
- The differential pressure LVDT
- The actuator piston position LVDT
- The actuator null LVDT.



AILERON AND FLAPERON CONTROL - FUNCTIONAL DESCRIPTION

AILERON AND FLAPERON CONTROL - FUNCTIONAL DESCRIPTION - ACE SERVO LOOP

General

The ACE contains a servo loop circuit to produce the command signals for the PCUs.

In normal and secondary mode, the PFC sends the command signals to the ACE. In direct mode the ACE calculates the command signals.

Servo Loop Operation

The ACEs use the aileron and flaperon command signals through a servo loop. The command signals then go to the EHSV of the PCUs. The ACEs also use the command signals to monitor for failures.

The movement of the EHSV sends hydraulic pressure to extend or retract the actuator.

The EHSV LVDT measures the movement of the EHSV and supplies a feedback signal to the ACEs. The ACEs use this feedback signal in the failure monitor.

The actuator position LVDT measures the movement of the actuator and supplies a feedback signal to the ACEs through the actuator null LVDT.

The actuator null LVDT is in series with the actuator position LVDT. The actuator null LVDT modifies the signal from the actuator position LVDT.

The actuator position LVDT supplies a feedback signal to the ACEs to close the servo loop. The ACEs use this feedback signal to monitor for failure. The signal also goes to the PFC.

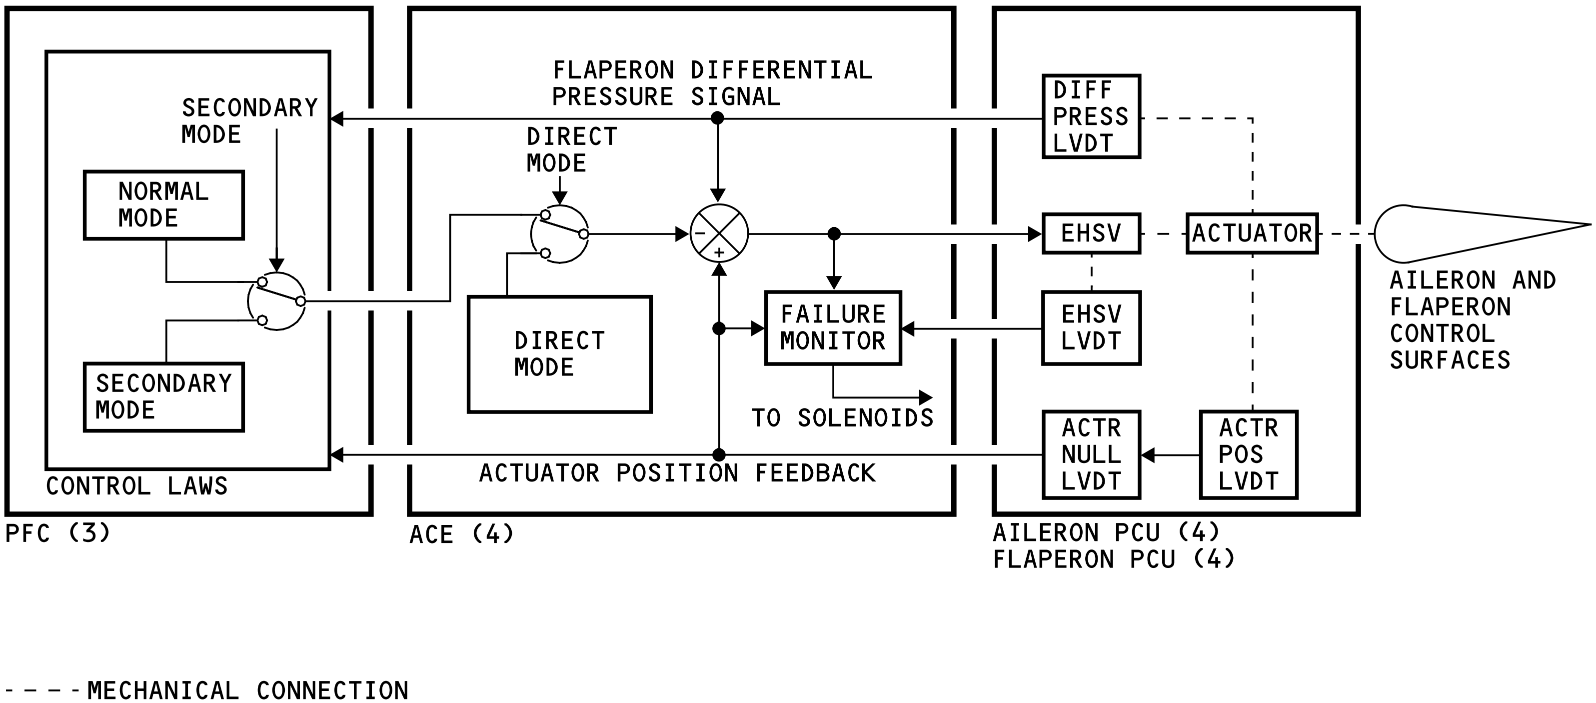
On the flaperon PCUs only, a differential pressure LVDT measures the differential pressure across the actuator piston. The signal from the differential pressure LVDT goes to the ACEs for the servo loop. The signal also goes to the PFCs for force fight equalization.

Failure Monitor

The ACE has a failure monitor to do a check of the correct operation of the PCU. The monitor uses the ACE command signal and the feedback signals from the EHSV LVDT and the actuator LVDT. When the failure monitor finds a fault with the PCU or the ACE, it de-energizes the bypass solenoid of the PCU.

Training Information Point

After installation of the aileron or the flaperon PCU, you do a MAT test and adjust the actuator null LVDT to have the control surface at the rig position.



27-11-00-022 Rev 5 01/08/96

AILERON AND FLAPERON CONTROL - FUNCTIONAL DESCRIPTION - ACE SERVO LOOP

AILERON AND FLAPERON CONTROL - AILERON AND FLAPERON DROOP

Purpose

The ailerons and flaperons of both wings move down (droop) to help the high lift system when the flaps are extended. When drooped, the ailerons and flaperons still operate for roll control.

Functional Description

The PFCs and the ACEs command the ailerons and flaperons to droop based on the flap position.

Both ailerons and flaperons droop in normal mode of operation of the PFCS. Only the flaperons droop in secondary and direct mode.

Normal Mode

In normal mode, the ailerons droop at a different rate and schedule than the flaperons.

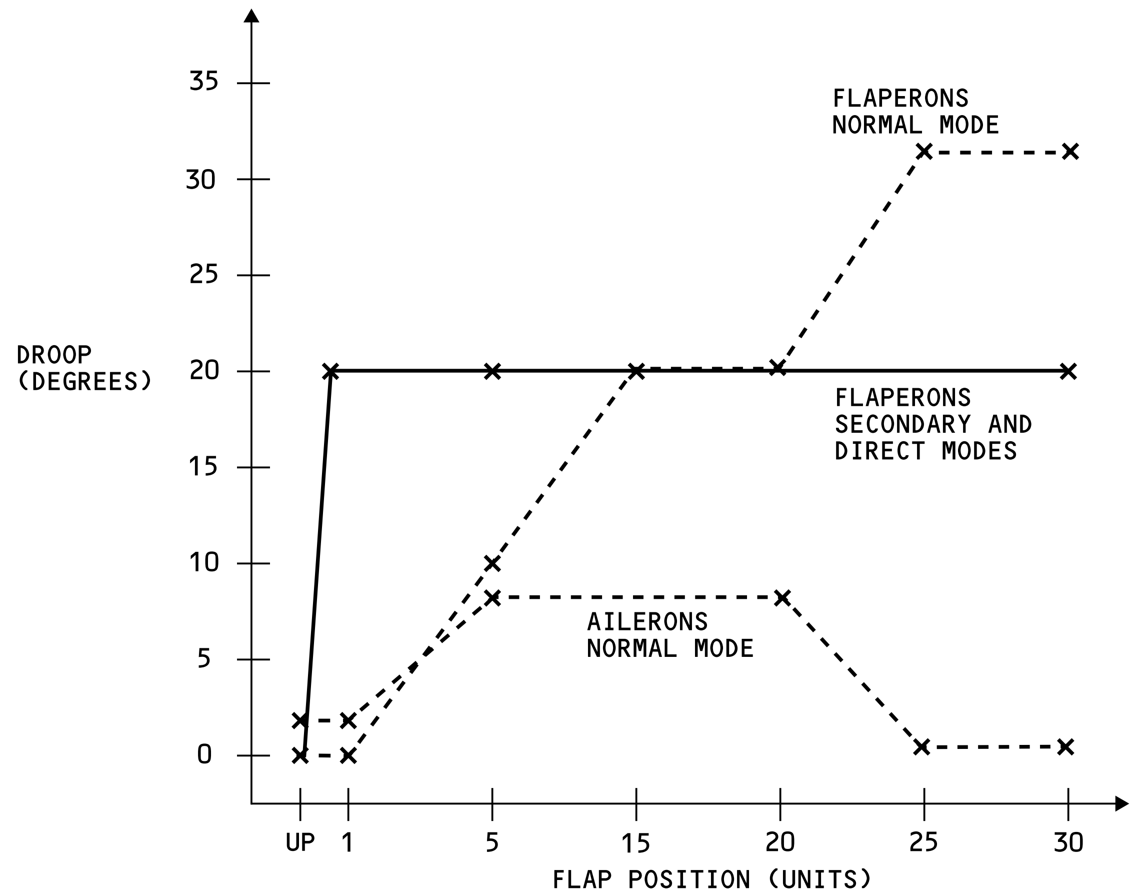
When the flaps are retracted, the ailerons are at the 2 degrees TED rig position in relation to the wing fixed trailing edge. With the flaps at the takeoff position (5 to 20), the ailerons droop by 8 degrees TED. With the flaps at the landing position (25 and 30), the ailerons move to 0.6 degrees TED.

The flaperons droop to 10 degrees TED when the flaps are at the 5 position. They droop to 20 degrees TED when the flaps are at the 15 or 20 position. They droop to 31 degrees TED when the flaps are at the landing position (25 or 30).

On the ground, the PFCs remove the flaperon droop command in proportion to the speedbrake lever movement from 17 to 55 degrees. When the speedbrake lever goes back to the DOWN position, the flaperons gradually droop to the position commanded by the flaps.

Secondary and Direct Modes

In the secondary and direct modes, the flaperons droop to a constant value of 20 degrees when the flaps and slats are not retracted. The ailerons do not droop.



27-11-00-026 Rev 3 03/04/1997

AILERON AND FLAPERON CONTROL - AILERON AND FLAPERON DROOP

THIS PAGE INTENTIONALLY LEFT BLANK

AILERON AND FLAPERON CONTROL - BANK ANGLE PROTECTION

Purpose

The bank angle protection (BAP) function of the PFC helps prevent the airplane from rolling to large bank angles. However, the pilot can always override the control wheel forces and remain in full control of roll.

Functional Description

When the bank angle exceeds the nominal value of 35 degrees, BAP increases the control wheel force to the pilot.

BAP operates only in PFCS normal mode and is available in both manual operation and in autopilot.

When the BAP function is active, the ELMS prevents the operation of the aileron trim.

BAP does not operate when the pitch attitude is more than 75 degrees (positive or negative). When the airspeed is between the maximum operating speed (Vmo/Mmo) and the maximum design dive speed (Vdive/Mdive), the BAP roll activation value decreases linearly from 35 to 20 degrees.

Manual Operation

The PFCs calculate backdrive actuator commands based on:

- Roll attitude
- Roll rate
- Mach number
- Computed airspeed
- Pitch attitude
- Wheel force.

When the bank angle is more than 35 degrees, the PFC BAP function sends a backdrive command to the AFDCs. The AFDCs send this command to one of the wheel backdrive actuators. The actuator motor applies a torque to turn the control wheels proportionally as the bank angle increases from 35 to 60 degrees.

If the pilot does not move the control wheel, the backdrive actuator moves the control wheels in the opposite direction to the airplane bank. This decreases the airplane bank to 30 degrees. BAP automatically disengages when the bank angle is less than 35 degrees and the pilot takes control of the wheel.

If the pilot wants to maintain or increase the bank angle more than 35 degrees, the pilot must apply a force to the control wheels to override the torque of the backdrive actuator. The wheel force transducer senses the pilot override force and sends a signal to the PFCs. The PFCs use this signal to limit the torque of the backdrive actuator and the force at the control wheels.

Autopilot Operation

In autopilot operation, the BAP function becomes active when the bank angle is more than 35 degrees or the roll rate is more than 15 degrees per second. BAP stops the autopilot roll commands and takes over control of the roll.

The PFC BAP function sends a backdrive command through the AFDCs to one of the wheel backdrive actuators. The backdrive actuator moves the control wheels to decrease the airplane bank below 35 degrees. When the airplane bank is at 35 degrees and the autopilot requests to engage roll control, BAP becomes inactive and returns roll control to the autopilot.

Indications

Indications for BAP are shown on the:

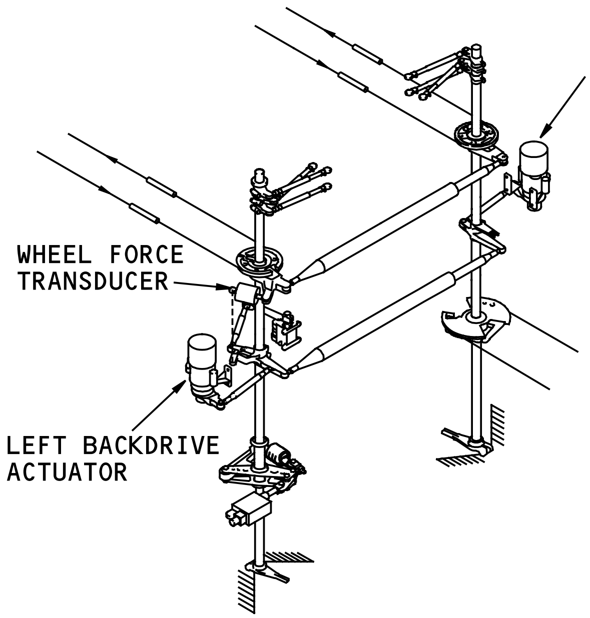
- Multi-function display (MFD) status display
- Primary flight display (PFD)
- Flight control maintenance page.

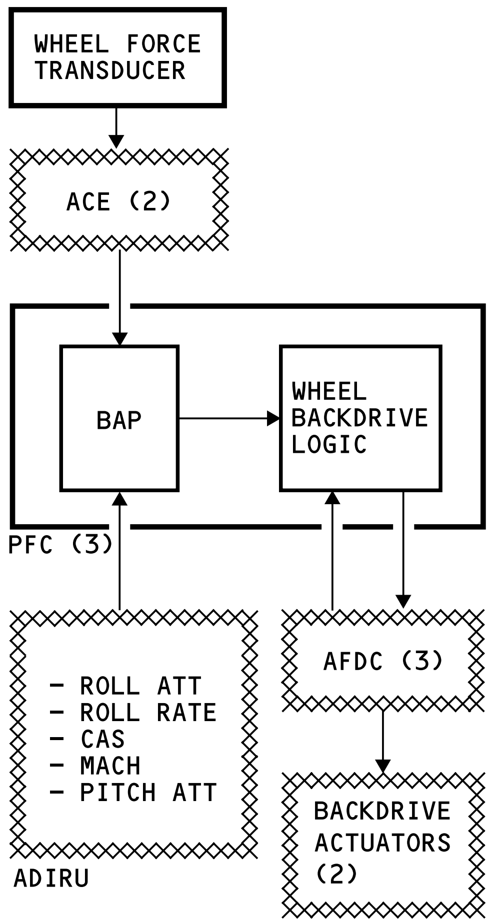
On the MFD format, the status message BANK ANGLE PROTECT indicates one of these faults:

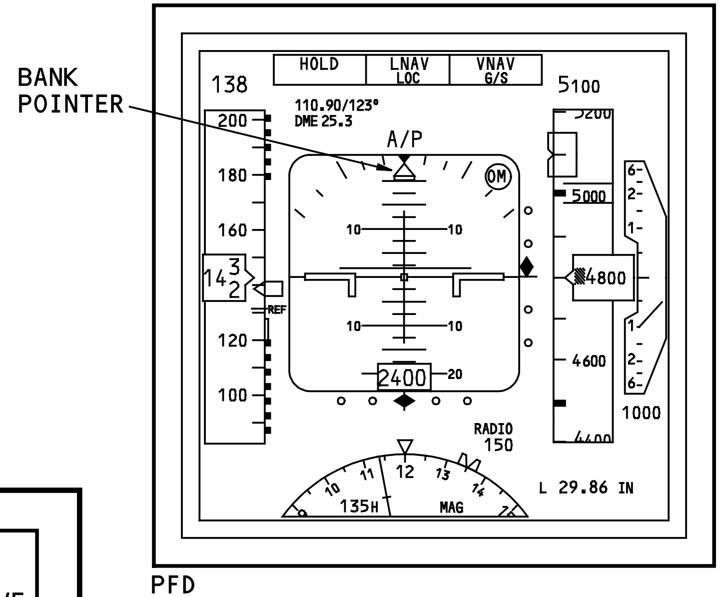
- Both wheel backdrive actuators are defective
- The wheel force transducer is defective
- The right and left AFDCs are inoperative.

On the PFD, the bank pointer changes to amber when the bank angle is 35 degrees or more.

Page 1 of the flight control maintenance pages has a protection mode activity which shows when BAP is active.







AILERON AND FLAPERON CONTROL - BANK ANGLE PROTECTION

THIS PAGE INTENTIONALLY LEFT BLANK

SPOILER AND SPEEDBRAKE CONTROL - INTRODUCTION

General

The spoilers help the ailerons and flaperons control airplane roll about the longitudinal axis. They also supply speedbrake control to reduce lift and increase drag for descent and landing.

There are seven spoilers on each wing. The five outboard spoilers are forward of the outboard flap. The two inboard spoilers are forward of the inboard flap.

Each spoiler has an assigned number, from left to right, of 1 through 14. Each spoiler is part of a symmetrical pair, for example, spoiler pair 4 and 11. One ACE and one hydraulic source control a pair.

Roll Control

During roll control, the spoilers on one wing move up and the spoilers on the other wing stay down.

The pilots manually control roll with the rotation of the control wheels. When engaged, the autopilot automatically commands the spoilers. During autopilot operation, the backdrive actuators backdrive the control wheels.

In roll control, all spoilers except for 4 and 11, are fly-by-wire. Spoilers 4 and 11 receive mechanical signals for roll control.

Spoiler Lockout

Symmetrical spoiler pairs fair and lock out if one actuator in the pair fails. Spoilers 5 and 10 fair and lock out as a function of altitude and airspeed.

Speedbrake Control

During speedbrake control, the spoilers on both wings move symmetrically.

The pilots manually command speed brake control with a conventional speedbrake lever on the aisle stand. The autopilot does not control the speedbrake function.

In speedbrake control, all spoilers are fly-by-wire, including spoilers 4 and 11.

Auto Speedbrake Control

The auto speedbrake system supplies automatic extension or retraction of the speedbrakes during landings and refused takeoffs.

To arm the system, the pilots must either place the speedbrake lever in the armed position or command reverse thrust.

See the auto speedbrake control section for more information (AMM PART I 27-62).

SPOILER AND SPEEDBRAKE CONTROL - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

SPOILER AND SPEEDBRAKE CONTROL - GENERAL DESCRIPTION

General

In roll control, the pilots manually command the spoilers and the autopilot automatically commands them. In speedbrake control, the pilots manually command the spoilers.

Roll Control - Manual Operation

The flight crew uses two conventional control wheels to control roll. All spoilers, except 4 and 11, have an electrical command path. Spoilers 4 and 11 have a mechanical command path in roll control.

Electrical Command Path

Six wheel position transducers change the flight crew control wheel commands to analog electrical signals. These signals go to the four actuator control electronics (ACEs). The ACEs change the signals to digital format and send them to the three primary flight computers (PFCs) through the flight controls ARINC 629 buses.

The PFCs use the control wheel position data, with data from the ADIRU and AIMS, to calculate control surface commands. The PFCs send the digital commands to the ACEs, which change them to analog signals. The ACEs send the analog position commands to the power control units (PCUs) which move the spoilers. The position transducers on the actuator pistons supply position feedback to the ACEs.

Mechanical Control Path

For spoilers 4 and 11, a cable system connects the control wheels to the spoiler PCUs. Cable movement supplies a mechanical input to the PCUs which move the spoilers. The movement of the PCU housing supplies mechanical position feedback.

Roll Control - Autopilot Operation

When engaged, the autopilot flight director computers (AFDCs) control the roll rate and attitude of the airplane. They supply roll commands to the PFCs through the flight controls ARINC 629 buses. The PFCs use these inputs to calculate position commands for the spoilers.

The PFCs also calculate wheel backdrive commands. The PFCs send these commands to the AFDCs, which calculate control wheel movement commands for the backdrive actuator. The backdrive actuator moves the control wheels the same amount as the pilot would move them manually for the same surface movement. This supplies the mechanical signal to move spoilers 4 and 11.

To override the autopilot, the flight crew applies more force on the control wheel than the backdrive actuator force.

Speedbrake Control

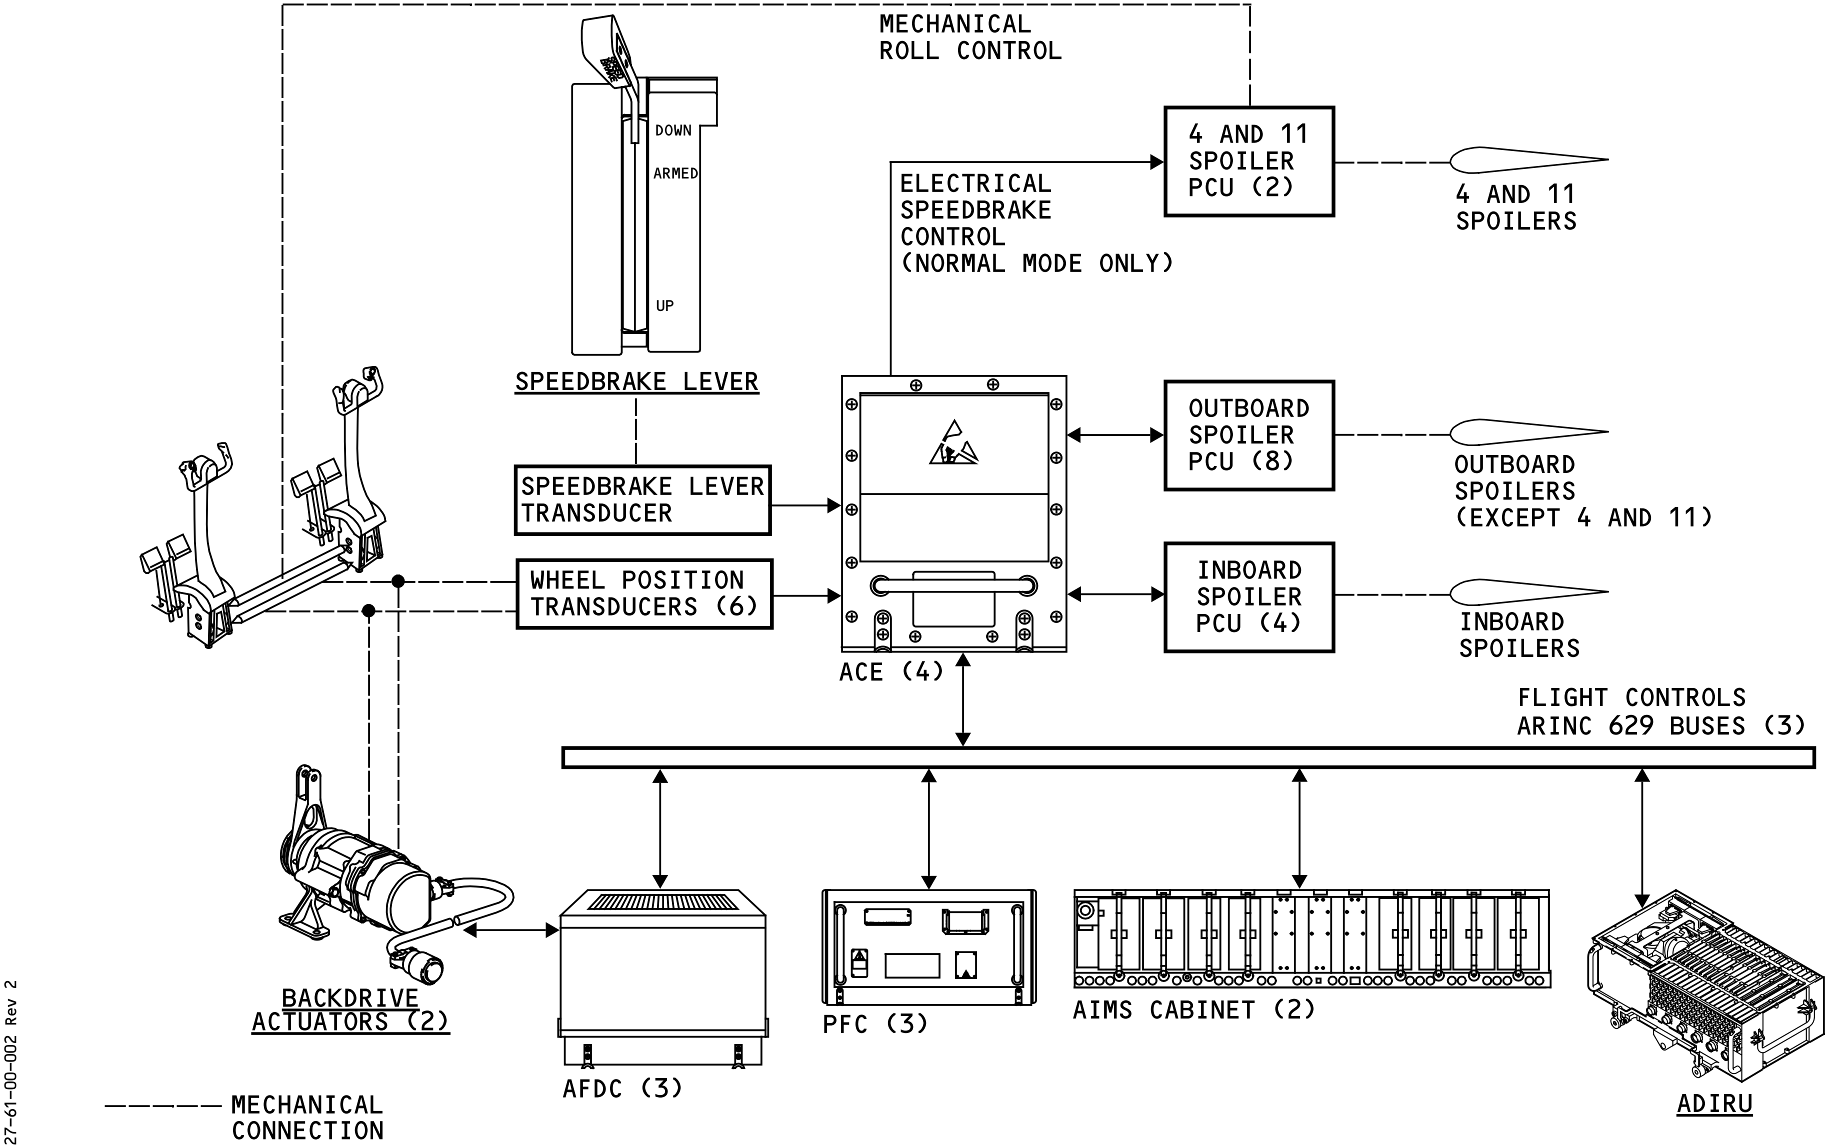
The speedbrake lever transducers change the speedbrake lever movements to analog electrical signals.

SPOILER AND SPEEDBRAKE CONTROL - GENERAL DESCRIPTION

These signals go to the four ACEs. The ACEs change the signals to digital format and send them to the three PFCs through the flight controls ARINC 629 buses.

The PFCs use the speedbrake lever position along with data from the ADIRU and AIMS, to calculate speedbrake commands. The PFCs mix these speedbrake commands with the spoiler roll commands. The PFCs send the mixed digital commands to the ACEs, which change them to analog signals. Except for spoilers 4 and 11, the ACEs send the analog position commands to the spoiler PCUs. The position transducers on the actuator pistons supply position feedback to the ACEs.

For spoilers 4 and 11, speedbrake control is only available in normal mode. When the pilot moves the speedbrake lever more than 54 degrees, the PFC commands the ACE to send an ON/OFF electrical signal to the two spoiler PCUs.



SPOILER AND SPEEDBRAKE CONTROL - GENERAL DESCRIPTION

SPOILER AND SPEEDBRAKE CONTROL - FLIGHT DECK COMPONENT LOCATIONS

General

Many spoiler and speedbrake control components are in the flight deck and below the flight deck floor.

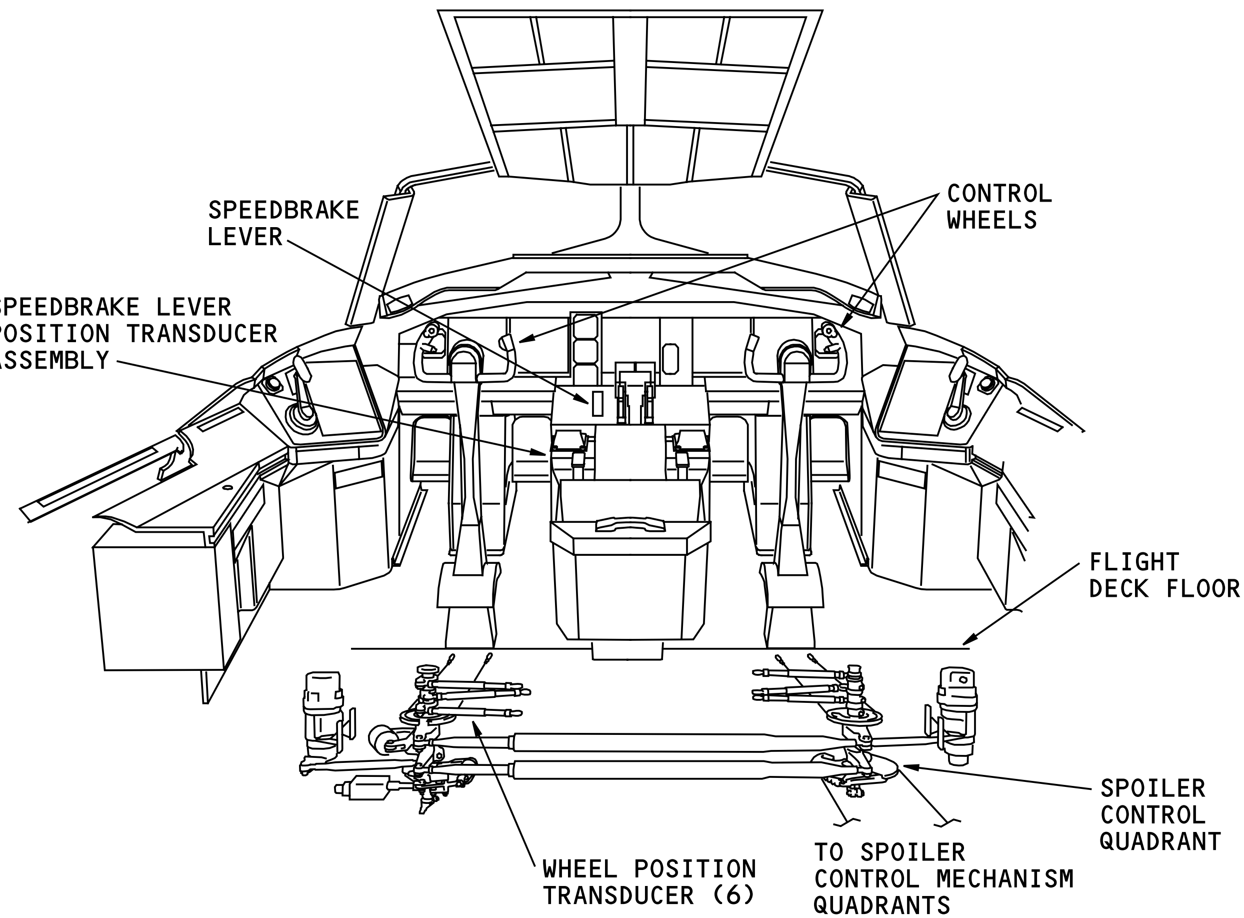
Flight Deck Components

The control wheels and speedbrake lever are in the flight deck. The speedbrake lever is on the captain's side of the control stand. The speedbrake lever transducer is in the control stand.

Components Below the Flight Deck

The spoiler forward controls are below the flight deck floor and above the nose gear wheel well. These include the wheel position transducers and the spoiler control quadrant.

Access to these components is by panels in the flight deck floor. Access is also through the main equipment center (MEC), and then forward along the nose gear wheel well.



27-61-00-003 Rev 2 01/08/96

SPOILER AND SPEEDBRAKE CONTROL - FLIGHT DECK COMPONENT LOCATIONS

SPOILER AND SPEEDBRAKE CONTROL - WING CENTER SECTION AND WING COMPONENT LOCATIONS

General

Several spoiler and speedbrake control components are in the wing center section and in the wings.

Wing Center Section Components

The control cables for spoilers 4 and 11 connect the forward quadrant to the spoiler control mechanism quadrants and to the spoiler PCU quadrants. The cables go below the flight deck and passenger compartment floor, along RBL 21, to the wing center section.

The spoiler control mechanism quadrants are in the wing center section of the airplane, above the slant pressure deck and below the passenger floor. The cables go from the control mechanism quadrants through the overwing floor beams, and out along the wing rear spar to the spoiler PCU quadrants.

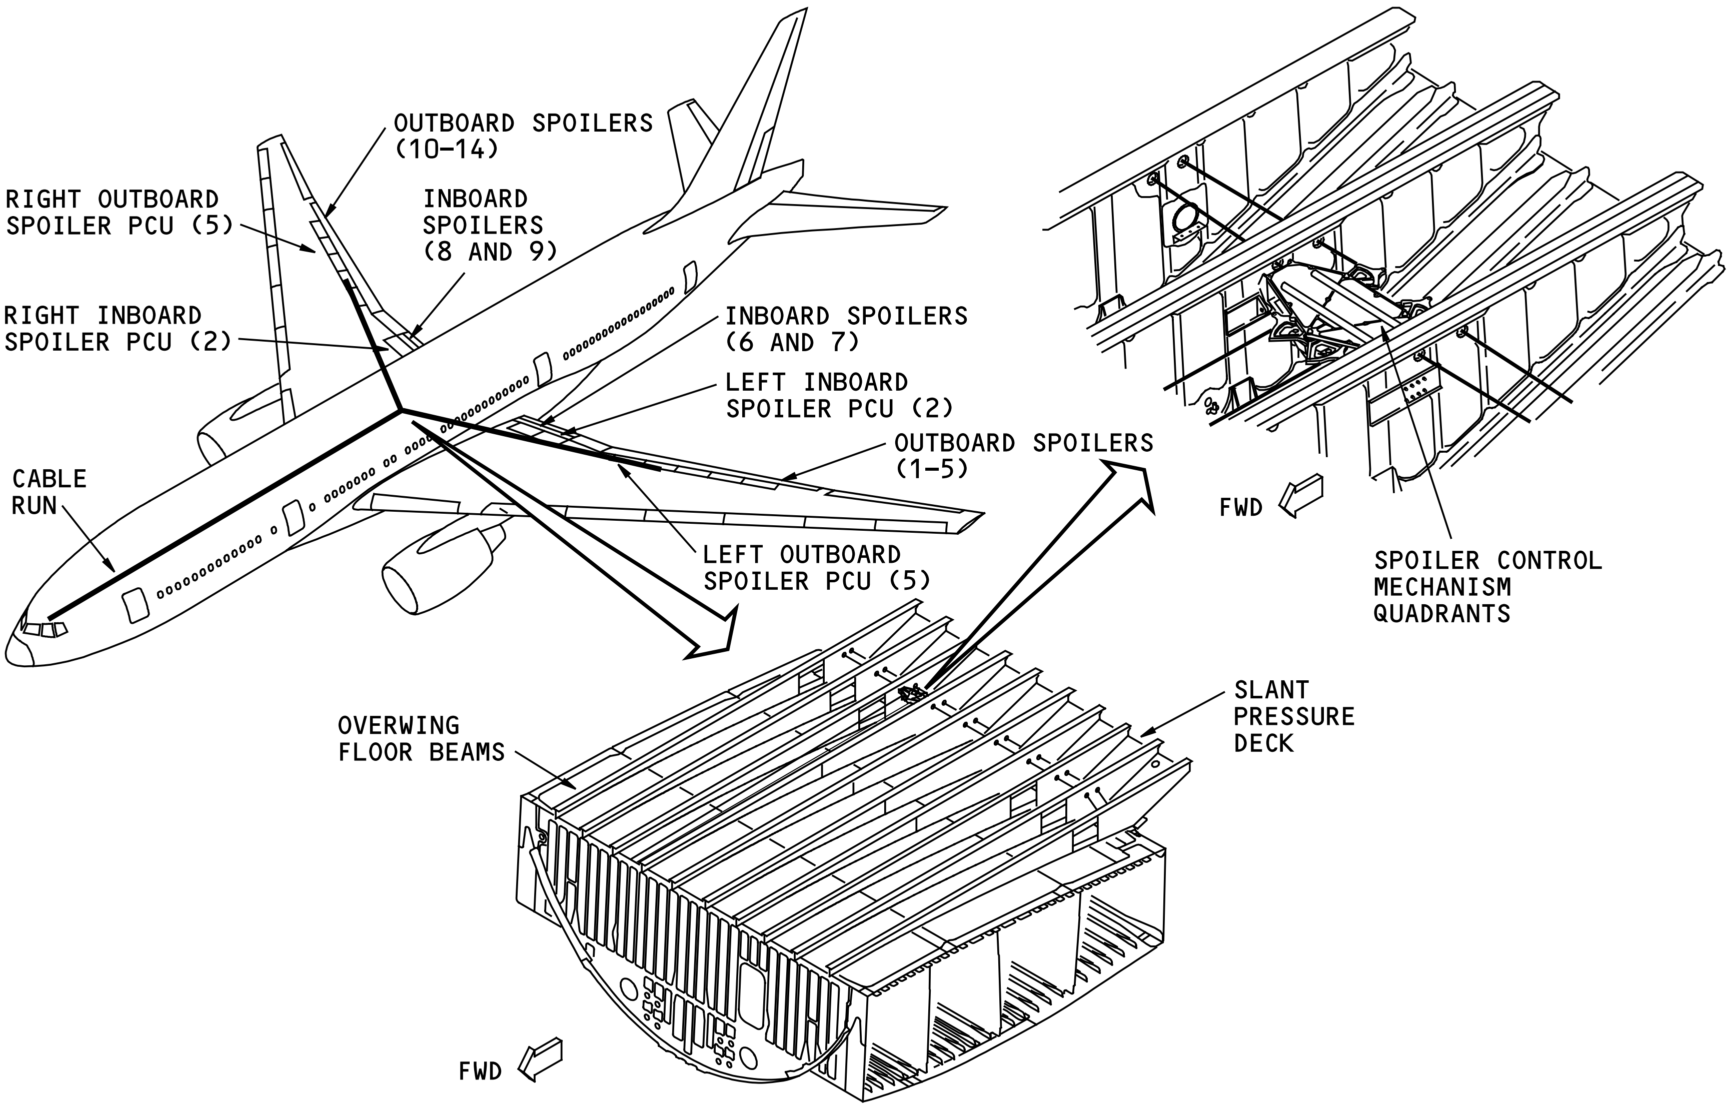
To get access to the control mechanism quadrants, you remove the floor panels in the passenger compartment.

Wing Components

The spoiler control surfaces and their PCUs are on the wings. One PCU connects to each surface.

The spoiler PCU quadrants for spoilers 4 and 11 are next to the PCUs.

To get access to the PCUs and quadrants, there are access panels on the lower wing.



SPOILER AND SPEEDBRAKE CONTROL - WING CENTER SECTION AND WING COMPONENT LOCATIONS

SPOILER AND SPEEDBRAKE CONTROL - ELECTRICAL INTERFACES

General

All of the roll and speedbrake control electrical interfaces with the PFCS go through the ACEs. The ACEs have interfaces with these components:

- Wheel position transducers
- Speedbrake lever transducer
- Inboard spoiler PCUs
- Outboard spoiler PCUs

Wheel Position Transducers

There are six position transducers, three for each control wheel. Each transducer is a linear variable differential transformer (LVDT) that sends analog signals to the ACEs. These analog signals represent the control wheel position and its movement.

See the aileron and flaperon control section for more information about the wheel position transducers (AMM PART I 27-11).

Speedbrake Lever Transducers

The speedbrake lever transducer contains four rotary variable differential transformers (RVDTs). These RVDTs send analog signals of the speedbrake lever position to the ACEs.

Inboard Spoiler PCUs

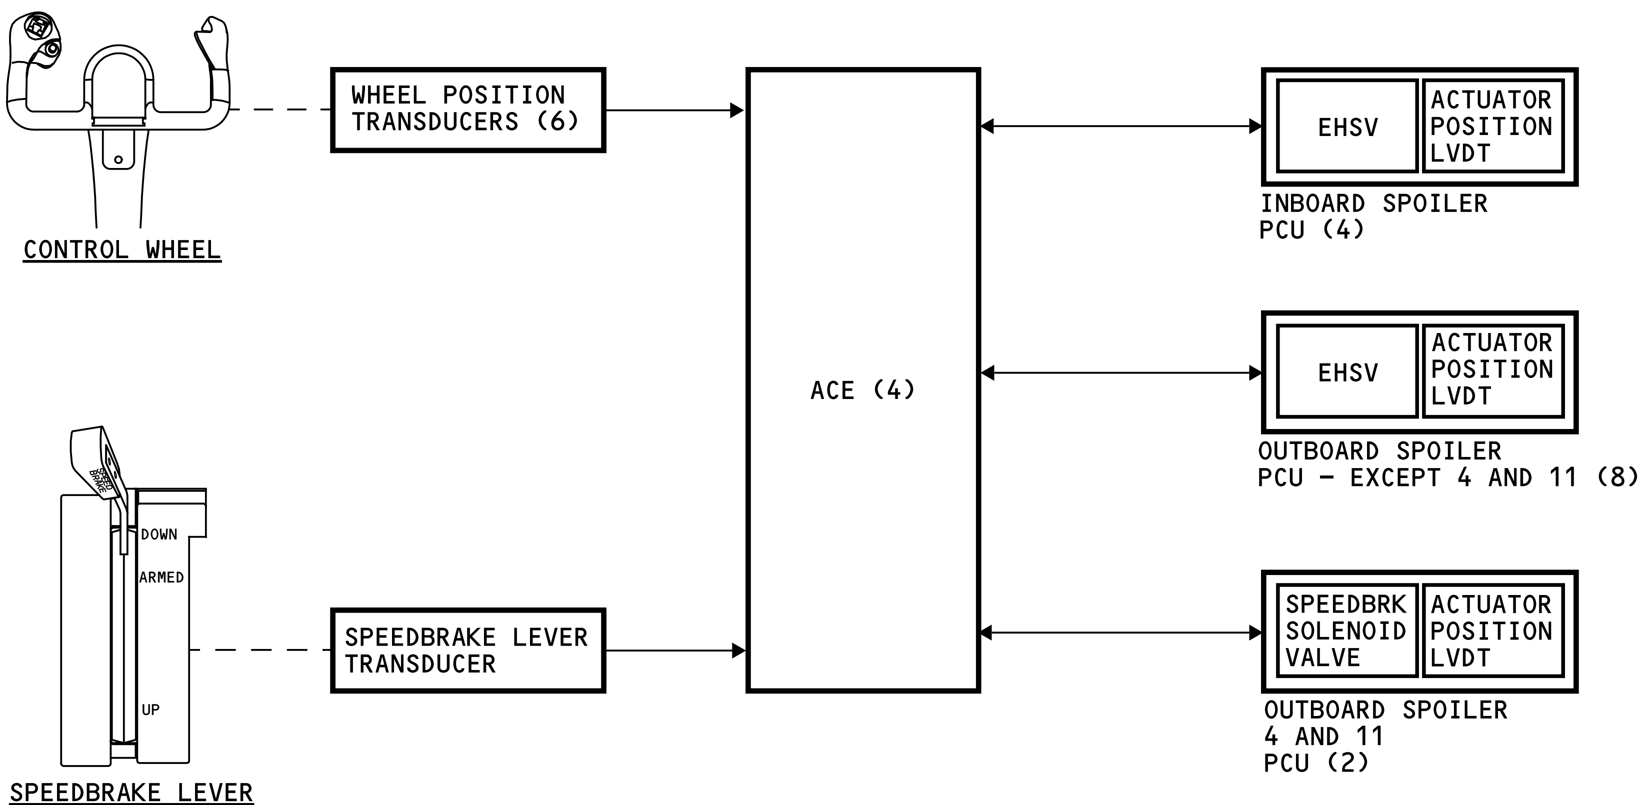
Each of the four inboard spoiler PCUs receives analog electrical signals from the ACEs. The analog signal goes to the electrohydraulic servo valve (EHSV).

Each of these PCUs sends an analog feedback signal to the ACEs from the actuator position LVDT.

Outboard Spoiler PCUs

Each outboard spoiler PCU receives analog electrical signals from the ACEs. For the outboard spoiler PCUs other than 4 and 11, the electrical signal is for the EHSV. For the spoiler 4 and 11 PCUs, the signal goes to the speedbrake solenoid valve.

All ten of the outboard spoiler PCUs send analog feedback signals to the ACEs. These signals are from the actuator position LVDTs.



27-61-00-005 Rev 5 02/11/1998

SPOILER AND SPEEDBRAKE CONTROL - ELECTRICAL INTERFACES

SPOILER AND SPEEDBRAKE CONTROL - MECHANICAL INTERFACES

General

The roll control mechanical interface for spoilers 4 and 11 is a cable system. The cable goes from the control wheels to the spoiler PCUs through these components:

- Forward spoiler quadrant
- Spoiler control mechanism quadrants
- Spoiler PCU quadrant.

Forward Spoiler Quadrant

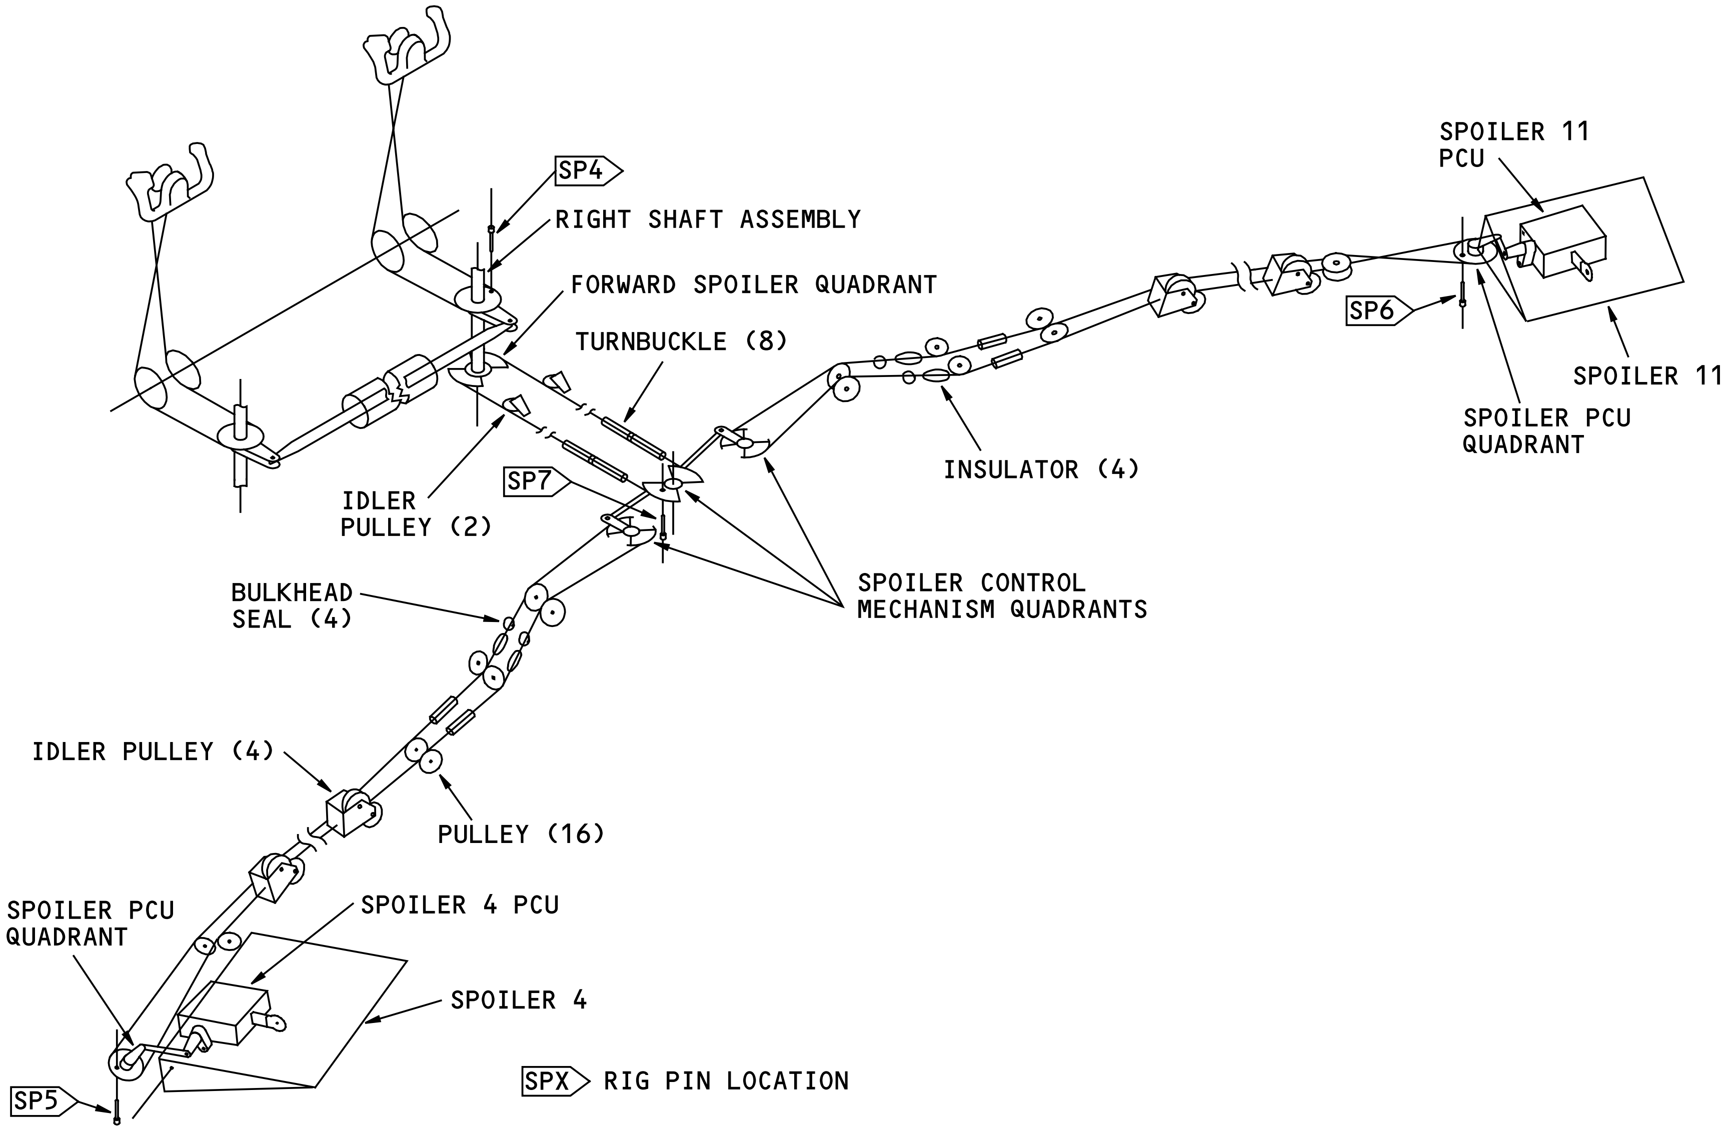
The forward spoiler quadrant connects to the lower end of the right control wheel shaft assembly. Cables connect the forward quadrant to the spoiler control mechanism quadrants through a series of idler pulleys and turnbuckles.

Spoiler Control Mechanism Quadrants

The three spoiler control mechanism quadrants link together to form a travel mechanism assembly. The central mechanism quadrant connects to the cables from the forward spoiler quadrant. The left and right mechanism quadrants connect to the central quadrant with two control rods. Cables go from the left and right quadrants out to the spoiler PCU quadrant on each wing. Pulleys and idler pulleys supply protection to the cables from wing bending. Insulators supply protection from lightning strikes.

Spoiler PCU Quadrants

The spoiler PCU quadrants connect to the PCUs with a mechanical input rod. The rod controls the position of the PCU main control valve.



27-61-00-006 Rev 3

SPOILER AND SPEEDBRAKE CONTROL - MECHANICAL INTERFACES

SPOILER AND SPEEDBRAKE CONTROL - SPEEDBRAKE LEVER AND SPEEDBRAKE LEVER TRANSDUCER

General

Pilots use the speedbrake lever to command the spoilers in speedbrake operation during descent and landing.

The speedbrake components in the control stand are the speedbrake lever, and the speedbrake lever position transducers. See the auto speedbrake control section for more information about the speedbrake components in the control stand (AMM PART I 27-62).

Physical Description

The speedbrake lever has a DOWN detent, an ARMED position for auto speedbrake control, and an UP position for full spoiler deflection.

The speedbrake lever transducer has four individual RVDTs with a common rotor input. The rotor attaches to the clutch output shaft with a spline. Each RVDT has a separate cable and connector. The ACEs supply 7v ac, 1800 Hz excitation power.

Location

The speedbrake lever is on the captain's side of the control stand. The speedbrake lever transducers are in an assembly inside the control stand on the captain's side. Access is through a panel on the left side of the control stand.

Functional Description

When the pilots lift the speedbrake lever out of its detent position, and then pull the lever aft, it moves a rod and crank assembly in the control stand. This movement turns the clutch and the input rotor of the transducers. The four RVDTs measure the rotor movement and supply an analog electrical signal to the four ACEs.

Indications

The EICAS warning message CONFIG SPOILERS indicates that the speedbrake lever is not in its down detent when either the left or right engine thrust exceeds the takeoff threshold and the airplane is on the ground.

The EICAS caution message SPEEDBRAKE EXTENDED indicates that the speedbrake lever is more than the armed position with the airplane above 15 feet of radio altitude and one of these conditions:

- Airplane below 800 feet radio altitude
- Flaps at landing position
- Either thrust lever is more than 5 degrees above the idle stop.

The EICAS memo message SPEEDBRAKE ARMED indicates that the speedbrakes are armed.

On the MFD status display, the message SPEEDBRAKE LEVER XDCR shows when one of the four speedbrake lever transducers has failed.

SPOILER AND SPEEDBRAKE CONTROL - SPEEDBRAKE LEVER AND SPEEDBRAKE LEVER TRANSDUCER

SPOILER AND SPEEDBRAKE CONTROL - CABLE-CONTROLLED SPOILER PCU - PHYSICAL DESCRIPTION

General

The cable-controlled PCUs move the outboard spoilers 4 and 11 in roll and speedbrake control. Mechanical command signals from the control wheels, and electrical command signals from the speedbrake lever control the PCUs. Each spoiler has one PCU.

Location

The cable-controlled PCUs are on the rear spar of the inboard wing. Access to the PCUs is through two hinged panels on the lower wing.

Trunnion pillow blocks connect the PCUs to the rear spar structural fitting. Each PCU actuator rod connects to its spoiler actuator fitting.

An electrical connector is near the cap end of the PCU. Hydraulic tubing connect to two ports next to the electrical connector.

Physical Description

The two cable-controlled spoiler PCUs are identical. Each weighs approximately 20 lb (9 kg).

The PCUs contain an unbalanced hydraulic actuator with a control module. The control module contains:

- A main control valve
- A speedbrake solenoid valve
- A speedbrake mode valve
- An extension check and relief valve with manual bypass
- An inlet filter.

The actuator piston has an LVDT that sends position feedback signals to the ACE.

Training Information Point

Use the manual bypass to extend the PCU for maintenance.

Install a spoiler PCU lock when the panel is in the up position.

Use the spoiler PCU rod end adjustment to rig the PCU.

The rod end of the actuator has a grease fitting.

SPOILER AND SPEEDBRAKE CONTROL - CABLE-CONTROLLED SPOILER PCU - PHYSICAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

SPOILER AND SPEEDBRAKE CONTROL - CABLE-CONTROLLED SPOILER PCU - FUNCTIONAL DESCRIPTION

General

The cable-controlled spoiler PCU operates in two different modes:

- Roll control
- Speedbrake control.

In roll control mode, the cable system supplies a mechanical input to the main control valve.

In speedbrake control mode, speedbrake lever movement causes the ACEs to energize the speedbrake solenoid. This bypasses the main control valve and sends a hardover command to the actuator.

The actuator LVDT supplies a position feedback signal to the ACEs.

Roll Control Mode

The PCU is in roll control mode when the ACE does not energize the speedbrake solenoid valve.

When there is no roll or speedbrake command, a spring forces the main control valve to the fully retracted position. Hydraulic fluid pressurizes the actuator to retract. The extension check valve stays closed. Its internal check valve permits the retract pressure to the actuator.

When the pilot turns the control wheel, the spoiler PCU quadrant moves the main control valve. This sends hydraulic system pressure through the speedbrake mode valve to the actuator, and results in the actuator extension or retraction. When the command is to extend, the extension check valve opens and permits flow to return. When the command is to retract, the hydraulic pressure flow goes through the closed extension check valve. The angular output movement of the PCU about the trunnion supplies mechanical loop feedback to the main control valve.

Speedbrake Control Mode

The PCU is in speedbrake control mode when the ACE energizes the speedbrake solenoid.

When the pilot moves the speedbrake lever more than 54 degrees, the ACE energizes the speedbrake solenoid. This moves the solenoid valve. Hydraulic pressure then moves the speedbrake mode valve to the speedbrake position. Under these conditions, hydraulic pressure goes directly through the speedbrake mode valve to the actuator. The extension check valve opens and permits flow to return. This results in full actuator extension.

When the pilot moves the speedbrake lever to less than 45 degrees, the ACE de-energizes the speedbrake solenoid. With no electrical input, internal springs force the speedbrake solenoid valve and the speedbrake mode valve to the closed position. This puts the PCU in the roll control mode of operation. If there is no roll command, the main control valve pressurizes the actuator to retract. Hydraulic pressure flows through the closed extension check valve.

Operation Without Hydraulic Pressure

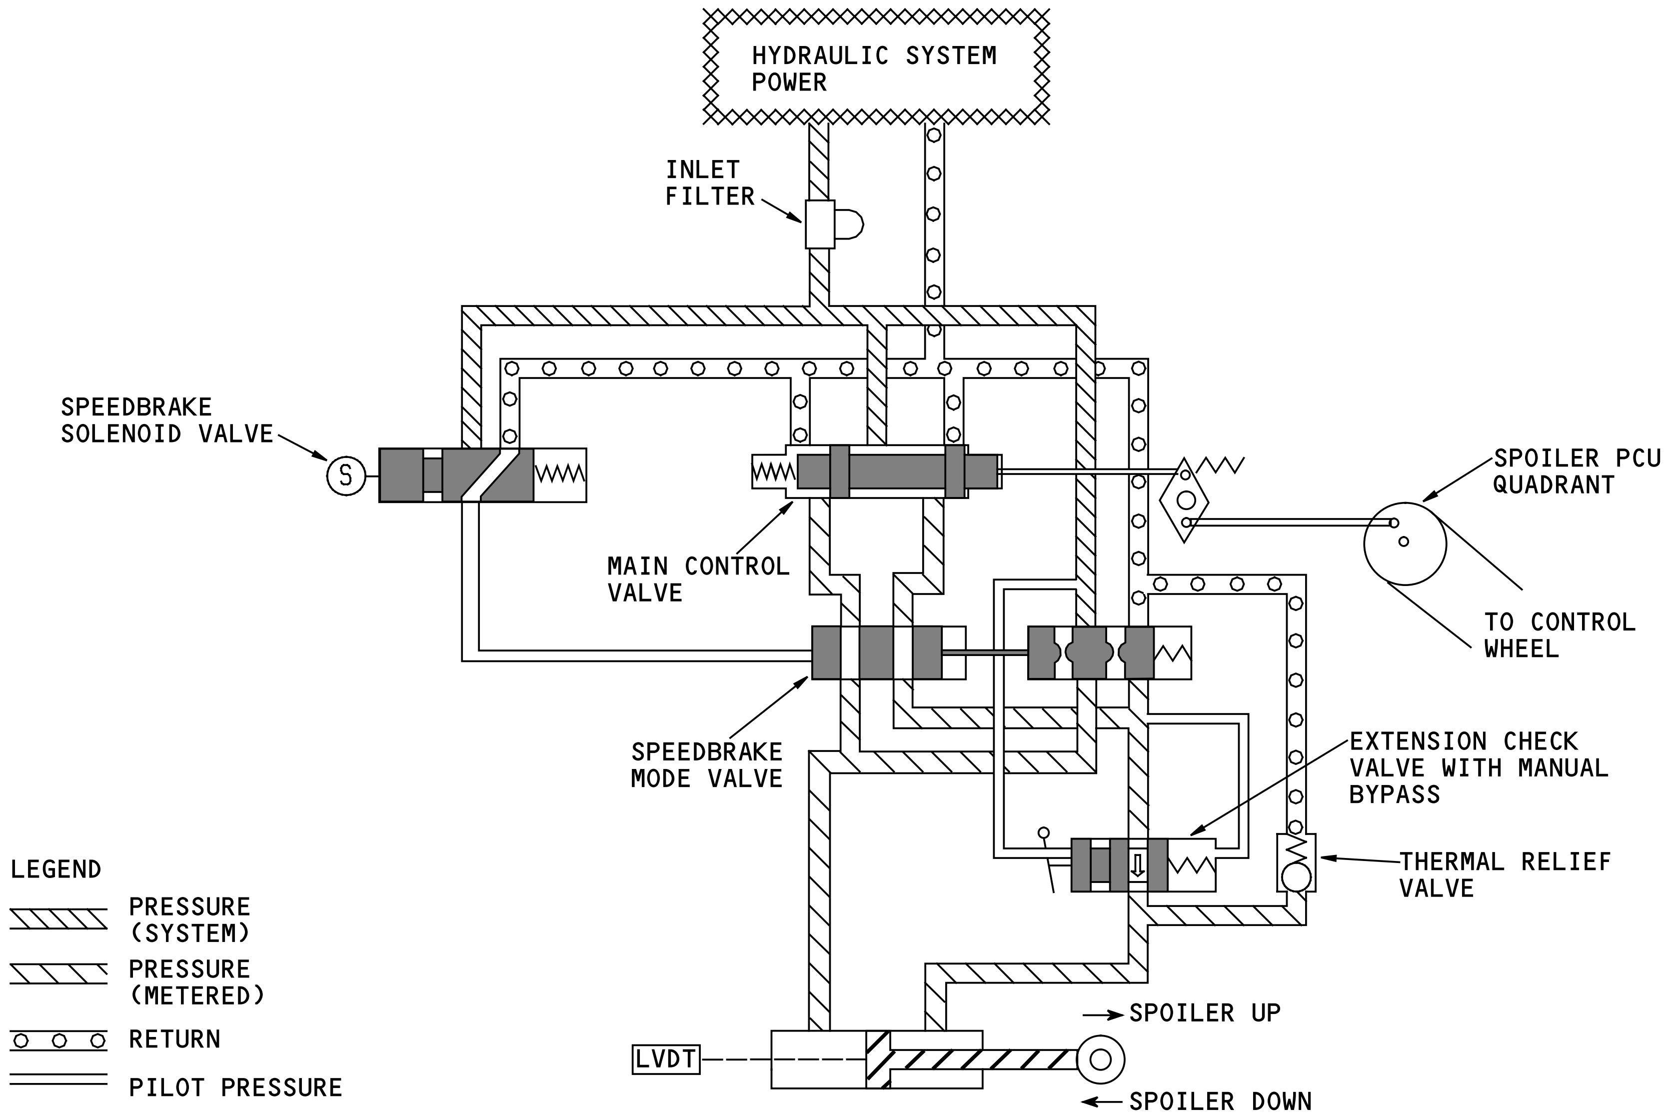
Without hydraulic pressure to the PCU, the extension check valve closes and prevents extension of the PCU actuator.

If the spoiler panel is raised at the time of hydraulic power loss, the airload on the spoiler causes hydraulic fluid to flow through the speedbrake mode valve and the main control valve. This permits the actuator to retract.

The thermal relief valve cracks open at about 3700 psid and closes at approximately 3100 psid.

Manual Operation

You can open the extension check valve with the manual bypass. With the extension check valve open, you can raise the spoiler without hydraulic power. You can lower the spoiler panel with the extension check valve closed.



27-61-00-012 Rev 2 01/19/95

SPOILER AND SPEEDBRAKE CONTROL - CABLE-CONTROLLED SPOILER PCU - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

SPOILER AND SPEEDBRAKE CONTROL - INBOARD AND OUTBOARD SPOILER PCU - PHYSICAL DESCRIPTION

General

Except for spoilers 4 and 11, the inboard and outboard spoiler PCUs move their spoiler panel with electrical command signals from the ACEs. Each spoiler has one PCU.

Location - Inboard Spoiler PCUs

The inboard spoiler PCUs are on the inboard wing spoiler beams. Access to the PCUs is by hinged panels on the lower wings.

Trunnion pillow blocks connect the PCUs to the spoiler beam structure. Each PCU actuator rod connects to its spoiler panel clevis fitting.

An electrical connector attaches forward and left of the cap end of the PCU.

Two hydraulic tubes connect to ports at the cap end of the PCU.

Location - Outboard Spoiler PCUs

The outboard spoiler PCUs are on the outboard wing rear spars. Access to the PCUs is by hinged panels on the lower wings.

Trunnion pillow blocks connect the PCUs to the rear spar structures. Each PCU actuator rod connects to its spoiler panel clevis fitting.

An electrical connector and two hydraulic tubes attach at the forward, left end of the PCU.

Physical Description

The inboard spoiler PCUs weighs about 25.2 lb (11 kg) each. The outboard spoiler PCUs weigh about 14.5 lb (6.4 kg) each. The electrically-controlled inboard and outboard spoilers PCUs are functionally identical.

The spoiler PCUs contains a hydraulic actuator with a control module. The inboard PCUs have a balanced actuator. The outboard PCUs have an unbalanced actuator. The control module contains:

- An electrohydraulic servo valve (EHSV)
- An extension check and relief valve with manual bypass
- An inlet filter.

The actuator piston has an LVDT that sends position feedback signals to the ACE.

Training Information Point

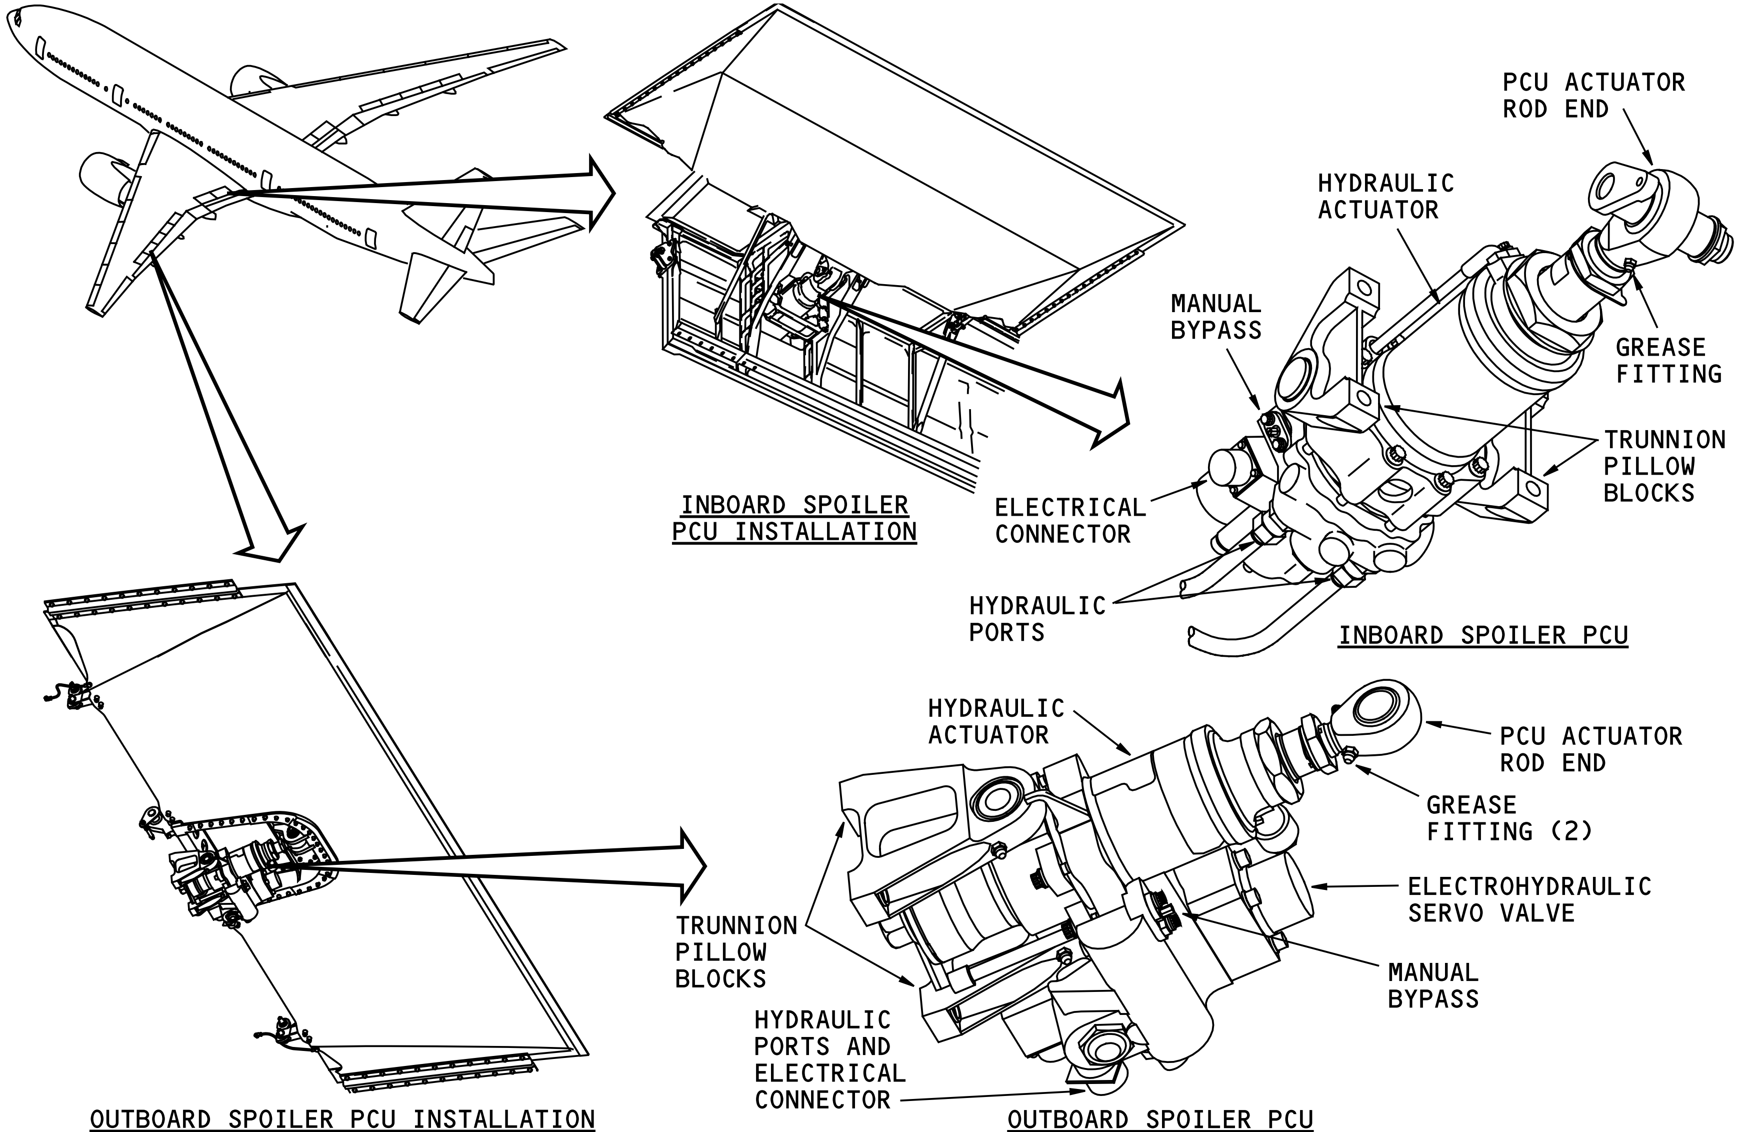
Use the manual bypass to extend the PCU for maintenance.

Install a spoiler PCU lock when the panel is in the up position.

Use the spoiler PCU rod end adjustment to rig the PCU.

SPOILER AND SPEEDBRAKE CONTROL - INBOARD AND OUTBOARD SPOILER PCU - PHYSICAL DESCRIPTION

The rod end of the actuator has a grease fitting.



27-61-00-013 Rev 2

SPOILER AND SPEEDBRAKE CONTROL - INBOARD AND OUTBOARD SPOILER PCU - PHYSICAL DESCRIPTION

SPOILER AND SPEEDBRAKE CONTROL - INBOARD AND OUTBOARD SPOILER PCU - FUNCTIONAL DESCRIPTION

General

The inboard and outboard spoiler PCUs, except for spoilers 4 and 11, have only one mode of operation.

Normal Operation

When the ACE energizes the EHSV to the extend or retract position, hydraulic system pressure moves the actuator. During a retraction command, the extension check valve stays closed and permits retract pressure to the actuator. During an extension command, the extension check valve opens and permits flow to return. The actuator LVDT supplies a position feedback signal to the ACEs. The ACEs use this signal to adjust the extend command current.

A spring forces the EHSV to the fully retracted position when there is no electrical signal. This permits hydraulic pressure through the closed extension check valve to keep the actuator retracted.

Operation Without Hydraulic Pressure

Without hydraulic pressure to the PCU, the closed extension check valve prevents extension of the PCU.

If the spoiler panel is up at the time of hydraulic power loss, the airload on the spoiler causes hydraulic fluid to flow through the extension check valve and the EHSV. This permits the actuator to retract.

The thermal relief valve cracks open at about 3700 psid and closes at about 3100 psid.

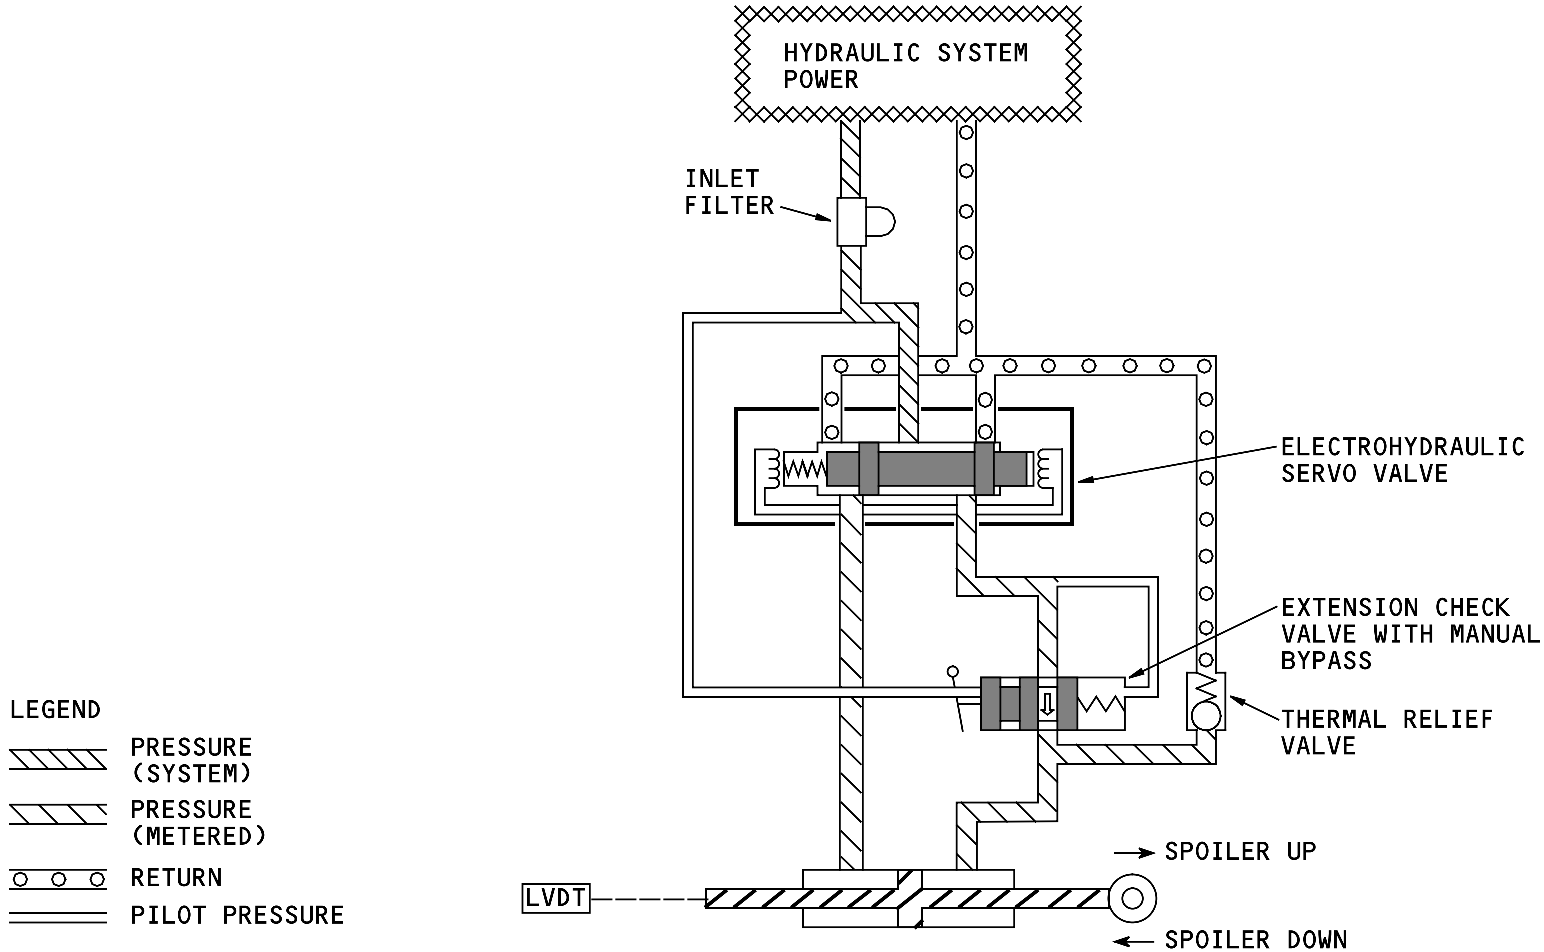
Manual Operation

You can open the extension check valve with the manual bypass. With the extension check valve open, you can raise the spoiler without hydraulic power. You can lower the spoiler panel with the extension check valve closed.

Indications

The advisory message SPOILERS shows when one or more pair of spoilers is shut down.

The status message FLIGHT CONTROL SYS shows when one or more spoiler actuator fails.



NOTE: BALANCED ACTUATOR SHOWN FOR INBOARD PCU ONLY
UNBALANCED ACTUATOR FOR OUTBOARD PCU NOT SHOWN

SPOILER AND SPEEDBRAKE CONTROL - INBOARD AND OUTBOARD SPOILER PCU - FUNCTIONAL DESCRIPTION

SPOILER AND SPEEDBRAKE CONTROL - SPOILER SURFACES

Purpose

The spoilers supply roll control in flight and speedbrake control during descent and landing.

Physical Description

The four inboard and ten outboard spoilers are light-weight composite materials structures. The skin is reinforced graphite/epoxy bonded to a core of Nomex honeycomb.

The inboard spoilers weigh about 47 lb (21 kg) each. The outboard spoilers weigh about 30 lb (14 kg) each.

The overall dimensions of the inboard spoiler are approximately 42 in by 80 in (1.1 m x 2.0 m). Each spoiler attaches to the outboard rear spar with two outer hinge fittings, and one center hinge. The PCU actuator rod end connects to the actuator fitting.

The overall dimensions of the outboard spoiler are approximately 28 in by 78 in (0.7 m x 2.0 m). Each spoiler attaches to the spoiler beam with two outer hinge fittings, and one center hinge. The PCU actuator rod end connects to the actuator fitting.

Rubber bulb aeroseals attach to the inboard and outboard edges of all spoiler panels.

Functional Description

The inboard and outboard spoilers have a maximum movement of 60 degrees trailing edge up (TEU), except for spoilers 4 and 11 which are limited to 45 degrees TEU.

SPOILER AND SPEEDBRAKE CONTROL - SPOILER SURFACES

SPOILER AND SPEEDBRAKE CONTROL - FUNCTIONAL DESCRIPTION

General

The roll and speedbrake control system for the inboard and outboard spoilers uses input command signals from the:

- Wheel position transducers
- Force transducer
- Speedbrake lever transducer assembly.

The ACEs receive the input signals and transmit them to the PFCs. The ACEs supply output command signals to the spoiler PCUs.

The roll control system for the cable-controlled spoilers uses input commands from the cable system. The speedbrake control system for these spoilers uses electrical command signals from the ACEs.

Wheel Position Transducers

The C ACE and R ACE each receive signals from two wheel position transducers. The L1 ACE and L2 ACE each receive signals from one wheel position transducer. After they change the signals to digital format, the ACEs send these signals to the PFCs through the flight controls ARINC 629 buses.

Each PFC receives input signals from all six wheel position transducers. Each PFC selects which signal to use by mid-value selection and averaging.

Force Transducer

The two LVDTs of the force transducer send signals to the L2 ACE and the C ACE. The ACEs transmit these signals to the PFCs.

Speedbrake Lever Transducer

The four speedbrake lever transducer RVDTs send signals to the four ACEs. The ACEs transmit these signals to the PFCs.

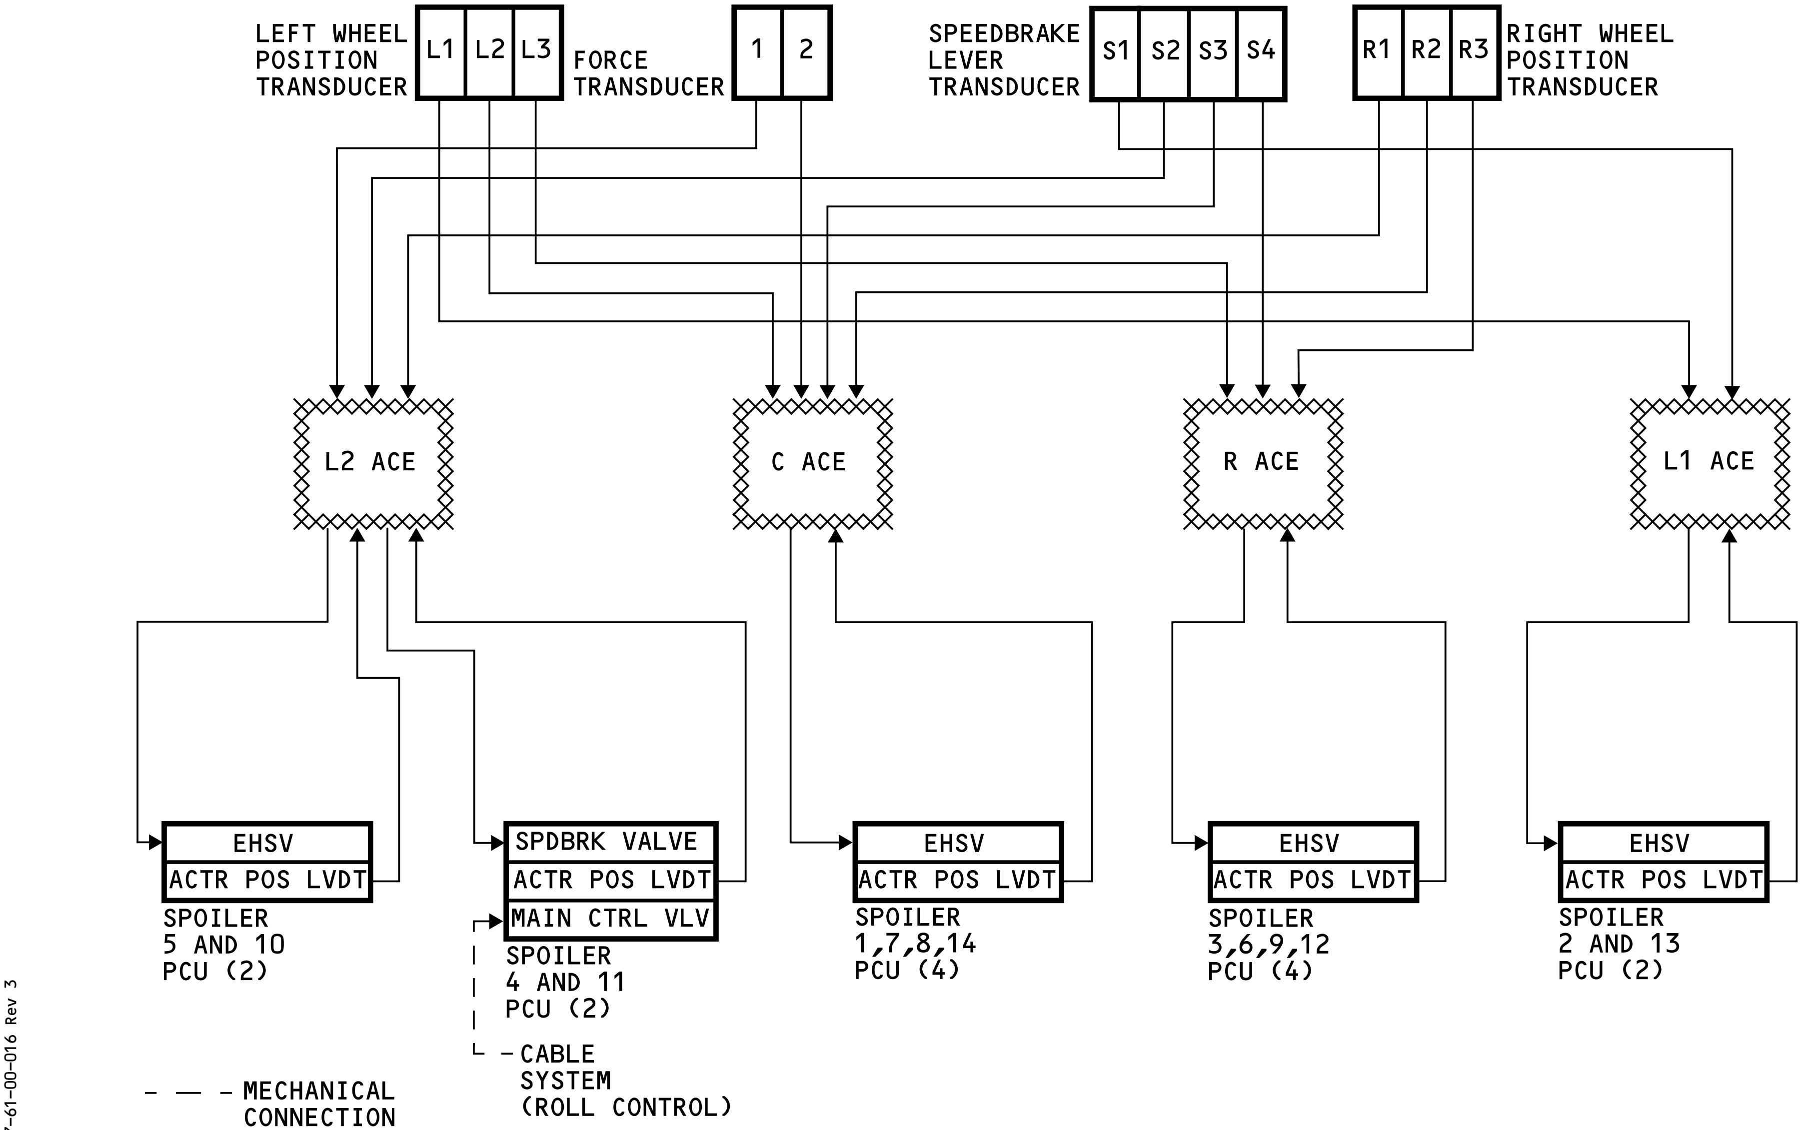
Electrically-Controlled PCUs

Each ACE sends command signals to the EHSV of the assigned spoiler PCUs. The PCU sends feedback signals to its assigned ACE from the actuator piston position LVDT.

Cable-Controlled PCUs

The L2 ACE sends speedbrake control command signals to the PCUs of spoilers 4 and 11. The speedbrake command signal goes to the speedbrake solenoid valve. The PCU sends feedback signals to its assigned ACE from the actuator piston position LVDT.

The cable system supplies mechanical roll command input to the main control valve of spoiler 4 and 11 PCUs.



SPOILER AND SPEEDBRAKE CONTROL - FUNCTIONAL DESCRIPTION

SPOILER AND SPEEDBRAKE CONTROL - FUNCTIONAL DESCRIPTION - ACE SERVO LOOP

General

The ACE contains a control servo loop circuit for all the electrically-controlled PCUs. This control servo loop circuit is also for the cable-controlled PCUs in speedbrake operation.

In normal and secondary modes of operation of the PFCS, the PFC sends mixed roll and speedbrake command signals to the ACE for the electrically-controlled PCUs. In direct mode, the ACE calculates the mixed command signals to these PCUs.

In normal mode of operation of the PFCS, the PFC sends speedbrake command signals to the cable-controlled PCUs (spoiler 4 and 11). In secondary and direct modes, there is no speedbrake command signal from the PFCs and ACEs to these PCUs.

Servo Loop Operation

The ACEs send the command signals to the EHSV of the electrically-controlled PCUs. In normal mode, they also go to the speedbrake solenoid valves of the cable-controlled PCUs. The ACEs monitor the PCU command signals for failures.

The actuator position LVDT measures the movement of the actuator and supplies a feedback signal to the ACEs to close the servo loop, and to monitor faults. This signal also goes to the PFC.

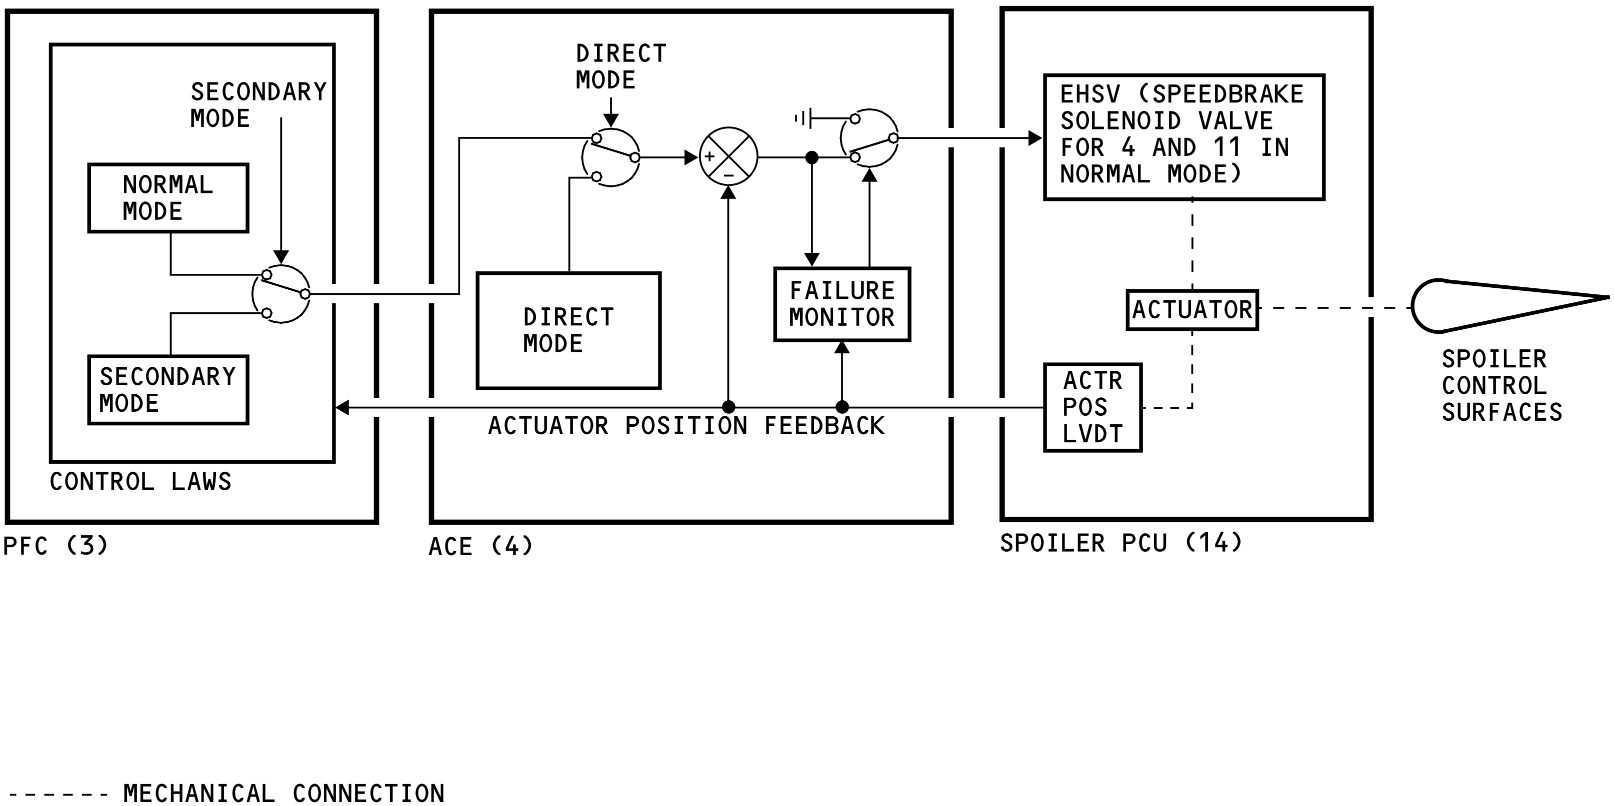
Failure Monitor

The ACE has a failure monitor to do a check of the correct operation of the PCU. The monitor uses the ACE command signal and the feedback signal from the actuator position LVDT.

If the ACE finds a failed spoiler PCU, it connects to ground the EHSV of both PCUs of the spoiler pair. The EHSV of each PCU has a mechanical and magnetic bias to command the actuator to retract when there is no electrical command to the EHSV.

Indications

The EICAS advisory message SPOILERS shows when one or more pair of spoilers does not operate. This condition causes the message to show in normal, secondary, and direct modes.



27-61-00-017 Rev 1 01/08/96

SPOILER AND SPEEDBRAKE CONTROL - FUNCTIONAL DESCRIPTION - ACE SERVO LOOP

AUTO SPEEDBRAKE CONTROL - GENERAL DESCRIPTION

General

The auto speedbrake controls the automatic movement of the speedbrake lever during airplane operation on the ground. The pilots use the auto speedbrake during landing and refused takeoff (RTO). Extension of the auto speedbrake causes all spoilers to deploy to their maximum position.

Auto Speedbrake Control

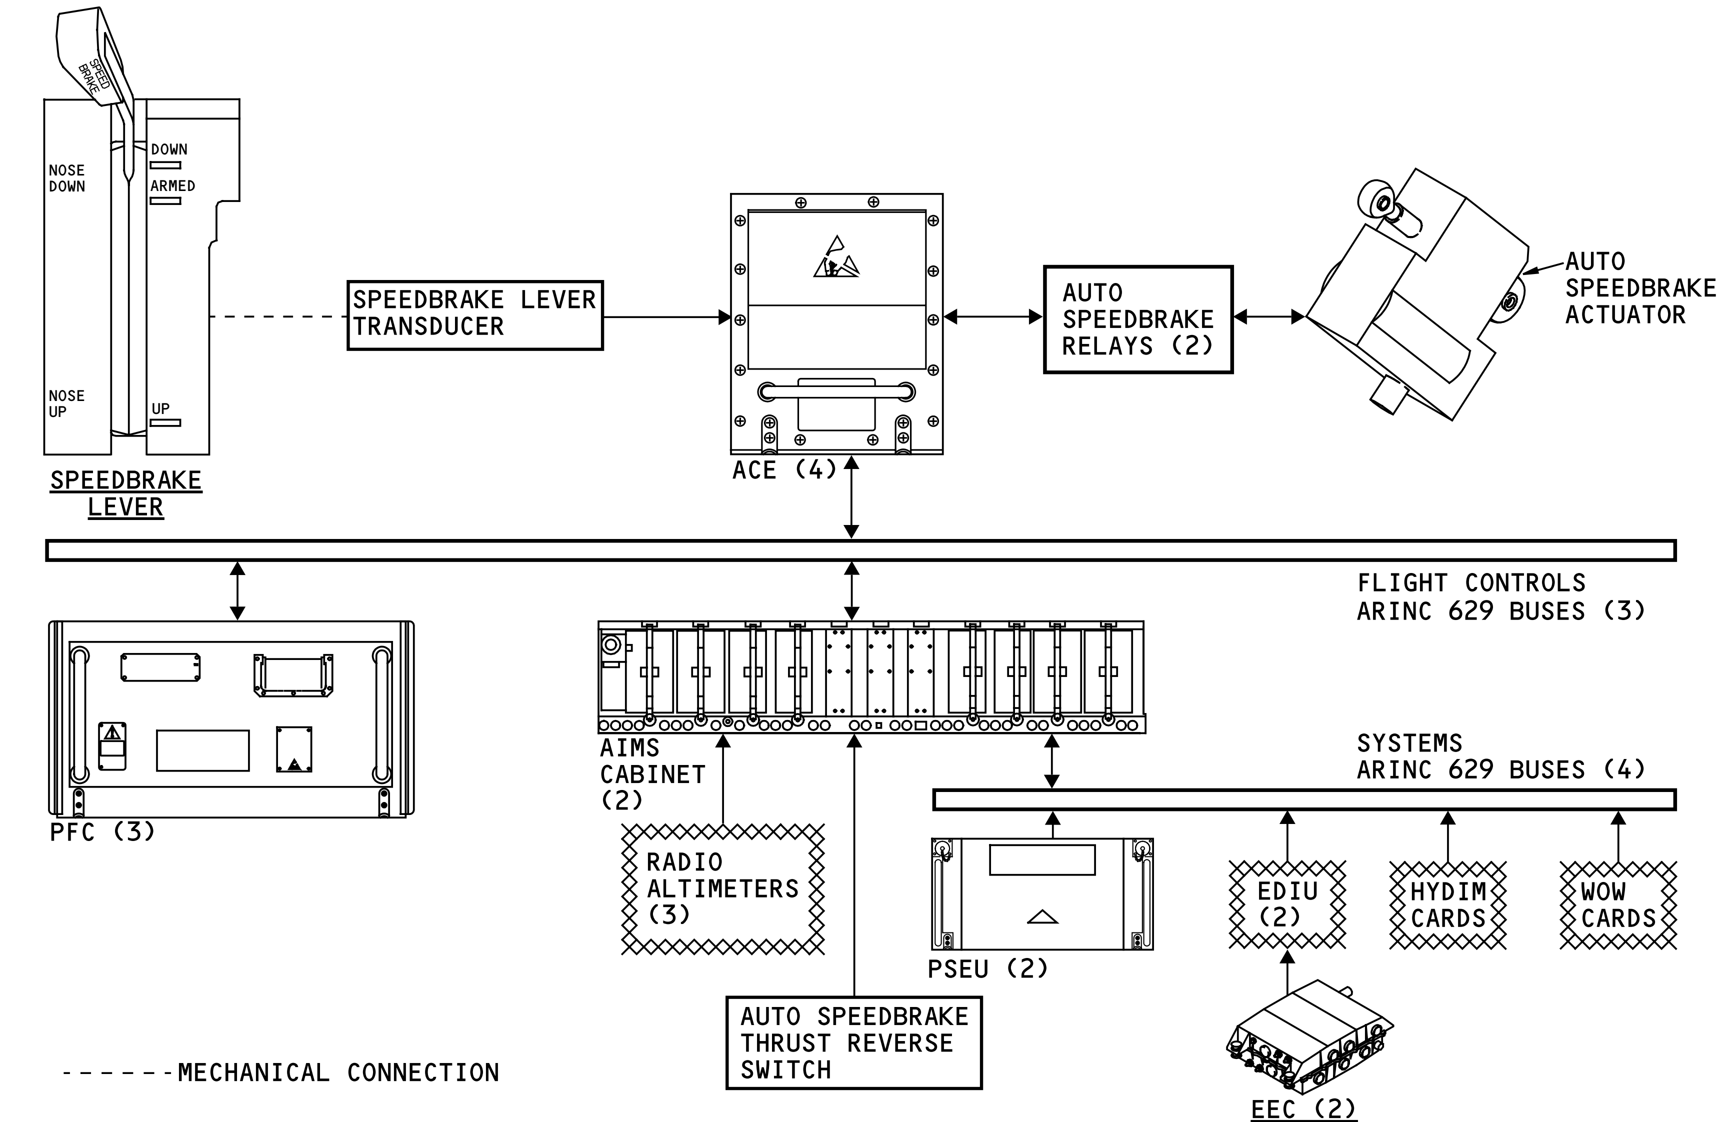
The PFCs control the automatic extension and retraction of the speedbrake lever. The PFC logic requires that a series of conditions be met to command the auto speedbrake actuator to operate.

When the pilot moves the speedbrake lever out of its DOWN detent to the ARM position, the speedbrake lever transducer supplies a signal to the PFCs through the ACEs. When the pilot operates the engine thrust reverser, the auto speedbrake thrust reverse switch supplies a signal to the PFCs through the AIMS cabinets.

The main landing gear truck tilt sensors supply signals to the proximity sensor electronic units (PSEUs). The electronic engine controls (EECs) supply signals through the engine data interface units (EDIUs) to show the position and validity of the thrust resolver angles. The hydraulic interface module (HYDIM) cards supply signals about the hydraulic pressure status of the truck tilt actuators. The weight-on-wheels (WOW) cards supply signals that the airplane is on the ground. The radio altimeters supply the airplane altitude near the ground. All these signals go through the AIMS to the PFCs.

When the extension or retraction conditions are met, the PFCs send command signals to the ACEs. The ACEs then control the auto speedbrake relays which control power to the auto speedbrake actuator. This causes the auto speedbrake actuator to extend or retract.

The auto speedbrake clutch transmits the movement from either the speedbrake lever or the auto speedbrake actuator to the speedbrake lever transducer. The auto speedbrake clutch permits the pilot to move the speedbrake lever and override the commands of the auto speedbrake actuator at anytime.



AUTO SPEEDBRAKE CONTROL - GENERAL DESCRIPTION

AUTO SPEEDBRAKE CONTROL - COMPONENT LOCATIONS

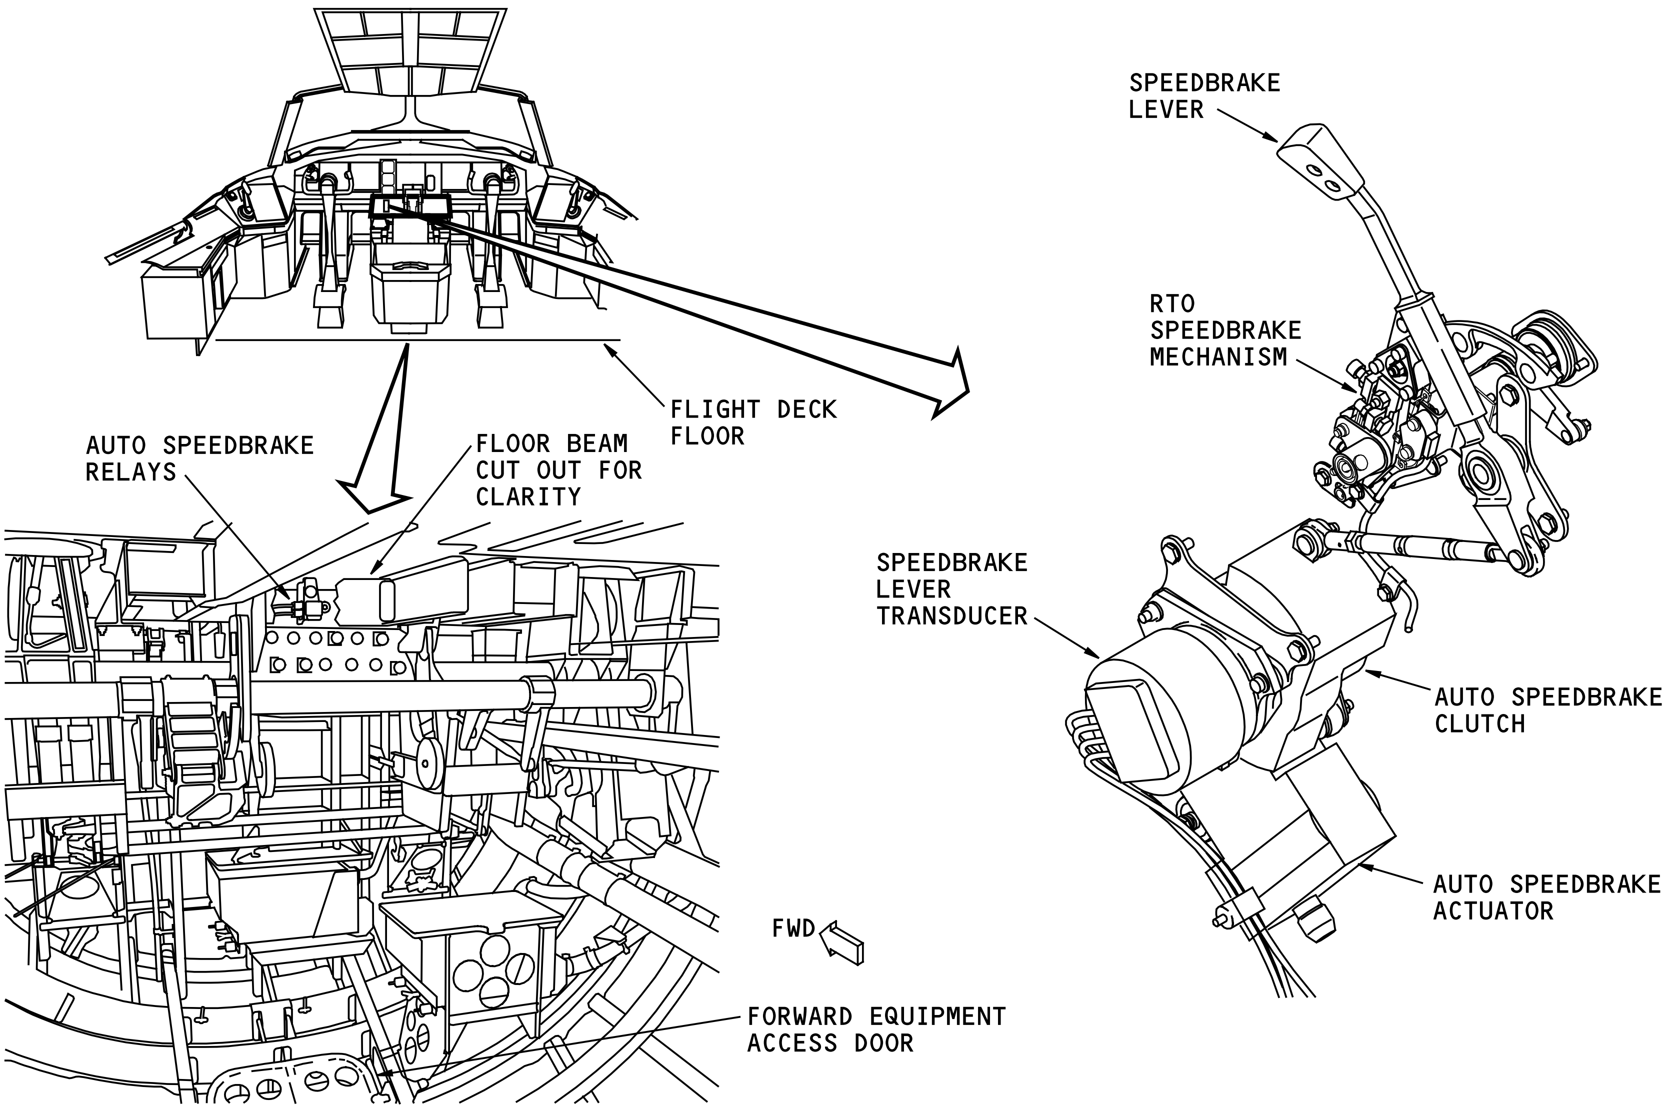
General

The auto speedbrake components are on the left side of the control stand in the flight deck. These components include:

- The auto speedbrake clutch
- The auto speedbrake actuator
- The RTO speedbrake mechanism.

Remove the left panel of the control stand to access the auto speedbrake components.

The two auto speedbrake relays are on a bracket below the control stand. Access to the relays is through the forward equipment access door.



27-62-00-002 Rev 1 03/04/1997

AUTO SPEEDBRAKE CONTROL - COMPONENT LOCATIONS

AUTO SPEEDBRAKE CONTROL - INTERFACES

General

The electrical interfaces with the PFCS for the auto speedbrake go through the ACEs. The ACEs have interfaces with these components:

- The speedbrake lever transducer
- The auto speedbrake thrust reverse switch
- The auto speedbrake actuator
- The auto speedbrake relays.

Speedbrake Lever Transducer

The speedbrake lever transducer supplies a signal that the speedbrake lever is in the ARMED position or beyond.

See the spoiler and speedbrake control section for more information about the speedbrake lever transducer (AMM PART I 27-61).

Auto Speedbrake Thrust Reverse Switch

The auto speedbrake thrust reverse switch supplies an electrical signal to the ACEs when there is movement of one or both thrust reverser levers. The signal goes from the auto speedbrake thrust reverse switch to the AIMS cabinets which transmit it to the ACEs through the flight controls ARINC 629 buses.

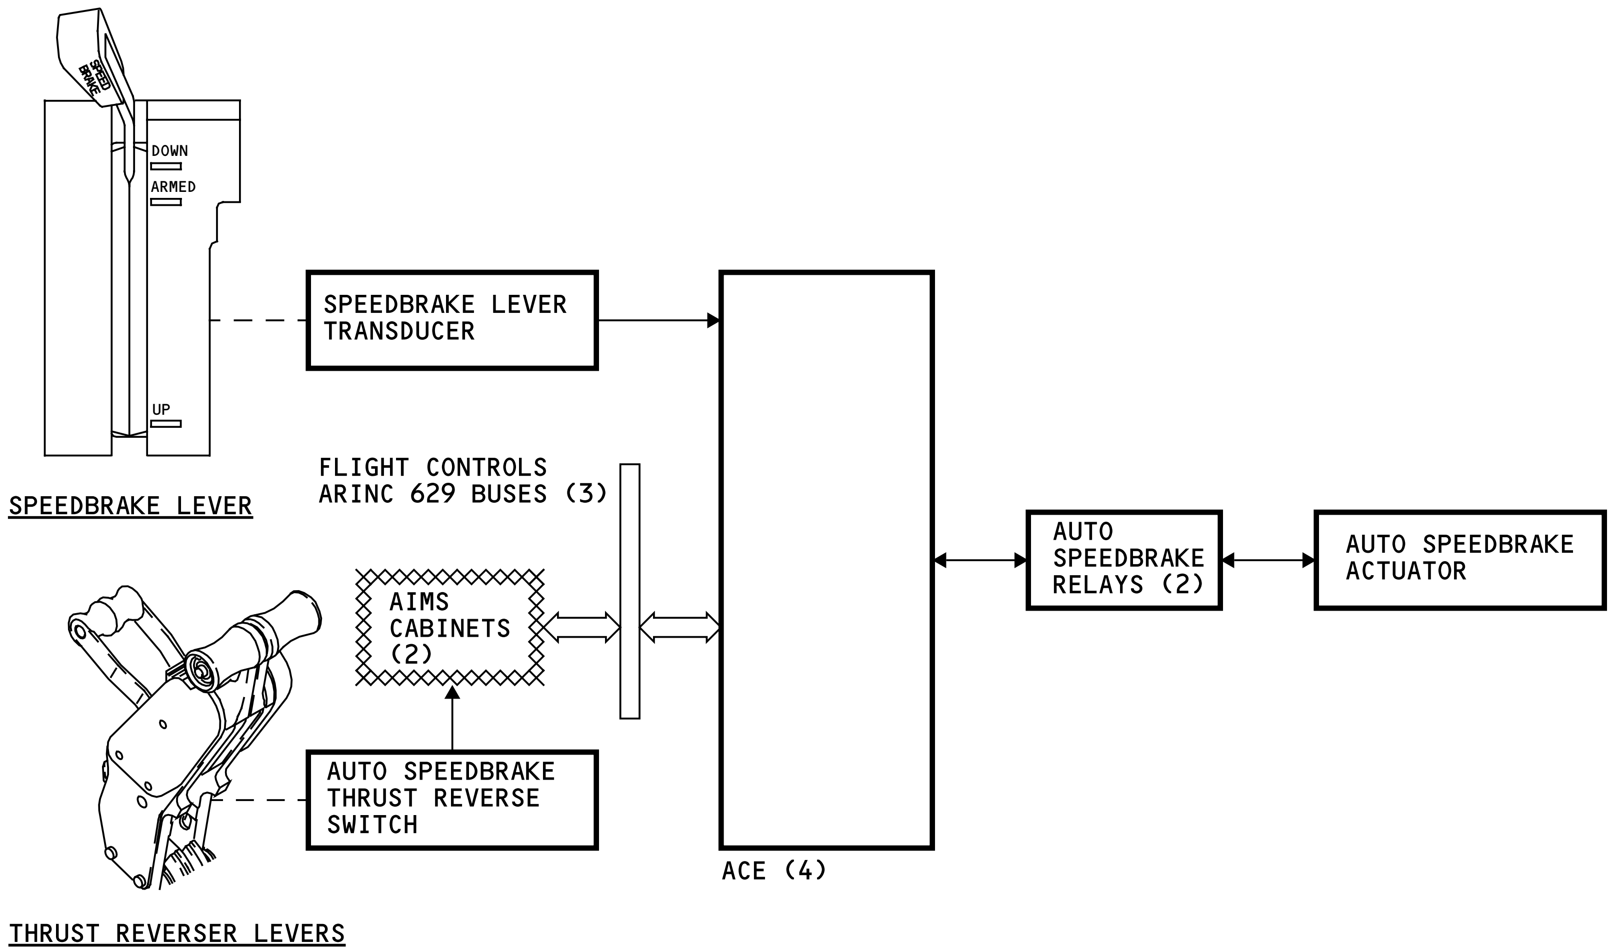
Auto Speedbrake Actuator

The auto speedbrake actuator receives electrical power through the auto speedbrake relays. Switches in the auto speedbrake actuator supply the actuator position feedback to the L1 and R ACEs.

Auto Speedbrake Relays

The auto speedbrake relays receive the command signals from the L1 and R ACEs. When both relays are energized, they supply electrical power to extend the auto speedbrake actuator. Extension of the actuator rod causes the speedbrake lever to move from the ARMED position to the UP position.

When both auto speedbrake relays are de-energized, they supply electrical power to retract the auto speedbrake actuator. Retraction of the actuator causes the speedbrake lever to move from the UP position to the DOWN position.



27-62-00-003 Rev 5

AUTO SPEEDBRAKE CONTROL - INTERFACES

AUTO SPEEDBRAKE CONTROL - AUTO SPEEDBRAKE CLUTCH

Purpose

The auto speedbrake clutch transmits the movement of the speedbrake lever or the auto speedbrake actuator to the speedbrake lever transducer. The auto speedbrake clutch prevents movement of the speedbrake lever without an input from the pilot or the auto speedbrake actuator.

The auto speedbrake clutch supplies friction for pilot feel. It also has a detent when the speedbrake lever reaches the ARMED position. The auto speedbrake clutch permits the pilot to move the speedbrake lever and to override the auto speedbrake actuator at anytime.

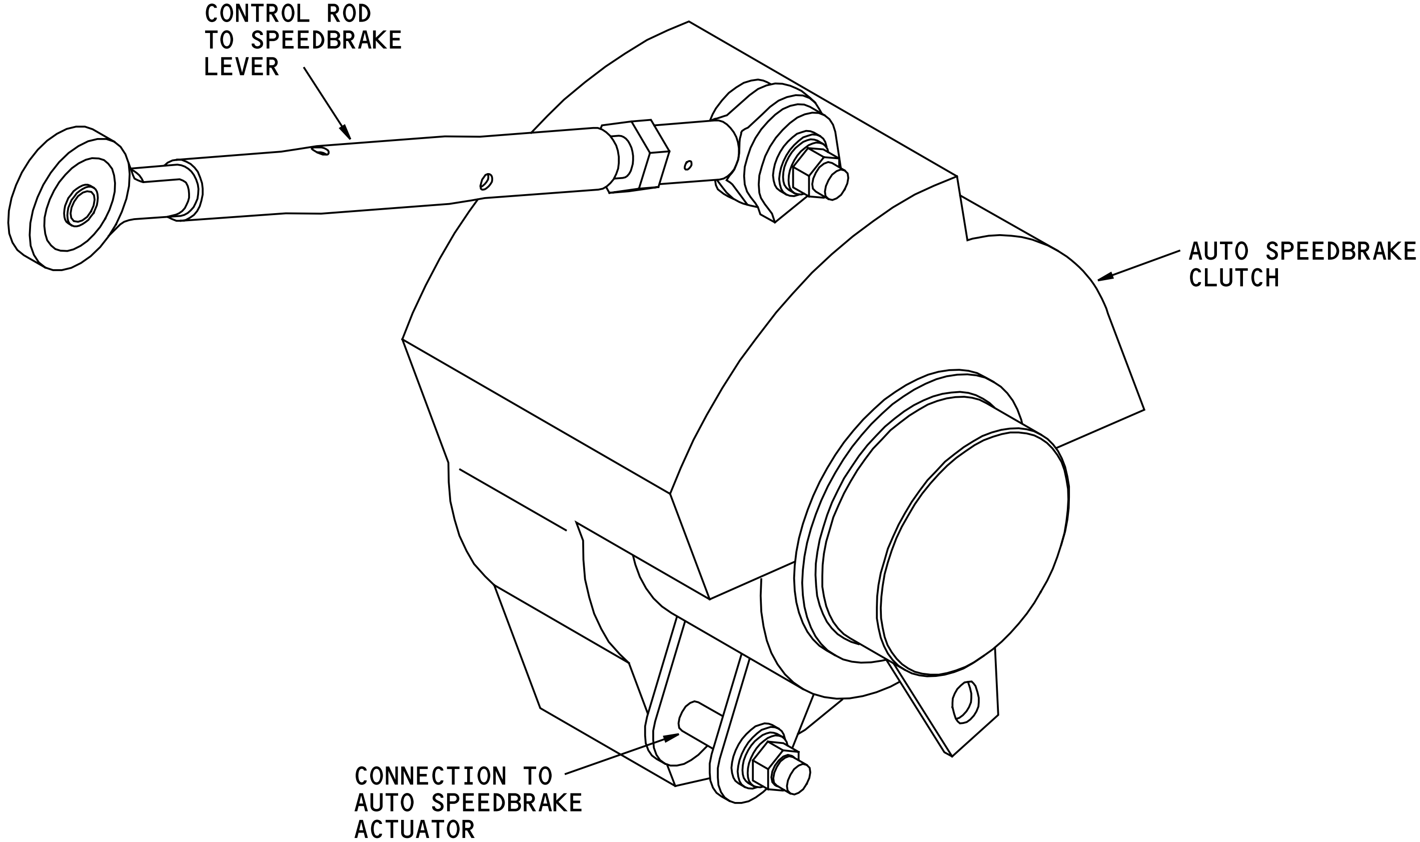
Physical Description

The auto speedbrake clutch attaches to the left support frame of the control stand. The speedbrake lever control rod attaches to the top lever of the auto speedbrake clutch. The auto speedbrake actuator attaches to the lower aft lever of the auto speedbrake clutch. The output shaft of the auto speedbrake clutch has a spline which connects to the shaft of the speedbrake lever transducer.

The auto speedbrake clutch is an LRU. It is not necessary to adjust the clutch. The clutch weighs about 2 lb (1.8 kg).

Location

The auto speedbrake clutch is on the left side of the control stand in the flight deck. Remove the left panel of the control stand to get access to the auto speedbrake clutch.



27-62-00-004 Rev 0

AUTO SPEEDBRAKE CONTROL - AUTO SPEEDBRAKE CLUTCH

AUTO SPEEDBRAKE CONTROL - RTO SPEEDBRAKE MECHANISM

Purpose

When the pilot commands reverse thrust, the RTO speedbrake mechanism lifts the speedbrake lever out of the DOWN detent and actuates the auto speedbrake thrust reverse switch. The PFC uses the auto speedbrake thrust reverse switch signal to command the auto speedbrake actuator to move the speedbrake lever to the UP position.

Physical Description

The RTO speedbrake mechanism consists of a pair of cam followers, each actuated by a thrust lever cam. Either cam follower turns the speedbrake lever lifter drive segment. The lifter drive segment connects with the speedbrake lever lifter assembly. A return spring returns the lifter to the down position when the thrust reverser lever moves to the idle position.

A switch adjust screw at the rear of the lifter assembly operates the auto speedbrake thrust reverse switch.

Location

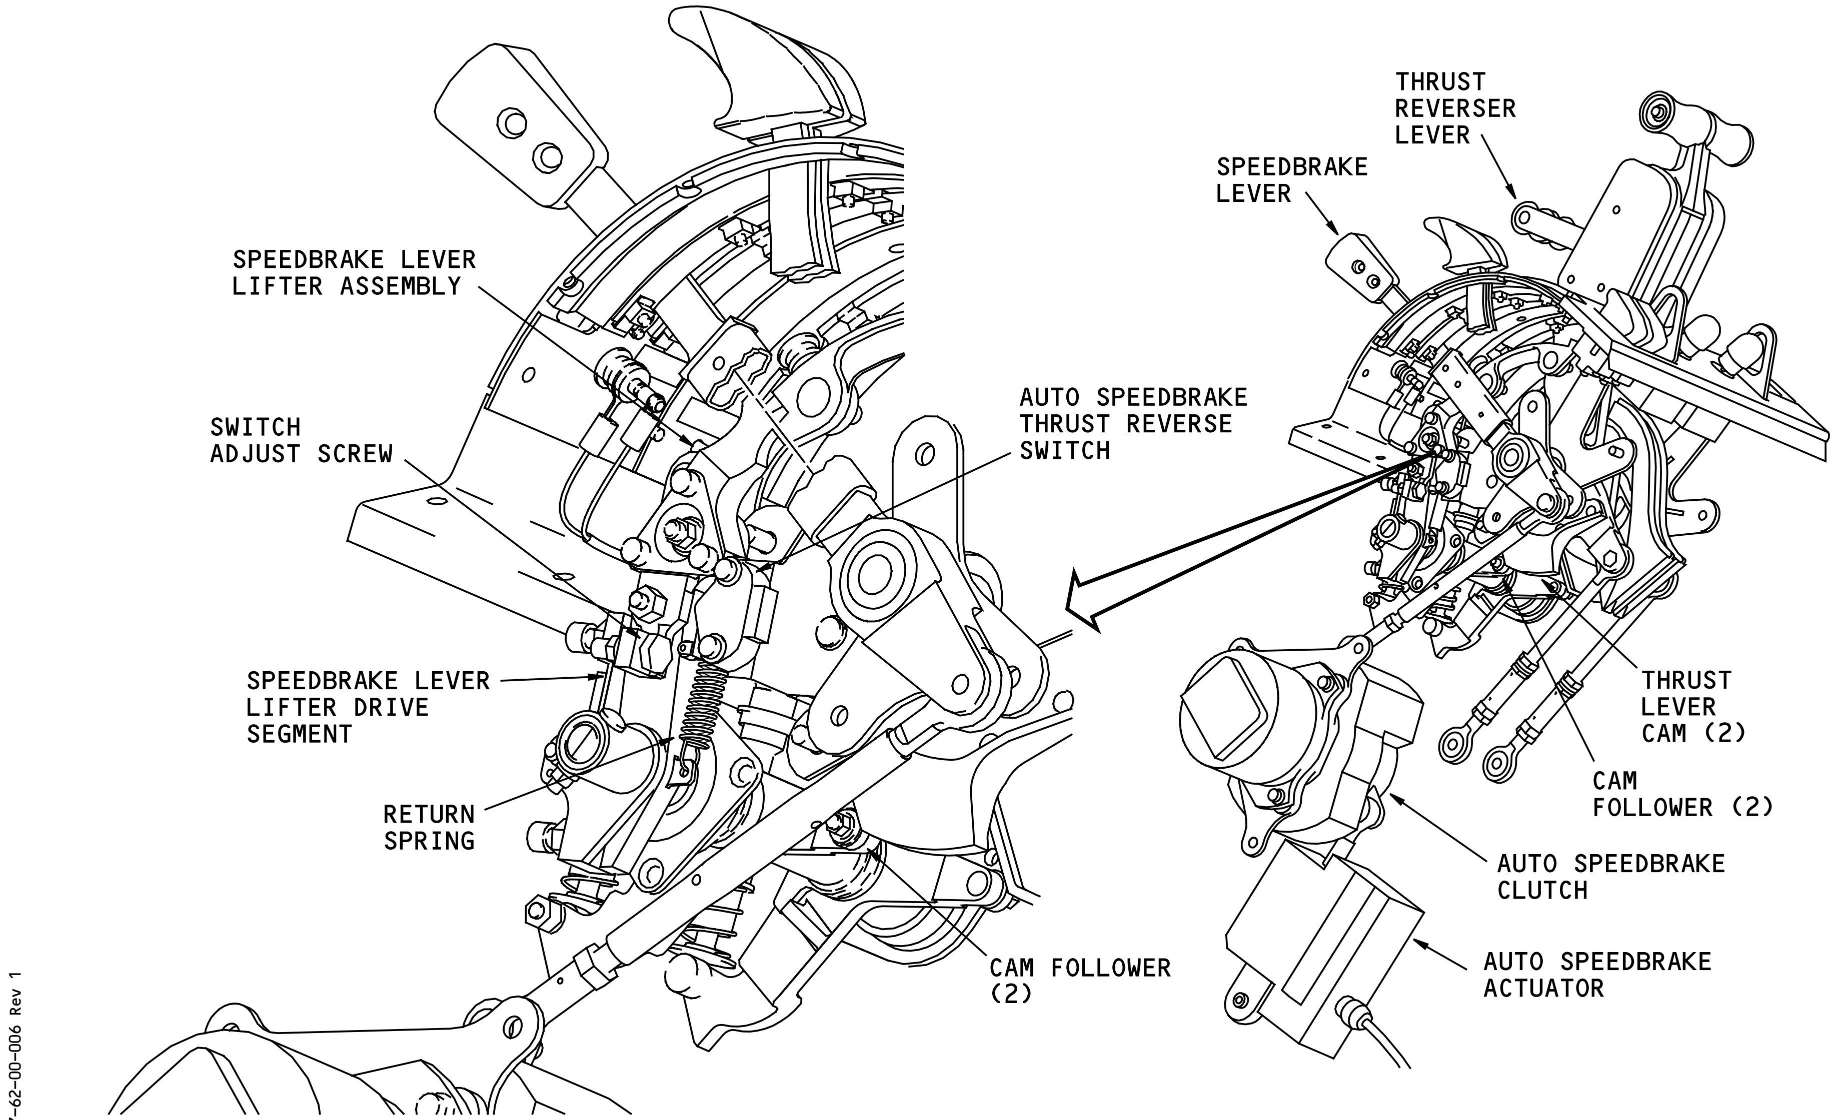
The RTO speedbrake mechanism is on the left frame of the thrust lever assembly in the control stand. Remove the left access panel of the control stand to access the RTO speedbrake mechanism.

Functional Description

When the pilot moves either or both thrust reverser levers, one or both thrust lever cams cause the cam followers to turn. This also turns the speedbrake lever lifter drive segment and causes the speedbrake lever lifter assembly to move. As the speedbrake lever lifter assembly turns, it lifts the speedbrake lever out of the DOWN detent. The switch adjust screw at the rear of the lifter assembly then contacts and actuates the auto speedbrake thrust reverse switch.

Training Information Point

The switch adjust screw at the back of the speedbrake lever lifter assembly is adjustable.



AUTO SPEEDBRAKE CONTROL - RTO SPEEDBRAKE MECHANISM

AUTO SPEEDBRAKE CONTROL - FUNCTIONAL DESCRIPTION

General

The PFCs control the extension and retraction of the auto speedbrake actuator. The auto speedbrake operates only when the PFCs are in normal mode. The PFCs send extend command signals to the L1 and R ACEs. These ACEs control two auto speedbrake relays.

The L1 ACE energizes the auto speedbrake control relay and the R ACE energizes the auto speedbrake arm relay. Both relays need to be energized to command the auto speedbrake actuator to extend. Both relays need to be de-energized to command the auto speedbrake actuator to retract.

If one relay is energized while the other is de-energized, the auto speedbrake actuator stops.

Auto Speedbrake Actuator

Two sets of limit switches control electrical power to the motor. The actuator position controls the limit switches. As the actuator starts to extend, the fully retracted switch operates. The fully extended switch operates only when the actuator has fully extended. The reverse happens during retraction.

The fully retracted switch has contacts that supply the L1 ACE and PFCs with the actuator status.

Auto Speedbrake Operation During Landing

During landing, the auto speedbrake operates when all these conditions occur:

- The main landing gear is on the ground
- The speedbrake lever is in the ARMED position
- Both left and right thrust resolver angles are not at the takeoff position
- Both thrust resolver angle signals are valid.

Before landing, the pilots arm the speedbrake lever. During the flare, the pilots move both thrust levers to idle. At touch down, the auto speedbrake actuator fully extends the speedbrake lever. This commands all spoilers to fully deploy.

The auto speedbrake retracts to the DOWN position if any of the above conditions changes after the auto speedbrake has fully extended.

The auto speedbrake retracts to the ARMED position if any of the above conditions changes when the auto speedbrake has partially extended.

Auto Speedbrake Operation During RTO

During a refused takeoff (RTO), the auto speedbrake operates when all these conditions happen:

- The main landing gear is on the ground
- Either engine thrust reverser is operated

AUTO SPEEDBRAKE CONTROL - FUNCTIONAL DESCRIPTION

- The thrust resolver angle signal that is operated is valid.

The auto speedbrake also operates during RTO when all these conditions happen:

- The main landing gear is on the ground
- The auto speedbrake thrust reverser switch is closed
- The auto speedbrake thrust reverser switch signal is valid
- There is no disagreement fault between the auto speedbrake thrust reverser switch and the thrust resolver angle signal.

During a RTO, when the pilot moves at least one of the thrust reverser levers, the auto speedbrake extends the speedbrake lever. This commands all spoilers to fully deploy.

The auto speedbrake retracts to the DOWN position if any of the above conditions changes after the auto speedbrake has extended.

Main Landing Gear On Ground

One of the conditions for the auto speedbrake actuator to extend is that the main landing gear is on the ground.

The PFCs determine that the main landing gear is on the ground from a combination of signals received through the AIMS.

During approach, the main landing gear is extended and the main gear trucks tilted by hydraulic pressure. On touch down, the main landing gear is on the ground when the main gear trucks are not tilted with hydraulic pressure on the truck tilt actuators. The radio altimeter signals verify that the main landing gear is on the ground.

The weight-on-wheel cards supply signals when the airplane is on the ground. These signals verify that the main landing gear is on the ground during RTO.

Indications

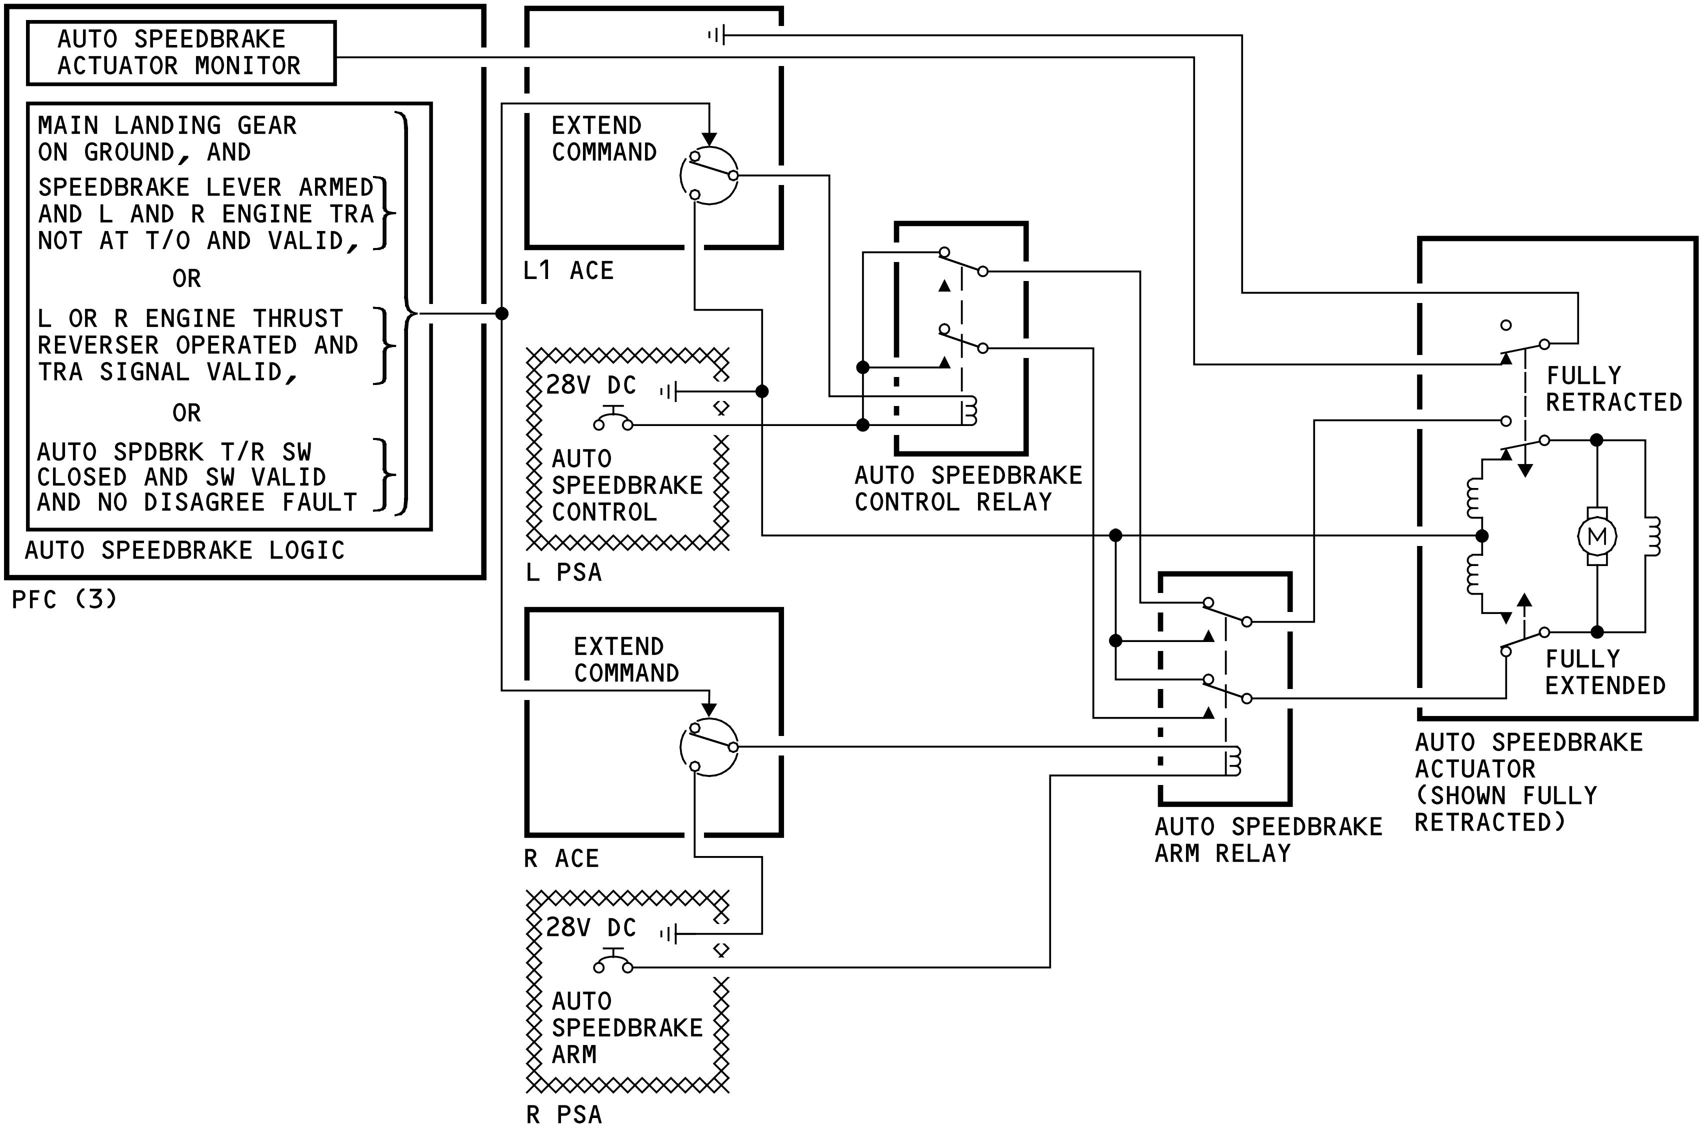
The EICAS advisory and status messages AUTO SPEEDBRAKE indicate that the auto speedbrake is defective and does not operate. This happens when one of these conditions is present:

- Either L1 ACE or R ACE is defective
- The auto speedbrake actuator does not retract within 2 seconds of command
- The auto speedbrake actuator stays retracted for 2 seconds after a command to extend
- Loss of data from one thrust resolver angle with the related engine running
- Loss of data from both thrust resolver angles
- Loss of valid data of the truck tilt pressure transducers from both the L and R HYDIM cards
- Loss of valid truck tilt position data from either PSEU 1 or PSEU 2
- The center hydraulic system is failed

AUTO SPEEDBRAKE CONTROL - FUNCTIONAL DESCRIPTION

- The truck tilt pressure is low with the main landing gear down and locked and the center hydraulic system pressure is high
- The radio altitude data is not valid
- The PFCS is not in normal mode.

Although the operation of the auto speedbrake is available only in normal mode, these conditions cause the message to show in normal, secondary and direct mode.



AUTO SPEEDBRAKE CONTROL - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

RUDDER CONTROL - INTRODUCTION

General

The rudder controls the flight attitude of the airplane about the vertical axis.

The rudder hinges on the rear spar of the vertical stabilizer. A rudder tab increases the effect of the rudder. The rudder tab moves further in the same direction as the rudder.

Yaw Control

The pilots make a manual yaw correction with the rudder pedals. The autopilot does not control the rudder during most phases of flight. When the autopilot is engaged during the approach and landing phases of flight, the autoland function commands the rudder. The backdrive actuators then backdrive the rudder pedals.

Rudder Ratio

During flight, the rudder ratio function reduces the movement of the rudder as the airspeed increases. The primary flight computers (PFCs) command the rudder ratio function of the yaw control.

Yaw Damper

The PFCs control the conventional yaw damper and turn coordination functions of the rudder.

Wheel-Rudder Cross-Tie

The wheel-rudder cross-tie function moves the rudder in response to control wheel inputs when the airspeed is less than 210 knots. This makes roll and yaw control better during one-engine-out operation. It also lets the pilot control yaw caused by an engine failure with the control wheel.

Gust Suppression

A gust suppression function reduces the effects of air gusts on the vertical stabilizer.

Modal Suppression Function

A modal suppression function reduces the forward and aft body lateral movements.

RUDDER CONTROL - INTRODUCTION

RUDDER CONTROL- GENERAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

RUDDER CONTROL- GENERAL DESCRIPTION

General

The pilots manually command the rudder; the autopilot automatically commands it.

Manual Operation - Rudder Pedals

The flight crew uses two conventional rudder pedals to control yaw.

Four rudder pedal position transducers change the flight crew rudder pedal commands to analog electrical signals. These signals go to the four actuator control electronics (ACEs). The ACEs change the signals to digital format and send them to the three primary flight computers (PFCs) through the flight controls ARINC 629 buses.

The PFCs use position data from the rudder pedals, data from the air data inertial reference unit (ADIRU) and the airplane information management system (AIMS), to calculate control surface commands. The PFCs send the digital commands to the ACEs, which change them to analog signals. The ACEs send the analog position commands to the power control units (PCUs), which move the rudder. The position transducers on the PCU actuator pistons supply position feedback to the ACEs.

Two gust suppression pressure transducers measure wind gusts on the vertical stabilizer. The transducer signals go to the ACEs and then to the PFCs through the flight controls ARINC 629 buses. The PFCs command the rudder PCUs to move. This movement of the rudder reduces the effect of the side gust.

Two modal accelerometers measure the lateral movement of the aft fuselage. The accelerometer signals go to the ACEs and then to the PFCs through the flight control ARINC 629 buses. The PFCs calculate command signals for the ACEs to move the rudder PCUs to decrease the lateral movement of the forward and aft cabin.

The PFCs operate the yaw damper and rudder ratio functions.

Manual Operation - Rudder Trim

The rudder trim control, on the aisle stand, and the trim actuator let the flight crew trim out unwanted rudder pedal forces. When the pilots move the rudder trim control, the switch sends a signal to the ACEs and the PFCs. The PFCs and the ACEs command the rudder trim actuator to move the rudder pedals and the position transducers through the feel and centering mechanism. The rudder pedal position transducers send a signal to the ACEs and PFCs to move the rudder.

The rudder trim indicator, also on the aisle stand, shows the position of the rudder trim. The rudder trim actuator position transducer sends a feedback signal to the ACEs and the PFCs. The PFCs then command the trim indicator through AIMS.

RUDDER CONTROL- GENERAL DESCRIPTION

The rudder manual trim cancel switch, on the aisle stand, sends a signal to the ACEs and the PFCs to command the rudder trim to zero.

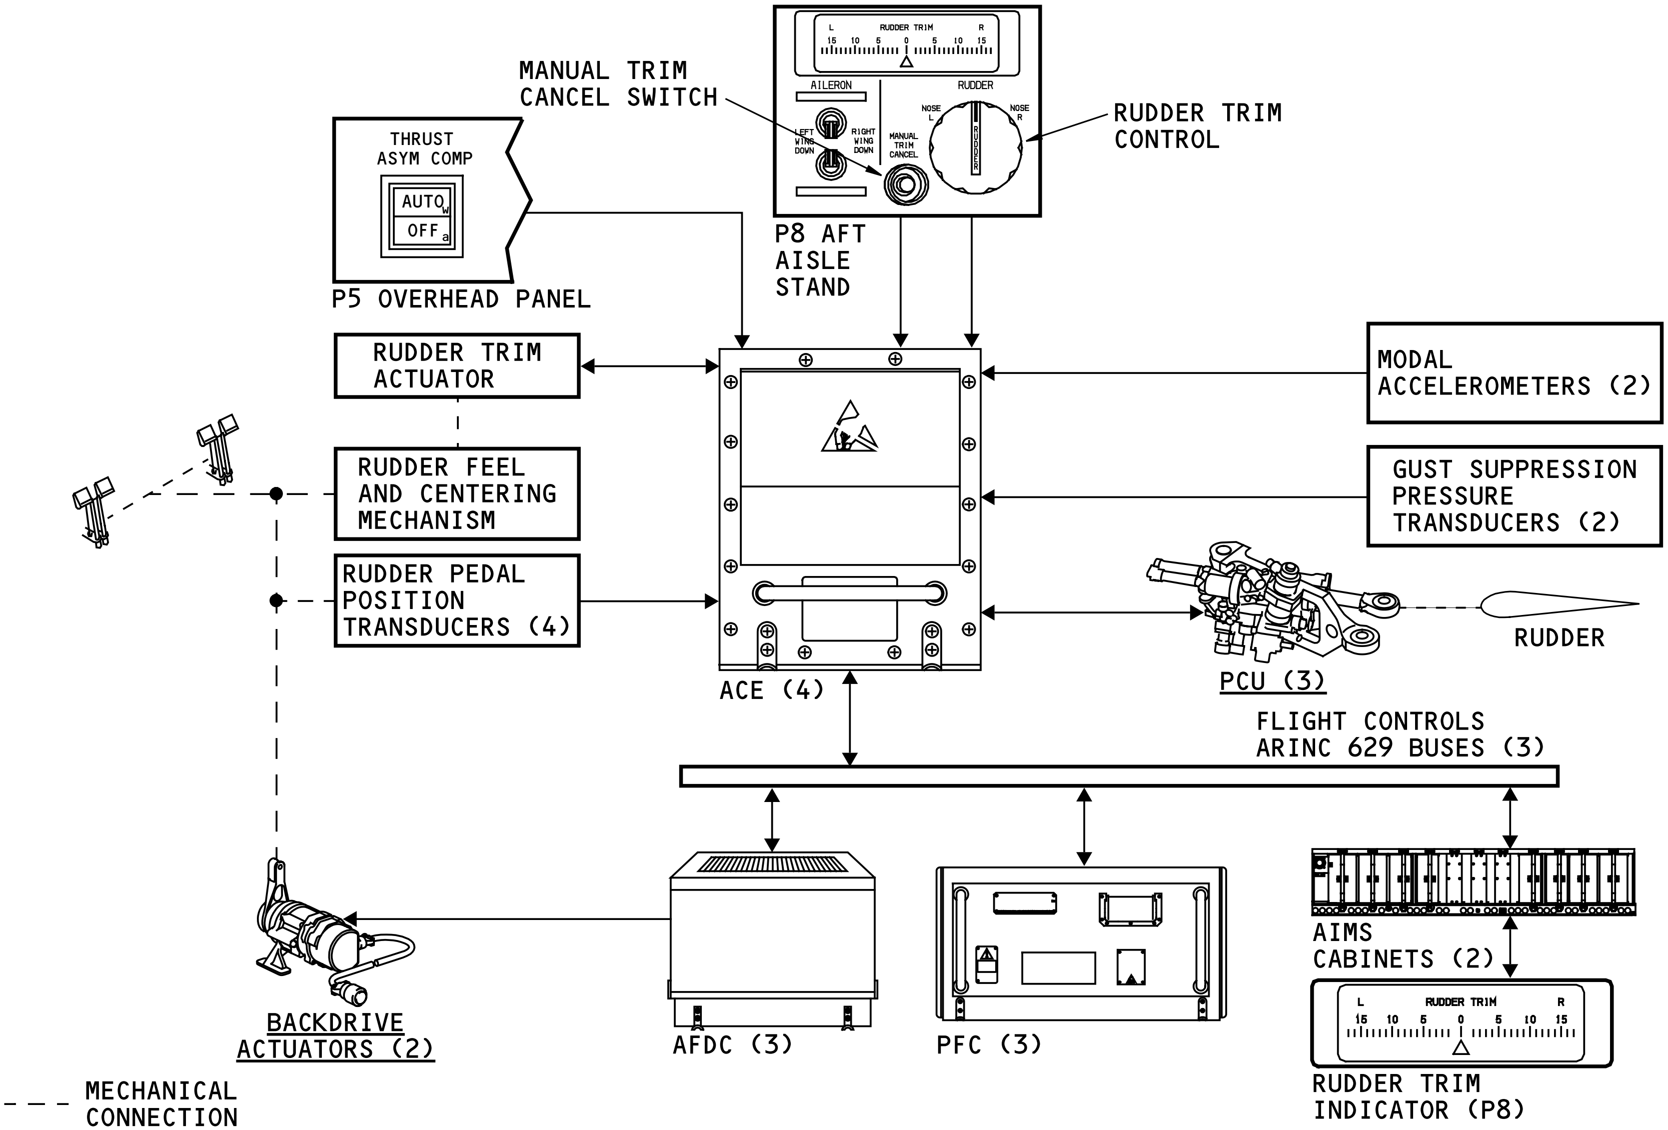
When the thrust asymmetry compensation (TAC) switch on the P5 panel is in the AUTO position, the PFCs automatically control the rudder trim. This control is to make allowance for asymmetrical thrust from the engines. The TAC function does not operate when the TAC switch is in the OFF position. The manual trim cancel switch does not remove any rudder trim caused by TAC.

Autopilot Operation

When autoland is active, the autopilot flight director computers (AFDCs) control the yaw attitude of the airplane for crosswind and engine-out conditions. The AFDCs supply yaw commands to the PFCs through the flight controls ARINC 629 buses. The PFCs use these inputs to calculate position commands for the rudder.

The PFCs also calculate rudder pedal backdrive commands. The PFCs send these commands to the AFDCs, which transmit rudder movement commands to the backdrive actuators. The backdrive actuators move the rudder pedals to a position to match the autopilot rudder command.

To override the autopilot, the flight crew applies more force on the rudder pedals than the backdrive actuator force. A pilot override disengages the autopilot.



RUDDER CONTROL– GENERAL DESCRIPTION

RUDDER CONTROL- COMPONENT LOCATIONS

General

The rudder control components are in three areas:

- The vertical stabilizer
- The flight deck
- Below the flight deck floor.

Tail Components

The rudder control surface and the rudder PCUs are on the vertical stabilizer. The rudder tab is aft of the rudder. Three PCUs directly connect to the rudder. Access to the PCUs is by access panels on the left side of the vertical stabilizer.

The two gust suppression pressure transducers are near the leading edge of the vertical stabilizer at about half span.

The two modal accelerometers are in the aft fuselage.

Flight Deck Components

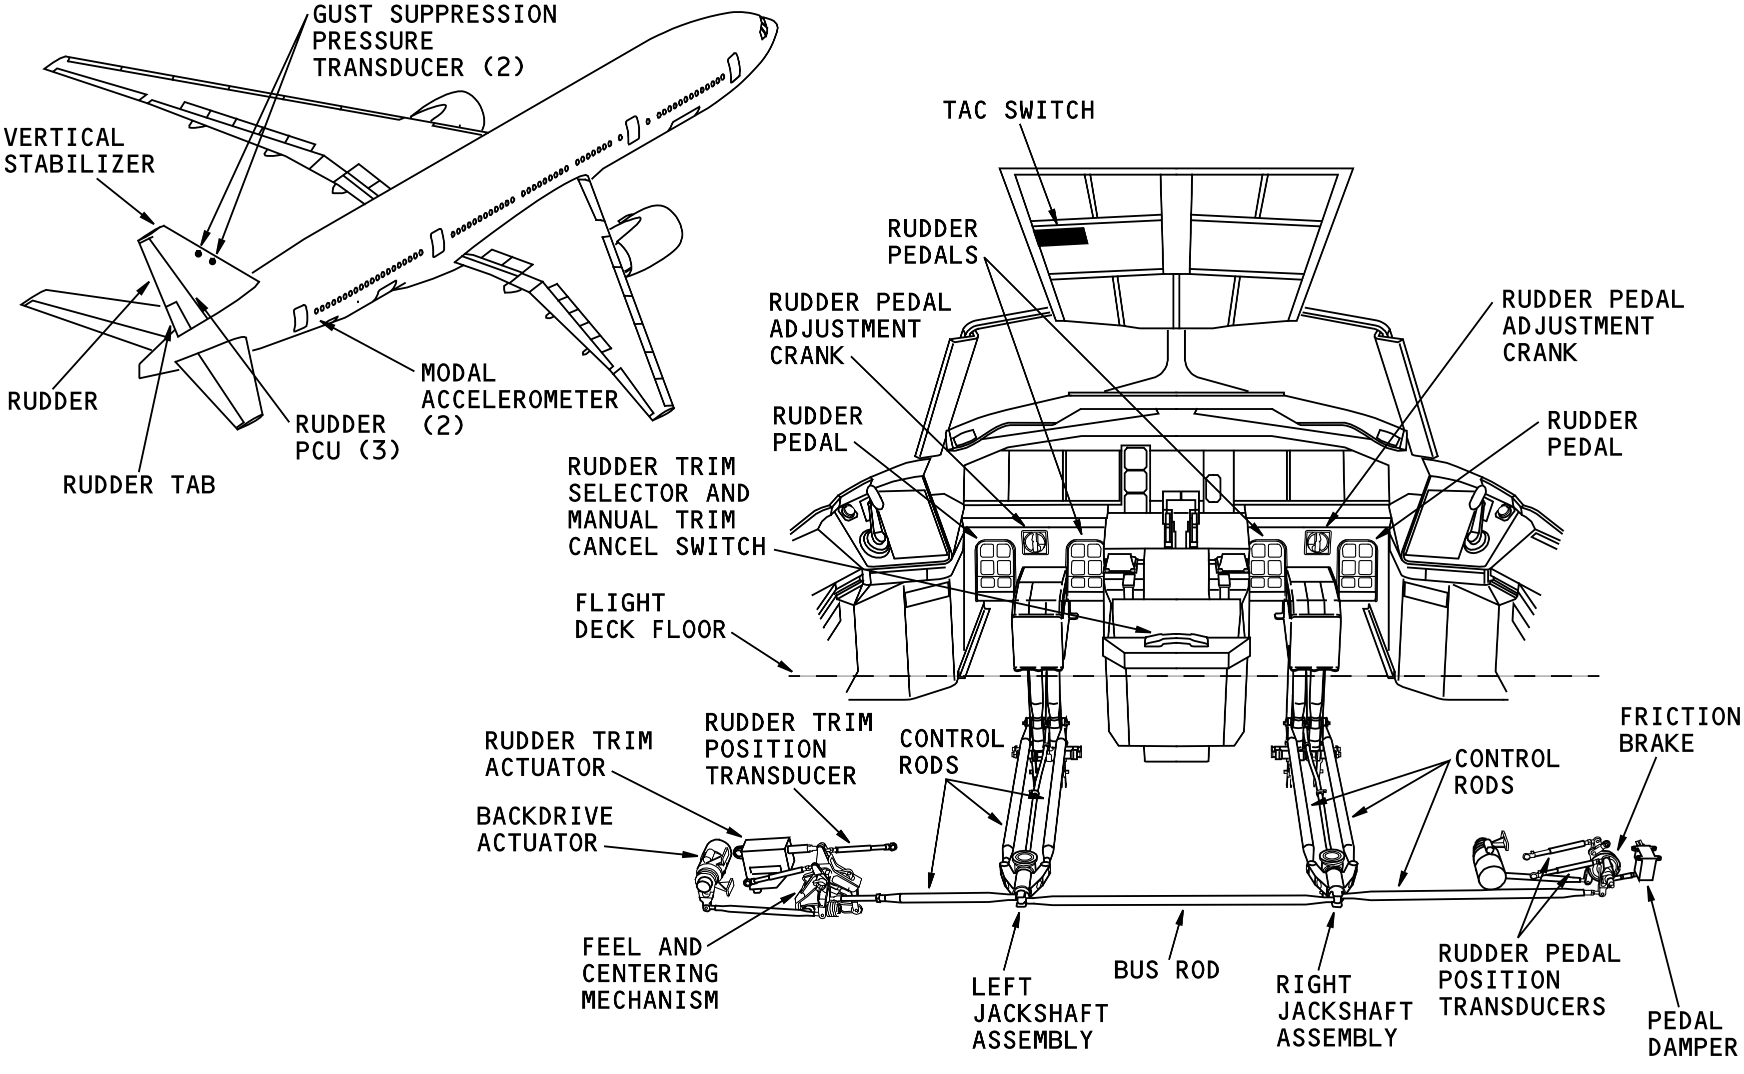
The rudder pedals, the rudder pedal adjustment cranks, the rudder trim selector and the manual trim cancel switch are in the flight deck. The rudder trim selector and the manual trim cancel switch are on the P8 aft aisle stand. The TAC switch is on the P5 overhead panel.

Components Below the Flight Deck

The rest of the forward controls are below the flight deck floor and above the nose gear wheel well. These are the:

- Control rods
- Left and right jackshaft assemblies
- Bus rod
- Rudder Feel and centering mechanism
- Rudder trim actuator
- Rudder trim position transducer
- Rudder pedal position transducers
- Pedal damper
- Friction brake
- Backdrive actuators.

Access to these components is through the forward equipment center.



NOTE: CONTROL WHEELS AND CONTROL COLUMNS NOT SHOWN FOR CLARITY.

27-21-00-003 Rev 2 03/31/95

RUDDER CONTROL- COMPONENT LOCATIONS

RUDDER CONTROL - ANALOG AND DISCRETE INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

RUDDER CONTROL - ANALOG AND DISCRETE INTERFACES

General

All of the rudder control electrical interfaces in the PFCS go through the ACEs. The ACEs have interfaces with these components:

- Thrust asymmetry compensation switch
- Rudder pedal position transducers
- Rudder trim selector
- Manual trim cancel switch
- Rudder trim actuator
- Rudder trim position transducer
- Gust suppression pressure transducers
- Modal accelerometers
- Rudder PCUs.

The rudder trim actuator connects mechanically with the rudder pedal control system.

Thrust Asymmetry Compensation Switch

The thrust asymmetry compensation (TAC) switch supplies a discrete signal to the C ACE. When the TAC switch is in the AUTO position, the PFCs automatically control the rudder trim actuator to make allowance for asymmetric thrust. TAC does not operate when the TAC switch is in the OFF position.

Rudder Pedal Position Transducers

There are four rudder pedal position transducers, two for each rudder pedal set. Each transducer is a linear variable differential transformer (LVDT) that sends analog signals to the ACEs. These analog signals are in proportion to the rudder pedal position and their movement.

Rudder Trim Selector, Manual Trim Cancel Switch, Trim Actuator and Position Transducer

The rotary trim selector and the manual trim cancel switch supply discrete signals to the L1 and R ACEs. The ACEs transmit these signals to the PFCs. The PFCs then command through the ACEs the rudder trim actuator to move the rudder pedals and the position transducers. The rudder trim actuator sends a feedback signal to the ACE. The rudder trim position transducer also sends a trim position signal to the ACE.

Gust Suppression Pressure Transducers

Two gust suppression pressure transducers, in the vertical stabilizer, supply analog signals to the L1 and C ACEs. These signals represent the differential pressure across the vertical stabilizer. This is a measure of the aerodynamic force.

Modal Accelerometers

Two modal accelerometers, in the aft body, supply analog signals to the L2 and R ACEs. These signals represent the lateral acceleration of the aft body movement.

RUDDER CONTROL - ANALOG AND DISCRETE INTERFACES

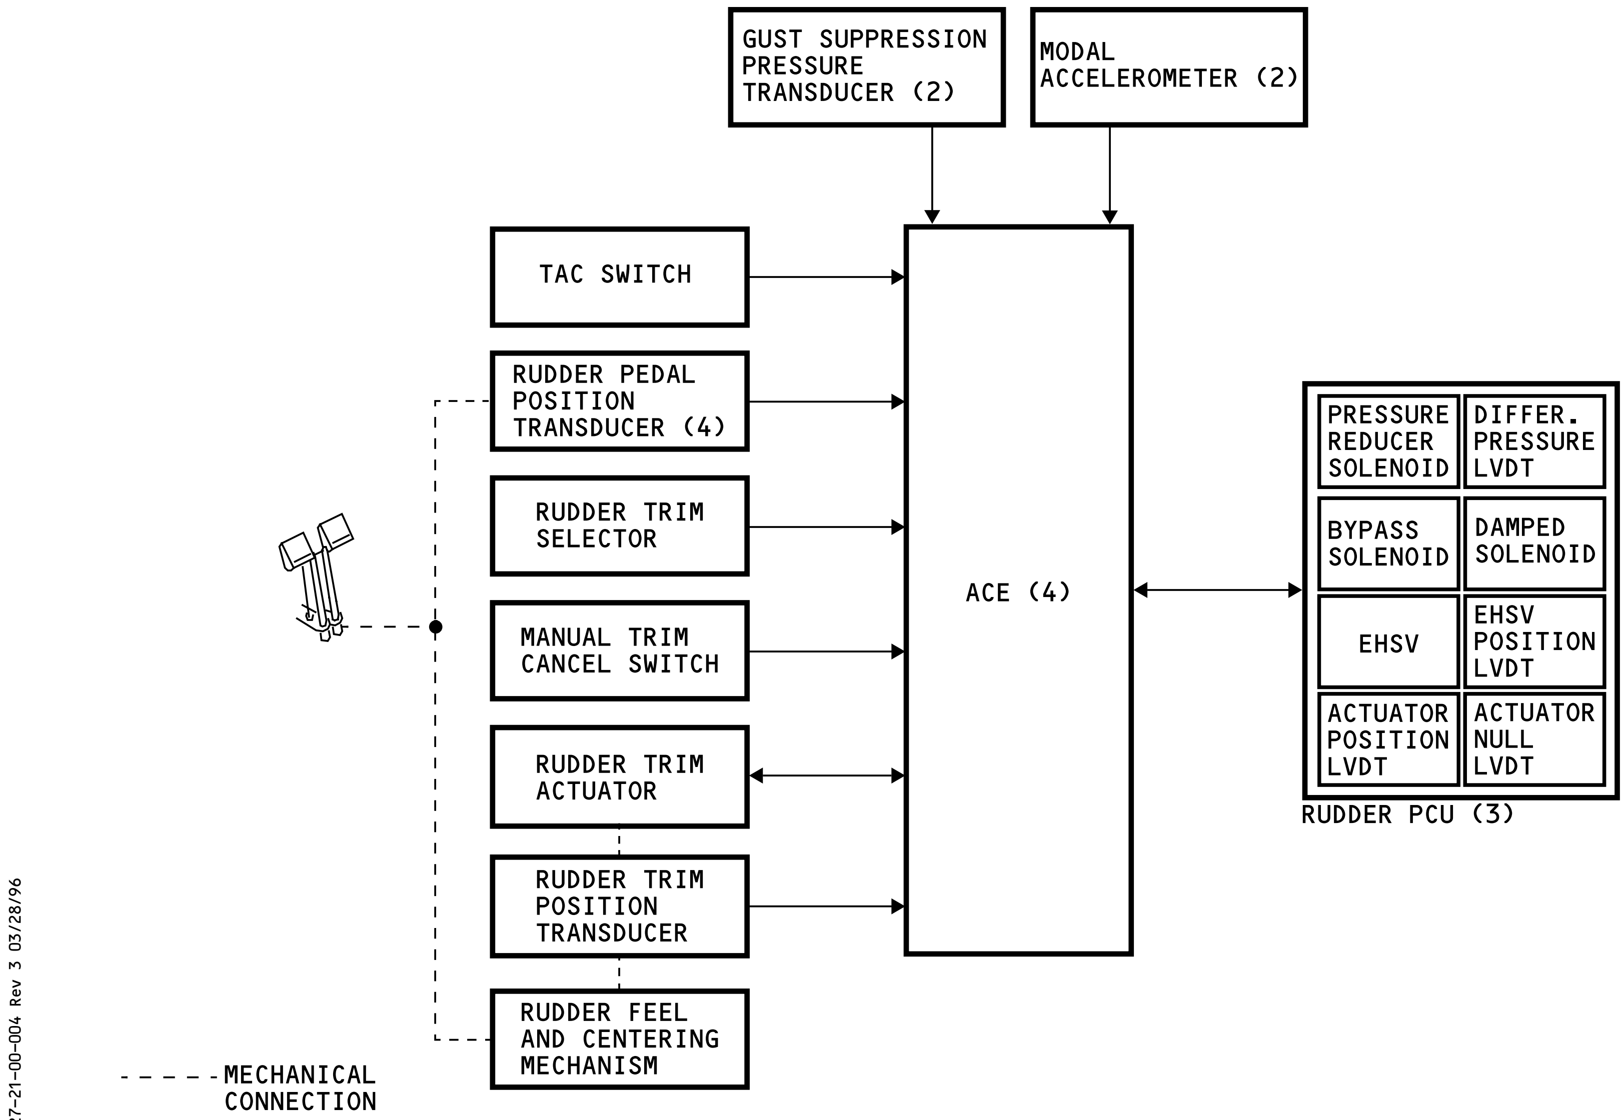
Rudder PCUs

Each of the three rudder PCUs receives analog and discrete electrical signals from the ACEs. The discrete signals go to:

- The pressure reducer solenoid
- The bypass solenoid
- The damped solenoid.

The analog signal goes to the electrohydraulic servo valve (EHSV).

Each of the three rudder PCUs sends analog feedback signals to the ACEs. These signals are from the EHSV position LVDT, the actuator position LVDT, the actuator null LVDT and the differential pressure LVDT.



RUDDER CONTROL - ANALOG AND DISCRETE INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

RUDDER CONTROL - FORWARD CONTROLS

General

The forward controls of the rudder control system include:

- The rudder pedal arms and jackshaft assemblies
- The rudder pedal position transducers
- The backdrive actuators
- The feel and centering mechanism
- The rudder trim actuator
- The friction brake
- The pedal damper
- The connection to the nose wheel steering
- The travel stops.

Rudder Pedal Arms and Jackshaft Assemblies

The rudder pedal arms connect by control rods to the jackshaft assemblies. The two jackshaft assemblies connect with a bus rod. Each jackshaft assembly contains a rudder pedal adjustment mechanism to permit each pilot to adjust the pedals to the most comfortable position.

Each jackshaft assembly connects with control rods and cranks to the left and right shaft assemblies.

There is no jam override mechanism for the rudder pedals. However, the control rods that connect the pedals to the jackshaft assemblies each have a one-way pogo. These supply some relief from jams that may occur as a result of a bird strike through the forward bulkhead.

Rudder Pedal Position Transducers

Four rudder pedal position transducers, installed on the airframe structure, connect to cranks on the left and right shaft assemblies.

Backdrive Actuators

Two backdrive actuators connect to a crank on the left and right shaft assemblies. The backdrive actuators are part of the autopilot system.

See the autopilot flight director system section for more information on the backdrive actuators (AMM PART I 22-11).

Feel and Centering Mechanism

The feel and centering mechanism is on the left shaft assembly.

Rudder Trim Actuator

The rudder trim actuator connects to the feel and centering mechanism. The rudder trim position transducer connects to the lever of the rudder feel and centering mechanism.

Friction Brake

A friction brake connects with a crank to the right shaft assembly. The friction brake supplies a resistance to the movement of the rudder pedal control mechanism.

Pedal Damper

A pedal damper connects with a crank to the right shaft assembly. The damper absorbs oscillations of the rudder pedal control mechanism.

Connection to Nose Wheel Steering

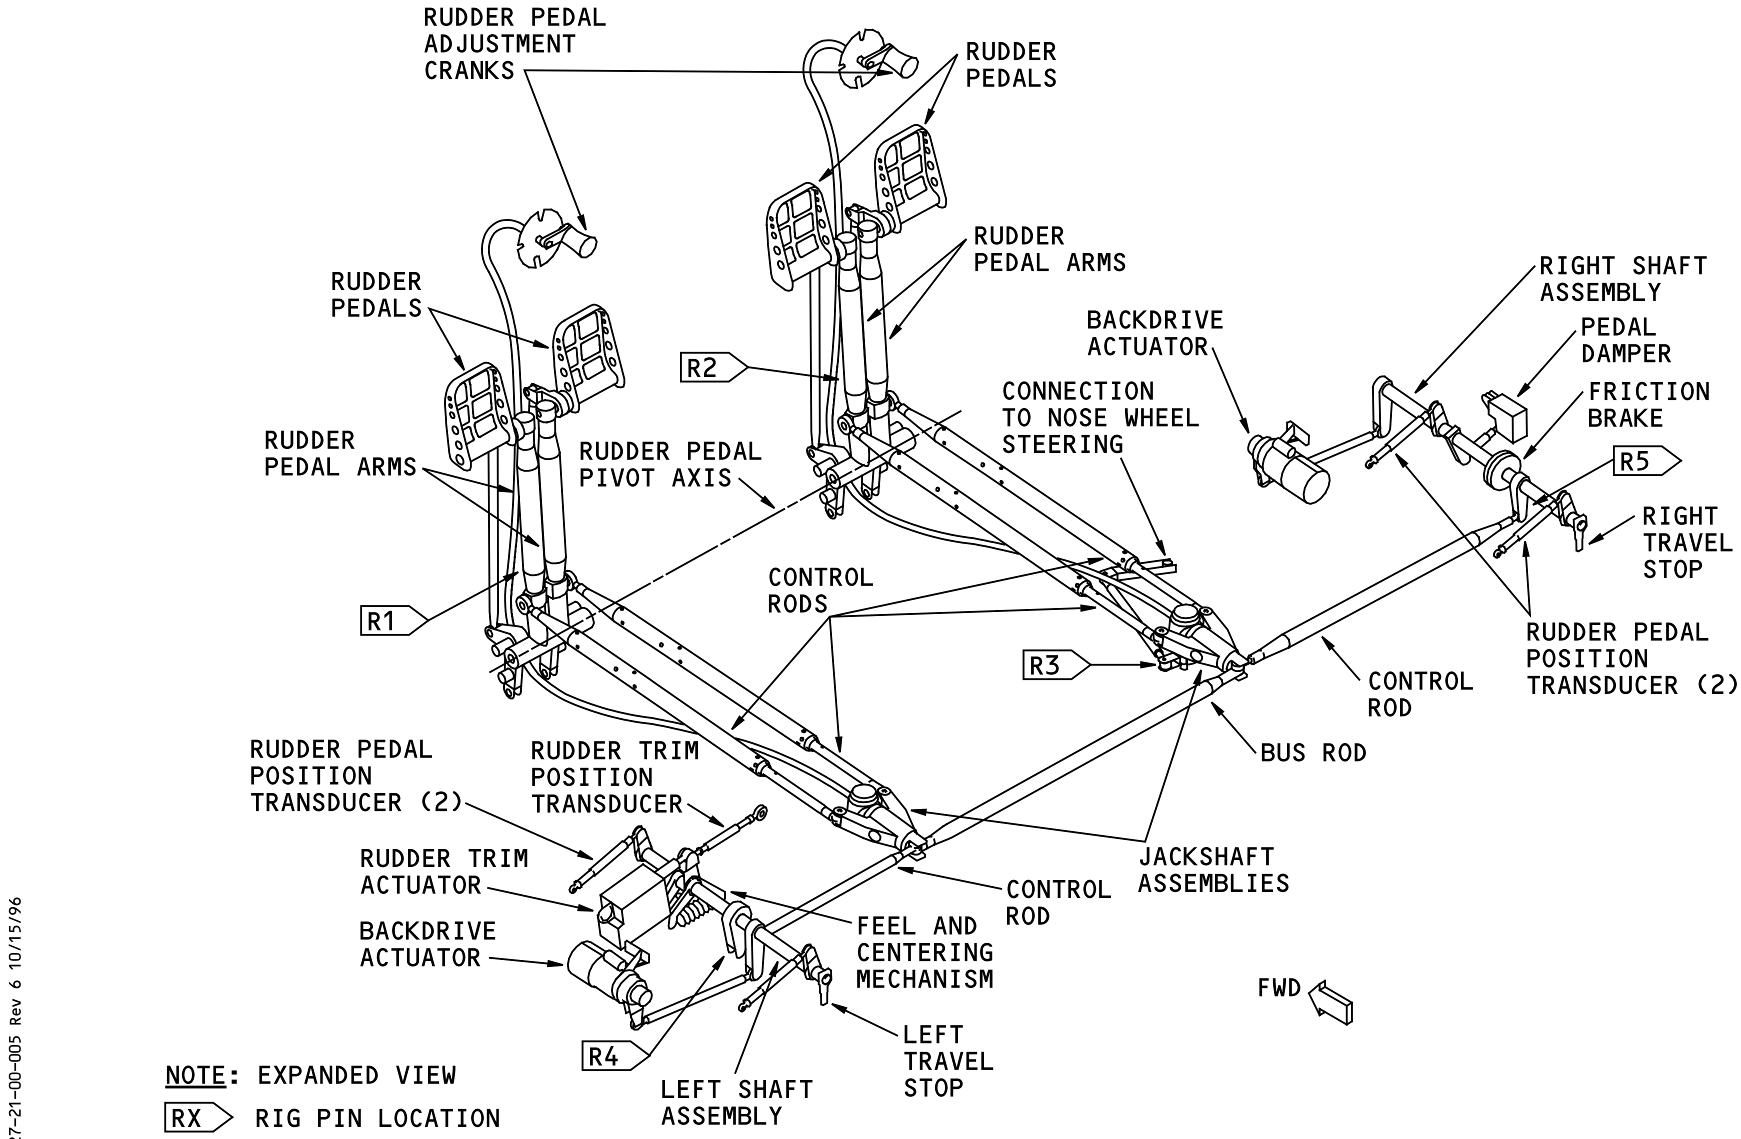
A crank and a connecting rod, from the right jackshaft assembly, supply the rudder pedal command to the nose wheel steering system. See the nose gear steering system section for more information (AMM PART I 32-51).

Travel Stops

Travel stops are at the aft end of the left and right shaft assemblies. They keep the movement of the rudder control system to a limit of 3.5 inches of rudder pedal movement in both directions.

Training Information Point

Rig pins lock the rudder forward controls during adjustment of the rudder control system.



RUDDER CONTROL - FORWARD CONTROLS

RUDDER CONTROL - FEEL AND CENTERING MECHANISM

Purpose

The rudder feel and centering mechanism supplies feel and centering forces to the yaw control system. The rudder trim actuator supplies rudder trim control. The rudder trim moves the neutral position of the rudder and the rudder pedals.

Physical Description

The feel and centering mechanism has a single cam and roller unit. The cam attaches by a spline to the left shaft assembly and turns with it. The follower assembly has a roller which rolls on the cam surface. An arm supports the follower assembly. The arm pivots on a lever bearing mounted on the left shaft assembly. The lever attaches to the trim actuator rod end. Two springs, between the lever and the arm of the follower assembly, keep the roller on the cam.

The rudder trim actuator attaches to the structure of the left shaft assembly. The rod end of the actuator connects to the lever of the feel and centering mechanism. The rudder trim position transducer also connects to the lever of the feel and centering mechanism.

Location

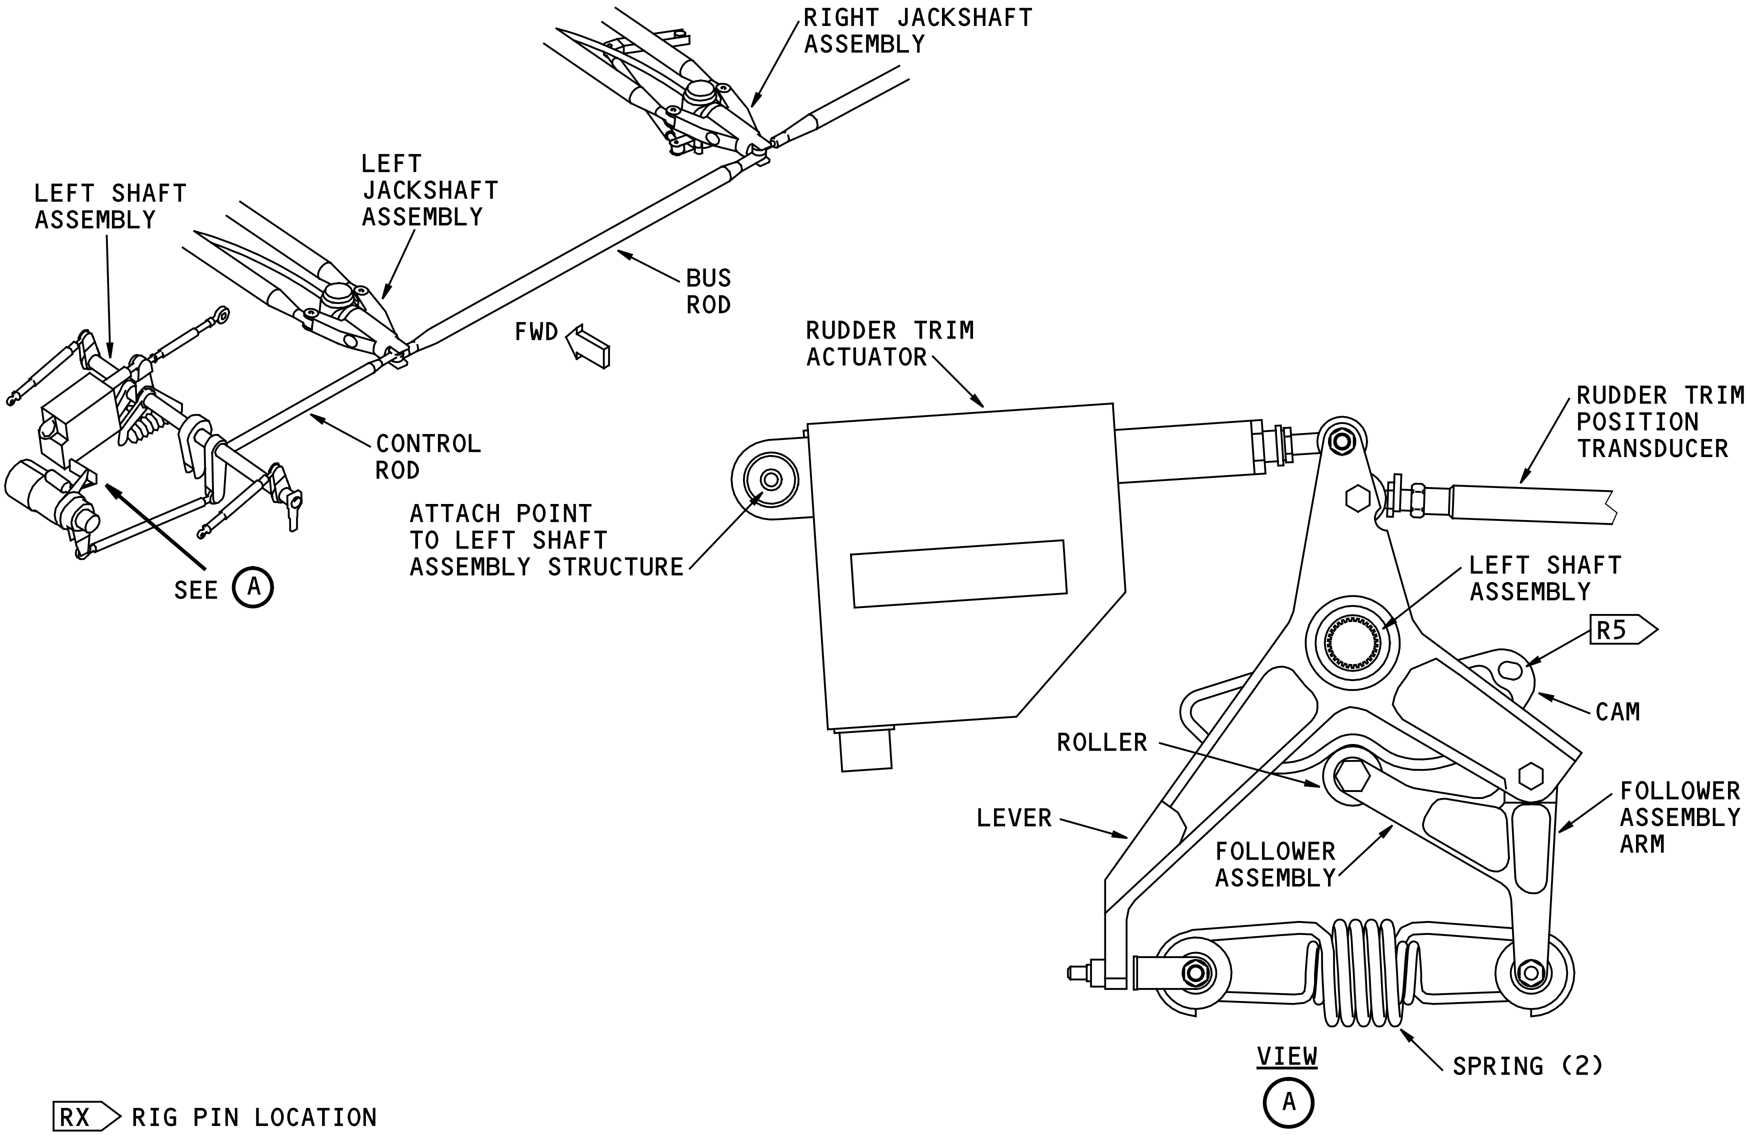
The feel and centering mechanism is in the mechanism of the left shaft assembly, between the flight deck floor and the nose gear wheel well. Access is through the MEC, then along the left side of the nose gear wheel well.

Functional Description

As the left shaft assembly and the cam turn, the cam follower moves, which extends the two springs. The springs supply a feel force to the rudder pedals. The feel force varies from 19.5 lb (8.8 kg) at breakout to a maximum of 50 lb (22.7 kg) at full displacement of the rudder pedals.

When the pilots release the rudder pedals, the springs force the cam follower back to the cam detent. This returns the system to the neutral trimmed position. The neutral, or zero feel force position, varies with trim input.

During trim operation, the rudder trim actuator moves the lever and the rudder trim position transducer, which then moves the arm and the cam follower assembly. Since the springs keep the cam follower in the cam detent, the trim actuator causes the cam and the left shaft assembly to turn. This also moves the rudder pedals and the rudder pedal position transducers.



27-21-00-009 Rev 1 03/27/95

RUDDER CONTROL - FEEL AND CENTERING MECHANISM

THIS PAGE INTENTIONALLY LEFT BLANK

RUDDER CONTROL - RUDDER TRIM CONTROLS AND TRIM ACTUATOR

Purpose

The pilots use two controls to adjust the trim of the airplane about the vertical axis. The two controls are the rudder trim control and the manual trim cancel switch.

The rudder trim control commands the direction and rate of rudder trim. The manual trim cancel switch commands the rudder to the center position and cancels any rudder trim input by the pilot. The manual trim cancel switch does not remove any rudder trim caused by TAC.

The rudder trim actuator extends and retracts to execute the pilot trim commands.

The rudder trim indicator shows the position of the rudder trim actuator.

Location

The two rudder trim controls are on the aft end of the P8 aft aisle stand. The rudder trim position indicator is in front of the trim switches.

The trim actuator is under the flight deck floor.

Trim Controls Physical Description

The rudder trim selector is a self-centering, dual-torque switch. It supplies the L1 and R ACEs with these electrical signals:

- Arm
- Trim direction (left or right)
- Trim rate.

The manual trim cancel switch is a momentary push button switch. It sends an electrical signal to the R ACE.

Trim Control Operation

When the pilot turns the rudder trim selector less than 25 degrees, the trim actuator does not move. When the pilot turns the trim selector more than 25 degrees, the trim actuator moves at 0.5 unit per second in the direction selected. When the pilot turns the trim selector more than 40 degrees with greater force, the trim actuator moves at 2 units per second in the direction selected.

When the pilot pushes on the manual trim cancel switch, it causes the rudder trim actuator to center the rudder control system at 2 units per second.

Rudder Trim Actuator Physical Description

The rudder trim actuator is a line replaceable unit (LRU). It weighs 4.1 lb (1.9 kg). Electrical commands limit the stroke of the actuator to 3 inches. Mechanical stops limit the actuator stroke to 3.2 inches.

RUDDER CONTROL - RUDDER TRIM CONTROLS AND TRIM ACTUATOR

Rudder Trim Position Indicator Physical Description

The rudder trim position indicator is an LRU. It weighs 1.7 lb (0.8 kg).

The rudder trim pointer shows the position of the rudder trim actuator. The indicator scale shows 17 units of actuator trim in both directions. Each unit of pointer movement is equivalent to about 1 degree of rudder movement at low airspeed.

Indications

The warning message CONFIG RUDDER shows on the EICAS display when all of these conditions occur:

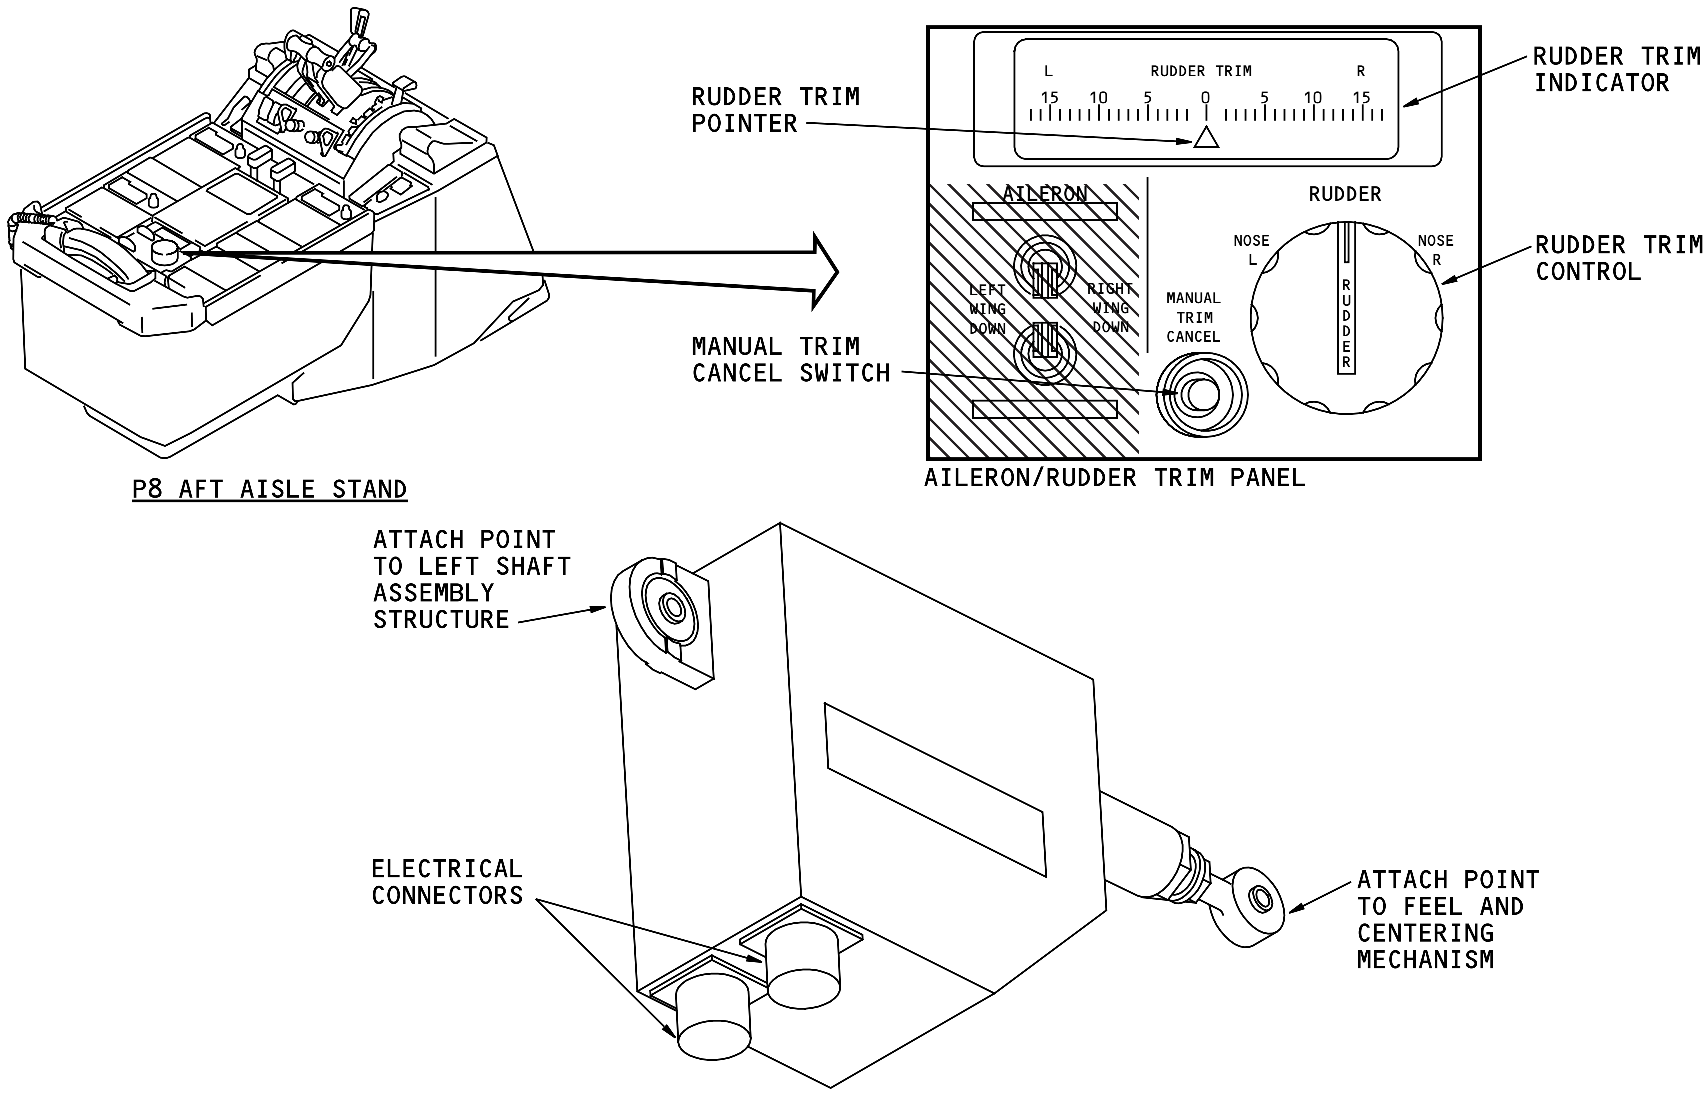
- The rudder trim is not within 2 units from center
- Either the left or right engine thrust is more than the takeoff threshold
- The airplane is on the ground.

The status message FLIGHT CONTROL SYS shows on the status display when the rudder trim system is defective.

Training Information Point

In case of a power supply failure to the indicator, the indicator pointer, scale, and nomenclature are not visible. In case of input signal loss, the indicator pointer is not visible but the scale and nomenclature stay visible.

There is an adjustment on the trim actuator rod end. You adjust the rudder trim actuator to make sure that the manual trim cancel switch function moves the trim actuator to the zero trim position.



RUDDER CONTROL - RUDDER TRIM CONTROLS AND TRIM ACTUATOR

27-21-00-010 Rev 5 07/02/1997

RUDDER CONTROL - RUDDER PEDAL POSITION TRANSDUCERS

Purpose

The four rudder pedal position transducers measure the position of the rudder pedals. The transducers send analog electrical signals to the ACEs.

Physical Description

Each position transducer is an LVDT. The ACEs supply 7v ac, 1800 Hz excitation power.

The four rudder pedal position transducers are identical to the six wheel position transducers, the six column position transducers and the rudder trim position transducer.

Two rudder pedal position transducers are on the right shaft assembly and two are on the left shaft assembly. The position transducers attach at one end to the support structure of the shaft assembly mechanisms. They attach to the transducer crank at the other end.

Each transducer crank attaches to its shaft assembly with a spline. The spline has a missing tooth to help locate the crank on the shaft. Each transducer crank has two shear rivets to allow override of a jammed position transducer.

Each position transducer has an electrical cable which connects to the ACE connector bracket. This bracket has two receptacles, one for each position transducer. The order in which each position transducer connects to the connector bracket determines the transducer-to-ACE relationship.

Location

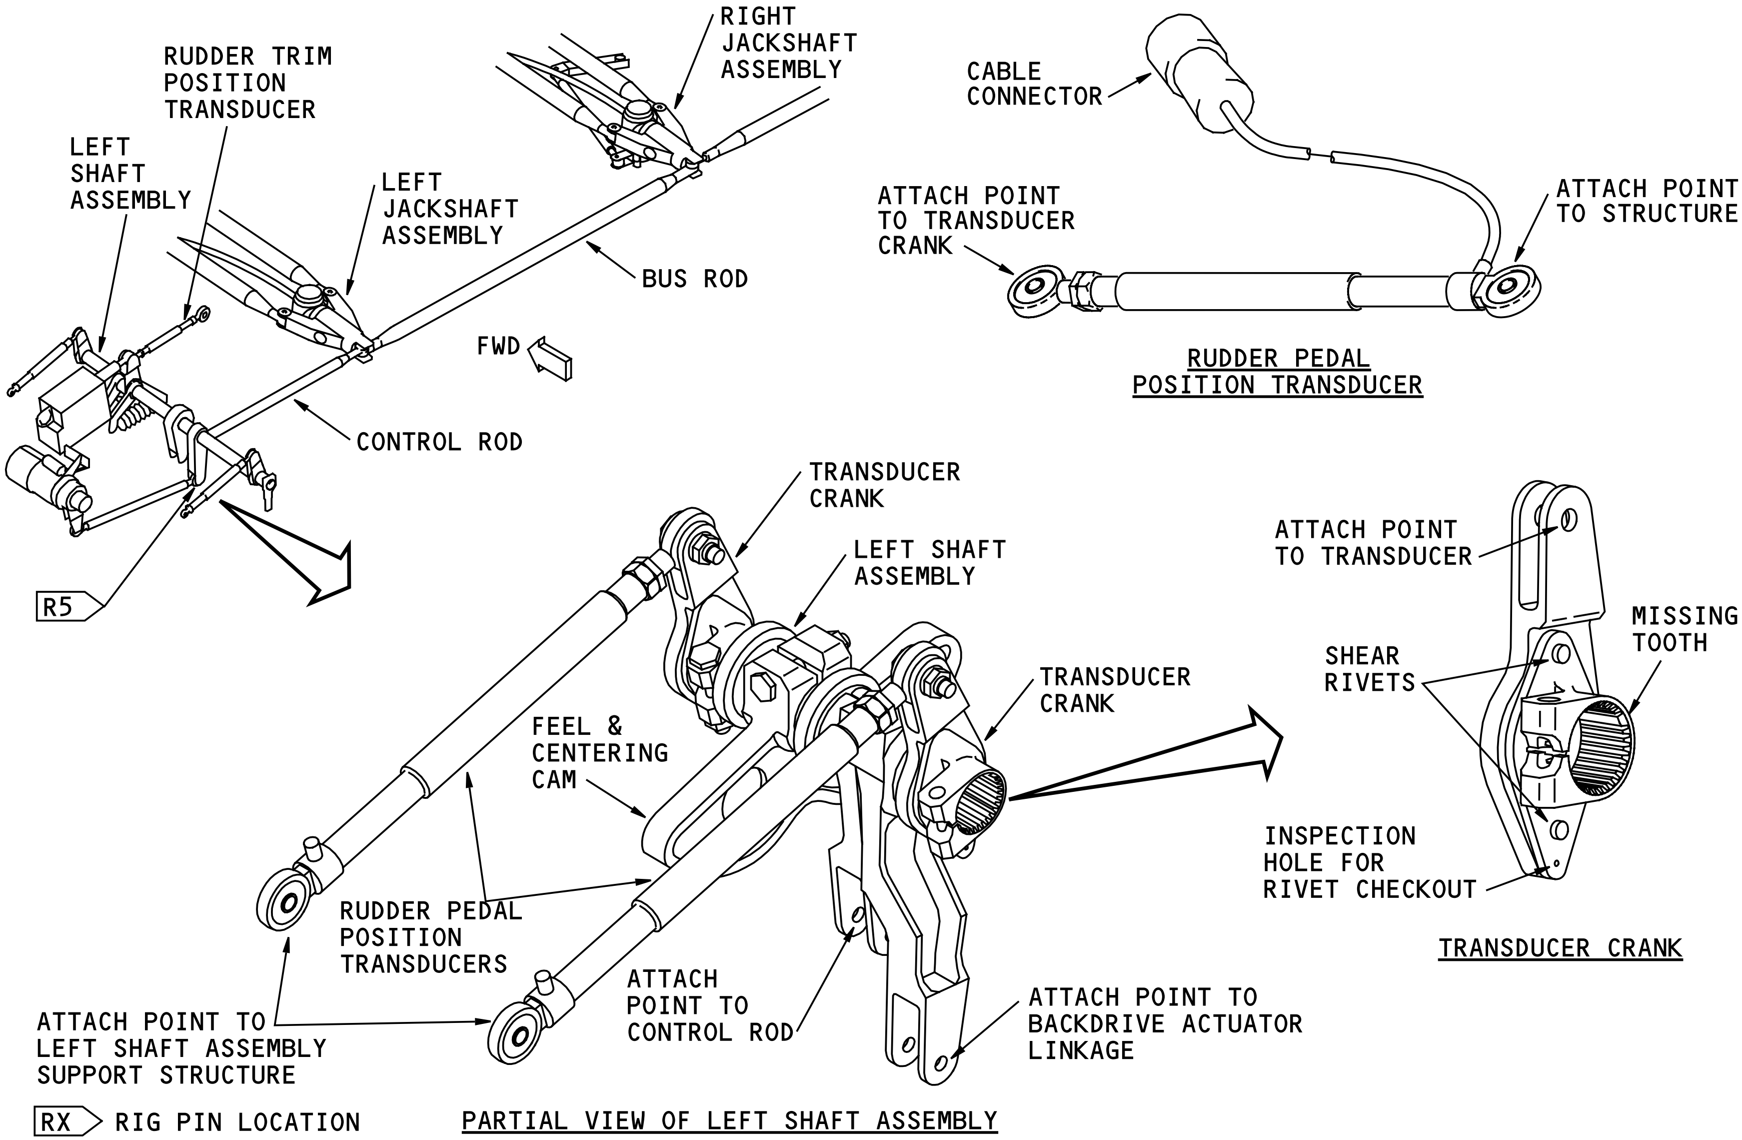
The four rudder pedal position transducers are outboard of the nose gear wheel well. Access is through the MEC, then along either side of the nose gear wheel well.

Functional Description

When the right and left shaft assemblies rotate in response to a rudder pedal command, the rudder pedal position transducers extend or retract. Each position transducer sends an analog electrical signal to one ACE.

Indications

When one or more pedal position transducer is defective, the status message FLIGHT CONTROL SYS shows.



RUDDER CONTROL - RUDDER PEDAL POSITION TRANSDUCERS

27-21-00-011 Rev 3 03/27/95

RUDDER CONTROL - MODAL ACCELEROMETERS

Purpose

The modal accelerometers measure the lateral acceleration of the aft fuselage. They send an analog signal to the ACEs.

The modal suppression function of the primary flight control system helps improve the quality of passenger ride in the forward and aft sections of the cabin.

Physical Description

There are two identical modal accelerometers. They are LRUs. Each accelerometer weighs about 0.8 lb (0.36 kg).

An electrical cable connects to a connector on each modal accelerometer.

Each modal accelerometer attaches to a support bracket.

Location

The modal accelerometers are on a cabin floor beam of the aft fuselage. One accelerometer is at each outboard side of the beam.

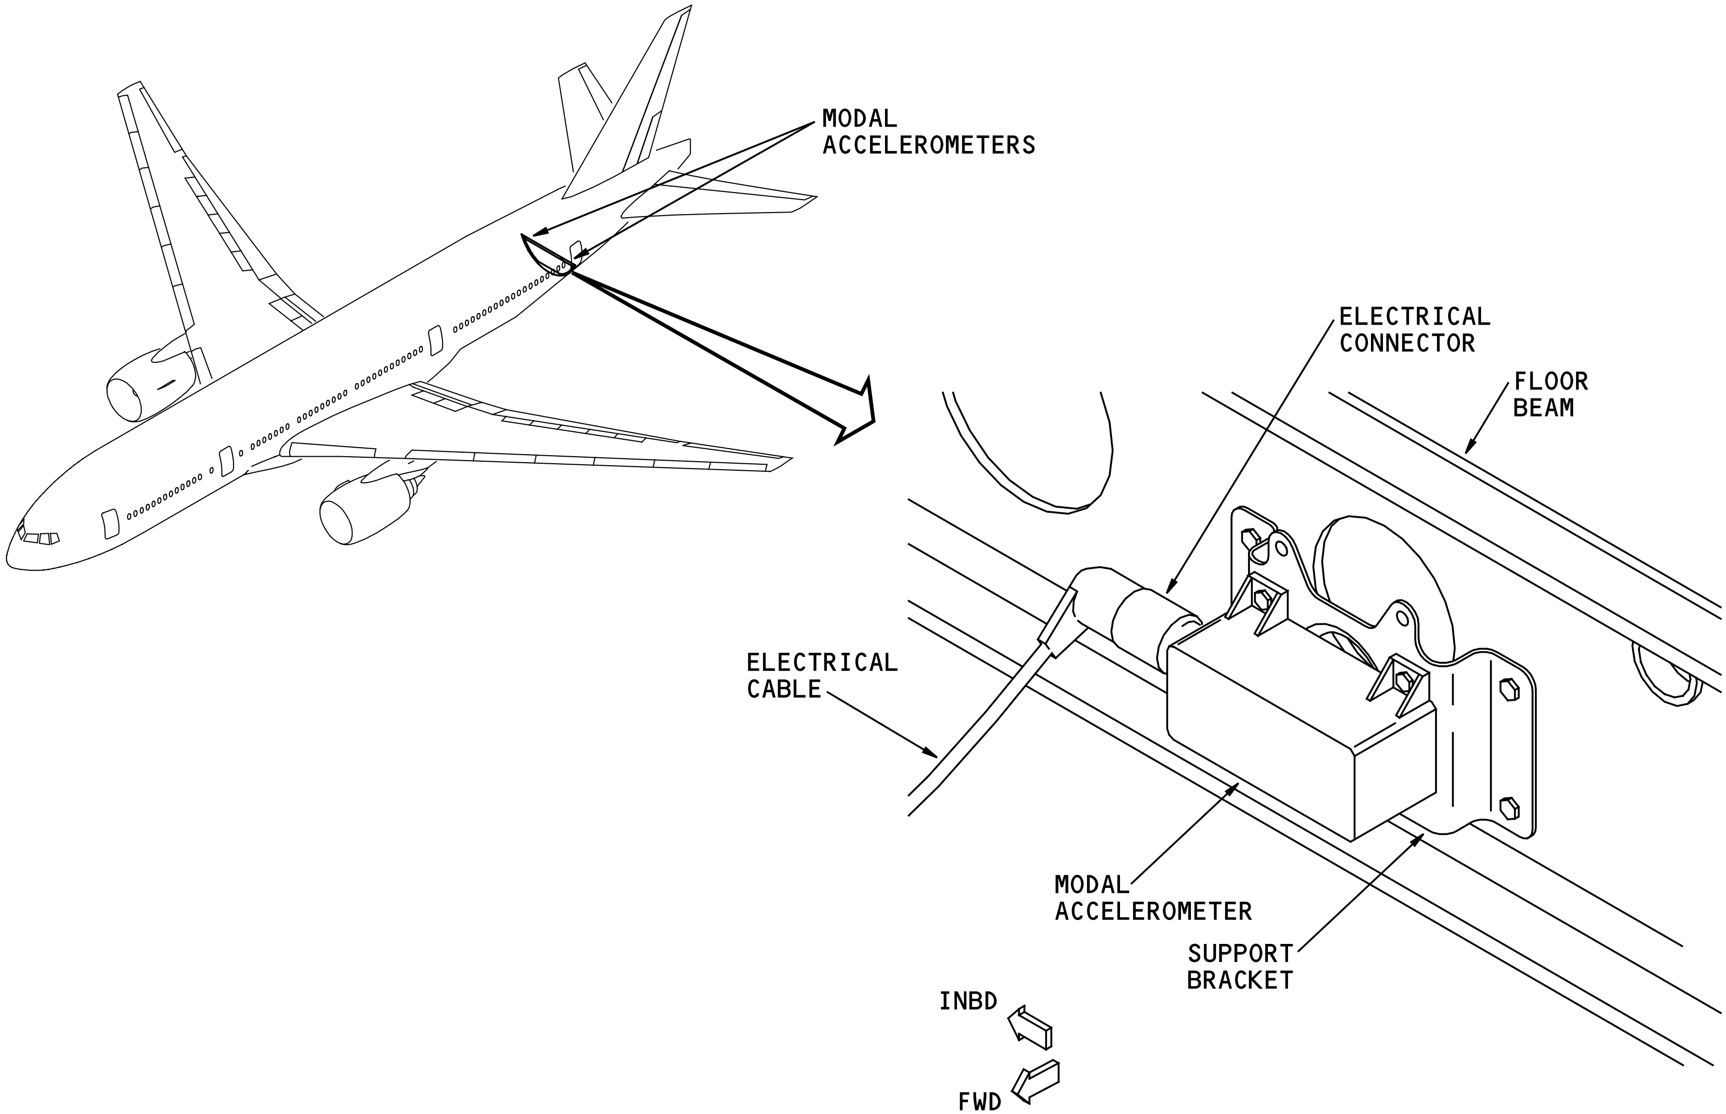
To get access to the modal accelerometers, it is necessary to remove the sidewall liners of the bulk cargo compartment. The modal accelerometers are outboard of the sidewall stanchions of the bulk cargo compartment.

Functional Description

Lateral movement of the aft fuselage causes a change of the analog signal from the modal accelerometer to the ACE.

Indications

There is no flight deck indication if one or both modal accelerometers are defective.



RUDDER CONTROL - MODAL ACCELEROMETERS

RUDDER CONTROL - GUST SUPPRESSION PRESSURE TRANSDUCERS

Purpose

The gust suppression pressure transducers measure the pressure difference between both sides of the vertical stabilizer. They also supply an electrical analog signal to the ACEs.

The gust suppression function helps improve the quality of passenger ride in the aft portion of the fuselage.

Physical Description

There are two identical pressure transducers and four identical pressure ports. The transducers and the ports are LRUs. Each transducer weighs about 2 lb (0.9 kg).

Each pressure transducer connects to two pressure ports. The ports are symmetrically positioned, one on each side of the vertical stabilizer. Non metallic hoses connect the ports to the pressure transducers. An electrical cable connects to one connector on the differential pressure transducer.

There is about 6 ft (1.83 m) separation between the two pressure transducers and their associated ports.

Location

The gust suppression pressure transducers are near the vertical stabilizer leading edge, on the aft side of the auxiliary spar. The ports are on the composite skin panels of the vertical stabilizer. The pressure transducers are above the pressure ports to permit drainage of moisture from the tubes and the ports.

To get access to each transducer, remove a skin panel of approximately 30 in x 48 in (0.76 m x 1.22 m) on the left side of the vertical fin.

RUDDER CONTROL - GUST SUPPRESSION PRESSURE TRANSDUCERS

RUDDER CONTROL - RUDDER PCU - INTRODUCTION

Purpose

Three rudder PCUs move the rudder. Electrical signals from the ACEs command the rudder PCUs. Each rudder PCU operates with hydraulic power from a different hydraulic system.

Location

The rudder PCUs are on the rear spar of the vertical stabilizer. Remove three panels on the left side of the vertical stabilizer to access the PCUs. Each panel is approximately 20 in x 20 in (0.5 m x 0.5 m).

Physical Description

The kick link connects the PCU to the rear spar fitting. The actuator rod and the reaction link connect to the rudder PCU fitting.

Two electrical connectors of different sizes connect to the lower side of the PCU.

Hydraulic tubing connects to ports on the upper side of the PCU.

The right hydraulic system supplies power to the lower rudder PCU, the left hydraulic system to the middle PCU, and the center hydraulic system to the upper PCU.

A rate fuse is on the center hydraulic system supply line to the upper PCU. A check valve is on the return line from the upper PCU to the center system.

Training Information Point

Remove and install the rudder PCU as one assembly with the reaction link. The rudder PCU disconnects from the kick link which stays on the airplane.

Install a hoist swivel fitting to the hoist attach point of the PCU. Use a ground support equipment (GSE) hoist to support the PCU during removal and installation.

After installation of the rudder PCU, the actuator null LVDT requires adjustment. Remove the null LVDT access cover to adjust the null LVDT.

Put the nose gear steering tow lever in the tow position before you move the rudder pedals to operate the rudder system.

RUDDER CONTROL - RUDDER PCU - INTRODUCTION

RUDDER CONTROL - RUDDER PCU - PHYSICAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

RUDDER CONTROL - RUDDER PCU - PHYSICAL DESCRIPTION

Physical Description

All three rudder PCUs are identical. Each rudder PCU, with its reaction link, weighs approximately 98 lb (44.5 kg).

The rudder PCU contains a hydraulic actuator with a control module. The control module contains:

- An electrohydraulic servo valve (EHSV)
- A pressure reducer solenoid valve
- A bypass solenoid valve
- A damped solenoid valve
- A mode selector valve
- A differential pressure sensor
- Two bypass check valves
- Two relief valves
- A thermal relief valve
- A compensator/relief valve
- Two anti-cavitation check valves
- An inlet check valve
- An inlet filter.

Hydraulic Actuator

The actuator piston has an LVDT that sends actuator position feedback signals to the ACE. The actuator piston also has a null LVDT to adjust the null position of the actuator piston LVDT during installation of the PCU.

EHSV

The EHSV controls the hydraulic power to the extend and retract sides of the actuator. The EHSV has an LVDT that sends EHSV position feedback signals to the ACE.

Pressure Reducer Solenoid Valve

The pressure reducer solenoid valve commands the pressure reducer valve to decrease the hydraulic pressure to 1850 psi. Reduced pressure on the actuator decreases the probability of leak and fatigue loads during normal operation.

If there is a PCU or hydraulic failure, the hydraulic pressure to one or both of the other two PCUs increases to the nominal hydraulic system pressure (3000 psi). The hydraulic pressure also increases to the nominal system pressure on all three PCUs during takeoff and landing.

Bypass Solenoid Valve

The bypass solenoid valve controls the pilot pressure from the hydraulic system to the mode selector valve.

Damped Solenoid Valve

The damped solenoid valve controls the pilot pressure from the actuator to the mode selector valve.

RUDDER CONTROL - RUDDER PCU - PHYSICAL DESCRIPTION

Mode Selector Valve

Pilot pressure from the bypass or the damped solenoid valves commands the mode selector valve in one of three positions:

- Normal
- Bypass
- Damped.

Differential Pressure Sensor

A differential pressure sensor measures the pressure difference between both sides of the actuator piston. The sensor operates an LVDT which sends signals to the ACE.

Bypass Check Valves

The two bypass check valves permit pressure from either side of the actuator to reach the damped solenoid valve.

Relief Valves

The two relief valves protect the actuator in case of high pressure due to a hardover of an adjacent PCU.

Thermal Relief Valve

The thermal relief valve protects the actuator from thermal expansion of the hydraulic fluid.

Compensator/Relief Valve

The compensator/relief valve holds a small quantity of fluid above the hydraulic system return pressure. This fluid is available to the actuator to prevent cavitation.

Anti-cavitation Check Valves

The two anti-cavitation check valves permit return fluid from the compensator to flow to the actuator. This prevents cavitation of the actuator during rapid backdriving of the PCU.

Inlet Check Valve

The inlet check valve keeps the hydraulic fluid in the actuator when the hydraulic system power is lost.

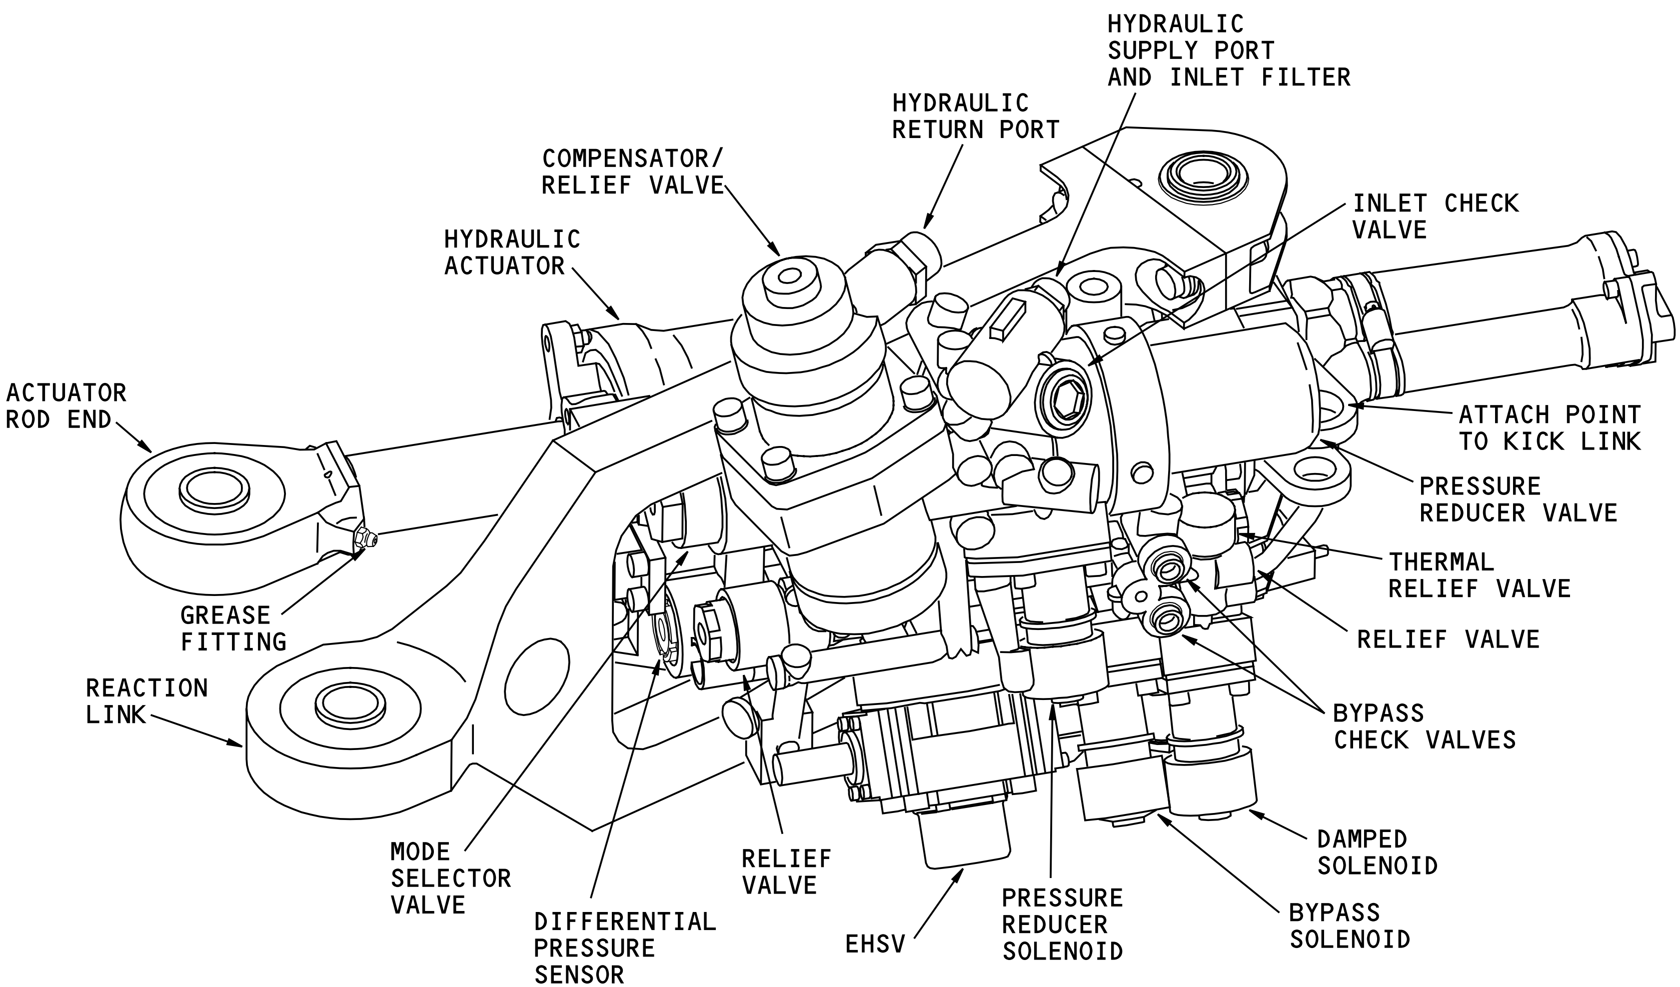
Inlet Filter

The inlet filter protects the actuator from solids in the hydraulic fluid.

Training Information Point

Only the bearings in the actuator rod end and the reaction link, where they attach to the rudder, require lubrication.

All other bearings on the actuator and reaction link are teflon coated bearings. They do not require lubrication.



27-21-00-016 Rev 7

RUDDER CONTROL - RUDDER PCU - PHYSICAL DESCRIPTION

RUDDER CONTROL - RUDDER PCU - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

RUDDER CONTROL - RUDDER PCU - FUNCTIONAL DESCRIPTION

General

The rudder PCU operates in three different modes:

- Normal
- Bypass
- Damped.

In the normal mode, the ACE energizes the bypass solenoid. The pressure reducer and the damped solenoid may or may not be energized.

In the bypass mode, the ACE de-energizes the bypass solenoid. The damped solenoid stays energized. The pressure reducer solenoid may or may not be energized.

In the damped mode, the ACE de-energizes the bypass solenoid and the pressure reducer solenoid. The damped solenoid is also de-energized.

PCU Operational Matrix

The table shows the various conditions of the PCU valve solenoids in the three modes of operation of the PCUs:

SOLENOID CONDITIONS	PCU MODES OF OPERATION		
	NORMAL	BYPASS	DAMPED
PRESSURE REDUCER SOLENOID	E/D	E/D	D
BYPASS SOLENOID	E	D	D
DAMPED SOLENOID	E/D	E	D
LEGEND: E = ENERGIZED D = DE-ENERGIZED			

27-21-00-017 Rev 4 03/10/96

Normal mode

The PCU is in normal mode when the ACE energizes the bypass solenoid. Hydraulic pilot pressure then moves the mode selector valve to the normal position.

For the conditions of the other PCUs, the ACE may or may not energize the pressure reducer solenoid and the damped solenoid. The status of the damped solenoid does not affect the operation in the normal mode.

When the pressure reducer solenoid is energized, the pressure reducer valve regulates the pressure to the EHSV to a lower nominal value. When the pressure reducer solenoid is de-energized, the pressure reducer valve allows full hydraulic system pressure to the EHSV.

Under these conditions, an electrical command to the EHSV results in the actuator extension or retraction.

Bypass Mode

The PCU is in bypass mode when the ACE de-energizes the bypass solenoid. The damped solenoid stays energized. This happens when there is a single hydraulic or electrical failure on the PCU or its ACE.

The bypass solenoid valve then blocks hydraulic pilot pressure to the mode selector valve. However, pressure from the actuator, trapped between the bypass check valves and the thermal relief valve, goes through the damped solenoid valve. This pilot pressure moves the mode selector valve to the bypass position.

Under these conditions, the mode selector valve blocks control pressure from the EHSV to the actuator cylinder. It also connects together both sides of the actuator.

When the PCU is in bypass mode, the other two PCUs backdrive it. These two PCUs then operate at full hydraulic system pressure.

During rapid backdrive of the PCU in bypass mode, the compensator/relief valve supplies fluid to the actuator through the anti-cavitation check valves.

Damped Mode

The PCU is in damped mode when the ACEs de-energize the bypass, pressure reducer and damped solenoids. This happens when the PCU has no power or there is a double or triple PCU or ACE failure.

In damped mode, there is no hydraulic pilot pressure on the mode selector valve. Its internal spring moves the valve to the damped position. The mode selector valve blocks control pressure from the EHSV to the actuator cylinder. It also connects both sides of the actuator piston through a restriction.

During rudder operation with a double failure, the good PCU moves the rudder very slowly.

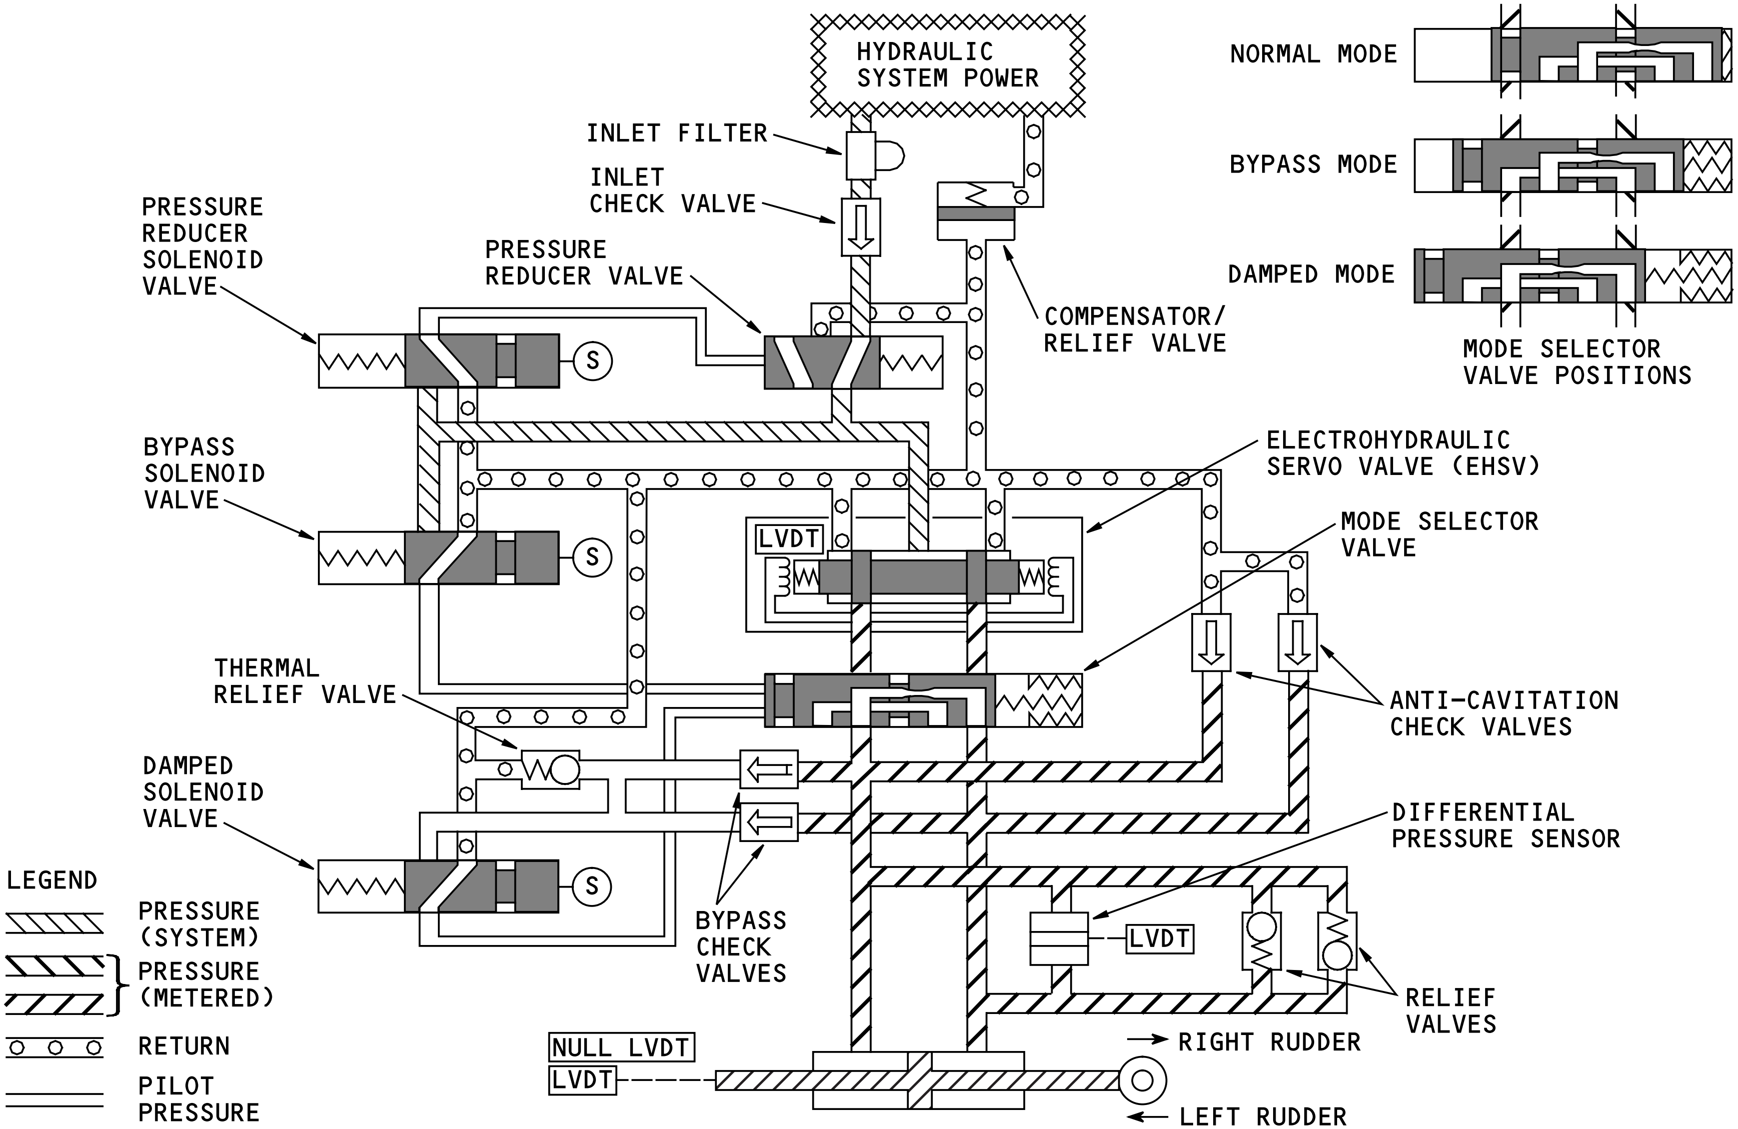
Training Information Point

On the ground with no power on the PCUs, all three PCUs are in damped mode. The rudder can move slowly when an outside force pushes on it.

Indications

The EICAS status message ACTUATOR PRESS SNSR shows that the differential pressure sensor on one of the rudder PCUs is defective. The flaperon also uses the same message.

The EICAS status message FLIGHT CONTROL SYS shows that one or more rudder PCU is not operative.



RUDDER CONTROL - RUDDER PCU - FUNCTIONAL DESCRIPTION

RUDDER CONTROL - RUDDER PCU - FUNCTIONAL DESCRIPTION - PCU MODES

General

The ACEs control the three modes of operation of the rudder PCUs. Each ACE controls the bypass solenoid of its on-side PCU. It also controls the pressure reducer and damped solenoid of one adjacent PCU.

In normal mode of the PFCS, the PFCs command the ACEs to control the pressure reducer solenoid of all the rudder PCUs. In secondary and direct mode of the PFCS, each ACE controls individually the pressure reducer solenoids.

Normal Mode

A rudder PCU operates in normal mode when there is no failure on the PCU and its on-side ACE.

If the PFCS is in normal mode, the rudder PCU operates with reduced hydraulic pressure during cruise flight and when there is no failure with any rudder PCU or ACE. The PFCs command the PCUs to operate with full system pressure when one of these conditions occurs:

- A failure of one or more PCU
- The airplane is below 500 feet above ground
- The flaps are extended.

If the PFCS is in secondary and direct mode, the ACEs command the PCUs to operate with reduced system pressure when there is no failure of a PCU or ACE.

Bypass Mode

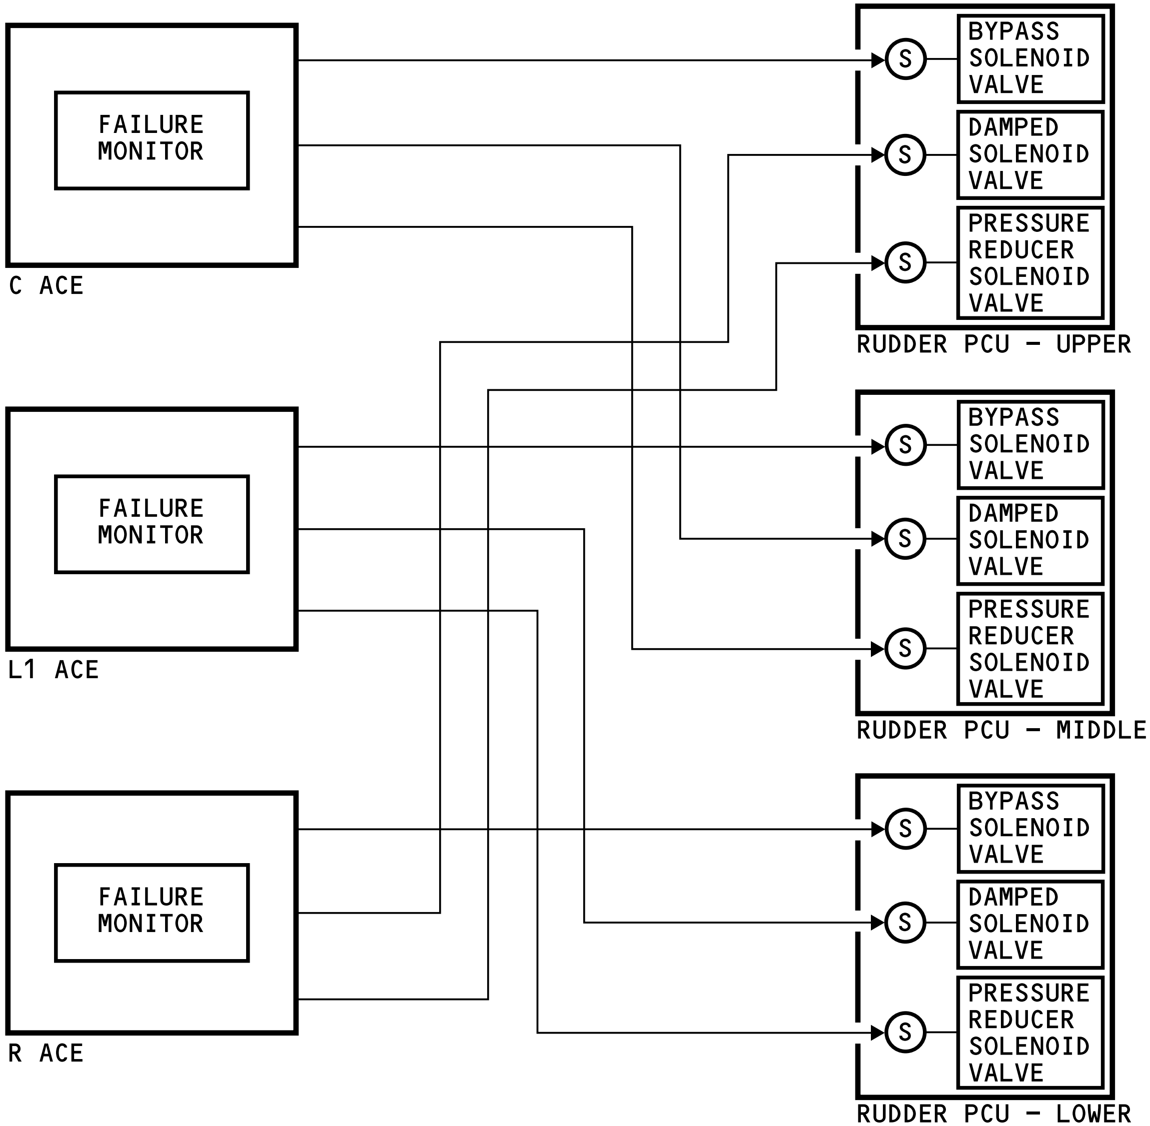
If the PCU has an electrical or hydraulic failure or there is a failure of its ACE, the ACE de-energizes the bypass solenoid. The PCU is then in bypass mode. The ACE also de-energizes the damped solenoid of the adjacent PCU which it also controls.

If the PFCS is in normal mode, the PFCs command all the ACEs to also de-energize the pressure reducer solenoid of all the PCUs. The two PCUs without failure then continue to operate with full hydraulic system pressure.

If the PFCS is in secondary or direct mode, the ACE de-energizes the pressure reducer solenoid of the adjacent PCU which it controls. In this case, one PCU is in bypass mode, one PCU operates in normal mode with full pressure and one PCU is in normal mode with reduced pressure.

Damped Mode

If there is a failure of a second PCU or its ACE, the ACE de-energizes the bypass solenoid of its on-side PCU. The ACE also de-energizes the pressure reducer and damped solenoid of one adjacent PCU. In this case, one PCU is in bypass mode, one PCU is in damped mode and one PCU operates with full hydraulic system pressure.



27-21-00-027 Rev 0 01/19/95

RUDDER CONTROL - RUDDER PCU - FUNCTIONAL DESCRIPTION - PCU MODES

RUDDER CONTROL - RUDDER ASSEMBLY

Purpose

The rudder supplies control of the airplane in the yaw direction. The rudder tab pivots on the lower trailing edge of the rudder.

Physical Description

The rudder is a light weight composite material structure. The skin is reinforced graphite/epoxy bonded to a core of Nomex honeycomb. The overall dimensions are approximately 98 in by 442 in (2.5 m by 11.2 m). The rudder weighs approximately 577 lb (262 kg).

A counterbalance at the tip of the rudder prevents flutter.

The rudder attaches to the vertical stabilizer with 10 hinges. Three PCUs attach to the rudder and move it. Jumpers and static dischargers supply electrostatic protection to airplane systems.

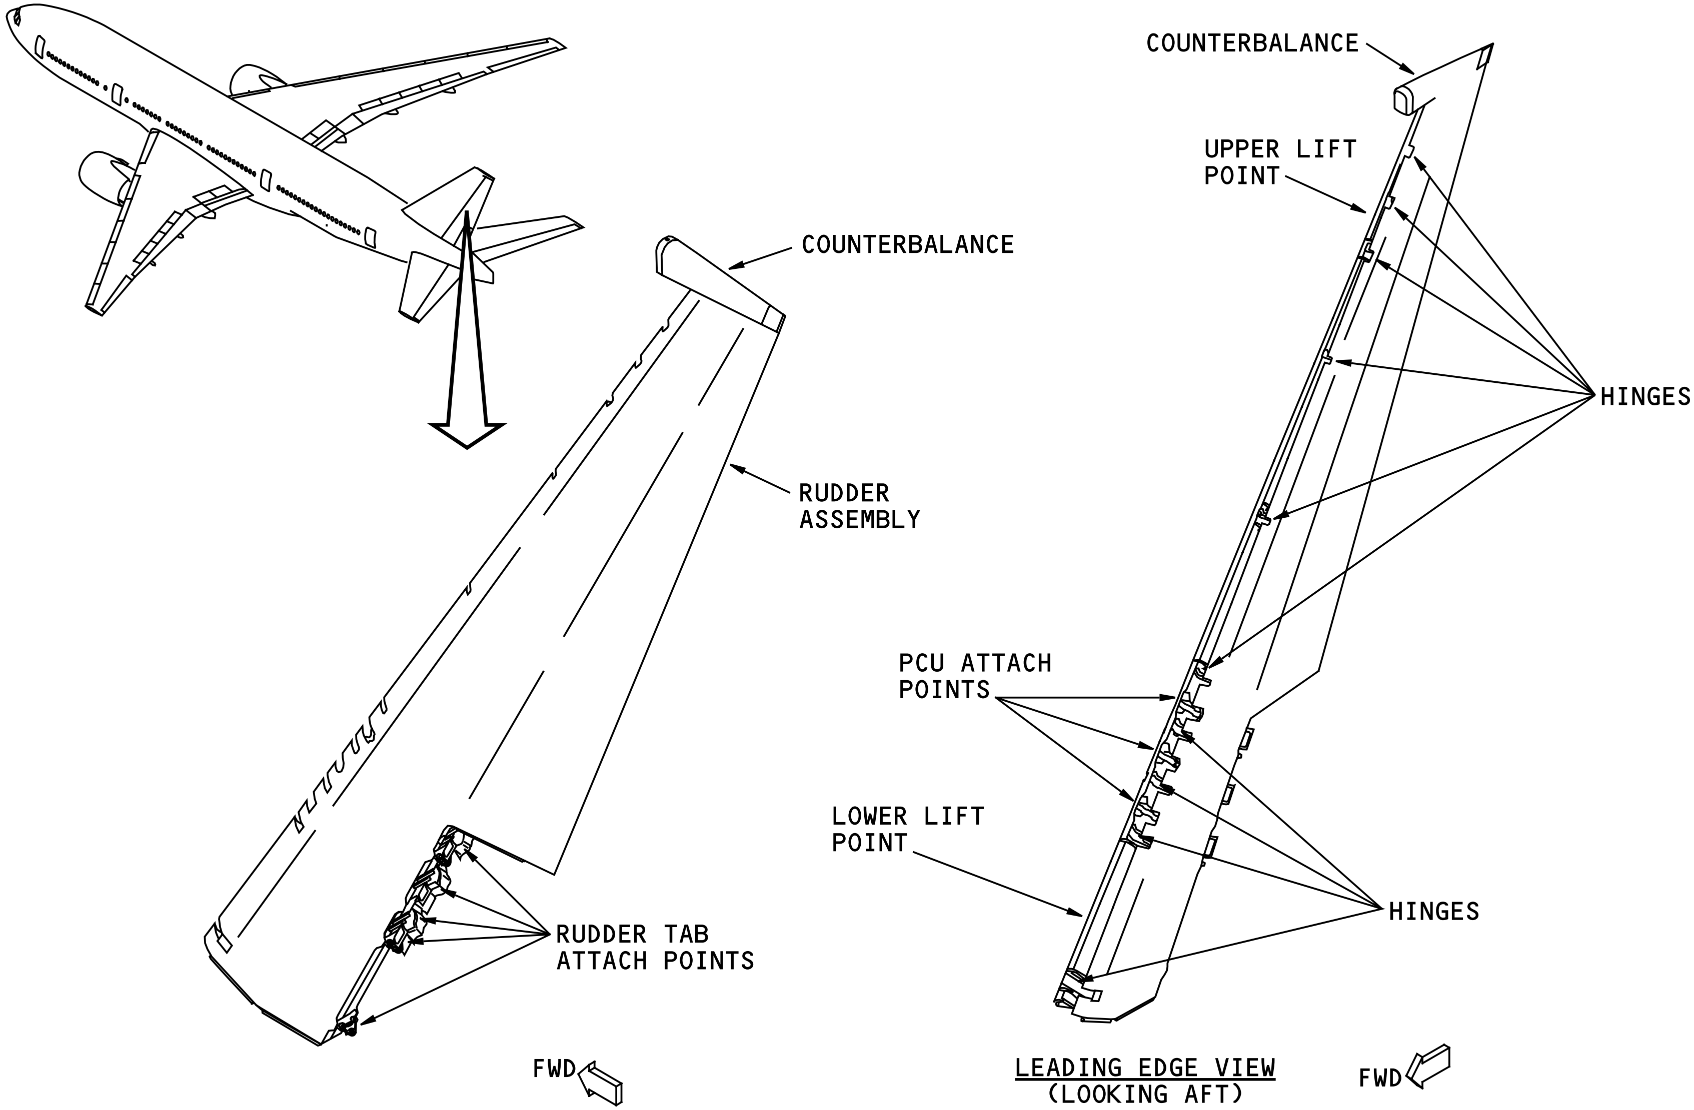
Functional Description

The rudder PCUs have internal stops that limit the rudder surface deflection. The rudder has a maximum movement of 27 degrees in both directions at low airspeed under no load conditions.

Under loads, the maximum PFCs and ACEs command signals move the rudder to a nominal position of 25 degrees in both direction at low air speed.

Training Information Point

Two hoist attach points are on the rudder. They are near the top and bottom rudder hinges. Remove a small hinge line seal panel to get access to the hoist attach points.



27-21-00-018 Rev 1

RUDDER CONTROL - RUDDER ASSEMBLY

RUDDER CONTROL - RUDDER TAB ASSEMBLY

Purpose

The rudder tab pivots on the lower trailing edge of the rudder. It moves in the same direction of the rudder to increase its effect.

Physical Description

The rudder tab is a light weight composite material structure. The skin is reinforced graphite/epoxy bonded to a core of Nomex honeycomb. The overall dimensions are approximately 50 in by 128 in (1.3 m by 3.2 m). The rudder tab weighs approximately 110 lb (50 kg).

The rudder tab attaches to the rudder by 5 hinges. Three adjustable control rods command the movement of the rudder tab based on the rudder movement. Three fairings cover the control rod connections to the rudder tab.

The rudder index plate, on the upper skin of the tail cone, shows the position of the rudder tab in relation to the airplane centerline.

Functional Description

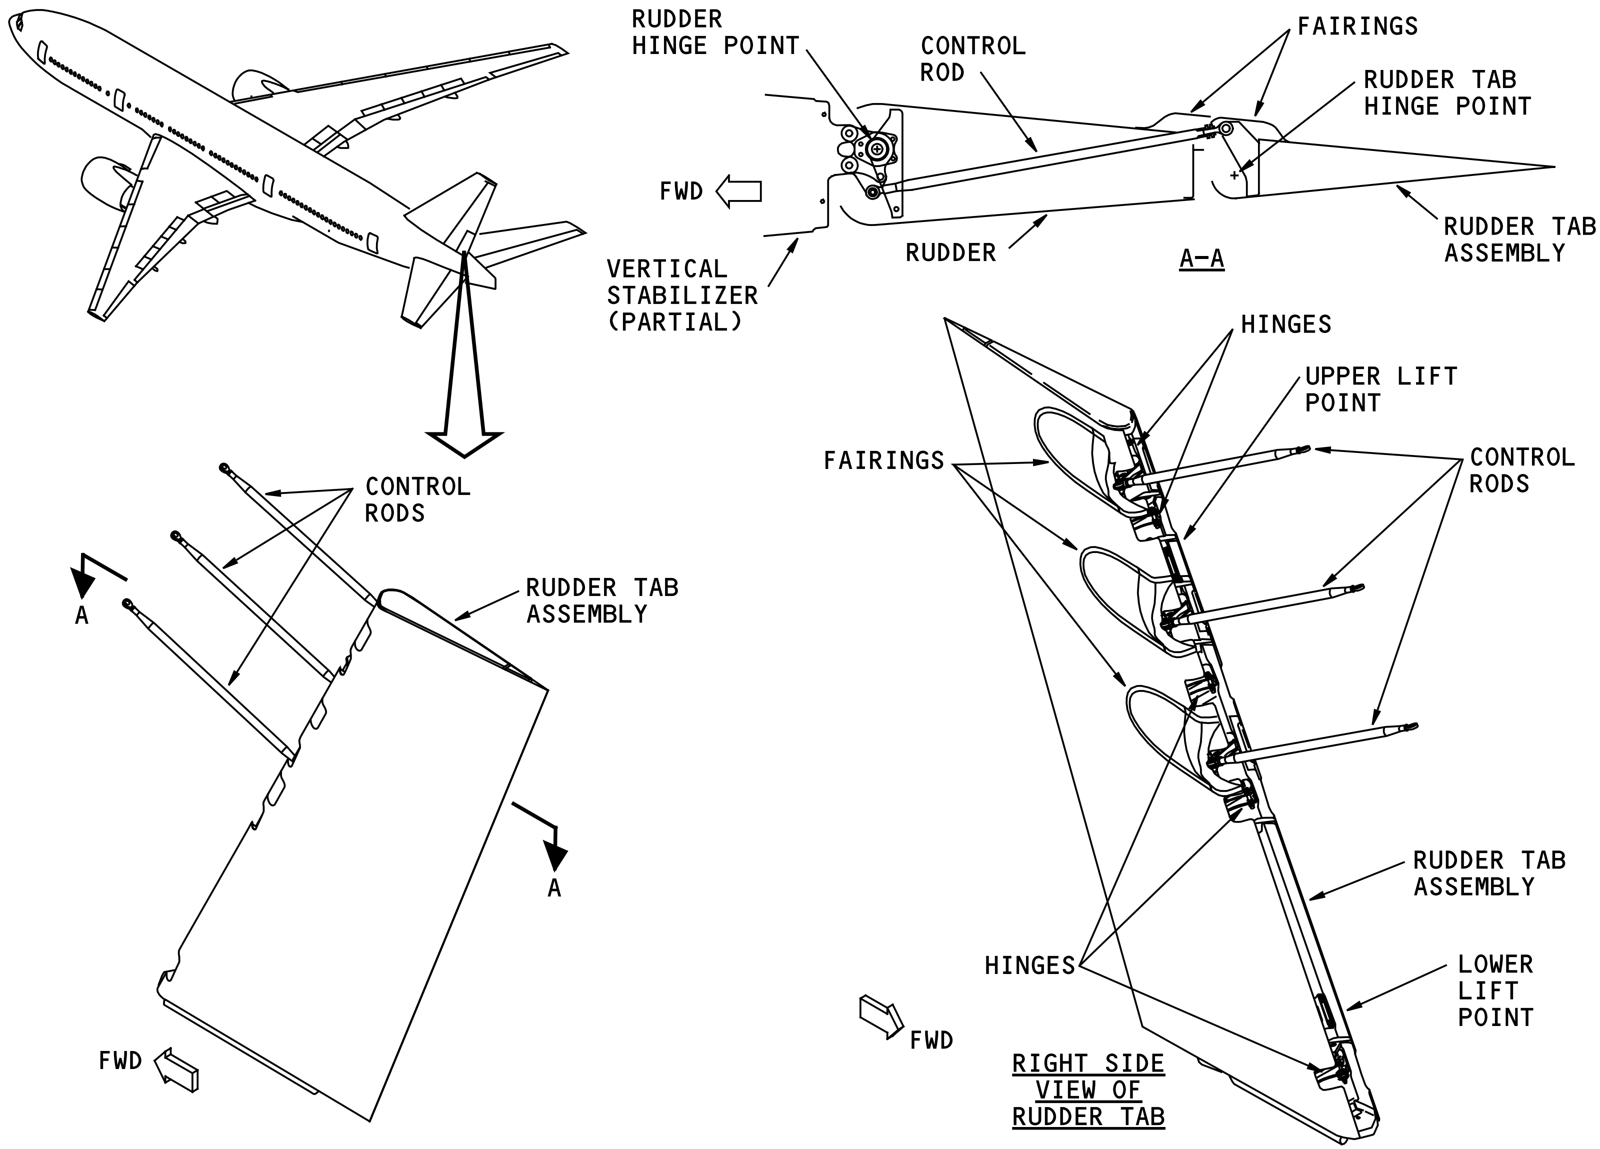
The rudder tab has a maximum movement of 27 degrees in both directions in relation to the rudder. For each degree of movement of the rudder, the rudder tab also moves one degree.

At full movement of the rudder (27 degrees), the rudder tab moves 27 degrees in relation to the rudder. This results in a 54 degree tab movement in relation to the centerline of the airplane.

Training Information Point

Two hoist attach points are on the rudder tab. They are near the top and bottom tab hinges. Remove a small hinge line seal panel and one fairing to get access to the hoist attach points.

When the airplane is on the ground with the rudder at center, the rudder tab control rods deflect the rudder tab to the left ofthe airplane centerline. This deflection is necessary for thermal expansion of the rudder tab control rods.



RUDDER CONTROL - RUDDER TAB ASSEMBLY

27-21-00-019 Rev 0

RUDDER CONTROL - FUNCTIONAL DESCRIPTION

General

The rudder control system uses input command signals from the rudder pedal position transducers.

The ACEs receive the input signals and transmit them to the PFCs. The ACEs supply output command signals to the rudder PCUs.

Rudder Pedal Position Transducers

Each ACE receives the signals from one rudder pedal position transducer. The L1 ACE and C ACE receive signals from the rudder pedal position transducers on the left shaft assembly. The L2 ACE and the R ACE receive signals from the rudder pedal position transducers on the right shaft assembly. After they change the signals to digital format, the ACEs send these signals to the PFCs through the flight controls ARINC 629 buses.

Each PFC receives input signals from all four rudder pedal position transducers. The PFC selects by mid-value selection and averaging which signal to process.

Gust Suppression Pressure Transducers

The C ACE receives signals from the upper gust suppression pressure transducer and the L1 ACE receives signals from the lower one.

Modal Accelerometers

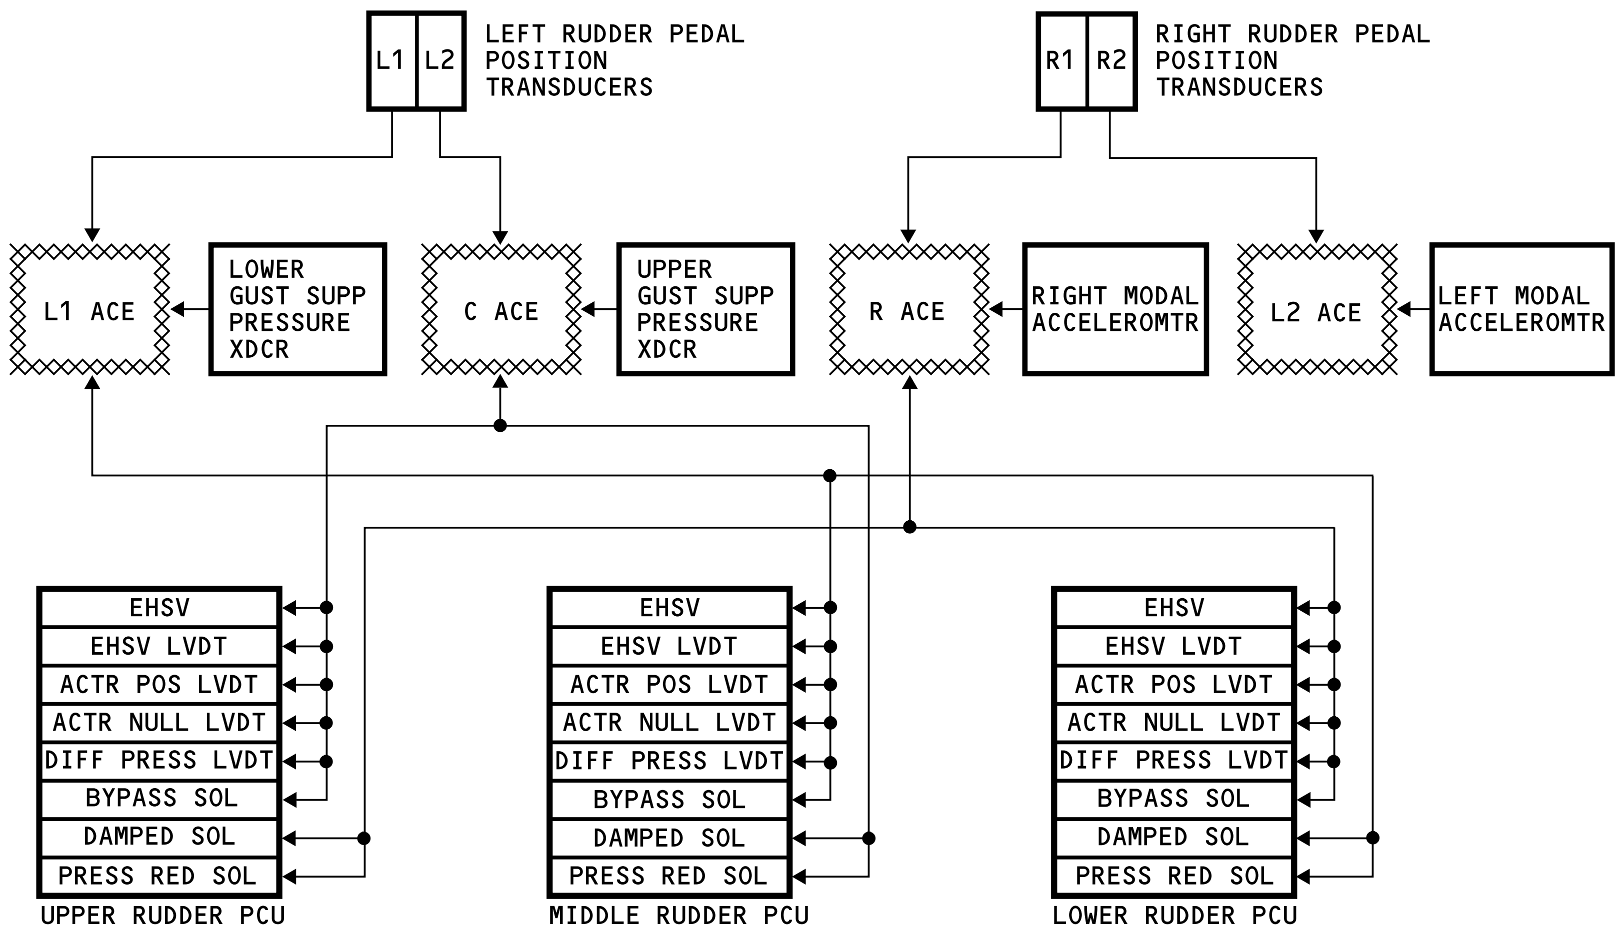
The R ACE receives signals from the right modal accelerometer and the L2 ACE receives signal from the left one.

Rudder PCUs

The L1 ACE, C ACE and R ACE send output command signals to their assigned rudder PCU and one adjacent rudder PCU.

The output command signals go from the ACE to the EHSV and the bypass solenoid of the assigned rudder PCU. The output command signals also go to the damped solenoid and the pressure reducer solenoid of one adjacent rudder PCU. The PCU sends feedback signals to its assigned ACE from:

- The EHSV position LVDT
- The actuator piston position LVDT
- The actuator null LVDT
- The differential pressure LVDT.



27-21-00-020 Rev 5 03/19/96

RUDDER CONTROL - FUNCTIONAL DESCRIPTION

RUDDER CONTROL - FUNCTIONAL DESCRIPTION - ACE SERVO LOOP

General

The ACE contains a servo loop circuit to control the command signals for the PCUs.

In normal and secondary mode, the PFC sends the command signals to the ACE. In direct mode, the ACE calculates the command signals.

Servo Loop Operation

The rudder command signals go through a servo loop in the ACEs. The command signals then go to the EHSV of the PCUs. The ACEs also use the command signals to monitor for failures.

The movement of the EHSV sends hydraulic pressure to extend or retract the actuator.

The EHSV LVDT measures the movement of the EHSV and supplies a feedback signal to the ACEs. The ACEs use this feedback signal to monitor failures.

The actuator position LVDT measures the movement of the actuator and supplies a signal to the actuator null LVDT.

The actuator null LVDT is in series with the actuator position LVDT. The actuator null LVDT modifies the signal from the actuator position LVDT.

The actuator null LVDT supplies a feedback signal to the ACEs to close the servo loop. The ACEs use this feedback signal to monitor for failures. This signal also goes to the PFC.

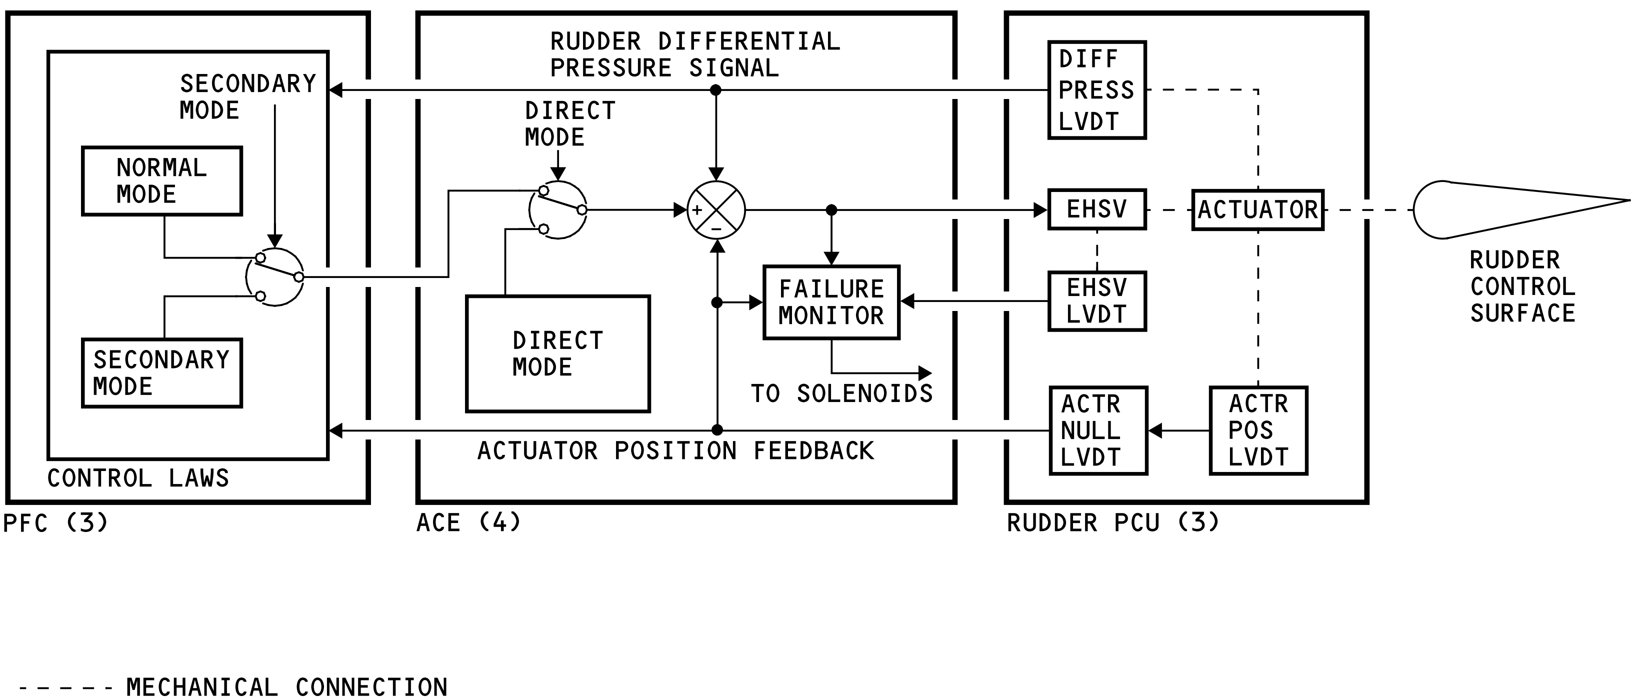
The differential pressure LVDT measures the differential pressure across the actuator. The signal from the differential pressure LVDT goes to the ACEs for the servo loop. The signal also goes to the PFCs for force fight equalization.

Failure Monitor

The ACE has a failure monitor to check the proper operation of the PCU. The monitor uses the ACE command signal and the feedback signals from the EHSV LVDT and the actuator LVDT. When the failure monitor finds a fault with the PCU or the ACE, it de-energizes the PCU bypass, damped and pressure reducer solenoids.

Training Information Point

During installation of the rudder PCU, the actuator null LVDT requires adjustment. Remove the LVDT access cover to adjust the LVDT.



27-21-00-021 Rev 3 01/08/96

RUDDER CONTROL - FUNCTIONAL DESCRIPTION - ACE SERVO LOOP

RUDDER CONTROL - FUNCTIONAL DESCRIPTION - RUDDER TRIM

General

The rudder trim selector and the manual trim cancel switch send discrete electrical signals to the L1 ACE and the R ACE. The ACEs transmit these signals to the PFCs via the flight controls ARINC 629 buses.

The L1 and R ACEs, and the PFCs operate the rudder trim function as a two channel system. The L1 ACE supplies rudder trim actuator engagement and servo loop control. The R ACE supplies rudder trim actuator engagement, arm, and brake status control.

In normal mode, when the thrust asymmetry compensation (TAC) function is active, the PFCs automatically control the rudder trim actuator through the L1 and R ACEs.

During normal and secondary modes of operation, the PFCs use pilot inputs from the rudder trim selector and the manual trim cancel switch to control the rudder trim actuator. The PFCs transmit the commands back to the ACEs which then control the rudder trim actuator.

During direct mode of operation, the ACEs execute the requests from the rudder trim selector and directly command the rudder trim actuator.

Rudder Trim Switches

The rudder trim selector has three pairs of contacts. The 15 degree contacts send an arm status discrete signal directly to the rudder trim actuator. The 25 degree contacts signal the L1 ACE to operate the rudder trim actuator at low rate of speed in the direction selected. The 40 degree contacts signal the R ACE to operate the rudder trim actuator at high rate of speed.

The MANUAL TRIM CANCEL switch signals the R ACE to remove any pilot commanded trim. The rudder trim actuator moves at high rate of speed.

Rudder Trim Actuator

The rudder trim actuator contains:

- A 28v dc electric motor with multiple speed electronic control
- An electromagnetic brake to lock the actuator when the brake is de-energized
- A tachometer to supply speed rate feedback signals to the servo loop internal to the actuator
- An actuator position RVDT.

The rudder trim actuator position RVDT sends position signals to the L1 ACE and the PFCs for servo loop control. These signals also go to the AIMS cabinets which control the rudder trim position indicator.

Rudder Trim Position Transducer

The rudder trim position transducer sends position signals to the R ACE and the PFCs. The PFCs monitor these signals and compare them with the rudder trim actuator position RVDT.

RUDDER CONTROL - FUNCTIONAL DESCRIPTION - RUDDER TRIM

Normal and Secondary Mode Control

During normal and secondary modes of operation of the PFCS, the PFCs control the rudder trim actuator through the L1 and R ACEs.

When the pilot turns the rudder trim selector, command signals from the 15 degree switch go to the rudder trim actuator. When the pilot turns the rudder trim selector further or pushes on the manual trim cancel switch, the switch command signals go to the PFCs through the L1 and R ACEs.

The rudder trim actuator supplies arm and brake status signals to the R ACE and the PFCs. The engage command from the PFCs, through L1 and R ACEs, causes the electromagnetic brake to release. The PFCs monitor the status of the brake release. With the brake released, the PFCs supply a servo loop command to the rudder trim actuator through the L1 ACE. The signal from the rudder trim actuator position RVDT closes the servo loop in the L1 ACE.

The tachometer supplies rate feedback to the speed control within the rudder trim actuator.

The PFCs compare the signals from the rudder trim actuator RVDT with the signals from the rudder trim position transducer. If the signals do not agree, the PFCs stop the operation of the rudder trim.

Rudder Trim Operation in Normal and Secondary Mode

With the rudder trim selector at less than 25 degree rotation, the PFCs and ACEs do not command the brake to release. Also they do not send a servo loop command. The rudder trim actuator then does not move.

When the pilot turns the rudder trim selector to 25 degree or more, the rudder trim actuator operates. The rudder trim actuator rate is a function of the rudder trim selector position. The trim rate of the rudder is also a function of the rudder ratio.

When the pilot moves the rudder trim selector to about 25 degrees, the PFCs and ACEs cause the rudder trim actuator to move at a rate of 0.5 unit per second.

With the selector turned to about 40 degrees, the PFCs and ACEs cause the rudder trim actuator to move at a rate of 2 units per second.

The manual trim cancel switch causes the rudder trim actuator to remove manual trim inputs at a rate of 2 units per second. The manual trim cancel switch does not remove trim commands caused by TAC.

In normal mode, when TAC is active, the PFCs and the L1 and R ACEs cause the rudder trim actuator to move at a rate as much as 6 units per second.

On the ground, the PFCs limit the rudder trim actuator movement to 17 units of rudder trim. In flight, the PFCs let the trim actuator move to its mechanical stops. This causes a maximum of about 22.5 units of rudder trim at low airspeed. Because the rudder trim indicator limit is 17 units, the indicator shows 17 units for a trim condition of 17 units or more.

If the R ACE does not operate, automatic trim by the TAC function does not operate. The pilot can control manual trim with the rudder trim selector. The PFCs then control the rudder trim actuator through the L1 ACE. In this condition, the rudder trim operates at 0.5 units per second. The 40 degree selector position and the manual trim cancel switch do not operate.

If the L1 ACE does not operate, the PFCs stop the operation of the rudder trim.

Direct Mode Control

During direct mode operation, the ACEs directly control the rudder trim actuator.

With the rudder trim selector at less than 25 degree position, the ACEs do not command the brake to release. Also the L1 ACE does not send a servo loop command. The rudder trim actuator then does not move.

When the selector is at 25 or 40 degree position, the ACEs cause the rudder trim actuator to move the rudder. The trim rate is at 1.4 units per second with the flaps and slats not retracted and 0.6 units per second with the flaps and slats retracted.

The manual trim cancel switch function is not operative in direct mode.

Indications

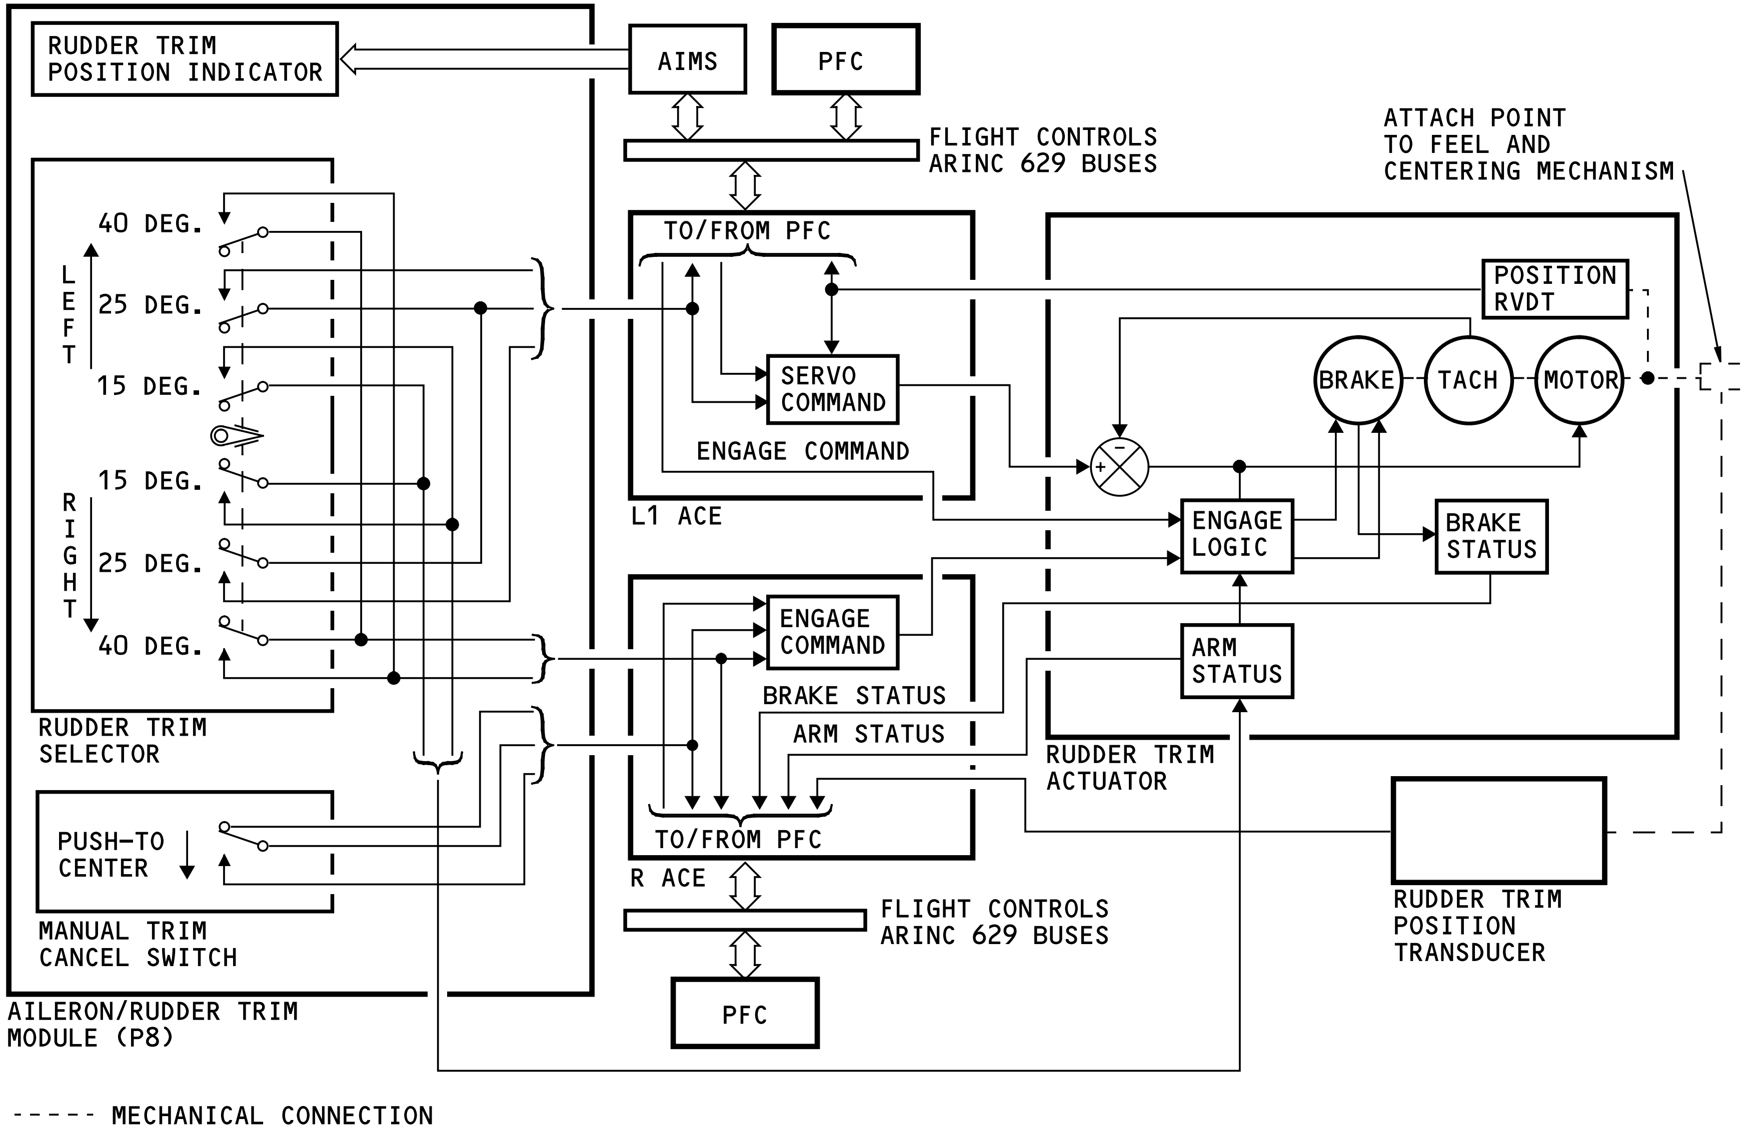
The warning message CONFIG RUDDER shows on the EICAS display when all of these conditions happen:

- The rudder trim is not within 2 units from center
- Either the left or right engine thrust is more than the takeoff threshold
- The airplane is on the ground
- TAC is not active.

The advisory message THRUST ASYM COMP shows when the rudder trim system is defective.

The status message FLIGHT CONTROL SYS shows when the rudder trim system has failed.

The rudder trim indicator on the center aisle stand is blank when the rudder trim system is defective.



27-21-00-025 Rev 7 03/27/95

RUDDER CONTROL - FUNCTIONAL DESCRIPTION - RUDDER TRIM

THIS PAGE INTENTIONALLY LEFT BLANK

RUDDER CONTROL - FUNCTIONAL DESCRIPTION - THRUST ASYMMETRY COMPENSATION

General

The thrust asymmetry compensation (TAC) helps control the airplane during asymmetrical engine thrust conditions. The TAC protection function operates in the PFCS normal mode only.

The pilot can disarm the TAC function with the TAC switch on the P5 panel.

Input Signals

The TAC function receives thrust data for the two engines from the engine data interface units (EDIU). The EDIUs use the N1 rotational speed signals from the electronic engine controls (EECs) to calculate the thrust values. The EECs also send other engine data to the EDIUs to make sure the N1 signal is accurate. The EDIUs send the engine thrust data to the PFCs through the AIMS.

TAC also uses the CAS signal from the ADIRU, flap position from the FSEUs and the TAC switch position from the C ACE.

Functional Description

The TAC function arms manually or automatically. TAC arms manually when you move the TAC switch from OFF to AUTO and all these conditions occur:

- All the signals used by TAC are satisfactory
- The rudder trim can operate
- The PFCS is in normal mode
- The L1 ACE and R ACE are not in direct mode.

When the TAC switch is in the AUTO position, the TAC function arms automatically. The conditions for TAC automatic arm are the manual arm conditions and these conditions:

- The PFCs find that the airplane is on the ground
- CAS is less than 70 knots
- One or both engines are running with the thrust levers at the idle position or the engines are not running.

The TAC function disarms when the TAC switch is in the OFF position. It also disarms for any one of these conditions:

- Any signal used by TAC is not satisfactory
- The rudder trim is defective
- The PFCS is not in normal mode
- The L1 ACE or R ACE is in direct mode
- The L1 ACE or R ACE status signal is not available.

The TAC function is active when it is armed and all of these conditions occur:

- CAS is more than 70 knots
- The thrust reversers do not have a command to deploy
- The thrust difference between the two engines is more than 6000 lbs, about 10 percent of the maximum rated thrust.

RUDDER CONTROL - FUNCTIONAL DESCRIPTION - THRUST ASYMMETRY COMPENSATION

When TAC is active, the PFCs use the difference between the thrust signals from the EDIUs to calculate rudder and rudder trim commands. The TAC function initially calculates a high rate rudder command to make allowance for the yaw moment caused by the thrust difference. This command goes to the ACEs to move the rudder PCUs.

The TAC function also sends rudder trim commands to the ACEs. The rudder trim actuator movement then backdrives the rudder pedals and the pedal position transducers. The PFCs make allowance for the input signals from the pedal position transducers to keep a near constant rudder PCU command.

The PFCs limit the TAC authority to 60 percent of available rudder.

If TAC is active when there is a command for thrust reverser deployment during landing or refused takeoff, the PFCs automatically ramp the TAC trim commands to zero trim. The trim actuator ramps to zero at a speed of 6 units per second.

When TAC is active, the pilot can use the rudder pedals or the rudder trim switches. The PFCs add these command signals to the TAC commands to control the rudder PCUs. If the pilot pushes on the manual trim cancel switch, the PFCs send a command to the rudder trim actuator to remove any input made with the rudder trim selector. The TAC command to the rudder trim actuator is not removed.

If TAC is active during autoland operation of the autopilot, the engine out correction of the autopilot is disabled. This is done so this function of the autopilot does not control during TAC operation. If the pilot moves the pedals, TAC stays active but the autopilot disengages.

The TAC function stops to be active when the thrust difference between the two engines is less than 3 percent of the maximum rated thrust.

If the airspeed data becomes unreliable, the TAC function uses the flap position signal to limit the gain of the rudder and rudder trim command.

<u>Indications</u>

The amber OFF light shows in the TAC switch on the P5 panel and the advisory and status messages THRUST ASYM COMP show when one of these conditions occurs:

- The rudder trim is defective
- Loss of the thrust data from 2 of 3 channels in one EDIU
- Loss of left and right engine running data
- The two engines are not running in the air
- The R, L1 or C ACE is failed or in direct mode
- The PFCS is not in normal mode
- The TAC switch is in the OFF position
- The TAC switch position signal is lost.

When the TAC function is armed after it was disarmed, the above indications do not show.

RUDDER CONTROL - FUNCTIONAL DESCRIPTION - THRUST ASYMMETRY COMPENSATION

ELEVATOR CONTROL - INTRODUCTION

General

The elevators supply short-term correction of the pitch attitude of the airplane. This movement is around the lateral axis of the airplane.

There is one elevator panel on each side of the aft fuselage. Hinges attach the elevator to the rear spar of the horizontal stabilizer. Two hydraulic power units move each elevator panel.

Pitch Control

The pilots manually command pitch correction with forward and aft movement of the control column.

When engaged, the autopilot automatically commands the elevators. During autopilot operation, actuators backdrive the control columns.

Elevator Off-load Function

The elevator off-load function transfers manual and autopilot commanded elevator deflection to the stabilizer. The stabilizer movement allows the elevators to move to the neutral position.

ELEVATOR CONTROL - INTRODUCTION

ELEVATOR CONTROL - GENERAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

ELEVATOR CONTROL - GENERAL DESCRIPTION

General

The pilots manually command the elevators and the autopilot automatically commands them.

Manual Operation

The flight crew uses two conventional control columns to command pitch. They connect to torque tubes joined by a break-out mechanism. This allows one control column to move if the other jams.

The flight crew can make manual commands to the elevator in the normal mode with the pitch trim switches. This is possible only if the airplane is in the air.

Six position transducers change flight crew control column commands to analog electrical signals. These signals go to the four actuator control electronics (ACEs) that change the signal to digital format. The digital signals go to the primary flight computers (PFCs) through the ARINC 629 buses.

The PFCs use data from these sources to calculate control surface commands:

- Column position
- Air data inertial reference unit (ADIRU)
- Airplane information management system (AIMS).

The PFCs send digital commands to the ACEs, which change them to analog signals. The ACEs then send the analog surface position commands to the power control units (PCUs). The PCUs move the elevators. The position transducers on the PCU hydraulic pistons send actuator position feedback to the PFCs through the ACEs.

The PFCs use data from the ADIRU to calculate elevator feel commands. The feel command goes through the ACE to the left and right feel actuators on the elevator feel units. The feel actuators supply to the column a variable feel based on airspeed.

The ACEs get analog signals from the force transducers and send them to the PFCs. The PFCs use these signals to verify control column null position.

Autopilot Operation

When engaged, the autopilot flight director computers (AFDCs) control airplane pitch. The AFDCs supply pitch commands to the PFCs through the flight controls ARINC 629 buses. The PFCs process these commands to supply position commands for the elevators. These position commands go through the ACEs to the PCUs.

The PFCs also supply column backdrive commands. The PFCs send these commands to the AFDCs, which supply column movement commands to the backdrive actuators. The backdrive actuators move the control columns the same amount as the pilot would move them manually for the same surface movement. This gives the flight crew visual feedback when the AFDS moves the flight control surfaces. The flight crew can override the autopilot with sufficient force on the control column to overcome the backdrive.

Protection Functions

Overspeed and stall protection functions in the PFCs supply flight envelope protection in both manual and autopilot operation. The overspeed protection supplies a pitch-up elevator command. The stall protection supplies a pitch-down elevator command.

ELEVATOR CONTROL - GENERAL DESCRIPTION

ELEVATOR CONTROL - COMPONENT LOCATIONS

General

Pitch control components are in these areas:

- The flight deck
- Below the flight deck floor
- The tail.

Flight Deck Components

The control columns are in the flight deck.

Components Below the Flight Deck

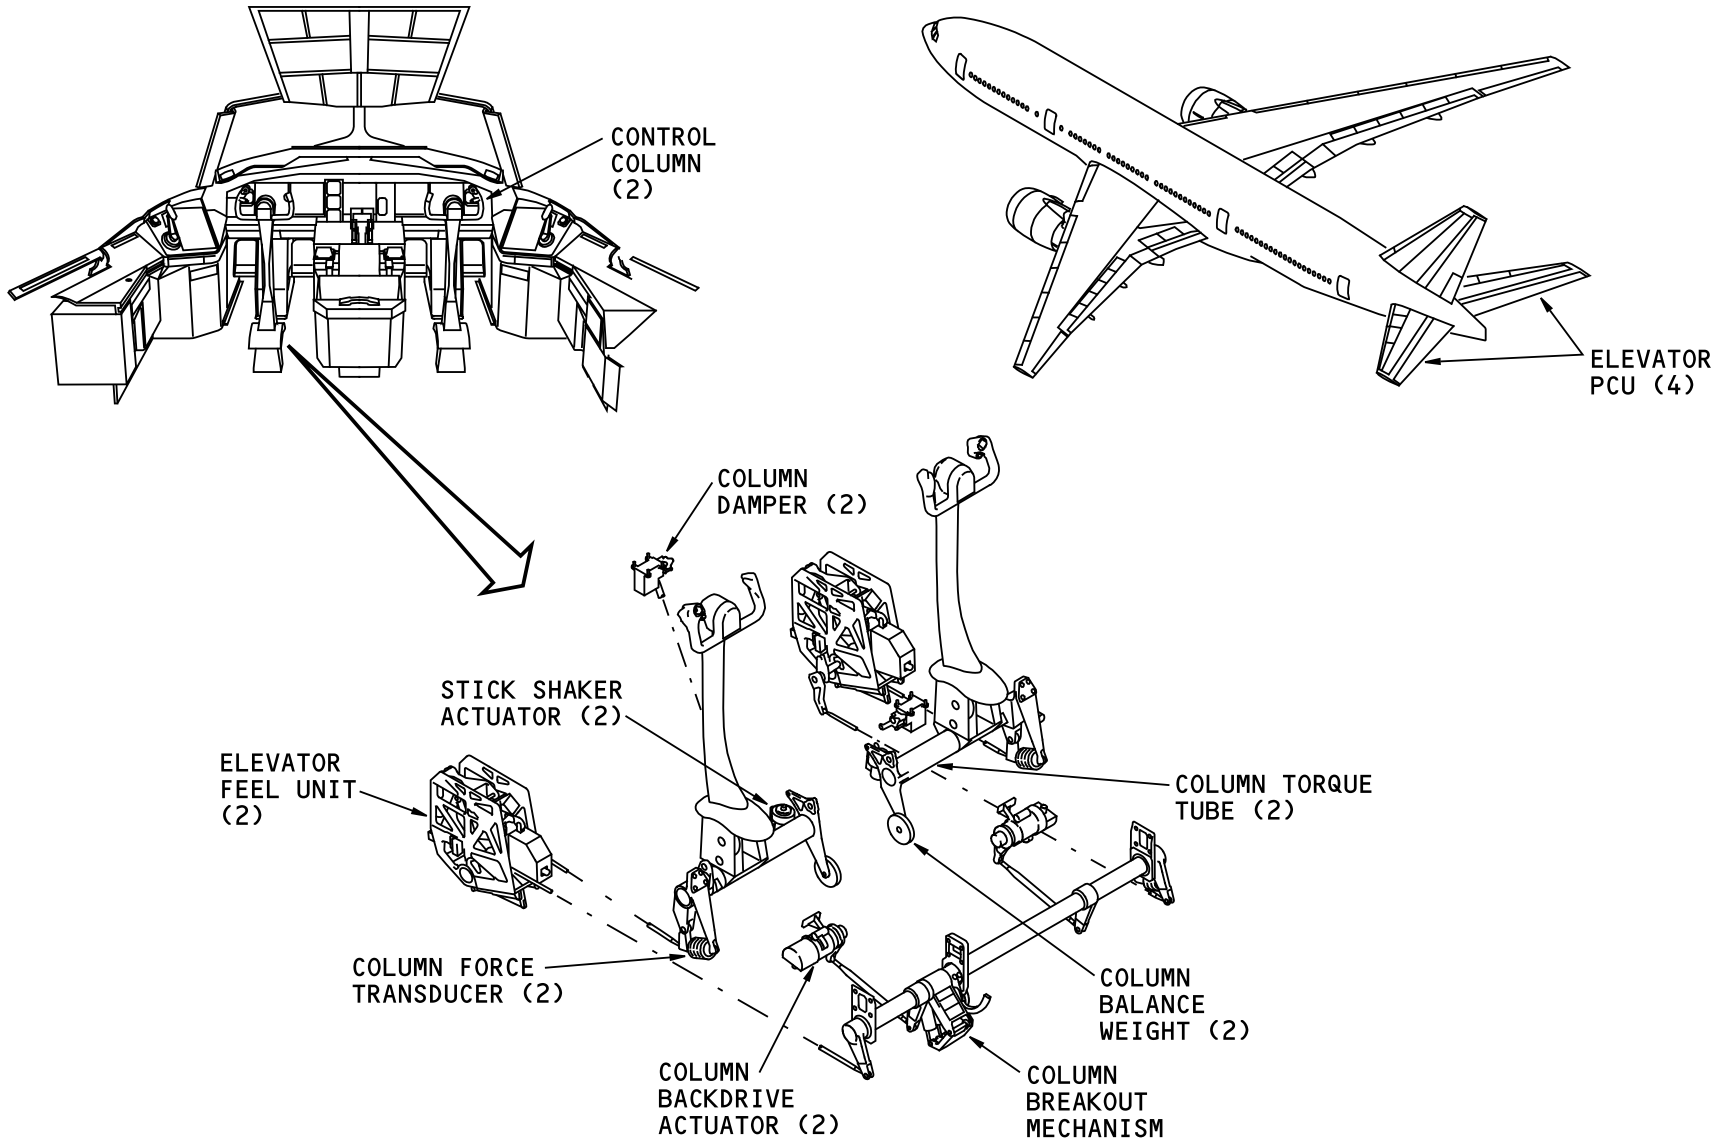
These forward controls are below the flight deck floor and above the nose gear wheel well:

- Column torque tubes
- Column balance weights
- Column dampers
- Stick shaker actuators
- Column force transducers
- Elevator feel units
- Column backdrive actuators
- Column breakout mechanism.

Access to these components is through the forward equipment center door.

Tail Components

The elevators and their PCUs are on the rear spar of the horizontal stabilizer. Two PCUs connect to each elevator. Access to the PCUs is by panels under the stabilizer.



ELEVATOR CONTROL - COMPONENT LOCATIONS

27-30-00-003 Rev 1 07/18/1997

ELEVATOR CONTROL - ANALOG AND DISCRETE INTERFACES

General

All pitch control analog interfaces within the PFCS go through the ACEs. Each ACE has interfaces with these components:

- Column position transducers
- Column force transducers
- Elevator feel actuators
- Elevator PCUs.

Column Position Transducers

There are six position transducers, three for each control column. The transducers send control column position and movement data to the ACEs.

Column Force Transducers

Two column force transducers measure the forces applied to the control column. The transducers send this data to the ACEs.

Elevator Feel Actuators

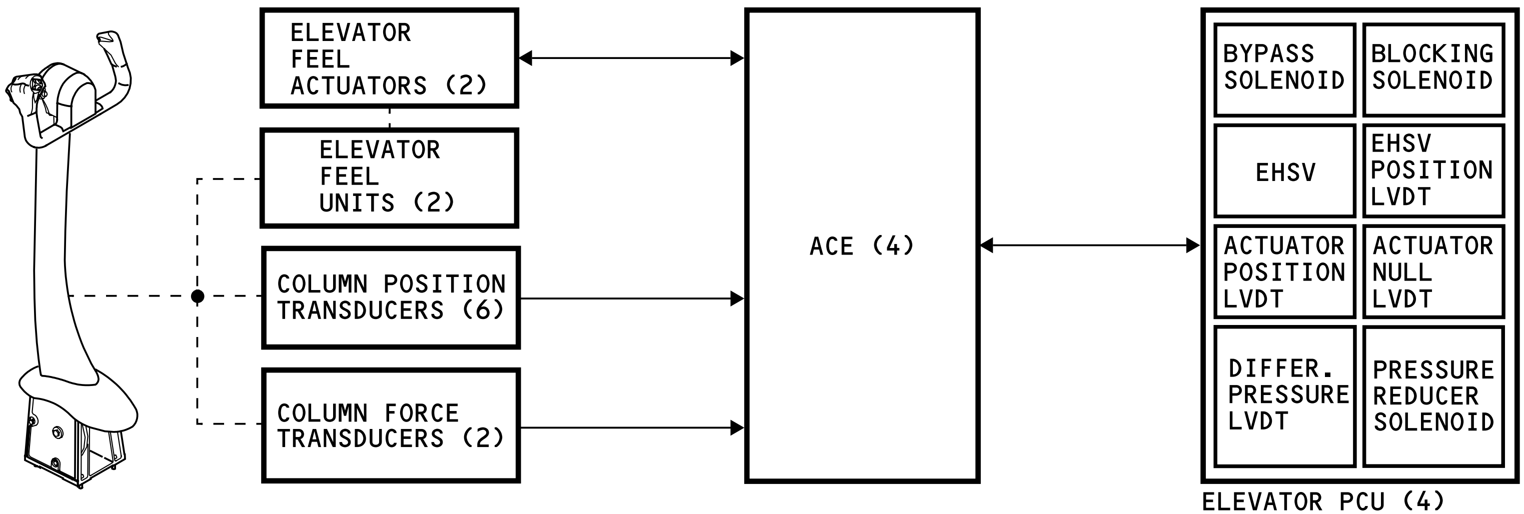
An elevator feel actuator is in each of the elevator feel units. They supply a feel force to the columns through the feel units. The ACEs command the elevator feel actuators. The elevator feel actuators also send position feedback signals to the ACEs.

Elevator PCUs

Each of the four elevator PCUs receive analog and discrete electrical signals from the ACEs. The discrete signals are for the bypass, blocking, and pressure reducer solenoids. The analog signal is for the electrohydraulic servo valve (EHSV).

Each of the four elevator PCUs sends these analog feedback signals to the ACEs:

- EHSV position LVDT
- Actuator position LVDT
- Actuator null LVDT
- Differential pressure LVDT.



27-30-00-004 Rev 2 07/18/1997

ELEVATOR CONTROL - ANALOG AND DISCRETE INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

ELEVATOR CONTROL - FORWARD CONTROLS

General

These are the forward controls of the pitch control system:

- Control columns
- Column torque tubes
- Column force transducers
- Compliance springs
- Column dampers
- Column balance weights
- Elevator feel units
- Elevator feel actuators
- Column position transducers
- Column breakout mechanism
- Backdrive actuators
- Stick shaker actuators
- Travel stops.

Control Columns

The two control columns are conventional in design and serve as the interface between the pilots and the flight controls. Forward and aft movement of the control columns command the movement of the elevators through flight control system electronics.

Each control column connects to a torque tube.

Column Torque Tubes

Each column torque tube moves when the control column moves. These are the components on the torque tube:

- Force transducer
- Compliance spring
- Column damper
- Column balance weight
- Column stick shaker.

The torque tubes connect to the elevator feel and centering mechanisms with a control rod.

Elevator Feel Units

The two elevator feel units supply feel forces to the pilots and column position data to the ACEs. Each feel unit has a feel and centering mechanism.

The elevator feel actuators on each elevator feel unit change the feel force on the control column.

Each elevator feel unit connects to the column breakout mechanism with a control rod.

Column Position Transducers

Three column position transducers are on each feel unit.

Column Breakout Mechanism

The column breakout mechanism connects the two control column systems together. The mechanism also makes it possible to move one control column should the other jam.

ELEVATOR CONTROL - FORWARD CONTROLS

Backdrive Actuators

Two backdrive actuators connect to cranks on the left and right sides of the column breakout mechanism. The backdrive actuators are part of the autopilot system.

See the autopilot flight director system section for more information on the backdrive actuators (AMM PART I 22-11).

Stick Shaker Actuator

One stick shaker actuator is on each column torque tube.

See the warning electronic system section for more information on the stick shaker actuators and stall warning function (AMM PART I 31-51).

Travel Stops

Travel stops are on the column torque tubes. They limit control column travel to 9.6 degrees forward and 10.5 degrees aft.

NOTE: EXPANDED VIEW
------- MECHANICAL CONNECTION
EX RIG PIN LOCATION

ELEVATOR CONTROL - FORWARD CONTROLS

ELEVATOR CONTROL - ELEVATOR FEEL UNIT

Purpose

Two elevator feel units supply feel forces to the control columns. They also supply a centering function that returns the control column to neutral.

Physical Description

The two elevator feel units are similar but not interchangeable.

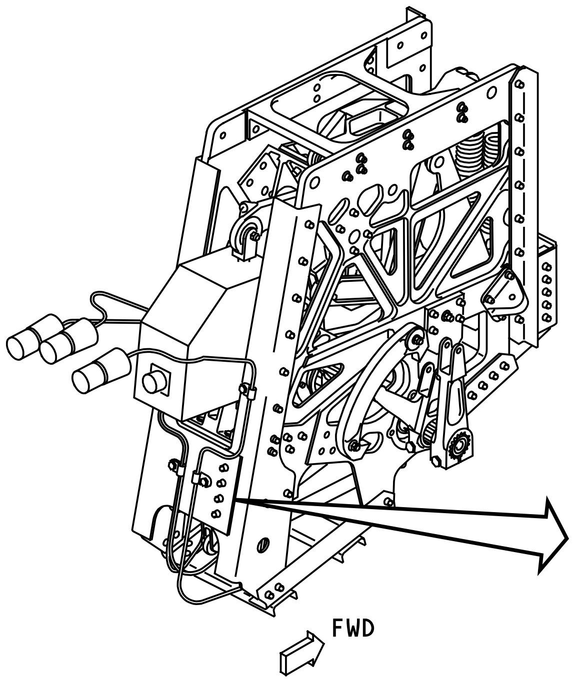
Each elevator feel unit has a single cam and roller unit. The cam attaches by a spline to the shaft of the feel unit. The input crank, connected to the column torque tube, turns the shaft and the cam. The follower assembly has a roller which rides on the cam. A centering arm, which pivots on the elevator feel unit structure, supports the follower assembly and attaches to the feel springs. Two feel springs, between the centering arm and the spring arm, keep the roller on the cam. The two feel springs provide the feel force and the centering function. The output crank also attaches to the shaft of the feel unit. The output crank connects to the aft torque tube with a control rod.

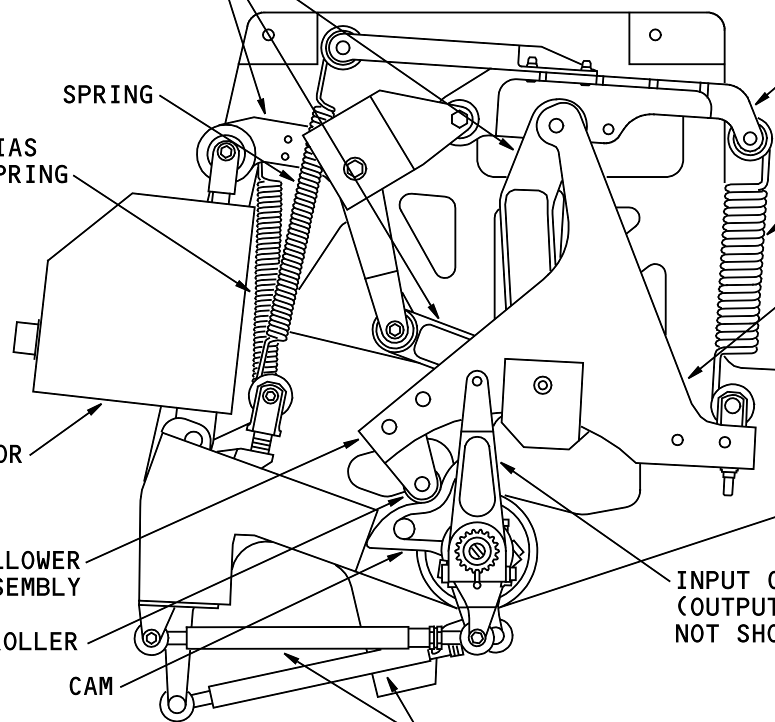
An elevator feel actuator and three column position transducers are on each elevator feel unit.

The elevator feel actuator connects to the variable feel mechanism. This mechanism consists of levers and a linkage which connect to the spring arm. A spring connects to the mechanism to take up any play in the mechanism. A bias spring, near the feel actuator, forces the feel actuator to fully retract when it does not operate.

Location

The two elevator feel units are under the flight deck. Access is by the forward equipment door or from the MEC.





ELEVATOR FEEL UNIT
(STRUCTURE NOT SHOWN FOR CLARITY)

ELEVATOR CONTROL - ELEVATOR FEEL UNIT

ELEVATOR CONTROL - ELEVATOR FEEL ACTUATOR

Purpose

The feel actuators change the geometry of the elevator feel units to change the feel force at the control columns.

Physical Description

The two actuators are identical and interchangeable LRUs.

The feel actuator has a 28v dc reversible electric motor. The actuator extends 2.5 inches (63.5) maximum. Each actuator weighs about 4.27 lb (1.6 kg).

The actuator attaches to the elevator feel unit structure. The actuator rod end attaches to the input lever of the variable feel mechanism.

Location

The elevator feel actuators are on the aft side of the elevator feel units.

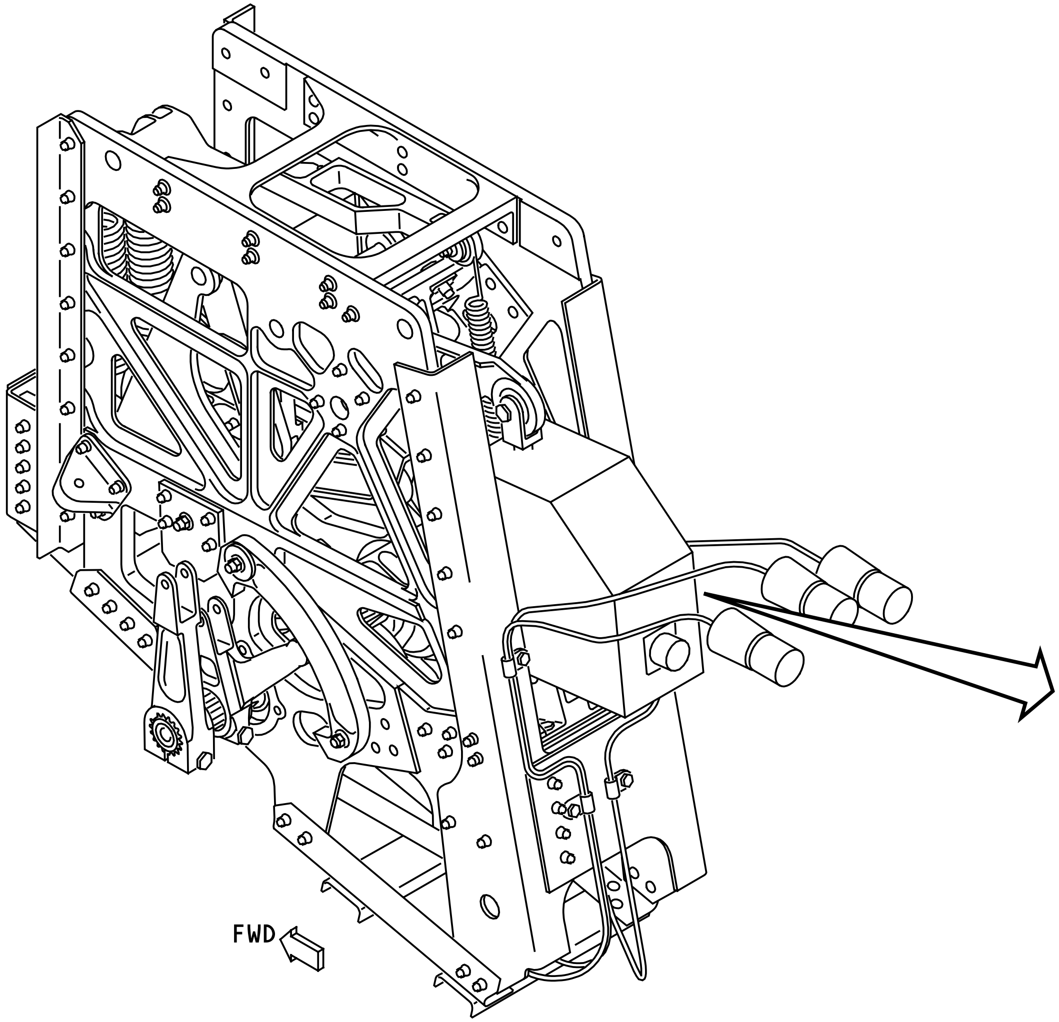
Functional Description

When the elevator feel actuator extends, it changes the configuration of the feel mechanism in the feel unit. When the column moves, this causes an increase in the extension of the feel springs. This increases the feel force at the columns.

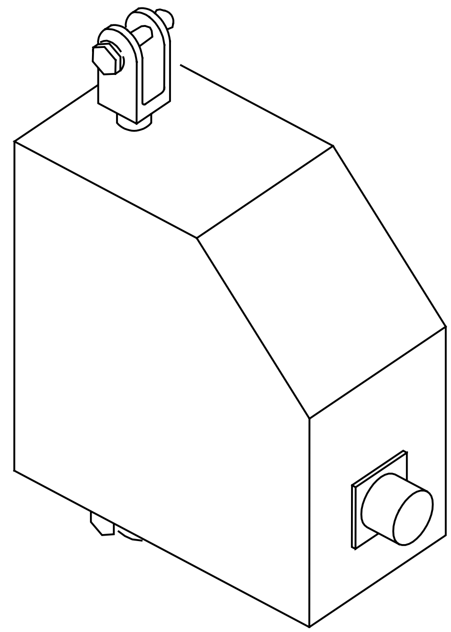
The rod end of the actuator moves in response to the commands from the ACEs. The L2 ACE sends commands to the left feel actuator and the C ACE sends commands to the right feel actuator. An RVDT in the feel actuator supplies a position feedback signal to the PFCs through the ACE.

Indications

The status message FLIGHT CONTROL SYS shows when one, or more, elevator feel actuator is defective.



ELEVATOR FEEL UNIT



FEEL ACTUATOR

ELEVATOR CONTROL - ELEVATOR FEEL ACTUATOR

ELEVATOR CONTROL - ELEVATOR FEEL - FUNCTIONAL DESCRIPTION

General

The elevator feel unit supplies a feel force to the control columns. The elevator feel actuator changes the feel force. The feel at the control column increases with the amount of column movement and the speed of the airplane.

Feel and Centering

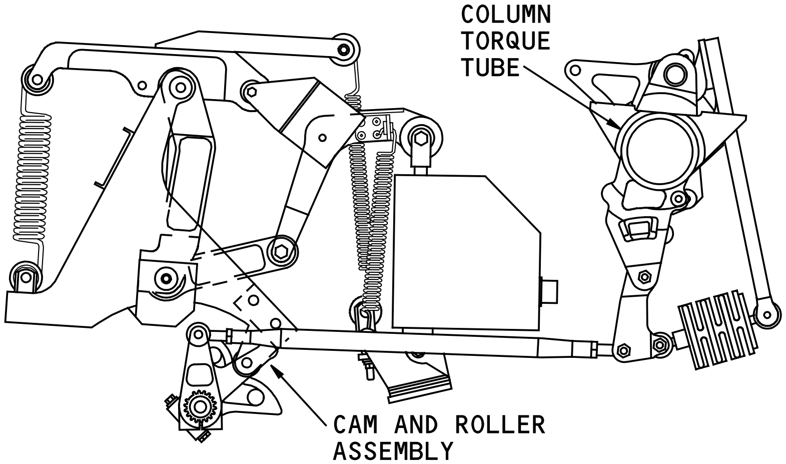
When the pilot moves the control column, the cam in the elevator feel unit rotates. This causes the cam follower to move and the centering arm to extend the feel springs. At low airspeed, the feel force at the control column is from 6.4 lb (2.9 kg) at breakout to a maximum of 43.3 lb (19.6 kg) at column maximum travel.

When the pilot releases the control column, the feel springs force the cam follower back to the cam detent. This returns the elevator control system to the neutral position.

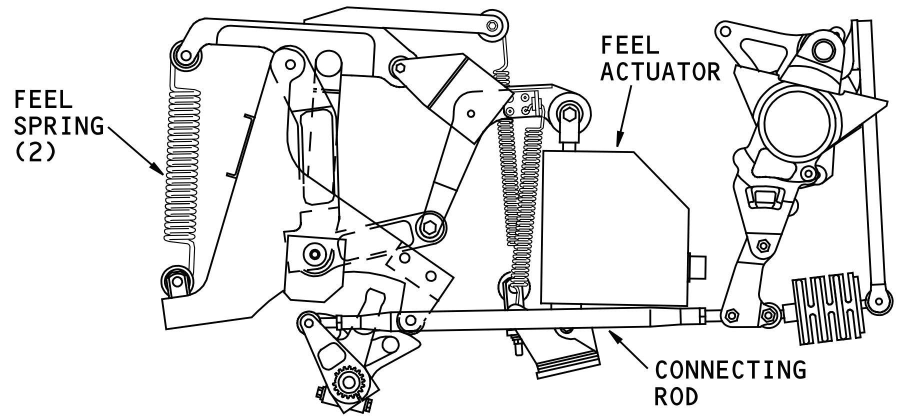
Variable Feel

As the speed of the airplane increases, the feel actuator extends gradually. This causes the levers of the variable feel mechanism to move the mechanism pivot point. The feel springs extend further with the mechanism in this position. When the pilot moves the column, the increased spring extension causes an increase of the column feel force.

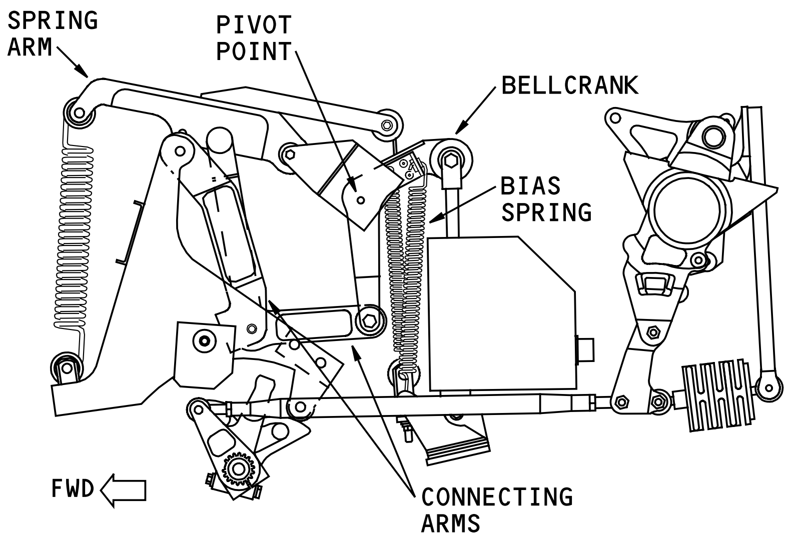
The feel actuator extends and retracts as the airspeed increases and decreases. This causes the column feel force, at full travel, to change from 43.3 lb (19.6 kg) at low airspeed to approximately 100 lb (45.4 kg) at high airspeed.



CONTROL COLUMN-NEUTRAL, FEEL ACTUATOR RETRACTED



CONTROL COLUMN INPUT, FEEL ACTUATOR RETRACTED



CONTROL COLUMN INPUT, FEEL ACTUATOR EXTENDED

ELEVATOR CONTROL - ELEVATOR FEEL - FUNCTIONAL DESCRIPTION

ELEVATOR CONTROL - COLUMN BREAKOUT MECHANISM

Purpose

The column breakout mechanism makes it possible to control the elevators if a jam occurs in a control column, the column torque tubes, or an elevator feel unit.

Physical Description

The column breakout mechanism has a cam on the right torque tube. The cam follower assembly roller is on the left torque tube. Two springs keep the roller on the cam. The two torque tubes have connections for the elevator feel unit and backdrive actuator rods.

Location

The breakout mechanism is under the flight deck, aft of the column torque tubes. Access is through the forward equipment center door.

Functional Description

During normal operation, the two torque tubes of the column breakout mechanism are held together by the springs of the cam and roller mechanism. This supplies a load path to transfer control column force from one side to the other. During normal operations, movement of one control column will cause approximately the same movement of the other column.

If a jam occurs in the elevator control mechanism on either pilot's side, the other side will be free to move. The roller then moves out of the cam detent which allows control column movement on the side opposite the jam.

A force at the control column of approximately 50 lb (23 kg) is necessary to move the roller out of the detent position.

ELEVATOR CONTROL - COLUMN BREAKOUT MECHANISM

ELEVATOR CONTROL - ELEVATOR PCU - INTRODUCTION

Purpose

The elevator PCUs move the elevators. Electrical signals from the ACEs command the elevator PCUs. Each elevator has two PCUs.

Location

The two PCUs are side by side on the rear spar of the horizontal stabilizer. To get access to each PCU, remove a 24 by 24 inch (Approx.) panel on the bottom of the stabilizer.

The kick link connects the PCU to the rear spar fitting. The actuator rod and the reaction link connect to the elevator structure at the PCU fitting.

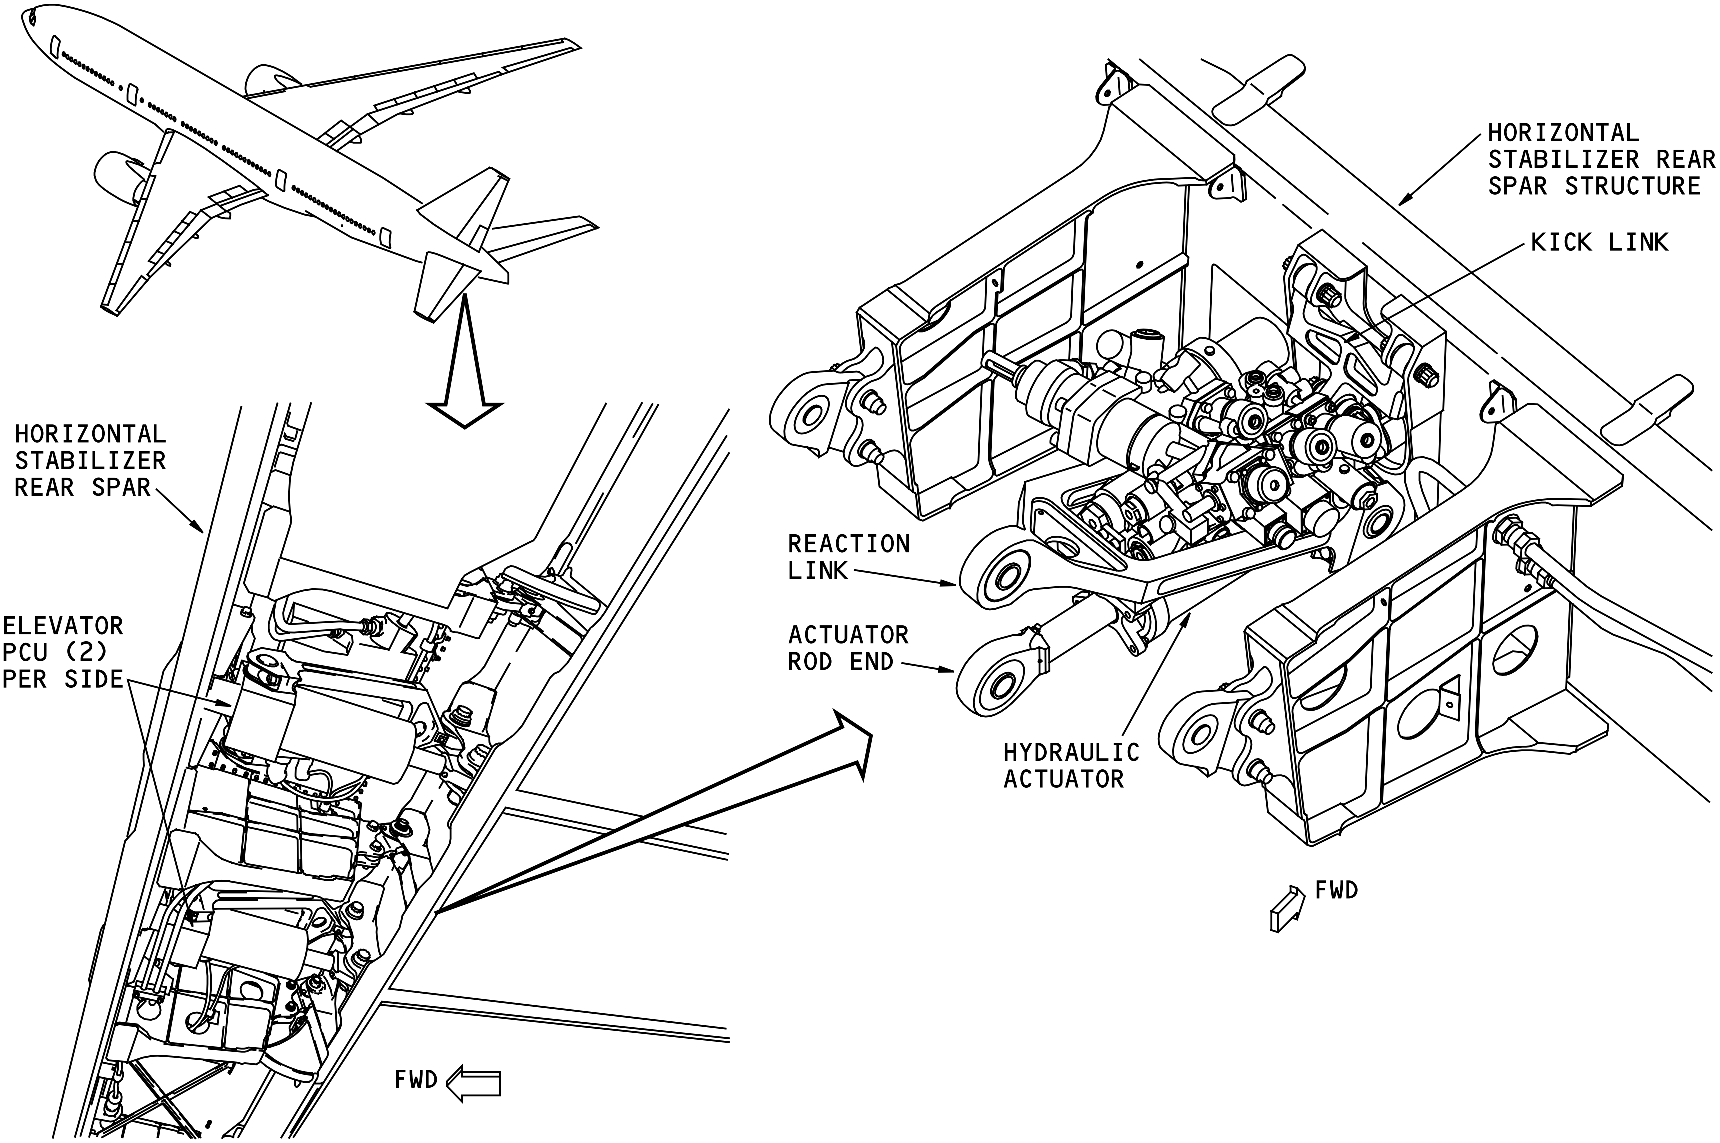
Two electrical connectors of different sizes connect to the upper side of the PCU.

Hydraulic tubing connects to ports on the upper side of the PCU.

Training Information Point

Remove and install the elevator PCU as one assembly with the reaction link. The elevator PCU disconnects from the kick link which stays on the airplane.

Use the cradle hoist ground service equipment (GSE) to support the PCU during removal and installation.



27-30-00-015 Rev 0

ELEVATOR CONTROL - ELEVATOR PCU - INTRODUCTION

ELEVATOR CONTROL - ELEVATOR PCU - PHYSICAL DESCRIPTION

Physical Description

All four elevator PCUs are identical. Each elevator PCU, with its reaction link, weighs about 85 lb (41 kg).

The outboard PCUs are powered by the left hydraulic system. The left inboard is powered by the center system and the right inboard is powered by the right system.

Each elevator PCU contains a hydraulic actuator with a control module. The control module contains:

- An electrohydraulic servo valve (EHSV)
- A pressure reducer solenoid valve which controls the pressure reducer valve
- A bypass solenoid valve
- A pressure sag check valve
- A blocking solenoid valve with two solenoid coils
- A mode selector valve with manual bypass
- A differential pressure sensor
- Two bypass check valves with restrictors
- A thermal relief valve
- A compensator/relief valve with quantity indicator
- A manual test valve for the compensator/relief valve
- Two anti-cavitation check valves with restrictors
- An inlet check valve
- An inlet filter.

Hydraulic Actuator

The actuator piston has an LVDT that sends actuator position feedback signals to the ACE. The actuator piston also has a null LVDT to adjust the null position of the actuator piston LVDT during installation of the PCU.

EHSV

The EHSV controls the hydraulic power to the extend and retract sides of the actuator. The EHSV has an LVDT that sends EHSV position feedback signals to the ACE.

Pressure Reducer Solenoid Valve

The ACE that commands the adjacent PCU controls the pressure reducer solenoid valve. The pressure reducer solenoid valve commands the pressure reducer valve to decrease the hydraulic pressure to 2140 psi. Reduced pressure on the actuator decreases the probability of a leak and decreases fatigue loads during normal operation.

In case of failure of a PCU or its hydraulic source, the hydraulic pressure to the other PCU increases to the nominal hydraulic system pressure of 3000 psi. This permits the other PCU to increase its capacity.

ELEVATOR CONTROL - ELEVATOR PCU - PHYSICAL DESCRIPTION

Bypass Solenoid Valve

The on-side ACE commands the bypass solenoid valve. The bypass solenoid valve controls the pilot pressure from the hydraulic system to the mode selector valve.

Pressure Sag Check Valve

The pressure sag check valve prevents pressure decreases from affecting the position of the mode selector valve.

Blocking Solenoid Valve

The on-side ACE controls one coil of the blocking solenoid valve, the ACE commanding the adjacent PCU controls the other coil. The blocking solenoid valve controls the pilot pressure from the actuator to the mode selector valve.

Mode Selector Valve

Pilot pressure from the bypass or the blocking solenoid valves commands the mode selector valve to one of these positions:

- Normal
- Bypass
- Blocking.

Differential Pressure Sensor

A differential pressure sensor measures the pressure difference between both sides of the actuator piston. The sensor operates an LVDT which sends signals to the ACE.

Bypass Check Valves with Restrictors

The two bypass check valves permit pressure from either side of the actuator to reach the damped solenoid valve. The restrictors prevent pressure fluctuations from affecting the position of the mode selector valve.

Thermal Relief Valve

The thermal relief valve protects the actuator from thermal expansion of the hydraulic fluid.

Compensator/Relief Valve with Quantity Indicator

The compensator/relief valve holds a small quantity of fluid at a pressure slightly above the hydraulic system return pressure. This fluid is available to the actuator to prevent cavitation.

The indicator shows the quantity of fluid in the compensator.

Manual Test Valve

You use the manual test valve to test the proper operation of the compensator/relief valve. With the

ELEVATOR CONTROL - ELEVATOR PCU - PHYSICAL DESCRIPTION

manual test valve open, the compensator/relief valve pressure decreases. Check that the quantity indicator moves to the empty position.

Anti-Cavitation Check Valves with Restrictors

The two anti-cavitation check valves permit return fluid from the compensator/relief valve to flow to the actuator. This prevents cavitation of the actuator during rapid backdriving of the PCU. The restrictors maintain elevator panel stiffness in case a check valve fails open.

Inlet Check Valve

The inlet check valve keeps the hydraulic fluid in the actuator when the hydraulic system power is lost.

Inlet Filter

The inlet filter protects the actuator from solids in the hydraulic fluid.

Training Information Point

A manual bypass valve permits movement of the PCU manually. Hydraulic power must be off before you use the manual bypass valve.

To move the elevator for maintenance, access the manual bypass valve. Turn the valve on both PCUs with the special tool while moving the elevator. After release of the manual bypass, it closes.

After installation of the elevator PCU, the actuator null LVDT requires adjustment. Remove the null LVDT access cover to adjust the actuator null LVDT.

During periodic inspection, you use the manual test valve to check the proper function of the compensator/relief valve. Remove hydraulic power from the PCU then move the manual test valve to release pressure internal to the compensator/relief valve. Do a check to see that the compensator/relief valve indicator moves all the way to its empty position.

The bearings in the actuator rod end and the reaction link require lubrication.

All other bearings on the actuator and the reaction link are teflon coated. They do not require lubrication.

ELEVATOR CONTROL - ELEVATOR PCU - PHYSICAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

ELEVATOR CONTROL - ELEVATOR PCU - FUNCTIONAL DESCRIPTION

General

The elevator PCU operates in three different modes:

- Normal
- Bypass
- Blocking.

In the normal mode, the ACE energizes the bypass solenoid and at least one of the coils of the blocking solenoid. The ACE energizes or de-energizes the pressure reducer solenoid.

In the bypass mode, the ACE de-energizes the bypass solenoid and energizes at least one of the coils of the blocking solenoid. The ACE energizes the pressure reducer solenoid.

In the blocking mode, the ACE de-energizes:

- The bypass solenoid
- Both coils of the blocking solenoid
- The pressure reducer solenoid.

The solenoid of the blocking valve has two coils. When both coils are de-energized, the valve is in its relaxed state. When one or both coils of the solenoid is energized, the valve moves.

PCU Operational Matrix

The table below shows the various conditions of the PCU valve solenoids in the three modes of operation.

SOLENOID CONDITIONS	PCU MODES OF OPERATION		
	NORMAL	BYPASS	BLOCKING
BYPASS SOLENOID	E	D	D
BLOCKING SOLENOID COIL 1	E	E/D	D
BLOCKING SOLENOID COIL 2	E/D	E	D
PRESSURE REDUCER SOLENOID	E/D	E	D
LEGEND:	E = ENERGIZED	D = DE-ENERGIZED	

Normal mode

The PCU is in the normal mode when the ACE energizes the bypass solenoid and at least one coil of the blocking solenoid. In the normal mode, the ACE energizes the pressure reducer solenoid when there is no failure of the ACE or the PCU.

With the bypass and blocking solenoids energized, hydraulic pressure moves the mode selector valve to the normal mode position. An electrical command to the EHSV results in the actuator extension or retraction.

When the ACE energizes the pressure reducer solenoid, the pressure reducer valve reduces the hydraulic pressure to 2140 psi. When there is a failure of the adjacent PCU, the ACE de-energizes the pressure reducer solenoid. The actuator then operates with full hydraulic system pressure (3000 psi).

ELEVATOR CONTROL - ELEVATOR PCU - FUNCTIONAL DESCRIPTION

Bypass Mode

The PCU is in the bypass mode when the ACE de-energizes the bypass solenoid and energizes one coil of the blocking solenoid.

This happens when there is a failure on the PCU or the ACE in control of the PCU.

Under these conditions, the bypass solenoid valve blocks hydraulic pressure to the mode selector valve. However, pressure trapped between the bypass check valves and the thermal relief valve moves the mode selector valve to the bypass position.

The mode selector valve blocks control pressure from the EHSV to the actuator cylinder. It also connects both sides of the actuator through a restriction.

During rapid backdrive of the failed PCU, the compensator/relief valve supplies fluid to the actuator through the anti-cavitation check valves.

Blocking Mode

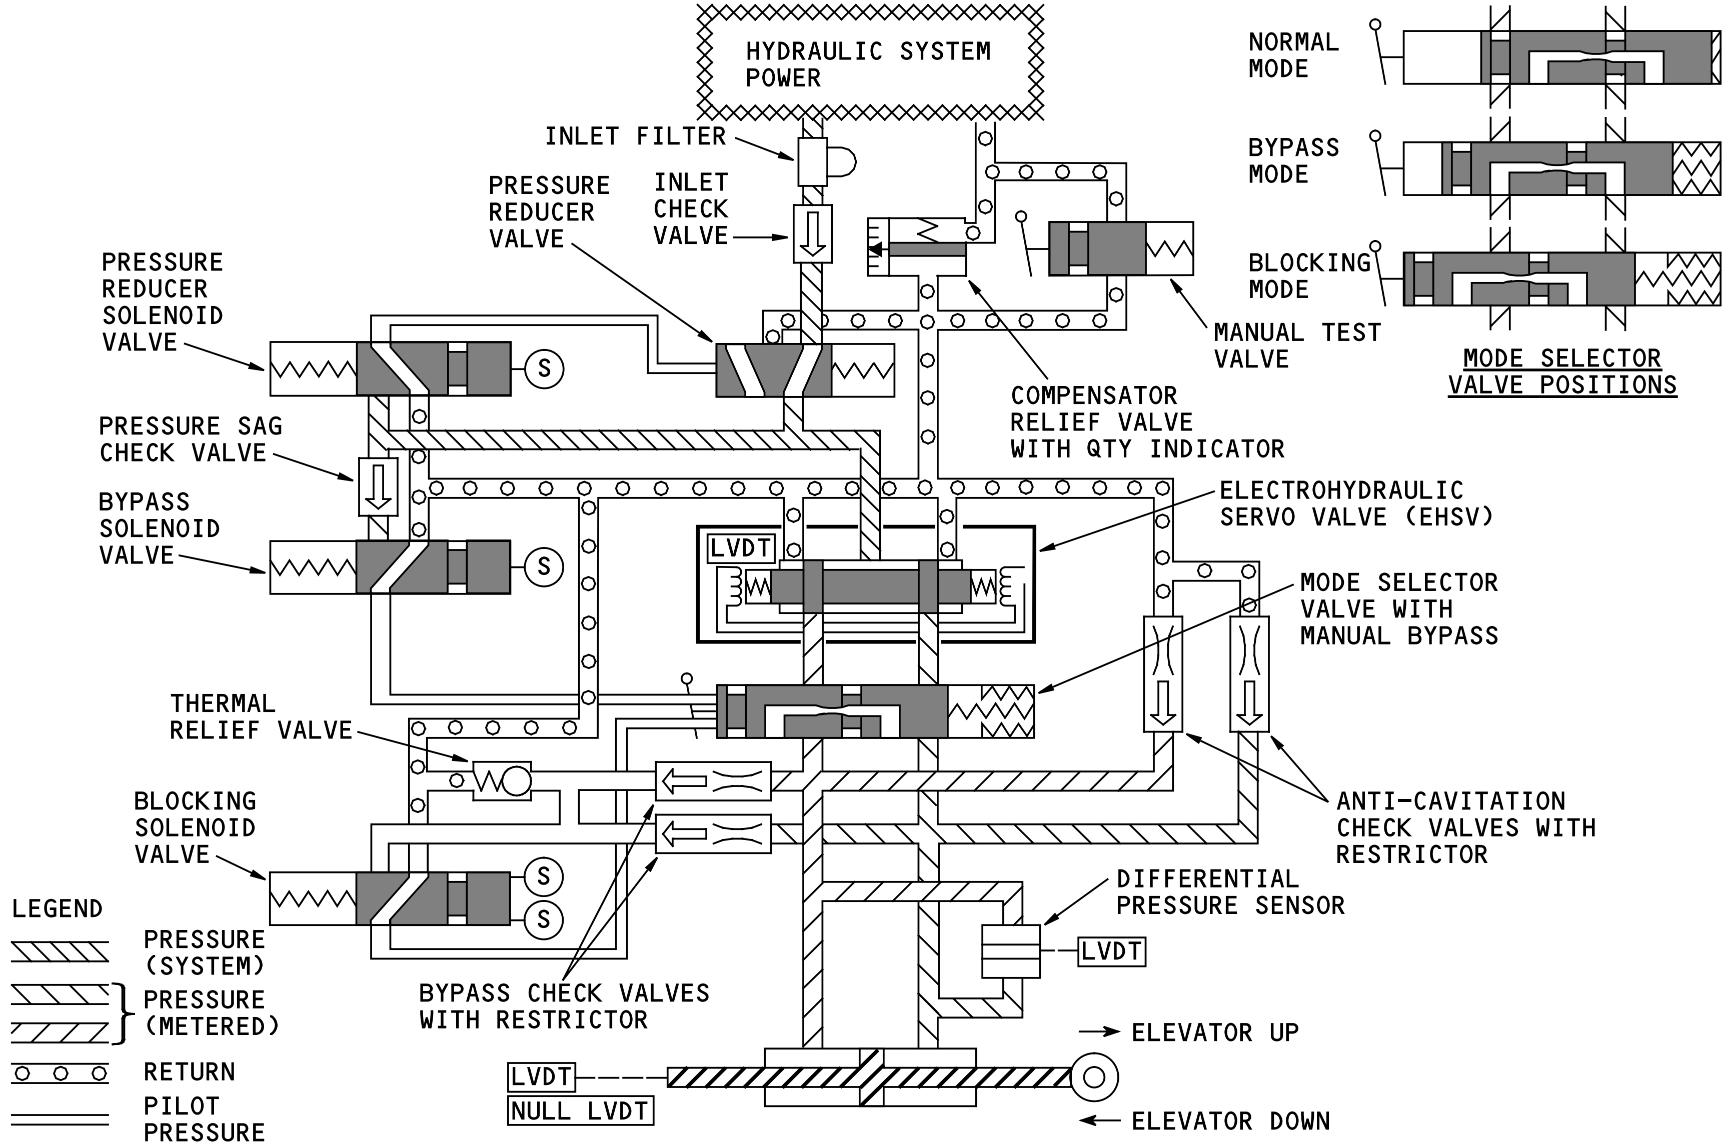
The PCU is in the blocking mode when the ACE de-energizes the bypass solenoid and both coils of the blocking solenoid. The ACE also de-energizes the pressure reducer solenoid. This happens when the PCU has no electrical and hydraulic power. Also, the PCU is in the blocking mode when there is a failure of both adjacent PCUs or their ACEs and the elevator is near the faired position.

In the blocking mode, there is no hydraulic pressure on the mode selector valve. Its internal spring moves the valve to the blocking position. The mode selector valve blocks control pressure from the EHSV to the actuator cylinder. It also blocks hydraulic flow between both sides of the actuator piston.

Under these conditions, the actuator cannot move. When both PCUs on an elevator are in blocking mode, they lock the elevator in its position.

Indications

The status message FLIGHT CONTROL SYS shows when one or more elevator actuator has failed.



ELEVATOR CONTROL - ELEVATOR PCU - FUNCTIONAL DESCRIPTION

27-30-00-017 Rev 3 03/28/96

ELEVATOR CONTROL - ELEVATOR PCU - FUNCTIONAL DESCRIPTION - PCU MODES

General

The ACEs control the mode of operation of the elevator PCU.

Normal Mode

An elevator PCU operates in the normal mode when there is no failure on the PCU and there is no failure of its on-side ACE.

If the adjacent PCU is also in the normal mode, the ACEs energize both coils of the blocking solenoid and the pressure reducer solenoid. When these conditions are true, both PCUs operate with reduced hydraulic pressure.

Bypass Mode

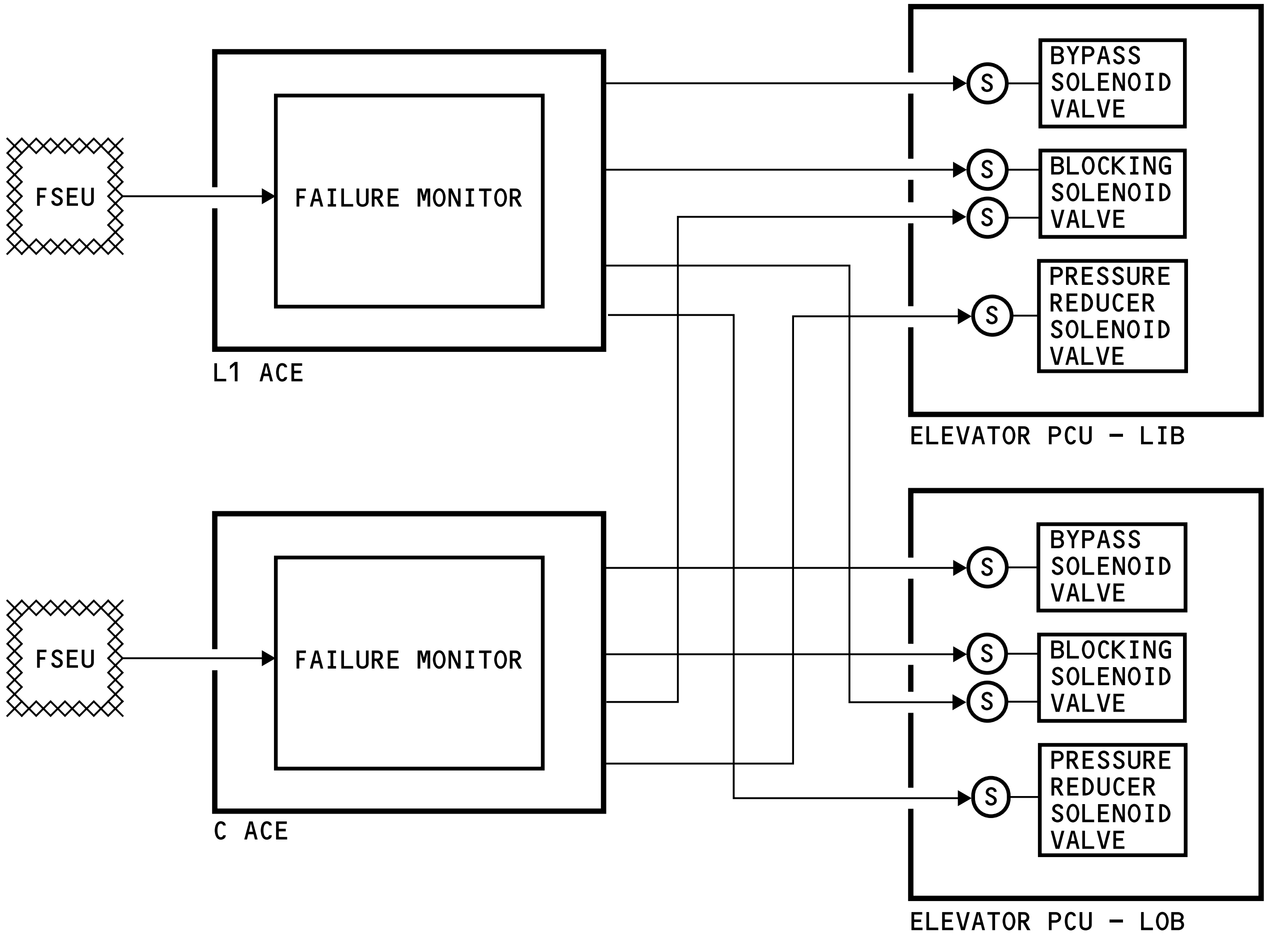
If the PCU has an electrical or hydraulic failure or there is a failure of its ACE, the ACE de-energizes the bypass solenoid. The PCU is then in the bypass mode. The ACE also de-energizes the pressure reducer solenoid of the adjacent PCU. The adjacent PCU then operates in normal mode with full hydraulic system pressure.

When the elevator position is less than two degrees from neutral with flaps retracted, or five degrees with flaps extended, it is near to being faired. When the elevator is near to being faired, the ACE also de-energizes one coil of the blocking solenoid on the failed and the adjacent PCU. This prepares the two PCUs to go into the blocking mode should there be a failure on the adjacent PCU or its ACE.

Blocking Mode

If there is a failure with the second PCU or its ACE when the elevator is near to being faired, all PCU solenoids de-energize. When it is not near to faired, the energized blocking solenoids on each PCU stay energized.

As soon as the airloads move the elevator panel near to faired, both blocking solenoids de-energize. At this time, a hydraulic lock in the PCUs keeps the elevator in the faired position.



27-30-00-018 Rev 1 06/20/1997

ELEVATOR CONTROL - ELEVATOR PCU - FUNCTIONAL DESCRIPTION - PCU MODES

ELEVATOR CONTROL - ELEVATOR ASSEMBLY

Purpose

The elevators supply short-term pitch control of the airplane.

Physical Description

The elevators are light weight composite material structures. The skin is reinforced graphite/epoxy bonded to a core of Nomex honeycomb. The overall dimensions are approximately 70 inches by 403 inches (1.7 m by 10.2 m). Each elevator panel weighs approximately 327 lb (148 kg).

The elevator attaches to the stabilizer rear spar with seven hinges. There are four PCU attach fittings on each elevator. Jumpers and static dischargers supply electrostatic protection.

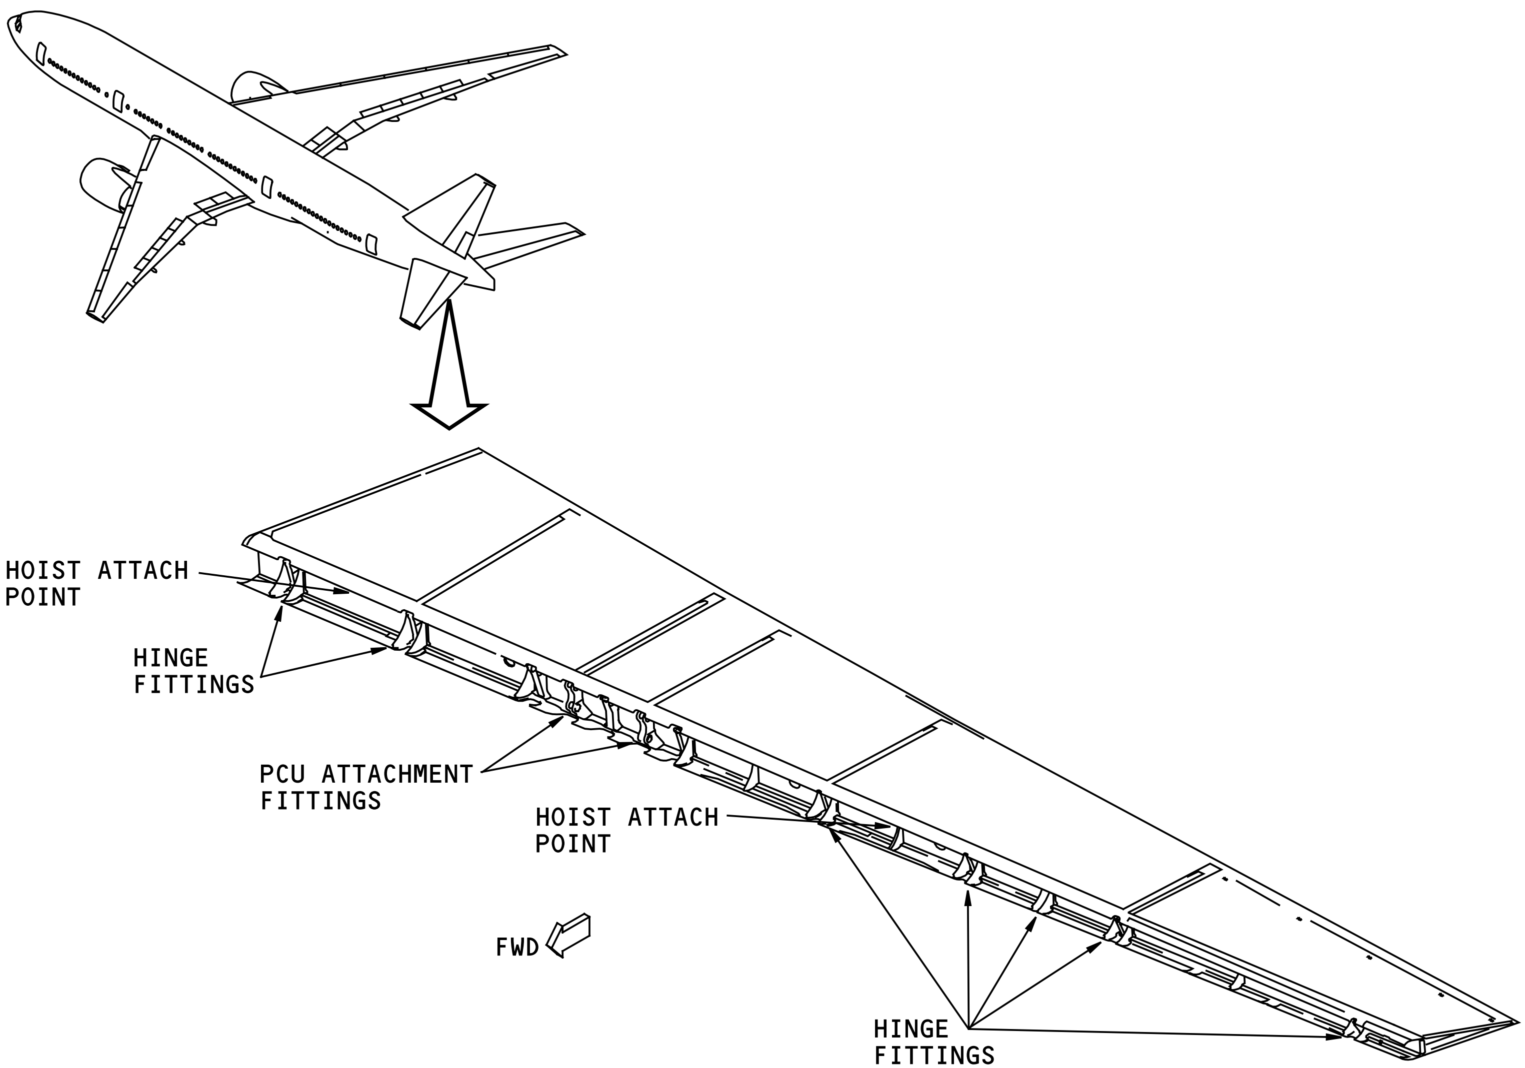
Functional Description

The elevator surface deflection limits are at the PCU internal stops. The elevators have a maximum movement of 33 degrees trailing edge up (TEU) and 27 degrees trailing edge down (TED) under no load conditions.

Under load conditions, the maximum PFC and ACE command signals move the elevators to a nominal position between 30 degrees TEU and 25 degrees TED. You adjust the elevator PCUs on the ground with the stabilizer at the neutral position. You adjust the PCUs so the elevator control surfaces are at neutral in reference to an index plate on the tail section of the fuselage.

Training Information Point

Two hoist attach points are on each elevator. They are on the upper leading edge spar flange. One is between the inboard hinge fittings. The other is between the hinge fittings outboard of the PCU fittings. Two fasteners at each attach point are removed so the GSE lifting tool may be attached. A clamp on the trailing edge to supplies the third lifting point.



27-30-00-021 Rev 2

ELEVATOR CONTROL - ELEVATOR ASSEMBLY

ELEVATOR CONTROL - FUNCTIONAL DESCRIPTION

General

The pitch control system for the elevators uses input command signals from the control column position transducers and the force transducers.

The ACEs receive the input signals and transmit them to the PFCs. The ACEs supply output command signals to the elevator feel actuators and the elevator PCUs.

Control Column Position Transducers

The C and R ACEs each receive signals from two control column position transducers. L1 and L2 ACEs receive signals from only one transducer. After they change the signals to digital format, the ACEs send these signals to the PFCs through the flight controls ARINC 629 buses.

Force Transducers

Each ACE receives one input from the four force transducer LVDTs. The ACEs change and transmit these signals to the PFCs.

Elevator Feel Actuators

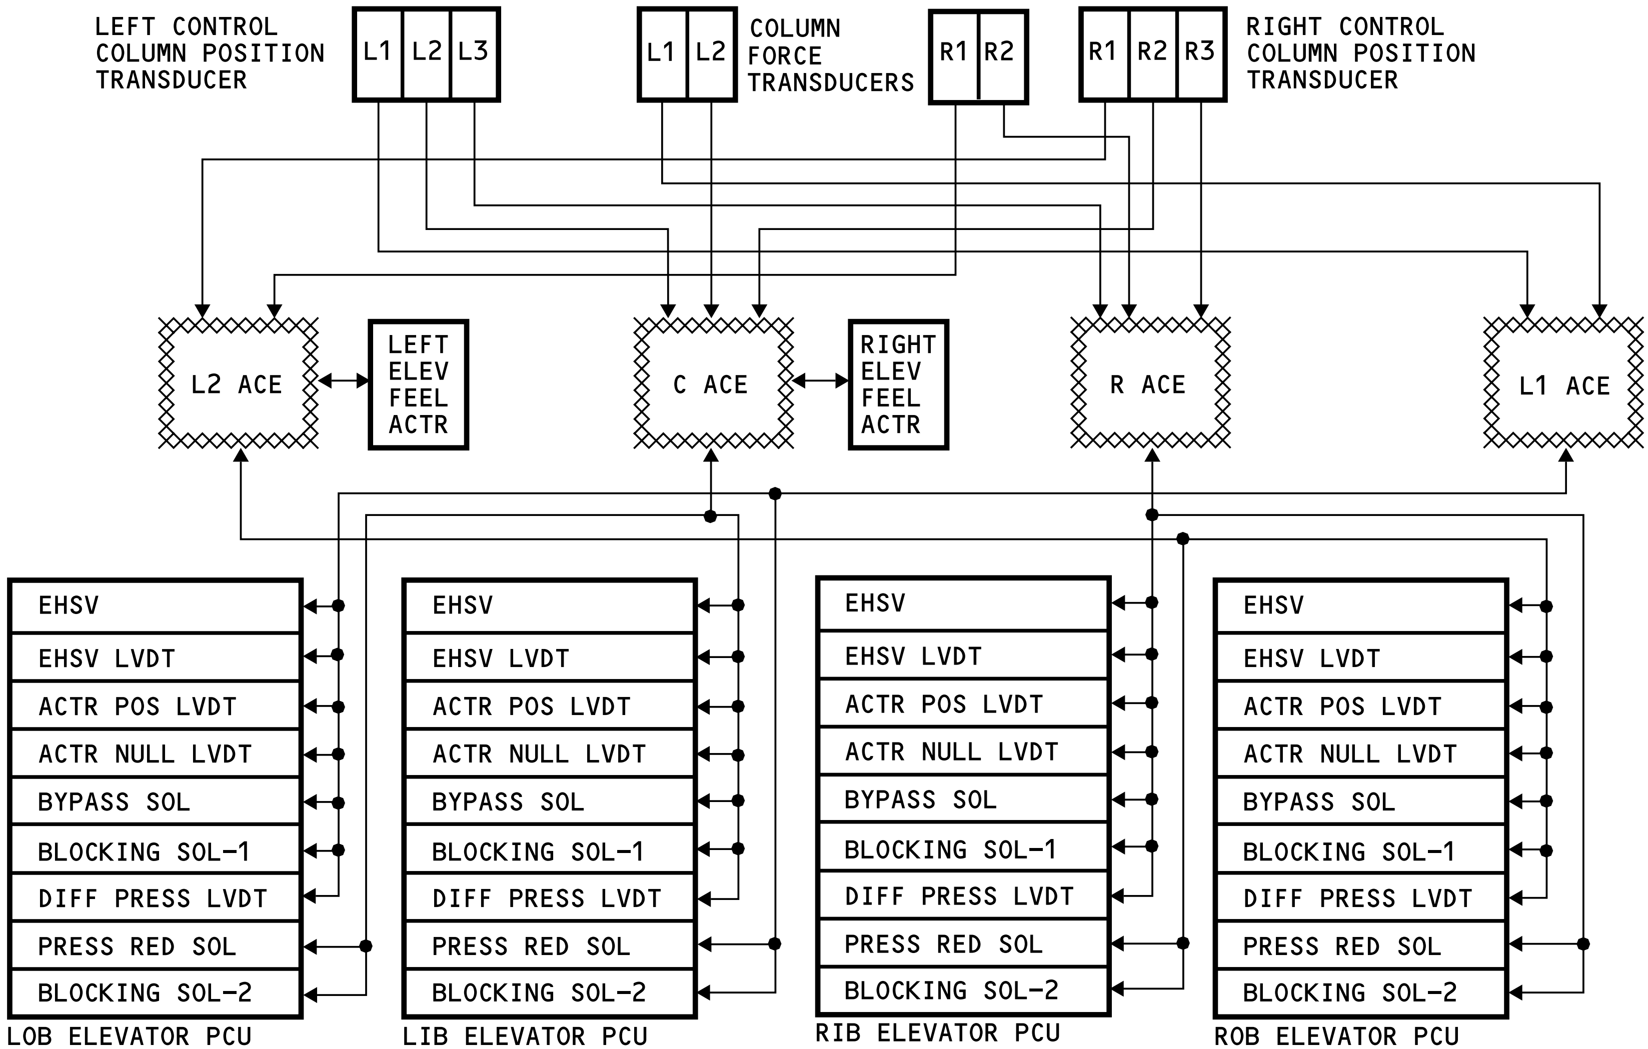
The L2 ACE controls the left elevator feel actuator and the C ACE controls the right one.

Elevator PCUs

Each ACE sends output commands to the assigned elevator PCU. It also sends control signals to the adjacent PCU on the same elevator. The pitch command goes to the EHSV. A control signal goes to the bypass and number one blocking solenoid. It sends pressure reducing and blocking solenoid signals to the adjacent PCU on the same elevator.

The PCU sends feedback signals to its assigned ACE from:

- The EHSV position LVDT
- The actuator piston position LVDT
- The actuator null LVDT
- The differential pressure LVDT.



27-30-00-019 Rev 2 07/18/1997

ELEVATOR CONTROL - FUNCTIONAL DESCRIPTION

ELEVATOR CONTROL - FUNCTIONAL DESCRIPTION - ACE SERVO LOOP

General

The ACE contains a servo loop circuit to give the command signals to the PCUs.

In normal and secondary mode, the PFC sends the command signals to the ACE. In direct mode, the ACE calculates the command signals.

Servo Loop Operation

The elevator command signals go through a servo loop in the ACEs. The command signals then go to the EHSV of the PCUs. The ACEs also use the command signals to monitor for failures. The movement of the EHSV sends hydraulic pressure to extend or retract the actuator.

The EHSV LVDT measures the movement of the EHSV and supplies a feedback signal to the ACEs. The ACEs use this feedback signal to monitor failures.

The actuator position LVDT measures the movement of the actuator and supplies a signal to the actuator null LVDT.

The actuator null LVDT is in series with the actuator position LVDT. The actuator null LVDT modifies the signal from the actuator position LVDT.

The actuator null LVDT supplies a feedback signal to the ACEs to close the servo loop. The ACEs use this feedback signal to monitor for failures. This signal also goes to the PFC.

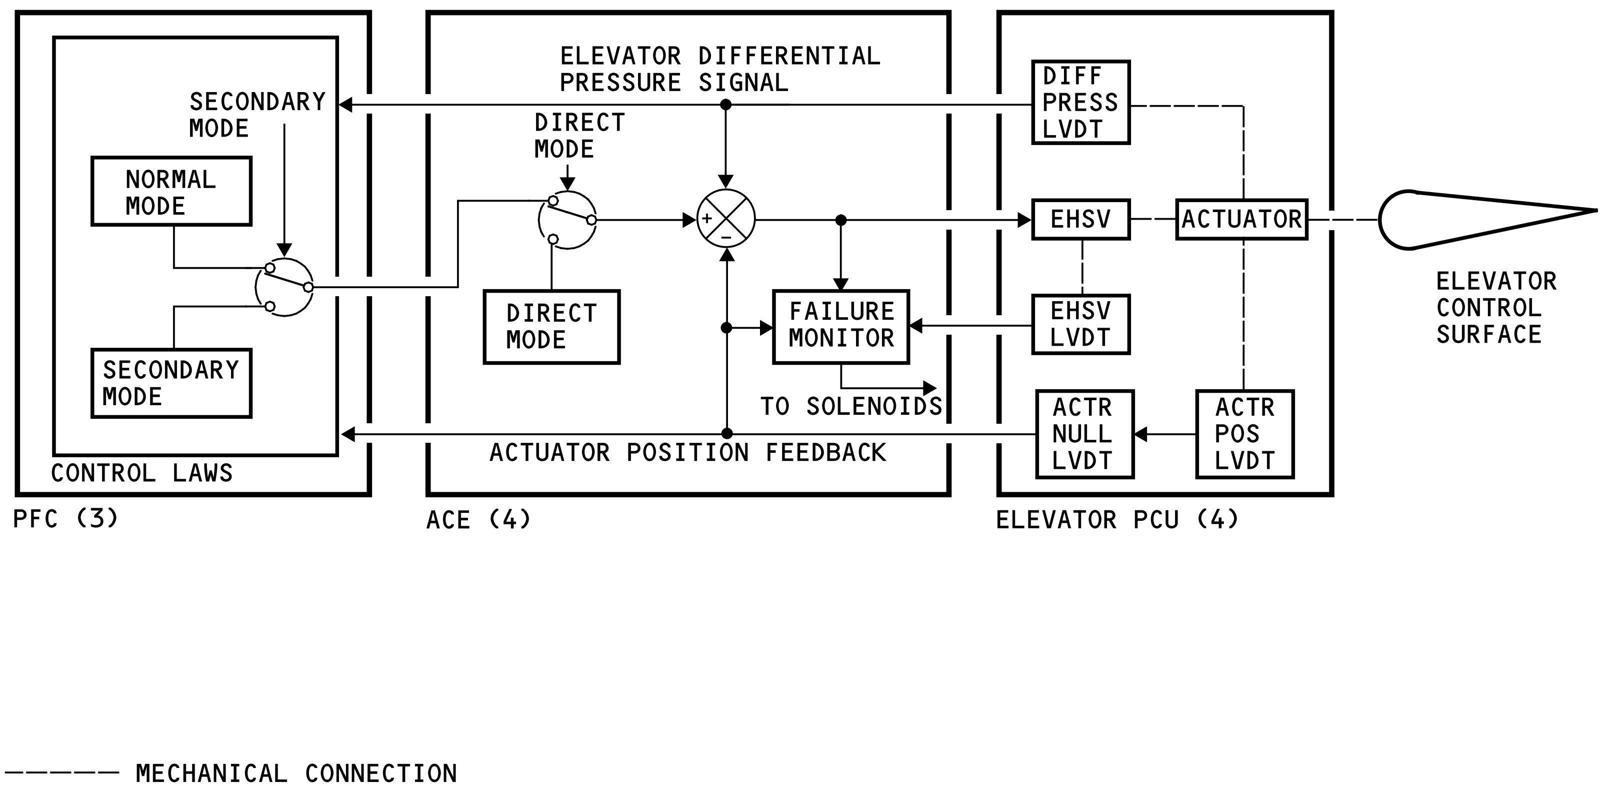
A differential pressure LVDT measures the differential pressure across the actuator. The signal from the differential pressure LVDT goes to the ACEs for the servo loop. The signal also goes to the PFCs for force fight equalization.

Failure Monitor

The ACE has a failure monitor to check the proper operation of the PCU. The monitor uses the ACE command signal and the feedback signals from the EHSV LVDT and the actuator LVDT. When the failure monitor finds a fault with the PCU or the ACE, it de-energizes the PCU bypass, blocking and pressure reducer solenoids.

Training Information Point

During installation of the elevator PCU, it is necessary to adjust the actuator null LVDT. Remove the null LVDT access cover to adjust the null LVDT.



27-30-00-020 Rev 3 12/08/95

ELEVATOR CONTROL - FUNCTIONAL DESCRIPTION - ACE SERVO LOOP

ELEVATOR CONTROL - FUNCTIONAL DESCRIPTION - ELEVATOR FEEL

THIS PAGE INTENTIONALLY LEFT BLANK

ELEVATOR CONTROL - FUNCTIONAL DESCRIPTION - ELEVATOR FEEL

General

The PFCS controls the elevator feel actuators and works with the elevator feel unit to supply resistance to the movement of the control column.

The PFCs control elevator feel in the normal and secondary modes and the L2 and C ACEs control it in the direct mode.

Elevator Feel Actuator

The elevator feel actuator contains a brushless 28v dc reversible motor, and a 7v RVDT to supply an actuator position signal.

Normal Mode

In the normal mode, the PFC calculates elevator feel commands as a function of airspeed. As airspeed increases, it commands the actuator to extend. As airspeed decreases, the PFC commands the actuator to retract. This results in more or less resistance (feel) to movement of the control column. The command goes to the feel actuator through the ACE.

During takeoff, the feel actuators disengage above 40 knots. The feel actuators engage to provide variable feel 5 seconds after the ground-to-air transition. On the ground with airspeed below 40 knots, the feel actuators engage to permit the flight crew to do a check of the feel forces during the freedom of controls check.

Secondary Mode

In the secondary PFCS mode, the PFC calculates feel commands as a function of flaps and slats position. The FSEUs supply through the ACEs a discrete flaps and slats retracted signal. When the flaps and slats are not retracted, a low feel command is made. When the flaps and slats are retracted, a high feel command is made.

Direct Mode

The ACE uses the FSEU discrete flaps and slats retracted signal to calculate feel actuator commands in the direct mode. When the flaps and slats are not retracted, it makes a low feel command. When the flaps and slats are retracted, it makes a high feel command.

Failure Monitor

In normal mode, if the PFC detects a difference between the output and the feed back signals from one of the feel actuators, it shuts off the signal to that actuator. The failed actuator is spring loaded to a zero force input.

The PFC then commands the other actuator with a doubled signal that compensates for the failed actuator. Because of this, the feel force at the control columns remains the same.

ELEVATOR CONTROL - FUNCTIONAL DESCRIPTION - ELEVATOR FEEL

Indications

The status message FLIGHT CONTROL SYS shows that there is a failure in one or more elevator feel actuators.

ELEVATOR CONTROL - FUNCTIONAL DESCRIPTION - ELEVATOR FEEL

Continental Airlines, Inc

Horizontal Stabilizer Control

WB371

TABLE OF CONTENTS

HORIZONTAL STABILIZER CONTROL - INTRODUCTION

General

The horizontal stabilizer supplies long-term correction of the pitch attitude of the airplane. This movement is around the lateral axis of the airplane.

Stabilizer Control

The elevator off-load function automatically sets the position of the stabilizer during manual flight or in autoflight. In this mode, the PFCs monitor elevator deflection and transfer pitch changes to the stabilizer. Once the stabilizer goes to its commanded position, the elevator moves to neutral.

The pilots command the stabilizer to move with either the pitch trim switches on the control wheels or the alternate pitch trim levers on the control stand.

The pilots stop unwanted stabilizer movement with the stabilizer cutout switches on the aisle stand.

Stabilizer Operation

Two hydraulic motors with two speeds move the horizontal stabilizer through a jackscrew mechanism. Four rates of horizontal stabilizer movement are available.

HORIZONTAL STABILIZER CONTROL - INTRODUCTION

HORIZONTAL STABILIZER CONTROL - GENERAL DESCRIPTION

General

The PFCS commands automatic movement of the stabilizer. The pilots manually command the stabilizer to move.

Flight Deck Controls

The pilots operate two pitch trim switches for manual pitch trim control. The switch modules are on the outboard side of each control wheel. They send electrical pitch trim signals to the ACEs.

Two alternate pitch trim levers are on the captain's side of the control stand. These levers mechanically control stabilizer movement.

Two guarded cutout switches on the aisle stand control hydraulic shutoff valves on the stabilizer trim control modules (STCMs). When the pilot moves the switches to the cutout position, hydraulic pressure is shut off to the hydraulic motors.

Two stabilizer position indicators on the control stand show the position of the stabilizer. A green band on the indicator shows the correct stabilizer position for takeoff. See the horizontal stabilizer position indication section for more information (AMM PART I 27-48).

Stabilizer Controls

Two stabilizer trim control modules (STCMs) receive commands from the ACEs and the alternate pitch trim levers to control the hydraulic pressure to the motors and brakes.

Two hydraulic motors that use different hydraulic system power sources, cause the ballscrew actuator to rotate. Two hydraulic brakes work with the motors and are powered by the same hydraulic systems. The brakes release and the motor runs with hydraulic pressure. With low pressure, the brakes set and the motors do not run. This prevents movement of the stabilizer.

The horizontal stabilizer is a one piece, negative lift airfoil. It pivots at its rear spar. A ballscrew actuator, attached to the front spar, moves the stabilizer leading edge to a maximum of 4 degrees up and 11 degrees down.

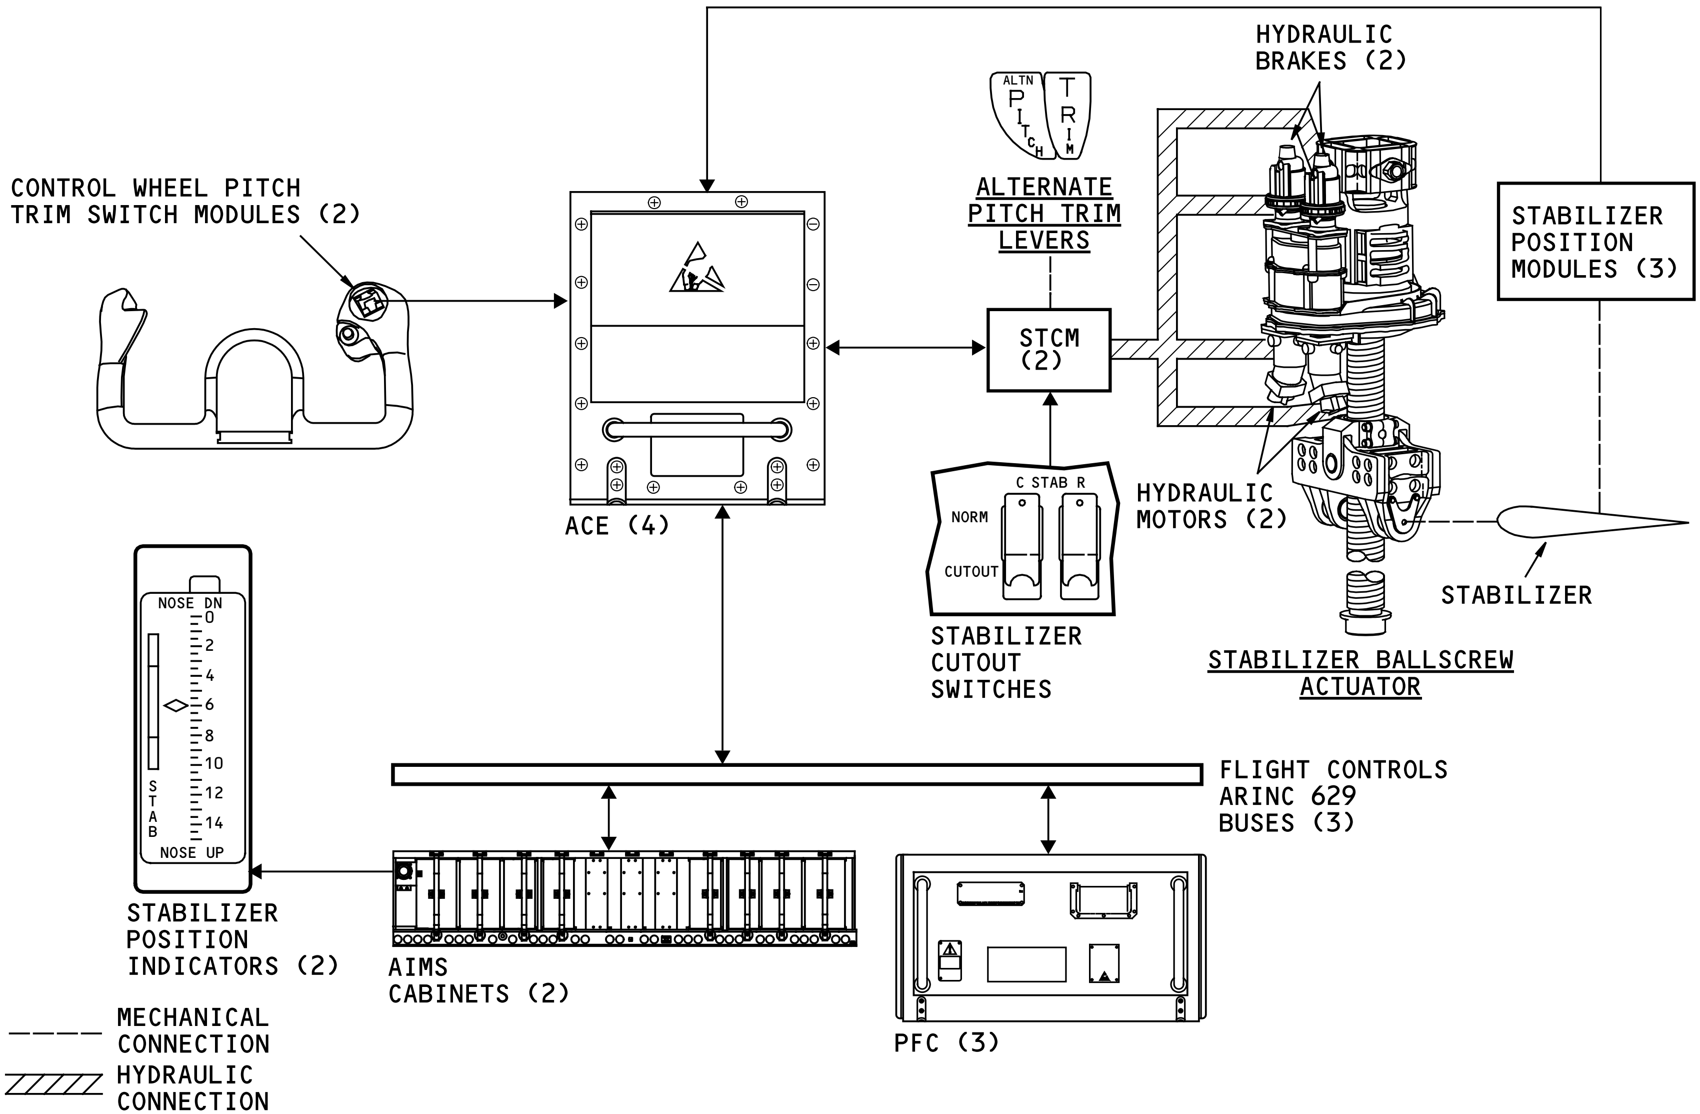
Cables transmit the stabilizer movement to three stabilizer position modules (SPMs) in the stabilizer compartment. The SPMs supply stabilizer position data to the ACEs.

Column Cutout

When the pilot moves the control column in the opposite direction of the pitch commanded by the pitch trim switches, the PFCs cut out the pitch command to the STCMs. This stops the stabilizer movement.

Stabilizer Automatic Cutout

In case of uncommanded pitch trim, the PFCs command the hydraulic shutoff valves on the STCMs to close.



27-41-00-002 Rev 3

HORIZONTAL STABILIZER CONTROL - GENERAL DESCRIPTION

HORIZONTAL STABILIZER CONTROL - COMPONENT LOCATIONS - FLIGHT DECK AND BELOW

General

Stabilizer system components are in the flight deck and below the flight deck.

Flight Deck Components

Two pitch trim switches are on the outboard side of each control wheel. The switches have three positions: nose-up, nose-down, and off.

Two alternate pitch trim levers are on the P10 control stand. They connect by cables to mechanical valves on the STCMs.

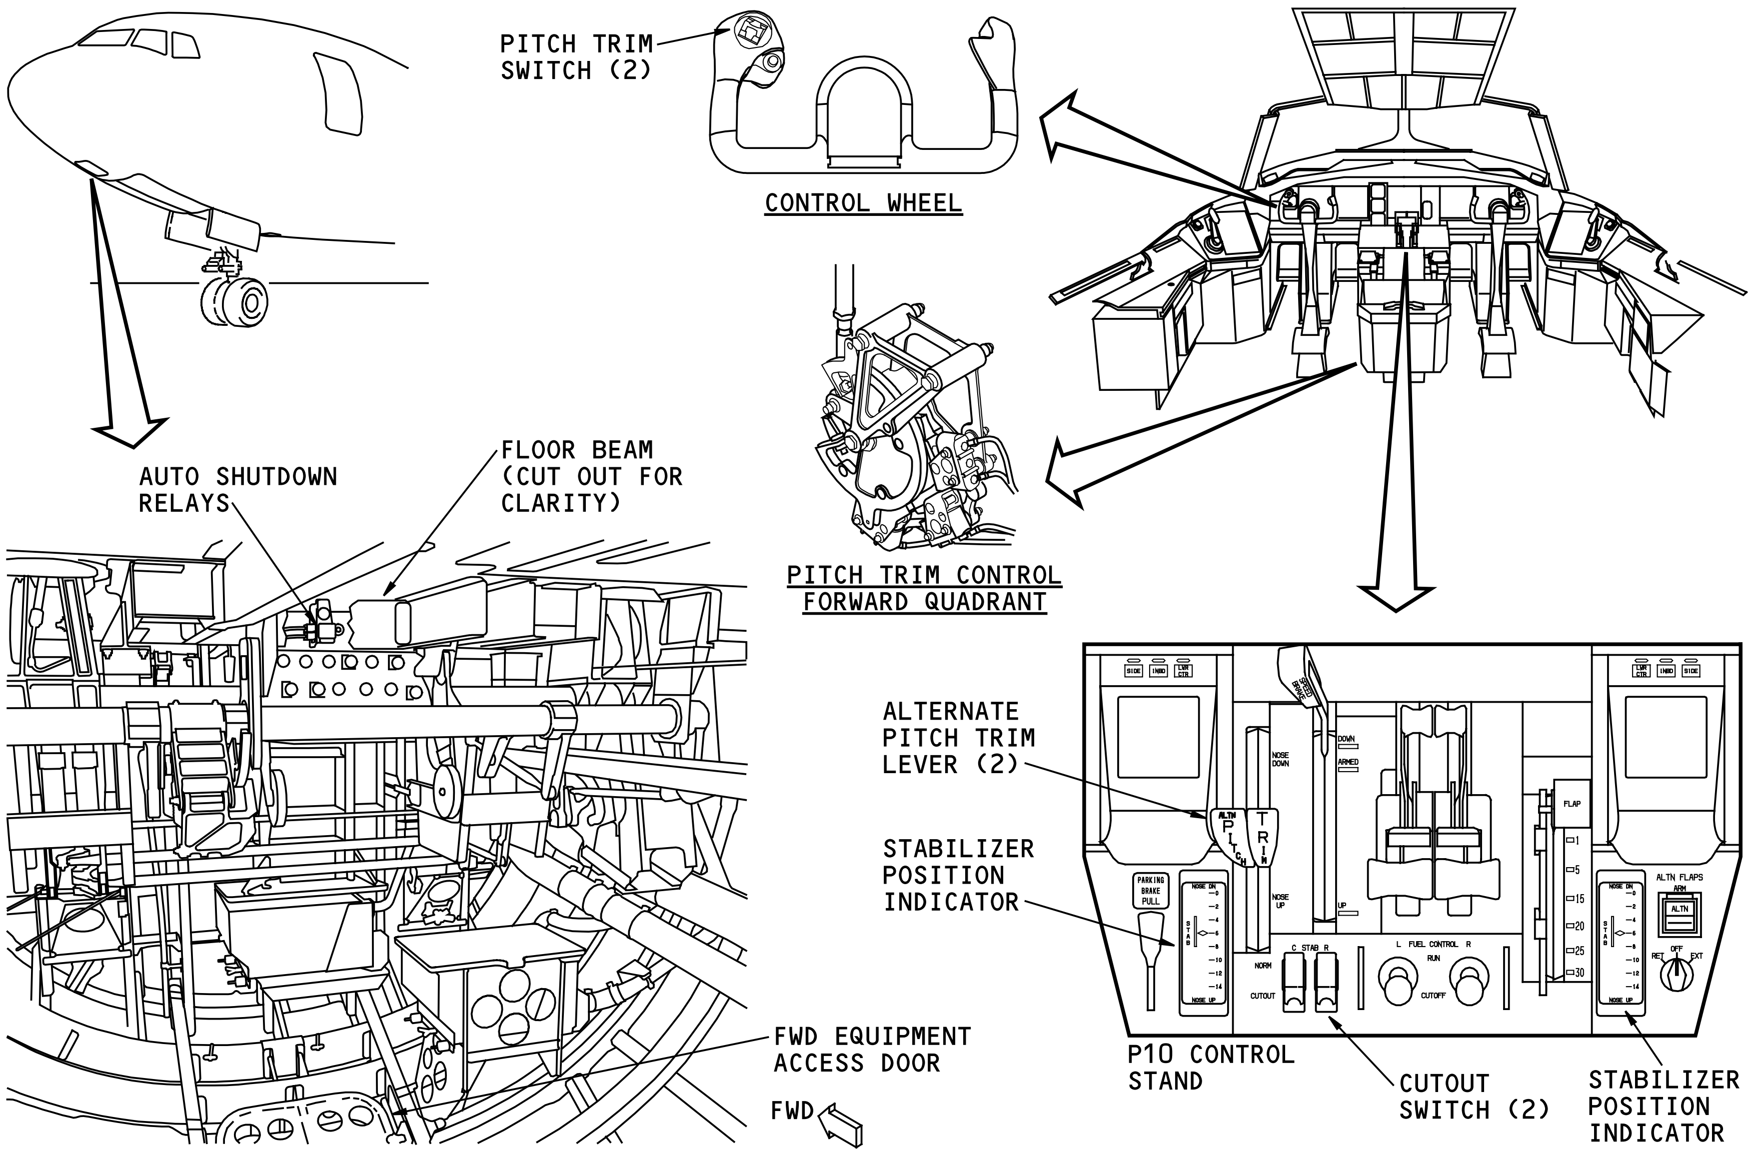
Two guarded stabilizer cutout switches are on the P10 control stand. Each switch removes hydraulic power from a hydraulic motor and brake when put in the CUTOUT position.

Two stabilizer position indicators are on the P10 control stand. They both have a green band to show when the stabilizer is in the proper position for take-off.

Components Below the Flight Deck

The auto shutdown relays are between flight deck floor beams in the forward equipment center.

The pitch trim control forward quadrants are below the control stand. Access is through the forward equipment center.



HORIZONTAL STABILIZER CONTROL - COMPONENT LOCATIONS - FLIGHT DECK AND BELOW

HORIZONTAL STABLIZER CONTROL - COMPONENT LOCATIONS - TAIL

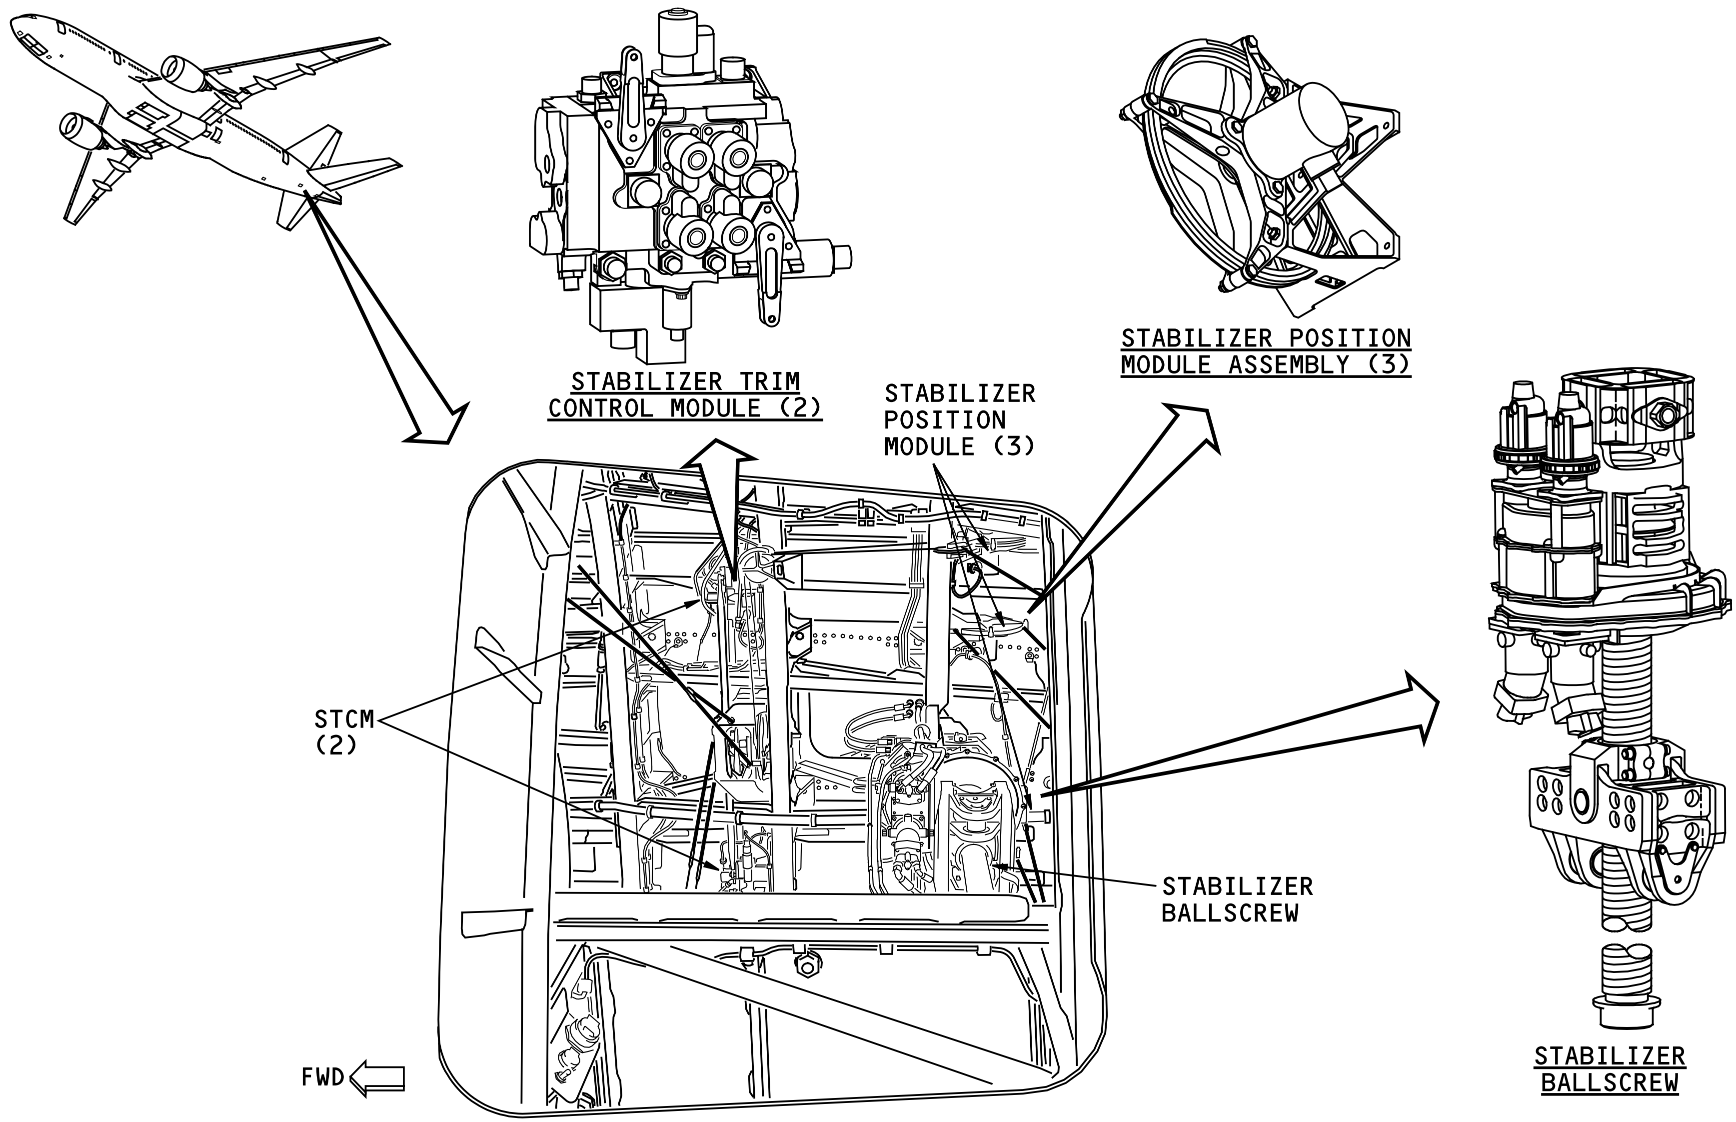
Tail Components

The stabilizer is a single unit. It attaches to the aft fuselage by hinges on the stabilizer rear spar. The forward stabilizer structure attaches to a ball nut on the stabilizer ballscrew. The stabilizer ballscrew is on the airplane structure in the stabilizer compartment. Access to this area is by a service access door on the left side of the lower aft fuselage.

Also in the stabilizer compartment are the three stabilizer position modules (SPMs) assemblies and the two stabilizer trim control modules (STCMs).

Cables connect to the forward end of the stabilizer structure and mechanically transmit stabilizer movement to the stabilizer position modules.

The STCMs are immediately aft of the pressure bulkhead near the ceiling of the stabilizer compartment.



VIEW LOOKING UP WITH THE SERVICE ACCESS DOOR OPEN

HORIZONTAL STABLIZER CONTROL - COMPONENT LOCATIONS - TAIL

HORIZONTAL STABILIZER CONTROL - ANALOG AND DISCRETE INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

HORIZONTAL STABILIZER CONTROL - ANALOG AND DISCRETE INTERFACES

General

All the analog interfaces for the stabilizer pitch control within the PFCS go through the ACEs. Each ACE has interfaces with these components:

- Alternate pitch trim lever switches
- Control wheel pitch trim switches
- Stabilizer position indicators
- Auto shutdown relays
- Stabilizer trim control modules (STCM)
- Stabilizer position modules.

Alternate Pitch Trim Lever Switches

The alternate pitch trim lever switches on the alternate pitch trim forward quadrants send discrete signals to the AIMS. The signals represent pitch up or pitch down commands.

Control Wheel Pitch Trim Switch Modules

The pitch trim switches on each control wheel send pitch up, pitch down or off discrete signals to the ACEs.

Stabilizer Position Indicators

The two stabilizer position indicators receive analog signals from the AIMS that show stabilizer position.

Stabilizer Cutout Switches

Each stabilizer cutout switch controls a motor-operated shutoff valve in an STCM.

Auto Shutdown Relays

The ACEs can send discrete signals to the auto shutdown relays to close the motor-operated shutoff valves in the STCMs.

Stabilizer Trim Control Modules

Each of the two STCMs receive discrete signals from the ACEs and the auto shutdown relays. The discrete signals are for the:

- Control and arm trim solenoids
- Rate control solenoids
- Motor operated shutoff valves.

The pressure switches send discrete signals back to the ACEs.

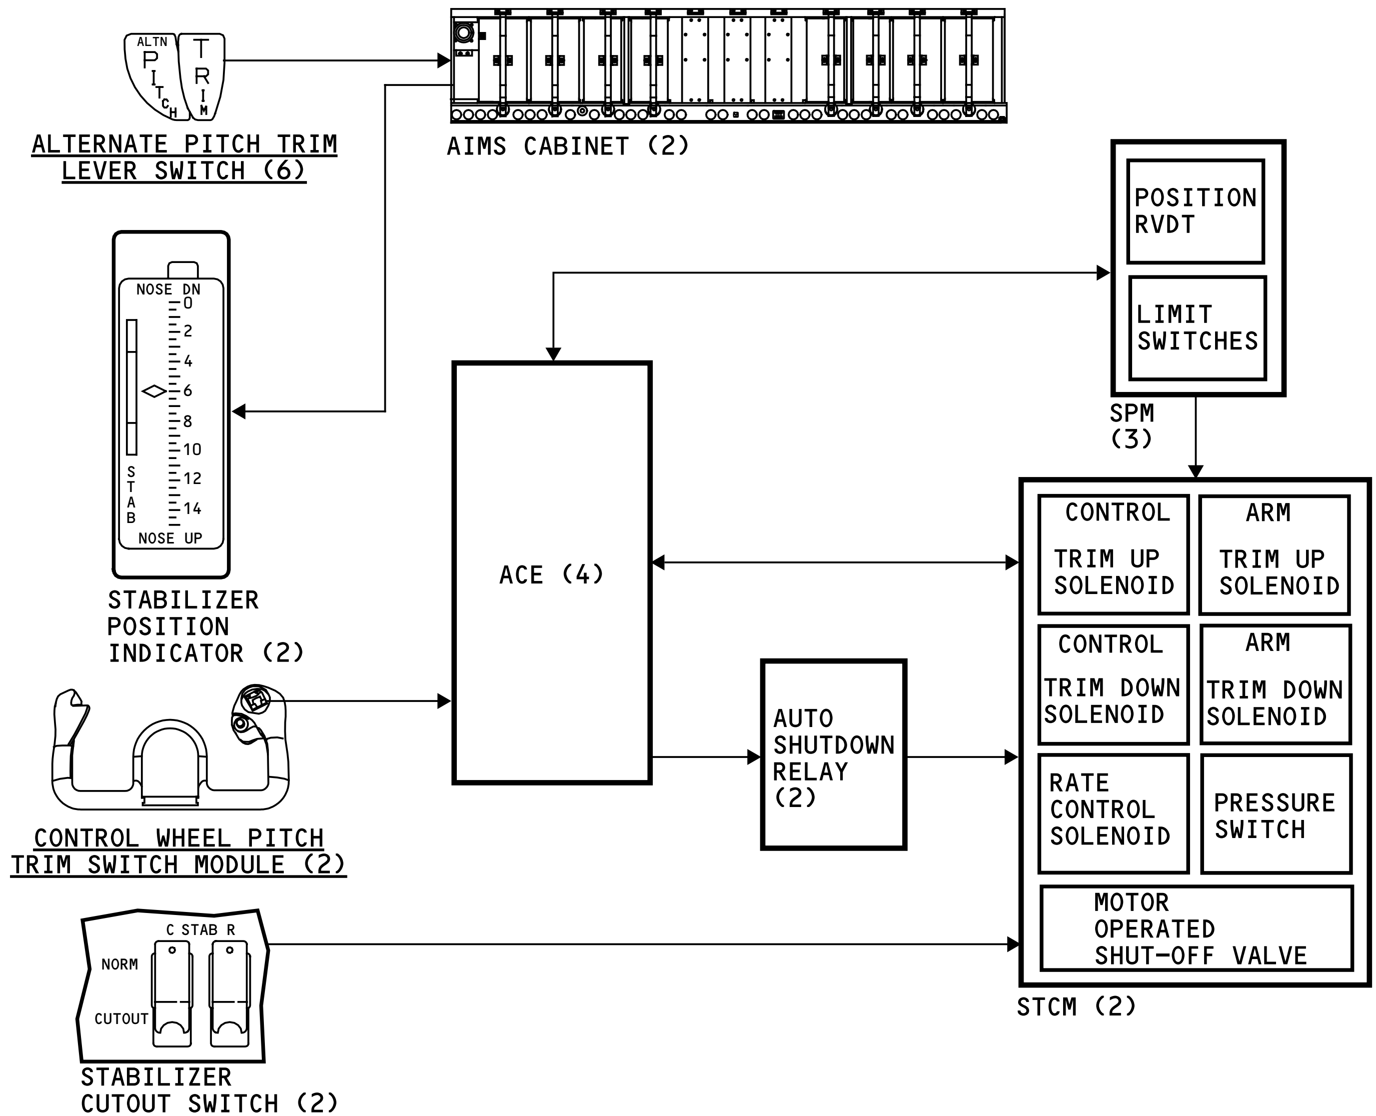
Stabilizer Position Module

Three stabilizer position modules contain a position RVDT and limit switches.

The RVDTs send an analog signal to the ACEs that represents the stabilizer position.

HORIZONTAL STABILIZER CONTROL - ANALOG AND DISCRETE INTERFACES

The ACEs send discrete signals through the limit switches to the STCMs.



27-41-00-004 Rev 1

HORIZONTAL STABILIZER CONTROL - ANALOG AND DISCRETE INTERFACES

HORIZONTAL STABILIZER CONTROL - ALTERNATE PITCH TRIM LEVERS AND FORWARD QUADRANT ASSEMBLY

Purpose

The alternate pitch trim levers give the pilots mechanical control of pitch trim. The forward quadrant assembly transmits the movement from the levers to the control cables.

Physical Description

Two alternate pitch trim levers supply arm and control mechanical commands to the STCMs. The two levers are independent of each other. Springs move the levers back to the center position. Each lever connects by rod to its own forward quadrant.

Each quadrant has three alternate pitch trim lever switches. Cams on the quadrants operate the switches. A pair of cables connects each quadrant to the aft control module in the stabilizer compartment.

Location

The two alternate pitch trim levers are on the captain's side of the P10 control stand. The forward quadrant assembly is just below the levers in the aisle stand.

Functional Description

To command pitch trim, the pilot moves both alternate pitch trim levers together in the same direction. The pilot moves the levers forward to command nose down trim, aft for nose up trim. Movement of the left lever supplies the control command, the right lever supplies the arm command.

Movement of the alternate pitch trim levers causes rotation of the forward quadrants and movement of the two pairs of cables.

The forward quadrant rotation causes cams to move the three alternate pitch trim lever switches on each quadrant. The switches send these discrete signals to the AIMS:

- Up command
- Down command
- Actuation command.

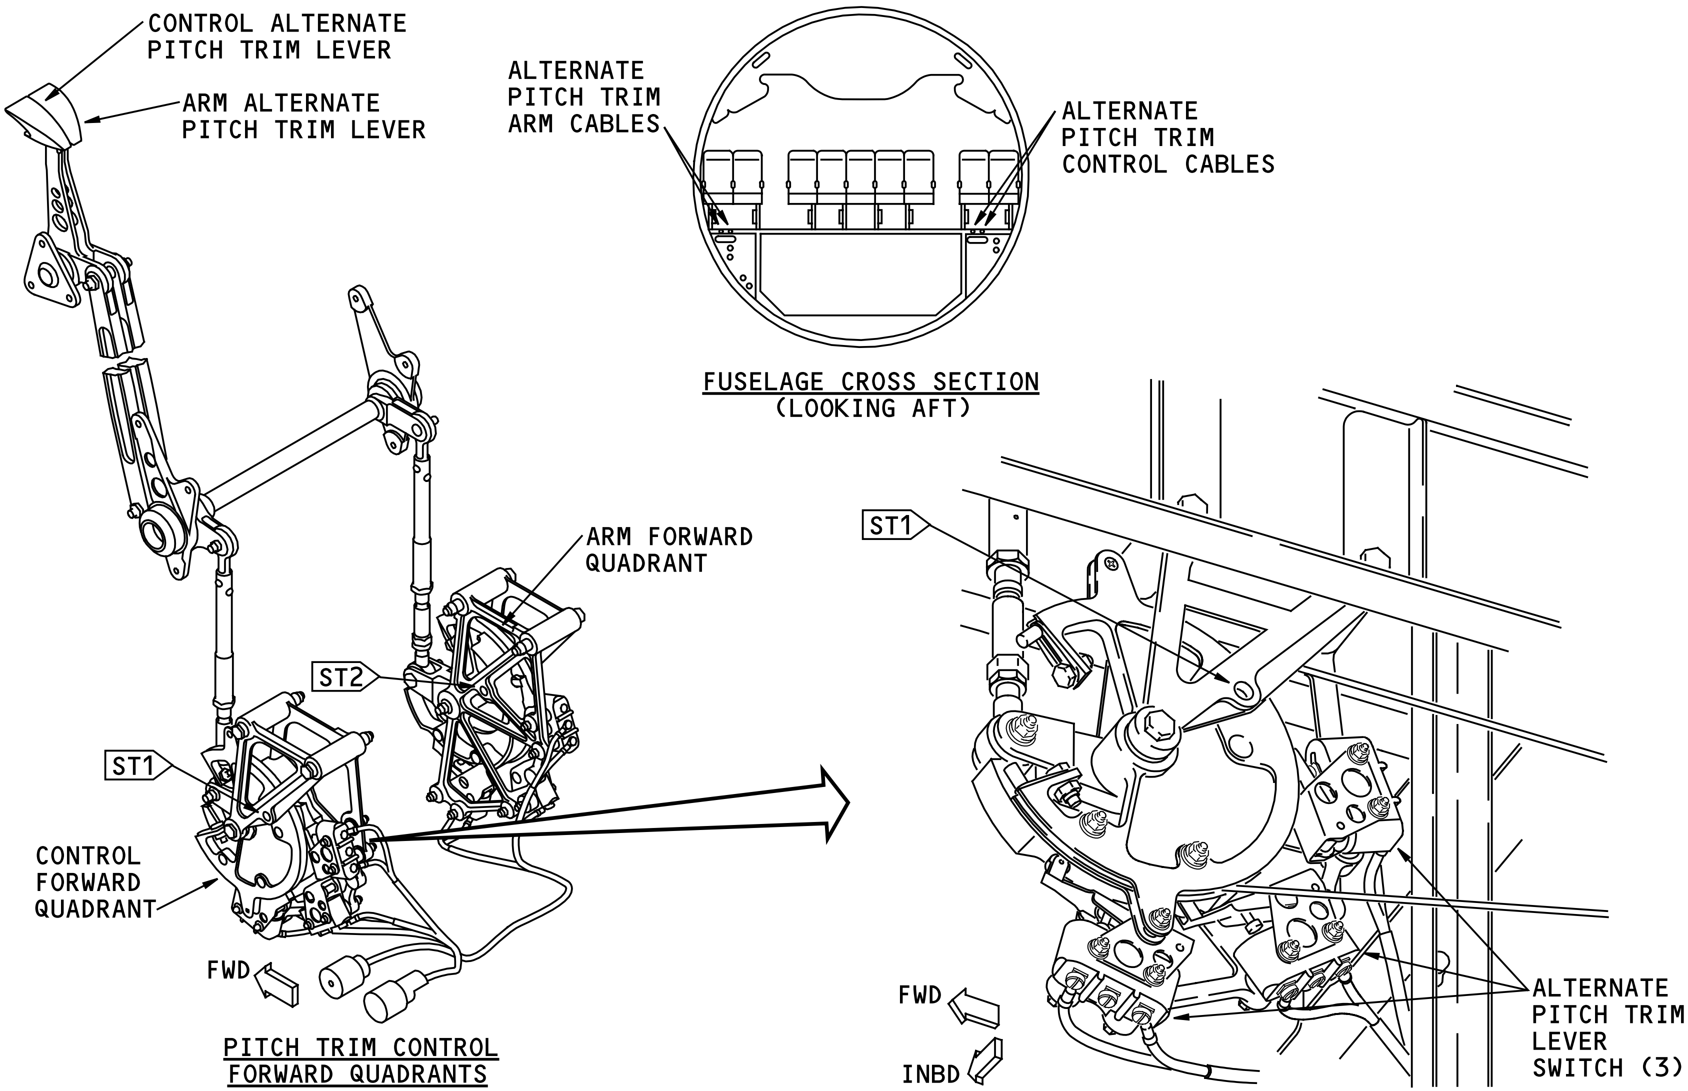
Training Information Point

There is a rig pin hole in the forward quadrants and on the support structure.

Indications

The status message ALT PITCH TRIM LEV shows when one alternate pitch trim lever switch is defective.

The status message FLIGHT CONTROL SYS shows when two or more alternate pitch trim lever switches are defective.



STX RIG PIN LOCATION

HORIZONTAL STABILIZER CONTROL - ALTERNATE PITCH TRIM LEVERS AND FORWARD QUADRANT ASSEMBLY

27-41-00-006 Rev 2 01/08/96

HORIZONTAL STABILIZER CONTROL - AFT STABILIZER QUADRANT ASSEMBLY

Purpose

The aft stabilizer quadrant assembly receives control movement from the two pairs of cables from the forward quadrant assembly. The aft stabilizer quadrant assembly transfers this movement to the input cranks on the STCMs.

Physical Description

The aft stabilizer quadrant assembly has an arm and a control quadrant on which the two alternate trim cable pairs attach. The arm quadrant is forward of the aft stabilizer quadrant assembly. The control quadrant is inside the quadrant assembly. Each quadrant connects to its own shaft by a spline which also connects to its output lever.

Control rods connect the output levers of the aft stabilizer quadrant assembly to the input cranks on the STCMs.

A travel limit drum assembly is at the aft of the quadrant assembly. The drum rotates on bearings on the aft quadrant assembly structure. A cable pair connects the drum assembly to the stabilizer structure.

Location

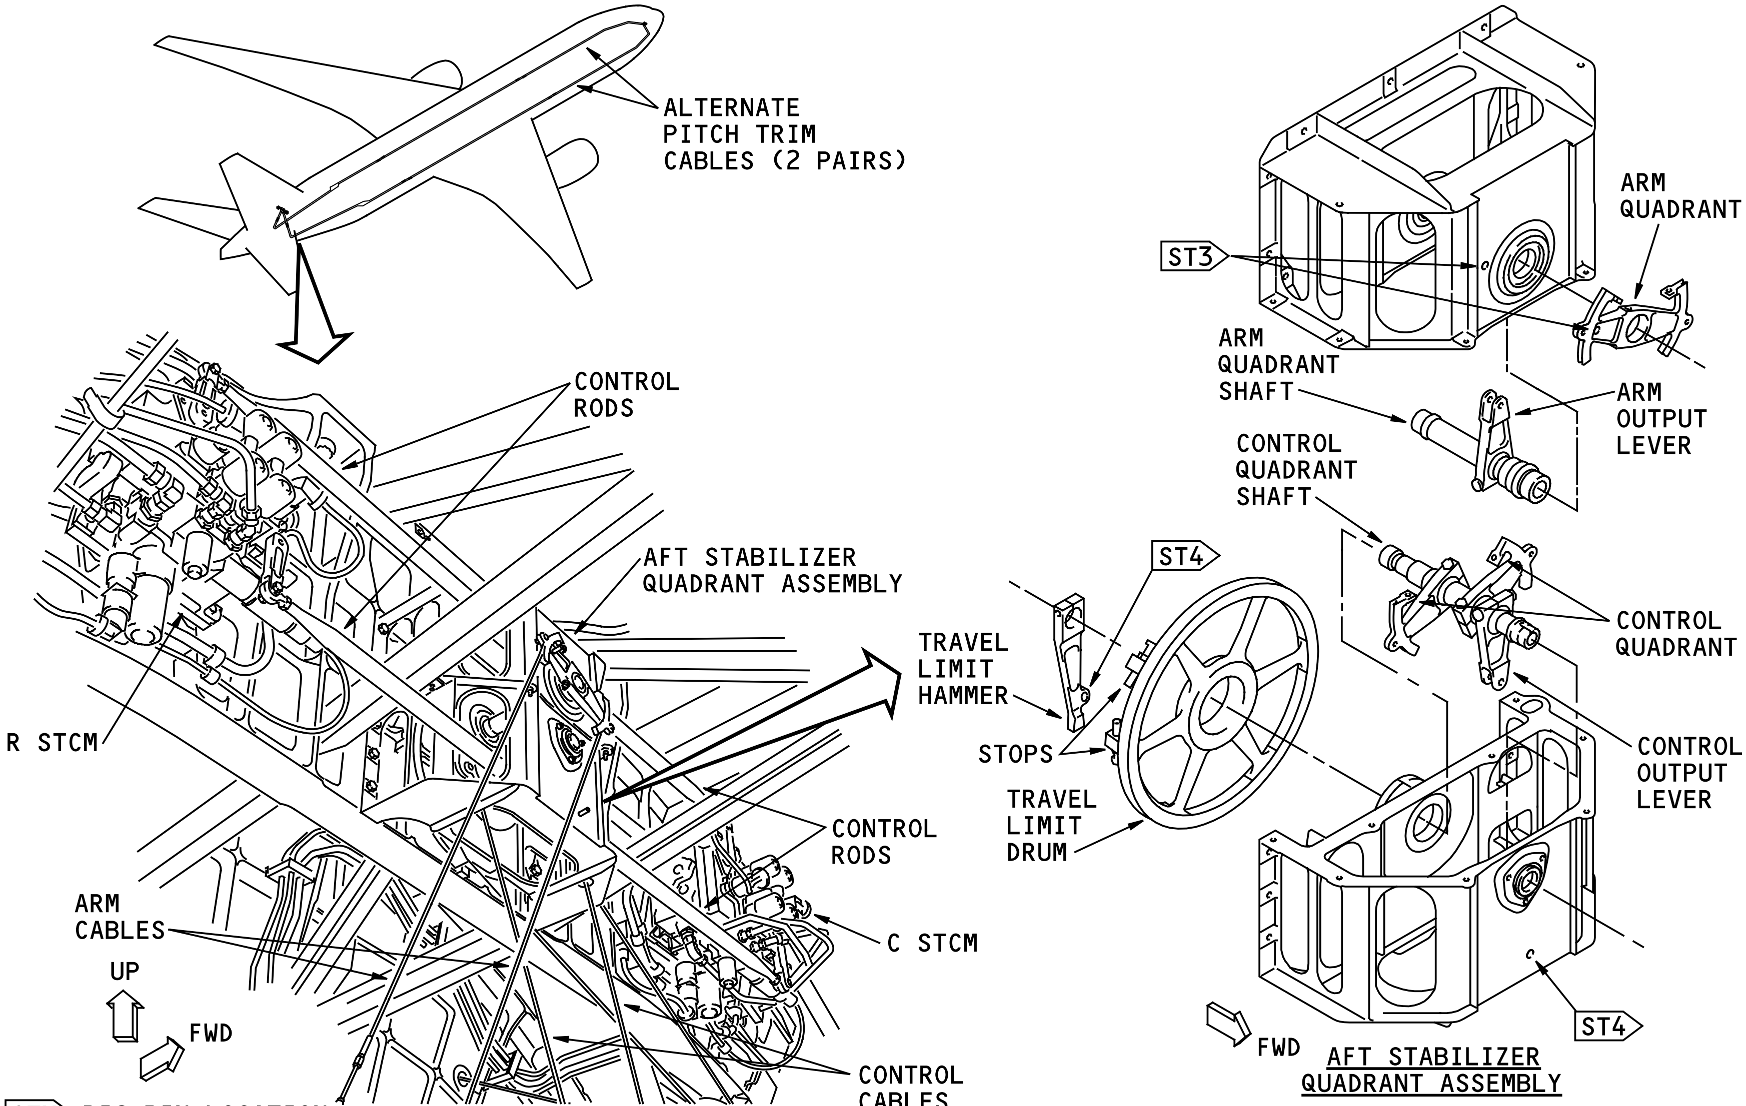
The aft stabilizer quadrant assembly is in the stabilizer compartment, near the ceiling just aft of the pressure bulkhead. The two STCMs are on either side of the quadrant assembly.

Functional Description

As the alternate pitch trim cable pairs move, in response to a movement of the alternate pitch trim levers, the arm and control quadrants rotate. Splined shafts transfer this rotation to the output levers. Control rods transfer the movement to the input cranks on the STCMs.

Training Information Point

There are rig pin holes in the arm quadrant, the travel limit hammer and aft stabilizer quadrant assembly structure.



HORIZONTAL STABILIZER CONTROL - AFT STABILIZER QUADRANT ASSEMBLY

HORIZONTAL STABILIZER CONTROL - AFT STABILIZER QUADRANT ASSY - TRAVEL LIMIT DRUM ASSEMBLY

Purpose

When the horizontal stabilizer is operated from the alternate pitch trim levers, the travel limit drum assembly stops the stabilizer at the up and down limits. These limits prevent contact between the stabilizer ballnut and the ballscrew stops.

Physical Description

The travel limit drum turns on bearings on the aft quadrant assembly structure. A cable pair connects the drum assembly to brackets attached on the front spar of the stabilizer. This cable also operates the left stabilizer position module. Stops on the drum assembly contact the travel limit hammer when the stabilizer reaches its travel limits. The travel limit hammer connects by splines to the control quadrant shaft of the aft stabilizer quadrant assembly.

Location

The travel limit drum assembly is at the aft side of the aft stabilizer quadrant assembly.

Functional Description

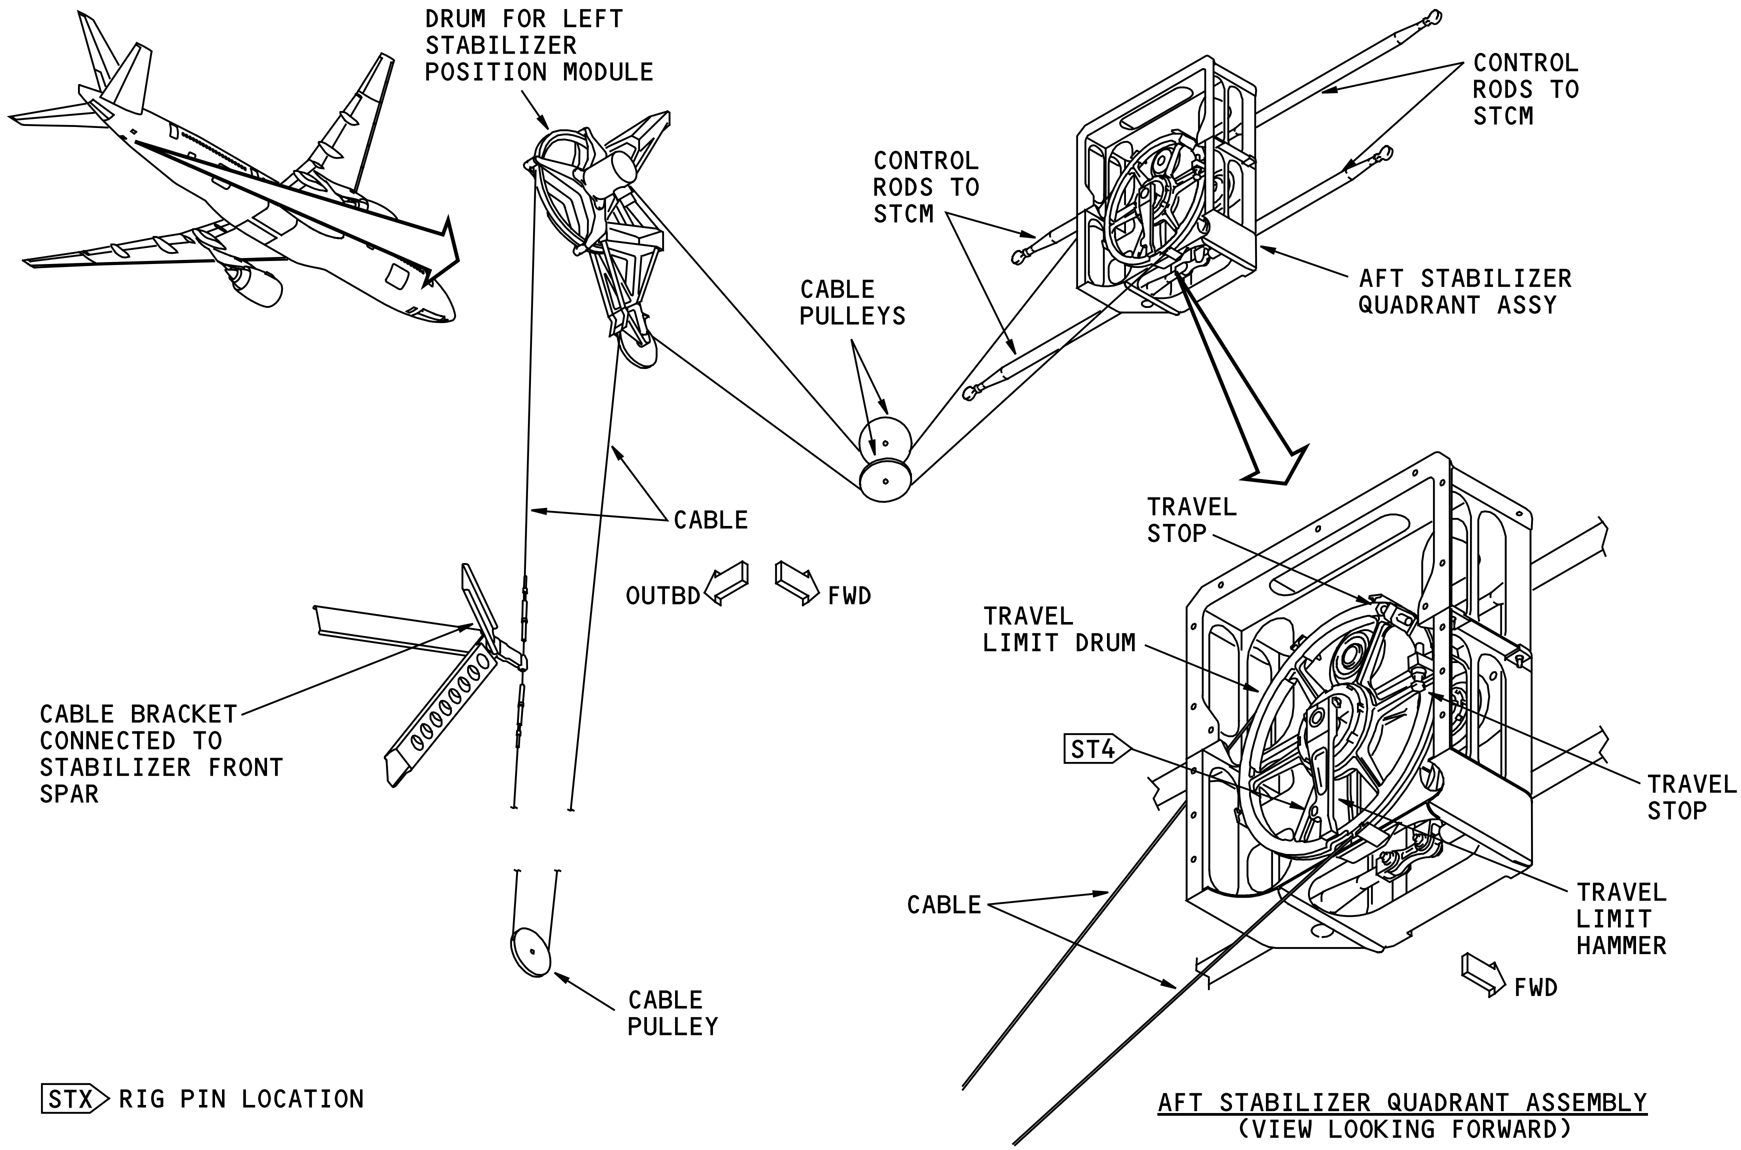
When you move the alternate pitch trim levers, the control quadrant shaft moves the travel limit hammer from its neutral position. The STCMs command causes the stabilizer to move. The pair of cables connected to the stabilizer front spar also moves. The cable movement causes the rotation of the travel limit drum assembly.

As the stabilizer reaches its up or down limit, stops on the drum contact the hammer and move it back to its neutral position. This moves the control lever of the alternate pitch trim levers to the neutral position and stops the stabilizer command.

Training Information Point

There is a rig pin hole in the travel limit hammer.

The travel stops on the travel limit drum assembly are adjustable.



27-41-00-026 Rev 0 12/16/1996

HORIZONTAL STABILIZER CONTROL - AFT STABILIZER QUADRANT ASSY - TRAVEL LIMIT DRUM ASSEMBLY

HORIZONTAL STABILIZER CONTROL - CUTOUT SWITCHES

Purpose

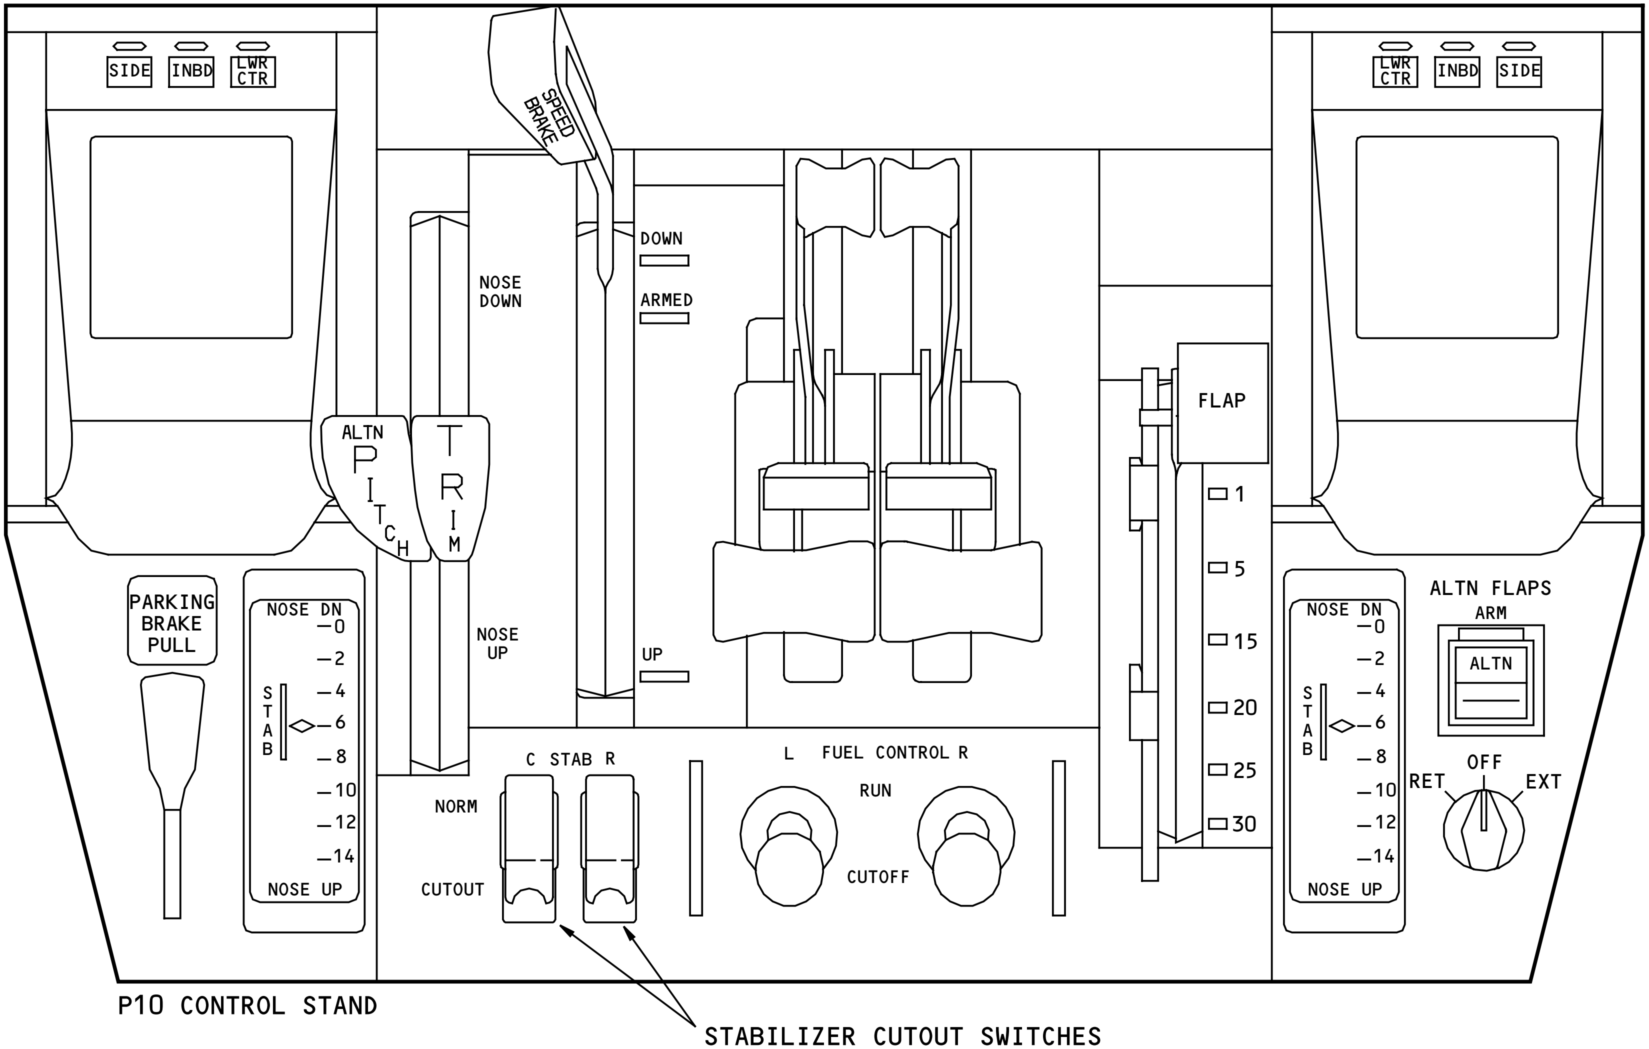
The two stabilizer cutout switches stop the stabilizer movement when they are in the CUTOUT position. The pilots use these switches in the unlikely event there is uncommanded stabilizer movement. You can move the switches to the CUTOUT position separately to control either the center or right STCM shutoff valves. These valves control hydraulic power to the stabilizer motors and brakes.

Physical Description

The cutout switches are two toggle switches, each guarded with a safety cover. To move the switches to the CUTOUT position, the pilot must raise the safety guards. The guards move the switches back to the NORM position when they are closed.

Location

The switches are on the aft, left hand side of the P10 control stand.



27-41-00-008 Rev 2 11/25/1996

HORIZONTAL STABILIZER CONTROL - CUTOUT SWITCHES

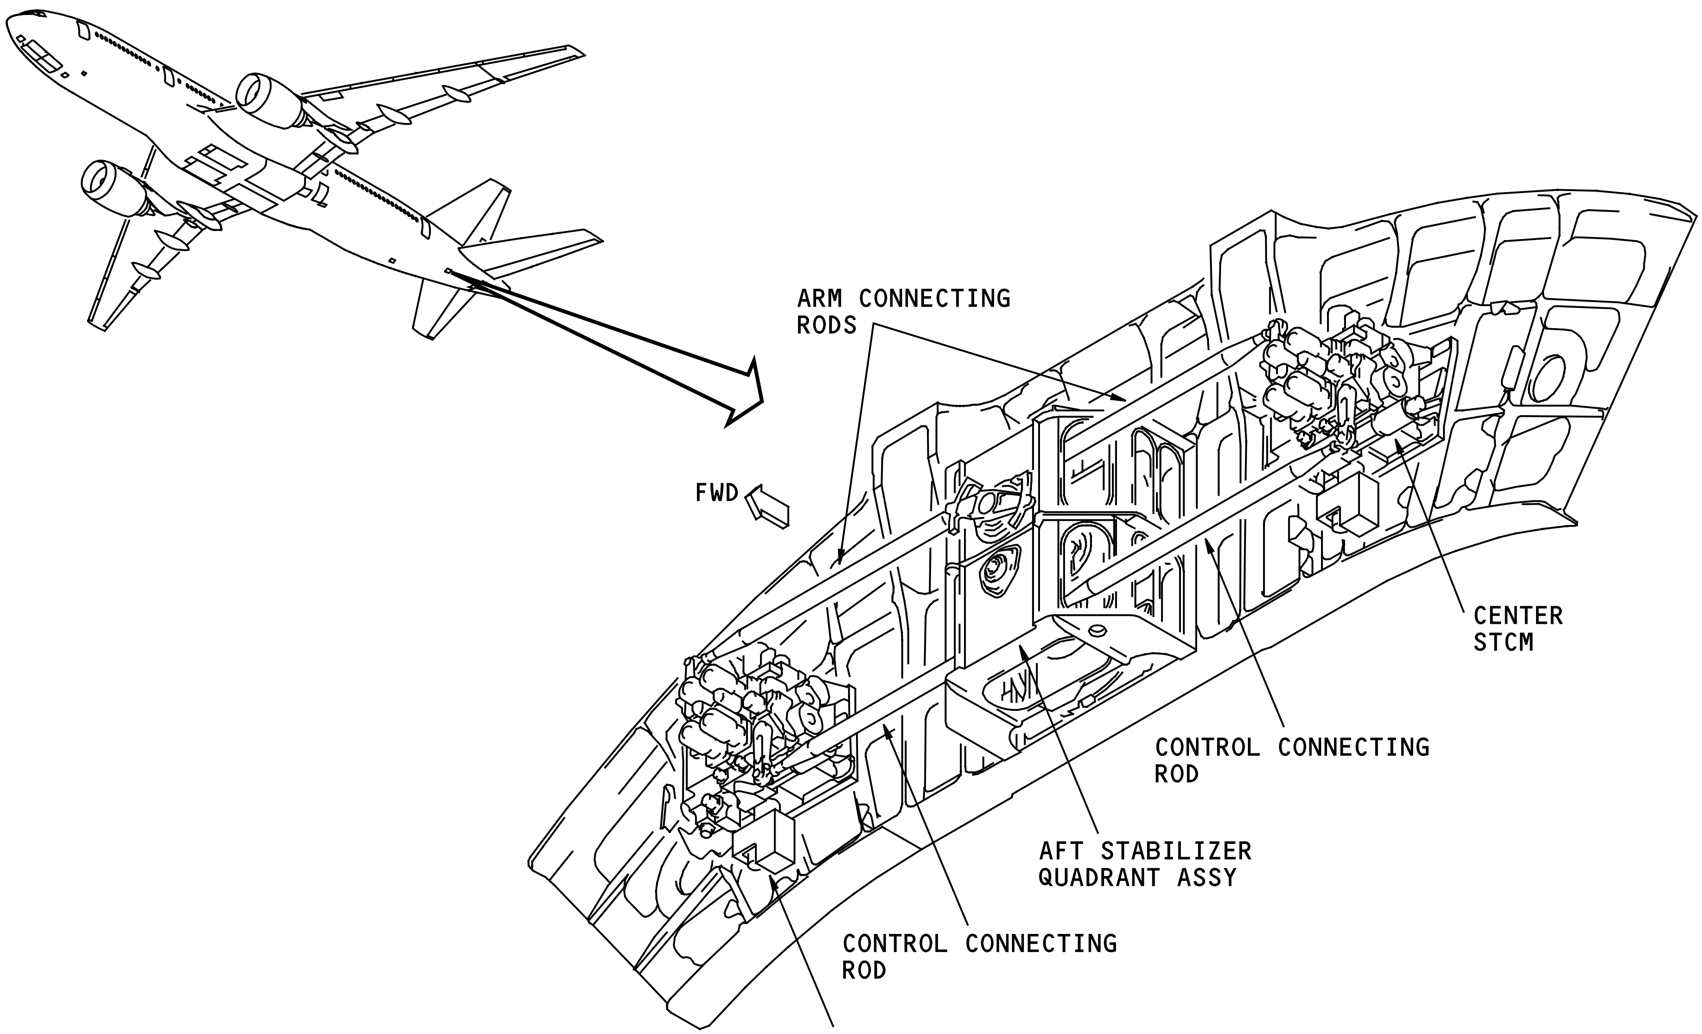
HORIZONTAL STABILIZER CONTROL - STCM - INTRODUCTION

Purpose

There are two stabilizer trim control modules. Each module controls hydraulic pressure to a hydraulic motor and brake. The STCMs receive electrical signal commands from the ACEs and mechanical commands from the alternate pitch trim levers.

Location

The two STCMs are near the ceiling of the stabilizer compartment just aft of the pressure bulkhead. Access to the compartment is by a hatch on the lower left side of the empennage.



27-41-00-009 Rev 1 02/25/1997

HORIZONTAL STABILIZER CONTROL - STCM - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

HORIZONTAL STABILIZER CONTROL - STCM - PHYSICAL DESCRIPTION

General

The two STCMs are on the airplane structure. Between the STCMs is the control module. Control rods transfer movement in the control module to the STCMs.

Electrical connectors of different sizes connect to the STCMs.

Hydraulic tubing connects to STCM input and output ports.

The center hydraulic system supplies power to the center STCM (located on the left side). The right hydraulic system supplies power to the right STCM.

The two STCMs are identical. Each STCM weighs approximately 29 lb (13 kg).

Each STCM contains an arming and control valve which controls hydraulic power to the hydraulic motor and brake. Movement of the two valves allows hydraulic pressure to release the hydraulic brake and to drive the motor in the commanded direction.

These components control the operation of the STCM:

- Motor operated shutoff valve
- Nose down control solenoid
- Nose down arm solenoid
- Arm input crank
- Rate control solenoid
- Nose up arm solenoid
- Nose up control solenoid
- Pressure switch
- Control input crank
- Brake bypass valve.

Motor Operated Shutoff Valve

The motor operated shutoff valve controls hydraulic power to the STCM. The cutout switches on the control stand, and the ACEs control power to the electric motor of the shutoff valve.

The motor operated shutoff valve has a manual override lever which is also a position indicator.

Nose Up and Nose Down, Arm and Control Solenoids

The ACEs control the nose up and nose down, arm and control solenoids. These solenoids operate valves which control hydraulic pilot pressure to move the arming and control valves.

Arm and Control Input Cranks

The arm and control input cranks connect to an arm and control manual valve in the STCM. The manual valves control hydraulic pilot pressure to move the arming and control valves.

Rate Control Solenoid

The ACEs control the trim rate solenoid. The solenoid operates a two position valve. It allows either full or restricted hydraulic flow to the hydraulic motor. This controls the rotation speed of the motor.

Pressure Switch

The pressure switch monitors the hydraulic pressure to the brake. The switch closes when the STCM sends hydraulic pressure to release the brake. The discrete brake release signal goes to the ACE.

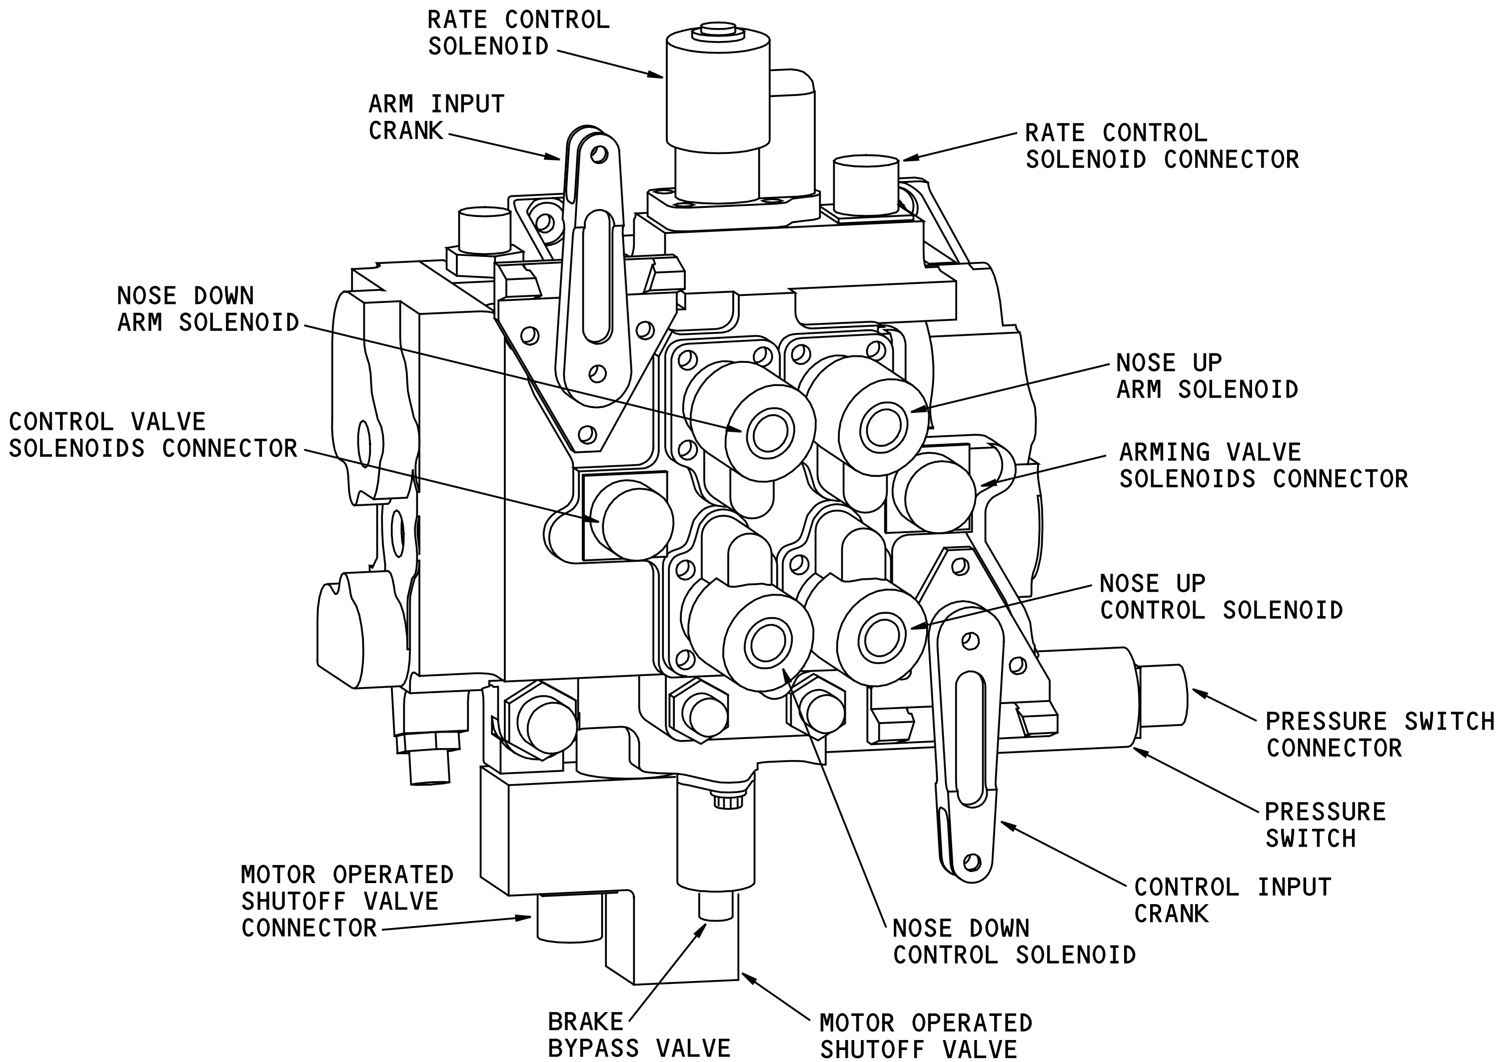
Brake Bypass Valve

Maintenance personnel use the brake bypass valve to periodically test the operation of the hydraulic brake. When you push on the brake bypass valve button, the valve shuts off hydraulic pressure to the brake. While you hold the button, you verify that the brake stops and holds the hydraulic motor. When released, a spring moves the brake bypass valve back to the open position.

Training Information Point

These are the LRUs on the STCMs:

- Rate control solenoid
- Nose up and down arm solenoids
- Nose up and down control solenoids
- Pressure switch
- Motor operated shutoff valve.



27-41-00-010 Rev 3 05/02/95

HORIZONTAL STABILIZER CONTROL - STCM - PHYSICAL DESCRIPTION

HORIZONTAL STABILIZER CONTROL - STCM - FUNCTIONAL DESCRIPTION

General

The STCM controls hydraulic power to the motor and brake of the stabilizer ballscrew actuator. It operates in two different modes of operation:

- Electrical
- Mechanical.

An inlet filter and check valve are in the hydraulic power supply line to the motor operated shutoff valve. In either mode of operation, the shutoff valve normally controls hydraulic power to the trim rate solenoid valve. The cutout switches on the control stand and the PFCs control the motor operated shutoff valve.

The PFC commands, through the ACE, the trim rate solenoid valve to high or low flow based on airspeed and flap position. A spring returns the trim rate solenoid valve to the high flow position when the solenoid is de-energized.

Arming and Control Valves

The arming and control valves have three positions:

- Null
- Trim up
- Trim down.

Hydraulic pilot pressure controls the position of the arming and control valves. This pilot pressure comes from one or both of these sources:

- The trim up and down, arm and control solenoid valves
- The arm and control manual valves.

Springs in the arming and control valves center and hold them in the null position when there is no hydraulic pressure. With the two valves in the null position, they stop hydraulic pressure to the brake and motor of the stabilizer ballscrew actuator.

The arming and control valves must move together in the same direction to permit hydraulic pressure to the hydraulic brake and motor.

When both arming and control valves move to the trim up position, hydraulic power goes to release the brake and drive the hydraulic motor in the nose up direction.

When both arming and control valves move to the trim down position, hydraulic power goes to release the brake and drive the hydraulic motor in the nose down direction.

Two anti-cavitation check valves supply hydraulic fluid to the motor. They prevent motor cavitation in the unlikely event of brake slip and backdrive of the motor.

Electrical Operation

When the trim up and trim down, arm and control solenoid valves are de-energized, they allow hydraulic pilot pressure on both sides of the arming and control valves. The two valves are in the null position.

When their solenoids are both energized, the trim up arm and control solenoid valves operate. They stop hydraulic pilot pressure to the trim up side of the arming and control valves and port it to the system return line. Both arming and control valves move to the trim up position and permit pressure to the brake and motor.

When the solenoids of the trim down arm and control solenoid valves are both energized, the same process occurs. But in this case, the arming and control valves move to the trim down position and permit hydraulic pressure to the brake and motor.

Mechanical Operation

The arm and control input cranks connect to the arm and control manual valves. These valves control hydraulic pilot pressure to the arming and control valves.

The arm and control manual valves have three positions:

- Null
- Trim up
- Trim down.

Springs in the arm and control manual valves center them in the null position when there is no force on the input cranks. With the two valves in the null position, they permit hydraulic pilot pressure to both sides of the arming and control valves.

Because they are directly upstream of the arming and control valves, the manual valves have first priority of control over the trim up and down, arm and control solenoid valves. This permits the pilot to manually override any electrical command to the stabilizer.

When the arm and control input cranks move to the trim up position, they command the manual valves to move to the trim up position. The manual valves stop hydraulic pilot pressure to the trim up side of the arming and control valves and port it to the system return line. Both arming and control valves move to the trim up position and permit pressure to the brake and motor.

When the input cranks move to the trim down position, the same process occurs. But in this case, the arming and control valves move to the trim down position and permit hydraulic pressure to the brake and motor.

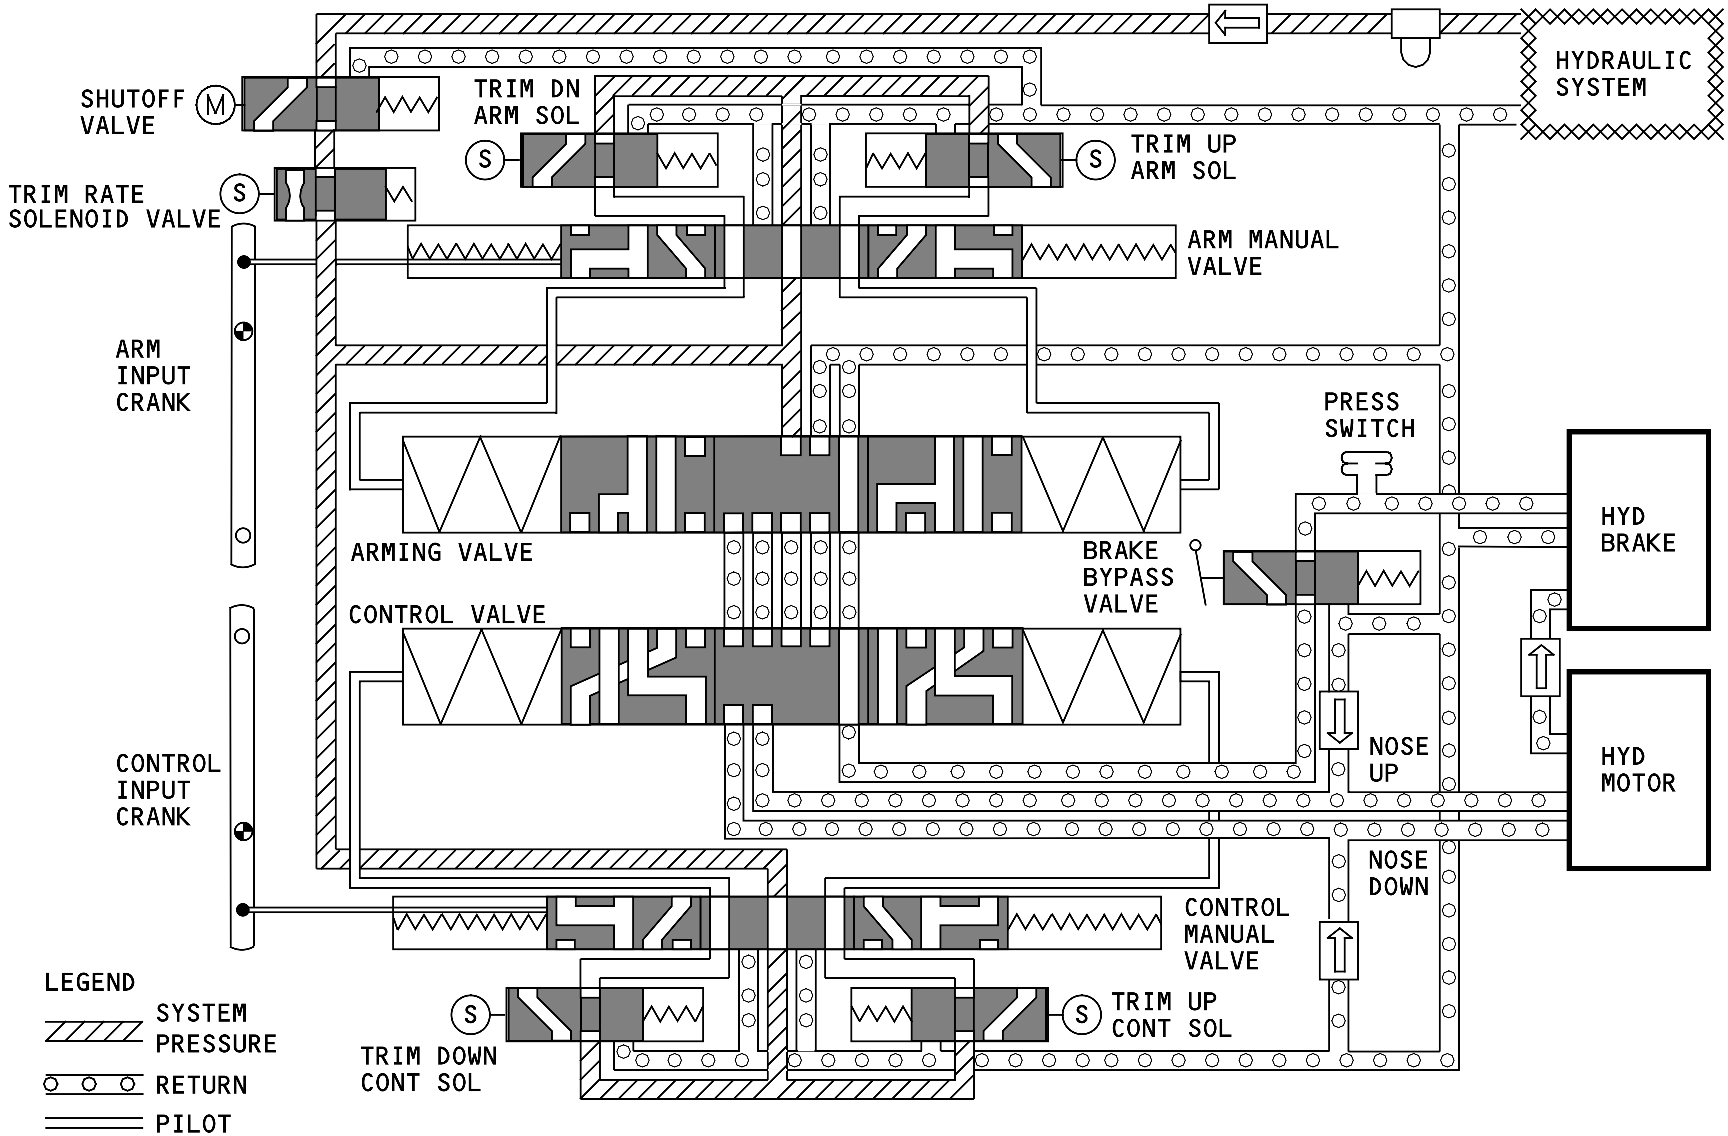
Brake Bypass Valve

The manually operated brake bypass valve permits maintenance personnel to test the effectiveness of the hydraulic brake. When activated, the valve blocks hydraulic pressure to the brake and ports it to the system return line. This prevents brake release when the hydraulic motor is pressurized.

HORIZONTAL STABILIZER CONTROL - STCM - FUNCTIONAL DESCRIPTION

Pressure Switch

The pressure switch closes at 1000 psi. It sends a discrete signal to the ACEs to indicate the pressure status to the brake.



27-41-00-011 Rev 0

HORIZONTAL STABILIZER CONTROL - STCM - FUNCTIONAL DESCRIPTION

HORIZONTAL STABILIZER CONTROL - POSITION MODULES

Purpose

The stabilizer position modules perform two functions. Limit switches within the modules electrically limit the travel of the stabilizer. An RVDT in each module sends an analog signal that represents stabilizer position. This signal goes to the ACEs.

Physical Description

There are three identical stabilizer position modules. The modules are on assemblies which include a pulley bracket base, a cable drum, and the stabilizer position module.

The module weighs approximately 1.6 lb (0.7 kg).

Location

The modules attach to airplane structure near the ceiling in the stabilizer compartment.

Functional Description

Three cables attach to the leading edge of the stabilizer and go around the cable drums. The cables go around pulleys attached to the structure at the bottom of the stabilizer compartment. The cables also attach to the cable drums of the stabilizer position module assemblies. When the stabilizer moves, the cable drums turn the splined shaft in the position module.

Internal gears within the module, cause rotation of an RVDT. It sends a variable analog signal to the ACEs. The signal represents the stabilizer position.

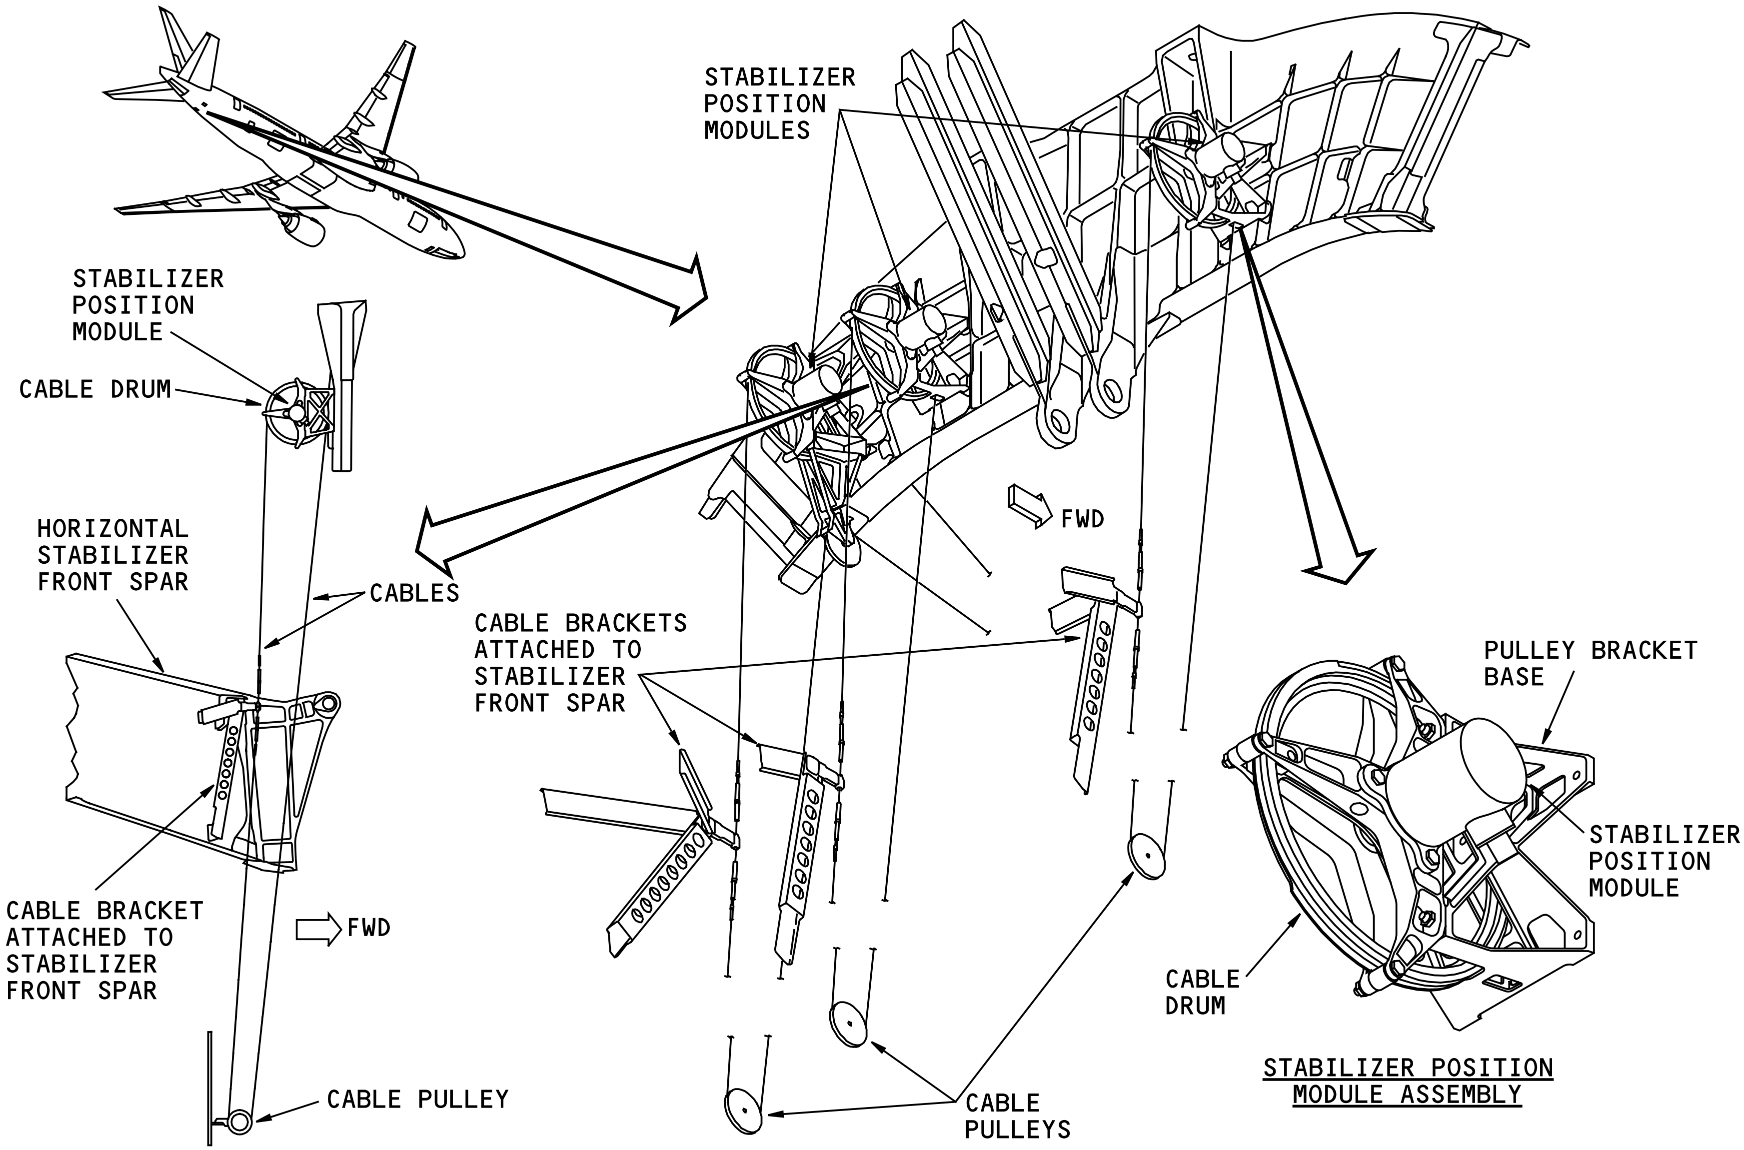
See the horizontal stabilizer position indication section for more information about the stabilizer position modules (AMM PART I 27-48).

Rotation of the shaft also causes two switches to open and close. As the stabilizer reaches +3.75 degrees nose down, the nose down control switch opens. This removes the control signal to the STCM and stops stabilizer movement.

The nose up control switch opens at -10.75 degrees to stop stabilizer travel in the nose up direction.

Training Information Point

No rigging is necessary for removal and installation of the module.



27-41-00-015 Rev 4 12/16/1996

HORIZONTAL STABILIZER CONTROL - POSITION MODULES

HORIZONTAL STABILIZER CONTROL - POSITION INDICATORS

Purpose

The stabilizer position indicators show the pilots stabilizer position in units of pitch trim.

The indicators also show the pilots if the stabilizer is in a safe position for take-off.

Physical Description

The two identical stabilizer position indicators are LRUs.

The stabilizer trim pointer shows the position of the stabilizer. The indicator scale has 15 units. Each unit of pointer movement is equivalent to about one degree of stabilizer movement.

Also on the indicator is a green band that shows take-off range. The PFCS calculates green band position from information entered into the FMCS during preflight. The information is sent through the ARINC 629 buses to the AIMS and then to the position indicators.

Location

The stabilizer position indicators are on the aft end of the P10 control stand.

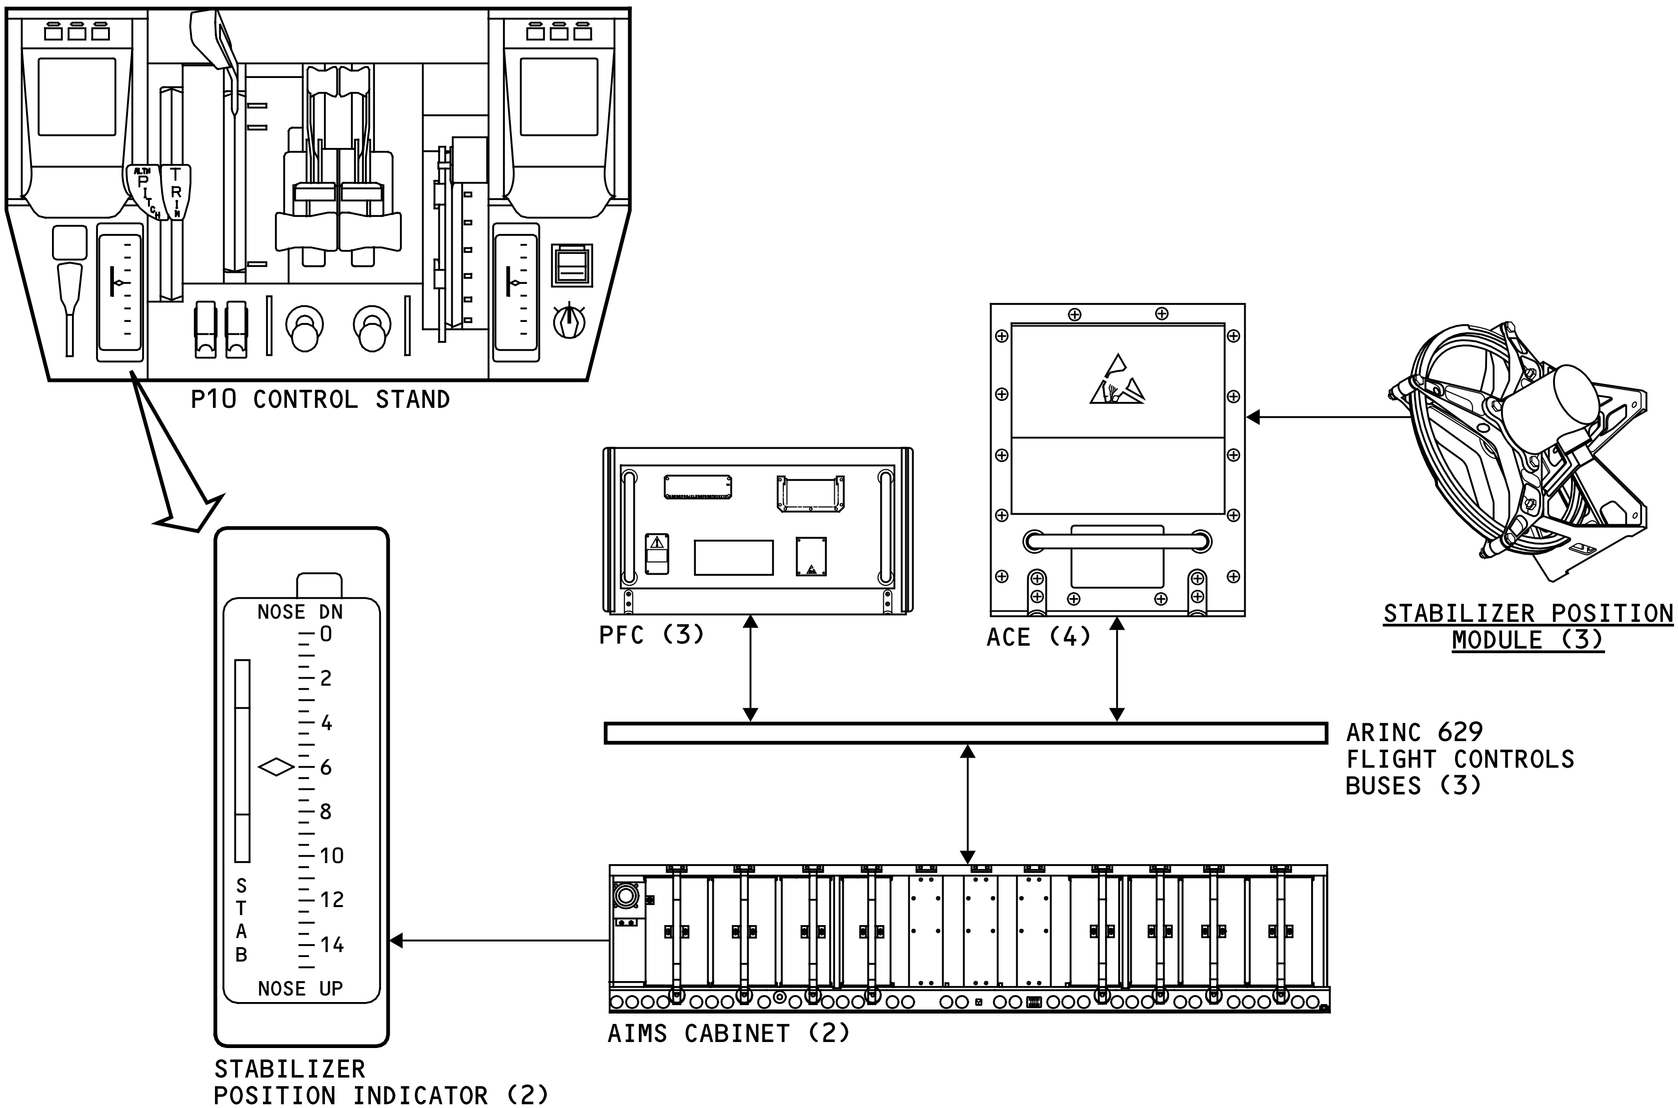
Functional Description

The analog signal from the RVDTs in the position modules go to the ACEs. These signals represent the stabilizer position.

The ACEs change the analog signal to digital and send them to the PFCs and the AIMS.

The AIMS uses ARINC 429 buses to transmit the digital signal to the stabilizer position indicator for display.

The PFCS uses center of gravity, aircraft gross weight and the take-off thrust setting information from FMCS to show the green band.



27-41-00-016 Rev 0

HORIZONTAL STABILIZER CONTROL - POSITION INDICATORS

HORIZONTAL STABILIZER CONTROL - STABILIZER ASSEMBLY

Purpose

The horizontal stabilizer supplies long-term pitch control of the airplane.

Physical Description

The stabilizer is a light-weight composite material structure. The main torque boxes are carbon fiber construction with aluminum trailing edge hinge ribs. Steel hinge plates with fiberglass honeycomb panel fairings attach to the trailing edge of these ribs.

Forward of the main torque boxes are auxiliary boxes formed by aluminum sheet metal ribs that have covers made of fiberglass honeycomb panels.

The leading edges and the tips of the stabilizer are aluminum skinned honeycomb panels.

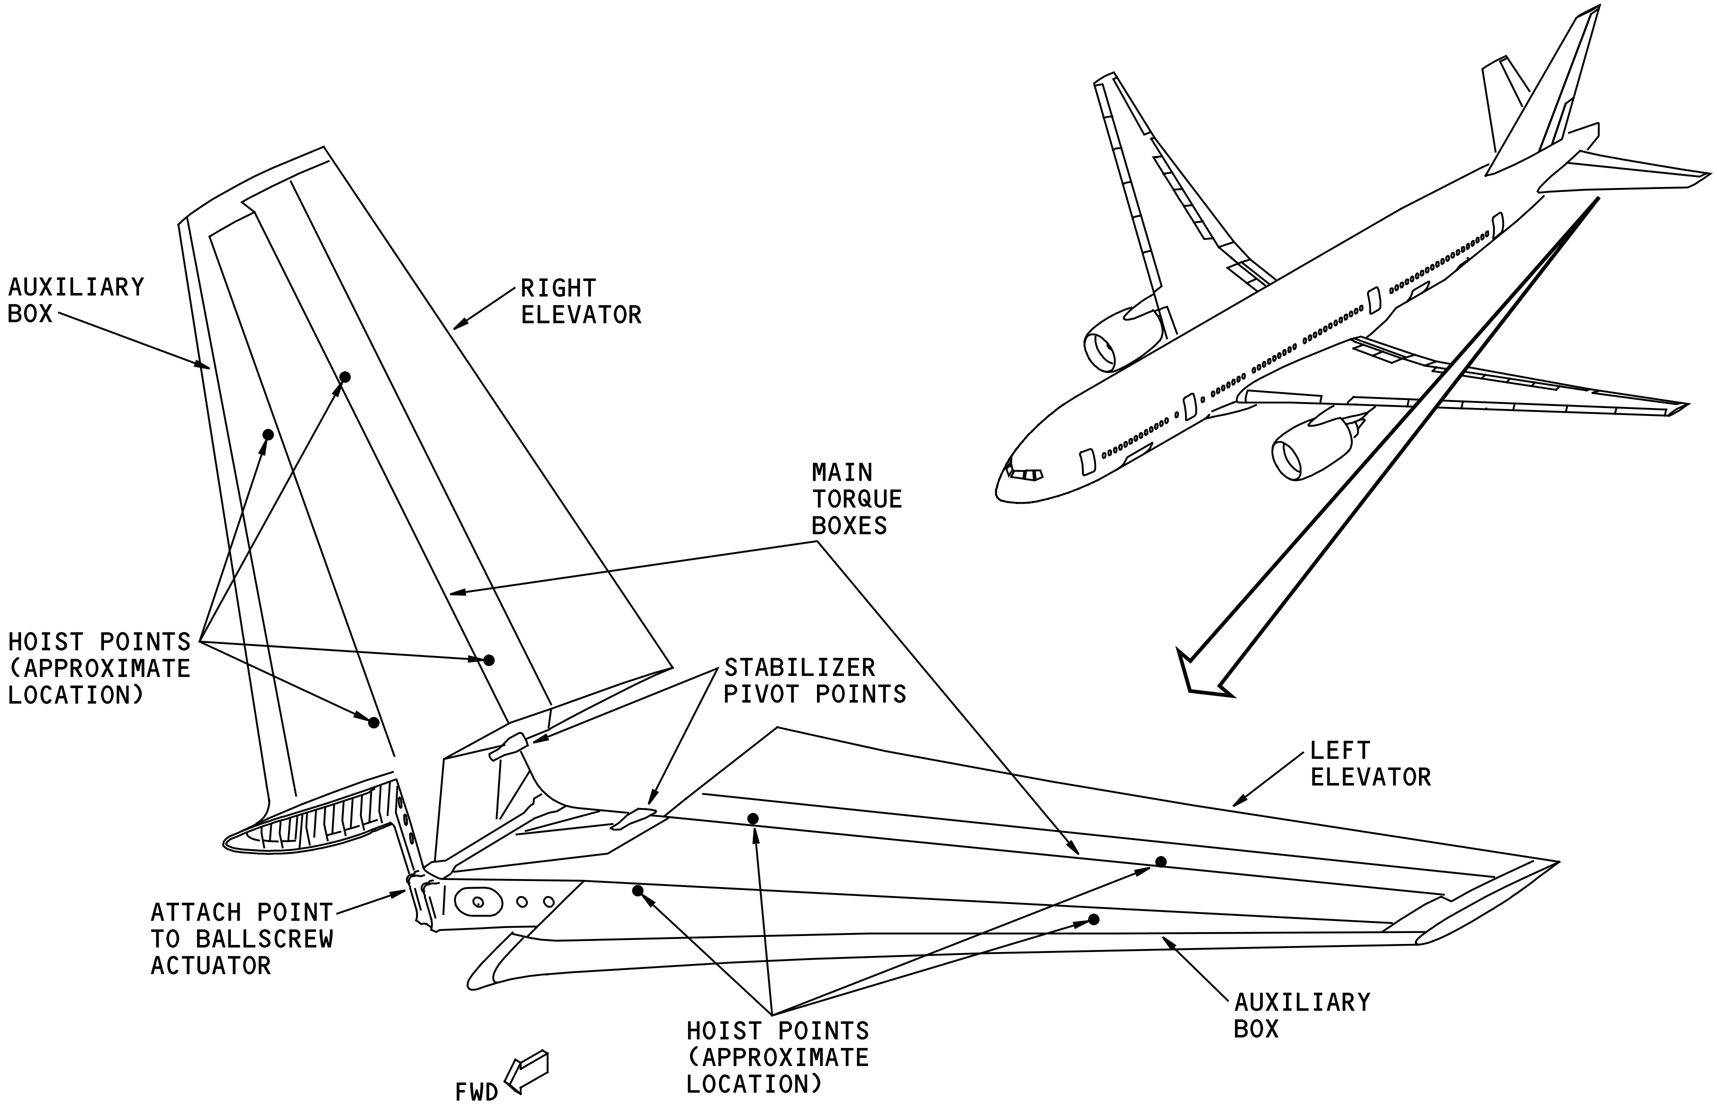
The horizontal stabilizer assembly weights approximately 6100 lbs (2765 kg). This includes the weight of the elevators and the PCUs. The horizontal stabilizer assembly measures about 71 feet wide by 34 feet long (21.6 meters by 10.4 meters).

There are four hoist points on the upper and lower surfaces on each side of the horizontal stabilizer assembly.

Functional Description

The stabilizer moves 15 degrees:

- 4 degrees leading edge up (4 degrees airplane nose down trim) from neutral
- 11 degrees leading edge down (minus 11 degrees airplane nose up) from neutral.



27-41-00-017 Rev 2 01/08/96

HORIZONTAL STABILIZER CONTROL - STABILIZER ASSEMBLY

THIS PAGE INTENTIONALLY LEFT BLANK

HORIZONTAL STABILIZER CONTROL - FUNCTIONAL DESCRIPTION - INTRODUCTION

General

The stabilizer control system uses input command signals from the captain's and first officer's pitch trim switches.

The ACEs receive the input signals and supply output command signals to the STCMs. The ACEs also receive feedback signals from the SPMs.

The stabilizer cutout switches and the auto shutdown relays send signals to the STCMs to close the motor operated shutoff valves.

The system also operates with mechanical commands from the alternate pitch trim levers directly to the STCMs.

Pitch Trim Switches

Each ACE receives a signal from a pitch trim switch. The L1 ACE receives the arm signal from the captain's arm switch and the L2 ACE from the first officer's arm switch. The C ACE receives the control signal from the captain's control switch and the R ACE from the first officer's control switch.

Stabilizer Cutout Switches and Auto Shutdown Relays

The stabilizer cutout switches directly control power to close the motor operated shutoff valve on the STCMs.

Two ACEs control the auto shutdown relays individually. When commanded, each relay sends power to close a motor operated shutoff valve on an STCM.

Stabilizer Trim Control Modules

The center STCM requires the operation of the C and L1 ACEs.

The C ACE sends command signals through the auto shutdown relay to close the shutoff valve of the center STCM. The shutoff valve also receives command signals directly from the center stabilizer cutout switch. The center STCM also receives from the C ACE the control up or down command signals. These signals initially go through the limit switches of the center SPM before they command the control solenoids.

The center STCM receives arm up or down command signals and the rate solenoid signals from the L1 ACE.

The right STCM requires the operation of the R and L2 ACEs.

The R ACE sends command signals through the auto shutdown relay to close the shutoff valve of the right STCM. The shutoff valve also receives command signals directly from the right stabilizer cutout switch. The right STCM also receives the control up and down command signals from the R ACE. These signals initially go through the limit switches of the right SPM before they command the control solenoids.

HORIZONTAL STABILIZER CONTROL - FUNCTIONAL DESCRIPTION - INTRODUCTION

The right STCM receives arm up or down command signals and the rate solenoid signals from the L2 ACE.

The brake pressure switch of the center STCM sends a feedback signal to the C ACE, the switch from the right STCM to the R ACE.

The alternate pitch trim levers mechanically operate the arm and control manual valves of both STCMs.

Stabilizer Position Modules

The RVDT of the left SPM sends a stabilizer position feedback signal to the L1 ACE, the RVDT of the center SPM to the C ACE, and the RVDT of the right SPM to the R ACE.

The limit switches in the center SPM control the signal from the C ACE to the center STCM. The limit switches in the right SPM control the signal from the R ACE to the right STCM. The limit switches of the left SPM are not used.

Alternate Pitch Trim Switches

The alternate pitch trim levers move alternate pitch trim switches which send signals to the AIMS cabinets.

HORIZONTAL STABILIZER CONTROL - FUNCTIONAL DESCRIPTION - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

HORIZONTAL STABILIZER CONTROL - FUNCTIONAL DESCRIPTION - HYDRAULIC CUTOUT AND AUTO SHUTDOWN

General

The stabilizer cutout switches and auto shutdown relays supply power to the shutoff valves in the STCMs. These valves control hydraulic power to the stabilizer motor and brake.

Cutout Switches

With the cutout switch in the CUTOUT position, 28v dc power goes directly to the close side of the shutoff valve motor. As the valve completes its travel to the closed position, limit switches in the motor assembly move to the ready-to-open position.

With the cutout switch back to the NORM position, power goes through the de-energized shutdown relay to drive the valve back to the open position. The motor limit switches then return to the ready-to-close position.

Auto Shutdown Relays

The PFCs command the ACEs to energize the auto shutdown relays for:

- An uncommanded stabilizer movement
- A no stabilizer motion fault
- An STCM defective response.

The PFCs monitor the left and right STCMs individually for stabilizer operation. If a PFC finds a system malfunction, it commands the ACE to energize the left or right stabilizer auto shutdown relay in relation to the STCM that has a defect. The ACE then latches the auto shutdown relay. The energized auto shutdown relay supplies power to close its shutoff valve.

Indications

Unscheduled stabilizer motion when there is an auto shutdown failure causes a STABILIZER warning message to show.

A FLIGHT CONTROLS caution message shows if both stabilizer channels are defective.

A STABILIZER C or a STABILIZER R advisory message shows if the center or right channel shuts down or if one of the cutout switches is in the CUTOUT position.

The advisory message STABILIZER CUTOUT shows when both cutout switches are in the CUTOUT position.

Training Information Point

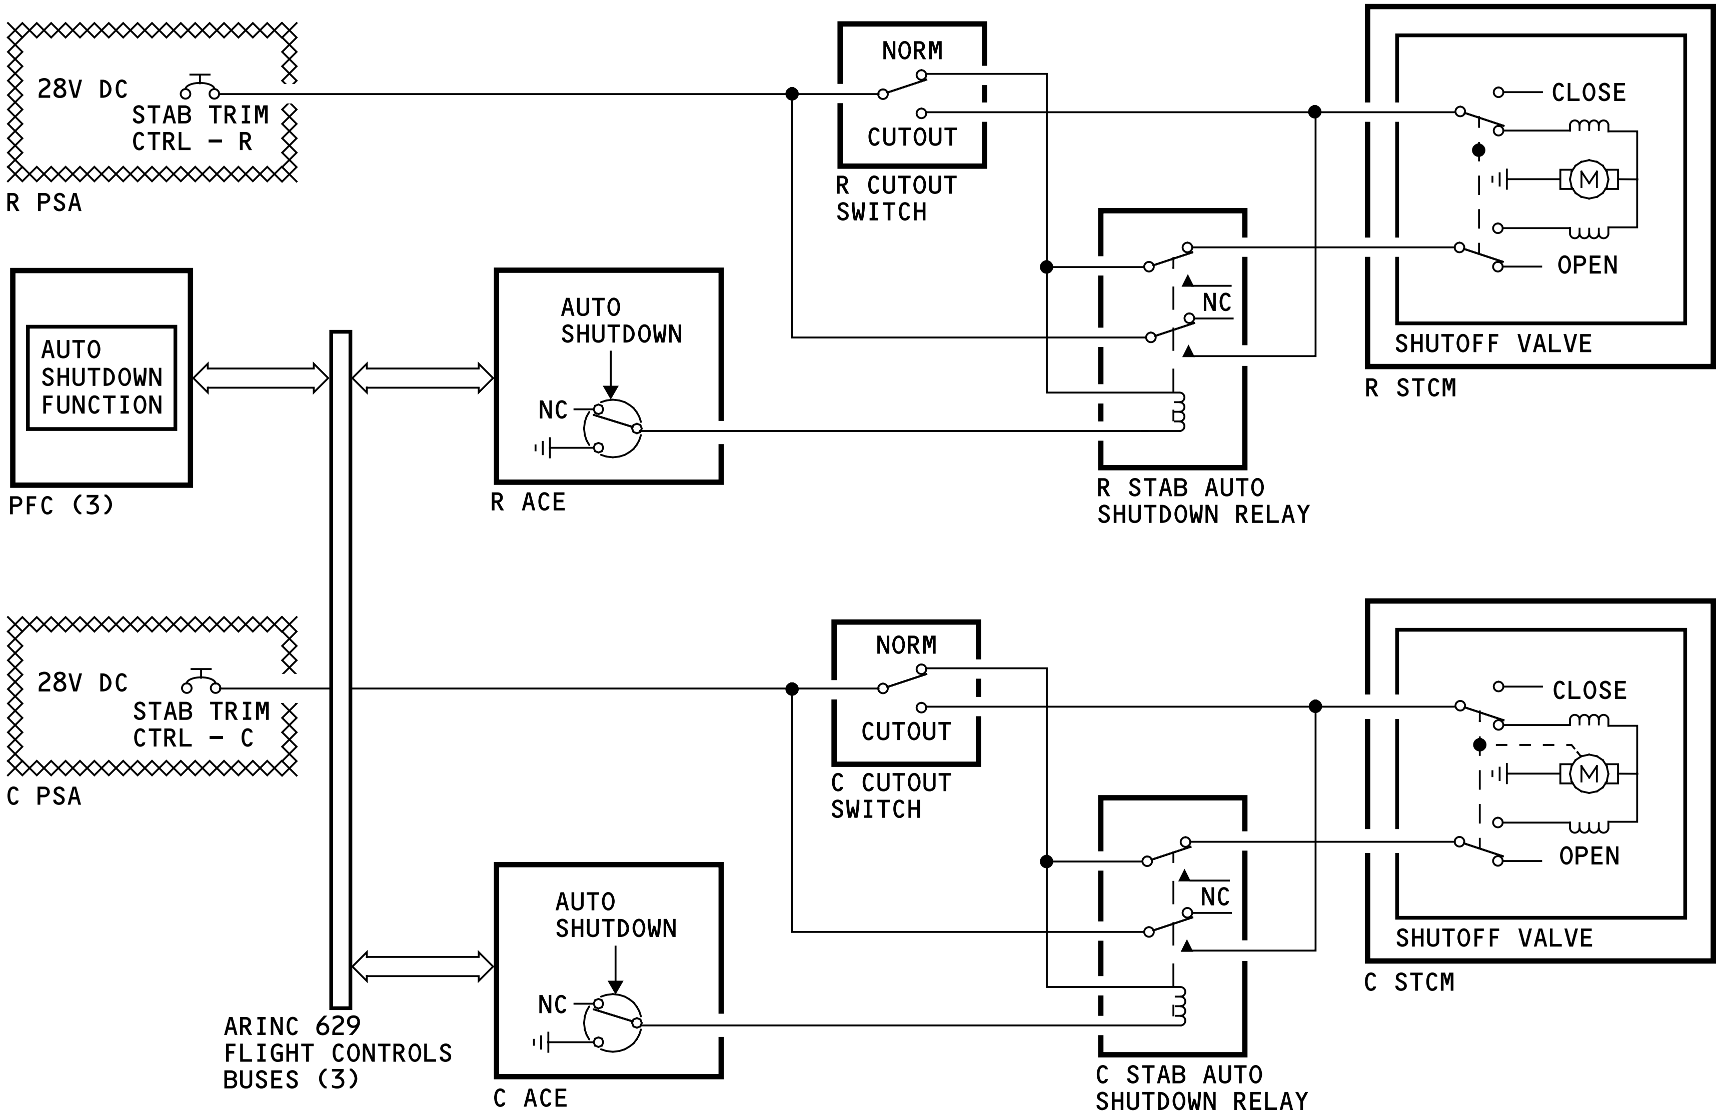
Maintenance personnel can use the stabilizer cutout switches to do fault isolation of stabilizer system malfunctions.

A maintenance action is necessary to unlatch the auto shutdown relays. After correction of the fault, the stabilizer system ground test unlatches the PFC auto shutdown commands to the ACEs when the system passes the test.

You can also use the PFC disconnect switch on the P5 panel with the C and R cutout switches to unlatch the auto shutdown relays. Because the ACE latch can be manually reset only in direct mode, the PFC disconnect switch first must be in the DISC position. With the cutout switch of the shutdown STCM in the CUTOUT position, the auto shutdown relay de-energizes. The ACE monitors the power removal from the auto shutdown relay and resets its auto shutdown latch.

When the cutout switch moves back to the NORM position, the auto shutdown relay stays de-energized and permits the STCM shutoff valve to open. This permits the pilot to control the stabilizer in direct mode.

If the stabilizer motion fault continues when the PFC disconnect switch moves back to the NORM position, the PFCs immediately command the ACEs to energize and latch the auto shutdown relays.



27-41-00-019 Rev 4 12/16/1996

HORIZONTAL STABILIZER CONTROL - FUNCTIONAL DESCRIPTION - HYDRAULIC CUTOUT AND AUTO SHUTDOWN

THIS PAGE INTENTIONALLY LEFT BLANK

HORIZONTAL STABILIZER CONTROL - FUNCTIONAL DESCRIPTION - STABILIZER ELECTRICAL CONTROL

General

The ACEs send the electrical commands to control the stabilizer. In normal and secondary modes, the PFC calculate the commands and send them to the ACEs. In the direct mode, the ACEs uses the commands from the pitch trim switches.

The STCM must have both an arm and a control signal from its two ACEs to operate the stabilizer ball screw assembly.

Normal Mode

In normal mode, the pitch trim switch signals operate in pairs. The signals from both the control and arm pitch trim switches are necessary from the captain (left) or the first officer (right) for the PFC logic to calculate a command for the ACEs.

In the air, a command from the pitch trim switches causes a command to the elevator. Only the elevator offload function of the PFCs can control the stabilizer while the airplane is in the air. The command can be for single or dual path, low or high rate.

On the ground, an input from the pitch trim switches causes a PFC stabilizer command to the ACEs. This command is for dual path at high rate.

When the flaps are retracted, the PFC logic stops the movement of the stabilizer at:

- +2.25 degrees of airplane nose down trim
- -10.25 degrees of airplane nose up trim.

When the flaps are extended, the SPM limit switches stop the stabilizer at +3.75 degrees of nose down trim. The PFC logic still stops the movement of the stabilizer at -10.25 degrees of airplane nose up trim.

If there is an ACE or an ARINC 629 flight control bus failure, the PFC permits a single pitch trim switch, arm or control, to command pitch trim as long as the signal path from the switch to the PFC is valid.

Secondary Mode

In secondary mode, the pitch trim switch signals also operate in pairs. Both arm and control signals are necessary for the PFC logic to calculate a command.

An input by the pitch trim switches always causes a stabilizer command for single path at high rate. The PFCs alternate which stabilizer path operates.

The stabilizer limits are the same as in the normal mode.

Direct Mode

In direct mode, the pitch trim switch signals operate individually through the ACE to which they connect. Pitch trim switch arm and control signals are necessary to the two ACEs that connect to the STCM. The captain's input causes a command to the C STCM while the first officer's input causes a command to the R STCM. The command is always at high rate.

The limit switches in the SPM that connect the ACE and the STCM stop the movement of the stabilizer at:

- +3.75 degrees of airplane nose down trim
- -10.75 degrees of airplane nose up trim.

If both pilots make a pitch trim switch command at the same time and in the same direction, the ACEs send commands in dual path. The two STCMs operate both motors and brakes. The stabilizer then moves at full speed.

If both pilots make a pitch trim switch command at the same time but in opposite direction, the ACEs send commands in dual path in opposite rotation. The two STCMs operate both motors and brakes. The stabilizer then does not move, or may move slowly if one motor turns faster than the other.

HORIZONTAL STABILIZER CONTROL - FUNCTIONAL DESCRIPTION - STABILIZER ELECTRICAL CONTROL

HORIZONTAL STABILIZER CONTROL - TRIM LIMITS

General

Structural stops and the travel limiter limit stabilizer movement mechanically. Electrical limit switches and the stabilizer position limit function in the PFCs limit stabilizer movement electrically.

Structural Stops

On the upper and lower portions of the stabilizer ball screw are structural stops that limit stabilizer travel to +4 degrees airplane nose down trim and -11 degrees airplane nose up trim.

Travel Limiter

Within the aft stabilizer quadrant assembly of the alternate stabilizer trim mechanism there are hammer and stops that keep stabilizer travel to a limit.

The mechanism forces the control lever of the alternate pitch trim levers back to the null position when the stabilizer reaches its travel limits.

The travel limits for operation with the alternate pitch trim levers are: +3.88 degrees airplane nose down trim and -10.88 degrees airplane nose up trim.

Limit Switches

In each of the three stabilizer position modules are two limit switches. One switch opens to stop stabilizer movement in the airplane nose up trim direction and the other stops stabilizer movement in the airplane nose down trim direction.

In the normal mode of operation, the limit switches restrict nose down trim if the flaps are not retracted. The PFCs control airplane nose down trim when the flaps are retracted.

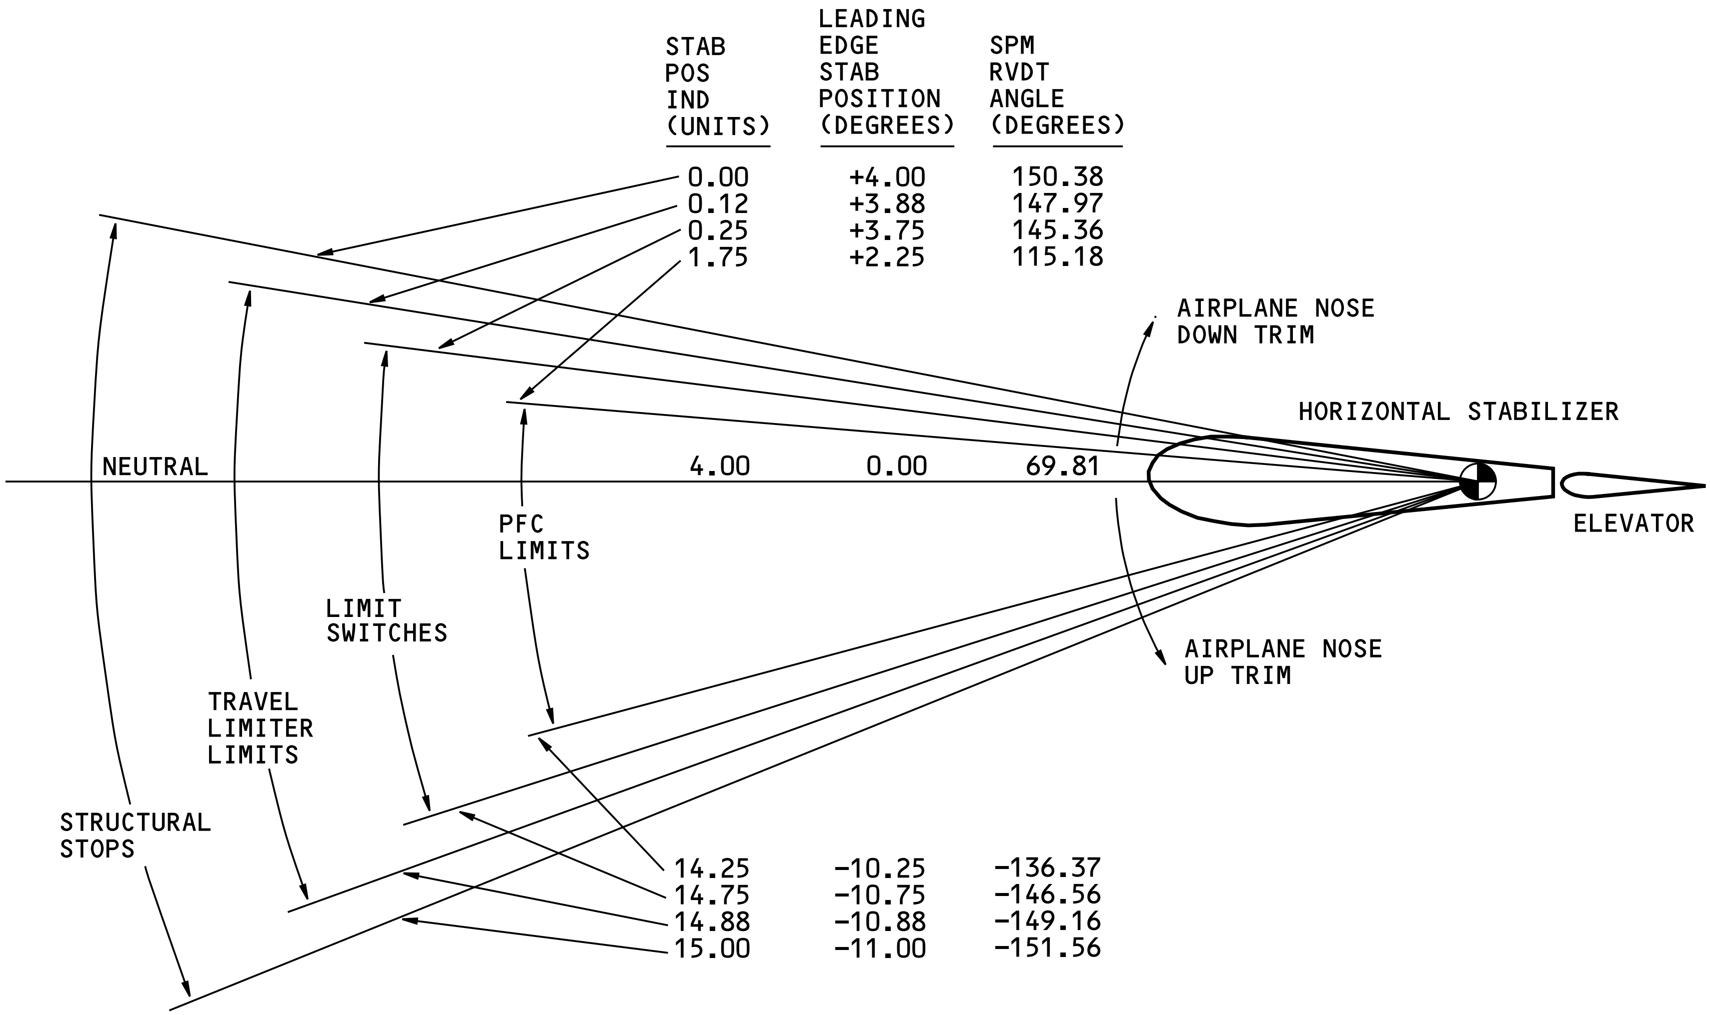
The limit switch trim limits are +3.75 degrees nose down and -10.75 degrees nose up.

PFC Limits

In the normal and secondary mode the PFCs supply limits to stabilizer movement.

With flaps retracted the PFCs limit stabilizer travel to +2.25 degrees airplane nose down to -10.25 degrees airplane nose up.

If the flaps are not retracted, the nose up PFC limitation remains at -10.25 degrees. The limit switches control the nose down limit at +3.75 degrees.



NOTE: THE SPM RVDT ANGLES IN DEGREES ARE NOMINAL VALUES. THEY ARE SHOWN FOR REFERENCE ONLY.

HORIZONTAL STABILIZER CONTROL - TRIM LIMITS

HORIZONTAL STABILIZER POSITION INDICATION - GENERAL DESCRIPTION

Purpose

The stabilizer position indication system measures the position of the stabilizer and sends this information to the ACEs. The ACEs send the information to the PFCs for stabilizer position calculation and control. The PFCs send the stabilizer position signals to the AIMS which controls the position indicators.

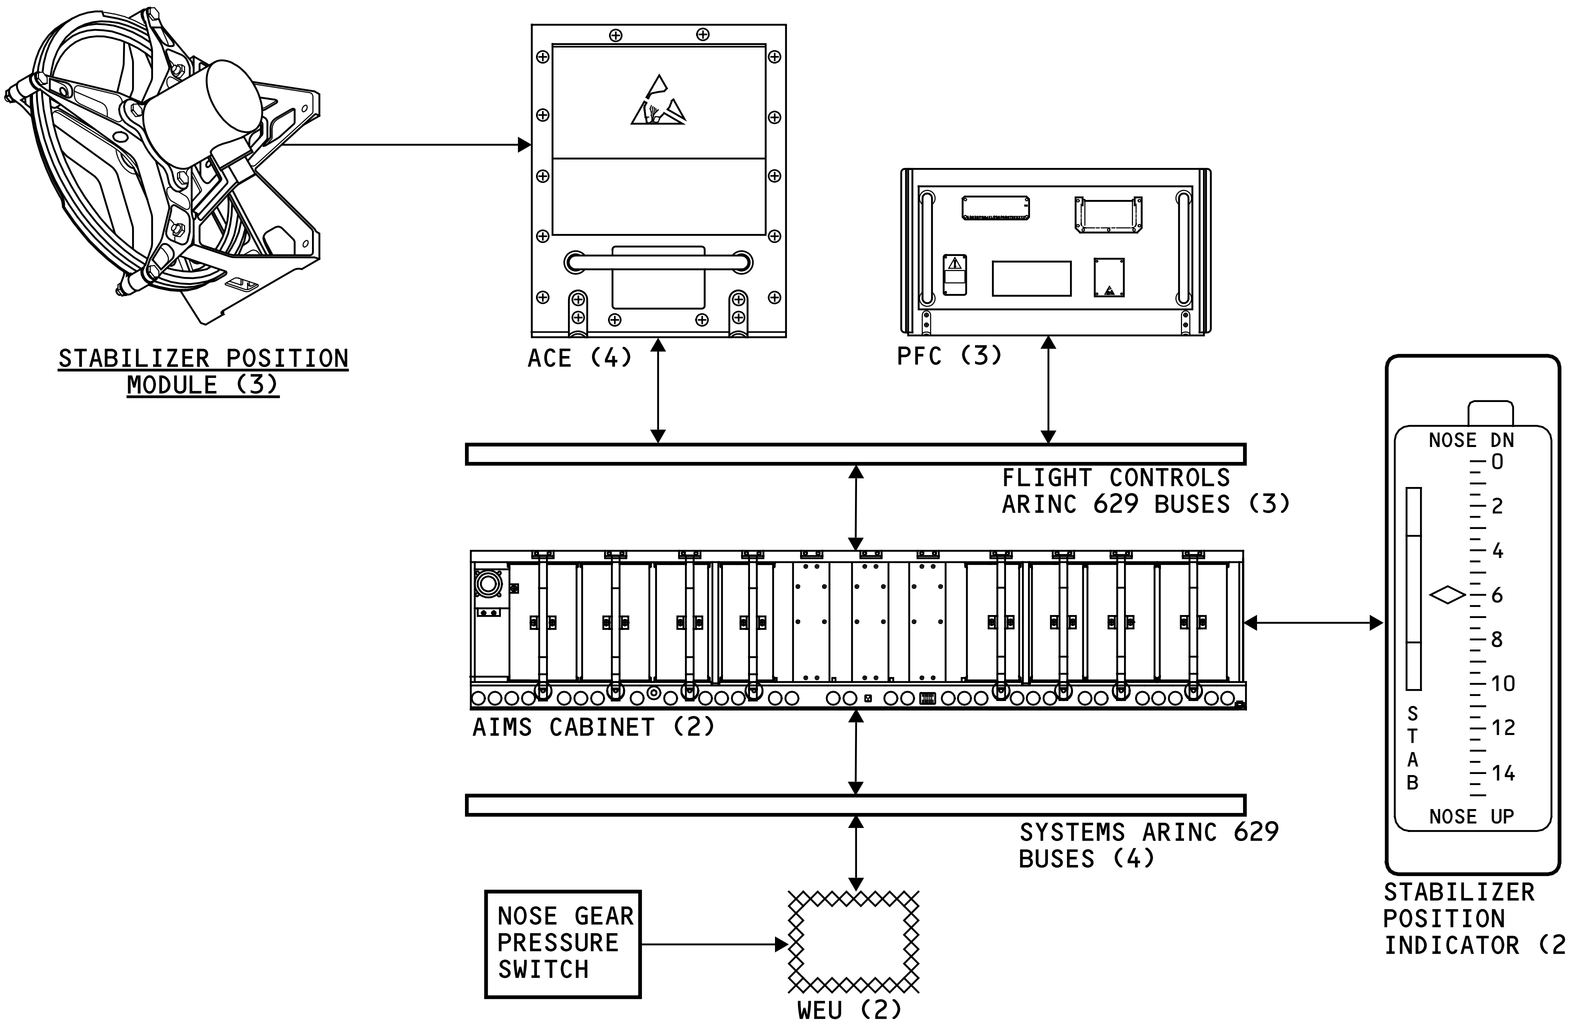
Stabilizer Position Indication

The three stabilizer position modules send signals to three ACEs. The ACEs change the signals from analog to digital and send them to the PFCs.

The PFCs use the position module signals to control the stabilizer position. The PFCs then send the stabilizer position signals to the AIMS. The AIMS sends them through the ARINC 429 bus to the stabilizer position indicators.

The AIMS also sets the green band display on each position indicator. The WEUs calculate which of the three green band segments to show on the position indicators. The WEUs use airplane weight, center of gravity position and engine thrust rating to calculate the green band display. The WEUs use a discrete signal from the nose gear pressure switch to verify the green band calculation. The calculated signals then go from the WEUs to the AIMS which selects and shows the green band on the stabilizer position indicators.

The stabilizer position indicating system operates in normal, secondary, and direct modes.



27-48-00-001 Rev 2 01/19/95

HORIZONTAL STABILIZER POSITION INDICATION - GENERAL DESCRIPTION

HORIZONTAL STABILIZER POSITION INDICATION - NOSE GEAR PRESSURE SWITCH

Purpose

The WEUs use a discrete signal from the nose gear pressure switch to make sure the stabilizer indicator green band calculation is correct.

Physical Description

The switch is a two position pressure sensing switch that sends an electrical discrete signal to the WEUs.

Location

The nose gear pressure switch is on the top of the nose gear strut.

Functional Description

The pressure switch receives pressure from the nose landing gear strut and sends a discrete to the WEUs. If the center of gravity of the airplane is forward, the pressure in the nose landing gear strut increases. This causes the pressure switch to close.

If the center of gravity of the airplane is aft, the pressure in the nose landing gear strut decreases. This causes the pressure switch to open.

The WEUs calculate the green band display for the stabilizer trim indicators to show the safe range of stabilizer trim for take-off. The WEUs use the discrete signal from the pressure switch to verify the green band calculation.

Indications

Disagreement between the green band calculation and the pressure switch discrete causes the STAB GREENBAND advisory message to show.

Training Information Point

To remove the pressure switch move the shutoff valve to the closed position and lock it with a rig pin. This isolates the switch from strut pressure.

HIGH LIFT CONTROL - INTRODUCTION

General

The high lift control system (HLCS) improves the takeoff and landing performance of the airplane. The HLCS includes the trailing edge flaps and the leading edge slats.

Trailing Edge Flaps

During takeoff, the trailing edge flaps increase the lift of the wing. During landing, the flaps increase the lift and drag. The flaps are not used during cruise. There is one double-slotted inboard flap and one single-slotted outboard flap on each wing.

Leading Edge Slats and Krueger Flaps

During takeoff and landing, the leading edge slats and Krueger flaps increase the lift of the wing. These surfaces are not used during cruise. There are seven slats and one Krueger flap on each wing.

HIGH LIFT CONTROL - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

HIGH LIFT CONTROL - GENERAL DESCRIPTION

General

The HLCS controls the operation of the:

- Trailing edge flaps
- Leading edge slats
- Krueger flaps.

The HLCS has these three modes of operation:

- Primary
- Secondary
- Alternate.

In the primary mode, hydraulic power moves the flaps and slats. In the secondary and alternate modes, electrical power moves the flaps and slats.

In the primary and secondary modes, the control is closed-loop. Closed-loop control stops the command when a feedback signal equals the command. In the alternate mode, the control is open-loop. Open-loop control stops the commands only when you stop the input or when the surfaces are at a limit.

Primary Mode

The flap lever position sensors send input signals to the flap/slat electronic units (FSEUs). The FSEUs use the flap lever position to calculate the flap and slat commands. The FSEUs also receive data from the systems ARINC 629 buses.

The FSEUs send the flap and slat commands to the flap and slat primary control valves. These valves supply hydraulic pressure to the flap and slat power drive units (PDUs). Hydraulic motors in the PDUs then move the flap and slat mechanisms.

The flap/slat priority valve controls the amount of hydraulic flow to the flap and slat primary control valves. The flap/slat priority valve gives priority of hydraulic power to the primary flight control system (PFCS) over the HLCS.

As the flaps and slats move, position sensors send a position feedback signal to the FSEUs. The FSEUs stop the flap and slat commands when the position feedback signals equal the commanded position.

The flap and slat skew sensors monitor the alignment of the flaps and slats. If the flaps or slats are out of alignment, the skew sensors send a signal to the FSEUs. The FSEUs then prohibit movement of the failed system in the primary and secondary modes.

The primary mode also uses the autoslat priority valve if the airplane approaches a stall condition. This valve gives the slats priority of the hydraulic power over the main landing gear system during an autoslat command.

Secondary Mode

In the secondary mode, the FSEUs receive input signals from the flap lever position sensor. The FSEUs then energize secondary/alternate control relays. These relays energize bypass solenoids in the primary control valves to stop hydraulic power to the hydraulic motors. These relays also control electrical power to the flap and slat electric motors in the PDUs. The electric motors then move the flap and slat mechanisms.

As the flaps and slats move, position sensors send a position feedback signal to the FSEUs. The FSEUs command the relays to stop the electric motors when the flaps and slats are at the commanded position.

The secondary mode also uses the flap and slat skew sensors. If the flaps are out of alignment, the FSEUs prohibit movement of the flaps in the secondary mode. This is also true for the slats.

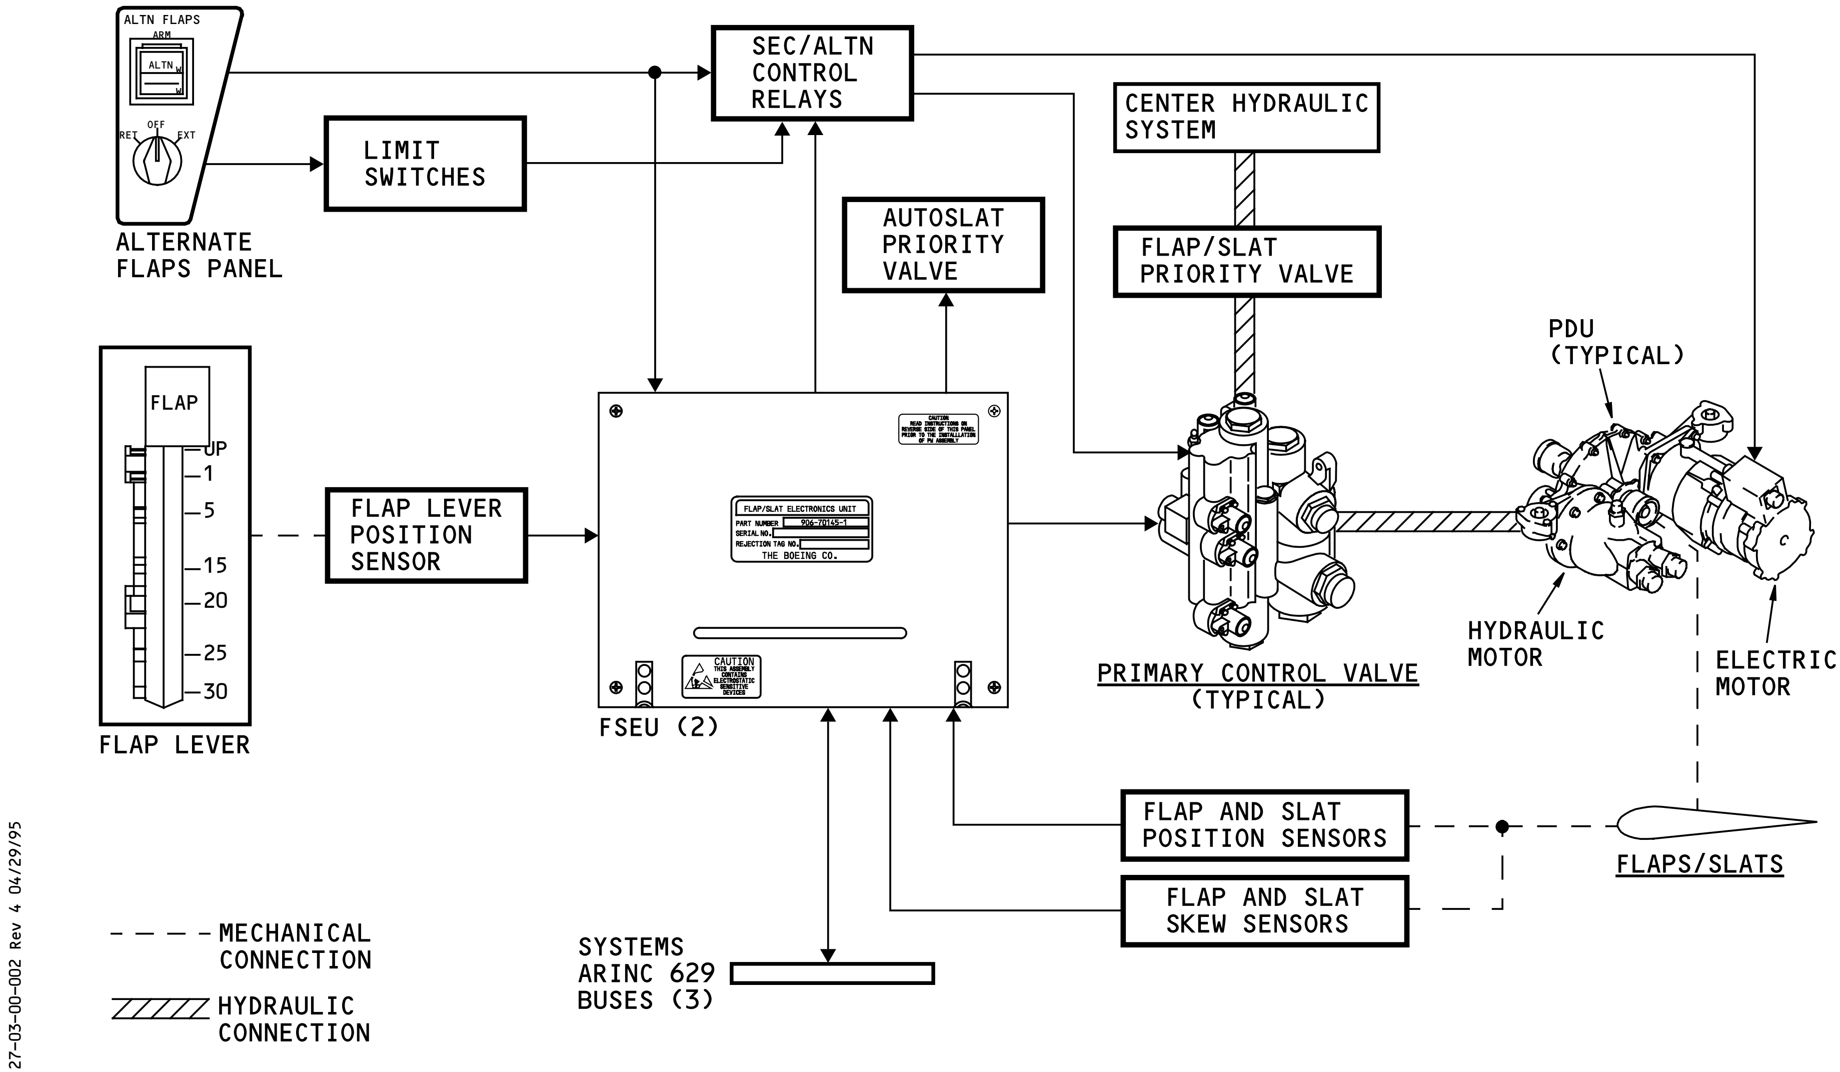
Alternate Mode

The pilots manually control the alternate mode with the switches on the alternate flaps panel. The arm switch on this panel sends a discrete to the FSEUs to disengage the primary and secondary modes. This switch also energizes two of the secondary/alternate control relays. These two relays energize bypass solenoids in the primary control valves to stop hydraulic power to the hydraulic motors. The primary control valves also create a hydraulic loop to permit the hydraulic motors to be backdriven.

The alternate flaps selector sends commands through limit switches to energize the other secondary/ alternate control relays. These relays control electrical power to the flap and slat electric motors on the PDUs. The limit switches remove electrical power from these relays when the flaps and slats are at their limits.

The electric motors then move the flap and slat mechanisms. The flaps and slats move until the pilot moves the alternate flaps selector to OFF, or the flaps and slats are at their limits.

The alternate mode control does not use the flap and slat position sensors or skew sensors. But, the FSEUs continue to receive signals from these sensors for EICAS messages and position indication.



HLCS - GENERAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

HIGH LIFT CONTROL - INTERFACES - SYSTEM REDUNDANCY

General

The HLCS has two identical lanes for the primary mode and the secondary mode. One lane has control of the HLCS. The other lane monitors the HLCS. The FSEUs automatically transfer control to the other lane after a post-flight self test of the FSEUs or after disengagement from the alternate mode. The FSEUs also switch control to the other lane if:

- A component fails in the control lane
- The command and feedback disagree.

Each lane has these components:

- An FSEU
- Two RVDTs in the flap lever position sensor
- Flap primary control valve solenoid coils
- Slat primary control valve solenoid coils
- Flap position sensors
- Slat position sensors.

The following components are not in the HLCS lanes:

- The flap and slat skew sensors
- The autoslat priority valves
- The secondary/alternate control relays

FSEUs

One FSEU is in each lane. Only the FSEU in the control lane sends the flap and slat commands to the flap and slat primary control valves.

Flap Lever Position Sensor

Each lane uses two of the four RVDTs in the flap lever position sensor.

Flap and Slat Primary Control Valve Solenoid Coils

The flap and slat primary control valves have dual-coil solenoids. Each lane controls one of the coils in each solenoid.

Flap and Slat Position Sensors

Each wing has two flap position sensors and two slat position sensors. Each lane uses one flap position sensor and one slat position sensor from each wing.

Flap and Slat Skew Sensors

There are four pairs of flap skew sensors and three pairs of slat skew sensors on each wing. One FSEU receives inputs from half of the skew sensors, and the other FSEU receives inputs from the other half.

Autoslat Priority Valve

Either FSEU can control the autoslat priority valves.

Secondary/Alternate Control Relays

Either FSEU can control the secondary/alternate control relays.

HIGH LIFT CONTROL - INTERFACES - SYSTEM REDUNDANCY

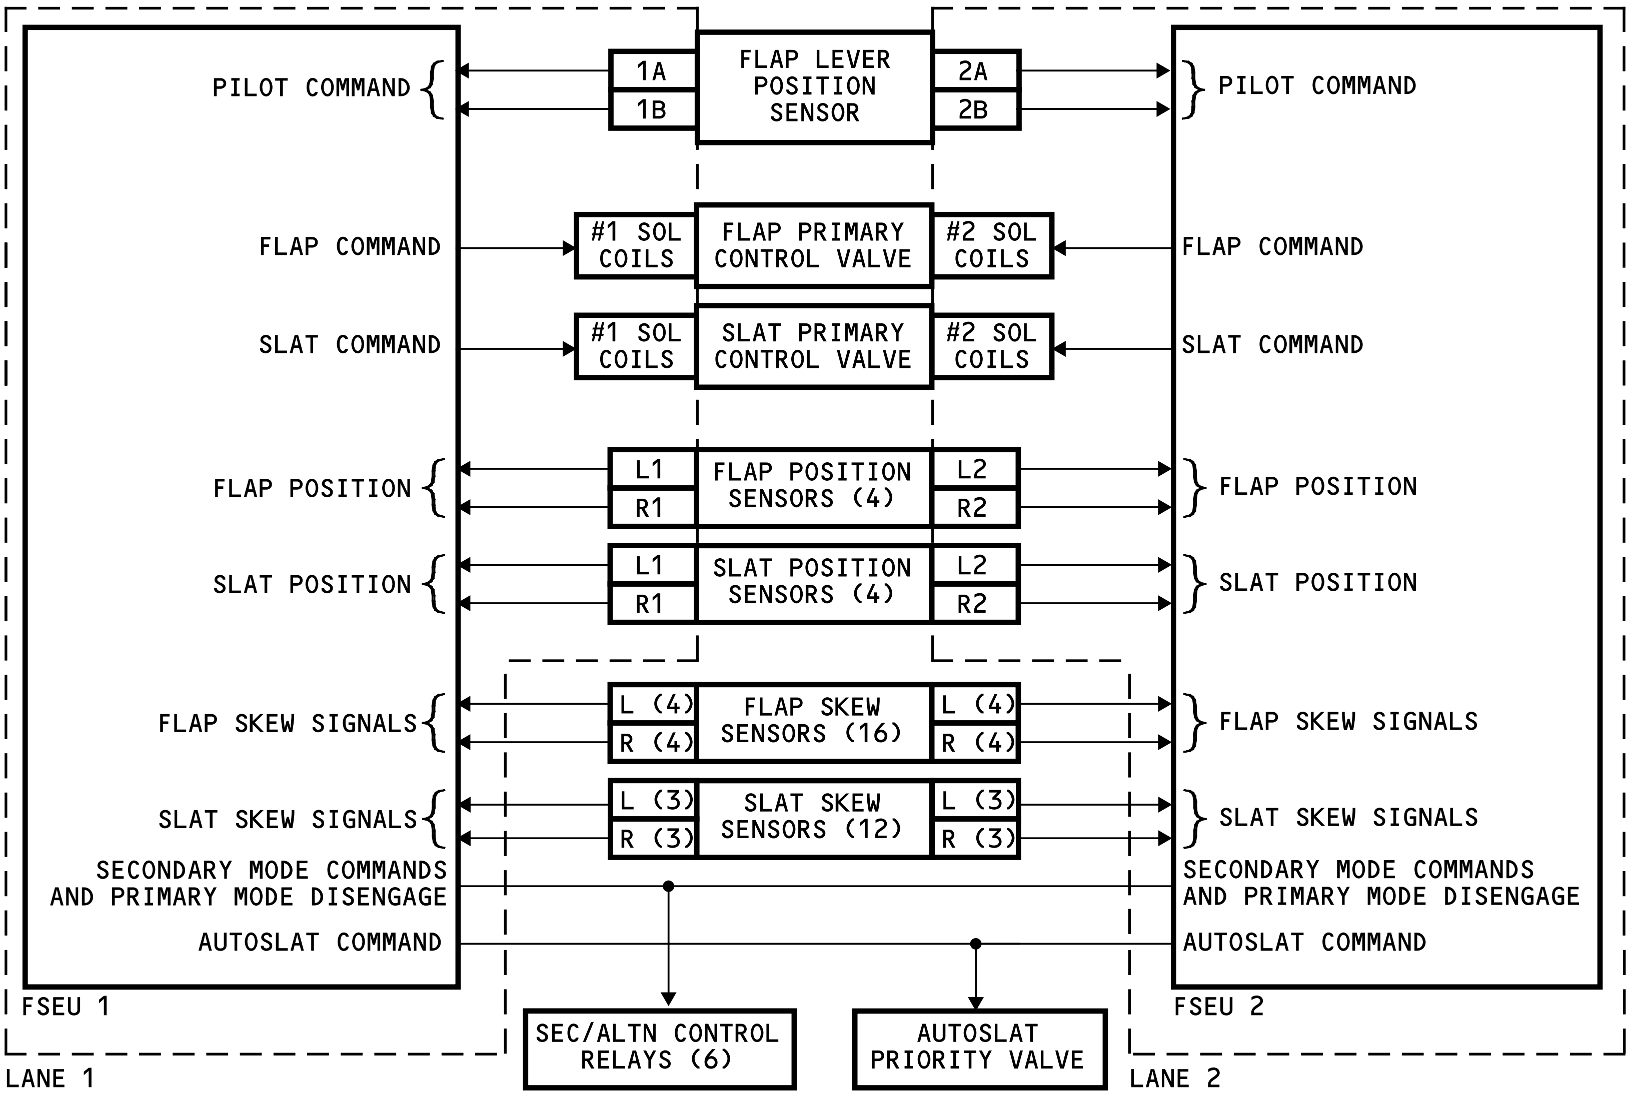
Fault Annunciation

The status message FLAP/SLAT CONTROL 1 shows if:

- A component fails in lane 1
- The command and feedback disagree in lane 1.

The same logic is true for the FLAP/SLAT CONTROL 2 status message in lane 2.

The caution message FLAP/SLAT CONTROL shows if both lanes fail.



27-03-00-003 Rev 5 10/15/96

HIGH LIFT CONTROL - INTERFACES - SYSTEM REDUNDANCY

HIGH LIFT CONTROL - INTERFACES - SYSTEMS ARINC 629 BUSES

General

The FSEUs connect the HLCS to many other airplane systems through the systems ARINC 629 buses. Some of these systems use these components:

- Two warning electronics units (WEUs)
- Two airplane information management system (AIMS) cabinets
- Two systems card files.

FSEU Interface

The FSEUs connect to three of the systems ARINC 629 buses. FSEU 1 transmits and receives data on the left and center 1 buses through separate connections. FSEU 1 receives data through two more connections for redundancy.

The connections for FSEU 2 are almost the same as the connections for FSEU 1. The difference is that the FSEU 2 communicates with the right and C1 buses instead of the left and C1 buses.

WEU Interface

The WEUs transmit data for the autoslat function.

AIMS Interface

The FSEUs supply information to the AIMS for:

- The flap/slat position indications on EICAS
- The flap/slat maintenance page
- The central maintenance computing system (CMCS)
- The protection functions in the primary flight control system (PFCS)
- And many other systems and functions.

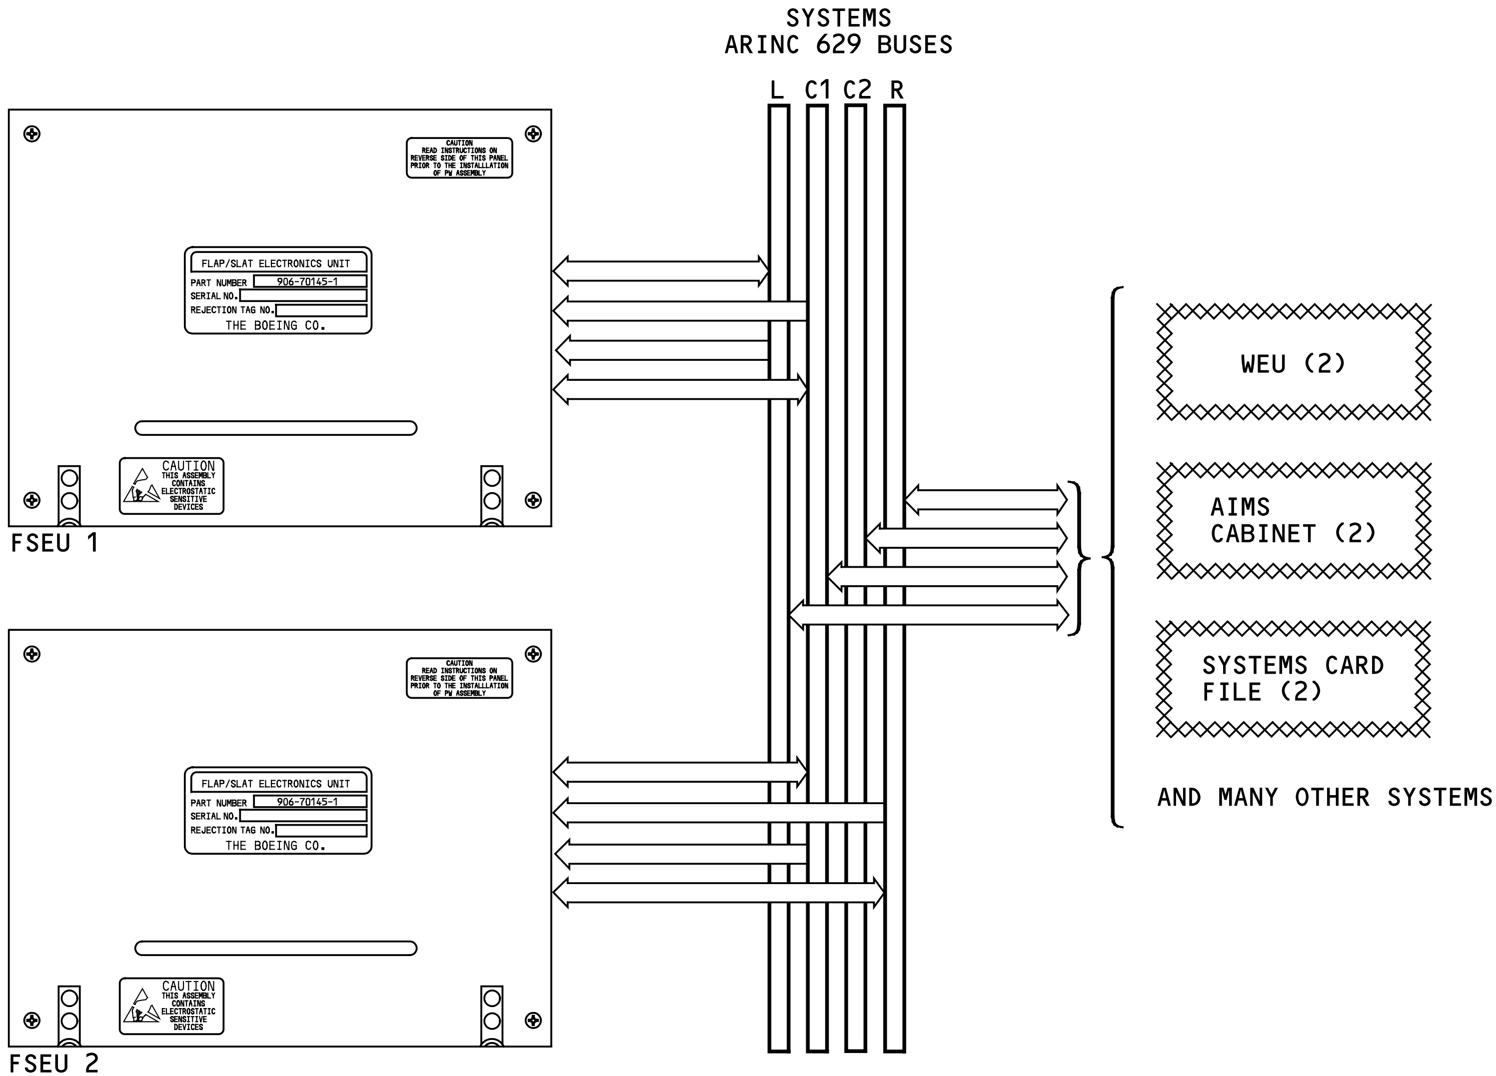
Information that the FSEUs receive from the AIMS cabinets include air data from the ADIRU and SAARU and data from many other systems.

Systems Card File Interface

The hydraulic interface module (HYDIM) and the weight on wheels (WOW) cards are in the systems card file.

The HYDIM cards supply hydraulic pressure data to the FSEUs. The center hydraulic isolation system command from the HYDIM cards disables the slats in the primary mode. The FSEUs also send the flap and slat commands to the HYDIM cards.

The WOW cards supply air/ground data to the FSEUs.



27-03-00-004 Rev 1

HIGH LIFT CONTROL - INTERFACES - SYSTEMS ARINC 629 BUSES

THIS PAGE INTENTIONALLY LEFT BLANK

HIGH LIFT CONTROL - INTERFACES - ANALOG AND DISCRETE SIGNALS

General

These components electrically control the flaps and slats in the primary, secondary, and alternate modes:

- FSEUs
- Flap lever position sensor
- Alternate flaps arm switch
- Alternate flaps selector
- Flap and slat primary control valves
- Autoslat priority valve
- Secondary/alternate control relays
- Flap and slat position sensors
- Flap and slat skew sensors.

The ACEs receive flap position discrete signals from the FSEUs for some of the functions in the PFCS.

FSEUs

The two FSEUs use analog and discrete inputs to calculate the flap and slat commands in the primary and secondary modes. They also use digital information on the systems ARINC 629 buses.

Flap Lever Position Sensor

The flap lever position sensor sends the flap lever commands to the FSEUs.

Alternate Flaps Arm Switch

The alternate flaps arm switch sends a discrete to the FSEUs to disengage the primary and secondary modes. This switch also controls two relays, which control power to a solenoid in the flap and slat primary control valves.

Alternate Flaps Selector

The alternate flaps selector controls the grounds for four relays, which control power to the flap and slat electric motors. The wiring for these grounds is through the flap and slat limit switches.

Flap and Slat Limit Switches

The flap and slat limit switches stop the movement of the flaps and slats in the alternate mode. When the flaps and slats are at their limits, the limit switches remove the grounds for some of the sec/altn control relays.

Secondary/Alternate Control Relays

The secondary/alternate control relays control power to the flap and slat electric motors in the secondary and alternate modes. These relays also control a solenoid in the flap and slat primary control valves to stop the hydraulic operation of the flaps and slats.

HIGH LIFT CONTROL - INTERFACES - ANALOG AND DISCRETE SIGNALS

Flap and Slat Electric Motors

The flap and slat electric motors move the flap and slat drive systems in the secondary and alternate modes. They receive electrical power through the sec/altn control relays.

Flap and Slat Primary Control Valves

The flap and slat primary control valves control the direction and speed of the flap and slat movement. The FSEUs control most of the solenoids in the flap and slat primary control valves. The sec/altn control relays control one solenoid in the flap and slat primary control valves. These two solenoids stop the hydraulic operation of the flaps and slats.

Autoslat Priority Valve

The autoslat priority valve limits the flow of hydraulic fluid to the main landing gear system. The FSEUs control a solenoid in this valve during autoslat operation.

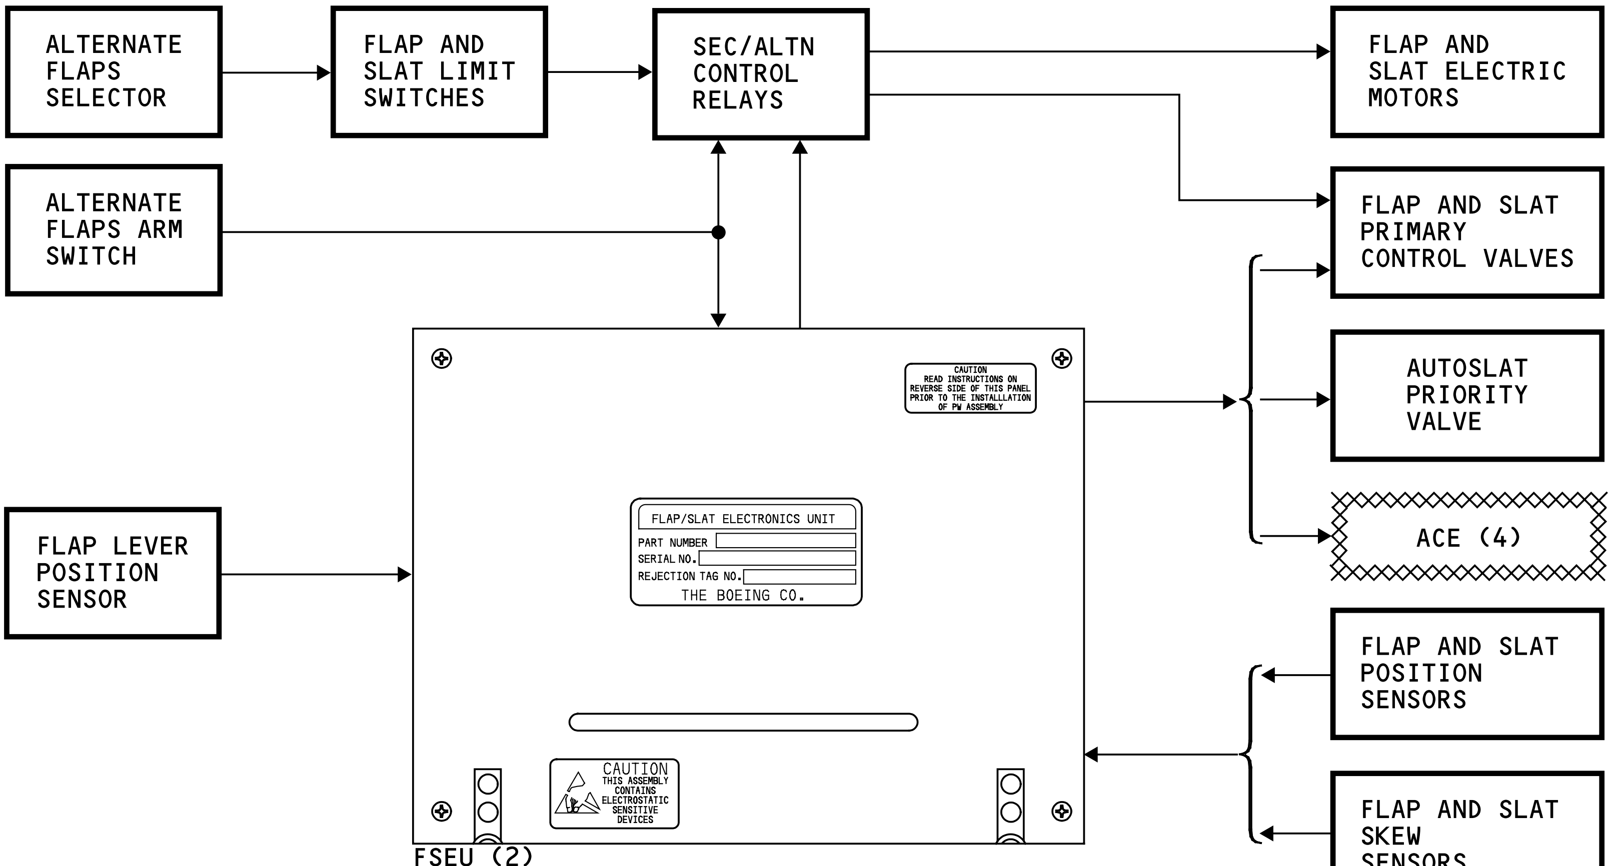
Flap and Slat Position Sensors

The flap and slat position sensors supply flap and slat position signals to the FSEUs. The FSEUs use this data for:

- Control feedback
- Position indication
- Fault monitoring.

Flap and Slat Skew Sensors

The flap and slat skew sensors supply signals to the FSEUs. The FSEUs use these signals to monitor the alignment of the flaps and slats.



27-03-00-005 Rev 3 03/14/1996

HIGH LIFT CONTROL - INTERFACES - ANALOG AND DISCRETE SIGNALS

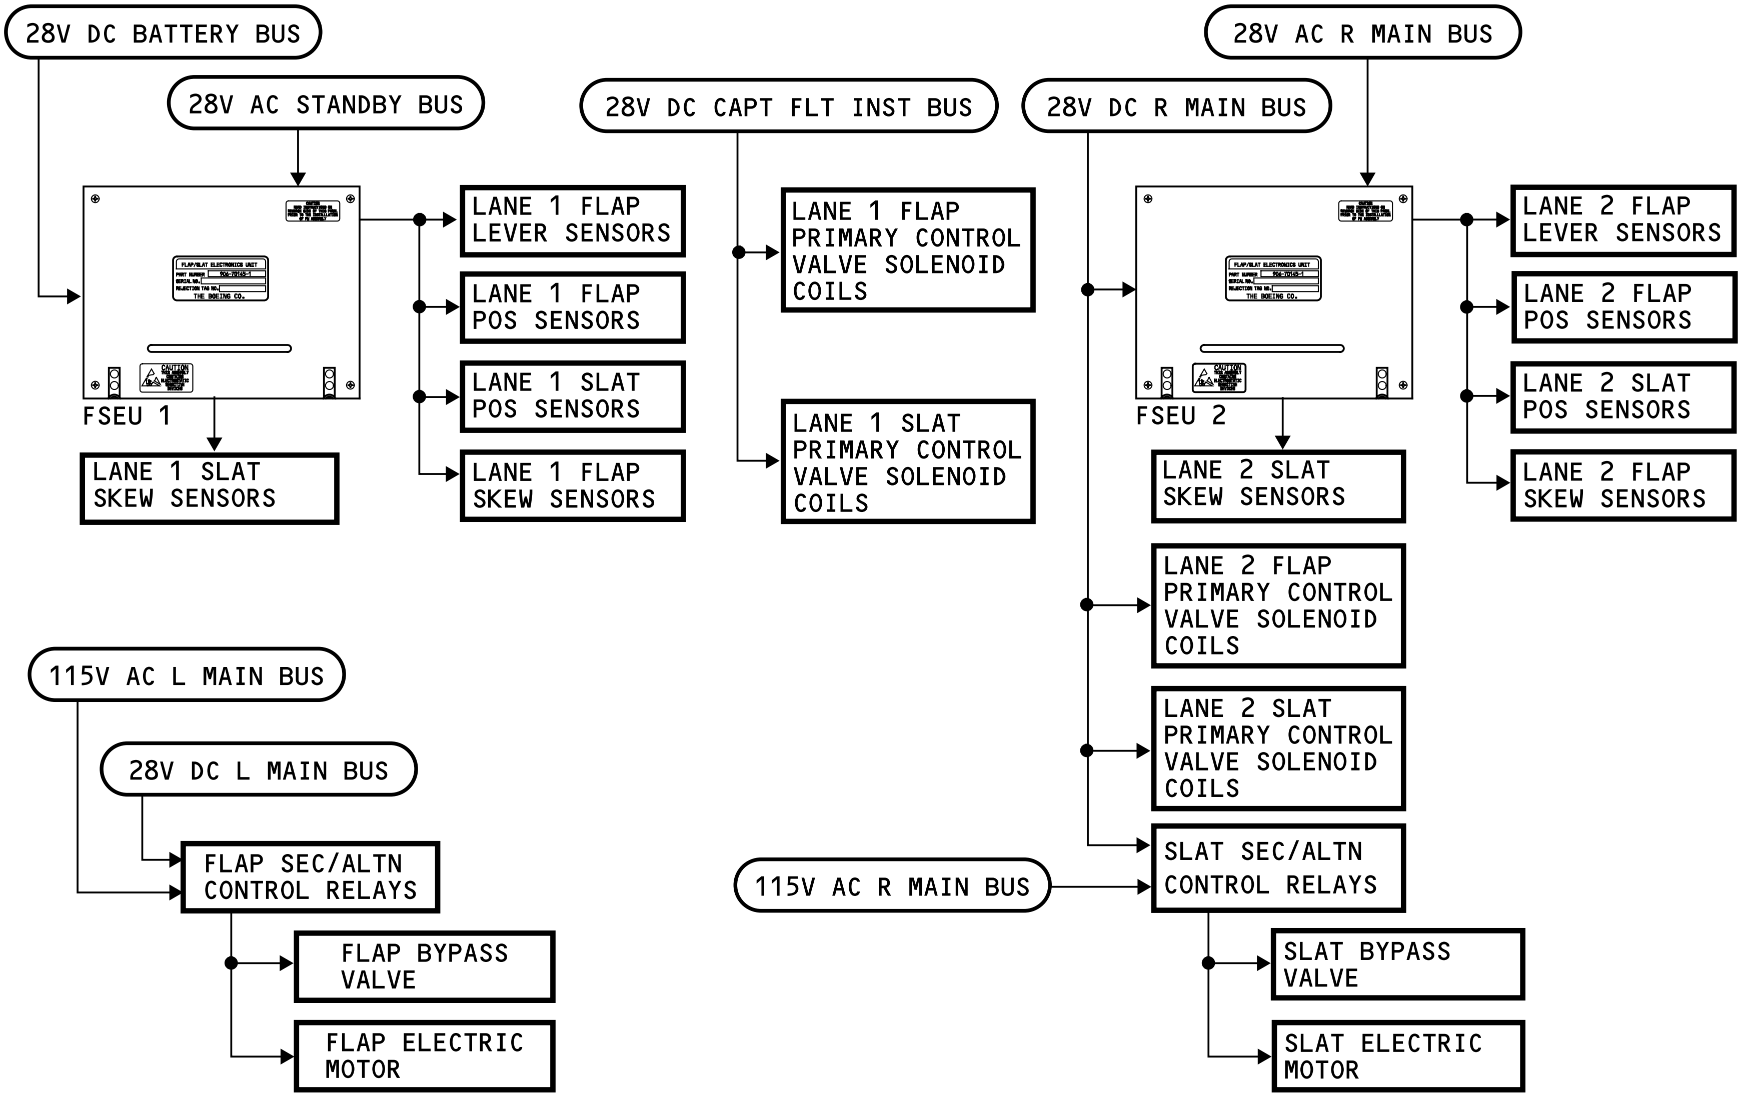
HIGH LIFT CONTROL - INTERFACES - ELECTRICAL POWER

General

Multiple buses supply electrical power to the HLCS. The HLCS receives electrical power from the:

- 28v dc battery bus
- 28v dc captain's flight instrument bus
- 28v ac standby bus
- 28v dc right main bus
- 28v ac right main bus
- 28v dc left main bus
- 115v ac left main bus
- 115v ac right main bus.

These buses permit the separation of electrical power between lane one and lane two. The components in lane one get power from separate buses than the components in lane two.



27-03-00-006 Rev 3 12/08/95

HIGH LIFT CONTROL - INTERFACES - ELECTRICAL POWER

HIGH LIFT CONTROL - MODE SELECTION

General

The flaps and slats operate in one of three modes:

- Primary mode
- Secondary mode
- Alternate mode.

The FSEUs change the operational mode for any of these conditions:

- There are component failures
- There are position failures
- The center hydraulic reservoir quantity is low
- The secondary mode auto test is active
- The airplane is in a ground maintenance condition
- You use the alternate flaps arm switch.

The primary and secondary flap modes are independent of the primary and secondary slat modes. Thus, the flaps may be in the secondary mode while the slats are in the primary mode. This supplies the fastest system response to the flap lever commands.

The alternate flap mode is not independent of the alternate slat mode. Thus, when the alternate mode engages, both the flaps and slats are in the alternate mode.

Primary Mode Selection

If there is a component failure in the control lane, it causes a lane change. The flaps and slats continue to operate in primary mode.

These are the four types of component failures that cause a lane change:

- Flap lever position sensor failure
- Solenoid coil failure on the primary control valve for the flaps or the slats
- Flap or slat position sensor failure
- FSEU failure.

During normal conditions, the flaps and slats operate in the primary mode. If a component fails in lane 1 and lane 1 is in control, lane 2 becomes the control lane. In this condition, the flaps and slats stay in the primary mode. This failure condition causes the FLAP/SLAT CONTROL 1 status message to show.

If lane 2 is in control when a component fails in lane 2, lane 1 becomes the control lane and the FLAP/SLAT CONTROL 2 status message shows.

If there is a detected component failure in the standby lane while the control lane operates properly, the applicable status message, FLAP/SLAT CONTROL 1 or 2, shows. The control lane remains in control.

HIGH LIFT CONTROL - MODE SELECTION

Secondary Mode Selection

After a lane change, if the original failure or an additional one prevents the flaps or slats to operate in primary mode, the FSEU in control changes to the secondary mode operation for the flaps or the slats.

If the failures are with flap components only, only the primary flap mode disengages and the flaps operate in secondary mode. The slats operation continues in the primary mode. This condition causes the FLAPS PRIMARY FAIL caution message to show. The same is true for the slats. But in this case, the SLATS PRIMARY FAIL caution messge shows.

If the failures affected both the flaps and slats, such as both FSEUs, both the primary flap mode and the primary slat mode disengage. This condition causes both the FLAPS PRIMARY FAIL and SLATS PRIMARY FAIL caution messages to show.

After the flaps and slats fully retract, the secondary mode disengages and the primary mode engages. Then the FLAPS PRIMARY FAIL and/or the SLATS PRIMARY FAIL message erases.

The FSEU in control engages the secondary mode for the flaps or slats if there is a flap or slat disagree in primary mode. There is a disagree when the flaps or slats do not move when commanded or move too slowly. The FSEU in control disengages the primary mode for the flaps or the slats and engage the secondary mode. This condition causes the FLAPS PRIMARY FAIL or the SLATS PRIMARY FAIL caution message to show.

When the center hydraulic system pressure is low, it does not permit the hydraulic motors to operate the flaps and slats. The FSEU in control engages the secondary mode for the flaps and slats. The operation stays in the secondary mode until the flaps and slats are in the retracted position or until the center hydraulic system pressure is more than 2000 psi after it was less than 1000 psi.

Flaps and Slats Drive Shutdown

If there are component failures that affect the operation of both flaps and slats, the flaps and slats can no longer operate in primary and secondary mode. The FLAP/SLAT CONTROL caution message shows. In addition, the FLAP/SLAT CONTROL 1 and the FLAP/SLAT CONTROL 2 status messages also show.

The FSEUs declare and latch a flaps or slats drive shut down for any one of these position failures:

- Disagreement in secondary mode (the flaps or slats do not move with a secondary mode command or move too slowly)
- Asymmetry (the flaps or slats on one wing do not align with the flaps or slats on the other wing)
- Skew (a flap or slat on one wing is out of alignment).

HIGH LIFT CONTROL - MODE SELECTION

If there is a secondary mode disagree, an asymmetry or a skew, the FSEUs disengage both the primary and secondary modes and shut down the drive system for the flaps or the slats.

A shut down of the slats drive with the slats at the UP position, at the sealed position, or between, causes the flaps operation to be limited to the 20-unit position. If the slats are at the gapped position when the slats drive shuts down, the flaps can operate to the full extend. A shut down of the flaps drive will not let the slats extend to the gapped position.

The shut down of the flaps or the slats drive causes the FLAPS DRIVE or the SLATS DRIVE caution message to show.

Alternate Mode Selection

The only way to engage and disengage the alternate mode is to use the alternate flaps arm switch. When the pilot pushes on the alternate flaps arm switch, the primary and secondary modes disengage in both FSEUs and the alternate mode engages. This causes the FLAP/SLAT CONTROL caution message to show.

When the pilot releases the alternate flaps arm switch, the alternate mode disengages and the FSEUs try to engage the primary mode. If the primary mode is disabled, the FSEUs try to engage the secondary mode. If the secondary mode is also disabled, you must use the alternate mode to move the flaps and slats.

Center Hydraulic Quantity

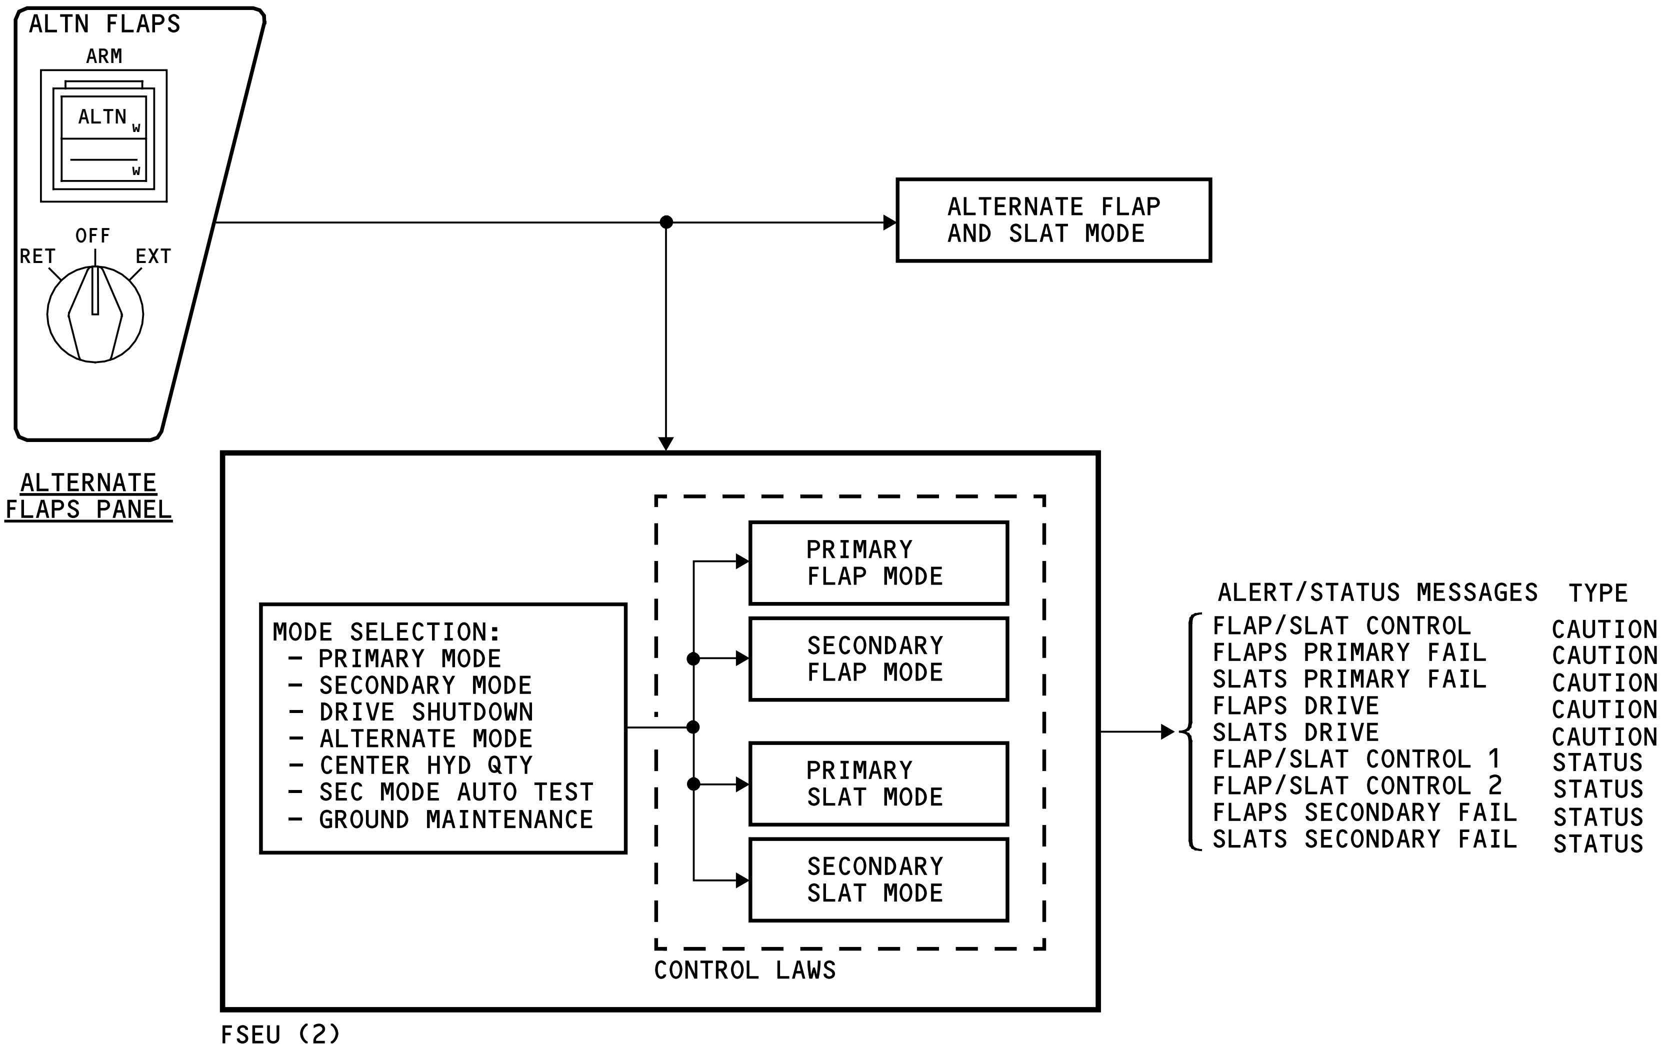
If the hydraulic quantity in the center hydraulic system reservoir is low, the FSEUs disengage the primary slat mode. The FSEUs then engage the secondary mode for the slats only. If both engines continue to operate for more than 10 seconds, then the primary mode re-engages.

Secondary Mode Auto Test

During the secondary mode auto test, both the primary flap mode and the primary slat mode disengage. The secondary mode engages for both the flaps and slats. If the flaps and/or slats fail to extend during the test, the FLAPS SECONDARY FAIL and/or SLATS SECONDARY FAIL status message shows.

Ground Maintenance Condition

The FSEUs inhibit the secondary mode operation when the airplane is in a ground maintenance condition. You must use the secondary mode inhibit override function on the MAT to enable the secondary mode in this condition.



27-03-00-018 Rev 6 07/10/1997

HIGH LIFT CONTROL - MODE SELECTION

THIS PAGE INTENTIONALLY LEFT BLANK

HIGH LIFT CONTROL - PRIMARY MODE FLAP AND SLAT SEQUENCE

General

The flaps and slats extend and retract in sequence. The extension and retraction sequence is different between the three modes.

Flap and Slat Positions

In the primary mode, the flap lever commands the flaps and slats to move to the commanded position. At flap lever positions UP and 1, the flaps are fully retracted. At flap lever positions 5 through 30, the flap positions are the same as the flap lever positions.

The slats have three positions: up, sealed, and gapped. The slats are at the sealed position when the flap lever is at 1, 5, 15, or 20. The slats are at the gapped position when the flap lever is at 25 or 30.

Flap load relief is available in the primary mode. Load relief operation is described later.

Flap lever detent up is for cruise. Detent 1 is for climb-out and approach. Detents 5, 15, and 20 are the takeoff settings. Detents 25 and 30 are the landing settings.

Flap and Slat Extension and Retraction

During extension from the retracted position, the slats extend to the sealed position while the flaps stay retracted. When the slats are at the sealed position, the flaps begin to extend. When the flaps are at the 20 unit position, the flaps stop moving. The slats then extend to the gapped position. When the slats are in the gapped position, the flaps move to the fully extended position.

The retraction sequence is the reverse of the extension.

Extension and Retraction Time

The extension time is the same as the retraction time.

It takes 54 seconds to move the slats and flaps from the UP position to the 30-unit position. The detailed times are:

- 11 seconds to move the slats from the retracted position to the sealed position
- 24 seconds to move the flaps from the retracted position to the 20-unit position
- 6 seconds to move the slats from the sealed position to the gapped position
- 13 seconds to move the flaps from the 20-unit position to the 30-unit position.

Flap Operation With Slats Drive Shutdown

When the slats fail to move to the commanded position in primary and secondary mode, the FSEUs shutdown the slats drive. With a slats drive shutdown, the flaps continue to operate in primary mode. The flaps move to their commanded position independently of the slat

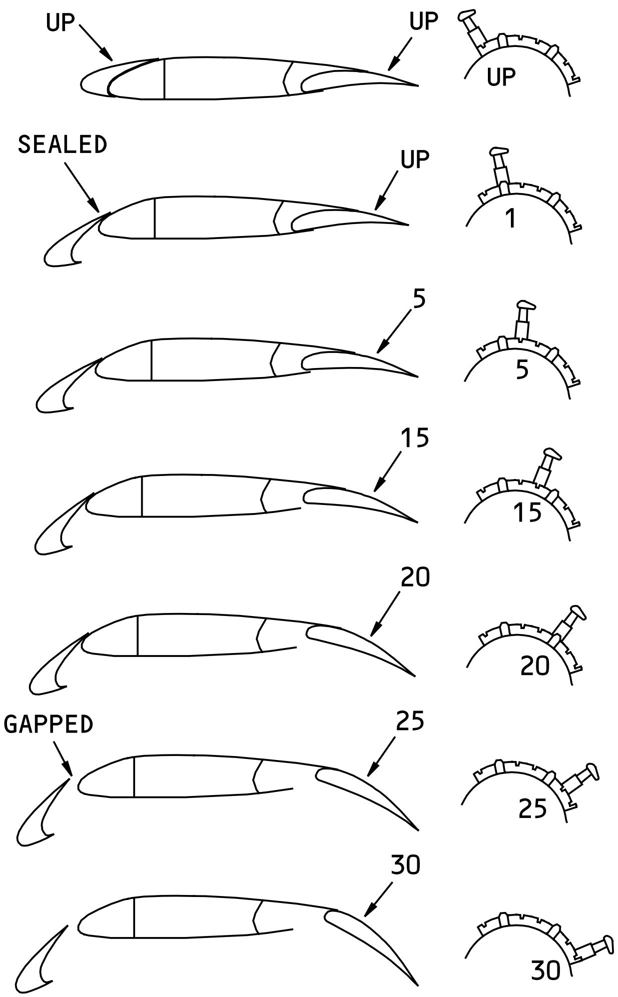
HIGH LIFT CONTROL - PRIMARY MODE FLAP AND SLAT SEQUENCE

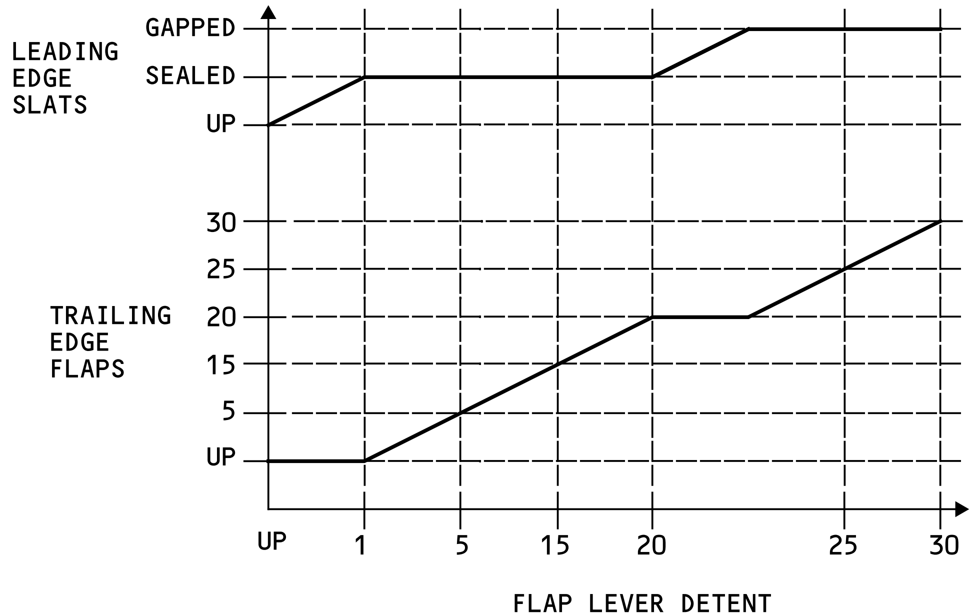
position. If the slats are not at the gapped position when the slats drive shutdown occurs, the flaps cannot move more than the 20-unit position. If the slats are at the gapped position when the slats drive shutdown occurs, the flaps can move more than the 20-unit position.

Training Information Point

CAUTION: YOU MUST WAIT 30 MINUTES AFTER 12 MINUTES OF OPERATION IN THE PRIMARY MODE. THE FLAP NO-BACK BRAKE CAN BECOME TOO HOT.

CAUTION: MAKE SURE THE ADP ACCESS DOOR IS FULLY OPEN OR FULLY CLOSED WHEN YOU MOVE THE TRAILING EDGE FLAPS. THE FLAPS CAN HIT THE DOOR IF IT IS NOT FULLY OPEN OR CLOSED. THIS CAN CAUSE DAMAGE TO EQUIPMENT.





27-03-00-010 Rev 7

HIGH LIFT CONTROL - PRIMARY MODE FLAP AND SLAT SEQUENCE

HIGH LIFT CONTROL - SECONDARY MODE FLAP AND SLAT SEQUENCE

General

The sequence of the flap and slat extension and retraction in the secondary mode is almost the same as in the primary mode.

Flap and Slat Positions

In the secondary mode, the flap lever commands the flaps and slats to move to the commanded position. The flap positions are the same as in the primary mode.

The slats extend to the gapped position when the flap lever is at any position except up.

Slat load relief is available in secondary mode. The slats retract to the sealed position when the airspeed is more than 239 knots. Load relief operation is described later.

Flap and Slat Extension and Retraction

During extension, the slats extend to the gapped position before the flaps extend. When the slats are at the gapped position, the flaps extend to the commanded position.

The sequence of the flap and slat retraction is the reverse of the flap and slat extension.

Extension and Retraction Time

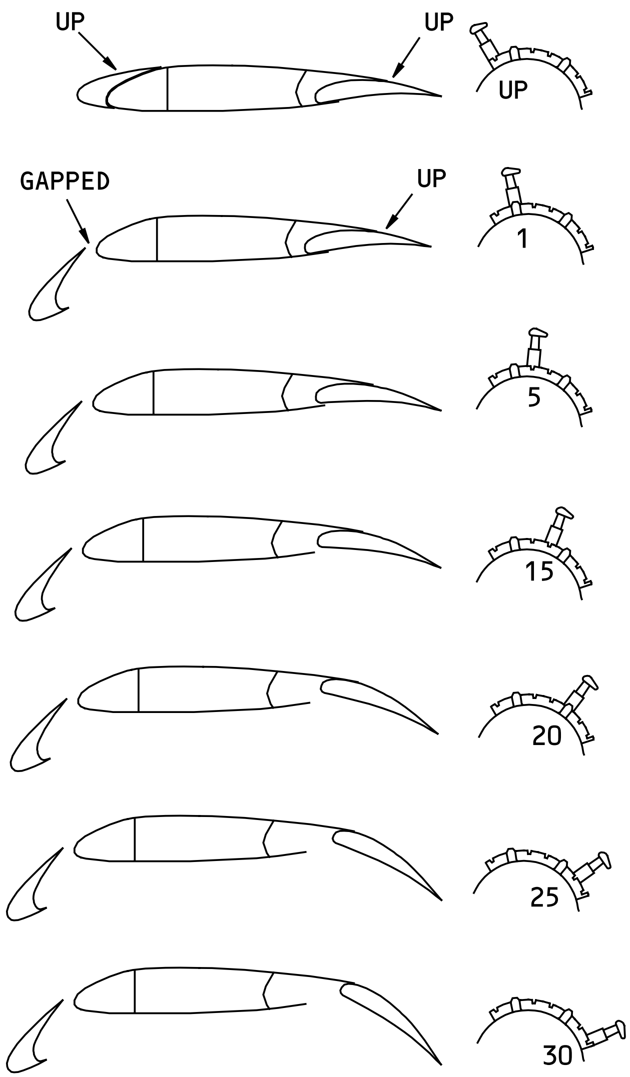
The extension time is the same as the retraction time.

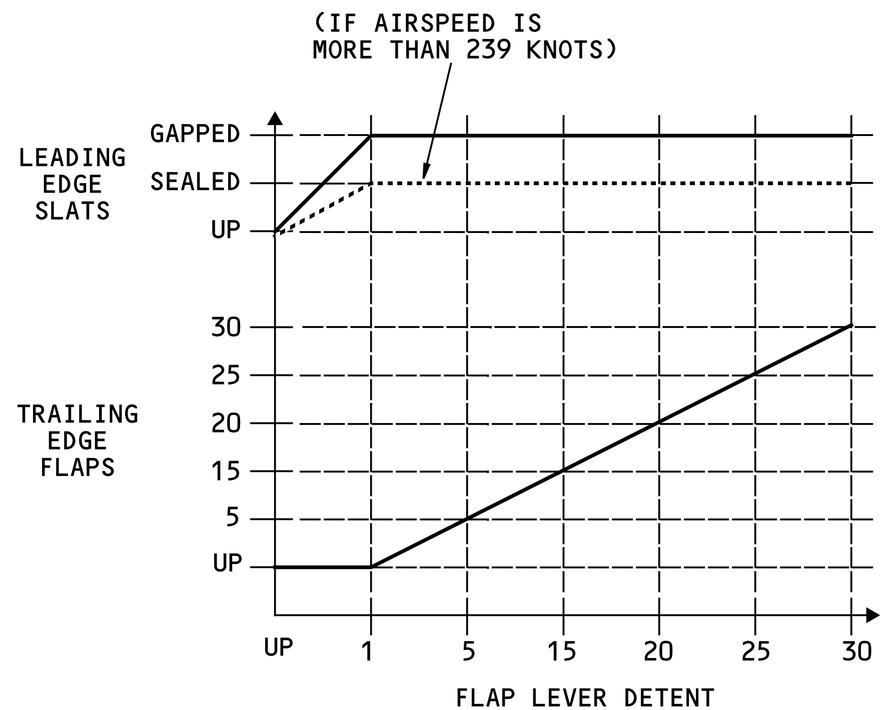
It takes 5 minutes and 8 seconds to move the slats and the flaps from the UP position to the 30-unit position. The detailed times are:

- 1 minute and 25 seconds to move the slats from the retracted position to the gapped position
- 3 minutes and 43 seconds to move the flaps from the retracted position to the 30-unit position.

Flap Operation With Slats Drive Shutdown

When the slats fail to move to the commanded position in primary and secondary mode, the FSEUs shutdown the slats drive. With a slats drive shutdown, the flaps continue to operate in primary mode. The flaps move to their commanded position independently of the slat position. If the slats are not at the gapped position when the slats drive shutdown occurs, the flaps cannot move more than the 20-unit position. If the slats are at the gapped position when the slats drive shutdown occurs, the flaps can move more than the 20-unit position.





27-03-00-011 Rev 6 06/20/1997

HIGH LIFT CONTROL - SECONDARY MODE FLAP AND SLAT SEQUENCE

HIGH LIFT CONTROL - ALTERNATE MODE FLAP AND SLAT SEQUENCE

General

The alternate flaps arm switch sets the alternate mode. The alternate flaps selector controls the direction of the flap and slat movement.

Extension

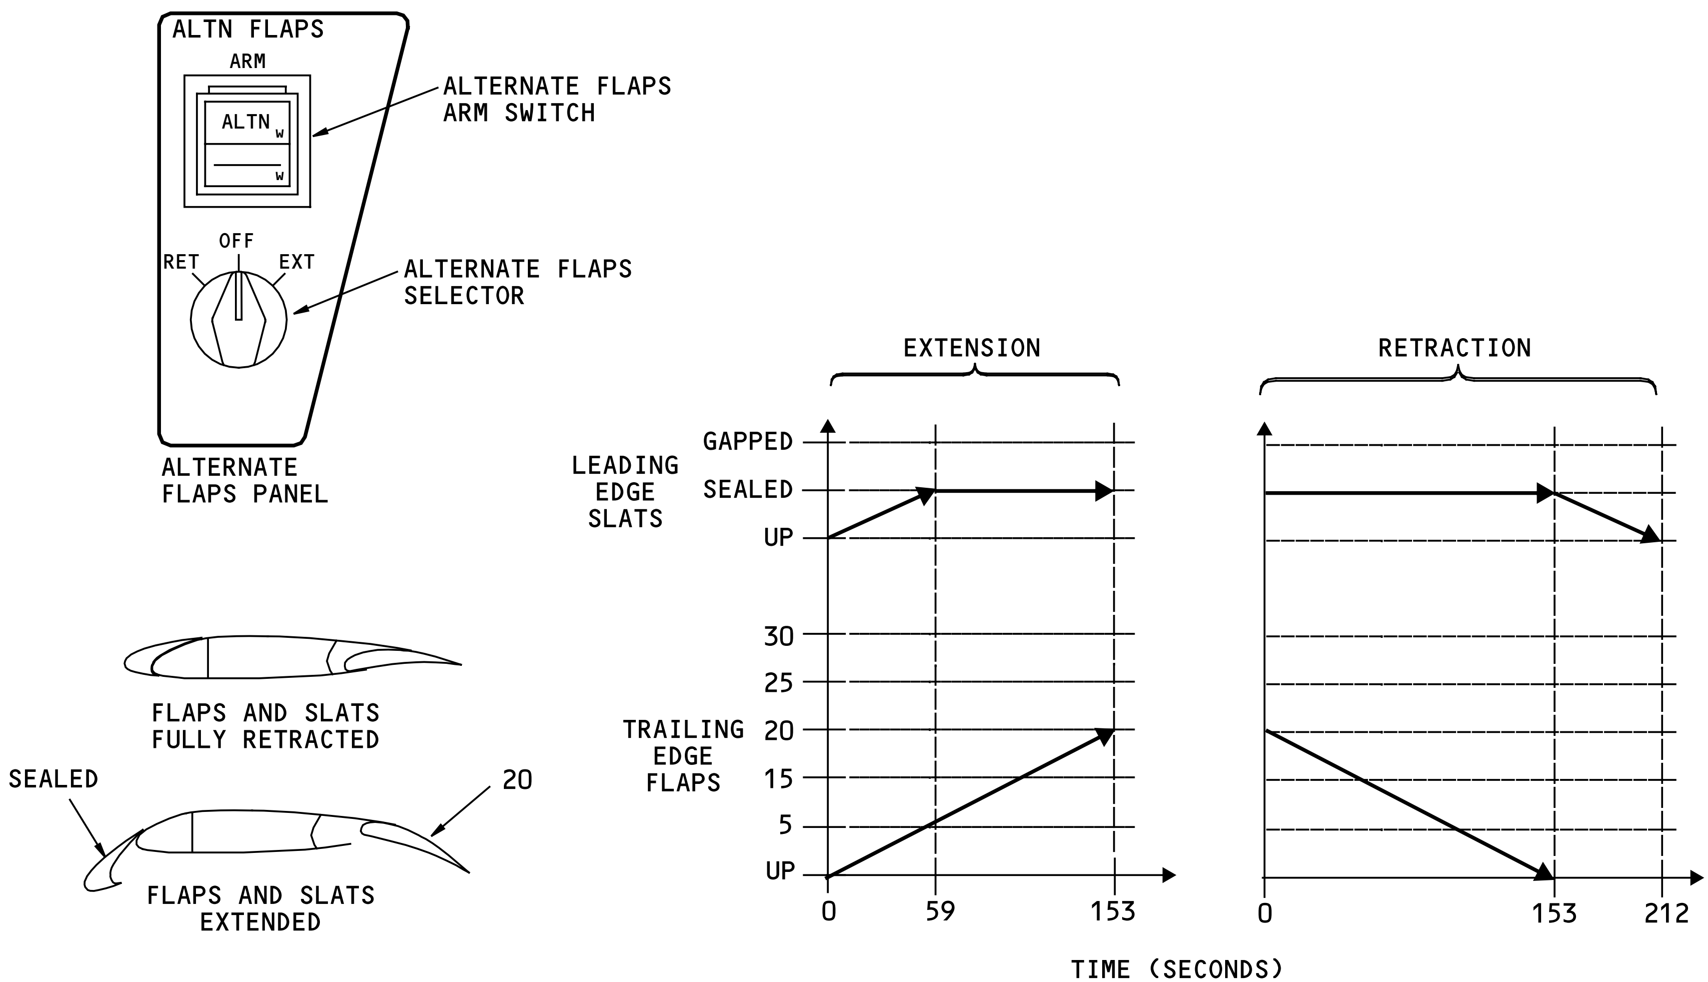
When the arm switch is set to ARM and the selector is set to EXT, the slats move to the sealed position and the flaps move to the 20 unit position. They move at the same time. It takes 2 minutes and 33 seconds.

A detent holds the selector in the EXT position. If the selector is set to OFF while the flaps and slats move, the movement stops.

Retraction

When the arm switch is set to ARM and the selector is set to RET, the flaps retract first, then the slats. Flap retraction takes 2 minutes and 33 seconds. The slats take 59 seconds. Total flap and slat retraction time is 3 minutes and 32 seconds.

A detent holds the selector in the RET position. If the selector is set to OFF while the flaps and slats move, the movement stops.



27-03-00-012 Rev 5 12/08/95

HIGH LIFT CONTROL - ALTERNATE MODE FLAP AND SLAT SEQUENCE

THIS PAGE INTENTIONALLY LEFT BLANK

HIGH LIFT CONTROL - INDICATIONS - POSITION DISPLAYS

General

The flap and slat position display is on the EICAS display or the EICAS compacted engine display. There are three different displays for the flaps and slats:

- Primary
- Secondary
- Alternate.

Only one display shows at a time.

Primary Mode Display

The primary mode display shows when both the flaps and slats are in the primary mode. This display shows the position of both the flaps and slats. The display is black when the flaps and slats are fully retracted. When the flaps or slats extend, a white tape fills the display from the top down.

A command bar and detent number show the flap lever position. When you move the flap lever, the flap lever detent number and command bar show. While the flaps and slats move, the command bar and detent number are magenta. When the flaps and slats are in the flap lever commanded position, the command bar and detent number change to green.

The primary mode display goes out of view 10 seconds after the flaps and slats are fully retracted.

Secondary Mode Display

The secondary mode display shows when either the flaps or slats are in the secondary mode. This display has separate indications for:

- The left wing flaps
- The right wing flaps
- The left wing slats
- The right wing slats.

The two upper indications show the slat positions. The two lower indications show the flap positions. All four indications are black when the flaps and slats are fully retracted. When the slats extend, a white tape fills the upper indications from the bottom up. When the flaps extend, a white tape fills the lower indications from the top down.

The secondary mode display shows a command bar and detent number. These operate the same as for the primary mode display.

After the flaps and slats are fully retracted, the secondary mode display goes out of view and the primary mode display shows. After 10 seconds, the primary mode display also goes out of view.

If the flaps (or slats) drive system fails, the related indications change from white to amber.

If the left (or right) slat position data is invalid, the left (or right) upper tape and command bar go out of view. If the left (or right) flap position data is invalid, the left (or right) lower tape and command bar go out of view. If the flap lever position data is invalid, the detent number goes out of view.

Alternate Mode Display

The alternate mode display shows when you push the alternate flaps arm switch.

The alternate mode display has almost the same format as the secondary mode display. The difference is that the alternate mode display does not have the command bar, but has tick marks and reference detent numbers to identify the flap and slat positions.

If the left (or right) slat position data is invalid, the left (or right) upper tape and tick marks go out of view. If the left (or right) flap position data is invalid, the left (or right) lower tape, tick marks, and reference detent numbers go out of view.

HIGH LIFT CONTROL - INDICATIONS - POSITION DISPLAYS

HIGH LIFT CONTROL - INDICATIONS - MAINTENANCE PAGE FORMAT

General

The high lift maintenance page format contains data from each FSEU. This includes the following data:

- Systems ARINC 629 data buses
- Flap lever position sensors
- Slat commands
- Slat position sensors
- Slat skew sensors
- Flap commands
- Flap position sensors
- Flap skew sensors.

There are three different display modes:

- Real time mode
- Manual event mode
- Auto event mode.

The word MANUAL or AUTO at the top of the page identifies the manual or auto event page. The message that caused the auto event is at bottom left of the page. The time of the event is at the bottom right.

Systems ARINC 629 Data Buses

The top of the page shows data that each FSEU receives from the systems ARINC 629 data buses. The first row shows the control status of each FSEU. The status of the FSEU is one of the following:

- IN CONTROL; the FSEU is in control of the HLCS
- ALTN ARM; the alternate mode is armed
- LOADING; the FSEU is loading software
- TEST; the FSEU is in test
- FAULT; the FSEU has detected a lane fault
- STANDBY; none of the other status words are applicable.

The page then shows the airspeed in knots and the center hydraulic system pressure in psi. If this data is invalid, there is no indication.

Below these are the status of the commands for autoslat, load relief, and to the autoslat priority valves. At the bottom of this list is the air/ground status.

Flap Lever Position Sensor

The top left of the page shows the voltage of each RVDT in the flap lever position sensor. If some of this data is invalid, there is no indication for the bad value.

Slat Commands

The left center of the page shows the status of the slat commands from the FSEU in control. The status of the slats drive command is one of the following:

- PRI EXT; the slats are commanded to extend in the primary mode
- PRI RET; the slats are commanded to retract in the primary mode

- SEC EXT; the slats are commanded to extend in the secondary mode
- SEC RET; the slats are commanded to retract in the secondary mode.

The status of the slat drive mode is one of the following:

- LO SPD; the slats are moving at low speed in the primary mode
- HI SPD; the slats are moving at high speed in the primary mode
- CLUTCH; the electric motor clutch is engaged.

The status of the shutoff valve command is either OPEN or CLOSED.

Slat Position Sensors

The right center of the page shows the position of the slat position sensors in degrees of sensor rotation. If some of this data is invalid, there is no indication for the bad value.

Slat Skew Sensors

The center of the page shows the status of the slat skew sensors. The page shows one of the following for each sensor:

- NEAR; the target is near the sensor
- FAR; the target is far from the sensor
- FAIL; the sensor is defective.

If some of this data is invalid, there is no indication for the bad value.

Flap Commands

The bottom left of the page shows the status of the flap commands from the FSEU in control. The status of the flap drive command is one of the following:

- PRI EXT; the flaps are commanded to extend in the primary mode
- PRI RET; the flaps are commanded to retract in the primary mode
- SEC EXT; the flaps are commanded to extend in the secondary mode
- SEC RET; the flaps are commanded to retract in the secondary mode.

The status of the flaps drive mode is one of the following:

- LO SPD; the flaps are moving at low speed in the primary mode
- HI SPD; the flaps are moving at high speed in the primary mode
- CLUTCH; the electric motor clutch is engaged.

The status of the shutoff valve command is either OPEN or CLOSED.

HIGH LIFT CONTROL - INDICATIONS - MAINTENANCE PAGE FORMAT

Flap Position Sensors

The bottom right of the page shows the position of the flap position sensors in degrees of sensor rotation. If some of this data is invalid, there is no indication for the bad value.

Flap Skew Sensors

The bottom of the page shows the voltage of the flap skew sensors in volts. If some of this data is invalid, there is no indication for the bad value.

HIGH LIFT CONTROL - INDICATIONS - MAINTENANCE PAGE FORMAT

HIGH LIFT CONTROL - SYSTEM TESTS

General

The FSEUs control the operation of the MAT tests. All the MAT tests for the HLCS are interactive tests. You are able to select which FSEU to control each of the tests. There are no MAT operational tests for the HLCS.

The system tests for the HLCS include:

- Primary System Test - FSEU 1
- Primary System Test - FSEU 2
- Secondary System Test - FSEU 1
- Secondary System Test - FSEU 2.

All of these tests can test the flaps only, the slats only, or both. Also, all of these tests will cause the flaps and slats to move.

Primary System Test - FSEU 1 (FSEU 2)

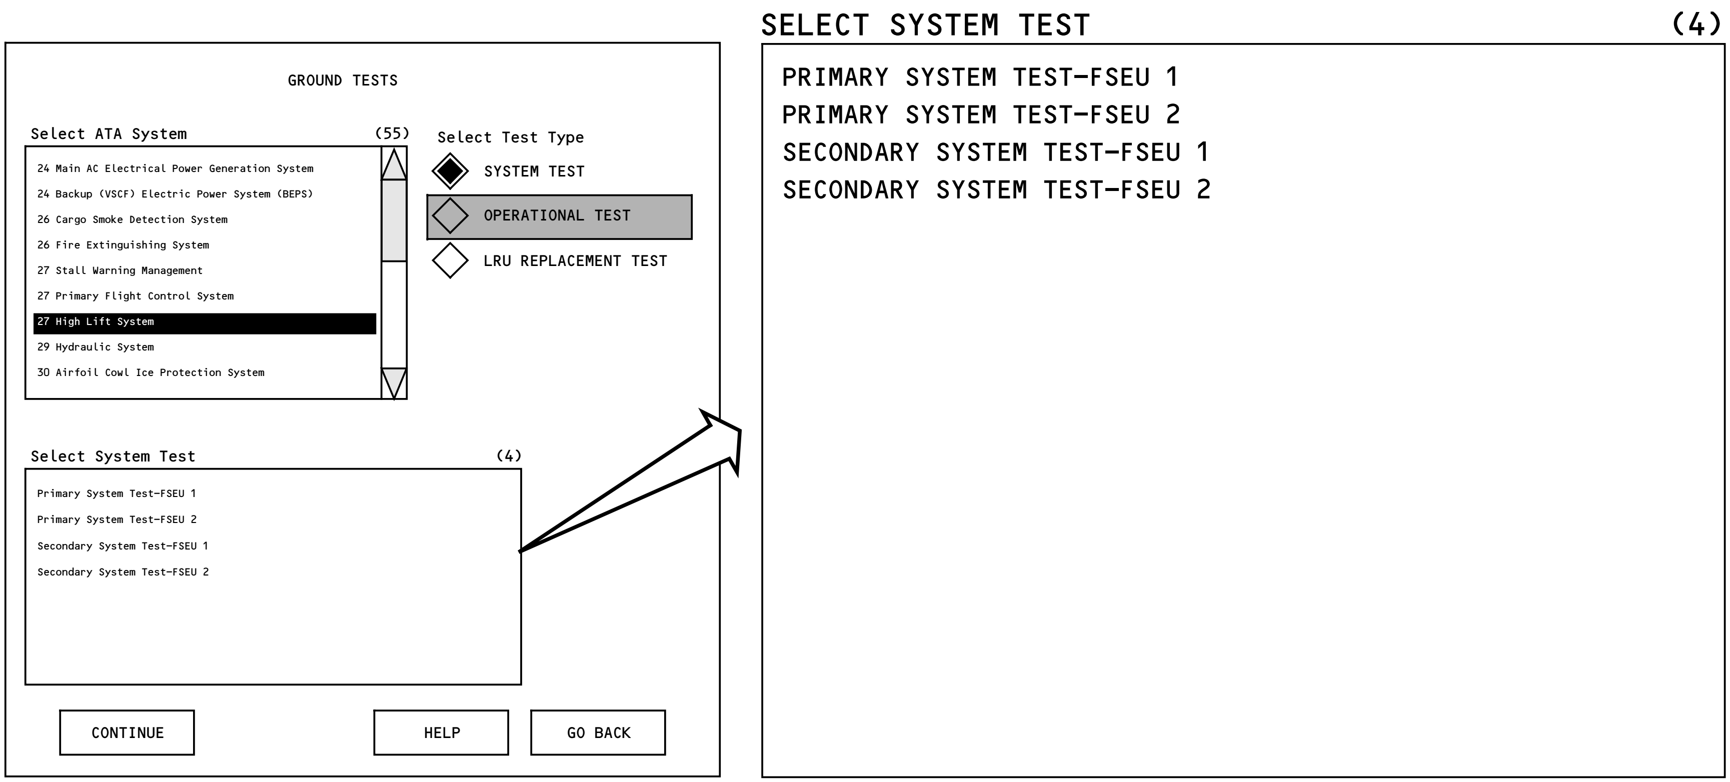
This test makes sure that FSEU 1 (FSEU 2) can control the HLCS correctly in hydraulic mode.

Secondary System Test - FSEU 1 (FSEU 2)

This test makes sure that FSEU 1 (FSEU 2) can control the HLCS correctly in electric mode.

Training Information Point

The MAT tests for the HLCS use a ground test software in the FSEUs that is different than the test software used during flight. If the MAT test fails, the maintenance message will be different than the maintenance message reported by the flight test software.



27-03-00-015 Rev 3 03/31/1998

HIGH LIFT CONTROL - SYSTEM TESTS

HIGH LIFT CONTROL - LRU REPLACEMENT TESTS

General

The LRU replacement tests for the HLCS include:

- FSEU 1
- FSEU 2
- Flaps primary control valve test - FSEU 1
- Flaps primary control valve test - FSEU 2
- Slats primary control valve test - FSEU 1
- Slats primary control valve test - FSEU 2
- Inboard slat skew test - FSEU 1
- Inboard slat skew test - FSEU 2.

FSEU 1 (FSEU 2)

This test makes sure that FSEU 1 (FSEU 2) is operating correctly.

Slats Primary Control Valve Test-FSEU 1 (FSEU 2)

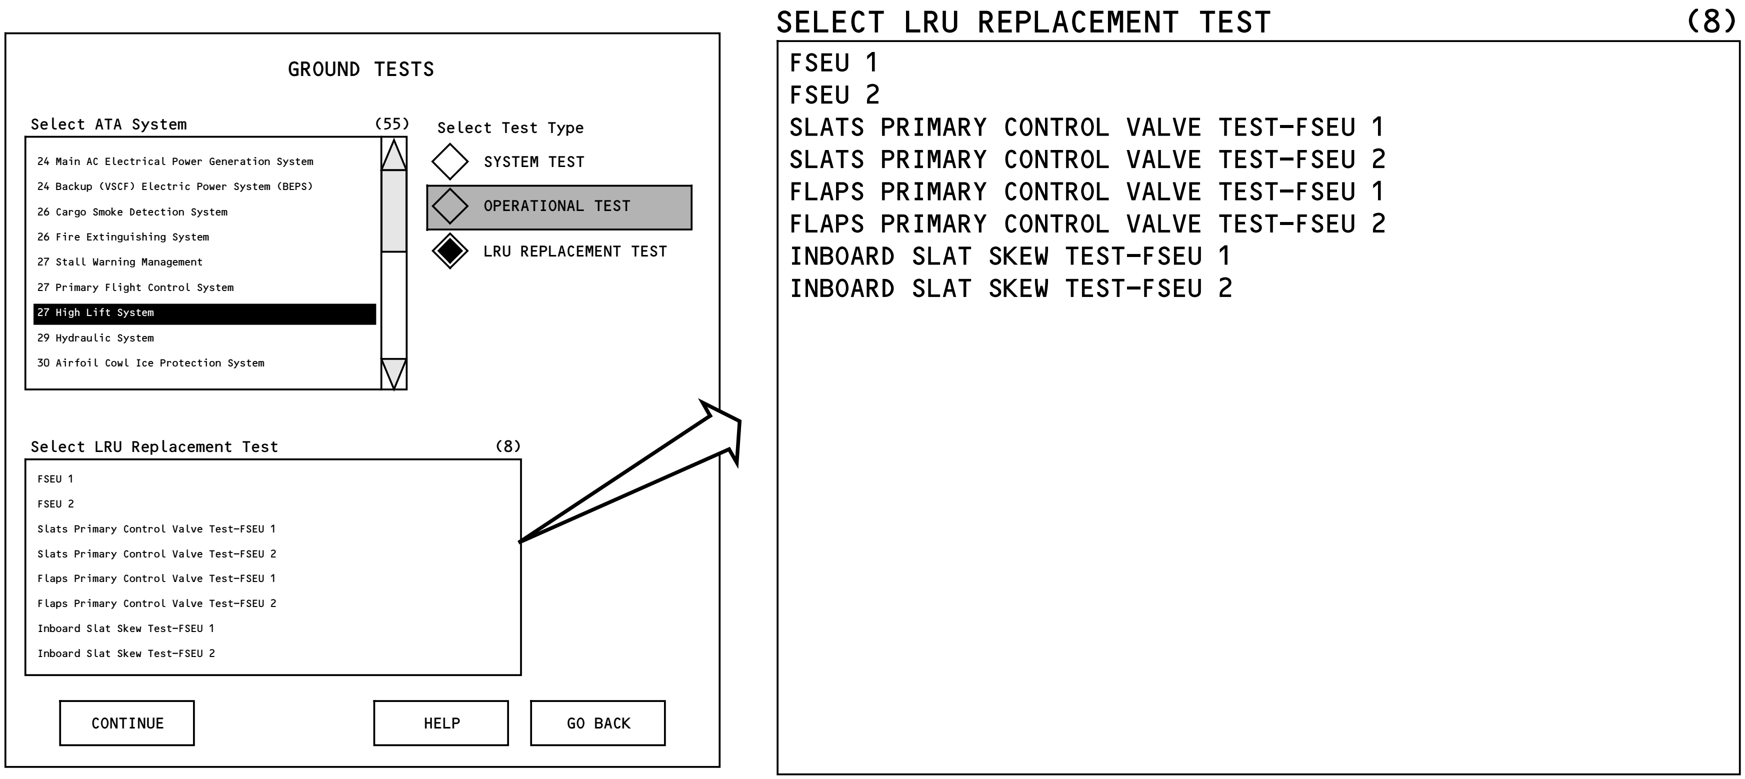
This test makes sure that FSEU 1 (FSEU 2) controls the slats primary control valve correctly. During this test, the slats will move.

Flaps Primary Control Valve Test-FSEU 1 (FSEU 2)

This test makes sure that FSEU 1 (FSEU 2) controls the flaps primary control valve correctly. During this test, the flaps will move.

Inboard Slat Skew Test-FSEU 1 (FSEU 2)

This test makes sure that FSEU 1's (FSEU 2's) inboard slat skew/loss sensors operate correctly. During this test, the slats will move.



27-03-00-016 Rev 2 03/31/1998

HIGH LIFT CONTROL - LRU REPLACEMENT TESTS

HIGH LIFT CONTROL - SPECIAL FUNCTIONS

General

The secondary mode inhibit override function permits movement of the slats and flaps with the PDU electric motors while on the ground.

You can select which FSEU controls the flaps and slats when you use this function.

The FSEUs inhibit the secondary mode operation when the airplane is in a ground maintenance condition. Three conditions are necessary for the ground maintenance condition to occur. First, the center hydraulic system pressure must be low. Second, either:

- The airplane is on the ground, or
- The ground speed is less than 40 knots.

Third, either:

- Both engines are not running, or
- One engine is not running and external power is available.

Operation

When you use this function, the FSEUs permit the use of the PDU electric motors to move the flaps and slats. You can then use the flap lever to control the position of the flaps and slats.

After you enable the secondary mode inhibit override, you have 15 seconds to move the flaps and slats using the flap lever. After 15 seconds, the secondary mode inhibit override stops. If the surfaces are in motion when the inhibit override stops, the surfaces continue to move to the commanded position.

If you use the secondary mode inhibit override when there is no failure of the primary mode, the flaps and slats operate the same as the primary mode. The FSEU sends commands to the electric motors of the flaps and slats power drive units. The flaps/slats sequence is the same as in primary mode (slats sealed with flap lever position 1 through 20, slats gapped with flap lever position 25 and 30). The flaps/slats indication on the EICAS display shows the primary mode display.

If you use the secondary mode inhibit override when there is a failure of the primary mode, the flaps/slats operate the same as the secondary mode. The FSEU sends commands to the electric motors of the flaps and slats power drive units. The flaps/slats sequence is the same as in secondary mode (slats gapped with flap lever position 1 through 30). The flaps/slats indication on the EICAS display shows the secondary mode display.

For example, you could cause a failure of the primary mode if on the ground you move the flap lever with the center hydraulic system depressurized before you enable the secondary mode inhibit override.

TRAILING EDGE FLAPS - INTRODUCTION

General

The trailing edge (TE) flaps improve the takeoff and landing performance of the airplane. When the flaps extend, they increase the lift of the wing. They also help to decrease the airspeed during landings and approaches.

The flaps are part of the high lift control system (HLCS). The HLCS electrically controls the flaps with a fly-by-wire system.

During takeoff and landing, the pilots use the flap lever to command the flaps to move to an extended position. During cruise, the pilots command the flaps to retract to the up position.

Each wing has an inboard flap and an outboard flap. The inboard flap is double-slotted and has a main flap and an aft flap. The outboard flap is single-slotted and is one piece.

Flap Operation

The flaps operate in sequence with the slats. At cruise speed and altitude, flap extension is inhibited.

The load relief function retracts the flaps to prevent structural damage to the flaps at high airspeeds.

The flaps are monitored for skew or asymmetry. When the system detects a skew or asymmetry, the flap drive shuts down.

TRAILING EDGE FLAPS - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

TRAILING EDGE FLAPS - GENERAL DESCRIPTION

General

The flaps operate in one of three modes:

- Primary mode
- Secondary mode
- Alternate mode.

The primary mode uses hydraulic power to operate the flaps. The secondary and alternate modes use electrical power to operate the flaps.

Primary Mode

The primary mode has a closed-loop control system. The pilot commands the flaps with the flap lever. The flap lever position sensor sends input signals to the FSEUs. The FSEUs use the flap lever position to calculate the flap commands. The FSEUs also receive data from the systems ARINC 629 buses.

The FSEUs send the flap commands to the flap primary control valve. This valve supplies hydraulic power to the flap power drive unit (PDU). The hydraulic motor on the PDU then moves the flap mechanisms.

The flap/slat priority valve controls the amount of hydraulic flow to the flap primary control valve. The flap/slat priority valve gives priority of hydraulic power to the primary flight control system (PFCS) over the HLCS.

As the flaps move, the flap position sensors send feedback signals to the FSEUs. The FSEUs stop the flap commands when the feedback signals equal the commanded position.

The FSEUs use the flap skew sensors to shutdown the primary mode (and the secondary mode) if there is a flap skew or asymmetry.

Secondary Mode

The FSEUs use the secondary mode when the primary mode disengages. The secondary mode is only available in the air or during special maintenance functions.

The secondary mode also has a closed-loop control system. The pilot commands the flaps with the flap lever. The FSEUs use the flap lever position to calculate the flap commands. The FSEUs then energize the secondary/alternate control relays. One relay energizes the bypass solenoid in the flap primary control valve and the clutch in the electric motor unit. This stops hydraulic power to the hydraulic motor and lets free flow through it. The electric motor clutch connects the motor shaft to the PDU gearbox. The other relays control electrical power to the flap electric motor on the flap PDU. The electric motor then moves the flap mechanisms.

As the flaps move, the flap position sensors send feedback signals to the FSEUs. The FSEUs command the relays to stop the electric motor when the flaps are at the commanded position.

TRAILING EDGE FLAPS - GENERAL DESCRIPTION

The FSEUs use the flap skew sensors to shutdown the secondary mode if there is a flap skew or asymmetry.

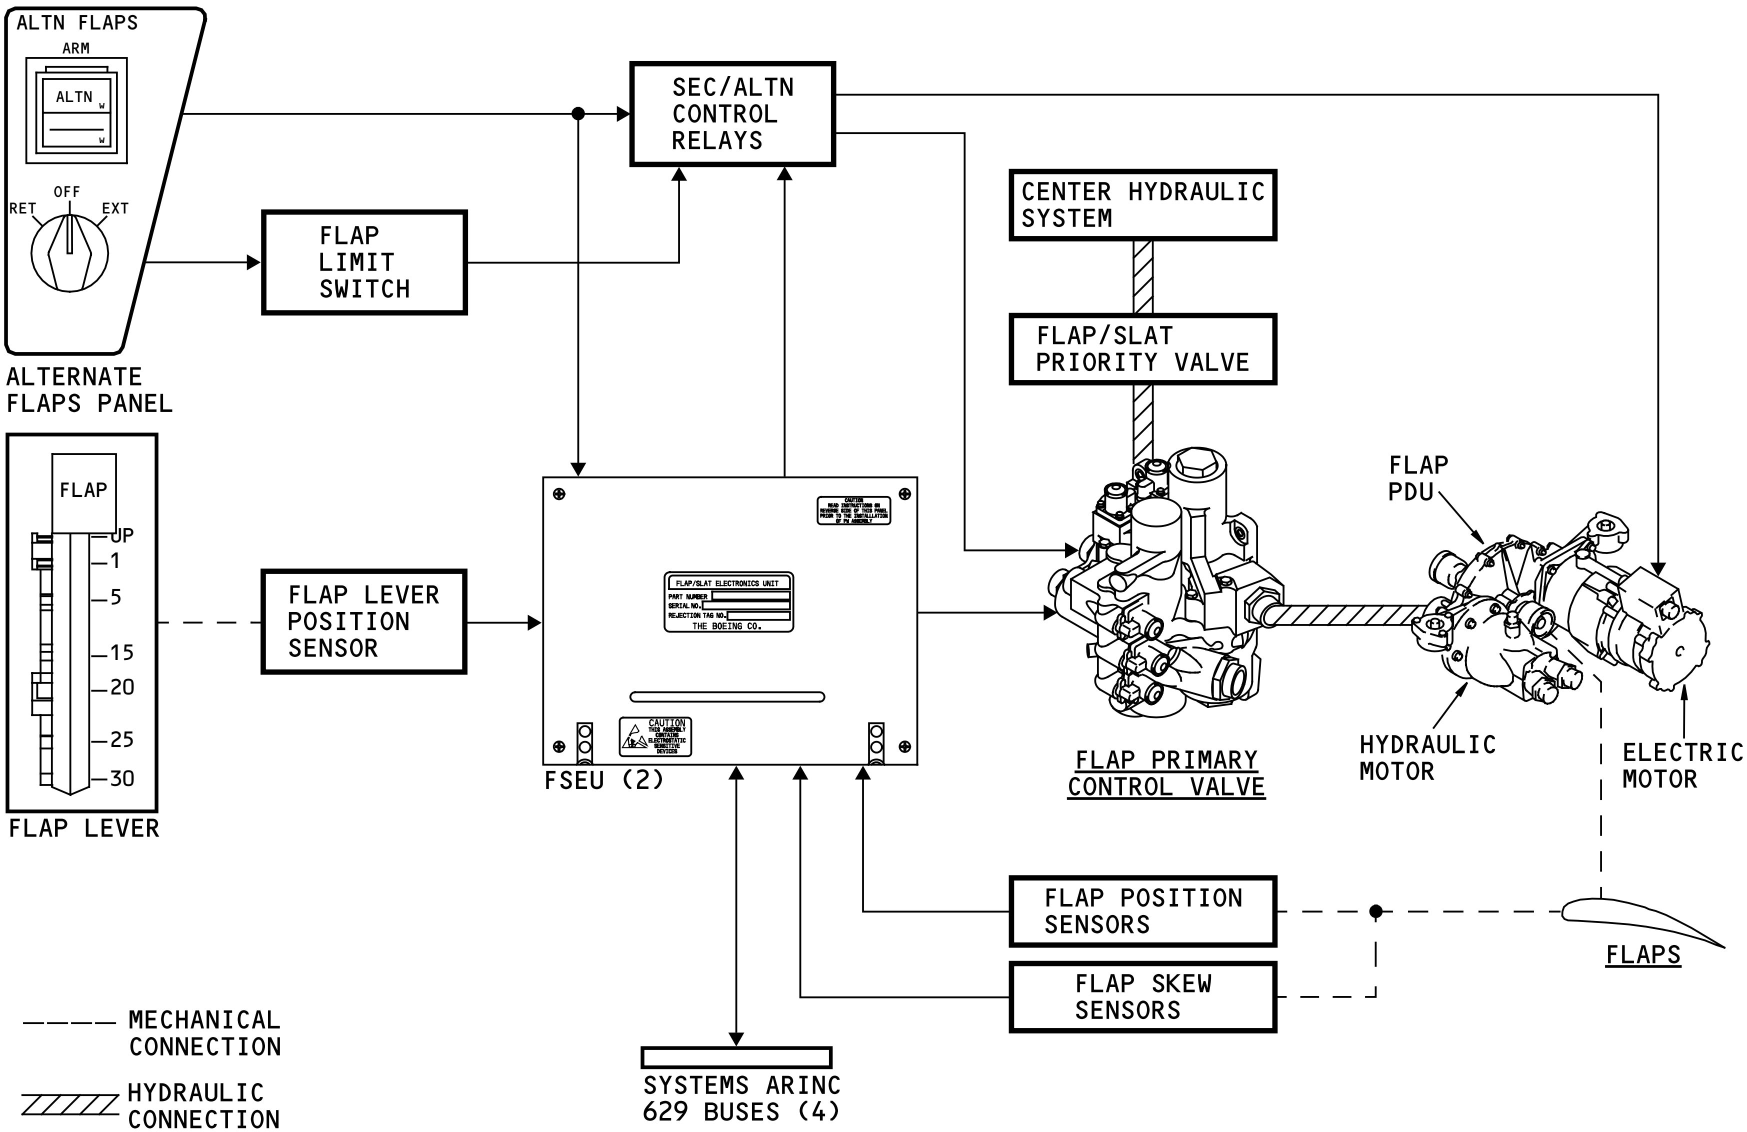
Alternate Mode

The alternate mode has an open-loop control system. The pilot uses the switches on the alternate flaps panel to command the flaps. An arm switch sends a discrete signal to the FSEUs to disengage the primary and secondary modes. This switch also energizes one of the secondary/alternate control relays. This relay energizes the bypass solenoid in the flap primary control valve and the clutch in the electric motor unit. This stops hydraulic power to the hydraulic motor and lets free flow through it. the electric motor clutch connects the motor shaft to the PDU gearbox.

The alternate flaps selector sends commands through the flap limit switch to energize the other secondary/ alternate control relays. These relays control electrical power to the flap electric motor in the PDU. The electric motor then moves the flap mechanisms.

The flaps move until the pilot moves the alternate flaps selector to the OFF position or the flap limit switch stops the motor when the flaps are at the limit.

There is no automatic shutdown of the alternate mode if there is a flap skew or asymmetry.



TRAILING EDGE FLAPS - GENERAL DESCRIPTION

TRAILING EDGE FLAPS - GENERAL DESCRIPTION - FLAP DRIVE SYSTEM

General

These are the components of the flap drive system:

- Flap PDU
- Torque tubes
- Torque tube supports
- Position sensor gearboxes
- Angle gearboxes
- Transmission assemblies
- No-back brakes.

Flap PDU

The flap PDU receives hydraulic power through the primary control valve and electric power through the flap extend/retract relays. Hydraulic and electric motors on the PDU move the flap drive system.

Torque Tubes

The torque tubes transmit power from the PDU to the transmission assemblies.

Torque Tube Supports

The torque tube supports hold the torque tubes.

Position Sensor Gearboxes

The position sensor gearboxes contain the flap position sensors and limit switch. The sensors send flap position signals to the FSEUs. The limit switch removes electrical power from the electric motor when the flaps move to their limit during operation in the alternate mode.

Angle Gearboxes

The angle gearboxes connect torque tubes that are at different angles to each other.

Transmission Assemblies

The transmission assemblies receive power from the torque tube to move the flap surfaces. There are two transmissions for each flap surface.

No-back Brakes

The no-back brakes prevent air loads from backdriving the flap mechanisms. There is one no-back brake on each wing. The no-back brakes attach to the torque tubes between the two transmission assemblies for the outboard flaps.

27-51-00-004 Rev 0

TRAILING EDGE FLAPS - COMPONENT LOCATIONS - 1

TRAILING EDGE FLAPS - COMPONENT LOCATIONS - 2

General

The flap components are in these areas:

- The main landing gear wheel wells
- The wings.

Main Landing Gear Wheel Well Components

The flap primary control valve and the flap/slat priority valve attach to the keel beam in the right wheel well.

The flap PDU attaches to the top of the keel beam. Access to the flap PDU is through the left or right wheel well.

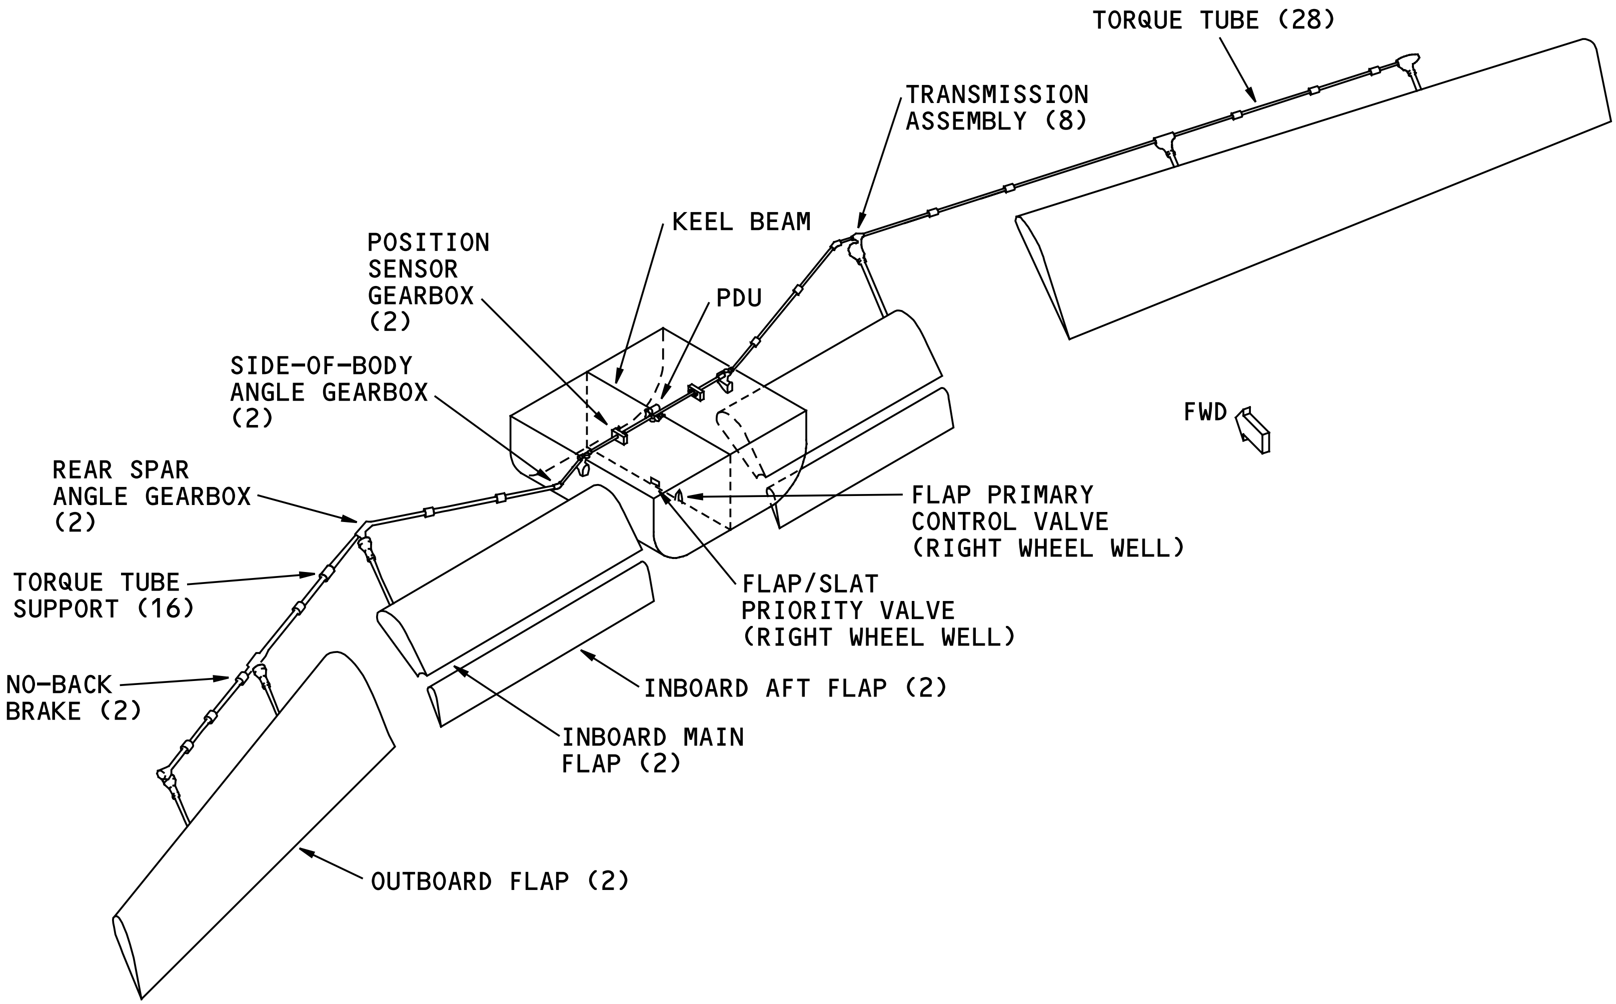
The flap position sensor gearboxes attach to brackets on the floor beams. One of these gearboxes is in the right wheel well and the other is in the left wheel well.

The inboard flap inboard transmissions, side-of-body angle gearboxes, and some of the torque tubes are also in the wheel wells.

Wing Components

The outboard flaps, inboard main flaps, and inboard aft flaps are on the wings. Most of the flap transmissions and ballscrews are under the wings. Remove the flap support fairings under the wing or extend the flaps to get access to the transmissions and ballscrews.

The rear spar angle gearboxes, the no-back brakes, and some of the torque tubes attach to the rear spar of the wings. Access to the gearboxes is through panels under the wings. Extend the flaps to get access to the torque tubes and the no-back brakes.



27-51-00-005 Rev 2 07/13/95

TRAILING EDGE FLAPS - COMPONENT LOCATIONS - 2

TRAILING EDGE FLAPS - FLAP LEVER AND FLAP LEVER POSITION SENSOR

Purpose

The pilots use the flap lever to control the position of the flaps and slats in the primary and secondary modes. The flap lever position sensor sends input position signals to the FSEUs.

Physical Description

The flap lever has detent positions at UP, 1, 5, 15, 20, 25, and 30. Gates at detents 1 and 20 help the flight crew to identify these positions during climb-out and go-around.

The flap lever connects with a crank and a control rod to the brake mechanism. The flap lever position sensor attaches to the brake mechanism. The position sensor has a splined shaft with a missing tooth to help align the position sensor with the brake mechanism.

The flap lever position sensor has four internal rotary variable differential transformers (RVDTs). The assembly is an LRU, but the RVDTs are not LRUs.

Location

The flap lever is on the right side of the P10 control stand. The brake mechanism and the flap lever position sensor are in the control stand.

Functional Description

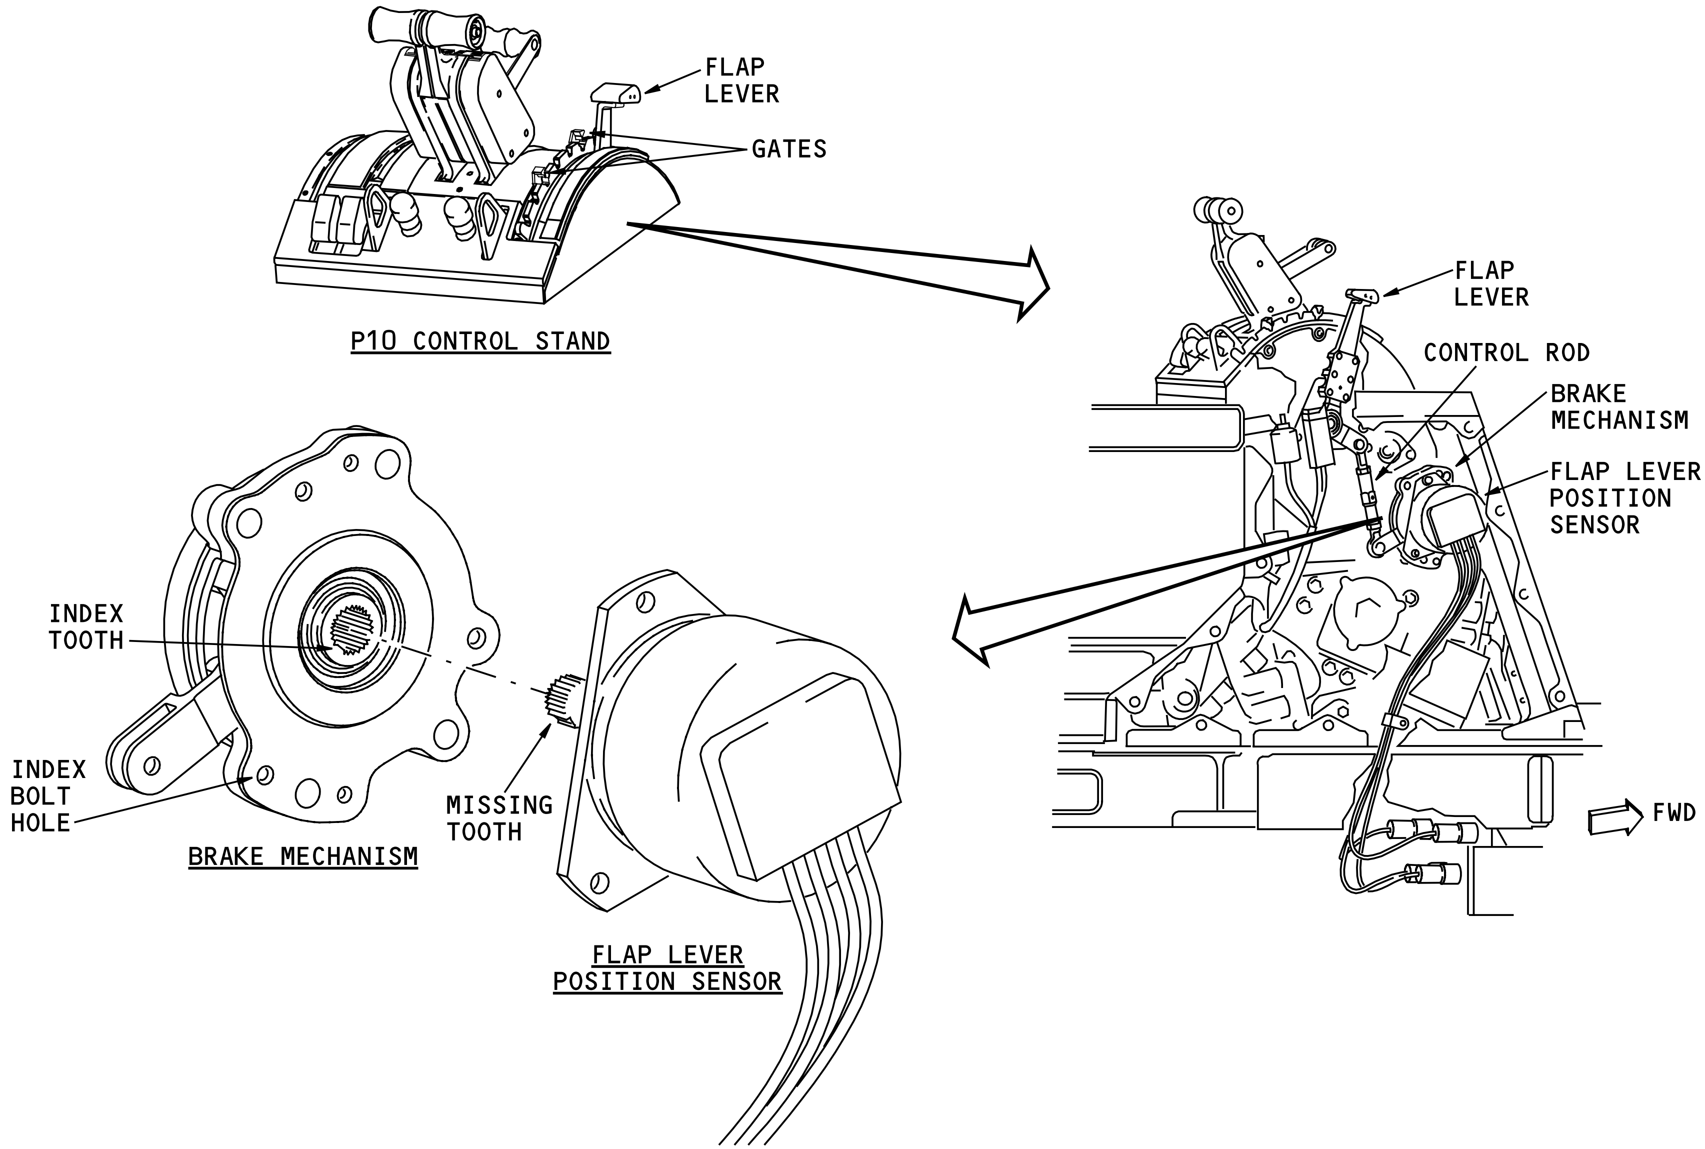
When the pilots move the flap lever, the control rod turns the spline in the brake mechanism. The spline then drives the position sensor. If the control rod disconnects, the brake mechanism prevents movement of the RVDTs.

Training Information Point

After you install the flap lever position sensor, do the LRU replacement test. To do this test, move the flap lever to each detent and check the value of each RVDT on the high lift maintenance page.

During installation of the brake mechanism, adjust the control rod to align the index tooth with the index bolt hole.

If you replace only the flap lever position sensor without removal of the brake mechanism, it is not necessary to adjust the control rod.



TRAILING EDGE FLAPS - FLAP LEVER AND FLAP LEVER POSITION SENSOR

TRAILING EDGE FLAPS - ALTERNATE FLAPS PANEL

Purpose

The two switches on the alternate flaps panel are:

- The alternate flaps arm switch
- The alternate flaps selector.

These switches control the flaps and slats in the alternate mode.

Physical Description

The alternate flaps arm switch is a guarded, alternate action switch. When you push the switch, ALTN shows.

The alternate flaps selector has these detents

- OFF
- RET
- EXT.

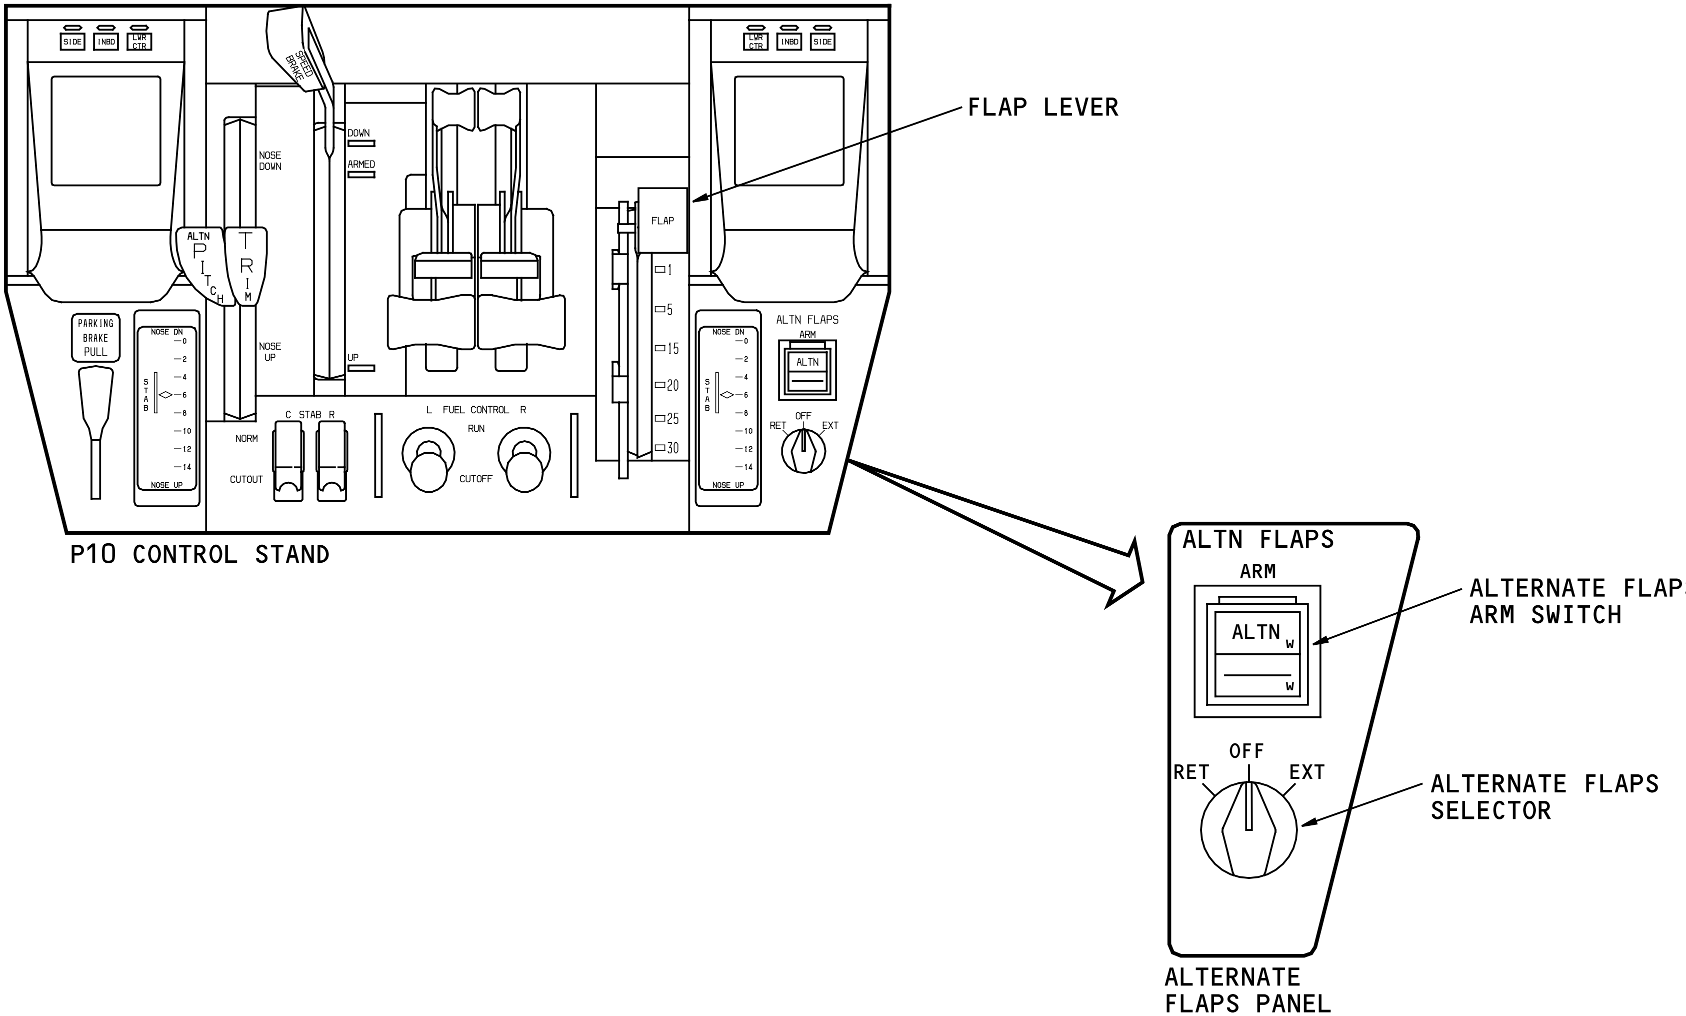
Location

The alternate flaps panel is on the right side of the P10 control stand.

Operation

To engage the alternate mode, push the alternate flaps arm switch. To extend the flaps and slats in the alternate mode, turn the alternate flaps selector to the EXT position. Turn the selector to the OFF position to stop the movement of the flaps and slats. To retract the flaps and slats, turn the selector to the RET position.

To disengage the alternate mode, push the alternate flaps arm switch again.



TRAILING EDGE FLAPS - ALTERNATE FLAPS PANEL

27-51-00-007 Rev 1 06/04/95

THIS PAGE INTENTIONALLY LEFT BLANK

TRAILING EDGE FLAPS - FLAP/SLAT ELECTRONICS UNIT (FSEU)

General

The two flap/slat electronics units (FSEUs) control the flaps and slats in the primary and secondary modes. Only one FSEU is in control of the flaps and slats at a time. The other FSEU does not send commands to the flaps and slats. The FSEUs automatically transfer control to the other FSEU after a post-flight self-test of the FSEUs or after disengagement from the alternate mode. There is also an automatic transfer after a fault in the FSEU in control.

Physical Description

The two FSEUs are the same and interchangeable. Each FSEU contains two independent channels: the control channel and the monitor channel. The two channels have different microprocessors, made by different manufacturers. The microprocessors have different part numbers. The two channels have the same capabilities and operate with the same software.

Program pins on each FSEU supply information on FSEU location and software. Cooling for both FSEUs is passive.

Channel Functions

The control channel and the monitor channel of each FSEU has:

- A set of HLCS sensor inputs
- An analog to digital (A/D) converter
- A set of control laws
- A failure monitor
- A cross-channel monitor
- A lane monitor
- Separate interfaces with the ARINC 629 buses.

HLCS Sensor Inputs

Each channel receives inputs from the HLCS sensors. Failure of a sensor can cause the control to change to the other FSEU.

A/D Converter

The FSEU changes the analog inputs to digital format before using them in the control laws.

Control Laws

The FSEUs use control laws to calculate the commands for the flaps and slats in the primary and secondary modes. Each channel sends the commands to output drivers. Both channels must agree on the commands to permit the FSEU to supply a ground for the flap and slat solenoids or relays.

Failure Monitor

Each channel monitors the HLCS for these conditions:

- Flap position failure
- Slat position failure
- Slat loss.

TRAILING EDGE FLAPS - FLAP/SLAT ELECTRONICS UNIT (FSEU)

If the FSEU detects one of these conditions, the FSEU stops the commands to the failed surface.

Cross-Channel Monitor

The cross-channel monitor compares the commands from the control and monitor channels. The output command signals to control the flaps and slats go to the opposite channel for comparison. If the commands disagree, then the FSEU stops all commands. Control then changes to the other FSEU.

The alternate arm switch position signals to the FSEU directly disable the output commands. If this switch is in the ARMED position, the FSEU stops all commands.

Lane Monitor

The lane monitor compares the input signals to both channels in each FSEU. The lane monitor receives the inputs from the other FSEU in two ways.

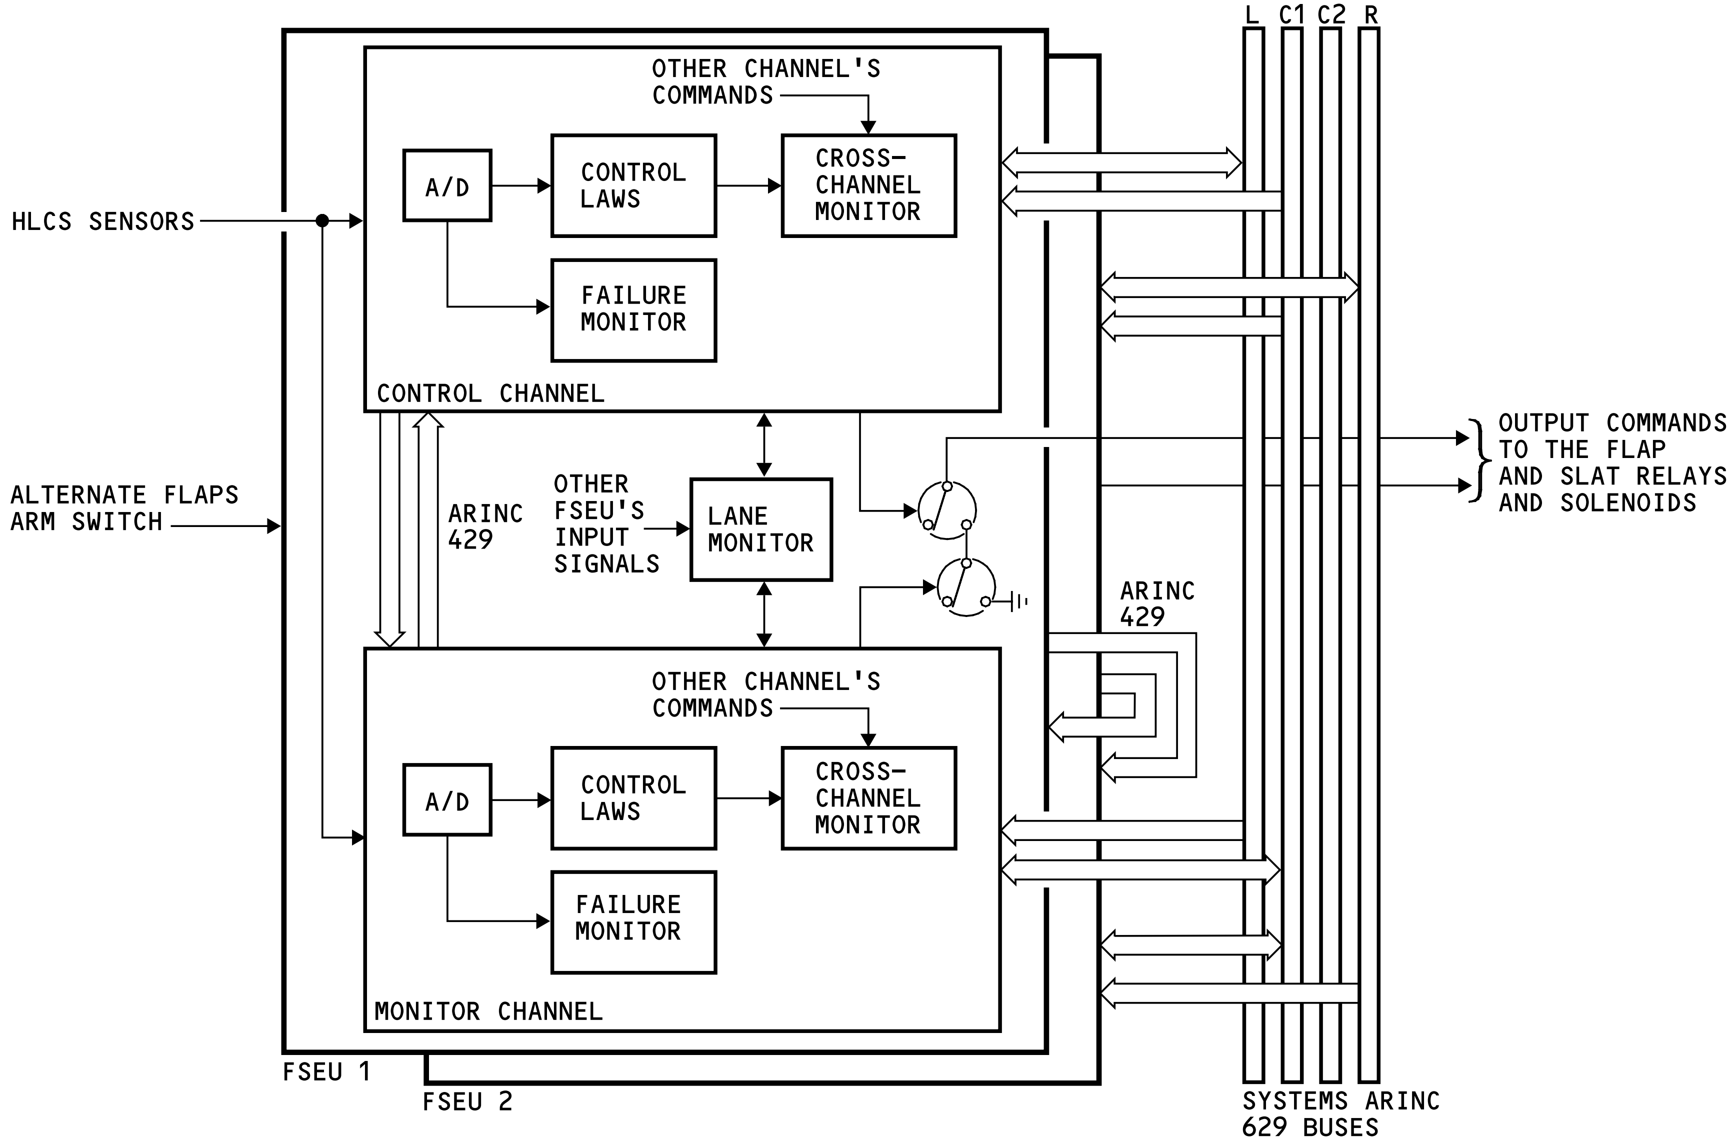
One way is through the cross-lane ARINC 429 buses. The other way is through the systems ARINC 629 buses. If the input signals to the FSEU in control fails, then the control changes to the other FSEU.

ARINC 629 Buses

Each channel transmits and receives data from the systems ARINC 629 buses. Each channel transmits its own commands, and receives commands from the other channel and from the other FSEU. Each channel receives data from two of the systems buses for redundancy.

Training Information Point

Use the maintenance access terminal (MAT) to load the software for the FSEUs. After you load the software, push the alternate flaps arm switch to the ARMED then NOT ARMED position. This removes any EICAS messages for the HLCS.



27-51-00-008 Rev 5 12/12/95

TRAILING EDGE FLAPS - FLAP/SLAT ELECTRONICS UNIT (FSEU)

TRAILING EDGE FLAPS - FLAP PRIMARY CONTROL VALVE

Purpose

The flap primary control valve controls hydraulic power to the hydraulic motor. In the primary mode, this valve controls the direction and speed of movement of the flap drive system. In the secondary and alternate modes, this valve prevents hydraulic power to the hydraulic motor.

Physical Description

The primary control valve is an LRU. These components on the primary control valve are LRUs:

- The shutoff solenoid
- The extend solenoid
- The retract solenoid
- The low-speed solenoid
- The bypass solenoid.

The low-speed solenoid is different than the other solenoids, but it is interchangeable with the low-speed solenoid on the slat primary control valve. All the other solenoids are interchangeable and they are interchangeable with the other solenoids on the slat primary control valve. The flap primary control valve is similar to, but not interchangeable with, the slat primary control valve.

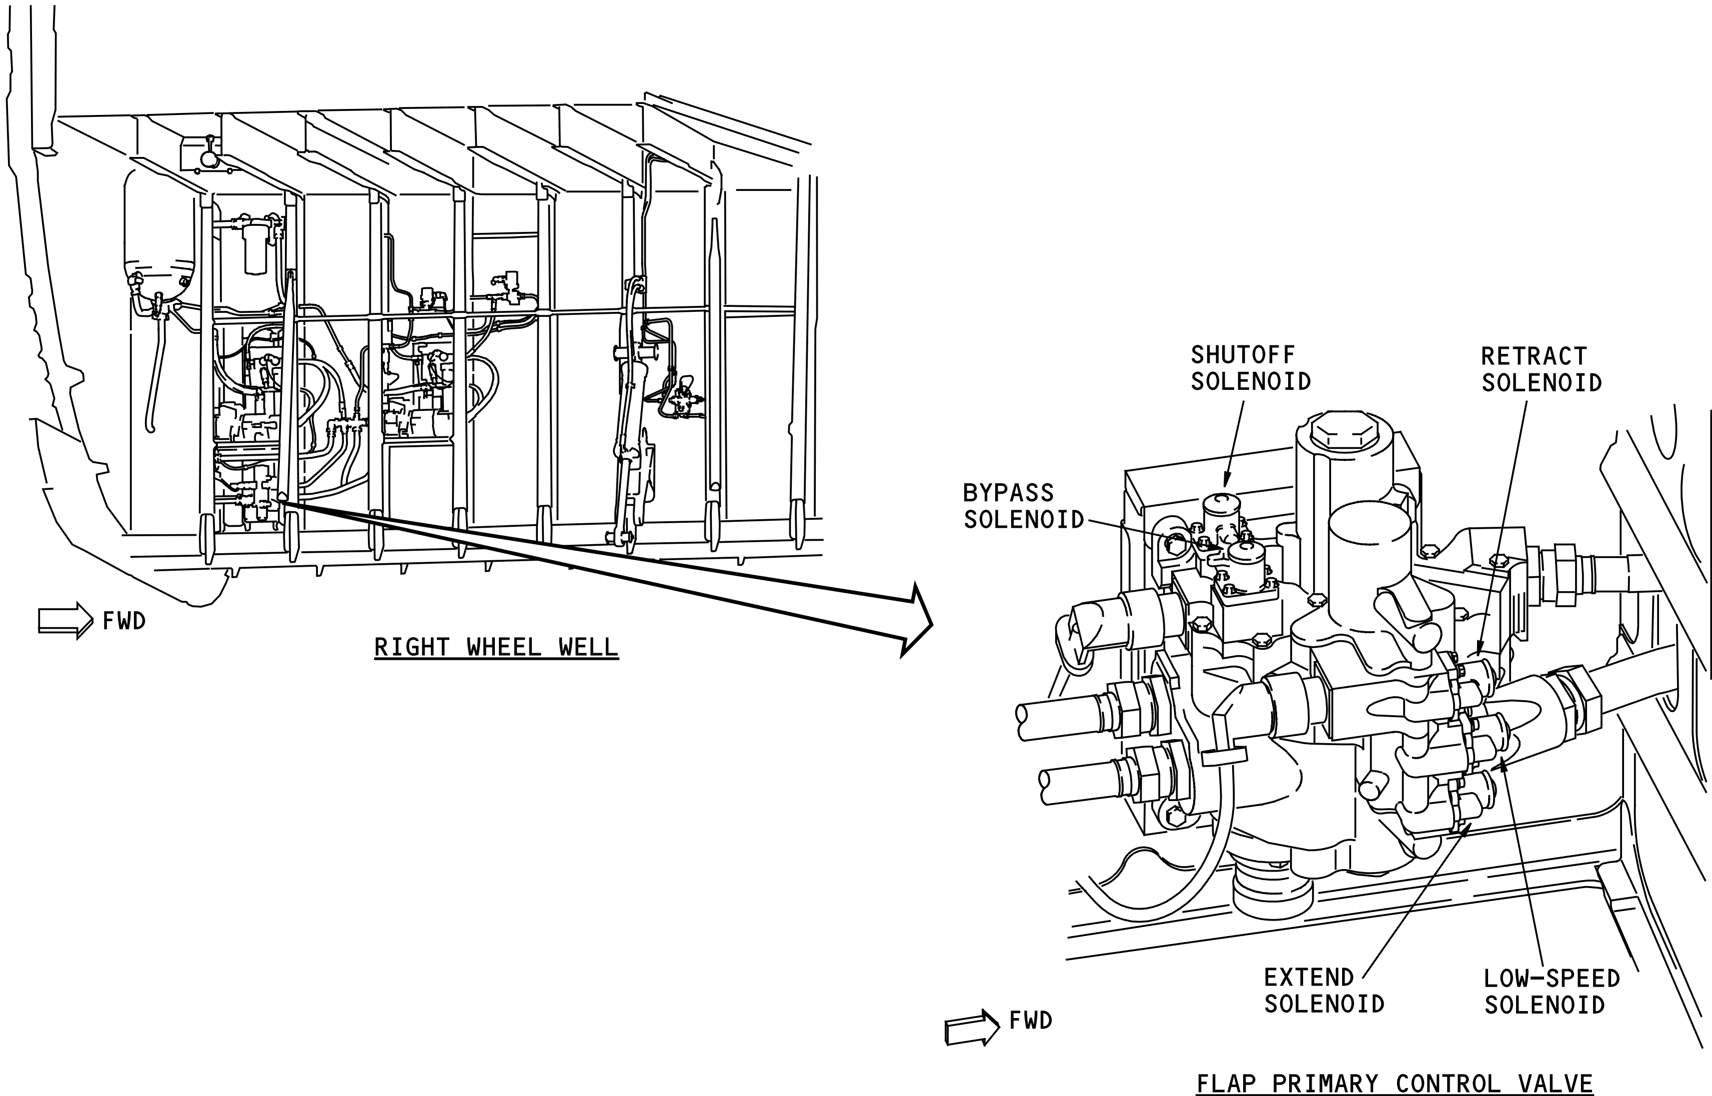
Location

The flap primary control valve attaches to the keel beam in the right wheel well.

Training Information Point

There is a small difference in the location of the mounting holes for the flap and slat primary control valves. This helps prevent the slat primary control valve from being installed where the flap primary valve should be. The reverse is also true.

The low-speed solenoid has a longer valve and different mounting hole locations. This helps prevent the low-speed solenoid from being installed where a different type of solenoid should be. This also helps prevent a different solenoid from being installed where the low-speed solenoid should be.



27-51-00-009 Rev 2 07/13/95

TRAILING EDGE FLAPS - FLAP PRIMARY CONTROL VALVE

TRAILING EDGE FLAPS - PRIMARY CONTROL VALVE - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

TRAILING EDGE FLAPS - PRIMARY CONTROL VALVE - FUNCTIONAL DESCRIPTION

General

The primary control valve has these components:

- Shutoff valve
- Shutoff solenoid valve
- Low-speed solenoid valve
- Low speed piston
- Flow regulator
- Retract solenoid valve
- Extend solenoid valve
- Selector valve
- Bypass solenoid valve
- Bypass valve.

The FSEUs electrically control the solenoid valves in the primary control valve. All the solenoid valves are normally de-energized.

Shutoff Valve and Shutoff Solenoid Valve

The shutoff valve supplies hydraulic pressure and hydraulic flow to the selector valve.

The shutoff valve has three positions: closed, open, and low-speed. The shutoff valve is spring-loaded and hydraulically controlled to the closed position. It moves to the open or low-speed positions when the shutoff solenoid valve removes pressure from one side of the valve.

The shutoff solenoid valve controls the pilot pressure to the shutoff valve. The shutoff valve solenoid has two coils. When both coils are de-energized, the shutoff solenoid valve lets pilot pressure close the shutoff valve. When either coil is energized, the shutoff solenoid valve removes pilot pressure from the shutoff valve. Hydraulic system pressure then lets the shutoff valve open.

When the shutoff valve is closed, it removes hydraulic pressure from the selector valve. When the shutoff valve is open, hydraulic system pressure goes to the selector valve to move the flaps at their normal rate. When the shutoff valve is in the low-speed position, the hydraulic flow to the selector valve is restricted.

Low-Speed Solenoid Valve, Low Speed Piston, and Flow Regulator

The low-speed solenoid valve, the low speed piston, and the flow regulator help to decrease the speed of the flap drive system.

The low-speed solenoid valve has two coils. It controls hydraulic pressure to the low speed piston. The low speed piston is a hydraulic piston that is spring-loaded to the retracted position.

When the FSEUs energize the low-speed solenoid valve, the low speed piston extends. This limits the position of the shutoff valve to the low-speed position.

When the FSEUs de-energize the low-speed solenoid valve, the pressure in the low speed piston decreases. An internal spring then forces the low speed piston to retract. This lets the shutoff valve move to the open position.

The flow regulator limits the flow of hydraulic fluid to 25 gpm at high speed, and 5 gpm at low speed.

Selector Valve

The selector valve controls the direction of operation of the hydraulic motor.

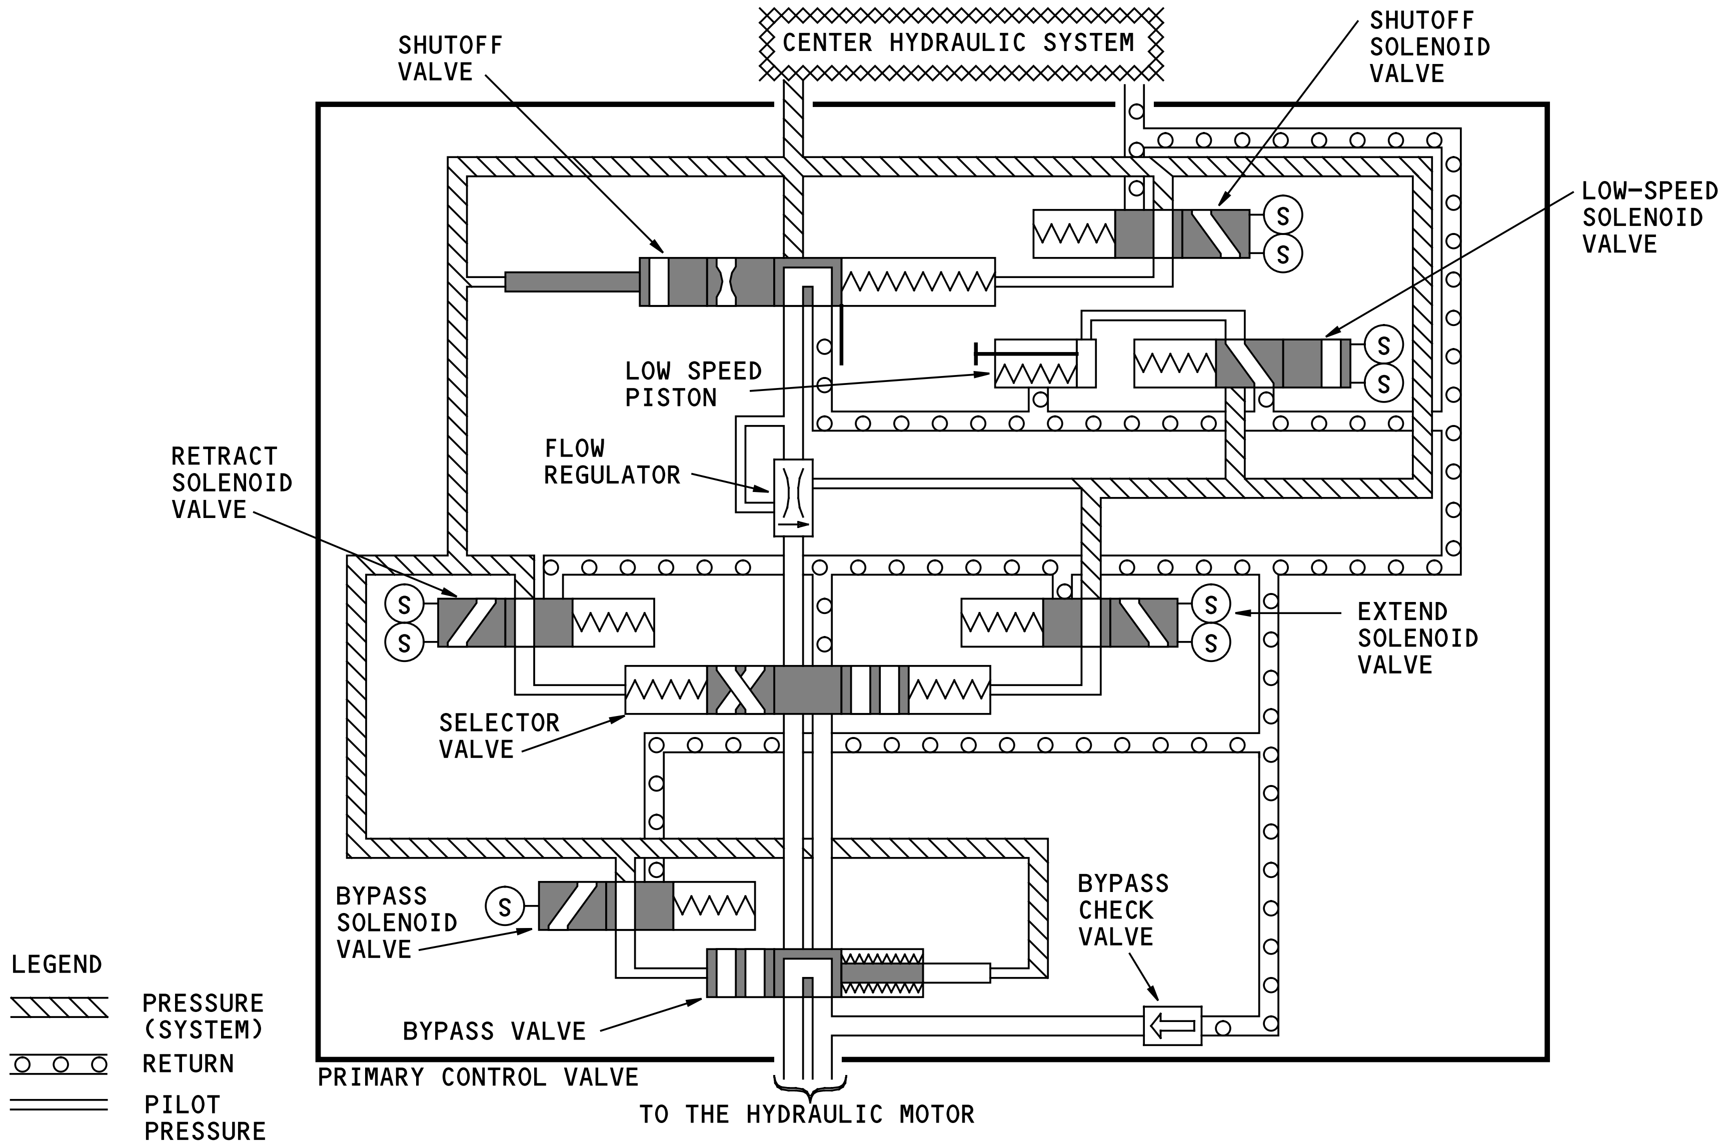
The selector valve is spring-loaded and hydraulically balanced to the center position and normally has pressure on both sides of the valve. The selector valve moves to the extend position when the extend solenoid valve removes pilot pressure from the extend side of the selector valve. The selector valve moves to the retract position when the retract solenoid valve removes pilot pressure from the retract side of the selector valve.

Bypass Valve and Bypass Solenoid Valve

The bypass valve isolates the hydraulic motor from hydraulic system pressure. The bypass valve also prevents a hydraulic lock and permits backdrive of the hydraulic motor.

A dual-coil bypass solenoid valve controls pilot pressure to the bypass valve, but only one coil of the solenoid is used. When the FSEUs energize the bypass solenoid valve, it removes pilot pressure from the open side of the bypass valve. This closes the bypass valve, which connects the hydraulic lines to both sides of the hydraulic motor.

The bypass valve is spring-loaded and hydraulically controlled to the closed position. The open side of the valve has a larger surface area for the pilot pressure than the close side of the valve. When the center hydraulic system pressure is low, springs automatically force the bypass valve to close. When the center hydraulic system pressure is high, the bypass valve opens.



27-51-00-010 Rev 3

TRAILING EDGE FLAPS - PRIMARY CONTROL VALVE - FUNCTIONAL DESCRIPTION

TRAILING EDGE FLAPS - FLAP/SLAT PRIORITY VALVE

Purpose

The flap/slat priority valve gives priority of hydraulic power to the primary flight controls over the flaps and slats. This priority valve makes sure that the primary flight control PCUs receive sufficient hydraulic power when both air driven pumps (ADPs) are not operating.

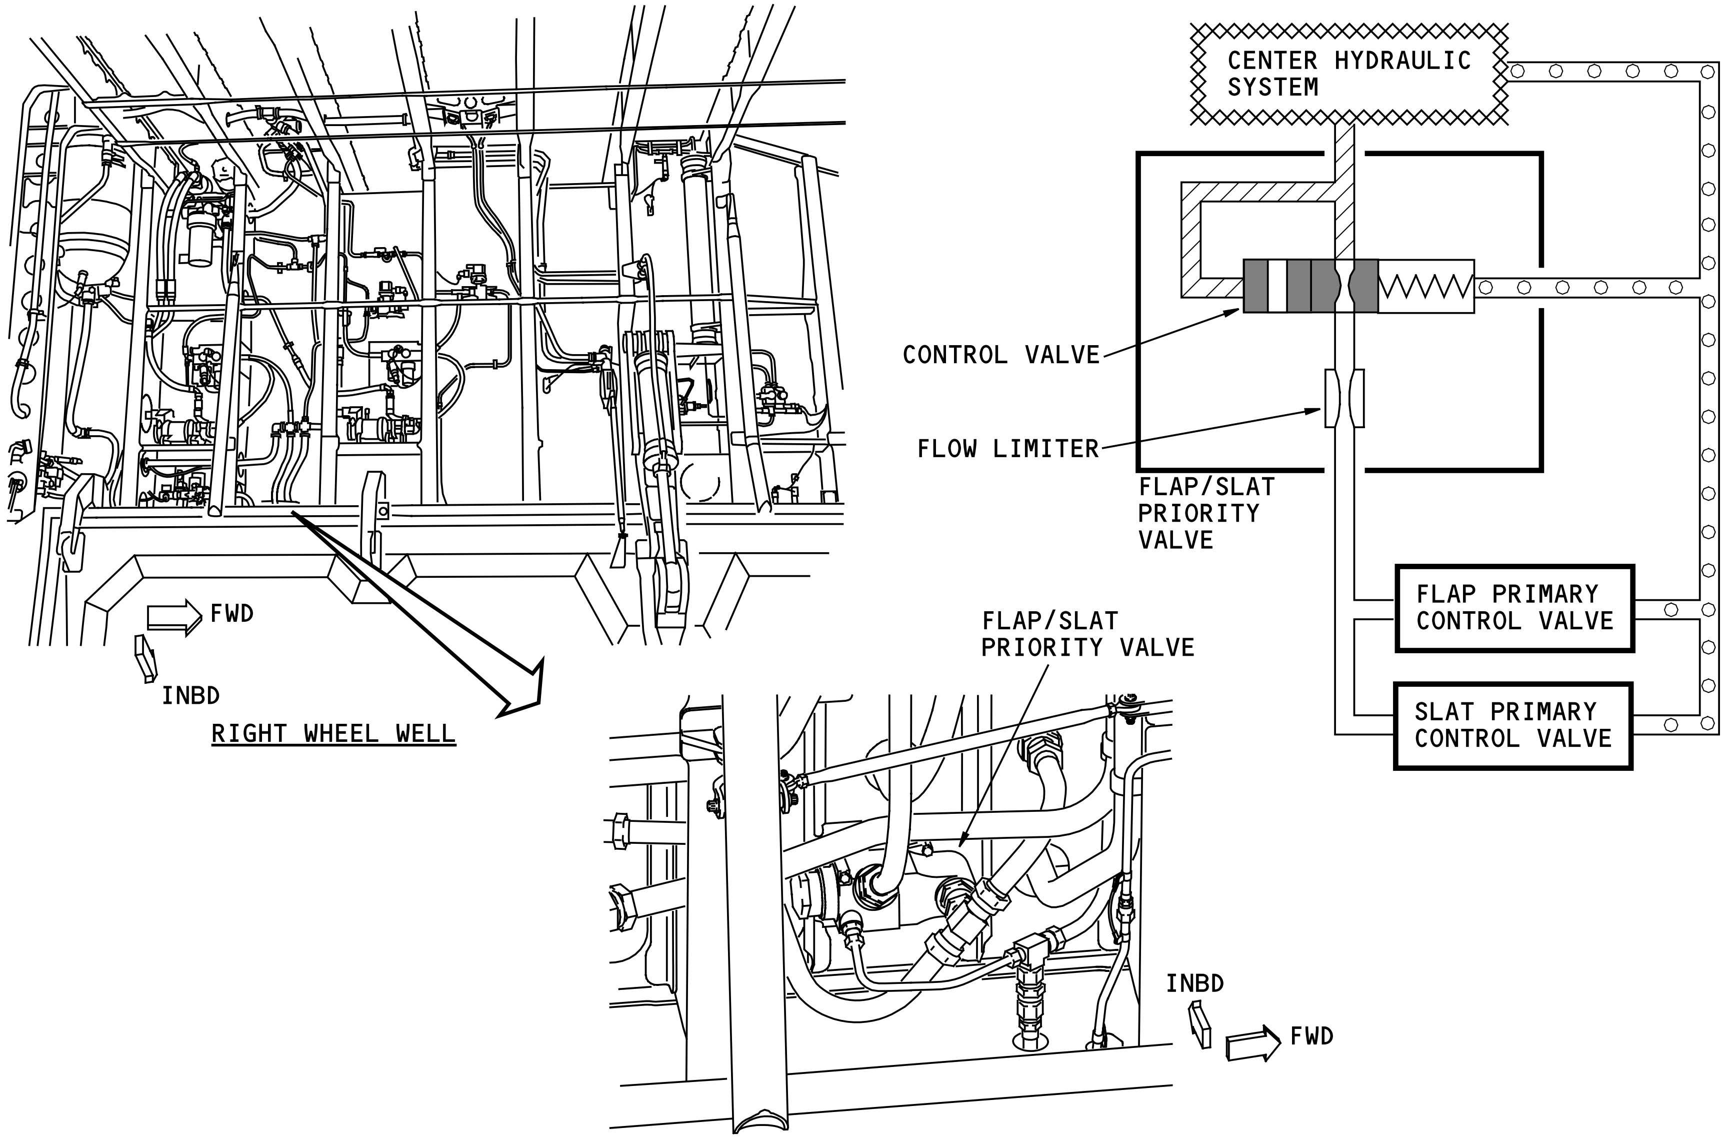
Location

The flap/slat priority valve is at the bottom of the keel beam in the right wheel well.

Physical Description

The flap/slat priority valve has a flow limiter and a control valve. When the pressure in the center hydraulic system is high, the control valve fully opens. The maximum flow through the flow limiter is then 43 gpm.

When the system pressure decreases, the control valve restricts the flow to the flap and slat primary control valves. In the fully restricted position, the control valve limits the flow to 0.4 gpm. Restriction of the flap/slat flow permits the control valve to modulate the system pressure to 1750 psi during high demand conditions.



27-51-00-033 Rev 0

TRAILING EDGE FLAPS - FLAP/SLAT PRIORITY VALVE

TRAILING EDGE FLAPS - FLAP POWER DRIVE UNIT (PDU)

Purpose

The flap PDU turns the flap torque tubes during operation in all three modes. The flap PDU has these LRUs:

- A hydraulic motor
- An electric motor
- A gearbox.

Information on the hydraulic motor and the electric motor is shown later.

Location

The flap PDU is above the keel beam in the main landing gear wheel wells. Access to the hydraulic and electric motors is through the right wheel well. Access to the gearbox is through the left wheel well.

Gearbox

The gearbox transmits the power from the hydraulic or electric motors to the torque tubes.

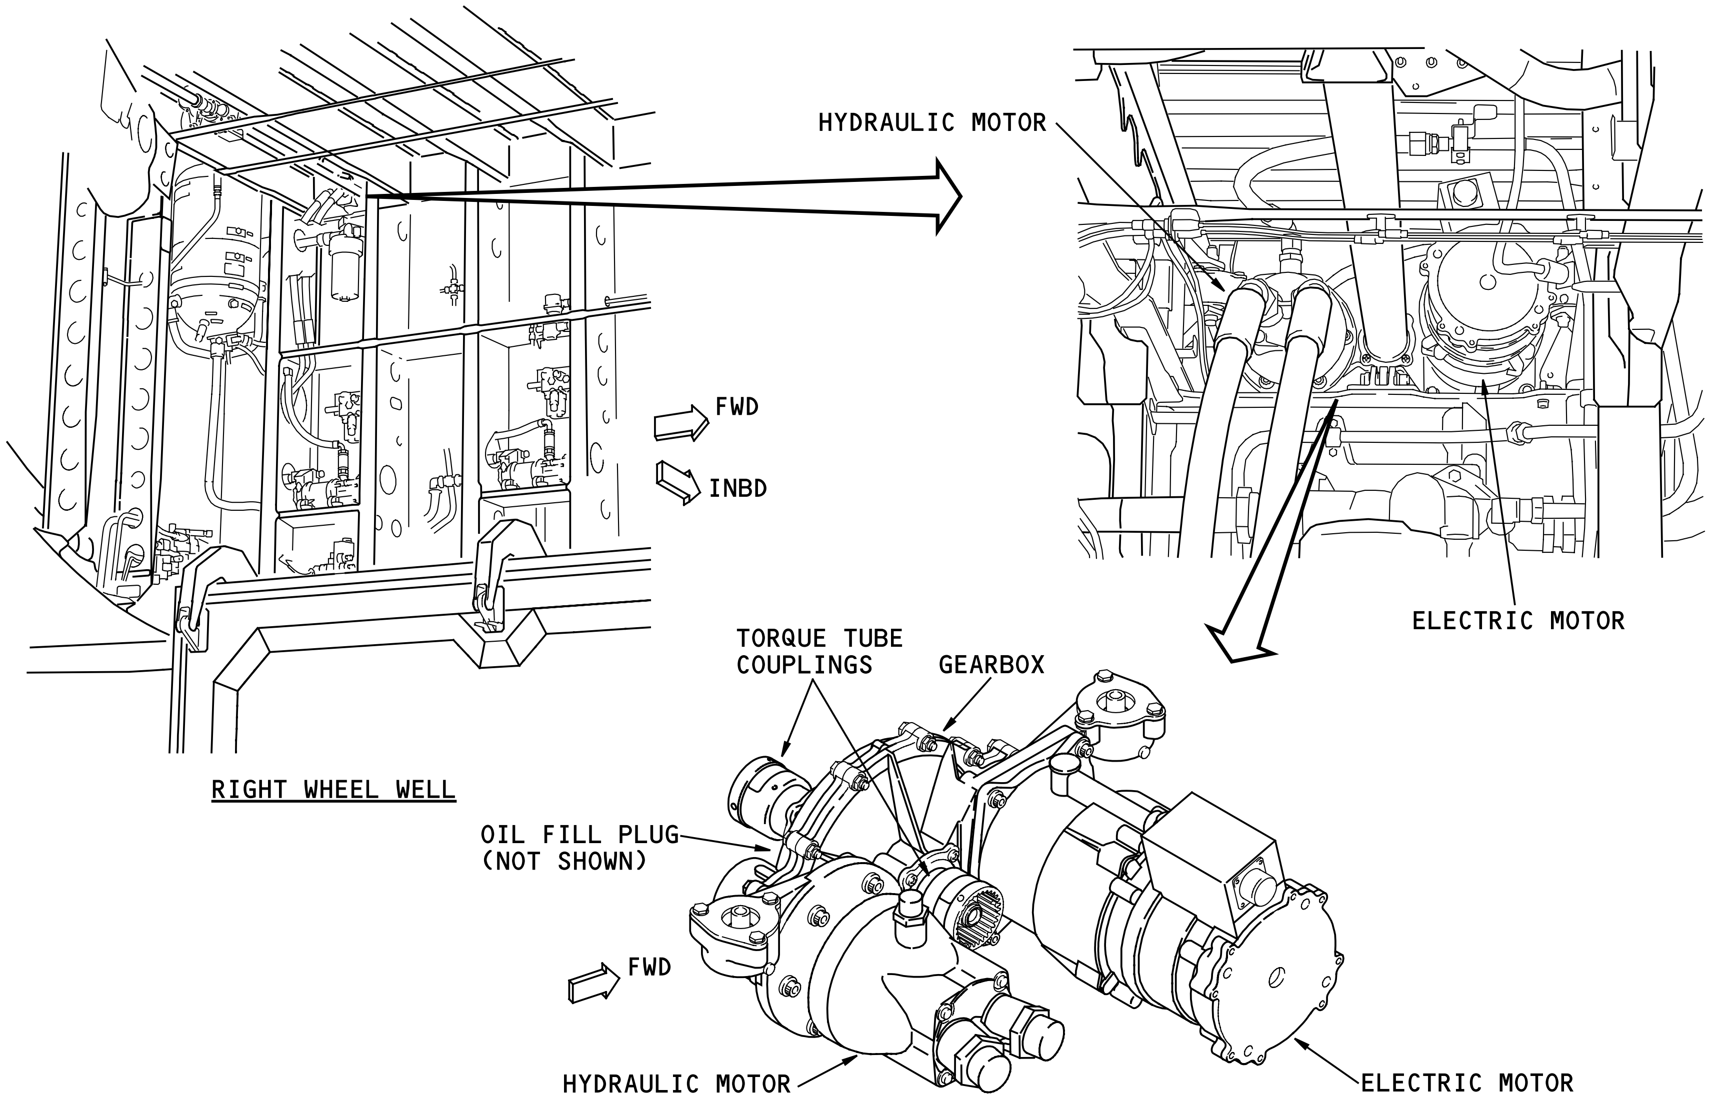
The hydraulic motor or the electric motor rotates gears in the gearbox. These gears increase the torque from the motors. The gearbox turns the torque tube couplings on both sides of the PDU. These couplings turn the torque tubes.

During high-speed operation in the primary mode, the gearbox turns the torque tubes at 550 rpm. During low-speed operation, the gearbox turns the torque tubes at 110 rpm.

During operation in the secondary and alternate modes, the gearbox turns the torque tubes at 74 rpm.

Training Information Point

The gearbox contains oil and it is necessary to do servicing at specified times. You get access to the oil fill plug through the left wheel well.



TRAILING EDGE FLAPS - FLAP POWER DRIVE UNIT (PDU)

27-51-00-011 Rev 1

TRAILING EDGE FLAPS - FLAP LIMIT SWITCH

Purpose

The flap limit switch limits the position of the flaps during alternate mode operation. The flap limit switch also prevents retraction of the slats in the alternate mode until the flaps are fully retracted.

Location

The flap limit switch is on the right flap position sensor gearbox in the right wheel well.

Functional Description

The limit switch is one LRU. It has two internal switches, up and 20.

The up switch controls the sequence of flap and slat retraction in the alternate mode. To do this, the up switch controls the electrical power to the flap and slat electric motors.

During retraction, the up switch permits retraction of the flaps but removes electrical power from the slat electric motor. When the flaps retract to the up position, the up switch removes power from the flap electric motor and permits retraction of the slats.

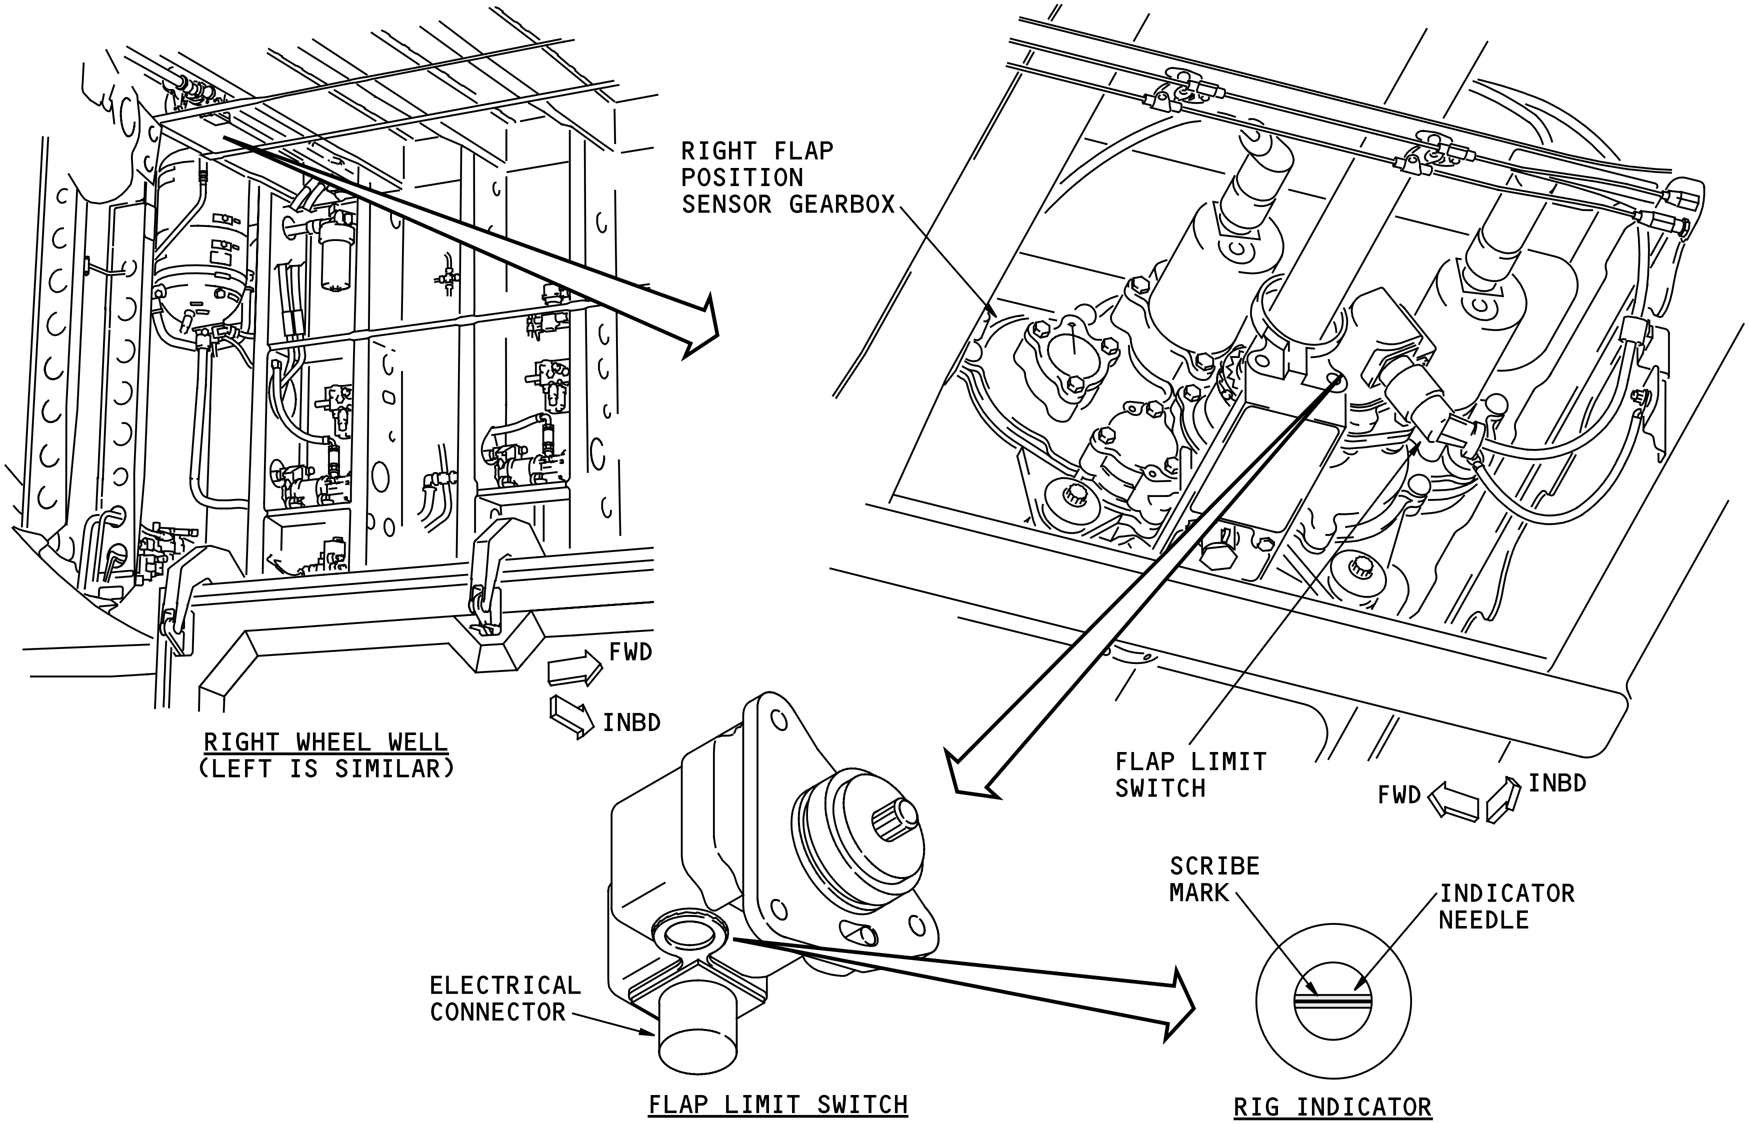
When the flaps extend to the 20 position, the 20 switch removes electrical power from the flap electric motor.

Training Information Point

The flap limit switch is interchangeable with the slat limit switch.

You install the flap limit switch with the trailing edge flaps in the retracted position. The limit switch rig indicator has a fixed scribe mark and an indicator needle. The indicator needle moves up or down in relation to the scribe mark as the shaft of the limit switch turns. Make sure you align the center of the indicator needle in the rig indicator with the scribe mark when you install the limit switch.

To retract the slats with the flaps extended and disabled, you must install a jumper wire on the electrical connector for the flap limit switch. This permits the slats to fully retract with the flaps extended.



TRAILING EDGE FLAPS - FLAP LIMIT SWITCH

27-51-00-013 Rev 4 03/19/96

TRAILING EDGE FLAPS - ANGLE GEARBOXES

Purpose

The angle gearboxes connect torque tubes that are at different angles to each other. There are six angle gearboxes:

- Two side-of-body angle gearboxes
- Two rear spar angle gearboxes
- Angle gearboxes on the output of the inboard transmissions for the inboard flap (transmissions 4 and 5).

Location

The side-of-body angle gearboxes are on the inboard flap support assemblies in the main landing gear wheel wells. Access is through the wheel wells.

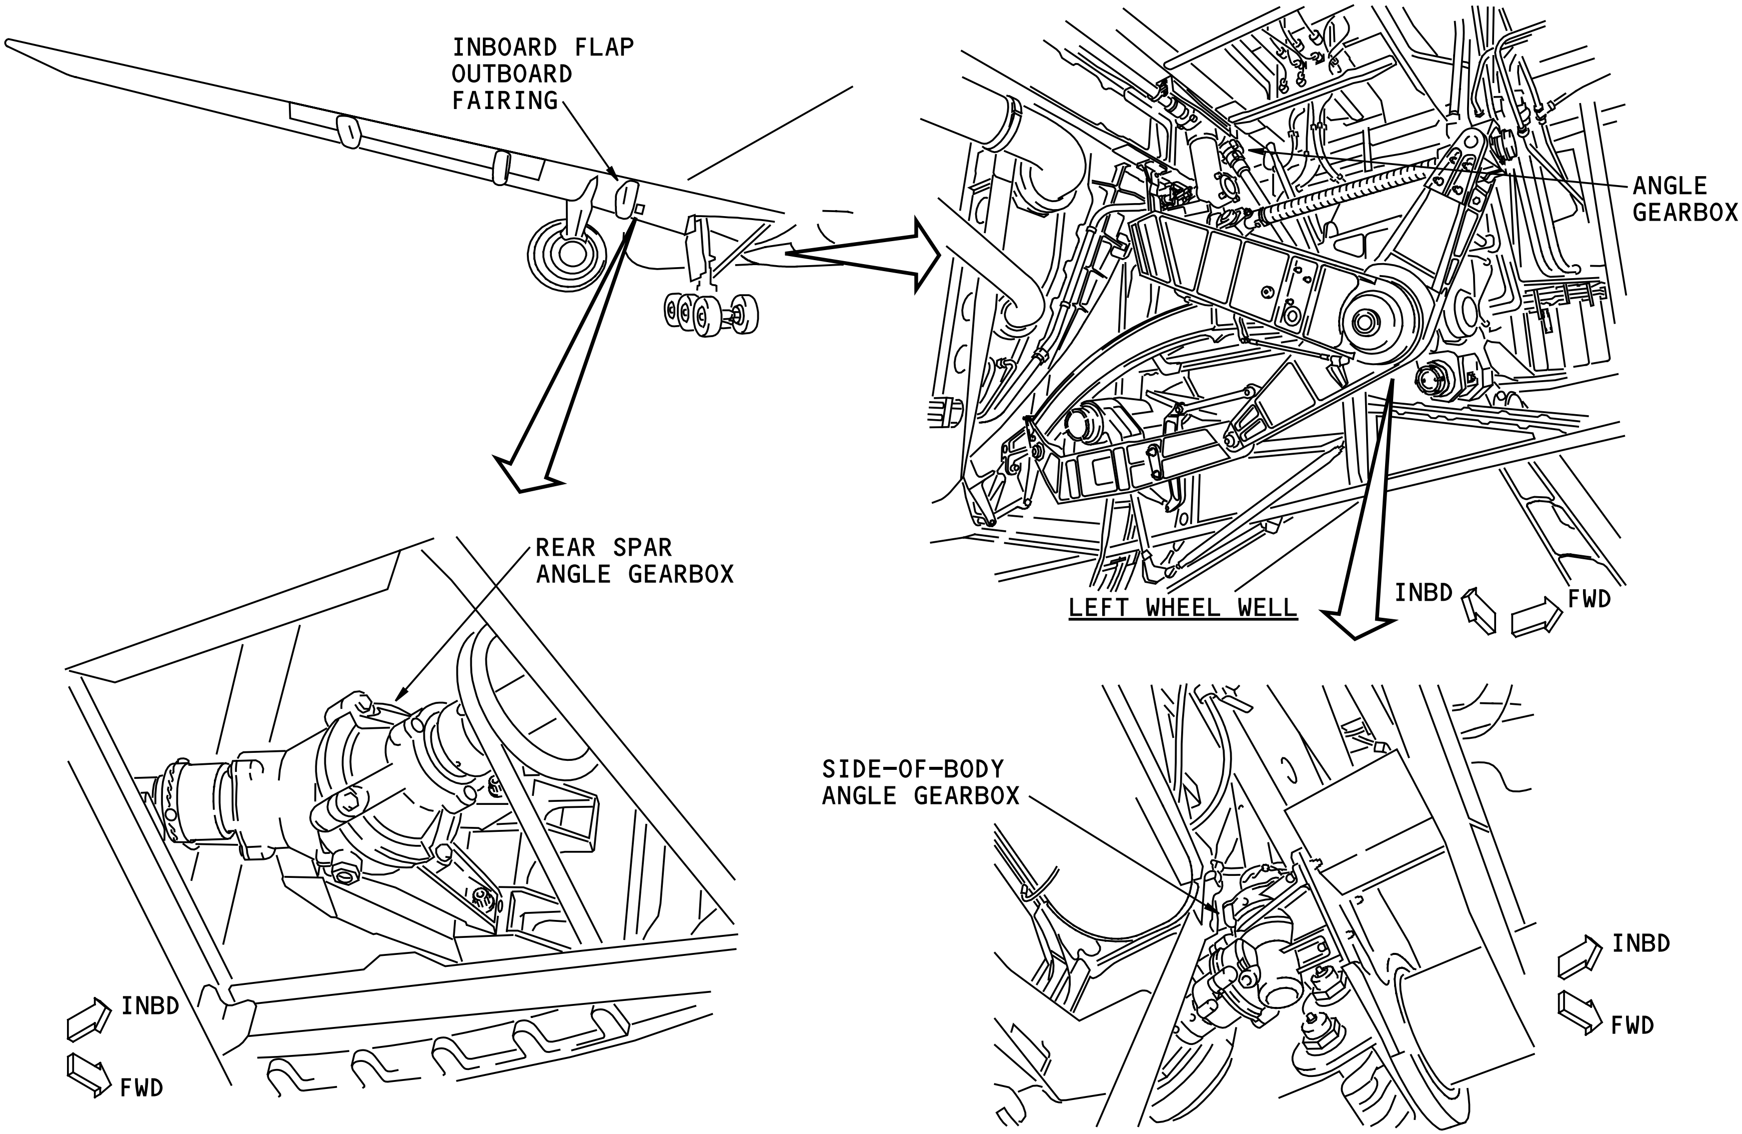
The rear spar angle gearboxes are on the rear spar of each wing, near the main landing gear beam. Access is through removable panels under the wings.

The other two angle gearboxes are on the output side of the inboard flap inboard transmissions (4 and 5).

Physical Description

The angle gearboxes are filled with grease and sealed.

The side-of-body angle gearbox weighs 10 lb (4.5 kg). The rear spar angle gearbox weighs 11 lb (5 kg). The angle gearboxes on transmissions 4 and 5 each weigh about 12.5 lb (5.7 kg).



27-51-00-015 Rev 3 03/19/96

TRAILING EDGE FLAPS - ANGLE GEARBOXES

TRAILING EDGE FLAPS - NO-BACK BRAKE

Purpose

The no-back brake helps prevent flap retraction if there is a PDU or torque tube failure.

Location

There is one no-back brake attached to the rear spar of each wing. The no-back brakes are between the two transmissions for the outboard flap on each wing.

Physical Description

The no-back brakes are spring-loaded, skewed-roller, ratchet brakes. They supply a resistive torque during retraction only.

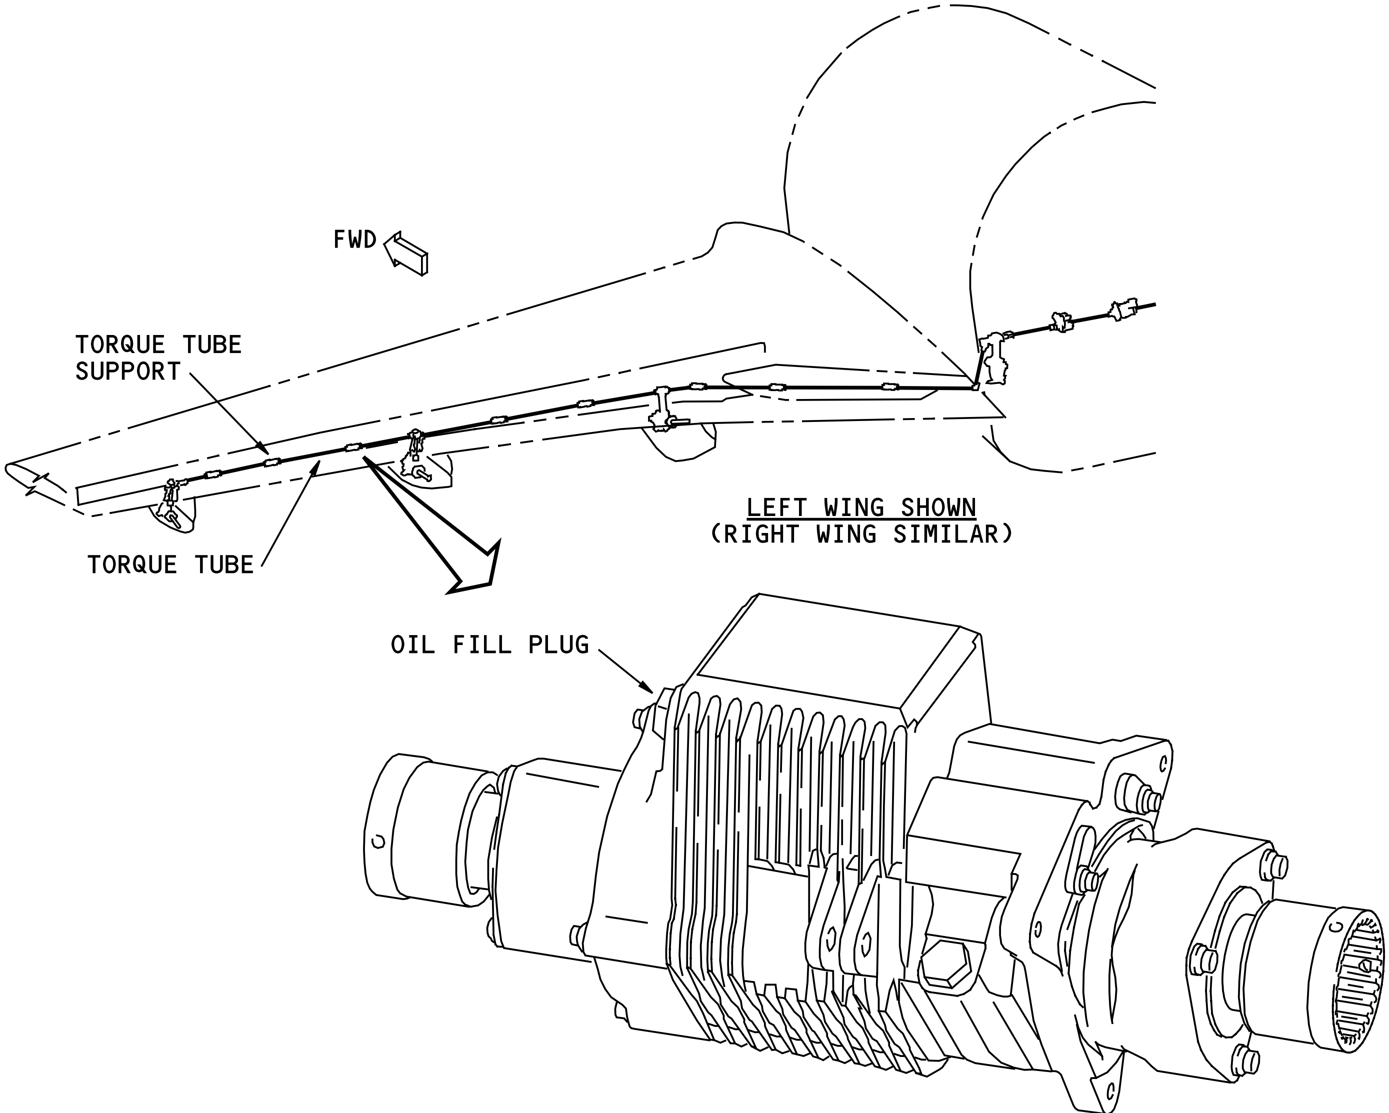
The no-back brakes are filled with oil and sealed. They each weigh 20 lb (9 kg).

Training Information Point

When you operate the flap drive system, observe this caution:

CAUTION: DO NOT OPERATE THE FLAPS CONTINUOUSLY FOR MORE THAN 12 MINUTES IN PRIMARY MODE WITHOUT A 30 MINUTE COOLING OFF PERIOD FOR THE NO-BACK BRAKES. THE NO-BACK BRAKES CAN BECOME TOO HOT.

The no-back brake contains oil and it is necessary to do servicing. Use the oil fill plug.



TRAILING EDGE FLAPS - NO-BACK BRAKE

TRAILING EDGE FLAPS - INBOARD FLAP INBOARD TRANSMISSION ASSEMBLY

THIS PAGE INTENTIONALLY LEFT BLANK

TRAILING EDGE FLAPS - INBOARD FLAP INBOARD TRANSMISSION ASSEMBLY

Purpose

There are two transmission assemblies for each flap surface, an inboard transmission assembly and an outboard transmission assembly.

The inboard flap inboard transmission assembly receives power from the torque tubes to move the inboard flap. This assembly has these components:

- A transmission
- A ballscrew
- A gimbal.

The transmission assembly weighs approximately 95 lb (43 kg).

Location

There is one inboard flap inboard transmission assembly in each main landing gear wheel well.

Transmission

The transmission connects to the torque tubes. Gears in the transmission transmit the power from the torque tubes to the U-joint. The U-joint then turns the ballscrew.

The transmission has a torque brake and a no-back brake. The torque brake prevents excessive loads on the ballscrew if the flap does not move freely. The torque brake is a ball ramp type brake with a torque trip indicator. The trip indicator must be manually reset if it activates.

The no-back brake is a skewed roller type brake. It engages by compression load in the ballscrew caused by airloads on the flap. It prevents flap movement if the PDU or torque tubes fail.

Ballscrew

The transmission turns the ballscrew through a U-joint. The ballscrew has a ballscrew nut which connects to the gimbal. As the ballscrew turns, the ballscrew nut moves the gimbal.

The ballscrew has stops at both ends. The ballscrew nut does not touch the stops during normal operation of the flaps.

Gimbal

The gimbal moves the flap surface. The gimbal connects to the ballscrew nut, and moves as the ballscrew turns.

Training Information Point

If you disconnect the ballscrew from the transmission at the U-joint, make sure that the ballscrew nut stays on the ballscrew.

The transmission contains oil and it is necessary to do servicing. Use the oil fill plug.

TRAILING EDGE FLAPS - INBOARD FLAP INBOARD TRANSMISSION ASSEMBLY

When manually operating the flap drive system, observe this caution:

CAUTION: DO NOT LET THE BALLSCREW NUTS HIT THE UPSTOPS OR THE DOWNSTOPS. YOU CAN CAUSE DAMAGE TO THE SHEAROUT IN THE POSITION SENSOR GEARBOX.

TRAILING EDGE FLAPS - INBOARD FLAP INBOARD TRANSMISSION ASSEMBLY

TRAINING EDGE FLAPS - INBOARD FLAP INBOARD SUPPORT MECHANISM

Purpose

The flap transmission, ballscrew, and gimbal use the flap support mechanism to extend and retract the inboard flap and aft flap.

Location

There is one inboard flap inboard support mechanism in each main landing gear wheel well.

Functional Description

During extension, the gimbal turns the drive arm about its fixed point. The drive arm moves the flap carrier beam. This beam attaches to the main flap support which attaches to the main flap. As the carrier beam moves, the main flap extends. The main flap roller and track control the position of the main flap as is extends.

The drive arm also moves the aft flap pushrods to extend the aft flap. Rollers and a track control the rotation of the aft flap as it extends. The aft flap extends beyond the trailing edge of the main flap only at flap positions greater than 20.

Retraction is the opposite of extension.

Training Information Point

When manually operating the flap drive system, observe this caution:

CAUTION: DO NOT LET THE BALLSCREW NUTS HIT THE UPSTOPS OR THE DOWNSTOPS. YOU CAN CAUSE DAMAGE TO THE SHEAROUT IN THE POSITION SENSOR GEARBOX.

TRAILING EDGE FLAPS - INBOARD FLAP INBOARD SUPPORT MECHANISM

TRAILING EDGE FLAPS - INBOARD FLAP OUTBOARD TRANSMISSION ASSEMBLY

Purpose

The inboard flap outboard transmission assembly receives power from the torque tubes to move the inboard flap.

Location

The inboard flap outboard transmission assembly is just inboard of the engines. Access to the assembly is through the fixed and moveable flap support fairings.

Physical Description

The transmission assembly is similar to the inboard flap inboard transmission assembly, but they are not interchangeable.

The transmission assembly weighs approximately 98 lb (45 kg).

Functional Description

The inboard flap outboard transmission assembly operation is similar to the inboard flap inboard transmission assembly.

Training Information Point

The transmission contains oil and it is necessary to do servicing at specified times. Use the oil fill plug.

When manually operating the flap drive system, observe this caution:

CAUTION: DO NOT LET THE BALLSCREW NUTS HIT THE UPSTOPS OR THE DOWNSTOPS. YOU CAN CAUSE DAMAGE TO THE SHEAROUT IN THE POSITION SENSOR GEARBOX.

TRAILING EDGE FLAPS - INBOARD FLAP OUTBOARD TRANSMISSION ASSEMBLY

TRAILING EDGE FLAPS - INBOARD FLAP OUTBOARD SUPPORT MECHANISM

Purpose

The flap transmission, ballscrew, and gimbal use the flap support mechanism to extend and retract the inboard flap and the aft flap.

Location

The inboard flap outboard support mechanism is inboard of the engines. Access requires the removal of the fixed and moveable flap support fairings.

Functional Description

During extension, the gimbal turns the drive arm about its fixed point. The drive arm moves the flap carrier to extend the main flap. The drive arm also moves the compression strut. This strut rotates the aft tension beam which uses the pivot link to control the rotation of the main flap.

The drive arm also moves the aft flap pushrods to extend the aft flap. Rollers and a track control the rotation of the aft flap as it extends. The aft flap extends beyond the trailing edge of the main flap only at flap positions greater than 20.

Retraction is the opposite of extension.

Training Information Point

When manually operating the flap drive system, observe this caution:

CAUTION: DO NOT LET THE BALLSCREW NUTS HIT THE UPSTOPS OR THE DOWNSTOPS. YOU CAN CAUSE DAMAGE TO THE SHEAROUT IN THE POSITION SENSOR GEARBOX.

TRAILING EDGE FLAPS - OUTBOARD FLAP SUPPORT MECHANISMS

TRAILING EDGE FLAPS - OUTBOARD FLAP AUXILIARY SUPPORTS

Purpose

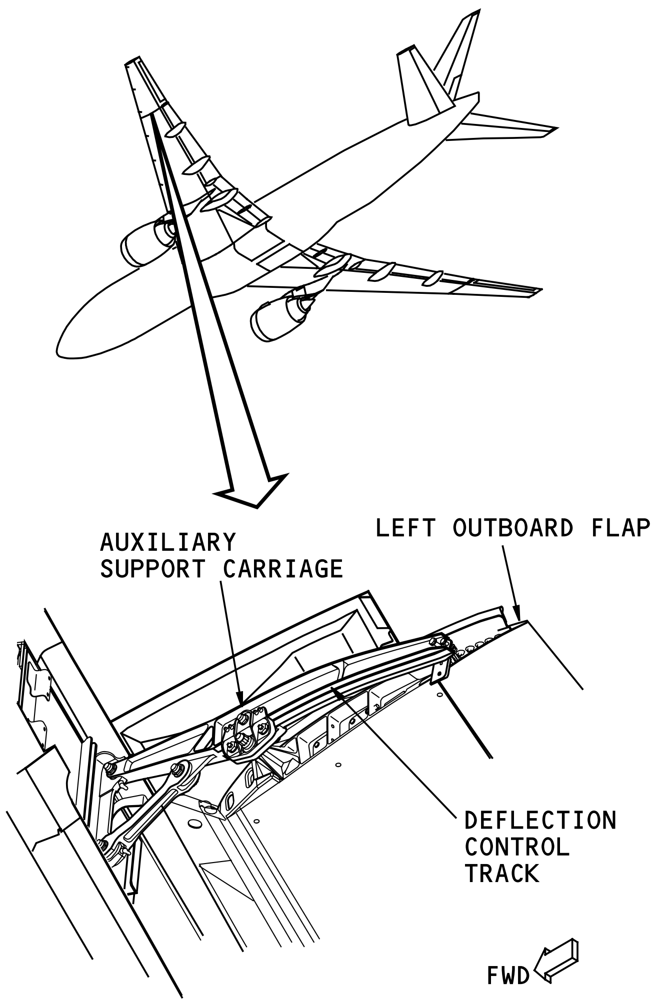
The outboard flap auxiliary supports make sure that the outboard flap deflection is similar to the wing deflection. When the flaps are extended, the outboard flap auxiliary supports prevent the ends of the flap from deflecting above the wing. When the flaps are retracted, the outboard flap auxiliary supports keep the flaps aligned with the wing.

Location

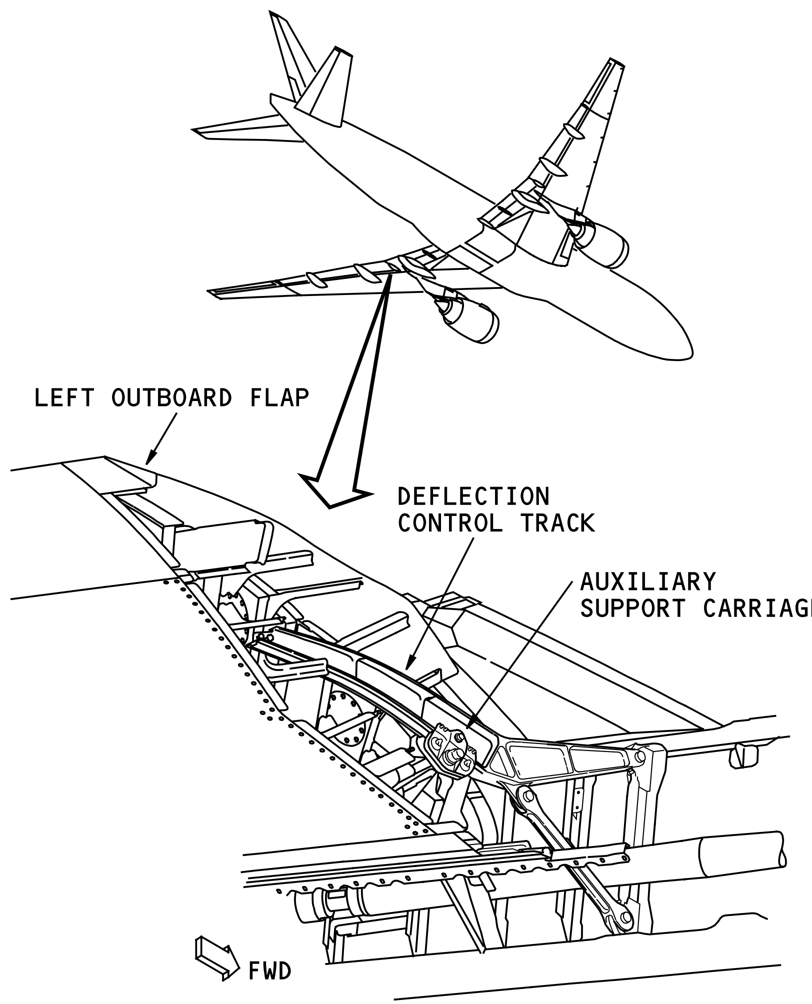
There is one support at each end of the outboard flap. Access to the supports is through access panels under the wing.

Physical Description

Each outboard flap auxiliary support has a deflection control track and a carriage. The carriage attaches to the flap structure. Rollers in the carriage move along the track.



OUTBOARD END OF LEFT OUTBOARD FLAP



INBOARD END OF LEFT OUTBOARD FLAP

27-51-00-024 Rev 1

TRAILING EDGE FLAPS - OUTBOARD FLAP AUXILIARY SUPPORTS

TRAILING EDGE FLAPS - INBOARD FLAP SUPPORT FAIRINGS

Purpose

The inboard flap support fairings cover the flap support mechanisms which are outside of the wing to body fairing and below the wing. The fairings supply an aerodynamic enclosure.

Physical Description

All the fairings are composite materials. They attach to their support structure by bearing points and by linkages.

The fairings have access panels to permit access to the components inside the fairings.

Location

The inboard flap has two flap support fairings on each wing. One is inboard near the wing to body fairing and one is outboard. There is also a center track fairing for the inboard aft flap.

Functional Description

The inboard support fairing has a forward fairing attached to the inboard main flap and an aft fairing attached to the inboard aft flap. The forward and aft fairings move with the main and aft flaps.

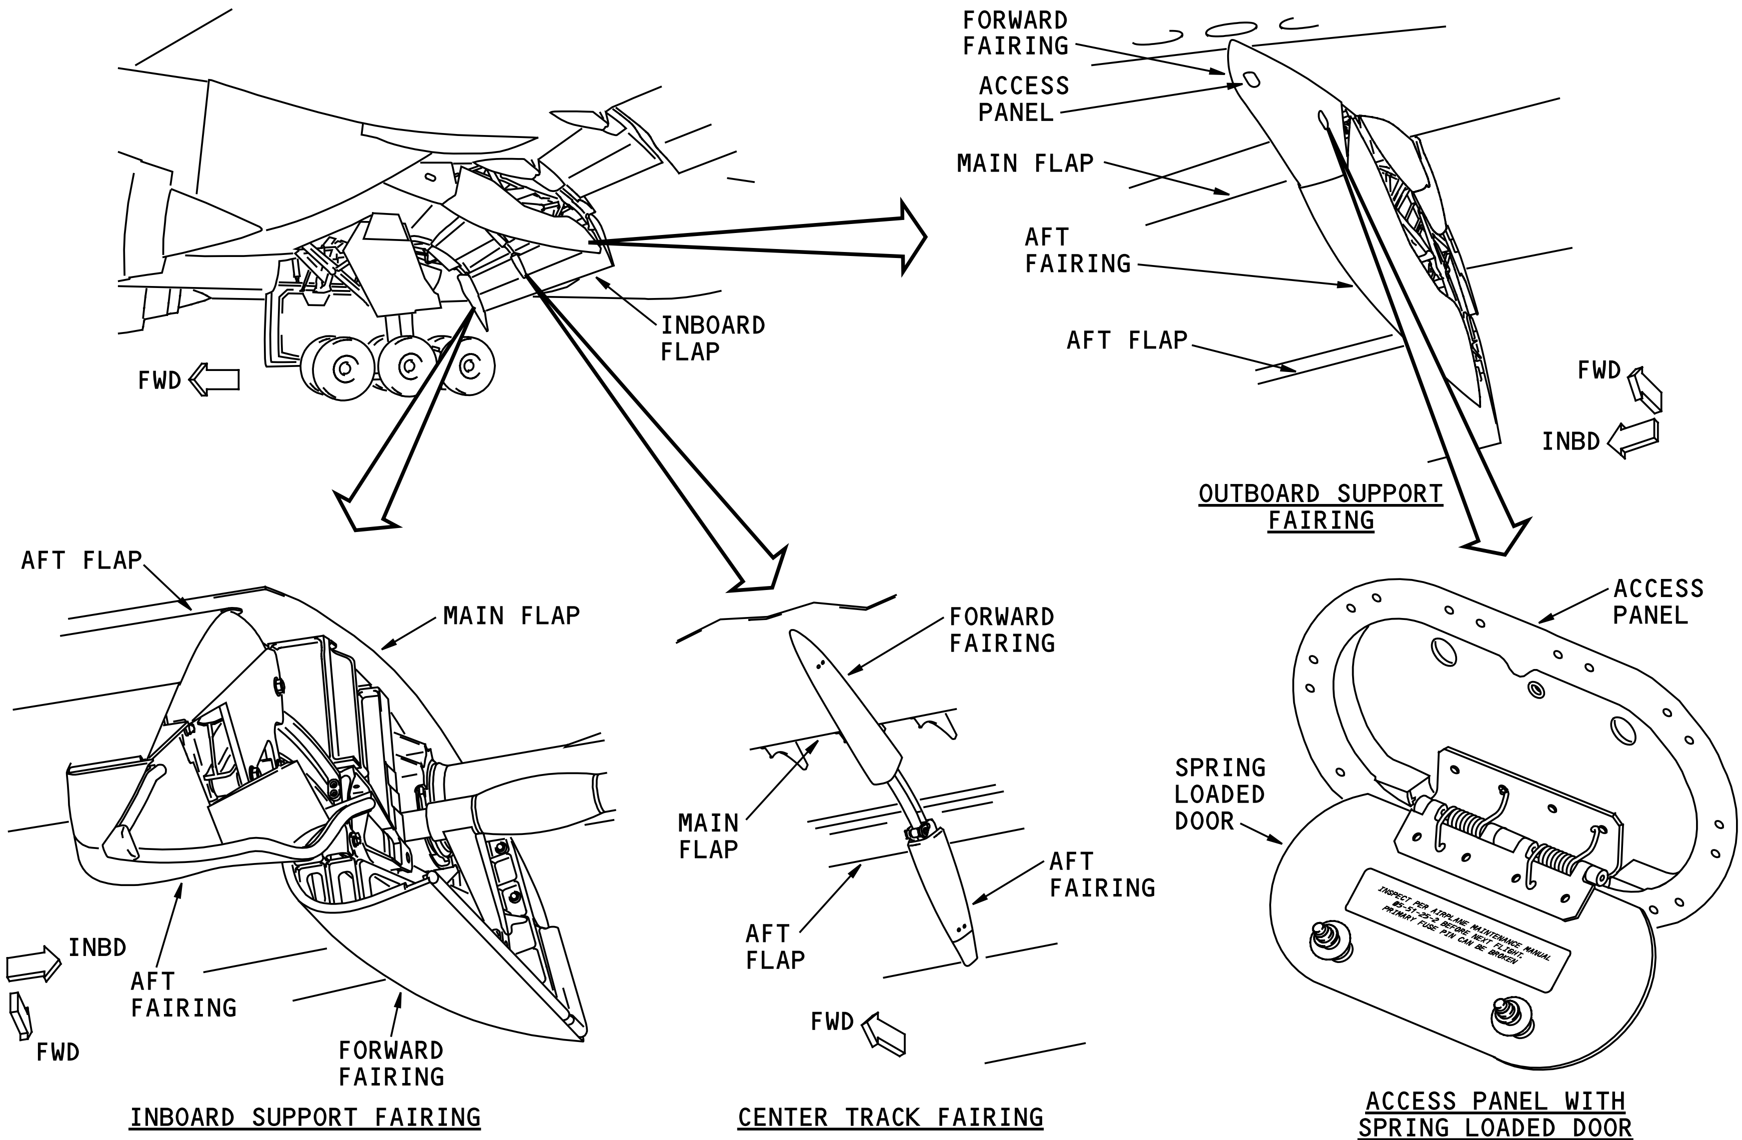
The center track fairing has a forward fairing attached to the inboard main flap and an aft fairing attached to the aft flap. The forward and aft fairings move with the main and aft flaps.

The outboard support fairing has a forward fairing attached to the wing lower surface and an aft fairing attached to the outboard flap support mechanism. The outboard support fairing moves down during the inboard flap extension to supply the clearance for the main and aft flap movement.

Training Information Point

There is a spring loaded door on the access panel on the outboard side of the outboard forward fairing for the inboard flap. This door is not for access to any components. It opens automatically to show that the primary fuse pin has sheared. The primary fuse pin connects the outboard support structure of the inboard flap to the wing. When the primary fuse pin shears, the load transfers to the secondary fuse pin. This causes the flap structure to move and to operate a mechanism that releases the door latch. Springs open the door and keep it open.

If you see this door open on the outboard forward fairing for the inboard flap, it is necessary to make an inspection of the fuse pins and make applicable corrections.



TRAILING EDGE FLAPS - INBOARD FLAP SUPPORT FAIRINGS

TRAILING EDGE FLAPS - FUNCTIONAL DESCRIPTION - PRIMARY MODE CONTROL

General

Only one FSEU commands the flaps in the primary mode.

In the primary mode, the FSEU controls:

- Flap retraction and extension
- Flap/slat sequence
- Cruise inhibit
- Flap load relief
- Low-speed control
- Shutoff control.

For redundancy, both channels in the FSEU must agree on the flap command. Each channel controls switches that are connected in series. Both channels must send the same command to the switches for the FSEU to energize the commanded solenoid.

The two coils in each solenoid of the primary control valve get electrical power from different power sources. Each FSEU controls the ground for one of the coils in each solenoid.

Flap Retraction and Extension

The FSEU compares the flap lever position to the flap position. The flaps retract if the flap lever position is less than the flap position. The flaps extend if the flap lever position is greater than the flap position.

Flap/Slat Sequence

This function controls the sequence of the retraction and extension of the flaps and slats. See the high lift control section for more information about the primary mode flap and slat sequence (AMM PART I 27-03).

Cruise Inhibit

This function prevents flap extension during cruise. This happens when the airspeed is more than 265 knots or the altitude is above 20,300 feet.

Flap Load Relief

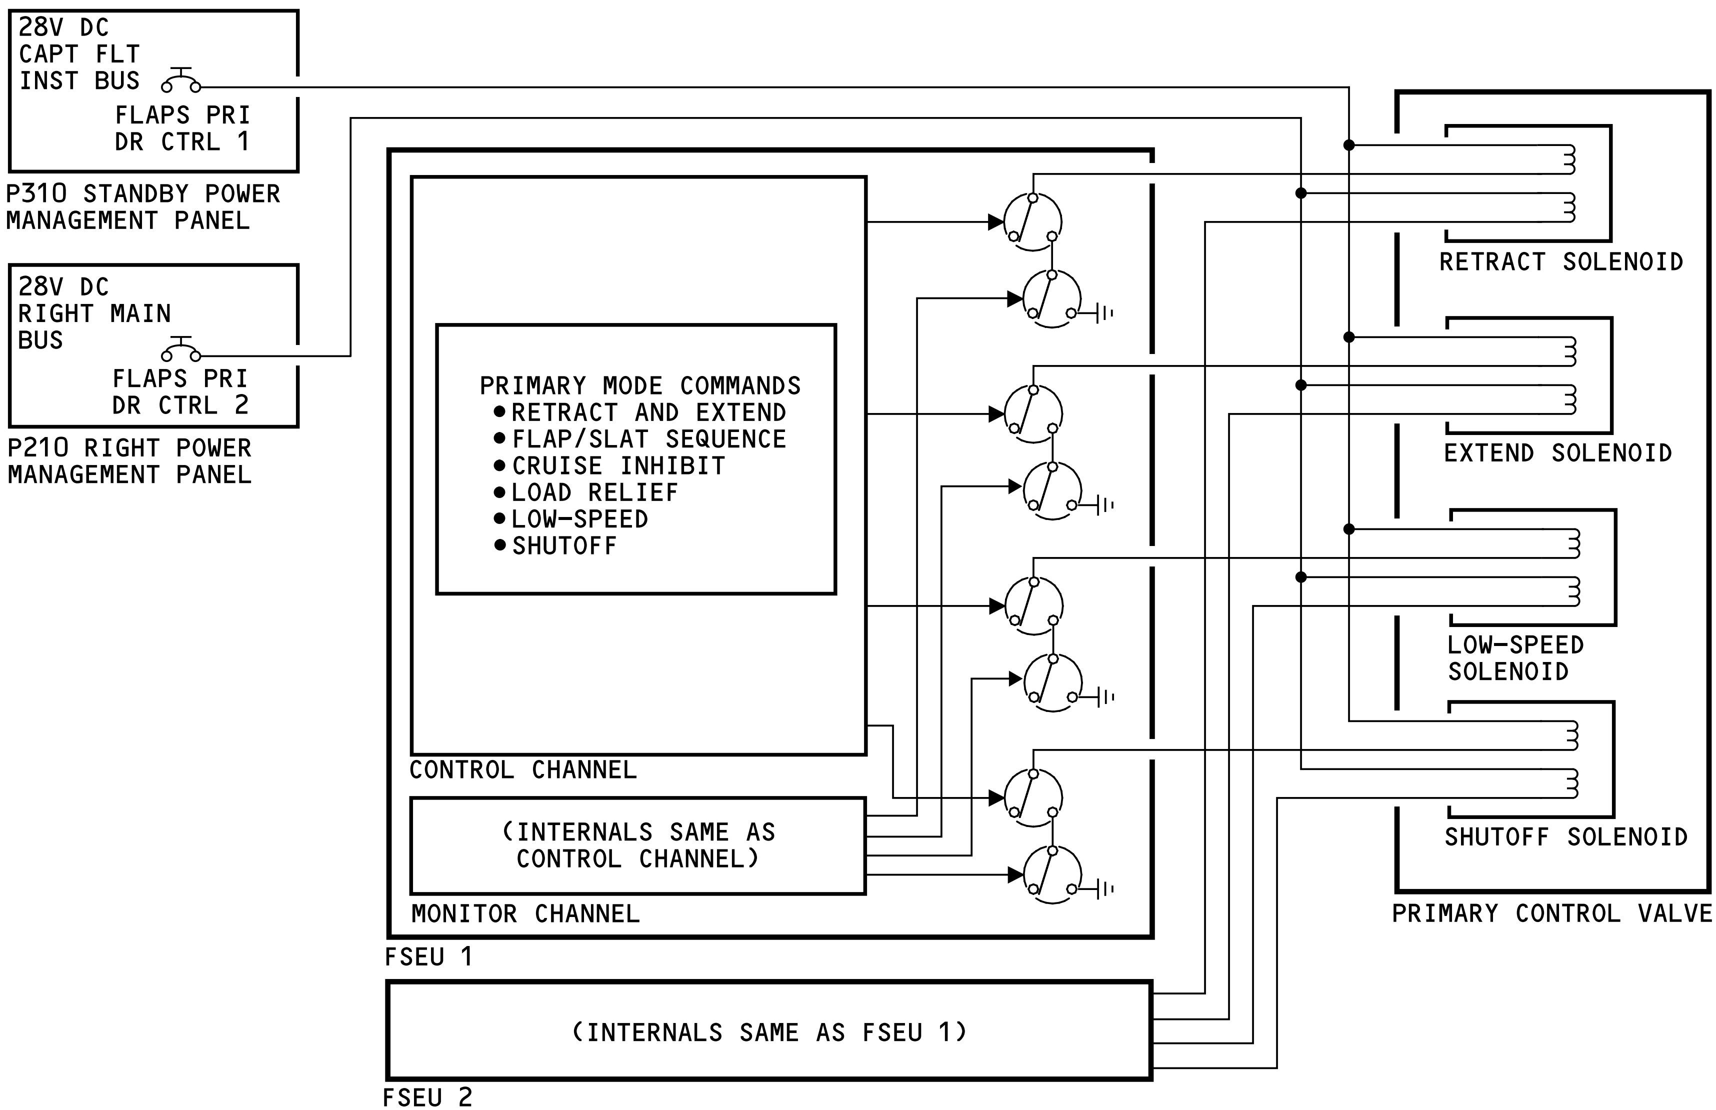
This function commands the flaps to retract if the airspeed increases above the flap load relief limit.

Low-Speed Control

This function reduces the speed of flap movement as the flaps approach the commanded position. The FSEU energizes the low-speed solenoid when the flaps are less than approximately seven torque tube turns from the commanded position.

Shutoff Control

The FSEU energizes the shutoff solenoid valve to open when there is a retract or extend command.



27-51-00-027 Rev 6

TRAILING EDGE FLAPS - FUNCTIONAL DESCRIPTION - PRIMARY MODE CONTROL

THIS PAGE INTENTIONALLY LEFT BLANK

TRAILING EDGE FLAPS - LOAD RELIEF - FUNCTIONAL DESCRIPTION

General

The flap load relief function prevents damage to the flaps and their support structures from large aerodynamic forces.

Flap load relief limits the position of the flaps as a function of airspeed. This function initiates when the airspeed is more than one knot more than the flap placard speeds.

Flap load relief operates only in the primary mode. It compares the flap lever command position to the airspeed.

Load relief is active if the airspeed increases above the load relief limit for more than one half second. Load relief then retracts the flaps or prevents the flaps from extending to the commanded position. Flap load relief retracts the flaps to these positions:

- 25
- 20
- 15
- 5.

The flap load relief command resets when the airspeed decreases below a set value. The load relief command also resets when the pilot moves the flap lever to or below the flap load relief position.

Load Relief - 25

Load relief retracts the flaps to 25 if the flap lever is at 30 and the airspeed is more than 171 knots. The load relief command resets if the airspeed decreases to less than 165 knots.

Load Relief - 20

Load relief retracts the flaps to 20 if the flap lever is at 30 or 25 and the airspeed is more than 186 knots. The load relief command resets if the airspeed decreases to less than 180 knots.

Load Relief - 15

Load relief retracts the flaps to 15 if the flap lever is at 30, 25, or 20 and the airspeed is more than 196 knots. The load relief command resets if the airspeed decreases to less than 190 knots.

Load Relief - 5

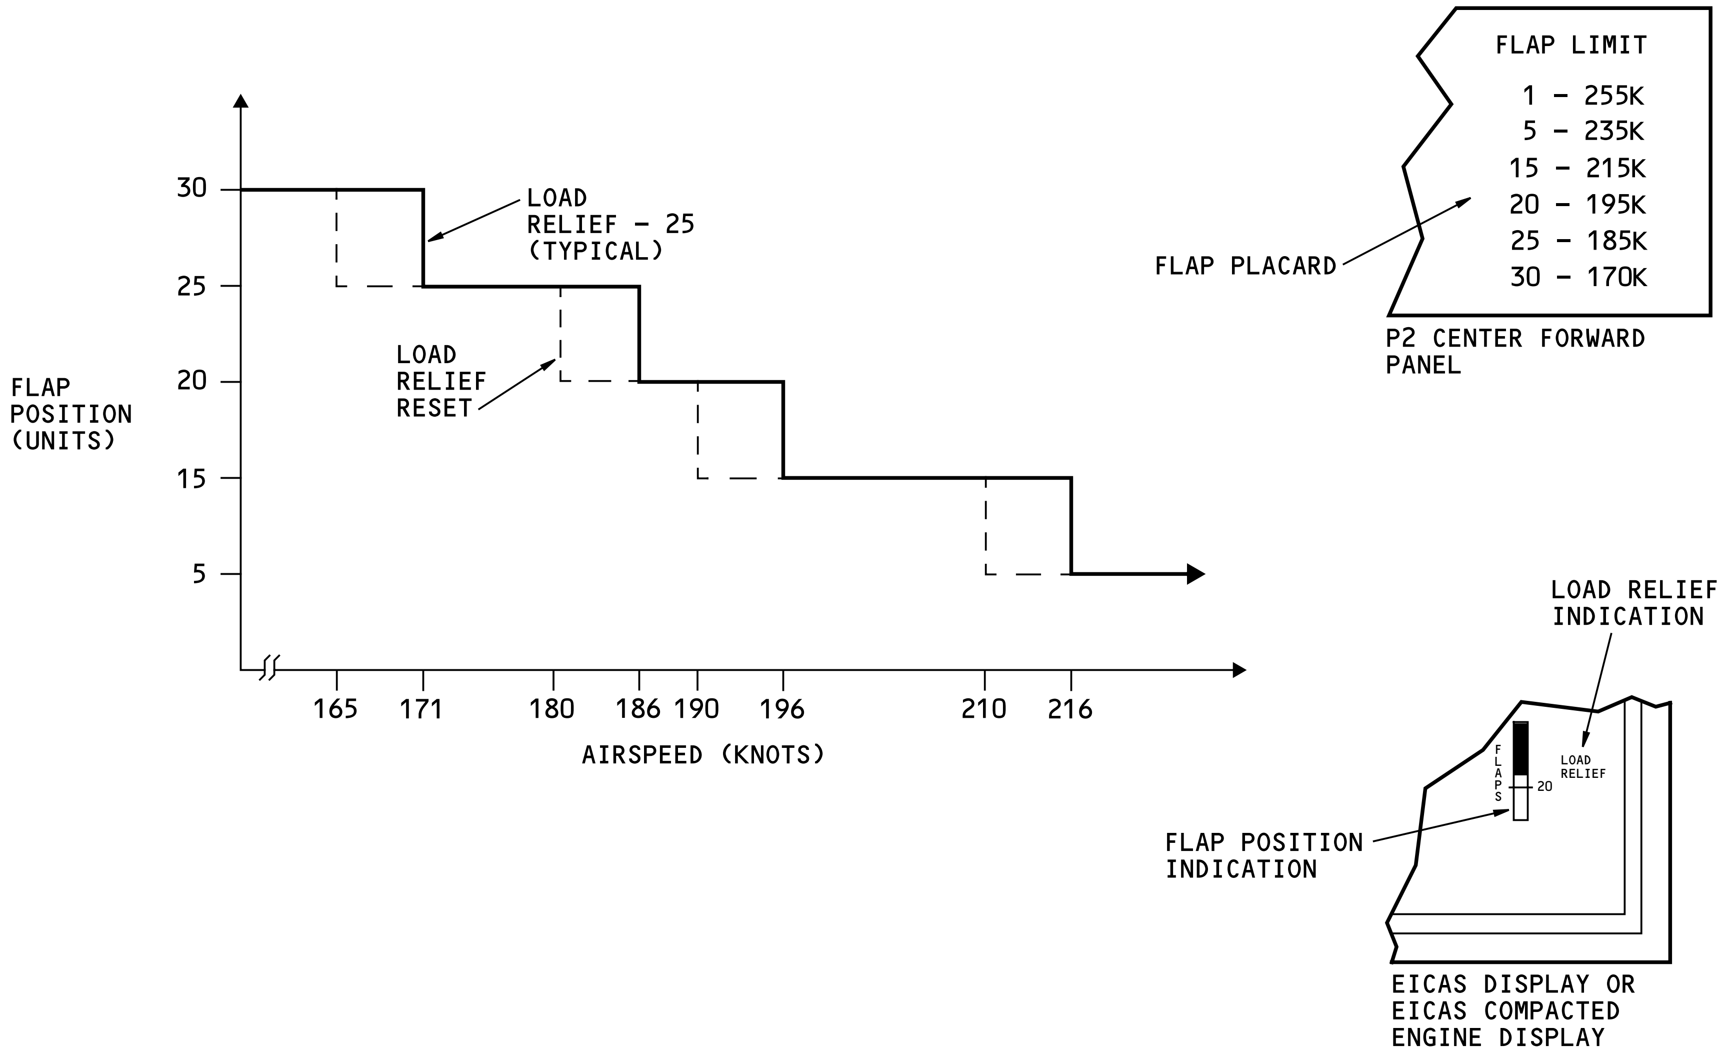
Load relief retracts the flaps to 5 if the flap lever is at 30, 25, 20, or 15 and the airspeed is more than 216 knots. The load relief command resets if the airspeed decreases to less than 210 knots.

Indication

When flap load relief is active, the LOAD RELIEF message shows on the EICAS display or on the EICAS compacted engine display.

TRAILING EDGE FLAPS - LOAD RELIEF - FUNCTIONAL DESCRIPTION

The flap position indication shows the position of the flaps. During load relief, the command bar and detent number change to magenta and do not agree with the flap position.



27-51-00-029 Rev 5 06/20/1997

TRAILING EDGE FLAPS - LOAD RELIEF - FUNCTIONAL DESCRIPTION

TRAILING EDGE FLAPS - FUNCTIONAL DESCRIPTION - SECONDARY MODE CONTROL

THIS PAGE INTENTIONALLY LEFT BLANK

TRAILING EDGE FLAPS - FUNCTIONAL DESCRIPTION - SECONDARY MODE CONTROL

General

Only one FSEU commands the flaps in the secondary mode.

The FSEU controls:

- Secondary mode engage
- Retraction and extension
- Flap/slat sequence
- Cruise Inhibit
- Secondary mode auto test.

For redundancy, both channels in the FSEU must agree on the flap command.

In the secondary mode, the FSEUs energize relays. The relays control the electrical power to the electric motor, clutch, and bypass solenoid. The alternate mode operation also uses these relays.

Secondary Mode Engage

When the FSEU engages the secondary mode, it energizes the bypass/clutch relay.

See the high lift control section for more information about the mode selection (AMM PART I 27-03).

This relay has three functions. First, the bypass/clutch relay supplies power to the bypass solenoid in the primary control valve. This prevents hydraulic operation in the primary mode.

Second, this relay supplies power to the clutch in the electric motor. This permits the electric motor to move the flap drive system.

Third, the bypass/clutch relay supplies power to the extend and retract relays. These relays do not energize until the FSEUs supply the grounds for them.

Retraction and Extension

The FSEU compares the flap lever position to the flap position. The flaps retract if the flap lever position is less than the flap position. The flaps extend if the flap lever position is greater than the flap position.

Either FSEU can energize the extend and retract relays to move the flaps. These relays supply 115v ac power to the electric motor.

Flap/Slat Sequence

This function controls the sequence of the retraction and extension of the flaps and slats. See the high lift control section for more information about the secondary mode flap and slat sequence (AMM PART I 27-03).

Cruise Inhibit

This function prevents flap extension during cruise. This happens when the airspeed is more than 265 knots or the altitude is above 20,300 feet.

TRAILING EDGE FLAPS - FUNCTIONAL DESCRIPTION - SECONDARY MODE CONTROL

Secondary Mode Auto Test

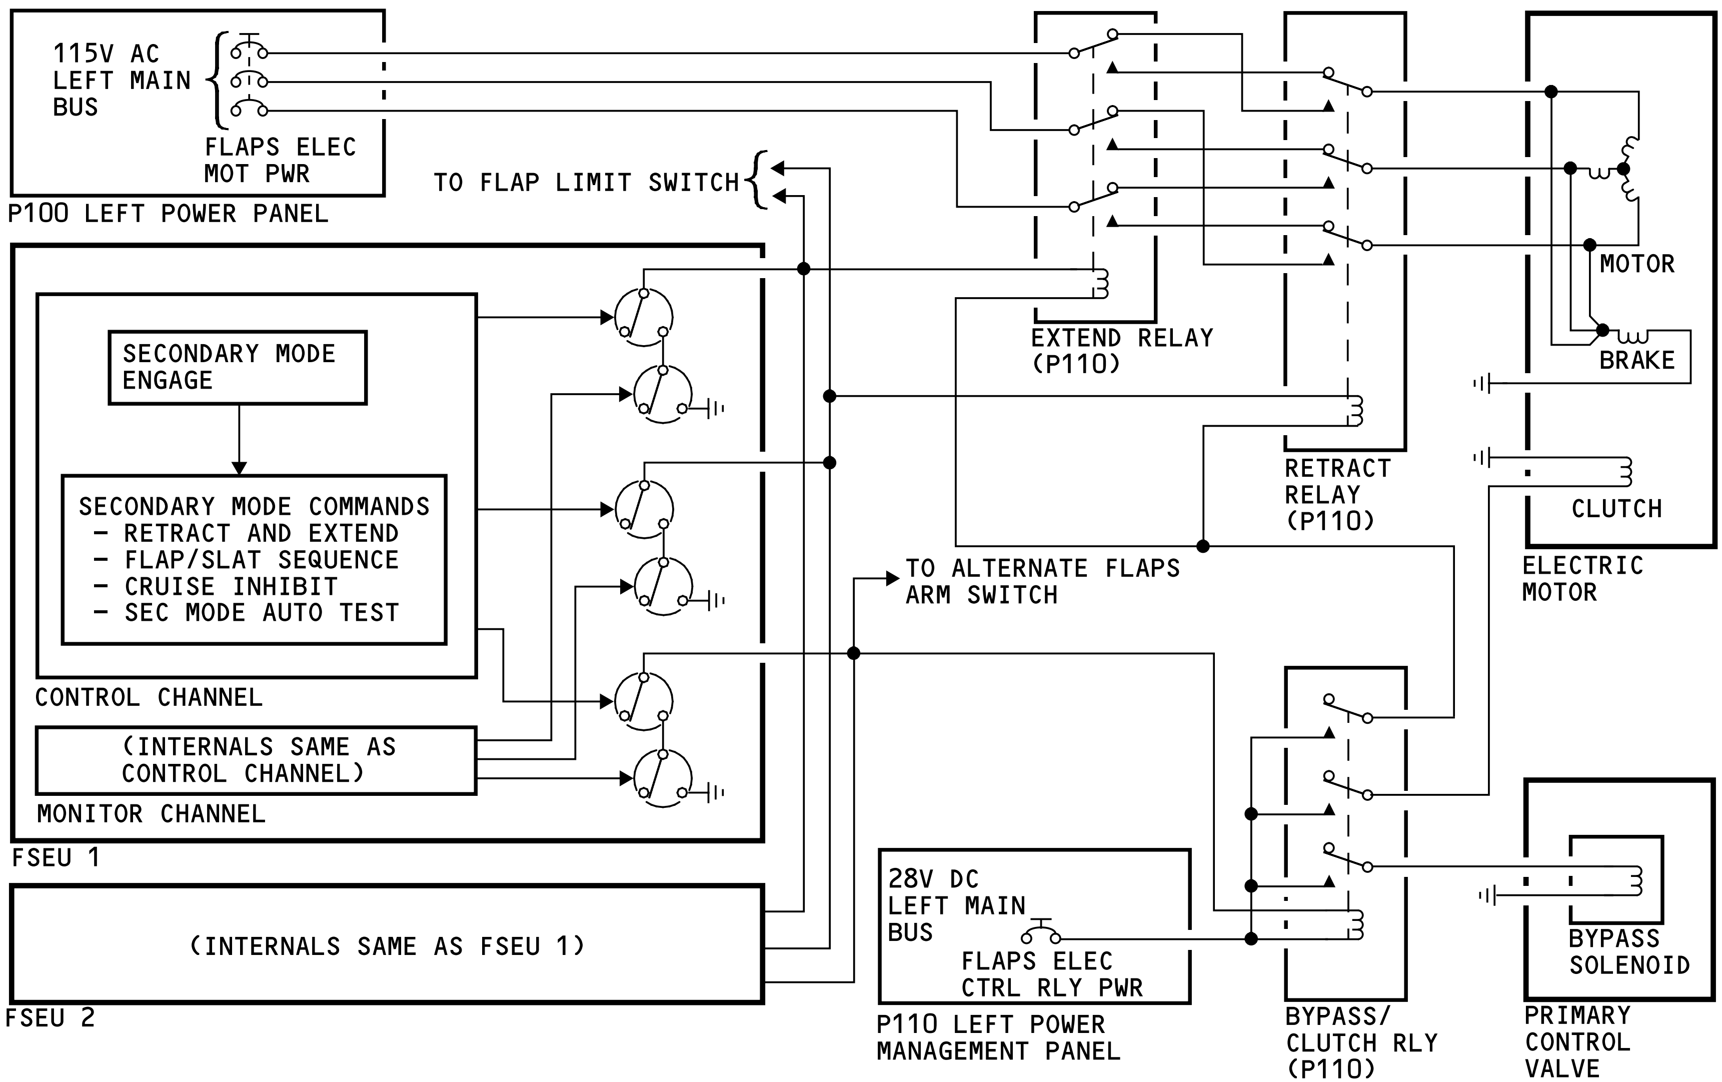
The secondary mode auto test checks the operation of the secondary mode. After 100 flight cycles, the FSEUs begin the test when the flaps are commanded to extend. The test does the following:

- Disengages the primary mode
- Engages the electric motor clutch
- Extends the flaps for two seconds using the electric motor.

One flight cycle is when all of these conditions occur for two seconds:

- Airplane not on the ground
- Airspeed is greater than 70 knots
- Flap lever is at up
- Flaps are at up.

If the flaps fail to extend during the secondary mode auto test, the FLAPS SECONDARY FAIL status message shows.



TRAILING EDGE FLAPS - FUNCTIONAL DESCRIPTION - SECONDARY MODE CONTROL

TRAILING EDGE FLAPS - FUNCTIONAL DESCRIPTION - ALTERNATE MODE CONTROL

THIS PAGE INTENTIONALLY LEFT BLANK

TRAILING EDGE FLAPS - FUNCTIONAL DESCRIPTION - ALTERNATE MODE CONTROL

General

The alternate mode operation of the flaps is almost the same as the alternate mode operation of the slats.

See the leading edge slats section for more information about the slats alternate mode control (AMM PART I 27-81).

In the alternate mode, the alternate flap/slat switches energize relays. The relays control the electrical power to the electric motor, clutch, and bypass solenoid.

In the alternate mode, these functions occur:

- Primary and secondary mode disengage
- Extend and retract control
- Flap/slat sequence.

Primary and Secondary Mode Disengage

When you push the alternate flaps arm switch, the FSEUs receive an alternate arm discrete. The FSEUs use this discrete to disengage the primary and secondary modes.

The alternate flaps arm switch also supplies a ground for the bypass/clutch relay. The operation of the bypass/clutch relay in the alternate mode is the same as in the secondary mode.

Extend and Retract Control

When the alternate flaps selector is in the extend (EXT) position, it supplies a ground for the extend relay to extend the flaps. When this relay energizes, it supplies 115v ac power to the electric motor. The flap limit switch de-energizes this relay when the flaps move to their extend limit. In the alternate mode, this limit is at the flap 20 position.

When the alternate flaps selector is in the retract (RET) position, it supplies a ground for the retract relay to retract the flaps. When this relay energizes, it supplies 115v ac power to the electric motor. The flap limit switch de-energizes this relay when the flaps move to the up position.

When the alternate flaps selector is in the off position, the grounds for the extend and retract relays is removed. This de-energizes the relays and stops the flap movement.

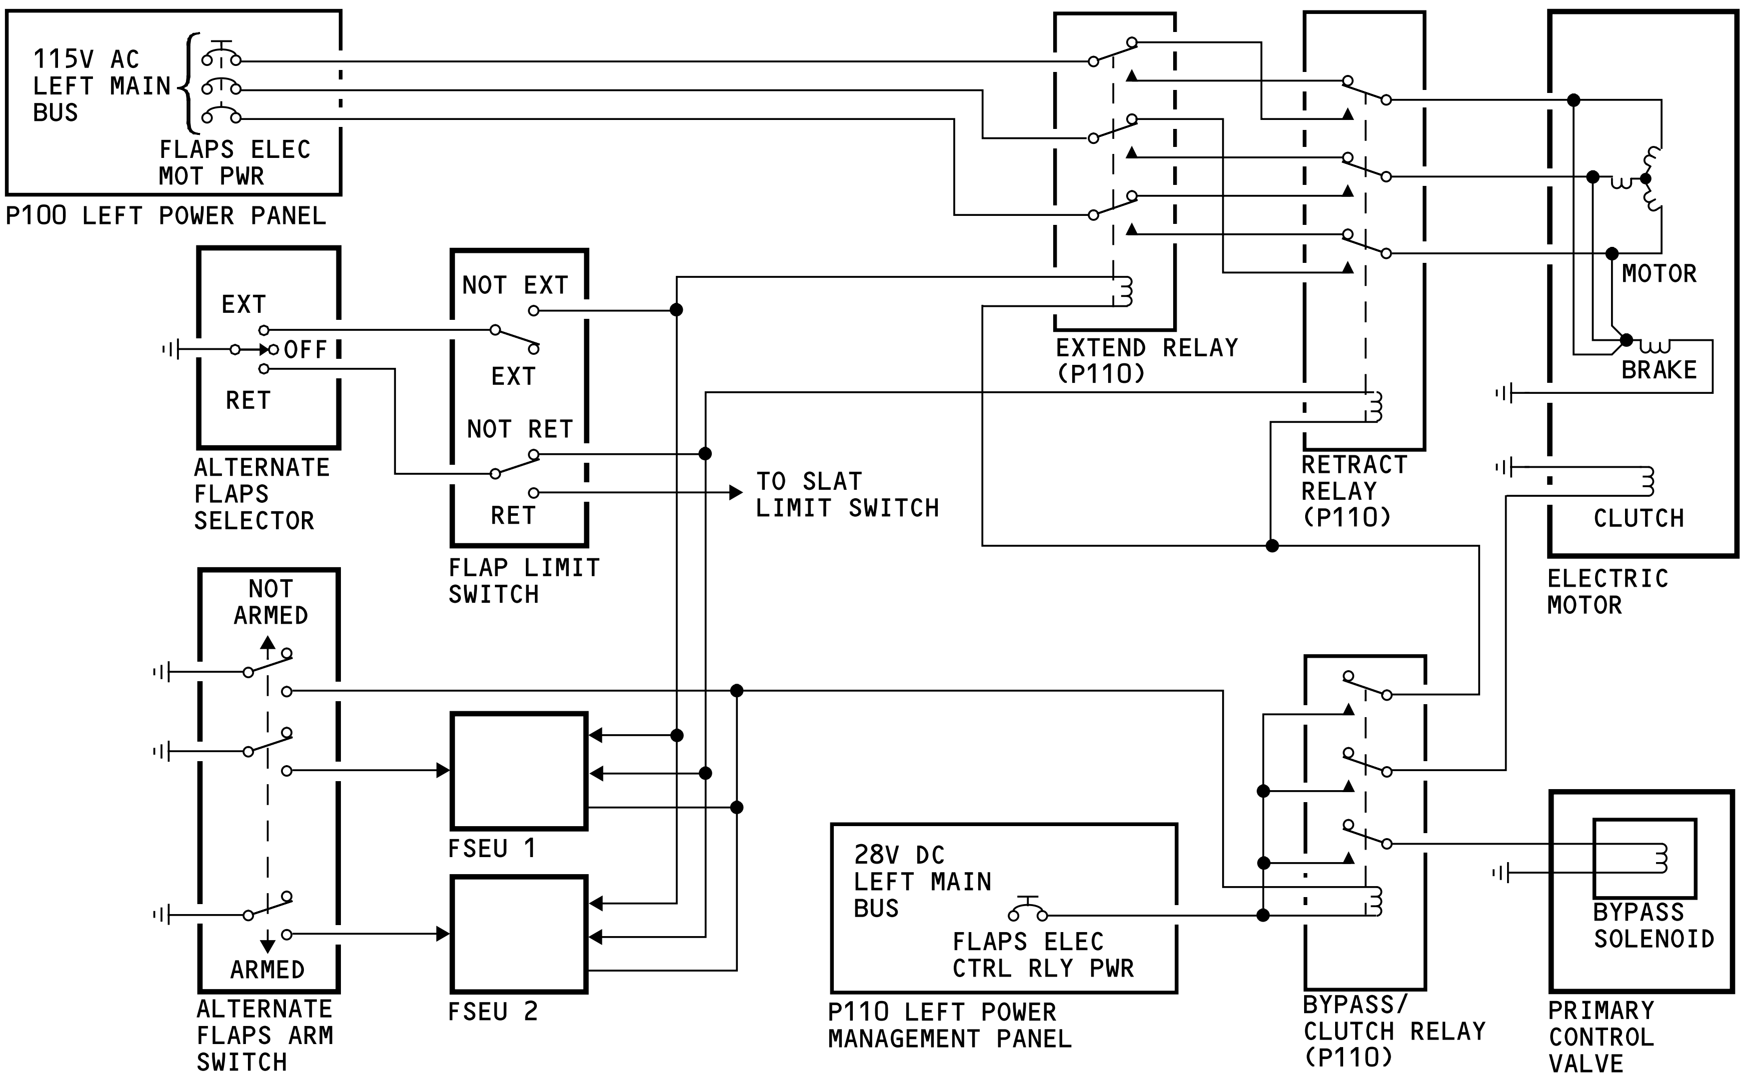
Flap/Slat Sequence

During extension, both the flaps and slats extend at the same time.

During retraction, the flap limit switch prevents retraction of the slats until the flaps are fully retracted.

TRAILING EDGE FLAPS - FUNCTIONAL DESCRIPTION - ALTERNATE MODE CONTROL

See the high lift control section for more information about the alternate mode flap and slat sequence (AMM PART I 27-03).



27-51-00-032 Rev 4 06/22/1995

TRAILING EDGE FLAPS - FUNCTIONAL DESCRIPTION - ALTERNATE MODE CONTROL

FLAP POSITION INDICATION - FLAP POSITION SENSORS AND GEARBOX

Purpose

The flap position sensor gearboxes transmit the flap torque tube position to the flap position sensors. The flap position sensors supply flap position data to the FSEUs for flap control, flap position indication, and failure detection.

Location

The flap position sensor gearboxes attach to the floor beams in the left and right main gear wheel wells. The gearboxes are between the flap PDU and the inboard flap inboard transmissions. The flap position sensors are on the flap position sensor gearboxes. The gearbox in the right wheel well also has the flap limit switch.

Physical Description

The flap position sensor gearboxes have a rig indicator that shows when the flaps are at the UP position. The indicator has a mark that turns with the flap drive. When the mark aligns with the fixed index, the flap drive is at the UP position.

There is a manual drive connection on each gearbox that permits you to manually drive the flaps. The manual drive input shaft has a shearout feature. Remove the manual drive cover to get access to the manual drive input shaft.

The flap position sensors are resolvers and they each have a rig indicator. The rig indicator has two marks that turn when the position sensor shaft turns. The two marks are in line when the flap drive line is at the UP position. All of these sensors are interchangeable with each other and with the slat position sensors.

Training Information Point

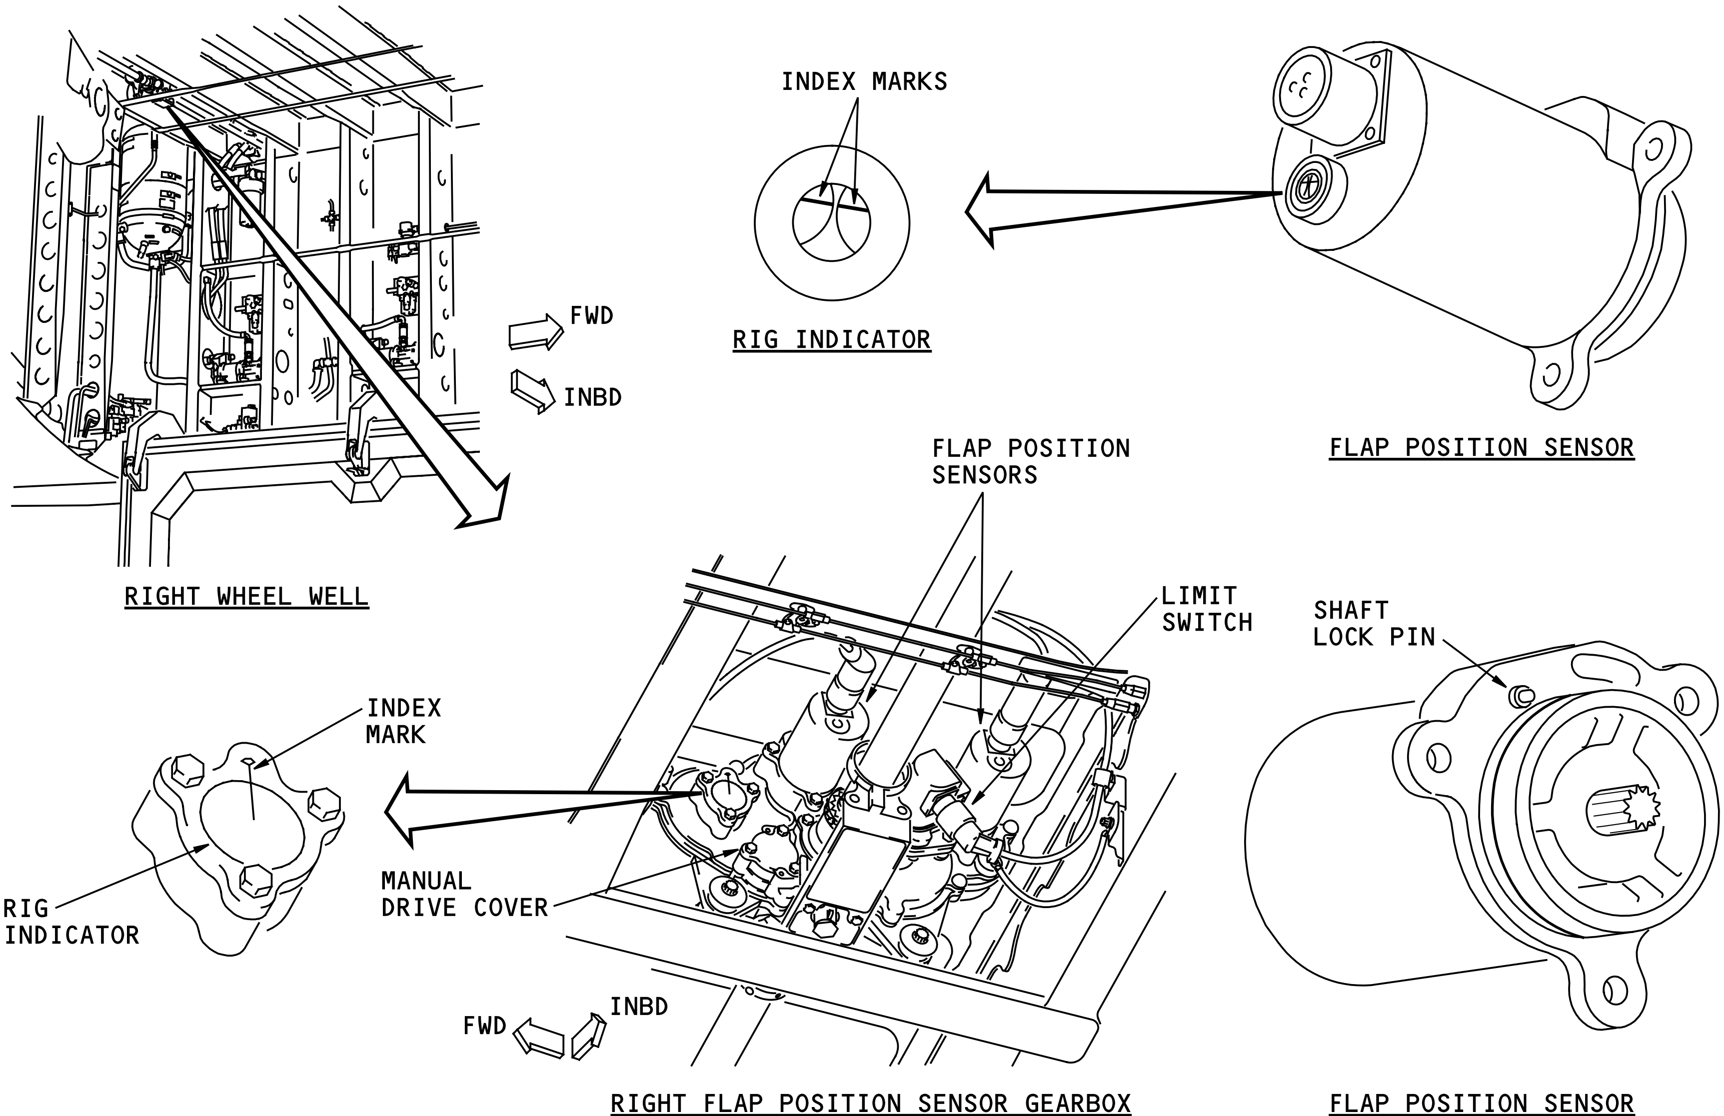
Install the flap position sensor gearboxes with the flaps at the UP position. Make sure the index mark for the rig indicator aligns with the fixed index.

Install the flap position sensor with the flap drive line in the UP position. Make sure that the index marks on the position sensor are aligned when you install the sensor. If the index marks on the position sensor are not aligned, you must push the shaft lock pin to turn the shaft. The shaft lock pin is next to the shaft.

When you manually operate the flap drive system, observe these cautions:

CAUTION: DO NOT TURN THE MANUAL DRIVE WITH MORE THAN 1200 POUND-INCHES TORQUE OR FASTER THAN 400 RPM. YOU CAN CAUSE DAMAGE TO THE POSITION SENSOR GEARBOX AND THE TORQUE TUBES.

CAUTION: DO NOT LET THE BALLSCREW NUTS HIT THE UPSTOPS OR THE DOWNSTOPS. YOU CAN CAUSE DAMAGE TO THE SHEAROUT IN THE POSITION SENSOR GEARBOX.



FLAP POSITION INDICATION - FLAP POSITION SENSORS AND GEARBOX

27-58-00-002 Rev 4 10/16/96

FLAP SKEW DETECTION - GENERAL DESCRIPTION

Purpose

The flap skew detection system monitors the position of the flaps. The FSEUs stop the primary and secondary mode flap operation if there is a skew, an asymmetry or a secondary mode disagree condition.

The flaps are in a skew condition if the inboard end of a flap does not align with its outboard end.

The flaps are in an asymmetry condition if the left flaps do not align with the right flaps.

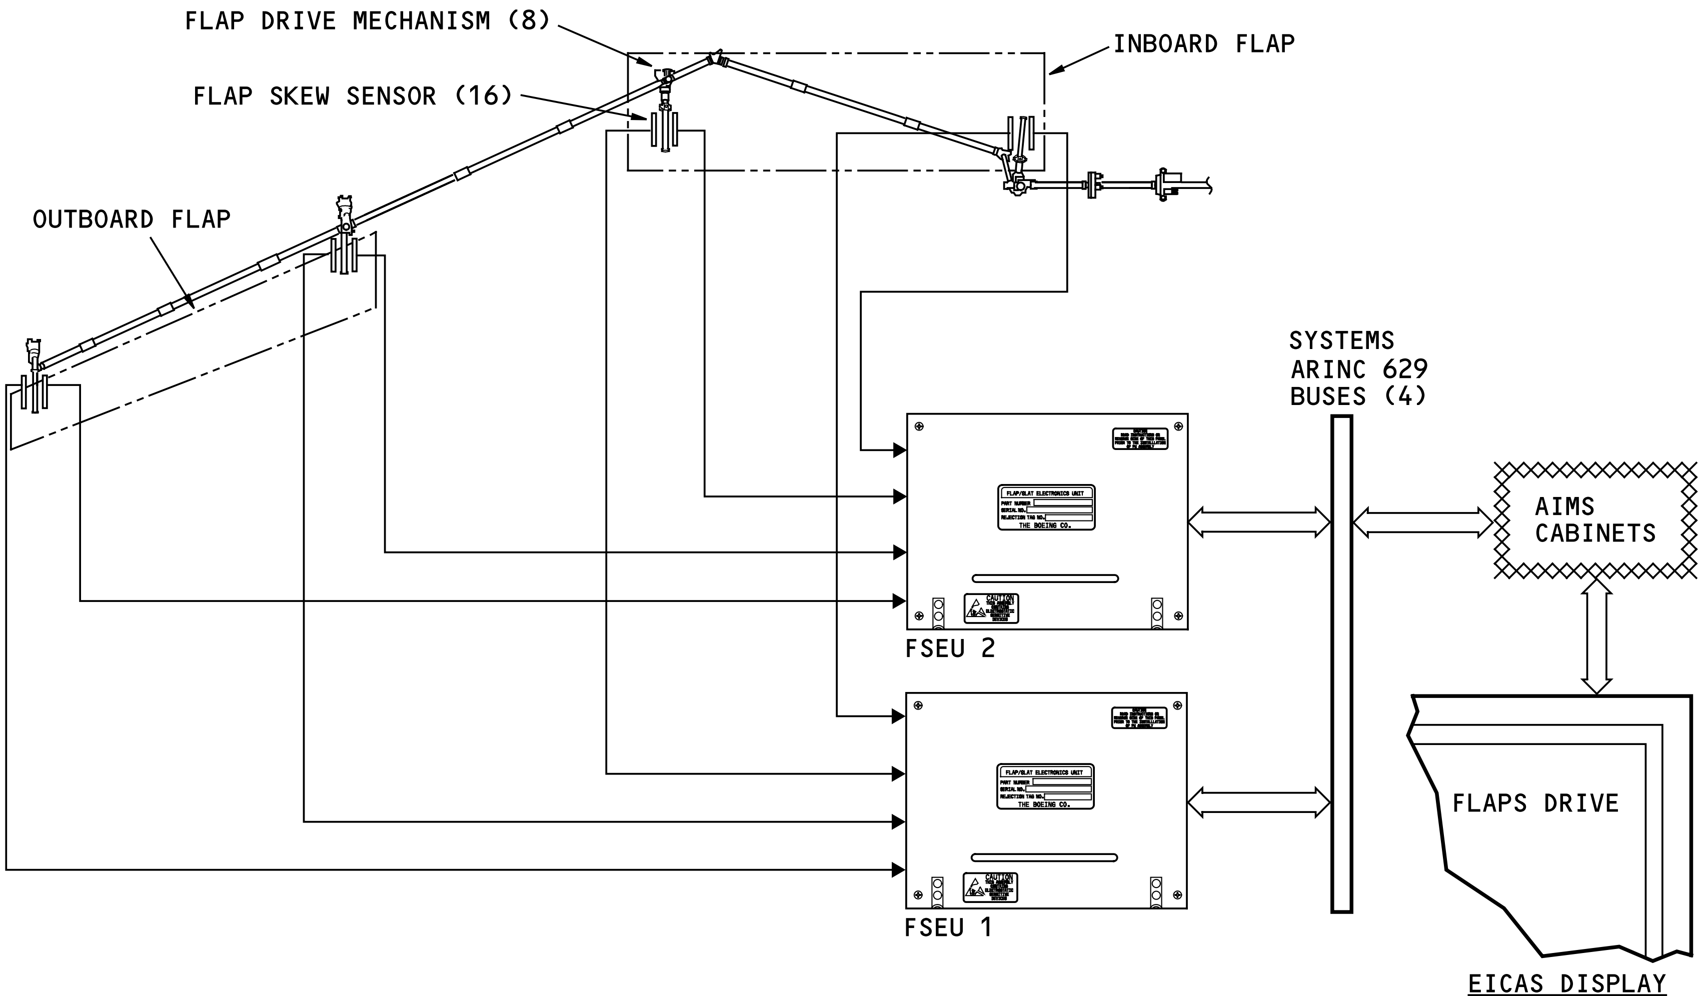
There is a secondary mode disagree if the flaps do not move or move too slowly after a command to move in secondary mode.

There is no automatic shutdown of the alternate mode if there is a flap skew, asymmetry, or secondary mode disagree.

Interface

There are 16 flap skew sensors. Each FSEU has interfaces with one sensor at each flap drive mechanism.

If the flaps are in a skew, an asymmetry or a secondary mode disagree condition, the FSEUs stop the flap drive in primary and secondary modes. The FSEUs also send a signal to the AIMS to show the FLAPS DRIVE caution EICAS message. If this happens, the flap position display on EICAS changes to the secondary mode display and the flap position indication shows in amber.



27-59-00-001 Rev 3

FLAP SKEW DETECTION - GENERAL DESCRIPTION

FLAP SKEW DETECTION - FLAP SKEW SENSORS

Purpose

The flap skew sensors monitor the position of the flaps at each flap drive mechanism.

Location

The flap skew sensors attach to the flap drive arm and the flap drive mechanism support. Access to these sensors is by extending the flaps to 30. Access to the sensors on the inboard flap inboard drive mechanism is through the main gear wheel wells.

Physical Description

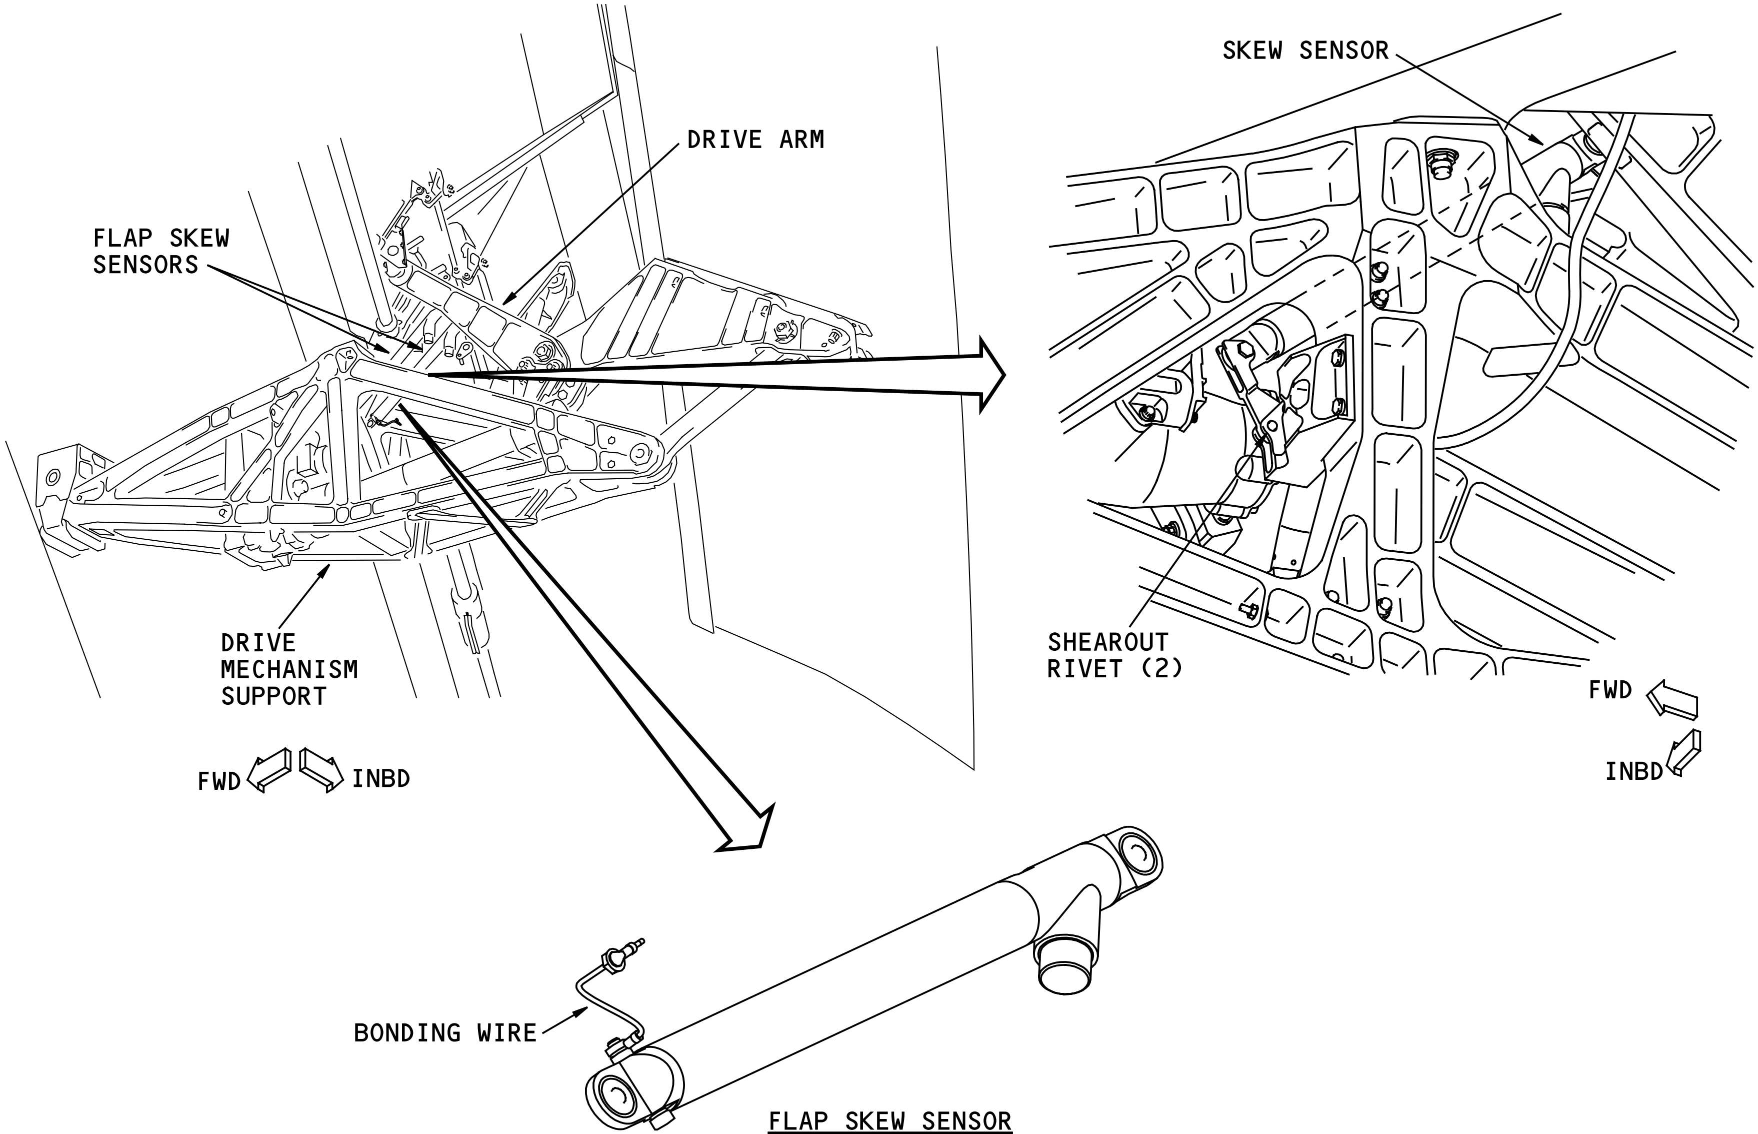
The flap skew sensors are linear variable differential transformers (LVDTs). Each sensor is a separate LRU.

The mounting bracket for each sensor has a shearout to prevent structural damage if the LVDT fails mechanically.

Training Information Point

The flap skew sensors do not need to be rigged after installation.

The electrical connectors for the outboard sensors on flap drive mechanisms 1, 2, 3, 6, 7, and 8 have a 45 degree bend. The connectors can be damaged if you install them on the wrong sensor.



FLAP SKEW DETECTION - FLAP SKEW SENSORS

27-59-00-002 Rev 4 01/19/95

FLAP SKEW DETECTION - FUNCTIONAL DESCRIPTION

General

There are 16 flap skew sensors. Each FSEU receives data from one of the skew sensors at each flap drive mechanism.

Both channels in the FSEUs use the flap skew data for failure detection. The FSEUs monitor for flap position failures and for sensor failures.

Flap Drive Shutdown

When both FSEUs find a failure, they stop the flap drive. There is a flap drive shutdown for any one of these conditions:

- Skew sensors on symmetrical flap drive mechanisms do not agree (asymmetry or skew)
- The left and right flap position sensors do not agree (asymmetry)
- The flaps do not move within 10 seconds after a flap command in the secondary mode or the flaps move too slowly (secondary mode disagree).

If there is a flap skew, asymmetry, or secondary mode disagree, the FSEUs latch the shutdown of the primary and secondary modes. The FSEUs also send signals to AIMS to show the FLAPS DRIVE caution message. The flap positon display changes to the secondary mode display and the flap position indication shows in amber.

To reset the latch, cycle the alternate flaps arm switch or do the primary system test on the MAT.

Skew Sensor Failure

If one of the flap skew sensors fail, the FSEUs send a signal to the AIMS to show the FLAP/SLAT SKEW SNSRS status message.

TABLE OF CONTENTS

THIS PAGE INTENTIONALLY LEFT BLANK

LEADING EDGE SLATS - INTRODUCTION

General

The leading edge (LE) slats improve the takeoff and landing performance of the airplane. When the slats extend, they increase the lift of the wing. They also increase the angle of attack (AOA) at which the wing stalls.

The slats are part of the high lift control system (HLCS). The HLCS electrically controls the slats with a fly-by-wire system.

During takeoff and landing, the pilots use the flap lever to command the slats to extend to the sealed or gapped positions. After takeoff, the pilots use the flap lever to command the slats to retract to the up position.

Each wing has an inboard slat, a krueger flap, and six outboard slats.

Slat Operation

The slats operate in sequence with the flaps. At cruise speed and altitude, slat extension is inhibited.

During secondary mode operation, the load relief function retracts the slats at high airspeed.

The autoslat function extends the slats to improve the airplane stall performance near stall conditions.

The slats are monitored for skew or asymmetry. When there is a skew or asymmetry, the slat drive shuts down.

LEADING EDGE SLATS - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

LEADING EDGE SLATS - GENERAL DESCRIPTION

General

The LE slats and krueger flaps operate in one of these three modes:

- Primary mode
- Secondary mode
- Alternate mode.

The primary mode uses hydraulic power to operate the slats. The secondary and alternate modes use electrical power to operate the slats.

Primary Mode

The primary mode has a closed-loop control system. The pilot commands the slats with the flap lever. The flap lever position sensor sends input signals to the FSEUs. The FSEUs use the flap lever position to calculate the slat commands. The FSEUs also receive data from the systems ARINC 629 buses.

The FSEUs send the slat commands to the slat primary control valve. This valve supplies hydraulic power to the slat power drive unit (PDU). The hydraulic motor on the PDU then moves the slat mechanisms.

The flap/slat priority valve controls the amount of hydraulic flow to the slat primary control valve. The flap/slat priority valve gives priority of hydraulic power to the primary flight control system (PFCS) over the HLCS.

As the slats move, the slat position sensors send feedback signals to the FSEUs. The FSEUs stop the slat commands when the feedback signals equal the commanded position.

The FSEUs use data from the systems ARINC 629 buses for the autoslat function. This function commands the autoslat priority valve to limit the flow of hydraulic fluid to the main landing gear system. This gives priority of the hydraulic power to the slats during autoslat operation. The autoslat priority valve also gives priority of hydraulic power to the HLCS over the main landing gear system during normal operations.

The FSEUs use the slat skew sensors to detect a slat skew and the position sensors to detect a slat asymmetry. In either condition, the FSEUs stop the slat drive.

Secondary Mode

The FSEUs use the secondary mode when the primary mode disengages. The secondary mode is only available in the air or during special maintenance functions.

The secondary mode also has a closed-loop control system. The pilot commands the slats with the flap lever. The FSEUs use the flap lever position to calculate the slat commands. The FSEUs then energize the secondary/alternate control relays. One relay energizes the bypass solenoid in the slat primary control valve and the clutch in the electric motor unit. This stops hydraulic power to the hydraulic motor and lets free flow through it. The electric motor clutch connects the motor shaft to the PDU gearbox. The other relays control electrical power to the slat electric motor on the slat PDU. The electric motor then moves the slat mechanisms.

As the slats move, the slat position sensors send feedback signals to the FSEUs. The FSEUs command the relays to stop the electric motor when the slats are at the commanded position.

The FSEUs use the slat skew sensors to detect a slat skew and the position sensors to detect an asymmetry or disagreement. In either condition, the FSEUs stop the slat drive.

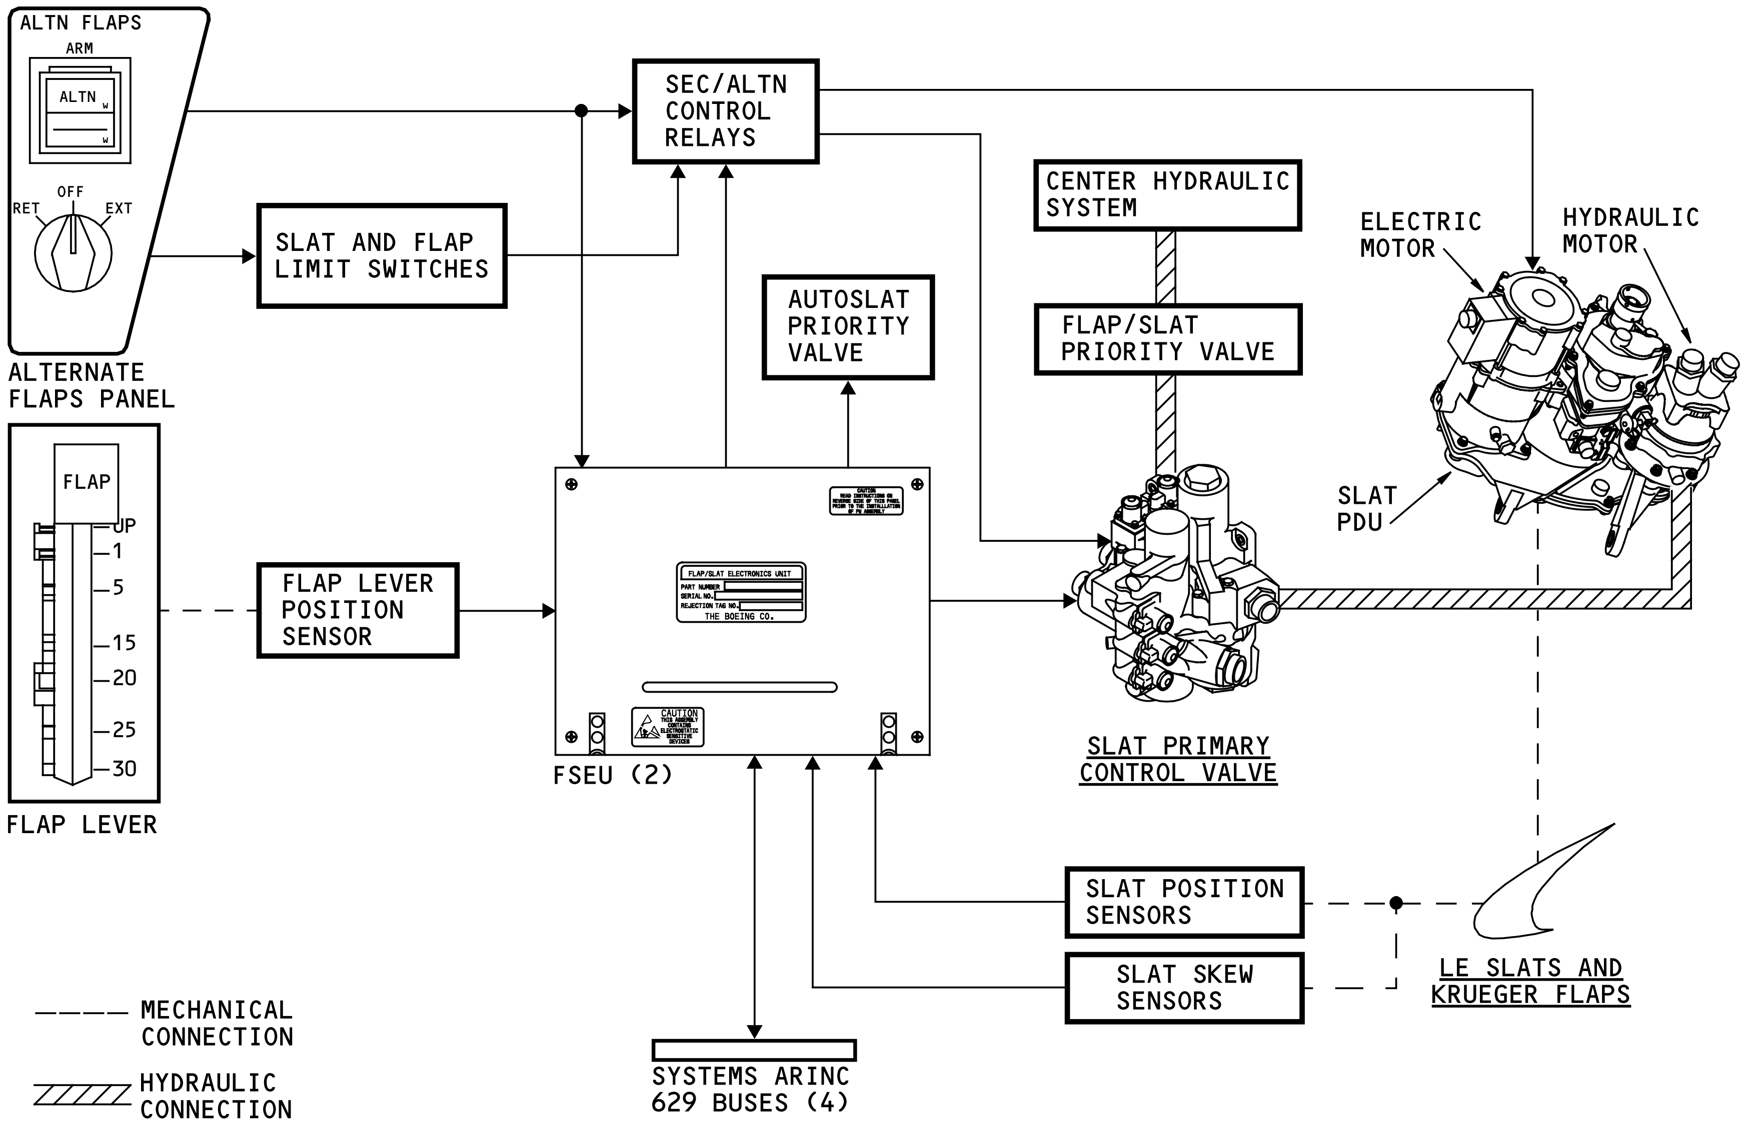
<u>Alternate Mode</u>

The alternate mode has an open-loop control system. The pilot uses the switches on the alternate flaps panel to command the slats. An arm switch sends a discrete signal to the FSEUs to disengage the primary and secondary modes. The switch also energizes one of the secondary/alternate control relays. This relay energizes the bypass solenoid in the slat primary control valve and the clutch in the electric motor. This stops hydraulic power to the hydraulic motor and lets free flow through it. The electric motor clutch connects the motor shaft to the PDU gearbox.

The alternate flaps selector sends commands through the slat and flap limit switches to energize the other secondary/alternate control relays. The relays control electrical power to the slat electric motor in the PDU. The electric motor then moves the slat mechanisms.

The slats move until the pilot moves the alternate flaps selector to the OFF position or the slat limit switch stops the motor when the slats are at their limits.

There is no automatic shutdown of the alternate mode if there is a slat skew or asymmetry.



27-81-00-002 Rev 5 03/28/96

LEADING EDGE SLATS - GENERAL DESCRIPTION

LEADING EDGE SLATS - GENERAL DESCRIPTION - SLAT DRIVE SYSTEM

General

There are six outboard slats, one inboard slat, and one krueger flap on each wing. The slats are numbered 1 through 14, left outboard to right outboard.

These are the components of the slat drive system:

- Slat PDU
- Torque tubes
- Torque tube supports
- Angle gearboxes
- Driveline offset gearboxes
- No-back brake offset gearboxes
- Krueger flap offset gearboxes
- Rotary actuators
- Slat main tracks.

Slat PDU

The slat PDU gets hydraulic power through the primary control valve and electric power through the slat extend/retract relays. Hydraulic and electric motors on the PDU move the slat drive system. The slat PDU also contains the slat limit switch. The switch removes electrical power from the electric motor when the slats move to their limit during operation in the alternate mode.

Torque Tubes

The torque tubes transmit power from the PDU to the slat actuation assemblies.

Torque Tube Supports

The torque tube supports hold the torque tubes in place.

Angle Gearboxes

The angle gearboxes connect torque tubes that are at different angles to each other.

Offset Gearboxes

The driveline offset gearboxes connect torque tubes that are offset from each other.

The no-back brake offset gearboxes transfer power from the torque tubes to the slat rotary actuators. These gearboxes also help prevent airloads from retracting the slats.

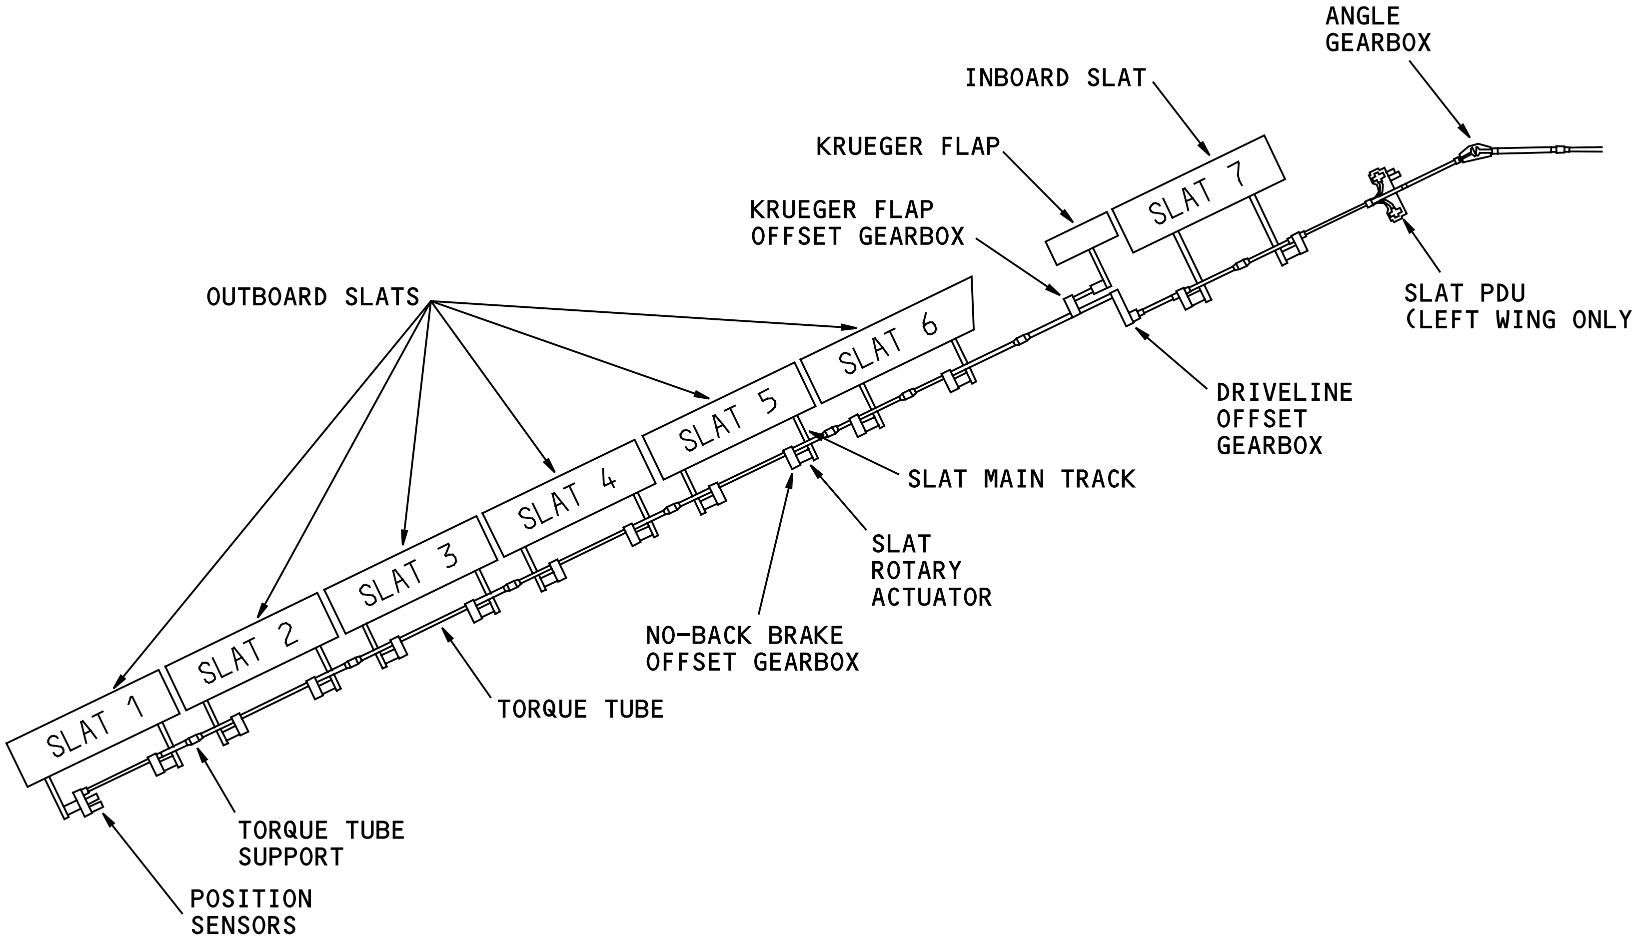
The krueger flap offset gearboxes transfer power from the torque tubes to the krueger flap rotary actuators.

Rotary Actuators

The slat rotary actuators move the slat main tracks. The krueger flap rotary actuators move the krueger flap.

Slat Main Tracks

As the slat rotary actuators turn, the slat main tracks move the slats.



<u>NOTE</u>: THE LEFT SLATS ARE SHOWN
(THE RIGHT SLATS ARE SIMILAR)

27-81-00-003 Rev 2 03/13/96

LEADING EDGE SLATS - GENERAL DESCRIPTION - SLAT DRIVE SYSTEM

LEADING EDGE SLATS - COMPONENT LOCATIONS

General

The slat components are in these areas:

- The main landing gear wheel wells
- The forward cargo compartment
- The wings.

Main Landing Gear Wheel Well Components

The slat primary control valve is on the keel beam in the left main landing gear wheel well. The autoslat priority valve is on the ceiling in the right main landing gear wheel well.

Forward Cargo Compartment Components

The floor angle gearboxes and some of the torque tubes are above and to the sides of the aft section of the forward cargo compartment. Remove the cargo lining in the aft section of the forward cargo compartment to get access.

Wing Components

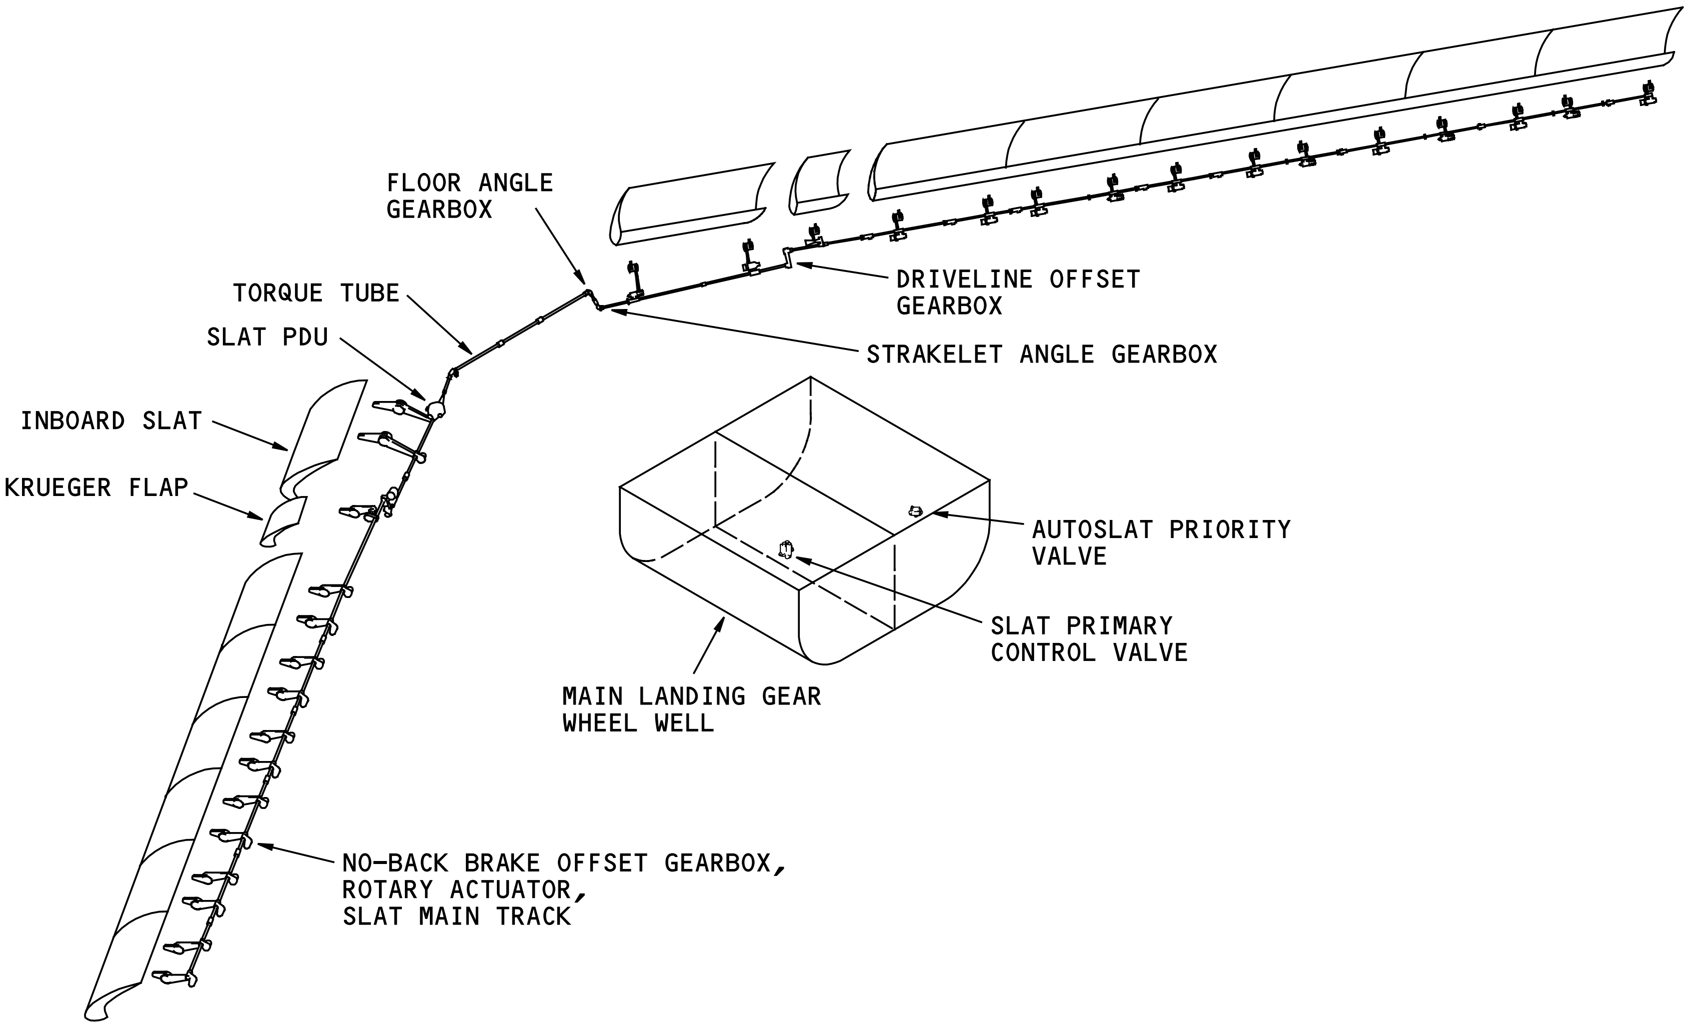
The slat PDU and one of the strakelet angle gearboxes are in the left wing root. The other strakelet angle gearbox is in the right wing root. Remove the access panels under the wings to get access to these components.

In the fixed leading edge of the wings are the following components:

- No-back brake offset gearboxes
- Rotary actuators
- Slat main tracks
- Some of the torque tube supports
- Driveline offset gearboxes.

Remove the access panels under the wings to get access to these components.

The inboard slats, krueger flaps, and outboard slats are on the leading edge of the wings. The krueger flap is between the inboard slat and the engine strut.



27-81-00-004 Rev 5

LEADING EDGE SLATS - COMPONENT LOCATIONS

LEADING EDGE SLATS - SLAT PRIMARY CONTROL VALVE

Purpose

The slat primary control valve controls hydraulic power to the hydraulic motor. In the primary mode, this valve controls the direction and speed of movement of the slat drive system. In the secondary and alternate modes, this valve prevents hydraulic power to the hydraulic motor.

Physical Description

The primary control valve is an LRU. These components on the primary control valve are LRUs:

- The shutoff solenoid
- The extend solenoid
- The retract solenoid
- The low-speed solenoid
- The bypass solenoid.

The low-speed solenoid is different than the other solenoids, but it is interchangeable with the low-speed solenoid on the flap primary control valve. All the other solenoids are interchangeable and they are interchangeable with the other solenoids on the flap primary control valve. The slat primary control valve is similar to, but not interchangeable with, the flap primary control valve.

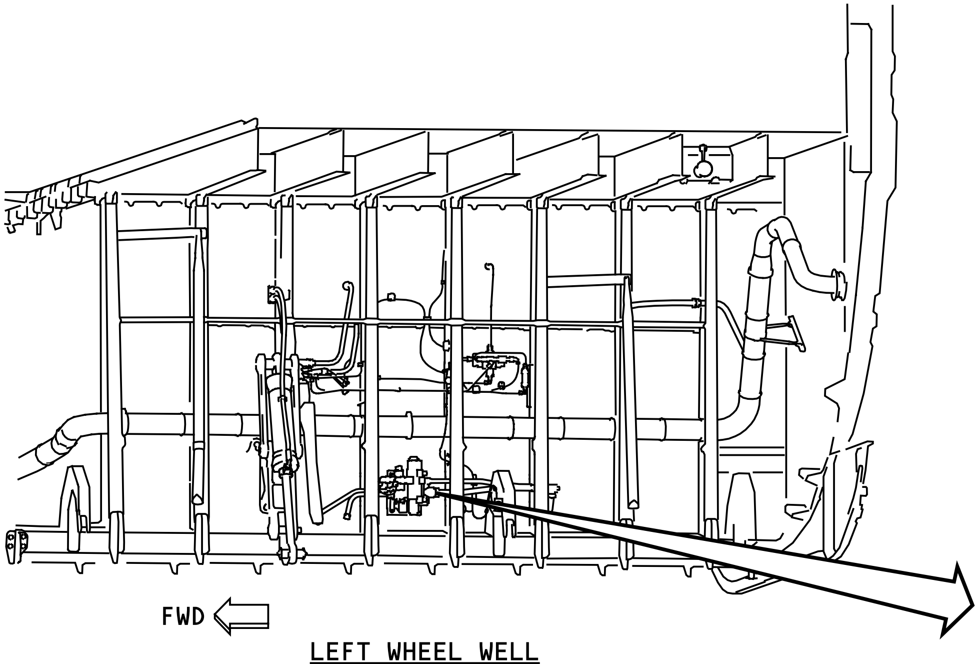
Location

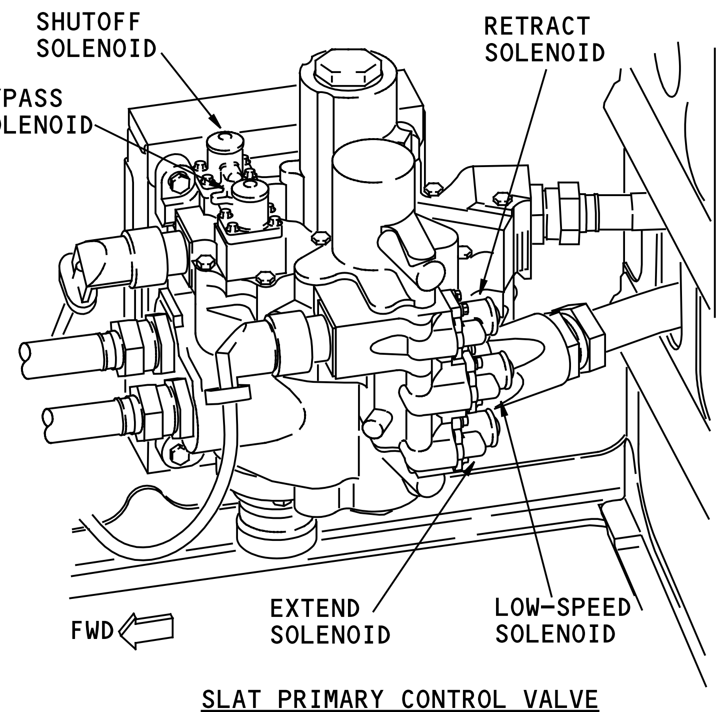
The slat primary control valve attaches to the keel beam in the left main landing gear wheel well.

Training Information Point

There is a small difference in the location of the mounting holes for the flap and slat primary control valves. This helps prevent the slat primary control valve from being installed where the flap primary valve should be. The reverse is also true.

The low-speed solenoid has a longer valve and different mounting hole locations. This helps prevent the low-speed solenoid from being installed where a different type of solenoid should be. This also helps prevent a different solenoid from being installed where the low-speed solenoid should be.





27-81-00-005 Rev 2 08/12/95

LEADING EDGE SLATS - SLAT PRIMARY CONTROL VALVE

LEADING EDGE SLATS - PRIMARY CONTROL VALVE - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

LEADING EDGE SLATS - PRIMARY CONTROL VALVE - FUNCTIONAL DESCRIPTION

General

The primary control valve has these components:

- Shutoff valve
- Shutoff solenoid valve
- Low-speed solenoid valve
- Low-speed piston
- Flow regulator
- Retract solenoid valve
- Extend solenoid valve
- Selector valve
- Bypass solenoid valve
- Bypass valve.

The FSEUs electrically control the solenoid valves in the primary control valve. All the solenoid valves are normally de-energized.

Shutoff Valve and Shutoff Solenoid Valve

The shutoff valve supplies hydraulic pressure and hydraulic flow to the selector valve.

The shutoff valve has three positions: closed, open, and low-speed. The shutoff valve is spring-loaded and hydraulically controlled to the closed position. It moves to the open or low-speed positions when the shutoff solenoid valve removes pressure from one side of the valve.

The shutoff solenoid valve controls the pilot pressure to the shutoff valve. The shutoff valve solenoid has two coils. When both coils are de-energized, the shutoff solenoid valve lets pilot pressure close the shutoff valve. When either coil is energized, the shutoff solenoid valve removes pilot pressure from the shutoff valve. Hydraulic system pressure then lets the shutoff valve open.

When the shutoff valve is closed, it removes hydraulic pressure from the selector valve. When the shutoff valve is open, hydraulic system pressure goes to the selector valve to move the slats at their normal rate. When the shutoff valve is in the low-speed position, the hydraulic flow to the selector valve is restricted.

Low-Speed Solenoid Valve, Low-Speed Piston and Flow Regulator

The low-speed solenoid valve, the low-speed piston and the flow regulator help to decrease the speed of the flap drive system.

The low-speed solenoid valve is a dual-coil solenoid valve that controls hydraulic pressure to the low-speed piston. The low-speed piston is a hydraulic piston that is spring-loaded to the retracted position.

When the FSEUs energize the low-speed solenoid valve, the low-speed piston extends. This limits the position of the shutoff valve to the low-speed position.

When the FSEUs de-energize the low-speed solenoid valve, the pressure in the low-speed piston decreases. An internal spring then forces the low-speed piston to retract. This lets the shutoff valve move to the open position.

The flow regulator limits the flow of hydraulic fluid to 35 gpm at high speed, and 7 gpm at low-speed.

Selector Valve

The selector valve controls the direction of operation of the hydraulic motor.

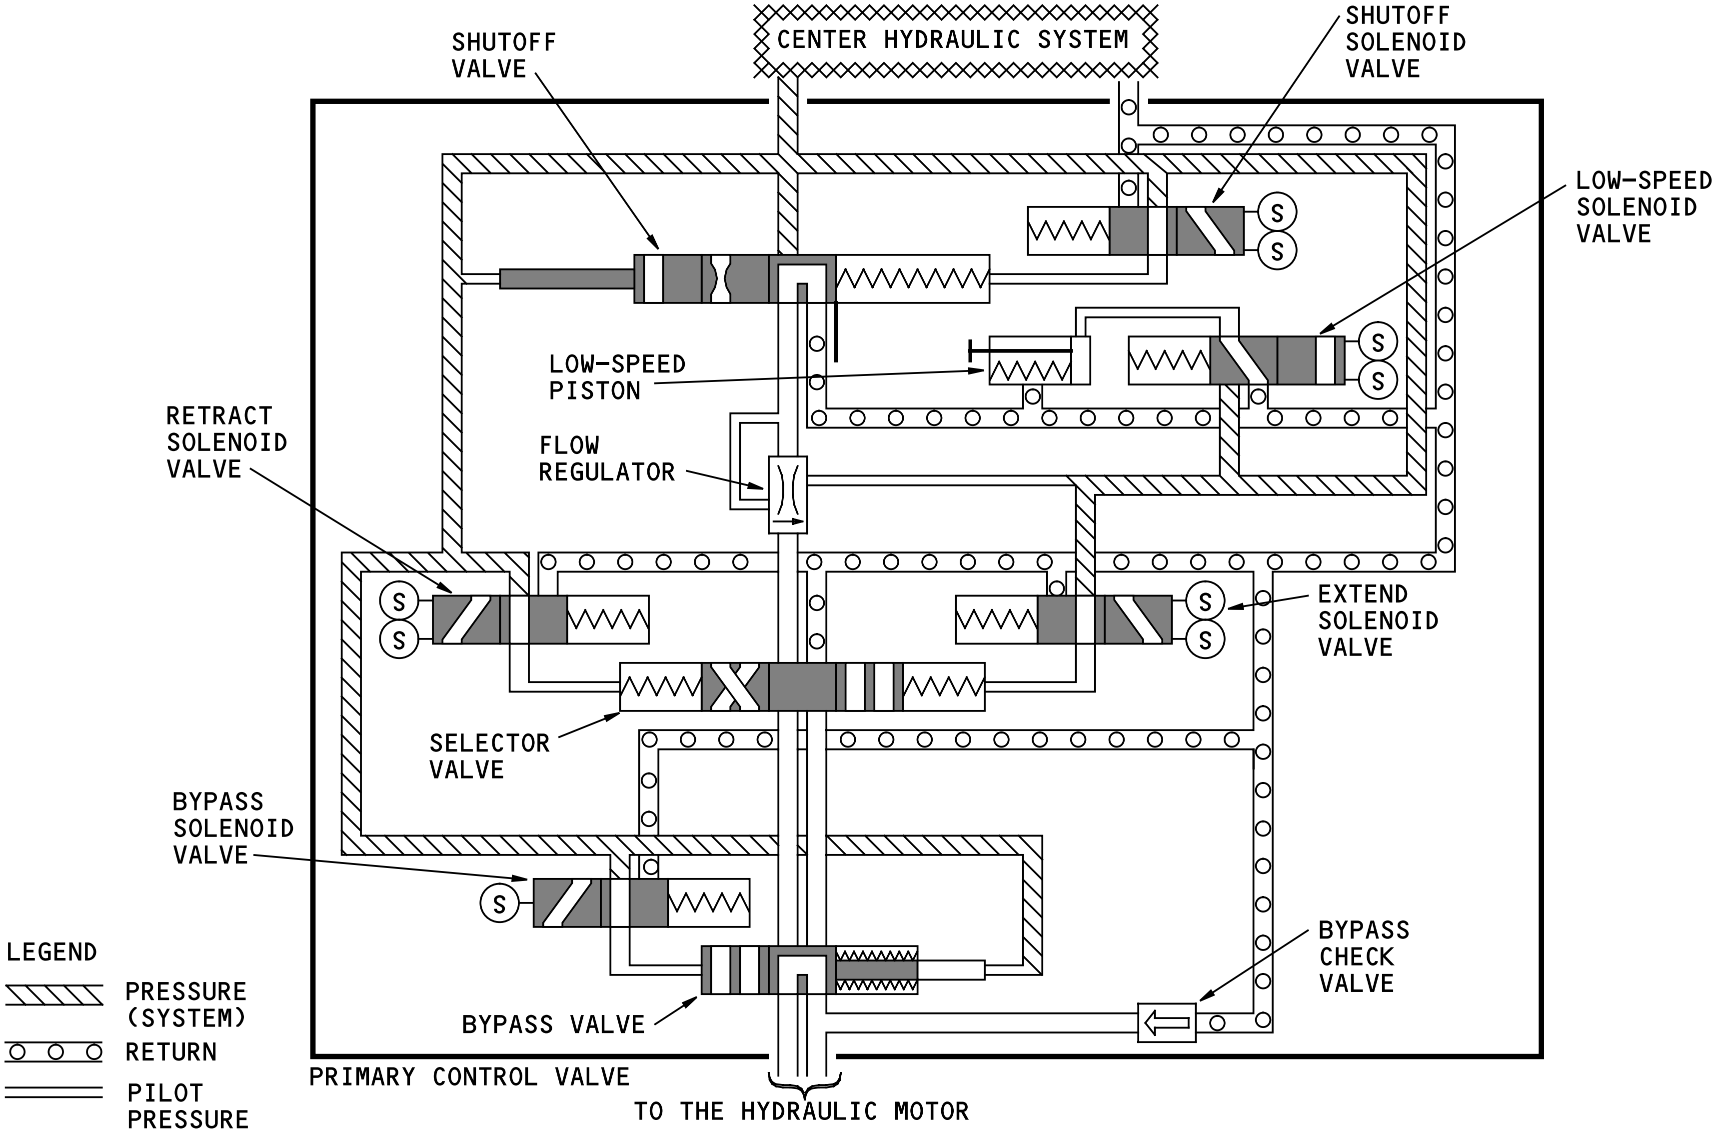
The selector valve is spring-loaded and hydraulically balanced to the center position and normally has pressure on both sides of the valve. The selector valve moves to the extend position when the extend solenoid valve removes pilot pressure from the extend side of the selector valve. The selector valve moves to the retract position when the retract solenoid valve removes pilot pressure from the retract side of the selector valve.

Bypass Valve and Bypass Solenoid Valve

The bypass valve isolates the hydraulic motor from hydraulic system pressure. The bypass valve also prevents a hydraulic lock and permits backdrive of the hydraulic motor.

A dual-coil bypass solenoid valve controls pilot pressure to the bypass valve, but only one coil of the solenoid is used. When the FSEUs energize the bypass solenoid valve, it removes pilot pressure from the open side of the bypass valve. This closes the bypass valve, which connects the hydraulic lines to both sides of the hydraulic motor.

The bypass valve is spring-loaded and hydraulically controlled to the closed position. The open side of the valve has a larger surface area for the pilot pressure than the close side of the valve. When the center hydraulic system pressure is low, springs automatically force the bypass valve to close. When the center hydraulic system pressure is high, the bypass valve opens.



27-81-00-006 Rev 3

LEADING EDGE SLATS - PRIMARY CONTROL VALVE - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

LEADING EDGE SLATS - SLAT POWER DRIVE UNIT (PDU)

Purpose

The slat PDU turns the slat torque tubes during operation in all three modes. The slat PDU has these LRUs:

- A hydraulic motor
- An electric motor
- A limit switch
- A gearbox.

Information on the hydraulic motor, the electric motor, and the limit switch is shown later.

Location

The slat PDU is in the left wing root. Remove the access panel or open the small access panel under the wing to get access.

Gearbox

The gearbox transmits the power from the hydraulic or electric motors to the torque tubes.

The hydraulic motor or the electric motor rotates gears in the gearbox. These gears increase the torque from the motors. The gearbox turns the torque tube couplings on both sides of the PDU. These couplings turn the torque tubes.

The gearbox contains a ball ramp torque brake to limit the output torque from either side of the PDU. When the torque brake activates, a torque trip indicator shows. There is a separate torque trip indicator for the PDU output to the left wing slats and to the right wing slats. The torque trip indicators have the labels LEFT WING and RIGHT WING. The indicators are reset manually.

The slat PDU has a rig pin that locks the PDU gearbox in the slats UP position. A ground lockpin next to the rig pin locks the rig pin in the rig position.

The gearbox also contains a stroke control mechanism to stop the PDU output if one of the motors on the PDU fails to stop. The stroke control mechanism stalls the hydraulic or electric motors within two torque tube rotations of the maximum normal slat positions.

During high-speed operation in the primary mode, the gearbox turns the torque tubes at 640 rpm. During low-speed operation, the gearbox turns the torque tubes at 128 rpm.

During operation in the secondary and alternate modes, the gearbox turns the torque tubes at 85 rpm.

Training Information Point

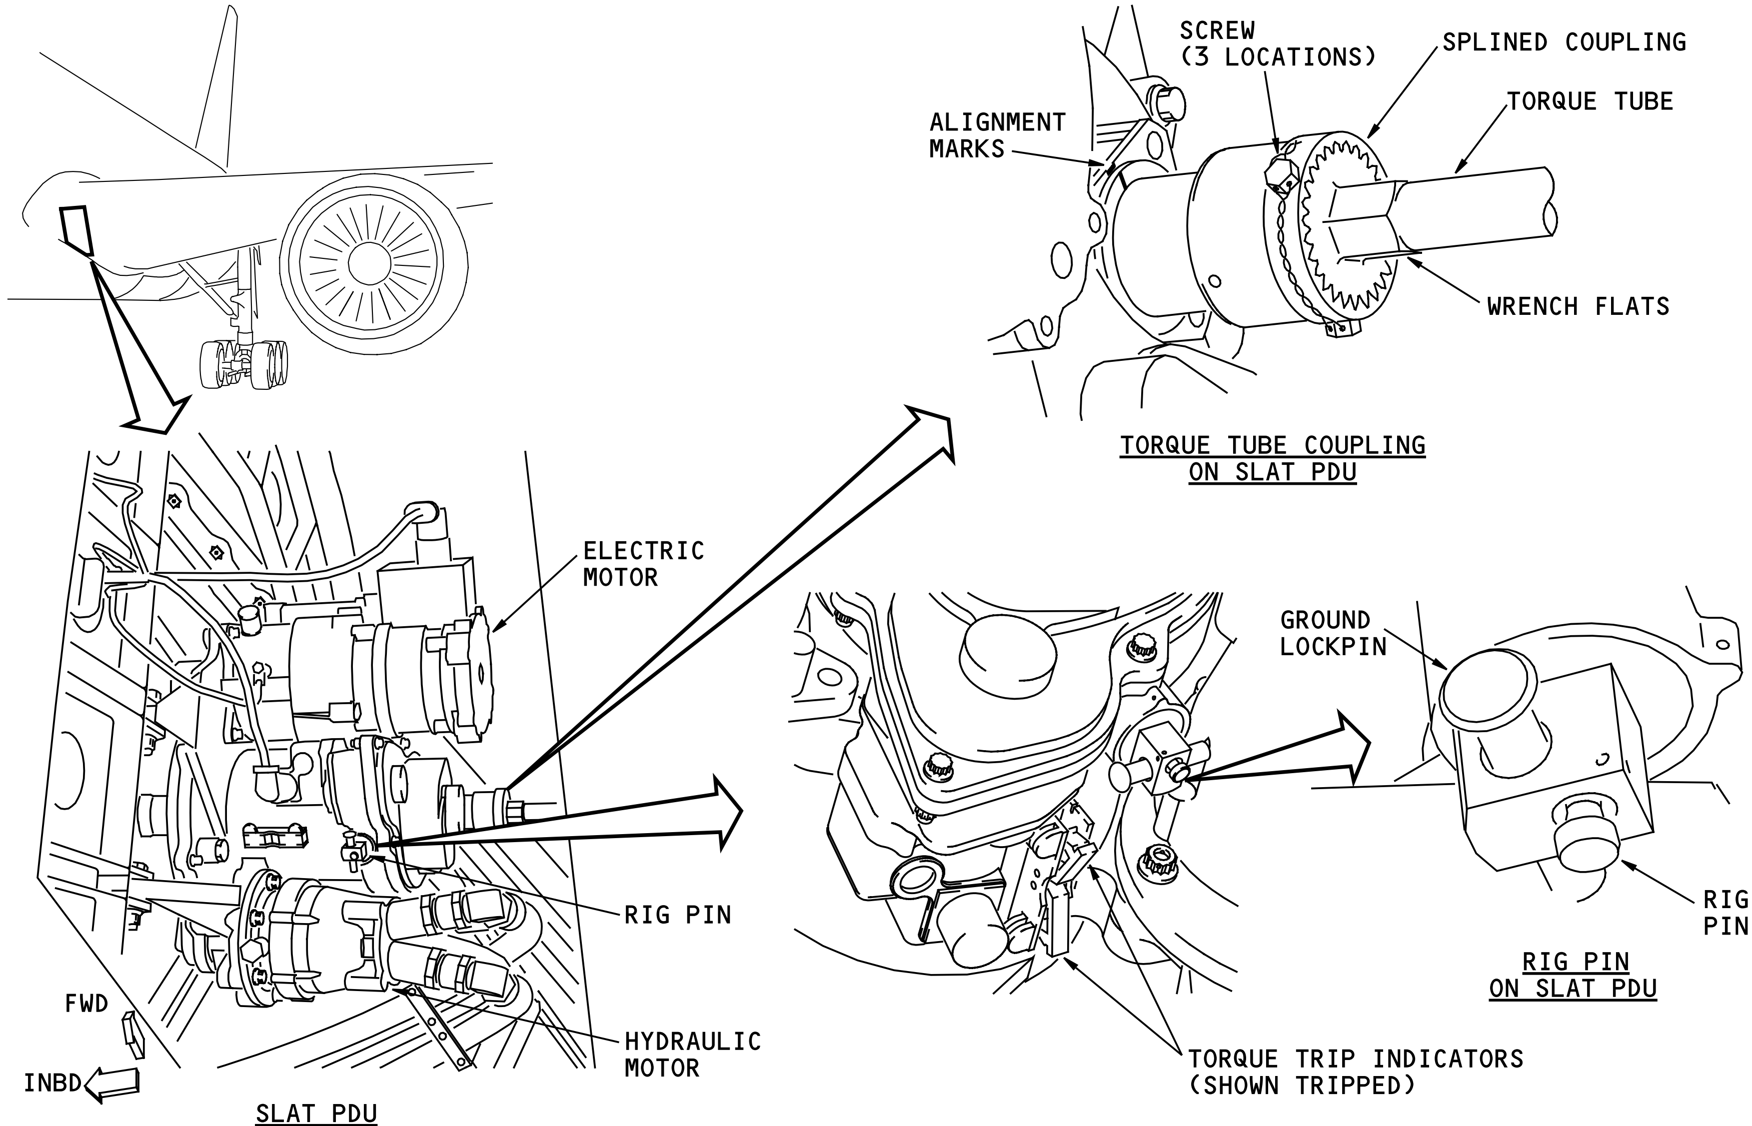
Wrench flats on the torque tube between the PDU and slat 7 let you manually rotate the slat system.

To install the rig pin in the slat PDU, retract the slats to the UP position. See that the alignment mark on the output shaft aligns with the fixed index mark on the PDU. If the alignment mark does not align with the

LEADING EDGE SLATS - SLAT POWER DRIVE UNIT (PDU)

index mark, use the wrench flats on the torque tube to turn the PDU in the extend direction, then in the retract direction until the marks align. Push the rig pin in the PDU and hold it while you lock it with the ground lockpin.

The gearbox contains oil and it is necessary to do servicing at specified times. Use the oil fill plug.



27-81-00-007 Rev 4 03/21/96

LEADING EDGE SLATS - SLAT POWER DRIVE UNIT (PDU)

LEADING EDGE SLATS - SLAT LIMIT SWITCH

Purpose

The slat limit switch limits the position of the slats during alternate mode operation.

Location

The limit switch is on the slat PDU.

Physical Description

The limit switch is one LRU. It has two internal switches, retracted and extended.

Functional Description

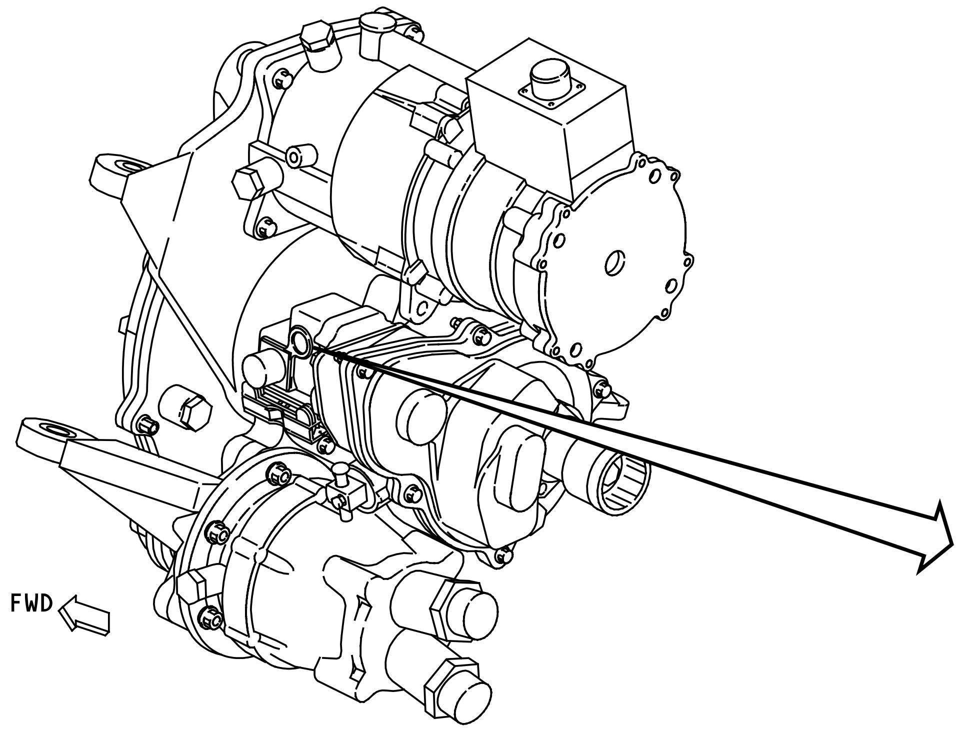
When the slats retract to the up position, the retracted switch removes electrical power from the slat electric motor.

When the slats extend to the sealed position, the extended switch removes electrical power from the slat electric motor.

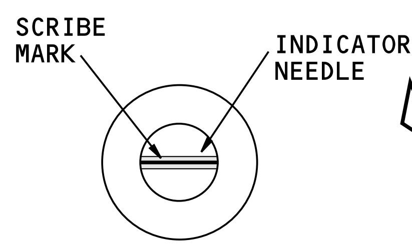
Training Information Point

The slat limit switch is interchangeable with the flap limit switch.

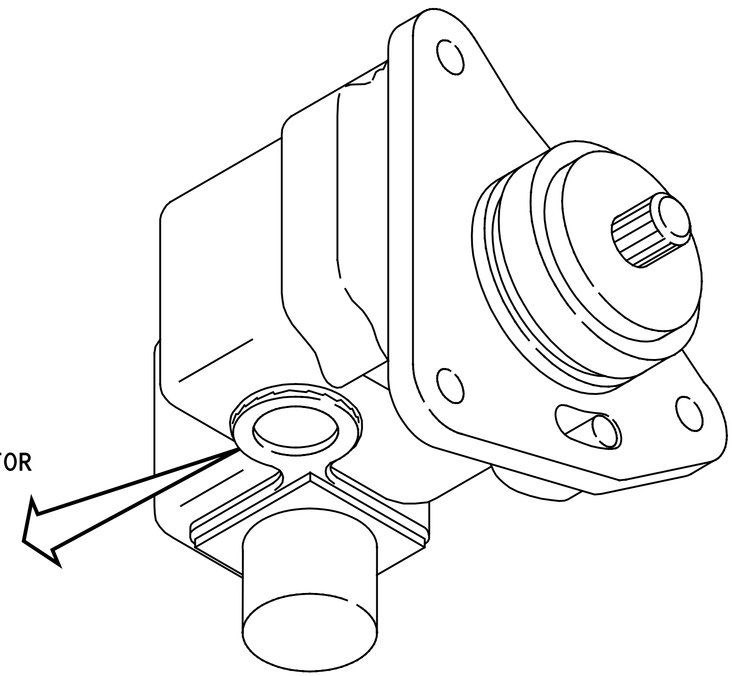
Install the slat limit switch with the slat PDU in the rigged position. The limit switch rig indicator has a fixed scribe mark and an indicator needle. The indicator needle moves up or down in relation to the scribe mark as the shaft of the limit switch turns. Make sure the center of the indicator needle in the rig indicator aligns with the scribe mark when you install the limit switch.



SLAT PDU



RIG INDICATOR



SLAT LIMIT SWITCH

27-81-00-009 Rev 2 03/19/96

LEADING EDGE SLATS - SLAT LIMIT SWITCH

LEADING EDGE SLATS - AUTOSLAT PRIORITY VALVE

Purpose

The autoslat priority valve controls the flow of hydraulic fluid to the main landing gear (MLG) system. This valve gives priority of center hydraulic system power to the slats during autoslat operation and to the flaps and slats during landing gear operation.

Location

The autoslat priority valve is on the ceiling of the right MLG wheel well.

Physical Description

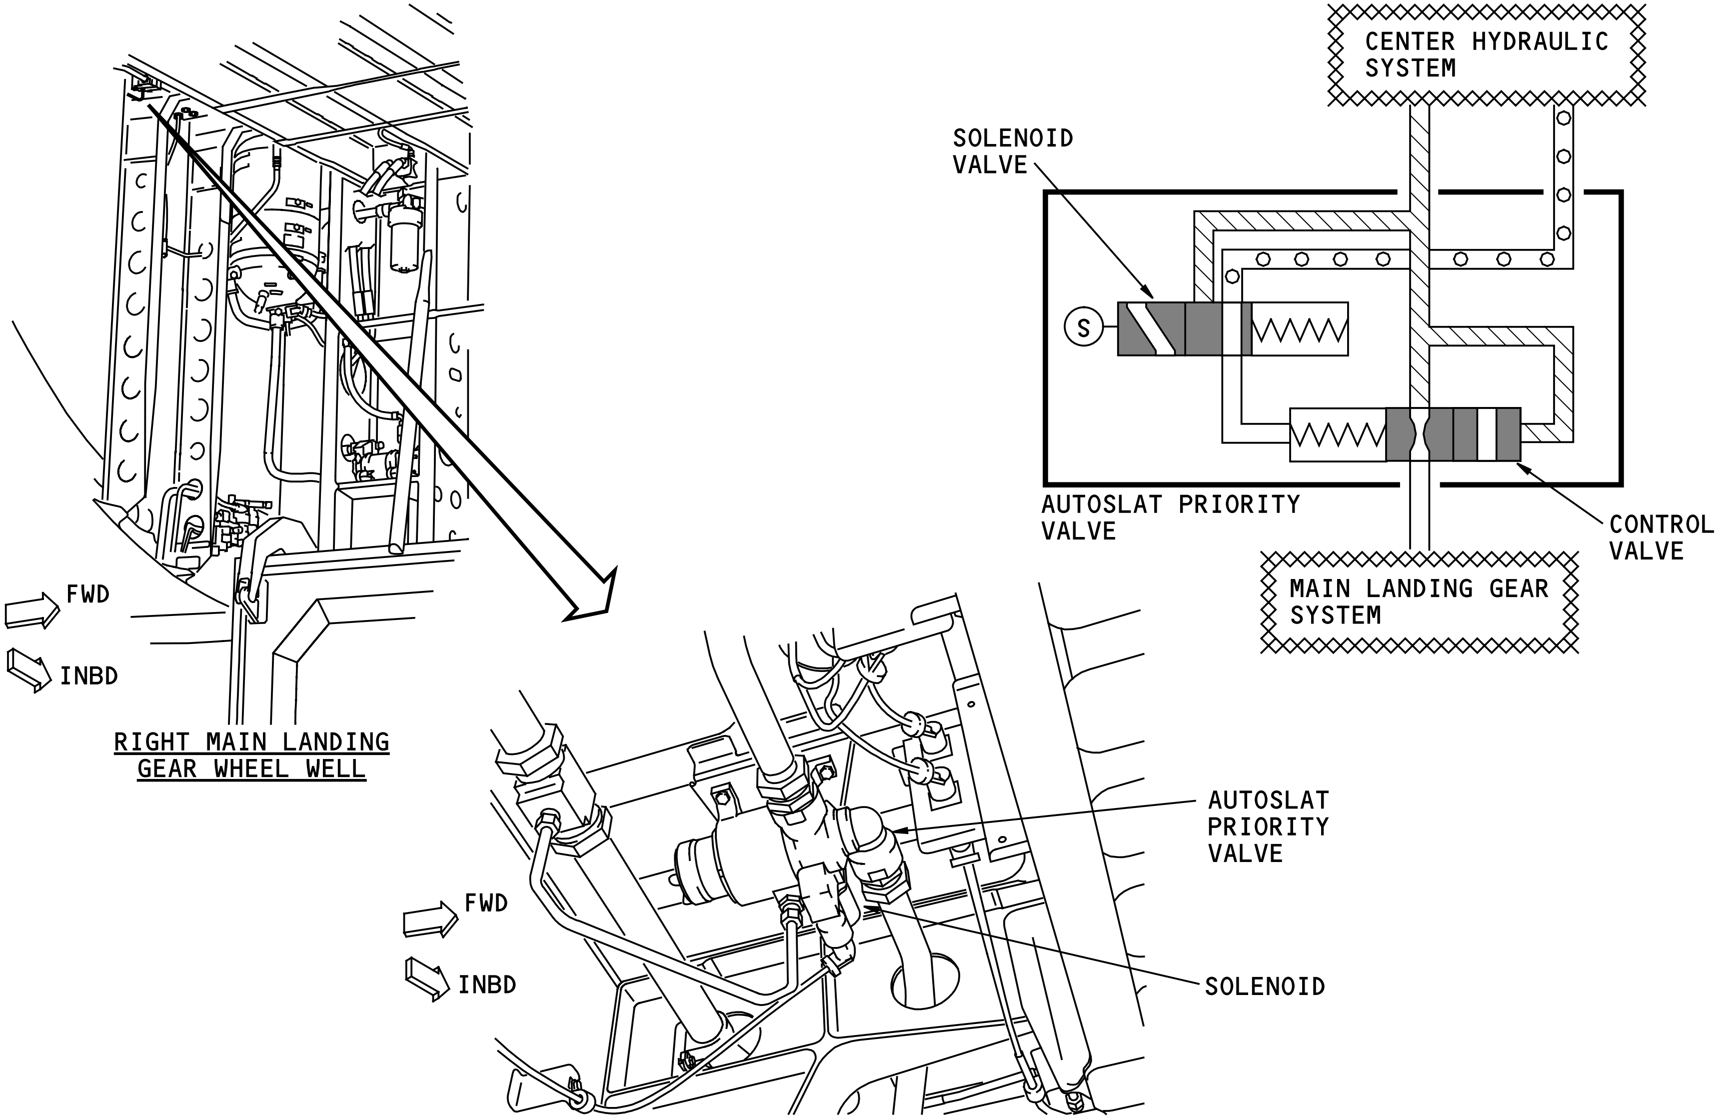
The autoslat priority valve includes a solenoid valve and a control valve.

Functional Description

The control valve receives pilot pressure from the solenoid valve and from the center hydraulic system. When the solenoid valve de-energizes, the control valve permits full hydraulic flow to the MLG system.

During autoslat operation, the solenoid valve energizes. This moves the control valve to the reduced flow position. This reduces the hydraulic flow to the MLG system and gives priority of the hydraulic power to the slats.

If the center hydraulic system pressure is less than approximately 2550 psi, springs force the control valve to the reduced flow position. This reduces the hydraulic flow to the MLG system and gives priority of the hydraulic power to the flaps and slats.



27-81-00-010 Rev 1 01/19/95

LEADING EDGE SLATS - AUTOSLAT PRIORITY VALVE

LEADING EDGE SLATS - ANGLE GEARBOXES

Purpose

The angle gearboxes connect torque tubes that are at different angles to each other. There are four separate angle gearboxes:

- Two floor angle gearboxes
- Two strakelet angle gearboxes.

Location

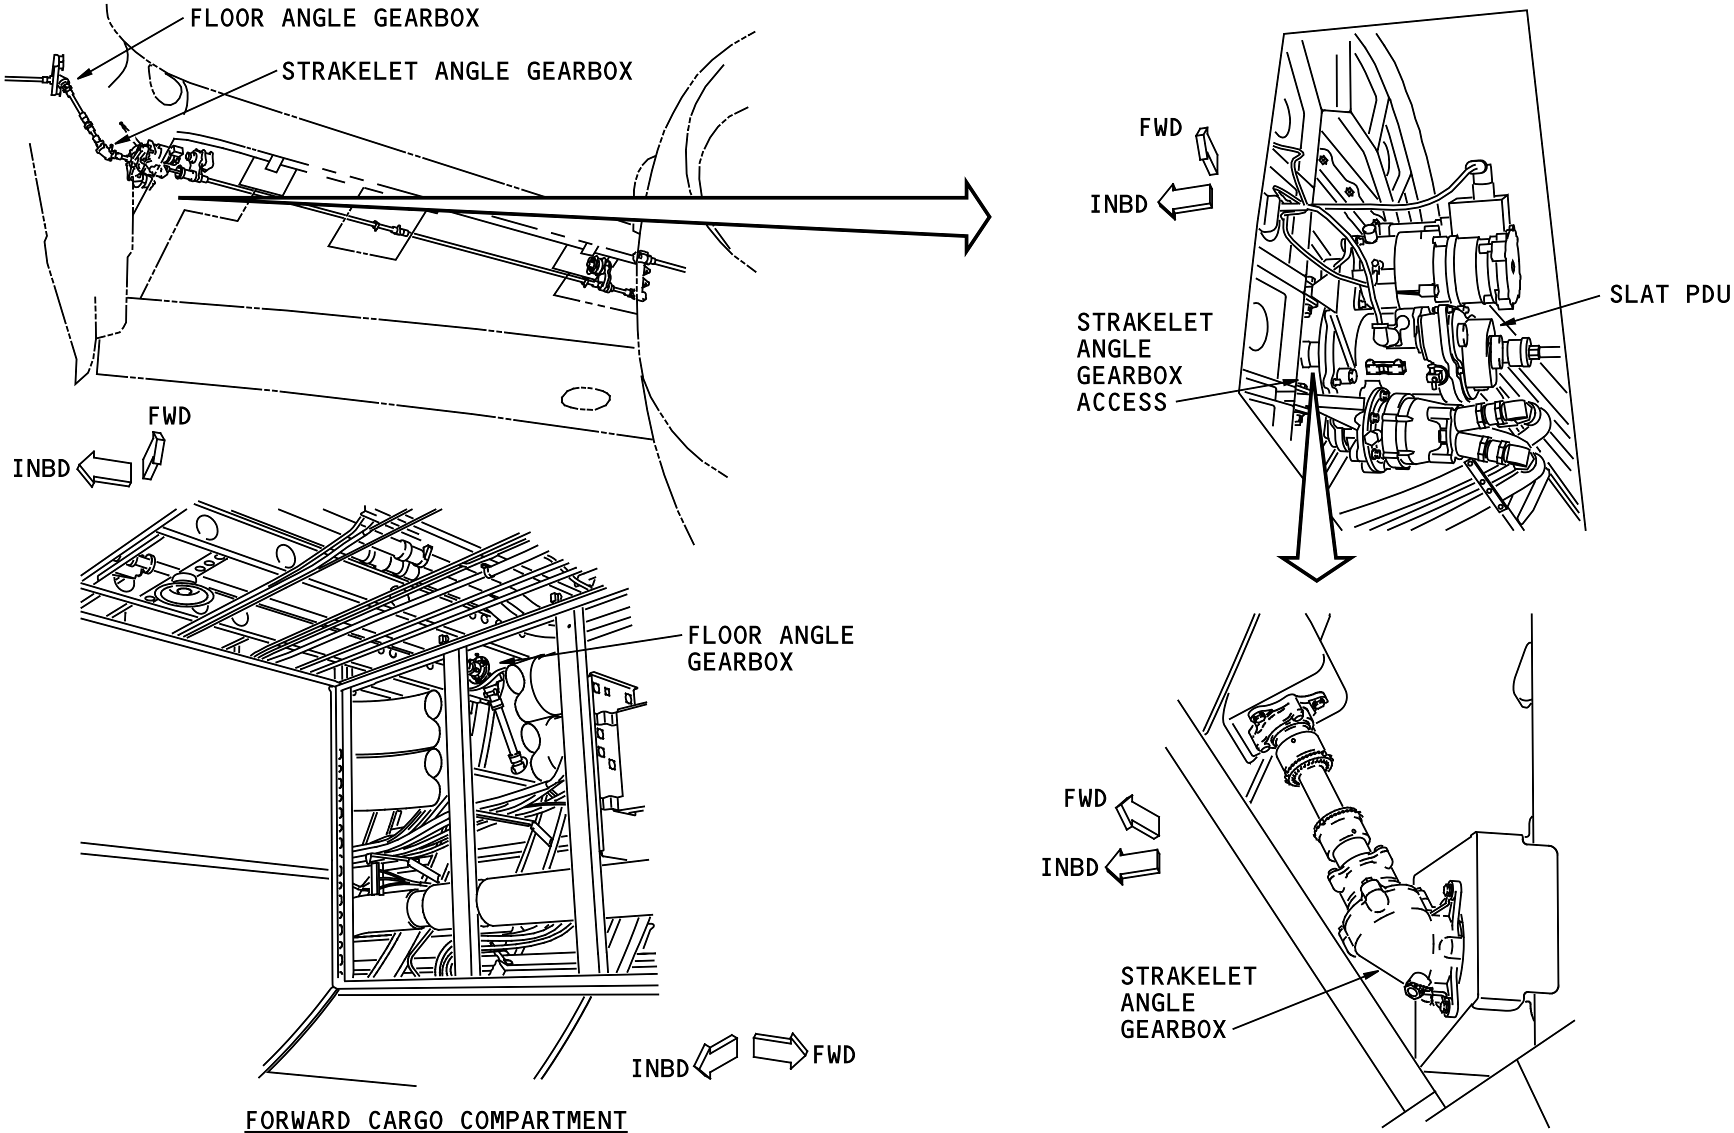
The floor angle gearboxes are just aft and outboard of the forward cargo compartment. Remove the cargo lining in the aft section of the forward cargo compartment to get access.

The strakelet angle gearboxes are on the inboard side of the first rib in the fixed leading edge of the wings. Remove the access panel under the inboard end of the wing to get access.

Physical Description

The angle gearboxes are filled with grease and sealed.

Both of the floor angle gearboxes are identical and both of the strakelet angle gearboxes are identical. Each gearbox weighs approximately 12 lb (5.5 kg).



LEADING EDGE SLATS - ANGLE GEARBOXES

LEADING EDGE SLATS - DRIVELINE OFFSET GEARBOXES

Purpose

The two driveline offset gearboxes connect torque tubes that are offset from each other.

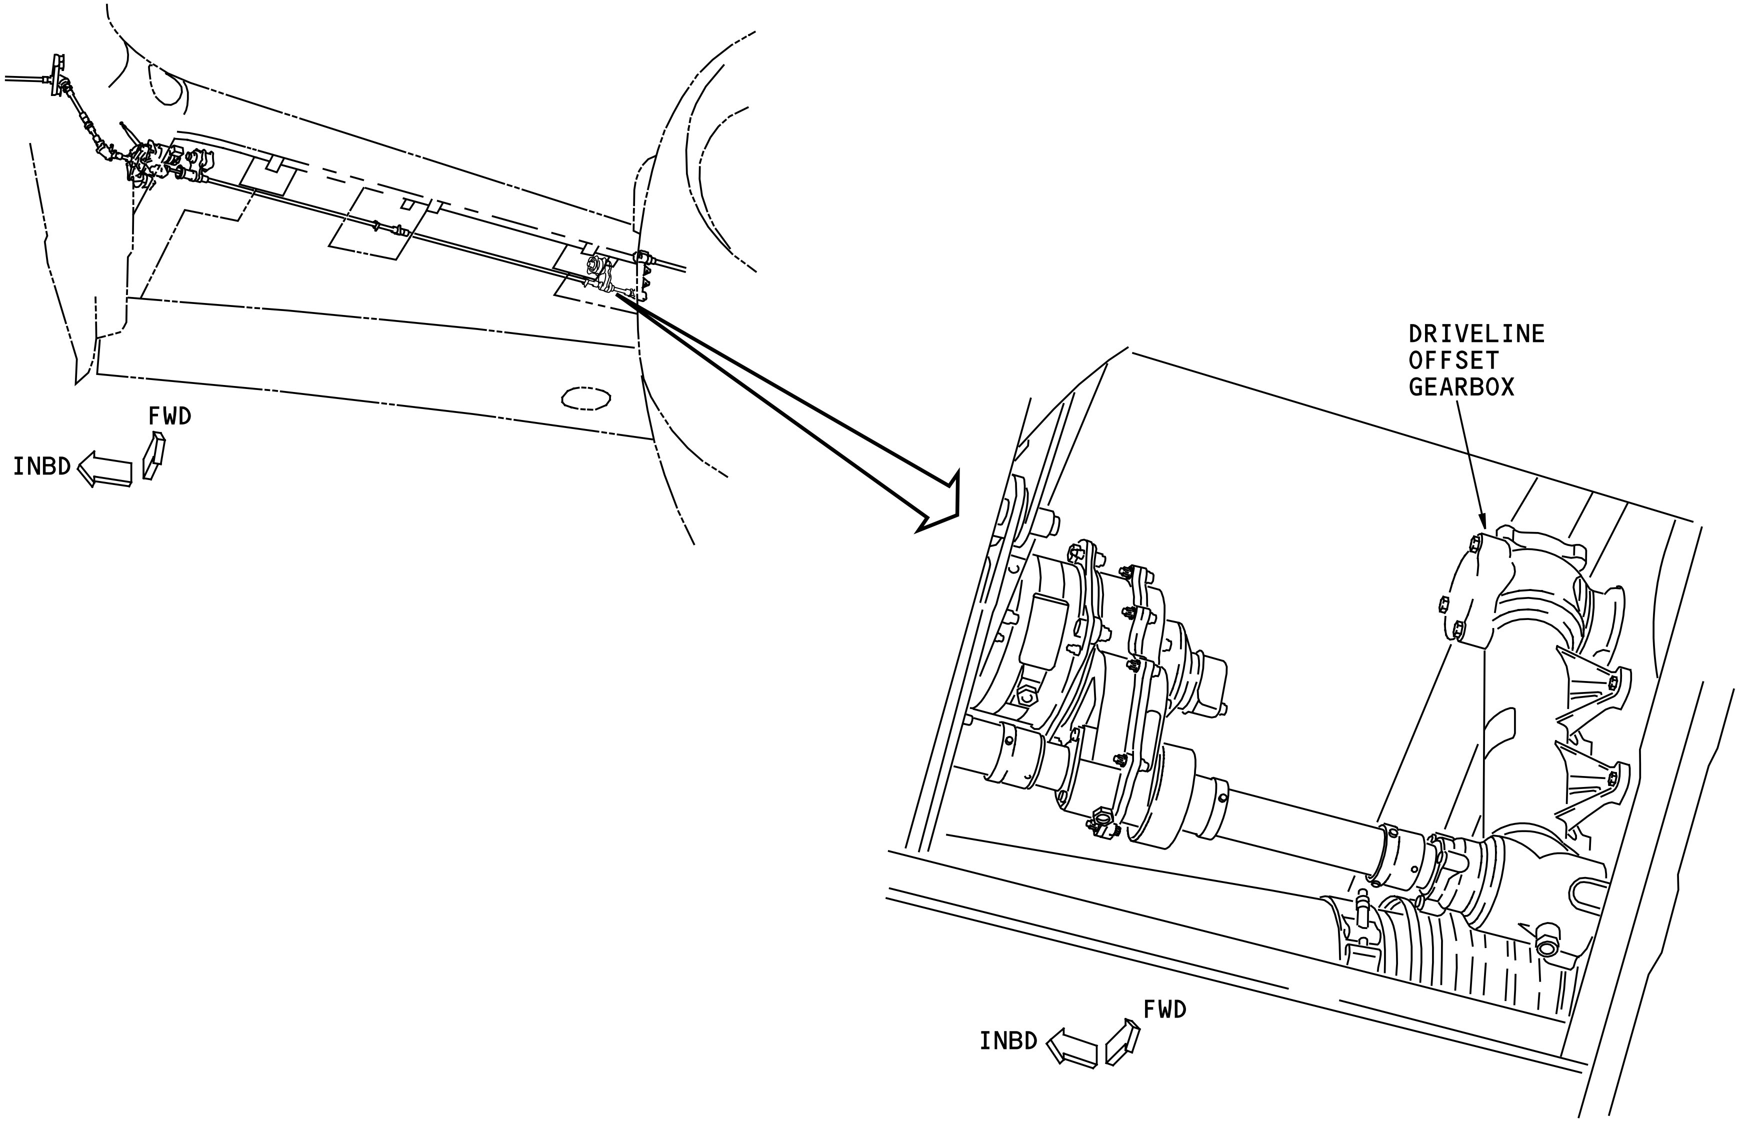
Location

There is one driveline offset gearbox in the fixed leading edge of each wing, between the inboard slat and the krueger flap. Remove the access panel under the wings to get access.

Physical Description

The gearboxes are filled with grease and sealed.

Both of the driveline offset gearboxes are identical. Each gearbox weighs approximately 28 lb (12.7 kg).



27-81-00-013 Rev 2 01/19/95

LEADING EDGE SLATS - DRIVELINE OFFSET GEARBOXES

LEADING EDGE SLATS - NO-BACK BRAKE OFFSET GEARBOXES

Purpose

The no-back brake offset gearboxes get power from the torque tubes to operate the rotary actuators.

Location

The no-back brake offset gearboxes are in the fixed leading edge of the wings. Remove the access panels under the leading edge of the wings to get access.

Physical Description

There are two no-back brake offset gearboxes for each slat. The gearboxes for the inboard slats are similar to the gearboxes for the outboard slats. The gearboxes at the outboard end of the wings are different than the other gearboxes and contain the slat position sensors.

The no-back brake offset gearbox has a no-back brake to help prevent slat retraction if the PDU or a torque tube fails. The no-back brake offset gearbox also has a shearout to prevent excessive loads on the pinion gear if the slat does not move freely.

The no-back brake offset gearboxes are filled with oil and sealed.

The no-back brake offset gearboxes for the inboard slats weigh approximately 16 lb (7 kg). The no-back brake offset gearboxes for the outboard slats weigh approximately 11 lb (5 kg).

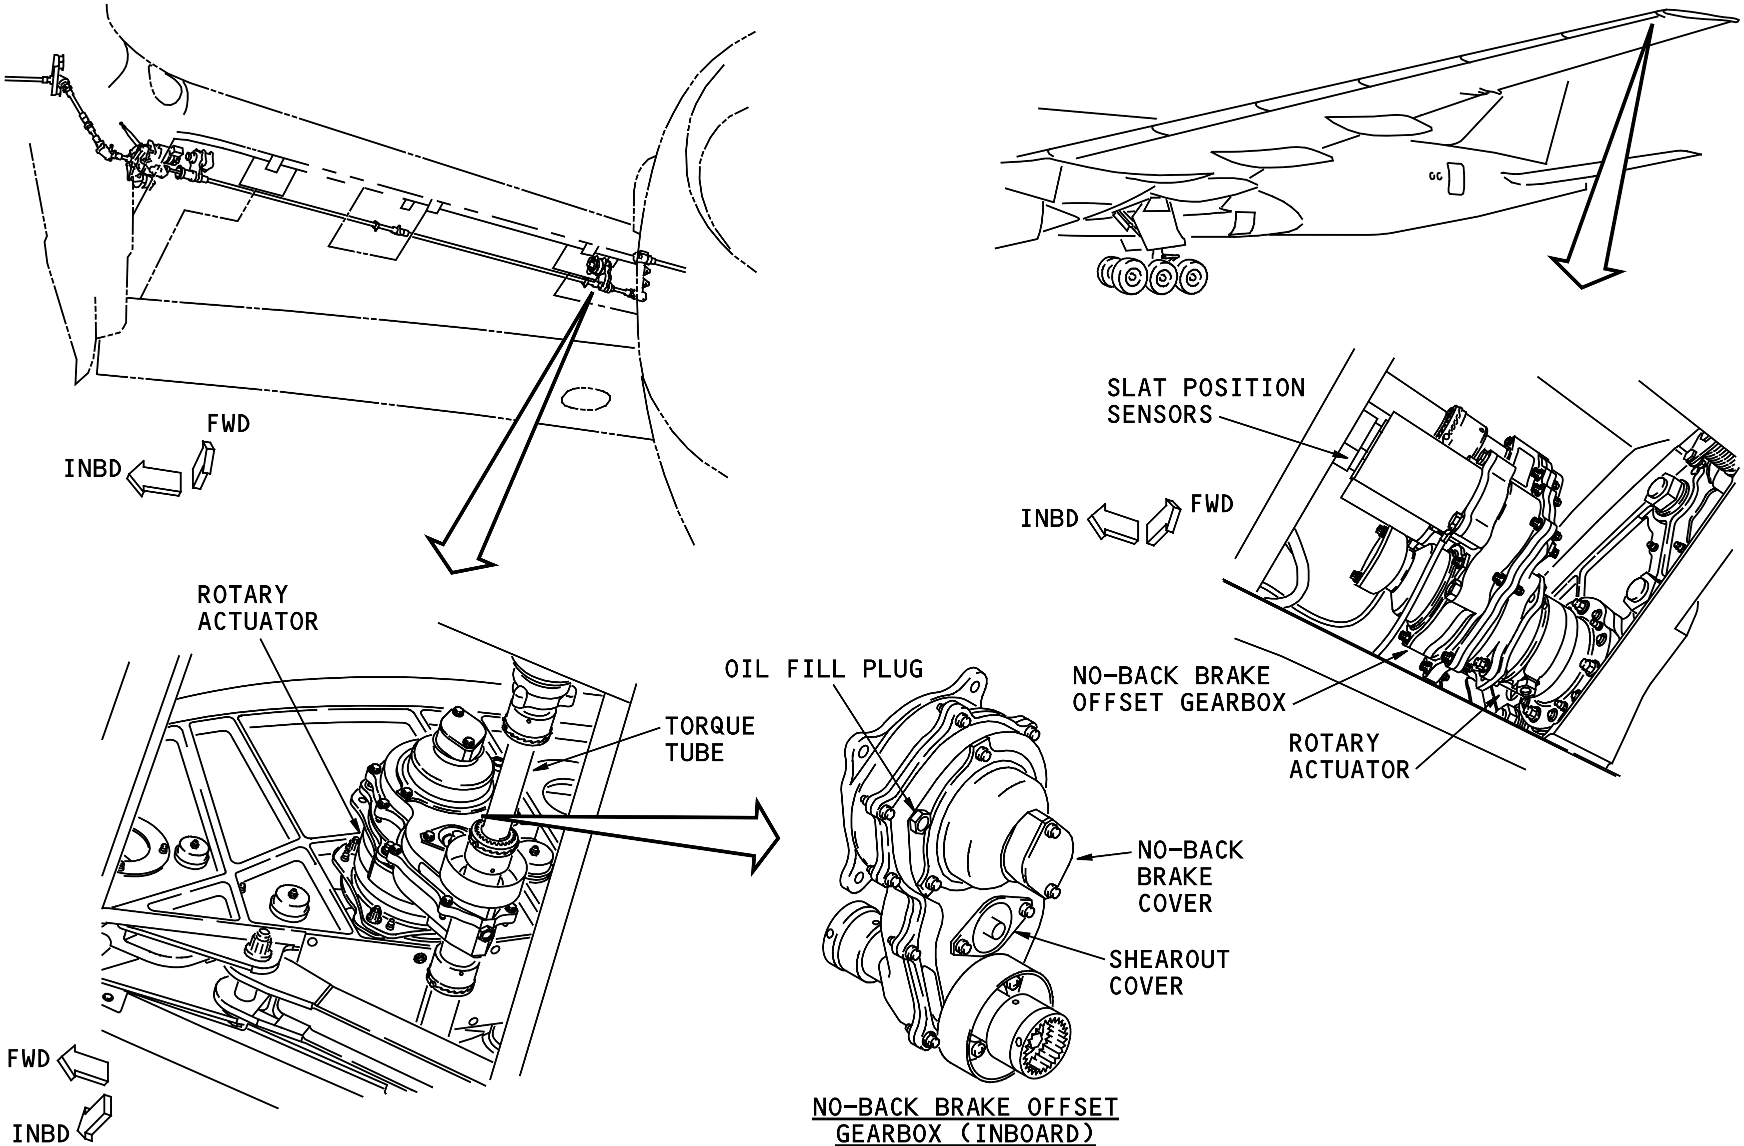
Training Information Point

To do a check of the no-back brake in the no-back brake offset gearbox, manually apply a backdrive torque to the gearbox. To do this, remove the no-back brake cover and connect a manual drive.

CAUTION: DO NOT REMOVE THE OFFSET GEARBOX IF IT HAS A BROKEN SHEAROUT UNTIL YOU REPLACE THE SHEAROUT. THE NO-BACK BRAKE CAN HOLD A HIGH TORQUE AFTER THE FAILURE OF THE SHEAROUT. YOU CAN CAUSE DAMAGE TO THE ROTARY ACTUATOR AND OFFSET GEARBOX.

If you do a check or replace the shearout in the no-back brake offset gearbox, you must drain all the oil in the gearbox. Then remove the shearout cover to gain access to the shearout.

The no-back brake offset gearbox contains oil and it is necessary to do servicing at specified times. Use the oil fill plug.



LEADING EDGE SLATS - NO-BACK BRAKE OFFSET GEARBOXES

LEADING EDGE SLATS - ROTARY ACTUATORS

Purpose

The rotary actuators get power from the no-back brake offset gearboxes to turn the pinion gears.

Location

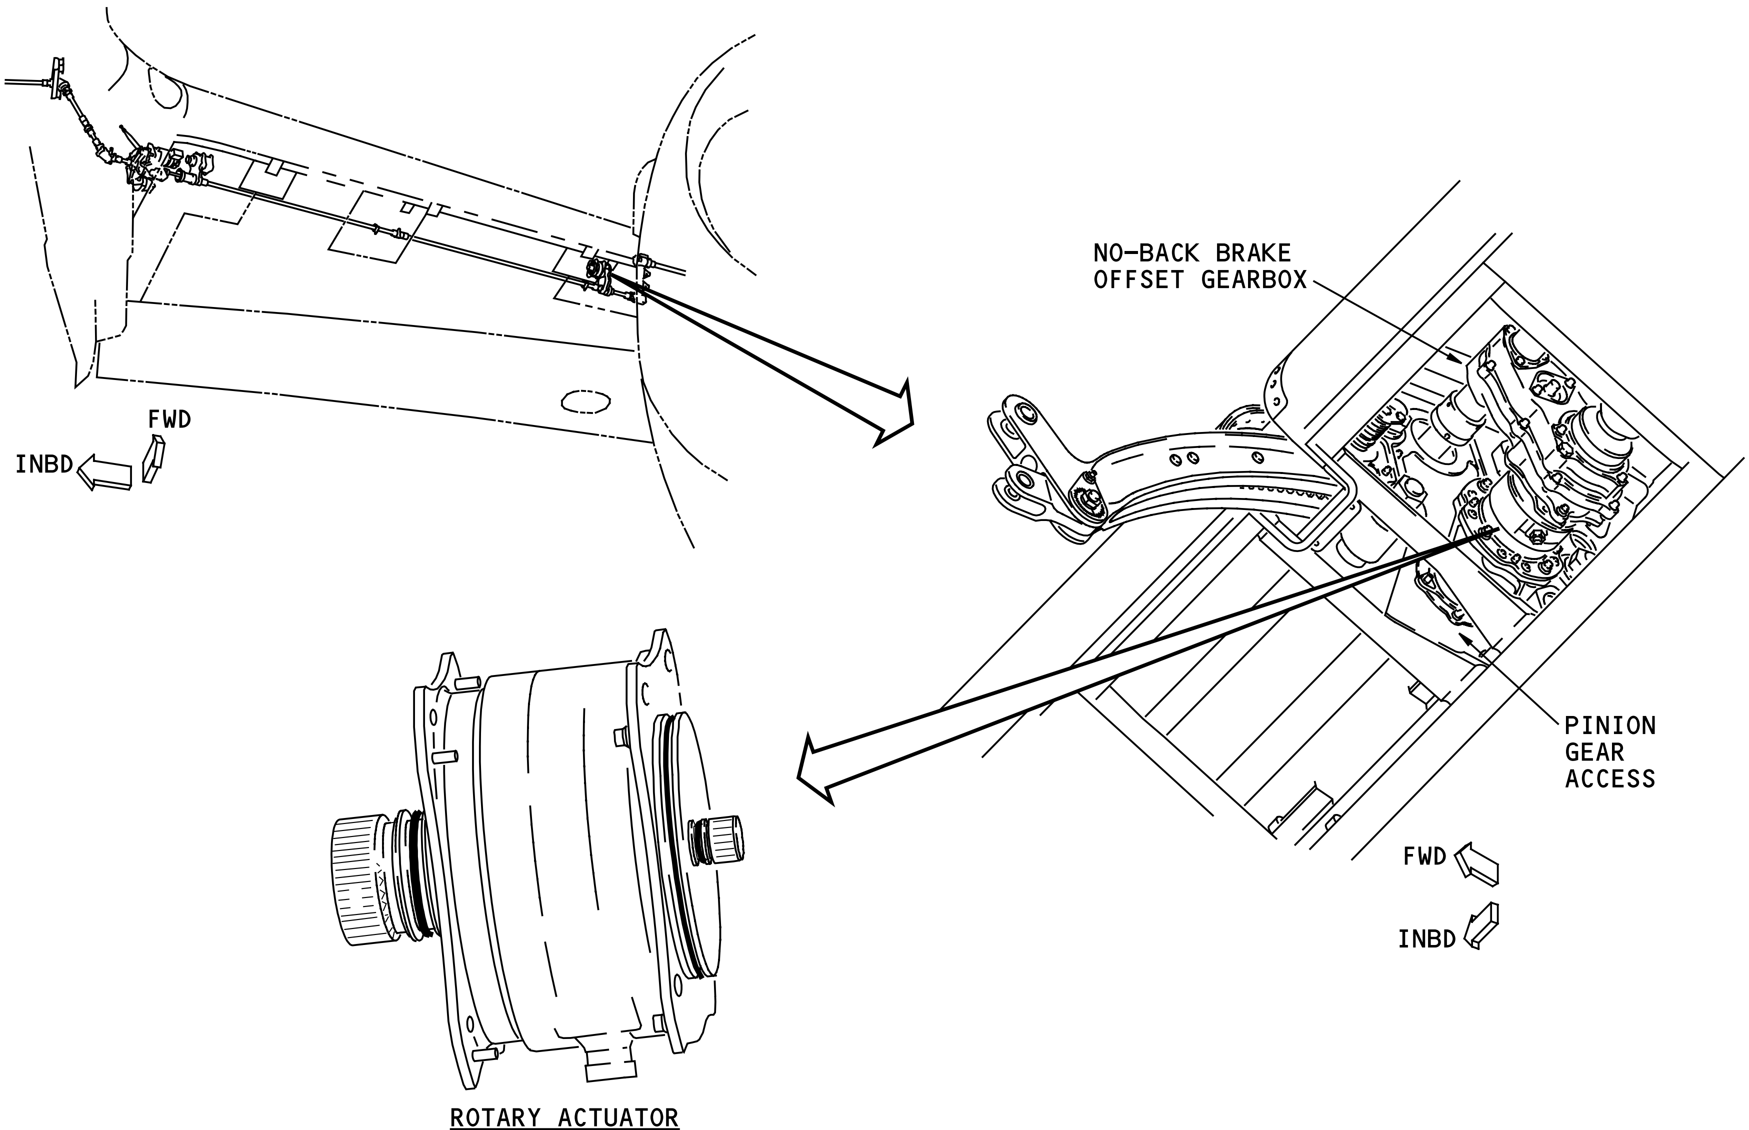
The rotary actuators are in the fixed leading edge of the wings. Remove the access panels under the leading edge of the wings to get access.

Physical Description

There are two rotary actuators for each slat. The rotary actuators for the inboard slats are similar to the rotary actuators for the outboard slats.

The rotary actuators are filled with grease and sealed.

The rotary actuators for the inboard slats weigh approximately 14 lb (6 kg). The rotary actuators for the outboard slats weigh approximately 6.8 lb (3 kg).



27-81-00-015 Rev 3 01/19/95

LEADING EDGE SLATS - ROTARY ACTUATORS

LEADING EDGE SLATS - PINION GEARS AND SLAT MAIN TRACKS

Purpose

The pinion gears receive power from the rotary actuators to move the slat main track. The slat main tracks move the slats.

Location

The pinion gears and main tracks are in the fixed leading edge of the wings. Remove the access panel under the leading edge of the wings to get access.

Pinion Gears

There are two pinion gears for each slat surface. The pinion gears for the inboard slats are different than the pinion gears for the outboard slats.

The pinion gears weigh approximately 4 lb (2 kg) for the outboard slats and 11 lb (5 kg) for the inboard slats.

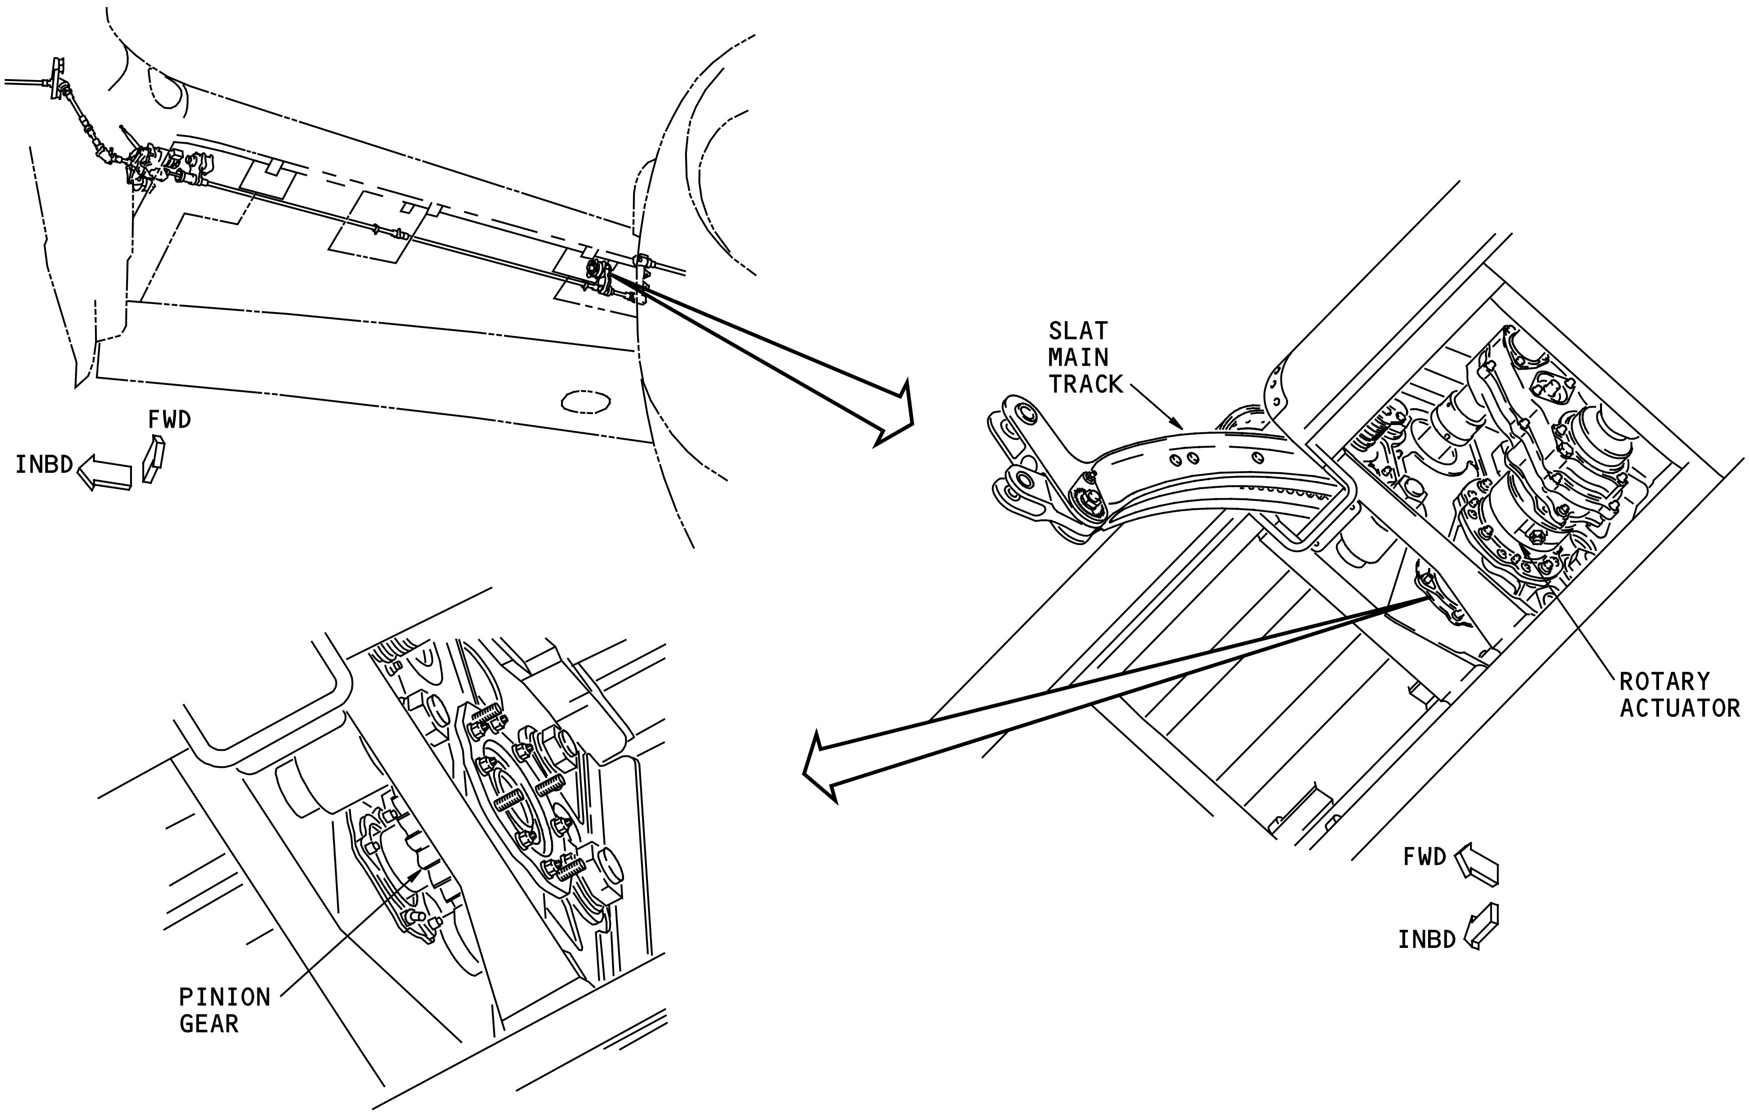
Slat Main Track

There are three slat main tracks (only two are driven by rotary actuators) for each inboard slat and two slat main tracks for each outboard slat. The slat main tracks for the inboard slats are different than the slat main tracks for the outboard slats.

The slat main tracks have stops at both ends to prevent over-travel of the slat surface. During normal slat operation, the main track does not touch the stops.

Training Information Point

The center main track of the inboard slats does not have stops. Make sure that you hold the center main track so it does not fall when you remove the inboard slat.



27-81-00-016 Rev 3 01/19/95

LEADING EDGE SLATS - PINION GEARS AND SLAT MAIN TRACKS

LEADING EDGE SLATS - AUXILIARY ARM AND TRACK

Purpose

The auxiliary arm and track control the rotation of the inboard slats as the slats extend.

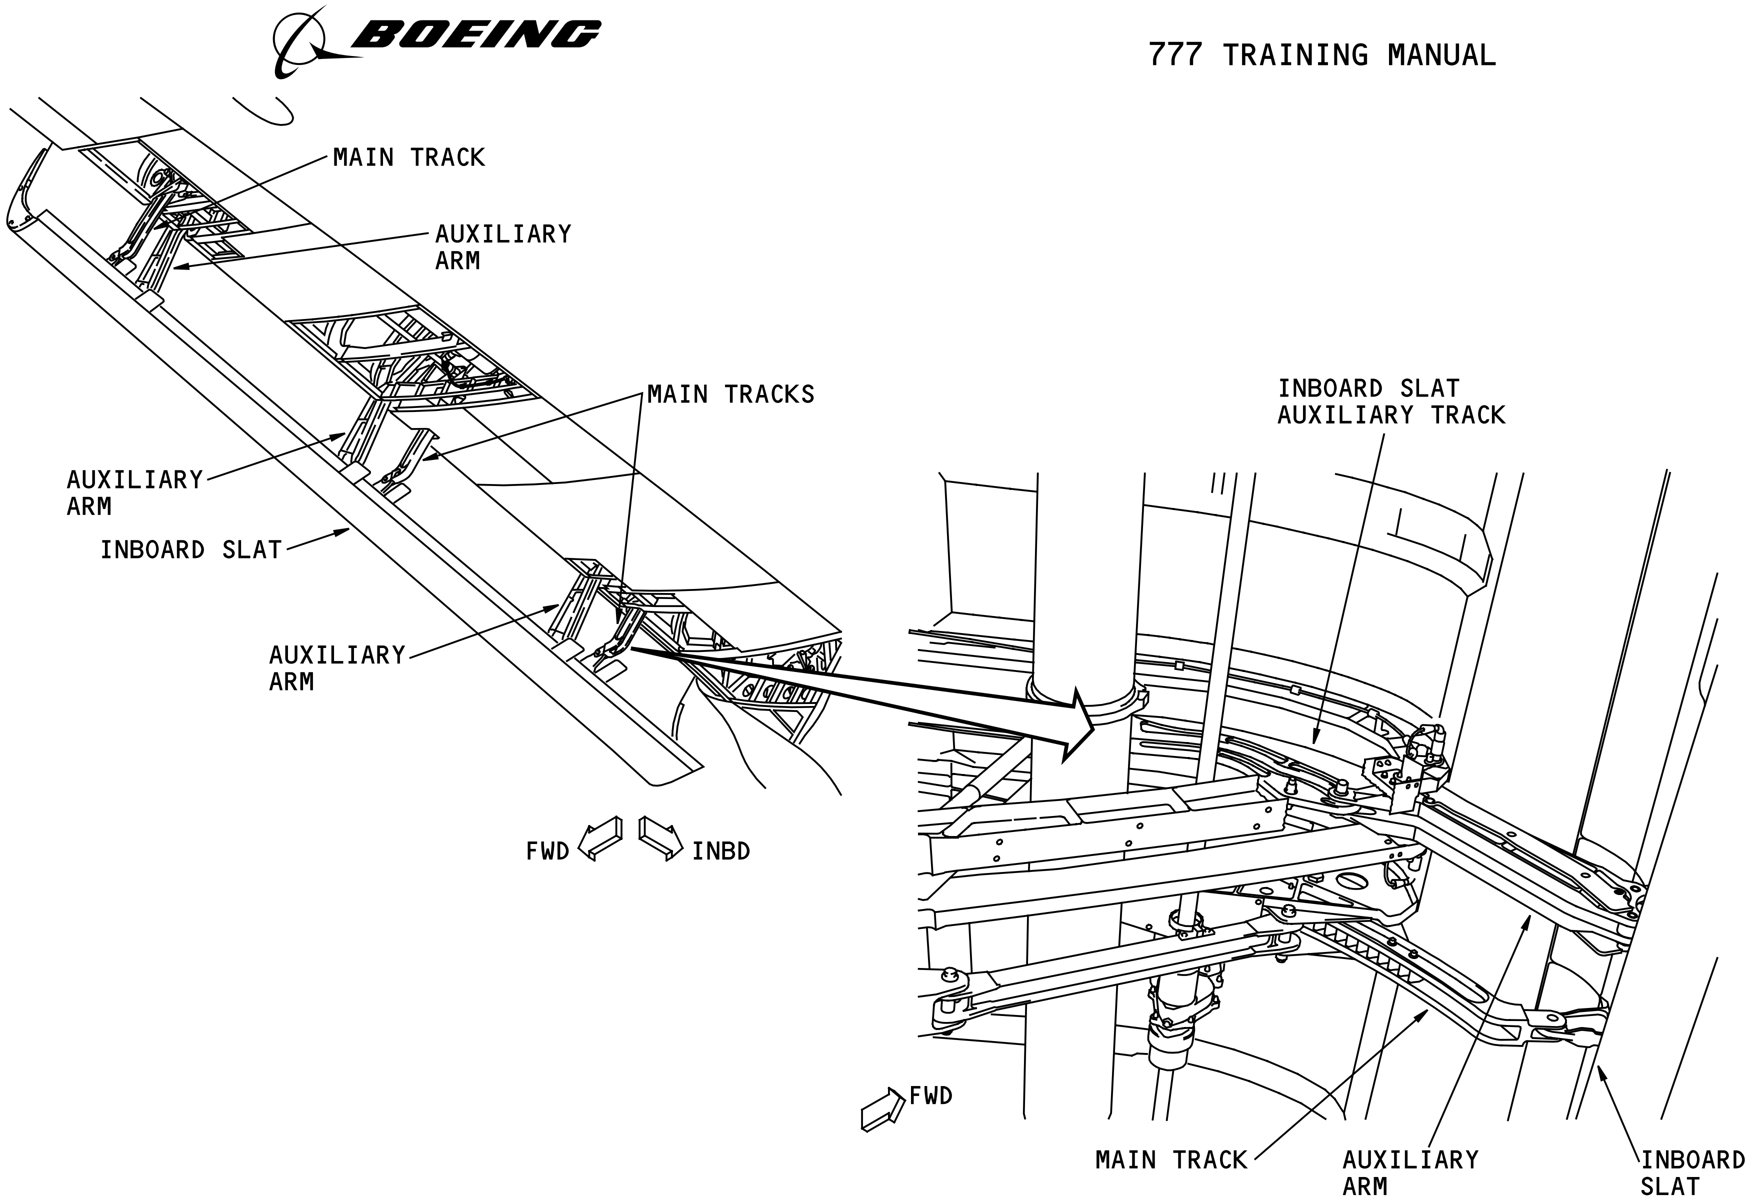
There are three auxiliary arms and tracks for each inboard slat. The outboard slats do not use auxiliary arms or tracks.

Location

The auxiliary arms attach to the slats. The auxiliary tracks are in the fixed leading edge of the wings. Remove the access panels under the wing to get access.

Physical Description

The auxiliary arms have rollers which move in grooves in the auxiliary tracks. As the slats move, the auxiliary arms force the slats to rotate.



LEADING EDGE SLATS - AUXILIARY ARM AND TRACK

LEADING EDGE SLATS - KRUEGER FLAP OFFSET GEARBOX, TORQUE TUBE, AND ROTARY ACTUATOR

General

The krueger flaps seal the gap between the inboard slat and the engine strut. This increases the effect of the slats. There is one krueger flap offset gearbox, torque tube, and rotary actuator for each krueger flap.

Location

The krueger flap is between the inboard slat and the engine strut, along the leading edge of each wing. The krueger flap actuation assembly is in the fixed leading edge of the wings, between the engine and the inboard slat. Remove the access panel on the upper side of the wing or extend the slats to get access.

Krueger Flap

The krueger flaps are made of aluminum skins and aluminum castings. The width of the krueger flaps is approximately 30 inches (0.76 m) and it weighs approximately 19 lb (9 kg).

The krueger flap has two positions: retracted and extended. It moves to the extended position when the slats are in the sealed or gapped positions. It moves to the retracted position when the slats are at the up position.

Offset Gearbox

The offset gearbox connects to the slat drive torque tubes. Gears in the offset gearbox transmit the power from the torque tubes to the rotary actuator.

The offset gearbox is filled with grease and sealed. The offset gearbox weighs approximately 8 lb (4 kg).

Torque Tube

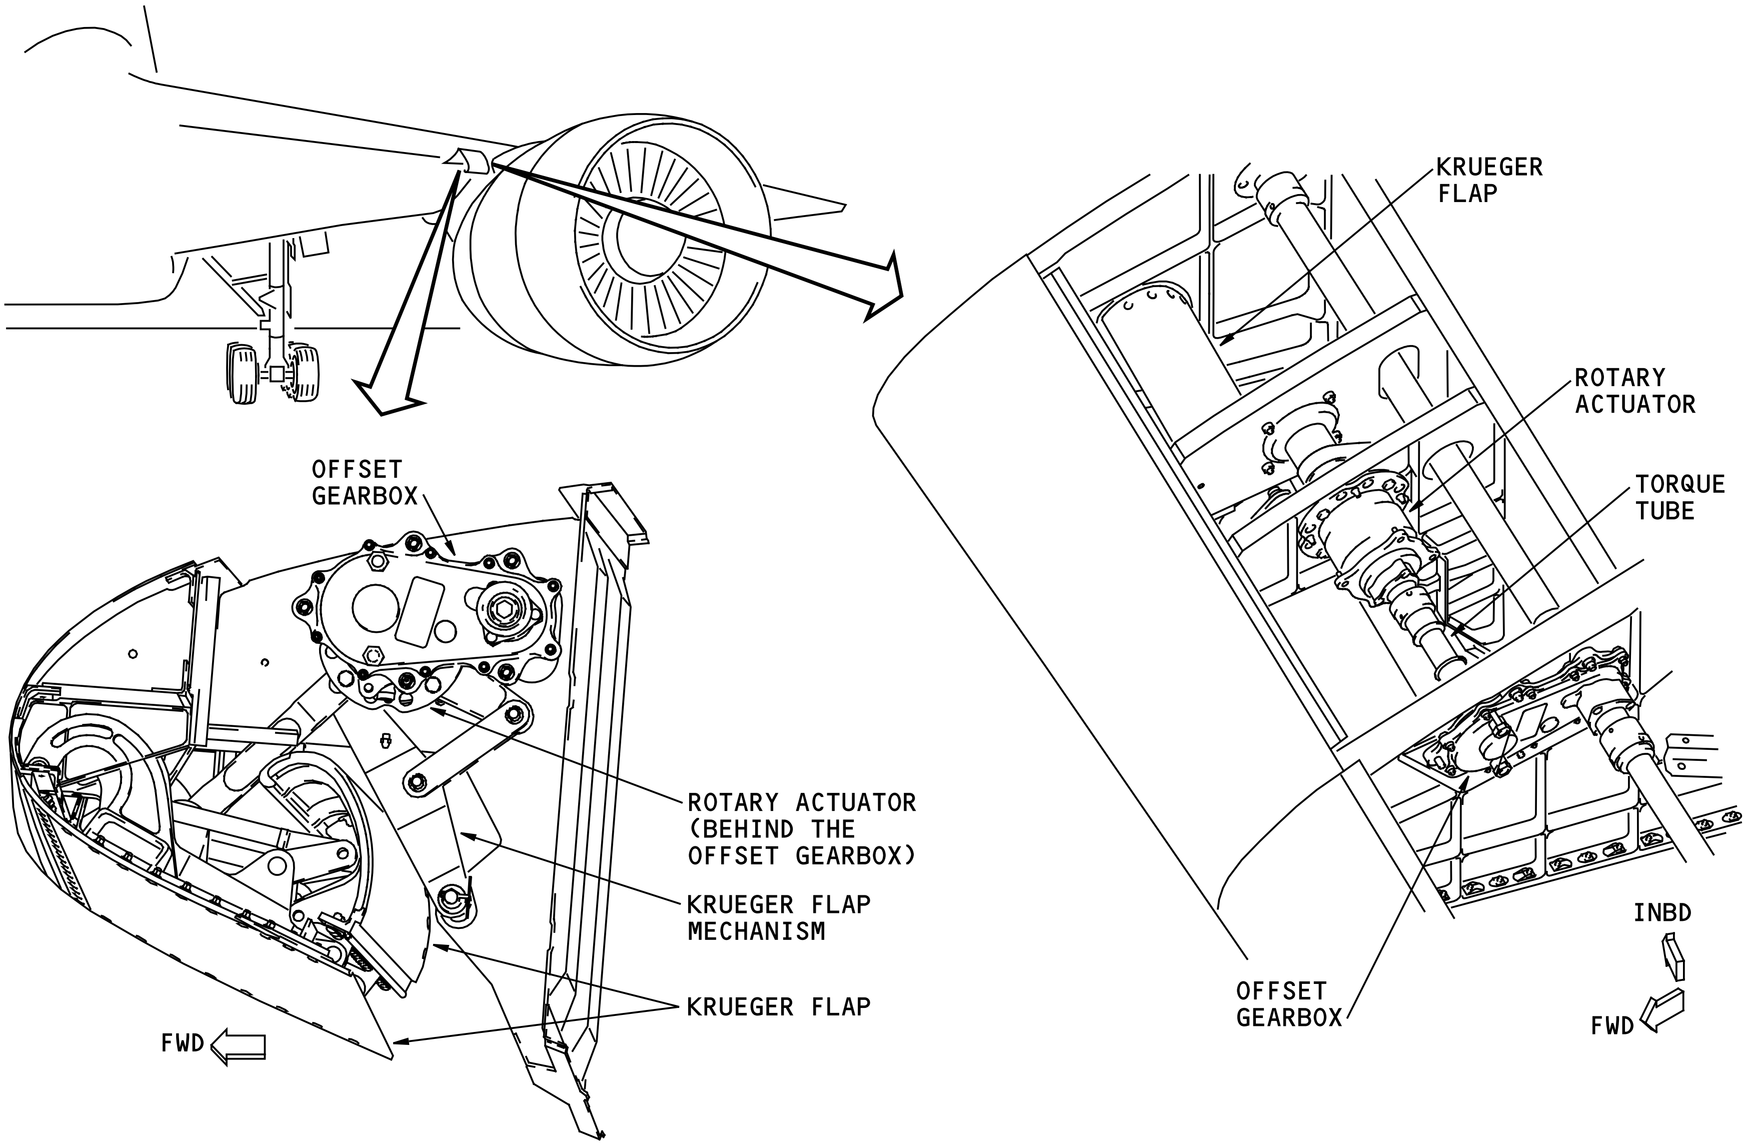
The torque tube transmits the power from the gearbox to the rotary actuator.

The end fittings are bolted on to the ends of the torque tube.

Rotary Actuator

The offset gearbox turns the rotary actuator. The rotary actuator moves the krueger flap mechanism.

The rotary actuator is filled with grease and sealed. The rotary actuator weighs approximately 6 lb (3 kg).



27-81-00-019 Rev 3 04/29/95

LEADING EDGE SLATS - KRUEGER FLAP OFFSET GEARBOX, TORQUE TUBE, AND ROTARY ACTUATOR

LEADING EDGE SLATS - KRUEGER FLAP MECHANISM

Purpose

The krueger flap mechanism moves the krueger flap.

Location

The krueger flap mechanism is in the fixed leading edge of the wings, between the engine and the inboard slat. Remove the access panel on the upper side of the wing to get access.

Functional Description

There is one krueger flap mechanism for each krueger flap.

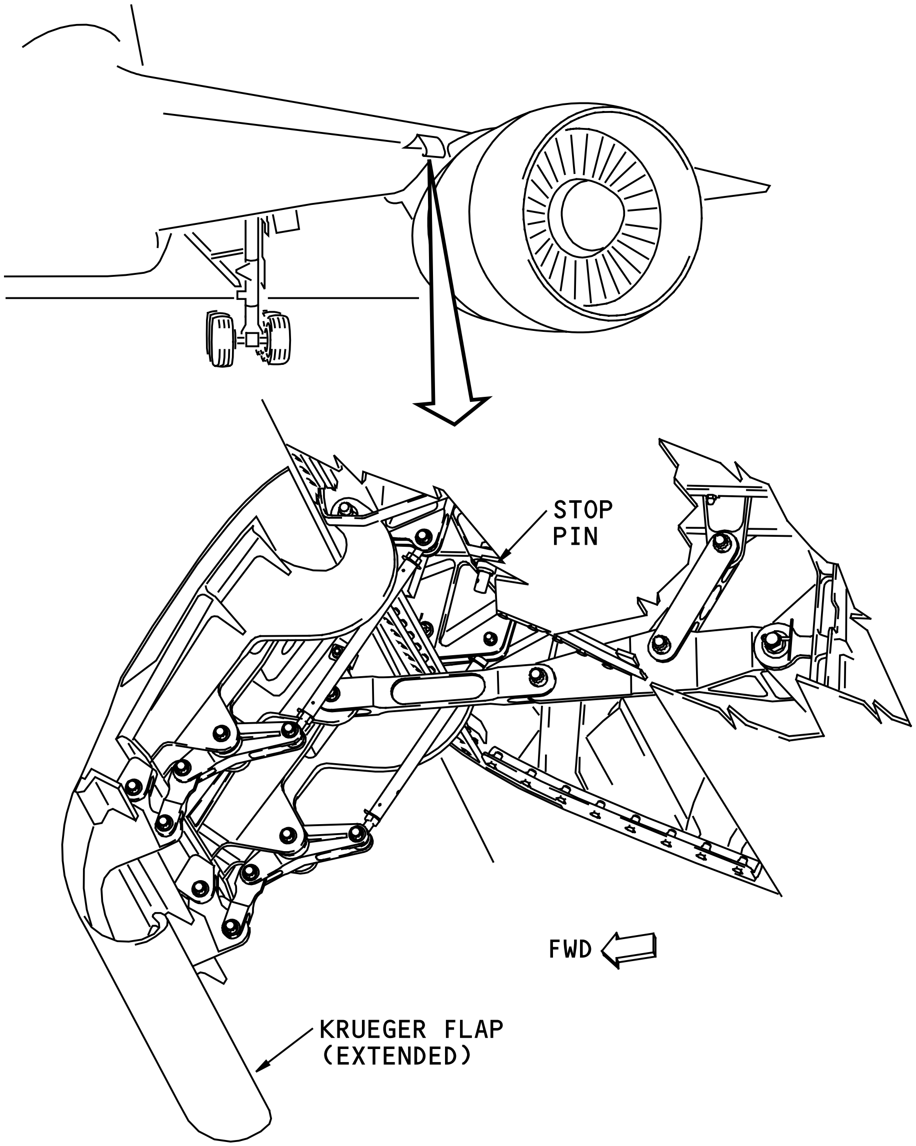
The krueger flap mechanism attaches to the rotary actuator. As the rotary actuator rotates, the links in the krueger flap mechanism move. These links force the krueger flap to extend or retract.

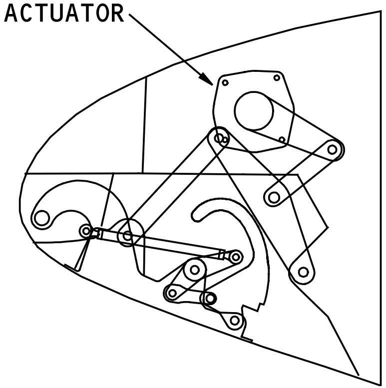
As the slats extend to the sealed position, the krueger flap moves to the extended position. As the slats extend to the gapped position, the geometry of the links in the krueger flap mechanism prevent more movement of the krueger flap.

Training Information Point

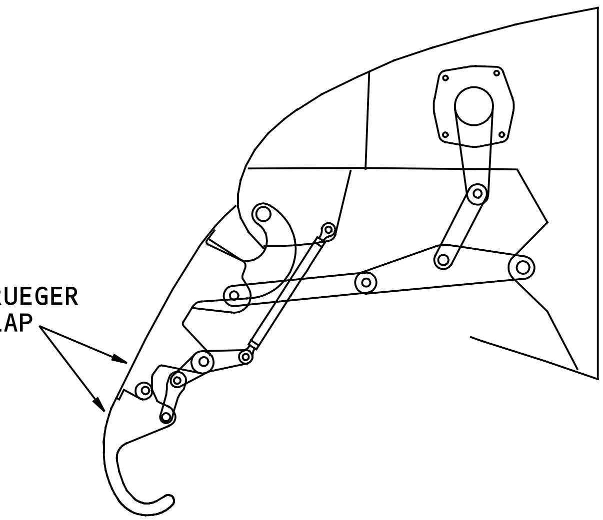
When you rig the LE slat system, preload the krueger flap rotary actuator with the slats in the retracted position.

Adjust the stop pin to align the krueger flap with the leading edge of the wing.





KRUEGER FLAP MECHANISM - RETRACTED



KRUEGER FLAP MECHANISM - EXTENDED

LEADING EDGE SLATS - KRUEGER FLAP MECHANISM

LEADING EDGE SLATS - FUNCTIONAL DESCRIPTION - PRIMARY MODE CONTROL

THIS PAGE INTENTIONALLY LEFT BLANK

LEADING EDGE SLATS - FUNCTIONAL DESCRIPTION - PRIMARY MODE CONTROL

General

Only one FSEU commands the slats in the primary mode.

In the primary mode, the FSEU controls:

- Slat retraction and extension
- Flap/slat sequence
- Cruise inhibit
- Hydraulic isolation (CHIS)
- Autoslat extension
- Low-speed control
- Shutoff control.

For redundancy, both channels in the FSEU must agree on the slat command. Each channel controls switches that are connected in series. Both channels must send the same command to the switches for the FSEU to energize the commanded solenoid.

The two coils in each solenoid of the primary control valve receive electrical power from different power sources. The FSEU controls the ground for one of the coils in each solenoid.

The FSEU also controls the solenoid in the autoslat priority valve.

Slat Retraction and Extension

The FSEU compares the flap lever position to the slat position. The slats retract if the flap lever position is less than the slat position. The slats extend if the flap lever position is greater than the slat position.

Flap/Slat Sequence

This function controls the sequence of the retraction and extension of the flaps and slats.

See the high lift control section for more information about the primary mode flap and slat sequence (AMM PART I 27-03).

Cruise Inhibit

This function prevents slat extension during cruise. This happens when the airspeed is more than 265 knots or the altitude is above 20,300 feet.

Hydraulic Isolation (CHIS)

If the hydraulic quantity in the center hydraulic system reservoir is below 0.40, the FSEUs disengage the primary slat mode. The FSEUs then engage the secondary mode for the slats only. If both engines continue operating for more than 10 seconds, then the primary mode re-engages.

See the main hydraulic system section for more information about the center hydraulic isolation system (AMM PART I 29-10).

LEADING EDGE SLATS - FUNCTIONAL DESCRIPTION - PRIMARY MODE CONTROL

Autoslat Extension

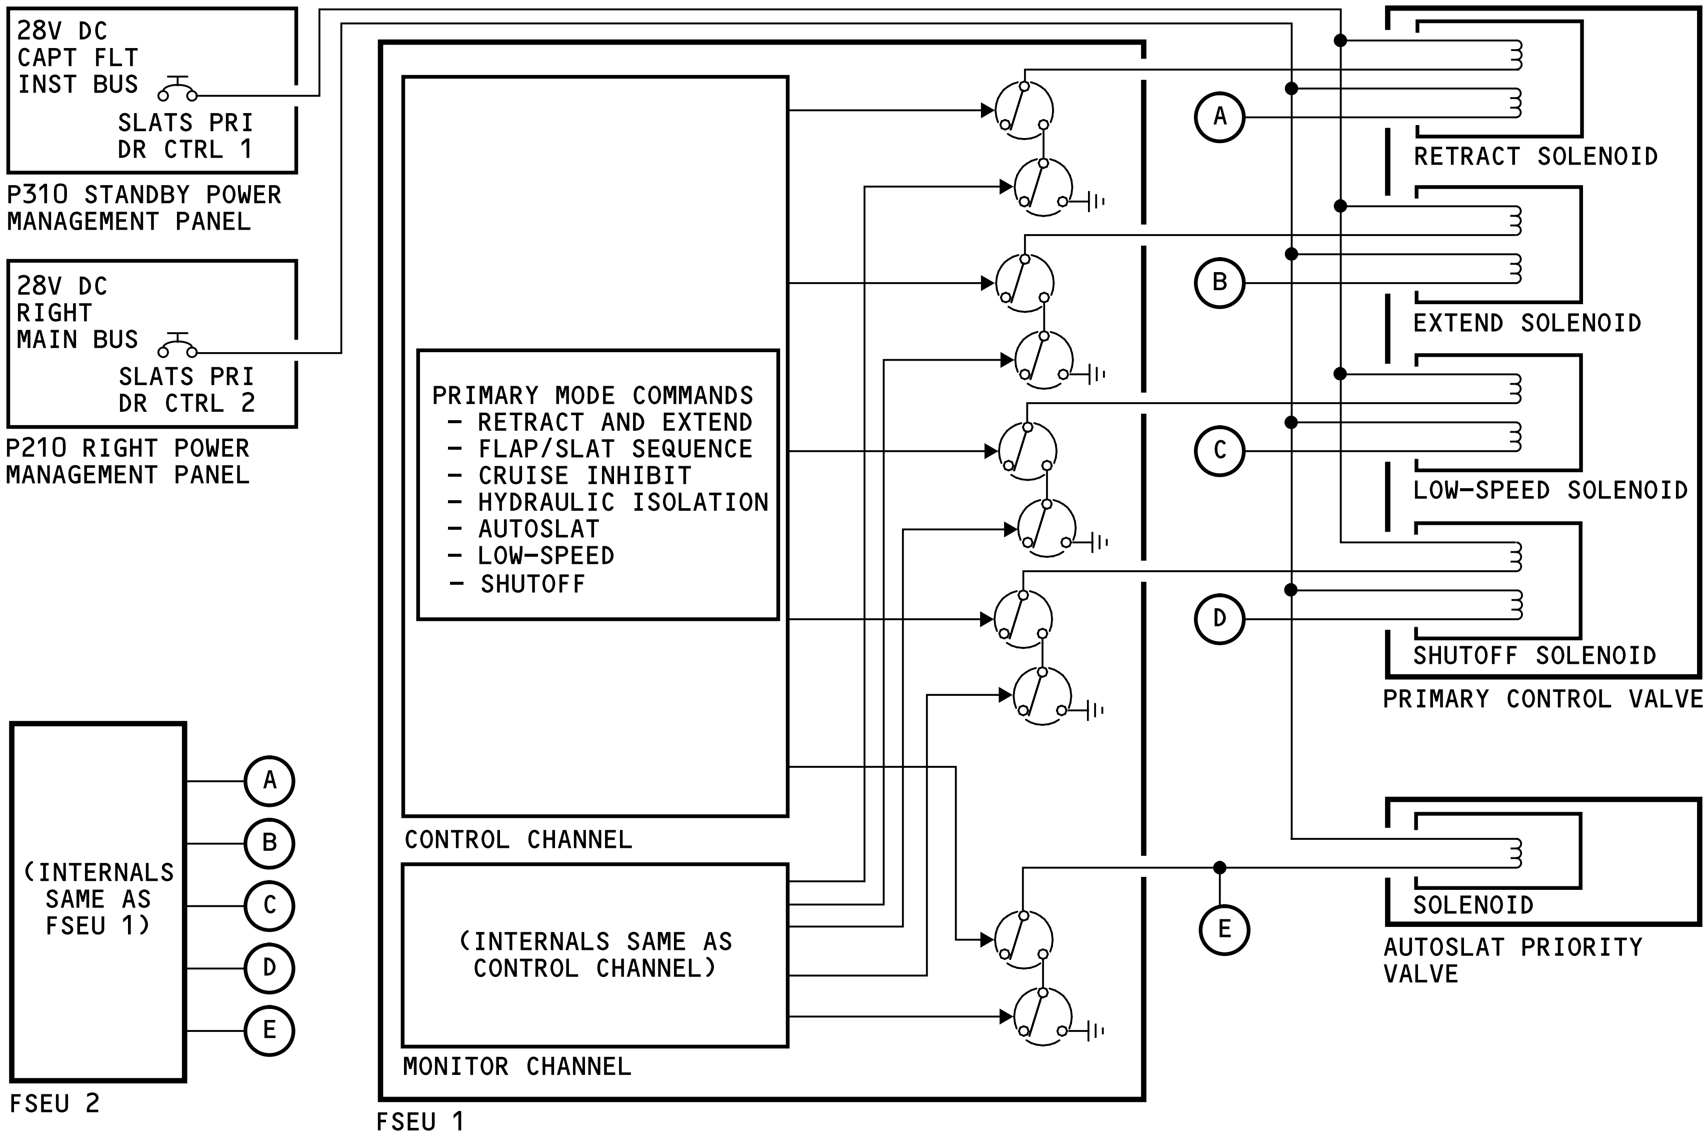
This function commands the slats to extend if the airplane approaches a stall condition. To make sure the slats receive enough hydraulic power, the FSEUs also command the autoslat priority valve to reduce the hydraulic flow to the main landing gear system.

Low-Speed Control

This function reduces the speed of slat movement as the slats approach the commanded position. The FSEU energizes the low-speed solenoid when the slats are less than approximately seven torque tube turns from the commanded position.

Shutoff Control

The FSEU energizes the shutoff solenoid valve to open when there is a retract or extend command.



LEADING EDGE SLATS - FUNCTIONAL DESCRIPTION - PRIMARY MODE CONTROL

LEADING EDGE SLATS - FUNCTIONAL DESCRIPTION - AUTOSLAT EXTENSION

General

The autoslat extension function improves the wing stall performance if the airplane approaches a stall condition. This function also makes sure the slats get enough hydraulic power when the autoslat function is active.

Autoslat

The autoslat function operates only in the primary mode and when the slats are in the sealed position. This function does not operate if the airspeed is more than 239 knots.

The warning electronics unit (WEU) sends an autoslat request to the FSEUs if the airplane approaches a stall condition. If the flap lever is in the 1, 5, 15, or 20 unit positions at this time, the FSEUs command the slats to extend to the gapped position. At this same time, the FSEUs energize the solenoid in the autoslat priority valve. This reduces the hydraulic flow to the landing gear systems. Thus, more hydraulic power can go to the slats.

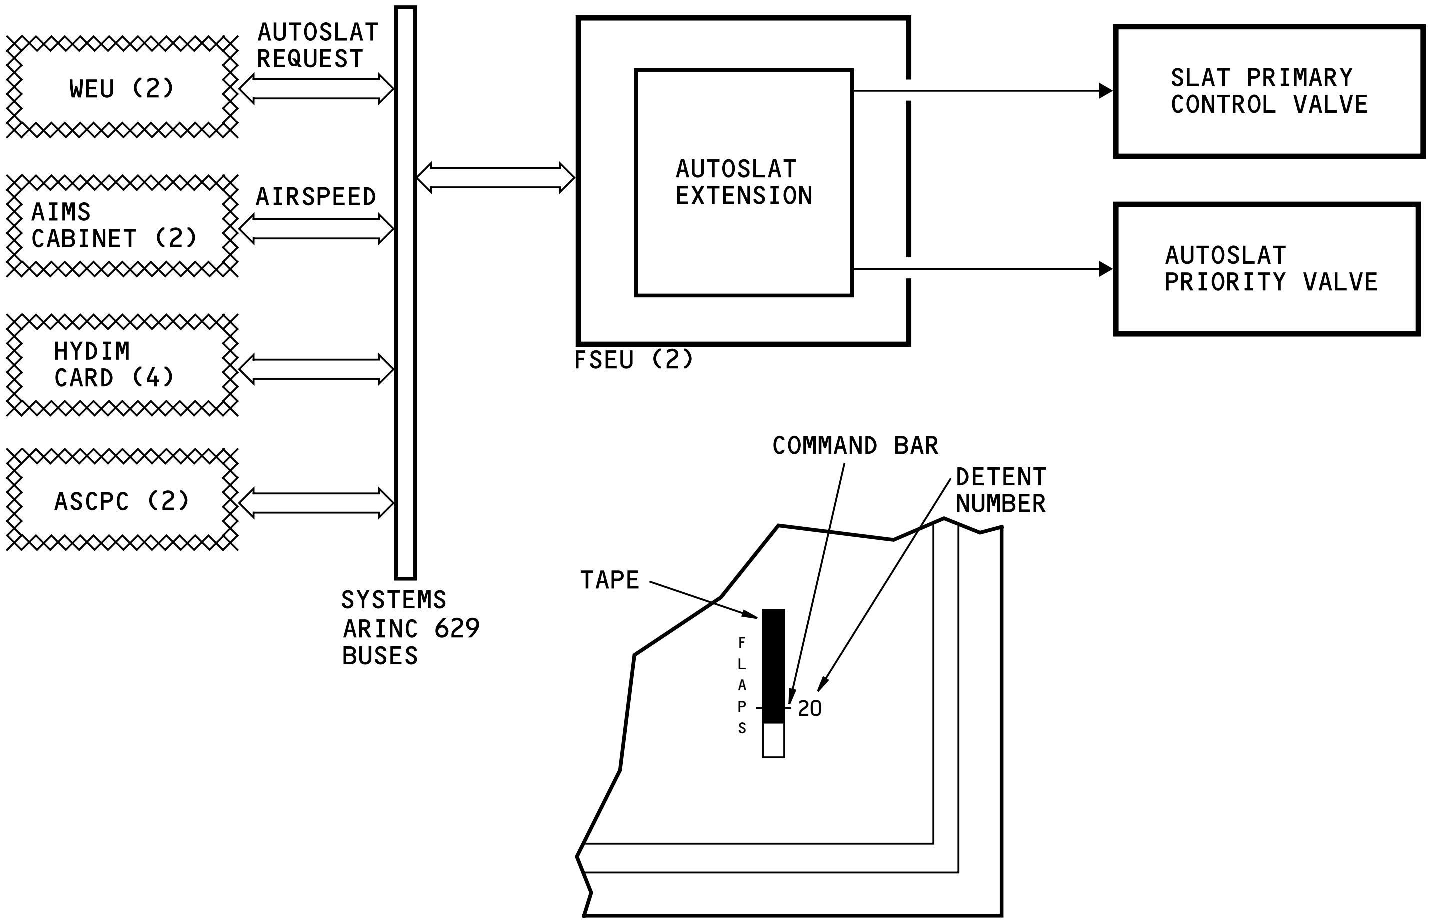
The WEU also sends an autoslat request to the HYDIM cards and the air supply-cabin pressure controllers (ASCPCs). The HYDIM cards turn on both air driven pumps (ADPs). The ASCPCs operate some pneumatic valves to make sure the ADPs get enough air power.

See the main hydraulic system section for more information about the center hydraulic system (AMM PART I 29-10). See the pneumatic chapter for more information about the ASCPCs and the pneumatic system (AMM PART I 36).

Five seconds after the WEU removes the autoslat request, the FSEUs command the slats back to their commanded position and de-energize the solenoid in the autoslat priority valve.

Indication

There are no messages to show that the autoslat function is active. The only indication is on the flap/slat position indication on the EICAS display and the EICAS compacted engine display. The tape in the indication extends beyond the commanded position. The color of the command bar and the detent number change to magenta.



27-81-00-025 Rev 5 01/08/96

LEADING EDGE SLATS - FUNCTIONAL DESCRIPTION - AUTOSLAT EXTENSION

THIS PAGE INTENTIONALLY LEFT BLANK

LEADING EDGE SLATS - FUNCTIONAL DESCRIPTION - SECONDARY MODE CONTROL

General

The operation of the slats in the secondary mode is the same as for the flaps.

See the trailing edge flaps section for more information about the flaps secondary mode control (AMM PART I 27-51).

Only one FSEU commands the slats in the secondary mode. The FSEU controls:

- Secondary mode engage
- Retraction and extension
- Flap/slat sequence
- Cruise inhibit
- Slat Load relief
- Secondary mode auto test.

For redundancy, both channels in the FSEU must agree on the slat command.

In the secondary mode, the FSEUs energize relays. The relays control the electrical power to the electric motor, clutch, and bypass solenoid. The alternate mode also uses these relays.

Secondary Mode Engage

When the FSEU engages the secondary mode, it energizes the bypass/clutch relay.

See the high lift control section for more information about the mode selection (AMM PART I 27-03).

This relay has three functions.

First, the bypass/clutch relay supplies power to the bypass solenoid in the primary control valve. This stops hydraulic operation in the primary mode.

Second, this relay supplies power to the clutch in the electric motor. This permits the electric motor to move the slat drive system.

Third, the bypass/clutch relay supplies power to the extend and retract relays. These relays do not energize until the FSEUs supply the grounds for them.

Retraction and Extension Control

The FSEU compares the flap lever position to the slat position. The slats retract if the flap lever position is less than the slat position. The slats extend if the flap lever position is greater than the slat position.

Either FSEU can energize the extend and retract relays to move the slats. These relays supply 115v ac power to the electric motor.

Flap/Slat Sequence

This function controls the sequence of the retraction and extension of the flaps and slats. See the high lift control section for more information about the the secondary mode flap and slat sequence (AMM PART I 27-03).

Cruise Inhibit

This function prevents slat extension during cruise. This happens when the airspeed is more than 265 knots or the altitude is above 20,300 feet.

Slat Load Relief

This function commands the slats to retract if the airspeed increases above the slat load relief limit.

Secondary Mode Auto Test

The secondary mode auto test does a test of the operation of the secondary mode. After 100 flight cycles, the FSEUs begin the test when the slats are commanded to extend. The test does these things:

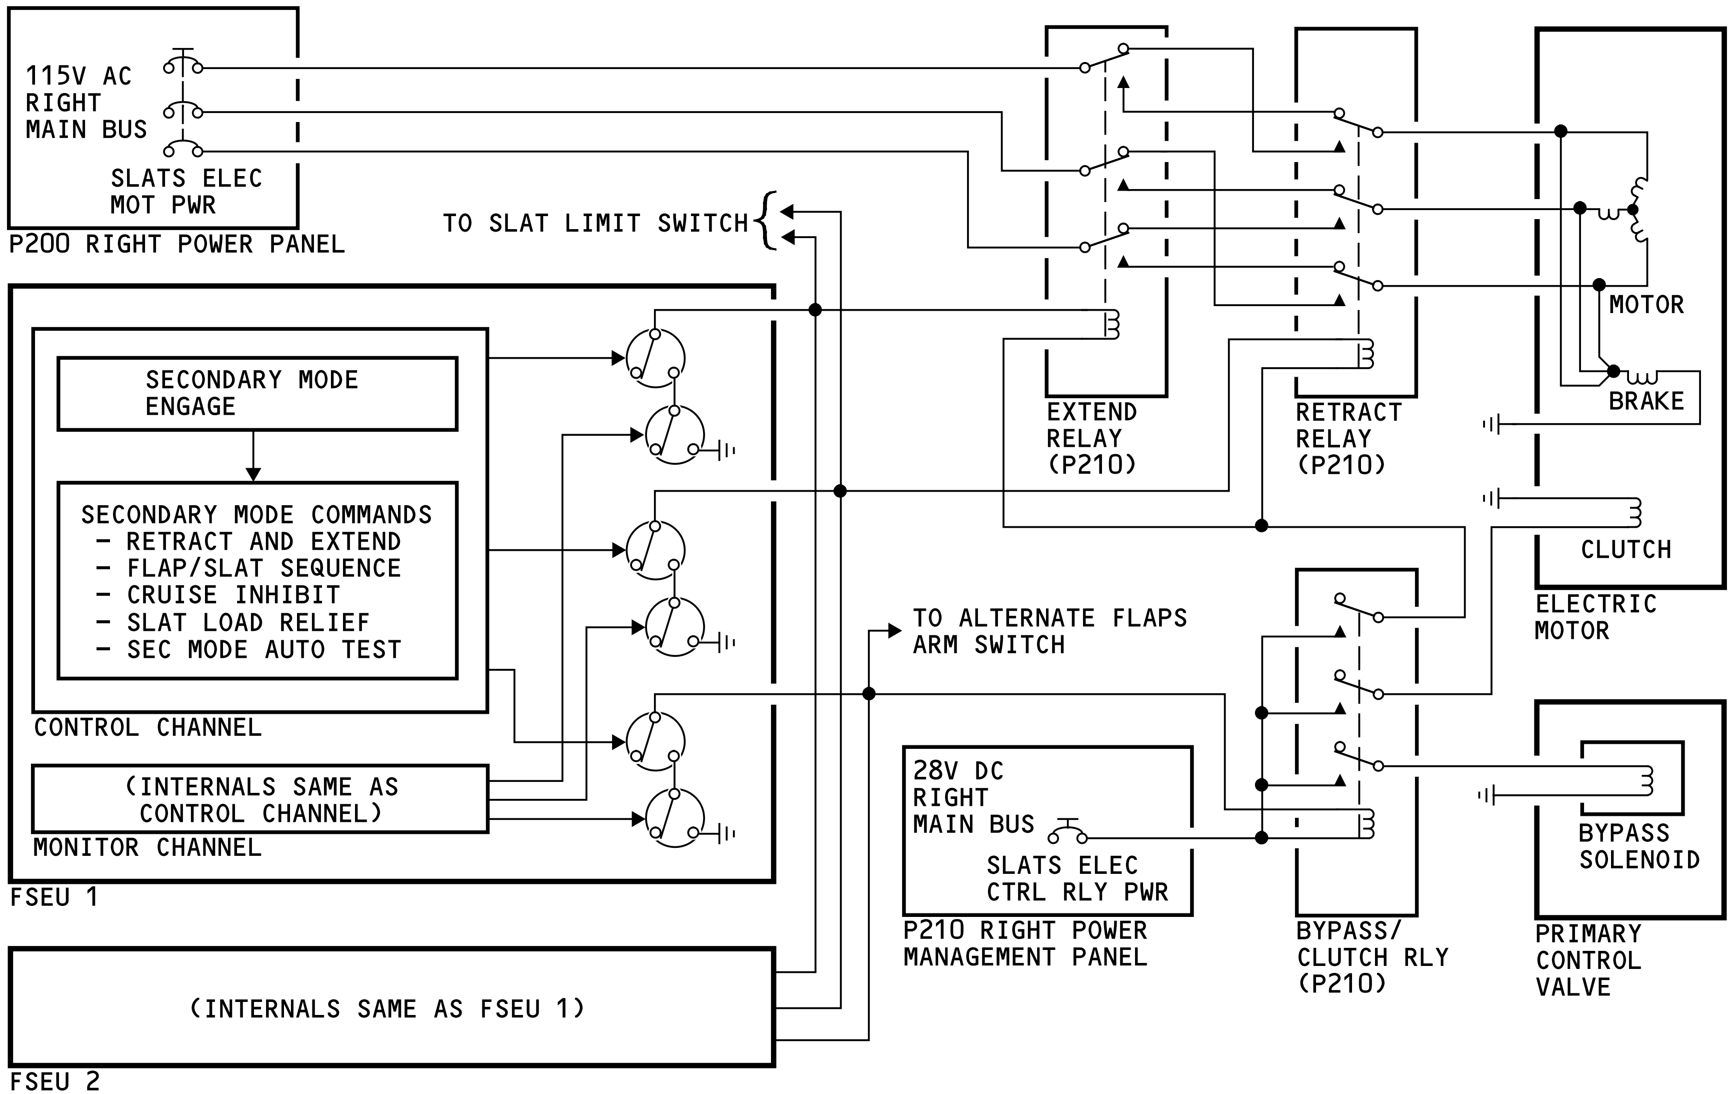
- Disengages the primary mode
- Engages the electric motor clutch
- Extends the slats for two seconds using the electric motor.

One flight cycle is when all of these conditions occur for two seconds:

- Airplane not on the ground
- Airspeed is greater than 70 knots
- Flap lever is at up
- Slats are at up.

When the slats extend for two seconds in the secondary mode, the test stops and the primary mode engages again. The slats then move to the commanded position in the primary mode.

If the slats fail to extend within four seconds during the secondary mode auto test, the SLATS SECONDARY FAIL status message shows.



27-81-00-026 Rev 7 06/22/1995

LEADING EDGE SLATS - FUNCTIONAL DESCRIPTION - SECONDARY MODE CONTROL

LEADING EDGE SLATS - FUNCTIONAL DESCRIPTION - SECONDARY MODE LOAD RELIEF

General

The slat load relief function prevents damage to the slats and their support structures from large aerodynamic forces. Slat load relief limits the position of the slats as a function of airspeed.

Slat load relief operates in the secondary mode only.

Load Relief - Secondary Mode

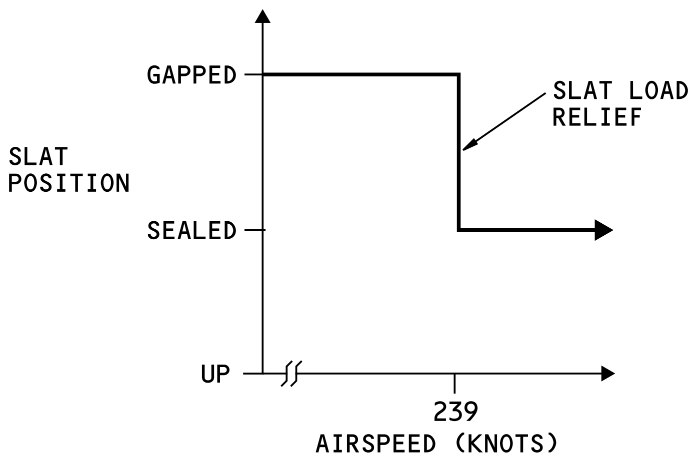
In the secondary mode, load relief is active if the flap lever is not in the up position and the airspeed is more than 239 knots. If the flap lever is not in the up position, the slats retract to the sealed position.

The load relief command resets if the airspeed is less than 239 knots or the pilot moves the flap lever to up. If the flap lever is not in the up position, the slats extend to the gapped position.

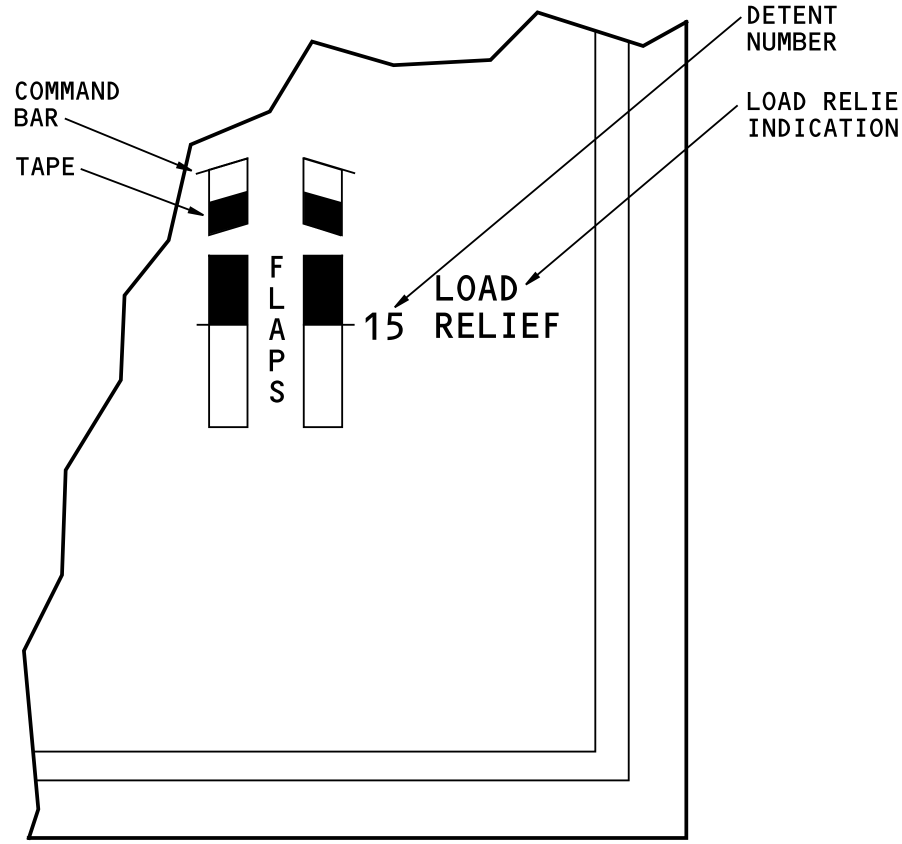
Indication

When slat load relief is active, the LOAD RELIEF message shows on the EICAS display and the EICAS compacted engine display.

The flap/slat position indication shows the position of the flap lever and the actual position of the slats. During slat load relief, the command bar and detent number change from green to magenta and the tape shows the actual position of the slats.



SLAT LOAD RELIEF - SECONDARY MODE



SECONDARY MODE DISPLAY (EICAS)

LEADING EDGE SLATS - FUNCTIONAL DESCRIPTION - SECONDARY MODE LOAD RELIEF

THIS PAGE INTENTIONALLY LEFT BLANK

LEADING EDGE SLATS - FUNCTIONAL DESCRIPTION - ALTERNATE MODE CONTROL

General

The alternate mode operation of the slats is almost the same as the alternate mode operation of the flaps.

See the trailing edge flaps section for more information about the flaps alternate mode control (AMM PART I 27-51).

In the alternate mode, the alternate flap/slat switches energize relays. The relays control the electrical power to the electric motor, clutch, and bypass solenoid.

The alternate mode has these functions:

- Primary and secondary mode disengage
- Extend and retract control
- Flap/slat sequence.

Primary and Secondary Mode Disengage

When you push the alternate flaps arm switch, the FSEUs receive an alternate arm discrete. The FSEUs use this discrete to disengage the primary and secondary modes.

The alternate flaps arm switch also supplies a ground for the bypass/clutch relay. The operation of the bypass/clutch relay in the alternate mode is the same as in the secondary mode.

Extend and Retract Control

When the alternate flaps selector is in the extend (EXT) position, it supplies a ground for the extend relay to extend the slats. When this relay energizes, it supplies 115v ac power to the electric motor. The slat limit switch de-energizes this relay when the slats move to their extend limit. In the alternate mode, this limit is at the sealed position.

When the alternate flaps selector is in the retract (RET) position, it supplies a ground for the retract relay to retract the slats. When this relay energizes, it supplies 115v ac power to the electric motor. The slat limit switch de-energizes this relay when the slats move to the up position.

When the alternate flaps selector is in the OFF position, the grounds for the extend and retract relays are removed. This de-energizes the relays and stops the slat movement.

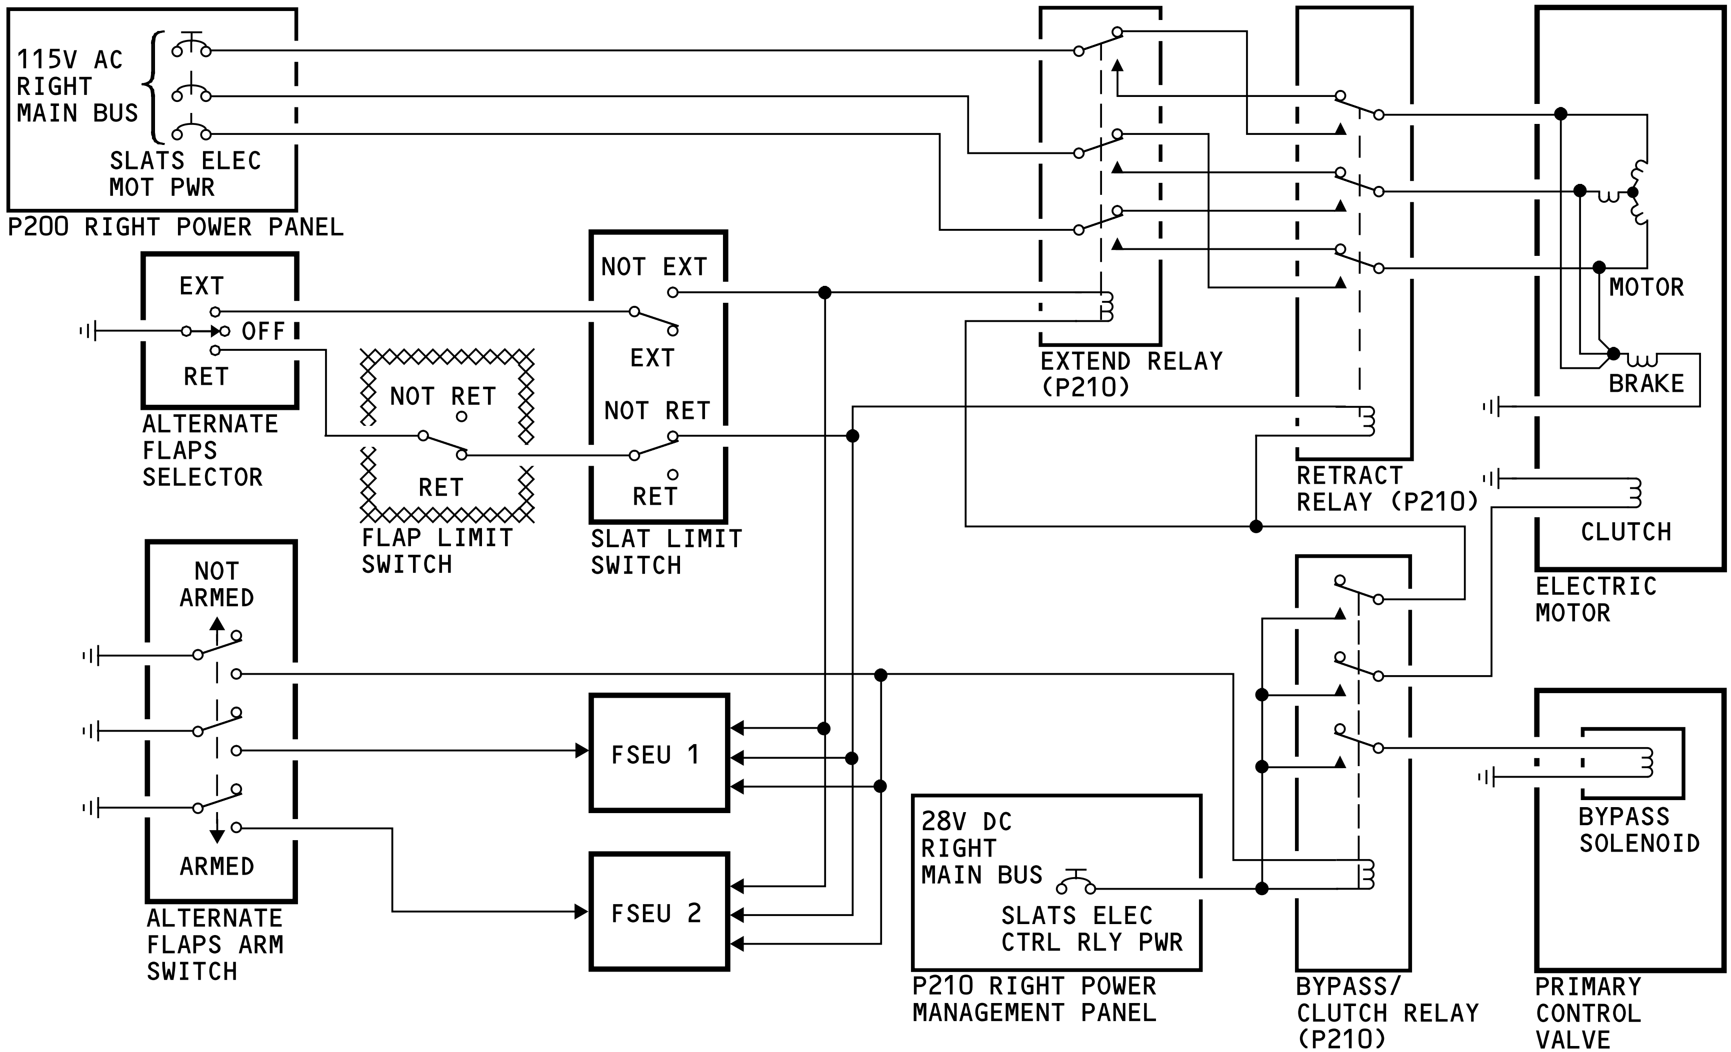
Flap/Slat Sequence

During extension, both the flaps and slats extend at the same time.

During retraction, the slats do not retract until the flaps are fully retracted. The flap limit switch controls this sequence.

LEADING EDGE SLATS - FUNCTIONAL DESCRIPTION - ALTERNATE MODE CONTROL

See the high lift control section for more information about the alternate mode flap and slat sequence (AMM PART I 27-03).



LEADING EDGE SLATS - FUNCTIONAL DESCRIPTION - ALTERNATE MODE CONTROL

SLAT POSITION INDICATION - GENERAL DESCRIPTION

Purpose

The slat position indication system measures the position of the slats and sends this data to the FSEUs. The FSEUs use this data for:

- Slat control
- Flap/slat position indication
- Failure detection.

Slat Control

The FSEUs use the slat position data during the slat operation in the primary and secondary modes. These modes have closed loop control of the slats. Closed-loop control stops the slat command when the slat position equals the command.

Flap/Slat Position Indication

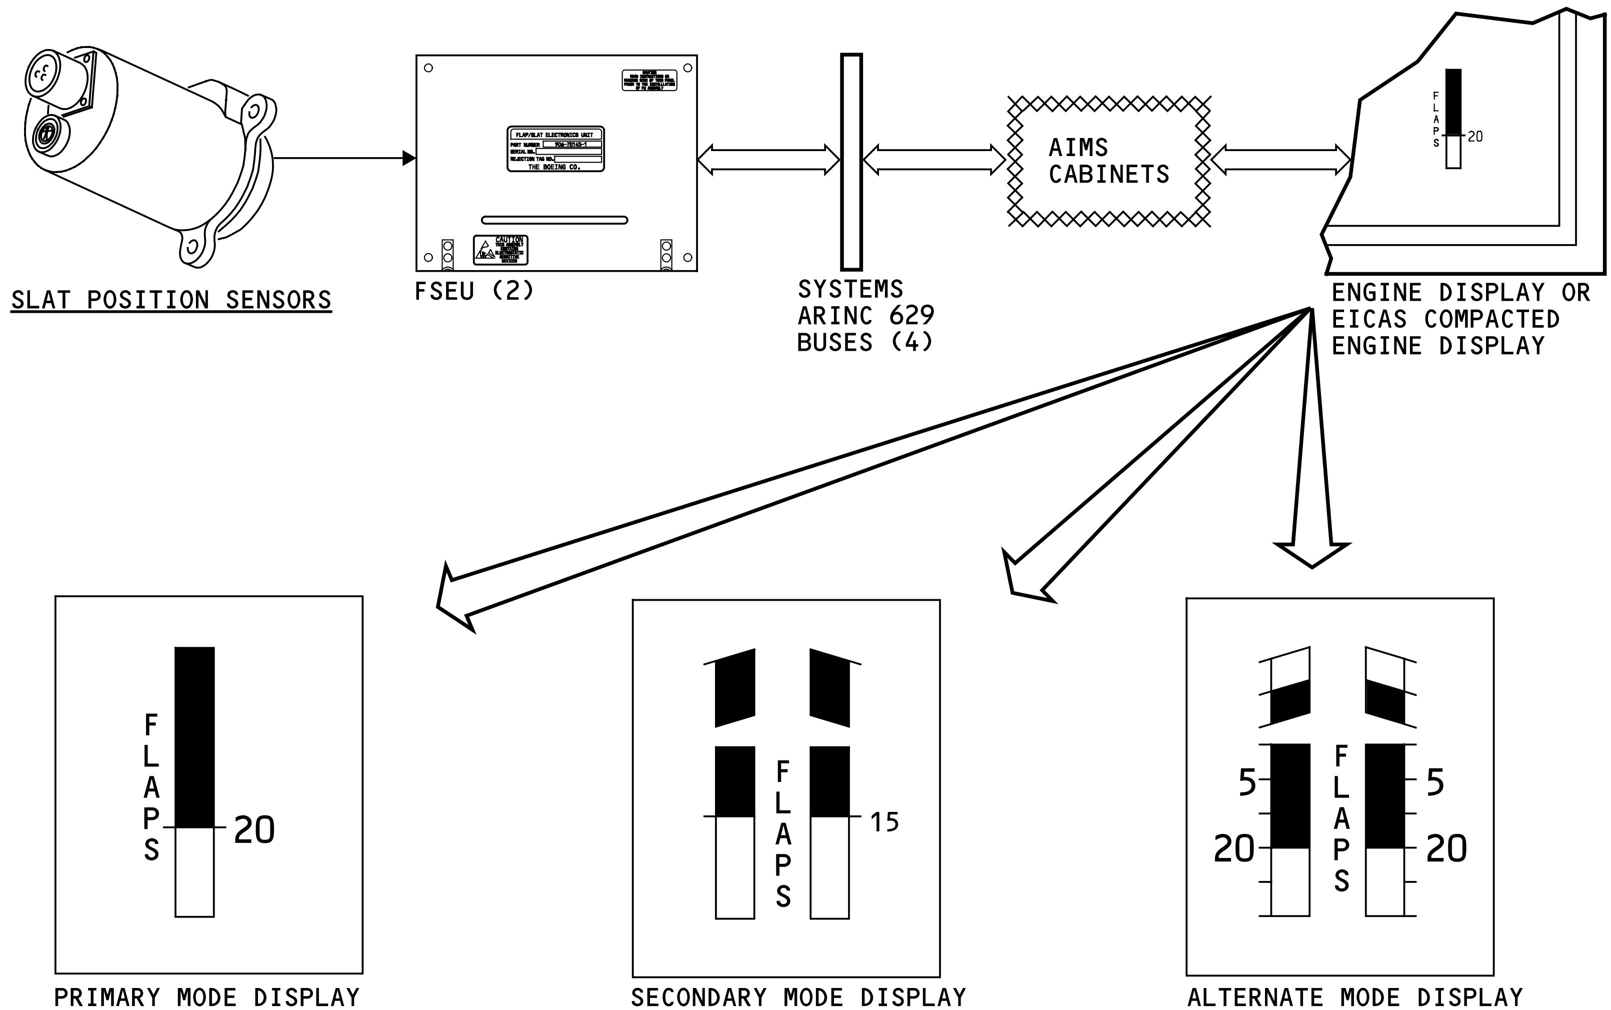
The FSEUs send the slat position data to the airplane information management system (AIMS). The AIMS uses this data to display the flap/slat position indication on the EICAS display or the EICAS compacted engine display.

The FSEUs send the slat position data to the AIMS whenever the data is valid. This permits flap/slat position indication in all three HLCS modes. The three flap/slat position indications are:

- Primary mode display
- Secondary mode display
- Alternate mode display.

Failure Detection

Monitors in the FSEUs compare the slat position data to the slat commands. These monitors find failures in the HLCS and the slat drive system.



27-88-00-001 Rev 2 01/08/96

SLAT POSITION INDICATION - GENERAL DESCRIPTION

SLAT POSITION INDICATION - SLAT POSITION SENSORS

Purpose

The slat position sensors supply slat position data to the FSEUs for slat control, flap/slat indication, and failure detection.

Location

The slat position sensors are on the two no-back brake offset gearboxes at the outboard ends of the slat torque tubes. Remove the access panel under the wing to get access.

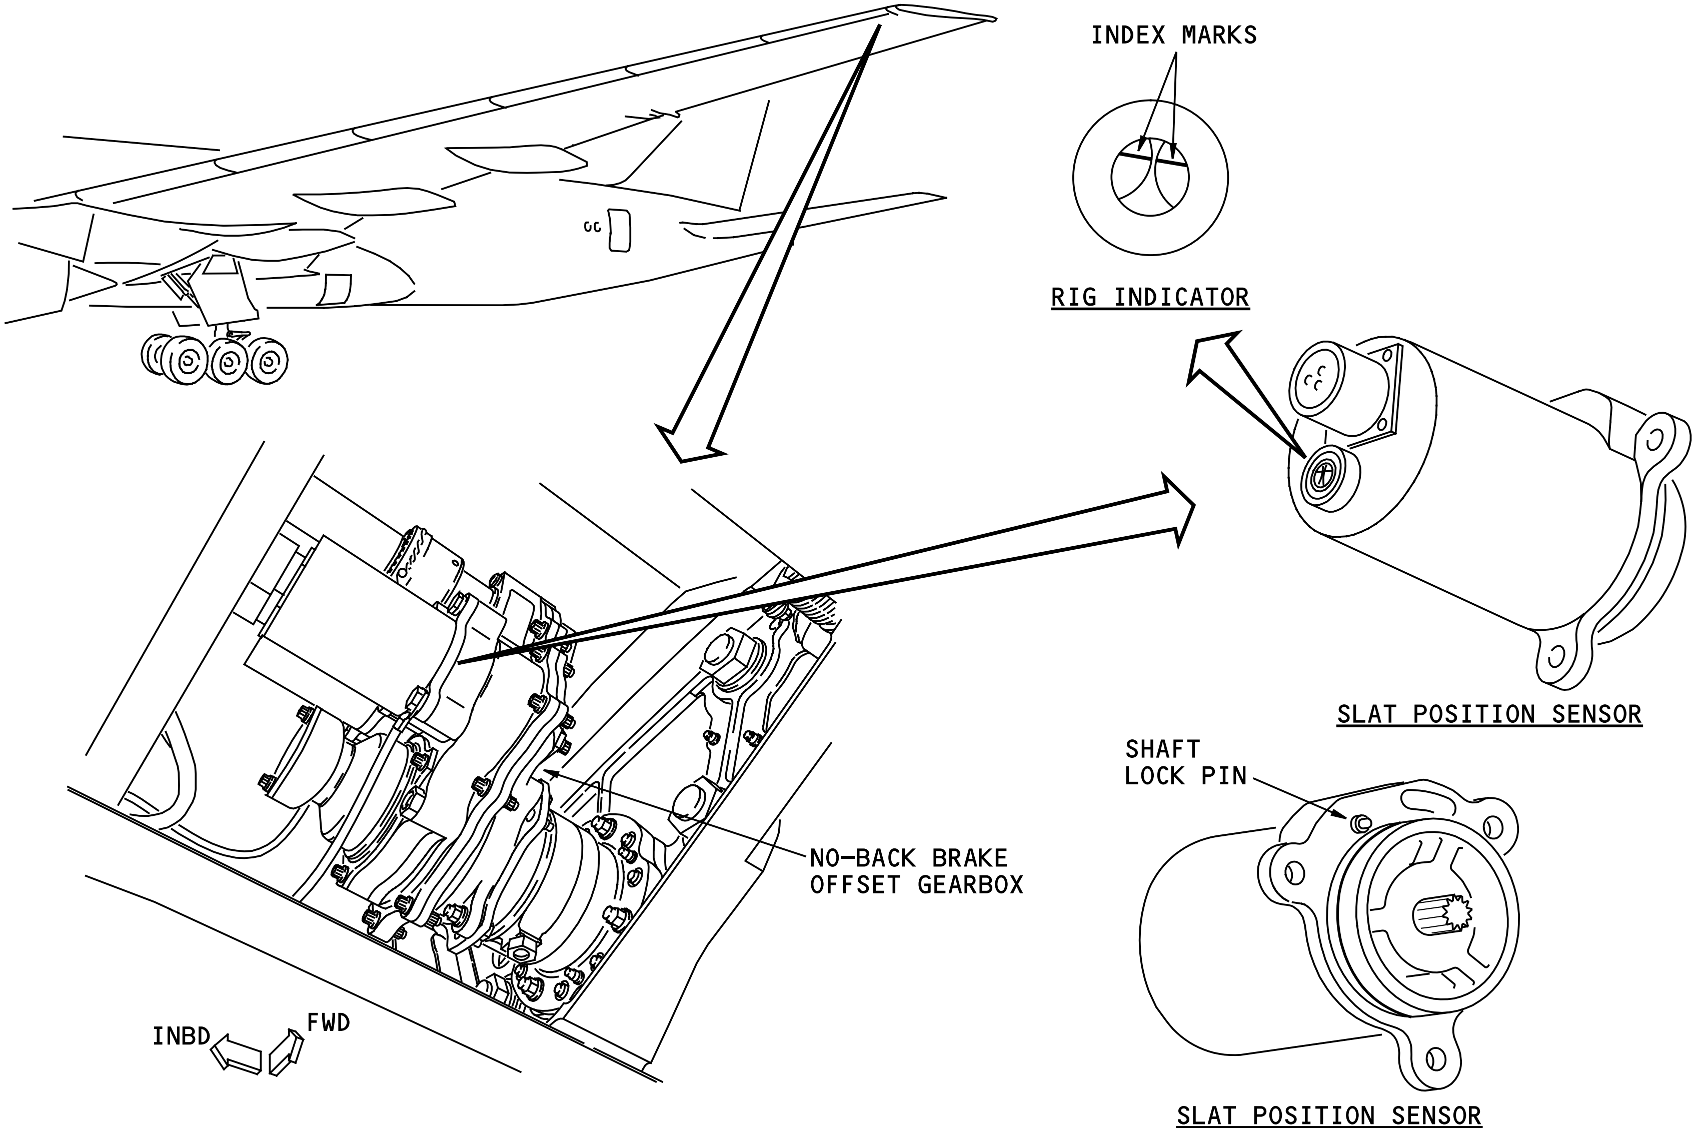
Physical Description

There are two slat position sensors on each of the no-back brake offset gearboxes at the outboard end of the wings. The slat position sensors are resolvers and they each have a rig indicator. The rig indicator has two marks that rotate when the position sensor shaft rotates. The two marks are in line when the slat drive line is at the UP position. All of these sensors are interchangeable with each other and with the flap position sensors.

Training Information Point

Install the slat position sensors with the slats rigged at the up position. Make sure the index marks for the rig indicator are aligned.

If the index marks on the position sensor are not aligned, you must push the shaft lock pin to turn the shaft.



27-88-00-002 Rev 3 03/28/96

SLAT POSITION INDICATION - SLAT POSITION SENSORS

SLAT SKEW DETECTION - GENERAL DESCRIPTION

Purpose

The slat skew detection system monitors the relative position of all the slats except for slats 1 and 14. The system does not monitor the outboard end of slats 2 and 13 and the inboard end of slats 6 and 9 for skew. The FSEUs stop the primary and secondary mode slat operation if there is a skew, an asymmetry or a secondary mode disagree condition.

Except for slats 1 and 14, the slats are in a skew when the inboard end of one or more slats is not aligned with its outboard end.

There is slat asymmetry condition when the slats on the left wing do not align with the slats on the right wing.

There is a secondary mode disagree when the slats do not move or move too slowly after a command to move in secondary mode.

Interface

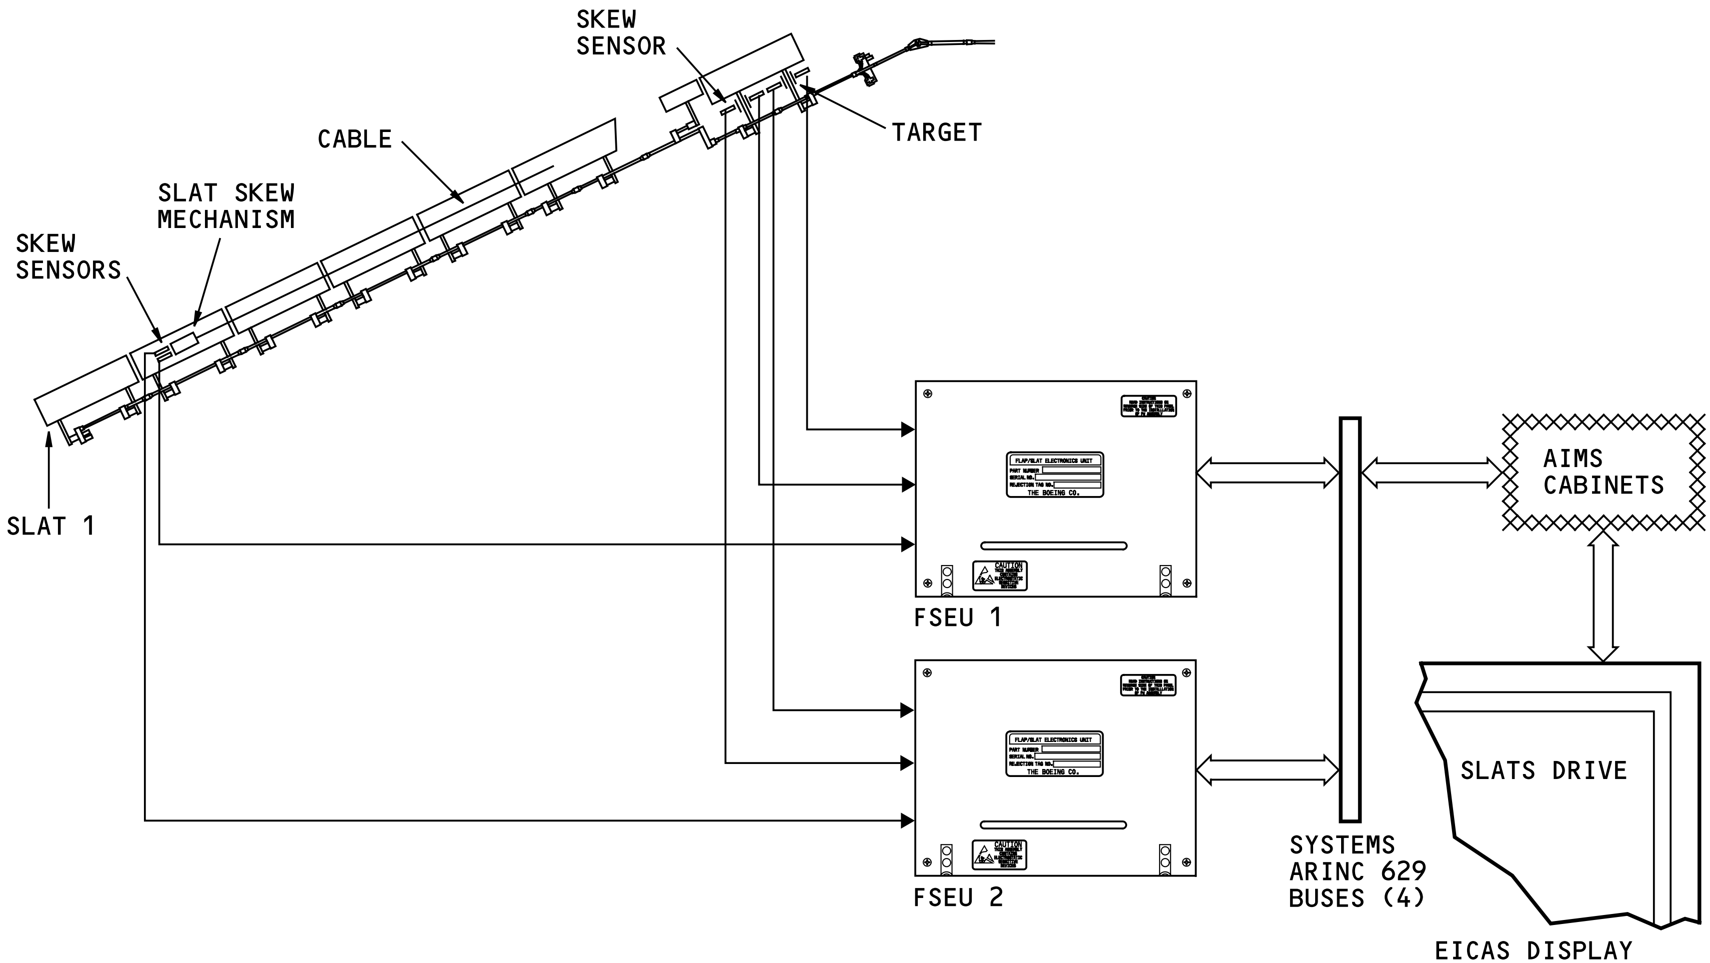
The slat skew detection system has 12 proximity sensors, two for the outboard slats and four for the inboard slat on each wing.

The sensors for the inboard slat do a check of the position of targets on the inboard slat auxiliary arms. The sensors for the outboard slats are on the slat skew mechanism. This mechanism attaches to a cable that is in slats 2 through 6 in the left wing and slats 9 through 13 in the right wing. If an outboard slat (except for the most outboard slat) moves out of alignment, the cable pulls a target on the mechanism away from the sensors.

Each FSEU has interfaces with one sensor at each skew sensor location to check for a skew condition. If a skew condition exists, the FSEUs stop the primary and secondary mode slat operation.

The slats are in a skew condition if a group of slats, a single slat, or the end of a slat is not in the correct position.

If the slats are in a skew, an asymmetry or a secondary mode disagree condition, the FSEUs stop the slat drive in primary and secondary modes. The FSEUs also send a signal to AIMS to show the SLATS DRIVE caution message. The slat position display changes to the secondary mode display and the slat position indication shows in amber.



NOTE: THE LEFT SLATS ARE SHOWN
(RIGHT SLATS ARE SIMILAR)

27-89-00-001 Rev 3

SLAT SKEW DETECTION - GENERAL DESCRIPTION

SLAT SKEW DETECTION - INBOARD SLAT SKEW SENSORS AND TARGETS

Purpose

The inboard slat skew sensors and targets monitor the relative position of the inboard slats.

Location

The inboard slat skew targets attach to the inboard and outboard auxiliary arms of the inboard slat. The skew sensors attach to the support structure of the inboard and outboard auxiliary tracks in the fixed leading edge of the wing. Remove the access panel under the wing to get access.

Physical Description

The slat skew sensors are proximity sensors. Each sensor is a separate LRU and is interchangeable with the skew sensors for the outboard slats.

The targets are made of an aluminum housing with four magnet zones and four cover plates. The magnets are spaced so that the sensors are in target-near condition when the slats are in the up, sealed, and gapped positions.

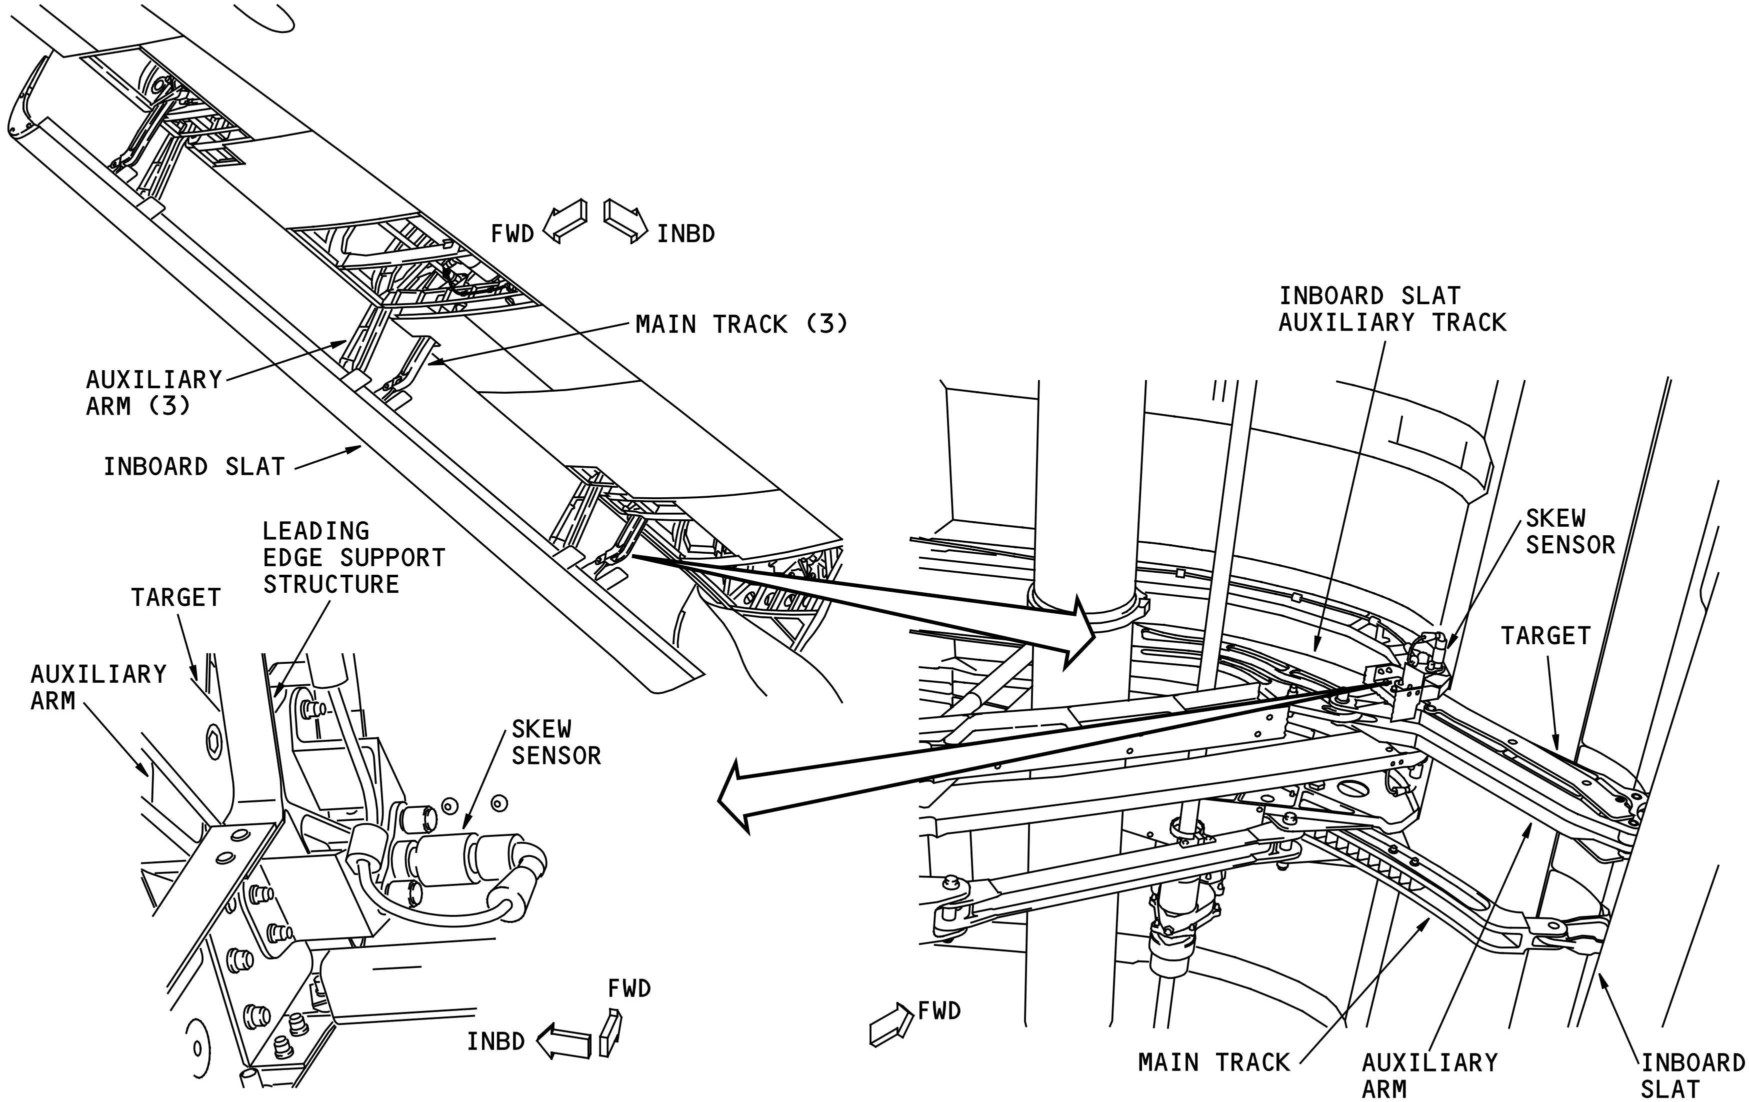
Functional Description

The FSEUs monitor the impedance of the skew sensors. The impedance has a relation to the position of the targets to the sensors. As the slats move, the targets move with them and the impedance of the skew sensors change.

The FSEUs detect a target-near condition when a magnet zone is directly in front of the sensor. When no part of a magnet zone is in front of the sensor, the FSEUs detect a target-far condition. The FSEUs use this data for skew monitoring and failure detection.

Training Information Point

It is not necessary to rig the inboard slat skew sensors and targets after installation.



INBOARD SLAT SKEW SENSOR INSTALLATION

SLAT SKEW DETECTION - INBOARD SLAT SKEW SENSORS AND TARGETS

SLAT SKEW DETECTION - OUTBOARD SLAT SKEW MECHANISM AND CABLE

Purpose

The outboard slat skew mechanisms and cables monitor the position of all the outboard slats except slats 1 and 14, the outboard end of slats 2 and 13, and the inboard end of slats 6 and 9.

Location

The outboard slat skew mechanisms are in slat 2 and slat 13. The left cable attaches to slat 6 and to the slat skew mechanism in slat 2. The right cable attaches to slat 9 and to the slat skew mechanism in slat 13. The routing of the cables is along the inside of the slat cove skins. Remove the cove skin panels to get access to the mechanisms and cables.

Physical Description

The slat skew mechanism has two proximity sensors, a target, two latches, and internal springs. A cable attaches to the slat skew mechanism.

When the cable pulls on the skew mechanism, the target moves to the far position. The latches lock the target in the far position. The internal springs permit some movement of the cable before the latch sets. This adjusts for minor changes of slat position caused by wing flex, temperature changes, and normal slat movement.

The proximity sensors measure the magnetic field of the target. When the position of the target changes, the impedance of the sensors change.

Each proximity sensor is a separate LRU and is interchangeable with the skew sensors for the inboard slats. But they are not interchangeable with the landing gear proximity sensors.

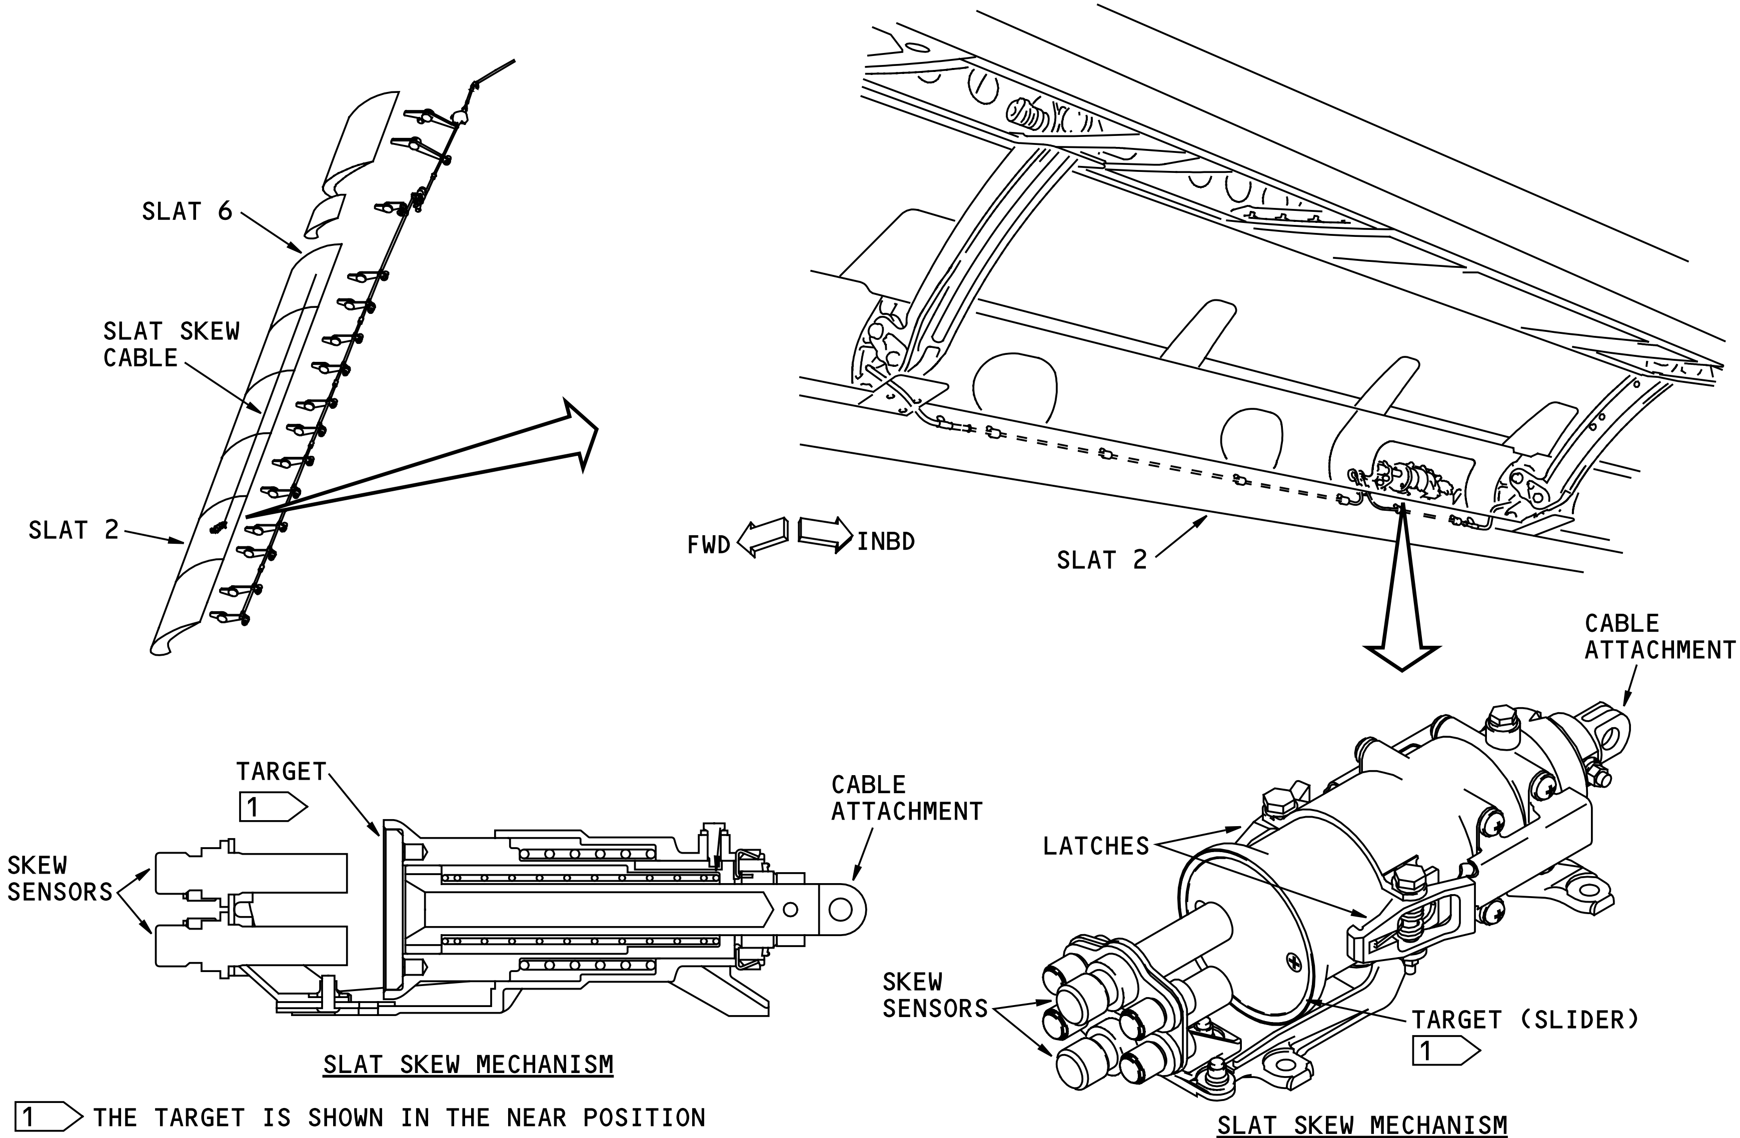
Functional Description

The FSEUs monitor the impedance of the skew sensors. If one of the outboard slats (except for the most outboard slat) do not align with all the others, the slat that is out of alignment pulls on the cable. This pulls on the skew mechanism, which moves the target to the far position. As the target moves away from the sensors, the impedance of the skew sensors change. The FSEUs use this data for skew monitoring and failure detection.

Training Information Point

It is necessary to rig the cable after installation of the skew mechanism or cable.

WARNING: KEEP ALL PERSONNEL CLEAR OF THE SPACE BETWEEN THE SLIDER AND THE SENSORS ON THE SLAT SKEW MECHANISM. WHEN YOU RELEASE THE LATCHES, THE SLIDER WILL QUICKLY MOVE OUTBOARD. THIS CAN CAUSE INJURY TO PERSONNEL AND DAMAGE TO EQUIPMENT.



1 THE TARGET IS SHOWN IN THE NEAR POSITION

SLAT SKEW DETECTION - OUTBOARD SLAT SKEW MECHANISM AND CABLE

SLAT SKEW DETECTION - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

SLAT SKEW DETECTION - FUNCTIONAL DESCRIPTION

General

There are 12 slat skew sensors. Each FSEU receives data from one of the skew sensors at each slat skew sensor location.

Both channels in the FSEUs use the slat skew data for:

- The inboard slat skew monitor
- The outboard slat skew monitor
- Failure detection.

Inboard Slat Skew Monitor

The inboard slat skew monitor receives data from the inboard and outboard skew sensors for slats 7 and 8. This monitor also receives data from the slat position sensors to predict the condition of the skew sensors.

The inboard slats are in a skew condition if:

- The condition of the inboard and outboard skew sensors for slat 7 (or 8) disagree with each other, or
- The condition of the inboard and outboard skew sensors for slat 7 (or 8) both disagree with the predicted condition.

Outboard Slat Skew Monitor

The outboard slat skew monitor receives data from the skew sensors in slats 2 and 13. Normally, these sensors are in the target-near condition. The outboard slats are in a skew condition (or a slat is lost) if these sensors are in the target-far condition.

Slats Drive Shutdown

The failure detection function in the FSEUs receives input from these sensors:

- The slat skew sensors
- The slat position sensors
- The flap lever position sensors.

When both FSEUs find a failure, they stop and shutdown the slats drive. There is a slats drive shutdown when any of these conditions occurs:

- The inboard or outboard slat skew monitors find a failure (slat skew or lost slat)
- The left slat position sensors do not agree with the right slat position sensors (slat asymmetry)
- The slats do not move within five seconds after a slat command in the secondary mode (disagree).

If there is a slat skew, asymmetry, or secondary mode disagree condition, the FSEUs latch the shutdown of the primary and secondary modes. The FSEUs also send signals to AIMS to show the SLATS DRIVE caution message. The slat position display changes to the secondary mode display and the slat position indication shows in amber.

A slats drive shutdown still permits the flaps to operate in primary or secondary mode. The flaps then

SLAT SKEW DETECTION - FUNCTIONAL DESCRIPTION

move to their commanded position independently of the slat position. If the slats are not at the gapped position when the slats drive shutdown occurs, the flaps cannot move more than the 20-unit position. If the slats are at the gapped position when the slats drive shutdown occurs, the flaps can move more than the 20-unit position.

To reset the latch, cycle the alternate flaps arm switch or do the primary system test on the MAT.

Skew Sensor Failure

If one or more of the slat skew sensors fails, the FSEUs send a signal to the AIMS to show the FLAP/SLAT SKEW SNSRS status message.

THIS PAGE INTENTIONALLY LEFT BLANK

PNEUMATIC - GENERAL DESCRIPTION

General

The pneumatic system has these three sections:

- Engine air supply
- Air supply distribution
- Indicating.

Two air supply cabin pressure controllers (ASCPC) give control, indication and BITE for all sections of the pneumatic system and for the pressurization system. See the air pressurization section for more information on the pressurization system (AMM PART I 21-30).

The controllers also set the amount of air that the air conditioning packs use (flow schedules) and give backup control to the cabin temperature controllers for air conditioning pack flow control and trim air control. See the air conditioning chapter for more information on air conditioning backup control (AMM PART I 21).

The left ASCPC controls the left engine air supply and the right ASCPC controls the right engine air supply. Both controllers control the isolation valves and APU shutoff valve.

Engine Air Supply

The engine air supply part of the pneumatic system can operate at any one of three levels (modes) of control:

- Digital (primary control)
- Analog (backup control)
- Pneumatic.

See the engine air supply section for more information about the engine air supply (AMM PART I 36-11).

The engine air supply system supplies the users with bleed air from two stages of the high pressure compressor (HPC). Low pressure bleed air comes from the 4th stage of the HPC. High pressure bleed air comes from the 10th stage of the HPC. These are the specified limits for pressure, temperature, and flow:

- Pressure - 0 through 75 psig (mode dependent)
- Temperature - 380F (193C) or 250F (121C) (mode dependent)
- Flow - 10 lbs/sec maximum (engine bleed airflow management).

The ASCPCs monitor the user systems to make decisions about how much air to supply. The ASCPCs manage engine bleed airflow three ways:

- Sheds user loads through an ARINC 629 signal (aft and bulk cargo heat, wing anti-ice)
- Sheds user loads by direct control (air conditioning packs, air conditioning trim air)
- Keeps engine bleed airflow to a limit.

The ASCPCs also monitor the user systems to make decisions about the temperature of air to supply. The ASCPCs manage engine bleed air temperature in two ways:

- Controls the flow of fan air though the precooler

- Keeps engine bleed air flow to a limit.

The ASCPCs use the pressure regulating and shutoff valve controller (PRSOVC) and the high pressure and fan air controller (HPFAC) to control the engine bleed air. The PRSOVC and HPFAC usually adjust the positions of the pressure regulating and shutoff valve (PRSOV) and the high pressure shutoff valve (HPSOV) as necessary to regulate pressure and flow. The HPFAC adjusts the position of the fan air modulating valve (FAMV) as necessary to regulate temperature. See the engine air supply section for more information about the engine air supply (AMM PART I 36-11).

Air Supply Distribution

The air supply distribution system supplies air from the sources to the user systems. The ASCPCs monitor the condition of the airplane, air sources and user systems to make decisions about which source to use and where the air is needed. The ASCPCs open and close the isolation valves and APUSOV as necessary to distribute the air to the user systems.

Indicating

Eight sensors monitor the air in the pneumatic system (right side sensors not shown):

- Manifold flow sensor (2)
- Manifold pressure sensor (2)
- Manifold dual temperature sensor (2)
- Intermediate pressure sensor (2).

RVDTs monitor valve position for these valves:

- Left, right, and center isolation valves
- APU shutoff valve
- Left and right fan air modulating valves.

The left and right ASCPCs monitor the sensors for flow, pressure, and temperature data. The ASCPCs monitor the RVDTs for valve position data. The ASCPCs use the data to control these components:

- Three isolation valves
- APU shutoff valve
- Two pressure regulating and shutoff valve controllers (PRSOVC)
- Two high pressure fan air controllers (HPFAC).

The ASCPCs send information to the airplane information management system (AIMS). The AIMS gives EICAS messages and synoptic and maintenance information.

Interfaces

The pneumatic system has interfaces with these systems and components:

- Left and right cabin temperature controllers (CTC)
- Overhead panel ARINC 629 system (OPAS)
- Electronic engine control (EEC)
- Airplane information management system (AIMS)
- Electrical load management system (ELMS)
- Warning electronic system (WES)
- Auxiliary power unit controller (APUC)

PNEUMATIC - GENERAL DESCRIPTION

- Flap slat electronics unit (FSEU)
- ARINC signal gateway (ASG)

See the section on the ASCPC for more information on interfaces.

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE AIR SUPPLY - GENERAL DESCRIPTION

General Description

The engine air supply system has three levels of control:

- Digital (primary mode)
- Analog (backup mode)
- Pneumatic.

The ASCPC supplies the primary and backup modes. The high pressure fan air controller (HPFAC) and the pressure regulating and shutoff valve controller (PRSOVC) are set to let the engine air supply system operate without ASCPC control. This is the pneumatic mode.

For usual operation, all functions that have a relation to the primary mode and some functions for the backup mode operate at the same time. The primary mode and backup modes work together to supply the most efficient control for the engine air supply system.

If the primary mode fails, all functions for the backup and the pneumatic modes operate together. The backup and the pneumatic modes give a limited amount of control, protection, and indications for the engine air supply system.

If the primary and backup modes fail, the pneumatic mode sets the engine air supply system to the default condition. In the default condition, the engine air supply system supplies air in the pneumatic mode with no protection or indications.

The primary mode is described below. See engine air supply functional description section for more information.

Bleed Port Selection

The ASCPC selects the lowest possible bleed air source while still satisfying the needs of the users systems. Selection is based on pressure, flow, altitude, air conditioning pack operation, and engine starting. The manifold pressure sensor, the intermediate pressure sensor and the EEC monitor the pneumatic duct pressure. The pneumatic duct pressure data goes to the ASCPC. If pressure goes below specified values, the ASCPC sends a command to the HPFAC. The HPFAC adjusts the position of the high pressure shutoff valve (HPSOV) so that high pressure air adds to low pressure air.

Pressure Control

The ASCPC controls the engine air supply pressure. The manifold pressure sensor and the intermediate pressure sensor monitor the pneumatic duct pressure. The pneumatic duct pressure data goes to the ASCPC. The ASCPC then sends a command to the HPFAC and the PRSOVC. The HPFAC adjusts the HPSOV and the PRSOVC adjusts the pressure regulating shutoff valve (PRSOV). The valves open and close as necessary to control the pressure.

The duct vent valve (DVV) releases high pressure to prevent overpressure indication when the engine is on and the bleed system is set to off.

ENGINE AIR SUPPLY - GENERAL DESCRIPTION

Temperature Control

The ASCPC controls the engine air supply temperature. The manifold dual temperature sensors monitor the pneumatic duct temperature. The pneumatic duct temperature data goes to the ASCPC. The ASCPC then sends a signal to the HPFAC. The HPFAC adjusts the fan air modulating valve (FAMV) to control the temperature.

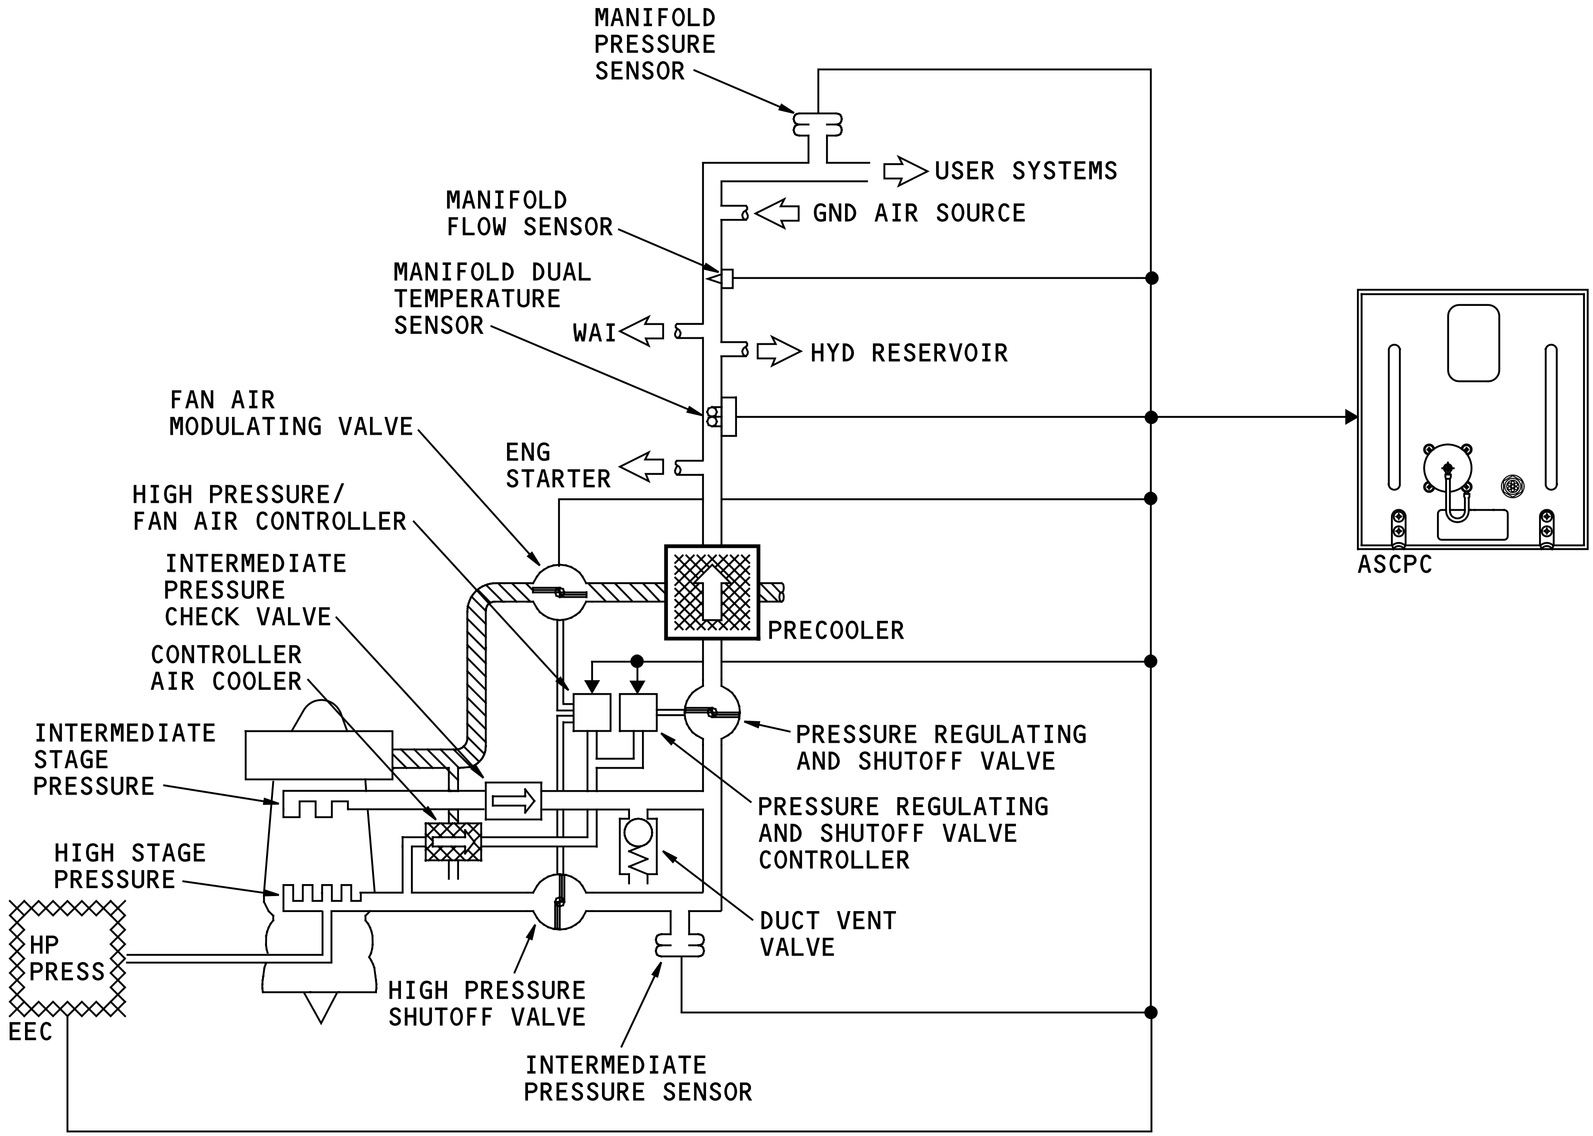
If the temperature of the bleed air gets above the usual limits, a signal goes to the PRSOVC. The PRSOVC adjusts the PRSOV as necessary to decrease the amount of hot bleed air supplied.

Flow Control

The ASCPC keeps the amount of bleed air that flows from the engine to a limit. The ASCPC uses inputs from these components or systems to monitor engine bleed airflow:

- Manifold flow sensor (FS)
- Engine anti-ice (EAI) system (not shown)
- Wing anti-ice (WAI) system (not shown).

The ASCPC uses the PRSOVC to control the flow. The PRSOVC adjusts the position of the PRSOV to regulate the bleed air flow into the air supply distribution system.



36-11-00-002 Rev 2 09/16/96

ENGINE AIR SUPPLY - GENERAL DESCRIPTION

ENGINE AIR SUPPLY SYSTEM - INTERMEDIATE PRESSURE CHECK VALVE

Purpose

The intermediate pressure check valve (IPCV) prevents air in the HP/IP manifold from going into the fourth stage bleed air source.

Physical Description

The IPCV is a pneumatically-operated check valve. The IPCV has these parts:

- Valve body
- Flapper
- Flapper stop
- Hinge pin.

The flow direction arrow is part of the valve body.

Location

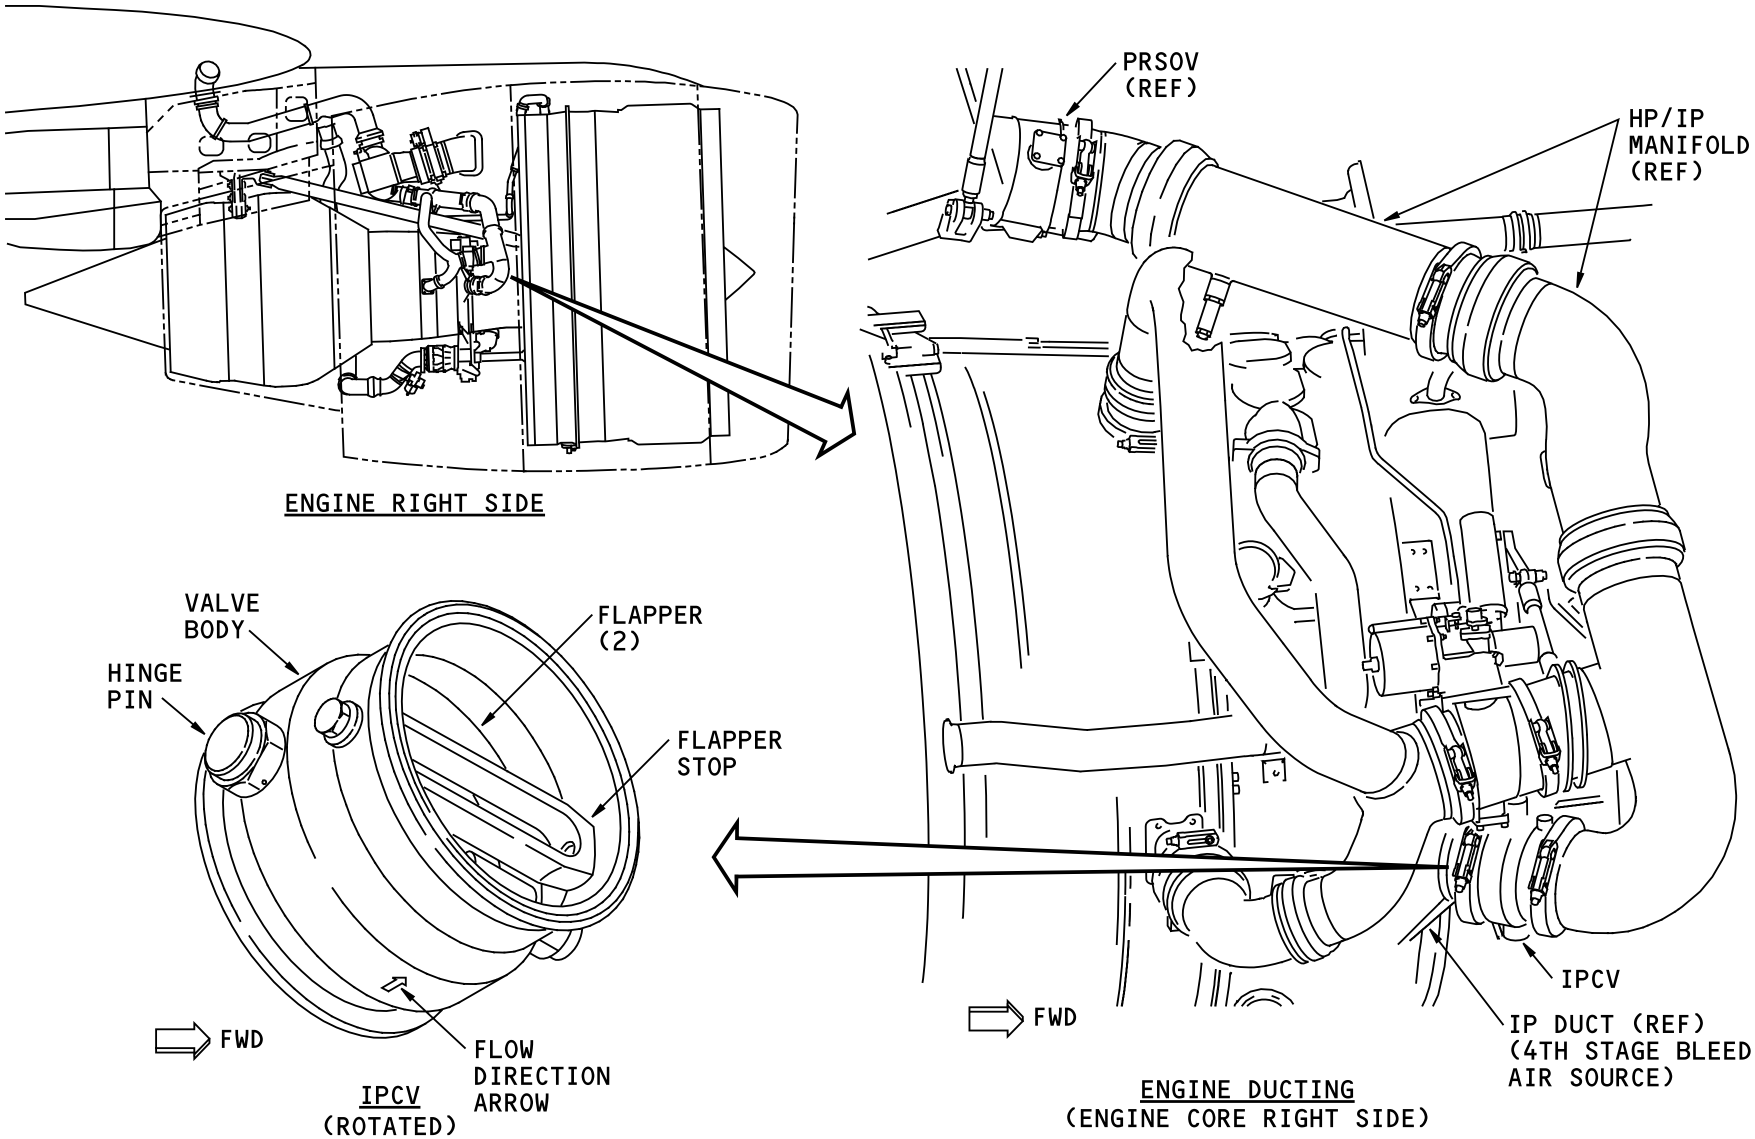
There is one IPCV on the right side of each engine. The valve is next to the fourth stage bleed air source at the 3:00 position in the engine ducting.

Functional Description

The flappers hinge around the hinge pin. The flapper stop keeps the flappers from opening too far. Fourth stage bleed air pressure and engine manifold pressure control the position of the flappers.

Training Information Point

A male and a female flange prevents the IPCV from incorrect installation. A flow direction arrow on the valve also helps prevent incorrect installation.



36-11-00-007 Rev 4 03/28/95

ENGINE AIR SUPPLY SYSTEM - INTERMEDIATE PRESSURE CHECK VALVE

ENGINE AIR SUPPLY SYSTEM - HIGH PRESSURE SHUTOFF VALVE / PRESSURE REGULATING & SHUTOFF VALVE

Purpose

The high pressure shutoff valve (HPSOV) controls the direction of flow and the pressure of the bleed air from the high stage of the high pressure compressor.

The pressure regulating and shutoff valves (PRSOV) control the direction of flow and the air pressure to the pneumatic distribution system.

Physical Description

The HPSOV and PRSOV are the same. They are of the spring loaded closed, pneumatically-operated type of valve. The valves have these parts:

- Pneumatic connector
- Manual override and position indicator assembly
- Flow direction arrow
- Valve body
- Valve disc
- Actuator.

The valves do not have any electrical parts.

Location

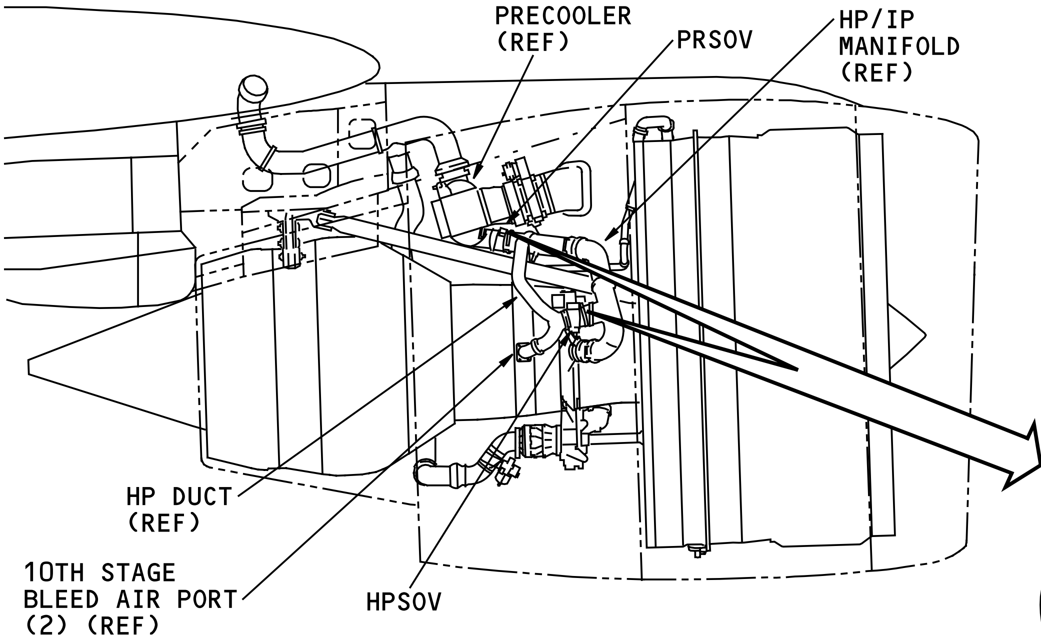
The HPSOV is on the right side of the engine core at the 2:30 position. The HPSOV is in the engine ducting between the HP duct and the HP/IP manifold downstream of the tenth stage bleed air ports.

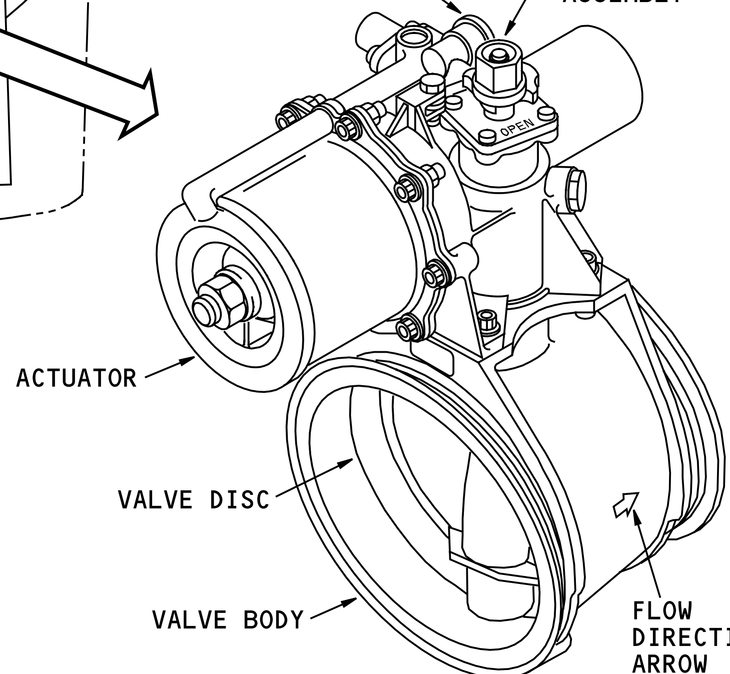
The PRSOV is above the engine core forward and below the precooler at the 12:00 position. It is between the HP/IP manifold and the precooler. The actuator side of the valve faces to the left. You can see the valve from either side of the engine. But you get access for removal/installation from the left side of the engine.

Training Information Point

Use the manual override and position indicator assembly to lock the valve in the closed position.

Each valve has a flow direction arrow and alignment marks (not shown). The arrow and alignment marks help install the valves correctly. A male flange and a female flange prevent incorrect installation.





36-11-00-008 Rev 2 02/17/95

ENGINE AIR SUPPLY SYSTEM - HIGH PRESSURE SHUTOFF VALVE / PRESSURE REGULATING & SHUTOFF VALVE

ENGINE AIR SUPPLY SYSTEM - PRESSURE REGULATING AND SHUTOFF VALVE CONTROLLER

Purpose

The pressure regulating and shutoff valve controller (PRSOVC) supplies control pressure to the PRSOV.

Location

The PRSOVC is on the left side of the engine fan case at the 7:00 position.

Physical Description

The PRSOVC is an electropneumatic controller. The PRSOVC has these parts:

- Two reference pressure regulators
- Torque motor
- Electrical connector
- Two pneumatic line connectors
- Filter (internal)
- Heater.

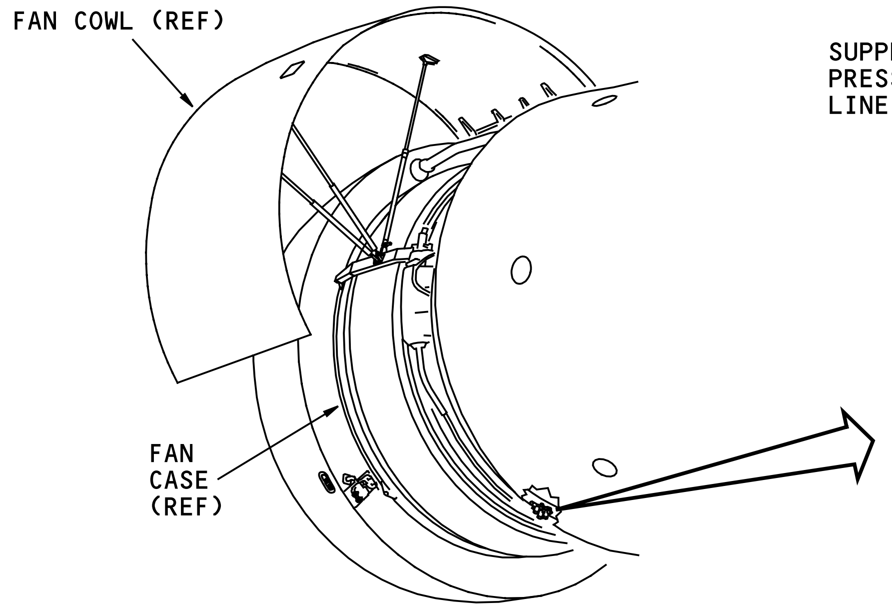
The reference pressure regulators set control pressure to a fixed value. The regulators are in series with each other. The torque motor adjusts the control pressure to values less than the reference pressure regulators. The torque motor always lets control pressure go to the PRSOV if it has no electrical power (fail safe on).

The heater prevents the controller from freezing.

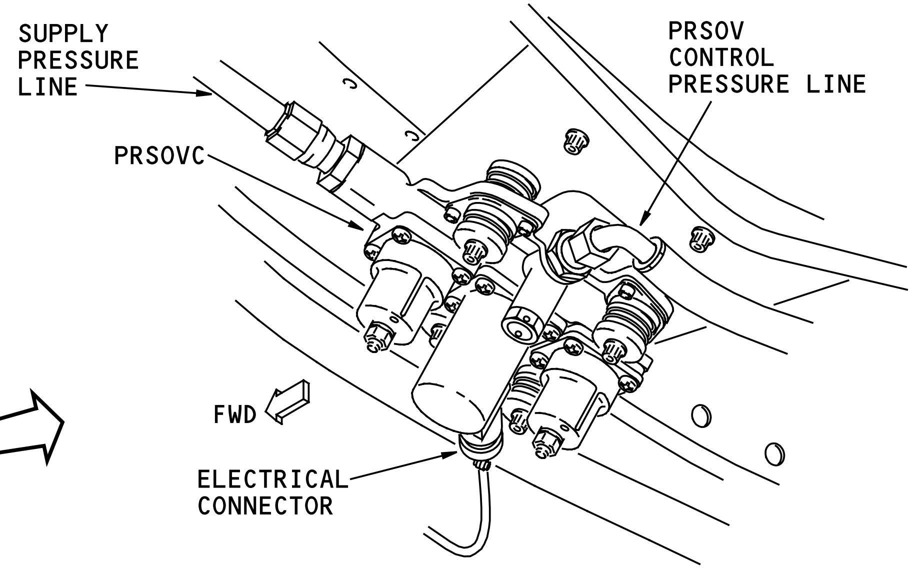
Training Information Point

The mounting bolt hole pattern on the PRSOVC helps you install it correctly. The two pneumatic line connectors are of different sizes. This also helps you install the PRSOVC correctly.

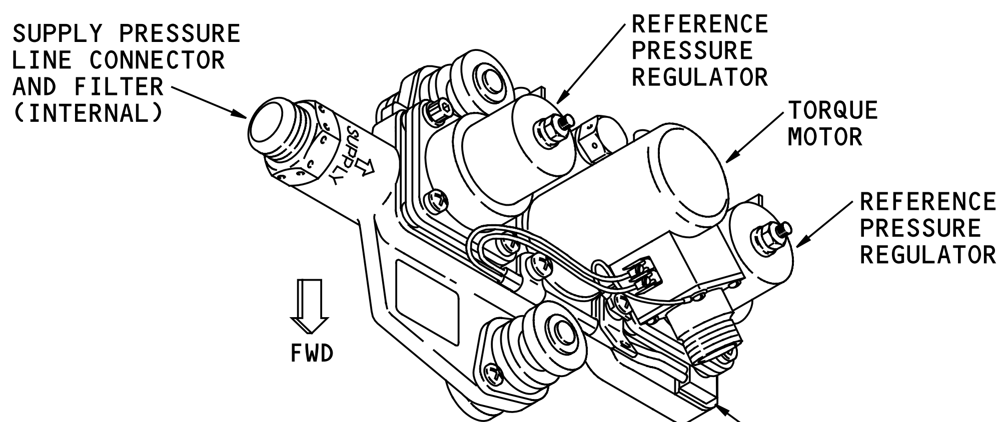
The filter is line replaceable.



ENGINE LEFT SIDE



FAN CASE



PRSOVC

ENGINE AIR SUPPLY SYSTEM - PRESSURE REGULATING AND SHUTOFF VALVE CONTROLLER

36-11-00-010 Rev 2 01/18/95

ENGINE AIR SUPPLY SYSTEM - PRECOOLER

Purpose

The precooler decreases the engine bleed air temperature.

Location

The precooler is attached to bottom of the engine strut above the high pressure turbine section of the engine.

Physical Description

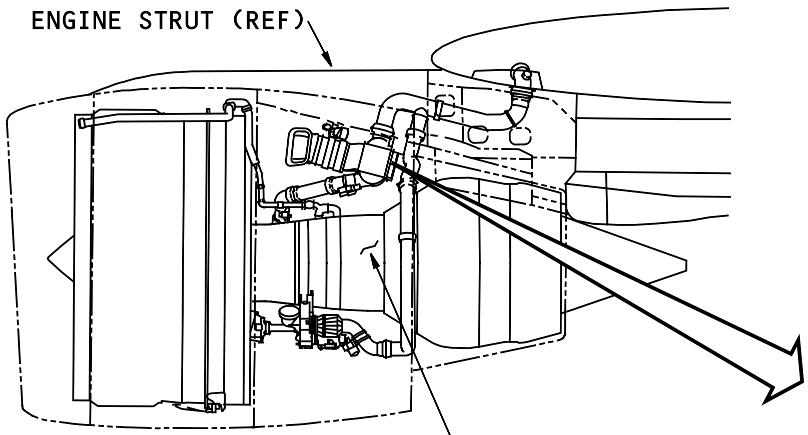
The precooler is a cross flow air-to-air heat exchanger. The precooler weights approximately 169.2 pounds (76.8 kg).

Functional Description

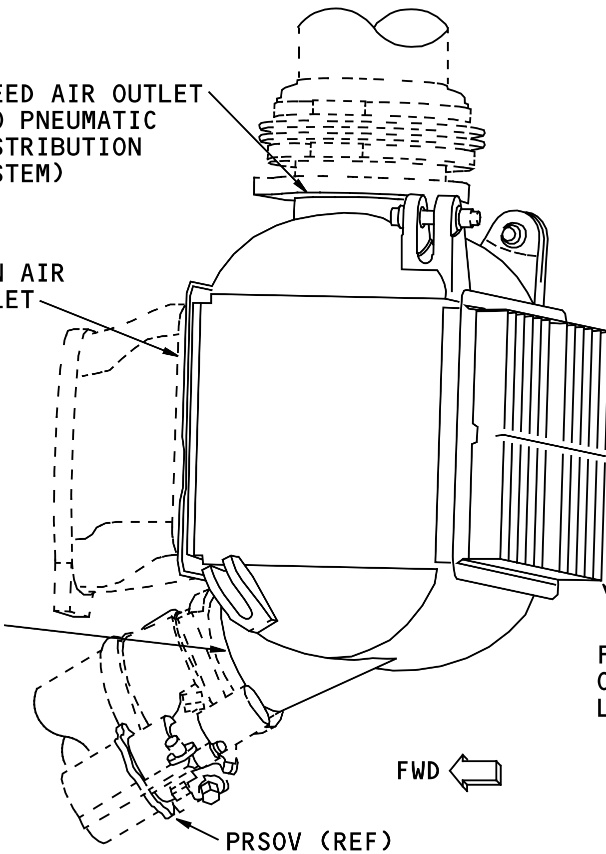
Engine bleed air flows through the precooler coils. Fan air flows over the precooler coils. This decreases the temperature of the engine bleed air.

Training Information Point

You can remove the precooler with special ground support equipment. The equipment permits you to remove the precooler with the engine on the wing.



ENGINE LEFT SIDE



PRECOOLER

36-11-00-011 Rev 2 01/19/95

ENGINE AIR SUPPLY SYSTEM - PRECOOLER

ENGINE AIR SUPPLY SYSTEM - FAN AIR MODULATING VALVE

Purpose

The fan air modulating valve (FAMV) controls the quantity of fan air that goes to the precooler.

Location

The FAMV is between the engine strut and the engine. The valve attaches to the FAMV inlet ducting forward of the precooler.

Physical Description

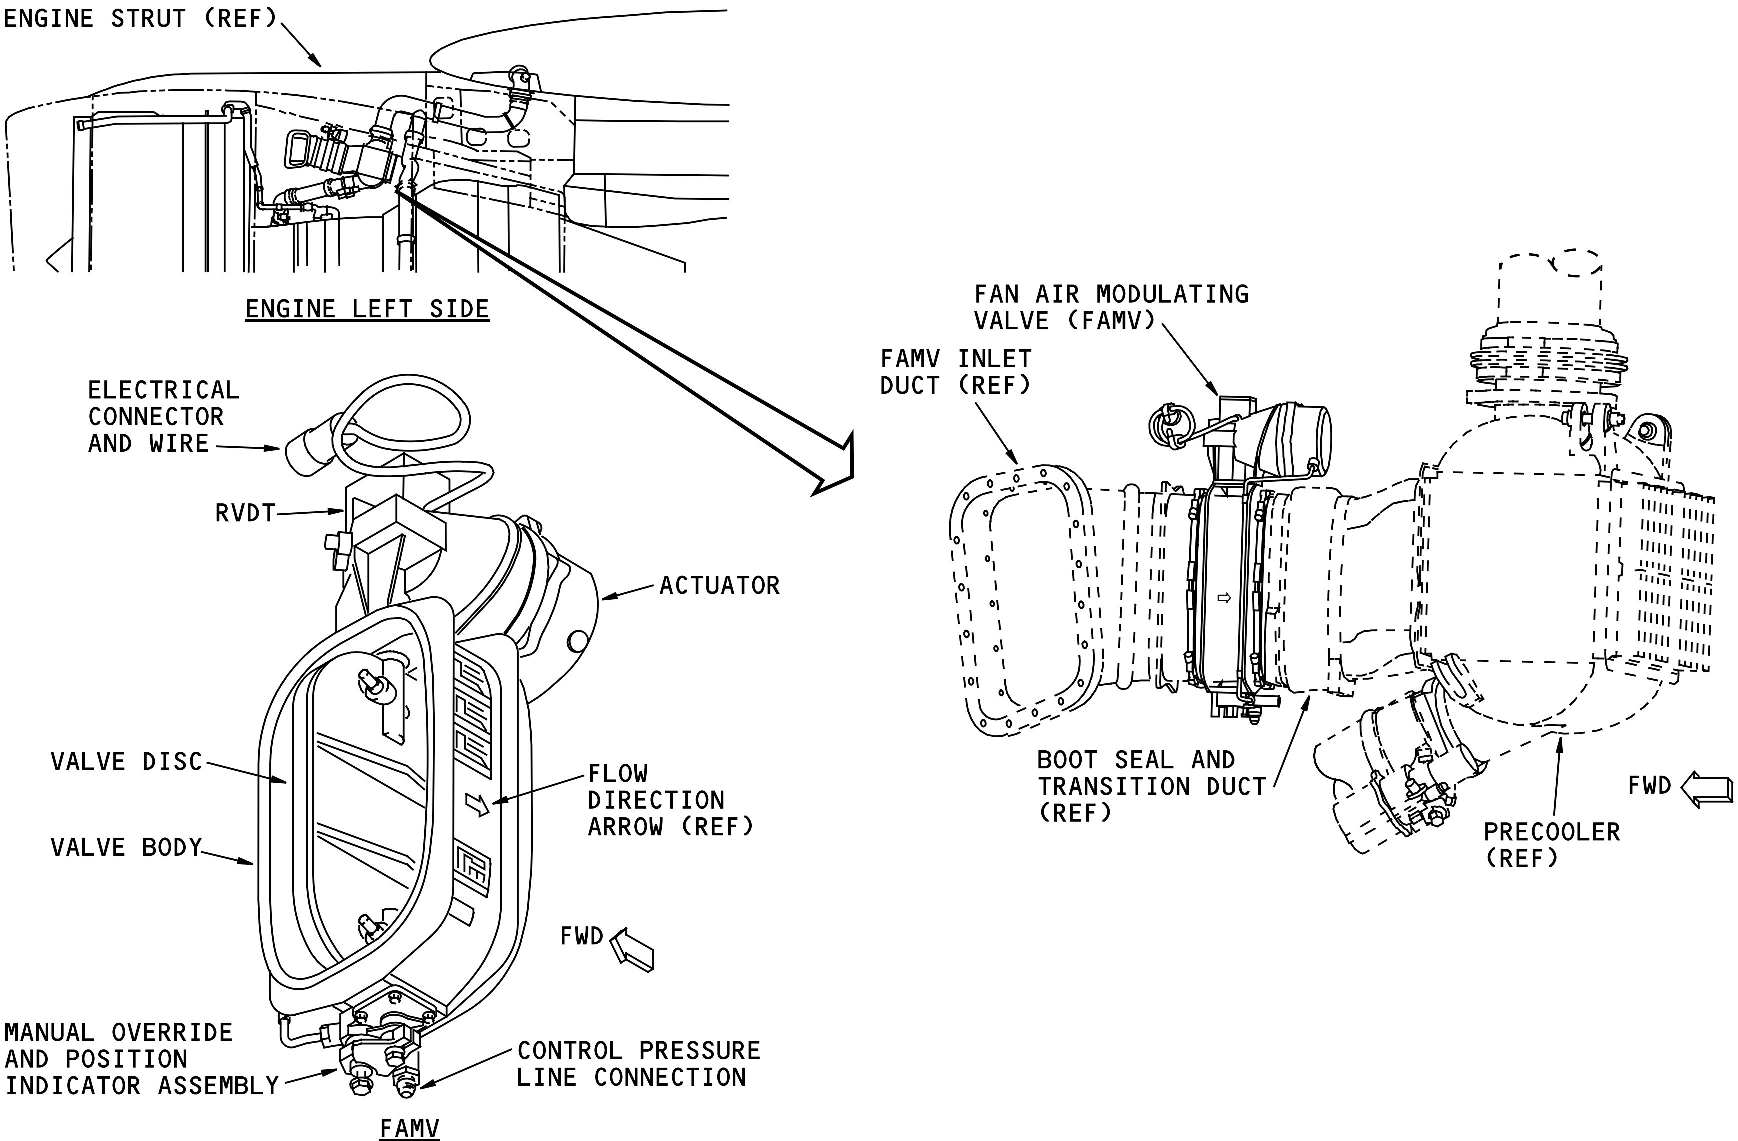
The FAMV is spring-loaded to the open position. It is pneumatically controlled and operated. The FAMV has these parts:

- Electrical lead and connector
- Actuator
- Control pressure line connection
- Manual override and position indicator assembly
- Valve body
- Valve disc
- RVDT.

Training Information Point

The FAMV has a flow direction arrow to help install it correctly.

The manual override and position indicator assembly locks the FAMV in the open or closed position. The valve must be locked in the closed position for removal or installation.



ENGINE AIR SUPPLY SYSTEM - FAN AIR MODULATING VALVE

36-11-00-012 Rev 1 02/17/95

ENGINE AIR SUPPLY SYSTEM - FAMV - TRAINING INFORMATION POINTS

General

The manual override and valve position indicator assembly lets you manually lock the valve closed or open and gives actual valve position.

Location

The assembly attaches to the valve body opposite from the actuator.

Physical Description

The assembly has these parts:

- Valve shaft
- Position indicator
- Lock plunger
- Locking cam.

Functional Description

The position indicator and locking cam attach to the valve shaft. As the valve shaft turns so does the indicator and locking cam.

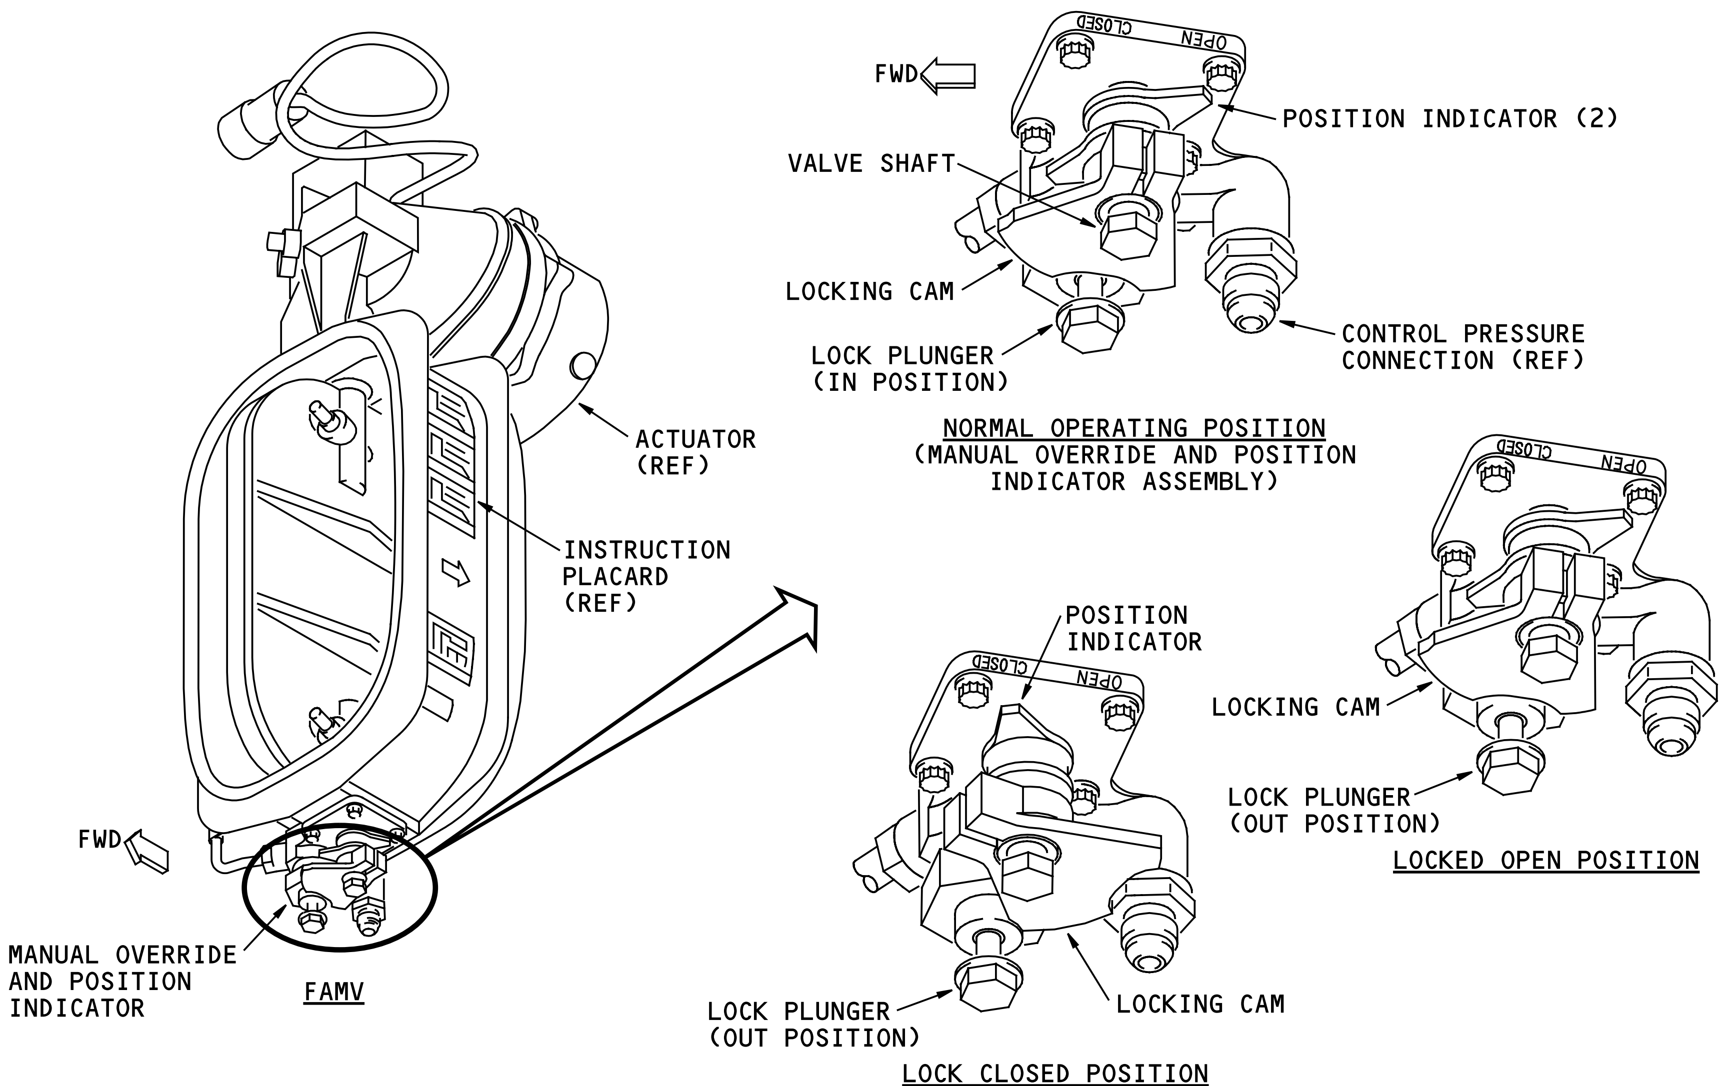
The locking cam has two slots. One is for the valve locked OPEN position and one is for the valve locked CLOSED position.

The lock plunger has two positions: in and out. The in position lets control pressure go to the valve actuator and permits free movement of the valve. The out position blocks control pressure, vents pressure from the valve actuator, and stops movement of the lock cam and valve. The plunger is spring-loaded out. The plunger is also threaded so you can push it in and turn it until it stays in (position for usual valve operation).

Operation

When the valve is in the open position, you turn the lock plunger counterclockwise (CCW) until it moves out to lock the valve open. To lock the valve closed, you first turn the lock plunger CCW until it moves out. Then push the plunger in and turn the valve shaft towards CLOSED position. The lock cam holds the plunger down as you turn the valve shaft to the closed position. The plunger moves out and stops movement of the cam and valve shaft when the valve is in the closed position.

You unlock the valve from the locked OPEN or CLOSED positions when you push the lock plunger in and turn it clockwise. The plunger must be torqued to make sure control pressure does not leak when you unlock the valve for usual operation.



ENGINE AIR SUPPLY SYSTEM - FAMV - TRAINING INFORMATION POINTS

ENGINE AIR SUPPLY SYSTEM - HIGH PRESSURE AND FAN AIR CONTROLLER

Purpose

The high pressure and fan air controller (HPFAC) regulates the control pressure that goes to the FAMV actuator and the HPSOV actuator.

Location

The HPFAC is inside the fan hub frame area of the engine at the 1:00 position.

Physical Description

The HPFAC is an electropneumatic controller. The controller has these parts:

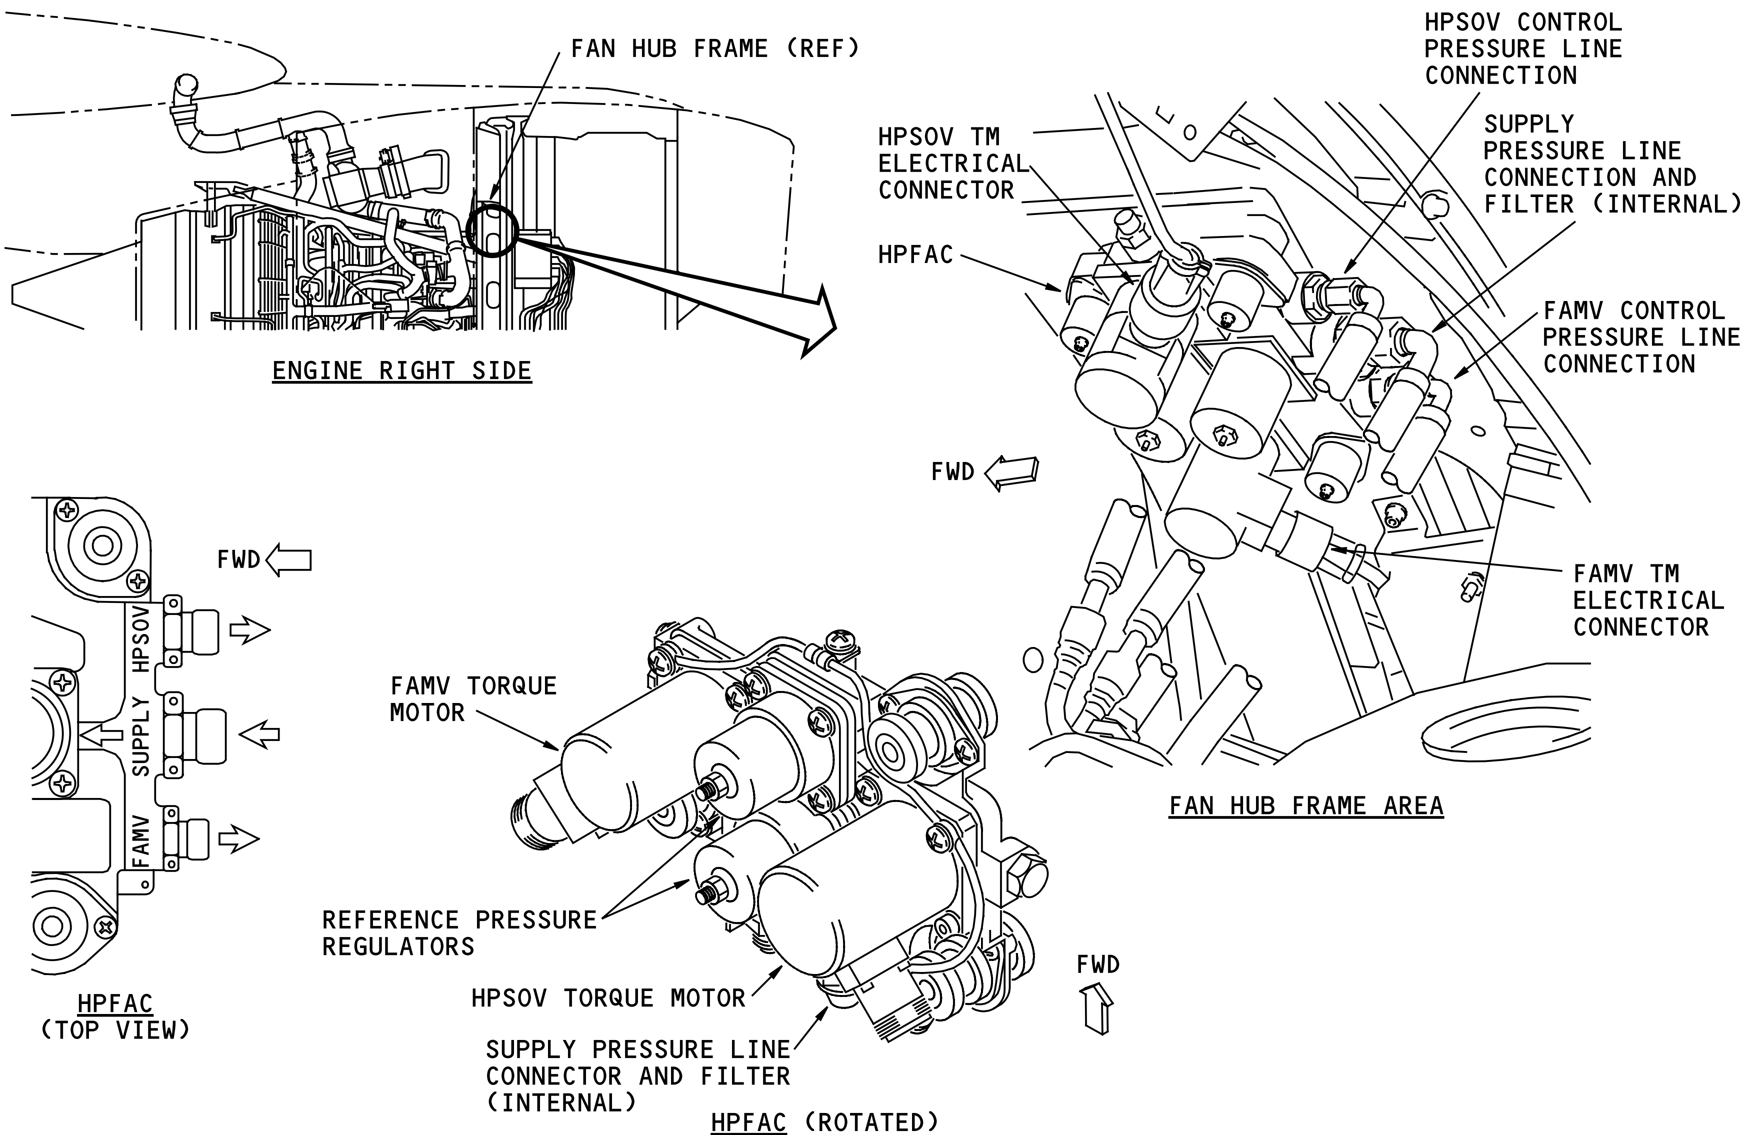
- Two electrical connectors (FAMV and HPSOV)
- Two control pressure line connectors (FAMV and HPSOV)
- One supply pressure line connector and filter
- Two torque motors (TM) (FAMV & HPSOV)
- Two reference pressure regulators (FAMV and HPSOV).

The reference pressure regulators set control pressure to a fixed value. The regulators are in series with each other. The torque motors regulate the control pressure to values less than the reference pressure regulators. The heater prevents the controller from freezing.

Training Information Point

The mounting bolt hole pattern on the HPFAC helps install it correctly. Three pneumatic line connectors are of different sizes on the HPFAC. This makes sure you connect the lines correctly. Two electrical connectors are of different sizes to help install the HPFAC correctly.

The filter is line replaceable.



36-11-00-014 Rev 2 02/17/95

ENGINE AIR SUPPLY SYSTEM - HIGH PRESSURE AND FAN AIR CONTROLLER

ENGINE AIR SUPPLY SYSTEM - CONTROLLER AIR COOLER

General

There are two controller air coolers (CAC) on each engine. There is one for the engine air supply part of the pneumatic system and there is one for the engine anti-ice system (not shown). See the engine anti-ice section for more information about the engine anti-ice CAC (AMM PART I 30-21).

The engine air supply controller air cooler decreases the temperature of the engine bleed air (HP10) that goes to these controllers:

- Pressure regulating and shutoff valve controller (PRSOVC)
- High pressure and fan air controller (HPFAC).

Physical Description

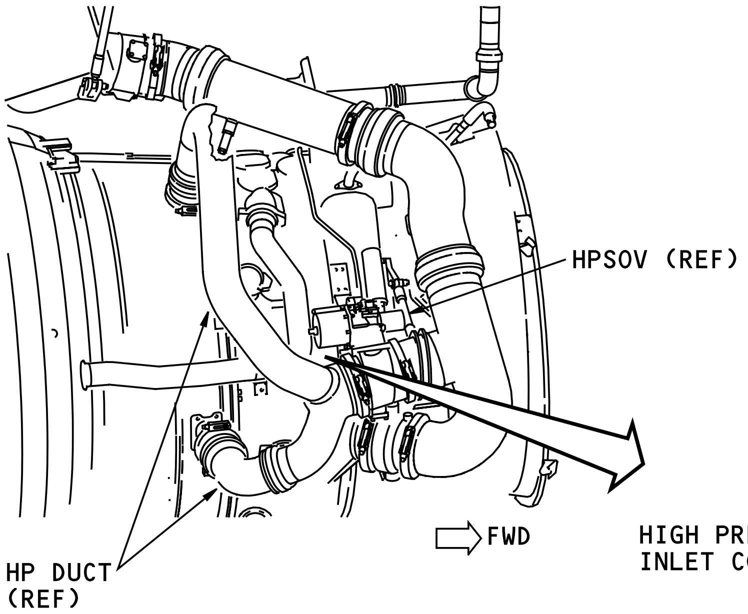
The controller air cooler is an air-to-air heat exchanger. It has three pneumatic line connectors, two high pressure and one low pressure (fan air).

Location

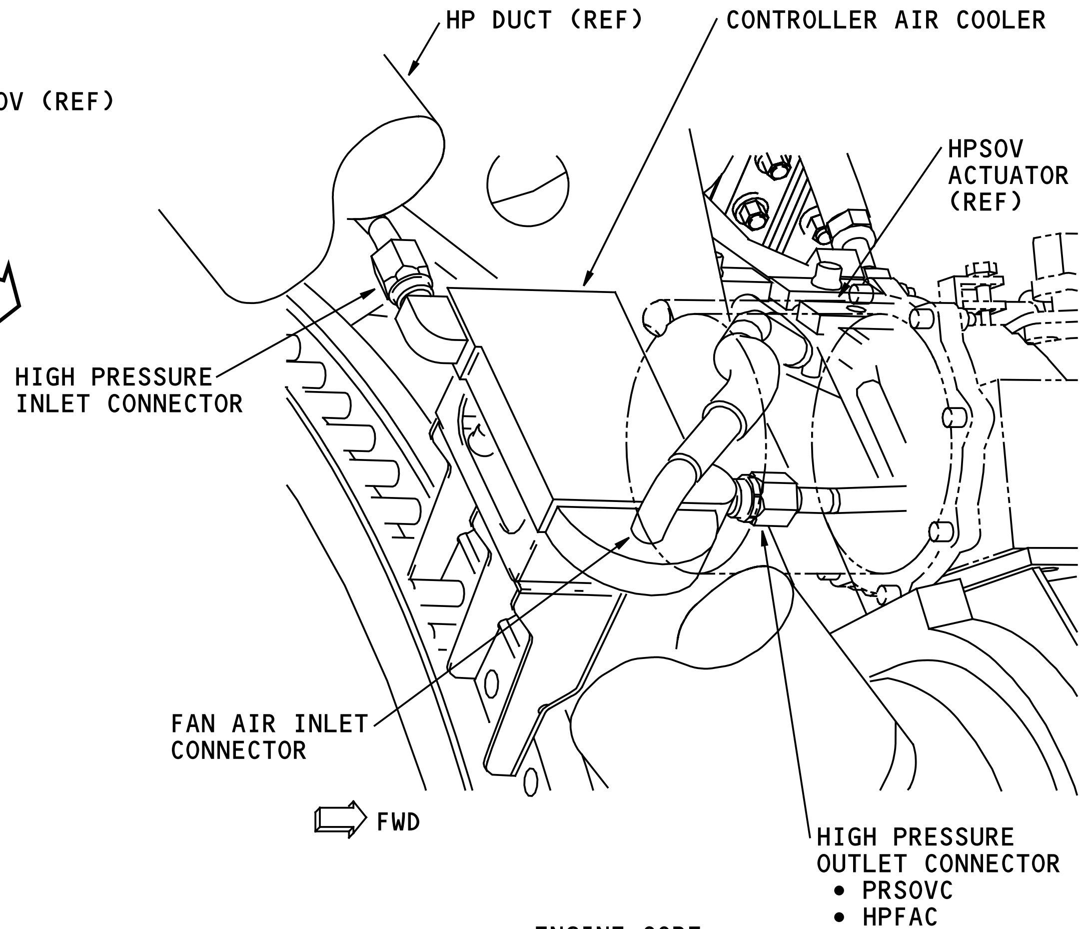
The controller air cooler is on the right side of the engine core at the 2:30 position. The cooler is under the actuator of the HPSOV.

Functional Description

Hot air from the high stage compressor section and cool fan air flows through the controller air cooler. The cool air carries heat away from the hot air. This decreases the temperature of the hot air.



ENGINE CORE - RIGHT SIDE



ENGINE CORE

36-11-00-015 Rev 3

ENGINE AIR SUPPLY SYSTEM - CONTROLLER AIR COOLER

ENGINE AIR SUPPLY SYSTEM - DUCT VENT VALVE

Purpose

The duct vent valve (DVV) releases air pressure from the engine duct when there is too much pressure in the duct. It prevents an overpressure condition if there is leakage through the HPSOV when the both HPSOV and PRSOV are closed. If the HPSOV is not fully closed, the flow out of the DVV is not sufficient to prevent an overpressure condition.

Location

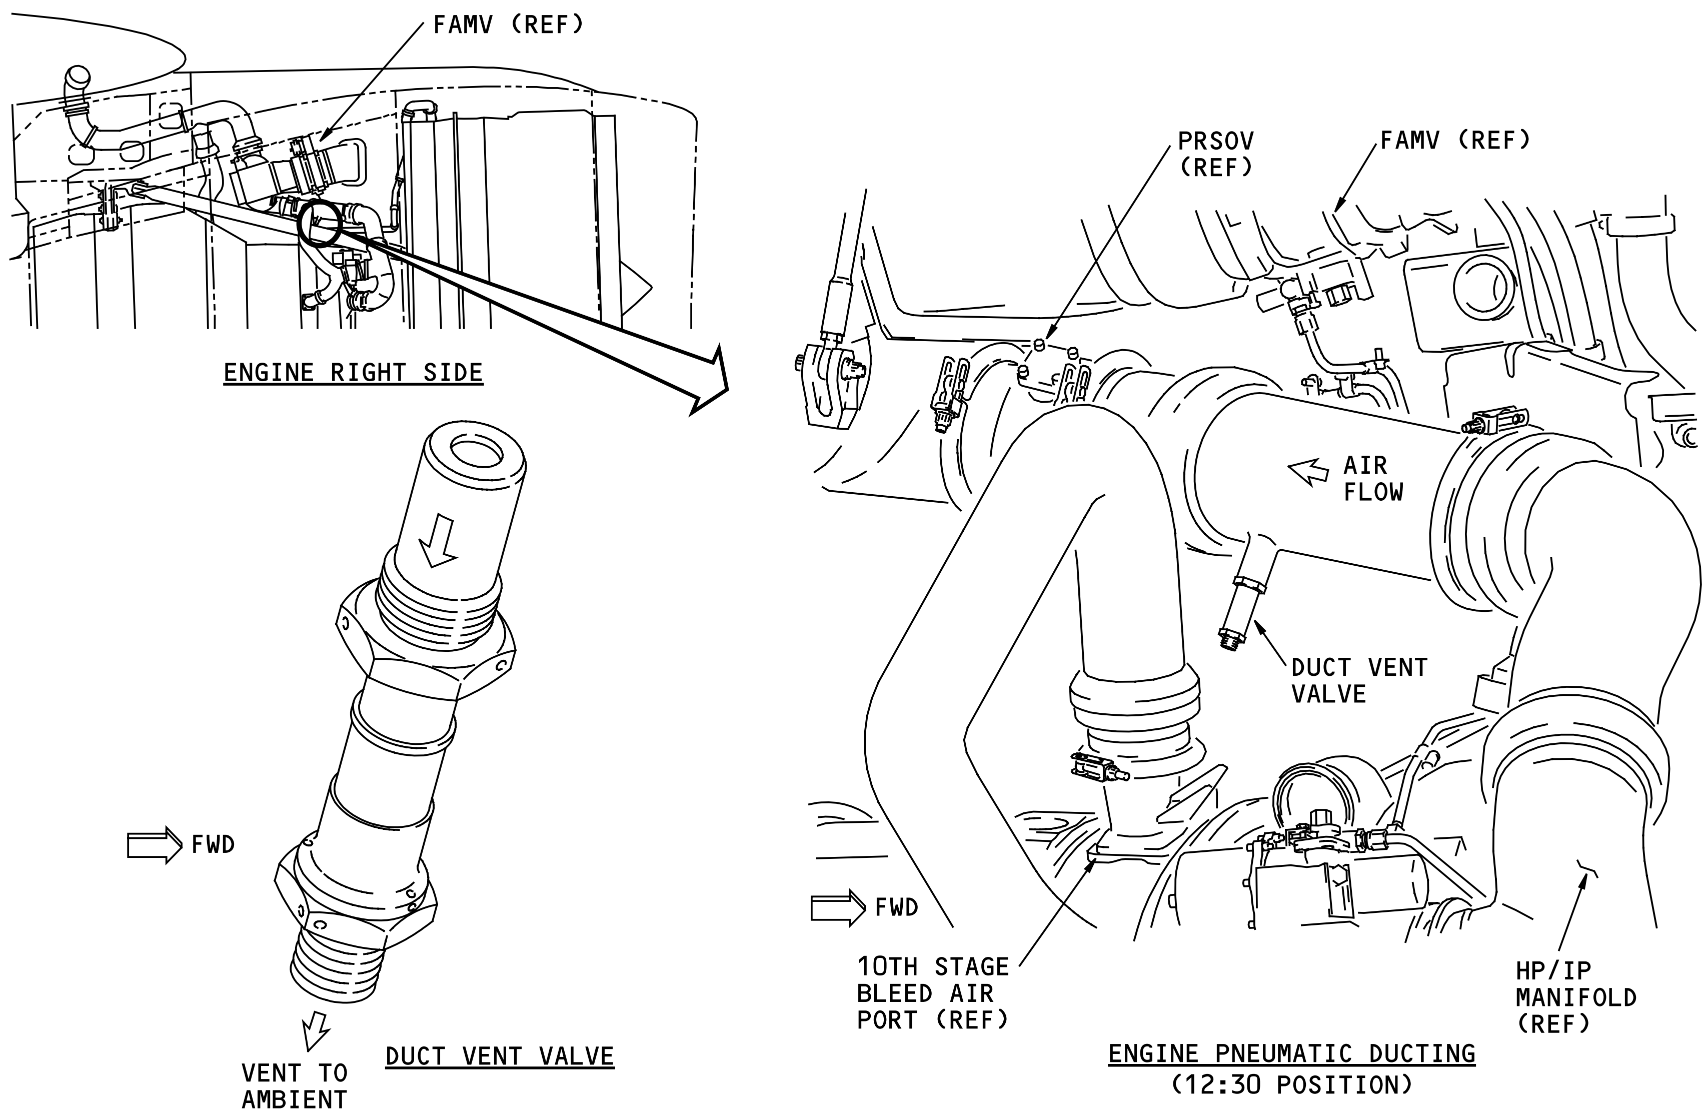
The DVV attaches to the engine HP/IP manifold on the right side of the engine core near the 12:30 position. The valve is forward of the PRSOV and below the FAMV adjacent to one of the tenth stage bleed air ports.

Physical Description

The DVV is a spring-loaded closed pressure relief valve. The valve is pneumatically actuated. The valve has a flow direction arrow on it.

Functional Description

The DVV opens when the pressure in the HP/IP manifold is more than 185 psig. The valve releases the air into the engine compartment at a flow of 6 to 8 lbs/min (2.72 to 3.63 kg/min). The valve resets at 145 psig.



36-11-00-016 Rev 5 03/28/95

ENGINE AIR SUPPLY SYSTEM - DUCT VENT VALVE

ENGINE AIR SUPPLY SYSTEM - AIR SUPPLY CABIN PRESSURE CONTROLLER - PHYSICAL DESCRIPTION

Location

The left and right air supply cabin pressure controllers (ASCPC) are in the MEC on the E1 and E2 racks.

Physical Description

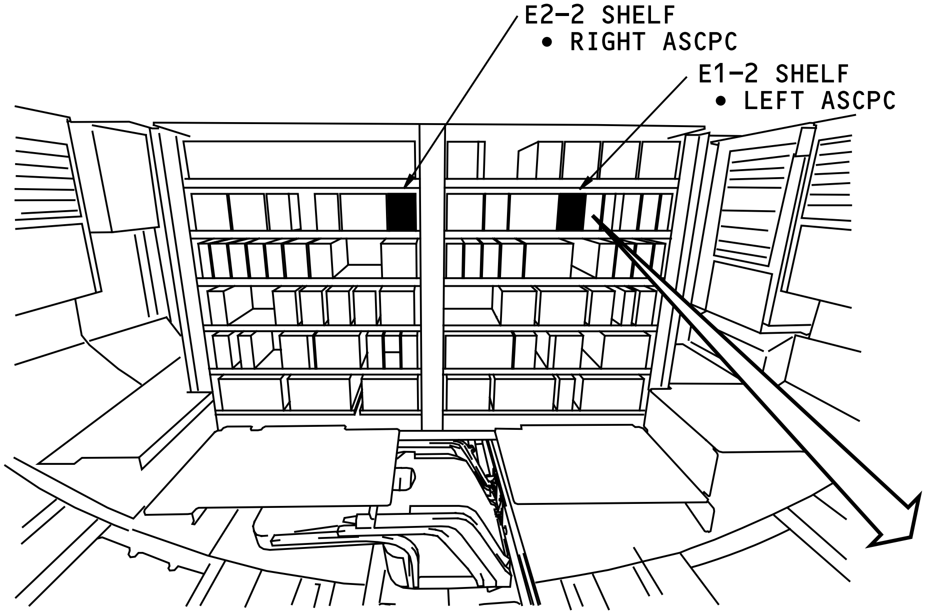
The ASCPCs have test and cabin pressure sense ports on the front. The test port is for in-shop service. The cabin pressure sense port lets the controllers monitor cabin pressure.

The ASCPCs use operational program software (OPS) that you can load.

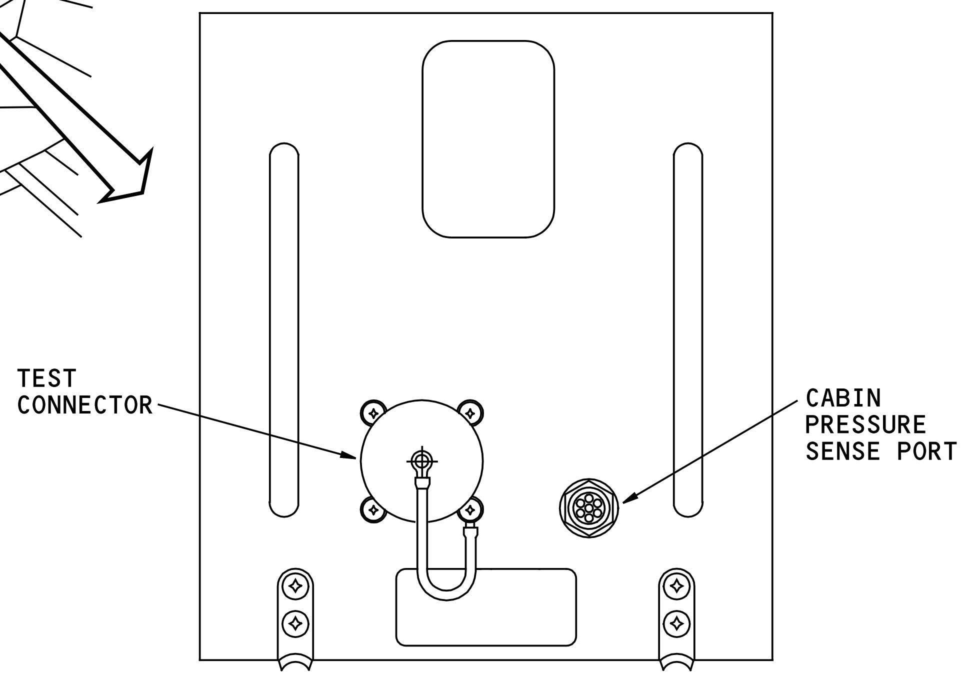
Training Information Point

The ASCPCs are LRUs. The circuit cards inside the ASCPC are not lRUs.

The left and right ASCPCs are interchangeable.



MAIN EQUIPMENT CENTER
(LOOKING AFT)



AIR SUPPLY CABIN PRESSURE CONTROLLER
(TYPICAL)

36-11-00-017 Rev 2

ENGINE AIR SUPPLY SYSTEM - AIR SUPPLY CABIN PRESSURE CONTROLLER - PHYSICAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE AIR SUPPLY SYSTEM - AIR SUPPLY CABIN PRESSURE CONTROLLER - PURPOSE

Purpose

The left and right air supply cabin pressure controllers (ASCPC) give control for these systems:

- Pneumatic (engine air supply and air supply distribution)
- Pressurization
- Air conditioning (pack flow schedule and backup pack control).

The controllers also give indications, have BITE, and have interfaces with other airplane systems to give engine bleed air flow management. See the engine bleed air flow management page in this section for more information about flow management.

Control Modes

The ASCPCs have two modes: digital and analog. The ASCPCs use the digital control mode for these systems:

- Engine air supply
- Air supply distribution
- Pressurization
- Pack flow schedule
- Backup pack flow control.

The ASCPCs use analog control mode as a backup to digital mode for the engine air supply system.

The digital mode of the ASCPCs controls in any one of three ways:

- At the same time
- Primary
- Backup control.

These are the systems controlled by the ASCPCs:

SYSTEM	ASCPC	CONTROL
L ENGINE AIR SUPPLY	L	PRIMARY
R ENGINE AIR SUPPLY	R	PRIMARY
AIR SUPPLY DISTRIBUTION	L & R	SAME TIME
PRESSURIZATION & PACK FLOW SCHEDULE	L	PRIMARY
PRESSURIZATION & PACK FLOW SCHEDULE	R	BACKUP
L PACK FLOW CONTROL	L	BACKUP TO L CTC
R PACK FLOW CONTROL	R	BACKUP TO R CTC

For the systems listed in the above table, the digital control mode supplies these functions:

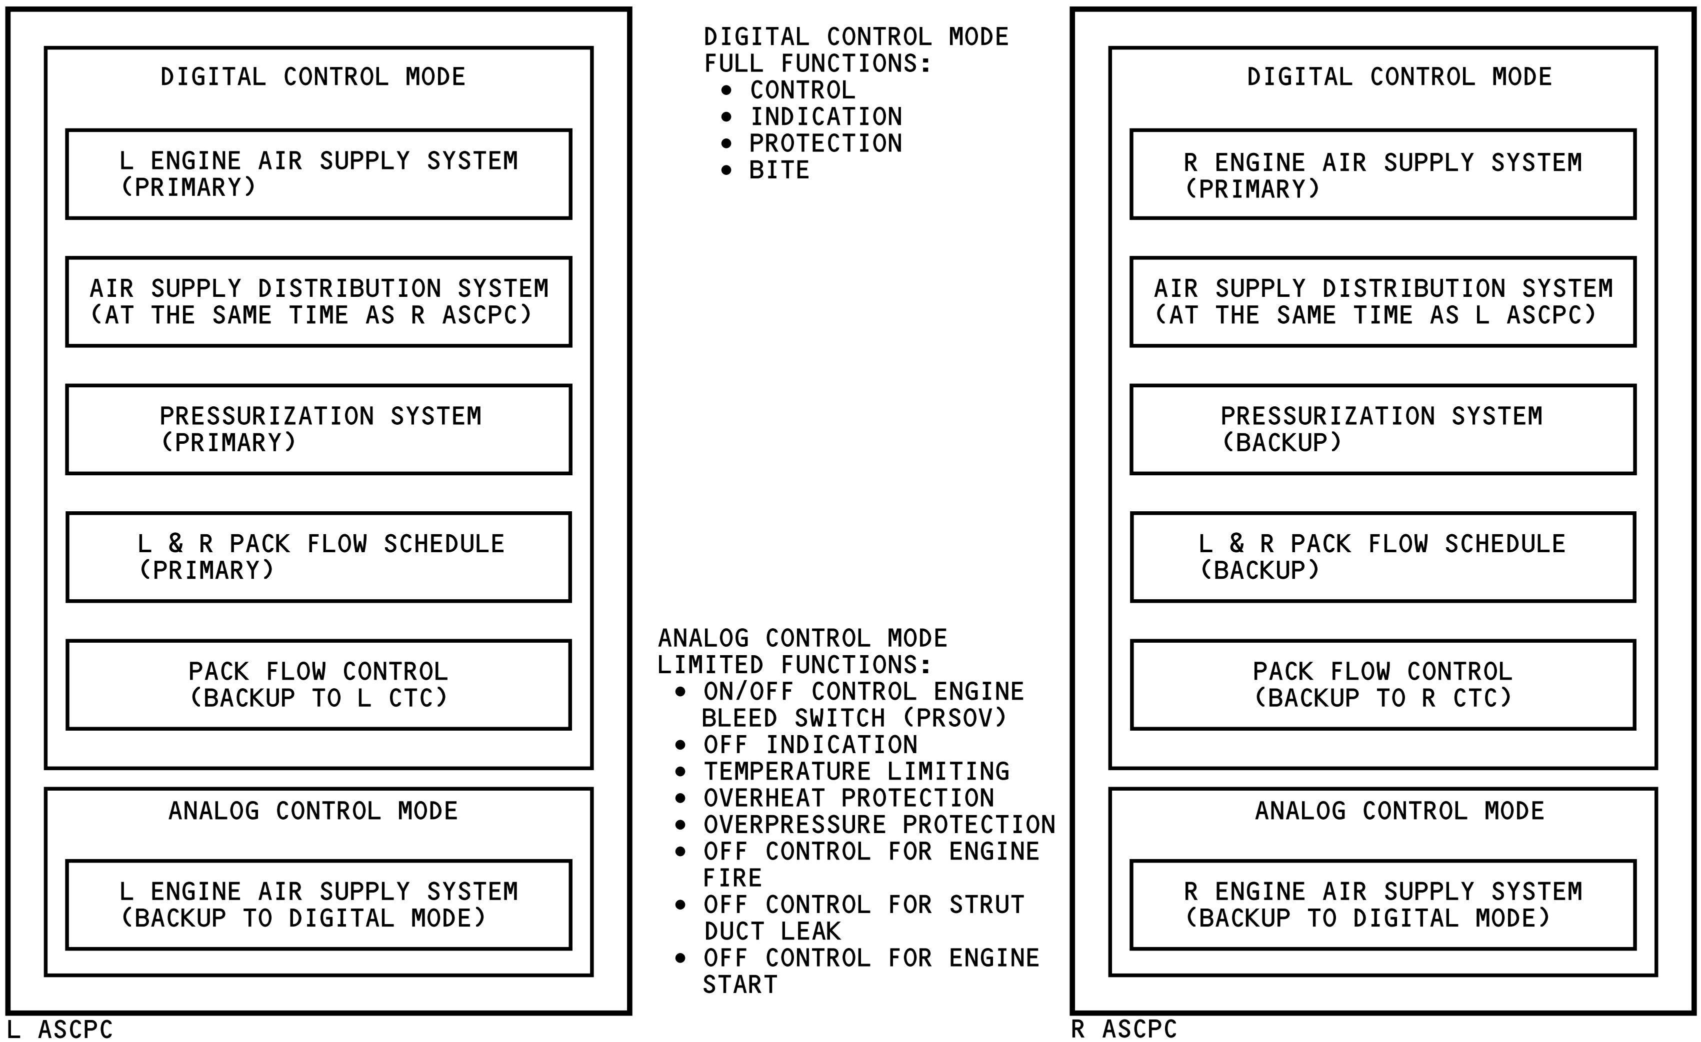
- Control
- Indication
- Protection
- BITE.

For the engine air supply system, the analog control mode gives these functions:

- ON/OFF control through the engine bleed air switch (PRSOV only)
- OFF indications
- Temperature limiting through the PRSOV

ENGINE AIR SUPPLY SYSTEM - AIR SUPPLY CABIN PRESSURE CONTROLLER - PURPOSE

- Overheat protection
- Overpressure protection
- OFF control through the engine fire switch
- OFF control through the duct leak detection system
- OFF control for the engine start condition.



36-11-00-018 Rev 2

ENGINE AIR SUPPLY SYSTEM - AIR SUPPLY CABIN PRESSURE CONTROLLER - PURPOSE

ENGINE AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION - 1

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION - 1

General

The left air supply cabin pressure controller (ASCPC) controls the left engine air supply system. The right ASCPC controls the right engine air supply system.

The engine air supply system has three modes:

- Primary (Digital)
- Backup (Analog)
- Pneumatic.

The ASCPC gives the primary and the backup modes of operation. The pneumatic mode is controlled by the reference pressure regulators in the HPFAC and the PRSOVC.

For usual operation, all of the functions of the primary mode operate and some of the functions of the backup mode operate at the same time.

If the primary mode does not operate, all of the functions for the backup and pneumatic modes operate at the same time.

If the primary and backup modes do not operate, the pneumatic mode controls the engine air supply without input from the flight deck or the ASCPC.

Primary Mode

The primary mode gives complete control and indications for the engine air supply system.

The operation monitor function in the ASCPC enables the primary mode if it finds no software or power supply faults related to the primary mode.

The primary mode uses the HPFAC and the PRSOVC to do these functions:

- On/off control
- Bleed source selection
- Pressure regulation
- Overpressure protection
- Temperature regulation
- Temperature limiting
- Overtemperature protection
- Flow limiting.

The primary mode gives power to these items:

- HPFAC
- FAMV RVDT
- PRSOVC
- Manifold flow sensor
- Manifold pressure sensor
- Manifold dual temperature sensor (TM 2)

The primary mode gets information directly from these sources:

- FAMV RVDT
- Manifold flow sensor
- Manifold pressure sensor
- Manifold dual temperature sensor (TM 2)
- Backup mode (IP data)

ENGINE AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION - 1

- AIMS
- DLODS
- Engine bleed air switch
- Engine fire switch
- Backup mode.

Information comes to the primary mode on the left and right ARINC 629 systems buses. These are the data sources and uses of this information in the primary mode:

- ACIPS - engine and wing anti-ice air flow rates for flow limiting
- ADIRU - primary source of altitude for bleed source selection
- AGS - airplane air/ground information for on/off control, temperature regulation and BITE
- AIMS - engine on/off information for engine air supply on/off
- CTC - request for lower precooler out temperature for temperature control
- CTC - request for high stage pressure increase for bleed air source selection
- CTC - pack inlet pressure for pressure regulation and overpressure functions
- CTC - pack flow information for flow limiting
- DLODS - strut/wing duct leak information for on/off
- EEC - high stage pressure for overpressure protection
- EEC - alternate ambient pressure source for bleed source selection
- FSEU - slat position for flow limiting
- HYDIM - ADP C1 and C2 on/off for flow limiting
- OPAS - position of the engine bleed air switches and the engine start selectors for on/off control
- WES - airplane stall for flow limiting.

These are some of the data sources and uses for information given directly to the primary mode:

- Engine bleed air switch - in/out position for on/off control function
- Engine start selector - START position information for on/off control function
- Engine fire switch - in/out position for on/off control function.

The backup mode gives information about its inputs to the primary mode.

The primary mode also has a BITE function.

<u>Backup Mode</u>

The backup mode monitors the primary mode for its on/off status and controls the engine air supply system when the primary mode is off.

The backup mode has functions that operate when the primary or backup modes are in control. Other backup mode functions only operate when the primary mode is off.

These backup functions operate when the primary or the backup mode is in control:

ENGINE AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION - 1

- On/off control - engine bleed air switch, engine fire switch, engine start selector
- Overtemperature protection.

These backup functions operate only when the primary mode is off:

- On/off control - strut/wing duct leak
- Overpressure protection
- Temperature limiting.

The backup mode controls the position of the PRSOV for these functions:

- On/off control
- Overpressure protection
- Temperature limiting.

With the engine air supply in backup control, the PRSOV and the HPSOV operate in the pneumatic mode to do pressure regulation and bleed source selection. The FAMV goes to the full open position.

The backup mode gives power to these items:

- PRSOVC
- Manifold dual temperature sensor (TM 1)
- Intermediate pressure sensor.

The backup mode gets information directly from these sources:

- Manifold dual temperature sensor (TM 1)
- Intermediate pressure sensor
- AIMS
- DLODS
- Engine bleed air switch
- Engine start selector
- Engine fire switch.

These are some of the data sources and uses in the backup mode:

- AIMS - engine on/off information for engine air supply on/off
- DLODS - strut/wing duct leak information for on/off.

<u>Pneumatic Mode</u>

The pneumatic mode does not use the ASCPC for control. It does not use electric power.

The pneumatic mode gives these functions for the engine bleed air supply system:

- Bleed source selection
- Pressure regulation.

The HPFAC is mechanically set to cause the FAMV to go full open. The HPFAC also causes the HPSOV to give bleed source selection and pressure regulation at a fixed value.

The PRSOVC is mechanically set to cause the PRSOV to give pressure regulation at a fixed value.

ENGINE AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION - 1

The engine bleed air system cannot be shut off unless the engine is stopped.

BITE

BITE for the ASCPC has:

- Continuous BIT
- Ground test.

Continuous BIT has these functions:

- Operates when the ASCPC has power and the ground test is not on
- Uses the HPFAC and PRSOVC to do a preflight test of the FAMV, PRSOV, and HPSOV and the related circuits.

Continuous BIT and ground tests do a check of the pneumatic system LRUs for correct operation. The preflight test and the ground test take approximately 20 seconds.

The preflight test operates when the related engine completes its start. To operate the ground test, select the appropriate test from the MAT.

Indications

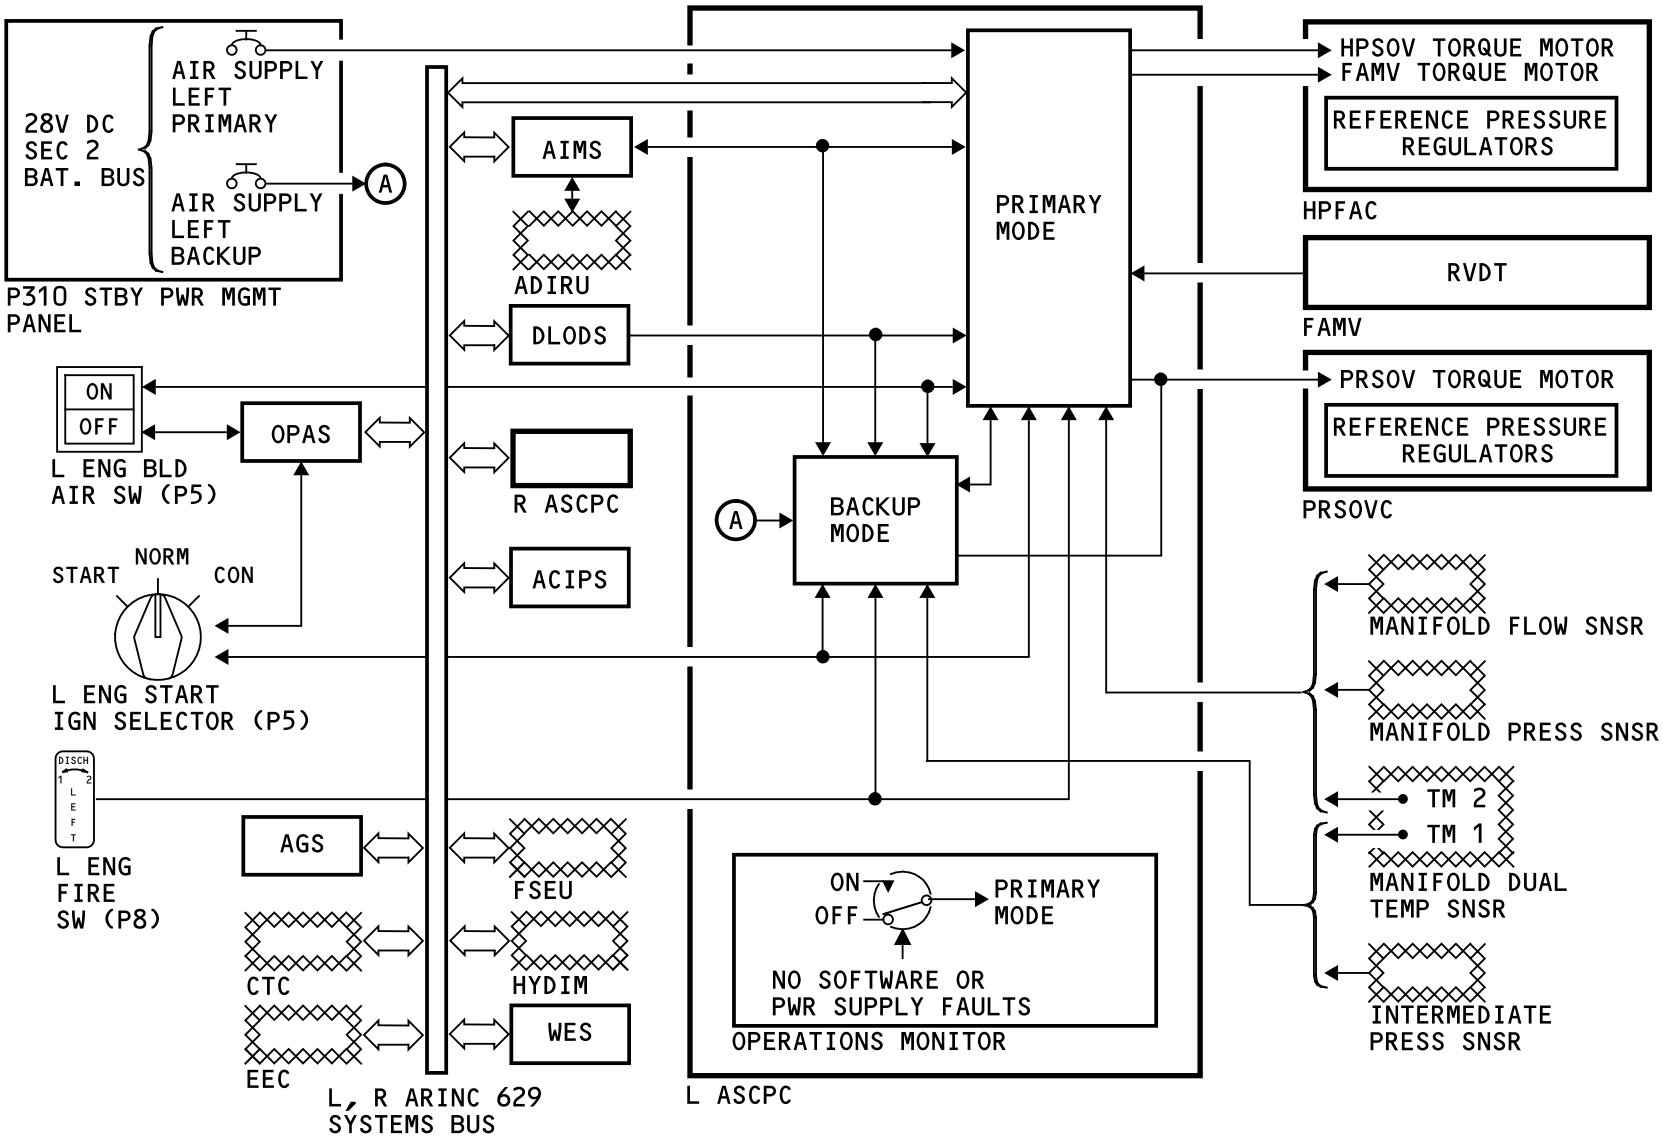
A status message (not shown) shows if the primary mode fails. No flight deck effects show if the backup or pneumatic mode fails.

See the indicating system section for more information about indications (AMM PART I 36-20).

Training Information Point

If the primary mode is off for the left or right ASCPC, it can affect the dispatch of the airplane. If a primary mode is off in one ASCPC, you must make sure the primary mode operates in the other ASCPC and that the backup mode operates in both ASCPCs.

See part II of the airplane maintenance manual for the dispatch deviations guide (DDG) maintenance procedure you use to check the condition of the backup mode.



36-11-00-024 Rev 4 12/16/1996

ENGINE AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION - 1

ENGINE AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION - 2

General

The primary and backup modes of the ASCPC and the pneumatic mode controls the engine air supply differently. The modes set the position of the HPSOV and PRSOV for these functions:

- On/off and reverse flow control - primary and backup modes
- Bleed source selection - primary and pneumatic modes
- Pressure regulation - primary and pneumatic modes
- Overpressure protection - primary and backup modes.

On/Off Control - Primary Mode

The following description is based on these conditions: the engine is on and set to idle.

When the engine bleed switch is set to the out (OFF) position, the primary mode commands the HPSOV and the PRSOV to close and the FAMV to open.

The primary mode also closes one or both of the valves, PRSOV and HPSOV if any of these conditions occur:

- Engine fire switch set to out (PRSOV, HPSOV)
- ASCPC looking for location of the duct leak (PRSOV)
- Source loss (PRSOV)
- This engine start on ground (PRSOV)
- Ground air source supplies air (PRSOV)
- Engine off (HPSOV)
- TM sensor failed (HPSOV)
- HPSOV clamp logic (HPSOV).

The primary mode latches the PRSOV and the HPSOV close if any of these conditions occur:

- Engine strut duct leak
- Wing duct leak
- Engine bleed overtemperature, 490F (254C)
- Engine bleed overpressure, 242 psig
- PRSOV failed closed
- Bleed pressure loss.

When the PRSOV is set to close or latched close, these indications show in the flight deck:

- OFF light (not shown) in the related engine bleed switch
- ENG BLEED OFF L (R) advisory message (not shown).

When the engine bleed switch is set to the in (ON) position, the primary mode commands the HPSOV and the PRSOV to open. The FAMV is usually set towards closed.

Source Loss Condition Logic

The source loss condition logic lets the ASCPCs sense when there is not sufficient air pressure to the ADPs for landing gear retraction immediately after takeoff. Source loss can occur in the left or right parts of the pneumatic distribution system.

ENGINE AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION - 2

There are two sets of conditions that cause the ASCPCs to set the left source loss condition to true. The first set is true if all of these conditions occur:

- Landing gear is down
- Less than 180 seconds since takeoff
- Left engine is off.

The second set is true if all of these conditions occur:

- Landing gear is down
- Less than 180 seconds since takeoff
- Left duct pressure is less than 20 psig and right duct pressure is more than 20 psig.

The conditions that cause a right source loss are equivalent.

See the distribution section for more information about the configuration of the pneumatic distribution system during source loss (AMM PART I 36-20).

Bleed Pressure Loss Condition Logic

The bleed pressure loss condition logic lets the ASCPCs sense when a pneumatic duct breaks. Engine starter duct failure is the primary reason for this logic.

There are two sets of conditions that cause the ASCPCs to set the left bleed pressure loss condition to true. The first set is true if all of these conditions occur for more than 10 seconds:

- Left duct pressure is less than 13 psig
- Left pack inlet pressure is less than 13 psig
- Right duct pressure is more than 13 psig
- Left PRSOV is open
- Right PRSOV is open
- No duct leak signal from the duct leak and overheat detection system (DLODS)
- Landing gear is up
- Less than 180 seconds after takeoff.

The second set is true if all of these conditions occur for more than 10 seconds:

- Left duct pressure is less than 13 psig
- Left pack inlet pressure is less than 13 psig
- Right PRSOV is open
- Left PRSOV is closed
- Landing gear is up or more than 180 seconds after takeoff
- Left engine bleed air flow is more than 2.0 lbs/sec
- No left engine start.

The conditions that cause a right bleed pressure loss are equivalent.

See the distribution section for more information about the configuration of the pneumatic distribution system during bleed pressure loss (AMM PART I 36-20).

ENGINE AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION - 2

On/Off Control - Backup Mode

The backup mode provides on/off control differently from the primary mode. The backup mode only sets the PRSOV to open or close. It does not control the position of the HPSOV or the FAMV.

The backup mode sets the PRSOV to closed for the applicable engine if any these conditions occur:

- Engine bleed air switch set to out
- Engine fire switch set to out (pulled)
- Engine start selected
- Engine is off.

The backup mode latches the PRSOV closed if any of these conditions occur:

- Engine strut duct leak
- Engine bleed overtemperature, 490F (254C)
- Engine bleed overpressure, 242 psig.

The backup mode gives the same flight deck indications as the primary mode when the PRSOV is set to close or latched closed.

Bleed Source Selection - Primary Mode

The bleed source selection function makes sure there is sufficient pressure downstream of the HPSOV for the systems that use engine bleed air. This is the same as the logic for the pressure regulation function.

The primary mode sets the position of the HPSOV to provide control of the bleed air source. When the intermediate pressure air source is not sufficient for the downstream systems, HP air is used.

These are three possible combinations for the engine bleed air source:

- HP air is the only source
- IP air is the primary source. HP air adds air as necessary
- IP air is the only source.

The primary mode uses the IP sensor to get data about the pressure downstream of the HPSOV. The IP data is used to calculate the position of the HPSOV necessary to keep the setpoint pressure. These are the duct pressure setpoints:

- 40 psig when the altitude is less than or equal to 27,000 feet (8230m)
- Decreasing value, 40 through 32.5 pisg when the altitude is more than 27,000 feet (8230m) and is less than or equal to 43,000 feet (13,106m)
- 32.5 psig when the altitude is more than 43,000 feet (13,103m).

The value of the setpoint pressure is biased by any of these conditions:

- CTC request for more pressure - 6 psig bias
- Engine cross bleed start - 9 psig bias.

ENGINE AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION - 2

The setpoint pressure increases by the amount of the highest request.

If the quantity of the intermediate pressure air is enough to supply the user systems, the HPSOV closes.

See the functional description part of the air conditioning - pack cooling and mix manifold temperature control section for the conditions that cause the CTC to request more pressure (AMM PART I 21-52).

Bleed Source Selection - Backup and Pneumatic Modes

The pneumatic mode automatically gives bleed source selection when the backup mode or the pneumatic mode controls the engine air supply.

Similar to the primary mode, the pneumatic mode provides three combinations for the source of engine bleed air:

- HP air alone
- IP air with HP air added as necessary
- IP air alone.

The pneumatic mode uses the HPFAC reference pressure regulators to control HPSOV position. The regulators are set to provide the HPSOV with the necessary control pressure so that the valve regulates to a setpoint of 55 +/- 15 psig. This setpoint is designed to make sure pressure downstream of the HPSOV is more than sufficient for the systems that use engine bleed air.

If IP air pressure is less than the setpoint, then HP is the only source for engine bleed air.

If IP air pressure is more than the setpoint but can not provide the necessary air flow to keep pressure downstream of the HPSOV above the setpoint, the HPSOV adds HP air as necessary.

If IP air provides the necessary air flow and keeps pressure downstream of the HPSOV to a value more than the setpoint, the HPSOV closes.

HPSOV Clamp Logic

HPSOV clamp logic closes the HPSOV when the HP air source pressure is high. Pneumatic distribution duct failure is the primary reason for the HPSOV clamp logic. The logic gets pressure information about the HP air source from the EEC. The set pressure changes with airplane altitude.

This is an example of the airplane altitudes and the HP air pressure values that cause the HPSOV to close:

- -2,000 feet (-610m) through 20,000 feet (6,100m) the set pressure is 270 psia
- > 20,000 feet (6,100m) through 43,000 feet (13,115m) the value decreases with altitude
- > 43,000 feet (13,115m) the value is 120 psia.

ENGINE AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION - 2

Pressure Regulation - Primary Mode

The pressure regulation function uses the HPSOV and PRSOV to control duct pressure. The HPSOV gives pressure regulation when the HP source gives air. The PRSOV gives pressure regulation when the HPSOV is closed. The HPSOV and the PRSOV regulate to different values.

Primary mode control of the HPSOV is the same as for the bleed source selection function.

The position of the PRSOV controls duct pressure to the usual setpoint value of 50 psig.

Pressure Regulation - Backup and Pneumatic Modes

The pneumatic mode automatically gives pressure regulation when the backup mode or the pneumatic mode controls the engine air supply.

The pneumatic mode uses the reference pressure regulators in the PRSOVC to give pressure regulation. The regulators are set to give the PRSOV the necessary control pressure so that the valve regulates to a usual setpoint of 60 +/- 15 psig. This setpoint is designed to make sure pressure downstream of the PRSOV is more than sufficient for the systems that use engine bleed air.

Overpressure Protection - Primary and Backup Modes

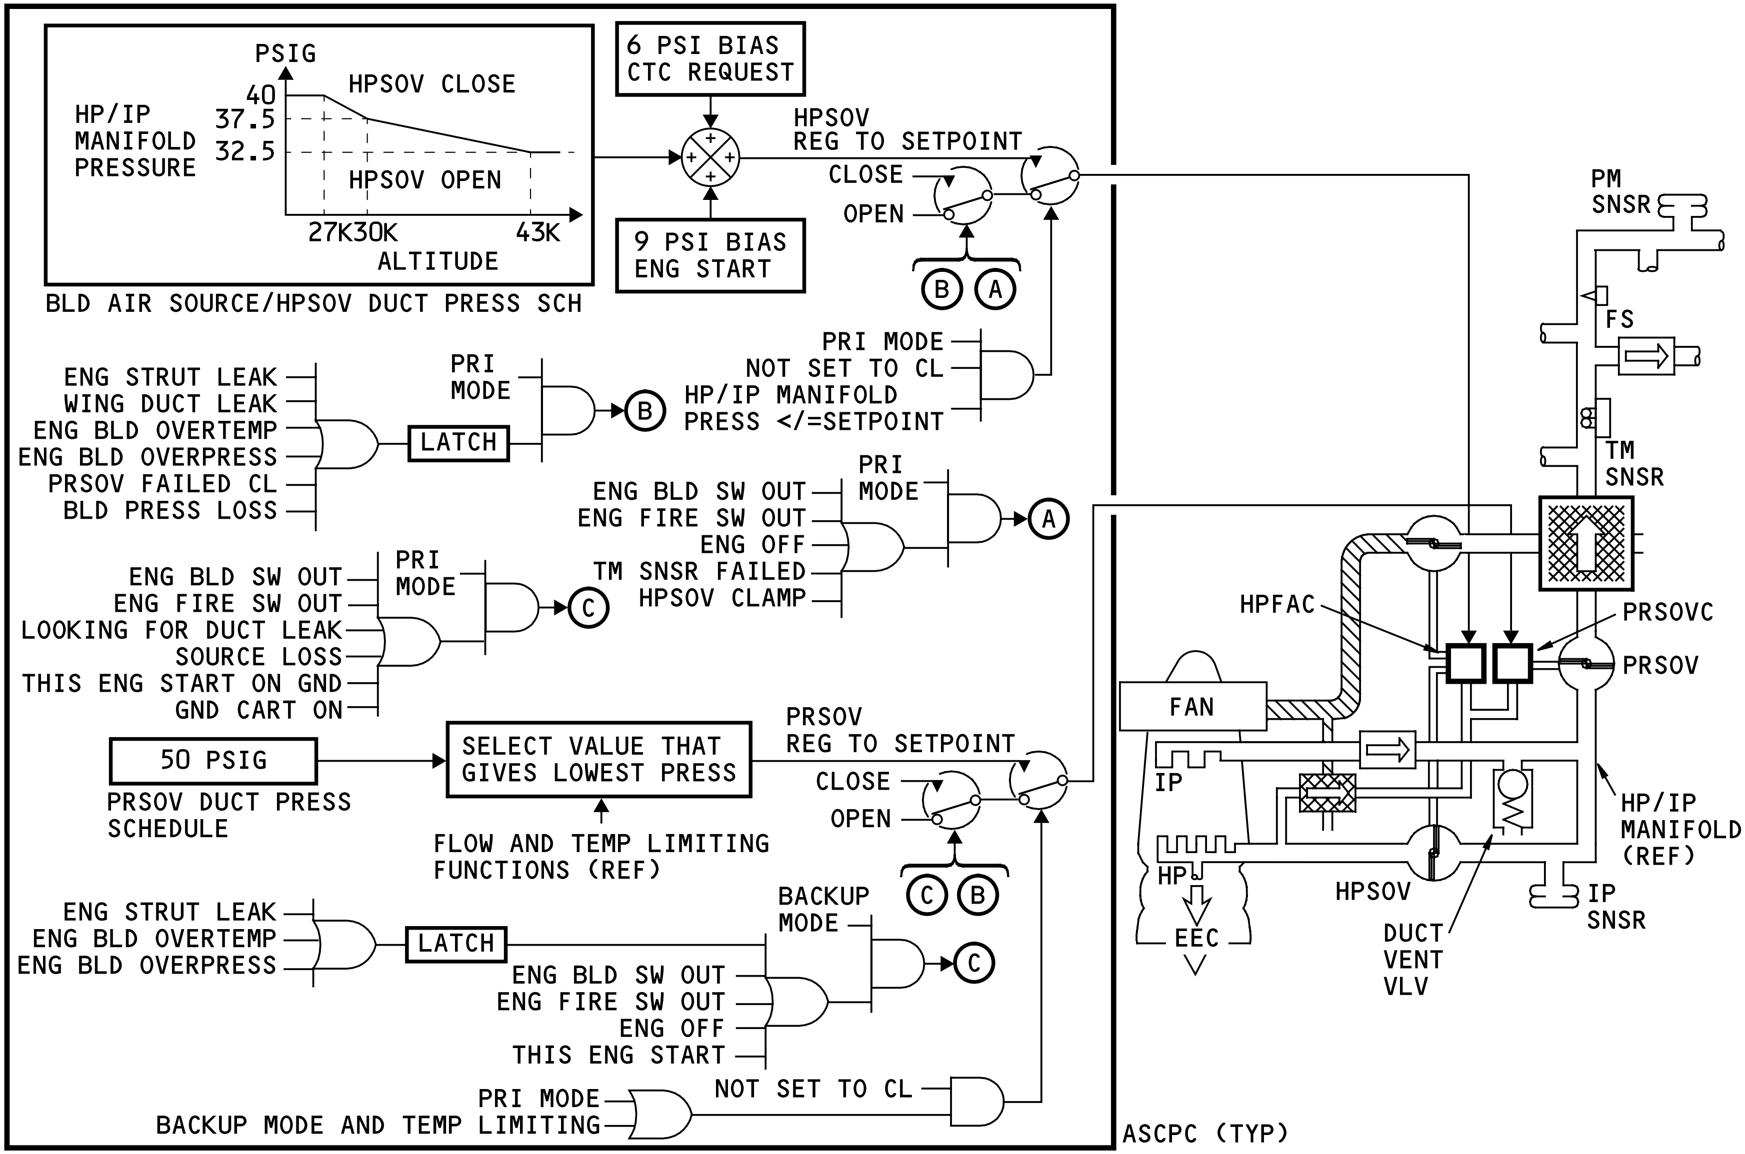
The logic used by the primary and backup modes for overpressure protection is similar. Both modes monitor the pressure in the HP/IP manifold. If the pressure is 242.5 psig or more for 5 seconds, the engine air supply latches off. The primary mode inhibits the latch if the landing gear is retracting.

These components give pressure information used by the overpressure protection function:

- Intermediate pressure (IP) sensor - HP/IP manifold pressure to the primary and backup modes
- EEC - gives pressure information about the HP source to the primary mode only.

Training Information Point

When a latched condition occurs, do not put the applicable engine bleed switch to out and then back to in. This will reset the latched condition and any active fault will disappear. Use the Fault Isolation Manual to troubleshoot a latched condition.



ENGINE AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION - 2

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION - 3

General

The ASCPC changes the position of the FAMV and the PRSOV for temperature control. The primary and backup modes use torque motors in the HPFAC and the PRSOVC to change the amount of control air to the valves.

The primary mode can change the position of the fan air modulating valve (FAMV) to give the usual temperature regulation function. The primary and backup modes can change the position of the pressure regulating and shutoff valve (PRSOV) to give these functions:

- Temperature limiting - primary and backup modes
- Overtemperature protection - primary and backup modes
- Flow limiting - primary mode.

The pneumatic mode gives no temperature control of any type and does not give flow limiting. When the backup mode or the pneumatic mode gives control, the FAMV goes to the default position of fully open.

Temperature Regulation

The primary mode usually controls the precooler outlet temperature to one of these fixed values:

- 380F (193C): usual value
- 250F (121C): if the CTC requests lower temperature and wing anti-ice off.

Element 2 in the manifold temperature sensor (TM2) gives the temperature information to the primary mode. If element 2 fails, the primary mode gets temperature information from element 1 (TM1) through the backup mode.

The primary mode usually uses the FAMV to control the precooler out temperature. The position of the FAMV is set to control the amount of fan air allowed through the precooler. The fan air cools the engine bleed air as it goes through the precooler.

The primary mode sets the usual temperature of 380F (193C) to make sure sufficient heat is in the air for the wing anti-ice system.

If the wing anti-ice system is off, the primary mode can set the temperature to 250F (121C) if the related cabin temperature controller (CTC) tells the ASCPC that a lower temperature is necessary.

See the functional description part of the air conditioning pack cooling and mix manifold temperature control section for more information about CTC request for lower precooler out temperature (AMM PART I 21-52).

Temperature Limiting

The primary and backup modes give the same temperature limiting function. When the precooler out temperature is 450F (232C) or more, the applicable mode sets the position of the PRSOV to limit the amount of bleed air allowed through the precooler.

ENGINE AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION - 3

Temperature information comes from TM2 for the primary mode or TM1 for the backup mode.

When the precooler out temperature is equal to or more than 450F (232C), the primary and backup modes command the PRSOV towards closed to limit bleed air flow. When bleed air flow is limited, the bleed air temperature usually goes down.

Overtemperature Protection

The engine bleed air overtemperature protection function is enabled at the same time by the primary and backup modes. Temperature information comes from TM2 for the primary mode or TM1 for the backup mode.

If the precooler out temperature is more than 490F (254C), the primary and backup modes command the PRSOV to the fully closed position.

Flow Limiting

The primary mode limits the flow of engine bleed air to 10 lbs/sec (4.5 kg/sec). The limit includes the amount of air used or measured by these systems or components:

- Wing anti-ice (WAI)
- Engine anti-ice (EAI)
- Air supply distribution, flow sensor (FS).

The primary mode calculates the total amount of engine bleed air used based on the inputs. If the flow is more than 10 lbs/sec (4.5 kg/sec), the primary mode commands the PRSOV towards closed to limit bleed air flow.

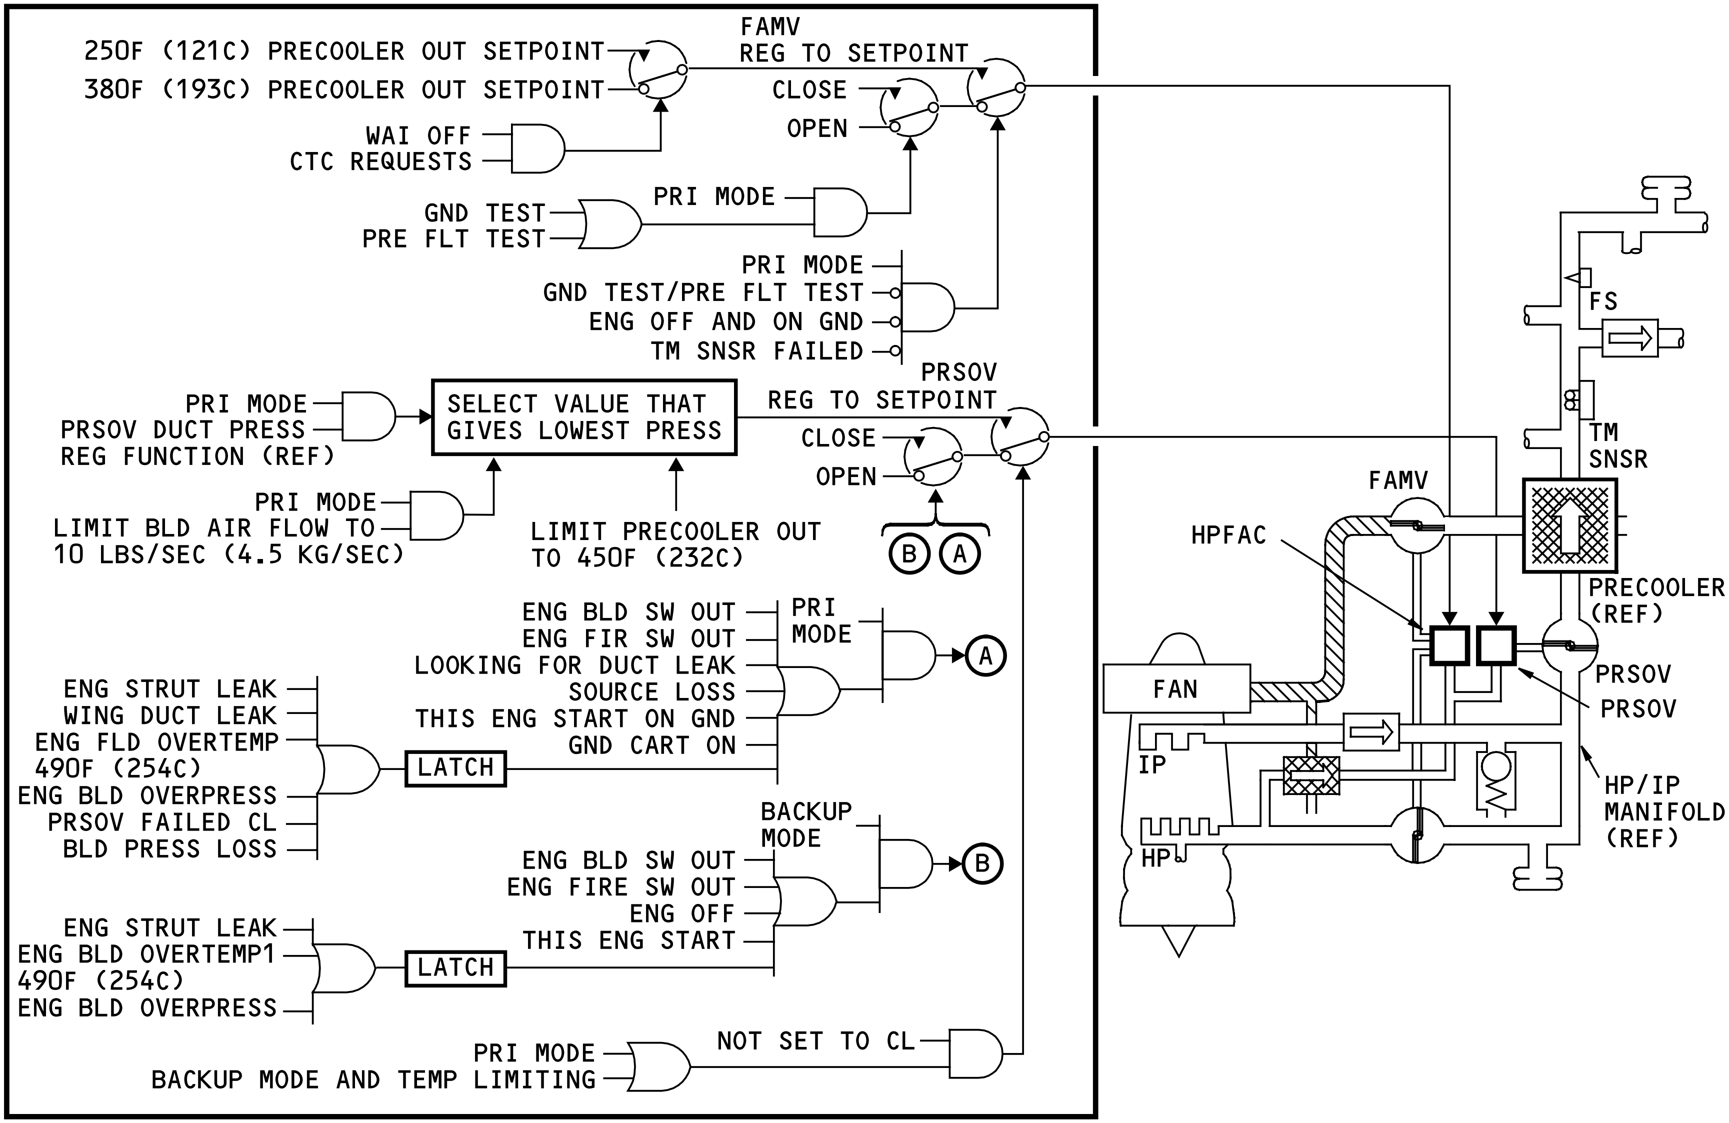
See the wing anti-ice section for more information about WAI (AMM PART I 30-11).

See the engine anti-ice section for more information about EAI (AMM PART I 30-21).

See the indicating system section for more information about the flow sensor (FS) (AMM PART I 36-20).

BITE

During the ground test or the preflight test, the FAMV will be closed and open to do a test of the valve and its related circuit.



ASCPC (TYP)

ENGINE AIR SUPPLY SYSTEM - FUNCTIONAL DESCRIPTION - 3

AIR SUPPLY DISTRIBUTION - INTRODUCTION

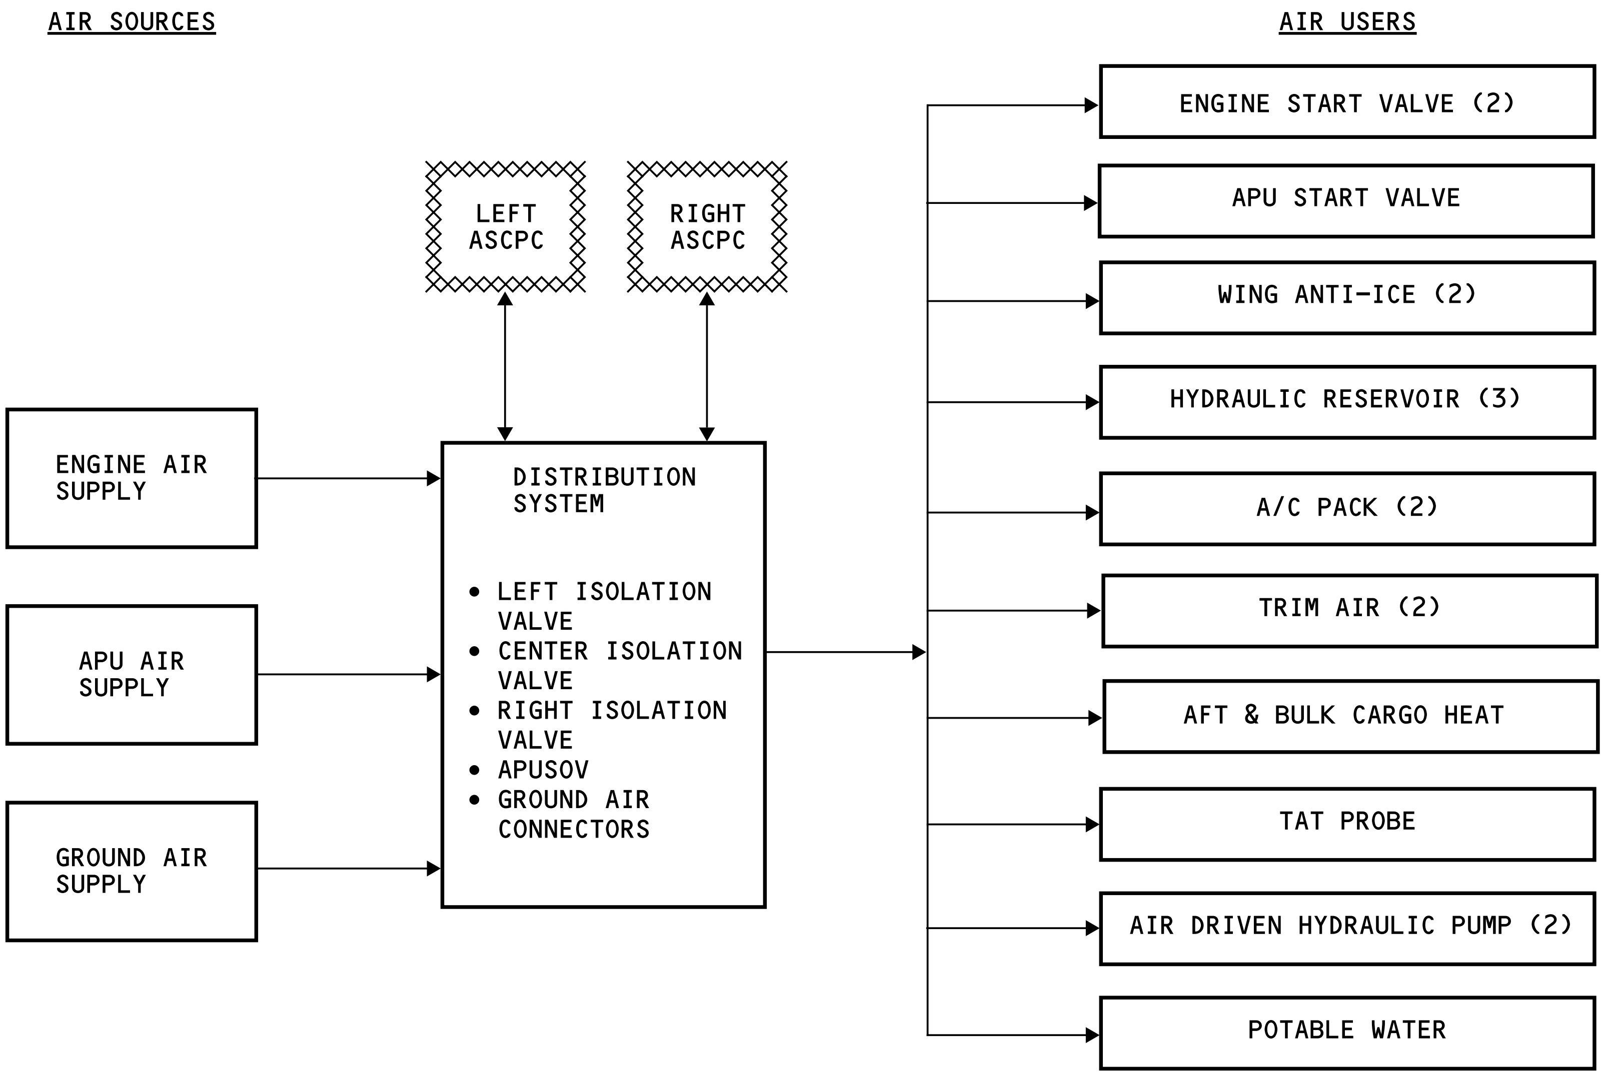
Purpose

The air supply distribution system supplies air from the air sources to users. The system also isolates the air sources from each other.

General

The air supply distribution system supplies compressed air from the engines, APU, and ground carts to user systems. The left and right air supply cabin pressure controllers (ASCPCs) control three isolation valves and the APUSOV in the distribution system. Both controllers control the valves at the same time. The valves then supply air to these components and systems:

- Engine start valve
- APU start valve
- Wing anti-ice
- Hydraulic reservoirs
- Air conditioning packs
- Aft and bulk cargo heat
- Trim air
- Total air temperature probe
- Air driven hydraulic pumps
- Potable water.



36-12-00-001 Rev 1

AIR SUPPLY DISTRIBUTION - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

AIR SUPPLY DISTRIBUTION - GENERAL DESCRIPTION

General

The air supply distribution system has these parts:

- Large main distribution ducts (wing, body)
- Small ducts
- Left isolation valve
- Center isolation valve
- Right isolation valve
- APU shutoff valve (APUSOV)
- Three high pressure ground connectors.

The large main distribution ducts connect to the engines and the APU. The smaller ducts connect the user systems to the main distribution ducts.

You use switches on the bleed air/pressurization panel to set the mode of control for the isolation valves and APUSOV. AUTO and CLOSED are the positions for the isolation valve switches. AUTO and OFF are the positions for the APUSOV switch. The switches also have annunciator lights that give you information about the system.

The left and right ASCPCs control the isolation valves and the APUSOV. The controllers use inputs from these systems/components to calculate when a valve should be open or closed:

- ELMS
- OPAS
- AIMS
- APU fire switch
- DLODS
- APUC
- ADIRU.

The ELMS tells the ASCPCs when the airplane is on standby power. The ASCPCs use this when calculating APUSOV position.

The OPAS is the interface between the ARINC 629 buses and the bleed air/pressurization panel. The ASCPCs get information about switch position and control the annunciator lights through the OPAS and the ARINC 629 buses. The ASCPCs use switch position when calculating valve positions.

The AIMS gives information about the system through the primary display system.

The APU fire switch gives switch position information directly to the ASCPCs. The ASCPCs use this when calculating valve positions.

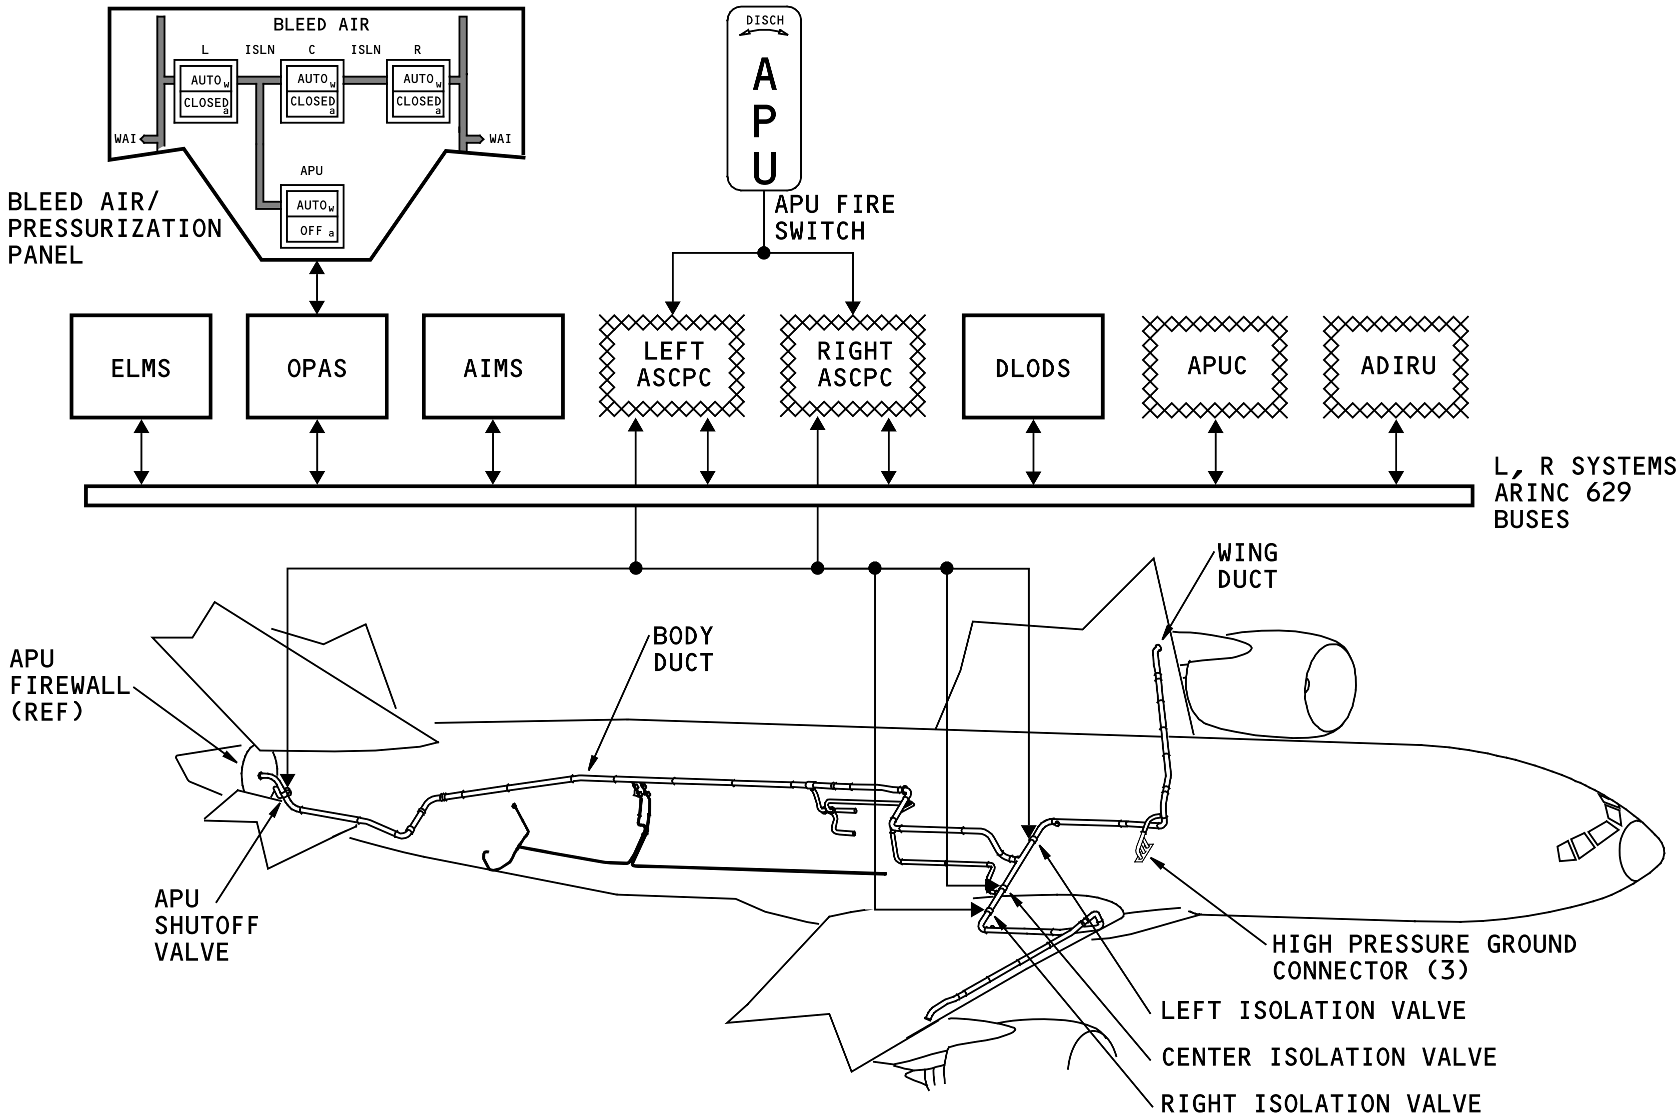
The DLODS monitors the pneumatic distribution ducts for leaks and sends a signal if there is a leak. The ASCPCs calculate valve positions to isolate the leak based on the duct leak signal from DLODS.

The APUC gives APU on or off information to the ASCPCs. It also sends a signal to open the APUSOV for an air start of the APU. The ASCPCs use APUC information when calculating valve positions.

AIR SUPPLY DISTRIBUTION - GENERAL DESCRIPTION

The ADIRU gives airplane altitude information to the ASCPCs. The ASCPCs use altitude information when they do a test of the system.

BITE circuits in the ASCPCs monitor the condition of the system. You use the MAT to do ground tests of the system.



36-12-00-002 Rev 1

AIR SUPPLY DISTRIBUTION - GENERAL DESCRIPTION

AIR SUPPLY DISTRIBUTION - ISOLATION VALVES

Purpose

The isolation valves control the air flow direction in the pneumatic manifold from both engines, the APU, and the ground air supply.

Physical Description

Each isolation valve has these parts:

- Actuator
- Solenoid
- Valve body
- Electrical connector
- Manual override and position indicator assembly
- Rotary variable differential transformer (RVDT).

Location

The left isolation valve is aft of the left environmental control system (ECS) access door. You open the access panel 195QL to get access to the left isolation valve.

The center isolation valve is aft of the right ECS access door. You open the access panel 196NR to get access to the center isolation valve.

The right isolation valve is aft of the right ECS door. You open the access panel 196QR to get access to the right isolation valve.

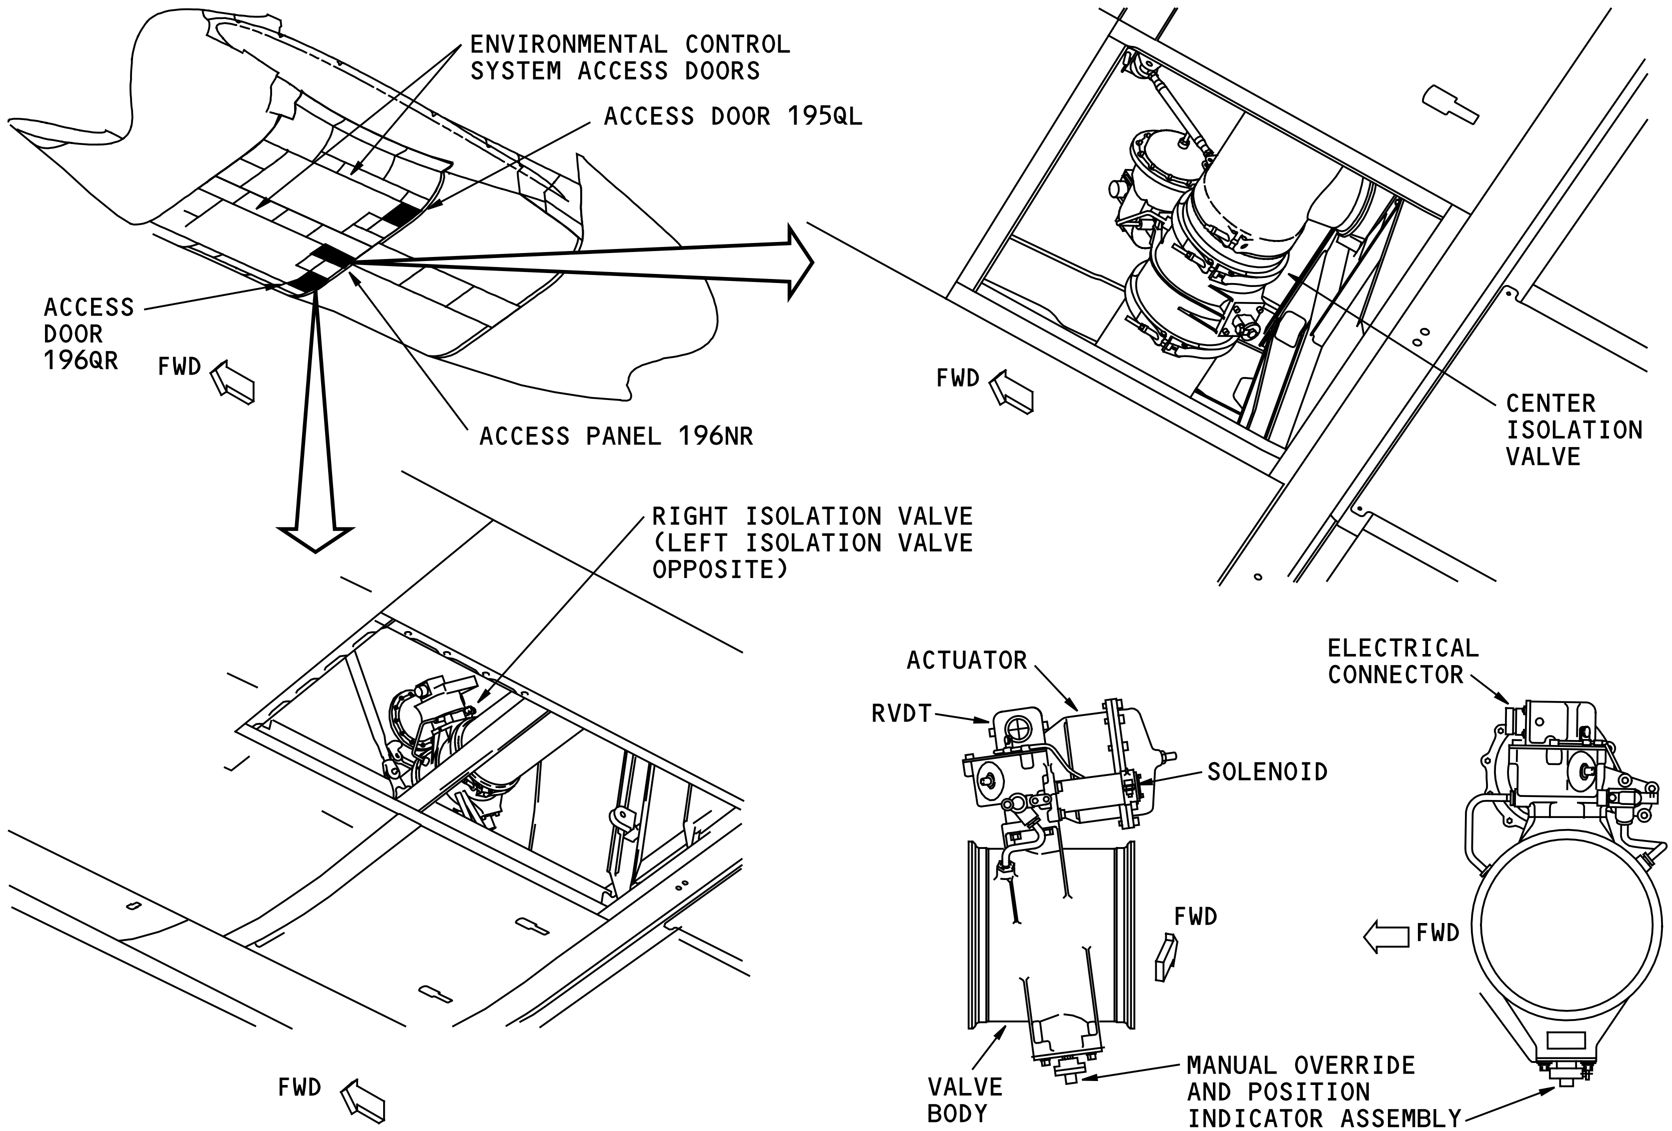
Functional Description

The isolation valves are two-position valves that are spring-loaded closed. The valves are electrically controlled and pneumatically actuated.

Training Information Point

Install the isolation valves with the placard in view and the electrical connection accessible.

The isolation valves are identical and interchangeable with each other and with the APU shutoff valve.



36-12-00-005 Rev 1

AIR SUPPLY DISTRIBUTION - ISOLATION VALVES

AIR SUPPLY DISTRIBUTION - APU SHUTOFF VALVE

Purpose

The APU shutoff valve (APUSOV) controls the flow of bleed air from the APU into the pneumatic manifold.

Location

The APUSOV is in the lower aft section of the airplane just forward of the APU firewall.

Physical Description

The APUSOV has these parts:

- Actuator
- Manual override and position indicator assembly
- Valve body
- Electrical connector
- Rotary variable differential transformer (RVDT)
- Solenoid.

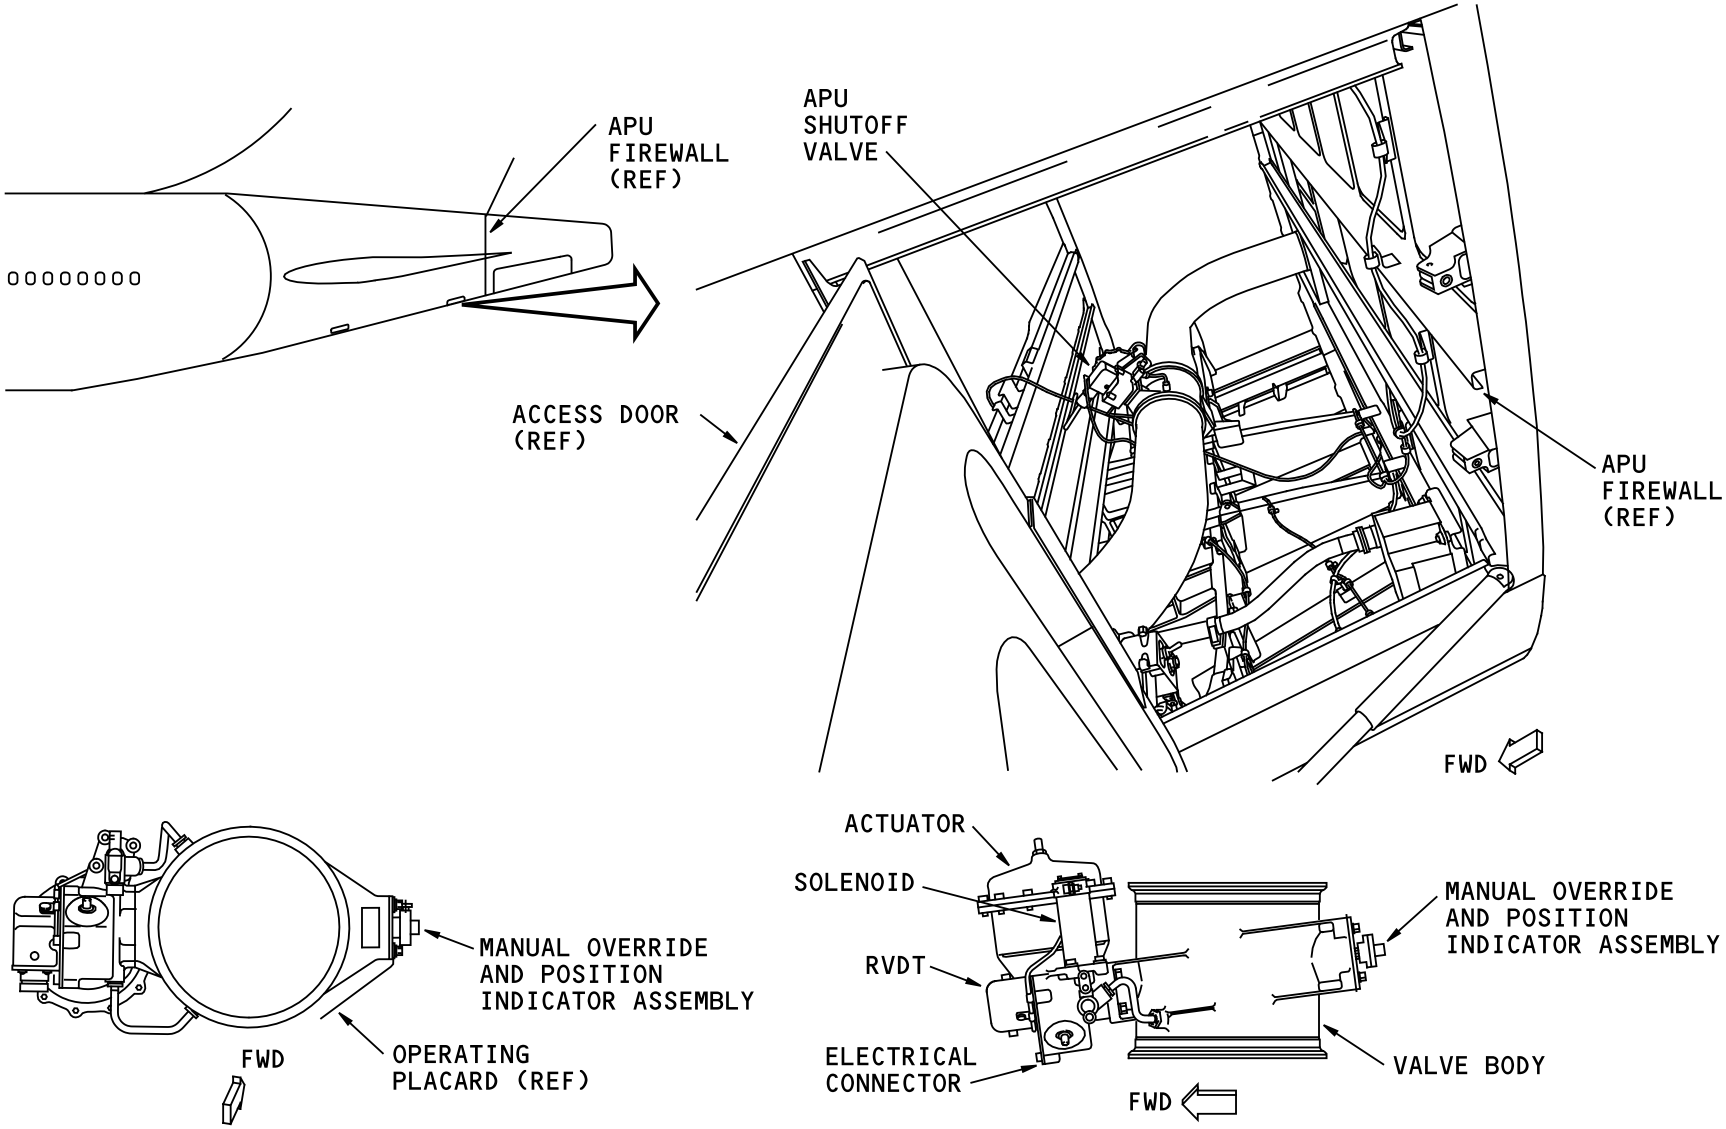
Functional Description

The APUSOV is a two position valve that is spring loaded closed. The valve is electrically controlled and pneumatically actuated.

Training Information Point

The APU shutoff valve should have the operating placard in view and the electrical connection accessible.

The APU shutoff valve is identical and interchangeable with the isolation valves.



36-12-00-006 Rev 1

AIR SUPPLY DISTRIBUTION - APU SHUTOFF VALVE

AIR SUPPLY DISTRIBUTION - ISOLATION/APU SHUTOFF VALVES - TRAINING INFORMATION POINTS

Purpose

The manual override and position indicator assembly lets you lock the valve closed or open and lets you see the position of the valve.

Location

The assembly is on the opposite side of the valve body as the actuator.

Physical Description

The manual override and position indicator assembly has these parts:

- Retainer plate
- Knob bolt
- Valve shaft hex
- Lock knob/position indicator
- OPEN / CLOSED placards.

Functional Description

The knob bolt lets you unlock or lock the lock knob/position indicator to the valve shaft.

The lock knob/position indicator shows you the actual valve disc position. You also use the indicator to lock the valve disc closed or open. The lock knob/position indicator has two positions: LATCH (in) and UNLATCH (out).

The retainer plate holds the lock knob/position indicator and valve shaft so they can not move when the lock knob/position indicator is in the LATCH position (pushed in position).

The hex part of the valve shaft lets you move the valve to OPEN or CLOSED.

Operation

Usually the lock knob/position indicator is locked by the knob bolt to the UNLATCH position. This lets the valve open and close freely.

When you loosen the knob bolt (UNLOCK), the lock knob/position indicator freely moves in or out along the valve shaft. This lets you set the lock knob/position indicator to any one these positions:

- LATCH: valve open
- LATCH: valve closed
- UNLATCH: valve free movement.

To keep the lock knob/position indicator in one of the above positions you tighten the knob bolt (LOCK).

You use standard hand tools to manually lock or unlock the isolation and APU shutoff valves. The valve shaft and knob bolt are sized for a 7/16 inch wrench.

(LATCH)

AIR SUPPLY DISTRIBUTION - ISOLATION/APU SHUTOFF VALVES - TRAINING INFORMATION POINTS

AIR SUPPLY DISTRIBUTION - HIGH PRESSURE GROUND CONNECTOR

Purpose

The high pressure ground connectors let an external air source connect to the main pneumatic distribution system. Check valves in the connectors prevent loss of pressurized air.

Location

The high pressure ground connectors are in the under wing fuselage area, forward of the ECS access door, 195EL. You open the access door 195BL to get access to the high pressure ground connectors.

Physical Description

The high pressure ground connector has these parts:

- Check valve
- Connector
- Flange.

Training Information Point

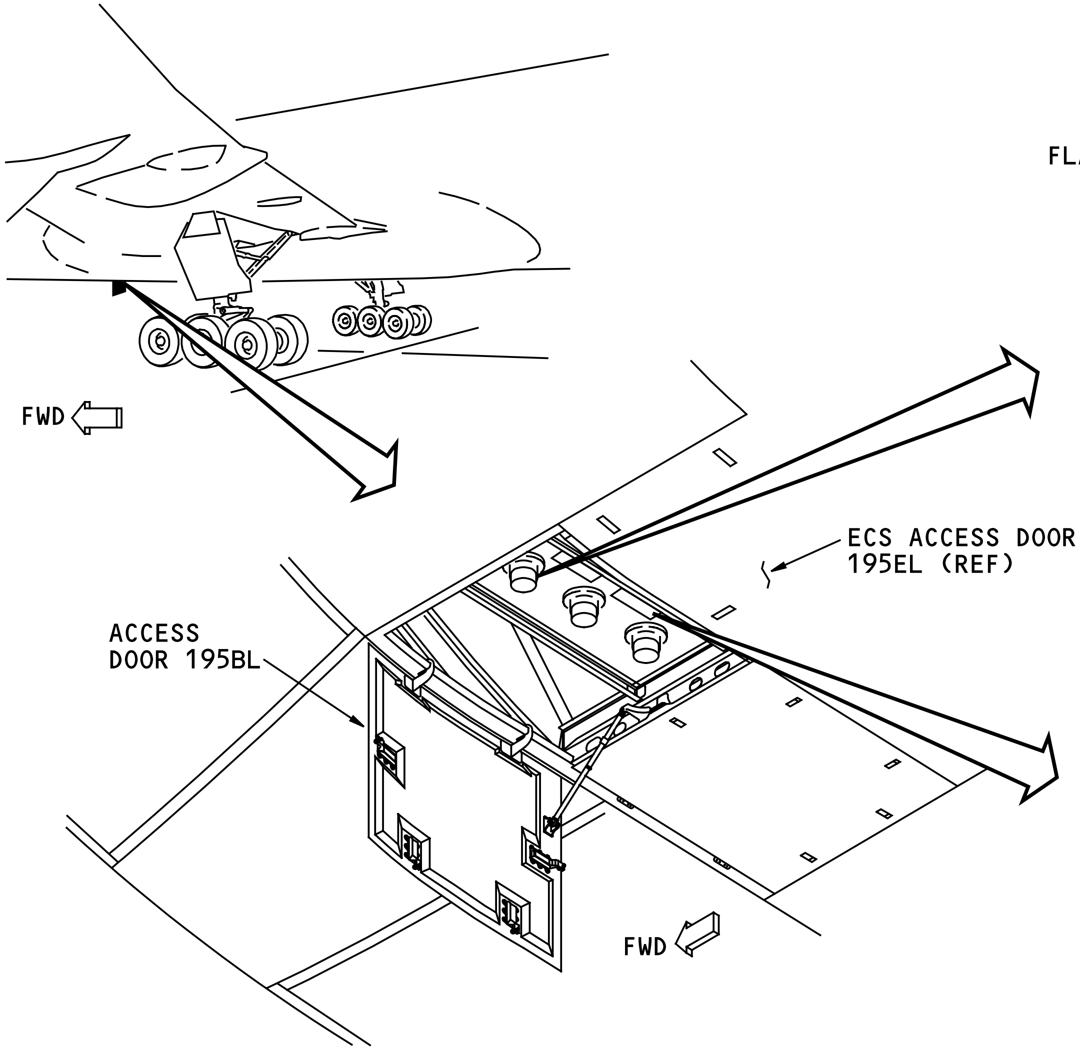
WARNING: DO NOT SUPPLY GREATER THAN 50 PSIG AND/OR 232C (450F) TO THE PNEUMATIC SYSTEM. IF YOU SUPPLY TO MUCH PRESSURE AND/OR TEMPERATURE DAMAGE TO EQUIPMENT AND INJURY TO PERSONAL CAN OCCUR.

CAUTION: TO PREVENT DAMAGE TO AIR CONDITIONING SYSTEM COMPONENTS, APPLY ELECTRICAL POWER BEFORE YOU APPLY PNEUMATIC POWER AND REMOVE PNEUMATIC POWER BEFORE YOU REMOVE ELECTRICAL POWER.

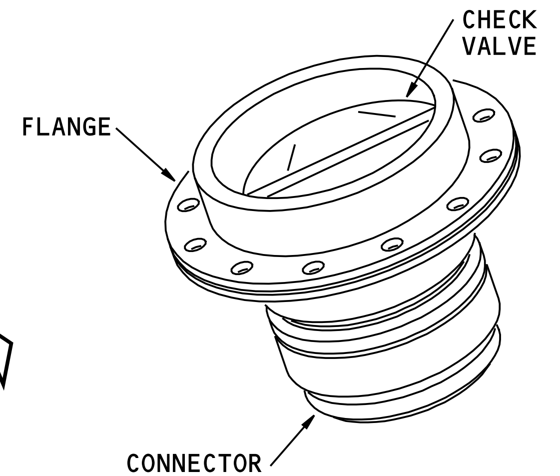
The air conditioning packs will operate without any protective functions if you pressurize the pneumatic system before you apply electrical power.

Before you depressurize the pneumatic system, make sure the air conditioning packs are off. If you depressurize the pneumatic system with the packs on, the packs will not do the normal pack shutdown on the ground sequence.

See the pack flow control section for more information on air conditioning pack start and shutdown sequences (AMM PART I 21-51).



UNDER WING FUSELAGE AREA



HIGH PRESSURE GROUND CONNECTOR
(TYPICAL)

WARNING

ENSURE THAT THE GROUND CART HOSE IS DEPRESSURIZED PRIOR TO REMOVAL. REFER TO AMM 36-00-00 / 201.

CAUTION

DO NOT EXCEED 50 PSIG AND/OR 232 C (450 F)

ENSURE APU, LEFT AND RIGHT ENGINES ARE NOT RUNNING PRIOR TO GROUND CART HOOK - UP

THIS PAGE INTENTIONALLY LEFT BLANK

AIR SUPPLY DISTRIBUTION - FUNCTIONAL DESCRIPTION - ISOLATION VALVES AND APUSOV

General

The left, center and right bleed isolation (L,C,R ISLN) switches and the APU bleed switch have two positions: in (AUTO) and out. The isolation switches have a CLOSED light. The APU bleed switch has an OFF light.

The AUTO position lets the ASCPCs set the position of the valves. The out position commands the ASCPCs to close the related valve. The CLOSED and OFF lights give indication for non-normal conditions.

These are the usual positions of the valves when the switches are set to AUTO and both engine air supply systems are on:

- Left isolation valve - open
- Center isolation valve - closed
- Right isolation valve - open
- APUSOV - closed.

The digital (primary) mode of both ASCPCs control the valves at the same time. The valves have a solenoid with two coils, one for each controller. A RVDT gives valve position information directly to one of the two ASCPCs. The other ASCPC monitors valve position through the ARINC 629 buses.

If the digital mode for both ASCPCs fail, the valves go to a default position. With duct pressure available, the valves open. With no duct pressure, a spring in the actuator closes the valves.

The left controller supplies BITE for the solenoid coils and RVDTs that connects to it. The right controller supplies BITE for the solenoid coils and RVDTs that connects to it.

The left ASCPC gets 28v dc for control and operation of the valves from the section 2 battery bus (not shown). The right ASCPC gets 28v dc for control and operation of the valves from the first officer's flight instrument bus (not shown).

See the engine air supply section for more information on ASCPC power (AMM PART I 36-11).

See the DC generation section for more information about DC power (AMM PART I 24-30).

Valve Functional Description

The internal parts for the left isolation valve is shown, the other isolation valves and the APUSOV have the same parts.

Air pressure to operate the valve comes from one of the two sides of the valve. The side of the valve that has the higher pressure supplies the air that goes through the shuttle valve to the switcher valve. The ASCPCs use the coils in the solenoid to control switcher valve position.

To open the valve, the ASCPCs remove power from the solenoid coils. The switcher valve spring moves to the position that lets air pressure go to the actuator. Pressure more than 10 psi opens the valve.

The RVDT sends a valve position signal to the ASCPC.

To close the valve, the ASCPCs energize the solenoid coils. The switcher valve moves to block pressure from the shuttle valve and releases pressure from the actuator. The spring in the actuator closes the valve.

The ASCPCs have control logic that sets the valves to one of these configurations:

- Open
- Closed
- Latched closed.

See the pages in this section about isolation valve and APUSOV control logic for more information on valve configurations.

Indications

These are the flight deck effects that have a relation to the position of the isolation valves and the APUSOV:

- Left, center, right bleed isolation CLOSED lights
- APU bleed OFF light
- Advisory message, BLEED ISLN CLOSED L,C,R
- Advisory message, BLEED ISLN OPEN L,C,R (not shown)
- Advisory message, BLEED OFF APU.

A status message, (not shown) also shows if a valve is not in its set position.

The CLOSED light lets the flight crew know that the valve is closed due to a non-normal condition of the valve or the pneumatic system. The OFF light lets the flight crew know that APU bleed air is not available due to a non-normal condition of the valve or the pneumatic system.

The advisory messages let the flight crew know that the related valve is:

- Not in the position set by the ASCPCs or
- Selected to a non-normal mode of control (related switch set to out).

The ASCPC logic that causes the CLOSED or OFF light, is different from that used to cause the related closed or off message. This means that the light and the related message do not always show at the same time.

The primary mode of the left ASCPC has the logic that calculates when to supply the indications related to the left and center isolation valves. The primary mode of the right ASCPC supplies the indications related to the right isolation valve and the APUSOV.

Valve Closed/Off Indications

The ASCPCs usually use RVDT valve position information and non-normal condition information to calculate when to show the valve closed/off indications. If the RVDT circuit fails, the ASCPCs use non-normal condition information to calculate when to show the valve closed/off indications.

The applicable bleed isolation CLOSED light comes on if any of these non-normal conditions occur:

- A bleed isolation switch is set to out
- An isolation valve is latched closed
- A valve is set to close as the ASCPCs try to find the location of a duct leak (wing, body)
- An isolation valve fails closed and the RVDT circuit functions correctly
- Source loss condition (L for L ISLN val, R for R ISLN val, L or R for C ISLN val).

The source loss condition logic lets the ASCPCs sense when there is not sufficient air pressure to the ADPs for landing gear retraction, immediately after takeoff.

There are two sets of conditions that cause the ASCPCs to set the left source loss condition to true. The first set is true if all of these conditions occur:

- Landing gear down
- Less than 180 seconds since takeoff
- Left engine off.

The second set is true if all of these conditions occur:

- Landing gear down
- Less than 180 seconds since takeoff
- Left duct pressure less than 20 psig and right duct pressure more than 20 psig.

The conditions that cause the right source loss condition to be true are equivalent to the conditions that cause the left source loss.

The APU bleed OFF light turns on if any of these non-normal conditions occur:

- APU bleed switch set to out
- APU shutoff valve latched closed
- Left wing or body duct leak
- APU shutoff valve failed close and the RVDT circuit functions correctly
- APU fire switch pulled.

For each valve there are two sets of conditions that cause the related closed or off advisory message, BLEED ISLN CLOSED L, C, R or BLEED OFF APU. The first set causes the applicable message if all of these conditions occur:

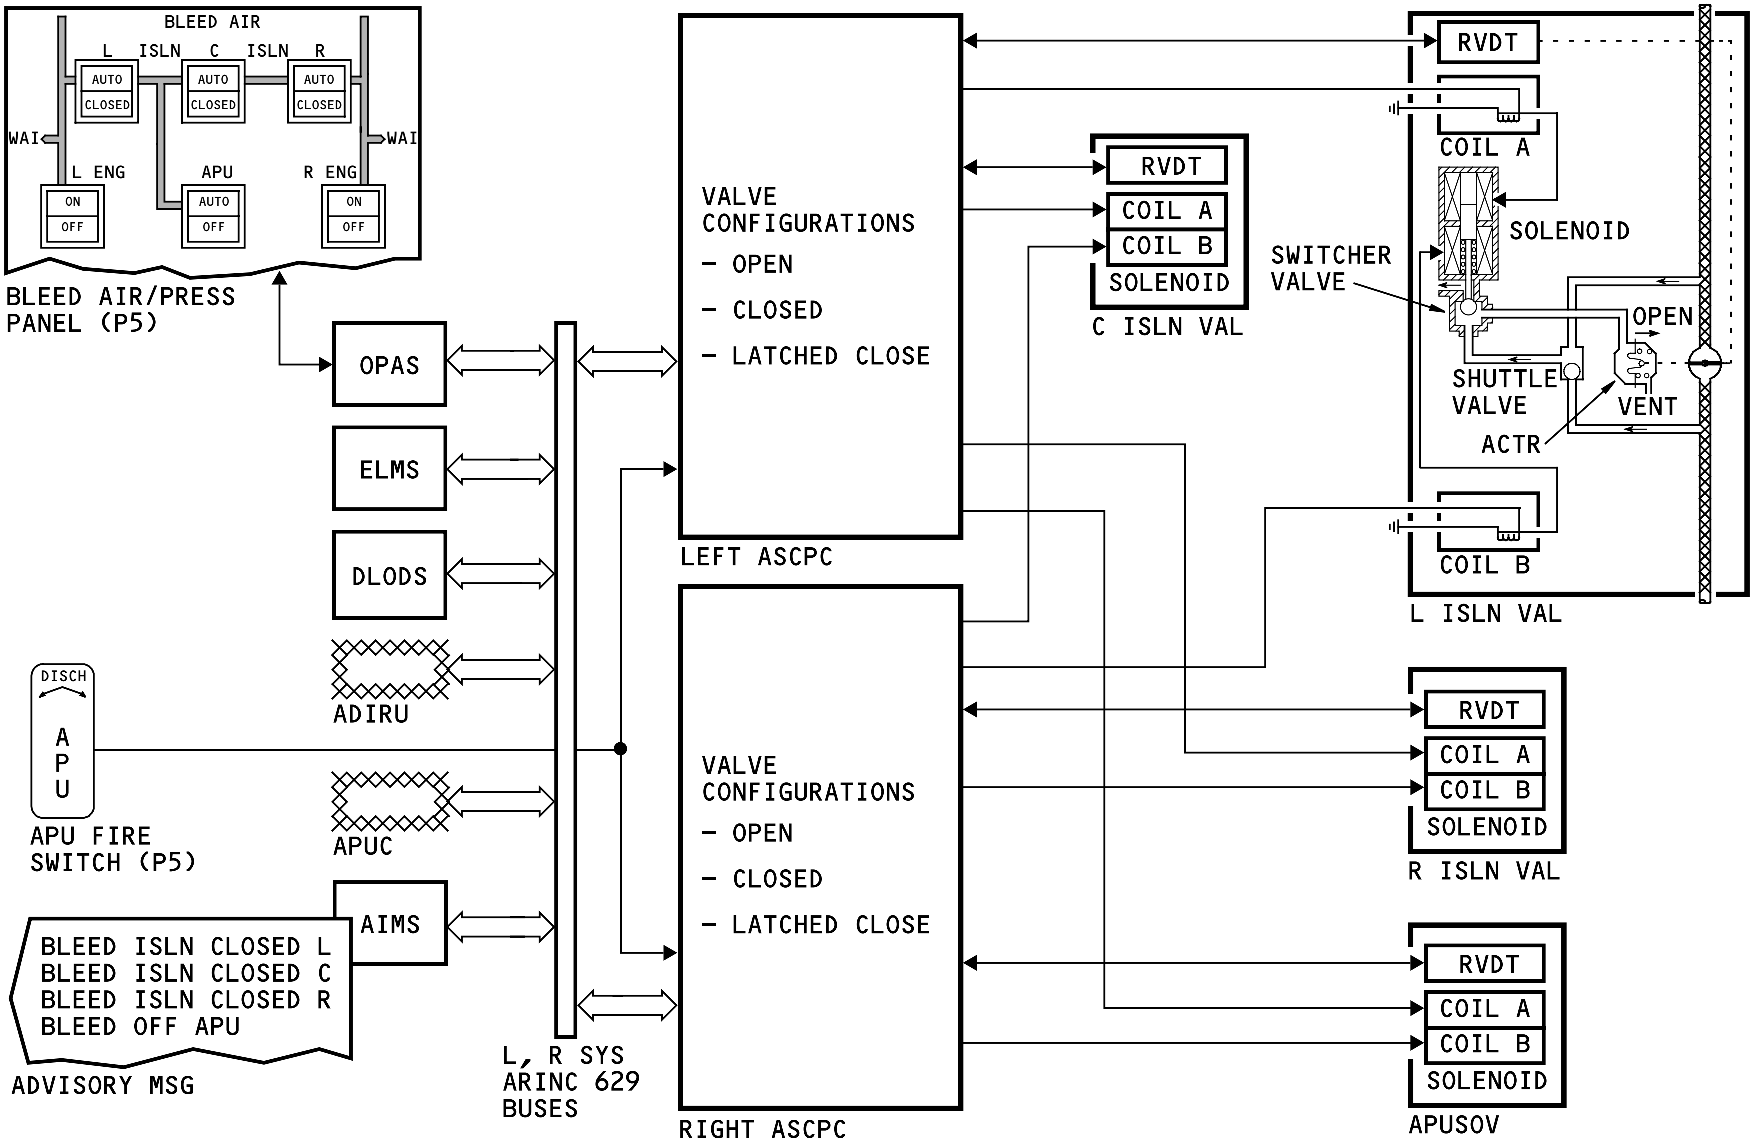
- Bleed isolation switch (L, R, C, APU) set to out
- Related valve is in the closed position or has a failed RVDT circuit.

The second set causes the applicable message if all of these conditions occur:

- Related valve fails in the closed position
- The RVDT circuit functions correctly.

Isolation Valve Open Indication Logic

The applicable advisory message, BLEED ISLN OPEN L,C,R shows if the RVDT circuit for the related valve operates correctly and the related valve fails in an open position.



AIR SUPPLY DISTRIBUTION - FUNCTIONAL DESCRIPTION - ISOLATION VALVES AND APUSOV

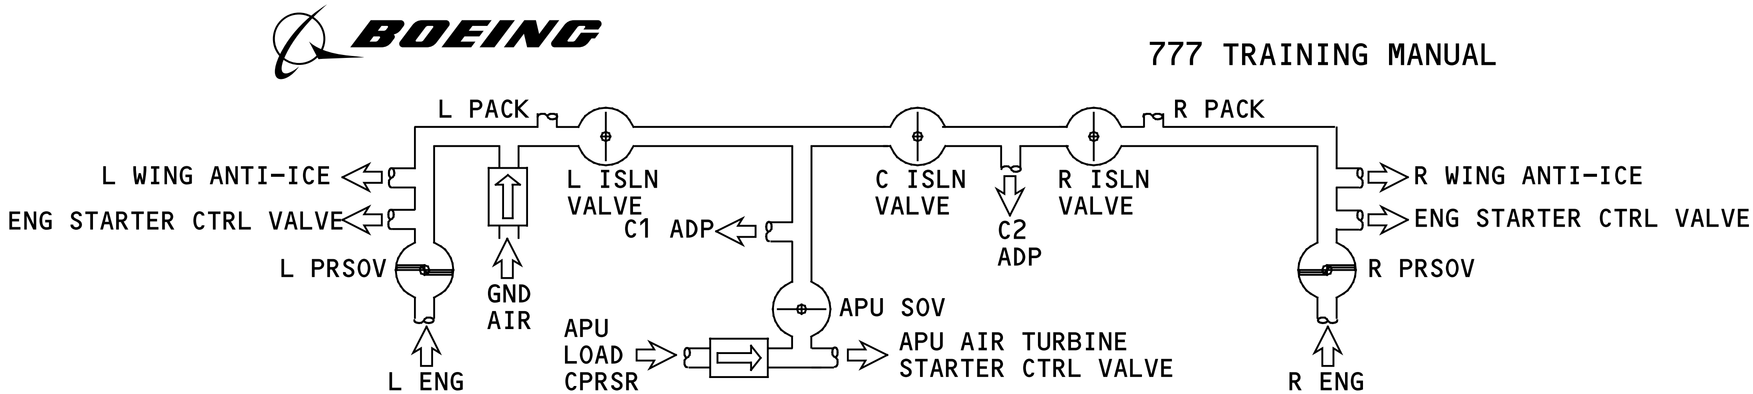
AIR SUPPLY DISTRIBUTION - FUNCTIONAL DESCRIPTION - SUMMARY - NORMAL CONDITIONS

Functional Description

The ASCPC controls the air supply distribution system.
It controls the position of these valves:

- Left isolation valve
- Center isolation valve
- Right isolation valve
- APU shutoff valve
- Left PRSOV
- Right PRSOV.

The table shows different configurations of the valves for normal conditions.



NORMAL CONDITIONS (ALL BLEED AIR SWS SET TO AUTO/ON POSITION)	ASCPC SET POSITIONS

AIR SUPPLY DISTRIBUTION - FUNCTIONAL DESCRIPTION - SUMMARY - NORMAL CONDITIONS

36-12-00-014 Rev 3 03/11/1997

THIS PAGE INTENTIONALLY LEFT BLANK

General

The ASCPCs monitor for non-normal conditions that affect the distribution of the air to the ADPs and other air user systems. The ADPs are most important. If a non-normal condition occurs, the ASCPCs limit the effect, by isolating parts of the pneumatic distribution system.

The table shows the different configurations of the isolation, APU shutoff, and the pressure regulating and shutoff valves for non-normal conditions.

Source Loss Condition

The source loss condition logic lets the ASCPCs sense when there is not sufficient air pressure to the ADPs for landing gear retraction immediately after takeoff.

There are two sets of conditions that cause the source loss condition. One set is true if all of these conditions occur:

- Landing gear down
- Less than 180 seconds since takeoff
- Left engine off.

The second set is true if all of these conditions occur:

- Landing gear down
- Less than 180 seconds since takeoff
- left duct pressure less than 20 psig and right duct pressure more than 20 psig.

Bleed Pressure Loss Condition

The bleed pressure loss condition logic lets the ASCPCs sense when a pneumatic duct comes apart. Possible engine starter duct failure is the primary reason for this logic.

There are two sets of conditions that cause the ASCPCs to set the left bleed pressure loss condition to true. One set is true if all of these conditions occur for more than 10 seconds:

- Left duct pressure is less than 13 psig
- Left pack inlet pressure is less than 13 psig
- Right duct pressure is more that 13 psig
- Left PRSOV is open
- Right PRSOV is open
- No duct leak signal from the duct leak and overheat detection system (DLODS)
- Landing gear is up
- Takeoff less than 180 seconds.

The second set is true if all of these conditions occur for more than 10 seconds:

- Left duct pressure is less than 13 psig
- Left pack inlet pressure is less than 13 psig
- Right PRSOV is open
- Left PRSOV is closed

- Landing gear is up or (takeoff more than 180 seconds)
- Left engine bleed air flow is more than 2.0 lbs/sec
- No left engine start.

Bleed Leak Conditions

Ducts in the pneumatic distribution system are monitored by the duct leak and overheat detection system (DLODS) for air leaks that cause an overheat condition. The DLODS provides the ASCPCs with this general location information:

- Bleed leak in the strut area L (R)
- Bleed leak in the wing area L (R)
- Bleed leak in the body area.

The DLODS can not tell the ASCPCs the duct that caused the overheat. One overheat condition can be caused by different ducts. This is an example. An overheat in the left pack area can be caused by a duct that connects any of these components:

- L PRSOV to L Pack and L ISLN valve
- L ISLN valve to C ISLN valve and APUSOV
- C ISLN valve to R ISLN valve and C2 ADP
- R ISLN valve to R Pack and R PRSOV.

The ASCPC closes a valve or valves to isolate a leak then waits to see if the leak conditions goes away.

A strut leak is a leak in the ducting at any of these areas:

- The engine strut
- The wing, between the engine strut and the inboard slat.

A wing duct leak is a leak in the ducting next to the inboard slat or in the under fuselage area forward of the main wheel wells.

A body duct leak is a leak in the ducting in the main wheel wells or aft fuselage area, aft of the ECS bays. There is a left and right body duct. The left body duct connects to the left wing duct between the left and center isolation valves and connects to the C1 ADP and the APU. The right body duct connects to the right wing duct between the right and center isolation valve and connects to the C2 ADP.

See the duct leak and overheat detection section for more information (AMM PART I 26-18).

AIR SUPPLY DISTRIBUTION - FUNCTIONAL DESCRIPTION - SUMMARY - NON-NORMAL CONDITIONS

36-12-00-015 Rev 3 04/10/1997

INDICATING SYSTEM - INTRODUCTION

General

The indicating system supplies the left and right air supply cabin pressure controllers (ASCPC) with air flow, pressure, and temperature data. The ASCPCs use the data for control of the pneumatic system and flight deck indications.

The pneumatic indicating system has these components:

- Manifold pressure sensor (PM)
- Manifold flow sensor (FS)
- Manifold dual temperature sensor (TM)
- Intermediate pressure sensor (PI).

The indicating system uses information from these components in the air conditioning system:

- Pack flow sensor (ASCPC pack inlet differential pressure sensor)
- ASCPC compressor discharge temperature sensor
- ASCPC pack discharge temperature sensor.

The ASCPCs also get pressure, temperature and air flow rate information from the cabin temperature controllers.

The RVDTs are not part of the indication system but they do give valve position data to the ASCPCs. These valves in the pneumatic system use RVDTs:

- Isolation valves (left, center, right)
- APU shutoff valve (APUSOV)
- Fan air modulating valve (FAMV).

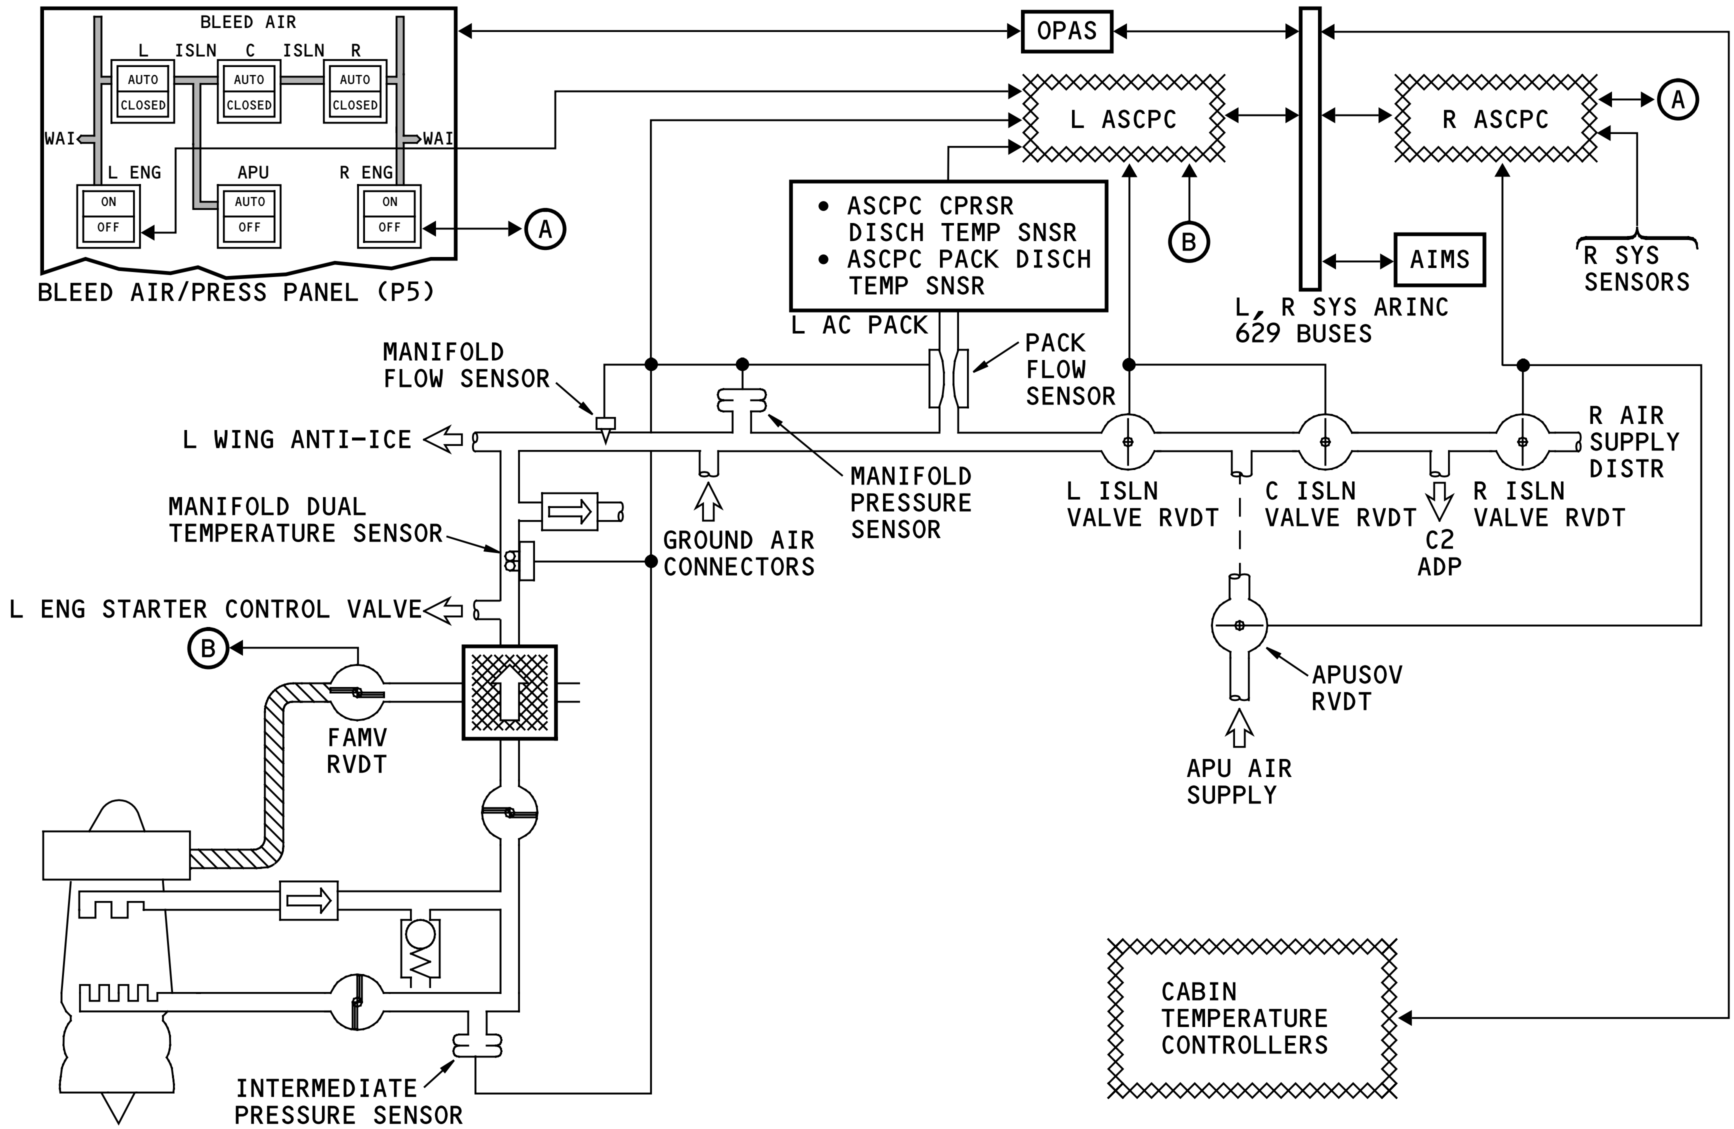
The ASCPC uses the data from the sensors and RVDTs to control the air supply flow, pressure, and temperature. The ASCPCs also use sensors to calculate open/close position data for valves that do not have RVDTs. The ASCPCs send the data to the AIMS and OPAS for flight deck indications. The ASCPCs also send the data to the cabin temperature controllers (CTC). The CTCs use the data for control and flight deck indications.

See the pack flow control section for more information on pack flow control and indication (AMM PART I 21-51).

See the pack flow cooling and mix manifold temperature control section for more information (AMM PART I 21-52).

See the engine air supply section for more information on the FAMV (AMM PART I 36-11).

See the air supply distribution section for more information on the isolation valves and the APUSOV (AMM PART I 36-12).



INDICATING SYSTEM - INTRODUCTION

INDICATING SYSTEM - MANIFOLD PRESSURE SENSOR

Purpose

The manifold pressure sensors monitor the pressure in the air supply distribution system.

Location

There are two manifold pressure sensors. One attaches to airplane structure forward and outboard of the left ECS bay near the distribution duct. The other one is opposite, on the right side of the airplane.

Physical Description

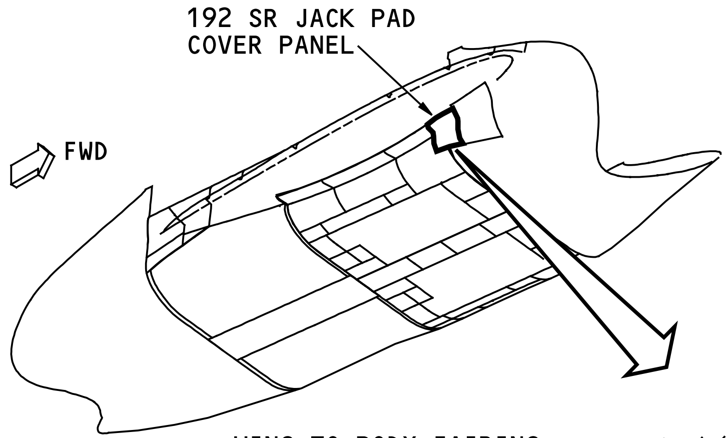
The pressure sensor is an electronic strain gage type. The sensor has these parts:

- Housing
- Electrical connector
- Vent hole (3)
- Pneumatic connector.

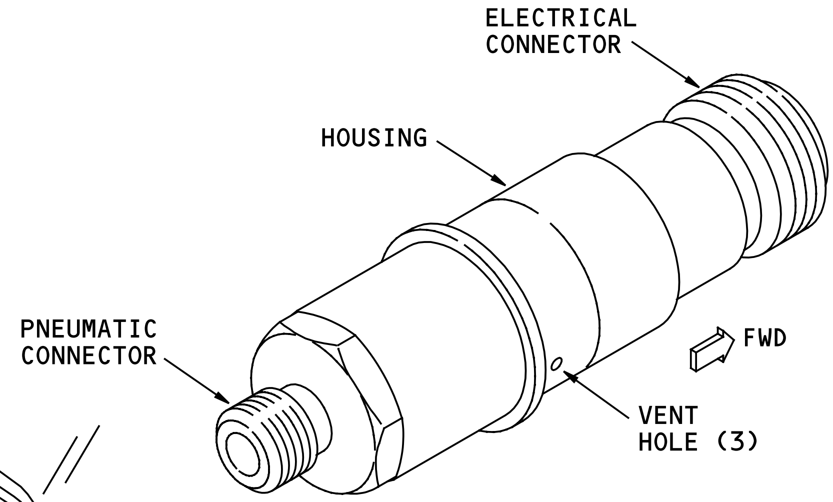
Training Information Point

You attach the sensor with band clamps around the housing. Do not attach the sensor so that the clamps cover the vents.

You remove the access panel 191SL (left wing primary jack point access panel) to get access to the left manifold pressure sensor. You remove access panel 192SR (right wing primary jack point access panel) to get access to the right manifold pressure sensor.



WING-TO-BODY FAIRING



MANIFOLD PRESSURE SENSOR
(ROTATED)

NOTE: RIGHT INSTALLATION
SHOWN, LEFT SIMILAR

36-20-00-004 Rev 3 08/28/1995

INDICATING SYSTEM - MANIFOLD PRESSURE SENSOR

INDICATING SYSTEM - INTERMEDIATE PRESSURE SENSOR

Purpose

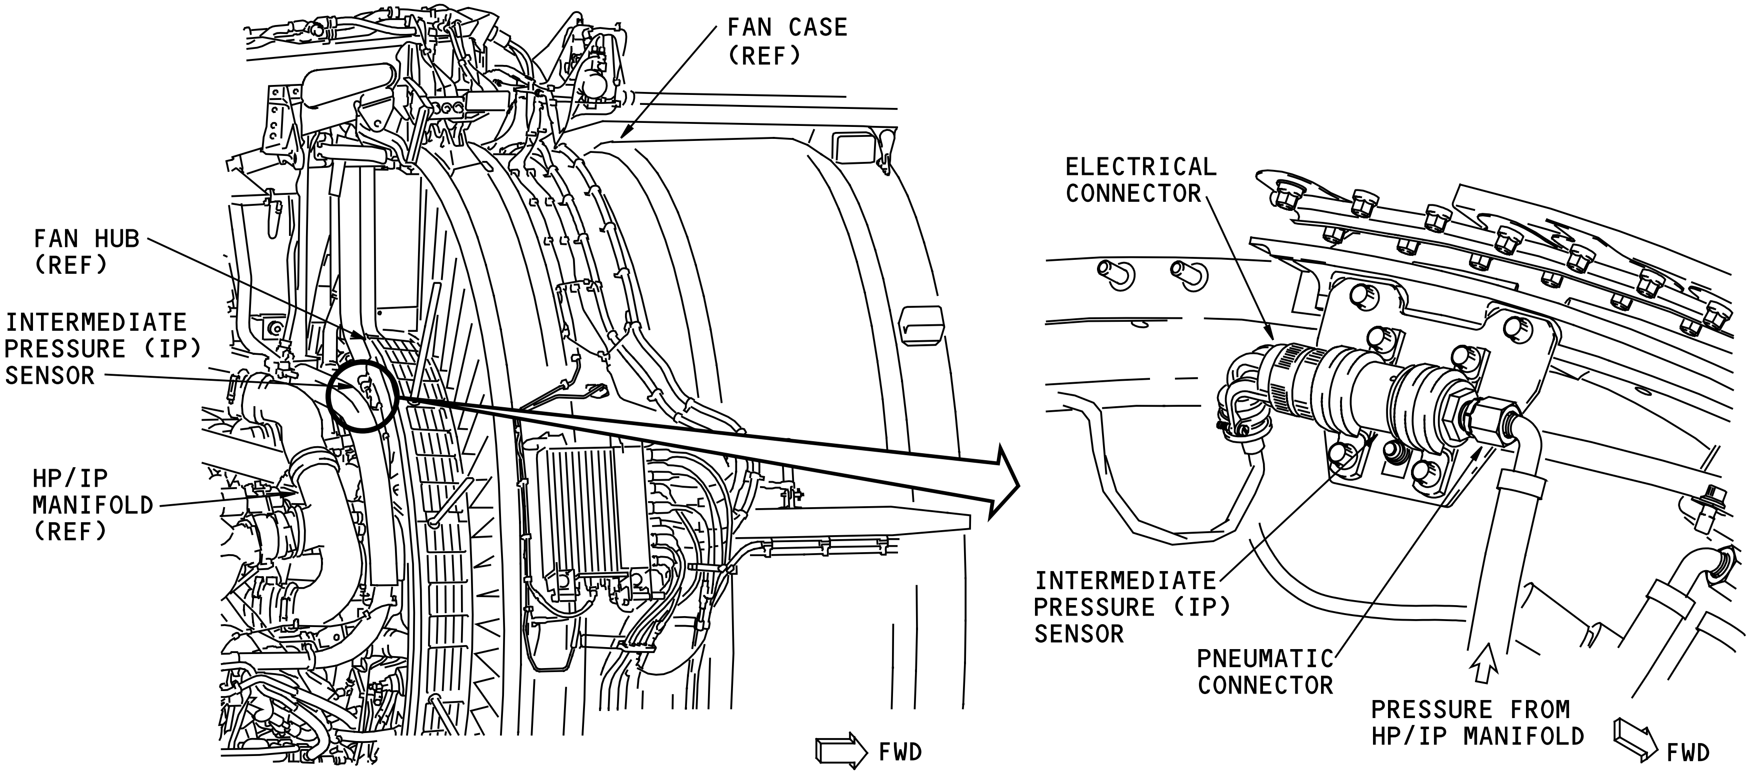
The intermediate pressure sensor (IP) monitors the pressure in the HP/IP manifold.

Location

There is one IP sensor on each engine fan hub at the 12:45 position.

Training Information Point

You open the right fan cowl and thrust reverser to get access to the IP sensor.



ENGINE RIGHT SIDE

ENGINE FAN HUB
(12:45 POSITION)

36-20-00-005 Rev 3 10/07/1997

INDICATING SYSTEM - INTERMEDIATE PRESSURE SENSOR

INDICATING SYSTEM - MANIFOLD FLOW SENSOR

Purpose

The manifold flow sensor monitors the flow rate of the air in the air supply distribution system.

Location

There are two manifold flow sensors in the distribution system ducts. One is in the left wing under the fixed leading edge. The other one is in the right wing under the fixed leading edge.

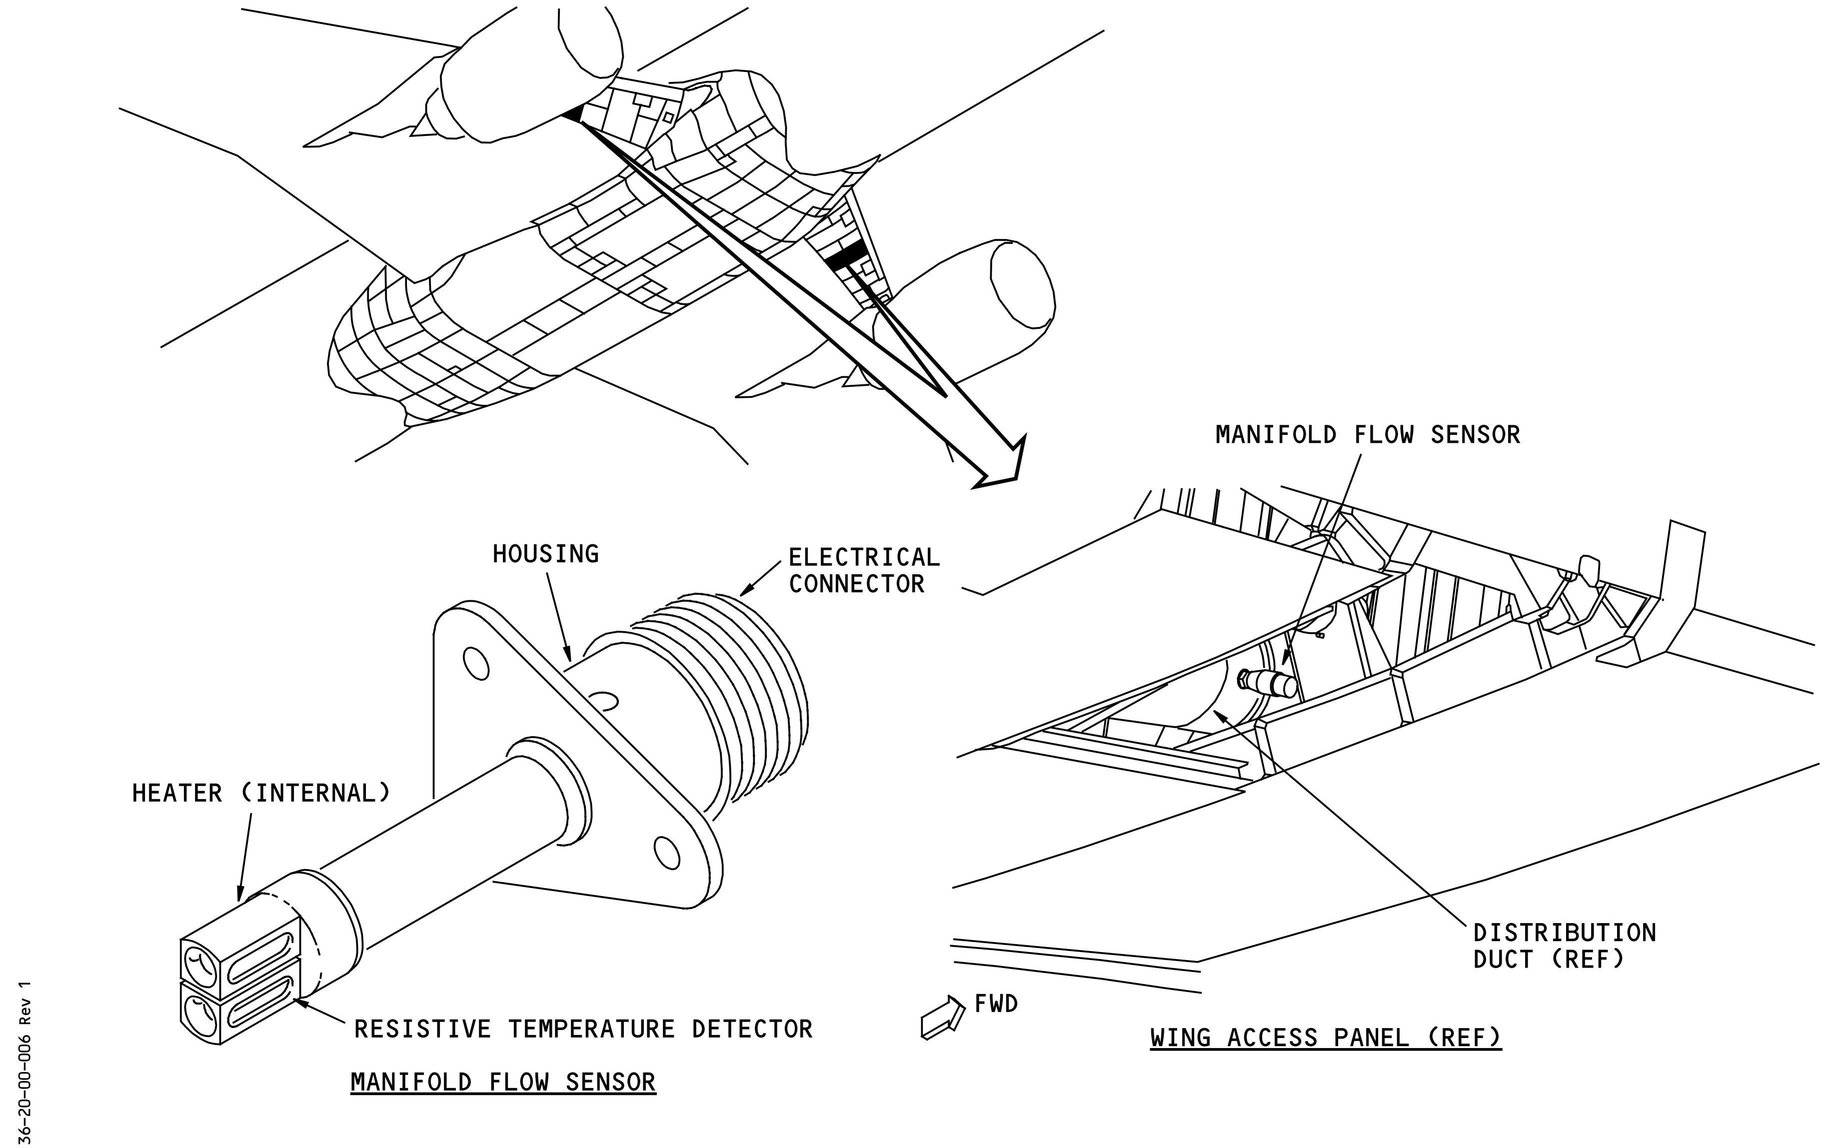
Physical Description

The sensor is an electrically heated unit. The sensor has these parts:

- Housing
- Electrical connector
- Resistive temperature detector
- Internal heater (not shown).

Training Information Point

You open access panel 511JB on the left wing to get access to the left manifold flow sensor. You open access panel 611JB on the right wing to gain access to right manifold flow sensor.



INDICATING SYSTEM - MANIFOLD FLOW SENSOR

INDICATING SYSTEM - MANIFOLD DUAL TEMPERATURE SENSOR

Purpose

The manifold dual temperature sensor monitors the air temperature downstream of the precooler.

Location

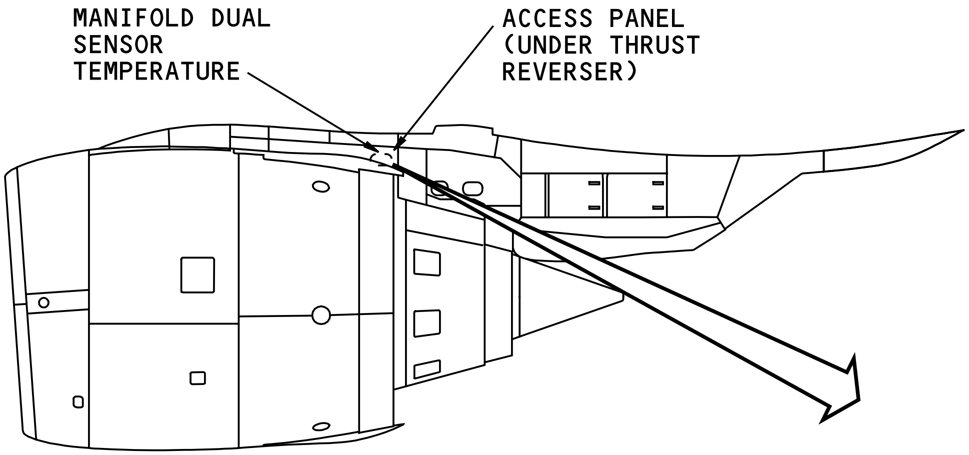
The temperature sensor is in the distribution duct downstream of the precooler in the engine strut.

Physical Description

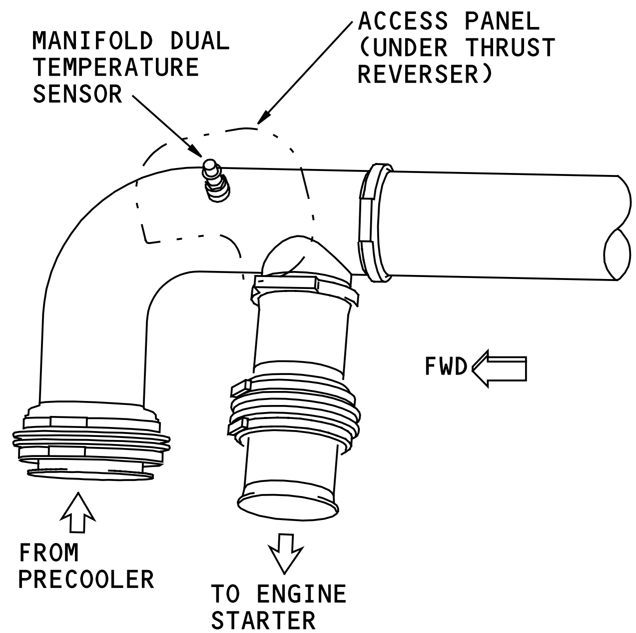
The temperature sensor is a dual sensor. Internally it has two separate sensing elements (not shown). The sensor has a housing and an electrical connector.

Training Information Point

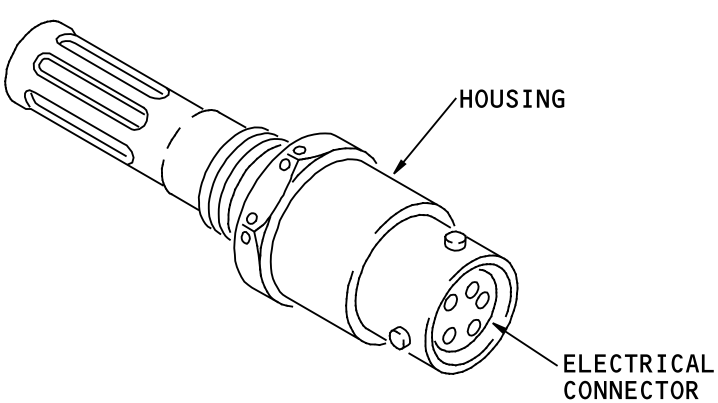
For the left temperature sensor, you open the left fan cowl and thrust reverser on the left engine. Then you remove access panel 432GL on the engine strut to gain access. For the right temperature sensor, you open the left fan cowl and thrust reverser on the right engine. Then you remove access panel 442GL on the engine strut to gain access.



ENGINE LEFT SIDE



DISTRIBUTION DUCT
(ENGINE STRUT AREA)



MANIFOLD TEMPERATURE SENSOR

36-20-00-007 Rev 3 08/13/96

INDICATING SYSTEM - MANIFOLD DUAL TEMPERATURE SENSOR

INDICATING SYSTEM - FUNCTIONAL DESCRIPTION

General

The ASCPC gives indications about the pneumatic system and its components. The ASCPC also give indications about the air conditioning packs to the cabin temperature controllers (CTC).

The digital (primary) mode of the ASCPC uses these sensors to monitor the system for control and indication purposes:

- Manifold pressure sensor (PM)
- Manifold flow sensor (FS)
- Manifold dual temperature sensor (sensor element TM2)
- Pack flow sensor (ASCPC pack inlet differential pressure sensor)
- ASCPC compressor discharge temperature sensor
- ASCPC pack discharge temperature sensor.

See the pack flow control section for more information on pack flow indication and control (AMM PART I 21-51).

See the pack cooling and mix manifold temperature control section for more information on pack cooling and mix manifold temperature indication and control (AMM PART I 21-52).

The analog (backup) mode of the ASCPC uses these sensors to monitor the system for control and indication purposes:

- Manifold dual temperature sensor (sensor element TM1)
- Intermediate pressure (IP) sensor.

Information monitored by the backup mode goes to the primary mode through an internal ASCPC interface.

The primary mode of the ASCPCs monitor valve positions through RVDTs in these valves:

- Left isolation valve
- Center isolation valve
- Right isolation valve
- APU shutoff valve (APU SOV)
- Left fan air modulating valve (FAMV)
- Right fan air modulating valve (FAMV).

Indications

The primary mode of the ASCPCs send signals to the AIMS two ways, directly and through the ARINC 629 buses. The AIMS shows information in these places:

- Air synoptic display - valve position and duct pressure
- Air supply maintenance page - valve position, pressure, temperature and air flow rates
- Ice protection maintenance page - duct pressure
- EICAS display - messages and duct pressure
- Secondary engine display - duct pressure
- Status display - messages
- Performance maintenance page - duct pressure.

INDICATING SYSTEM - FUNCTIONAL DESCRIPTION

The backup mode of the ASCPCs send signals to the AIMS directly. The AIMS shows a message on EICAS for an engine bleed air off condition.

EICAS advisory messages show when any of these conditions occur:

- An isolation valve not in the commanded position or a bleed isolation switch is set to out
- APU SOV not in the commanded position or APU bleed switch is set to out
- Left PRSOV is close for non-normal condition(s)
- Right PRSOV is close for non-normal condition(s).

Status messages show when any of these conditions occur:

- ASCPC incompatible software
- ASCPC primary mode failure
- Isolation valve failure
- APU SOV failure
- HPSOV failure
- PRSOV failure
- FAMV failure
- Manifold dual temperature sensor failure
- Manifold pressure sensor failure
- Manifold flow sensor failure
- Intermediate pressure sensor failure
- ASCPC pack inlet differential pressure sensor failure
- ASCPC compressor discharge temperature sensor failure
- ASCPC pack discharge temperature sensor failure.

See the pneumatic section for more information on conditions that cause messages related to the pneumatic system operation (AMM PART I 36-00).

The primary and backup modes of the left ASCPC directly control the left engine bleed OFF light. The primary and backup modes of the right ASCPC directly controls the right engine bleed OFF light. The applicable ASCPC sends a signal directly to the AIMS to cause the related BLEED OFF ENG L (R) advisory message (not shown).

The primary mode of the left ASCPC controls the CLOSED lights for the left and center isolation valves through the ARINC buses and OPAS. The primary mode of the right ACSPC controls the APU OFF light and the CLOSED lights for the right isolation valve through the ARINC buses and OPAS. The applicable ASCPC sends signals through the ARINC buses to the AIMS to cause the related advisory messages (not shown) and for status messages (not shown).

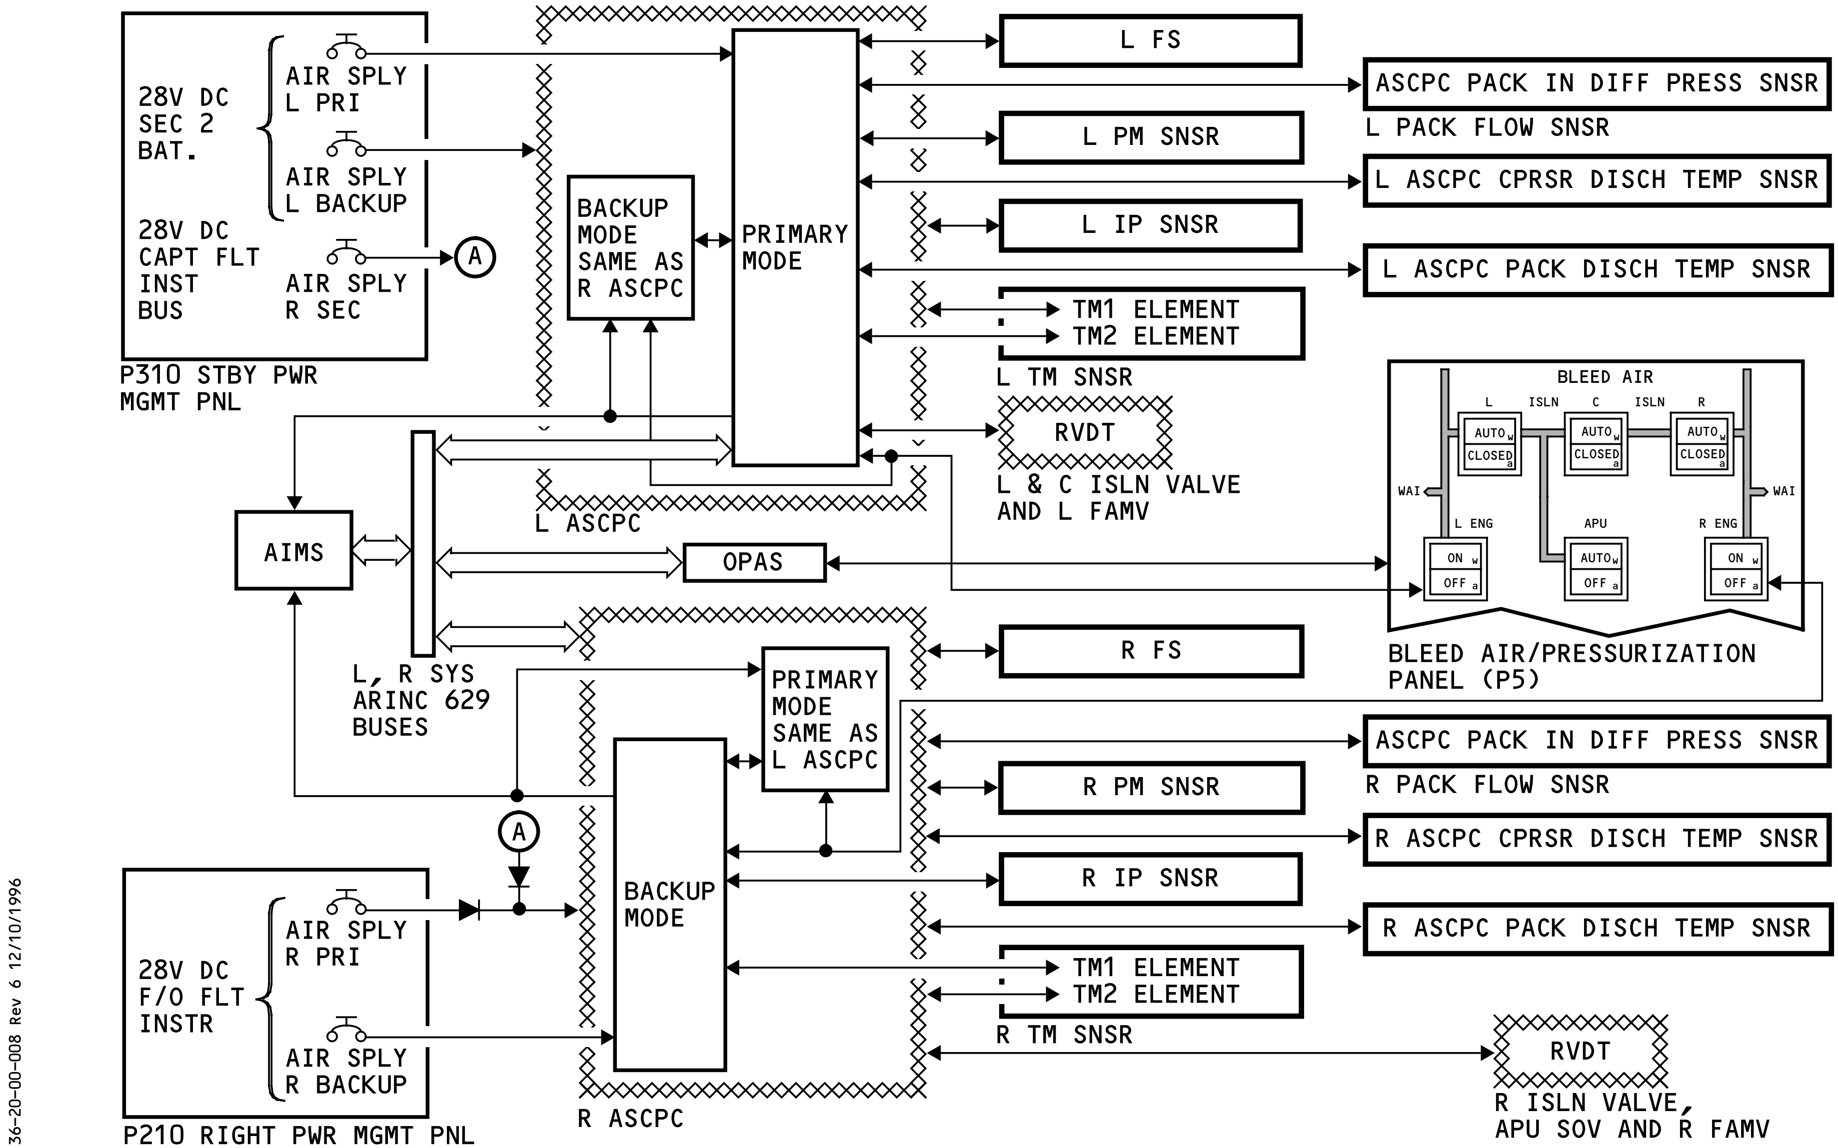
See the engine air supply section for more information about conditions that cause indications to the engine air supply system (AMM PART I 36-11).

See the air supply distribution section for more information about conditions that cause indications to the isolation valves and the APUSOV systems (AMM PART I 36-12).

INDICATING SYSTEM - FUNCTIONAL DESCRIPTION

Training Information Point

If the primary mode of an ASCPC fails, then all indications controlled by that mode for the related ASCPC do not show.



INDICATING SYSTEM - FUNCTIONAL DESCRIPTION

PNEUMATIC - OPERATION

Bleed Air/Pressurization Panel

Switches on the bleed air/pressurization panel (P5) have interfaces with the left and right ASCPCs to give control and supply indications for the pneumatic system. These switches control and give indications for the pneumatic sources:

- Left engine bleed switch (L ENG)
- APU bleed switch (APU)
- Right engine bleed switch (R ENG).

These switches control and give indications for the pneumatic distribution:

- Left isolation valve (L ISLN)
- Center isolation valve (C ISLN)
- Right isolation valve (R ISLN).

See the indicating section for more information about the indicating system (AMM PART I 36-20).

Engine Bleed Switches

The L ENG and the R ENG switches have an annunciator light that comes on when the pressure regulation and shutoff valve (PRSOV) is set to off by the related ASCPC. The switches have two positions:

- In (usual position)
- Out (non-normal).

The ON position (switch in) lets the related engine bleed air system supply air when the engine is running.

The switch out position sets the related engine bleed air system so it does not supply air and turns on the OFF light in the switch. The OFF light gives an indication that the PRSOV is set to OFF and does not relate to the actual position of the PRSOV.

When the switch is in, the OFF light comes on if the engine is off or if any of the these protective shutdown, non-normal conditions occurs:

- Wing or strut duct overheat (wing bleed loss)
- Bleed air overtemperature
- Bleed air overpressure
- Engine fire switch pulled.

When the OFF light is on, the BLEED OFF ENG L(R) advisory message usually shows. This message does not show if the engine is off or if the OFF light comes on because of wing or strut overheat. See the duct leak and overheat detection section for more information (AMM PART I 26-18).

See the engine air supply section for more information on engine bleed air control and operation (AMM PART I 36-11).

APU Bleed Switch

The APU switch has an annunciator light that comes on when the APUSOV is closed because of a non-normal condition. The APU switch has two positions:

- In (usual position)
- Out (non-normal).

The AUTO position (switch in) lets the APU shutoff valve (APUSOV) OPEN/CLOSE as necessary to supply air to the pneumatic distribution system.

See the air supply distribution section for more information about the APU shut off valve OPEN/CLOSE position control (AMM PART I 36-12).

The switch out position sets the APU shutoff valve to close. With the switch set to out, the OFF light in the switch comes on when the valve closes.

When the switch is in, the OFF light comes on when the valve is closed and any of the these non-normal conditions occurs:

- Wing or body duct overheat
- APUSOV failed closed
- APU fire switch pulled.

When the OFF light comes on, the BLEED OFF APU advisory message usually shows. This message does not show if the APU is off. See the duct leak and overheat detection system section for more information (AMM PART I 26-18).

Isolation Bleed Switches

The isolation bleed switches have an annunciator light that comes on when the related isolation valve is closed because of a non-normal condition. The switches have two positions:

- In (usual position)
- Out (non-normal position.)

The AUTO position (switch in) lets the related isolation valve, left, center, or right OPEN/CLOSE as necessary to control the direction of air flow in the pneumatic distribution system.

The switch out position sets the related isolation valve to close. The CLOSED annunciator light in the switch comes on when the valve is closed.

The AUTO position with CLOSED indication (switch in) can occur when the related valve is closed and any of the these non-normal conditions occurs:

- Wing or body duct overheat
- Related isolation valve failed closed
- Left (right) bleed source loss.

When the CLOSED light comes on because the related valve is failed closed or the related switch is set to out, the advisory message, BLEED ISLN CLOSED L (C, R) shows.

See the air supply distribution section for more information on the isolation valve OPEN/CLOSE position control (AMM PART I 36-12).

Training Information Point

Annunciator lights and EICAS messages on the bleed air/ pressurization panel usually relate to valve positions that the left and right ASCPCs control and monitor.

The isolation valves and APUSOV have RVDTs that the ASCPCs use to calculate when to turn on the related CLOSED or OFF lights. If a RVDT fails, the ASCPCs calculate when to turn on or show the related indications without the use of the failed RVDT. The calculation for the lights is based on the ASCPC set position for the related valve. The calculation for the message is based on switch position for the related valve.

The PRSOVs do not have any direct feedback to the ASCPC, no RVDTs, no limit switches and no proximity switches. The ASCPCs calculate the related valve position for all indications based on set position.

The primary control (digital) part of the ASCPCs usually gives control and indications for the related engine bleed air system, the isolation valves and APUSOV. If primary control fails in one controller, the other controller controls the isolation valves and APUSOV. All indications that are related to the ASCPC that has the failed primary control are lost. These are the indications lost related to the bleed air/ pressurization panel:

BLEED AIR/PRESSURIZATION PANEL	
FAILED PRIMARY CONTROL	INDICATIONS LOST FOR THESE VALVES
LEFT ASCPC	L ISLN
	C ISLN
RIGHT ASCPC	R ISLN
	APUSOV

The backup control (analog) part of the ASCPCs that has a failed primary control gives limited engine bleed air control and engine OFF indications.

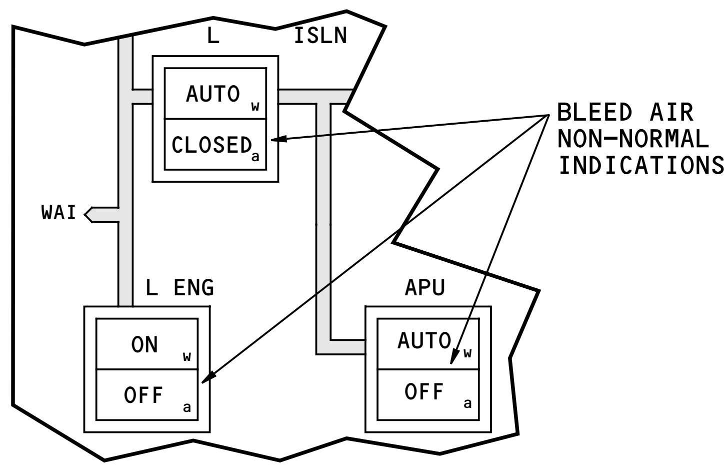
EICAS DISPLAY - ADVISORY MESSAGES



PNEUMATIC - OPERATION

36-00-00-004 Rev 6

PNEUMATIC - INDICATIONS - EICAS DISPLAY AND SECONDARY ENGINE DISPLAY

General

You can see duct pressure for the left and right parts of the pneumatic distribution system on these displays:

- EICAS display
- Secondary engine display
- Air synoptic display (not shown)
- Air supply maintenance page (not shown)
- Ice protection maintenance page (not shown)
- Performance maintenance page (not shown).

The synoptic display and the maintenance pages are described later in this section.

The units of duct pressure are psig. The color of the pressure readout changes from white to amber when pressure is less than 11 psig. No pressure will show if any of these conditions occurs:

- Related ASCPC primary (digital) control fails
- Fault in the indication circuit.

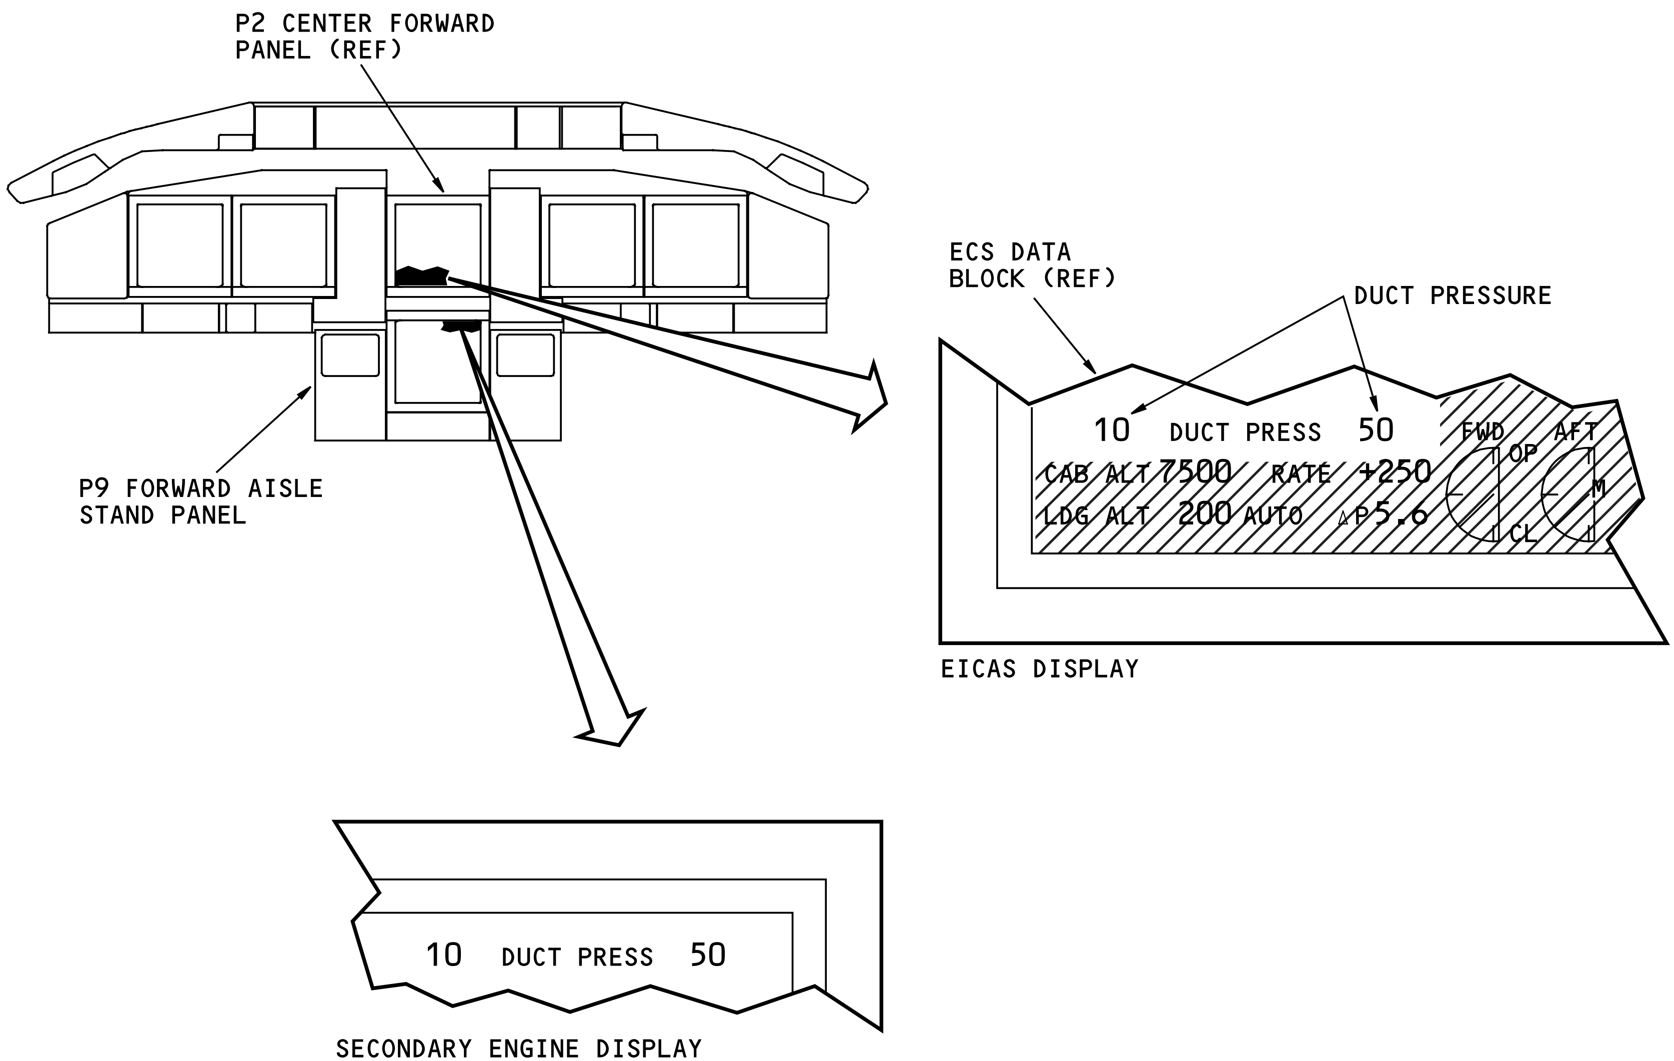
EICAS Display

Duct pressure shows in the ECS data block part of the EICAS display. This block shows if any of these conditions occur:

- Loss of landing altitude, FMC to ASCPCs
- Loss of automatic pressurization control
- Loss of automatic fwd or aft pressurization outflow valve control
- MAN selected for outflow valve control
- Exceedance for cabin altitude or cabin differential pressure
- Duct pressure less than 11 psig and the related engine is on
- Air synoptic display shows.

Secondary Engine Display

Duct pressure shows on the secondary engine display if one or both engines are off and the related engine fire switch is not pulled.



36-00-00-005 Rev 3

PNEUMATIC - INDICATIONS - EICAS DISPLAY AND SECONDARY ENGINE DISPLAY

PNEUMATIC - INDICATIONS - AIR SYNOPTIC DISPLAY

THIS PAGE INTENTIONALLY LEFT BLANK

Air Synoptic Display

The lower part of the air synoptic display gives information about the pneumatic system, air conditioning zone temperature control system, cargo heat systems, and air user system.

See the air conditioning chapter for more information about the temperature control and cargo heat systems (AMM PART I 21).

For the pneumatic system the display shows:

- Air flow direction and user systems
- Isolation valve position
- Duct pressure (manifold duct pressure)
- Engine bleed valve (PRSOV) calculated position
- APU shutoff valve position
- Air source status (engine, APU and ground).

Green flow bars show air flow direction and identify which sources and users are on.

Valve positions show as one of the following symbols:

- Open (white circle with flow bar in-line with duct)
- Closed (white circle with flow bar 90 degrees to duct)
- Failed open (amber valve open symbol with amber X)
- Failed closed (amber valve closed symbol with amber X)
- Selected closed (amber valve closed symbol with amber X) for isolation and APU shutoff valves only
- Invalid (white circle with no flow bar).

The units of duct pressure are psig. The color of the pressure readout changes from white to amber when pressure is less than 11 psig. No pressure will show if any of these conditions occurs:

- Related ASCPC primary (digital) control fails
- Fault in the indication circuit.

Air source status for the engines is not shown on the air synoptic display. Air source status for the APU shows by color change of the APU symbol. The APU symbol is white for APU off and green for APU on. The ground air symbol shows if manifold duct pressure is more than 11 psig and all of the following are true:

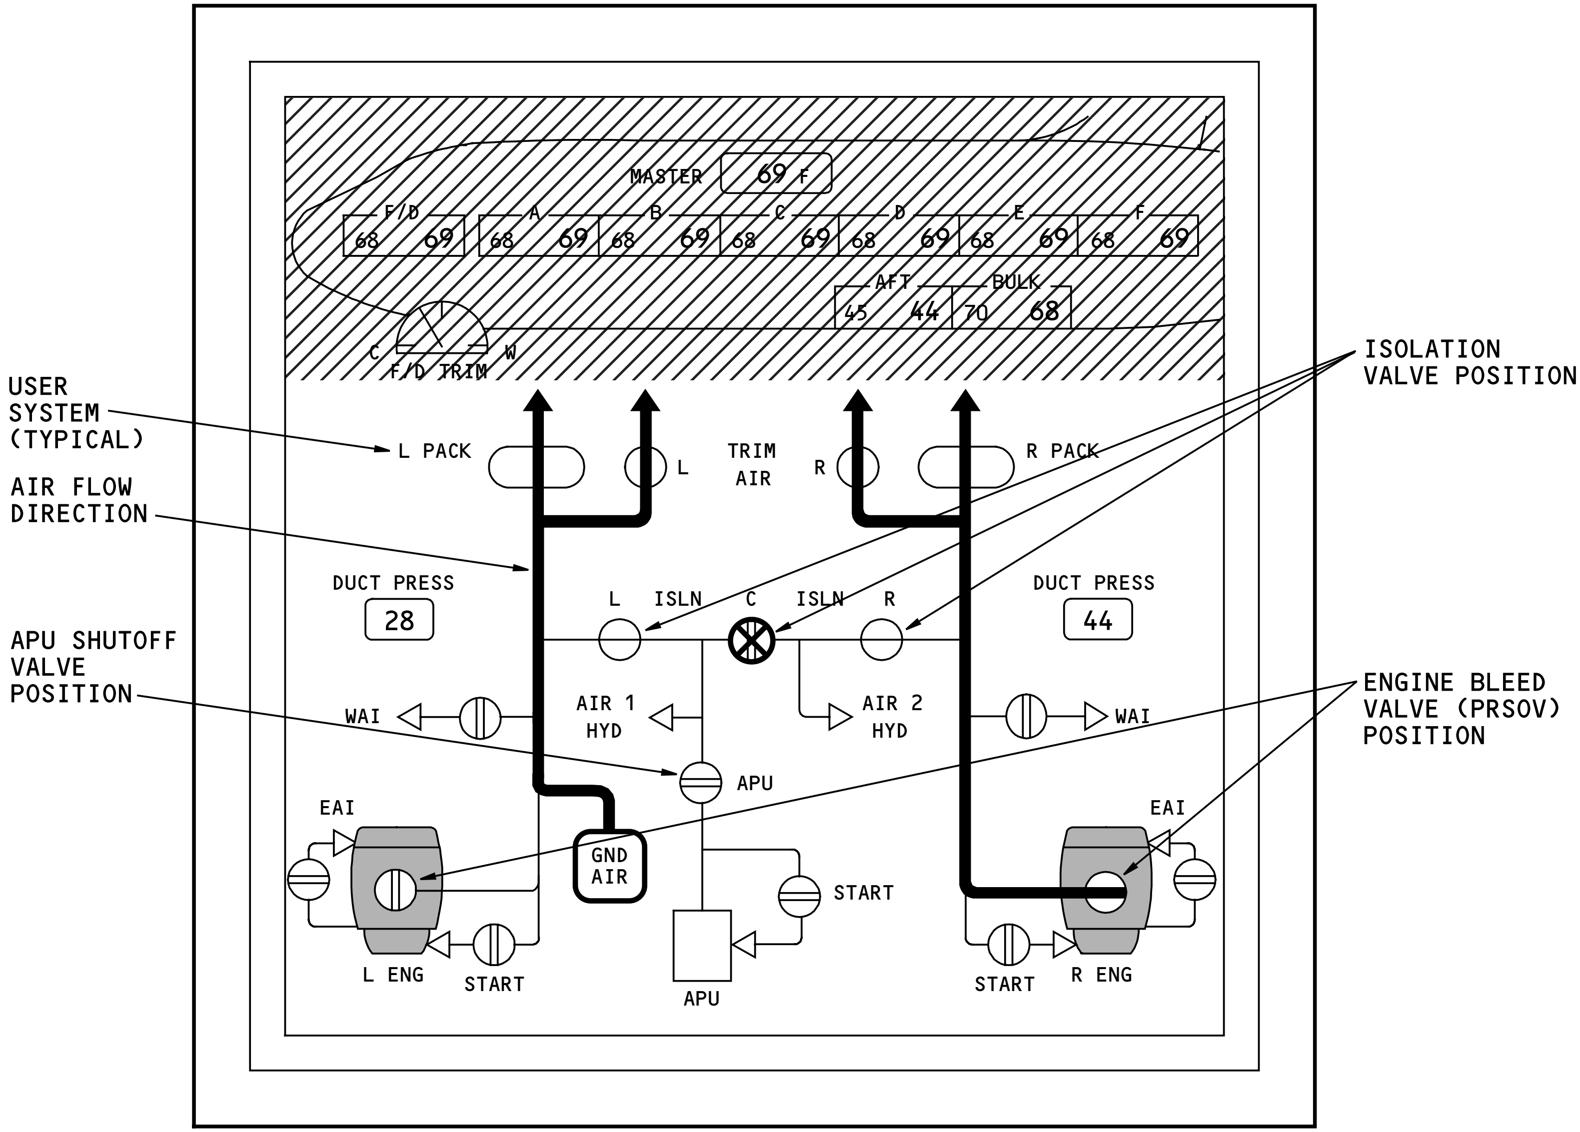
- Airplane on the ground
- No active engine or APU bleed air sources or any active bleed sources isolated from ground air source
- User system on (pack, trim air, WAI, starter, ADP).

Training Information Point

The related ASCPC calculates engine bleed valve (PRSOV) position. Actual valve position does not always agree with the position shown on the air synoptic display. If you must make sure that the PRSOV is open or closed, do a check the position indicator on the valve.

PNEUMATIC - INDICATIONS - AIR SYNOPTIC DISPLAY

The positions of the isolation valves and the APUSOV, are usually based on actual valve position measured by RVDTs. If a RVDT fails, the related valve position is calculated by the related ASCPC. If the related ASCPC has a failed primary control, then valve position information will show as invalid.



PNEUMATIC - INDICATIONS - AIR SYNOPTIC DISPLAY

36-00-00-006 Rev 7 03/16/95

PNEUMATIC - INDICATIONS - AIR SUPPLY MAINTENANCE PAGE

Air Supply Maintenance Page

The upper part of the air supply maintenance page contains information about the pneumatic system. The primary control (digital) part of left and right ASCPCs and the EEC supply the information. The ASCPCs supply most of the information. This information comes from the EECs:

- STARTER VLV position
- ENG HIGH STAGE PRESS
- ENG N1 FAN SPEED.

Valve positions are shown as OPEN or CLOSED. Pressure values are shown in psig. Temperature values are shown in degrees F. Flow rate values are shown in lbs/min.

Flight phase may be any one of these:

- Initialization (INIT)
- GND
- TAKEOFF
- CLIMB
- CRUISE
- DESCENT
- LANDING.

Either ASCPC can give the flight phase information; the left is the primary source.

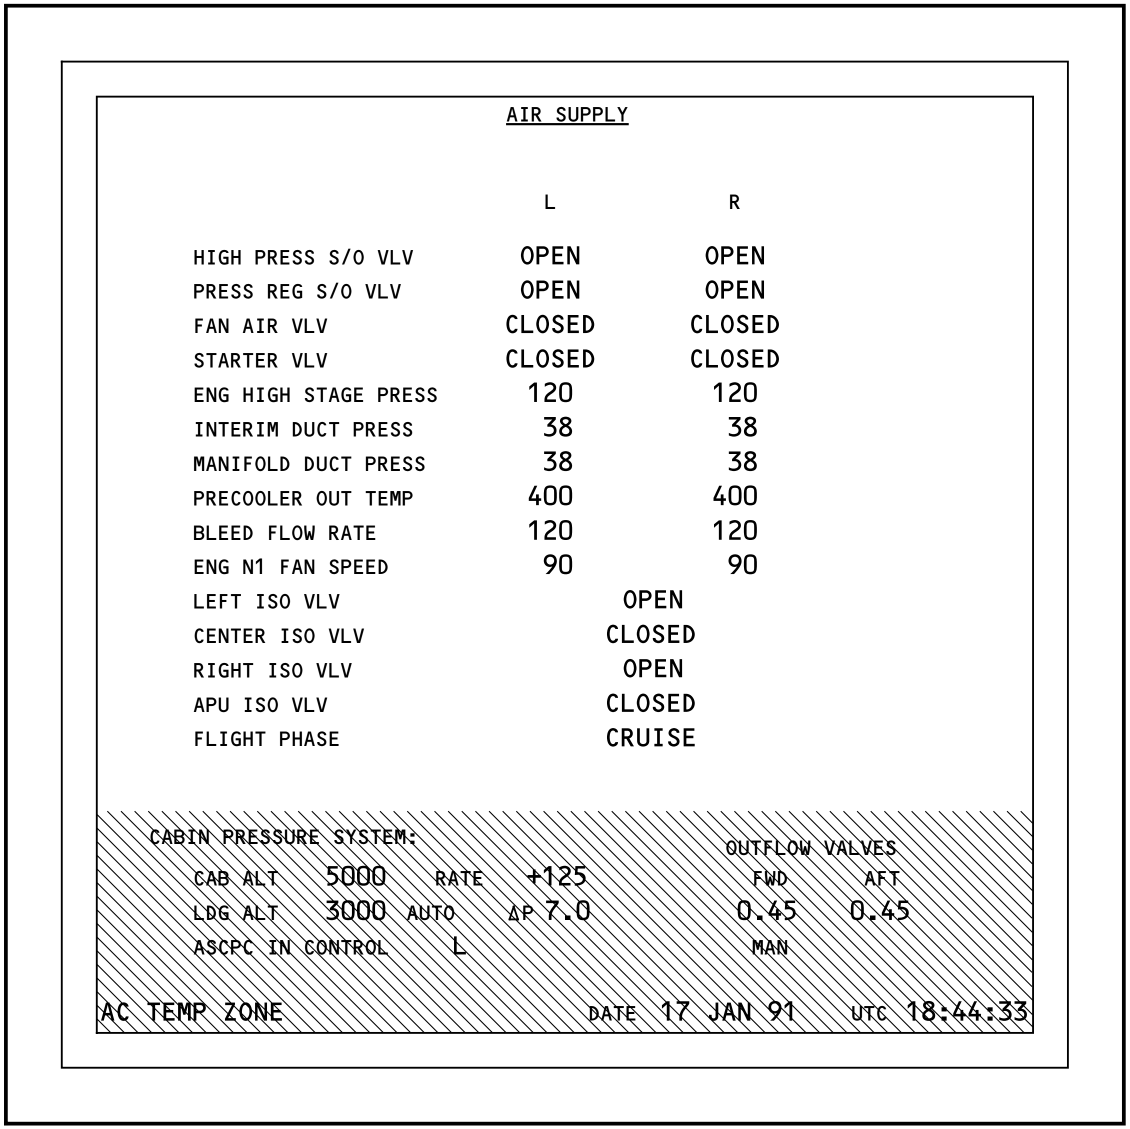
If any information is not available, the indication is blank.

Training Information Point

The related ASCPC calculates valve position information for the PRSOV and the HPSOV. Actual valve position does not always agree with the position shown. If you must make sure that the PRSOV or the HPSOV is open or closed, do a check of the position indicator on the valve.

The positions of the isolation valves and the APUSOV, are usually based on actual valve position measured by RVDTs. If a RVDT fails, the related valve position is calculated by the related ASCPC.

If an ASCPC has a failed primary control, then all information that normally comes from that controller will not show. The left ASCPC gives indications for the left part of the pneumatic system plus the center isolation valve. The right ASCPC gives indications for the right part of the pneumatic system plus the APU isolation valve (APUSOV).



36-00-00-007 Rev 3

PNEUMATIC - INDICATIONS - AIR SUPPLY MAINTENANCE PAGE

PNEUMATIC - SYSTEM TESTS

General

These are the pneumatic system tests that show when you select ATA 36 Air Supply System:

- Left air supply control system
- Right air supply control system.

Left and Right Air Supply Control System

These tests make sure that the electrical circuits for these air supply control system LRUs operate correctly:

- Valves
- Controllers
- Interfaces.

You must remove pressure in the pneumatic ducts for this test. During the test, the torque motors and solenoids move. The tests each take less than 1 minute.

AIR CONDITIONING - GENERAL DESCRIPTION - CONTROL

General

These flight deck panels let you control the air conditioning system:

- Air conditioning panel
- Bleed air/pressurization panel
- Cargo temperature select panel
- Sidewall panels (Capt. and F/O foot and shoulder heater controls).

These passenger compartment panels let you control the air conditioning system:

- Cabin system control panel (CSCP)
- Cabin area control panels (CACPs)
- Galley heat controls in the galleys.

These components in the MEC control the functions of the air conditioning system:

- Two cabin temperature controllers (CTCs)
- Two air supply cabin pressure controllers (ASCPCs)
- Two environmental control system miscellaneous cards (ECSMCs)
- Two equipment cooling controllers (ECCs).

Cabin Temperature Controller

The CTCs control these functions of the air conditioning system:

- Pack flow, regulation (on) or off
- Pack cooling/mix manifold temperature
- Trim air, regulation (on) or off
- Zone temperature
- Recirculation air.

Air Supply Cabin Pressure Controller

The ASCPCs control these functions:

- Pack flow schedule
- Pack flow, on or off
- Backup pack flow (CTC failed)
- Trim air, on or off
- Pressurization system
- Pneumatic system.

Environmental Control System Miscellaneous Cards

The ECSMCs control these functions of the air conditioning system:

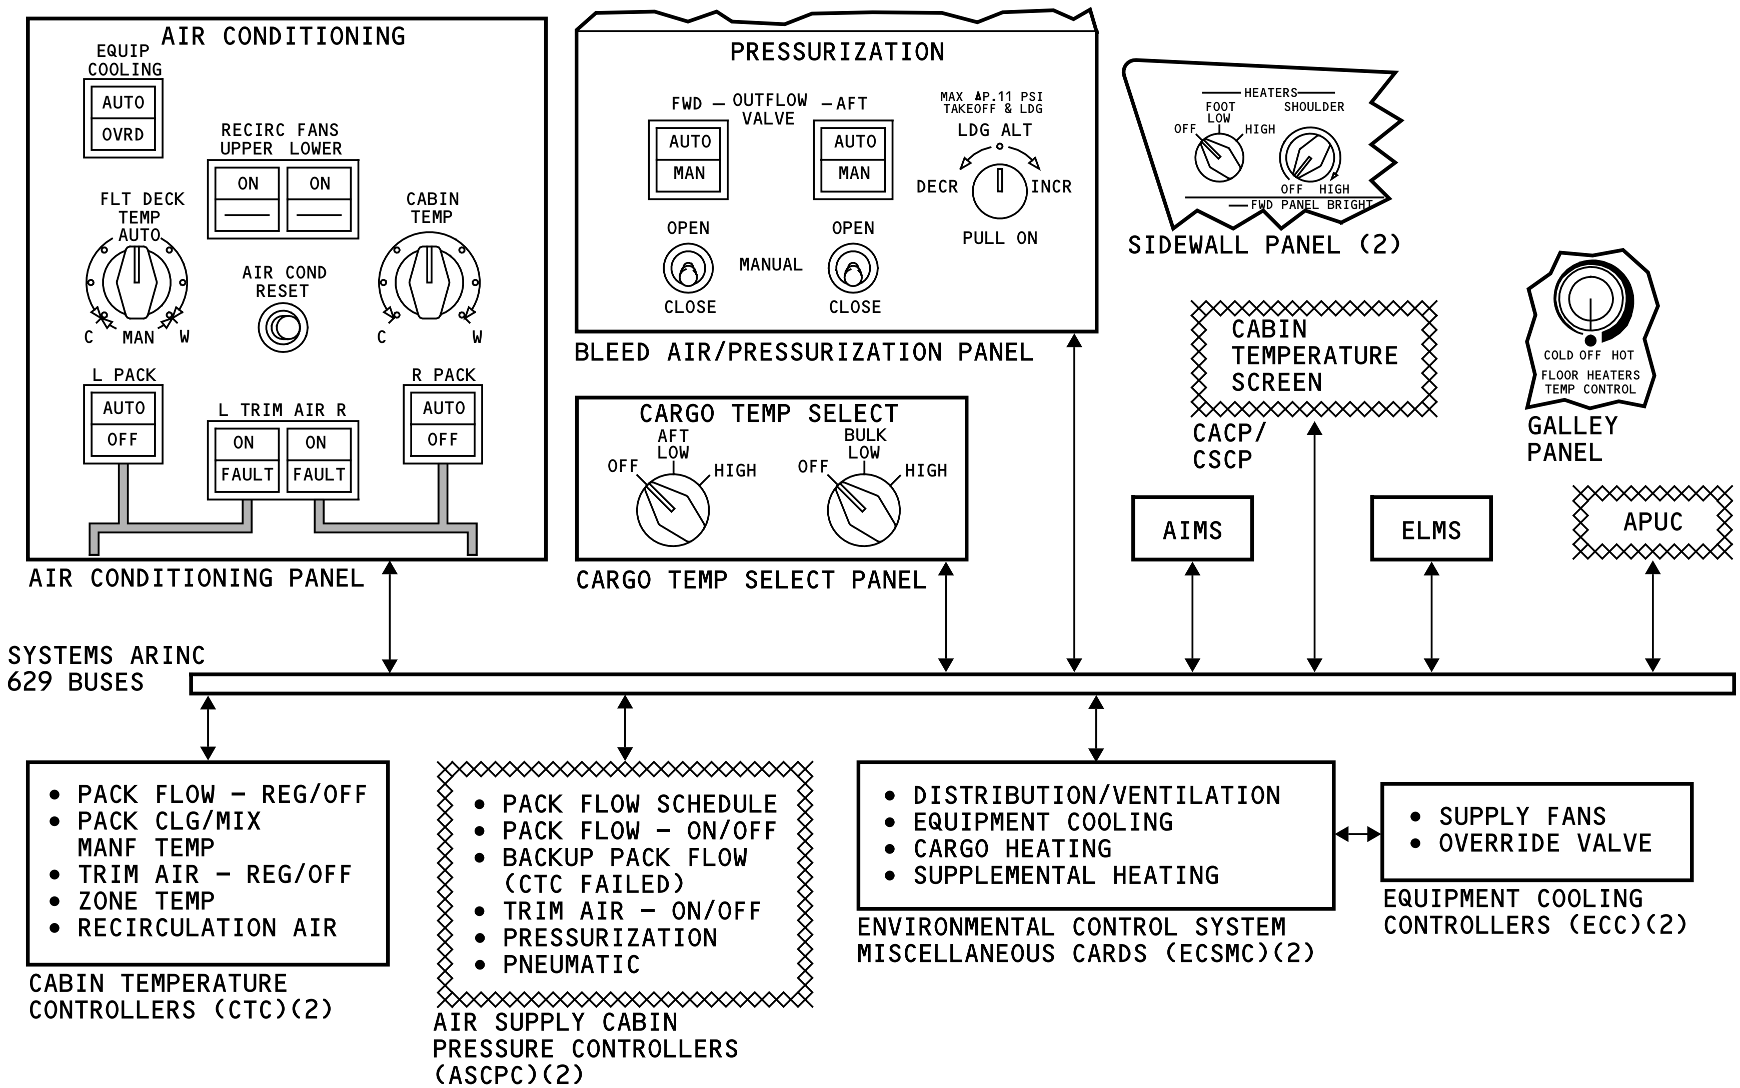
- Air distribution and ventilation
- Equipment cooling
- Cargo heating
- Supplemental heating.

Equipment Cooling Controller

The ECCs control the supply fans and override valve in the equipment cooling system.

Interfaces

The air conditioning controls have interfaces with each other, the AIMS, the electrical load management system (ELMS), and the auxiliary power unit controller (APUC).



AIR CONDITIONING - GENERAL DESCRIPTION - CONTROL

AIR CONDITIONING - FLIGHT DECK CONTROLS

General

These flight deck panels give the flight crew control of the air conditioning subsystems:

- Air conditioning panel on the P5 overhead panel
- Bleed air/pressurization panel on the P5 overhead panel
- Cargo temperature select panel on the P61 overhead maintenance panel.

Cargo Temperature Select Panel

These controls are on the cargo temperature select panel:

- Aft cargo temperature selector
- Bulk cargo temperature selector.

Air Conditioning Panel

These controls are on the air conditioning panel:

- Equipment cooling switch
- Upper and lower recirculation fan switches
- Flight deck temperature control
- Cabin temperature control
- Air conditioning reset switch
- Left and right pack switches
- Left and right trim air switches.

Sidewall Panels

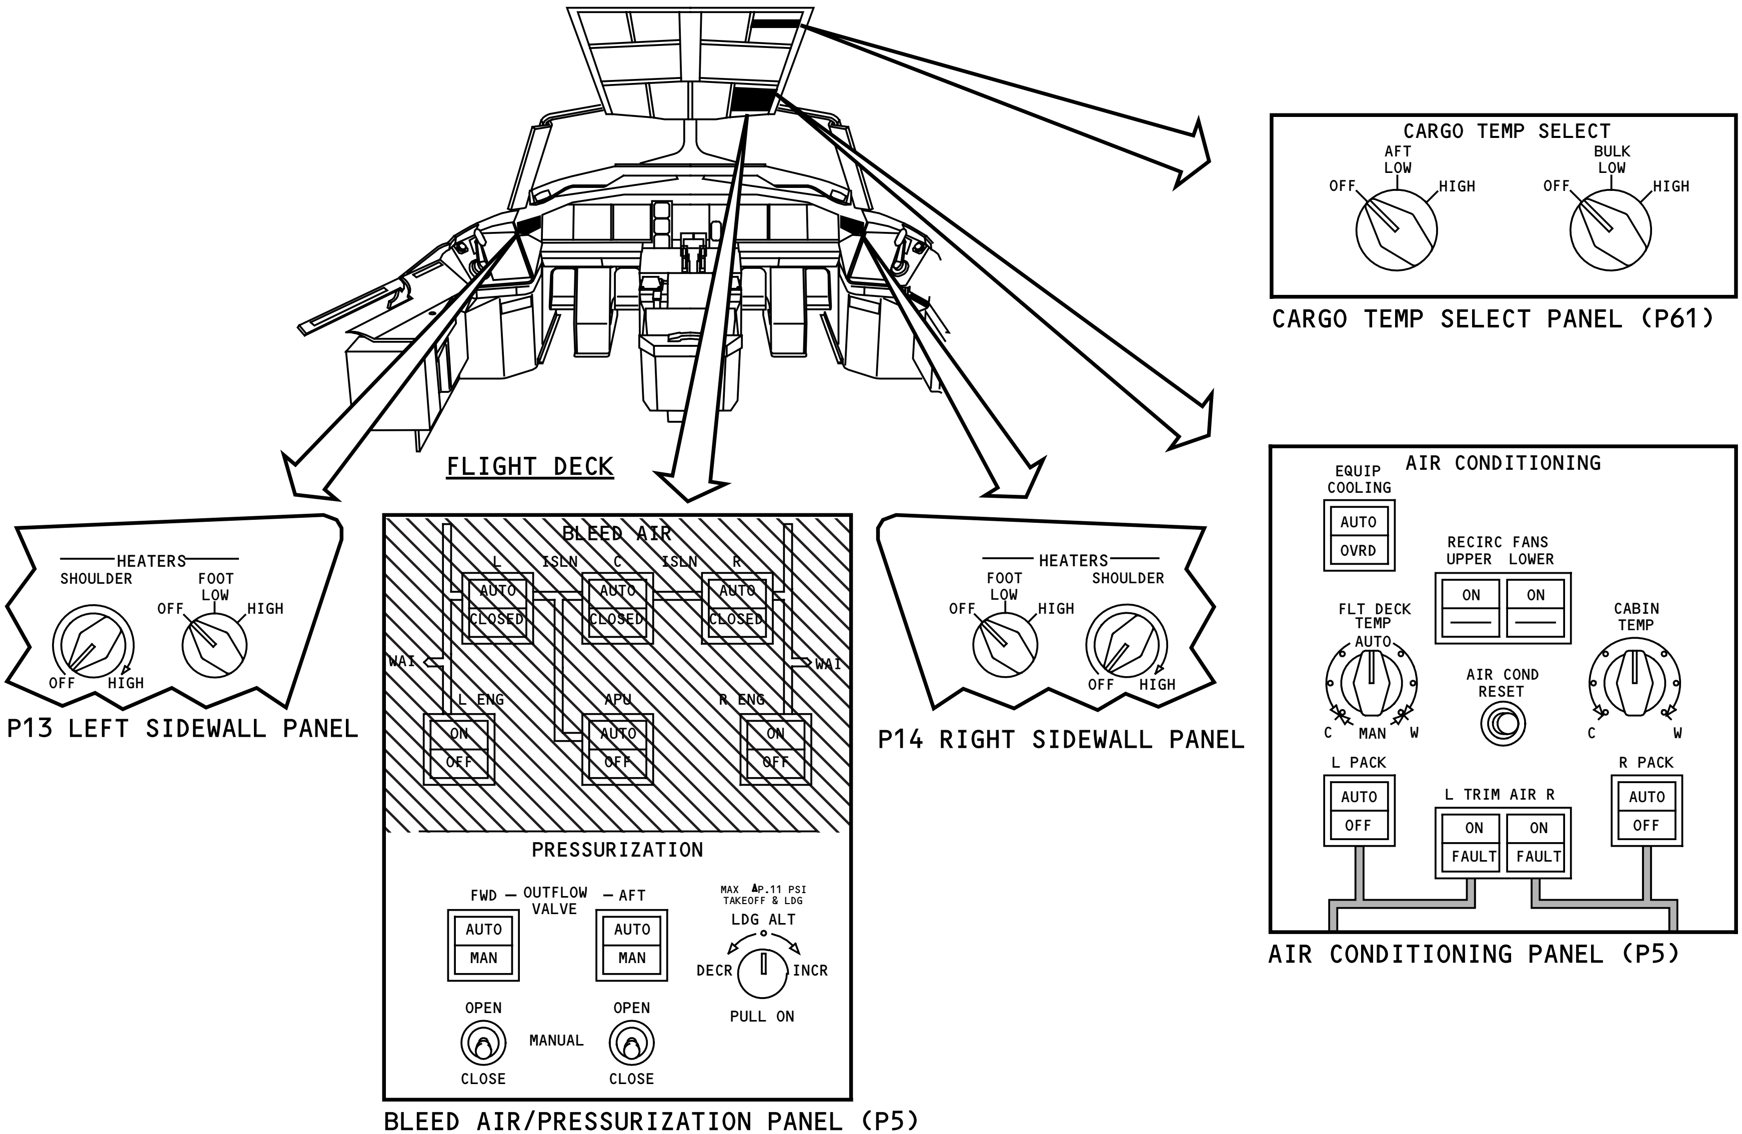
These controls, related to the air conditioning system are on the left and right sidewall panels:

- Captain's foot heater selector (left sidewall panel)
- Captain's shoulder heater control (left sidewall panel)
- First office's foot heater selector (right sidewall panel)
- First office's shoulder heater control (right sidewall panel).

Bleed Air/Pressurization Panel

These controls are on the pressurization part of the bleed air/pressurization panel:

- Forward and aft outflow valve AUTO switches
- Forward and aft outflow valve manual switches
- Landing altitude selector.



AIR CONDITIONING - FLIGHT DECK CONTROLS

AIR CONDITIONING - CONTROLLERS

General

The air conditioning system uses these controllers:

- Cabin temperature controllers (CTCs)
- Air supply cabin pressure controllers (ASCPCs)
- Equipment cooling controllers (ECCs).

These controllers are in the main equipment center.

AIR CONDITIONING - ECS MISCELLANEOUS CARDS - INTRODUCTION

Purpose

The environmental control system miscellaneous cards (ECSMCs) give control, indication, and BIT for some functions of these systems:

- Equipment cooling system
- Air conditioning distribution system
- Air conditioning supplemental heating system
- Cargo compartment heating systems.

Location

The left and right system card files each contain one of the ECSMCs. The system card files are in the main equipment center.

Interfaces

The left and right ECSMCs have interfaces with the left and right systems ARINC 629 buses through the ASG cards.

Training Information Point

The left and right ECSMCs are interchangeable. You can use the MAT to install new software in the cards.

There is a switch on each card file to remove power from the ECSMC when you remove or install the ECSMC. See the indication and recording systems chapter for more information about the systems card files (AMM PART I 31-09).

AIR CONDITIONING - ECS MISCELLANEOUS CARDS - INTRODUCTION

AIR CONDITIONING - ECS MISCELLANEOUS CARDS - GENERAL DESCRIPTION

Primary and Back-up Control/Indication

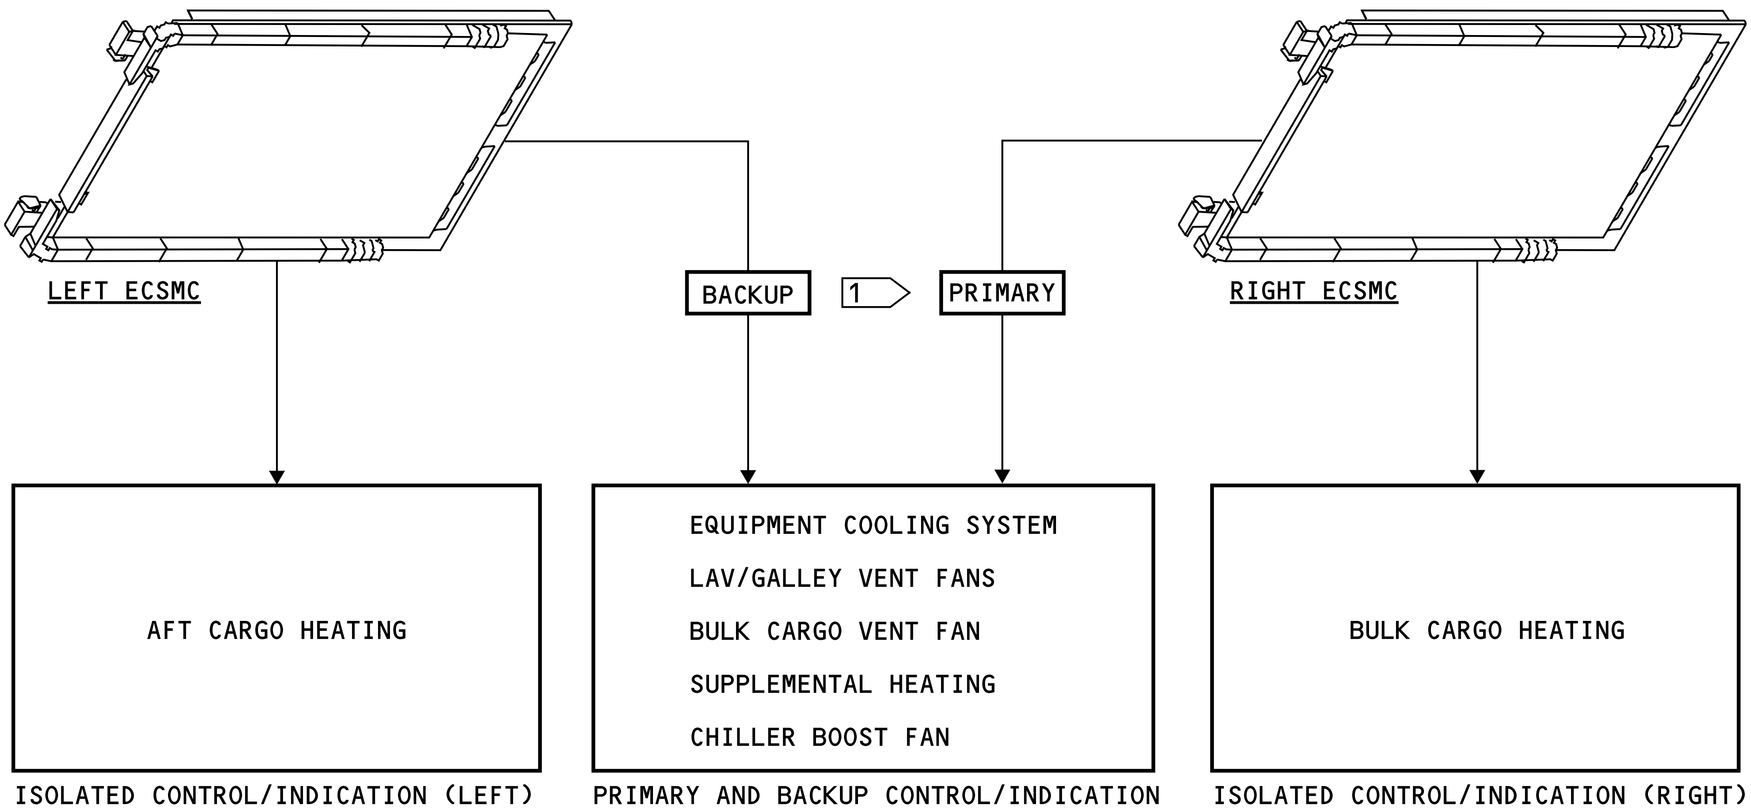
When the card files first get power, the right ECS miscellaneous card (ECSMC) is primary and the left ECSMC is backup. The primary and backup configuration changes at each air-ground transition. The primary card gives control and indication for these functions:

- Equipment cooling (includes ground crew call horn and SATCOM backup cooling)
- Lavatory/galley ventilation
- Bulk cargo ventilation
- Chiller exhaust boost ventilation
- L and R door area supplemental heating
- Forward and aft galley area supplemental heating
- Flight crew rest area heating
- Captain and first officer supplemental heating.

Isolated Control/Indication

The left ECSMC gives control and indication for the aft cargo heating system. The left card also monitors duct pressure and air flow in part of the equipment cooling system (not shown).

The right ECSMC gives control and indication for the bulk cargo heating system. The right card also monitors duct pressure and air flow in part of the equipment cooling system (not shown). See the equipment cooling system for more information about the ECSMC (AMM PART I 21-27).



1 AT CARD FILE POWER-UP, THE RIGHT CARD IS PRIMARY AND THE LEFT CARD IS BACKUP. EVERY AIR-GROUND TRANSITION CHANGES THE PRIMARY/BACKUP CONFIGURATION.

AIR CONDITIONING - ECS MISCELLANEOUS CARDS - GENERAL DESCRIPTION

AIR CONDITIONING - GENERAL DESCRIPTION - AIR FLOW

General

These are the primary parts of the air conditioning (A/C) system that have an effect on the supply of fresh air or the recirculation of conditioned air:

- Pack flow control
- Pack cooling and mix manifold temperature control
- Zone temperature control
- Recirculation
- Air distribution.

The primary parts of the A/C system have these functions:

- Control fresh air flow for airplane pressurization and ventilation
- Control the flight deck and passenger cabin temperature
- Recirculate cabin air for ventilation.

Pack Flow Control

This part of the A/C system controls the quantity of fresh air that flows into the airplane. It also controls when the ozone converter removes ozone. These are the primary components shown:

- Pack flow sensors
- Upper and lower flow control valves
- Pack inlet temperate sensor.

The quantity of fresh air necessary for ventilation is more than for pressurization. The ventilation quantity is based on a fixed value for the crew and allowable leakage, and on the number of passenger seats.

Usually the left and right flow control systems provide the same quantity of fresh air. Fresh air flow changes when airplane conditions change. For example during takeoff, the quantity decreases to make sure a sufficient quantity of engine bleed air goes to the air driven pumps (ADPs). This type of change usually does not last for very long. See the pack flow control section for more information about the control of fresh air into the airplane (AMM PART I 21-51).

When an airplane operates above 26,000 feet (7930 meters) for long periods of time, it is necessary to remove ozone from the fresh air. The upper and lower flow control valves let fresh air flow through the ozone converter or bypass it. Above 26,000 feet (7930 meters), air flows through the converter. Below 24,000 feet (7315 meters), air bypasses the converter. See the ozone control section for more information about the ozone converter (AMM PART I 21-73).

Pack Cooling and Mix Manifold Temperature Control

This part of the A/C system removes water as necessary and controls the temperature of the fresh air before it flows into the air distribution part of the air conditioning system. The primary components are the left and right packs.

The usual control for the left pack makes sure that it supplies air at a temperature that gives the necessary cooling for the flight deck. If the mix manifold needs more cooling than the flight deck, the left pack supplies air at a temperature that gives the necessary cooling for the mix manifold.

The control for the right pack makes sure that it supplies air at a temperature that gives the necessary cooling for the mix manifold. See the pack cooling and mix manifold temperature control section for more information about the control of the packs (AMM PART I 21-52).

Zone Temperature Control

This part of the A/C system increases the temperature of the conditioned air that flows into the occupied areas of the airplane. It also gives pressure regulation and on/off control for the trim air part of the system. These are the primary components:

- Trim air pressure regulating and shutoff valves
- Trim air pressure sensors
- Zone trim air modulating valves
- Temperature sensors.

The system calculates the necessary pack outlet temperatures to satisfy the cooling needs of the flight deck and the mix manifold. The system also calculates the heating necessary for each temperature control zone. These are the temperature control zones:

- Flight deck zone
- Passenger cabin zones (6).

Air from the pneumatic system adds heat to a zone that needs warmer air. The trim air pressure regulating and shutoff valve gives on/off control and keeps trim air pressure at a necessary limit. See the trim air pressure regulation and shutoff control section for more information about the trim air PRSOV (AMM PART I 21-62). The zone trim air modulating valves control the heat added to the conditioned air for each zone. See the zone temperature control and indication section for more information about the zone temperature control system (AMM PART I 21-61).

Recirculation

This part of the A/C system recycles approximately 50 percent of the cabin air for ventilation purposes. This reduces the quantity of fresh air needed from the pneumatic system for ventilation. These are the primary components:

- Upper recirculation fans and filters
- Lower recirculation fans and filters.

See the recirculation section for more information about the recycling of cabin air (AMM PART I 21-25).

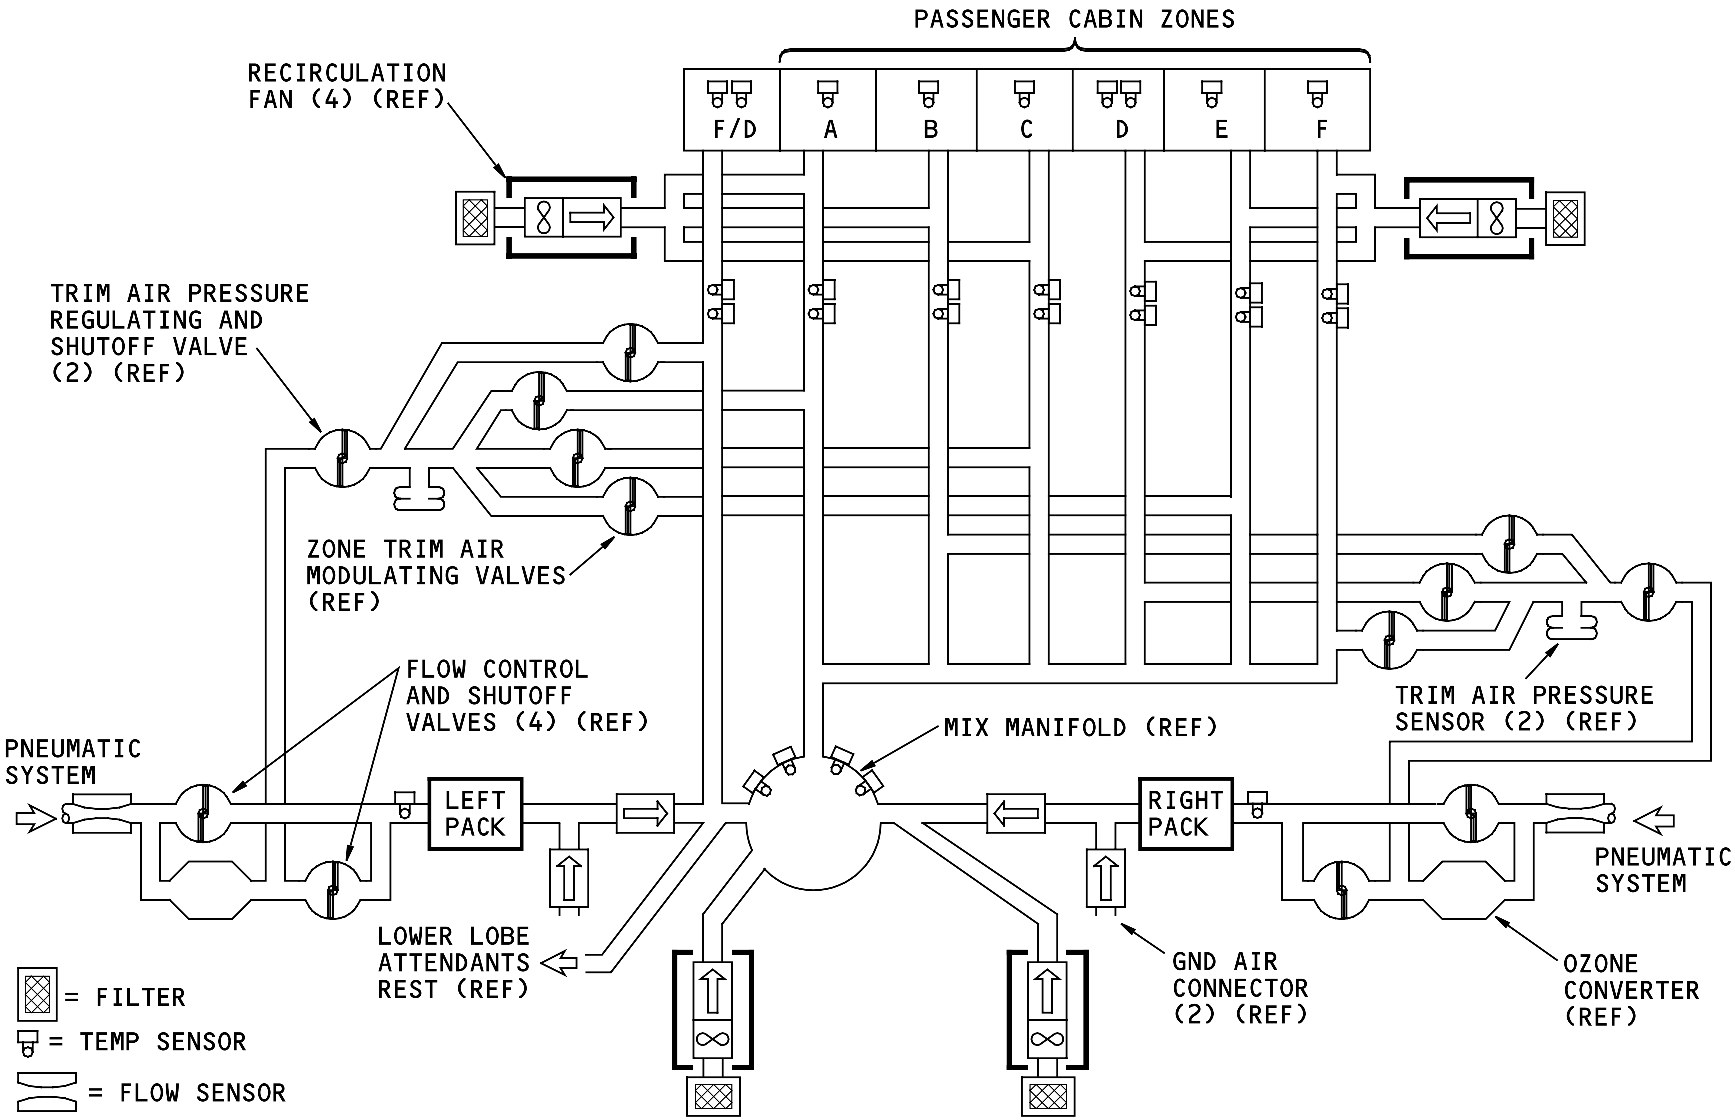
AIR CONDITIONING - GENERAL DESCRIPTION - AIR FLOW

Air Distribution

This part of the A/C system moves conditioned air from the packs or ground air sources to the temperature control zones. These are the primary components:

- Ground air connector (2)
- Mix manifold
- Distribution ducts/risers.

See the distribution section for more information about the air distribution systems (AMM PART I 21-20).



AIR CONDITIONING - GENERAL DESCRIPTION - AIR FLOW

THIS PAGE INTENTIONALLY LEFT BLANK

CTC Functions

The CTCs control air flow into the air conditioning packs and control the mix manifold temperature. Two identical control channels in each CTC give redundancy.

With the APU off and the pack switches in AUTO, the CTCs use flow schedule data from the ASCPCs to control pack air flow. If the APU supplies air to the packs, the CTCs tell the APUC the amount of air necessary. Then, the CTCs do not use the flow schedule from the ASCPCs.

For some conditions when pack air flow is too low, the CTCs send bleed bias signals to the ASCPCs.

ASCPC Functions

The ASCPCs set the flow schedule for the CTCs, give backup pack flow control, and control the engine bleed air system.

The ASCPCs get information about bleed air users and about airplane operating conditions from the left and right system ARINC 629 buses. The ASCPCs use the information to set the pack air flow schedule and send the flow schedule data to the CTCs. The left ASCPC is primary for this function and the right ASCPC is the backup.

The ASCPCs cause the pack flow control valves to close for some conditions. The ASCPC is redundant with the CTC for these conditions.

The ASCPCs are also able to keep the pack outlet temperature in limits by controlling the pack air flow. This is called backup pack flow control. Backup pack flow control is a degraded mode of operation that maintains cabin pressurization but does not give accurate temperature control. The packs operate in this mode if the CTCs do not have electrical power.

If an ASCPC gets a bleed bias signal from the CTC, the ASCPC adjusts the engine bleed air system. This decreases the engine bleed air temperature or increases the HPSOV regulation set point.

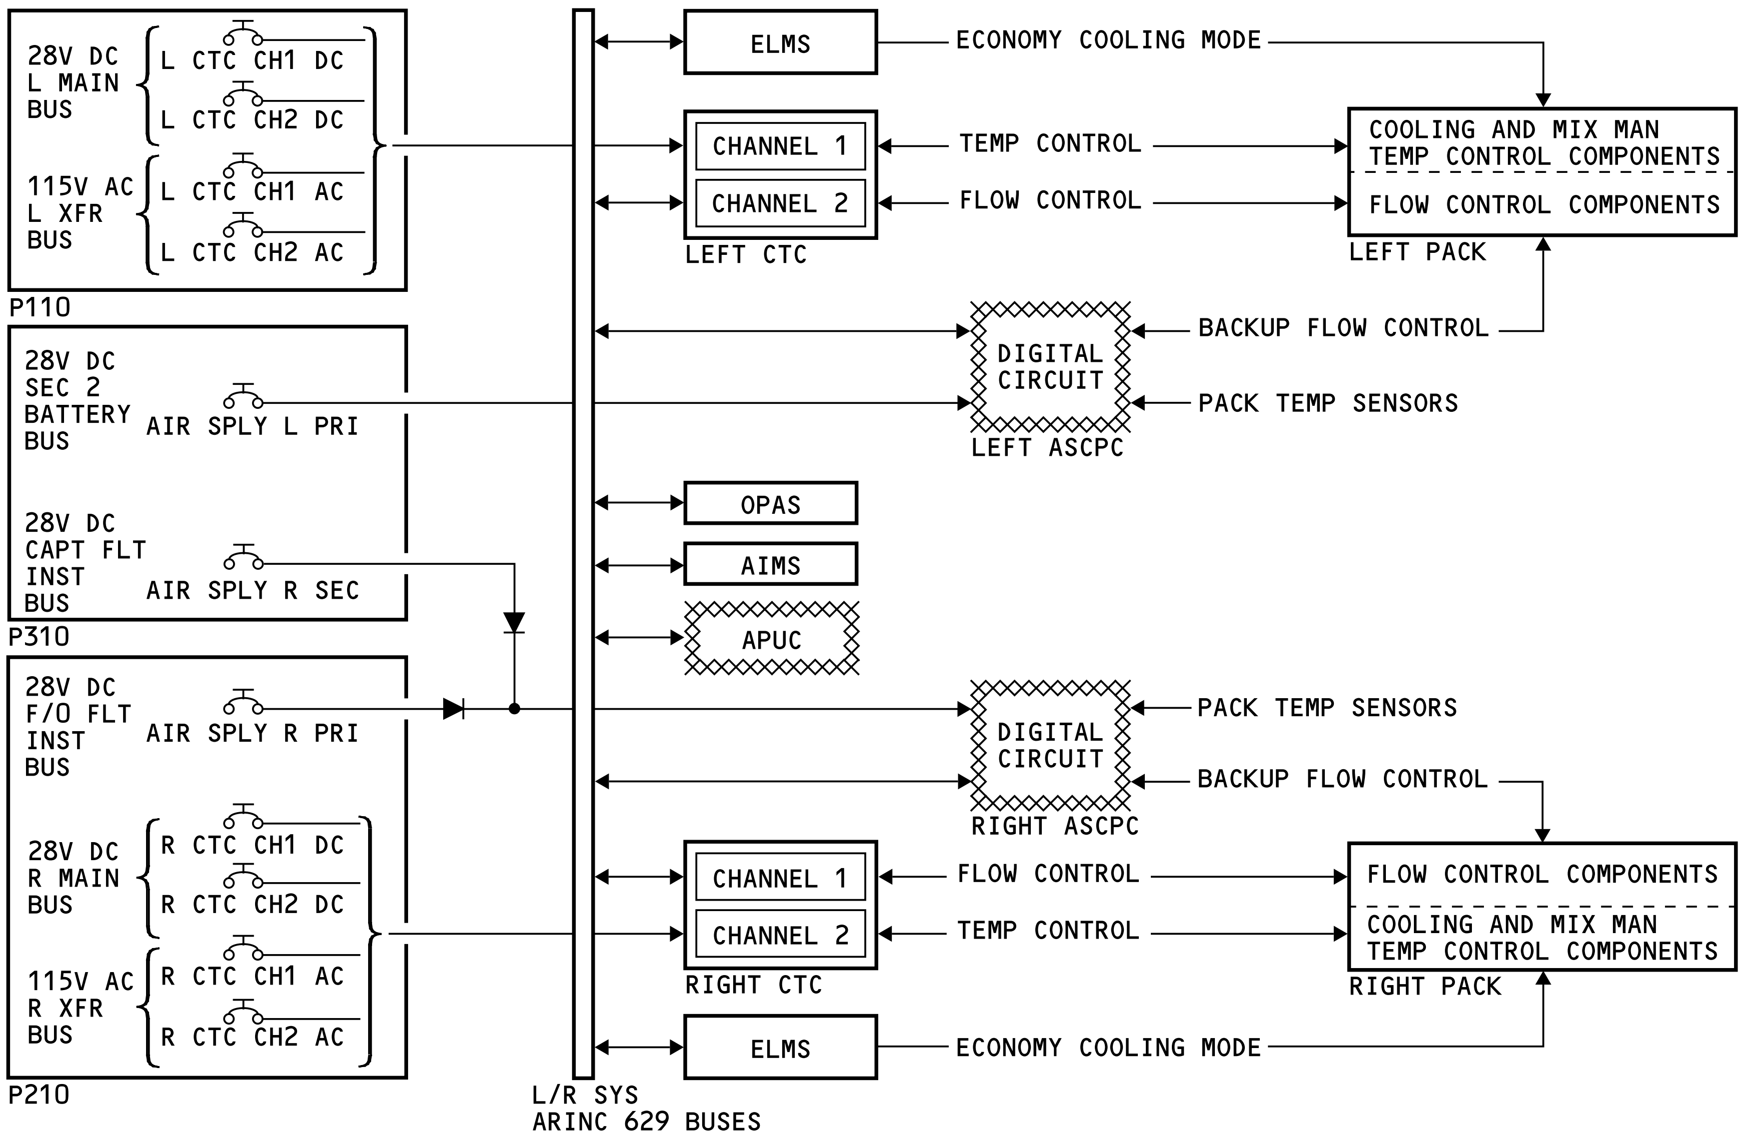
See the pack flow control section for more information about the ASCPC functions that have a relation to the air conditioning pack flow control (AMM PART I 21-51).

Electrical Power

The CTCs get electrical power from the 28v dc main buses and the 115v ac transfer buses. The ASCPC digital circuits get 28v dc power from the section 2 battery bus, the captain's flight instrument bus and the first officer's flight instrument bus. The left ASCPC can operate on battery power. The right ASCPC can operate on standby power from the captain's and first officer's flight instrument buses. The CTCs can not operate with only battery or standby power.

Economy Cooling Mode

For some conditions when pack air flow is too low, the CTC adjusts the pack temperature control components to help increase flow. An ARINC 629 signal from the CTC to ELMS puts the pack into the economy cooling mode.



AIR CONDITIONING - COOLING - GENERAL DESCRIPTION - CONTROL

21-50-00-003 Rev 4 03/21/96

THIS PAGE INTENTIONALLY LEFT BLANK

AIR CONDITIONING - PACK FLOW CONTROL - INTRODUCTION

Purpose

The flow control system controls the quantity of air that goes from the pneumatic system into the air conditioning packs. These are the functions of the pack flow control system:

- Pack air on/off control
- Pack air flow regulation
- Ozone converter bypass
- Backup pack flow control
- Engine air supply system bias.

The CTCs and the ASCPCs have logic that control the pack air flow. The ASCPCs have the backup pack flow control.

Components

The pack flow control system has these components:

- Pack flow sensor
- Upper flow control and shutoff valve
- Lower flow control and shutoff valve
- Primary heat exchanger inlet temp sensor.

The systems for the left and right packs are the same.

Pack Air On/Off Control

With the air conditioning pack switch off, the two flow control and shutoff valves close. With the pack switch in AUTO, the flow control valves control pack air flow. The valves close if the pack fails, has an overheat condition, or if a higher priority bleed user is on.

Pack Air Flow Regulation

The flow control system makes decisions about the amount of air the packs can have. These decisions take into account the needs of other bleed air users and airplane operating conditions.

Ozone Converter Bypass

The ozone converter decreases the amount of atmospheric ozone that goes into the cabin. Ozone is in the atmosphere at high altitudes. The ozone converter is serviceable for a longer time if it operates only at high altitudes. At low altitudes the lower flow control valve closes and the upper valve controls flow. At high altitude the upper valve closes and the lower valve controls flow.

Backup Pack Flow Control

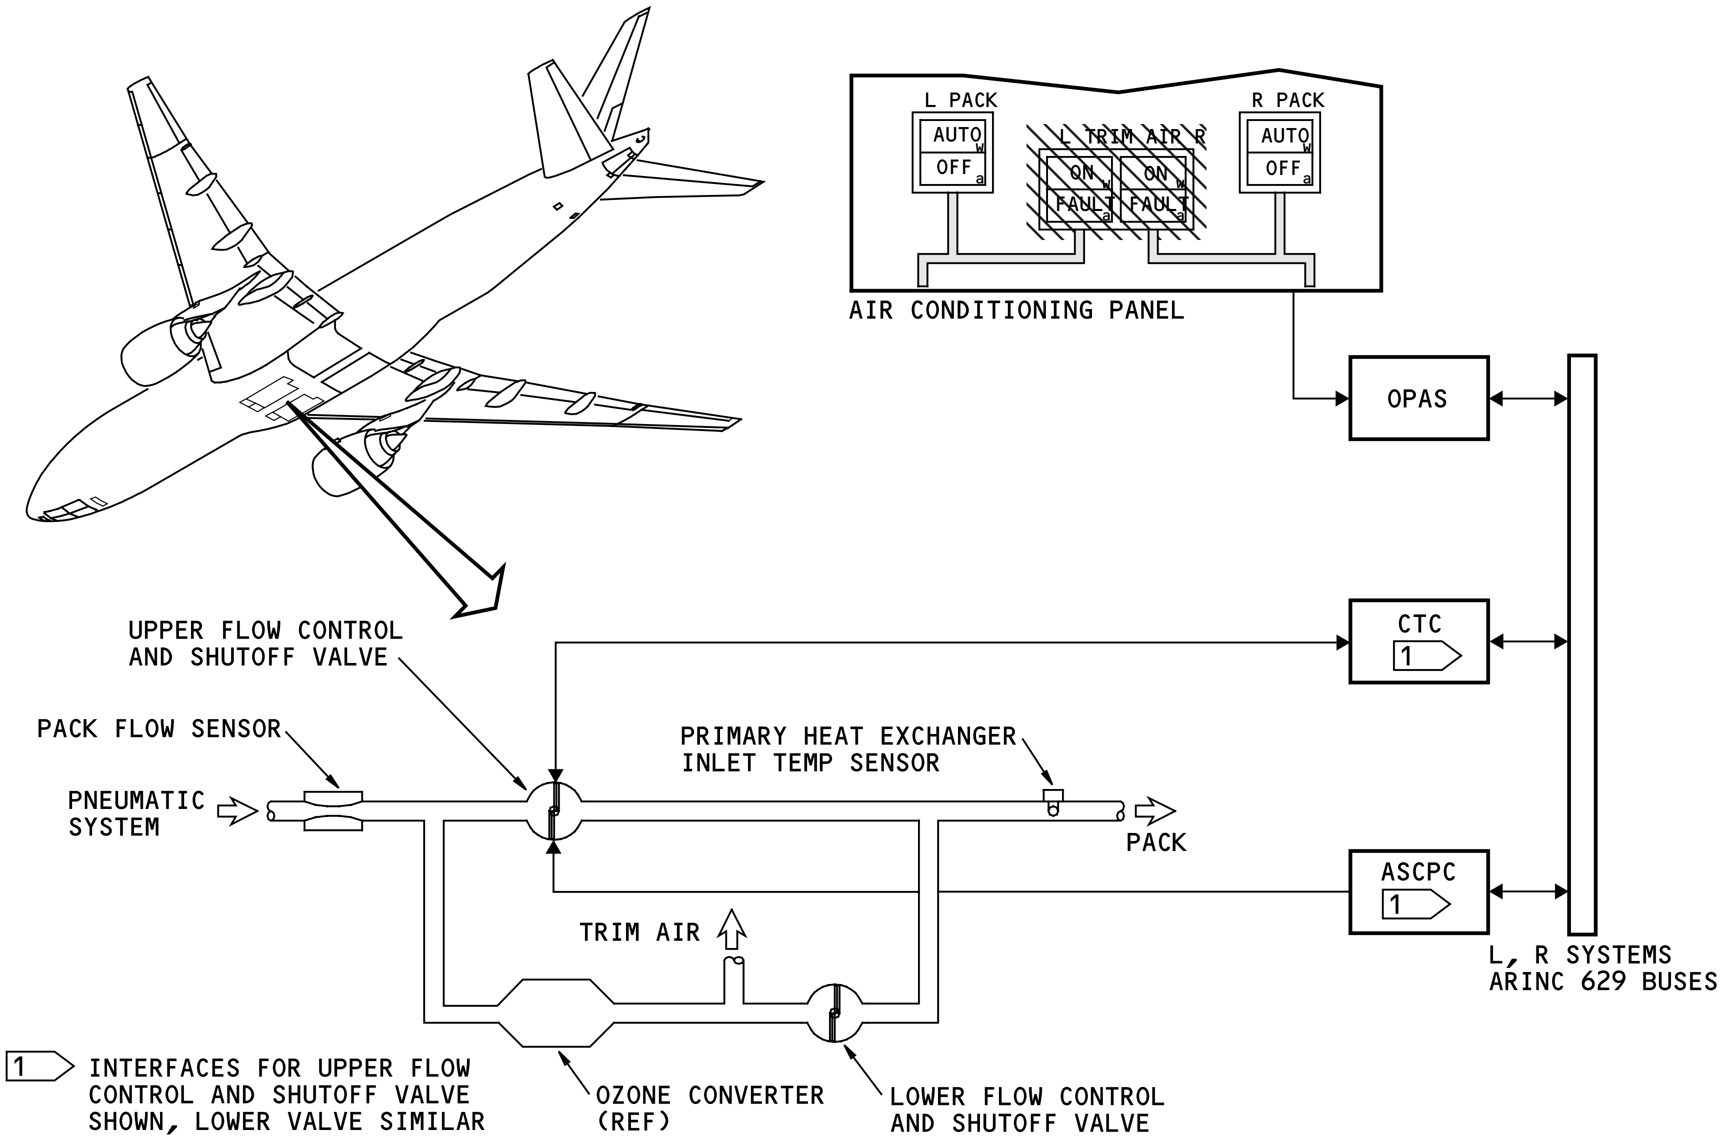
If only battery or standby power are available, the packs operate in a backup mode. The flow control system adjusts the pack air flow to keep the pack outlet temperature in limits.

Engine Bleed System Bias

For some low flow conditions, the flow control system sends signals to the pneumatic system. These signals adjust the engine bleed air temperature or HPSOV set-

AIR CONDITIONING - PACK FLOW CONTROL - INTRODUCTION

point. Lower bleed air temperature lets the pack operate with less restriction to air flow. A higher HPSOV set point lets the pneumatic system supply more air at low engine power settings.



AIR CONDITIONING - PACK FLOW CONTROL - INTRODUCTION

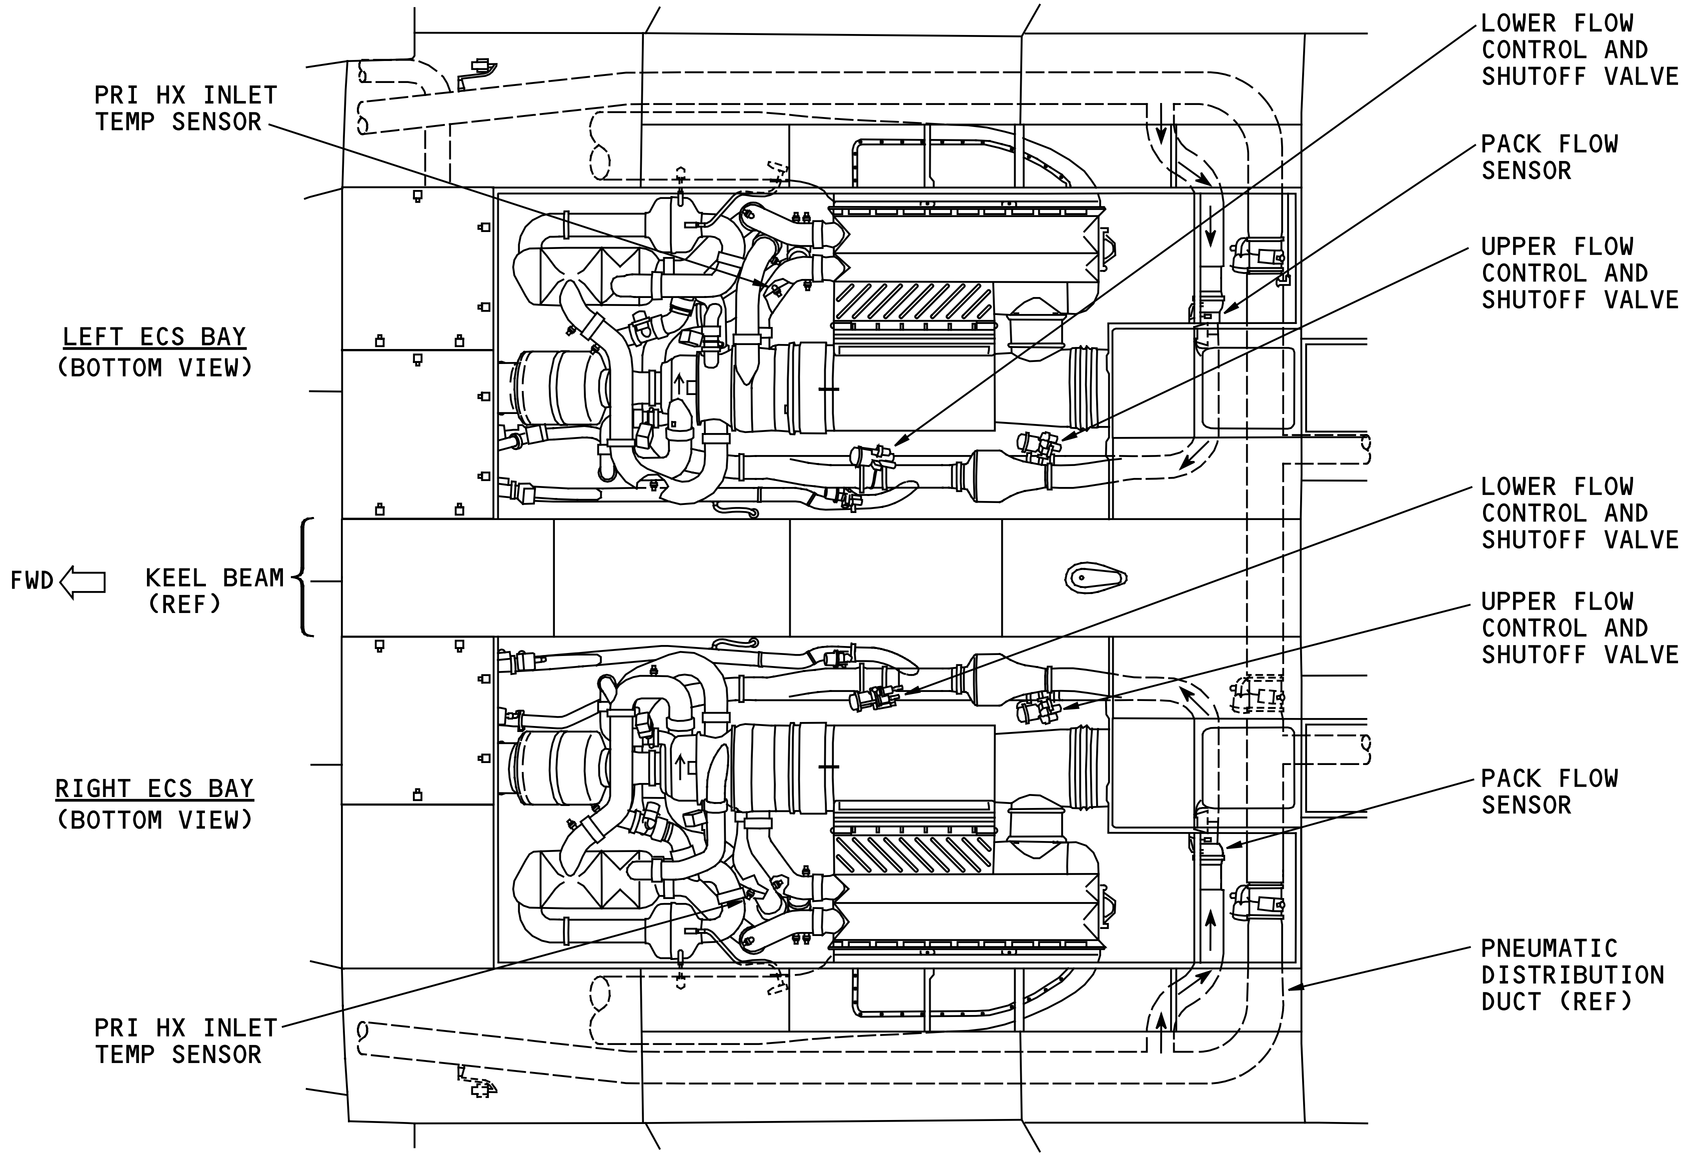
AIR CONDITIONING - PACK FLOW CONTROL - COMPONENT LOCATIONS

Component Locations

Each pack has these flow control components in the ECS bay:

- Primary heat exchanger inlet temperature sensor
- Lower flow control and shutoff valve
- Pack flow sensor
- Upper flow control and shutoff valve.

The components are interchangeable between packs.



21-51-00-002 Rev 3 07/15/1997

AIR CONDITIONING - PACK FLOW CONTROL - COMPONENT LOCATIONS

AIR CONDITIONING - PACK FLOW CONTROL - FLOW CONTROL AND SHUTOFF VALVES

Purpose

The flow control and shutoff valves control the air flow to the packs.

Physical Description

The upper and lower flow control and shutoff valves are interchangeable. These are the parts of the valve:

- A proximity switch
- A locking plug
- A locking crank/position indicator
- A pneumatic actuator
- A disc
- Two torque motors.

Functional Description

The flow control and shutoff valves operate by a pneumatic actuator which moves the disc in the valve. If there is no air pressure from the pneumatic system, a spring in the actuator closes the valve.

With no power to the torque motors, the connections to ambient air pressure close. Supply pressure pushes the valve open against the force of the spring in the actuator.

With power applied, the torque motors bleed air from one side of the pneumatic actuator. This permits the spring to move the valve disc to decrease the flow rate.

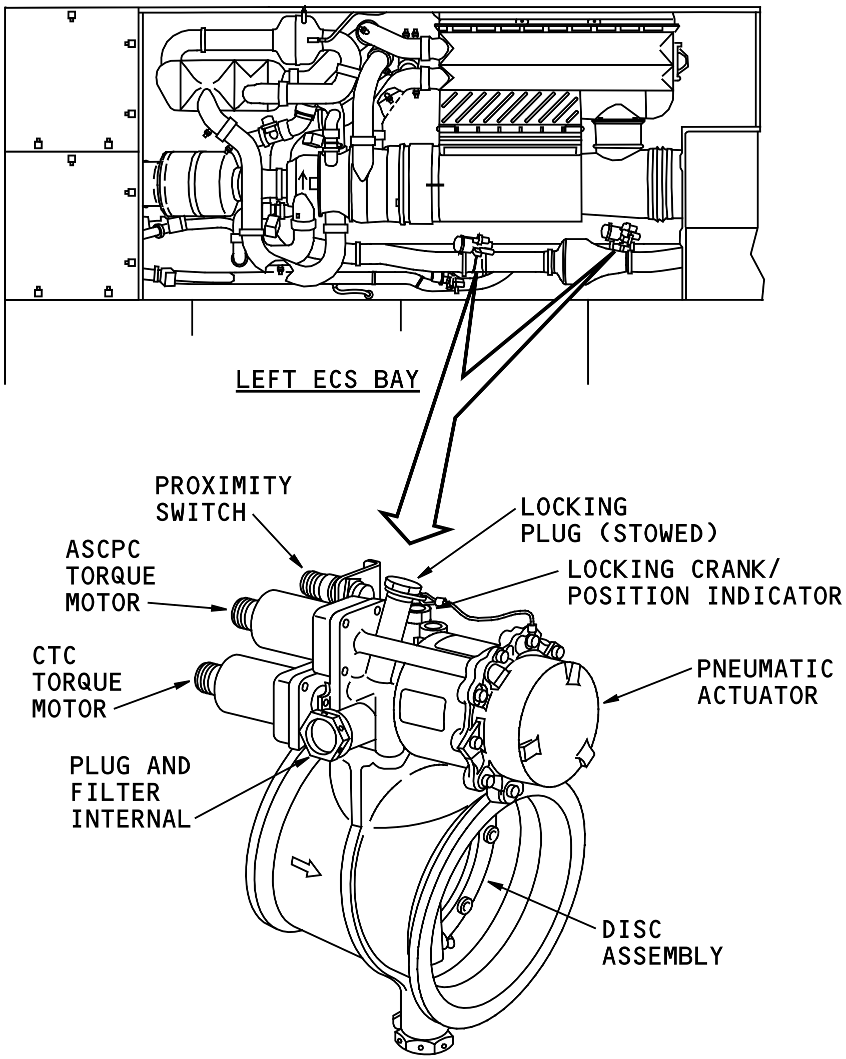
One torque motor connects to the CTC. The other torque motor connects to the ASCPC. Each torque motor can independently control the actuator. The CTC gives normal control of the valve. The ASCPC gives backup pack flow control if the CTC can not operate.

A proximity switch sends a signal to the CTC when the valve is closed.

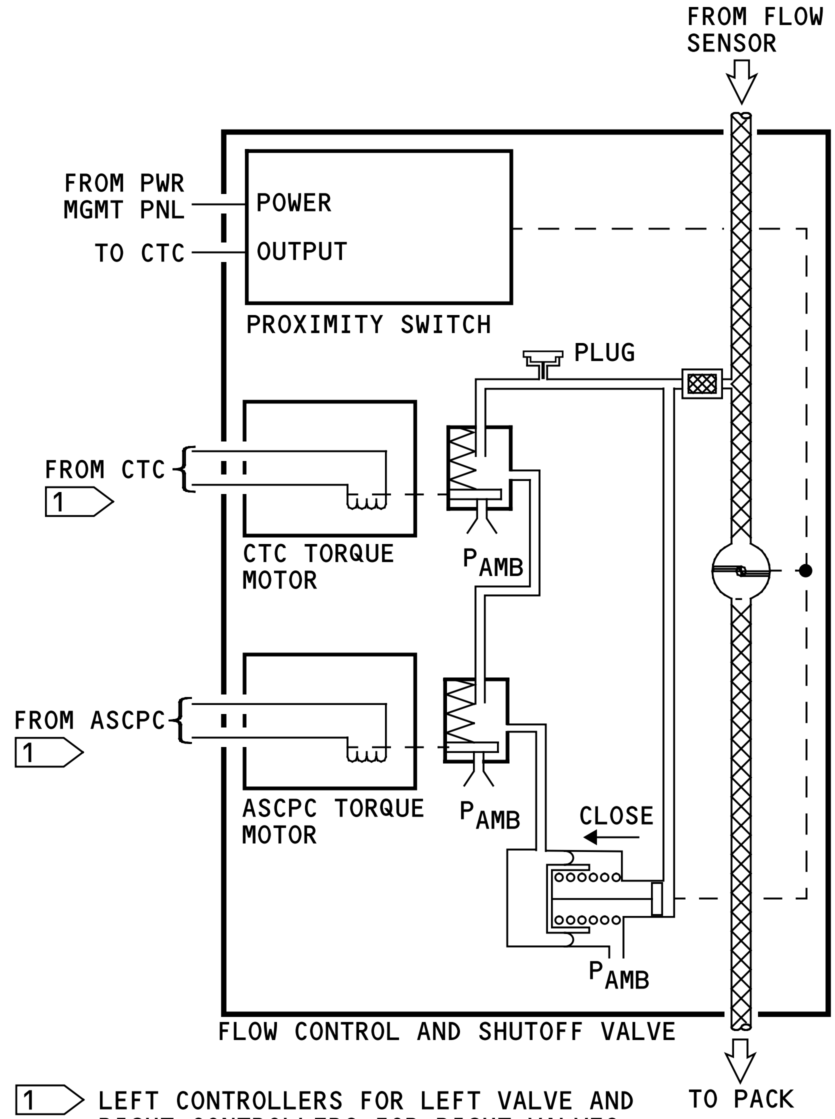
Training Information Point

You use the locking plug and locking crank to lock the valve closed.

The filter is an LRU.



FLOW CONTROL AND SHUTOFF VALVE
(TYPICAL)



1 LEFT CONTROLLERS FOR LEFT VALVE AND RIGHT CONTROLLERS FOR RIGHT VALVES.

AIR CONDITIONING - PACK FLOW CONTROL - FLOW CONTROL AND SHUTOFF VALVES

21-51-00-003 Rev 4 10/23/96

AIR CONDITIONING - PACK FLOW CONTROL - FLOW SENSOR

Purpose

The pack flow sensor supplies two types of air pressure information, pack inlet and pack inlet differential to the related CTC and ASCPC. The controllers use the pressure information to help calculate the rate of air flow from the pneumatic system into the airplane.

Physical Description

There are two pack flow sensors, one for each air conditioning pack/trim air system. Each sensor has these parts:

- High pressure (inlet) line (2)
- Inlet pressure sensor
- Differential pressure sensor (2)
- Electrical connector (3)
- Bracket (pressure sensor attachment)
- Titanium body
- Low pressure (venturi) line (2).

The titanium body is in the shape of a venturi. The pressure sensors attach to a bracket that attaches to the body. The pressure sensors use lines to connect to the body.

Location

The pack flow sensors are in the aft part of the left and right ECS bays. You get access through these blowout doors:

- 195QL left pack flow sensor
- 196QR right pack flow sensor.

Functional Description

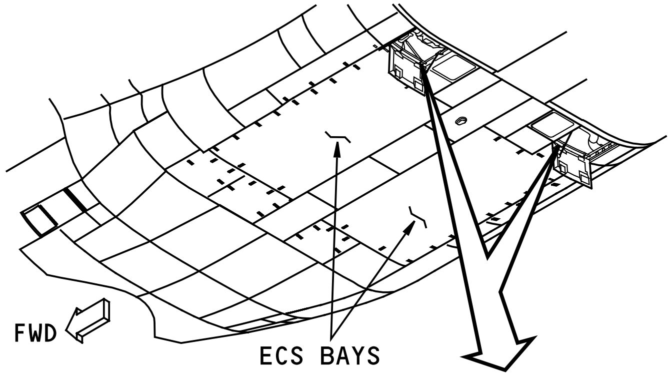
The CTC differential pressure sensor gives an output in proportion to the pressure difference across the venturi part of the pack flow sensors body. The inlet pressure sensor gives an output in proportion to the pack inlet air pressure. These outputs go to the CTC.

Power for the CTC differential pressure sensor and inlet pressure sensor comes from the power management panel that supplies the pack.

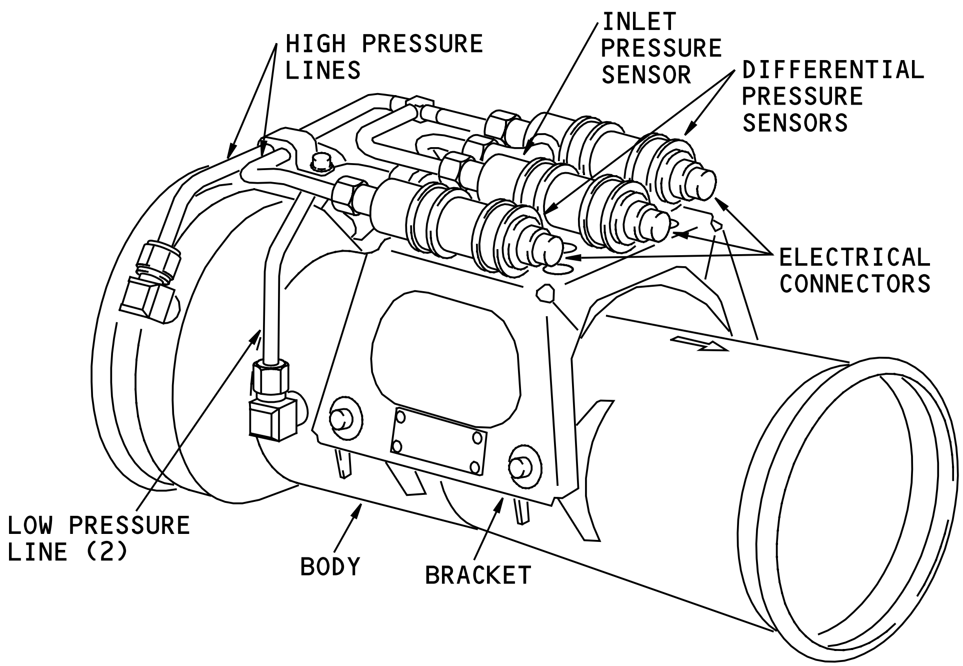
The ASCPC differential pressure sensor is the same as the CTC differential pressure sensor. The ASCPC gets differential pressure information and gives power to its differential pressure sensor.

Training Information Point

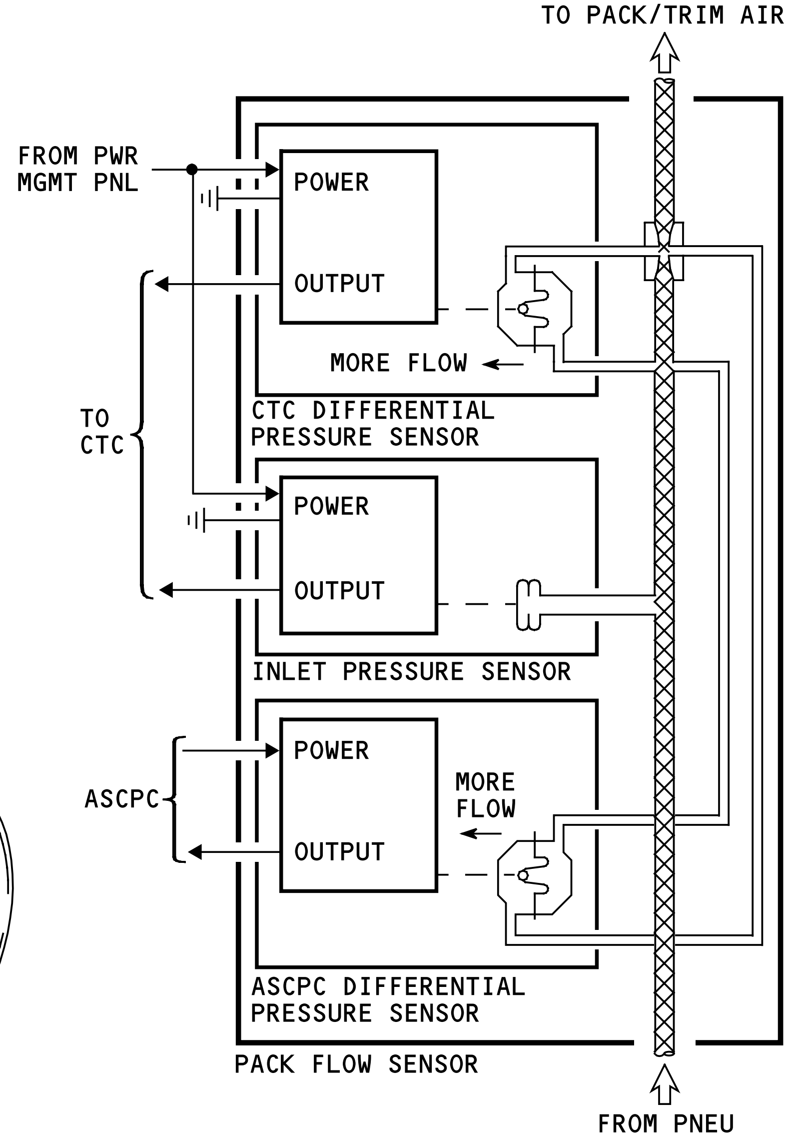
The pack flow sensor is an LRU. The individual inlet and differential pressure sensors are not LRUs.



UNDERWING FUSELAGE AREA



PACK FLOW SENSOR



AIR CONDITIONING - PACK FLOW CONTROL - FLOW SENSOR

AIR CONDITIONING - PACK FLOW CONTROL - PRIMARY HEAT EXCHANGER INLET TEMPERATURE SENSOR

General

The primary heat exchanger (PRI HX) inlet temperature sensor monitors the PRI HX inlet temperature.

Temperature data goes to the cabin temperature controller (CTC). It uses the data with data from the flow sensor to calculate pack mass air flow.

See the zone temperature control and indication section for more information about the CTC (AMM PART I 21-61).

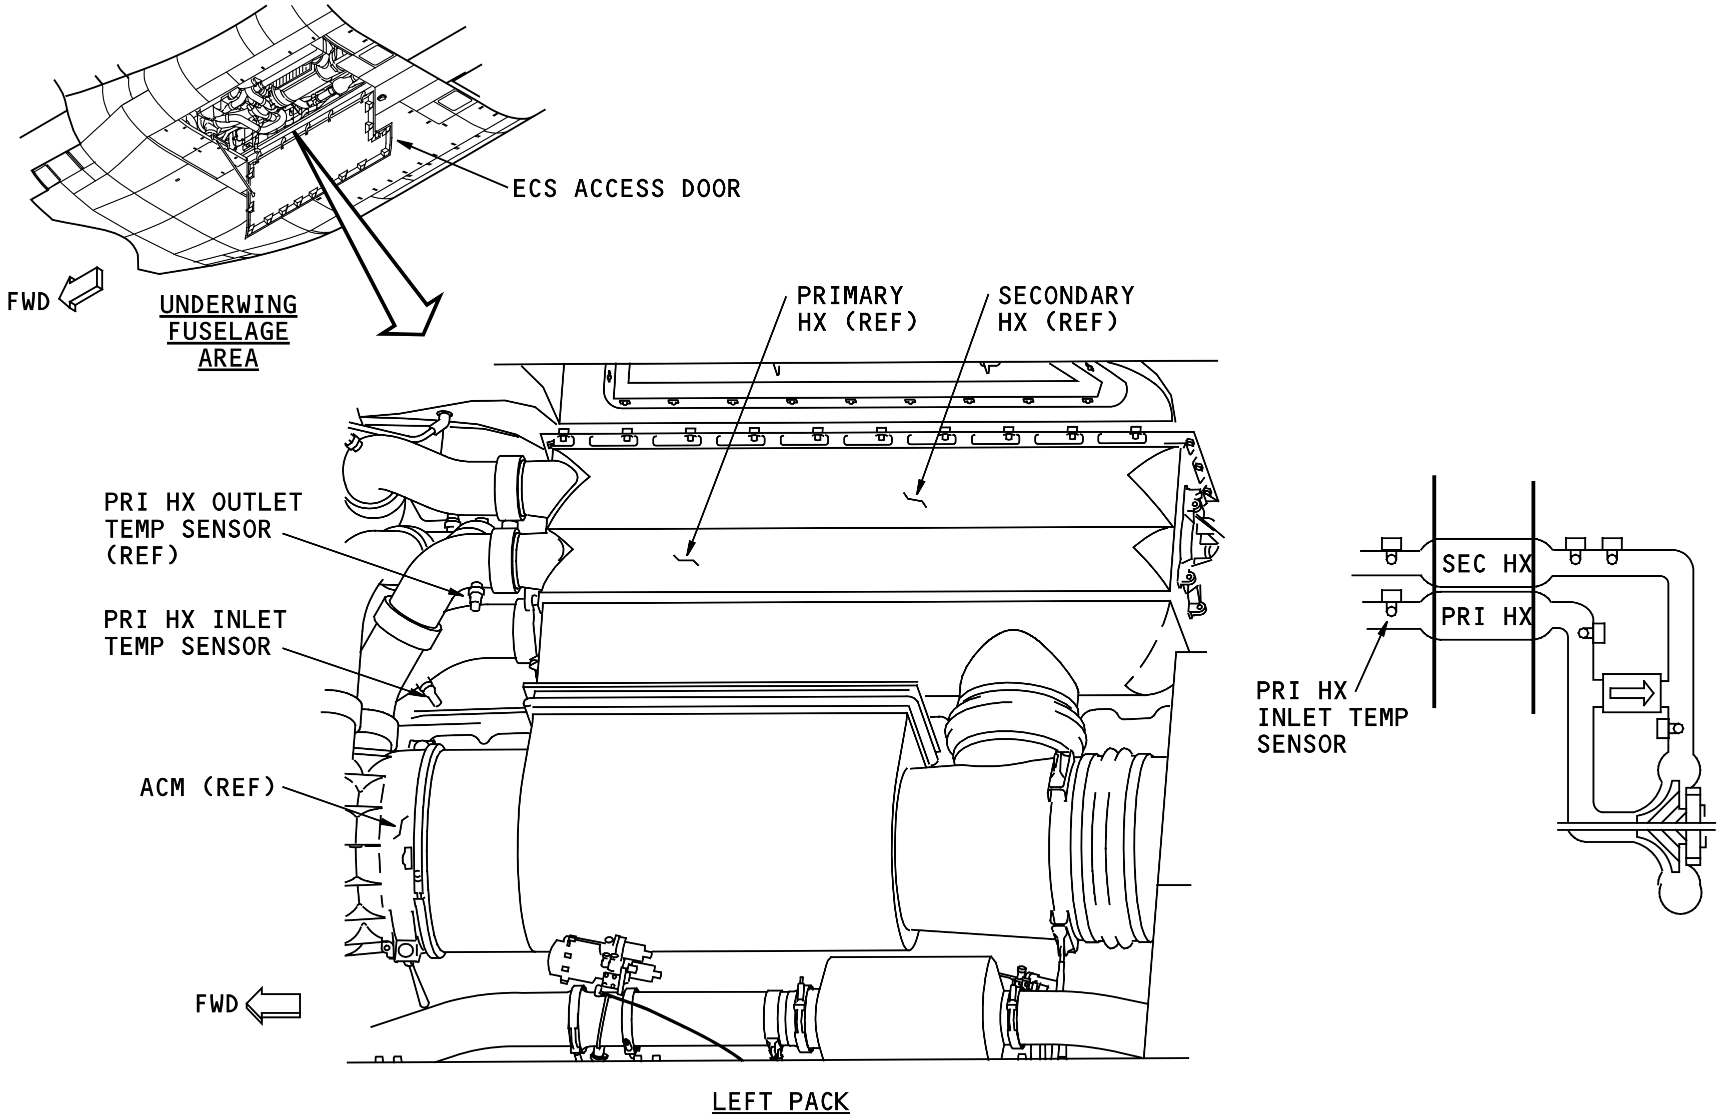
Physical Description

The sensor is a single element resistance temperature device (RTD). Threads on the sensor connect it to the boss in the duct. The sensor electrical connector is also threaded.

Training Information Point

This sensor is interchangeable with the other high temperature sensors in the pack.

See the pack cooling and mix manifold temperature control section for more information about sensors on the pack (AMM PART I 21-52).



AIR CONDITIONING - PACK FLOW CONTROL - PRIMARY HEAT EXCHANGER INLET TEMPERATURE SENSOR

General

The air supply cabin pressure controller (ASCPC) sets the flow schedule that the cabin temperature controllers (CTC) use to control air flow into the packs. Flow schedule 1 gives the largest air flow to the air conditioning packs and is the usual flow schedule.

Schedules 2, 3, and 4 give less and less air to the packs. Schedule 0 stops the air flow into the packs. The ASCPC sets these schedules when necessary to reduce the engine bleed air load or to make more air available to other systems.

These flow schedules operate only when the engines supply air to the packs. APU flow gets control a different way.

Schedules 1, 2, and 3 give a constant volumetric air flow to the packs. The related mass air flow decreases as cabin altitude increases. The chart shows the total air flow for two packs. For most conditions, the two packs operate at the same schedule.

Flow Schedule 1

The amount of air that flow schedule 1 supplies is related to the number of passenger seats in the airplane. The schedule 1 maximum is calculated for 440 seats. The schedule 1 minimum is calculated for 348 seats. Airplanes with less than 348 seats use the schedule 1 minimum.

Total flow from the two packs in flow schedule 1 increases approximately 67 lb/min for each inoperative recirculation fan.

Flow Schedule 2

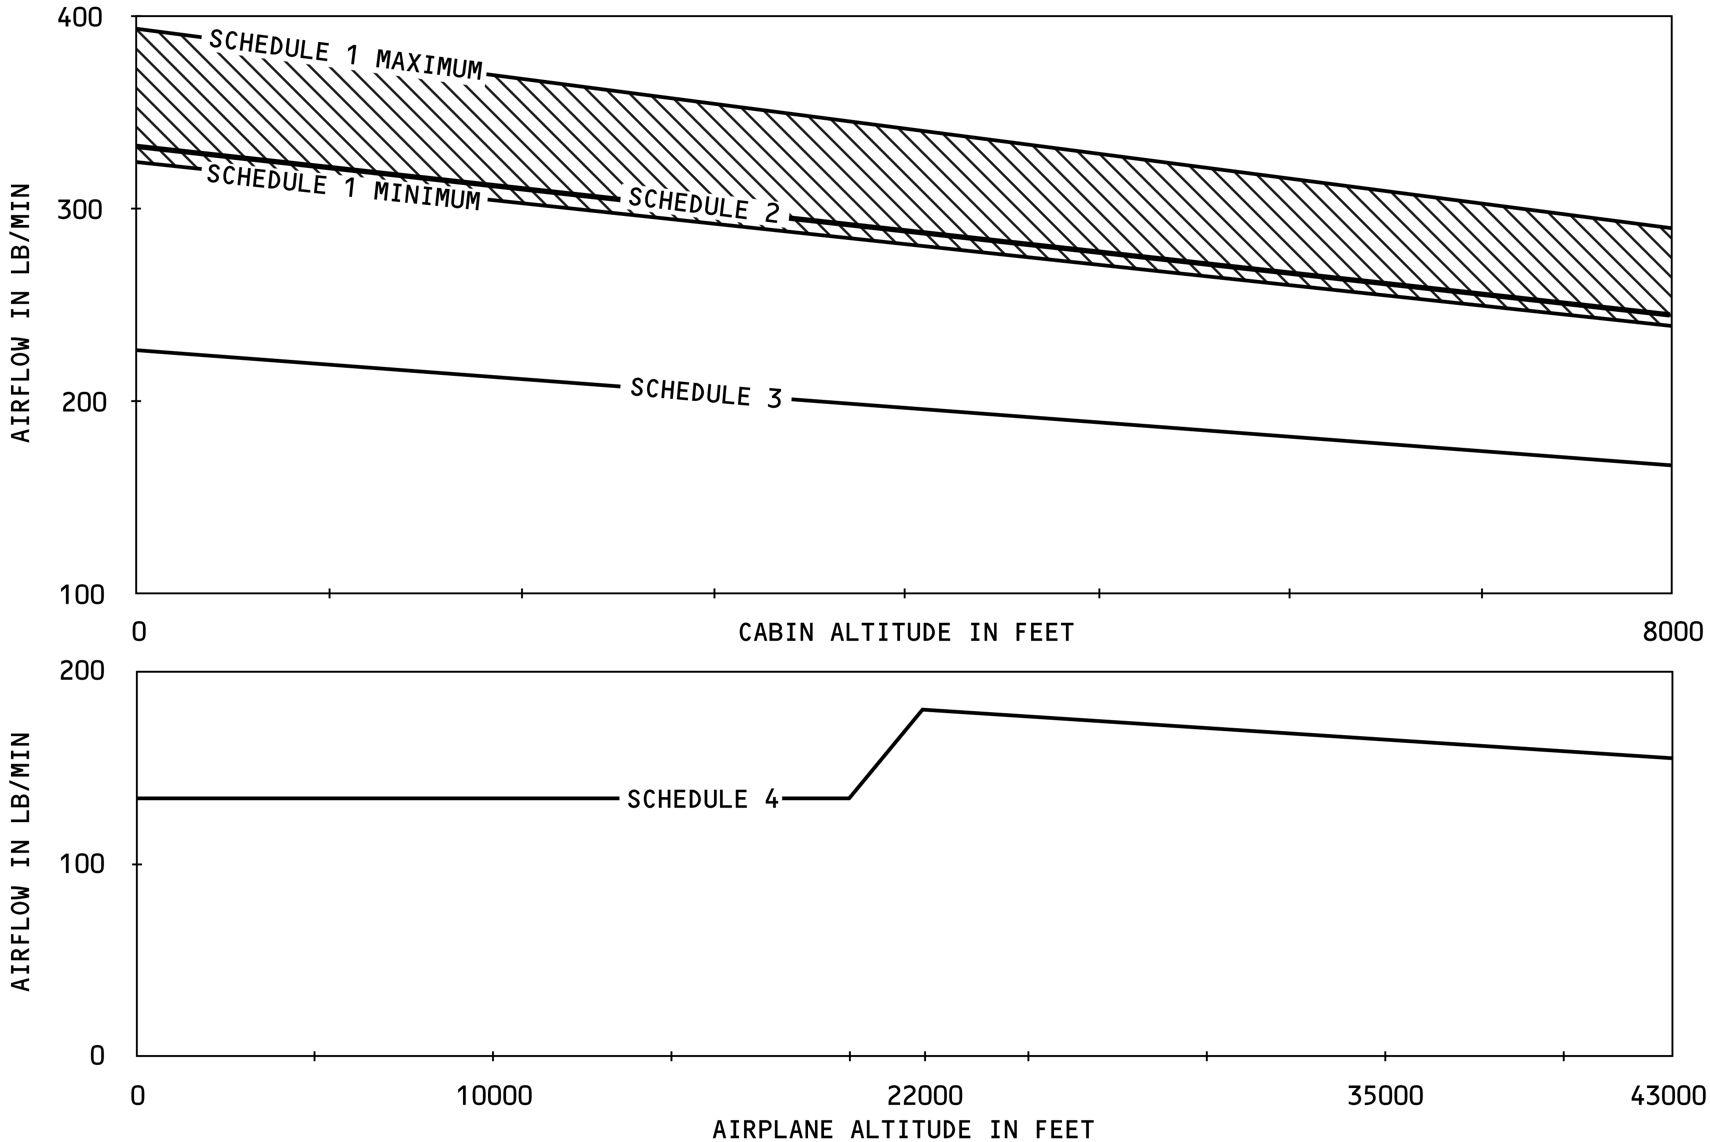
Flow schedule 2 is the same for all airplanes. However, when the ASCPC sets schedule 2, the actual flow rate is the schedule 2 or the schedule 1 rate, whichever is less.

Flow Schedule 3

Flow schedule 3 is the same for all airplanes. The flow rate is not related to the number of seats in the airplane.

Flow Schedule 4

Flow schedule 4 gives the minimum flow to pressurize the airplane and to operate the air cycle machine. The flow rate has a relation to the airplane altitude.



AIR CONDITIONING - PACK FLOW CONTROL - FUNCTIONAL DESCRIPTION - PACK FLOW SCHEDULES

AIR CONDITIONING - PACK FLOW CONTROL - FUNCTIONAL DESCRIPTION - ASCPC FLOW SCHEDULES

General

The ASCPC sets the flow schedules for the left and right CTCs. The left ASCPC is primary for this function, and the right ASCPC is the backup. The CTCs use the flow schedule data to calculate the amount of air to send to the packs.

The ASCPC has an ARINC 629 interface with other systems and LRUs. These interfaces give the ASCPC data about airplane operating conditions and about other bleed air users. The ASCPC uses these inputs to set the pack air flow schedules.

The ASCPC sends the selected flow schedules to the CTCs through the left and right ARINC 629 systems buses (not shown).

Flow Schedules

Flow schedule 1 gives the greatest airflow to the air conditioning packs and is the usual flow schedule.

Schedules 2, 3, and 4 give less and less air to the packs. In general, these schedules are in effect for one or more of these conditions:

- The amount of bleed air available is less than usual
- More than the usual number of bleed air user systems are on
- Takeoff or single engine operation.

When the APU supplies air to the pack, schedules 3 and 4 are not used. Also, if the forward or aft cargo fire switches are armed, schedules 3 and 4 are not used.

Schedule 0 stops the air flow into the packs. During an engine start on the ground, the packs shut off to make air available to the starter. The packs stay off for 2 minutes to allow time to start the two engines. For a stall warning during takeoff, schedule 0 makes sure the air driven hydraulic pumps get enough air for auto-slat deployment.

Training Information Point

If you start just one engine, the pack does not operate until two minutes after the start. The pack OFF light stays on during the two minutes.

2 C1 ADP FOR LEFT PACK FLOW SCHEDULE
C2 ADP FOR RIGHT PACK FLOW SCHEDULE

AIR CONDITIONING - PACK FLOW CONTROL - FUNCTIONAL DESCRIPTION - ASCPC FLOW SCHEDULES

THIS PAGE INTENTIONALLY LEFT BLANK

Upper/Lower Valve Selection

If the airplane altitude is low, the cabin temperature controllers (CTCs) use the upper flow control and shutoff valves to control air flow into the packs. These are the altitudes:

- Below 26,000 feet (7930 meters) on climb
- Below 24,000 feet (7315 meters) on descent.

If the airplane altitude is high, the CTC use the lower flow control and shutoff valves to control air flow into the packs. These are the altitudes:

- 26,000 feet (7930 meters) or above on climb
- 24,000 feet (7315 meters) or above on descent.

If one of the valves fails, the CTC controls the other valve at all altitudes.

Flow Regulation

The CTC calculates four flow rates. The flow schedule from the ASCPC tells the CTC which flow rate to use. The usual air flow rate for the left and right packs is the same. The flow rate of one pack can be 10 percent more or 10 percent less than the other pack.

If the right CTC decreases its pack flow rate to keep pack operation in limits, the right CTC sends a signal to the left CTC. The left CTC adds this R CTC flow bias signal to the flow rate for the left pack. The total is the flow command. A single pack has a flow command limit of 81% of the total flow into the airplane. See the pack cooling and mix manifold temperature control section for more information about the functional description of the packs (AMM PART I 21-52).

The CTC compares the flow command with the measured pack flow. The difference makes a drive signal for the flow control and shutoff valve. The valve moves until the measured pack flow equals the flow command.

Flow Rate Adjustments

If any recirculation fans are inoperative when the CTC uses schedule 1, the CTC increases the flow rate. The total flow into the airplane increases 67 lbs/min for each fan that is off, 33.5 lbs/min per pack. This keeps the total airplane ventilation rate constant.

If the forward or aft cargo fire switch is armed, the CTC sets the schedule 2 flow rate (except when schedule 0 is active). The ASCPC does not send schedules 3 or 4 if a cargo fire switch is armed. Schedule 2 supplies sufficient fresh air for the airplane occupants and keeps smoke out of the passenger compartment and flight deck.

The CTC closes the flow control and shutoff valve for these conditions:

- Flow schedule 0 from the ASCPC
- Pack outlet overheat
- Compressor discharge overheat
- Pack failure.

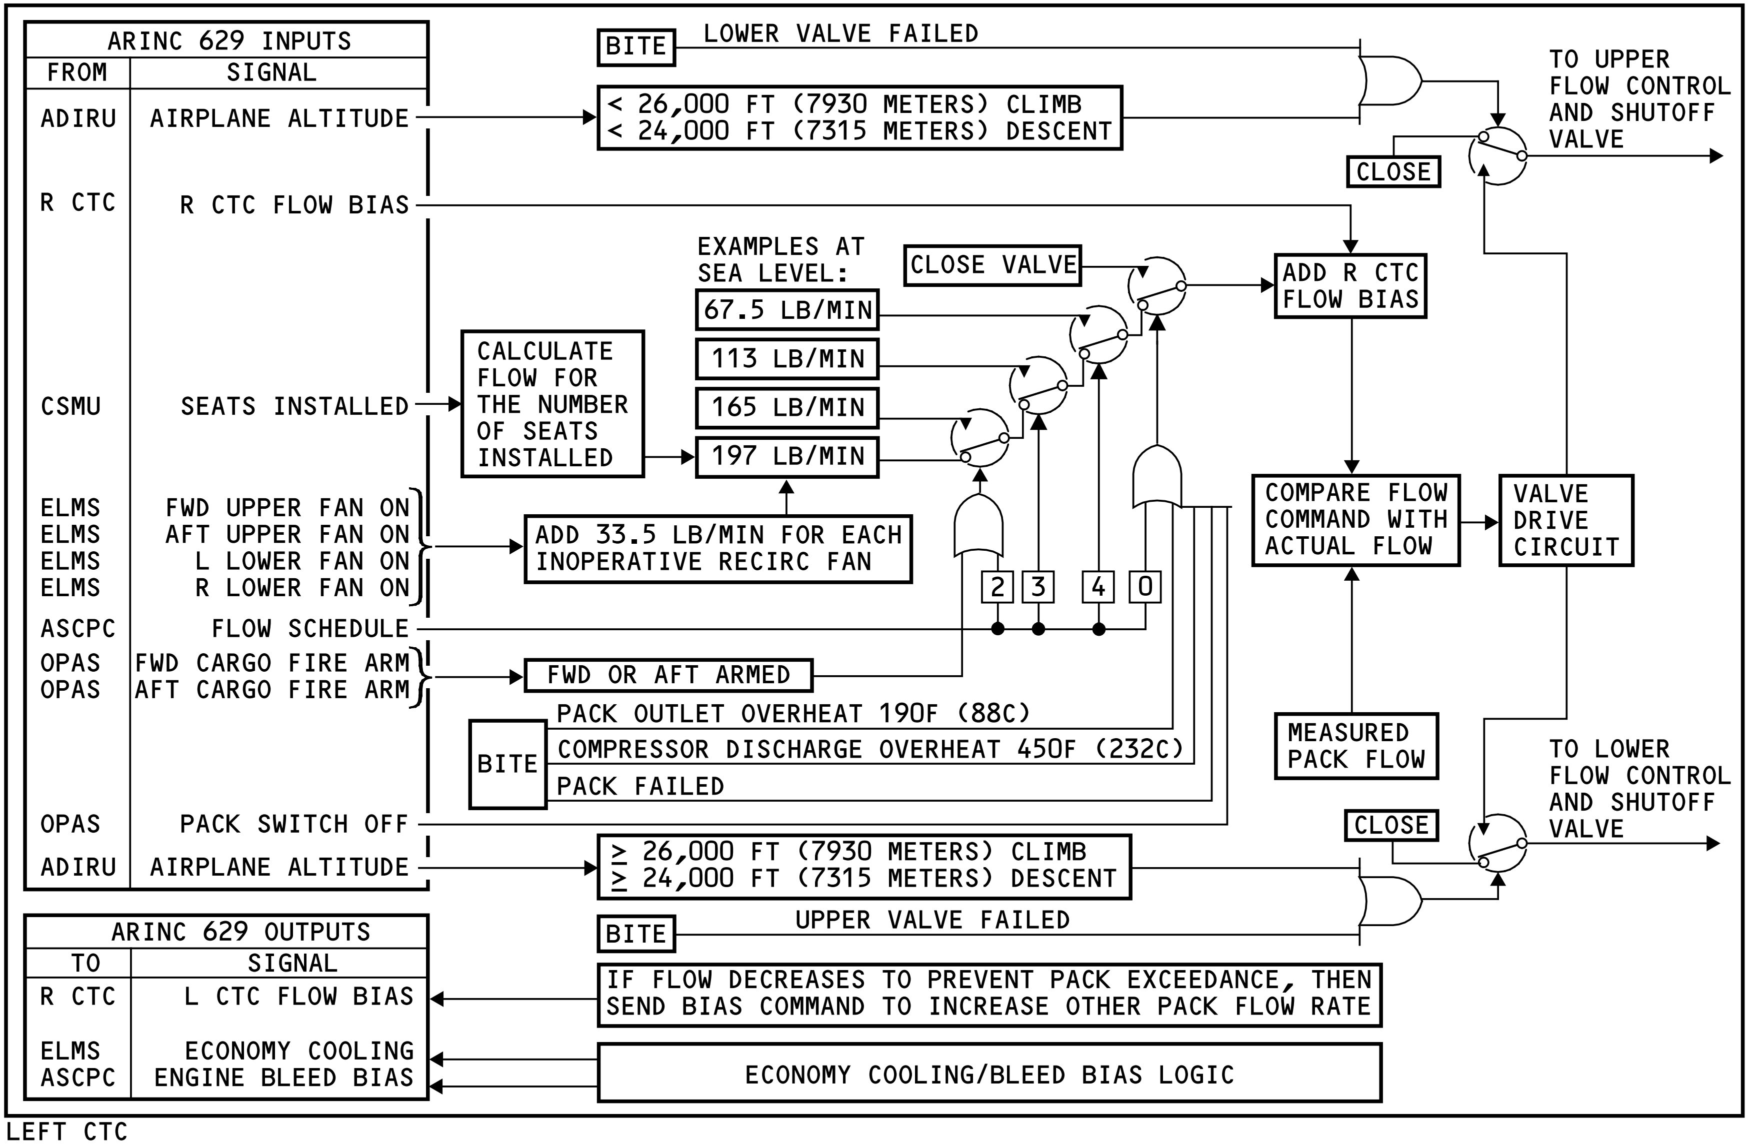
Other Flow Control Functions

At times, the air flow into the pack is not enough even with a flow control and shutoff valve full open. For some low flow conditions, the pack operates in economy cooling mode to help increase the air flow. An ARINC 629 input signal to the ELMS puts the pack into the economy cooling mode. See the pack cooling and mix manifold temperature control section for more information about the economy cooling mode (AMM PART I 21-52).

The CTC can also tell the ASCPC to adjust the engine bleed air supply system to help increase pack air flow. ARINC 629 signals tell the ASCPC to reduce the engine bleed air temperature or increase the HPSOV set point. See the engine air supply section for more information about the engine bleed bias (AMM PART I 21-52).

APU Demand

When the APU supplies the air for pack operation, the CTCs do not use the flow schedules from the ASCPCs. The CTCs set the flow control valve to fully open. The CTCs send an APU DEMAND signal to the APU controller (APUC) to tell it the amount of air necessary for the ventilation and the heating or the cooling of the airplane. See the zone temperature control and indication section for more information on APU DEMAND (AMM PART I 21-61).



21-51-00-010 Rev 4 03/07/1997

AIR CONDITIONING - PACK FLOW CONTROL - FUNCTIONAL DESCRIPTION - CTC FLOW CONTROL

AIR CONDITIONING - PACK FLOW CONTROL - FUNCTIONAL DESCRIPTION - START-UP AND SHUTDOWN

General

The flow control and shutoff valves open and close at specified rates. The rates are different for different conditions. When one valve starts to open, the OFF light in the pack switch goes out. When the two valves close, the OFF light comes on.

Pack Start-up

When you put the pack switch to AUTO, the flow control and shutoff valve opens. The valve opens at a rate that gives efficient air cycle machine acceleration. The air flow increases to 60 lb/min in 5 seconds, then increases to the schedule rate in 15 more seconds.

Normal Pack Shutdown On The Ground

When you put the pack switch to OFF, the flow control and shutoff valve closes. The valve closes at a rate that permits condensed water to evaporate from the pack.

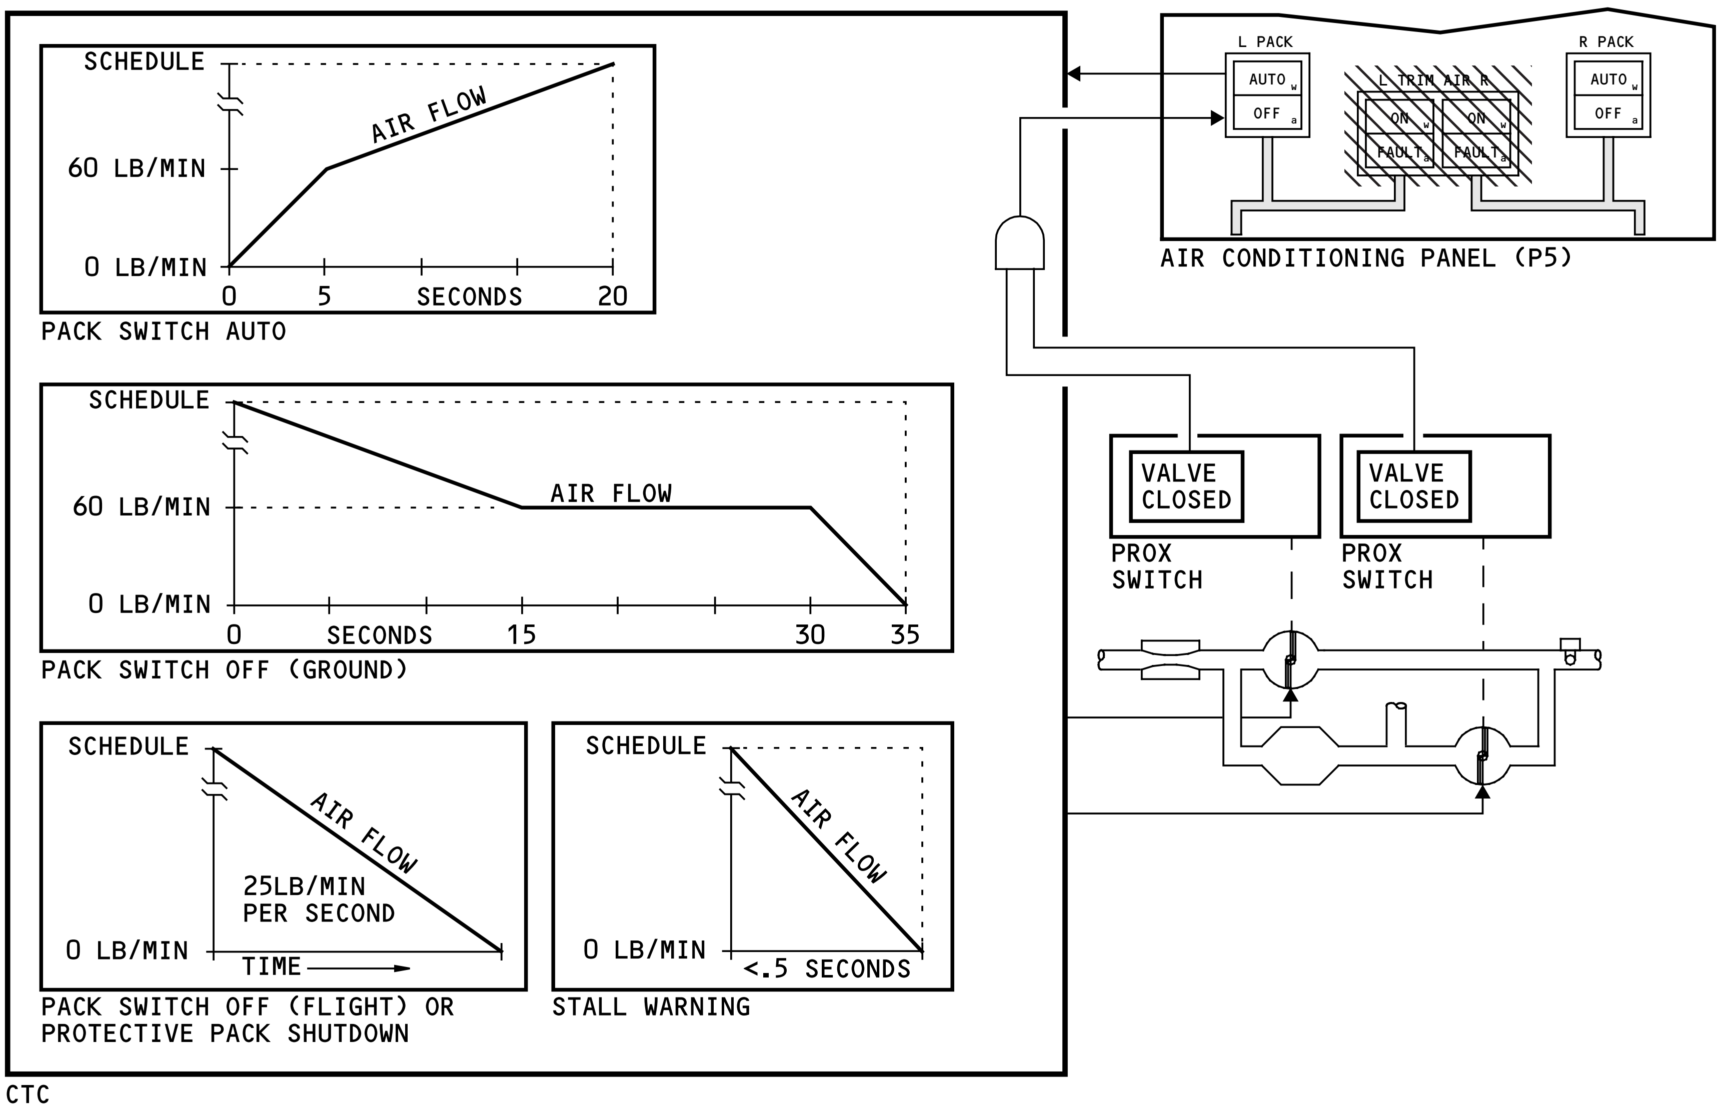
The air flow decreases to 60 lb/min in 15 seconds, stays at 60 lb/min for 15 seconds, then goes to 0 in 5 seconds. This sequence lets the pack temperature increase. Water condensation stops, and any water left in the pack evaporates.

Pack Shutdown In Flight Or Protective Pack Shutdown

If you put the pack switch OFF in flight, the flow control and shutoff valve closes slowly. The pack air flow decreases by 25 lb/min per second as the valve closes. The valve closes at this same rate for a protective pack shutdown from an overheat condition or a pack failure.

Stall Warning

The valve closes quickly for a stall warning condition. Air flow goes to 0 in less than 1/2 second



21-51-00-012 Rev 1 07/18/1997

AIR CONDITIONING - PACK FLOW CONTROL - FUNCTIONAL DESCRIPTION - START-UP AND SHUTDOWN

AIR CONDITIONING - PACK FLOW CONTROL - FUNCTIONAL DESCRIPTION - ASCPC FLOW CONTROL

General

The ASCPC is a backup to the CTC for these functions:

- Backup pack flow control
- Pack shutdown.

Backup Pack Flow Control

The CTC gives a CTC status signal to the ASCPC. If the status signal is not valid or if the CTC fails, the ASCPC gives backup flow control. The upper flow control valve closes and the lower valve controls air flow into the pack.

The ASCPC keeps the flow rate at 150 pounds per minute as long as the pack outlet temperature is more than 40F (4C). If the pack outlet temperature is low, the ASCPC increases the flow to 200 pounds per minute. After 30 seconds, if the temperature is still low, the ASCPC increases the flow to 250 pounds per minute.

If the pack outlet temperature becomes more than 110F (43C), the ASCPC decreases the flow rate in a similar way.

Pack Shutdown

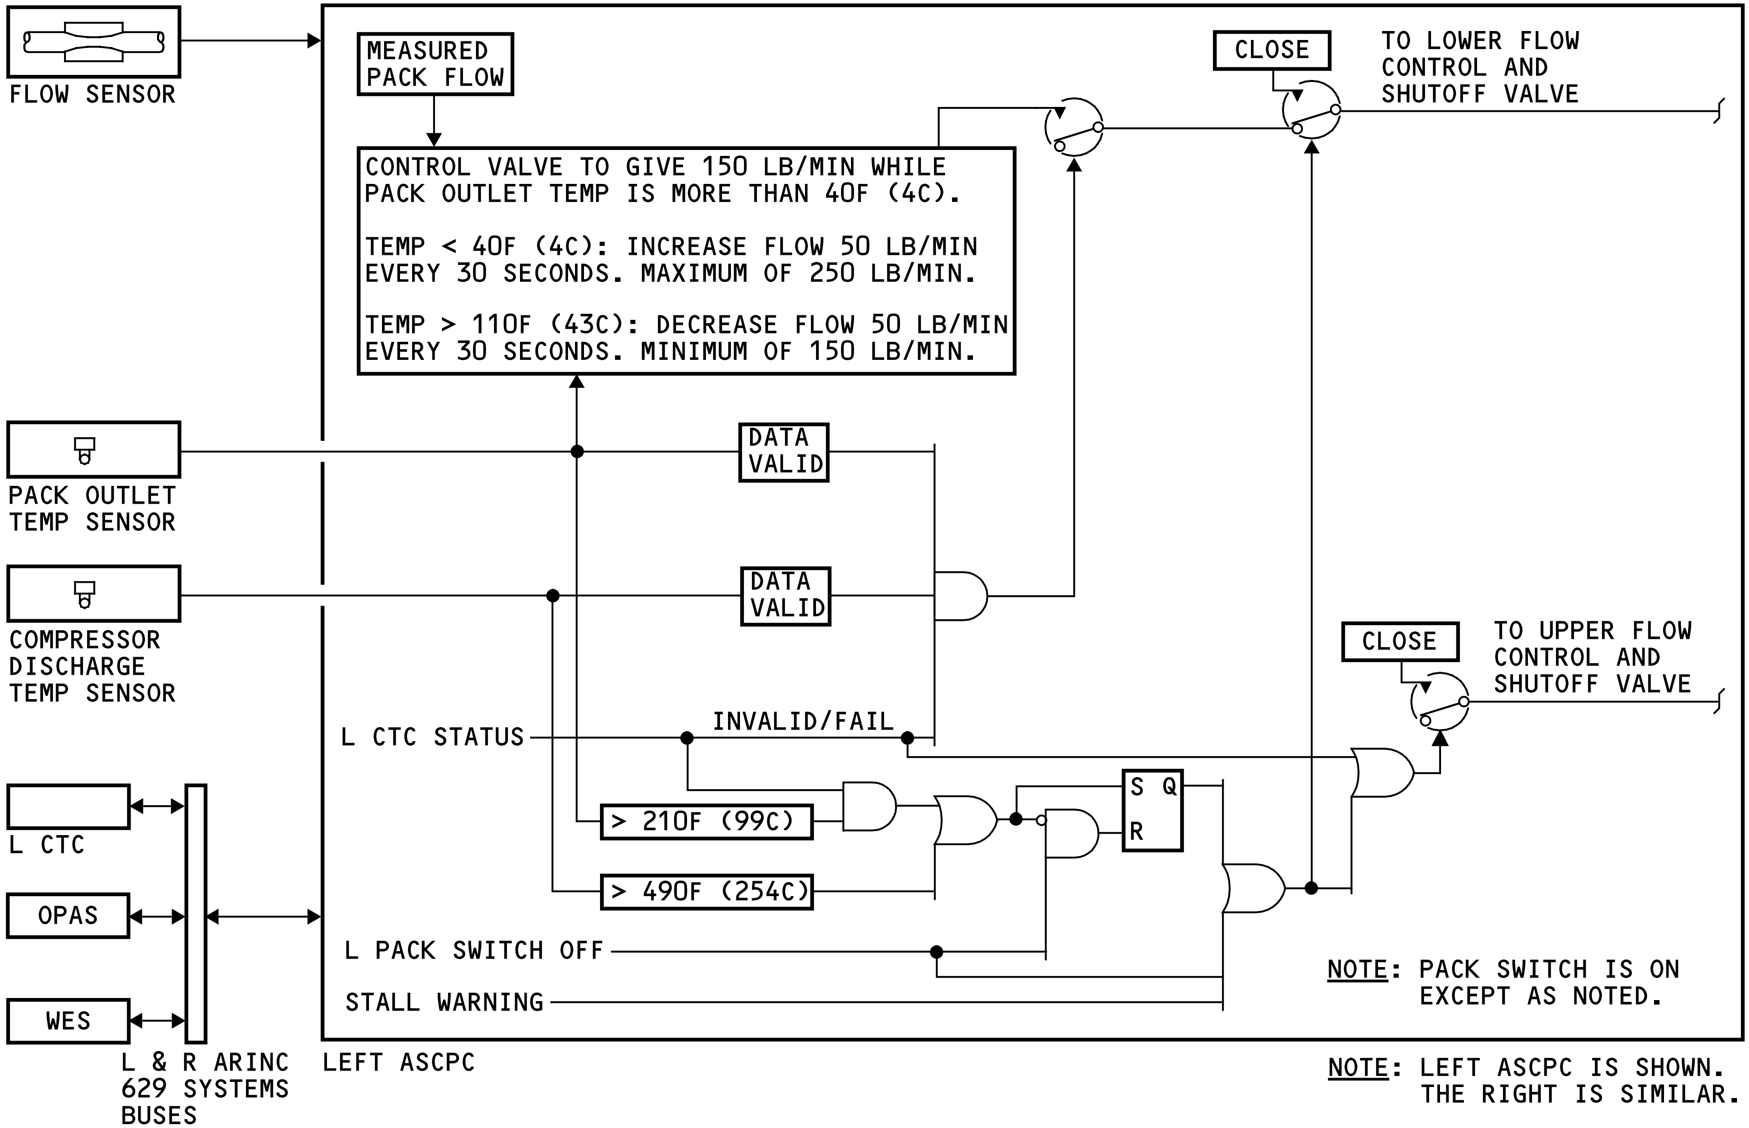
The backup flow control mode must have valid data from the pack outlet temperature sensor and the compressor discharge temperature sensor. If the temperature data is not valid, the ASCPC closes the flow control and shutoff valves.

The ASCPC also closes the flow control and shutoff valves for these conditions:

- Pack outlet overheat with CTC status invalid or failed
- Compressor discharge overheat
- Pack switch OFF
- Stall warning.

For all conditions except the first, the ASCPC pack shutdown function is redundant with the CTC shutdown function.

The overheat shutdown function resets when you put the pack switch OFF then ON, if the overheat condition no longer exists.



21-51-00-011 Rev 1 04/27/95

AIR CONDITIONING - PACK FLOW CONTROL - FUNCTIONAL DESCRIPTION - ASCPC FLOW CONTROL

AIR CONDITIONING - OZONE CONTROL

Purpose

Ozone control keeps ozone concentrations in the air flow to a satisfactory limit when the airplane is at higher altitudes.

Physical Description

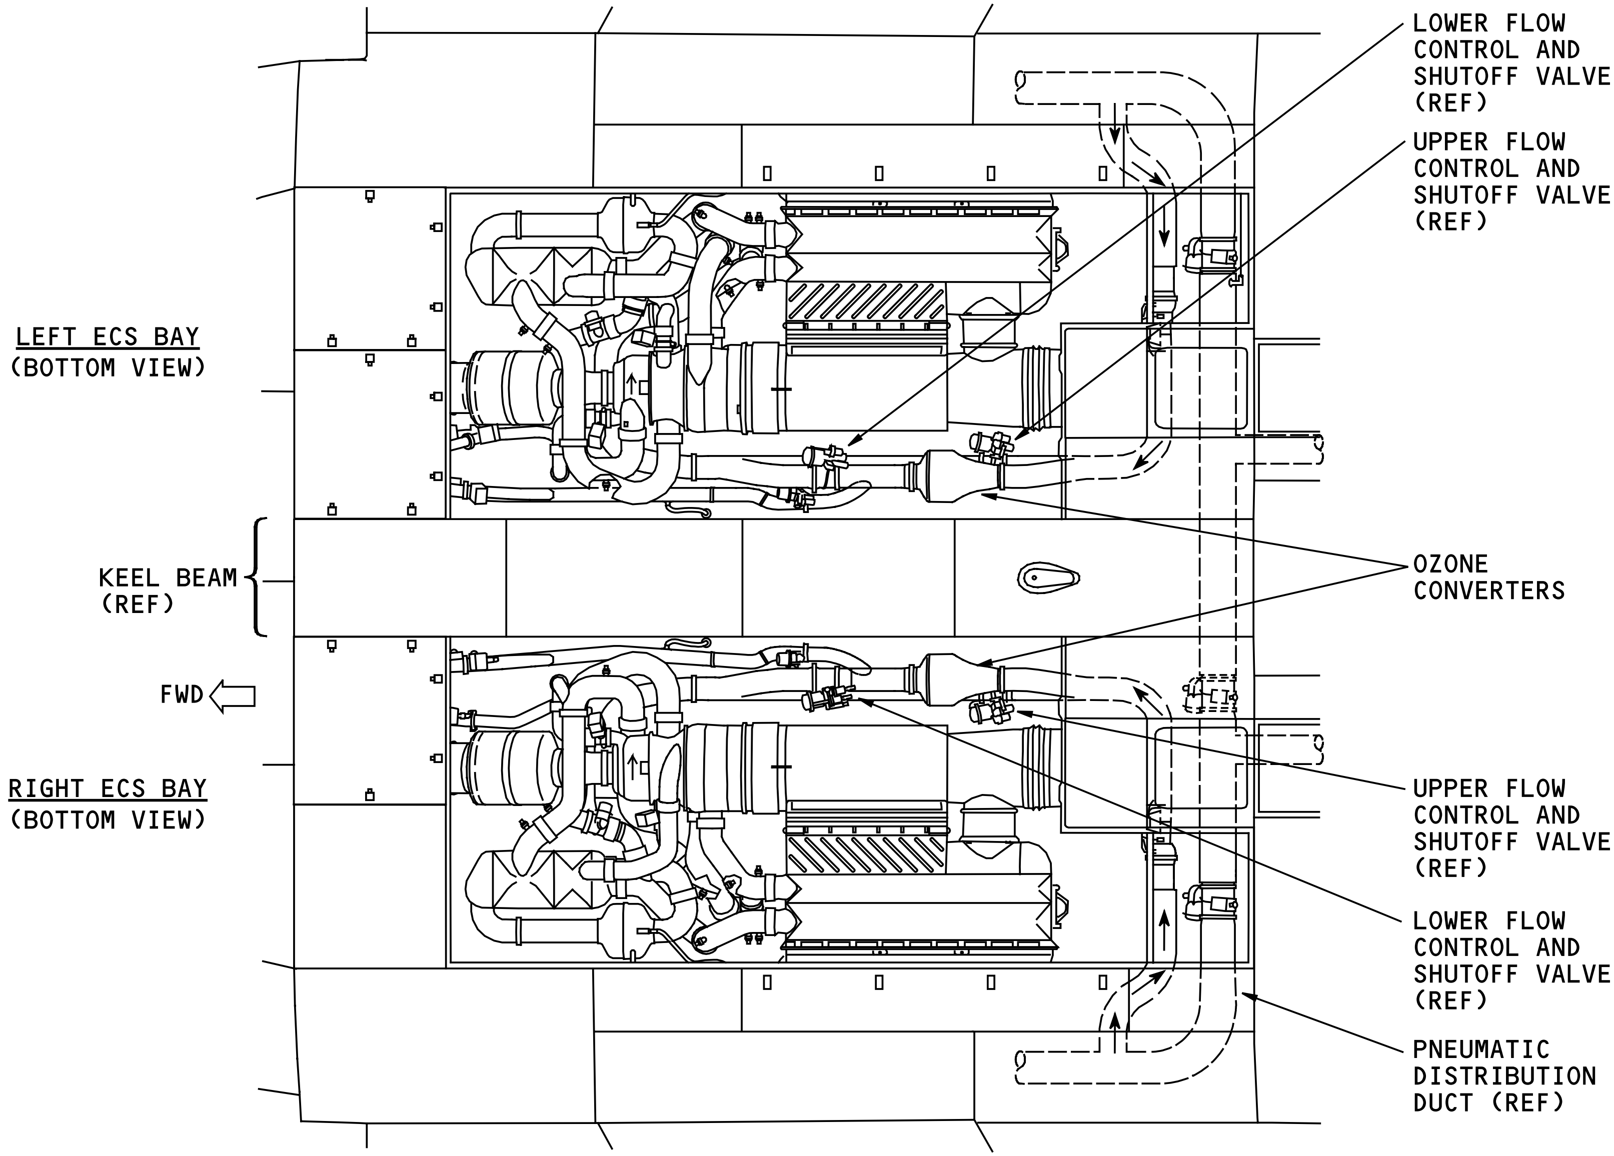
The ozone converter has no moving parts. It contains a catalytic material through which the air flows.

Location

An ozone converter is part of each pack in the ECS bay. It attaches to the lower air ducts that supply each pack. The converter is aft of the lower flow control valve and below the upper flow control valve.

Functional Description

The ozone converter is a catalytic device that removes ozone concentrations. Air goes through the converter before it flows into the pack. A chemical reaction in the converter changes ozone molecules to oxygen molecules.



AIR CONDITIONING - OZONE CONTROL

AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - INTRODUCTION

Purpose

Pack cooling and mix manifold temperature control operates the pack to control pack discharge air temperature to a value that supplies sufficient cooling air to the flight deck and the mix manifold.

General Description

The air conditioning (A/C) pack has components that give these functions:

- Ram air and heat exchanger cooling
- Air cycle machine cooling
- Water removal.

Air from the flow control system usually flows through the pack in this sequence:

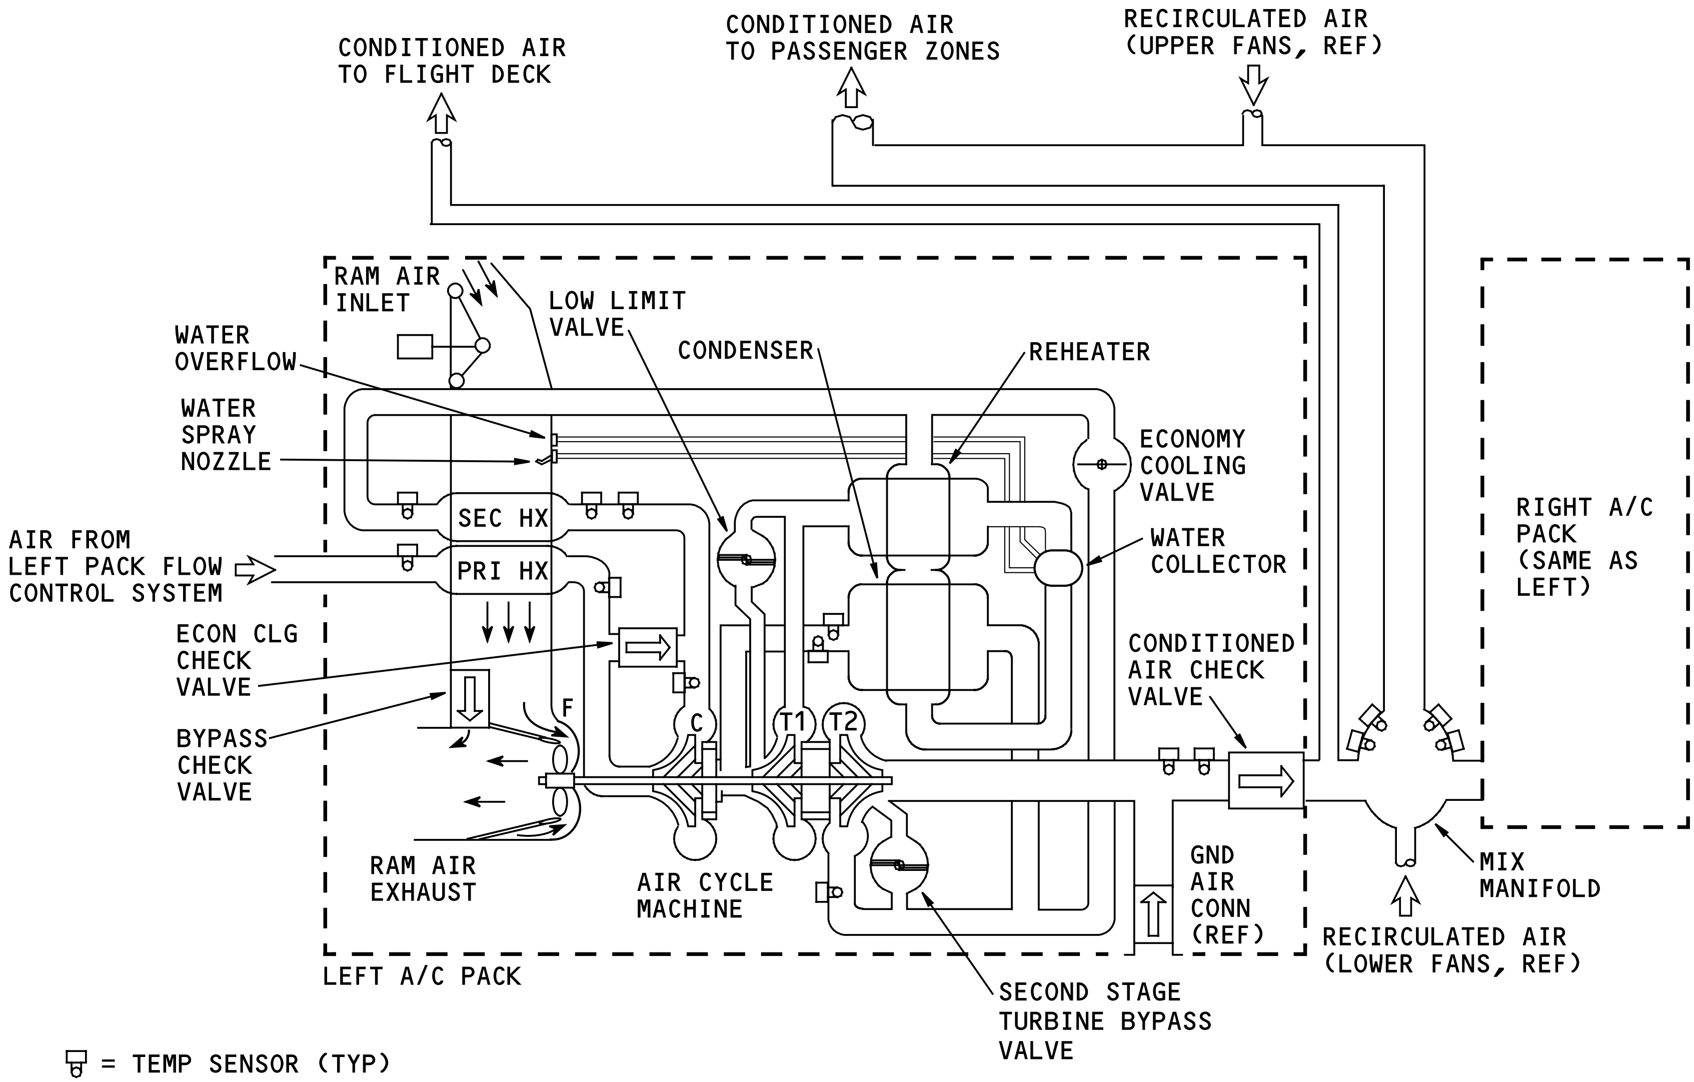
- Primary heat exchanger (PRI HX)
- Air cycle machine (ACM) compressor
- Secondary heat exchanger (SEC HX)
- Over the reheater and condenser cores
- Water collector
- Reheater
- ACM turbine 1
- Condenser
- ACM turbine 2
- Conditioned air check valve
- Mix manifold.

Air from the pack mixes with recirculated air in the mix manifold. This air moves through the distribution system to the passenger cabin zones. The flight deck gets air directly from the left pack.

The ram air part of the pack keeps the compressor outlet temperature in limits. It also gives pack outlet temperature control.

The right pack operates the same as the left pack.

See the functional description page on pack cooling and mix manifold temperature control in this section for more information about pack operation (AMM PART I 21-52).



21-52-00-001 Rev 5 02/27/1997

AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - INTRODUCTION

Component Locations

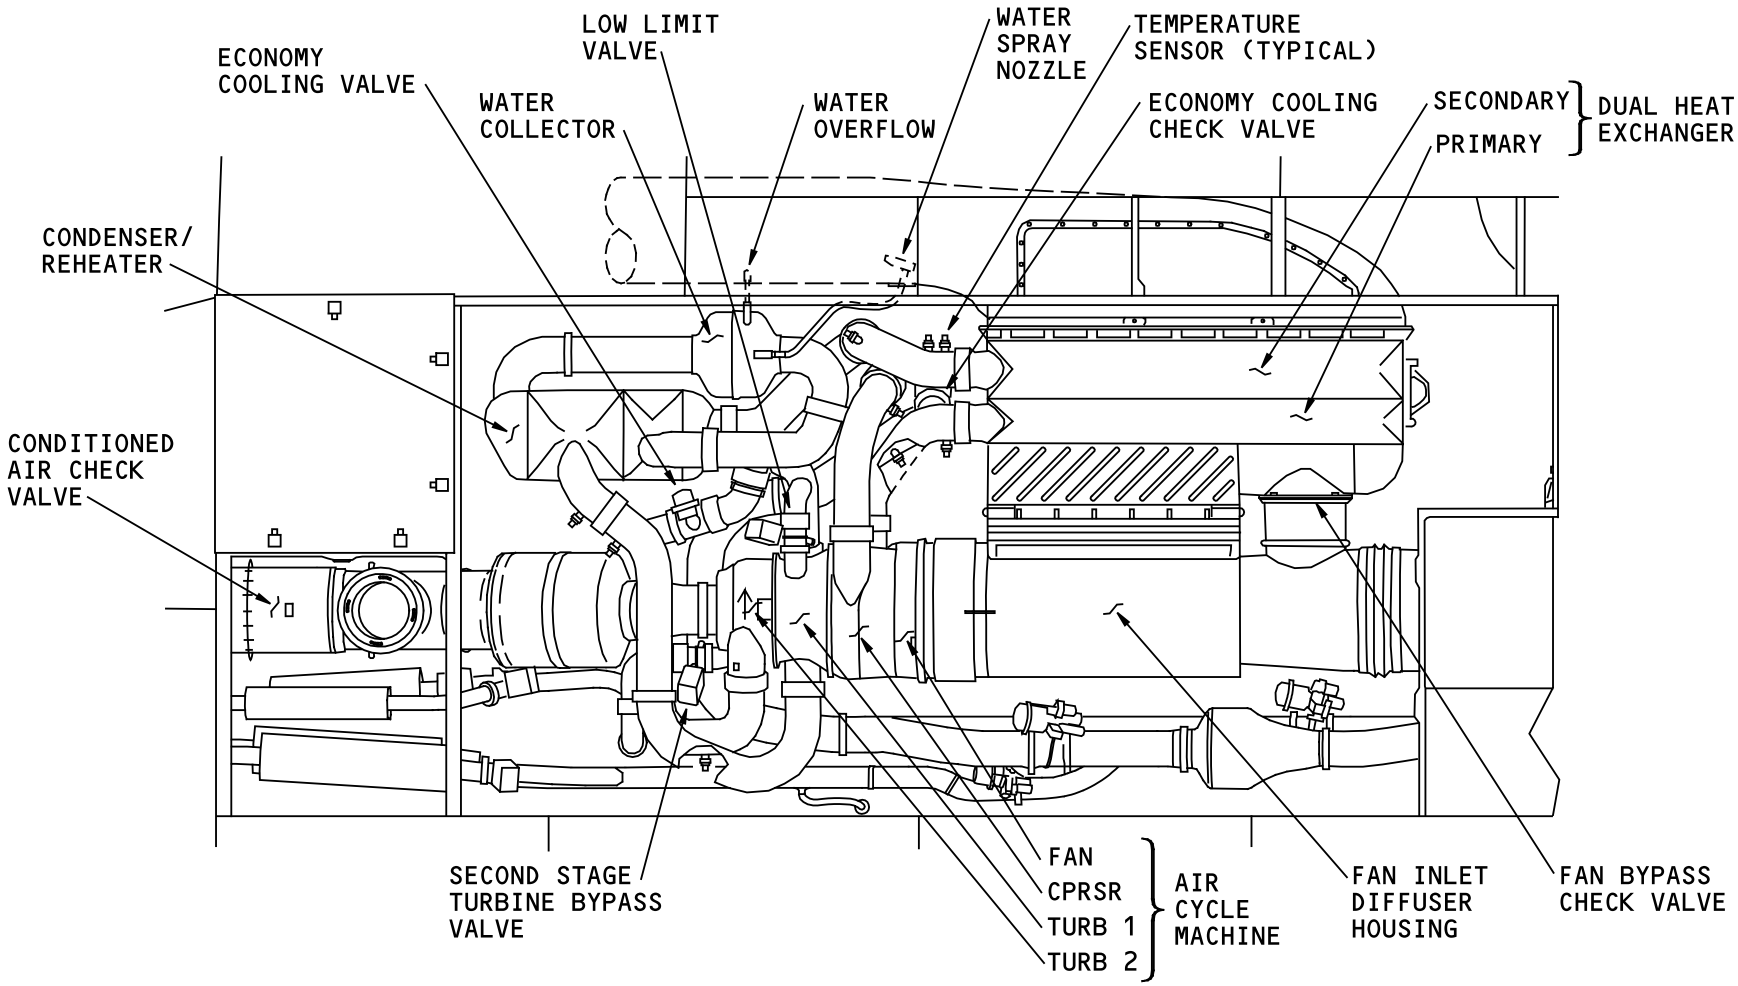
Most of the pack cooling and mix manifold temperature control components are in the ECS bay. Four mix manifold temperature sensors are in the aft part of the forward cargo compartment (not shown). The left and right ECS bays have a pack, a conditioned air check valve, and ram air system components (not shown).

The ram air system component locations are described in another part of this section.

Each pack has these components:

- Economy cooling valve
- Water collector
- Low limit valve
- Water overflow
- Water spray nozzle
- Temperature sensors (10 places)
- Economy cooling check valve
- Dual heat exchanger
- Fan bypass check valve
- Fan inlet and diffuser housing
- Air cycle machine (ACM)
- Second stage turbine bypass valve
- Condenser/reheater.

All of the components in the left and right packs are the same except for five of the ducts that connect the pack components together. The orientation of the components in one pack is a mirror image of the other. The airflow is also a mirror image. The difference in the ducts lets the inlets to the dual heat exchangers always be on the top and the outlets on the bottom.



LEFT ECS BAY

AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - COMPONENT LOCATIONS

Component Locations

All of the ram air components of the left and right air conditioning packs are in the underwing fuselage area. Each pack has these ram air components:

- Ram air inlet door (two sections)
- Ram air inlet door actuator (not shown)
- Ram air inlet duct
- Ram air inlet duct clean out panel
- Fan bypass check valve
- Fan inlet and diffuser housing
- Fan section of the ACM
- Ram air exhaust housing.

AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - RAM AIR - COMPONENT LOCATIONS

AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - DUAL HEAT EXCHANGER

Purpose

The dual heat exchanger removes heat from pneumatic system air and from air compressed by the air cycle machine.

Physical Description

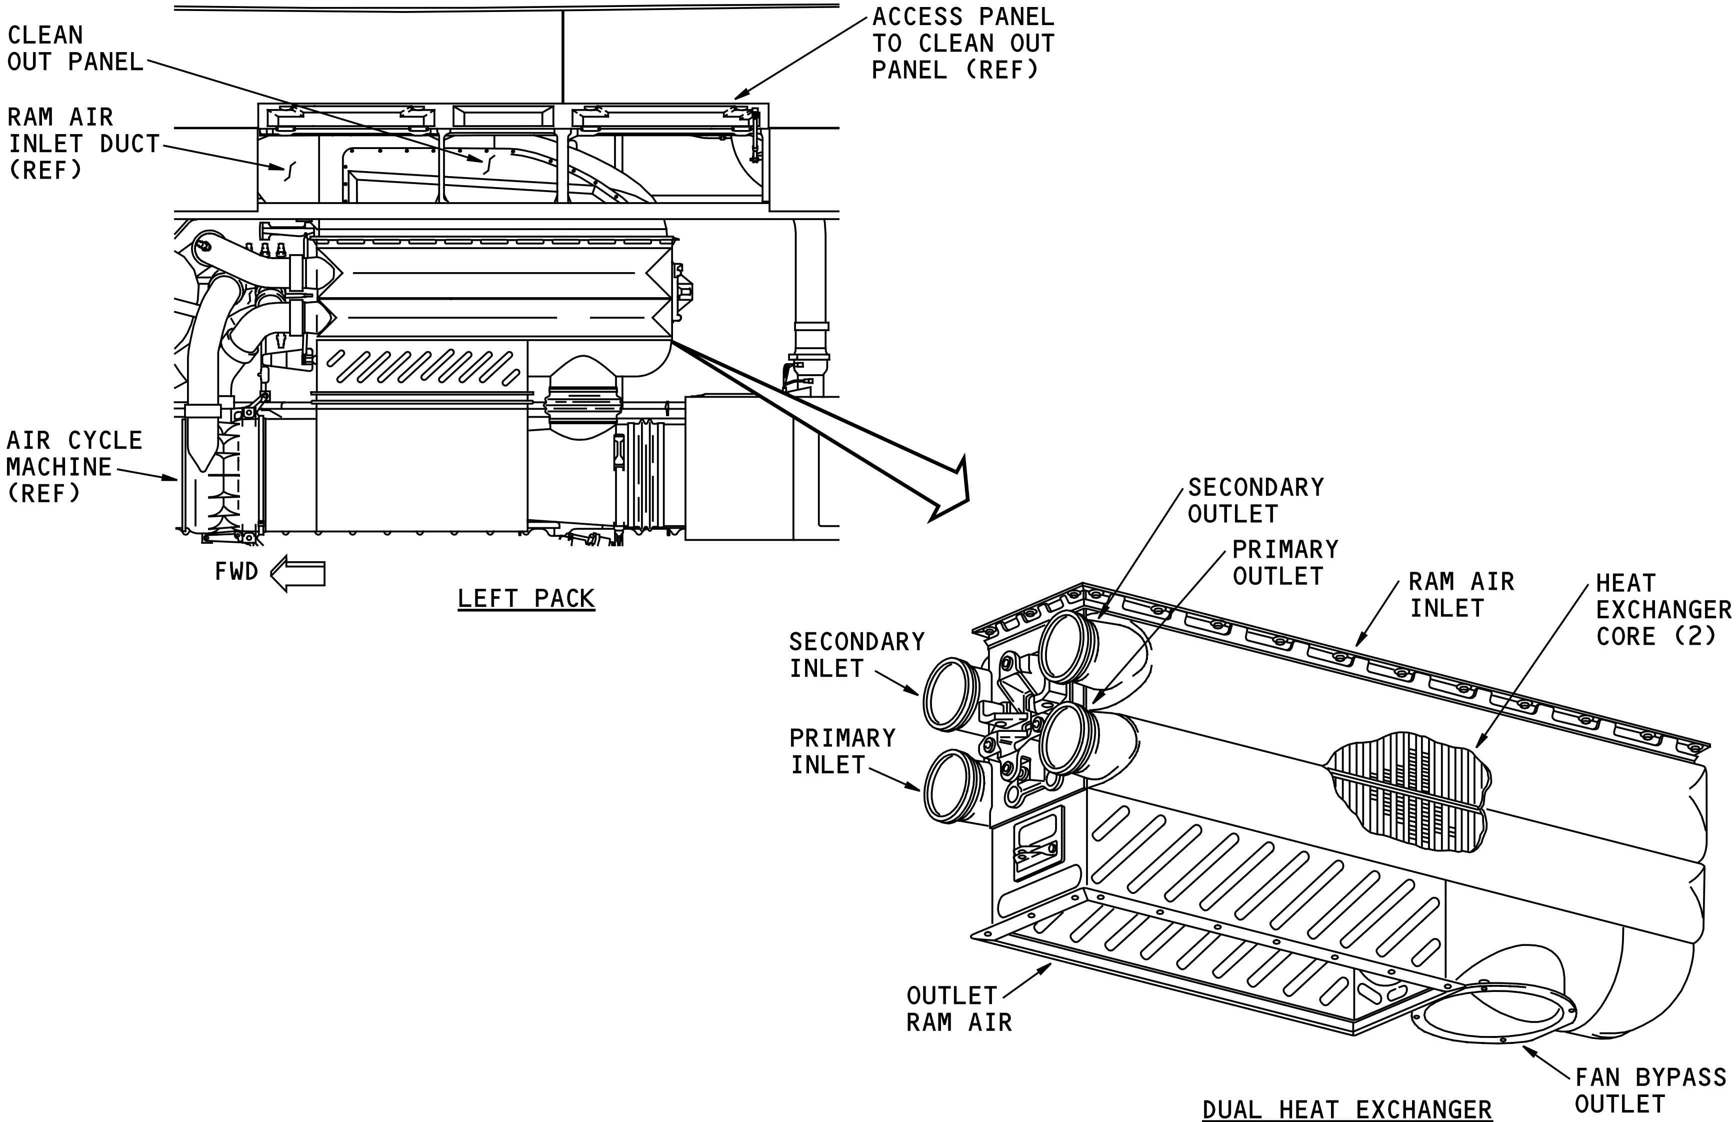
The dual heat exchanger has a primary and secondary heat exchanger core. There are inlets and outlets for the pneumatic system air and the ram air.

You remove and install the dual heat exchanger as a single unit. It weights 194 Lb (88 Kg).

The heat exchanger for the left pack and the right pack are identical. The orientation of the heat exchanger in one pack is a mirror image of the other. The airflow is also a mirror image. The pneumatic system air inlets are always on the top and the outlets are on the bottom. The ram air always flows from outboard to inboard.

Training Information Point

A panel outboard of each ECS access door gives access to the heat exchanger cleanout panels. Use high pressure water or air to loosen dirt.



AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - DUAL HEAT EXCHANGER

AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - AIR CYCLE MACHINE

Purpose

The air cycle machine (ACM) compresses air in the compressor stage and expands air in the two turbine stages.

Physical Description

The air cycle machine has one compressor stage and two isolated turbine stages. These stages turn on the same shaft. A fan in the ram air flow also connects to this shaft.

Air bearings hold the shaft of the air cycle machine in position when the shaft turns.

Functional Description

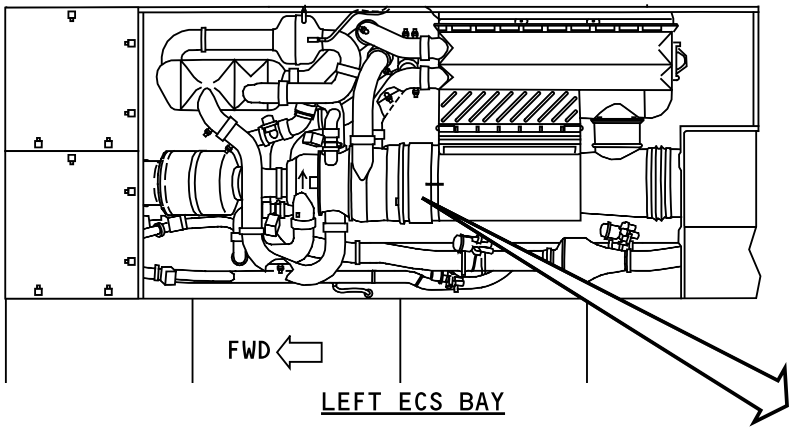
The compressor compresses the air from the primary heat exchanger. The compressed air flows out to other pack components.

Each turbine receives air from different points in the pack. The air expands and decreases in temperature as it goes through the turbine. The energy released in the turbines turns the shaft of the air cycle machine.

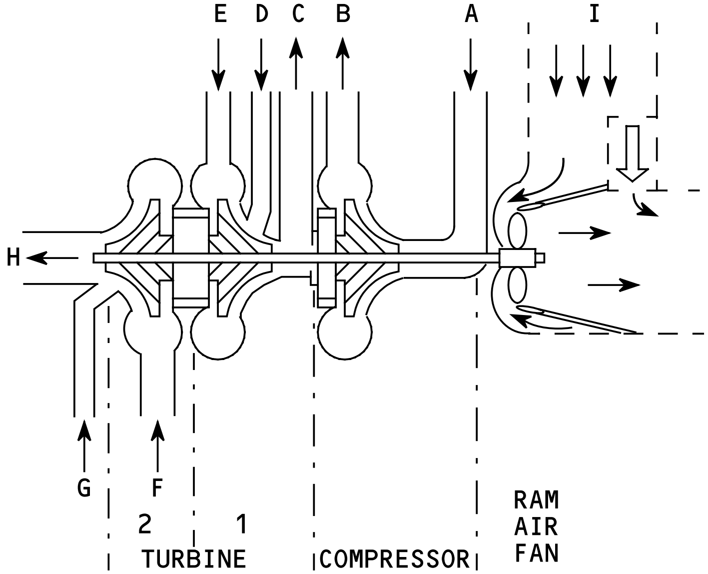
The ram air fan moves ambient air through the ram air ducts when the airplane is on the ground.

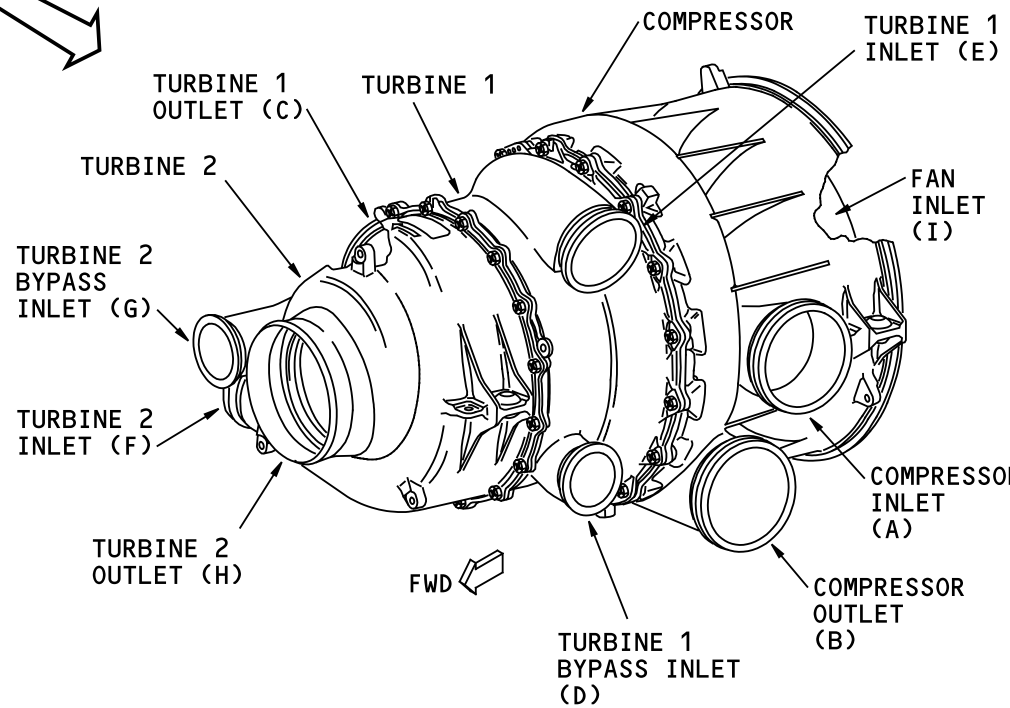
Training Information Point

There is a direction arrow near a placard on the ACM that shows the direction to rotate the ACM before you do a torque check. Damage can occur if you manually turn the ACM in the incorrect direction. The placard has the maximum allowable torque.



LEFT ECS BAY





AIR CYCLE MACHINE

21-52-00-005 Rev 2 03/23/95

AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - AIR CYCLE MACHINE

Purpose

The condenser/reheater has two functions. It cools the air in the pack before it goes through the water collector. This lets the moisture in the air collect in the water collector. The condenser/reheater heats pack air to add energy to the air. The heated air helps operate the turbine in the air cycle machine.

Physical Description

The condenser/reheater has condenser and reheater heat exchanger cores. These cores are within a container through which pack air flows. The condenser/reheater weighs approximately 70 lb (32kg).

Functional Description

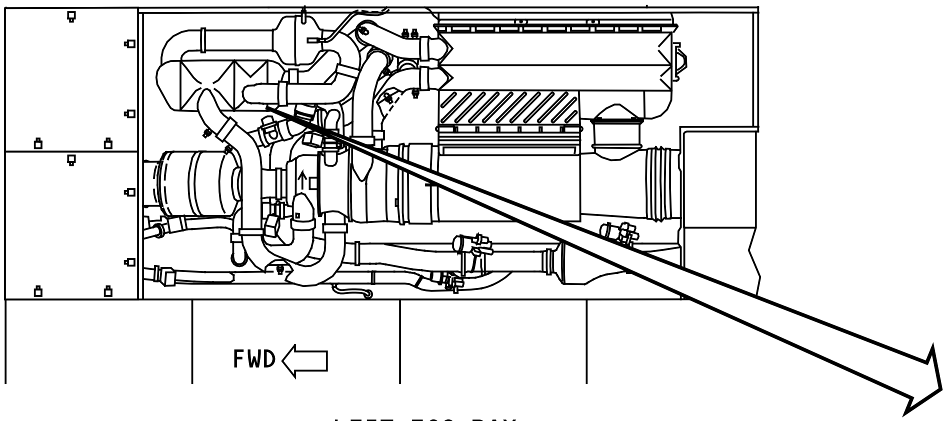
Air comes into the condenser/reheater from the secondary heat exchanger at A. This air flows over both heat exchanger cores. The heat exchangers absorb heat from this air. The decrease in air temperature condenses water so that the water collector can remove it from the air. The air flows out of the condenser/reheater at B.

The air from the water collector goes into the reheater at C. This air absorbs heat from the air that flows over the reheater core. The air flows out of the reheater at D.

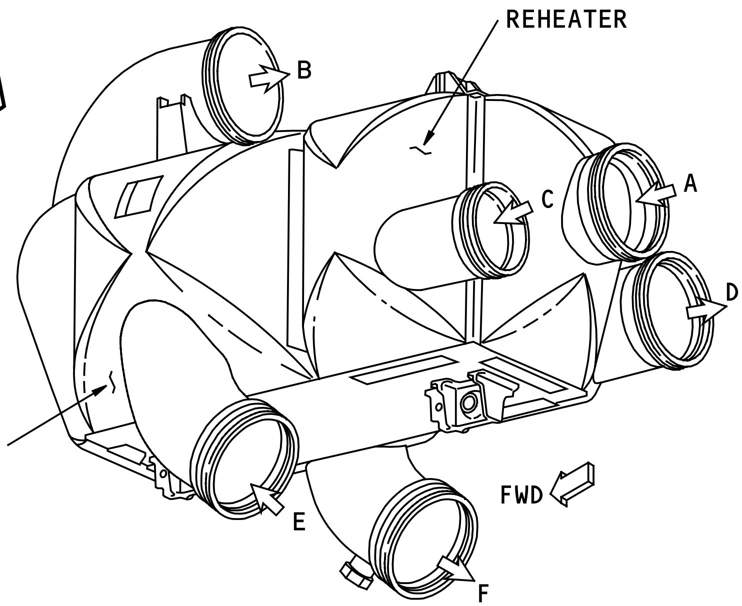
The air from turbine 1 goes into the condenser at E. This air absorbs heat from the air that flows over the condenser core. The air flows out of the condenser at F.

Training Information Point

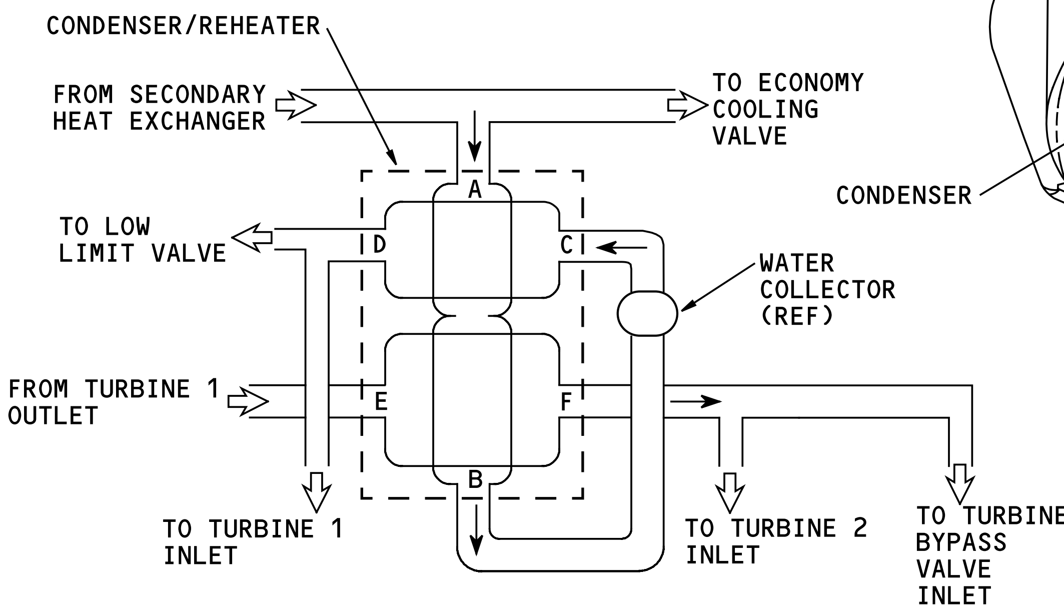
Remove and install the condenser/reheater with the water collector as an assembly. This balances the condenser/reheater weight on the hoist adapter.



LEFT ECS BAY



CONDENSER/REHEATER



AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - CONDENSER/REHEATER

AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - WATER COLLECTOR AND SPRAY NOZZLE

Purpose

The water collector removes water from pack air. The spray nozzle sprays the water into the air in the ram air inlet duct. The overflow lets water dump directly into the ram air inlet duct if the water collector has too much water in it.

Physical Description

The water collector is a device with no movable parts. Internal vanes are set to push air into a circular flow.

The spray nozzle has no moving parts. The nozzle has these parts:

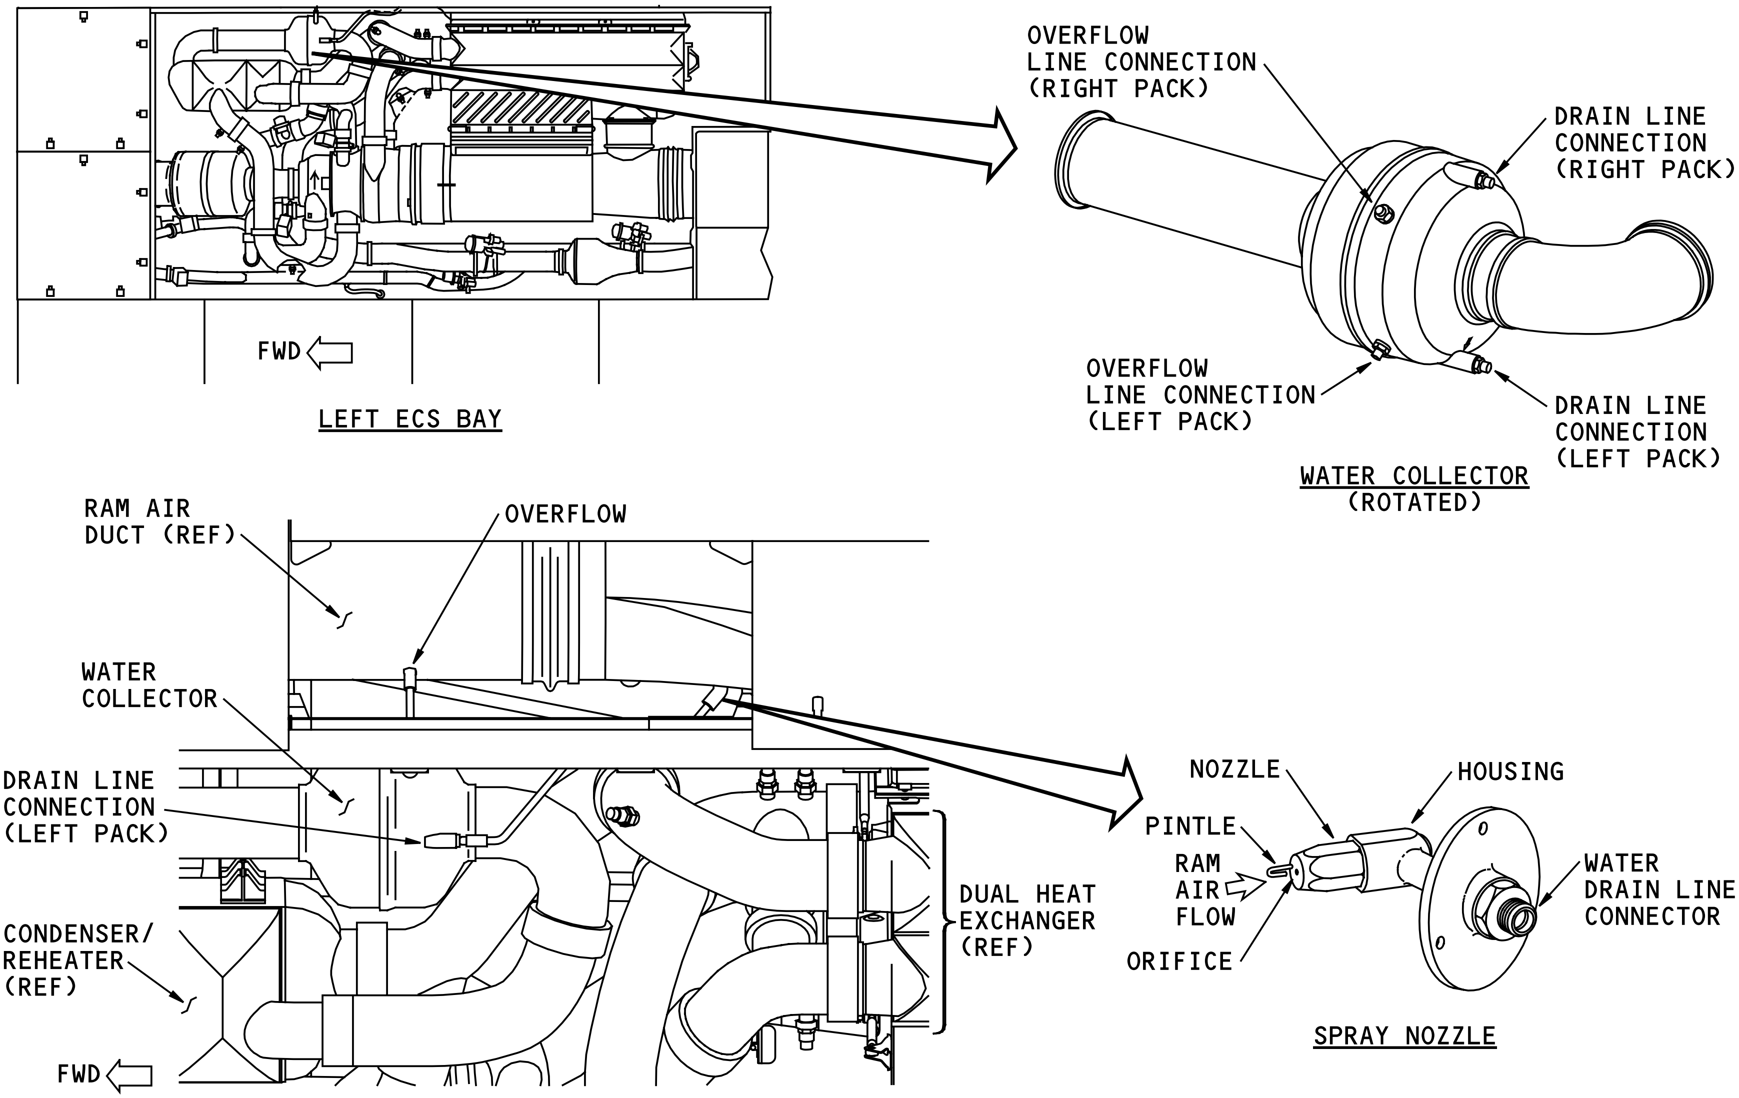
- Pintle
- Nozzle
- Housing
- Water drain line connector.

Location

A water collector and spray nozzle are outboard of the condenser/reheater in each ECS bay.

Functional Description

Air in the water collector turns in a circular flow. This pushes condensed water out of the air. A collector removes the water. Air pressure sends the water to the spray nozzle. The nozzle sprays the water in the incoming ram air near the secondary heat exchanger. The water added to the ram air inlet duct increases the heat removal by the secondary heat exchanger.



21-52-00-007 Rev 2 03/23/95

AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - WATER COLLECTOR AND SPRAY NOZZLE

Purpose

The low limit valve controls the amount of reheater air that goes around the first stage turbine of the ACM. The CTC uses this valve to limit the output air temperature of the first stage turbine above 34F (1C) so water in the air does not freeze.

The second stage turbine bypass valve controls the amount of condenser air that goes around the second stage turbine of the ACM. The CTC uses turbine bypass valve to control pack outlet temperature.

These valves function together with the ram air doors to control the output temperature of the pack.

Physical Description

The valve has these parts:

- Position indicator
- Disc
- Valve body
- Manual open/close knob
- Electrical actuator
- Electrical connector (not shown).

The low limit valve and the second stage turbine bypass valve are the same. Each uses a disc which rotates to adjust air flow. The disc is driven by a motor that can be turned in both directions. The motor uses 115v ac to operate the valve.

An RVDT gives an electrical indication of the disc position. An indicator on top of the electrical actuator gives a visual indication of disc position.

Functional Description

The CTC controls the operation of the low limit valve and the second stage turbine bypass valve. Both valves operate the same. A close or open signal from the CTC turns the motor in the necessary direction.

The RVDT in each valve sends the position of the valve to the CTC. The CTC use the position information for control and valve position indication.

Training Information Point

Manually open or shut the valve with the manual open/shut knob. You must disconnect the electrical connector first. The valve will move to the commanded position when the valve gets power if you do not remove the electrical connector.

AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - LOW LIMIT AND TURBINE BYPASS VLVS

AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - ECONOMY COOLING VALVE

General

The economy cooling valve opens to let air go around the air cycle machine turbine 1 and the water separation parts of the pack. The valve opens when the pack functions in the economy cooling mode or the standby cooling mode. See the functional description of the packs in this section for more information about these modes.

Physical Description

The economy cooling valve has these parts:

- Locking crank/position indicator
- Pneumatic actuator
- Locking plug
- Plug and filter
- Solenoid
- Electrical connector
- Valve body
- Disc.

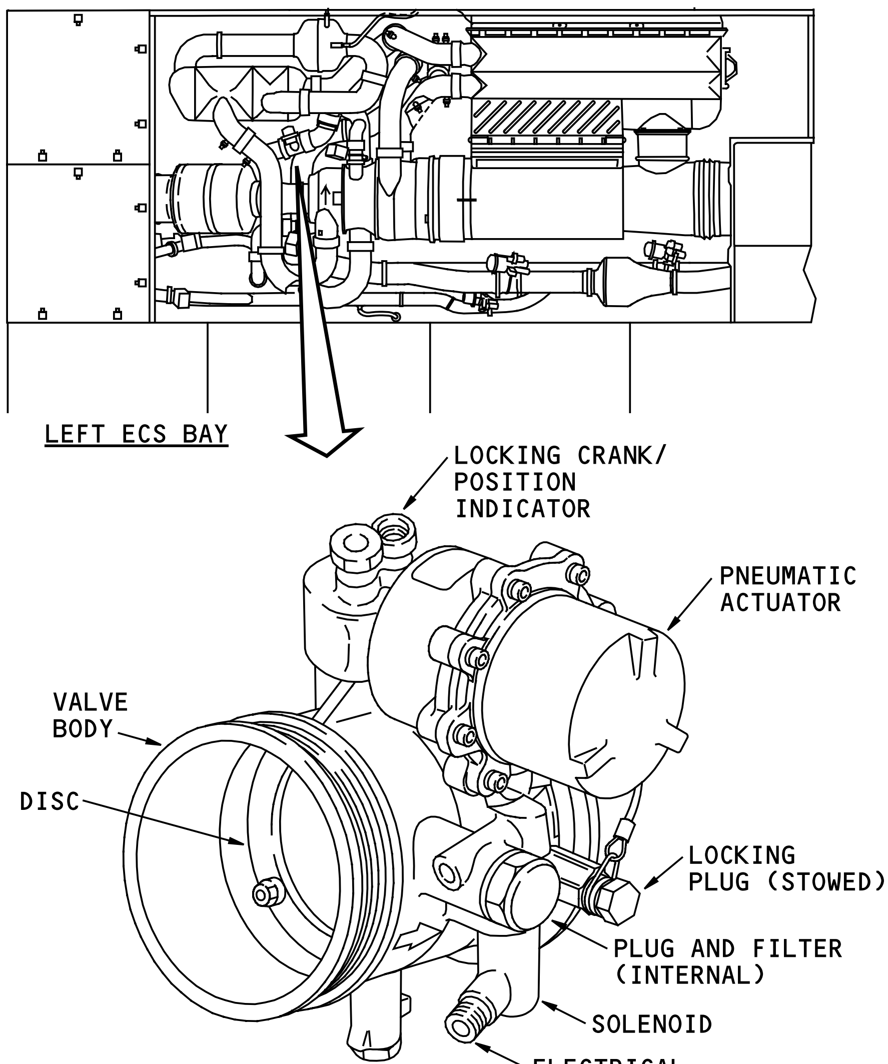
A pneumatic actuator moves the disc to open or close the valve.

Functional Description

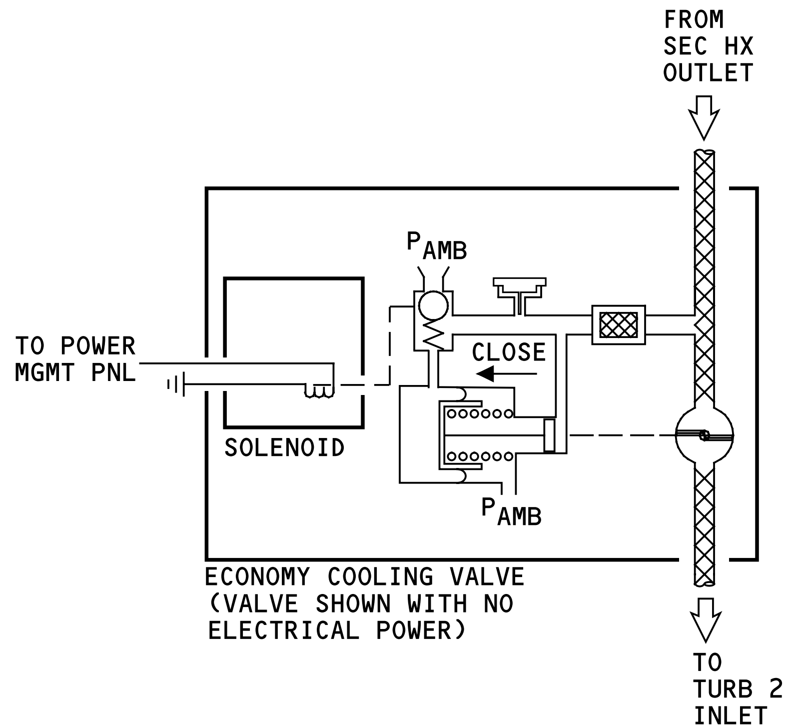
The economy cooling valve is electrically controlled and pneumatically actuated. The valve is spring-loaded closed. With no power to the solenoid, control pressure in the actuator opens the valve. When the solenoid energizes, control pressure bleeds from the actuator and the valve closes.

Training Information Point

Use the locking plug to manually lock the valve to the closed position.



ECONOMY COOLING VALVE



ECONOMY COOLING VALVE

AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - ECONOMY COOLING VALVE

THIS PAGE INTENTIONALLY LEFT BLANK

Purpose

The pack cooling temperature sensors monitor the air temperatures at eight different locations in the pack.

These are the pack cooling temperature sensors:

- Primary heat exchanger outlet temperature sensor
- Compressor discharge temperature sensors 1 and 2 (CTC)
- Secondary heat exchanger outlet temperature sensor
- Compressor discharge temperature sensor (ASCPC)
- Condenser inlet temperature sensors 1 and 2
- Pack discharge temperature sensor (CTC)
- Pack discharge temperature sensor (ASCPC)
- Secondary turbine inlet temperature sensor.

The primary heat exchanger inlet temperature sensor supplies data for flow control. See the pack flow control section for more information about flow control (AMM PART I 21-51).

The cabin temperature controller (CTC) uses the pack cooling temperature data for control, BIT, and indications. See the zone temperature control and indication section for more information about the CTC (AMM PART I 21-61).

Physical Description

The sensors have an electrical connection and a threaded housing. The sensors install into a threaded boss on the air conditioning duct. There are single element resistance/temperature sensors and single element thermistor sensors.

These sensors are single element resistance/temperature sensors:

- Primary heat exchanger outlet temperature sensor
- Compressor discharge temperature sensors 1 and 2 (CTC)
- Compressor discharge temperature sensor (ASCPC)
- Secondary heat exchanger outlet temperature sensor.

These sensors are single element thermistor sensors:

- Condenser inlet temperature sensors 1 and 2
- Secondary turbine inlet temperature sensor
- Pack discharge temperature sensor (CTC)
- Pack discharge temperature sensor (ASCPC).

Location

The sensors are in air ducts in the ECS bay.

Training Information Point

These sensors are interchangeable:

- Primary heat exchanger outlet temperature sensor
- Compressor discharge temperature sensor (2) (CTC)
- Compressor discharge temperature sensor (ASCPC)
- Secondary heat exchanger outlet temperature sensor.

The primary heat exchanger inlet temperature sensor is also interchangeable with the above sensors.

These sensors are interchangeable:

- Condenser inlet temperature sensor (2)
- Secondary turbine inlet temperature sensor.

The ASCPC and CTC pack discharge temperature sensors are interchangeable.

AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - MANIFOLD TEMP SENSORS

Purpose

The ram air inlet door controls the flow of ram air supplied to the dual heat exchanger. This is to control the amount of air used to cool the dual heat exchanger. This functions with other components to control air temperature from the pack.

Physical Description

The ram air inlet door is a two part assembly. The forward part has a hinge attached at a permanent position at the ram air inlet.

The aft part has a free hinge attached on the aft side of the forward part. The aft side of the aft part mounts on rollers.

The actuator turns a torque tube that attaches to the aft part of the door behind the hinge.

Location

The ram air inlet doors are on the bottom of the airplane forward of the ECS bay doors.

Functional Description

A close or open signal from the CTC operates the actuator motor in the necessary direction.

A rotary variable differential transformer (RVDT) in the actuator sends the position of the door to the CTC.

Training Information Point

When you change a component of the ram air inlet system, measure the closed position of the door. If it is necessary, adjust the actuator to get the correct measurement.

WARNING: MAKE SURE THAT PERSONNEL ARE CLEAR OF THE RAM AIR INLET DOOR, LINKAGE AND ACTUATOR BEFORE YOU DO THIS SPECIAL FUNCTION. POSSIBLE INJURY TO PERSONNEL CAN OCCUR.

The ram air inlet doors are normally open with the airplane on the ground. You use a MAT special function to close the ram air door if necessary.

AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - RAM AIR INLET DOOR AND ACTUATOR

Purpose

The fan inlet diffuser housing connects the dual heat exchanger to the ACM fan and ram air exhaust duct.

The fan bypass check valve permits air to go around the ACM fan at higher ram air flow.

Physical Description

The fan inlet diffuser housing is a metal container with flexible connections at the ram air inlet and fan bypass. An inner assembly separates the air flow that goes to and from the ACM fan.

The fan bypass check valve is a flapper-type valve.

Training Information Point

The fan inlet diffuser housing has a strap that attaches to the upper support fitting and to airplane structure (not shown). The strap supports the housing when the ACM or dual heat exchanger is removed. Make sure you install this strap when you install the fan inlet diffuser housing.

AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - FAN INLET DIFFUSER HOUSING AND CK VLV

THIS PAGE INTENTIONALLY LEFT BLANK

General

The CTCs control the related air conditioning pack. The CTCs usually set the packs to keep the temperature in the mix manifold to a calculated value and to keep pack outlet temperatures within 10F (5.5C) of each other.

The calculated temperature value for the mix manifold is called integrated mix manifold temperature error (IMMTE) reference. The IMMTE reference is based on cooling and heating requirements of the zones that usually get conditioned air from the mix manifold. The right CTC usually calculates this reference. The left CTC follows the right CTC. The left can make the calculation if the right CTC fails. See the zone temperature control and indication section for more information about the calculation of the IMMTE reference (AMM PART I 21-61).

The left and right CTCs can control the related pack outlet temperature to different values. This occurs when the flight deck needs more cooling than the request by the IMMTE reference. If the flight deck needs more cooling, the left CTC controls the left pack outlet temperature to satisfy the flight deck requirements. The right CTC controls the right pack outlet to satisfy the IMMTE reference.

The left and right CTCs control the temperature of air from the related pack by direct adjustment of these components:

- Second stage turbine bypass valves (TBV)
- Low limit valves (LLV)
- Ram air door actuators.

The CTCs use the economy cooling valve (ECV) to bypass the water removal part of the pack. The CTC opens the ECV when water removal is not necessary or when the CTC must increase airflow into the airplane. The CTC controls the economy cooling valve through the ELMS electronics (ELEX) unit.

For usual control, the CTCs set the speed and direction of valve/actuator movement based on the difference between actual (RVDT) and desired position. Desired position is a CTC calculated position for valve/actuator based on these conditions:

- Pack on or off, pre-positioning for off
- Pack control, usual or backup.

When a pack is on, the desired position for a valve or an actuator is usually set to a preset schedule for each valve/actuator. The schedules for the ram air door actuators, TBV, and LLV do these functions:

- Keeps the use of ram air to a minimum
- Adjust ram air flow to keep ACM fan surge margins
- Keeps the compressor outlet temperatures within limits.

The position schedules for the ram air door actuators and the TBV and LLV automatically adjusts for low (less than.5 MACH) and high (more than or equal to.5 MACH) airspeeds. The schedule for the ram air door actuators also adjusts for the economy cooling mode.

Ram Air Door Actuator

CTC control of the ram air inlet actuator has these functions. The functions are listed with the most important first and the least important last:

- Limit closed position if the LLV or the TBV fails (ACM surge protection)
- Limit compressor outlet temperature (prevents compressor overheat)
- Keep the mix manifold temperature equal to or more than 35F (2C) if the TBV is full open (prevents water freezing in mix manifold)
- Control pack outlet temperature to satisfy the IMMTE reference (valve/actuator preset schedules).

A rotary variable differential transformer (RVDT) in the actuator sends the door position to the CTC.

Second Stage Turbine Bypass Valve

CTC control of the second stage turbine bypass valve has these functions. The functions are listed with the most important first and the least important last:

- Limit open position if ram air door actuator fails (ACM surge protection)
- TBV full open if ACM fails (standby cooling, lets the pack continue to operate)
- Change position to control pack flow if flow control valve is full open and pack in economy cooling mode (lets pack satisfy pack flow schedule)
- Keep the mix manifold temperature more than or equal to 35F (2C) (prevents water freezing in mix manifold)
- Control pack outlet temperature to the IMMTE reference (valve/actuator preset schedules).

An RVDT in the valve sends the valve position to the related CTC.

Low Limit Valve

CTC control of the low limit valve has these functions. The functions are listed with the most important first and the least important last:

- Keep condenser inlet temperature more than or equal to 34F (1C) (prevents water freezing in the hot side of the condenser)
- Control pack outlet temperature if TBV is full open and the mix manifold temperature less than the IMMTE reference or less than 35F (2C).

Economy Cooling Valve

The CTC tells the electrical load management system (ELMS) electronics unit to open or close the economy cooling valve (ECV). The ELMS electronics unit uses the economy cooling valve relay to set the position of the ECV. To open the valve, ELMS removes electrical power from the relay. This causes air pressure in the pack to open the valve. To close the valve, ELMS energizes the relay which gives 28v dc to a solenoid in the ECV. This causes air pressure in the pack to close the valve.

Sensors - Temperature and RVDT

The CTCs monitor pack temperature sensors and valve/ actuator RVDTs. The CTCs use this information for control, BIT and indications for the related air conditioning pack.

See the zone temperature control and indication section for more information about the pack temperature sensors (AMM PART I 21-61).

Indication - Standby Cooling

When the related CTC sets the related pack to operate in the standby cooling mode, the AIMS shows these two indications:

- EICAS advisory message PACK MODE L (R)
- STBY COOLING message on the air synoptic display.

The STBY COOLING message shows next to the related pack symbol.

See the cooling section for more information about the pack indications (AMM PART I 21-50). See the pack cooling and mix manifold temperature control section for more information about standby cooling (AMM PART I 21-52).

Pack Off Positioning

The CTC sets the positions of the ram air door actuators, LLV, TBV and ECV when a pack is off. These are the related positions for a pack when the airplane is in the air:

- Ram air inlet is at 0.98 percent of heating (98 percent closed)
- LLV is at 0.00 percent of heating (full closed)
- TBV is at 0.15 percent of heating (part open)
- ECV is closed.

These are the related positions for a pack when the airplane is on the ground:

- Ram air inlet is at 0.00 percent of heating (full open)
- LLV is at 0.00 percent of heating (full closed)
- TBV is at 0.00 percent of heating (full closed)
- ECV is closed.

ASCPC Interface

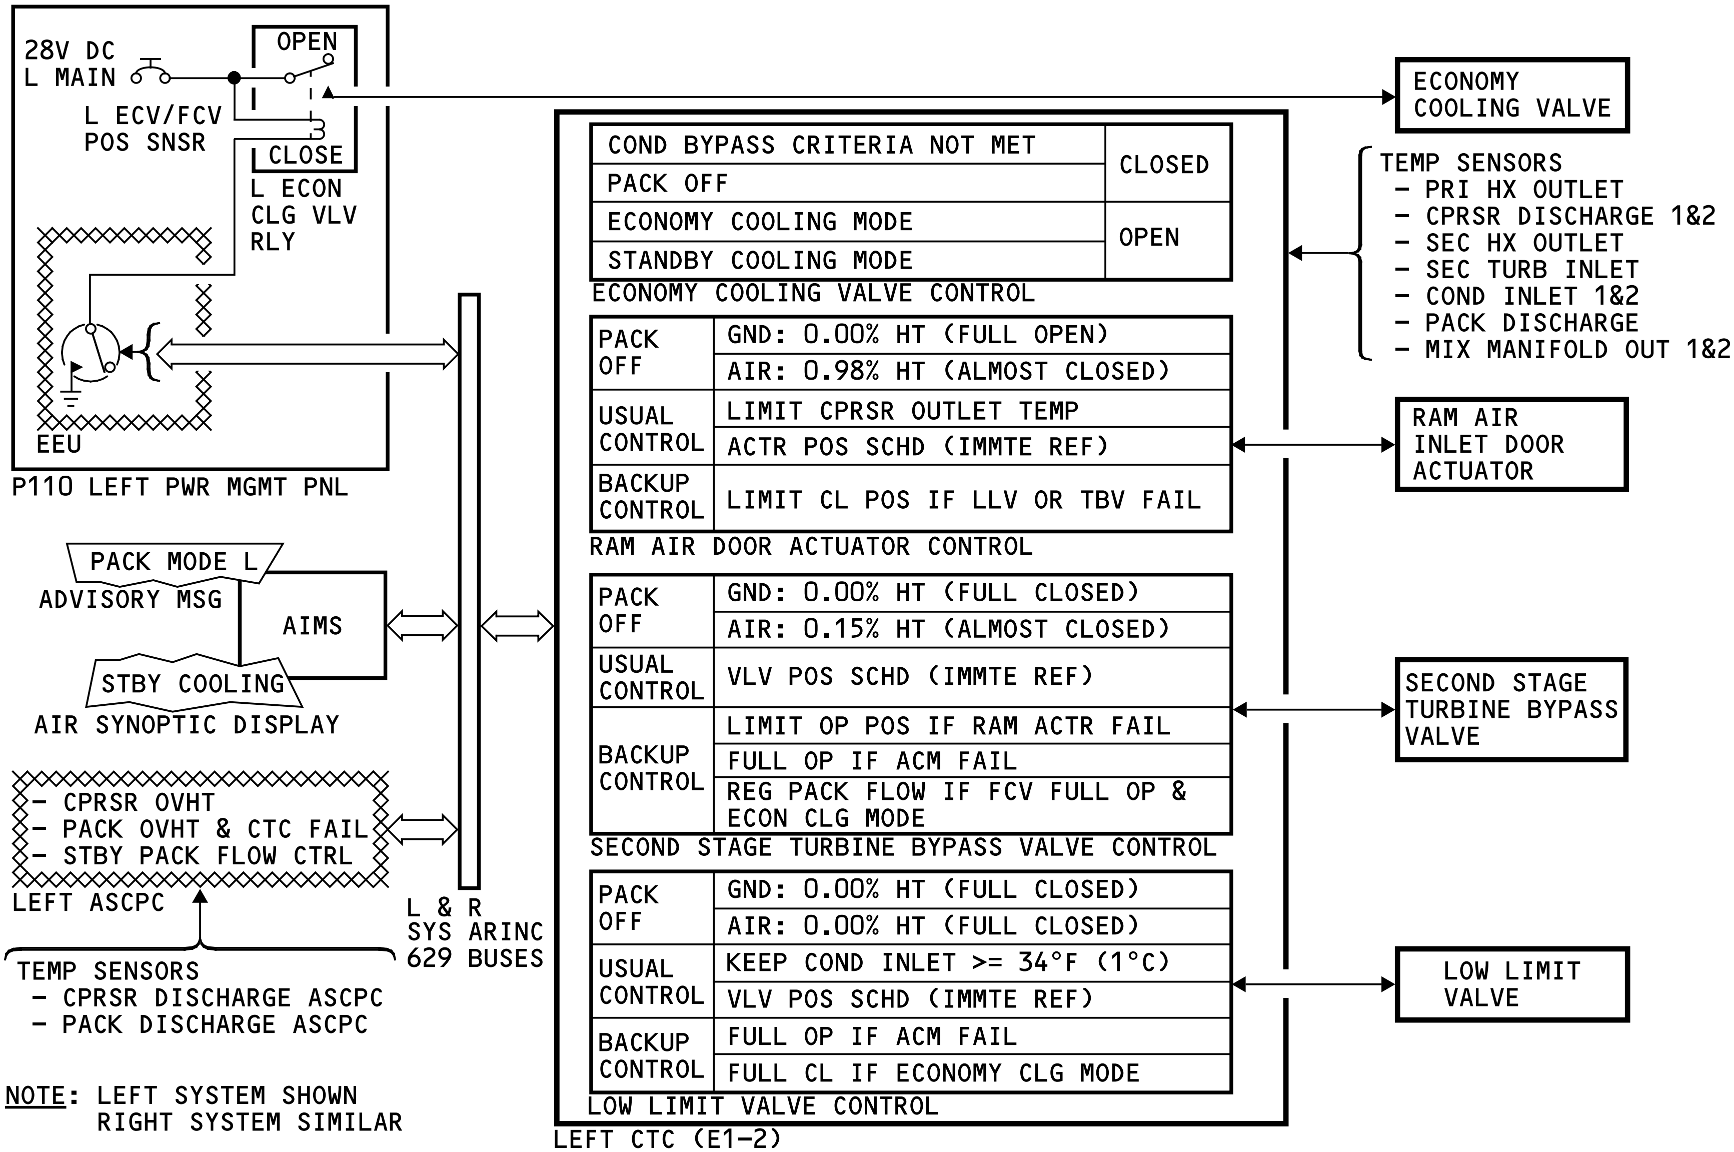
The ASCPCs monitor the compressor and pack discharge temperatures. The ASCPCs have there own temperature sensors, they do not use the same sensors as the CTCs.

The related ASCPC uses the compressor and pack discharge temperature information to set the related pack to off if any of these conditions occur:

- Compressor overheat more than 490F (254C) for 5 seconds
- Pack overheat, 210F (99C) for 10 seconds and the related CTC has failed.

The related ASCPC also uses the temperature information to keep discharge temperatures in limits when it gives backup pack flow control.

See the pack flow control section for more information about backup pack flow control (AMM PART I 21-51).



21-52-00-017 Rev 7 12/02/1996

AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - FUNCTIONAL DESCRIPTION - CONTROL

General

The left CTC controls the left pack, and the right CTC controls the right pack.

In full air cycle machine (ACM) operation, the CTC controls the pack internal air temperatures and the pack output air temperature by adjustment of these components:

- Second stage turbine bypass valve (TBV)
- Low limit valve (LLV)
- Ram air door actuator.

These components operate in sequence to keep the necessary air temperature from the pack. This temperature is called the integrated mix manifold temperature error (IMMTE) reference. The CTC uses the TBV for primary control of pack output air temperature. The LLV and the ram air door actuator operate if the TBV is full open and the CTC still must increase pack outlet temperature. This keeps the necessary ram air flow to a minimum.

The right CTC is the primary controller of the mix manifold temperature. The left CTC usually follows the right in this condition. This type of operation makes the left and right pack outlet temperatures stay within 10F (5.5C) of each other. If the right pack is off or is in an overtemperature condition, the left CTC takes control of the mix manifold temperature.

The left and right CTCs can also control pack outlet temperatures to different values if it is necessary for the flight deck to have more cooling than the mix manifold.

The CTC usually uses the economy cooling valve (ECV) to help keep the scheduled air flow through the pack when the airplane is at high altitudes and low pneumatic duct pressure (economy cooling mode). The valve can be used to bypass the ACM if the ACM fails (STBY COOLING mode).

Compressor Outlet Temperatures Control

The CTC usually uses the ram air part of the system to control air temperature at the compressor outlet. The CTC can adjust pack air flow to limit compressor outlet temperature or stop pack operation to give protection. The CTC controls compressor out temperature in these limits:

COMPRESSOR OUT TEMP F (C) < 25,000FT	COMPRESSOR OUT TEMP F (C) > 25,000FT	CTC RESPONSE
< 340 (171)	< 400 (204)	MODULATE RAM AIR DOORS FOR PACK OUT TEMP CTRL
>= 340 (171)	>= 400 (204)	RAM AIR DOORS FULL OPEN
>= 355 (179) (*1)	>= 415 (213) (*1)	REQUEST LOWER PRECOOLER OUT TEMP FROM ASCPC (250F, 121C)
>= 355 (179)	>= 415 (213)	DECREASE PACK FLOW (LOWEST VALUE >= SCHEDULE 4)
>= 450(232) > 10 SEC	>= 450(232) > 10 SEC	CLOSE FCV & LATCH PACK OFF (*2)
*1) SINGLE PACK OPERATION OR PACK FAILURE OR ACM FAILED.		
*2) RESET WITH PACK SW OR AIR COND RESET SW		

See the pack flow control section for more information about the pack flow schedules and control (AMM PART I 21-51).

See the air conditioning section for more information about the air conditioning reset switch (AMM PART I 21-00).

Condenser Inlet Temperatures Control

The CTC usually uses the LLV to prevent the formation of ice in the condenser. The CTC can adjust pack air flow to keep the condenser from freezing. The CTC always controls the condenser inlet temperature so that it does not go to a value less than 34F (1C).

Pack Outlet Temperatures Control

The CTC usually uses the TBV, ECV, and the ram air part of the system to control the pack outlet air temperature. The CTC can adjust pack air flow to limit pack outlet temperature or stop pack operation to give protection. The CTC controls pack outlet temperature within these limits:

PACK OUTLET TEMP F (C)	CTC RESPONSE
< 160 (71)	MODULATE TBV & RAM AIR DOORS FOR PACK OUT TEMP CTRL
>= 160 (71) < 180 (82)	MODULATE PACK TO FULL COLD: * AIR DOORS TOWARDS FULL OPEN * TBV TOWARDS FULL CLOSED
>= 180 (82) (*1)	REQUEST LOWER PRECOOLER OUT TEMP FROM ASCPC (250F, 121C)
>= 180 (82)	DECREASE PACK FLOW (LOWEST VALUE >= SCHEDULE 4)
>= 190 (88) > 10 SEC	CLOSE FCV & LATCH PACK OFF (*2)
*1) SINGLE PACK OPERATION OR PACK FAILURE OR ACM FAILED	
*2) RESET WITH PACK SW OR AIR COND RESET SW	

To prevent ice in the mix manifold, the CTC controls the pack valves and ram air doors to keep the mix manifold outlet temperature to a value more than 35F

(2C). If the temperature at the mix manifold outlet decreases to a value less than this level, the CTC increases pack outlet temperature.

See the pack flow control section for more information about the pack flow schedules and control (AMM PART I 21-51).

See the air conditioning section for more information about the air conditioning reset switch (AMM PART I 21-00).

Economy Cooling Mode

The CTC selects the economy cooling mode if the all of these conditions occur:

- ACM operates
- One or both condenser inlet temperature senors operate
- ECV operates
- Pack flow is less than the scheduled value or ambient temperature is less than 20F (-7C)
- Conditions for ACM not failed - condenser bypass are true.

The conditions for ACM not failed - condenser bypass change with altitude. The chart shows five examples.

ACM NOT FAILED - CONDITIONS FOR CONDENSER BYPASS	
ALTITUDE	AMBIENT TEMP F (C)
<= 0	<= 14 (-10)
10,000	<= -9 (-23)
20,000	<= -18 (-28)
>= 30,000	<= -24 (-31)
IF AMBIENT TEMP <= INDICATED VALUE, THEN CONDENSER BYPASS CAN OCCUR.	

In the economy cooling mode, air goes directly from the secondary heat exchanger to turbine two of the ACM. The CTC sets the second stage turbine bypass valve to control pack output temperature and the low limit valve to keep the condenser inlet above 34F (1C).

The CTC keeps a pack in the economy cooling mode until any one of these conditions is true:

- Conditions for condenser bypass are not true
- TBV full closed, ram air doors more than 80 percent open and pack outlet temperature 5F (2.7C) more than IMMTE
- Pack flow schedule 4 is active
- Actual pack flow less than 100 ppm or more than two times the value of pack flow schedule 2.

There are no flight deck effect when the pack operates in the economy cooling mode.

Non-Normal Operations

In addition to compressor and pack outlet overheat conditions, these cause non-normal operations:

- ACM failure
- Pack temperature sensor failures
- Economy cooling value failure
- Low limit valve failure
- Turbine bypass valve failure
- Ram air door failures
- Single pack operation.

Standby Cooling Mode

These faults cause the related pack to operate in the standby cooling mode:

- ACM failure
- Condenser inlet temperature sensors 1 and 2 fail
- Economy cooling valve failed open.

There are two ways the pack can operate when in the standby cooling mode: heat exchanger cooling or condenser bypass. The related CTC sets how the pack operates in the standby cooling mode based on which of these components have failed:

- Heat exchanger cooling occurs if the ACM fails
- Condenser bypass occurs if both condenser sensors, 1 and 2 fail or if the economy cooling valve fails in the open position.

These indications show when a pack operates in the standby cooling mode: the advisory message PACK MODE L (R) shows and the message STBY COOLING shows next to the related pack symbol on the air synoptic display.

See the air conditioning section for more information about the air synoptic display (AMM PART I 21-00).

ACM Failure (Heat Exchanger - STBY COOLING mode)

If an ACM failure occurs, the pack continues to operate in the STBY COOLING mode only if the ACM failed - condenser bypass criteria is met or when the other pack cannot meet the minimum flow necessary for schedule 4. If not, the pack stops. The pack can start again if the above conditions make it necessary.

The conditions for ACM failed - condenser bypass change with altitude. The chart shows five examples.

ACM FAILED - CONDITIONS FOR CONDENSER BYPASS	
ALTITUDE	AMBIENT TEMP F (C)
<= 0	<= 35 (2)
10,000	<= 25 (-4)
20,000	<= 18 (-8)
>= 30,000	<= 12 (-11)
IF AMBIENT TEMP <= INDICATED VALUE, THEN CONDENSER BYPASS CAN OCCUR.	

When the pack operates in the heat exchanger - STBY COOLING mode, the related CTC sets these valves fully open:

- Economy cooling valve
- Low limit valve
- Turbine bypass valve.

In this mode, the CTC adjusts the position of the ram air doors to control the pack outlet air temperature, heat exchanger cooling only. If the pack can not hold the necessary temperature (pack out temperature 5F (2.7C) greater than IMMTE) and the TBV is not full open, the CTC sends a signal to the ASCPC for a lower precooler outlet temperature, (250F, 121C).

See the engine air supply section for more information about the precooler out temperature control and bleed air control (AMM PART I 36-11).

Condenser Sensor/Economy Cooling Valve Failure (Condenser Bypass - STBY COOLING mode)

If both condenser inlet temperature sensors 1 and 2 fail or if the economy cooling valve fails open, the pack continues to operate in the STBY COOLING mode only if the ACM not failed - condenser bypass criteria is met. If not, the pack stops. The pack can start again if the condenser bypass criteria is met. When the pack operates in the condenser bypass - STBY COOLING mode, the related CTC controls the pack outlet temperature with these pack components:

- Economy cooling valve, set to full open
- Low limit valve, set to full close
- Second stage turbine bypass valve, modulating
- Ram air doors, modulating.

Pack Sensor Failures

These sensors have an effect on pack operation if they fail:

- Pack inlet differential pressure sensor, part of the pack flow sensor (not shown)
- Compressor out temperature sensors 1 and 2
- Condenser inlet temperature sensors 1 and 2.

The CTC has these two sources for pack inlet differential pressure: the pack flow sensor and the related ASCPC. If both sources fail, the pack stops.

See the pack flow control section for more information about the pack flow sensor (AMM PART I 21-51).

The CTC has three sources for compressor out temperature: compressor out temperature sensors 1 and 2 and the related ASCPC. If all sources fail, the pack stops.

The CTC has two sources for condenser inlet temperature, condenser inlet temperature sensors 1 and 2. If both fail, the pack operates in the standby cooling mode or stops.

See the zone temperature control and indication section for more information about the effects of other failed sensors on the air conditioning system (AMM PART I 21-61).

Ram Air Door Failure

If the temperature cannot stay within limits if there is a ram air door failure, the CTC decreases pack flow. The amount of decrease in flow has a relation to the temperature limits. The minimum flow is schedule 4. The serviceable pack increases flow to keep total fresh air ventilation constant.

If the ram air door RVDT fails, the CTC moves the actuator to the full open position. The CTC sends a command to the actuator for the correct amount of time to set the door to full open. After this, the CTC identifies the condition as an actuator failure.

Low Limit and Second Stage Turbine Bypass Valve Failures

If a low limit valve failure occurs, the CTC adjusts pack flow to keep condenser inlet temperature at or above 34F (1C). If a second stage turbine bypass valve failure occurs, the CTC sets the position of the ram air doors to control the pack outlet temperature. If the pack can not hold the necessary temperature, the CTC adjusts pack flow to control air temperature to the mix manifold.

If the low limit or second stage turbine bypass valve RVDT fails, the CTC moves the related valve to the 60 percent open position. The CTC times the movement of the valve to set it at 60 percent open. After this the CTC identifies the condition as a valve failure.

Single Pack Operation

In single pack operation, the CTC controls the TBV, LLV, ECV, and ram air doors actuators as usual to keep the necessary temperature in the mix manifold (IMMTE reference). The CTC also increases pack air flow to keep it close to the usual amount when two packs are on. The maximum flow has a limit so it is not more than the value set for flow schedule 2.

If the CTC can not keep pack flow or temperature (pack out temperature 5F (2.7C) more than IMMTE reference) at the necessary value, it can select one or all of these conditions to increase pack flow and to help control the pack out temperature:

- Operate the pack in the economy cooling mode if the conditions for this mode permit it
- Tell the ASCPC to supply a lower precooler outlet temperature (250F, 121C) if the turbine bypass valve is not full open
- Adjust the position of the second stage turbine bypass valve to control flow and temperature
- If the second stage turbine bypass valve is fully open, or a lower precooler out temperature is not available (wing anti-ice if on) or does not let the pack operate to the necessary temperature, the CTC tells the ASCPC to supply a higher pneumatic pressure (6 psi bias for HPSOV control).

When the CTC must choose to control pack flow or pack out temperature, pack flow is usually first in the order of control. Pack overheat protection control, always overrides pack flow control.

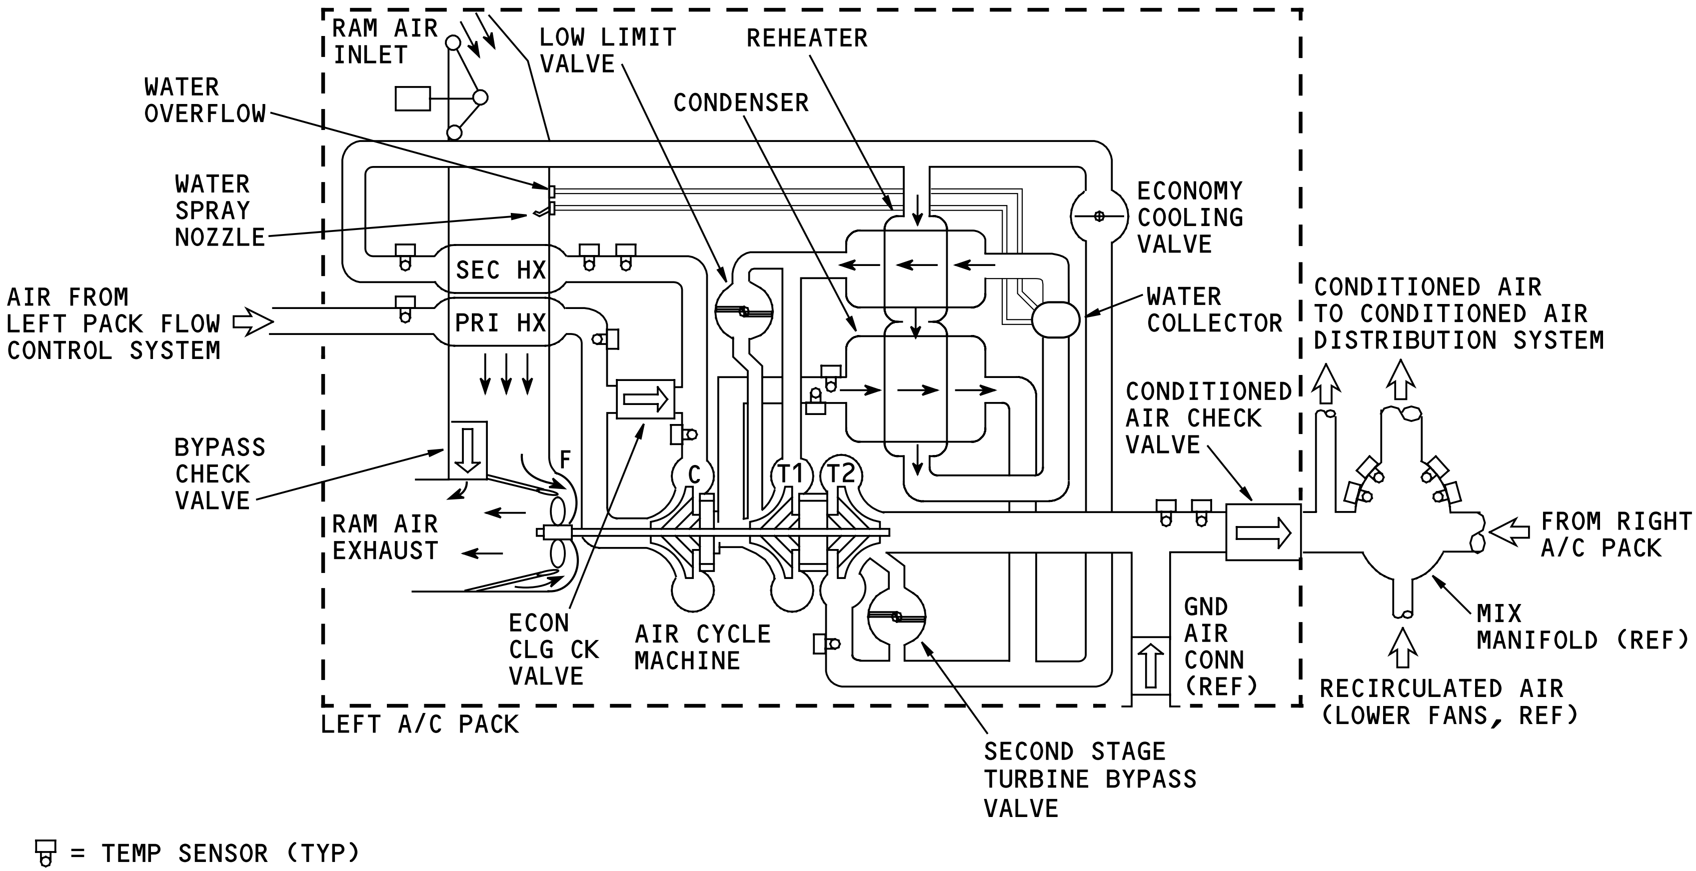
See the pack flow control section for more information about the pack flow schedules (AMM PART I 21-51).

Single pack operation can cause the related lower recirculation fan (not shown) to stop if these conditions occur:

- Airplane on the ground
- Pack at maximum cooling
- Mix manifold temperature 12F (6.7C) > IMMTE reference.

When a fan is set to off, this helps the related pack meet the necessary IMMTE reference by reducing the amount of cabin air put in to the mix manifold.

See the recirculation system section for more information about the recirculation fan control (AMM PART I 21-25).



21-52-00-018 Rev 10 10/17/96

AIR CONDITIONING - PACK CLG AND MIX MANIFOLD TEMP CTRL - FUNCTIONAL DESCRIPTION - PACKS

AIR CONDITIONING - COOLING - OPERATION

General

The air conditioning panel has these controls for pack operation:

- Left and right pack switches
- Air conditioning reset switch.

Location

The air conditioning panel is on the P5 overhead panel in the flight deck.

Pack Control

The L PACK and R PACK switches are alternate-action switches. AUTO shows when you push the switch in for selection of automatic pack operation.

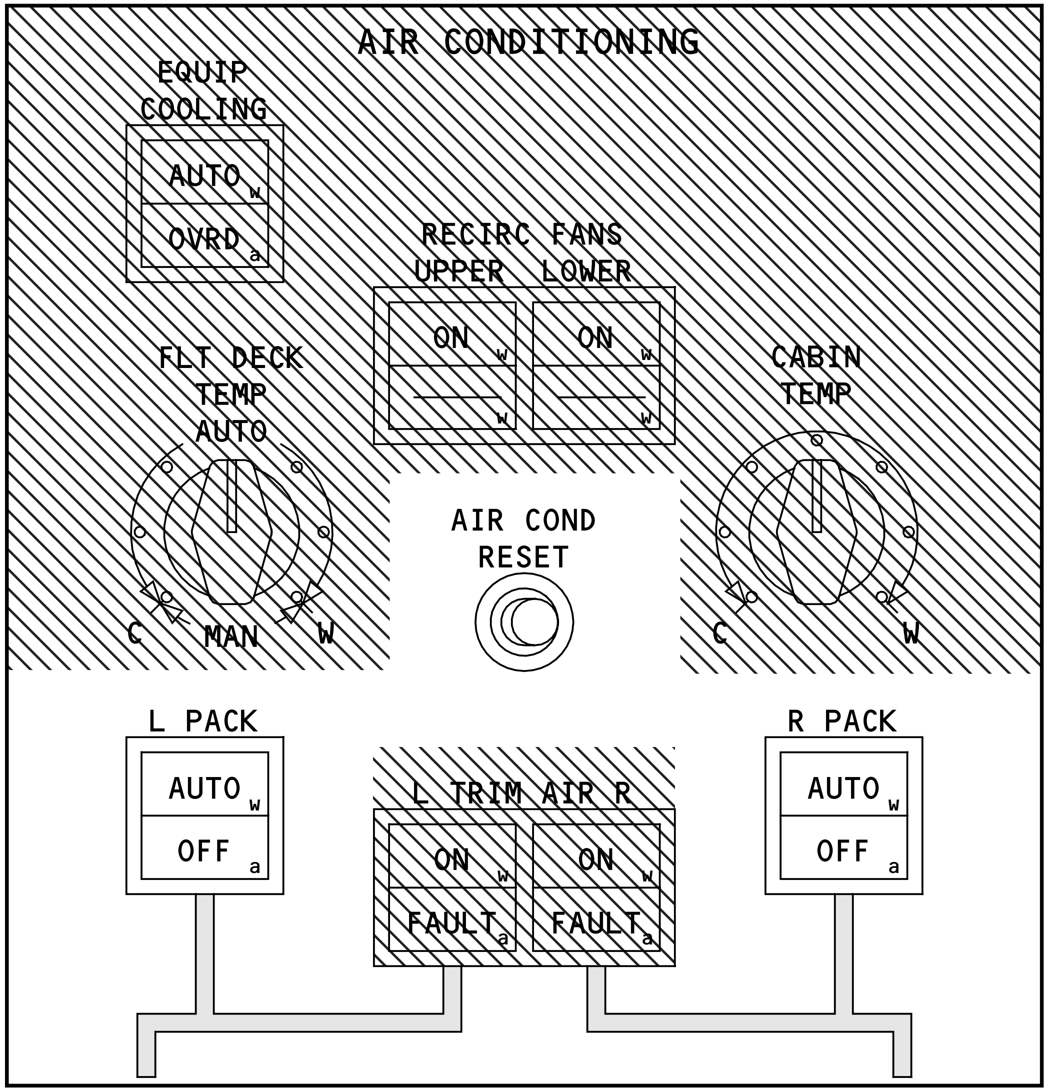
The OFF indication is not a function of switch position. It shows when the flow control and shutoff valves are closed.

Air Conditioning Reset Control

The AIR COND RESET switch is a momentary-action switch. This switch starts the system after a failure.

Training Information Point

The left and right main buses supply power for the OFF indications on the pack switches. If these buses have no power, the OFF indication does not show.



AIR CONDITIONING PANEL

AIR CONDITIONING - COOLING - OPERATION

THIS PAGE INTENTIONALLY LEFT BLANK

AIR CONDITIONING - COOLING - AIR SYNOPTIC DISPLAY AND AIR CONDITIONING MAINTENANCE PAGE

Air Synoptic Display

The top part of the air synoptic display shows information about the air conditioning system.

Green flow bars show air flow through the left and right packs. These symbols show the status of the packs:

- Pack on - green oval
- Pack off or pack status data invalid - white oval
- Pack failed - amber oval with amber X.

The STBY COOLING message and an advisory message PACK MODE L (R) show when a pack is on and has any of these faults:

- Air cycle machine (ACM) failed
- Both condenser inlet temperature sensors failed
- Economy cooling valve failed open.

If the pack stops, the STBY COOLING message shows.

Air Conditioning Maintenance Page

All the temperatures on the air conditioning maintenance page are in degrees F.

The air conditioning maintenance page has this information:

- MIX MANIFOLD TEMP - Temperature in the mix manifold
- FLOW SCHEDULE - Right air conditioning pack flow schedule: 0,1,2,3, or 4. Usual left pack flow schedule is the same as the right
- PACK FLOW-VOLUME - Pack flow rate in cubic feet per minute
- PACK FLOW-MASS - Pack flow rate in pounds per minute
- PRI HX IN TEMP - Temperature at the inlet of the primary heat exchangers
- PRI HX OUT TEMP - Temperature at the outlet of the primary heat exchangers
- CPRSR OUT TEMP - Temperature at the outlet of the air cycle machine compressors
- SEC HX OUT TEMP - Temperature at outlet of the secondary heat exchangers
- CONDENSER IN TEMP - Temperature at the inlet of the condensers
- STG 2 TURB IN TEMP - Temperature at the inlet of turbine 2 in the air cycle machines
- TRIM AIR PRESS - The difference, in psid, between cabin pressure and trim air pressure
- PACK CTRL CH - Shows the channel in control for the left and right cabin temperature controllers
- PACK IN PRESS - Pressure, in psia, at the inlet to the air conditioning packs
- LOW LIM VLV POS - Position of the low limit valve (0.00 is closed, 1.00 is open)
- TURB BYP VLV - Position of the turbine bypass valve in percent heat (0.00 is closed, 1.00 is open)
- RAM AIR INLET - Position of the ram air inlet in percent heat (0.00 is open, 1.00 is closed)

- RAM AIR EXIT - The ram air exit is a fixed opening; the position display is blank
- ECON COOL VLV - Open or closed position of the economy cooling valve
- LOWER FLOW CTRL VLV - Open or closed position of the lower flow control valve
- UPPER FLOW CTRL VLV - Open or closed position of the upper flow control valve.

See the primary display system for more information about the air conditioning maintenance page (AMM PART I 31-61).

AIR CONDITIONING - COOLING - GROUND TESTS

General

These are the cooling ground tests that show when you select ATA 21 Cabin Temperature Control System:

- Left pack actuators
- Left system air on
- Left system air off
- Right pack actuators
- Right system air on
- Right system air off.

Left and Right Pack Actuators

This test makes sure that the related cabin temperature controller can control these air conditioning pack LRUs:

- Ram air inlet door
- Turbine bypass valve
- Low limit valve.

During this test, the related pack operation stops, and the ram air doors move. The test takes approximately 3-5 minutes.

This test shows for these ground test types:

- System test
- Operational test
- LRU replacement test.

Left and Right System Air On

This test makes sure that the related cabin temperature controller can control these air conditioning pack and trim air LRUs:

- Upper flow control valve
- Lower flow control valve
- Economy cooling valve
- Air cycle machine
- Trim air pressure regulation and shutoff valve.

During this test, the related pack operation stops, and the ram air doors move. The test takes approximately 5-10 minutes.

This test shows for these ground test types:

- System test
- Operational test
- LRU replacement test.

Left and Right System Air Off

This test makes sure that the related cabin temperature controller can control these air conditioning pack LRUs:

- Ram air inlet door
- Turbine bypass valve
- Low limit valve.

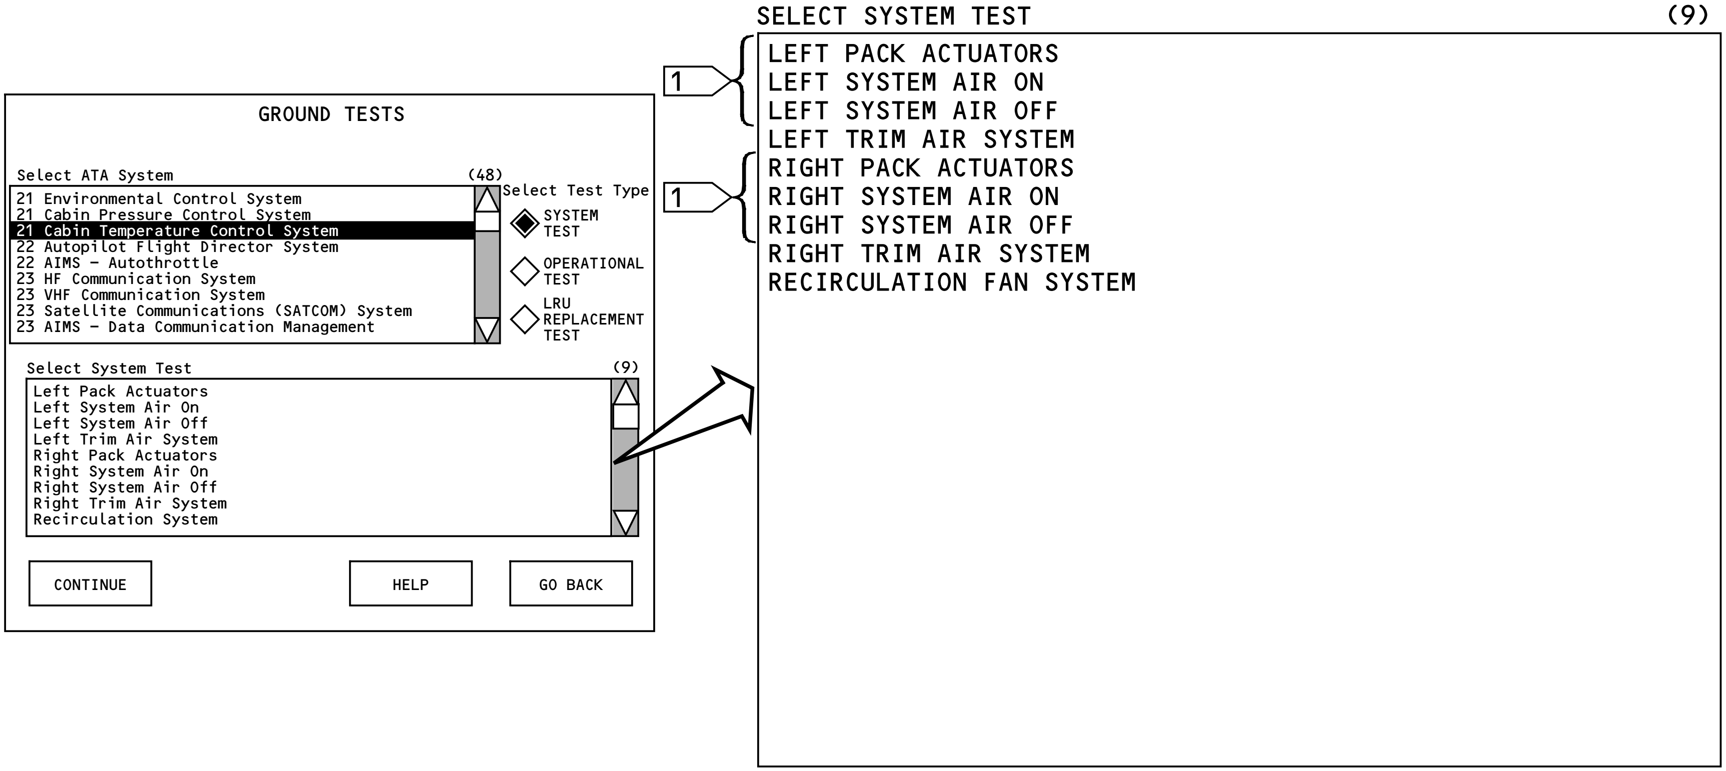
AIR CONDITIONING - COOLING - GROUND TESTS

This test also makes sure that the related cabin temperature controller can control the trim air system on that side.

During this test, the related pack and trim air operation stops, and the ram air doors move. The test takes approximately 2-3 minutes.

This test shows for these ground test types:

- System test
- Operational test
- LRU replacement test.



NOTE: SYSTEM TESTS SHOW.
OPERATIONAL AND LRU REPLACEMENT TESTS ARE SIMILAR.

1 THESE ARE THE AIR CONDITIONING - COOLING TESTS.

21-50-00-008 Rev 2 08/17/96

AIR CONDITIONING - COOLING - GROUND TESTS

AIR CONDITIONING - TEMPERATURE CONTROL - INTRODUCTION

Purpose

The temperature control system controls the temperature in these locations:

- Flight deck
- Passenger cabin.

The system sets the target temperature for the air conditioning packs. The system also sets the amount of air necessary from the APU when the APU supplies air to the packs.

The system has these parts:

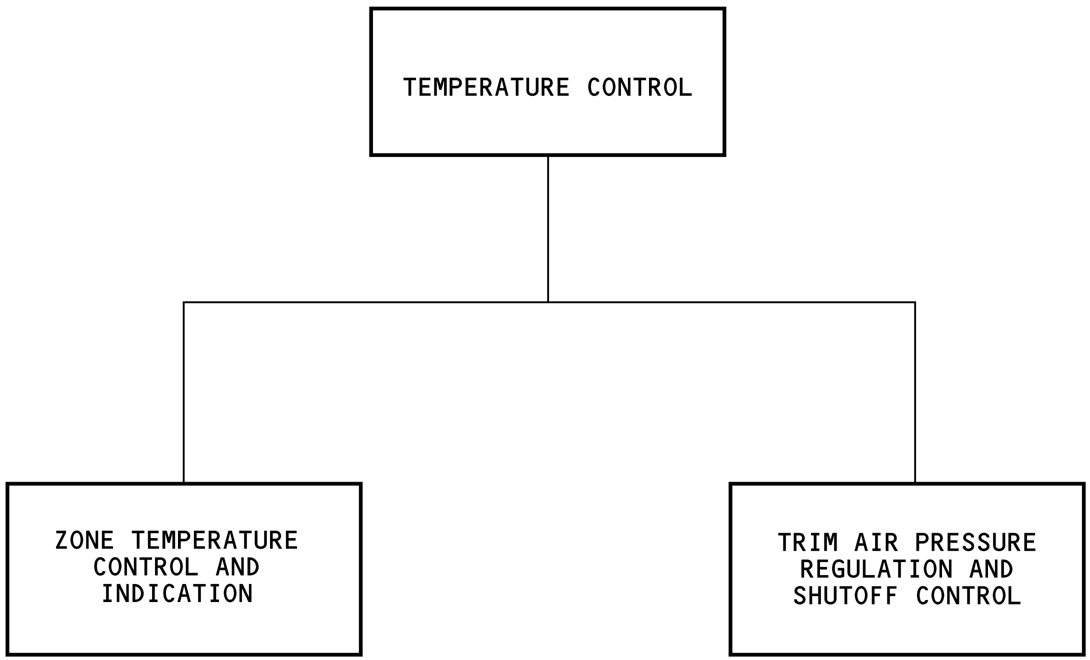
- Zone temperature control and indication
- Trim air pressure regulation and shutoff control.

Zone Temperature Control and Indication

The zone temperature control and indication system adjusts flight deck and passenger cabin zone temperatures to set values.

Trim Air Pressure Regulation and Shutoff Control

The trim air pressure regulation and shutoff control adjusts, monitors, and distributes trim air supply pressure to the trim air modulating valves.



21-60-00-001 Rev 3 02/25/1997

AIR CONDITIONING - TEMPERATURE CONTROL - INTRODUCTION

AIR CONDITIONING - TEMPERATURE CONTROL - GENERAL DESCRIPTION - CONTROL

General

The cabin temperature controllers (CTCs) adjust the trim air temperature components. The CTCs control these components to get the necessary air pressure and temperatures in the cabin zones and flight deck. The controls are on these panels:

- Air conditioning panel on the P5 overhead panel in the flight deck
- Cabin system control panel (CSCP) in the passenger cabin
- Cabin area control panels (CACP) in the passenger cabin.

The system has an interface with the ECSMCs. The cards give information about the condition of the lavatory/ galley vent fans. If both fans are off, the CTCs do not use the sensors in the zones to control zone temperatures. See the zone temperature control and indication section for more information about the control of zone temperatures with failed sensors (AMM PART I 21-61).

Trim Air Pressure Regulation and Shutoff Control

The trim air pressure regulation and shutoff valve controls trim air supply pressure to a set value. The trim air pressure sensor gives trim air duct pressure information to the CTC. The CTC uses it for control and indication. The air supply cabin pressure controller (ASCPC) supplies alternative control of the trim air pressure regulation and shutoff valve.

Zone Temperature Control

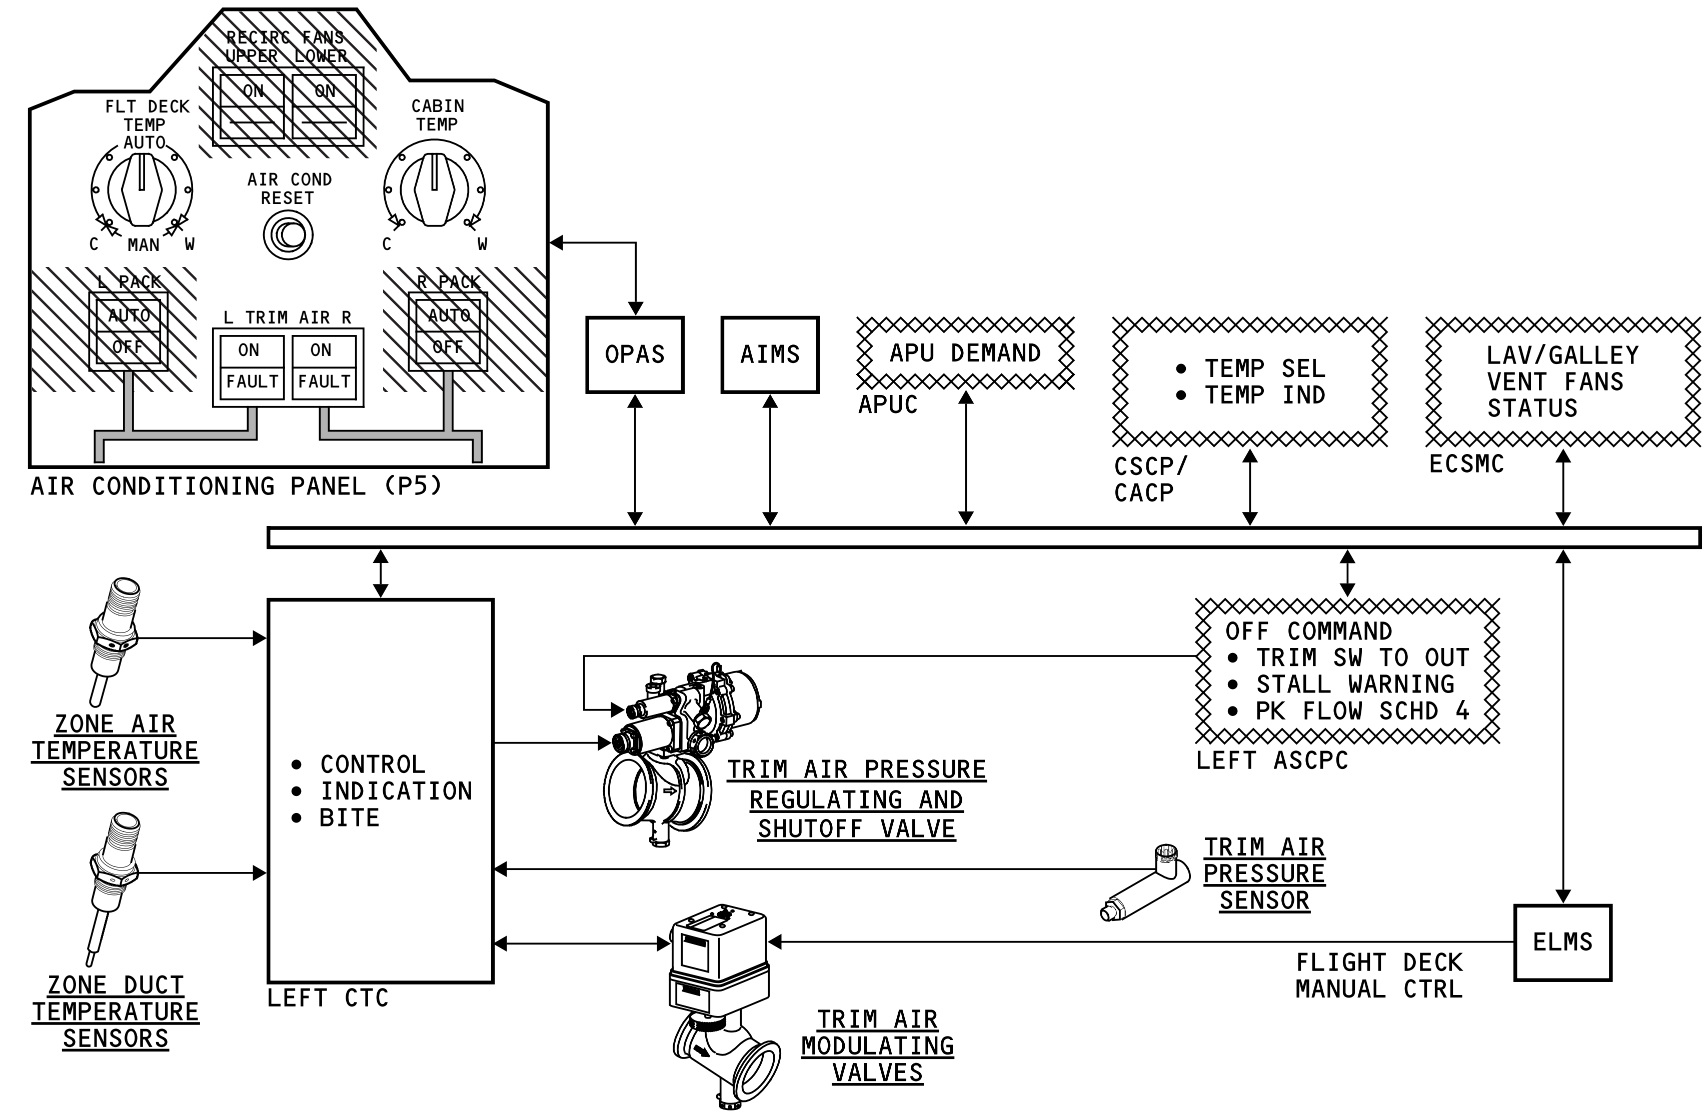
The trim air modulating valves adjust the flow of warm air added to the cold air that goes to the temperature control zones.

The FLT DECK TEMP control let the flight crew set the target temperatures for the flight deck zone. The CABIN TEMP control let the flight crew set the master temperature for all of the passenger zones. The minimum selectable temperature is 65F (18C) and the maximum is 85F (29C).

The CSCP and the CACP let the attendants adjust the target temperature for the cabin by area. The area temperature can be set 10F (6C) more or less than the master. The temperatures can not be set less than 65F (18C) or more than 85F (29C).

Zone air temperature sensors and zone duct temperature sensors give temperature information to the CTC. The CTC use the information for control and indication.

The CTC has an interface with the APU controller (APUC). When the APU supplies air for pack operation and temperature control, the CTC tells the APUC the amount of air to supply. The CTC uses the APU DEMAND signal to tell the APUC the amount of air that is needed. See the zone temperature control and indication section for more information about the APU DEMAND signal (AMM PART I 21-61).



NOTE: LEFT SYSTEM SHOWN, RIGHT SIMILAR

AIR CONDITIONING - TEMPERATURE CONTROL - GENERAL DESCRIPTION - CONTROL

AIR CONDITIONING - TEMPERATURE CONTROL - GENERAL DESCRIPTION - MECHANICAL

Trim Air Pressure Regulation and Shutoff Control

A left side and a right side trim air pressure regulating and shutoff valves make sure the trim air supply is between 2 and 8.5 psi above cabin pressure. The usual pressure is 5 psi above cabin pressure. This allows sufficient flow and keeps pneumatic system noise to a minimum. The trim air pressure sensors give trim air pressure information to the cabin temperature controllers (not shown) for control and indication.

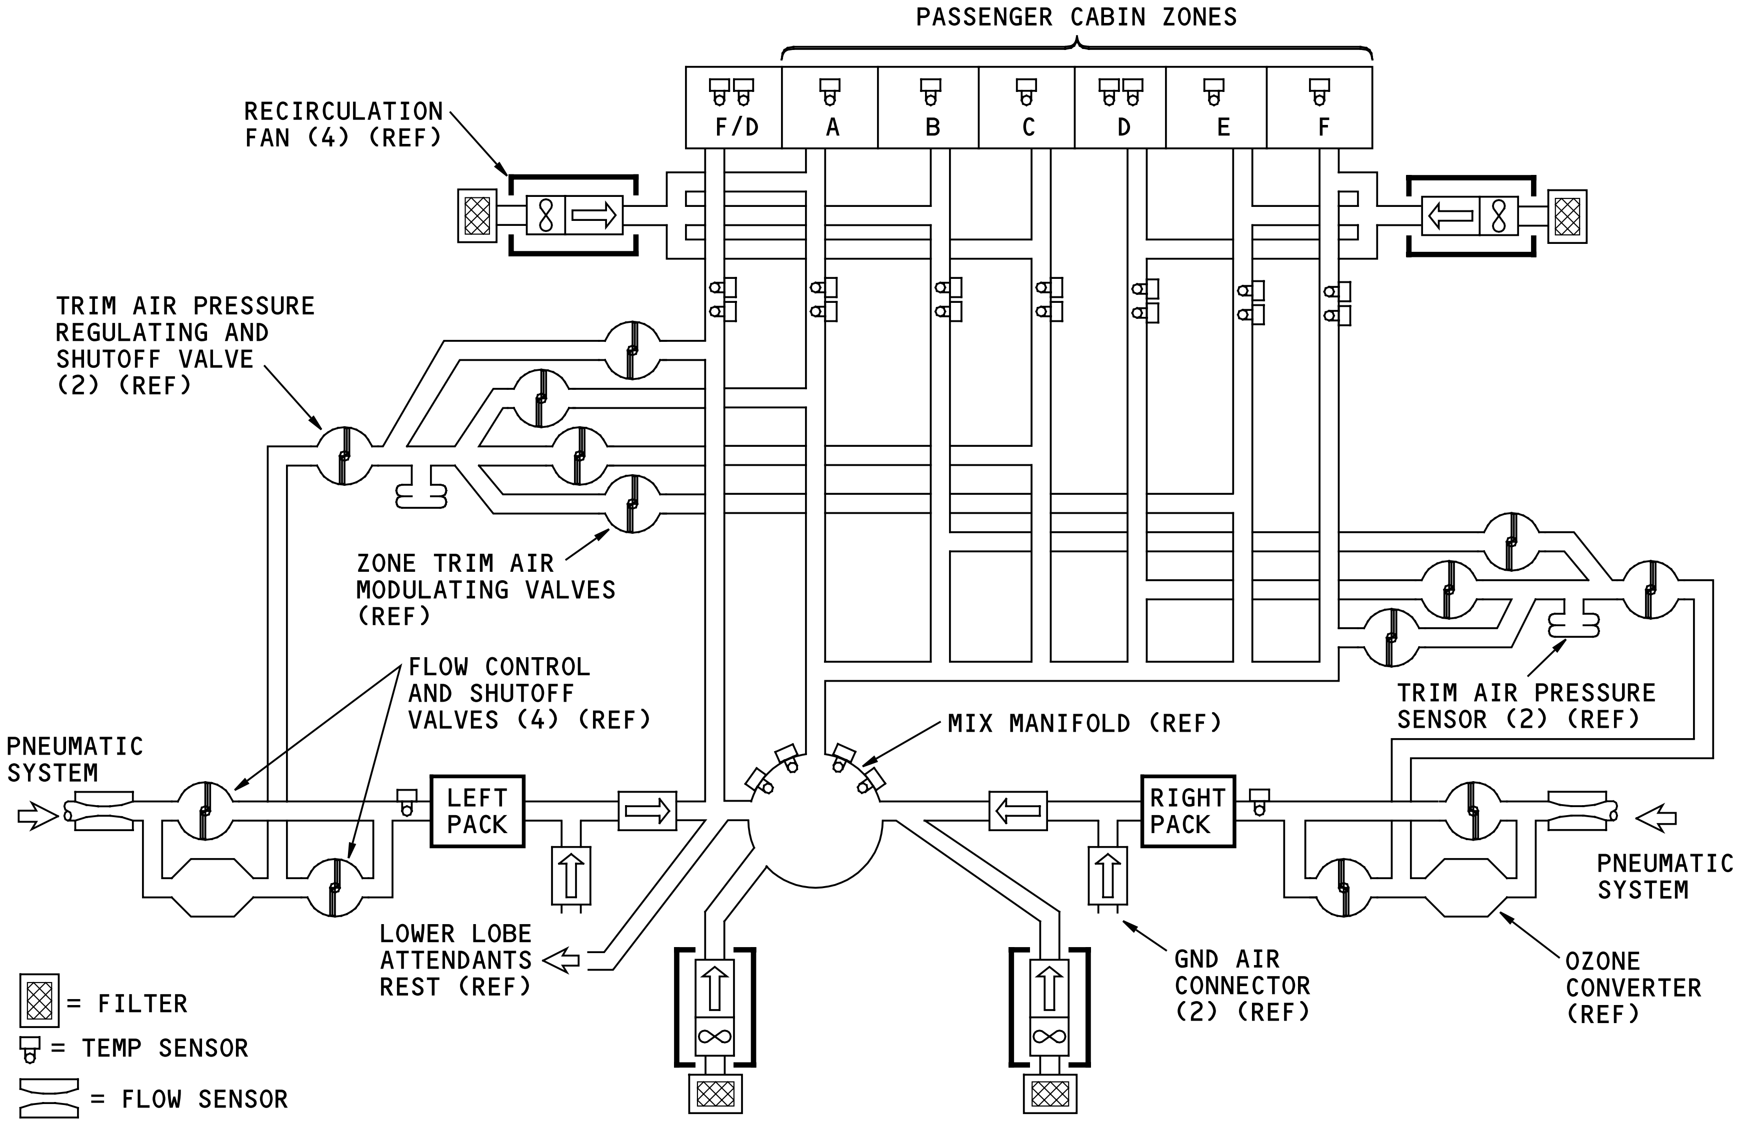
Zone Temperature Control

The cabin temperature controllers use the packs to control cooling for the flight deck and the mix manifold.

The trim air modulating valves control the quantity of trim air supplied to each zone. Trim air for the passenger zones mixes with the air from the mix manifold. Trim air for the flight deck mixes with the air from the left pack.

Each trim air modulating valve adjusts the amount of trim air to control the zone temperature. Zones that need a higher temperature get more trim air. Zones that need a lower temperature get less trim air.

The zone air temperature sensors and zone duct temperature sensors give air temperature information to the cabin temperature controllers (not shown) for control and indication.



21-60-00-003 Rev 5 10/28/1997

AIR CONDITIONING - TEMPERATURE CONTROL - GENERAL DESCRIPTION - MECHANICAL

AIR CONDITIONING - TRIM AIR PRESS REGULATION AND SHUTOFF CTRL - INTRODUCTION

General

Trim air pressure regulation and shutoff control system adjusts, monitors and distributes trim air supply pressure to the trim air modulating valves.

The related CTC controls and monitors the operation of this part of the air conditioning system. The CTCs use the trim air PRSOV to keep the trim air supply pressure between 2 and 8.5 psi above cabin pressure. The usual pressure is 5 psi above cabin pressure.

The related ASCPC gives backup off control for the trim air PRSOV. The ASCPCs are the usual sources for cabin pressure data.

The remote cabin pressure sensor is a backup source for cabin pressure data.

The trim air switches enable trim air operation when they are set to ON. The switches turn off the trim system when they are in the out position. The FAULT light turns on and the advisory message TRIM AIR L (R) shows when any of these conditions occur:

- Related zone duct overheat
- Related trim air switch set to out
- Related trim air system has a fault (trim air PRSOV, controller, pressure sensor).

See the zone temperature control and indication section for more information about the zone temperature control system (AMM PART I 21-61).

Location of Components

These components are in each ECS bay:

- Trim air pressure regulating and shutoff valve (PRSOV)
- Trim air pressure sensor (on the keel beam, forward of the trim air pressure regulating and shutoff valve).

TRIM AIR PRESSURE REGULATION AND CONTROL SCHEMATIC

21-62-00-001 Rev 2 04/10/1997

AIR CONDITIONING - TRIM AIR PRESS REGULATION AND SHUTOFF CTRL - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

General

The CTC uses the trim air pressure regulating and shutoff valve (PRSOV) to give shutoff control and to control the pressure of the air that goes to the trim air modulating valves. The CTC can also use the valve to give backup zone temperature regulation. See the zone temperature control and indication section for more information about the zone temperature control system (AMM PART I 21-61).

Location

The left and right trim air PRSOVs are in the related ECS bays next to the keel beam. You open the related ECS access door to get access to the valves.

Physical Description

These are the parts of the valve:

- Pneumatic actuator
- Locking crank/position indicator
- Shutoff solenoid
- Torque motor
- Valve disc
- Valve body
- Plug and filter (internal)
- Locking plug.

The valve is electrically controlled and pneumatically operated. This valve is not spring-loaded open or closed. The valve is fail safe off, if no power goes to the torque motor.

Functional Description

Control air pressure pushes on the open side of the pneumatic actuator to move the valve to open. Supply air pressure pushes on the close side of the pneumatic actuator to move the valve towards close. A change in the amount of the control air pressure makes the valve control trim air pressure downstream of the valve. The CTC uses the torque motor to set the amount of control air that goes to the pneumatic actuator.

The torque motor operates like a spring-loaded-closed modulating valve. With no current to the torque motor, it is spring-loaded to stop control air and vents control pressure from the open side of the pneumatic actuator. This lets supply pressure move the actuator to close the trim air PRSOV (fail safe off). The amount of current that goes to the torque motor is directly related to the value to which the trim air PRSOV controls trim air pressure to. When the CTC increases current to the torque motor, control pressure to the pneumatic actuator increases, the valve disc opens more and downstream pressure increases.

The ASCPC uses the solenoid to give backup shutoff control for the trim air PRSOV. With no voltage to the solenoid, it is spring-loaded to let control pressure go from the torque motor to the open side of the pneumatic actuator. With 28v dc to the solenoid, it stops control air and vents control pressure from the open side of the pneumatic actuator.

See the page on the functional description of the trim air pressure regulation and shutoff control section for more information on trim air pressure control.

Training Information Point

You can use the locking plug and locking crank/position indicator to lock the trim air PRSOV closed. When you remove the locking plug from its stowed position, control pressure is vented.

21-62-00-003 Rev 1

AIR CONDITIONING - TRIM AIR PRESS REGULATION AND SHUTOFF CTRL - TRIM AIR PRESSURE SENSOR

THIS PAGE INTENTIONALLY LEFT BLANK

CTC Control

The left cabin temperature controller (CTC) gives usual control of the trim air pressure regulating and shutoff valve (PRSOV). The left CTC uses information about airplane conditions to calculate the position of the trim air PRSOV. These components and systems give information to the left CTC:

- AIR COND RESET switch, resets latched conditions in the CTCs
- L TRIM AIR switch, in or out position
- Remote cabin pressure sensor, backup source for cabin pressure
- AGS, airplane on the ground condition used during the ASCPC preflt test
- AIMS, ground test conditions and indications
- WES, stall condition
- Left trim air pressure sensor, trim air supply duct pressure
- ASCPCs, primary source for cabin pressure and alternative close control for the trim air PRSOV.

The left trim air PRSOV opens only if all of these conditions occur:

- One or both air conditioning packs are on
- Pack flow schedule 4 is not selected
- Airplane is not in a stall condition
- Left trim air switch is set to the ON position
- Left trim air pressure sensor is not failed
- One of both channels of the left CTC operates
- No duct overheat condition in zones B, C, E, or F/D.

The usual pressure regulation value for the trim air PRSOV is 5 psi above cabin pressure.

The CTC can adjust the regulation value between 2 - 8.5 psi above cabin pressure. The CTC can adjust the regulation value as necessary to control zone temperature. The CTC does this only when a trim air modulating valve fails more than 10 percent open. See the zone temperature control and indication section for more information about the control of the trim air modulating valves (AMM PART I 21-61).

Duct Overheat

A duct overheat (190F, 88C) for zones that get conditioned air from the mix manifold causes the related trim air PRSOV to latch closed. A duct overheat (190F, 88C) for the flight deck zone can operate one of these two ways:

- If the left pack outlet temperature is less than 160F (71C), then the trim air PRSOV is latched closed
- If the left pack outlet temperature is equal to or more than 160F (71C), then the trim air PRSOV closes but does not latch.

This type of control makes sure the left trim system does not latch off when the left pack gives air to the flight deck at a high temperature. See the pack cooling and mix manifold temperature control section for more information about the temperature control function of the air conditioning pack (AMM PART I 21-52).

ASCPC Control

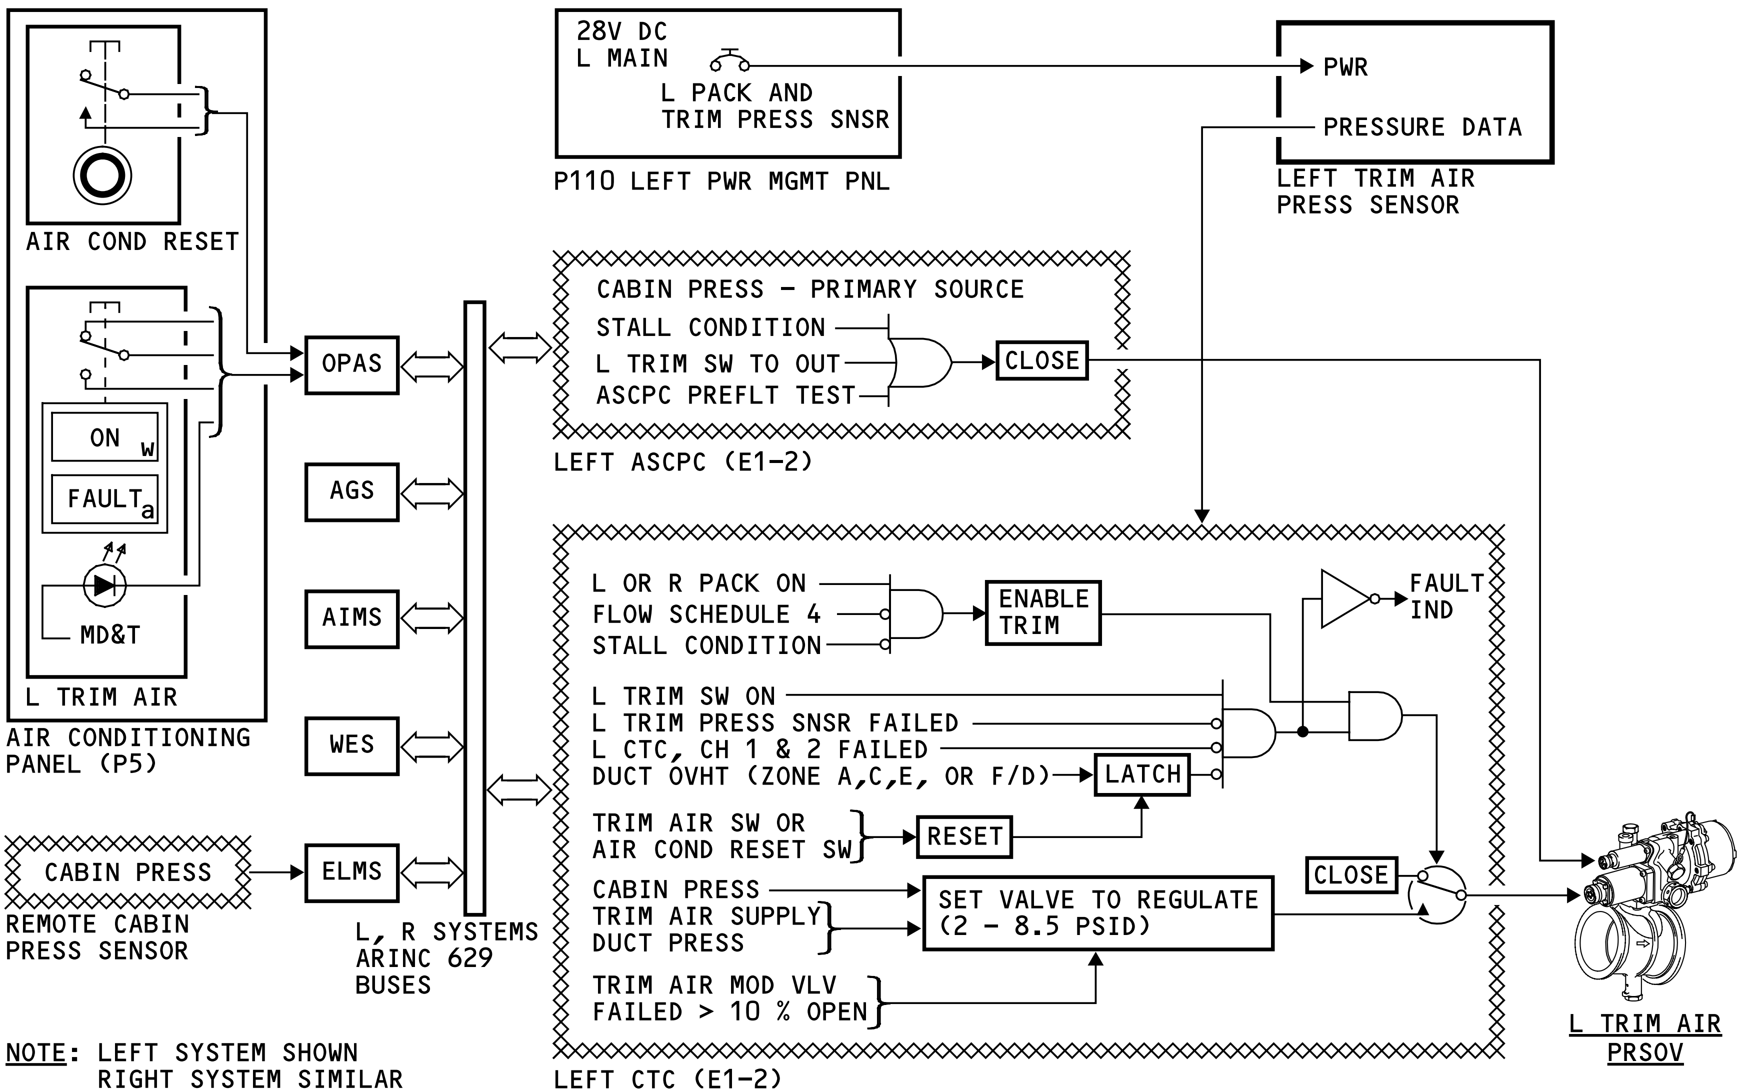
The air supply cabin pressure controller (ASCPC) can close the trim air pressure regulating and shutoff valve to decrease the load on the pneumatic system. The ASCPC closes the valve if any of these conditions occur:

- Airplane is in a stall condition
- Left trim air switch is set to the out position.

For the trim air system, the stall condition has a maximum time limit of 8 seconds. After 8 second the trim system returns to normal operation.

ASCPC Preflight Test

Immediately after an engine start, the ASCPCs send flow schedule 1 to the CTCs. The CTCs set the trim air pressure regulating and shutoff valves to the open position while the ASCPC does a test of its control over these valves. When the ASCPC completes this test (15 sec), the CTC sets the valves to the correct position, and the ASCPC releases control.



NOTE: LEFT SYSTEM SHOWN
RIGHT SYSTEM SIMILAR

AIR CONDITIONING - TRIM AIR PRESS REGULATION AND SHUTOFF CTRL - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

Purpose

The zone temperature control and indication system adjusts flight deck and passenger cabin zone temperatures to set values. Mufflers in the trim air duct distribution ducts decreases noise in the trim air system.

General Description

The left and right cabin temperature controllers (CTCs) monitor and give temperature control for all zones. The left controller monitors and controls these zones:

- Flight deck (F/D)
- Passenger zone A
- Passenger zone C
- Passenger zone E.

The right controller monitors and controls these zones:

- Passenger zone B
- Passenger zone D
- Passenger zone F.

The CTCs use the air conditioning packs for cooling and the trim air modulating valves to adjust the temperature in zones that need more heat. See the air conditioning chapter for more information about the pack cooling and mix manifold temperature control system (AMM PART I 21-52).

You use the flight deck temperature control on the air conditioning panel to control the flight deck temperature. AUTO lets you set the target temperature between 65F (18C) and 85F (29C). MAN selection lets you manually adjust the temperature in the flight deck.

You use the cabin temperature control on the air conditioning panel to select the (master) target temperature for all zones in the passenger cabin area. You use the cabin temperature screen on the cabin area control panels or cabin system control panel to bias the target temperature for passenger cabin areas. You can adjust the temperature 10F (6C) above or below the master target value. The bias does not let you select a temperature below 65F (18C) or above 85F (29C).

For the passenger cabin zones there is an auto comfort correction feature. This feature biases up the cabin master target temperature when the airplane is in a cruise condition. The temperature is biased up a maximum of 4F (2C).

Interfaces

The CTCs use sensors in the zones and in the air conditioning distribution ducts to monitor air temperature in these areas. The temperature data is used for control and indication.

The CTCs use RVDTs in the modulating valves to monitor valve position. Valve position data is used for control and indication.

AIR CONDITIONING - ZONE TEMP CTRL AND INDICATION - INTRODUCTION

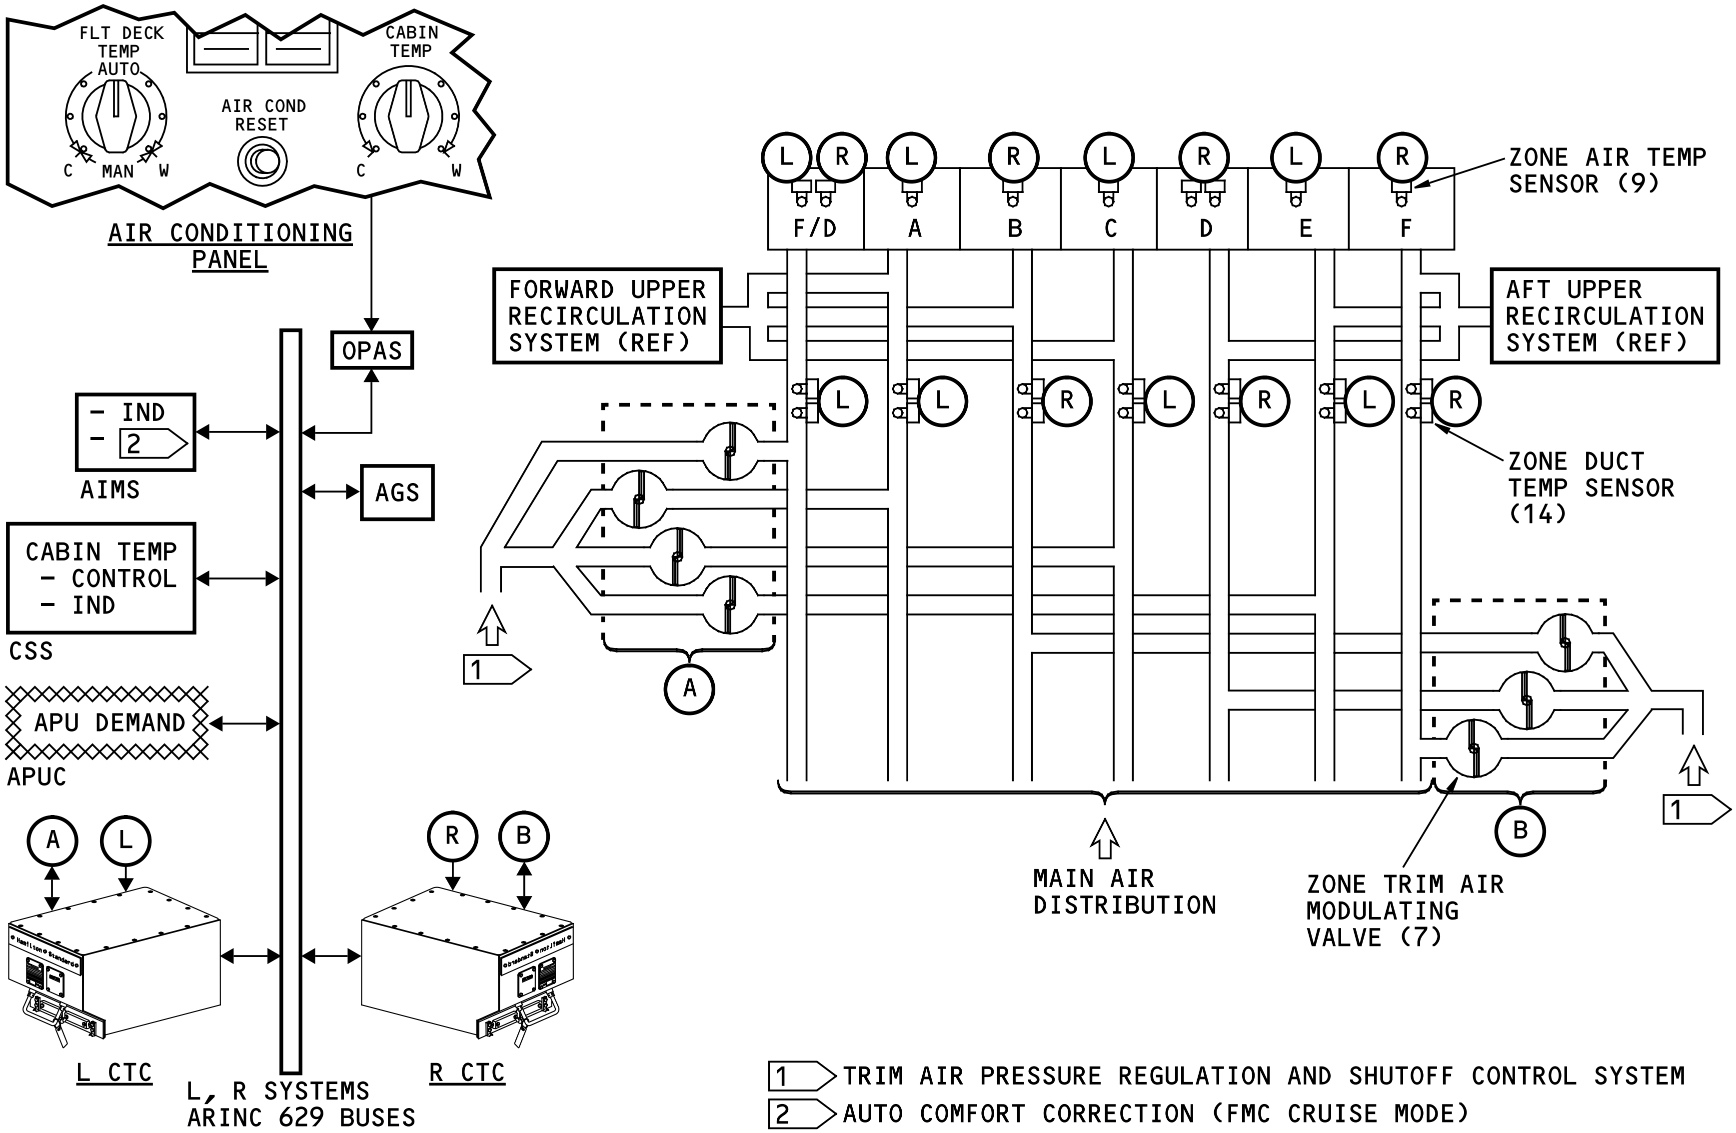
The CTCs get air ground information from the air ground system. The CTCs use this information to calculate the APU DEMAND signal.

AIMS give these functions for the zone temperature control system:

- Indication
- Airplane at cruise, FMC data
- Ground test.

A status message shows if a CTC fails. AIMS also gives maintenance messages that relate to sensor and valve faults.

The CTCs give the APU controller (APUC) an APU DEMAND signal when the APU supplies air for pack operation on the ground. The signal is used to control the quantity of air necessary for ventilation and heating or cooling in the airplane.



1 TRIM AIR PRESSURE REGULATION AND SHUTOFF CONTROL SYSTEM
2 AUTO COMFORT CORRECTION (FMC CRUISE MODE)

AIR CONDITIONING - ZONE TEMP CTRL AND INDICATION - INTRODUCTION

Location

The left and right cabin temperature controllers (CTC) are in the main equipment center on the E1 and E2 racks.

Physical Description

The CTCs weigh 25 lbs (11.5 kg) each. The controllers have two test connectors on the front. The connectors are for shop service.

The CTCs use operational program software (OPS) that you can load.

Training Information Point

The CTCs are LRUs. The circuit cards in the CTCs are not LRUs.

The Left and right CTCs are interchangeable.

CABIN TEMPERATURE CONTROLLER
(TYPICAL)

21-61-00-002 Rev 1 03/17/95

AIR CONDITIONING - ZONE TEMP CTRL AND INDICATION - CTC - PHYSICAL DESCRIPTION

Purpose

The zone trim air modulating valves control the flow of air from the pneumatic system to each zone. The mufflers reduce the noise in the flight deck and passenger cabin caused by the flow of trim air.

Location

The valves and the mufflers are in the forward part of the left and right ECS bays. There is one valve and one muffler for each temperature control zone.

You get access to the mufflers and the valves through the left and right ground conditioned air panels and the ECS bay doors.

Physical Description

Each valve has these parts:

- Electrical actuator
- Valve body
- Manual open/shut knob
- Electrical connector.

All of the trim air modulating valves are the same. Each has an internal disc in the valve body. The electrical actuator has these internal parts:

- Motor
- RVDT and position indicator
- Gears.

The motor controls disc position. The RVDT gives an electrical indication of the disc position and a visual indication of disc position.

Functional Description

A close or open signal from the CTC operates the actuator motor in the necessary direction.

The RVDT gives valve position to the CTC.

Training Information Point

Manually open or shut the valve with the manual open/shut knob. You must disconnect the electrical connector first. If you do not remove the electrical connector the valve will move to the commanded position when the valve gets power.

AIR CONDITIONING - ZONE TEMP CTRL AND INDICATION - CABIN ZONE DUCT TEMP SENSORS

AIR CONDITIONING - ZONE TEMP CTRL AND INDICATION - FLIGHT DECK ZONE AIR TEMP SENSORS

Purpose

The cabin temperature controllers (CTCs) use the flight deck zone temperature sensors to monitor the flight deck temperature.

Physical Description

The sensors are dual element thermistors. Each sensor has a threaded housing with an electrical connection.

The sensors are interchangeable with the ones in passenger cabin zones.

Location

The sensors are in an air inlet plenum that connects to the lavatory/galley ventilation system. This inlet is in the flight deck ceiling, to the right of the P11 circuit breaker panel.

Training Information Point

One sensor supplies temperature information to the left CTC for usual flight deck temperature control. The other supplies temperature information to the right CTC. The right CTC can control the mix manifold temperature to supply cooling air for the flight deck when the left pack is off.

The sensors have dual elements so that one element supplies data to channel 1 of the related CTC and the other supplies data to channel 2.

AIR CONDITIONING - ZONE TEMP CTRL AND INDICATION - FLIGHT DECK ZONE AIR TEMP SENSORS

21-61-00-006 Rev 2 01/24/96

Purpose

The cabin temperature controllers (CTC) use the cabin zone temperature sensors to monitor the temperature of air pulled from the zones by the ventilation system.

Physical Description

The sensors are thermistors with two elements. Each sensor has a threaded housing with an electrical connection.

The sensors are interchangeable with the ones in the flight compartment.

Location

The sensors are in the same area as the left outboard passenger service units (PSUs). Each sensor is in a plenum that attaches to a zone air temperature sensor panel. The plenum has an air inlet grille on the lower side of the panel. The plenum has a hose that connects it to the lavatory/galley ventilation system on the upper side of the panel. The sensors are at these station locations:

- Zone A: station 464
- Zone B: station 629
- Zone B: station 673 (wiring provisions only)
- Zone C: station 821 (wiring provisions only)
- Zone C: station 901
- Zone D (forward): station 1021
- Zone D (aft): station 1122
- Zone E: station 1364
- Zone F: station 1796.

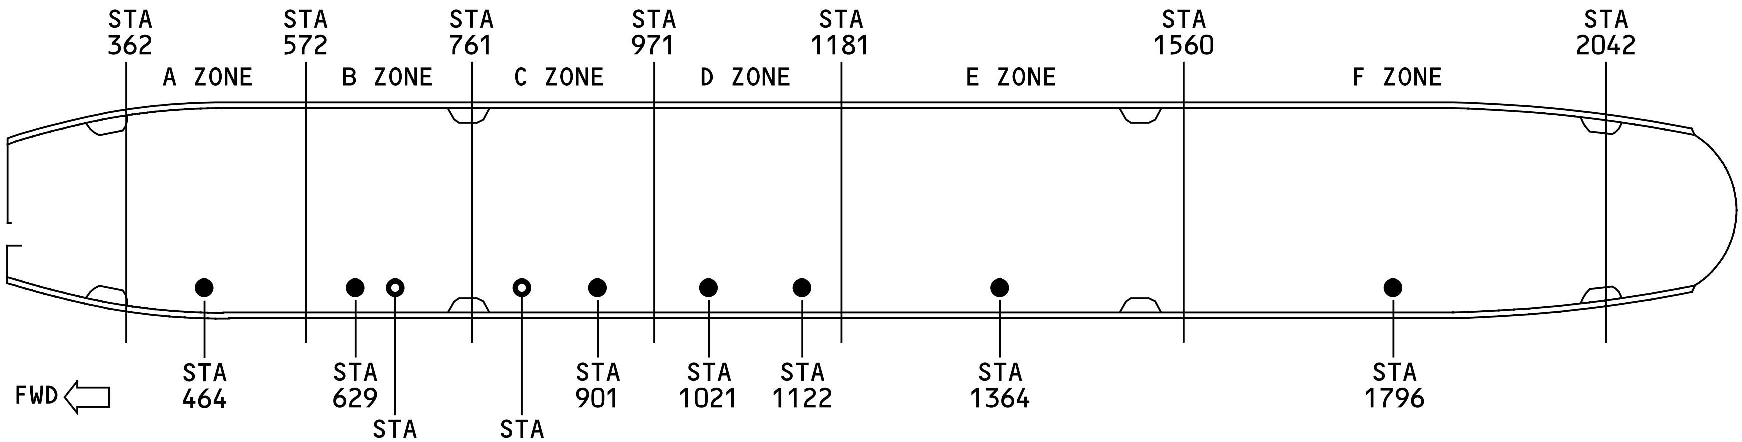
Training Information Point

Cabin temperature control zones can have one or two temperature sensors. A second sensor permits different interior configurations. Galleys, lavatories, closets, and partitions can prevent one sensor from accurately measuring the temperature in a zone. When there are two sensors in one zone, the cabin temperature controllers use an average of the temperature information from the sensors.

Any zone can have two sensors. Zone D always has two sensors. Zones B and C have wiring for a second sensor. If you install a second sensor, you must also load a new operational program configuration (OPC) software in the CTCs.

Sensors in these zones connect to the left CTC: A, C and E. Sensors in these zones connect to the right CTC: B, D and F.

The sensors have two elements so that one element supplies data to channel 1 of the related CTC and the other element supplies data to channel 2.



CABIN TEMPERATURE CONTROL ZONES

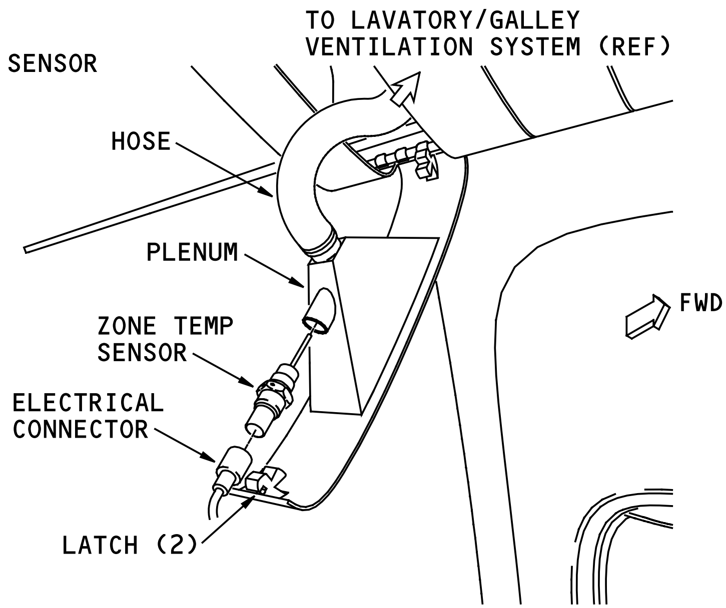
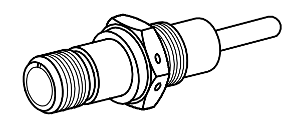
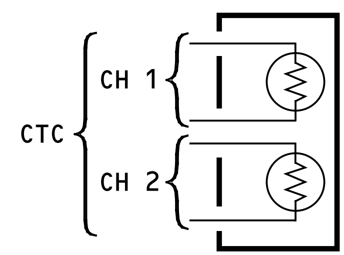
(LEFT SIDE)



ZONE AIR TEMPERATURE SENSOR PANEL
(TYPICAL)



TEMP SENSOR
(TYPICAL)



TEMP SENSOR CIRCUIT
(TYPICAL)

AIR CONDITIONING - ZONE TEMP CTRL AND INDICATION - CABIN ZONE AIR TEMP SENSORS

General

The flight crew uses the flight deck temperature control on the P5 overhead panel to set the target temperature for the flight deck. The low temperature value (C on the control) is 65 F (18 C). The high temperature value (W on the control) is 85 F (29 C).

The manual area on the flight deck temperature control is spring-loaded to MAN. In the W or C positions the flight deck temperature control sets the position of the flight deck trim air modulating valve.

Automatic Mode

The left CTC controls the flight deck trim air modulating valve to keep the zone temperature at the target value. The valve open and close commands go from the left CTC through the contacts of the auto/manual control flight deck trim air relay. The RVDT of the flight deck trim air modulating valve gives valve position to the left CTC. Flight deck sensors send actual temperature data to both CTCs.

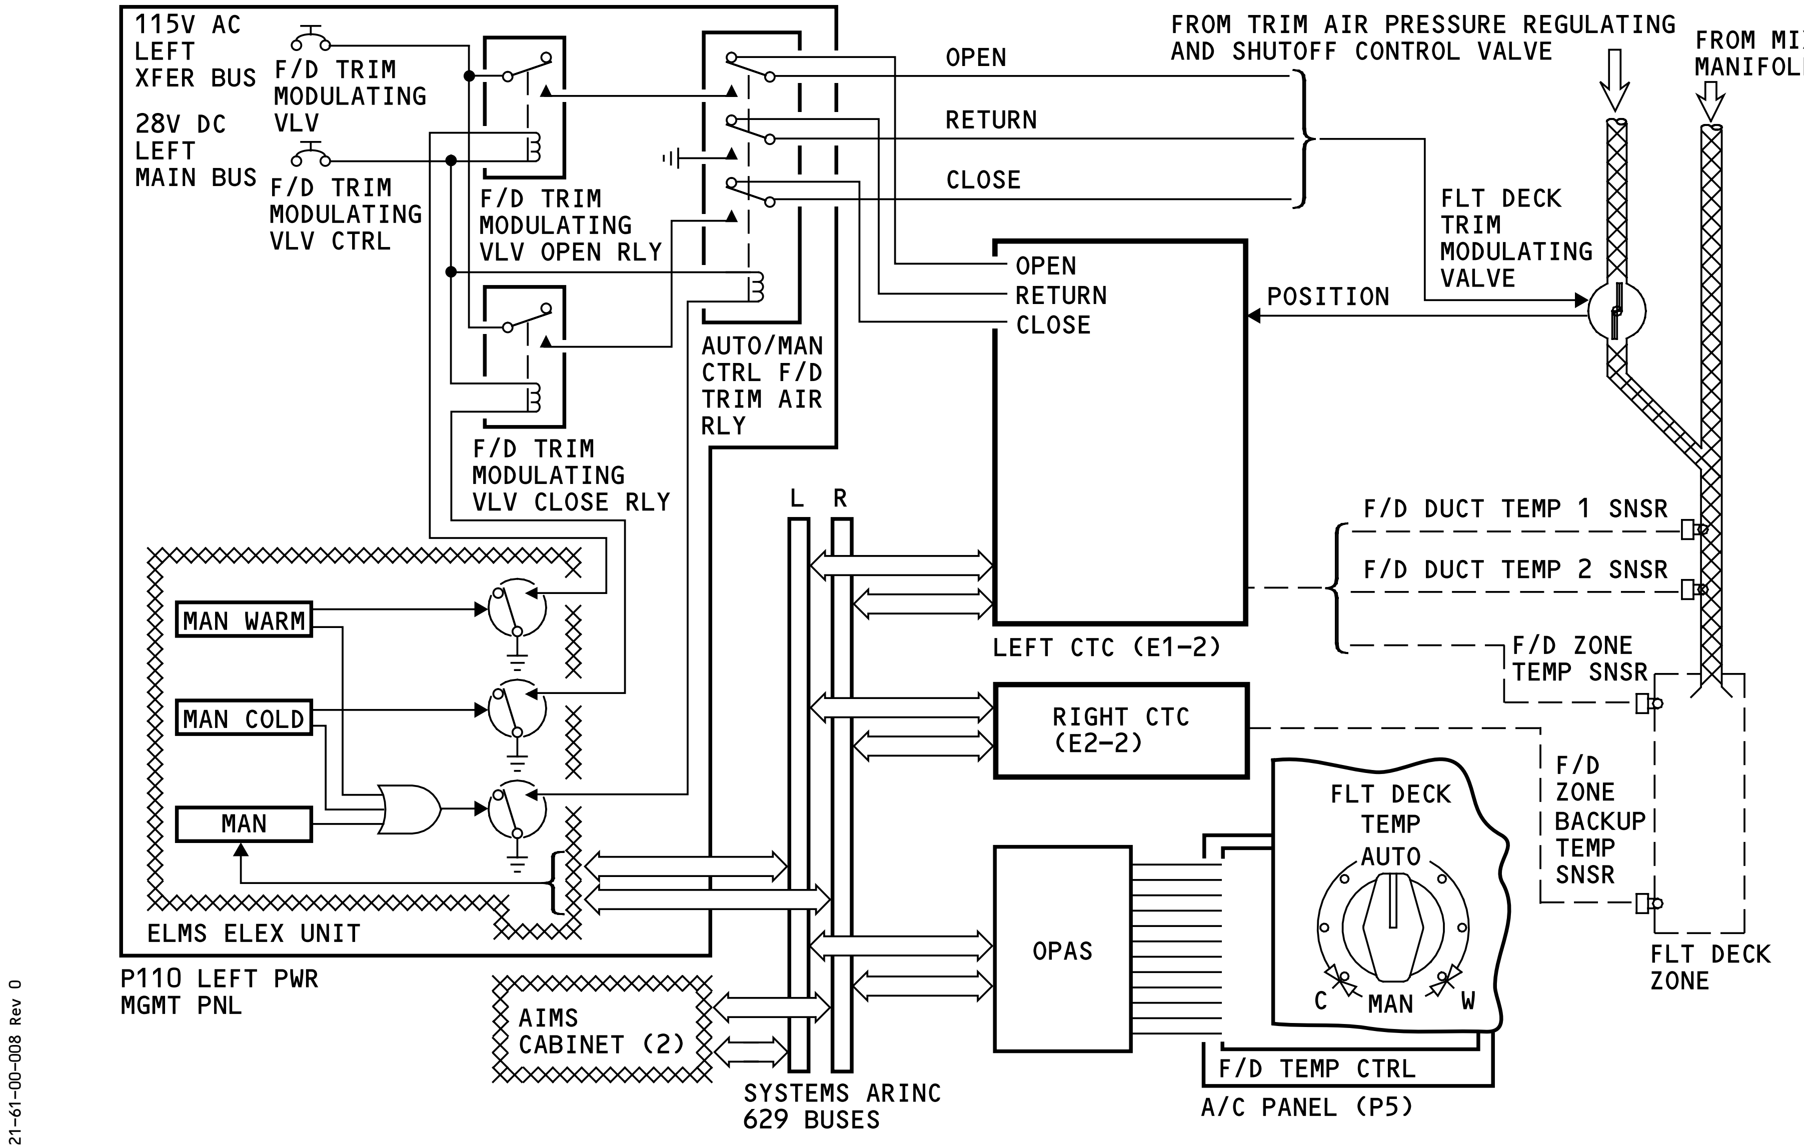
Manual Mode

With the flight deck temperature control in MAN the electrical load management system (ELMS) electronics (ELEX) unit removes control of the flight deck trim air modulating valve from the CTC.

In the W position the ELMS ELEX unit supplies power to the open coil of the flight deck trim air modulating valve.

In the C position the ELMS ELEX unit supplies power to the close coil of the flight deck trim air modulating valve.

When released, the flight deck temperature control moves back to the MAN position. In this position no power is at the contacts of the auto/manual control flight deck trim air relay. This keeps the trim air modulating valve in the set position.



AIR CONDITIONING - ZONE TEMP CTRL AND INDICATION - FLIGHT DECK FUNCTIONAL DESCRIPTION

General

The cabin temperature control on the air conditioning panel sets the master temperature value for all cabin areas. The low temperature value (C on the control) is 65F (18C). The high temperature value (W on the control) is 85F (29C).

The number of cabin areas will not always be the same as the number of temperature control zones. Each cabin area may have one or more temperature control zones. The number of cabin areas is set by the CSS configuration database. See the cabin services system section for more information about the configuration database (AMM PART I 23-39).

The cabin temperature screen on the cabin system control panel (CSCP) or on the cabin area control panels (CACP) lets you adjust the temperature in each cabin area. You can set the temperature in each area plus or minus 10F (6C) from the master temperature value set on the air conditioning panel. You cannot set the temperature in the cabin areas below 65F (18C) or above 85F (29C).

Cabin Zone Temperature Control

The CTCs calculate a zone target temperature for each temperature control zone. The zone target temperature is used in other calculations for the control of these components:

- Zone trim air modulating valves
- Zone trim air PRSOV (backup control if the modulating valve fails open)
- Second stage turbine bypass valve (A/C pack component)
- Low limit valve (A/C pack component)
- Ram air actuator (A/C pack component).

The CTCs use these inputs to calculate the zone target temperatures:

- Selected master temperature from the CABIN TEMP control
- Bias to the master temperature (± 10F, 6C) from the CABIN TEMPERATURE screen
- Airplane at cruise data from the FMCF of AIMS, auto comfort correction bias.

The zone target temperatures shows on these screens:

- Cabin temperature screen, CSCP/CACP
- Air synoptic display
- Air conditioning maintenance page.

The airplane at cruise condition causes the CTCs to adjust the cabin temperature up. This function is called the auto comfort correction. The correction makes sure the cabin stays at a comfortable temperature when the airplane skin get cold.

Zone air temperature sensors send the CTCs actual compartment temperature data. The CTCs set the actual compartment temperatures equal to the average of elements 1 and 2. If there are two sensors in a temperature control zone, the appropriate CTC averages the data from both sensors.

If both elements of the zone air temperature sensor fails, the CTCs use the duct temperature sensors as an alternate. This is called the alternate mode. The alternate mode does not give the best control. The cabin area temperature may need adjustment to keep the temperature at a comfortable level.

The lavatory/galley ventilation system pulls cabin air across the zone air temperature sensors. If the lavatory/galley ventilation system is off, the CTCs use the alternate mode to calculate the necessary duct temperatures for all temperature control zones.

Zone Duct Temperature Control

The CTCs calculate a zone duct target temperature for each temperature control zone. The target temperature has a high and a low limit. The high limit is 160F (71C) and the low limit changes with altitude. These are the low limits:

- 35F (1.7C) when the airplane is less than 29,000 feet (8845 meters)
- Decreases to 29F (-1.7C) when the airplane is at 31,000 feet (9455 meters)
- Decreases to 21F (-6C) when the airplane is at 35,000 feet (10,675 meters) or above.

The CTCs use zone duct temperature data to control the position of the trim air modulating valves. The CTCs use the data to calculate the necessary A/C pack outlet temperatures. See the zone temperature control and indication - zone temperature calculation page in this section for more information about the calculation of the trim air modulating valve position and the calculation of the necessary A/C pack outlet temperature. The CTCs also used the data to control one or both of the trim air PRSOVs when a trim air modulating valve fails open. See the trim air pressure regulation and shutoff control section for more information about the control of the trim air PRSOV (AMM PART I 21-62).

Zone duct temperature sensors send the CTCs duct temperature data. The CTCs set the duct temperature equal to the average of sensors 1 and 2. The CTCs make a zone duct temperature error signal for each temperature control zone. The CTCs move the trim air modulation valves to supply the quantity of trim air to keep the duct temperature at the target value.

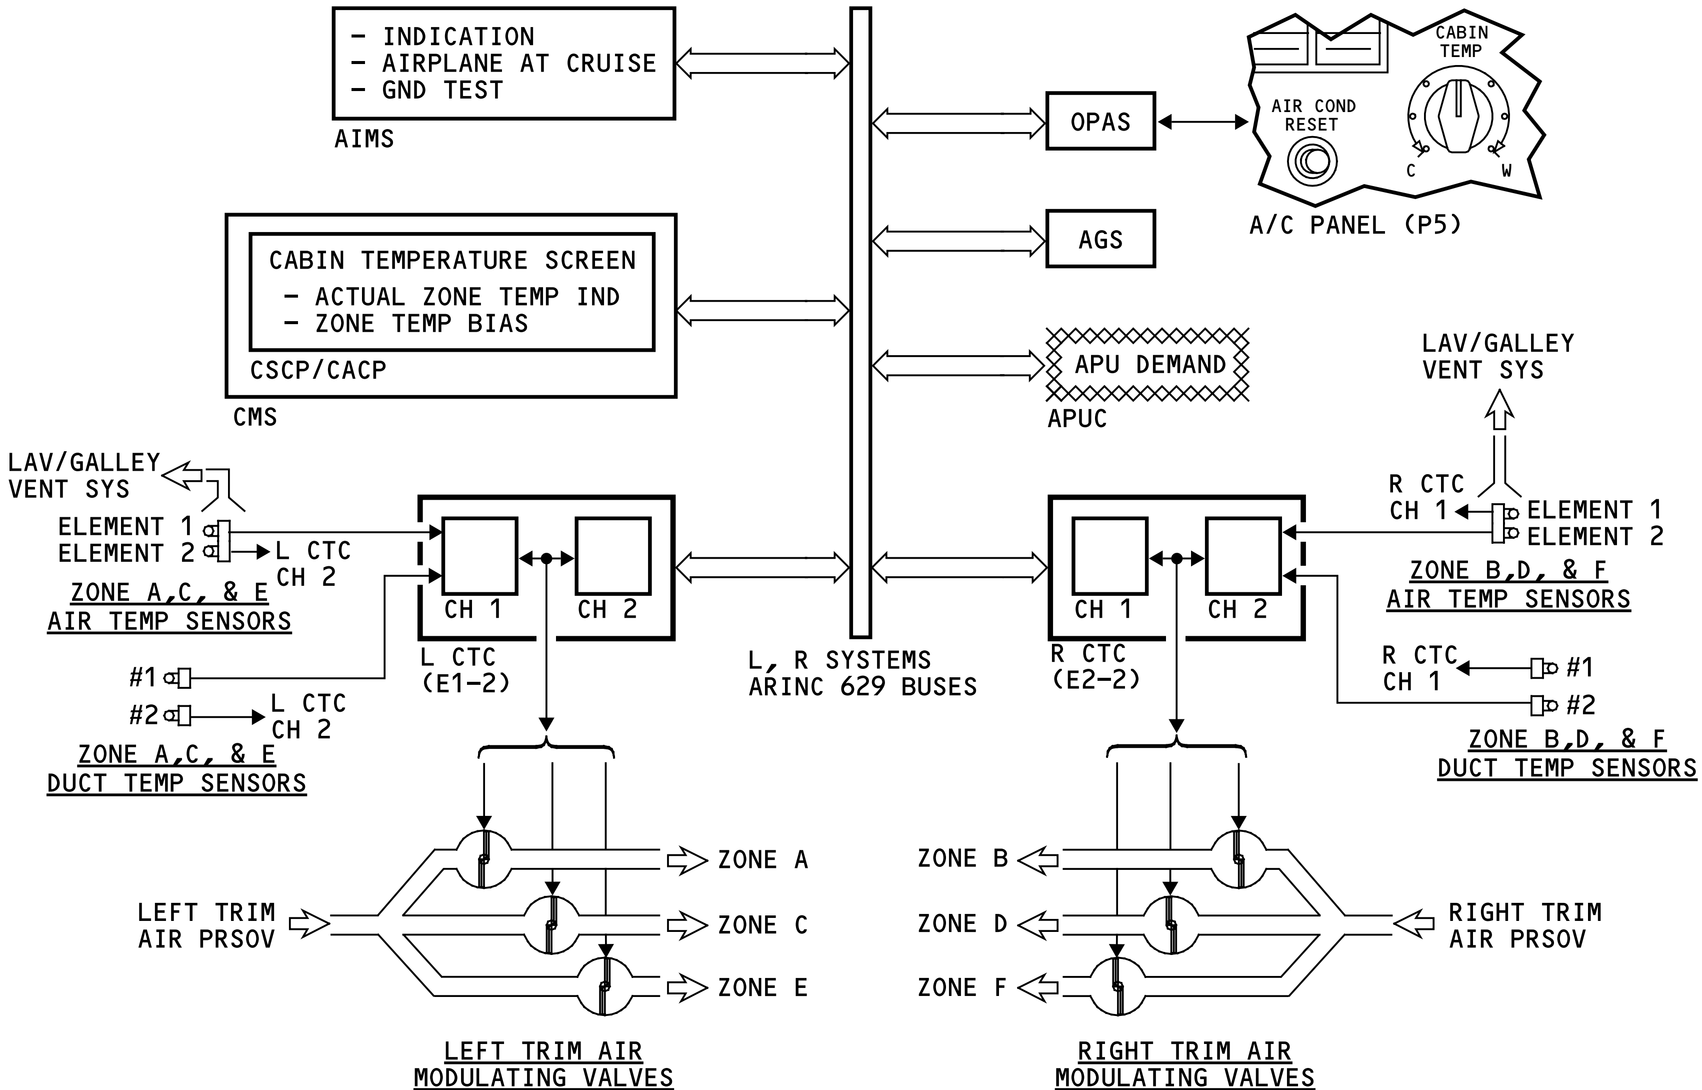
APU DEMAND

When the APU gives air for pack operation on the ground, the right CTC calculates the quantity of air necessary for ventilation and for heating or cooling. The CTC compares these inputs to calculate the APU demand signal:

- Zone duct temperature error signal for the most cooling
- Zone duct temperature error signal for the most heating

- Passenger seat count
- A preset minimum limit.

The CTC calculates the APU demand signal and sends it to the APUC. The APUC controls the quantity of air to the packs and the trim air system.



AIR CONDITIONING - ZONE TEMP CTRL AND INDICATION - CABIN ZONE FUNCTIONAL DESCRIPTION

21-61-00-009 Rev 1 04/10/1997

AIR CONDITIONING - TEMPERATURE CONTROL - FUNCTIONAL DESCRIPTION

General

Warm trim air from the pneumatic system mixes with cold air from the mix manifold to keep each zone temperature at its target value. The cabin temperature controllers (CTCs) use the trim air pressure regulating and shutoff valves (PRSOVs) to keep the trim air pressure between 2 and 8.5 psi above cabin pressure. The CTCs control the trim air modulating valves to add the necessary quantity of warm air for zone temperature control.

The CTCs use sensors in the ducts and at zone locations to monitor air temperature for control.

The CTCs sets the packs to supply the coldest air necessary for the zone that needs the lowest mix manifold temperature. Zones that need higher temperatures get pack air mixed with trim air. The CTCs set each trim air modulating valve to keep the related zone at its target temperature.

Normal Function

The flight crew sets target temperatures for the flight deck and the master temperature for the passenger cabin. The minimum selectable temperature is 65F (18C) and the maximum is 85F (29C). The cabin crew can adjust the target temperature for each zone in the passenger cabin. This temperature can be 10F (6C) higher or lower than the master temperature set by the flight crew.

Immediately after an engine start the ASCPCs sends flow schedule 1 to the CTC. The CTC sets the trim air pressure regulating and shutoff valves to the open position while the ASCPC tests its control over these valves. When the ASCPC completes this test, the CTC sets the valves to the correct position, and the ASCPC releases control. The usual pressure for the trim air PRSOVs is 5 psi above cabin pressure.

The CTC closes the trim air pressure regulating and shutoff valves for these conditions:

- CTC channel 1 and 2 failed
- Pack flow at flow schedule 4
- Stall recovery
- Trim air pressure sensor failed
- Trim air switch set to OFF
- Duct temperature greater than 190F (88C).

Both trim air pressure regulating and shutoff valves function if at least one pack operates.

When the APU supplies air for pack operation and airplane ventilation, the CTCs tell the APUC the quantity of air to supply with the APU DEMAND signal. See the zone temperature control and indication section for more information about the APU DEMAND signal (AMM PART I 21-61).

Non-Normal Function

These conditions cause non-normal operations:

- Loss of left side trim
- Loss of right side trim

- Overheat conditions (190F, 88C)
- Single trim modulating valve failure.

Loss of Left Side Trim

If there is a failure of the left side trim system, the left CTC sets the left pack to hold the flight deck target temperature. The right CTC sets the right pack to hold the necessary mix manifold temperature.

The left CTC decreases or increases the flight deck target temperature up to a maximum of 10F (6C) for any of these conditions:

- Average cabin zone temperature is 2F (1C) above or below the average target temperature
- Single cabin zone temperature is 5F (3C) above or below its target temperature.

This type of control lets the cabin area have priority over the flight deck. It does this when the right pack and right trim system does not keep the cabin areas at the necessary temperatures.

Loss of Right Side Trim

If there is a failure of the right side trim system, The right CTC sets the right pack to hold the necessary mix manifold temperature. The left pack follows the right pack until flight deck trim modulating valve is closed. The left CTC then controls the left pack to keep the flight deck at the target temperature down to a minimum of 65F (18C).

The left CTC does not keep the flight deck at its target temperature if the right pack operates at full heat and any of these conditions occur:

- Average cabin zone temperature is 5F (3C) below the average reference temperature
- Single cabin zone temperature is 5F (3C) below its target temperature.

When the right pack does not keep the cabin area at the necessary temperature, the left CTC increases the flight deck target temperature up to a maximum of 10F (6C).

Overheat Conditions

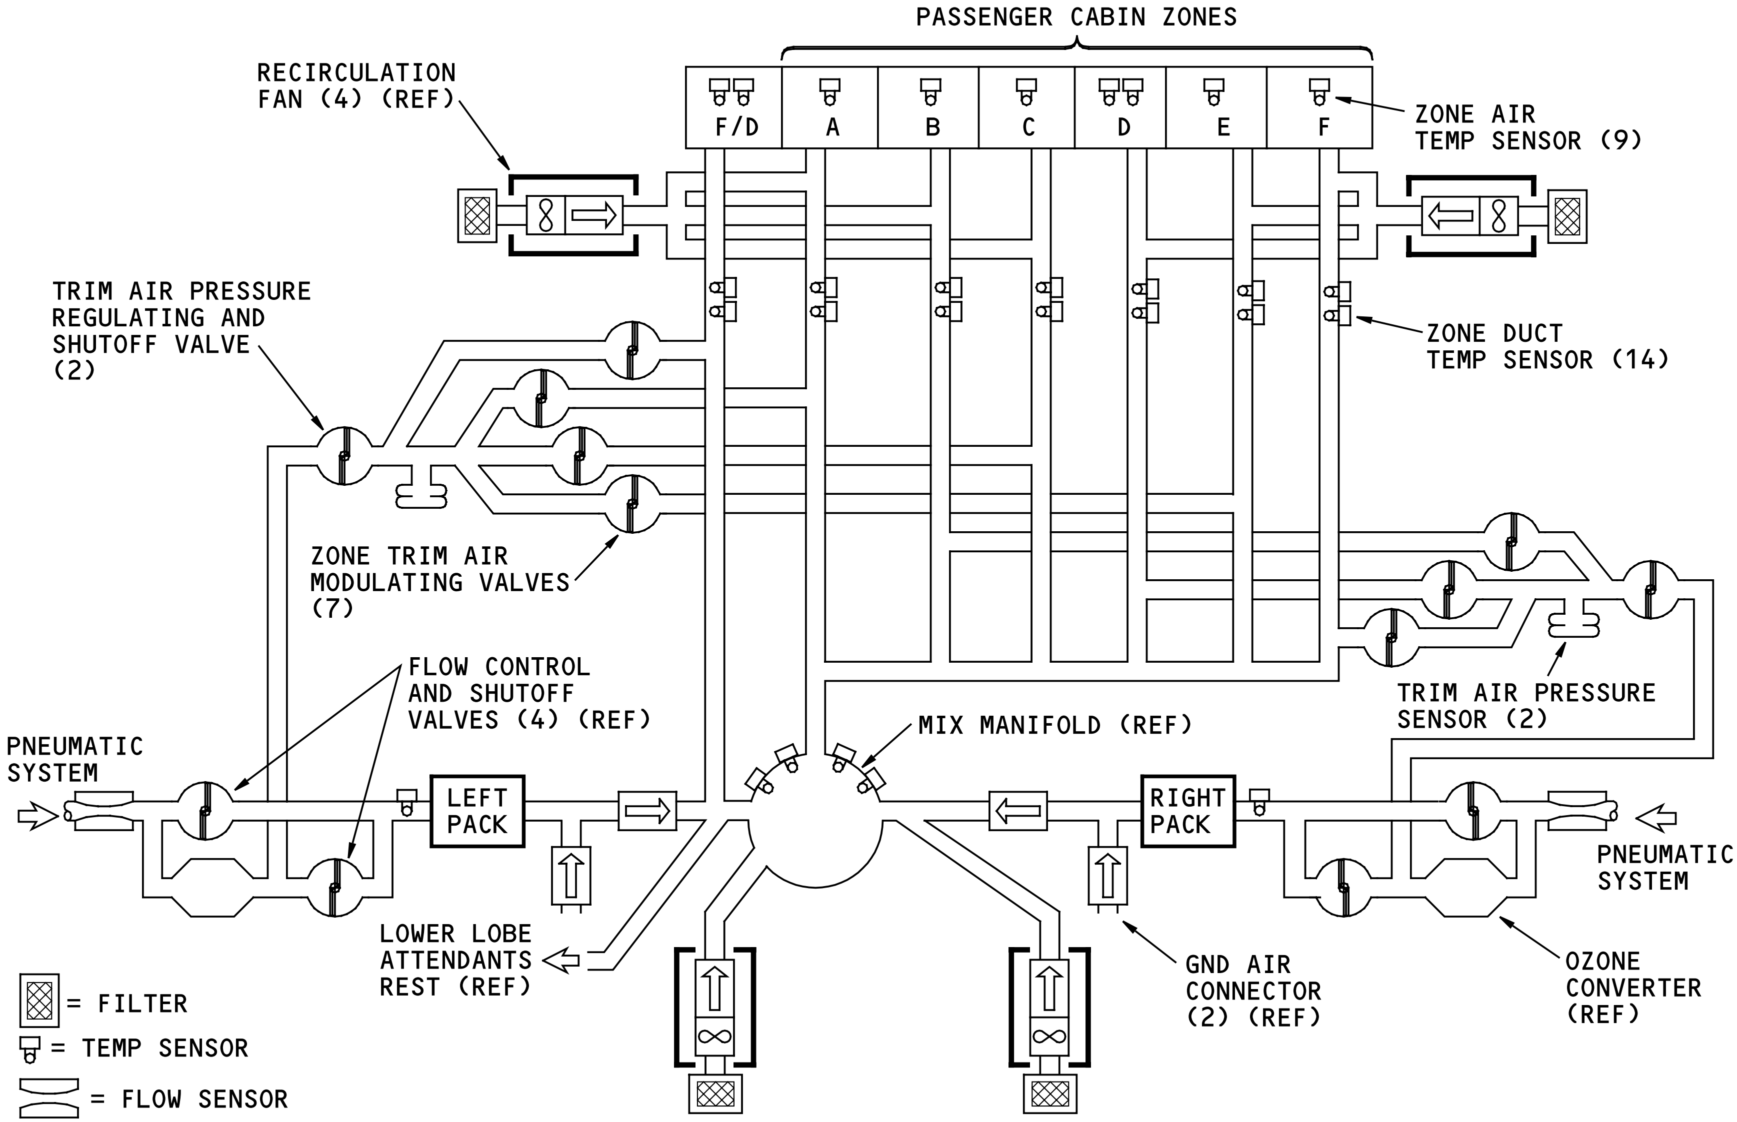
The applicable CTC starts to close the trim air modulating valve if the related zone duct air temperature increases to 160F (71C). The related trim air pressure regulating and shutoff valve latches closed if duct temperature increases to 190F (88C) for 10 seconds.

Single Trim Modulating Valve Failure

If a trim air modulating valve is not fully closed and has a failure, the applicable CTC controls the pressure reference for the related trim air pressure regulating and shutoff valve to keep zone duct temperature to a limit (zone duct temperature backup control mode). The applicable CTC does not use this mode if the valve is less than 10 degrees open (1 percent heating) and has a failure.

AIR CONDITIONING - TEMPERATURE CONTROL - FUNCTIONAL DESCRIPTION

If the RVDT in a valve has a failure, The applicable CTC operates the valve with no position feedback. This type of control is called open loop control. The applicable CTC looks at temperature change downstream of a valve to monitor movement.



AIR CONDITIONING - TEMPERATURE CONTROL - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

AIR CONDITIONING - TEMPERATURE CONTROL - OPERATION - FLIGHT DECK

General

The air conditioning panel has these controls for temperature control operation:

- Left and right trim air switches
- Flight deck temperature control
- Cabin temperature control
- Air conditioning reset switch.

Location

The air conditioning panel is on the P5 overhead panel in the flight deck.

Trim Air Control

L and R TRIM AIR switches are alternate-action switches. ON shows when you push the switch in for automatic operation of the trim system.

The applicable FAULT light and the applicable advisory message TRIM AIR L (R) (not shown) are not a function of switch position. They show when any of these conditions occur:

- The related trim air switch is set to the out position
- The related trim air PRSOV is latched closed.

The left trim air PRSOV is latched closed if any of these conditions occur:

- Flight deck zone duct overheat (190F, 88C)
- Passenger cabin zone A duct overheat (190F, 88C)
- Passenger cabin zone C duct overheat (190F, 88C)
- Passenger cabin zone E duct overheat (190F, 88C)
- Left trim air PRSOV fault
- Left CTC fault (both channels)
- Left trim air pressure sensor fault.

The right trim air PRSOV is latched closed if any of these conditions occur:

- Passenger cabin zone B duct overheat (190F, 88C)
- Passenger cabin zone D duct overheat (190F, 88C)
- Passenger cabin zone F duct overheat (190F, 88C)
- Right trim air PRSOV fault
- Right CTC fault (both channels)
- Right trim air pressure sensor fault.

Air Conditioning Reset Control

The AIR COND RESET switch is a momentary-action switch. This switch starts the system after a failure.

Flight Deck Temperature Control

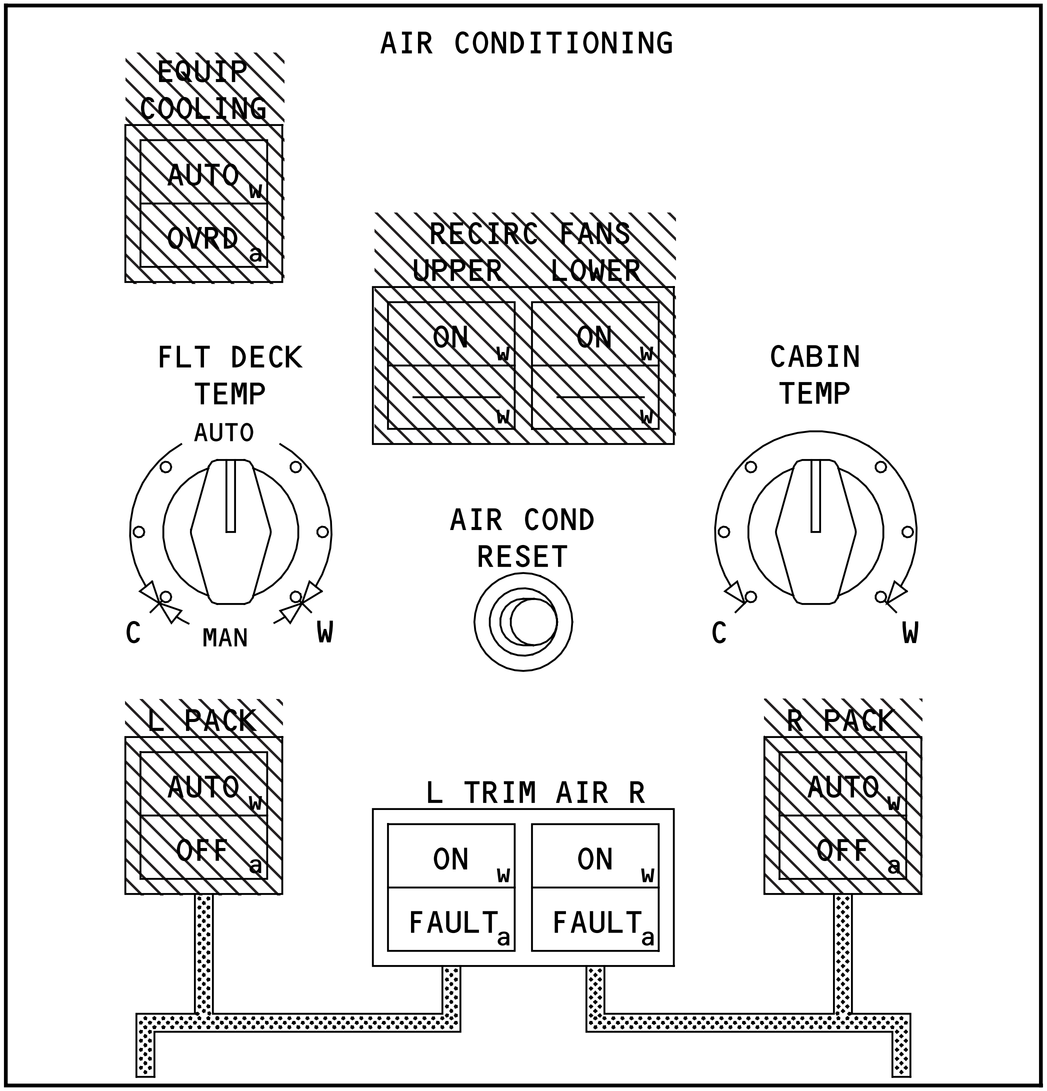
The FLT DECK TEMP control lets the flight crew set the temperature for the flight deck. The control can be set to MAN or to AUTO. The MAN position lets the flight crew manually adjust the temperature to any value. The AUTO position lets the left CTC control the temperature to a target value. The minimum selectable target temperature is 65F (18C) and the maximum is 85F (29C).

AIR CONDITIONING - TEMPERATURE CONTROL - OPERATION - FLIGHT DECK

Cabin Temperature Control

The CABIN TEMP control lets the flight crew set the master target temperature for the passenger compartment. The minimum selectable target temperature is 65F (18C) and the maximum is 85F (29C).

The left and right main buses power the FAULT indications on the trim air switches. If these buses have no power, the FAULT indication does not show.



AIR CONDITIONING PANEL

21-60-00-006 Rev 1 03/19/1997

AIR CONDITIONING - TEMPERATURE CONTROL - OPERATION - FLIGHT DECK

AIR CONDITIONING - TEMPERATURE CONTROL - OPERATION - CABIN CONTROLS

Cabin Controls

The flight attendants use the cabin system control panel (CSCP) or the cabin area control panel (CACP) to set temperatures for each passenger zone. The cabin temperature selection on the cabin controls main menu selects the cabin temperature screen.

Operation

The left and right arrows on the screen select a zone. The temperature of that zone in degrees C and degrees F is at the lower left area of the screen. The up and down arrows in the lower right area of the screen select the target temperature for that zone.

ECS Inactive

The ECS NO COMMUNICATION pop-up window shows when all of these conditions occur:

- The cabin temperature screen shows
- The CTCs do not give temperature data for more than 5 seconds.

The pop-up window goes away when the cabin temperature window does not show or when the CTCs send temperature data.

Invalid Temperature Information from ECS

The INVALID DATA message shows in the actual temperature boxes or in the target temperature box when any of these conditions occur:

- Applicable data is not supplied
- Applicable data is not in limits.

The message goes away when the temperature data is supplied and is in limits.

Training Information Point

The CSS configuration database sets the text for the AREA DESCRIPTION and sets the number of areas. The text has a limit of 40 characters. The number of areas has a limit of 15. The usual number of areas is 3. See the cabin services system section for more information about the configuration database (AMM PART I 23-39).

AIR CONDITIONING - TEMPERATURE CONTROL - AIR SYNOPTIC DISPLAY AND AIR CONDITIONING MAINT PAGE

General

All temperatures on the air synoptic display and the air conditioning maintenance page are in degrees F.

Air Synoptic Display

The top part of the MFD air synoptic display shows these cabin temperature indications:

- The MASTER box shows the cabin temperature set by the flight crew.
- The number at the left in the F/D box is the flight deck target temperature set by the flight crew. The number at the right is the actual flight deck temperature.
- The number at the left in the zone boxes A-F is the target zone temperature set by the cabin crew. The number at the right in each box is the actual zone temperature.

The flight deck trim air modulating valve position shows on the indication on the left of the display.

Normal flow of left and right trim air shows as open valve symbols and flow arrows.

Air Conditioning Maintenance Page

The top part of the air conditioning maintenance page shows these cabin temperature indications:

- MASTER TEMP - Temperature selected on the cabin temperature control on the P5 panel
- ZONE TEMP - Actual temperature in each zone
- TRGT TEMP - Target (selected) temperature for each zone
- DUCT TEMP - Temperature measured in each zone distribution duct
- TRIM VLV - Position of each trim air modulating valve in percent heat (0.00 is closed, 1.00 is open)
- CTRL CH - Shows which CTC channel is in control. Left CTC controls zones F/D, A, C, & E. Right CTC controls zones B, D, & F
- TRIM AIR PRESS - The difference, in psid, between cabin pressure and trim air pressure.

See the primary display system section for more information about the air synoptic display and the air conditioning maintenance page (AMM PART I 31-61).

AIR CONDITIONING - TEMPERATURE CONTROL - GROUND TESTS

General

These are the temperature control ground tests that show when you select ATA 21 Cabin Temperature Control System:

- Left cabin temperature controller
- Right cabin temperature controller
- Left trim air system
- Right trim air system.

Left and Right Cabin Temperature Controller

These tests make sure that the related cabin temperature controller can change control between channels 1 and 2. This test also does a continuous built-in-test.

The test takes approximately 1-2 minutes.

This test shows for these ground test types:

- Operational test
- LRU replacement test.

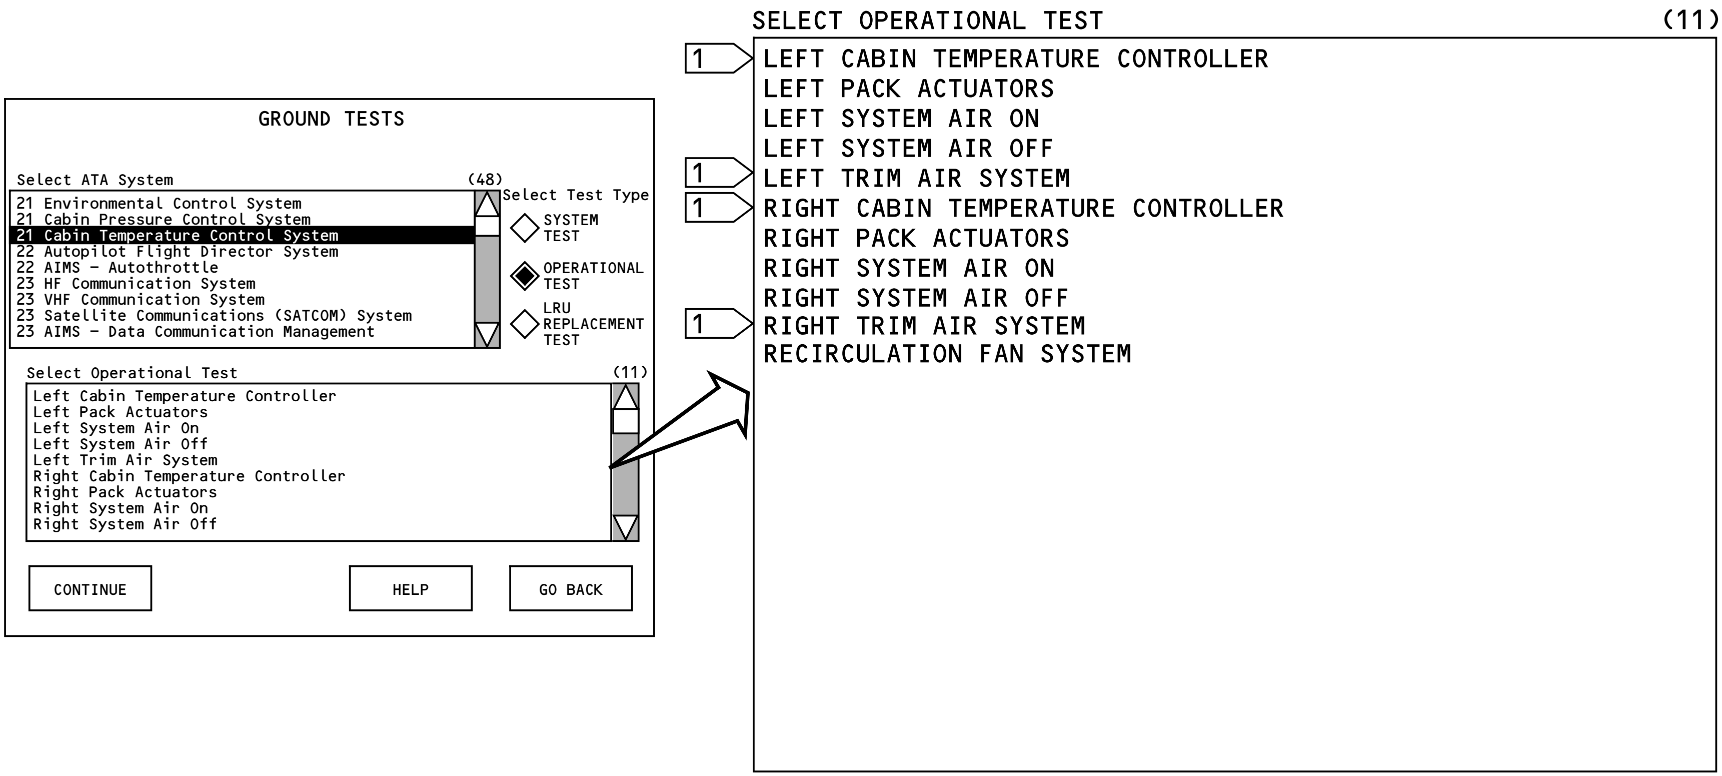
Left and Right Trim Air System

This test makes sure that the related cabin temperature controller can control the trim air modulating valves of the trim air system on that side.

You must pressurize the pneumatic system for this test. During this test, the related trim air modulating valves open one at a time. The test takes approximately 2-3 minutes.

This test shows for these ground test types:

- System test
- Operational test
- LRU replacement test.



NOTE: OPERATIONAL TESTS SHOW.
LRU REPLACEMENT TESTS ARE THE SAME.
SYSTEM TESTS DO NOT INCLUDE LEFT AND RIGHT CABIN TEMPERATURE CONTROLLER.

1 THESE ARE THE AIR CONDITIONING - TEMPERATURE CONTROL TESTS.

21-60-00-010 Rev 1 08/17/96

AIR CONDITIONING - TEMPERATURE CONTROL - GROUND TESTS

AIR CONDITIONING - DISTRIBUTION - INTRODUCTION

General

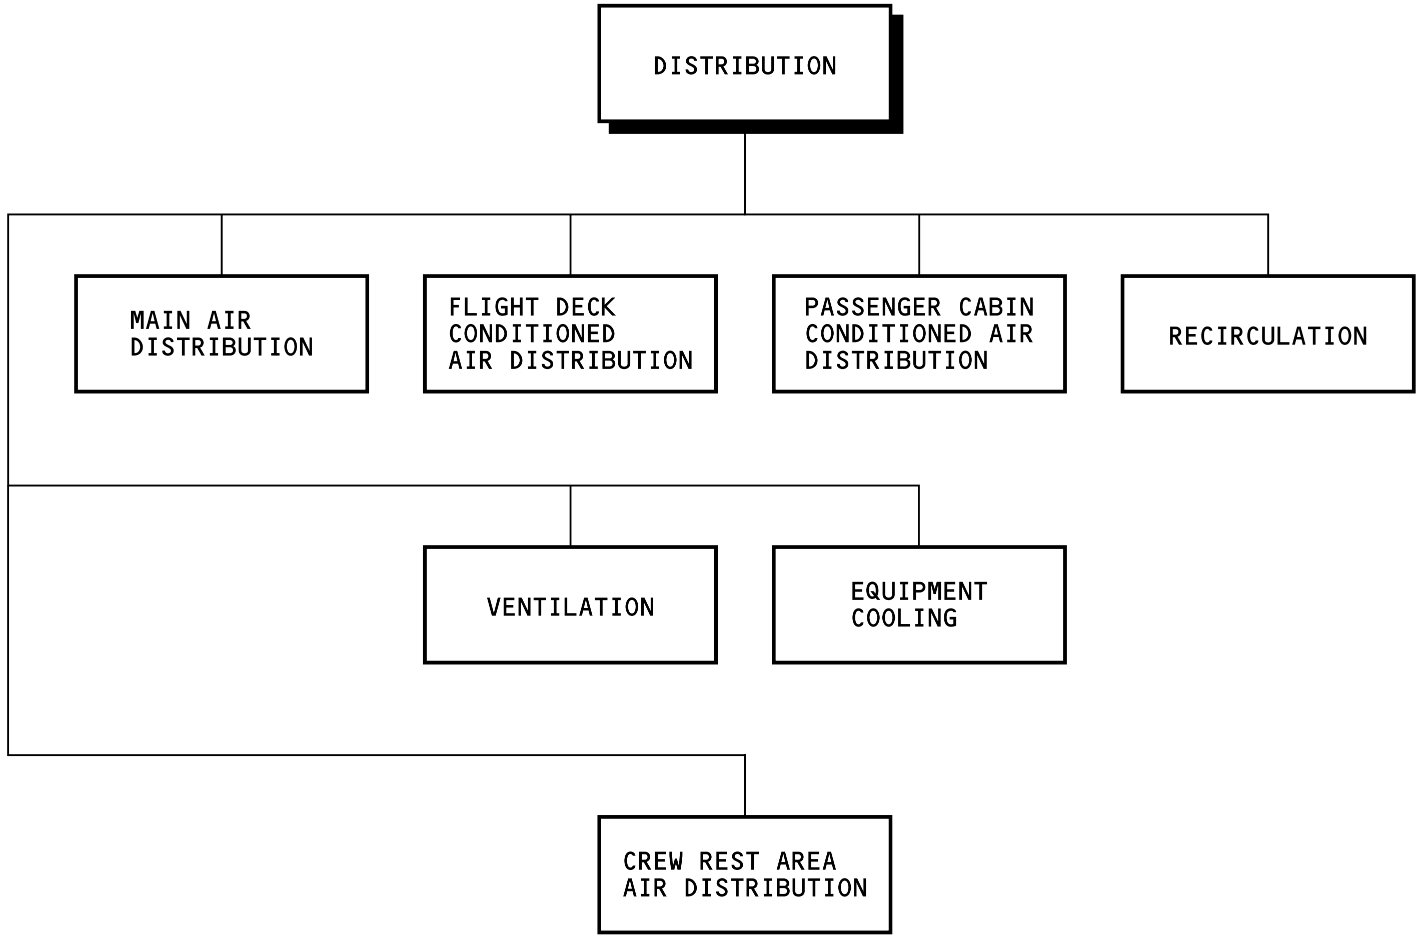
The distribution system has these parts:

- Main air
- Flight deck conditioned air
- Crew rest area air
- Passenger cabin conditioned air
- Recirculation
- Ventilation
- Equipment cooling.

The distribution system lets air from the packs and mix manifold flow to locations in the flight deck, crew rest area, and passenger compartment. The ventilation part of the system removes odors from the lavatories and galleys. The equipment cooling part of the system cools electrical and electronic equipment.

See the distribution - ventilation section for more information about the ventilation in the airplane (AMM PART I 21-26).

See the equipment cooling section for more information about the forward and aft equipment cooling systems (AMM PART I 21-27).



21-20-00-001 Rev 6 10/28/1997

AIR CONDITIONING - DISTRIBUTION - INTRODUCTION

AIR CONDITIONING - DISTRIBUTION - GENERAL DESCRIPTION

General

The distribution system includes ducts and fans that move conditioned and recirculated air through the airplane.

Main Air Distribution

Air from the packs flow through the main air distribution ducts to these locations:

- Flight deck distribution
- Mix manifold.

Mix Manifold

The usual flow of air from the mix manifold goes to the passenger cabin conditioned air distribution. The mix manifold also gives air to the flight deck conditioned air distribution if the left air conditioning pack is off. See the main air distribution section for more information about the mix manifold (AMM PART I 21-21).

Flight Deck Conditioned Air Distribution

The flight deck distribution duct lets conditioned air go from the left pack to the flight deck and to the flight crew rest area. See the flight deck conditioned air distribution section for more information about air distribution to the flight deck and to the flight crew rest area (AMM PART I 21-22).

Lower Lobe Attendants Rest Conditioned Air Distribution

An air distribution duct for the optional lower lobe attendants rest attaches to the left pack outlet duct, upstream of the mix manifold.

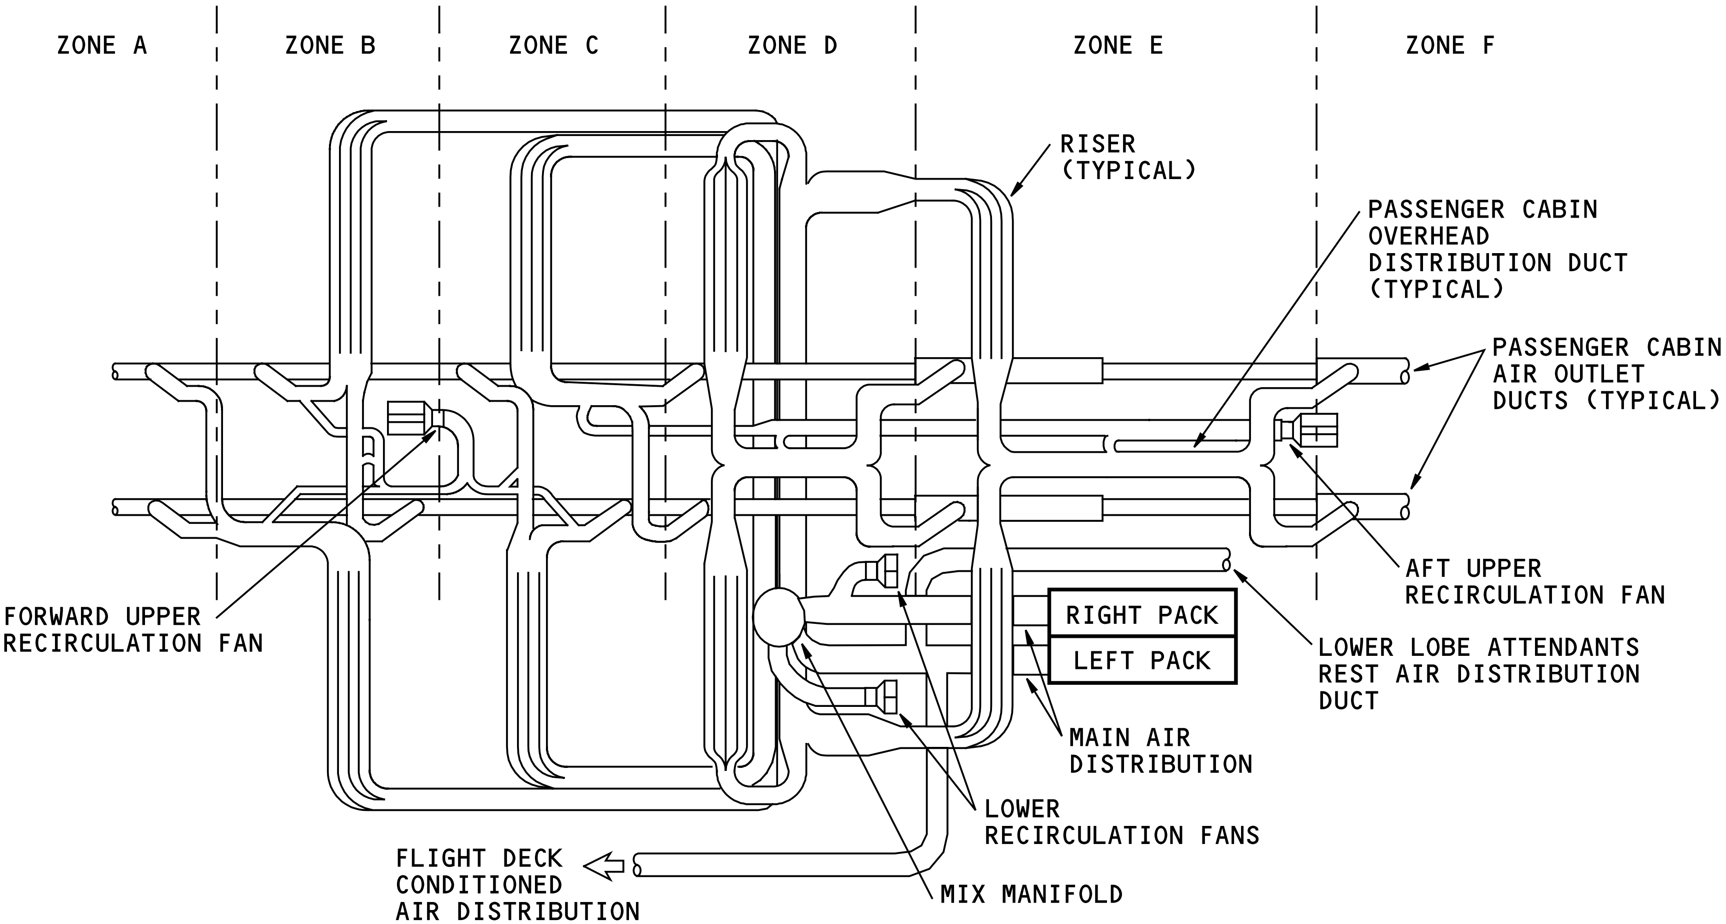
Passenger Cabin Conditioned Air Distribution

Eight risers carry air from the mix manifold, below the passenger cabin floor to the overhead distribution ducts above the passenger cabin ceiling. The overhead distribution ducts carry the air to the air outlet ducts in each of the passenger zones. See the passenger cabin conditioned air distribution section for more information about air distribution to the passenger cabin (AMM PART I 21-23).

Recirculation

Air from the lower recirculation fans mix with the conditioned air in the mix manifold. Air from the upper recirculation fans mix with the conditioned air in the overhead distribution ducts. See the recirculation system section for more information about the recirculation air distribution (AMM PART I 21-25).

PASSENGER CABIN CONDITIONED AIR DISTRIBUTION



21-20-00-002 Rev 5 10/28/1997

AIR CONDITIONING - DISTRIBUTION - GENERAL DESCRIPTION

AIR CONDITIONING - MAIN AIR DISTRIBUTION - DUCT

General

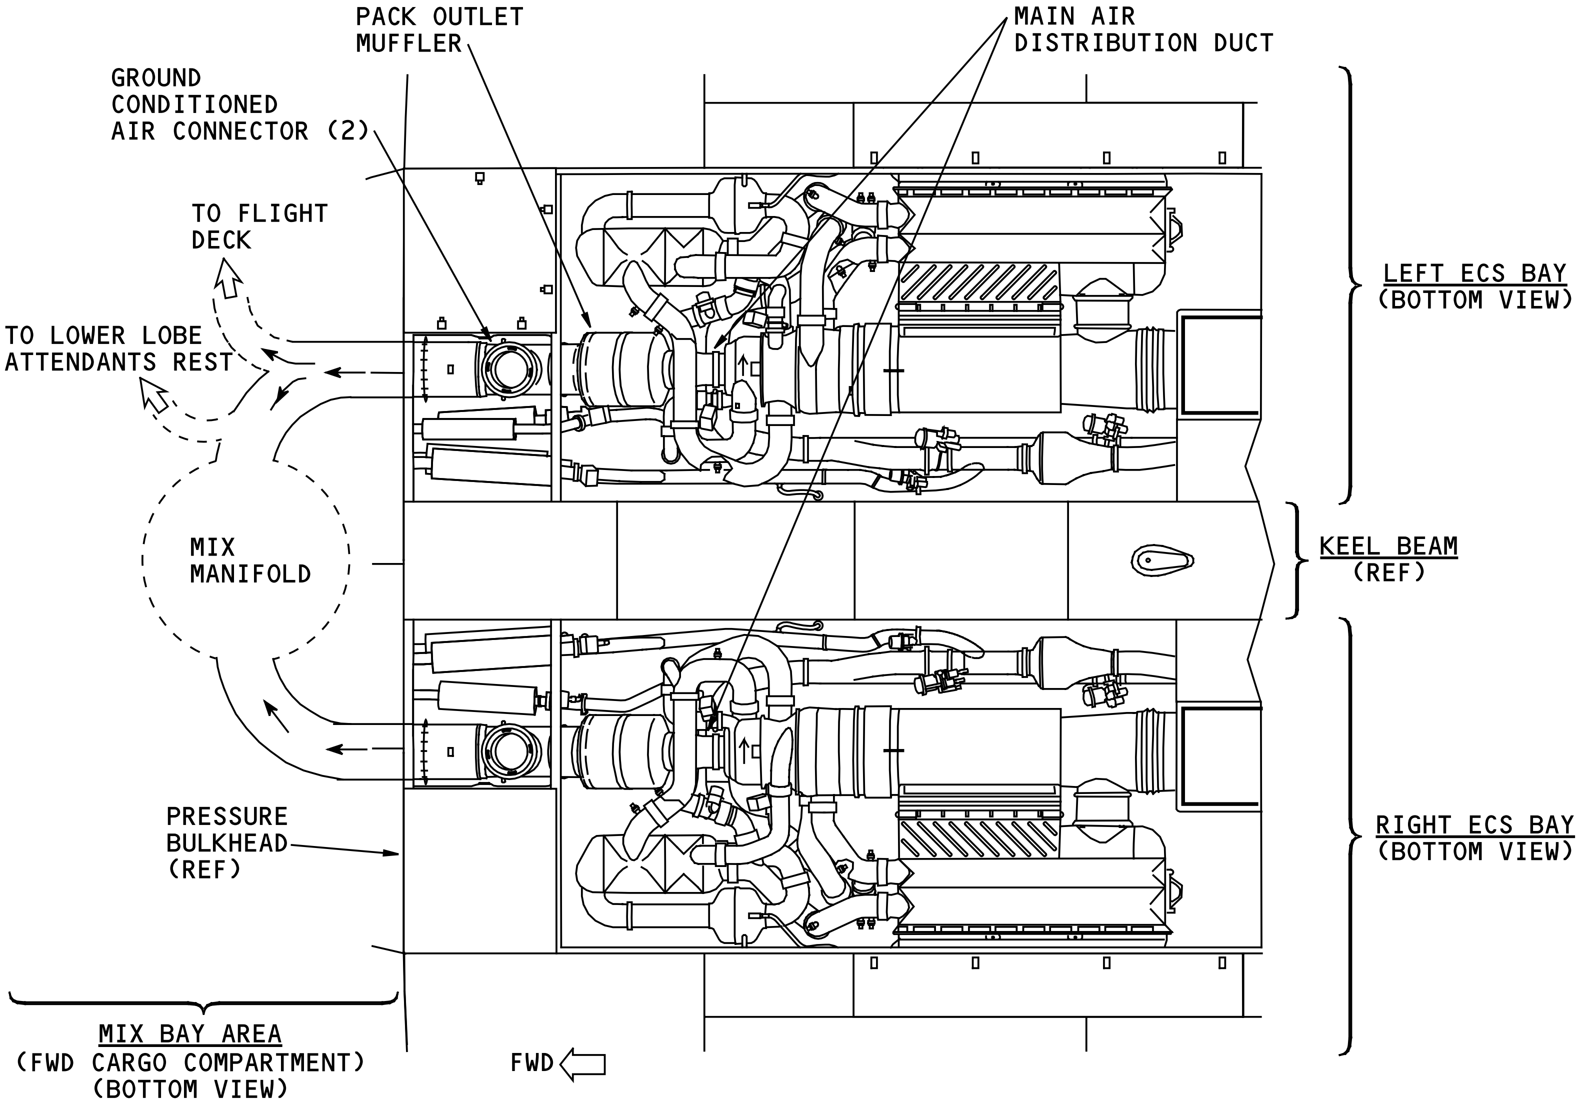
The main air distribution system moves air from the pack or ground conditioned air connector to the mix manifold. It then goes to the flight deck conditioned air distribution duct and to the lower lobe attendants rest air distribution duct.

Pack Outlet Muffler

A muffler in the pack outlet duct decreases noise in the main air distribution system.

Ground Conditioned Air Connector

The ground conditioned air connector lets ground carts supply conditioned air to the cabin zones and the flight deck. A check valve in the connector closes the opening when the pack supplies conditioned air.



21-21-00-001 Rev 6 10/07/1997

AIR CONDITIONING - MAIN AIR DISTRIBUTION - DUCT

THIS PAGE INTENTIONALLY LEFT BLANK

AIR CONDITIONING - MAIN AIR DISTRIBUTION - MIX MANIFOLD

Purpose

The mix manifold mixes fresh air from the main air distribution duct (ground conditioned air or pack air) and cabin air from the lower recirculation system.

The manifold usually gives air to the passenger cabin conditioned air distribution ducts. The manifold can also give air to the lower lobe attendants rest air distribution duct and to the flight deck conditioned air distribution duct when the left air conditioning pack is off.

Location

The mix manifold is aft of the forward cargo compartment in the mix bay area. You remove the cargo compartment end wall to get access to the manifold.

Physical Description

The outer diameter of the mix manifold is approximately 26 inches (66 cm) and is approximately 85 inches (216 cm) high. The manifold has a lower and upper part. The lower part has these features:

- A connection that is the same for the right main air distribution duct and right lower air recirculation system
- A connection for the left main air distribution duct
- A connection for the left lower air recirculation system
- Ice collection screen (internal)
- Water collector (internal)
- Water drain (3 places).

The ice collection screen is in the bottom part of the manifold. It collects ice that can form when the fresh air from the packs or a ground conditioned air source mix with hot humid recirculated air.

The manifold has three water drains at these locations:

- Forward side
- Aft side (not shown)
- Bottom (not shown).

The water drains let water move from inside the manifold to the bilge area below the manifold.

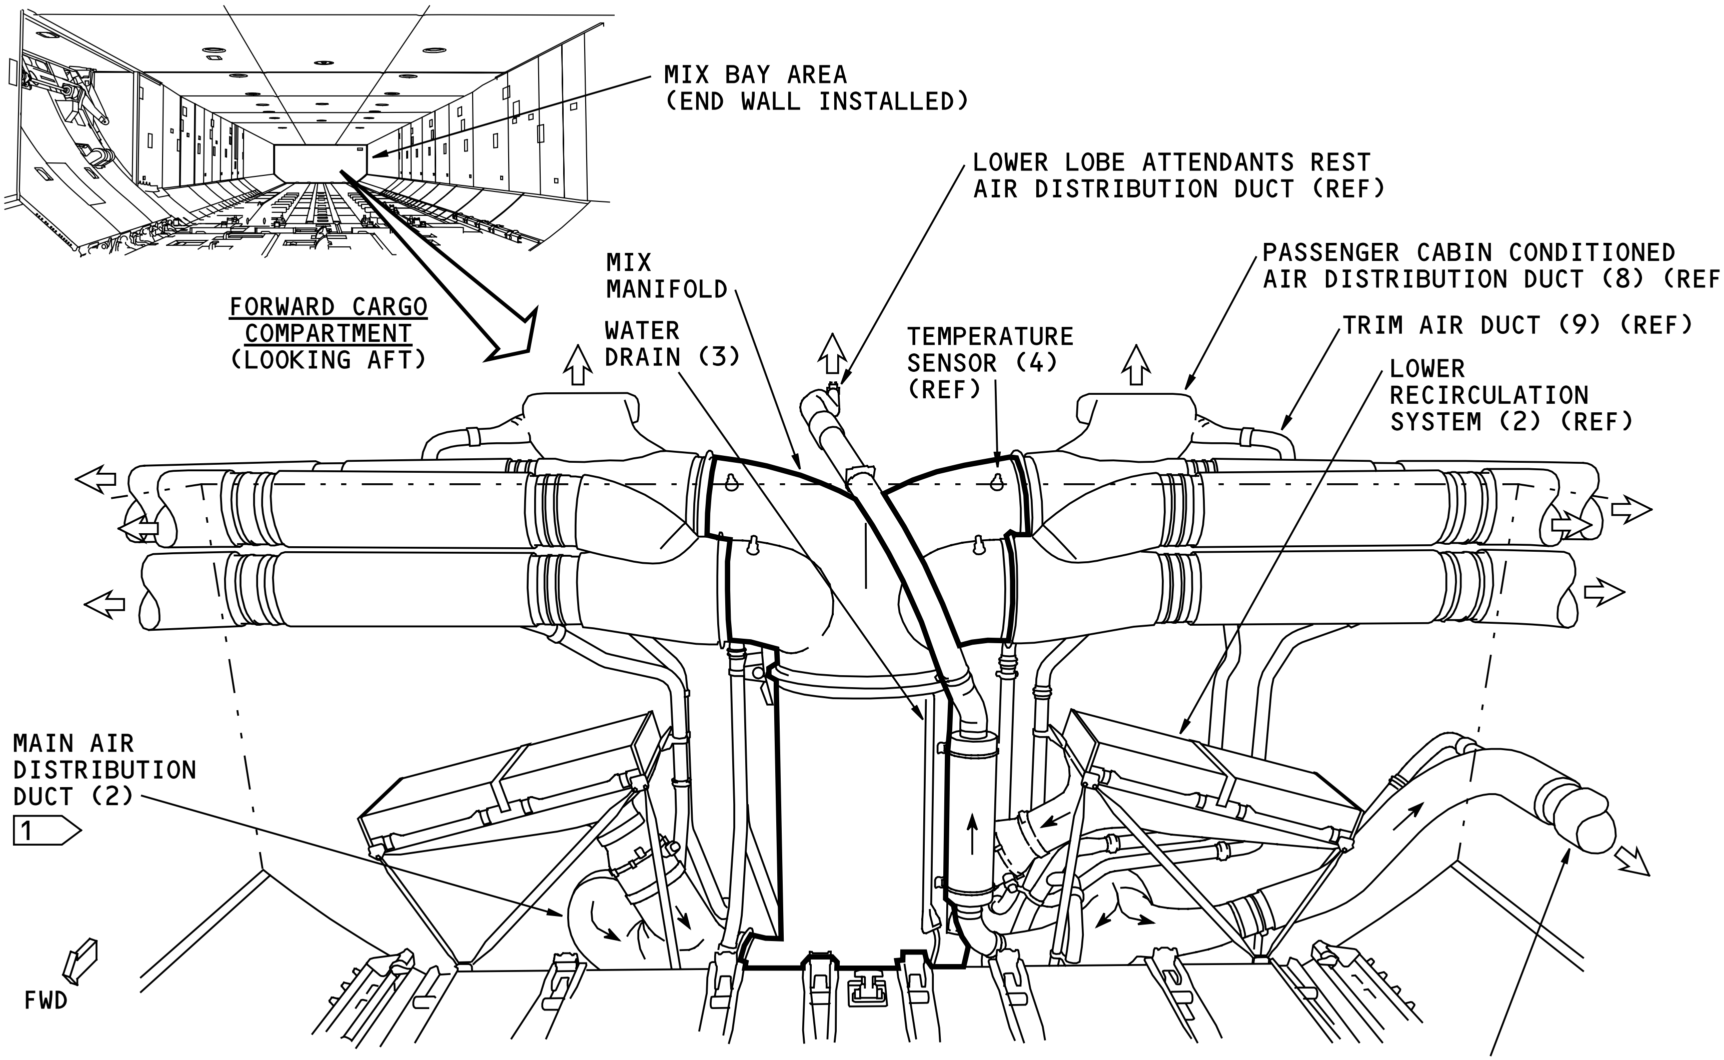
The upper part has these features:

- Four connectors for the passenger cabin conditioned air distribution ducts
- Temperature sensors for the air conditioning pack and mix manifold temperature control system.

See the pack cooling and mix manifold temperature control section for more information about the mix manifold temperature sensors (AMM PART I 21-52).

The manifold is kevlar.

The left main air distribution duct (air from left pack or a ground conditioned air source) gives air to the mix manifold, to the lower lobe attendants rest air distribution duct and to the flight deck conditioned air distribution duct.



1 GROUND CONDITIONED AIR OR PACK AIR

AIR CONDITIONING - MAIN AIR DISTRIBUTION - MIX MANIFOLD

AIR CONDITIONING - FLIGHT DECK CONDITIONED AIR DISTRIBUTION

Purpose

The flight deck conditioned air distribution system moves air from the left pack to the flight compartment. If the left pack is off, the system moves air from the mix manifold to the flight compartment.

Conditioned air for the flight crew rest area comes from the flight deck conditioned air distribution system.

Physical Description

The flight deck conditioned air distribution system has these components:

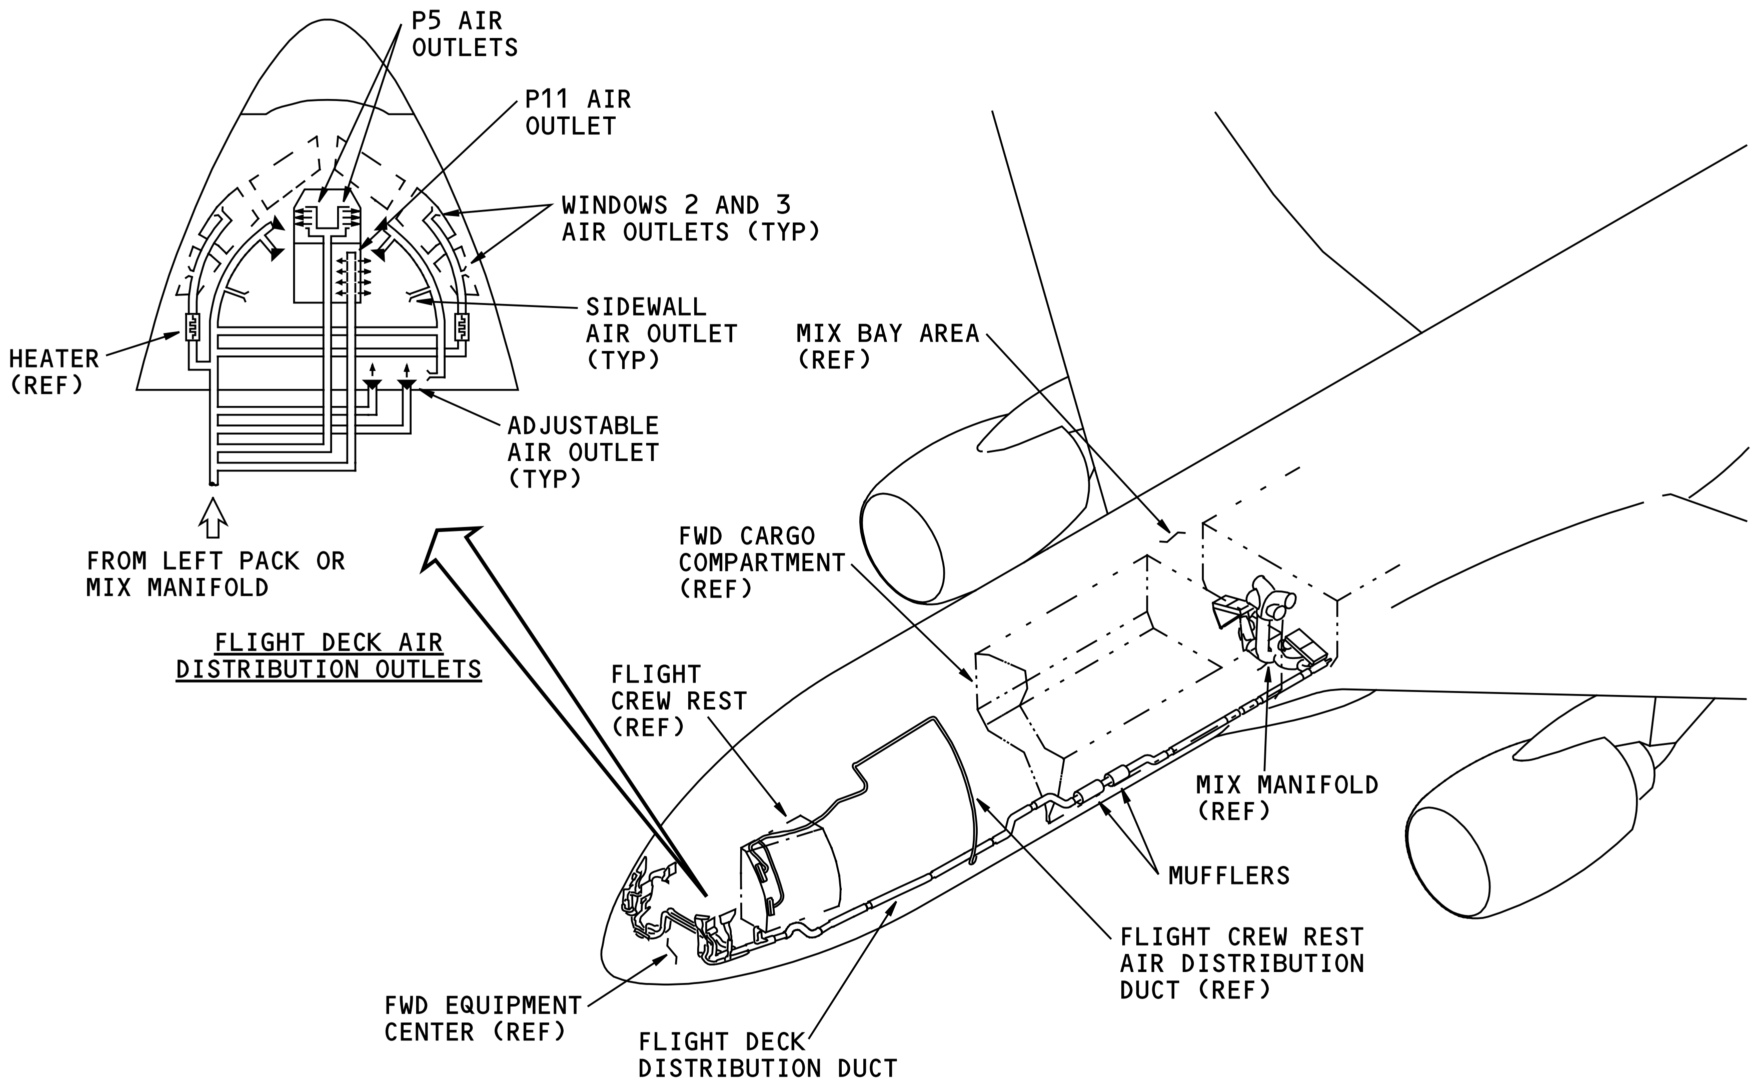
- Ducts
- Muffler (2)
- P5 air outlet (2)
- P11 air outlet
- Windows 2 and 3 air outlet (4)
- Sidewall air outlet (3)
- Adjustable air outlet (6).

Location

Components are in these areas:

- Mix bay
- Forward cargo compartment, left sidewall area
- Left side of the main equipment center
- Forward equipment center
- Flight deck.

There are ducts in all areas. Two mufflers are in the left sidewall area of the forward cargo compartment, aft of the cargo door. Air outlets are in the flight compartment.



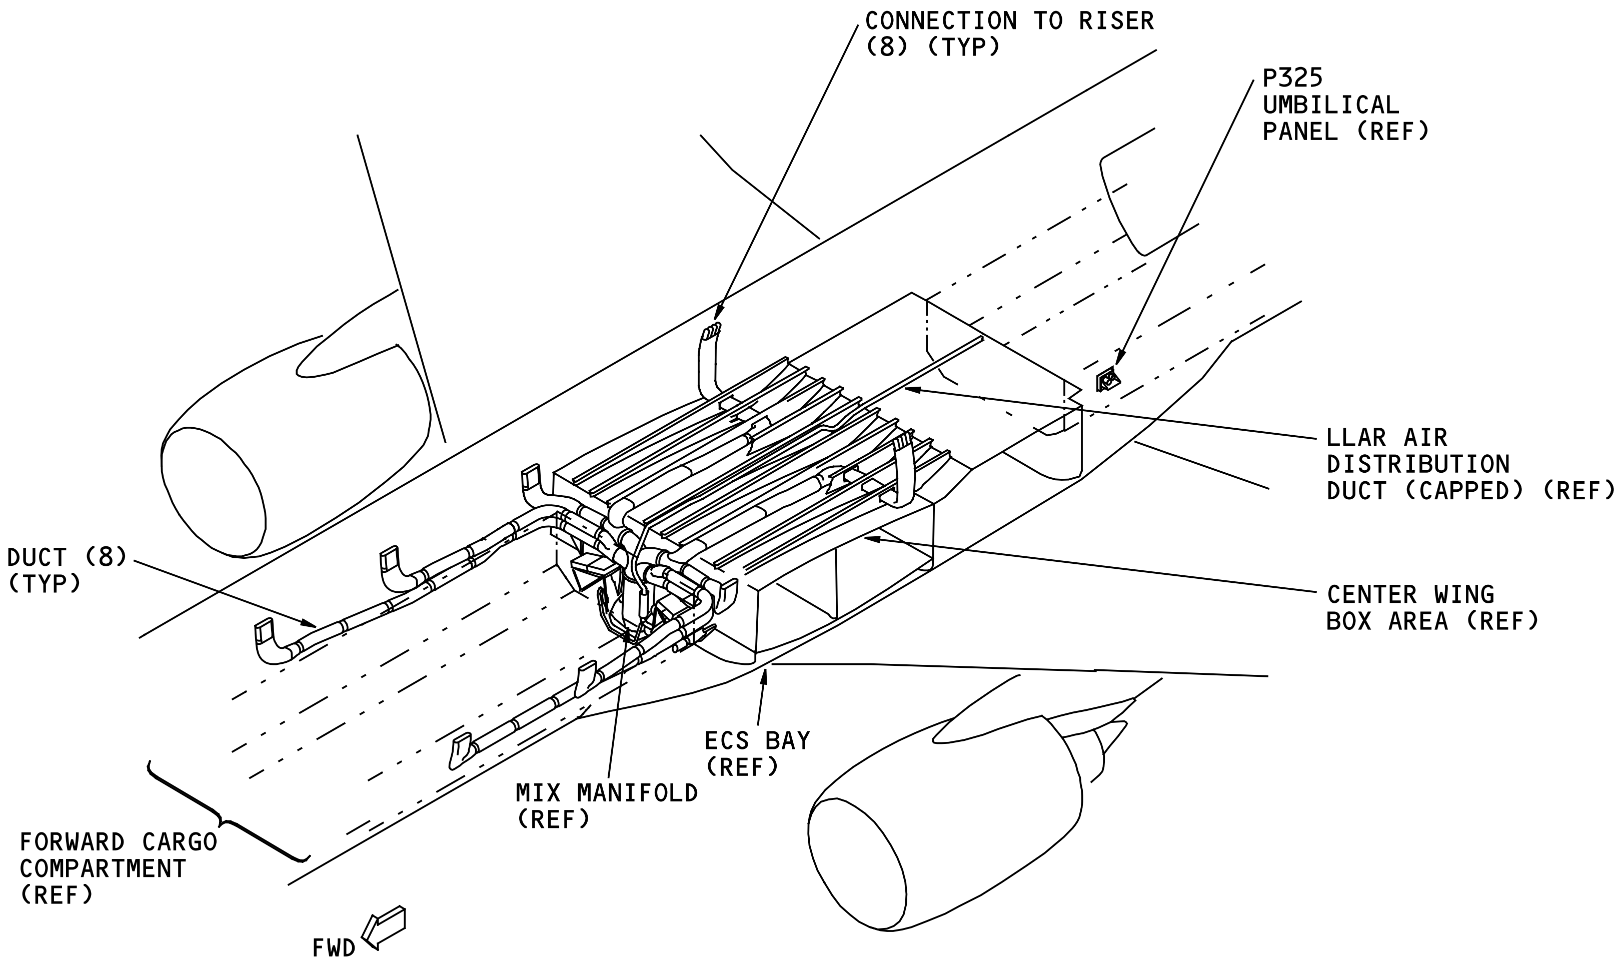
AIR CONDITIONING - FLIGHT DECK CONDITIONED AIR DISTRIBUTION

AIR CONDITIONING - PASSENGER CABIN CONDITIONED AIR DISTRIBUTION - LOWER LOBE AREA

General

The passenger cabin air distribution system moves air from the mix manifold to the passenger cabin area.

In the lower lobe area, conditioned air moves from the mix manifold through eight ducts that connect to risers. Six of the ducts are outboard of the forward cargo compartment, three on each side. Two of the ducts are above the center wing box area.



21-23-00-001 Rev 3 10/28/1997

AIR CONDITIONING - PASSENGER CABIN CONDITIONED AIR DISTRIBUTION - LOWER LOBE AREA

THIS PAGE INTENTIONALLY LEFT BLANK

AIR CONDITIONING - PASSENGER CABIN CONDITIONED AIR DISTRIBUTION - PASSENGER CABIN AREA

General

In the cabin area, the system moves conditioned air to the passenger cabin from the ducts in the lower lobe area (not shown).

The system has these components in the cabin area:

- Risers
- Overhead distribution ducts
- Air outlets.

Riser

There are eight risers, four on each side of the cabin. The risers connect the conditioned air ducts (not shown) in the lower lobe area to conditioned air ducts above the passenger cabin ceiling. To decrease noise, each riser has four round ducts that have insulation over them. The insulation also decreases the collection of water on the outside of the ducts. The risers are identified by the zone that they give air to. These are the risers:

- Zone A, first riser on the left
- Zone B, first riser on the right
- Zone C, second riser on the left
- Zone D, second riser on the right
- Zone E, third set of risers
- Zone F, fourth set of risers.

Overhead Distribution Ducts

The overhead distribution ducts connect the risers to the conditioned air outlet ducts. The ducts have different sizes and shapes. Insulation on the ducts decrease noise and the collection of water on the outside of the ducts. The ducts have connections for the upper recirculation system (not shown) and the door area heating system (not shown). See the recirculation section for more information about the upper recirculation system (AMM PART I 21-25). See the supplemental heating section for more information about the door heating system (AMM PART I 21-45).

Air Outlet Ducts

There are two air outlet ducts for each passenger cabin temperature control zone. Each zone has a duct above the left and right passenger aisles. The air outlet ducts control the flow of conditioned air into the passenger cabin zones. The air outlets ducts collect water that can be in the air from the recirculation system. Insulation on the ducts decrease noise and the collection of water on the outside of the ducts. Each duct has these parts:

- Flow straightener
- Baffle tube
- Antifungal felt
- Plenum sidewall
- Plenum duct.

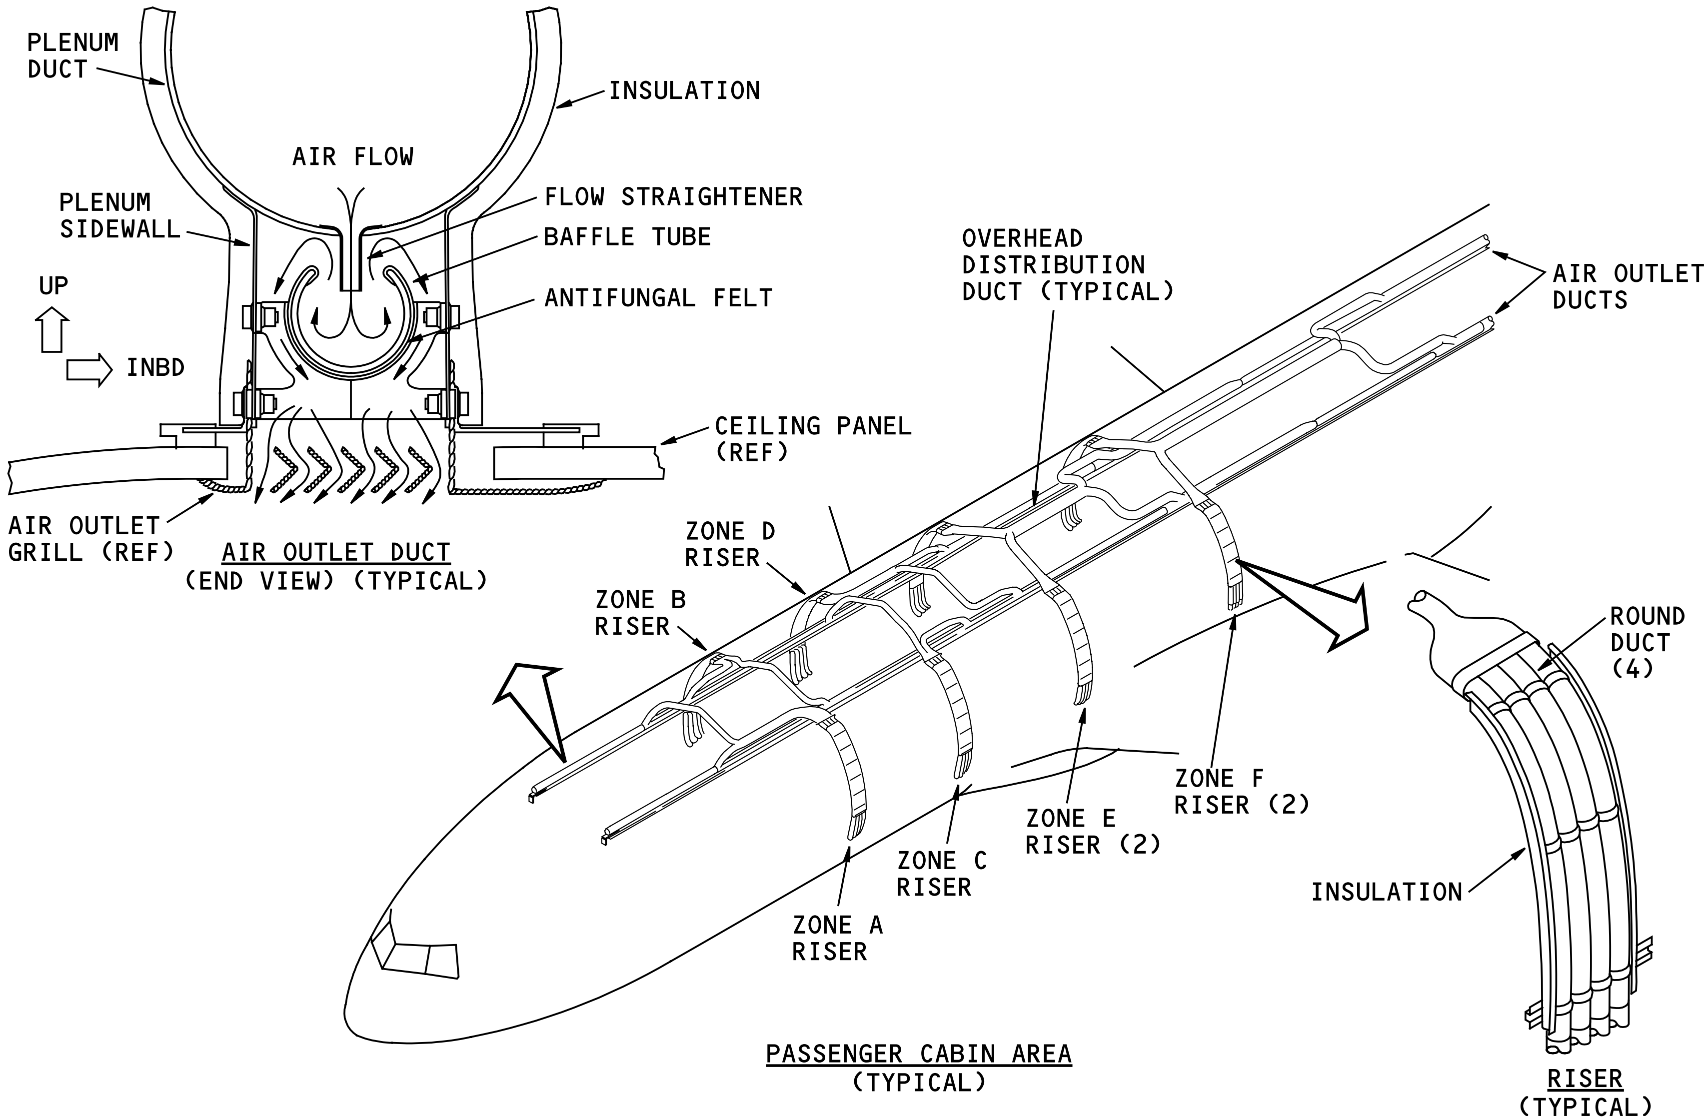
Ceiling panels and the air outlet grill attach to the lower part of the air outlet duct. See the passenger compartment section for more information about the ceiling panels and the air outlet grill (AMM PART I 25-20).

Return Air Grills

Return air grills (not shown) below the sidewall panels in the passenger cabin let air move from the passenger cabin area to the lower lobe area. Cabin air in the lower lobe can flow out of the airplane through the outflow valves or into these systems:

- Lower recirculation system
- Forward equipment cooling system
- Bulk cargo ventilation system.

See the passenger compartment section for more information about the return air grills and sidewall panels (AMM PART I 25-20).



21-23-00-002 Rev 1 10/28/1997

AIR CONDITIONING - PASSENGER CABIN CONDITIONED AIR DISTRIBUTION - PASSENGER CABIN AREA

AIR CONDITIONING - RECIRCULATION - INTRODUCTION

Purpose

The recirculation system puts cabin air back in the air conditioning distribution system.

General Description

Upper recirculation fans, above the passenger compartment ceiling pull in cabin air and put the air back in the overhead distribution ducts. Lower recirculation fans, aft of the forward cargo compartment pull in cabin air and put the air in the mix manifold.

The upper and lower recirculation fan switches on the air conditioning panel enable the operation of these fans.

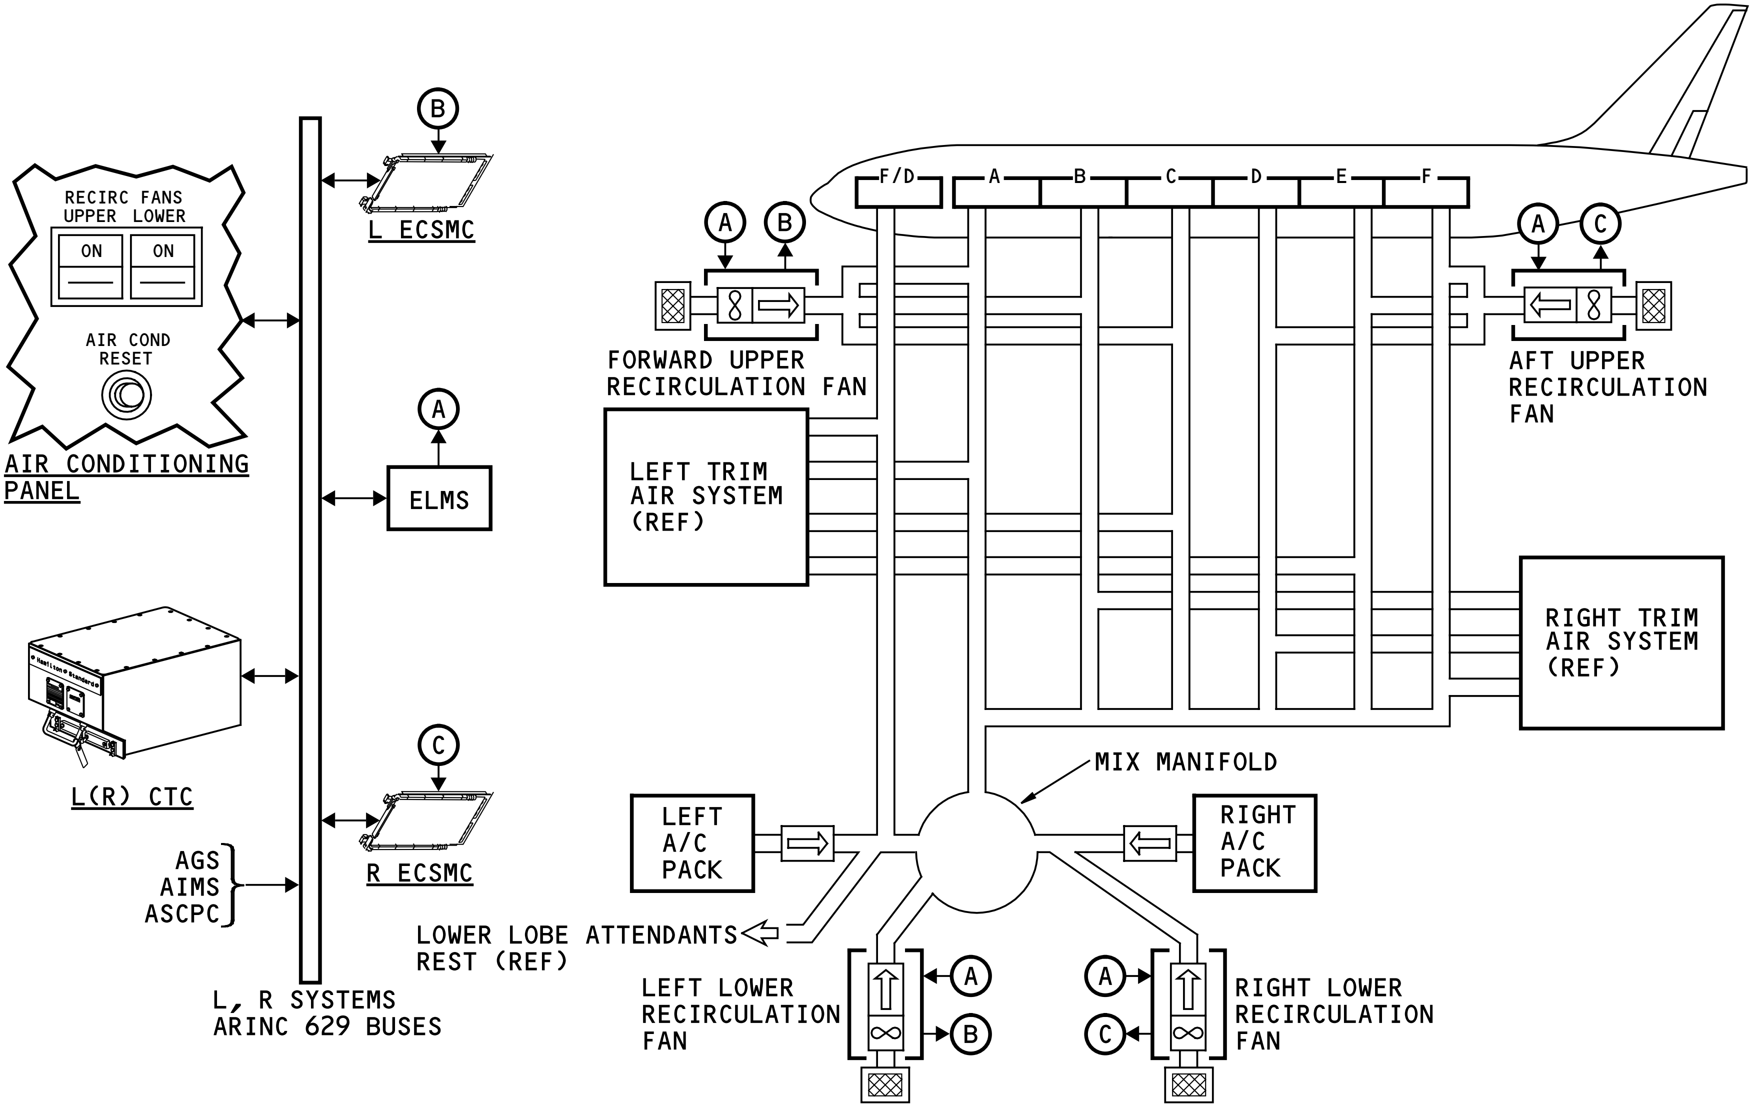
The right cabin temperature controller (CTC) supplies usual control for all recirculation fans. The left CTC supplies backup control.

The left and right ECSMCs monitor for fan overheat conditions.

ELMS controls power to the fans.

The CTCs get information about airplane conditions from these systems/components:

- Air ground system (AGS)
- Electrical load management system (ELMS), load shed and power status
- Airplane information management system (AIMS), cruise clamp information
- Air supply cabin pressure controllers (ASCPC), pack flow schedule.



AIR CONDITIONING - RECIRCULATION - INTRODUCTION

21-25-00-001 Rev 3 10/28/1997

AIR CONDITIONING - RECIRCULATION - LOWER RECIRCULATION FANS AND FILTERS

Purpose

The lower recirculation fans put cabin air back in the distribution system. The air goes through filters at the inlets of the fans.

Physical Description

The fans are axial flow type with a three-phase electric motor. A check valve is part of the fan.

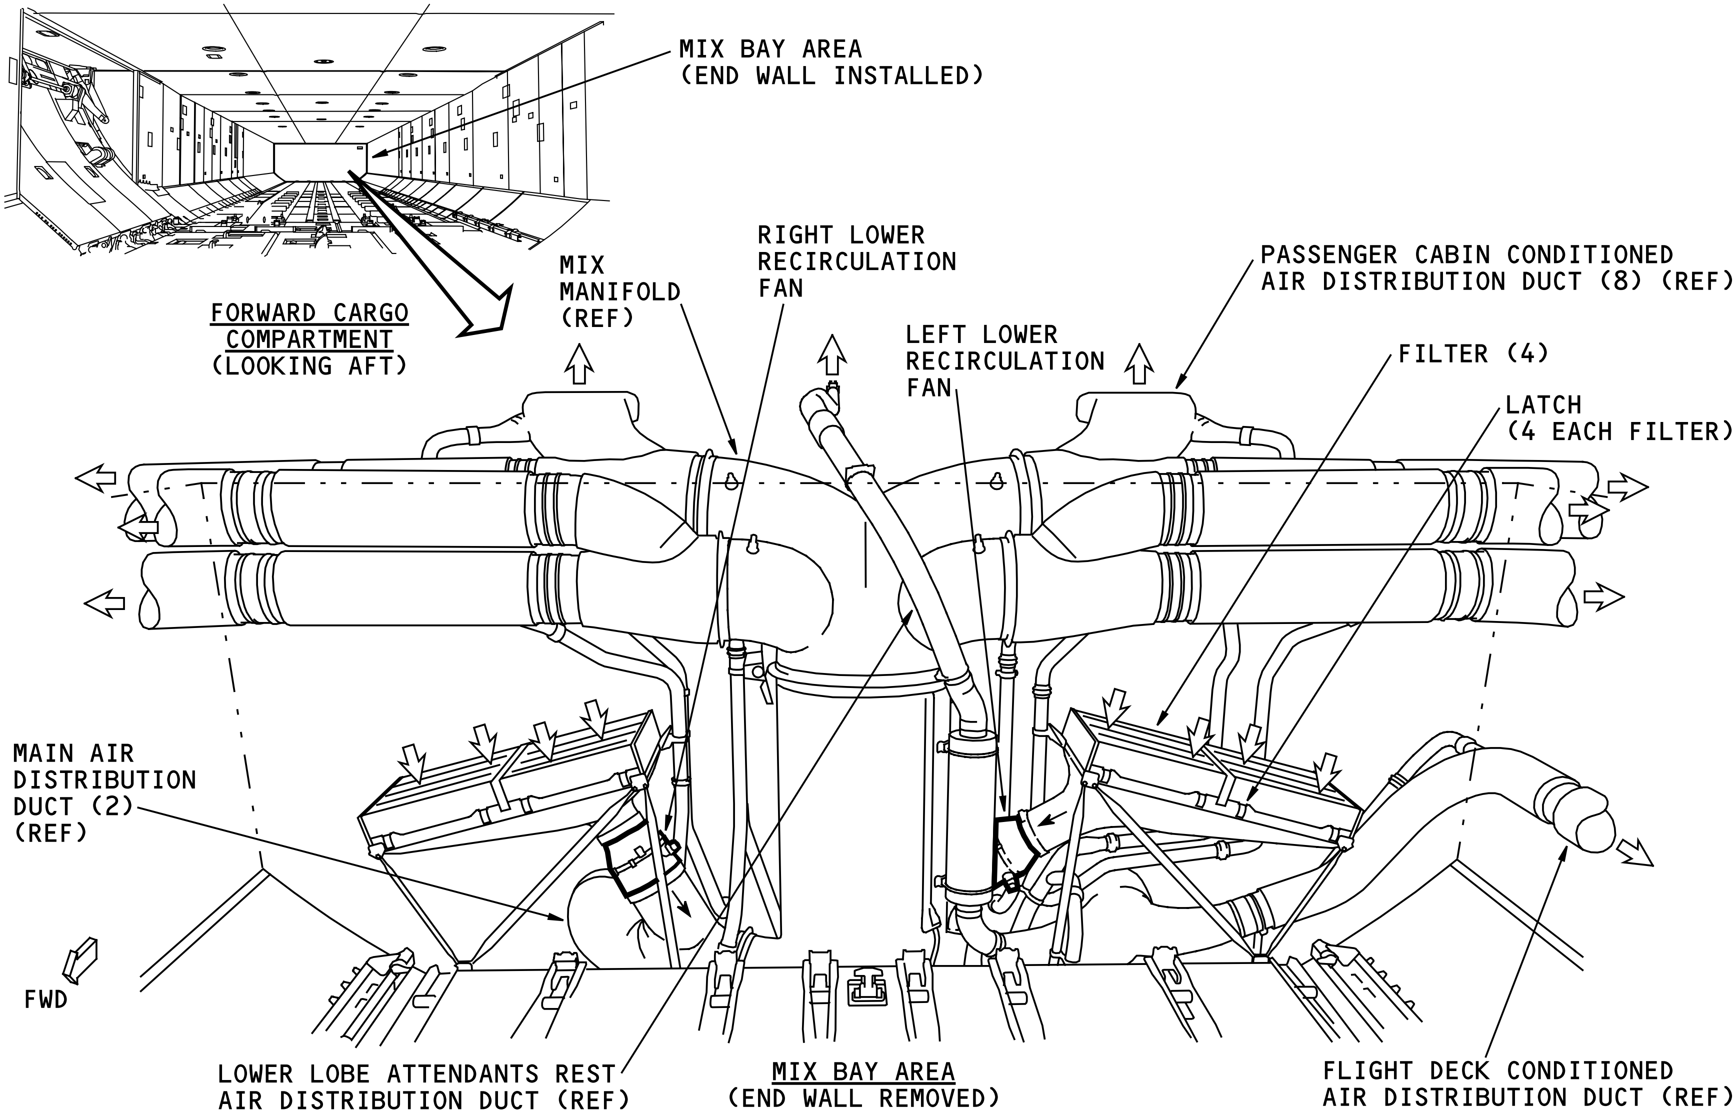
There are four interchangeable lower recirculation fan filters. The filters are a paper type. The filters for the upper and lower recirculation fans are interchangeable.

Location

The fans and filters are aft of the forward cargo compartment in the mix bay area. You remove the cargo compartment end wall to get access to the fans and filters.

Training Information Point

The fans are interchangeable with each other.



AIR CONDITIONING - RECIRCULATION - LOWER RECIRCULATION FANS AND FILTERS

21-25-00-002 Rev 5 10/28/1997

AIR CONDITIONING - RECIRCULATION - UPPER RECIRCULATION FANS AND FILTERS

Purpose

The upper recirculation fans put cabin air back in the overhead conditioned air distribution ducts. The air goes through filters at the inlets of the fans.

Physical Description

The fans are axial flow type with a three-phase electric motor. A check valve is part of the fan.

There are four interchangeable upper recirculation fan filters. The filters are a paper type. The filters for the upper and lower recirculation fans are interchangeable.

Location

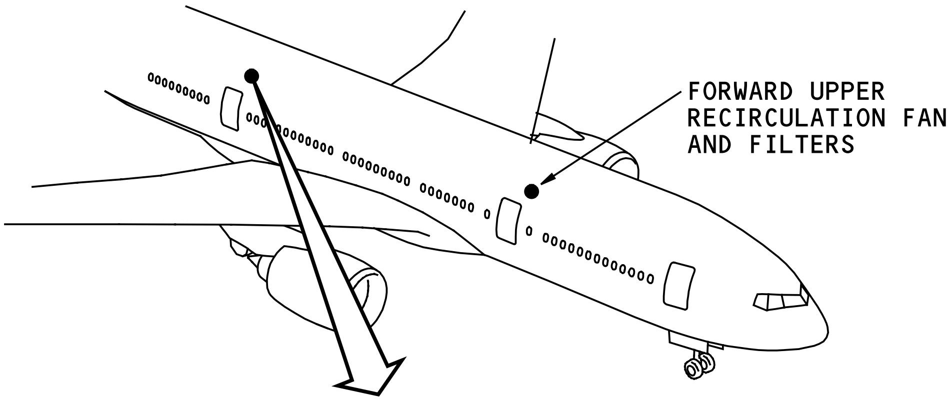
The upper recirculation fans and filters are on the right side of the airplane above the passenger compartment ceiling.

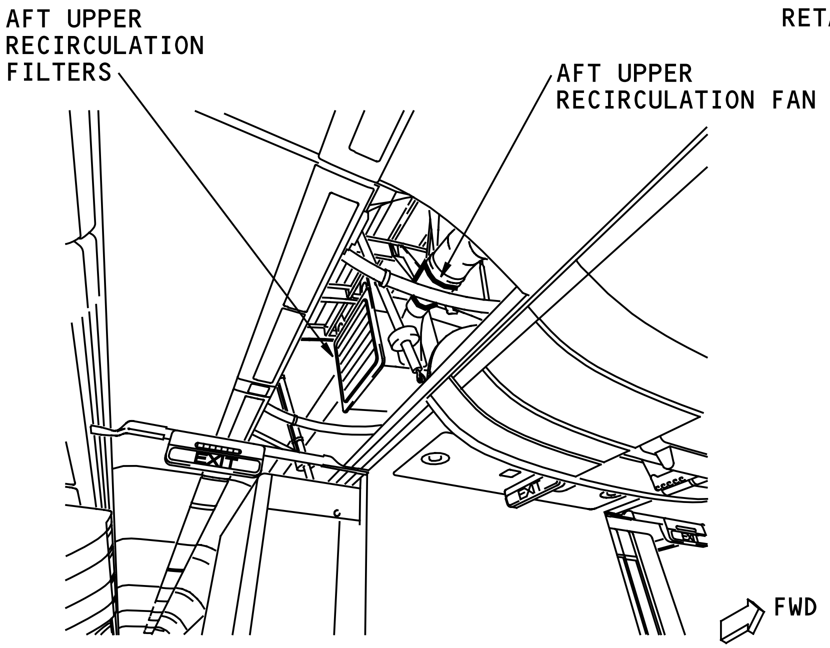
The forward upper recirculation fan and filters are adjacent to door 2 above the center overhead bins.

The aft upper recirculation fan and filters are adjacent to door 3 above the center overhead bins.

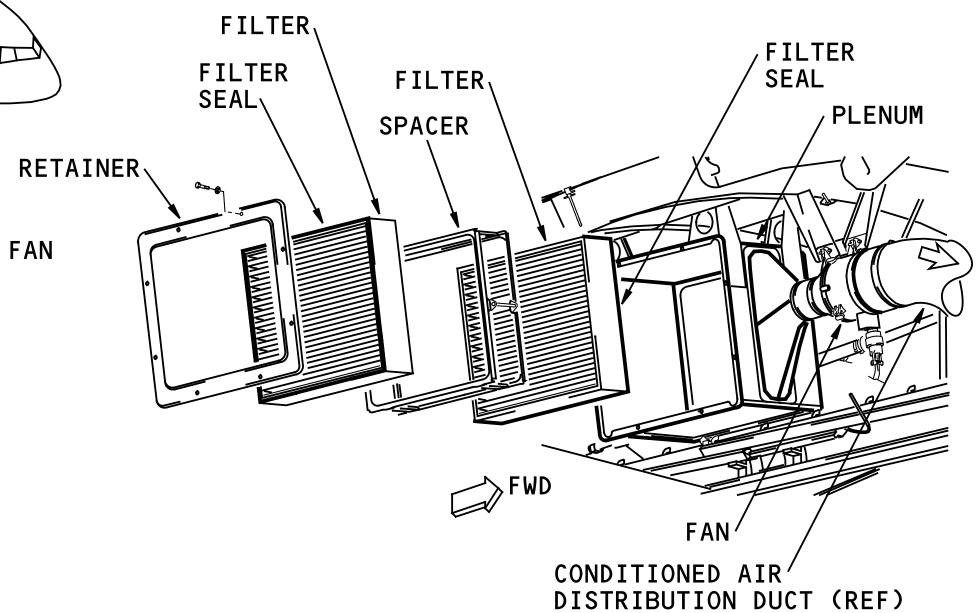
The fans attach to the outlet of a filter plenum assembly and to an overhead passenger cabin conditioned air distribution duct.

The filters are attached inside the filter plenum assembly.





AREA ABOVE THE CENTER OVERHEAD BINS
NEAR DOOR 3 RIGHT
(TYPICAL)



AFT UPPER RECIRCULATION FILTERS AND FAN
(TYPICAL)

AIR CONDITIONING - RECIRCULATION - UPPER RECIRCULATION FANS AND FILTERS

AIR CONDITIONING - RECIRCULATION - FUNCTIONAL DESCRIPTION

Functional Description - Normal

When the two recirculation fan switches on the P5 are ON, the OPAS sends signals to the CTCs. This sets the fans for automatic operation. The right CTC is the primary controller for the recirculation fans. If both channels of the right CTC fail, the left CTC controls the fans.

The CTC sends fan on signals to the ELMS electronic units (EEUs) in the left and right power management panels. The EEUs supply grounds to energize the recirculation fan relays. The relays supply power to each recirculation fan. The CTC turns the fans on and off with a 5 second delay between fans. This helps prevent a sudden load.

Functional Description - Overheat

The ECSMCs monitor overheat switches in the recirculation fans. The left ECSMC monitors the left lower and forward upper fans. The right ECSMC monitors the right lower and aft upper fans (not shown). If an overheat switch opens, the ECSMC sends an overheat signal to the CTC. The CTC latches the fan off. The CTC also latches the related fans off if there is a loss of data from an ECSMC.

Operation - Normal

The lower and upper recirculation fan switches are alternate-action switches. When the switches are off, the recirculation fans are off. When the switches are on, operation of the recirculation fans is automatic.

The upper and lower fans usually operate continuously on the ground and in flight. Single pack ground operation with high ambient temperature may cause a lower fan to stop. The CTC turns off the fan on the same side as the unserviceable pack. This decreases the amount of warm air put into the mix manifold and helps cool the airplane.

See the pack cooling and mix manifold temperature control section for more information (AMM PART I 21-52).

Operation - Non-normal

If the forward or aft cargo fire arm switches are in the ARMED position, the ELMS and the CTC turn off the lower fans.

If an upper or lower fan has a failure and pack flow schedule 1 is in effect, the pack flow rate increases 67 lbs/min (33.5 lbs/min per pack). This keeps the total cabin ventilation rate constant. The increased bleed air flow causes a small increase in fuel consumption, approximately .3% for each failed fan.

A status message shows if a recirculation fan has a failure. If the fan latches off because of an overheat condition, you can cycle the recirculation fan switch OFF then ON to release the latch. You can also use the AIR COND RESET switch to release the latch.

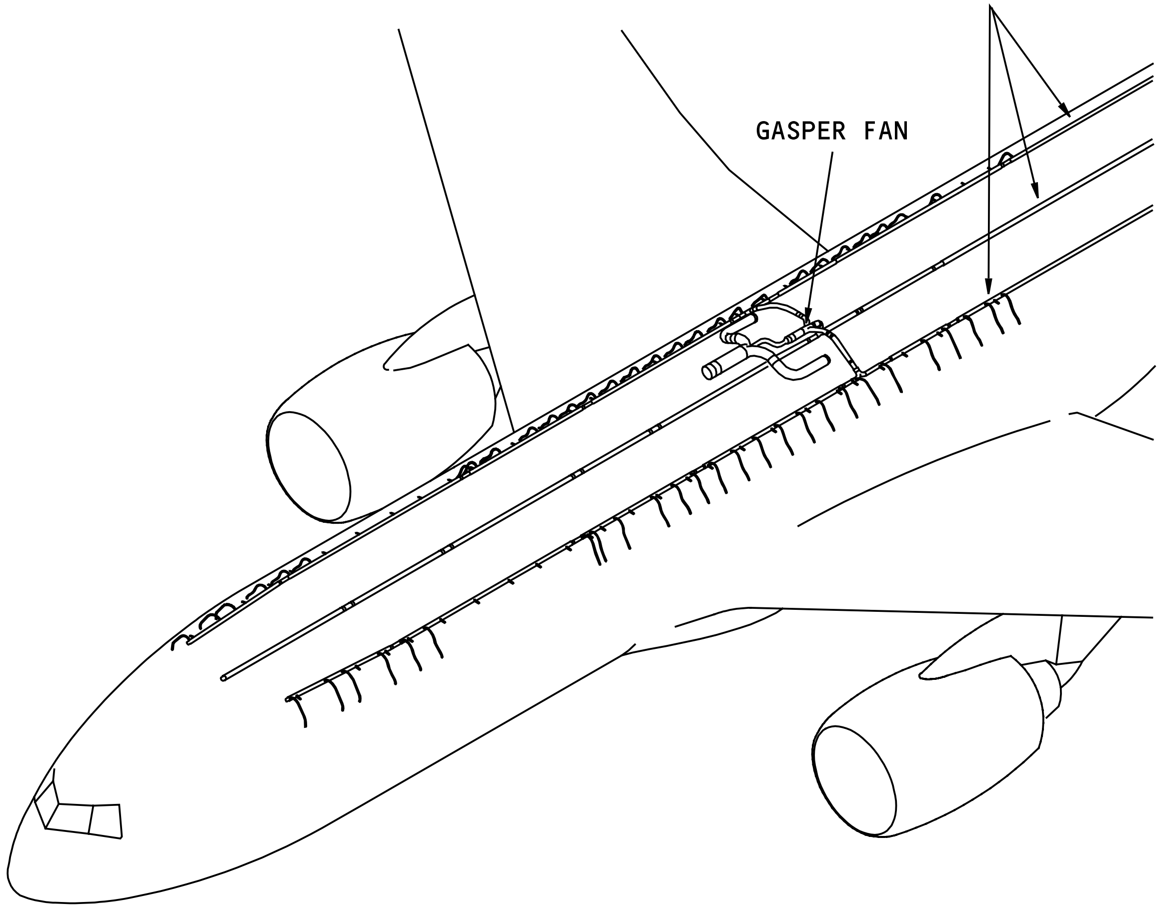
AIR CONDITIONING - RECIRCULATION - FUNCTIONAL DESCRIPTION

21-25-00-004 Rev 5 09/07/96

AIR CONDITIONING - GASPER AIR DISTRIBUTION - INTRODUCTION

Purpose

The gasper air distribution system supplies additional air flow to each passenger seat through outlets in the passenger service units.



21-24-00-001 Rev 0

AIR CONDITIONING - GASPER AIR DISTRIBUTION - INTRODUCTION

AIR CONDITIONING - GASPER AIR DISTRIBUTION - GASPER FAN AND OUTLETS

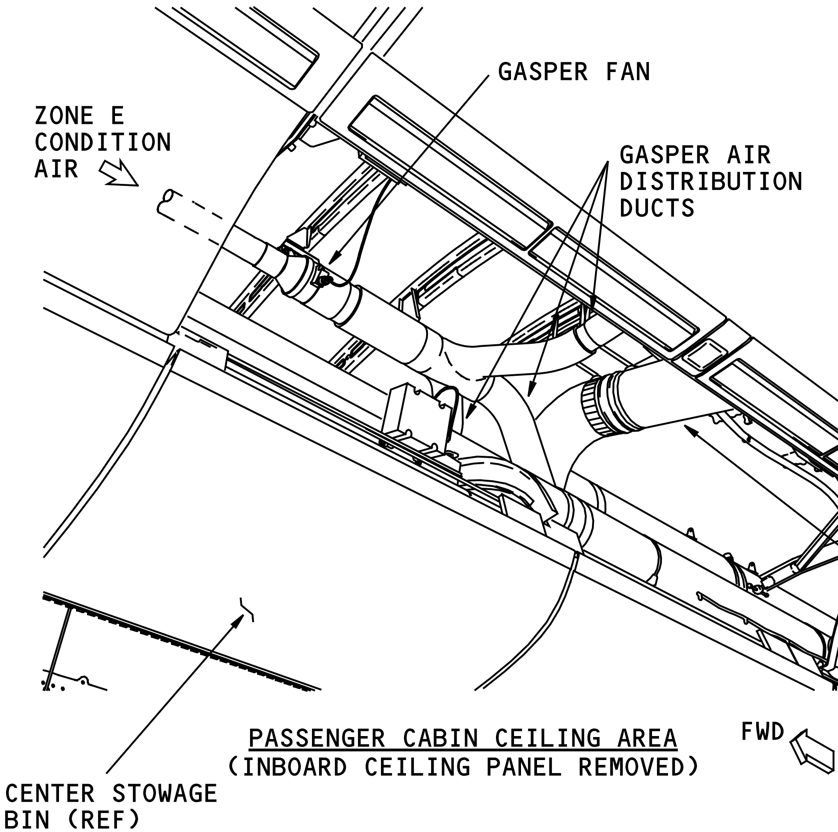
General Description

The gasper fan pulls air from the zone E part of the passenger cabin conditioned air distribution system. The fan moves this air to gasper air outlets at each group of passenger seats. The air moves from the fan to the outlets through three gasper air distribution ducts: left, center and right. The fan supplies approximately 640 cfm of total airflow, this is equal to a flow of 3 cfm to each air outlet with 50 percent of the outlets open.

The gasper switch on the air conditioning panel (not shown) enables the operation of the gasper fan. The ECSMCs (not shown) control fan operation.

Location

The gasper fan and the distribution ducts are in the ceiling area of the passenger cabin. The fan is approximate 52 inches (132 cm) forward of the left zone F riser, above the center stowage bins. The ducts are adjacent to the related passenger service units.



PASSENGER CABIN CEILING AREA
(INBOARD CEILING PANEL REMOVED)

(ABOVE EACH GROUP
OF PASSENGER SEATS)

21-24-00-002 Rev 1 04/18/1997

AIR CONDITIONING - GASPER AIR DISTRIBUTION - GASPER FAN AND OUTLETS

Functional Description

When the gasper fan switch on the P5 is on, a signal goes to the environmental control system miscellaneous card (ECSMC) in each of the system card files. This sets the fan control for automatic operation.

The ECSMC that is in control sends a fan ON signal to the left power management panel. A switch in the electrical load management system (ELMS) electronics (ELEX) unit supplies a ground to energize the gasper fan relay. This relay supplies power to the gasper fan.

Fault Monitoring

ELMS monitors fan current and relay status during operation. ELMS sends these signals to the ECSMCs:

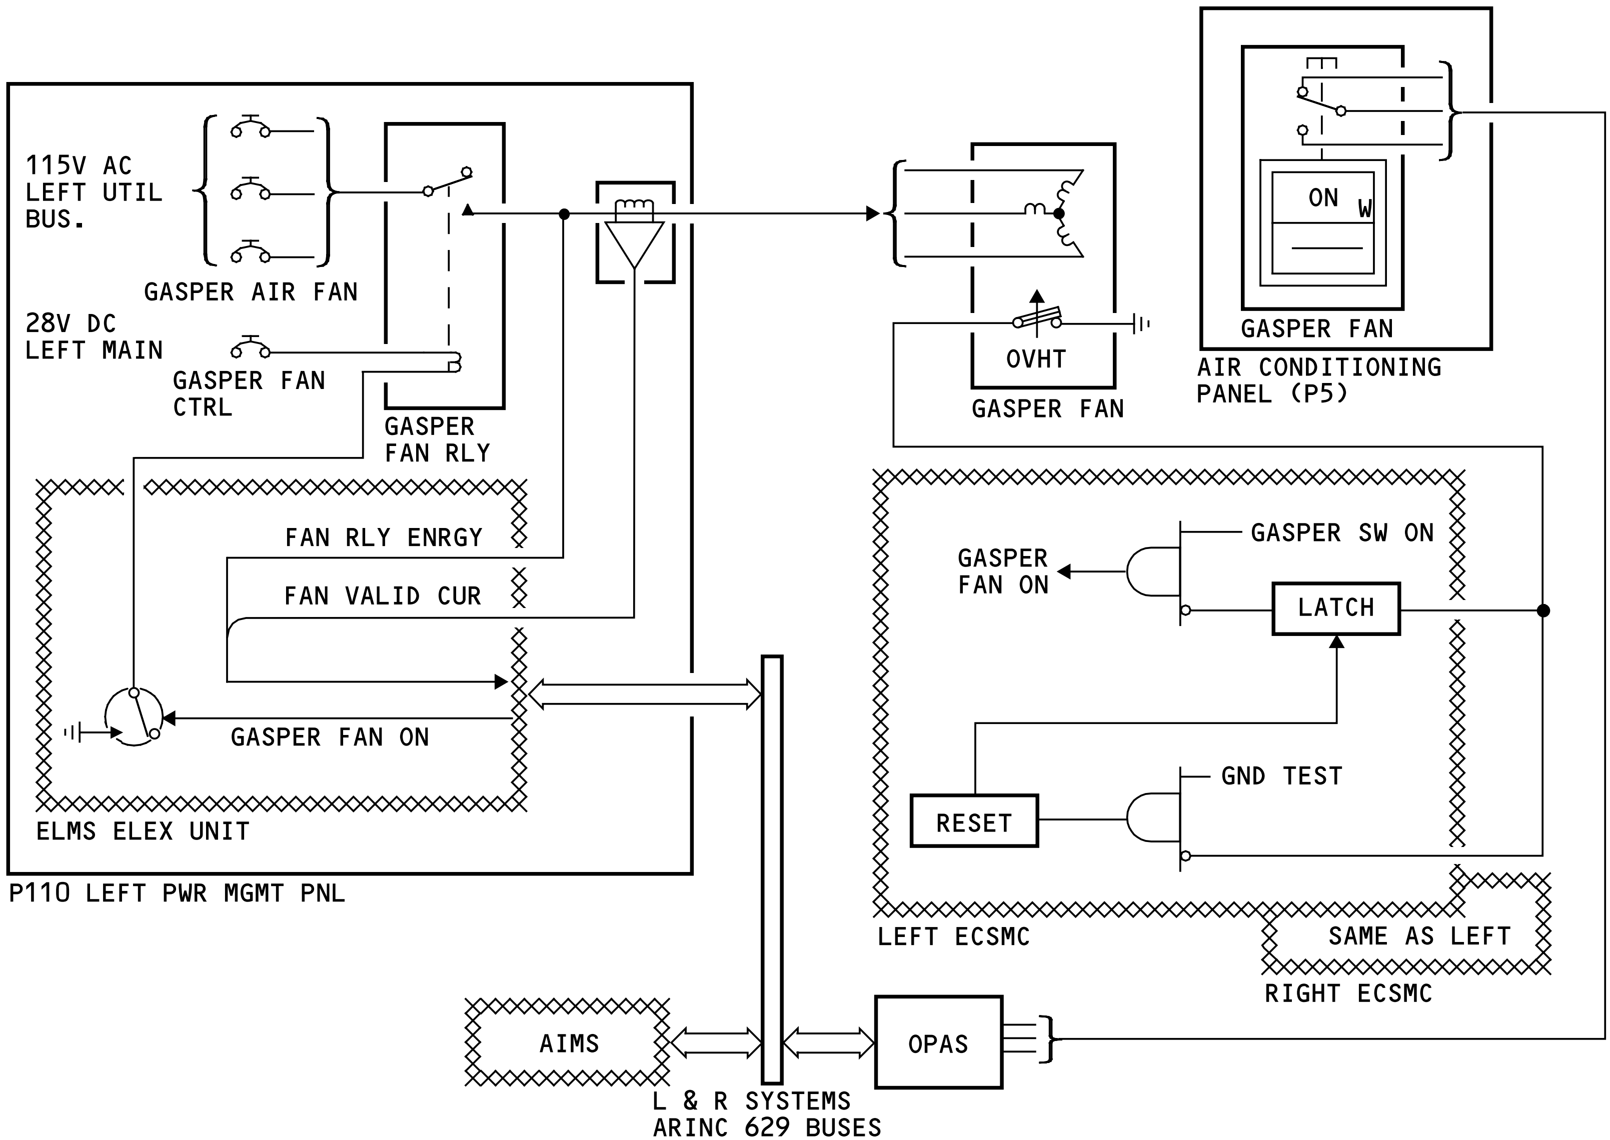
- Valid fan current
- Fan relay energized.

A switch in the gasper fan supplies an indication to the ECSMC. If the fan becomes too hot or does not start or stop on command, the ECSMCs send a signal to AIMS. The central maintenance computing function makes a maintenance message.

Fan Overheat

If the fan overheats, the ECSMCs latch the gasper fan off. The fan stays off until both of these conditions are true:

- Mat ground test
- Not overheat.



AIR CONDITIONING - GASPER AIR DISTRIBUTION - FUNCTIONAL DESCRIPTION

AIR CONDITIONING - VENTILATION - GENERAL DESCRIPTION - MECHANICAL

Purpose

The ventilation system has these functions:

- Removes odors from the lavatories and galleys
- Causes air flow across the zone temperature sensors for the flight, passenger, and cargo compartments
- Causes air flow through electrical and electronic equipment
- Removes warm air from above the passenger compartment ceiling and from the galley chiller units in the forward part of the airplane
- Supplies air flow into the bulk cargo compartment.

These are the types of ventilation:

- Galley chiller unit ventilation
- Bulk cargo ventilation
- Lavatory/galley ventilation.

Galley Chiller Unit Ventilation

The chiller boost fan removes warm air from galley chillers and the area above the passenger compartment ceiling. Only chillers in the passenger compartment ceiling area above the galleys and forward of the wings connect to the fan.

The air from the chiller boost fan goes to the mix bay area. The lower recirculation fans (not shown) move the air from the mix bay into the mix manifold part of the air conditioning distribution system.

Holes in the duct let hot air from the chiller exhaust go into the ceiling when the fan is off.

The chiller boost fan operates automatically.

Bulk Cargo Ventilation

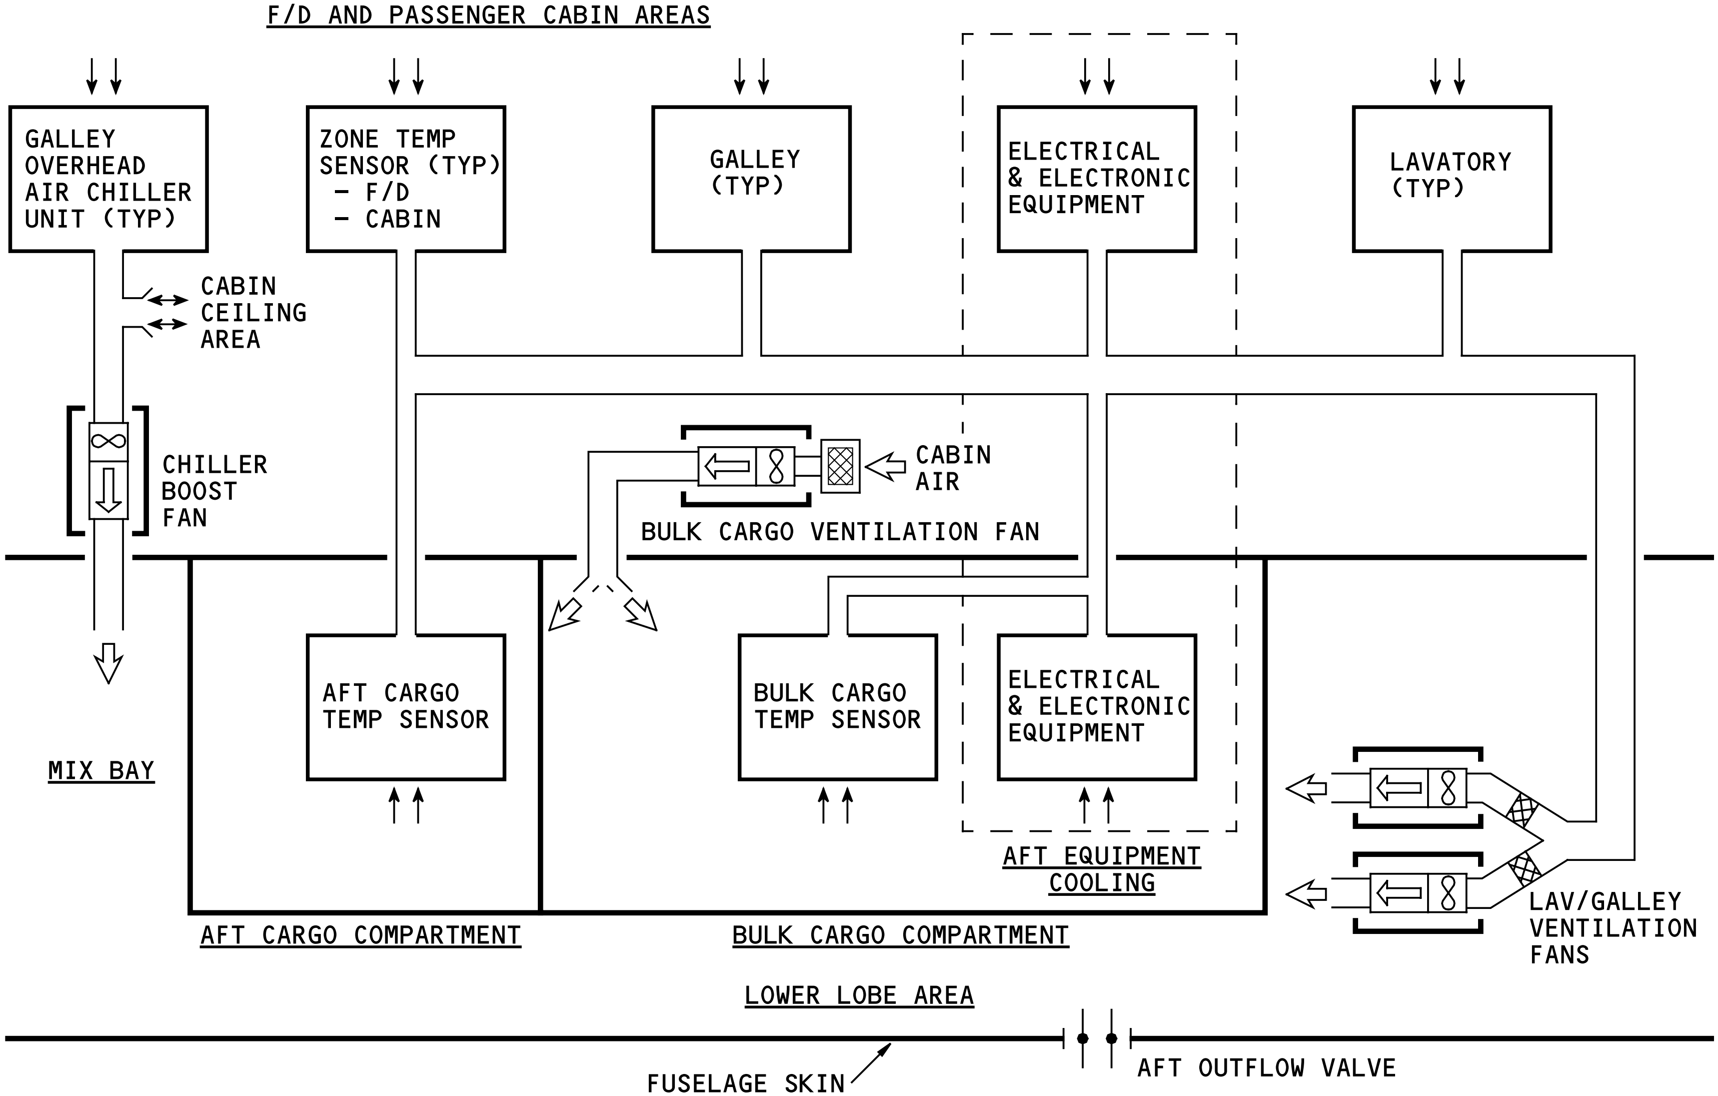
The bulk cargo ventilation fan increases the ventilation when there are animals in the bulk cargo compartment. The fan pulls air from the passenger compartment and moves it into the bulk cargo compartment. The fan operates when the bulk cargo heating system is set to HIGH.

Lavatory/Galley Ventilation

There are two lavatory/galley ventilation fans. Only one fan operates at a time. The right fan is primary and the left fan is the backup. At airplane power up, the left fan comes on, is tested, and goes off. The right fan then comes on, is tested, and stays on. The fan that operates pulls air from these areas and components:

- Lavatories
- Galleys
- Zone temperature sensors
- Cargo temperature sensors
- Electrical and electronic equipment.

The air from the lavatory/galley ventilation fan goes to the area next to the aft pressurization outflow valve.



AIR CONDITIONING - VENTILATION - GENERAL DESCRIPTION - MECHANICAL

THIS PAGE INTENTIONALLY LEFT BLANK

AIR CONDITIONING - VENTILATION - GENERAL DESCRIPTION - ELECTRICAL

General

The environmental control system miscellaneous cards (ECSMCs) in the system card files control the ventilation fans. At power-up, the right ECSMC controls the fans. The left ECSMC gives backup. Each time the airplane goes from air to ground, the card in control changes.

Interfaces

The ECSMCs make decisions about operation and indications for the ventilation fans based on these inputs:

- Airplane in the air or on the ground (WOW)
- Fan overheat switches
- AC power available for fan operation (ELMS)
- Fan load shed status (ELMS)
- Fan control relay status, energized or not (ELMS)
- Valid current for fan on or off status (ELMS)
- Bulk cargo heat selector position, OFF, LOW, HIGH (OPAS)
- Forward and aft cargo fire switches, ARMED or not armed (OPAS)
- Equipment cooling switch position (OPAS)
- Left and right air conditioning packs on or off (CTC)
- Total air temperature (TAT) (ADIRU).

The ECSMCs interface with AIMS. The primary display system gives a status message for a failed ventilation fan. The central maintenance computing function gives a maintenance message for any failed fan and lets you do a ground test for the ventilation fans.

The ECSMCs interface with the CTCs. The ECSMCs give on/off information about the lavatory/galley ventilation fans. If both fans are off, the CTCs use an alternate mode to calculate the necessary duct and mix manifold temperatures for zone temperature control. See the zone temperature control and indication section for more information about the alternate mode (AMM PART I 21-61).

Lavatory/Galley Ventilation

Control of the fans is automatic and requires no crew action for fan operation.

There are two lavatory/galley ventilation fans. Only one fan operates at a time. The right fan is primary and the left fan is the backup. At airplane power up, the left fan comes on, is tested, and goes off. The right fan then comes on, is tested, and stays on.

Galley Overhead Air Chiller Unit Ventilation

Control of the chiller boost fan is automatic and no crew action for fan operation is necessary.

The fan comes on when these conditions occur:

- Airplane is on the ground
- One or two packs are on
- TAT is more than 45F (7C)

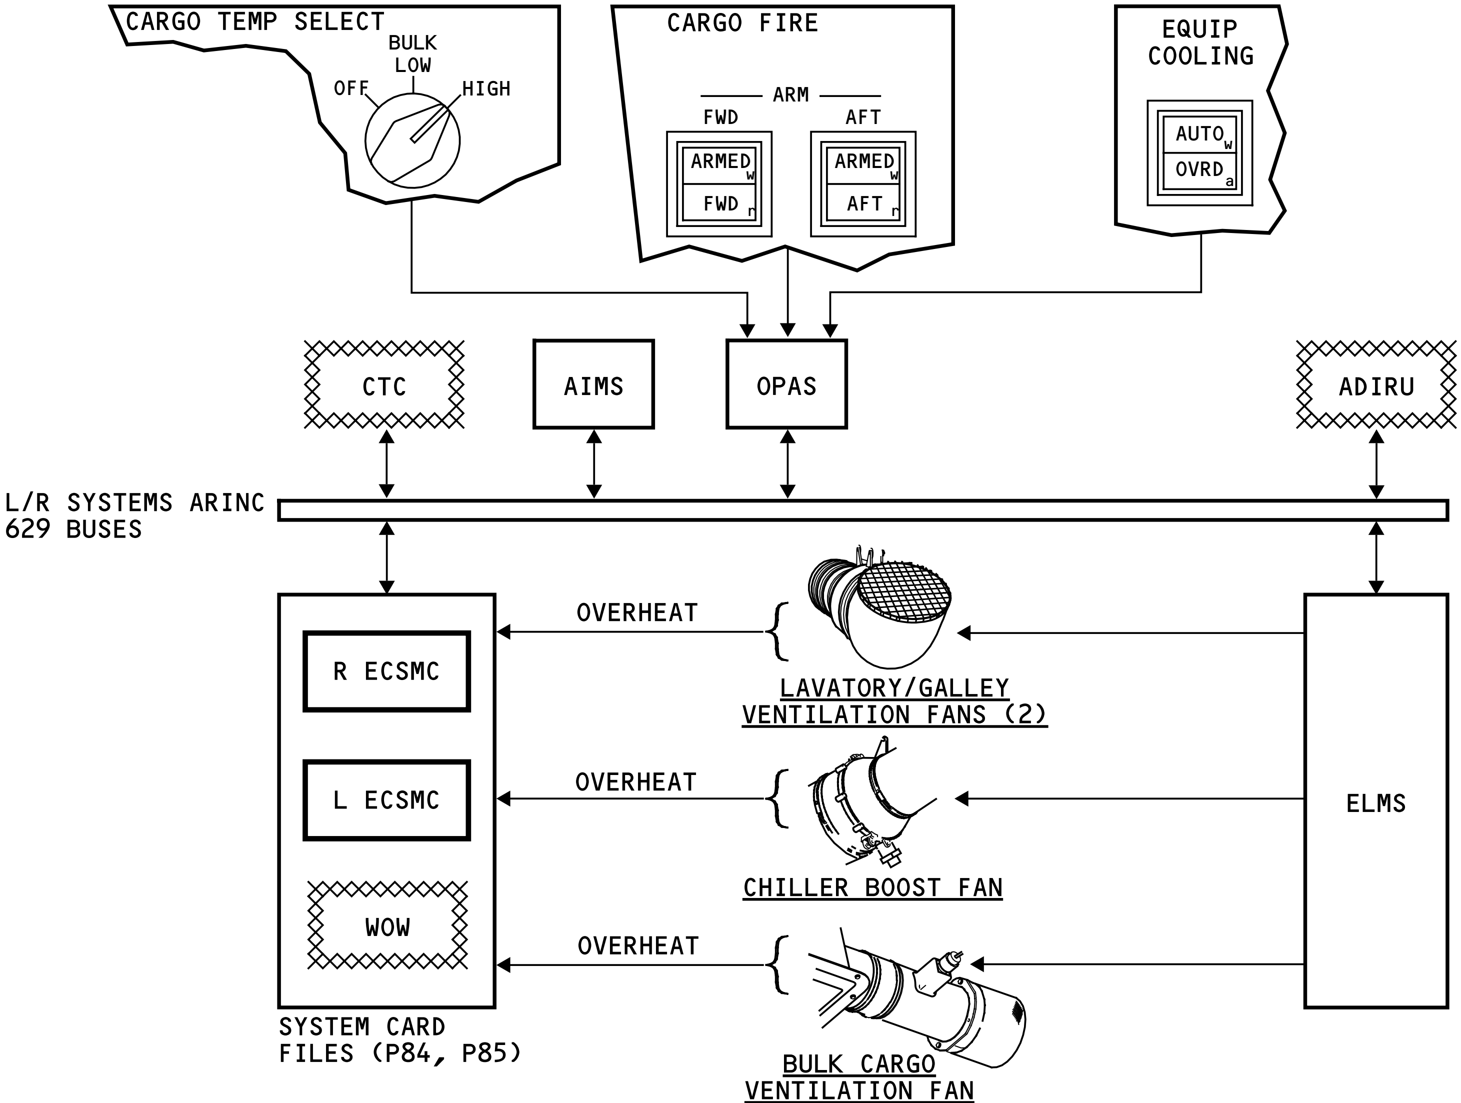
- FWD cargo fire switch is not armed.

The fan will go off when the airplane is in the air.

Bulk Cargo Ventilation

The bulk cargo ventilation fan operates when the crew sets the bulk cargo heating system to HIGH.

Selection of the equipment cooling switch to the OVRD position or the selection of the aft cargo fire switch to ARMED inhibits the operation of the fan.



AIR CONDITIONING - VENTILATION - GENERAL DESCRIPTION - ELECTRICAL

AIR CONDITIONING - VENTILATION - CHILLER BOOST FAN

Purpose

The chiller boost fan removes the warm air that comes from the forward galley chillers. This air vents around the area of the mix manifold.

Location

The fan is at station 957 above the center overhead bins. This location is adjacent to the seventh window aft of door 2 in the passenger cabin.

AIR CONDITIONING - VENTILATION - BULK CARGO VENTILATION FAN

AIR CONDITIONING - VENTILATION - LAVATORY GALLEY VENTILATION FANS, INLET DUCT AND SCREEN

Purpose

The lavatory galley ventilation fans pull air from the lavatories and galleys in the passenger cabin. A single ventilation duct (not shown) above the ceiling connects the lavatories and galleys to the fans. The fans are aft of the bulk cargo compartment end wall. Hoses (not shown) from the ventilation duct pull air across the zone temperature sensors in these areas:

- Passenger cabin
- Aft and bulk cargo compartments
- Flight deck.

Lavatory Galley Ventilation Fans

The lavatory galley ventilation fans are aft of the bulk cargo compartment endwall. The fans pull air from the lavatories and galleys. The fans have these components:

- Fan rotation arrow
- Flow direction arrow
- Stator housing assembly and check valve
- Electrical connector
- Inlet housing assembly.

Inlet Duct and Screen

There is an inlet duct and screen on the aft side of the two lavatory galley ventilation fans. The screen prevents unwanted material from going through the lavatory galley ventilation fans.

Training Information Point

The lavatory galley ventilation fans are interchangeable with the lower recirculation fans and the chiller boost fan.

AIR CONDITIONING - VENTILATION - GALLEY VENTILATION FILTERS

AIR CONDITIONING - DISTRIBUTION - OPERATION

General

The cargo temperature select panel has the control for the bulk cargo ventilation system. The ventilation system uses the bulk cargo heat selector.

The air conditioning panel has these controls for distribution:

- Equipment cooling control
- Upper and lower recirculation fan controls
- Air conditioning reset control.

These ventilation systems have no flight deck controls, their control is automatic:

- Galley chiller unit ventilation
- Lavatory/galley ventilation (aft equipment cooling).

See the distribution - ventilation section for more information about the ventilation systems that do not have controls in the flight deck (AMM PART I 21-26).

Bulk Cargo Ventilation Operation

The bulk cargo heat selector is a three position selector. The selector enables the bulk cargo heating and ventilation systems. The HIGH position enables the ventilation system. The LOW or OFF position sets the ventilation system off. See the aft and bulk cargo compartment heating section for more information about the bulk cargo heating system (AMM PART I 21-44). See the ventilation section for more information about the bulk cargo ventilation system (AMM PART I 21-26).

Equipment Cooling Operation

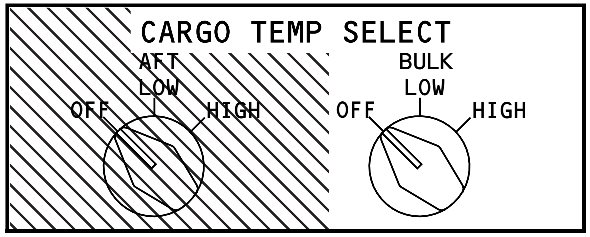
The equipment cooling switch sets the mode of operation for the forward equipment cooling system. The AUTO position on the switch shows that the system is set to automatic operation. The OVRD indication shows that the system is in the override mode of operation. See the equipment cooling section for more information about the operation of the forward equipment cooling system (AMM PART I 21-27).

Recirculation Fan Operation

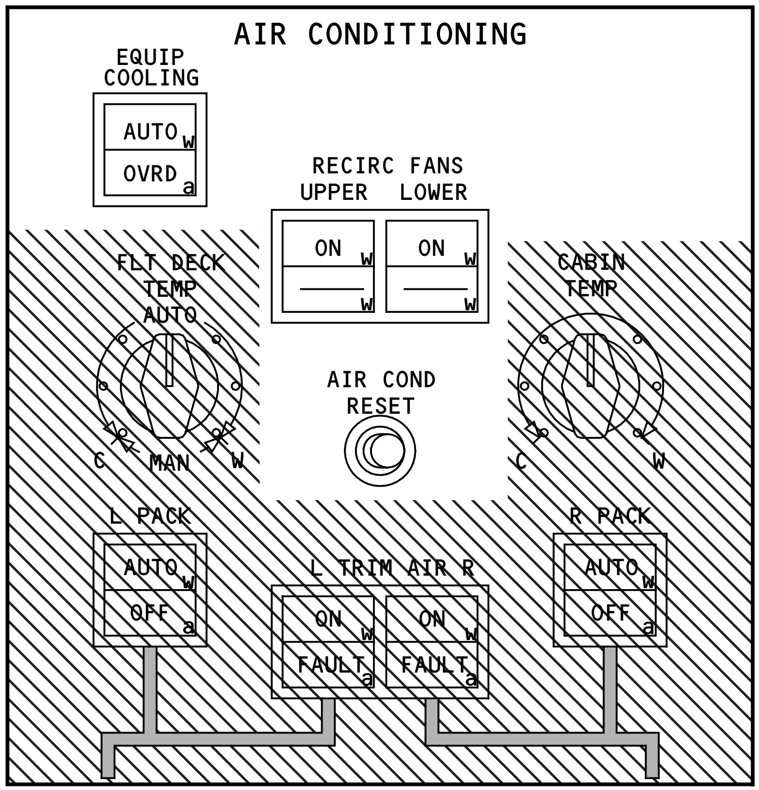
The UPPER and LOWER RECIRC FANS switches are alternate-action switches. The ON indication on the switch shows the fan is set to automatic operation. When the ON indication does not show, the fan is off. See the recirculation section for more information about the recirculation fans (AMM PART I 21-25).

Air Conditioning Reset Operation

The AIR COND RESET switch is a momentary-action switch. This switch starts the system after a failure.



CARGO TEMPERATURE SELECT PANEL (P61)



AIR CONDITIONING PANEL (P5)

AIR CONDITIONING - DISTRIBUTION - OPERATION

21-20-00-003 Rev 1 03/04/1997

AIR CONDITIONING - DISTRIBUTION - GROUND TESTS

General

These are the air conditioning distribution ground tests that show when you select ATA 21 Environmental Control System:

- Chiller boost fan
- Lavatory/galley ventilation fan.

This is the distribution ground test that shows when you select ATA 21 Cabin Temperature Control System:

- Recirculation fan system.

Chiller Boost Fan

This test makes sure that the chiller boost fan installation is correct.

The test takes approximately 1-2 minutes.

This test shows for these ground test types:

- System test
- LRU replacement test.

Lavatory/Galley Ventilation Fan

This test makes sure that these LRU installations are correct:

- Left lavatory/galley ventilation fan
- Right lavatory/galley ventilation fan
- Bulk cargo compartment ventilation fan.

During this test, there will be airflow from the lavatory/galley ventilation fans. The test takes approximately 2-3 minutes.

This test shows for these ground test types:

- System test
- LRU replacement test.

Recirculation Fan System

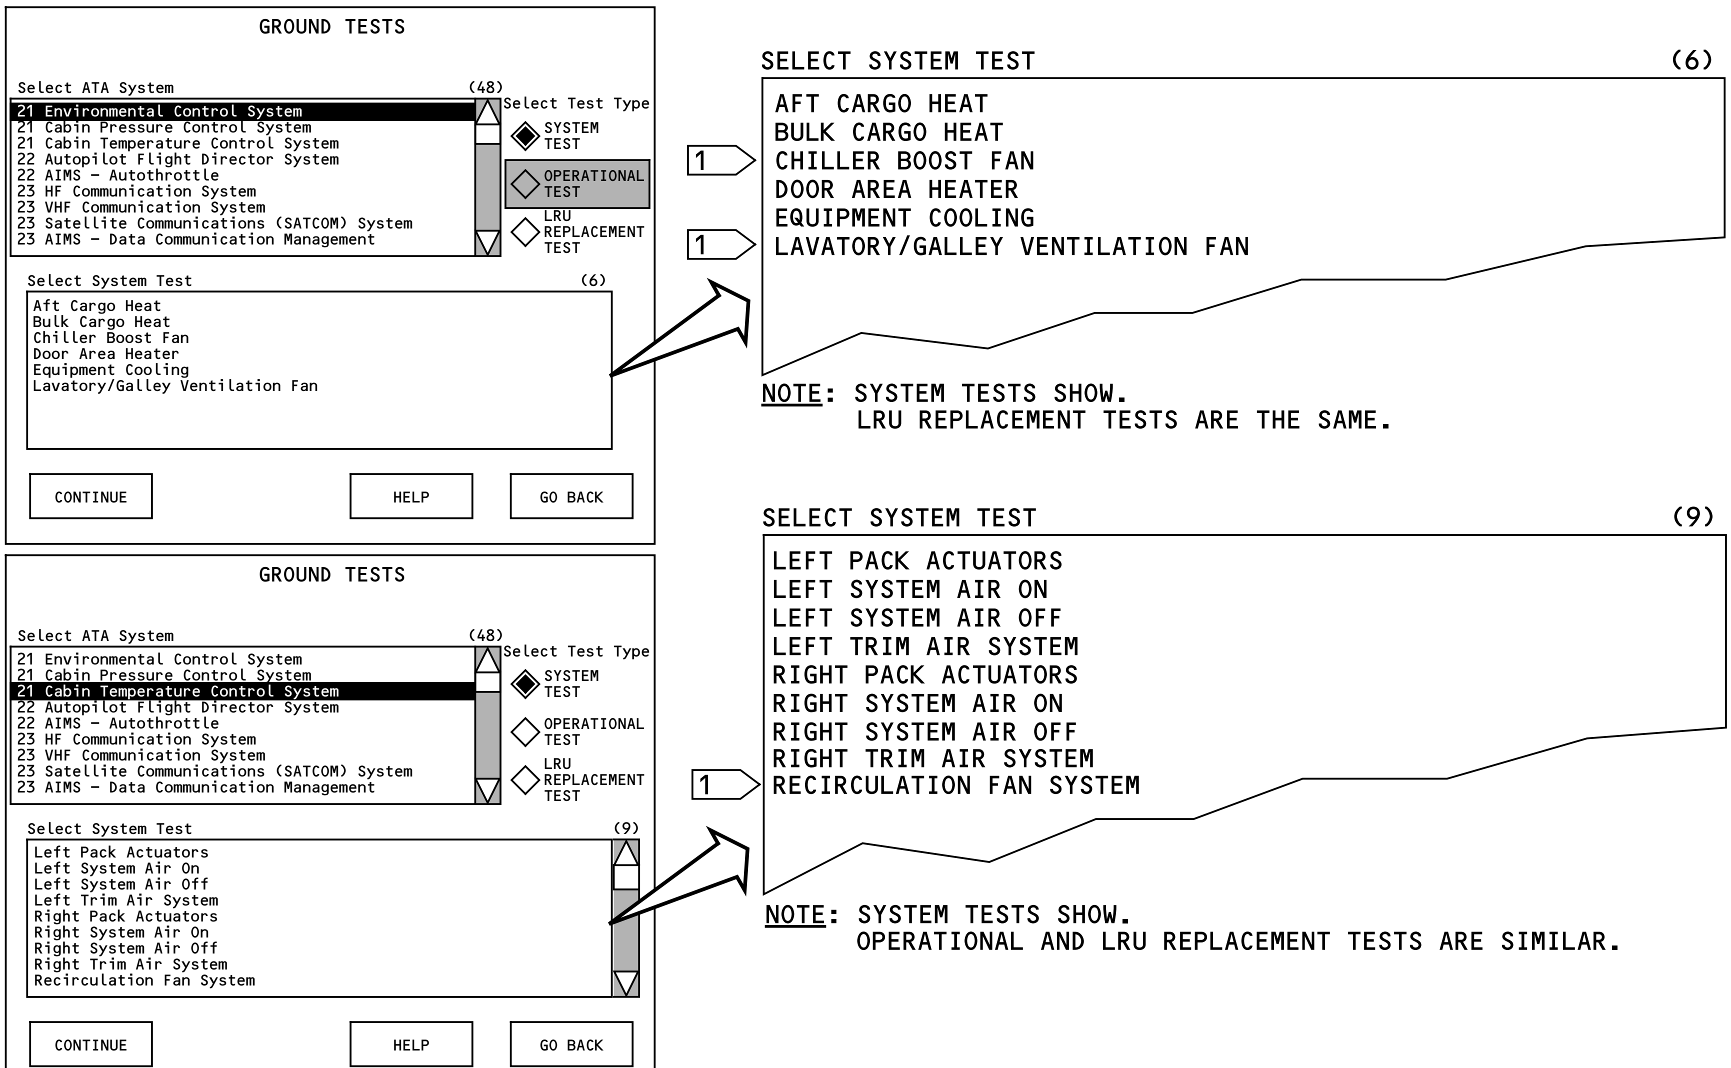
This test makes sure that the cabin temperature controller can control these LRUs:

- Forward upper recirculation fan
- Aft upper recirculation fan
- Left lower recirculation fan
- Right lower recirculation fan.

The electrical load management system P110 and P210 energize these fans. The test takes approximately 2-3 minutes.

This test shows for these ground test types:

- System test
- Operational test
- LRU replacement test.



1 THESE ARE THE AIR CONDITIONING - DISTRIBUTION TESTS.

AIR CONDITIONING - DISTRIBUTION - GROUND TESTS

AIR CONDITIONING - HEATING - INTRODUCTION

Purpose

Heat sources add heat to cabin areas and cargo compartments to keep temperatures at necessary levels.

Crew Rest Area Heating

An in-line electric heater keeps the flight crew rest area warm. See the crew rest area heating system section for more information about the crew rest area heating (AMM PART I 21-41).

Forward Cargo Heating

The forward cargo compartment uses warm air from the equipment cooling system to keep temperature in limits. See the forward cargo compartment heating section for more information about the forward cargo compartment heating (AMM PART I 21-43).

Aft and Bulk Cargo Heating

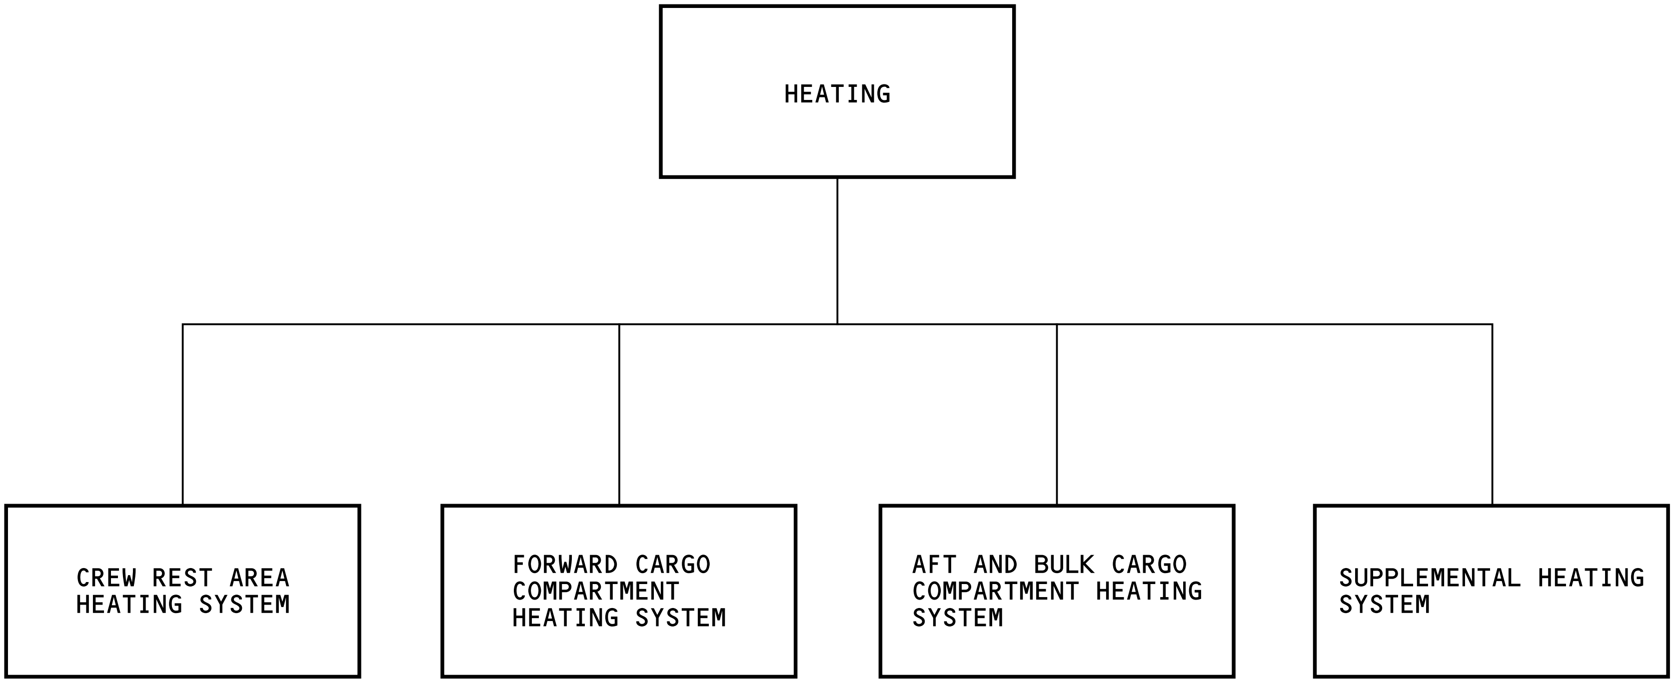
The aft and bulk cargo compartments use air from the pneumatic system to keep temperature in limits. See the aft and bulk cargo compartment heating section for more information about the aft and bulk cargo compartment heating (AMM PART I 21-44).

Supplemental Heating

These areas use electric heaters to keep temperature in limits.

- Flight deck foot and shoulder heaters
- Door heaters
- Galley heaters.

See the supplemental heating section for more information about the supplemental heating system (AMM PART I 21-45).



21-40-00-001 Rev 3 03/05/1997

AIR CONDITIONING - HEATING - INTRODUCTION

AIR CONDITIONING - FORWARD CARGO COMPARTMENT HEATING - INTRODUCTION

Purpose

The forward cargo compartment heating system keeps the compartment temperature above freezing.

General Description

The forward cargo heating system interfaces with the forward equipment cooling system. These systems include the components and the necessary logic to give cargo heating.

The forward cargo heating system has these components:

- Ducts.

The duct moves air from the forward equipment cooling exhaust duct into the compartment.

The equipment cooling system uses these valves to control the movement of exhaust air:

- Equipment vent valve
- Forward cargo heat valve.

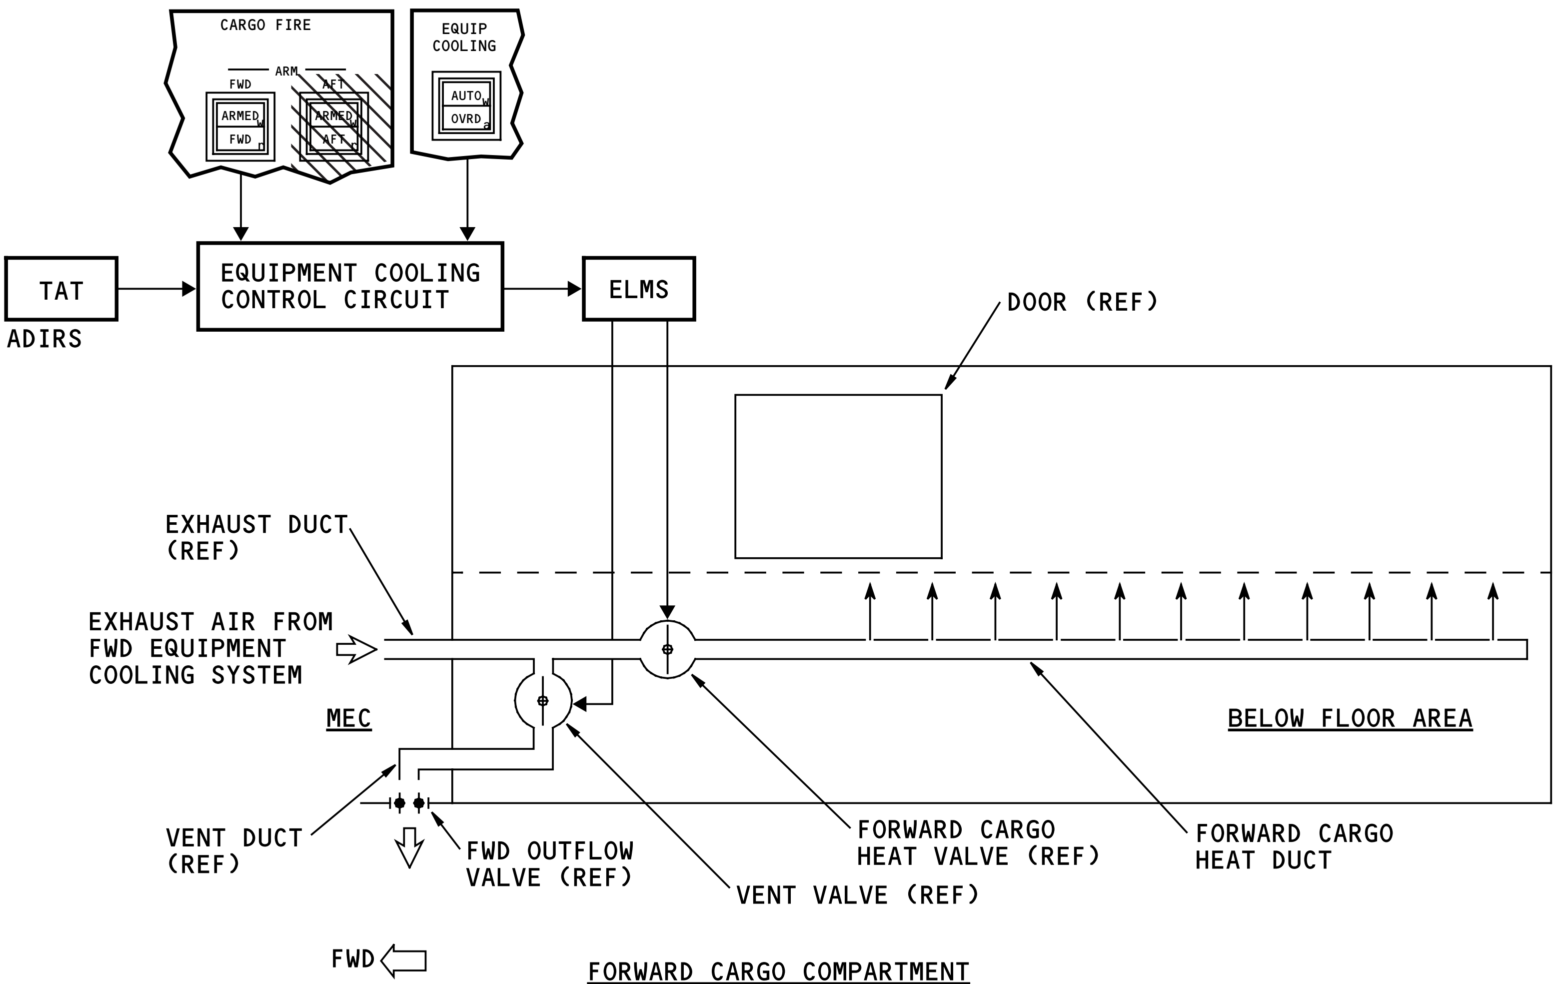
The equipment vent valve and the forward cargo heat valve control the movement of exhaust air into the forward cargo heat duct or into the vent duct. The cargo heat duct supplies air equally into the compartment. The overboard exhaust duct controls the movement of exhaust air to the area near the forward pressurization outflow valve.

On the ground, the forward cargo heat valve normally moves between the open and the closed position as ambient temperature changes. The valve closes when the temperature at the TAT probe is more than 55F (13C). It opens when the temperature is less than 50F (10C).

The forward cargo heat valve is open in the air.

The position of the heat valve changes so that its position is opposite the position of the vent valve. For example, when the vent valve is open the heat valve is closed.

See the equipment cooling section for more information about the control and operation of the equipment cooling vent and forward cargo heating (AMM PART I 21-27).



FORWARD CARGO COMPARTMENT
(TYPICAL)

21-43-00-001 Rev 4 12/23/1997

AIR CONDITIONING - FORWARD CARGO COMPARTMENT HEATING - INTRODUCTION

AIR CONDITIONING - FORWARD CARGO COMPARTMENT HEATING - HEAT DUCT

Purpose

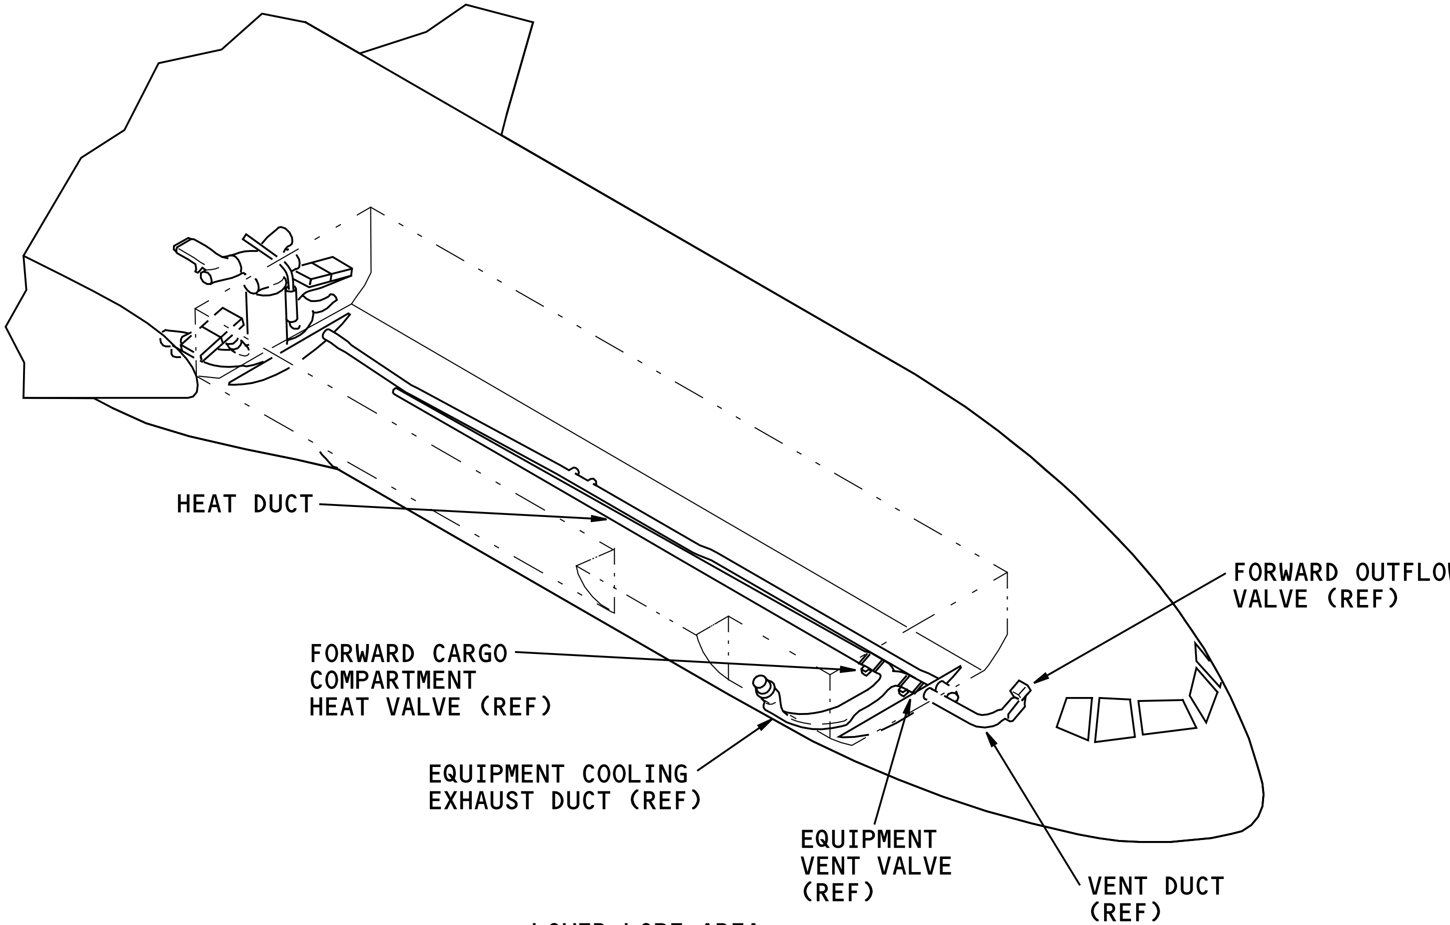
The forward cargo heat duct supplies equipment exhaust air into the forward cargo compartment.

Location

The forward cargo heat duct is below the floor of the forward cargo compartment, on the left side.

Physical Description

The rigid type duct connects to the forward cargo compartment heat valve. The diameter of the duct decreases aft of the valve. Near the valve, the diameter is approximately nine inches (23 cm). At the end of the duct, the diameter is approximately four inches (10 cm). The duct has holes on the inboard and outboard sides. There are more holes on the inboard side than on the outboard side. The holes supply air into the forward cargo compartment.



LOWER LOBE AREA
(TYPICAL)

21-43-00-002 Rev 3 12/23/1997

AIR CONDITIONING - FORWARD CARGO COMPARTMENT HEATING - HEAT DUCT

AIR CONDITIONING - AFT AND BULK CARGO COMPARTMENT HEATING - INTRODUCTION

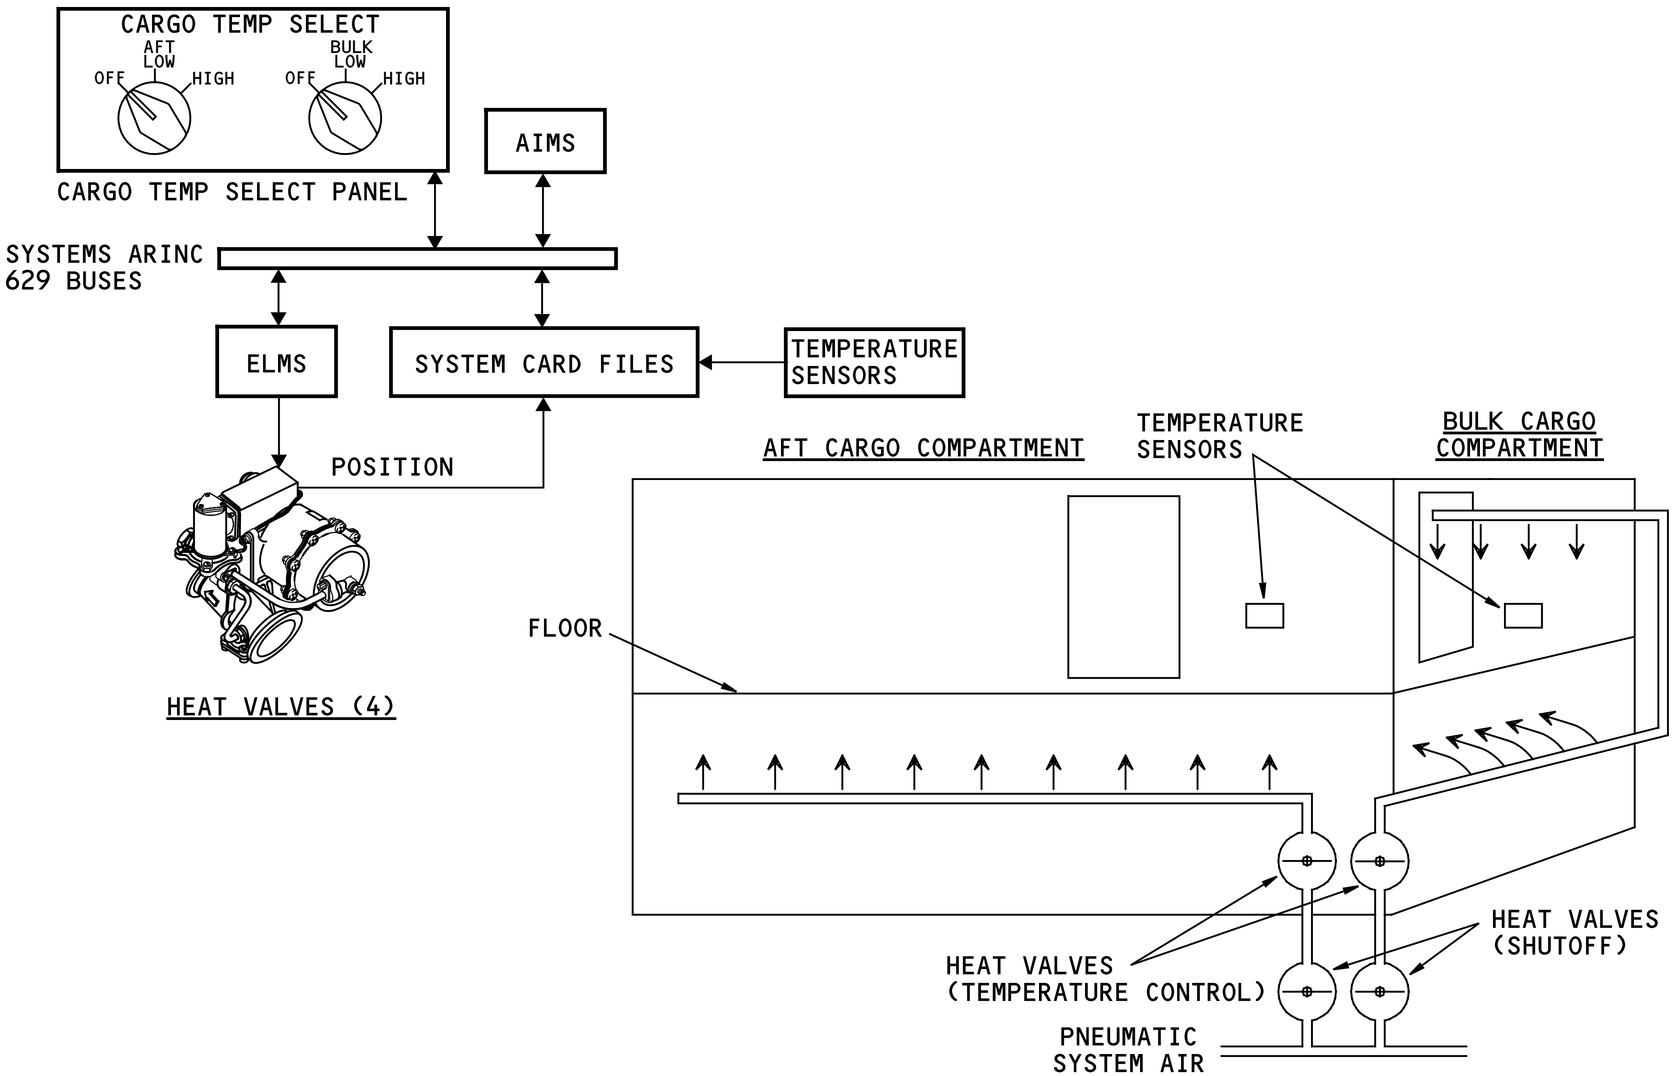
Purpose

Aft and bulk cargo compartment heating controls the amount of pneumatic system air supplied to heat these cargo compartments.

General Description

The aft and bulk cargo compartments receive warm air from the pneumatic system. The aft and bulk cargo compartments each have two heat valves. One functions as a shutoff valve. The other functions as a temperature control valve. These valves open or close to supply more or less warm air to keep compartment temperatures within limits.

The cargo temperature select panel on the flight deck gives manual control of the temperature for the aft and bulk cargo compartments. Operation of the valves is from environmental control system miscellaneous cards (ECSMCs) in the system card files.



21-44-00-001 Rev 0

AIR CONDITIONING - AFT AND BULK CARGO COMPARTMENT HEATING - INTRODUCTION

AIR CONDITIONING - AFT AND BULK CARGO COMPARTMENT HEATING - HEAT VALVES

Purpose

The aft and bulk cargo heat valves control the amount of air added from the pneumatic system to heat these compartments. Each cargo compartment has two heat valves that do these functions:

- Shutoff
- Temperature control.

Physical Description

The aft and bulk cargo heat valves have these parts:

- Relief valve
- Flow assembly
- Electrical solenoid valve
- Optical switch assembly
- Actuator assembly.

Location

The aft and bulk cargo heat valves are in the left side wall where the aft and bulk cargo compartments come together.

Functional Description

With no power to the solenoid valve, the butterfly valve (not shown) in the flow assembly is closed. When the solenoid gets power and pneumatic air is available to the valve, the butterfly valve will fully open.

The optical switch assembly tells the ECSMC when the valve is completely open or closed.

Training Information Point

The aft and bulk cargo heat valves are all the same.

AIR CONDITIONING - AFT AND BULK CARGO COMPARTMENT HEATING - HEAT VALVES

AIR CONDITIONING - AFT AND BULK CARGO COMPARTMENT HEATING - TEMPERATURE SENSORS

Purpose

The aft and bulk cargo compartment temperature sensors monitor the temperature in the related compartment. The ECS miscellaneous cards (ECSMCs) use these temperatures to control the amount of heat added to the cargo compartments.

Physical Description

These sensors are solid state electronic devices.

Location

The aft cargo compartment temperature sensor is on the left side wall of the aft cargo compartment. The bulk cargo compartment temperature sensor is on the right side wall of the bulk cargo compartment.

THIS PAGE INTENTIONALLY LEFT BLANK

AIR CONDITIONING - AFT AND BULK CARGO COMPARTMENT HEATING - FUNCTIONAL DESCRIPTION

General

The aft and bulk cargo temperature selectors set the temperature range for these compartments.

Each cargo compartment has two heat valves that do these functions:

- Shutoff
- Temperature control.

Valve Open

The open signal for the aft cargo heat valves comes from the left environmental control system miscellaneous card (ECSMC) in the left system card file. The open signal for the bulk cargo heat valves comes from the right ECSMC in the right system card file.

An open signal for the aft cargo heat valves goes to the left power management panel. An open signal for the bulk cargo heat valves goes to the right power management panel. Switches in the electrical load management system (ELMS) electronics (ELEX) unit supply a ground to energize the related cargo heat shutoff valve relay and cargo heat temperature control relay. These relays apply power to the open solenoid on the related valve.

When the heat valves are enabled, the shutoff valve is open. The temperature control valve cycles open and closed to keep the temperature in the cargo compartment to within 5F (3C) of the selected temperature.

Indication

An optical sensor monitors valve position. An open and closed discrete from each valve goes to the related ECSMC for control.

A sensor in each compartment supplies temperature data to the related ECSMC.

Operation

Cargo temperature selectors for aft and bulk cargo compartments set cargo compartment temperatures for HIGH, LOW, or OFF. The HIGH selection sets the compartments to 70F (21C). The LOW selection sets the compartments to 45F (7C).

Inhibits

The operation of the valves is not enabled if any of these conditions occur:

- The temperature in the aft cargo compartment is more than 90F (32C) and the shutoff or temperature control valve is closed
- The airplane is on the ground with a cargo door open
- The cargo heat selector is set to off
- The aft cargo fire system is armed

- The two lavatory/galley ventilation fans are failed off
- TAT is more than the selected temperature
- The cargo temperature sensor is failed
- Limitations on the use of bleed air.

If the cargo compartment temperature is more than 90F (32C) and the SOV and the TCV are not closed, the system latches the two valves closed.

Limitations on the Use of Bleed Air

The cargo heat valves are commanded closed for certain airplane conditions to minimize the use of bleed air. These are the conditions:

- Engine start
- Takeoff
- Autoslat extension
- Only one engine is running and one or more wing anti-ice valve is open.

AIR CONDITIONING - AFT AND BULK CARGO COMPARTMENT HEATING - FUNCTIONAL DESCRIPTION

AIR CONDITIONING - SUPPLEMENTAL HEATING - INTRODUCTION

General

In locations where the heat from trim air is not sufficient, auxiliary heaters add more heat. Heaters supply heat to these areas.

- Flight crew feet
- Flight crew shoulders
- Doors
- Galleys.

The foot heater selectors and shoulder heater controls on the flight deck give manual control of these heaters. A manual control for the galley heaters is on each galley complex. The door heaters have no manual control.

Automatic operation of the heaters is from environmental control system miscellaneous cards (ECSMCs) in the system card files.

AIR CONDITIONING - SUPPLEMENTAL HEATING - INTRODUCTION

AIR CONDITIONING - SUPPLEMENTAL HEATING - FLIGHT DECK FOOT HEATERS

Purpose

Flight deck foot heaters add heat to the foot areas of the flight crew.

Physical Description

These are electrical heaters.

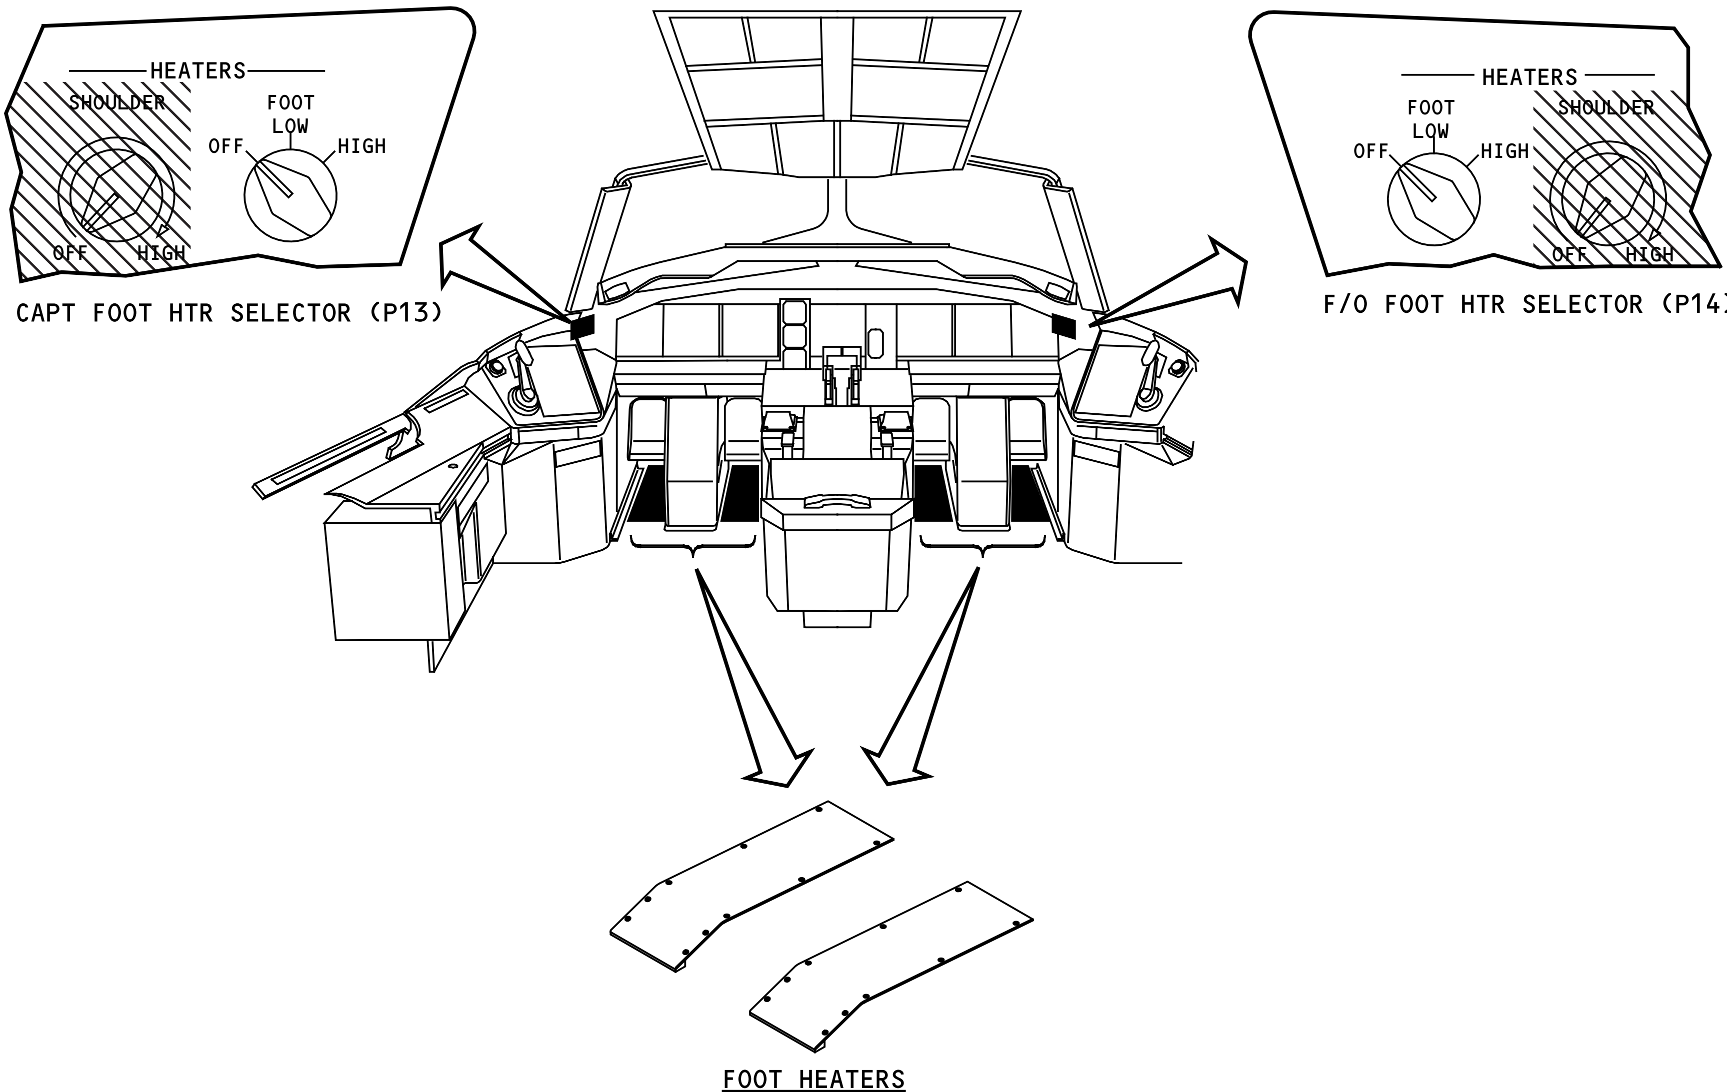
Location

One set of foot heaters is on the floor under each set of rudder pedals.

The captain foot heater selector is on the P13 sidewall panel - captain. The first officer foot heater selector is on the P14 sidewall panel - first officer.

Operation

The foot heater selectors permit selection of a high or low heat.



AIR CONDITIONING - SUPPLEMENTAL HEATING - FLIGHT DECK FOOT HEATERS

AIR CONDITIONING - SUPPLEMENTAL HEATING - FLIGHT DECK SHOULDER HEATERS

Purpose

Flight deck shoulder heaters add heat to the air supplied to the shoulder areas of the flight crew.

Physical Description

These are electrical heaters.

Location

One heater is on each side of the nose wheel well in the main equipment center.

The captain shoulder heater control is on the P13 sidewall panel - captain. The first officer shoulder heater control is on the P14 sidewall panel - first officer.

Operation

The shoulder heater controls set the level of heat from the shoulder heaters.

AIR CONDITIONING - HEATING - GROUND TESTS

General

These are the heating ground tests that show when you select ATA 21 Environmental Control System:

- Aft cargo heat
- Bulk cargo heat
- Door area heater.

Aft Cargo Heat

This test makes sure that these LRU installations are correct:

- Aft cargo heat shutoff valve
- Aft cargo heat temperature control valve
- Aft cargo compartment temperature sensor.

You must pressurize the pneumatic system for this test. During this test, hot air comes out of the aft cargo heat duct. This test takes approximately 2-5 minutes.

This test shows for these ground test types:

- System test
- LRU replacement test.

Bulk Cargo Heat

This test makes sure that these LRU installations are correct:

- Bulk cargo heat shutoff valve
- Bulk cargo heat temperature control valve
- Bulk cargo ventilation fan
- Bulk cargo compartment temperature sensor.

You must pressurize the pneumatic system for this test. During this test, hot air comes out of the bulk cargo heat duct. This test takes approximately 2-5 minutes.

This test shows for these ground test types:

- System test
- LRU replacement test.

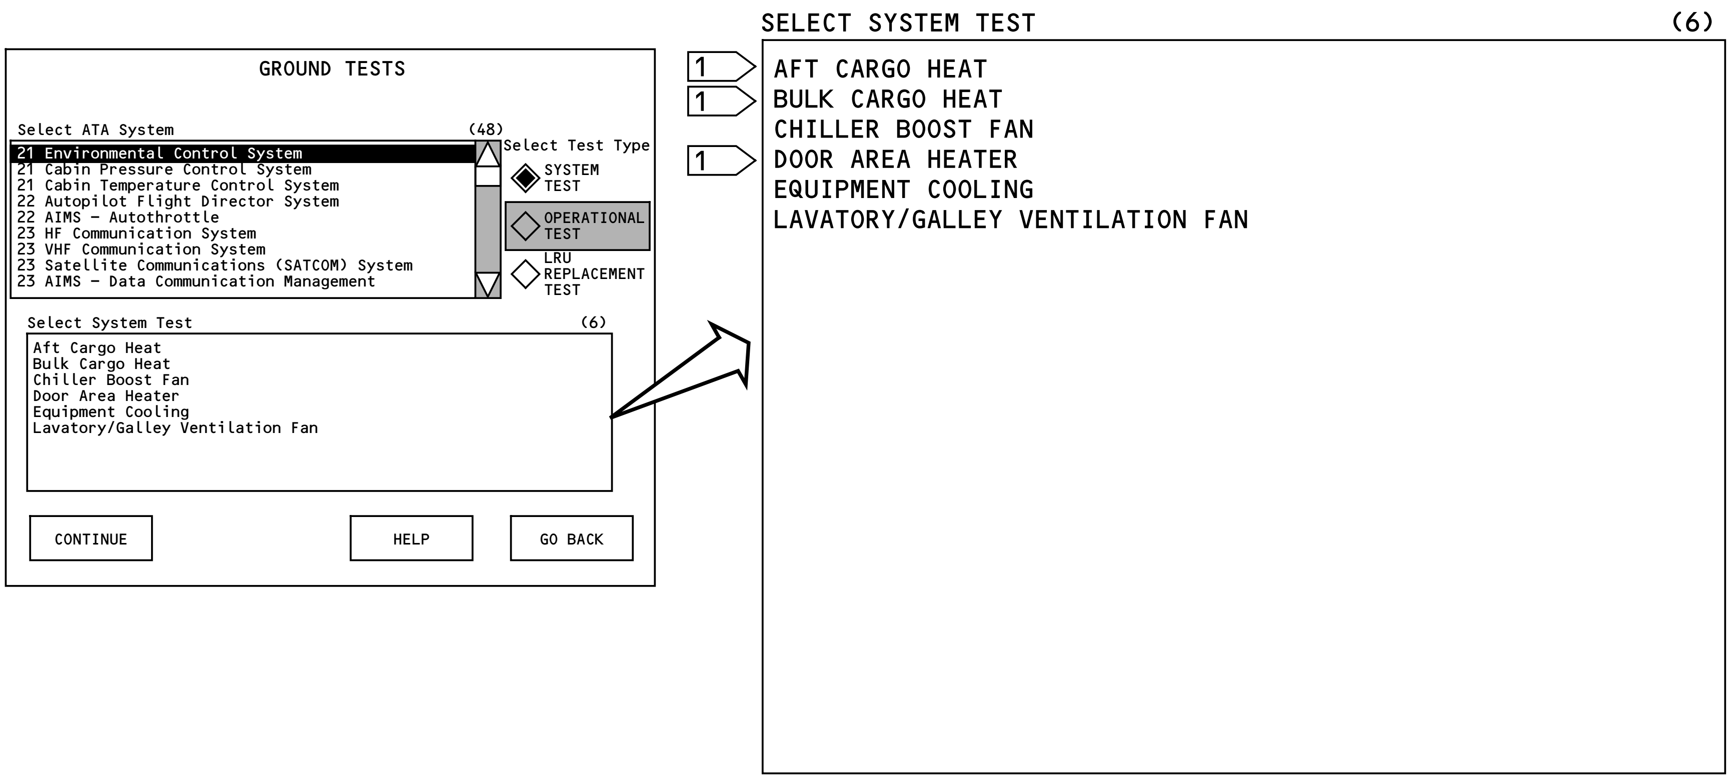
Door Area Heater

This test makes sure that all passenger door area heater installations are correct.

This test takes approximately 2-5 minutes.

This test shows for these ground test types:

- System test
- LRU replacement test.



NOTE: SYSTEM TESTS SHOW.
LRU REPLACEMENT TESTS ARE THE SAME.

1 THESE ARE THE AIR CONDITIONING - HEATING TESTS.

AIR CONDITIONING - HEATING - GROUND TESTS

THIS PAGE INTENTIONALLY LEFT BLANK

Air Synoptic Display

The top part of the air synoptic display shows information about the air conditioning system.

- The MASTER box shows the passenger compartment target temperature set by the flight crew. It has a minimum of 65F (18C) and a maximum of 85F (29C).
- The number at the left in the F/D box is the flight deck target temperature set by the flight crew. It has a minimum of 65F (18C) and a maximum of 85F (29C) when AUTO is selected. If the selector is in the MAN position, no value shows. The number at the right is the actual flight deck temperature.
- The number at the left in the zone boxes A-F is the zone target temperature set by the flight crew or the cabin crew. It has a minimum of 65F (18C) and a maximum of 85F (29C). The number at the right in each box is the actual zone temperature.
- The number at the left in the AFT and BULK boxes is the temperature set on the flight deck for that cargo compartment. They can be set to 45F (7C) or 70F (21C) or to off. The number at the right in each box is the actual cargo compartment temperature. If the selector is in the OFF position, no value shows.

Target and actual temperatures show in degrees F.

The flight deck trim air modulating valve position shows on the indication on the left of the display. If the valve position signal is not valid, the valve position pointer does not show.

Green flow bars show air flow through the left and right packs. These symbols show the status of the packs:

- Green oval - pack on
- White oval - pack off or pack status data invalid
- Amber oval with amber X - pack failed.

The STBY COOLING message on the air synoptic display and an advisory message PACK MODE L (R) (not shown) show when a pack is on and has any of these faults:

- ACM failure
- Condenser inlet temperature sensors 1 and 2 fail
- Economy cooling valve failed open.

If the pack stops, the STBY COOLING message and the advisory message PACK MODE L (R) do not show. See the pack cooling and mix manifold temperature control section for more information about the standby cooling mode (AMM PART I 21-52).

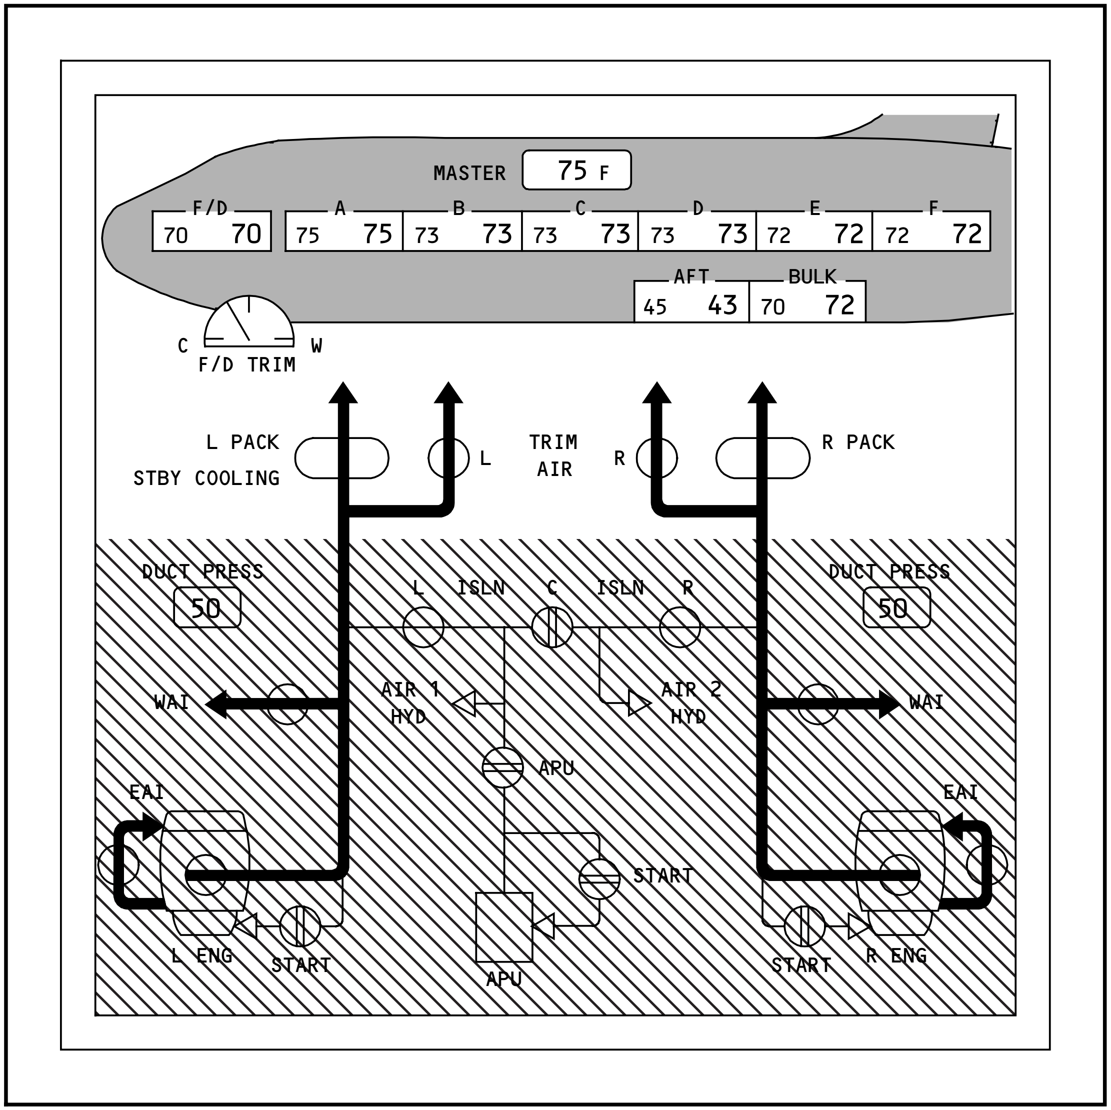
Green flow bars show air flow through the trim air pressure regulating and shutoff valves. Valve positions show as one of these symbols:

- White circle with one bar in-line with duct - open
- White circle with two bars 90 degrees to duct - closed
- Amber valve open symbol with amber X - failed open
- Amber valve closed symbol with amber X - failed closed

AIR CONDITIONING - AIR SYNOPTIC DISPLAY

- White circle with no bars - valve position data not valid.

See the primary display system section for more information about the air synoptic display (AMM PART I 31-61).



AIR SYNOPTIC DISPLAY

AIR CONDITIONING - AIR SYNOPTIC DISPLAY

Air Conditioning Maintenance Page

All temperatures on the air conditioning maintenance page are in degrees F.

The air conditioning maintenance page has this information:

- MASTER TEMP - Temperature selected on the cabin temperature control on the P5 panel
- SEATS - Number of passenger seats installed, used by the CTCs to calculate pack air flow rates
- TRGT TEMP - Target (selected) temperature for each zone and for the aft and bulk cargo compartments
- ZONE TEMP - Actual temperature in each zone and in the aft and bulk cargo compartments
- DUCT TEMP - Temperature measured in each zone distribution duct
- TRIM VLV - Position of each trim air modulating valve in percent heat (0.00 is closed, 1.00 is open)
- LOWER RECIR FAN - On or off status of the left and right lower recirculation fans
- UPPER RECIR FAN - On or off status of the left and right upper recirculation fans
- MIX MANIFOLD TEMP - Temperature in the mix manifold
- FLOW SCHEDULE - Right air conditioning pack flow schedule: 0,1,2,3, or 4. Usual left pack flow schedule is the same as the right
- PACK FLOW-VOLUME - Pack flow rate in cubic feet per minute
- PACK FLOW-MASS - Pack flow rate in pounds per minute
- PRI HX IN TEMP - Temperature at the inlet of the primary heat exchangers
- PRI HX OUT TEMP - Temperature at the outlet of the primary heat exchangers
- CPRSR OUT TEMP - Temperature at the outlet of the air cycle machine compressors
- SEC HX OUT TEMP - Temperature at outlet of the secondary heat exchangers
- CONDENSER IN TEMP - Temperature at the inlet of the condensers
- STG 2 TURB IN TEMP - Temperature at the inlet of turbine 2 in the air cycle machines
- TRIM AIR PRESS - The difference, in psid, between cabin pressure and trim air pressure
- PACK CTRL CH - Shows the channel in control for the left and right cabin temperature controllers
- PACK IN PRESS - Pressure, in psia, at the inlet to the air conditioning packs
- LOW LIM VLV POS - Position of the low limit valve (0.00 is closed, 1.00 is open)
- TURB BYP VLV - Position of the turbine bypass valve in percent heat (0.00 is closed, 1.00 is open)
- RAM AIR INLET - Position of the ram air inlet in percent heat (0.00 is open, 1.00 is closed)
- RAM AIR EXIT - The ram air exit is a fixed opening; the position display is blank
- ECON COOL VLV - Open or closed position of the economy cooling valve
- LOWER FLOW CTRL VLV - Open or closed position of the lower flow control valve

- UPPER FLOW CTRL VLV - Open or closed position of the upper flow control valve.

See the primary display system section for more information about the air conditioning maintenance page (AMM PART I 31-61).

AIR CONDITIONING (A/C) - EQUIPMENT COOLING - INTRODUCTION

A/C - EQUIPMENT COOLING - AFT SYS - GENERAL DESCRIPTION - MECHANICAL

Purpose

The aft part of the equipment cooling system gives pull-through cooling for equipment in the aft part of the airplane that needs active cooling. The system also gives backup cooling for SATCOM equipment.

General Description

The aft part of the system has these components:

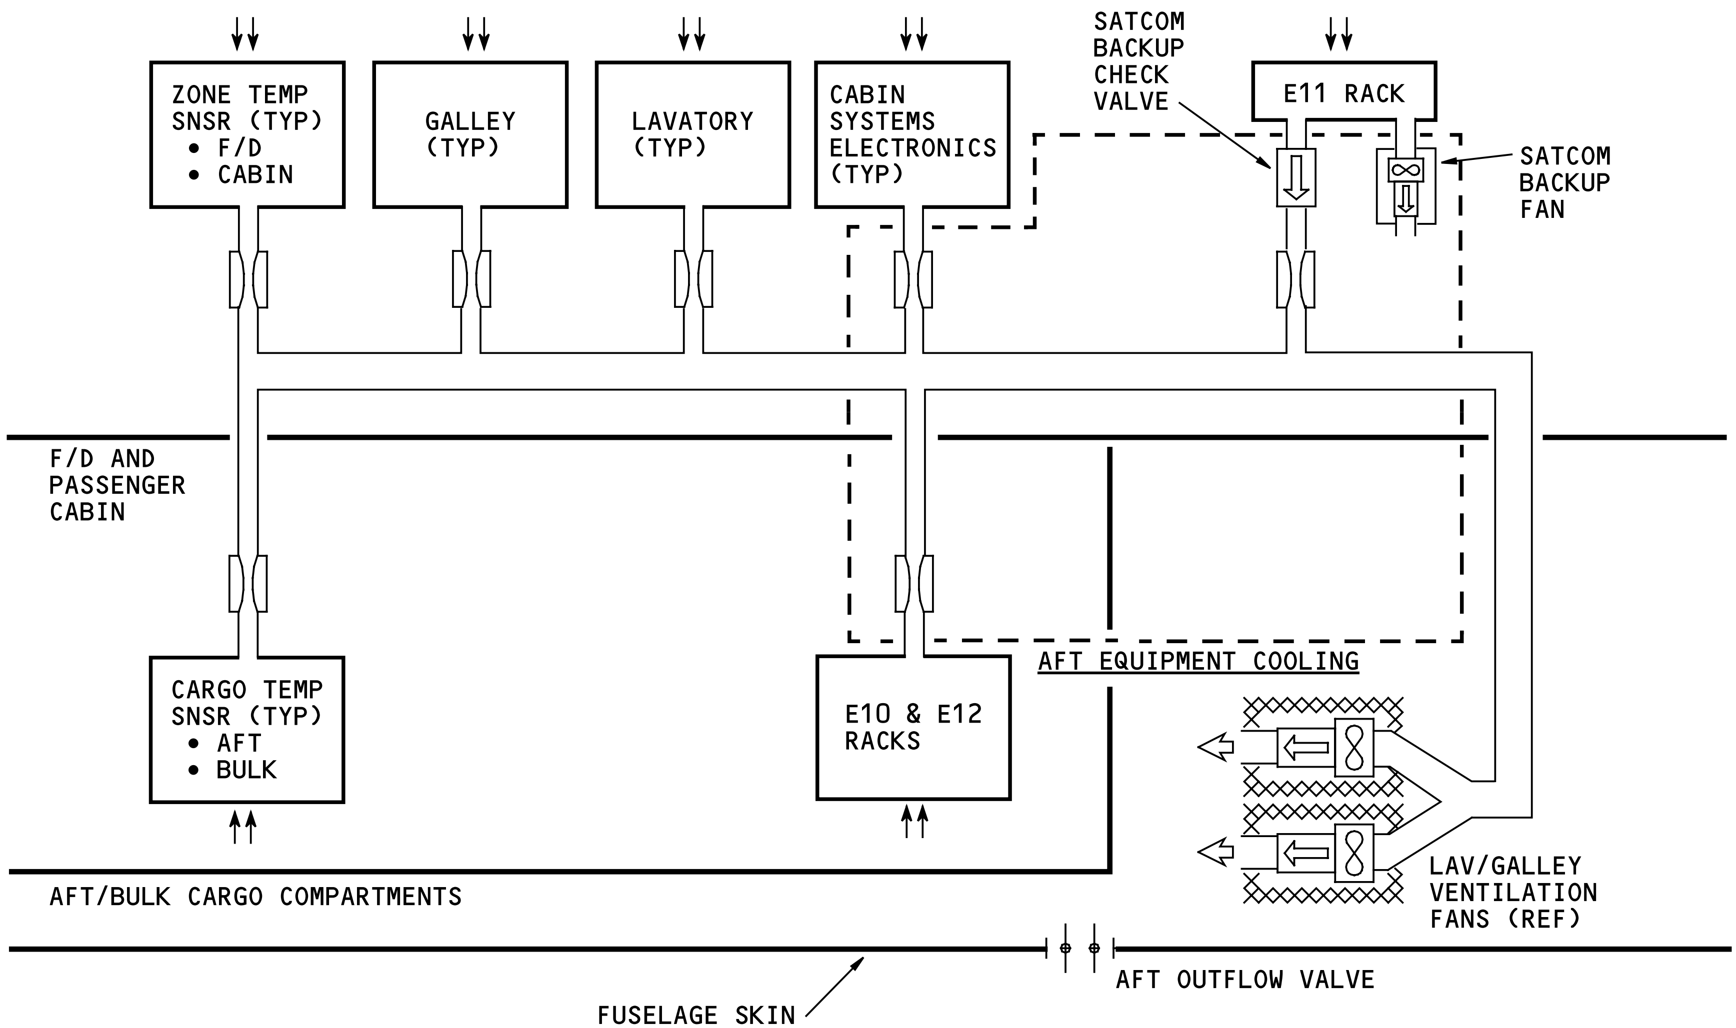
- Satellite communications (SATCOM) backup fan
- SATCOM check valve
- Ducts and hoses.

The system has interfaces with the lavatory/galley ventilation system. The ventilation system pulls cabin air though the equipment to cool it.

The lavatory/galley ventilation fans are part of the air conditioning system. One fan operates at a time.

See the ventilation system for more information about the lavatory/galley vent fans (AMM PART I 21-26).

The SATCOM fan comes on if both lavatory/galley ventilation fans do not operate. It pulls cabin air through the SATCOM equipment on the E11 rack.



A/C - EQUIPMENT COOLING - AFT SYS - GENERAL DESCRIPTION - MECHANICAL

A/C - EQUIPMENT COOLING - PASSENGER COMPARTMENT COMPONENT LOCATIONS

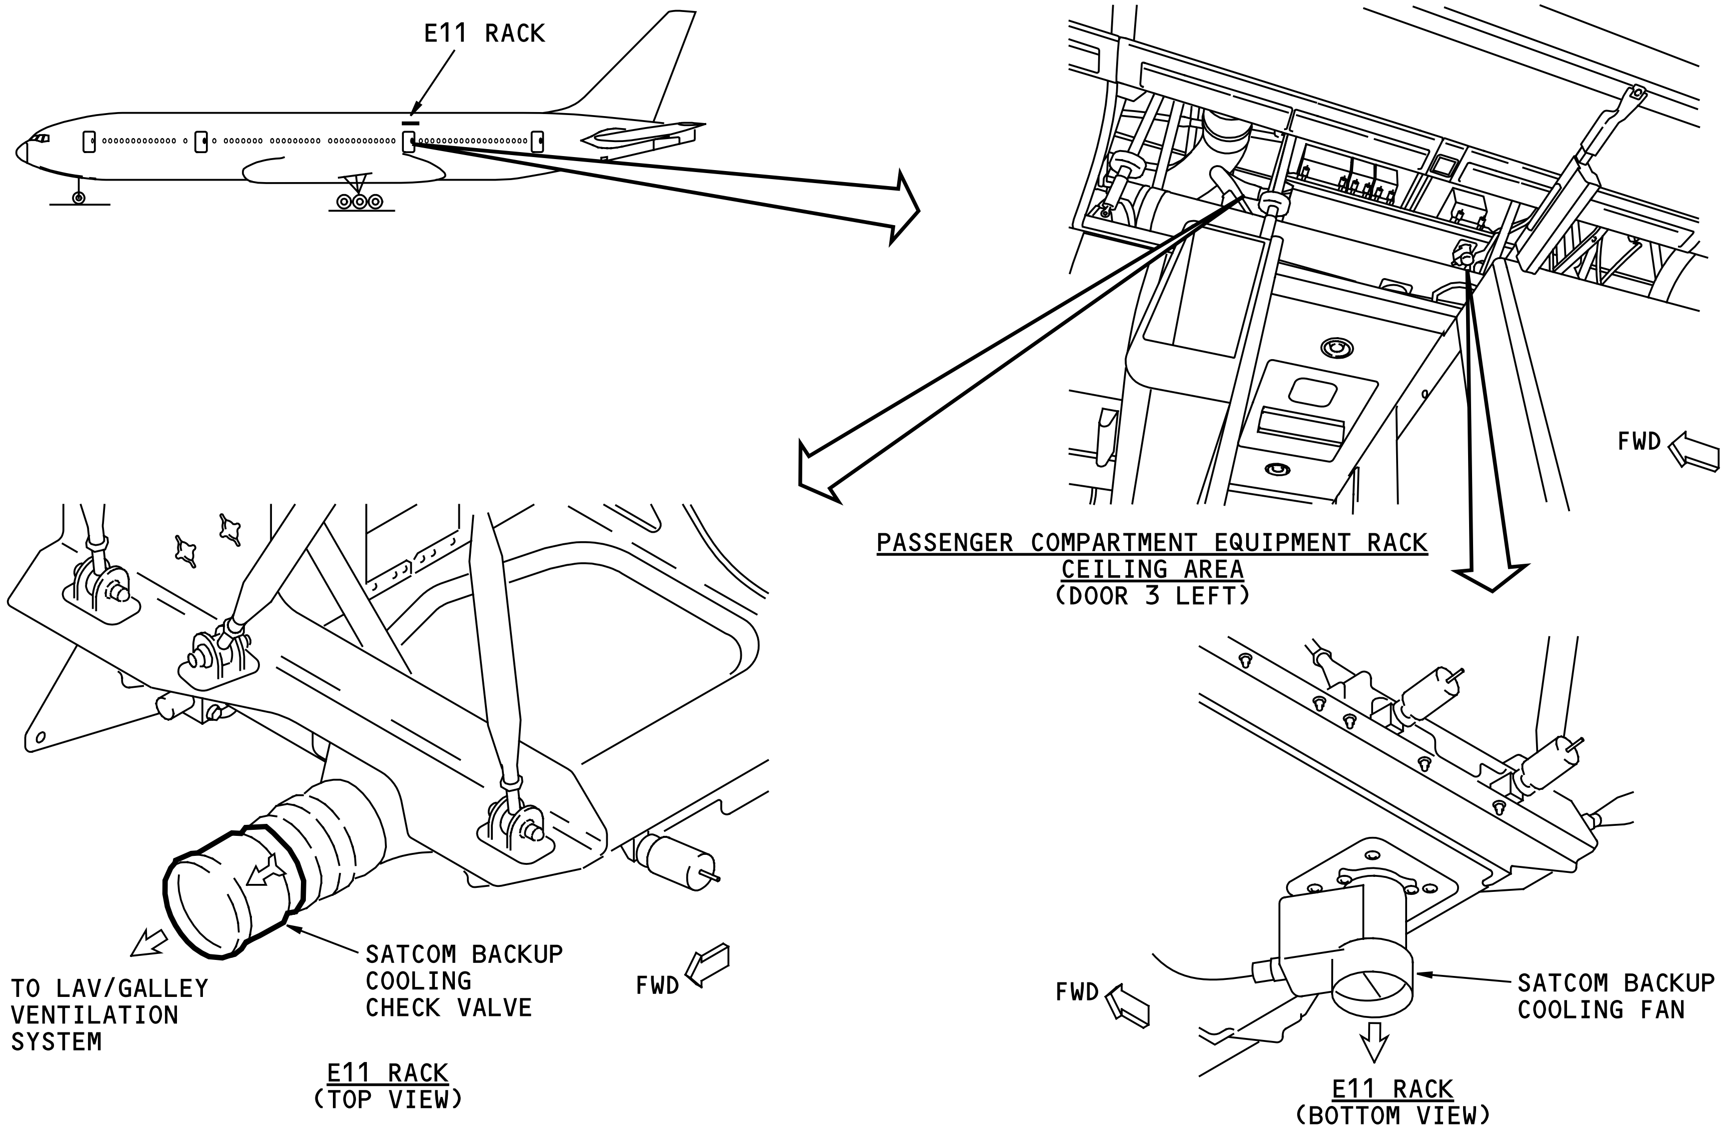
Component Locations

These components are above the passenger compartment ceiling:

- Satellite communications (SATCOM) backup cooling fan
- SATCOM backup cooling check valve.

The SATCOM backup cooling fan attaches to the bottom aft side of the E11 rack. The rack is near door 3 left, above the passenger compartment ceiling.

The SATCOM backup cooling check valve is in the vent duct that connects the rack to the lavatory/galley ventilation system. The duct is on the forward end of the equipment rack.



A/C - EQUIPMENT COOLING - PASSENGER COMPARTMENT COMPONENT LOCATIONS

A/C - EQUIPMENT COOLING - SATCOM BACKUP COOLING FAN AND CHECK VALVE

Purpose

The SATCOM backup cooling fan pulls air through the E11 rack if the lavatory/galley ventilation system does not operate.

The SATCOM backup cooling check valve makes sure that the fan pulls air through the SATCOM equipment on the rack and not out of the duct to the lavatory/galley ventilation system.

Location

The SATCOM fan and check valve are above the passenger compartment ceiling.

The SATCOM backup cooling fan attaches to the bottom aft side of the E11 rack. The E11 rack is near door 3 left.

The SATCOM backup cooling check valve is in the vent duct that connects the rack to the lavatory/galley ventilation system. The duct is on the opposite end of the equipment rack as the fan.

Physical Description

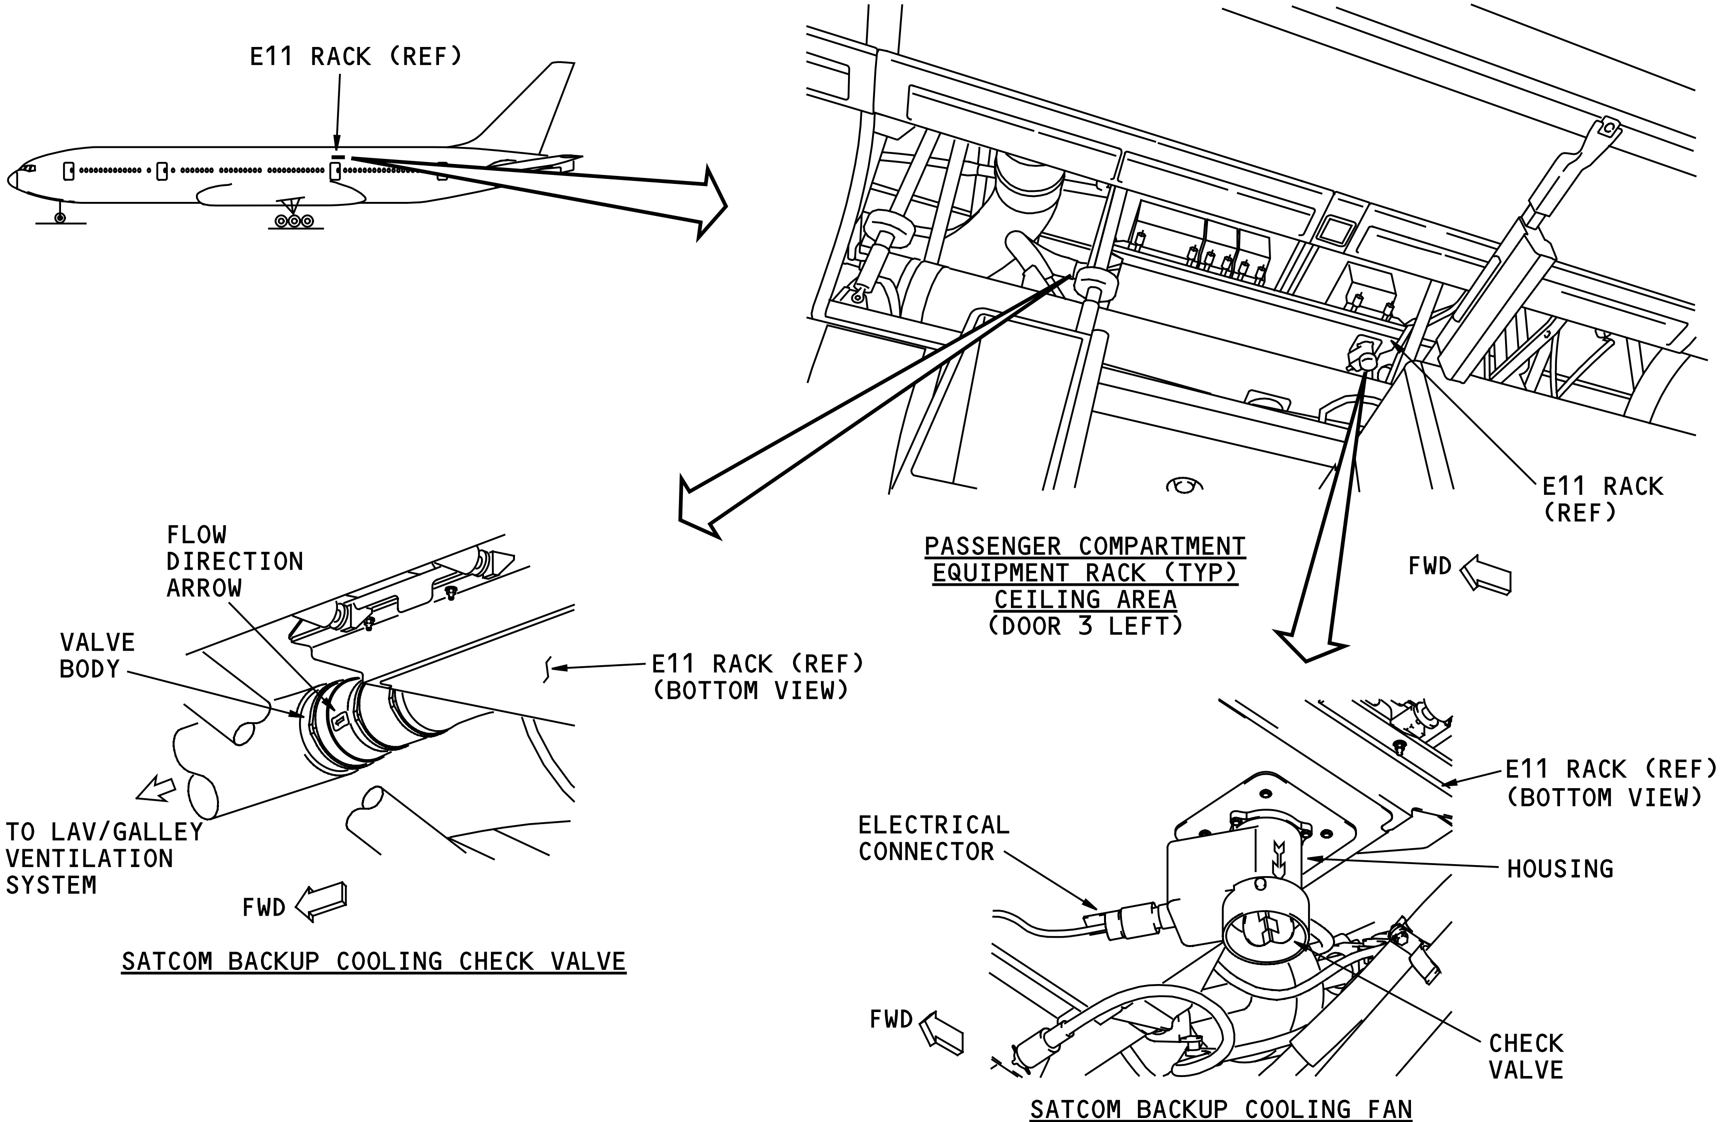
The SATCOM backup cooling fan has these components:

- Fan assembly (not shown)
- Housing
- Check valve
- Electrical connector.

The SATCOM backup cooling check valve has a valve body and a set of flapper doors (not shown).

Training Information Point

The check valve has a small inlet and a larger outlet and has an air flow direction arrow on it to help install the valve correctly.



21-27-00-018 Rev 2 02/09/1998

A/C - EQUIPMENT COOLING - SATCOM BACKUP COOLING FAN AND CHECK VALVE

A/C - EQUIPMENT COOLING - FWD SYS - MECHANICAL - GENERAL DESCRIPTION

General

The forward part of the equipment cooling system cools the equipment that needs active cooling and removes smoke from the flight deck. The system also gives cooling to some rack-installed passively cooled equipment.

The forward equipment cooling system uses cabin air to cool electrical and electronic equipment. The system has two parts: supply and vent (exhaust). The supply part gives blow-through cooling (supply fans). The vent part gives pull-through cooling (vent fan). The system uses cabin differential pressure and the override valve to remove smoke from the flight deck.

The inflight entertainment (IFE) cooling system uses cabin air to give pull-through cooling for the entertainment equipment. Exhaust air from the system goes into the exhaust part of the forward equipment cooling system. See the general description page in this section for more information about IFE cooling system.

Forward Equipment Cooling Components

The forward part of the system has these components:

- Vent fan
- Forward cargo heat valve
- Vent valve
- Air filter
- Supply fan (2)
- Override valve
- Duct pressure sensor (4)
- Low flow sensor (2)
- Converter supplemental cooling check valve
- Equipment cooling controller (2) (not shown).

The left and right ECS miscellaneous cards (ECSMCs) (not shown) give control, BIT, and indications for the system. The right card gives primary control when the airplane gets power and the left gives backup control. When the airplane changes from air to ground, the card that is in control changes. Two equipment cooling controllers (ECC) (not shown) control the supply fans and the override valve.

The low flow sensors supply both flow and temperature information.

The converter supplemental cooling check valve is part of the equipment cooling system. The converter supplemental cooling fan is part of the electrical system. See the AC generation section for more information on the converter (AMM PART I 24-20).

The smoke detector is part of the fire protection system. See the electrical and electronic cooling smoke detection section for more information about the equipment cooling smoke detector (AMM PART I 26-19).

The forward part of the equipment cooling system has two modes of operation: auto and override (OVRD).

A/C - EQUIPMENT COOLING - FWD SYS - MECHANICAL - GENERAL DESCRIPTION

Forward Equipment Cooling Auto Mode

One supply fan operates. The right fan is primary. The left fan gives automatic backup. The fan that operates pulls air through the air filter and pushes it through the override valve.

The override valve is closed to ambient and open (NORM position) to let the air from the supply fan go to these areas:

- Forward cargo compartment: E5 and E16 racks
- Main equipment center (MEC): E1, E2, E3, and E4 racks
- Forward equipment center: weather radar (WXR)
- Flight deck: instrument, center aisle stand and overhead panels and the maintenance access terminal (MAT).

The vent fan pulls air from these areas:

- Main equipment center (MEC): E1, E2, E3, and E4 racks
- Flight deck: instrument, center aisle stand and overhead panels and the MAT.

When electrical power is available, the vent fan operates most of the time. The fan is off for engine start. This logic helps to keep fumes from outside the aft pressurization outflow valve out of the airplane during engine start.

The air from the vent fan goes to the vent valve and the forward cargo heat valve. Only one of the valves is open at a time. When the total air temperature (TAT) goes above 55F (12.8C), the vent valve opens and the cargo heat valve closes. The air goes to the area near the forward outflow valve in the MEC. When TAT goes below 50F (10C), the forward cargo heat valve opens and the vent valve closes. The air goes to heat the forward cargo compartment.

Forward Equipment Cooling Override Mode

The override mode cools the equipment without the supply and vent fans. This mode uses cabin differential pressure to cause airflow through the equipment. The override mode gives sufficient cooling when the airplane is pressurized and above 25,000 feet (7625 meters). The flight crew also selects this mode when they want to clear smoke from the flight compartment.

Any of these conditions causes the system to operate in the override mode:

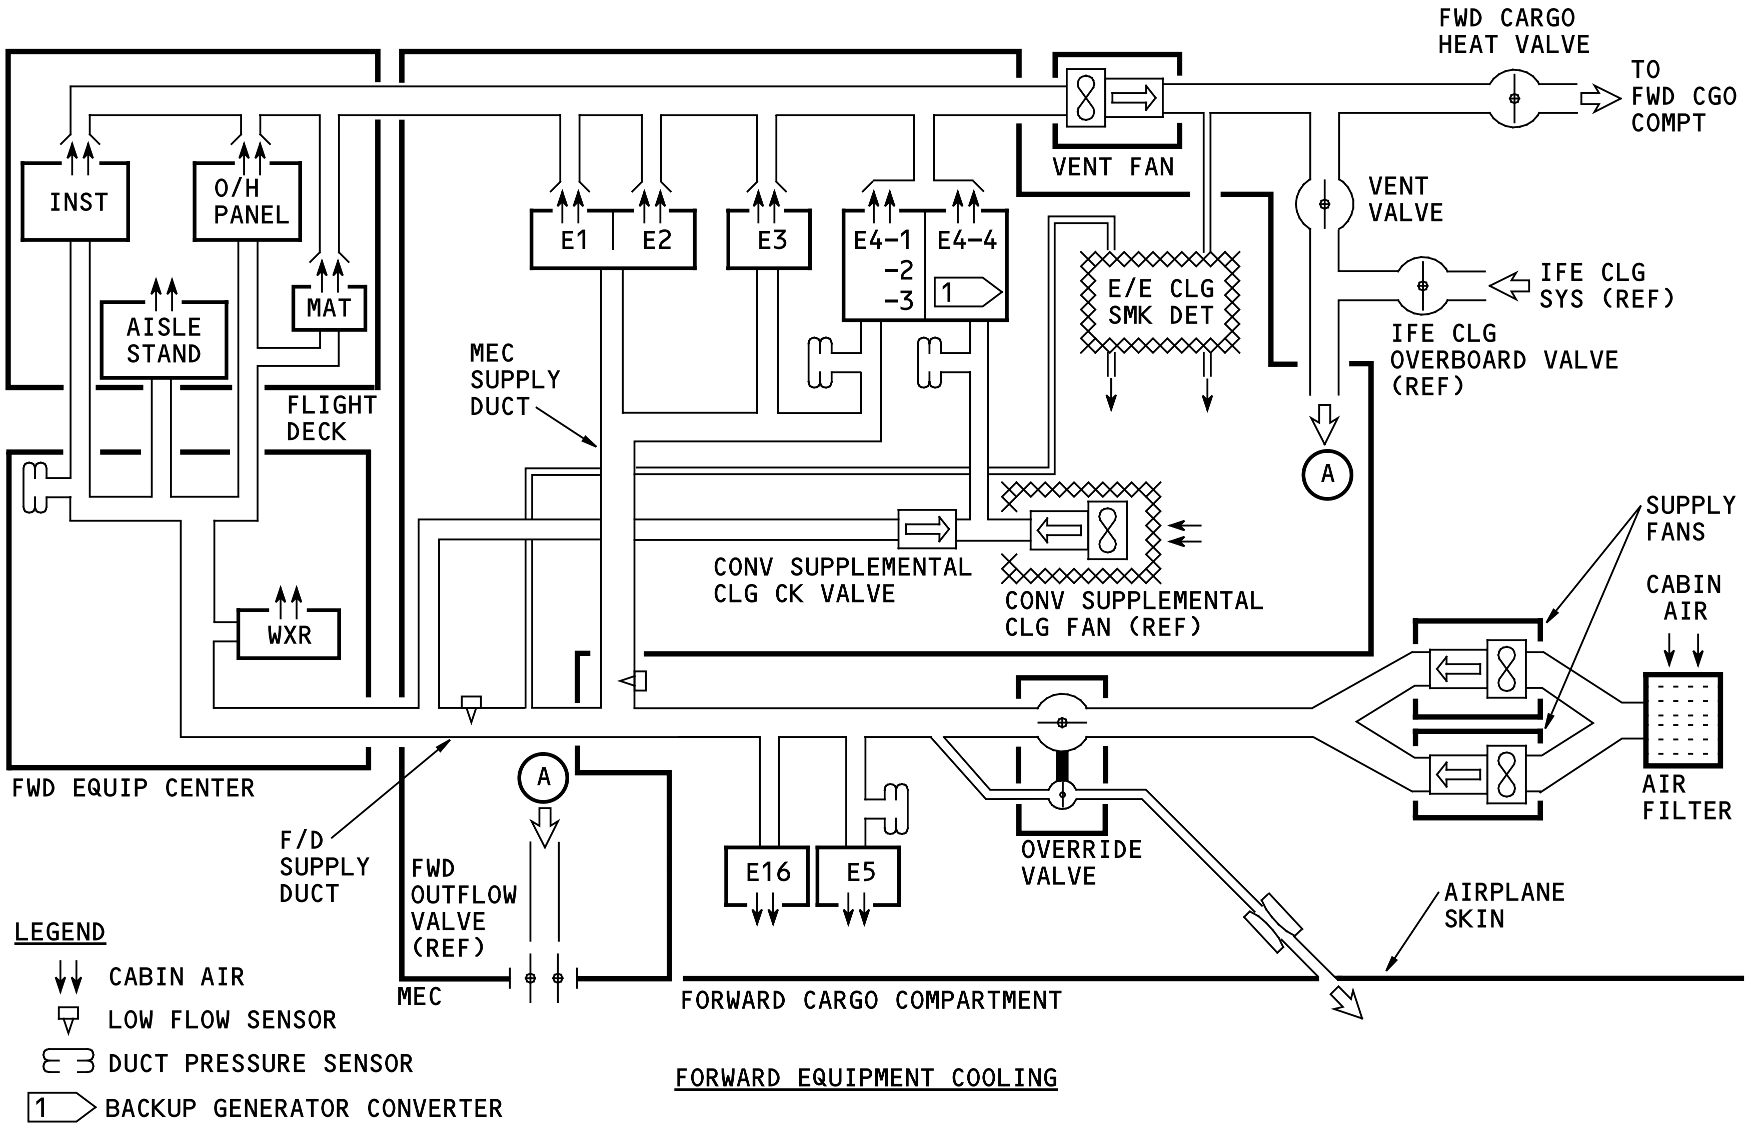
- Equipment cooling switch on the air conditioning panel (not shown) set to OVRD
- Low flow in MEC and F/D supply ducts and airspeed more than 150 knots
- Left and right supply fans failed off
- Smoke in supply or vent duct
- Forward cargo fire extinguishing system armed.

The override mode causes these effects:

A/C - EQUIPMENT COOLING - FWD SYS - MECHANICAL - GENERAL DESCRIPTION

- The bulk cargo ventilation fan goes off (only with equipment cooling switch in the OVRD position)
- Both supply fans stop
- The override valve goes to the OVRD position which opens the supply duct to ambient
- Cabin differential pressure pushes cabin air through the components and out of the airplane
- The converter supplemental cooling fan comes on
- The vent fan stops
- The forward cargo heat valve closes if it is open (low flow does not cause the valve to change position)
- The vent valve closes if it is open (low flow does not cause the valve to change position).

The override mode also causes the IFE cooling system to stop operation.



FORWARD EQUIPMENT COOLING

A/C - EQUIPMENT COOLING - FWD SYS - MECHANICAL - GENERAL DESCRIPTION

A/C - EQUIPMENT COOLING - ELECTRICAL - GENERAL DESCRIPTION

General

Equipment cooling control components supply automatic or manual mode selection (AUTO/OVRD), indications, and BIT for the system. These are the control components:

- Equipment cooling switch
- Left and right environmental control system miscellaneous cards (ECSMC)
- Left and right equipment cooling controllers (ECC).

The equipment cooling switch gives indication for mode selection and lets you manually set the mode of operation to AUTO or OVRD.

The left and right ECSMCs give automatic control (AUTO or OVRD), indications (AIMS and equipment cooling switch), and BIT for the equipment cooling system. The cards control:

- Which supply fan is primary and which is backup
- When the supply and the vent fans operate.
- The direction of air flow for the equipment cooling exhaust air. Directs the air to the cargo compartment for heating or vents the air overboard
- When to set the system to the override mode
- When to turn on the SATCOM cooling fan
- When to give indications for mode selection and malfunctions.

The left and right equipment cooling controllers (ECCs) usually control the left and right equipment cooling supply fans and the override valve with inputs from the ECSMCs. The ECCs take control of the fans and valve if the airplane is in the air and the ECCs find low flow for an extended time (6.5 min in supply fan mode or 20 min in OVRD mode).

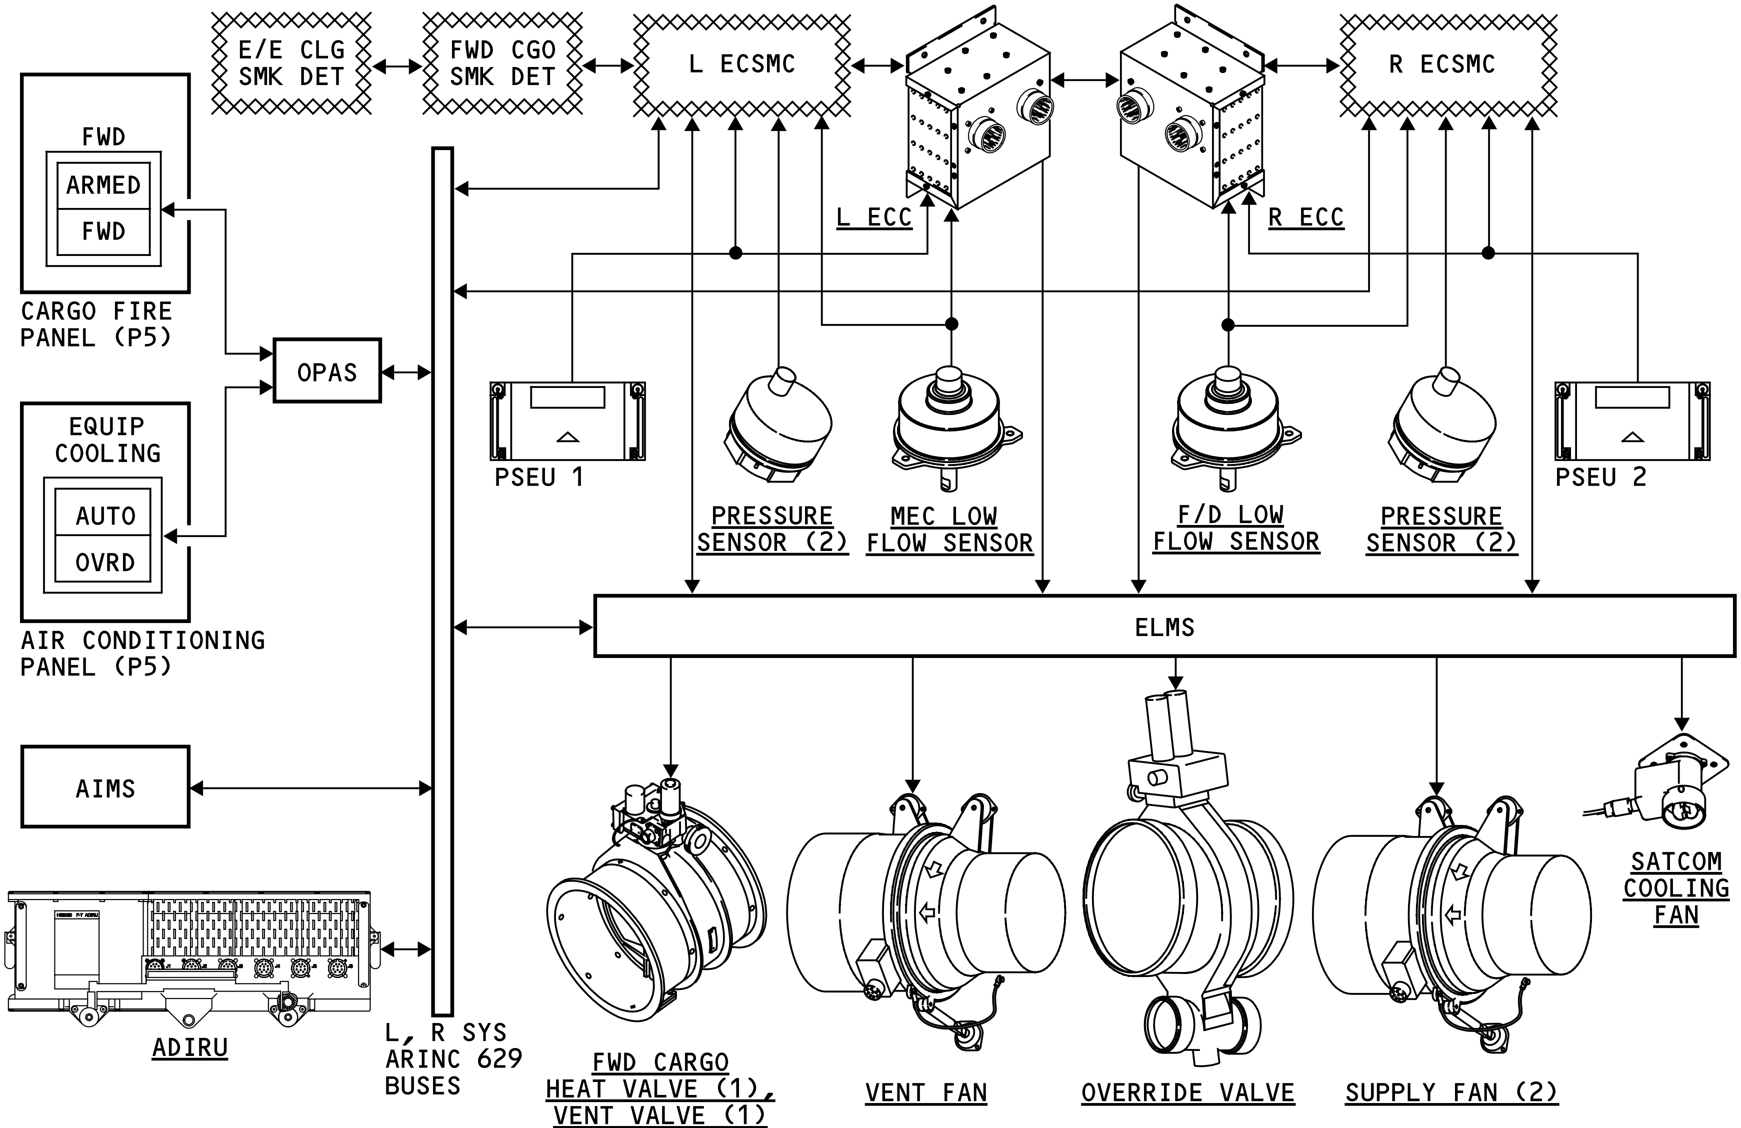
Interfaces

The ECSMCs have three types of input/output interfaces with system components and with other systems. One is through the left and right system ARINC 629 buses. These are the ARINC 629 interfaces:

- OPAS
- AIMS
- ELMS.

The second type is through hard-wired inputs to ELMS. The third type is by hard-wired inputs/outputs from system components and the PSEUs 1 and 2.

See the INTERFACES page in this section for more information about the system components that are hard-wired to the ECSMCs.



A/C - EQUIPMENT COOLING - ELECTRICAL - GENERAL DESCRIPTION

21-27-00-030 Rev 3 05/19/1997

A/C - EQUIPMENT COOLING - AIR FILTER

Purpose

The air filter removes particles from the air before the air cools the equipment.

Physical Description

The filter is a nonwoven fabric and is made of polyester and glass fibers.

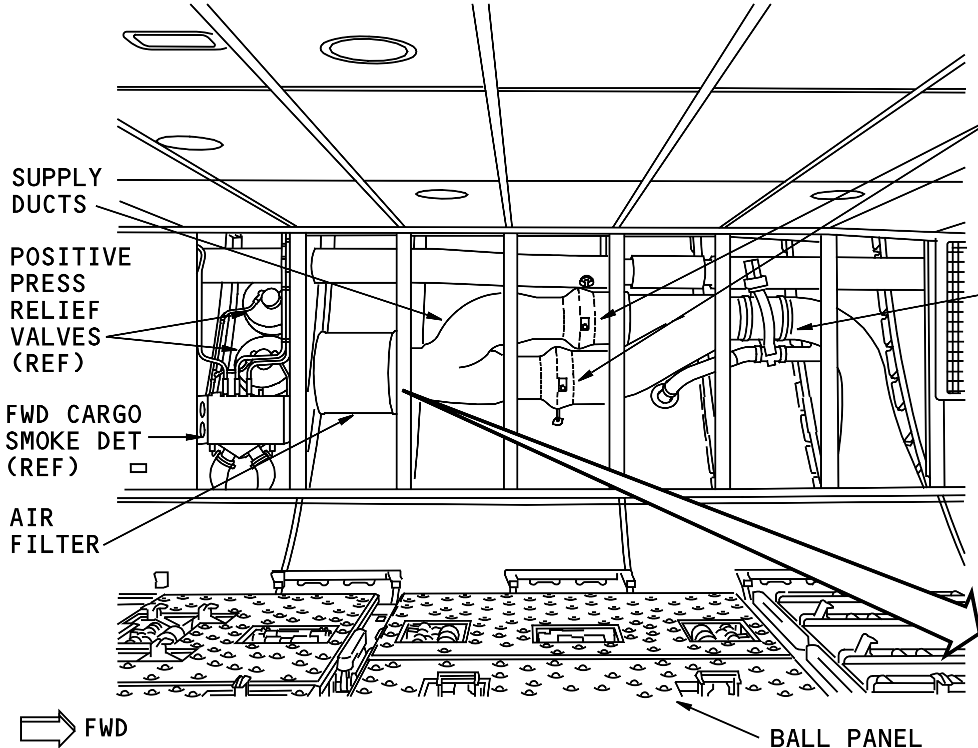
Location

The air filter is outboard of the left sidewall panel. It is near the forward ball panel in the forward cargo compartment.

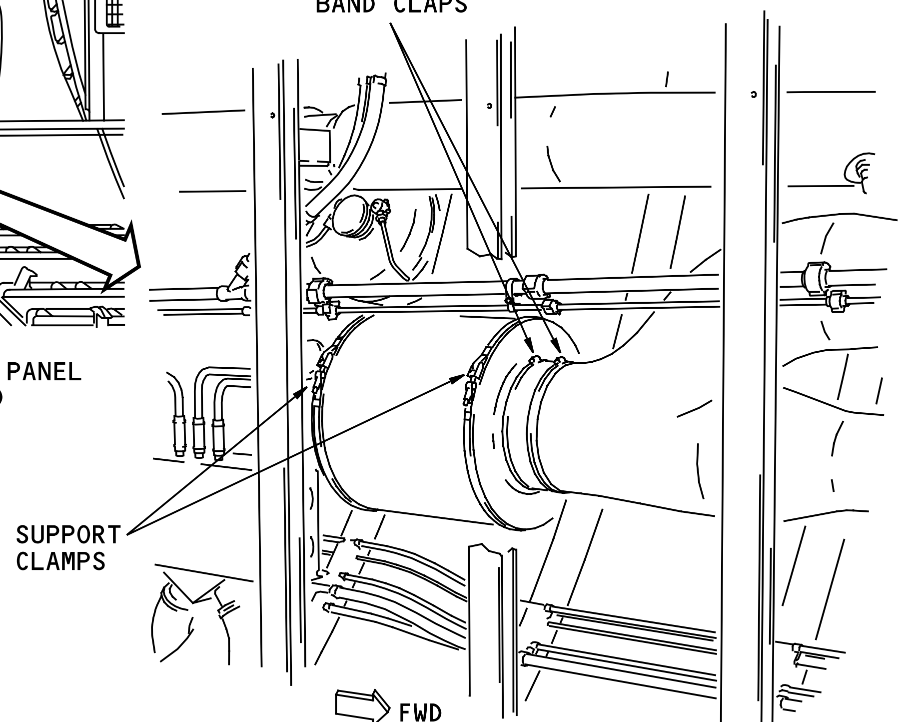
Training Information Point

Remove the sidewall lining to get access to the air filter.

You clean the filter with detergent. You can also blow air from the inside out to clean the filter. You remove two band clamps that attach to the duct and two support clamps to remove the filter from the airplane.



FORWARD CARGO COMPARTMENT
(LOOKING AT LEFT SIDEWALL AREA)



FILTER

A/C - EQUIPMENT COOLING - AIR FILTER

A/C - EQUIPMENT COOLING - SUPPLY FANS

Purpose

The two supply fans give air to the supply part of the forward equipment cooling system for blow-through cooling.

Physical Description

The supply fan has these components:

- Stator housing assembly
- Check valve (not shown)
- Electrical connector
- Electric motor (not shown)
- Inlet housing assembly.

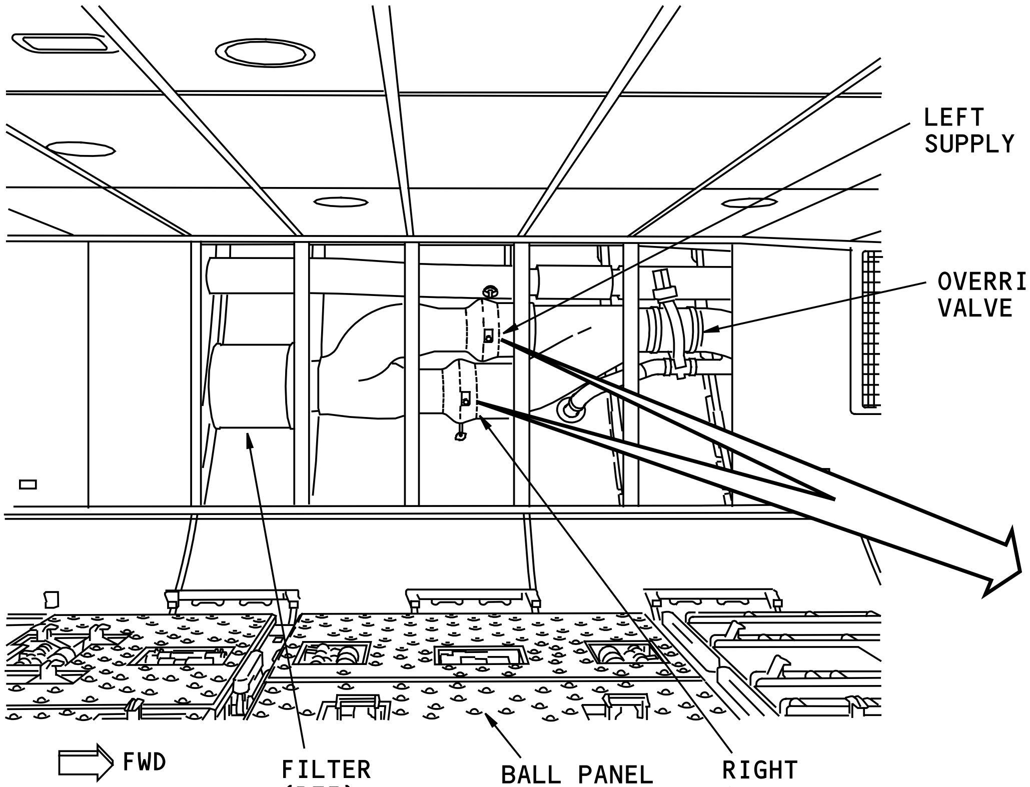
Location

The two supply fans are outboard of the left sidewall panel near the forward ball panel in the forward cargo compartment. The supply fans are between the override valve and the air filter. The left supply fan is above the right supply fan.

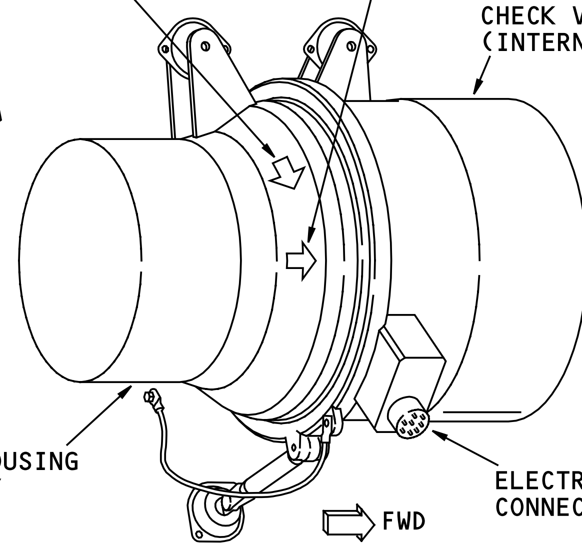
Training Information Point

One fan operates at a time. The right fan is primary and the left fan is backup.

The fans have flow and rotation arrows. The arrows help install the fans correctly.



FORWARD CARGO COMPARTMENT



SUPPLY FAN

21-27-00-010 Rev 3

A/C - EQUIPMENT COOLING - SUPPLY FANS

A/C - EQUIPMENT COOLING - OVERRIDE VALVE

Purpose

The override valve permits differential cabin pressure to remove smoke and cool the electronic and electrical components.

Location

The override valve is outboard of the left sidewall panel near the forward ball panel in the forward cargo compartment.

Physical Description

The override valve has these three primary components:

- Actuator
- Cooling valve
- Smoke removal valve.

The actuator has these components:

- Electric motor (2)
- Position indicator
- Electrical connector (2)
- Manual override knob.

Each motor can operate the override valve.

The cooling valve has a valve body and a butterfly plate assembly (not shown).

The smoke removal valve has a valve body and a butterfly plate assembly (not shown).

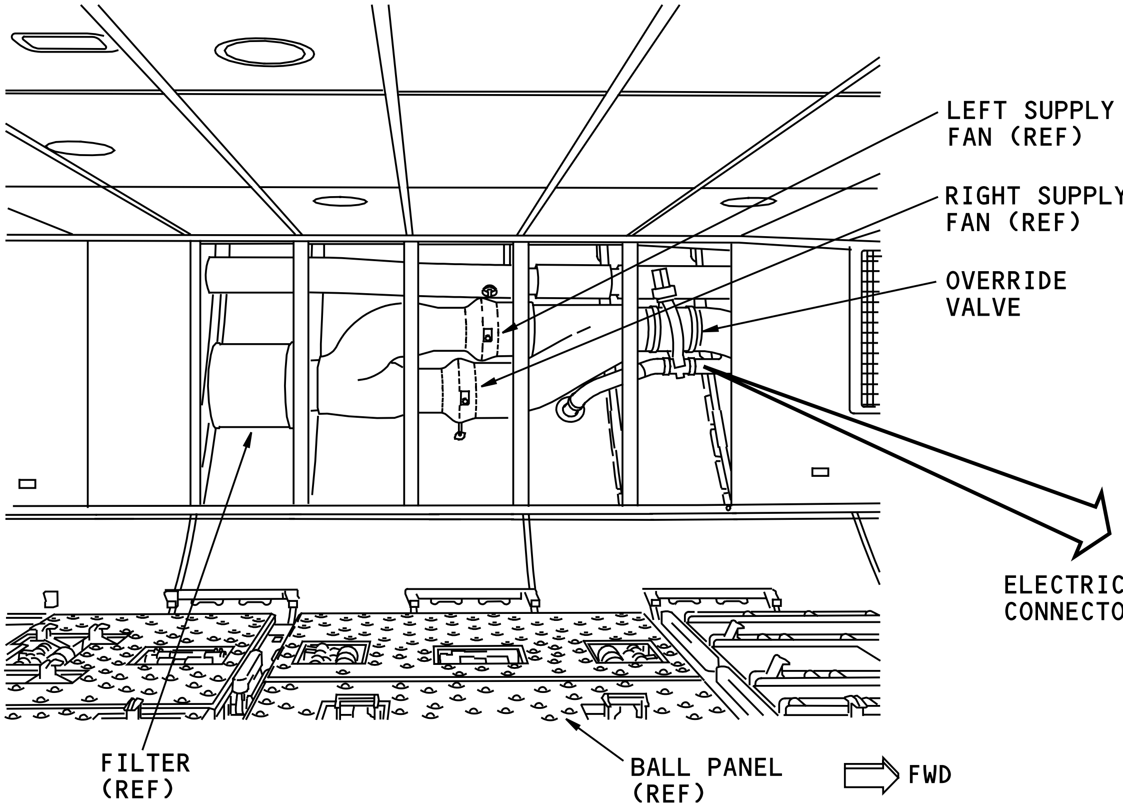
Functional Description

A shaft connects the two valves. When one valve is open the other is closed. The override valve has two positions: normal and override. In the normal position, the cooling valve is open and the smoke removal valve is closed. In the override position, the cooling valve is closed and the smoke removal valve is open.

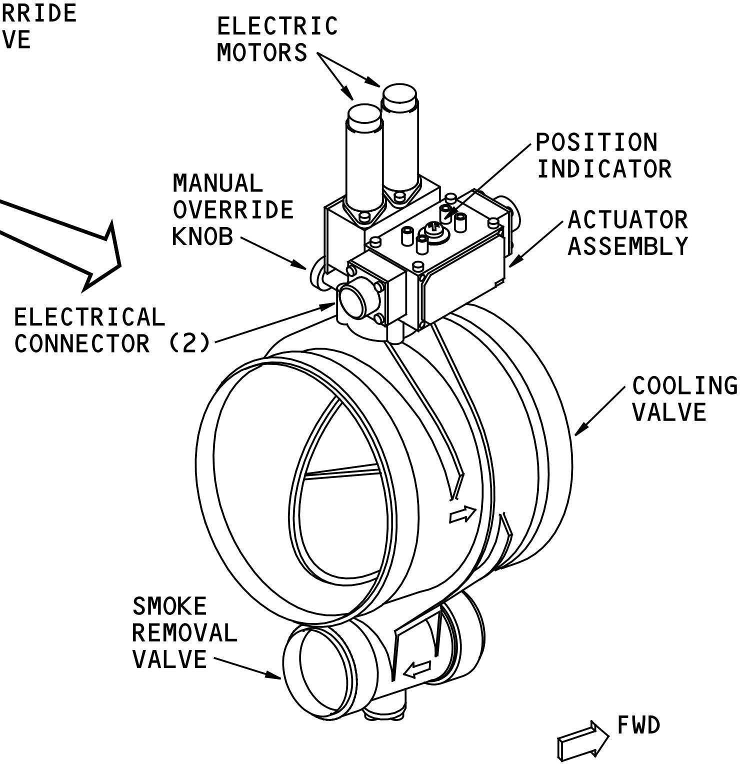
Training Information Point

The override valve has two air flow direction arrows. The arrows help you install the valve correctly.

A position indicator shows the position of the valve. You can use the manual override knob to change the position of the override valve when there is no electric power to the valve.



FORWARD CARGO COMPARTMENT



OVERRIDE VALVE

21-27-00-011 Rev 3

A/C - EQUIPMENT COOLING - OVERRIDE VALVE

A/C - EQUIPMENT COOLING - DUCT PRESSURE SENSORS

Purpose

Four duct pressure sensors tell the ECSMCs the pressure at each sensor location.

Physical Description

Each duct pressure sensor has these components:

- Sense port
- Electrical connector
- Sensor housing.

Location

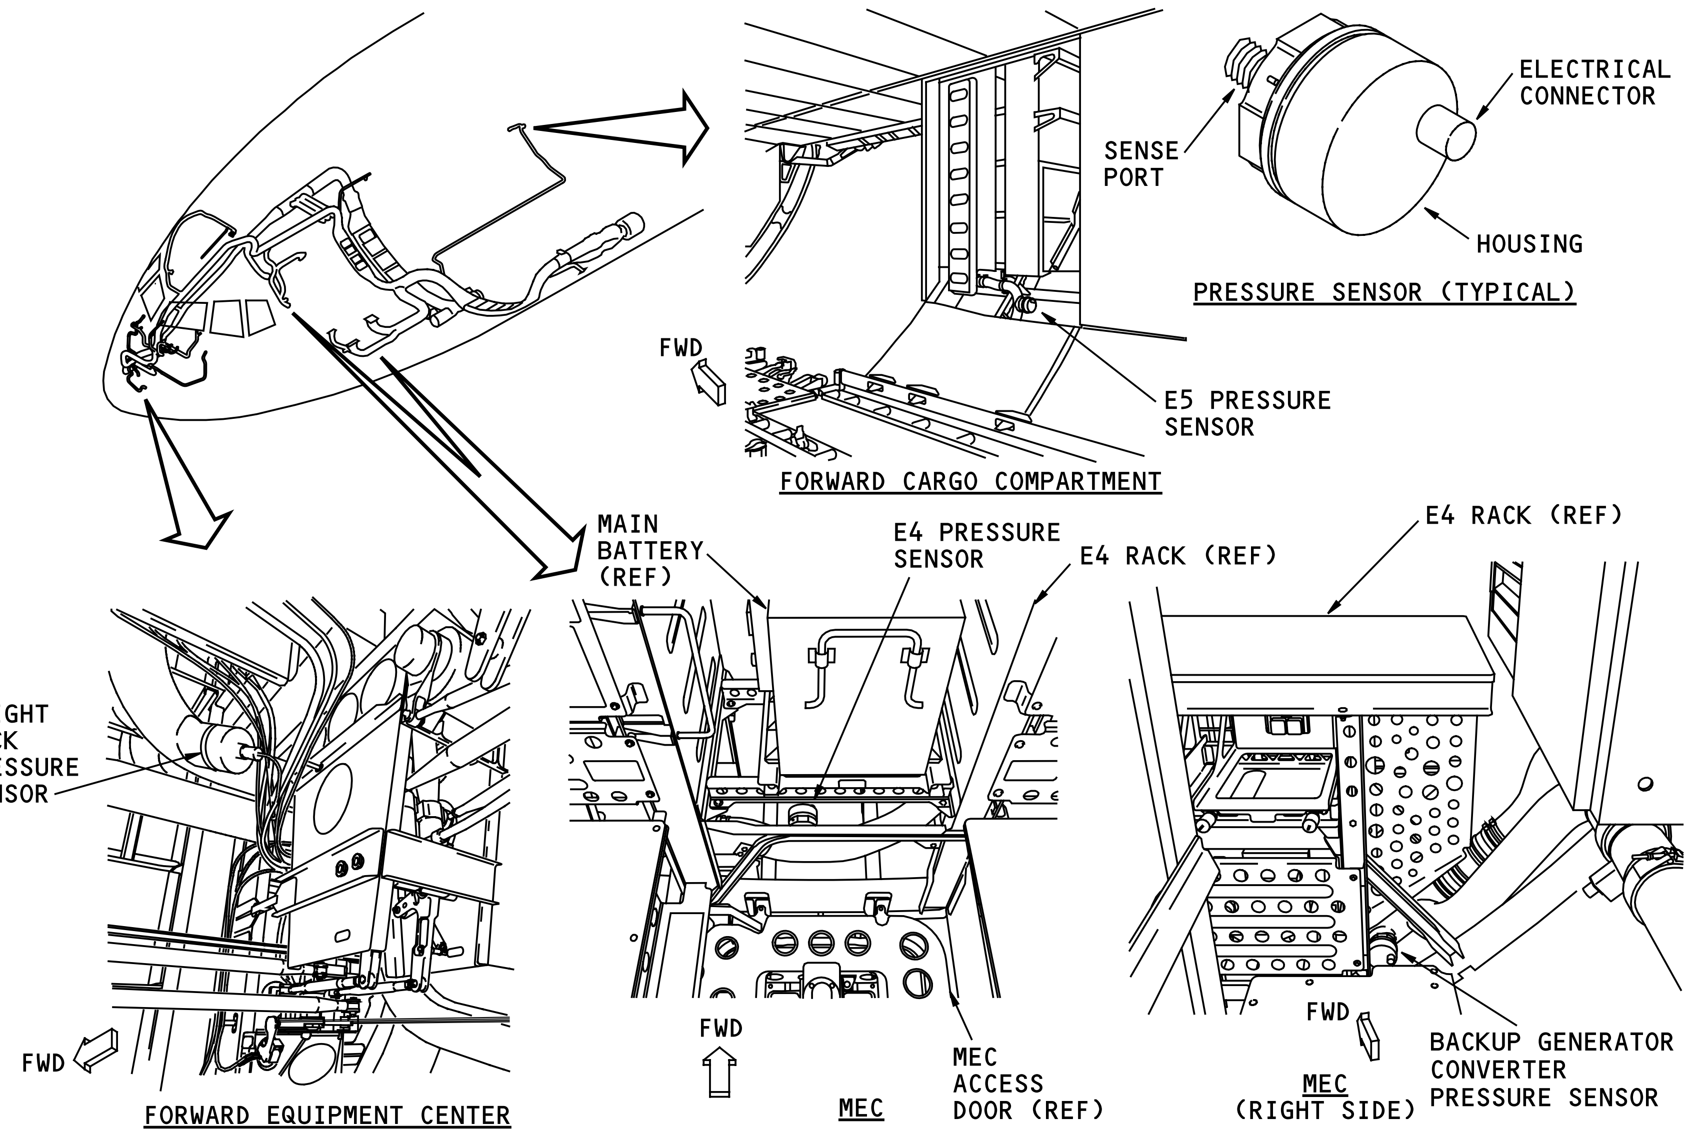
These are the four duct pressure sensor locations.

The sensor for the E5 rack is aft and below the E5 rack. Access is through the forward cargo compartment right sidewall panel, aft of the cargo door.

The duct pressure sensor for the backup generator converter (E4-4 shelf) is to the right side and below the E4 rack.

The duct pressure sensor for the E4-1, E4-2 and E4-3 shelves is just forward of the MEC access door, below the main battery.

The duct pressure sensor for the flight deck is in the forward equipment center. It is directly forward of the cutout for the forward access door



21-27-00-012 Rev 1

A/C - EQUIPMENT COOLING - DUCT PRESSURE SENSORS

A/C - EQUIPMENT COOLING - LOW FLOW SENSORS

Purpose

The two low flow sensors tell the ECSMCs if there is low air flow or high air temperature in the equipment cooling air.

Physical Description

The low flow sensor has these components:

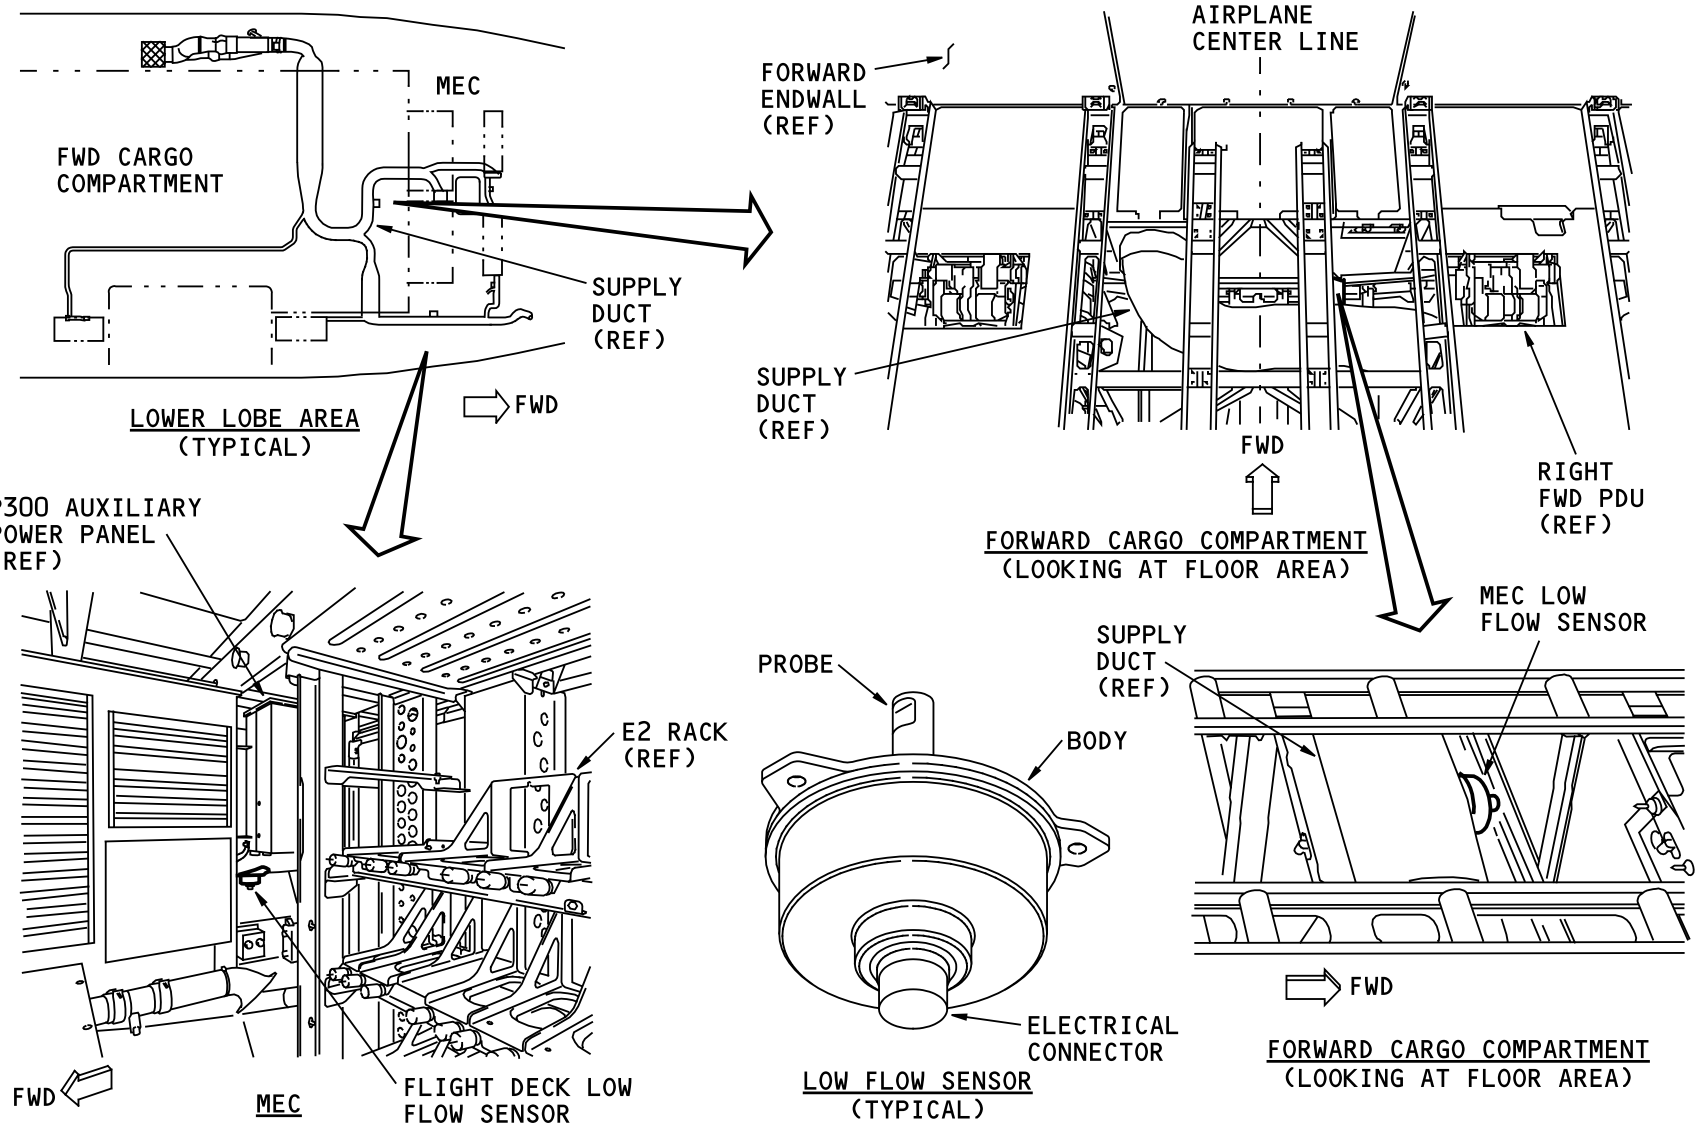
- Probe
- Body
- Electrical connector.

Location

The flight deck low flow sensor is in the MEC. The sensor is below and outboard of the forward corner of the P300 auxiliary power panel.

The MEC low flow sensor is in the forward cargo compartment below the floor. The sensor is inboard of the forward right powered drive unit.

Remove the floor panel inboard of the right forward powered drive unit (PDU) to get access to the MEC low flow sensor.



21-27-00-013 Rev 1 04/24/1997

A/C - EQUIPMENT COOLING - LOW FLOW SENSORS

A/C - EQUIPMENT COOLING - CONVERTER SUPPLEMENTAL COOLING CHECK VALVE (VSCF)

Purpose

The converter supplemental cooling check valve makes sure the air from the converter supplemental cooling fan goes to E4-4 shelf and does not go into the equipment cooling supply duct.

Physical Description

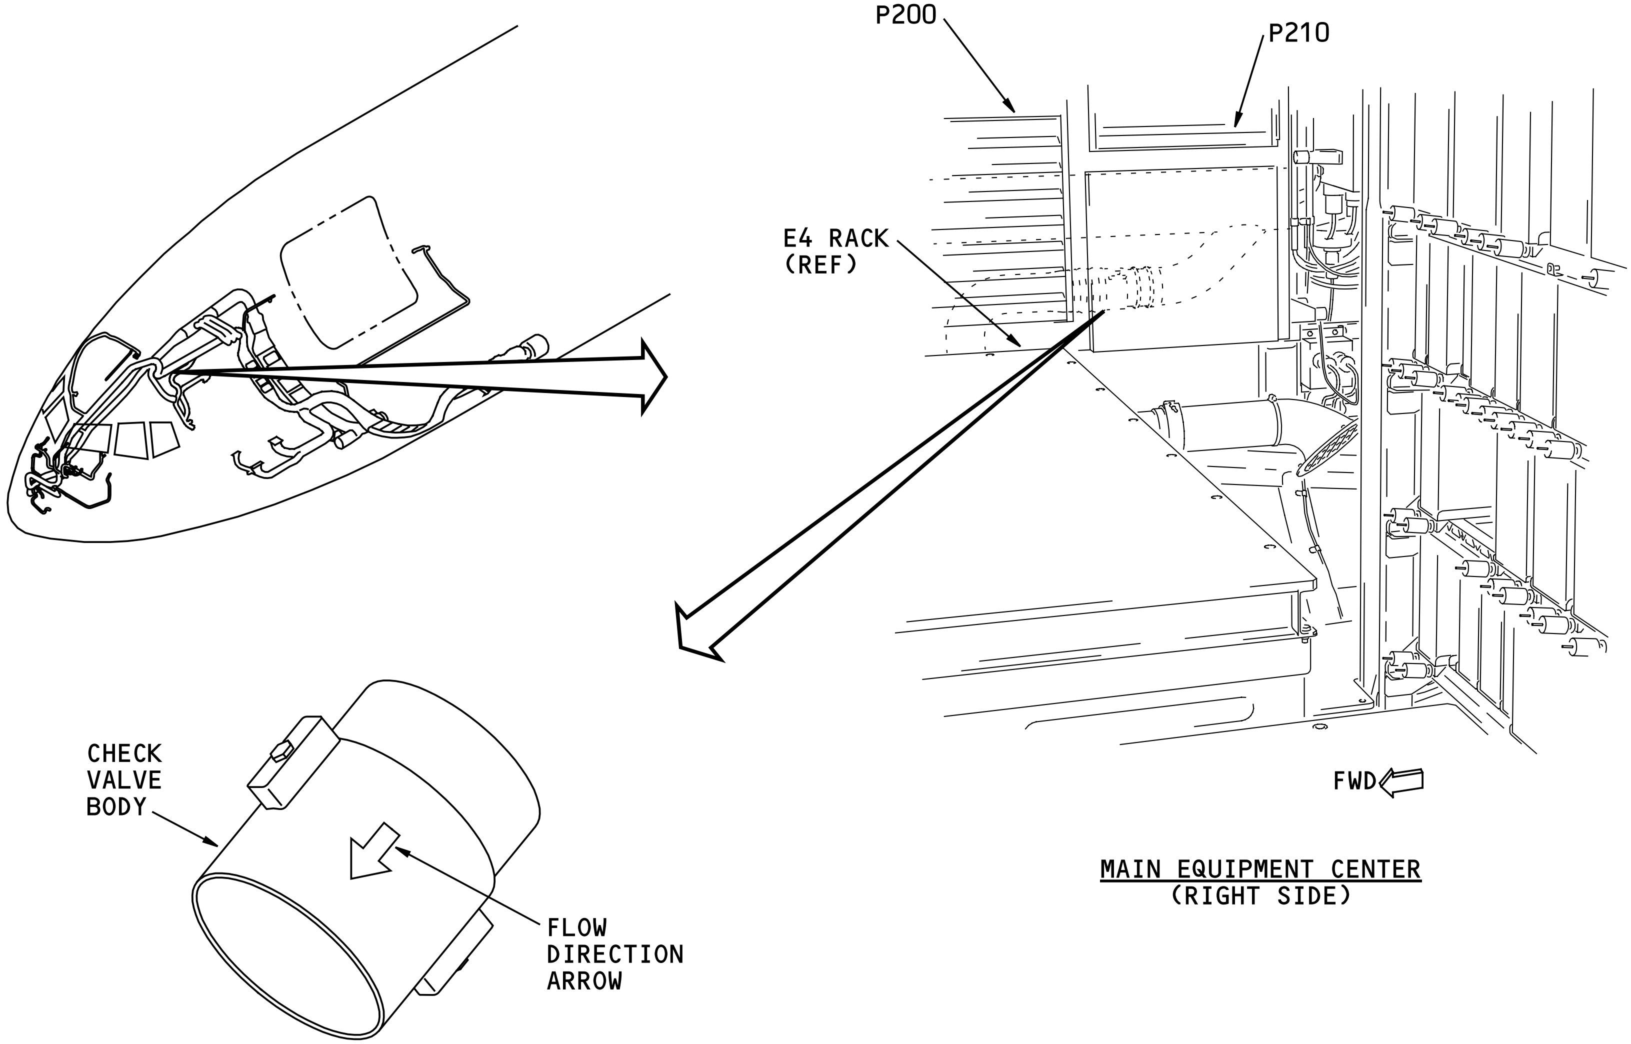
The check valve is a flapper-type valve. The valve is spring-loaded to the closed position.

Location

The check valve is on the right side of the MEC behind the P210 panel. The valve is in the supply duct that gives air to the E4-4 shelf.

Training Information Point

The check valve has an air flow direction arrow on the valve to help you install the valve correctly.



MAIN EQUIPMENT CENTER
(RIGHT SIDE)

CONVERTER SUPPLEMENTAL COOLING CHECK VALVE

21-27-00-014 Rev 3 04/29/96

A/C - EQUIPMENT COOLING - CONVERTER SUPPLEMENTAL COOLING CHECK VALVE (VSCF)

A/C - EQUIPMENT COOLING - VENT FAN

Purpose

The vent fan pulls air from the vent part of the forward equipment cooling system to give cooling. It sends the air to the forward cargo heat valve and the vent valve.

Physical Description

The vent fan has these components:

- Stator housing assembly
- Check valve (not shown)
- Electrical connector
- Electric motor (not shown)
- Inlet housing assembly.

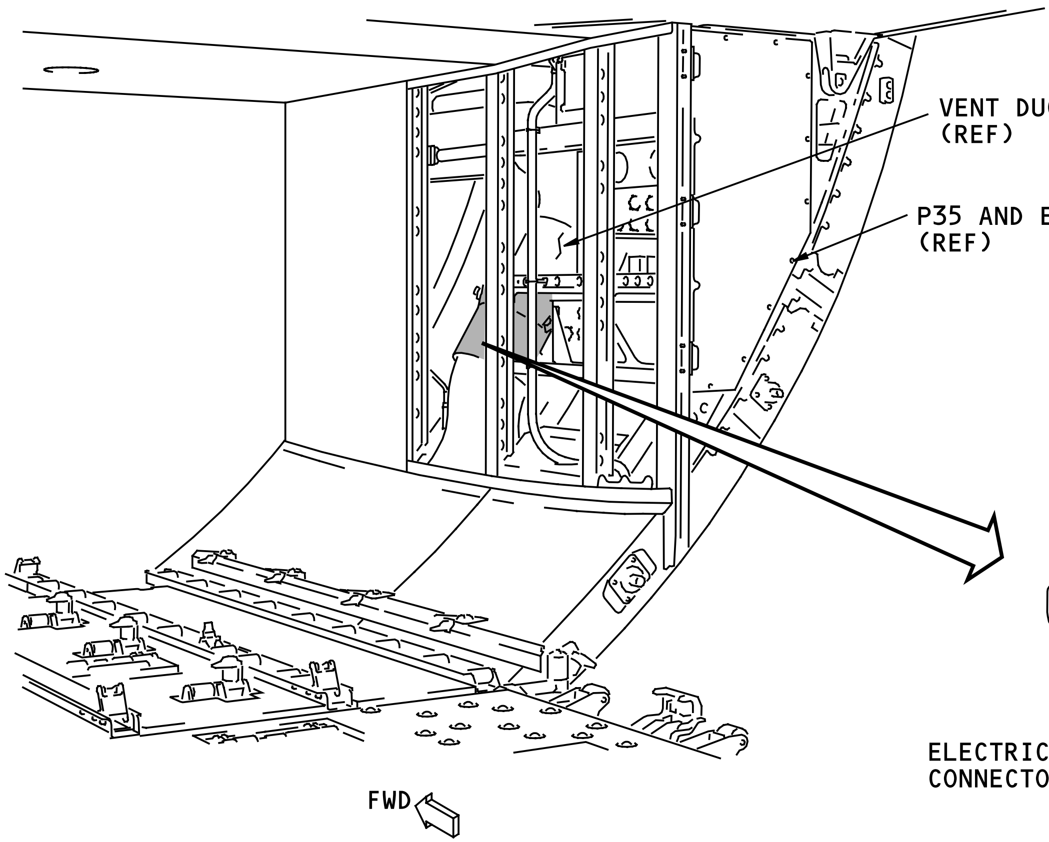
Location

The vent fan is in the forward cargo compartment forward of the P35 and the E16 rack in the right sidewall area.

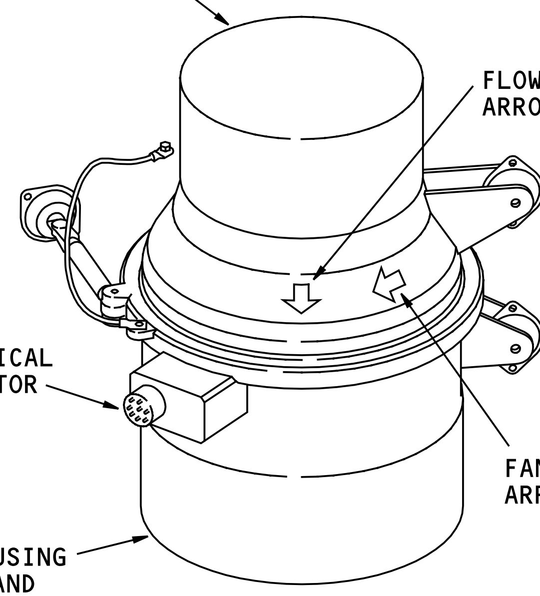
Training Information Point

Remove the sidewall panel to get access to the vent fan.

The vent fan has an air flow direction arrow on the fan to help you install the fan correctly.



FORWARD CARGO COMPARTMENT



VENT FAN

21-27-00-015 Rev 2

A/C - EQUIPMENT COOLING - VENT FAN

A/C - EQUIPMENT COOLING - VENT VALVE AND FORWARD CARGO HEAT VALVE

zPurpose

The vent valve lets equipment cooling vent (exhaust) air go to the area near the forward pressurization outflow valve.

The forward cargo heat valve lets equipment cooling vent (exhaust) air flow to the forward cargo compartment.

Physical Description

The valves have these components:

- Valve body
- Actuator
- Electrical connector
- Position indicator
- Manual override knob.

The diameter of the valve body is nine inches (23 cm).

Location

The valves are in the floor area of the forward cargo compartment, forward of the ball panels, below the left powered drive units.

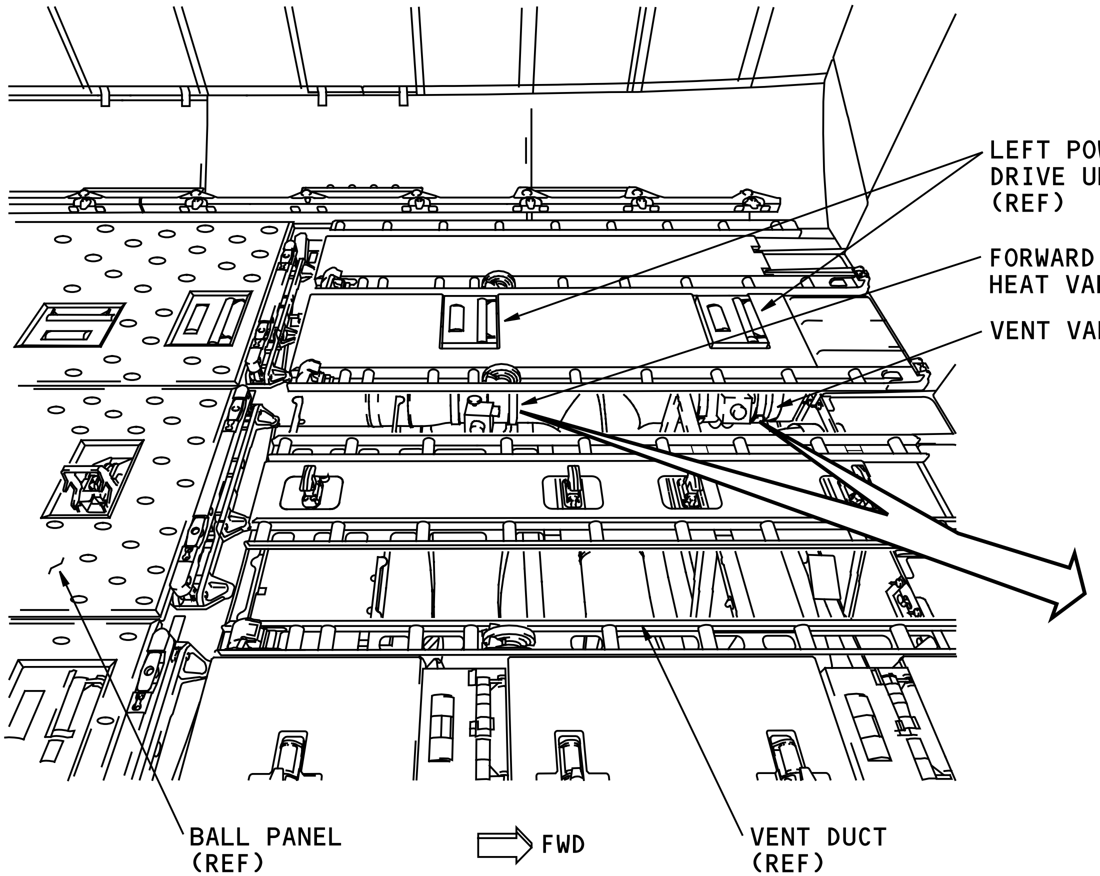
The vent valve is the forward most valve and the forward cargo heat valve is the aft valve.

Training Information Point

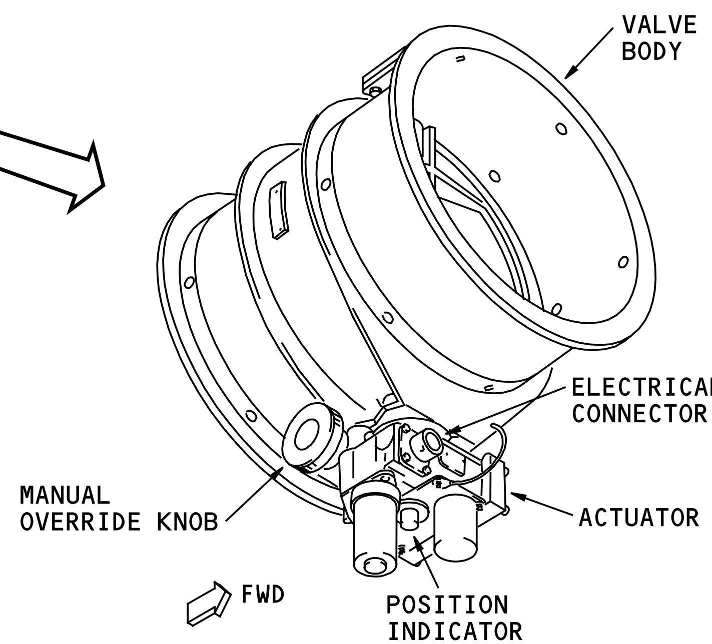
Remove the floor panel inboard of the left forward powered drive unit to get access to the valves.

Install the valves with the manual override knob up. This permits better access to the manual override knob.

The valves are interchangeable.



FORWARD CARGO COMPARTMENT



VENT VALVE/FORWARD CARGO HEAT VALVE

21-27-00-016 Rev 2 04/24/1997

A/C - EQUIPMENT COOLING - VENT VALVE AND FORWARD CARGO HEAT VALVE

A/C - EQUIPMENT COOLING - DUCTING

General

The equipment cooling system has these ducts:

- Supply ducts
- Smoke clearance duct
- Exhaust ducts
- Vent duct.

The supply ducts give cabin air to equipment and areas that need blow-through cooling.

The smoke clearance duct moves smoke from the supply part of the system or vents the system for differential cooling when necessary.

The exhaust ducts move air from equipment and areas that need pull-through cooling.

The vent duct moves air from the exhaust duct to the area next to the forward pressurization outflow valve.

Physical Description

There are different types of equipment cooling ducts. Some are flexible and some are rigid. The ducts can have different shapes; round, oval, and rectangle.

Location

The supply ducts are in these locations:

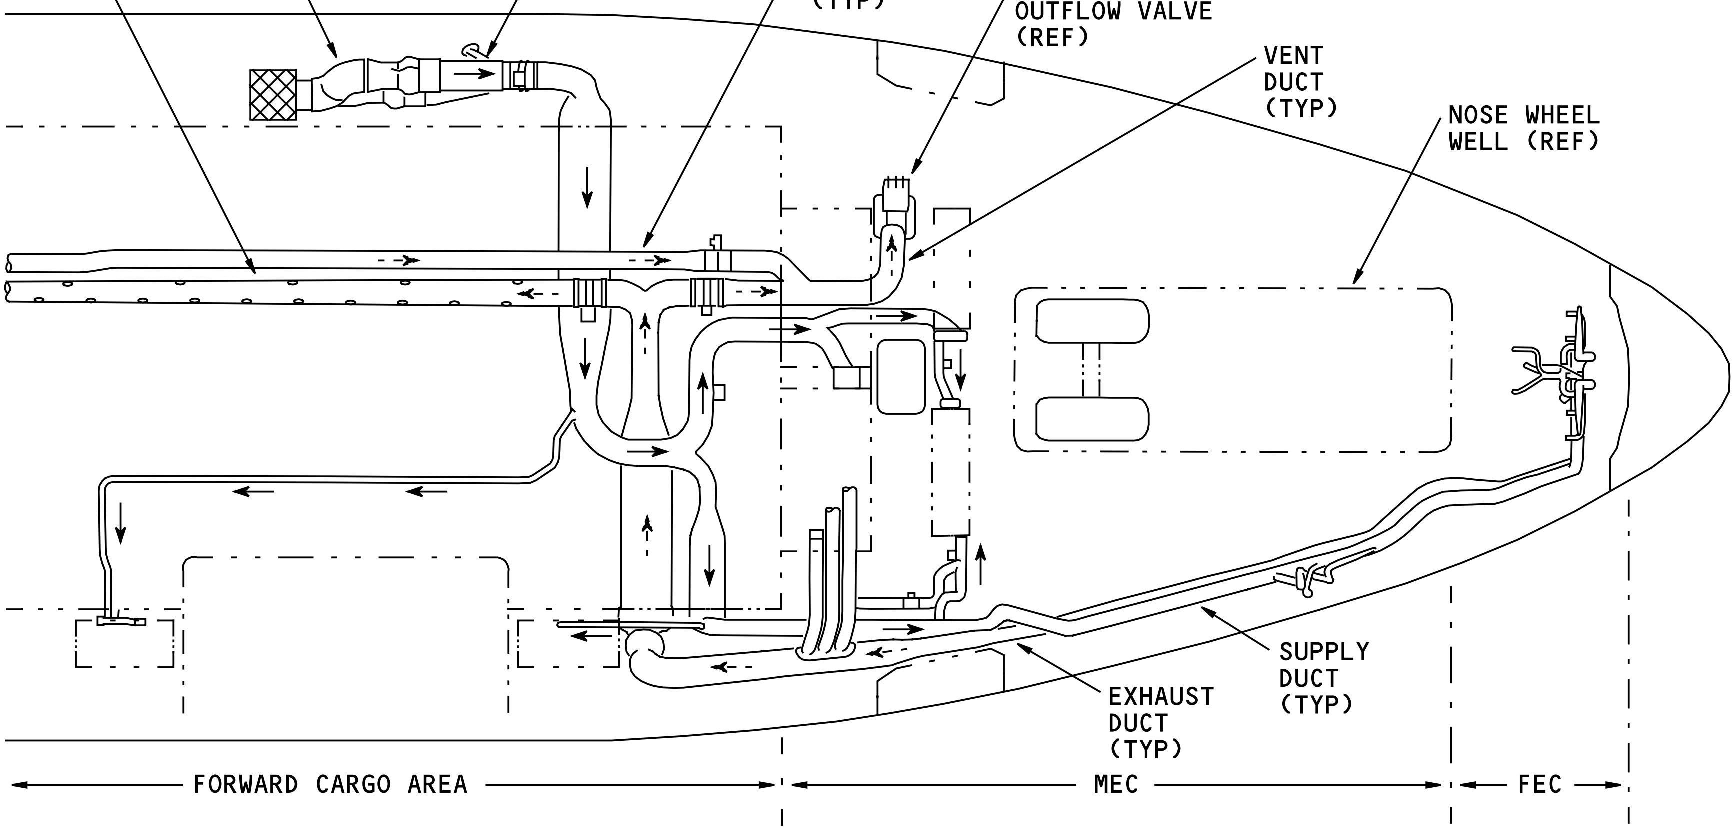
- Forward cargo compartment, left sidewall area
- Forward cargo compartment, under the floor area
- Forward cargo compartment, right sidewall area
- Main equipment center (MEC)
- Forward equipment center (FEC)
- Flight deck (not shown).

The smoke clearance duct is in the left sidewall area of the forward cargo compartment.

The exhaust ducts are in these locations:

- Flight deck (not shown)
- Forward equipment center (FEC)
- Main equipment center (MEC)
- Forward cargo compartment, right sidewall area
- Forward cargo compartment, under the floor area.

The vent duct is under the floor of the forward cargo compartment and the MEC.



LOWER LOBE AREA

21-27-00-040 Rev 0 04/24/1997

A/C - EQUIPMENT COOLING - DUCTING

A/C - EQUIPMENT COOLING - CONTROLLER

Purpose

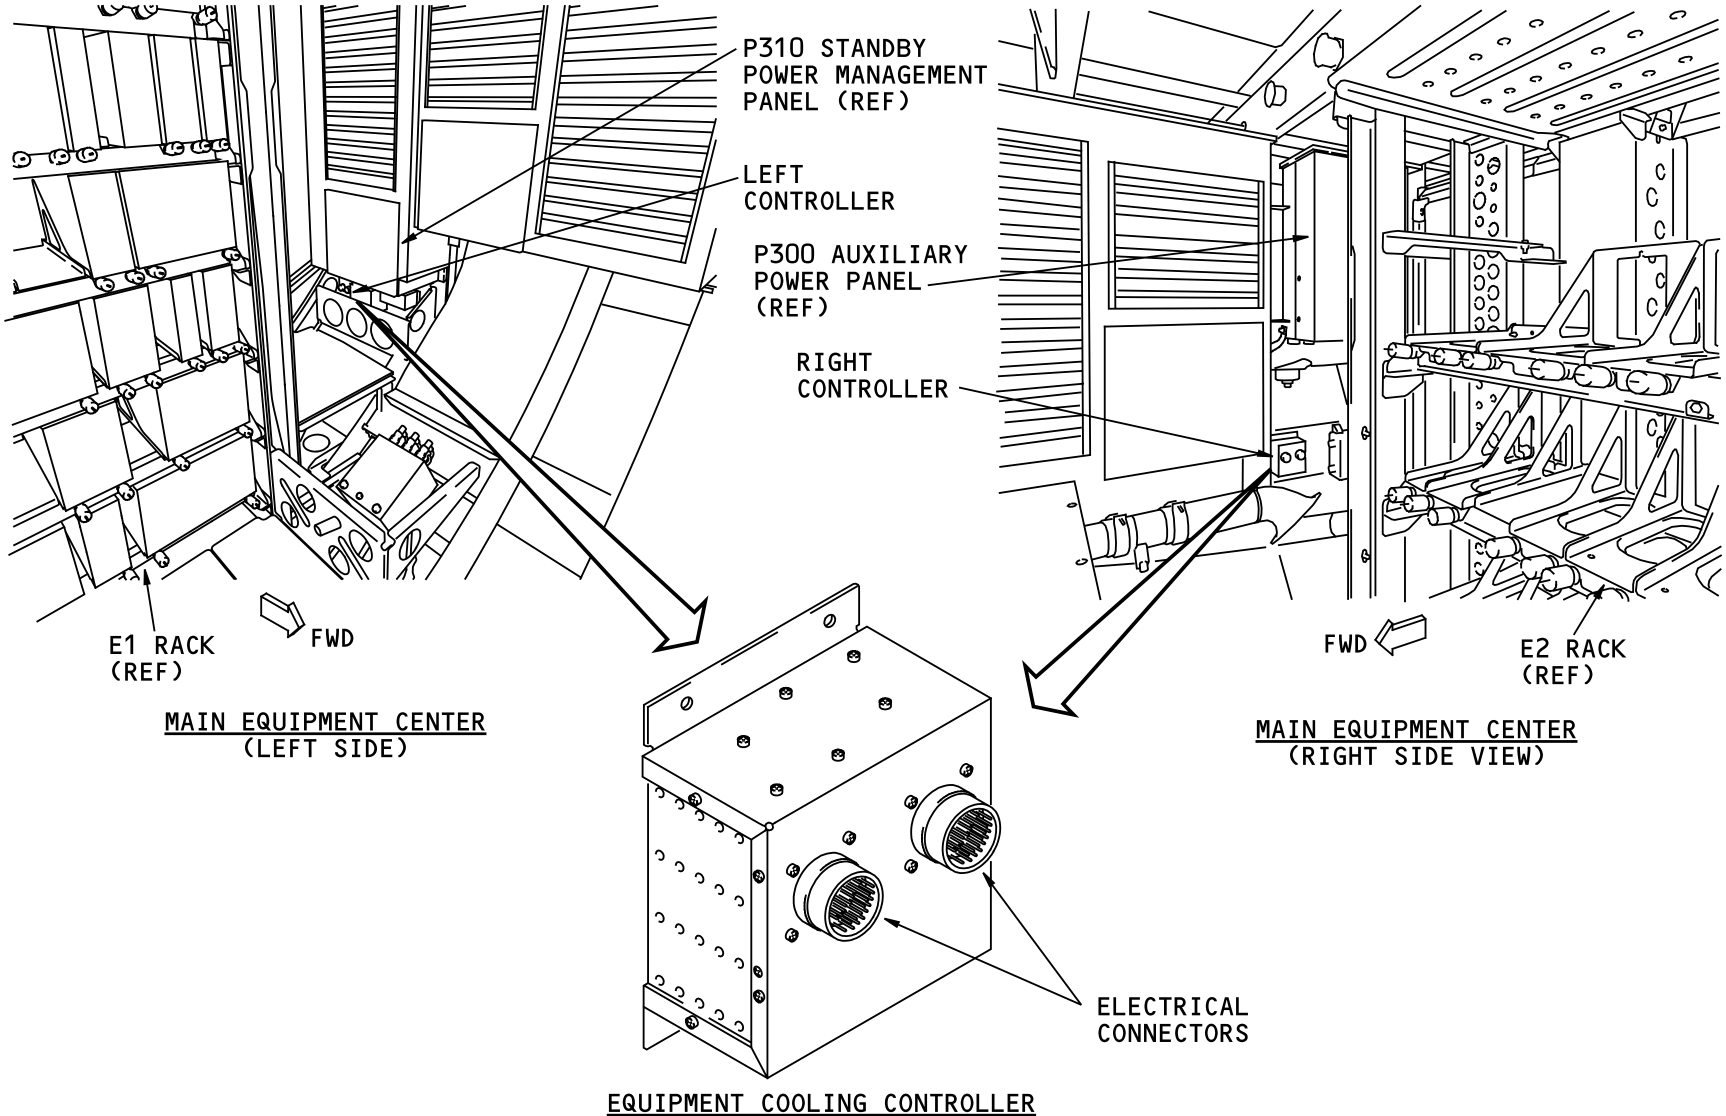
The equipment cooling controllers (ECC) supply control of the supply fans and the override valve.

Location

Both controllers are in the main equipment center (MEC). The left controller is below the P310 standby power management panel. The right controller is below the P300 auxiliary power panel.

Physical Description

The controllers are identical, solid state units. Each ECC has two independent channels, one for supply fan control and one for override valve control. The controllers have two electrical connectors.



21-27-00-008 Rev 2

A/C - EQUIPMENT COOLING - CONTROLLER

THIS PAGE INTENTIONALLY LEFT BLANK

A/C - EQUIPMENT COOLING - FUNCTIONAL DESCRIPTION - LOW FLOW SENSORS

General

The sensors calculate when the flow of air is below the amount necessary to cool the electrical and electronic equipment.

The flight deck (F/D) low flow sensor sends low flow information to the right ECC and to the right ECSMC. The sensor sends air temperature information to the right ECSMC.

The main equipment center (MEC) low flow sensor sends low flow information to the left ECC and to the left ECSMC. The sensor air temperature information to the left ECSMC.

Power

The sensors get power from the P210 right power management panel and the P310 standby power management panel.

ECC

The ECCs use low flow information in their takeover control logic. See the section on the controller for more information how the ECCs use low flow information.

The ECCs share low flow information through a cross talk connection.

ECSMC

The ECSMC in control uses the flow and temperature information to make low flow override mode signals and low flow indication signals.

The left and right ECSMCs share the signals for low flow and give it to the AIMS and the P310 standby power management panel through the ARINC 629 buses. The low flow logic is different when the airplane is on the ground than when it is in the air.

On the ground, only the low flow indication signal goes to the AIMS and P310. The cards do not give the low flow override mode signal on the ground. The override mode needs the airplane to be pressurized for it to cool the equipment. The low flow indication signal is sent if any of these conditions occur for more than five minutes:

- F/D or MEC duct air temperature more than 136F (58C)
- F/D or MEC duct air flow is low.

In the air, both the low flow indication signal (5 minute delay) and low flow override mode signal (60 second delay) are sent if all of these conditions occur:

- F/D air flow is low or the F/D sensor circuit has a malfunction
- MEC air flow is low or the MEC sensor circuit has a malfunction.

A/C - EQUIPMENT COOLING - FUNCTIONAL DESCRIPTION - LOW FLOW SENSORS

Flight Deck Indication

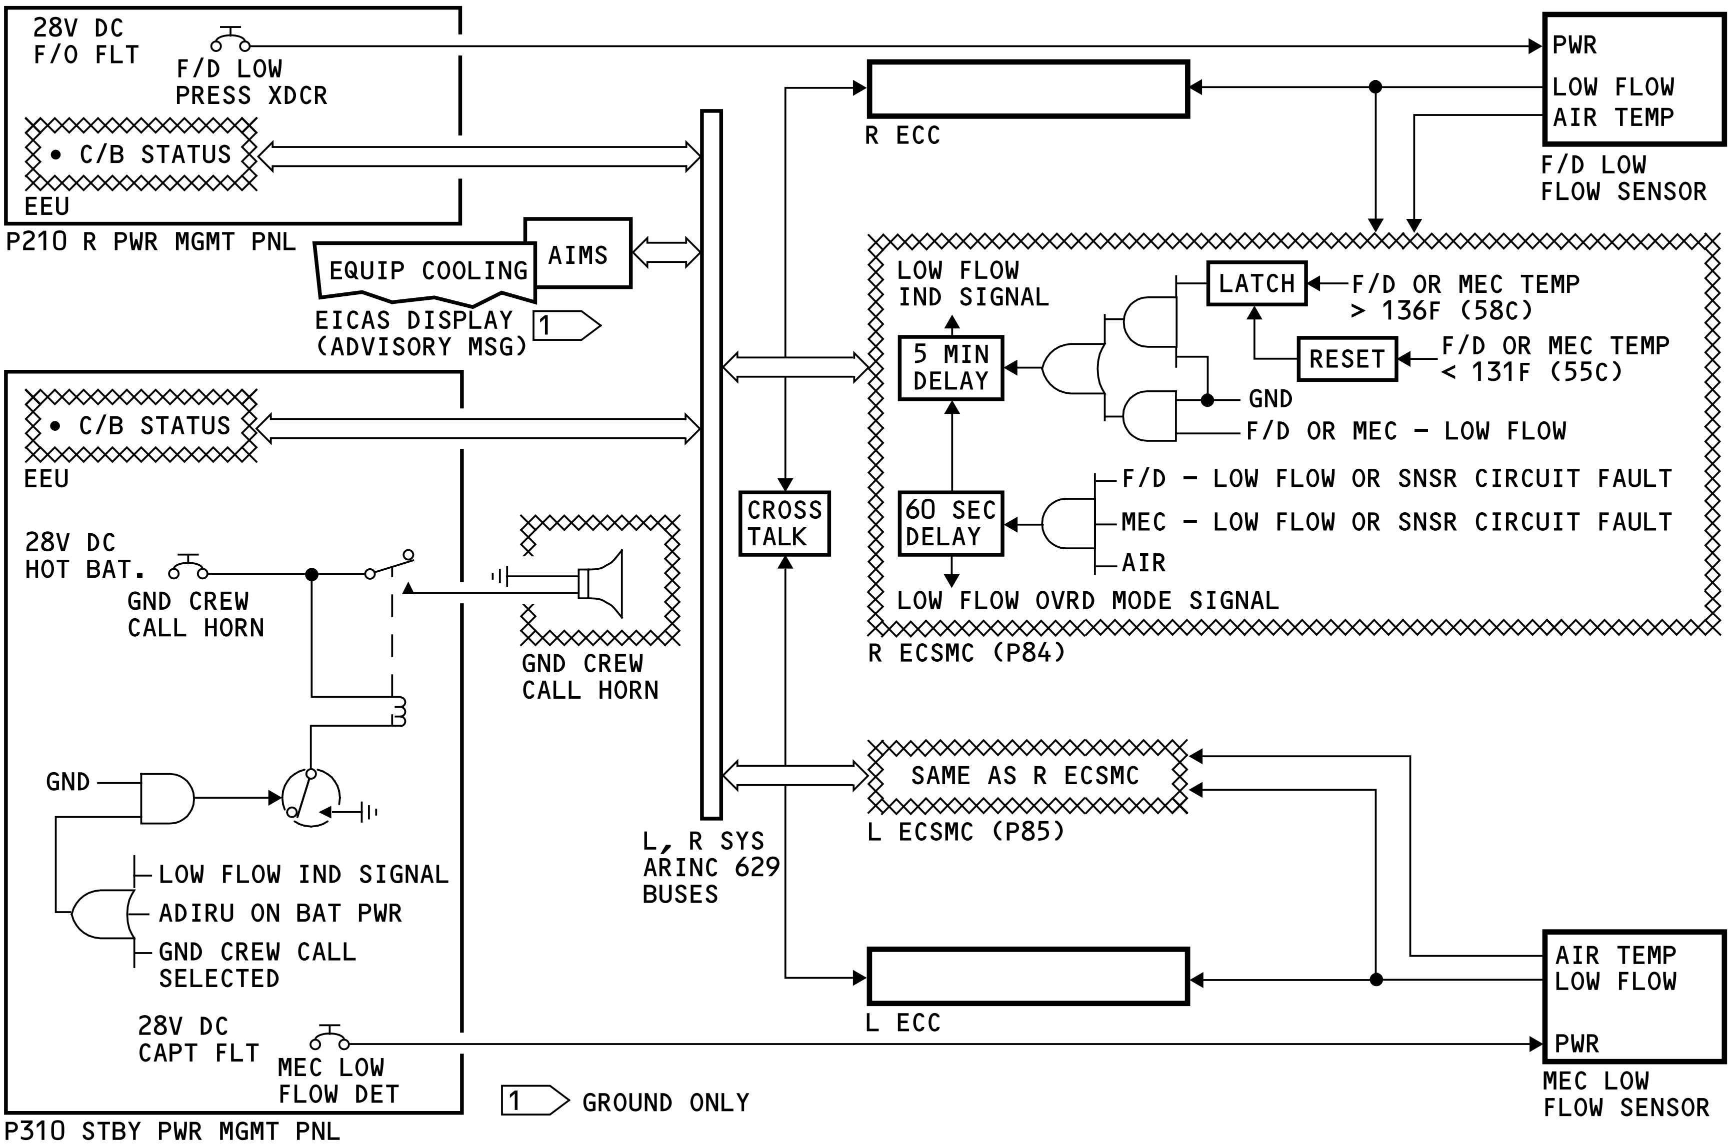
The low flow indication signal causes the EQUIP COOLING advisory message. The advisory message is inhibited in the air.

If a sensor fails, status messages show to tell you which sensor has a malfunction.

Ground Crew Call Horn

The ground crew call horn operates if the airplane is on the ground and any one of these conditions occur:

- Low flow - indication
- ADIRU on battery power
- Ground crew call selected (center CDU or flight deck hand set).



A/C - EQUIPMENT COOLING - FUNCTIONAL DESCRIPTION - LOW FLOW SENSORS

THIS PAGE INTENTIONALLY LEFT BLANK

A/C - EQUIPMENT COOLING - FUNCTIONAL DESCRIPTION - OVERRIDE MODE

General

The ECSMCs control the override (OVRD) mode. The card in control puts the forward equipment cooling system into the override mode. The override mode occurs if any of these conditions occur:

- LOW FLOW - OVRD MODE signal when the airspeed is more than 150 knots
- The left and right supply fans failed off and the airspeed is more than 150 knots
- Smoke alarm from the equipment cooling smoke detector
- Forward cargo fire switch in the ARMED position
- Equipment cooling switch in the OVRD position.

Low Air Flow

The ECSMCs use special logic to find a low air flow condition. See the section on the low flow sensors for more information. If a LOW FLOW - OVRD MODE signal occurs, the ECSMC in control latches the system to the override mode.

Supply Fans Malfunction

The ECSMC in control latches the system to the override mode if the two supply fans are off because of a malfunction.

For more information on the supply fans, see the functional description of the supply fans in this section.

Smoke Alarm

The ECSMC in control latches the system to the override mode if it gets a smoke alarm signal from form the equipment cooling smoke detector.

Reset

The latch caused by the LOW FLOW - OVRD MODE signal or a smoke alarm will reset if the condition that caused it goes away and any of these conditions occur:

- Airspeed is less than 70 knots
- Nose gear compressed (PSEU 2)
- Power cycled off then to on
- Forward cargo fire switch in the ARMED position
- Equipment cooling switch in the OVRD position.

Forward Cargo Fire Switch Set to ARMED

The ECSMC in control puts the system into the override mode when the forward cargo fire switch is in the ARMED position. The system stays in this mode as long as the switch is set to ARMED.

Equipment Cooling Switch to OVRD

The ECSMC in control puts the system into the override mode when the equipment cooling switch is set to OVRD. The system stays in this mode as long as the switch is in the OVRD position.

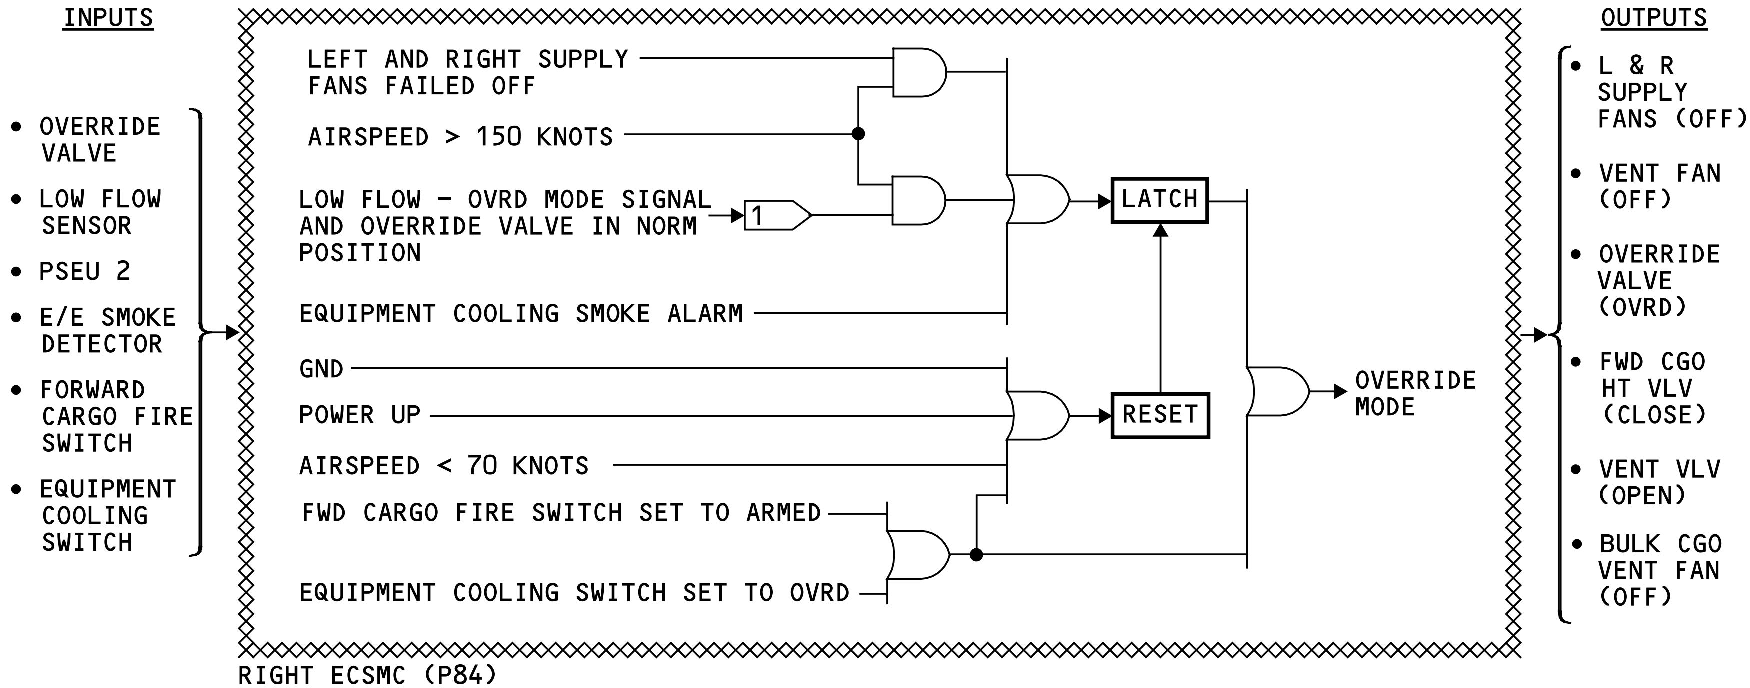
A/C - EQUIPMENT COOLING - FUNCTIONAL DESCRIPTION - OVERRIDE MODE

Override Mode

The override mode causes the forward part of the equipment cooling system to make these changes:

- Both supply fans and the vent fan go to off
- The override valve goes to the OVRD position
- Forward cargo heat valve closes (except for low flow)
- The bulk cargo ventilation fan goes off (only if the equipment cooling switch is in the OVRD position)
- Vent valve opens (except for low flow).

The LOW FLOW - OVRD MODE signal applies only to the supply fans, vent fan, and the override valve.



NOTE: RIGHT ECSMC SHOWN, LEFT SIMILAR.

1 THIS CONDITION APPLIES TO: L & R SUPPLY FANS, VENT FAN, AND OVERRIDE VALVE

21-27-00-027 Rev 4 09/04/96

A/C - EQUIPMENT COOLING - FUNCTIONAL DESCRIPTION - OVERRIDE MODE

THIS PAGE INTENTIONALLY LEFT BLANK

A/C - EQUIPMENT COOLING - FUNCTIONAL DESCRIPTION - CONTROLLER

General

Control logic for the right equipment cooling controller (ECC) is shown; the left is similar.

The right ECC gives control for the supply fans and the override valve. The ECC normally controls the fans and valve with inputs from the right or left ECSMC. The ECC does not use the inputs from the ECSMC if takeover control logic (see below) is true.

Inputs

The right ECC gets control power from the P210 right power management power. The controller gets inputs from these components for takeover control logic and to control the fans and the valve:

- Right ECSMC
- Left ECC, L ECSMC and MEC low flow sensor through the ECC cross talk
- PSEU 2
- Flight deck low flow sensor.

The controller uses the inputs to calculate if it should control the fans and override valve. It can use ECSMC inputs for normal control, or it can takeover control and use ECC fan/valve control logic.

Takeover Control Logic

The ECC takes control away from the ECSMCs when the airplane is in the air and any one of the following sets of conditions occur:

- Both ECSMCs try to control the fans and valve at the same time and both ECCs operate normally
- Left ECC is failed or there is low flow in the MEC supply duct and in the flight deck supply duct and the override valve is in the NORM position for more than 6.5 minutes
- Left ECC is failed or there is low flow in the MEC supply duct and in the flight deck supply duct and the override valve is in the OVRD position for more than 20 minutes.

Once the controller takes control it will not return control to the ECSMCs until the airplane is on the ground.

ECC Fan/Valve Control Logic

The controller uses the ECC fan/valve control logic to make the low flow condition go away. The controller uses a combination of supply fans on/off and override valve positions to do this. There are six combinations (modes). The controller tries each mode for 60 seconds. After 60 seconds the controller will try the next mode. If the low flow goes away the controller stays in that mode. If the low flow condition returns, the controller will select the next mode. After all modes have been tried, the controller starts over with mode 1. These are the six sets of modes:

- Left supply fan off, right supply fan off, and left override valve motor selected to the OVRD position
- Left supply fan off, right supply fan off, and right override valve motor selected to the OVRD position
- Left supply fan on, right supply fan off, and left override valve motor selected to the NORM position
- Left supply fan on, right supply fan off, and right override valve motor selected to the NORM position
- Left supply fan off, right supply fan on, and left override valve motor selected to the NORM position
- Left supply fan off, right supply fan on, and right override valve motor selected to the NORM position.

Outputs

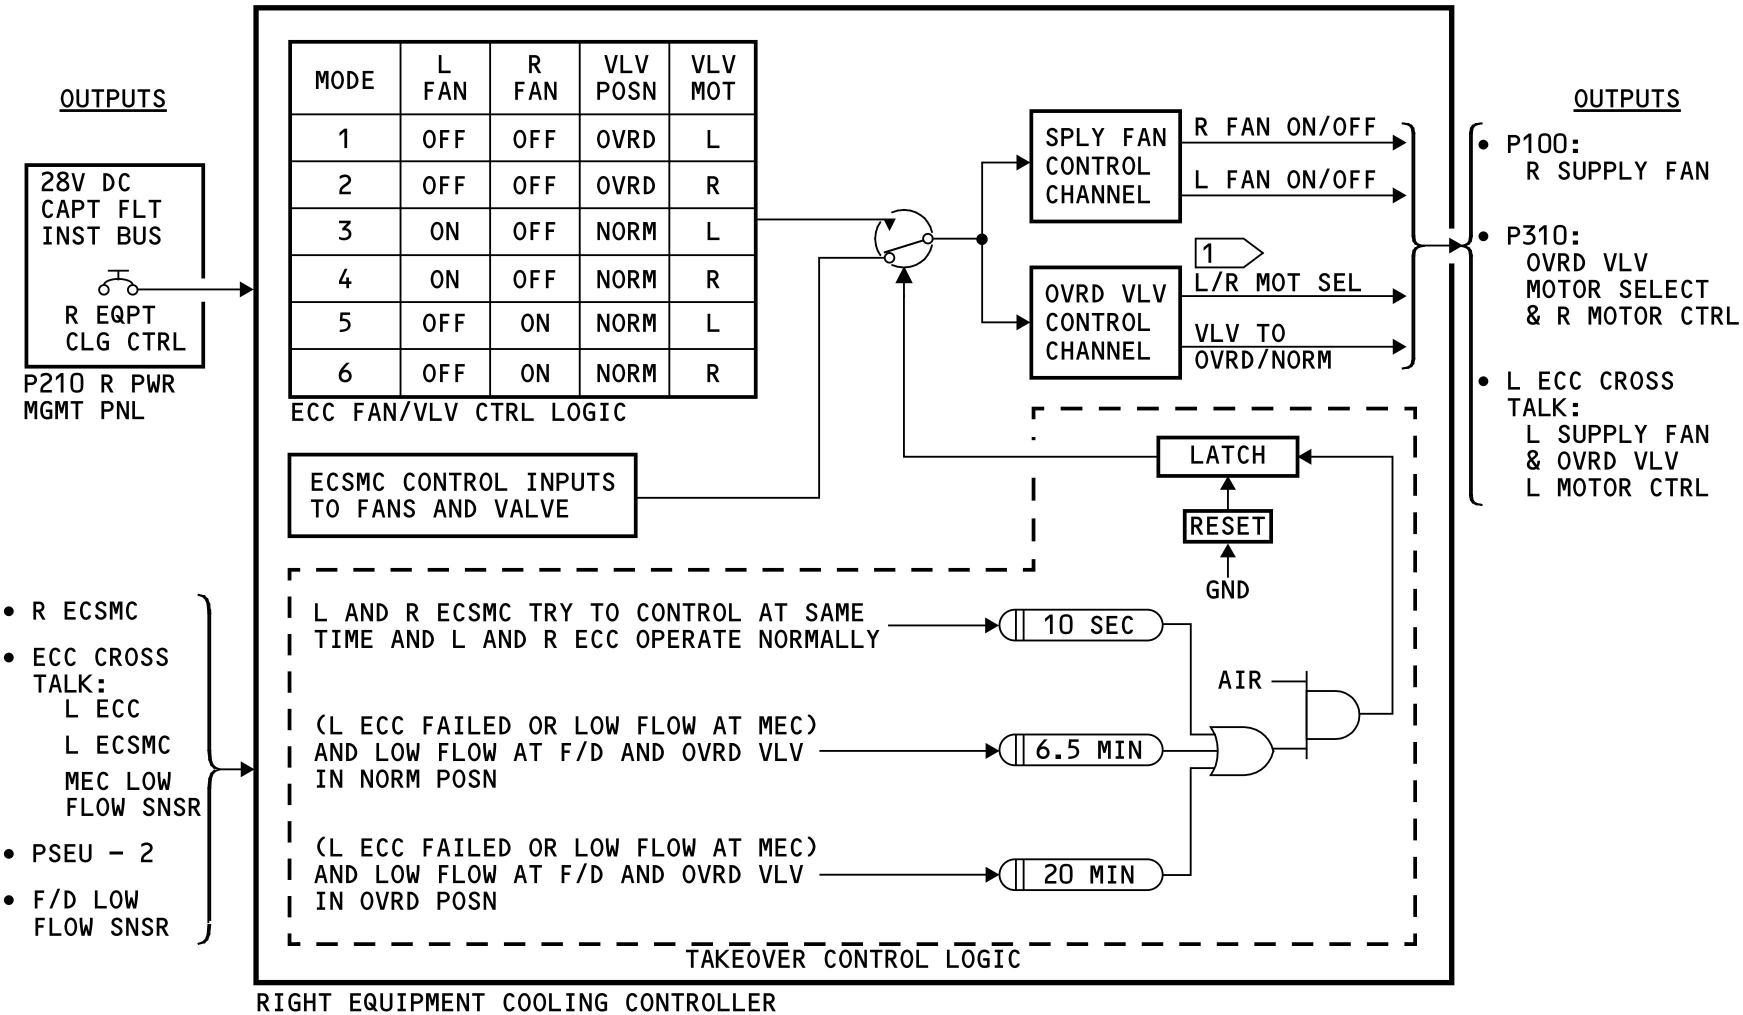
The ECC controls the supply fans and the override valve through separate control channels. The right ECC sends output control signals to these items:

- Right supply fan ON/OFF (through the P100 left power panel)
- Selection of which override valve motor to use (through the P310 standby power management panel)
- Control of the position (OVRD/NORM) of the right motor in the override valve (through the P310 standby power management panel).
- Left supply fan ON/OFF and left motor of the override valve OVRD/NORM position (through the left ECC cross talk)

The left ECC outputs are similar except it does not control which motor of the override valve to use.

Fault Indication

Status messages show if a controller has a malfunction.



NOTE: RIGHT ECC SHOWN, LEFT SIMILAR

1 R ECC ONLY

A/C - EQUIPMENT COOLING - FUNCTIONAL DESCRIPTION - CONTROLLER

21-27-00-019 Rev 3

A/C - EQUIPMENT COOLING - FUNCTIONAL DESCRIPTION - SUPPLY FANS

General

Only one of the two fans operate at a time. The right fan is primary and the left fan is the backup. Each time the airplane gets power, the right ECSMC does a test of the left fan. The right fan is set to off and the left fan is set to on. At the end of the test of the left fan, it is set to off and the right fan is set to on and tested.

The right ECSMC gives primary control of the supply fans when the airplane gets power and the left card gives backup control. When the airplane changes from air to ground, the card in control changes.

Supply Fan Control

The ECSMCs control through the right and left ECCs and the right and left power panels. Either card can control both fans. For example, these signals occur when the right card wants to turn on the left fan:

- Right ECSMC sends FAN ON signal to right ECC
- Right ECC sends FAN ON signal to left ECC (cross talk)
- Left ECC sends FAN ON signal to left power panel
- Left power panel turns on the left fan if no overcurrent condition is detected.

Both cards get information about the left and right fan overheat switches either directly from the fan or from the other card through the ARINC 629 buses.

During ground test the fans operate in the ground test sequence. See the section on equipment cooling - ground test for more information.

During normal conditions, the right fan operates if none of these conditions are true:

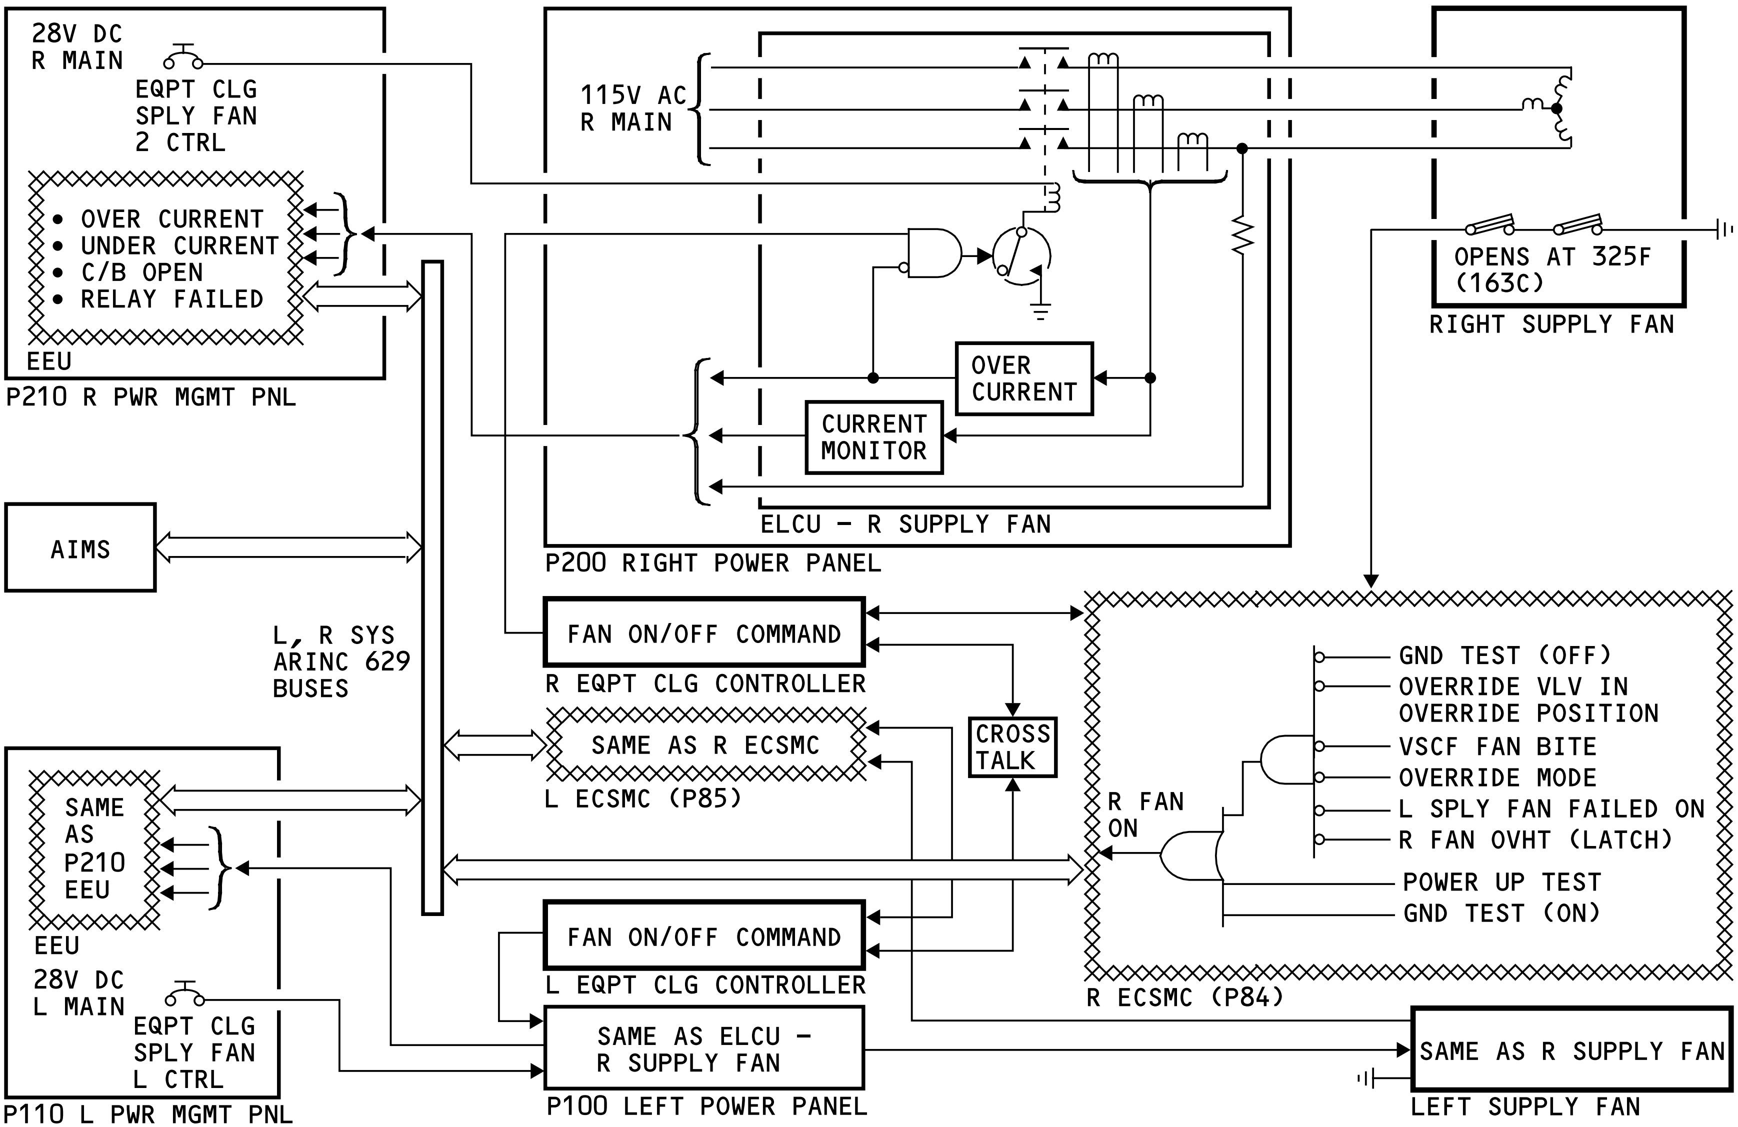
- System commanded to override
- Override valve in the override position
- ELMS detected fault conditions (no power, open circuit breaker, overcurrent, no current, or failed relay)
- Supply fan motor overheat
- Converter supplemental cooling fan (VSCF fan) in test (automatic)
- Ground test - fan off command.

If the right fan stops, the left fan starts automatically.

Fault Indication

Status messages show if a fan or the circuit that controls a fan has a malfunction.

The ECSMCs monitor information from ELMS. This information helps the cards isolate supply fan malfunctions.



A/C - EQUIPMENT COOLING - FUNCTIONAL DESCRIPTION - SUPPLY FANS

A/C - EQUIPMENT COOLING - FUNCTIONAL DESCRIPTION - OVERRIDE VALVE

THIS PAGE INTENTIONALLY LEFT BLANK

A/C - EQUIPMENT COOLING - FUNCTIONAL DESCRIPTION - OVERRIDE VALVE

General

The override valve has two positions: NORM and OVRD. The valve is usually in the NORM position. The override valve has two motors: left and right. Only one motor will operate the valve at a time.

The right ECSMC gives primary control of the override valve when the airplane gets power and the left card gives backup control. When the airplane changes from air to ground, the card in control changes.

Normal Control

The ECSMC controls the primary motor through the left and right equipment cooling controllers and the P310 standby power management panel. Either card can control both motors and can set which motor is primary. For example, these signals occur when the right card wants to set the left motor as primary and make it go to the NORM position:

- The right ECSMC sends L MOTOR PRIMARY and NORM signals to the right ECC
- The right ECC sets the left motor as the primary motor through a relay in the standby power management panel.
- The right ECC sends the NORM signal to left ECC (through cross talk)
- The left ECC sets the override valve to the NORM position through a relay in the standby power management panel
- The standby power management panel gives power so that the left motor moves the valve to NORM.

Limit switches (not shown) in each motor remove power from the motor when the valve gets to the commanded position. The same limit switches give valve position feedback directly to the ECSMCs.

The valve will stay in the NORM position if none of these conditions occur:

- System commanded to override
- Right and left equipment cooling supply fans off
- Ground test command to override.

The override valve relays in P310 standby power management panel are fail safe to make the valve go to the OVRD position. This makes sure the override valve will go the OVRD position if the ECCs or the ECSMCs have a malfunction.

Override Indication

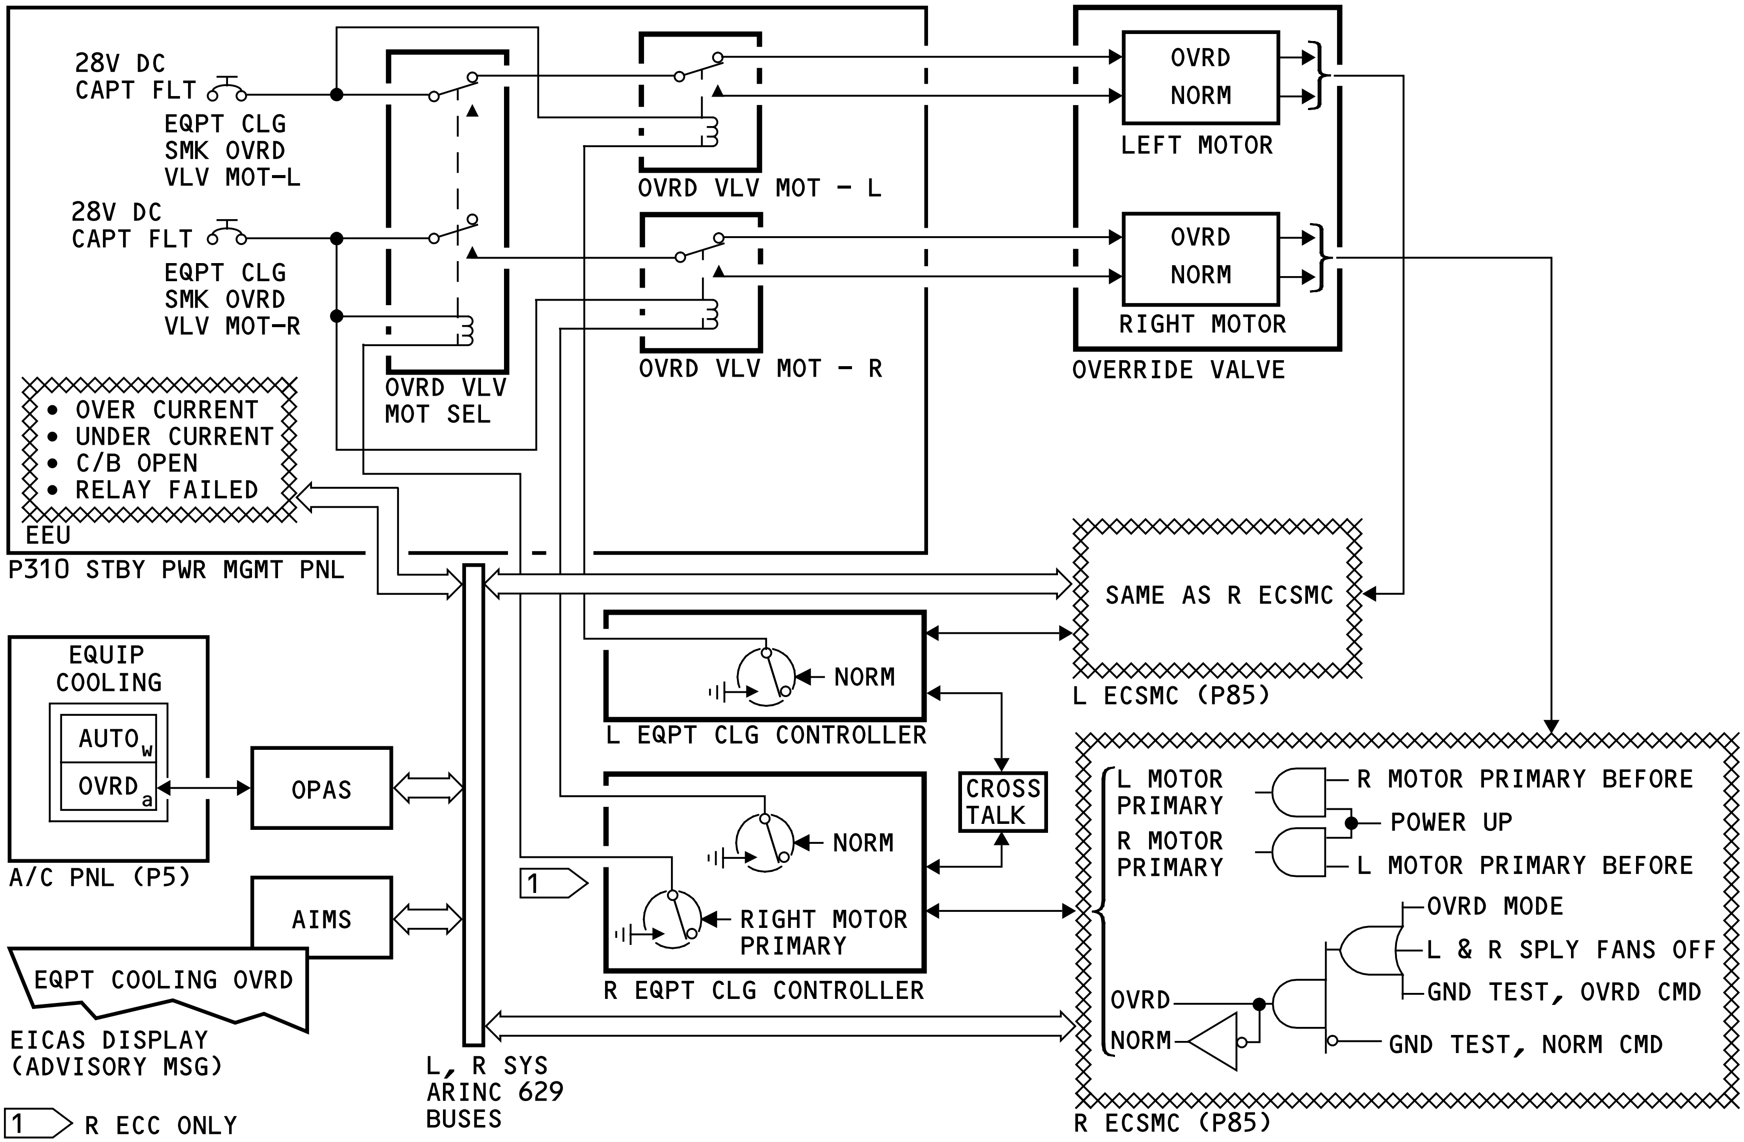
The EQUIP COOLING OVRD advisory message shows and the OVRD light comes on when the equipment cooling override valve is in the OVRD position.

Fault Indication

Status messages show when a motor or the circuit that controls the motor have a malfunction.

A/C - EQUIPMENT COOLING - FUNCTIONAL DESCRIPTION - OVERRIDE VALVE

The ECSMCs monitor information from ELMS. This information helps the ECSMCs isolate malfunctions with the override valve.



A/C - EQUIPMENT COOLING - FUNCTIONAL DESCRIPTION - OVERRIDE VALVE

A/C - EQUIPMENT COOLING - FUNCTIONAL DESCRIPTION - DUCT PRESSURE SENSORS

Functional Description

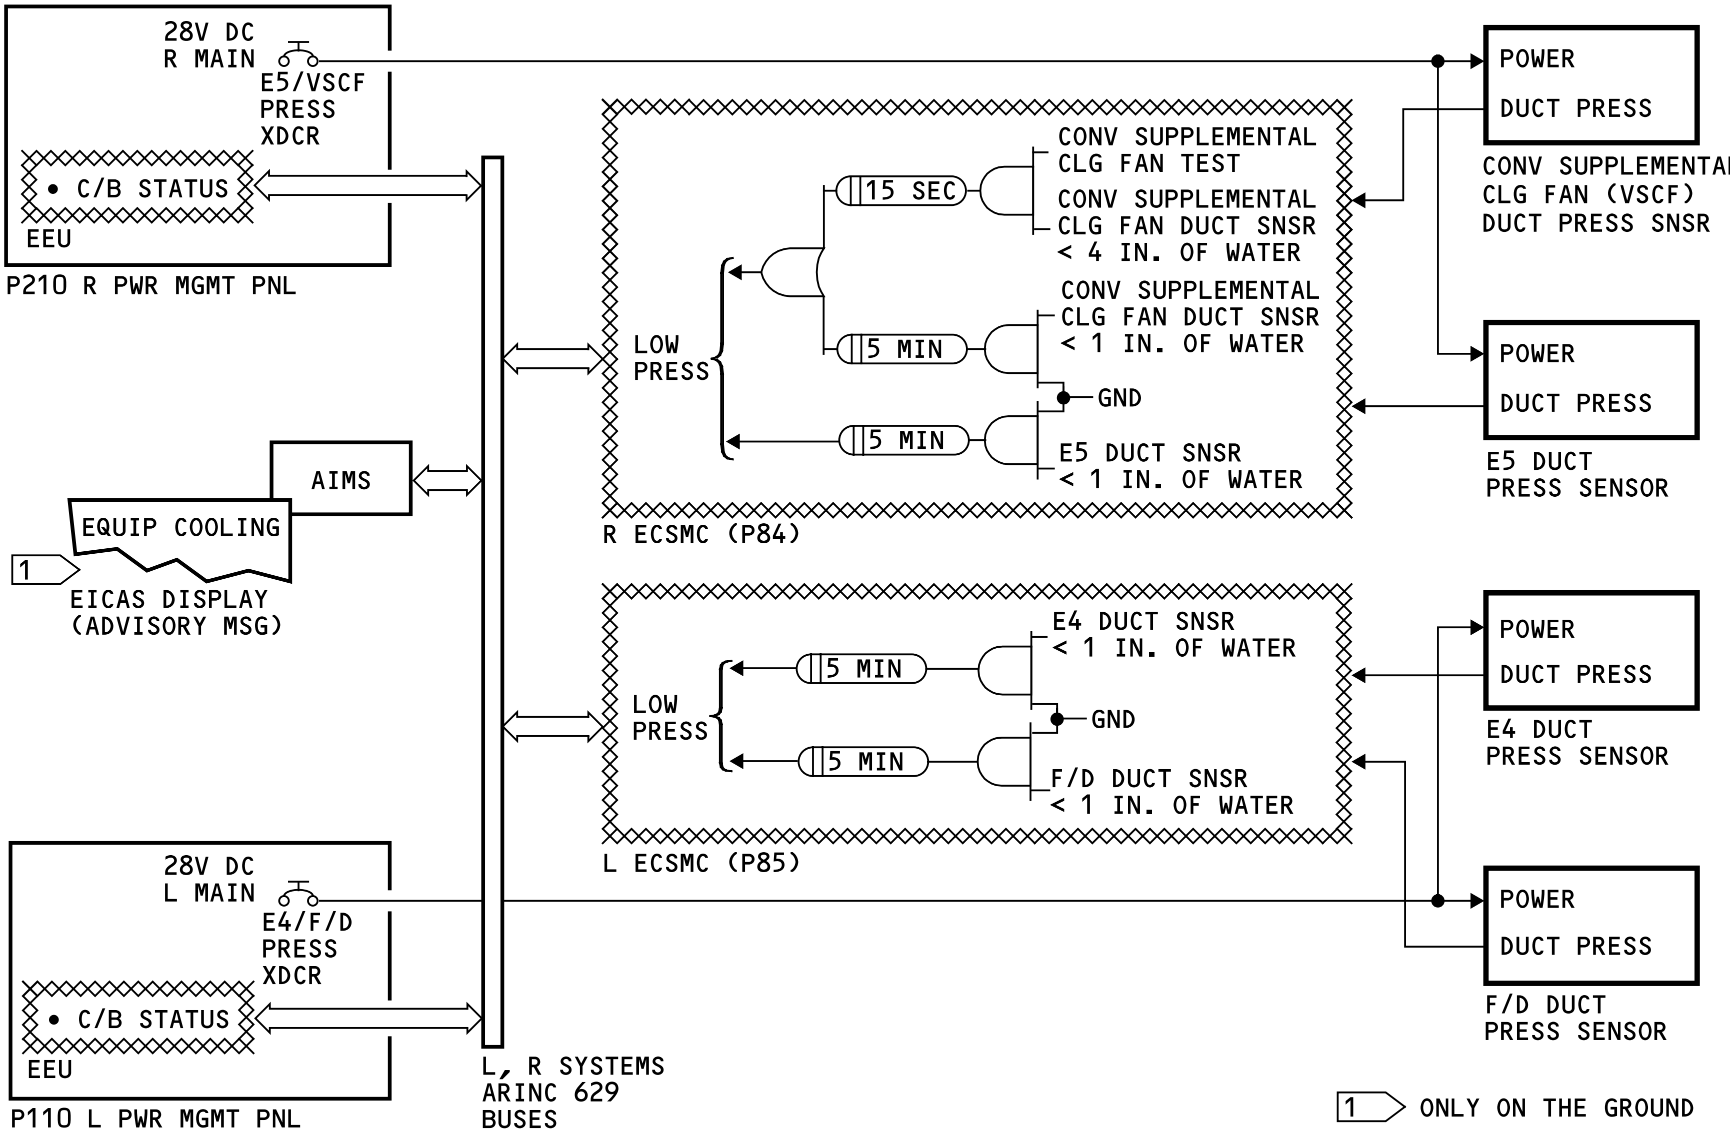
The duct pressure sensors measures the pressure in the equipment cooling ducts. The E5 and converter supplemental cooling fan duct pressure sensors send information to the right ECSMC. The E4 and flight deck duct sensors send information to the left ECSMC. The cards use the low pressure information for indication purposes only.

Low Pressure Indication

The EQUIP COOLING advisory message shows when there is a low pressure condition on the ground for more than five minutes. The advisory message also shows when there is a test of the converter (CONV) supplemental cooling fan and there is a low pressure condition for more than fifteen seconds. There are no flight deck indications for a low pressure condition when the airplane is in the air.

Fault Indication

Status messages show when a sensor has a malfunction.



A/C - EQUIPMENT COOLING - FUNCTIONAL DESCRIPTION - DUCT PRESSURE SENSORS

A/C - EQUIPMENT COOLING - OPERATION

General

An equipment cooling switch lets you set the desired mode of operation for the equipment cooling system.

Automatic Operation

The equipment cooling switch is an alternate-action switch. AUTO shows when you push the switch. This selects automatic operation (normal mode of operation) of the equipment cooling.

The OVRD light comes on when the override valve is in the OVRD position. The system puts the valve in the override position automatically or when the switch is out (non-normal mode of operation). The override mode gives cooling above a sufficient cabin differential pressure when the airplane is above 25,000 feet (7625 meters).

The override mode removes power to the supply and vent fans and sets the override valve to the OVRD position. This lets air vent from the supply part of the system overboard through the override valve. See the OVERRIDE MODE page in this section for more information on the override mode.

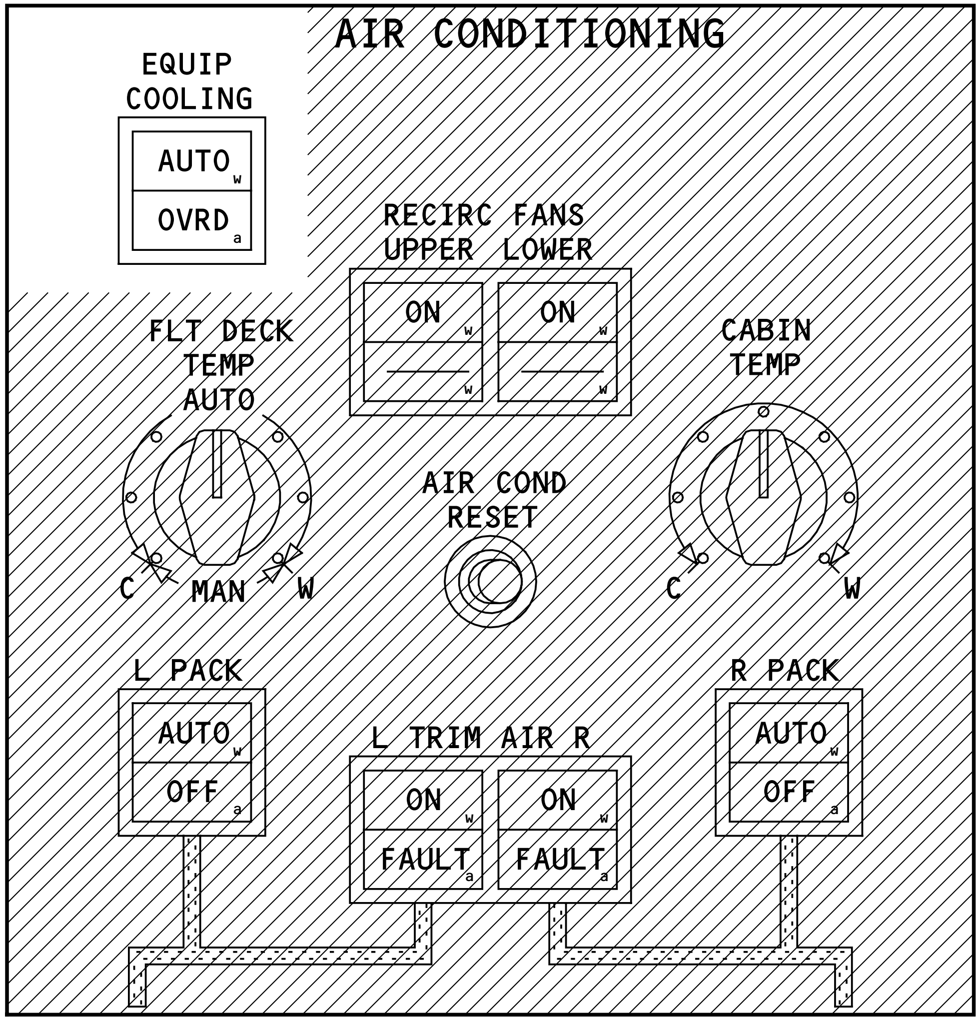
Ground Operation

Operation of the system on the ground normally does not require any inputs from you except to make sure that AUTO is selected.

If ambient temperature is equal to or greater than 110F (43C), you must supply conditioned air to the airplane.

Training Information Point

You can operate the system on the ground with a malfunction of the vent fan as long as ambient temperature is below 86F (30C). If the temperature goes above 86F (30C), then you must supply conditioned air to the airplane.



AIR CONDITIONING PANEL (P5)

21-27-00-028 Rev 1

A/C - EQUIPMENT COOLING - OPERATION

A/C - EQUIPMENT COOLING - IFE - INTRODUCTION

Purpose

The IFE cooling fan and related ducts pull cooling air through the in-flight entertainment (IFE) components in the passenger cabin. An IFE cooling smoke detector monitors for smoke in the air from the IFE components.

Location

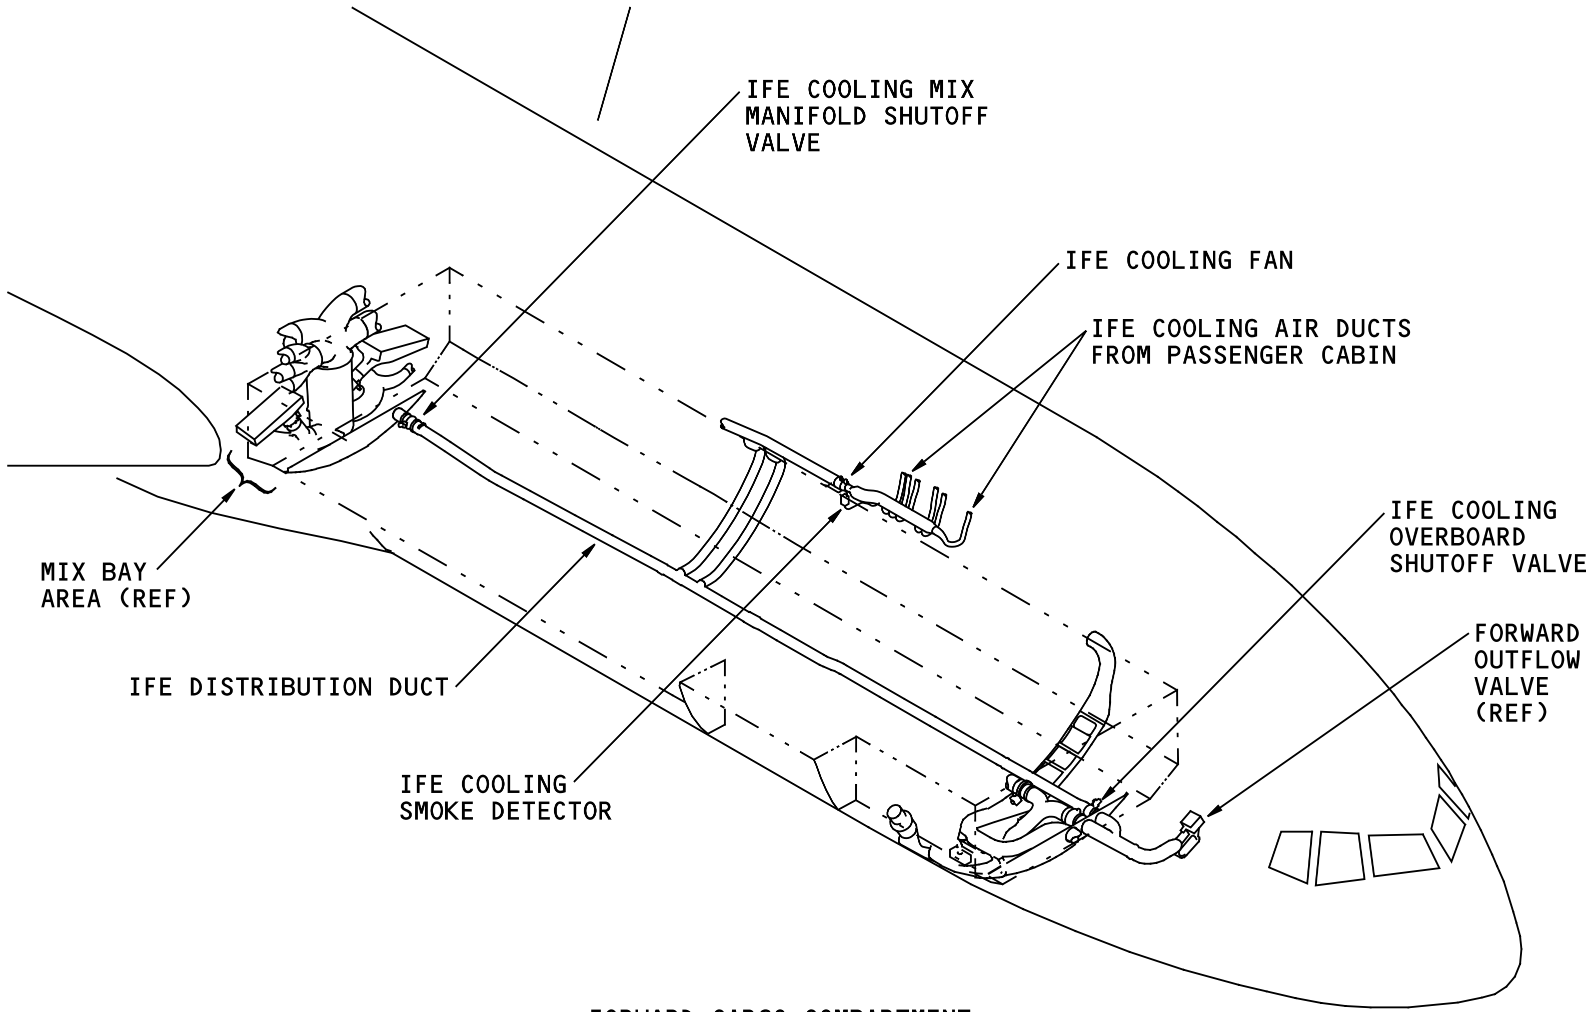
The IFE cooling fan is outboard of the forward cargo compartment sidewall on the left side. The IFE cooling smoke detector is adjacent to the fan at the same location.

Six small ducts connect the IFE components in the passenger cabin to the fan. These ducts are forward of the fan.

Two larger ducts aft of the fan connect it to a distribution duct under the cargo floor. This distribution duct goes forward and aft to shutoff valves at each end of the forward cargo compartment.

The IFE cooling overboard shutoff valve is at the front of the forward cargo compartment. It connects the distribution duct to the MEC.

The IFE cooling mix manifold shutoff valve is at the back of the forward cargo compartment. It connects the distribution duct to the mix bay area.



FORWARD CARGO COMPARTMENT
(TYPICAL)

21-27-00-033 Rev 0 04/23/1997

A/C - EQUIPMENT COOLING - IFE - INTRODUCTION

A/C - EQUIPMENT COOLING - IFE - GENERAL DESCRIPTION

General

The IFE cooling fan pulls cooling air through IFE components in the passenger cabin. ELMS opens the IFE cooling overboard shutoff valve to let air go forward to the MEC. ELMS opens the IFE cooling mix manifold shutoff valve to let air go aft to the mix bay area.

The ECS miscellaneous cards (ECSMC) give data to ELMS for operation of the fan and control of the valves. Fan overheat and valve position indications go directly to the ECSMCs. The ECSMCs gets these other inputs for control logic:

- OPAS, forward cargo arm
- AIMS, engine off or engine starting
- AGS, airplane on ground.

The mix manifold shutoff valve is open for these conditions:

- Overboard shutoff valve failed closed
- One or two engines on
- Engine start on ground
- Test.

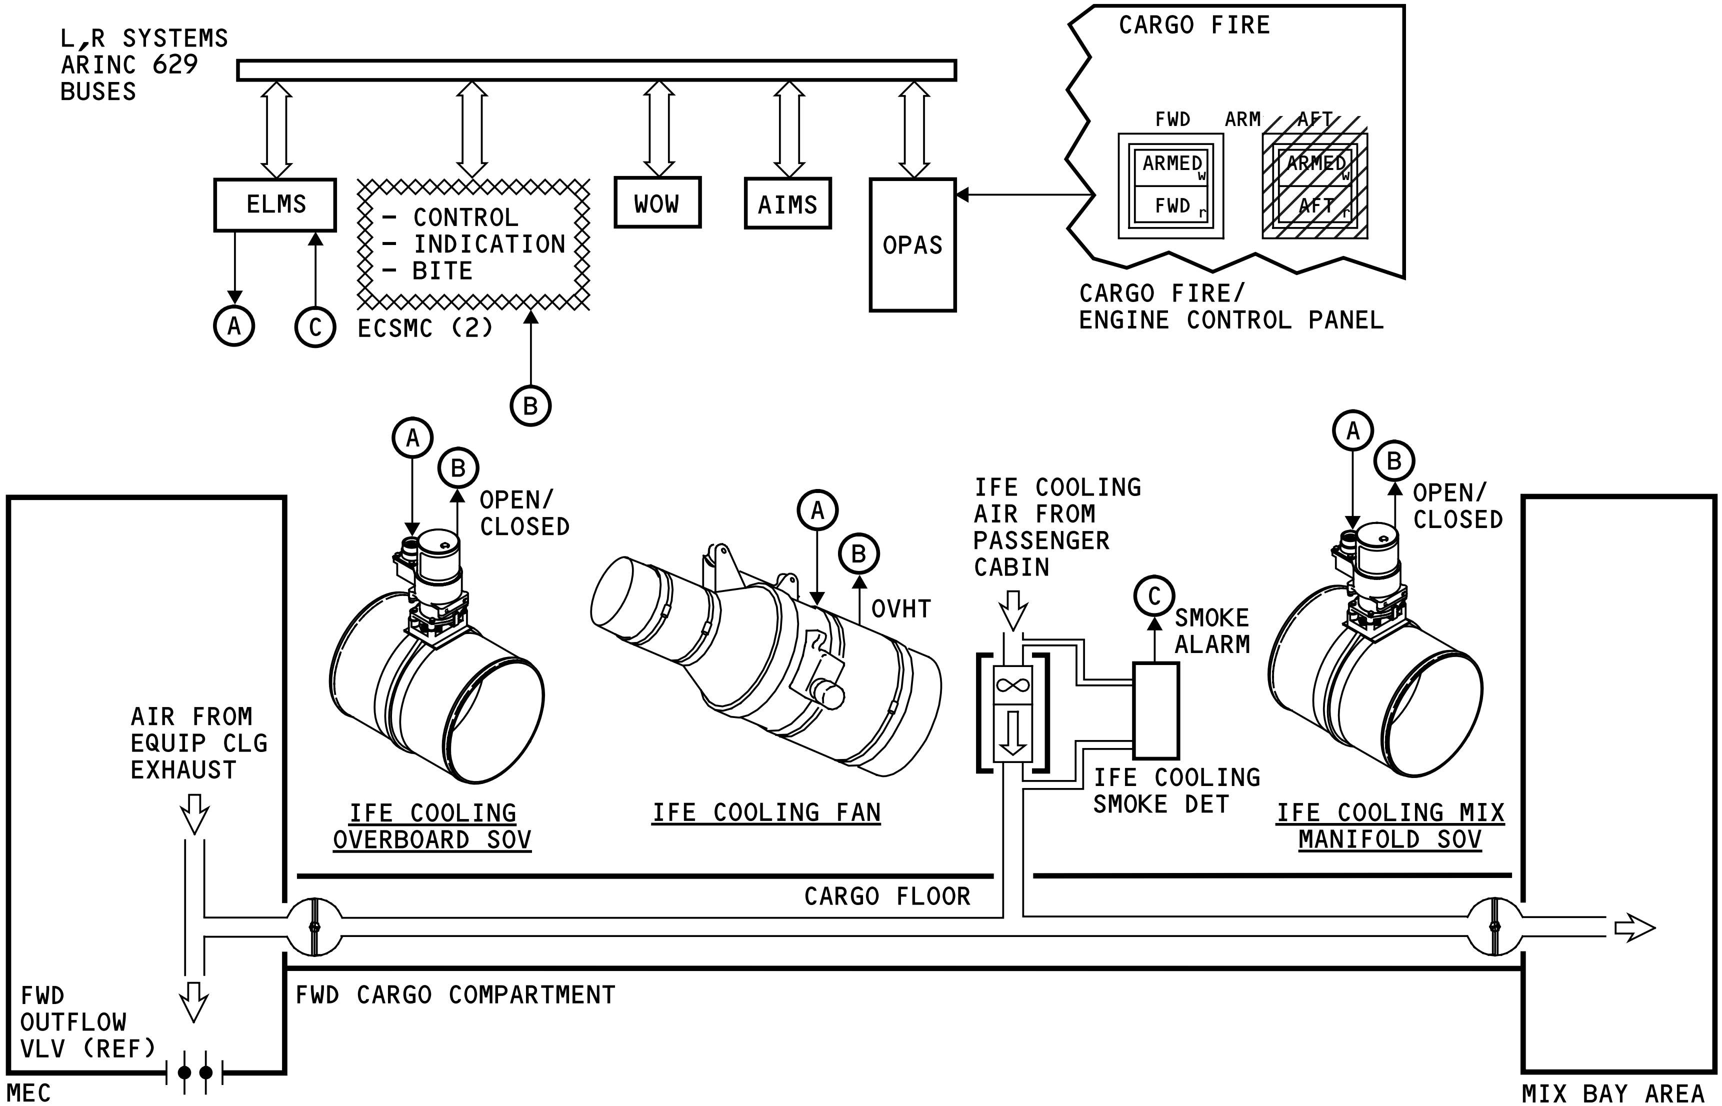
The overboard shutoff valve is open if all of these conditions are true:

- Engines off or mix manifold shutoff valve closed
- No engine start on ground
- Test.

An IFE cooling smoke detector monitors the cooling air at the fan. The smoke detector gives a smoke alarm indication to ELMS if it finds smoke in the air. For a smoke condition, ELMS does these things:

- Removes power from the IFE components
- Turns off the IFE cooling fan
- Closes the two shutoff valves.

No EICAS or CSCP/CACP indications show for IFE cooling air smoke.



A/C - EQUIPMENT COOLING - IFE - GENERAL DESCRIPTION

21-27-00-034 Rev 0 04/23/1997

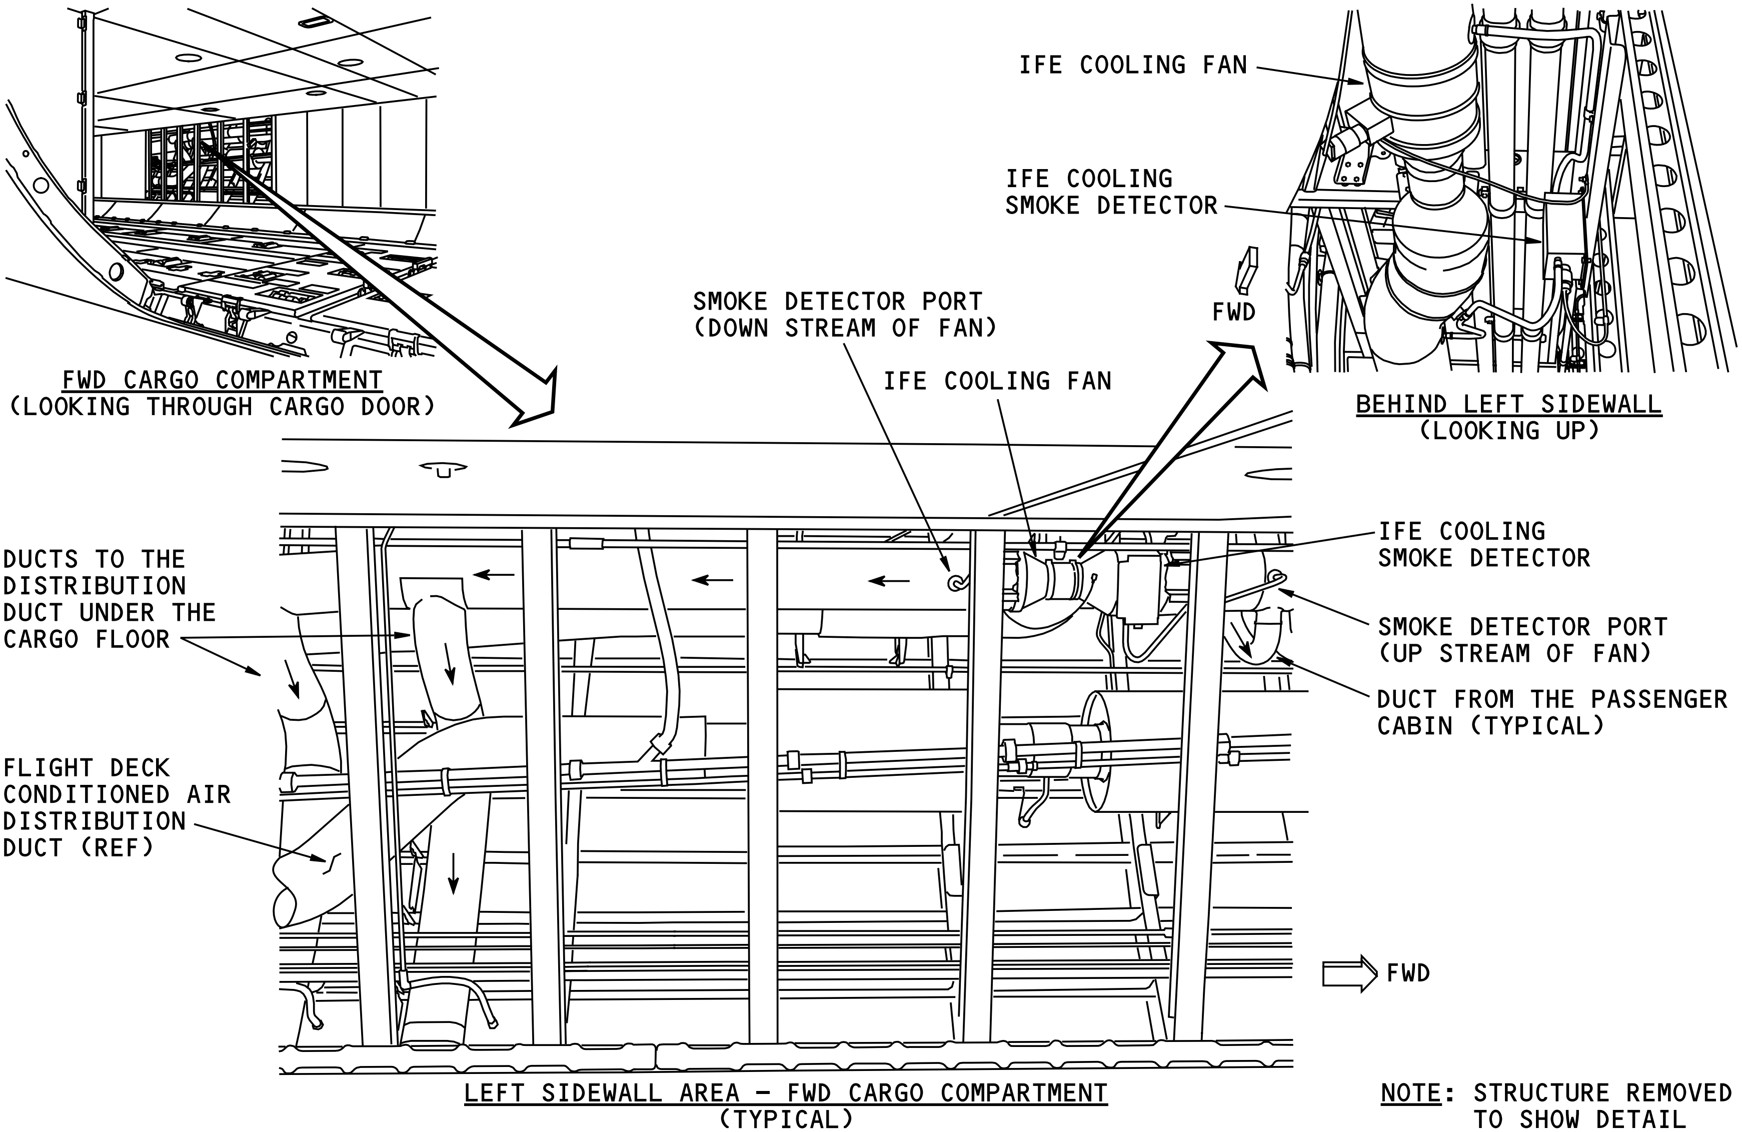
A/C - EQUIPMENT COOLING - IFE - COOLING FAN AND SMOKE DETECTOR

General

The IFE cooling fan and IFE cooling smoke detector are behind the left side wall in the forward cargo compartment. The smoke detector attaches to structure that holds the side wall panel on.

Cooling air from the IFE components in the passenger cabin comes through six small ducts forward of the fan. The smoke detector has ports that connect forward and aft of the fan.

Air that comes from the fan goes through two ducts that connect to a distribution duct under the cargo floor.



A/C - EQUIPMENT COOLING - IFE - COOLING FAN AND SMOKE DETECTOR

A/C - EQUIPMENT COOLING - IFE - SHUTOFF VALVES

Purpose

These are the two IFE cooling shutoff valves:

- IFE cooling overboard shutoff valve
- IFE cooling mix manifold shutoff valve.

The IFE cooling overboard shutoff valve lets IFE cooling air go forward from the distribution duct to the forward outflow valve.

The IFE cooling mix manifold shutoff valve lets IFE cooling air go aft from the distribution duct to the mix bay area.

The valves operate electrically.

Physical Description

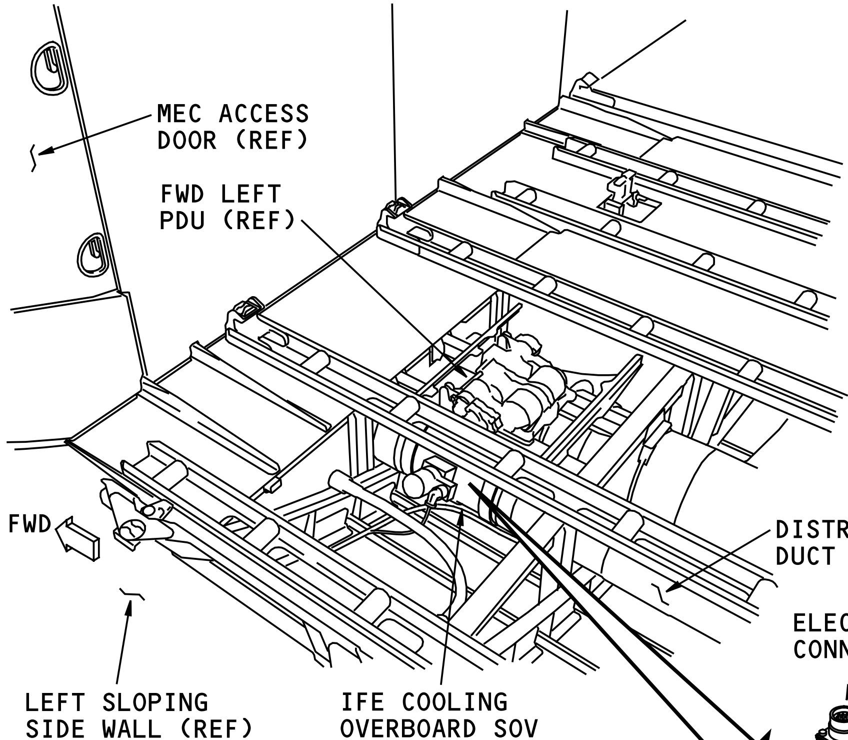
The two valves are interchangeable. They have these components:

- Valve body
- Electrical connector
- Motor
- Position indicator/manual override lever
- Valve disc.

The diameter of the valve body is seven inches (17.8 cm).

Location

These valves are under the floor at each end of the forward cargo compartment.



FWD CARGO COMPARTMENT
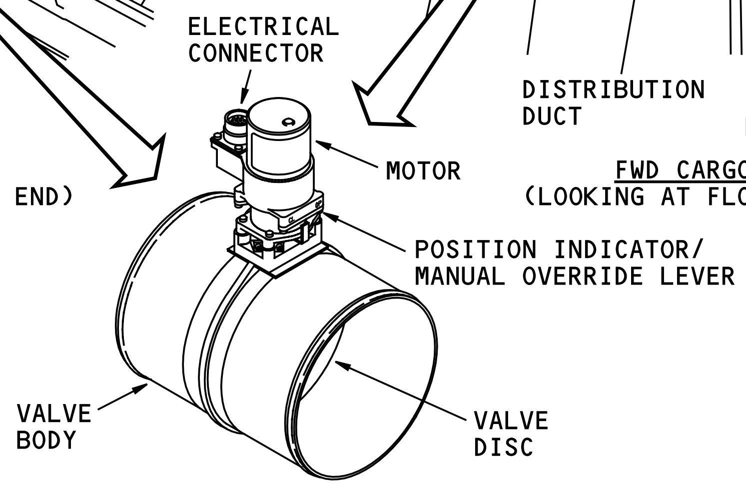
(LOOKING AT FLOOR AREA - AFT END)



IFE COOLING SHUTOFF VALVE
(TYPICAL)

A/C - EQUIPMENT COOLING - IFE - SHUTOFF VALVES

21-27-00-036 Rev 0 04/23/1997

A/C - EQUIPMENT COOLING - IFE - FUNCTIONAL DESCRIPTION

General

The 28v dc left main bus supplies power to the IFE cooling overboard shutoff valve. The 28v dc right main bus supplies power to the IFE cooling mix manifold shutoff valve. These valves function in the same way.

The ECS miscellaneous card (ECSMC) in control sends data to ELMS to open the valves. ELMS closes the valves if the ECSMC sends no open signal. Each ECSMC has logic for valve control.

In the fully closed or fully open position, switches in the valves send valve position to the related ECSMC. The IFE cooling overboard shutoff valve sends position indications to the left ECSMC. The IFE cooling mix manifold shutoff valve sends position indications to the right ECSMC.

The 115v ac left main section 2 bus supplies power to the IFE cooling fan. The ECSMC in control sends data to ELMS to turn on the fan. Each ECSMC has logic to control the fan. The fan sends an overheat indication to the left ECSMC. The EICAS status message IFE COOLING FAN shows for an overheat condition of the fan.

The 28v dc left main bus supplies power to the IFE smoke detector. The smoke detector monitors the opacity of the IFE cooling air that goes through it. It gives an alarm to ELMS if smoke is in the air. ELMS latches off the power to the IFE components if this occurs. No EICAS or CSCP/CACP indications show for IFE cooling air smoke.

The ECSMC in control turns off the fan and closes the two shutoff valves for these conditions:

- Cooling fan overheat
- Forward cargo arm
- IFE cooling smoke found
- IFE cooling smoke detector test failed
- IFE cooling system test.

Test

The ECSMC in control does a power-up test of the IFE cooling system. This test does a check to find if the control logic can operate the fan and two shutoff valves. This test also does a check of the operation of the smoke detector. You can do a ground test of the IFE cooling system from the maintenance access terminal, 21 ENVIRONMENTAL CONTROL SYSTEM, SYSTEM TEST, IFE COOLING SYSTEM. The EICAS status message IFE SMOKE DETECTOR shows if the power-up or ground test finds a smoke detector malfunction. No EICAS messages show if the power-up or ground test finds a fan or valve malfunction.

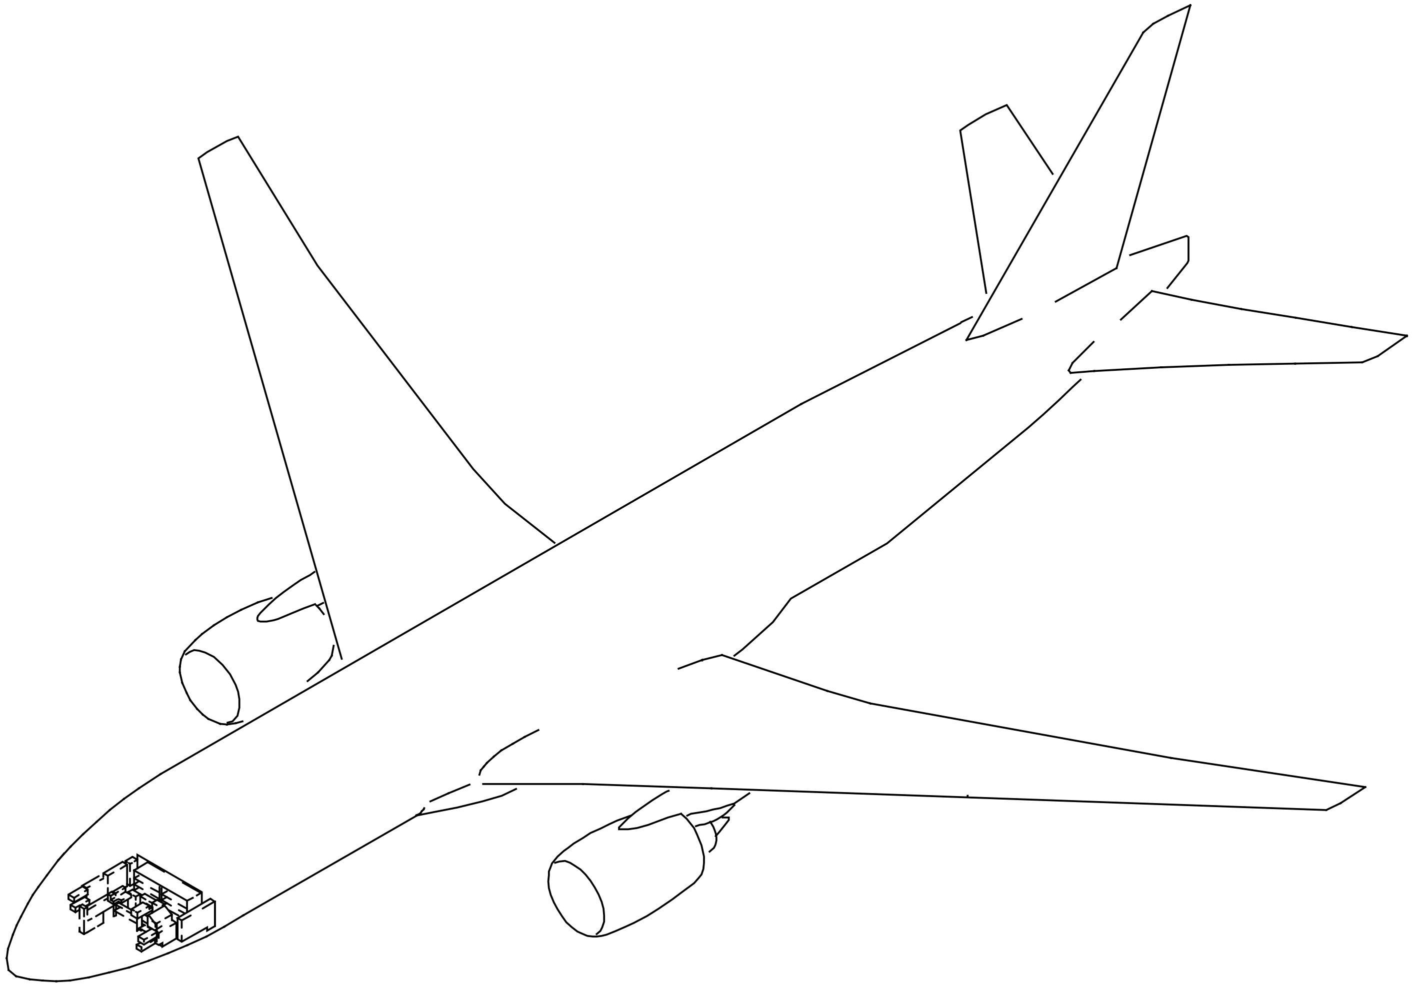
ELECTRICAL/ELECTRONIC (E/E) COOLING SMOKE DETECTION - INTRODUCTION

Purpose

The electrical/electronic cooling smoke detection system monitors the forward equipment cooling system airflow for smoke.

General

The the smoke detection system has an interface with the equipment cooling system. If there is smoke in the equipment cooling system supply or exhaust, the system operates in the override mode. This removes the smoke from the airplane.



ELECTRICAL/ELECTRONIC (E/E) COOLING SMOKE DETECTION - INTRODUCTION

E/E COOLING SMOKE DETECTION - GENERAL DESCRIPTION

General

The electrical/electronic (E/E) cooling smoke detector monitors air from the supply and exhaust parts of the forward equipment cooling system. If the detector finds smoke in the air, the equipment cooling system goes into the override mode. When the airplane is pressurized, cabin differential pressure causes the smoke to go overboard.

Interfaces

The E/E cooling smoke detector has interfaces with the AIMS and the ECS miscellaneous cards (ECSMCs) through the forward cargo smoke detector and the ASG cards.

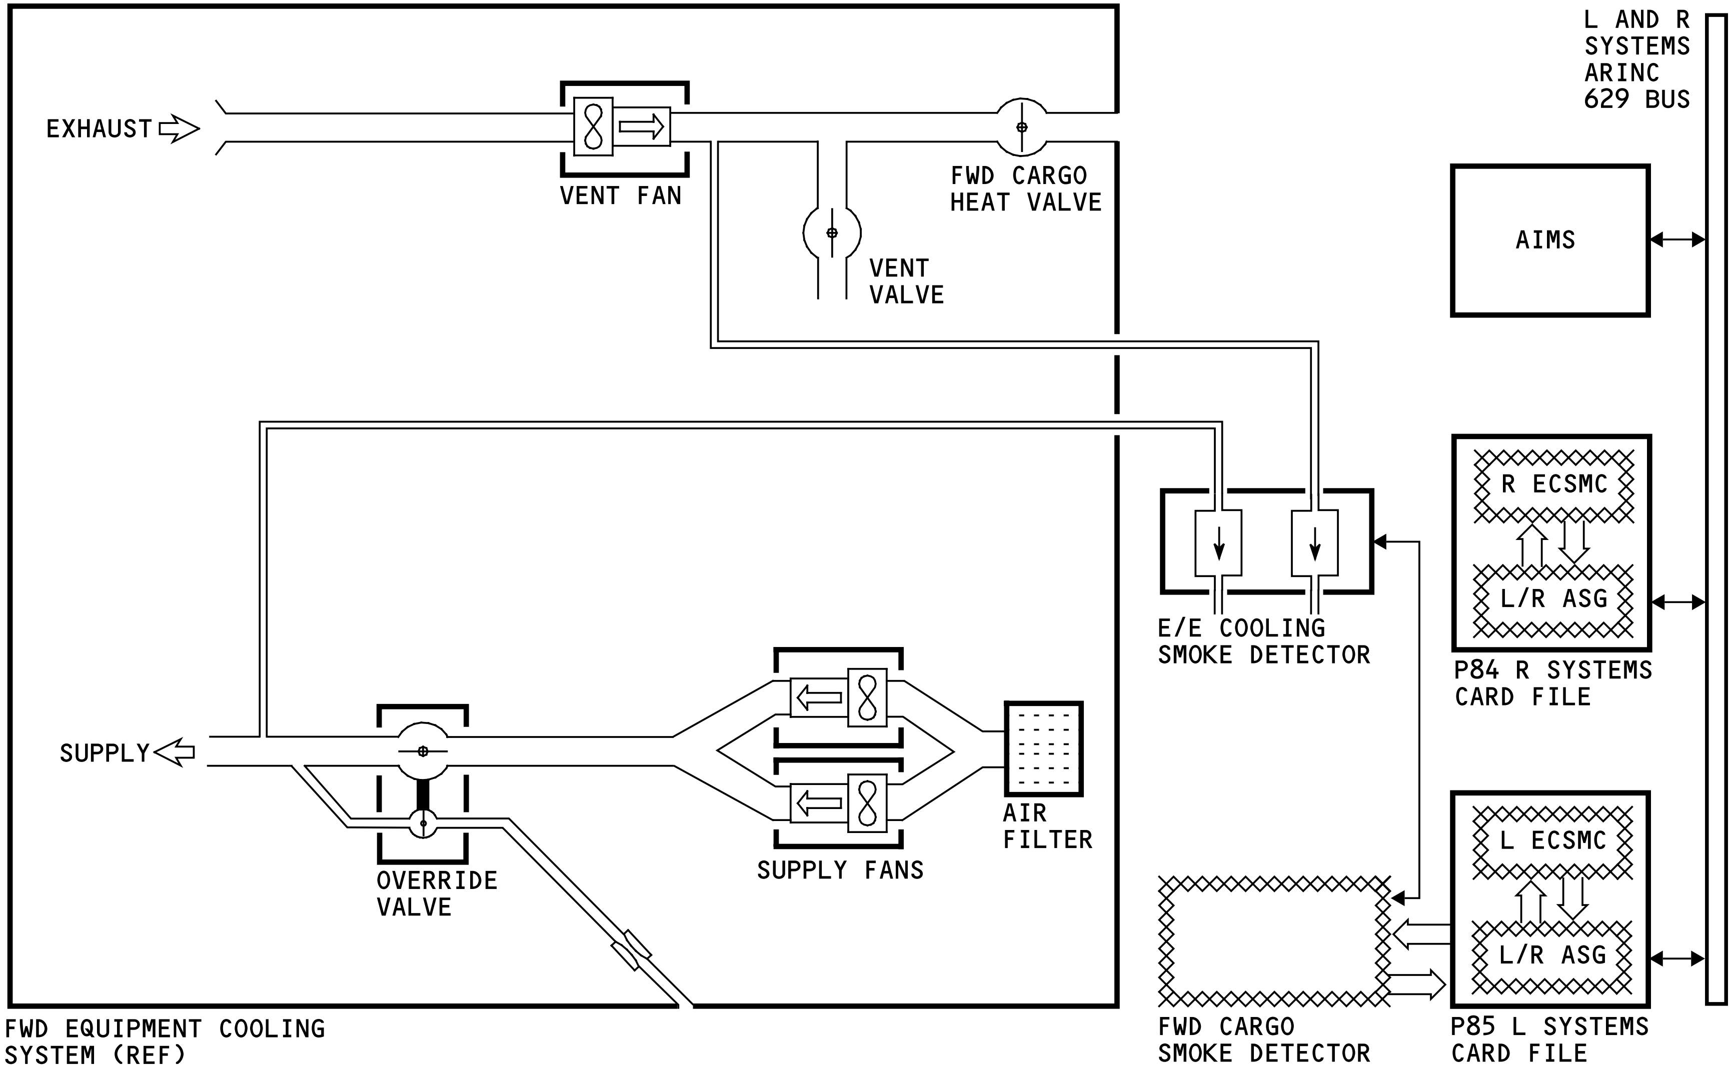
The forward cargo smoke detector controls the E/E cooling smoke detector, supplies electrical power to it, and gets smoke alarms from it.

General Operation

If there is smoke in the equipment cooling airflow, the E/E cooling smoke detector sends an alarm signal to the forward cargo smoke detector. The forward cargo smoke detector sends alarm data to the systems card files. In the card files, the alarm data goes to the ECSMCs. The ECSMC that is in control of the equipment cooling system puts the system into the override mode.

System Tests

The E/E cooling smoke detector has BITE. Fault data goes to the forward cargo smoke detector, to the left systems card file, then to the AIMS. Faults cause EICAS status messages.



E/E COOLING SMOKE DETECTION - GENERAL DESCRIPTION

E/E COOLING SMOKE DETECTION - E/E COOLING SMOKE DETECTOR - INTRODUCTION

Purpose

The E/E cooling smoke detector monitors air in the forward equipment cooling system for smoke.

Physical Description

The E/E cooling smoke detector has these components:

- Two air inlet ports
- Four mounting brackets
- Two smoke detection chambers (internal)
- Two electronic control channels (internal)
- Two air outlet ports
- Two electrical connectors.

Location

The E/E cooling smoke detector is on the right side of the main equipment center, outboard of the E2 rack.

Training Information Point

There is no scheduled maintenance of the E/E cooling smoke detector. Status and maintenance messages show if there is a fault condition.

The smoke detector is an LRU. Four bolts attach the smoke detector to the structure. Two sampling tubes connect to the air inlet ports. The sampling tubes are made of aluminum and attached to the structure with clamps. This makes it difficult to connect them to the wrong inlet ports on the detector. Each smoke detector channel has its own electrical connector. The two connectors are different so you cannot cross-connect the wires.

The smoke detector has no internal LRUs.

E/E COOLING SMOKE DETECTION - E/E COOLING SMOKE DETECTOR - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

E/E COOLING SMOKE DETECTION - E/E COOLING SMOKE DETECTOR - FUNCTIONAL DESCRIPTION

General

The two channels contain identical circuits. The forward cargo smoke detector makes a decision about which channel operates. The operating channel monitors the optical smoke detectors.

Optical Smoke Detectors

The optical smoke detector has these parts:

- Two source light emitting diodes (LEDs)
- Two intensity monitor photodiodes
- Two scatter detector photodiodes.

One set of diodes connects to channel 1. The other set of diodes connects to channel 2.

Inside the smoke detection chamber, air flows between a source LED and a scatter detector photodiode. Normally, only a small amount of light from the lED reaches the scatter detector. If the air has smoke in it, the smoke particles reflect more light onto the scatter detector. This causes a smoke alarm signal.

The intensity monitor photodiode makes sure the source LED is on and keeps the output of the source LED constant. This configuration also finds contamination of the LED and photodiodes.

BITE

The detector does power-up and periodic BITE tests. The power-up BITE includes these tests:

- Supply voltage
- Source LED intensity
- Optical contamination
- Scatter detector operation.

The periodic BITE test monitors the source LED intensity and the scatter detector operation.

If the operating channel fails, BITE sends a signal to the forward cargo smoke detector. That smoke detector causes the other E/E cooling smoke detector channel to operate.

Inputs And Outputs

The smoke detector gets these inputs from the forward cargo smoke detector:

- 10.5v dc power
- LED 1 and 2 on/off

The smoke detector sends these outputs to the forward cargo smoke detector:

- Smoke alarm, chamber 1, channel 1
- Smoke alarm, chamber 2, channel 1
- Smoke alarm, chamber 1, channel 2
- Smoke alarm, chamber 2, channel 2

- Channel 1 BITE test pass/fail
- Channel 2 BITE test pass/fail.

E/E COOLING SMOKE DETECTION - E/E COOLING SMOKE DETECTOR - FUNCTIONAL DESCRIPTION

E/E COOLING SMOKE DETECTION - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

E/E COOLING SMOKE DETECTION - FUNCTIONAL DESCRIPTION

General

The E/E cooling smoke detector connects to the forward lower cargo smoke detector. The cargo smoke detector has two identical electronic channels. Channel 1 controls during one electrical power cycle, channel 2 controls during the next power cycle.

Each channel of the E/E cooling smoke detector connects to the related channel in the forward lower cargo smoke detector. The E/E cooling smoke detector gets these inputs from the cargo smoke detector control channel:

- DC power
- LED 1 and 2 on/off signals.

The E/E cooling smoke detector sends these outputs to the Lower cargo smoke detector control channel:

- Alarm 1 (smoke in detection chamber 1
- Alarm 2 (smoke in detection chamber 2)
- BITE pass/fail.

Smoke Detection

If there is smoke in one or two detection chambers, the E/E cooling smoke detector sends an alarm signal to the forward cargo smoke detector. The forward cargo smoke detector sends the alarm signal through the ARINC 429 bus to the ASG cards and left ECS miscellaneous card. The ASG cards transmit the alarm signal over the ARINC 629 buses to these systems and components:

- Overhead panel ARINC 629 system (OPAS)
- AIMS
- Right systems cardfile.

The OPAS makes a ground to turn on the E/E cooling override light. The AIMS causes a status message to show. The central maintenance computing function records the event as a flight deck effect for the in-bound flight. In the right systems cardfile, the ASG cards send the alarm signal to the right ECS miscellaneous card. The ECS miscellaneous cards put the equipment cooling system into the override mode. This sends the smoke overboard.

BITE

The forward cargo smoke detector controls the BITE circuits in the E/E cooling smoke detector. BITE tests occur when the system first gets power and regularly during operation. If the E/E cooling smoke detector fails a BITE test, it sends a BITE fail signal to the cargo smoke detector. The signal causes these things to occur:

- The cargo smoke detector operates the other channel in the E/E cooling smoke detector
- The cargo smoke detector puts the fault data in memory
- The cargo smoke detector sends the fault information to the AIMS. The CMCS shows status and maintenance messages.

E/E COOLING SMOKE DETECTION - FUNCTIONAL DESCRIPTION

You can do a test of the system from the MAT. AIMS tells the cargo smoke detector to do a power-up BIT sequence.

Training Information Point

Use the MAT to get E/E cooling smoke detector fault data from the cargo smoke detector memory.

AIR CONDITIONING - PRESSURIZATION - INTRODUCTION

AIR CONDITIONING - PRESSURIZATION - GENERAL DESCRIPTION

General

There are two parts that have a relation to the pressurization system: cabin pressure control and cabin pressure relief.

The cabin pressure control system controls the amount of air that flows out of the airplane. This keeps the cabin air pressure in limits at altitude.

The cabin pressure relief system keeps the internal pressure of the airplane to a limit.

The pneumatic system usually supplies more than a sufficient quantity of air through the air conditioning packs to pressurize the airplane. Outflow valves in the forward and aft areas of the airplane control the amount of air that goes out of the airplane. This keeps the cabin air pressure within limits.

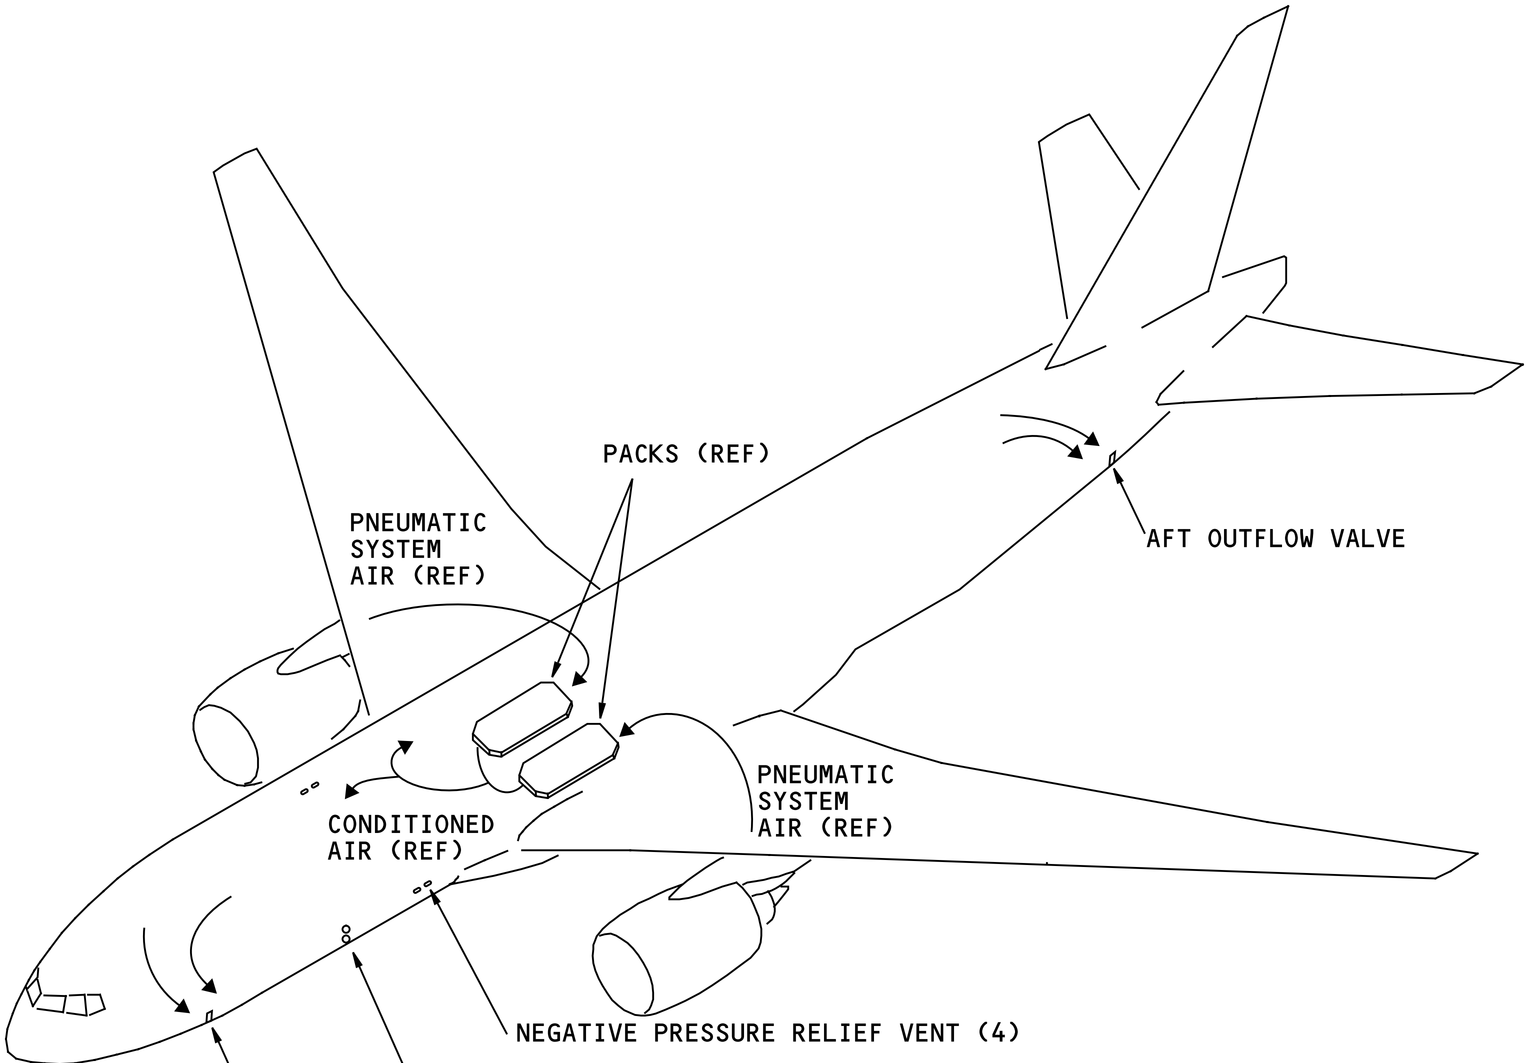
Outflow Valves

The flight crew sets automatic or manual control for one or both of the outflow valves from the flight deck. In the automatic mode, the usual position of the valves is controlled so that they are not the same. Valve position is set so that 20 percent of the total air outflow goes through the forward valve and 80 percent goes through the aft valve.

In the manual mode, the flight crew controls the position of one or both of the valves.

Pressure Relief

Positive pressure relief valves and negative pressure relief vents, in the forward part of the airplane keep the difference between cabin pressure and ambient pressure in limits.



AIR CONDITIONING - PRESSURIZATION - GENERAL DESCRIPTION

21-30-00-002 Rev 3 11/02/95

THIS PAGE INTENTIONALLY LEFT BLANK

Purpose

The cabin pressure control system controls the amount of air that flows out of the airplane. This keeps the cabin air pressure in limits at all airplane operating altitudes (-2,000 through 43,100 feet, -610 through 13,146 meters).

Physical Description

The cabin pressure control system has these components:

- One remote cabin pressure sensor
- Flight deck controls
- Two outflow valves.

Interfaces

The air supply cabin pressure controllers (ASCPCs) provide control, indications, and bit for this system. The controllers also have an internal sensor that they use to monitor cabin pressure. The sensor is used for control and to give an output on the ARINC 629 buses. The ASCPCs are part of the engine air supply system. See the engine air supply section for more information about the ASCPC interfaces related to cabin pressure control (AMM PART I 36-11).

The remote cabin pressure sensor sends data to the AIMS, the ASCPCs, and ELMS. AIMS uses the remote sensor data as an alternative to the ASCPC cabin pressure data.

The ASCPCs use the remote cabin pressure sensor to cross check data from there internal cabin pressure sensor.

ELMS sends the remote cabin pressure sensor data on the ARINC system buses. ELMS also uses the remote cabin pressure sensor data as an alternative to the ASCPC cabin pressure data.

See these section for more information about the ELMS interfaces related to cabin pressure:

- Passenger compartment illumination (AMM PART I 33-21)
- Information signs (AMM PART I 33-22)
- Passenger oxygen (AMM PART I 35-21).

The ASCPCs usually get landing altitude from the flight management computing function (FMCF) of the AIMS. As an alternative to the FMCF, the flight crew can manually set landing altitude from the bleed air/pressurization panel.

The cabin pressure control system also interfaces with these systems/LRUs:

- ADIRS
- CMCF
- EFIS
- FMCF
- PDF
- OPAS
- AFDS

- EEC
- Left (right) WOW card.

See the engine air supply section for more information about the interfaces related to the ASCPCs and cabin pressure control (AMM PART I 36-11).

General Description

The flight crew sets automatic or manual control of the outflow valves from the flight deck.

Each valve is controlled independently. You can set auto for one and manual for the other.

Auto Control

In the automatic mode, the left ASCPC usually controls the position of the valves. The right ASCPC gives backup control. Automatic control supplies these functions, most important first:

- Controls the cabin-to-ambient differential pressure to a maximum of 8.6 ±.05 psid
- Limits the cabin pressure rate-of-change
- Controls the cabin altitude to no more than 8000 feet (2440 meters)
- Limits takeoff and landing pressure bump
- Controls the ratio of air outflow between the forward and aft outflow valves.

Manual Control

For manual control the flight crew controls cabin rate-of-change and cabin altitude by manually controlling the position of the outflow valves. They use the outflow valve switches to turn on/off manual control.

Once manual control is selected, the flight crew uses the outflow valve manual switches to control the position of the outflow valves.

AIR CONDITIONING - CABIN PRESSURE CONTROL SYSTEM - INTRODUCTION

AIR CONDITIONING - CABIN PRESSURE CONTROL SYSTEM - AIR SUPPLY CABIN PRESSURE CONTROLLER

General

The air supply cabin pressure controllers (ASCPCs) control the pneumatic system and cabin pressure. These functions operate independently.

Location

The left and right ASCPCs are in the MEC on the E1 and E2 racks.

Physical Description

The ASCPCs have test and cabin pressure sense ports on the front. The test port is for in-shop service. The cabin pressure sense port lets the controllers monitor cabin pressure.

The ASCPCs use operational program software (OPS) that you can load.

Training Information Point

The ASCPCs are LRUs. The circuit cards inside the ASCPC are not lRUs.

The left and right ASCPCs are interchangeable.

See the engine air supply section for more information about the ASCPCs (AMM PART I 36-11).

(TYPICAL)

21-31-00-008 Rev 1

AIR CONDITIONING - CABIN PRESSURE CONTROL SYSTEM - AIR SUPPLY CABIN PRESSURE CONTROLLER

AIR CONDITIONING - CABIN PRESSURE CONTROL SYSTEM - OUTFLOW VALVE - INTRODUCTION

Purpose

Forward and aft outflow valves control the flow rate of pressurized cabin air out of the airplane.

Location

The aft outflow valve is adjacent to the aft waste tank. Access is through the aft waste tank enclosure panel at the rear of the bulk cargo compartment.

The forward outflow valve is below the P110 left power management panel in the main equipment center.

Physical Description

Both forward and aft outflow valves are the same. The valve weighs approximately 30.25 lbs (13.72 kg). Each valve has these assemblies:

- Actuator assembly
- Frame assembly
- Gearbox assembly.

The actuator assembly has these line replaceable components:

- Outflow valve control unit
- Left outflow valve motor
- Right outflow valve motor
- Outflow valve gearbox assembly.

The frame assembly has these parts:

- Door (2)
- Nut plate (18)
- Push rod (2).

The valve control unit is a two channel controller. The unit has these parts:

- Airplane electrical connectors (3)
- RVDT electrical connector (1)
- Motor electrical connector (2).

The gearbox assembly has reduction gears, two internal RVDTs and an actuator crank.

Training Information Point

You can remove the forward outflow only from inside the airplane. You can remove the aft outflow valve from outside the airplane or from inside the airplane.

To prepare for pressurized flight with an outflow valve that does not operate, set the position of the valve to a specified position, then open the applicable circuit breakers.

To prepare the airplane for unpressurized flight with outflow valves that do not operate, lock the valves open.

ACTUATOR ASSEMBLY

AIR CONDITIONING - CABIN PRESSURE CONTROL SYSTEM - OUTFLOW VALVE - INTRODUCTION

General

The outflow valve control unit (VCU) has two channels. The left channel controls the left outflow valve motor, and the right channel controls the right outflow valve motor. Each channel has a separate power supply.

The left channel has an interface with the left ASCPC and the right channel has an interface with the right ASCPC. The channels have interfaces with the ASCPC on an ARINC 429 bus. For manual mode operation, both channels have an interface with the bleed air/ pressurization panel.

Outflow Valve Control Unit

The valve control unit has these functions:

- Controls motor speed and position
- Monitors valve position (RVDTs)
- Supplies BITE.

In the automatic mode, the motor control logic uses information from the related ASCPC to set motor speed and the position of the outflow valve. The valve can open or close completely in less than 10 seconds for the automatic mode. ASCPC information usually causes the VCU to change motor speed for smooth changes in cabin pressure.

In the manual mode, the motor control logic uses the signal from the outflow valve manual switches on the bleed air/pressurization panel to open or close the outflow valve. The valve can open or close completely in approximately 27 seconds for the manual mode.

Two RVDTs that are part of the gearbox send valve position information back to the VCU and ASCPCs in automatic and manual modes.

Outflow Valve Motors

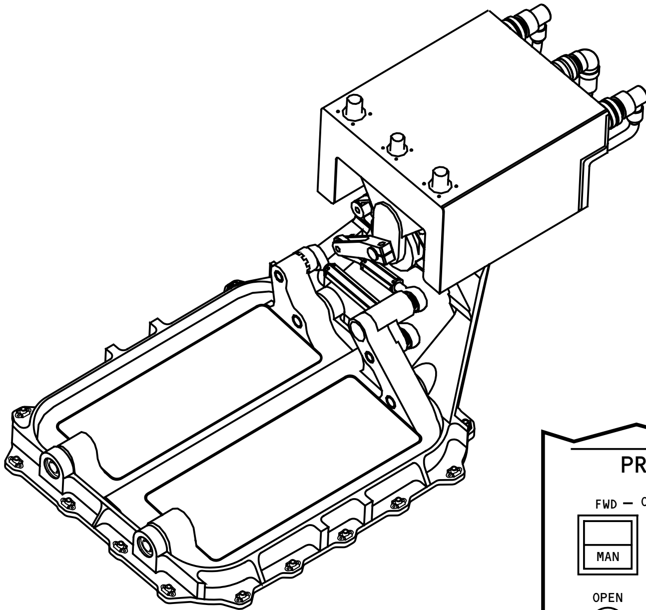
A brake solenoid in the motor stops movement when the motor does not have a command to turn. Sensors in the motor give rotor position information to the VCU. The VCU uses rotor position to monitor motor speed. Both motors mechanically connect to the gearbox.

Gearbox

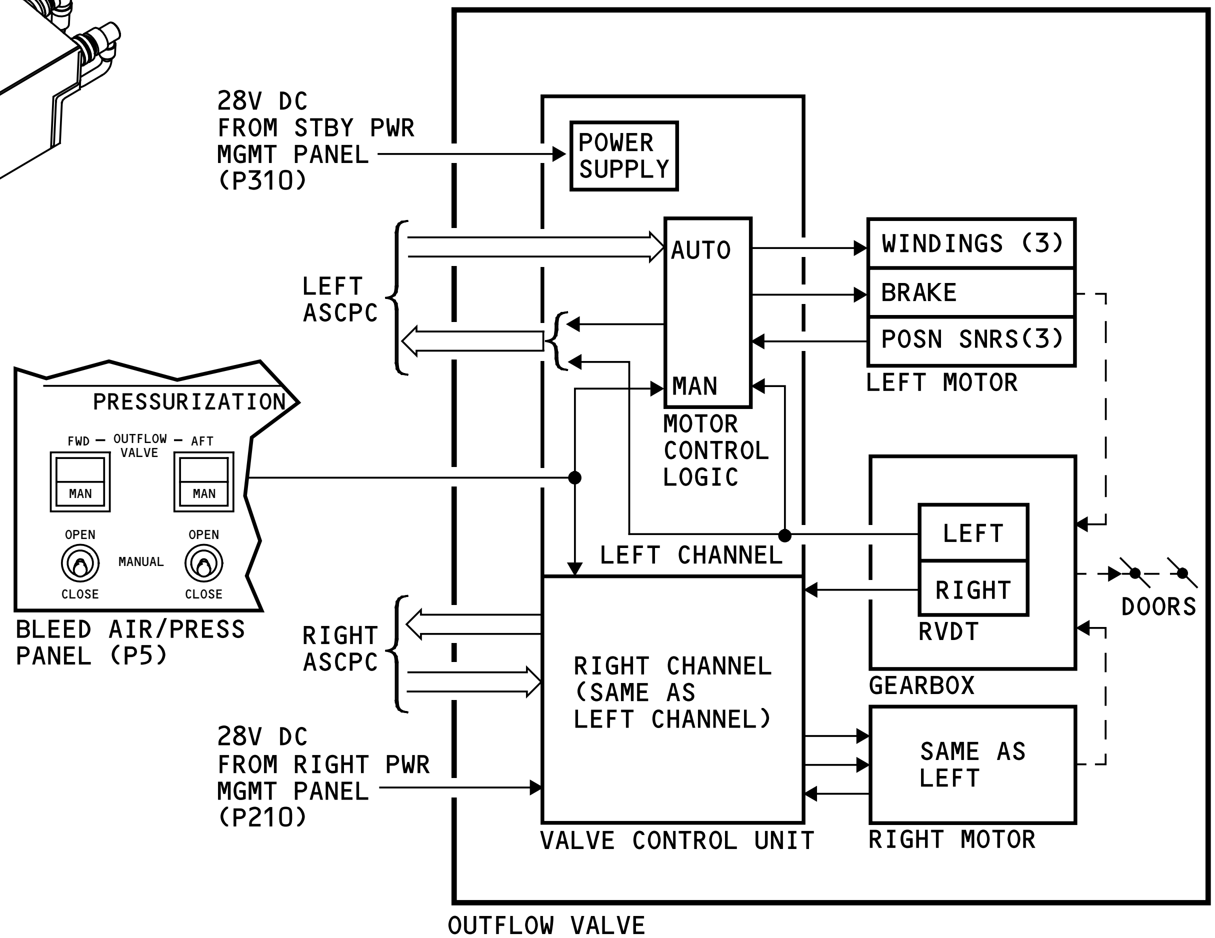
The gearbox changes the motor inputs to door and RVDT positions.

BITE

The VCU continuously monitors for outflow valve faults. If the VCU finds a fault, the VCU supplies the fault data to the ASCPCs for indication and to keep in memory.



OUTFLOW VALVE



21-31-00-003 Rev 2 09/16/96

AIR CONDITIONING - CABIN PRESSURE CONTROL SYSTEM - OUTFLOW VALVE - FUNCTIONAL DESCRIPTION

AIR CONDITIONING - CABIN PRESSURE CONTROL SYSTEM - REMOTE CABIN PRESSURE SENSOR

Purpose

The remote cabin pressure sensor measures cabin air pressure independently of the ASCPCs.

Physical Description

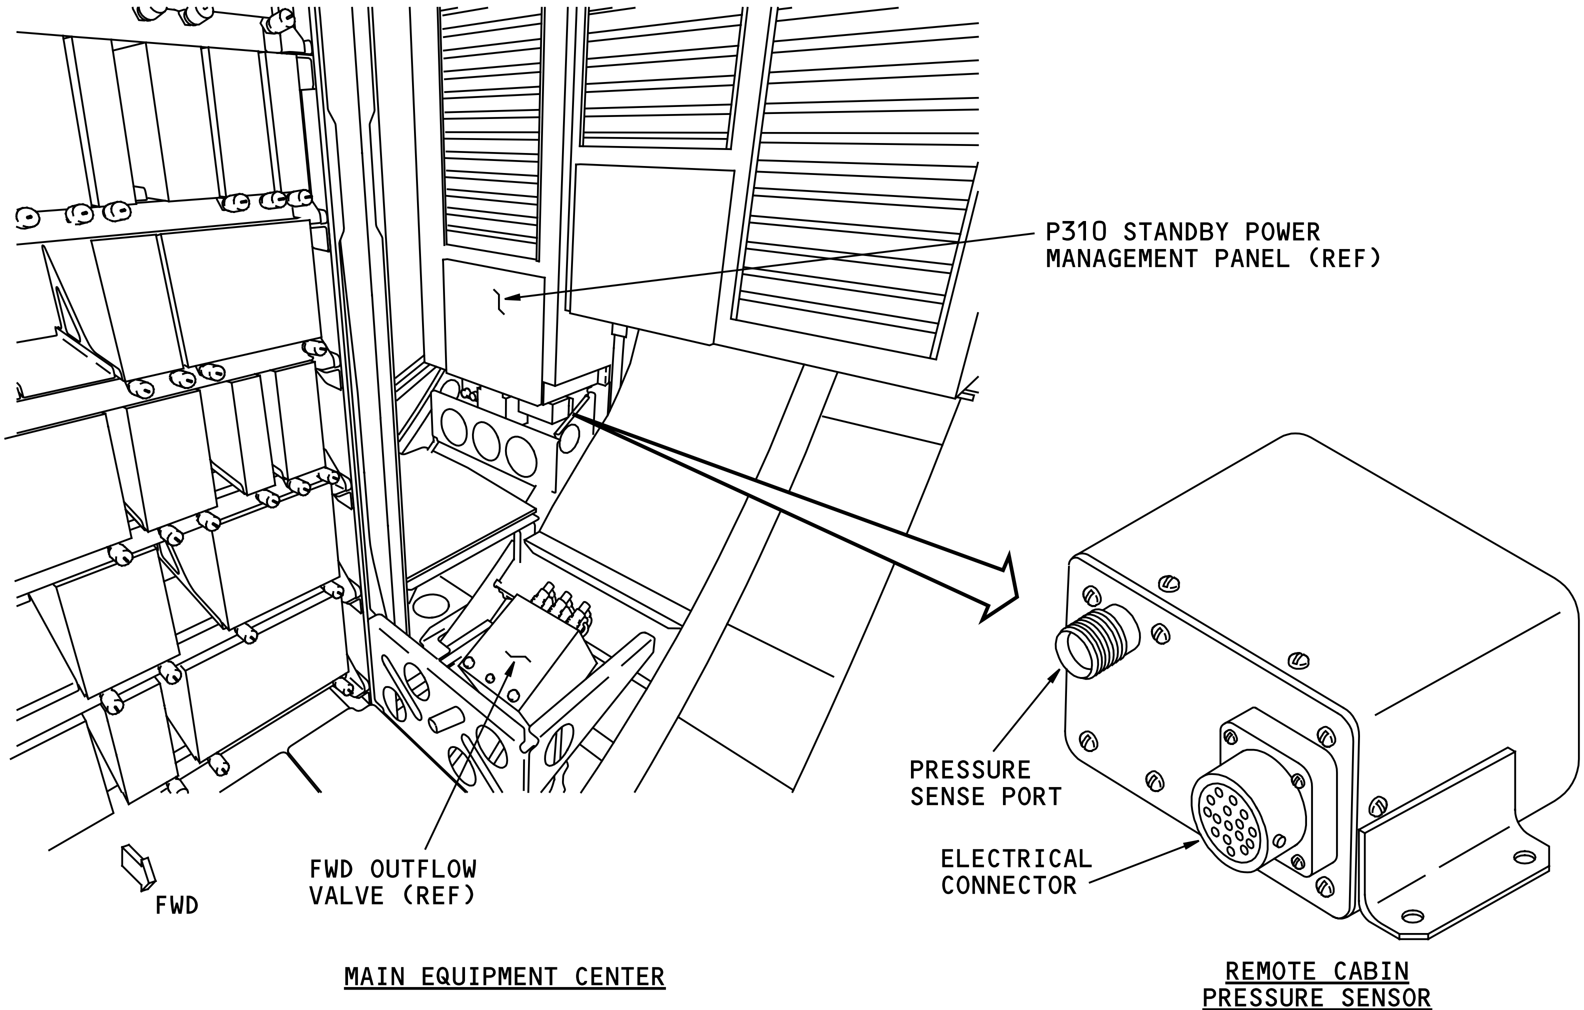
The sensor is an electronic device. It has an internal pressure sensor

Location

The remote cabin pressure sensor is in the main equipment center below the P310 standby power management panel.

The remote cabin pressure sensor mounts with the pressure sense port down. This keeps air velocity effects to a minimum.

The central maintenance computing system (CMCS) does not test the remote cabin pressure sensor.



21-31-00-004 Rev 0

AIR CONDITIONING - CABIN PRESSURE CONTROL SYSTEM - REMOTE CABIN PRESSURE SENSOR

Bleed Air/Pressurization Panel

These controls are on the bleed air/pressurization panel:

- Forward and aft outflow valve switches
- Forward and aft outflow valve manual switches
- Landing altitude selector.

Outflow Valve Switches

The forward and aft outflow valve switches set the outflow valves to automatic or manual operation. The switches are alternate-action switches. The AUTO indication on the switch shows the valves in automatic operation. When the MAN indication shows, the valves are in manual operation. In the MAN position, the ECS (environmental control system) data block shows on the EICAS display. The selection of the MAN position causes these indications:

- The related advisory message, OUTFLOW VALVE FWD (AFT) shows on the EICAS display
- The caution message, CABIN ALTITUDE AUTO shows on the EICAS display if both valves are set to MAN
- An M shows on the related valve position indicator in the ECS data block
- MAN shows below the valve position data on the air supply maintenance page (not shown).

Outflow Valve Manual Switches

The forward and aft outflow valve manual switches set the position of the outflow valves. The switches are toggle type switches with a spring-loaded center off position. These switches only function when the outflow valve switches are in the MAN position. Valve position shows in the ECS data block.

Landing Altitude Control

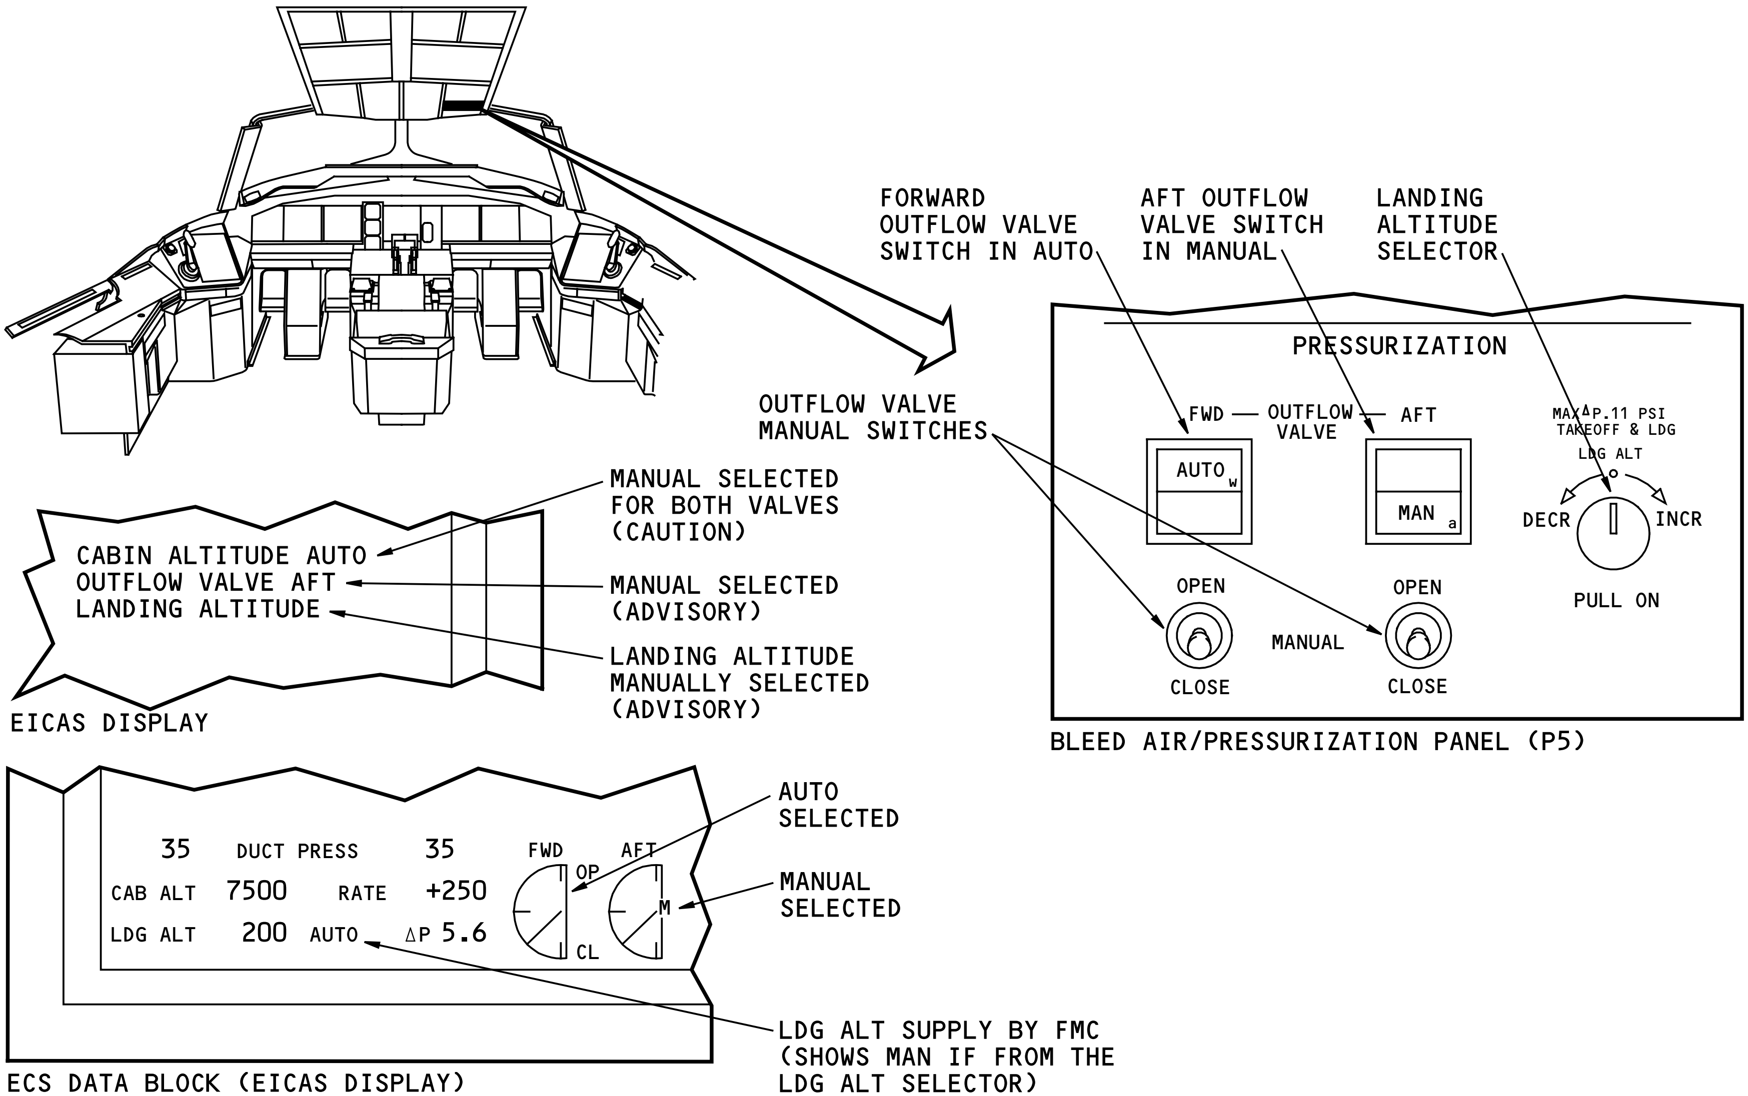
When the knob on the landing altitude selector is in, the ASCPC uses landing altitude data from the flight management computing function (FMCF) of AIMS.

When the landing altitude selector is out, the ECS data block shows and MAN shows next to the landing altitude data. MAN also shows on the air supply maintenance page (not shown) next to the landing altitude data. The landing altitude selector sets the landing altitude value. The ASCPC uses this value for landing altitude.

The flight crew moves the landing altitude control to the right to increase or to the left to decrease the landing altitude. The control is spring-loaded to the center position. The landing altitude limits are 2,000 feet below sea level to 15,000 feet above sea level.

Training Information Point

One outflow valve can operate in automatic mode and the other can operate in manual mode at the same time.



21-31-00-005 Rev 1 09/12/96

AIR CONDITIONING - CABIN PRESSURE CONTROL SYSTEM - BLEED AIR/PRESSURIZATION PANEL

AIR CONDITIONING - CABIN PRESSURE CONTROL SYSTEM - FUNCTIONAL DESCRIPTION

General

The air supply cabin pressure controllers (ASCPCs) supply control, indications, and BIT for the cabin pressure control system. ARINC 429 buses connect the ASCPCs to their related valve control unit (VCU) channels. The left and right VCU channels get power from a different bus. The outflow valve switches on the bleed air/pressurization panel set automatic or manual mode.

The ASCPCs have these modes of operation:

- Initialization (power up)
- Preflight BIT
- Automatic.

Initialization

The initialization mode is when power is first supplied to the ASCPCs or when new software is installed.

When the initialization mode is on, the ASCPCs do a check of these components and functions:

- Memory functions
- Checks if ground test is selected
- Software compatibility (left ASCPC to right ASCPC).

The initialization mode takes approximately 2 seconds to complete.

Preflight BIT

Both ASCPCs do a preflight BIT when the airplane is on the ground and one or both of the outflow valves are set to AUTO.

Preflight BIT is complete in 90 seconds or less. When the preflight BIT mode is on, the ASCPCs do internal checks and an operational check of the outflow valves. During these checks, the outflow valves move. If there are faults, flight deck indications will occur.

Automatic Mode

When the outflow valve switches are in AUTO, the OPAS sends a signal to the ASCPCs. This sets the outflow valves for automatic operation.

Usually, the left ASCPC controls the left motor in each outflow valve through the left VCU channels. If, because of system failures, the left ASCPC cannot control both valves, the control configuration changes. This is the control sequence:

- L ASCPC is in control if it can control both valves
- R ASCPC is in control if it can control both valves
- L ASCPC is in control if it can control the aft valve
- R ASCPC is in control if it can control the aft valve
- L ASCPC is in control if it can control the forward valve

- R ASCPC is in control if it can control the forward valve.

Usually the ASCPC uses the VCUs to set the positions of the valves so that 20 percent of the outflow is through the forward valve and 80 percent is through the aft valve. This changes if one of the ASCPCs cannot control both valves. In that condition, each valve permits 50 percent of the outflow. This helps prevent loss of cabin pressure control if one valve fails so that it can not be controlled by the left or right ASCPC.

The same change occurs if you arm the forward or aft cargo fire switches. This keeps smoke from the cargo compartment out of the cabin area and keeps a sufficient concentration of extinguishing agent in the cargo compartment.

The ASCPCs use the VCUs to control cabin pressure and cabin pressure rate of the change. The VCUs get speed commands from the ASCPC. The speed commands can make the VCU move the outflow valve slowly or fast. The valve can move fully open or close in less than 10 seconds.

The ASCPCs use this data to control cabin pressure:

SIGNAL	PRI SOURCE	BU SOURCE
Cabin Pressure	Active ASCPC	Other ASCPC
Ambient pressure	ADIRU	EEC
Ground speed	ADIRU	
Landing altitude	AIMS (FMCF)	Ldg Alt Selector
Differential press	AIMS (FMCF)	
Cruise altitude	AIMS (FMCF)	
Time for climb	AIMS (FMCF)	
Time for descent	AIMS (FMCF)	
ETA top of descent	AIMS (FMCF)	
Barometric correction	AIMS (PDF)	
Vertical nav on/off	AFDC	
Air or ground mode	WOW	

Cabin pressure

The controllers monitor cabin pressure from an internal sensor. The sensors also give an output on the ARINC 629 buses.

The remote cabin pressure sensor sends an analog pressure signal to the electrical load management system (ELMS). The ELMS puts this signal on the ARINC 629 buses. The ASCPCs use this data to do a BITE check of the internal cabin pressure sensors.

The remote sensor also gives an analog pressure output to the AIMS. The AIMS uses this signal if the cabin pressure data is not available from the ASCPCs or from ELMS.

Ambient Pressure

The ASCPCs usually get ambient pressure data from the ADIRU. If that data is not available or is not valid, the ASCPCs use ambient pressure data from the electronic engine control (EEC).

Landing Altitude

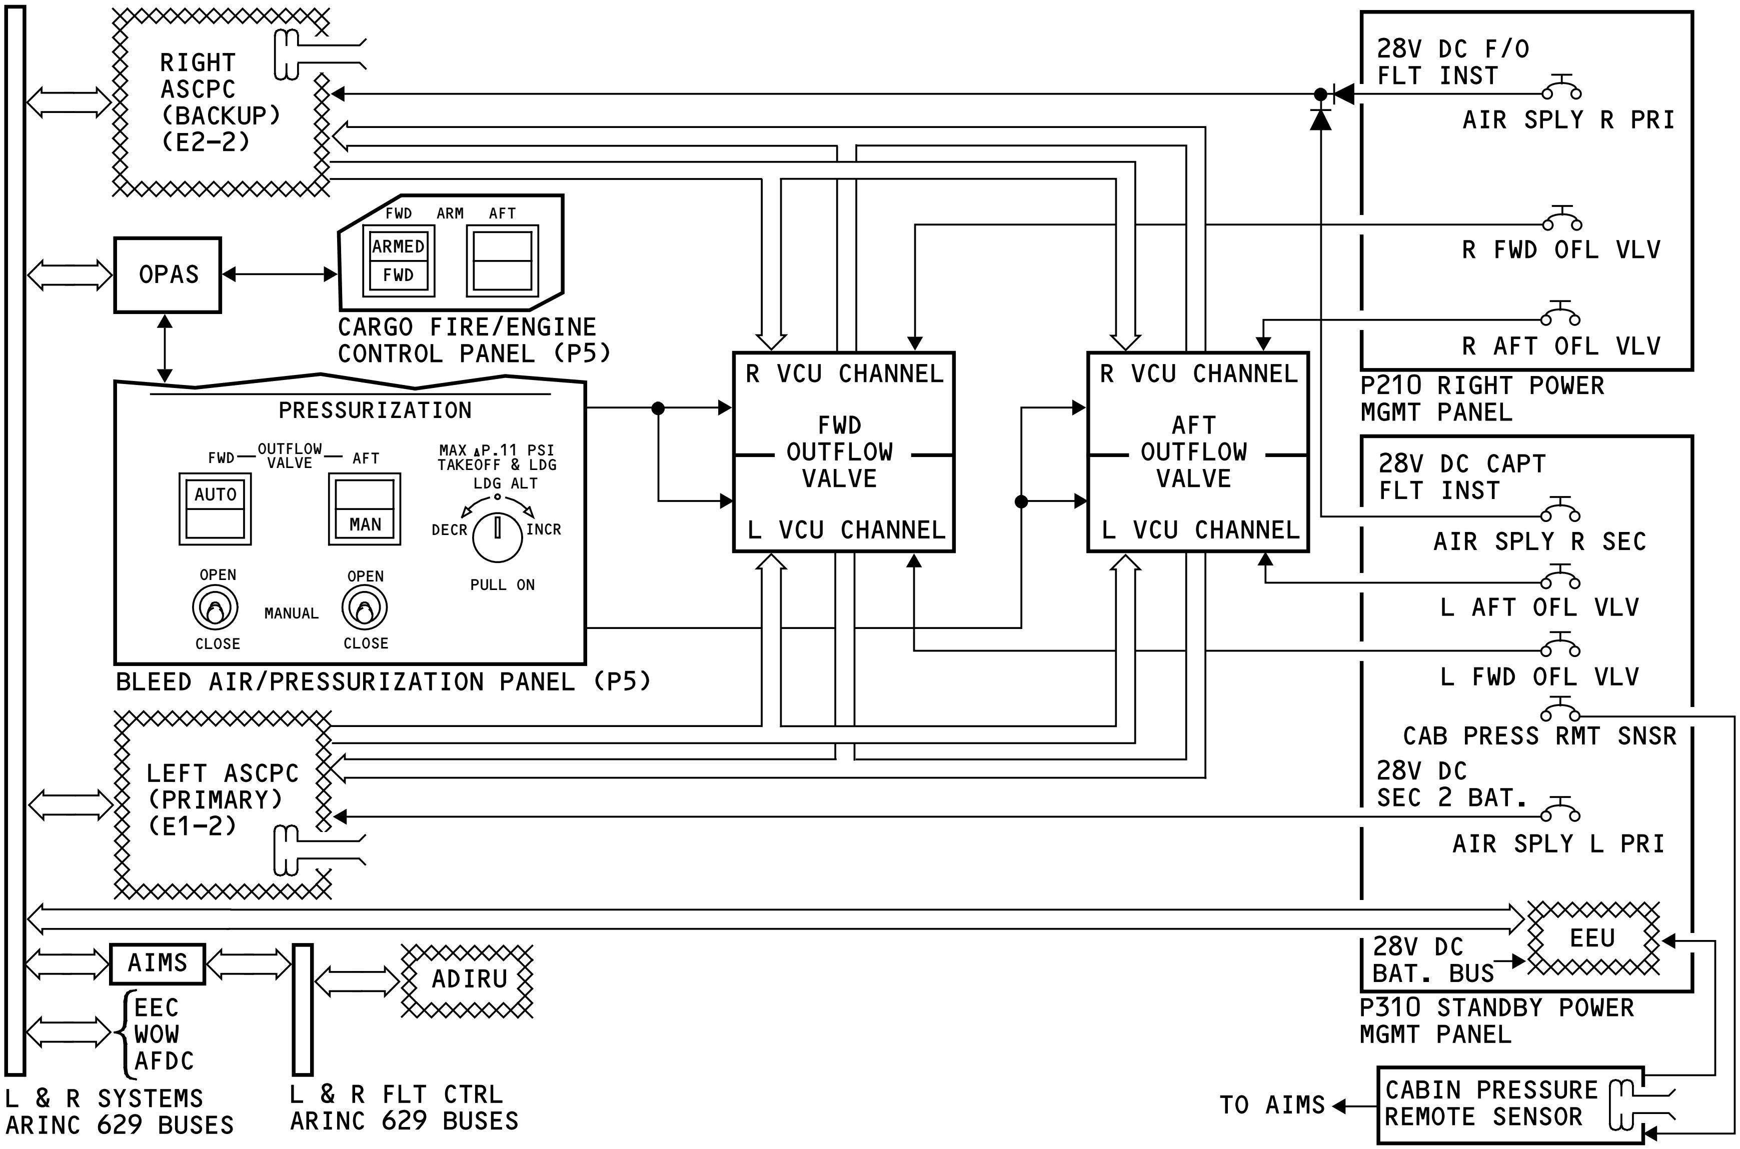
In usual operation, the flight management computing function (FMCF) of the AIMS sends landing altitude data to the ASCPCs. Alternatively, the flight crew manually sets the data with the landing altitude selector on the bleed air/pressurization panel.

Manual Mode

When an outflow valve switch is in the MAN position, the ASCPC releases control of that outflow valve. The outflow valve manual switch sends open or close signals to the left and right channels of the VCU. The VCU opens or closes the outflow valve at a fixed speed. In the manual mode the valve can open or close fully in approximately 27 seconds.

Training Information Point

You can use the MAT to do a ground test of the cabin pressure control system. The ground test is the same as the preflight BIT.



AIR CONDITIONING - CABIN PRESSURE CONTROL SYSTEM - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

AIR CONDITIONING - CABIN PRESSURE CONTROL SYSTEM - FLIGHT PROFILE

General

The air supply and cabin pressure controllers (ASCPCs) use data from the flight management computing function (FMCF) of AIMS to control cabin pressure. These are the FMCF modes that the ASCPCs use:

- Ground mode/takeoff
- Climb
- Cruise
- Descent
- Landing/ground mode.

Ground Mode/Takeoff

When the ground mode is on, the ASCPC sets the outflow valves to fully open. This makes sure the airplane does not pressurize on the ground.

When the ground mode is on more than one minute, both ASCPCs do a preflight BIT. This test does a test of the operation of the ASCPCs and the outflow valve. The test takes approximately 90 seconds.

When the engine N1 speed is more than 60%, and the airplane speed is above 25 knots and increasing, the ASCPC moves the outflow valves to a more closed position. This pre-pressurizes the airplane to 0.1 psi above takeoff field pressure, approximately 189 feet (58 meters) below the takeoff field. The valves continue to close as the airplane speed increases. This keeps cabin pressure surges due to the force of ram air at a minimum as the airplane rotates.

Climb

The ASCPC enables the climb mode when any of these conditions occur:

- The takeoff mode is enabled and the airplane goes from the ground to the air
- The airplane climbs more than 1000 feet (305 meters)
- The FMCF shows a climb mode.

During climb, the ASCPC has these functions:

- Calculates and sets the target value for cabin altitude at cruise
- Calculates and sets the cabin rate of climb to a value less than or equal to 500 feet/minute (153 meters/minute)
- Limits the cabin to ambient pressure differential to 8.6 psi
- Limits cabin altitude to 8000 feet (2440 meters) or less
- Adjusts the outflow valves to give a smooth change in cabin pressure.

The climb mode has two ways that it can operate:

- FMC climb mode
- Internal climb mode.

The FMC climb mode is enabled if all of these conditions occur:

- FMC data is correct
- Autopilot is on
- Vertical navigation is on.

When the FMC climb mode is enabled, the ASCPC calculates and sets the target value for cabin altitude based on these inputs:

- The FMCF airplane cruise altitude data
- The FMCF landing field elevation data
- The cabin limits.

The target value is set to 0.1593 psi more that the set landing field pressure if these conditions occur:

- The cabin differential pressure does not go above its limit
- The cabin altitude does not go above its limit.

The 0.1593 psi value makes the cabin altitude approximately 300 feet (92 meters) below the landing field elevation. This helps to prevent cabin pressure surges when the airplane lands.

If the landing field is more than 8000 feet (2440 meters), the target value for cabin altitude is set to 7950 feet (2425 meters). This only occurs if the calculated cabin altitude target value is less than 8.6 psid.

The cabin altitude target value is set to a value that gives a differential pressure of 8.6 psi if the calculated target is more than 8.6 psid.

The internal climb mode is enabled when the FMC climb mode is not enabled. The internal climb mode causes these conditions to occur:

- The cruise altitude is set to 43,100 feet (13,146 meters)
- The target cabin altitude is set to 7950 feet (2425 meters).

If the FMC climb mode is enabled, the ASCPC uses cruise altitude data and the time to the cruise altitude from the FMCF to calculate the necessary climb schedule. The schedule makes sure the cabin reaches the target cabin altitude at the same time the airplane gets to the cruise altitude. The usual climb schedule sets the cabin rate of change to less than 0.266 psi/minute, approximately 500 ft./min (53 m/min).

Cruise

The ASCPC enables the cruise mode if the airplane altitude does not change more than 100 feet (31 meters) for more than three minutes. The ASCPC also enables the cruise mode if the FMCF mode is cruise.

At cruise altitude the ASCPC adjusts the outflow valves to keep the cabin pressure constant at the value calculated for the cabin altitude target.

Descent

The ASCPC enables the descent mode if the airplane descends more than 1000 feet (305 meters) or if the FMCF mode is descent.

During descent, the ASCPC adjusts the outflow valves to give a smooth change in cabin pressure. The descent mode sets the target cabin altitude to a cabin pressure value of 0.1593 psi more than landing field pressure.

For descent, the landing altitude can be equal to the airport that the airplane departed from. It can also be equal to the destination airport. The ASCPC uses the destination airport if any of these conditions occur:

- More than 400 nautical miles from departure airport
- More than halfway to the destination airport
- Two minutes or less before start of FMC planned descent.

The descent mode has two ways that it can operate:

- FMC descent mode
- Internal descent mode.

When the FMC descent mode is enabled, the ASCPC uses landing altitude data from the FMCF to calculate the necessary descent schedule. The descent schedule makes sure the cabin pressure gets to the target for the cabin altitude when the airplane gets to the landing altitude. The usual schedule for the FMC descent mode sets the cabin rate of change to 0.159 psi/minute, approximately 300 ft./min (92 m/min) or less.

If the internal descent mode is enabled, the cabin pressure changes at a maximum rate until one of these conditions occurs:

- The target cabin altitude is reached
- The 8.6 psi cabin differential pressure limit controls cabin pressure.

If the landing field elevation is above the cabin altitude, the cabin rate of changes is 0.266 psi/minute, approximately 500 ft./min (153 m/min). If the landing field elevation is below the cabin altitude, the cabin rate of change is 0.239 psi/minute, approximately 451 ft./min (138 m/min).

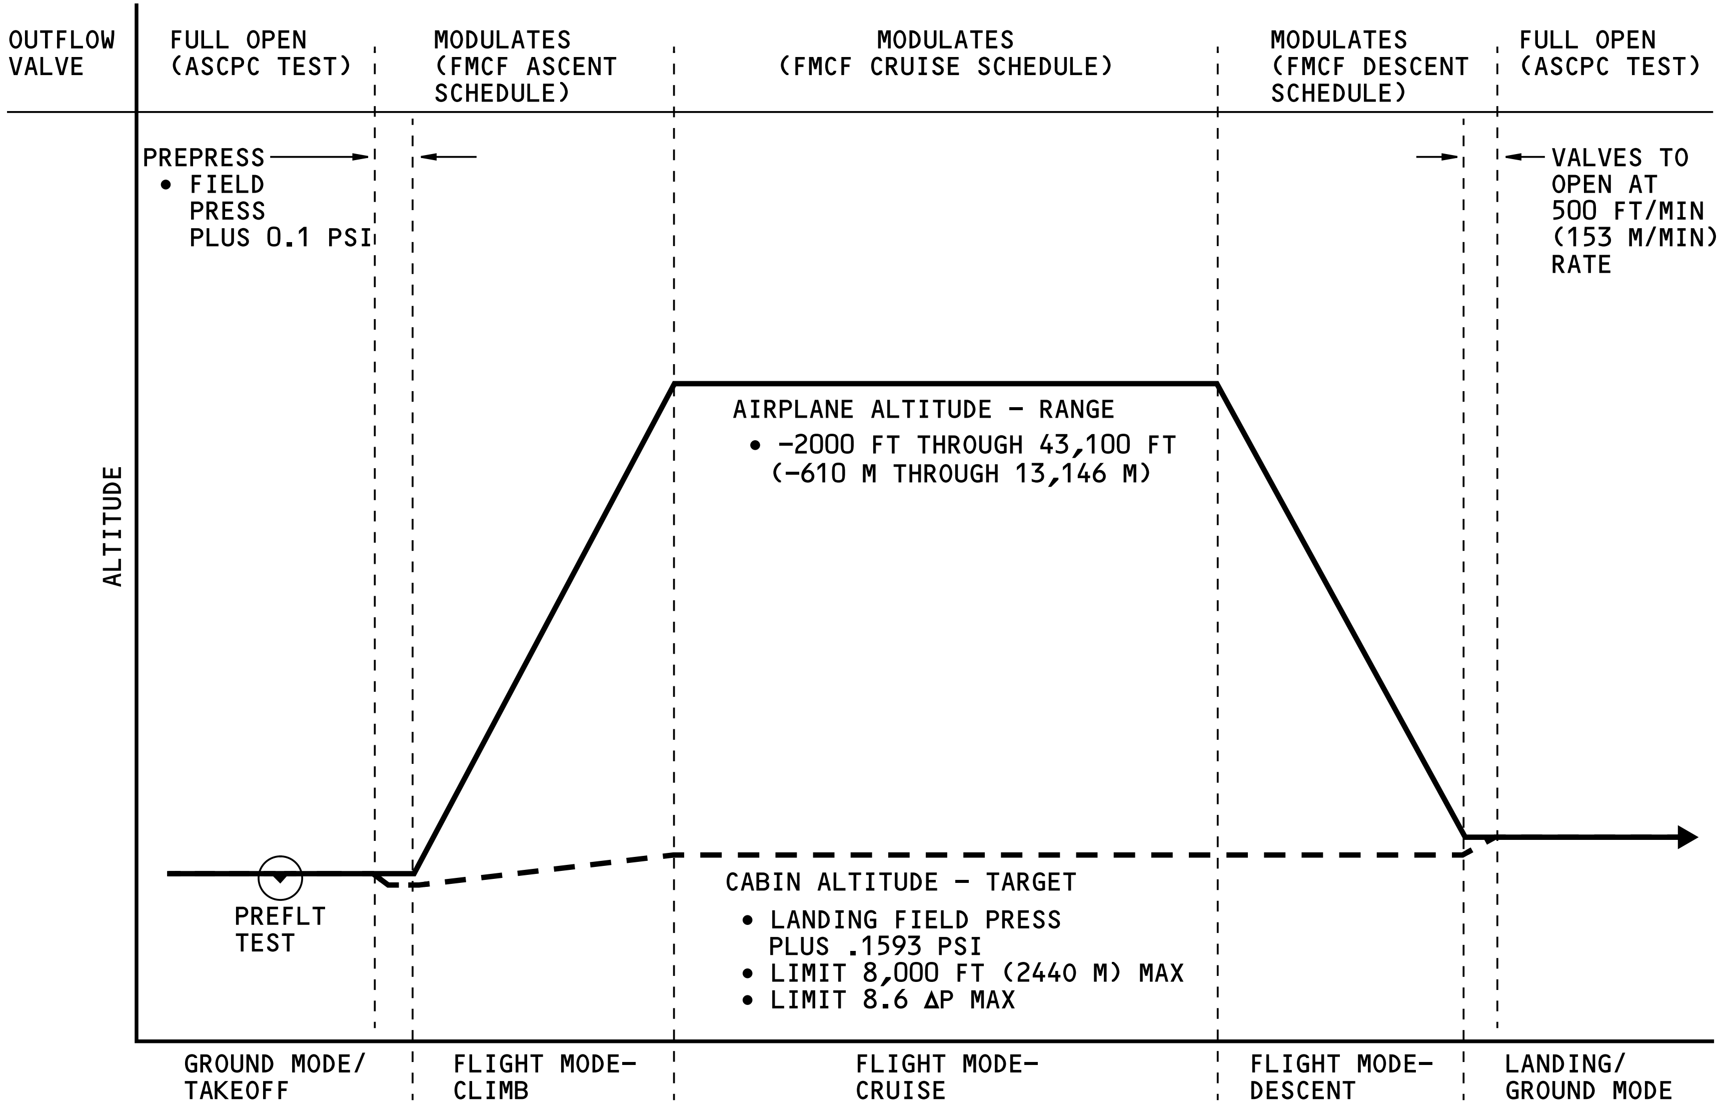
If the landing altitude is more than 8000 feet (2440 meters), the descent schedule lets the cabin altitude go above the usual limit of 8000 feet (2440 meters).

If landing altitude data from the FMCF is incorrect, the flight crew manually sets the landing altitude. If there is no landing altitude data given, 1000 feet (305 meters) is the default value.

Landing/Ground Mode

When the airplane lands, the ASCPC in control puts the outflow valves in the full open position. The valves move at a rate that makes the cabin pressure change 0.2655 psi/minute, approximately 500 ft./min (153 m/

min). If the valves are not full open after 45 seconds, the rate changes to 2000 feet/minute (610 m/min.). One minute after landing, the ASCPCs do a preflight BIT.



21-31-00-007 Rev 2 12/18/1996

AIR CONDITIONING - CABIN PRESSURE CONTROL SYSTEM - FLIGHT PROFILE

AIR CONDITIONING - CABIN PRESSURE RELIEF SYSTEM - INTRODUCTION

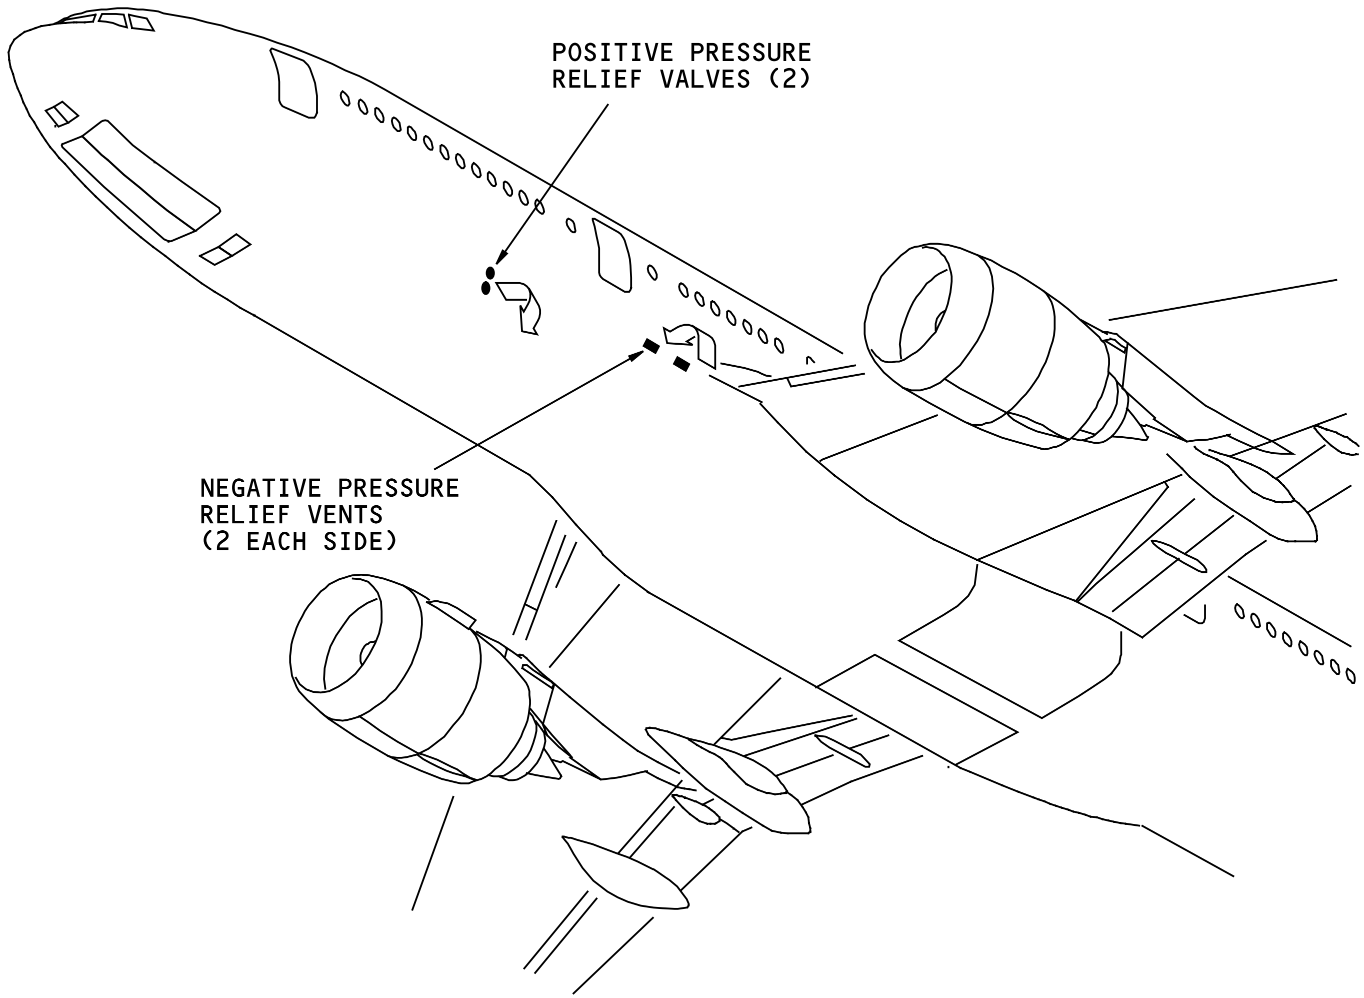
Purpose

The cabin pressure relief system limits the internal pressure of the airplane.

General Description

Two positive pressure relief valves bleed air overboard if the internal pressure increases above a safe limit. This limit is above the normal pressure in the airplane.

Four negative pressure relief vents bleed air into the airplane if ambient pressure is higher than the pressure in the airplane. This can occur during rapid airplane descent.



21-32-00-001 Rev 1

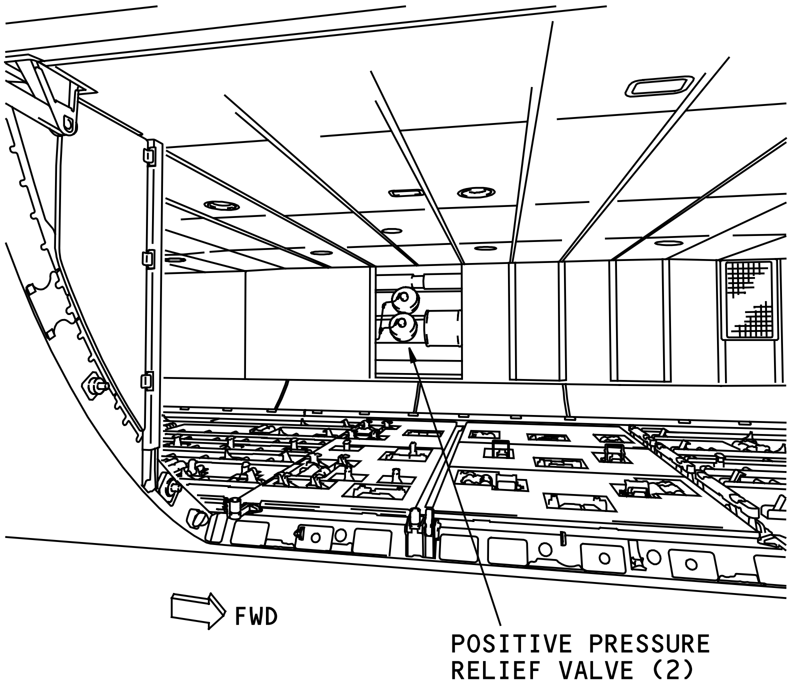
AIR CONDITIONING - CABIN PRESSURE RELIEF SYSTEM - INTRODUCTION

AIR CONDITIONING - CABIN PRESSURE RELIEF SYSTEM - COMPONENT LOCATIONS

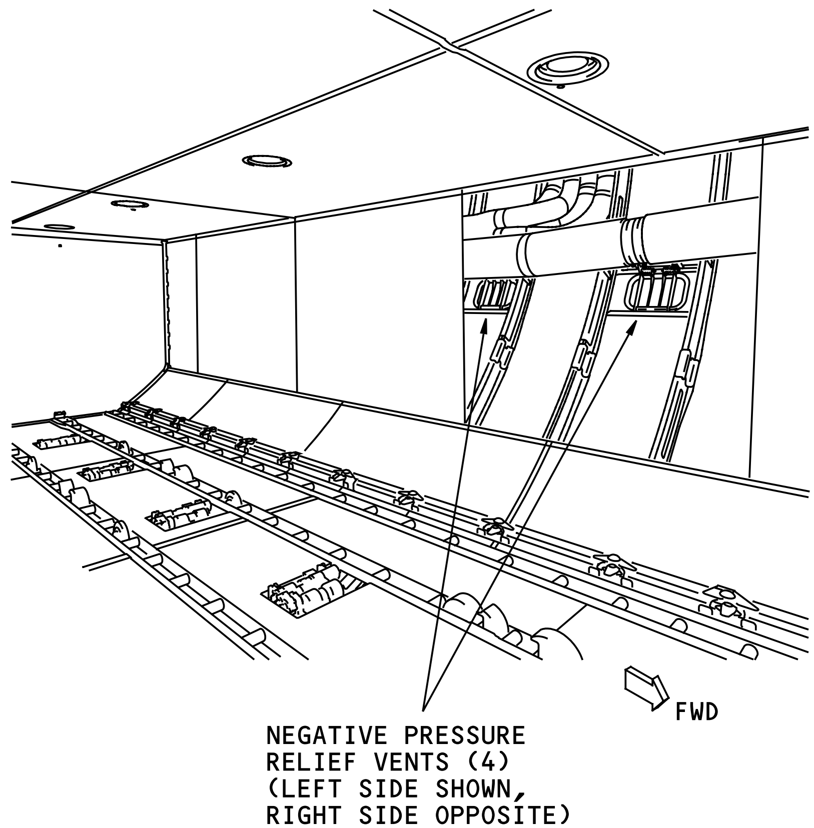
Component Locations

The positive pressure relief valves are adjacent to each other and behind the left sidewall lining of the forward cargo compartment. The valves are opposite the forward cargo door at station 603.

Two negative pressure relief vents are on each side of the airplane. These vents are at stations 815 and 857, behind the sidewall lining of the forward cargo compartment.



FORWARD CARGO COMPARTMENT
(LOOKING THROUGH FWD CARGO DOOR)



FORWARD CARGO COMPARTMENT
(LEFT SIDE LOOKING AFT)

21-32-00-002 Rev 1

AIR CONDITIONING - CABIN PRESSURE RELIEF SYSTEM - COMPONENT LOCATIONS

AIR CONDITIONING - CABIN PRESSURE RELIEF SYSTEM - POSITIVE PRESS RELIEF VALVE AND FILTER

Purpose

The positive pressure relief valve opens when cabin air pressure is higher than ambient pressure by a set value. This permits air to go out of the airplane to keep differential pressure below a safe limit.

Physical Description

The positive pressure relief valve is a mechanical device. It has an air filter and two ambient pressure sense connections. The air filter supplies cabin pressure to the valve. The ambient pressure connections supply ambient pressure to the valve.

An integral ambient sense port (not shown) is in the base of the valve. A remote ambient sense port is in the side of fuselage aft of the pressure relief valves. Tubing connects the sense ports to the valve.

Functional Description

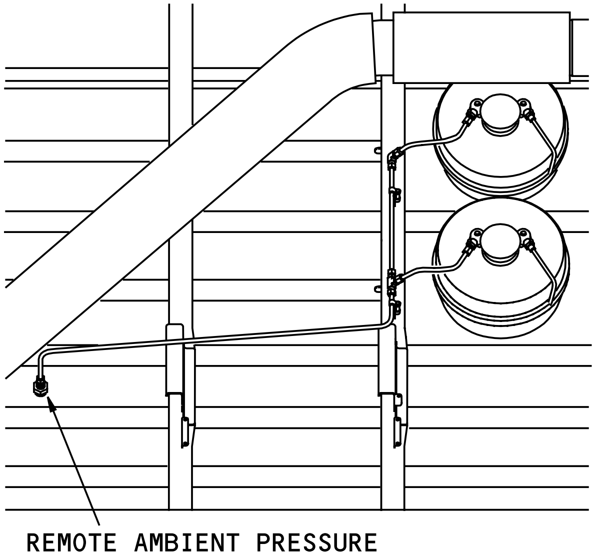
When cabin pressure differential at the remote ambient pressure sense port increases to 8.95 psi, the relief valve opens. This permits air to go out of the airplane. If the remote pressure sense port does not function, the relief valve opens when cabin pressure differential at the integral ambient sense port increases to 9.42 psi.

When cabin pressure differential goes below the limit, the positive pressure relief valve closes.

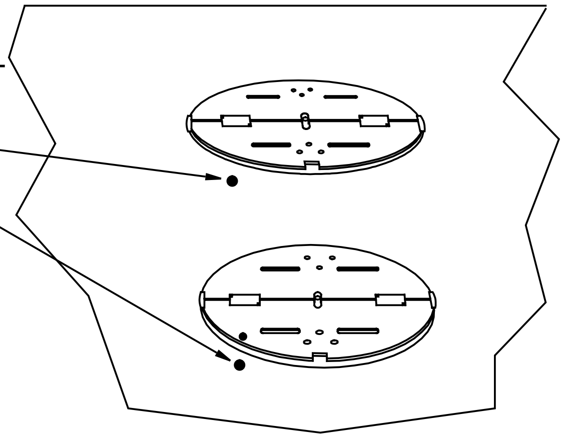
If the positive pressure relief valve opens, small doors open on the outer surface of the valve. This shows a brightly colored edge on the valve doors. These doors stay open when the valve closes. The maintenance technician must close these doors manually.

Training Information Point

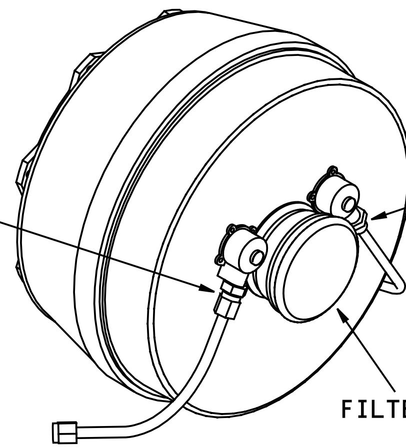
You can replace the air filter.



POSITIVE PRESSURE RELIEF VALVES
(INTERNAL VIEW)



POSITIVE PRESSURE RELIEF VALVES
TRIPPED OPEN
(EXTERNAL VIEW LOOKING UP)



POSITIVE PRESSURE RELIEF VALVE

21-32-00-003 Rev 1

AIR CONDITIONING - CABIN PRESSURE RELIEF SYSTEM - POSITIVE PRESS RELIEF VALVE AND FILTER

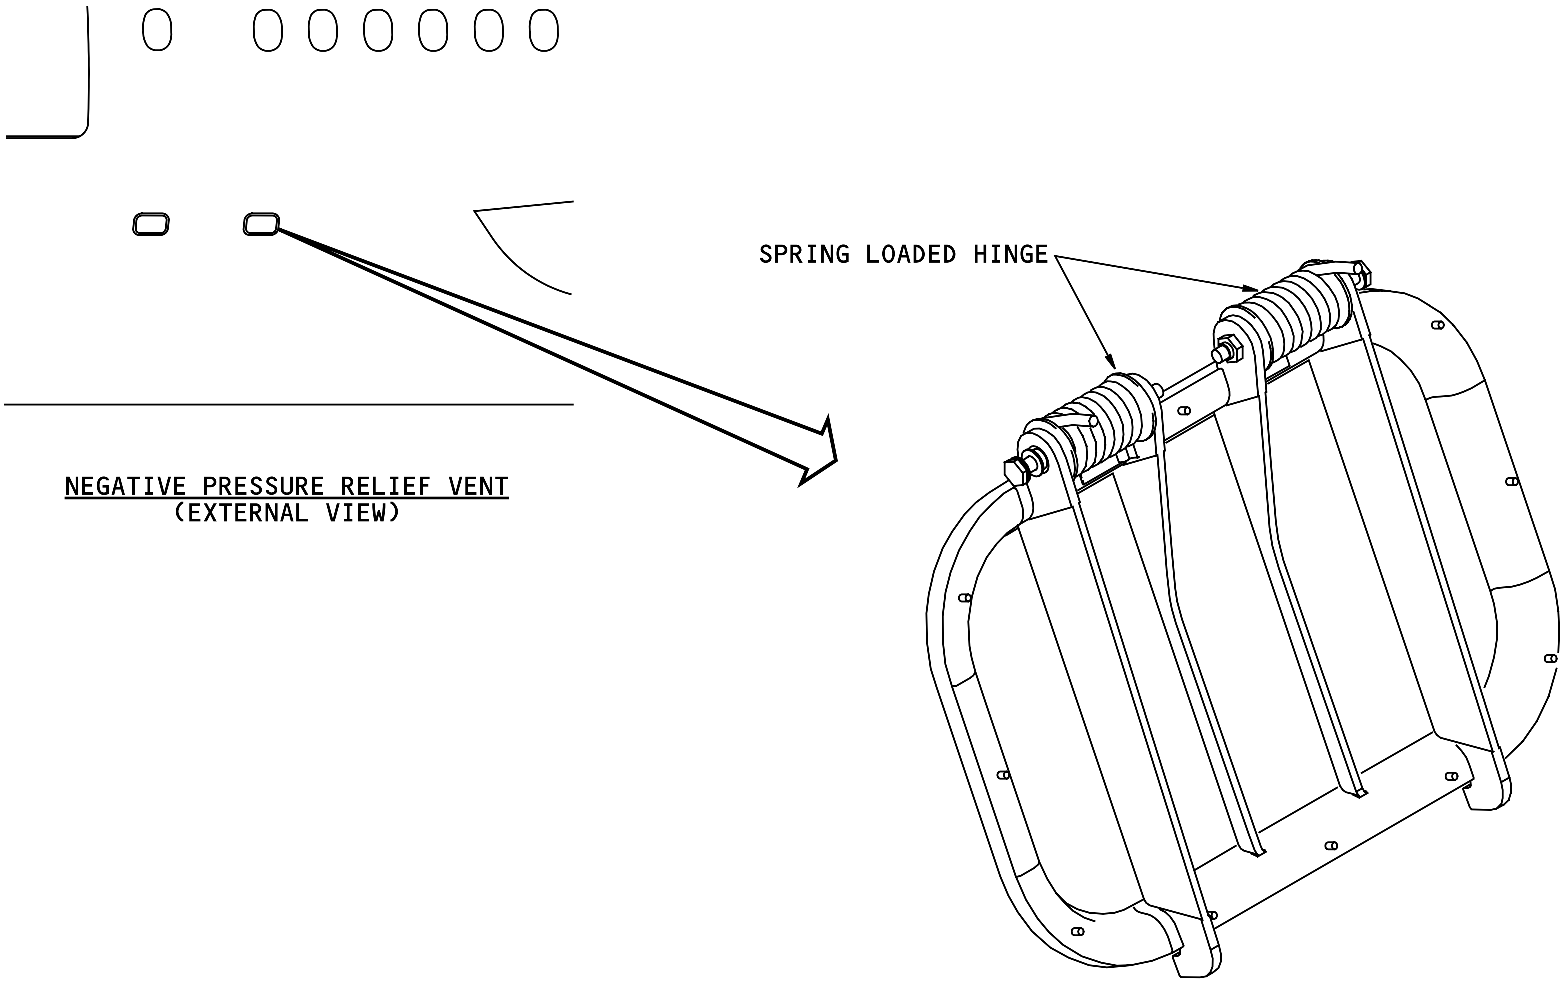
AIR CONDITIONING - CABIN PRESSURE RELIEF SYSTEM - NEGATIVE PRESS RELIEF VENT

Purpose

The negative pressure relief vent opens when cabin pressure is less than ambient pressure. This prevents negative cabin pressure. Too much negative cabin pressure could damage the fuselage structure.

Physical Description

The negative pressure relief vent is a spring-loaded door. The door starts to open at a differential pressure of 0.2 psi. It is full open at a differential pressure of 0.5 psi.



NEGATIVE PRESSURE RELIEF VENT
(EXTERNAL VIEW)

NEGATIVE PRESSURE RELIEF VENT
(INTERNAL VIEW)

21-32-00-004 Rev 1

AIR CONDITIONING - CABIN PRESSURE RELIEF SYSTEM - NEGATIVE PRESS RELIEF VENT

ECS Data Block

This pressurization information shows in the ECS (environmental control system) data block on the EICAS display:

- Duct pressure
- Cabin altitude (CAB ALT)
- Rate in feet per minute
- Forward and aft outflow valve position
- Landing altitude (LDG ALT)
- Indication of landing altitude from AIMS (AUTO) or from bleed air/pressurization panel (MAN).
- Cabin differential pressure (ΔP)

The ECS data block shows for these conditions:

- Duct pressure less than 11 psi with the related engine running
- Cabin altitude exceedance
- Selection of manual outflow valve operation
- Manual input of landing altitude
- Differential pressure exceedance
- Display of a related alert message
- Selection of the air synoptic display.

The ECS data block goes away after the condition which caused it goes away.

Duct pressure shows these colors for these conditions:

- White when duct pressure is 11 psi or more
- Amber if duct pressure is less than 11 psi.

Cabin altitude shows these colors for these conditions:

- White for a cabin altitude of 8500 feet or lower
- Amber if cabin altitude is higher than 8500 feet
- Red if the cabin altitude warning message shows.

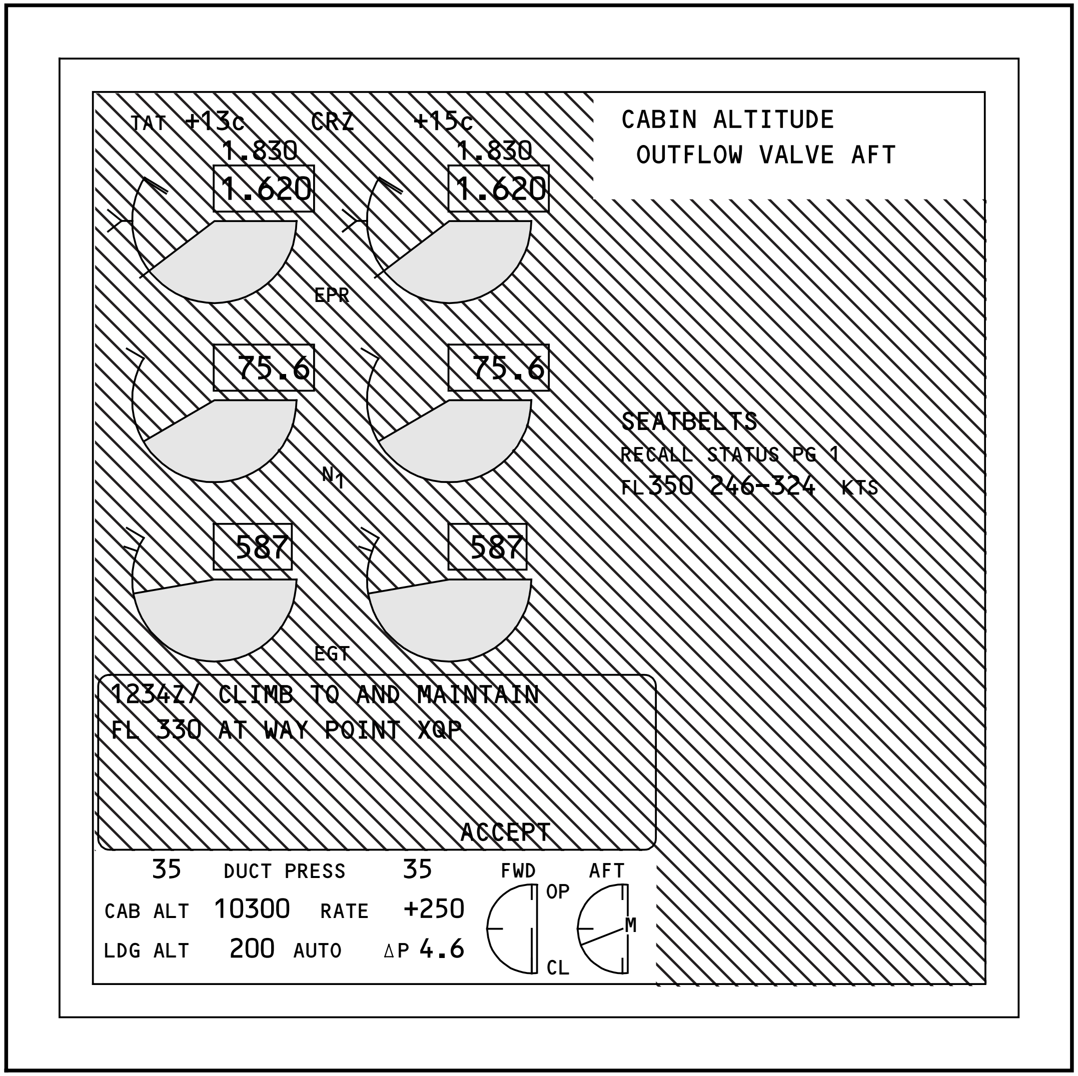
Differential pressure shows these colors for these conditions:

- White when ΔP is 8.95 psi or less
- Amber if ΔP is more than 8.95 PSI
- Red if ΔP is more than 9.42 PSI.

Cabin Altitude Warning Message

A warning message shows if cabin altitude is higher than a safe limit. The cabin altitude at which the warning message shows is related to the selected landing altitude:

- If the landing altitude is 9,650 feet or lower, then the warning message shows at 10,000 feet
- If the landing altitude is higher than 9,650 feet, then the warning message shows at 14,200 feet
- If the landing altitude data is not valid, then the warning message shows at 15,000 feet.



EICAS DISPLAY

21-30-00-004 Rev 1

AIR CONDITIONING - PRESSURIZATION - INDICATIONS - EICAS DISPLAY

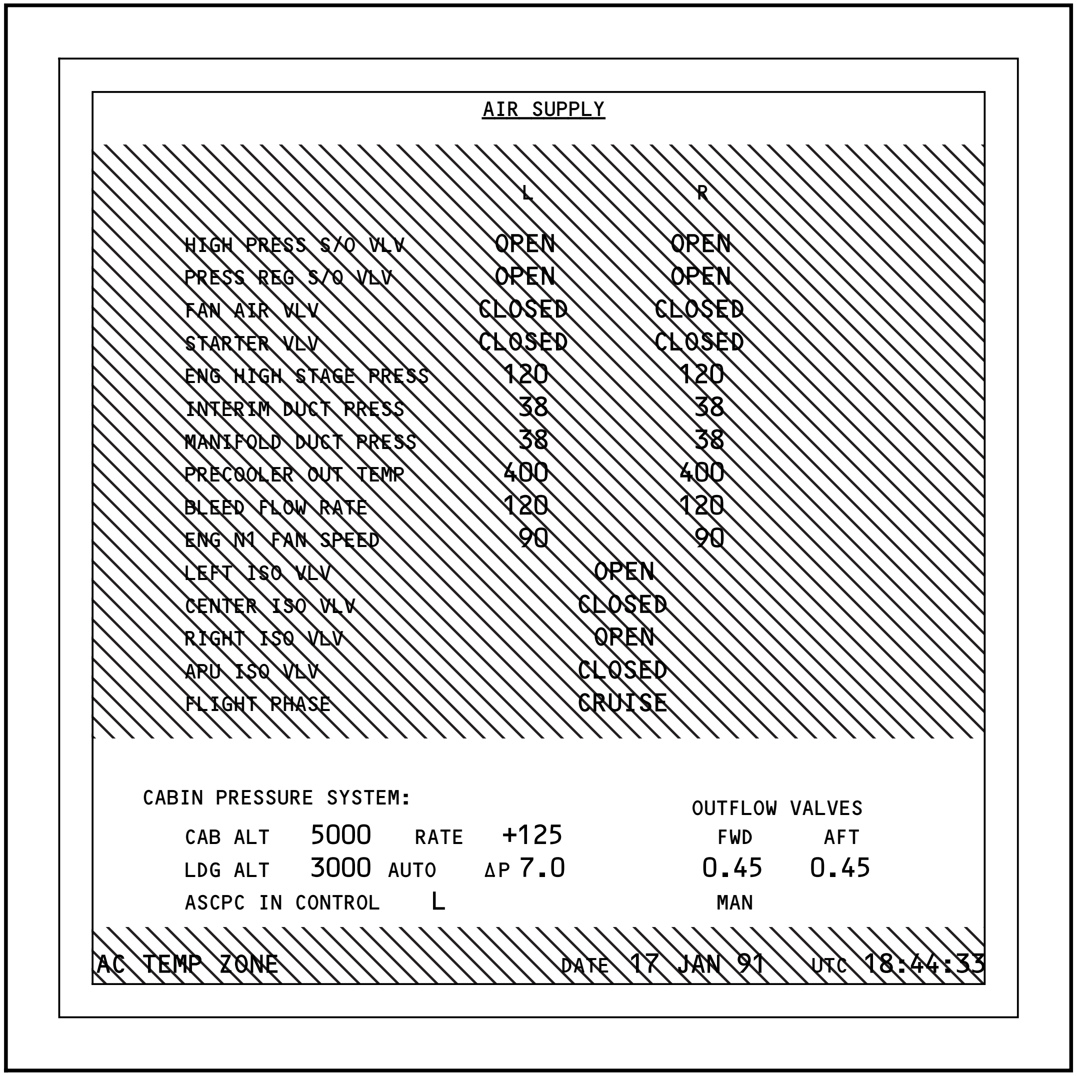
Air Supply Maintenance Page

The air supply maintenance page shows this cabin pressure system information:

- Cabin altitude (CAB ALT)
- Rate in feet per minute
- Landing altitude (LDG ALT)
- Indication of landing altitude from AIMS (AUTO) or from bleed air/pressurization panel (MAN)
- Differential pressure (ΔP)
- Indication of left (L) or right (R) air supply/ cabin pressure controller (ASCPC) in control (message goes away if none are in control).

The air supply maintenance page shows this outflow valve information:

- Forward and aft outflow valve position (0.00 closed, 1.00 fully open)
- Indication of manual (MAN) control of each outflow valve (no indication shows for automatic control).



AIR SUPPLY MAINTENANCE PAGE

21-30-00-005 Rev 1

AIR CONDITIONING - PRESSURIZATION - INDICATIONS - AIR SUPPLY MAINTENANCE PAGE

AIR CONDITIONING - PRESSURIZATION - SYSTEM TESTS

General

These are the pressurization system tests that show when you select ATA 21 Cabin Pressure Control System:

- Left cabin pressure control system
- Right cabin pressure control system.

Left and Right Cabin Pressure Control System

These tests make sure that these LRUs operate correctly:

- Cabin pressure control function of the related ASCPC
- Forward outflow valve
- Aft outflow valve.

During the test, the outflow valves move. The tests take approximately 1-2 minutes each.

WARNING: MAKE SURE THAT PERSONS ARE CLEAR OF THE FORWARD AND THE AFT OUTFLOW VALVE ASSEMBLIES BEFORE YOU DO THIS TEST. INJURY TO PERSONS CAN OCCUR.

EQUIPMENT AND FURNISHINGS - INTRODUCTION

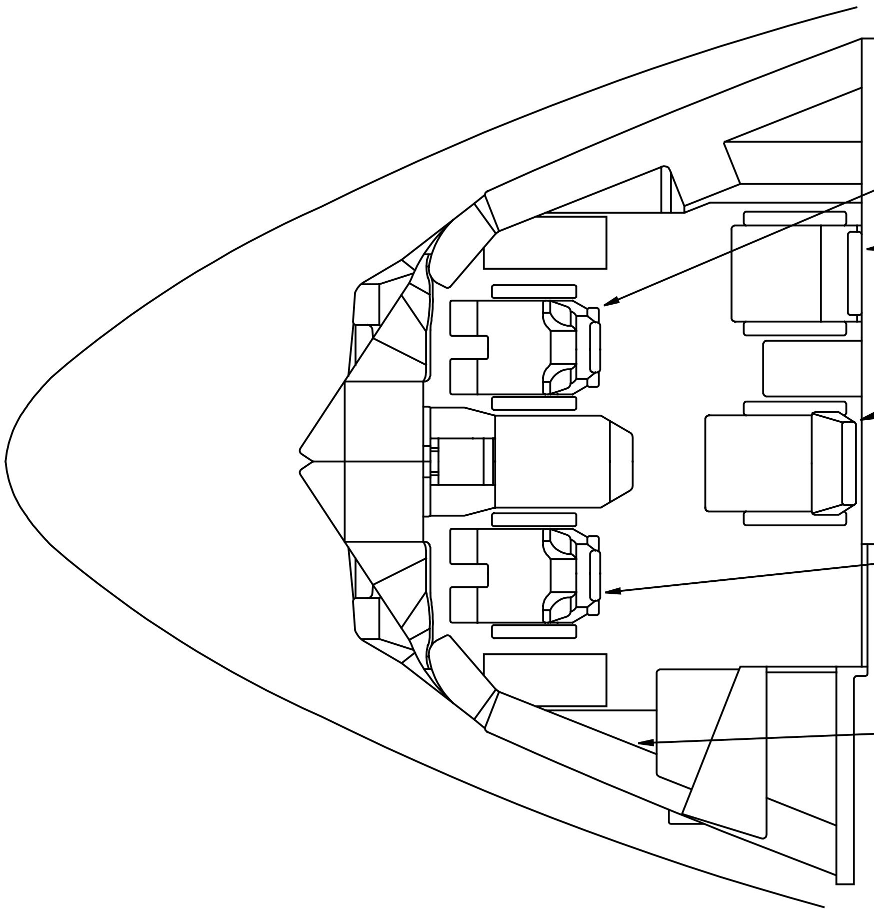
FLIGHT COMPARTMENT - INTRODUCTION

General

The flight compartment equipment and furnishings include these items:

- Captain and first officer seats
- Observer seats
- Flight compartment linings.



FLIGHT COMPARTMENT
(TOP VIEW)

25-10-00-001 Rev 0

FLIGHT COMPARTMENT - INTRODUCTION

FLIGHT COMPARTMENT - CAPTAIN/FIRST OFFICER SEAT - INTRODUCTION

Physical Description

The captain and first officer seats are opposite units. The main controls are on the right side of the pilot seat and the left side of the first officer seat. The seats have these parts:

- Headrest
- Back Cushion
- Seat cushion
- Armrests
- Restraint system
- Support base
- Electric actuator (2).

The height and angle of the headrest is manually adjustable.

The back cushion has a lumbar support with manual adjustment up/down and forward/aft. The angle of the seat back (recline) is also adjustable.

The seat cushion has adjustable thigh pads. The angle of the thigh pads is manually adjustable. The pads fold downward under pressure from rudder or brake application. When you remove the pressure, the pads return to their initial position.

The angle of each armrest is manually adjustable. The armrests lifts to a vertical position for entry and exit.

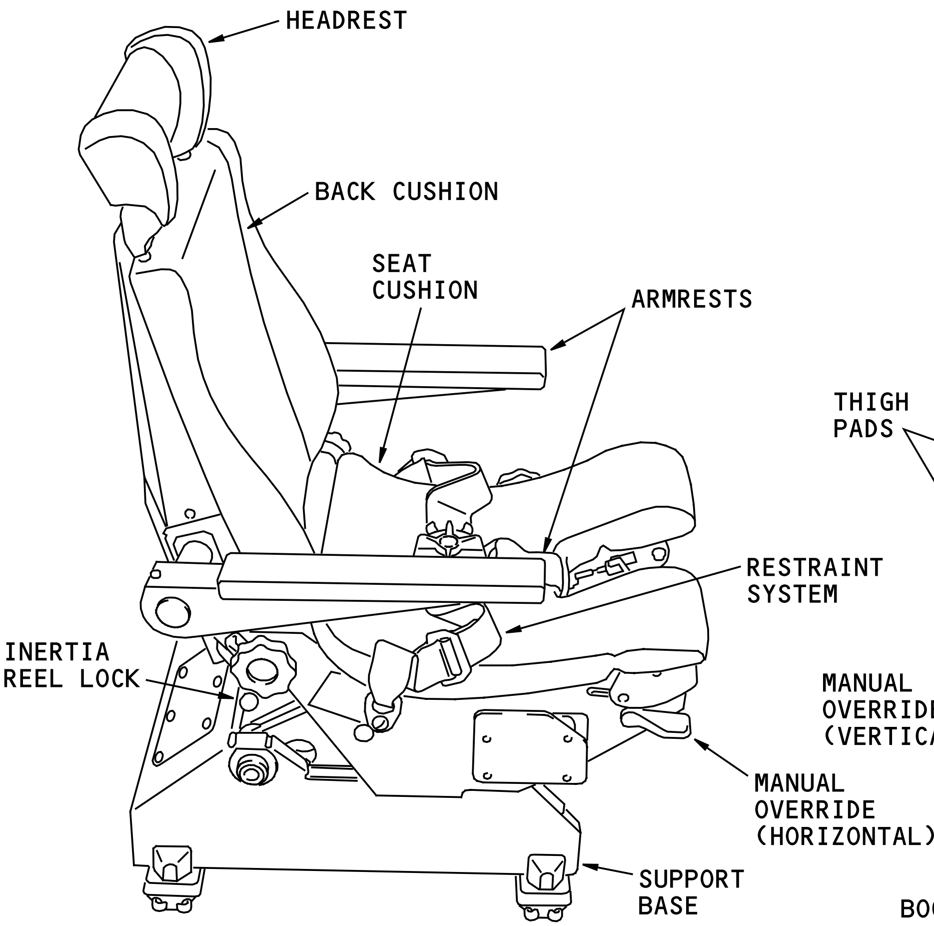
The restraint system has a shoulder harness (not shown), lap belt, and crotch strap. The inertia reel for the shoulder harness has a manual lock.

The support base has bogies which attach the seat to the floor tracks. The shape of the floor tracks give forward/aft adjustment as well as inboard/outboard movement for entry and exit.

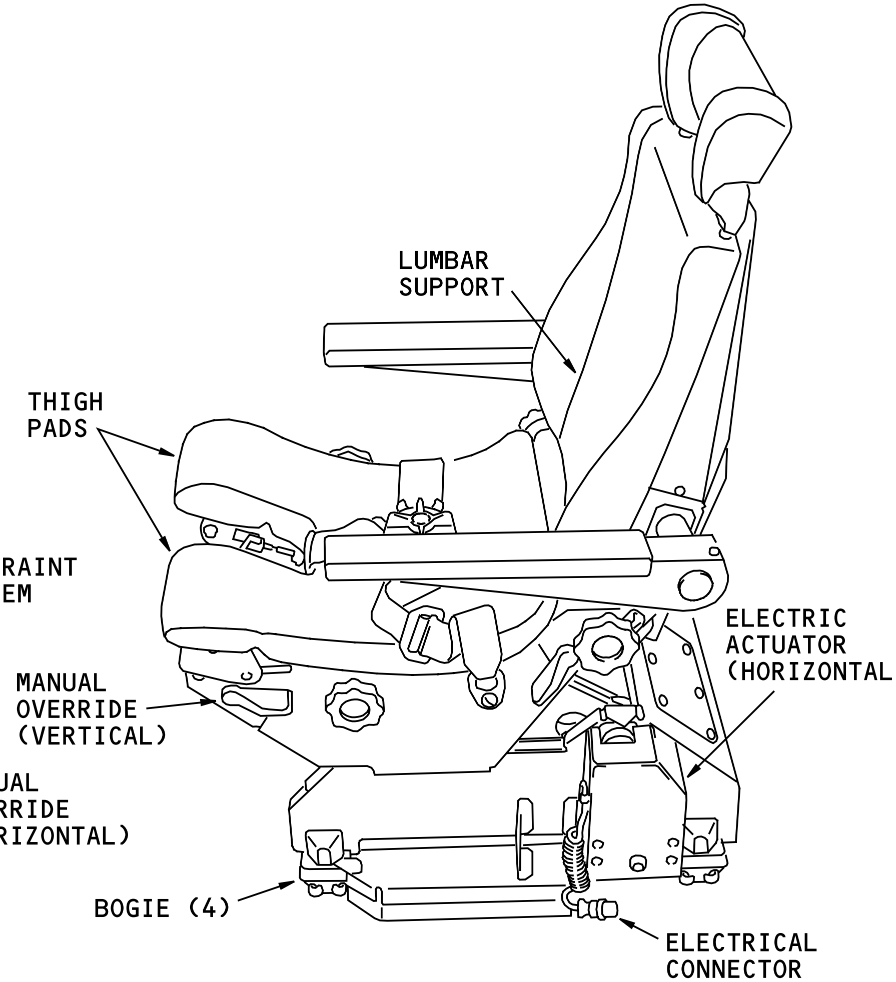
An electric actuator moves the seat horizontally on the seat tracks. The horizontal actuator drives a gear (not shown) which engages a toothed rack on the floor track. The horizontal adjustment has a manual override.

An electric actuator (internal) moves the seat vertically. The vertical adjustment has a manual override.

A coiled cord with an electrical connector connects the seat electrical system to the airplane wiring.



CAPTAIN SEAT - RIGHT SIDE



CAPTAIN SEAT - LEFT SIDE

25-10-00-002 Rev 0

FLIGHT COMPARTMENT - CAPTAIN/FIRST OFFICER SEAT - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

Headrest

Pull up or push down on the headrest to adjust the vertical position. Move the headrest cushion to the right and turn it to adjust the headrest angle. The angle adjustment has eight positions.

Recline

To increase the recline angle, pull up and hold the recline control then push aft on the seat back. Release the control to lock the seat back in the new position.

To decrease the recline angle, pull up and hold the recline control. Let the seat back move toward the upright position. Release the control to lock the seat back in the new position.

Lumbar Support

The back cushion has a built in lumbar support. Turn the left lumbar support control to move the back cushion up or down. Turn the right lumbar support control to move the back cushion forward or aft.

Armrests

Adjustment knobs are under the forward end of the armrests. Turn the knob to move the armrest up or down.

The armrests fold to a vertical position for entry and exit. Lift up on the front of the armrest to fold it up. When the armrest is folded up as far as it will go, you can push it in toward the center of the seat.

Thigh Pads

Turn the thigh pad control to lift or lower the thigh pad.

Horizontal Adjustment

Hold the horizontal control switch in the forward position to move the seat inboard and forward. The seat stops automatically when it is all the way forward. Hold the switch in the aft position to move the seat aft and outboard. The seat stops automatically when it is all the way outboard.

If the power adjustment fails, adjust the horizontal position of the seat manually. Pull up and hold the horizontal movement manual override. This disengages the electric actuator from the track. Move the seat to the desired position. Release the manual override to lock the seat in the new position. Stops on the seat tracks keep the horizontal movement to a limit.

Vertical Adjustment

Hold the vertical control switch in the up position to move the seat up. The seat stops automatically when it is all the way up. Hold the switch in the down position to move the seat down. The seat stops automatically when it is all the way down.

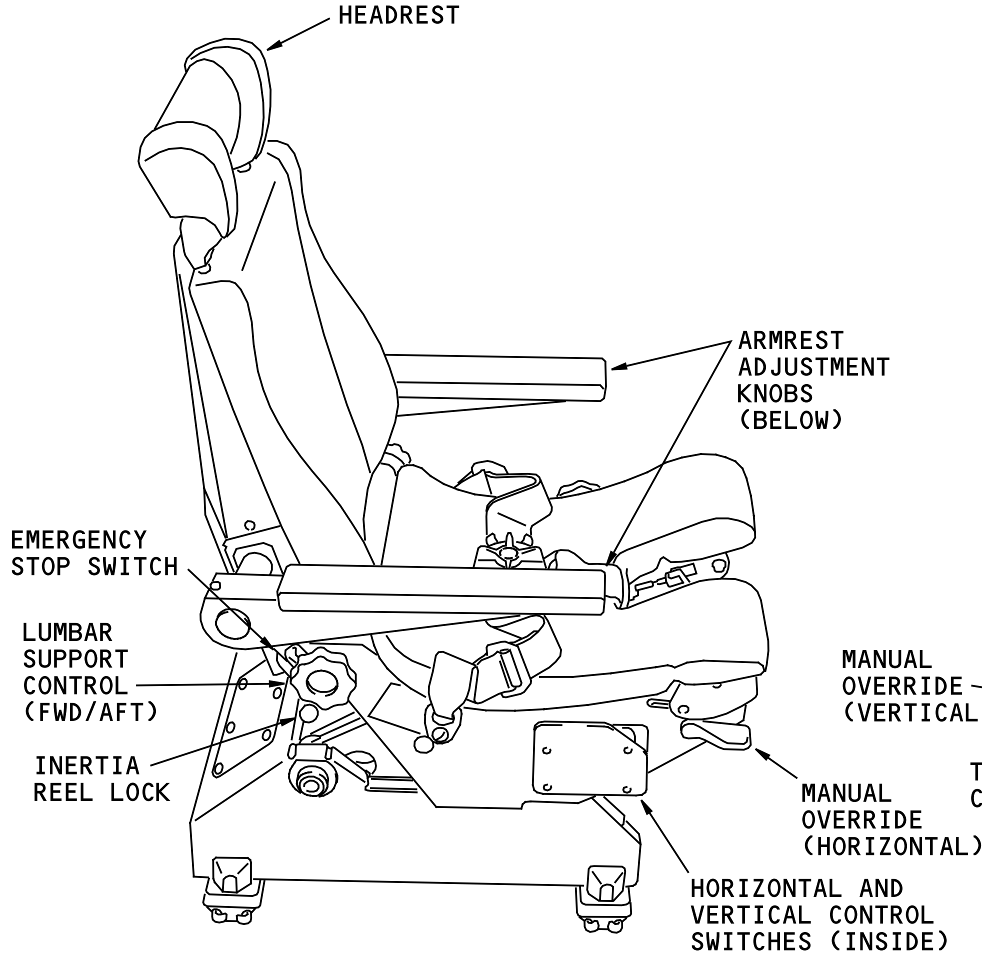
If the power adjustment fails, adjust the vertical position of the seat manually. Move some of your weight off the seat then pull up and hold the vertical movement manual override. This disengages the electric actuator. Move the seat to the desired position. Release the manual override to lock the seat in the new position. Internal stops keep the vertical movement to a limit.

Emergency Stop

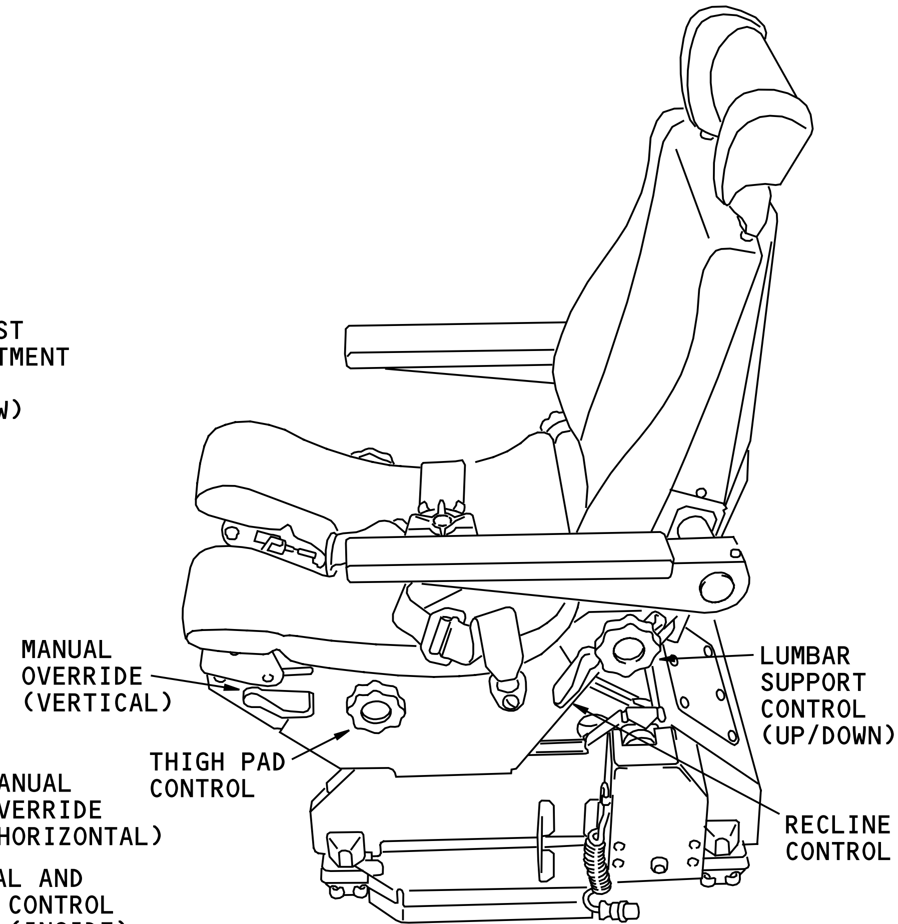
If the seat continues to move when you release an adjustment switch, use the emergency stop switch.

Inertia Reel Lock

The inertia reel lock has positions for lock and unlock.



CAPTAIN SEAT - RIGHT SIDE



CAPTAIN SEAT - LEFT SIDE

25-10-00-003 Rev 0

FLIGHT COMPARTMENT - CAPTAIN/FIRST OFFICER SEAT - OPERATION

FLIGHT COMPARTMENT - CAPTAIN/FIRST OFFICER SEAT - FUNCTIONAL DESCRIPTION

General

The left utility bus supplies 115v ac three phase power to the circuits. The vertical and horizontal control circuits are similar. Phase-switching relays control the direction of the motors. An emergency switch lets you stop the motors if the normal control circuits fail.

The circuits for the captain and first officer seats are similar except for the power source; power for the first officer seat comes from the right utility bus.

Up Operation

Phase C supplies power to the UP/DOWN switch. When you hold the switch in the UP position, power goes through the motor thermal protectors and the emergency switch to the power relay. The relay energizes and supplies three phase power to the up and down relays.

Another set of contacts in the UP/DOWN switch permits power to go through the up limit switch and the down relay to energize the up relay. Three phase power operates the vertical motor to move the seat up. When the seat is up as far as it will go, the up limit switch opens and removes power from the up relay coil. The relay de-energizes and removes power from the motor.

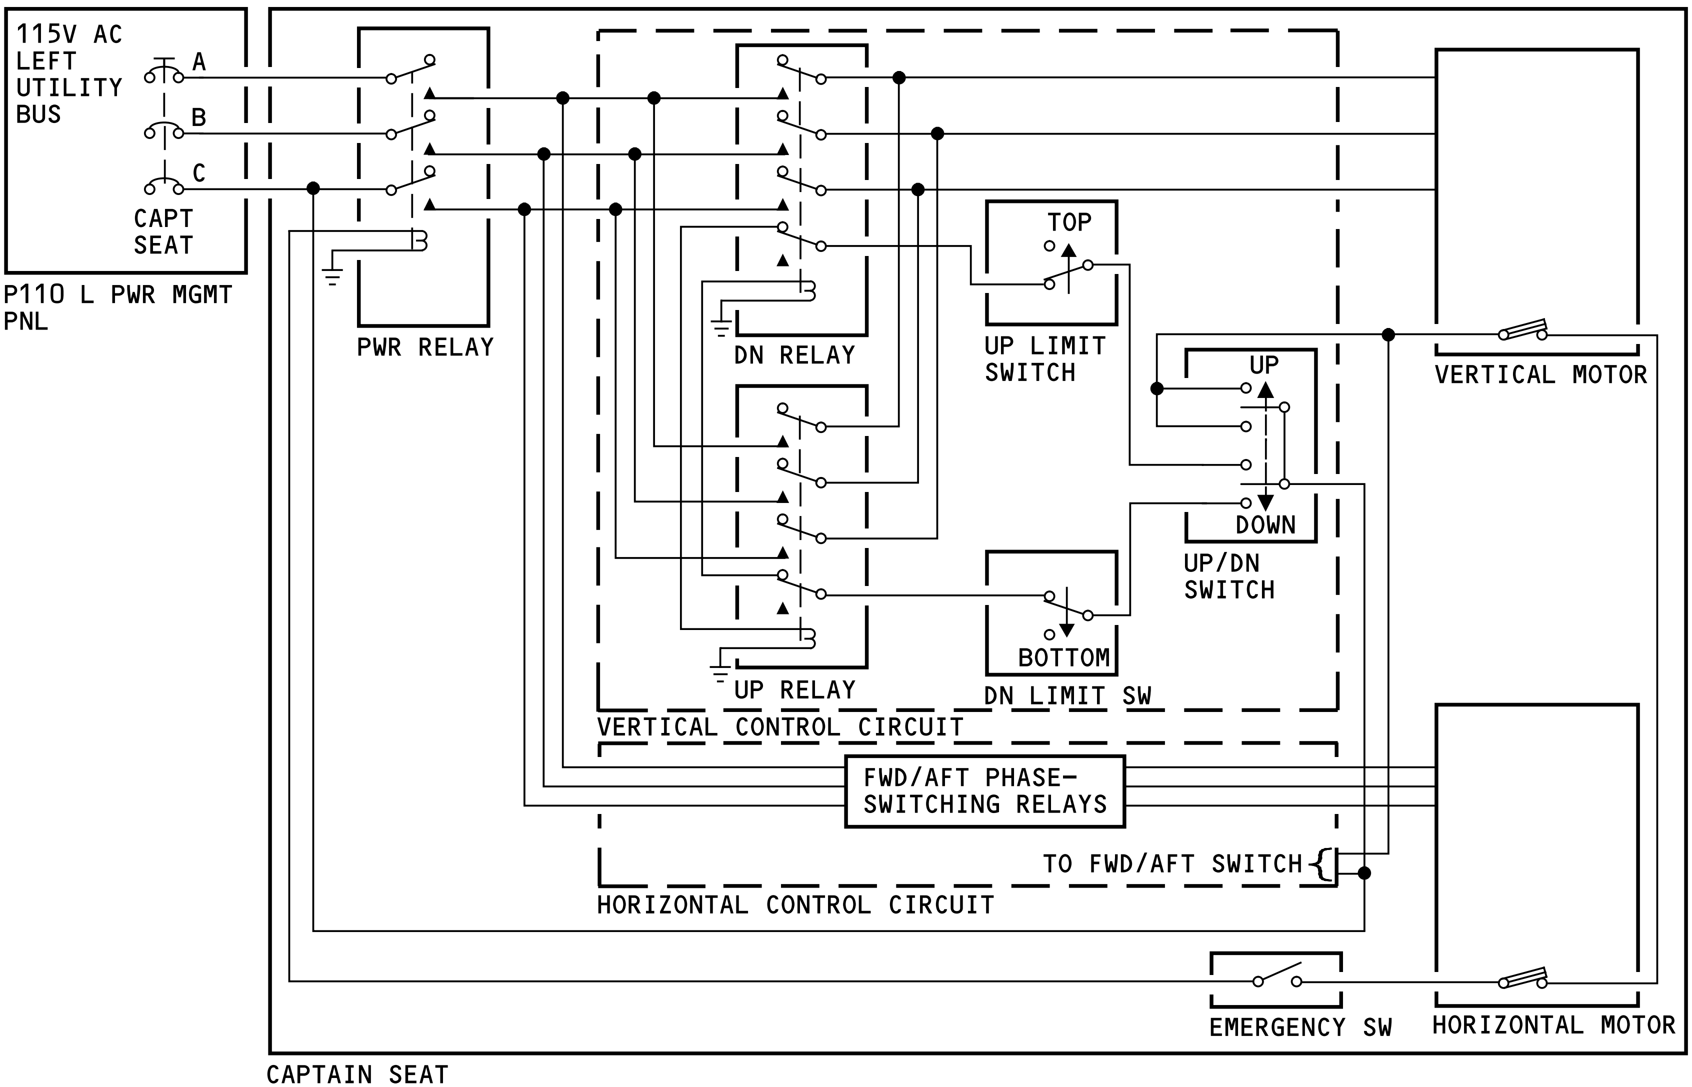
Down Operation

When you hold the switch in the DOWN position, power goes through the motor thermal protectors and the emergency switch to the power relay. The relay energizes and supplies three phase power to the up and down relays.

Another set of contacts in the UP/DOWN switch permits power to go through the down limit switch and the up relay to energize the down relay. Three phase power operates the vertical motor to move the seat down. When the seat is down as far as it will go, the down limit switch opens and removes power from the down relay coil. The relay de-energizes and removes power from the motor.

Horizontal Operation

The horizontal control circuit is similar to the vertical control circuit. A FWD/AFT switch controls the horizontal motor through phase-switching relays and limit switches.



25-10-00-004 Rev 0

FLIGHT COMPARTMENT - CAPTAIN/FIRST OFFICER SEAT - FUNCTIONAL DESCRIPTION

FLIGHT COMPARTMENT - CAPTAIN/FIRST OFFICER SEAT - TRAINING INFORMATION POINTS

Seat Removal

To remove the seat, do these steps:

- Disconnect the electrical connector
- Remove the forward stops from the seat tracks
- Use the horizontal control manual override to disengage the actuator gear from the seat track
- Slide the seat forward off the tracks.

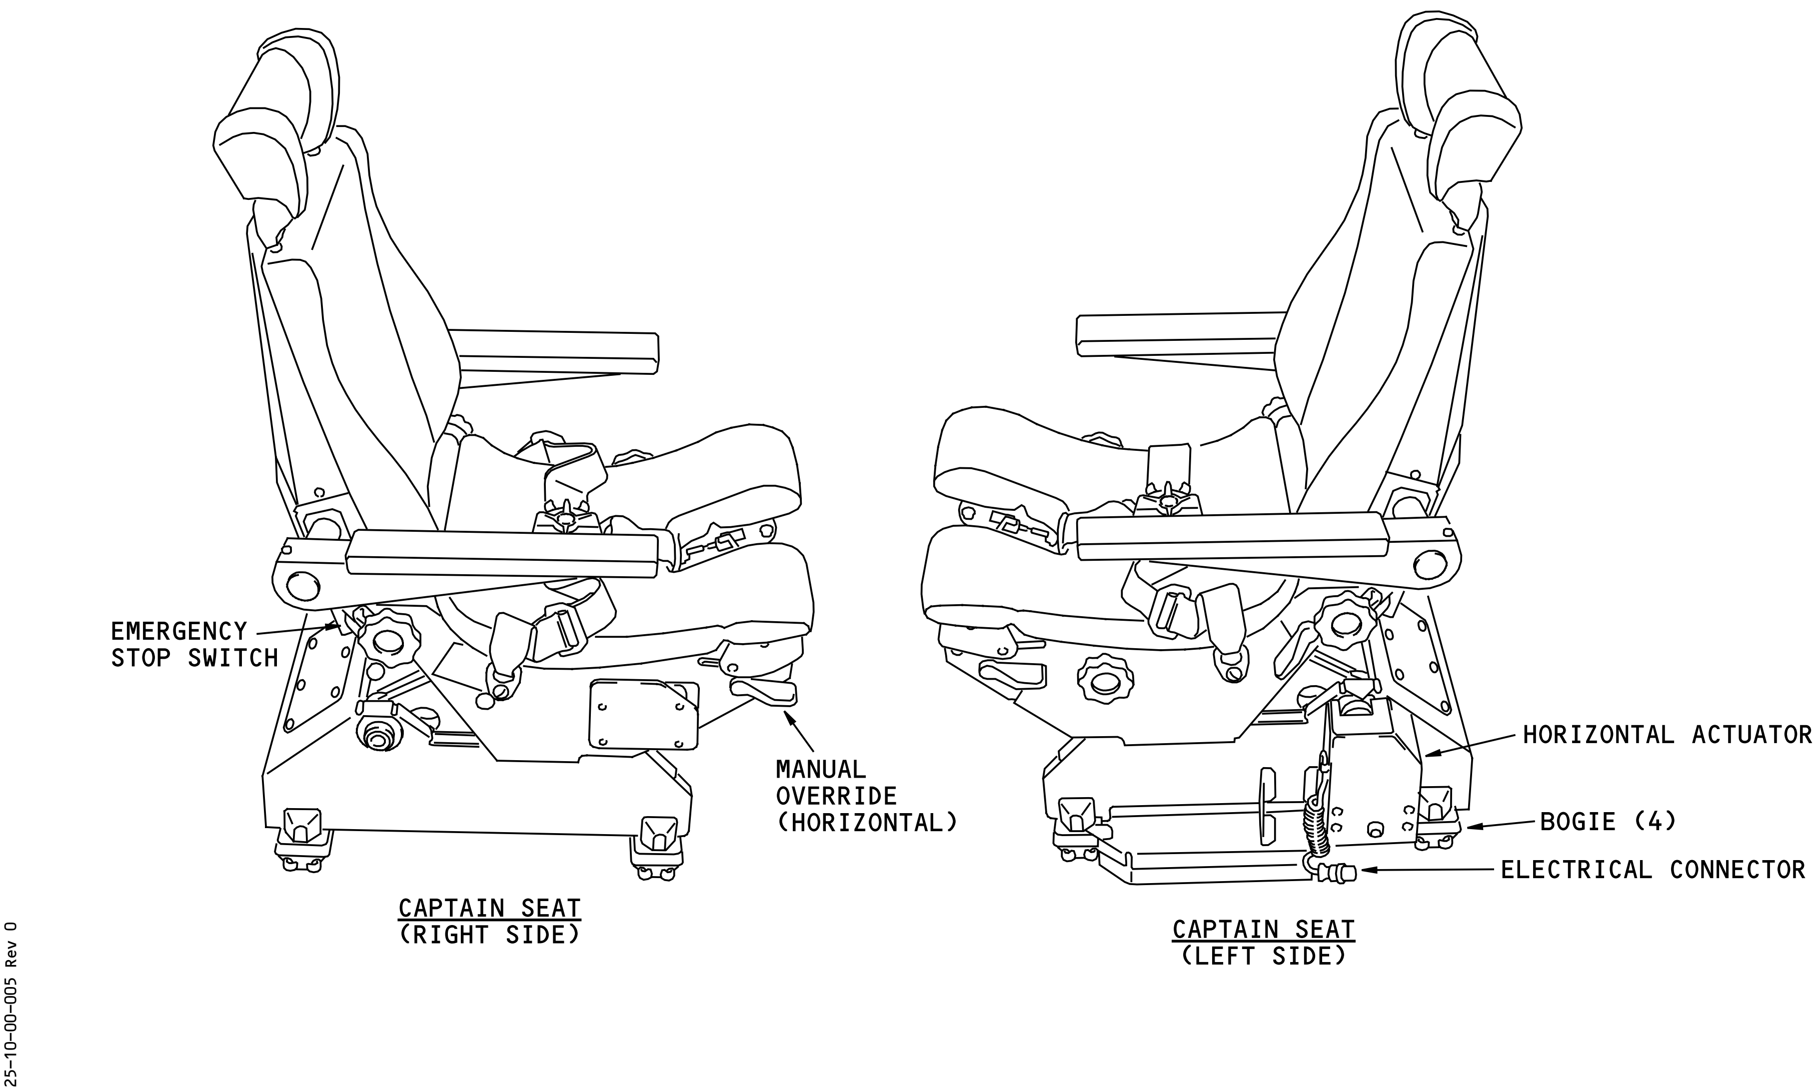
Seat Installation

To install the seat do these steps:

- Put the seat just forward of the seat tracks
- Turn the bogies so the roller with the angled face is inboard
- Align and engage the bogies with the seat tracks as you slide the seat aft
- Roll the seat aft until the actuator gear reaches the rack on the seat track
- Use the horizontal control manual override to raise the gear out of the way
- Turn the gear so it meshes with the rack, then release the manual override control
- Install the seat stops
- Connect the electrical connector.

Power Removal

The emergency stop switch removes power from the horizontal and vertical control circuits, but does not remove power from the seat. Disconnect the electrical connector if you need to remove power from the seat for maintenance.



FLIGHT COMPARTMENT - CAPTAIN/FIRST OFFICER SEAT - TRAINING INFORMATION POINTS

FLIGHT COMPARTMENT - OBSERVER SEATS - OPERATION

General

The second observer seat has no adjustments. To stow the seat, fold the armrests and seat bottom up. Fasten two retaining straps (not shown) to hold the seat bottom up.

The following adjustments are for the first observer seat.

Headrest

Pull up or push down on the headrest to adjust the vertical position. Move the top of the headrest forward or aft to adjust the headrest angle.

Recline

Pull back and hold the recline control to unlock the seat. Push aft on the seat back to increase the recline angle. Release the control to lock the seat back in the new position. To decrease the recline angle, pull back and hold the recline control. Let the seat back move toward the upright position. Release the control to lock the seat back in the new position.

Lumbar Support

Turn the upper lumbar support control to move the support up or down. Turn the lower lumbar support control to move the support forward or aft.

Armrests

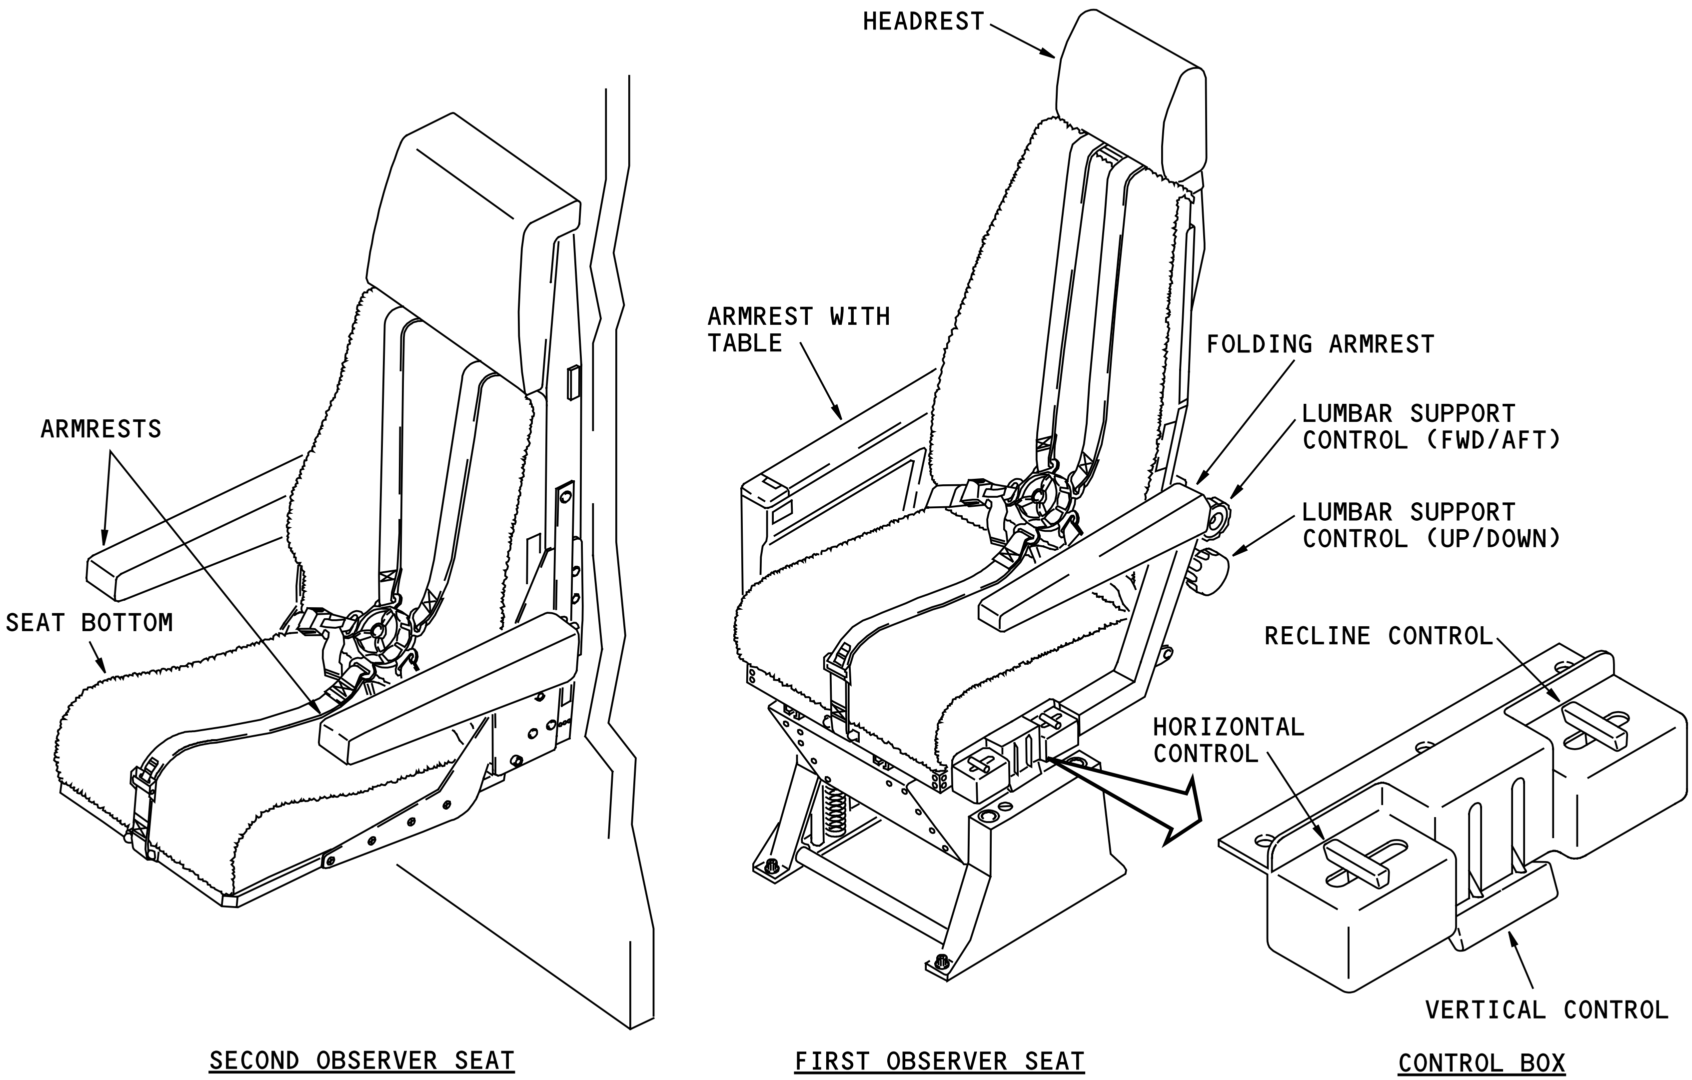
The left armrest folds to a vertical position for entry and exit. Lift up on the front of the armrest to fold it up. The right armrest contains a folding table. Open the top of the armrest, lift and unfold the table.

Horizontal

Pull back and hold the horizontal control to unlock the seat. Move the seat forward or aft. Release the control to lock the seat in the new position.

Vertical

Move some of your weight off the seat then pull up and hold the vertical control. Spring pressure pushes up on the seat. Move the seat up or down to the desired position. Release the control to lock the seat in the new position.



25-10-00-007 Rev 0

FLIGHT COMPARTMENT - OBSERVER SEATS - OPERATION

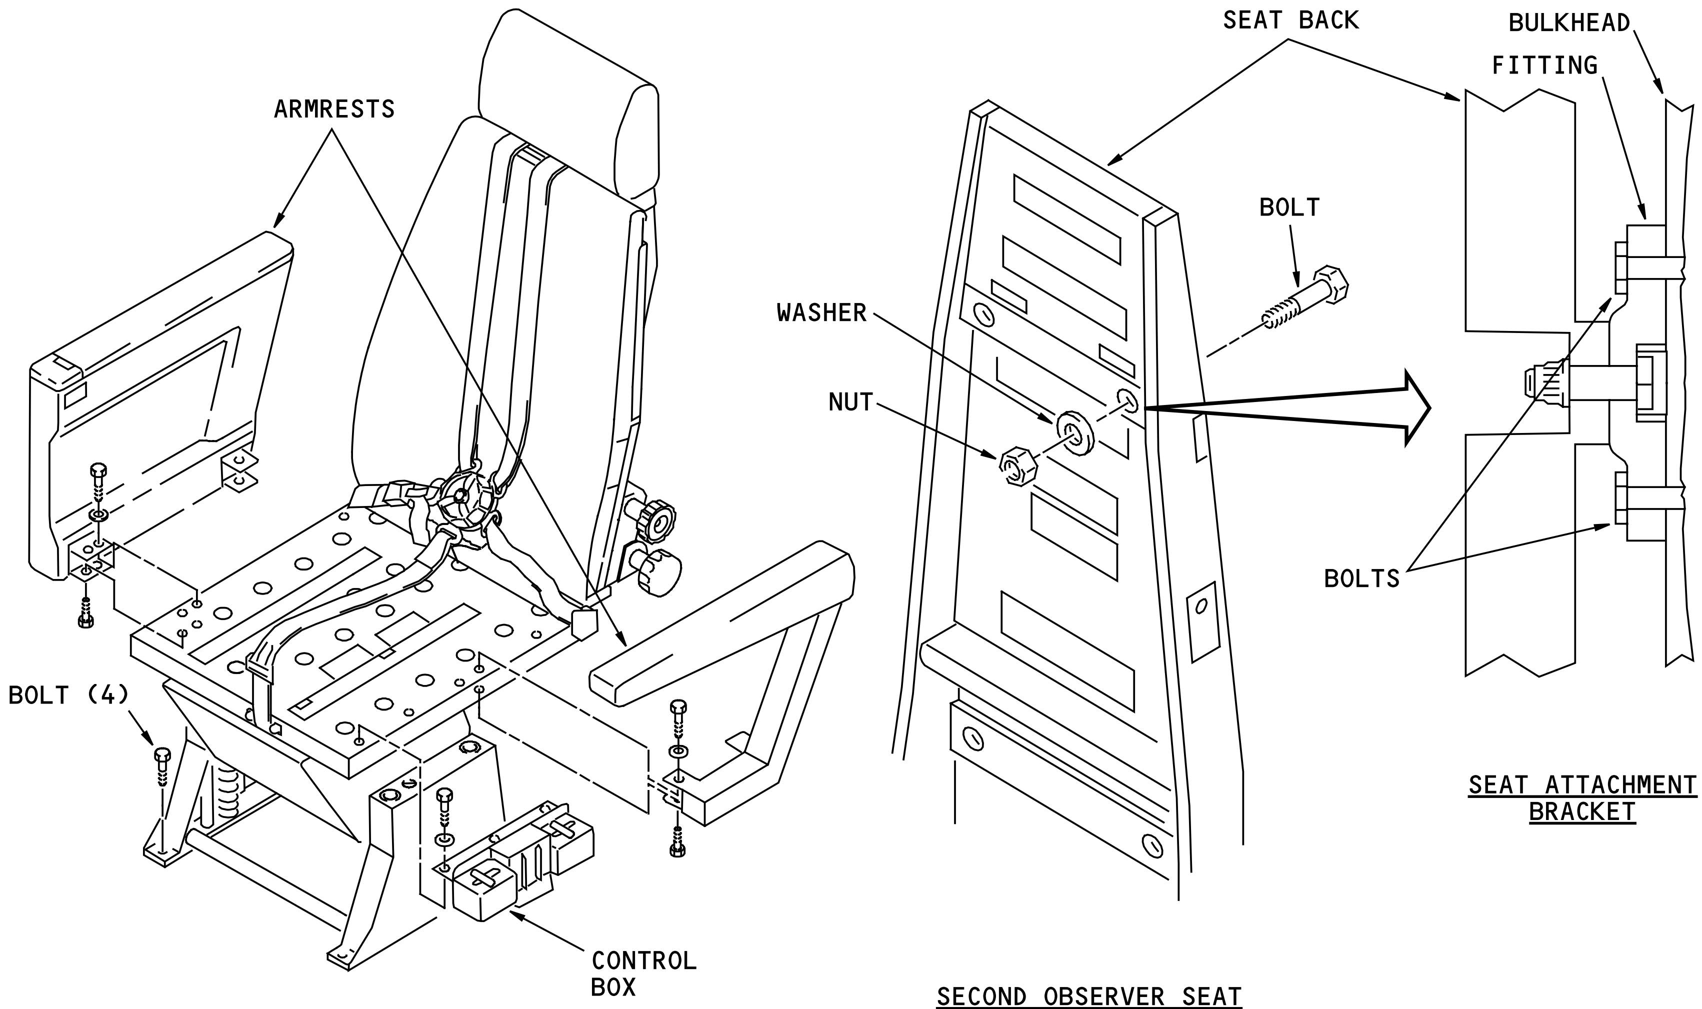
FLIGHT COMPARTMENT - OBSERVER SEATS - TRAINING INFORMATION POINTS

First Observer Seat

Four bolts attach the first observer seat to the floor. To move the seat through the flight deck door, remove both armrests and the control box from the seat. Do not disconnect the control cables from the box or the seat.

Second Observer Seat

Four bolts and fittings attach the second observer seat to the aft flight deck bulkhead. To remove the seat, remove the four nuts and washers. If you remove the fittings from the bulkhead, label the fittings so you can install them again in their original positions.



FIRST OBSERVER SEAT

SECOND OBSERVER SEAT

SEAT ATTACHMENT BRACKET

25-10-00-008 Rev 1

FLIGHT COMPARTMENT - OBSERVER SEATS - TRAINING INFORMATION POINTS

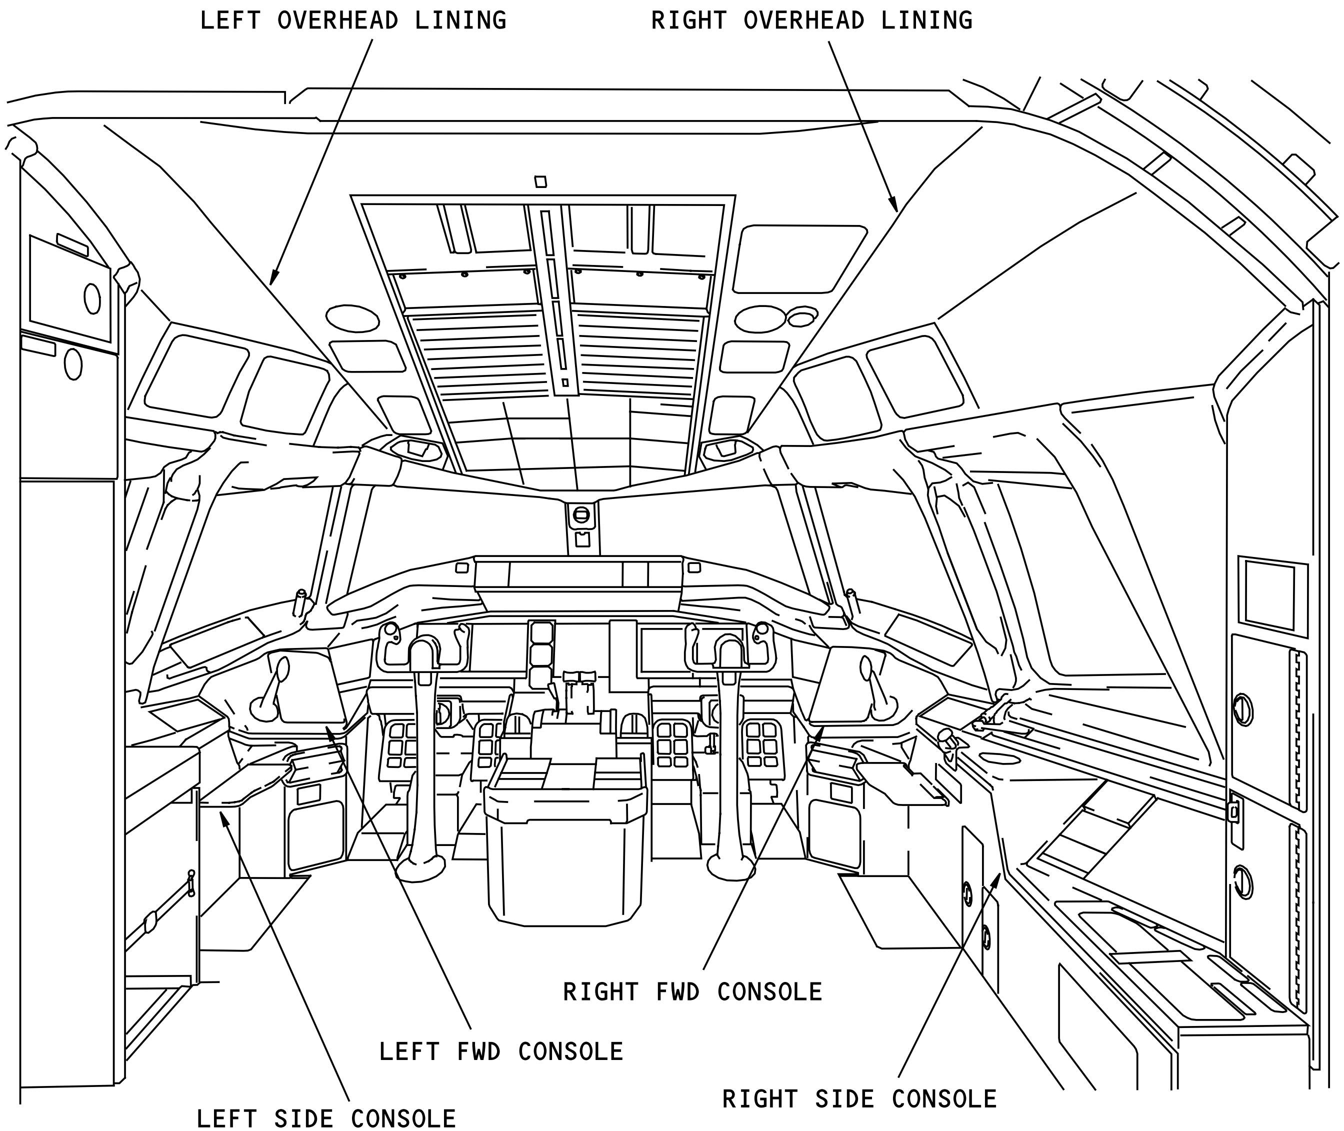
FLIGHT COMPARTMENT - FLIGHT COMPARTMENT LINING

Physical Description

Flight compartment linings are made of fiberglass-faced honeycomb material. The inboard surfaces are a washable and scratch-resistant decorative laminate. Screws attach the linings to the structure.

The flight deck has these linings:

- Left and right overhead lining
- Left and right forward console
- Left and right side consoles.



FLIGHT COMPARTMENT - FLIGHT COMPARTMENT LINING

PASSENGER COMPARTMENT - SIDEWALL PANELS

Location

The sidewall panels are on the outer sides of the passenger compartment on the walls.

Physical Description

The sidewall panels are made of a graphite composite that have a Tedlar lamination.

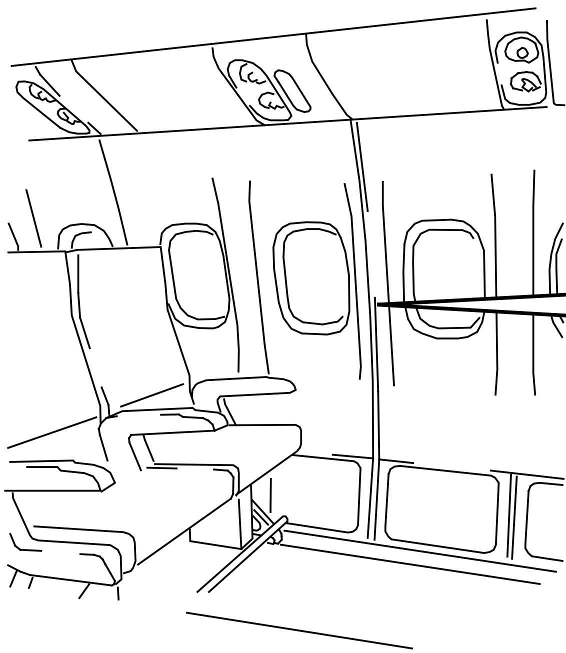
The panels have either zero, one, or two openings for the windows. They attach to the airplane structure with screws. Decorative covers go above the screws. The passenger service unit support holds the top of the panel.

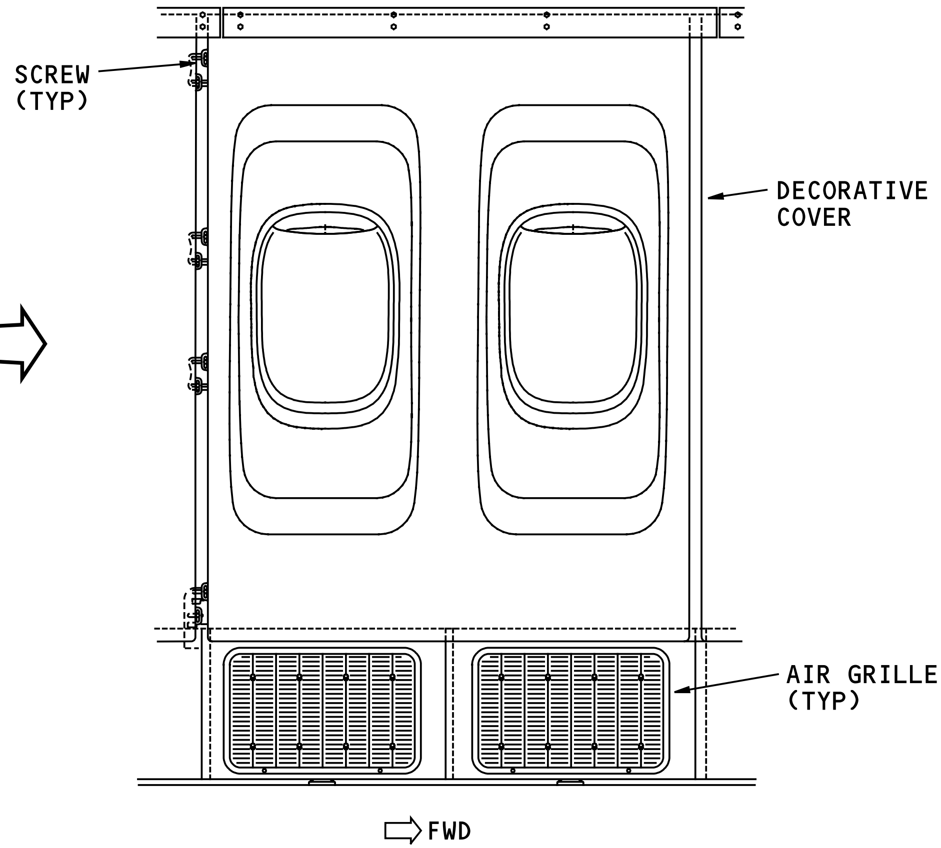
The panels have air grilles. The air grilles attach to the panel with quarter turn fasteners.

Training Information Point

To remove a sidewall panel, you must do these steps:

- Remove the passenger seats
- Remove the air grilles
- Remove the decorative covers between the panels
- Pull the lower edge of the panel inboard to release the top of the panel
- Remove the panel.





25-20-00-002 Rev 0

PASSENGER COMPARTMENT - SIDEWALL PANELS

PASSENGER COMPARTMENT - WINDOW REVEALS

Location

The window reveals are in openings in the sidewall panels.

Physical Description

The reveal assembly has:

- A shade
- Engagement points for upper reveal support
- A seal
- An inner reveal
- A dust cover
- Latch access hole
- A latch.

The inner window reveal holds the dust cover. The dust cover is clear plastic.

The seal closes the space between the passenger window assembly and the dust cover.

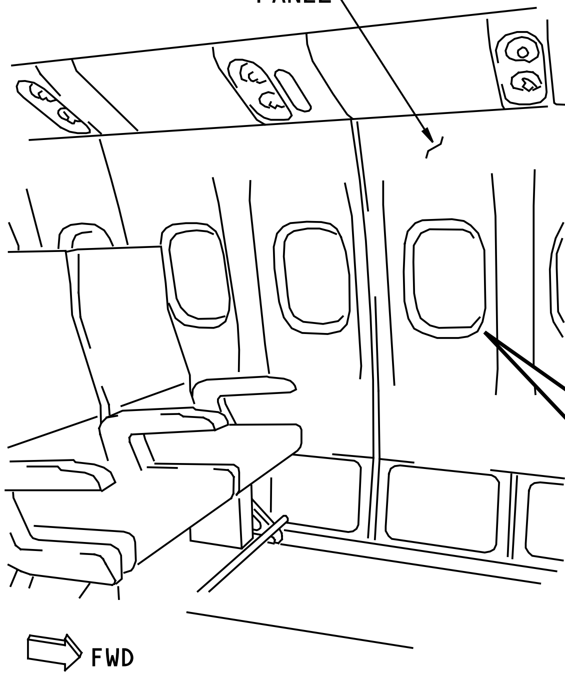
The outboard side of the sidewall panel has these components (not shown) that engage the window reveal:

- Shade track
- Upper reveal support
- Lower reveal support.

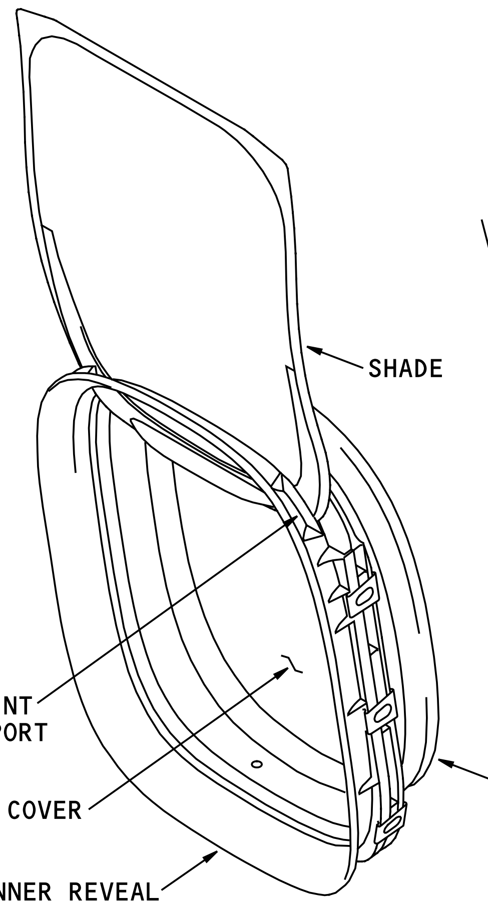
The upper reveal support engages the top of the window reveal assembly. The lower reveal support engages the latch. The shade track guides the movement of the shade.

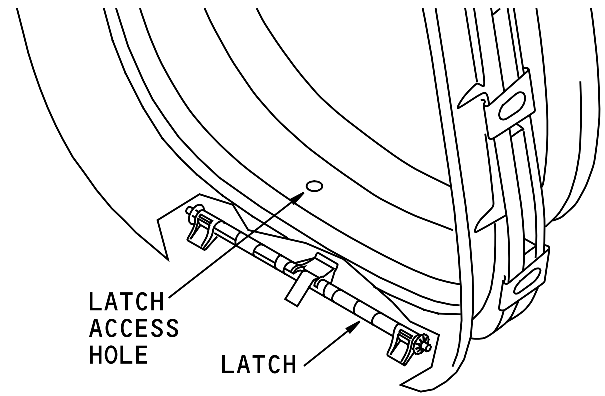
Training Information Point

You put a pin type tool through the latch access hole to release the latch. Put the shade in the down position when you move the shade out of and into the sidewall.



PASSENGER COMPARTMENT





WINDOW REVEAL

PASSENGER COMPARTMENT - WINDOW REVEALS

25-20-00-027 Rev 1 04/26/96

PASSENGER COMPARTMENT - MAIN CEILING PANEL

Location

The main ceiling panels are above the aisles in the passenger compartment. They are on both sides of the conditioned air outlet grilles.

Physical Description

The panels are made of graphite that have a Tedlar lamination.

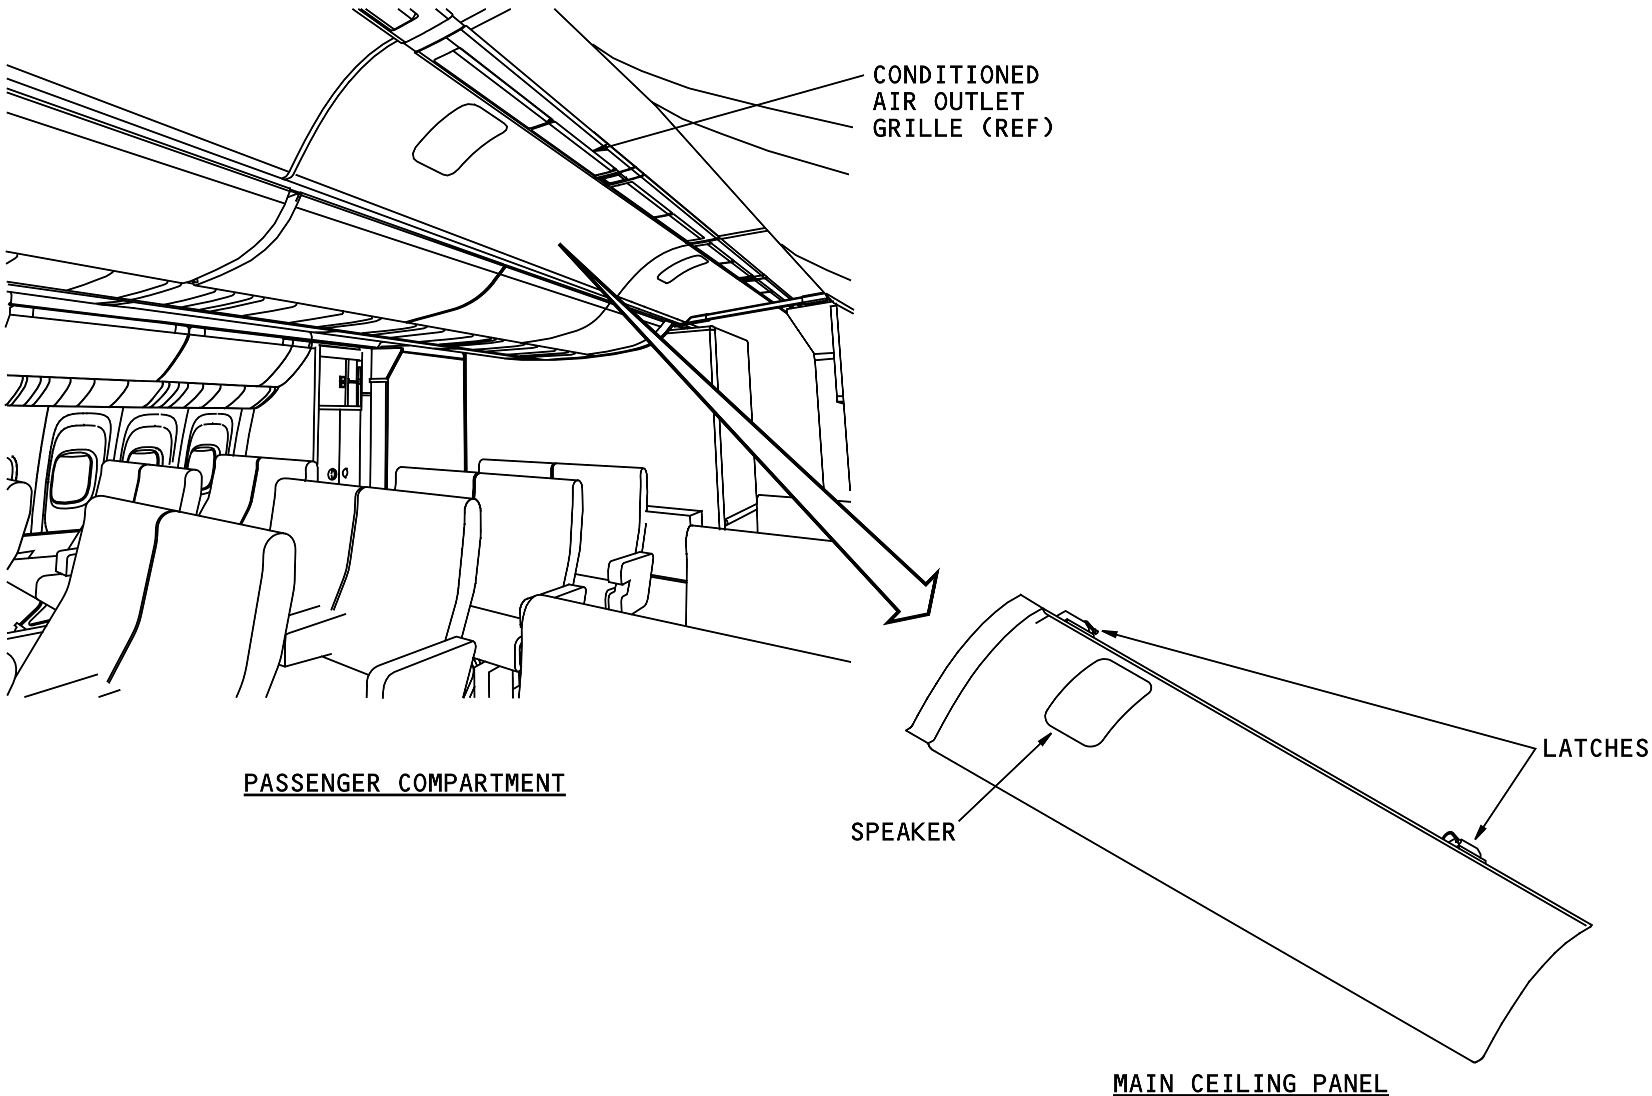
The main ceiling panels attach with lanyards (not shown), latches, and hinges (not shown). Some panels have speakers.

Training Information Point

For some panels you must disconnect the speaker wires to remove the panel.

To lower a main ceiling panel you do these things:

- Remove the air grilles between the inboard and outboard main ceiling panels
- Turn the latches above the panel, there is one latch at each end of the panel
- Let the panel hang by the lanyards
- Disconnect the lanyards
- Lift the panel out of the hinges.



25-20-00-004 Rev 0

PASSENGER COMPARTMENT - MAIN CEILING PANEL

PASSENGER COMPARTMENT - OVERDOOR PANEL

Location

The overdoor panels are on the ceiling, inboard from each passenger entry door.

Physical Description

The panels are made of a graphite composite material and have a Tedlar lamination.

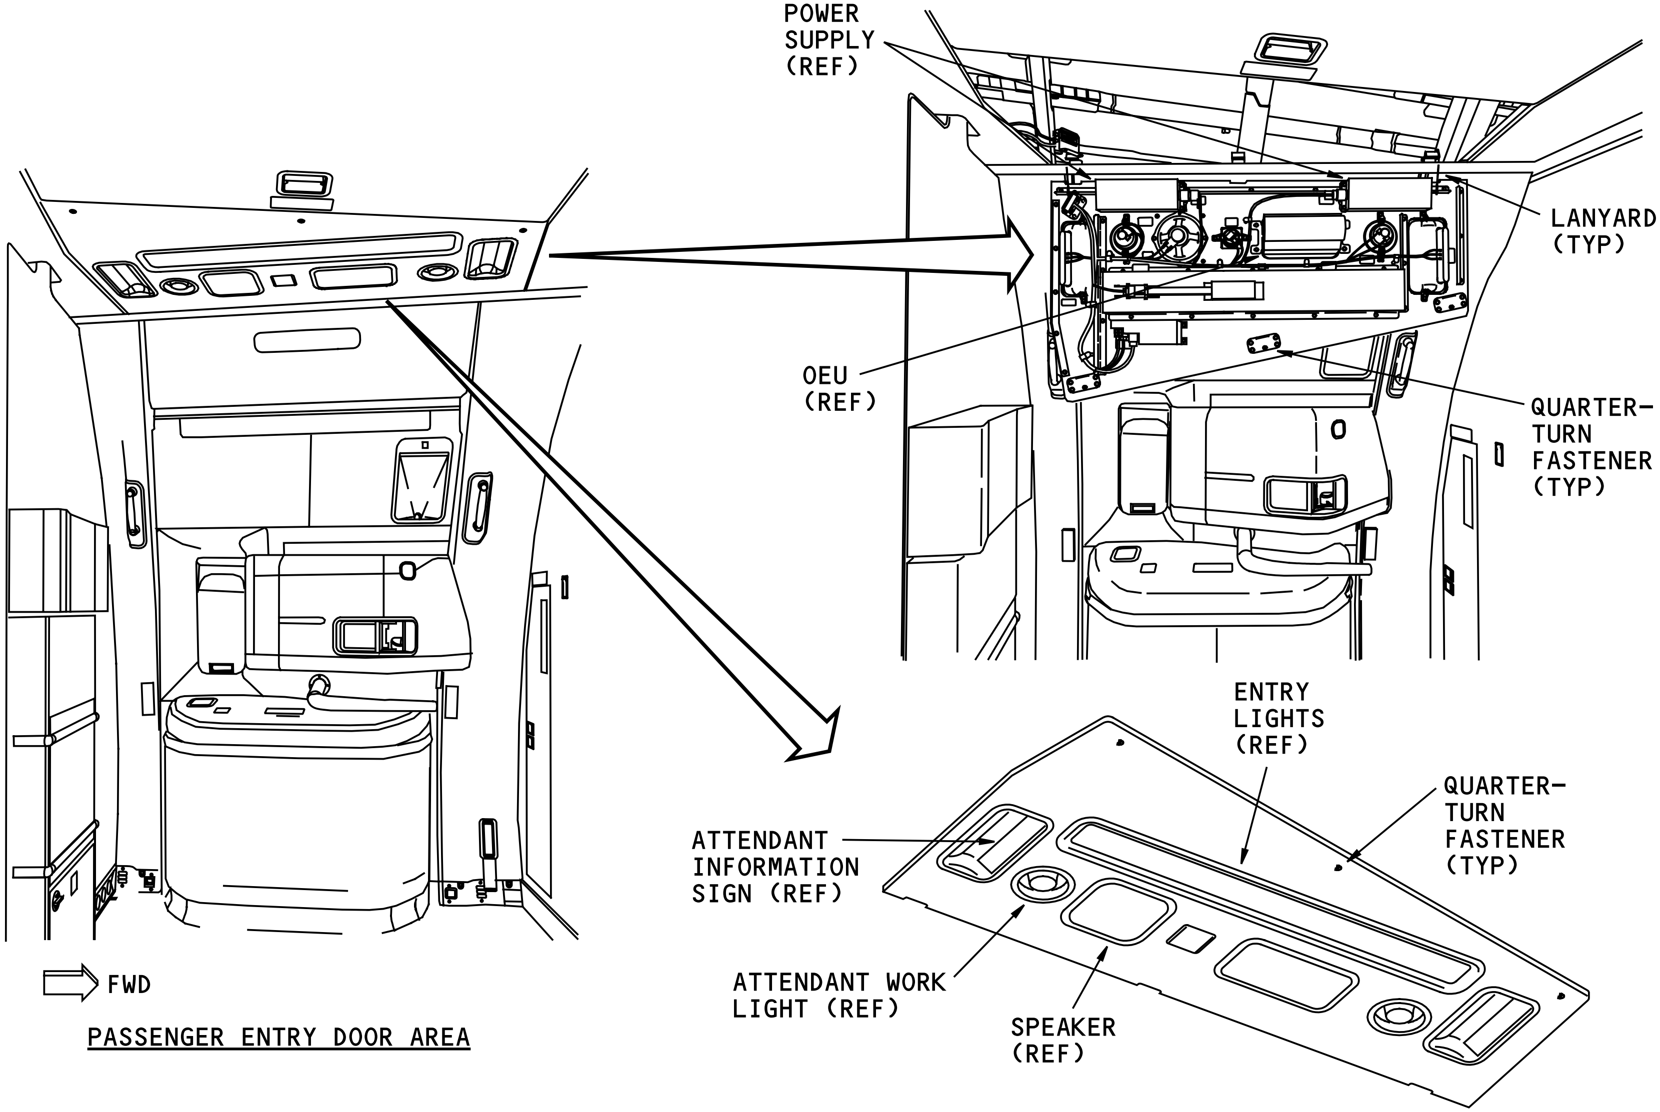
These components attach to the overdoor panels:

- Power supply for the emergency lights
- Lights
- Speaker
- Attendant information sign
- Overhead electronics unit (OEU).

The panels attach with two lanyards and quarter turn fasteners.

Training Information Point

To open an overdoor panel you turn the quarter turn fasteners and lower the panel. If you need to remove the overhead panel you disconnect the lanyards from the outboard side of the panel.



25-20-00-006 Rev 0

PASSENGER COMPARTMENT - OVERDOOR PANEL

PASSENGER COMPARTMENT - CONDITIONED AIR OUTLET GRILLE

Location

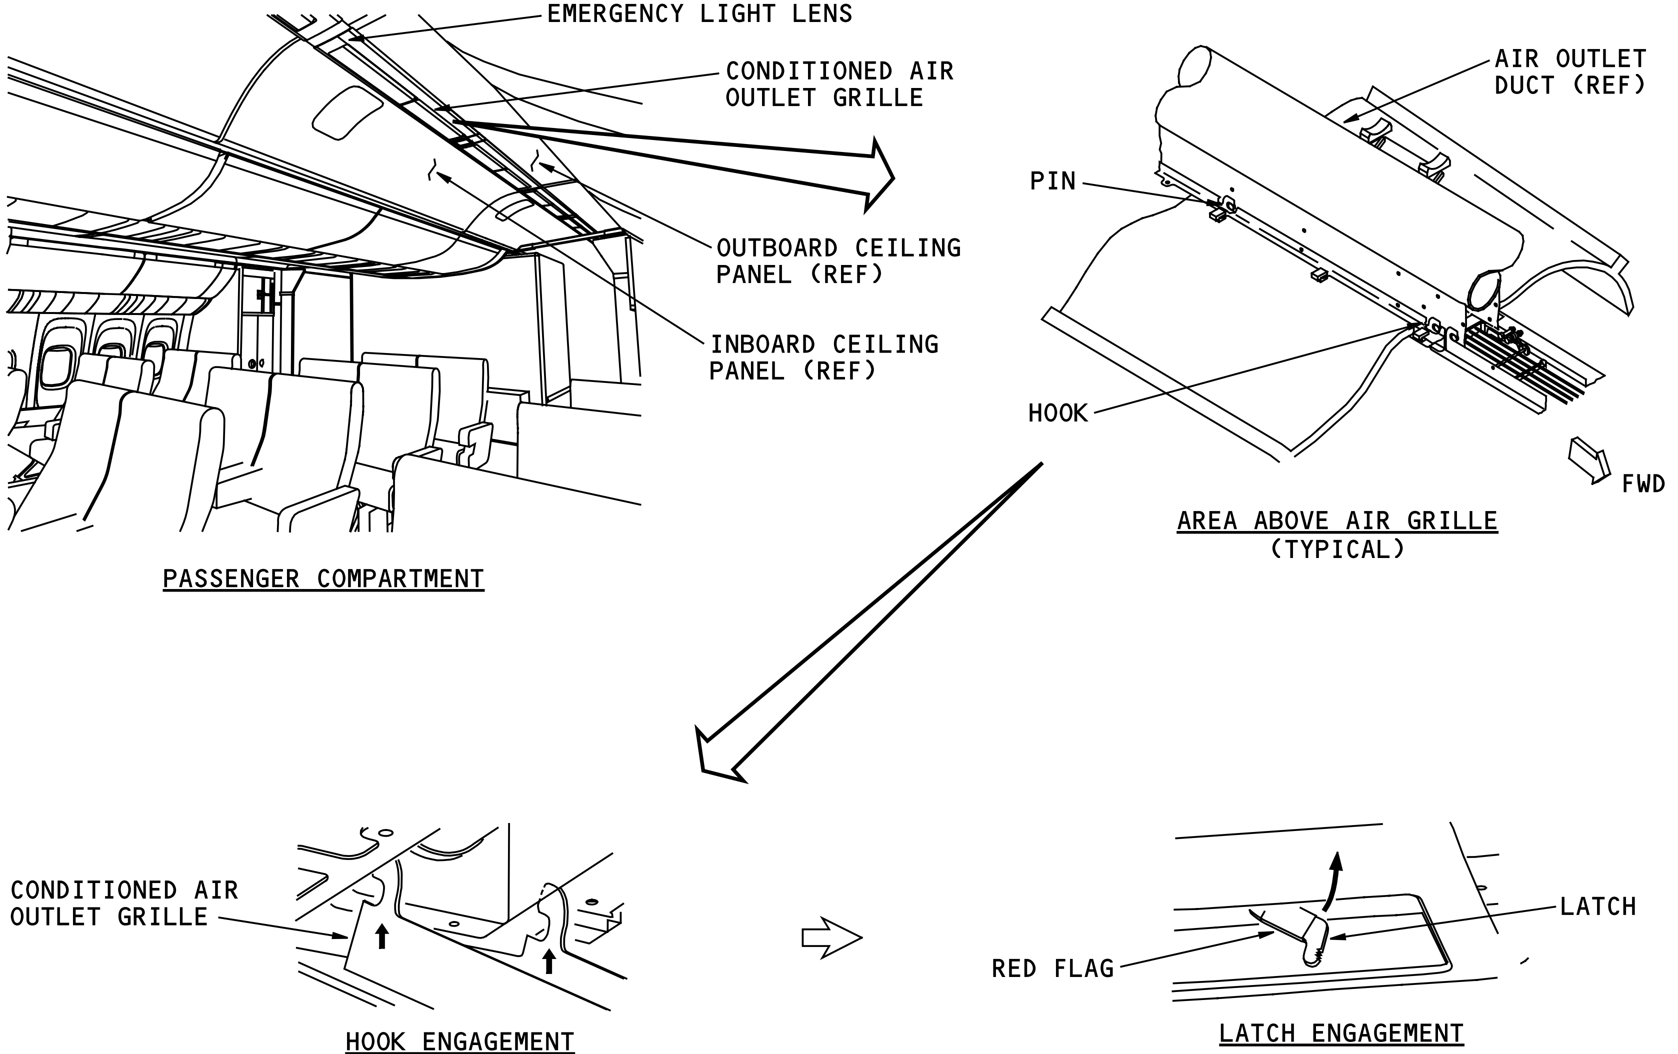
The conditioned air outlet grilles are above the aisles in the passenger compartment. They are between the inboard and outboard ceiling panels.

Physical Description

The grilles are made of plastic. Each grille has hooks and a latch to attach the grille to structure.

Training Information Point

To remove the air outlet grilles, remove the grille with the emergency light lens first. When you install the grilles, install the grille with the emergency light lens last. Also, make sure each hook on the grille is correctly engaged with the pin in the ceiling structure. The red flag on the latch will not show when you latch the grille correctly.



25-20-00-025 Rev 1 04/26/96

PASSENGER COMPARTMENT - CONDITIONED AIR OUTLET GRILLE

PASSENGER COMPARTMENT - PASSENGER SERVICE UNITS

General

These are the different types of passenger service units (PSUs):

- Gasper air
- Oxygen
- Spacer
- Reading Light
- Passenger information sign (not shown)
- Temperature sensor (not shown)
- Ambient noise sensor (not shown).

The PSUs may be installed in any order. This makes it easy for you to put the PSUs in sequence for different passenger compartment layouts.

Physical Description

The PSUs attach to the PSU rails with two or four latches. The latches are also the hinges for the PSUs.

Location

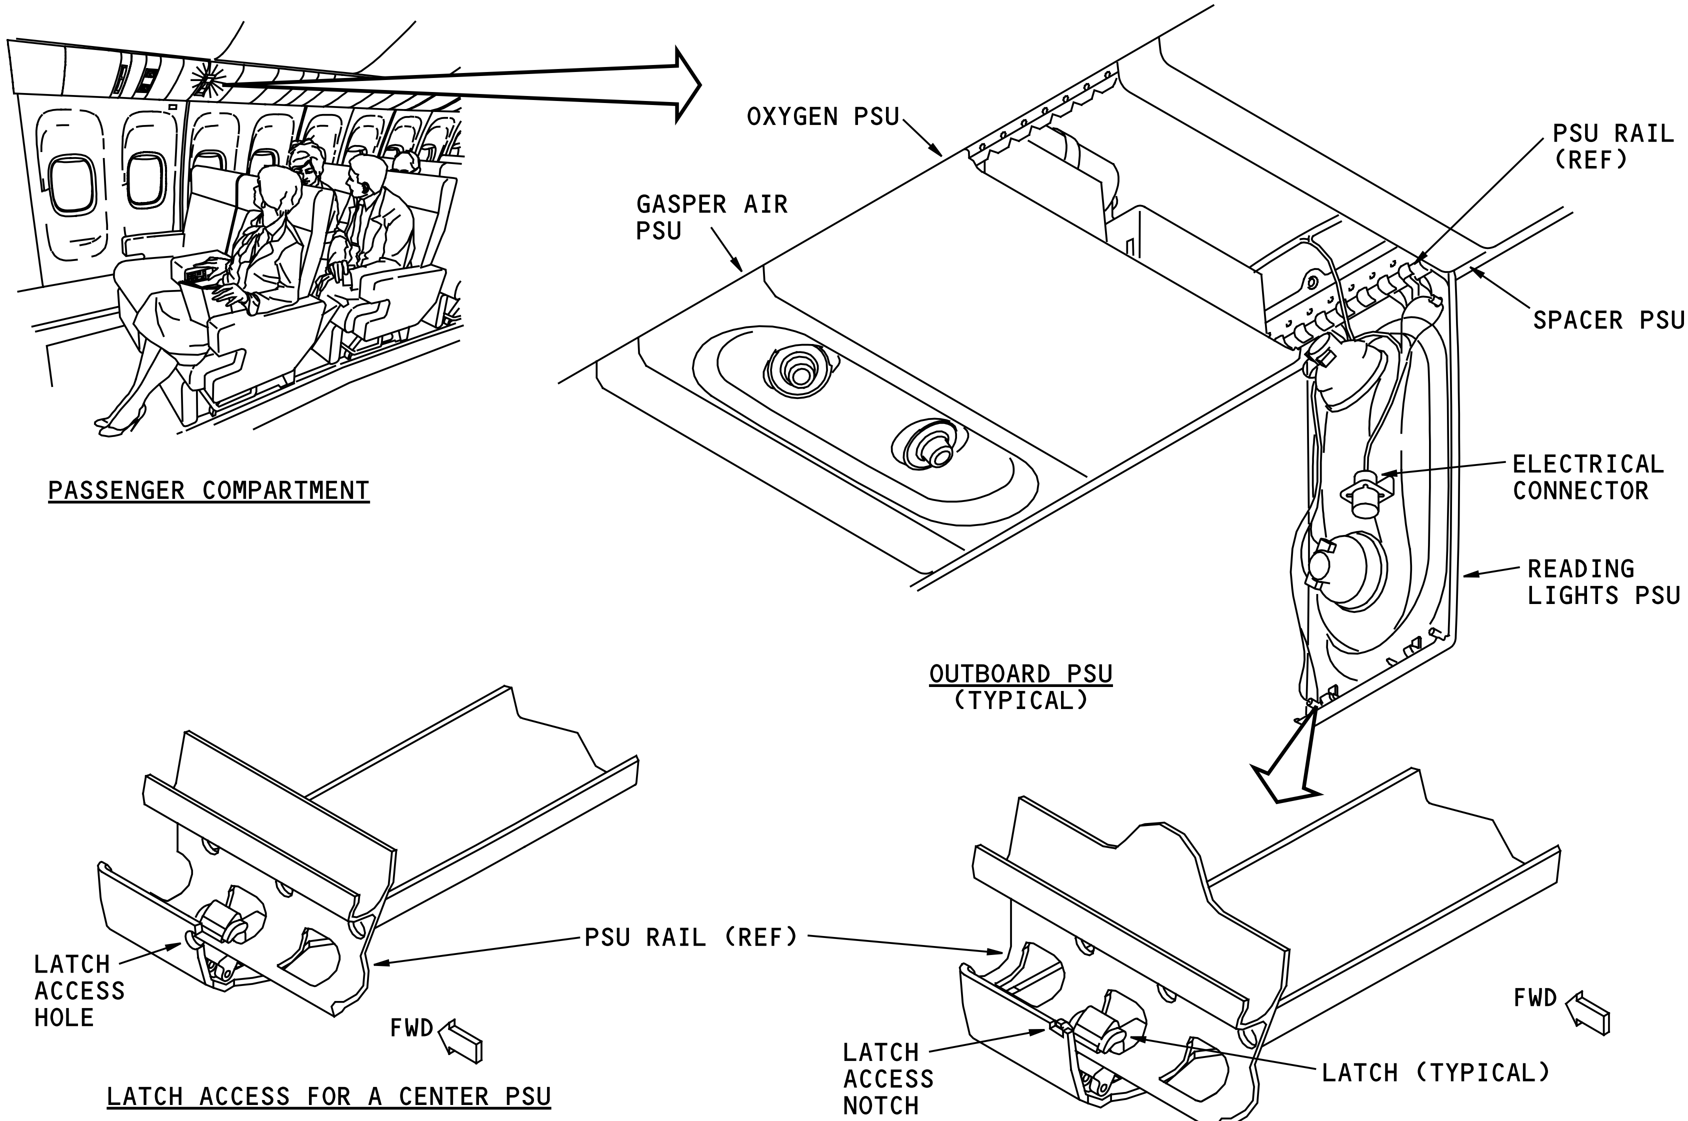
There are PSUs under the outboard and center stowage bins, above the passenger seats. There are also PSUs at attendant stations (not shown) and in lavatories (not shown).

Training Information Point

You use an allen wrench or a cylindrical rod to open a PSU. You put the tool through the access notch (outboard PSUs) or hole (center PSUs) and push on the latch. You can open the PSU from either side. To remove a PSU you open it from one side and then release the other latches from inside the PSU.

The outboard PSUs are interchangeable.

When you replace a PSU, make sure you install it so that the correct end points forward.



25-20-00-007 Rev 0

PASSENGER COMPARTMENT - PASSENGER SERVICE UNITS

PASSENGER COMPARTMENT - PASSENGER SEATS

General

First class and business class seats have electric controls for recline, lumbar support, and leg rest adjustments. Economy class seats have manual adjustments for recline.

Physical Description

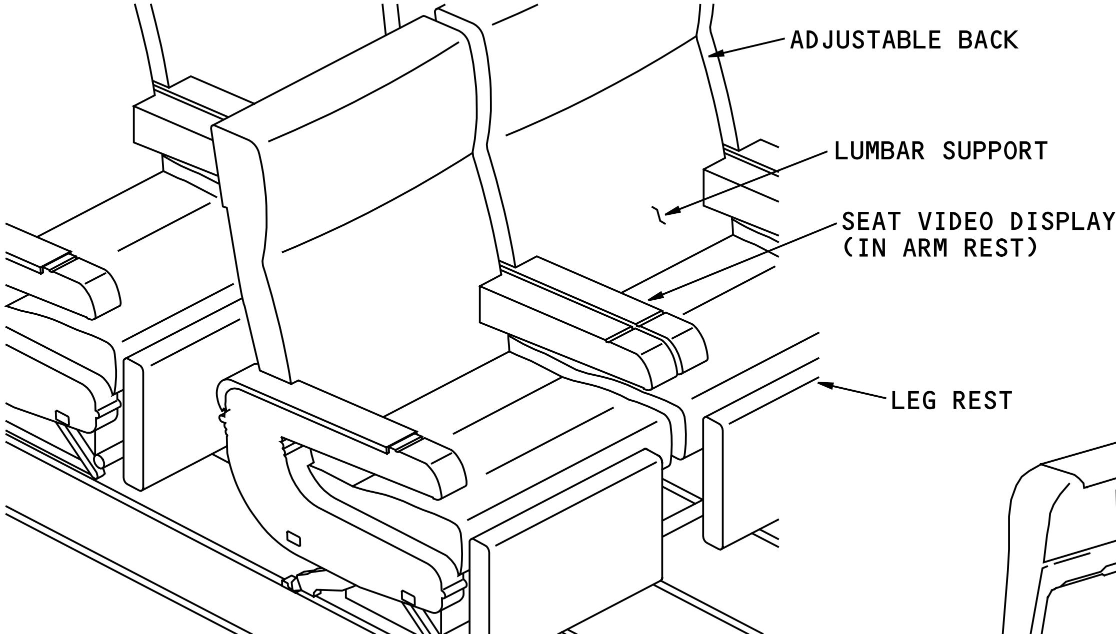
The seats have several components of the passenger entertainment system. The seats can have these components:

- Integrated telephone handset
- Seat video unit (SVU)
- Seat electronics unit (SEU)
- Seat video display.

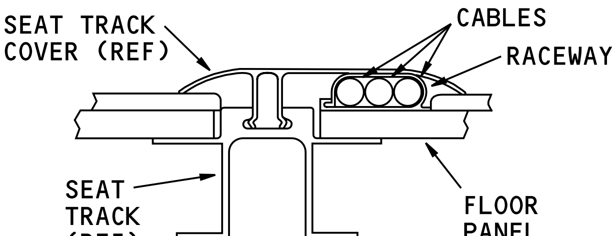
In some seats, the seat video folds and stows in the armrest. In other seats, the seat video display is in the seat back. (For seats immediately behind a bulkhead, the seat video display usually attaches to the bulkhead instead of the seat).

Training Information Point

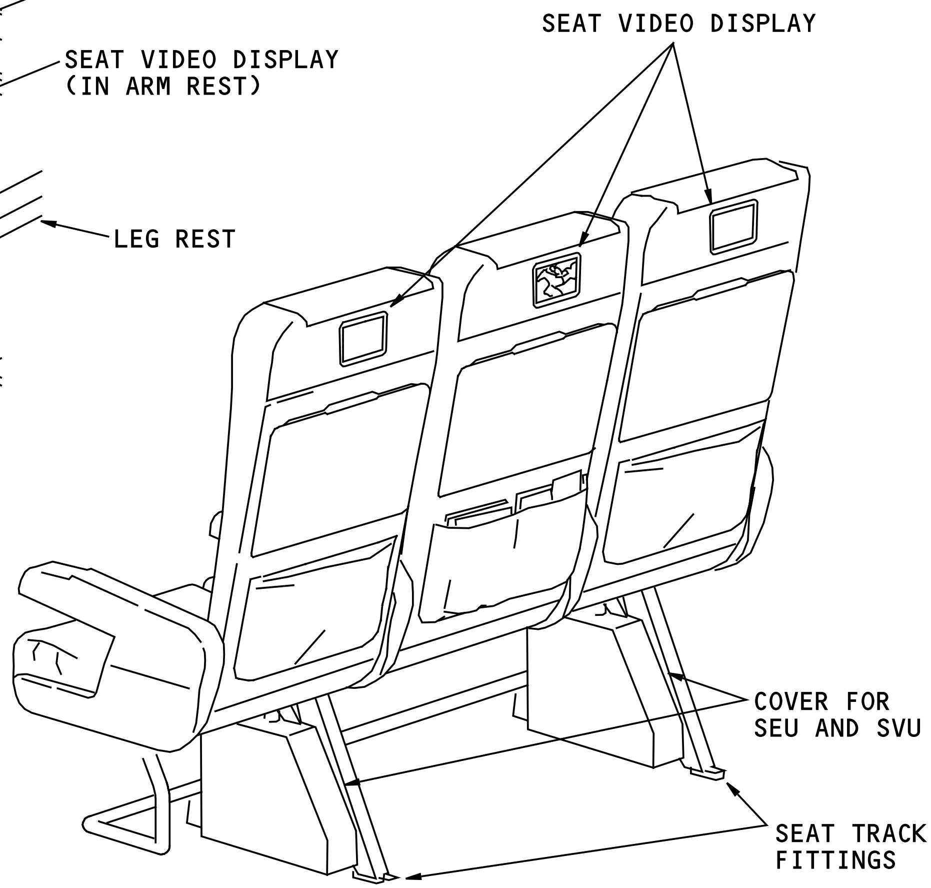
Passenger entertainment system cables connect to the seat electronic units and the seat video units. The cables are inside a plastic raceway adjacent to the seat tracks. A cover hides the seat tracks and cable raceways. Disconnect the seat cables before you remove a seat group.



FIRST CLASS SEATS (TYPICAL)



SEAT CABLES
(CROSS SECTION)



ECONOMY CLASS SEATS (TYPICAL)

THIS PAGE INTENTIONALLY LEFT BLANK

PASSENGER COMPARTMENT - ATTENDANT SEATS

General

The seat track mounted attendant seats attach to the seat tracks. The wall mounted attendant seats attach to the walls of the lavatories, galleys, or partitions. The seats have no adjustments.

There are two stowage compartments in the seat track mounted seat.

Physical Description

The seat track mounted attendant seats have these parts:

- Headrest cushion
- Backrest cushion
- Seat pan
- Seat cushion
- Seat belt and shoulder harness (not shown)
- Seat structure
- Stowage compartment doors.

The wall mounted attendant seats have these parts:

- Headrest cushion
- Backrest cushion
- Seat cushion
- Seat belt and shoulder harness (not shown)
- Seat structure.

The cushions attach to the seat structure with hook and loop tape. Remove the covers from the cushions to dry clean the covers.

Clips (not shown) attach the seat belts and shoulder harness to the seat structure. You can remove the seat belts and shoulder harness to clean them.

Functional Description

The seat structure has a seat pan which folds down. A spring folds the seat pan up when there is no weight on it. A damper (not shown) causes the seat pan to fold up slowly.

The seat track mounted attendant seats have springs (not shown) which cause the stowage compartment doors to close. Latches hold the doors closed. The latch striker plates are adjustable.

The stowage compartment below the seat of the wall mounted attendant seat has a door which folds down. To unlatch the door, move the door latch left or right.

Training Information Point

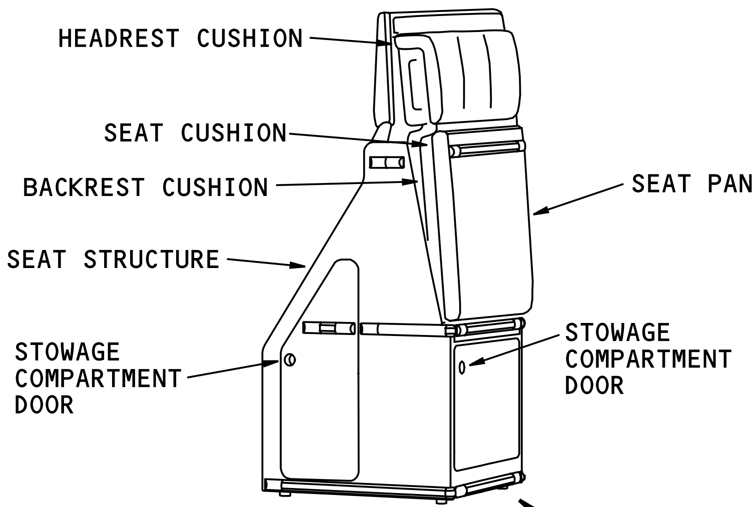
In seats with handsets or switch panels, electrical connectors (not shown) connect the seat wiring to the airplane wiring.

Four seat track fittings attach the seat track mounted attendant seat to the seat tracks.

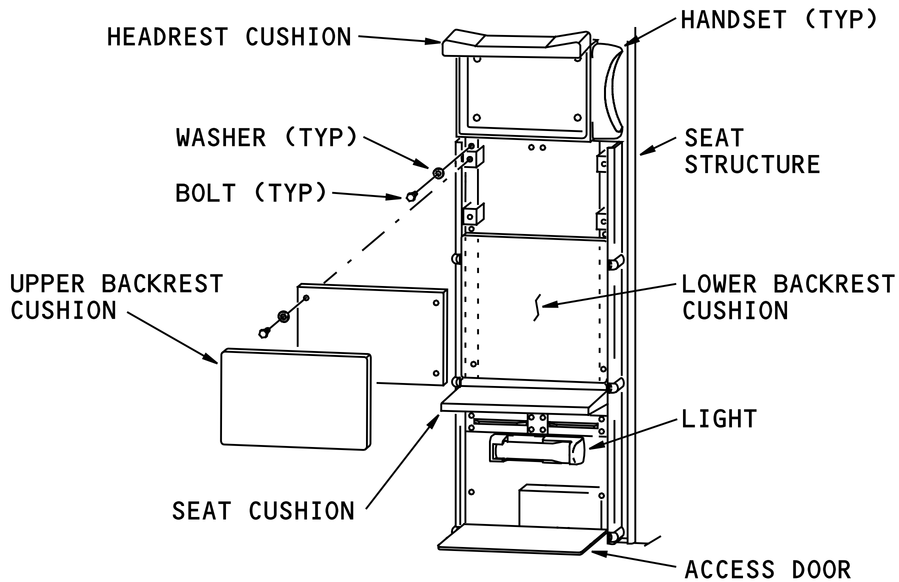
PASSENGER COMPARTMENT - ATTENDANT SEATS

The wall mounted attendant seats attach with bolts to vertical structure. To remove the seat, you must get access to the bolts as follows:

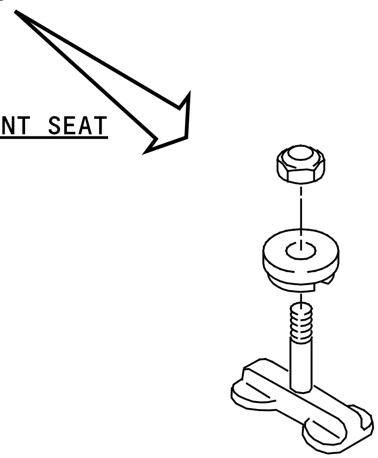
- Move the head rest up
- Remove the back rest
- Open the lower stowage compartment door.



FLOOR MOUNTED ATTENDANT SEAT



WALL MOUNTED ATTENDANT SEAT



SEAT TRACK FITTING

25-20-00-016 Rev 2 04/30/96

PASSENGER COMPARTMENT - ATTENDANT SEATS

PASSENGER COMPARTMENT - OUTBOARD STOWAGE BIN

Purpose

The outboard stowage bin supplies a location above the passenger for carry-on baggage.

Physical Description

The outboard stowage bin module has these components:

- Snubber (2)
- Latch
- Bin
- Strongback assembly.

The outboard stowage bin modules have four lengths:

- 21 inches
- 35 inches
- 42 inches
- 84 inches.

The 84 inch module has two stowage bins that attach to one strongback assembly. The other sizes have only one bin that attaches to the strongback assembly.

Location

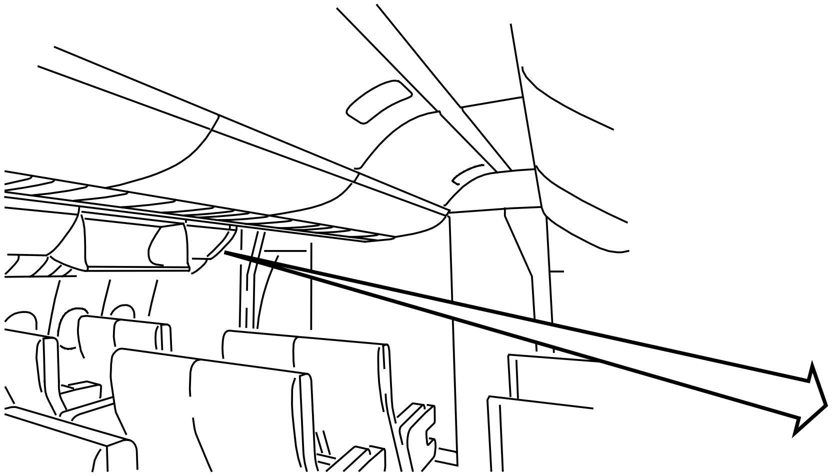
The outboard stowage bins are above the seats outboard of the aisle.

Functional Description

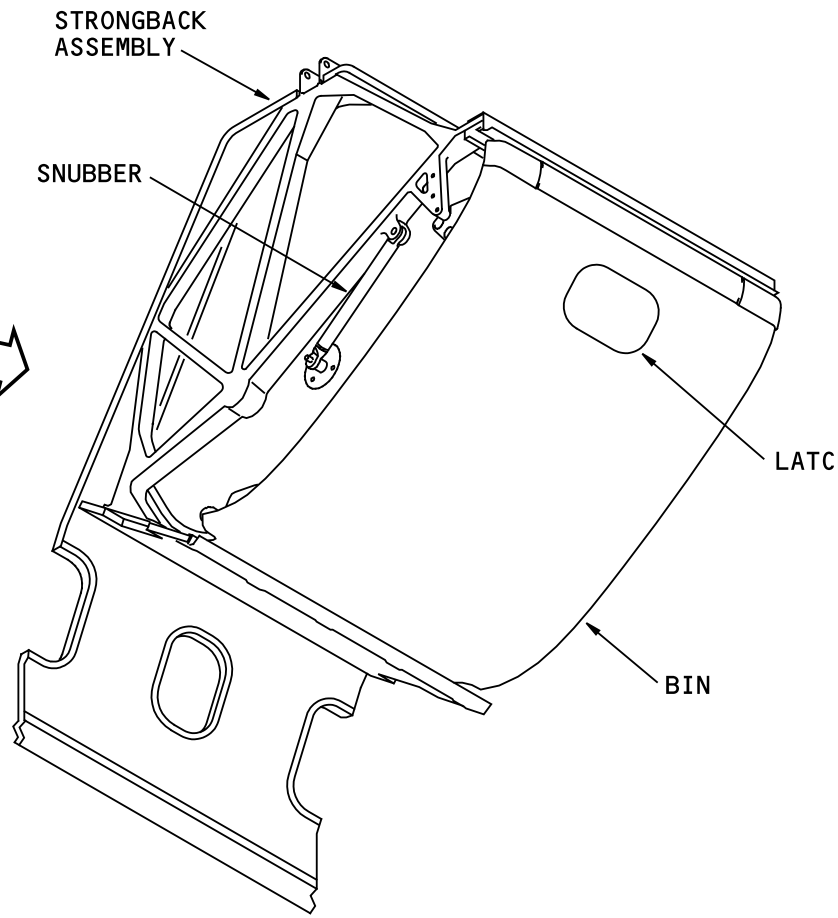
A latch on the face of the stowage bin lets you open the stowage bin. The stowage bin has two snubbers. The snubbers control the speed at which you can open the stowage bin. The bin latches when you close it.

Training Information Point

You can remove the stowage bin from the module and leave the strongback assembly in the airplane. Or you can remove the module with the strongback from the airplane.



PASSENGER COMPARTMENT



OUTBOARD STOWAGE BIN MODULE

25-20-00-017 Rev 1 08/21/95

PASSENGER COMPARTMENT - OUTBOARD STOWAGE BIN

PASSENGER COMPARTMENT - CENTER STOWAGE BIN

Purpose

The center stowage bin supplies a location above the passenger for carry-on baggage. The stowage bins in first class open vertically. The stowage bins in economy class open horizontally or vertically, depending on the seating configuration.

Physical Description

The center stowage bin has these components:

- Snubber (4)
- Spring (2)
- Latch
- Bin.

The center stowage bins have three lengths:

- 21 inches
- 35 inches
- 41 inches.

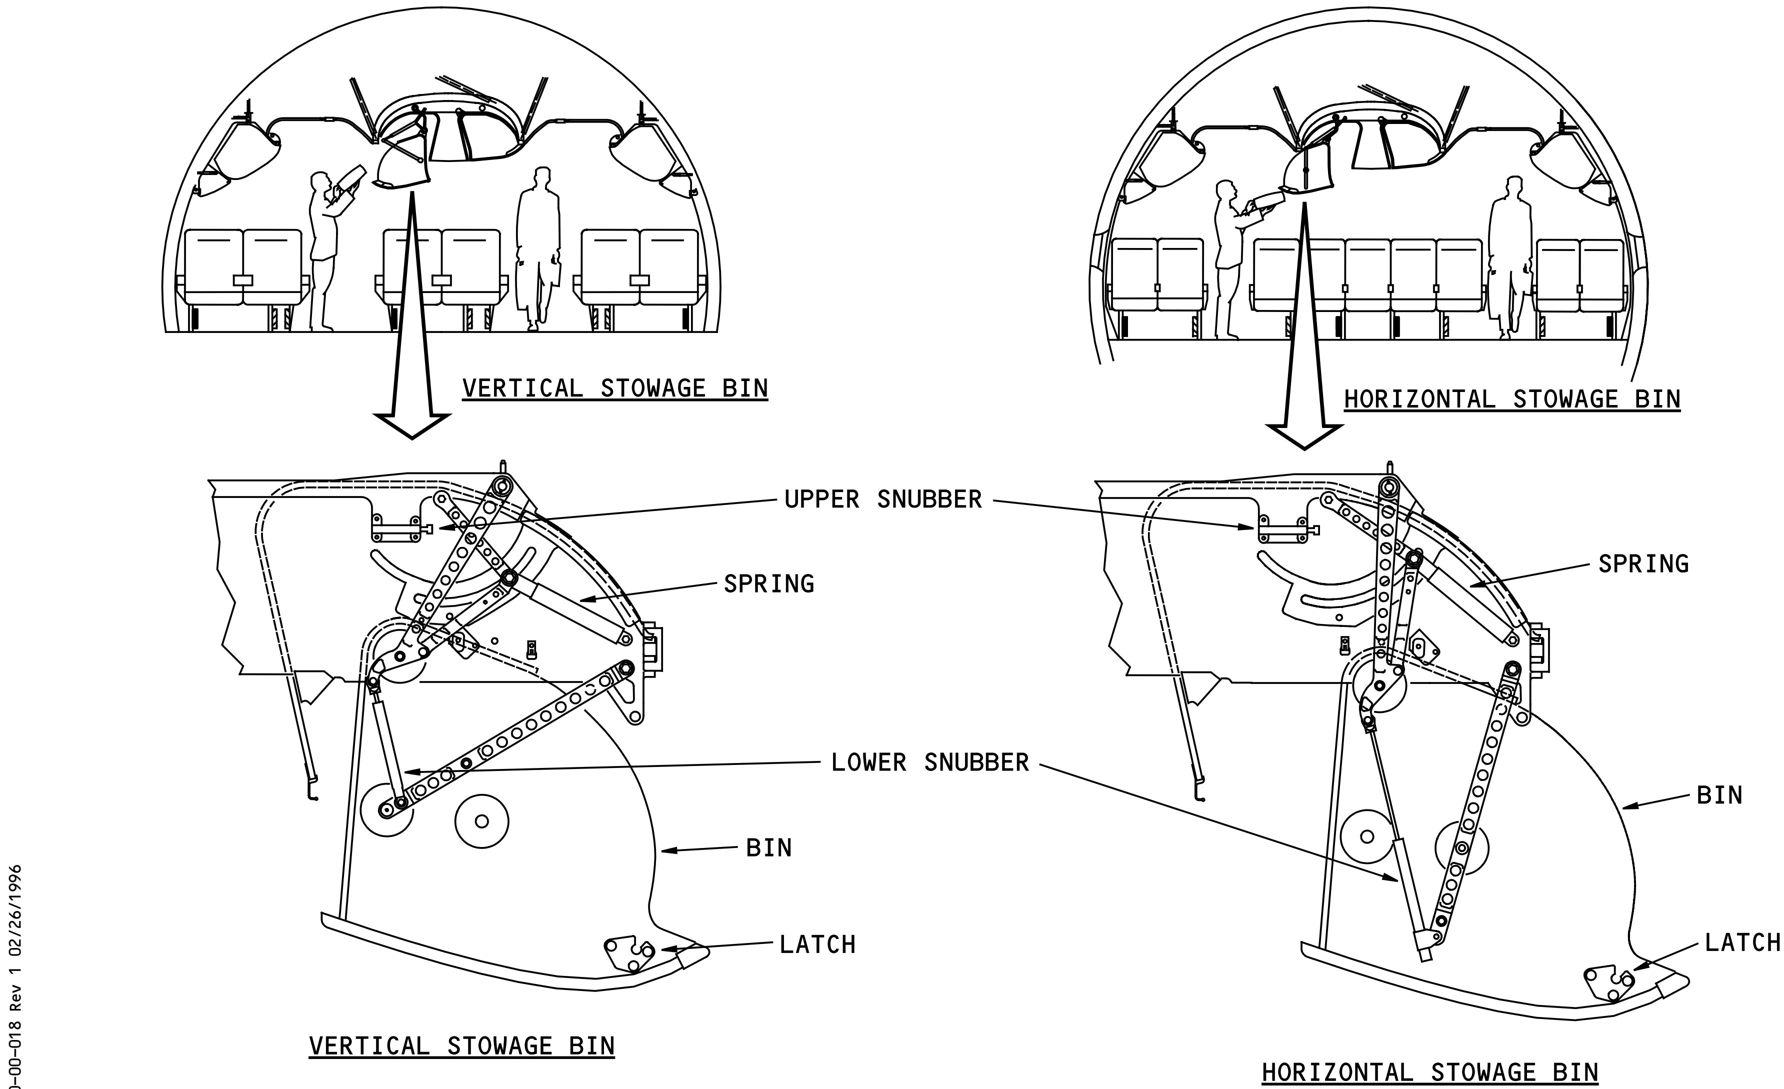
Location

The center stowage bins are above the center seats.

Functional Description

A latch on the face of the stowage bin lets you open the stowage bin. The stowage bin has four snubbers. The two lower snubbers control the speed at which you can open the stowage bin. The two upper snubbers control the speed at which you can close the stowage bin. The bin latches when it closes.

The center stowage bins in first class open vertically. The center stowage bins in economy class open horizontally or vertically, depending on the seating configuration. The bins that open horizontally extend further outboard than the vertical bins when open. This makes it easier to put baggage in the bins. The difference between the vertical and the horizontal stowage bin is the length and attachment point of the lower snubber.



PASSENGER COMPARTMENT - CENTER STOWAGE BIN

PASSENGER COMPARTMENT - STOWAGE BIN SNUBBER

Purpose

The stowage bin snubber controls the rate at which a stowage bin opens or closes.

Outboard Stowage Bin

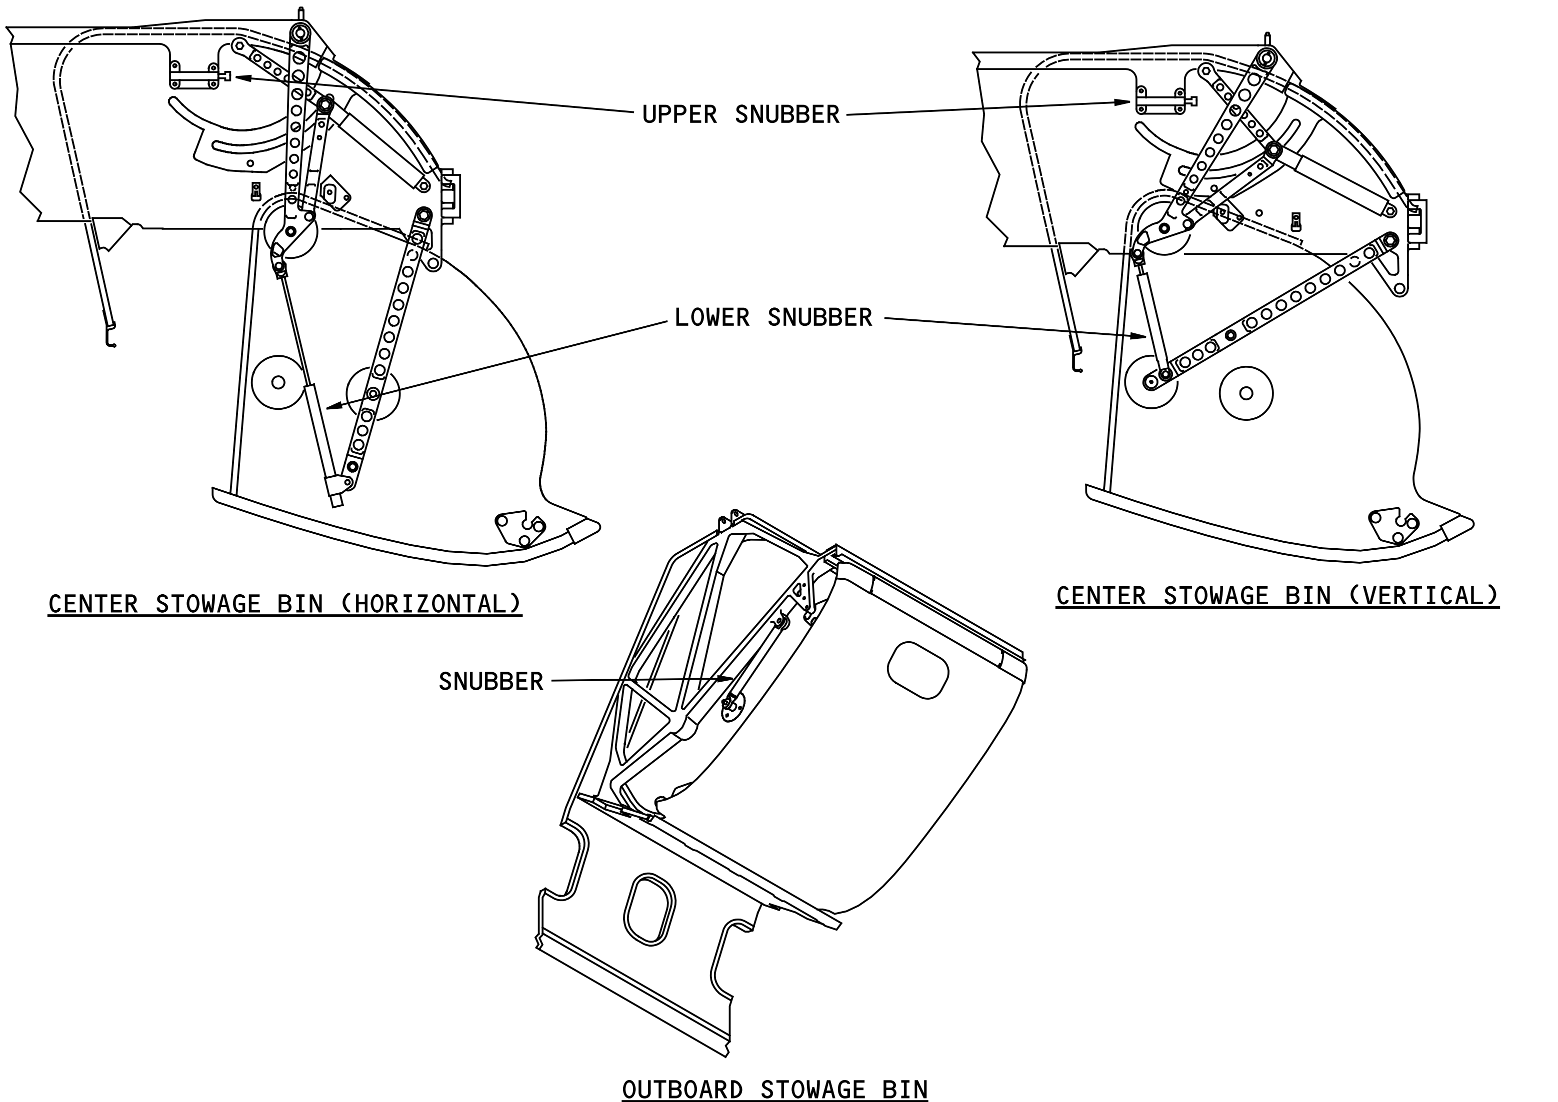
Two snubbers control the rate at which a outboard stowage bin opens.

Center Stowage Bin

Four snubbers control the rate at which a center stowage bin opens and closes. Two lower snubbers control the speed the stowage bin opens. Two upper snubbers control the speed a stowage bin can close.

Location

A snubber is at each end of the outboard stowage bin. Two snubbers are at each end of the center stowage bin.



25-20-00-019 Rev 0

PASSENGER COMPARTMENT - STOWAGE BIN SNUBBER

PASSENGER COMPARTMENT - STOWAGE BIN LATCH

Purpose

A stowage bin latch holds a stowage bin closed. You release the latch to open a stowage bin.

Physical Description

Stowage bin latch has these components:

- End assembly(2)
- Torque tube (2)
- Actuator
- Emergency release (2)
- Bezel.

Location

Stowage bin latch is on the face of these stowage compartments

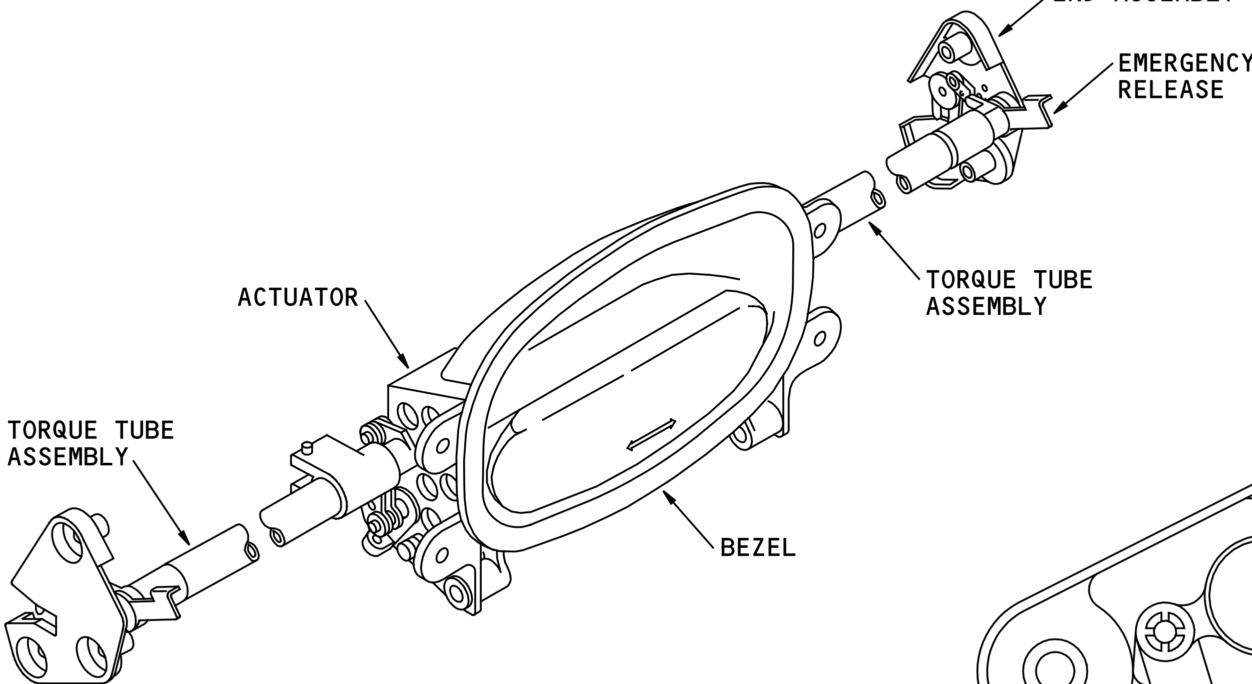
- Outboard stowage bins
- Center stowage bins
- Overhead stowage box.

Functional Description

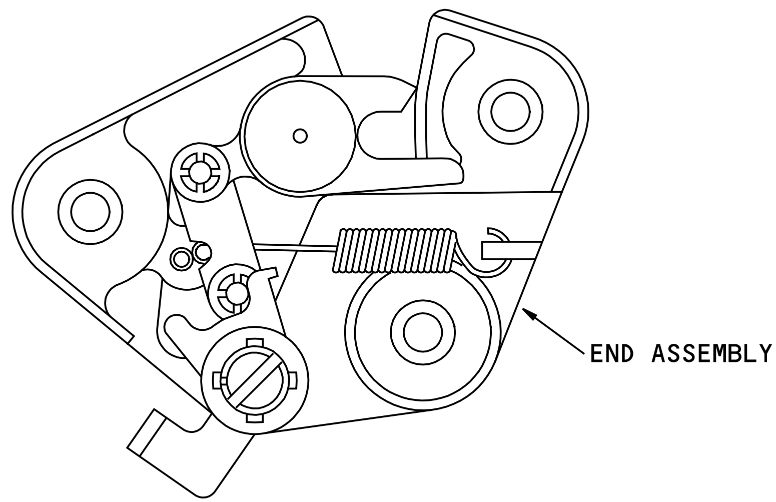
You pull on the bezel to unlatch the latch. The bezel turns the actuator which is attached to the torque tubes. The torque tubes then turns the end assembly and allow the latch to unlatch.

Training Information Point

The bezel extends past the stowage bin if it is not latched at both ends. You can see a red decal if the stowage bin is not latched. The emergency release lets you externally open the stowage bin if the actuator does not operate correctly.



STOWAGE BIN LATCH



LATCH
(END VIEW)

CREW REST AREAS AND CREW ACCOMMODATIONS - FLIGHT CREW REST AREA

Purpose

The flight crew rest (FCR) is an area for off-duty flight crew to rest during long flights. Crew members use the FCR only during cruise flight.

Location

The flight crew rest is in the passenger compartment, forward of door 1 left.

General Description

The FCR contains bunks for two crew members and storage compartments (not shown) for their belongings. The FCR has these systems and equipment (not shown):

- Lighting
- Attendant call switches
- Audio entertainment
- Cabin interphone handset
- Passenger address speakers
- Ventilation
- Temperature control
- Smoke detection
- Supplemental oxygen.

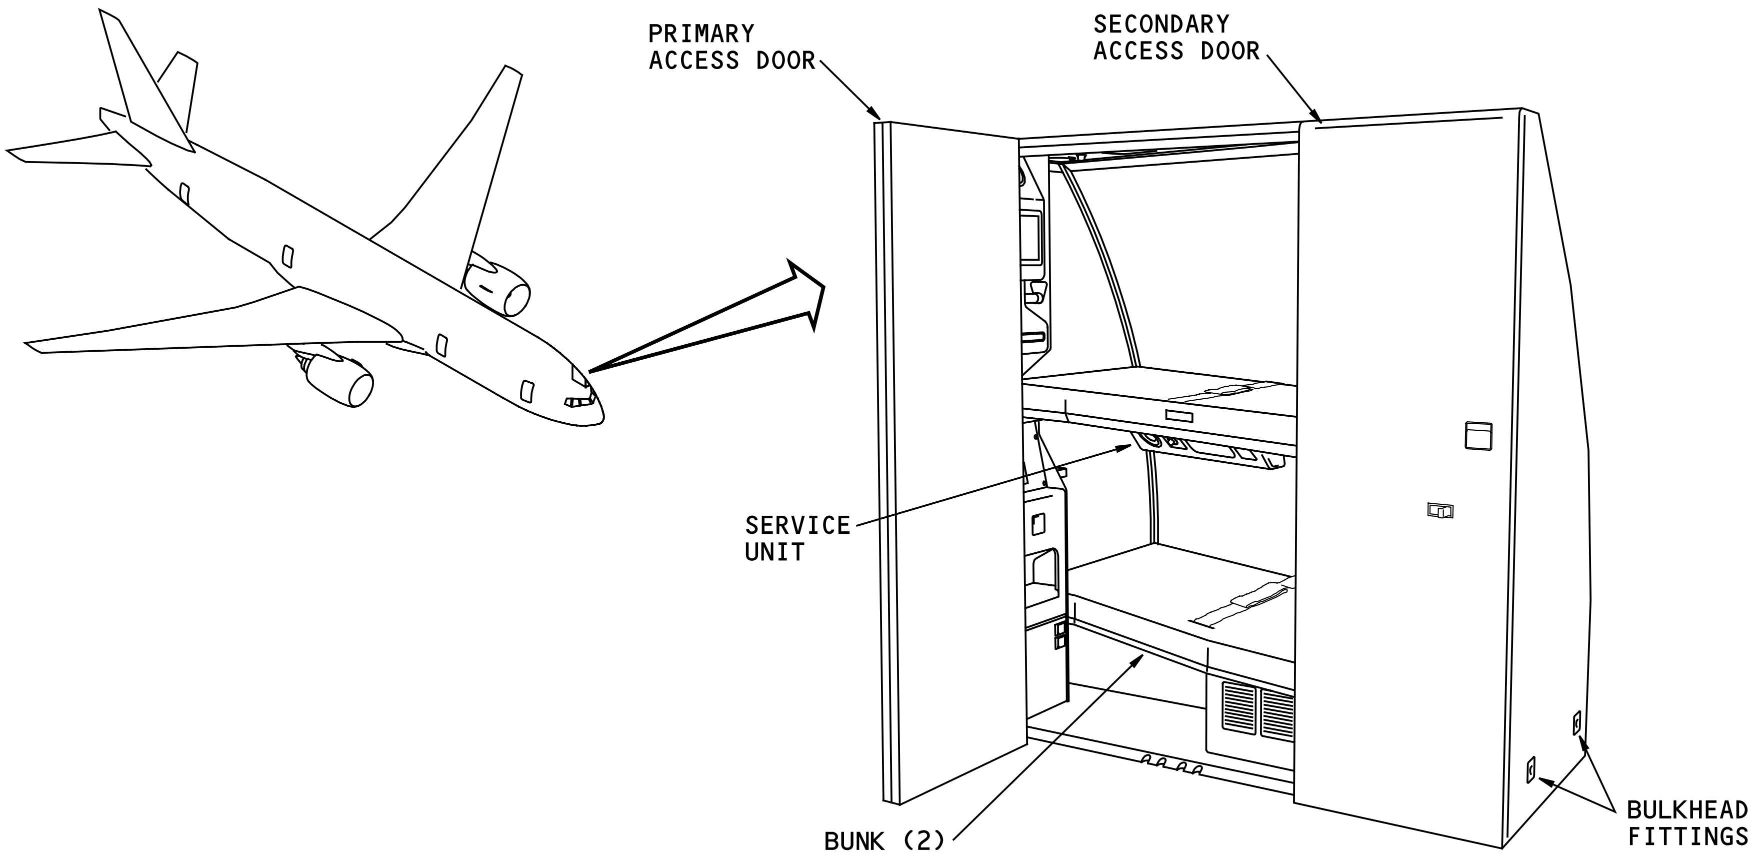
Physical Description

Two doors give access to the flight crew rest area. The primary access door latches open to block the adjacent aisle. This isolates the flight crew rest from the passenger compartment and makes an area where the crew members can change clothes. The secondary access door gives access to the bunks when it is open. You can close and latch the two doors from the top or the bottom bunk. A step and handle (not shown) help access to the upper bunk.

Three seat track fittings and one hard point (not shown) attach the FCR to the floor. Two tie rods attach the top of the FCR to the airplane structure. The FCR also attaches to the flight deck bulkhead. You can disassemble the FCR and remove the parts through a passenger entry door.

Training Information Point

Electrical connections (not shown) for the FCR equipment are on top of the FCR ceiling. Access to these connections is through a ceiling panel in the adjacent aisle.



FLIGHT CREW REST

25-29-00-003 Rev 1 04/10/1997

CREW REST AREAS AND CREW ACCOMMODATIONS - FLIGHT CREW REST AREA

BUFFET AND GALLEY - FORWARD FIXED GALLEY - INTRODUCTION

Physical Description

The forward fixed galleys can include one or more of these units:

- F1 galley
- F2 galley
- F3 galley.

The F1 galley is at the right side of the passenger compartment, forward of door 1. The galley faces aft.

The F2 galley is in the center of the passenger compartment, forward of door 1. The galley faces to the right.

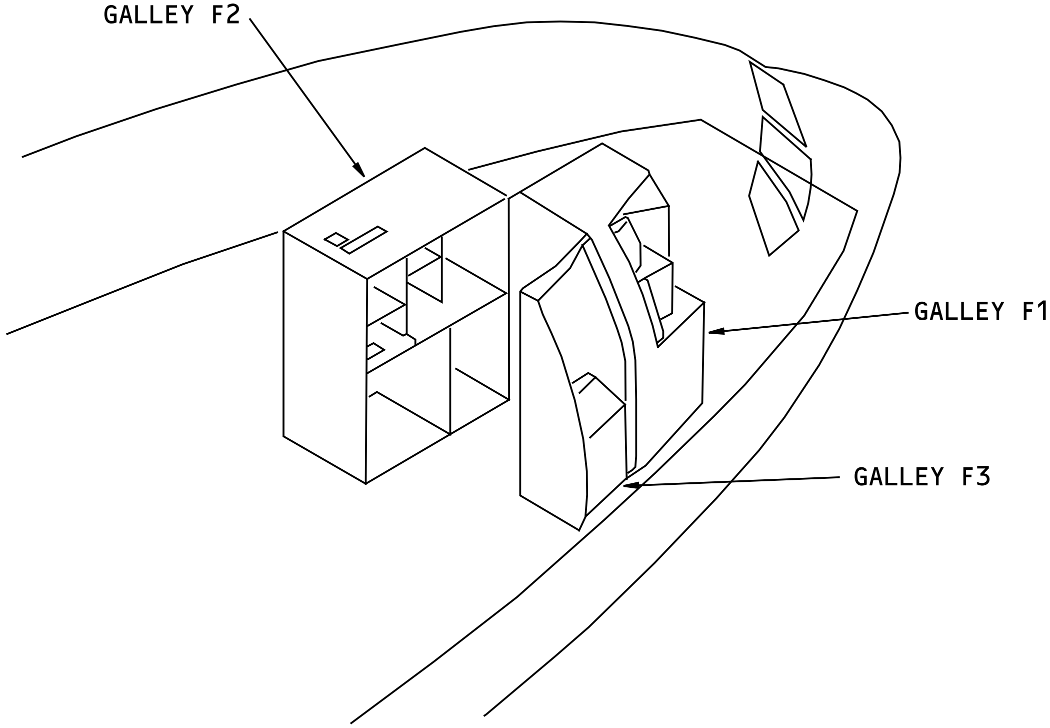
The F3 galley is at the right side of the passenger compartment, forward of door 1. The galley faces inboard.

Air Chillers

Air chillers can be attached to the top of the forward fixed galleys. The chiller supplies cold air to the refrigeration compartments.

The F1 galley has an air chiller.

The F2 galley has an air chiller.



FORWARD FIXED GALLEYS
(TYPICAL)

25-30-00-004 Rev 2 03/19/96

BUFFET AND GALLEY - FORWARD FIXED GALLEY - INTRODUCTION

BUFFET AND GALLEY - AFT FIXED GALLEY - INTRODUCTION

Physical Description

The aft fixed galleys can include one or more of these units:

- A1 galley
- A2 galley
- A3 galley.

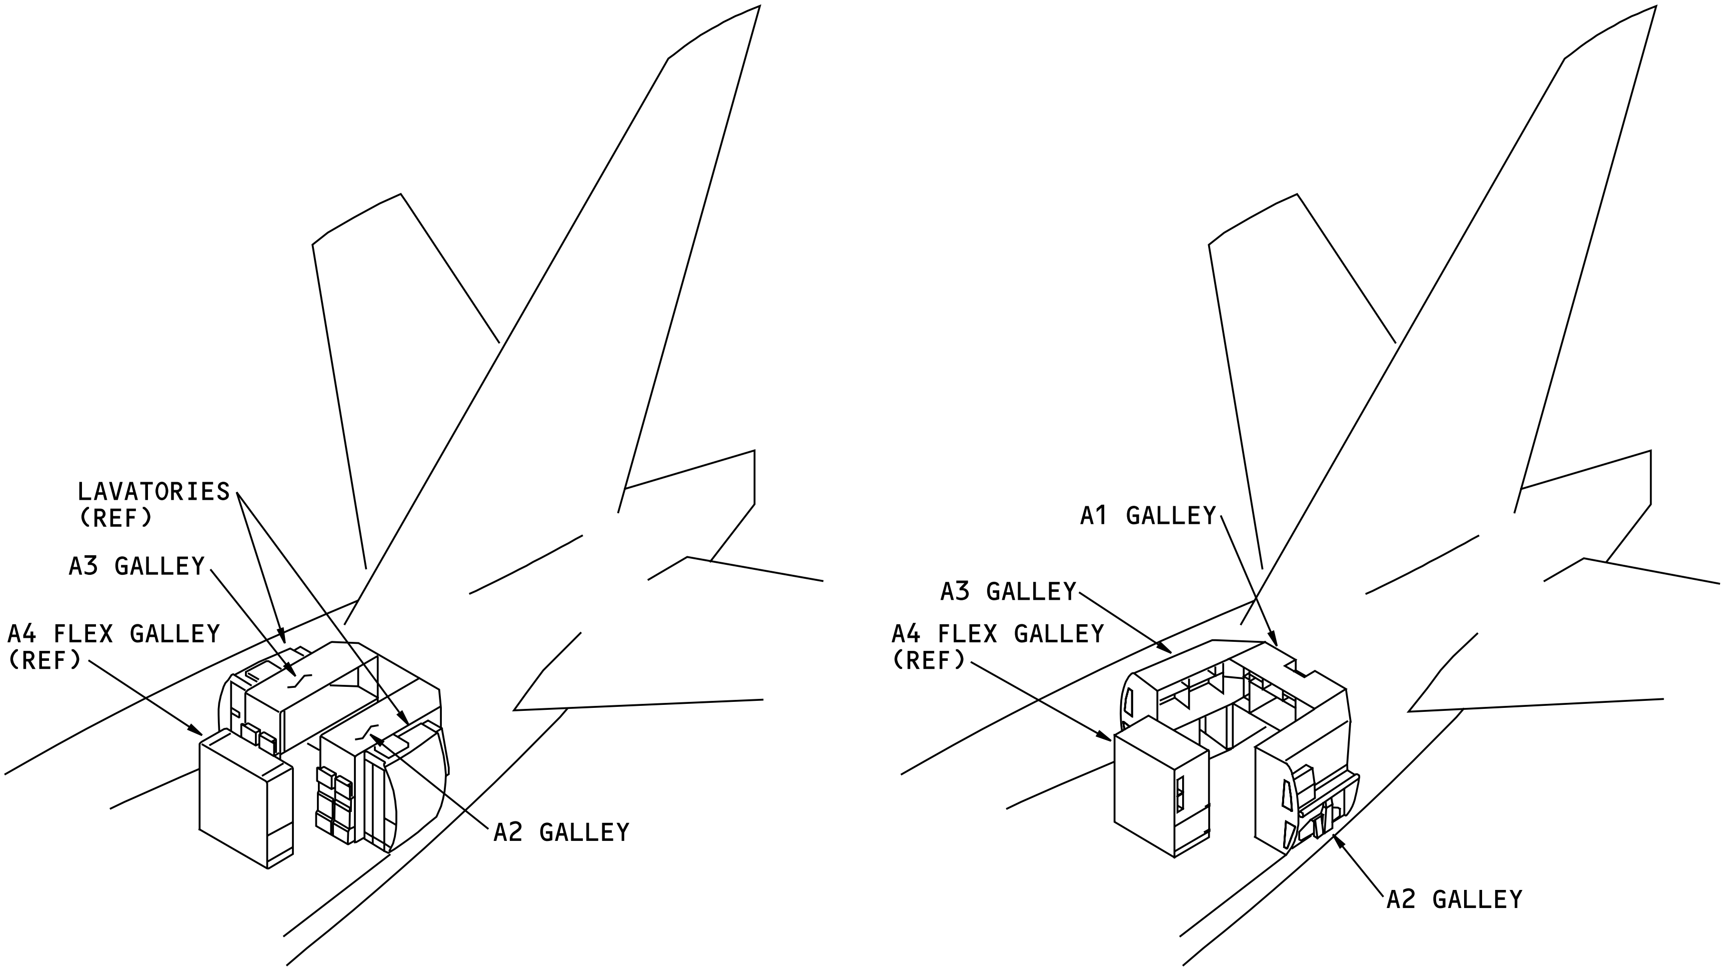
The A1 galley is at the center of the passenger compartment, aft of aft door. The galley faces forward.

The A2 galley is on the left side of the passenger compartment, aft of aft door. The galley faces inboard.

The A3 galley is at the right side of the passenger compartment, aft of aft door. The galley faces inboard.

Air Chillers

One or two air chillers (not shown) can be installed in the lower lobe area aft of the bulk cargo compartment. A chiller supplies cold air for refrigeration compartments in the aft fixed galleys.



AFT FIXED GALLEY
(POSSIBLE LOCATIONS)

BUFFET AND GALLEY - AFT FIXED GALLEY - INTRODUCTION

BUFFET AND GALLEY - LOWER LOBE AIR CHILLER

Purpose

The air chillers supply cold air to the carts or compartments of the aft fixed galleys that need refrigeration.

Location

One or two air chillers can be installed in the lower lobe area, aft of the bulk cargo compartment. Remove the left aft end wall panel to get access.

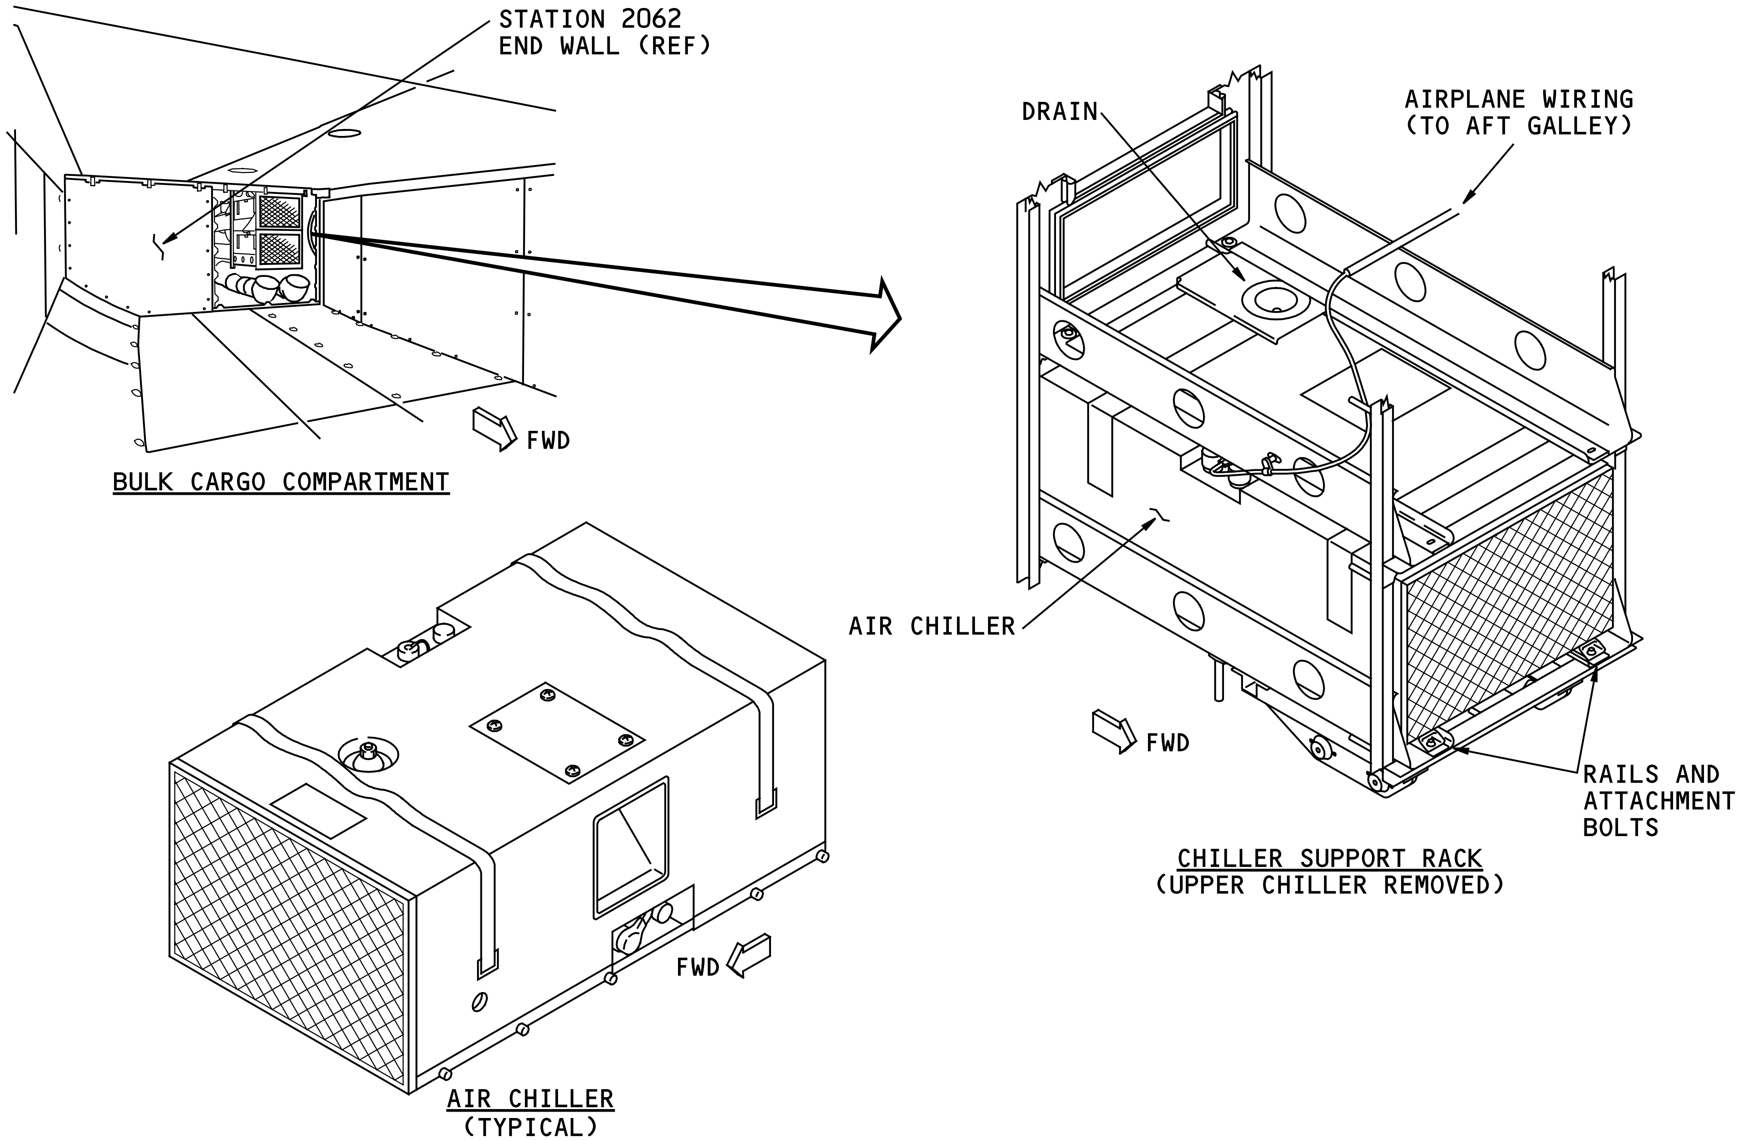
Supply and return air ducts (not shown) connect the air chillers to the appropriate galley. One or more of the galleys can have a supply and return duct connected to it. The ducts go aft and outboard of the chillers, near the aft pressure bulkhead (not shown).

Features

The air chiller is a vapor-cycle cooling unit.

The chiller attaches to rails with bolts. The rails attach with bolts to a support rack which hangs from the passenger compartment floor. When you remove a chiller, remove the bolts that attach the rails to the support rack. Remove the chiller with the rails attached to it.

Electrical power and control for the chiller comes from the aft galley. A wire bundle (not shown) connects the air chiller to the aft galley.



25-30-00-008 Rev 1 03/05/1998

BUFFET AND GALLEY - LOWER LOBE AIR CHILLER

BUFFET AND GALLEY - AIR CHILLER - PHYSICAL DESCRIPTION

Physical Description

The air chiller is a vapor-cycle cooling unit. It has these parts:

- Lifting strap (2)
- Condenser air exhaust (top)
- Chilled air outlet (evaporator outlet)
- Chilled air return (evaporator inlet)
- Condenser air exhaust (side)
- Electrical connector (2)
- Refrigerant sight glass
- Air filter (condenser air inlet).

The chiller weighs approximately 85 pounds (39 kg). A drain in the bottom of the chiller (not shown) carries the water away. Shop technicians use the refrigerant sight glass during servicing.

Exhaust Ports

The chiller has two condenser air exhaust ports to permit alternate installations. When you install a chiller, make sure that one port is open and the other port has a cover plate.

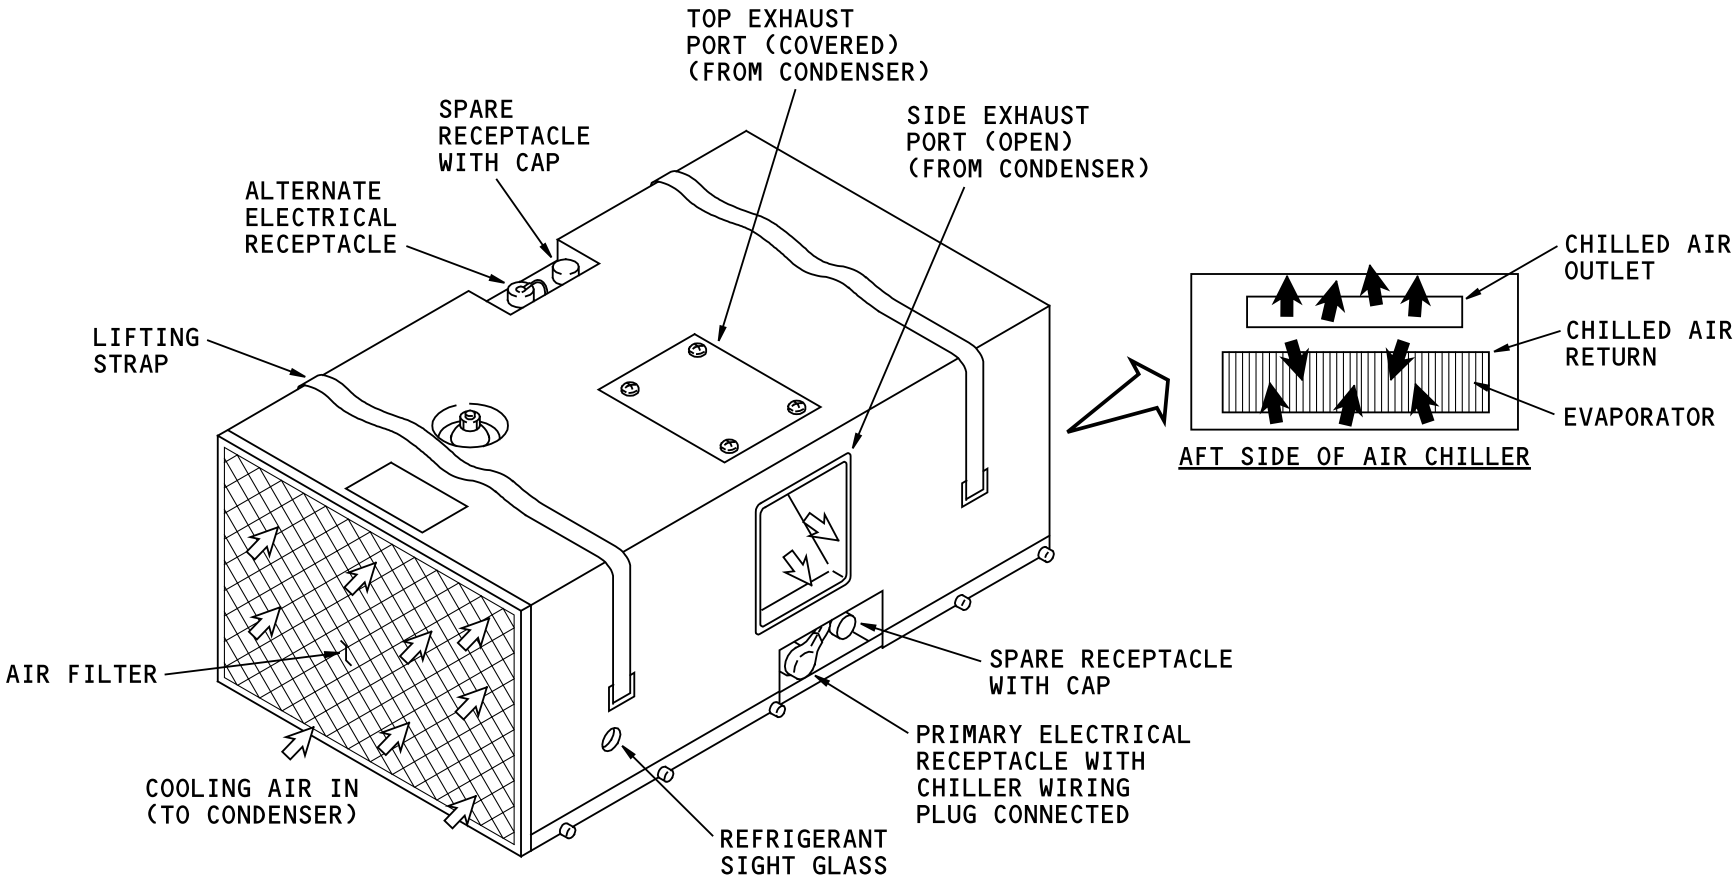
Electrical Receptacles

The chiller has two electrical receptacles. The primary receptacle (W4J1) is on the side of the chiller. The alternate receptacle (W3J1) is on top of the chiller. If you connect the airplane wiring to the alternate (top) receptacle. Connect the chiller wiring plug W3P1 to the primary (side) connector. Stow the two connector caps on the adjacent spare receptacles.

If you connect the airplane wiring to the primary receptacle (W4J1), stow the chiller wiring plug (W3P1) on the adjacent spare receptacle. Put one of the space caps on the alternate receptacle (W3J1).

Air Inlet Filter

You can clean the condenser air inlet filter. Remove the filter from the chiller. Wash the filter with soap and water then rinse the filter with clean water. Dry the filter with compressed air.



GALLEY AIR CHILLER
(TYPICAL)

25-30-00-010 Rev 1 02/27/1998

BUFFET AND GALLEY - AIR CHILLER - PHYSICAL DESCRIPTION

BUFFET AND GALLEY - OVERHEAD AIR CHILLER

Purpose

Overhead air chillers supply cold air for refrigeration.

Location

One or two air chiller can be above a galley to which it supplies chilled air. Usual refrigeration for a galley requires only one chiller. The forward galley area is shown as an example for a typical installation of an overhead chiller. These galleys have an overhead chiller(s):

- F-1.
- F-2.
- M-1.
- M-2.

Features

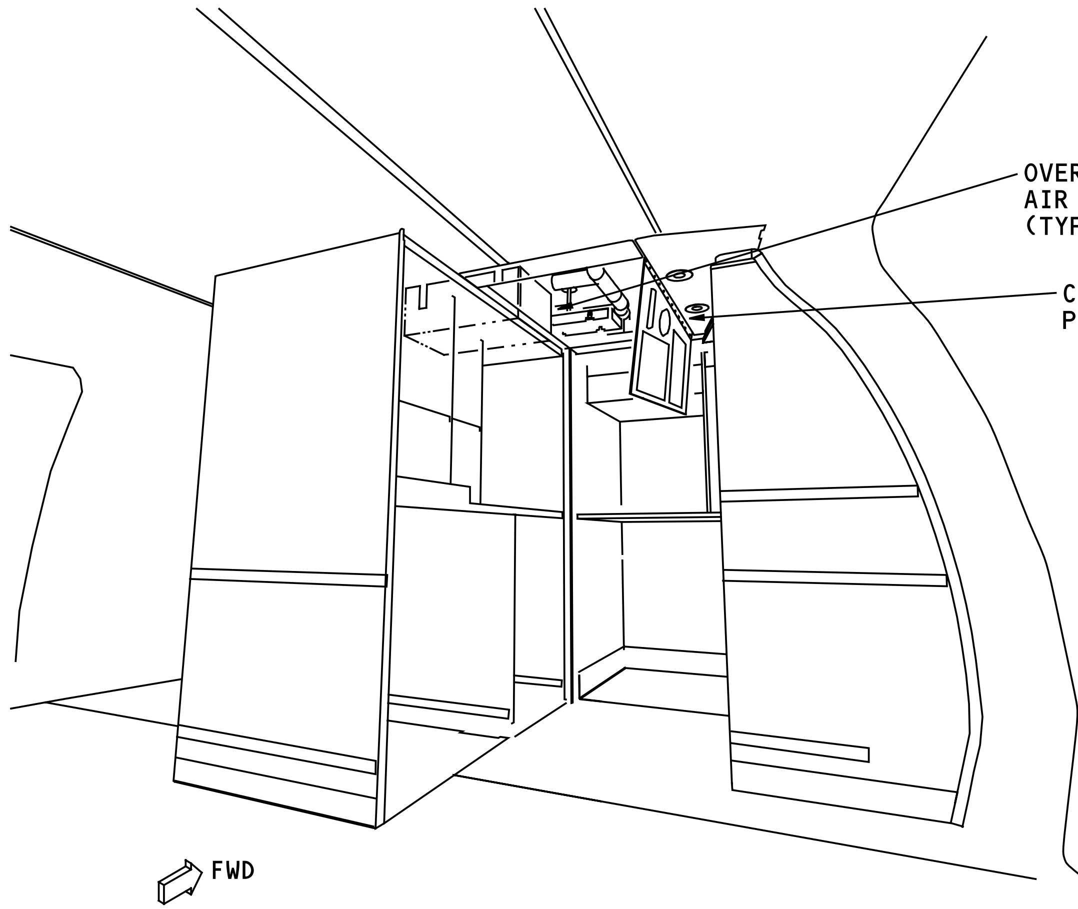
The air chiller is a vapor-cycle cooling unit.

The chiller attaches to a carriage with bolts. The carriage has wheels that fit into a rail assembly. The carriage and the rail assembly lets you move the chiller horizontally. The carriage and rail assembly also let you rotate the chillier to a vertical position. When you remove a chiller, remove the bolts that attach the carriage to the rails. Pull the chiller until the wheels on the carriage move into a detent in the rails. Pull down on the chillers to make it rotate to the vertical position. Lift the chiller and carriage up and off of the rails. Lower the chiller and carriage to the floor.

Electrical power and control for the chiller come from its related galley. A wire bundle connects the air chiller to the galley.

Training Information Point

Lower the ceiling panel adjacent to the galley to get access to the air chiller.



FORWARD GALLEY AREA
(TYPICAL)

BUFFET AND GALLEY - OVERHEAD AIR CHILLER

LOWER LOBE CARGO COMPARTMENT - INTRODUCTION

General Description

The lower lobe cargo compartments include forward, aft, and bulk cargo compartments. Heating and ventilating systems control the temperature and air quality in the lower lobe cargo compartments. The airplane can carry live animals in the bulk cargo compartment.

The lower lobe cargo compartments are class C for fire protection and have these features:

- Smoke detection systems tell the crew of smoke in the cargo compartments
- Cargo compartments have fire extinguishing systems which operate from the flight deck
- Compartment linings and the environmental control systems keep dangerous quantities of smoke and extinguishing agent out of the passenger and crew cabins
- Compartment linings meet specified burn through requirements.

Cargo linings make a closed area for the cargo compartments but permit access to other systems. Closed compartments are necessary for fire protection and temperature control.

WARNING: SEAL THE COMPARTMENT WITH THE LINERS. OBEY THE INSTRUCTIONS IN THE SPECIFIED PROCEDURE WHEN YOU INSTALL THE LINERS. IF YOU INSTALL THE LINERS INCORRECTLY, THE FIRE WILL NOT BE CONTAINED AND THE EXTINGUISHING AGENT OR SMOKE CAN GET INTO THE PASSENGER COMPARTMENT DURING A FIRE.

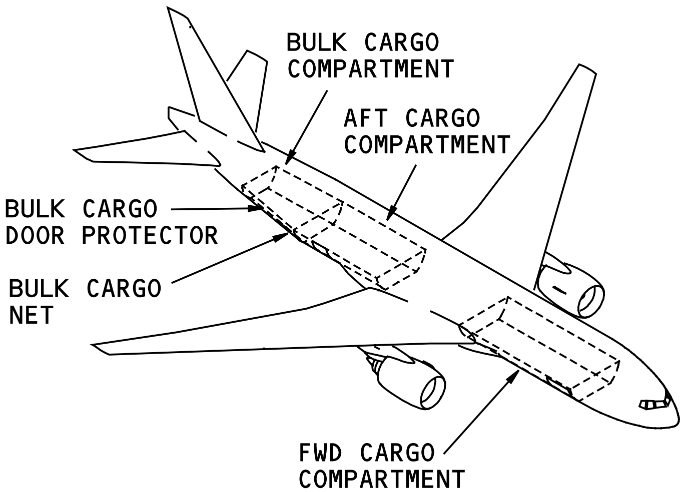
Lower lobe cargo compartments have these items:

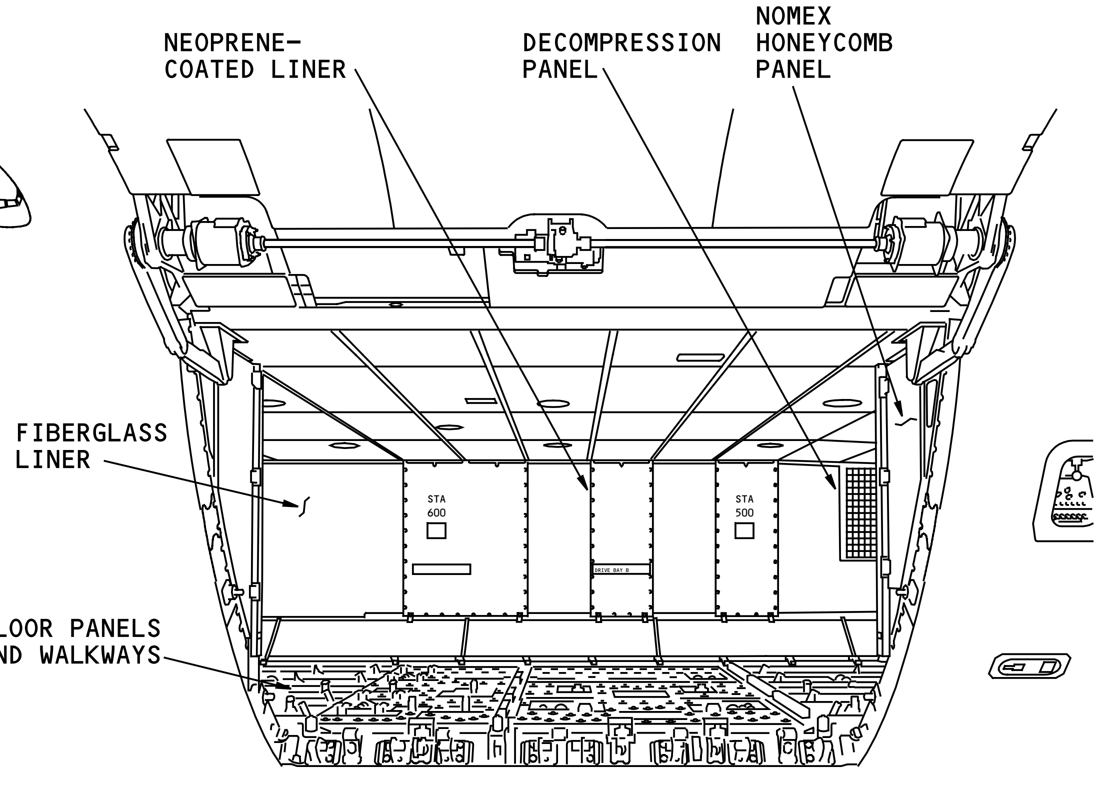
- Bulk cargo door protector
- Bulk cargo net
- Floor panels and walkways
- Fiberglass liners
- Neoprene-coated liner
- Decompression panels
- Nomex honeycomb panels.

Training Information Point

When you work in the cargo compartment, install a safety barrier in the doorway.

WARNING: INSTALL THE SAFETY BARRIER CORRECTLY WHEN THE CARGO DOOR IS OPEN. IF YOU DO NOT CORRECTLY INSTALL THE SAFETY BARRIER, PERSONS CAN FALL OUT OF THE CARGO COMPARTMENT AND INJURY CAN OCCUR.





FWD CARGO COMPARTMENT
(TYPICAL)

25-52-00-001 Rev 1 04/10/1997

LOWER LOBE CARGO COMPARTMENT - INTRODUCTION

LOWER LOBE CARGO COMPARTMENT - FIBERGLASS LINERS

Purpose

Fiberglass liners help isolate the cargo compartments from other parts of the airplane for fire protection and temperature control. The bulk cargo compartment liners also help transmit cargo loads to the airplane structure.

Physical Description

These cargo compartment liners are made from rigid fiberglass material:

- Sidewall liners
- Ceiling liners
- Station 1437 end wall.

These devices attach the fiberglass liners to the structure:

- Bolts
- Screws
- Scrivets
- Hook-and-loop tape.

Tape seals the edges and seams.

Location

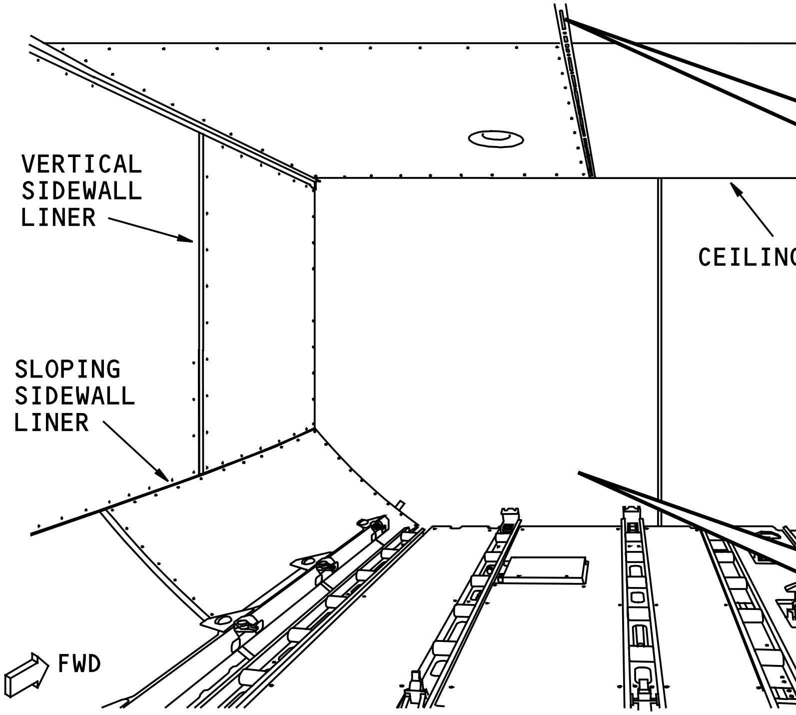
Sidewall liners extend from the floor to the ceiling along both sides of the forward, aft and bulk cargo compartments. The upper liner is a vertical sidewall liner. The lower liner is a sloping sidewall liner.

Ceiling liners make the ceilings of the cargo compartments.

The station 1437 end wall is at the forward end of the aft cargo compartment.

Training Information Point

You must repair fiberglass liners which have cuts, tears or holes. If the damage is in specified limits, you can repair the liner with a patch. Otherwise you must replace the damaged liner. Special patch kits permit you to make bonded patch repairs without removing the liner from the airplane.



AFT CARGO COMPARTMENT

(AFT CARGO COMPARTMENT)

25-52-00-002 Rev 0

LOWER LOBE CARGO COMPARTMENT - FIBERGLASS LINERS

LOWER LOBE CARGO COMPARTMENT - NEOPRENE-COATED LINER

Purpose

Neoprene-coated liners help isolate the cargo compartments from other parts of the airplane for fire protection and temperature control. Neoprene-coated liners are also access panels to equipment behind them.

Physical Description

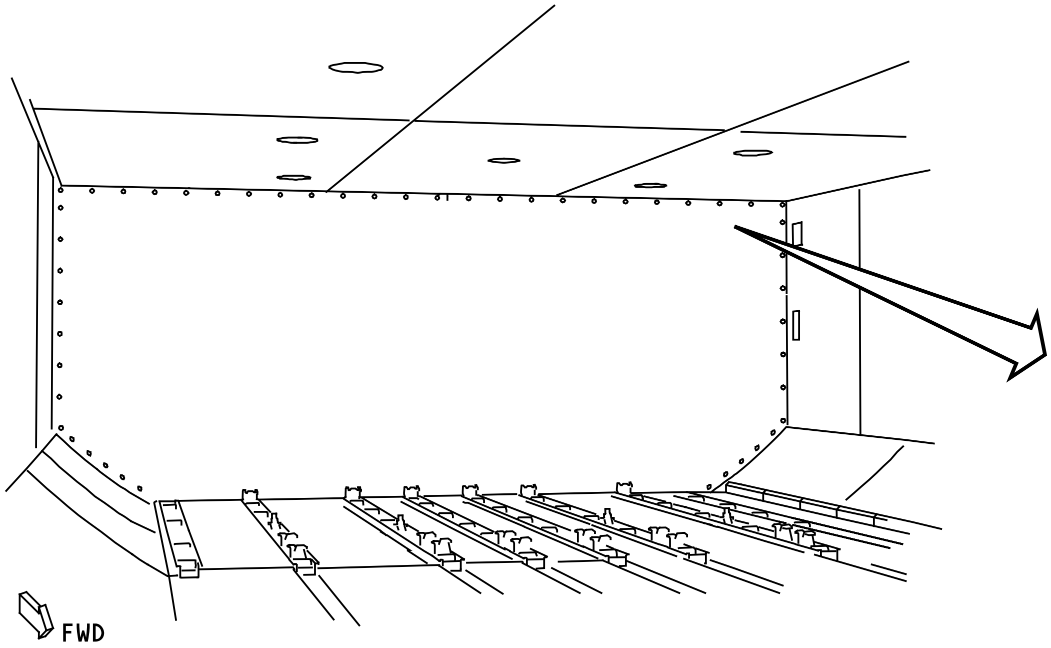
The liners are made from flexible neoprene-coated fiberglass. Snaps hold the liners in place.

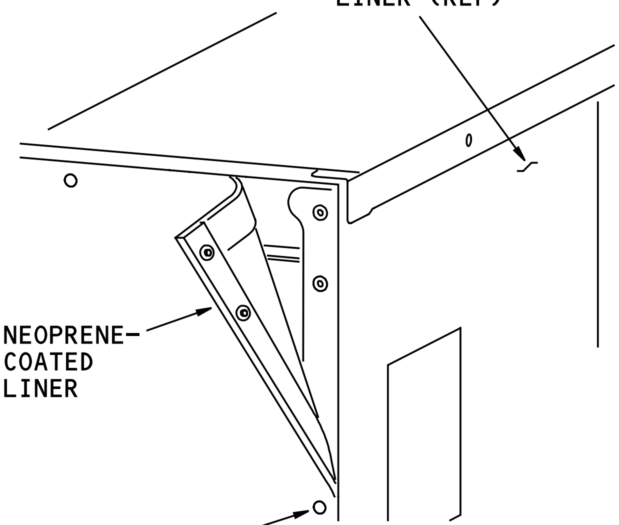
Location

The station 998 end wall is a neoprene-coated liner. It is at the aft end of the forward cargo compartment. Some of the vertical sidewall linings (not shown) in the forward and aft cargo compartments are also this type.

Training Information Point

You must repair cuts, tears or holes in the neoprene-coated liners. If the damage is in specified limits, you can repair the liner with a patch. Otherwise, you must replace the damaged liner.





25-52-00-003 Rev 0

LOWER LOBE CARGO COMPARTMENT - NEOPRENE-COATED LINER

LOWER LOBE CARGO COMPARTMENT - NOMEX HONEYCOMB PANELS

Purpose

The Nomex honeycomb panels help isolate the cargo compartments from other parts of the airplane for fire protection and temperature control. The panels also transmit cargo loads to the airplane structure.

Physical Description

These cargo compartment liners are made from Nomex honeycomb panels:

- Station 2062 end wall
- Waste tank enclosure panels
- Main equipment center bulkhead liner.

Latches and quarter-turn fasteners attach the station 2062 end wall to the structure.

Quarter-turn fasteners attach the waste tank enclosure panels to the structure.

The access door to the main equipment center has a hinge on the outboard side. A door restraint holds the door open. The door restraint folds to let the door close. Latches hold the door closed. Quarter-turn fasteners attach the stationary main equipment center bulkhead liners to the structure.

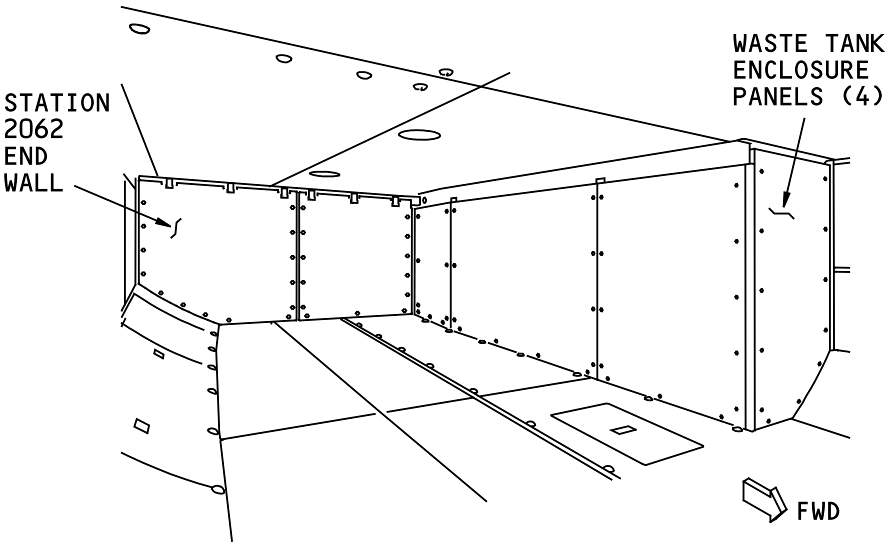
The main equipment center access door and all the panels have built-in seals.

Location

The station 2062 end wall is at the aft end of the bulk cargo compartment.

The waste tank enclosure panels are on the left side of the bulk cargo compartment.

The main equipment center bulkhead liner is at the forward end of the forward cargo compartment.



BULK CARGO COMPARTMENT

LOWER LOBE CARGO COMPARTMENT - NOMEX HONEYCOMB PANELS

LOWER LOBE CARGO COMPARTMENT - EQUIPMENT RACK ACCESS DOORS

Physical Description

These equipment rack access doors are made from Nomex honeycomb sandwich material:

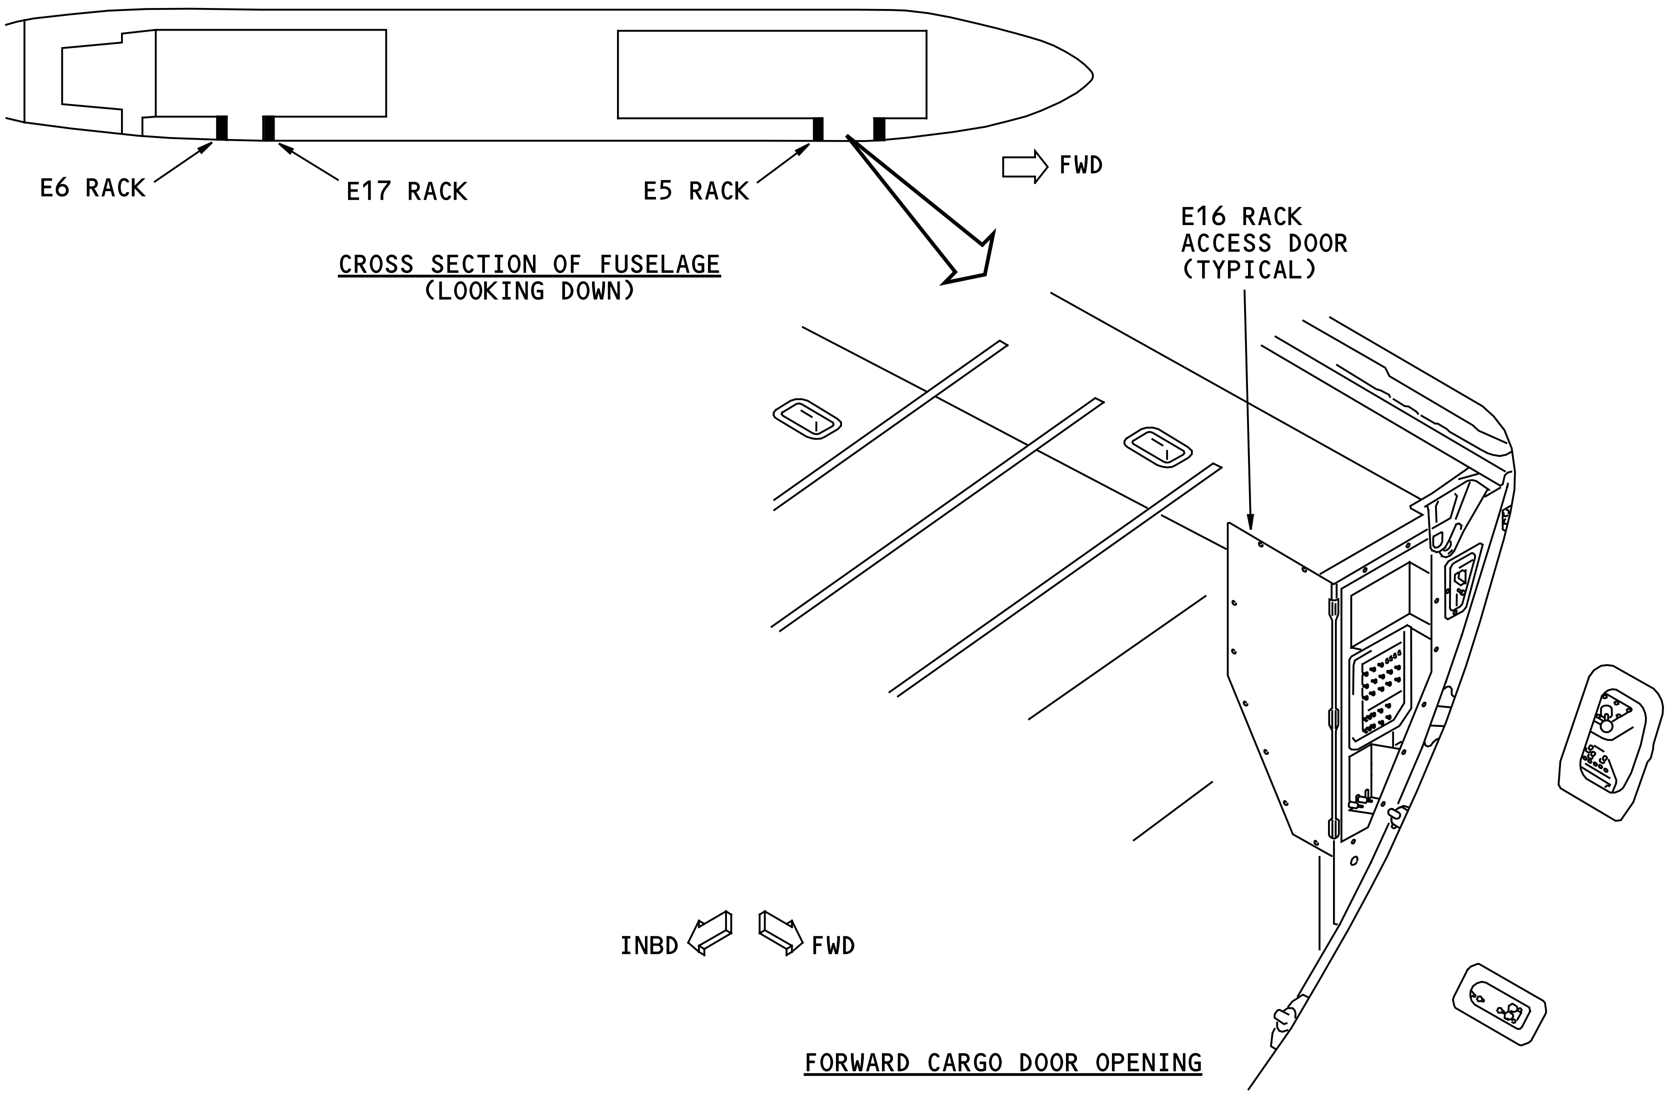
- E6 equipment rack
- E17 equipment rack
- E5 equipment rack
- E16 equipment rack.

The doors have a hinge on the inboard side. Quarter-turn fasteners hold the doors closed. The access doors have built-in seals.

Location

The E6 rack is at the aft edge of the aft cargo door opening. The E17 rack is at the forward edge of the aft cargo door opening.

The E5 rack is at the aft edge of the forward cargo door opening. The E16 rack is at the forward edge of the forward cargo door opening.



25-52-00-005 Rev 0

LOWER LOBE CARGO COMPARTMENT - EQUIPMENT RACK ACCESS DOORS

LOWER LOBE CARGO COMPARTMENT - DECOMPRESSION PANELS

Purpose

Decompression panels prevent fuselage structural damage if there is sudden decompression of the passenger compartment.

Physical Description

The decompression panel has these parts:

- Frame
- Vent
- Seal
- Blowout panel.

The blowout panel is a thin sheet of fiberglass held in the frame by seals. The vent is an aluminum grate which protects the blowout panel from impact. Bolts (not shown) hold the vent to the frame.

Screws go through the frame to hold the decompression panel in place. Tape seals the frame to the cargo compartment liner.

Location

Two decompression panels are in the forward cargo compartment, one on the left side and one on the right side. Two panels are in the aft cargo compartment on the left side.

Functional Description

The blowout panel normally seals air inside the cargo compartment. If there is a rapid decompression of the passenger compartment, differential pressure pushes the blowout panel from the frame. Pressure in the cargo compartment quickly becomes equal to the reduced pressure in the passenger compartment. This prevents damage to the passenger compartment floor from too much pressure against the underside.

Training Information Point

The decompression panel must be air-tight for proper fire protection; the panel must be installed and sealed correctly. The blowout panel must be held to the frame on all four sides by the seals.

25-52-00-006 Rev 1 04/10/1997

LOWER LOBE CARGO COMPARTMENT - DECOMPRESSION PANELS

LOWER LOBE CARGO COMPARTMENT - FLOOR PANELS AND WALKWAYS

Purpose

Floor panels and walkways make it easy for the ground crew to move around inside the cargo compartments.

The aft end of the floor panels and walkways make a smoke barrier between the cargo compartments and other areas of the airplane.

Physical Description

The floor panels and walkways are made of fiberglass-faced Nomex honeycomb core sandwich panel material. Countersunk screws attach the panels to the support structure.

Location

Floor panels and walkways are in the floor of the forward and aft cargo compartments.

EMERGENCY - INTRODUCTION

General Description

The airplane has this emergency equipment:

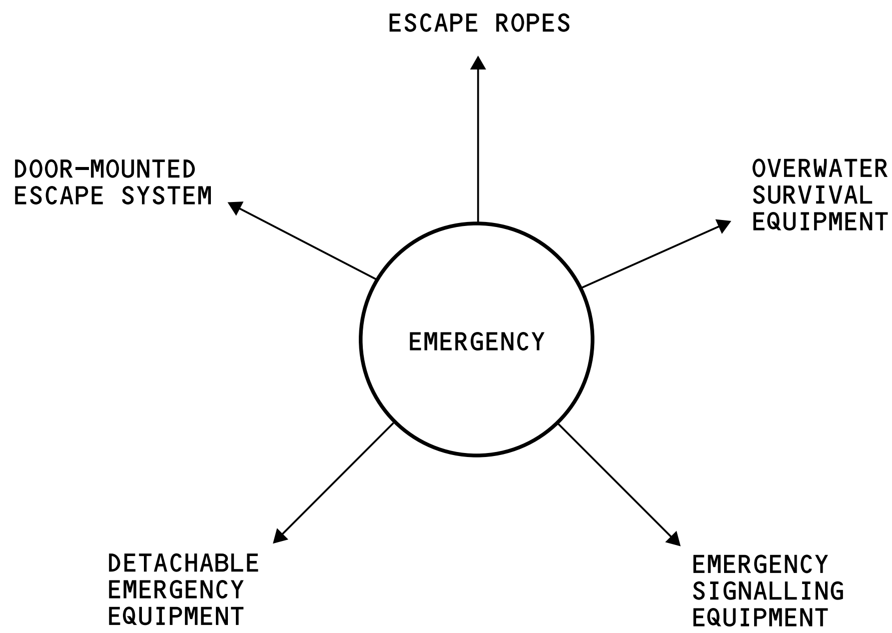
- Escape ropes
- Overwater survival equipment
- Emergency signaling equipment
- Detachable emergency equipment
- Door-mounted escape system.

The door-mounted escape system and escape ropes help passengers and crew get out of the airplane in an emergency. See the door-mounted escape system section for more information about the door-mounted escape system (AMM PART I 25-66).

Life vests are the overwater survival equipment.

Emergency signalling equipment includes emergency locator transmitters and the emergency evacuation signal system.

Detachable emergency equipment includes fire-fighting equipment, medical equipment, megaphones, and flashlights.



25-60-00-001 Rev 2 02/24/1997

EMERGENCY - INTRODUCTION

EMERGENCY - ESCAPE ROPES

Purpose

The escape ropes permit the flight crew to make their way safely to the ground through the number 2 windows.

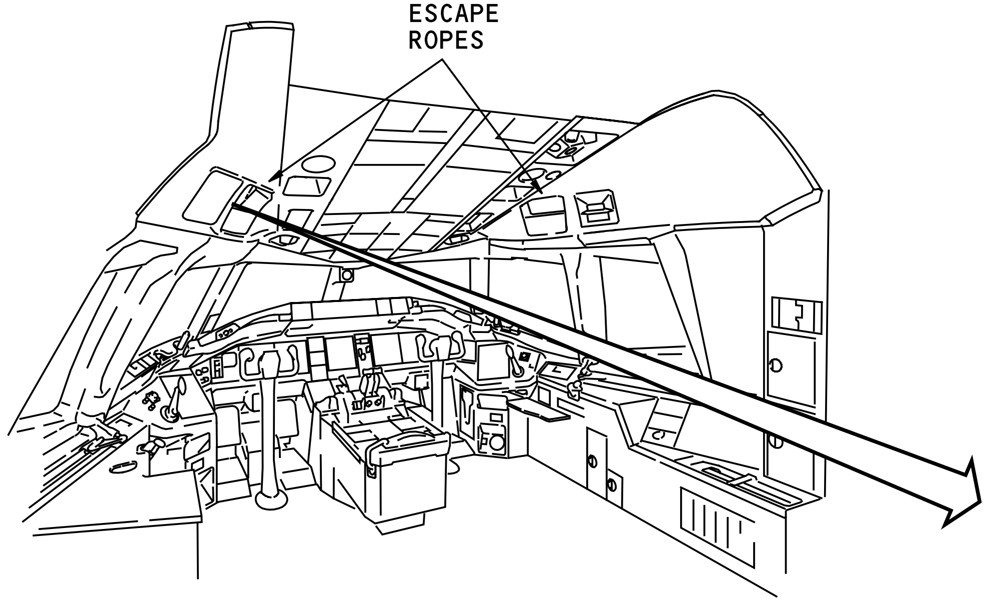
Physical Description

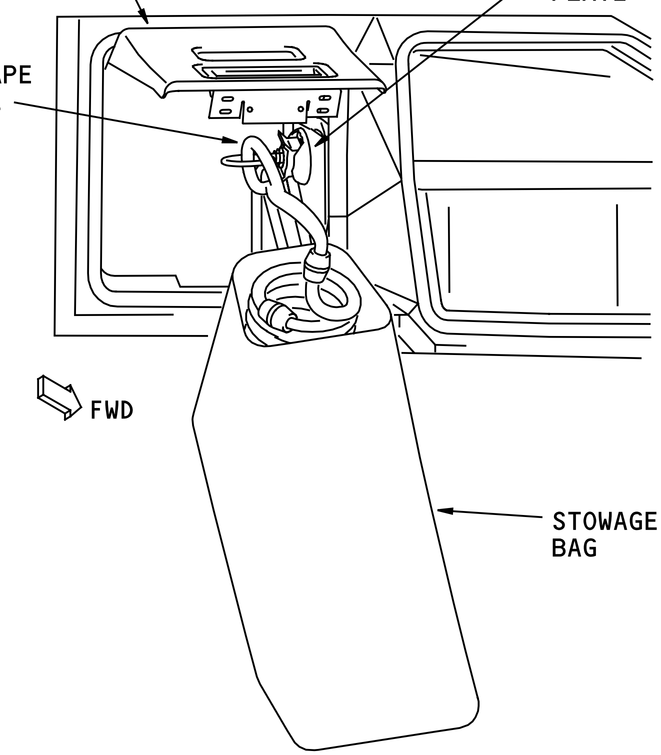
One end of the escape rope attaches to the airplane structure. The other end is coiled and stored in a stowage bag.

Location

The rope and stowage bag are behind doors in the flight deck lining above the number 2 windows.

WARNING: DO NOT CLOSE OR ATTACH THE BAG. IF THE BAG IS CLOSED OR ATTACHED, THE BAG AND THE ROPE WILL NOT FALL FROM THE POCKET IN AN EMERGENCY. INJURY TO PERSONS CAN RESULT.





ESCAPE ROPE STOWAGE BAG

25-60-00-002 Rev 1 07/02/1997

EMERGENCY - ESCAPE ROPES

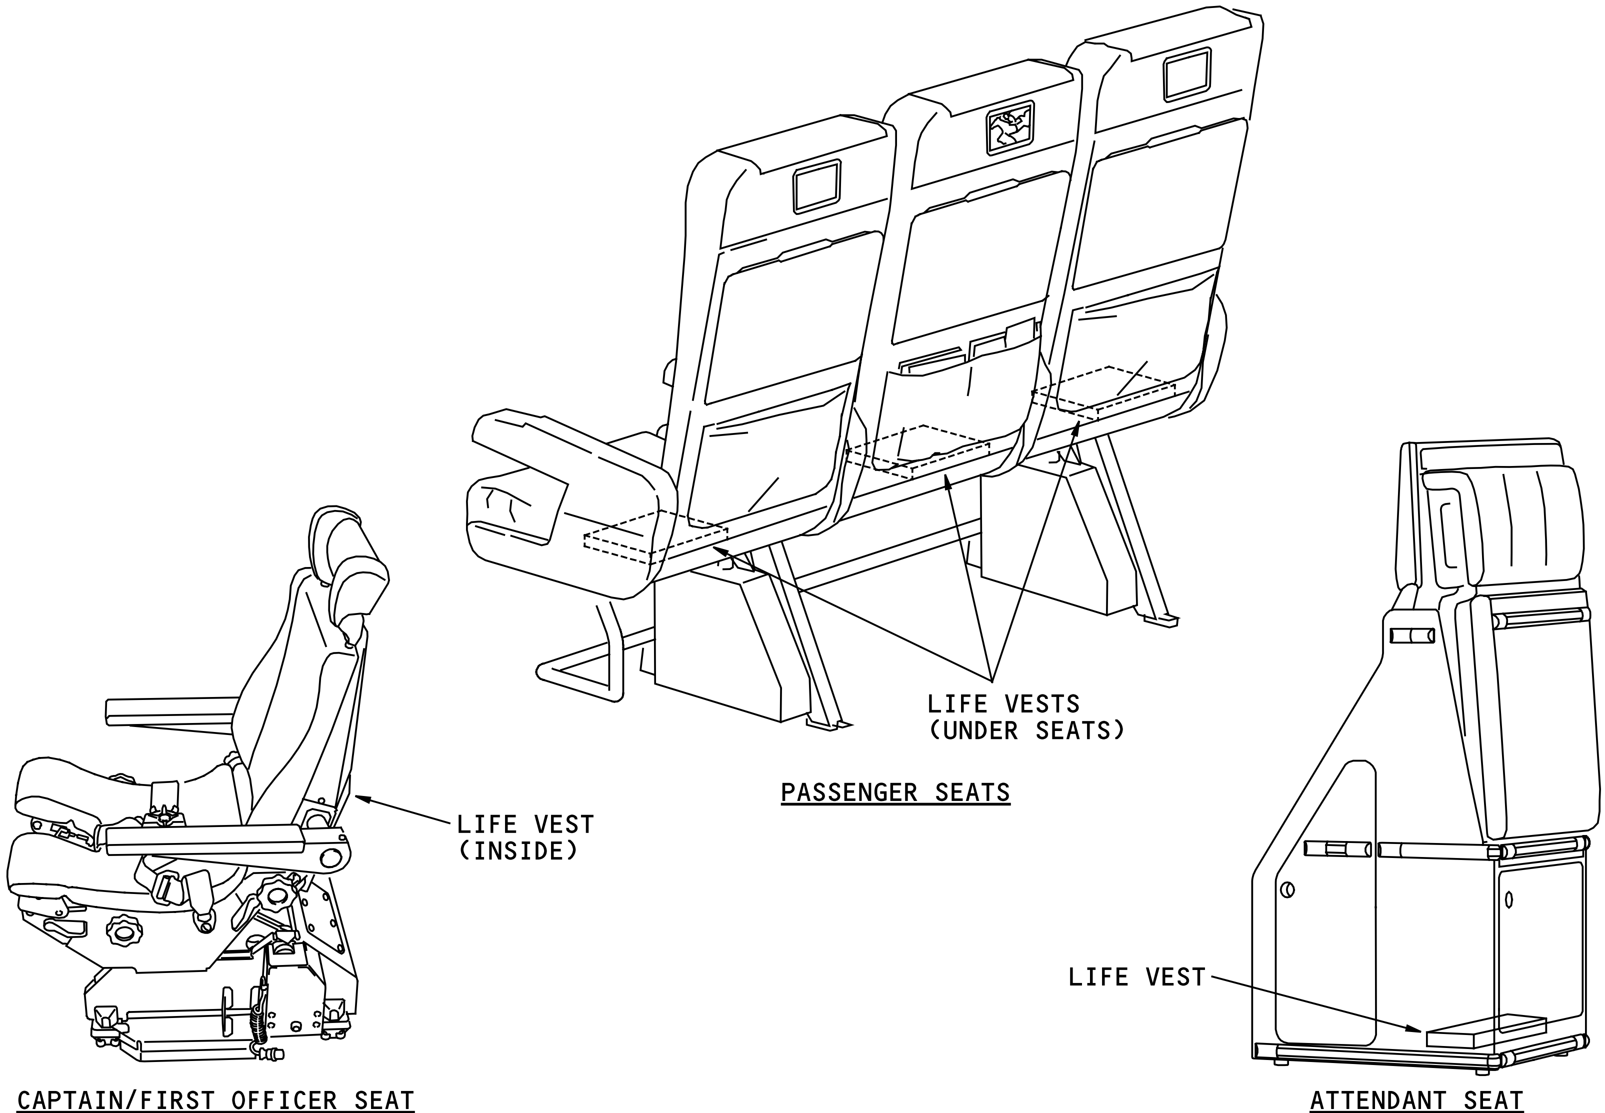
EMERGENCY - OVERWATER SURVIVAL EQUIPMENT - LIFE VESTS

General

The airplane has life vests for each passenger and crewmember. The vests are sealed in protective packages and stored in seat pouches.

Training Information Point

Make sure there is a life vest at every seat in the airplane. Make sure each vest is in a sealed protective package. If the package is damaged, make sure there is no damage to the life vest.



25-60-00-003 Rev 0

EMERGENCY - OVERWATER SURVIVAL EQUIPMENT - LIFE VESTS

EMERGENCY - EMERGENCY LOCATOR TRANSMITTER

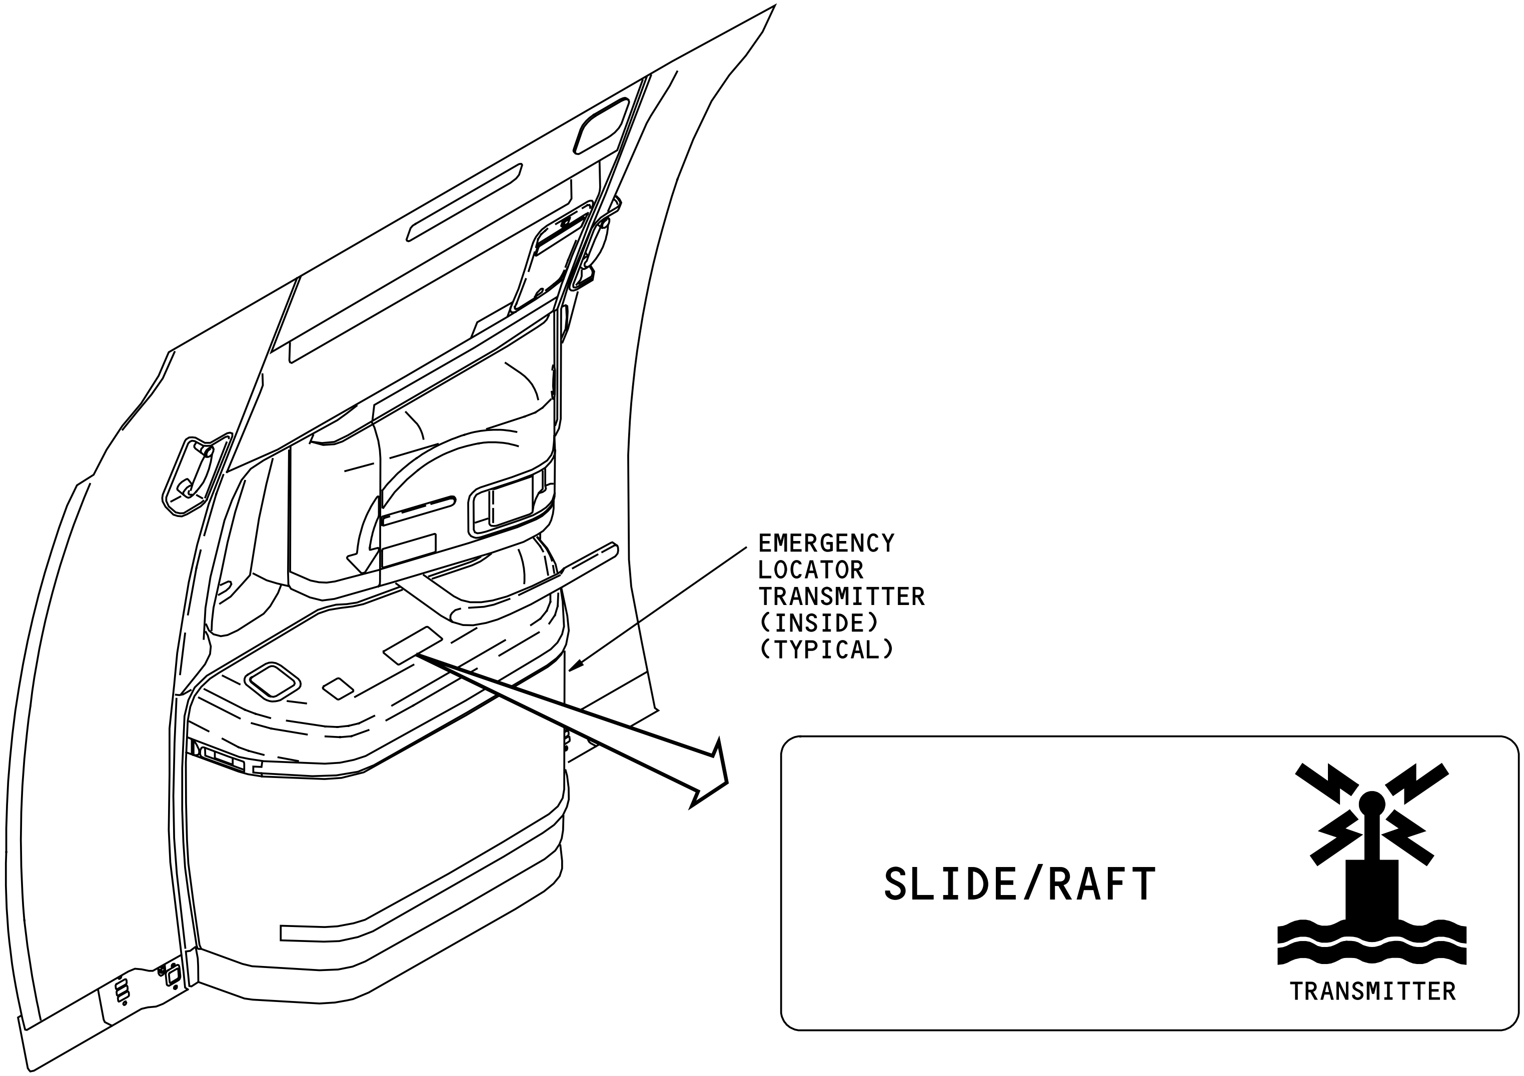
General

Emergency locator transmitters help rescue crews find airplanes which have landed away from an airport. The transmitters send a radio signal to satellites, other airplanes, or air traffic control facilities. Rescue crews use information from these sources to find the airplane.

Location

There are emergency locator transmitters at one or more of the these locations:

- Escape slide pack on the passenger entry door
- Emergency storage compartments (not shown).



25-60-00-004 Rev 0 12/18/1995

EMERGENCY - EMERGENCY LOCATOR TRANSMITTER

EMERGENCY - DETACHABLE EMERGENCY EQUIPMENT

General

These items of detachable emergency equipment are in the flight deck:

- Crash axe
- Fire gloves
- Smoke goggles
- Portable fire extinguisher
- Protective breathing equipment
- First aid kit.

These items of detachable emergency equipment are in the passenger compartment:

- Megaphones
- Flashlights
- Portable oxygen bottles
- Portable fire extinguishers
- Protective breathing equipment
- First aid kits.

Placards in the airplane mark the locations of these items.

WATER AND WASTE - INTRODUCTION

General

The water system supplies potable water to the lavatories and galleys. The waste system keeps waste from the toilets and gives a way to remove it.

The potable water system has these subsystems:

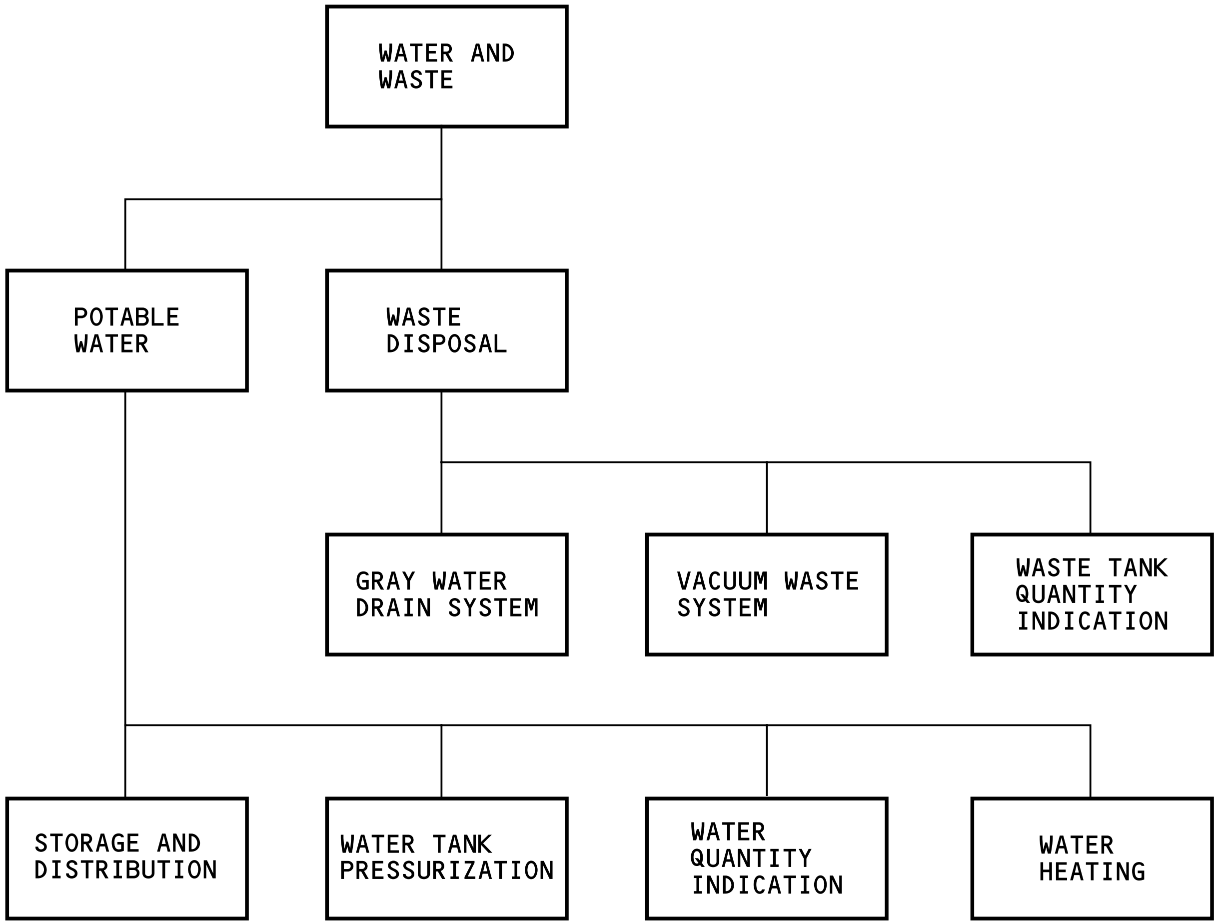
- Storage and distribution
- Water tank pressurization
- Water quantity indication
- Water heating.

These subsystems are in the waste disposal system:

- Gray water drain system
- Vacuum waste system
- Waste tank quantity indication.

Abbreviations and Acronyms

CACP	- cabin area control panel
CPRSR	- compressor
CSCP	- cabin system control panel
CSS	- cabin services system
FCU	- flush control unit
INTLK	- interlock
LCM	- logic control module
SW	- switch



38-00-00-001 Rev 1 03/12/1997

WATER AND WASTE - INTRODUCTION

WATER AND WASTE - GENERAL DESCRIPTION

Potable Water System

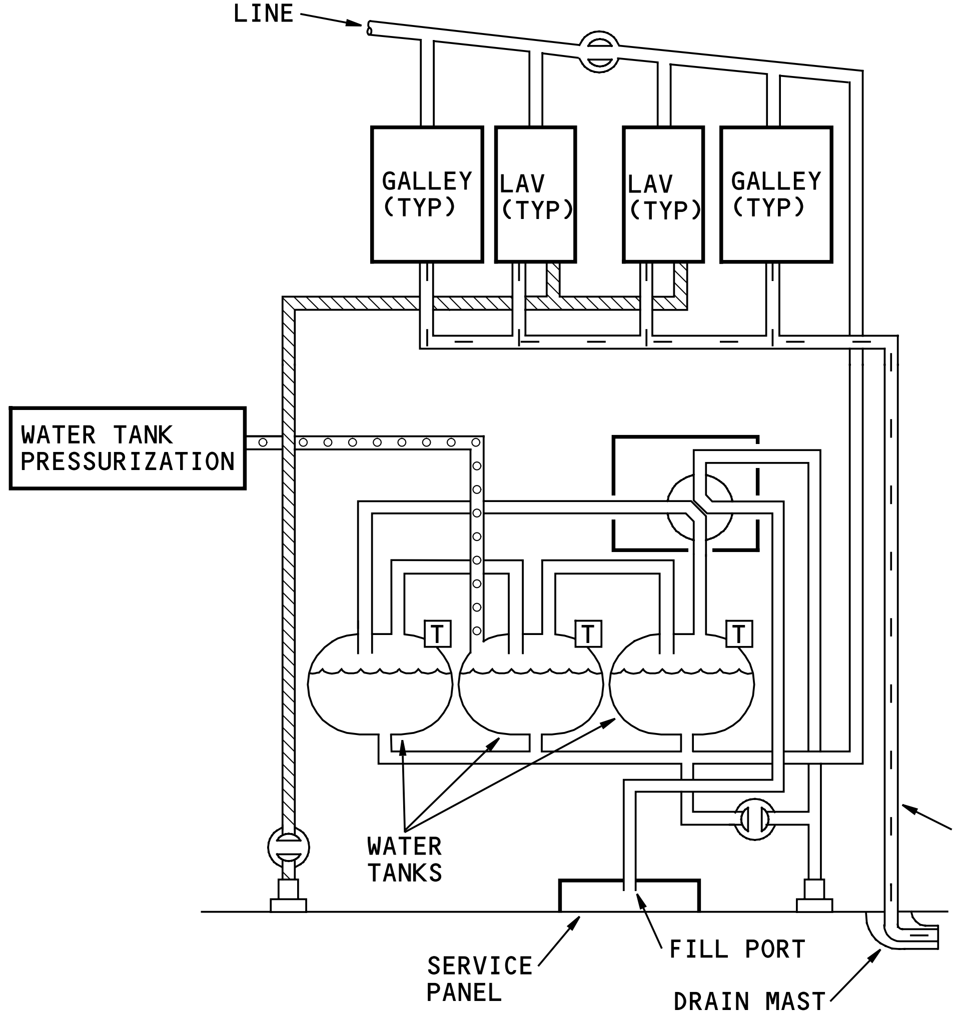
There are three potable water tanks. The pneumatic system or a compressor pressurizes the tanks. The pressure inside the tanks pushes the water through distribution lines to the lavatories and galleys. Potable water also goes to the toilets in the lavatories to flush the vacuum toilet bowls.

Waste Disposal System

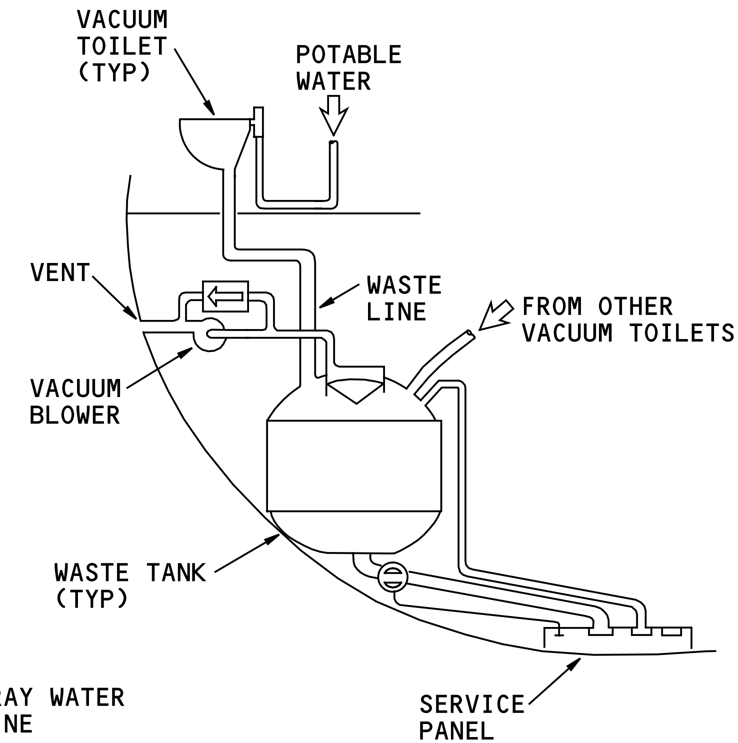
Gray water drains from the sinks in the lavatories and galleys. This gray water goes through drain lines to either of two drain masts on the bottom of the fuselage.

Each lavatory has a vacuum toilet. Waste lines connect the lavatories to one of three waste tanks. Each tank gets waste from a specified group of lavatories.

A vacuum in the tank pulls the waste from the toilet into the tank.



POTABLE WATER AND GRAY WATER SYSTEMS
(TYPICAL)



VACUUM WASTE SYSTEM
(TYPICAL)

38-00-00-002 Rev 3 07/18/1997

WATER AND WASTE - GENERAL DESCRIPTION

WATER STORAGE AND DISTRIBUTION - INTRODUCTION

Purpose

The water storage and distribution system supplies potable water to the lavatories and galleys.

General Description

There are three water tanks that contain potable water.

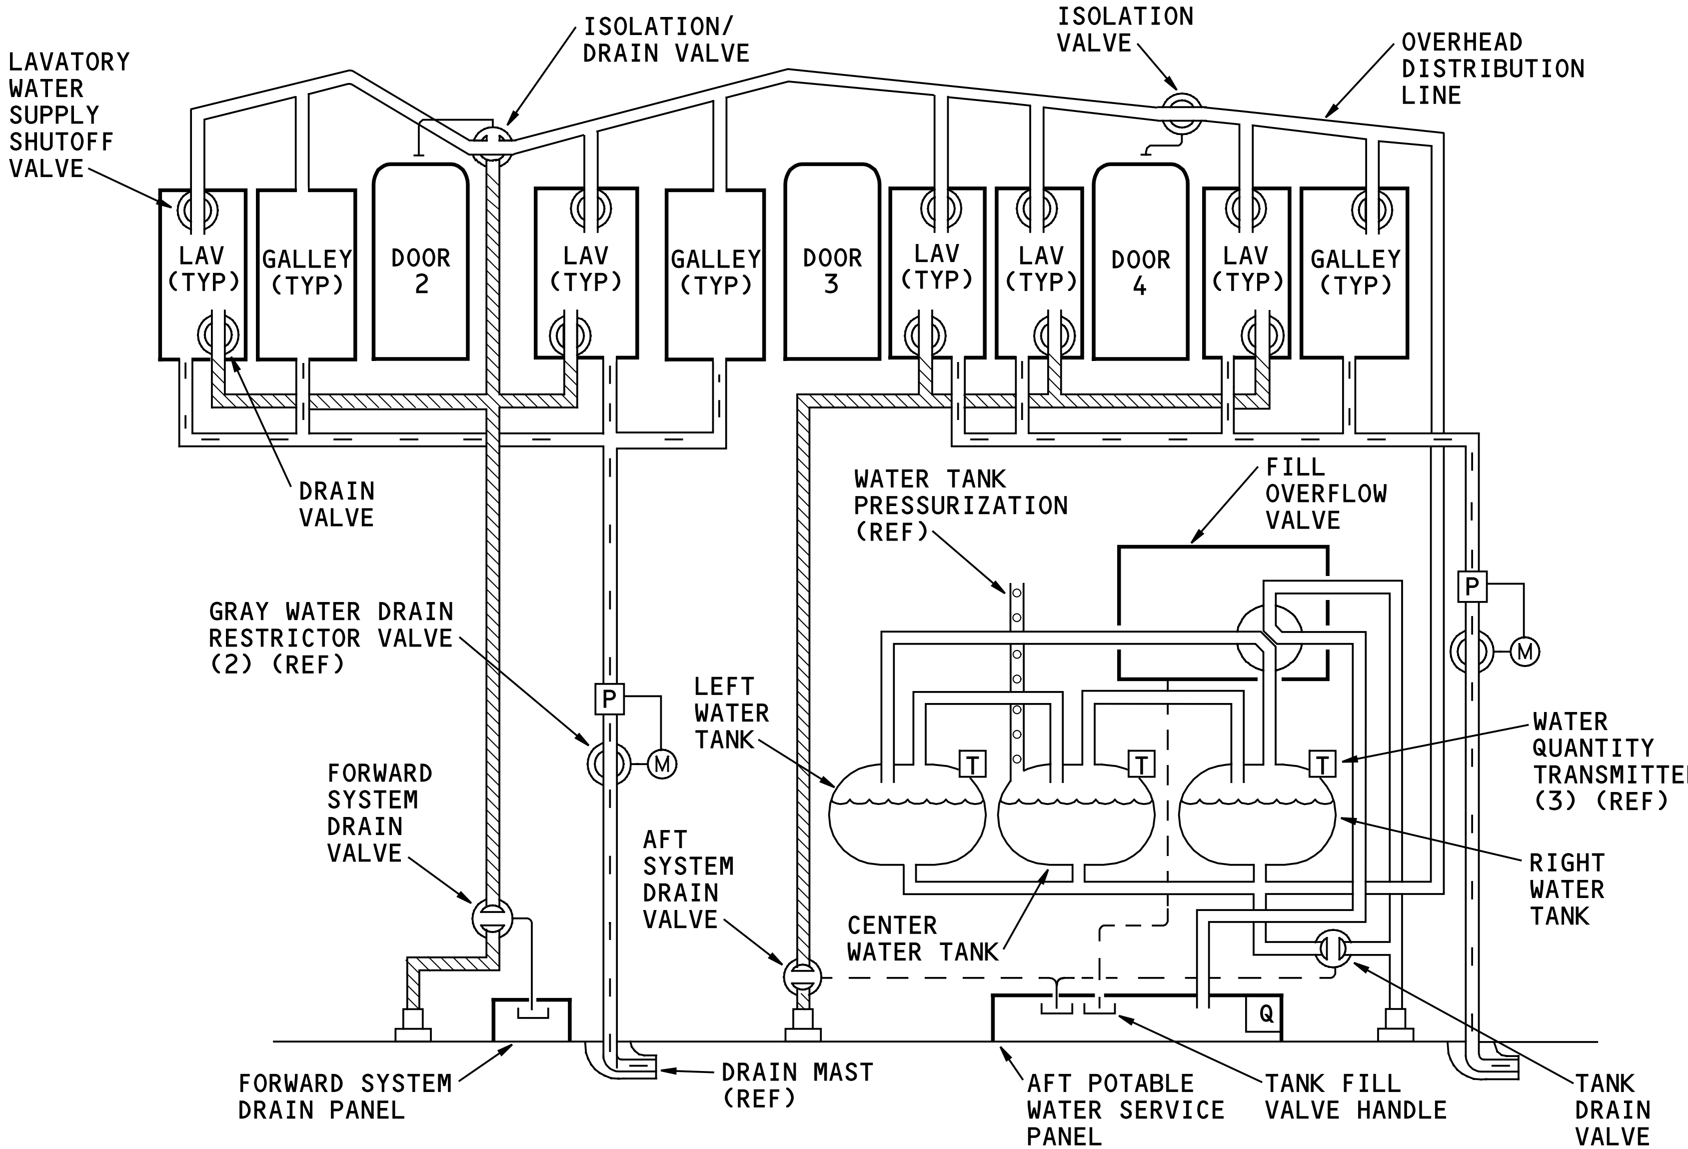
You fill the tanks from aft potable water service panel. You use the fill/overflow valve to fill the water tanks. The overhead distribution line supplies water to the lavatories and galleys. There is a water supply shutoff valve in each lavatory and galley.

There is an isolation/drain valve in the forward part of the system and an isolation valve in the aft part of the system. These two valves let you isolate parts of the system. The isolation/drain valve also lets you drain the forward part of the system to the forward drain valve.

There is a water supply shutoff valve in each lavatory and galley. There is a drain valve in each lavatory. It lets water drain from the distribution lines in the lavatory. You use the galley faucet to drain the galley distribution lines.

These are the three drain valves that let you drain water from the distribution system and the water tanks:

- Forward system drain valve
- Aft system drain valve
- Tank drain valve.



WATER STORAGE AND DISTRIBUTION - INTRODUCTION

WATER STORAGE AND DISTRIBUTION - BULK CARGO COMPARTMENT COMPONENT LOCATIONS

Component Locations

These components are behind the bulk cargo compartment end wall:

- Three water tanks (left, center, and right)
- Fill overflow valve and control cable (cable not shown)
- Three water tank support shear fittings
- Potable water distribution line
- Tank drain valve.

The drain valve for the aft part of the overhead distribution system is in the aft cargo compartment, under the floor.

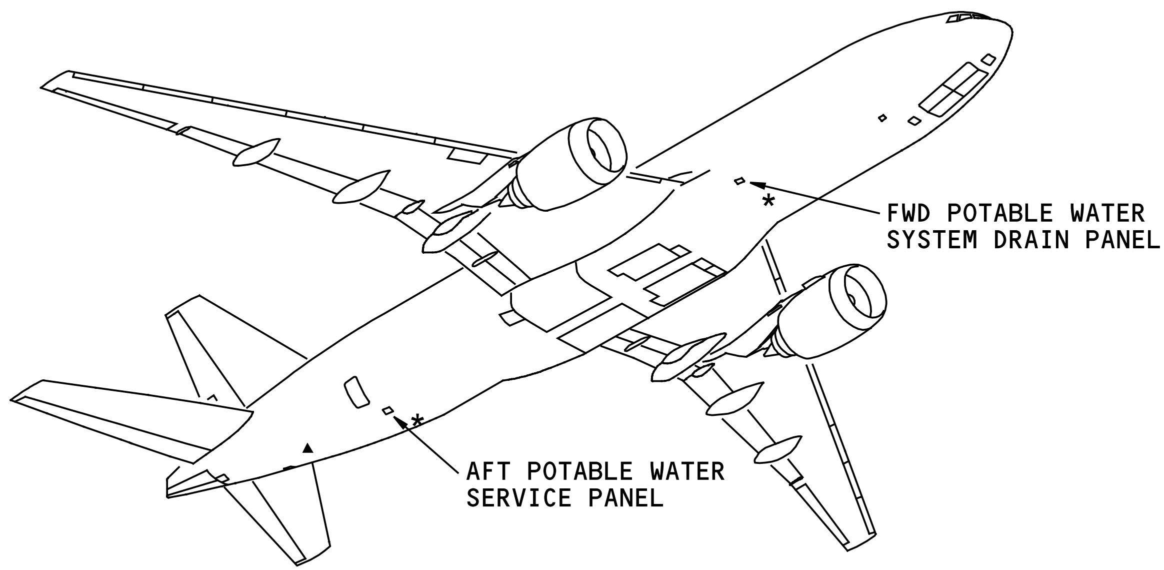
There are three water drains. One is near the forward potable water system drain panel. The second one is near the aft potable water service panel. The third is aft of the passenger entry door 4, on the right lower side of the fuselage.



▲ = TANK DRAIN/OVERFLOW
* = DISTRIBUTION DRAIN

38-11-00-005 Rev 3 07/21/1997

WATER STORAGE AND DISTRIBUTION - SERVICE PANEL COMPONENT LOCATIONS

WATER STORAGE AND DISTRIBUTION - WATER TANK

Purpose

There are three water tanks to hold potable water.

Physical Description

Each water tank has a capacity of 120 gallons (454 liters). There is a standpipe that limits the amount of water in each tank to 109 gallons (413 liters).

The water tanks have these components:

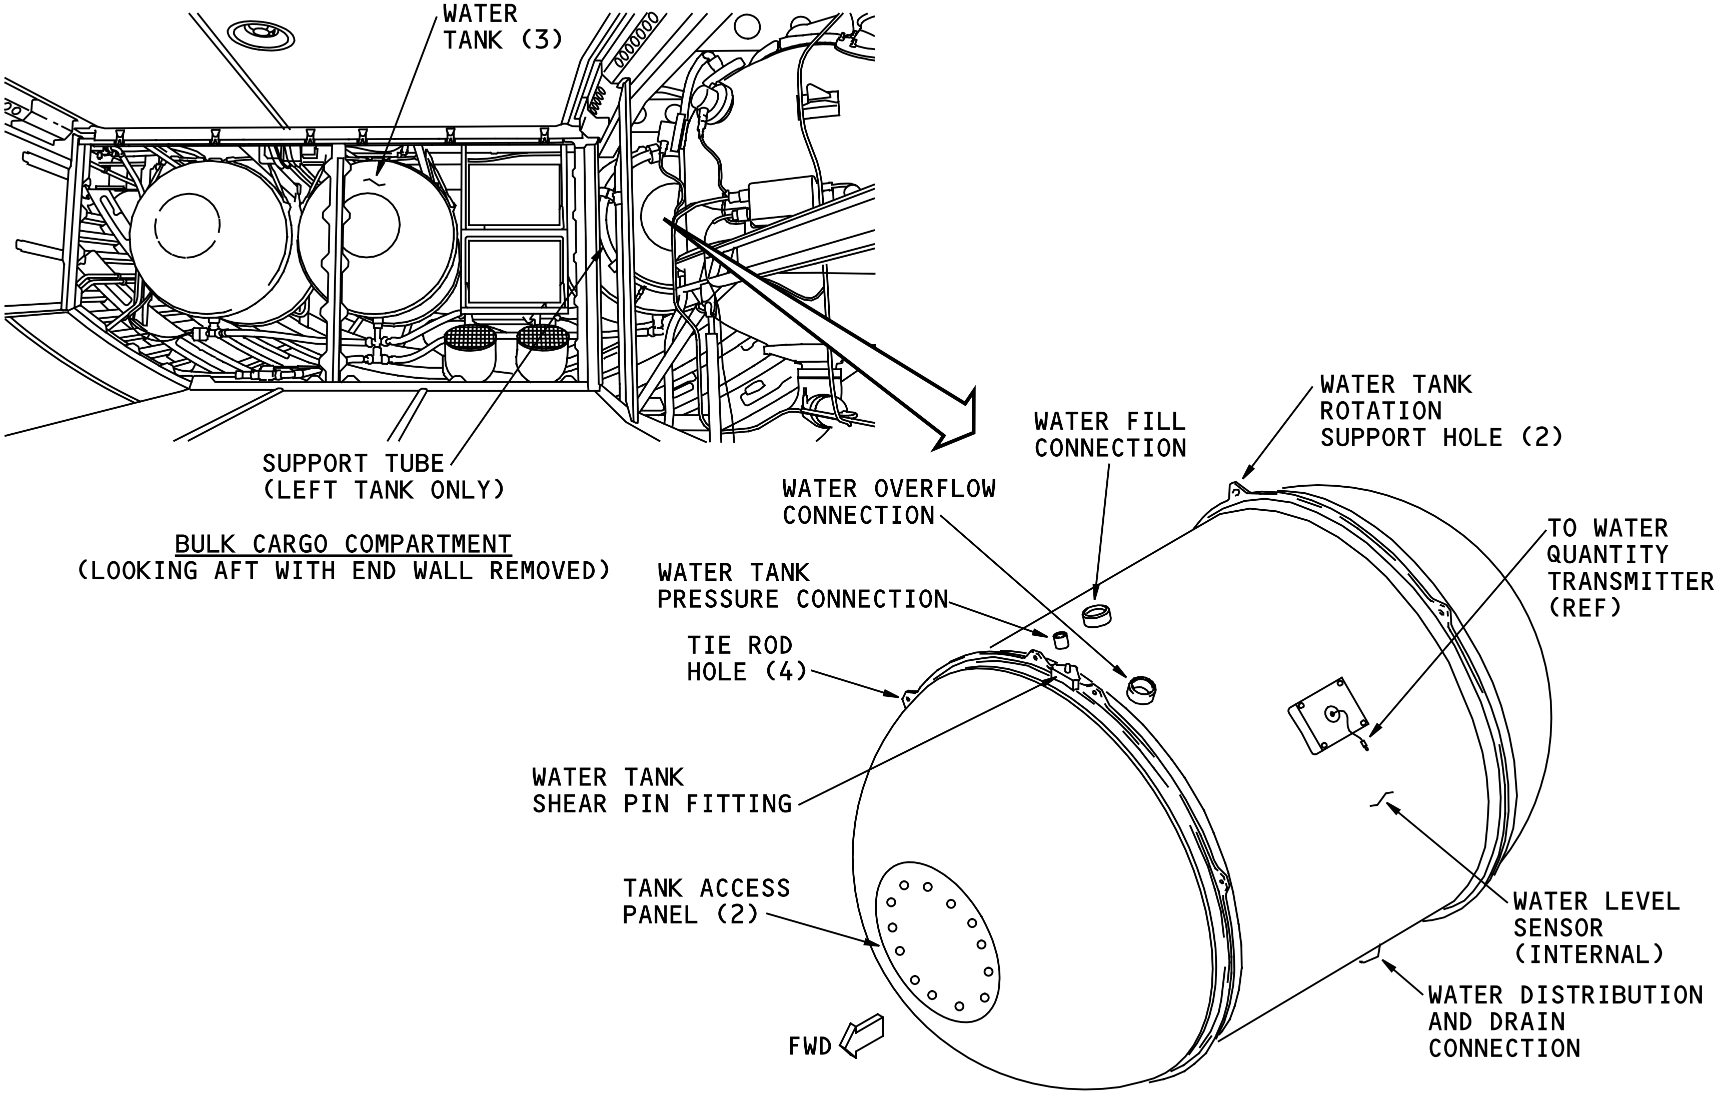
- Access panel (2)
- Water tank shear pin fitting
- Tie rod hole (4)
- Water tank pressure connection
- Water overflow connection
- Water fill connection
- Water tank rotation support hole (2)
- Water level sensor (internal)
- Water distribution and drain connection.

The left water tank has a support tube around the forward end of the tank.

Location

The water tanks are aft of the bulk cargo compartment end wall.

The left water tank is aft of the aft waste tank.



38-11-00-006 Rev 2 12/10/1996

WATER STORAGE AND DISTRIBUTION - WATER TANK

WATER STORAGE AND DISTRIBUTION - WATER TANK SUPPORT SHEAR FITTING

Purpose

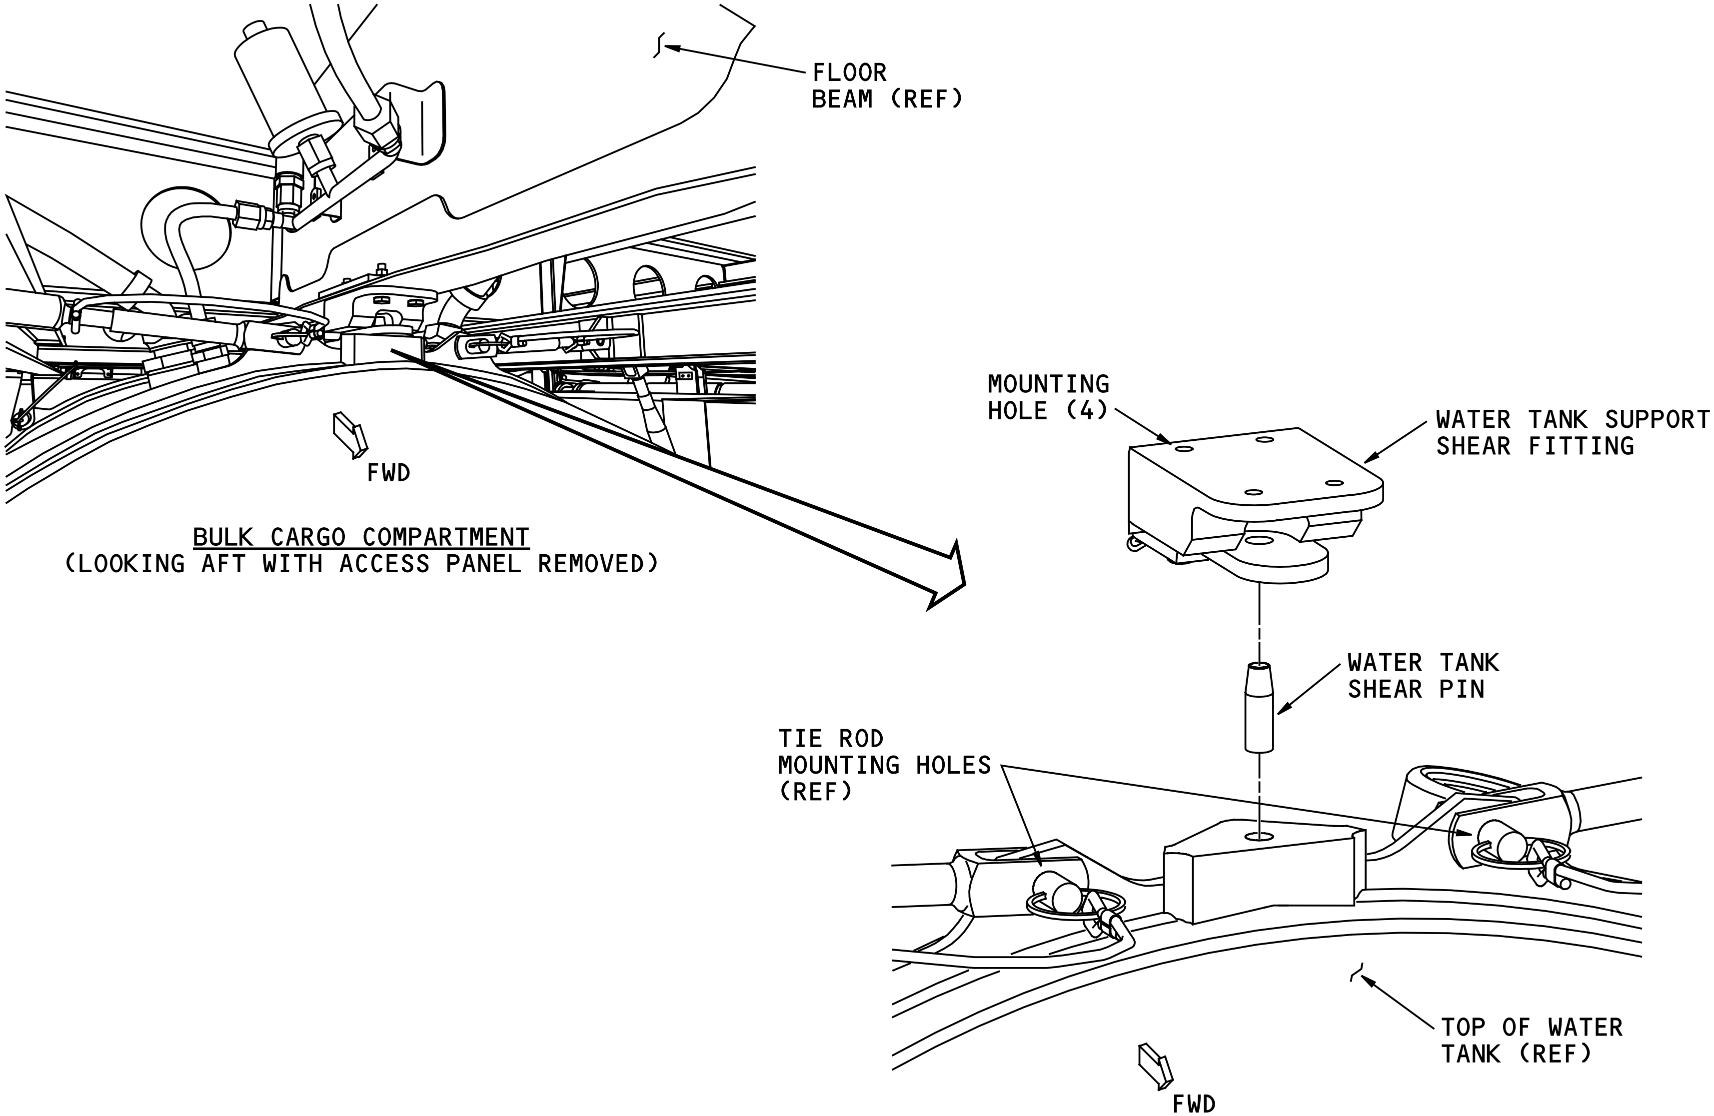
The water tank support shear fitting holds the water tank shear pin. The shear pin holds the water tank in place during forward loads.

Physical Description

The fitting has four mounting holes.

Location

The fitting is installed above the water tank. It attaches to the floor beams with four bolts.



38-11-00-007 Rev 0

WATER STORAGE AND DISTRIBUTION - WATER TANK SUPPORT SHEAR FITTING

WATER STORAGE AND DISTRIBUTION - FILL/OVERFLOW VALVE AND CONTROL CABLE

Purpose

The fill/overflow valve has these functions:

- Lets water flow into the potable water tanks from the aft potable water service panel
- Lets the air in the water tanks vent overboard as water flows into the tanks
- Lets water flow overboard when the tanks are full
- Does not let the air compressor operate when the valve is in the open position.

Physical Description

The valve has:

- A cable connection to the aft service panel
- Four water line connections
- An interlock switch for the tank pressurization compressor.

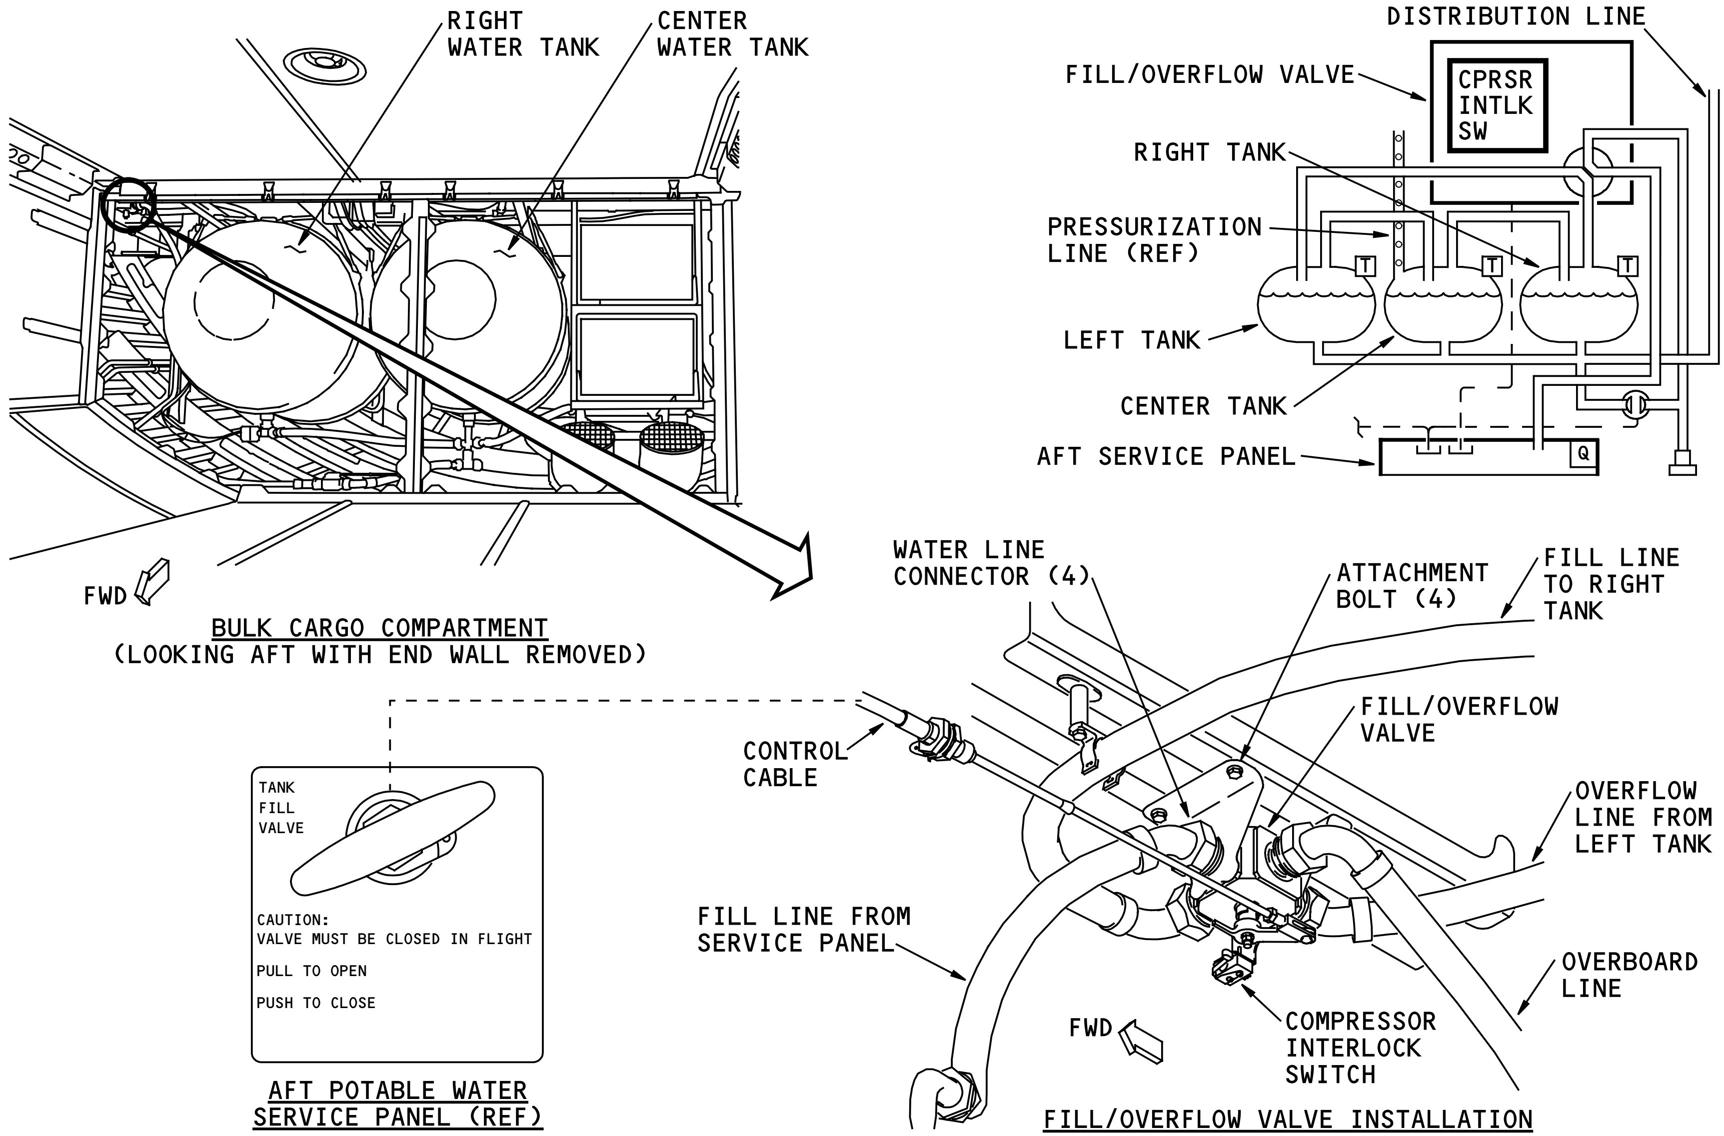
Location

The fill/overflow valve is behind the bulk cargo compartment end wall. It is above and outboard of the right water tank. The valve attaches to the passenger compartment floor structure with four bolts.

Functional Description

To open the valve you pull out on the handle. Water flows from the service panel to the right tank. Some of the water flows from the right tank to the center and left tanks through the water distribution line. This connection lets all three tanks fill at the same time. A vent line that does not go through the valve connects the standpipe of the right tank to the top of the center tank. When the right tank is full, water flows through this line to the center tank. Another vent line connects the standpipe of the center tank to the top of the left tank. When the center tank is full, water flows through this line to the left tank. When the left tank is full, the water flows through the valve, then overboard. Push the control handle in to close the valve.

When the valve is in the closed position, the fill line from the service panel connects to the overboard line.



38-11-00-022 Rev 4 07/21/1997

WATER STORAGE AND DISTRIBUTION - FILL/OVERFLOW VALVE AND CONTROL CABLE

WATER STORAGE AND DISTRIBUTION - DRAIN VALVE AND CONTROL CABLE

Purpose

The two drain valves let water drain overboard from the overhead water distribution line, the galleys, and the lavatories.

Physical Description

The two system drain valves are identical and interchangeable. The valve has two positions: open and closed.

The valves are a single-ball type of valve. The valves have these parts:

- Drain line connection (2)
- Actuator
- Ball (internal)
- Body.

The valve attaches with four bolts.

The aft system drain valve has two control cables. One attaches to the aft system drain valve control handle and to the valve actuator. The other attaches to the valve actuator and to the tank drain valve (not shown).

The forward system drain valve (not shown) has one cable that attaches to the valve actuator and to the forward system drain valve control handle (not shown).

The control cables are a push-pull type.

Location

The aft system drain valve is below the floor of the aft cargo compartment. It is near the bulk cargo compartment, inboard of the last powered drive unit on the left side (PDU 13L).

The forward system drain valve is below the floor of the forward cargo compartment. It is near the aft part of the compartment, inboard of powered drive unit number 14 right (PDU 14R).

The control handle for the forward potable water system drain valve is on the forward potable water system drain panel (not shown).

The control handle for the aft valve is on the aft potable water service panel (not shown).

Functional Description

The control cables open the related valve(s) when you pull on the system drain valve control handle. The valve(s) closes when you push the handle.

WATER STORAGE AND DISTRIBUTION - DRAIN VALVE AND CONTROL CABLE

WATER STORAGE AND DISTRIBUTION - TANK DRAIN VALVE AND CONTROL CABLE

Purpose

The tank drain valve lets water drain overboard from the water tanks and the aft section of the overhead water distribution lines. The control cable sets the position of the tank drain valve.

Physical Description

The tank drain valve is dual-ball type of valve. The valve has these parts:

- Handle
- Shaft (2)
- Cover assembly with two internal gears
- Ball (internal) (2)
- Drain line connection (2)
- Body.

The tank drain valve has an open and a closed position.

The valve has a control cable that attaches to the valve handle and to the aft system drain valve (not shown). The control cable is a push-pull type.

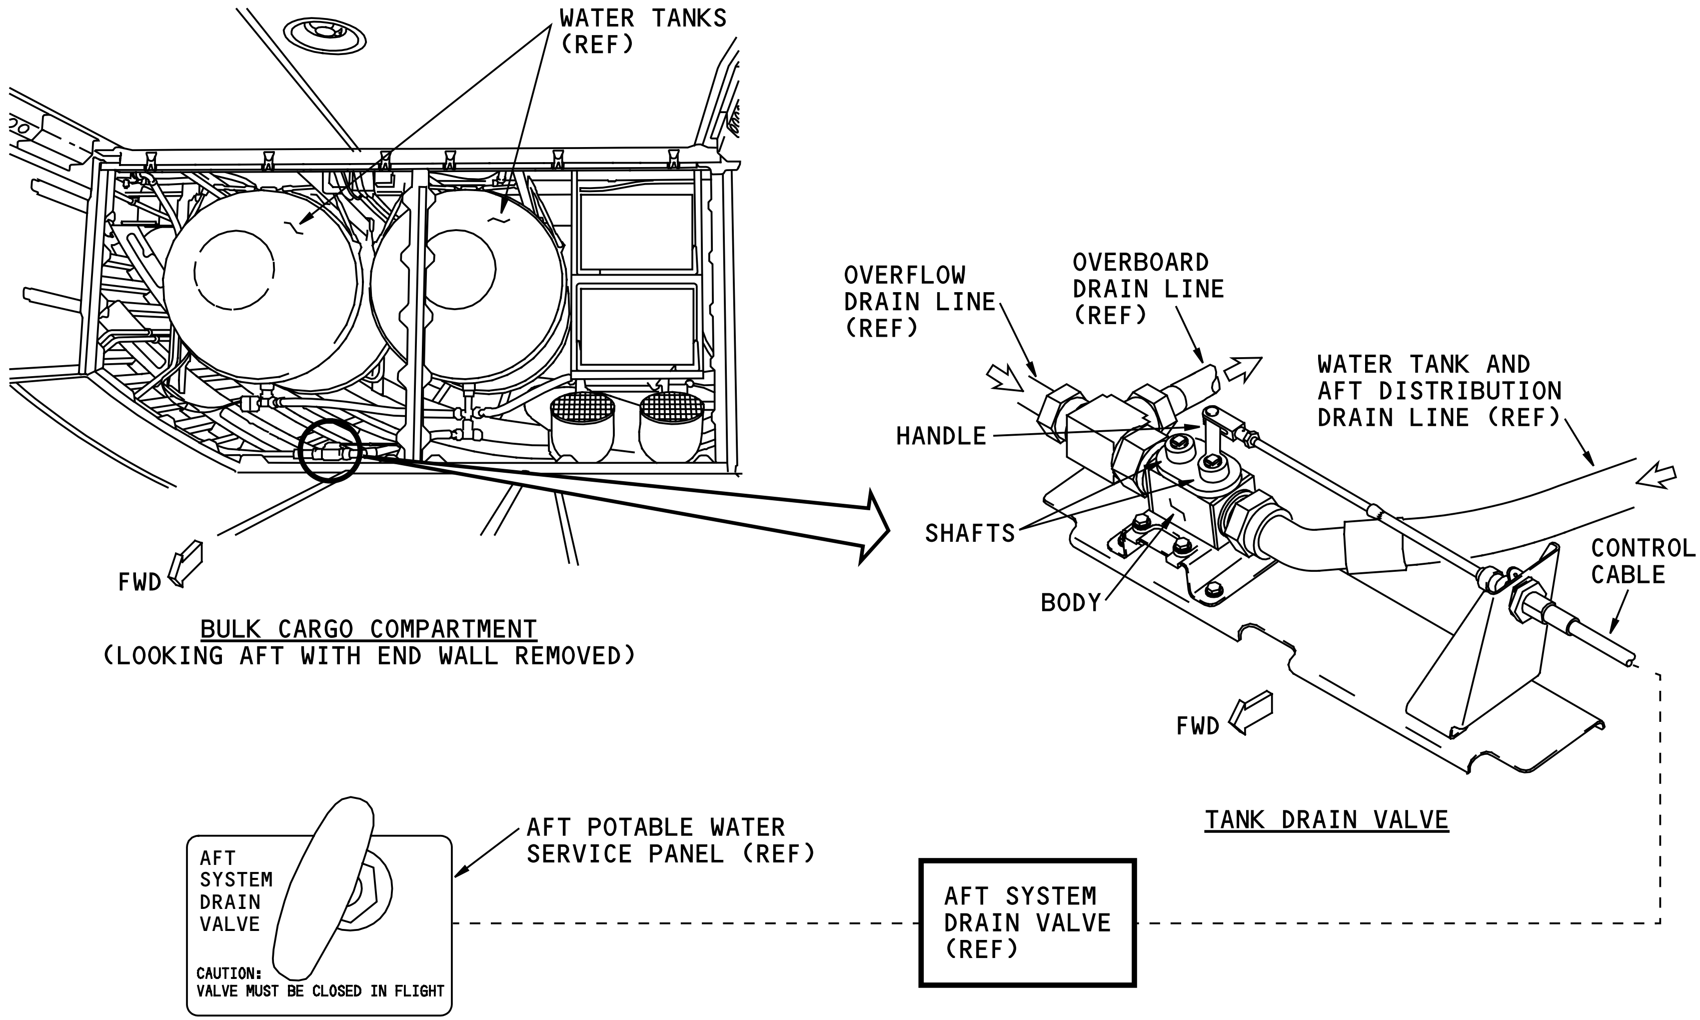
Location

The drain valve is behind the right end wall of the bulk cargo compartment. It is below the space between the right and center water tanks.

Functional Description

The control cable sets the position of the valve handle to the same position as the aft system drain valve. The handle is on a shaft connected by internal gears to a second shaft. Each shaft has a ball that attaches to it (internal to the body). The handle turns the gears and balls when the handle moves.

Control cables open the aft system drain valve and the tank drain valve when you pull on the aft system drain valve control handle (not shown). The valves closes when you push the handle. The aft system drain valve control handle is on the aft potable water service panel (not shown).



38-11-00-011 Rev 2 12/11/1996

WATER STORAGE AND DISTRIBUTION - TANK DRAIN VALVE AND CONTROL CABLE

WATER STORAGE AND DISTRIBUTION - ISOLATION VALVE AND CONTROL CABLE

Purpose

The isolation valve lets you isolate the overhead distribution lines that supply water to the forward and mid lavatories and galleys.

Physical Description

The valve has two positions: open and closed.

The valve has a manual actuator. A control cable attaches to the actuator. This allows you to manually open and close the valve.

The valve attaches with four bolts. It has two water line connectors.

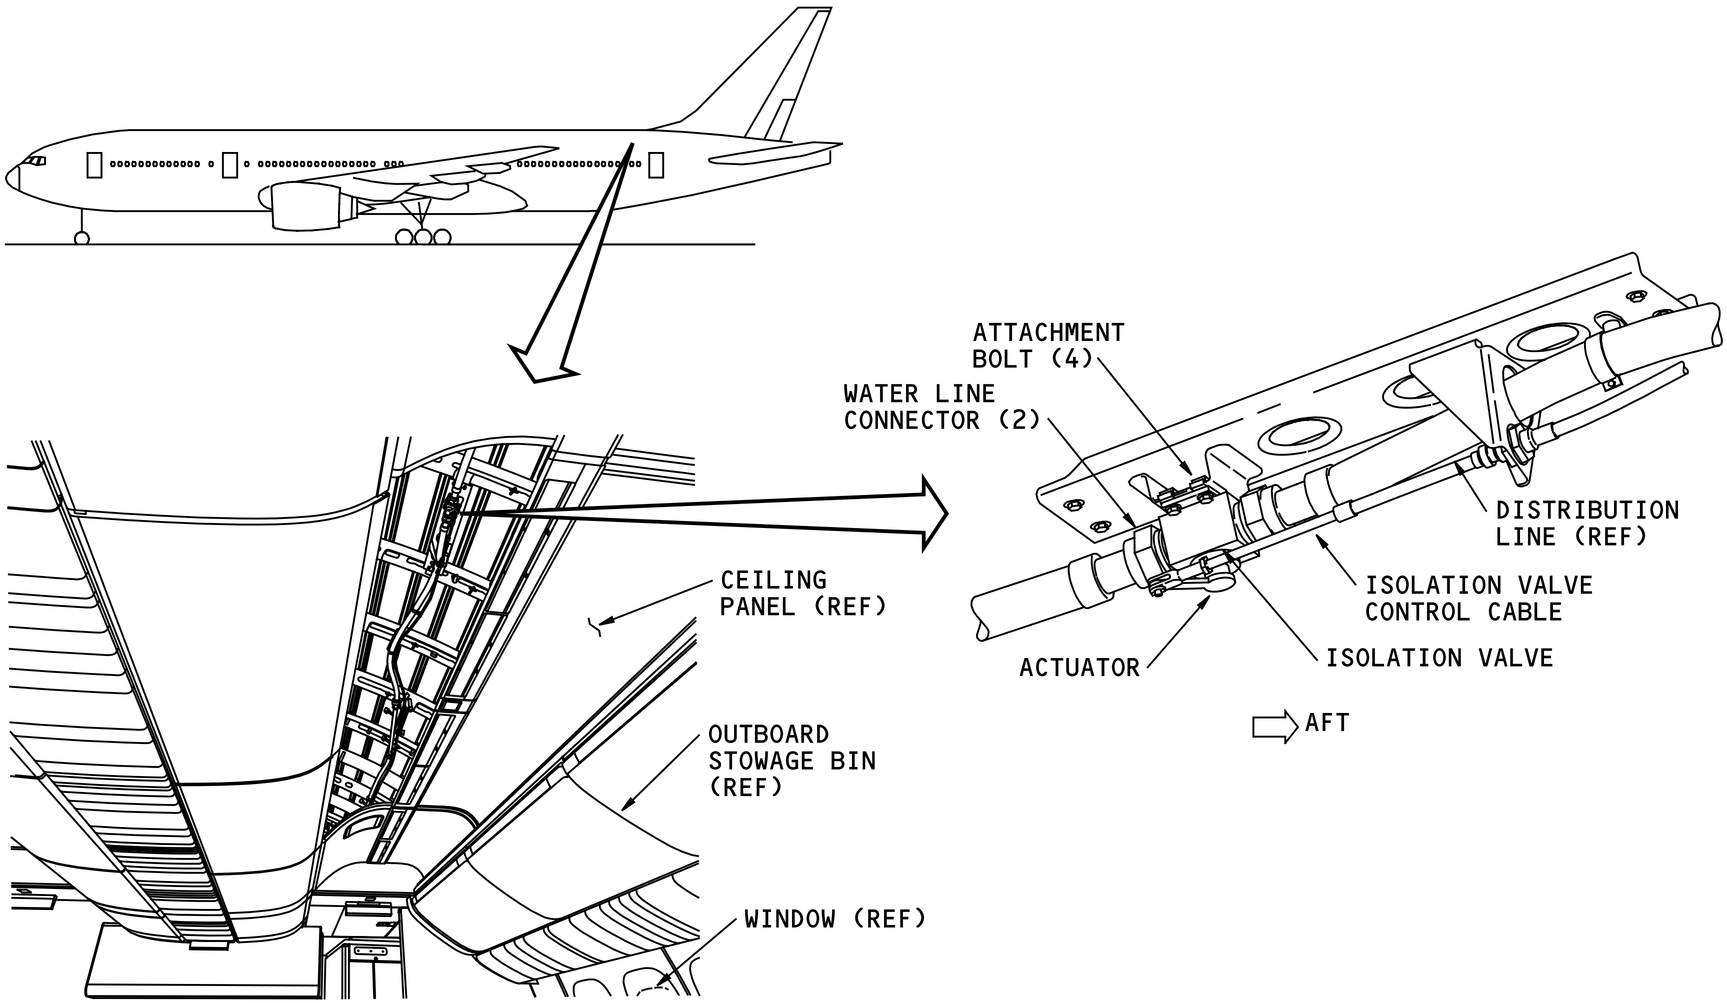
Location

The isolation valve is above the ceiling in the aft part of the passenger compartment. To get access, remove the ceiling panel that is above the left aisle next to a center overhead stowage bin.

The isolation handle is behind a panel above the passenger/entry door 4 left.

Functional Description

The control cable opens and closes the valve when you operate the isolation handle.



LEFT SIDE OF PASSENGER COMPARTMENT
(LOOKING AFT WITH CEILING PANEL REMOVED)

38-11-00-012 Rev 2 01/07/1998

WATER STORAGE AND DISTRIBUTION - ISOLATION VALVE AND CONTROL CABLE

WATER STORAGE AND DISTRIBUTION - ISOLATION/DRAIN VALVE AND CONTROL CABLE

Purpose

The isolation/drain valve lets you isolate the overhead distribution lines that supply water to the forward lavatories and galleys. It also permits you to drain the forward part of the overhead distribution line overboard.

Physical Description

The isolation/drain valve is a three-way, three-position valve. The positions are open, isolation, and drain.

The valve has a manual actuator. A control cable attaches to the actuator.

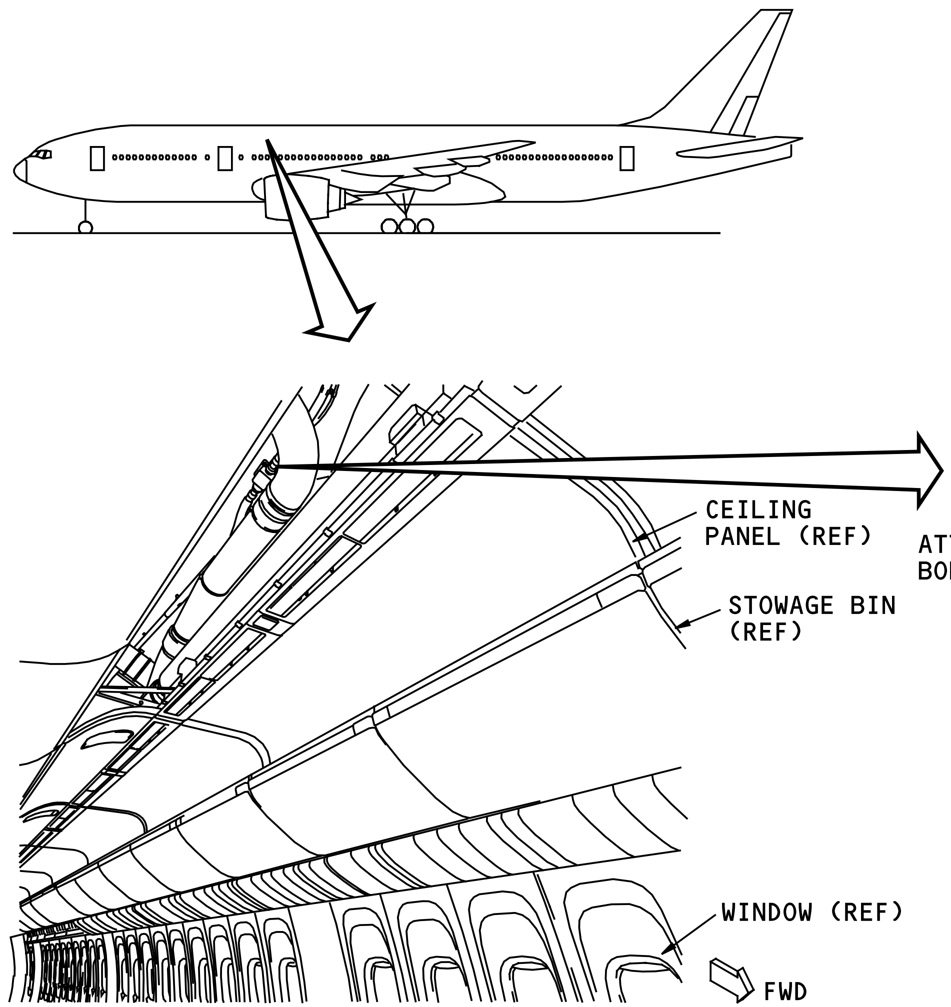
The valve attaches to the support with four bolts. It has three water line connectors, two for the overhead distribution lines, and one for the overboard drain line.

Location

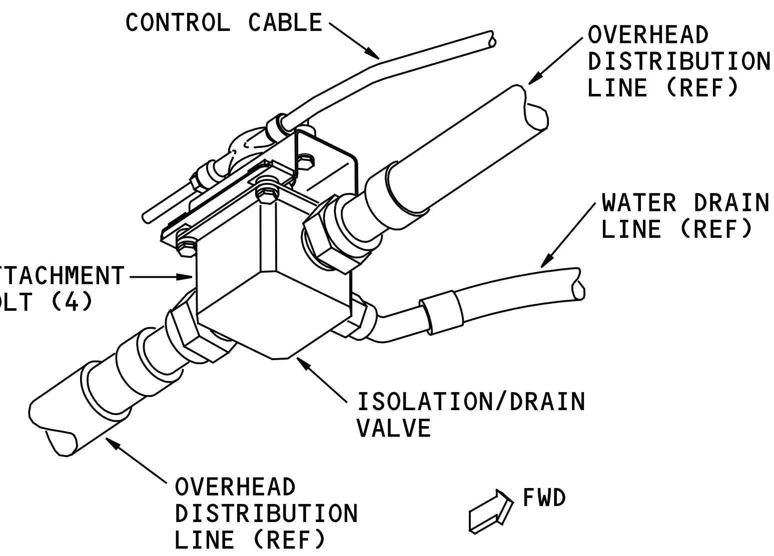
The isolation/drain valve is above the ceiling in the forward part of the passenger compartment. The ceiling panel that gives access is above the left aisle next to an inboard overhead stowage bin. It is near door 2.

Functional Description

The control cable operates the valve to any of the three positions when you operate the isolation/drain valve handle.



LEFT SIDE OF PASSENGER COMPARTMENT NEAR DOOR 2
(LOOKING AFT WITH CEILING PANEL REMOVED)



ISOLATION/DRAIN VALVE

38-11-00-013 Rev 1 01/21/1998

WATER STORAGE AND DISTRIBUTION - ISOLATION/DRAIN VALVE AND CONTROL CABLE

WATER STORAGE AND DISTRIBUTION - ISOLATION HANDLE AND ISOLATION/DRAIN VALVE HANDLE

Purpose

The isolation handle and isolation/drain valve handle let you operate the isolation valve and the isolation/drain valve.

Physical Description

The isolation/drain valve handle and the isolation handle are similar. Each handle connects the valve with a control cable.

The isolation/drain valve handle has three positions, open, closed, and drain. The isolation handle has two positions, open and closed.

Each handle attaches with two bolts.

Location

The isolation/drain handle is behind a panel above the passenger/entry door 2 left. The isolation handle is behind a panel above the passenger entry door 4 left.

Functional Description

When you turn the isolation handle clockwise, the isolation valve closes. This isolates the overhead distribution line. When you turn the handle counterclockwise, the valve opens.

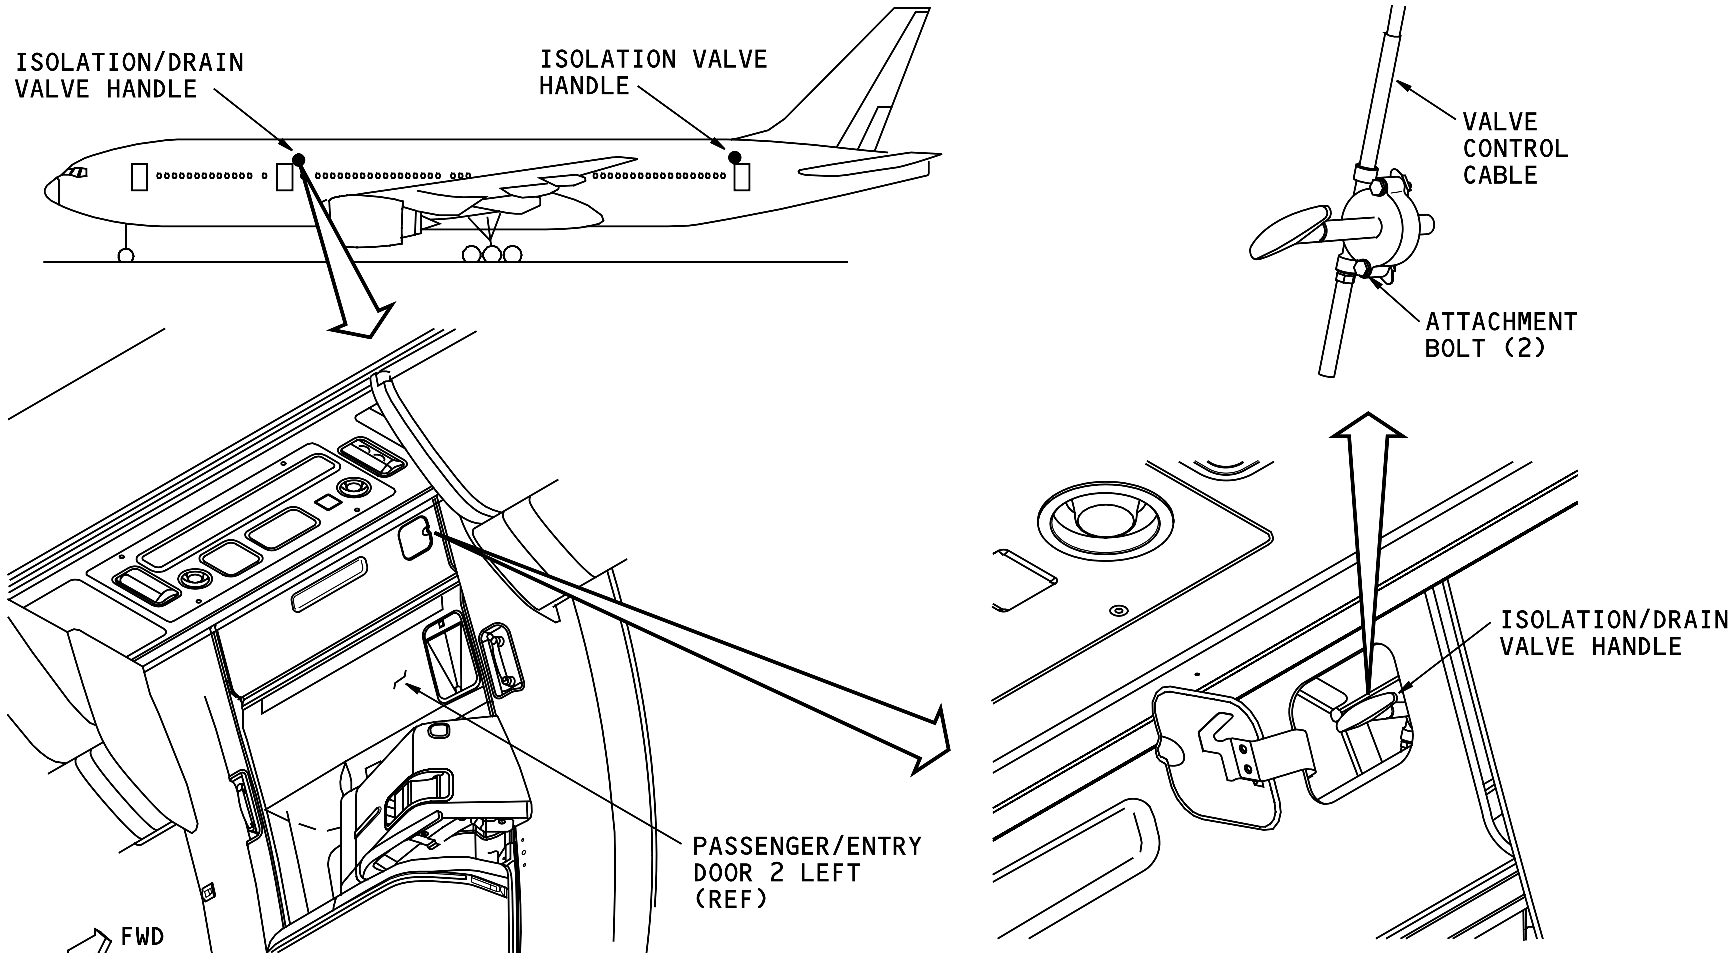
When you turn the isolation/drain valve handle clockwise to the closed position, the isolation/drain valve closes. This isolates the overhead distribution line.

Operation

You turn the isolation and isolation/drain valve handles clockwise to move them to the isolation position. You must pull the isolation/drain valve and turn it to move it to the drain position.

Training Information Point

If the panel for the isolation valve is closed, the valve is in the open position.



ACCESS PANEL

LEFT PASSENGER/ENTRY DOOR 2
(LOOKING UP AND AFT)

NOTE: ISOLATION/DRAIN VALVE HANDLE INSTALLATION SHOWN. ISOLATION VALVE HANDLE SAME, THE INSTALLATION IS SIMILAR.

WATER STORAGE AND DISTRIBUTION - ISOLATION HANDLE AND ISOLATION/DRAIN VALVE HANDLE

WATER STORAGE AND DISTRIBUTION - INTRODUCTION - LAVATORY

Purpose

The part of the water storage and distribution system that is in the lavatory does these functions:

- Lets you control the flow of water into the lavatory
- Distributes water to components in the lavatory
- Lets you drain water from the lavatory.

Physical Description

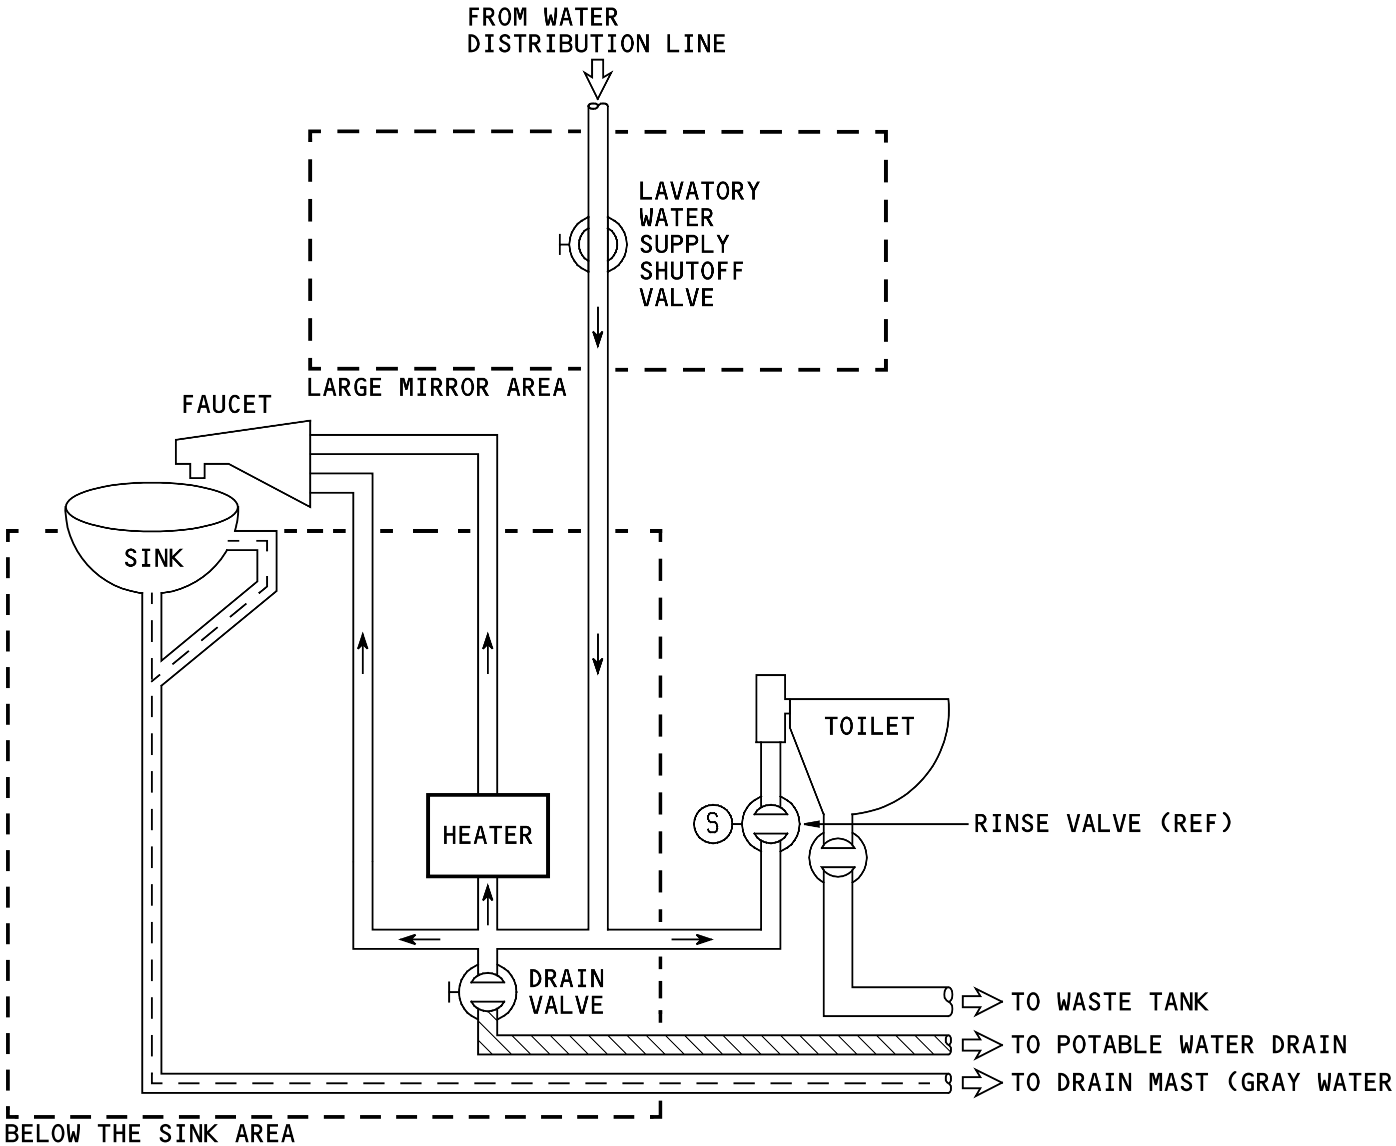
A typical lavatory has these water storage and distribution system components:

- Lavatory water supply shutoff valve
- Distribution lines and fittings (not shown)
- Drain valve
- Faucet.

The system has interfaces with the water heating system and the vacuum waste system.

See the water heating section or more information on water heating (AMM PART I 38-13).

See the vacuum waste system section for more information on the vacuum waste system (AMM PART I 38-32).



WATER STORAGE AND DISTRIBUTION - INTRODUCTION - LAVATORY

WATER STORAGE AND DISTRIBUTION - LAVATORY WATER SUPPLY SHUTOFF VALVE

Purpose

The lavatory water supply shutoff valve lets you control the flow of water into the lavatory.

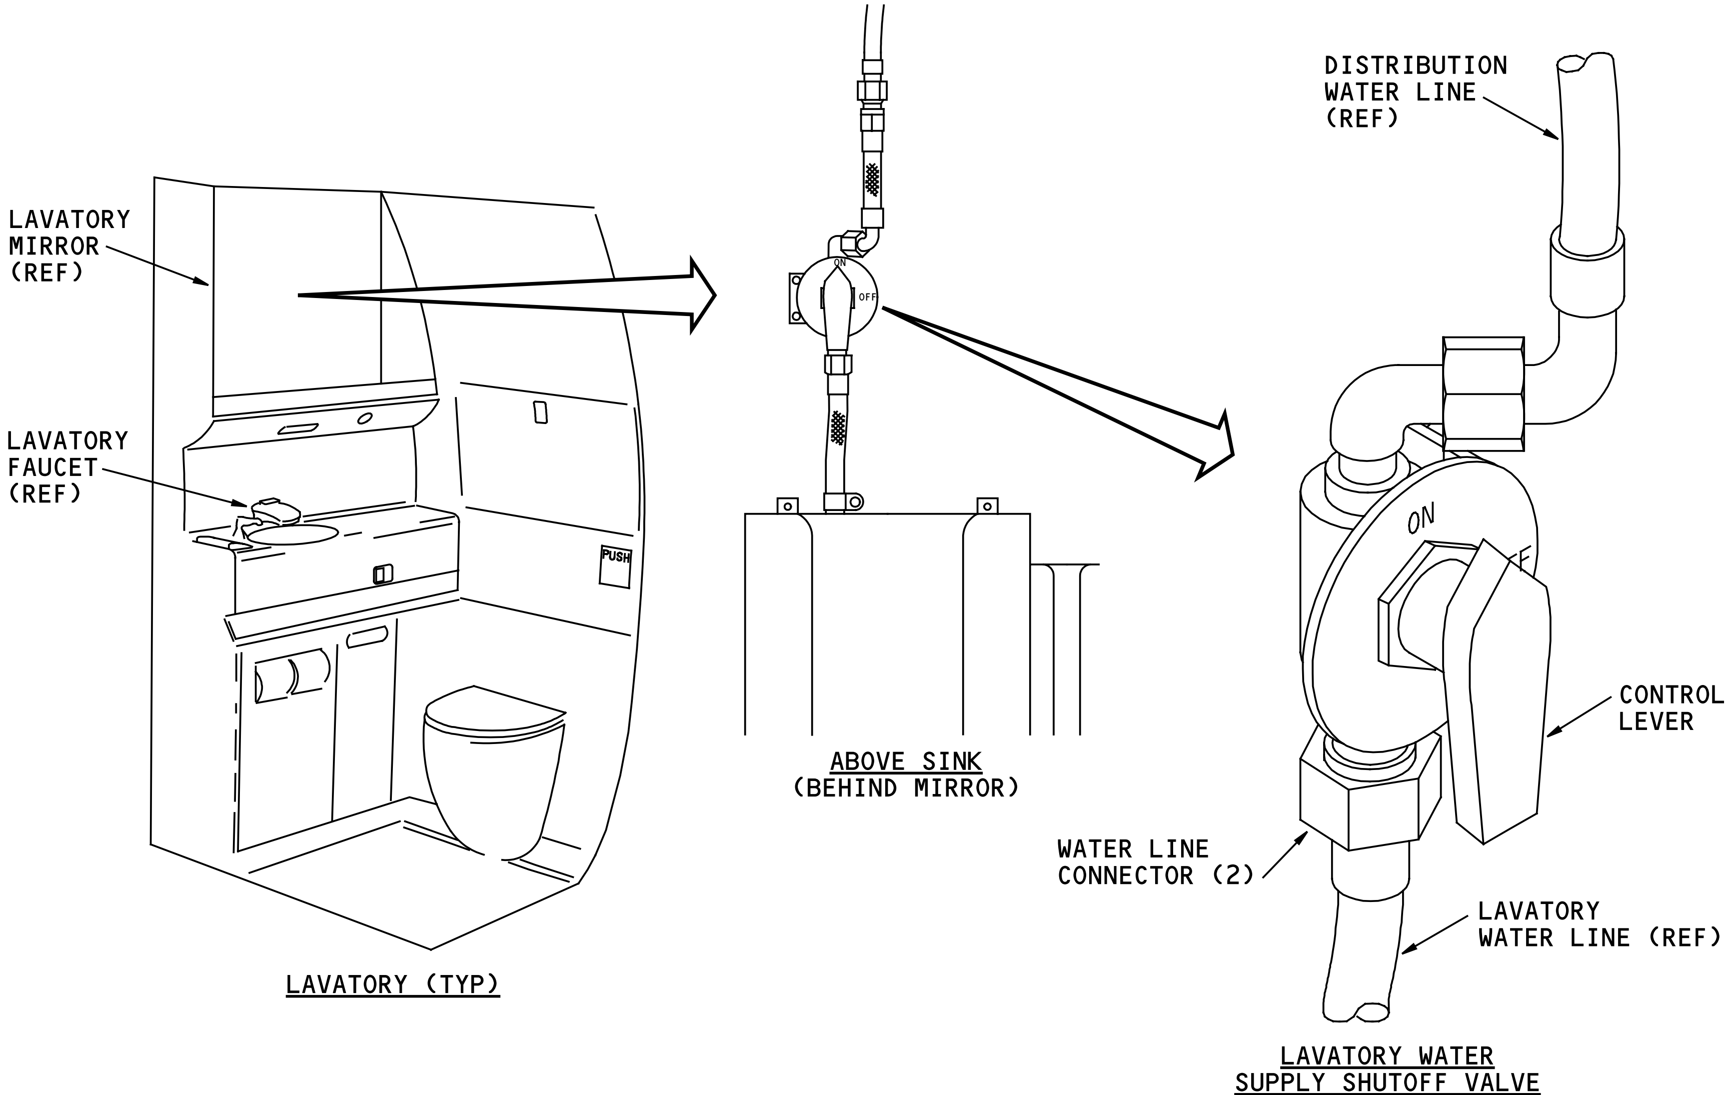
Physical Description

The valve has two positions, off and on.

It has two water connectors and a control lever.

Location

There is a valve in each lavatory. It is above the sink and behind the mirror.



38-11-00-015 Rev 0

WATER STORAGE AND DISTRIBUTION - LAVATORY WATER SUPPLY SHUTOFF VALVE

WATER STORAGE AND DISTRIBUTION - OPERATION - DRAIN

Forward System Drain Valve

This is a summary of the procedure to drain the water storage and distribution system:

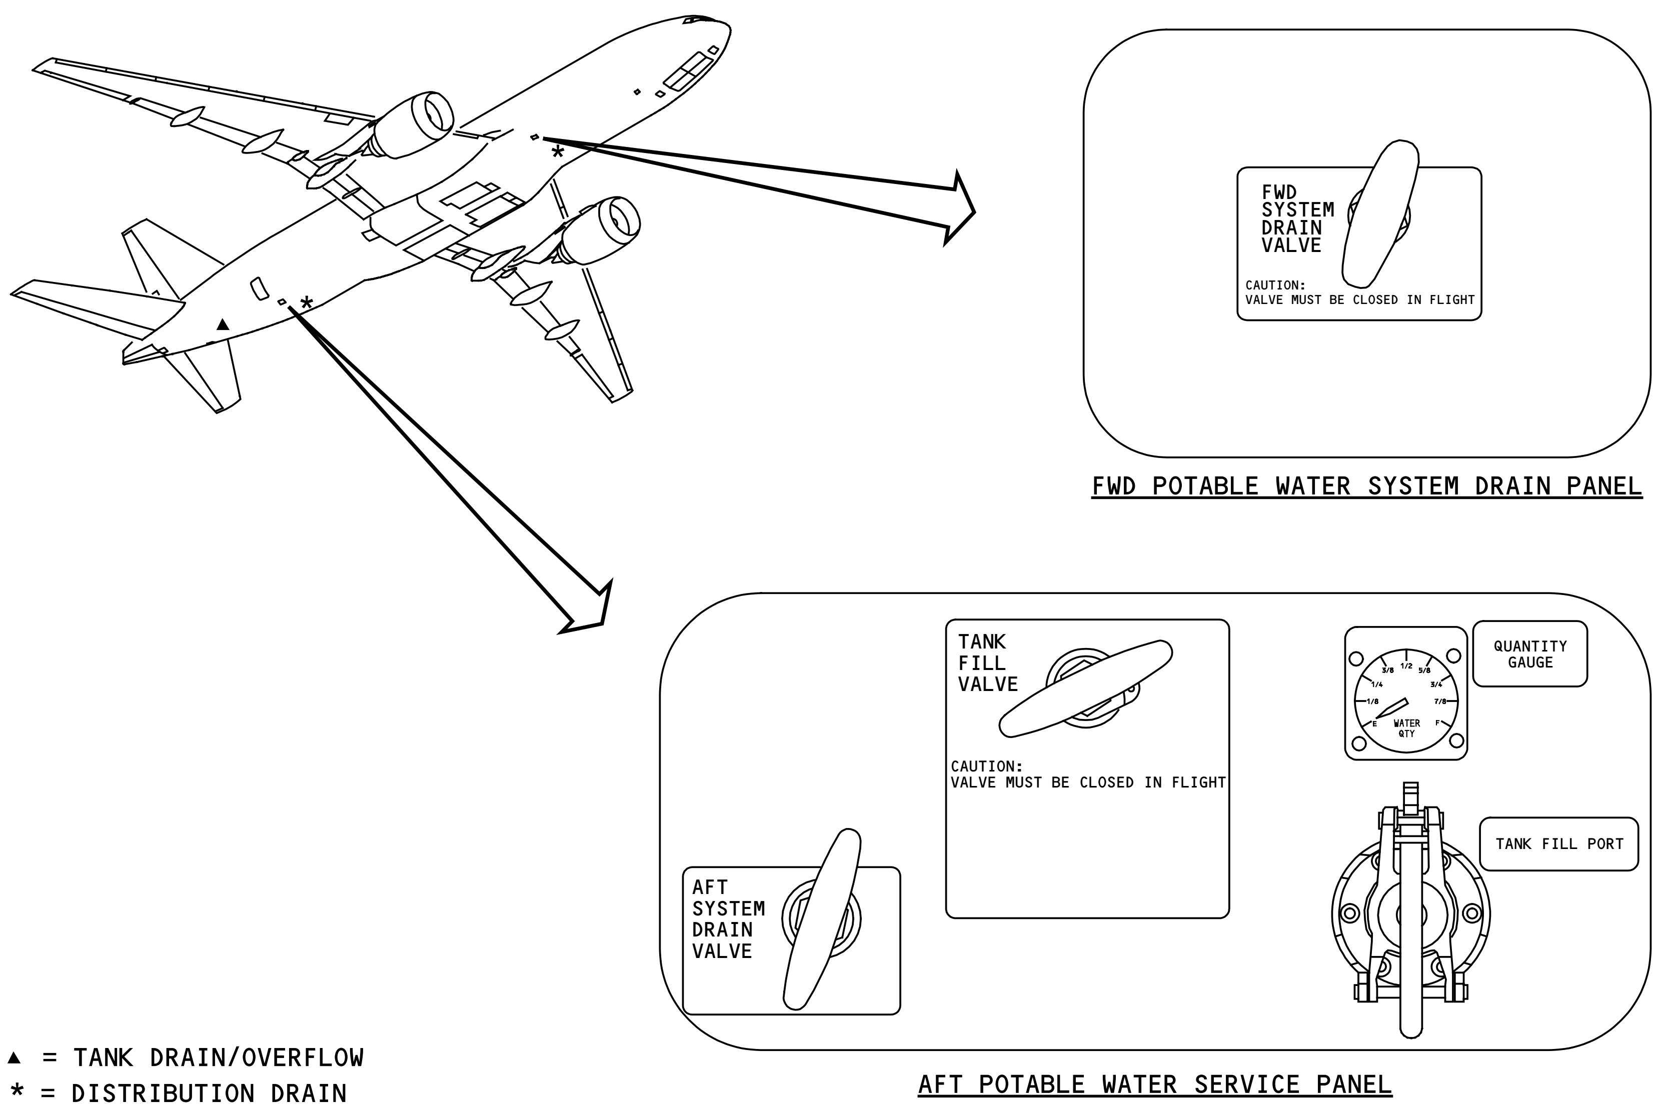
- Open the lavatory water heater circuit breakers
- Put the isolation/drain valve in the drain position
- Make sure the isolation valve is in the open position
- Open the distribution drain shutoff valves
- Pull the forward system drain valve handle
- Pull the aft system drain handle.

The water flows overboard through these three places:

- Forward system drain
- Aft system drain
- Overflow/tank drain.

The forward system drain is on the right side of the airplane and below the leading edge of the wing. The aft system drain is on the left side of the airplane, directly across from the aft service panel. The overflow/tank drain is almost straight aft of the aft service panel.

WARNING: DRAIN THE POTABLE WATER SYSTEM AT A MINIMUM OF 1 TIME EACH 3 DAYS IN ORDER TO PREVENT THE GROWTH OF BACTERIA. CONTAMINATION CAN OCCUR IF YOU DO NOT DRAIN THE SYSTEM REGULARLY. CONTAMINATION IN THE WATER CAN CAUSE ILLNESS TO PERSONS THAT DRINK THE WATER.



38-11-00-021 Rev 4 07/21/1997

WATER STORAGE AND DISTRIBUTION - OPERATION - DRAIN

WATER AND WASTE - WATER COOLING - INTRODUCTION

Purpose

The lavatory water cooler cools water for drinking. The cooler cools the water between 50F (10C) maximum and 35F (1.7C) minimum.

Physical Description

The water cooler has these components:

- Motor-driven fan
- Electrical connector
- Overheat warning light
- Water line connection (2)
- Air filter (2)
- Air fins
- Manual reset button
- Overheat thermal switch (Internal).

The water cooler and the air filter are LRUs.

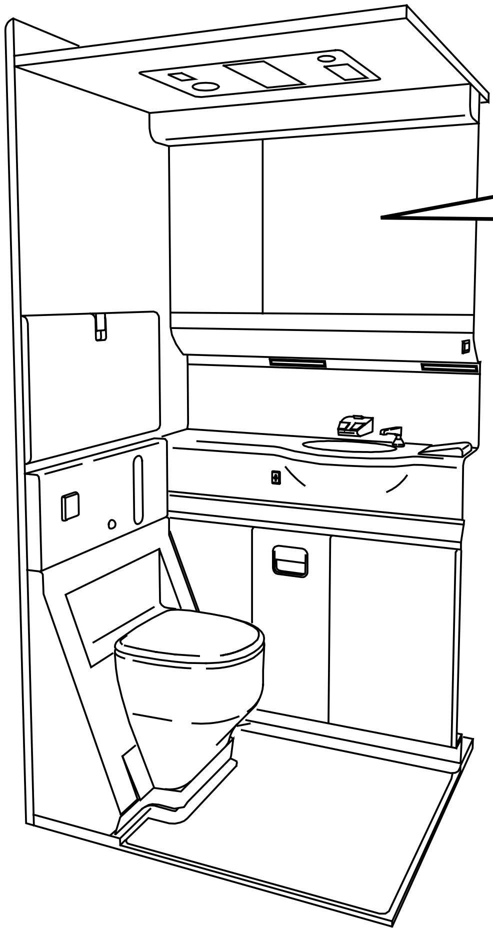
Location

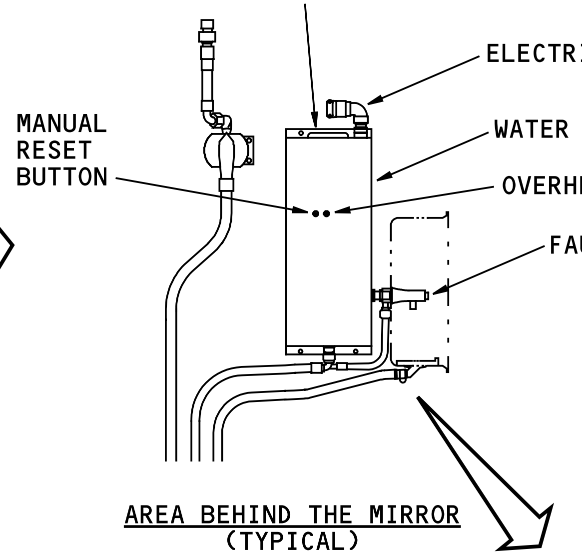
The water cooler is in the sidewall of the lavatory behind the large mirror. You open the mirror to get access to the cooler.

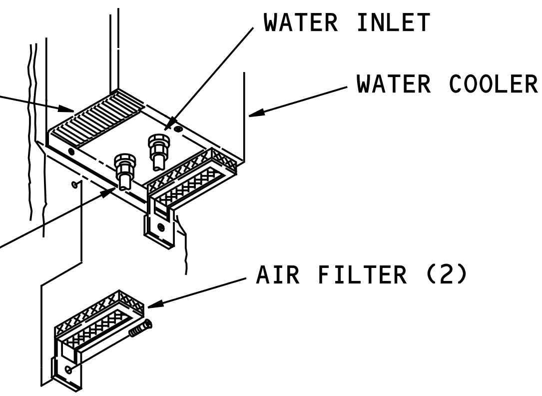
Operation

The water coolers will operate when the water temperature is more than 50F (10C).

If an overheat condition occurs, the overheat switch opens and the overheat warning light comes on. You push the manual reset button on the cover of the cooler to reset the overheat switch.







38-12-00-001 Rev 0 03/05/96

WATER AND WASTE - WATER COOLING - INTRODUCTION

WATER AND WASTE - WATER COOLING - FUNCTIONAL DESCRIPTION

Functional Description

The control thermal switch closes when the water temperature is more than 50 F (10 C). This energizes the relay and sends power to the thermoelectric modules and the cooling fan through the rectifier.

The control thermal switch opens when the water temperature is between 40F (4.4C) and 50F (10C). This removes power from the thermoelectric modules and the fan.

The overheat switch opens when the water temperature in the cooler is approximately 140F (60C).

The water cooler can get power from one of these two buses:

- Left utility bus in the P110 Power Management Panel
- Right utility bus in the P210 Power Management Panel (not shown).

Indication

There is a red light on the outside of the water cooler. The light comes on when the overheat thermal switch opens.

Training Information Point

Open the circuit breakers for the water coolers when you drain the potable water system.

Before you can reset the cooler after an overheat condition, do these steps:

- Let the water to cool until it will not burn your skin when you touch it.
- Clean the cooler fins
- Replace or clean the air filter.

WATER AND WASTE - WATER COOLING - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

WATER HEATING - INTRODUCTION

Purpose

The lavatory water heaters heats water for use in the lavatory sink.

Physical Description

The water heater is a cylindrical tank assembly of 2.0 quarts (1.89 L) capacity. The water heater has these components:

- Lid
- Indicator light
- Power switch
- Pressure relief valve
- Water outlet
- Tank
- Heater element (3) (internal)
- Temperature sensor (internal)
- Printed Circuit (PC) card (internal)
- Cold/hot water mixing/bypass device (internal)
- Water inlet
- Temperature selection switch
- Overheat switch and reset button
- Electrical connector.

The power switch has two positions, ON and OFF. The temperature selector has these positions and approximate water temperature:

- Low (105F, 40.6C)
- Medium (115F, 46C)
- High (125F, 51.7C).

The overheat switch is normally closed. It latches open when the tank temperature is approximately 170F (76.7C). The overheat switch can be manually reset (closed) when the tank temperature is less than 120F (48.9C).

The pressure relief valve opens when tank pressure is approximately 140 psig. This valve resets automatically when tank pressure goes below the opening value.

Location

There is a water heater in each lavatory, under the sink.

The overheat switch is under the heater lid.

Indication

The indicator light comes on when both of these conditions occur:

- The power switch is ON
- The overheat switch is closed.

It goes out for any of these conditions:

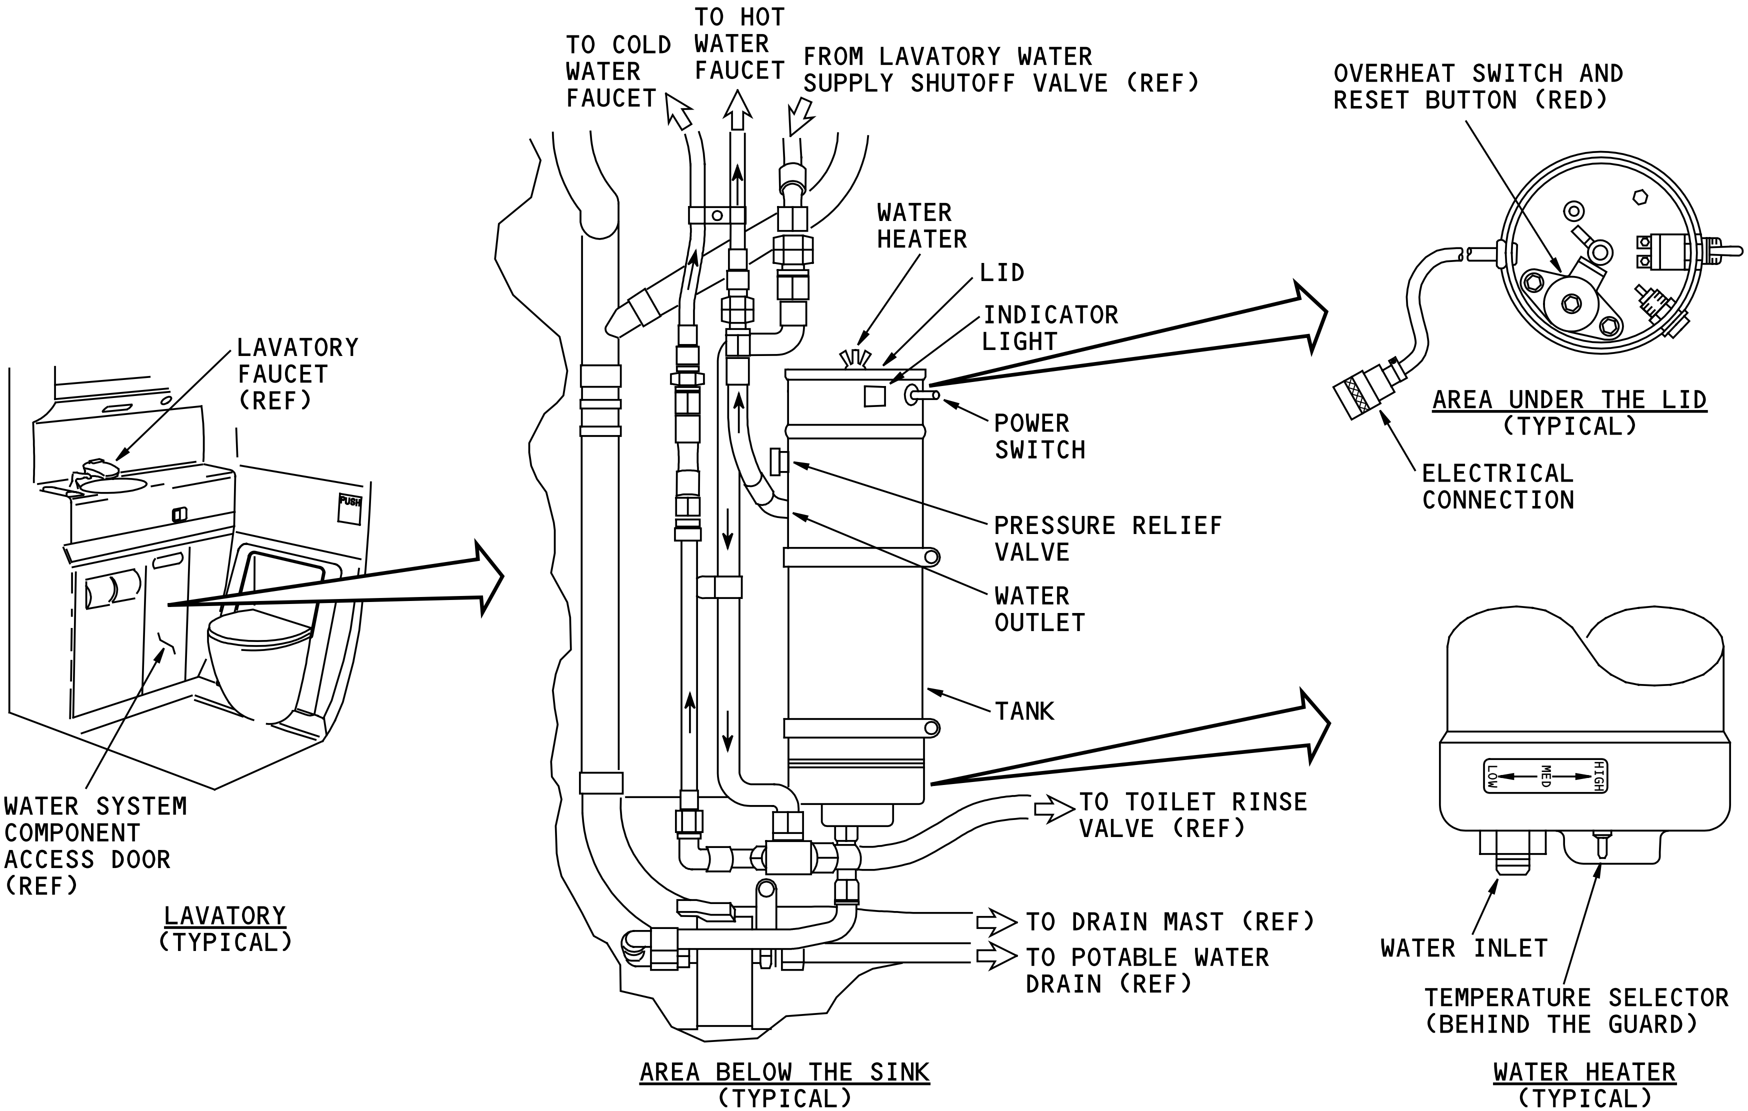
- The power switch is OFF
- The overheat switch is open.

WATER HEATING - INTRODUCTION

Training Information Point

If you use all of the hot water from the tank, the water heater takes approximately 15 minutes to heat the water to the set temperature.

When you drain the potable water system, remove power from the water heaters to prevent an overheat condition.



38-13-00-001 Rev 5 04/26/96

WATER HEATING - INTRODUCTION

WATER QUANTITY INDICATION - INTRODUCTION

Purpose

The water quantity indication system shows the water quantity in the tanks.

Physical Description

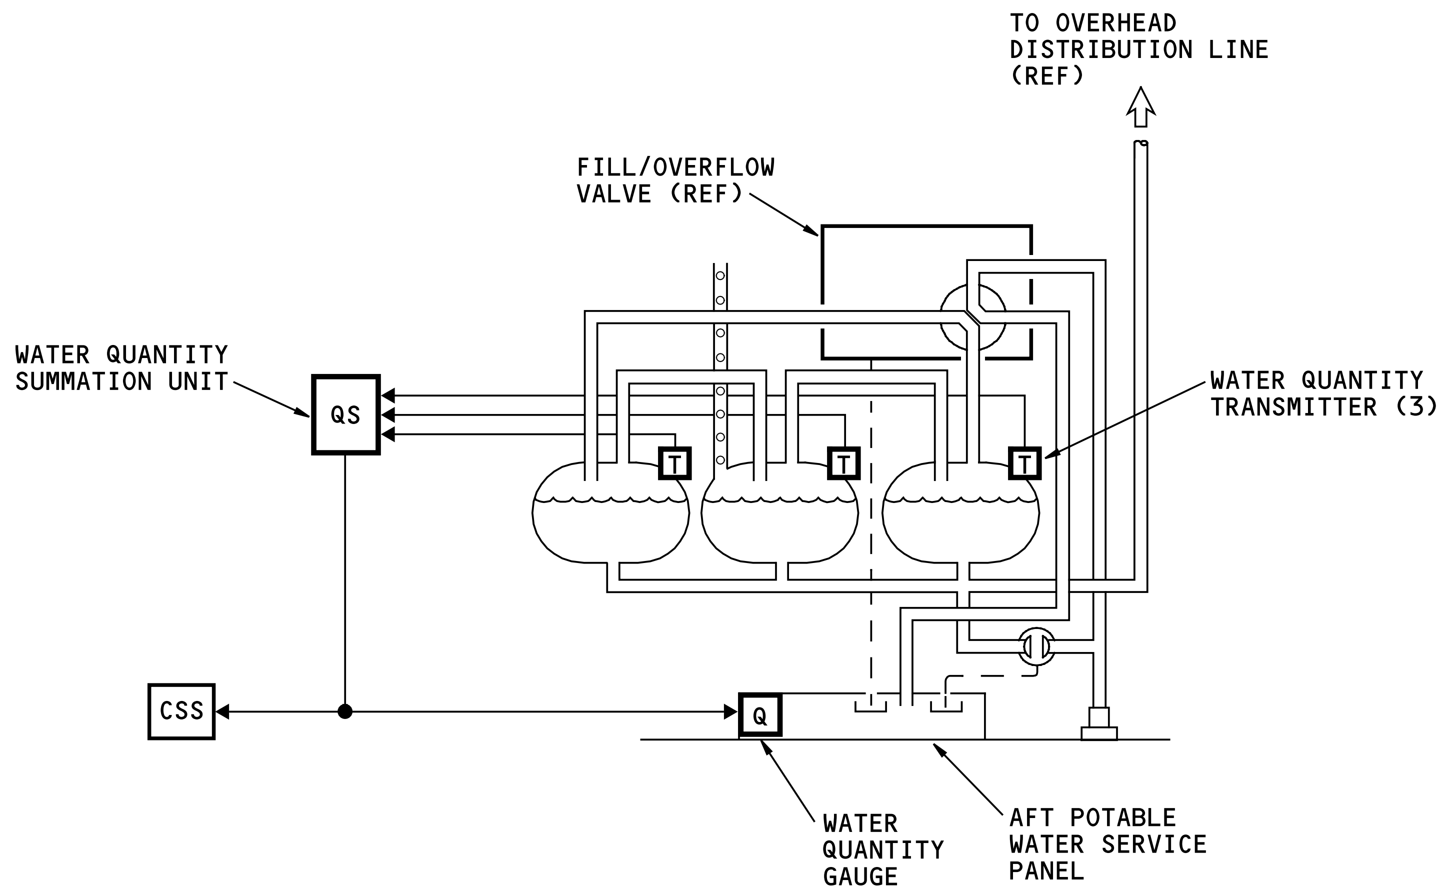
These are the water quantity indication components:

- Water quantity gauge
- Water quantity transmitter (3)
- Water quantity summation unit
- Water level sensors (part of tanks, not shown).

General Description

The water quantity transmitters send water quantity information to the summation unit. The summation unit sends quantity information to the:

- Cabin services system (CSS) panels
- Aft potable water service panel gauge.



WATER QUANTITY INDICATION - INTRODUCTION

WATER QUANTITY INDICATION - COMPONENT LOCATIONS

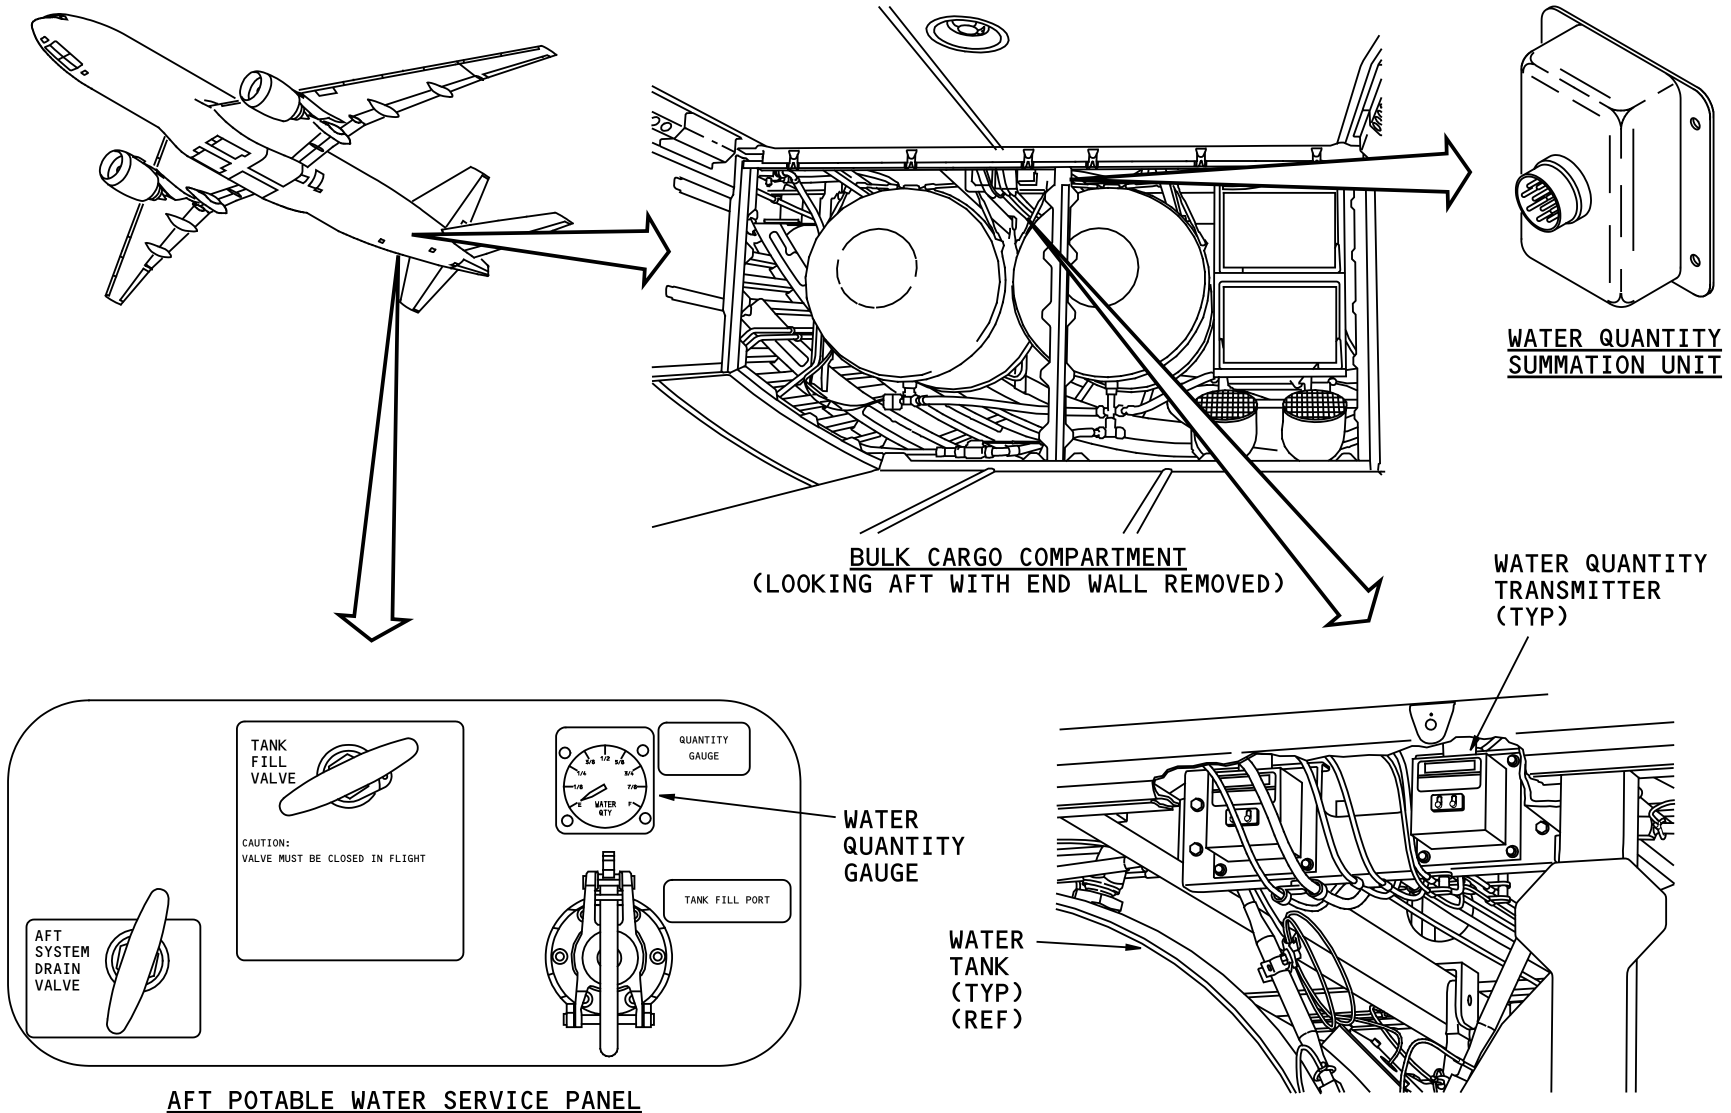
Component Locations

There is a water quantity gauge on the aft potable water service panel.

The water quantity summation unit is aft of the bulk cargo compartment end wall. It is on a passenger compartment floor beam.

There is a water level sensor that is part of each water tank.

There is a water quantity transmitter installed on a bracket near the forward side of each tank.



WATER QUANTITY INDICATION - COMPONENT LOCATIONS

WATER QUANTITY INDICATION - WATER QUANTITY TRANSMITTER

Purpose

The water quantity transmitter sends a signal to the water quantity summation unit.

Physical Description

The transmitter attaches to the transmitter mounting pad. The pad is part of the tank. The transmitter connects to the tank sensor through a terminal connector and a terminal screw.

The empty and full tank quantity adjustment screws are beneath an access plate on the transmitter.

Location

There is a transmitter installed on a bracket near the forward side of each tank.

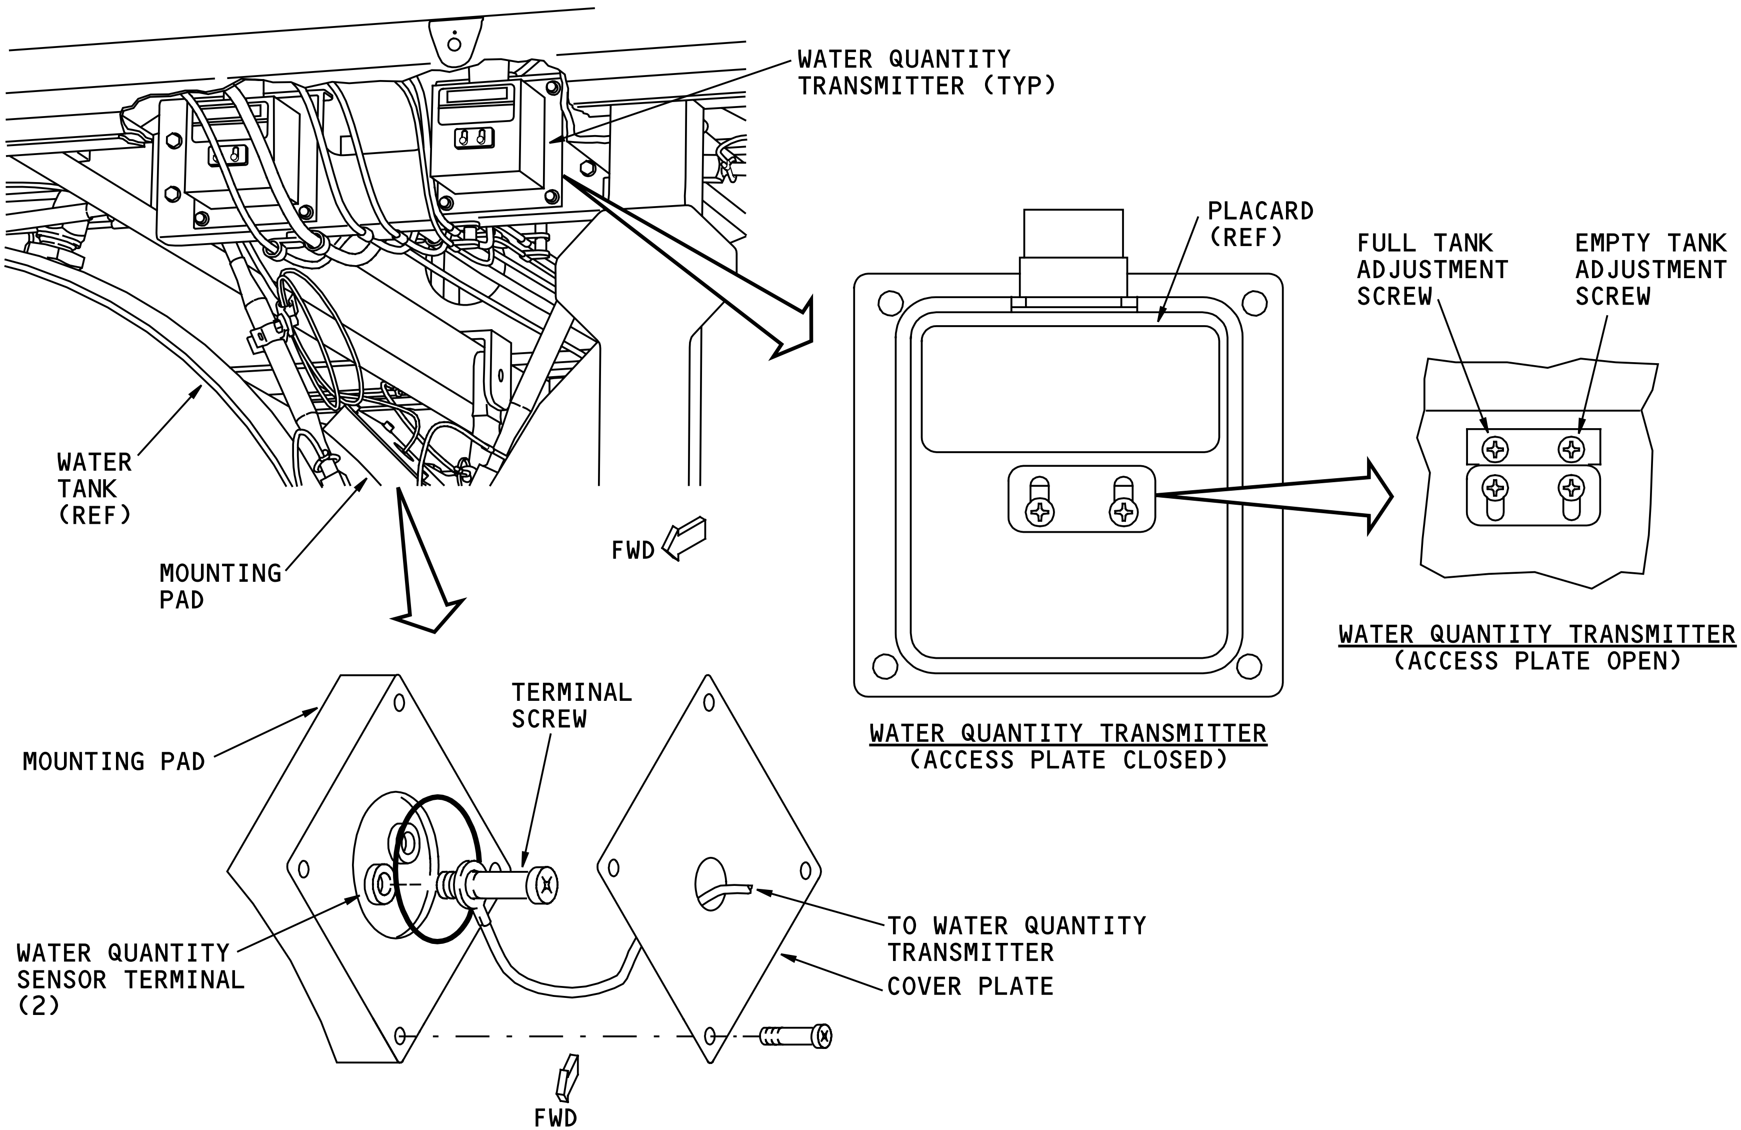
Functional Description

The transmitter uses a capacitance-type water level senor to find the water level in the tank. The sensor is part of the tank. The transmitter gives a signal to the water quantity summation unit.

There are two water quantity sensor terminals on each mounting pad. The transmitter can connect to either terminal. The two terminals are in parallel. If one does not operate, the other one will not operate either.

Training Information Point

To adjust the transmitter, you must fill the tanks to full, then drain them, before you make adjustments. The inner surface of the tank must be wet to make an accurate calibration of the transmitter.



38-14-00-005 Rev 2 12/18/1996

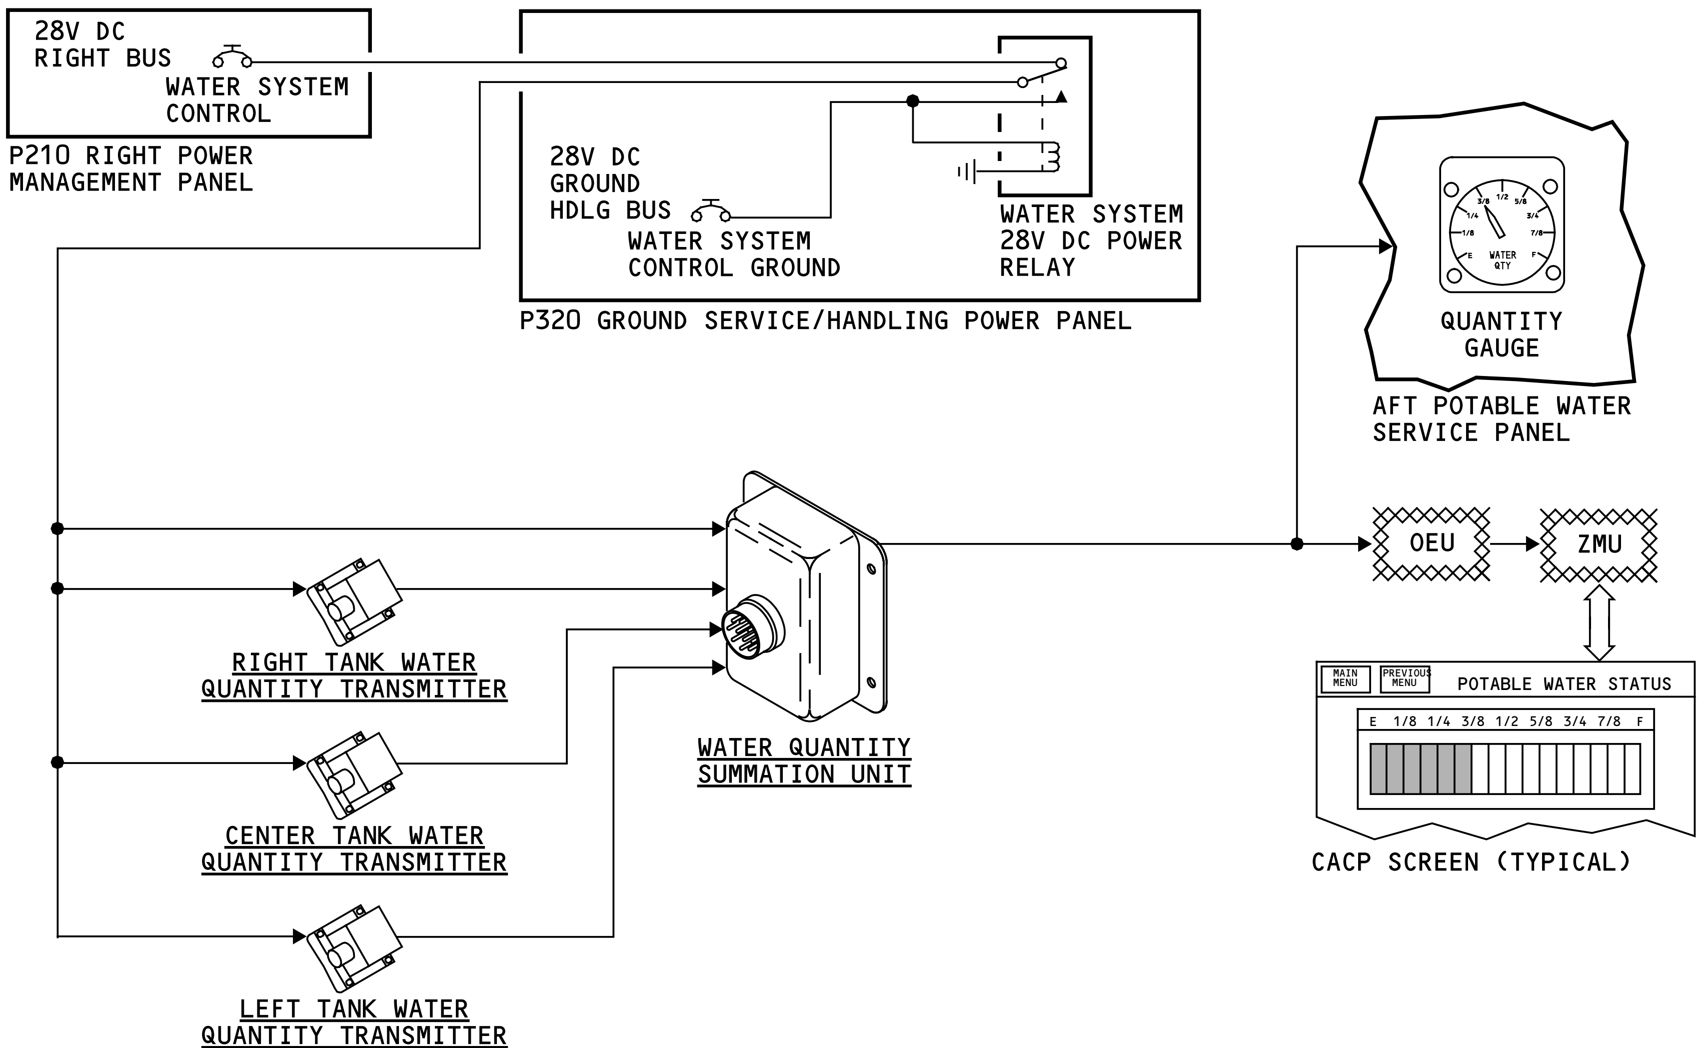
WATER QUANTITY INDICATION - WATER QUANTITY TRANSMITTER

WATER QUANTITY INDICATION - FUNCTIONAL DESCRIPTION - INDICATION

Functional Description

The water quantity transmitters give water quantity data to the water quantity summation unit.

The summation unit calculates the total amount of water in the water tanks. This data goes to the water quantity gauge on the aft potable water service panel and to the cabin services system.



NOTE: CACP SHOWN, CSCP SIMILAR

WATER QUANTITY INDICATION - FUNCTIONAL DESCRIPTION - INDICATION

38-14-00-007 Rev 5 07/24/1997

WATER QUANTITY INDICATION - OPERATION - CSCP/CACP INDICATIONS

Operation

The CMS gives data on the potable water.

This data is on the cabin system control panel (CSCP) and the cabin area control panels (CACPs).

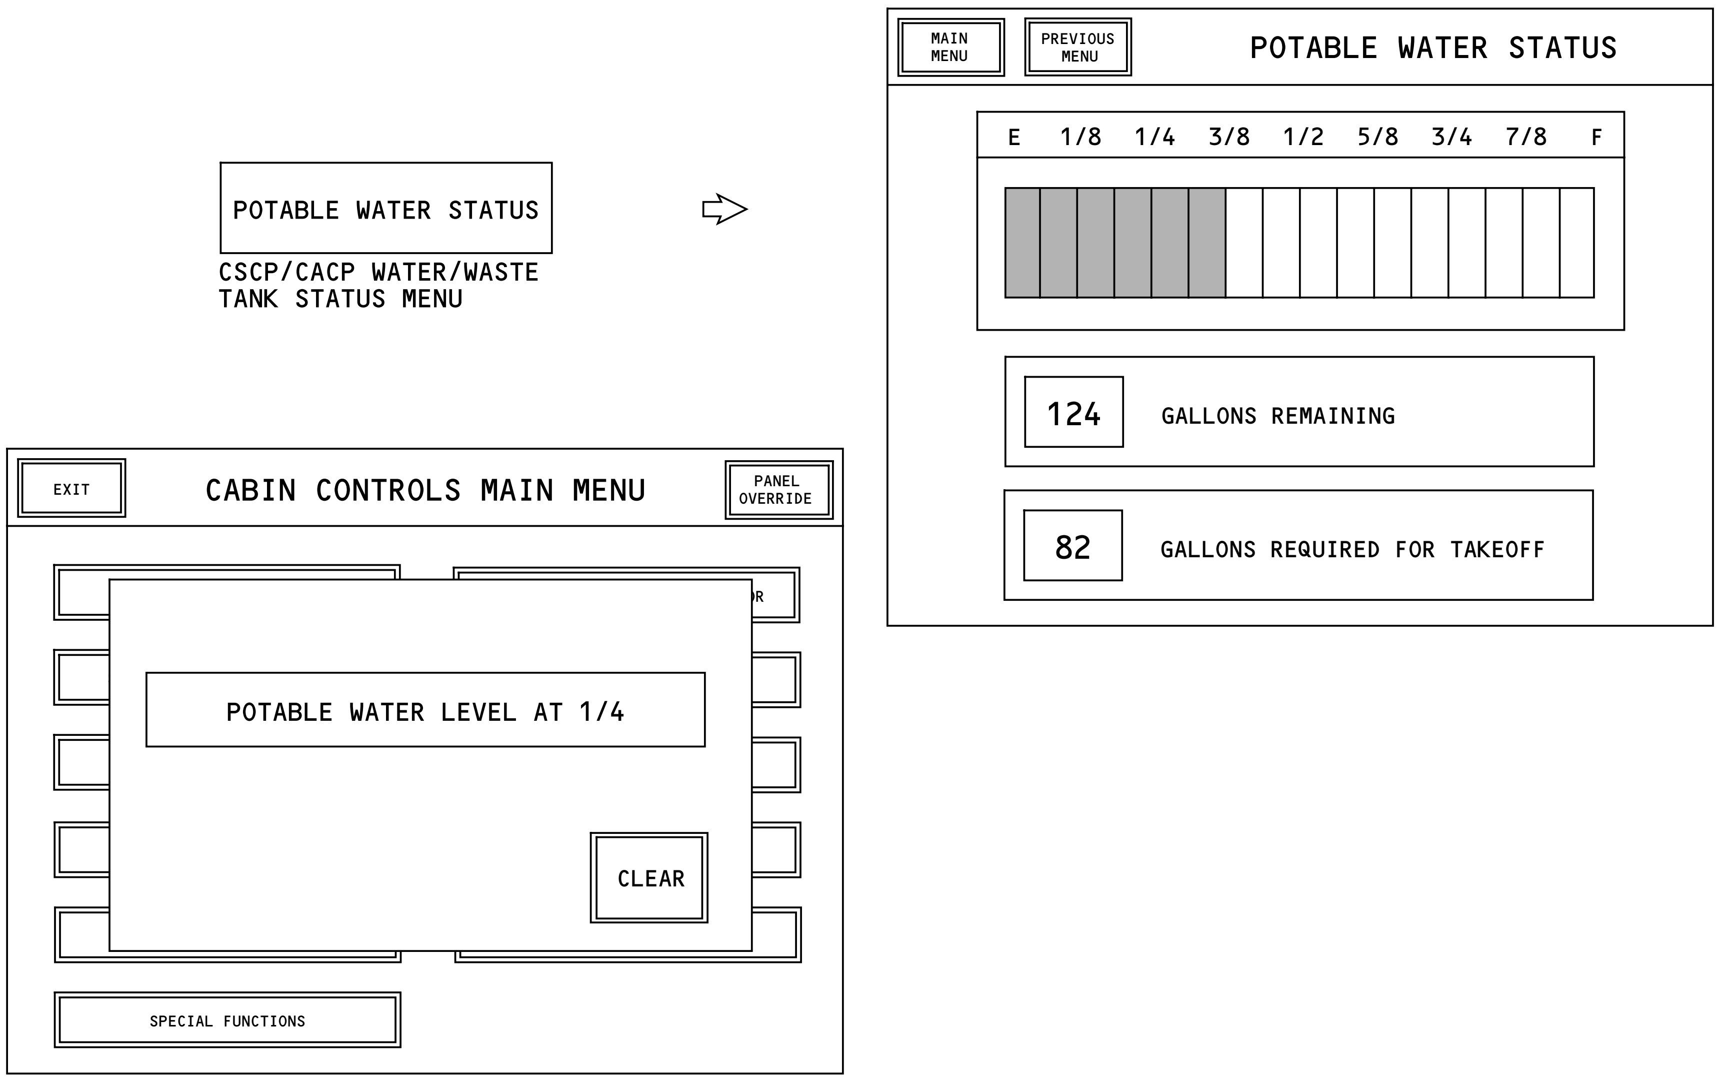
On the cabin controls main menu, select the water/waste status area. This causes the water/waste tank status menu to show. Then select the potable water status area. This causes the potable water status screen to show.

The potable water status screen shows the total amount of water in the tanks.

The quantity required for takeoff is a value set in the CSS configuration database. You can also use the CSS configuration database to make this area of the potable water status screen not show.

A screen automatically shows on the CSCP/CACP when the amount of water in the tanks is low. You touch the CLEAR button to remove the screen.

See the cabin services system section for more information (AMM PART I 23-39).



CSCP/CACP

WATER QUANTITY INDICATION - OPERATION - CSCP/CACP INDICATIONS

WATER TANK PRESSURIZATION - INTRODUCTION

Purpose

The water tank pressurization system pressurizes the potable water tanks for distribution.

General Description

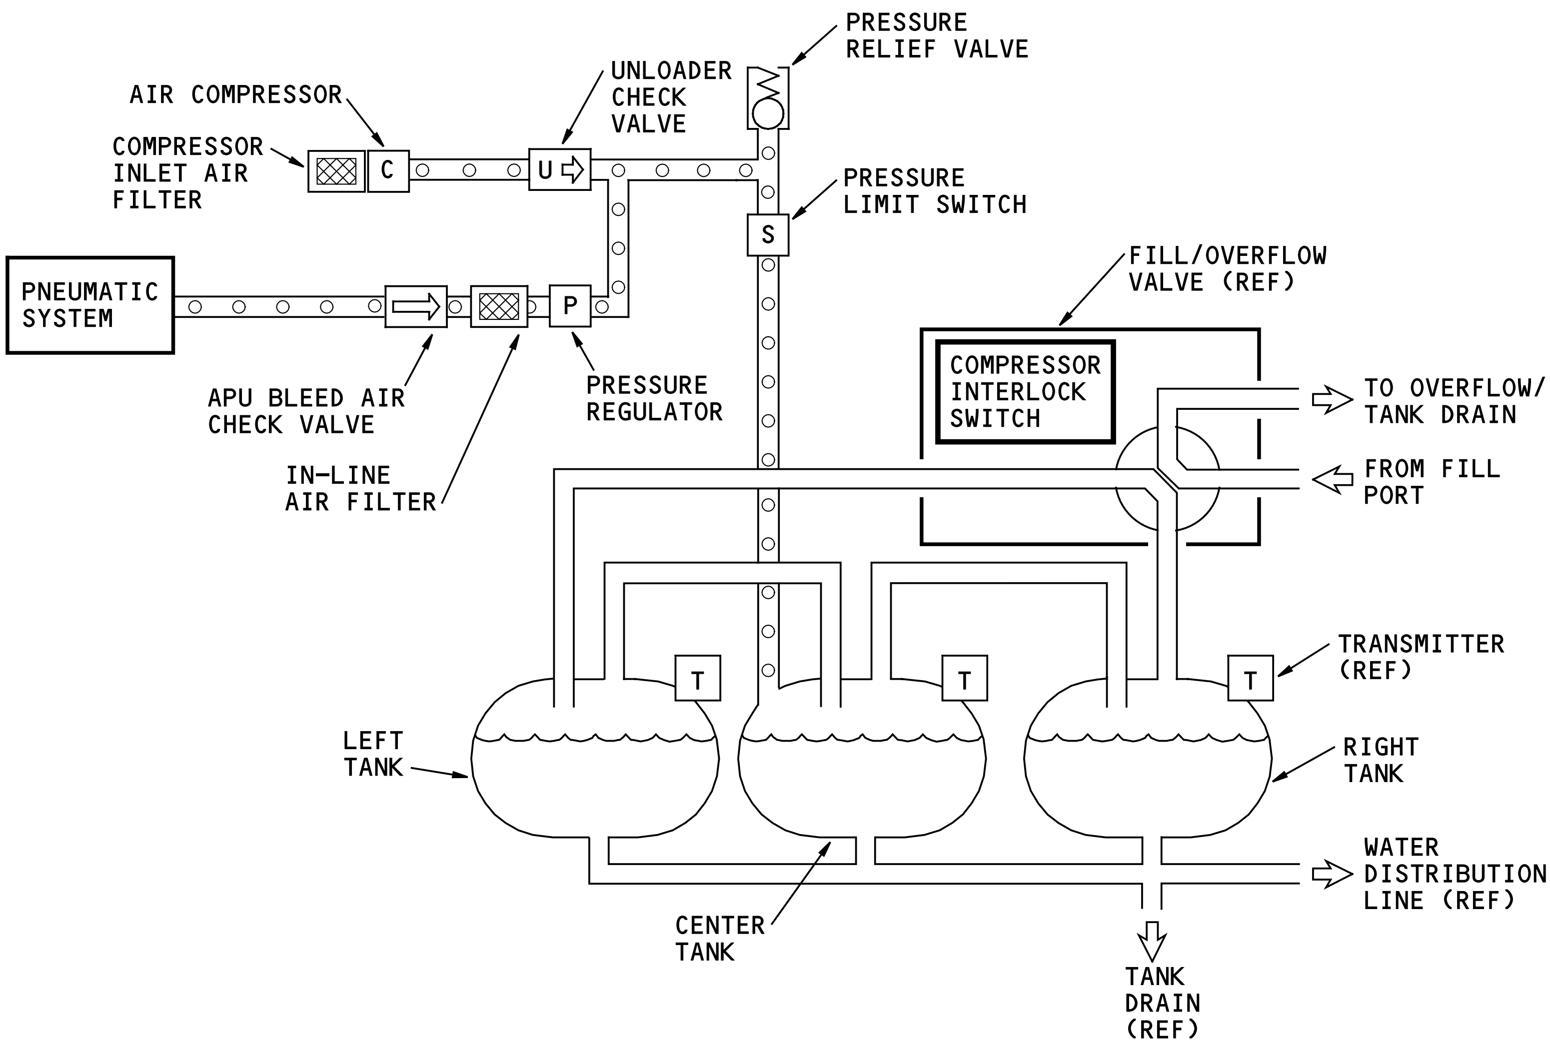
Pressure for the water tanks comes from the pneumatic system or from a compressor. The air compressor supplies pressure to the tanks when pressure from the pneumatic system is not sufficient.

These components control the amount of pressure that goes to the tanks:

- Pressure relief valve
- Pressure limit switch
- Pressure regulator
- Compressor interlock switch.

The APU bleed air check valve and the unloader check valve do not let pressure from one source go to the other source.

The compressor inlet air filter and the in-line air filter remove particles from the air.



WATER TANK PRESSURIZATION - INTRODUCTION

WATER TANK PRESSURIZATION - COMPONENT LOCATIONS - 1

Component Locations

These components are behind the end wall of the bulk cargo compartment:

- Pressure relief valve
- Pressure limit switch.

These components are above the ceiling panels in the aft section of the bulk cargo compartment.

- Pressure regulator
- APU bleed air check valve
- In-line air filter
- Unloader check valve.

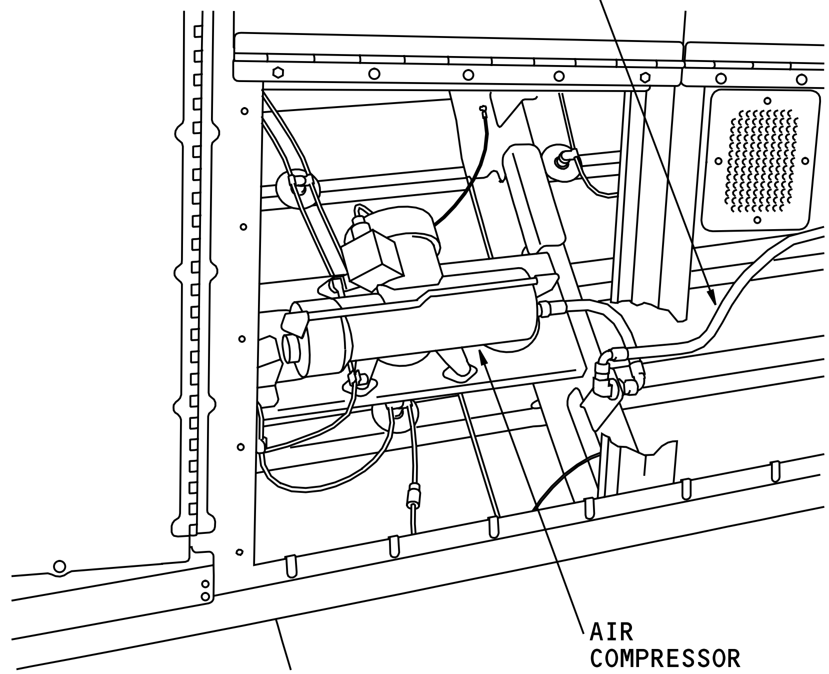
RIGHT SIDE OF BULK CARGO COMPARTMENT
(LOOKING FORWARD WITH PANELS REMOVED)



WATER TANK PRESSURIZATION - COMPONENT LOCATIONS - 2

WATER TANK PRESSURIZATION - FUNCTIONAL DESCRIPTION - CONTROL

General

The compressor or the pneumatic system pressurize the potable water tanks. The compressor operates if pressure from the pneumatic system is not sufficient.

Power

The water system 28v dc power relay supplies power for control from the ground handling bus. If the ground handling bus has no power, the relay supplies power from the right bus.

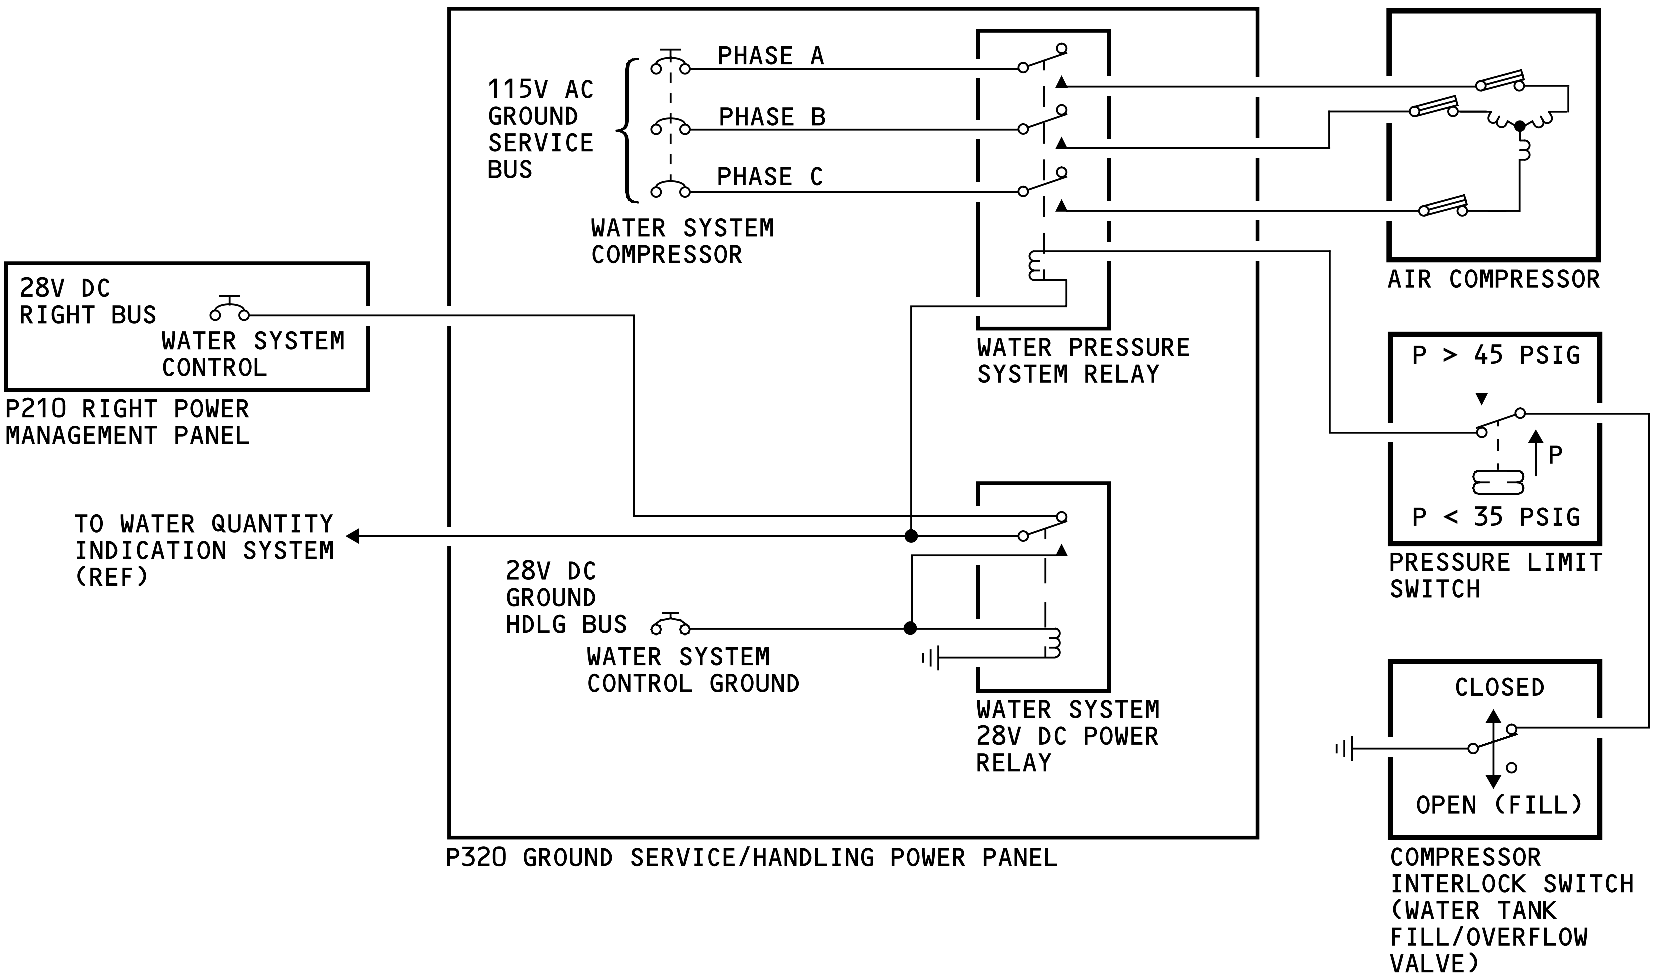
Power for compressor operation comes through the water pressure system relay. The compressor operates when the relay is energized. The relay energizes when the pressure limit switch and the compressor interlock switch are closed.

The pressure limit switch closes when tank pressure is 35 psig or less. It opens when tank pressure is 45 psig.

The compressor interlock switch is on the fill/overflow valve. The switch is closed when the valve is closed. The switch is open when you open the valve to fill the tanks.

Overcurrent and Overtemperature Protection

Three overheat switches give protection to the compressor motor. They stop the motor when the temperature of a phase is too high or there is too much current. The switches automatically go back to the normal position when the motor is cool.



38-42-00-014 Rev 3 05/27/95

WATER TANK PRESSURIZATION - FUNCTIONAL DESCRIPTION - CONTROL

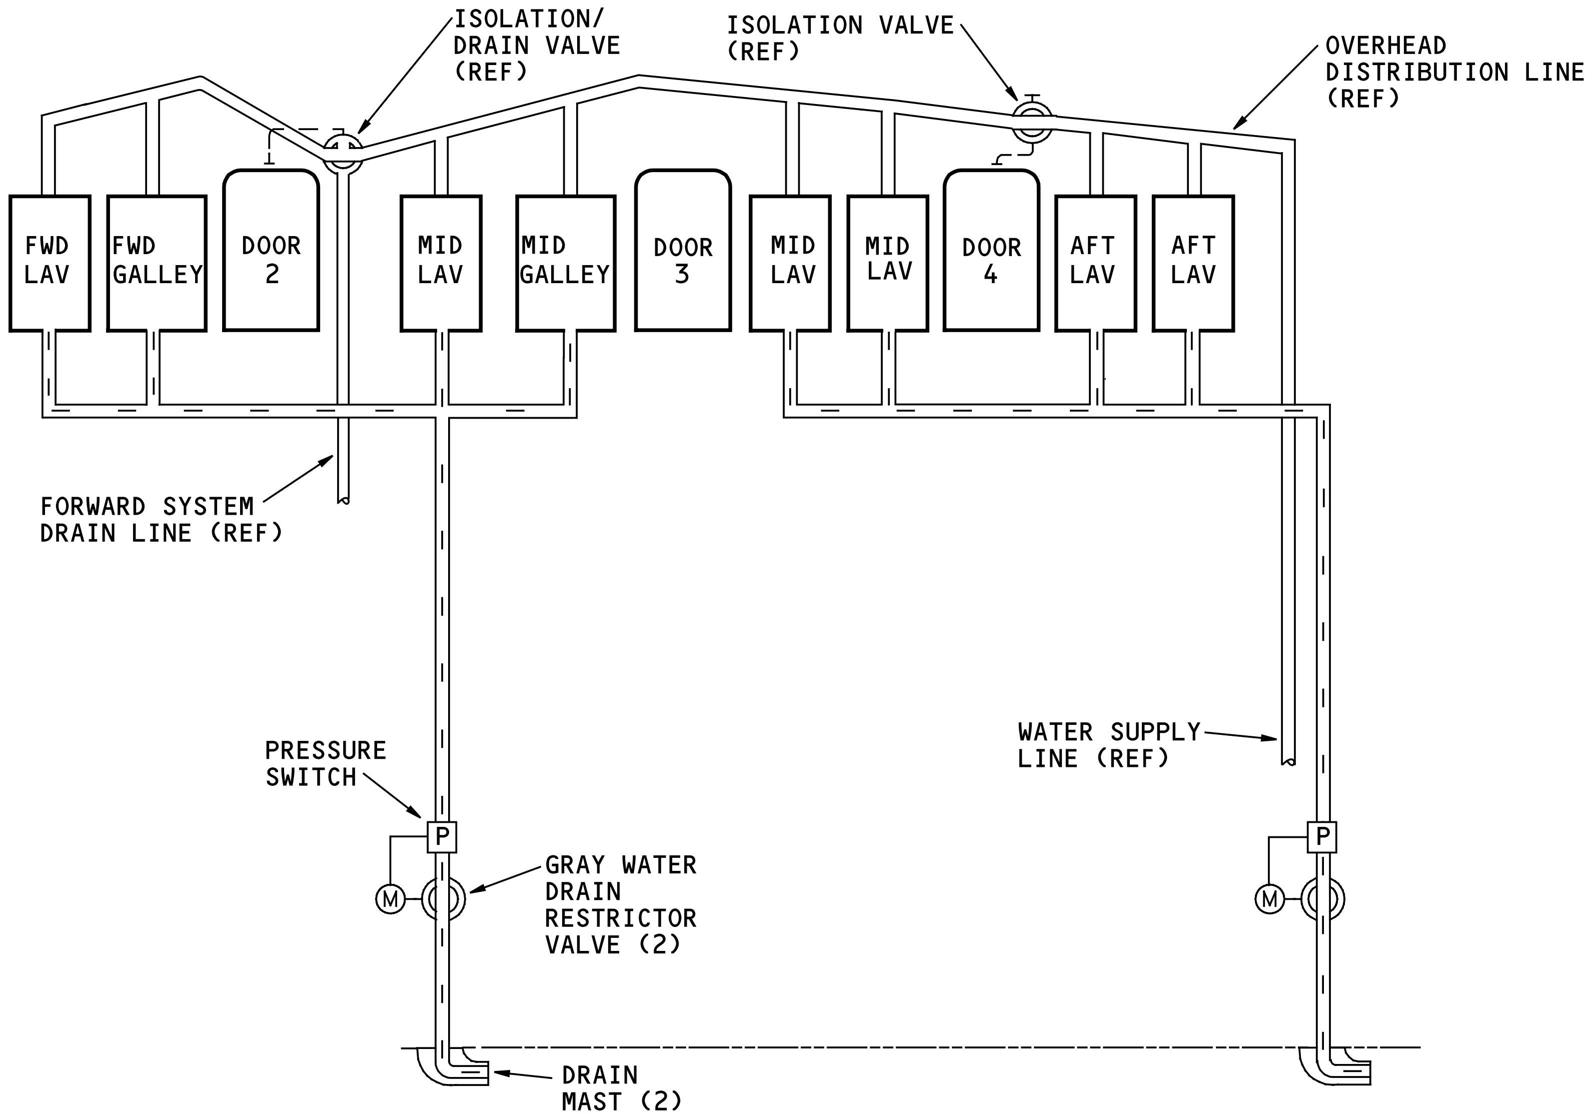
GRAY WATER DRAIN SYSTEM - INTRODUCTION

Purpose

The gray water drain system permits waste water from lavatory and galley sinks to drain overboard.

General Description

Waste water from the sinks goes through lines and flows overboard through the forward or aft drain mast. A gray water drain restrictor valve keeps the amount of air flow out of the plane to a limit when the airplane is in the air. This helps to decrease noise in the lavatories and galleys.



GRAY WATER DRAIN SYSTEM - INTRODUCTION

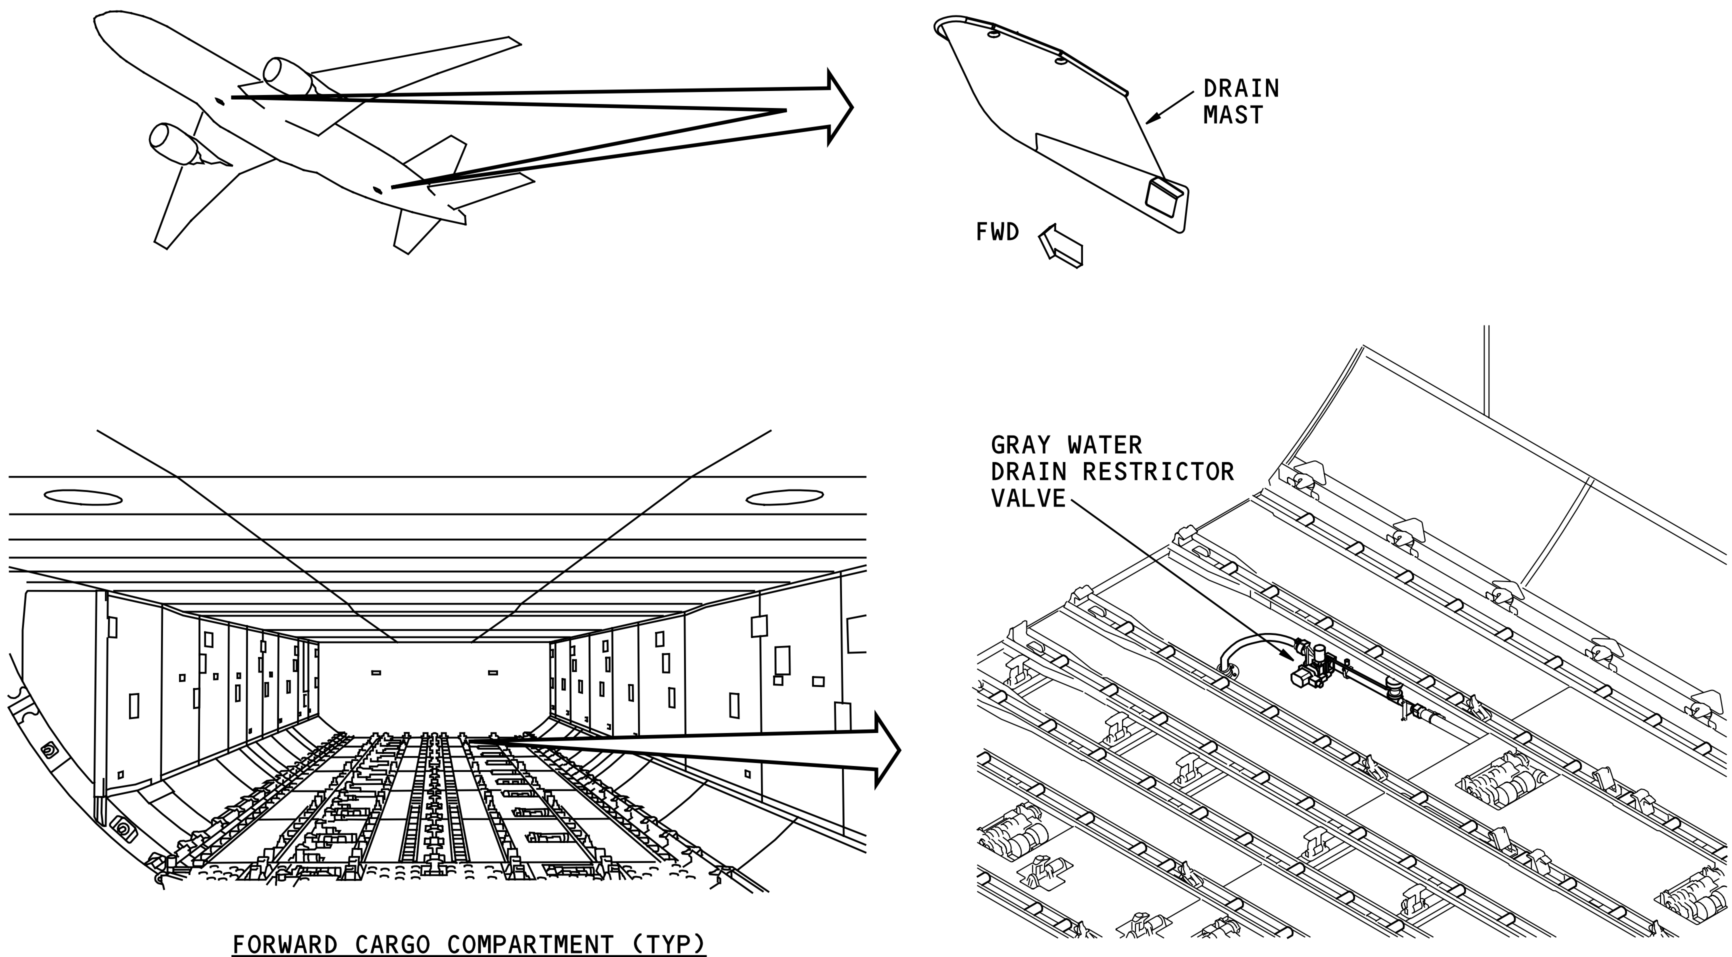
38-31-00-001 Rev 3 01/07/1998

GRAY WATER DRAIN SYSTEM - COMPONENT LOCATIONS

Component Locations

The forward and aft drain masts are on the bottom of the airplane.

The forward gray water drain restrictor valve is under the floor of the forward cargo compartment. The aft valve is under the floor of the aft cargo compartment.



38-31-00-002 Rev 1

GRAY WATER DRAIN SYSTEM - COMPONENT LOCATIONS

GRAY WATER DRAIN SYSTEM - DRAIN MAST

Purpose

The drain masts drain waste water from the lavatory and galley sinks overboard.

Heaters in the drain masts do not permit the gray water to freeze and cause a blockage of the line.

Physical Description

There are heaters that are a part of the forward and aft drain masts.

Each drain mast has these components:

- Power wire
- Ground wire
- Ground connector.

Location

The forward mast is on the left wing-to body fairing. It is forward and outboard of the left ECS bay.

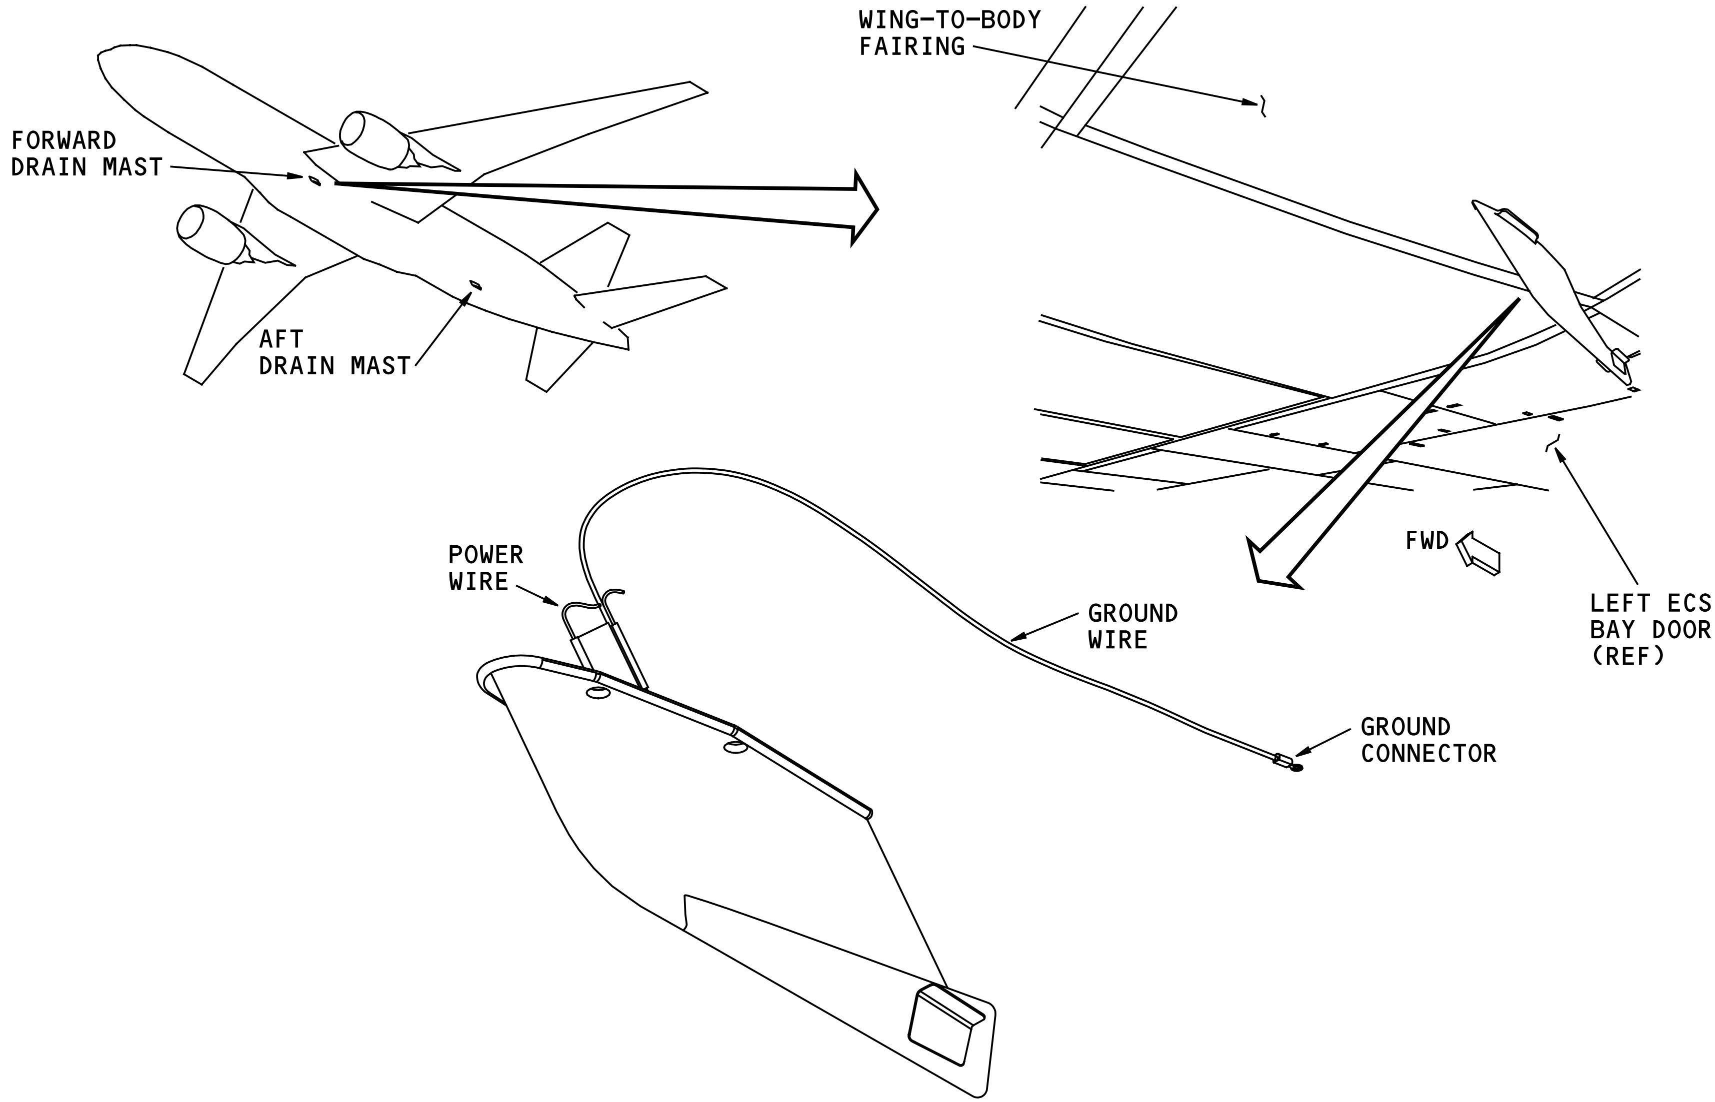
The aft mast is behind the aft cargo compartment door, on the bottom of the airplane.

Drain Mast Heater

See the drain and water supply line heating section for more information about the drain mast heaters (AMM PART I 30-71).

Training Information Point

You must make a splice in the wires when you replace a drain mast.



FORWARD DRAIN MAST

GRAY WATER DRAIN SYSTEM - DRAIN MAST

GRAY WATER DRAIN SYSTEM - GRAY WATER DRAIN RESTRICTOR VALVE

Purpose

The gray water drain restrictor valves keep the air flow out of the drain masts to a limit. They prevent noise in the drain lines.

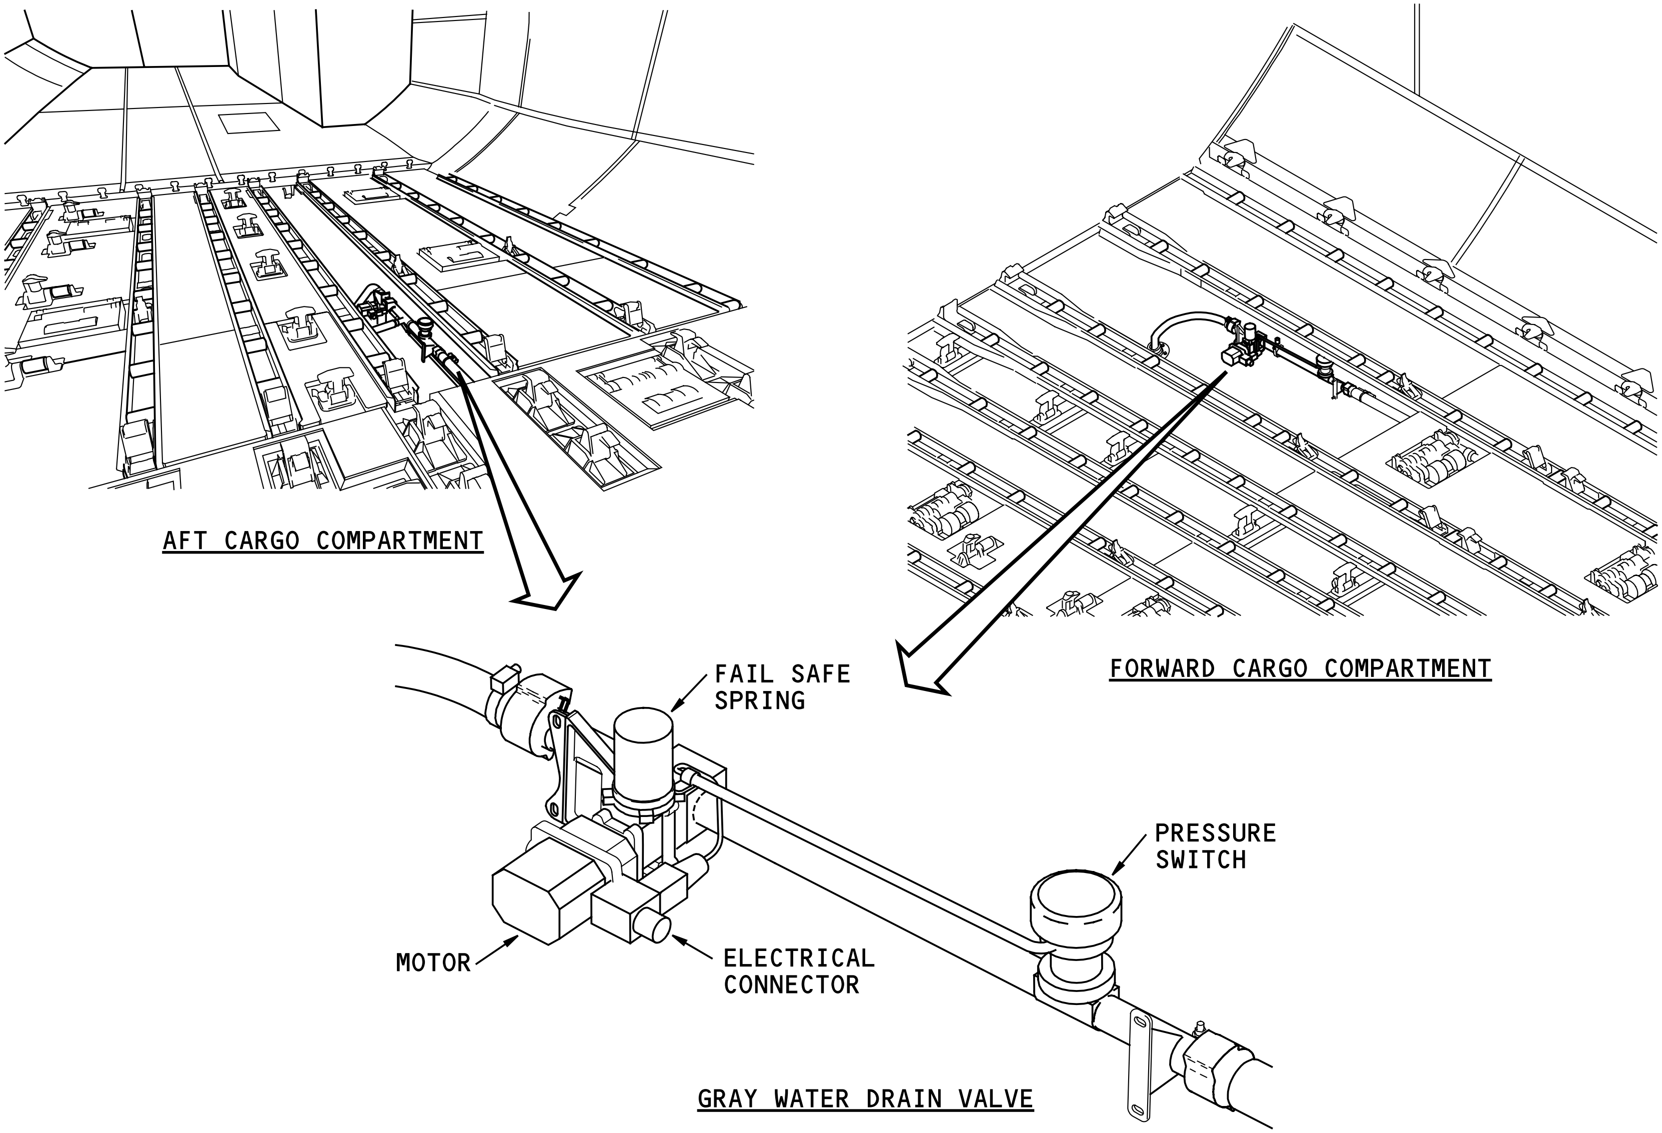
Physical Description

The valve has these components:

- Motor
- Fail safe spring
- Pressure switch
- Electrical connector.

Location

The forward valve is under the floor in the forward cargo compartment. The aft valve is under the floor of the aft cargo compartment.



38-31-00-004 Rev 1

GRAY WATER DRAIN SYSTEM - GRAY WATER DRAIN RESTRICTOR VALVE

GRAY WATER DRAIN SYSTEM - FUNCTIONAL DECSRIPTION

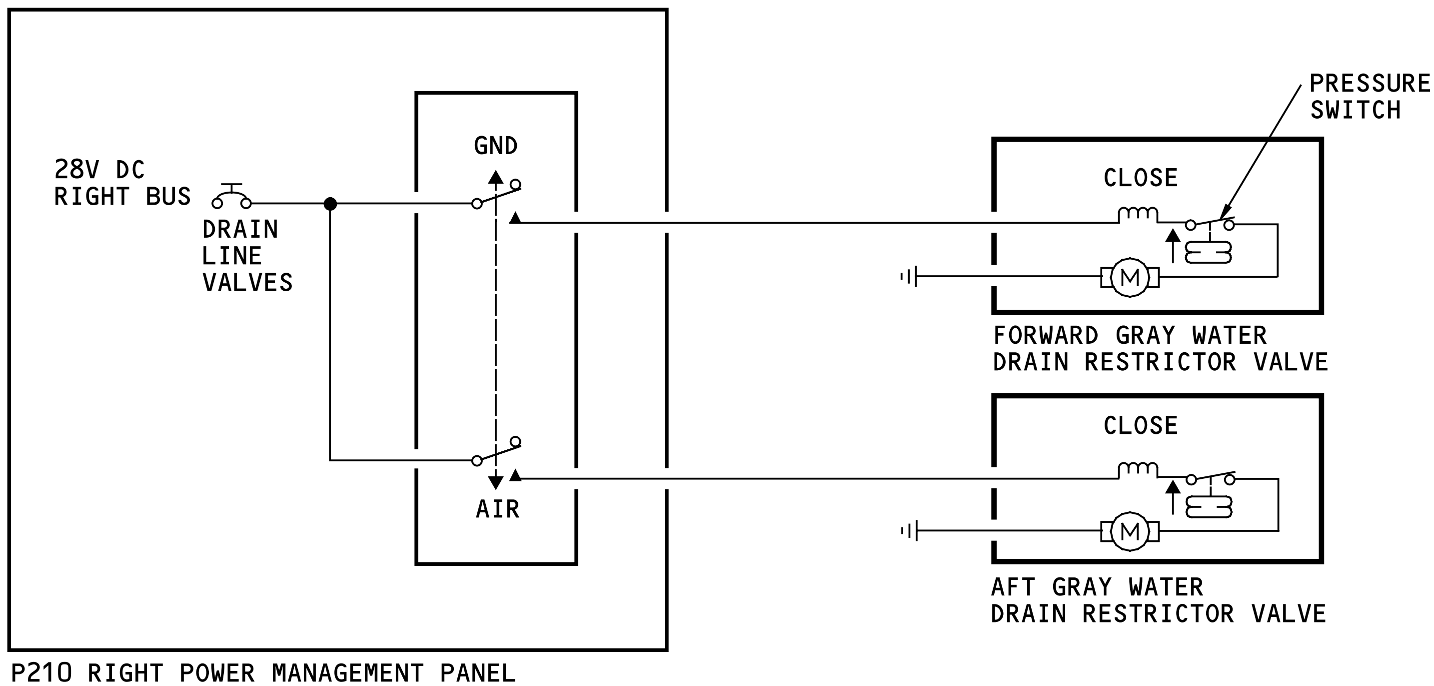
Gray Water Drain Restrictor Valve

The forward and aft gray water drain restrictor valves get power from the right main bus.

The motors move the valves so they are almost closed when the airplane is in the air.

Functional Description

When the pressure in the drain line increases beyond a limit, the pressure switch opens. This de-energizes the motor and the valve opens. This removes any blockage in the line. The pressure switch closes when the pressure decreases.



38-31-00-005 Rev 1

GRAY WATER DRAIN SYSTEM - FUNCTIONAL DECSRIPTION

VACUUM WASTE SYSTEM - INTRODUCTION

Purpose

The vacuum waste system removes waste from the toilets and stores it in the waste tanks. The waste stays in the waste tanks until they are serviced.

General Description

Waste collects in the toilet. Suction then moves the waste to the waste tanks. The suction is made by the vacuum blower. The difference between the cabin pressure and the outside pressure also moves the waste to the waste tanks. You remove the waste in the waste tanks through the waste service panel. The T handle in the service panel opens the waste tank drain ball valve. When you open the waste drain valve assembly, you permit the waste tanks to drain.

These components make up the vacuum waste system:

- Vacuum toilet assembly
- Waste tank
- Vacuum blower and filter
- Vacuum blower barometric switch (not shown)
- Vacuum check valve
- Vacuum waste system tubing
- Liquid separator
- Waste tank drain ball-valve
- Waste drain valve assembly
- Waste tank rinse fitting assembly
- Waste tank rinse filter
- Waste tank rinse nozzle.

(ROTATED)

VACUUM WASTE SYSTEM - LAVATORY COMPONENT LOCATIONS

38-32-00-006 Rev 2 08/21/1997

VACUUM WASTE SYSTEM - VACUUM TOILET ASSEMBLY

Purpose

The vacuum toilet assembly collects waste.

Physical Description

The vacuum toilet assembly has these parts:

- Rinse ring
- Toilet bowl
- Anti-siphon valve
- Rinse valve
- Flush valve
- Manual shutoff handle
- Assembly mounting stand
- Manual shutoff valve handle
- Flush control module (FCM).

Location

A vacuum toilet assembly is in each lavatory. It is under the toilet shroud (not shown).

Functional Description

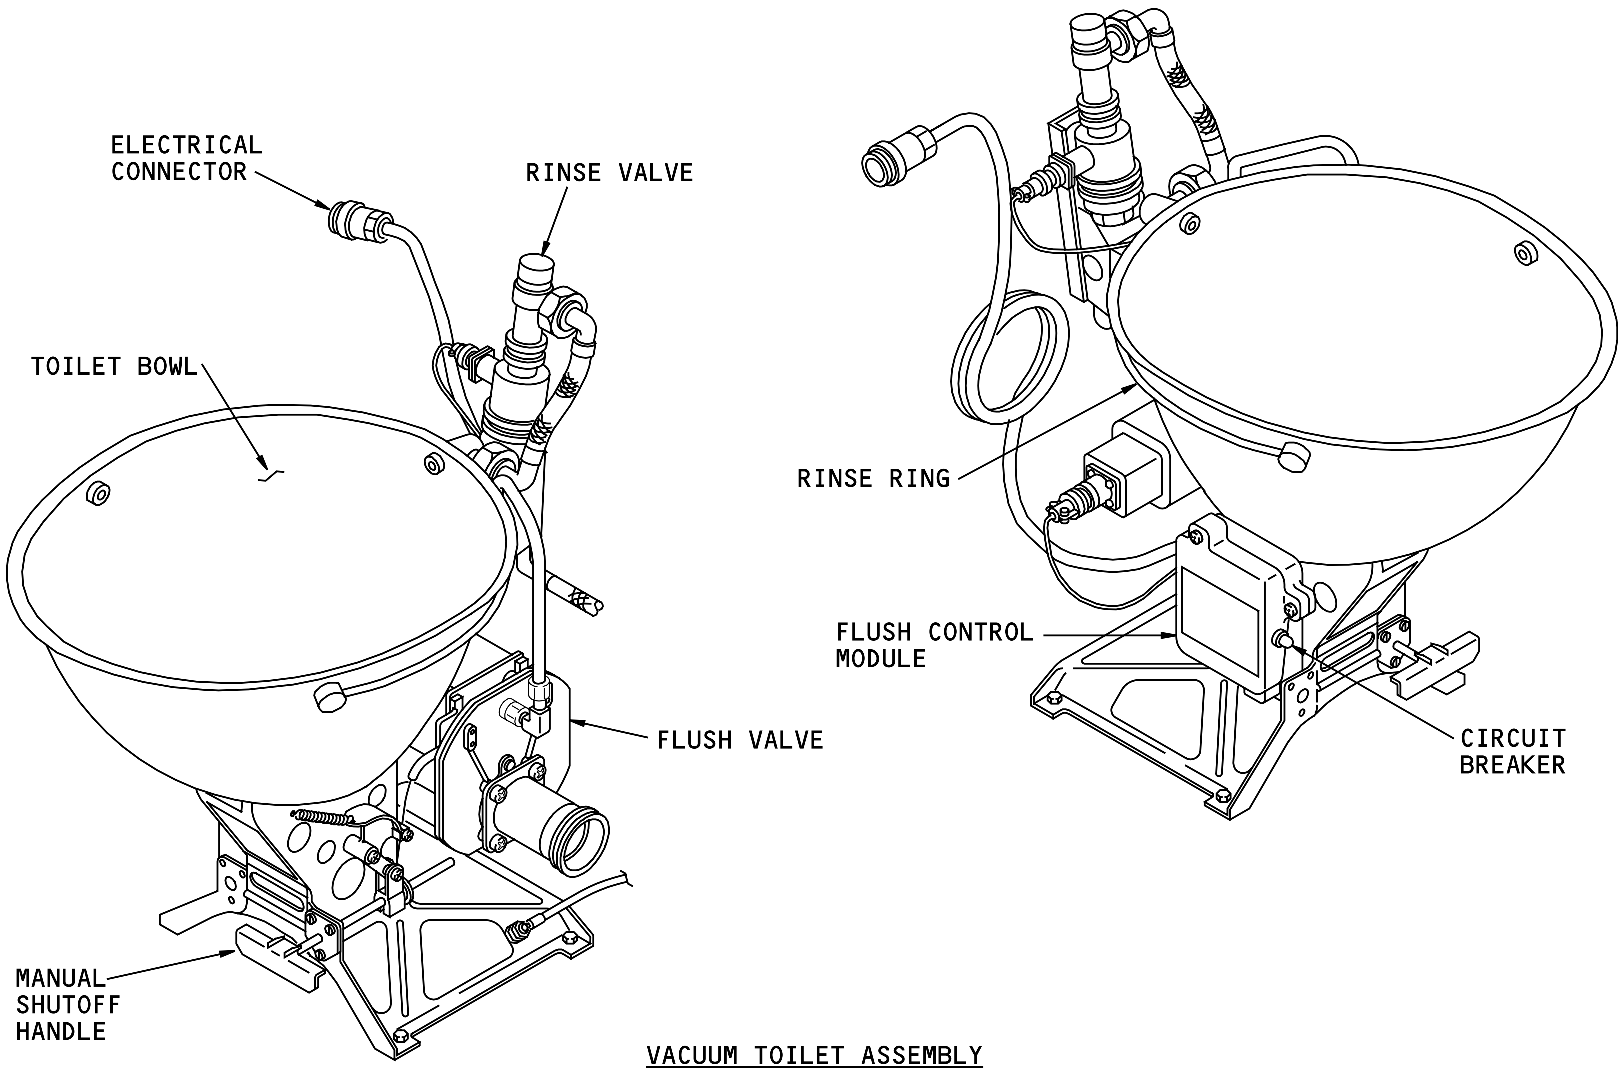
The rinse valve supplies potable water to the rinse ring. When the toilet flushes, the FCM opens the valve for 0.7 seconds and releases water. The rinse ring uses the water to rinse the toilet bowl.

The anti-siphon valve keeps water that is in the rinse ring and the toilet bowl out of the potable water system. This valve makes an air gap between the bowl and the potable water supply.

The flush valve keeps the flow path between the toilet bowl and the waste line closed. The valve opens to let waste move from the toilet bowl to the waste tank. The FCM controls the flush valve.

Training Information Point

If the flush valve fails in the open position, cabin pressure goes out through the vacuum waste system. To prevent this until you make repairs, manually close the flush valve. Pull the handle that is below the toilet shroud to close the flush valve.



VACUUM TOILET ASSEMBLY
(TYPICAL)

38-32-00-007 Rev 3 08/21/1997

VACUUM WASTE SYSTEM - VACUUM TOILET ASSEMBLY

VACUUM WASTE SYSTEM - WASTE TANK

Purpose

Waste tanks collect waste from the toilets.

Physical Description

There are three waste tanks on the airplane. The forward and mid tanks are 100-gallon (379 liters) tanks and they hold 83 gallons (314 liters) of waste. The aft tank is an 80-gallon (303 liters) tank and it holds 63 gallons (239 liters) of waste.

The waste tank is made out of composite materials and has a stainless steel inner liner. The tank has an opening and a cover at each end. The upper cover connects to two vent lines. The lower cover connects to tank drain line.

Two waste inlet fittings attach to the upper part of the tank. Two point level sensors and one rinse nozzle are attached to the inboard side of the tank. The rinse nozzle is above the point level sensors.

See the waste tank quantity indication section for more information on the point level sensors (AMM PART I 38-33).

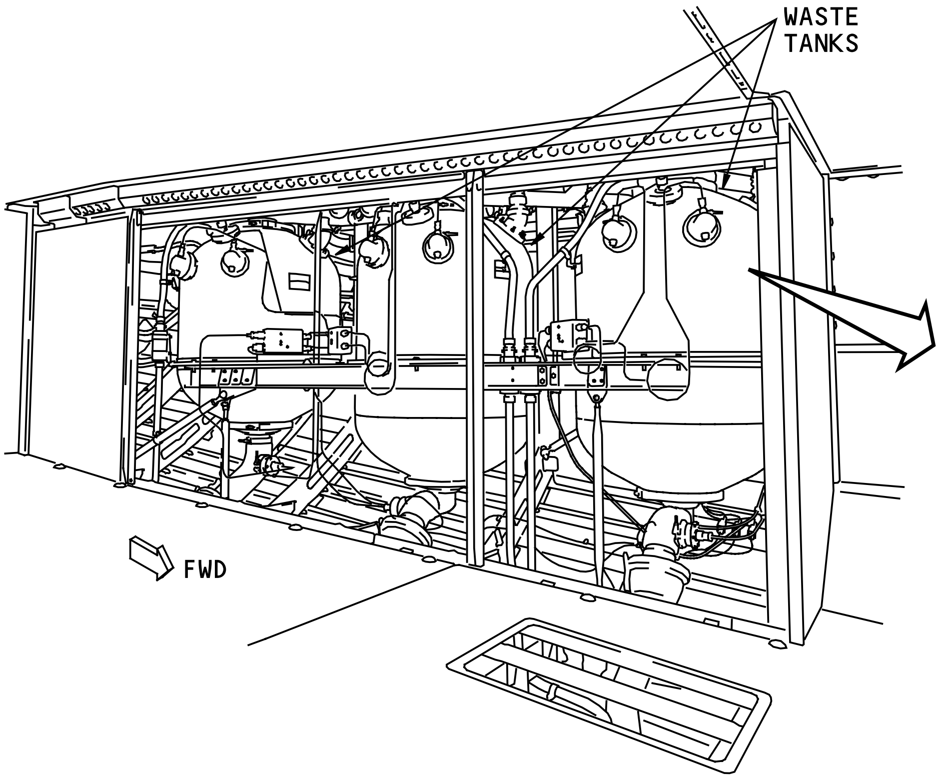
The waste tank has a lower mounting ring. Bolts attach the mounting ring to the tank cradle.

Location

The waste tanks are in the bulk cargo compartment on the left side of the airplane.

Training Information Point

You use the service panel to drain and flush the waste tank before you remove it.



LEFT SIDE OF BULK CARGO COMPARTMENT
(LOOKING OUTBOARD AND AFT

WASTE TANK
(TYP)

38-32-00-008 Rev 3 08/07/96

VACUUM WASTE SYSTEM - WASTE TANK

VACUUM WASTE SYSTEM - VACUUM BLOWER AND FILTER

Purpose

The vacuum blower supplies suction for the waste system. The suction moves the toilet rinse water and its contents to the waste tank. The filter removes particles from the air that cools the blower motor.

Physical Description

The vacuum blower has these parts:

- Intake port
- Cooling air filter
- Exhaust port.

Location

Two vacuum blowers are in the aft cargo compartment on the left side. The vacuum blowers are forward of the waste tanks on a shelf.

Functional Description

The vacuum blowers cause a pressure difference large enough to move the waste from the lavatories to the waste tanks. The vacuum blowers operate if the airplane is below 16,000 feet. When the airplane is above 16,000 feet, the vacuum blowers do not operate. Lower pressure outside the airplane creates a vacuum.

When the airplane is below 16,000 feet, the vacuum blower operates when you select the flush switch.

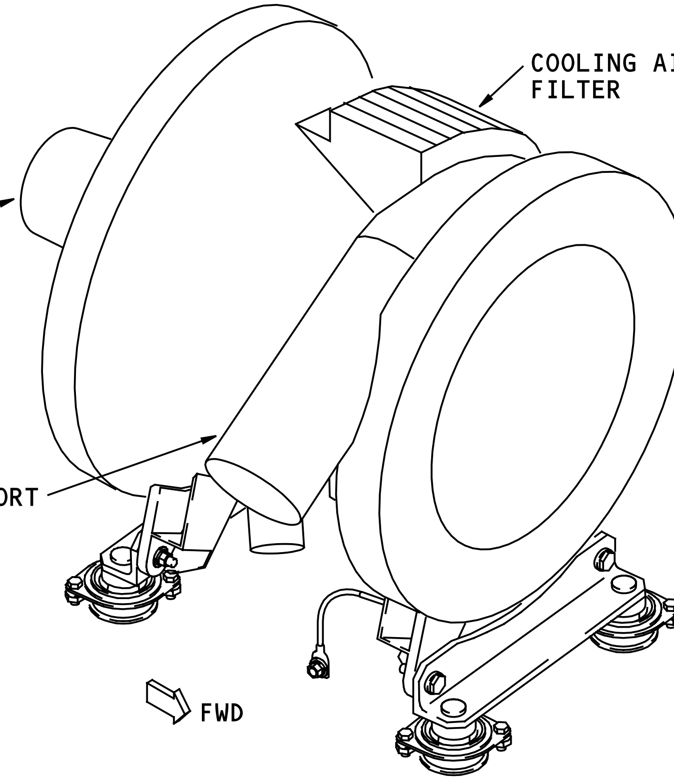
WITH PANELS AND FWD TANK REMOVED)



38-32-00-009 Rev 2 01/06/1997

VACUUM WASTE SYSTEM - VACUUM BLOWER AND FILTER

VACUUM WASTE SYSTEM - VACUUM CHECK VALVE

Purpose

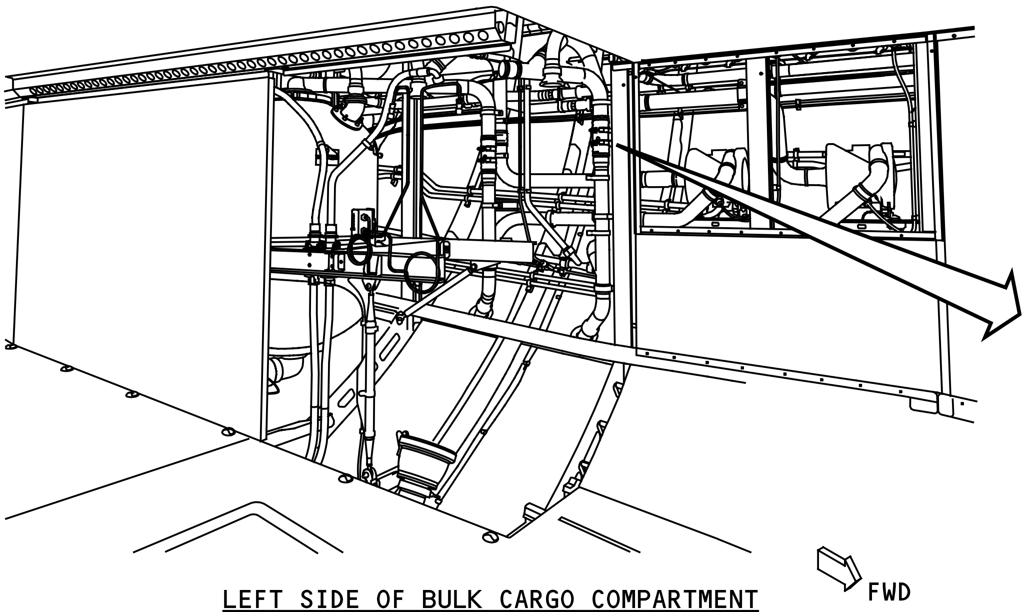
The vacuum check valve prevents reverse air flow through the bypass line when the blower is on.

Physical Description

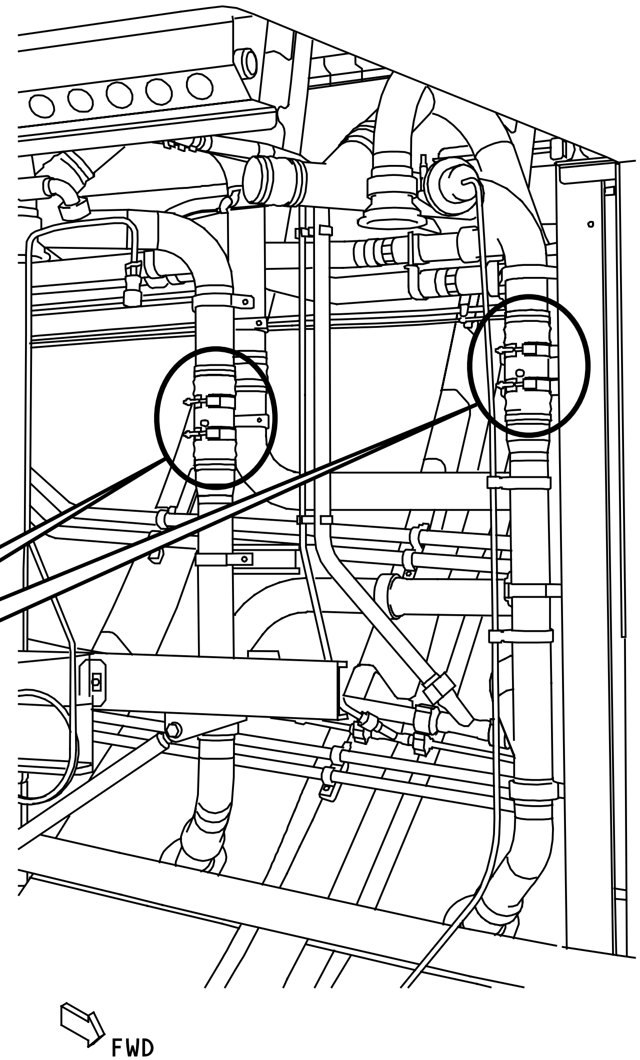
The check valve is a flapper-type valve.

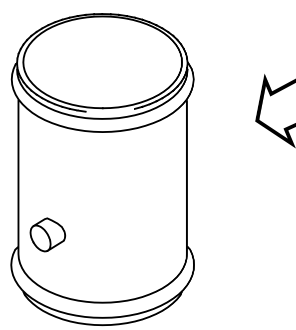
Location

The check valve is in the aft cargo compartment on the left side. The valve is in the blower bypass line that vents overboard. The valve is aft of the blowers and outboard of the forward waste tank.



LEFT SIDE OF BULK CARGO COMPARTMENT
(LOOKING OUTBOARD AND AFT
WITH PANELS AND FWD TANK REMOVED)





VACUUM CHECK VALVE
(TWO PLACES)

VACUUM WASTE SYSTEM - VACUUM CHECK VALVE

VACUUM WASTE SYSTEM - LIQUID SEPARATOR

Purpose

The liquid separator removes moisture and waste particles from the waste tank air before venting the air overboard.

Physical Description

The liquid separator has these parts:

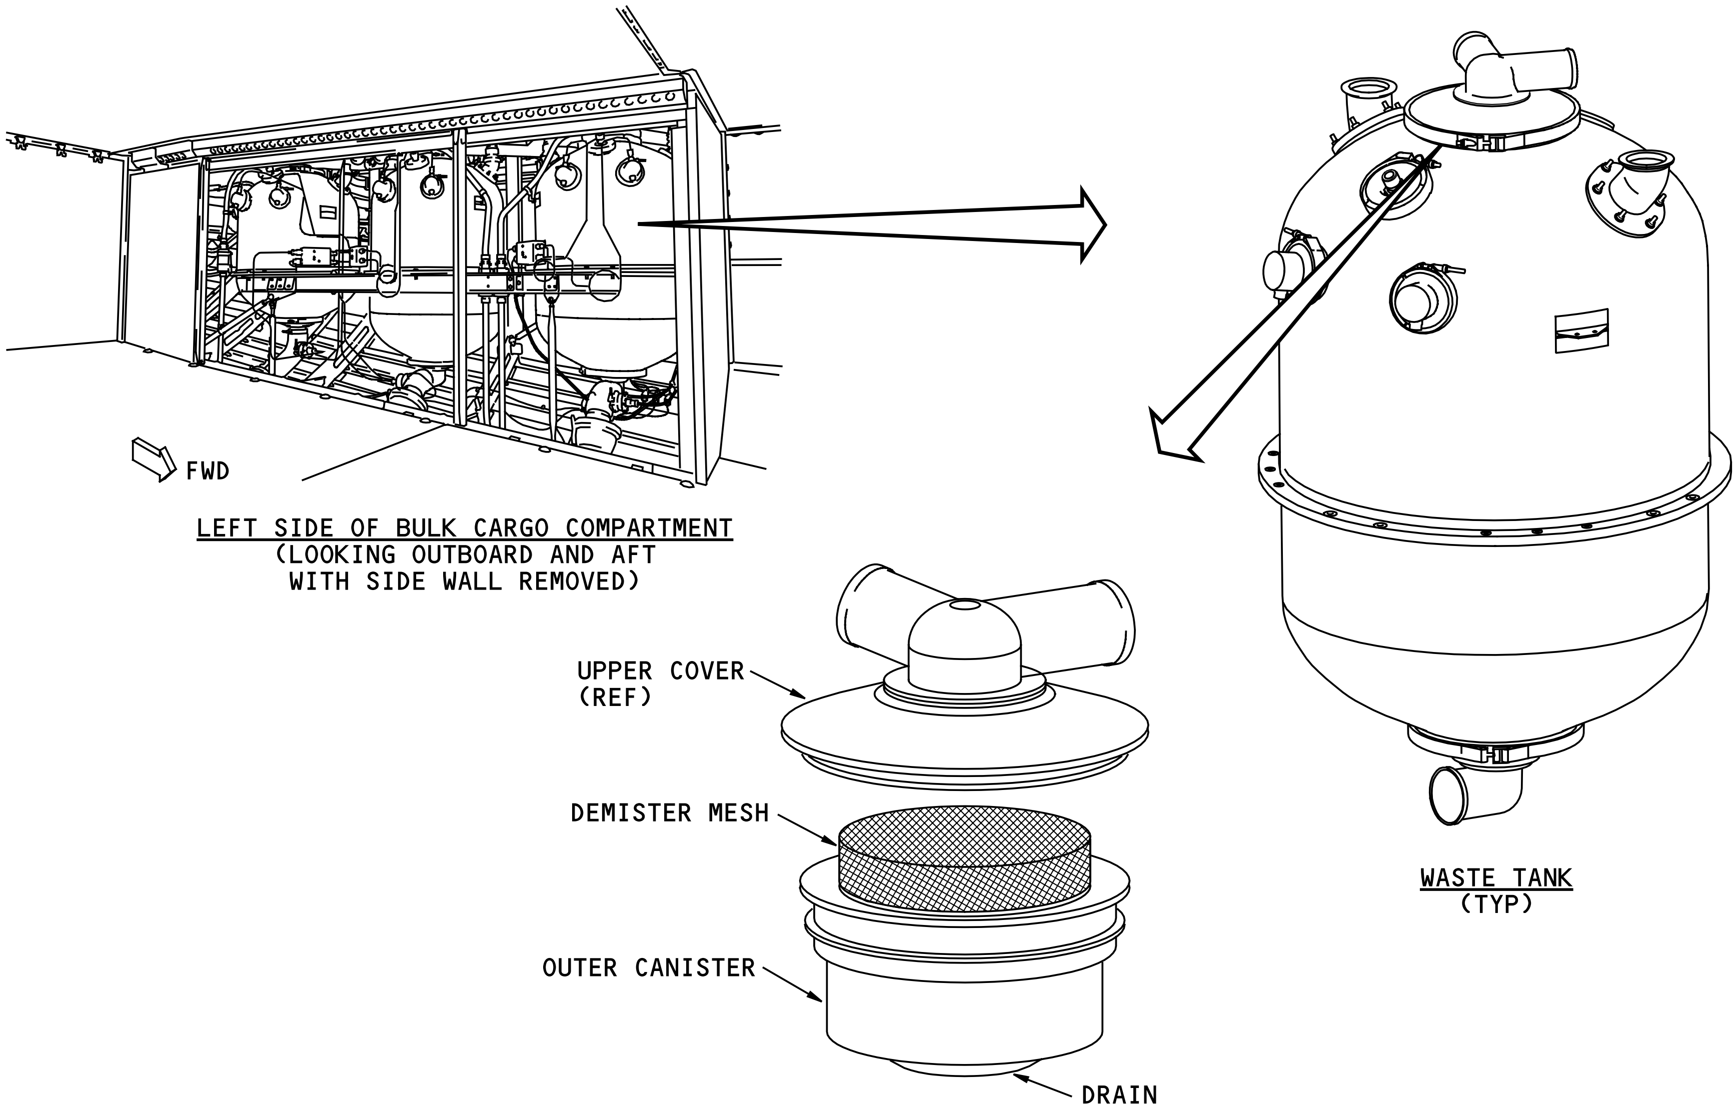
- Demister mesh
- Outer canister
- Inner bowl canister (not shown)

Location

The liquid separator is at the top of each waste tank.

Functional Description

Vents on the outer canister makes sure the air goes in a circular path when air goes into the canister. Centrifugal force removes moisture from the air. The moisture drains out the bottom of the liquid separator. The air then goes into the inner canister and through a demister mesh. The demister mesh removes any material still in the air. The air then goes to the overboard vent line.



38-32-00-012 Rev 1 08/07/96

VACUUM WASTE SYSTEM - LIQUID SEPARATOR

VACUUM WASTE SYSTEM - WASTE TANK DRAIN BALL-VALVE AND CONTROL CABLE

Purpose

The waste tank drain ball-valve and control cable permit the waste tank to drain.

Physical Description

The waste tank drain ball-valve has these parts:

- Housing
- Actuation lever
- Limit switch.

A T-handle attaches to one end of the control cable. The other end attaches to the actuation lever.

Location

The waste tank drain ball-valve and control cable are in the bulk cargo compartment on the left side. There is a valve and cable for each waste tank. The valve is under the waste tank and the cable goes between the valve and the waste service panel.

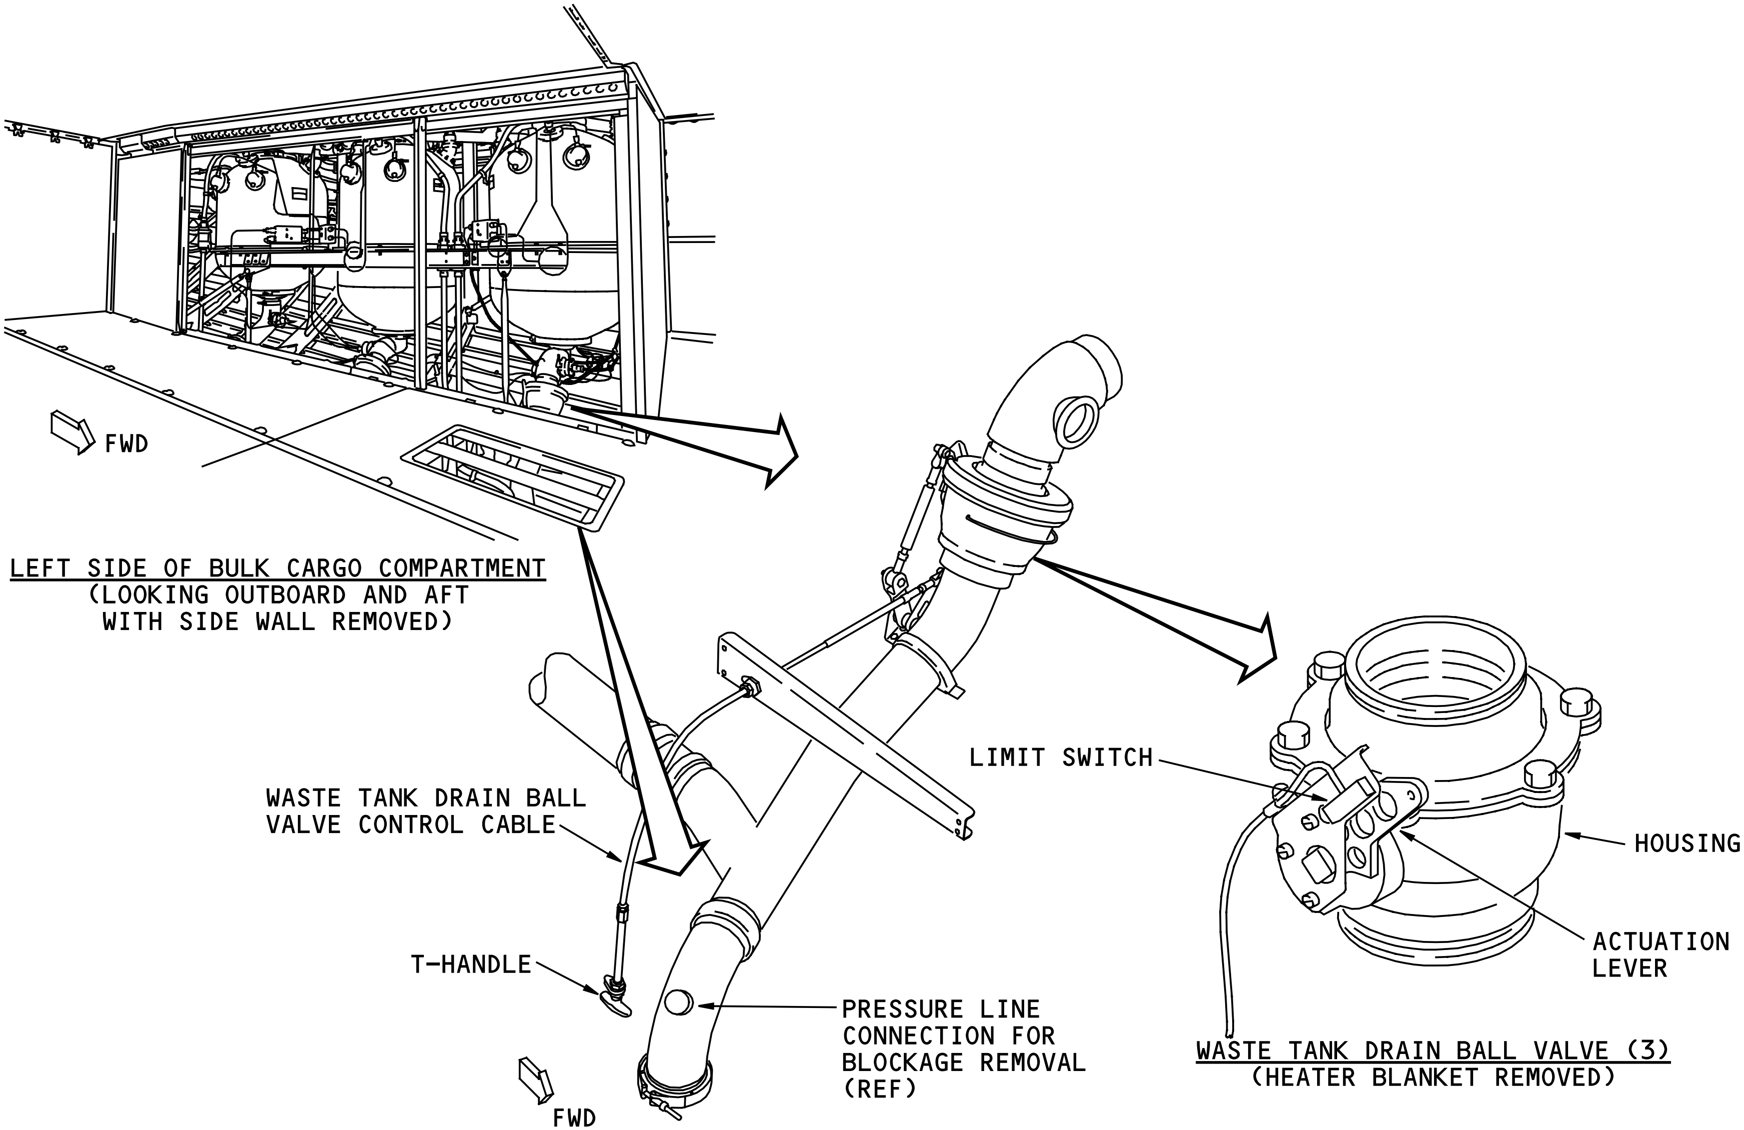
Functional Description

The actuation lever opens and closes the valve. The limit switch stops the operation of the vacuum blower when the valve is not closed. You operate the valve from the service panel. Pull the T handle to open the valve.

Training Information Point

There is a heater blanket around the ball-valve. This prevents any liquid in the valve from freezing.

See the drain and water supply system section for more information on the heater blanket (AMM PART I 30-71).



38-32-00-013 Rev 3 08/21/96

VACUUM WASTE SYSTEM - WASTE TANK DRAIN BALL-VALVE AND CONTROL CABLE

VACUUM WASTE SYSTEM - WASTE TANK RINSE FILTER

Purpose

The waste tank rinse filter removes small particles as the rinse water goes through it.

Location

The filter is in the bulk cargo compartment on the left side. The filter is between the waste tank rinse fitting assembly and the rinse nozzle. There are three filters. One is inboard of each waste tank.

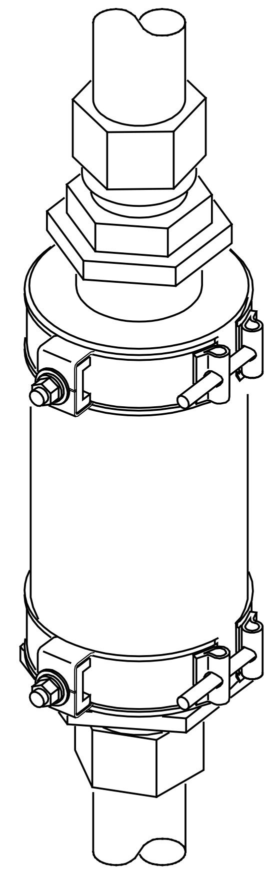
(LOOKING OUTBOARD AND AFT
WITH SIDE WALL REMOVED)



38-32-00-016 Rev 2 08/07/96

VACUUM WASTE SYSTEM - WASTE TANK RINSE FILTER

VACUUM WASTE SYSTEM - WASTE TANK RINSE NOZZLE

Purpose

The waste tank rinse nozzle points rinse water at the point level sensors and the waste tank interior surface. The rinse nozzle removes waste material from the point level sensors. The rinse nozzle also supplies precharge into the waste tanks.

Physical Description

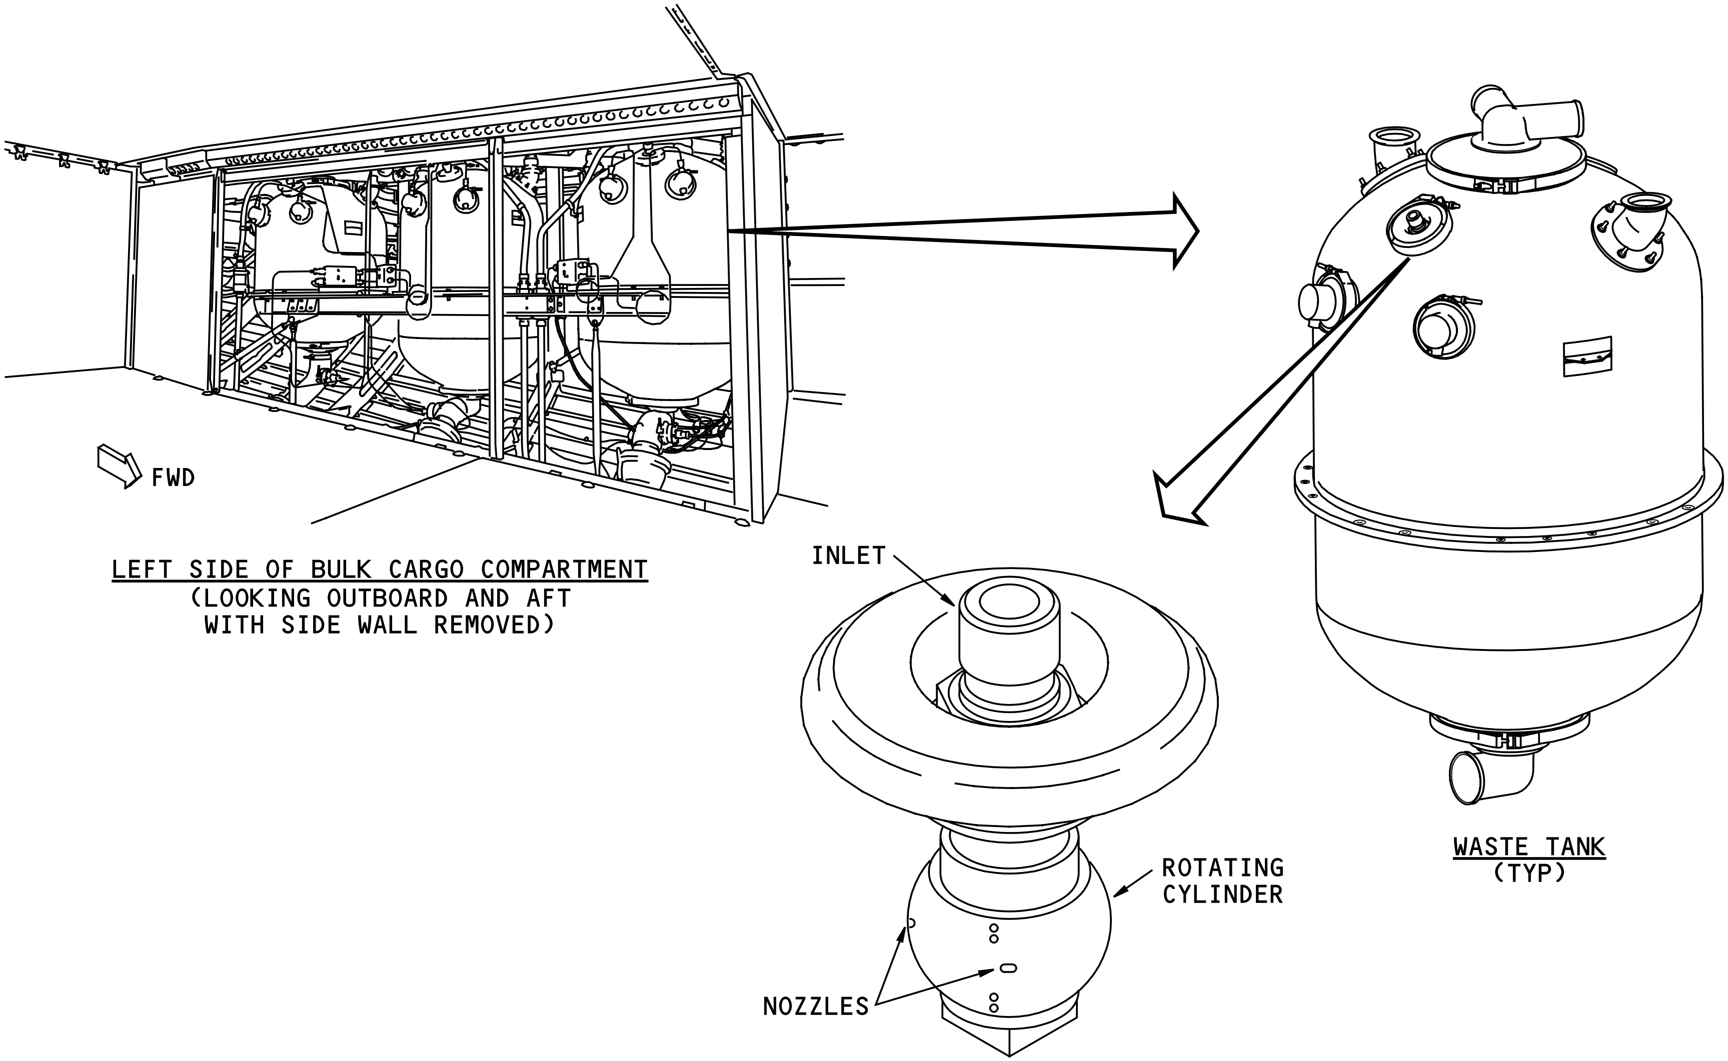
The nozzle has an inlet and rotating cylinder with a shaft. The nozzle inlet is stainless steel. The rotating cylinder and shaft are teflon-filled nylon.

Location

The rinse nozzle attaches to the waste tank. The rinse nozzle is near the top of the waste tank on the inboard side.

Functional Description

The rinse water goes in the inlet and out the rotating rinse nozzle. The nozzle has ports that point the rinse water at the point level sensors.



38-32-00-017 Rev 1 08/07/96

VACUUM WASTE SYSTEM - WASTE TANK RINSE NOZZLE

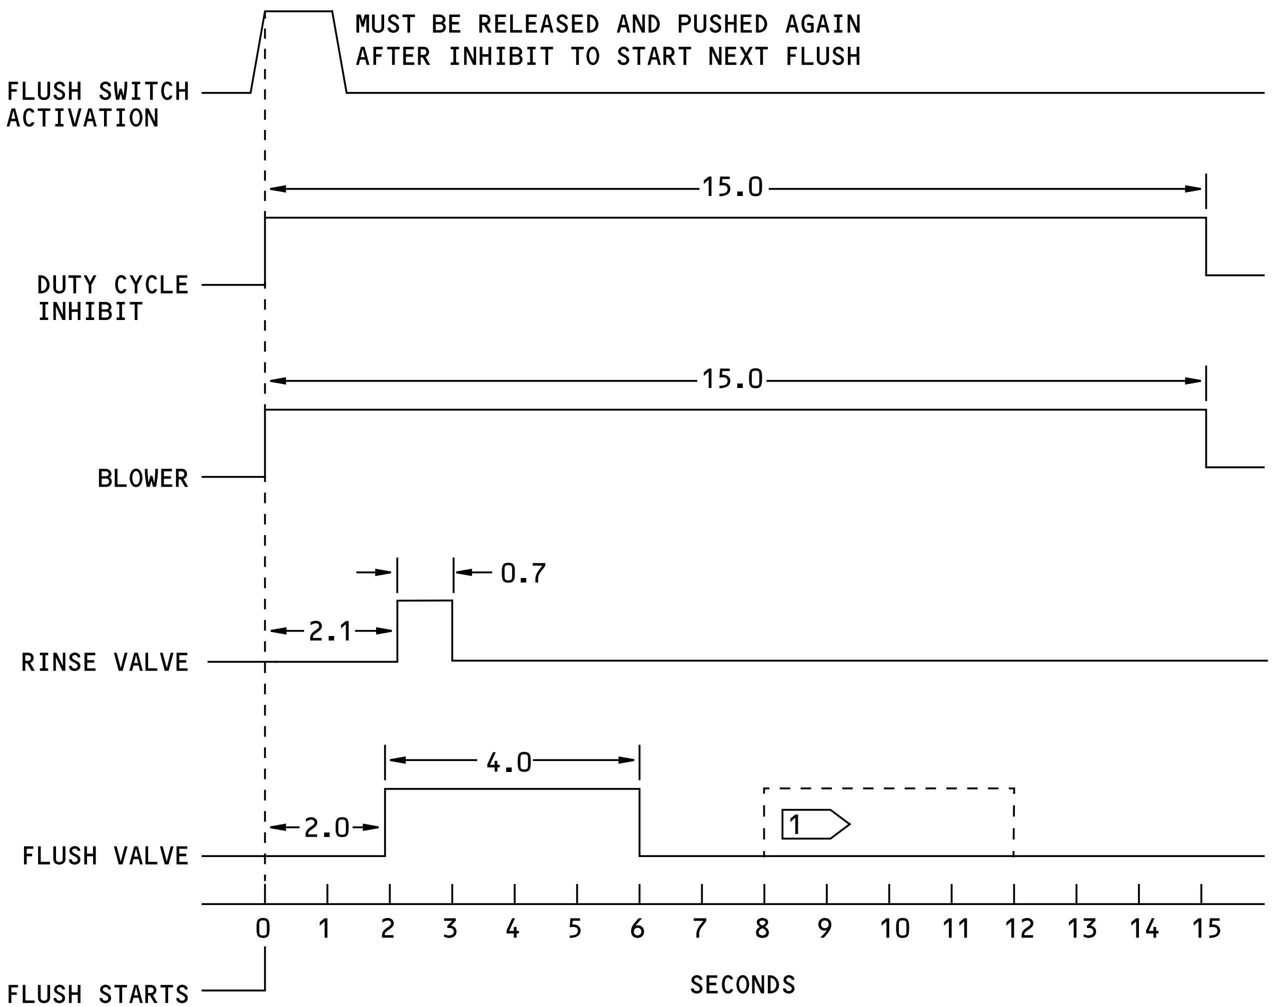
VACUUM WASTE SYSTEM - FLUSH CYCLE - FUNCTIONAL DESCRIPTION

Lavatory Flush Cycle Operation

One second after you push the flush switch, the rinse valve opens. The rinse valve stays open for 0.7 seconds. Eight ounces of potable water goes into the toilet bowl during this time. Two seconds after the flush cycle starts, the flush valve opens. The flush valve opens for four seconds then closes.

If the flush valve does not close eight seconds after the flush cycle starts, the valve has a jammed condition. During each jammed condition, one automatic dry flush occurs. During a dry flush, the rinse valve does not open. Then a dry flush follows each normal cycle. The flush valve automatically resets when the flush valve does not have a jammed condition.

There is no flush cycle if the tank ball valve is open or if the related waste tank if full.



1 DRY FLUSH

38-32-00-018 Rev 1 08/21/1997

VACUUM WASTE SYSTEM - FLUSH CYCLE - FUNCTIONAL DESCRIPTION

VACUUM WASTE SYSTEM - FUNCTIONAL DESCRIPTION - LAVATORY FLUSH CONTROL

THIS PAGE INTENTIONALLY LEFT BLANK

VACUUM WASTE SYSTEM - FUNCTIONAL DESCRIPTION - LAVATORY FLUSH CONTROL

General

There are three lavatory waste systems:

- Waste system one (forward waste tank)
- Waste system two (middle waste tank)
- Waste system three (aft waste tank).

The waste systems have these control circuits:

- Toilet flush
- Vacuum blower control.

There is one toilet flush circuit for each lavatory. A typical circuit is shown.

There are two vacuum blower control circuits. Waste system one uses one of the circuits (shown). Waste systems two and three use the other circuit (not shown). The two vacuum blower control circuits are independent.

For the control circuits, these are the most important components and their functions:

- Flush control module (FCM): supplies the control logic for blower and toilet operation
- Tank ball-valve limit switch: prevents blower operation when the valve is open
- Barometric switch: prevents blower operation when airplane altitude is above 16,000 feet (4877 meters)
- Vacuum blower overheat switches: stops the blower if it gets too hot
- The tank logic control module: controls when power goes to the flush control modules (enables/ disables toilet flushing).

Toilet Flush/Vacuum Blower Control

When you push the flush switch, the flush control module starts a flush cycle that continues for 15 seconds. The flush control logic sets the sequence of operation for the blower, rinse valve, and the flush valve.

All of these conditions must occur before a flush cycle can start:

- Waste tank: not full
- Point level sensors: one or both serviceable
- Flush switch: push
- Operation power: available, left (right) bus
- Control power: available, left (right) bus or ground handling bus.

All of these conditions must occur before the vacuum blower operates as part of the flush cycle:

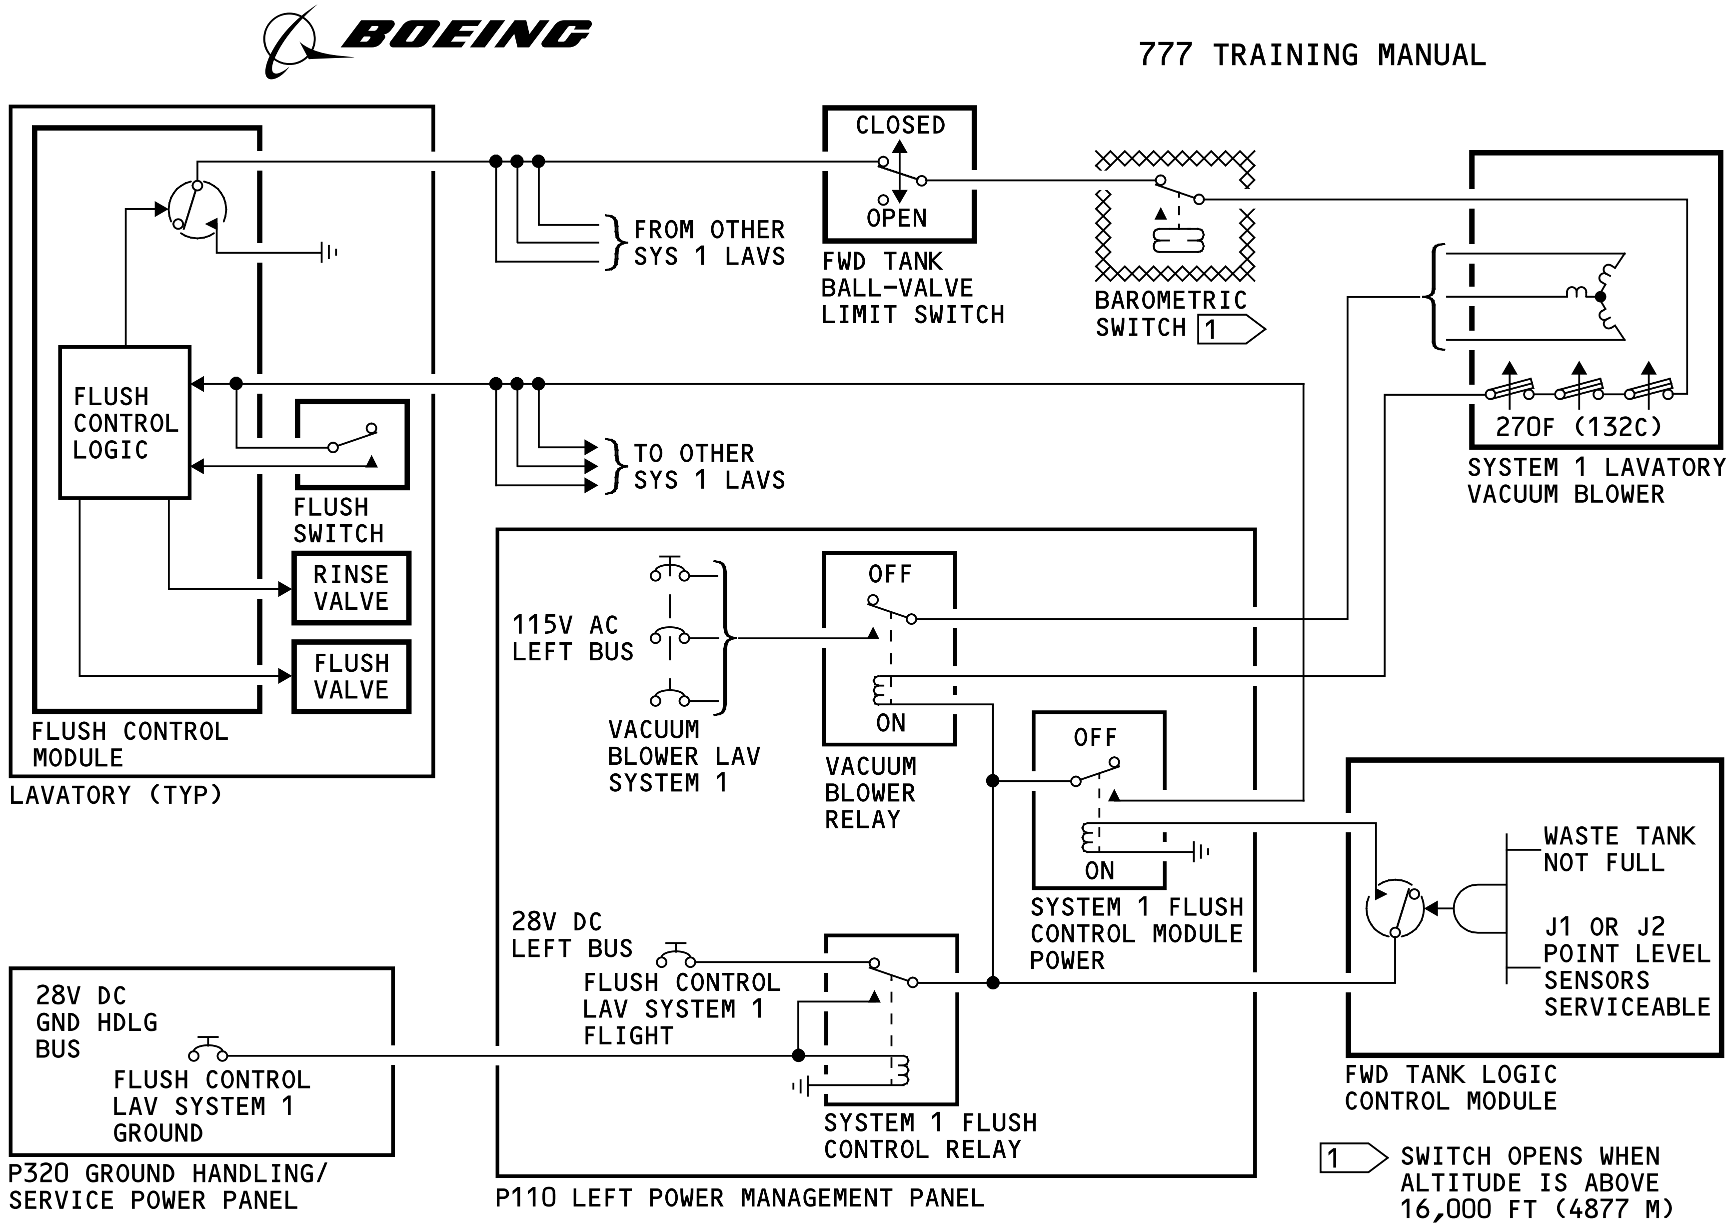
- Tank ball valve: closed
- Airplane altitude: below 16,000 feet (4877 meters)
- Vacuum blower motor: no overheat.

VACUUM WASTE SYSTEM - FUNCTIONAL DESCRIPTION - LAVATORY FLUSH CONTROL

If you push the flush switch when a cycle is active, a new cycle will not start. You can only start a new cycle when a flush cycle is complete.

Training Information Point

If a vacuum blower motor overheats, make sure the cooling air filter on the blower is clean. A dirty filter can cause the motor to overheat.



38-32-00-019 Rev 2 08/21/1997

VACUUM WASTE SYSTEM - FUNCTIONAL DESCRIPTION - LAVATORY FLUSH CONTROL

VACUUM WASTE SYSTEM - TRAINING INFORMATION POINTS - SERVICING

General

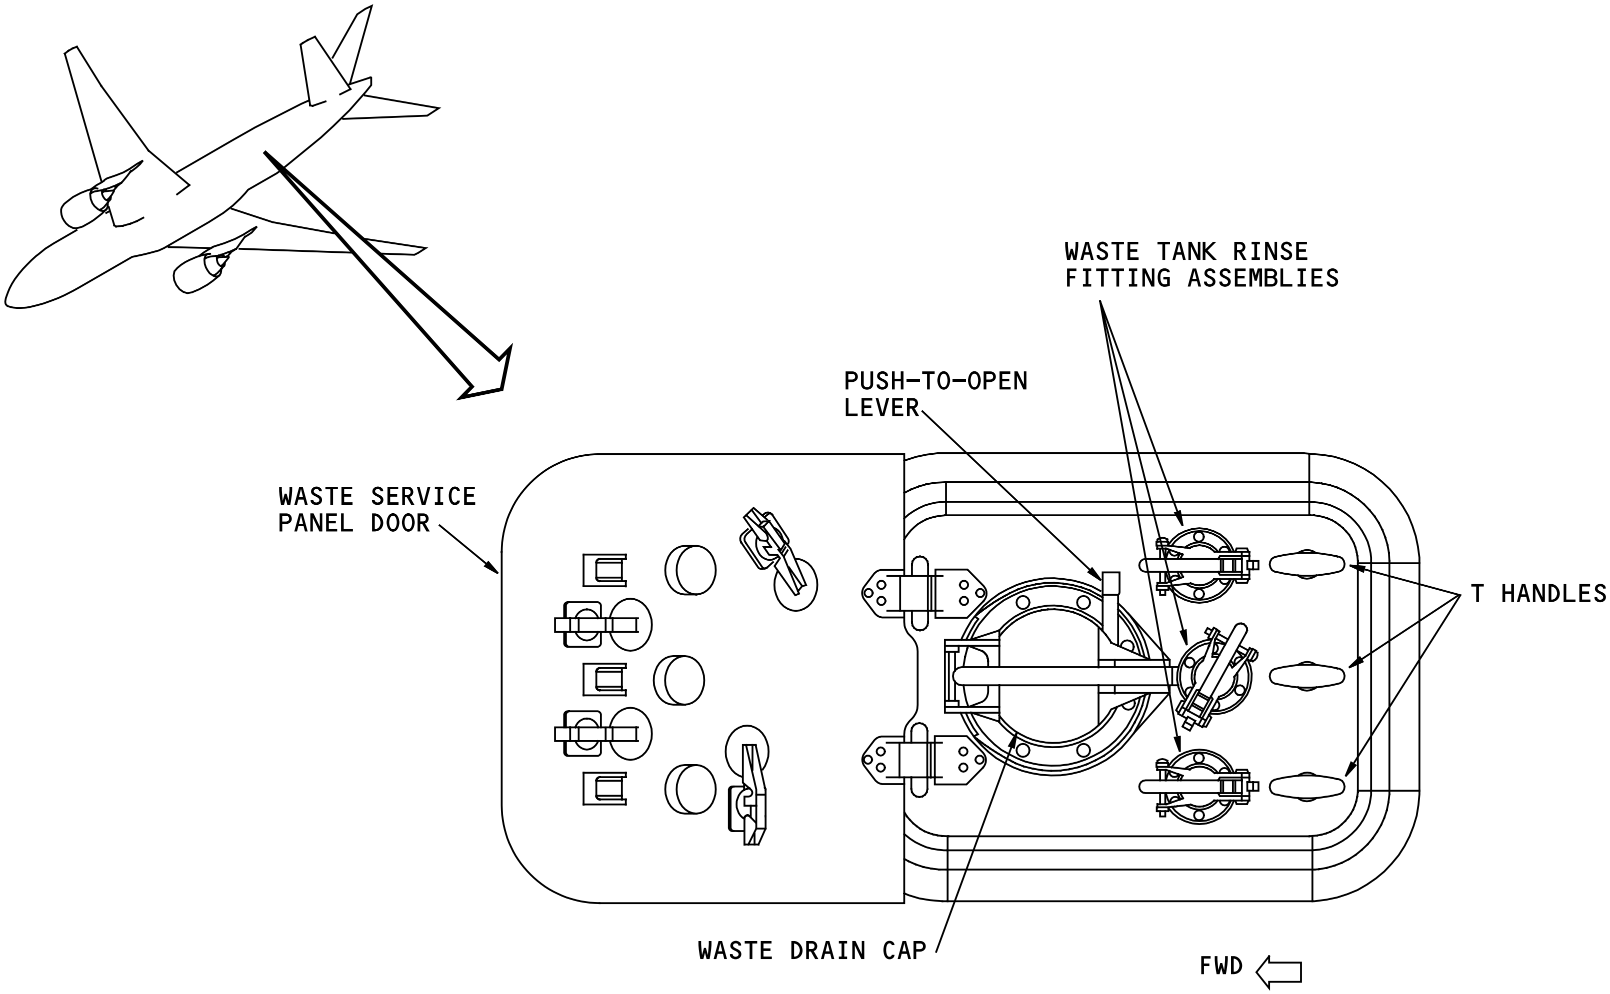
Service the waste tanks through the service panel. The service panel has these components:

- Waste drain cap
- Rinse fitting (3)
- T handle (3).

Toilet Waste System Servicing

To drain and flush the waste system you must do these tasks:

- Open the waste drain cap
- Connect support equipment to the waste drain fitting
- Push the push-to-open lever on the waste drain valve assembly
- Pull each T handle to open the waste tank drain ball-valves (this empties the waste tanks)
- Connect ground flush lines to the rinse fittings
- Flush the waste tanks with at least ten gallons of flushing liquid
- Drain each tank of the flushing liquid
- Push up each T handle to close the waste tank drain ball-valve after each waste tank has drained
- Remove the support equipment
- Close the waste drain cap
- Add a wet or dry precharge to the each waste tank
- Disconnect ground flush lines
- Close the rinse fittings
- Close the service panel.



WASTE SERVICE PANEL

VACUUM WASTE SYSTEM - TRAINING INFORMATION POINTS - SERVICING

WASTE TANK QUANTITY INDICATION - INTRODUCTION

General

The waste tank quantity indication system gives data about the amount of waste in the tanks. It also stops power to the toilets if the waste tank is full.

These components are in the waste tank quantity indication system:

- Waste tank point level sensors (6)
- Waste tank continuous level sensors (3)
- Logic control modules (LCM) (3).

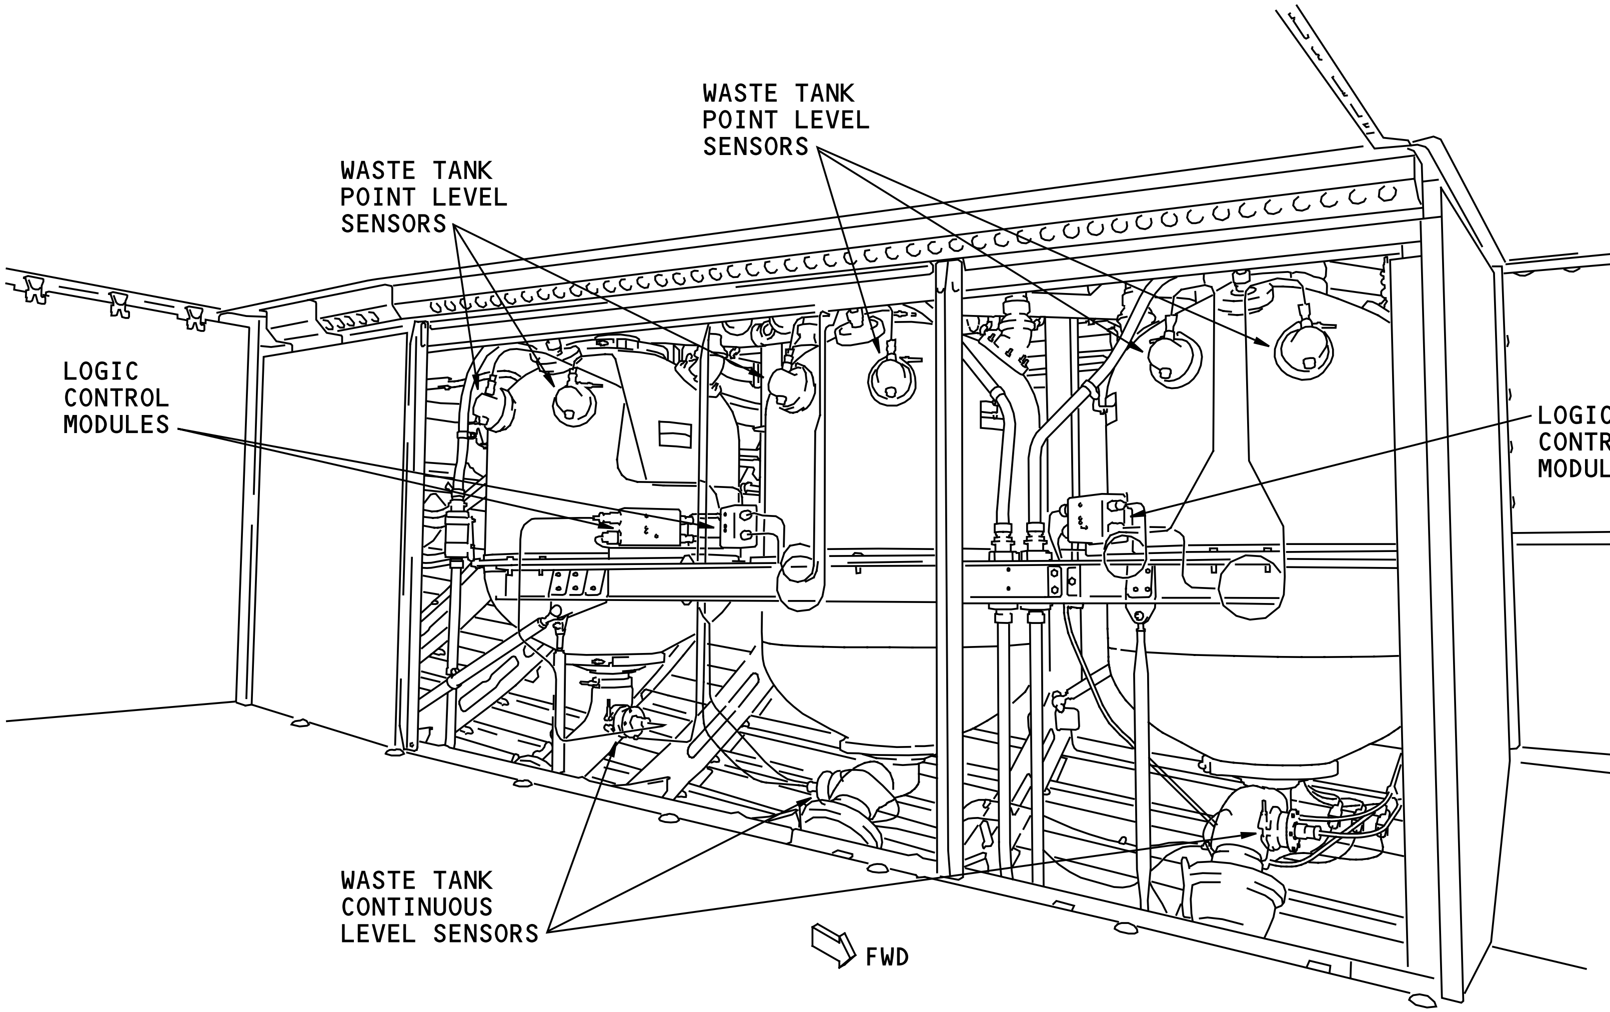
Location

The point level sensors, the continuous level sensors, and the LCMs are in the bulk cargo compartment, behind the panels on the left side. The LCMs attach to the support fitting inboard of each waste tank.

The point level sensors attach to the upper part of the tanks. The continuous level sensors are in the tank drain lines. Each continuous level sensor has a remote diaphragm (not shown) in the vent line above the tank.

Interface

The waste tank quantity indication system gives data about the amount of waste in the tanks to the cabin services system (CSS). They also give tank full data to the lavatory flush circuit in the vacuum waste system.



LEFT SIDE OF BULK CARGO COMPARTMENT
(LOOKING OUTBOARD AND AFT
WITH SIDE WALL REMOVED)

38-33-00-001 Rev 3 08/07/96

WASTE TANK QUANTITY INDICATION - INTRODUCTION

WASTE TANK QUANTITY INDICATION - WASTE TANK POINT LEVEL SENSOR

Purpose

The waste tank point level sensor sends a signal to the LCM when the waste tank is full. There are six waste tank point level sensors, two on each waste tank.

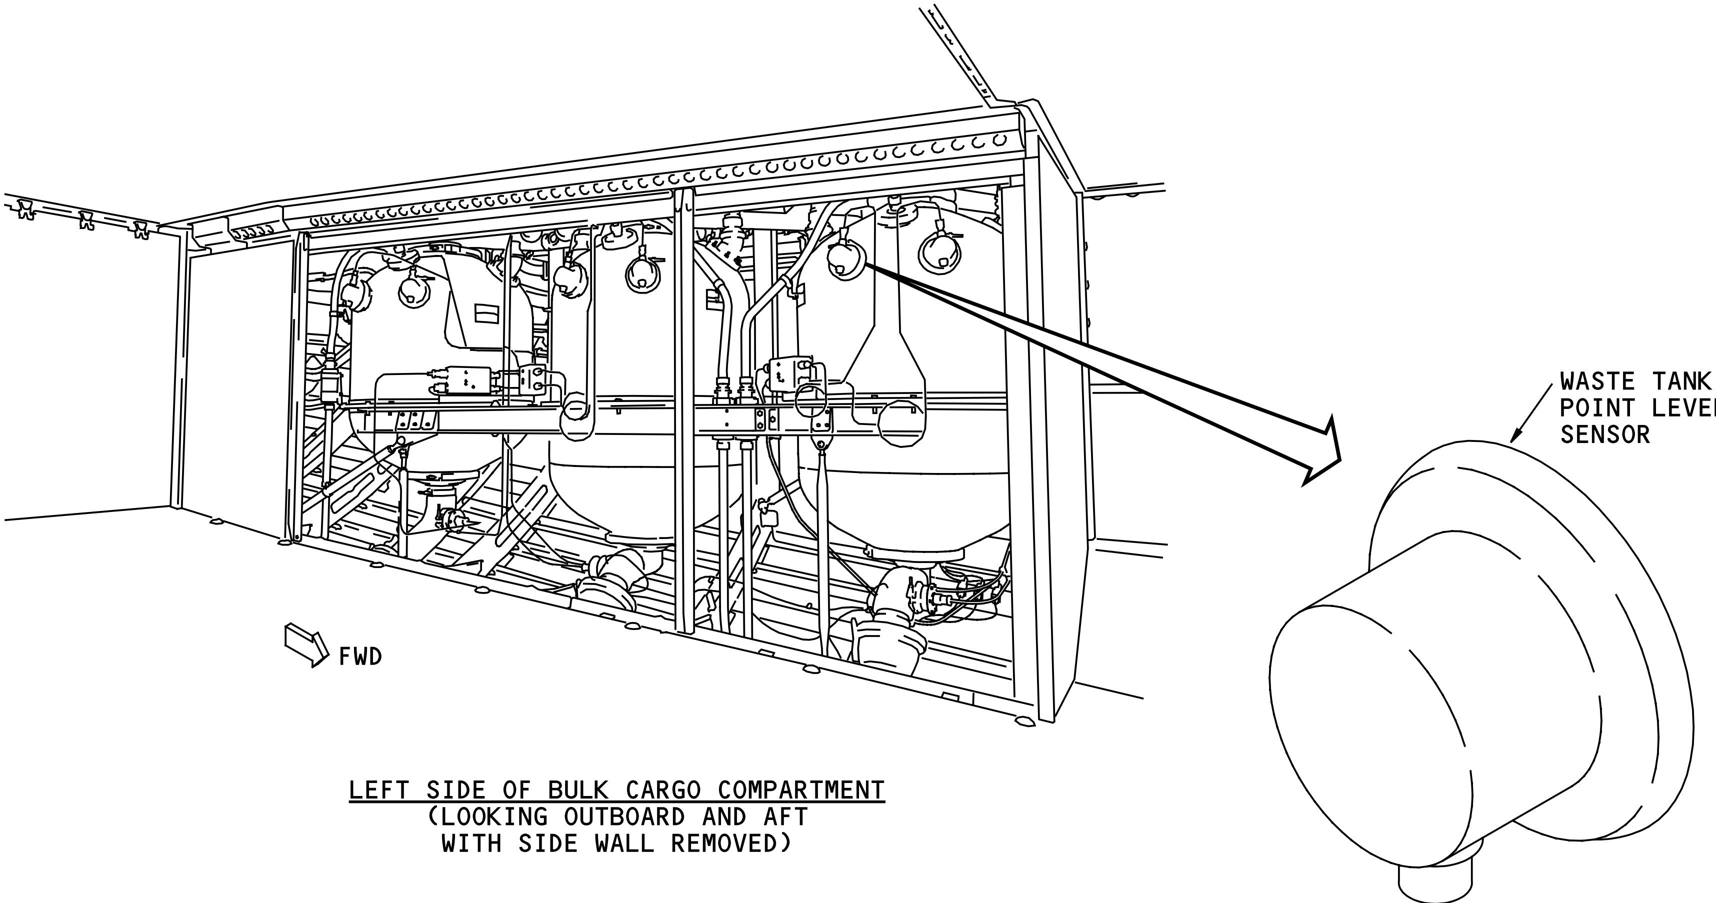
Physical Description

The sensor is a capacitance type sensor.

It has an electrical connector.

Location

The sensors are behind the left side panels of the bulk cargo compartment. They are on the upper part of the waste tanks.



LEFT SIDE OF BULK CARGO COMPARTMENT
(LOOKING OUTBOARD AND AFT
WITH SIDE WALL REMOVED)

38-33-00-002 Rev 1 08/07/96

WASTE TANK QUANTITY INDICATION - WASTE TANK POINT LEVEL SENSOR

WASTE TANK QUANTITY INDICATION - WASTE TANK CONTINUOUS LEVEL SENSOR

Purpose

The waste tank continuous level sensor calculates the amount of waste in the tanks. This data is only for indications that show on the cabin area control panels (CACP) and cabin system control panels (CSCP).

Physical Description

The waste tank continuous level sensor is a capacitance-type pressure sensor. The sensor has these components:

- Remote diaphragm
- Capillary tube
- Electrical connector J3
- Sensor module.

Wires connect the electrical connector to the logic control module (LCM).

Location

The continuous level sensors are in the bulk cargo compartment, behind the left side wall. There is a sensor for each waste tank. The sensor module is in the drain line below the tank. The remote diaphragm is in the vent line above the tank. The capillary tube goes from the remote diaphragm to the remote sensor.

Functional Description

The remote diaphragm and the capillary tube find the pressure of the air in the tank. The sensor finds the difference between the air pressure in the tank and the liquid in the drain line. It uses the difference to calculate the amount of waste in the tanks.

Training Information Point

You use the (LCM) to do a zero adjustment when you install a continuous level sensor.

You can test the operation of the sensor with the LCM or with an all test through the cabin services system (CSS).

WASTE TANK QUANTITY INDICATION - WASTE TANK CONTINUOUS LEVEL SENSOR

38-33-00-003 Rev 1 08/21/96

WASTE TANK QUANTITY INDICATION - LOGIC CONTROL MODULE

THIS PAGE INTENTIONALLY LEFT BLANK

WASTE TANK QUANTITY INDICATION - LOGIC CONTROL MODULE

General

The logic control module (LCM) gives information about the amount of waste in the waste tanks to the cabin services system. The LCM does not let the vacuum waste system operate for the lavatories connected to a waste tank that is full.

There are three LCMs, one for each tank. It also has BITE for itself, the point level sensors, and the continuous level sensor.

Physical Description

The LCM has four electrical connections. Three are for the sensors and one connects the LCM to the airplane wiring. The LCM also has a three-position switch.

It has five lights:

- Sensor J1, red
- Sensor J2, red
- Sensor J3, red
- Tank full, red
- Power on, green.

The first two lights are for the point level sensors. The third is for the continuous level sensor.

Location

The LCMs attach to the support fitting inboard of each waste tank.

Operation

To do a test of the LCM, first push the switch down. All five lights come on. When you release the switch the lights go off.

Next, push up on the switch. All five lights come on. If any light stays on when you release the switch, that sensor fails the test.

When you do an ALL TEST from the CSCP, the LCM does a test of the sensors and the LCM circuit.

See the cabin services system section for more information about the ALL TEST (AMM PART I 23-39).

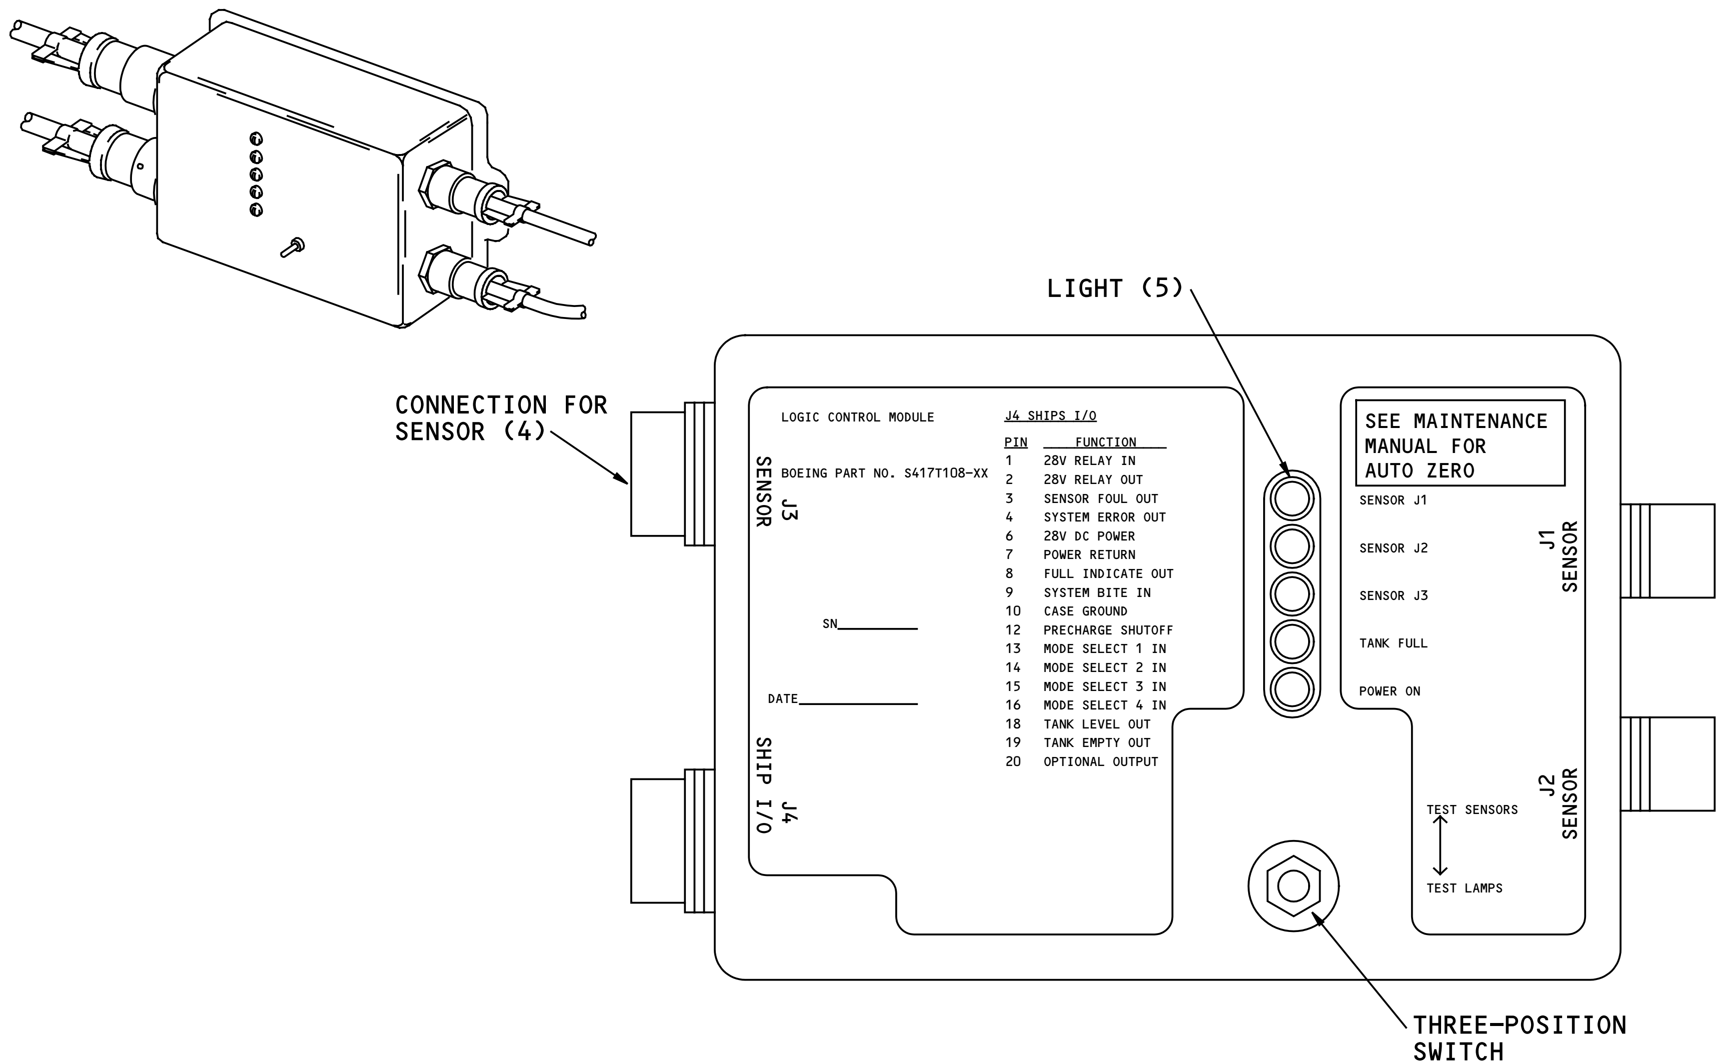
After you replace a continuous level sensor, you must do an auto zero adjustment of the LCM. You use the three-position switch to do an auto zero adjustment.

When a sensor detects that the tank is full, the associated sensor light on the LCM will come on. The tank full light turns on if any of these conditions occur:

- The two point level sensor detect the tank is full
- The two point level sensors fail
- One point level sensor fails or is fouled and the other point level sensor detects the tank is full
- The continuous level sensor detects the tank is almost full.

WASTE TANK QUANTITY INDICATION - LOGIC CONTROL MODULE

If any of the sensors are failed or the point level sensors are fouled, the light for that sensor will flash on the LCM. If the LCM fails, the tank full light flashes.



38-33-00-004 Rev 1

WASTE TANK QUANTITY INDICATION - LOGIC CONTROL MODULE

WASTE TANK QUANTITY INDICATION - FUNCTIONAL DESCRIPTION

General

The continuous level sensor sends data about the quantity of waste in the tanks to the LCM. The LCM sends the data to the cabin services system (CSS). The cabin area control panels (CACPs) (not shown) and the cabin system control panel (CSCP) (not shown) in the CSS show the waste tank level information.

When the tank is almost full, the CACPs and CSCP show a pop-up screen to tell the flight attendants. The waste tank status screen on the CACPs and CSCP show full. A chime sounds when a waste tank is full.

Control

The LCM gets data from the two point level sensors.

Normally, the flush module power relay is energized. It lets power to go to the lavatories.

When both point level sensors give a signal that the waste tank is full, the flush module power relay de-energizes. This removes power from all toilets that connect to the full tank. A pop-up screen shows on the CSCP/CACP.

If a sensor has an error, it gives the same signal that it does when the tank is full. When the other sensor finds that the tank is full the flush module power relay de-energizes.

If both sensors have errors, the LCM removes power to the related lavatories is removed.

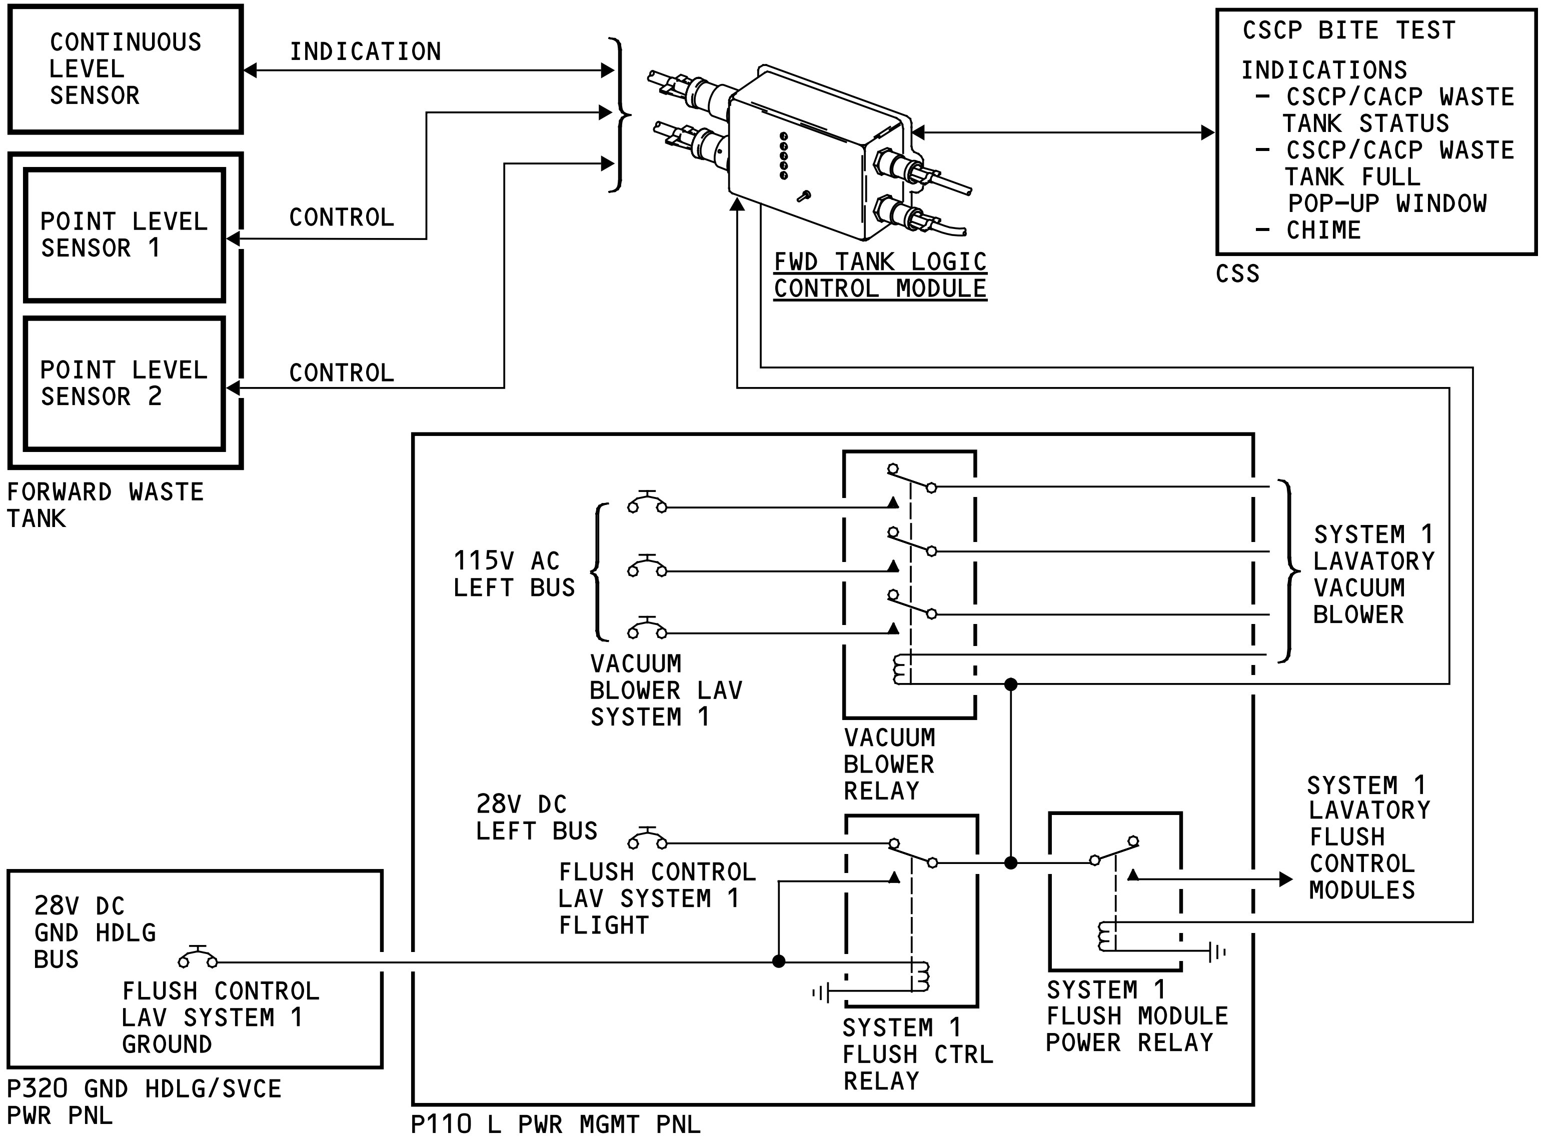
Interface

The LCM sends signals to an overhead electronics unit (OEU) (not shown). The OEU sends the signal to a zone management unit (ZMU) (not shown) on the OEU bus. The ZMU sends a signal to the CACPs on the CACP bus and to the CSCP on the intersystem (I/S) bus.

See the cabin services system section for more information on the OEU, CACP and the intersystem buses (AMM PART I 23-39).

Power

The ground service bus or the left main bus must have power for the LCM to operate.



WASTE TANK QUANTITY INDICATION - FUNCTIONAL DESCRIPTION

WASTE TANK QUANTITY INDICATION - OPERATION - CSCP/CACP INDICATIONS - 1

General

You use the cabin system control panel (CSCP) or cabin area control panels (CACP) to control and monitor lavatory functions and waste tank levels.

Lavatory/Waste Tank Status Screen

You use the lavatory waste tank status screen to monitor the conditions of the lavatories and waste tanks.

The lavatories area of the screen shows lavatory locations and status. The area to the right of the lavatories shows the related waste tank and the amount of waste in it.

When the waste level is less than 1/4, the vertical bars are green. When the waste level is 1/4 to 3/4 full, the vertical bars are yellow. When the waste level is more than 3/4, the vertical bars are red.

When the waste tank level shows full (F), all related lavatories show INOP.

Lavatory Inoperable Control Screen

You use the lavatory inoperable control screen to show the conditions of the lavatories.

The screen shows the lavatories and assigned waste tanks. The status area of the screen shows the condition of each lavatory.

You touch OP or INOP to show that lavatory operational or inoperative. The OP and INOP selections show green.

INOP shows automatically for all lavatories with the same waste tank if the waste tank is full. FULL TANK shows in the area where OP would normally be. You cannot change this condition.

Use the up and down arrows at the right of the display to scroll the lavatory information up and down.

LIGHTS - INTRODUCTION

FLIGHT COMPARTMENT LIGHTS - INTRODUCTION

General

Lights in the flight deck do these tasks:

- Give general light
- Give light to panels
- Supply light for system indications
- Supply specified light for tasks.

The flight compartment lights has these sections:

- Flight compartment illumination
- Integral panel lights
- Flight compartment miscellaneous lights
- Master dim and test.

The flight compartment illumination lights give general light in the flight compartment. These are the lights:

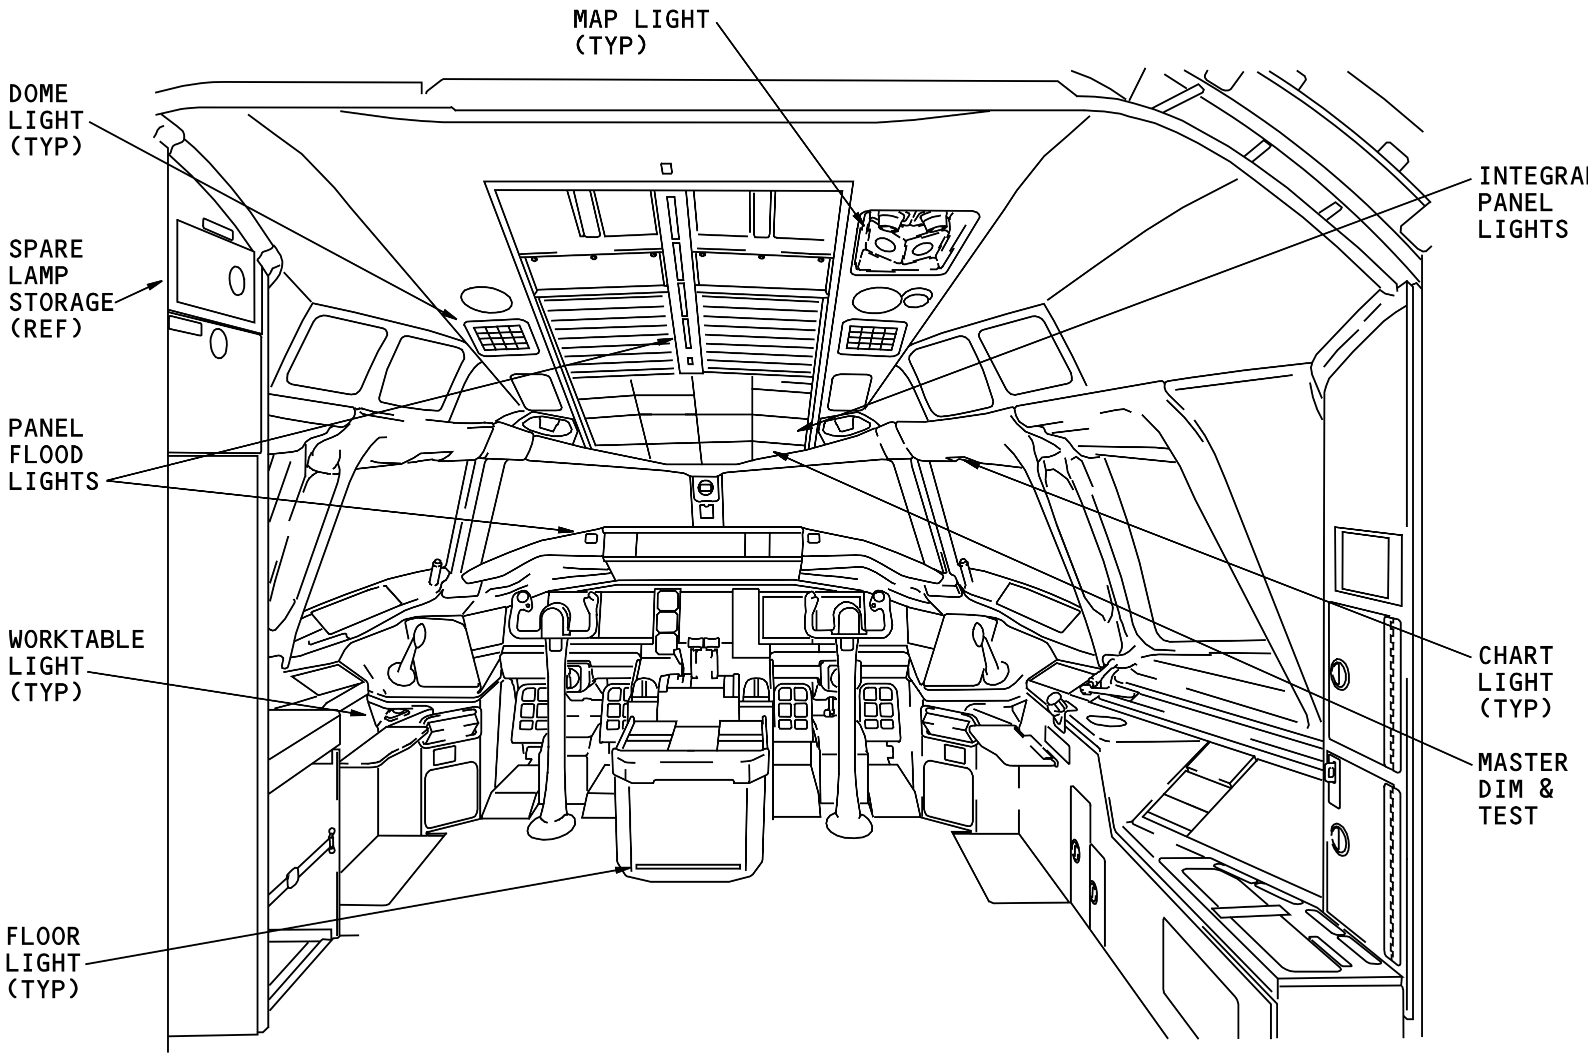
- Map lights
- Dome lights.

The integral panel lights give light to the controls and indications on panels in the flight compartment.

The flight compartment miscellaneous lights give light to work areas, the floor, and panels. These are the lights:

- Chart lights
- Floor lights
- Worktable lights
- Floodlights
- Utility light (not shown).

The master dim and test system controls the amount of light that comes from the system annunciators.

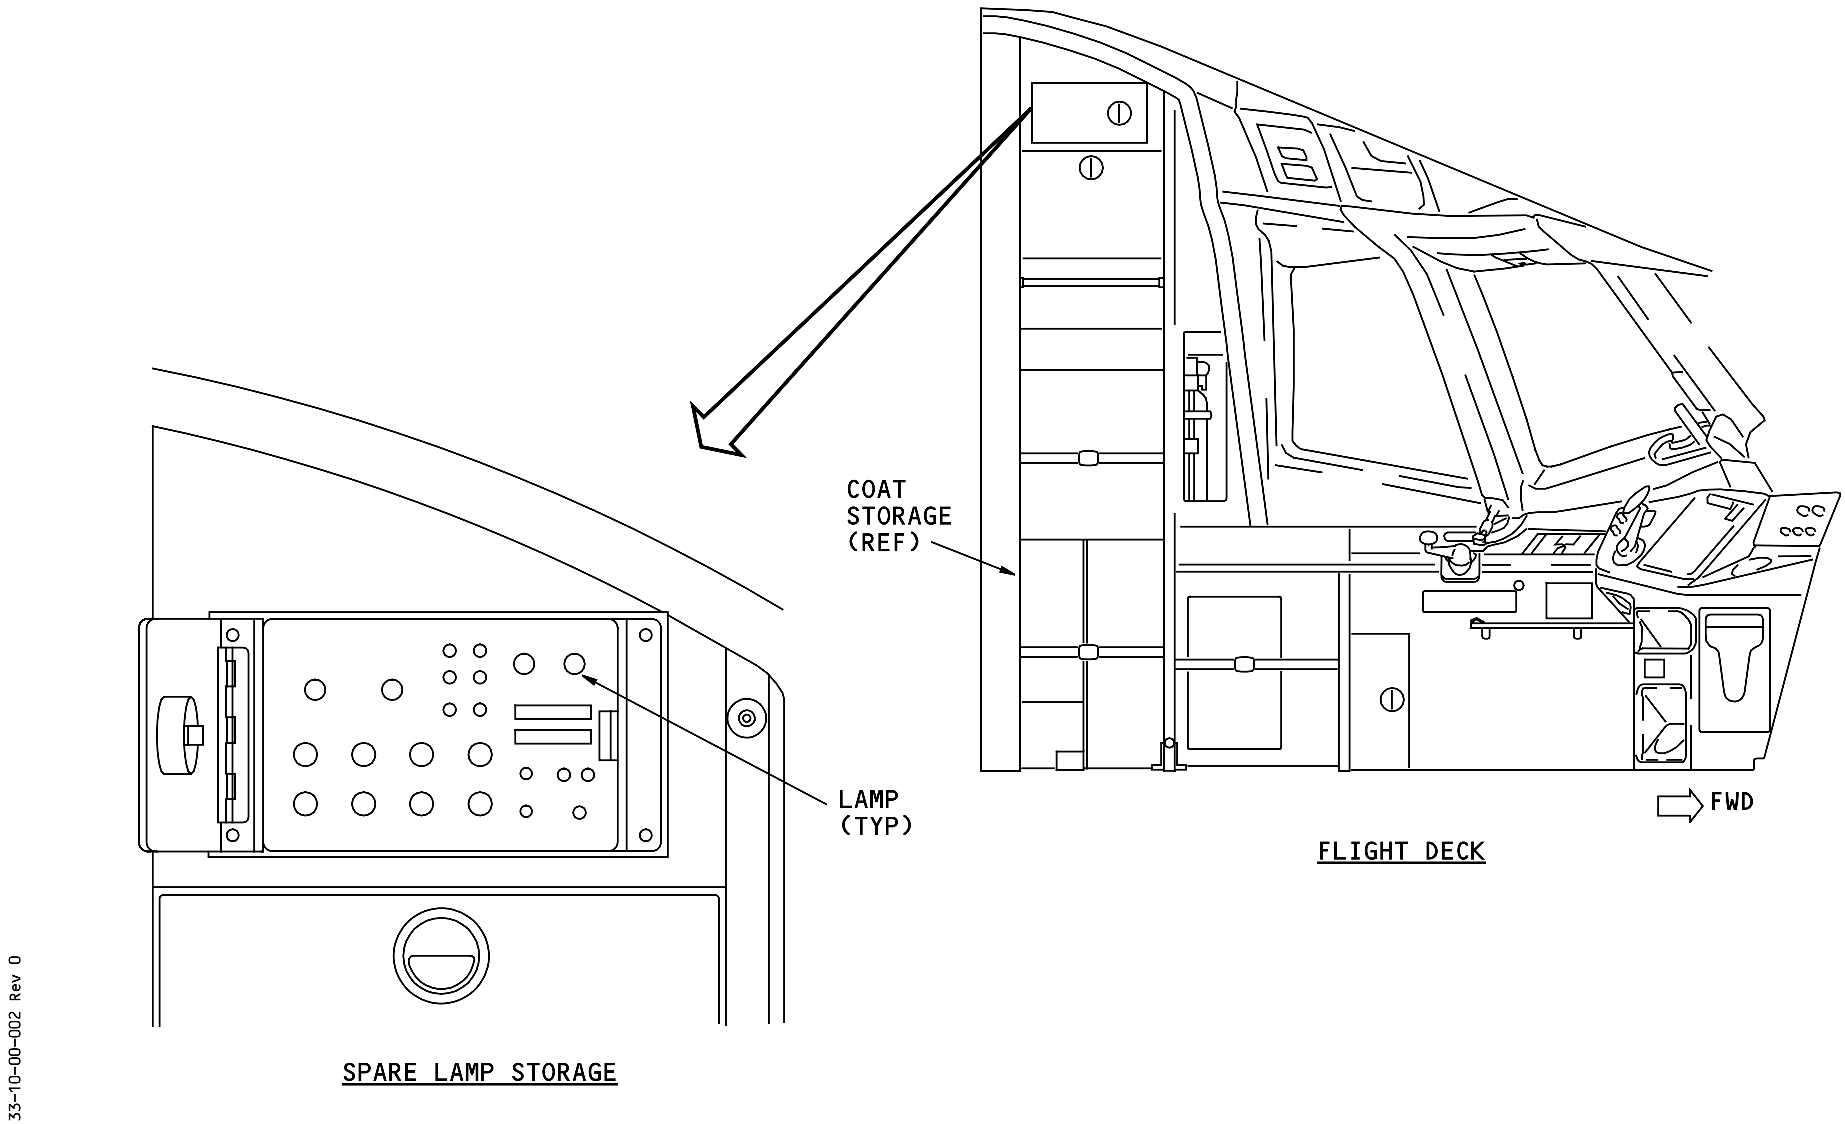


FLIGHT COMPARTMENT LIGHTS - INTRODUCTION

FLIGHT COMPARTMENT LIGHTS - SPARE LAMPS

General

The replacement lamps for the lights in the flight deck are above the coat storage area.



FLIGHT COMPARTMENT LIGHTS - SPARE LAMPS

FLIGHT COMPARTMENT LIGHTS - TRAINING INFORMATION POINTS - P96 OVERHEAD DIMMER PANEL

Purpose

The P96 overhead dimmer panel gives a place to attach dimmer control units, relays and resistors related to the flight compartment lights.

Location

The P96 is in the ceiling, aft of the flight compartment door.

Physical Description

The P96 has relays in the upper left corner, resistors in the upper right corner and dimmer control units (DCU) on the rest of the panel. The relays and resistors are part of the lighting circuits that give floodlighting and dome lighting to the flight deck. Some of the floodlighting circuits (6v ac lights) use the dimmer control units. The overhead panel/instrument lighting circuits for the P5 and P11 panels also use these units.

Relays for these circuits are on the P96 overhead dimmer panel:

- Dome lights dimmer
- Standby (power) - dome and floodlight (4)
- Storm - dome and floodlight (2).

Resistors for these circuits are on the P96 overhead dimmer panel:

- Standby dome lights
- Captain's panel floodlight (2)
- Glareshield floodlight (2)
- First officer's floodlight (2)
- Aisle stand floodlight.

Dimmer control units for these circuits are on the P96 overhead dimmer panel:

- P11 overhead circuit breaker panel light (2)
- P5 overhead instrument and panel light (2)
- Captain's floodlights
- Glareshield floodlights
- First officer's floodlights.

Dimmer control units step-down 115v ac to 5-6v ac for the lights connected to them.

See the integral panel lights section for more information on dimmer control units (AMM PART I 33-13).

FLIGHT COMPARTMENT LIGHTS - TRAINING INFORMATION POINTS - P96 OVERHEAD DIMMER PANEL

FLIGHT COMPARTMENT LIGHTS - TRAINING INFORMATION POINTS - FLIGHT COMPARTMENT DIMMERS AND RELAYS

Location

Dimmer control units (DCU) and relays related to these lights attach to the center aisle stand and the main instrument panels:

- Captain's instruments and panel lights
- Glareshield instruments and panel lights
- First officer's instruments and panel lights
- Aisle stand instruments and panel light.

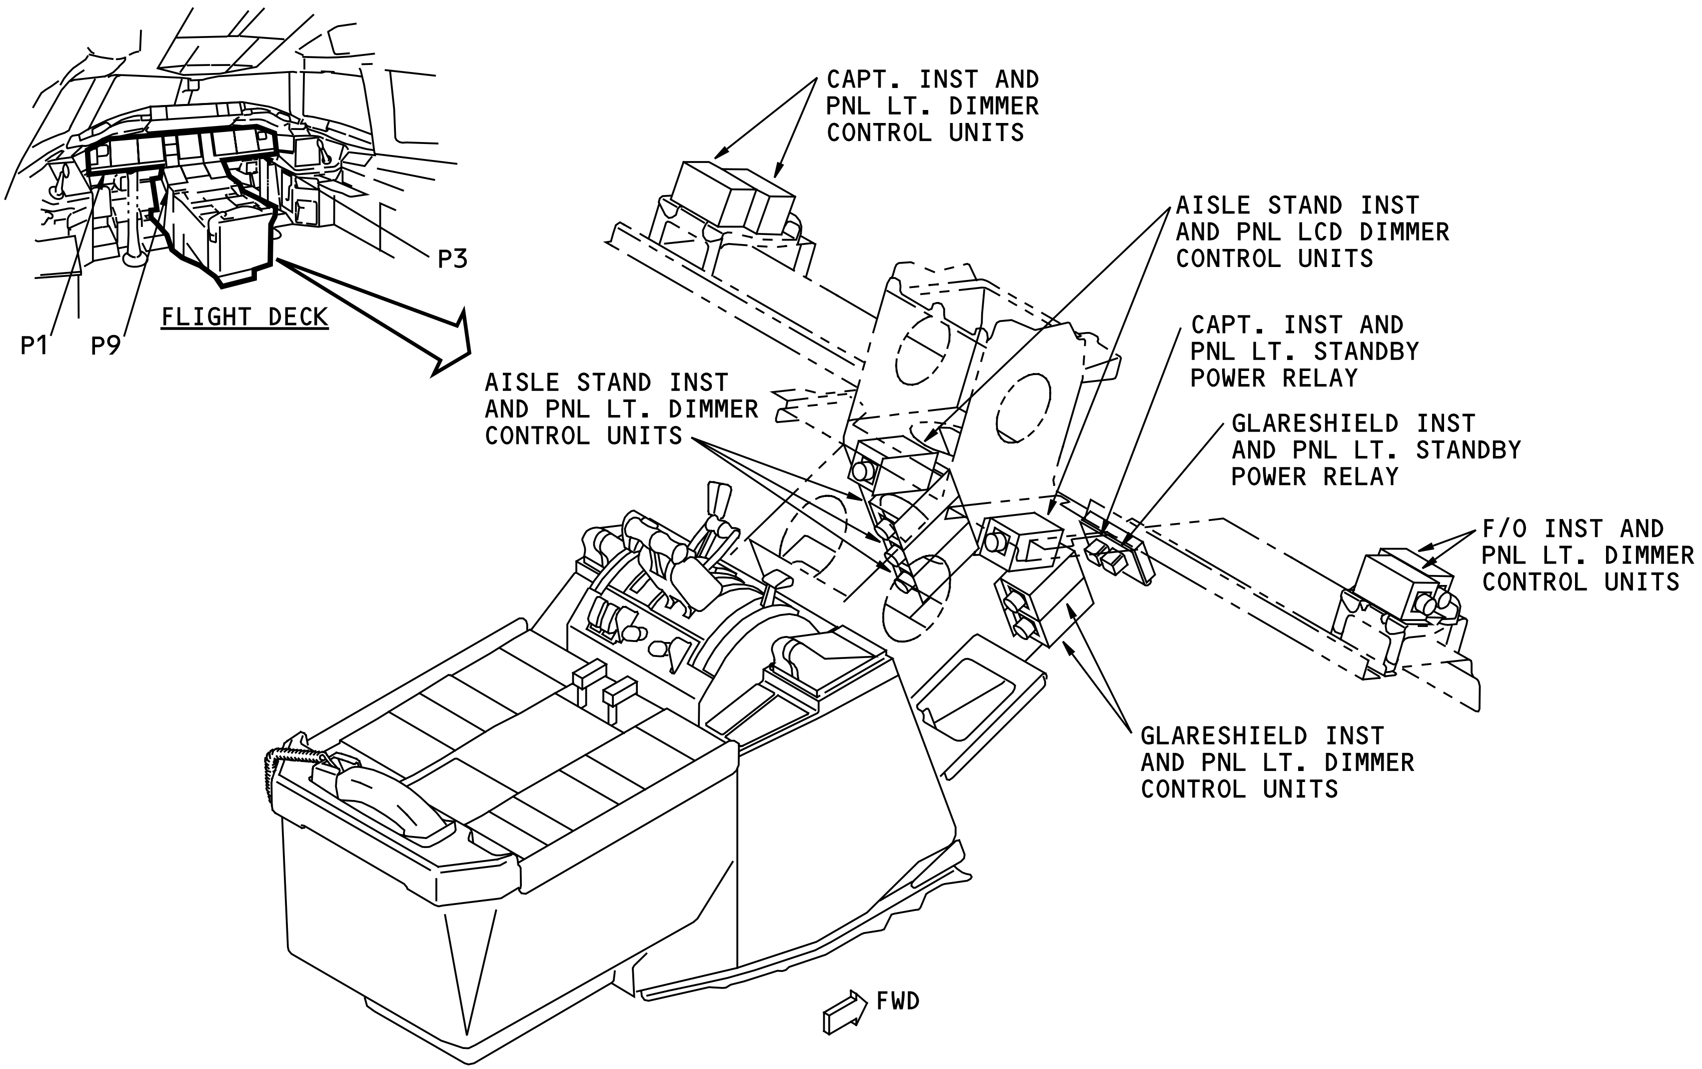
The captain's instrument and panel light DCUs are forward and outboard of the left outboard display unit on the P1. The first officer's instruments and panel light DCUs are forward and outboard of the right outboard display unit on the P3. The other DCUs and relays are forward of the P9 forward aisle stand panel.

Dimmer control units filter and change the 115v ac to 5-6v ac for the lights that connect to them.

Training Information Point

All dimmer control units are the same. All units in the flight compartment connect to the master brightness control (MBC) card (not shown) in the P29 master dim and test card file.

See the integral panel lights section for more information about the dimmer control units (AMM PART I 33-13).



CENTER AISLE STAND AND MAIN INSTRUMENT PANEL AREA

FLIGHT COMPARTMENT LIGHTS - TRAINING INFORMATION POINTS - FLIGHT COMPARTMENT DIMMERS AND RELAYS

FLIGHT COMPARTMENT ILLUMINATION - DOME LIGHTS - INTRODUCTION

Location

There are two dome lights, one is above the captain's seat and the other is above the first officer's seat.

Physical Description

Each light has these components:

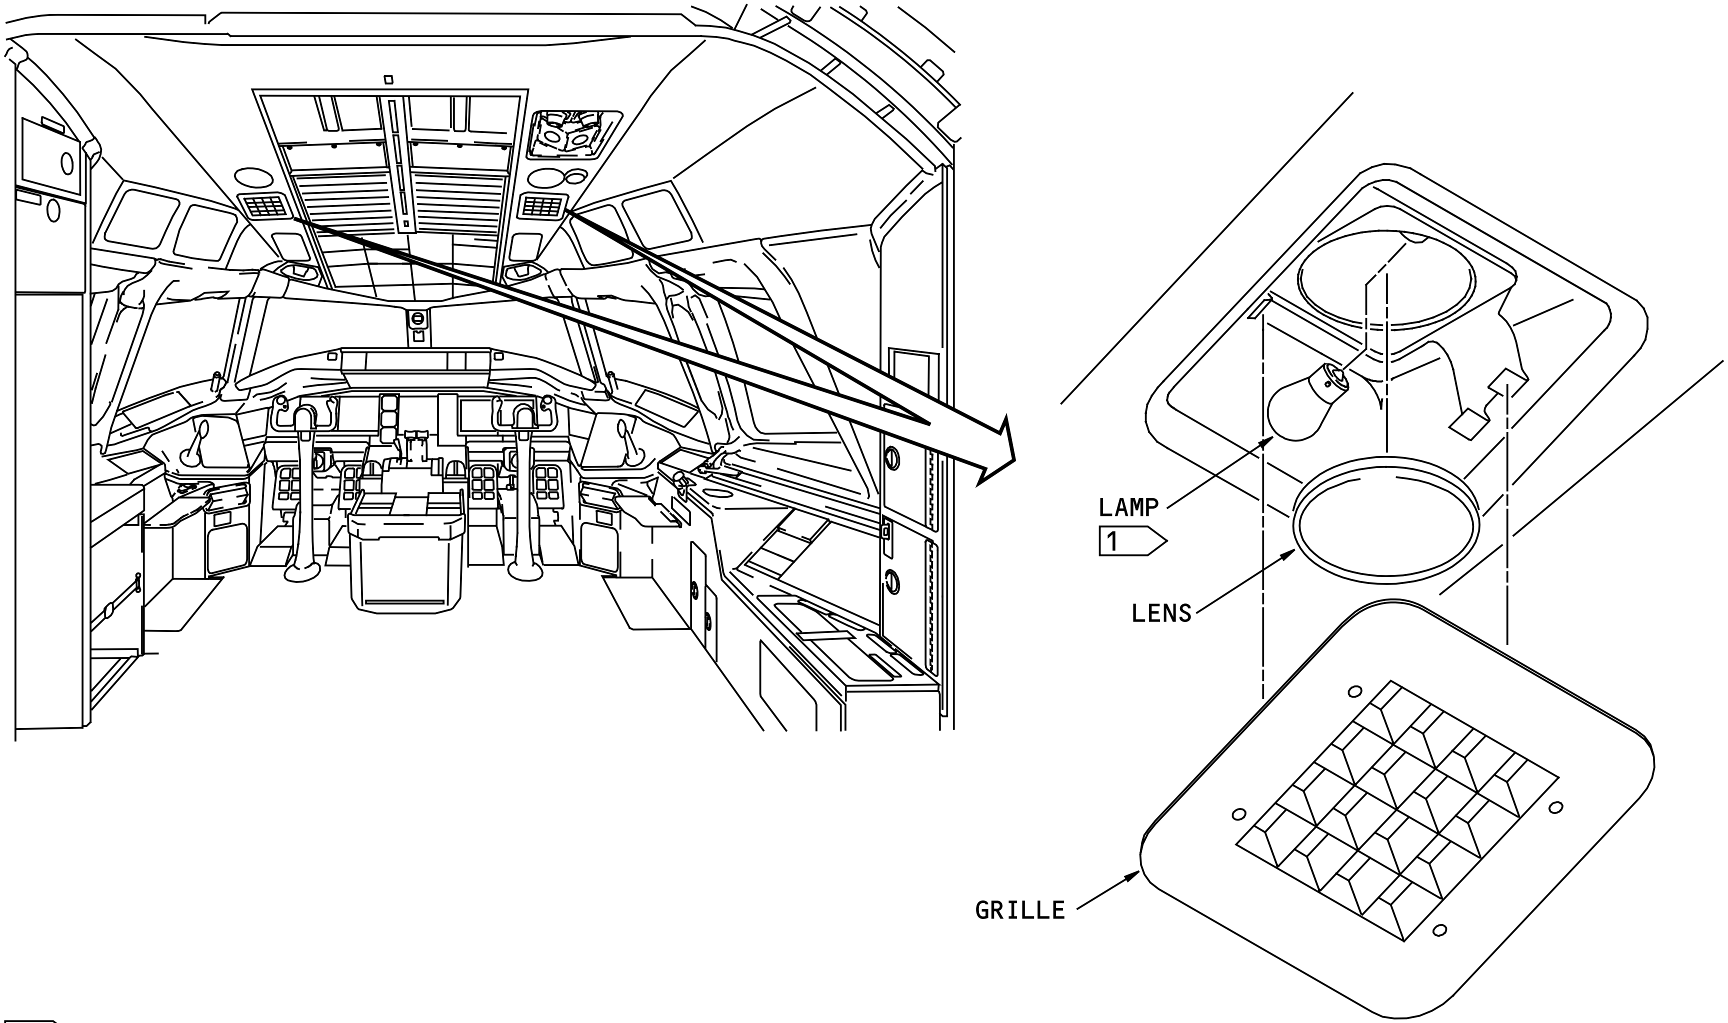
- Lamp
- Lens
- Grille.

The captain's dome light has two lamps. One is the normal lamp and the other is the lamp for the emergency light system.

See the emergency lights section for more information about the emergency lights (AMM PART I 33-50).

Training Information Point

To get access to the lamp you pull down on the grate and remove the lens. The lens has a bayonet-style mount. The lamp is a bayonet-style lamp.



DOME LIGHT

1 THE CAPTAIN'S DOME LIGHT HAS TWO LAMPS. ONE IS THE NORMAL LIGHT AND THE OTHER IS THE LAMP FOR THE EMERGENCY LIGHTS SYSTEM.

33-11-00-002 Rev 3 07/14/1997

FLIGHT COMPARTMENT ILLUMINATION - DOME LIGHTS - INTRODUCTION

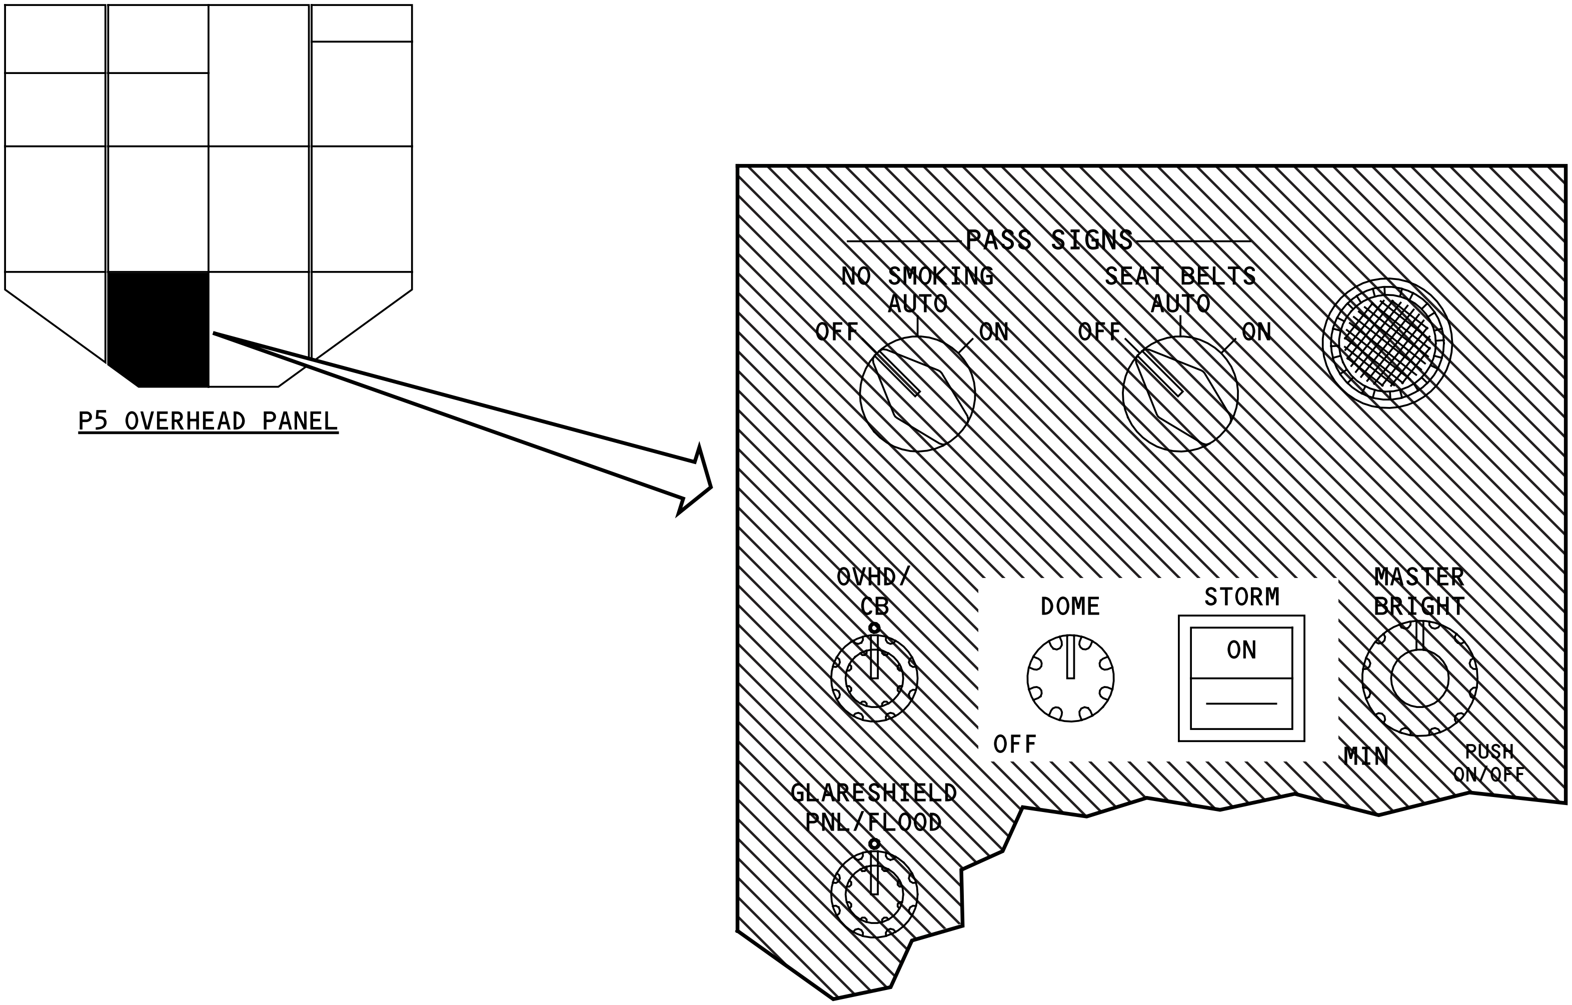
FLIGHT COMPARTMENT ILLUMINATION - DOME LIGHTS - OPERATION

Operation

You use the dome light control (DOME) to operate the dome lights. The control is on the passenger signs/ lighting panel on the P5 overhead panel. The control is a rotary-type control that controls the intensity of the lights.

You use the storm light switch (STORM) to make the dome and floodlights come on fully bright. It will also make the lights in the master dim and test system operate at the fully bright level.

See the master dim and test section for more information about the master dim and test system (AMM PART I 33-16).



PASSENGER SIGNS/LIGHTING PANEL

33-11-00-003 Rev 3 08/08/96

FLIGHT COMPARTMENT ILLUMINATION - DOME LIGHTS - OPERATION

FLIGHT COMPARTMENT ILLUMINATION - DOME LIGHTS - FUNCTIONAL DESCRIPTION

General

The dome lights have four modes of operation:

- Normal
- Backup
- Standby
- Storm.

In the normal and backup modes the amount of light that comes from the light is adjustable. In the standby mode the amount of light is not adjustable. In the storm mode the lights come on fully bright.

Normal Mode

When the ground service bus has power, the dome lights dimmer relay energizes. This supplies power to the dimmer on the passenger signs/lighting panel on the P5. It also energizes the standby lights relay.

When the standby lights relay is energized and the control is not in the OFF position, power from the ground service bus goes to the lights and makes them come on. When you adjust the control it adjusts the variable transformer in the dimmer. This adjusts the amount of light that comes from the dome lights.

Backup Mode

If the ground service bus does not have power and the right transfer bus has power, the dome lights operate in the backup mode. In the backup mode the dome lights operate the same as in the normal mode. The only difference is that the right transfer bus supplies power to the dome lights dimmer and the standby lights relay. The dome lights dimmer relay is de-energized to the backup position.

Standby Mode

If the ground service bus and the right transfer bus do not have power, the standby lights relay is de-energized to the standby position. Power from the standby power system goes to the captains flight instrument bus. It then goes through the standby dome lights resistor to decrease the voltage. The dome lights come on, but they are not at the fully bright level.

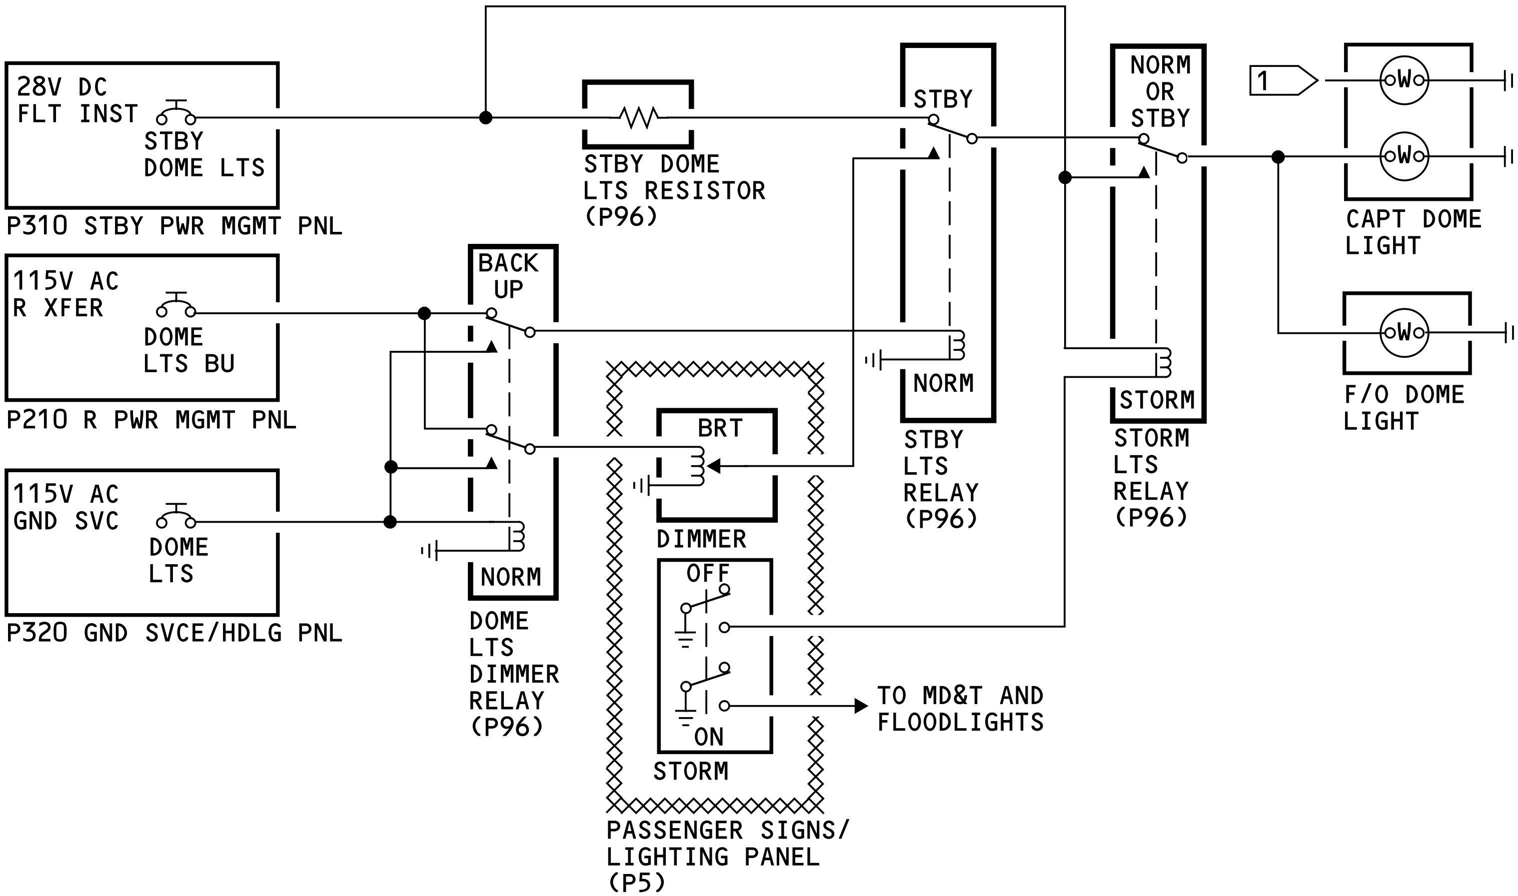
Storm Mode

When you push the storm light switch (STORM), the storm lights relay energizes. It energizes in every mode of operation because its power comes from the standby power system. When the relay energizes, 28v dc goes to the lights and they come on fully bright.

Training Information Point

The emergency lighting system turns on the second captain's dome light.

See the emergency lighting section for more information (AMM PART I 33-50).



1 POWER COMES FROM EMERGENCY LIGHTING SYSTEM.

33-11-00-004 Rev 3 04/10/1997

FLIGHT COMPARTMENT ILLUMINATION - DOME LIGHTS - FUNCTIONAL DESCRIPTION

FLIGHT COMPARTMENT ILLUMINATION - FLOODLIGHTS - INTRODUCTION

Purpose

The floodlights give light to these panels:

- P1 left forward panel
- P2 center forward panel
- P3 right forward panel
- P8 aft aisle stand panel
- P9 forward aisle stand panel
- P55 glareshield center panel.

Location

The floodlights for the P1, P2, and P3 panels are above the panels. The floodlight for the P8 and P9 panels is above the aisle stand in the P5 panel. The floodlights for the P55 are above the P55 panel.

Physical Description

There are two different kinds of floodlights, strip and spot. The strip flood lights have several incandescent lights attached to a lens. Each spot floodlights is an incandescent bulb.

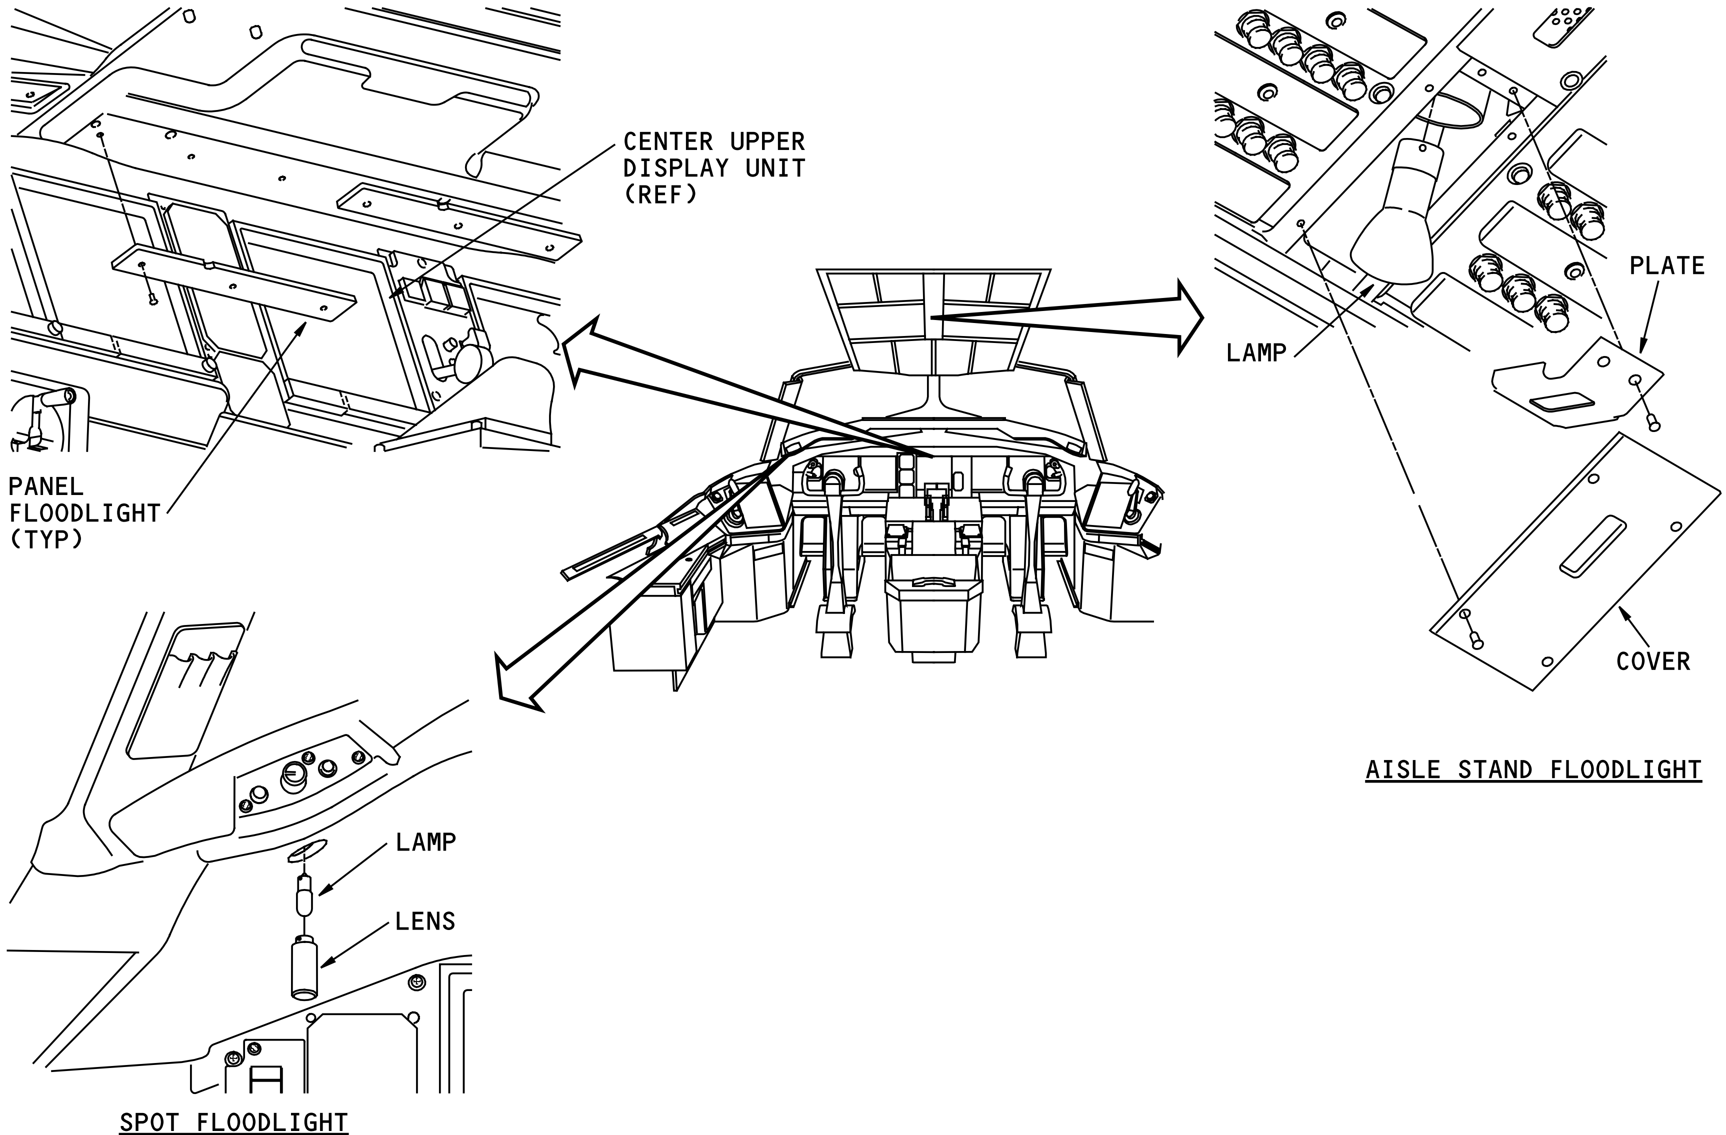
Training Information Point

The strip floodlights are above the P1, P2, P3, and P55 panels. The spot floodlights are above the P1, P3, and P8 and P9 panels.

When there is not sufficient light that comes from the strip floodlights, you replace the assembly. You remove two screws to release the assembly.

You remove the lens on the spot floodlights above the P1 and P3 panel to get access to the lamp. The lens and the lamp are bayonet-type.

You remove two plates to get access to the lamp that gives light to the aisle stand. The lamp is a bayonet-type.



33-11-00-005 Rev 1 07/14/1997

FLIGHT COMPARTMENT ILLUMINATION - FLOODLIGHTS - INTRODUCTION

FLIGHT COMPARTMENT ILLUMINATION - FLOODLIGHTS - OPERATION

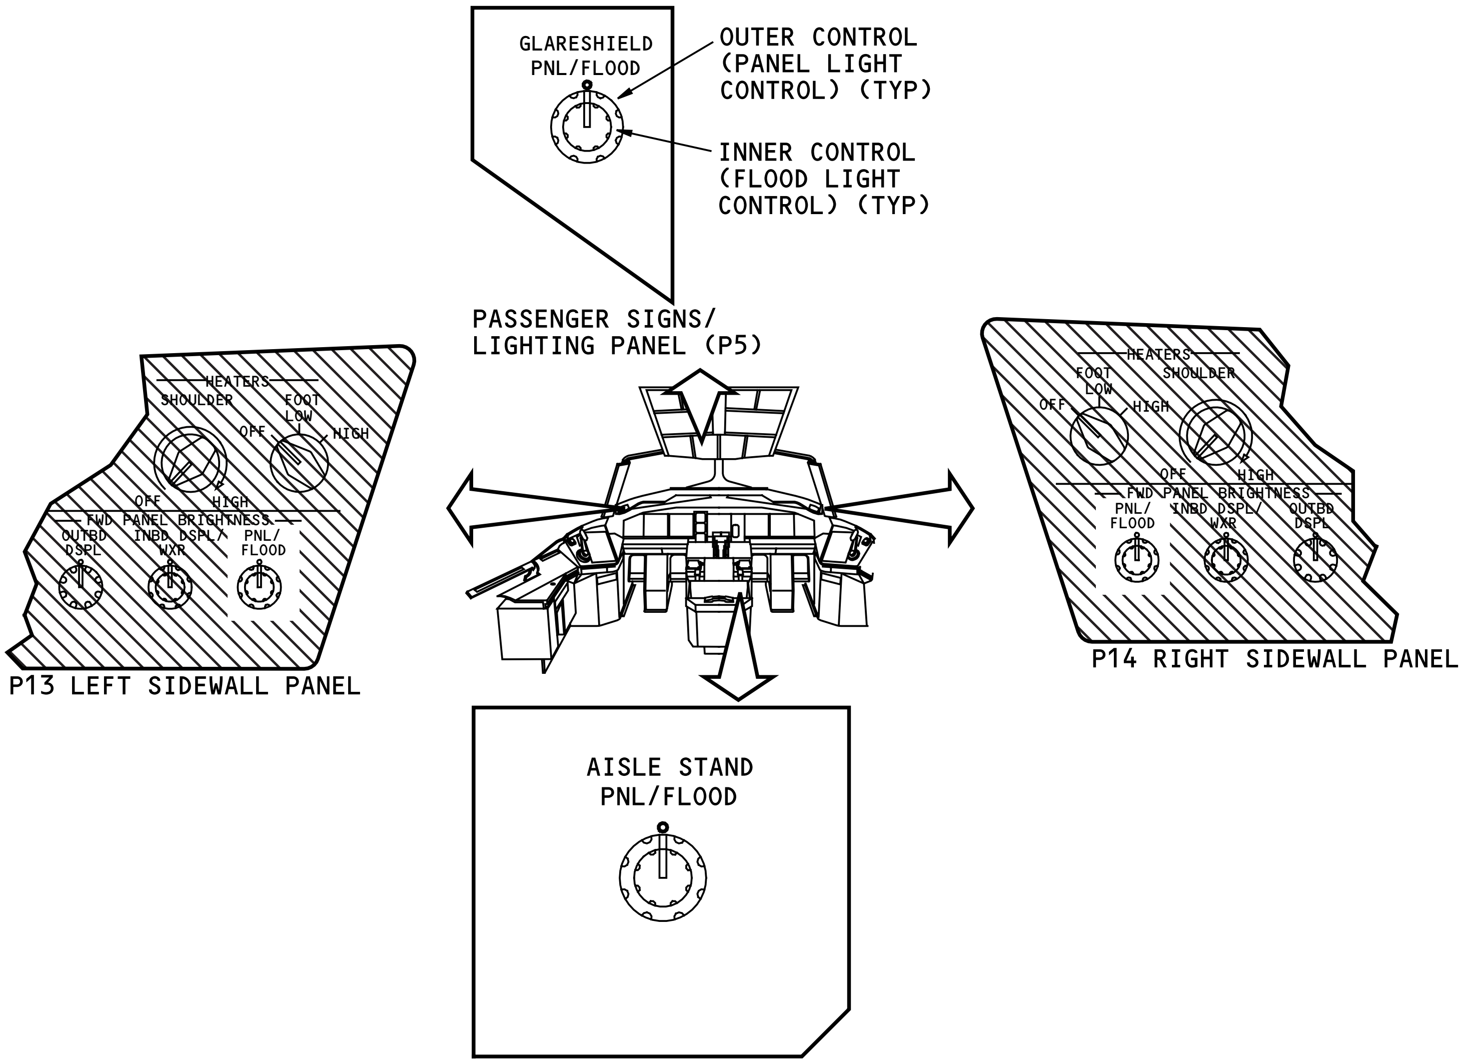
Operation

You use the inner control of the GLARESHIELD PNL/FLOOD light control to adjust the amount of light that comes from the two strip floodlights above the P55 panel. The control is on the passenger signs/lighting panel on the P5 overhead panel.

You use the inner control of the FWD PANEL BRIGHTNESS PNL/FLOOD light control to adjust the amount of light that comes from the captain's spot floodlight and the two strip flood lights above the P1 and P2 panels. The control is on the P13 left sidewall panel.

You use the inner control of the FWD PANEL BRIGHTNESS PNL/FLOOD light control to adjust the amount of light that comes from the first officer's spot floodlight and the two strip flood lights above the P2 and P3 panels. The control is on the P14 right sidewall panel.

You use the inner control of the AISLE STAND PNL/FLOOD light control to adjust the amount of light that comes from the aisle stand spot floodlight. The control is on the aisle stand brightness control panel on the P8 aft aisle stand panel.



FLIGHT COMPARTMENT ILLUMINATION - FLOODLIGHTS - OPERATION

FLIGHT COMPARTMENT ILLUMINATION - FLOODLIGHTS - FUNCTIONAL DESCRIPTION

General

The floodlights have these three modes of operation:

- Normal
- Standby
- Storm.

In the normal mode, the amount of light that comes from the floodlights is adjustable. In the standby mode, the amount of light is not adjustable. In the storm mode, the lights come on fully bright.

Normal Mode

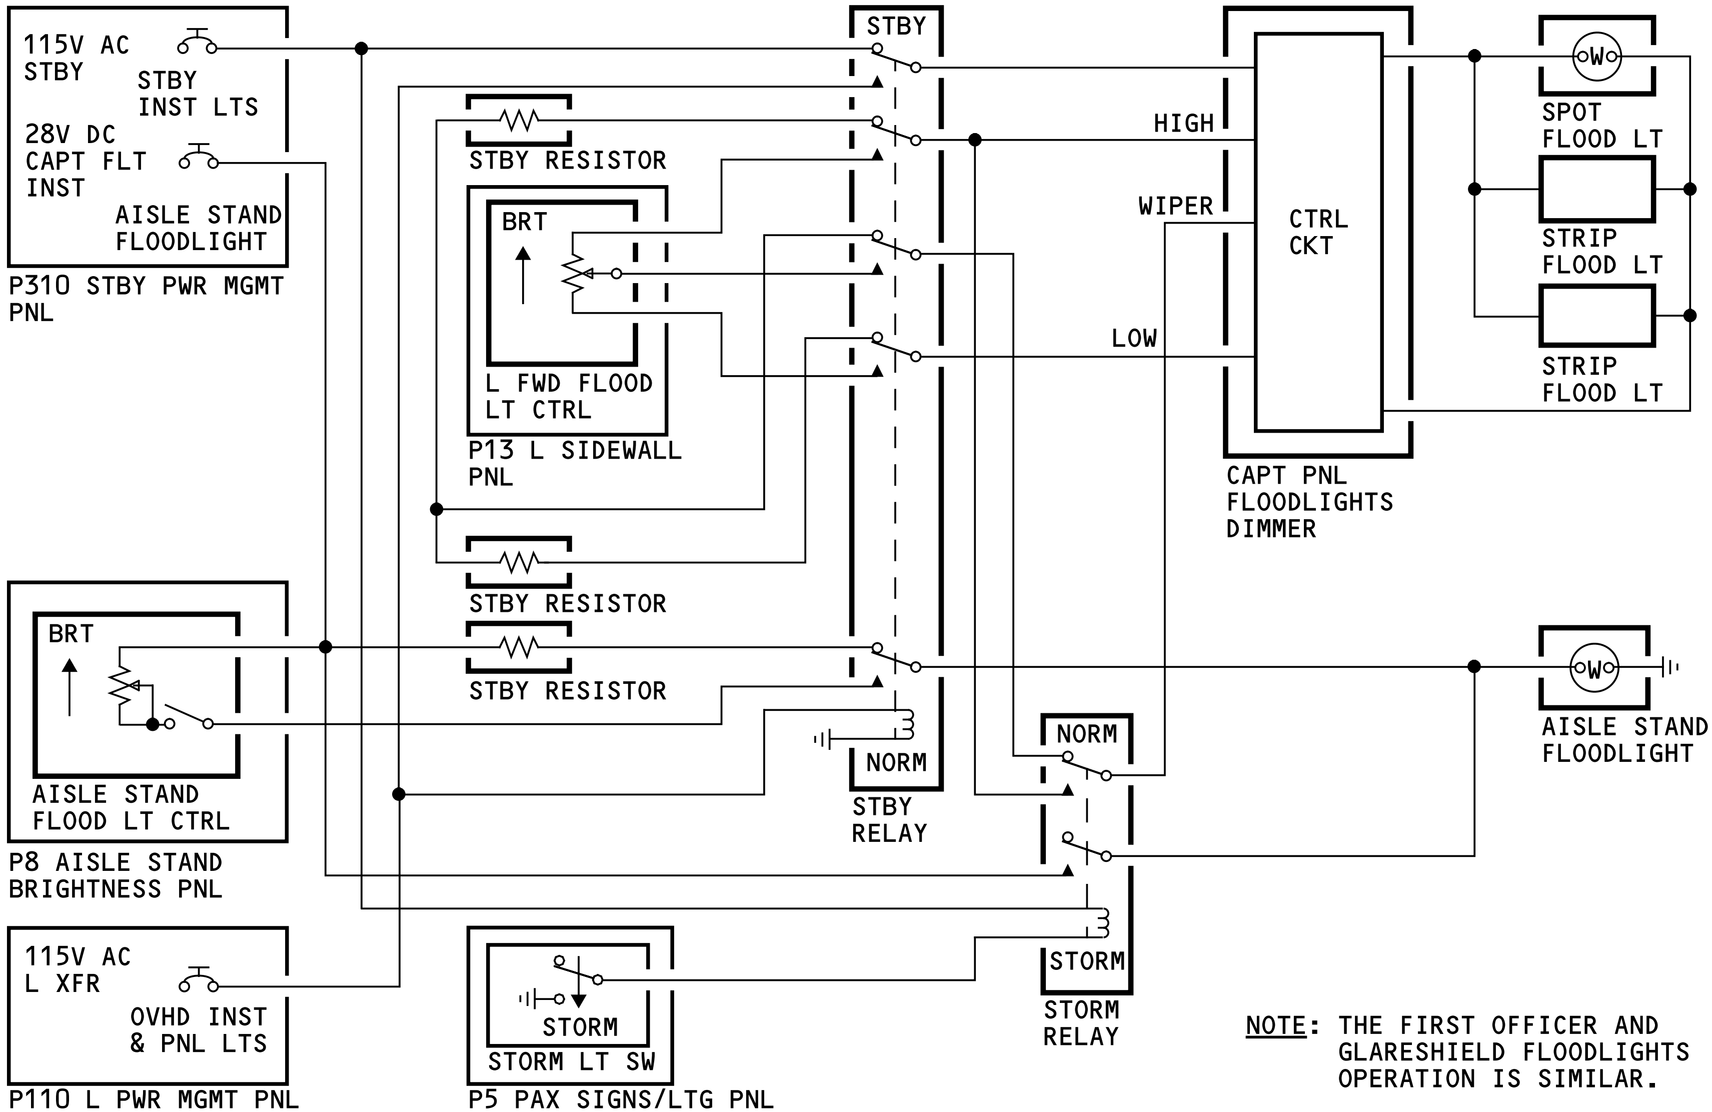
When the left transfer bus has power, the standby relay energizes to the normal position. This connects the floodlight dimmer with the floodlight control. When you rotate the control on the P13 left sidewall panel, it adjusts the position of the wiper. This adjusts the amount of light that comes from the captains floodlights. When you turn the control on the P8 aisle stand brightness panel, it adjusts the position of a wiper. This adjusts the amount of light that comes from the aisle stand floodlight.

Standby Mode

When the left transfer bus does not have power, the standby relay goes to the standby position. When the captain's flight instruments have power from the standby power system, the lights operate. In this mode, input to the control circuit comes from resistors. For the aisle stand floodlight, the voltage for the light must go through a resistor. The amount of light that comes from the floodlights is not as bright as it is in the fully bright position.

Storm

When you push the storm light switch on the P5 passenger signs/lighting panel, the storm relay energizes. The signal goes to the control circuit in the dimmer to make the lights come on full bright.



NOTE: THE FIRST OFFICER AND GLARESHIELD FLOODLIGHTS OPERATION IS SIMILAR.

FLIGHT COMPARTMENT ILLUMINATION - FLOODLIGHTS - FUNCTIONAL DESCRIPTION

FLIGHT COMPARTMENT ILLUMINATION - TRAINING INFORMATION POINTS - RELAY LOCATIONS

Location

These relays are on the P96 overhead dimmer panel:

FLIGHT COMPARTMENT ILLUMINATION - TRAINING INFORMATION POINTS - RELAY LOCATIONS

INTEGRAL PANEL LIGHTS - ANNUNCIATOR LIGHTS

Purpose

The annunciator lights give the flight or maintenance crew status, caution, or warning information about an airplane system.

Location

The annunciator lights are on the P5 overhead panel and the P8 aft aisle stand panel.

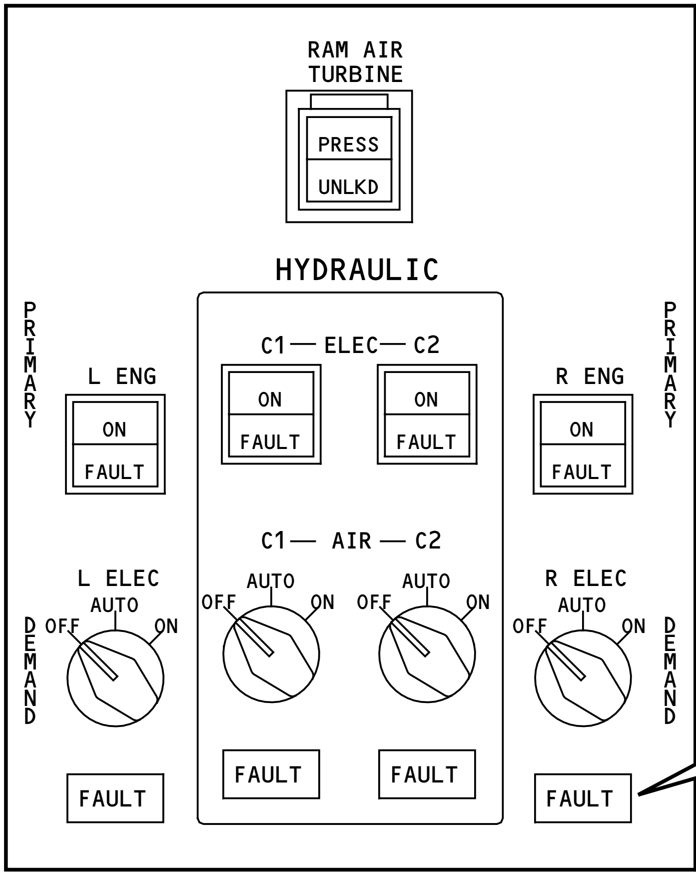
Physical Description

The annunciator lights use light emitting diodes (LEDs). Each light has these components:

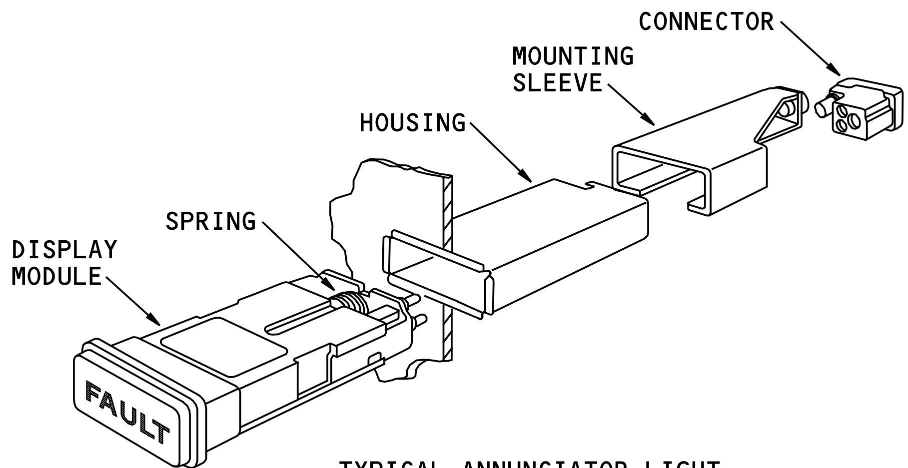
- Display module
- Mounting sleeve
- Connector
- Housing
- Spring.

Training Information Point

To remove a display module you push on the surface of the display module to compress the spring. This will release the module. Pull the module straight out to remove it. Make sure you apply equal pressure on the surface of the display module when you push it.



TYPICAL PANEL



TYPICAL ANNUNCIATOR LIGHT

33-13-00-003 Rev 0

INTEGRAL PANEL LIGHTS - ANNUNCIATOR LIGHTS

INTEGRAL PANEL LIGHTS - LIGHTED PUSH-BUTTON SWITCHES

Purpose

Lighted push-button switches give control inputs to their associated systems. They can also give information on system status.

Location

There lighted push-button switches on the P5 overhead and P9 forward aisle stand panel.

Physical Description

There are two kinds of push-button switches: momentary action and alternate action.

The lighted push-button switches have these components:

- Switch guard (not all switches) (not shown)
- Cap module
- Switch module
- Housing.

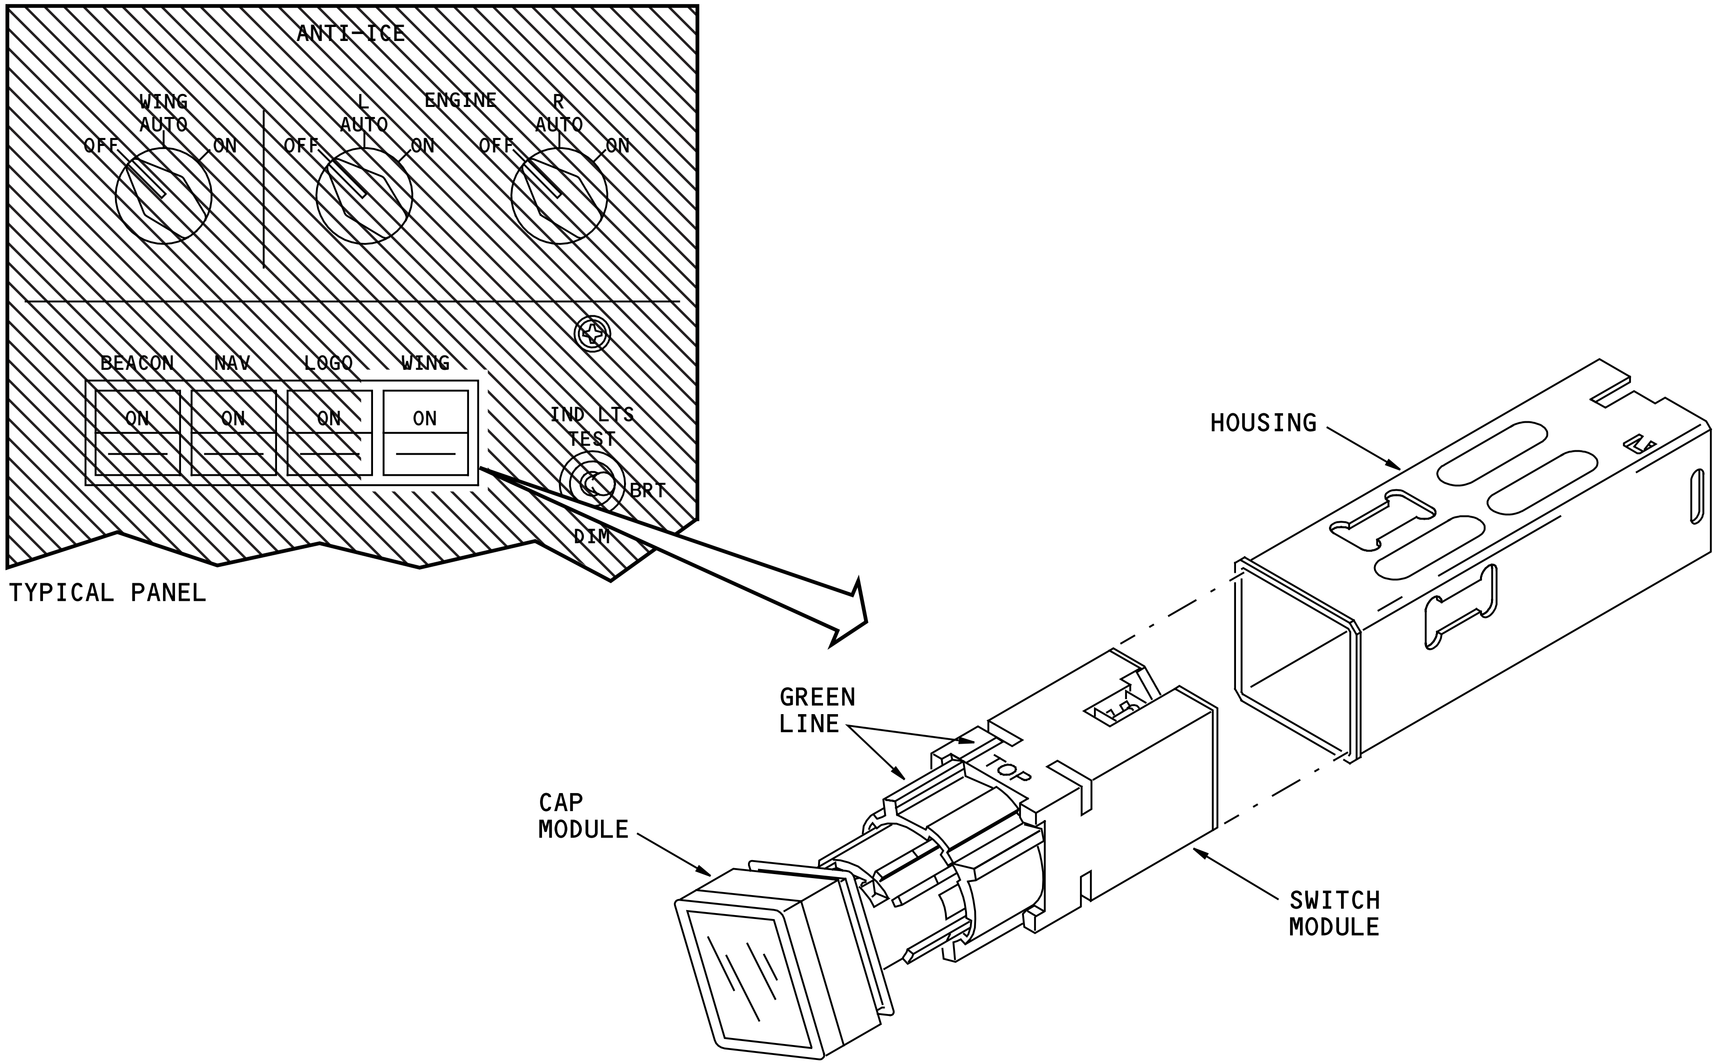
Training Information Point

To remove the lighted push-button switch, pull the cap module and turn the cap module counterclockwise and pull again. This will release the switch module from the panel.

To install the switch make sure the green lines on the top of the switch align before you install the switch.

Once this is done, insert the switch into the panel and turn the cap module clockwise.

See integral panel lights in AMM Part II for more information about switch removal and installation.



TYPICAL LIGHTED PUSH-BUTTON SWITCH

INTEGRAL PANEL LIGHTS - OPERATION

General

These are the controls for the integral panel lights:

- Outer control of the OVHD/CB light control on the passenger signs/lighting panel for the P5 overhead panel
- Inner control of the OVHD/CB light control on the passenger signs/lighting panel for the P11 circuit breaker panel
- Outer control of the GLARESHIELD PNL/FLOOD light control on the passenger signs/lighting panel for the P7 glareshield panel
- MASTER BRIGHT control on the passenger signs/ lighting panel
- MASTER BRIGHT switch on the passenger signs/ lighting panel
- Outer control of the FWD PANEL BRIGHTNESS PNL/ FLOOD light control on the P14 right sidewall panel for the P3 right forward panel
- Outer control of the FWD PANEL BRIGHTNESS PNL/ FLOOD light control on the P13 left sidewall panel for the P1 left forward and P2 center forward panels
- Outer control of the AISLE STAND PNL/FLOOD light control on the aisle stand brightness panel for the P8 aft aisle stand panel.

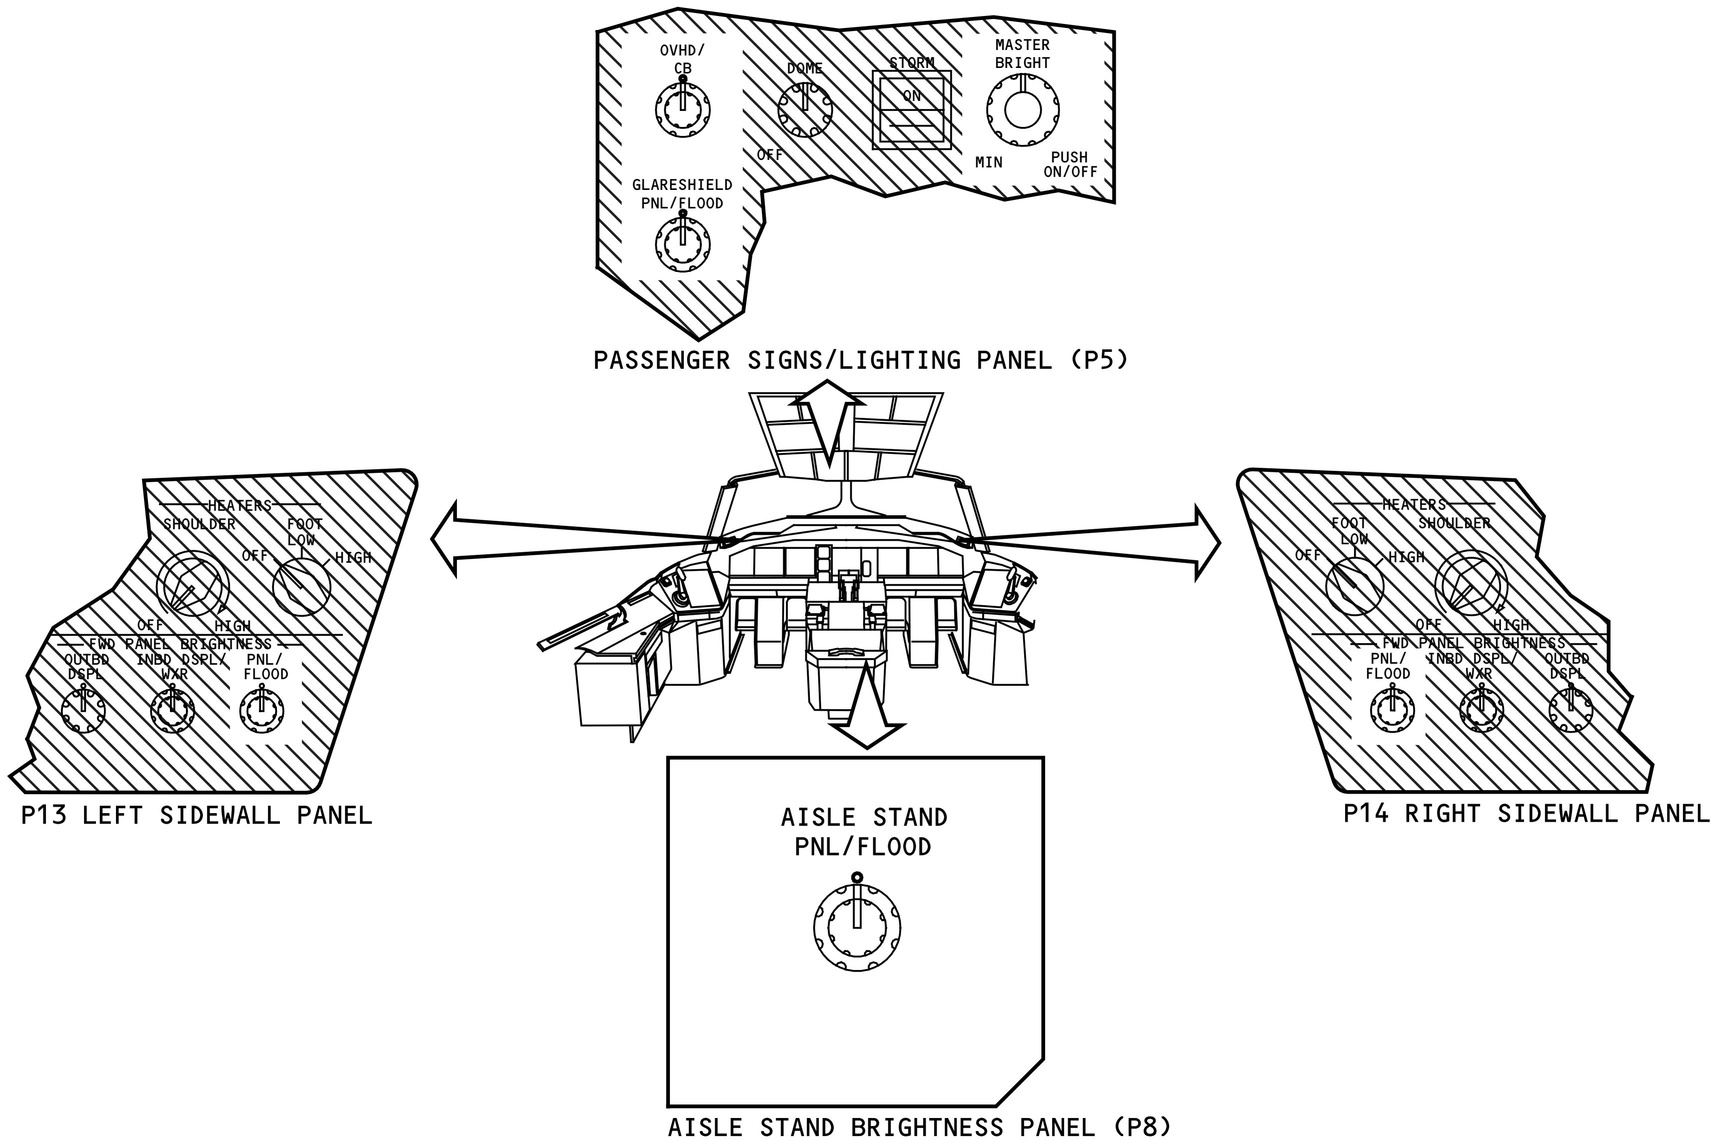
Operation

You use the controls to adjust the amount of light that comes from the integral panel lights. When the MASTER BRIGHT switch is in the OFF position, you can adjust the lights from fully dim to fully bright.

Master Brightness

With the MASTER BRIGHT switch in the ON position, you set the lighting level for all of the integral panel lights at the same time. You turn the MASTER BRIGHT control to adjust the amount of light that comes from the integral panel lights.

When the MASTER BRIGHT switch is in the ON position, you can use any panel control to adjust the amount of light for the related panel. The range of adjustment is ±20 percent.



INTEGRAL PANEL LIGHTS - OPERATION

33-13-00-005 Rev 3 08/08/96

INTEGRAL PANEL LIGHTS - DIMMER CONTROL UNITS

Purpose

The dimmer control units (DCUs) filter and control the voltage that goes to integral panel lights (lighted instruments and lightplate panels) and some floodlights in the flight deck. The units control the voltage based on inputs from controls in the flight deck.

Location

The DCUs are on the P96 overhead dimmer panel and in the flight deck. There are seven units on the P96. There are eleven units in the flight deck at these locations:

- P1 area: two units forward and outboard of the left outboard display unit (not shown)
- P3 area: two units forward and outboard of the right outboard display unit (not shown)
- P9 area: seven units, four on the left and three on the right, are forward and below left and right control display units (not shown).

See the flight compartment section for more information about the dimmer control units and their related light circuits (AMM PART I 33-10).

Physical Description

The DCUs are LRUs. Each DCU has these parts:

- Electrical connector
- Control card (internal)
- EMI filter (internal)
- Power transformer (internal).

The DCUs are static sensitive.

Functional Description and Interfaces

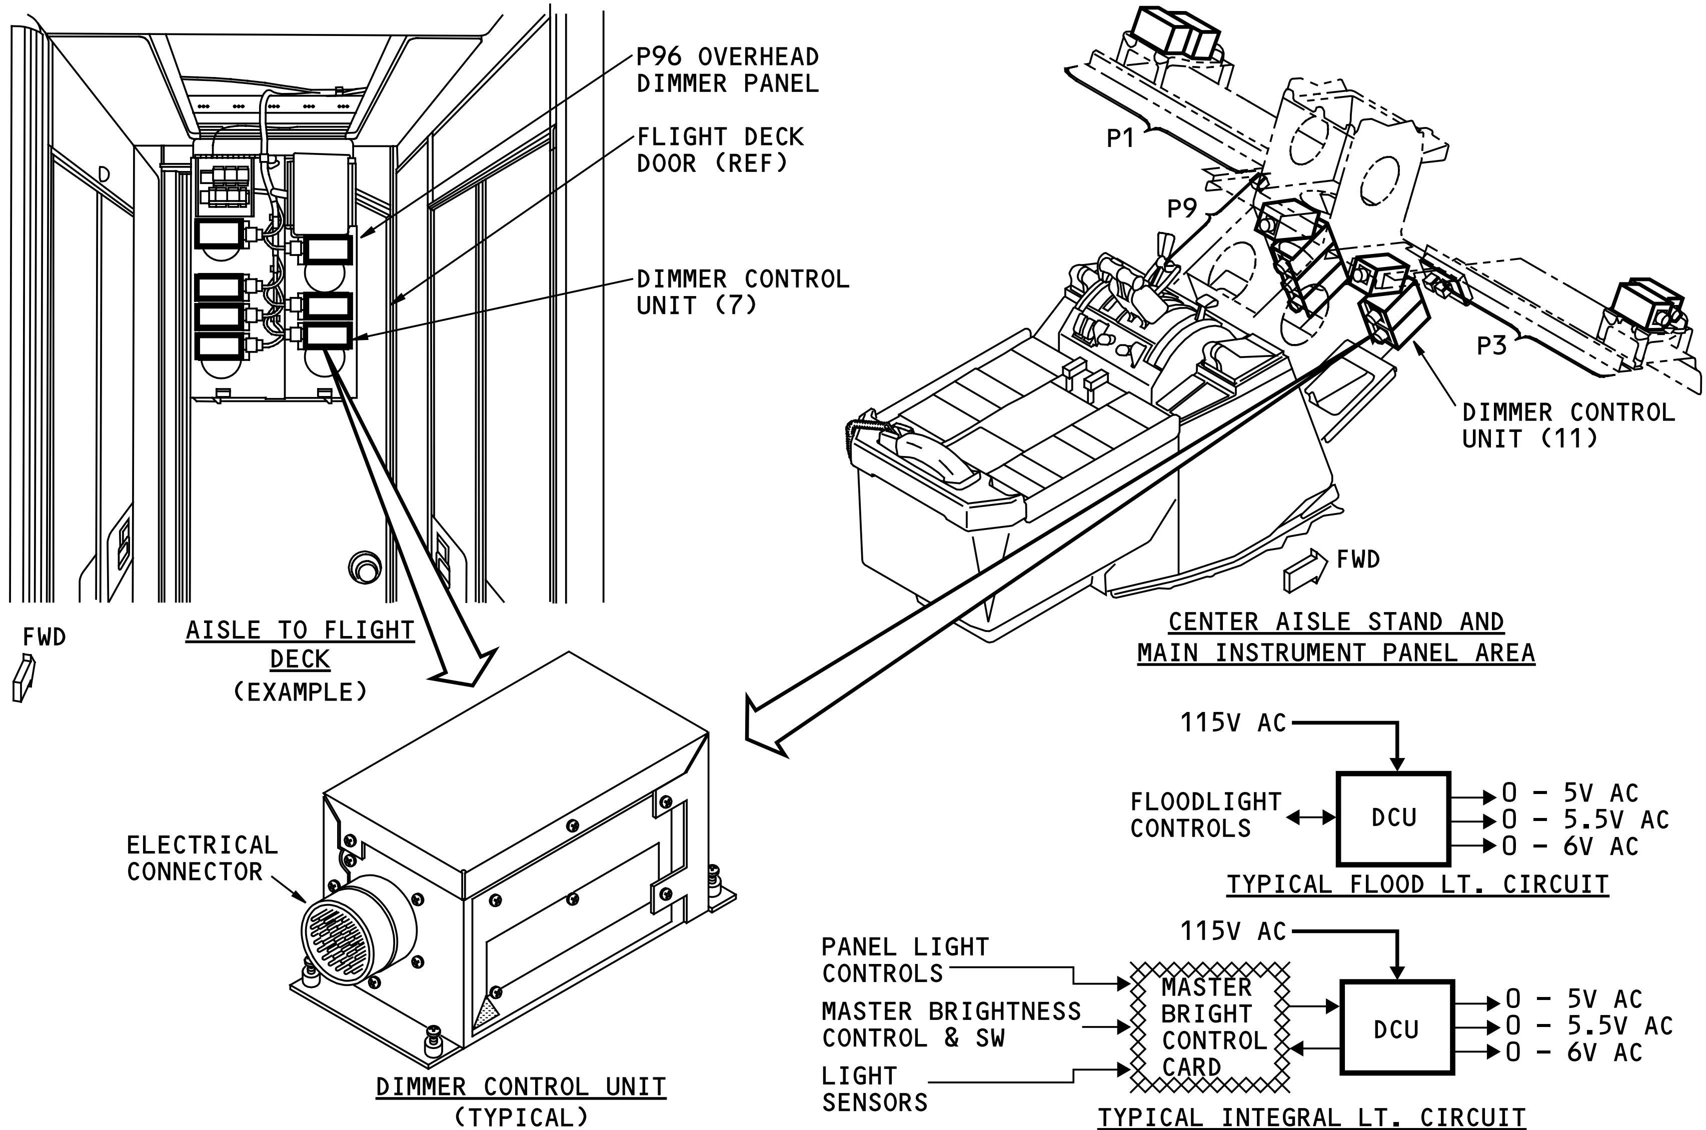
The DCUs use 115v ac for control and operation. The control card, EMI filter, and power transformer operate together to give any one of these outputs:

- 0 to 5v ac
- 0 to 5.5v ac
- 0 to 6v ac.

The DCUs in the flood light circuits monitor floodlight controls for operator input. Based on the operator input, the DCU adjusts output voltage to the floodlights.

The DCUs in the integral panel light circuits connect to the master brightness control (MBC) card. The card tells the DCUs the intensity for the lights based on operator inputs (panel light and master brightness controls). The card also monitors light sensors and can cause the DCUs related to the aisle stand LCDs to adjust for increased brightness inside or outside of the flight deck.

See the flight compartment illumination section for more information about the operation of the dimmer control units in the floodlight circuits (AMM PART I 33-11).



INTEGRAL PANEL LIGHTS - DIMMER CONTROL UNITS

33-13-00-009 Rev 1 06/23/95

INTEGRAL PANEL LIGHTS - FUNCTIONAL DESCRIPTION - MANUAL ADJUSTMENTS

THIS PAGE INTENTIONALLY LEFT BLANK

INTEGRAL PANEL LIGHTS - FUNCTIONAL DESCRIPTION - MANUAL ADJUSTMENTS

General

The light intensity for the integral panel lights is adjustable manually from the master bright control (MBC) and the individual panel light controls. You can adjust the light intensity from both controls if the master bright switch (MBS) is in the ON position.

When the master bright switch is ON, the master bright control has full control of the intensity of all the integral panel lights. The individual panel light controls let you bias the light intensity up or down by 20 percent.

When the MBS is off, the individual panel light controls have full control of the panel lights.

You can manually adjust these integral panel lights:

- P1
- P2
- P3
- P5
- P7
- P8
- P9
- P10
- P11
- P13
- P14
- P15
- P16
- P55.

Power Supply

The master brightness control (MBC) card gets 28v dc from the left main bus.

The dimmer control units for the captain's integral panel lights get power from these sources:

- 115v ac left transfer bus: usual power source
- 115v ac standby bus: backup power source.

The dimmer control units for other integral panel lights (not shown) get power from these sources:

- 115v ac left transfer bus: overhead panel
- 115v ac right transfer bus: glareshield, F/O and observer panels
- 115v ac left main bus, section 1: overhead circuit breaker panel.

The dimmer control units decrease the 115v ac to these values:

- 0 to 5v ac
- 0 to 5.5v ac
- 0 to 6v ac.

The dimmer control units supply power to the integral panel lights. The amount of power the dimmer control units supplies to the integral panel lights usually comes from operator input through the master bright control card. Some integral panel light circuits also

INTEGRAL PANEL LIGHTS - FUNCTIONAL DESCRIPTION - MANUAL ADJUSTMENTS

get inputs from light sensors through the master bright control card.

See the automatic adjustments training information points section for more information about the light sensors.

Manual Brightness Inputs

When the MBS is ON, the MBC adjusts the integral panel lights from full bright to full dim. The individual panel light controls can adjust the light brightness up or down 20 percent from the level set by the MBC.

The master bright control card has a master bright control blend function. The master bright control blend function mixes the inputs from the MBC and the individual panel light control. This is the function that lets you bias the panel lights by 20 percent. The master bright control blend function then sends a single output to the respective dimmer control unit. The dimmer control units then adjust the light intensity of the respective integral panel light.

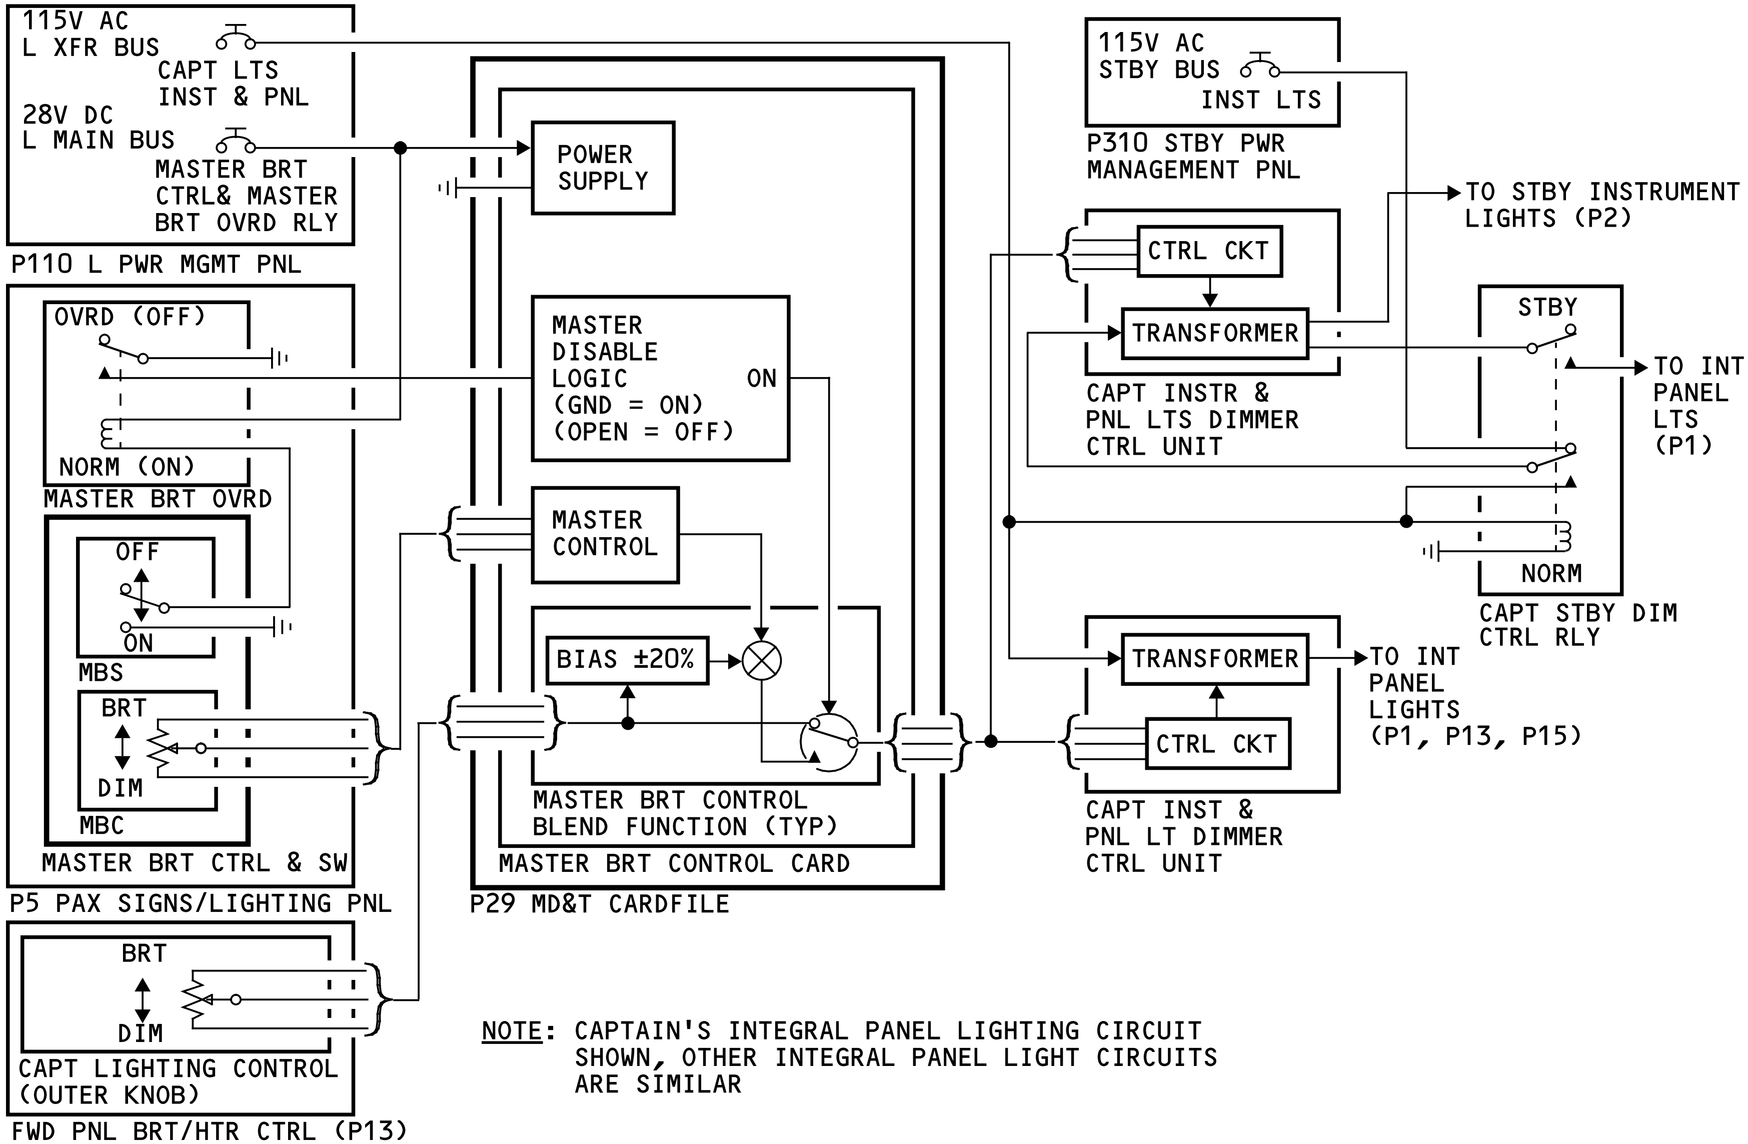
When the MBS is OFF, the master bright control card disables the master bright control blend function. The individual panel light controls adjust the integral panel lights from full bright to full dim. The master bright control card then sends the output to the respective dimmer control unit. The dimmer control unit then adjusts the light intensity of the related integral panel light.

Standby Power Mode

Critical dimmer control units get power from the 115v ac standby bus when power is not available from the left 115v ac transfer bus. 115v ac standby bus power then goes to the critical dimmer control units. The critical dimmer control units then supply power to the respective panel lights.

When standby power is the power source, you can not adjust the light intensity from the MBC. You can only adjust the light intensity from the related individual panel light control. These integral panel lights and instruments have power when the lights are in the standby mode:

- Standby attitude indicator
- Standby airspeed indicator
- Standby altimeter
- Standby compass
- Captains radio tuning frequency window
- TCAS/ATC control panel.



NOTE: CAPTAIN'S INTEGRAL PANEL LIGHTING CIRCUIT SHOWN, OTHER INTEGRAL PANEL LIGHT CIRCUITS ARE SIMILAR

33-13-00-006 Rev 3 01/06/1997

INTEGRAL PANEL LIGHTS - FUNCTIONAL DESCRIPTION - MANUAL ADJUSTMENTS

INTEGRAL PANEL LIGHTS - FUNCTIONAL DESCRIPTION - AUTOMATIC ADJUSTMENTS

THIS PAGE INTENTIONALLY LEFT BLANK

INTEGRAL PANEL LIGHTS - FUNCTIONAL DESCRIPTION - AUTOMATIC ADJUSTMENTS

General

The integral lights in some components have automatic brightness control and manual brightness control. These components have automatic brightness control:

- TCAS/ATC control integral panel
- Captain radio tuning frequency windows
- Center radio tuning frequency windows
- First officer tuning frequency windows
- Rudder trim indicator
- Left stab position indicator
- Right stab position indicator
- Standby instruments
- Primary display system.

See section 34-11 for more information on the automatic brightness control for the standby instruments.

See section 31-61 for more information on the automatic brightness control for the primary display system.

Functional Description

There are two sets of light sensors. Two remote light sensors (RLS) are on the glare shield and three bezel-light sensors (BLS) are on the aisle stand. There are bezel-light sensors in these components:

- Rudder trim indicator
- Right stab position indicator
- Left stab position indicator.

The bezel-light sensors send ambient light information to the MBC card. The MBC card uses the manually selected brightness level and adjusts the output signal based on inputs from the bezel-light sensors. The MBC card then uses the remote light sensor inputs and adjusts the output signal more. The MBC card then sends an output to the dimmer control units. The dimmer control units adjust the brightness for these components:

- TCAS/ATC control integral panel lights
- Captain radio tuning frequency windows
- Center radio tuning frequency windows
- First officer tuning frequency windows.

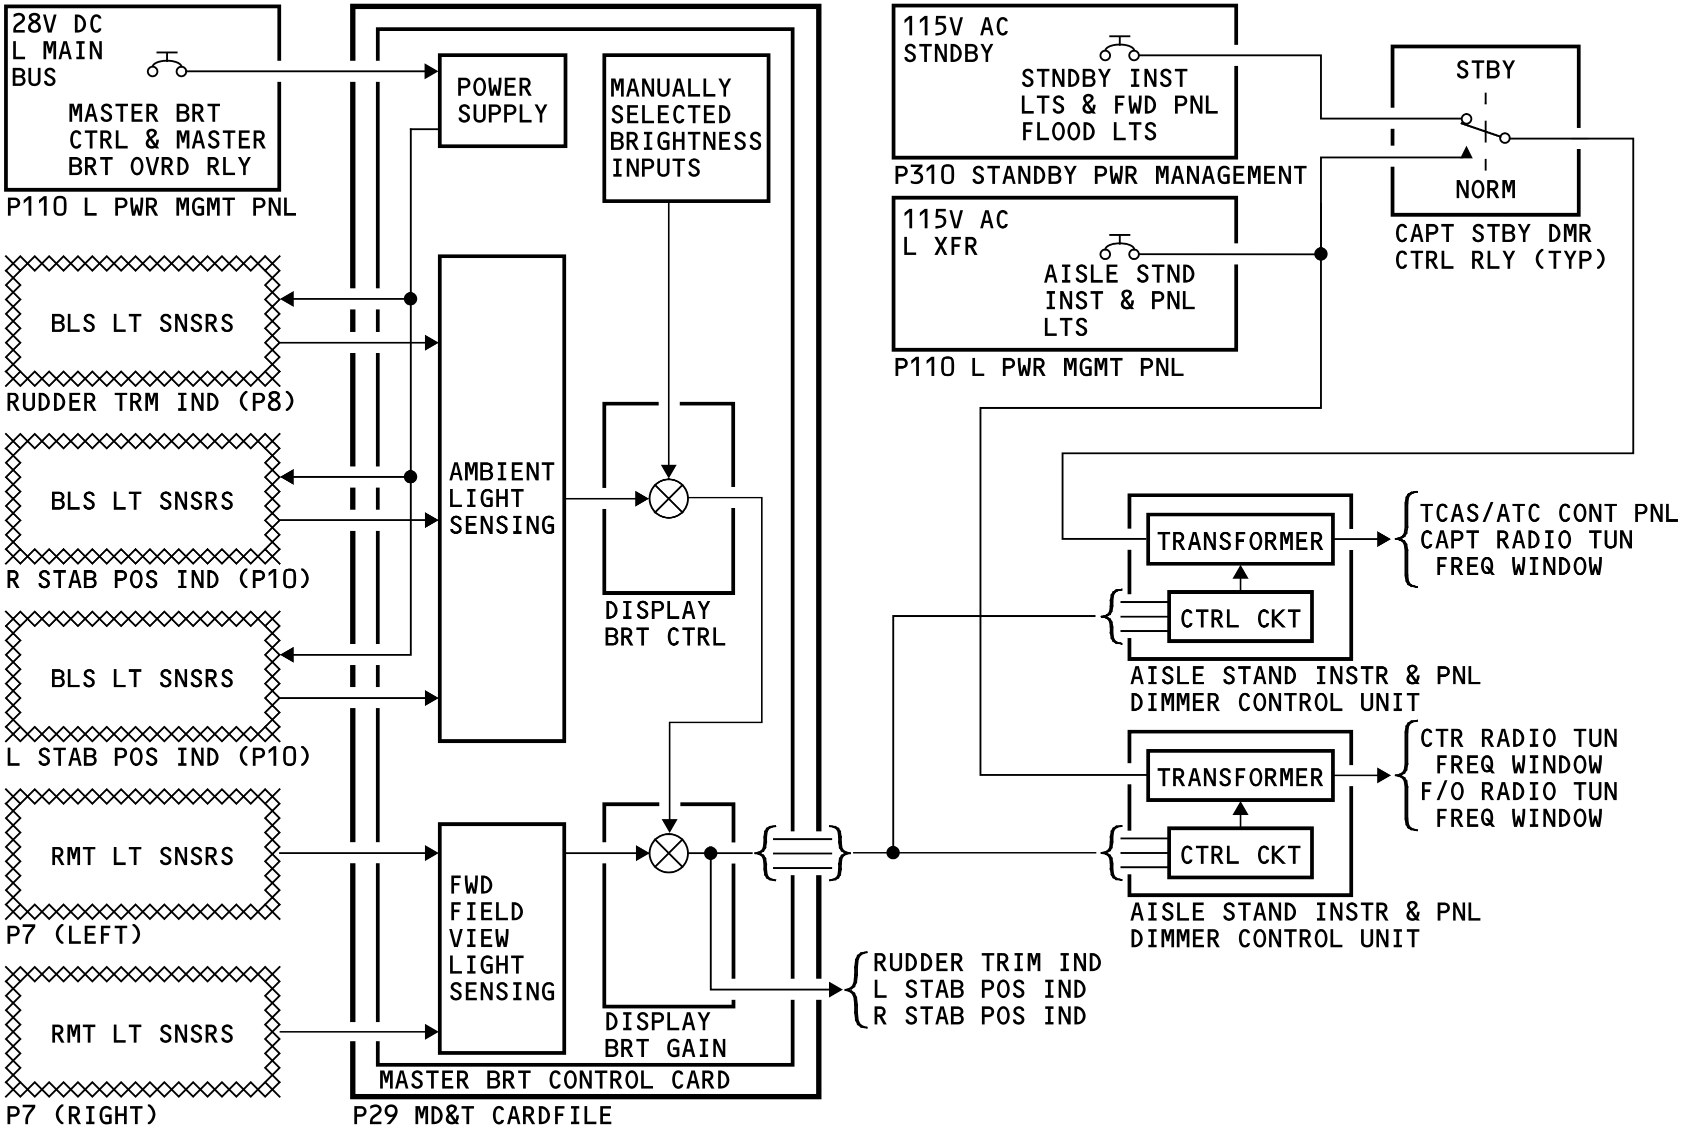
The MBC card also adjusts the brightness for these components without the use of a dimmer control unit:

- Rudder trim indicator
- Right stab position indicator
- Left stab position indicator.

Standby Mode

Critical dimmer control units get power from the 115v ac standby bus when power is not available from the left 115v ac transfer bus. The 115v ac standby bus energizes the standby dimmer control relay. 115v ac standby bus power then goes to the critical dimmer control units. The critical dimmer control units then supply power to the respective panel lights. You can not adjust the light intensity of these panel lights from the MBC. You can only adjust the light intensity from the related individual panel light control. These integral panel lights and instruments have power when the lights are in the standby mode:

- Captains radio tuning frequency window
- TCAS/ATC control panel.



33-13-00-007 Rev 0 09/03/1996

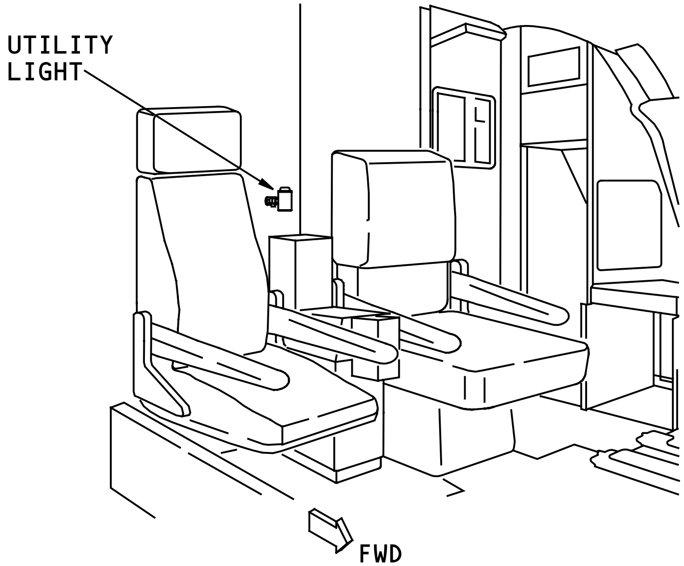
INTEGRAL PANEL LIGHTS - FUNCTIONAL DESCRIPTION - AUTOMATIC ADJUSTMENTS

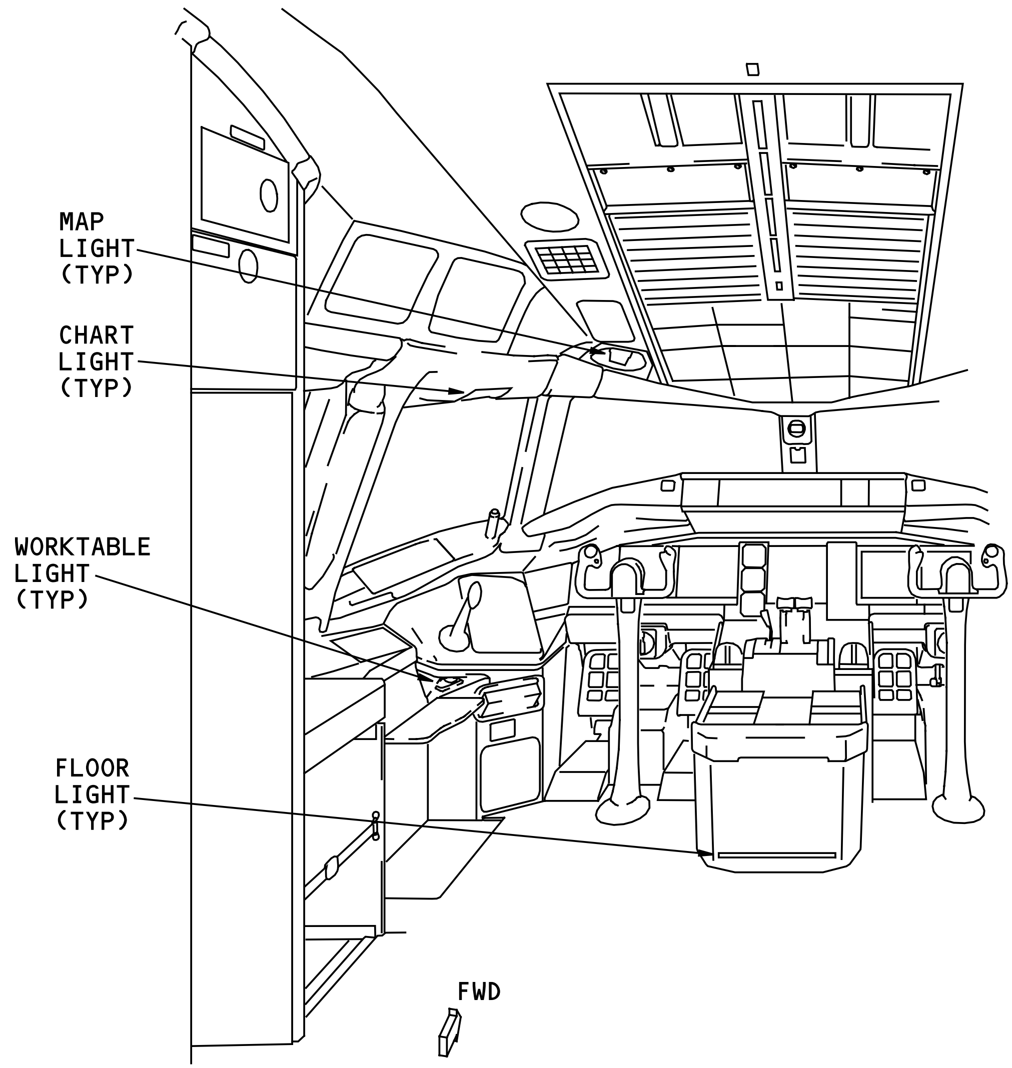
FLIGHT COMPARTMENT MISCELLANEOUS LIGHTS - INTRODUCTION

General

The flight compartment miscellaneous lights give light to specific areas in the flight compartment. These lights are the flight compartment miscellaneous lights:

- Utility light
- Map light (4)
- Chart light (2)
- Worktable light (2)
- Floor light (3).





33-14-00-001 Rev 0

FLIGHT COMPARTMENT MISCELLANEOUS LIGHTS - INTRODUCTION

FLIGHT COMPARTMENT MISCELLANEOUS LIGHTS - MAP LIGHTS

Purpose

The map lights give adjustable light for the captain, first officer, and observers.

Location

There are four map lights in the flight deck. There is one above each of the captain's and first officer's seats. They are forward of the flight deck handles. There are two on the ceiling above the first observers seat.

Physical Description

Each map light has these components:

- Lamp
- Bezel
- Lens.

Operation

There are rotary-type controls for the map lights on these panels:

- P7 glareshield panel
- P17 first observers panel
- P18 MAT/second observers panel.

The diameter and amount of light is adjustable. You can also point the light.

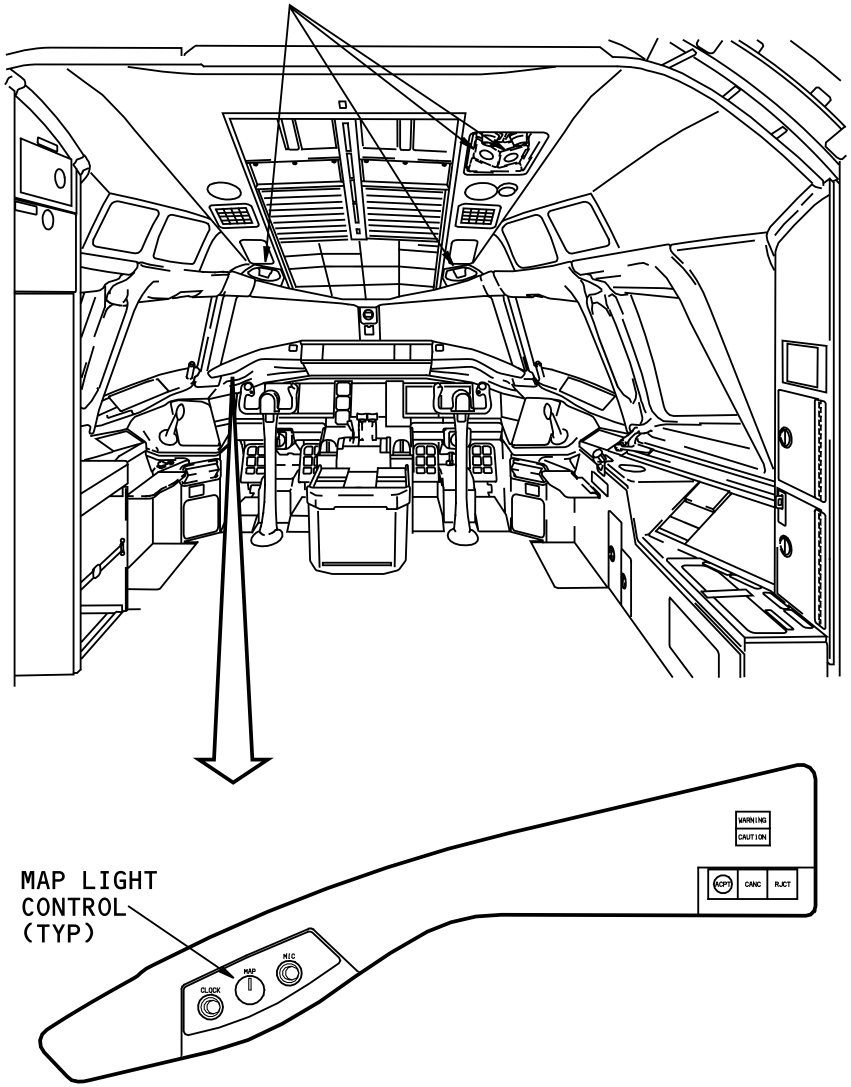
You pull the control to make the light come on. You turn the control to adjust the amount of light that comes from the map light. You turn the bezel to adjust the diameter of the light.

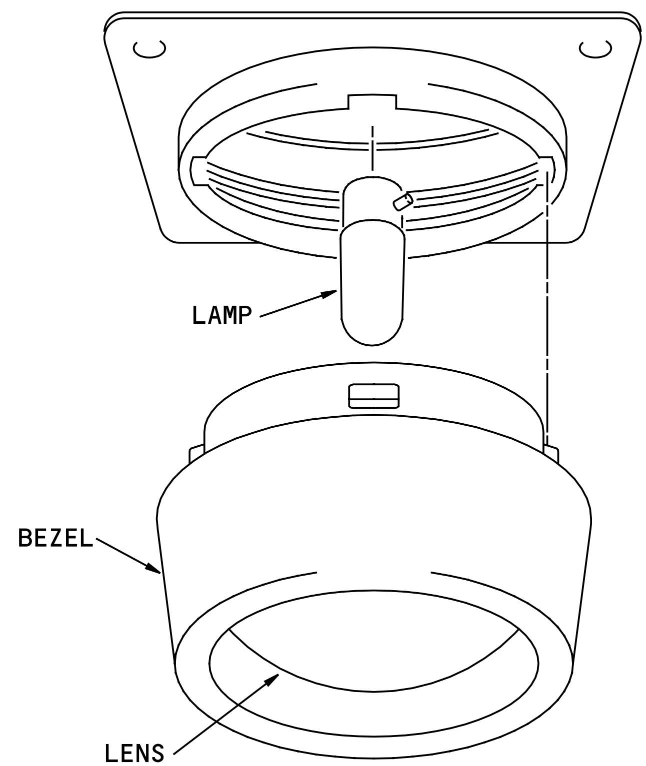
Training Information Point

To replace the map light you do these things:

- Compress the bezel/lens assembly
- Turn it counterclockwise to disconnect it
- Replace the lamp.

The lamp is a bayonet-type lamp.





MAP LIGHT

33-14-00-002 Rev 1 07/14/1997

FLIGHT COMPARTMENT MISCELLANEOUS LIGHTS - MAP LIGHTS

MASTER DIM AND TEST - INTRODUCTION

Purpose

The master dim and test (MD&T) system lets you do these tasks:

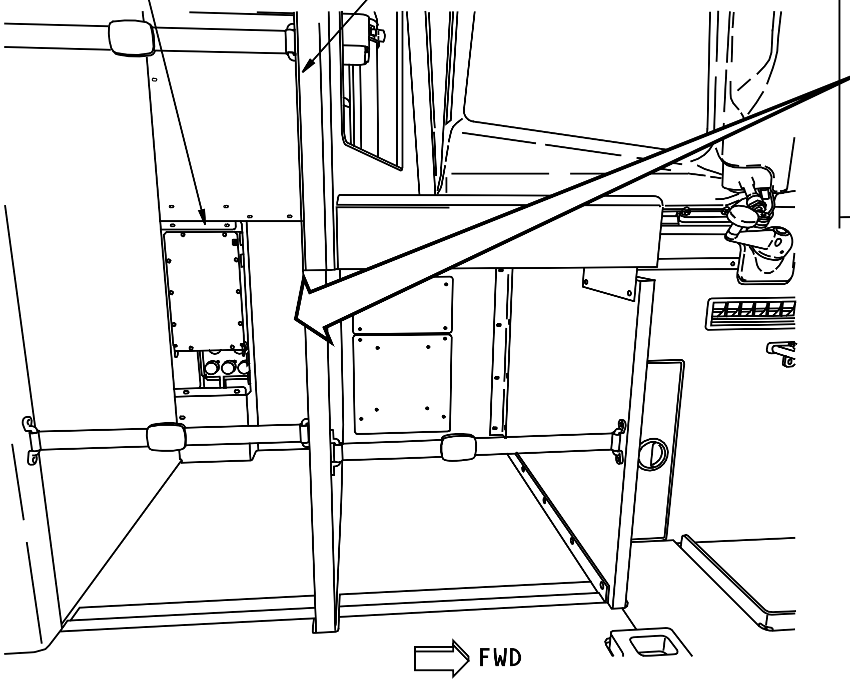
- Do a test of the flight deck annunciators and lighted push button switches
- Set annunciators and lighted push-button switches to the bright or dim mode.

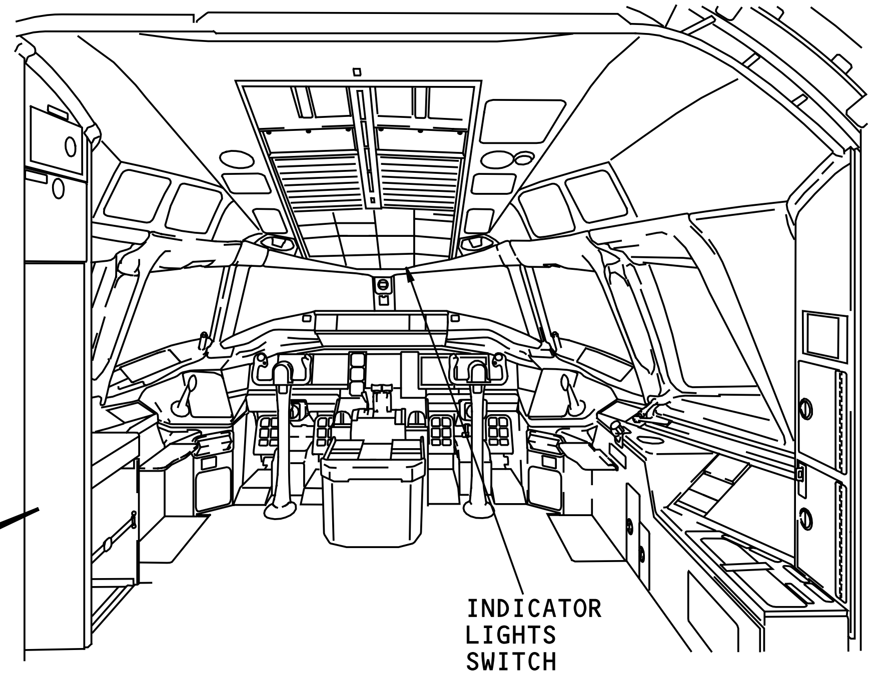
Location

The indicator lights switch is on the P5 overhead panel. The P29 MD&T card file is behind a panel in the coat storage closet in the flight deck.

Interface

The MD&T system has interfaces with the overhead panel ARINC 629 system (OPAS) and the AIMS.





33-16-00-001 Rev 1 07/14/1997

MASTER DIM AND TEST - INTRODUCTION

MASTER DIM AND TEST - MASTER DIM AND TEST CARD FILE

Purpose

The P29 master dim and test (MD&T) card file controls the amount of power that goes to the annunciator and lighted push-button switch lights.

Location

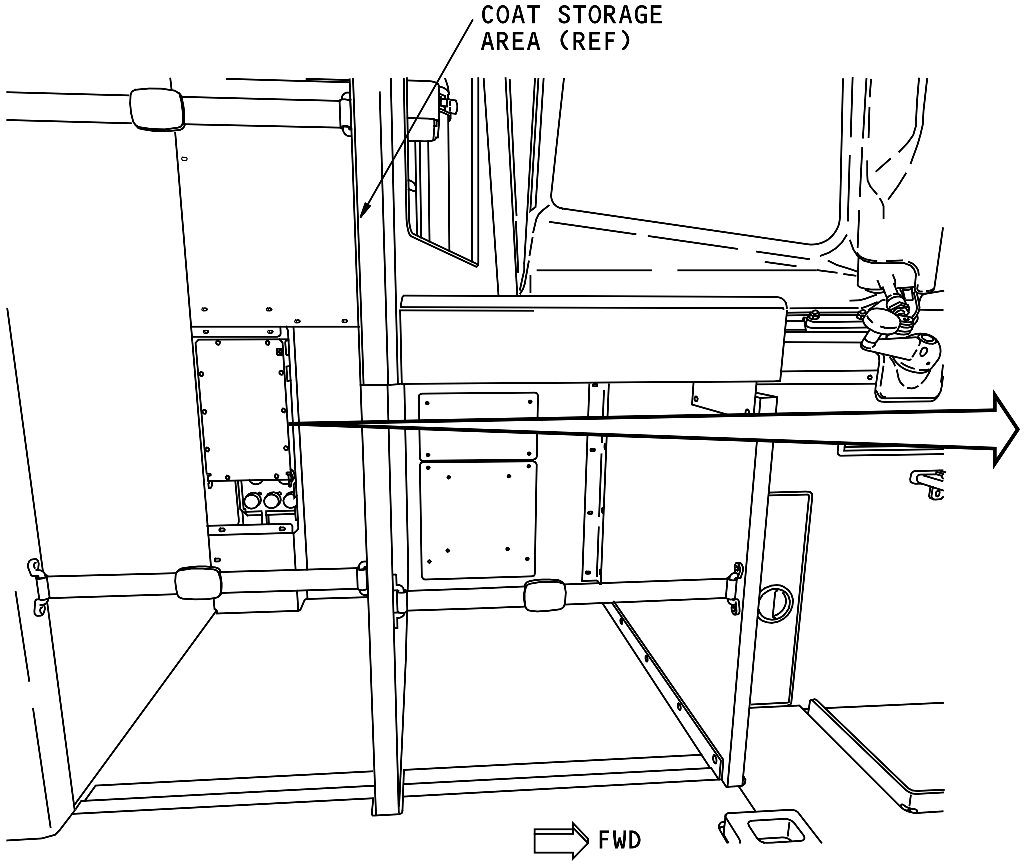
The card file is behind a panel in the coat storage area in the flight deck.

Physical Description

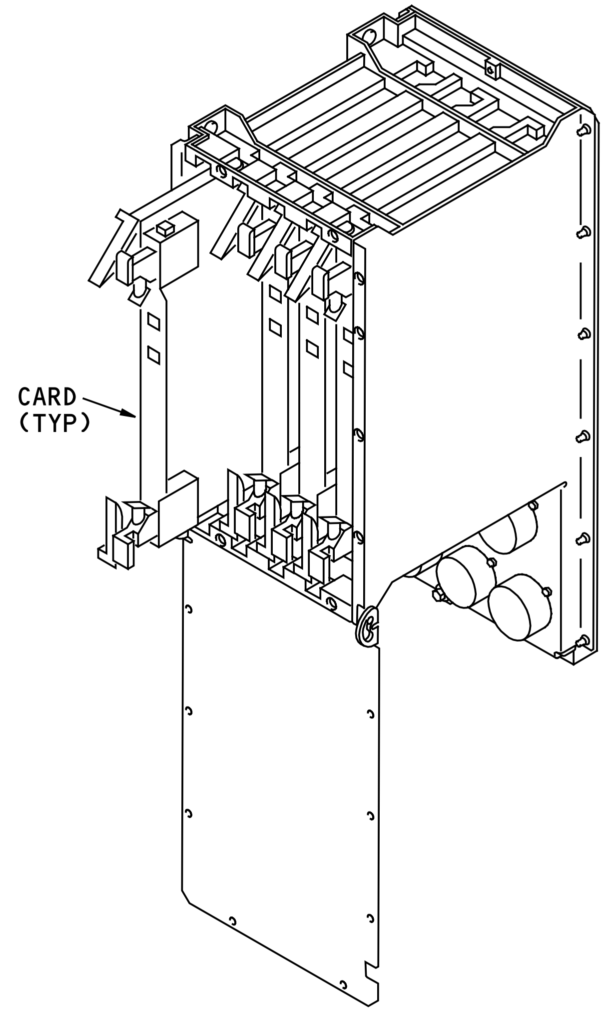
The card file contains three MD&T printed circuit (PC) dimmer cards and one master brightness control card.

Training Information Point

You release eight fasteners to open the MD&T card file.



FLIGHT DECK



P29 MASTER DIM AND TEST CARD FILE
(ACCESS DOOR OPEN)

33-16-00-002 Rev 0

MASTER DIM AND TEST - MASTER DIM AND TEST CARD FILE

MASTER DIM AND TEST - OPERATION

Operation

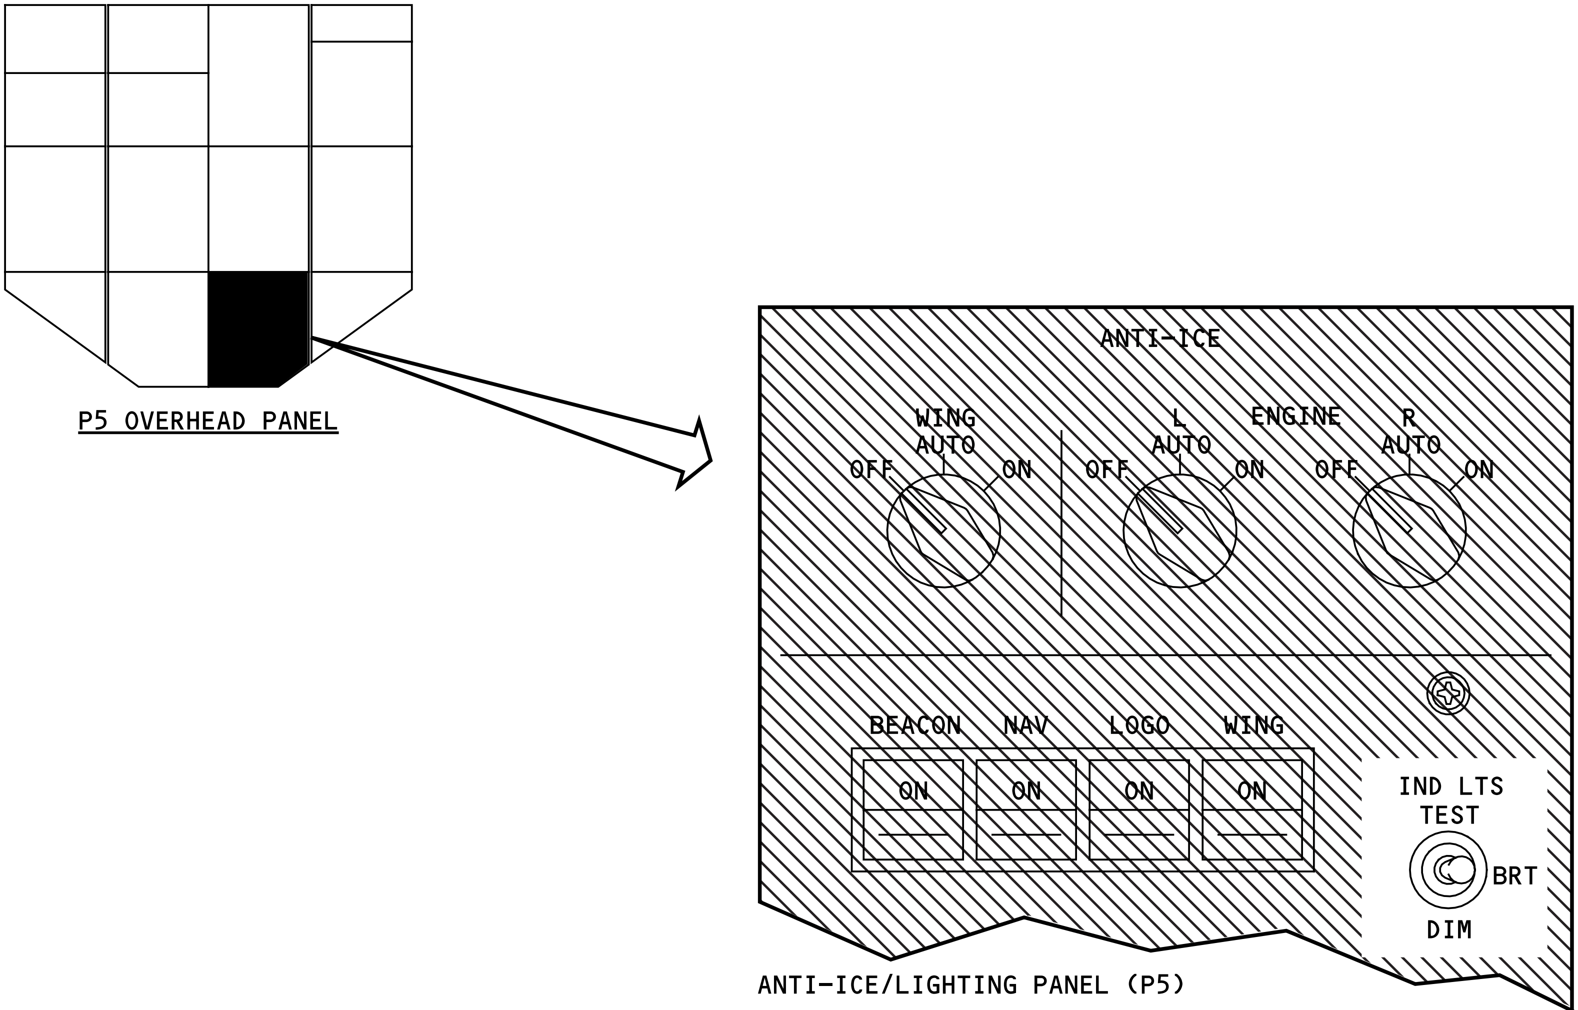
You use the indicator lights switch (IND LTS) to operate the master dim and test. When you hold the switch in the TEST position most of the flight deck annunciators and push-button switch indicator lights come on full bright. The lights stay full bright for 10 seconds and then come on in the dim mode. This permits the flight crew to see if the lights operate normally. When you release the switch it goes to the bright position. The fire warning lights will not come on during this test.

When you put the switch in the bright (BRT) position, if an annunciator or indicator light comes on, it will come on fully bright. When you put the switch in the dim (DIM) position, the lights are not as bright as in the bright mode. The fire warning lights will always come on in the bright mode.

Training Information Point

The storm light switch on the P5 passenger sign/ lighting panel makes the lights come on fully bright when it is on.

See the flight compartment illumination section for more information about the storm light switch (AMM PART I 33-11).



ANTI-ICE/LIGHTING PANEL (P5)

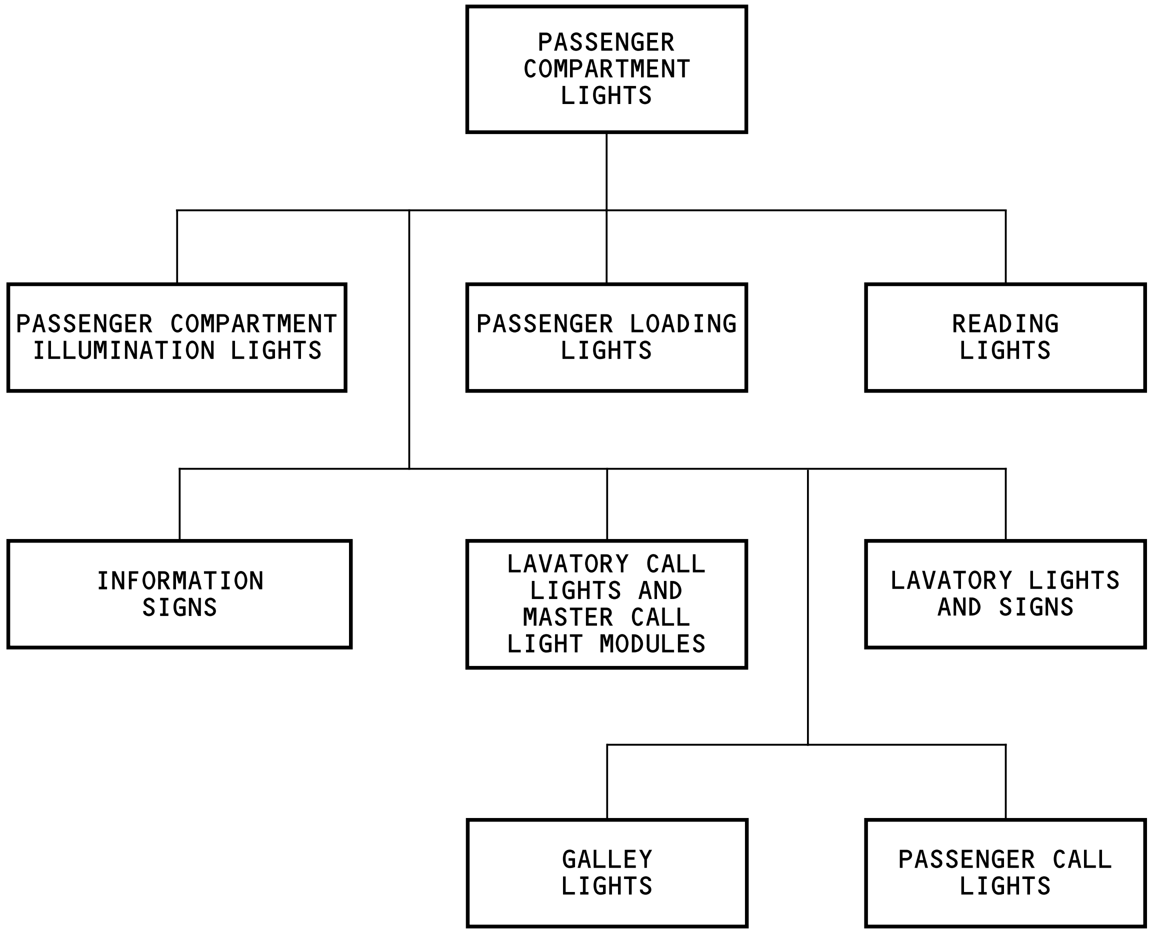
MASTER DIM AND TEST - OPERATION

PASSENGER COMPARTMENT LIGHTS - INTRODUCTION

General

The passenger compartment lights has these subsystems:

- Passenger compartment illumination lights
- Passenger loading lights
- Reading lights
- Information signs
- Lavatory call lights and master call light modules
- Lavatory lights and signs
- Galley lights
- Passenger call lights.



33-20-00-001 Rev 2 03/26/96

PASSENGER COMPARTMENT LIGHTS - INTRODUCTION

PASSENGER COMPARTMENT ILLUMINATION - INTRODUCTION

General

Passenger compartment illumination has these types of lights:

- Indirect ceiling lights
- Night lights
- Sidewall lights.

Location

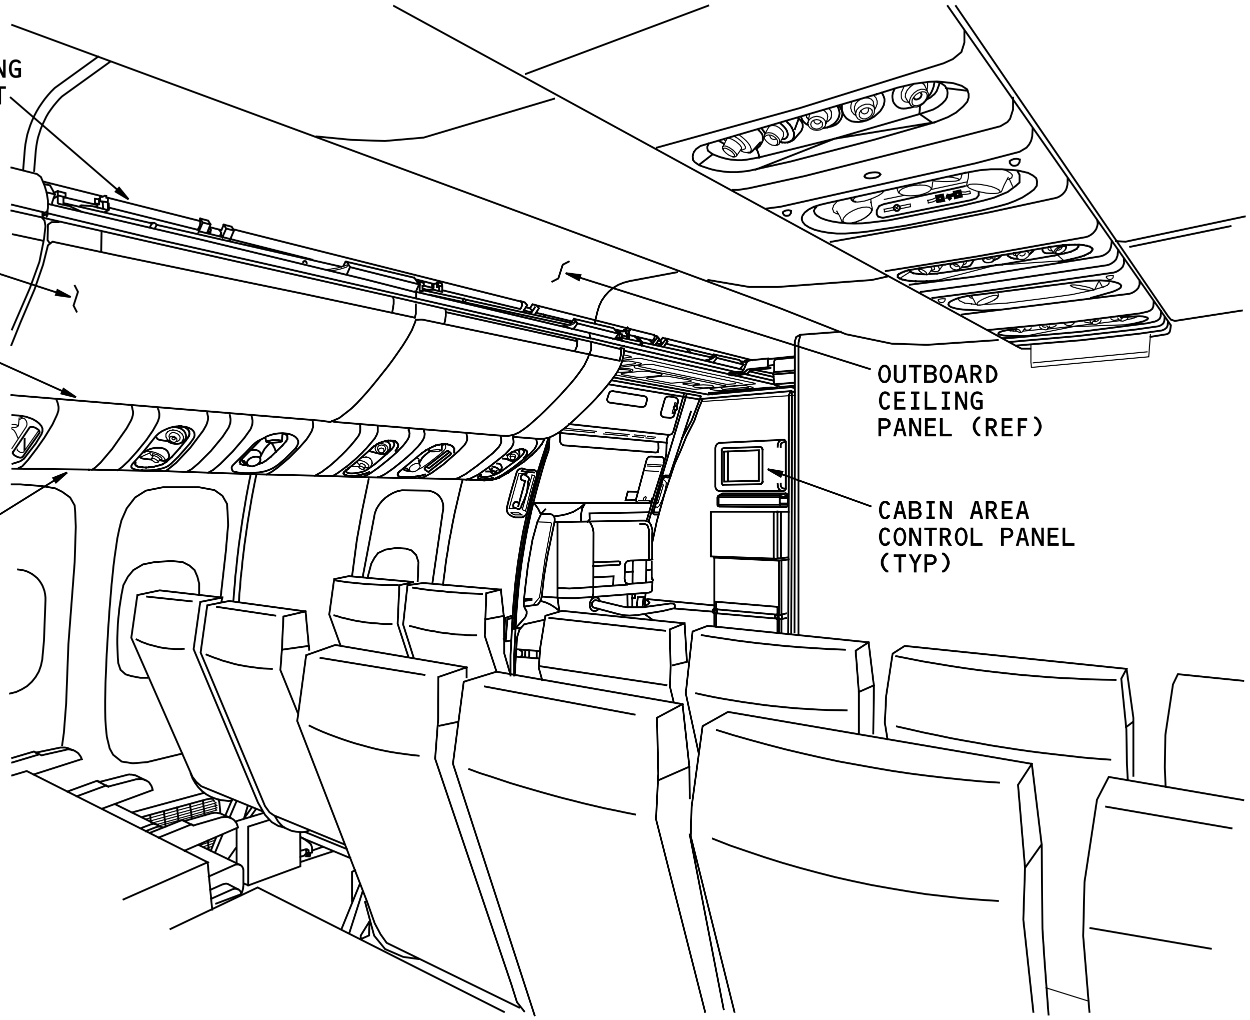
The indirect ceiling lights and night lights are above the outboard stowage bins.

The sidewall lights are between the outboard PSUs and the sidewall panels.

Controls for passenger compartment illumination are on the cabin lighting screen. This screen is on the cabin system control panel (CSCP) and the cabin area control panel (CACP).

You use the same screen for the passenger loading direct ceiling lights.

See the passenger loading lights section for more information (AMM PART I 33-22).



PASSENGER COMPARTMENT
(TYPICAL)

PASSENGER COMPARTMENT ILLUMINATION - INTRODUCTION

PASSENGER COMPARTMENT ILLUMINATION - INDIRECT CEILING AND NIGHT LIGHTS

Purpose

The indirect ceiling and night lights put light on the ceiling to illuminate the passenger compartment.

Physical Description

The indirect ceiling lights have a fluorescent lamp and a ballast. There are releases at both ends of the lamps. The length of the light is in proportion to the length of the stowage bin.

Night lights attach to some of the indirect ceiling lights. The lamp is an incandescent, bayonet-style lamp.

Location

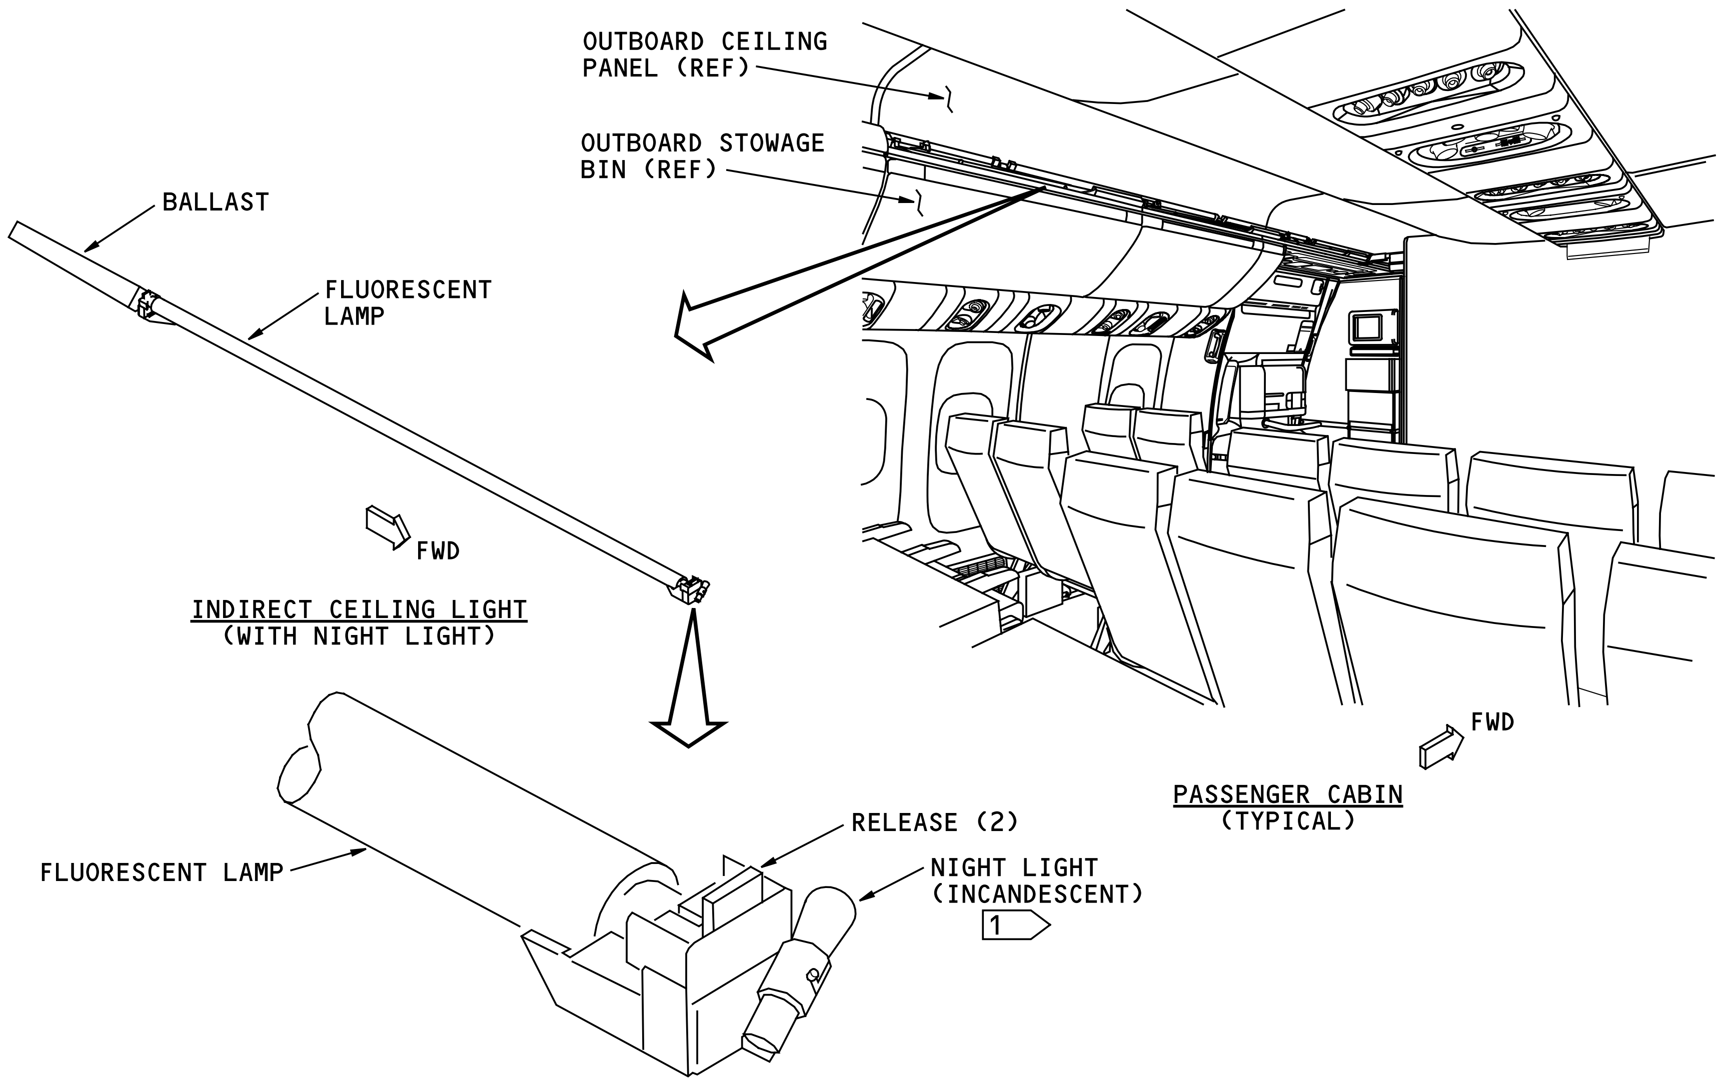
The indirect ceiling lights are on the inboard, top edge of the outboard stowage bins. The assemblies are set at an angle so they overlap each other. This prevents dark areas on the ceiling between light fixtures.

There are usually 14 night lights. The night lights are with the indirect ceiling lights near the passenger entry doors (PEDs) and between PEDs number two and three.

Training Information Point

You push the releases to remove the fluorescent light.

NOTE: The ballast for the indirect ceiling light or sidewall light is part of the light assembly. If the ballast does not operate, replace the light assembly. The light assembly can be repaired in a shop.



1 LOCATED NEAR THE PASSENGER ENTRY DOORS

PASSENGER COMPARTMENT ILLUMINATION - INDIRECT CEILING AND NIGHT LIGHTS

33-21-00-002 Rev 3 04/22/1997

PASSENGER COMPARTMENT ILLUMINATION - SIDEWALL LIGHTS

Purpose

The sidewall lights give fluorescent lighting below the stowage bins in the passenger compartment.

Location

The lights are under the outboard stowage bins, between the outboard PSUs and the sidewall panels.

Physical Description

Each sidewall light has these components:

- Ballast
- Fluorescent lamp
- Lens.

The length of the light is in proportion to the length of the stowage bin it is under.

Training Information Point

You squeeze the lens to remove it.

NOTE: The ballast for the indirect ceiling light or sidewall light is part of the light assembly. If the ballast does not operate, replace the light assembly. The light assembly can be repaired in a shop.

PASSENGER LOADING LIGHTS - INTRODUCTION

General

These are the passenger loading lights subsystems:

- Direct ceiling lights
- Standby lights
- Entry lights
- Attendant work lights
- Closet lights
- Attendant switch panel.

The passenger loading lights supply light in the:

- Passenger entry areas
- Attendant work areas
- Cross-aisles
- Closets.

There are two types of direct ceiling lights:

- Fluorescent
- Incandescent.

Location

The possible locations for fluorescent direct ceiling lights are in these lowered ceilings:

- Door 1 cross-aisles
- Door 4 cross-aisles
- Aisle to the flight deck.

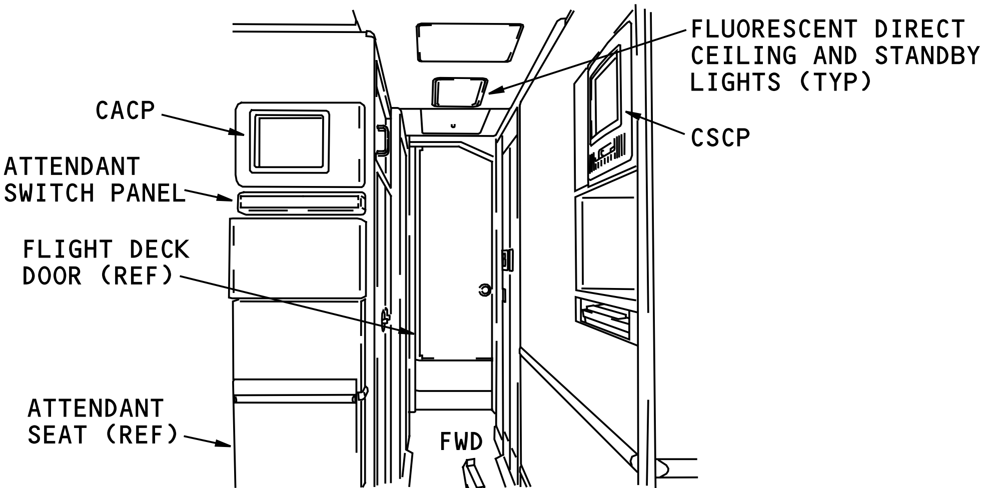
The possible locations for incandescent direct ceiling lights are in the door 2 and 3 cross-aisle lowered ceilings.

Controls for fluorescent and incandescent direct ceiling lights are on the cabin lighting screen. This screen is on the cabin system control panel (CSCP) and the cabin area control panel (CACP).

The entry lights are in the overdoor panels above the passenger entry doors. Controls for entry lights are on the entry way lighting screen. This screen is on the cabin system control panel (CSCP) and the cabin area control panels (CACPs).

The attendant work lights are in the overdoor panels and lowered ceilings in areas where there are attendant seats. Control is on the attendant switch panel. These panels are also in areas where there are attendant seats.

The closet lights are in the closets. A control switch is in the closet.



AISLE TO FLIGHT DECK

DOOR THREE CROSS AISLE
(TYPICAL)

PASSENGER LOADING LIGHTS - INTRODUCTION

PASSENGER LOADING LIGHTS - DIRECT CEILING LIGHTS - FLUORESCENT

Purpose

The fluorescent direct ceiling lights give light to aisles.

Location

These are the possible locations in lowered ceiling panels for fluorescent direct ceiling lights:

- Passenger entry door 1 cross-aisle
- Passenger entry door 4 cross-aisle
- Aisle to the flight deck.

Controls for fluorescent direct ceiling lights are on the cabin lighting screen. This screen is on the cabin system control panel (CSCP) and the cabin area control panel (CACP).

You use the same screen for the incandescent direct ceiling lights, and the passenger compartment illumination indirect ceiling, sidewall, and night lights.

See the passenger compartment illumination section for more information (AMM PART I 33-21).

See the cabin services system section for more information about the CSCP/CACP (AMM PART I 23-39).

Physical Description

Each light assembly has two fluorescent lamps, a ballast, and a lens in a bezel.

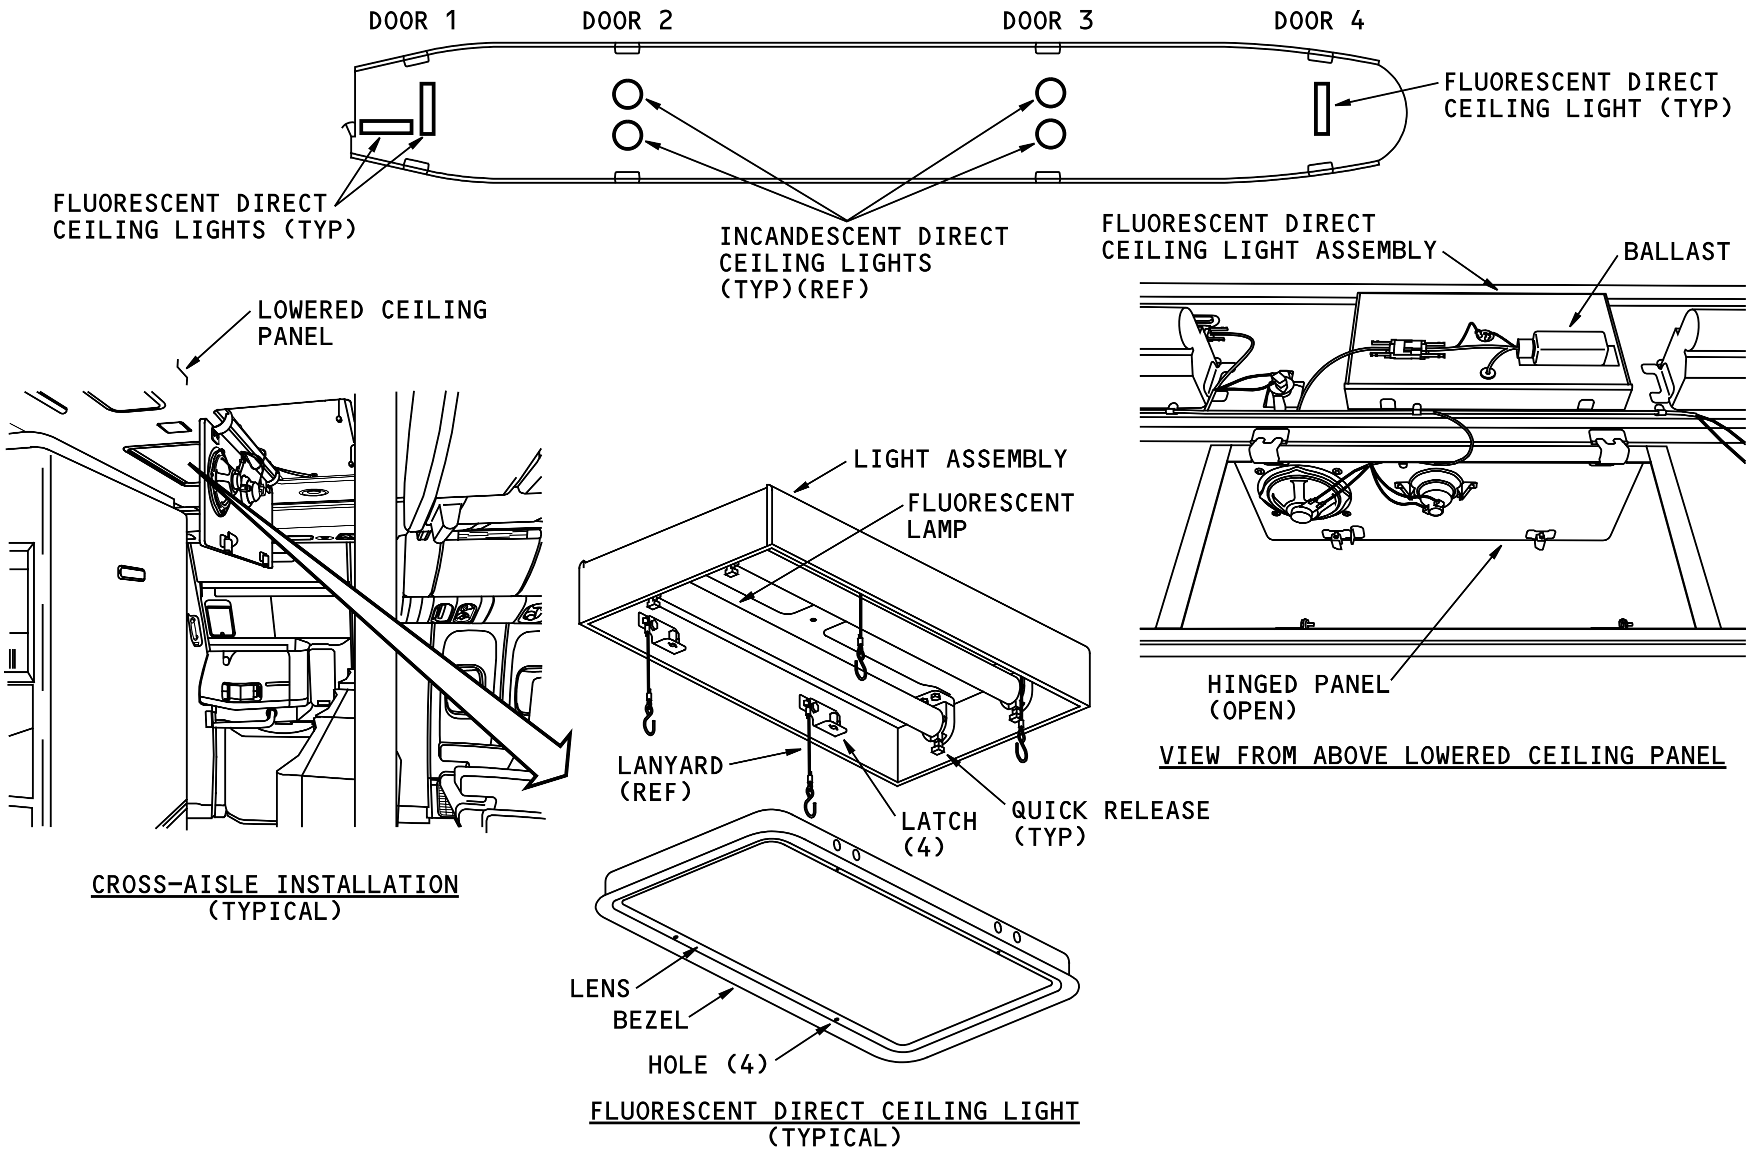
Training Information Point

Four holes in the bezel let you use a pin type tool to release the bezel. Four lanyards hold the bezel when it releases from the assembly.

Each light assembly has quick release fasteners for the lamps.

The ballast is an LRU.

A hinged panel in the lowered ceiling panel gives you access to the ballast.



PASSENGER LOADING LIGHTS - DIRECT CEILING LIGHTS - FLUORESCENT

PASSENGER LOADING LIGHTS - FLIGHT DECK DOOR SWITCH

Purpose

The flight deck door switch controls the direct ceiling light immediately aft of the flight deck door.

General

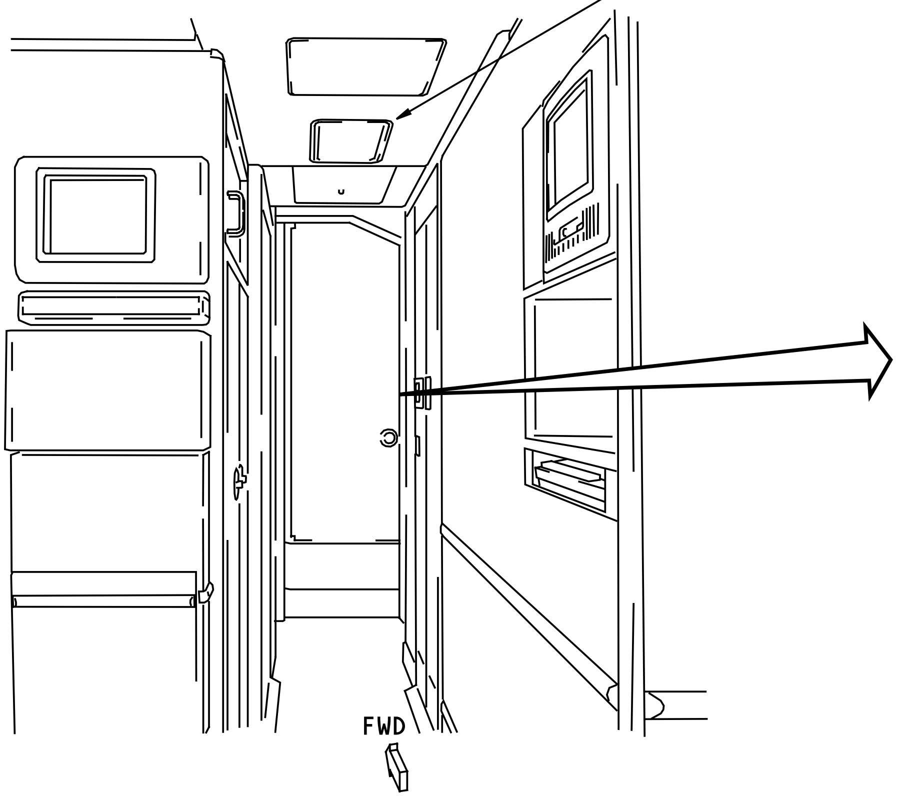
If you open the flight deck door when the engines are running, the direct ceiling light immediately aft of the flight deck door goes off. The reflection on the flight displays would make them difficult to see.

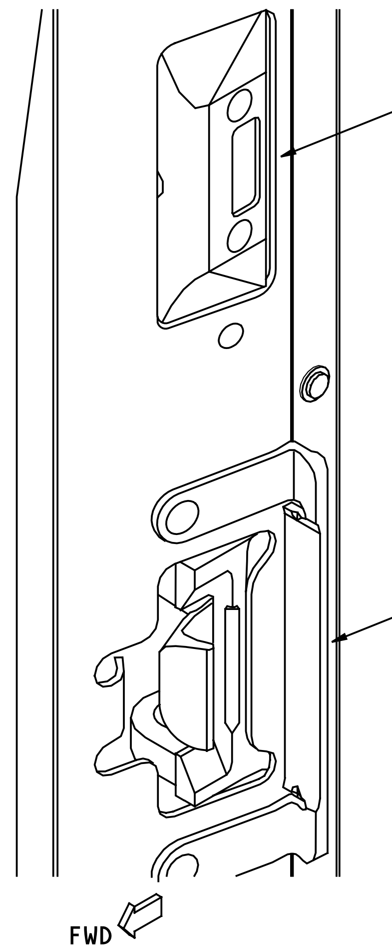
Location

The switch is on the door post, above the door stop.

Physical Description

The switch is a magnetic-reed type switch.





33-22-00-005 Rev 3 03/27/96

PASSENGER LOADING LIGHTS - FLIGHT DECK DOOR SWITCH

PASSENGER LOADING LIGHTS - ATTENDANT SWITCH PANELS - PASSENGER COMPARTMENT

Purpose

The attendant switch panels (ASPs) in the passenger compartment give control and indications for:

- Attendant work lights
- Passenger address system
- Cabin interphone system
- Emergency lights.

Panel Locations

Passenger compartment ASPs are in areas where there are attendant seats.

Lights

The lights in the switches and indicators are LEDs.

Switches and Indicators

Work light switches are on all ASPs in the passenger compartment. The number of work light switches on a panel depends on the panel location.

These switches are on the panel at passenger entry door (PED) number two left:

- PA NORM/ALT
- CI NORM/ALT.

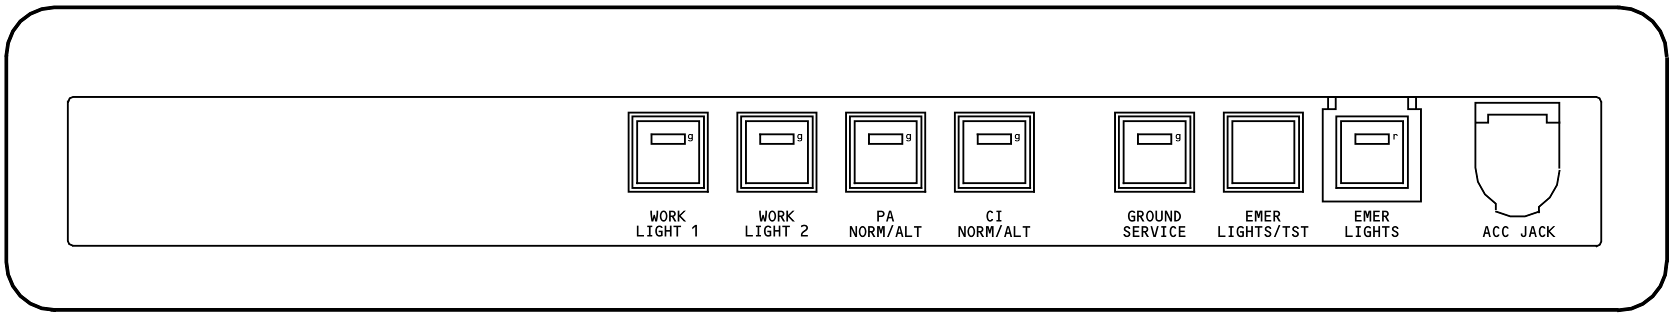
These switches are on the ASP at PED number two left:

- GROUND SERVICE
- EMER LIGHTS
- EMER LIGHTS/TEST.

See the passenger address system section for more information about the passenger address system (AMM PART I 23-31).

See the cabin interphone system section for more information about the cabin interphone system (AMM PART I 23-42).

See the emergency lighting section for more information about the emergency lights (AMM PART I 33-50).



ATTENDANT SWITCH PANEL (TYPICAL)

PASSENGER LOADING LIGHTS - ATTENDANT SWITCH PANELS - PASSENGER COMPARTMENT

READING LIGHTS - INTRODUCTION

Purpose

The reading lights supply light from above the passenger seats.

Location

The reading lights are in the passenger service units (PSU).

Physical Description

A reading light has these parts:

- Slot (4)
- Bezel/lens retainer
- Lens
- Tab (4)
- Lamp
- Lever.

You use the lever to lock the light in position.

Operation

You operate the reading lights with the switch on the passenger control unit or through the reading light control (not shown) on the CSCP/CACP.

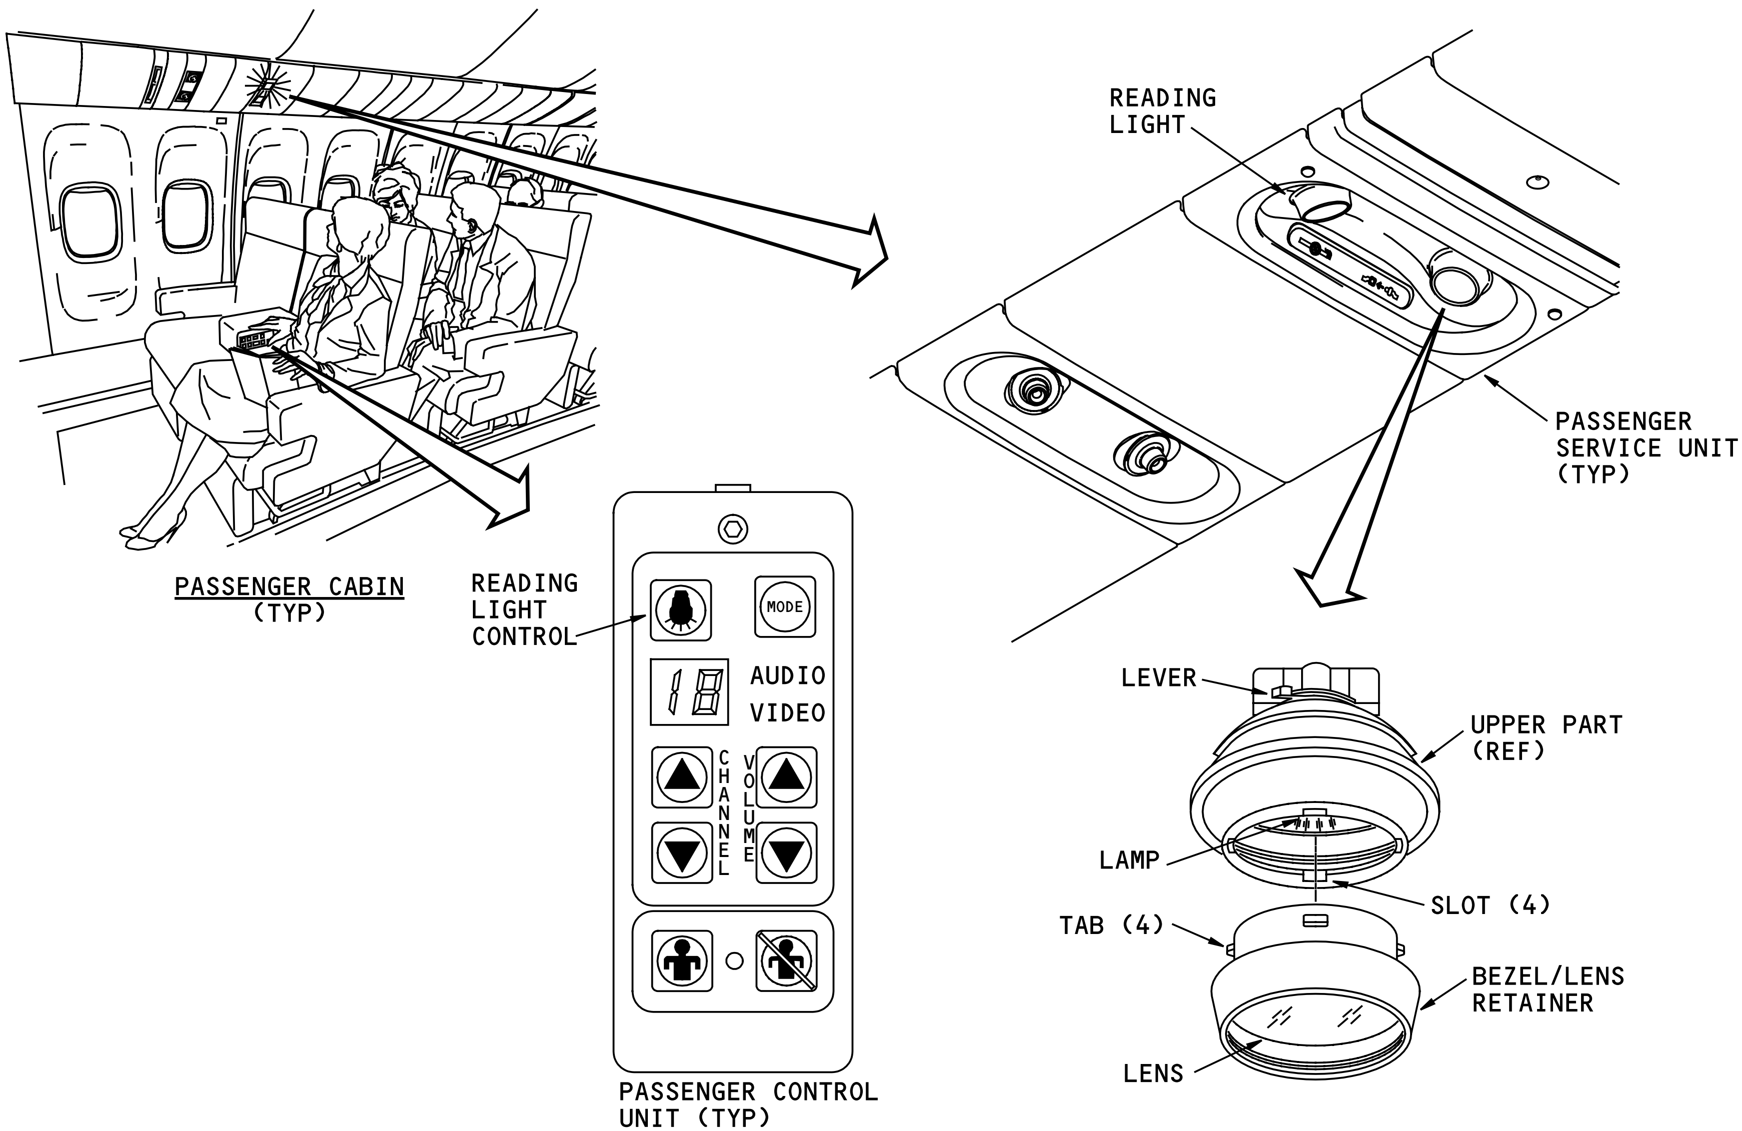
Training Information Point

You can replace the lamps from the front of the PSU. You do not have to lower the PSU to replace the lamps.

To replace a lamp:

- Compress the bezel/lens retainer
- Turn it counterclockwise to disconnect it from the slots on the upper part
- Replace the lamp.

You do the opposite procedure to install the bezel/lens retainer.



READING LIGHTS - INTRODUCTION

INFORMATION SIGNS - INTRODUCTION

Purpose

These information signs give information to the passengers and attendants:

- No smoking sign
- Fasten seat belt sign
- Return to seat sign.

Location

There are information signs in these locations:

- Passenger service units (PSUs)
- Overdoor panels
- Purser station (not shown)
- Lavatories.

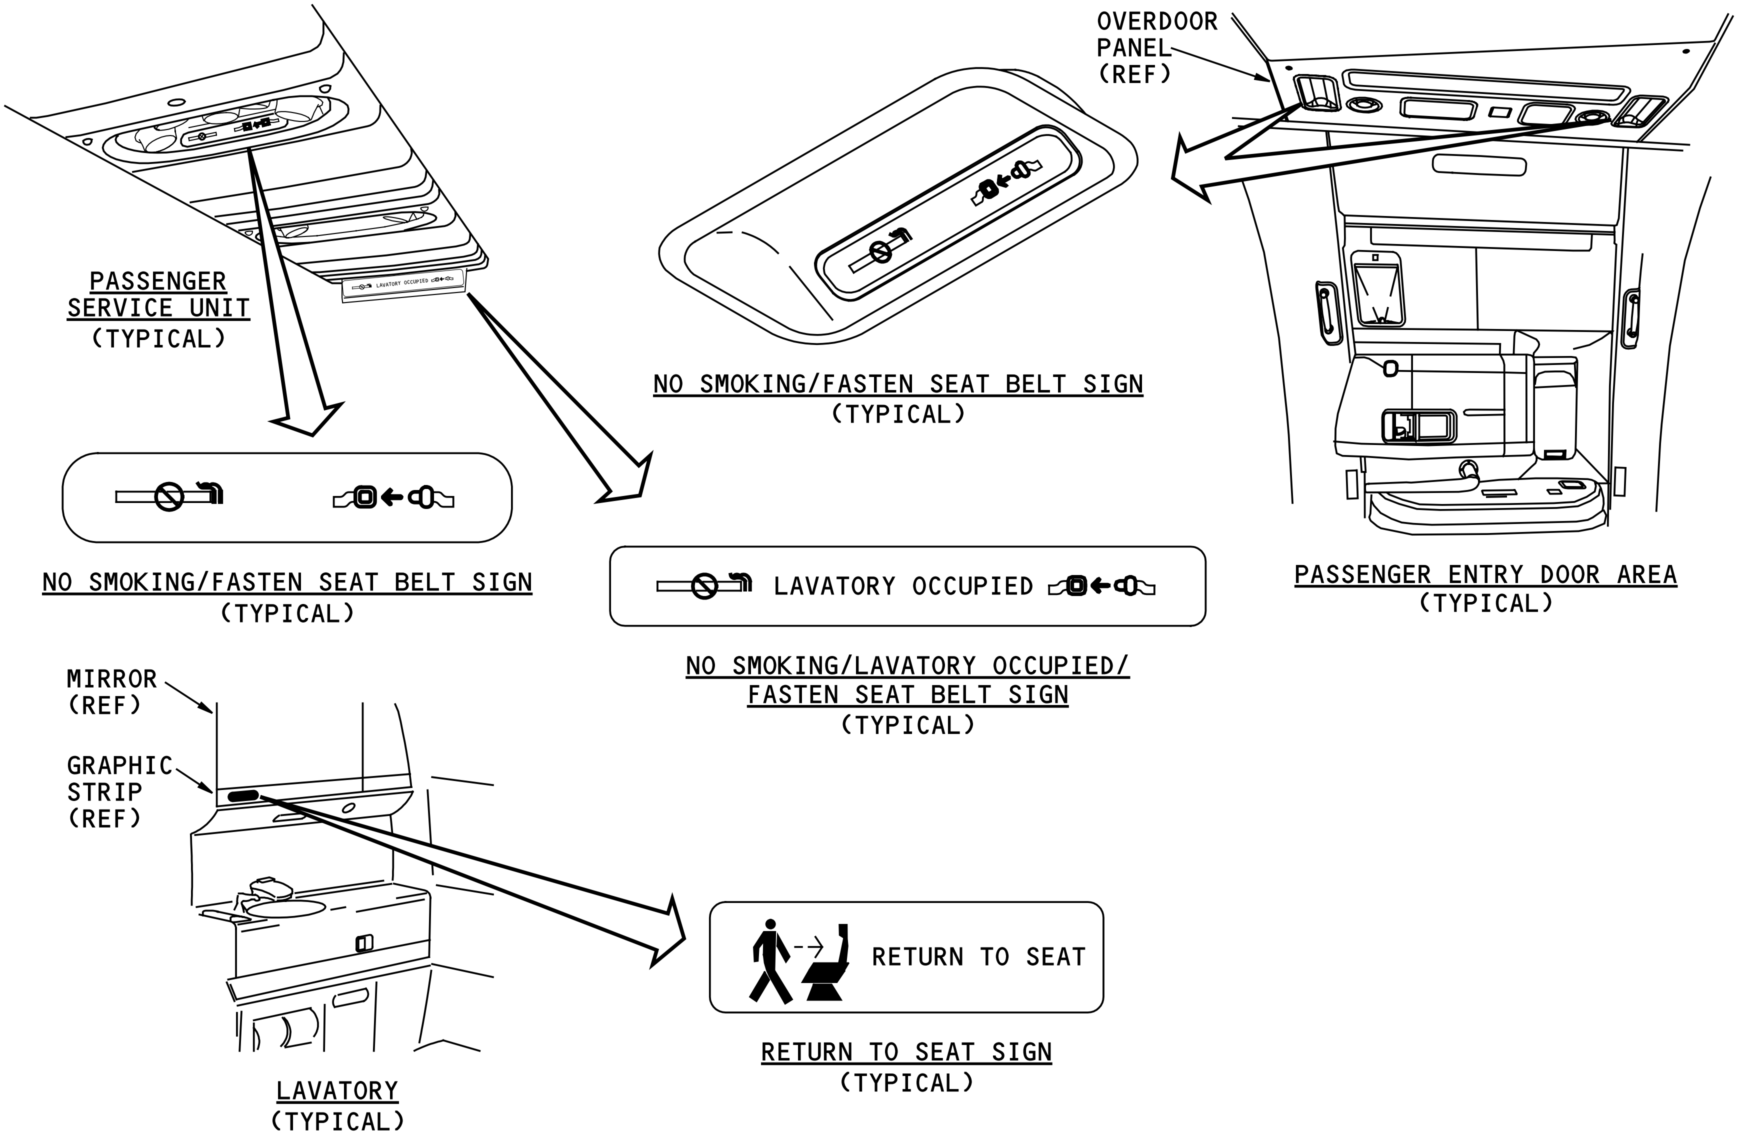
There are no smoking and fasten seat belts signs on the passenger service units (PSUs) and in the overdoor panels near the attendant seats.

There are return to seat signs in the lavatories.

Training Information Point

The no smoking and fasten seat belt signs have lamps that you can replace. You remove the lens to get access to the lamps.

The return to seat signs use LEDs. You replace the sign if the LEDs fail.



33-24-00-001 Rev 3 03/19/1997

INFORMATION SIGNS - INTRODUCTION

INFORMATION SIGNS - GENERAL DESCRIPTION

General

The passenger service system (PSS) supplies control signals for the information signs. The PSS gets inputs from the left and right systems ARINC 629 buses, the flight attendants, and the cabin services system configuration database.

Components

These are the main components of the information signs system:

- No smoking selector
- Seat belt selector
- No smoking sign
- Fasten seat belt sign
- Return to seat sign.

The PSS also supplies control for the lavatory-occupied signs and the lavatory door-lock signs (not shown). These signs are not part of the information signs system.

See the lavatory lights and signs section for more information about lavatory lights (AMM PART I 33-26).

These other systems and components have an interface with the information signs system:

- Overhead panel ARINC 629 system (OPAS)
- Airplane information management system (AIMS)
- Electrical load management system (ELMS)
- Flap/slat electronics unit (FSEU)
- Proximity sensor electronics unit (PSEU)
- Cabin services system (CSS)
- Passenger service system (PSS).

PSS Control

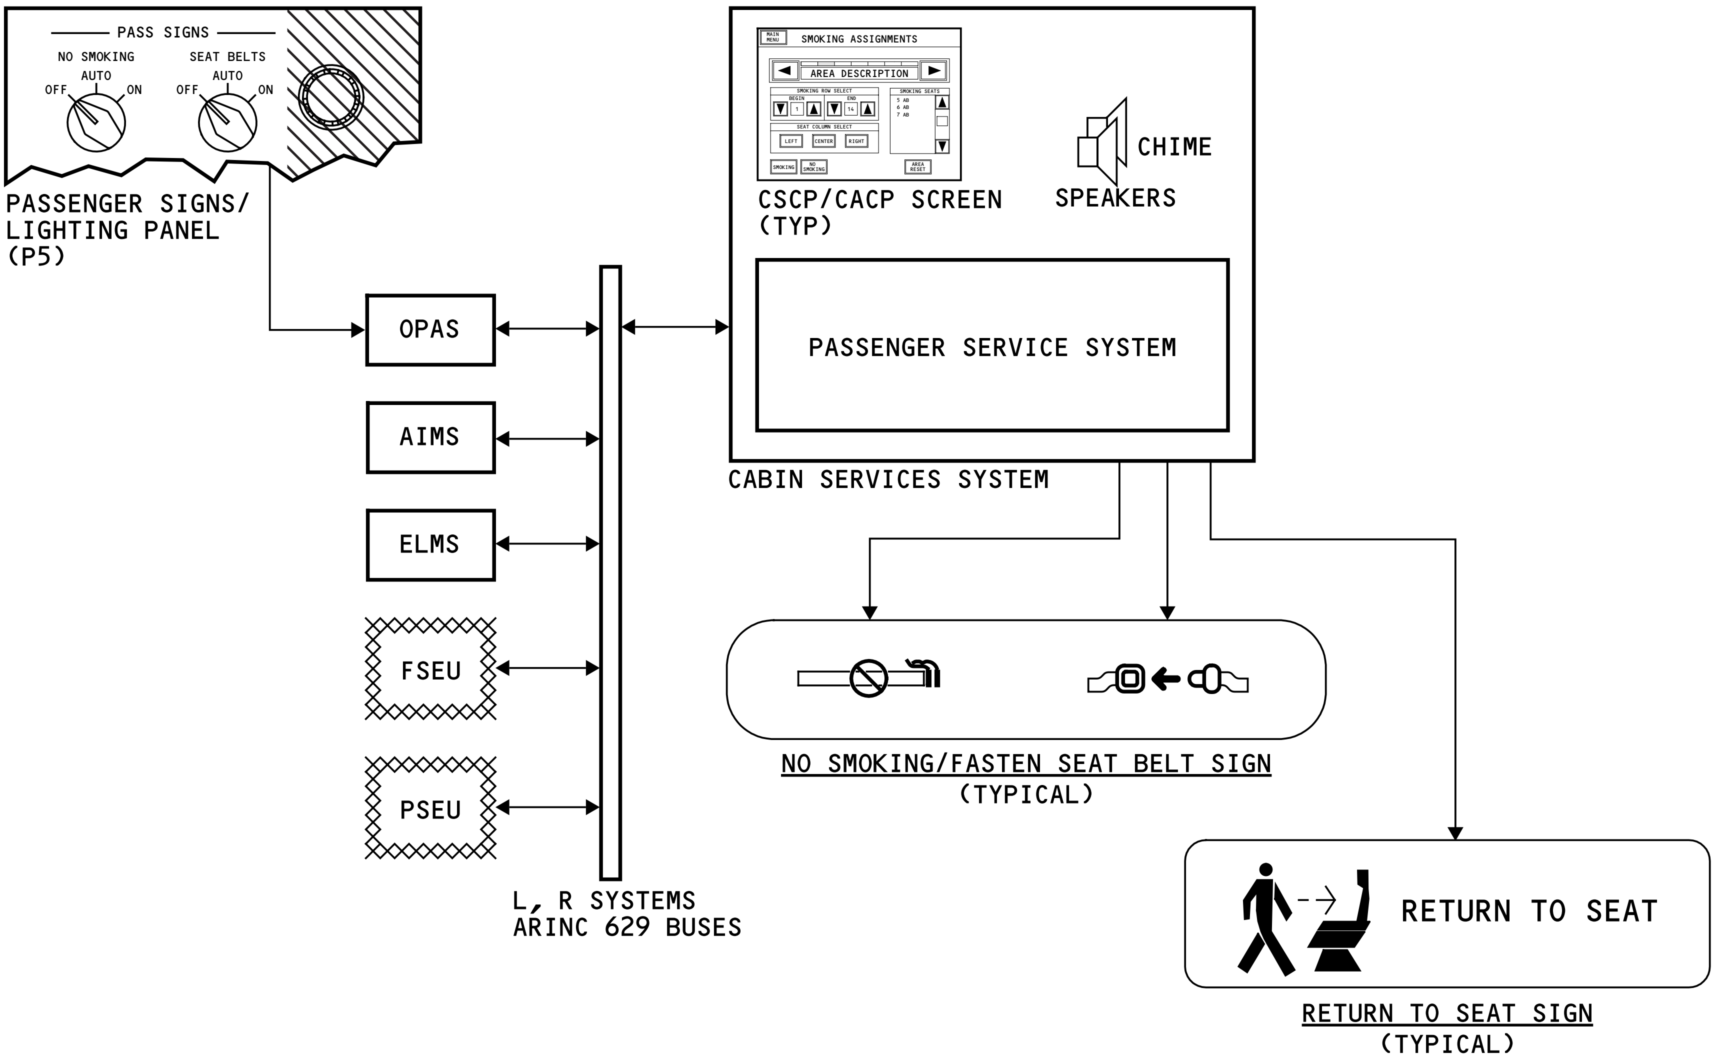
The PSS controls these information signs:

- No smoking sign
- Fasten seat belts sign
- Return to seat sign.

The PSS makes the signs come on or go off and sounds a chime based on selector position and airplane conditions.

The PSS causes an all airplane chime when the signs come on or go off. The configuration data base specifies the chime type (HI, LO, HI/LO, LO/HI).

For more information about the conditions that cause the signs to turn on or go off, see the information about information sign control logic in this section.



33-24-00-004 Rev 2 02/27/1997

INFORMATION SIGNS - GENERAL DESCRIPTION

LAVATORY CALL LIGHTS AND MASTER CALL LIGHT MODULES - INTRODUCTION

Purpose

The light in the lavatory call switch tell the flight attendants when a person in the lavatory needs aid.

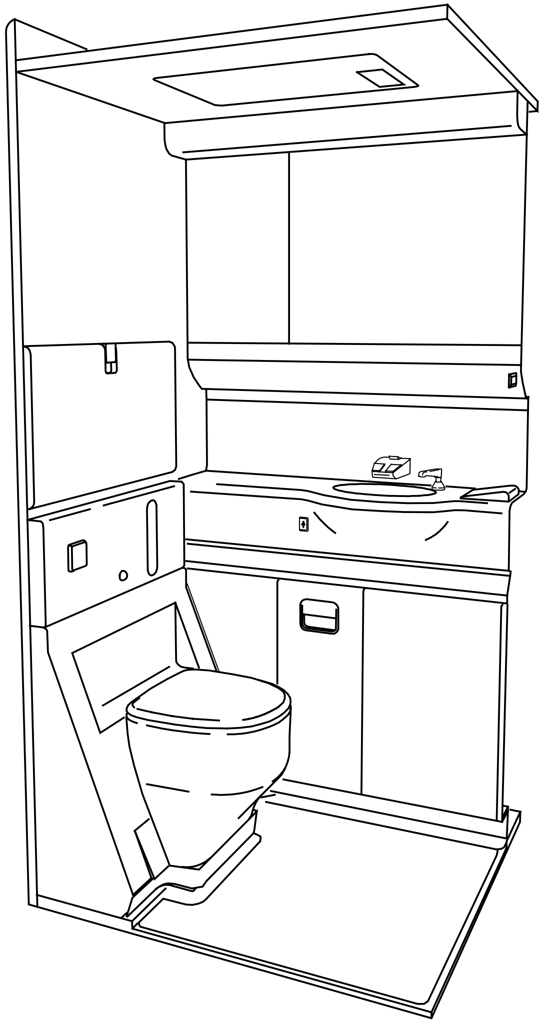
The master call light module tells the flight attendants when someone:

- Pushes a lavatory call switch
- Pushes an attendant call switch (not shown)
- Calls an attendant station (not shown).

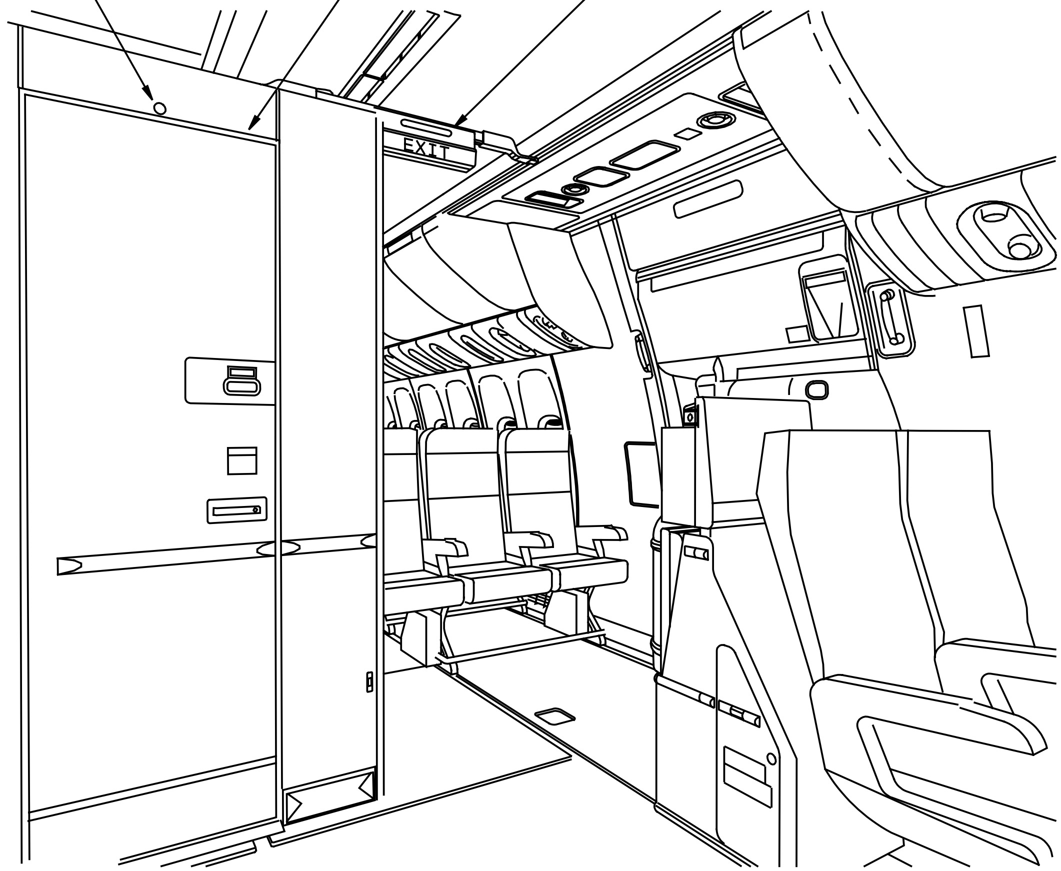
Location

There is a lavatory call switch in each lavatory and a lavatory call reset switch above the door on the external wall of the lavatory.

The master call light modules are on some exit signs.



LAVATORY (TYP)



PASSENGER COMPARTMENT (TYP)

33-25-00-001 Rev 0

LAVATORY CALL LIGHTS AND MASTER CALL LIGHT MODULES - INTRODUCTION

LAVATORY LIGHTS AND SIGNS - LIGHTS - INTRODUCTION

Purpose

The lavatory lights supply light in the lavatories.

Location

The lavatory lights are in the ceiling and on the sidewall of the lavatories.

The mirror light is above the mirror.

The dome light is in the passenger service unit (PSU).

Physical Description

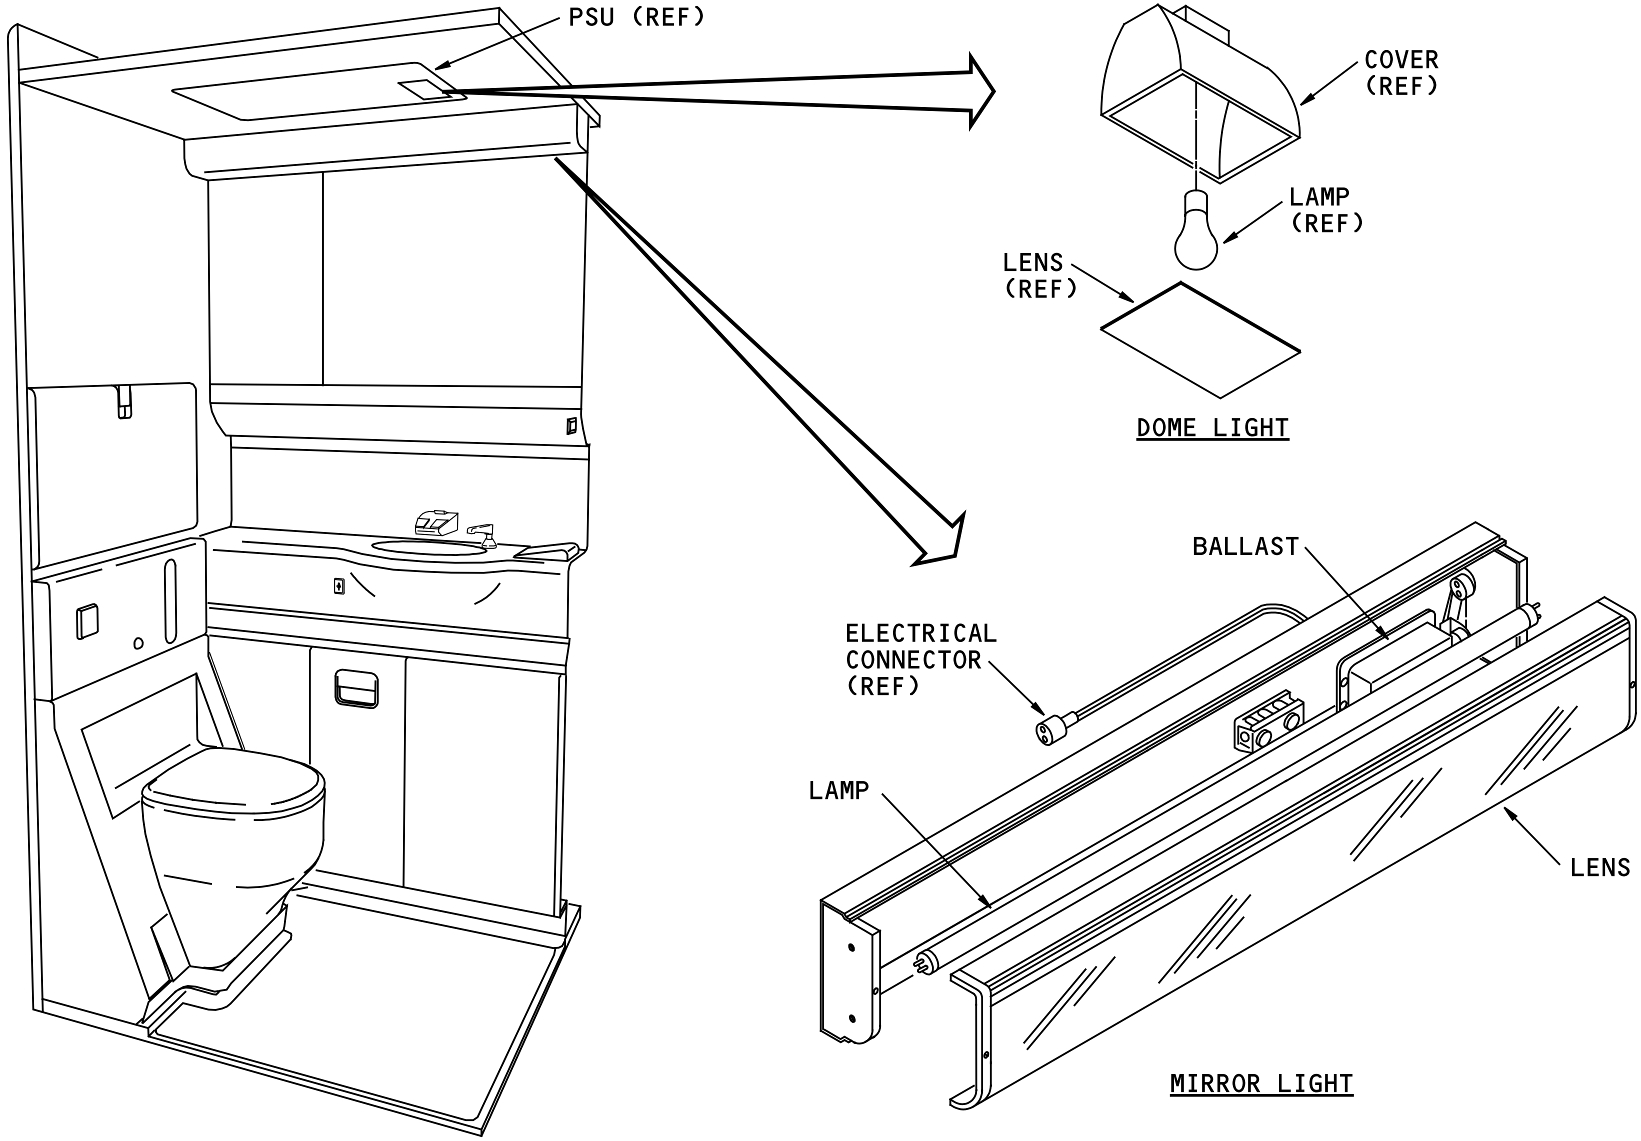
The light above the mirror is fluorescent. It has a ballast and an electrical connector.

The light in the lavatory PSU is incandescent.

Training Information Point

You compress the mirror light lens to remove it. You can get access to the lamp and the ballast when you remove the lens.

You lower the PSU and lift up on the cover to get access to the lamp.



33-26-00-001 Rev 0

LAVATORY LIGHTS AND SIGNS - LIGHTS - INTRODUCTION

LAVATORY LIGHTS AND SIGNS - SIGNS - INTRODUCTION

Purpose

Signs tell when all the lavatories in an area are in use and when to lock the lavatory door.

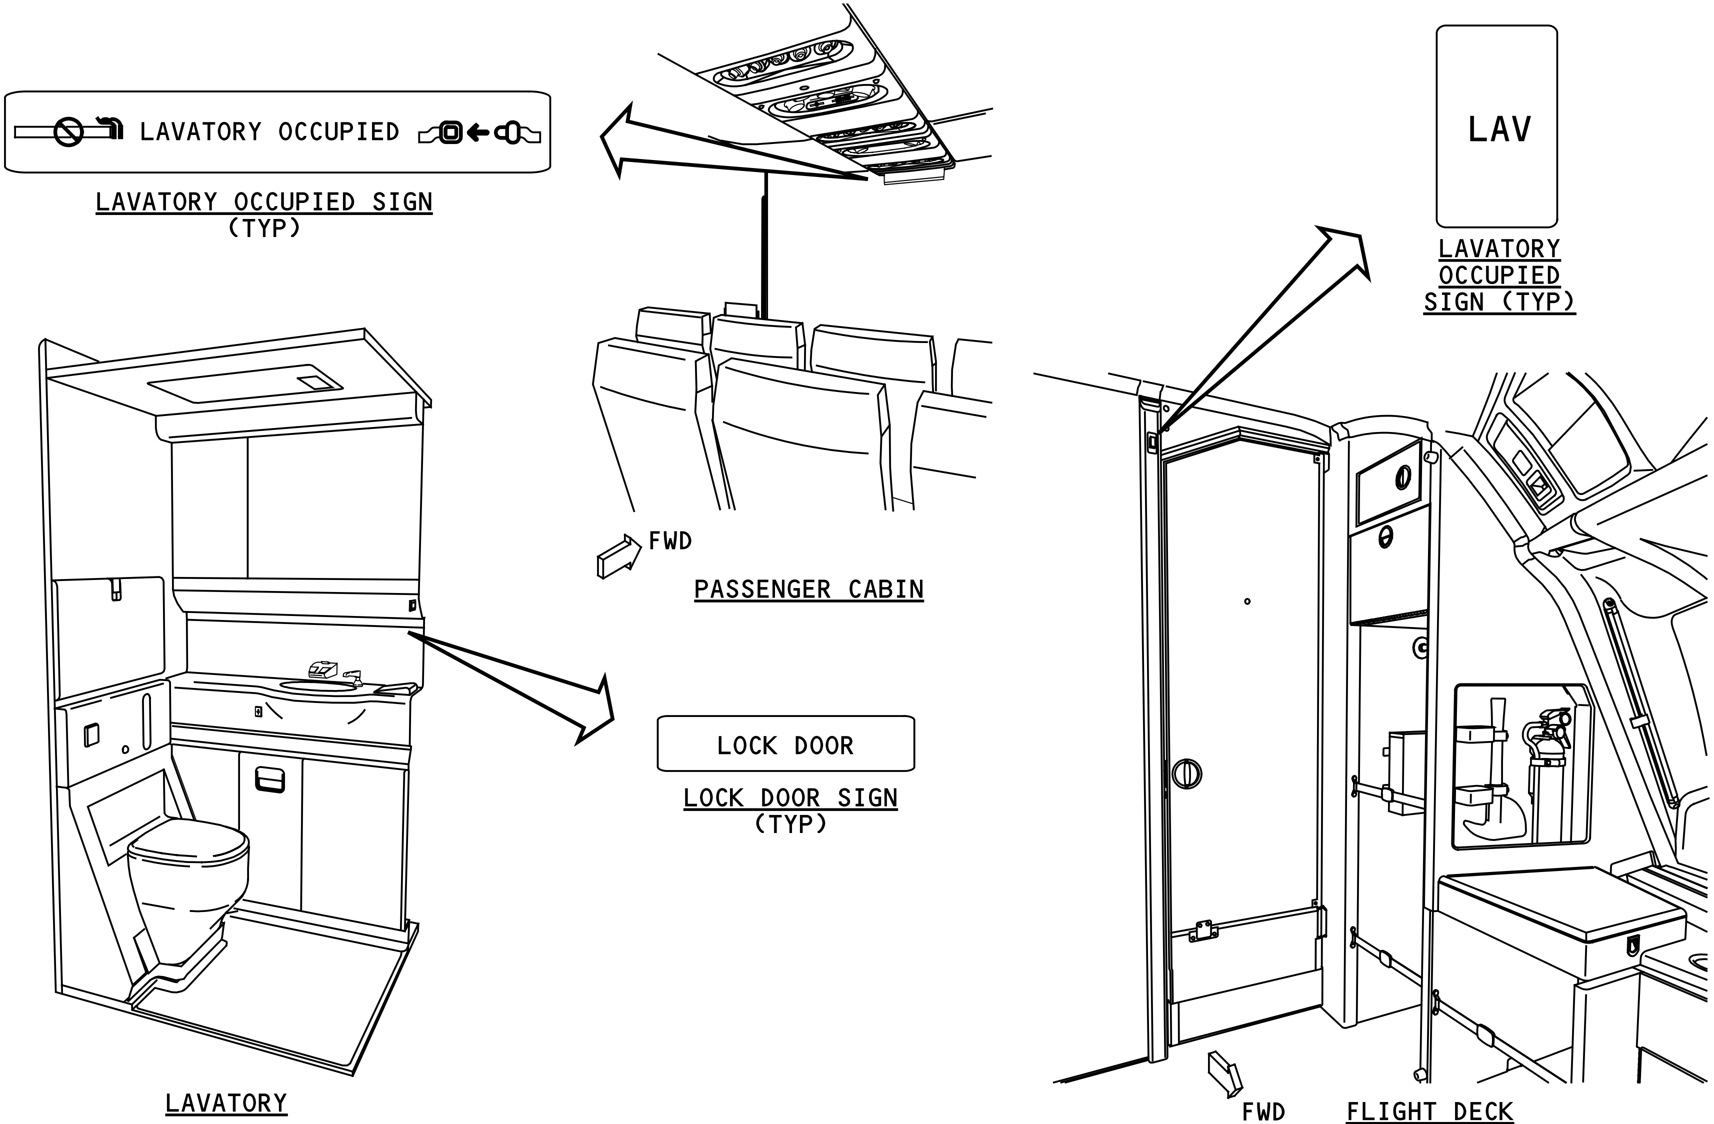
Location

The lavatory occupied signs are below the PSUs at the front or rear of a zone. They are above the passenger seats and below the PSUs. Also there is a lavatory occupied sign in the flight deck.

Training Information Point

There is a lock door sign in the lavatory.

You can use the configuration database in the cabin services system to program which lavatories make up an area.



33-26-00-002 Rev 1 03/04/1997

LAVATORY LIGHTS AND SIGNS - SIGNS - INTRODUCTION

GALLEY LIGHTS - INTRODUCTION

Purpose

The galley lights give light in the galleys.

Physical Description

These are the galley lights:

- Main galley lights
- Supplemental galley lights
- Standby lights.

The main galley lights are fluorescent lights. They have a lens.

The standby light has an incandescent lamp. The lamp is a bayonet-style lamp. The standby light is in the main galley light.

A supplemental galley light has these parts:

- Slot (4)
- Bezel/lens retainer
- Lens
- Tab (4)
- Lamp
- Lever.

You use the lever to lock the light in position.

Location

The the main and supplemental lights are in the ceiling in the galleys. The main galley lights have standby lights with them.

Training Information Point

To replace the main galley lights you use the fasteners in the corners of the lens to remove the lens and bezel. They are one part. This gives you access to the fluorescent lights.

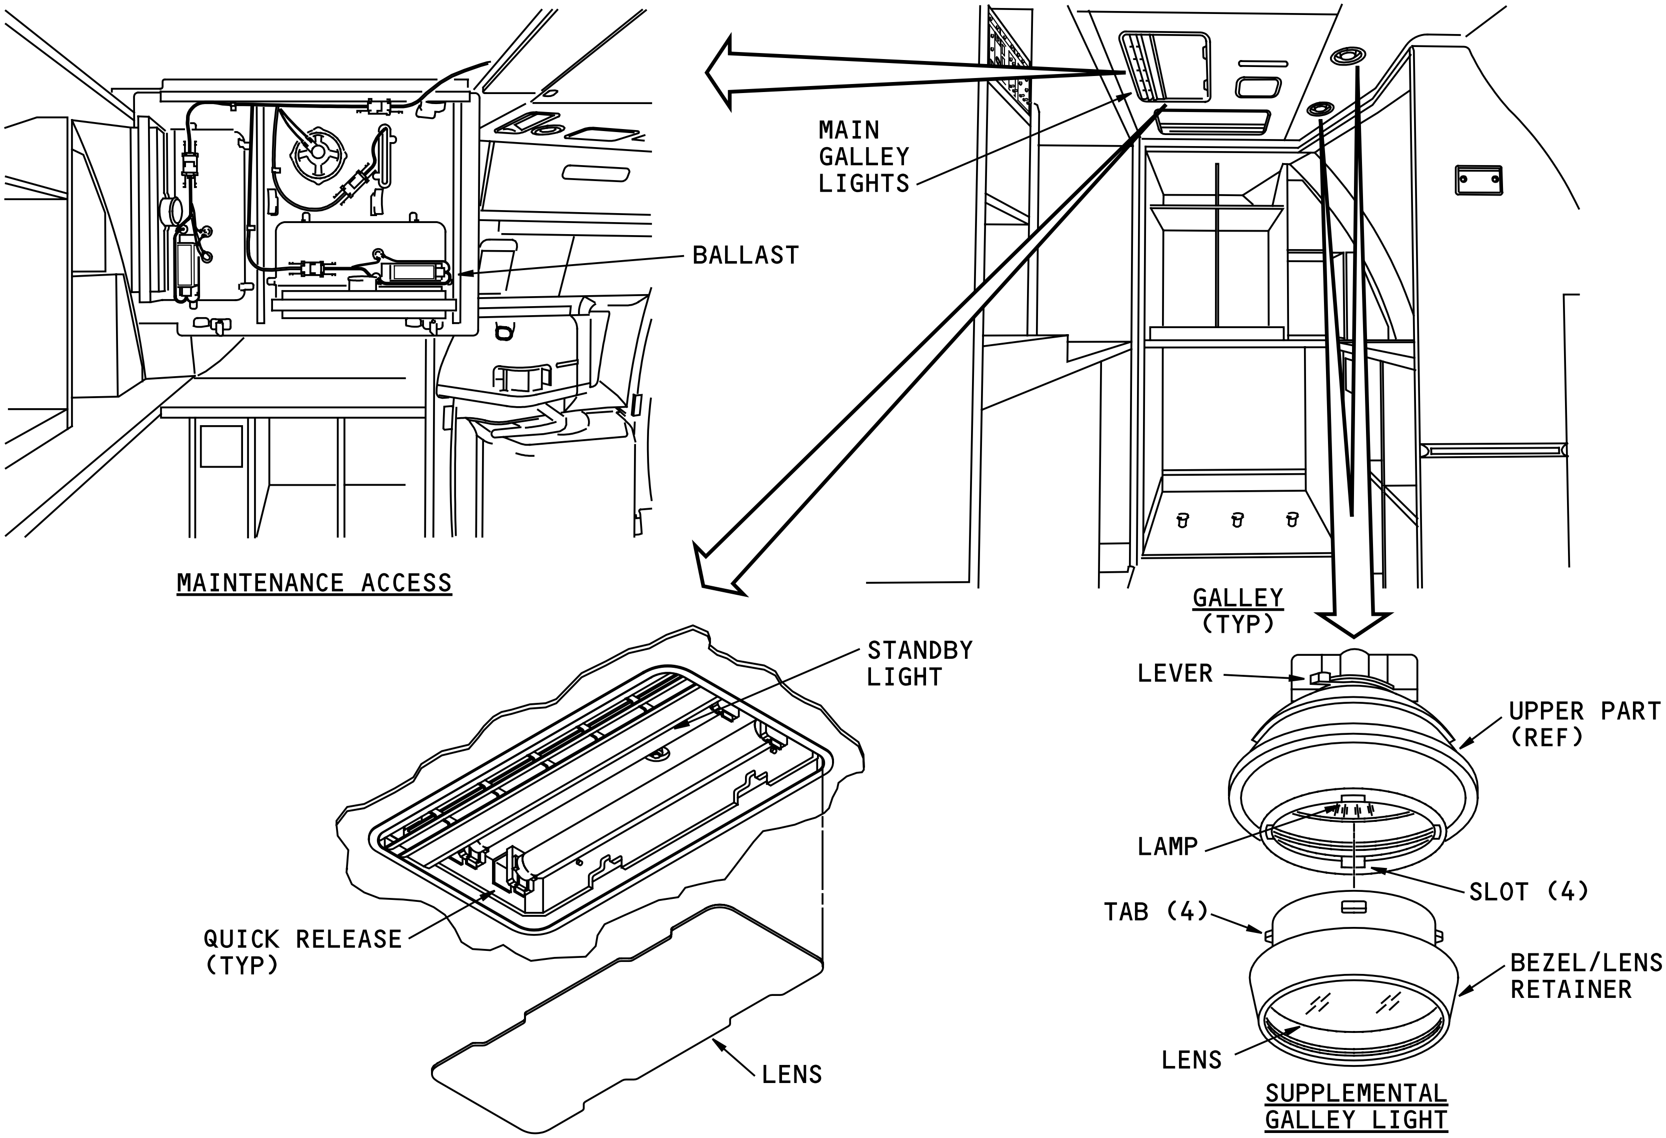
You use the quick releases to remove the fluorescent lights.

You lower the ceiling panel to get access to the ballast.

To replace a supplemental light you:

- Compress the lens/bezel retainer
- Turn it counterclockwise to disconnect it from the slots
- Replace the lamp.

You do the opposite procedure to install the bezel/lens retainer.



33-27-00-001 Rev 0

GALLEY LIGHTS - INTRODUCTION

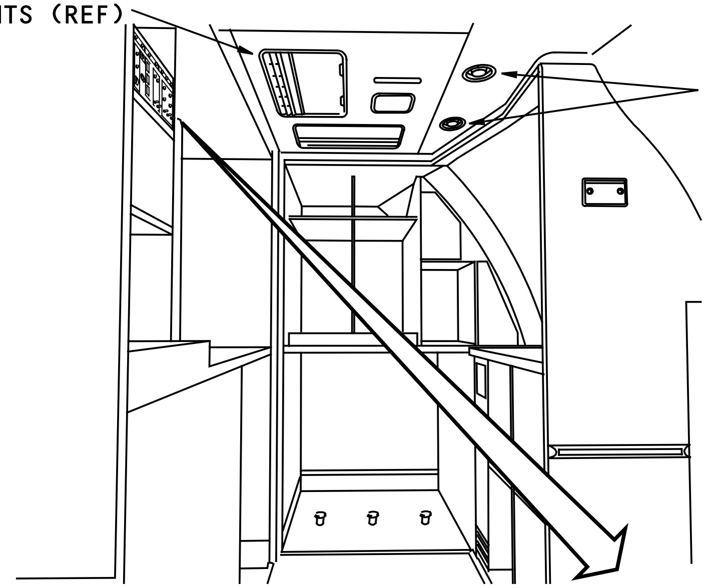
GALLEY LIGHTS - OPERATION

Operation

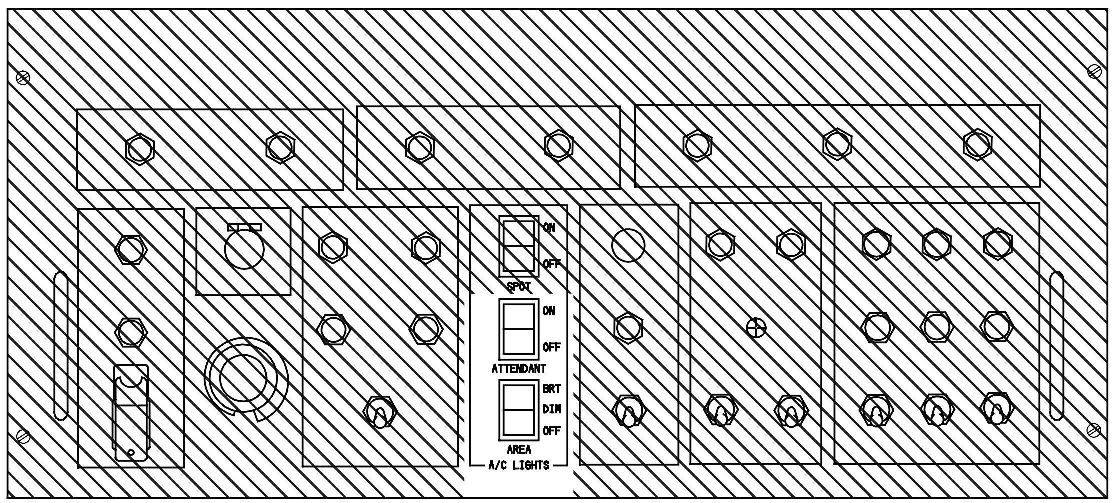
You use the area light switch to make the main galley lights come on in the dim or bright mode.

You use the attendant light switch to operate the supplemental lights.

The standby lights come on when the transfer buses have power and the ground service bus does not have power.



GALLEY (TYP)



GALLEY LIGHTS - OPERATION

PASSENGER CALL LIGHTS - INTRODUCTION

Purpose

The passenger call lights tell the flight attendants when aid is necessary.

Location

There is an attendant call switch and attendant call reset switch on the passenger control unit (PCU) at each seat.

There are two passenger call lights on each center passenger service unit (PSU). There is one on each outboard PSU.

Interface

The passenger call lights give signals to the master call module, the passenger address/cabin interphone (PA/CI) system and the CACP and CSCP screens.

PASSENGER CALL LIGHTS - INTRODUCTION

PASSENGER CALL LIGHTS - STERILE COCKPIT LIGHT

Purpose

The sterile cockpit light shows the cabin crew when the airplane is in a critical phase of flight.

General Description

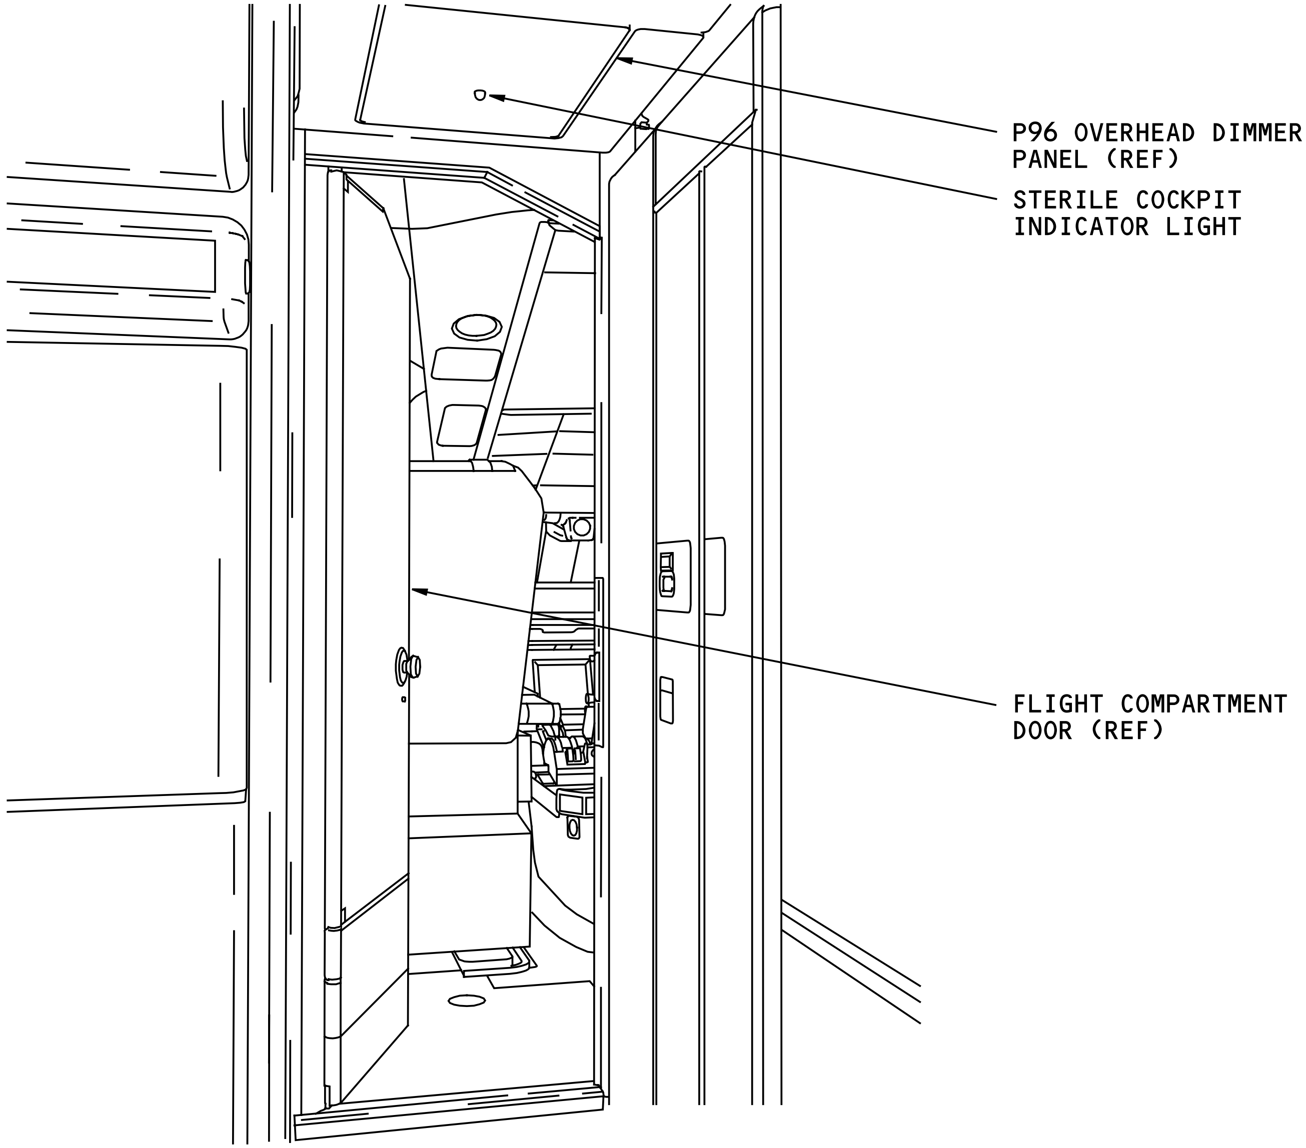
Federal aviation regulations make it necessary for the flight crew to keep a sterile cockpit during critical phases of flight. During these conditions, the crew is permitted to do only those tasks necessary for the safe operation of the airplane.

Critical phases of flight include taxi, takeoff, landing, and flight operations below 10,000 feet.

The sterile cockpit light comes on automatically when the airplane is below 10,000 feet and the parking brake is not set.

Location

The light is in the P96 overhead dimmer panel. This panel is part of the lowered ceiling aft of the flight compartment door.



PASSENGER CALL LIGHTS - STERILE COCKPIT LIGHT

PASSENGER CALL LIGHTS - STERILE COCKPIT LIGHT - FUNCTIONAL DESCRIPTION

Functional Description

The ADIRU gives airplane altitude data to AIMS through the ARINC 629 flight control buses. AIMS sends altitude and parking brake information to the cabin services system (CSS) through the ARINC 629 systems buses.

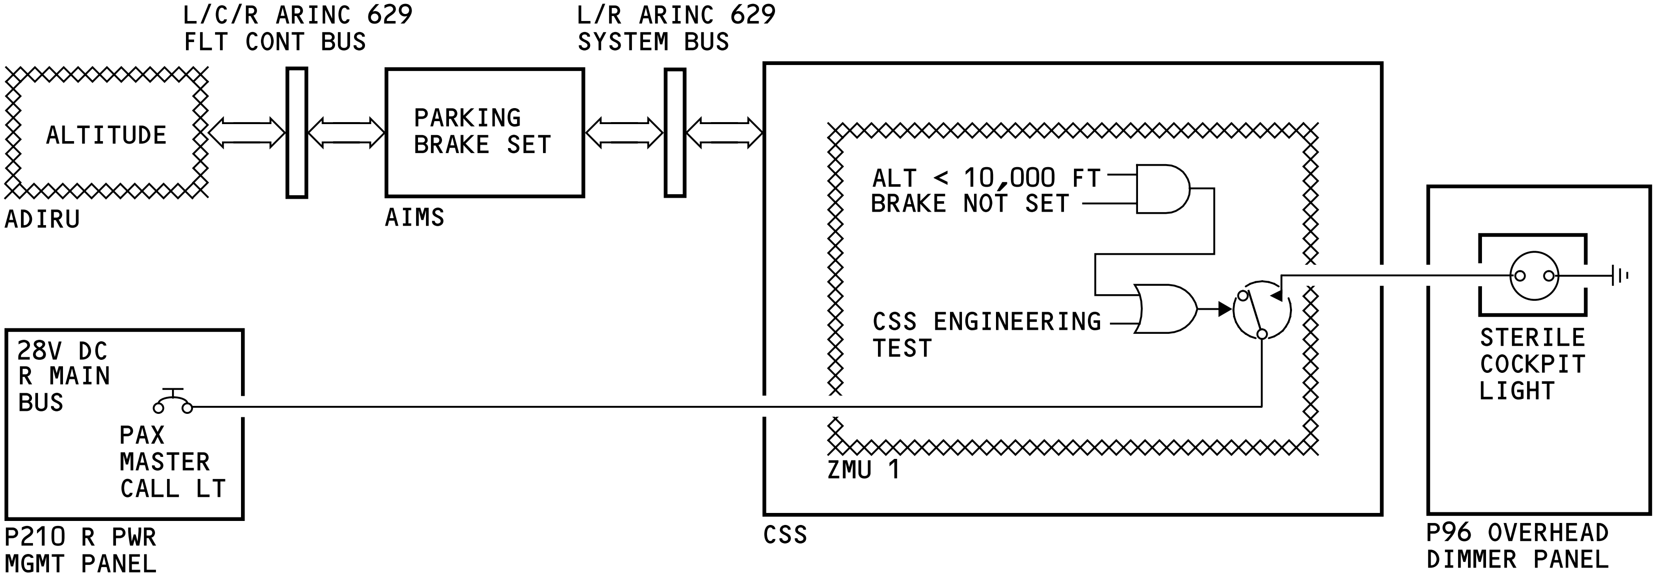
When the airplane altitude is less than 10,000 feet and the parking brake is not set, the zone management unit (ZMU) turns on the sterile cockpit light.

Power

The right main bus gives 28 volt dc power for the sterile cockpit light.

Training Information Point

You do a test of this light on the ground with the CSS engineering tests feature. See the cabin services system section for more information (AMM PART I 23-39).



33-28-00-005 Rev 1 03/12/1997

PASSENGER CALL LIGHTS - STERILE COCKPIT LIGHT - FUNCTIONAL DESCRIPTION

EMERGENCY LIGHTING - INTRODUCTION

Purpose

The emergency lights give light when normal power sources are not available.

They give light:

- In the aisles
- To identify exits
- To identify routes to the exits.
- Outside the airplane at the slides.

Physical Description

The emergency lighting system has these components:

- Area lights
- Exit signs
- Slide lights
- Floor proximity lights
- Power supplies
- Emergency dome light.

Location

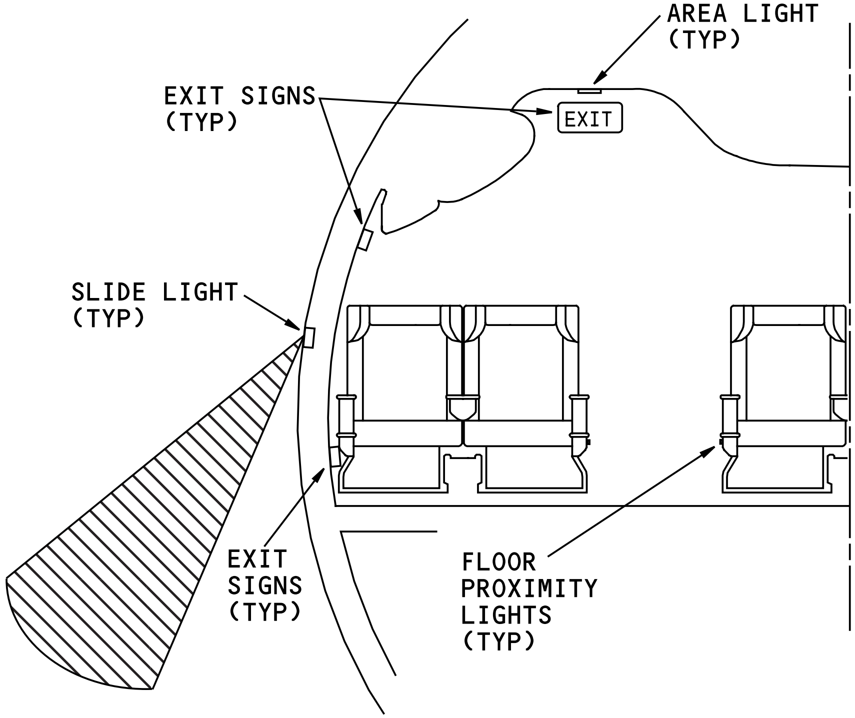
There are emergency lights:

- In the aisle ceilings
- Near the door
- On the center aisle seats
- On the lavatories
- On the closets
- On the galleys
- In the flight compartment.

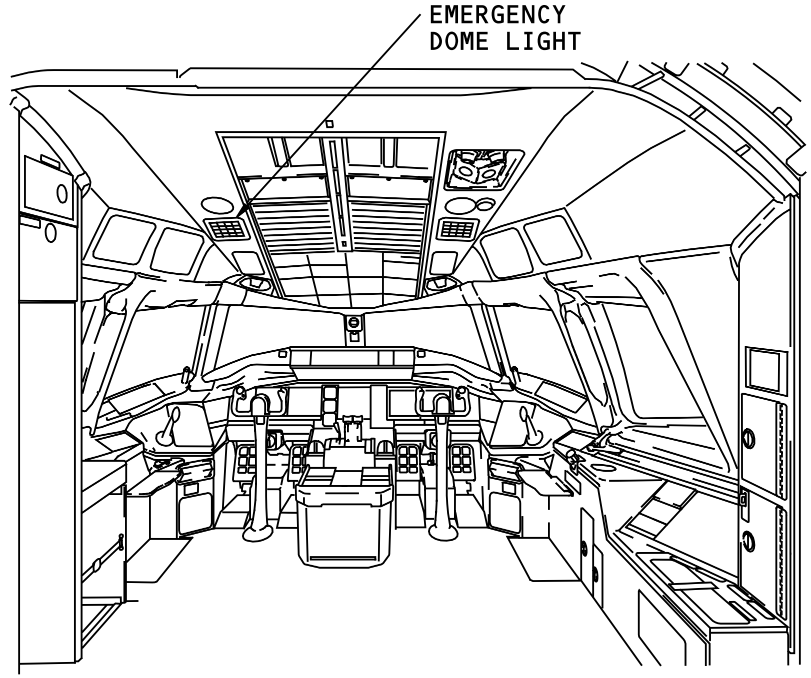
The power supplies (not shown) are above the ceiling, near each passenger entry door.

There are controls (not shown):

- In the flight compartment
- On some attendants panels
- On the nose gear.



PASSENGER COMPARTMENT
(RIGHT SIDE)



EMERGENCY LIGHTING - INTRODUCTION

EMERGENCY LIGHTING - EXIT SIGNS - GENERAL DESCRIPTION

Purpose

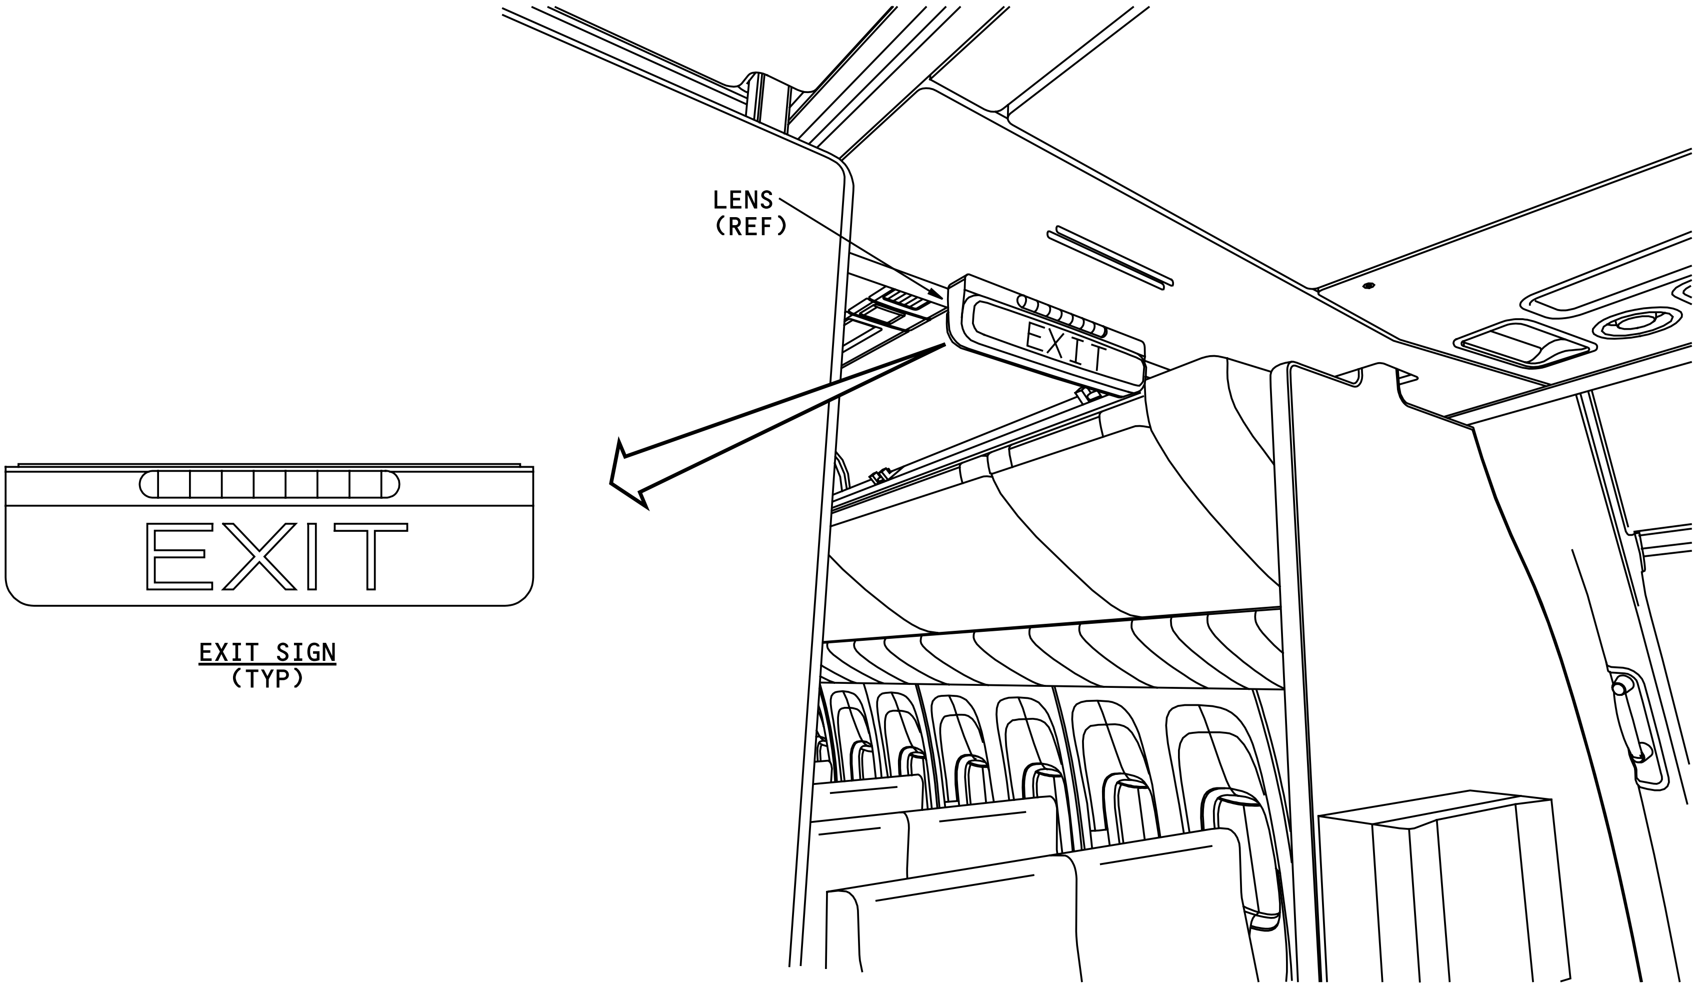
The exit sign lights come on to show where the exits are.

Location

The exit signs are on lowered ceiling panels near all the doors and in the cross aisles.

Training Information Point

You compress the lens of the exit sign to remove it and get access to the bulbs. There are twelve bulbs in each sign.



33-50-00-002 Rev 0

EMERGENCY LIGHTING - EXIT SIGNS - GENERAL DESCRIPTION

EMERGENCY LIGHTING - AREA LIGHTS - GENERAL DESCRIPTION

Purpose

The area lights give light to the aisles when the main buses do not have power. They help passengers and crew to see in an emergency.

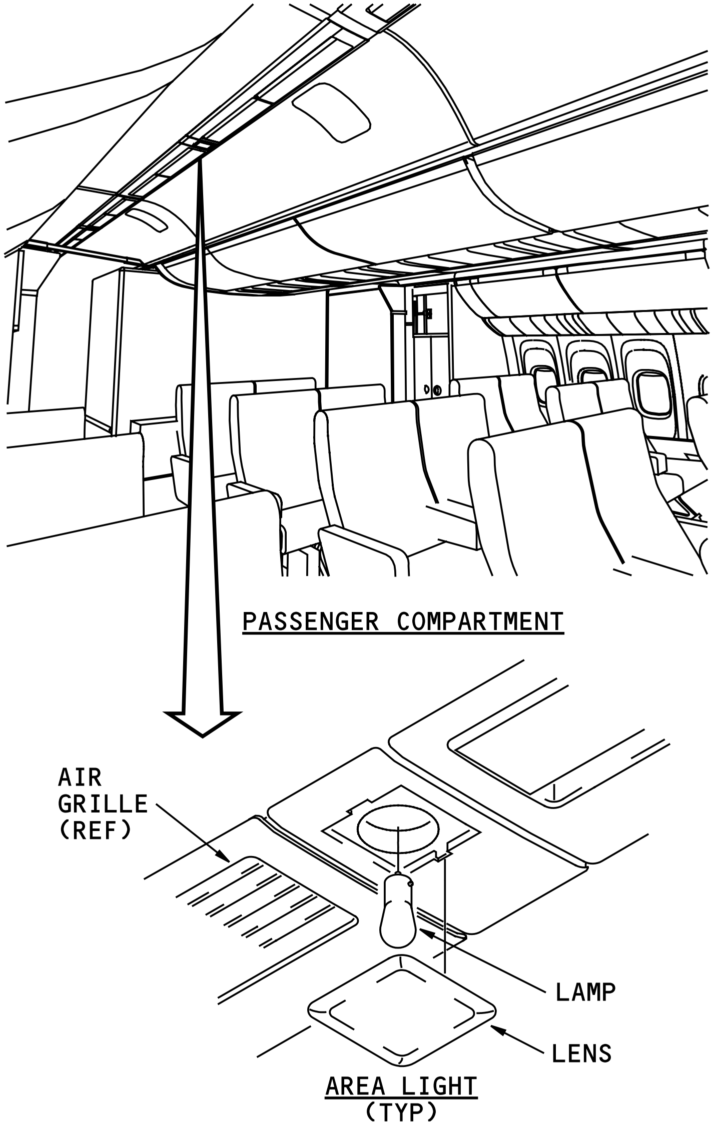
Location

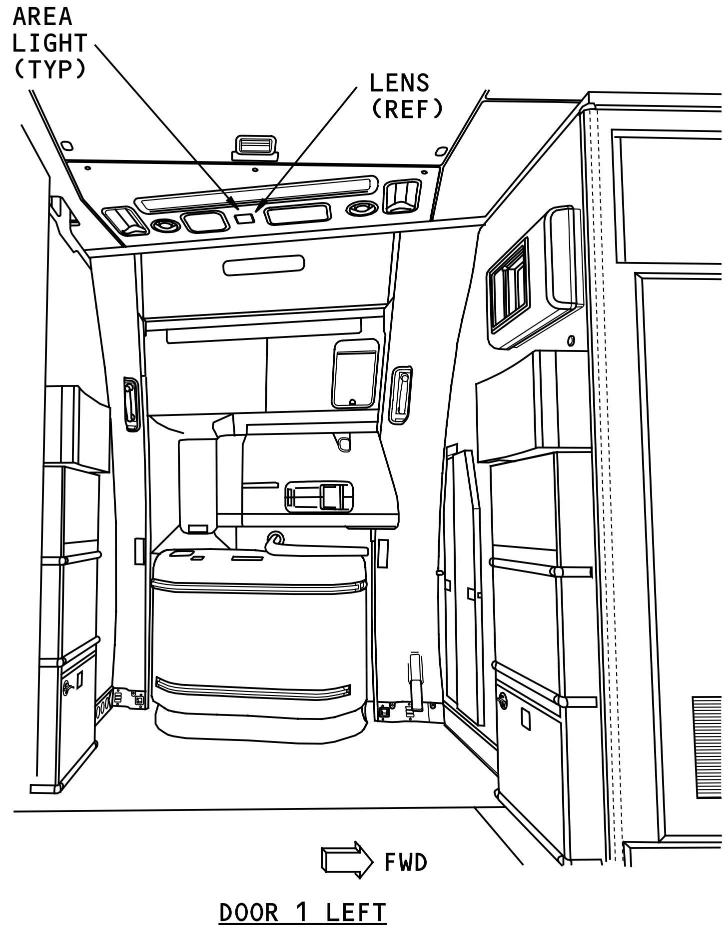
The area lights are in the ceiling:

- In the aisles of the passenger compartment
- In the galleys
- Near the doors.

Training Information Point

You compress the lens to get access to the lamp. The lamp is a bayonet-style lamp. All area lights use the same type lamp.





33-50-00-003 Rev 0

EMERGENCY LIGHTING - AREA LIGHTS - GENERAL DESCRIPTION

EMERGENCY LIGHTING - FLOOR PROXIMITY LIGHTS - GENERAL DESCRIPTION

Purpose

The floor proximity lights give light to the floor to help passengers and crew find the exits.

Location

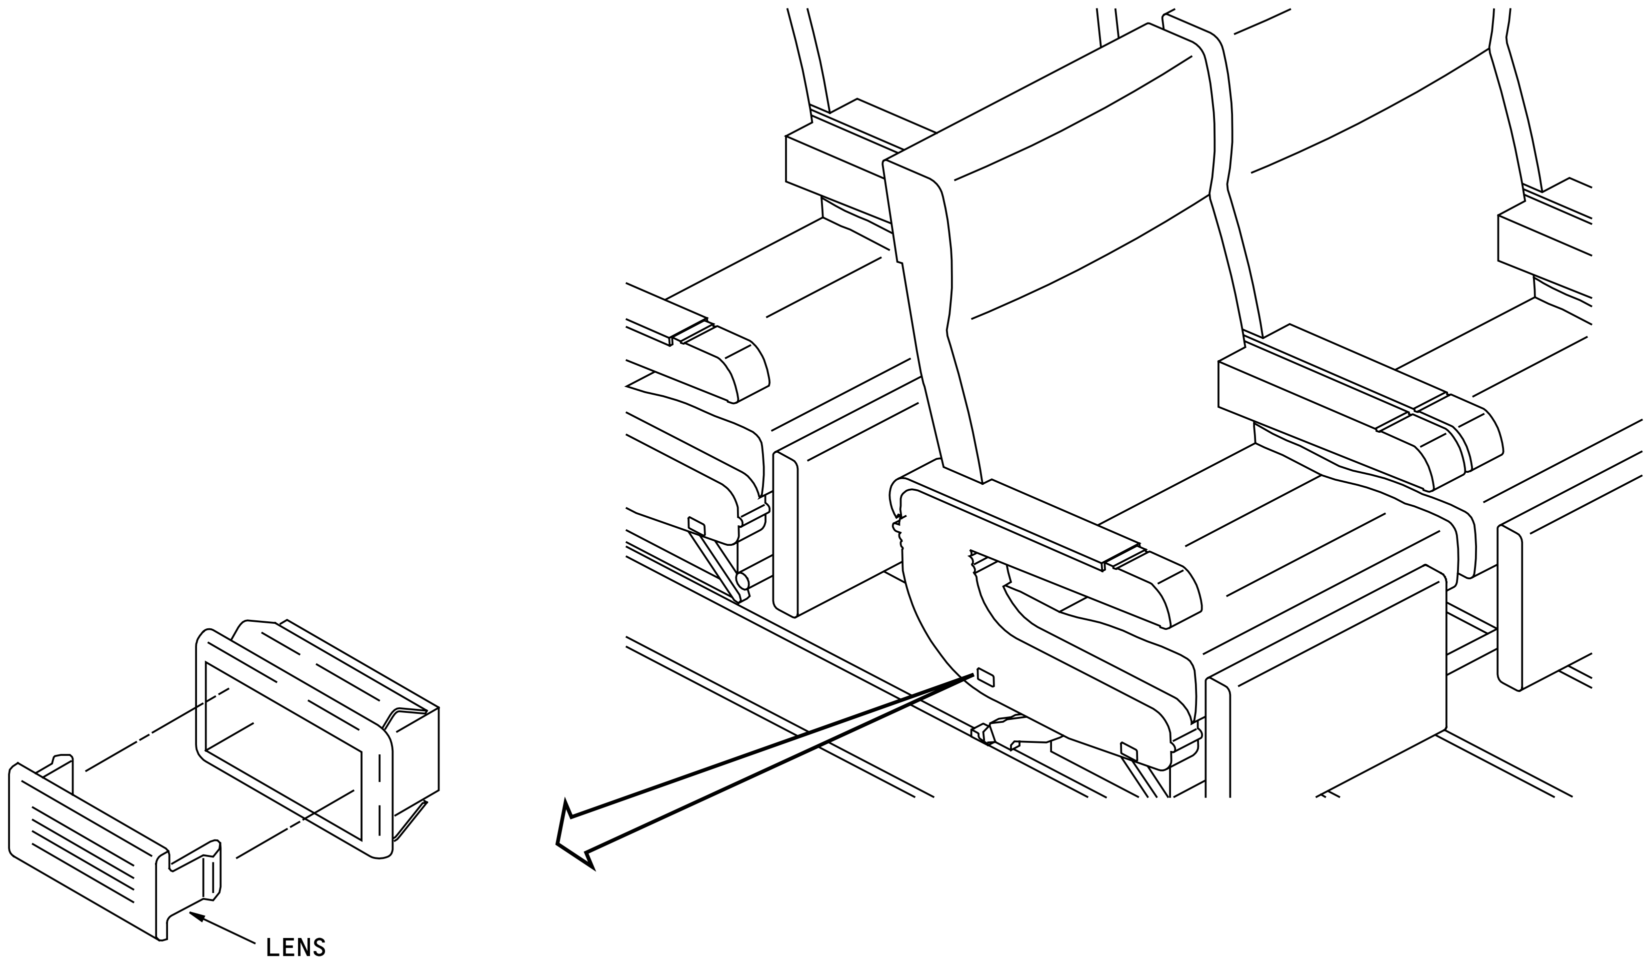
The lights are on the:

- Center aisle seats that are next to an aisle
- Center lavatories (not shown)
- Center closets (not shown)
- Center class dividers (not shown)
- Center galleys (not shown).

Physical Description

The lights on the seats have spring clips that hold the light assembly in place. The lights on other surfaces have screws that hold the light assembly in place. The lens has tabs to hold it in the assembly.

The light is bayonet-style. There is one light in each assembly in economy class and two lights in each assembly in first and business class.



33-50-00-004 Rev 2 08/07/96

EMERGENCY LIGHTING - FLOOR PROXIMITY LIGHTS - GENERAL DESCRIPTION

EMERGENCY LIGHTING - EMERGENCY DOME LIGHT - GENERAL DESCRIPTION

Purpose

The emergency dome light gives light in the flight deck when the main buses do not have power. It helps the crew to see in an emergency.

Location

The emergency dome light is part of the captain's dome light. It is above the captain's seat.

Physical Description

The light has these components:

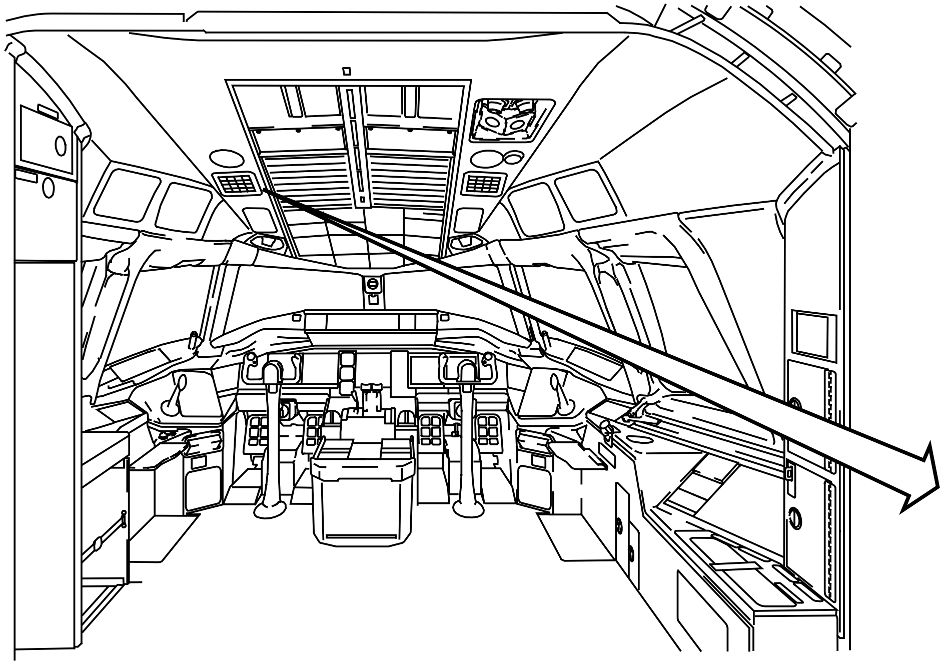
- Lamp
- Lens
- Grill.

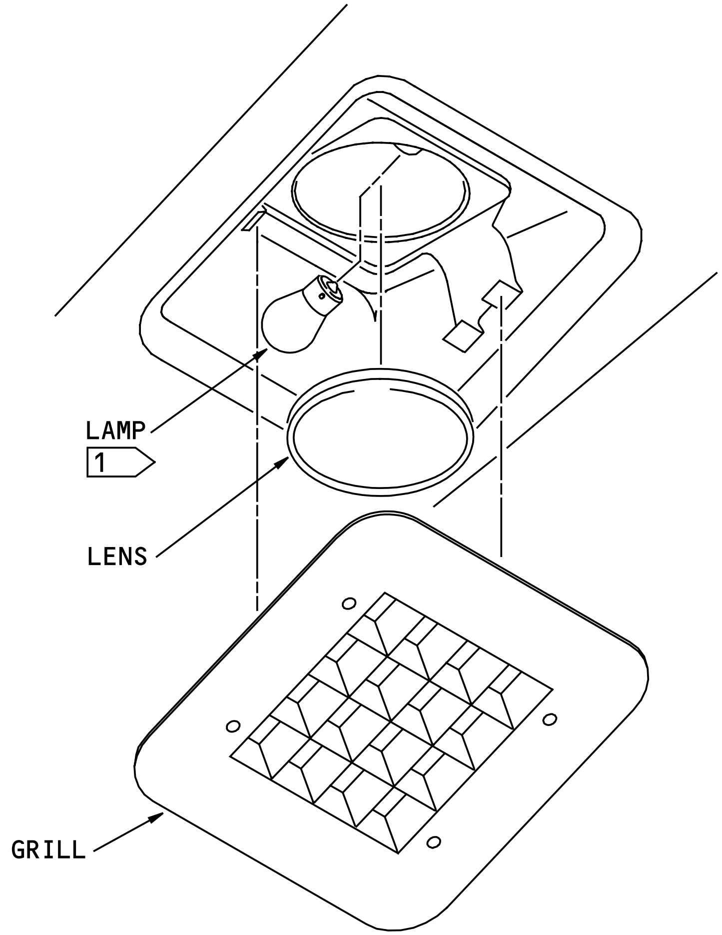
The captain's dome light has two lamps. One is the emergency light system and the other is the normal lamp.

See the flight compartment illumination section for more information about the captain's dome light (AMM PART I 33-11).

Training Information Point

To get access to the lamp you pull down on the grill and remove the lens. The lens has a bayonet-style mount. The lamp is a bayonet-style lamp.





DOME LIGHT

1 THE CAPTAIN'S DOME LIGHT HAS TWO LAMPS. ONE IS FOR THE EMERGENCY LIGHTS AND THE OTHER IS THE NORMAL LAMP.

33-50-00-005 Rev 3 07/17/1997

EMERGENCY LIGHTING - EMERGENCY DOME LIGHT - GENERAL DESCRIPTION

EMERGENCY LIGHTING - SLIDE LIGHTS - GENERAL DESCRIPTION

Purpose

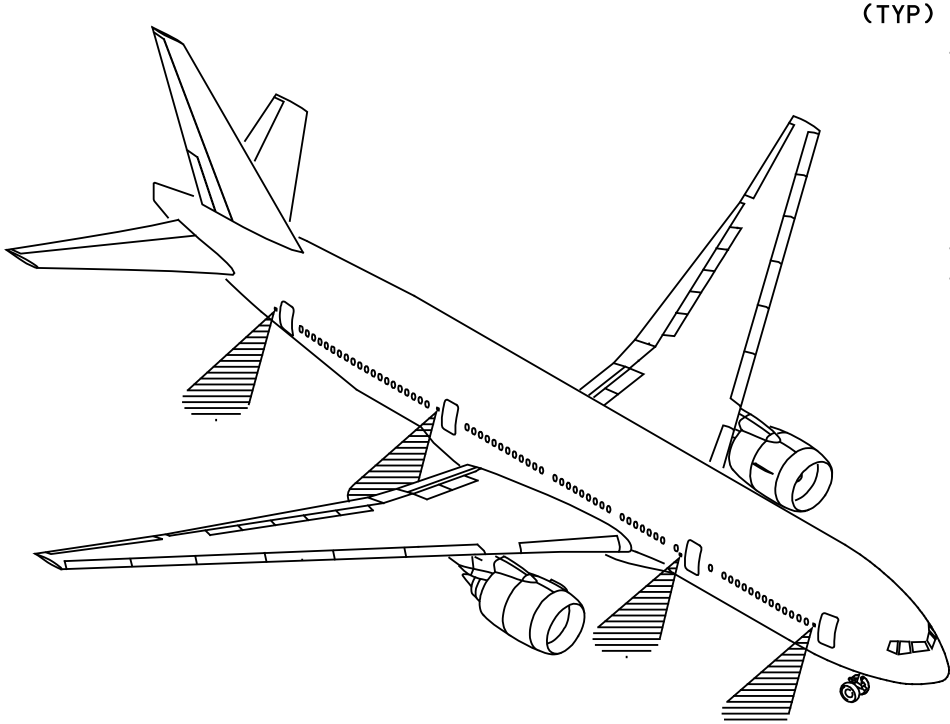
The slide lights give light to the slide on the outside of the airplane.

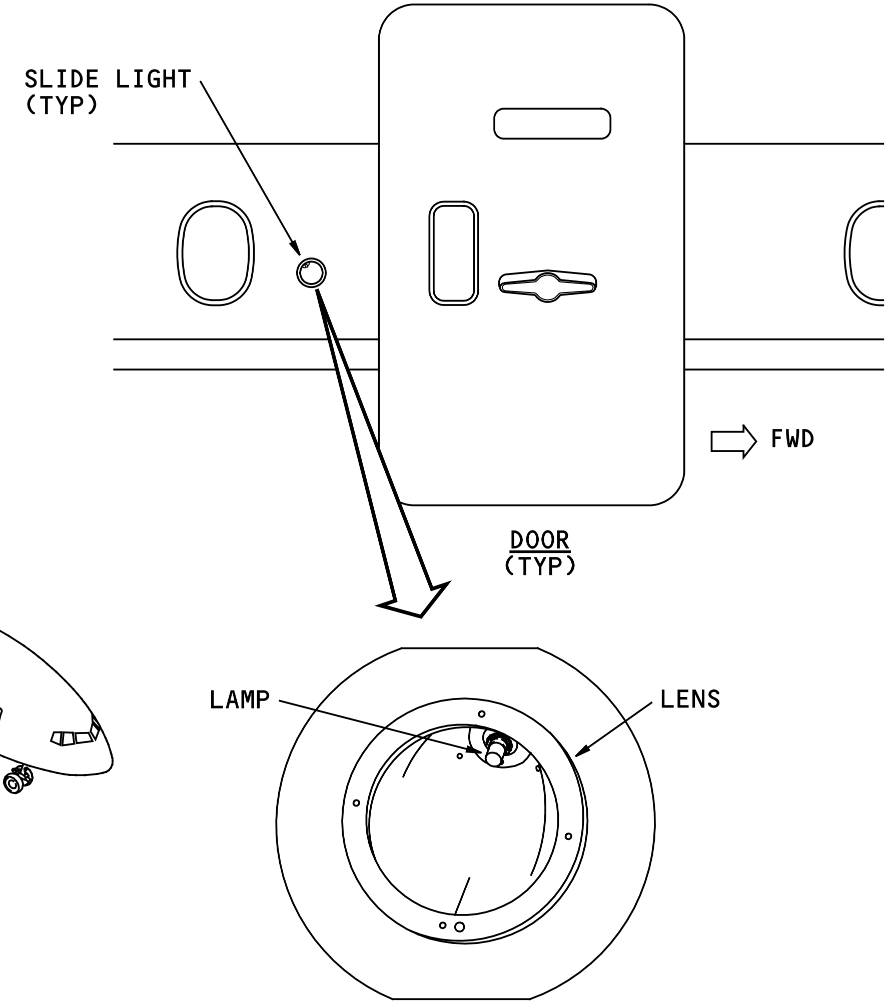
Location

The lights are on the outer surface of the airplane aft of each door.

Training Information Point

You remove the four retaining screws on the lens retainer to get access to the light bulb. There is a lanyard that does not let the lens fall. The light bulb is a bayonet-style bulb.





33-50-00-006 Rev 2 05/16/1997

EMERGENCY LIGHTING - SLIDE LIGHTS - GENERAL DESCRIPTION

EMERGENCY LIGHTING - POWER SUPPLIES - INTRODUCTION

Purpose

The power supplies for the emergency lighting system have these functions:

- Controls the rate of charge for its batteries
- Controls when the emergency lights turn on and off
- Controls the selection of airplane power or its batteries to operate the emergency lights.

Location

The power supplies are in the ceiling, above the passenger entry doors. There can be 2, 3, or 4 power supplies at each door.

Power supplies at doors 1 and 4 attach to the upper side of the overdoor panel.

Power supplies attach to the strong back assembly above the overdoor panel at these doors:

- 2
- 3.

The strong back assembly is related to the outboard stowage bin.See the passenger compartment section for more information about the outboard stowage bins (AMM PART I 25-20).

Physical Description

The power supplies weigh 2.8 pounds (1.3 kg). They supply 6v dc to the emergency lights.

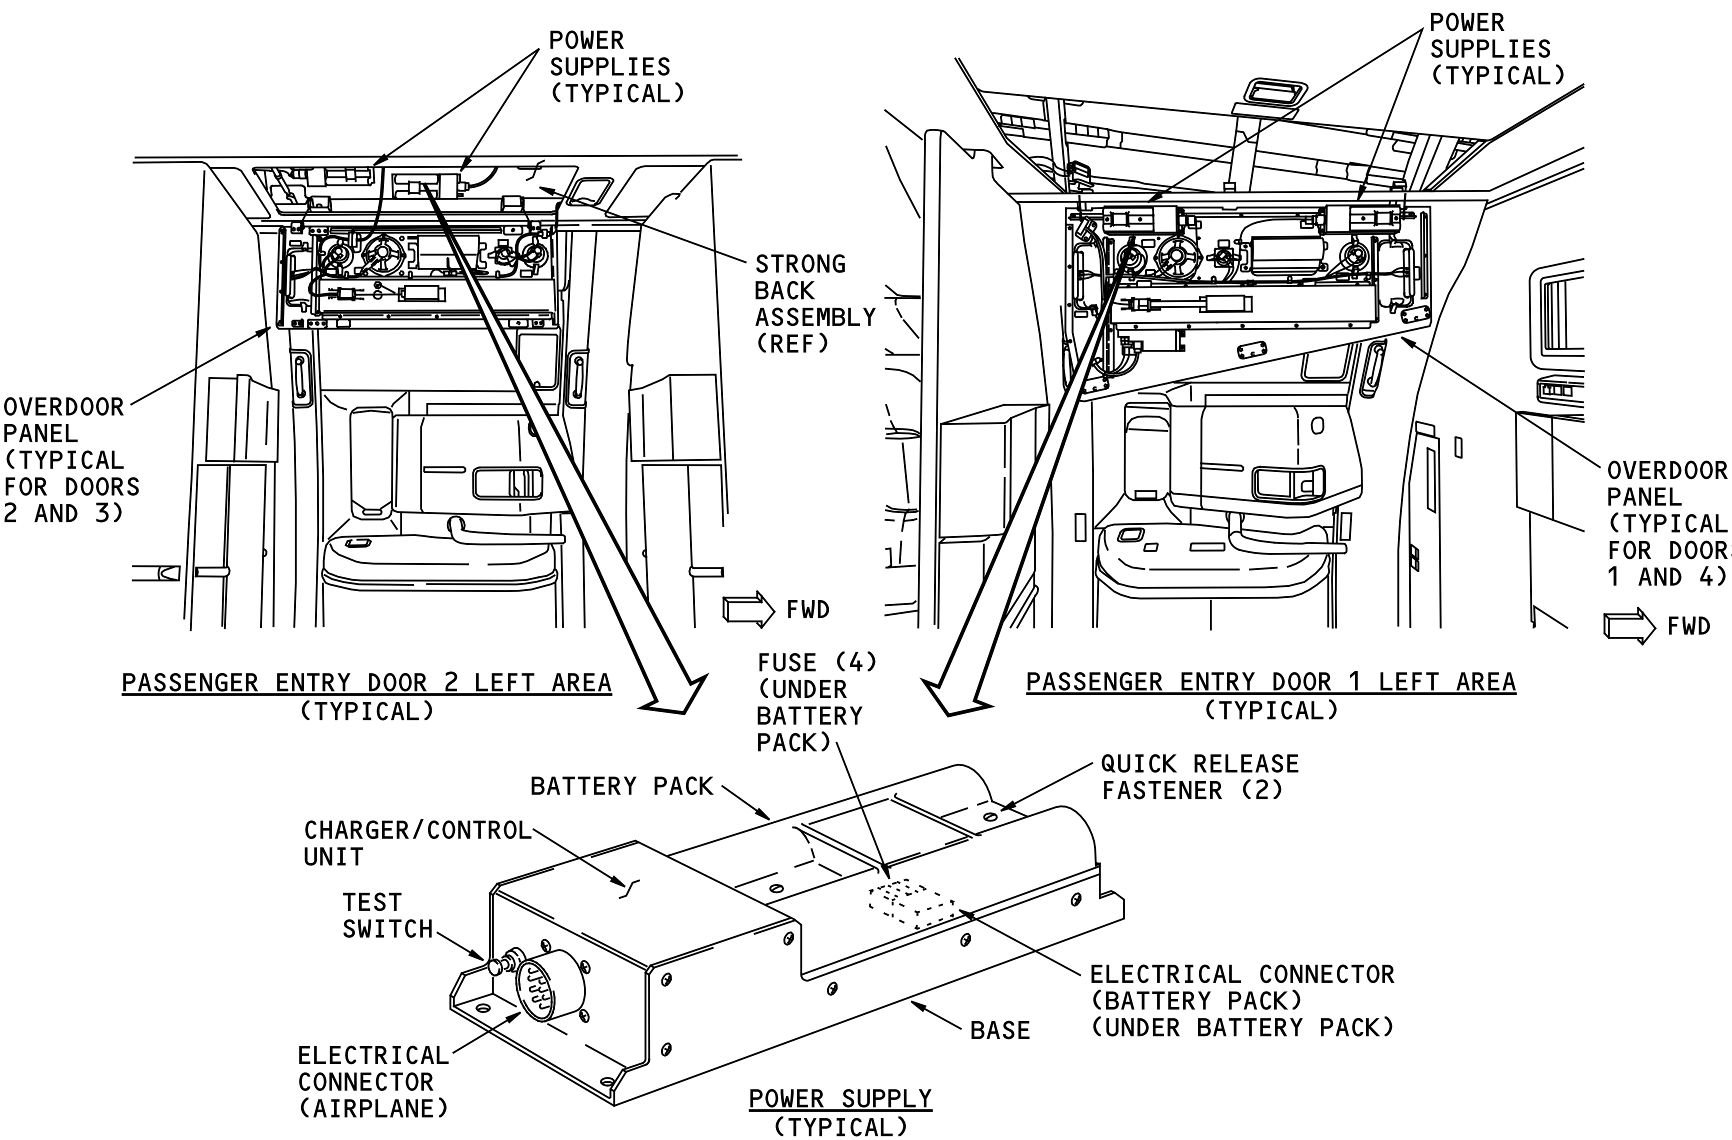
Each power supply has these parts:

- Test switch
- Charger/control unit
- Battery pack
- Fuse (4)
- Quick release fastener (2)
- Electrical connector (battery pack)
- Base
- Electrical connector (airplane).

The fuses and the battery pack are replaceable. The fuses attach to the base under the battery pack. The battery pack attaches to the base with two quick release fasteners. When fully charged, the battery pack provides power for a minimum of 15 minutes.

Training Information Point

The power supplies give power to the lights that are in the same airplane section as the power supplies. They are all the same and interchangeable. They continuously self-charge (L or R main dc buses). If the batteries discharge, they do a fast charge. It takes approximately 90 minutes for a fast charge.



33-50-00-007 Rev 4 02/10/1998

EMERGENCY LIGHTING - POWER SUPPLIES - INTRODUCTION

EMERGENCY LIGHTING - OPERATION

Operation

You use the emergency lights switch in the flight deck or on the P87 attendant switch panel (ASP) to operate (control) the emergency lights.

Either switch turns on the lights. The switch used to turn on the lights must be used to turn off the lights. The OFF position of the flight deck switch does not affect the function of the switch on the ASP.

In normal operation, the switch in the flight deck is in the ARMED position. The ARMED position lets all lights come on if there is no electrical power on the left and right main dc buses.

The ARMED position also lets a limited number of lights come on when a passenger entry door is opened in the armed mode.

To do a test of the lights, you use the test switches on these components:

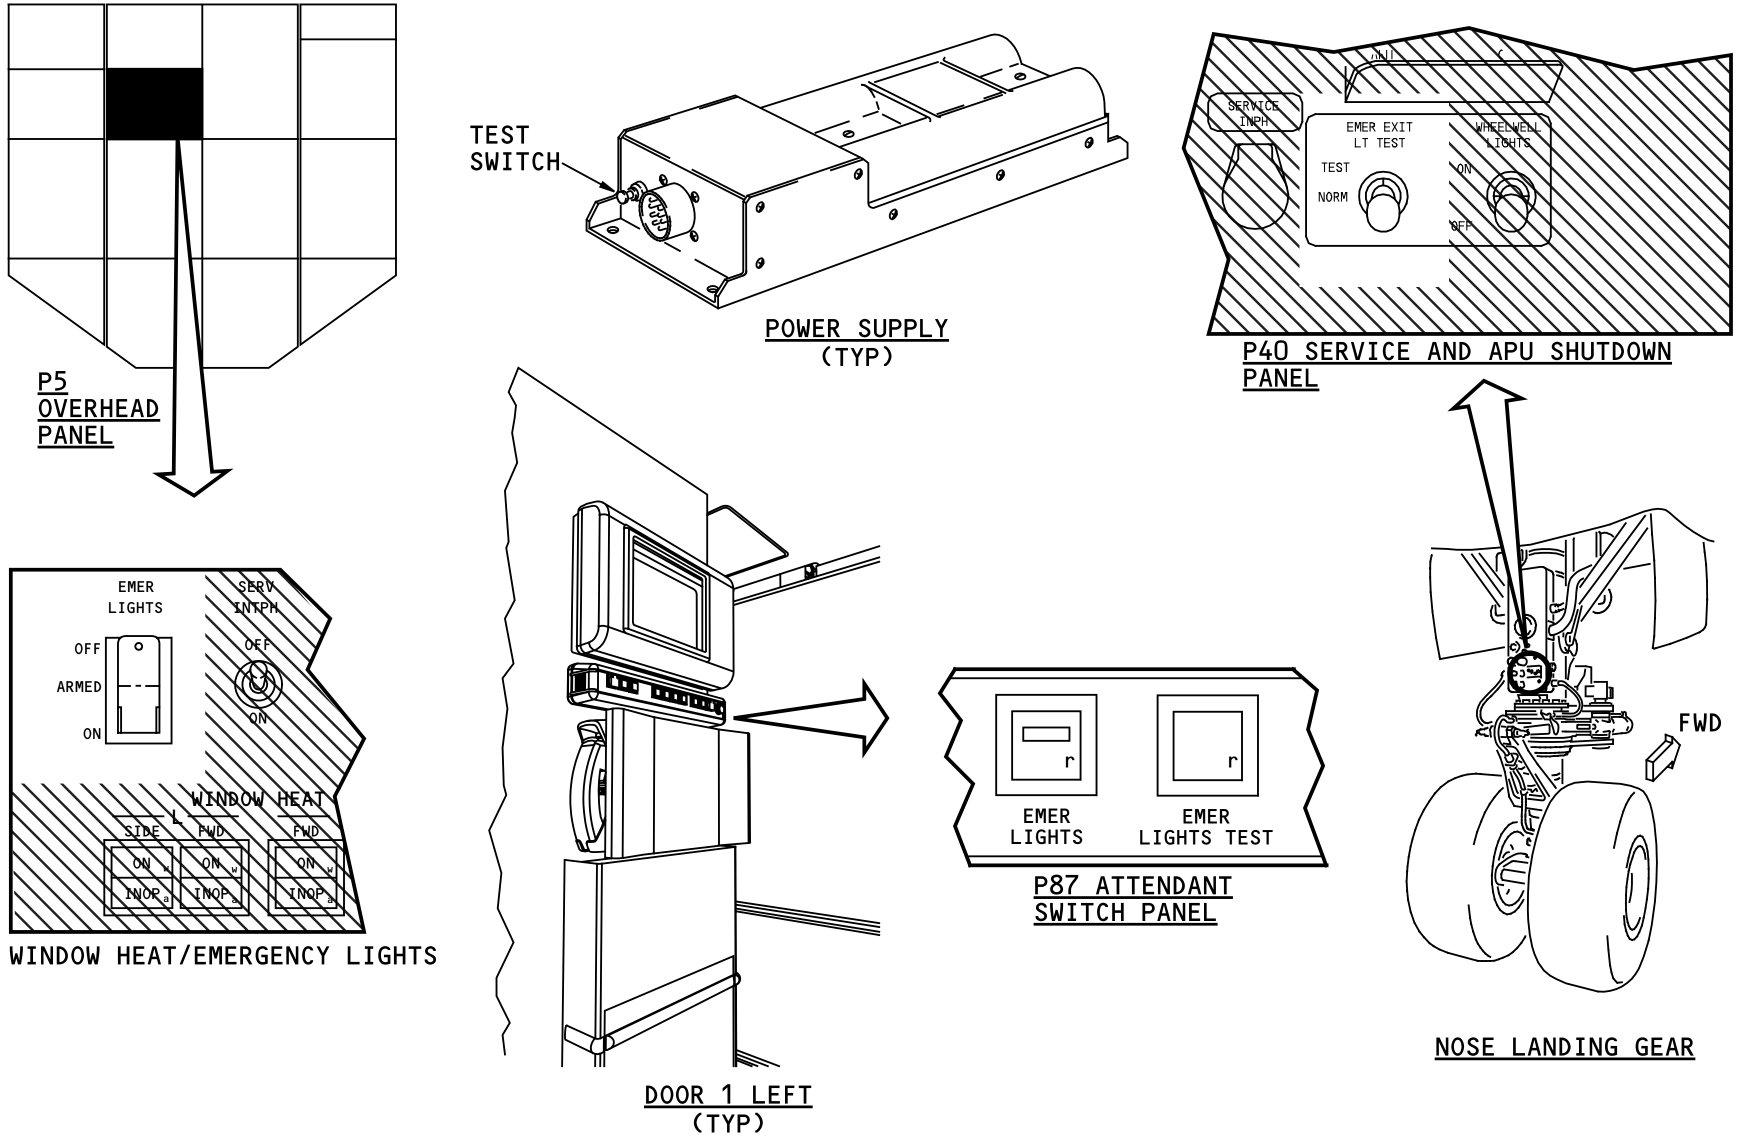
- P87 attendant switch panel at door 1 left
- P94 attendant switch panel at door 4 right (not shown)
- P40 service and APU shutdown panel
- Power supply.

The emergency lights come on for one minute.

Training Information Point

When you push the test switch on the power supply, only the emergency lights that connect to that power supply come on. When you use the test switch on one of the attendant switch panel or on the P40, all emergency lights come on.

Make sure that the test switches return to their usual position when you release them. The usual position for the test switches on the ASPs is out. If a switch is in the test (in) position, red LEDs inside the switch come on. The test switch on the P40 has labels that show the TEST and NORM (usual) positions. If any test switch does not return to its usual position, the battery packs can discharge fully.



EMERGENCY LIGHTING - OPERATION

THIS PAGE INTENTIONALLY LEFT BLANK

EMERGENCY LIGHTING - FUNCTIONAL DESCRIPTION - CONTROL

General

There are six separate emergency light circuits. All circuits are similar. A typical circuit is shown.

Functional Description

The emergency lights use power from the main dc bus if available or from battery packs. The battery packs usually last for 15 minutes or more. All emergency lights (slide and interior) come on when any of these conditions occur:

- The emergency lights switch in the flight deck (P5) is in the ARMED position and the related main dc bus does not have power (left main dc bus for power supplies above doors 1 and 2, right main dc bus for power supplies above doors 3 and 4)
- The emergency lights switch in the flight deck (P5) is in the ON position
- The emergency lights switch on the P87 attendant switch panel (door 1L) is in the ON position.

When a passenger entry door is set to the armed mode (mode select switch set to AUTO) and is open (door open switch) these lights come on:

- The related slide light
- The interior emergency lights, near and on the same side as the related passenger entry door.

The lights stay on until none of the above conditions is true or until the battery packs do not have sufficient charge.

Test

You can find test switches for the emergency lights at these locations:

- P87 attendant switch panel (door 1L)
- P94 attendant switch panel (door 4R)
- P40 nose gear electrical service panel.

When you push and release an emergency light test switch, all power supplies do a check of the condition of their battery pack. All emergency lights (slide and interior) related to power supplies with a good battery pack, come on for one minute.

When you push and release the test switch on a power supply, only the lights that connect to the power supply come on for one minute.

Indications

The advisory message EMER LIGHTS shows when any of these conditions occur:

- Emergency lights switch (P5) is in the ON or OFF position
- Emergency lights switch (P87) is in the ON position.

EMERGENCY LIGHTING - FUNCTIONAL DESCRIPTION - CONTROL

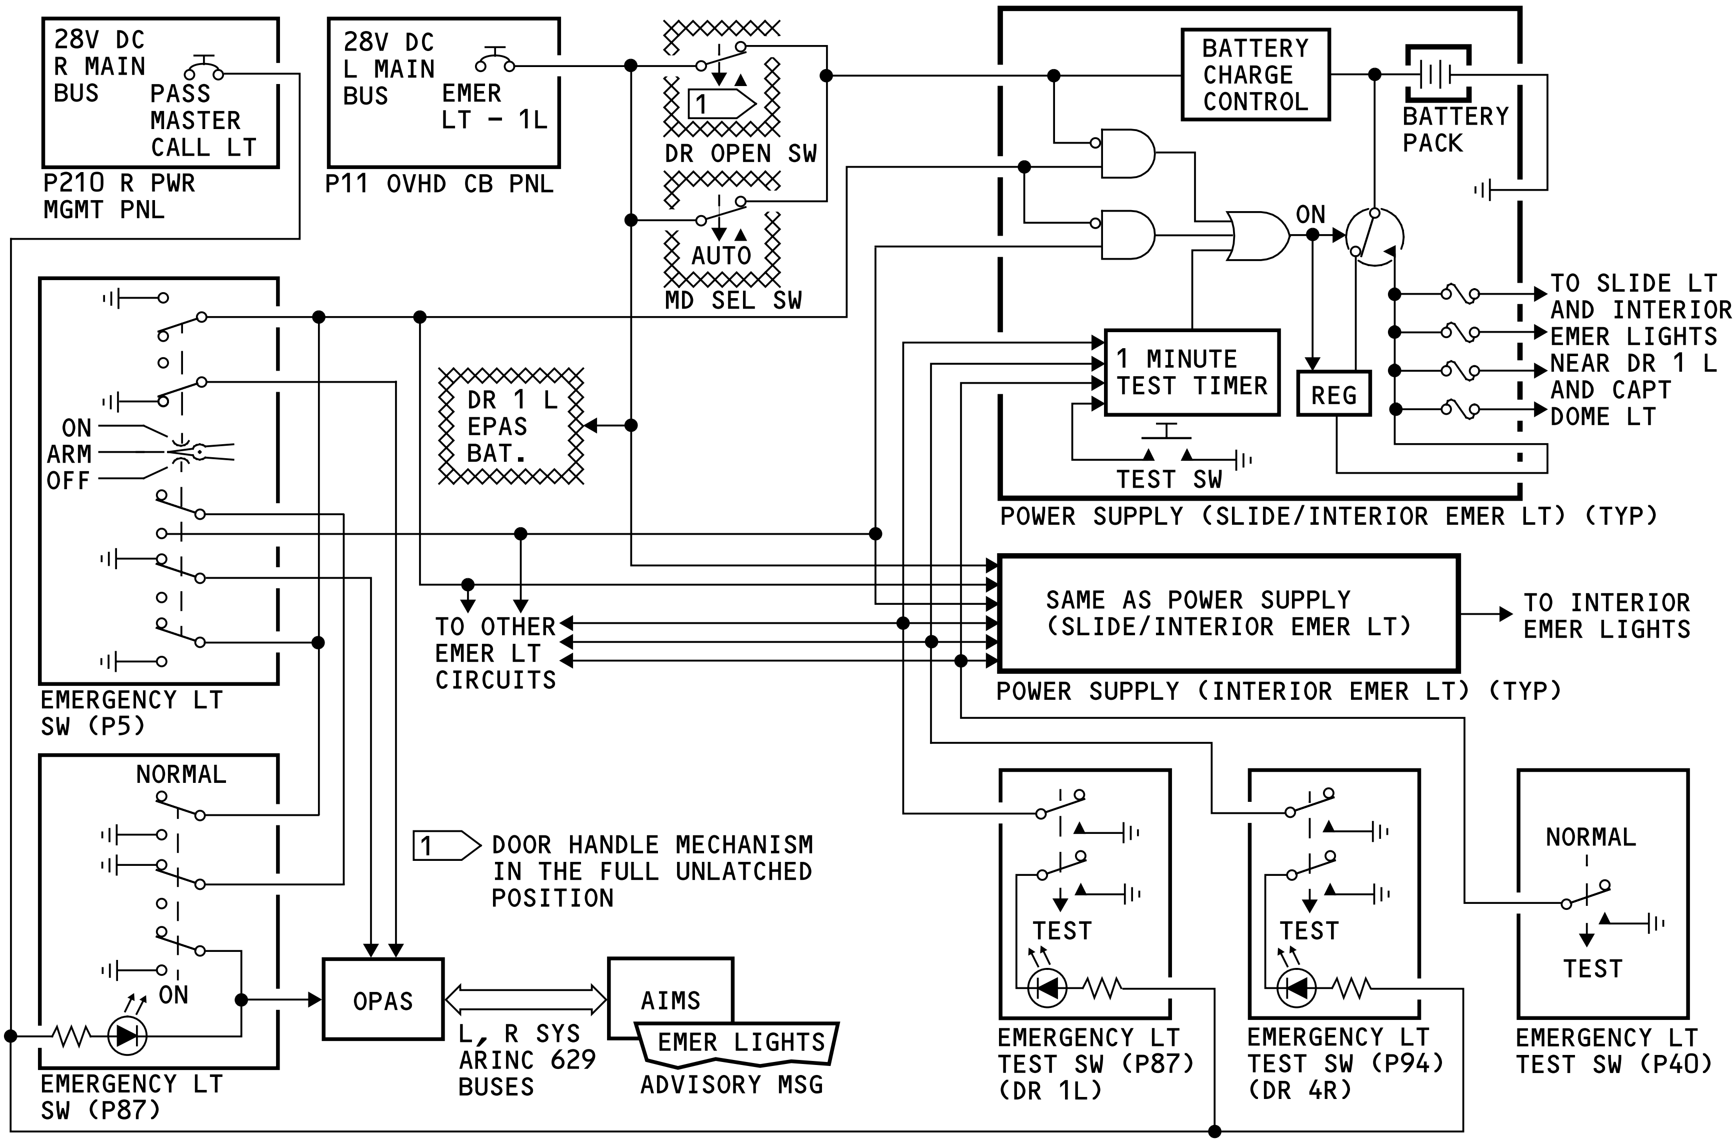
When the emergency lights switch on the attendants switch panel is in the ON position, a red light in the switch comes on.

There are no lights in the test switches.

Training Information Point

When you do a test of the emergency lights, make sure you use a test switch and not one of the emergency lights switches. If you use an emergency lights switch, the condition of the battery packs will not be checked if the main buses have power.

When you do a test of the emergency lights in the passenger cabin, you should also do a check of the condition of the emergency light found in the captain's dome light assembly.



EMERGENCY LIGHTING - FUNCTIONAL DESCRIPTION - CONTROL

SERVICE AND CARGO LOADING LIGHTS - INTRODUCTION

Purpose

The service and cargo loading lights give light to aid maintenance personnel and the ground crew.

Location

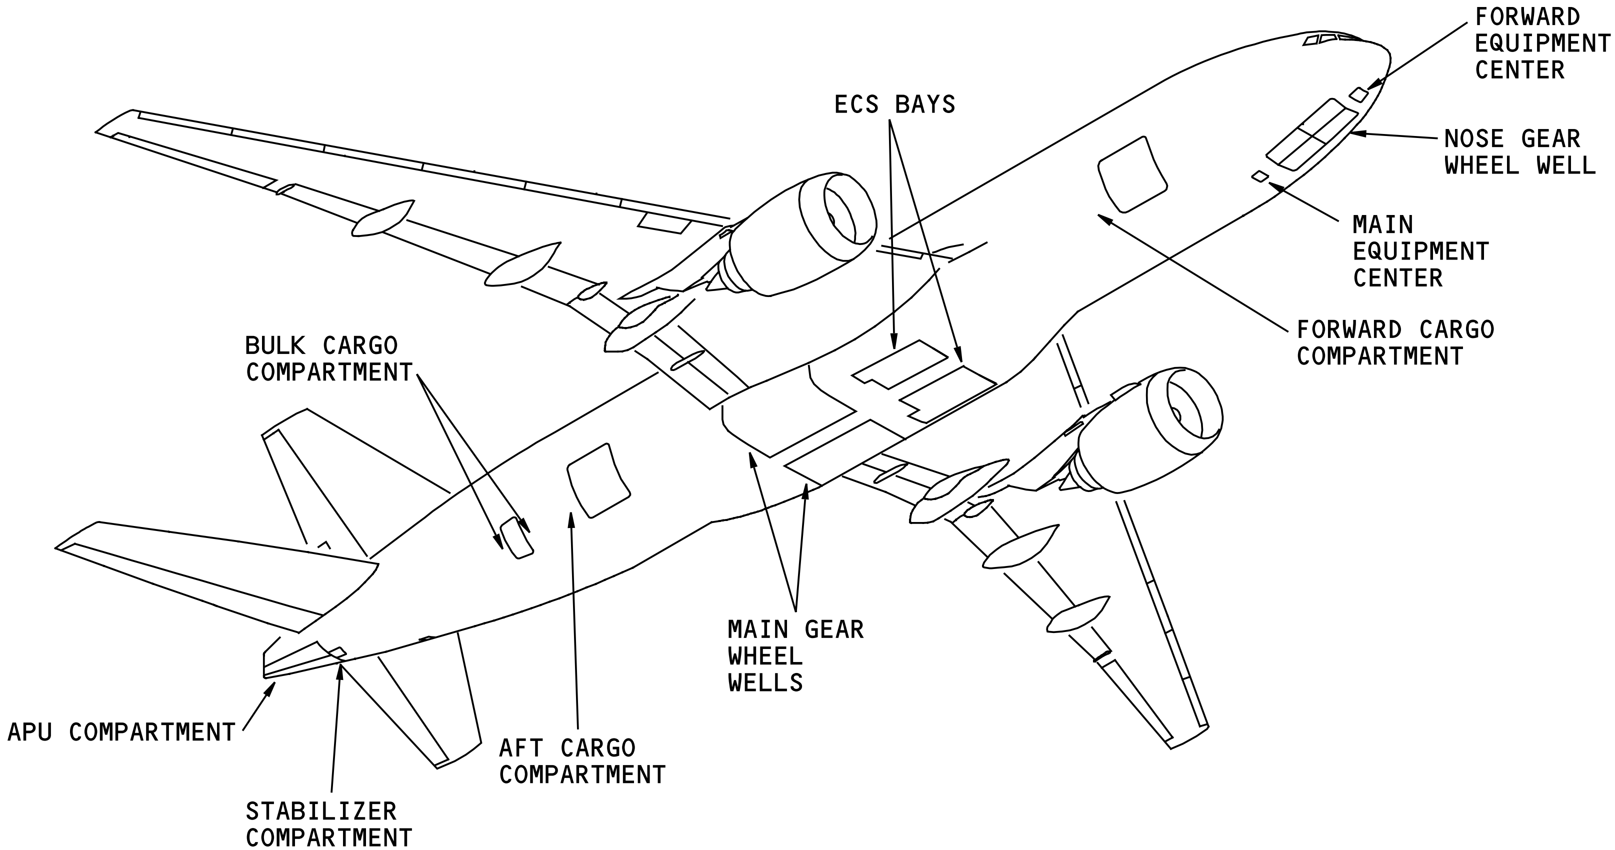
There are service lights in these areas:

- Forward equipment center
- Nose gear wheel well
- Main equipment center
- Environmental control system (ECS) bay
- Main gear wheel wells
- Stabilizer compartments
- APU compartment.

There are cargo loading lights on the external side of the airplane in these areas:

- Forward cargo compartment
- Aft cargo compartment
- Bulk cargo compartment.

There are also lights on the inside of the cargo doors that give light to the door area when the door is open (not shown).



33-31-00-001 Rev 1 04/10/1997

SERVICE AND CARGO LOADING LIGHTS - INTRODUCTION

SERVICE AND CARGO LOADING LIGHTS - EQUIPMENT CENTER LOCATIONS

Forward Equipment Center

There are six lights in the forward equipment center.

There are two FWD E/E BAY LTS switches that control the lights in the forward equipment center. One is in the forward equipment center, forward of the access door. It is adjacent to the cabin interphone jack. The other switch is in the main equipment center (MEC). It is above the MEC door.

Main Equipment Center

There are ten lights on the ceiling of the MEC.

There are three light switches that control the lights in the MEC:

- GND E/E BAY LTS
- FLT E/E BAY LTS
- CARGO DR E/E LTS.

The GND E/E BAY LTS switch is above the MEC door, next to the FWD E/E BAY LTS switch. The FLT E/E BAY LTS switch is below the MEC access hatch and inboard from the P320. It is above and aft of the ladder. The CARGO DR E/E LTS switch is forward of the access panel between the forward cargo compartment and MEC. It is aft of the ladder.

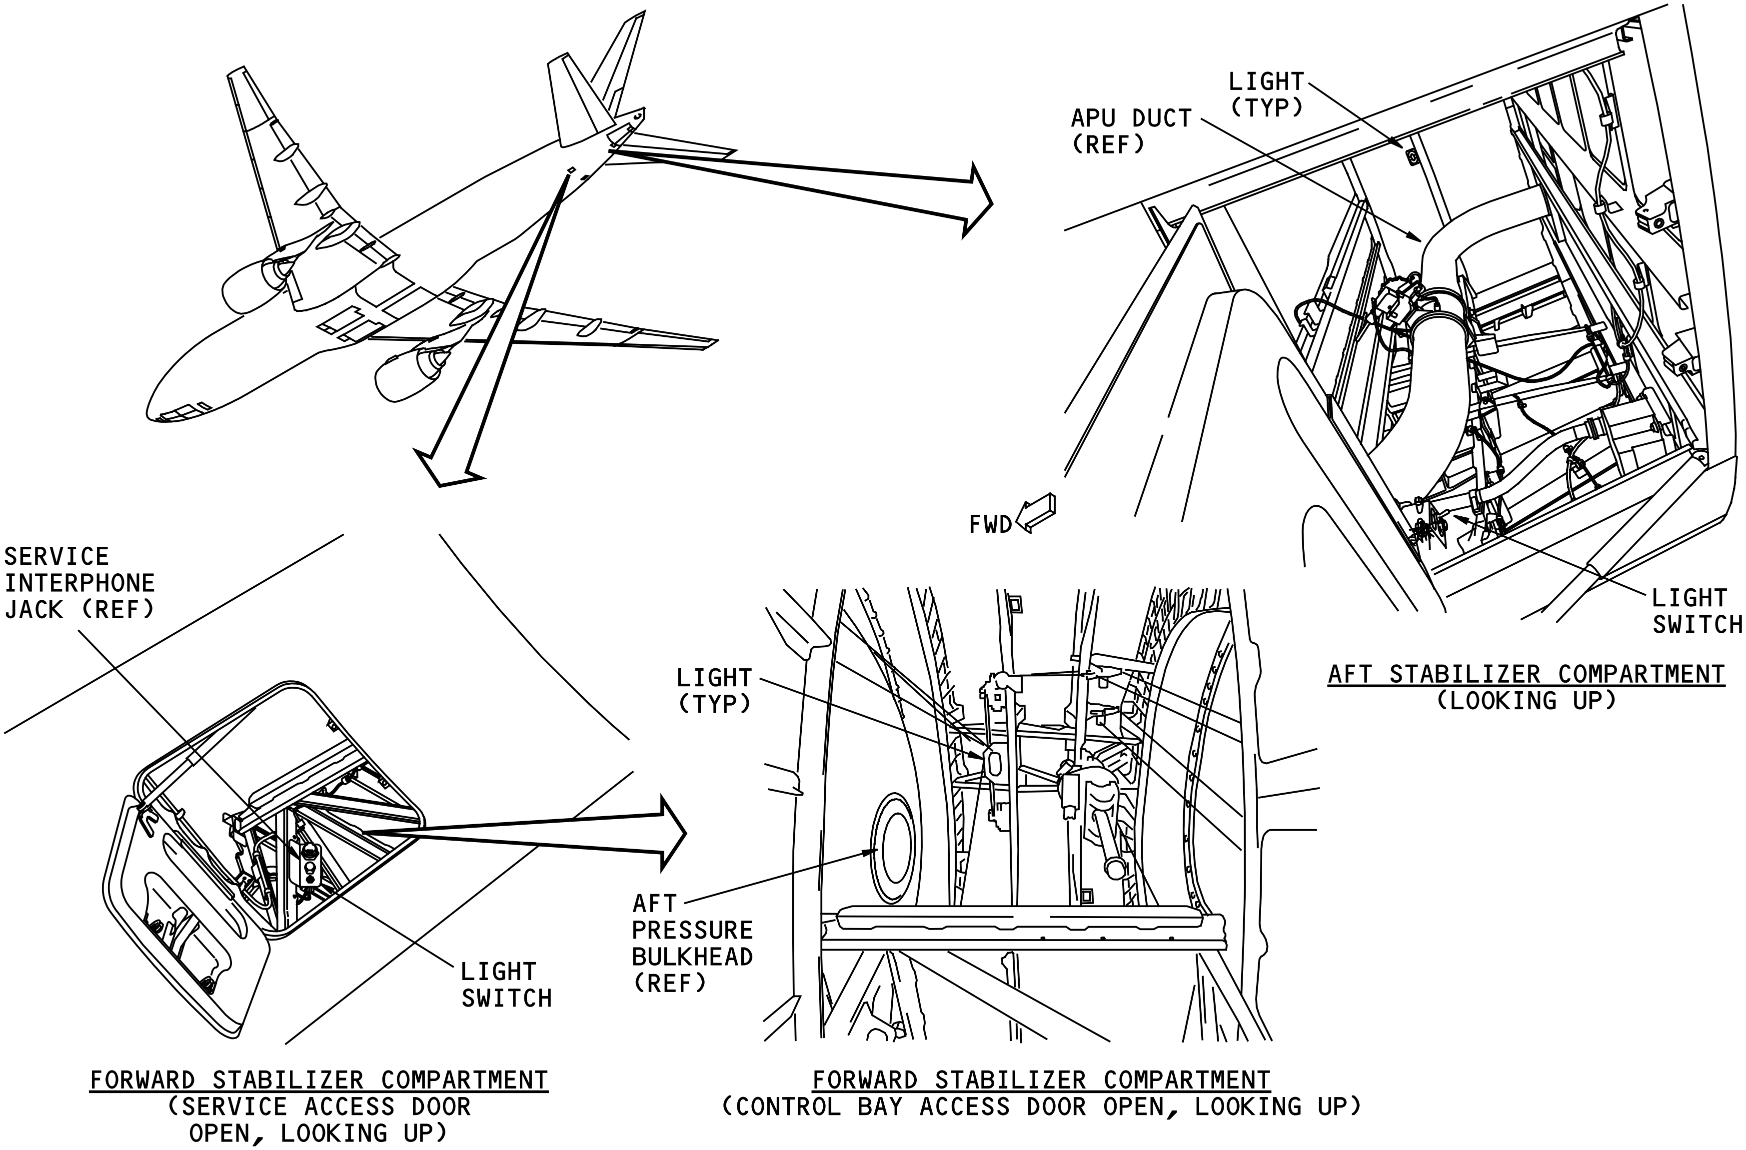
SERVICE AND CARGO LOADING LIGHTS - STABILIZER COMPARTMENT LOCATIONS

Forward Stabilizer Compartment

There are two lights on the ceiling of the forward stabilizer compartment. The switch is above the service access door.

Aft Stabilizer Compartment

There is one light on the ceiling of the aft stabilizer compartment. The switch is above the control bay access door. It is on the right side of the door opening.



SERVICE AND CARGO LOADING LIGHTS - STABILIZER COMPARTMENT LOCATIONS

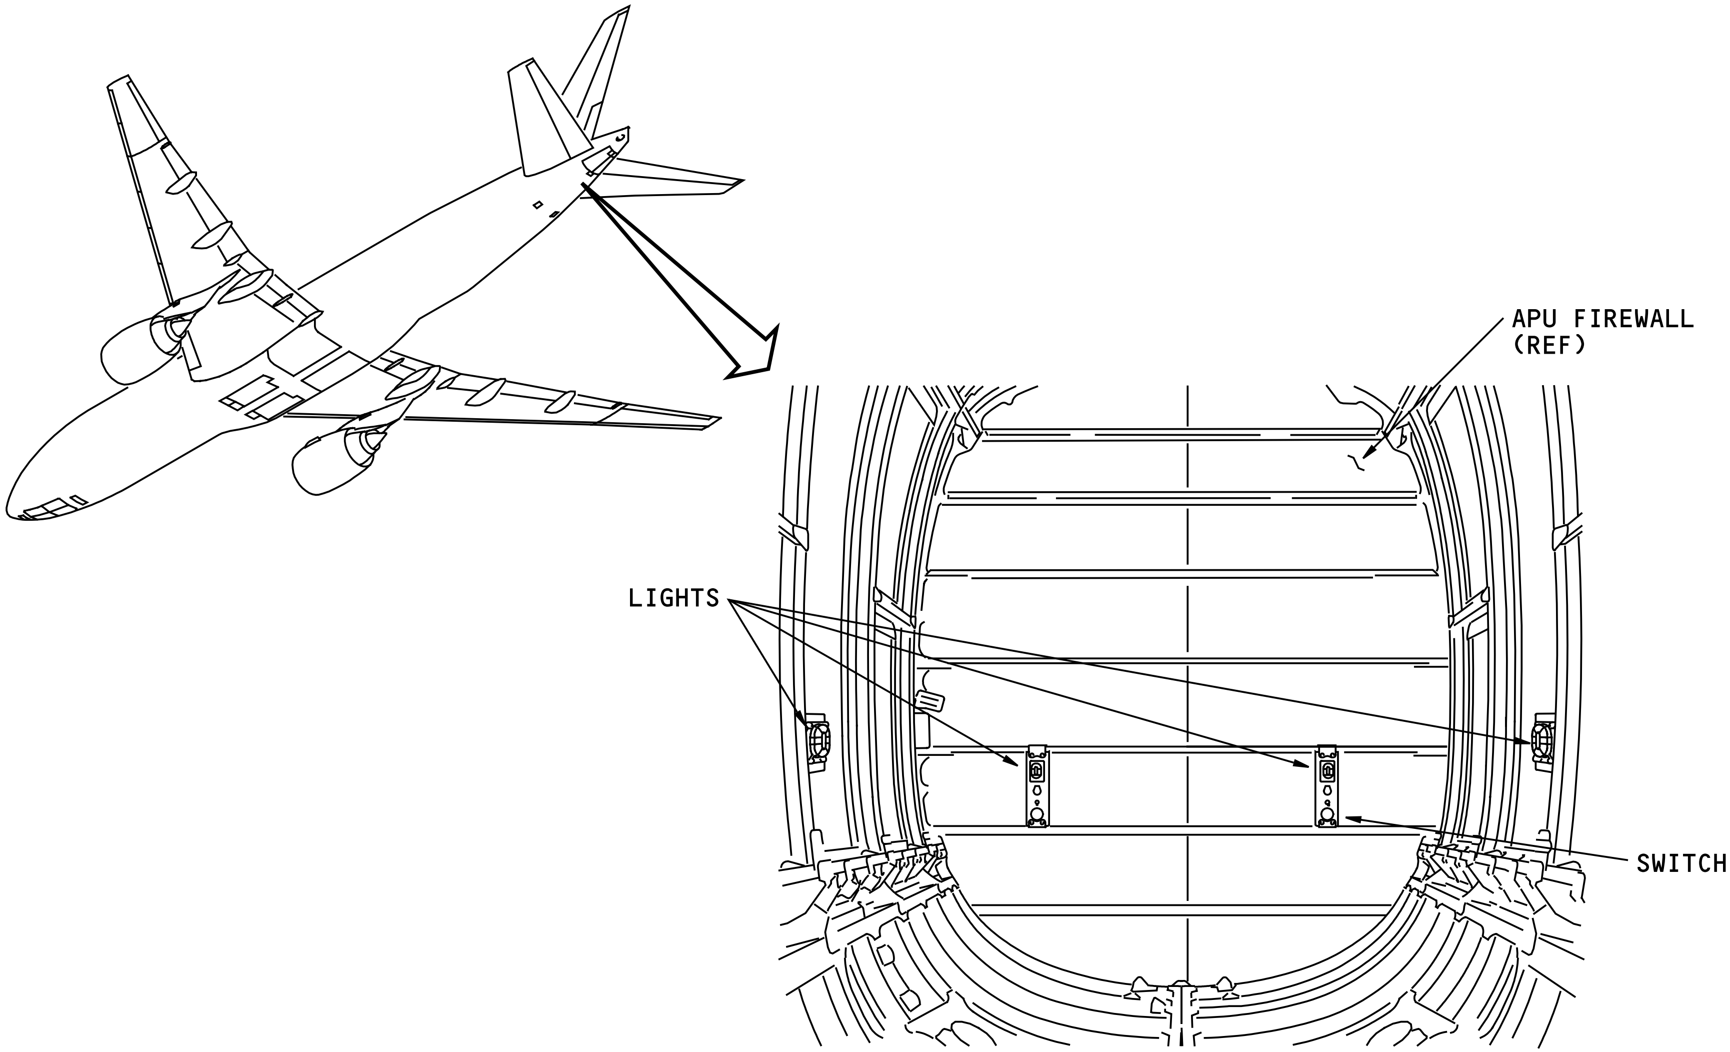
SERVICE AND CARGO LOADING LIGHTS - APU COMPARTMENT LOCATIONS

APU Compartment Lights

There are four lights in the APU compartment. There are two lights on the forward APU fire wall and two lights on the side walls.

APU Compartment Lights Switch

The switch for the APU compartments lights is under the right light on the fire wall.



APU COMPARTMENT
(APU REMOVED, LOOKING FORWARD)

SERVICE AND CARGO LOADING LIGHTS - APU COMPARTMENT LOCATIONS

33-31-00-008 Rev 1 04/10/1997

SERVICE AND CARGO LOADING LIGHTS - CARGO LOADING LIGHTS - INTRODUCTION

Purpose

The cargo loading lights give light near the cargo compartment loading areas to help the ground crew.

Location

There are 12 cargo loading lights. Four lights are body-mounted and eight are cargo door-mounted. The forward and aft cargo doors each have four door-mounted lights.

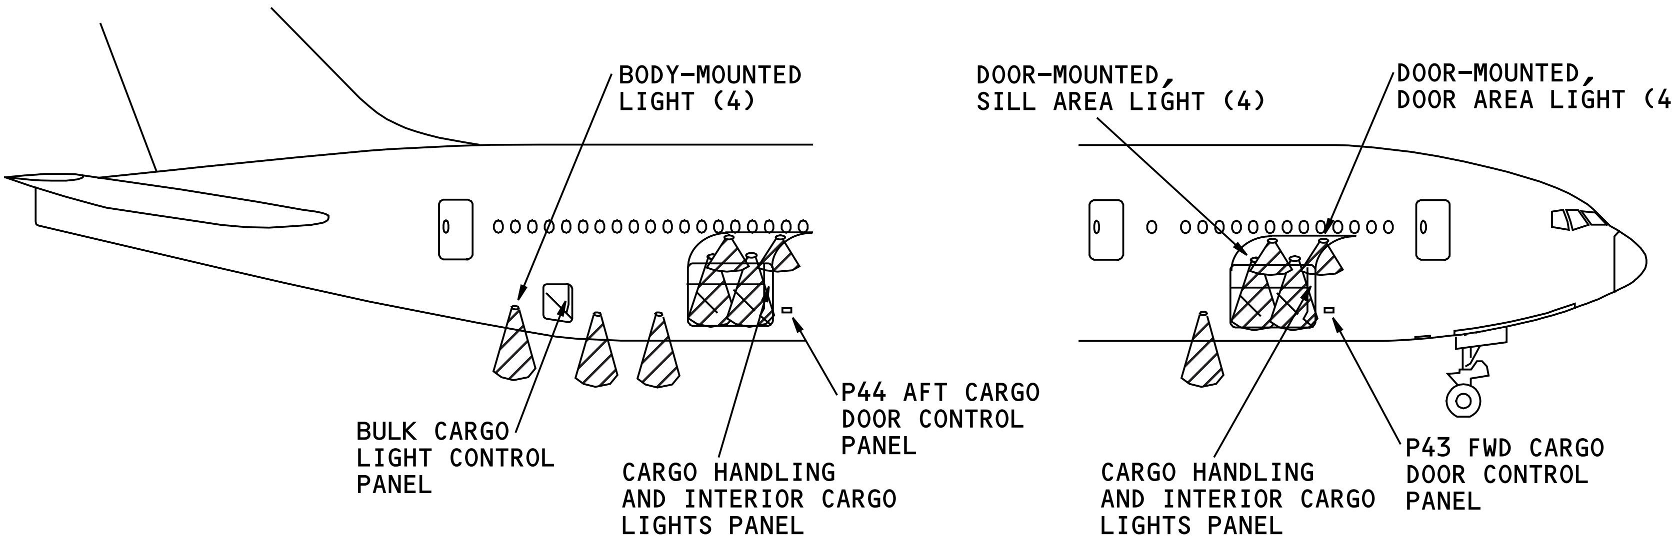
General Description

The cargo loading lights get power from the ground handling bus.

You use control switches near the cargo doors to operate the cargo Loading lights.

Some door-mounted lights automatically come on when you open the access door between the forward cargo compartment and the MEC.

Door-mounted lights operate only if the cargo door is full open.



33-31-00-018 Rev 0 02/12/96

SERVICE AND CARGO LOADING LIGHTS - CARGO LOADING LIGHTS - INTRODUCTION

SERVICE AND CARGO LOADING LIGHTS - CARGO LIGHTS TRANSFORMER - LOCATION

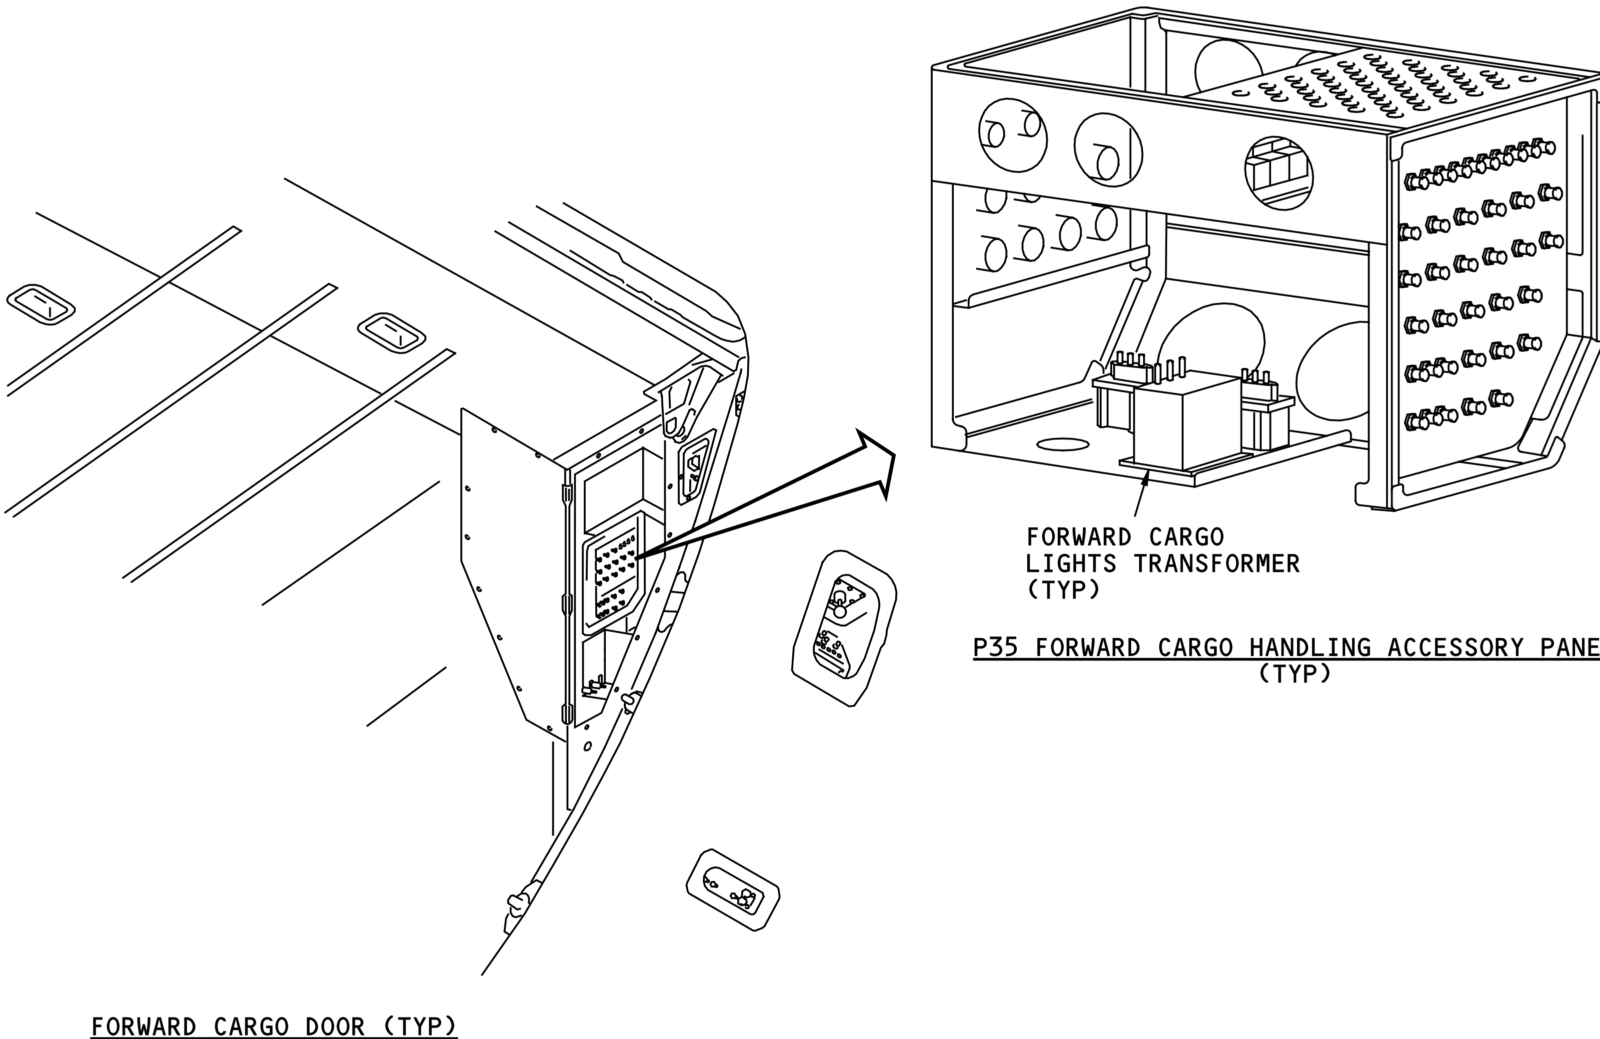
Purpose

The forward and aft cargo compartment light transformers decrease the amount of power that go to these lights:

- Interior cargo lights
- Exterior cargo lights
- ECS bay lights
- Door lights
- Sill lights.

Location

The forward transformer is in the P35 forward cargo handling accessory panel. The aft transformer is in the P39 aft cargo handling accessory panel.



33-31-00-015 Rev 0

SERVICE AND CARGO LOADING LIGHTS - CARGO LIGHTS TRANSFORMER - LOCATION

SERVICE AND CARGO LOADING LIGHTS - CARGO LOADING LIGHTS - OPERATION

General

The cargo loading lights get power from the ground handling bus. Door-mounted cargo loading lights (door and sill area) operate only when the related door is full open and a related control switch is on.

External - Cargo Loading Area Lighting

You use EXTERNAL (EXTERIOR) cargo light control switches to operate the body-mounted and the door-mounted door area lights. There is one switch for each of the cargo compartment loading areas. The switches operate only the lights in the related area. The switches are in these areas:

- Forward cargo area uses the switch on the P43
- Aft cargo area uses the switch on the P44
- Bulk cargo area uses the switch on the bulk cargo light control panel (forward of the door, in the compartment).

Internal - Cargo Door Sill Area Lighting

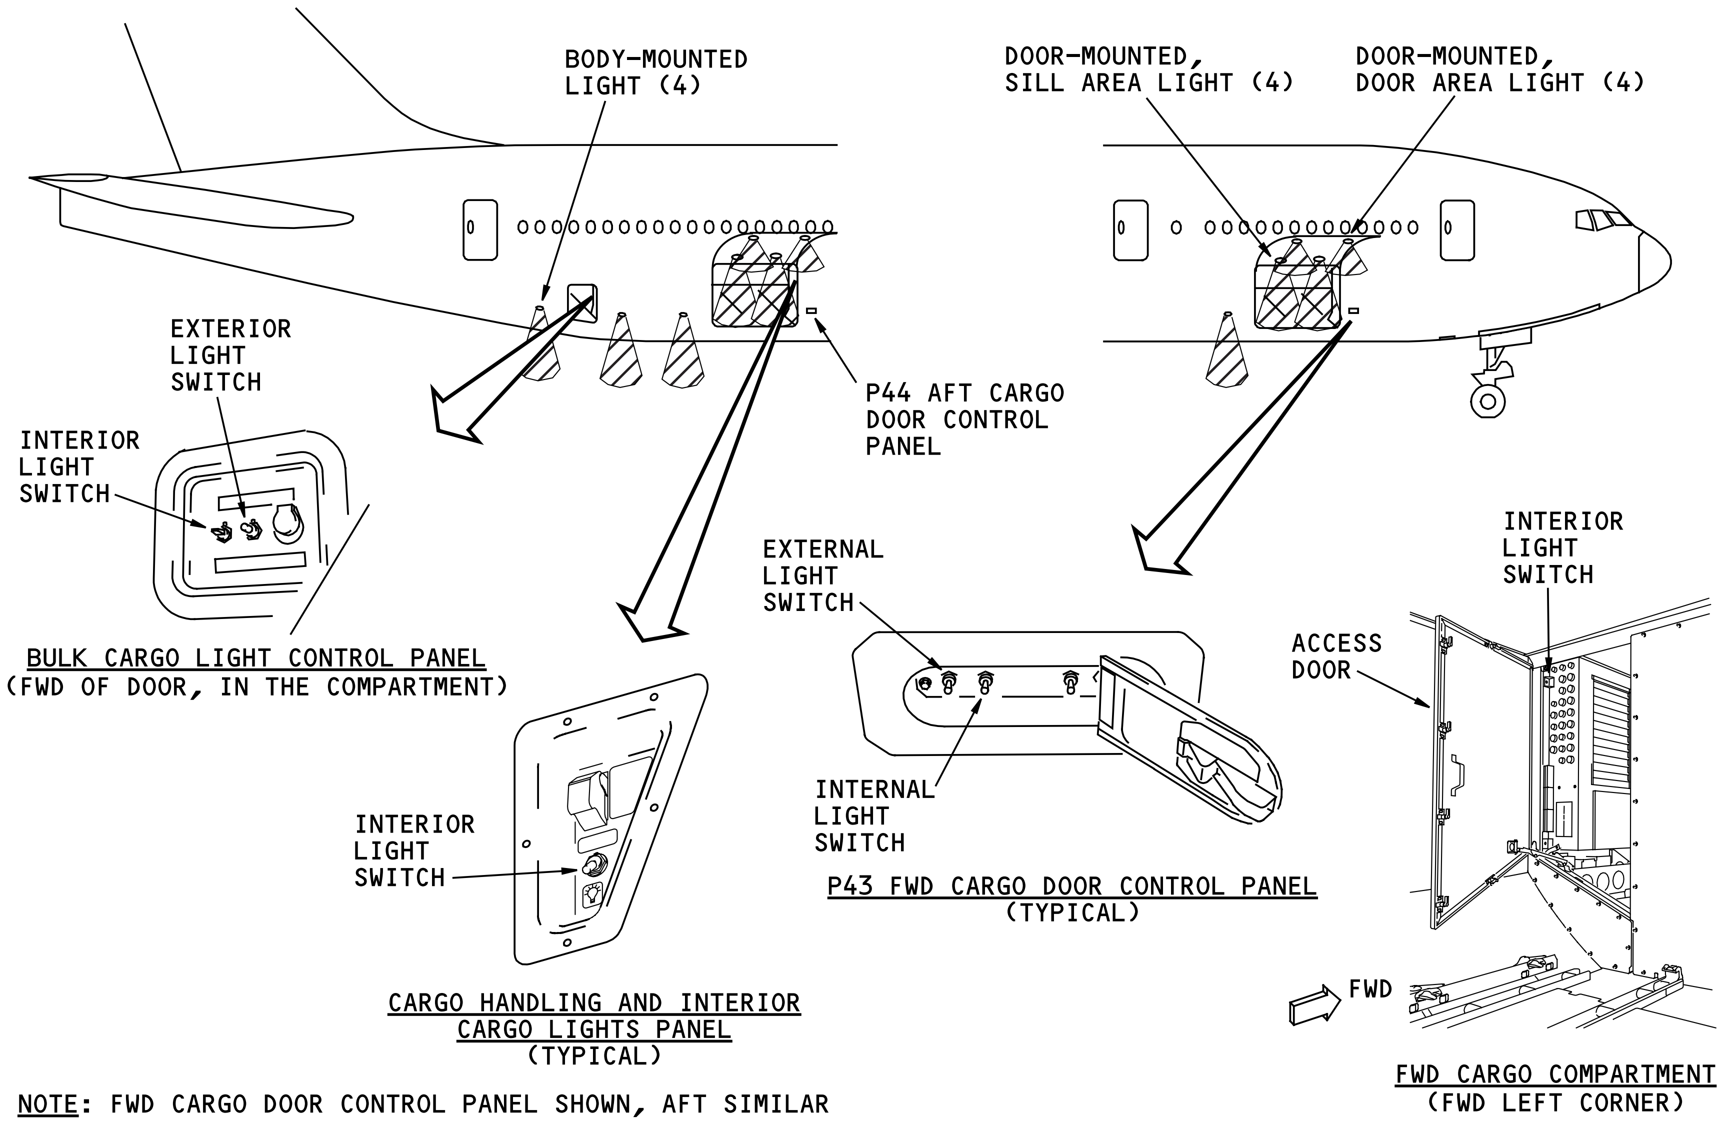
You use INTERNAL (INTERIOR) cargo light control switches to operate the door-mounted, door sill area lights. For internal lighting, the aft and bulk cargo compartment areas are one area. The forward and aft cargo areas have three switches. The switches for the forward cargo area are in these areas:

- P43
- Cargo handling and interior cargo lights panel (forward of the door, inside the compartment)
- A switch that is near the main equipment center/ cargo compartment access door

The switches for the aft cargo area are in these areas:

- P44
- Cargo handling and interior cargo lights panel (forward of the aft cargo door, in the compartment)
- Bulk cargo light control panel (forward of bulk cargo door, in the compartment).

See the lower lobe cargo compartment lights section for more information about the cargo lights (AMM PART I 33-37).



NOTE: FWD CARGO DOOR CONTROL PANEL SHOWN, AFT SIMILAR

SERVICE AND CARGO LOADING LIGHTS - CARGO LOADING LIGHTS - OPERATION

LOWER LOBE CARGO COMPARTMENT LIGHTS - INTRODUCTION

Purpose

The lower lobe cargo compartment lights give light in the forward, aft, and bulk cargo compartments.

Location

The lights are in the ceiling of the cargo compartments and in the sidewall near the bulk cargo door (not shown). There are light switches in these locations:

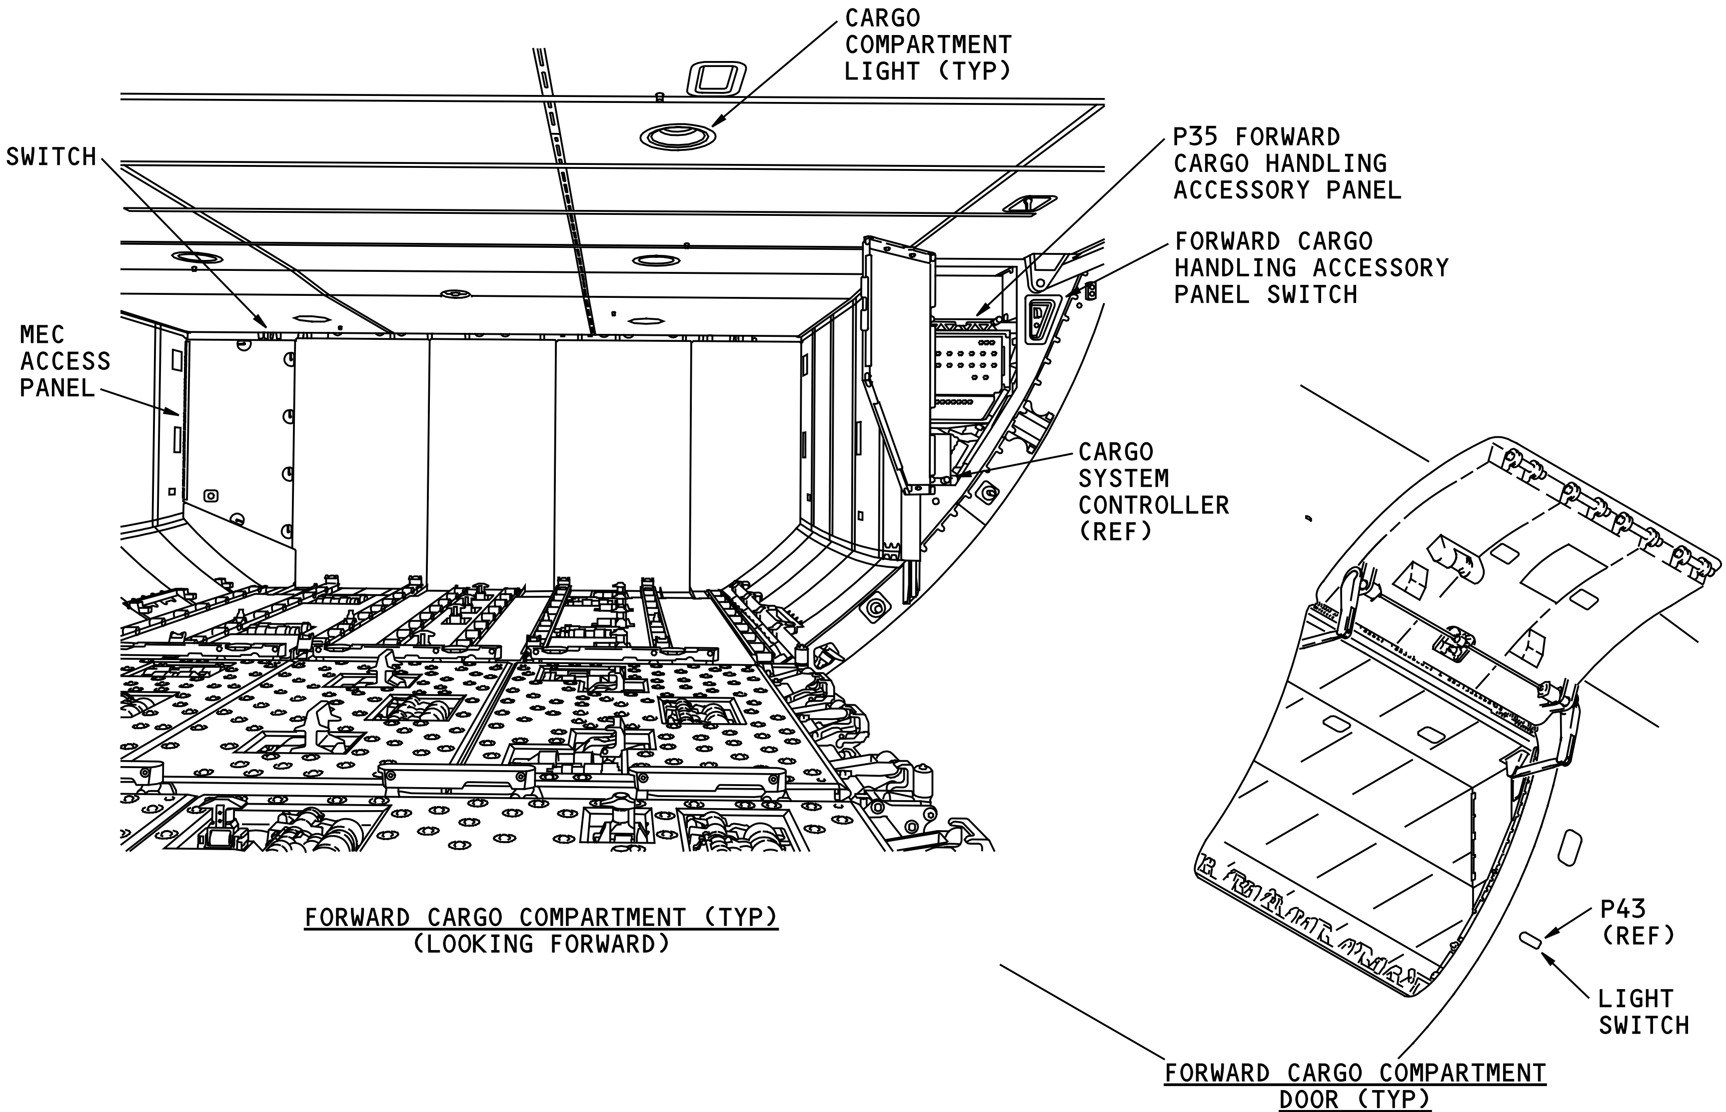
- On the exterior door control panels
- Near the door in the interior of the compartments
- Near the access panel to the main equipment center (MEC).

There are relays and transformers in the P35 and P39 forward and aft cargo handling accessory panels.

See the service and cargo loading lights section for more information about the relays and transformers (AMM PART I 33-31).

Interface

The cargo lights use information from a proximity sensor electronics unit (PSEU). Power for the lights comes from the cargo system controllers.



33-37-00-001 Rev 2

LOWER LOBE CARGO COMPARTMENT LIGHTS - INTRODUCTION

LOWER LOBE CARGO COMPARTMENT LIGHTS - COMPARTMENT LIGHTS

Location

The lights are in the ceiling of the forward, aft, and bulk cargo compartments. There is also a light near the forward edge of the bulk cargo compartment door.

Physical Description

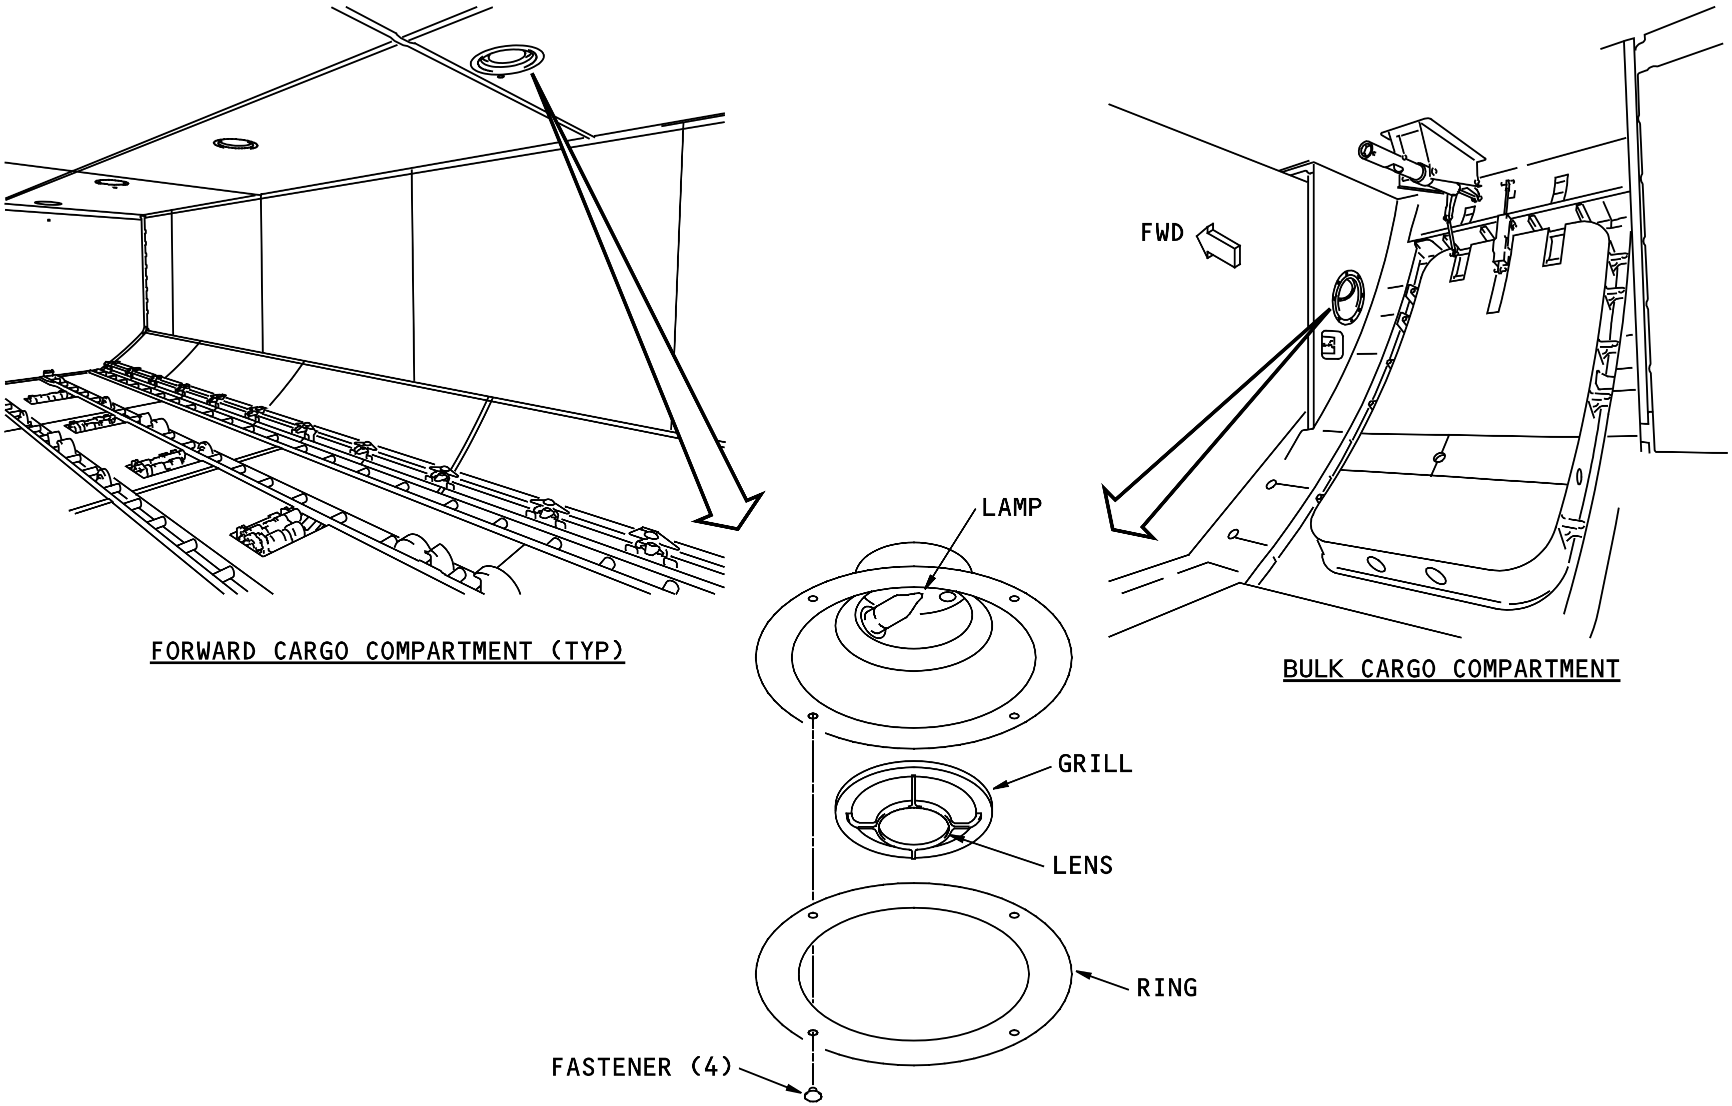
Each light has a:

- Lamp
- Grill
- Lens
- Ring
- Fastener (4)
- Micro switch (not shown).

Training Information Point

All of the lights in the ceiling of the cargo compartments are the same. To get access to the lamp you pull out the grill. There is a lanyard that holds the grill.

The light will not operate if the grill is not in position.



33-37-00-002 Rev 0

LOWER LOBE CARGO COMPARTMENT LIGHTS - COMPARTMENT LIGHTS

EXTERIOR LIGHTS - INTRODUCTION

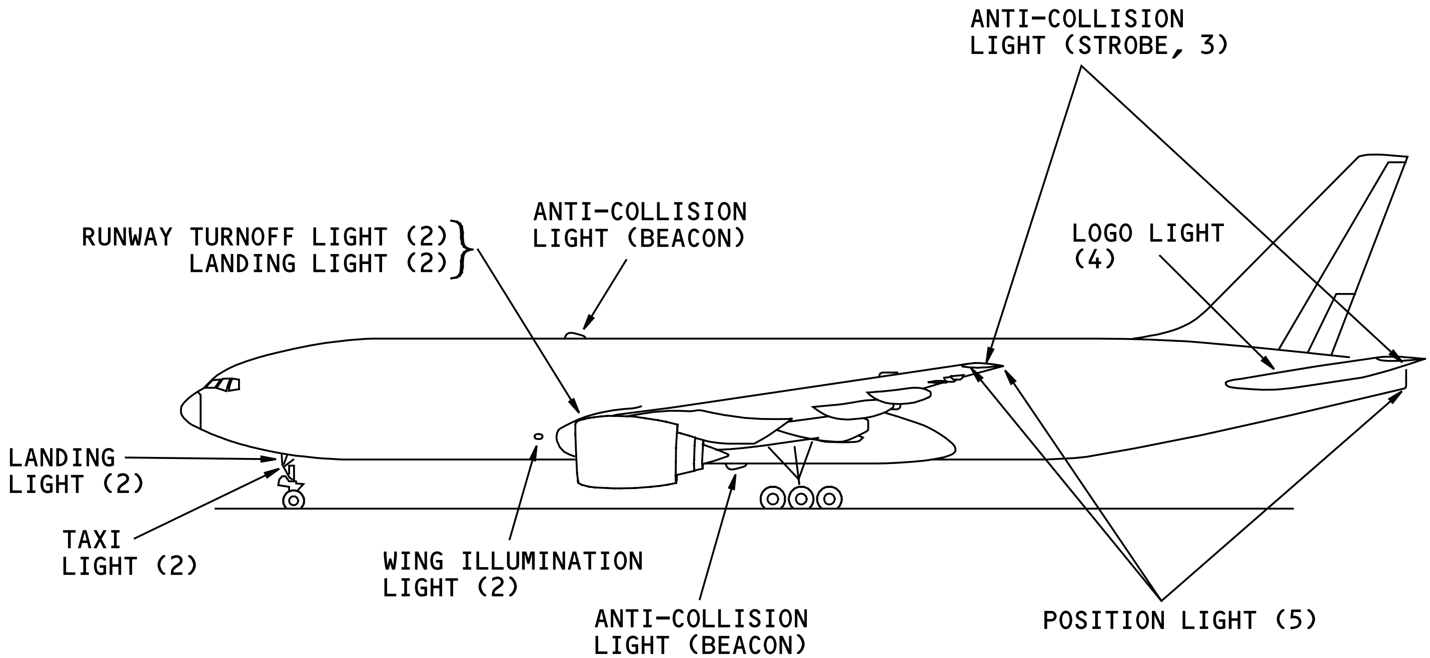
Purpose

The exterior lights give light to make the airplane more visible and to aid in safe operation of the airplane.

Location

These lights make up the exterior lights:

- Runway turnoff (2)
- Landing (4)
- Anti-collision (beacon) (2)
- Position (5)
- Logo (4)
- Anti-collision (strobe) (3)
- Wing illumination (2)
- Taxi (2).



33-40-00-001 Rev 2 04/30/1997

EXTERIOR LIGHTS - INTRODUCTION

WING ILLUMINATION LIGHTS - INTRODUCTION

Purpose

The wing illumination lights give light on the leading edge of the wings and the front of the nacelles. This lets the crew to see if there is ice on the leading edge.

The transformers decrease the amount of voltage that goes to the lights.

Location

The lights are on the right and left sides of the airplane, forward of where the wing connects to the fuselage.

The transformers are behind the sidewall panels in the forward cargo compartment. There is one transformer on each side.

Physical Description

The light has these components:

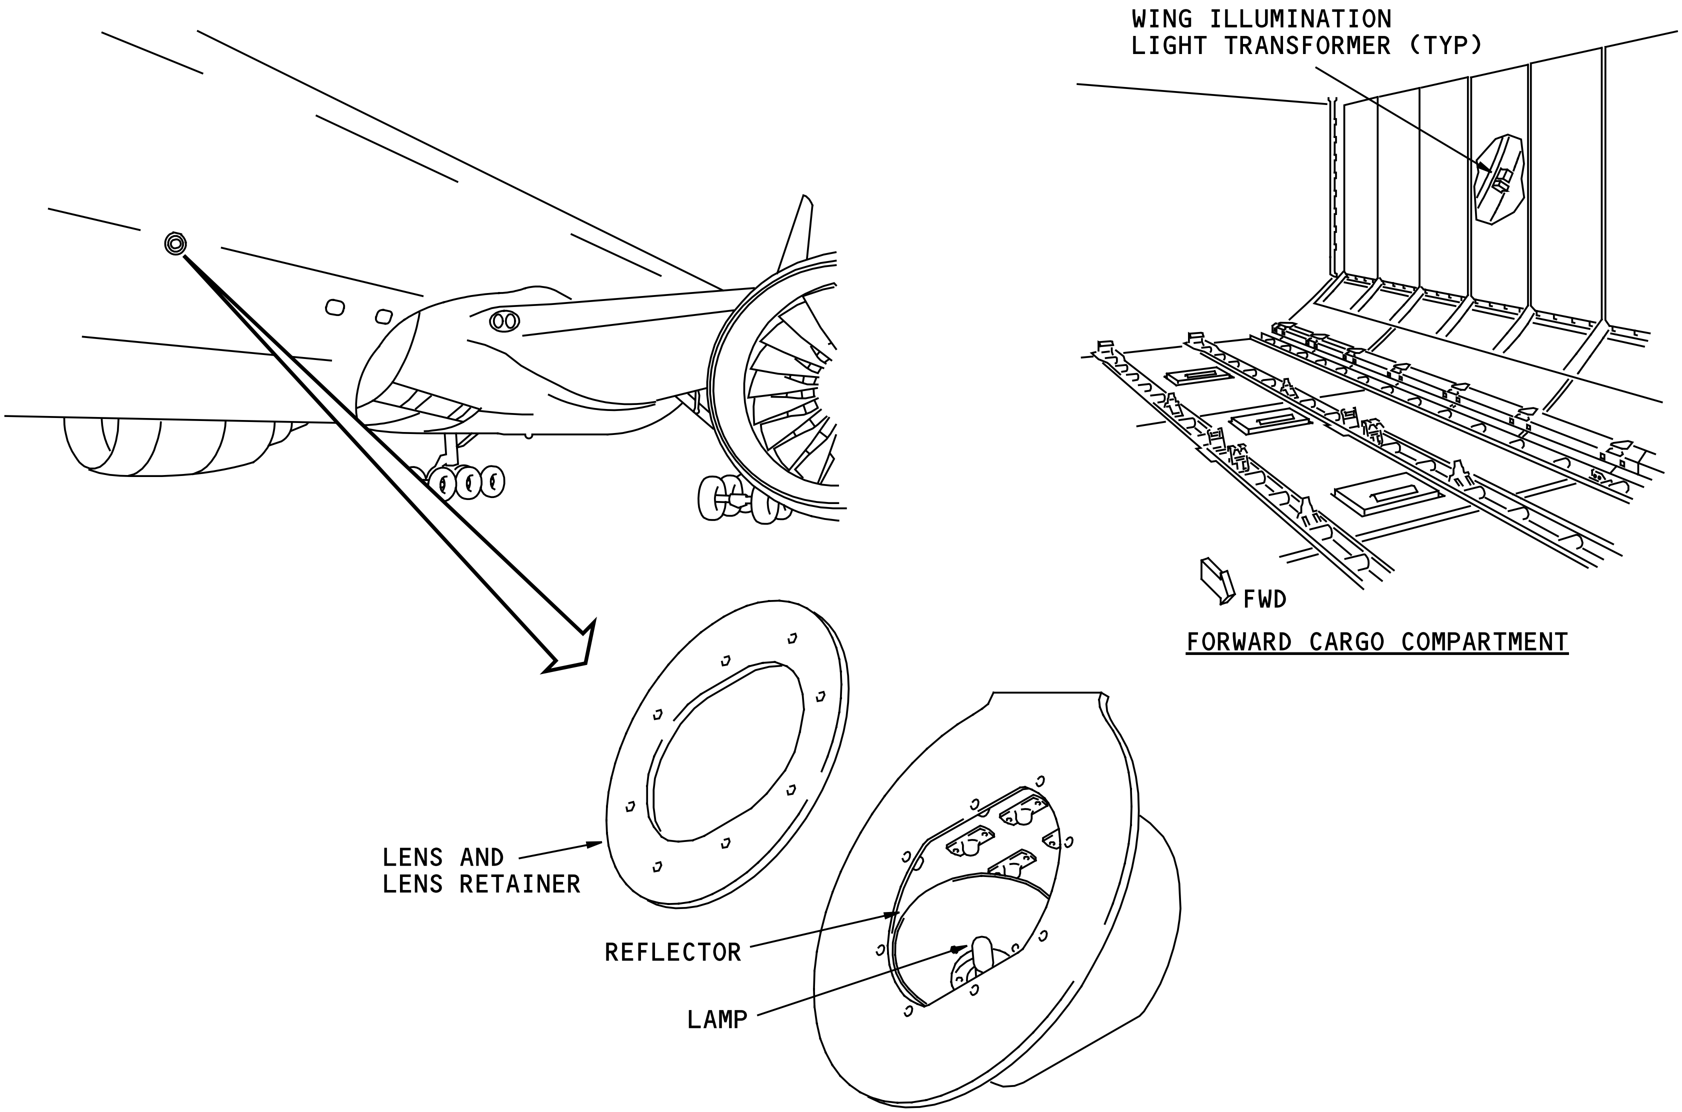
- Lens
- Lens retainer
- Lamp
- Reflector.

There are six captive screws that hold the lens retainer. There are two captive screws that hold the reflector.

Training Information Point

You replace the wing illumination light from outside the airplane.

You remove panels on the sidewalls of the forward cargo compartment to get access to the transformers.

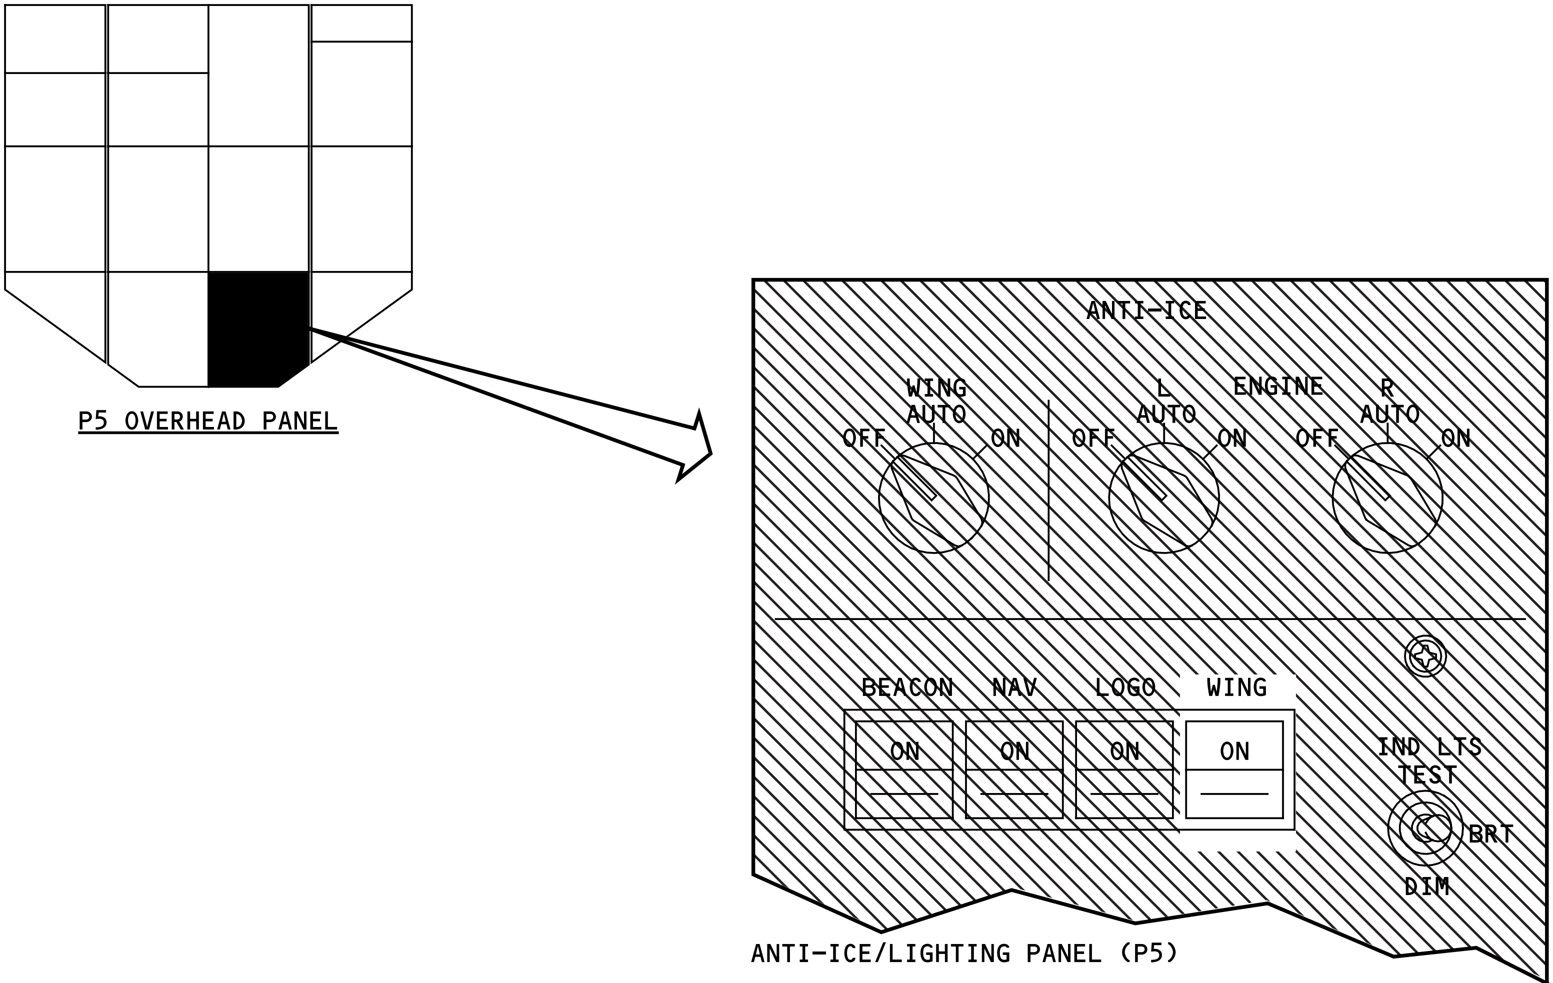


WING ILLUMINATION LIGHTS - INTRODUCTION

WING ILLUMINATION LIGHTS - OPERATION

Operation

You use the wing light switch (WING) to operate the wing illumination lights. It is on the anti-ice/ lighting panel on the P5 overhead panel. It is an alternate action switch.



ANTI-ICE/LIGHTING PANEL (P5)

33-41-00-002 Rev 1 08/09/96

WING ILLUMINATION LIGHTS - OPERATION

LANDING, RUNWAY TURNOFF, AND TAXI LIGHTS - INTRODUCTION

Purpose

The nose gear landing lights and the wing landing lights give light to the runway for takeoff and landing.

The runway turnoff lights give light to the side of the airplane so the crew can see the runway and taxiway turnoffs.

The taxi lights give light in front of the airplane for taxiing.

Transformers (not shown) decrease the voltage that goes to the lights.

Location

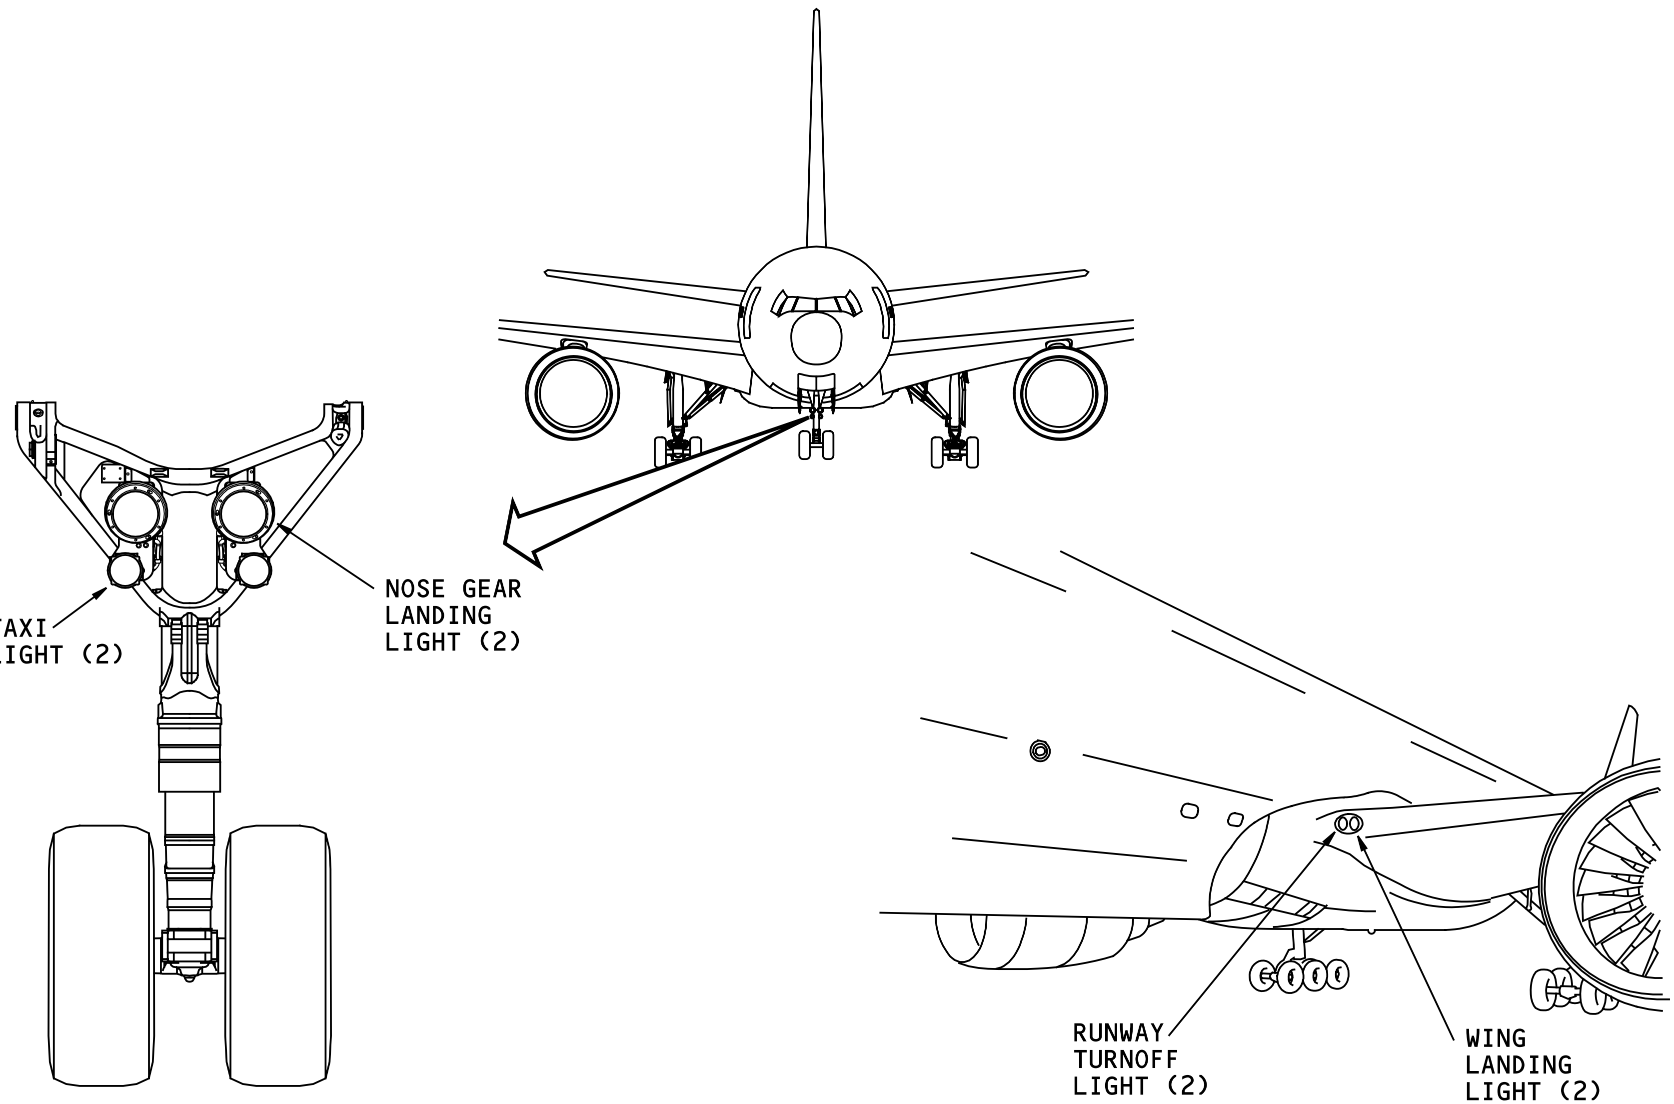
The nose gear landing lights and the taxi lights are on the front of the nose gear.

The wing landing lights and runway turnoff lights are on the left and right side of the fuselage. They are on the wing-to-body fairing.

There are transformers on the nose landing gear and in the forward cargo compartment.

Interface

The proximity sensor electronic (PSEU) unit gives information to control the level of light that comes from the landing lights.



LANDING, RUNWAY TURNOFF, AND TAXI LIGHTS - INTRODUCTION

LANDING, RUNWAY TURNOFF, AND TAXI LIGHTS - NOSE GEAR LANDING LIGHTS

Purpose

The nose gear landing lights give light to runways and taxiways when the airplane is on the ground.

Location

The nose gear landing lights are on the front of the nose gear. They are above the taxi lights. There is one light on each side of the nose gear strut.

Physical Description

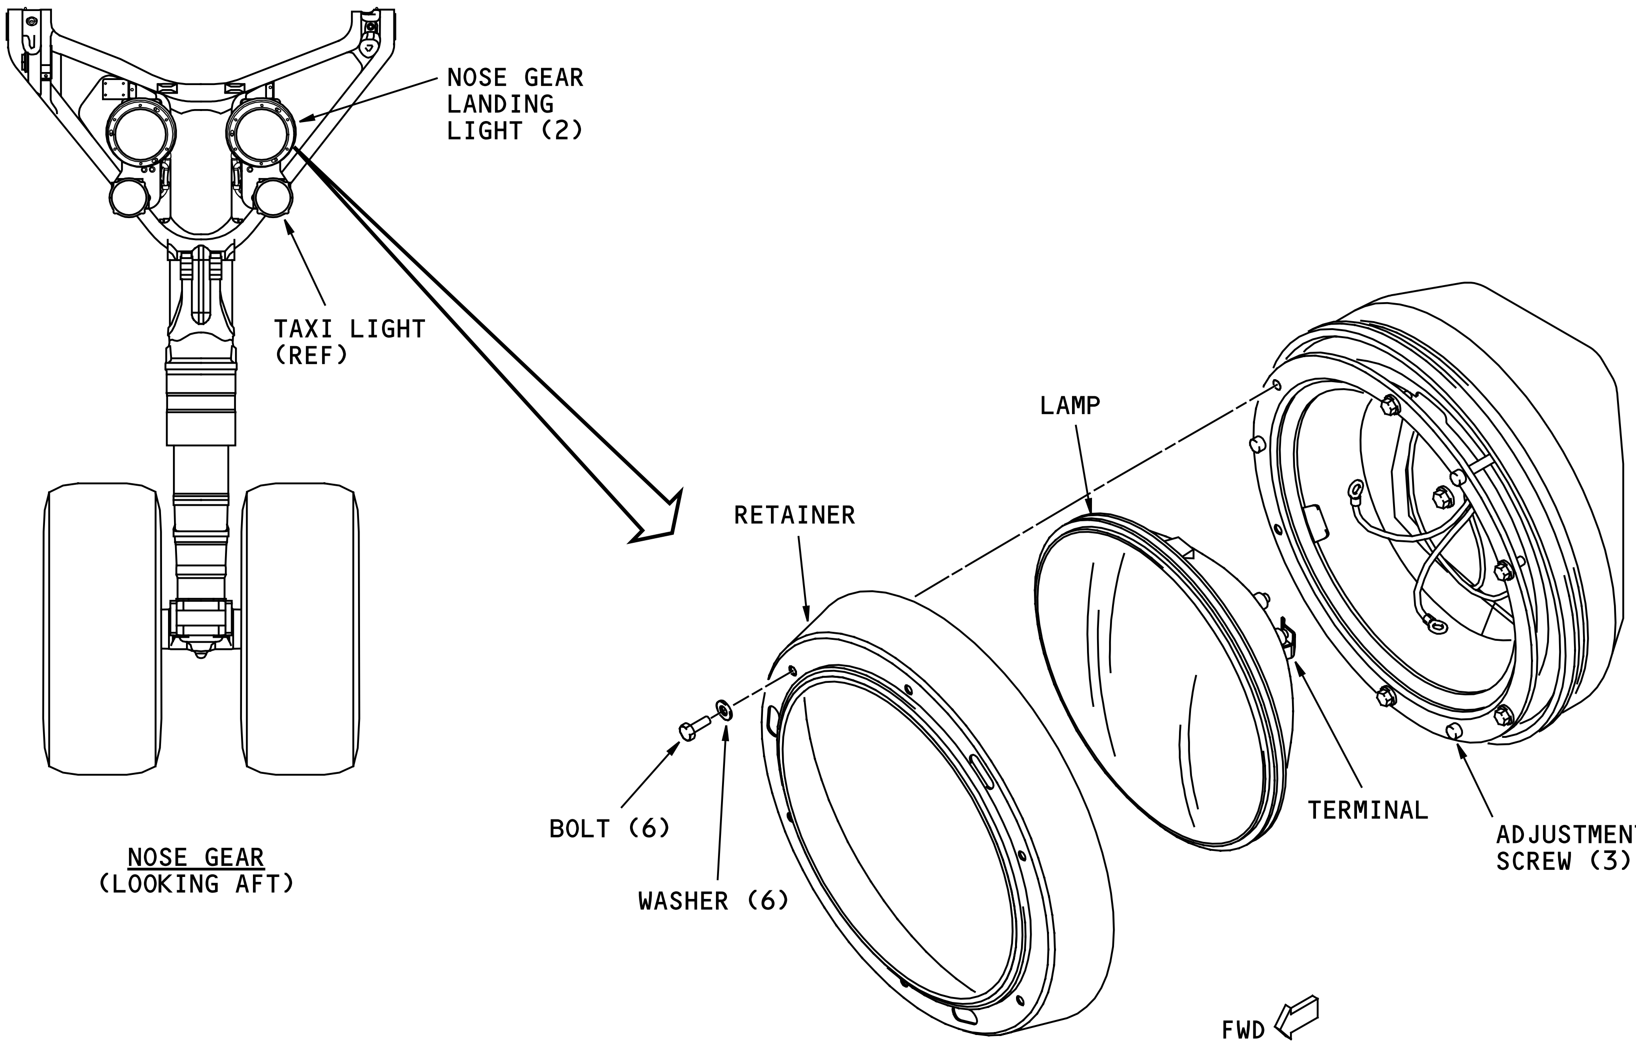
The nose gear landing lights have these components:

- Retainer
- Lamp
- Adjustment screw (3)
- Terminal.

Training Information Point

There are six bolts that hold the lamp. You remove these bolts to get access to the lamp. There are three adjustment screws that you use to point the lamp.

There is a gasket that is part of the retainer.



33-42-00-002 Rev 1

LANDING, RUNWAY TURNOFF, AND TAXI LIGHTS - NOSE GEAR LANDING LIGHTS

LANDING, RUNWAY TURNOFF, AND TAXI LIGHTS - WING LANDING LIGHTS

Purpose

The wing landing lights give light in front of the airplane. They give light to the runway when the airplane is landing. They also give light in front of the airplane when it is taking off.

Location

The lights are on the front edge of each wing-to-body fairing.

Physical Description

The wing landing lights have these components:

- Retainer
- Lamp
- Terminal.

Training Information Point

You remove the lens assembly to get access to the wing landing light. There are six screws that hold the lamp.

You use the three adjustment screws to point the light.

There is a gasket that is part of the retainer.

LANDING, RUNWAY TURNOFF, AND TAXI LIGHTS - TAXI LIGHTS

LANDING, RUNWAY TURNOFF, AND TAXI LIGHTS - TRANSFORMERS

Purpose

The transformers decrease the voltage that goes to the lights.

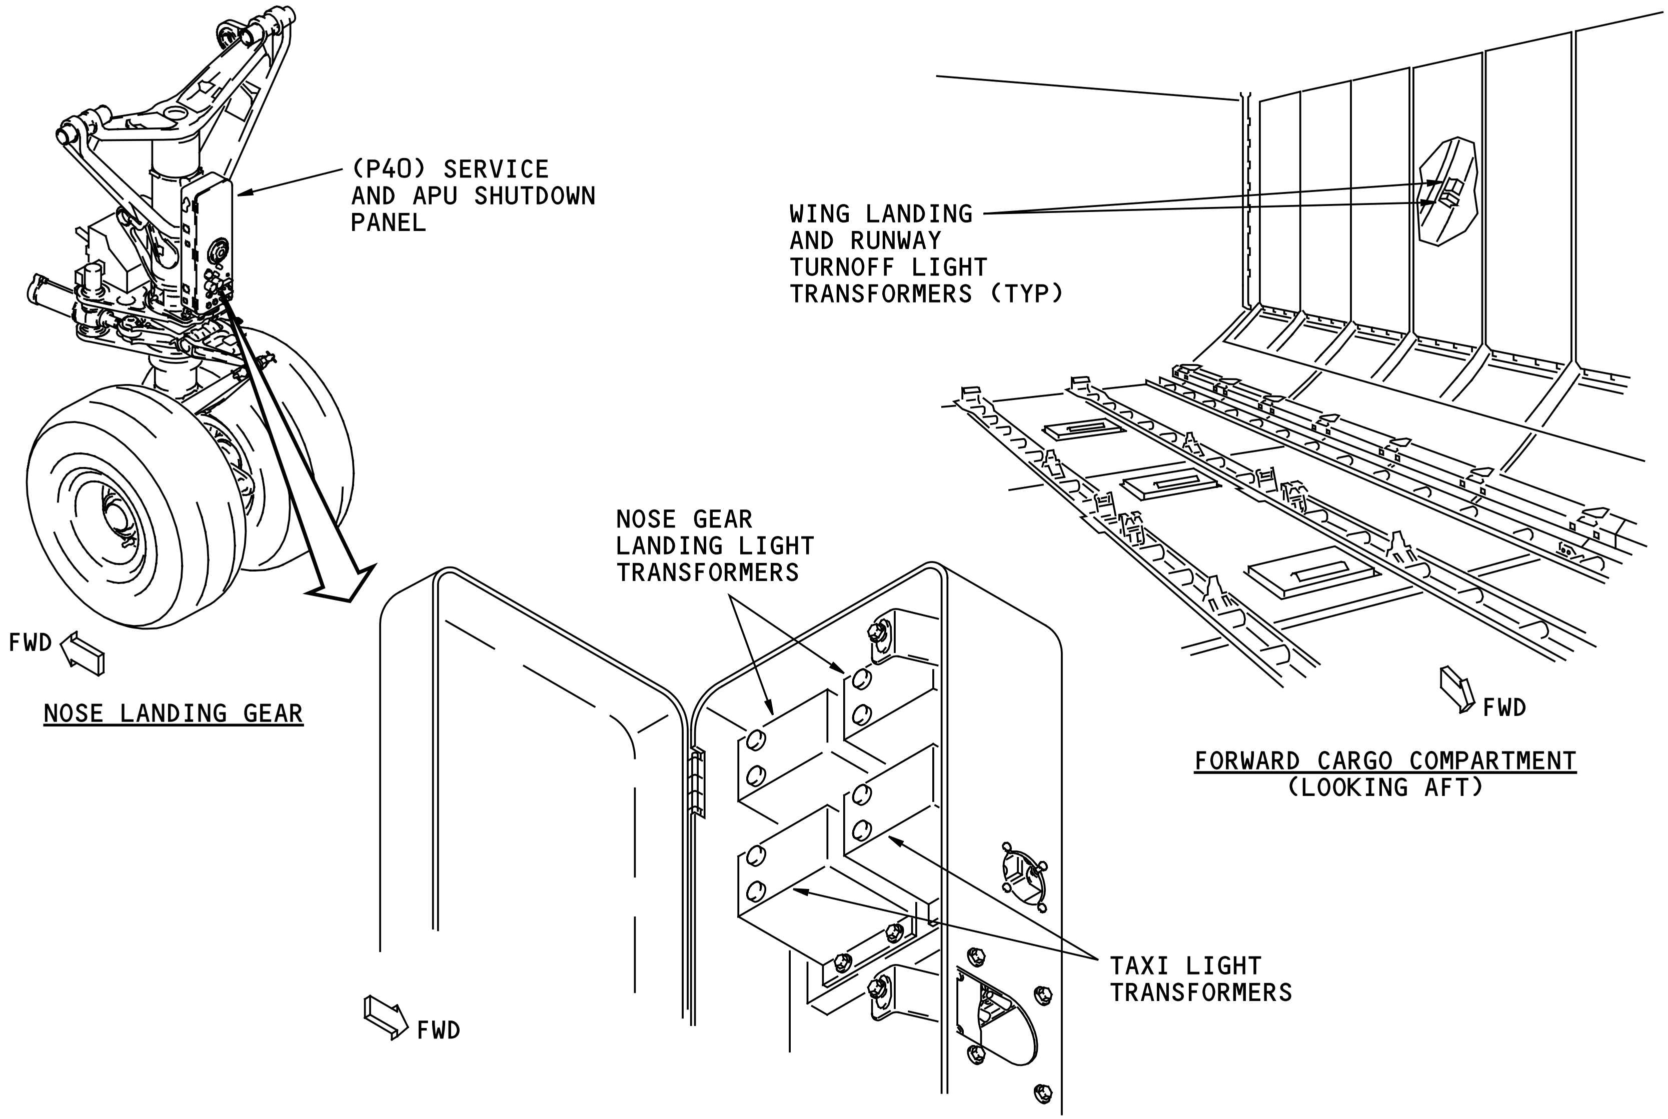
Location

The transformers for the nose gear landing lights and the taxi lights are in the P40 service and APU shutdown panel. The panel is on the nose landing gear.

The transformers for the wing landing lights and the runway turnoff lights are outboard of the left and right sidewall liners in the forward cargo compartment.

Physical Description

Each transformer attaches with four bolts and has two electrical connectors.



33-42-00-006 Rev 0

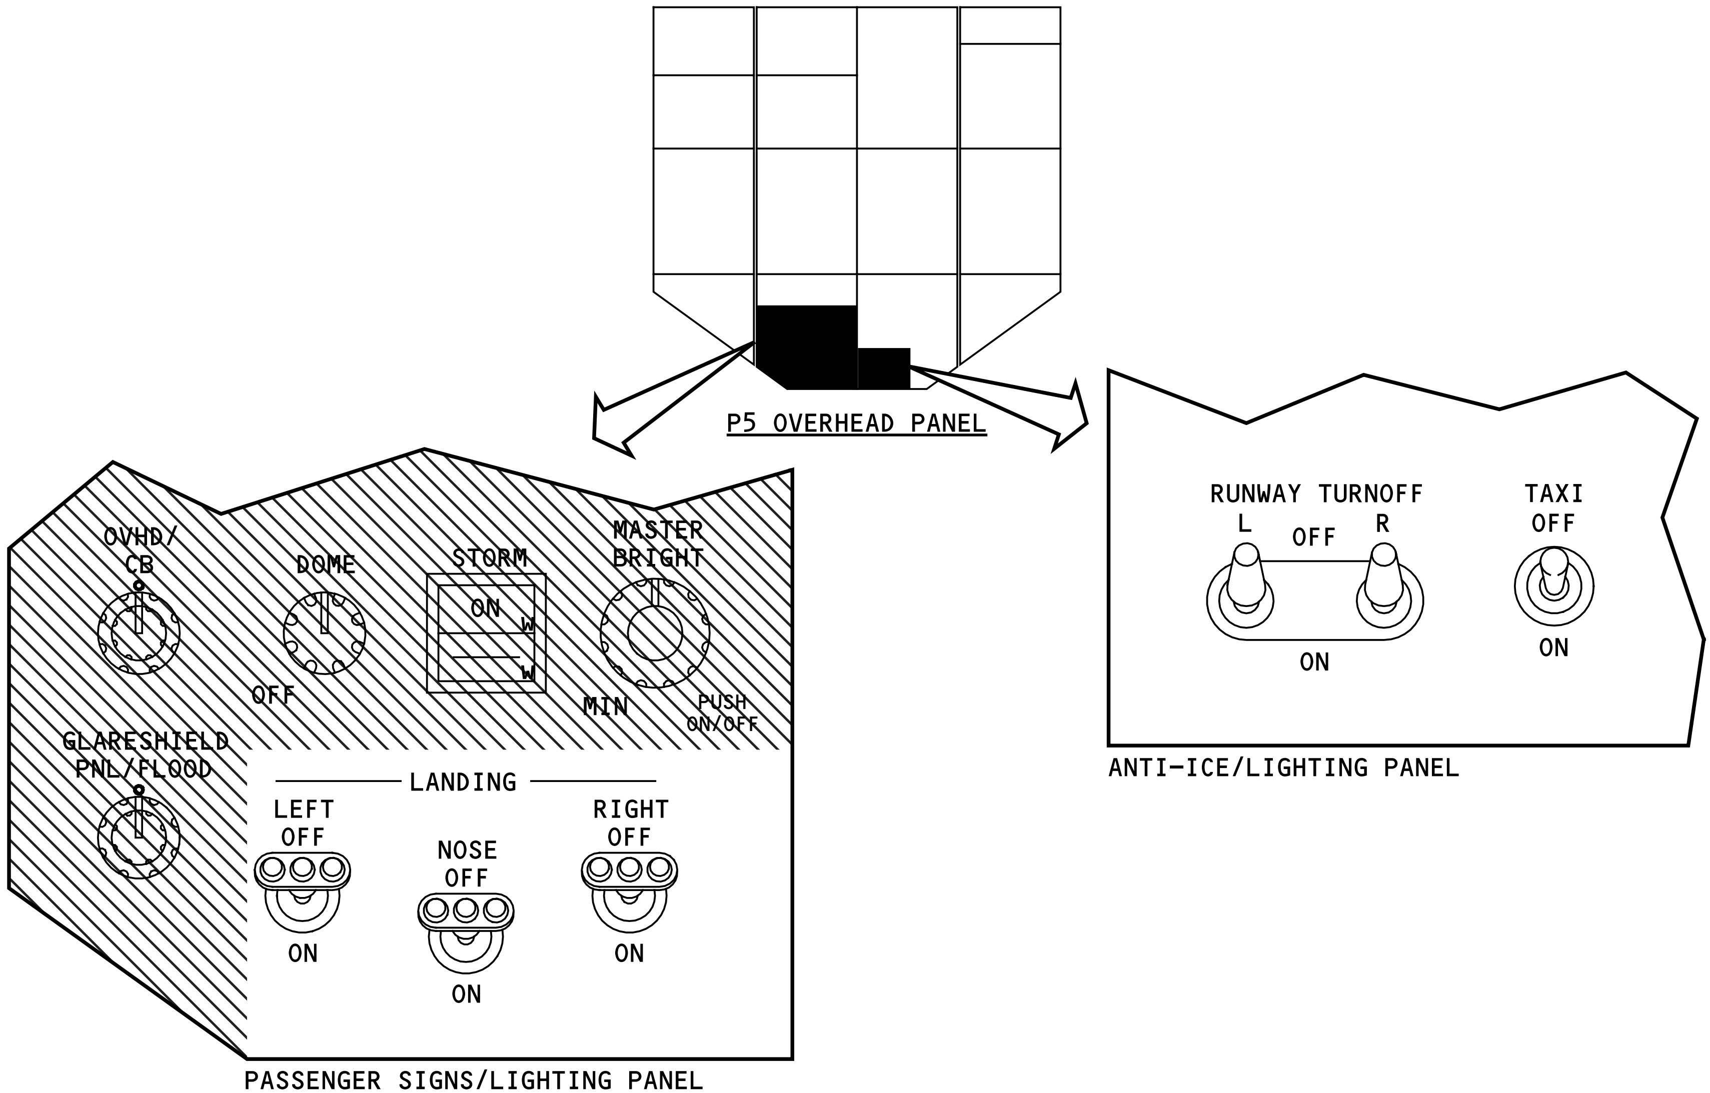
LANDING, RUNWAY TURNOFF, AND TAXI LIGHTS - TRANSFORMERS

LANDING, RUNWAY TURNOFF, AND TAXI LIGHTS - OPERATION

Operation

You use the left, nose, and right landing light switches (LEFT, NOSE, RIGHT LANDING) to operate the landing gear lights. These switches are on the passenger signs/lighting panel on the P5 overhead. The switches are the toggle-type.

You use the left and right runway turnoff light switches (L, R RUNWAY TURNOFF) to operate the runway turnoff lights. You use the taxi light switch (TAXI) to operate the taxi lights. These switches are on the anti-ice/lighting panel on the P5 overhead panel. The switches are the toggle-type.



33-42-00-007 Rev 1 08/21/96

LANDING, RUNWAY TURNOFF, AND TAXI LIGHTS - OPERATION

LANDING, RUNWAY TURNOFF, AND TAXI LIGHTS - LANDING LIGHTS - FUNCTIONAL DESCRIPTION

General

The LEFT, NOSE, and RIGHT landing lights switches give signals to the overhead panel ARINC systems (OPAS). These signals go to the electronic load management system (ELMS) electronics unit. There is an ELMS electronics unit in each power management panel.

The panel gets gear position data from the proximity sensor electronics unit (PSEU).

Wing Landing Lights

When the LEFT or RIGHT landing light switch is in the ON position, a control relay energizes. This makes the wing landing (WG LDG) light come on.

The lights have two modes, bright and dim. A bright/dim control relay energizes when the landing gear is down and locked. This makes the lights operate in the bright mode. When the relay is not energized the lights operate in the dim mode.

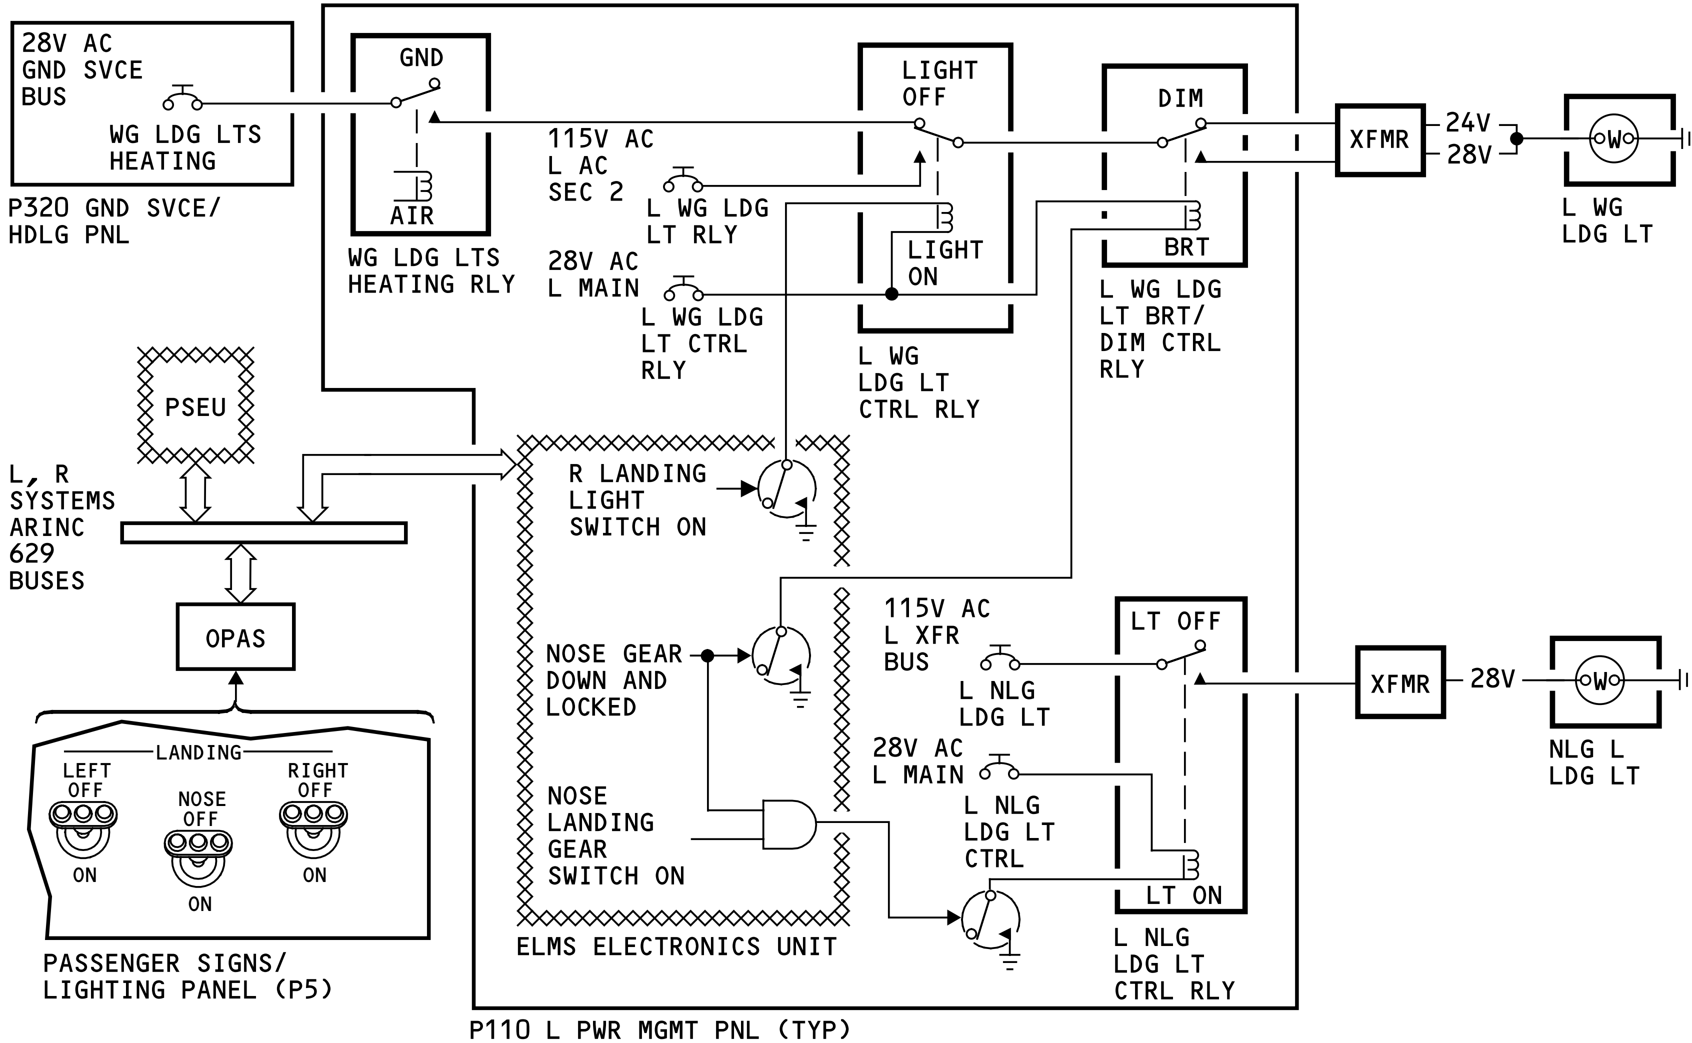
In the bright mode the transformer decreases the voltage to 28 V AC. In the dim mode it decreases the voltage to 24 V AC.

A small amount of power goes to the wing landing lights to prevent thermal shock when the lights comes on and to increase the life of the lights. The small amount of power goes to the lights when the:

- Airplane is in the air
- LEFT and RIGHT landing light switches are OFF
- Nose gear is not down and locked.

Nose Gear Landing Lights

When the NOSE landing light switch is in the ON position, a control relay energizes. This makes the nose landing gear (NLG) lights come on. A transformer decreases the voltage to 28 V AC.



NOTE: LEFT SYSTEM IS SHOWN. THE RIGHT SYSTEM IS SIMILAR.

33-42-00-008 Rev 1 08/21/96

LANDING, RUNWAY TURNOFF, AND TAXI LIGHTS - LANDING LIGHTS - FUNCTIONAL DESCRIPTION

POSITION LIGHTS - INTRODUCTION

Purpose

The position lights aid in collision avoidance.

The position light transformers (not shown) decrease the voltage that goes to the lights.

Physical Description

The position lights are red, green, or white.

Location

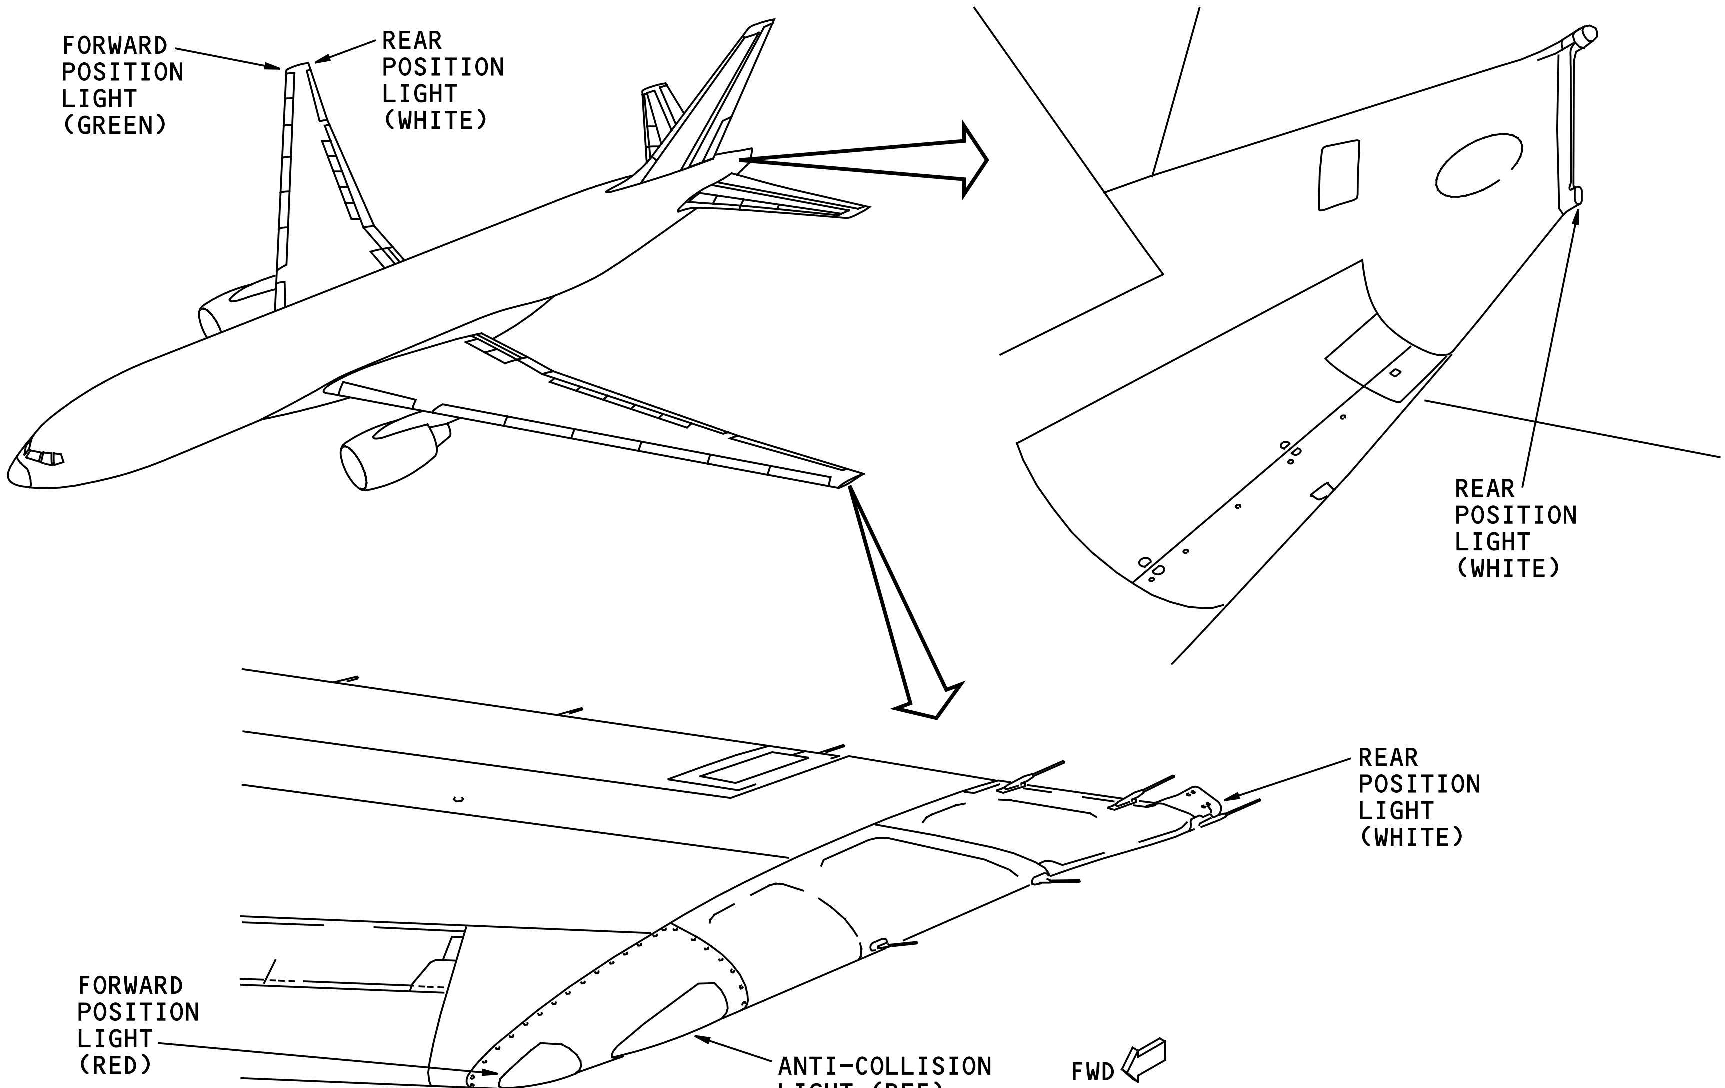
There are position lights on the forward and aft tips of each wing. There is a position light on the airplane tailcone.

The transformers are in the tip of each wing and in the airplane tailcone.

Training Information Point

CAUTION: DO NOT TOUCH THE LAMP WITH YOUR HANDS. FINGERPRINTS DECREASE LIGHT OUTPUT AND CAN CAUSE FAILURE OF THE LAMPS BEFORE THE USUAL TIME.

WARNING: REMOVE POWER AND ALLOW LAMPS TO COOL BEFORE YOU REPLACE THEM. IF YOU TOUCH THE LAMPS WHEN THEY ARE HOT, THEY CAN BREAK AND CAUSE INJURY TO PERSONS AND DAMAGE TO EQUIPMENT.



POSITION LIGHTS - INTRODUCTION

POSITION LIGHTS - WING POSITION LIGHTS

General

The wing position lights show the position, attitude, and direction of flight of the airplane. There are forward position lights and rear position lights.

Location

The forward position lights are on the wing tips, forward of the wing anti-collision light. There are two lamps in each light assembly.

The rear position lights are on the rear of the wing at the tip, aft of the wing anti-collision light. There are two lamps in each light assembly.

Physical Description

The left forward position light has a red lens. The right light has a green lens. The aft position lights have a clear lens, thus the light is white.

The forward and rear position lamps are two-prong-flange-type lamps.

Each forward position light assembly has these parts:

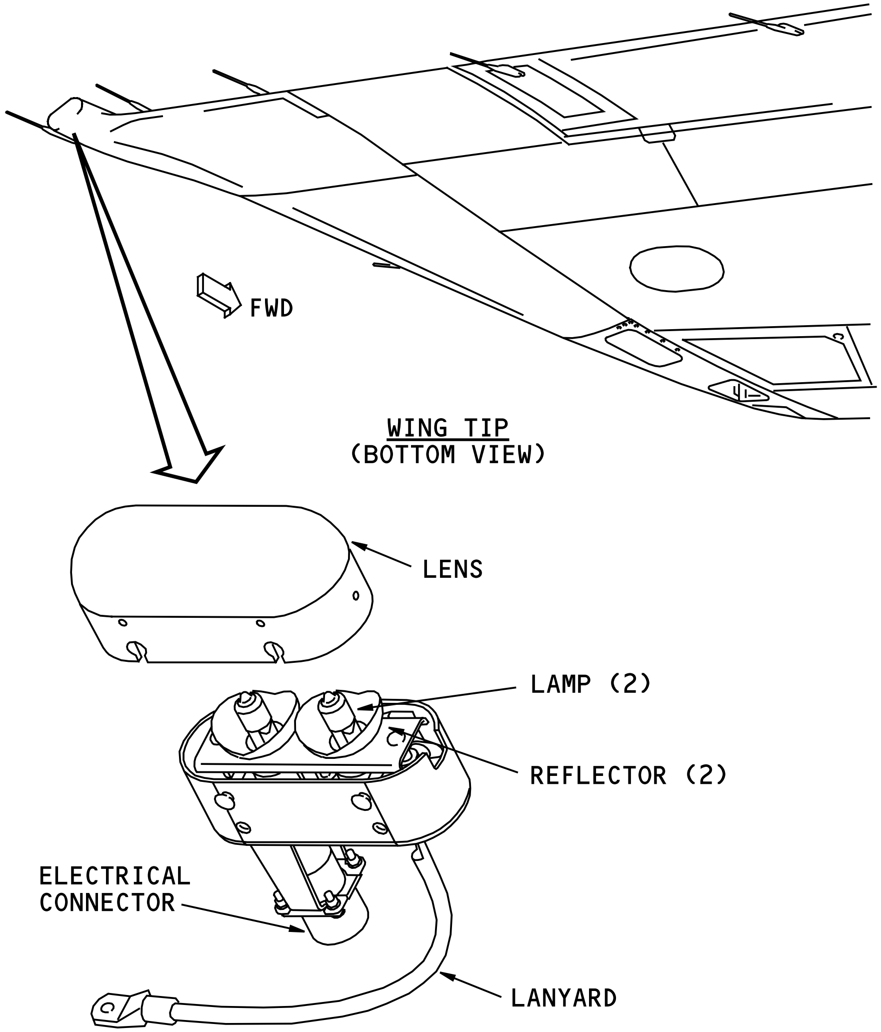
- Hinge bracket
- Reflector (2)
- Lamp (2)
- Lanyard (not shown)
- Electrical connector (not shown).

Each rear position light has these parts:

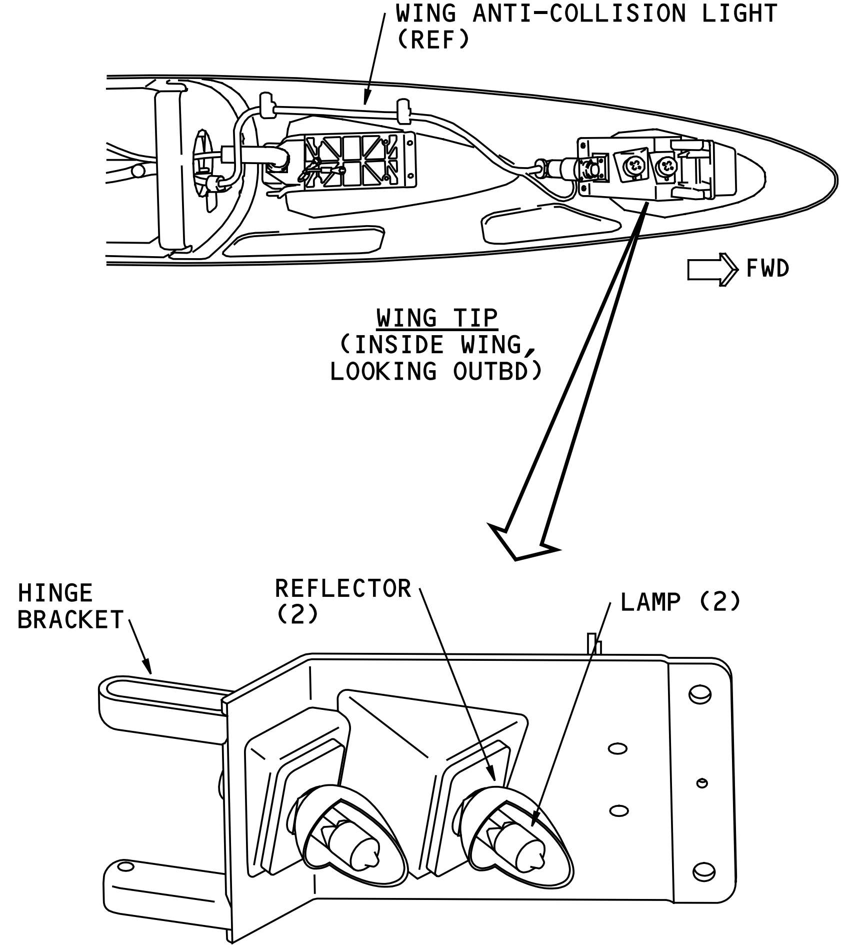
- Lens
- Lamp (2)
- Reflector (2)
- Lanyard
- Electrical connector.

Training Information Point

To get acces to the forward position lamps, loosen the captive screws to release the panel on the bottom side of the wing at the tip. Loosen two captive screws; rotate, and unhook the light assembly to get it out of the wing. The light assembly hangs by a lanyard. This gives you access to the lamps.



REAR POSITION LIGHT ASSEMBLY



FORWARD POSITION LIGHT ASSEMBLY

POSITION LIGHTS - WING POSITION LIGHTS

33-43-00-002 Rev 1 12/06/1996

POSITION LIGHTS - WING POSITION LIGHT TRANSFORMERS

Purpose

The position light transformers decrease the amount of voltage that goes to the position lights.

Location

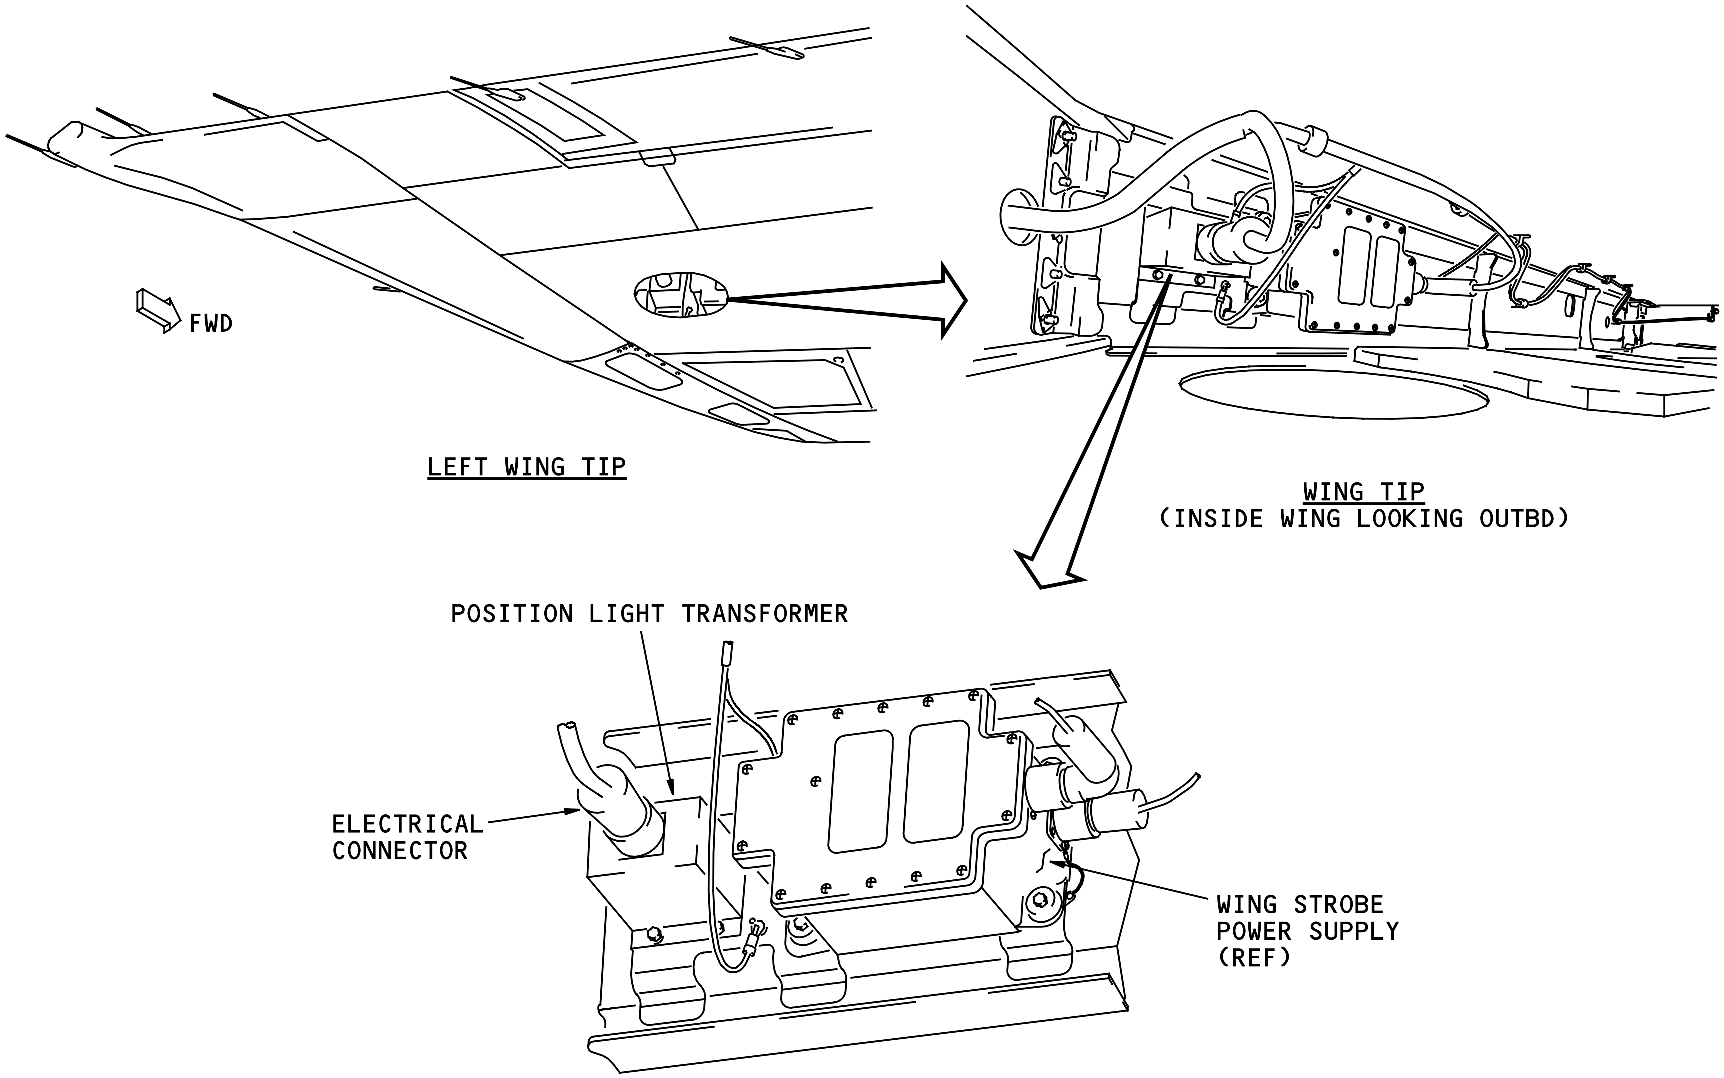
There is one transformer in each wing tip, inboard from the position lights. They are near the wing anti-collision light power supplies.

Physical Description

Each transformer has an electrical connector and four fasteners.

Training Information Point

You loosen captive screws to release the panel on the bottom of the wing at the tip to get access to the transformer.



33-43-00-003 Rev 0 10/17/96

POSITION LIGHTS - WING POSITION LIGHT TRANSFORMERS

POSITION LIGHTS - TAILCONE POSITION LIGHT

Purpose

The tailcone position light lets people outside the airplane see the location of the aft end of the airplane.

Location

The light is on the lower corner of the airplane tailcone.

Physical Description

The tailcone position light has a clear lens, thus the light is white.

There are two lamps in the position light. The lamps are two-prong-flange-type lamps. There is a reflector for each lamp.

The position light has an electrical connector and lanyard.

POSITION LIGHTS - OPERATION

ANTI-COLLISION LIGHTS - INTRODUCTION

Purpose

The anti-collision lights aide in collision avoidance and make the airplane easier to see.

Power supplies give power to the lights and make them flash.

Location

The upper body anti-collision light is on the top of the fuselage. The lower body anti-collision light (not shown) is on the bottom of the fuselage. These lights are referred to as beacons.

The wing anti-collision lights are on the tips of the wings. The tailcone anti-collision light is on the tailcone. These lights are referred to as strobes.

The power supplies (not shown) are near the beacons and strobes. There is one power supply for each light.

General Description

The beacons and strobes are redundant systems.

The two beacon lights flash at the same time. The three strobe lights also flash at the same time, but not at the same time as the beacon lights.

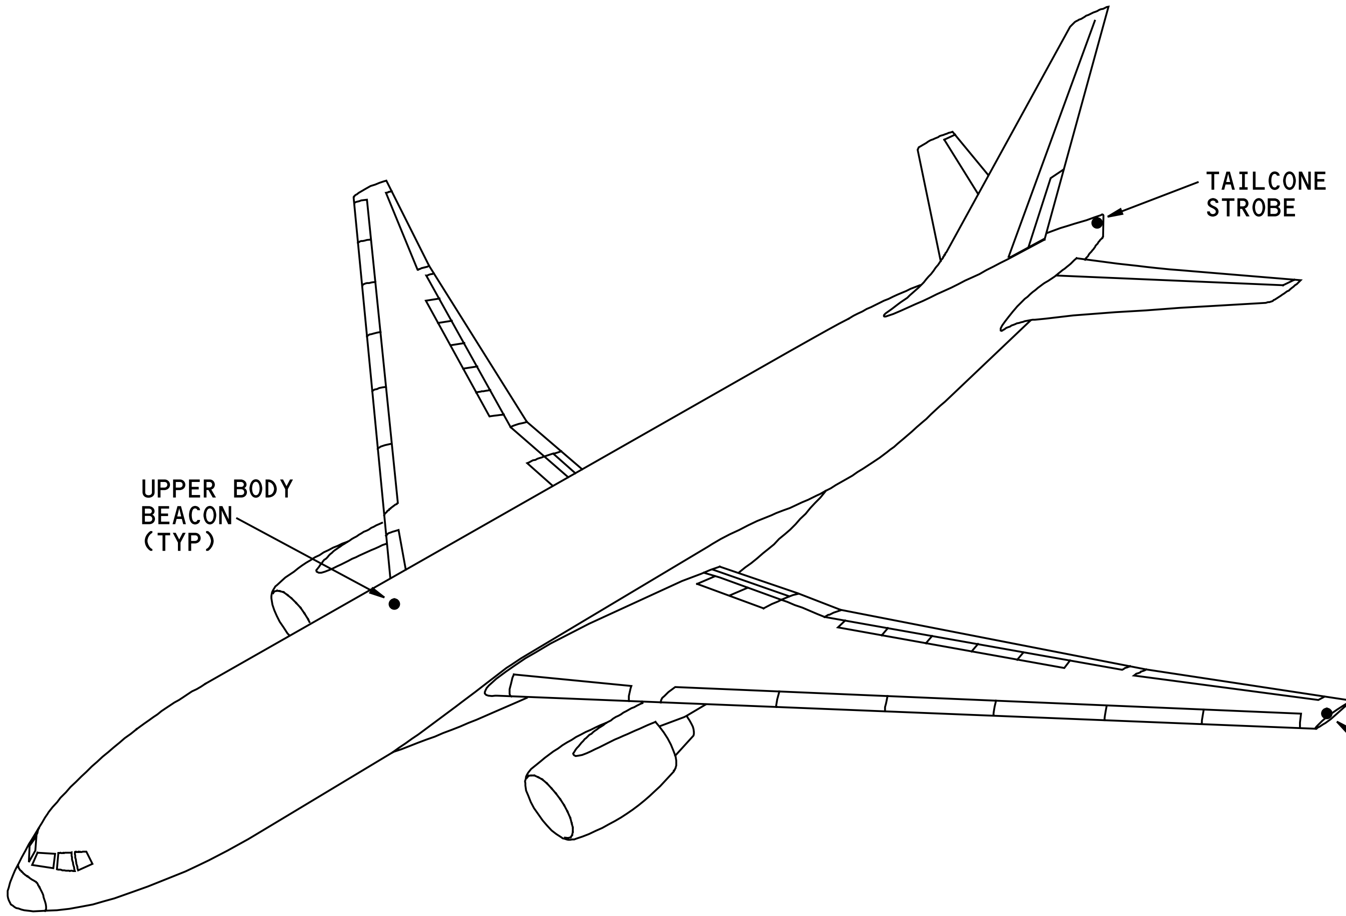
Training Information Point

WARNING: DO NOT LET THE LIGHTS FLASH DIRECTLY IN YOUR EYES. THE INTENSITY OF THE LIGHT CAN CAUSE INJURY TO YOUR EYES TEMPORARILY.

WARNING: WAIT TEN MINUTES BEFORE YOU REMOVE A LIGHT. IF YOU TOUCH THE LIGHT WHEN IT IS HOT, INJURY TO PERSONS CAN OCCUR.

WARNING: DO NOT TOUCH THE POWER SUPPLY FOR THREE MINUTES AFTER YOU REMOVE THE POWER. IF YOU TOUCH A POWER SUPPLY BEFORE YOU BLEED IT, INJURY TO PERSONS OR DAMAGE TO EQUIPMENT CAN OCCUR.

CAUTION: DO NOT TOUCH THE LAMP WITH YOUR BARE HANDS. FINGERPRINTS DECREASE LIGHT OUTPUT AND CAN CAUSE FAILURE OF THE LAMP BEFORE THE USUAL TIME.



33-44-00-001 Rev 1 04/15/1997

ANTI-COLLISION LIGHTS - INTRODUCTION

ANTI-COLLISION LIGHTS - UPPER AND LOWER BODY BEACONS

Component Locations

The upper body beacon is on the top of the fuselage, above the forward wing to body fairing.

The lower body beacon is on the bottom of the fuselage, forward of the main gear wheel wells.

Physical Description

The lamps in the beacons are the xenon strobe type. They flash approximately 48 times per minute.

The beacon light has these components:

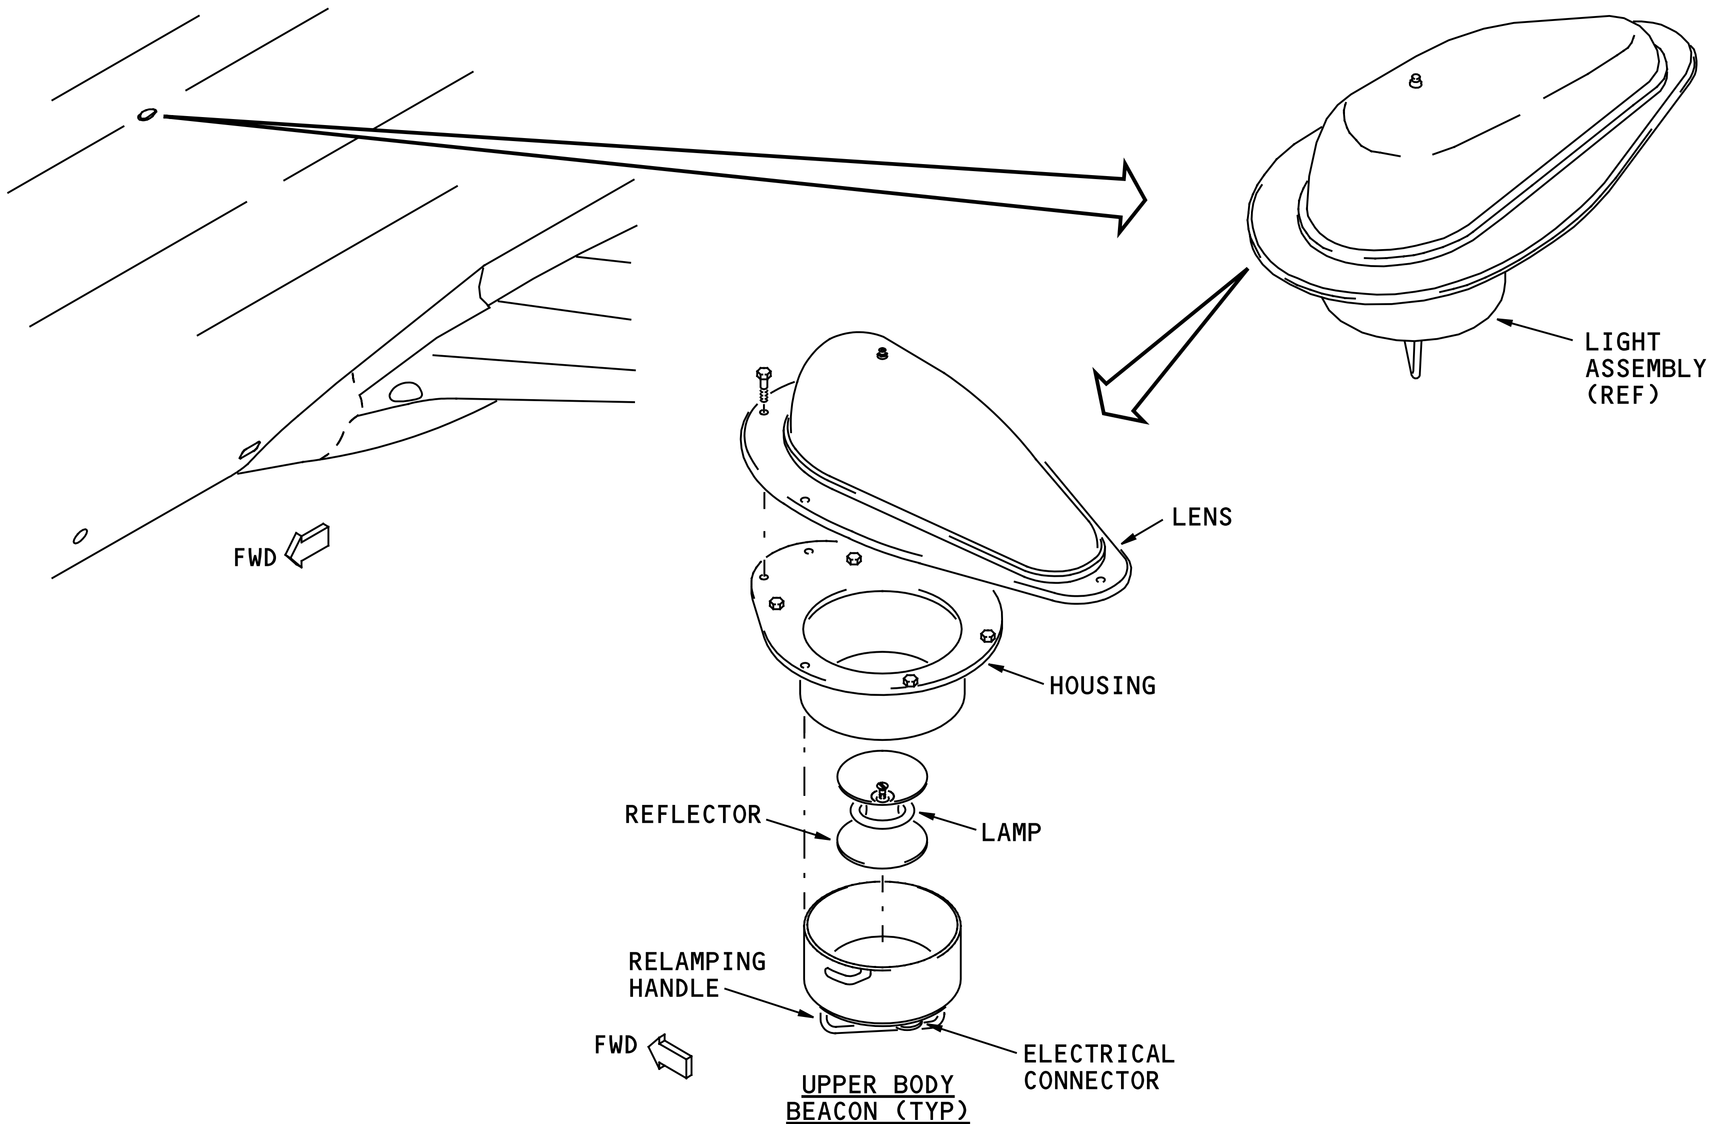
- Lens
- Lamp
- Housing
- Electrical connector
- Relamping Handle
- Reflector.

The lens is red.

Training Information Point

You lower the ceiling panel at station 876 to get access to the upper body beacon. There are station markers above each center ceiling panel. They are on the center bin stowage bin rail.

You get access to the lower body beacon from the outside of the airplane.



ANTI-COLLISION LIGHTS - UPPER AND LOWER BODY BEACONS

ANTI-COLLISION LIGHTS - WING STROBE

Location

The wing strobes are on the tips of the wings. They are aft of the red or green position light.

Physical Description

The lamps in the wing strobes are the xenon strobe type.

Each light has a:

- Lanyard
- Lamp assembly.

Each lamp assembly has a:

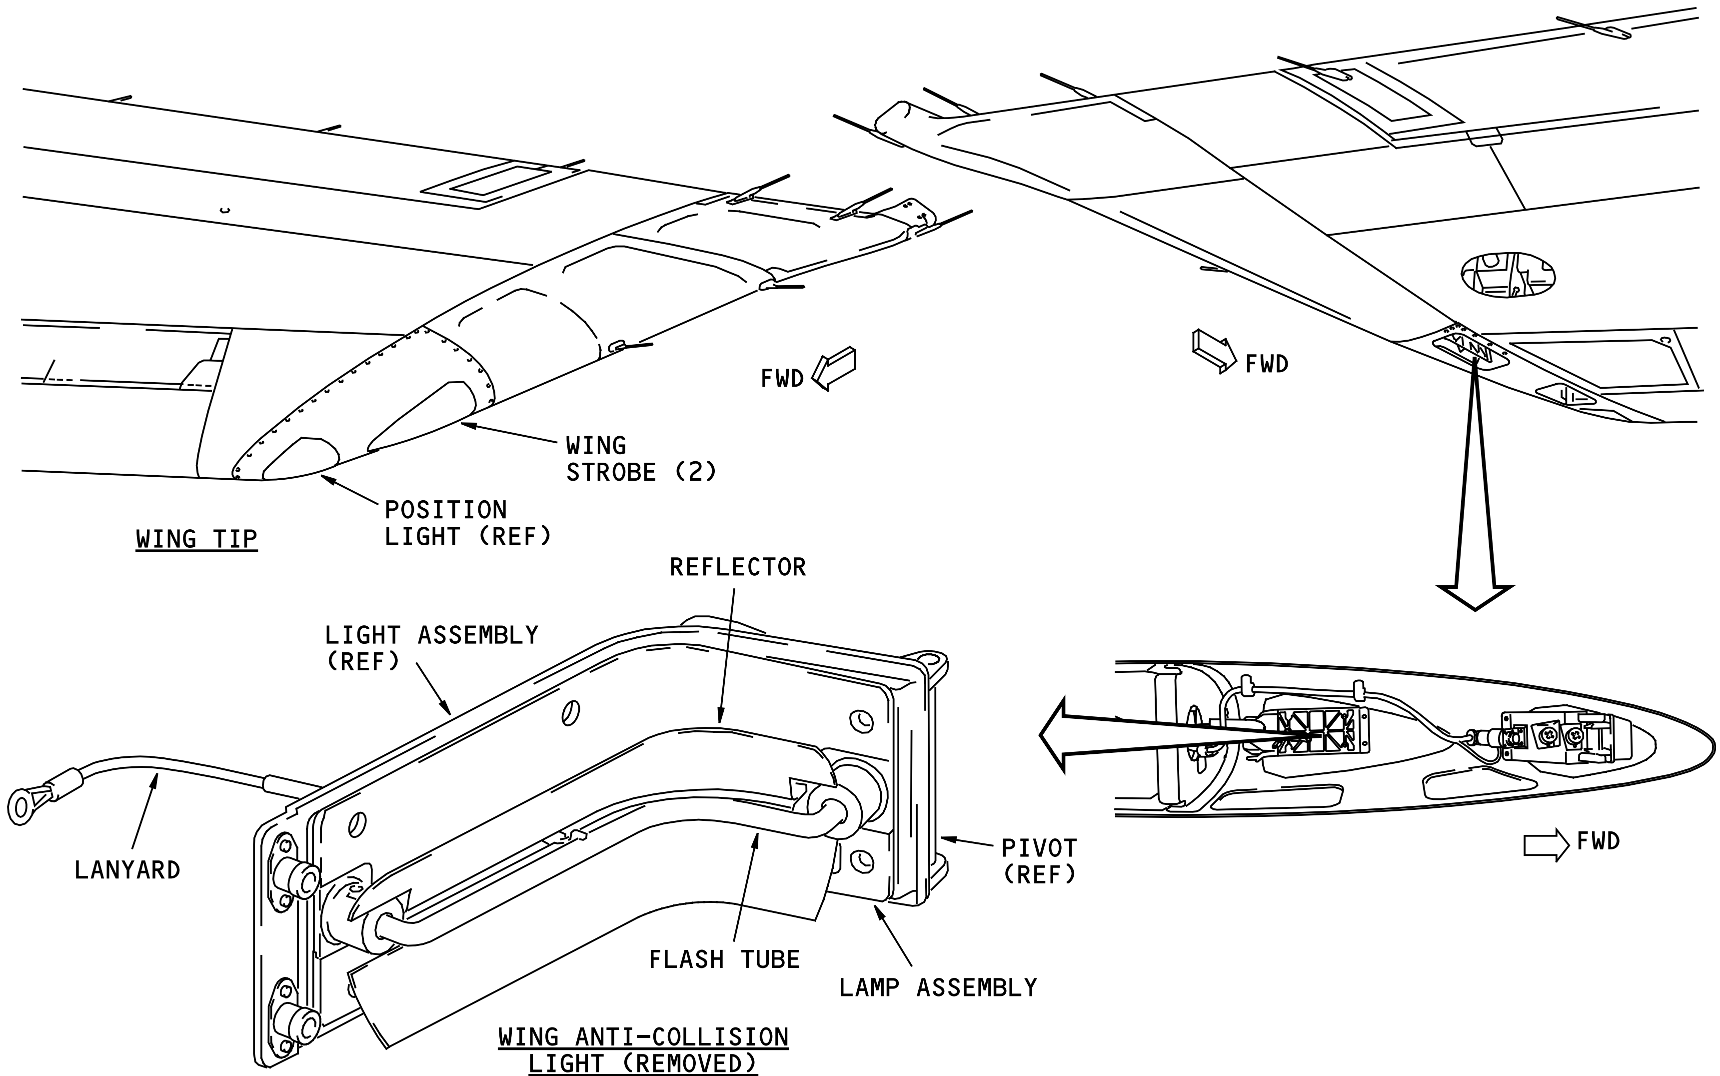
- Reflector
- Flash tube.

The lamp assembly attaches to the light assembly. There is a lanyard that does not allow the light assembly to fall when you remove the fasteners. There is an electrical connector on the back of the light assembly.

You loosen the captive screws to release the panel on the bottom side of the wing tip to access the position light lamps. You loosen two quick release fasteners and rotate the assembly around the pivot to get it out of the wing. This gives you access to the lamp assembly.

Training Information Point

You replace the lamp assembly. The flash tube is not an LRU.



33-44-00-003 Rev 1

ANTI-COLLISION LIGHTS - WING STROBE

ANTI-COLLISION LIGHTS - TAILCONE STROBE

Location

The tailcone strobe is on the end of the fuselage.

Physical Description

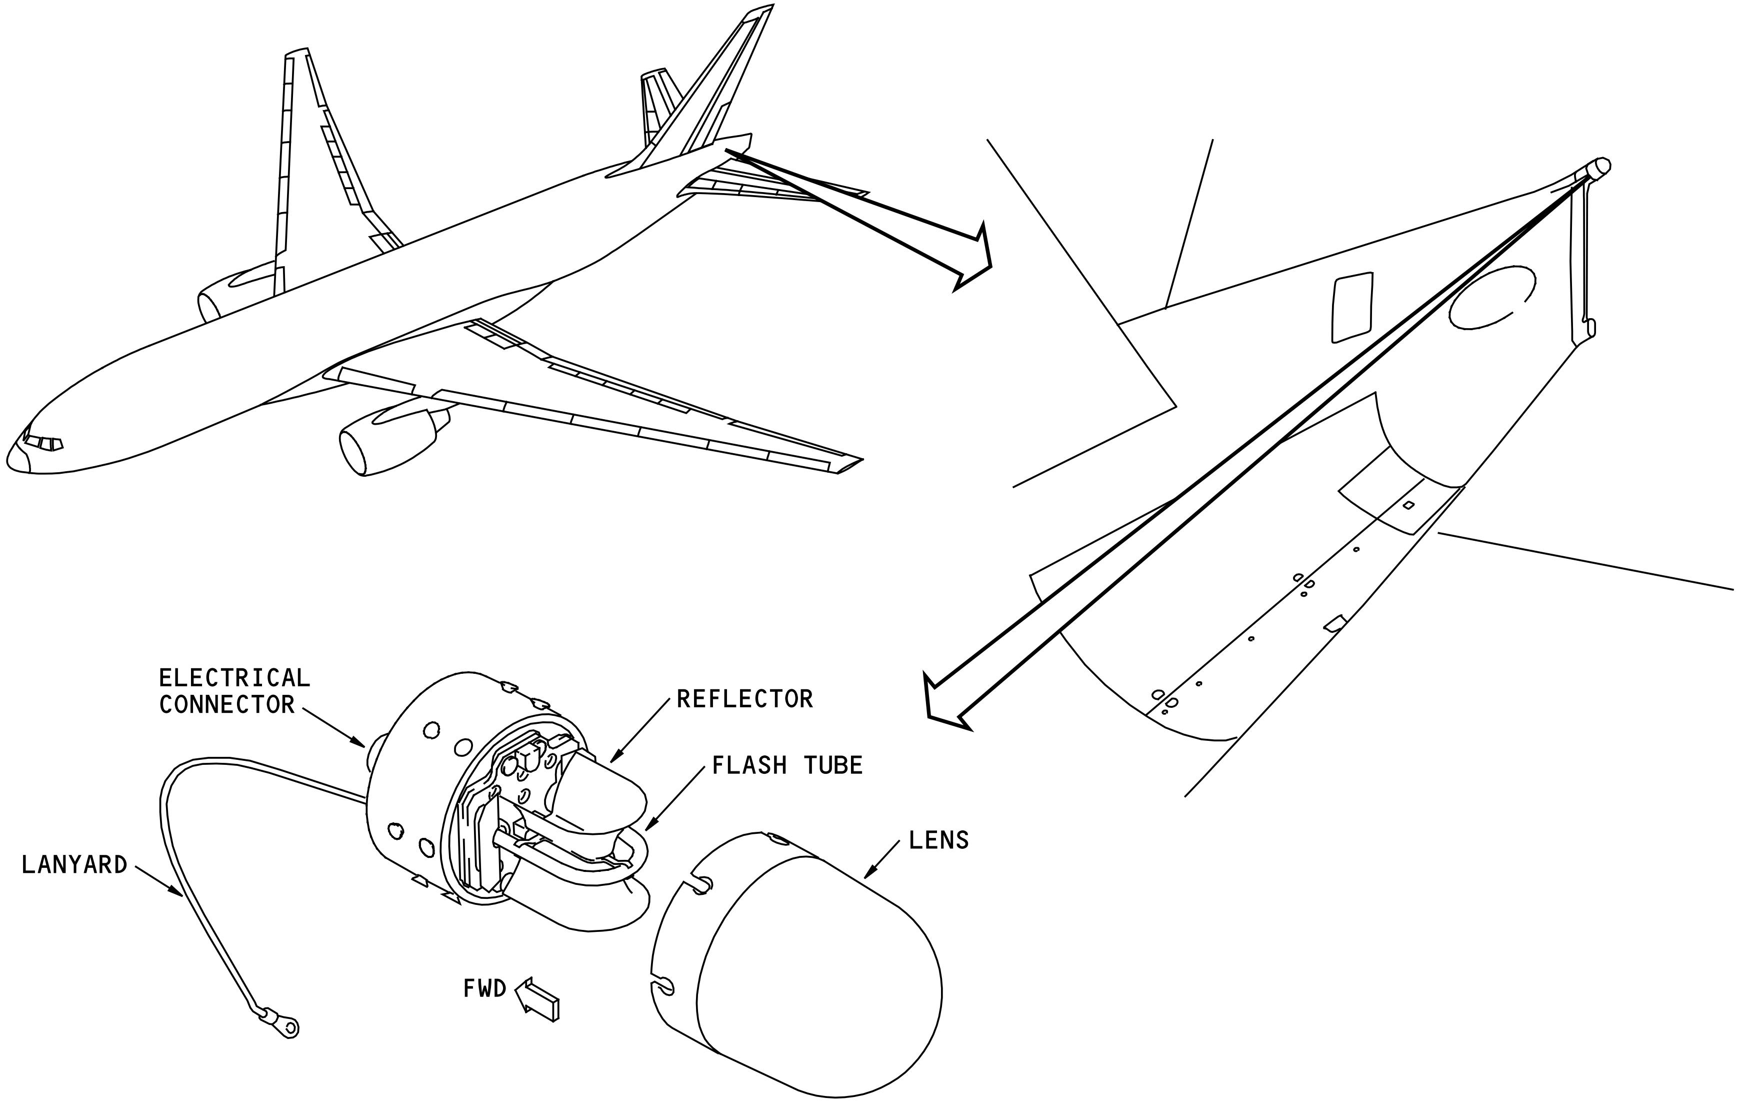
The lamp in the tailcone strobe is the xenon-strobe type.

The strobe has a:

- Lanyard
- Electrical connector
- Reflector
- Flash tube
- Lens.

Training Information Point

You get access to the tailcone strobe from the outside of the airplane.



TAILCONE STROBE LIGHT ASSEMBLY

ANTI-COLLISION LIGHTS - TAILCONE STROBE

ANTI-COLLISION LIGHTS - POWER SUPPLY - INTRODUCTION

Purpose

The power supplies give power to the beacons and the strobes. They make the beacons and the strobes flash.

Location

The power supplies for the wing strobes are behind a panel on the bottom side of the wing at the tip.

The power supply for the tailcone beacon is in the stabilizer compartment. It is on the forward side of the APU compartment bulkhead.

Physical Description

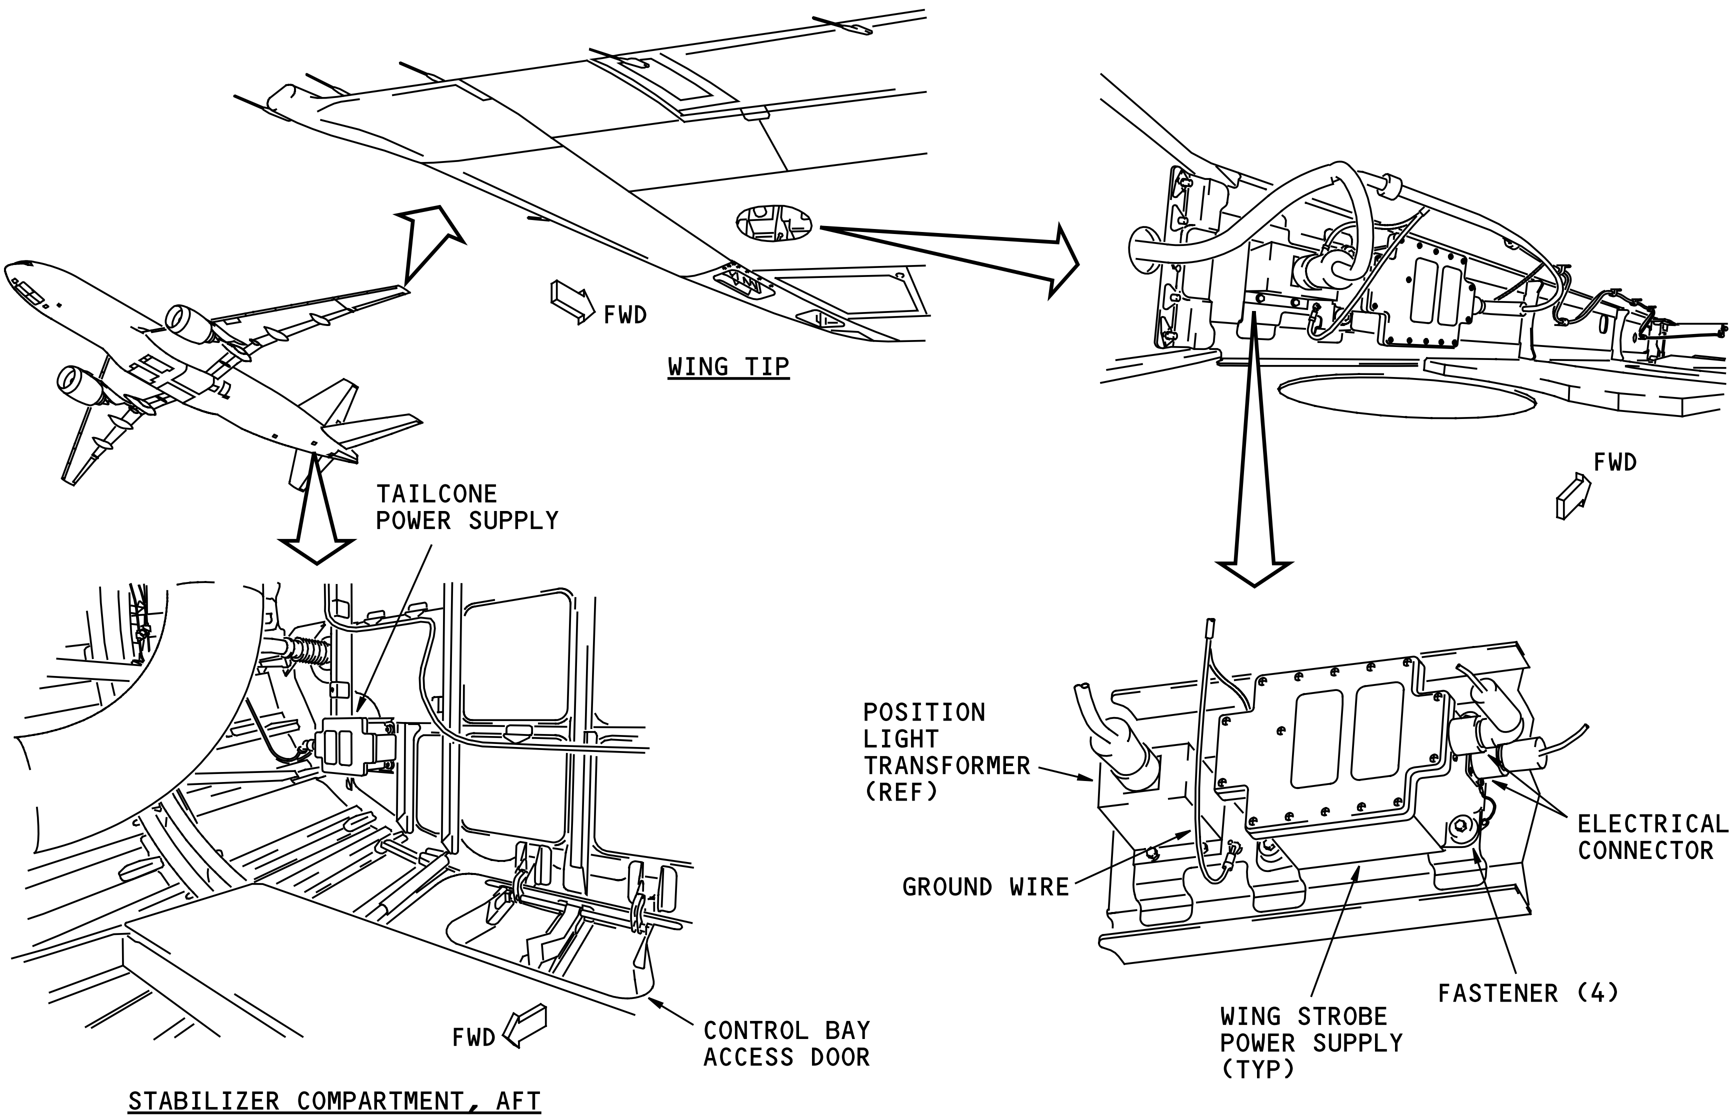
Each power supply has an:

- Electrical connector
- Fastener (4)
- Ground wire.

The power supplies make the beacons and strobes flash.

Training Information Point

The power supplies are the same and interchangeable.



33-44-00-005 Rev 1 04/15/1997

ANTI-COLLISION LIGHTS - POWER SUPPLY - INTRODUCTION

ANTI-COLLISION LIGHTS - POWER SUPPLY - BODY BEACON LOCATION

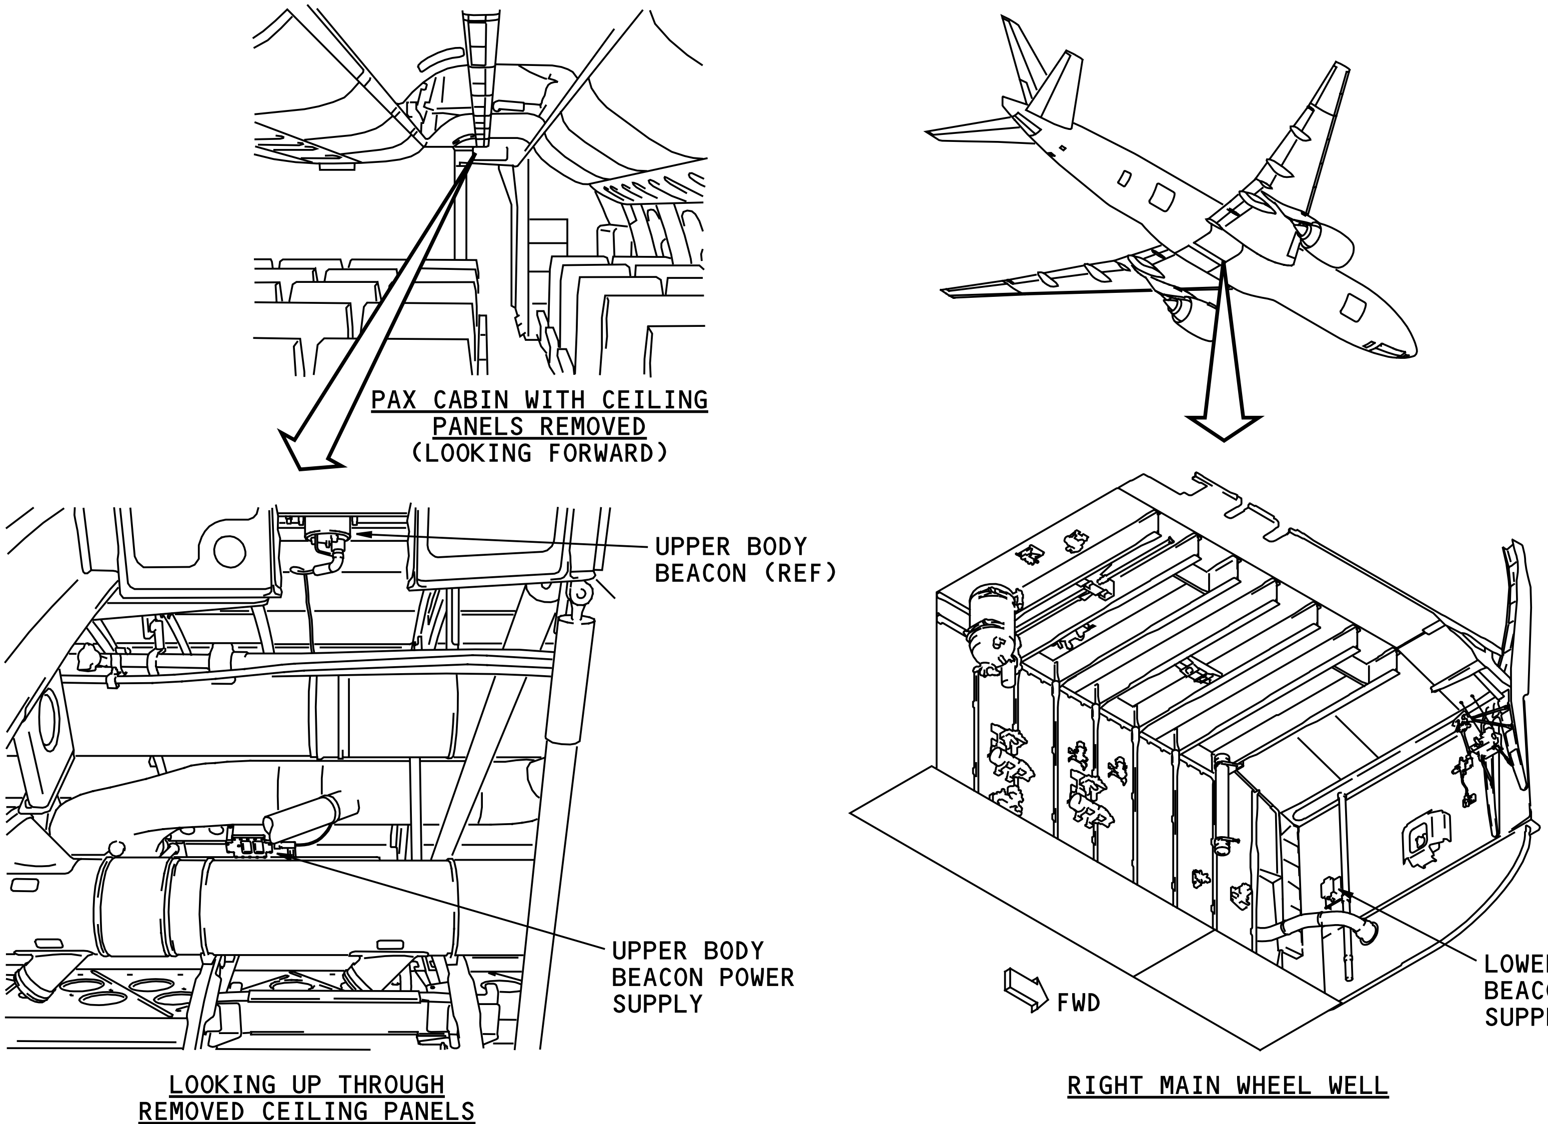
Location

The power supply for the upper body beacon is above the ceiling at approximately the same station line as the forward wing to body fairing. It is forward of the upper beacon.

The power supply for the lower body beacon is in the right main wheel well, on the forward wall.

Training Information Point

The power supplies are the same and interchangeable.



33-44-00-006 Rev 1 04/15/1997

ANTI-COLLISION LIGHTS - POWER SUPPLY - BODY BEACON LOCATION

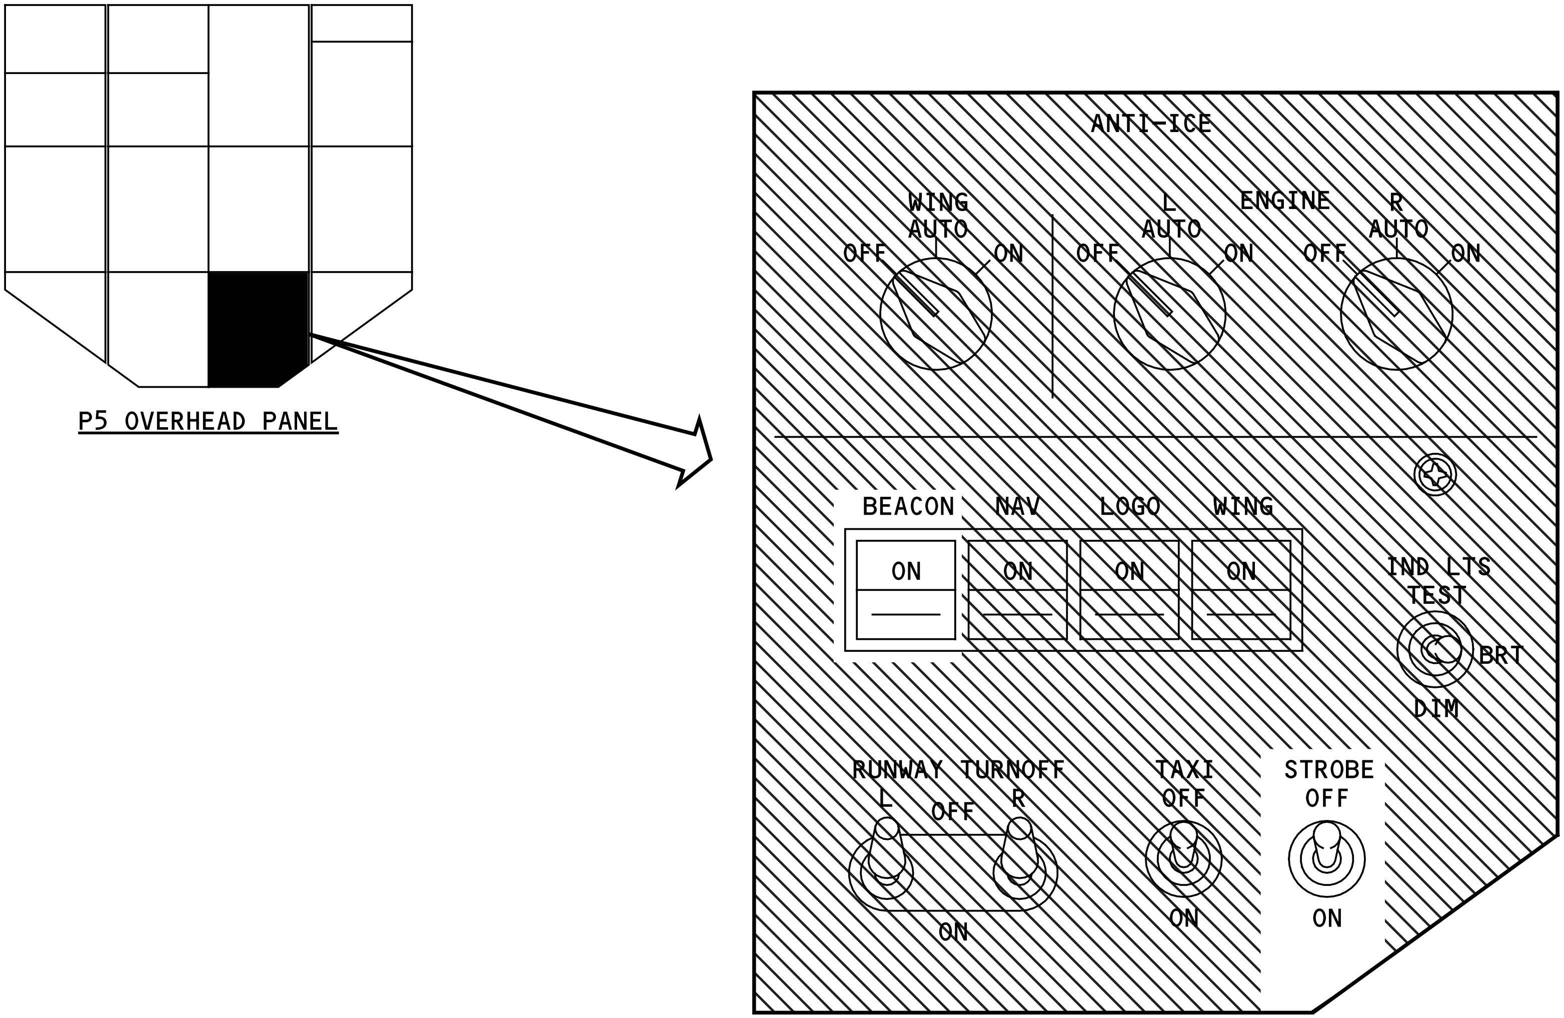
ANTI-COLLISION LIGHTS - OPERATION

Operation

You use the beacon light switch (BEACON) to operate the upper and lower body beacons.

You use the strobe light switch (STROBE) to operate the wing and tailcone strobes.

The switches are on the anti-ice/lighting panel on the P5 overhead panel. The beacon switch is an alternate action switch. The strobe switch is a toggle switch.



ANTI-ICE/LIGHTING PANEL (P5)

33-44-00-007 Rev 1 08/21/96

ANTI-COLLISION LIGHTS - OPERATION

LOGO LIGHTS - INTRODUCTION

Purpose

The logo lights give light to both sides of the vertical stabilizer.

Location

The lights are on the upper side of the horizontal stabilizer. They are near the leading edge. There are two on each side of the vertical stabilizer.

Physical Description

The logo light is a two-pin, flange-mounted light. It has these components:

- Reflector
- Lens
- Lens retainer
- Transformer (not shown).

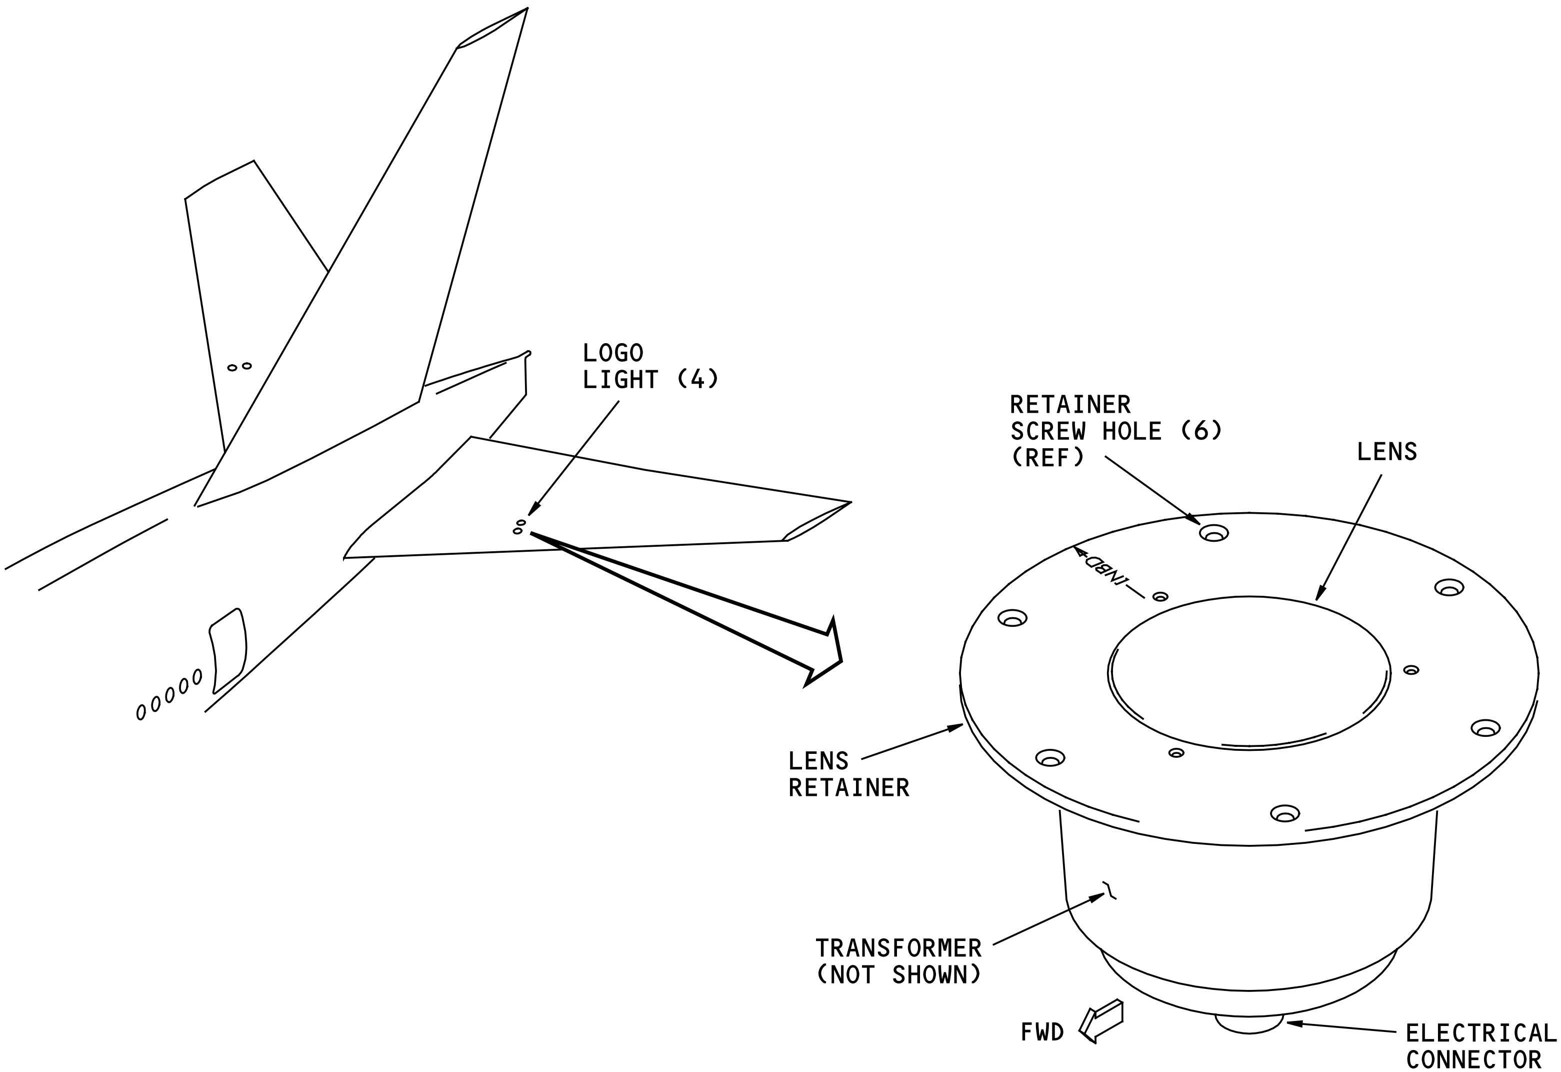
The transformer is part of the light. Two captive screws hold the reflector in position.

You remove the lens retainer and lens as one part. This gives you access to the light. There are six screws that hold the lens retainer.

Training Information Point

When you replace the lens retainer make sure the INBD arrow points inboard.

Since there are two lights on each side of the stabilizer, one indication of a failed light is a decrease in the amount of light on that side.



33-45-00-001 Rev 0

LOGO LIGHTS - INTRODUCTION

LOGO LIGHTS - OPERATION

Operation

You use the logo lights switch (LOGO) to operate the logo lights. It is on the anti-ice/lighting panel on the P5 overhead panel. It is an alternate-action switch.

TABLE OF CONTENTS

THIS PAGE INTENTIONALLY LEFT BLANK

OXYGEN - INTRODUCTION

Purpose

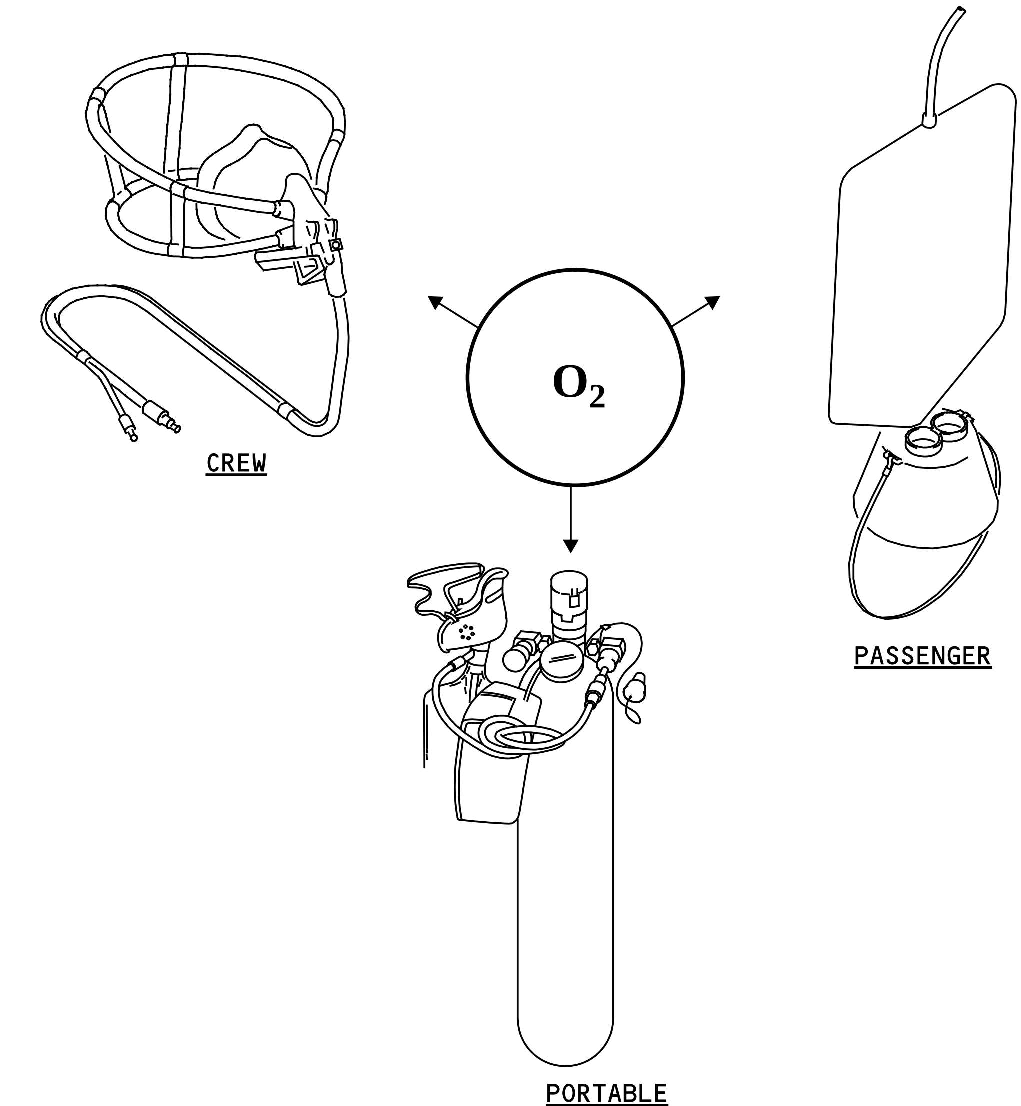
The oxygen systems supply oxygen to the flight crew, cabin attendants, and passengers.

Location

There are separate systems in the flight deck and passenger compartment. There are also portable oxygen units.

Abbreviations and Acronyms

AIMS	- airplane information management system
CSS	- cabin services system
EEU	- ELMS electronics unit
EICAS	- engine indicating and crew alerting system
ELMS	- electrical load management system
MEC	- main equipment center
MFD	- multi-functional display
PSU	- passenger service unit



OXYGEN - INTRODUCTION

CREW OXYGEN - INTRODUCTION

Purpose

The crew oxygen system gives oxygen to the flight crew for emergencies and procedures that make its use necessary.

Component Locations

The crew oxygen masks and storage boxes are in the flight compartment.

The oxygen cylinders and the bleed valve are in the main equipment center (MEC).

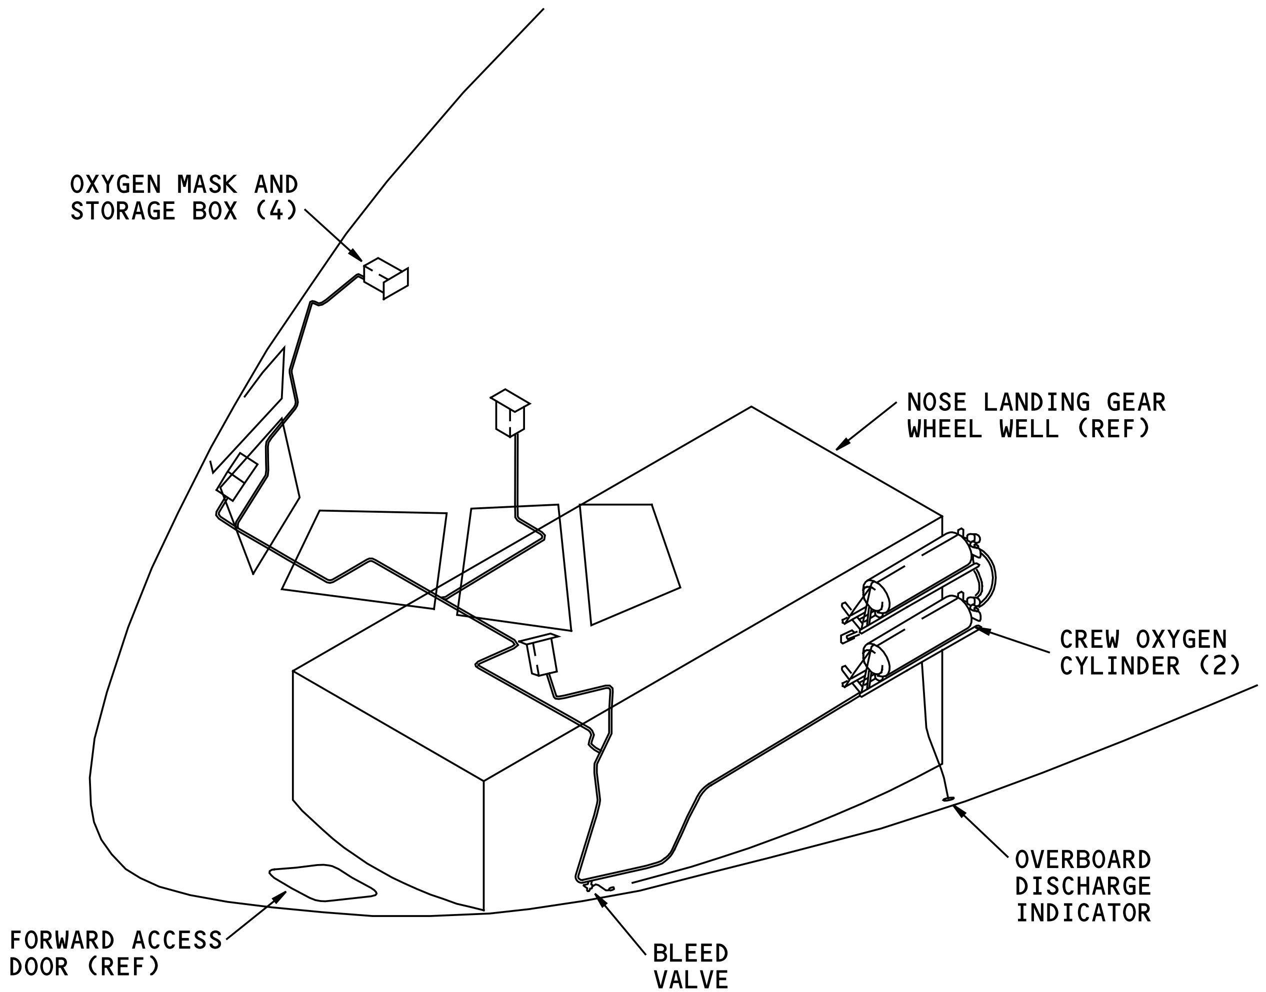
The overboard discharge indicator is external, on the airplane skin.

General Description

The cylinders in the MEC hold pressurized oxygen. A line connects the cylinders to oxygen masks in the flight deck. A regulator at the cylinders and diluter/ demand valves at the masks decrease oxygen pressure to the correct pressure for crew use.

The diluter/demand valve also mixes an applicable amount of flight deck air with the oxygen. The valve uses flight deck air pressure to make the decision on the quantity of oxygen to mix. The crew can also set the valve for 100 percent oxygen.

You can get oxygen cylinder pressure information from the gages at the cylinders and from the primary display system (PDS).



35-11-00-001 Rev 4 08/13/96

CREW OXYGEN - INTRODUCTION

CREW OXYGEN - CYLINDER

Purpose

The crew oxygen cylinders contain oxygen for the flight crew.

Location

The cylinders are on the left side of the main equipment center (MEC), forward of the E3 rack and the ladder to the MEC access hatch.

General Description

The cylinder is made of composite materials. It holds 115 cubic feet (3150 liters) of oxygen at 1850 psi. It has a fitting at one end. These items are on the fitting:

- Direct reading pressure gage
- Shutoff valve
- Threaded connection (not shown) for B-nut on the thermal compensator and overboard discharge line
- Thermal relief frangible disc (not shown).

A cylinder support structure holds the cylinder to the airplane. There are retainer rings at both ends of the structure. The forward ring is set and cannot move. The aft ring is movable. Fittings on the bottom of the aft ring let you connect it to the structure and turn it up over the end of the cylinder.

One end of the retainer strap connects to the set ring. The other end of the strap has a tee bolt. It goes through the top of the movable ring. A nut holds the ring and bolt together.

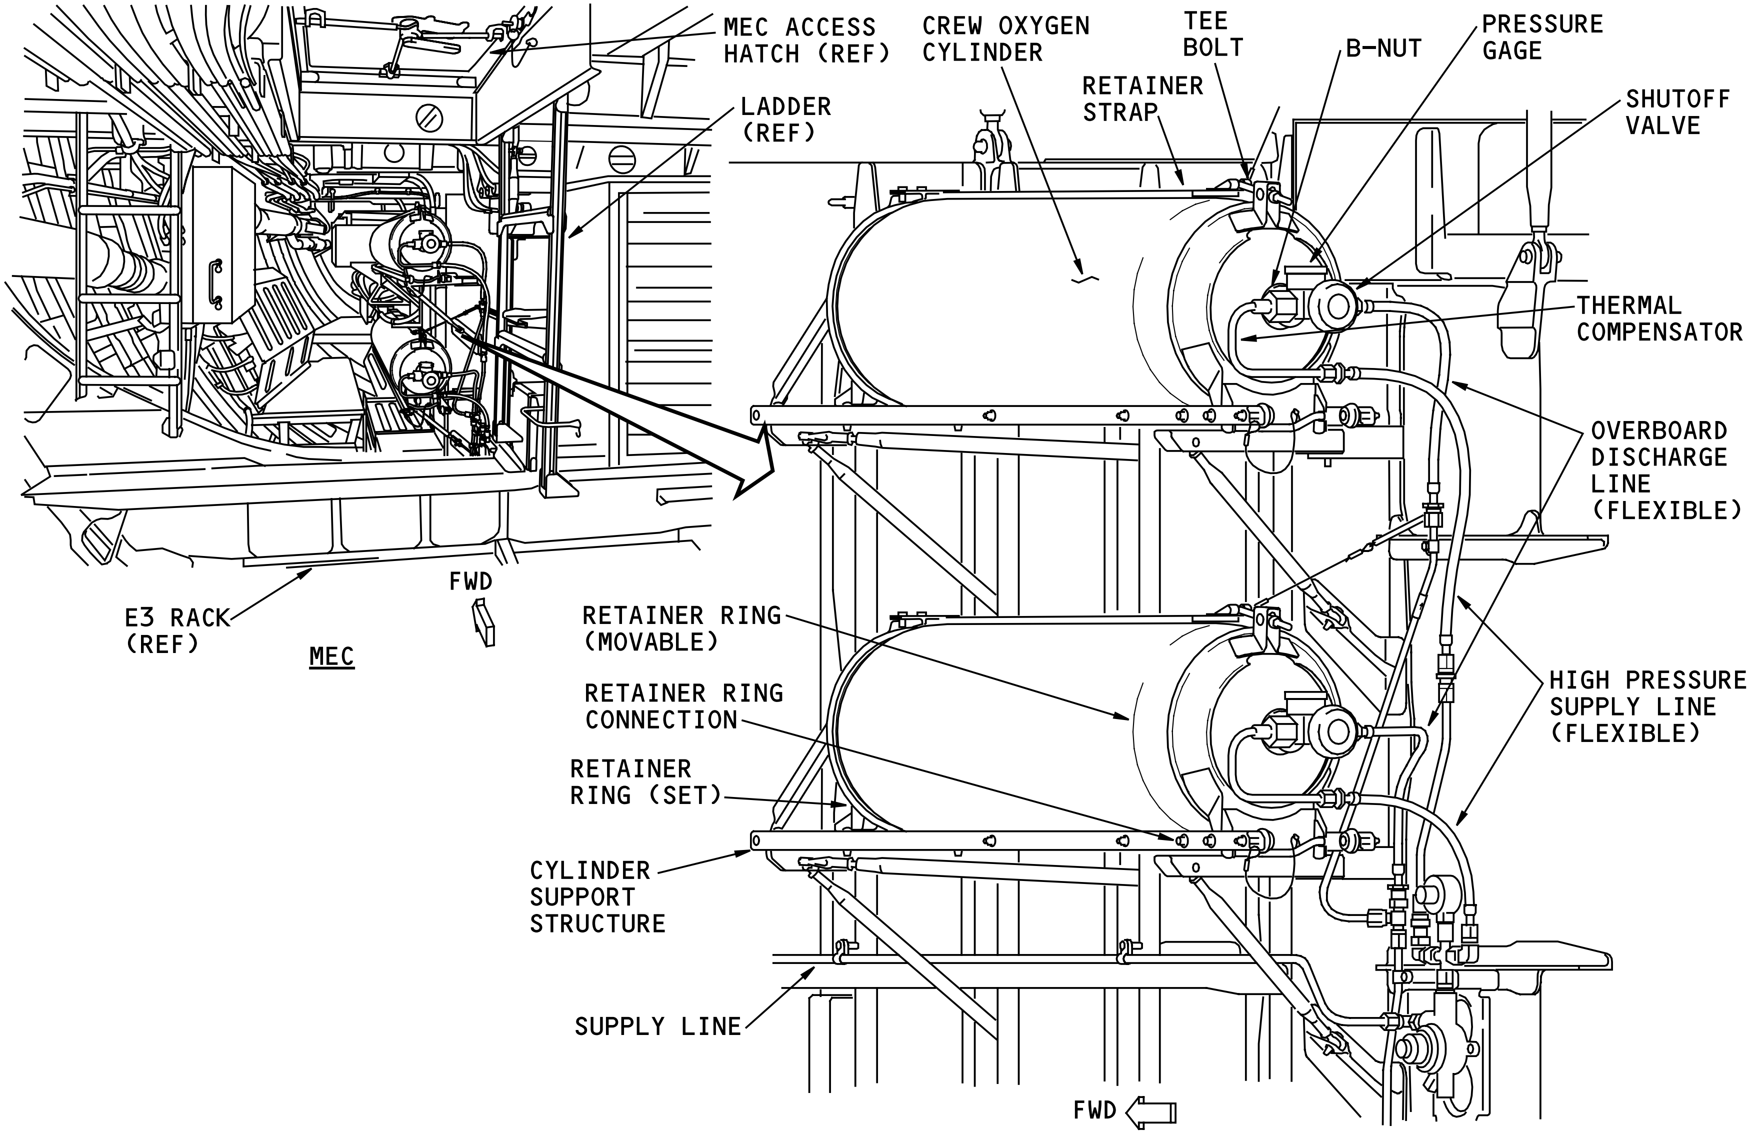
The B-nuts on the thermal compensator and overboard discharge line connect them to the cylinder fitting.

The high pressure supply line lets oxygen flow into the thermal compensator and cylinder. It also lets oxygen flow out of the cylinder to the mask supply line.

The thermal relief frangible disc in the fitting breaks to release oxygen to the overboard discharge line when cylinder pressure gets above safe cylinder limits.

Training Information Point

There are two positions for the movable retainer ring on the cylinder support structure. One position lets the structure hold a composite cylinder. The other lets it hold a steel oxygen cylinder.



CREW OXYGEN - CYLINDER

35-11-00-003 Rev 3 08/16/96

CREW OXYGEN - OVERBOARD DISCHARGE INDICATOR

Purpose

The overboard discharge indicator shows when overpressure causes an oxygen release from the flight crew oxygen cylinders.

Location

The indicator is to the left of the nose landing gear wheel well.

Physical Description

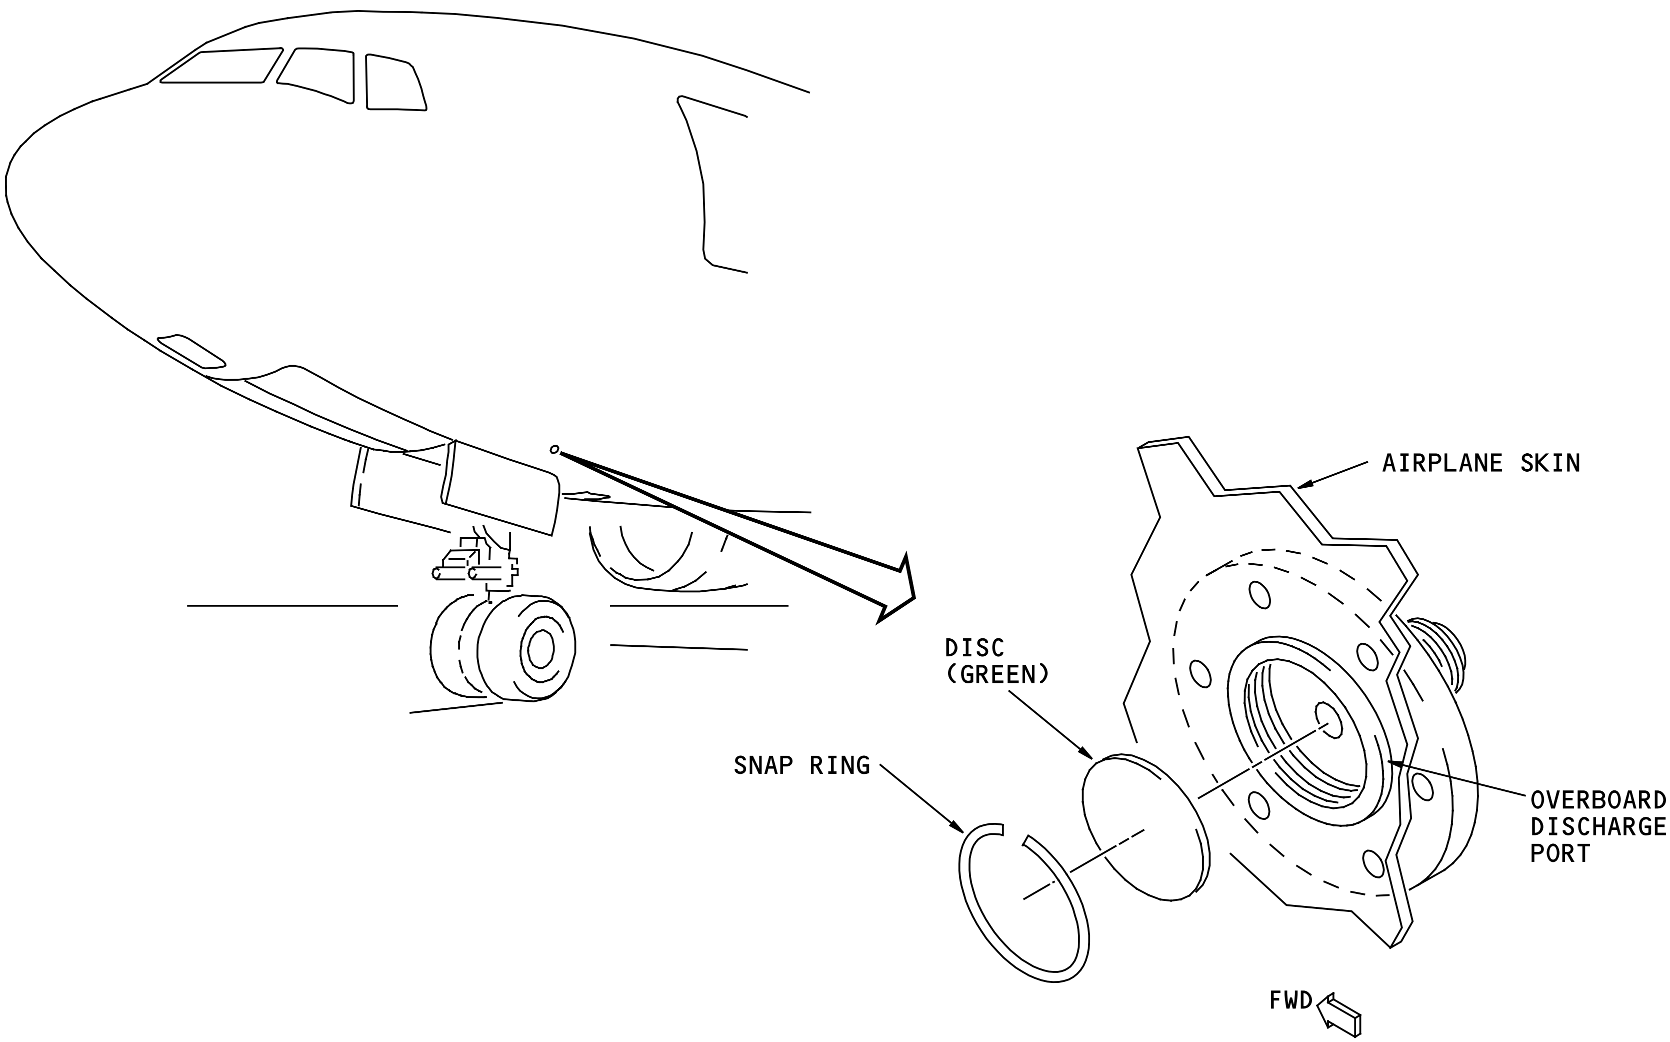
The indicator is a green disc. A snap ring holds it in position.

Functional Description

An overpressure condition causes the frangible disc in the oxygen cylinder to break. The oxygen flows through the overboard discharge line to the overboard discharge port. The pressure pushes the indicator disc out of the snap ring. The disc falls away.

Training Information Point

If the disc is gone, do a check to see if the oxygen cylinders are empty.



35-11-00-004 Rev 2

CREW OXYGEN - OVERBOARD DISCHARGE INDICATOR

CREW OXYGEN - BLEED VALVE

Purpose

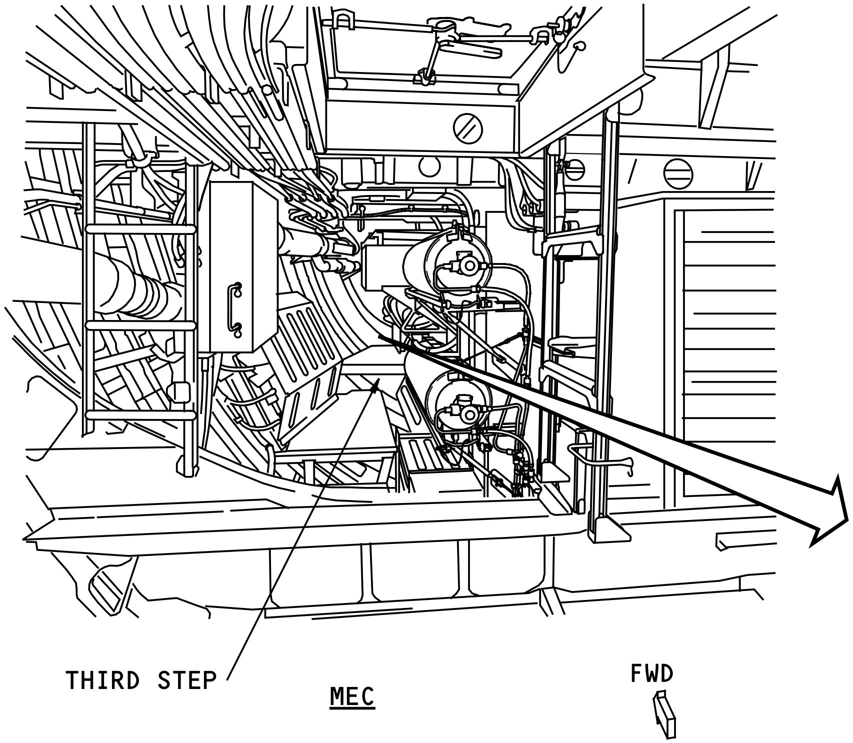
The bleed valve helps to make sure that the AIMS gets correct oxygen cylinder pressure information.

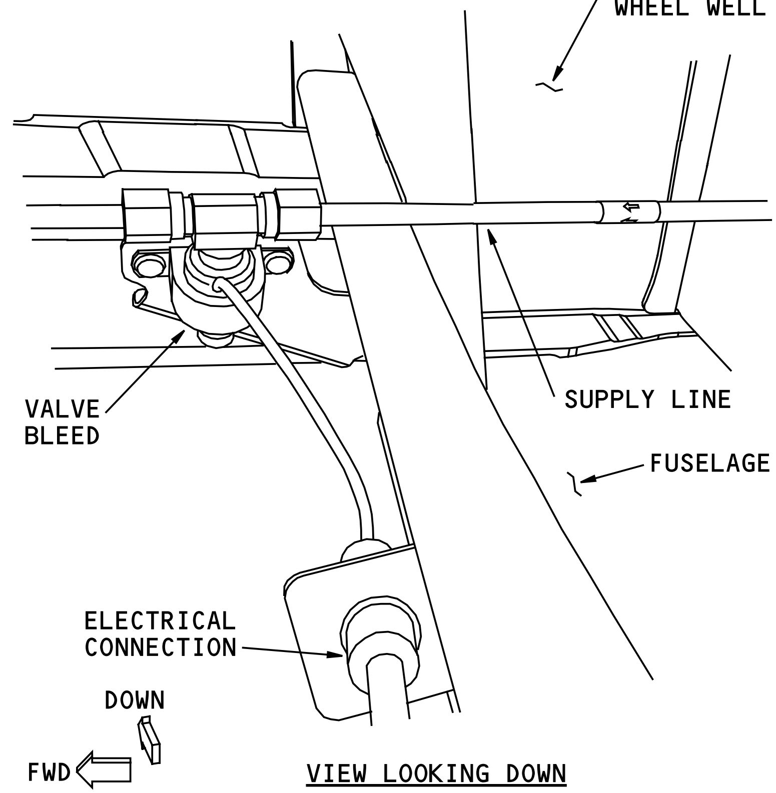
Location

The valve is on the lower, left side of the MEC. It is below and forward of the third step of the walkway.

Physical Description

The valve has a solenoid which supplies the force to open the valve.





35-11-00-006 Rev 3 08/07/96

CREW OXYGEN - BLEED VALVE

CREW OXYGEN - OPERATION

Operation

Pull on the release levers of the diluter/demand regulator to remove the mask from the box. The shutoff valve opens when the left door opens. You hold the left release lever (inflation control) in as you hold the mask by the diluter/demand regulator. This makes oxygen inflate the pneumatic harness.

You put the harness around your head with the mask over your nose and mouth. When you release the release levers, the oxygen that inflates the harness shuts off and bleeds from the harness. Elastic in the harness pulls the mask tight to the face.

Normally you breathe a mixture of oxygen and compartment air when you set the oxygen dilution control to N (normal). The percent of oxygen has a relation to the pressure altitude in the flight deck. At or above a preset pressure altitude the regulator gives you 100 percent oxygen. You breathe only oxygen at any pressure altitude when you set the dilution control to 100 percent.

Normally, oxygen flows only when you breathe (on demand). The flow indicator shows flow each time you breathe. If you set the emergency demand control to emergency, oxygen will flow continuously (pressure breathing). The flow indicator shows continuous flow.

The vent valve (not shown) is part of the mask. The valve lets air and oxygen flow from the mask into the goggles (not shown).

You manually open and close the vent valve with the push-pull control (not shown).

If you close the left door on the box, the oxygen on indicator shows.

You can turn oxygen off at the oxygen box with the shutoff valve. Close the left door and push the reset/ test lever sets the valve to the close position.

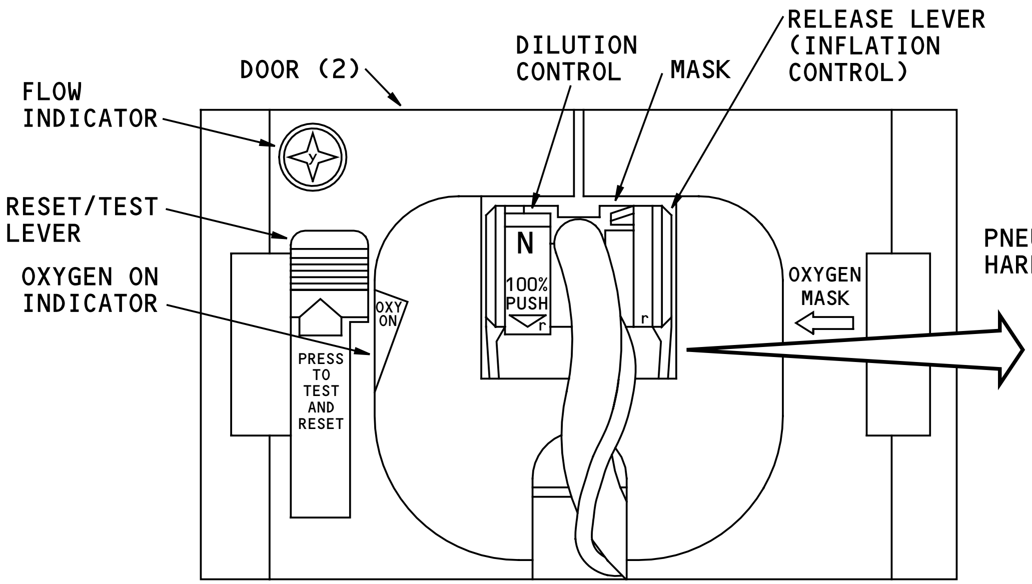
Mask Storage

To return the mask to the box, set the test and emergency demand control to the normal position. Put the wire, hose, and harness into the box. Place the mask into the box so the tabs are against the upper stop and the mask is against the lower stop in the box. Close the left door. Push down on the reset/test lever to close the shutoff valve and retract the oxygen on indicator. Move the mask to the left. Close the right door.

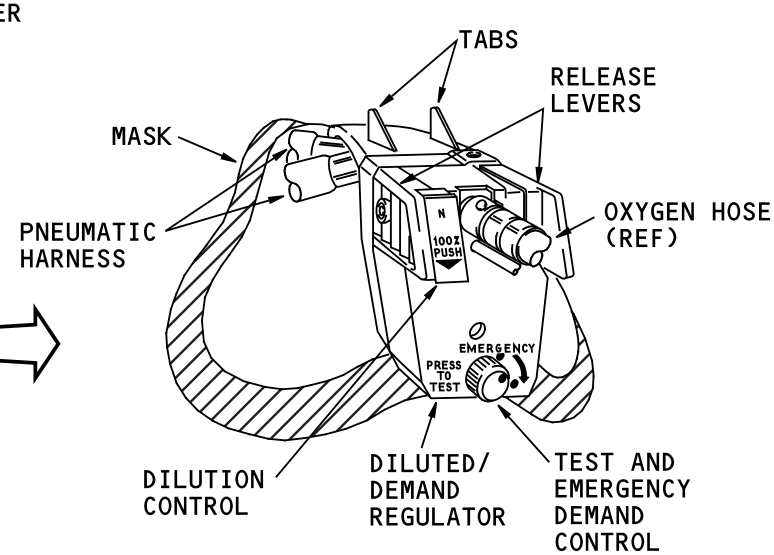
Test

Push down and hold the reset/test lever. The flow indicator should show a momentary flow.

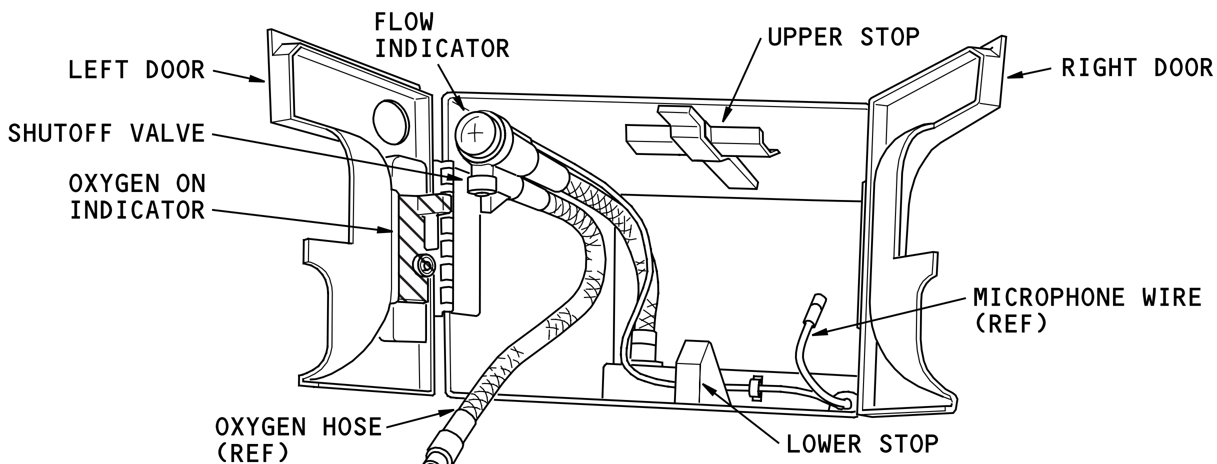
Push down and hold the reset/test lever. Push in on the test and emergency demand control. The flow indicator should show a continuous flow.



CREW OXYGEN BOX AND MASK



DILUTER/DEMAND REGULATOR
(TYPICAL)



CREW OXYGEN BOX

CREW OXYGEN - OPERATION

35-11-00-008 Rev 7 03/19/1998

CREW OXYGEN - FUNCTIONAL DESCRIPTION

Supply and Regulation

The cylinders supply oxygen through the shutoff valves, pressure regulator, and supply line to the masks in the flight deck. The supply line pressure regulator decreases the bottle pressure to 70 psi. The diluter/ demand regulator/mask supplies the flow and pressure that the crew needs.

Indications

The gauge on the cylinder shows cylinder pressure. A pressure transducer also measures the pressure. The information goes to the AIMS. The pressure shows on the status display. An advisory message shows if the bottle pressure goes below 500 psi.

Bleed Valve

The bleed valve operates one time after the airplane lands (air to ground change) and when all of these conditions occur:

- Airplane is on the ground
- Both engines off
- You start an engine.

The ELMS electronics unit (EEU) causes electrical power to go to a solenoid for 25 seconds. The solenoid opens the bleed valve to let oxygen pressure out of the line. If the cylinder shutoff valve is closed, the line will not repressurize when the bleed valve closes. The pressure transducer sends the line pressure information to the AIMS.

Overboard Discharge

The frangible disc breaks if cylinder pressure gets above safe limits (2500 - 2750 psi). The oxygen flows overboard through the overboard discharge indicator.

Oxygen Shutoff Valve/Indicator

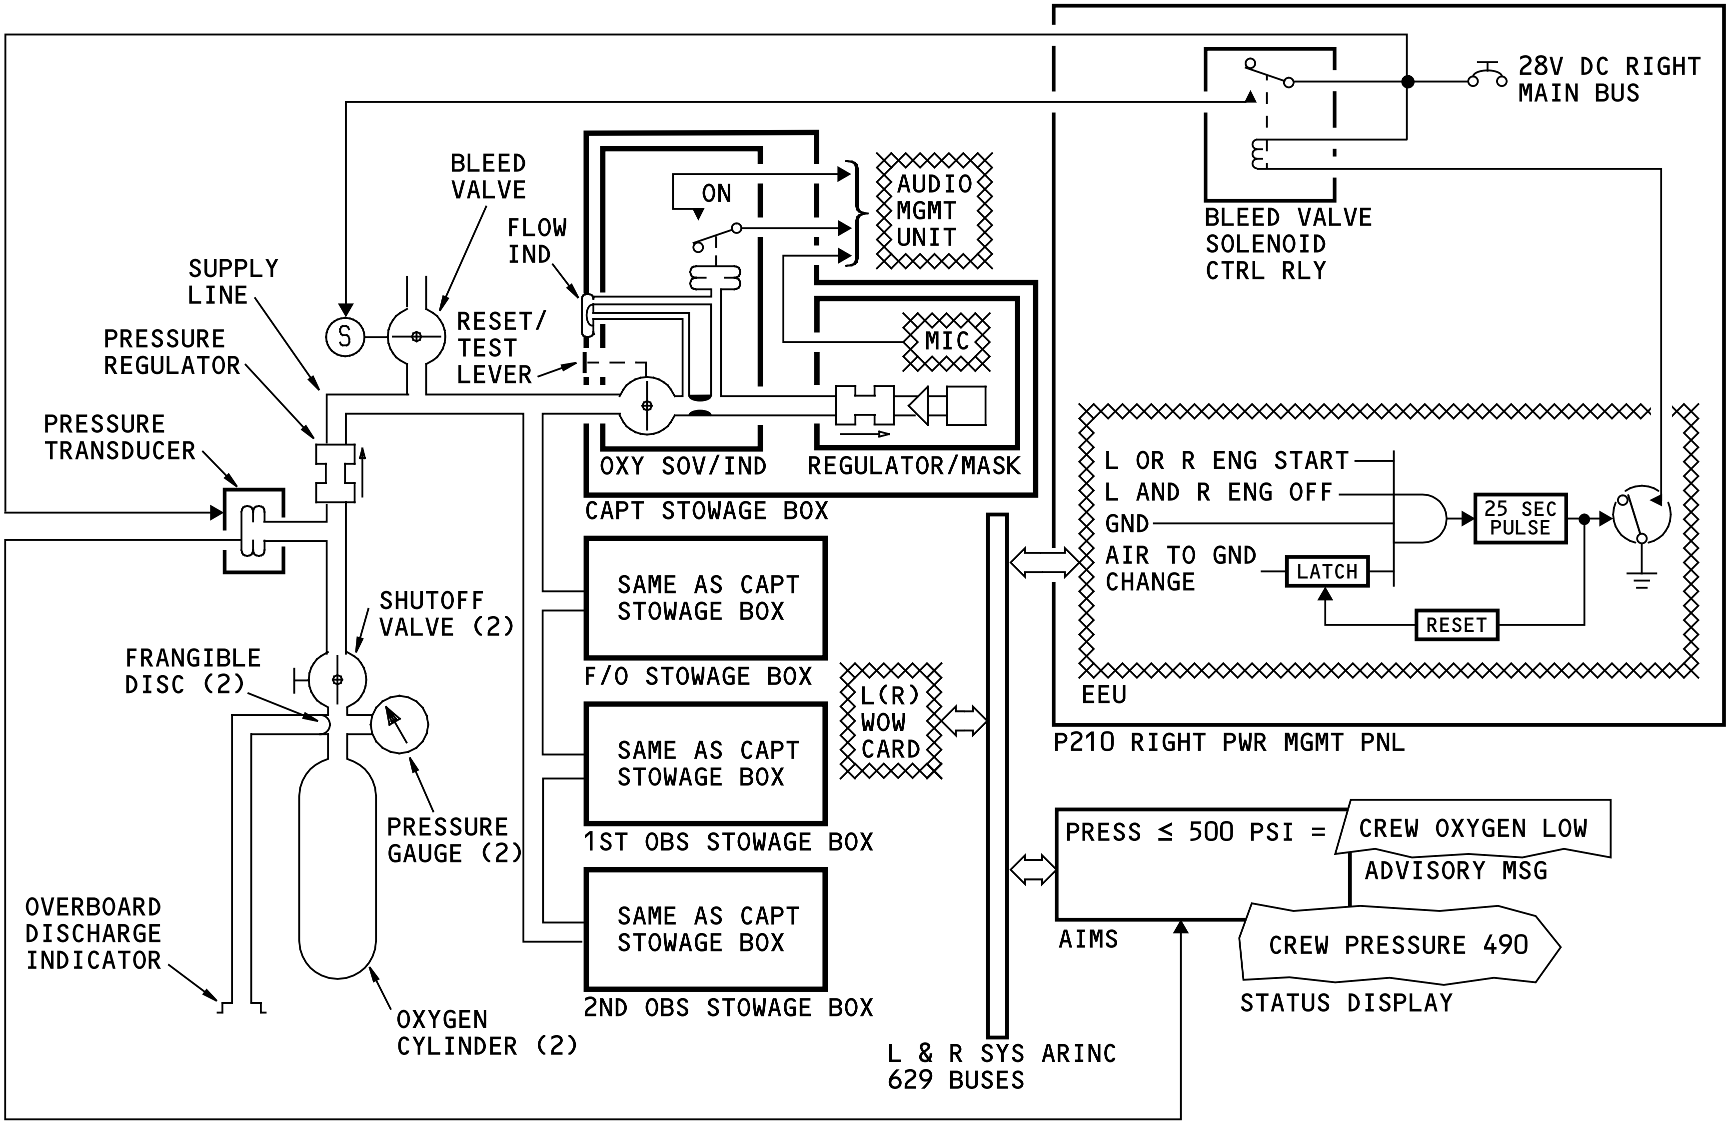
The oxygen shutoff valve/indicator supplies these functions:

- On/off control
- Flow indication
- Starts the oxygen regulator/mask-mounted microphone.

The valve automatically opens when the left door (not shown) on the stowage box is open. The valve stays open until you close the door and push the RESET/TEST LEVER.

The valve supplies flow indication when oxygen flows through the valve.

A switch in the valve supplies an oxygen ON signal to the audio management unit when there is oxygen pressure between the valve the regulator/mask. The audio management unit uses this signal to start the operation of the microphone. See the flight interphone system section for more information about the audio management unit (AMM PART I 23-51).



CREW OXYGEN - FUNCTIONAL DESCRIPTION

PASSENGER OXYGEN - INTRODUCTION

Purpose

The passenger oxygen system supplies oxygen to the passengers and cabin attendants if the airplane loses cabin pressurization.

General Description

The passenger oxygen system uses chemical generators to make the oxygen. The passenger oxygen masks can drop automatically or manually.The masks drop automatically when all these conditions are true:

- The airplane is in the air with an airspeed of more than 80 knots
- The cabin altitude goes above 13,500 feet (4115 meters).

Push the passenger oxygen switch to drop the masks manually. The chemical reaction that generates oxygen starts when you pull down on the mask.

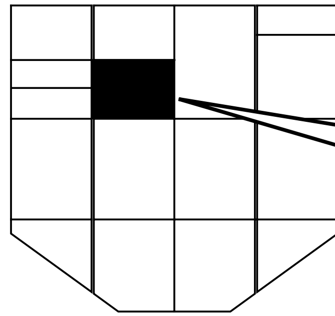
Location

The oxygen generators and masks are in these locations:

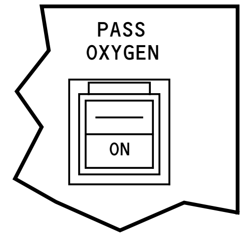
- In passenger service units (PSU)
- In the lavatory PSUs
- In the flight crew rest (FCR) service units
- In the overdoor panels.

Oxygen generators and masks can also be in lowered ceiling panels in cross aisles and in other areas of the airplane.

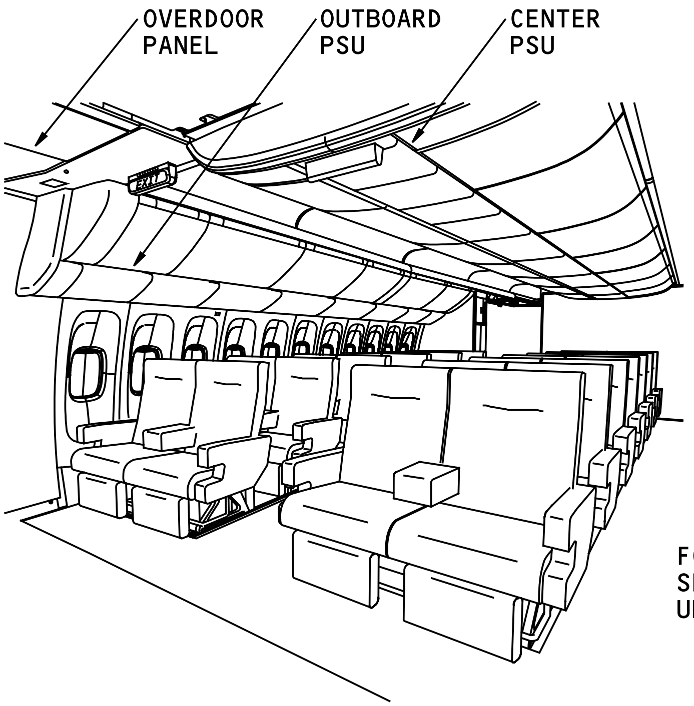
The control switch is on the P5 overhead panel in the flight compartment.



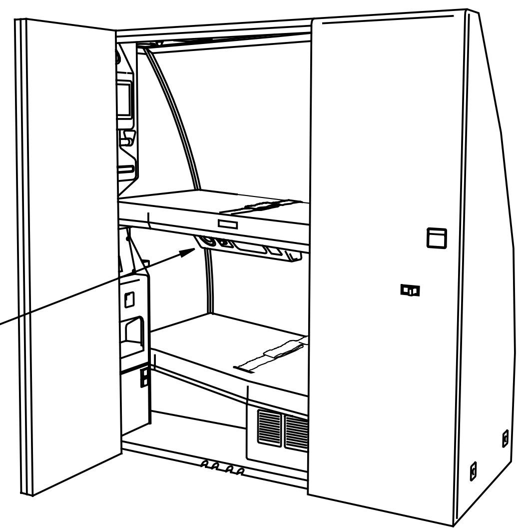
P5 OVERHEAD PANEL



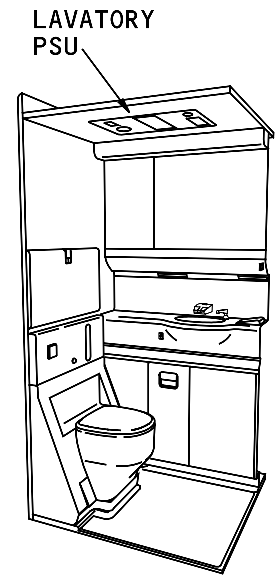
WINDOW HEAT/EMERGENCY LIGHTS PANEL (P5)



PASSENGER COMPARTMENT (EXAMPLE)



FLIGHT CREW REST AREA



LAVATORY (EXAMPLE)

PASSENGER OXYGEN - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

PASSENGER OXYGEN - PASSENGER OXYGEN BOX AND PASSENGER OXYGEN MASK

Purpose

The passenger oxygen boxes contain the oxygen masks for the passengers and flight attendants. The oxygen masks supply oxygen to the passengers and attendants if the airplane loses cabin pressure.

Location

Oxygen mask boxes are in these locations:

- Center passenger service units (PSUs)
- Outboard PSUs
- Lavatory PSUs
- Above the flight crew rest bunks
- On overdoor panels
- On some lowered ceiling panels.

Passenger Oxygen Box

A chemical oxygen generator attaches to each box. The center PSUs have two generators if they supply oxygen to more than three seats. A manifold (not shown) in the box distributes oxygen from the generator to the masks. A door with an electrically operated latch keeps the masks in the box until the oxygen deployment circuit operates.

The total quantity of oxygen masks is greater than the quantity of passenger and attendant seats. These are the quantities of masks in each type of oxygen box:

- Outboard PSUs - one more mask than the quantity of related seats
- Center PSUs - one more mask than the quantity of related seats
- Overdoor and lowered ceiling boxes - two masks
- Flight crew rest oxygen boxes - two masks
- Lavatory boxes - two masks.

Latches attach the outboard and center PSUs to the airplane structure. Release the latches and lower the PSU for access to the oxygen generators.

Lower the overdoor panel for access to the oxygen generators above those panels. To get access to the generators in the lavatories or lowered ceiling panels, remove the adjacent lowered ceiling panel.

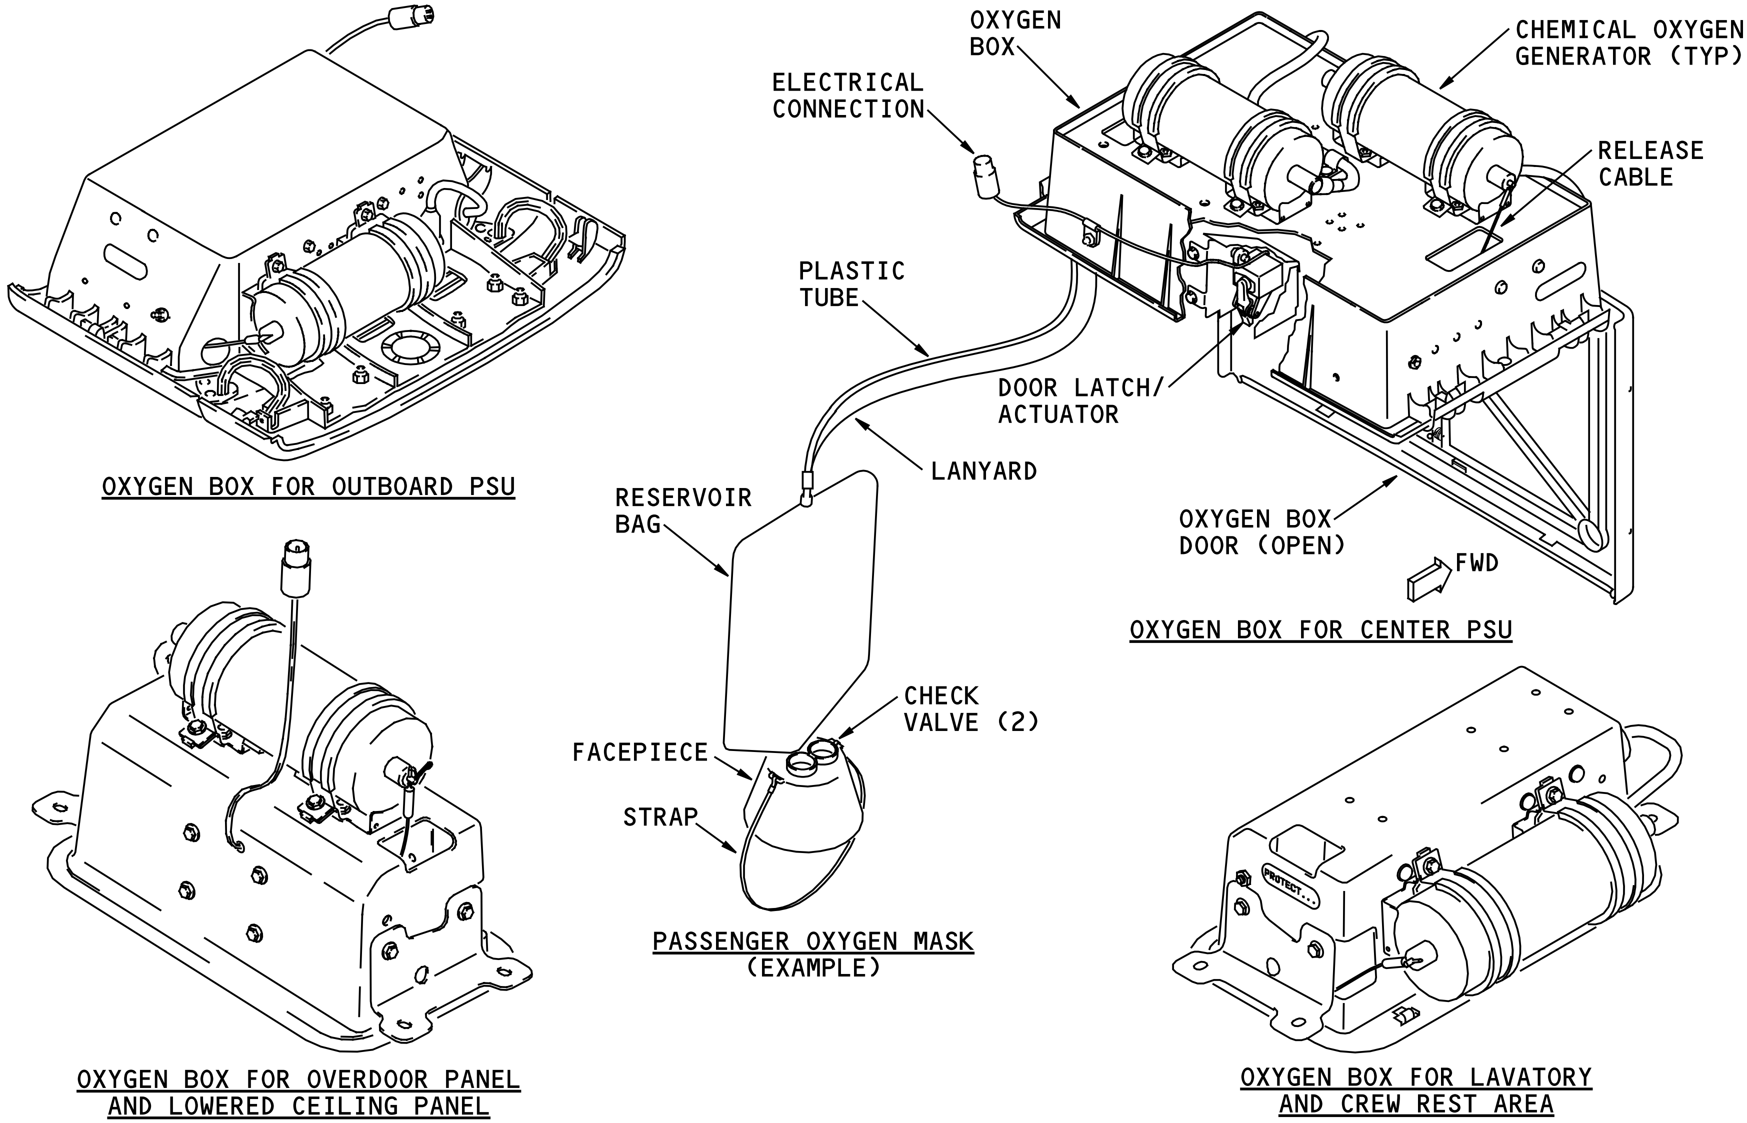
In the flight crew rest area, access to the oxygen generators is different for the two bunks. Open the PSU for access to the oxygen generator for the lower bunk. Remove the lowered ceiling panel above the aisle for access to the oxygen generator for the upper bunk.

See the equipment and furnishings chapter for more information about the PSUs, overdoor panels, lowered ceiling panels and crew rest areas (AMM PART I 25).

Passenger Oxygen Mask

The masks are continuous-flow units. A plastic tube connects the oxygen box manifold to a mask reservoir bag. A flexible facepiece with two check valves attaches to the reservoir bag. An elastic strap holds

the facepiece in place over the user's nose and mouth.
A lanyard connects the mask to the release cable in the oxygen box.



PASSENGER OXYGEN - PASSENGER OXYGEN BOX AND PASSENGER OXYGEN MASK

35-21-00-002 Rev 6 08/16/96

PASSENGER OXYGEN - DOOR LATCH/ACTUATOR - INTRODUCTION

Purpose

The latch part of the door latch/actuator holds the oxygen door closed. The actuator causes the latch to release the door.

Physical Description

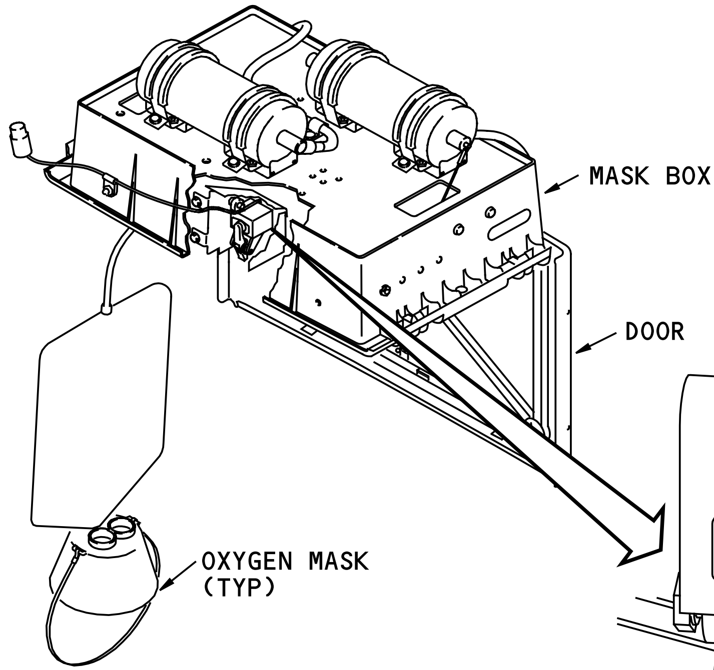
The latch/actuator has these parts:

- Electrical connector
- Housing
- Spring
- Lever arm with metal plate.

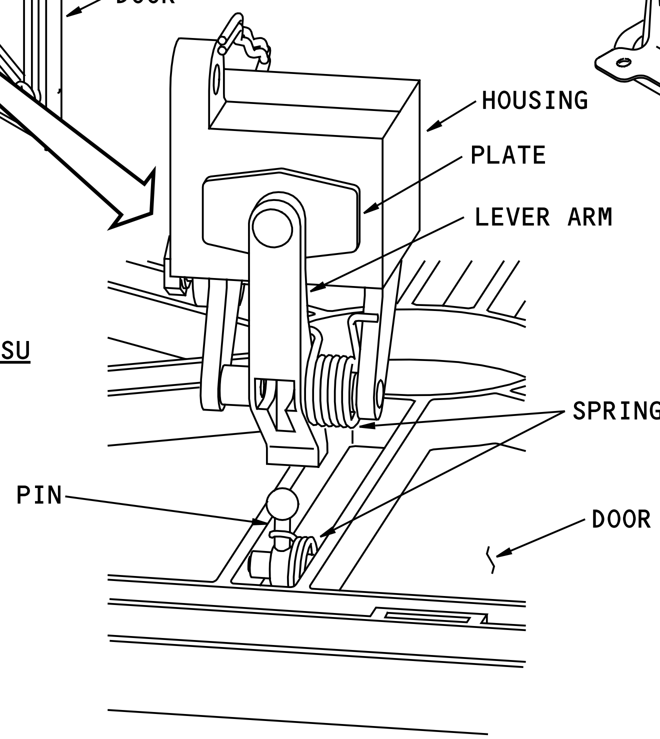
The housing contains a permanent magnet with an electric coil around it.

There is a spring-loaded latch pin on the oxygen door. It fits into a notch on the bottom of the lever arm to hold the door closed.

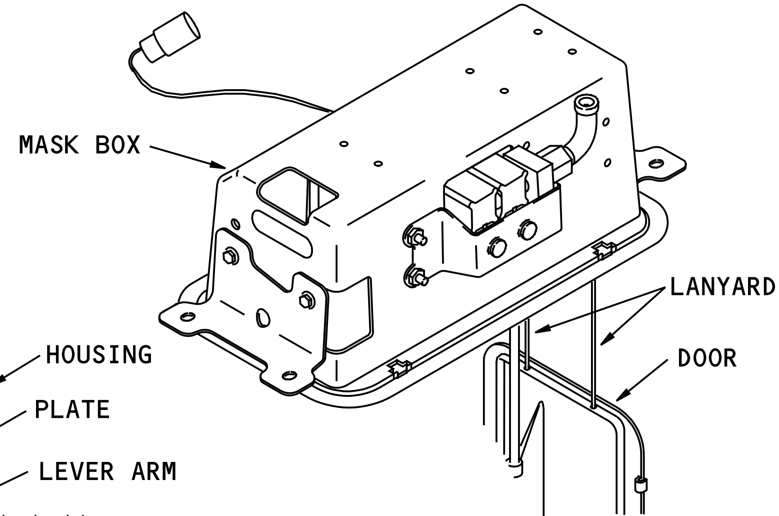
The hinge on the mask box in the lavatory at door one left has a design that is different from the other boxes. When the door is released and moves to open, the hinge separates and lets the door fall. It hangs on lanyards. In this position, the box door will not interfere with the operation of the lavatory bifold door.



MASK BOX FOR CENTER PSU
(EXAMPLE)



DOOR LATCH/ACTUATOR



MASK BOX AT DOOR
ONE LEFT LAVATORY

35-21-00-003 Rev 1 03/29/96

PASSENGER OXYGEN - DOOR LATCH/ACTUATOR - INTRODUCTION

PASSENGER OXYGEN - DOOR LATCH/ACTUATOR - FUNCTIONAL DESCRIPTION

General

Either of these two conditions releases the oxygen masks:

- The passenger oxygen switch on the P5 is set to the ON position
- Two of the three cabin pressure sensors give a signal that the cabin pressure altitude is above 13,500 feet (4115 meters) and the airplane is in the air with an airspeed more than 80 knots.

Functional Description

When you operate the passenger oxygen switch, a signal goes from OPAS to the ELMS. The ELMS latches a ground for the channel A and B oxygen deployment relays for fifteen seconds. (The channel B relay is not shown. It is redundant with the channel A relay.) The relays let 115v ac energize the oxygen module door latch/ actuators.

When the deployment relays energize, the ELMS sends a signal to these systems:

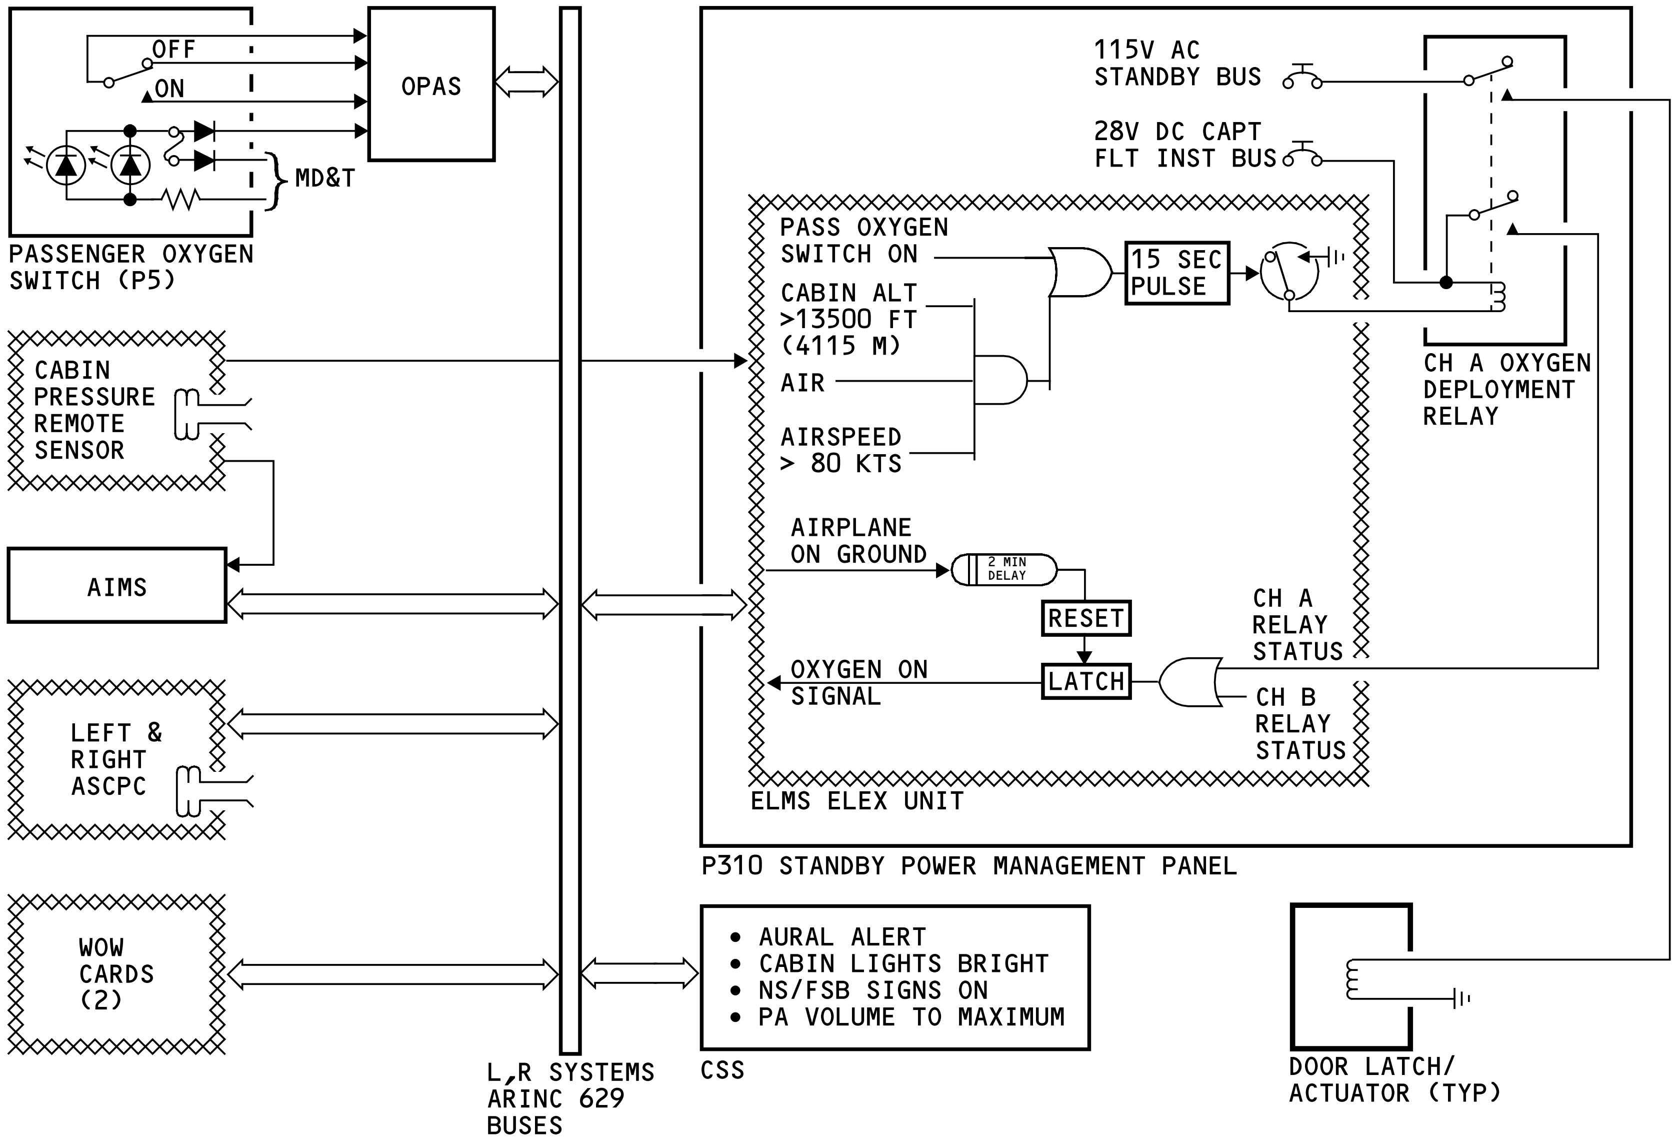
- AIMS
- Cabin services system (CSS)
- OPAS.

The OPAS turns on the light in the passenger oxygen switch. The AIMS shows an advisory message.

The CSS causes these events in the passenger compartment:

- Aural alert
- The passenger compartment lights come on bright
- The no smoking and fasten seat belt signs come on
- Passenger address volume increases to maximum.

The ELMS cancels the oxygen on signal two minutes after the airplane lands.



PASSENGER OXYGEN - DOOR LATCH/ACTUATOR - FUNCTIONAL DESCRIPTION

PASSENGER OXYGEN - CHEMICAL OXYGEN GENERATOR

Purpose

The chemical oxygen generators supply oxygen for the passengers and flight attendants.

Physical Description

The size of the generator has a relation to the number of oxygen masks that connect to it. The masks connect to a manifold at one end of the generator.

A firing pin is at the other end. A release pin holds the firing pin against the spring force. A release cable connects to a lanyard that goes to the mask. A safety pin holds the firing pin when the release pin is not installed.

The generator contains iron and sodium chlorate.

An expended indicator is around the middle of the generator. It goes to a dark color to show that the generator has been used.

Functional Description

When a passenger or attendant pulls on an oxygen mask, the lanyard and release cable pull the release pin out of the firing pin. The spring moves the firing pin into the primer. This causes the iron and sodium chlorate to react to release oxygen.

You cannot stop the reaction after it starts. There is full oxygen flow 10 seconds after the reaction starts. The oxygen flows at least 22 minutes.

Training Information Point

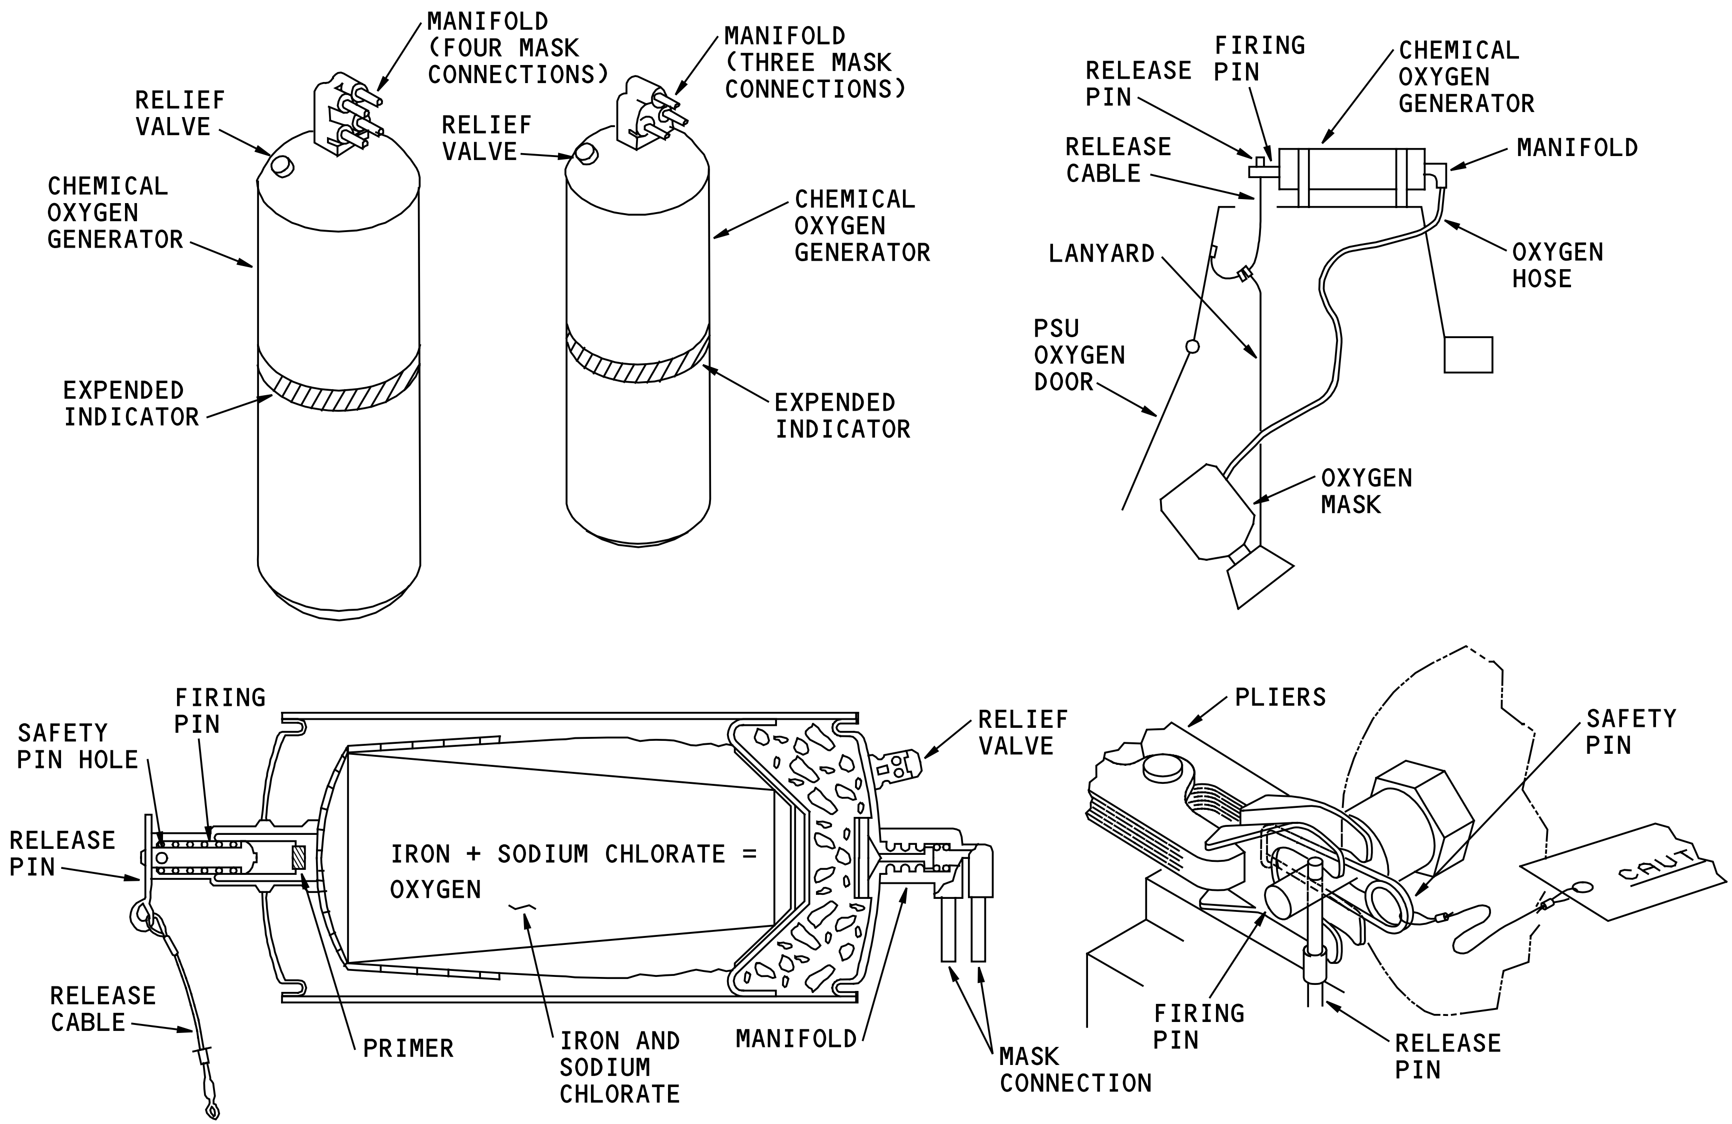
The expended indicator turns a dark color because of the heat of the reaction. This shows you that you must replace the generator.

There are pliers you use to pull out on the firing pin so you can put in a safety pin.

WARNING: MAKE SURE THE SAFETY PIN IS INSTALLED. THE GENERATOR IS A PYROTECHNIC ARMED DEVICE. IF THE GENERATOR FIRES, IT WILL GET VERY HOT (450 F OR MORE), WHICH CAN CAUSE INJURY TO PERSONS OR CAN CAUSE DAMAGE TO EQUIPMENT.

WARNING: MAKE SURE TO REMOVE THE SAFETY PIN FROM THE GENERATOR. THE GENERATOR WILL NOT FIRE IN AN EMERGENCY IF THE SAFETY PIN IS IN THE GENERATOR.

NOTE: If the firing pin is in the fired position (you cannot install the release pin), the generator has fired.



PASSENGER OXYGEN - CHEMICAL OXYGEN GENERATOR

PASSENGER OXYGEN - DOOR LATCH/ACTUATOR - TRAINING INFORMATION POINT

Door Latch/Actuator Test

There is a restraint tool you use when you test the door latch/actuator. The tool goes through a slot in the PSU oxygen door. Push up on the tool until it locks in position.

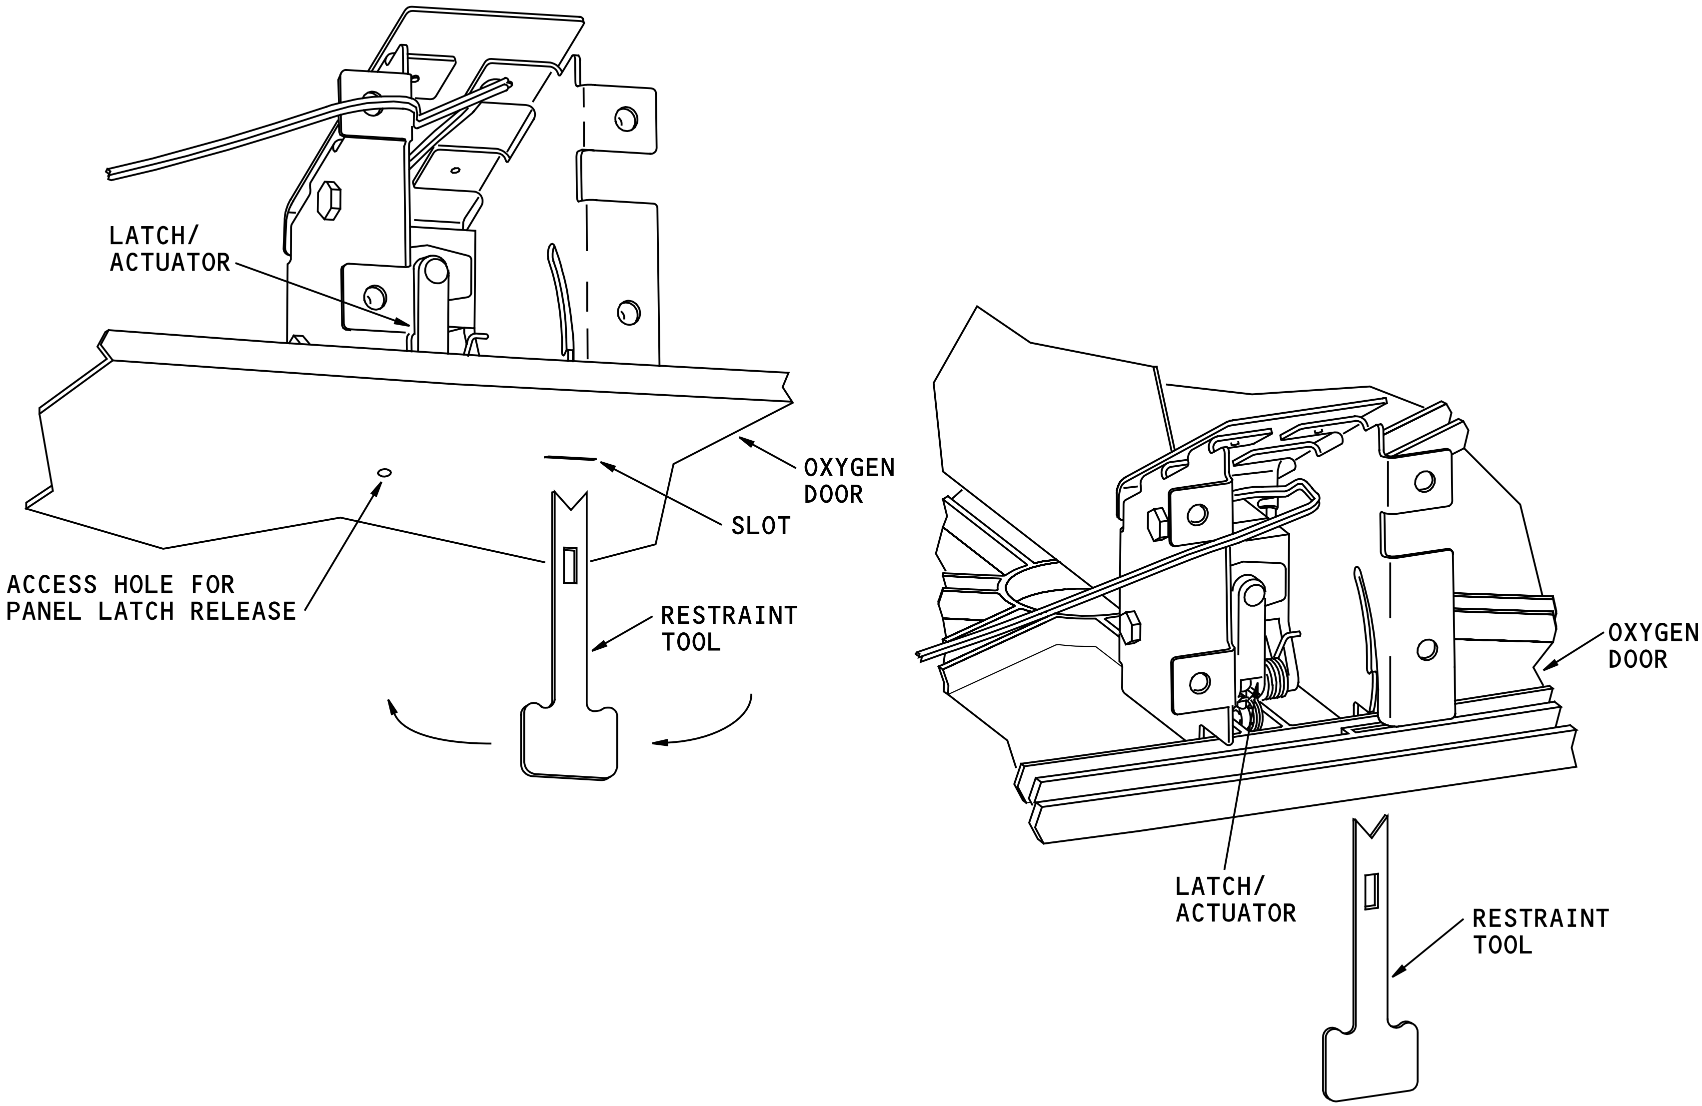
When you push the passenger oxygen switch on the P5 overhead panel, you release the oxygen doors on the PSUs so they can open. The restraint tool will let the door open sufficiently so you can see that the latch/ actuator operates correctly. The door cannot open sufficiently to let the masks drop.

Door Latch/Actuator Reset

The electric circuit that causes the latch/actuator to open will reset automatically after two minutes.

After the test you must reset the latch/actuators and close the doors. The open space between the door and the PSU is sufficient to let you touch the latch/ actuator. Push the lever arm of the latch/actuator against the force of its spring so the lever goes against the housing. The magnet in the housing will hold the lever arm in this position.

Close the door. To remove the restraint tool, push up on the tool, pull it to the side, and then pull it down.



35-21-00-006 Rev 1

PASSENGER OXYGEN - DOOR LATCH/ACTUATOR - TRAINING INFORMATION POINT

PORTABLE OXYGEN - GENERAL DESCRIPTION

Purpose

Portable oxygen equipment lets the flight attendants move in the airplane when oxygen is in use. It is also a gaseous oxygen supply for medical emergencies.

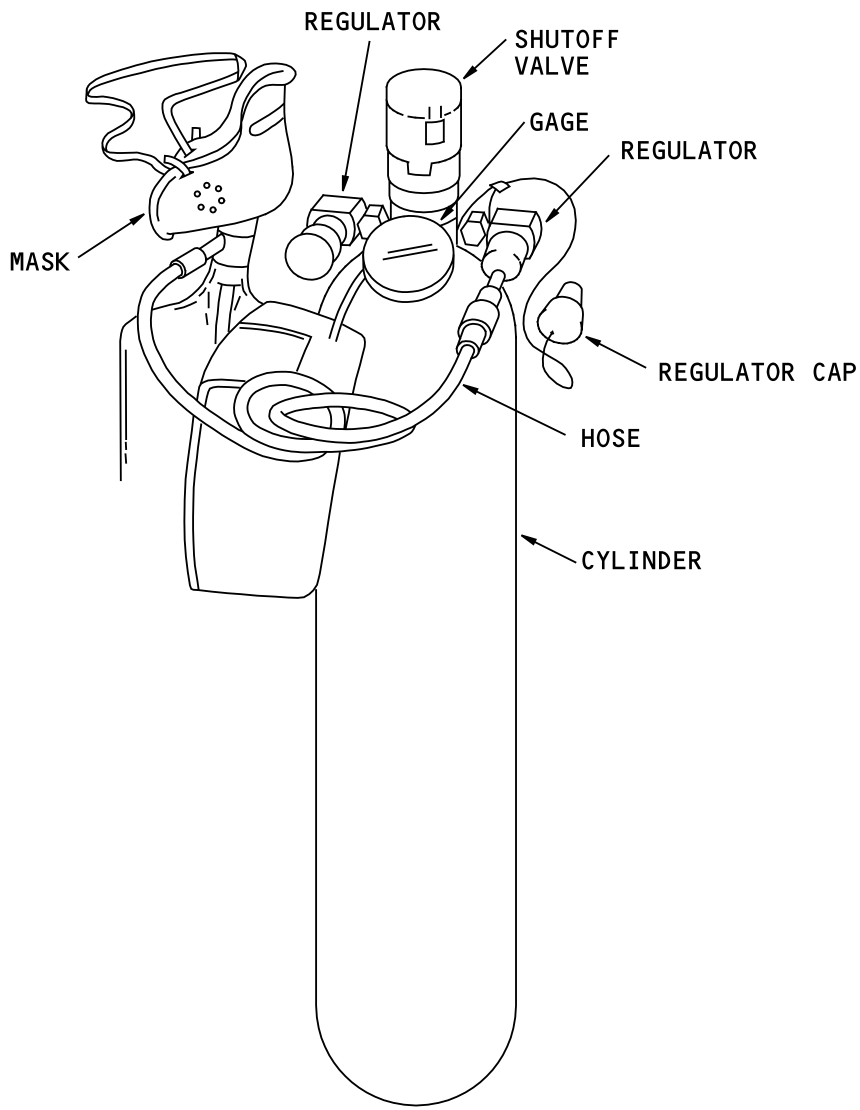
Physical Description

The portable oxygen equipment has these components:

- Regulator (2)
- Shutoff valve
- Gage
- Hose
- Cylinder
- Mask.

Operation

You connect the mask hose to the regulator that gives the oxygen flow that you want. One regulator supplies four liters per minute. The other supplies two liters per minute. Oxygen will flow through the regulator when you connect the mask and open the shutoff valve.



PORTABLE OXYGEN - GENERAL DESCRIPTION

ICE AND RAIN PROTECTION - INTRODUCTION

Purpose

The ice and rain protection system keeps ice from forming on these airplane components:

- Wing leading edges
- Engine cowl leading edges
- Air data probes
- Flight deck windows
- Water and waste system lines and drains.

Windshield wipers and a permanent chemical coating give rain protection to the flight deck windows.

Abbreviations and Acronyms

30-00-00-001 Rev 2 03/26/96

ICE AND RAIN PROTECTION - INTRODUCTION

ICE AND RAIN PROTECTION - GENERAL DESCRIPTION

Wing and Engine Anti-Ice Systems

The wing anti-ice (WAI) and engine anti-ice (EAI) systems use hot air to prevent ice.

Ice Detection System

The ice detection system detects ice and automatically controls the WAI and EAI systems.

Air Data Sensor Heat

Air data sensors have electric heaters to prevent ice.

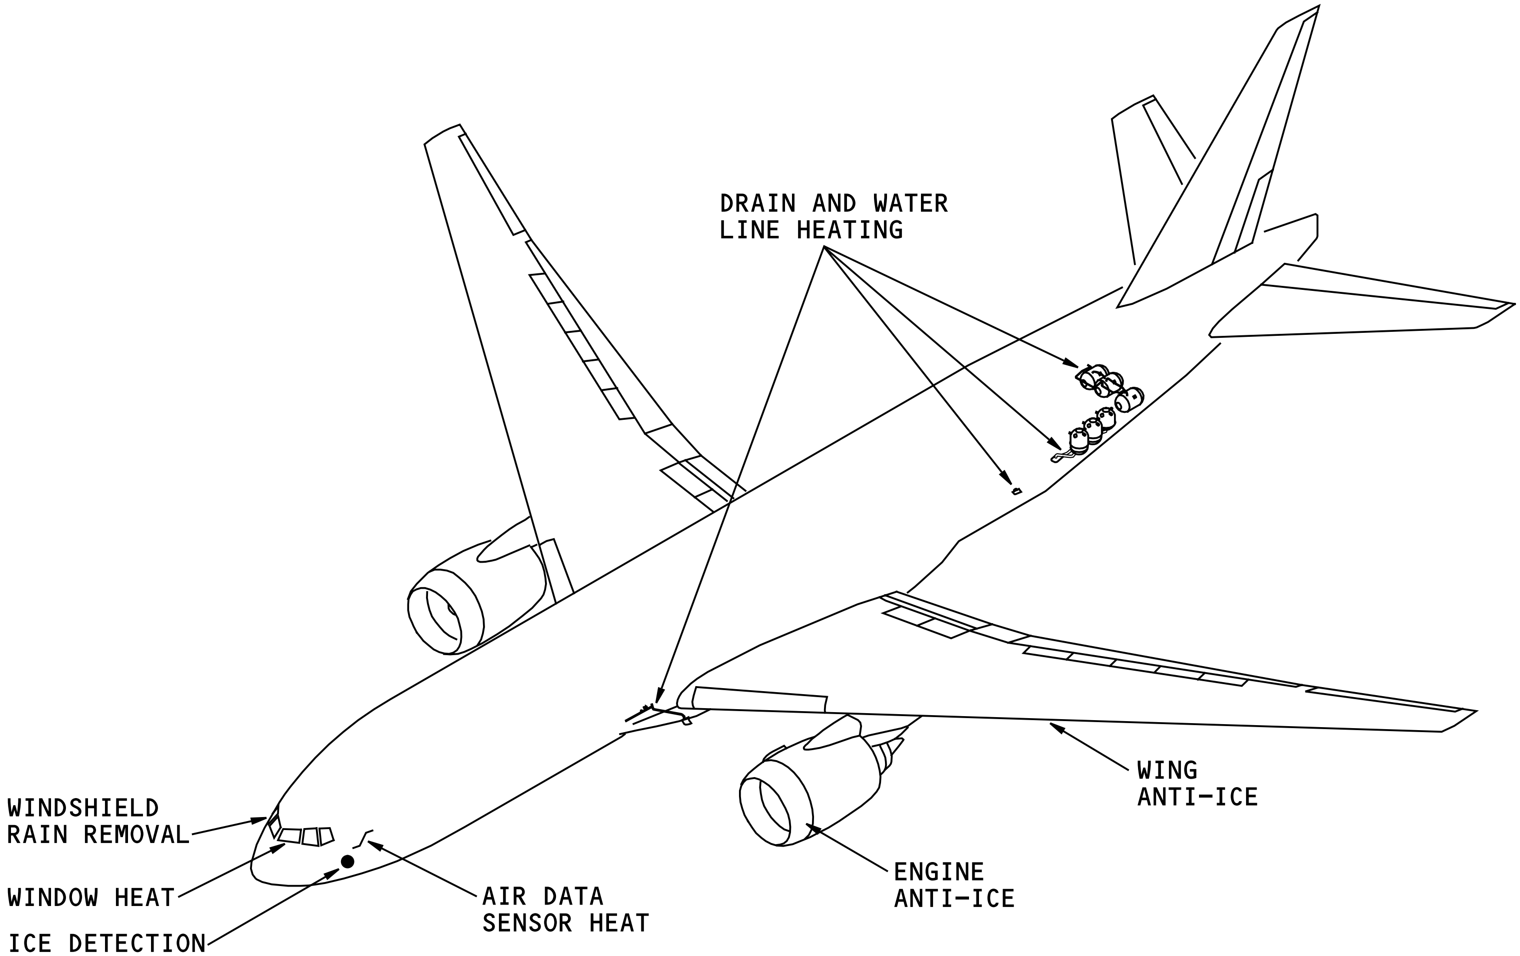
Flight Deck Windows

Flight deck windows have electrical heaters to prevent fog and ice.

The windshields have wipers to remove rain. They also have a hydrophobic coating to keep rain off (repel rain). The coating helps flight crew vision in rain but is not necessary for operation in rain.

Drain and Water Line Heating

Electric heaters prevent freezing in water and waste system lines and fittings.



ICE AND RAIN PROTECTION - GENERAL DESCRIPTION

WING ANTI-ICE - INTRODUCTION

Purpose

The wing anti-ice system heats some of the leading edge slats so that ice does not collect on them in flight.

General Description

The pneumatic system supplies bleed air to heat the leading edge slats. Slats 3, 4, and 5 on the left wing and slats 10, 11, and 12 on the right wing are heated. Two wing anti-ice (WAI) valves control the air flow from the pneumatic system to WAI ducts. The WAI ducts carry the air to the slats. Holes in the bottom of each slat let the air out.

The airfoil and cowl ice protection system (ACIPS) control card - WAI controls the wing anti-ice valves. WAI pressure sensors send WAI duct air pressure data to the control card.

The wing anti-ice selector in the flight deck lets the crew set automatic or manual control. With AUTO selected, the WAI system comes on when the ice detection system finds ice. The OFF and ON positions are for manual control.

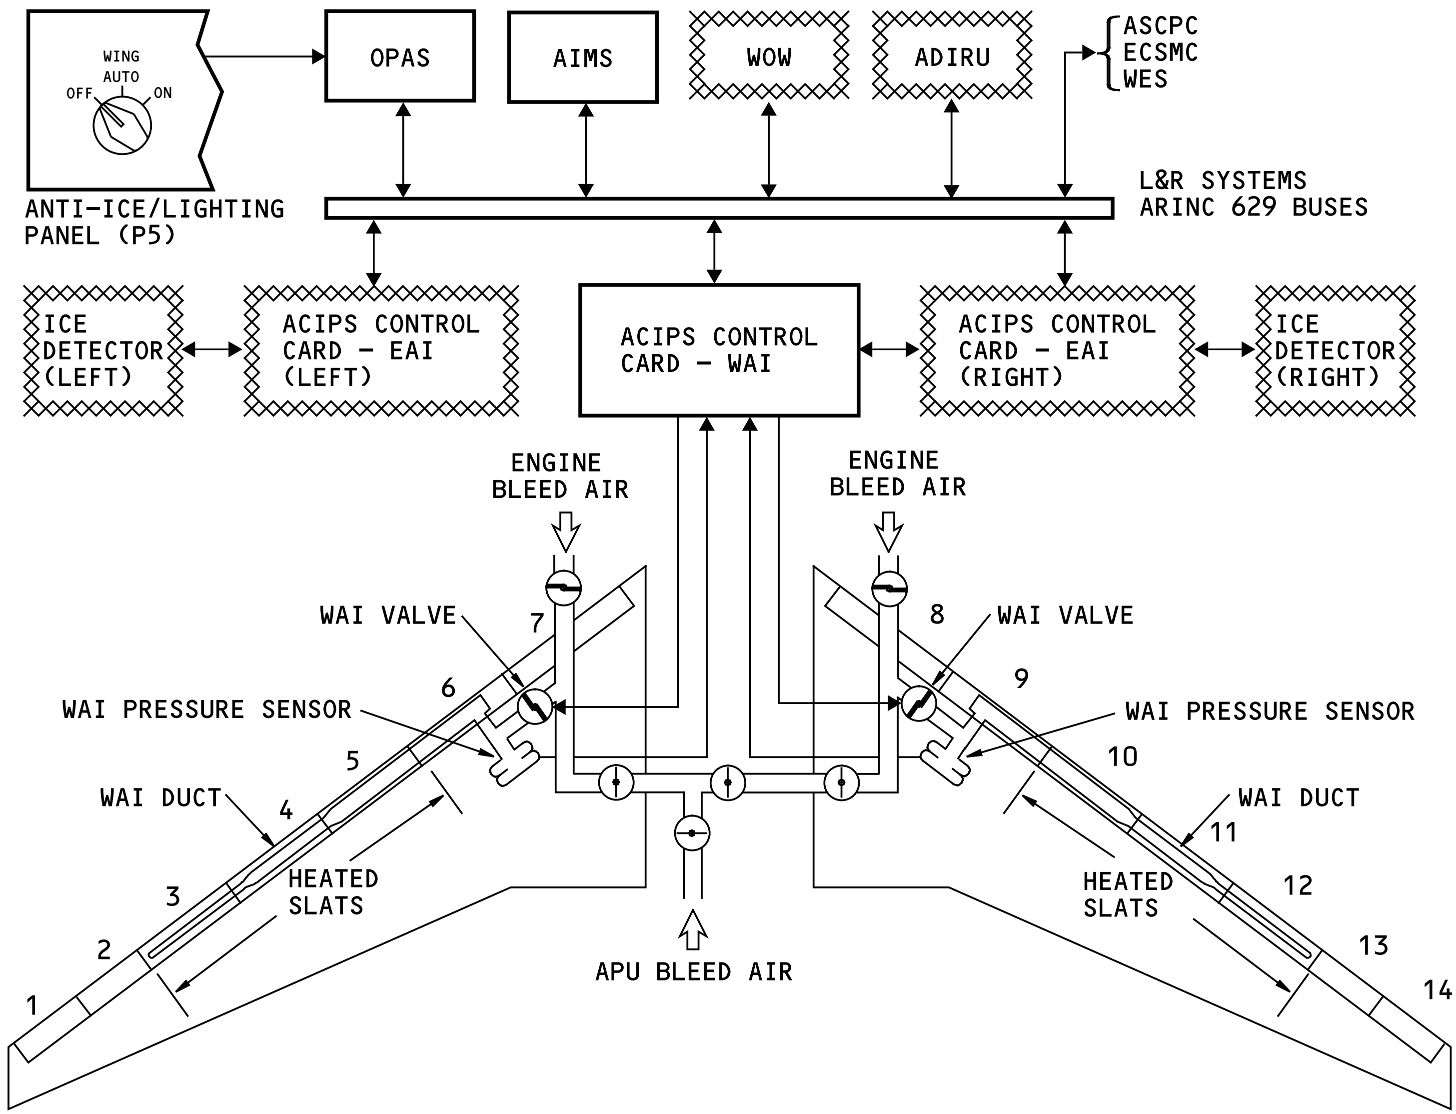
See the ice detection system section for more information (AMM PART I 30-81).

BITE circuits in the control card monitor the condition of the system. The AIMS gives information about the system through the EICAS display, status display, and maintenance pages. You use the MAT to do ground tests of the system.

Except for ground tests, the WAI system only operates in flight. Air/ground information from the weight on wheels (WOW) cards or airspeed data from the air data inertial reference unit (ADIRU) tells the control card when the airplane is in flight.

The wing anti-ice system has these other interfaces:

- ASCPC (air supply cabin pressure controller)
- ECSMC (ECS miscellaneous card)
- WES (warning electronic system).



WING ANTI-ICE - INTRODUCTION

WING ANTI-ICE - WING COMPONENT LOCATIONS

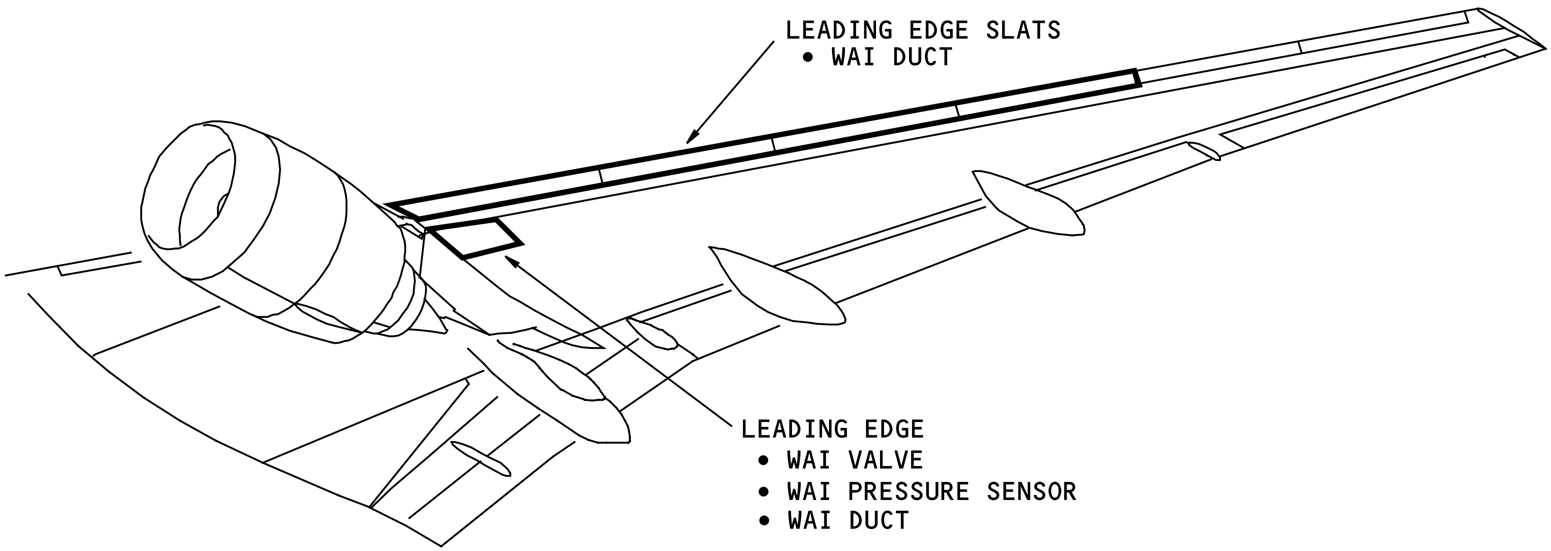
Component Locations

These components are in the wing leading edge next to the outboard side of the engine strut:

- WAI valve
- WAI pressure sensor
- WAI ducts.

There are also WAI ducts in the leading edge slats.

All of these components are LRUs.



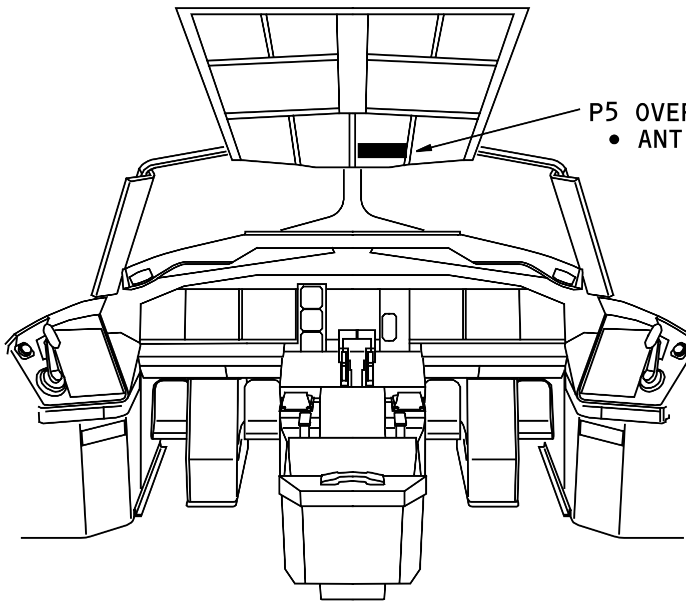
30-11-00-002 Rev 1

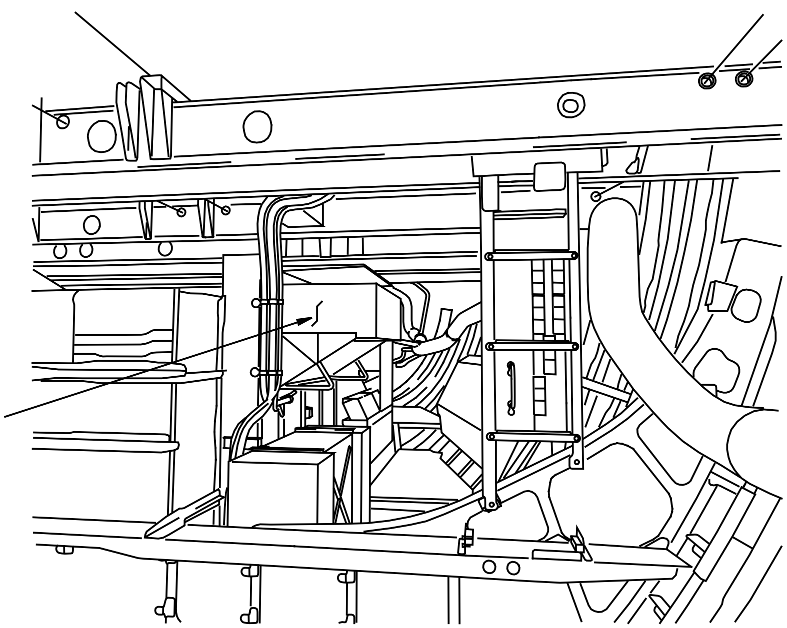
WING ANTI-ICE - WING COMPONENT LOCATIONS

WING ANTI-ICE - FLIGHT DECK AND MEC COMPONENT LOCATIONS

Component Locations

The anti-ice control panel is on the P5 overhead panel. The WAI airfoil and cowl ice protection system control card (WAI ACIPS control card) is in the P84 right systems card file.





MAIN EQUIPMENT CENTER
(RIGHT SIDE LOOKING FORWARD)

30-11-00-003 Rev 1

WING ANTI-ICE - FLIGHT DECK AND MEC COMPONENT LOCATIONS

WING ANTI-ICE - WAI VALVE

Purpose

The WAI valve controls the flow of bleed air from the pneumatic system to the wing anti-ice ducts.

Physical Description

The WAI valve has these parts:

- Body
- Pneumatic actuator
- Torque motor
- Electrical connector
- Locking crank and position indicator
- Locking screw.

The valve is electrically controlled and pneumatically actuated.

Location

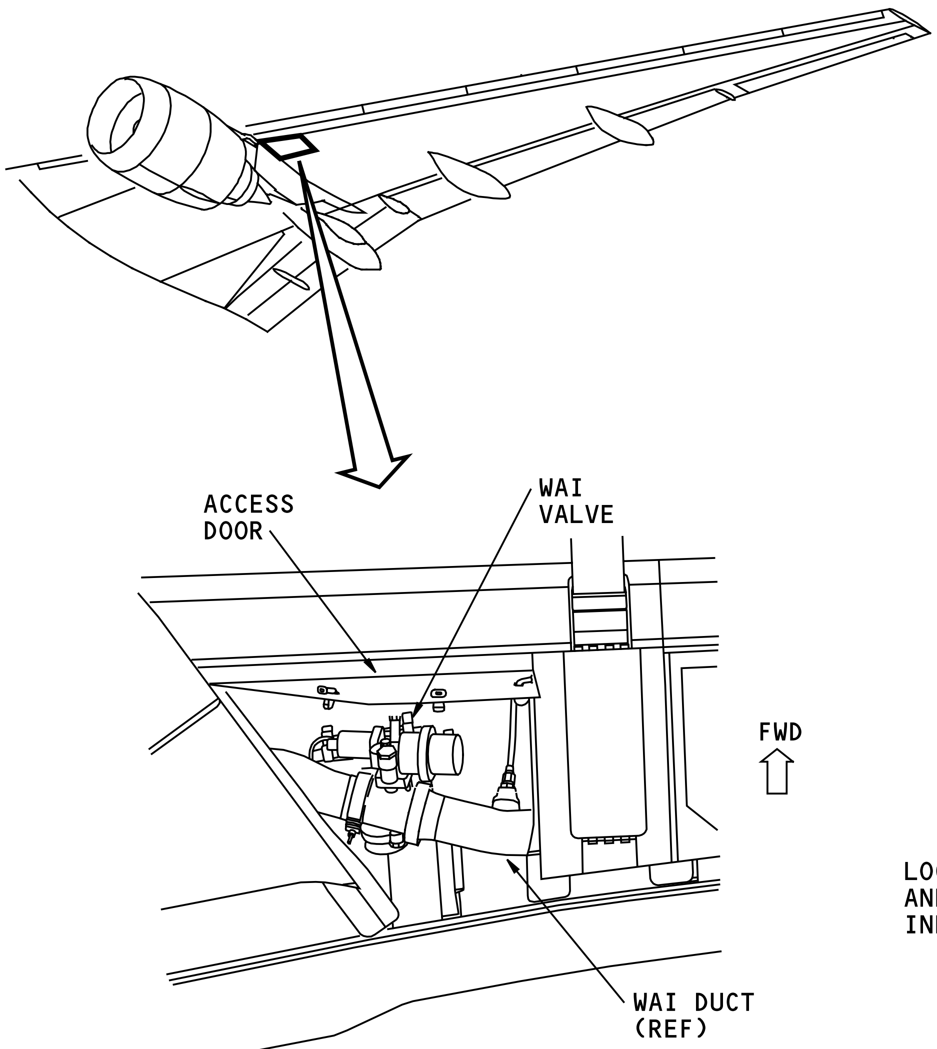
The WAI valve is in the WAI duct in the leading edge of the wing. The WAI valve access door is on the bottom of the wing leading edge, outboard of the engine strut.

Functional Description

The WAI ACIPS control card controls the current through the torque motor. The torque motor controls operation of the valve. With no electrical power to the torque motor, air pressure on one side of the actuator holds the valve closed. Electrical current through the torque motor allows air pressure to open the valve. As the torque motor current increases, the valve opening increases.

Training Information Point

If a WAI valve does not operate, you can lock the valve closed. Remove the locking screw from the actuator. Set the locking crank to the closed position and install the locking screw into the hole in the locking crank.



WING LEADING EDGE

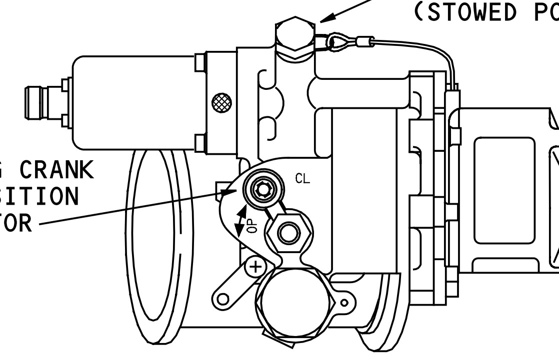
(SIDE VIEW)



WAI VALVE
(TOP VIEW)

30-11-00-004 Rev 1 01/25/95

WING ANTI-ICE - WAI VALVE

WING ANTI-ICE - WAI PRESSURE SENSOR

Purpose

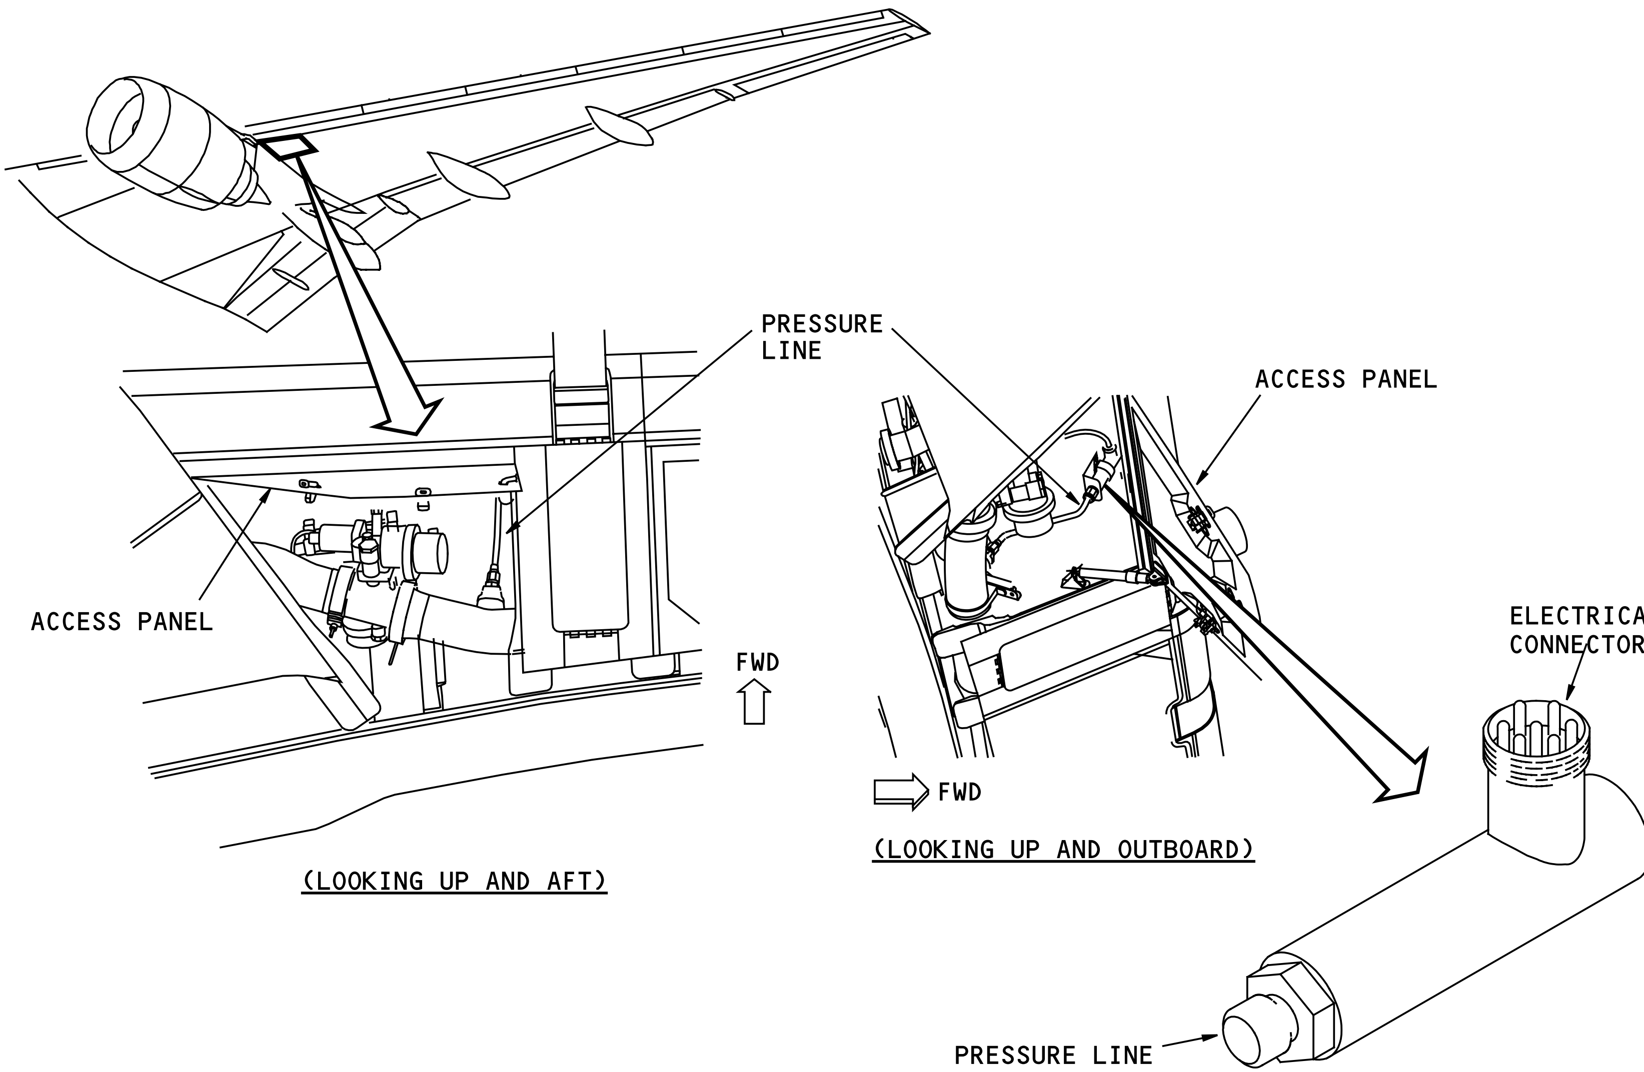
The WAI pressure sensor gets input from the air pressure in the WAI duct after the WAI valve. The center ACIPS card uses the pressure information to control the WAI system.

Physical Description

The WAI pressure sensor has a pressure line connector on one end and an electrical connector on the other end.

Location

The sensor is installed above the WAI duct in the leading edge of the wing. The access panel for the sensor is on the bottom surface of the wing leading edge next to the outboard side of the engine strut.



30-11-00-005 Rev 1

WING ANTI-ICE - WAI PRESSURE SENSOR

WING ANTI-ICE - WAI DUCTS

Purpose

The WAI ducts move air from the pneumatic system to leading edge slats which are outboard of the engines.

Physical Description

Some of the WAI ducts are perforated. The holes allow air to flow into the space in the leading edge slats. The air leaves the slats through holes in the bottom of each slat.

Some of the WAI ducts can telescope. Each telescoping duct has two sections. One section is to a duct in the wing. The other section attaches to a duct in the leading edge slat. The sections can move into each other. This permits the duct to extend or retract when the slat extends or retracts.

Locations

The perforated ducts are inside these slats:

- 3, 4, and 5 on the left wing
- 10, 11, and 12 on the right wing.

The ducts that can telescope are in the wings and in these slats:

- 6 on the left wing
- 9 on the right wing.

Access

There are duct joints between adjacent slats. The inboard and outboard end of each slat has an access panel for the duct joints between adjacent slats.

There is an access panel in the slat for the telescoping duct.

WING ANTI-ICE - WAI DUCTS

WING ANTI-ICE - FUNCTIONAL DESCRIPTION - ELECTRICAL

General

The WAI ACIPS control card controls both wing anti-ice valves. The required positions of the WAI valves change as bleed air temperature and altitude change. The left and right valves operate at the same time to heat both wings equally. This keeps the airplane aerodynamically stable in icing conditions.

The WAI pressure sensors supply feedback information to the WAI ACIPS card for WAI valve control and position indication. If either pressure sensor fails, the WAI ACIPS card sets the related WAI valve to either fully open or fully closed. If either valve fails closed, the WAI card keeps the other valve closed.

The WAI ACIPS control card receives ice detector data from the systems ARINC 629 buses. The data comes from the left and right ice detectors through the EAI ACIPS control cards.

There is one selector for the WAI system. The selector has three positions: AUTO, ON, and OFF.

Operational Modes

With the selector in AUTO and no operational mode inhibits, the WAI ACIPS card sends a signal to open the WAI valves when either ice detector finds ice. The valves close after a three minute delay when the ice detector no longer finds ice. The time delay prevents frequent on/off cycles during intermittent icing conditions.

With the selector ON and no operational mode inhibits, the wing anti-ice valves open. With the selector OFF, the wing anti-ice valves close.

Operational Mode Inhibits

With AUTO or ON selected, any of these operational mode inhibits keeps the WAI valves closed:

- Airplane on the ground (except during an initiated or periodic BITE test)
- TAT is more than 50F and the time since takeoff is less than 5 minutes
- Takeoff mode and airplane in the air less than 10 minutes
- Auto slat operation
- Air-driven hydraulic pump operation
- Engine start
- Bleed air temperature less than 200F (93C).

The valves stay closed as long as the operational mode inhibit is active. If the valves are already open, the operational mode inhibit causes the valves to close.

ARINC 629 Interfaces

The OPAS sends WAI selector position and engine start selector position to the WAI ACIPS control card.

The EAI ACIPS control cards send ice detector data to the WAI system. With AUTO selected, the ice detection system controls operation of the wing anti-ice system.

WING ANTI-ICE - FUNCTIONAL DESCRIPTION - ELECTRICAL

The weight on wheels cards (WOW) send air/ground status to the WAI system. Wing anti-ice does not operate on the ground.

The air data inertial reference unit (ADIRU) sends mach number, static pressure, and total air temperature data to the WAI system. Mach number is an alternative to air/ground status if air/ground data is missing or not valid. The WAI BITE compares static pressure with WAI duct air pressure to make sure the WAI duct pressure sensors work correctly.

The warning electronic system (WES) sends auto slat operation data to the WAI system. The WAI valves close for a short time during auto slat operation. This makes more bleed air available to the air-driven hydraulic pumps.

The air supply and cabin pressure controller (ASCPC) sends a WAI shutoff signal to the WAI ACIPS control card if the air-driven hydraulic pumps are on or intermittent. Wing anti-ice does not operate during ADP operation.

The ASCPC sends pneumatic manifold temperature and pressure data to the WAI ACIPS control card. The control card uses this data to calculate the WAI air flow rate and valve position. The flow rate and valve position show on the ice protection maintenance page. Also, bleed air temperature less than 200F (93C) prevents wing anti-ice operation.

The ASCPC receives anti-ice air flow data from the WAI ACIPS control card. The ASCPC needs this data to calculate the bleed flow rate in the pneumatic system. The engine bleed air system flow limit function uses this flow rate. The flow rate shows on the air supply maintenance page. The ASCPC also needs anti-ice air flow data to set the air conditioning pack flow schedule.

The ECS miscellaneous cards (ECSMC) receive WAI valve position data from the WAI ACIPS control card. The ECSMCs need this data to control the aft and bulk cargo heating systems.

The AIMS primary display function gives EICAS messages, status messages, air synoptic information and maintenance page information related to the WAI system. The central maintenance computing function helps you isolate faults and lets you do ground tests.

The flight management computing system (FMCS) gives takeoff mode information to the WAI ACIPS card. In takeoff mode, WAI does not operate for 10 minutes after the ground to air transition.

BITE

BIT circuits in the WAI ACIPS control card continuously monitor the wing anti-ice system. Faults that affect dispatch cause status messages. Other faults cause CMCS maintenance messages.

WING ANTI-ICE - FUNCTIONAL DESCRIPTION - ELECTRICAL

The BITE in the WAI ACIPS control card also does automatic power-up and periodic tests. Faults found during these tests that affect dispatch cause status messages. Other faults cause CMCS maintenance messages.

The power-up test occurs when the card gets power. BITE does a test of the card hardware and software functions and the valve and pressure sensor interfaces. The valves do not move during this test.

The periodic test occurs when all these conditions are true:

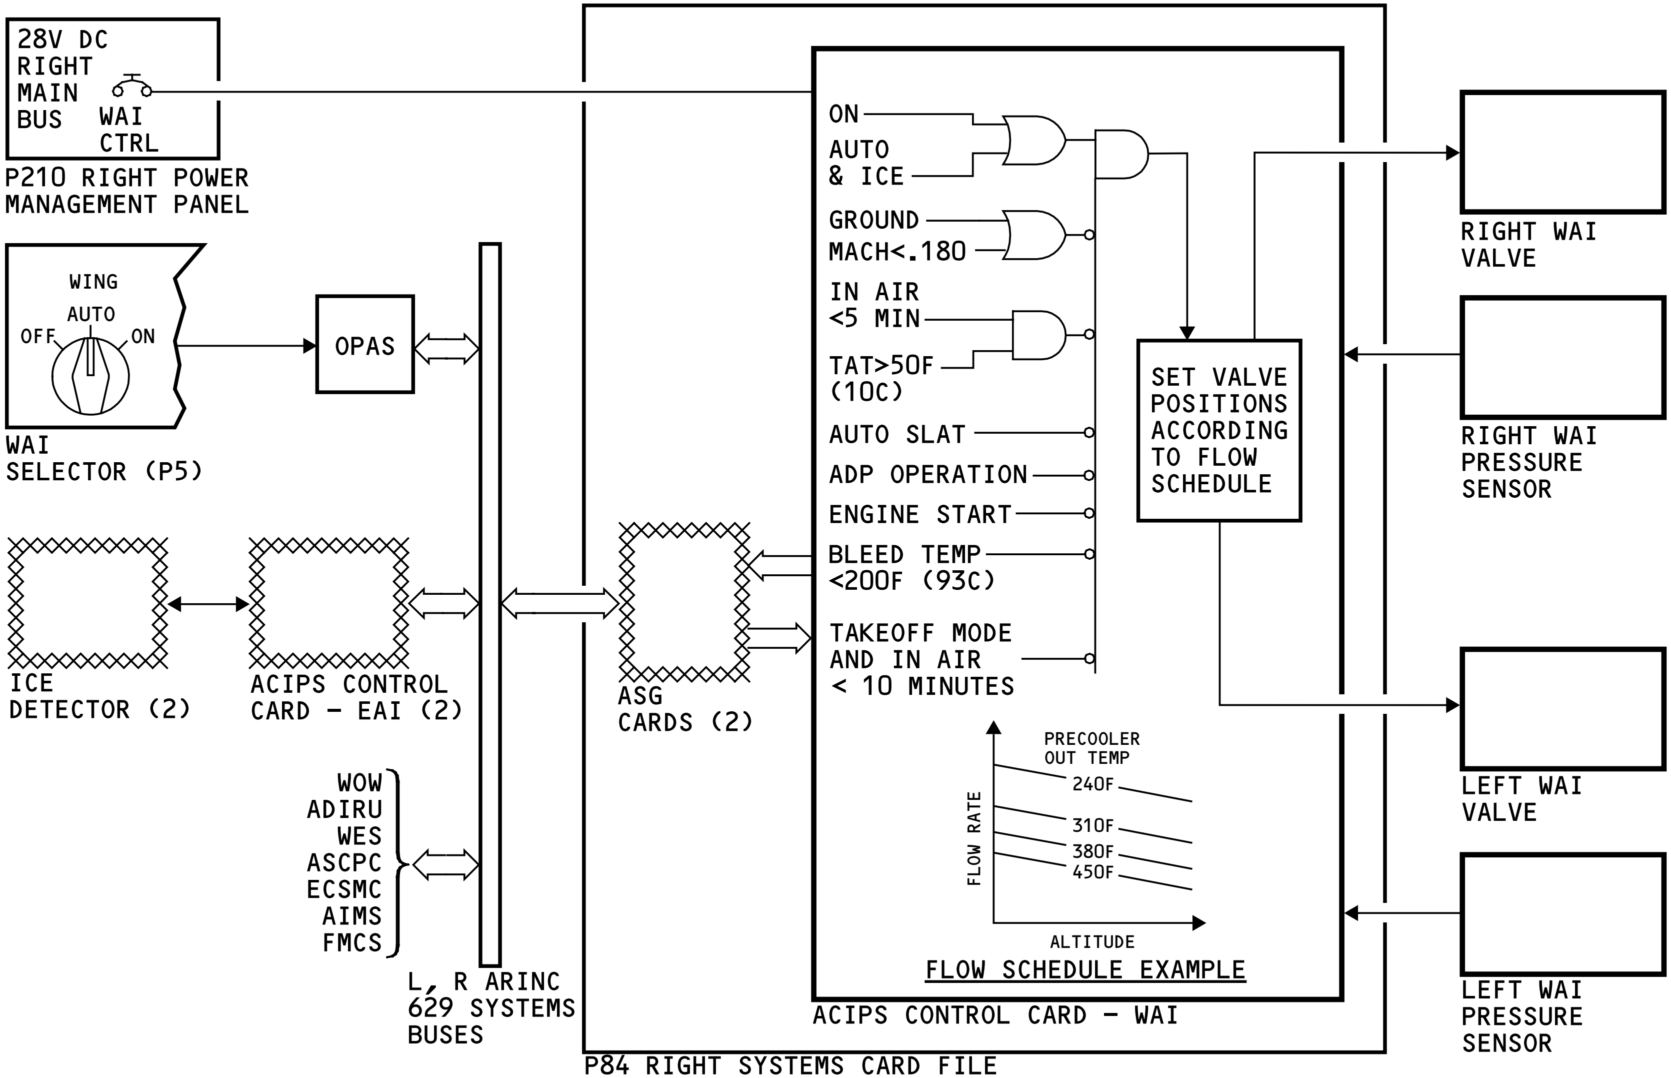
- The airplane has been on the ground between 1 and 5 minutes
- The WAI selector is set to AUTO or ON
- Air-driven hydraulic pumps are not in intermittent operation
- Bleed pressure is sufficient to open the WAI valves
- The time since the last periodic test is more than 24 hours.

During this test, the WAI valves cycle open and closed. This test makes sure that valve malfunctions are detected.

Training Information Point

You do wing anti-ice system ground tests with the MAT. Two tests are available: one with bleed air and one without bleed air.

You use the MAT data load function to replace the WAI ACIPS control card software.



30-11-00-007 Rev 2 07/18/1997

WING ANTI-ICE - FUNCTIONAL DESCRIPTION - ELECTRICAL

WING ANTI-ICE - OPERATION

General

The wing anti-ice selector lets the flight crew select the operational mode of the system. Indications on the EICAS display and on the air synoptic display show when the WAI valves are open.

Operation

The selector is on the anti-ice/lighting panel (P5). With the selector set to OFF, the WAI system does not operate. The WAI valves stay closed. The EICAS advisory message ICING WING shows if the ice detection system finds ice. The OFF selection prevents the WAI BITE periodic ground test.

For normal operation, the crew keeps the selector in AUTO. The wing anti-ice system operates automatically. The ice detection system controls wing anti-ice system operation as long as operational mode inhibits are not active. The AUTO position enables the BITE periodic ground test.

For manual operation, the crew sets the selector to ON when wing anti-ice is needed. The WAI valves stay open as long as no operational mode inhibits are active. The EICAS advisory message ANTI-ICE ON shows if the WAI selector is on, no ice is detected, and the TAT is more than 50F (10C).

Air Synoptic Display

The valve symbols show these conditions:

- Valve open - white circle with a horizontal green flow bar
- Valve closed - white circle with two vertical white bars
- Valve not in commanded position - amber circle with an amber cross through it
- Valve position data not available - white circle.

WING ANTI-ICE - OPERATION

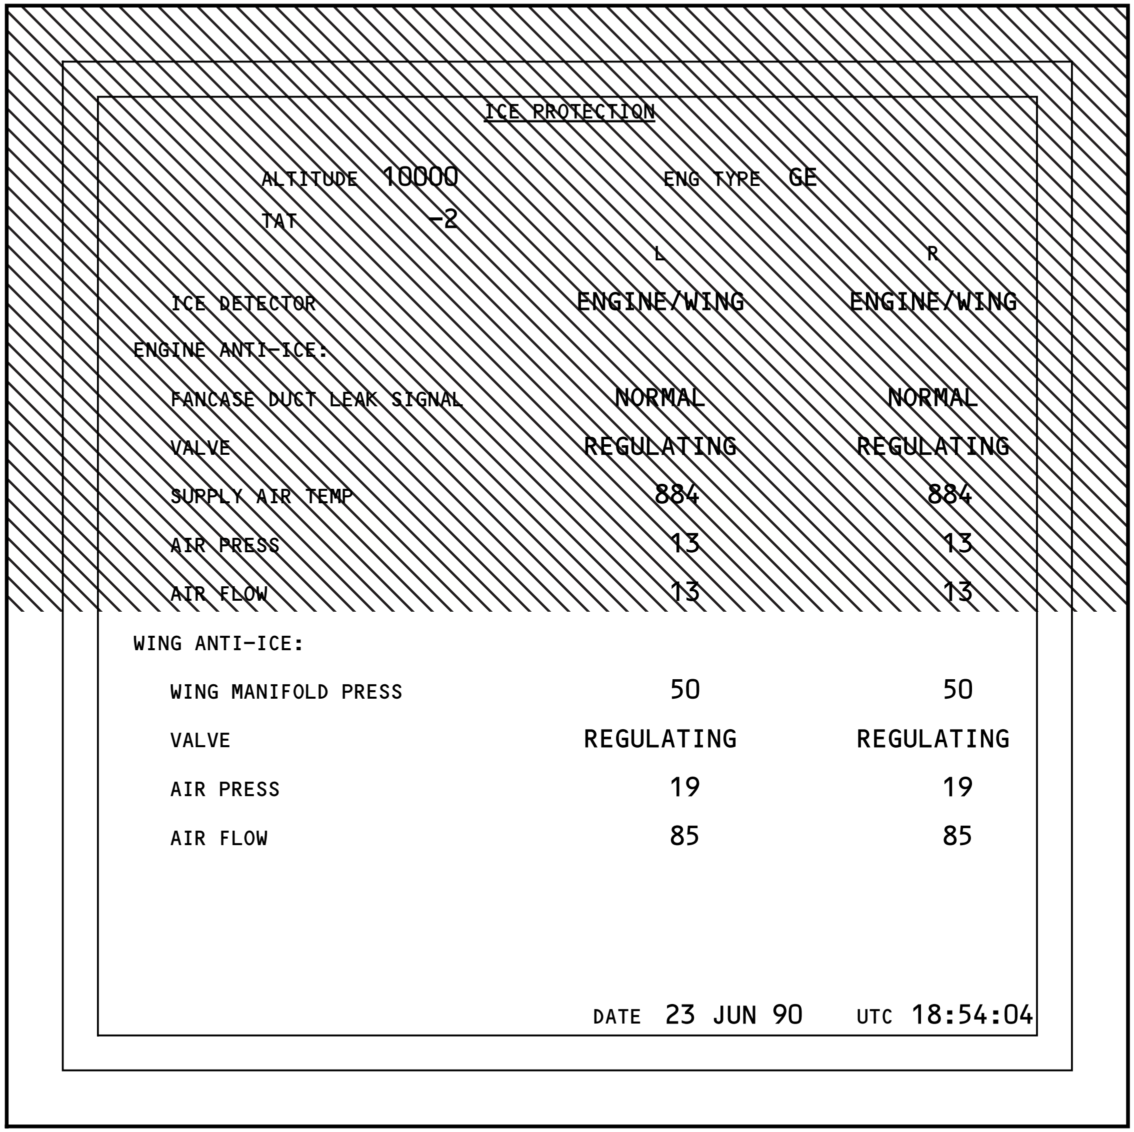
WING ANTI-ICE - INDICATIONS - ICE PROTECTION MAINTENANCE PAGE

Ice Protection Maintenance Page

The ice protection maintenance page shows this data for the wing anti-ice system:

- WING MANIFOLD PRESSURE - Pneumatic duct pressure in psig
- VALVE - WAI valve open, closed, or regulating
- AIR PRESSURE - Pressure downstream of the WAI valves in psig
- AIR FLOW - Air flow through the WAI valves in lb/min or kg/min.

Valve positions and air flow rates are calculated from air pressure measurements upstream and downstream of the WAI valves.



30-11-00-009 Rev 1 01/25/95

WING ANTI-ICE - INDICATIONS - ICE PROTECTION MAINTENANCE PAGE

WING ANTI-ICE - SYSTEM TESTS

General

These are the wing anti-ice system tests that show when you select ATA 30 Airfoil Cowl Ice Protection System:

- Wing anti-ice (pneumatics available)
- Wing anti-ice (pneumatics not available).

Wing Anti-Ice (Pneumatics Available)

This test makes sure that the wing anti-ice system can control the bleed airflow to each wing.

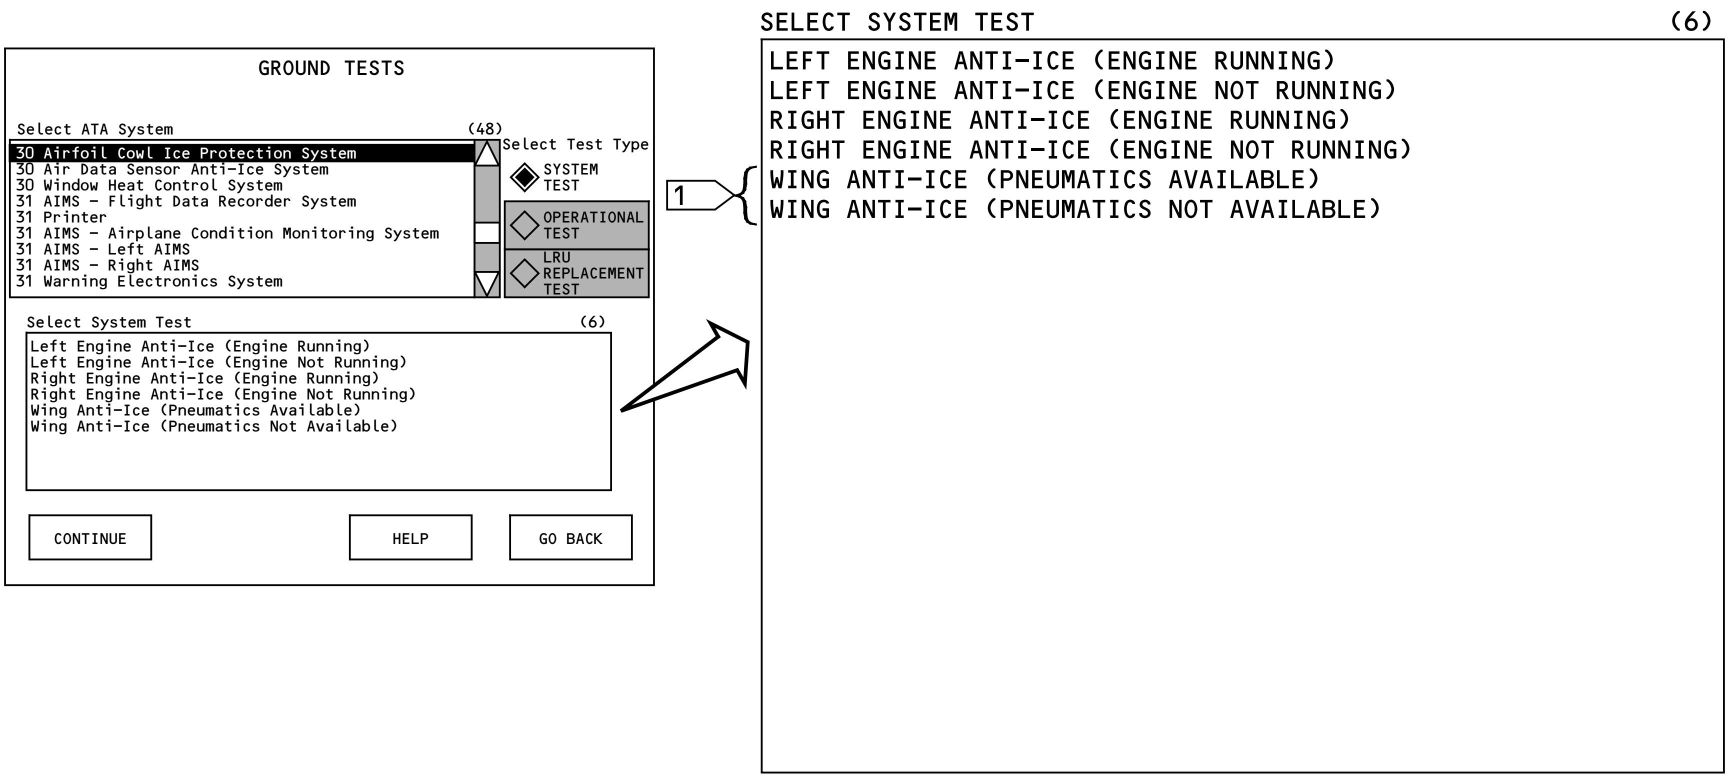
During the test, hot air flows out of the leading edge on each wing. The test takes approximately 1-2 minutes.

WARNING: DO NOT OPERATE THE WAI SYSTEM UNTIL ALL PERSONS ARE CLEAR OF THE WING LEADING EDGE. THE HOT AIR CAN BURN YOU.

Wing Anti-Ice (Pneumatics Not Available)

This test makes sure that the electrical interface connections of the wing anti-ice system are correct.

The test takes approximately 1-2 minutes.



1 THESE ARE THE WING ANTI-ICE TESTS.

WING ANTI-ICE - SYSTEM TESTS

30-11-00-010 Rev 0 08/17/96

ENGINE ANTI-ICE - INTRODUCTION

Purpose

The engine anti-ice (EAI) system heats the leading edge of the engine cowls so that ice does not collect on them.

General

The EAI systems for the left and right engines are identical. A high stage bleed port (HP7) on the engine supplies bleed air to heat the cowl leading edge. This is a different stage than the high stage port for the pneumatic system. An engine anti-ice valve controls the air flow from the bleed port to the EAI duct. The EAI duct moves the air to the cowl leading edge. Overboard vents in the cowl let the air out.

The EAI valve is pneumatically actuated. Control pressure for the valve comes from an EAI controller.

ACIPS Control Cards - EAI

Two airfoil and cowl ice protection system (ACIPS) control cards - EAI control the systems. The left card controls the left engine system and the right card controls the right engine system. The cards send electric signals to the EAI controllers to control the valves. EAI pressure sensors give control feedback.

Fan Case Overheat

A fan case overheat detector monitors the EAI duct for leaks. The detector is part of the duct leak and overheat detection system (DLODS). The DLODS sends a signal to the EAI ACIPS control card. The card sends a signal to close the EAI valve. See the duct leak and overheat detection system section for more information (AMM PART I 26-18).

Flight Deck Controls

The engine anti-ice selectors in the flight deck let the crew set automatic or manual control for each engine. With AUTO selected, the EAI system comes on when the ice detection system finds ice. The OFF and ON positions are for manual control.

See the ice detection system section for more information (AMM PART I 30-81).

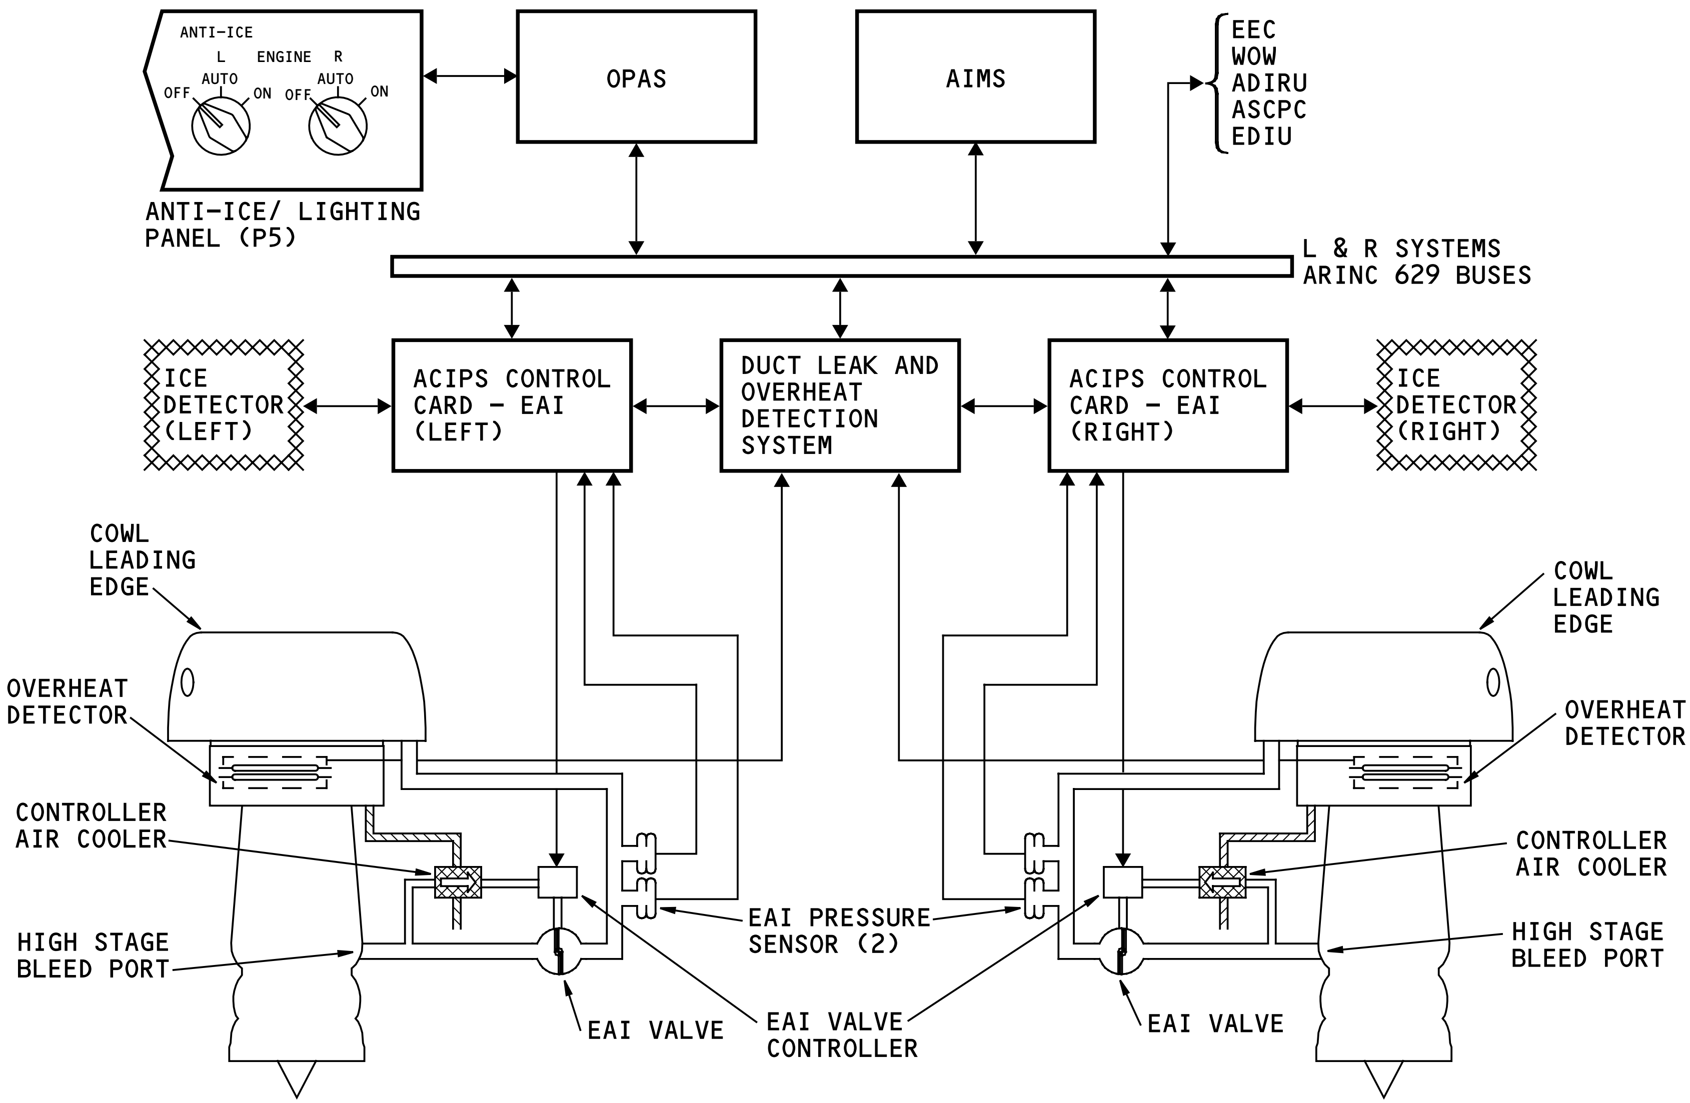
BITE

BITE circuits in the control cards monitor the condition of the systems. The AIMS gives information about the systems through the EICAS display, status display, and maintenance page.

Interfaces

The engine anti-ice system has these other interfaces:

- EEC (electronic engine control)
- WOW (weight on wheels cards)
- ADIRU (air data inertial reference unit)
- ASCPC (air supply cabin pressure controller)
- EDIU (engine data interface unit).



ENGINE ANTI-ICE - INTRODUCTION

ENGINE ANTI-ICE - ENGINE COMPONENT LOCATIONS

Component Locations

The engine anti-ice (EAI) components are in these locations:

- Engine fan case - upper left side
- Engine core - upper left side
- Engine fan hub - left side
- Engine inlet - left side.

These are the components on the engine core:

- EAI valve
- Controller air cooler
- EAI duct.

The EAI duct is in the area of the fan case on the left side the engine.

These are the components on the fan hub:

- EAI valve controller
- EAI pressure sensors.

The left side of the engine inlet has the EAI exhaust port.

ENGINE ANTI-ICE - FLIGHT DECK AND MEC COMPONENT LOCATIONS

ENGINE ANTI-ICE - EAI VALVE

Purpose

The EAI valve controls the flow of engine bleed air though the EAI duct to the engine cowl leading edge.

Physical Description

The EAI valve is a pneumatically-operated, piston-type valve. The valve has these parts:

- Body
- Locking screw
- Locking crank
- Control pressure line connector.

Location

The EAI valve is on the left side of the engine core at the 11:00 position. The valve is in the EAI duct aft of the fan hub.

Functional Description

The piston freely slides on the guide tube. Control pressure pushes on the inner part of the piston to open the valve and control flow. Air from the high pressure bleed air source pushes on the outer part of the piston to move it to the closed position.

The locking screw and locking crank let you manually set the EAI valve for normal operation (unlocked position) or to the locked closed position. The locking screw keeps the locking crank in its unlocked position for normal valve operation or in the valve locked closed position. When you remove the screw from its stowed position, it lets control pressure vent and the locking crank move. When you move the locking crank to CLOSED and install the locking screw, the crank holds the piston in the closed position.

Training Information Point

You use the EAI valve controller (not shown) to manually set the EAI valve open.

See the procedure in part II of the AMM, Preparation - Engine Anti-ice Systems Inoperative, for more information on deactivation of the engine anti-ice valve open.

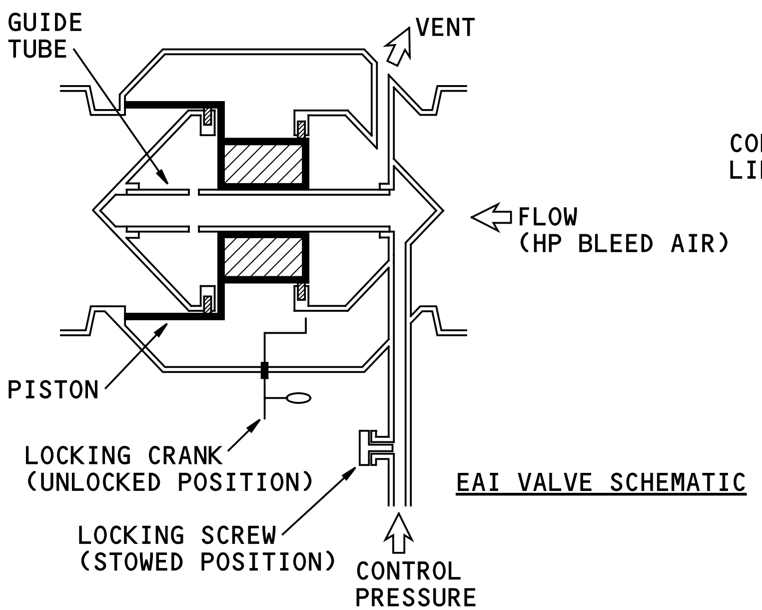
(ROTATED)



EAI VALVE SCHEMATIC

ENGINE ANTI-ICE - EAI VALVE

30-21-00-004 Rev 2 02/22/95

ENGINE ANTI-ICE - EAI VALVE CONTROLLER

Purpose

The EAI valve controller supplies control pressure to the EAI valve.

Physical Description

The EAI valve controller is an electropneumatic controller. The controller has these parts:

- Two pressure line connectors
- Body
- Torque motor
- Electrical connector.

Location

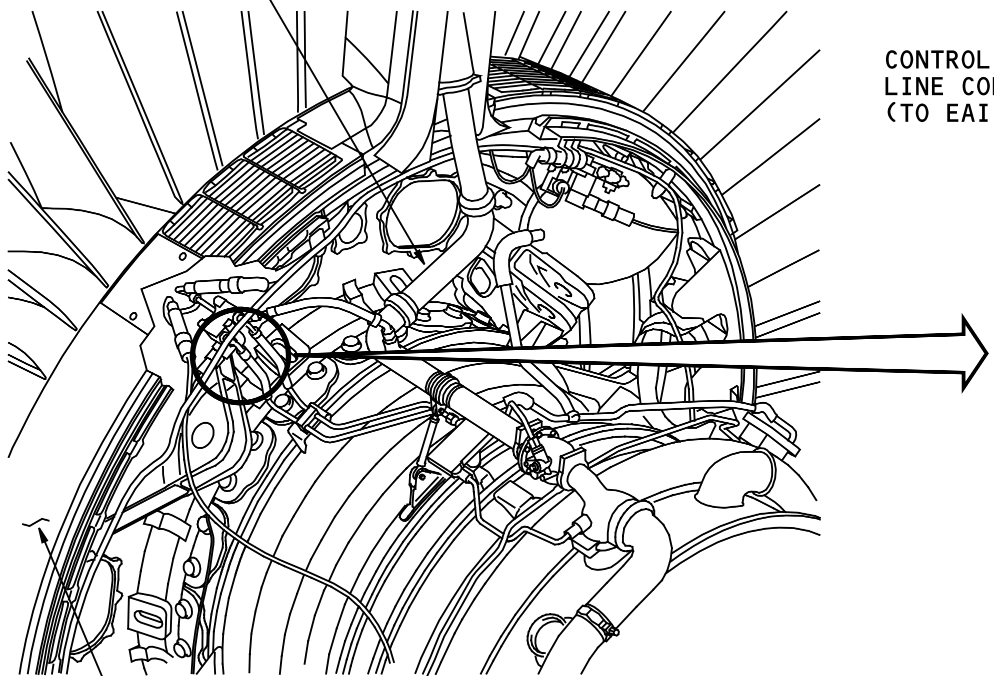
The controller is on the left side of the fan hub at the 11:00 position. The controller is inside the fan hub above the engine core.

Functional Description

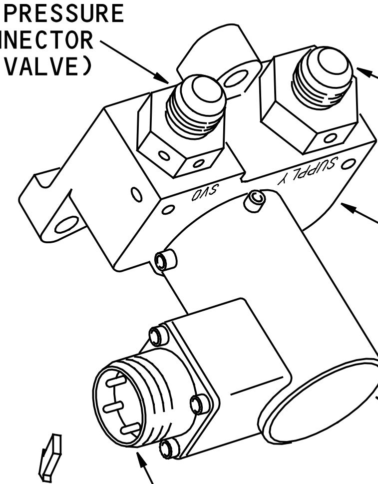
The EAI controller uses the torque motor to regulate control pressure to the EAI valve. The controller gives control pressure to the valve if the torque motor has no power (fail safe on).

Training Information Point

You remove, cap, and stow the torque motor electrical connector when you want to manually set the EAI valve open.



ENGINE CORE - LEFT SIDE



EAI VALVE CONTROLLER

ENGINE ANTI-ICE - EAI VALVE CONTROLLER

ENGINE ANTI-ICE - EAI PRESSURE SENSOR

General

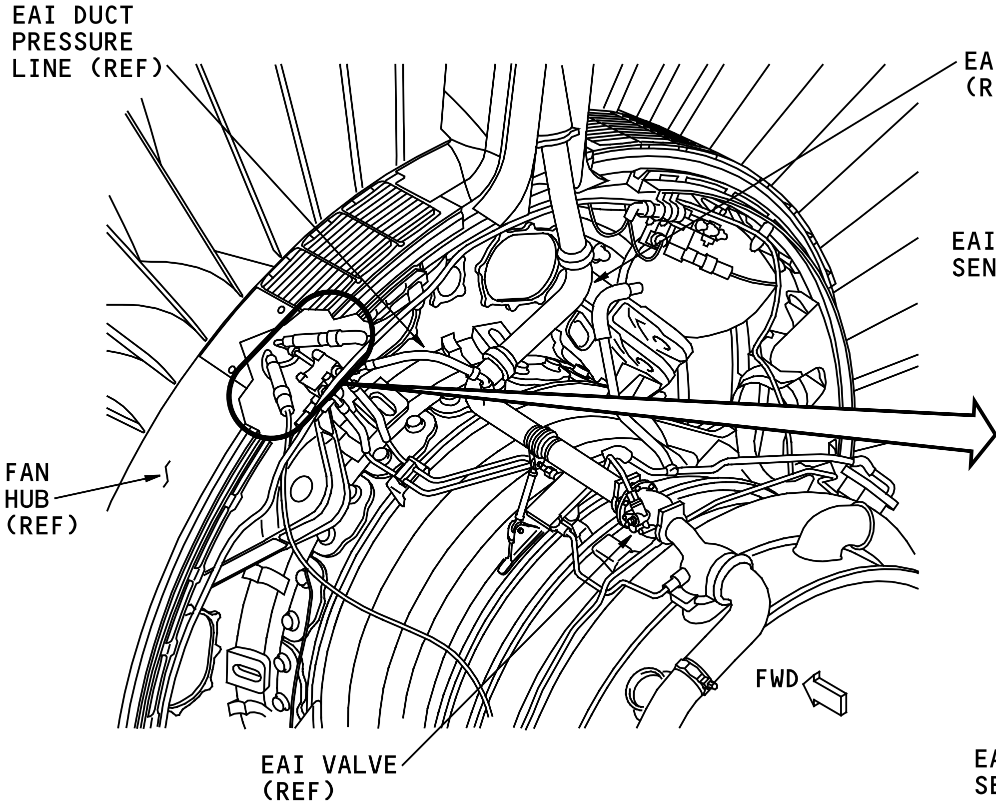
Each engine has two EAI pressure sensors. The sensors are the same. They both measure the pressure in the EAI duct downstream of the EAI valve. The left and right ACIPS - EAI control cards use the information from the pressure sensors to control the EAI system.

The pressure sensors are redundant. If one sensor fails, the system operates the same.

Each pressure sensor has a pressure line connector, a housing and an electrical connector.

Location

The sensors are on the left side of the fan hub at the 11:00 position. The sensors attach to the same mount plate as the EAI valve controller.



ENGINE CORE - LEFT SIDE

ENGINE ANTI-ICE - EAI PRESSURE SENSOR

ENGINE ANTI-ICE - EAI DUCT

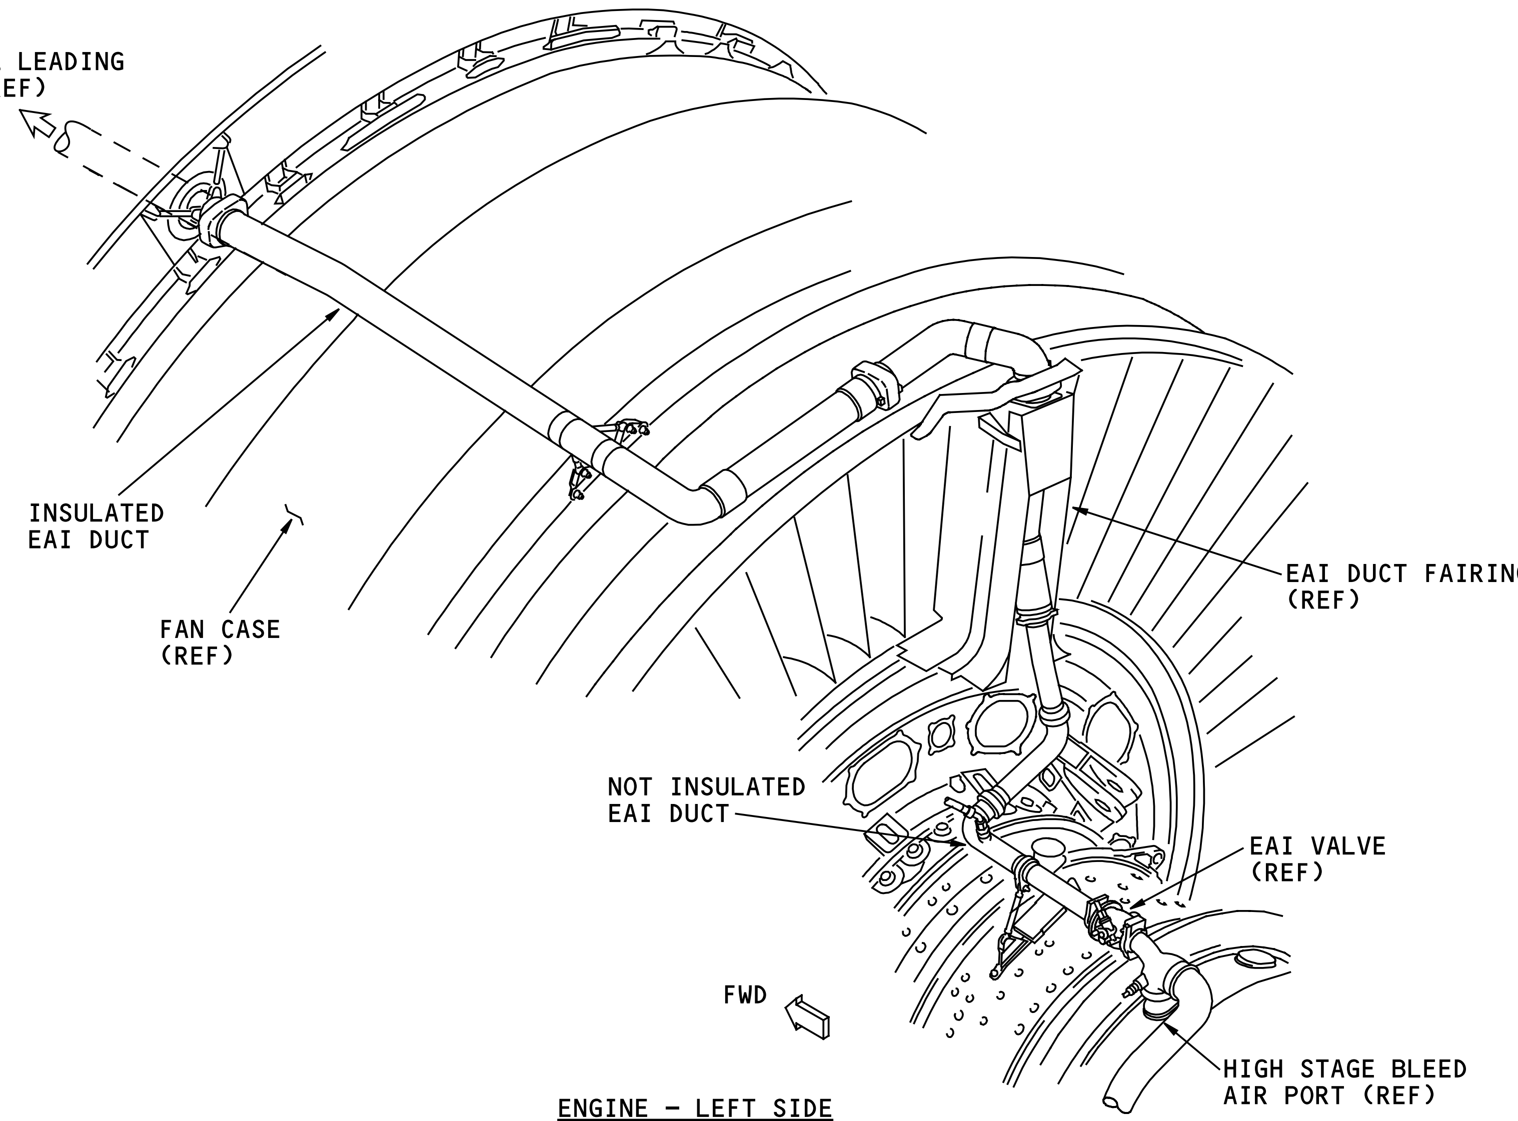
General

The EAI ducts move air from the engine high stage bleed port to the cowl leading edge.

There are two EAI ducts. One is not insulated and the other is insulated.

Locations

The not insulated EAI duct is on the left sides of the engine core forward of the EAI valve. The insulated EAI duct is in the EAI duct fairing and on the left side of the fan case.



ENGINE - LEFT SIDE

ENGINE ANTI-ICE - EAI DUCT

ENGINE ANTI-ICE - CONTROLLER AIR COOLER

General

There are two controller air coolers (CAC) on each engine. There is one for the engine air supply part of the pneumatic system (not shown) and there is one for the engine anti-ice system.

The EAI controller air cooler decreases the temperature of the engine bleed air (HP7) that goes to the EAI valve controller.

See the engine air supply section for more information about the engine air aupply system CAC (AMM PART I 36-11).

Physical Description

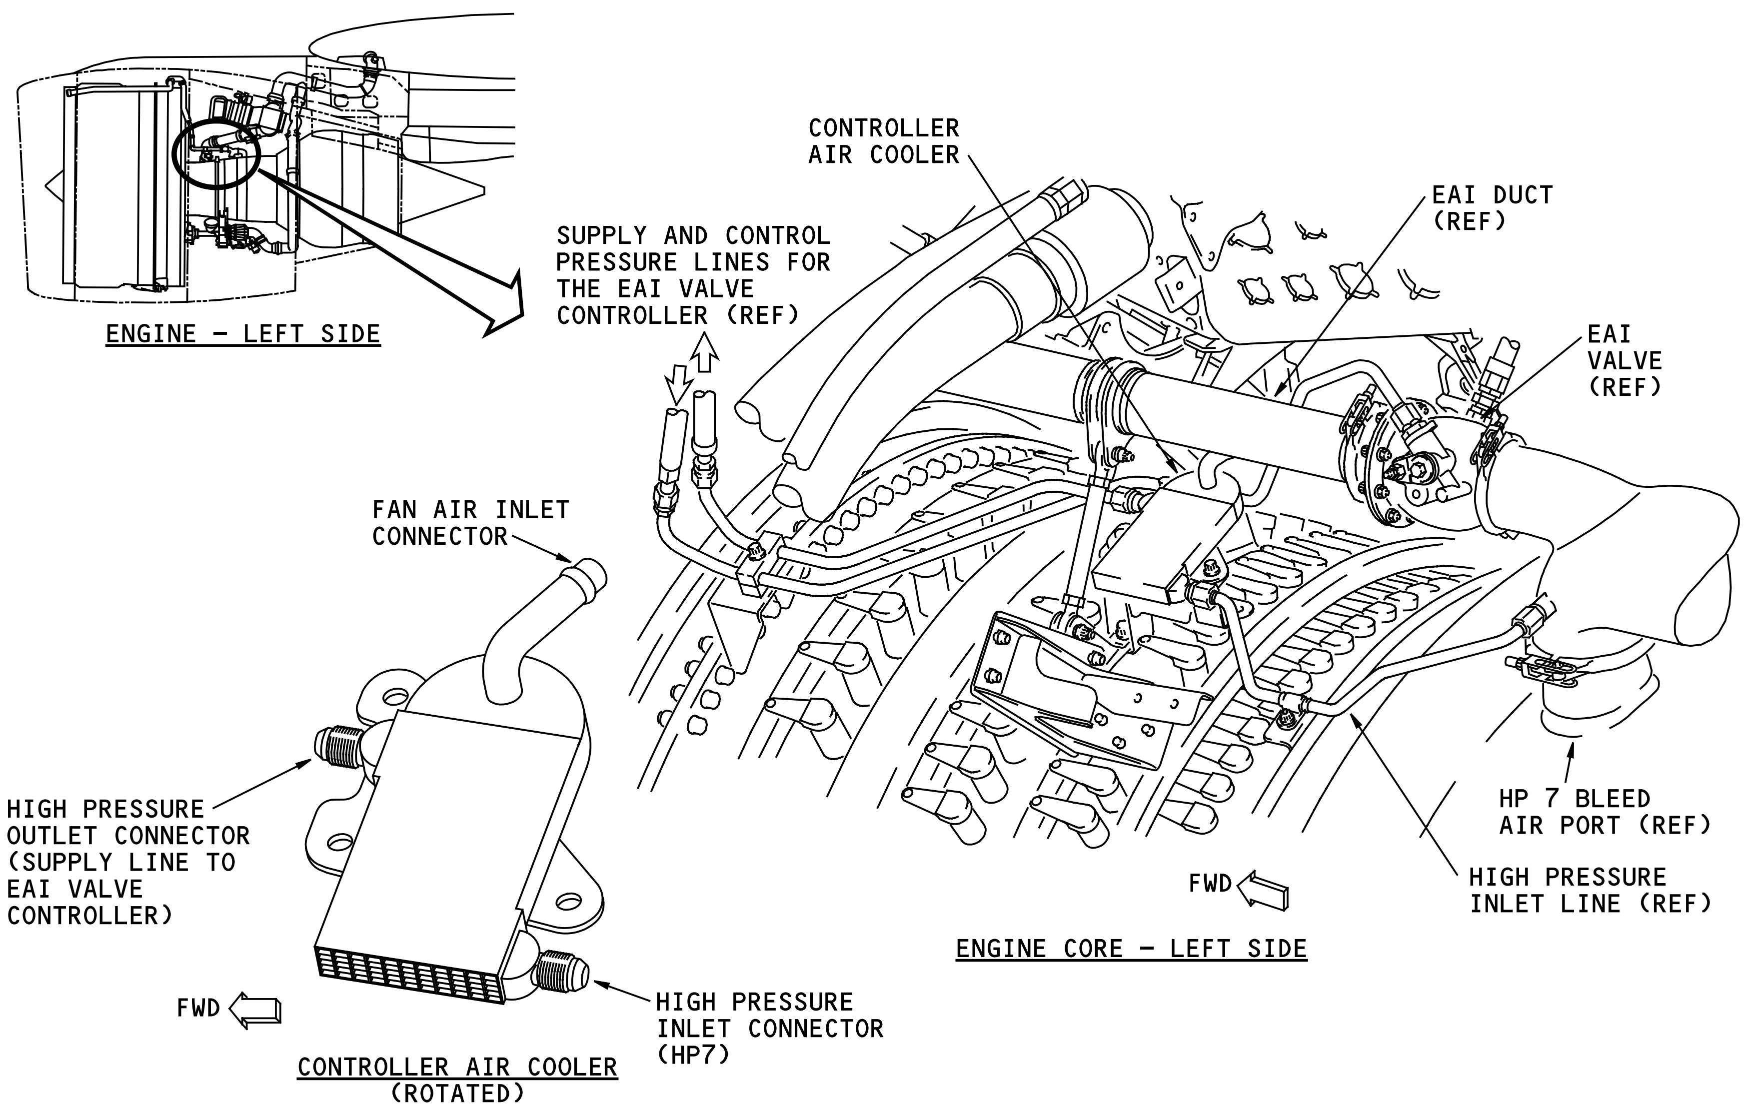
The controller air cooler is an air-to-air heat exchanger. It has three pneumatic line connectors, two high pressure and one low pressure (fan air).

Location

The controller air cooler is on the left side of the engine core at the 11:00 position. The cooler is below and forward of the engine anti-ice valve.

Functional Description

Hot air from the high stage compressor section and cool fan air flows through the controller air cooler. The cool air removes heat from the hot air. This decreases the temperature of the hot air.



30-21-00-008 Rev 6 05/16/95

ENGINE ANTI-ICE - CONTROLLER AIR COOLER

ENGINE ANTI-ICE - FUNCTIONAL DESCRIPTION

General

An EAI selector for each engine lets the flight crew operate the EAI system independently on each engine. Each selector has three positions: OFF, AUTO, and ON.

The left ACIPS control card controls the left EAI system. The right ACIPS control card controls the right EAI system. The ice detectors supply analog inputs to the EAI ACIPS control cards. The left detector connects to the left card. The right detector connects to the right card. Each card gives its ice detector data to the other card through the systems ARINC 629 buses.

See the ice detection system section for more information about the ice detectors (AMM PART I 30-81).

Operational Modes

The ACIPS control cards have two operational modes, AUTO and ON. The AUTO mode lets the ACIPS control card enable the related EAI valve if all of these conditions occur:

- EAI selector is set to AUTO
- Conditions do not inhibit operation.

If the EAI selector position shows invalid on the 629 data bus, the ACIPS control card operates in the AUTO mode.

The ON mode lets the ACIPS control card enable the related EAI valve if all of these conditions occur:

- EAI selector is set to ON
- Conditions do not inhibit operation.

The ACIPS control cards use torque motors in the related EAI valve controller to control the position of the EAI valve. The controller causes the valve to go full open if it has no power to its torque motor. The ACIPS control cards give power to the torque motor to cause the valve to regulate or to fully close.

When an ACIPS control card enables an EAI valve, the card sets the valve to one of these positions:

- Regulating
- Full open.

The regulating position is the usual position. In usual operation, the EAI ACIPS control card calculates a heat flow necessary for the engine cowl. The card adjusts the EAI valve to set a pressure in the EAI duct that causes this quantity of heat flow. The card keeps the mass flow to a limit if the airplane operates in these limits:

- Altitude; -2500 feet to 37,500 feet
- Temperature; -40F to 50F (-40C to 10C).

When the valve is set to regulate, the EAI ACIPS control card limits the minimum pressure in the EAI duct to 10 psig.

The EAI valve is set to full open when any of these conditions occur:

- Both EAI pressure sensors fail
- The torque motor circuit is open.

The EAI pressure sensors supply feedback information to the ACIPS control card for valve control and indications. There are two pressure sensors on each engine. These sensors do the same function.

Operational Mode Inhibits

The ACIPS control card closes the EAI valve if any of these conditions occur:

- Engine start
- Fan case overheat
- EAI selector set to OFF
- EAI selector set to AUTO with no ice detected.

The fan case overheat condition causes the ACIPS control card to close the EAI valve and set a latch. This keeps the system off after the overheat condition goes away. The flight crew must move the EAI selector to OFF, then to AUTO or ON to remove the latch.

See the duct leak and overheat detection system section for more information (AMM PART I 26-18).

BITE Operation

At power-up, the ACIPS control cards do built-in test (BIT) on internal hardware and software functions and interfaces.

The ACIPS control cards do a periodic BIT if all of these conditions are true:

- It is more than 20 seconds and less than five minutes after landing
- No fan case overheat is present
- Time since the last periodic test is more than 24 hours.

You can use the maintenance access terminal (MAT) or portable maintenance access terminal (PMAT) to do these EAI ground tests:

- Engine running
- Engine not running.

The BITE in the ACIPS control card can find short and open circuits in the system. The BITE does a check of these components:

- ACIPS control cards
- EAI valve controller
- EAI valve
- EAI pressure sensors
- Ice detector.

The BITE finds a failure if either EAI valve does not:

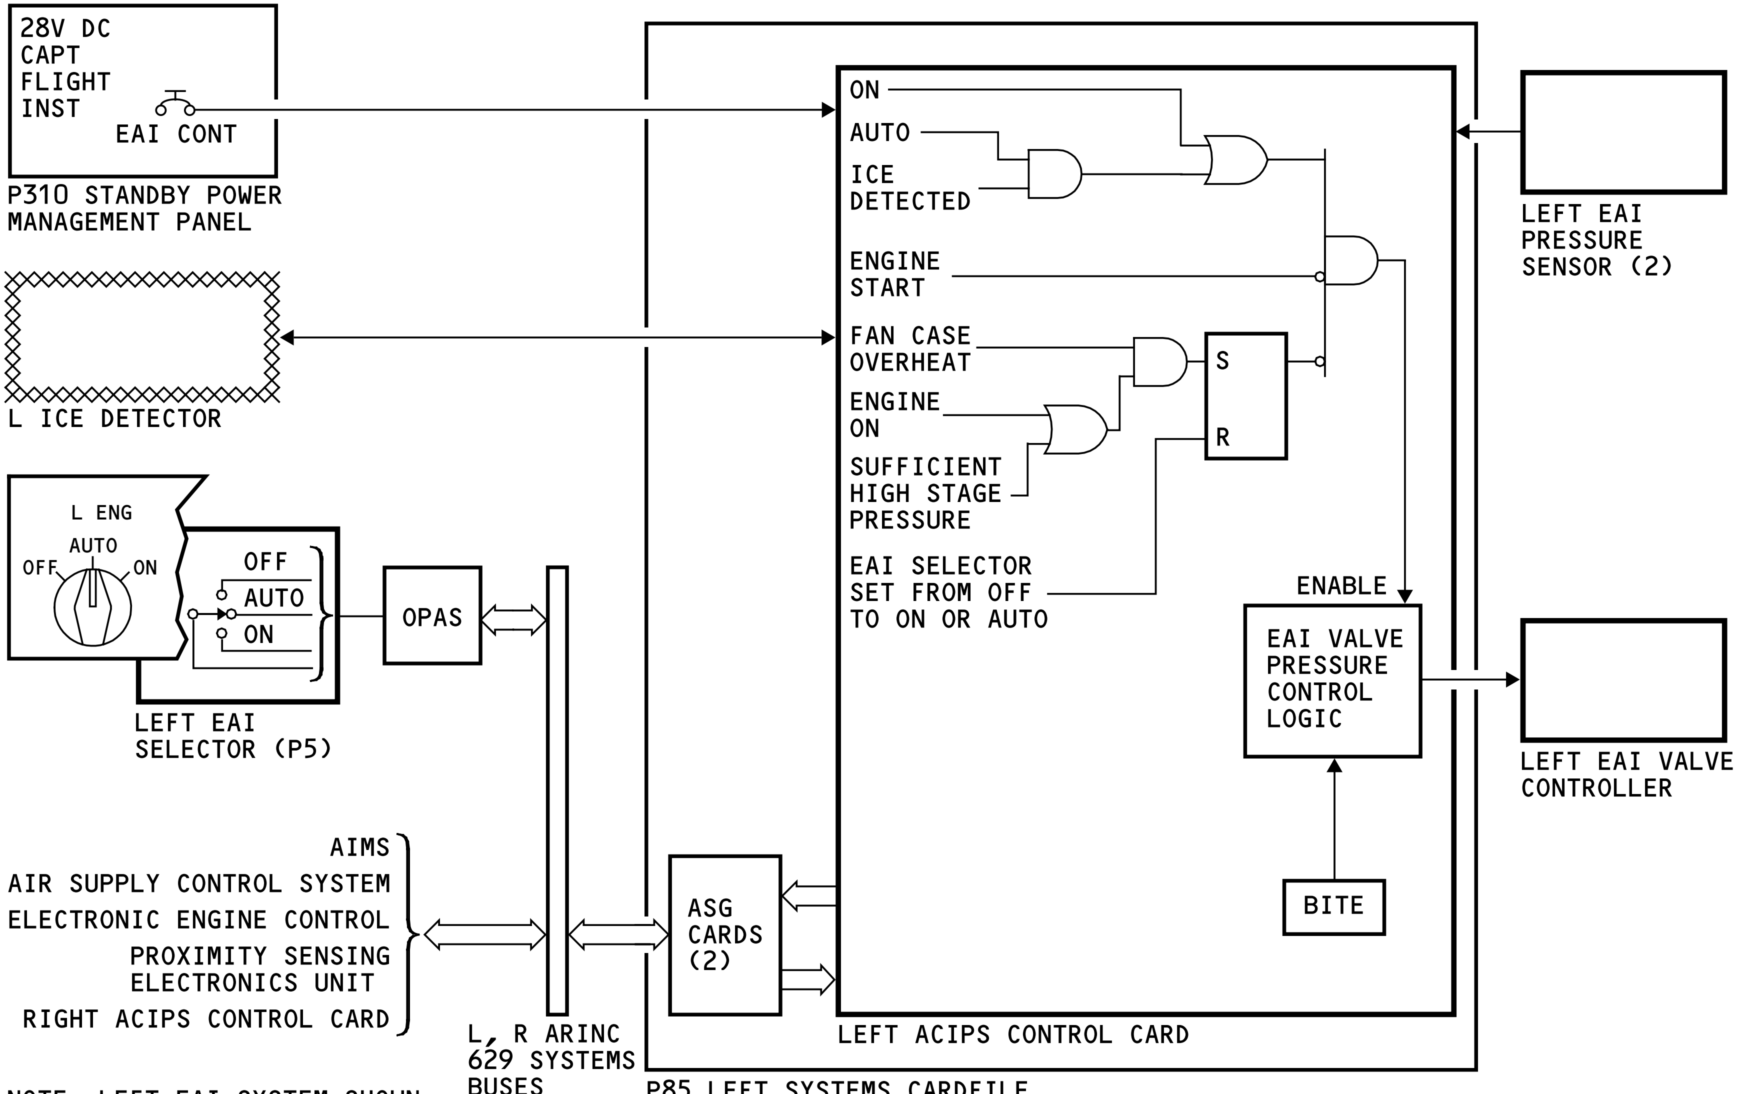
- Open
- Close
- Regulate.

ENGINE ANTI-ICE - FUNCTIONAL DESCRIPTION

Interfaces

The ACIPS control cards gets data from these systems:

- Opposite ACIPS control card; ice detected, failed ice detection
- OPAS; EAI switch position, engine start switch position
- DLODS; fancase overheat
- FMC; engine type, flight phase
- AIMS; engine on
- AGS; air/ground status
- ADIRU; mach number, static pressure, static air temperature, total air temperature
- EEC; P3 burner pressure, T3 selected temperature.



NOTE: LEFT EAI SYSTEM SHOWN.
RIGHT EAI SYSTEM SIMILAR.

ENGINE ANTI-ICE - FUNCTIONAL DESCRIPTION

ENGINE ANTI-ICE - OPERATION

General

The engine anti-ice selectors let the flight crew select the operational mode independently for each engine. Indications on the EICAS display and on the air synoptic display show when the EAI valves are open.

Operation

The selectors are on the anti-ice/lighting panel (P5). With the selector set to OFF, the EAI system does not operate. The EAI valve stays closed. The EICAS caution message ICING ENG shows if the ice detection system finds ice. The OFF selection prevents the EAI BITE periodic ground test.

In flight, when the EAI selector is in AUTO, engine anti-ice system operation is automatic. The ice detection system controls engine anti-ice system operation as long as operational mode inhibits are not active. The AUTO positions enable the BITE periodic ground test.

For manual operation, the crew sets the selectors to ON when engine anti-ice is needed. The EAI valves stay open as long as no operational mode inhibits are active. The EICAS advisory message ANTI-ICE ON shows if the EAI selector is on, no ice is detected, and the TAT is more than 50F (10C). The selectors must be ON for the EAI system to operate on the ground.

Air Synoptic Display

The EAI valve symbols show these conditions:

- Valve open - white circle with a vertical green flow bar
- Valve closed - white circle with two horizontal white bars
- Valve not in commanded position - amber circle with an amber cross through it
- Valve position data not available - white circle.

Non-Normal Indications

These EICAS messages (not shown) show non-normal conditions:

- ANTI-ICE LEAK ENG L,R (Caution) - The fan case overheat detector signals a duct leak condition
- ANTI-ICE LOSS ENG L,R (Advisory) - The EAI valve closes because of a duct leak
- ANTI-ICE ENG L,R (Advisory) - The EAI valve fails closed.

ICE AND RAIN PROTECTION - ICE PROTECTION MAINTENANCE PAGE

General

The ice protection maintenance page shows this information:

- ALTITUDE - Airplane altitude in feet
- ENG TYPE - Engine manufacturer (GE, PW, or RR)
- TAT - Total air temperature in degrees C
- ICE DETECTOR - Status of the left and right ice detectors (OFF, ENGINE, ENGINE/WING, or FAIL)

Engine Anti-Ice

The engine anti-ice part of the maintenance page shows this information:

- FANCASE DUCT LEAK SIGNAL - Status of the fan case overheat detector (NORMAL, OVERHEAT, or FAIL)
- VALVE - EAI valve open, closed, or regulating
- SUPPLY AIR TEMP - EAI air supply temperature in degrees F
- AIR PRESS - Pressure downstream of the EAI valves in psig
- AIR FLOW - Air flow through the EAI valves in lb/min.

Wing Anti-Ice

The wing anti-ice part of the maintenance page shows this information:

- WING MANIFOLD PRESS - Pneumatic duct pressure in psig
- VALVE - WAI valve open, closed, or regulating
- AIR PRESS - Pressure downstream of the WAI valves in psig
- AIR FLOW - Air flow through the WAI valves in lb/min.

Valve positions and air flow rates are calculated from air pressure measurements upstream and downstream of the anti-ice valves.

ICE DETECTION SYSTEM - INTRODUCTION

Purpose

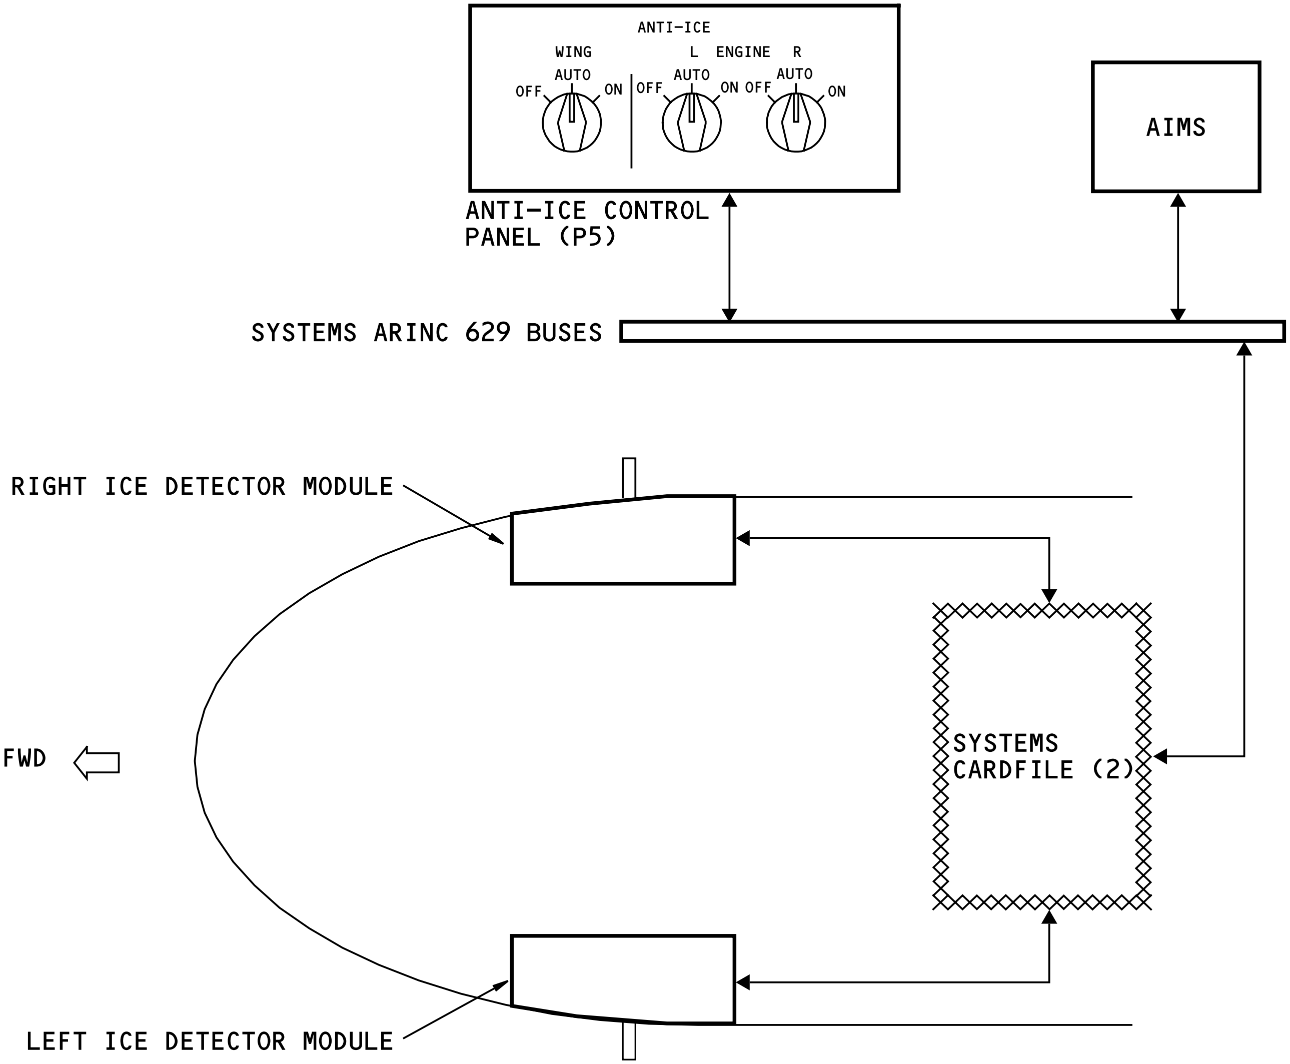
The ice detection system (IDS) operates the WAI and EAI systems when there is ice.

General Description

The IDS has two ice detection modules. If either detection module finds conditions that can cause ice, it sends an ice signal to the WAI and EAI systems. This automatically causes the anti-ice systems to operate.

Component Locations

There is an ice detection module on each side of the airplane nose.



30-81-00-001 Rev 0

ICE DETECTION SYSTEM - INTRODUCTION

ICE DETECTION SYSTEM - ICE DETECTORS

General

The ice detectors monitor for ice conditions. The ice detectors give an ice signal for use by the AIMS and the EAI and WAI ACIPS control cards.

Physical Description

There are two identical ice detectors. An ice detector has an ice detection probe and an electrical connector. There is a microprocessor in the detector.

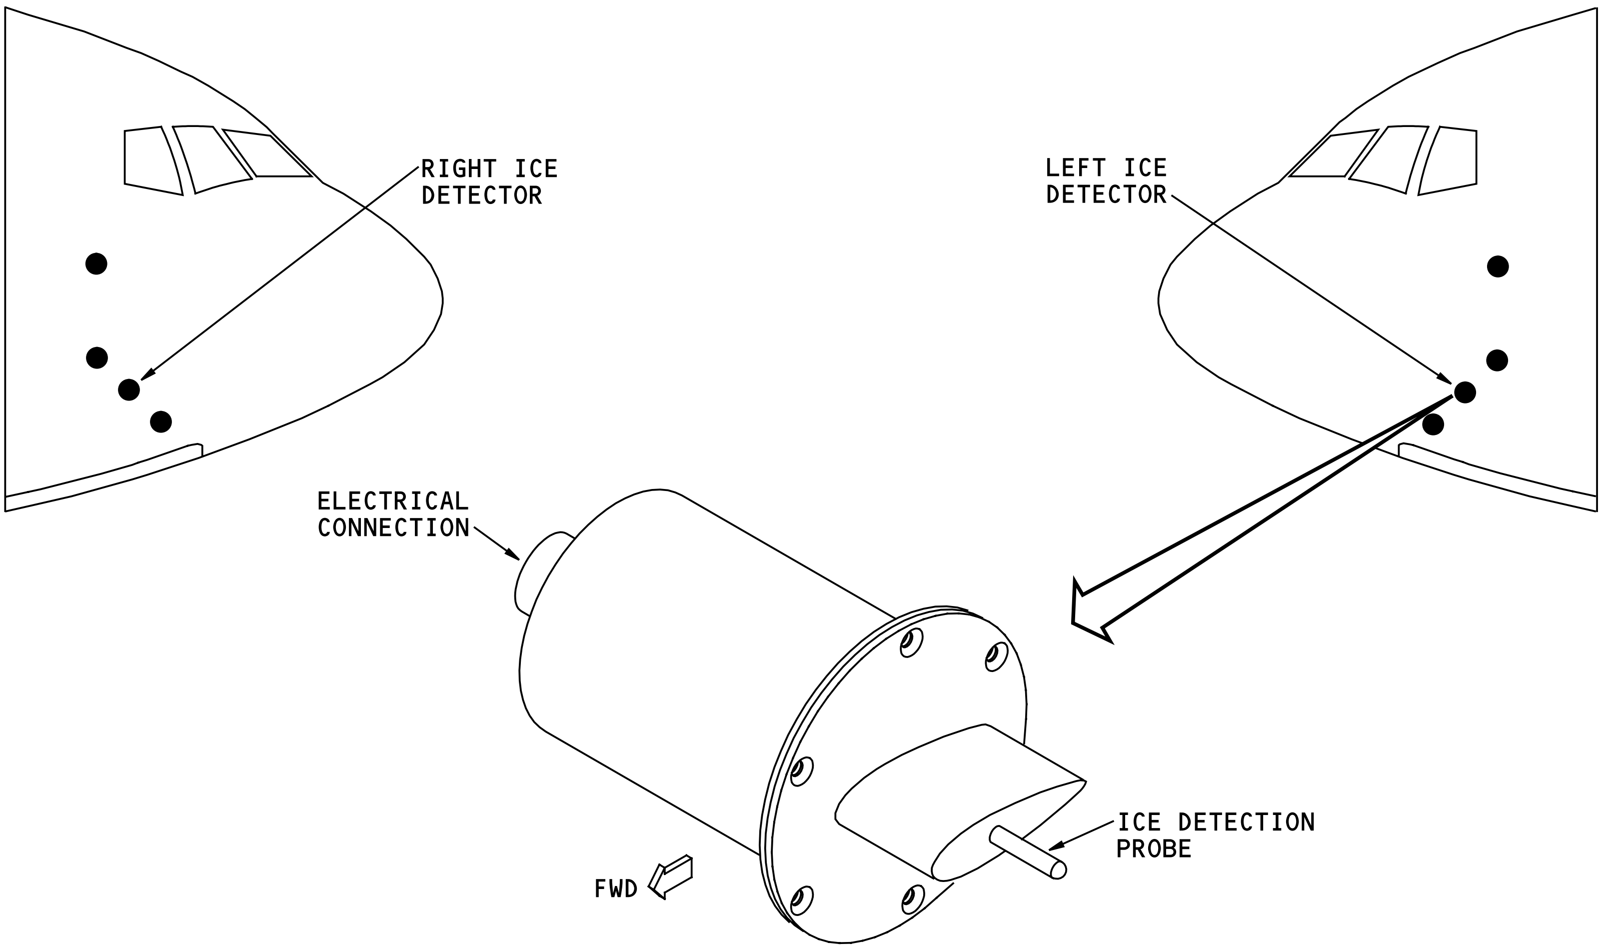
Location

The ice detectors are on the left and right sides of the fuselage on the nose of the airplane.

Functional Description

Each ice detector operates independently from the other. The ice detection probe vibrates. The probe vibrates differently when it collects ice. When ice is detected for a necessary period, the related ice detector sends an ice signal to the related (left or right) EAI ACIPS control card (not shown).

See the wing anti-ice section for more information about wing anti-ice (AMM PART I 30-11). See the engine anti-ice section for more information about engine anti-ice (AMM PART I 30-21).



ICE DETECTOR
(TYPICAL)

30-81-00-002 Rev 2 04/27/95

ICE DETECTION SYSTEM - ICE DETECTORS

PITOT AND STATIC (AIR DATA SENSORS) - INTRODUCTION

General

Some probes and sensors have heaters to keep ice off, so their data is reliable. The static system does not have any heaters. These are the probes and sensors that have heaters:

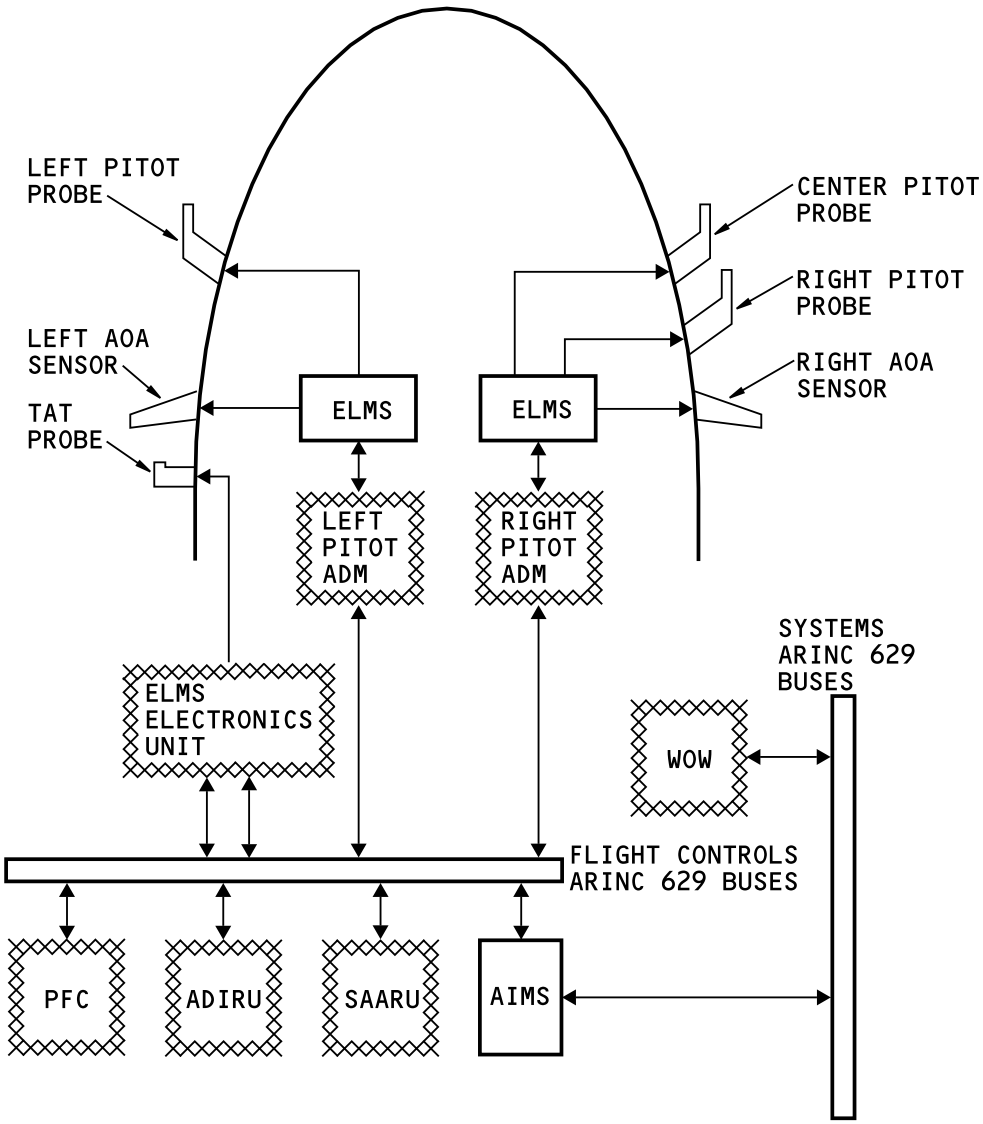
- Left, right, and center pitot probes
- Total air temperature (TAT) probe
- Left and right angle of attack (AOA) sensors

The pitot air data modules (ADMs) control the heat for the pitot probes and the AOA sensors. The pitot probes get low heat after an engine starts. They get high heat when the airplane reaches 50 knots airspeed or is in the air. The AOA probe heats when an engine starts.

See the attitude and direction section for more information about the ADMs (AMM PART I 34-20).

An electronics unit in the electrical load management system (ELMS) controls the heat for the TAT probe. The TAT probe heats when the airplane is in the air.

See the electrical load management (ELM) system section for more information about the ELMS (AMM PART I 24-09).



PITOT AND STATIC (AIR DATA SENSORS) - INTRODUCTION

30-30-00-001 Rev 5 01/19/95

PITOT AND STATIC (AIR DATA SENSORS) - GROUND TESTS

General

These are the pitot and static (air data sensors) operational tests that show when you select ATA 30 Air Data Sensor Ice System:

- Pitot/AOA heat (left) test
- Pitot/AOA heat (right) test
- Pitot heat (center) test
- TAT probe heat.

Left and Right Pitot/AOA Heat Tests

These tests make sure that the related pitot probe and the AOA sensor heaters operate correctly.

During the test, the related pitot probe and AOA sensor become very hot. The tests each take less than 1 minute.

WARNING: KEEP PERSONS AND EQUIPMENT AWAY FROM THE LEFT (RIGHT) PITOT PROBES AND THE LEFT (RIGHT) ANGLE OF ATTACK VANE. THESE COMPONENTS WILL BECOME VERY HOT AND CAUSE INJURY TO PERSONS AND DAMAGE TO EQUIPMENT.

Center Pitot Heat Test

This test makes sure that the center pitot probe heater operates correctly.

During the test, the center pitot probe becomes very hot. The test takes less than 1 minute.

WARNING: KEEP PERSONS AND EQUIPMENT AWAY FROM THE CENTER PITOT PROBE. THESE COMPONENTS WILL BECOME VERY HOT AND CAUSE INJURY TO PERSONS AND DAMAGE TO EQUIPMENT.

TAT Probe Heat

This test makes sure that the TAT probe heater operates correctly.

During the test, the TAT probe becomes very hot. The test takes less than 1 minute.

WARNING: KEEP PERSONS AND EQUIPMENT AWAY FROM THE TAT PROBE. THESE COMPONENTS WILL BECOME VERY HOT AND CAUSE INJURY TO PERSONS AND DAMAGE TO EQUIPMENT.

PITOT AND STATIC (AIR DATA SENSORS) - GROUND TESTS

PITOT AND STATIC (AIR DATA SENSORS) - PITOT PROBE HEAT - FUNCTIONAL DESCRIPTION

General

The left, center, and right pitot probe heat systems operate the same. The left, right, and center pitot air data modules (ADMs) supply control and indications for the pitot probe heat systems.

Ground Mode

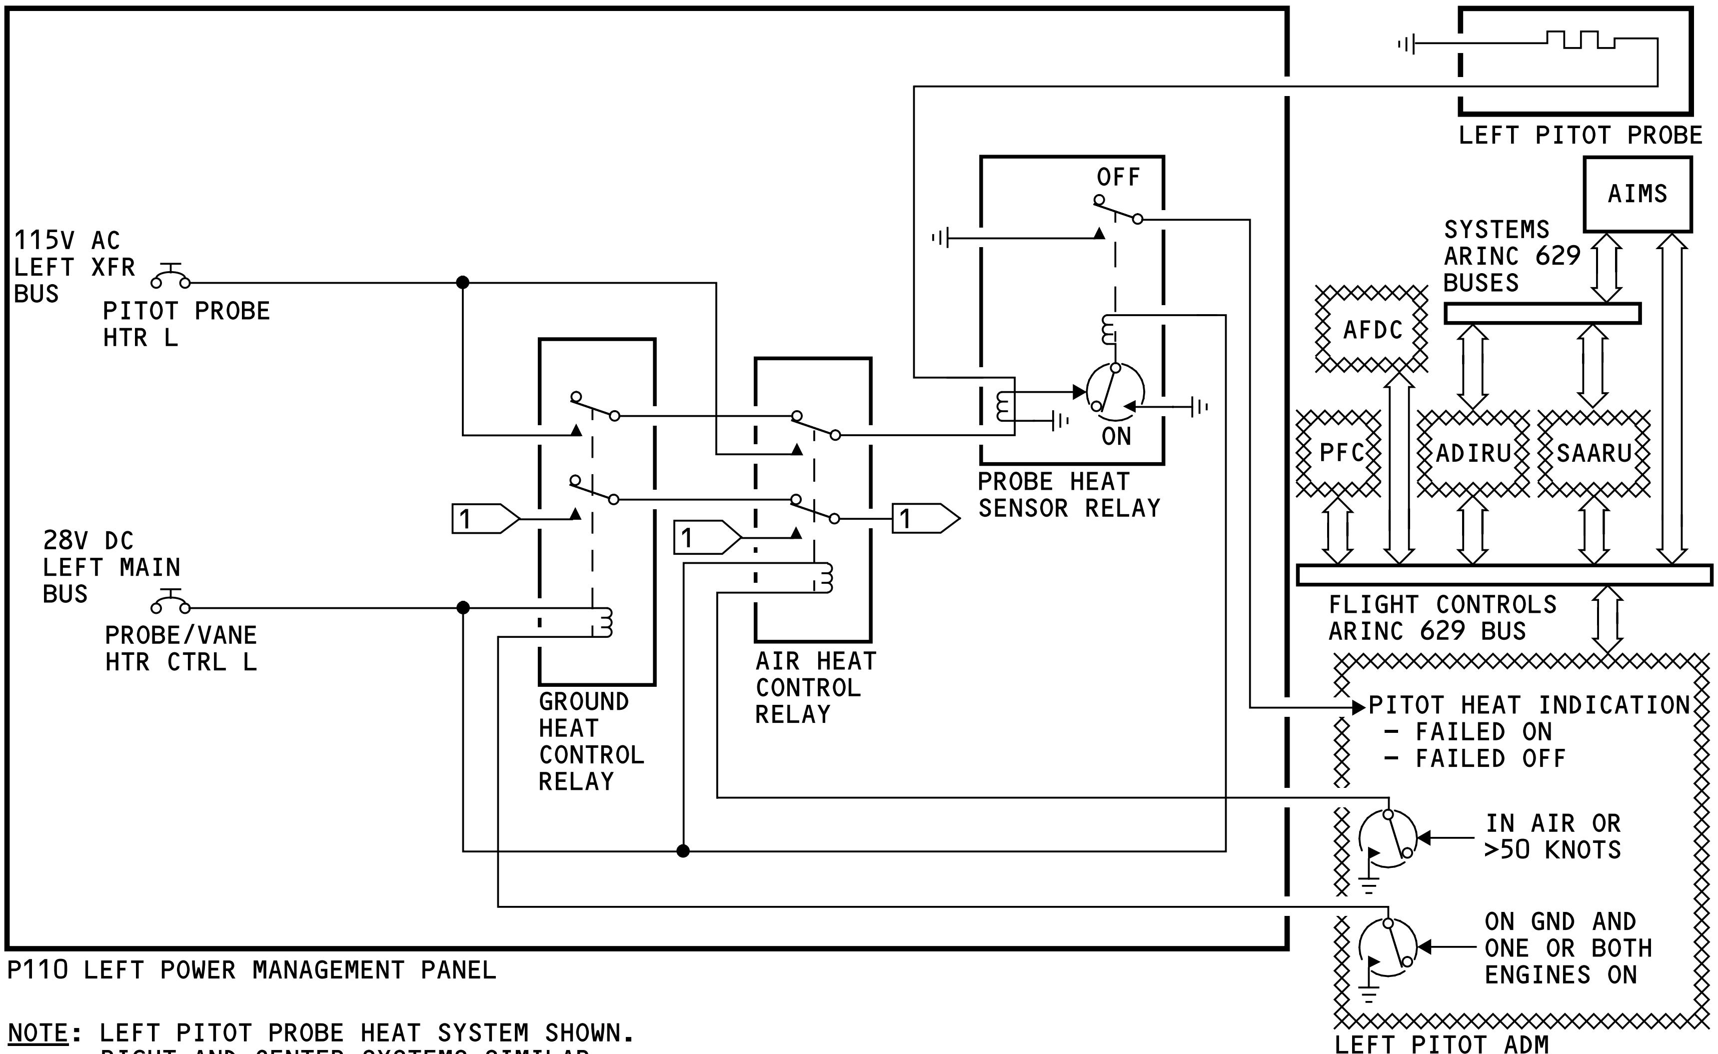
The primary flight computer (PFC) supplies air/ground signals for the ADM to energize the ground and air heat control relays. When the airplane is on the ground and either engine is on, the pitot probe gets 115v ac through the ground and the air heat control relays.

Air Mode

When the airplane gets to 50 knots or is in the air, the air heat control relay supplies 115v ac.

Indications

The probe heat sensor relay supplies a ground signal to the ADM when the pitot heat is on. The ADM supplies the pitot heat fault information directly through the data buses to the AIMS. It also supplies the information through the air data inertial reference unit (ADIRU) and the secondary attitude air data reference unit (SAARU) for advisory and status messages.



NOTE: LEFT PITOT PROBE HEAT SYSTEM SHOWN. RIGHT AND CENTER SYSTEMS SIMILAR.

1 SEE AOA PROBE HEAT

PITOT AND STATIC (AIR DATA SENSORS) - PITOT PROBE HEAT - FUNCTIONAL DESCRIPTION

FLIGHT DECK WINDOW ANTI-ICE SYSTEM - INTRODUCTION

Purpose

The window heat system prevents ice and fog on the flight deck windows.

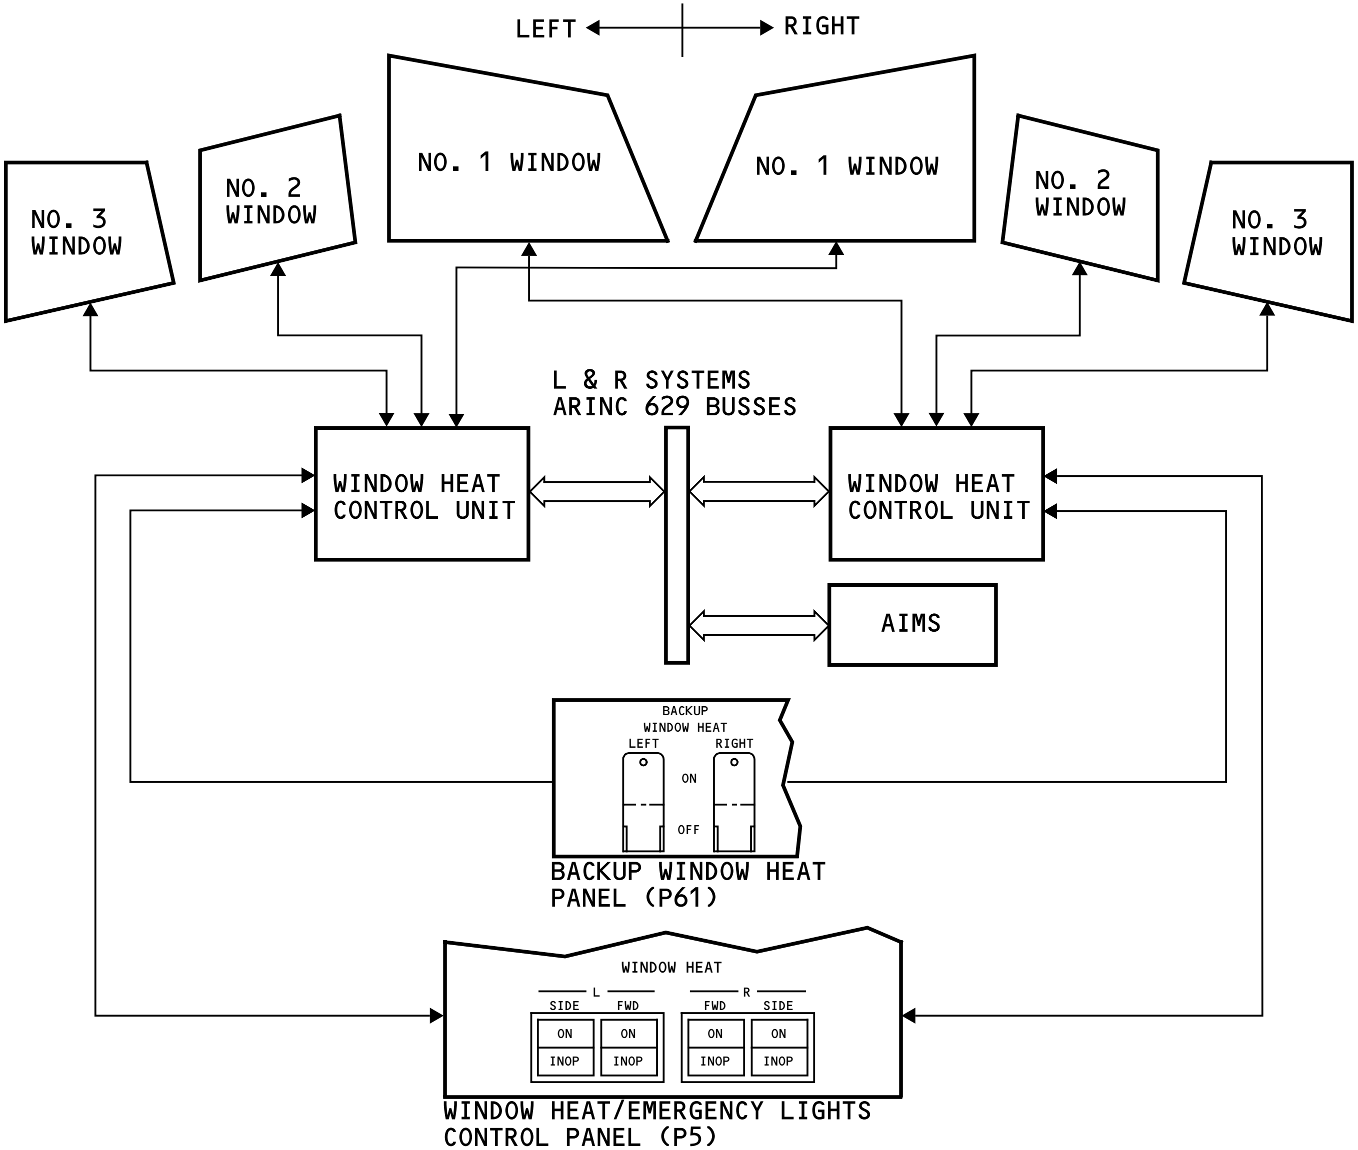
General Description

Electric heaters in the window laminations heat the flight deck windows.

The window heat switches enable the window heat system. With window heat ON, the window heat control units (WHCUs) control the power to the windows. With window heat OFF, the backup window heat system can operate.

The number 1 windows have a backup heat system. The backup window heat switches let you remove power from the backup window heat system for maintenance.

There are no test switches for the window heat system. The BITE automatically tests the system. You can use the MAT to do initiated BITE tests of the window heat system.



FLIGHT DECK WINDOW ANTI-ICE SYSTEM - INTRODUCTION

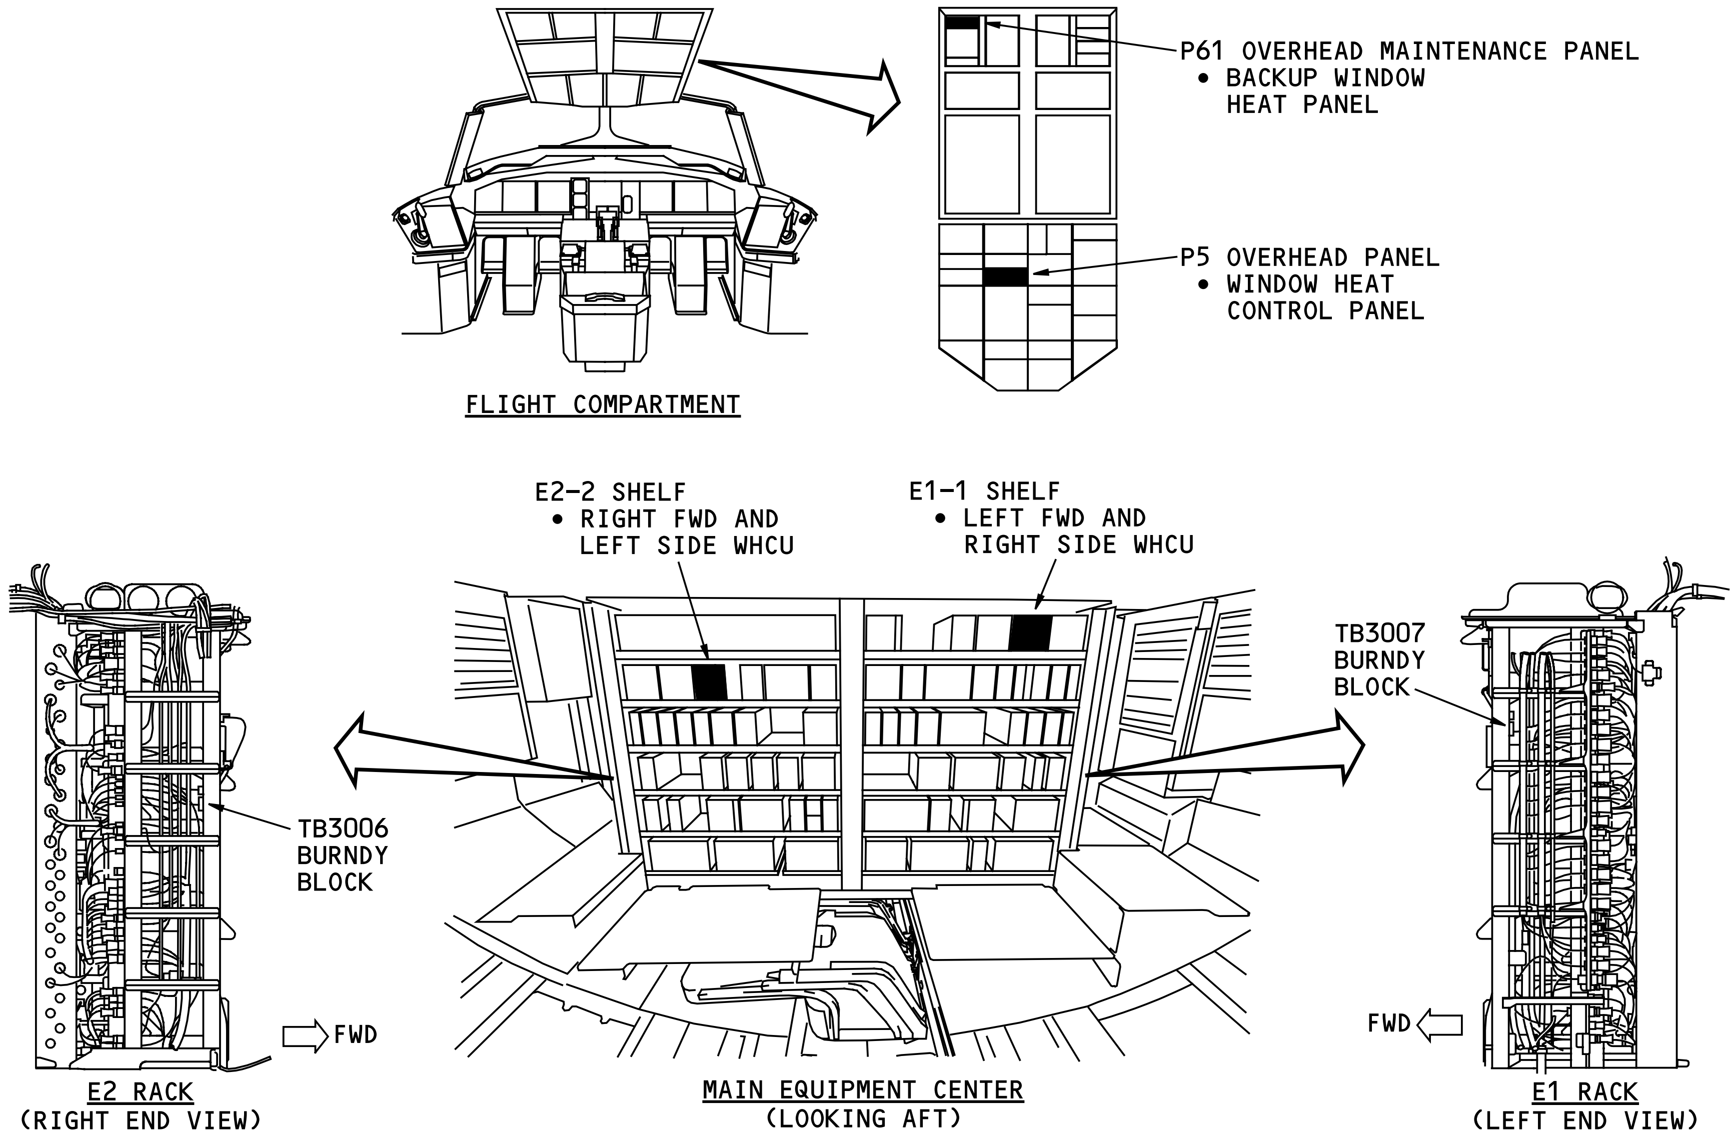
FLIGHT DECK WINDOW ANTI-ICE SYSTEM - COMPONENT LOCATIONS

Component Locations

The window heat control panel is on the P5 overhead panel. The backup window heat panel is on the P61 overhead maintenance panel.

The two window heat control units (WHCUs) are on the E1 and E2 main equipment racks. The left forward and right side WHCU is on the E1-1 shelf. The right forward and left side WHCU is on the E2-2 shelf.

Burndy blocks for the spare window heat sensors are on the outboard ends of the E1 and E2 rack.



FLIGHT DECK WINDOW ANTI-ICE SYSTEM - COMPONENT LOCATIONS

30-41-00-002 Rev 1 08/03/95

FLIGHT DECK WINDOW ANTI-ICE SYSTEM - FUNCTIONAL DESCRIPTION - 1

General

There are two WHCUs. One WHCU is for the left forward and right side windows. The other WHCU is for the right forward and left side windows. The WHCUs are the same.

Each WHCU has a separate power supply for each heater circuit in the flight deck windows. Each WHCU also has a separate power supply for BITE.

The power supplies for the heater circuits are 115v ac. The power supply for the BITE is 28v dc.

Each WHCU receives air/ground status from two air/ground relays. The inputs are analog. They are redundant.

Power Supply Circuits

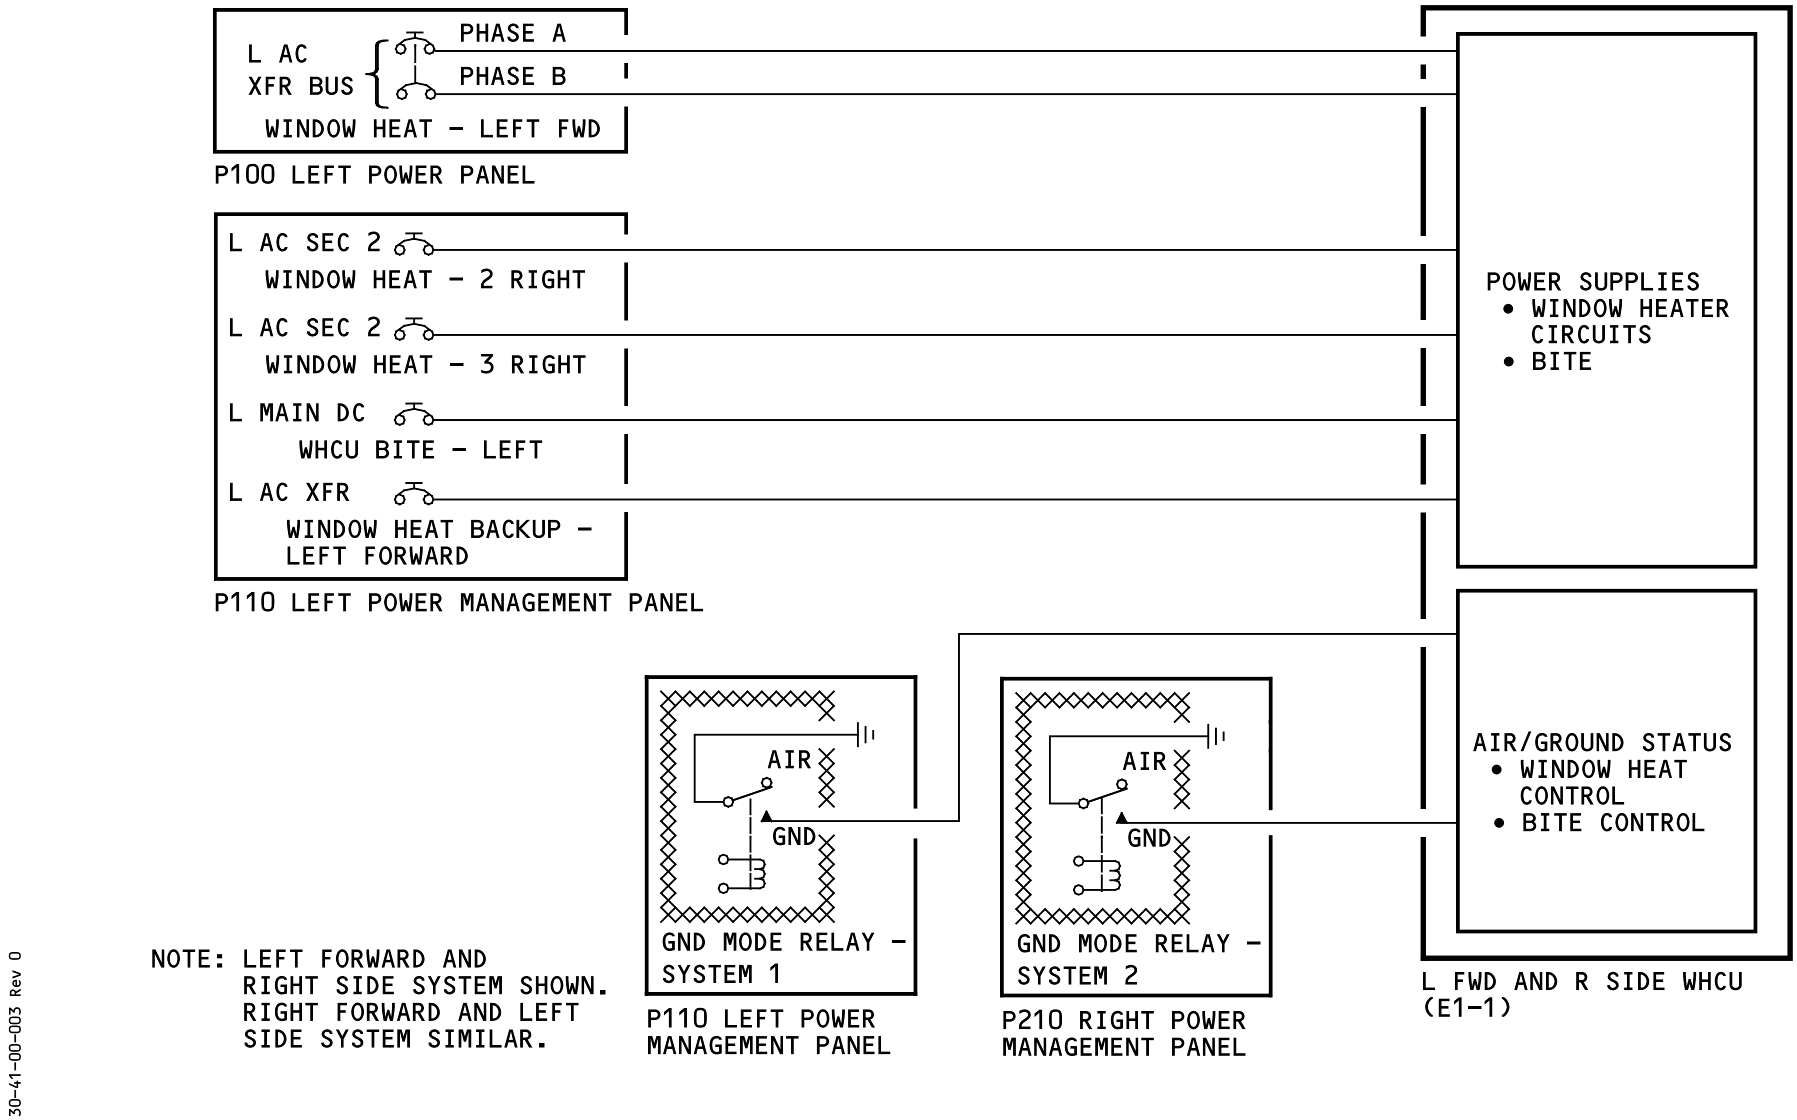
The number 1 window uses two phase ac. The number 2 and 3 windows use single phase ac.

Air/Ground Inputs

The WHCU uses the air/ground status for these functions:

- The WHCUs decrease the power to all of the window heaters during the first four minutes of operation on the ground
- The WHCU inhibits initiated BITE tests in flight.

The initiated BITE tests occur during power-up of the WHCU, and when you do the window heat ground test on the MAT.



FLIGHT DECK WINDOW ANTI-ICE SYSTEM - FUNCTIONAL DESCRIPTION - 1

FLIGHT DECK WINDOW ANTI-ICE SYSTEM - FUNCTIONAL DESCRIPTION - 2

THIS PAGE INTENTIONALLY LEFT BLANK

FLIGHT DECK WINDOW ANTI-ICE SYSTEM - FUNCTIONAL DESCRIPTION - 2

General

These control switches connect to one WHCU (left forward and right side WHCU):

- Left forward window heat switch
- Right side window heat switch
- Left backup window heat switch.

The other switches connect to the other WHCU (right forward and left side WHCU).

Each window heat switch has an ON light and an INOP light. The backup window heat switches do not have indications.

These heater circuits are for normal operation:

- Number 1 window anti-ice heater circuit
- Number 2 window anti-fog heater circuit
- Number 3 window anti-fog heater circuit.

The anti-fog heater circuit in the number 1 window is for backup operation.

The WHCU supplies control power to the window heaters. The WHCU also has BITE.

Window Heat Enable

The left forward window heat switch enables the anti-ice heater circuit in the left number 1 window. The right side window heat switch enables the anti-fog heaters in the right number 2 and 3 windows.

The INOP lights are on when the window heat switches are OFF. The INOP light shows that the heater circuit is not enabled.

When you push the switches, a mechanical ON label shows switch position. The ON light comes on if the instrument lights system has power. The INOP light goes out to show the heater circuit is enabled.

Window Heat Control

A temperature sensor in each window supplies control feedback to the WHCU. The WHCU controls the temperature of each window independently. The WHCU does not supply power to the heater circuit if the window temperature is too warm.

BITE Operation

The BITE in the WHCU tests for failures in these components:

- WHCU
- Heater
- Temperature sensor.

The WHCU can remove all power to a window heater if the BITE in the WHCU finds a failure. The INOP light comes on to show that the heater circuit is not enabled.

FLIGHT DECK WINDOW ANTI-ICE SYSTEM - FUNCTIONAL DESCRIPTION - 2

There are continuous BITE tests and initiated BITE tests. The continuous BITE tests occur during normal operation. The initiated BITE tests occur during power-up of the WHCU and when you do the window heat ground test on the MAT.

Window Heat Backup

The WHCU supplies electrical power to the anti-fog heater in the number 1 window if the backup window heat switch is ON and either of these conditions exists:

- Forward window heat switch OFF
- Forward window heat switch ON and no power to the anti-ice heater in the number 1 window.

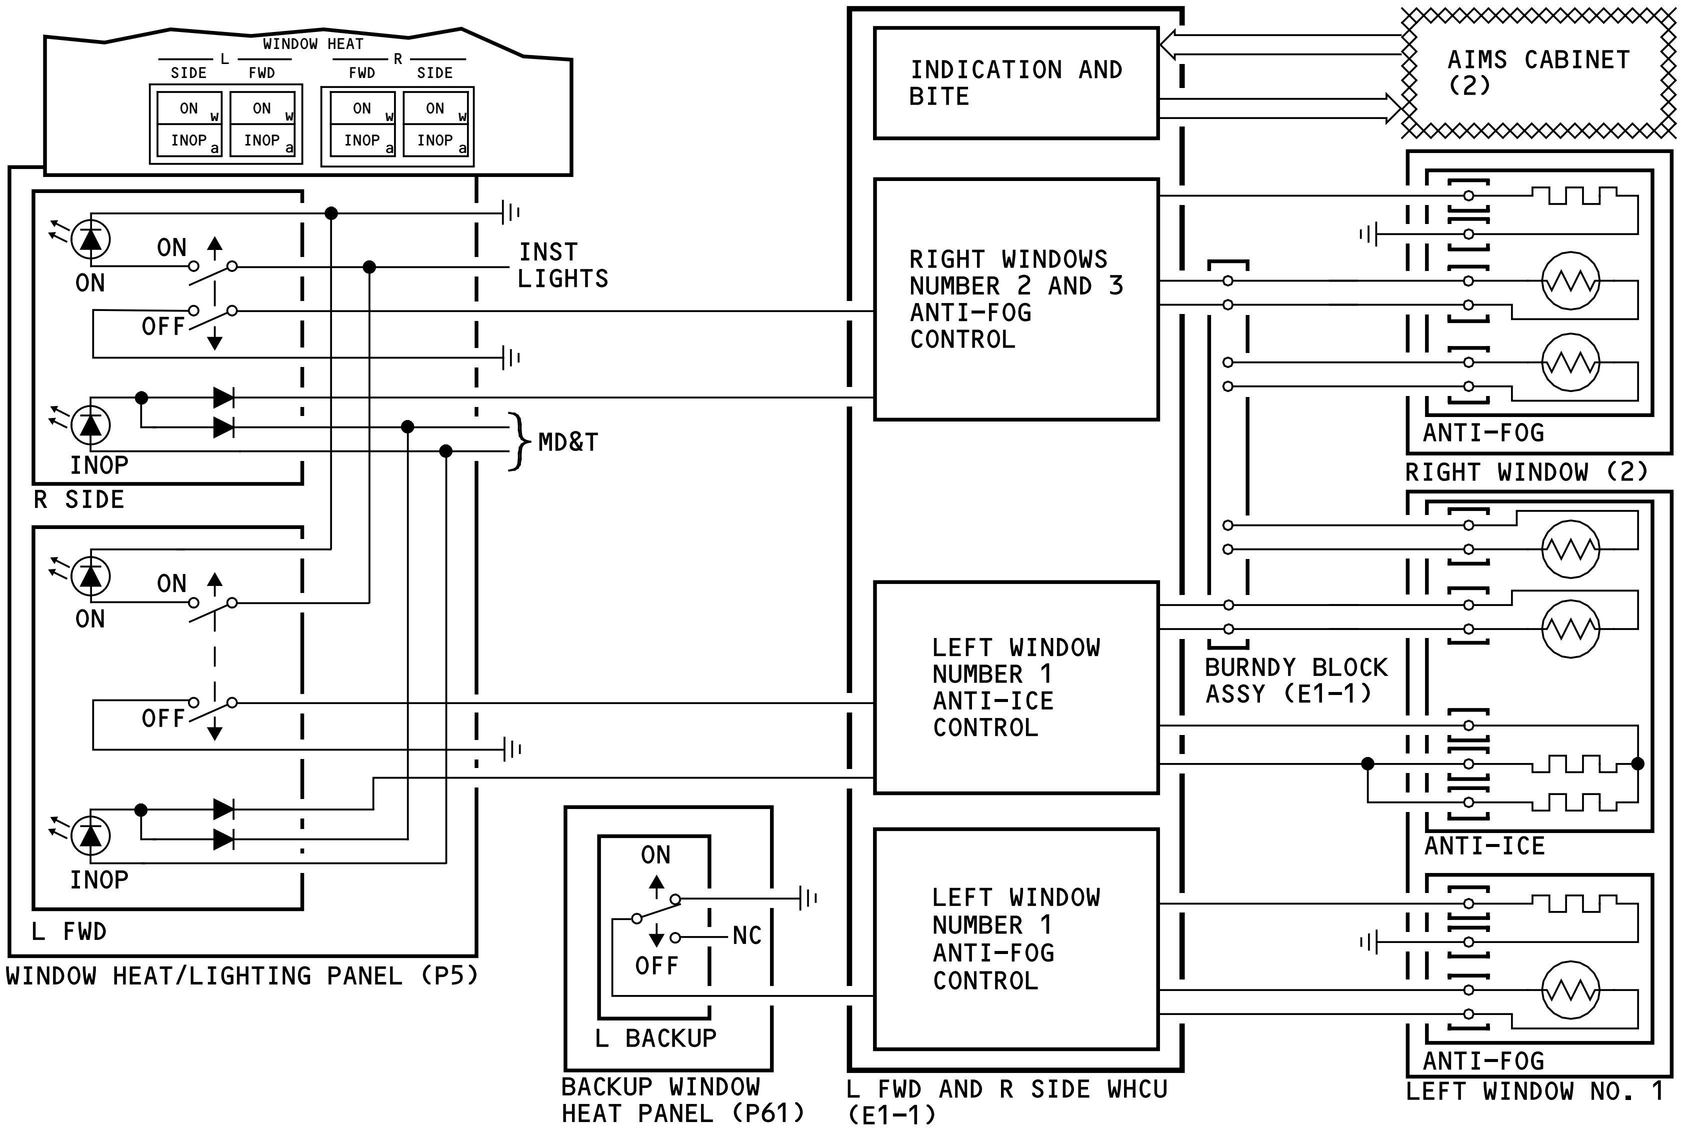
A backup temperature sensor supplies feedback.

To remove backup heat from the number 1 window, move the backup window heat switch to the OFF position.

Training Information Point

To remove power from the window heater circuits, select the window heat switches and the backup window heat switches OFF. You need to do this for safety before you clean the windows or do maintenance on the windows.

The window anti-ice system has burndy blocks on the left of the E1 rack and right of the E2 rack. This lets you switch to the spare sensor if the primary sensor fails.



FLIGHT DECK WINDOW ANTI-ICE SYSTEM - FUNCTIONAL DESCRIPTION - 2

FLIGHT DECK WINDOW ANTI-ICE SYSTEM - OPERATION

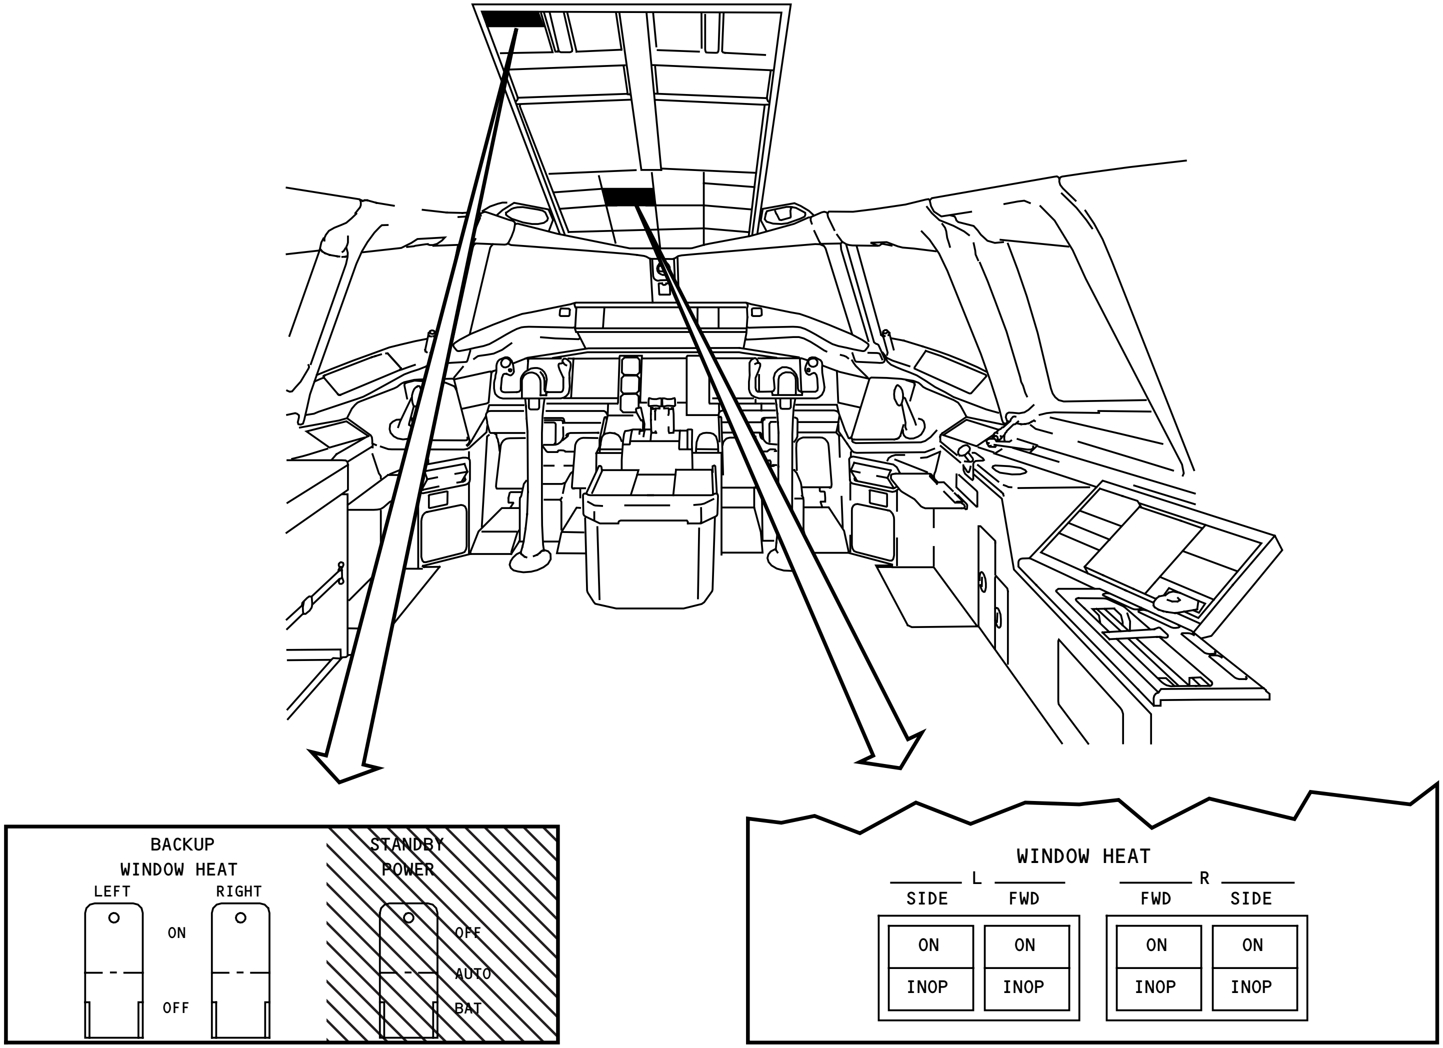
Window Heat Switches

There are four window heat switches, two for the windows on the left side of the flight compartment, and two for the windows on the right side of the flight compartment.

The left and right forward window heat switches enable the heater circuits in the left and right number 1 windows. The left and right side window heat switches enable the heater circuits for the left and right number 2 and 3 windows.

Backup Window Heat Switches

There are two backup window heat switches, one for each of the left and right number 1 windows. The switches are normally in the ON position. The switches have guards. You move the backup window heat switch to the OFF position to remove power from the backup window heat system.



BACKUP WINDOW HEAT/STANDBY POWER PANEL (P61)

WINDOW HEAT/EMERGENCY LIGHTS PANEL (P5)

FLIGHT DECK WINDOW ANTI-ICE SYSTEM - OPERATION

FLIGHT DECK WINDOW ANTI-ICE SYSTEM - SYSTEM TESTS

WINDSHIELD WIPER SYSTEM - INTRODUCTION

Purpose

The windshield wiper system removes water from the left and right number one flight deck windows.

Windshield Wipers

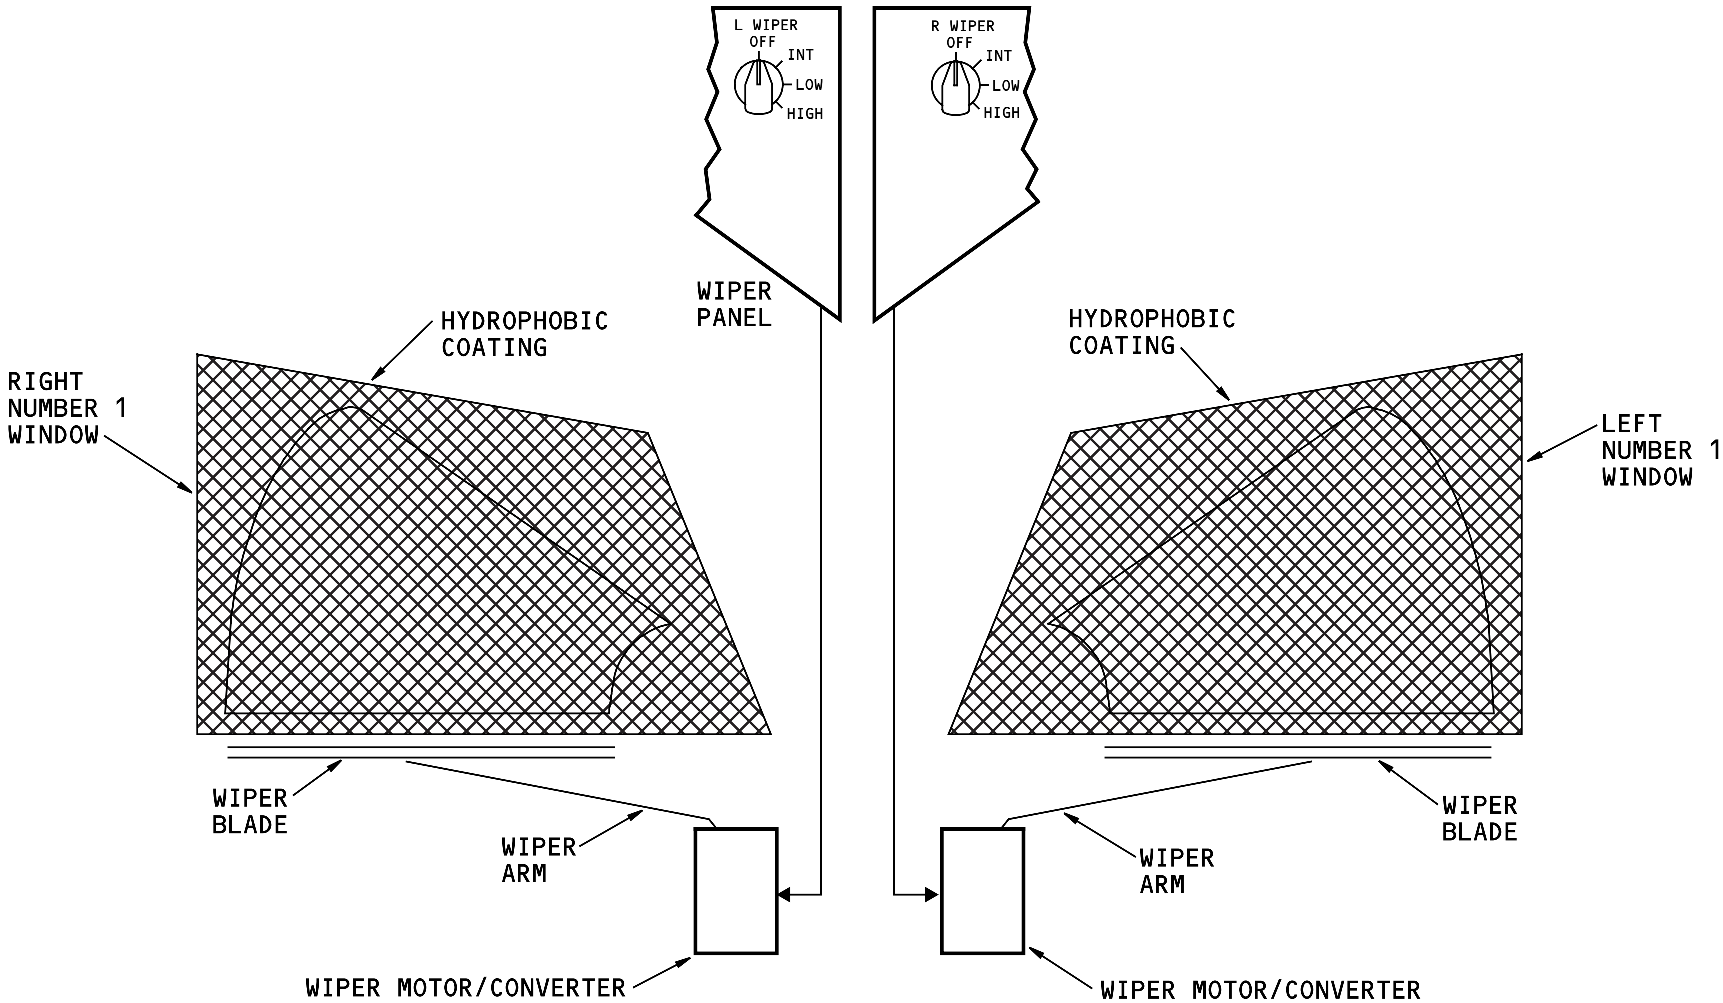
There are two windshield wipers, one for each of the number one windows. Each windshield wiper assembly has these components:

- Wiper
- Wiper arm
- Wiper motor/converter.

There is a switch on the P5 overhead panel for each wiper.

Hydrophobic Coating

A hydrophobic coating on each forward window repels rain. The windshield does not have a liquid rain repellent system because there is a hydrophobic coating.



30-42-00-001 Rev 1 08/08/96

DRAIN AND WATER SUPPLY LINE HEATING - INTRODUCTION

Purpose

Electric heaters prevent ice in the water and waste systems.

General Description

These heaters are in the potable water system:

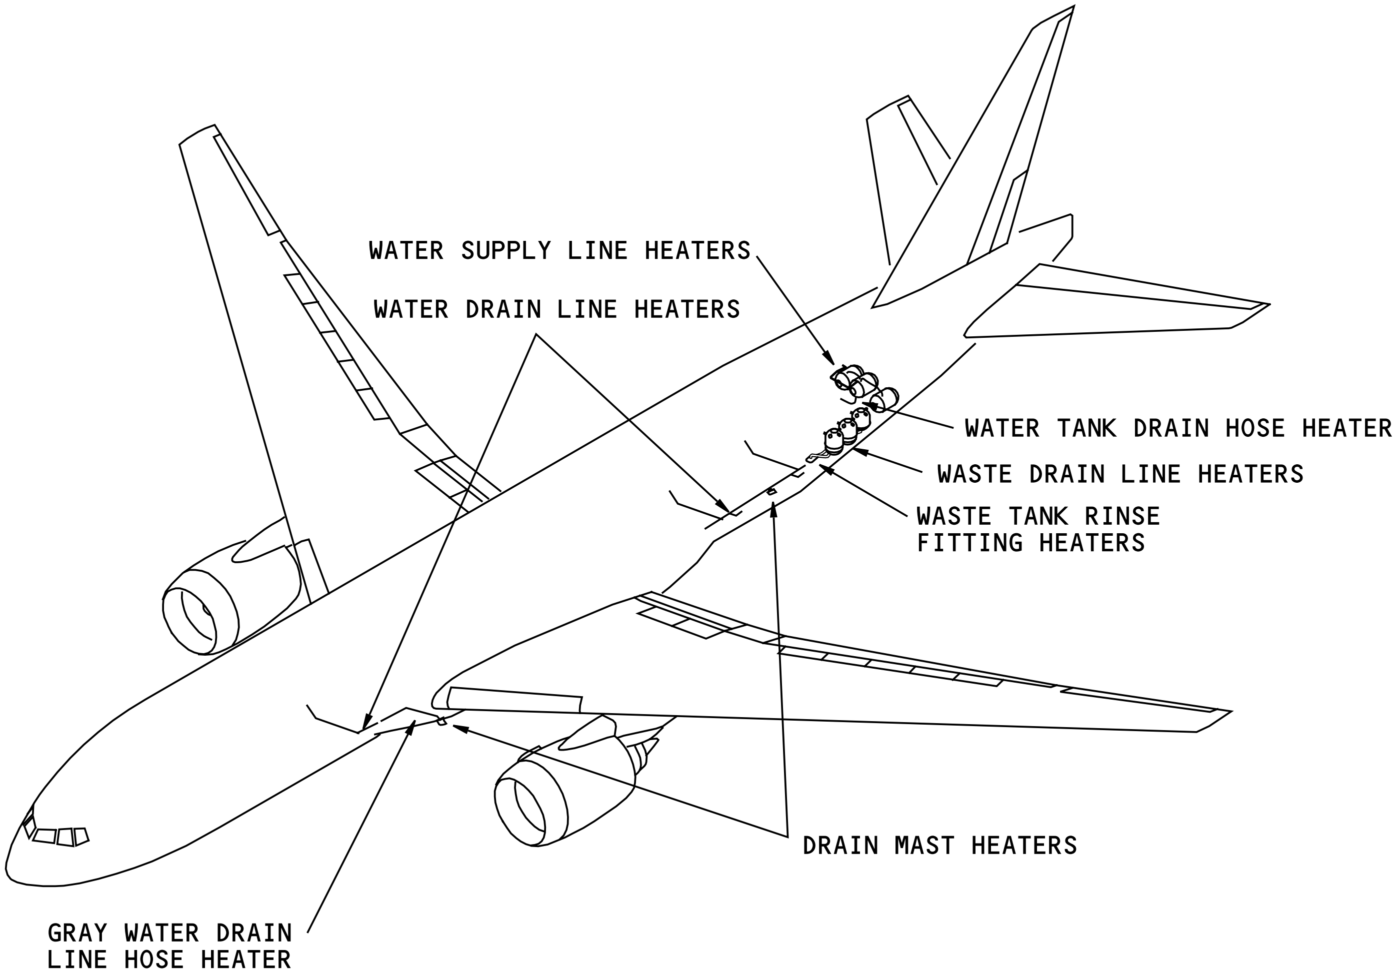
- Water supply line heaters
- Water tank drain hose heater.

These heaters are in the waste system:

- Waste drain line heaters
- Waste tank rinse fitting heaters.

These heaters are in the gray water drain system:

- Drain mast heaters
- Gray water drain line hose heater
- Water drain line heaters.



30-71-00-001 Rev 2 05/06/1997

DRAIN AND WATER SUPPLY LINE HEATING - INTRODUCTION

DRAIN AND WATER SUPPLY LINE HEATING - WATER SUPPLY IN-LINE HEATER - INTRODUCTION

General

Water lines carry water from the potable water tanks to the lavatories and galleys.

Each water line has a water supply in-line heater, controller and thermostat.

Some heaters have remote thermostats. The heaters and the remote thermostats are LRUs. Each LRU has an electrical connector.

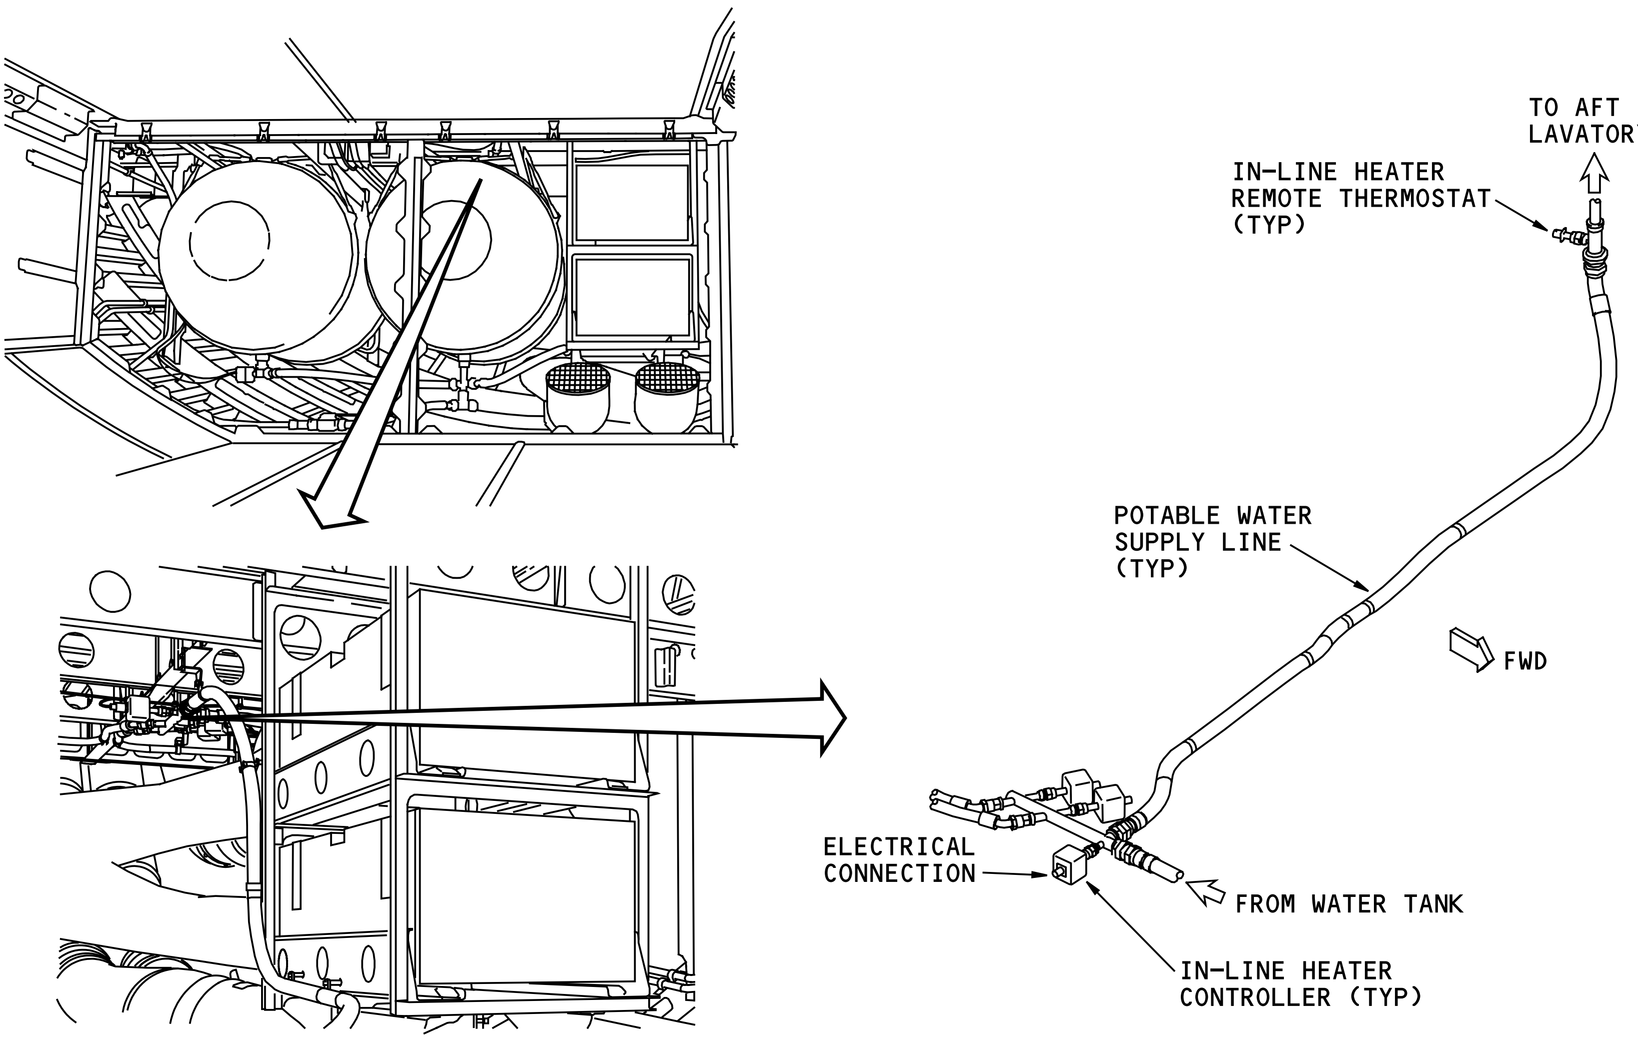
Two heaters have integral thermostats in the controllers. These thermostats are not separate LRUs.

Location

The water supply in-line heaters are near the potable water tanks. Access to the heaters is through the end wall of the bulk cargo compartment.

Training Information Point

It is not necessary to splice the wires when you replace an LRU.



BULK CARGO COMPARTMENT
(LOOKING AFT WITH END WALL REMOVED
AND POTABLE WATER TANK REMOVED)

30-71-00-002 Rev 2 12/11/1996

DRAIN AND WATER SUPPLY LINE HEATING - WATER SUPPLY IN-LINE HEATER - INTRODUCTION

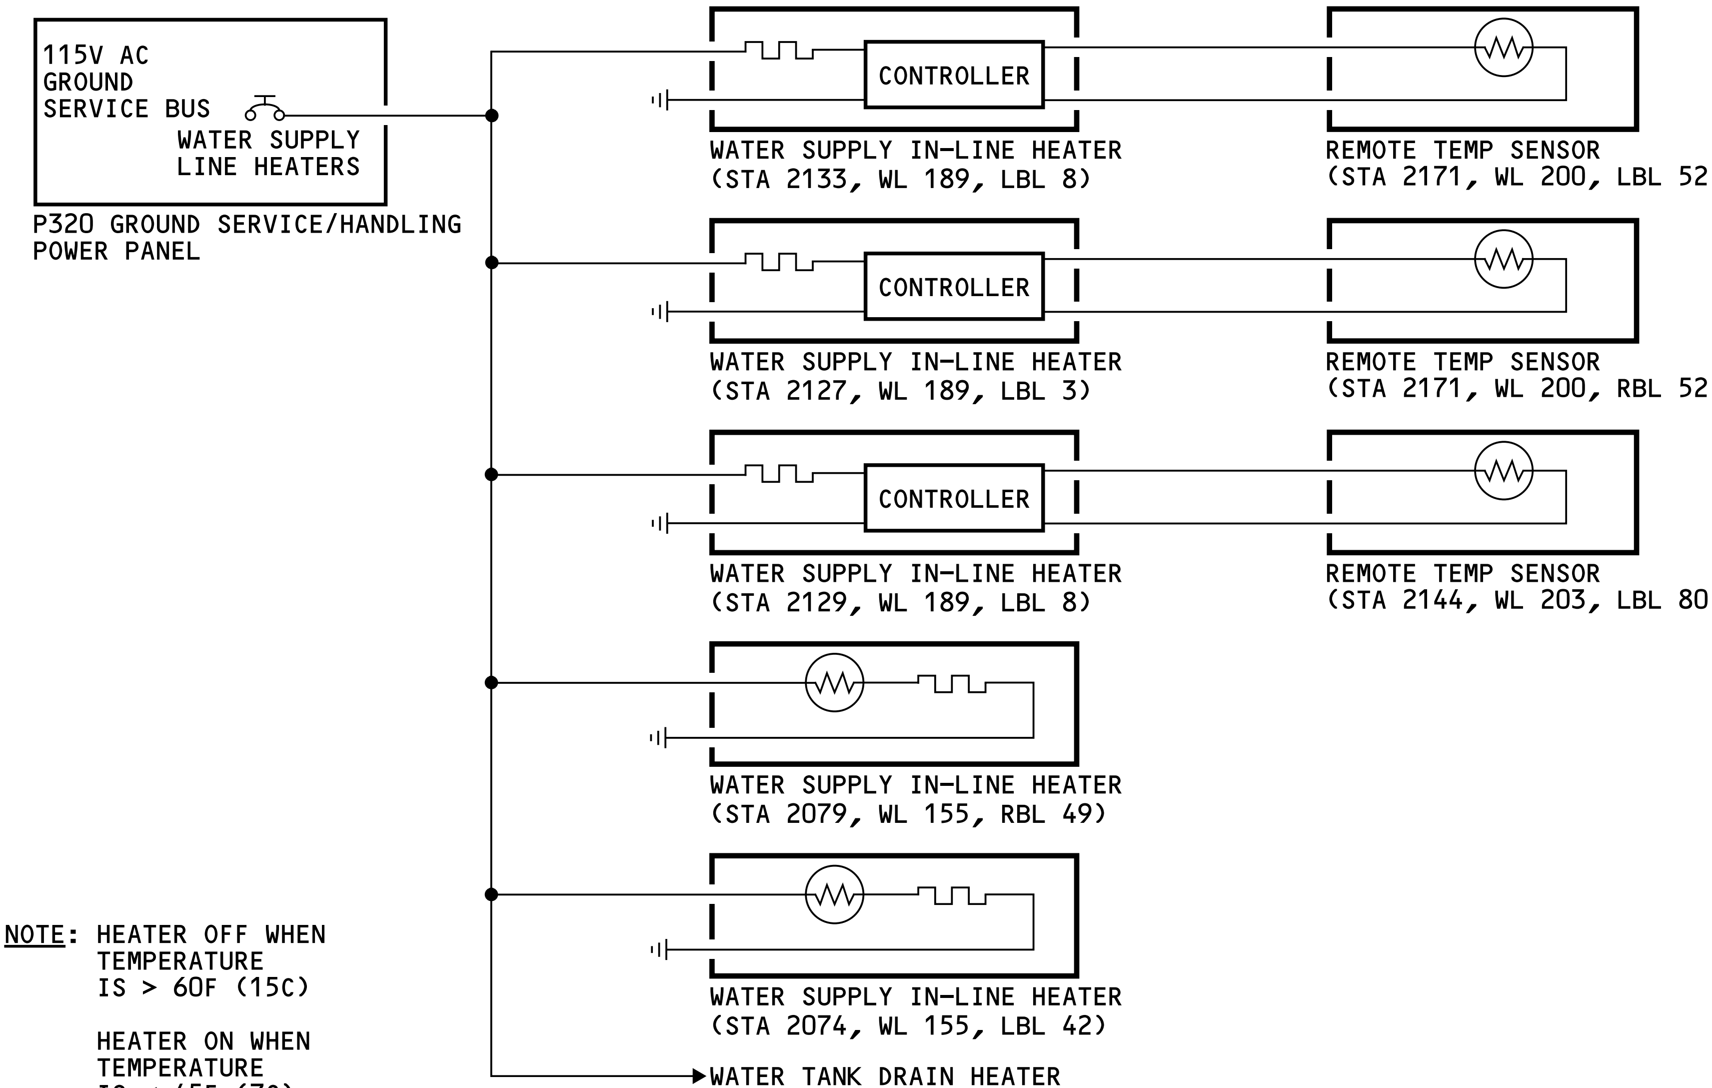
DRAIN AND WATER SUPPLY LINE HEATING - WATER SUPPLY IN-LINE HEATER - FUNC. DESC.

General

The heaters in the distribution lines have remote thermostats. The heaters below the left and right potable water tanks have integral thermostats in the controllers. The heaters operate the same.

Functional Description

The thermostat supplies electrical continuity as temperature decreases below freezing. As temperature increases, the thermostat stops continuity to prevent too much heat. The thermostat stops continuity when the temperature is greater than 60F (15C). Continuity comes back when the temperature is less than 45F (7C).



30-71-00-003 Rev 2 02/20/95

NOTE: HEATER OFF WHEN TEMPERATURE IS > 60F (15C)

HEATER ON WHEN TEMPERATURE IS < 45F (7C)

DRAIN AND WATER SUPPLY LINE HEATING - WATER SUPPLY IN-LINE HEATER - FUNC. DESC.

DRAIN AND WATER SUPPLY LINE HEATING - WATER TANK DRAIN HEATER

General

The drain line for the potable water tanks has an integral water tank drain heater. The heater prevents freezing in the line. This heated hose is an LRU.

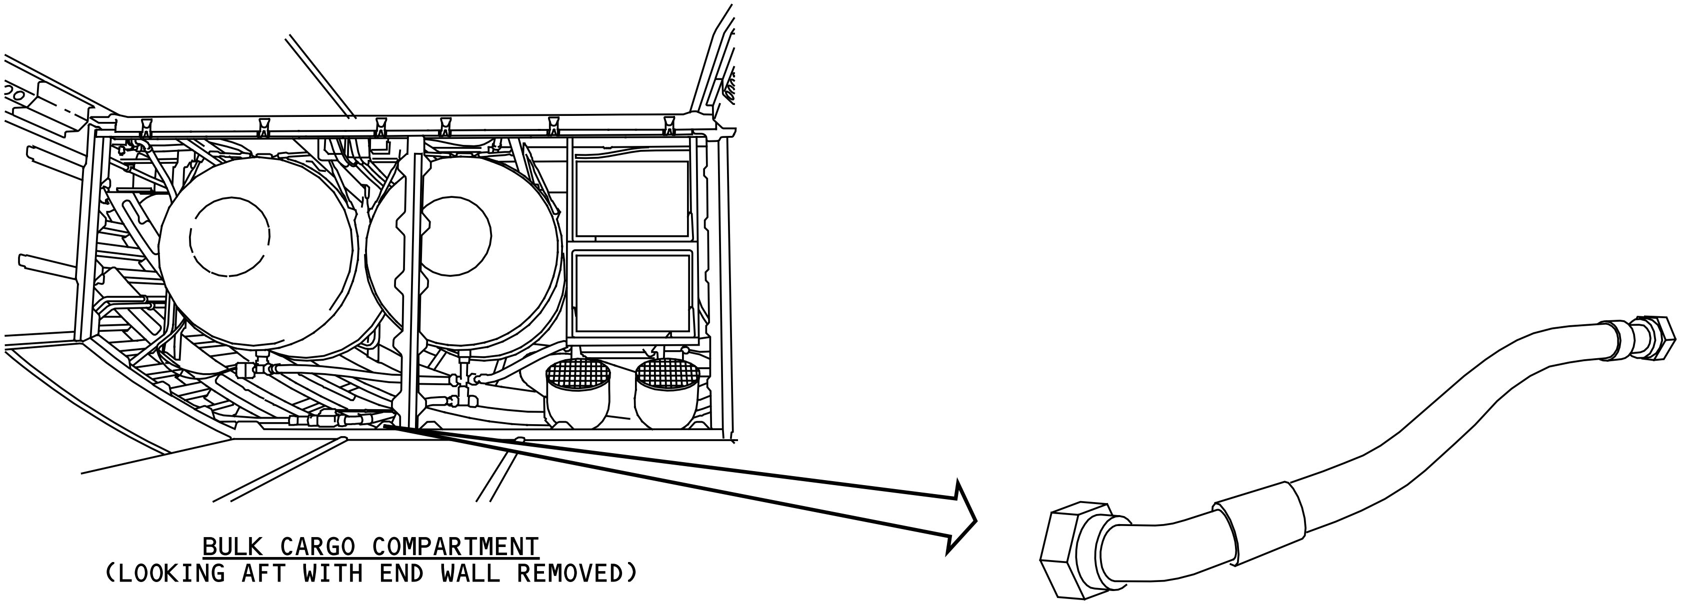
The heater wires on the heated hose do not have electrical connectors. You must splice the wires when you replace a drain hose.

Location

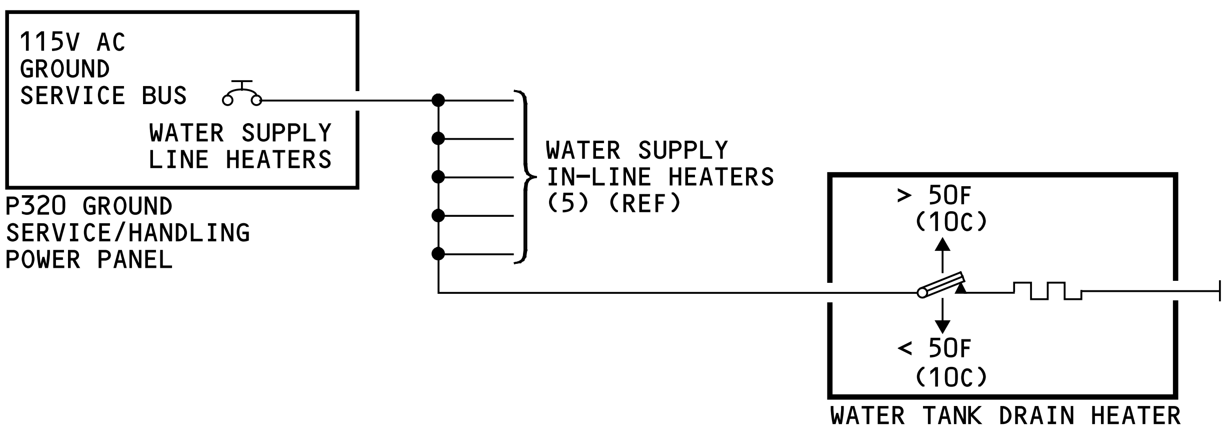
The heated hose is below the space between the right and center potable water tanks. Removable panels provide access to the hose through the aft cargo compartment.

Functional Description

The heated hose has an integral thermostat. The thermostat supplies electrical continuity as temperature decreases below the freeze point. As temperature increases, the thermostat opens the circuit to prevent too much heat. The thermostat opens the circuit when the temperature is greater than 50F (10C). The thermostat closes the circuit when the temperature is less than 50F (10C).



BULK CARGO COMPARTMENT
(LOOKING AFT WITH END WALL REMOVED)



DRAIN AND WATER SUPPLY LINE HEATING - WATER TANK DRAIN HEATER

DRAIN AND WATER SUPPLY LINE HEATING - GRAY WATER DRAIN LINE HEATER AND THERMOSTAT

General

The forward drain mast has a heated hose identified as the gray water drain line hose heater.

The heated hose has a remote thermostat identified as the gray water drain line hose heater thermostat.

Each component, the hose and the thermostat, is an LRU. The wires do not have electrical connectors. To replace a component you must splice the wires together.

The aft drain mast does not have a heated hose.

Location

The heated hose and its thermostat are in the forward left wing-to-body fairing.

An access panel aft of the drain mast supplies access to the thermostat.

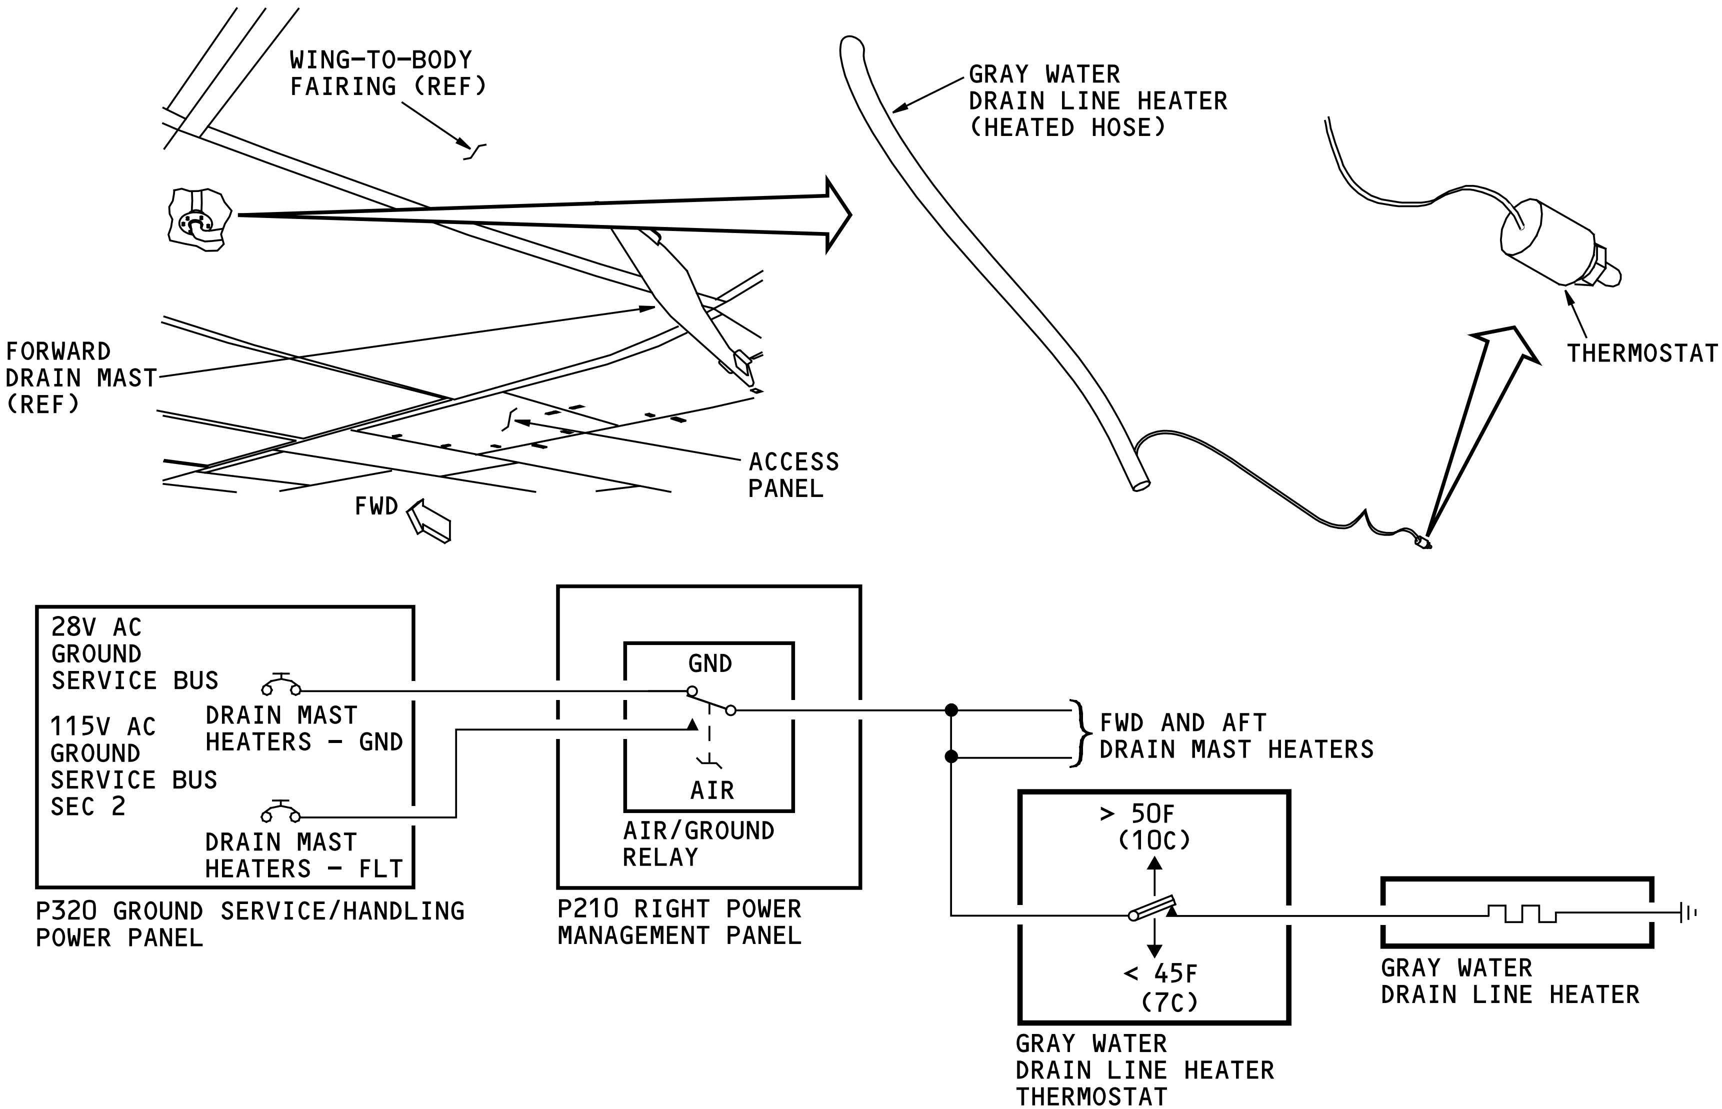
Functional Description

Power for the drain mast heaters comes through an air/ground relay. The heaters get 28v ac on the ground and 115V ac in the air.

The thermostat opens the circuit when the temperature is more than 50F (10C). The circuit closes when the temperature is less than 45F (7C).

Training Information Point

You can remove the drain mast to get better access to the heated hose.



30-71-00-005 Rev 3 04/29/96

DRAIN AND WATER SUPPLY LINE HEATING - GRAY WATER DRAIN LINE HEATER AND THERMOSTAT

DRAIN AND WATER SUPPLY LINE HEATING - DRAIN MAST HEATER

General

There are drain mast heaters in the forward and aft drain masts to prevent freezing. Each drain mast is an LRU and is interchangeable with the other.

The heater wires on the drain masts do not have electrical connectors. You must splice the wires when you replace a drain mast.

Location

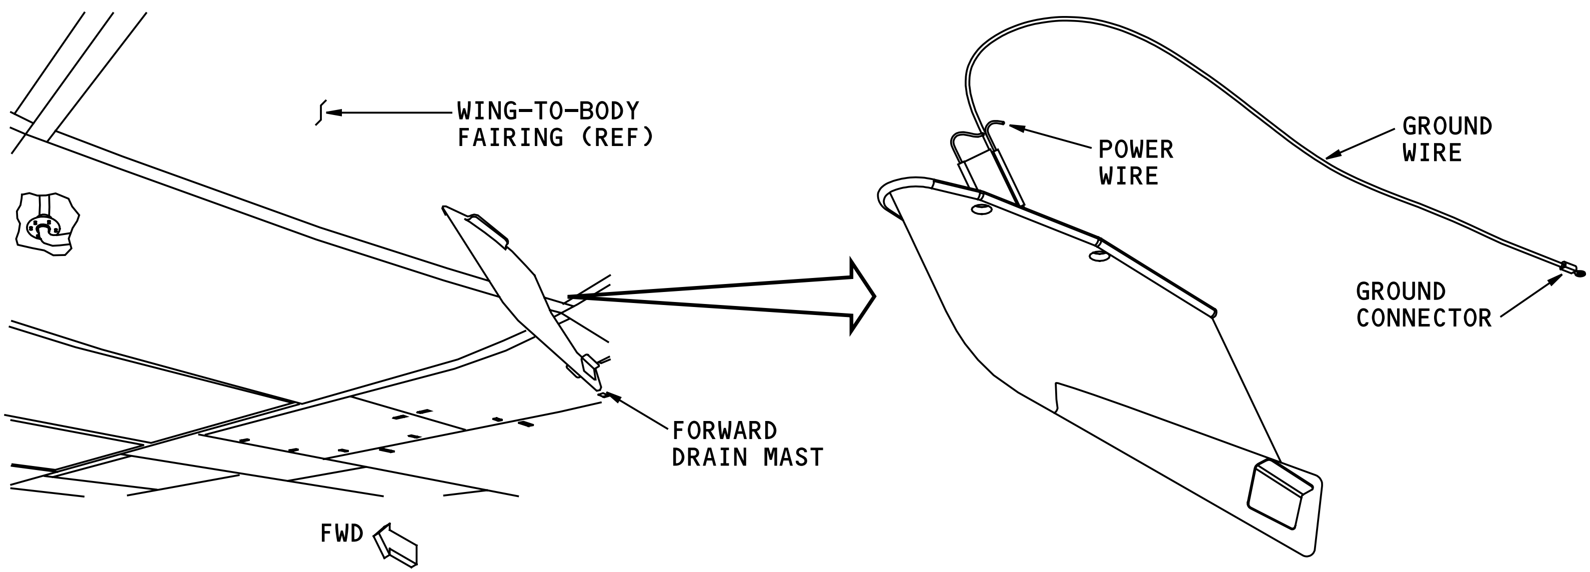
Both drain masts are on the left wing-to-body fairing.

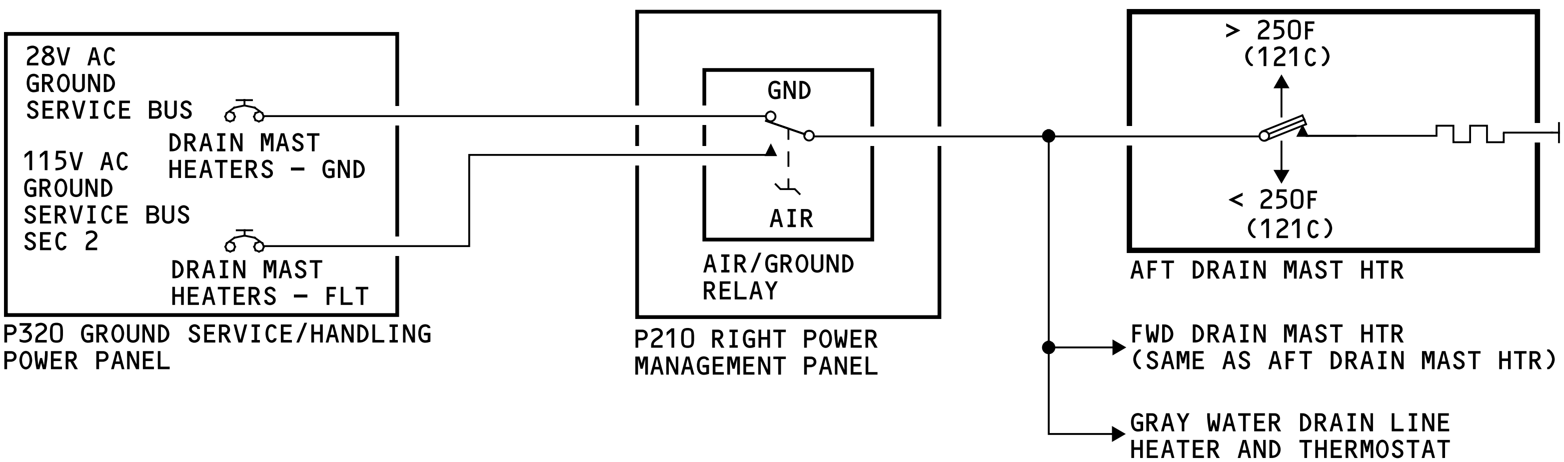
You can remove the drain mast from the fairing. It is not necessary to open a panel to get access to the drain mast.

Functional Description

Power for the drain mast heaters comes through an air/ground relay. The heaters get 28v ac on the ground and 115v ac in the air.

An overheat thermostat will opens the circuit when the temperature is greater than 250F (121C). The circuit closes when the temperature is less than 250F (121C).





DRAIN AND WATER SUPPLY LINE HEATING - DRAIN MAST HEATER

30-71-00-006 Rev 3 04/29/96

DRAIN AND WATER SUPPLY LINE HEATING - WATER DRAIN LINE HEATERS - INTRODUCTION

Purpose

Water drain line heaters keep the gray water drain lines in the lower part of the fuselage from freezing.

General Description

The heater is a flexible element installed around the drain line. The heater also includes an overheat switch (not shown). Electrical connectors attach to the heater and to ground studs. Metal clamps attach the ground studs to the drain line. (Some assemblies have only one connector and ground stud.)

Thermal insulation (held in place with tape) covers the drain line and heating element. Adhesive markers identify the flow direction and part number. On some drain lines, a clamp holds a thermostat.

Location

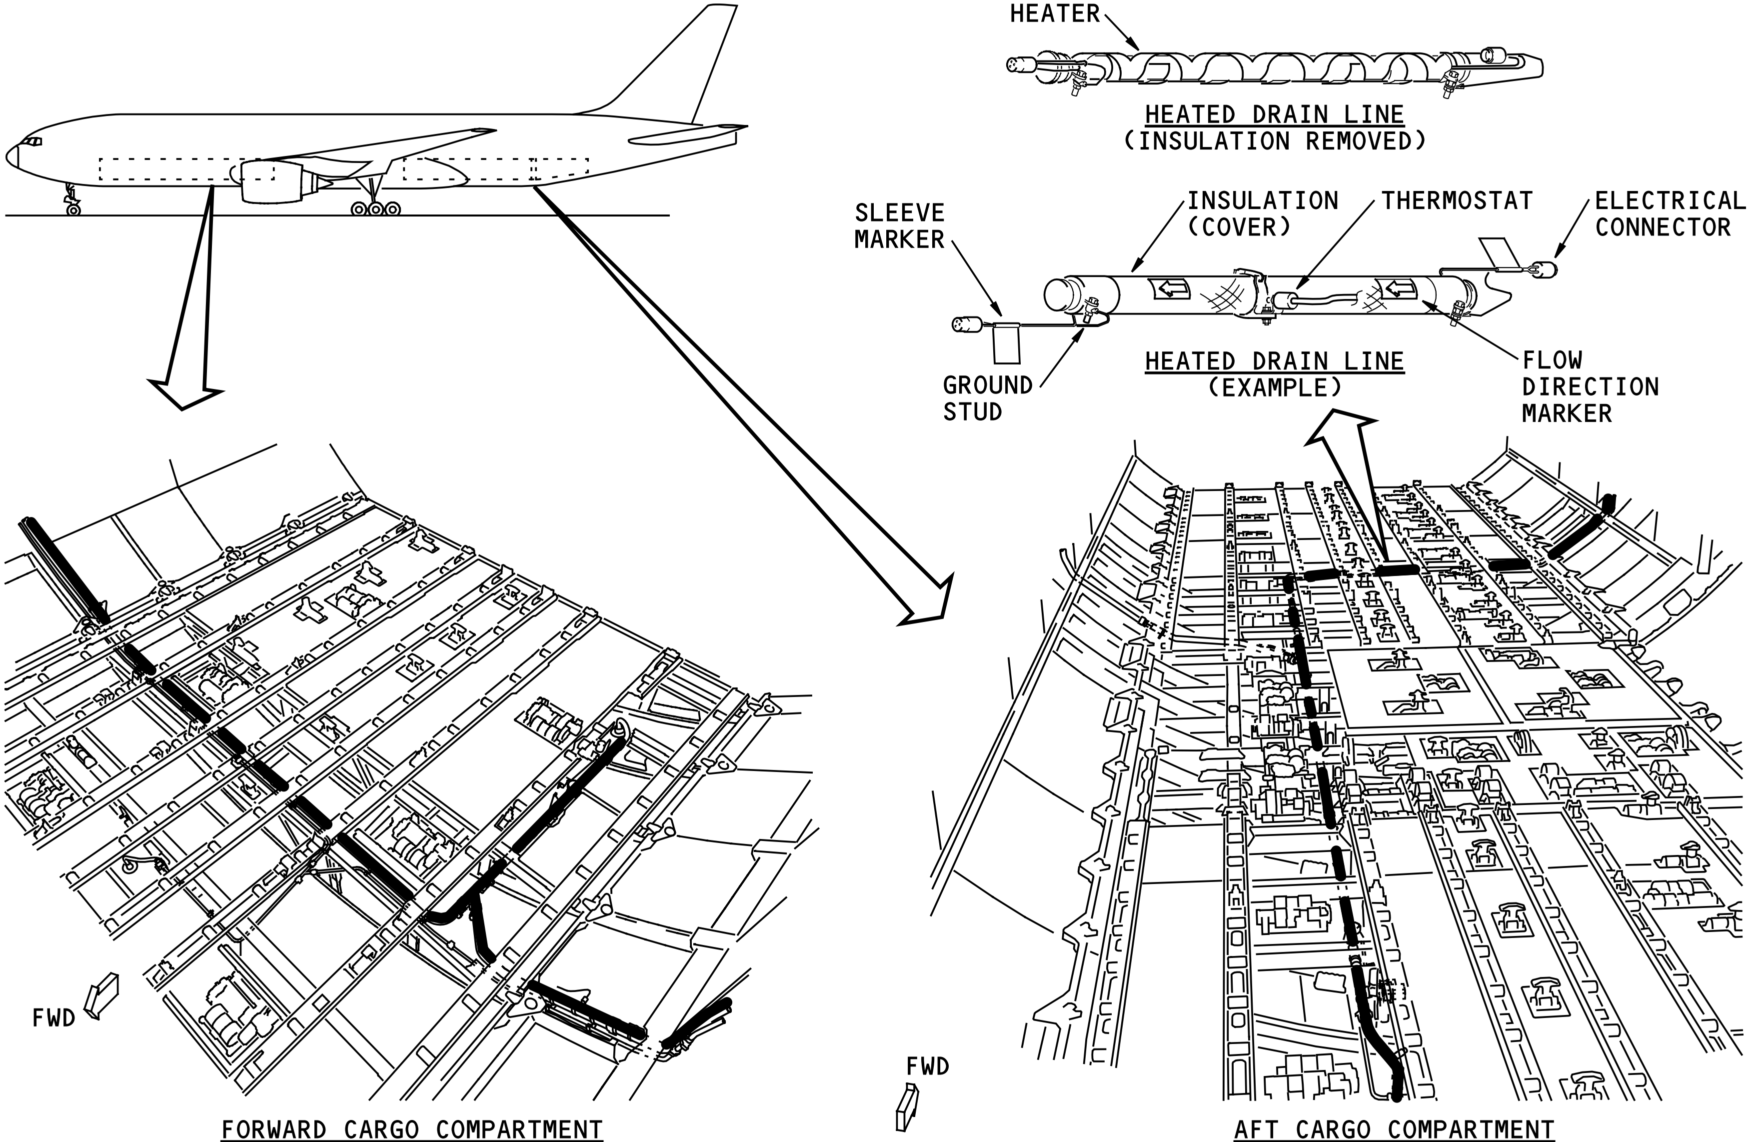
The heated gray water drain lines are below the floor panels and walkways of the forward, aft, and bulk cargo compartments.

Training Information Point

The heater is an LRU. In some places it is easier to replace the heater if you remove the drain line from the airplane. If you do this, you must do a leak check when you install the drain line.

When you replace a heater, you need to do an operational test. Cool the thermostat with crushed ice or freeze spray and use a clamp-on ammeter to measure current through the heater.

CAUTION: MAKE SURE YOU PUT THE CORRECT HEATER ASSEMBLY ON THE TUBE ASSEMBLY. IF THE HEATER ASSEMBLY IS INCORRECT, IT WILL CAUSE THE DRAIN LINES TO FREEZE OR BECOME TOO HOT.



DRAIN AND WATER SUPPLY LINE HEATING - WATER DRAIN LINE HEATERS - INTRODUCTION

DRAIN AND WATER SUPPLY LINE HEATING - WATER DRAIN LINE HEATERS - FUNCTIONAL DESCRIPTION

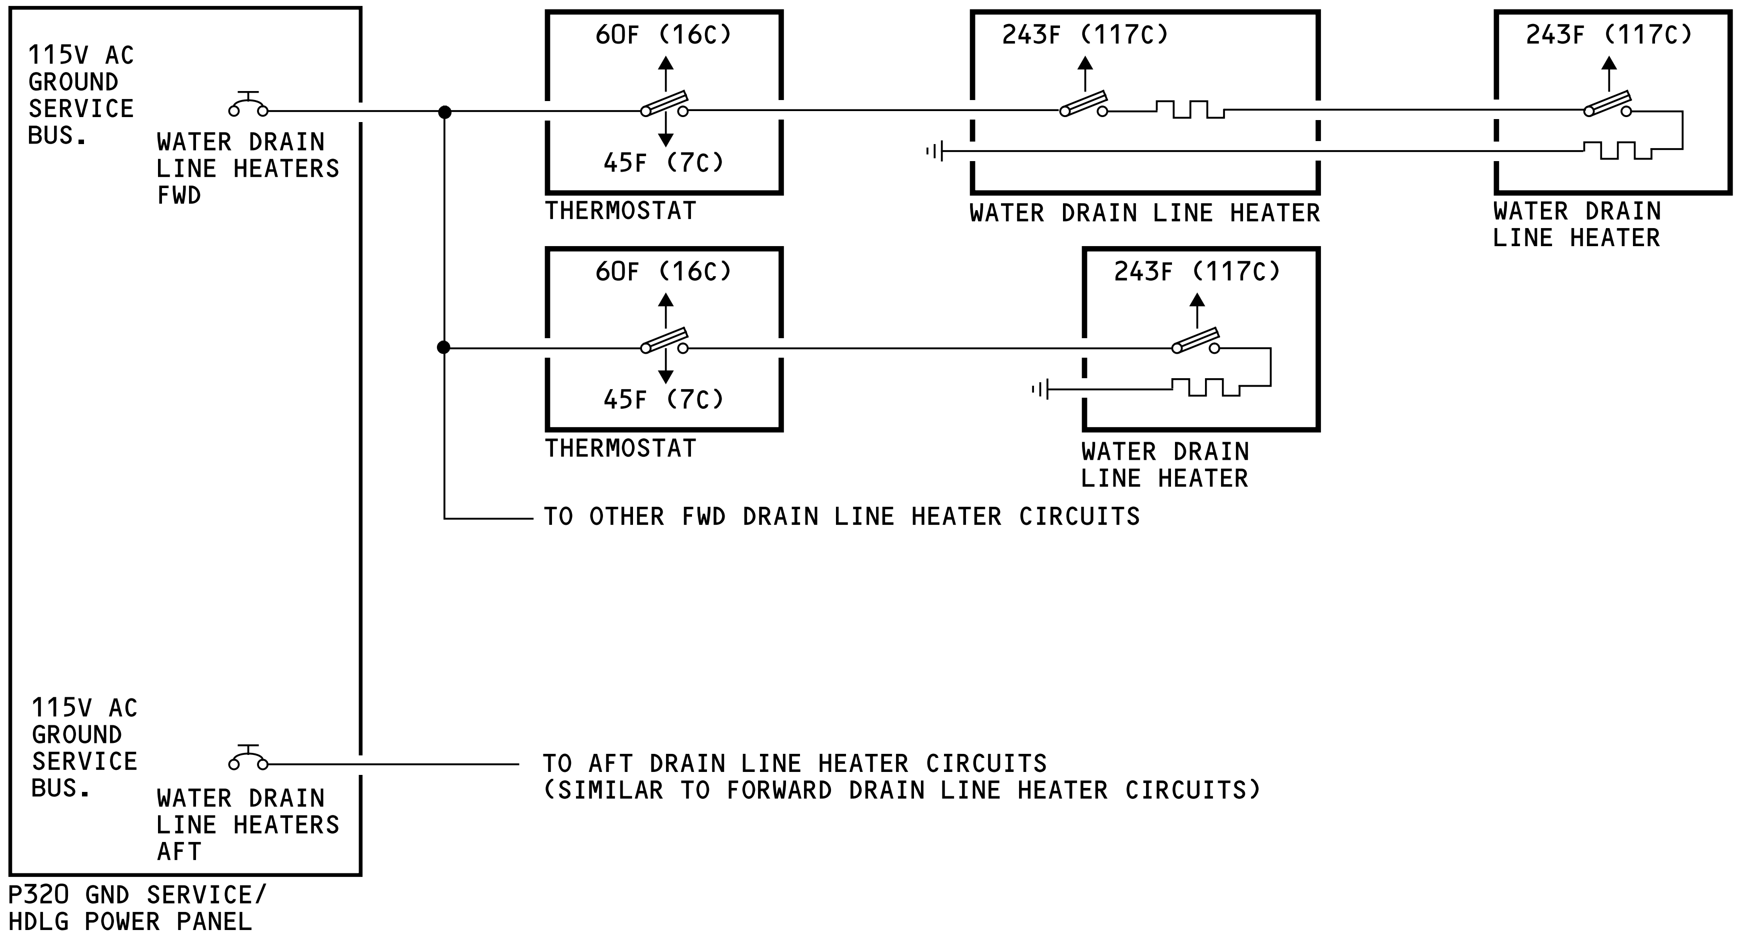
General

The ground service bus supplies 115v ac power to the water drain line heater circuits. There is one circuit breaker for the forward drain line heaters and one circuit breaker for the aft drain line heaters. The forward drain lines connect to the forward drain mast and the aft drain lines connect to the aft drain mast.

Functional Description

A thermostat (bi-metallic switch) opens the heater circuit when the temperature at the thermostat is 60F (16C) or more. When the temperature is 45F (7C) or less, the thermostat closes the heater circuit. In most circuits, the thermostat controls power to more than one heater.

An overheat switch in the heater opens if the temperature is 243F (117C) or more. The overheat switch does not reset. Most circuits have several heaters in series. If an overheat switch opens, it removes power from all the heaters in the series circuit.



30-71-00-011 Rev 0 05/06/1997

DRAIN AND WATER SUPPLY LINE HEATING - WATER DRAIN LINE HEATERS - FUNCTIONAL DESCRIPTION

DRAIN AND WATER SUPPLY LINE HEATING - WASTE TANK RINSE FITTING HEATERS

General

There are three waste tank rinse fittings. The rinse fittings connect the waste tank rinse lines to the waste drain service panel. Each rinse fitting has a heater boot identified as the waste tank rinse fitting heater. The rinse fitting heaters are interchangeable LRUs.

The waste tank rinse fitting heater has a power wire and a ground wire. The power wire does not have an electrical connector. You need to splice the power wire when you replace a rinse fitting heater.

The waste tank rinse fitting heater has an integral thermostat and an integral overheat thermostat.

Location

The waste tank rinse fitting heaters are below the bulk cargo compartment floor. You can access the heaters through an access panel on the floor of the bulk cargo compartment.

Functional Description

The integral thermostat controls the power for the waste tank rinse fitting heater. The thermostat closes the circuit as temperature decreases below the freeze temperature. The thermostat opens the circuit to prevent too much heat.

The integral overheat thermostat prevents damage to the heater if the integral thermostat fails.

The integral thermostat opens the circuit when the temperature is greater than 80F (26C). The circuit closes when the temperature is less than 45F (7C). The integral overheat switch opens the circuit when the temperature is greater than 110F (47C). The circuit closes when the temperature is less than 80F (26C).

FIRE PROTECTION - INTRODUCTION

Purpose

The fire protection systems monitor the airplane for these conditions:

- Fire
- Smoke
- Engine overheat
- Pneumatic duct leak.

The fire protection systems also include fire extinguishers.

Fire/Overheat Detection

The airplane has these fire/overheat detection systems:

- Engine fire detection
- Lavatory smoke detection
- Miscellaneous modules (flight crew rest) smoke detection
- APU fire detection
- Lower cargo compartment smoke detection
- Wheel well fire detection
- Duct leak and overheat detection
- Electrical and electronic (E/E) cooling smoke detection.

Extinguishing

The airplane has these fire extinguishing systems:

- Engine fire extinguishing
- Lavatory waste compartment fire extinguishing
- APU fire extinguishing
- Lower cargo fire extinguishing
- Portable fire extinguishers.

FIRE PROTECTION - INTRODUCTION

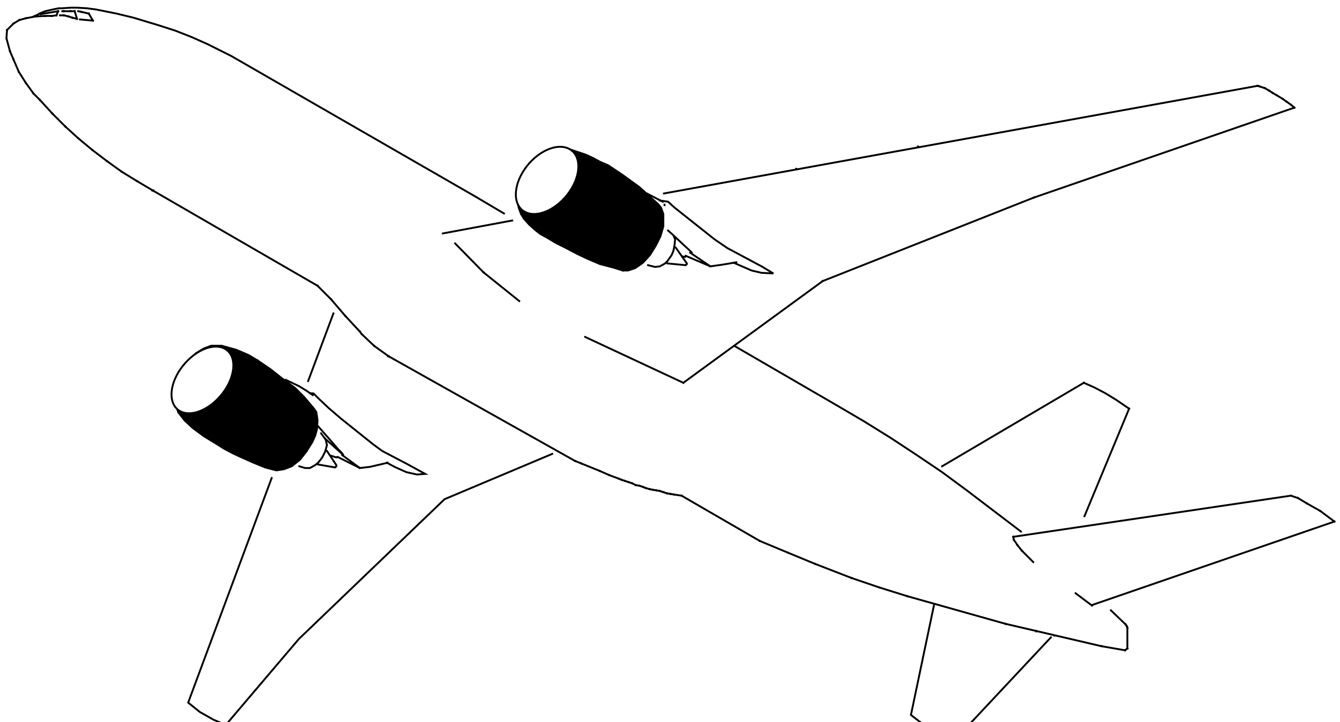
ENGINE FIRE DETECTION - INTRODUCTION

Purpose

The purpose of the engine fire detection system is to:

- Give warnings in the flight deck if there is a fire in an engine nacelle
- Give caution indications in the flight deck if an engine has an overheat condition
- Measure nacelle temperature for the airplane condition monitoring system (ACMS).

The system has built in test equipment. Failures cause EICAS messages, status messages, or maintenance messages.



ENGINE FIRE DETECTION - INTRODUCTION

ENGINE FIRE DETECTION - GENERAL DESCRIPTION

General

Each engine has two fire detection loops, loop 1 and loop 2. A fire detection card in the system card file monitors the loops for fires, overheat conditions, and faults. There is a fire detection card for each engine.

Overheat Detection

If the fire detection loops find an overheat condition, the fire detection card sends a signal to the AIMS and to the warning electronics unit. The AIMS shows a caution message and turns on the master caution light. The warning electronics unit turns on the caution aural.

When the overheat condition goes away, the indications go away.

Fire Detection

If an engine fire occurs, the fire detection card sends a signal to the AIMS and to the warning electronics unit. A warning message shows. The warning electronics unit turns on the master warning lights and the fire warning aural. Another fire alarm signal causes the fuel control switch fire warning light and the engine fire warning light to come on.

When the fire is extinguished, the indications go out of view.

Nacelle Temperature Recording

The fire detection card measures the average temperature of the loops. This data goes to the AIMS through the systems ARINC 629 buses. The airplane condition monitoring function records this data.

Continuous Fault Monitoring

The fire detection card monitors the two loops and their wiring for defects. In normal (dual loop) operation, both loops must have a fire or overheat condition to cause the flight deck indications.

If a failure occurs in a loop, the fire detection card sends the data to the AIMS. A status message shows and the system changes to single loop operation. In this mode, fire/overheat indications occur when one loop is defective and the other has a fire or overheat condition.

System Tests

Use the FIRE/OVHT TEST switch on the P5 overhead panel to do a test of the system. Test results show on the primary display system.

The fire and overheat detection system has a built-in-test function which does tests of the loops, system logic, and interface electronics. System failures show on the primary display system and the MAT.

ENGINE FIRE DETECTION - ENGINE COMPONENT LOCATIONS

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE FIRE DETECTION - ENGINE FIRE DETECTORS

Purpose

The engine fire detectors monitor the temperature in the engine nacelles.

Physical Description

Each detector has two elements that attach to a support tube. The elements connect to make loop 1 and loop 2.

The element is an inconel tube filled with a thermistor core material. Two electrical conductors go through the length of the core. One conductor has a ground connection to the tube. The other conductor connects to the fire detection card.

Functional Description

As the temperature of the core increases, electrical resistance to ground decreases. The fire detection card monitors this resistance. If the resistance decreases to the overheat set point, an overheat indication occurs in the flight deck. There is a 9.6 second time delay for the overheat indication. If the resistance decreases more to the fire set point, a fire warning occurs. When the fire or overheat condition is gone, the resistance increases to the reset point and the flight deck indications go away.

The tables show temperatures in degrees F (and degrees C) which cause overheat and fire indications. Reset temperatures are also shown.

DETECTOR	OVERHEAT TEMP	RESET TEMP
FWD LOWER	501 (261)	486 (252)
AFT LOWER	706 (374)	689 (365)
AFT LEFT	706 (374)	689 (365)
AFT RIGHT	706 (374)	689 (365)

DETECTOR	FIRE TEMP	RESET TEMP
FWD LOWER	610 (321)	595 (313)
AFT LOWER	826 (441)	810 (432)
AFT LEFT	826 (441)	810 (432)
AFT RIGHT	826 (441)	810 (432)

The rate of change of resistance identifies an electrical short or a fire. The resistance decreases more quickly with an electrical short than with a fire.

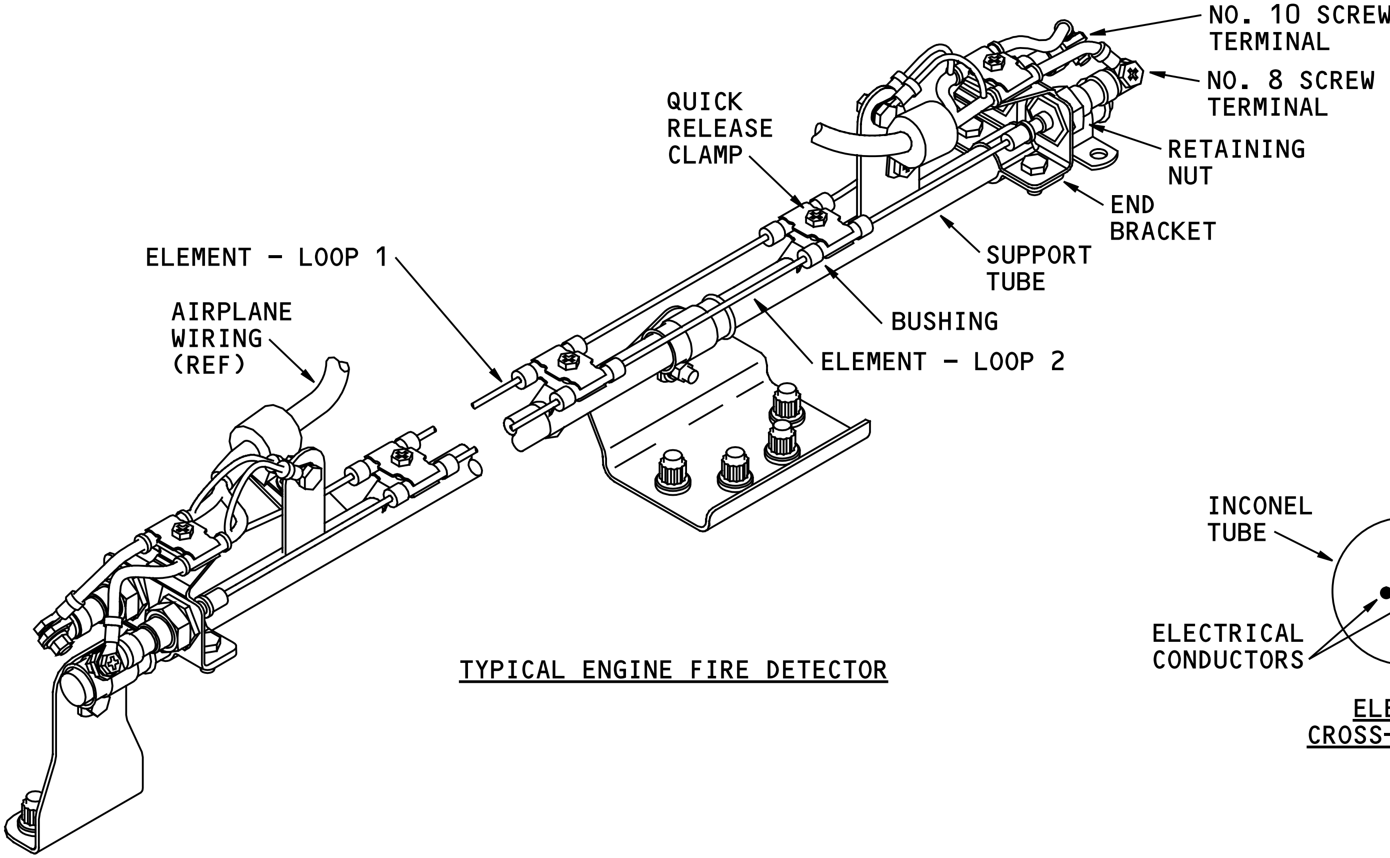
In addition to fire and overheat detection, the engine fire detectors continuously supply nacelle temperature data to the airplane condition monitoring function of the AIMS.

Training Information Point

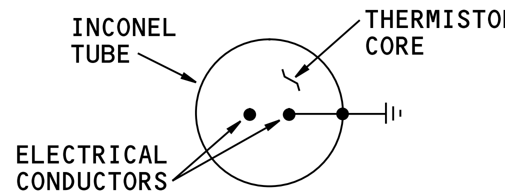
Each element uses a #10 screw wire-termination on one end and a #8 screw wire-termination on the other end. The elements are installed so each end of the detector has a #8 terminal and a #10 terminal. This prevents crossed wiring. The #10 terminal and the mating wire terminal have a black stripe around the insulation.

ENGINE FIRE DETECTION - ENGINE FIRE DETECTORS

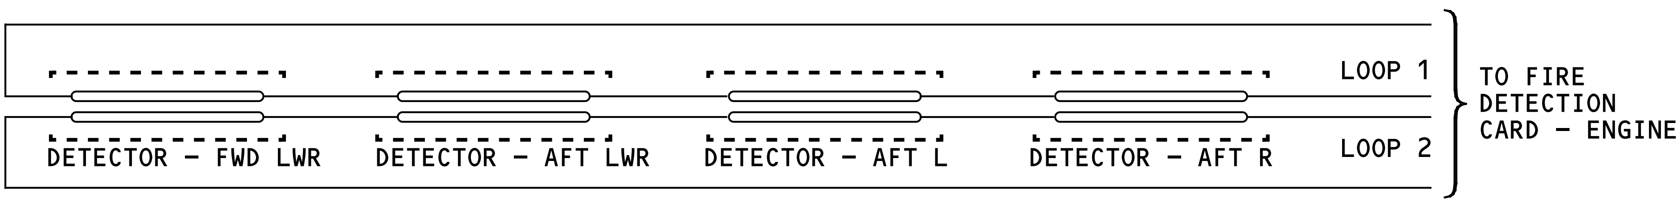
The ends of the element attach to the support tube bracket with retaining nuts. Quick-release clamps and bushings support the element along its length.



TYPICAL ENGINE FIRE DETECTOR



ELEMENT
CROSS-SECTION



ENGINE FIRE DETECTION LOOP CIRCUITS

26-11-00-005 Rev 3

ENGINE FIRE DETECTION - ENGINE FIRE DETECTORS

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE FIRE DETECTION - FIRE DETECTION CARDS

Purpose

The fire detection card has these purposes:

- Measures the nacelle temperature and sends it to the airplane condition monitoring system (ACMS)
- Monitors the fire detectors for a fire or overheat condition and supplies alarm signals
- Monitors the fire detectors for defects and sends fault data to AIMS
- Sets the logic (and/or logic) for the detector loops
- Does tests of the engine fire detection system.

Fire Detection Circuits

The fire detection circuits monitor the resistance of the fire detector element thermistor core. The resistance of the core is normally high. If the resistance goes low, the circuit supplies a FIRE output.

A short circuit in the loop also causes low resistance. The rate at which the resistance changes identifies an electrical short or a fire. A short circuit causes the resistance to decreases very quickly. A fire causes the resistance to decrease more slowly.

If the resistance decreases quickly, the circuit supplies a SHORT output for the life of the short circuit. If the short circuit stays for more than 0.2 seconds, the circuit supplies a DESELECT output. A deselect output also occurs if a power-up BIT finds an open circuit in the loop.

Program Logic Device

Output signals from the fire detection circuits go to the program logic device. The device normally causes dual-loop operation. Both Loop 1 and loop 2 must have a fire to cause fire alarms. If a detection circuit sends a FAULT signal, the logic device causes single-loop operation. A FAULT is a short, deselect, or power loss. The table shows alarm and fault conditions:

LOOP 1	LOOP 2	CARD OUTPUT
NORMAL	NORMAL	-
FIRE	NORMAL	FAULT (SEE TEXT)
FIRE	FIRE	ALARM
NORMAL	FIRE	FAULT (SEE TEXT)
FAULT	NORMAL	FAULT - LOOP 1
NORMAL	FAULT	FAULT - LOOP 2
FIRE	FAULT	ALARM
FAULT	FIRE	ALARM
FAULT	FAULT	FAULT - BOTH LOOPS

If one loop reports a fire and the other loop is normal, a 15 second timer starts. During this time, if the loop status changes from fire to normal, the timer stops. If the status of the normal loop changes to fire, the card sends a fire alarm.

ENGINE FIRE DETECTION - FIRE DETECTION CARDS

If neither loop changes status in 15 seconds, the card does a test of the normal loop. If the test fails, the card removes the selection of that loop and sends a fire alarm. If the test passes, the card removes the selection of the other loop and reports a fault.

Temperature Monitor Circuit

This circuit measures the average temperature of the fire detection loops. The ARINC 429 transmitter sends temperature data to AIMS.

The circuit also compares average temperature to an overheat set point kept in memory. If the temperature is more than the set point for 9.6 seconds, the temperature monitor circuit sends an overheat alarm through the ARINC 429 transmitter to AIMS.

Software in the temperature monitor circuit selects single or dual loop logic as applicable.

Built-In-Test Circuit

BIT continuously monitors the fire detection circuits. The ARINC 429 transmitter sends failure data to the AIMS as soon as BIT finds the condition.

BIT also does a test of the complete engine fire detection system at these times:

- At power-up
- After power interrupt
- Every five minutes of operation.

BIT signals a fire on both loops at the same time and does a check of the system. The ARINC 429 transmitter sends a fire alarm signal to AIMS. The CMCS uses this signal to make sure the fire detection system transmits ARINC data. Fire warnings do not occur during the tests.

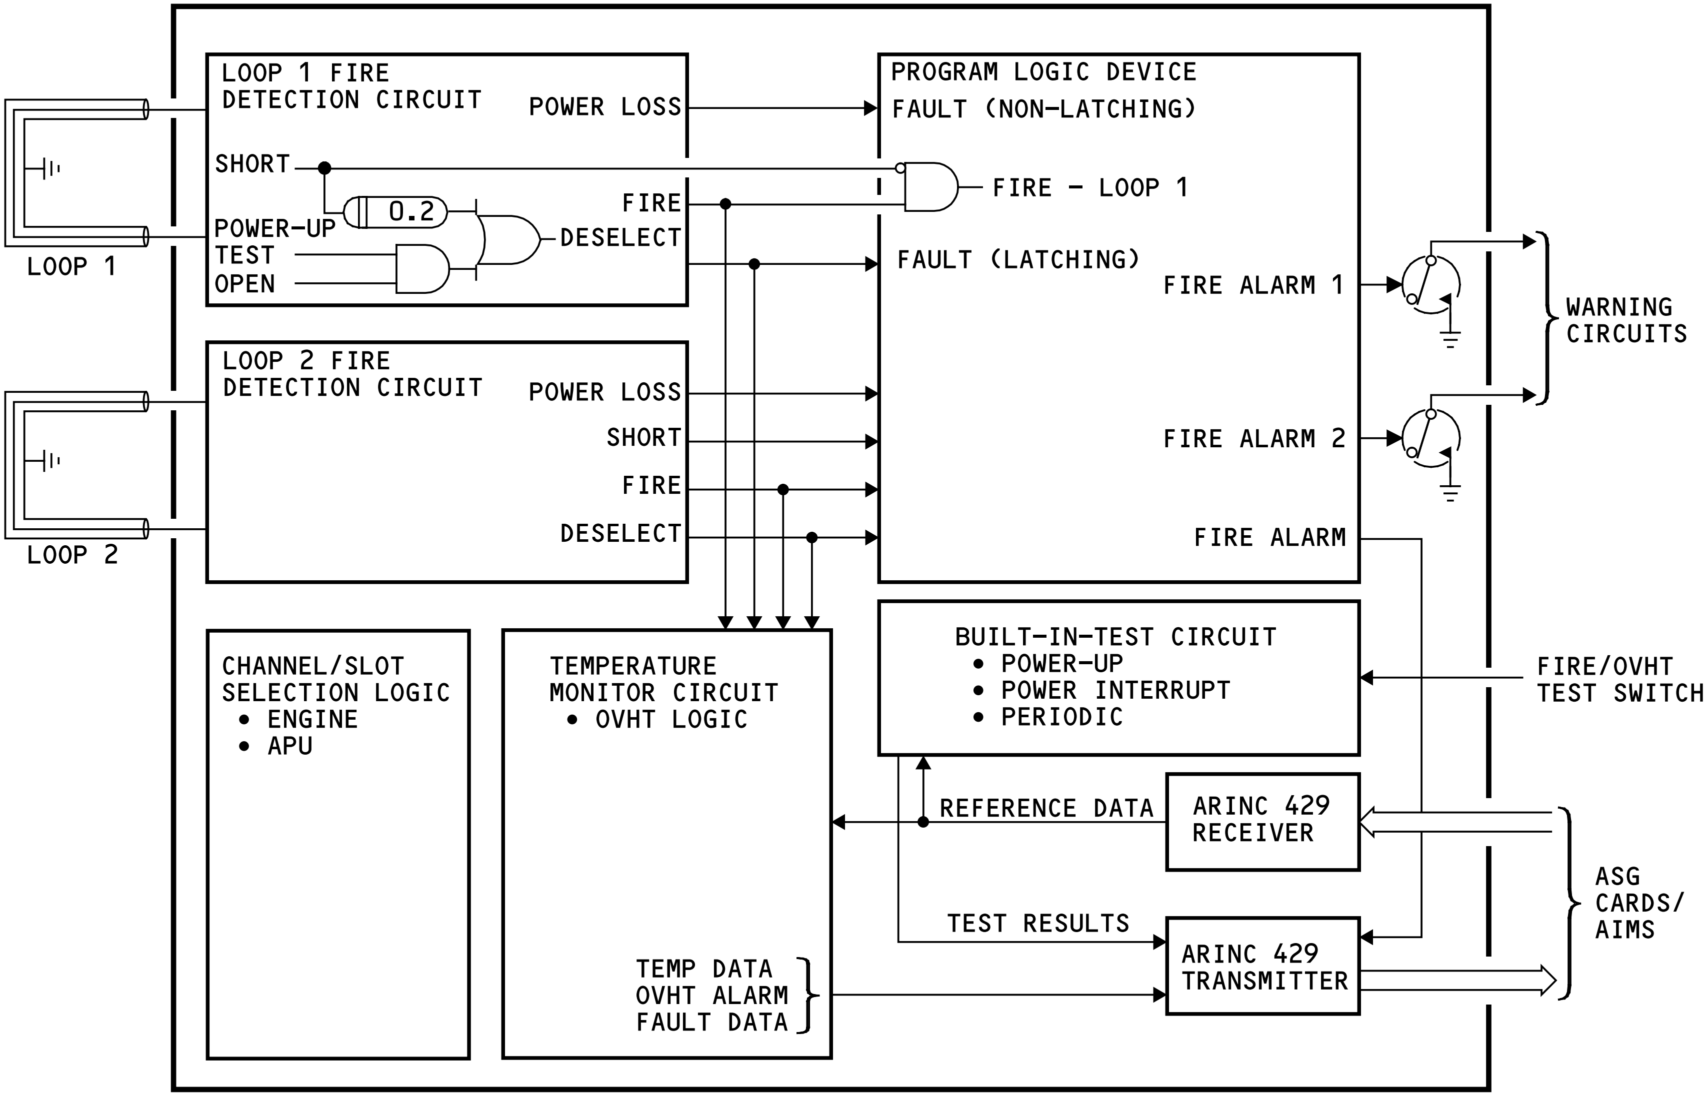
If there is a failure, the ARINC 429 transmitter sends fault data to the AIMS. The system changes to single loop operation if necessary.

The fire/ovht test switch in the flight deck starts a similar test. If there is a fault, the ARINC 429 transmitter sends fault data to the AIMS. Fire warnings occur during this test.

Training Information Point

The engine and APU fire detection cards function differently but are interchangeable. Program pins in the cardfile interface with the channel/slot selection logic circuit. That circuit tells the card whether to function as an APU fire detection card or as a left or right engine fire detection card.

The fire detection cards are electrostatic discharge sensitive (ESDS) devices. Be careful to obey the procedures in part II of the maintenance manual (Standard Practices - Airframe, Electrostatic Discharge Sensitive Devices - Maintenance Practices) before you touch the cards.



26-11-00-006 Rev 1

ENGINE FIRE DETECTION - FIRE DETECTION CARDS

ENGINE FIRE DETECTION - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE FIRE DETECTION - FUNCTIONAL DESCRIPTION

Fire Detection

If there is a fire in an engine nacelle, the fire detection card supplies three fire alarm outputs. Alarm 1 supplies a ground for these components:

- The fire switch unlocking solenoid
- The engine fire warning lights
- The fuel control switch fire warning light.

Alarm 2 supplies a signal to AIMS and to the warning electronics unit. An EICAS warning message shows. The master warning lights and fire warning aural come on.

A third fire alarm output goes to the AIMS through the ASG (ARINC signal gateway) cards. The CMCS uses this signal to make sure the engine fire detection system transmits ARINC data.

The indications go away when the fire is out.

Overheat Detection

If the fire detection loops find an overheat condition, the fire detection card sends a signal to AIMS through the ASG cards. An EICAS caution message shows. The master caution light and caution aural come on. When the overheat condition is gone, the indications go away.

Nacelle Temperature Recording

The fire detection card measures the average temperature of the engine fire detectors. This data is sent to AIMS through the ASG cards. The ACMF (airplane condition monitoring function) of the AIMS puts this data in memory.

Single/Dual Loop Operation

The fire detection card monitors the loops for faults. In normal (dual loop) operation, both loops must have a fire or overheat condition to cause the flight deck indications.

If one detection loop fails, the card sends data about the failure to the AIMS. A status message shows. The card changes to single loop operation if necessary.

If both detection loops fail, an advisory message and status messages show. The fire detection system does not operate.

BITE

BITE does a test of the engine fire detection system for these conditions:

- When the system first gets power
- After a power interrupt
- Every 5 minutes of operation.

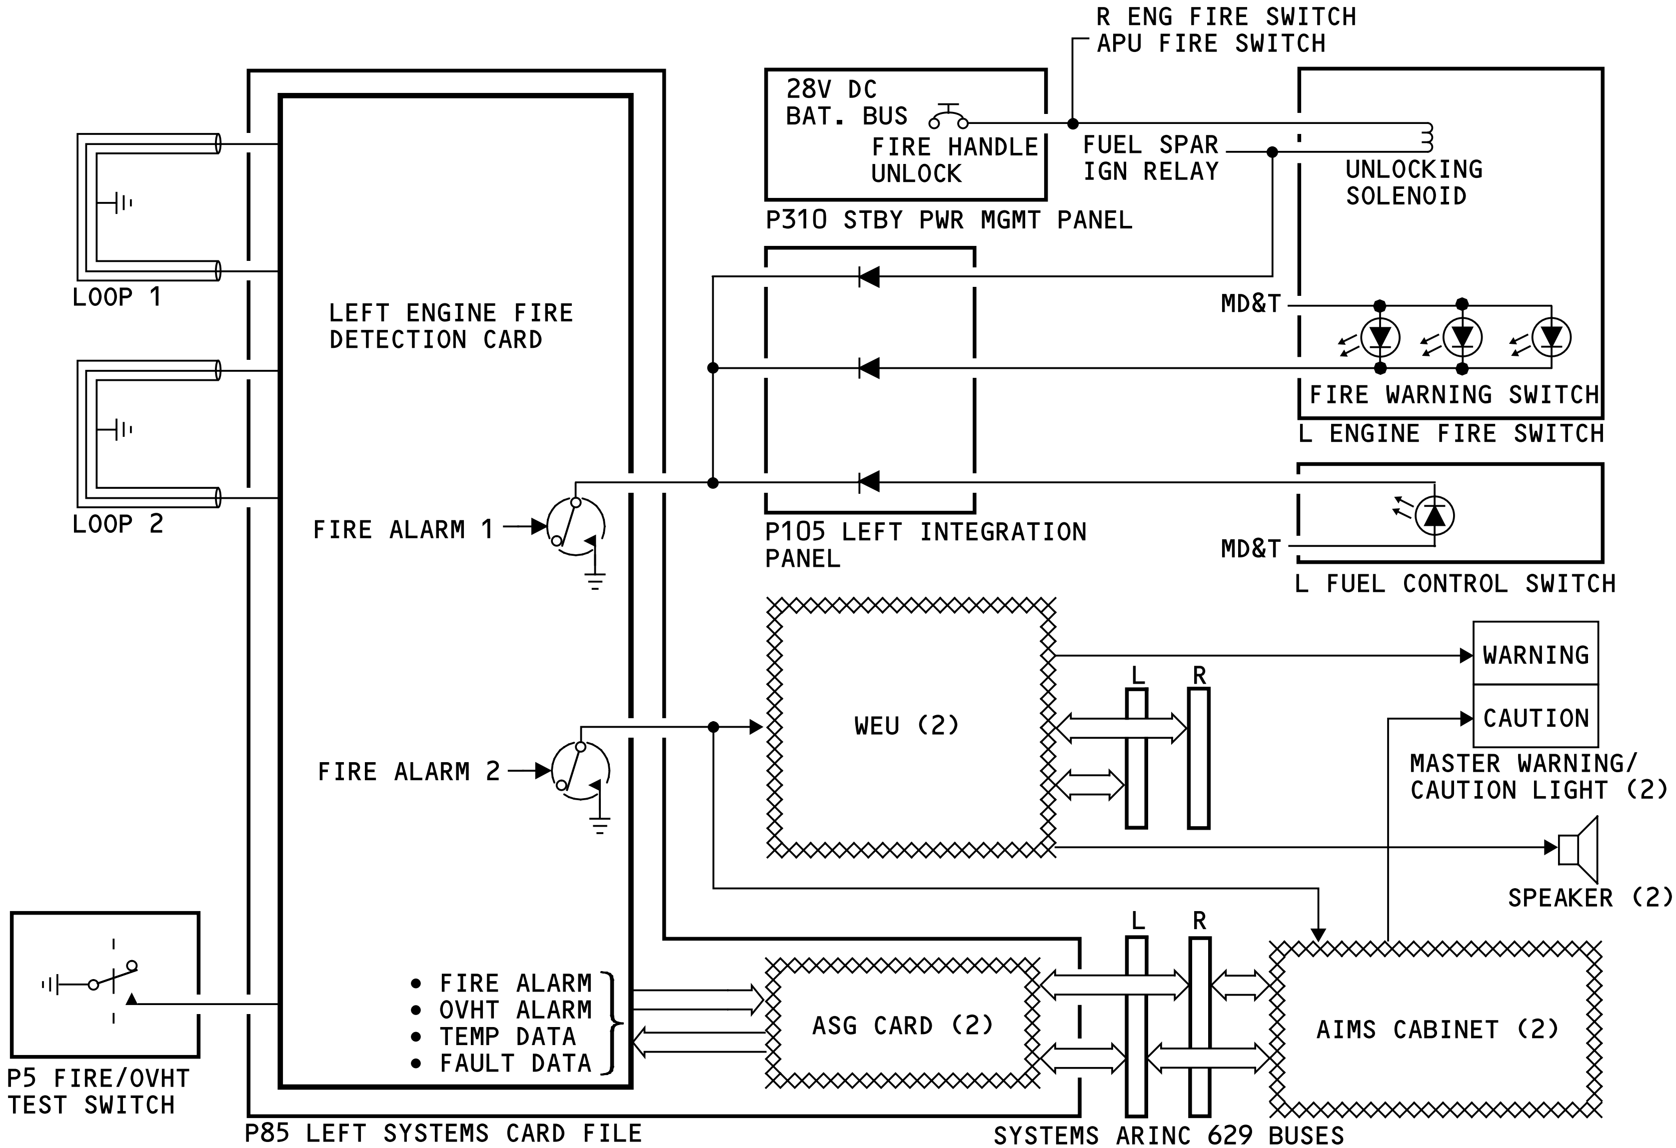
ENGINE FIRE DETECTION - FUNCTIONAL DESCRIPTION

BIT data goes to the AIMS. If the system has a malfunction, the primary display system shows advisory or status messages. The MAT shows maintenance messages.

If a loop opens after the power-up BIT, the system stays in the dual-loop mode until you apply electrical power again. A loop which is open in only one place still operates. If the power-up BIT finds an open loop, the system changes to single-loop operation. Both ends of the loop are possibly disconnected.

After you do maintenance, use the FIRE/OVHT TEST switch to make sure the system operates correctly.

You can use the MAT to see the nacelle temperature data kept in memory by the ACMF.



ENGINE FIRE DETECTION - FUNCTIONAL DESCRIPTION

ENGINE FIRE DETECTION - INDICATIONS

Overheat Indication

If an engine has an overheat condition, these indications occur in the flight deck:

- The master caution lights come on
- The caution aural operates
- An engine overheat caution message shows.

Fire Indication

If an engine has a fire, these indications occur in the flight deck:

- The master warning lights come on
- The fire warning aural operates
- An engine fire warning message shows
- The engine fire warning light comes on
- The fuel control switch fire warning light comes on.

Failure Indications

If continuous fault monitoring or built-in-test finds a fault, indications show in the flight deck.

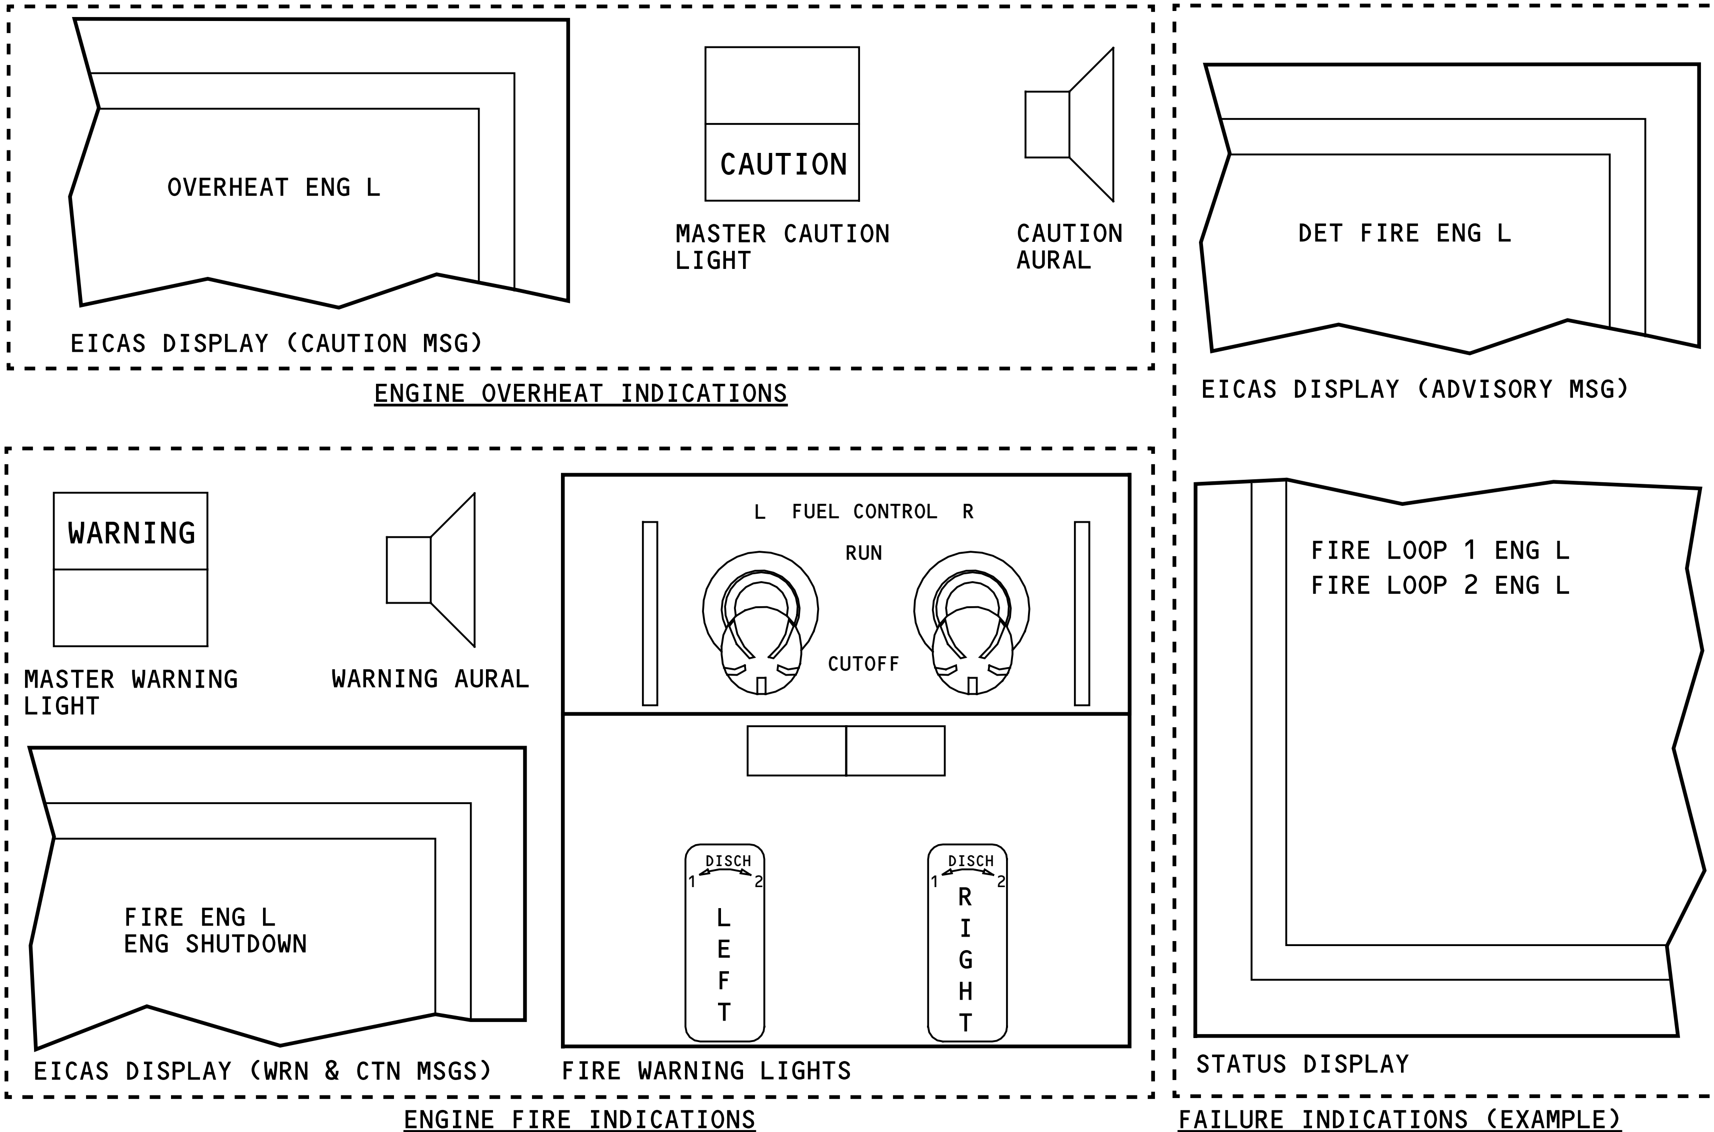
Dual loop failures in the engine fire detection system cause advisory messages and status messages. The engine fire detection system does not operate.

Single loop failures in the engine fire detection system cause status messages. The engine fire detection system still operates.

Failures in the temperature monitor function cause a status message.

Training Information Point

Maintenance messages, that you get from the maintenance access terminal, generally give more details about the failure condition. For example, if a loop fails, the maintenance message tells you that the loop is open or shorted or connected incorrectly. If the loop is shorted, the maintenance message tells which detector element or wiring segment has the short.



ENGINE FIRE DETECTION - INDICATIONS

ENGINE TURBINE OVERHEAT DETECTION - INTRODUCTION

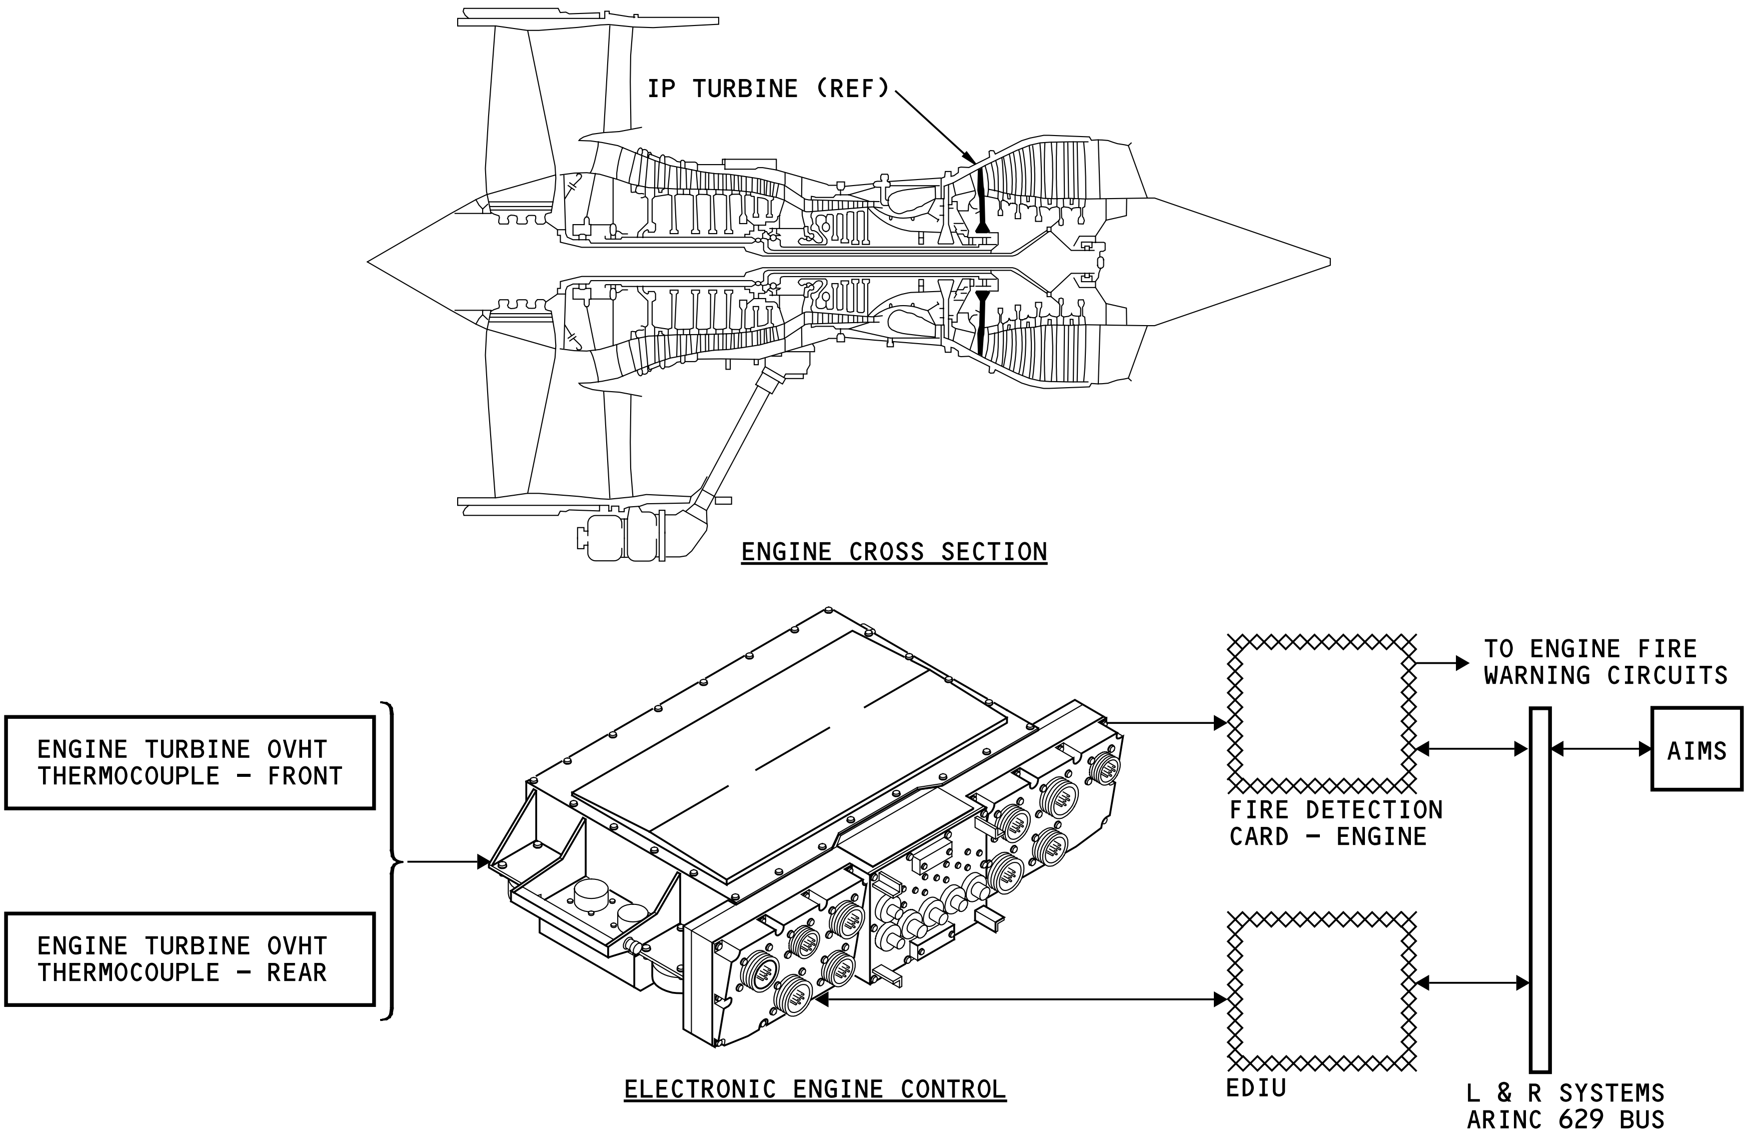
Purpose

The engine turbine overheat detection system monitors the temperature of the cooling air at the front and rear of the IP turbine. Engine fire warnings occur in the flight deck if the front or rear temperature is more than limits.

General Description

Two thermocouples give IP cooling air temperature information to the electronic engine control (EEC). The EEC makes an analysis of the temperature information. If the EEC finds an overheat condition, it sends a signal to the engine fire detection card. The fire detection card turns on the engine fire warning indications in the flight deck.

BITE does a check of the condition of the system. Status and maintenance messages give information about system failures. The fire detection card monitors its interface with the EEC for failures and sends information about the failure to the AIMS. The EEC monitors the thermocouple circuits for failures. The EEC sends information about the failure through the engine data interface unit (EDIU) to the AIMS. The FIRE/OVHT TEST switch in the flight deck does not do a test of this system.



ENGINE TURBINE OVERHEAT DETECTION - INTRODUCTION

ENGINE TURBINE OVERHEAT DETECTION - ENGINE TURBINE OVERHEAT THERMOCOUPLES

Purpose

The engine turbine overheat thermocouples monitor the temperature of engine cooling air at the front and rear of the IP turbine.

Physical Description

Each thermocouple has a probe that fits through an opening in the IP turbine case. Each probe contains two elements: loop 1 and loop 2. The thermocouples have four electrical connections. Two connections are for loop 1 and the other two connections are for loop 2.

Location

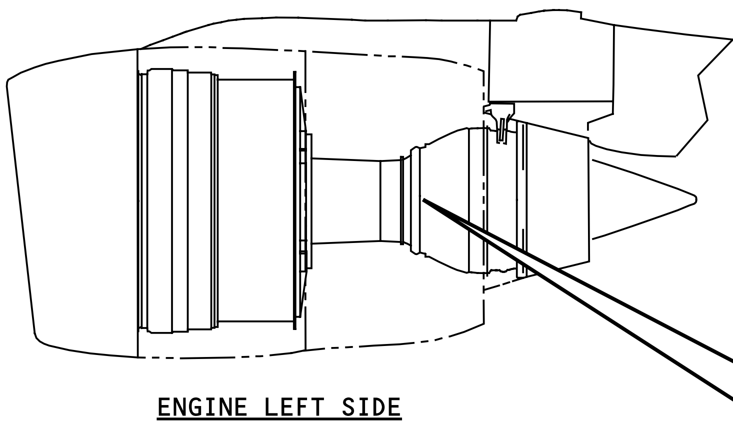
The front and rear thermocouples are on the left side of the engine IP turbine case. Open the thrust reverser to get access to the thermocouples.

Functional Description

The front thermocouple monitors the engine cooling air in front of the IP turbine. The air that flows over the front thermocouple bleeds overboard.

The rear thermocouple monitors the engine cooling air temperature behind the IP turbine. The air that flows over the rear thermocouple goes back into the engine gas path through holes in the LP1 nozzle guide vane.

The electrical signal output from each thermocouple loop is in proportion to the cooling air temperature.



ENGINE LEFT SIDE

ENGINE TURBINE OVERHEAT DETECTION - ENGINE TURBINE OVERHEAT THERMOCOUPLES

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE TURBINE OVERHEAT DETECTION - FUNCTIONAL DESCRIPTION

General

Each thermocouple loop gives an input signal to the EEC. The fire detection card monitors the EEC turbine overheat interface circuit.

An overheat condition causes fire alarm 1 and fire alarm 2 outputs from the fire detection card. These outputs cause fire warning indications in the flight deck. See section 26-11 for more information about the engine fire detection system and fire indications.

EEC Overheat Logic

The EEC gives an overheat signal if these conditions occur for the front or the rear thermocouple:

- BIT finds no loop failures
- Loop 1 and loop 2 have an overheat condition

With a single loop failure in a thermocouple, the EEC gives an overheat signal if the serviceable loop has an overheat condition.

Fire Detection Card Interface

The fire detection card continuously monitors the resistance of the circuit from the fire detection card through the EEC. If the EEC finds an overheat condition, the two switches in the EEC close and connect the two resistors in parallel. This amount of resistance in the circuit causes the fire detection card to send the fire alarm signals.

BITE

The status message DET TURB OVHT ENG L(R) shows a failure of the turbine overheat detection system. The status message TURB OVHT SNSR ENG L(R) shows a single loop fault in the system.

The EEC monitors the thermocouple loops. If the EEC finds a failure, it sends information about the failure to the AIMS through the EDIU. A failure in one thermocouple loop causes the single loop fault status message. A failure in both front or both rear thermocouple loops causes the system failure status message to show.

The fire detection card monitors the circuit from the fire detection card through the EEC. If the resistance is less than the value of the two EEC resistors in parallel, the circuit has a short. Information about the short goes to AIMS through the ASG cards.

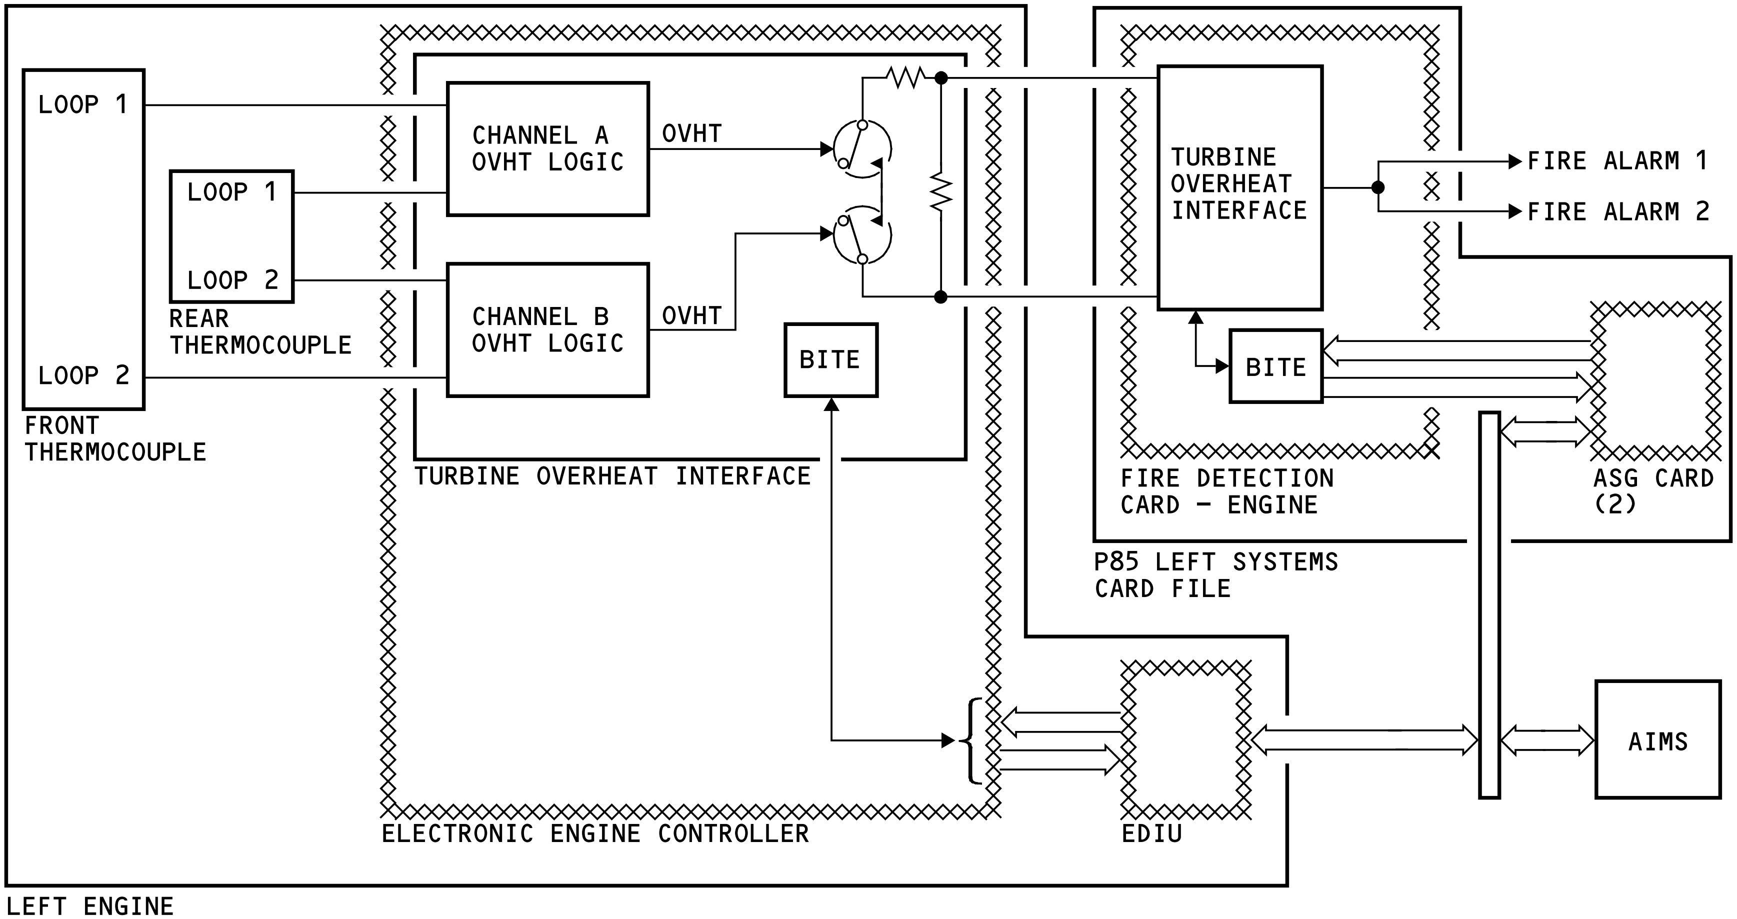
The fire detection card also does a check of the circuit through the EEC for an open condition. The open circuit check is not continuous, but is part of the power-up and periodic BIT.

A short or open in the circuit from the fire detection card through the EEC causes the system failure status message to show.

ENGINE TURBINE OVERHEAT DETECTION - FUNCTIONAL DESCRIPTION

Training Information Point

The fire/overheat test switch in the flight deck does not do a test of the engine turbine overheat detection system.



NOTE: LEFT ENGINE SYSTEM IS SHOWN.
RIGHT ENGINE SYSTEM IS SIMILAR.

ENGINE TURBINE OVERHEAT DETECTION - FUNCTIONAL DESCRIPTION

ENGINE FIRE EXTINGUISHING - INTRODUCTION

Purpose

The engine fire extinguishing system extinguishes fires in the engine nacelles.

General Description

The two fire extinguishing bottles contain halon fire extinguishing agent pressurized with nitrogen. You use the engine fire switches in the flight deck to release the halon. Halon from each bottle can go to the right or left engine. EICAS messages, status messages, and indicator lights show when the bottle pressure is low.

THIS PAGE INTENTIONALLY LEFT BLANK

ENGINE FIRE EXTINGUISHING - ENGINE FIRE EXTINGUISHING BOTTLES

Purpose

The engine fire extinguishing bottles contain the fire extinguishing agent.

Location

The two fire extinguishing bottles are outboard of the right sidewall lining of the forward cargo compartment. The access panel is identified ENGINE FIRE EXTINGUISHER ACCESS PANEL.

Physical Description

The two engine fire extinguishing bottles are identical. Each bottle has these components:

- A safety relief and fill port
- A handle for removal and installation
- A pressure switch
- Two discharge assemblies
- An identification plate
- Four mounting lugs.

The engine fire extinguishing bottles are interchangeable with the APU fire extinguishing bottle.

Functional Description

The bottles contain halon fire extinguishing agent pressurized with nitrogen. If the pressure in the bottle becomes too high, the safety relief and fill port opens so the bottle does not explode. The discharge assembly has an explosive squib. An electric current from the fire extinguishing circuit fires the squib. This releases the halon through the discharge port.

The pressure switch gives flight deck indications when bottle pressure decreases. The switch monitors the pressure inside the bottle and is normally open. When the pressure decreases because of a leak or because of bottle discharge, the switch closes an indicating circuit.

Training Information Point

A special service platform is available which makes bottle replacement easier.

When you replace bottles, handle them carefully to prevent damage. Compare the weight of the new bottle with the weight on the identification plate. This prevents installation of a bottle which is not full.

The discharge ports for the left and right engines are different sizes. This prevents crossed connections. Install the bottle with the identification plate inboard.

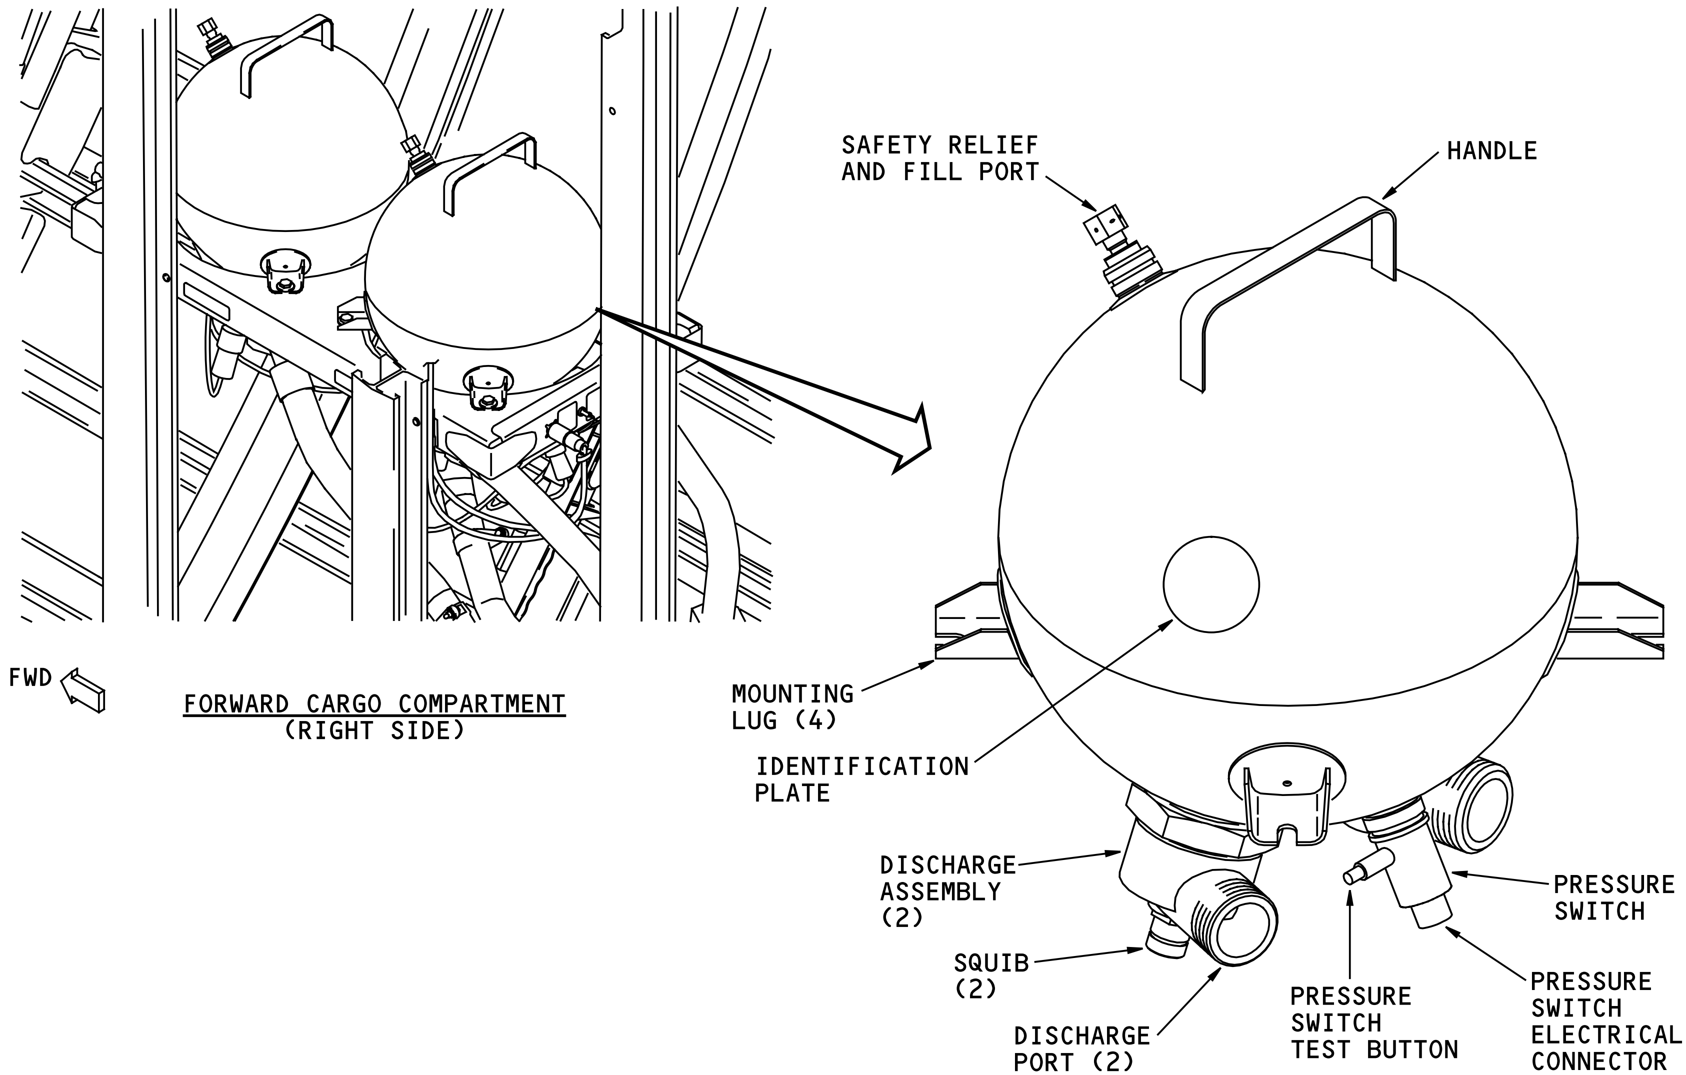
The fire extinguishing bottles must have a hydrostatic test every 5 years. The date of the last test is stamped on one of the mounting lugs and on an inspection tag. The tag is attached to one of the discharge assemblies.

ENGINE FIRE EXTINGUISHING - ENGINE FIRE EXTINGUISHING BOTTLES

WARNING: BE CAREFUL WHEN YOU MOVE THE FIRE EXTINGUISHING BOTTLE. THE FIRE EXTINGUISHING BOTTLE IS HIGHLY PRESSURIZED AND HAS AN EXPLOSIVE CARTRIDGE AS A COMPONENT. ACCIDENTAL DISCHARGE OF THE FIRE EXTINGUISHING BOTTLE CAN CAUSE INJURY TO PERSONS OR DAMAGE TO EQUIPMENT.

WARNING: DO NOT TOUCH THE SQUIB BEFORE YOU DO THE PROCEDURES FOR DEVICES THAT ARE SENSITIVE TO ELECTROSTATIC DISCHARGE. ELECTROSTATIC DISCHARGE CAN CAUSE THE FIRE BOTTLE TO RELEASE ITS CONTENTS SUDDENLY AND CAUSE INJURY TO PERSONS AND DAMAGE TO EQUIPMENT.

WARNING: PUT A PROTECTIVE COVER ON THE SQUIB. IF YOU DO NOT PUT A PROTECTIVE COVER ON THE SQUIB, THE FIRE EXTINGUISHING BOTTLE CAN RELEASE ITS CONTENTS SUDDENLY AND CAUSE INJURY TO PERSONS.



26-21-00-003 Rev 6 07/10/1997

ENGINE FIRE EXTINGUISHING - ENGINE FIRE EXTINGUISHING BOTTLES

ENGINE FIRE EXTINGUISHING - ENGINE FIRE BOTTLE SQUIB

Purpose

The squib releases the halon from the engine fire extinguishing bottle.

Location

The squib is in the discharge assembly at the bottom of the fire bottle. A fire bottle has two squibs, one for each engine.

Physical Description

The squib is an electrically operated explosive device. It is adjacent to a bottle diaphragm that can break. The diaphragm normally seals the pressurized bottle.

Functional Description

The squib fires when you put the fire switch to the DISCH 1 or DISCH 2 position. The explosion opens the diaphragm. Nitrogen pressure inside the bottle pushes the halon through the discharge port.

Training Information Point

The ELMS does an automatic squib test for these conditions:

- When ELMS first gets power
- At engine shutdown with the airplane on the ground.

You can also use the maintenance access terminal (MAT) to do a squib test. See the fire protection section for more information about the squib tests (AMM PART I 26-00).

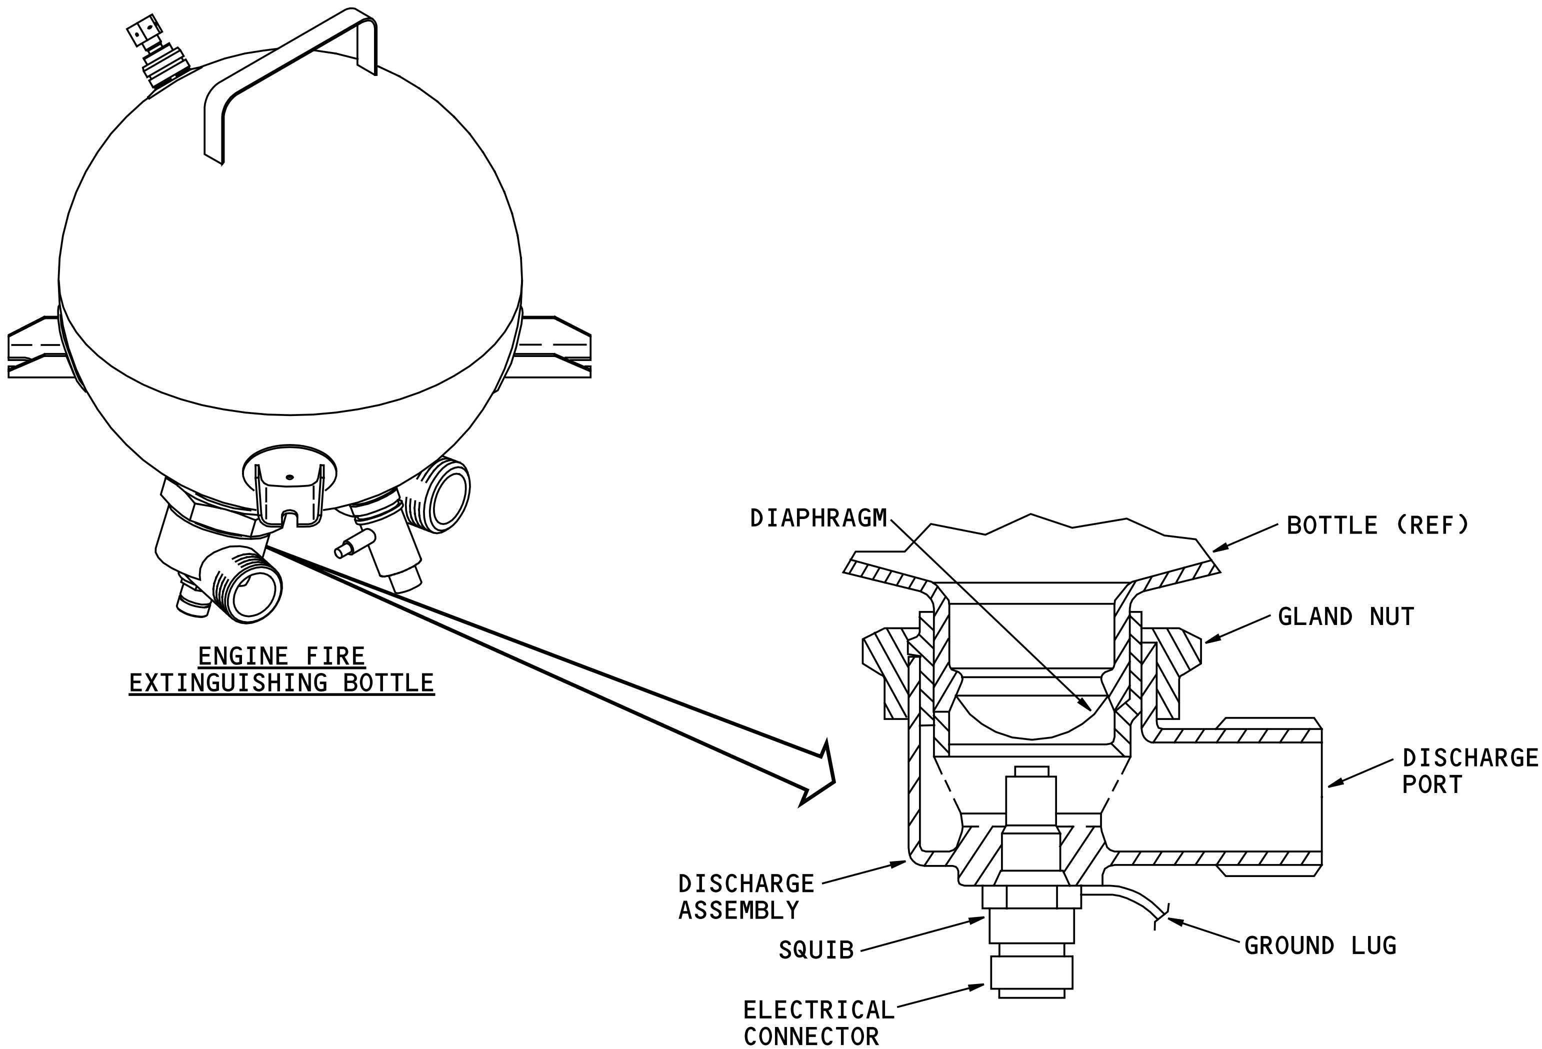
You must replace The squib every 10 years. The service date is on one of the squib wrench flats. You can replace the squib without removing the fire extinguishing bottle.

WARNING: MAKE SURE THERE IS NO VOLTAGE AT THE ELECTRICAL CONNECTOR. IF THERE IS A VOLTAGE AT THE ELECTRICAL CONNECTOR, THE SQUIB CAN ACCIDENTALLY FIRE AND CAUSE THE FIRE EXTINGUISHING BOTTLE TO RELEASE ITS CONTENTS. ACCIDENTAL DISCHARGE OF THE FIRE EXTINGUISHING BOTTLE CAN CAUSE INJURY TO PERSONS OR DAMAGE TO EQUIPMENT.

WARNING: PUT A PROTECTIVE COVER ON THE SQUIB. IF YOU DO NOT PUT A PROTECTIVE COVER ON THE SQUIB, THE FIRE EXTINGUISHING BOTTLE CAN RELEASE ITS CONTENTS SUDDENLY AND CAUSE INJURY TO PERSONS.

CAUTION: DO NOT PUT A SHUNT PLUG ON THE SQUIB. THE SHUNT PLUG CAN CAUSE DAMAGE TO THE SQUIB PINS.

The electrical connectors and the discharge assembly interface threads are different sizes for the left and right engine squibs. This prevents incorrect connection.



ENGINE FIRE EXTINGUISHING - ENGINE FIRE BOTTLE SQUIB

ENGINE FIRE EXTINGUISHING - ENGINE FIRE PANEL

Purpose

The engine fire panel keeps the engine fire switches and engine fire bottle discharge lights together and in easy reach of the flight crew.

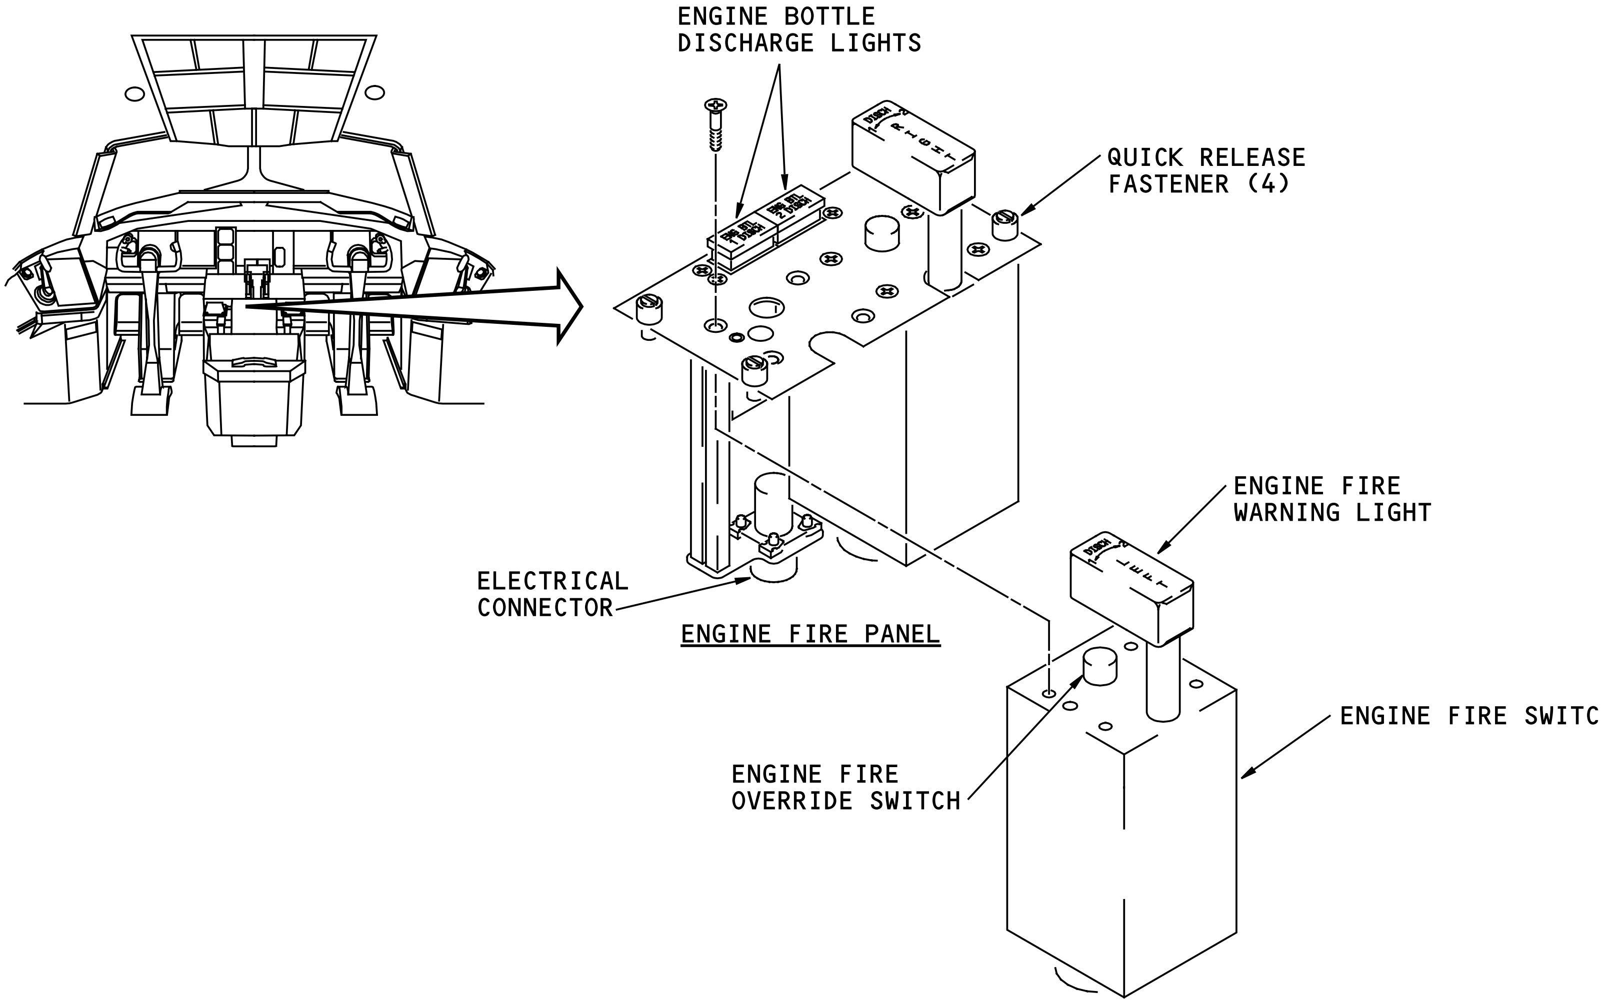
Location

The engine fire panel is in the flight deck on the P8 aisle stand.

Physical Description

The engine fire panel has a fire switch for each engine and a discharge light for each fire bottle.

Quick release fasteners attach the panel to the aisle stand structure. Electrical connectors connect the airplane wires to the panel.



ENGINE FIRE EXTINGUISHING - ENGINE FIRE PANEL

ENGINE FIRE EXTINGUISHING - ENGINE FIRE SWITCH

Purpose

The engine fire switch does four things:

- Gives an indication of an engine fire
- Stops the engine
- Isolates the engine from the airplane systems
- Controls the engine fire extinguishing system.

Physical Description

The engine fire switch includes these parts:

- Engine fire warning light
- Solenoid
- Engine fire override switch
- Push-pull switch contacts (internal)
- Rotary switch contacts (internal)
- Electrical connector.

Functional Description

The solenoid locks the fire switch so you cannot pull it accidently. If an engine has a fire, the fire warning light comes on and the solenoid energizes to release the switch.

The fire override switch lets you pull the fire switch when the solenoid is not energized.

When you pull the fire switch, the push-pull switch contacts operate electrical circuits which stop the engine and isolate it from the airplane systems.

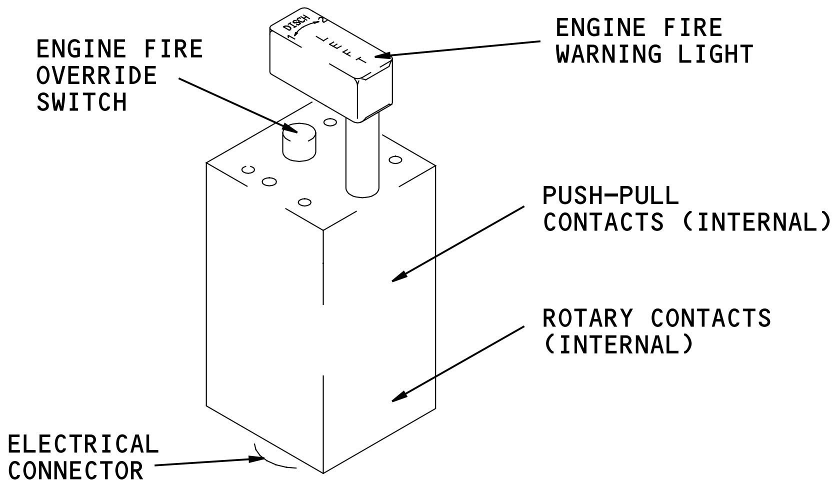
With the switch pulled, you can rotate it left or right to a mechanical stop at the discharge position. The rotary switch contacts close and operate the fire extinguishing system.

When you release the switch, a spring moves the switch a small distance from the discharge position to open the rotary switch contacts.

You must put the switch back to the center position before you can push the switch in.

Training Information Point

The left and right engine and APU fire switches are not interchangeable. The fire warning light labels and the electrical connectors are different. The engine fire switches have a hole that engages a peg in the control panel. The hole position is different in the left and right switches.



ENGINE FIRE SWITCH (P8)

ENGINE FIRE EXTINGUISHING - FUNCTIONAL DESCRIPTION - BOTTLE DISCHARGE

General

Each bottle has two discharge assemblies. The discharge assemblies connect the bottles to the discharge manifolds. One manifold goes to discharge nozzles in the left engine nacelle. The other manifold goes to discharge nozzles in the right engine nacelle.

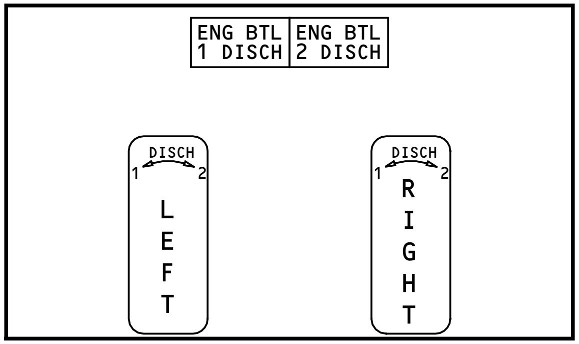
Functional Description

Explosive squibs inside the discharge assemblies connect to the fire switches in the flight deck. Squibs for the left engine connect to the left switch; squibs for the right engine connect to the right switch. A squib for bottle 1 fires when you put the related fire switch to DISCH 1. A squib for bottle 2 fires when you put the related switch to DISCH 2. When a squib fires, the bottle releases the halon into the engine nacelle.

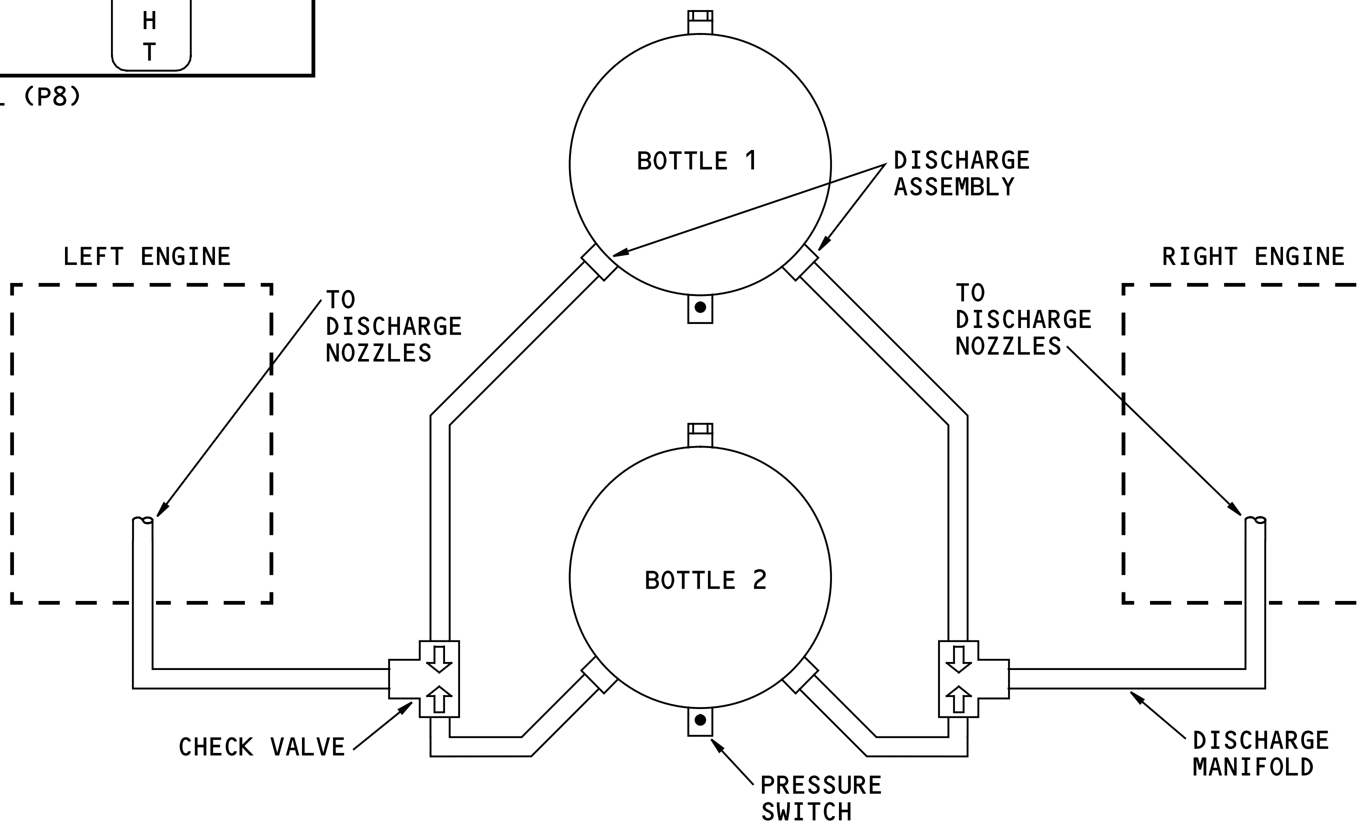
A pressure switch monitors the pressure in each bottle. The switch turns on the discharge indicator light when the bottle pressure decreases. The switch also causes advisory and status messages to show.

Training Information Point

Rigid tubing connects the bottles to the check valves. The diameter of the tubing is different for the left and right engines. This prevents incorrect connection.



ENGINE FIRE PANEL (P8)



ENGINE FIRE EXTINGUISHING - FUNCTIONAL DESCRIPTION - BOTTLE DISCHARGE

ENGINE FIRE EXTINGUISHING - ENGINE FIRE SWITCH CIRCUIT - FUNCTIONAL DESCRIPTION

General

The engine fire switch includes a solenoid, fire warning lights, and two sets of electrical contacts. One set of contacts controls engine functions. The other set of contacts controls the engine fire extinguishing system.

Solenoid and Warning Light Operation

The solenoid energizes if an engine has a fire. This releases the fire switch so you can pull it. The engine fire warning lights come on to help you identify the correct switch to use.

The same condition normally occurs in both engine fire switches while you do a fire/overheat test.

The solenoid also energizes when the battery switch is ON and the fuel control switch is in CUTOFF.

You can override the solenoid with the engine fire override switch.

Out Position

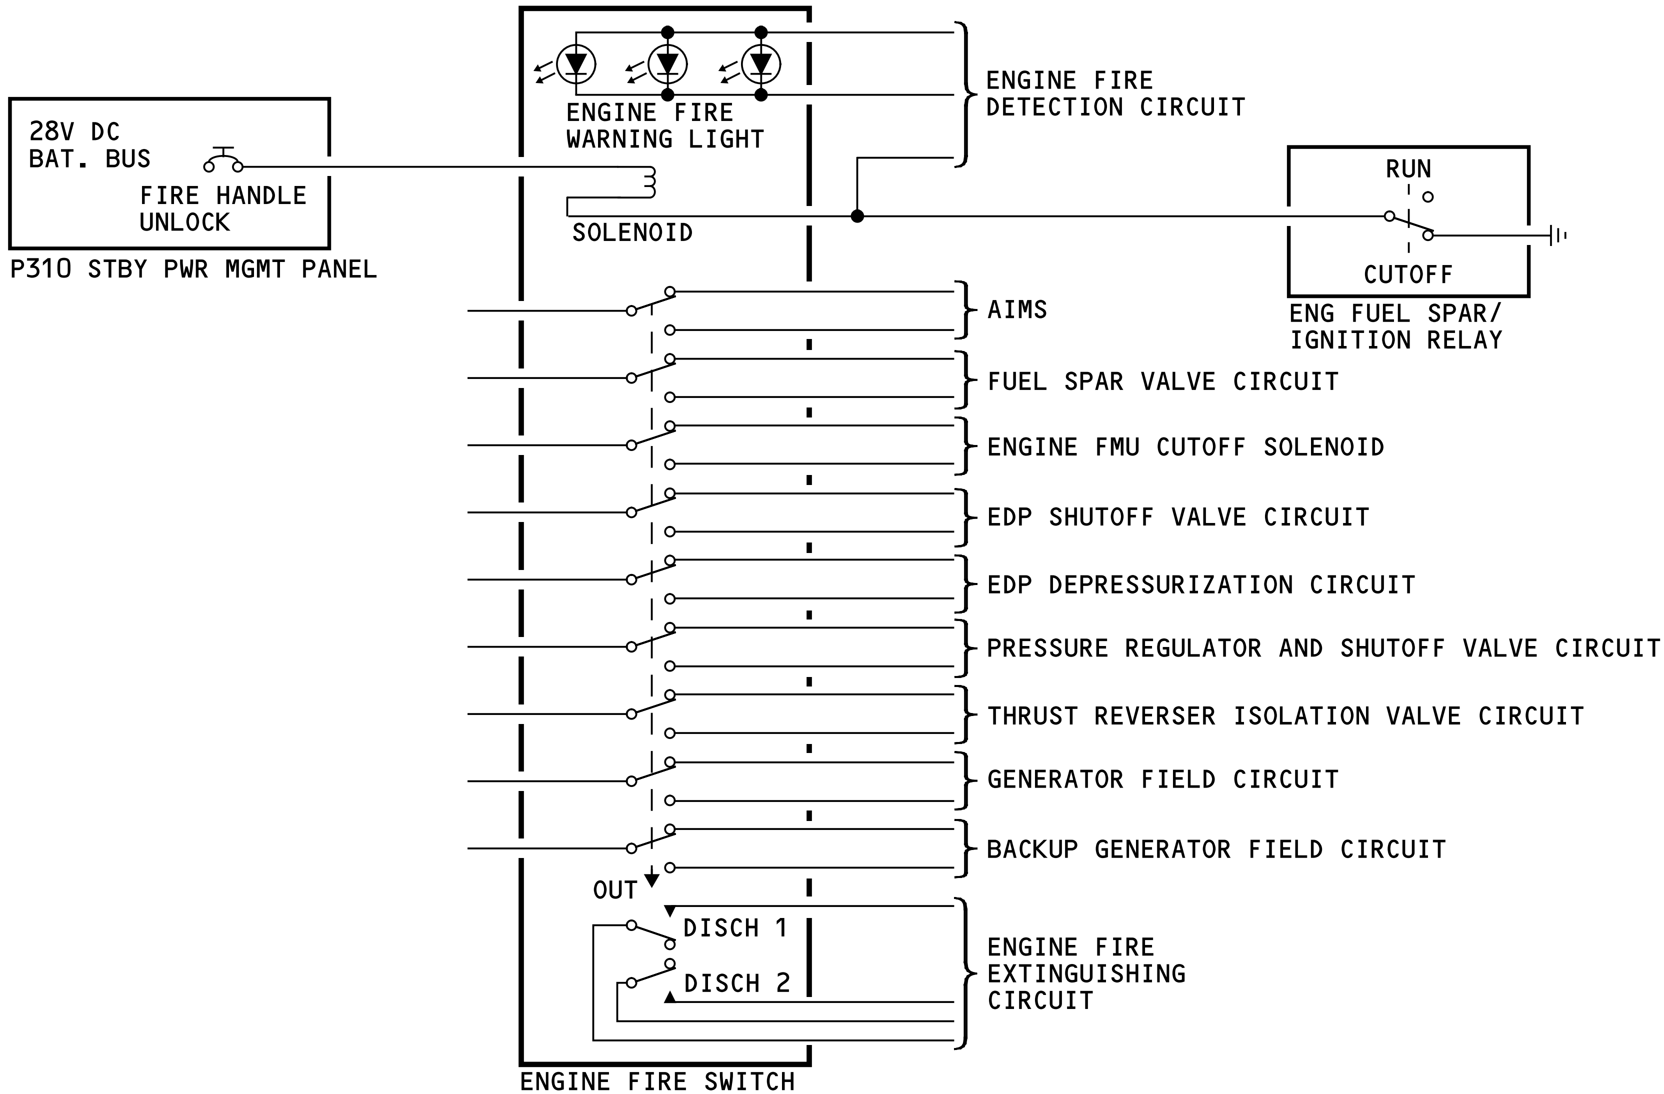
When you pull the fire switch, this is how the switch isolates the engine:

- Closes the fuel spar valve
- De-energizes the engine fuel metering unit (FMU) cutoff solenoid
- Closes the engine hydraulic pump shutoff valve
- Depressurizes the engine driven hydraulic pump valve
- Closes the pressure regulator and shutoff valve
- Removes power from thrust reverser isolation valve
- Trips the generator field
- Trips the backup generator field.

A signal to the AIMS cancels messages related to these isolation functions.

Discharge Positions

The DISCH 1 position fires the squib for bottle 1. The DISCH 2 position fires the squib for bottle 2.



26-21-00-008 Rev 2 09/08/1997

ENGINE FIRE EXTINGUISHING - ENGINE FIRE SWITCH CIRCUIT - FUNCTIONAL DESCRIPTION

Bottle Discharge

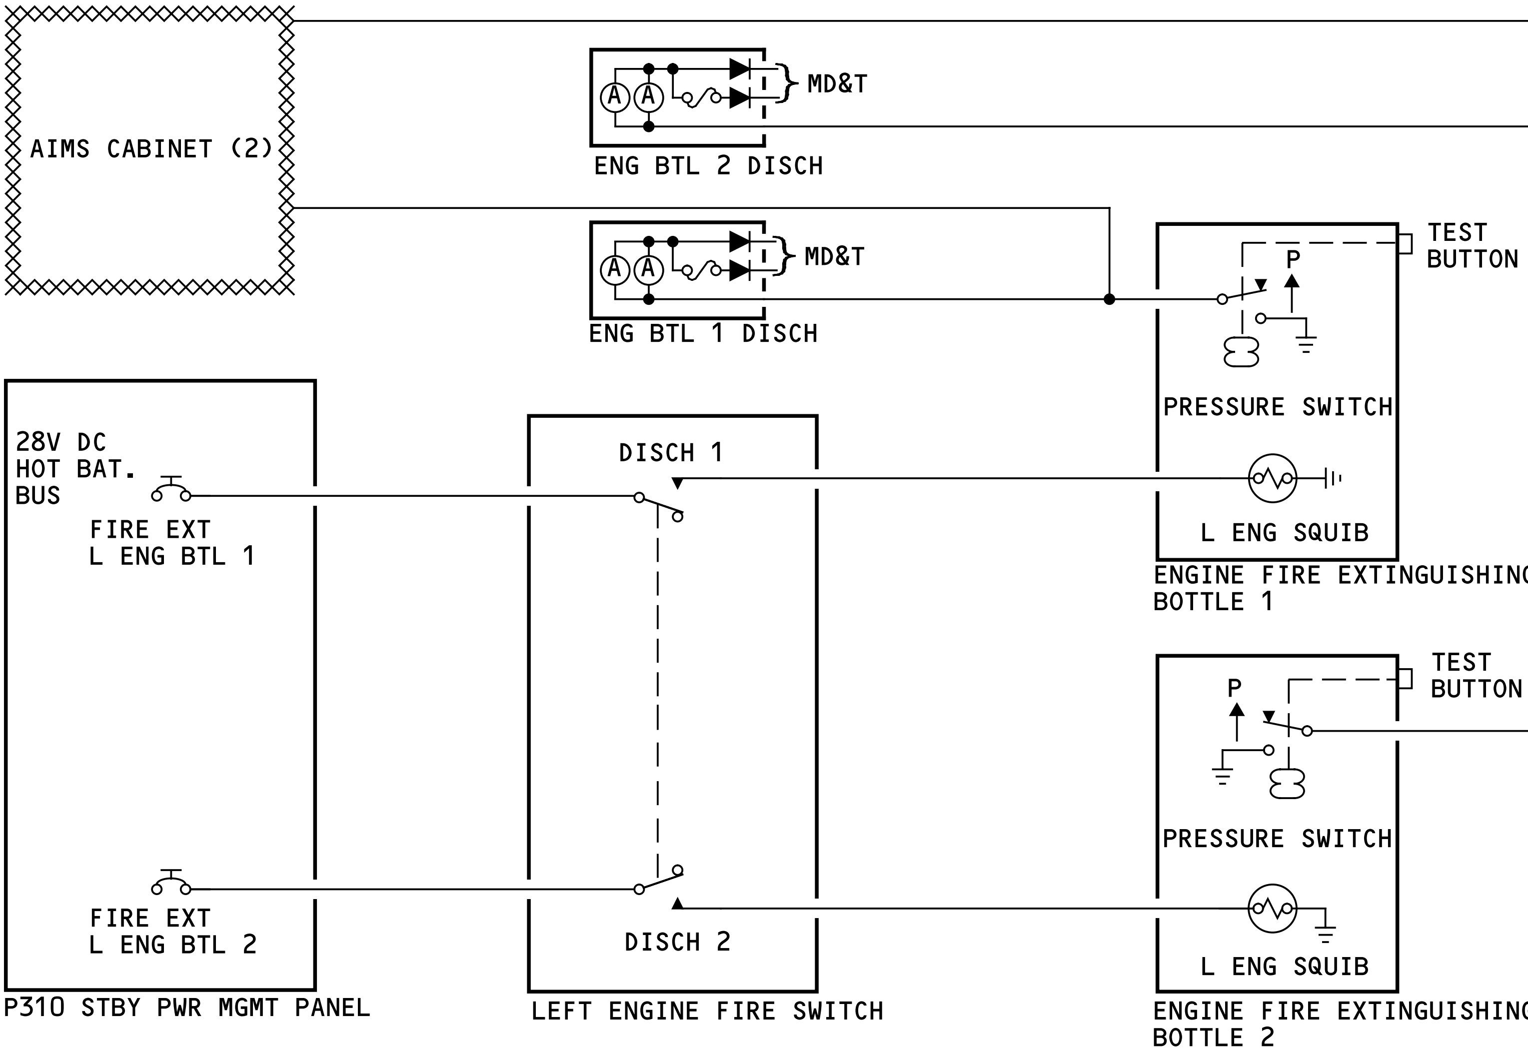
The engine fire switch supplies power from the hot battery bus to the engine fire extinguishing bottle squibs. The DISCH 1 position fires the squib for bottle 1. The DISCH 2 position fires the squib for bottle 2.

Discharge Indication

When pressure inside the bottle decreases, the pressure switch closes and makes a ground for the discharge indicator light. The ground also causes AIMS to show advisory and status messages.

Training Information Point

You can do a check of the pressure switch circuit on the ground. Push and hold the test button to close the switch. The bottle discharge light in the flight deck should come on. Bottle discharge advisory and status messages should show.



26-21-00-009 Rev 0

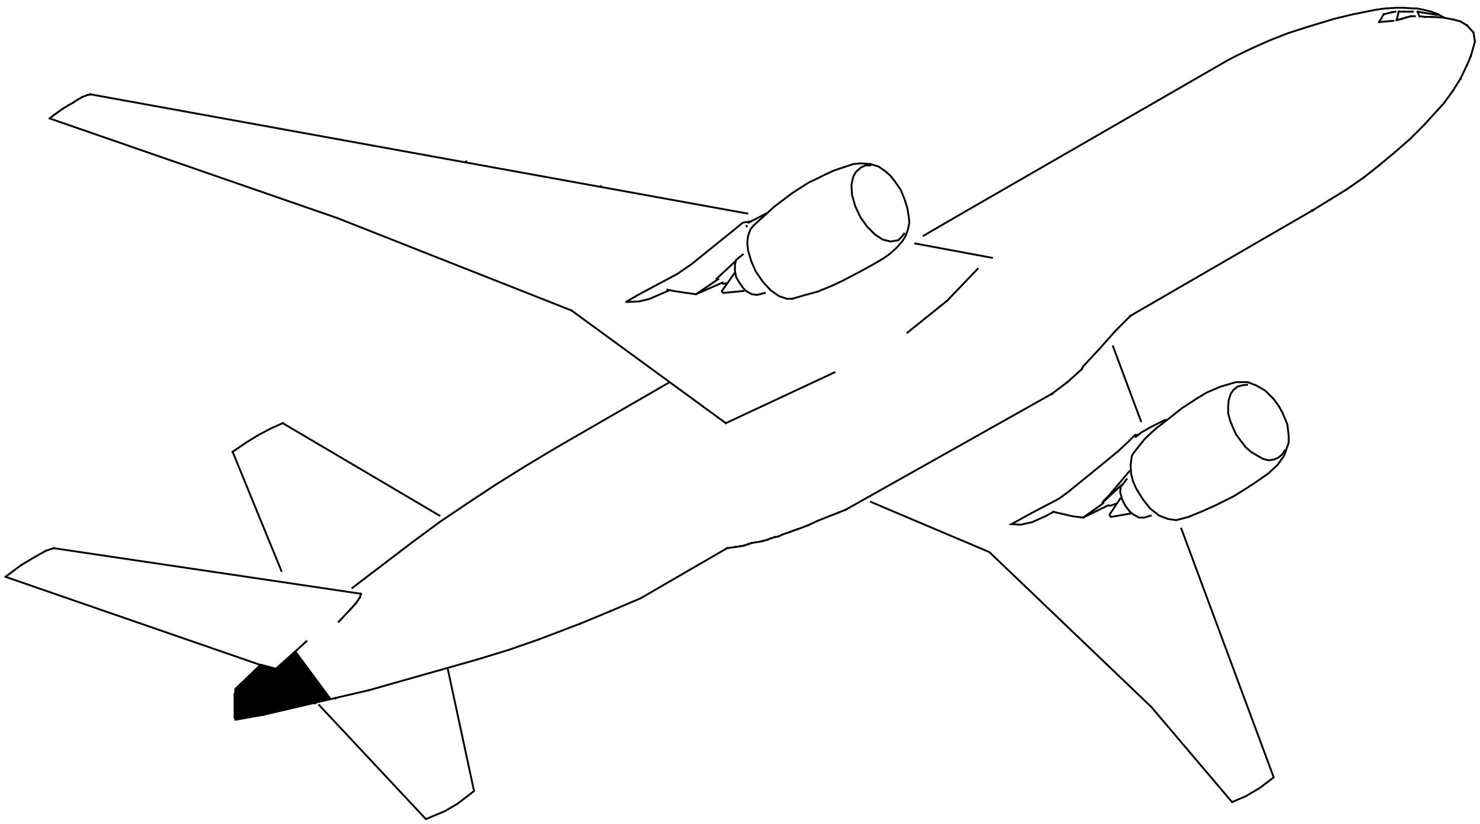
ENGINE FIRE EXTINGUISHING - FUNCTIONAL DESCRIPTION - ENGINE FIRE EXTINGUISHING CIRCUIT

APU FIRE DETECTION - INTRODUCTION

Purpose

The APU fire detection system warns the flight or ground crew of an APU fire. The APU stops automatically if there is a fire.

If a fire occurs on the ground and the engines are not running, the APU fire extinguisher discharges automatically. This permits unattended operation of the APU.



APU FIRE DETECTION - INTRODUCTION

APU FIRE DETECTION - GENERAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

APU FIRE DETECTION - GENERAL DESCRIPTION

General

The APU fire detection system has these components:

- APU fire detectors
- Fire detection card - APU.

There are two modes of operation: unattended mode and attended mode. A signal from the electrical load management system (ELMS) puts the card in the unattended mode when the airplane is on the ground with the engines not running. When the airplane is in the air, or an engine is running, the system operates in the attended mode.

Built-in-test equipment does tests of the system. Faults cause alert messages, status messages, and maintenance messages. Use the fire/overheat test switch to do a manual test of the system. See the fire protection section for more information about the fire/ overheat test (AMM PART I 26-00).

Fire Detection Loops

The APU has two fire detection loops, loop 1 and loop 2. The APU fire detection card continually monitors the two loops for faults. If there are no faults, the card monitors both loops for fires. This is dual loop operation.

If a loop fails, the card sends the data to the AIMS. Status and maintenance messages show. The system changes to single loop operation and monitors only the loop that has not failed. Fire alarms occur if the loop that has not failed has a fire.

Operation

If there is an APU fire, the detection card sends an alarm signal to these components and systems:

- The electrical load management system (ELMS)
- The APU controller
- The AIMS
- The warning electronics system (WES).

The ELMS and the APU controller stop the APU. The AIMS causes a warning message. The WES turns on the master warning lights and the fire warning aural.

A second fire alarm signal turns on the APU fire warning light in the fire switch. If the airplane is on the ground, a warning horn and a light come on at the P40 service and APU shutdown panel.

Attended Mode

Normal operation in the attended mode is dual loop with AND logic. Loop 1 AND loop 2 both must have a fire to cause fire alarms. AND logic helps prevent false alarms. A crew member decides whether or not to use the fire extinguishing system.

APU FIRE DETECTION - GENERAL DESCRIPTION

Unattended Mode

Normal operation in the unattended mode is dual loop with OR logic. Loop 1 OR loop 2 must have a fire to cause fire alarms. OR logic gives maximum safety for unattended operation. The fire extinguishing system operates automatically.

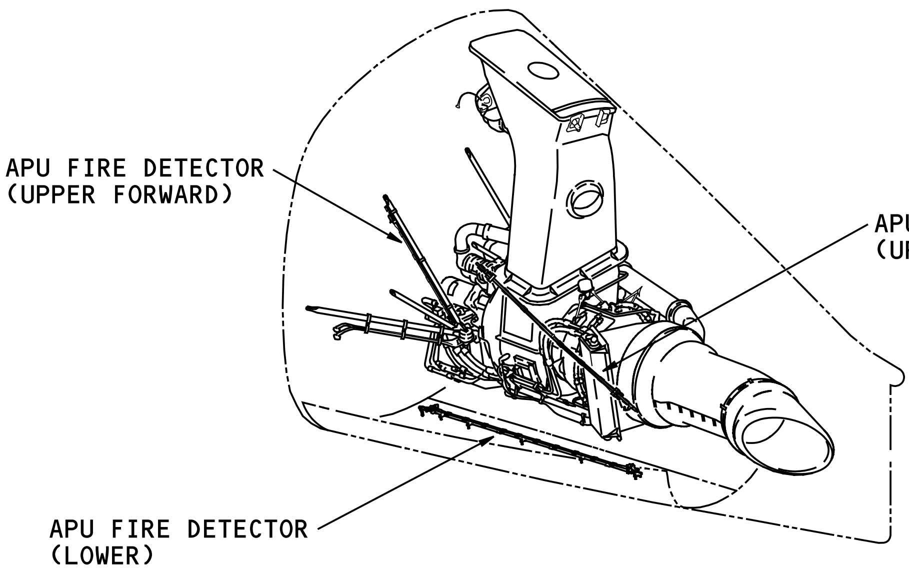
Component Locations

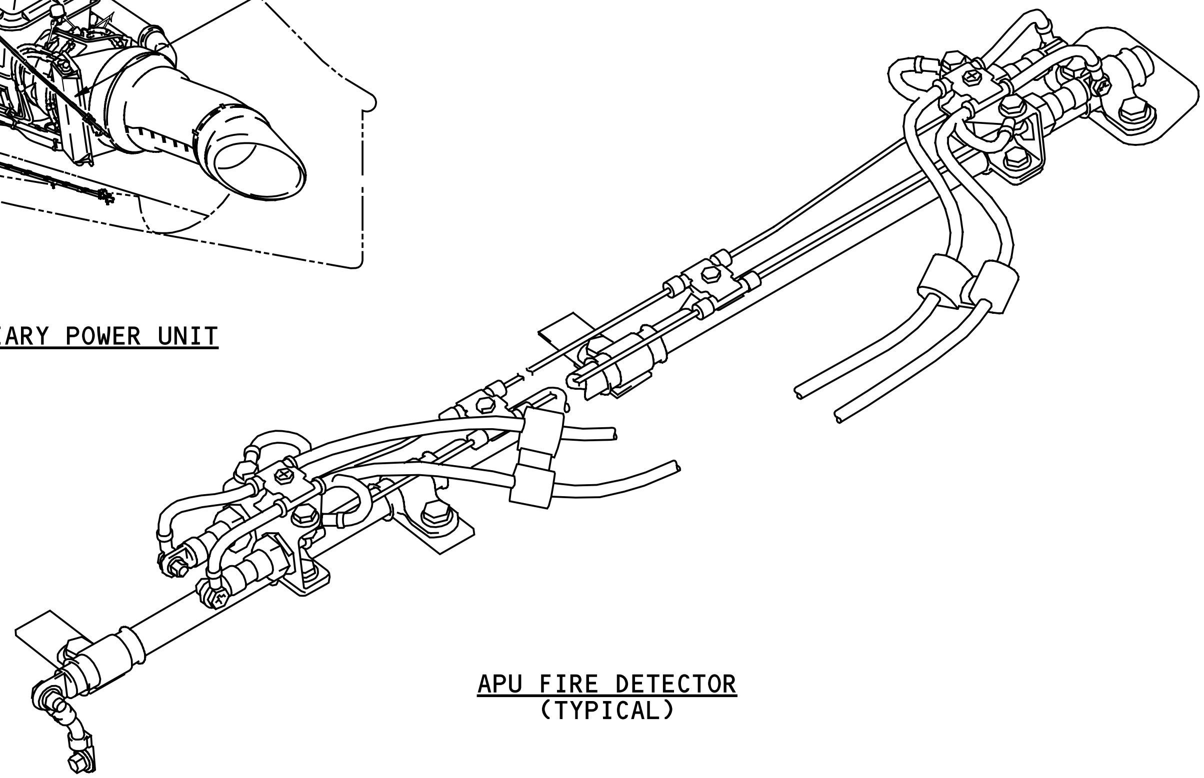
These are the APU fire detection system components in the APU compartment:

- APU fire detector - upper forward
- APU fire detector - upper aft
- APU fire detector - lower.

The upper forward detector is on the forward support and vibration isolation mount. The upper aft detector is on the left side of the APU compartment. The lower detector is on the left APU access door.



AUXILIARY POWER UNIT



APU FIRE DETECTOR
(TYPICAL)

APU FIRE DETECTION - APU COMPONENT LOCATIONS

APU FIRE DETECTION - APU FIRE DETECTORS

Purpose

The APU fire detectors monitor the temperature in the APU compartment.

Physical Description

Each detector has two elements attached to a support tube. The elements connect to make loop 1 and loop 2.

The element is an inconel tube filled with a thermistor core material. Two electrical conductors go through the length of the core. One conductor has a ground connection to the tube. The other conductor connects to the APU fire detection card.

Functional Description

As the temperature of the core increases, electrical resistance to ground decreases. If the resistance decreases to the set point, a fire alarm occurs. When the fire is gone, the resistance increases to the reset point and the alarm signal goes away.

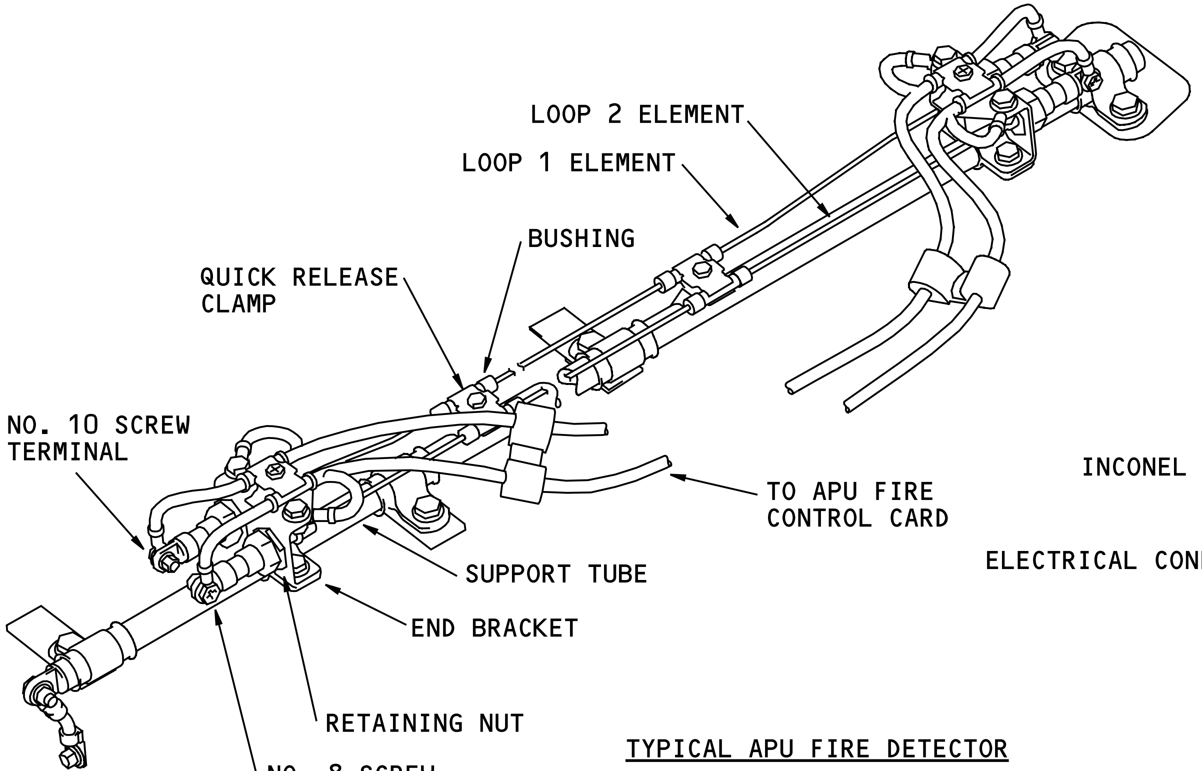
The tables show approximate temperatures in degrees F (and degrees C) which cause a fire alarm. Reset temperatures are also shown.

DETECTOR	FIRE TEMP	RESET TEMP
UPPER FWD	479 (248)	468 (242)
UPPER AFT	511 (266)	499 (259)
LOWER	488 (253)	478 (248)

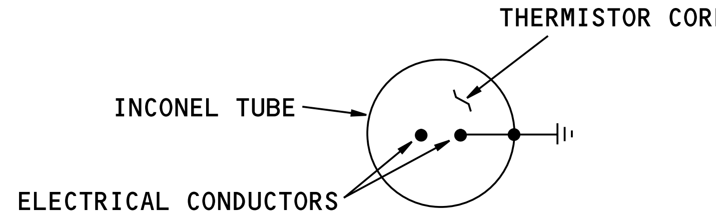
Training Information Point

Each element uses a #10 screw wire-termination on one end and a # 8 screw wire-termination on the other end to prevent crossed wiring. The #10 terminal and the mating wire terminal have a black stripe around the insulation.

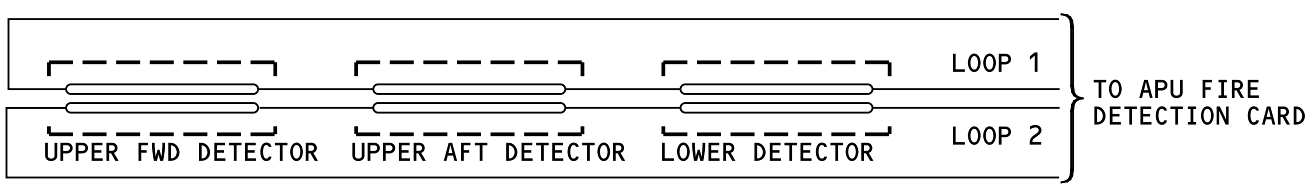
The ends of the element attach to the support tube bracket with retaining nuts. Quick-release clamps and bushings support the element along its length.



TYPICAL APU FIRE DETECTOR



ELEMENT CROSS-SECTION



APU FIRE DETECTION LOOP CIRCUITS

APU FIRE DETECTION - APU FIRE DETECTORS

APU FIRE DETECTION - FIRE DETECTION CARD - APU

Purpose

The APU fire detection card has these purposes:

- Operate in attended or unattended mode
- Monitor the detectors for a fire condition
- Monitor the detectors for failures and send the data to AIMS
- Set the correct logic for the loops (and/or logic)
- Do tests of the APU fire detection system.

Location

The APU fire detection card is in the P85 system card file in the A9 slot. The cardfile slots have labels.

Fire Detection Circuits

The fire detection circuit monitors the resistance of the detector element thermistor core. The resistance of the core is normally high. If the resistance goes low, the card supplies a FIRE output.

A short circuit in the loop also cause low resistance. The rate at which the resistance changes identifies an electrical short or a fire. A short circuit causes the resistance to decreases quickly. A fire causes the resistance to decrease more slowly.

If the resistance decreases quickly, the circuit supplies a SHORT output for the life of the short circuit. If the short circuit stays for more than 0.2 seconds, the circuit supplies a DESELECT output. A deselect output also occurs if a power-up BIT finds an open circuit in the loop.

Program Logic Device

The program logic device gives attended or unattended mode of operation. A signal from the ARINC 429 receiver puts the device in the correct mode.

The device sets the correct logic for the fire detection circuits. Dual-loop operation is normal. If a detection circuit sends a short, deselect, or power loss signal, the logic device changes to single-loop operation.

The program logic device supplies the fire alarm signals to the other circuits which have interfaces with the card.

Attended Mode Operation

The program logic device operates with AND logic. Loop 1 and loop 2 both must have a fire to cause the alarms. The table shows alarm and fault conditions:

APU FIRE DETECTION - FIRE DETECTION CARD - APU

ATTENDED MODE - AND LOGIC		
LOOP 1	LOOP 2	CARD OUTPUT
NORMAL	NORMAL	-
FIRE	NORMAL	FAULT (SEE TEXT)
FIRE	FIRE	ALARM
NORMAL	FIRE	FAULT (SEE TEXT)
FAULT	NORMAL	FAULT - LOOP 1
NORMAL	FAULT	FAULT - LOOP 2
FIRE	FAULT	ALARM
FAULT	FIRE	ALARM
FAULT	FAULT	FAULT - BOTH LOOPS

If one loop reports a fire and the other loop is normal, a 15 second timer starts. During this time, if the loop status changes from fire to normal, the timer stops. If the status of the normal loop changes to fire, the card sends a fire alarm.

If neither loop changes status in 15 seconds, the card does a test of the normal loop. If the test fails, the card removes the selection of that loop and sends a fire alarm. If the test passes, the card removes the selection of the other loop and reports a fault.

Unattended Mode Operation

The program logic device operates with OR logic. A fire at loop 1 OR loop 2 causes fire alarms. The table shows alarm and fault conditions:

UNATTENDED MODE - OR LOGIC		
LOOP 1	LOOP 2	CARD OUTPUT
NORMAL	NORMAL	-
FIRE	NORMAL	ALARM
FIRE	FIRE	ALARM
NORMAL	FIRE	ALARM
FAULT	NORMAL	FAULT - LOOP 1
NORMAL	FAULT	FAULT - LOOP 2
FIRE	FAULT	ALARM
FAULT	FIRE	ALARM
FAULT	FAULT	FAULT - BOTH LOOPS

The unattended fire alarm signal causes the fire extinguishing system to operate automatically.

Built-In-Test Circuit

BIT continuously monitors the fire detection circuits. The ARINC 429 transmitter sends failure data to the AIMS as soon as BIT finds the condition.

BIT also does a test of the full fire detection system:

- At power-up
- After power interrupt
- Every five minutes of operation.

BIT signals a fire on both loops at the same time and does a check of the system. The ARINC 429 transmitter sends a fire alarm signal to AIMS. The central maintenance computing system (CMCS) uses this signal to

APU FIRE DETECTION - FIRE DETECTION CARD - APU

make sure the fire detection system transmits ARINC data. Fire warnings and APU shutdown do not occur during the tests.

If there is a failure, the ARINC 429 transmitter sends the data to the AIMS.

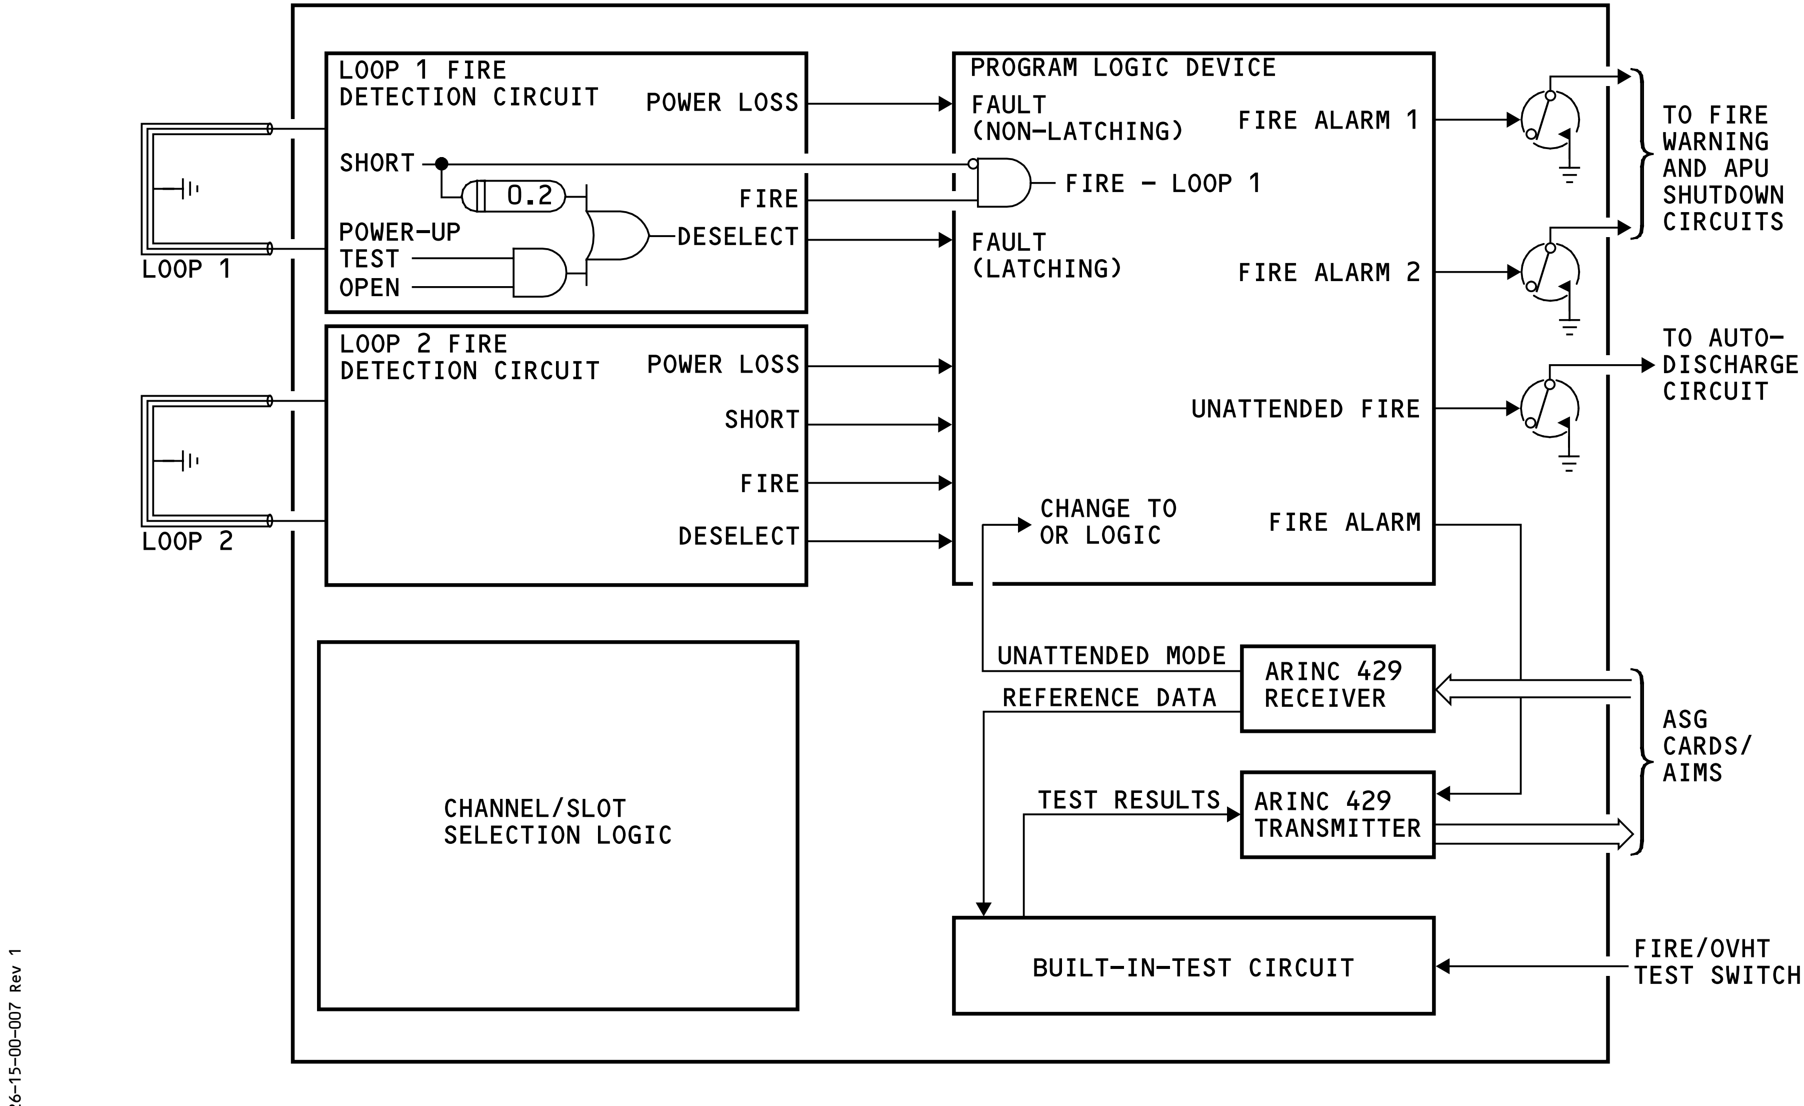
The system changes to single loop operation if necessary.

The fire/overheat test switch starts a similar test. If there is a failure, the ARINC 429 transmitter sends the data to the AIMS. Fire warnings occur during this test.

Training Information Point

The engine and APU fire detection cards function differently but are interchangeable. Program pins in the cardfile have an interface with the channel/slot selection logic circuit. This circuit tells the card whether to function as an APU or engine fire detection card.

The fire detection cards are electrostatic discharge sensitive (ESDS) devices. Be careful to obey the procedures in part II of the maintenance manual (Standard Practices - Airframe, Electrostatic Discharge Sensitive Devices - Maintenance Practices) before you touch the cards.



APU FIRE DETECTION - FIRE DETECTION CARD - APU

APU FIRE DETECTION - FUNCTIONAL DESCRIPTION - P40 PANEL INDICATION CIRCUIT

General

Fire indications at the P40 service and APU shutdown panel are different on the ground and in the air. For both conditions, the battery bus supplies power to the circuit through the APU fire switch in the flight deck.

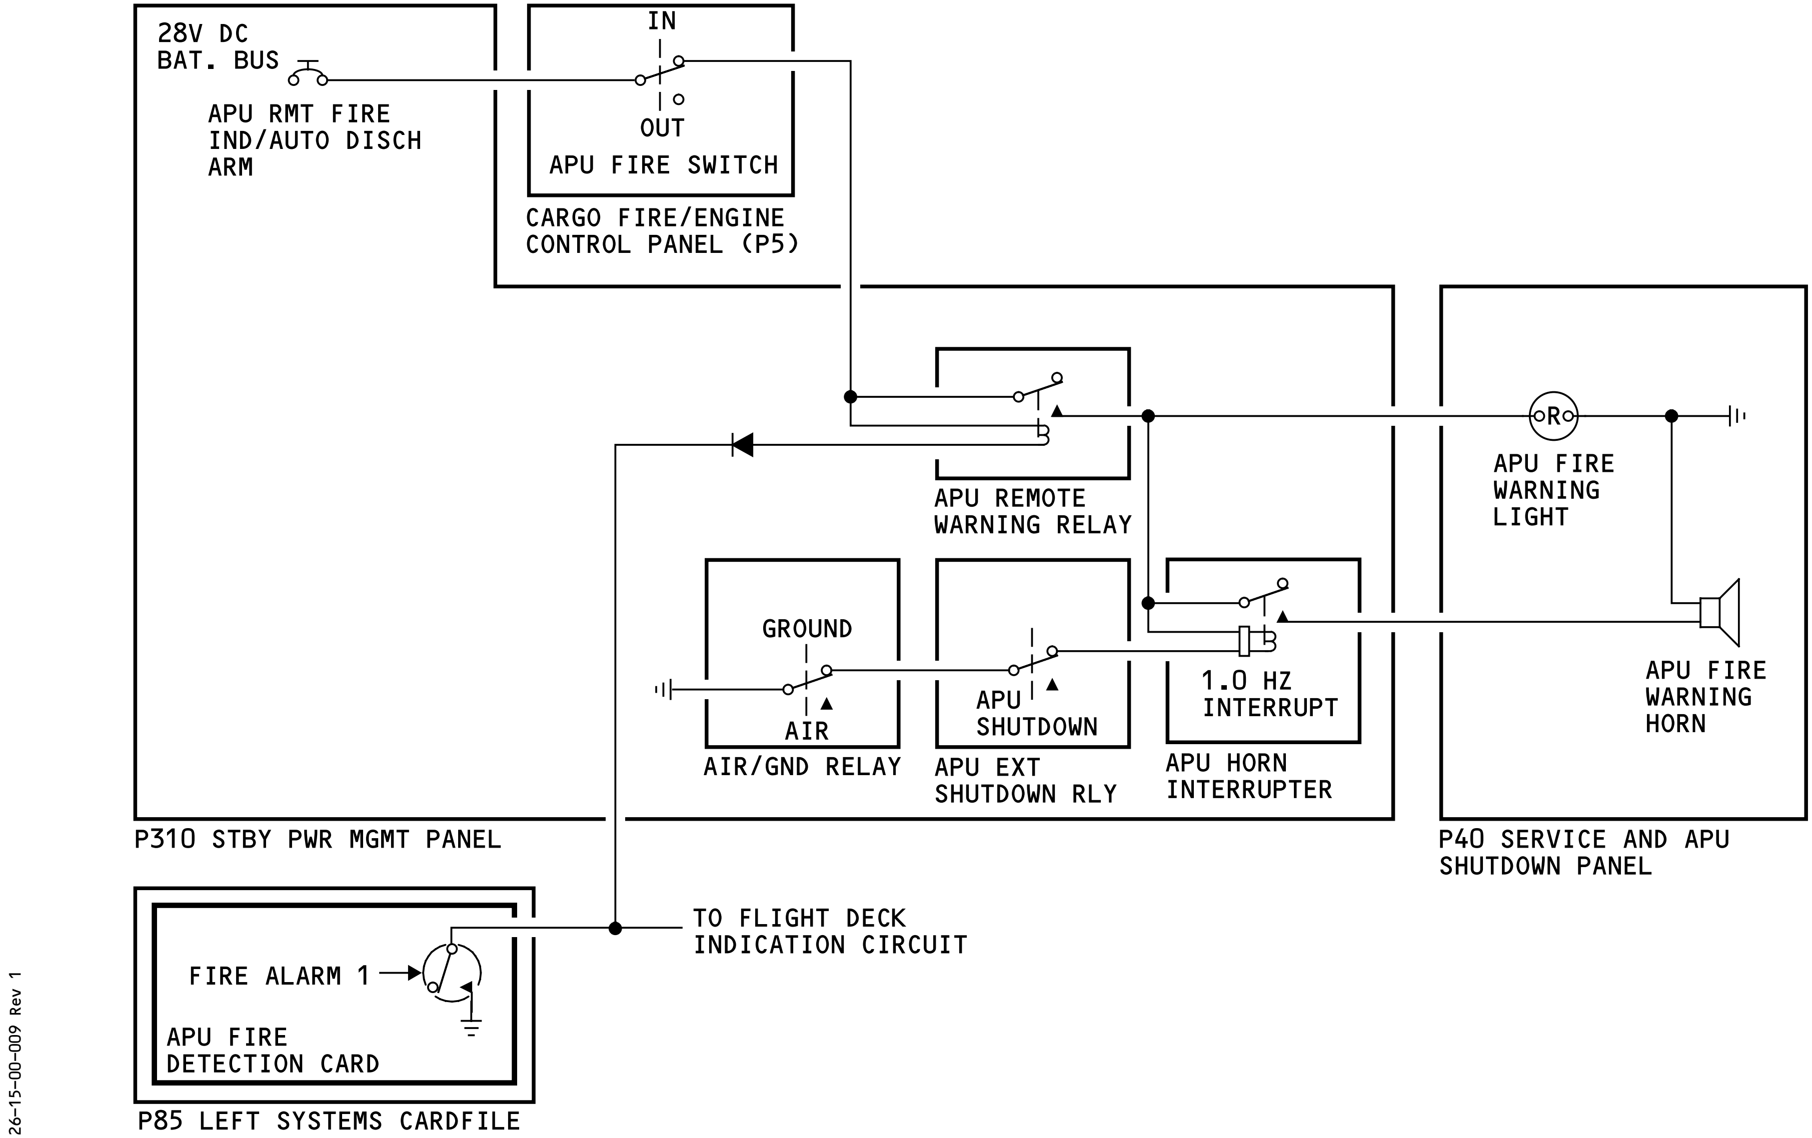
Ground Operation

If there is an APU fire, the APU fire detection card makes a ground for the APU remote warning relay. The relay energizes and supplies power to the APU fire warning light and the horn interrupter. If the airplane is on the ground and the APU external shutdown relay is not energized, the APU horn interrupter energizes. This supplies power to the APU fire warning horn. The horn interrupter causes the warning horn to sound intermittently.

If you pull the APU fire switch in the flight deck, the warnings at the P40 service and APU shutdown panel go away. If you push the APU fire shutdown switch on the P40 panel, the APU external shutdown relay energizes and stops the horn.

Air Operation

In flight, the air/ground relay is in the AIR position. The warning horn does not operate.



APU FIRE DETECTION - FUNCTIONAL DESCRIPTION - P40 PANEL INDICATION CIRCUIT

APU FIRE DETECTION - INDICATIONS

Flight Deck Indications

If there is an APU fire, these indications occur in the flight deck:

- The master warning lights come on
- The fire warning aural operates
- An APU fire EICAS warning message shows
- The APU fire warning light comes on.

Also, because the APU stops automatically, the APU fault light comes on and an EICAS advisory message shows APU shutdown.

Service and APU Shutdown Panel Indications

If the airplane is on the ground, these indications occur at the P40 service and APU shutdown panel:

- The APU fire warning horn operates intermittently
- The APU fire warning light comes on.

APU FIRE DETECTION - INDICATIONS

THIS PAGE INTENTIONALLY LEFT BLANK

APU FIRE EXTINGUISHING - APU FIRE EXTINGUISHING BOTTLE

Purpose

The APU fire extinguishing bottle contains the halon fire extinguishing agent.

Location

The fire extinguishing bottle is on the forward side of the APU firewall, inside the control bay access door.

Physical Description

The fire extinguishing bottle has these components:

- A safety relief and fill port
- An identification plate
- A pressure switch
- A handle
- Two squibs
- Two discharge assemblies
- Four mounting brackets.

The APU fire extinguishing bottle is interchangeable with the engine fire extinguishing bottles. Caps cover one squib and discharge port.

Functional Description

The bottle contains halon fire extinguishing agent pressurized with nitrogen. If the pressure in the bottle becomes too high, the safety relief and fill port opens so the bottle does not explode.

The discharge assembly has an explosive squib. An electric current from the fire extinguishing circuit fires the squib. This releases the halon through the discharge port.

The pressure switch gives control panel indications when bottle pressure decreases. The switch monitors the pressure inside the bottle and is normally open. When the bottle pressure decreases because of a leak or because of bottle discharge, the switch closes an indicating circuit.

Training Information Point

A special service platform is available to use during bottle replacement.

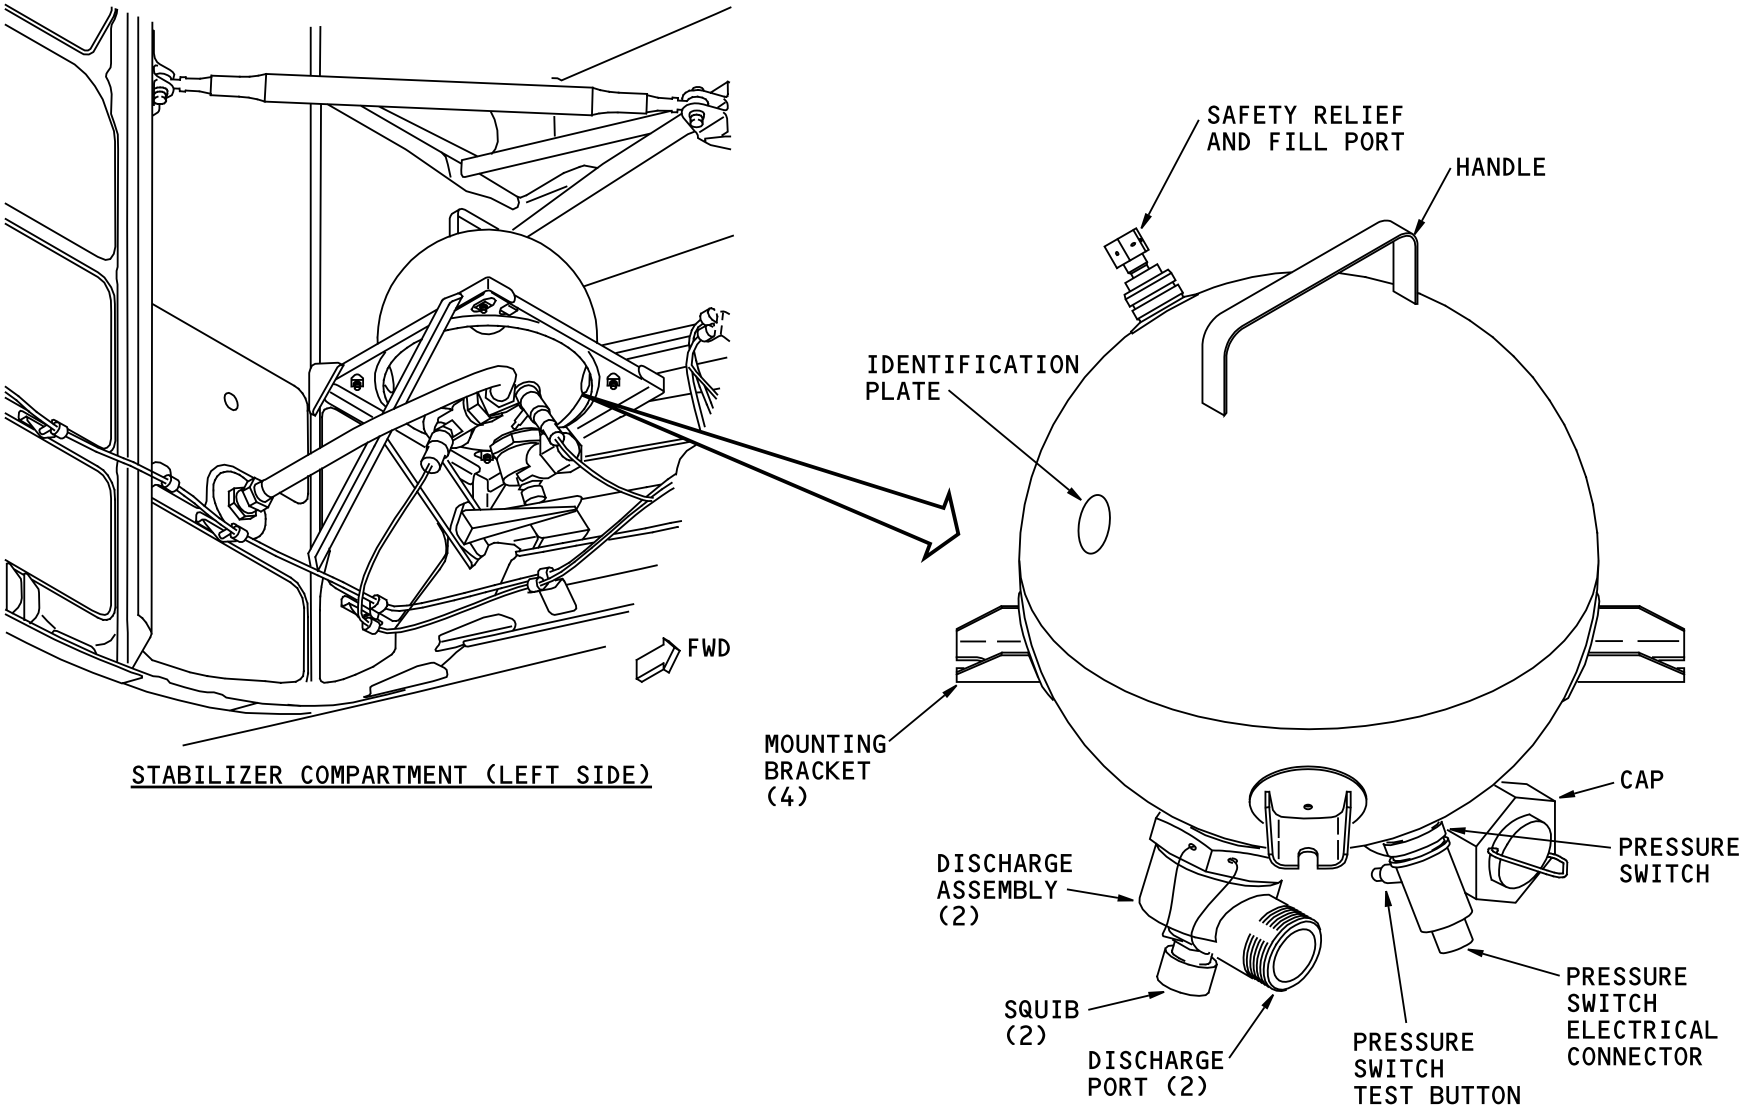
When you replace the bottle, compare the weight of the new bottle with the weight on the bottle identification plate. This prevents installation of a bottle which is not full.

The fire extinguishing bottle must have a hydrostatic test every 5 years. The date of the last test is on one of the mounting brackets and on an inspection tag. The tag is attached to one of the discharge assemblies.

APU FIRE EXTINGUISHING - APU FIRE EXTINGUISHING BOTTLE

WARNING: BE CAREFUL WHEN YOU MOVE THE FIRE EXTINGUISHING BOTTLE. THE FIRE EXTINGUISHING BOTTLE IS HIGHLY PRESSURIZED AND HAS AN EXPLOSIVE CARTRIDGE AS A COMPONENT. ACCIDENTAL DISCHARGE OF THE FIRE EXTINGUISHING BOTTLE CAN CAUSE INJURY TO PERSONS OR DAMAGE TO EQUIPMENT.

WARNING: STAY OFF THE CONTROLS BAY ACCESS DOOR, 313AL. YOUR WEIGHT CAN RELEASE THE SPRING-LOADED LATCHES. IF YOU FALL THROUGH THE DOOR, INJURIES WILL OCCUR.



26-22-00-005 Rev 3 05/08/96

APU FIRE EXTINGUISHING - APU FIRE EXTINGUISHING BOTTLE

APU FIRE EXTINGUISHING - FUNCTIONAL DESCRIPTION - APU FIRE EXTINGUISHING CIRCUIT

General

The APU fire extinguishing bottle squib fires for three conditions:

- If there is an unattended fire alarm
- If you operate the controls on the P40 service and APU shutdown panel
- If you operate the flight deck fire switch.

For each condition, power comes from the 28v dc hot battery bus.

Unattended Fire Alarm

Fire alarm 1 from the APU control card makes a ground for the APU remote warning relay. The relay energizes if the APU fire switch on P5 is not out. The unattended fire alarm makes a ground for the APU auto fire bottle discharge relay. The relay energizes after a 10 second delay. Power from the hot battery bus goes through the relay contacts to the squib.

Service and APU Shutdown Panel

The APU external shutdown relay energizes when you push the APU fire shutdown switch. The relay latches through its own contact and the fire/overheat test switch. With the relay energized, the fire bottle armed light comes on and power goes to the APU bottle discharge switch. When you push the APU bottle discharge switch, the squib fires.

Flight Deck Fire Switch

With the APU fire switch in the left or right discharge position, power from the hot battery bus fires the squib.

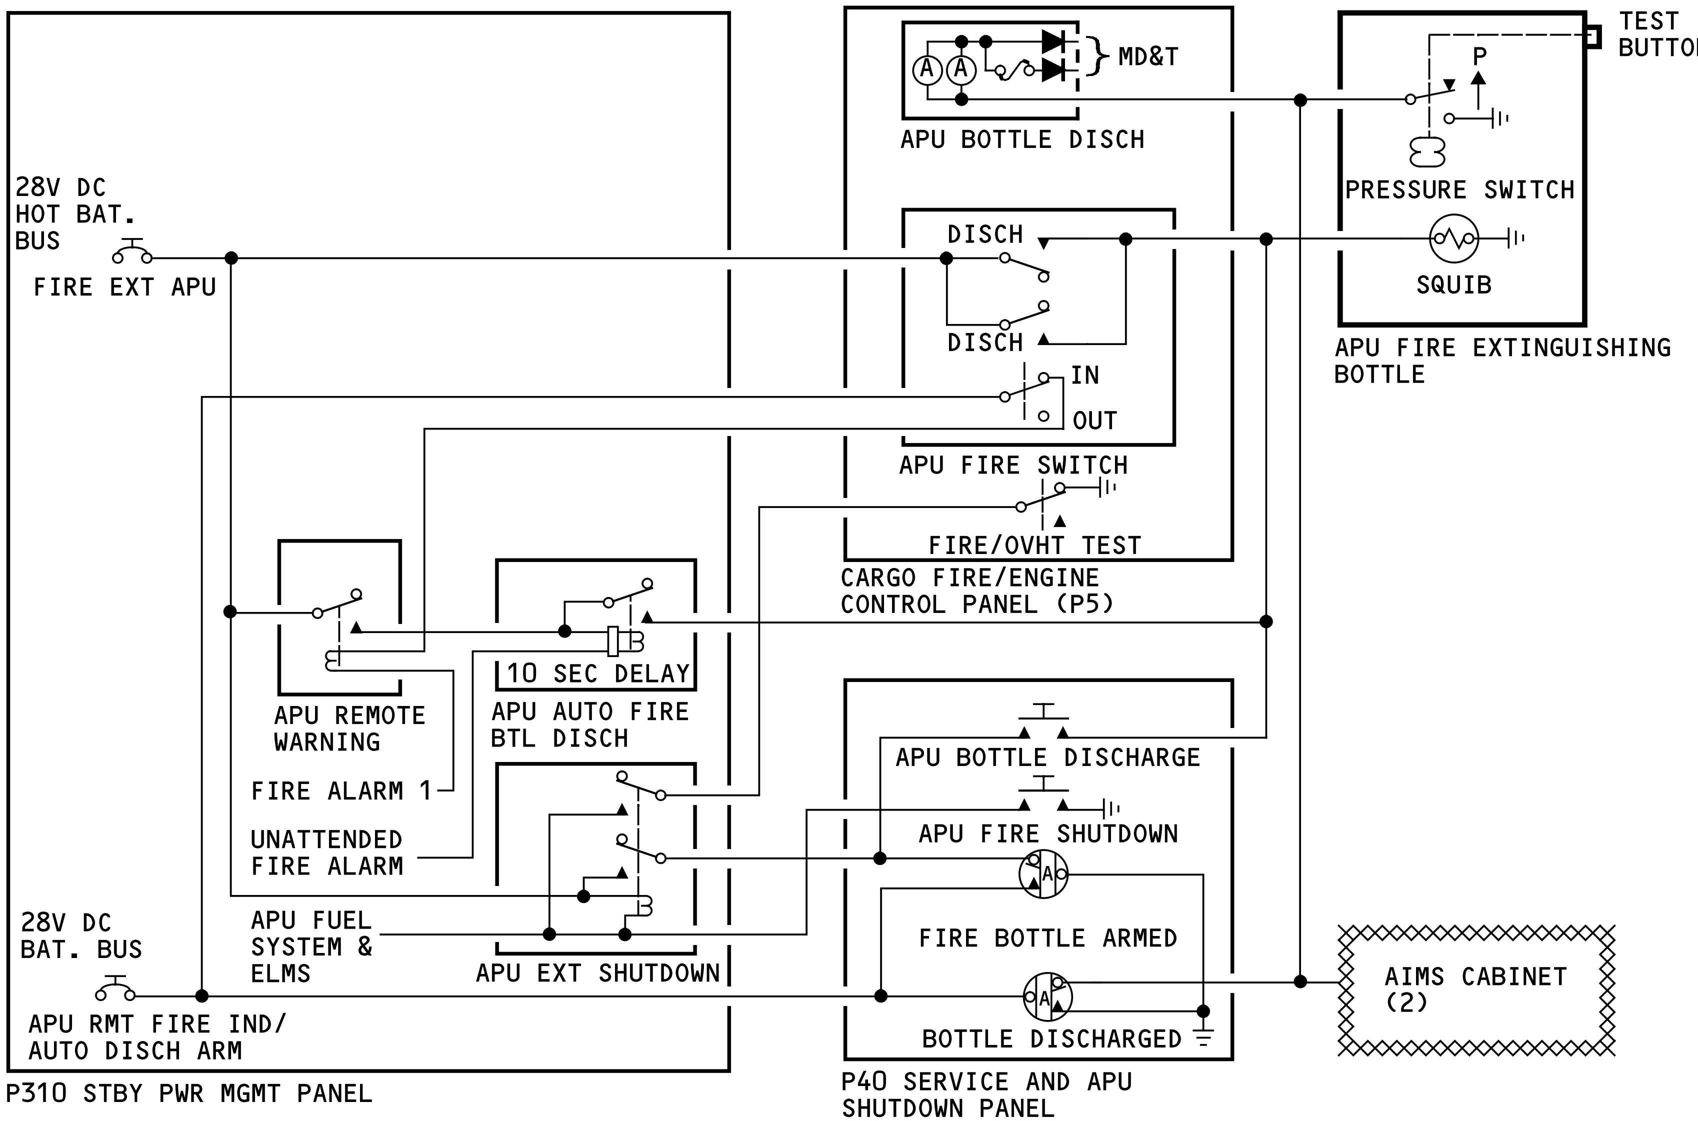
Indications

When pressure inside the bottle decreases, the pressure switch closes and makes a ground for the discharge indicator lights. The ground also causes advisory and status messages to show.

When you push the APU fire shutdown switch, the APU external shutdown relay latches through its own contact and the fire/overheat test switch. A ground for the APU fuel system closes the APU fuel shutoff valve. The ground signal to ELMS causes an EICAS status message. The message shows a remote APU shutdown and stays until you do a fire/overheat test to release the relay. You cannot start the APU with the relay latched.

Training Information Point

You can do a check of the pressure switch circuit on the ground. Push and hold the bottle pressure switch test button to close the switch. The bottle discharge lights on the P5 and P40 panels must come on. Bottle discharge advisory and status messages must show.



26-22-00-011 Rev 0

APU FIRE EXTINGUISHING - FUNCTIONAL DESCRIPTION - APU FIRE EXTINGUISHING CIRCUIT

APU FIRE EXTINGUISHING - OPERATION - P40 SERVICE AND APU SHUTDOWN PANEL

General

If the APU has a fire during ground operation, the APU fire detection system gives a fire warning at the P40 service and APU shutdown panel. The APU fire warning light comes on and the APU fire warning horn operates intermittently.

APU Fire Extinguishing

When you push the APU fire shutdown switch, these things happen:

- The fire extinguishing system arms
- The fire warning horn stops
- If the APU is still running it stops
- The APU fuel shutoff valve closes.

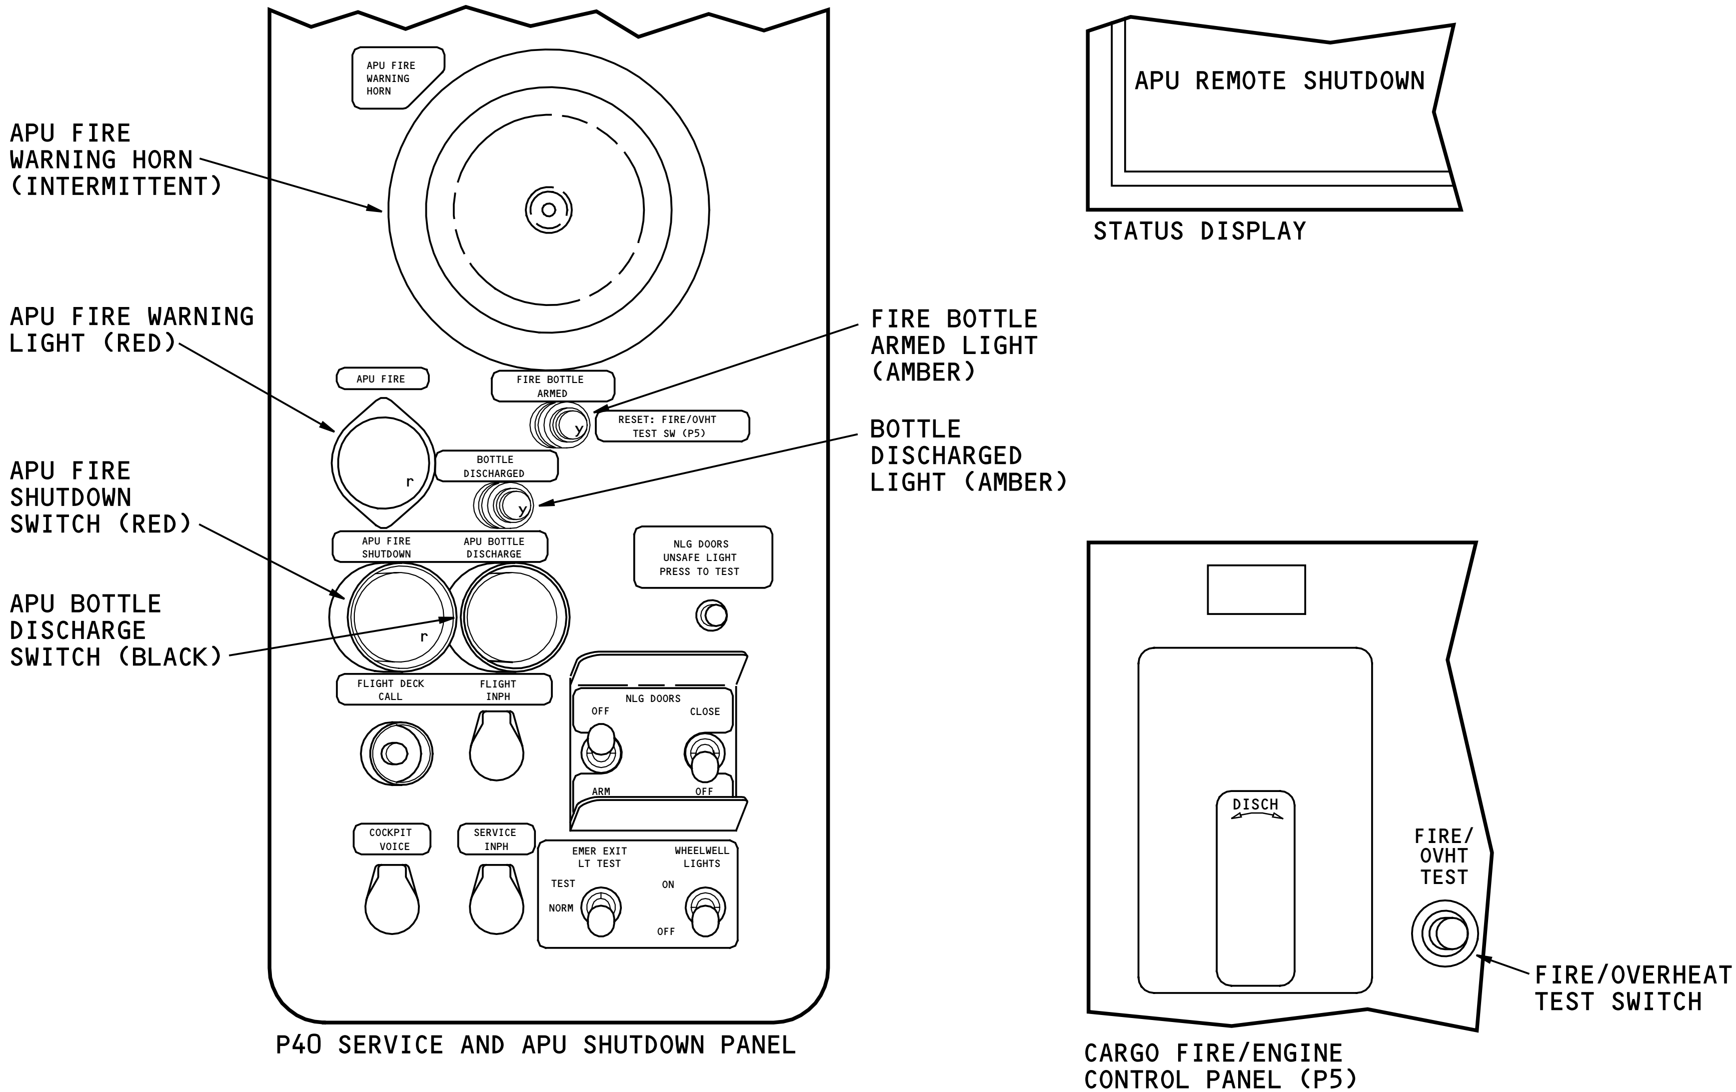
Make sure the fire bottle armed light comes on.

If the fire warning light stays on after you push the fire shutdown switch, push the bottle discharge switch to discharge the fire extinguisher bottle. Make sure the bottle discharged light comes on.

Training Information Point

When you push the APU fire shutdown switch, the circuit latches through the fire/overheat test switch in the flight deck. A status message shows a remote APU shutdown. You cannot start the APU with the circuit latched. Do a fire/overheat test to release the circuit and remove the status message. Also make sure the circuit is released before you replace the fire extinguishing bottle.

NOTE: The APU fire switches connect to the hot battery bus. If you push the APU fire shutdown switch and the bottle discharge switch, the APU fire bottle discharges. This happens with the battery switch ON or OFF, and with or without ground power on the airplane.



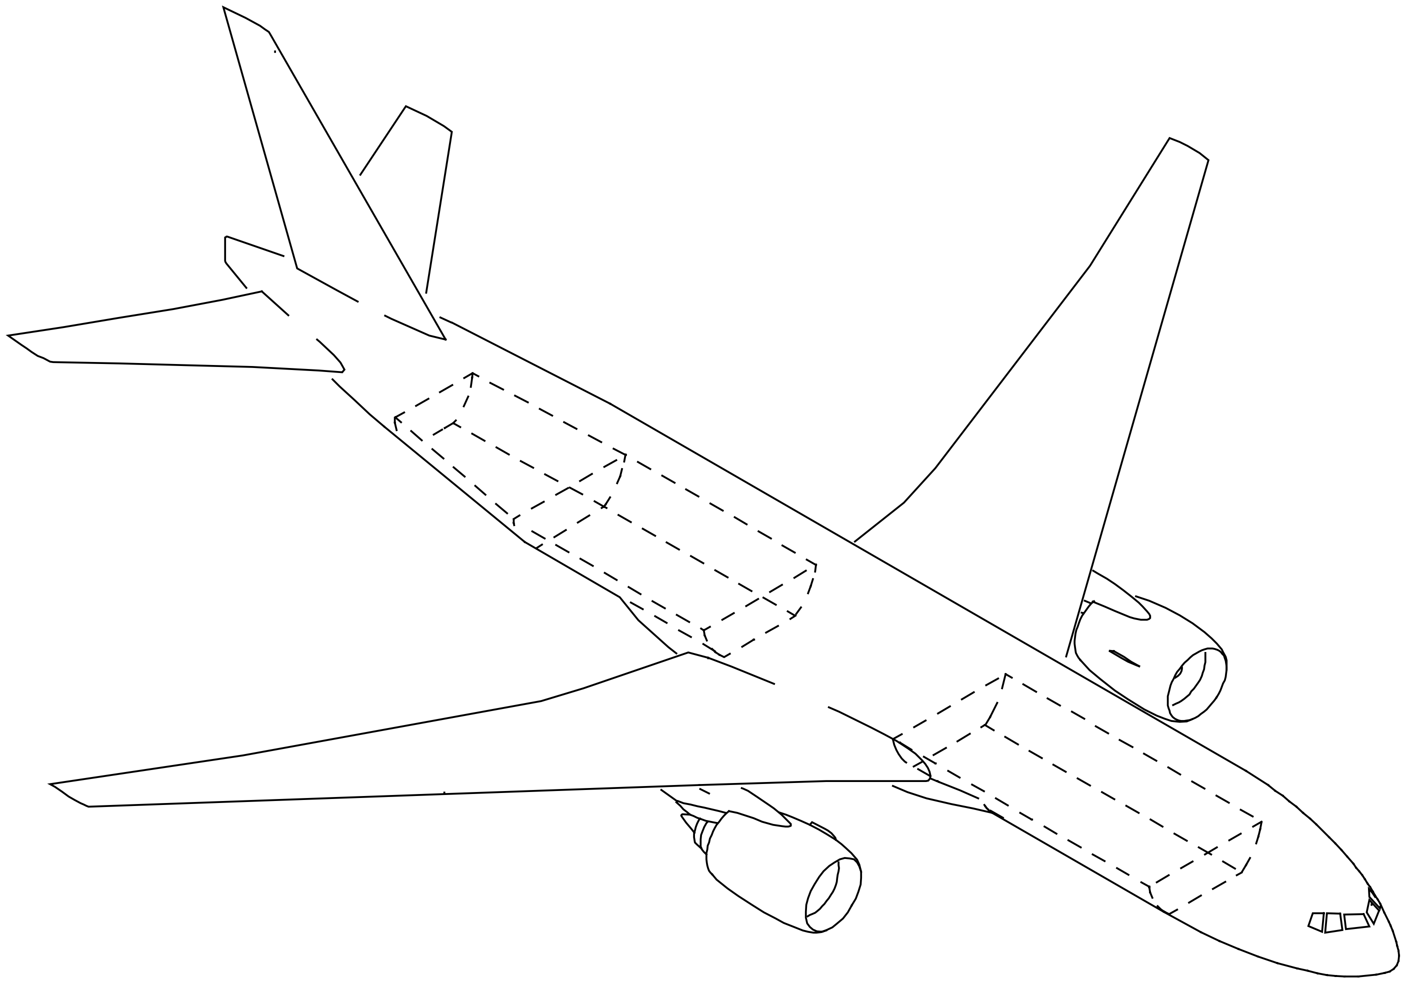
APU FIRE EXTINGUISHING - OPERATION - P40 SERVICE AND APU SHUTDOWN PANEL

LOWER CARGO COMPARTMENT SMOKE DETECTION - INTRODUCTION

Purpose

The lower cargo compartment smoke detection system gives warnings in the flight deck if there is smoke in a lower cargo compartment.

The system also monitors and controls a remote smoke detector for the electronic equipment cooling system.



26-16-00-001 Rev 2 07/08/1997

LOWER CARGO COMPARTMENT SMOKE DETECTION - INTRODUCTION

LOWER CARGO COMPARTMENT SMOKE DETECTION - GENERAL DESCRIPTION

General

The forward and aft lower cargo compartments each have one smoke detector. The smoke detector monitors the cargo compartment air for smoke. Before the air goes in the smoke detector, in-line water separators remove condensation and heaters increase the air temperature.

The forward cargo smoke detector also controls an electrical/electronic cooling smoke detector and supplies electrical power to it.

See the electrical and electronic cooling smoke detection section for more information about the electrical/electronic cooling smoke detector (AMM PART I 26-19).

Interfaces

The lower cargo compartment smoke detection system has these interfaces:

- E/E cooling smoke detector
- Left and right systems card files
- AIMS
- Warning electronics system (WES)
- Overhead panel ARINC 629 system (OPAS)
- Proximity sensor electronics unit (PSEU)
- Equipment cooling system
- Cargo fire/engine control panel.

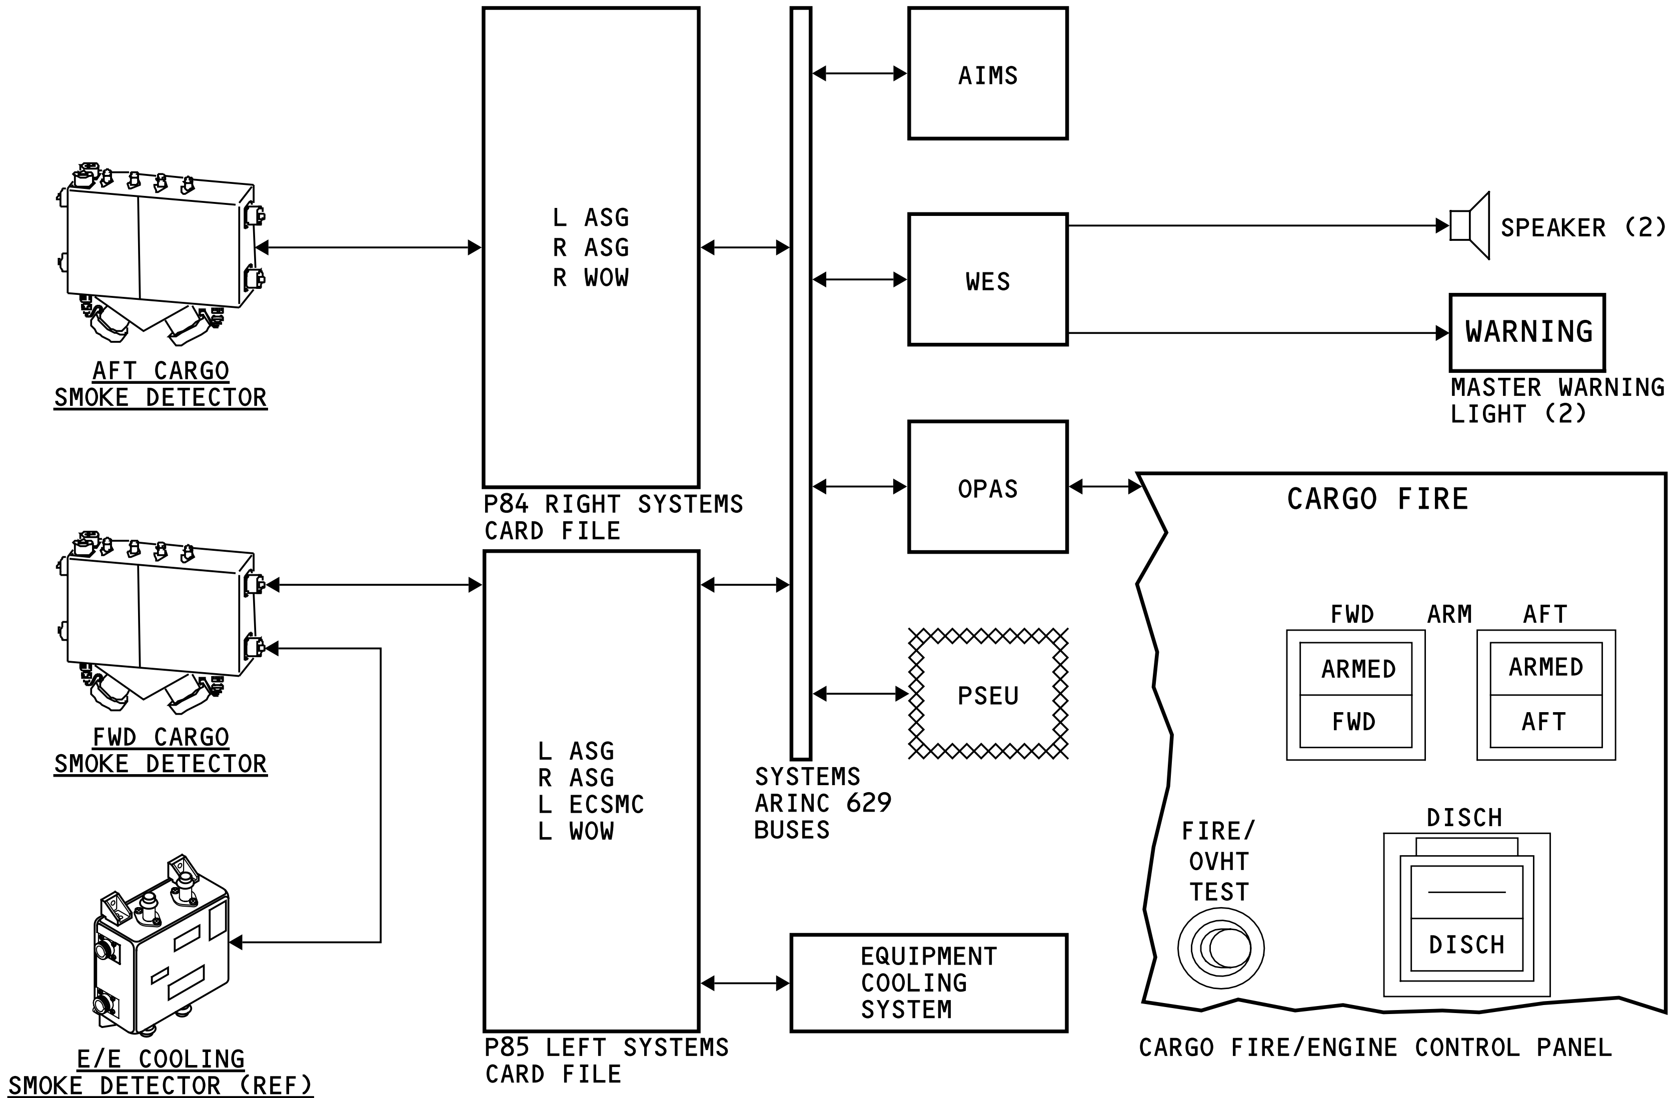
General Operation

If there is smoke in a cargo compartment, AIMS causes a cargo fire warning message. The WES turns on the fire warning aural and the master warning lights. The OPAS turns on the FWD or AFT cargo fire warning light on the cargo fire/engine control panel.

System Tests

The smoke detectors have built-in-test-equipment (BITE). The BITE does power-up and periodic tests of the system. Faults cause alert messages, status messages, or maintenance messages.

You can also use the fire/overheat test switch to do a test of the system. See the fire protection section for more information about the fire/overheat test (AMM PART I 26-00).



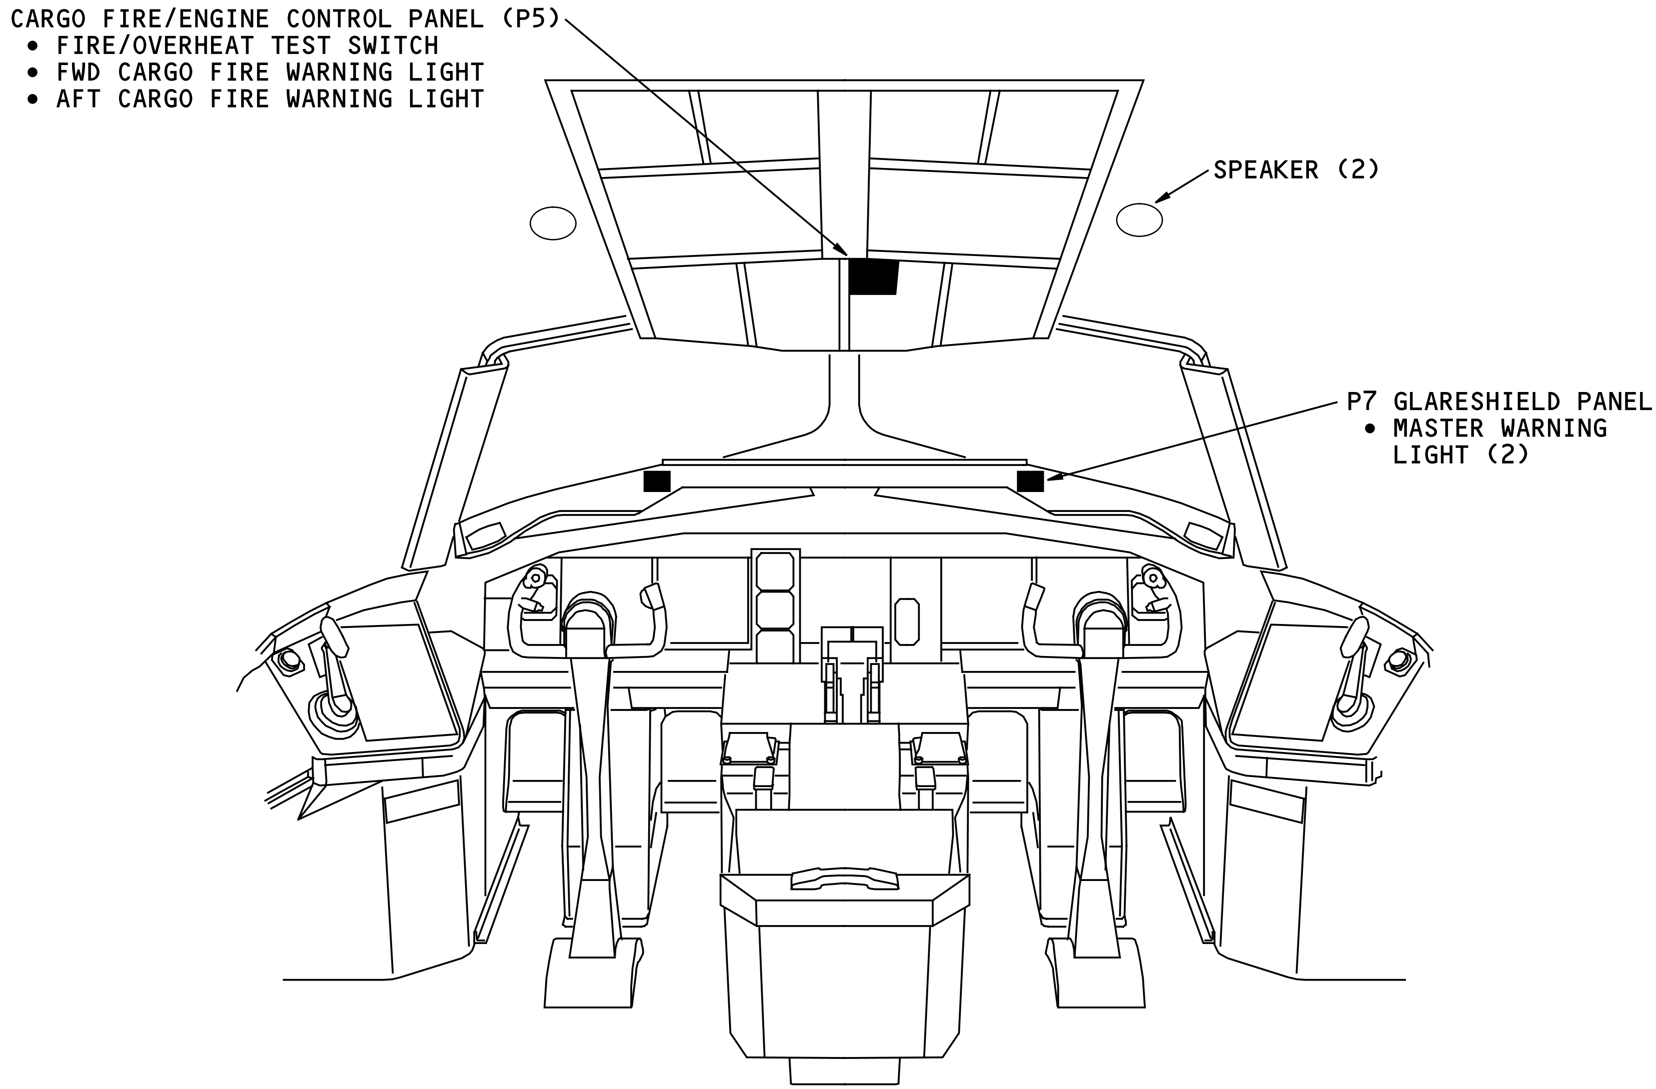
LOWER CARGO COMPARTMENT SMOKE DETECTION - GENERAL DESCRIPTION

LOWER CARGO COMPARTMENT SMOKE DETECTION - FLIGHT DECK COMPONENT LOCATIONS

Component Locations

These are the components in the flight deck that have an interface with the lower cargo compartment smoke detection system:

- Speakers
- Cargo fire/engine control panel
- Master warning lights.



26-16-00-003 Rev 0

LOWER CARGO COMPARTMENT SMOKE DETECTION - FLIGHT DECK COMPONENT LOCATIONS

Lower Cargo Compartments

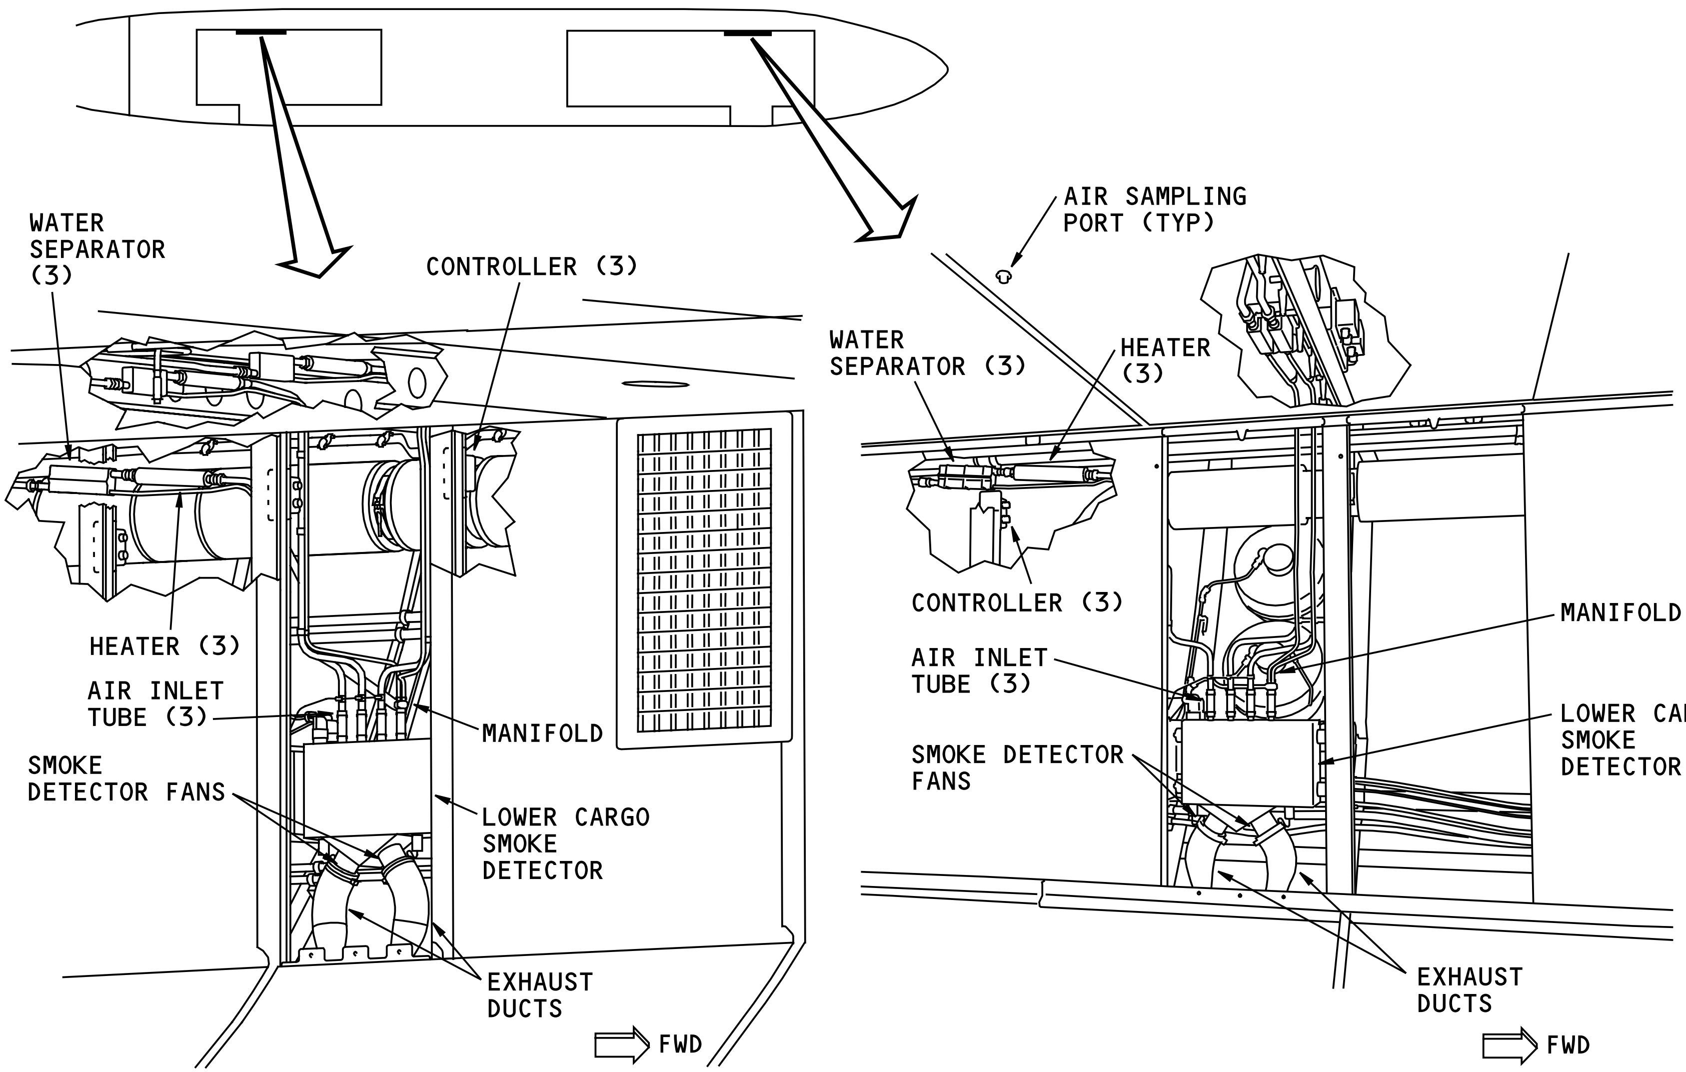
The forward and aft lower cargo compartments each have one smoke detector. Each smoke detector has two fans. Air sampling ports in the cargo compartment ceiling connect to air inlet tubes. The air inlet tubes are above the ceiling and behind the left side of the cargo compartments. The tubes connect to air inlet ports at the top of the smoke detectors. Exhaust ducts take air from the fans and release it behind the sidewall lining.

A water separator and heater are in line with each air inlet tube. Suction lines go from each water separator to a manifold at an inlet port of the smoke detector. Each heater connects to a controller.

Training Information Point

Open the cargo compartment sidewall lining that is opposite the cargo doors to get access to the smoke detectors.

To get access to the water separators, heaters and controllers, open the sidewall lining adjacent to the smoke detectors or the ceiling lining above the smoke detectors.



AFT CARGO COMPARTMENT

FORWARD CARGO COMPARTMENT

LOWER CARGO COMPARTMENT SMOKE DETECTION - LOWER CARGO COMPARTMENT COMPONENT LOCATIONS

LOWER CARGO COMPARTMENT SMOKE DETECTION - LOWER CARGO SMOKE DETECTOR AND FANS - INTRODUCTION

Purpose

The smoke detectors monitor air in the cargo compartments for smoke. The fans bring air from the cargo compartment into the smoke detector. Only one fan on each detector operates at a time.

Physical Description

The forward and aft lower cargo smoke detectors are identical. The smoke detectors have these components:

- Two electrical connectors
- Four air inlet ports
- Four shock mounts
- Two fans
- Four airflow sensors (internal)
- Four smoke detection chambers (internal)
- Two electronic control channels (internal).

The smoke detectors use light emitting diode (LED) optical smoke detectors and acoustic air flow sensors.

Location

There is a smoke detector in the forward and aft lower cargo compartments. The detectors are behind the cargo compartment sidewall lining opposite the cargo doors.

Training Information Point

The smoke detector is an LRU and the fans are LRUs. The smoke detector has no internal LRUs. There is no scheduled maintenance of the cargo smoke detectors or fans. Alert messages or status messages show if there is a fault condition.

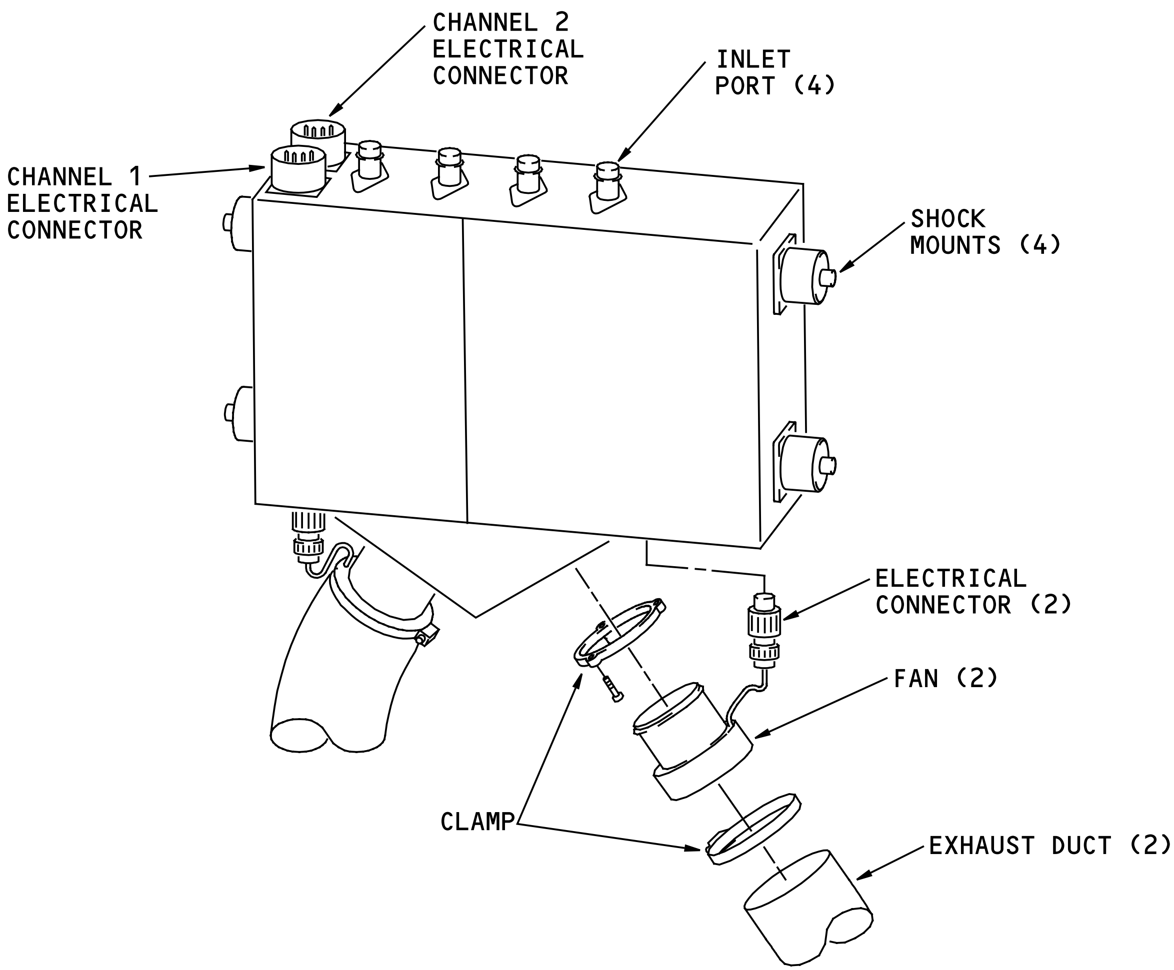
The forward lower cargo smoke detector and the aft lower cargo smoke detector are interchangeable. Four bolts attach the smoke detector to the structure.

Each smoke detector channel has its own electrical connector. The two connectors are different so you cannot cross-connect the wires. Program pins in the connectors give the detector this information:

- Location in the airplane, forward or aft
- If a remote smoke detector is connected
- The active air inlet ports.

Clamps attach the fans to the smoke detector. The length of the wire connected to the fan is such that you cannot connect the wire to the wrong connector on the smoke detector.

The lower cargo smoke detectors are onboard software loadable LRUs. You use the maintenance access terminal (MAT) to load software into the smoke detectors.



26-16-00-005 Rev 2 11/30/1995

LOWER CARGO COMPARTMENT SMOKE DETECTION - LOWER CARGO SMOKE DETECTOR AND FANS - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

LOWER CARGO COMPARTMENT SMOKE DETECTION - LOWER CARGO SMOKE DETECTOR - FUNCTIONAL DESCRIPTION

General

The smoke detector has two identical channels that control and monitor these components:

- Airflow sensor
- Optical smoke detector
- Fans.

Airflow Sensors

The airflow sensor has these parts:

- Transmitter
- Receiver.

The sensor monitors the amount of air going through each air inlet port. The smoke detector sends fault message on an ARINC 429 bus for these conditions:

- Too much airflow
- Not enough airflow
- Failed airflow sensor.

Optical Smoke Detectors

The optical smoke detector has these parts:

- Two source light emitting diodes (LEDs)
- Two intensity monitor photodiodes
- Two scatter detector photodiodes.

One set of diodes connects to channel 1. The other set of diodes connects to channel 2. Only one set of diodes operates at a time.

Inside the smoke detection chamber, air flows between a source LED and a scatter detector photodiode. Normally, only a small amount of light from the LED reaches the scatter detector. If the air has smoke in it, the smoke particles reflect more light on the scatter detector. This causes an alarm signal.

The intensity monitor photodiode makes sure the source LED is on and keeps the output of the source LED constant. This configuration also finds contamination of the LED and photodiodes. Diode failure or contamination causes the detector to switch to the other set of diodes. The detector sends a fault message.

Condensation from the in-line water separators flows through one of the chambers. The airflow sensor and optical smoke detectors in this chamber are not active.

Channel 1 And 2 Circuits

One channel does continuous BITE while the other channel controls the smoke detector. Channel 1 controls during one electrical power cycle, channel 2 controls during the next power cycle. If the control channel or its diodes fail, the other channel takes over. The detector sends a fault message.

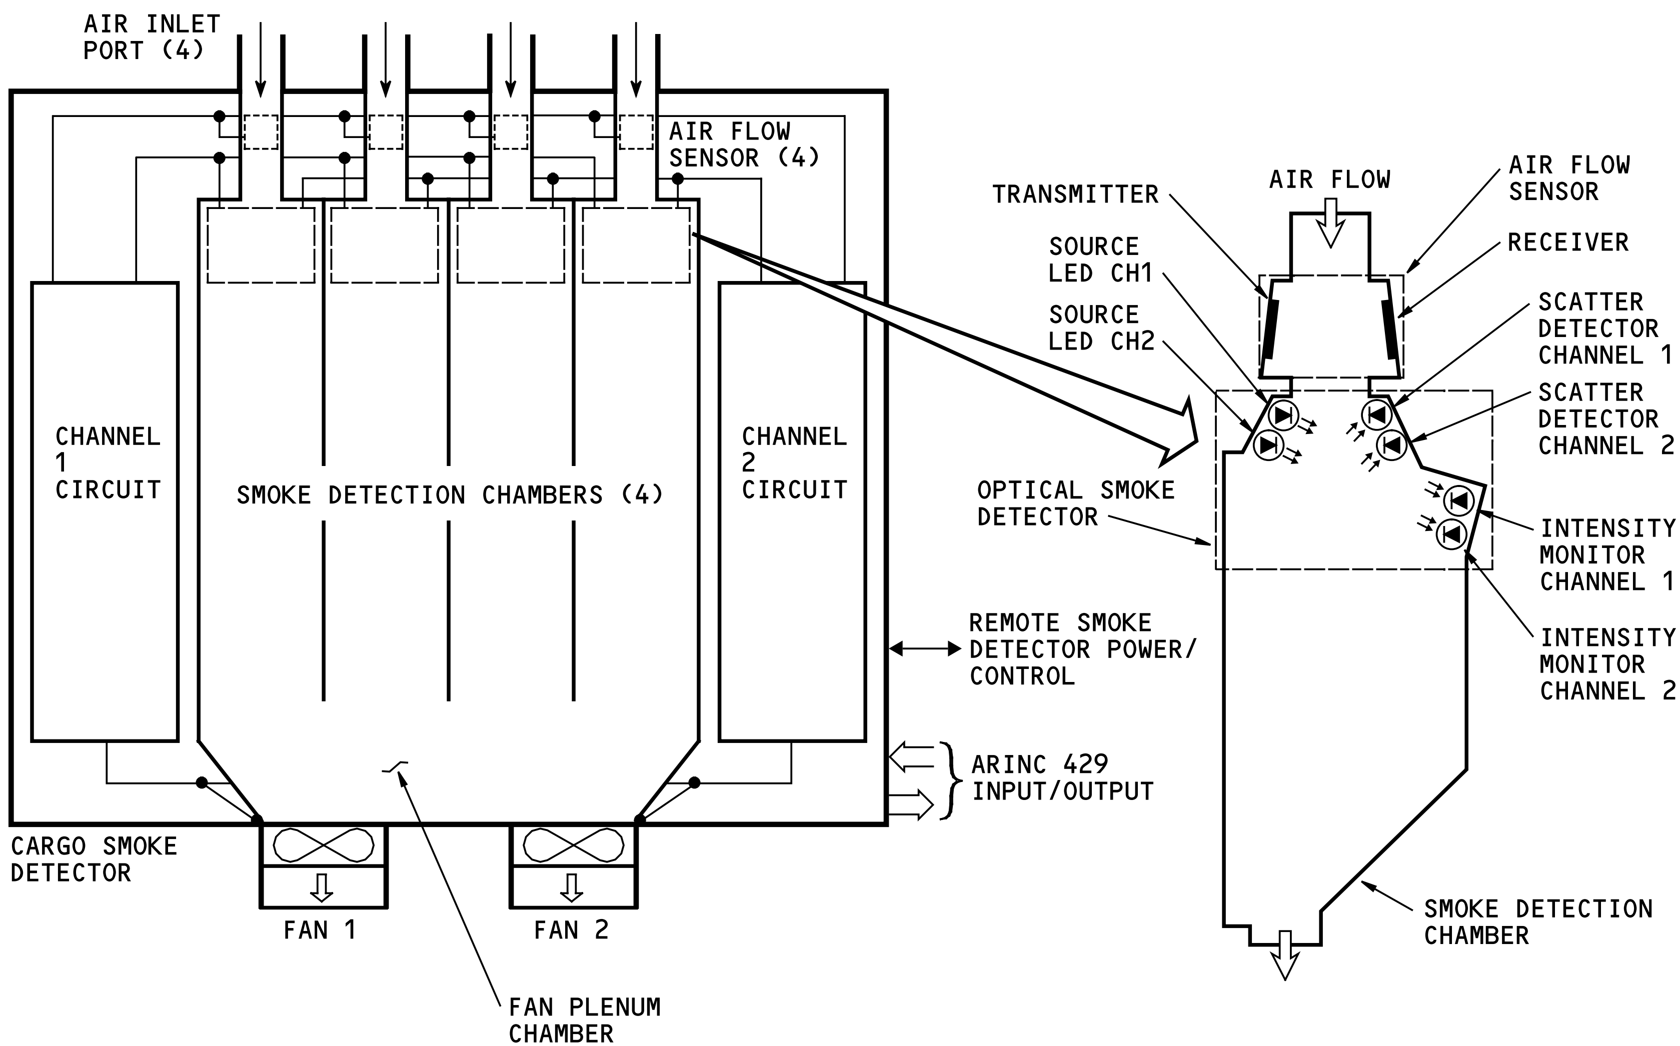
Fans

Channel 1 normally controls fan 1, and channel 2 normally controls fan 2. If a fan fails, the control channel turns on the other fan. The detector sends a fault message. The fans have a built in check valve which prevents reverse air flow through the fan that is off.

Condensation from the in-line water separators goes through the fan. An internal splash shield (not shown) keeps water spray out of the active chambers.

Remote Smoke Detector Control

The smoke detector can supply electrical power to a remote smoke detector and control its operation.



26-16-00-006 Rev 2 07/08/1997

LOWER CARGO COMPARTMENT SMOKE DETECTION - LOWER CARGO SMOKE DETECTOR - FUNCTIONAL DESCRIPTION

LOWER CARGO COMPARTMENT SMOKE DETECTION - FUNCTIONAL DESCRIPTION - AIR SAMPLING

General

The smoke detector installation for the forward lower cargo compartment is shown. The smoke detector installation in the aft cargo compartment operates the same.

The smoke detector has four air inlet ports. Three of the inlet ports connect to air sampling tubes. The fourth inlet port has a manifold that connects to the suction lines from the water separators. The sampling tubes are above the cargo compartment ceiling and in the left sidewall. Silicone rubber sampling ports attach to the ends of the tubes and go through the ceiling into the cargo compartment.

Air Sampling

The forward and aft cargo compartments each have three smoke sampling zones. Each smoke detector inlet port gets an air sample from one zone. Zone 1 is at the back of the compartments and zone 3 is at the front of the compartments.

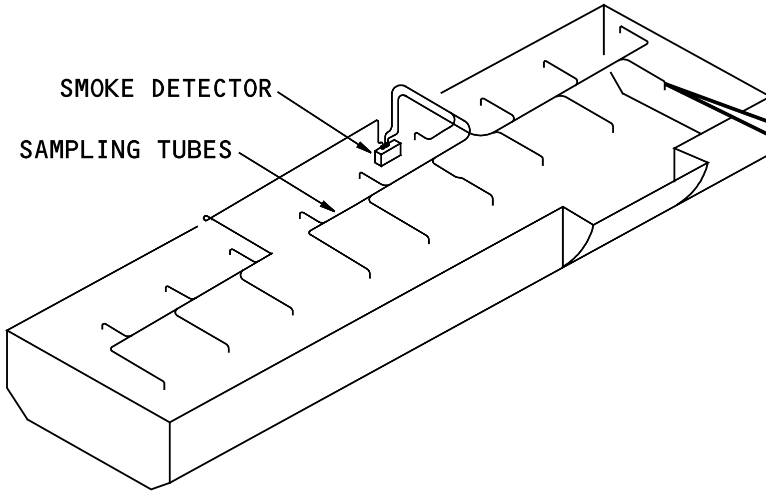
The smoke detector fan pulls air in through the sampling ports and tubes. It also pulls condensation from the water separators. Exhaust air and water spray from the fan goes into the space behind the cargo compartment sidewall.

Training Information Point

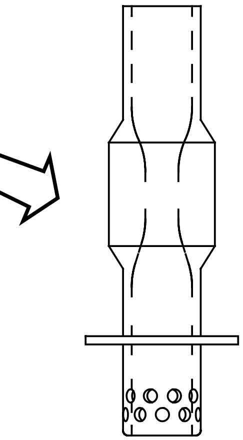
Squeeze a blocked sampling port with your fingers to clean it, or blow compressed air laterally through the holes.

If a sampling tube is blocked, remove the sampling ports and disconnect the other end of the tube. Use compressed air to clean the tube.

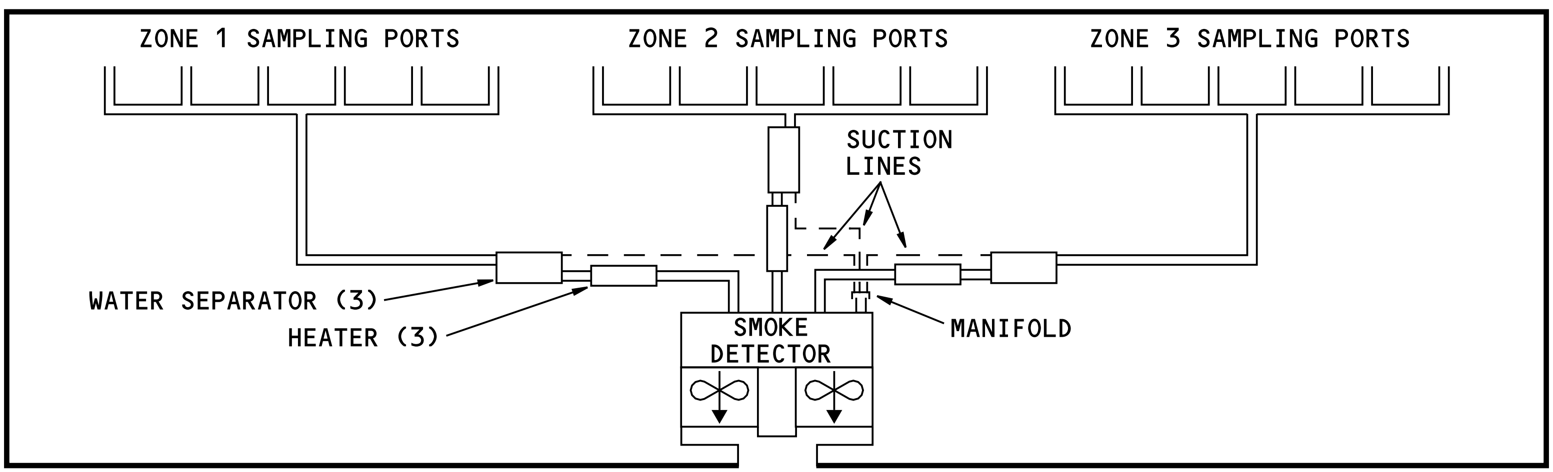
The sampling tubes are made of aluminum and attach to the structure with clamps. This makes it difficult to connect them to the wrong inlet ports on the detector.



FORWARD LOWER CARGO COMPARTMENT



AIR SAMPLING PORT



LOWER CARGO COMPARTMENT (TYPICAL)

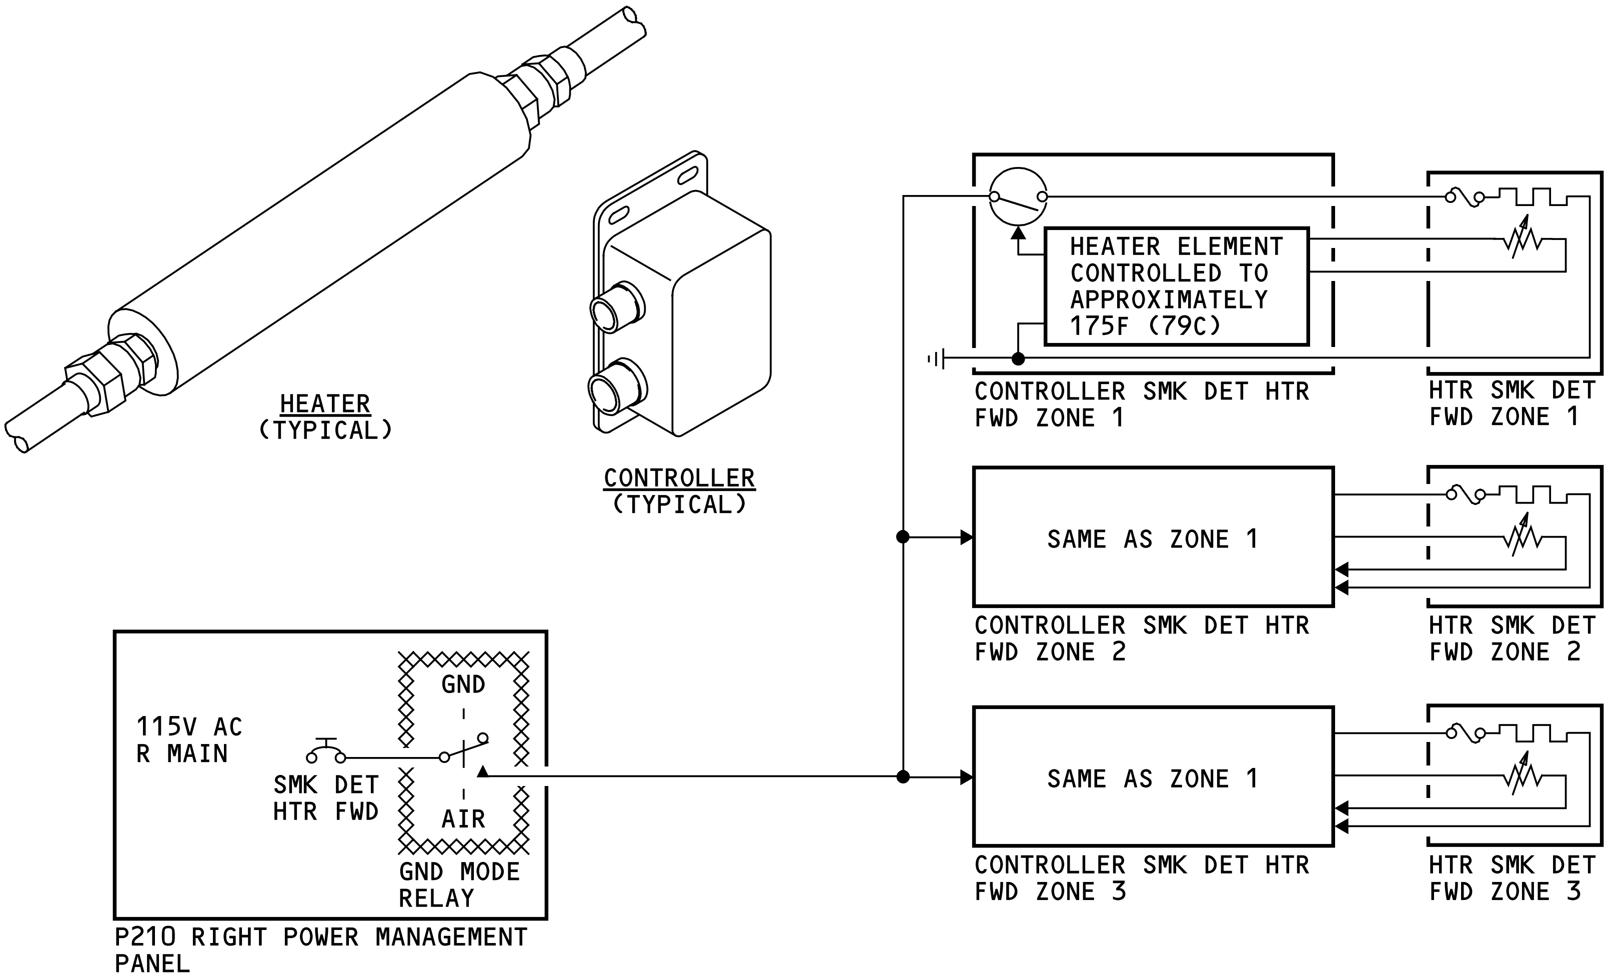
LOWER CARGO COMPARTMENT SMOKE DETECTION - FUNCTIONAL DESCRIPTION - AIR SAMPLING

LOWER CARGO COMPARTMENT SMOKE DETECTION - IN-LINE HEATER AND CONTROLLER

General

The in-line heater increases the temperature of the air that flows to the smoke detector. There is a controller for each in-line heater. The controller uses a sensor in the heater to control the temperature of the heater element to approximately 175F (79C). This increases the air temperature approximately 30F (17C).

The controllers only get power when the airplane is in the air.



NOTE: FORWARD CARGO COMPARTMENT IN-LINE HEATERS AND CONTROLLERS SHOWN.
AFT CARGO COMPARTMENT IN-LINE HEATERS AND CONTROLLERS SIMILAR.

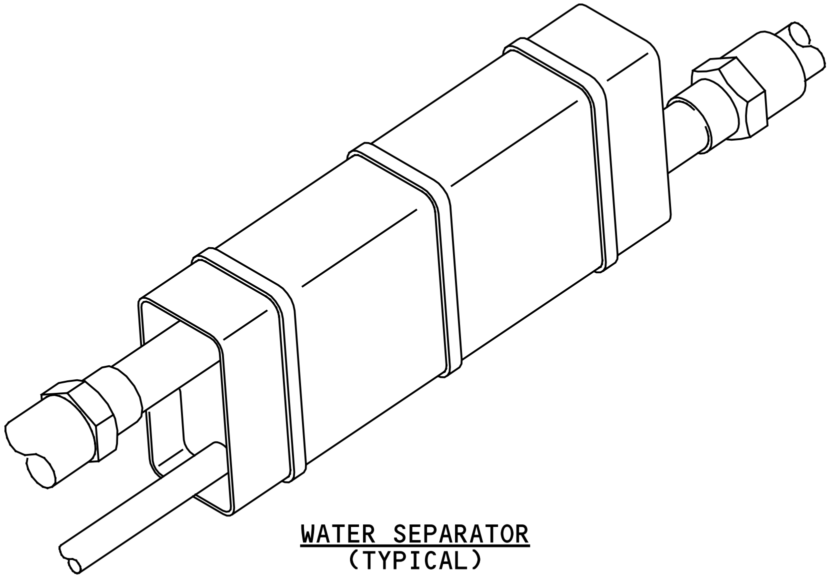
LOWER CARGO COMPARTMENT SMOKE DETECTION - IN-LINE HEATER AND CONTROLLER

LOWER CARGO COMPARTMENT SMOKE DETECTION - WATER SEPARATOR

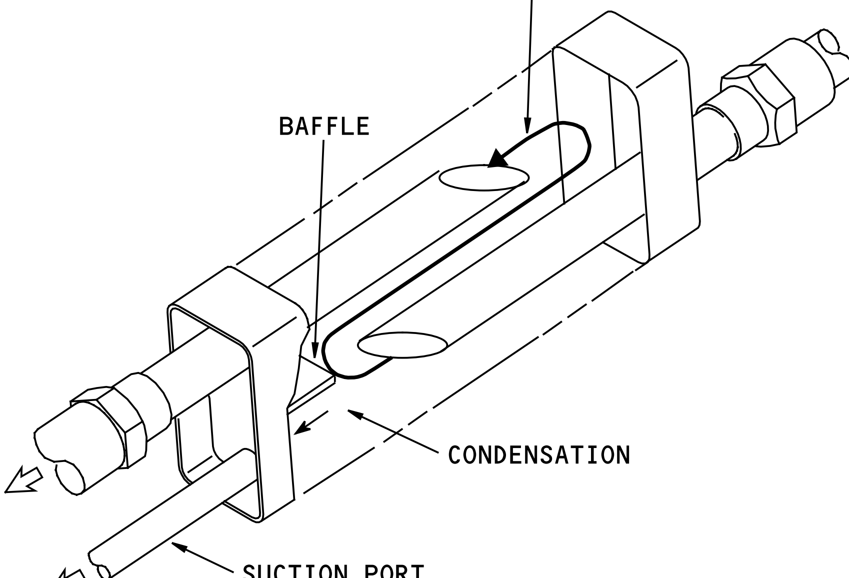
General

The water separator removes condensation from the air that flows to the smoke detector. The air that comes in changes direction quickly at the suction port. This lets condensation collect for removal.

The water separator is a sealed unit. It has no moving parts.



WATER SEPARATOR
(TYPICAL)



WATER SEPARATOR
(INNER VIEW)

26-16-00-013 Rev 0 01/06/1997

LOWER CARGO COMPARTMENT SMOKE DETECTION - WATER SEPARATOR

THIS PAGE INTENTIONALLY LEFT BLANK

LOWER CARGO COMPARTMENT SMOKE DETECTION - FUNCTIONAL DESCRIPTION - CIRCUIT

General

The circuit for the forward lower cargo compartment is shown. The circuit for the aft lower cargo compartment operates the same. The left and right main ac buses supply power to the smoke detectors. The smoke detector gets inputs from these:

- Left ECS miscellaneous card (ECSMC)
- Weight-on-wheels (WOW) card
- Overhead panel ARINC 629 system (OPAS)
- Proximity sensor electronics unit (PSEU) 2
- AIMS.

The smoke detector sends data to these:

- Overhead panel ARINC 629 system (OPAS)
- Warning electronics system (WES)
- AIMS.

Electrical Power

Each channel continuously monitors the electrical power input to the opposite channel. If power to one channel is not within limits, the smoke detector sends a fault message to AIMS. This condition shows on the fire protection maintenance page.

System Tests

The smoke detectors have built-in-test equipment (BITE). BITE does a power-on test automatically when it gets electrical power, and a periodic test regularly during operation.

You can do a test (initiated test) with the fire/overheat test switch or the maintenance access terminal. The test switch sends a signal through the overhead panel cardfile and ASG cards to the smoke detector. BITE does a test of the system. When you use the MAT, AIMS tells the smoke detector to do a power-up BIT sequence.

Smoke Detection

If there is smoke in the cargo compartment, the detector sends an alarm signal through the ARINC 429 bus to the ASG cards. The ASG cards send the alarm signal through the systems ARINC 629 buses to these systems and components:

- OPAS
- WES
- AIMS.

OPAS makes a ground to turn on the cargo fire warning light. The WES turns on the master warning lights and fire aural warning. The AIMS causes a warning message.

Ground Operation

The cargo smoke detector fans do not operate during cargo handling. This keeps contamination of the detectors to a minimum. The fans in the forward and aft compartments do not operate when all these conditions occur:

- The airplane is on the ground
- The forward cargo door is open
- The aft or bulk cargo door is open
- The right engine is not operating.

The WOW card supplies the air/ground signal. The proximity sensor electronics unit (PSEU 2) supplies the cargo door open signal. AIMS supplies the engine operating/not operating signal.

If the smoke detector does not receive the expected inputs, it continues to operate with these default values:

- Air
- Cargo doors closed
- Right engine operating.

Airflow Sensing

The smoke detector airflow sensors make allowance for changes in air density. The detector uses air temperature and pressure data to do this. Cargo compartment temperature data comes from the left ECSMC. Cabin altitude comes from the AIMS.

If the smoke detector does not receive the expected inputs, it continues to operate with these default values:

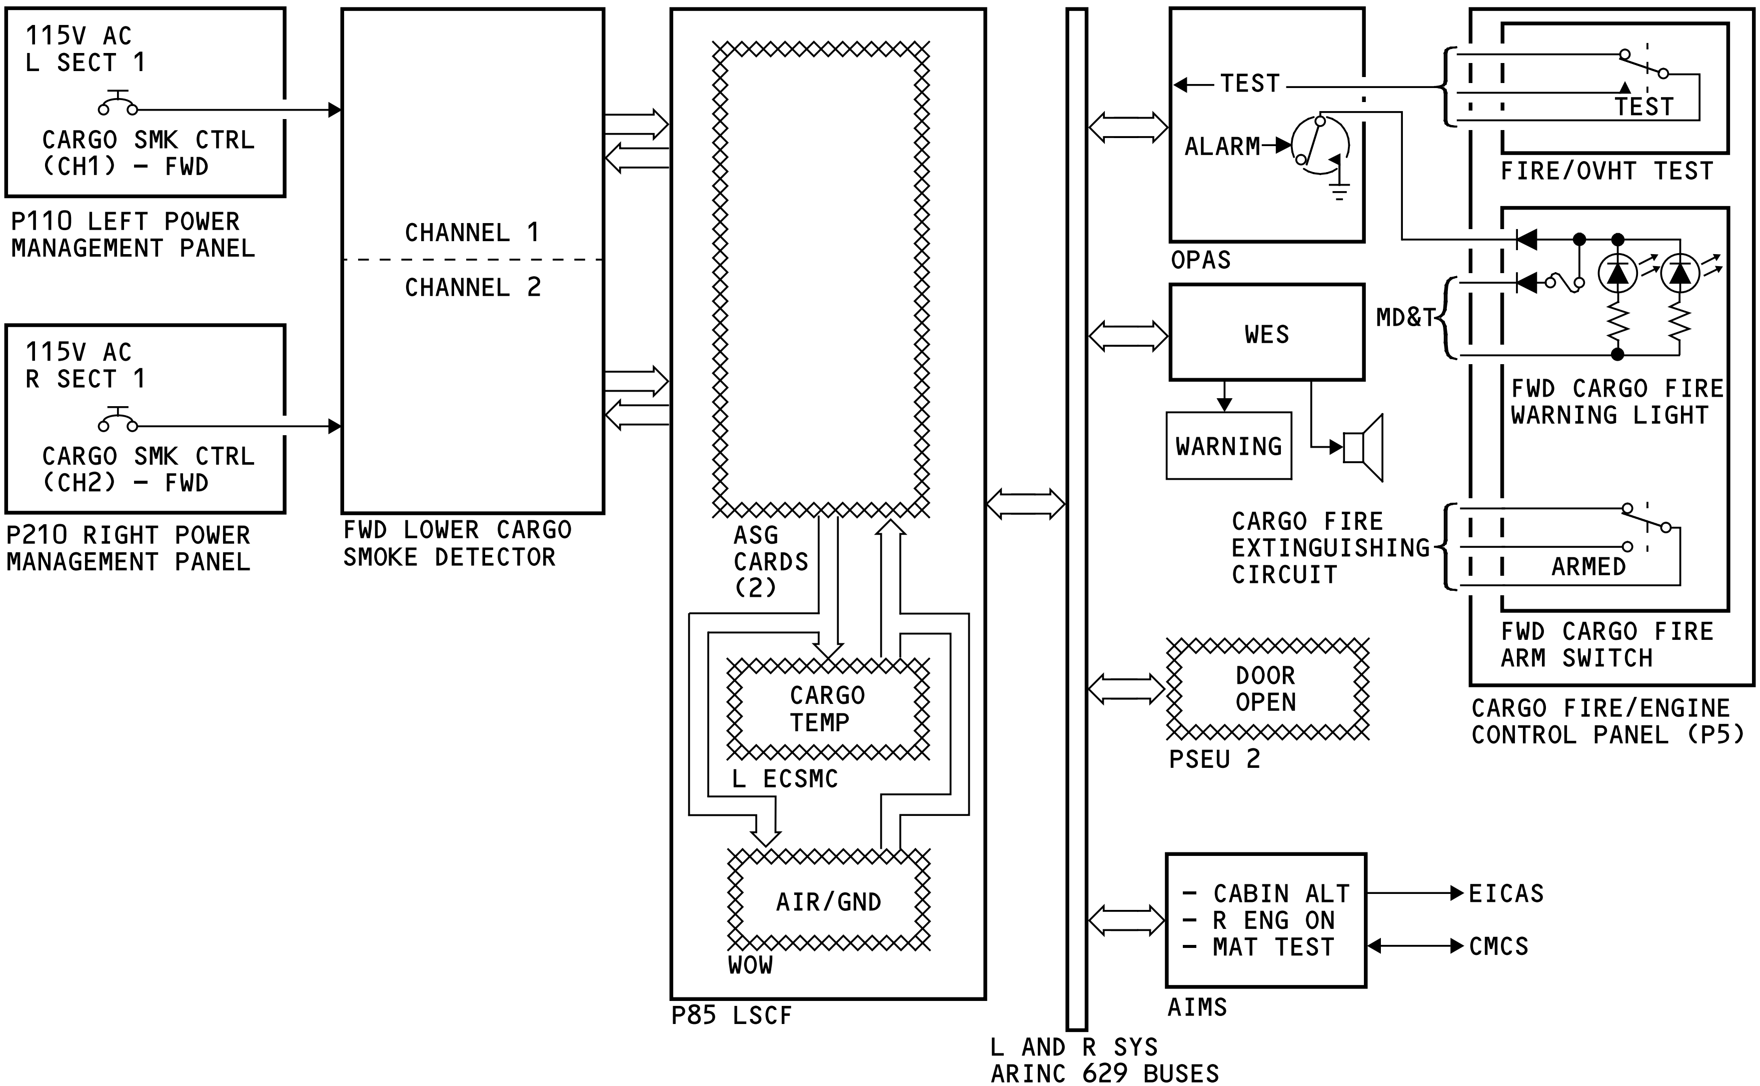
- Cabin altitude 8000 feet
- Cargo compartment temperature 40 degrees F.

Training Information Point

The CMCS shows status and maintenance messages for the smoke detectors. A fire protection maintenance page shows information about the system.

The cargo smoke detectors keep fault data in memory. You can use the MAT to access this fault data. You can also use the MAT to access smoke detector hardware and software part numbers.

Use the CMCS download function to load new software into the smoke detector.



26-16-00-008 Rev 3 07/08/1997

LOWER CARGO COMPARTMENT SMOKE DETECTION - FUNCTIONAL DESCRIPTION - CIRCUIT

LOWER CARGO COMPARTMENT SMOKE DETECTION - INDICATIONS

General

Operation of the lower cargo compartment smoke detection system is automatic and does not need crew action. The system operates when the main ac buses have power.

Cargo Smoke Indication

If there is smoke in a lower cargo compartment, these indications occur in the flight deck:

- A cargo fire EICAS warning message shows
- The master warning lights come on
- The fire warning aural operates
- The cargo fire warning light comes on.

The master warning lights and fire warning aural do not operate during part of the takeoff if there is a fire.

Training Information Point

If the smoke detector fails while it supplies a fire alarm signal, the alarm signal latches. This condition occurs if soot from a cargo fire causes contamination of the smoke detector optics.

All these conditions must be true to make the alarm signal stop:

- Airplane is on the ground
- Related cargo fire arm switch is off
- There is no cargo smoke
- There is no failure condition.

You can use the fire/overheat test switch or the MAT to do a test of the system at any time. Test results show on the primary display system.

LOWER CARGO COMPARTMENT SMOKE DETECTION - INDICATIONS

LOWER CARGO COMPARTMENT SMOKE DETECTION - TRAINING INFORMATION POINTS

Maintenance Page

Operational status of the cargo smoke detection system shows on the fire protection maintenance page.

Advisory, Status, And Maintenance Messages

Advisory, status, or maintenance messages show for these fault conditions:

- Low airflow at the zone 1, 2, or 3 air inlet port (blocked air sampling tube)
- Too much airflow at the zone 1, 2, 3, or 4 air inlet port (air sampling tubes not connected to ports 1, 2, 3 or port 4 not capped)
- Faulty air flow sensor
- Smoke detector optic contamination
- Smoke detector internal failure
- Fan failure
- Power source failure
- ARINC 429 bus failure
- Program pin parity error
- Software not compatible with hardware.

LOWER CARGO COMPARTMENT SMOKE DETECTION - SYSTEM TESTS

LOWER CARGO FIRE EXTINGUISHING - INTRODUCTION

Purpose

The lower cargo fire extinguishing system extinguishes fires in the forward or aft lower cargo compartments.

General Description

The lower cargo fire extinguishing system has these components:

- Three fire extinguishing metered bottles
- A filter regulator
- Fwd and aft in-line pressure switches
- Two flow valves
- Two fire extinguishing dump bottles
- Eight discharge nozzles.

The five fire extinguishing bottles contain halon 1301 fire extinguishing agent pressurized with nitrogen. Tubing connects the bottles to discharge nozzles in the cargo compartment ceilings. Flow valves send the halon to the forward or aft compartment.

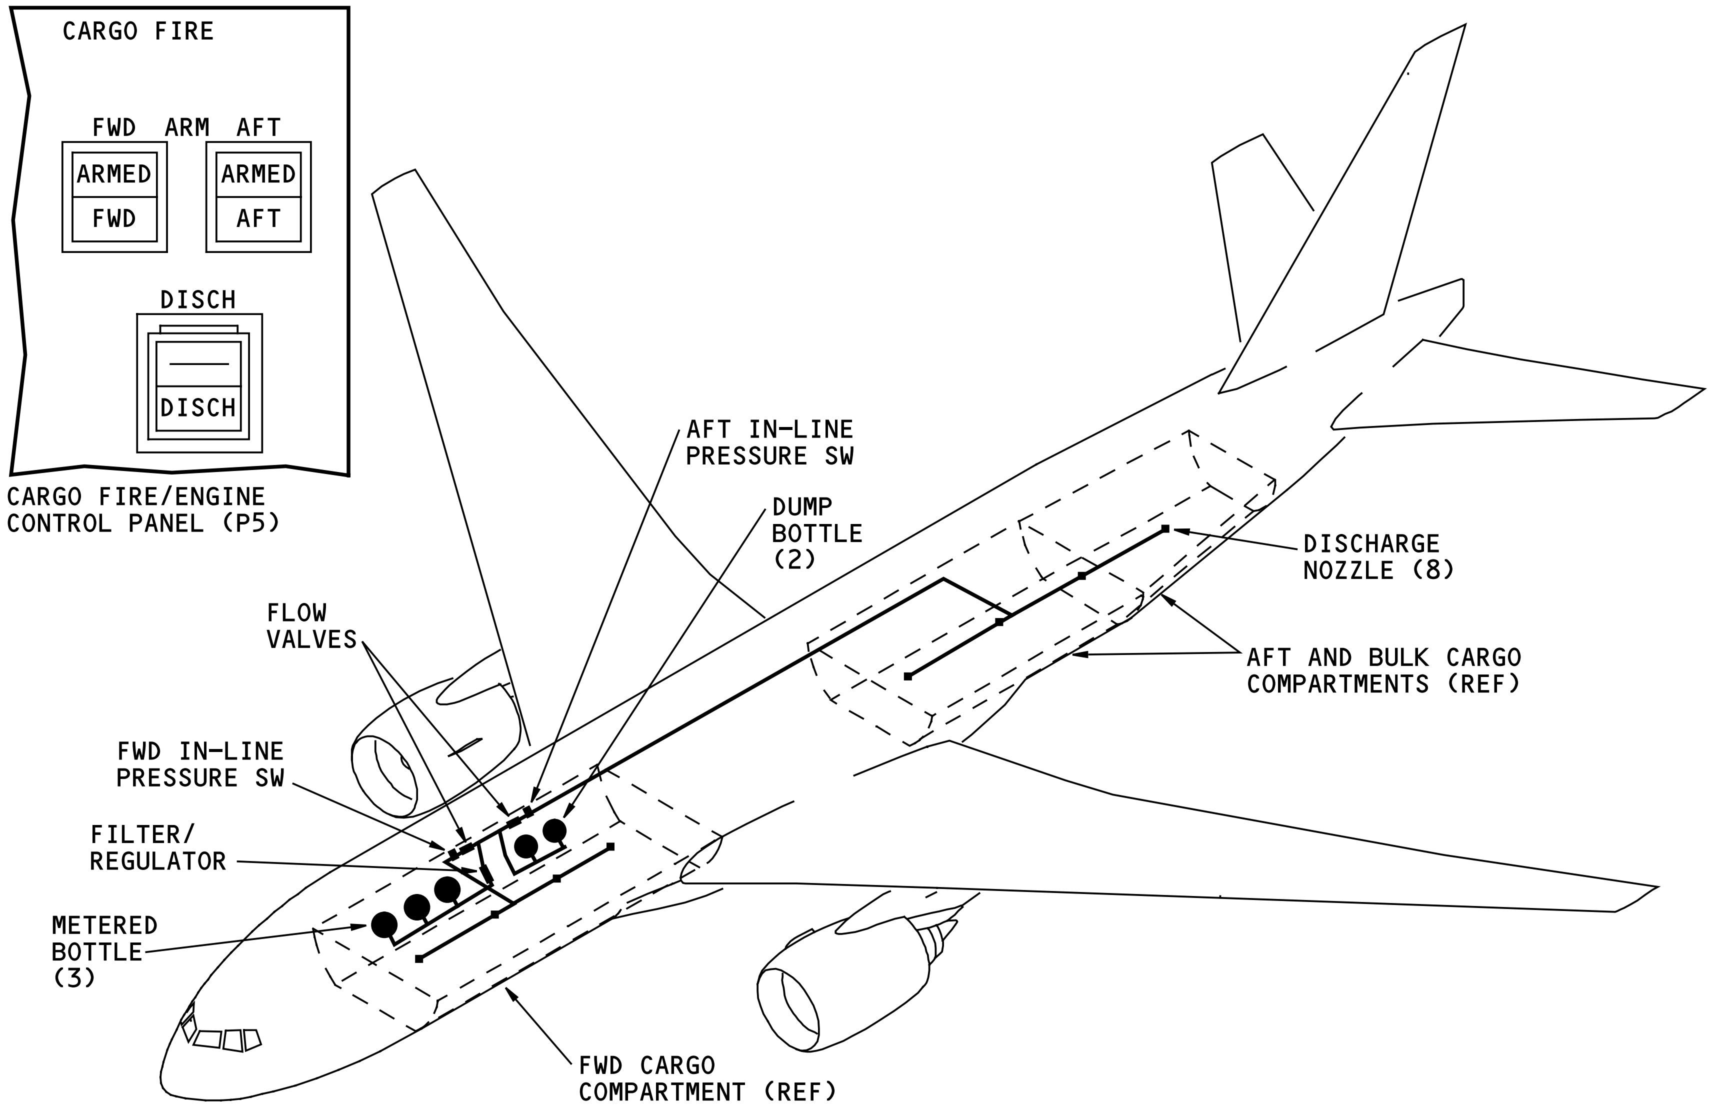
In the flight deck, cargo fire arming switches set the discharge to the forward or aft compartment. The discharge switch starts the fire bottle discharge sequence. A line pressure switch turns on the DISCH indication to show that the discharge sequence has started.

The two dump bottles discharge into the selected compartment as soon as you push the discharge switch. The bottles discharge quickly to extinguish the fire.

After a time delay, the metered bottles discharge slowly and at a controlled rate through the filter regulator. Halon from the metered bottles replaces the extinguishing agent leakage. This keeps the correct concentration of extinguishing agent in the cargo compartment to make sure the fire stays out.

The metered bottles operate differently in flight and on the ground. If the airplane is on the ground when you push the discharge switch, one metered bottle starts to discharge after a twenty minute time delay. The discharge continues for an hour, until the bottle is empty. The other metered bottles do not discharge.

If you push the discharge switch in flight, none of the metered bottles start to discharge immediately. If the airplane lands in less than twenty minutes, one metered bottle starts to discharge when the airplane lands. The other metered bottles do not discharge. If the airplane does not land in twenty minutes, all three metered bottles start to discharge twenty minutes after you push the discharge switch. The discharge continues for three hours, until the bottles are empty.



LOWER CARGO FIRE EXTINGUISHING - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

LOWER CARGO FIRE EXTINGUISHING - INTERFACES

General

The lower cargo fire extinguishing system has these interfaces:

- Cargo fire/engine control panel (P5)
- Overhead panel ARINC 629 system (OPAS)
- AIMS
- ELMS
- Cabin temperature controllers
- Left and right ASCPCs
- Left and right ECS miscellaneous cards.

Cargo Fire Extinguishing System Interfaces

These are the results when you push the FWD or AFT arm switches on the P5 panel:

- The circuit for the forward or aft flow valve arms
- The circuit for the two dump bottles arms
- The switch gives OPAS a FWD or AFT ARMED signal
- OPAS transmits the ARMED signal on the 629 buses

These are the results when you push the DISCH switch on the P5 panel:

- The selected flow valve opens
- The dump bottles discharge
- The DISCH switch gives the OPAS a DISCH signal
- OPAS transmits the DISCH signal on the 629 buses
- The in-line pressure switch turns on the DISCH light on the P5 overhead panel
- ELMS discharges the metered bottles after a delay

As the pressure in each bottle decreases, a pressure switch on the bottle sends a signal to the ELMS. The ELMS sends this data to the AIMS. The AIMS shows advisory and status messages to show that the bottle pressure is low.

Environmental Control System Interfaces

These are the results in the environmental control system when OPAS transmits the FWD ARMED signal:

- Lower recirculation fans - off
- Air conditioning packs - flow schedule 2
- Pressurization air outflow - 50 percent forward, 50 percent aft
- Equipment cooling system - override mode
- Galley chiller boost fan - off
- Equipment cooling vent valve - closed.

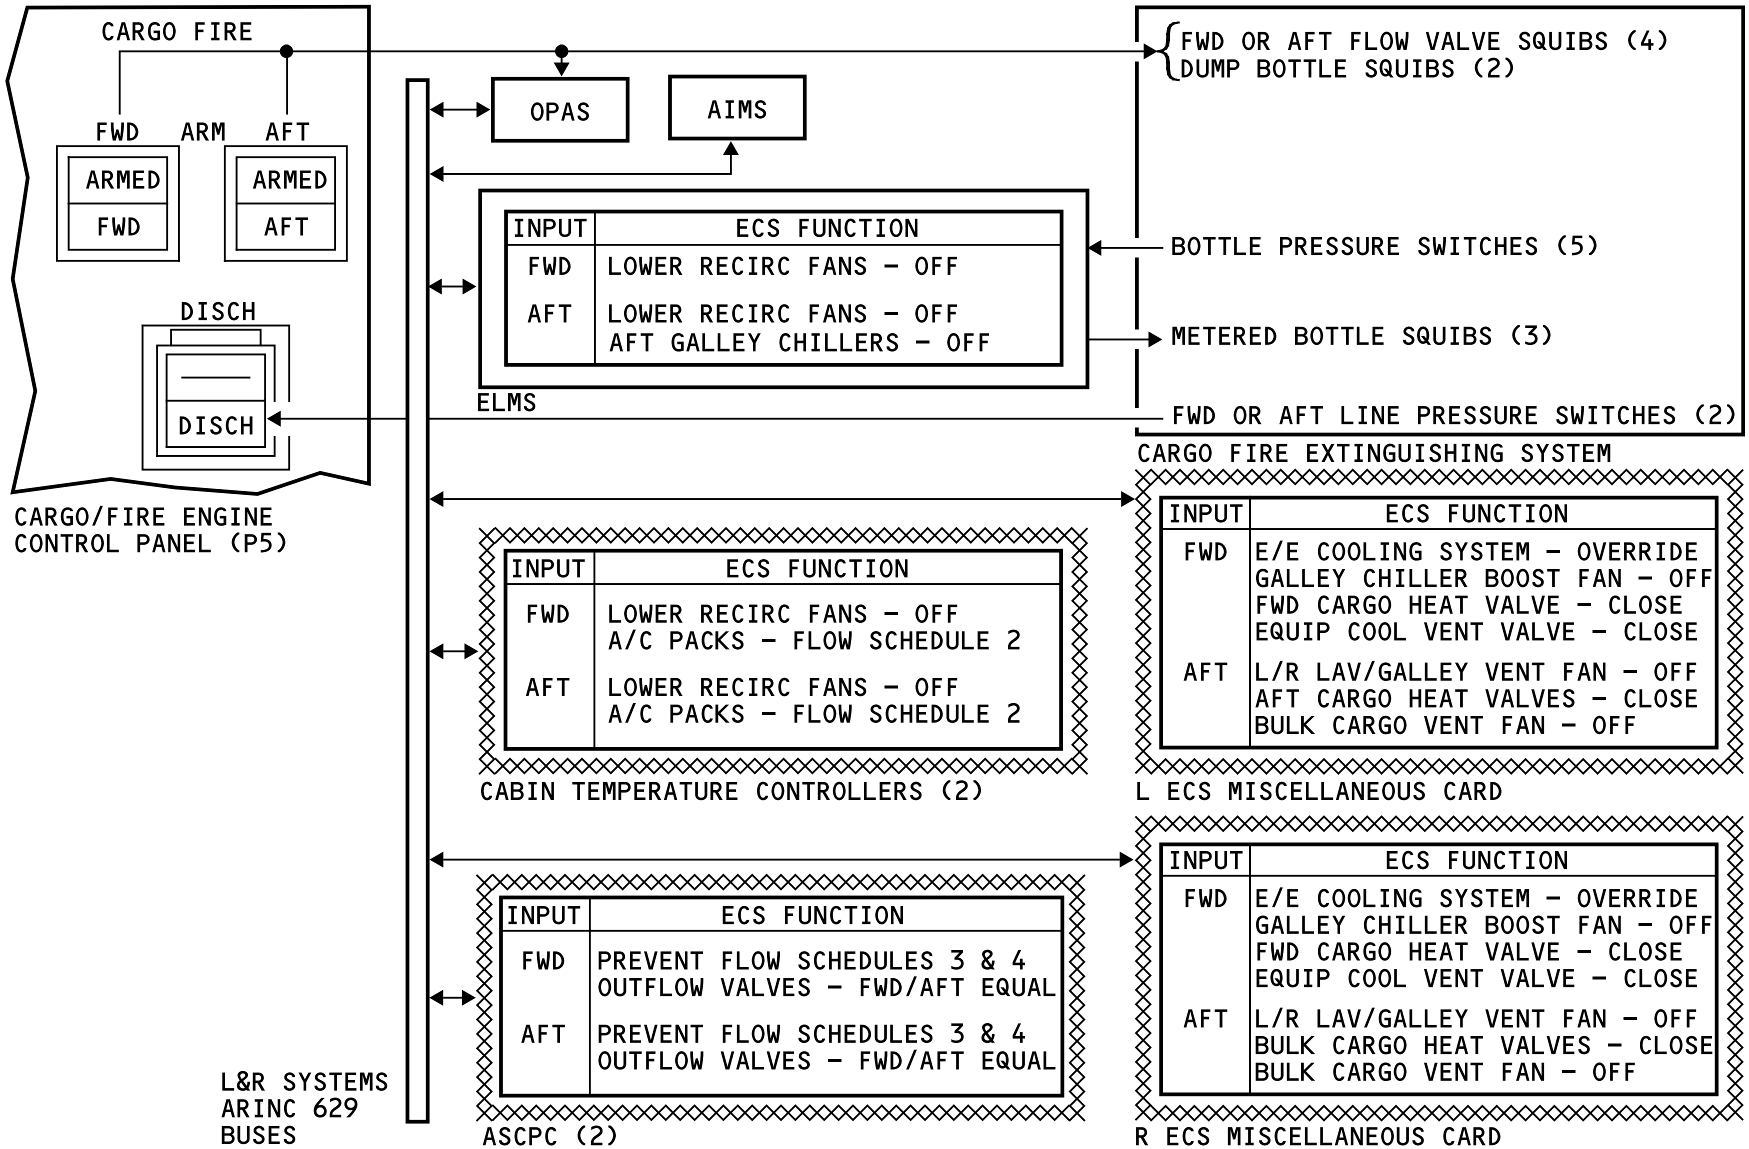
These are the results in the environmental system when OPAS transmits the AFT ARMED signal:

- Lower recirculation fans - off
- Air conditioning packs - flow schedule 2
- Pressurization air outflow - 50 percent forward, 50 percent aft
- Lav/galley vent fans - off
- Aft cargo heat valves - closed
- Bulk cargo vent fan - off
- Bulk cargo heat valves - closed.

These functions change the air flow around and through the cargo compartments. This keeps the fire

LOWER CARGO FIRE EXTINGUISHING - INTERFACES

extinguishing agent in the cargo compartment and keeps smoke out of the passenger compartment and flight deck.



LOWER CARGO FIRE EXTINGUISHING - INTERFACES

LOWER CARGO FIRE EXTINGUISHING - COMPONENT LOCATIONS

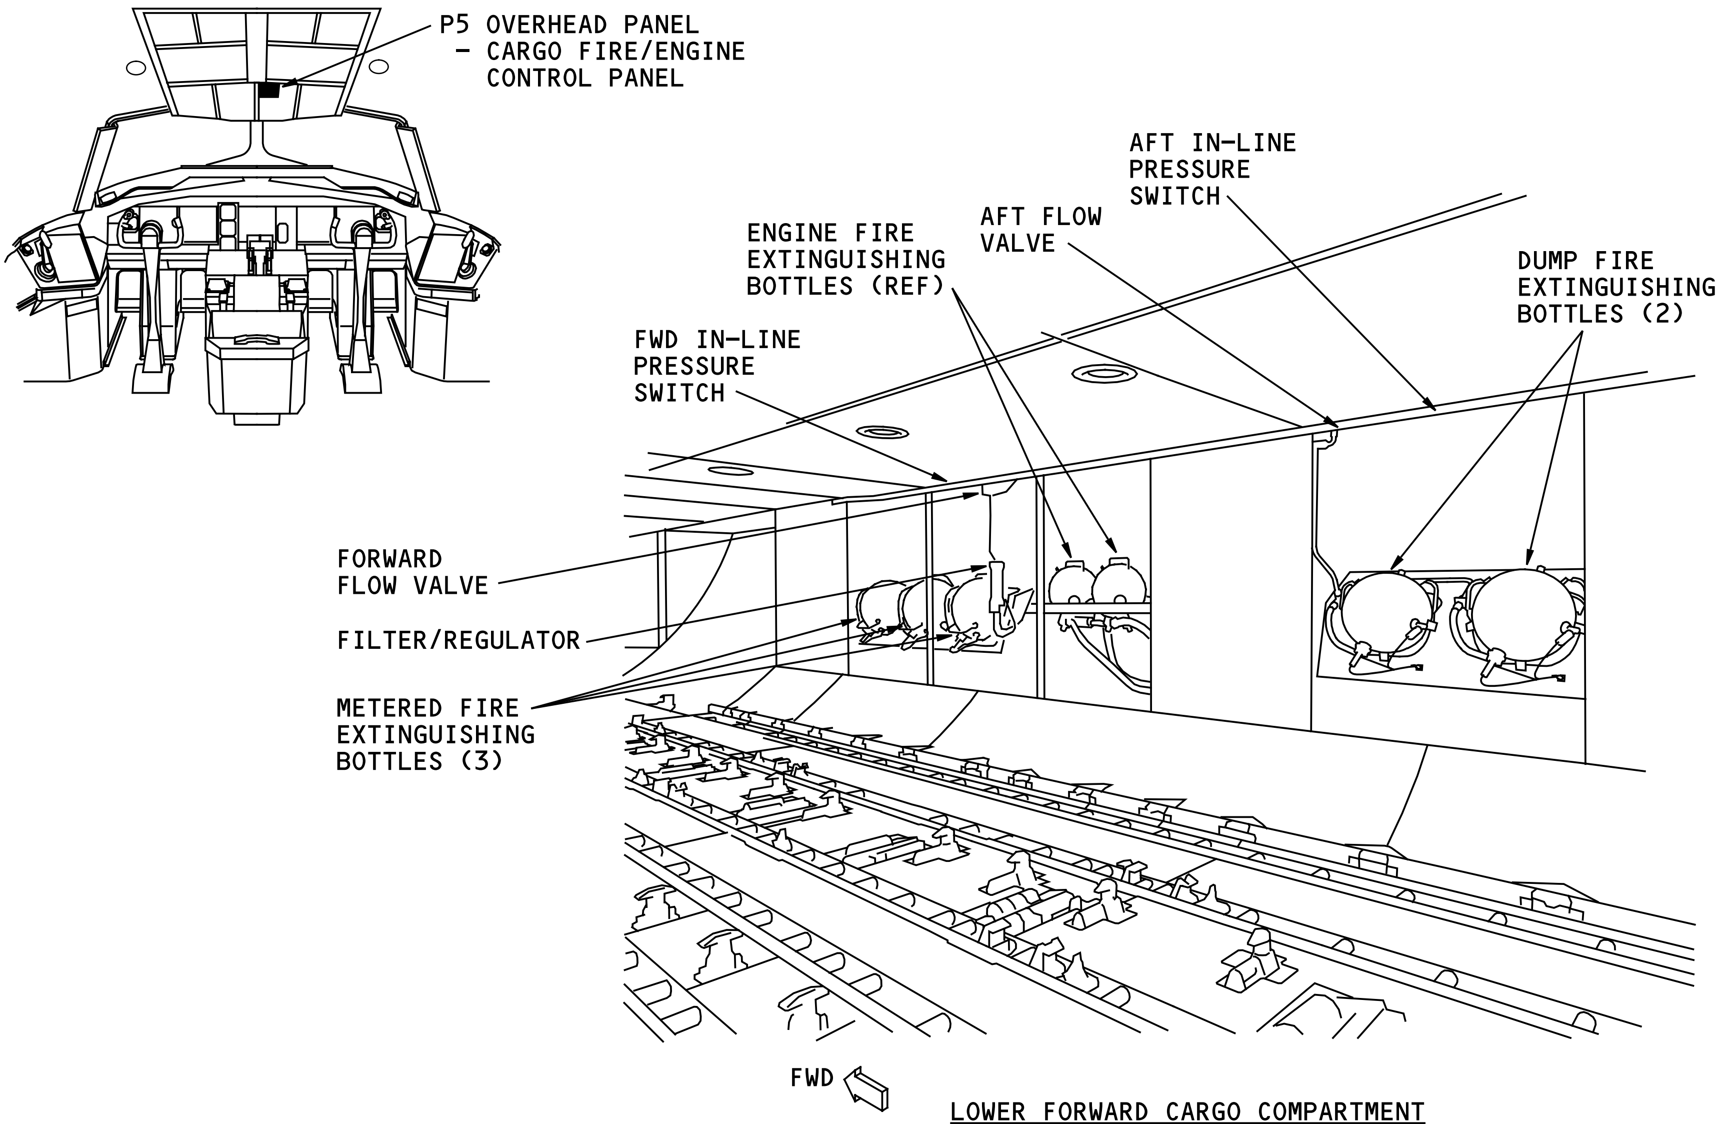
Flight Deck

The cargo fire/engine control panel is in the flight deck on the P5 overhead panel.

Lower Forward Cargo Compartment

These components of the lower cargo fire extinguishing system are in the lower forward cargo compartment:

- Filter/regulator
- Metered fire extinguishing bottles
- Forward flow valve
- Forward in-line pressure switch
- Aft flow valve
- Aft in-line pressure switch
- Dump fire extinguishing bottles.



LOWER CARGO FIRE EXTINGUISHING - COMPONENT LOCATIONS

LOWER CARGO FIRE EXTINGUISHING - LOWER CARGO FIRE EXTINGUISHING BOTTLES - INTRODUCTION

Purpose

The lower cargo fire extinguishing bottles contain the fire extinguishing agent.

Location

The bottles are on the right side of the forward lower cargo compartment, behind the cargo compartment lining. Release the snaps then roll up the lining for access.

Physical Description

The bottles contain halon 1301 fire extinguishing agent pressurized with nitrogen. The metered bottles and dump bottles are different sizes. The metered bottles weigh approximately 80 lb (36 kg). The dump bottles weigh approximately 65 lb (30 kg). The three metered bottles are identical. The two dump bottles are identical.

The fire extinguishing bottles have these components:

- Identification plate
- Safety relief and fill port
- Handles
- Pressure switch
- Mounting brackets
- Discharge assembly
- Warning Label.

Indications

Status messages, maintenance messages, and a fire protection maintenance page show if the bottle pressure is low.

Functional Description

The discharge assembly has an explosive squib which releases the halon through the discharge port.

The pressure switch monitors the pressure inside the bottle and is normally open. When the bottle pressure decreases, the switch closes and sends a signal for indication.

The safety relief and fill port is a single fitting on the bottle. The safety relief opens to make sure the bottle does not break if internal pressure is too high.

LOWER CARGO FIRE EXTINGUISHING - LOWER CARGO FIRE EXTINGUISHING BOTTLES - INTRODUCTION

LOWER CARGO FIRE EXTINGUISHING - FIRE EXTINGUISHING BOTTLES - TRAINING INFORMATION POINTS

Bottle Weight

You cannot fill an empty bottle on the airplane. You must replace the bottle. Compare the weight of the new bottle with the weight on the bottle identification plate. This prevents installation of a bottle which is not full.

Removal/Installation

WARNING: BE CAREFUL WHEN YOU DISCONNECT THE HOSE ASSEMBLY FROM THE FIRE EXTINGUISHER BOTTLE. IF THE FIRE EXTINGUISHING BOTTLE DISCHARGED, THE TUBING MAY BE PRESSURIZED. WHEN YOU RELEASE THE PRESSURE IN THE TUBING YOU CAN CAUSE INJURY TO PERSONS.

WARNING: DO NOT TOUCH THE SQUIB BEFORE YOU DO THE PROCEDURE FOR DEVICES THAT ARE SENSITIVE TO ELECTROSTATIC DISCHARGE. ELECTROSTATIC DISCHARGE CAN CAUSE THE FIRE BOTTLE TO RELEASE ITS CONTENTS SUDDENLY AND CAUSE INJURY TO PERSONS AND DAMAGE TO EQUIPMENT.

WARNING: PUT A PROTECTIVE COVER ON THE SQUIB. IF YOU DO NOT PUT A PROTECTIVE COVER ON THE SQUIB, THE FIRE EXTINGUISHING BOTTLE CAN RELEASE ITS CONTENTS SUDDENLY AND CAUSE INJURY TO PERSONS.

WARNING: BE CAREFUL WHEN YOU MOVE THE FIRE EXTINGUISHING BOTTLE. THE FIRE EXTINGUISHING BOTTLE IS HIGHLY PRESSURIZED AND HAS AN EXPLOSIVE CARTRIDGE AS A COMPONENT. ACCIDENTAL DISCHARGE OF THE FIRE EXTINGUISHING BOTTLE CAN CAUSE INJURY TO PERSONS OR DAMAGE TO EQUIPMENT.

The discharge tubing and electrical wires are not long enough to connect to the wrong bottle. The electrical connectors for the squib and the pressure switch are different. You cannot connect the airplane wiring to the wrong device.

A platform is available to stand on while you remove and install the fire bottles.

Tests

You must remove the fire extinguishing bottle every five years for a hydrostatic test. The date of the last test is on the identification plate.

Operate the pressure switch with a hex wrench to do a test of the pressure switch and indicating circuit. If the circuit operates properly, bottle discharge indications show in the flight deck when you operate the pressure switch.

LOWER CARGO FIRE EXTINGUISHING - FIRE EXTINGUISHING BOTTLES - TRAINING INFORMATION POINTS

LOWER CARGO FIRE EXTINGUISHING - IN-LINE PRESSURE SWITCH

Purpose

The in-line pressure switch gives a flight deck indication when there is pressure in the discharge line downstream of a flow valve. The cargo fire discharge light comes on to show that the fire extinguishing system operates. A maintenance message also shows.

Physical Description

The in-line pressure switch has these parts:

- Electrical connector
- Reset button
- Inlet fitting.

A bolt and clamp attaches the switch to the airplane structure.

Location

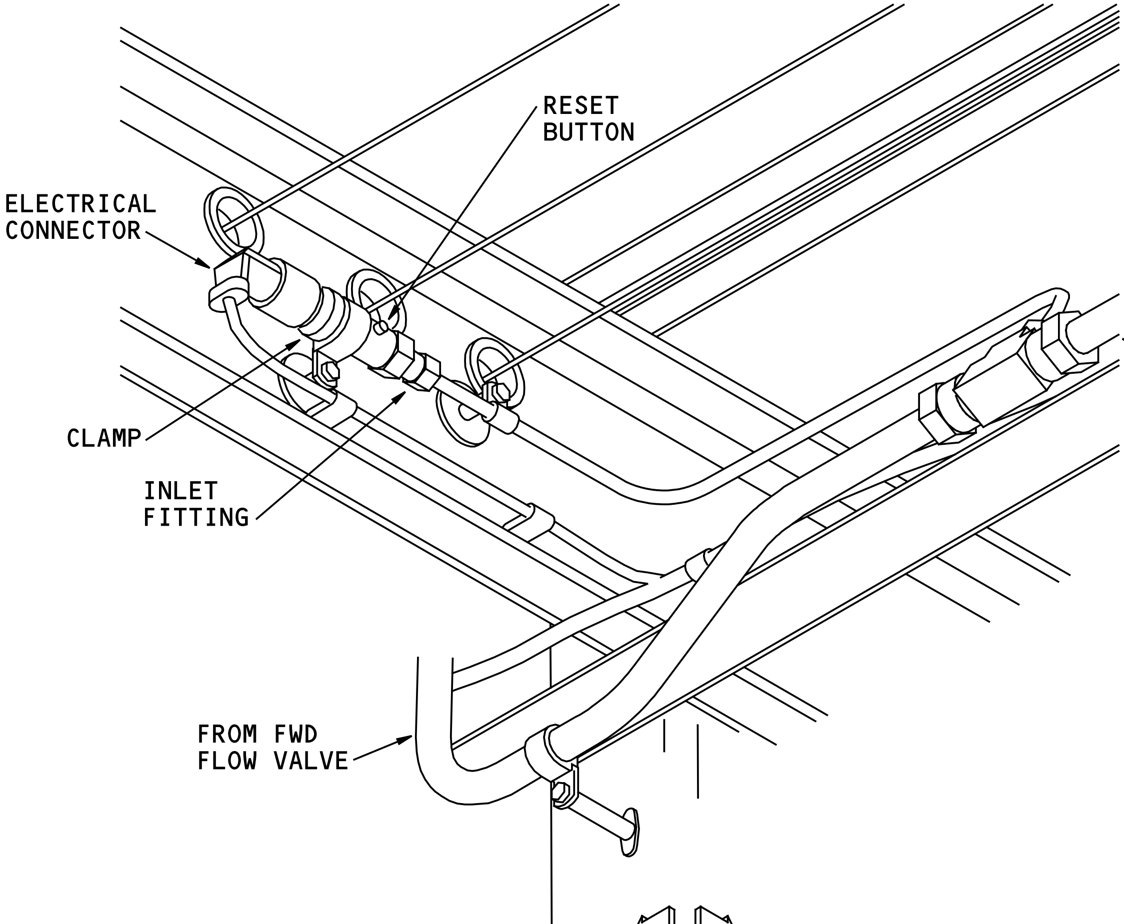
The forward in-line pressure switch is just forward of the forward flow valve. The aft in-line pressure switch is just aft of the aft flow valve. Access is through the lower cargo fire extinguishing bottle access panels.

Functional Description

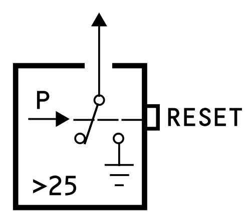
The switch is normally open. When halon pressurizes the discharge line, the switch closes. Indicating circuits give the flight deck indications. The switch latches in the closed position.

Training Information Point

The in-line pressure switch latches closed when the fire extinguishing system operates. A maintenance message and the fire protection maintenance page show this condition. Use the reset button to set the switch contacts open.



FWD IN-LINE PRESSURE SWITCH
(AFT INSTALLATION SIMILAR)



IN-LINE PRESSURE
SWITCH CIRCUIT

26-23-00-007 Rev 0

LOWER CARGO FIRE EXTINGUISHING - IN-LINE PRESSURE SWITCH

LOWER CARGO FIRE EXTINGUISHING - FILTER/REGULATOR

Purpose

The filter/regulator causes a slow and continuous flow of halon from the metered bottles into the cargo compartment to keep the fire out.

Physical Description

The filter regulator has these parts:

- Inlet port
- Outlet port
- Filter/drier element (internal)
- Regulator (internal).

Location

The filter regulator is near the metered bottles, behind the lining of the lower forward cargo compartment. Access is through the metered bottle access panel.

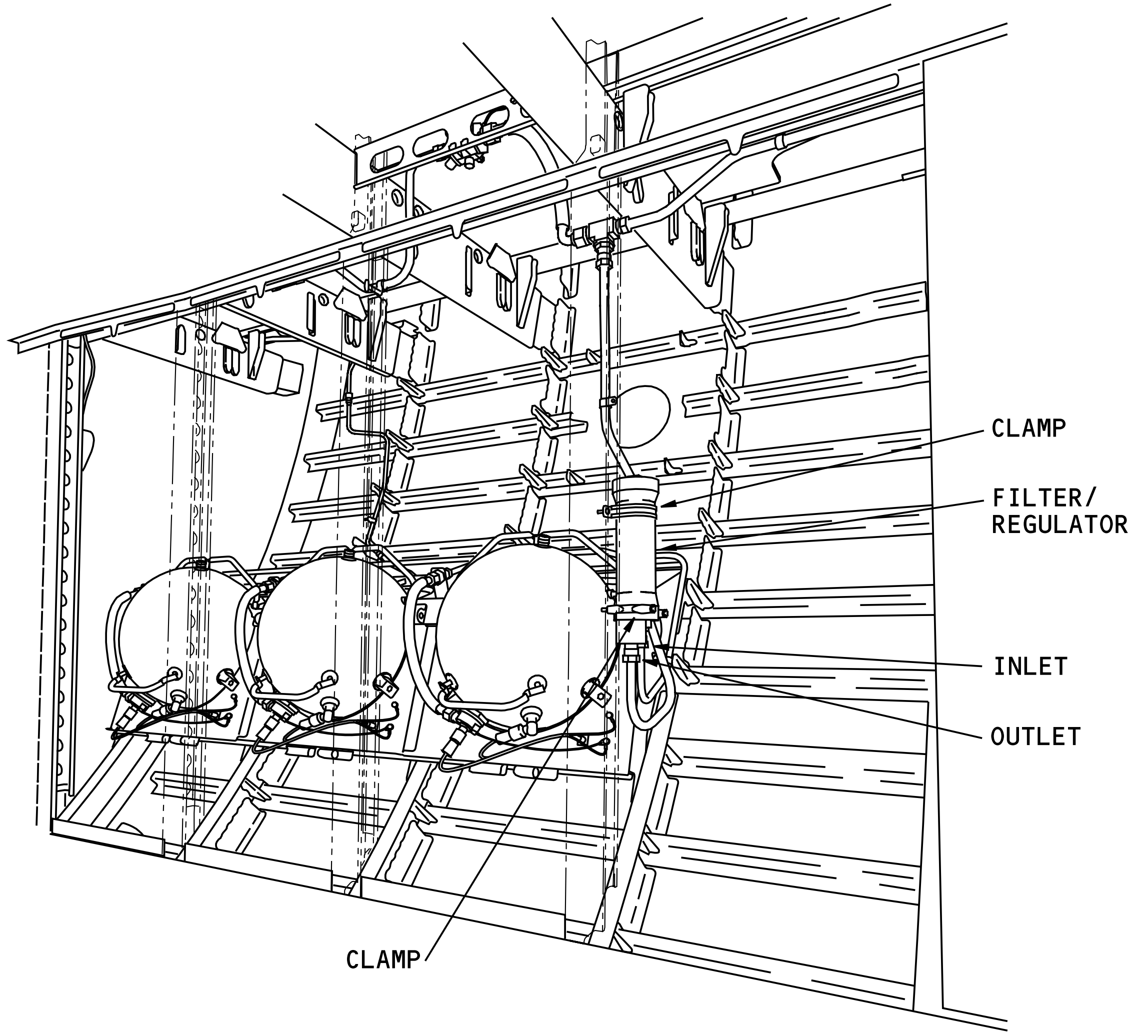
Functional Description

From the inlet port, halon goes through the filter/drier element, then through the regulator to the outlet port. The filter/drier makes sure no contamination goes to the regulator. The regulator controls the flow of halon to the discharge nozzles.

Training Information Point

The filter/regulator is internally sealed at the inlet and outlet. Pressurized halon opens the seals when the fire extinguishing system operates.

Replace the filter/regulator after the fire extinguishing system operates. The inlet and outlet are different sizes so you cannot install it incorrectly.



METERED BOTTLES

26-23-00-008 Rev 0

LOWER CARGO FIRE EXTINGUISHING - FILTER/REGULATOR

LOWER CARGO FIRE EXTINGUISHING - FLOW VALVE

Purpose

The forward flow valve lets fire extinguishing agent from the bottles go to the forward cargo compartment. The aft flow valve lets fire extinguishing agent from the bottles go to the aft cargo compartment.

Physical Description

The flow valve has these parts:

- Two protective caps
- Two cap rests
- Inlet port
- Diaphragm
- Two squibs
- Outlet port
- Debris screen.

Location

The two flow valves are behind the right sidewall lining of the forward cargo compartment, near the ceiling. The forward flow valve is above the metered bottles. The aft flow valve is above the dump bottles. Access is through the fire bottle access panels.

Functional Description

The inlet port connects to the fire extinguishing bottles. The outlet port connects to the discharge line. The valve is normally closed by the diaphragm between the inlet and outlet.

Two explosive squibs are adjacent to the diaphragm. The squibs fire when you operate the related fire extinguishing controls. The explosion tears the diaphragm and lets halon go through the valve. The debris screen catches pieces of the disc and squibs to prevent contamination of downstream components. Only one squib is necessary to tear the diaphragm. Two squibs are used to make sure the valve opens.

Training Information Point

Replace the correct flow valve after the fire extinguishing system operates. Different size inlet and outlet ports prevent incorrect installation. The two squibs have the same purpose. Connect the airplane wiring to the squibs in any sequence. The forward and aft flow valves are interchangeable.

WARNING: INSTALL THE PROTECTIVE CAPS ON THE ELECTRICAL CONNECTORS ANY TIME THE AIRPLANE WIRING IS NOT CONNECTED. ACCIDENTAL DISCHARGE OF THE SQUIBS CAN CAUSE INJURY.

26-23-00-009 Rev 1 07/09/1997

LOWER CARGO FIRE EXTINGUISHING - FLOW VALVE

LOWER CARGO FIRE EXTINGUISHING - FUNCTIONAL DESCRIPTION - FLOW

General

An explosive squib inside the discharge assembly releases halon from the bottles. Flow valves, also operated by explosive squibs, let the halon go to the forward or aft cargo compartment. Flight and ground operation are different.

Operation - Flight

This is what happens when you operate the controls for a lower cargo fire:

- The squibs for bottles 1A and 1B fire
- The squibs in the selected flow valve fire
- A twenty-minute timer in the ELMS starts.

The squib explosion opens the diaphragms in the dump bottles and in the selected flow valve. Nitrogen pressure pushes the halon from the bottles, through the open flow valve, and into the selected cargo compartment. Pressure in the discharge line operates the in-line pressure switch. This switch gives a flight deck indication of bottle discharge.

Pressure switches monitor the pressure in the dump bottles. When the pressure decreases, the switches causes low pressure indications to show in the flight deck.

After twenty minutes, the ELMS fires the squibs for bottles 2A, 2B, and 2C. Halon from the bottles goes through the filter/regulator and into the selected cargo compartment. The filter/regulator causes a slow and continuous flow of halon into the cargo compartment to keep the fire out.

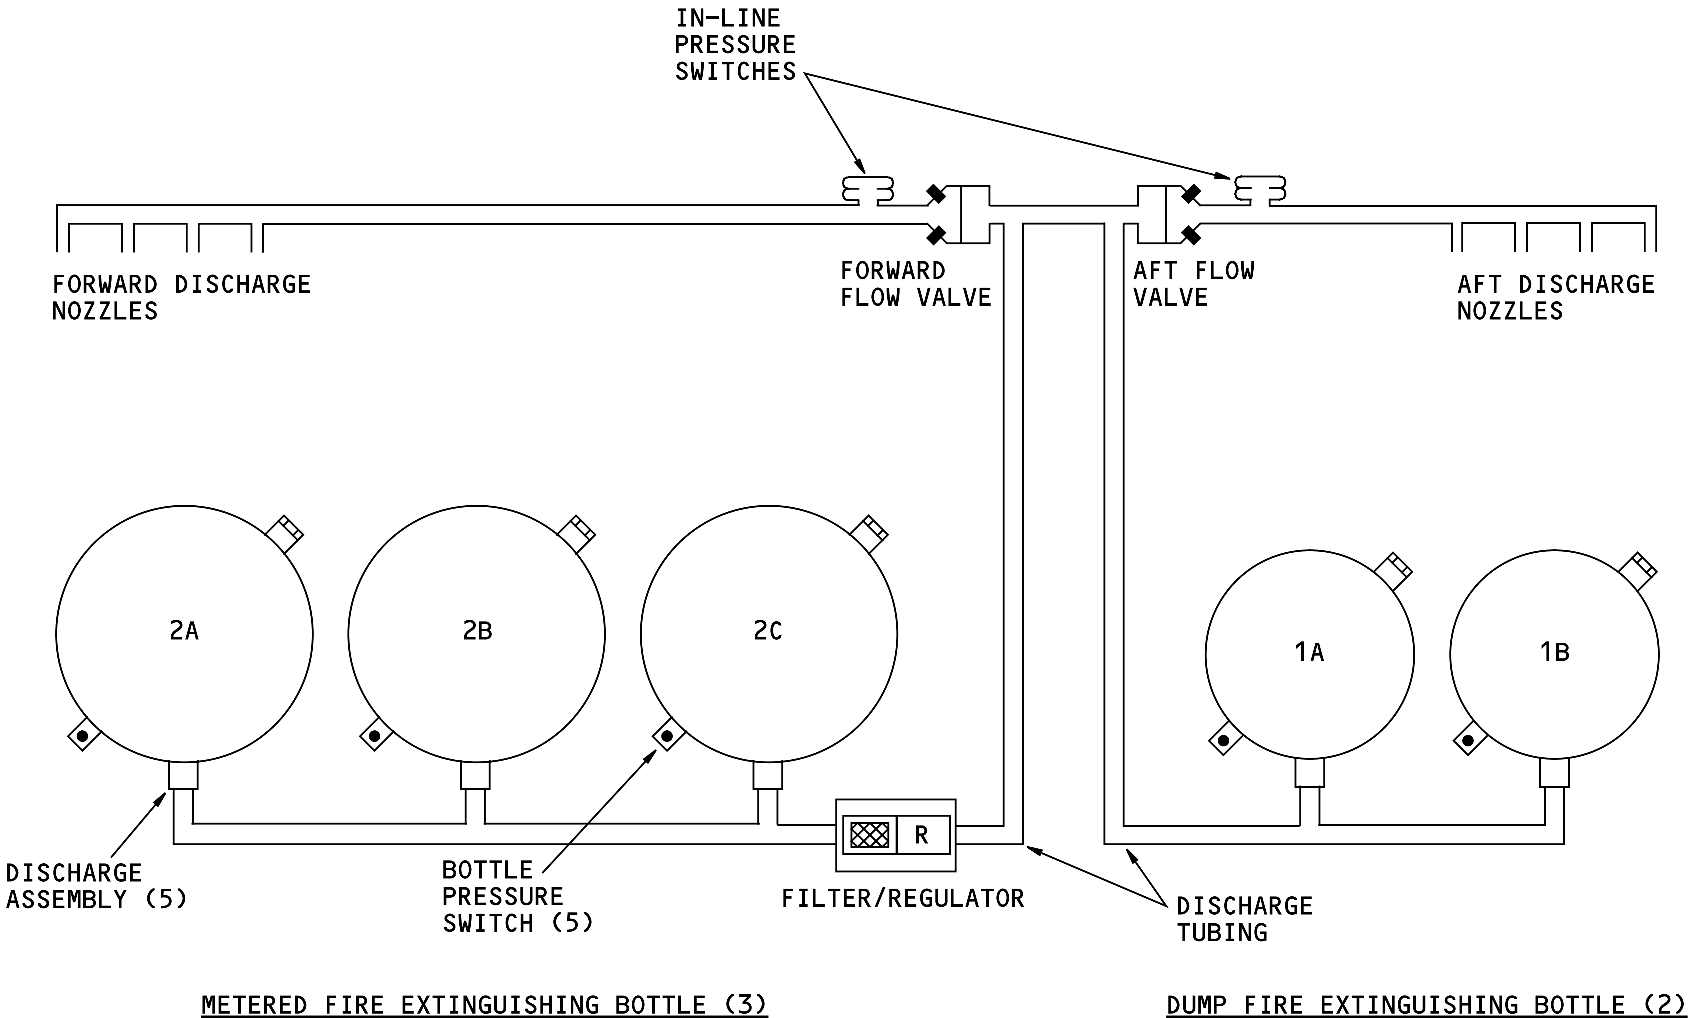
If the airplane lands before the twenty minute time delay ends, bottle 2A discharges at landing. Bottles 2B and 2C do not discharge.

When pressure in a metered bottle decreases, the bottle pressure switch causes advisory and status low pressure messages to show.

Operation for an aft cargo fire is almost the same. The aft flow valve opens instead of the forward flow valve. This causes the fire extinguishing agent to go to the aft lower cargo compartment.

Operation - Ground

If you operate the system when the airplane is on the ground, the metered bottle discharge is different. After the twenty minute time delay, the squib for bottle 2A fires. Bottles 2B and 2C do not discharge when the airplane is on the ground.



26-23-00-011 Rev 2 07/09/1997

LOWER CARGO FIRE EXTINGUISHING - FUNCTIONAL DESCRIPTION - FLOW

LOWER CARGO FIRE EXTINGUISHING - FUNCTIONAL DESCRIPTION - DUMP BOTTLES CIRCUIT

Bottle Discharge

Push the forward or aft cargo fire arm switch to arm the cargo fire extinguishing system. The switch makes a ground for the squib bottles 1A, 1B control relay. Push the cargo fire discharge switch to fire the squibs. That switch lets power from the hot battery bus go to energize the relay. With the relay energized, power from the hot battery bus goes to the bottle 1A and 1B squibs. At the same time, power goes through the discharge switch and the arm switch to the forward or aft flow valve squibs.

Discharge Indication

Pressure in the discharge line closes the forward or aft in-line pressure switch. The EEU makes a ground for the cargo fire discharge light and sends a signal to the AIMS. Advisory and maintenance messages show that the forward or aft in-line pressure switch is closed. The fire protection maintenance page also shows this condition.

When pressure inside a bottle decreases, the bottle pressure switch closes and makes a ground. The EEU sends a signal to the AIMS. Status and maintenance messages show low bottle pressure. The fire protection maintenance page also shows this condition.

Squib Test

The ELMS monitors the electrical continuity of the squib circuits. The ELMS does this check one time during each flight leg. The ELMS transmits data about an open squib circuit to the AIMS. Status and maintenance messages show that a squib circuit is faulty. The fire protection maintenance page also shows this condition.

You can also do a test of the squib circuits with the MAT.

Training Information Point

You can do a check of the bottle pressure switch circuits on the ground. Use a hex key to rotate the bottle pressure switch test socket to close the switch. A bottle low pressure status messages must show

The in-line pressure switch latches closed when the fire extinguishing system operates. Use the reset button to set the switch contacts open.

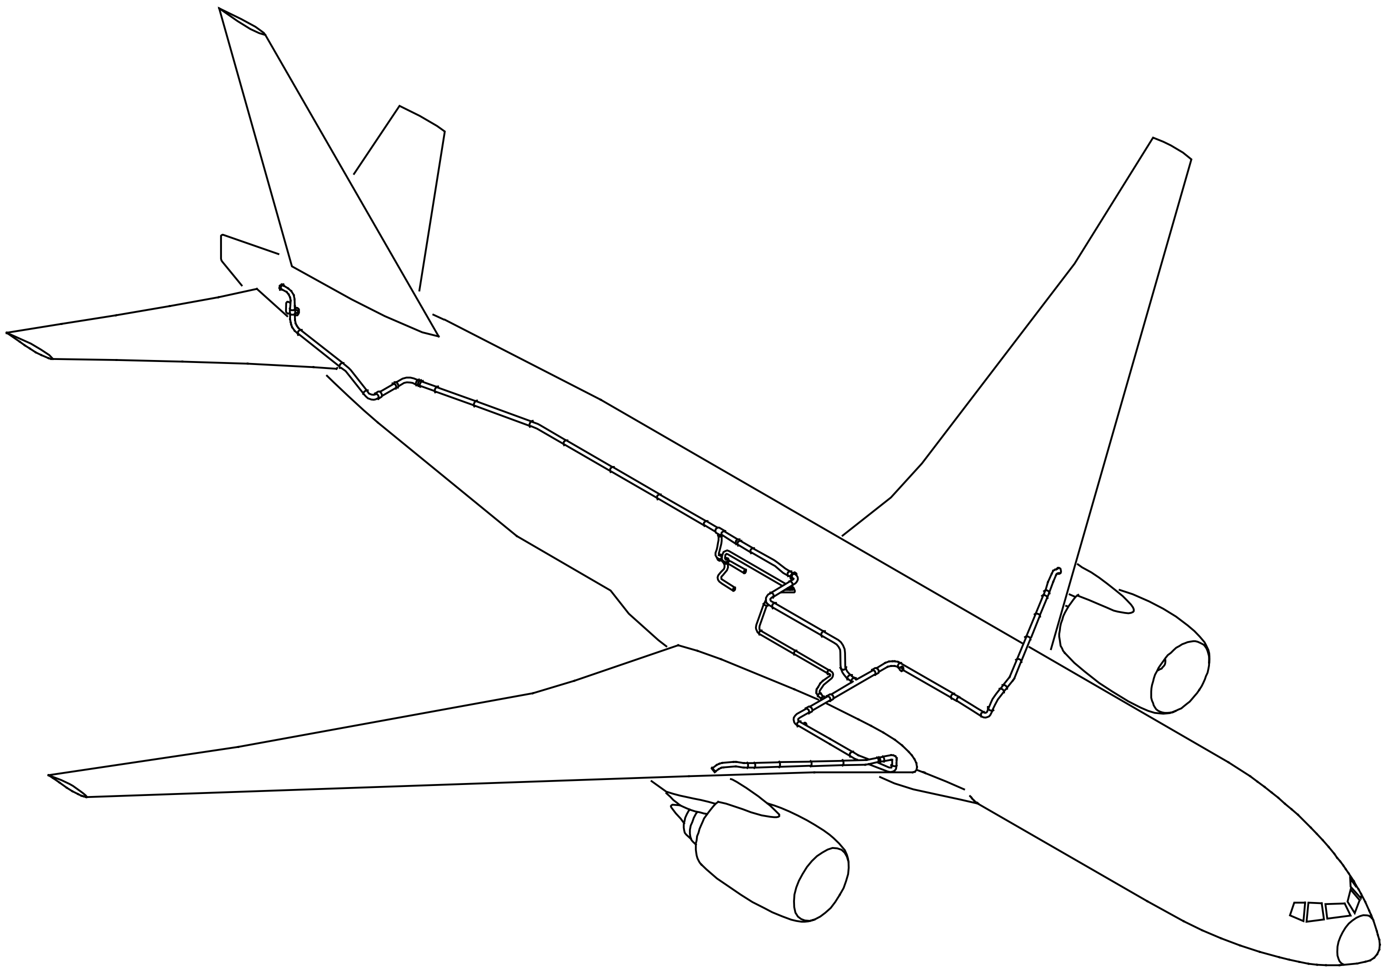
DUCT LEAK AND OVERHEAT DETECTION - INTRODUCTION

Purpose

The duct leak and overheat detection system (DLODS) monitors the pneumatic ducts and engine anti-ice ducts for leaks.

General

DLODS has an interface with the pneumatic and engine anti-ice systems. Valves in these systems close automatically to stop the leak. A duct leak that does not stop can cause structural damage to the airplane. EICAS messages tell the crew about the duct leak.



DUCT LEAK AND OVERHEAT DETECTION - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

DUCT LEAK AND OVERHEAT DETECTION - GENERAL DESCRIPTION

General

The duct leak and overheat detection system (DLODS) has these detectors:

- Wheel well fire detectors (ref)
- Fan case overheat detectors
- Strut overheat detectors
- Wing duct leak detectors
- Body duct leak detectors.

Three identical DLODS control cards monitor the detectors:

- Left DLODS control card
- Center DLODS control card
- Right DLODS control card.

Interfaces

The DLODS control cards have these interfaces:

- Pneumatic system (ASCPC)
- Engine anti-ice system (ACIPS cards - EAI)
- Overhead panel ARINC 629 system (OPAS)
- APU controller (APUC)
- Warning electronic system (WES)
- AIMS primary display system and central maintenance computing function.

Wheel Well Fire Detection

If a wheel well fire detector finds a fire, the DLODS control cards send a signal on the data bus. The warning electronic system turns on the fire bell and the master warning lights. The AIMS shows an EICAS warning message.

When you do a fire/overheat test, you test the wheel well fire detection part of DLODS, but not the duct leak and overheat detection part.

See the fire protection section for more information about the fire/overheat test (AMM PART I 26-00).

See the wheel well fire detection system section for more information about the wheel well fire detection system (AMM PART I 26-17).

Duct Leak and Overheat Detection

If a detector finds an overheat condition, the DLODS control cards send a signal on the data bus. The warning electronic unit turns on the master caution aural. The AIMS turns on the master caution lights and shows an EICAS caution message. For a fan case overheat condition, the DLODS control cards also send a signal to the EAI ACIPS cards to close the engine anti-ice valve. For a strut overheat condition, a wing duct leak, or a body duct leak, the DLODS control cards send a signal to the ASCPC. Pneumatic system valves close automatically to isolate the leak. A signal to the APUC causes the APU surge valve to open if necessary.

DUCT LEAK AND OVERHEAT DETECTION - GENERAL DESCRIPTION

BITE

The DLODS cards continuously monitor the detectors for open and short circuits. For either condition, the DLODS control cards send a signal to the AIMS. A status message shows which detector has failed.

DUCT LEAK AND OVERHEAT DETECTION - COMPONENT LOCATIONS

DUCT LEAK AND OVERHEAT DETECTION - FAN CASE OVERHEAT DETECTORS

Purpose

The fan case overheat detector monitors the temperature in the area around the engine fan case. A leak in the engine anti-ice duct causes an overheat condition.

Physical Description

The fan case overheat detector has two elements: loop 1 and loop 2, attached to a metal support. Bolts connect the elements to the airplane wiring.

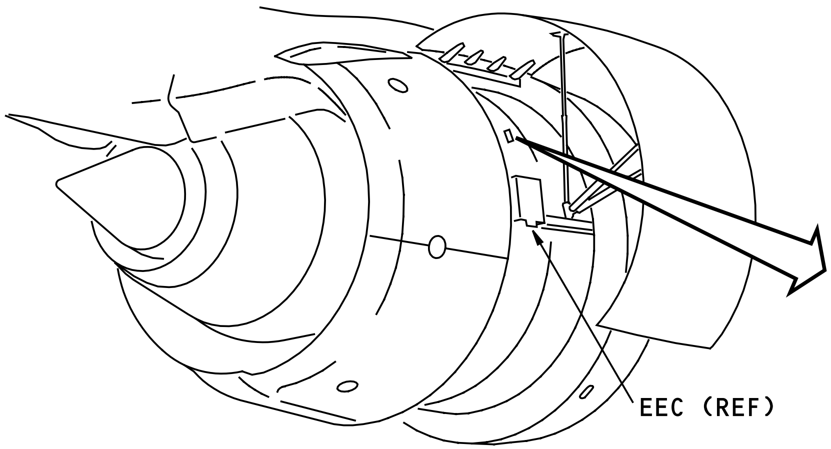
Each element has an outer conductor around an inner conductor. The separator between these conductors is an electrical insulator at temperatures less than the overheat set point (255F, 124C).

Functional Description

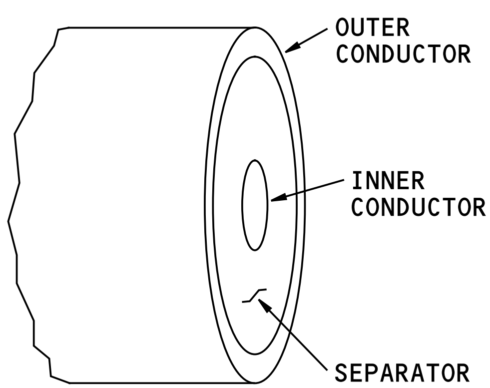
When the temperature is more than the set point, the separator conducts electricity. The electrical continuity between the inner and outer conductors gives an input to the DLODS control card.

Location

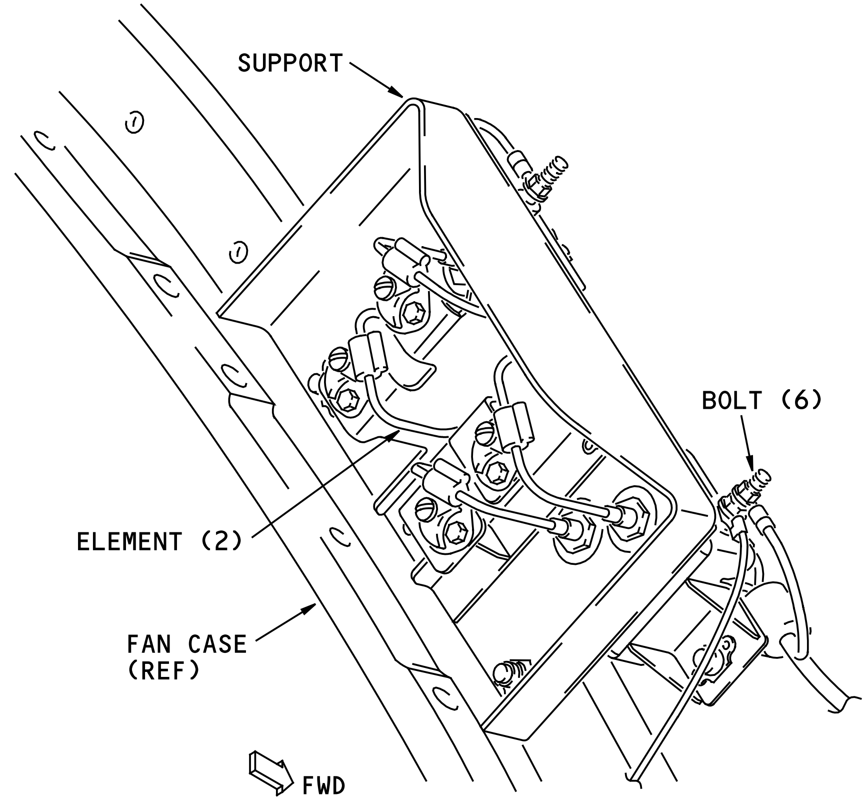
The fan case overheat detector attaches to the right side of the fan case above the electronic engine control.



ENGINE RIGHT SIDE



CROSS SECTION OF ELEMENT



FAN CASE OVERHEAT DETECTOR

26-18-00-004 Rev 1

DUCT LEAK AND OVERHEAT DETECTION - FAN CASE OVERHEAT DETECTORS

DUCT LEAK AND OVERHEAT DETECTION - STRUT OVERHEAT DETECTORS

Purpose

The strut overheat detectors monitor the temperature in the engine strut and the wing leading edge immediately inboard of the strut. A leak in the pneumatic duct causes an overheat condition.

Physical Description

Each side of the airplane has a dual loop strut overheat detector circuit. Each loop in the circuit has a set of elements that connect in series. Clips attach one long pair of elements to the front of the wing spar. A metal frame assembly contains another pair of elements. Electrical connectors and bolts connect the elements to the airplane wiring.

Each element has an outer conductor around an inner conductor. The separator between these conductors is an electrical insulator at temperatures less than the overheat set point (310F, 154C).

Functional Description

When the temperature is more than the set point, the separator conducts electricity. The electrical continuity between the inner and outer conductors gives an input to the DLODS control card.

Location

The strut overheat detectors are in two locations. One type is in the wing leading edge and another type is in the engine strut.

Access to the detector in the wing is through two panels on the bottom of the fixed leading edge. The panels are immediately inboard of the strut.

Access to the detector in the strut is through the pressure relief door in the right side of the strut.

Training Information Point

The strut overheat detection system has a fault locating feature for the detector loops. Maintenance messages include a zone number to help you find the location of a duct leak or a short circuit.

DUCT LEAK AND OVERHEAT DETECTION - STRUT OVERHEAT DETECTORS

DUCT LEAK AND OVERHEAT DETECTION - WING DUCT LEAK DETECTORS

Purpose

Wing duct leak detectors monitor the pneumatic distribution ducts in the wing leading edges and in the environmental control system (ECS) bays for leaks.

Physical Description

Each side of the airplane has a dual loop wing duct leak detector circuit. Each loop in the circuit has five elements that connect in series. Clips along the length of the detectors attach the elements to the structure.

Each element has an outer conductor around an inner conductor. The separator between these conductors is an electrical insulator at temperatures less than the overheat set point (255F, 124C).

Functional Description

When the temperature is more than the set point, the separator conducts electricity. The electrical continuity between the inner and outer conductors gives an input to the DLODS control card.

Location

The wing duct leak detectors are near the pneumatic distribution system ducts in the wing leading edges and in the ECS bays.

Training Information Point

Where loop 1 uses a male connector, loop 2 uses a female connector to prevent cross connection of the loops.

The wing duct leak detection system has a fault locating feature for the detection loops. Maintenance messages include a zone number to help you find the location of a duct leak, short circuit, or open circuit.

26-18-00-006 Rev 1 03/16/95

DUCT LEAK AND OVERHEAT DETECTION - WING DUCT LEAK DETECTORS

DUCT LEAK AND OVERHEAT DETECTION - BODY DUCT LEAK DETECTORS

Purpose

Body duct leak detectors monitor the pneumatic distribution ducts for leaks in these areas:

- Main wheel wells
- Outboard of the aft and bulk cargo compartments, left side
- Fuselage from the aft pressure bulkhead to the APU firewall
- Air driven pump area.

Physical Description

The airplane has a dual loop body duct leak detector circuit. Each loop in the circuit has twelve elements that connect in series. Clips along the length of the assembly attach the elements to the structure.

Each element has an outer conductor around an inner conductor. The separator between these conductors is an electrical insulator at temperatures less than the overheat set point (255F, 124C).

Functional Description

When the temperature is more than the set point, the separator conducts electricity. The electrical continuity between the inner and outer conductors gives an input to the DLODS control card.

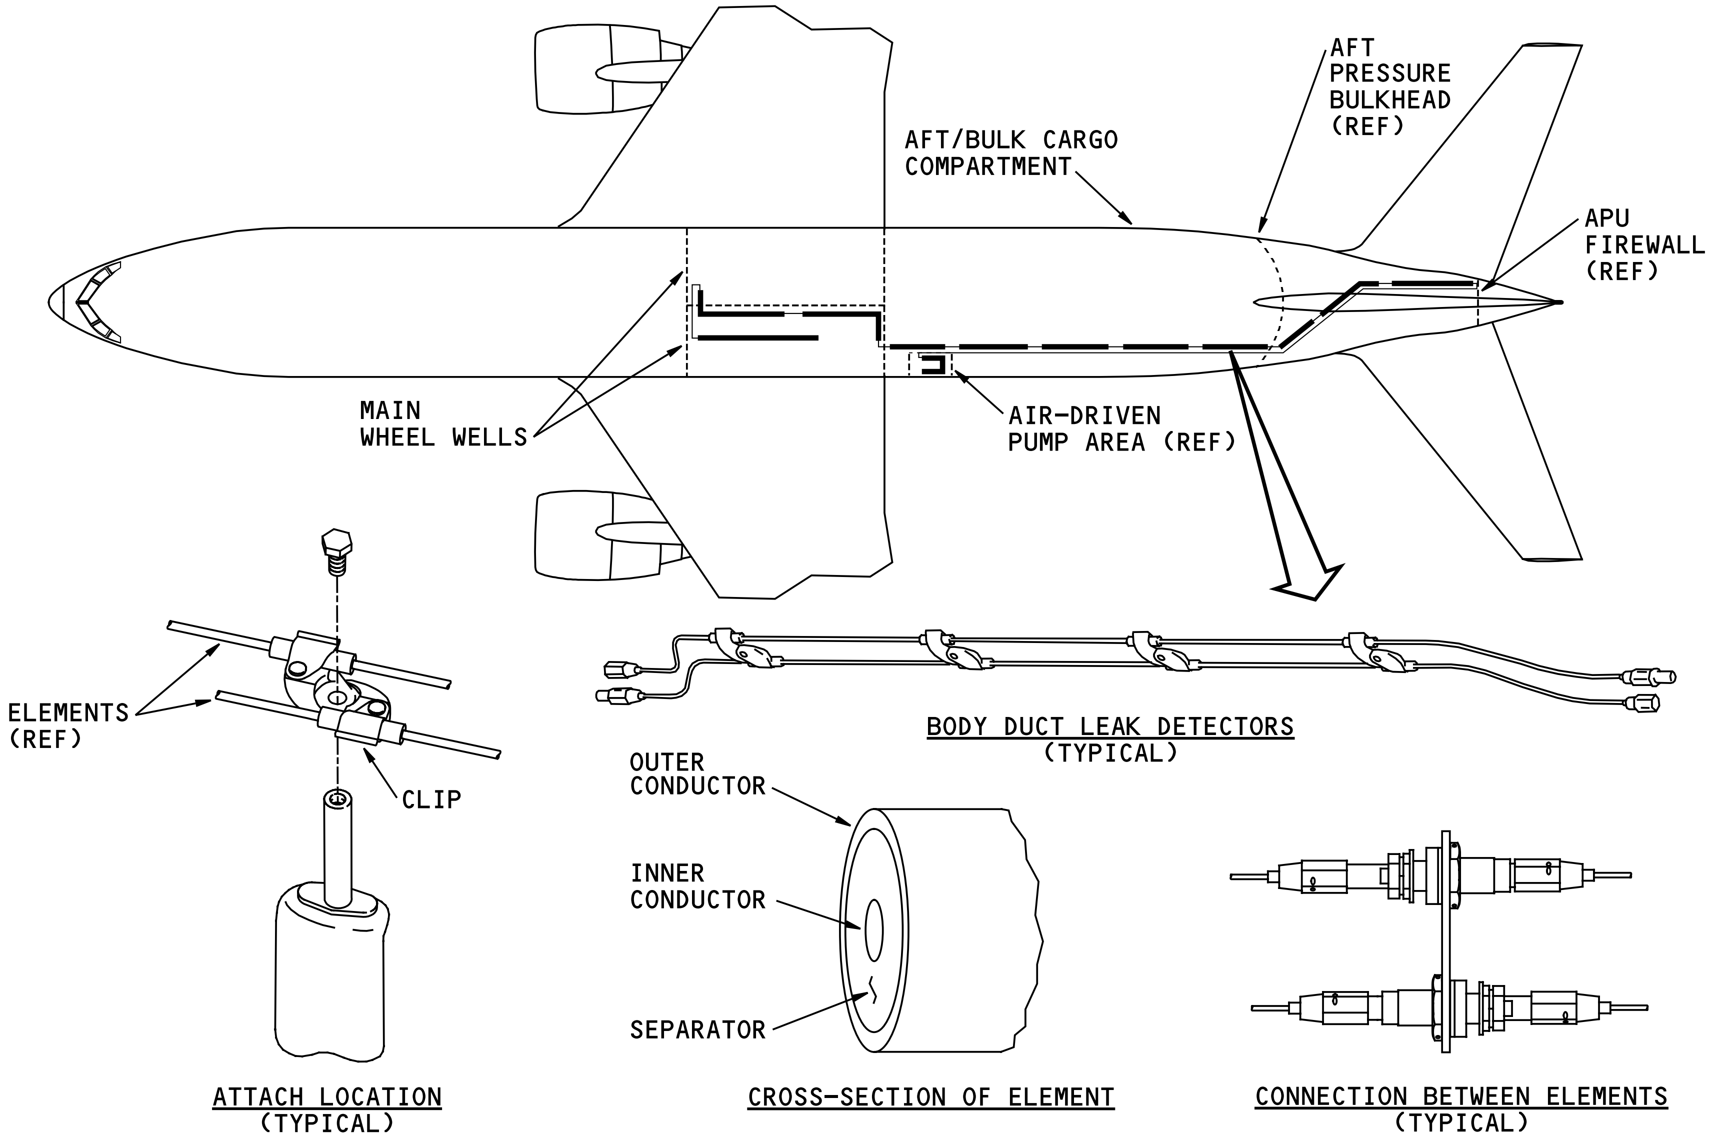
Location

The body duct leak detectors are near the pneumatic distribution ducts in the body areas. The detectors extend from the main wheel wells to the APU firewall.

Training Information Point

Where loop 1 uses a male connector, loop 2 uses a female connector to prevent cross connection of the loops.

The body duct leak detection system has a fault location feature for the detector loops. Maintenance messages include a zone number to help you find the location of a duct leak, short circuit, or open circuit.



26-18-00-007 Rev 2 07/10/1997

DUCT LEAK AND OVERHEAT DETECTION - BODY DUCT LEAK DETECTORS

THIS PAGE INTENTIONALLY LEFT BLANK

DUCT LEAK AND OVERHEAT DETECTION - FUNCTIONAL DESCRIPTION

General

The three DLODS control cards monitor the detector loops. Each DLODS control card uses ARINC 429 buses and two ARINC signal gateway (ASG) cards as an interface with the ARINC 629 systems buses. The DLODS control cards use this configuration to send data to each other and to other systems and LRUs.

Detector Status

Each detector loop has three possible conditions:

- Usual - low impedance in the inner conductor loop circuit and high impedance between the inner and outer conductors
- Open circuit - high impedance in the inner conductor loop circuit
- Short circuit - low impedance between the inner and outer conductors.

A loop in the usual condition has no electrical defects and no overheat condition. A loop with an open circuit is broken or disconnected from the card. A loop with a short circuit is damaged or has an overheat condition.

Control Card Logic

The cards compare the condition of both loops of a detector to find an overheat condition. The cards transmit an overheat signal if both loops have a short circuit. The cards also transmit an overheat signal if one loop has a short circuit while the other loop has an open circuit.

If a DLODS control card fails, the remaining cards do not get information about the loops connected to the failed card. The operating cards transmit an overheat signal if one loop has a short and the other loop connects to a failed card.

Interfaces

A wheel well fire causes an EICAS warning message and master warning indications. The fire/overheat test switch does a test of the wheel well fire detection part of DLODS.

Duct leak or overheat conditions cause EICAS caution messages and master caution indications. The duct leak or overheat input to the ASCPCs causes pneumatic system valves to close and isolate the leak. The input to the APUC causes the APU surge valve to open if it is necessary. A fan case overheat input to the ACIPS cards causes the engine anti-ice valve to close.

Training Information Point

The AIMS shows a loop failure status messages if a loop is not in the usual condition. The message specifies the detector circuit and the loop. The message shows for loops with open or short circuits. If there is an overheat condition, loop failure messages show for both detector loops. If a DLODS control card fails, loop

DUCT LEAK AND OVERHEAT DETECTION - FUNCTIONAL DESCRIPTION

failure messages show for all the loops that connect to that card.

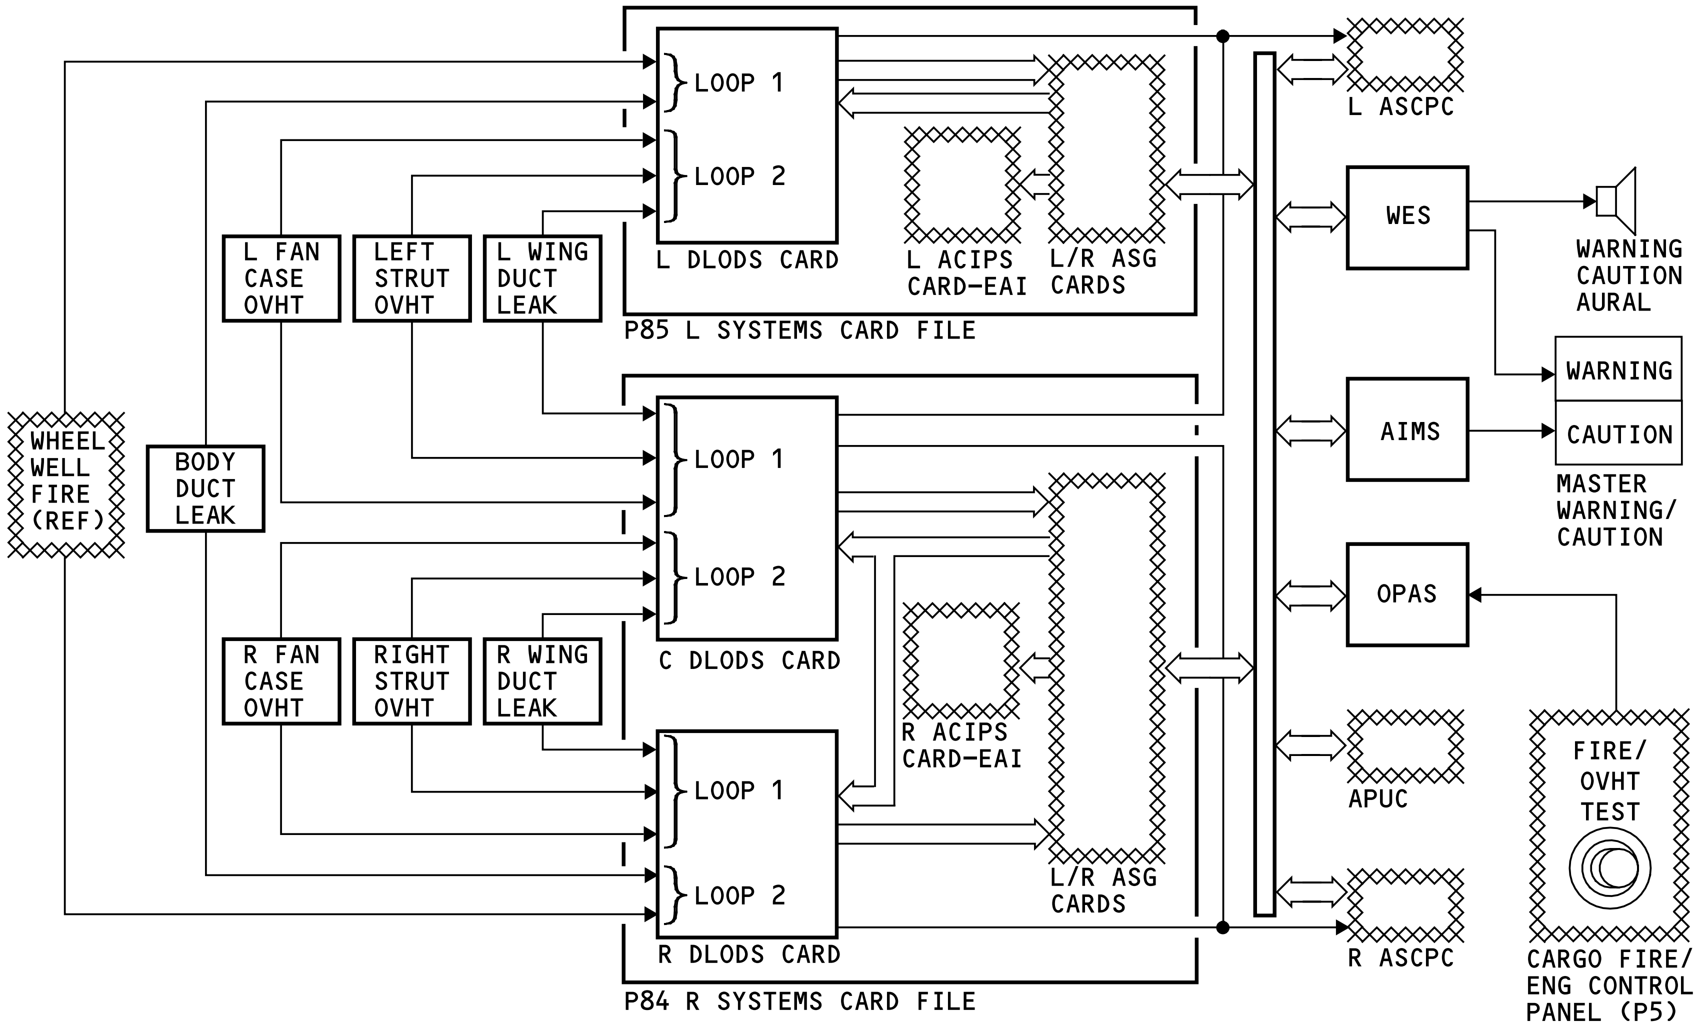
The central maintenance computing system also shows messages for loops not in the usual condition. The maintenance message specifies the detector circuit, loop, and if the problem is an open or short. The message also specifies the zone location for these failures:

- Strut overheat detectors - short circuit
- Wing duct leak detectors - short and open
- Body duct leak detectors - short and open.

The zone location for a short circuit helps you find electrical defects and duct leaks.

The CMCS also shows a maintenance message for a failed DLODS control card.

You use the MAT data load function to replace the software in the DLODS control cards.



26-18-00-008 Rev 1

DUCT LEAK AND OVERHEAT DETECTION - FUNCTIONAL DESCRIPTION

DUCT LEAK AND OVERHEAT DETECTION (DLODS) - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

Overheat Detection

Each DLODS control card monitors its related detector loops. If the two loops of a detector have low resistance, the DLODS control cards send a signal to the AIMS to indicate an overheat condition at that detector. This causes an EICAS caution message.

If there is a fan case overheat, the DLODS control cards send a signal to the airfoil and cowl ice protection system (ACIPS) control cards. These cards close the engine anti-ice valve.

If there is a strut overheat or a wing duct leak, the DLODS control cards send a signal to the air supply and cabin pressure controllers (ASCPCs). The ASCPCs close the related isolation valve to isolate the problem duct.

Loop Failure

The DLODS control cards continuously monitor the detector loops for open and short circuits. If a card finds a short circuit in only one loop of a detector, the cards send a signal to AIMS to show a short circuit failure of the detector.

If the signal from a loop shows an open circuit, the DLODS control cards send a signal to AIMS to show an open failure of the detector.

Short and open failures of the detectors cause status and maintenance messages.

Isolation of a Short Circuit in an Overheat Detector

A DLODS control card isolates the zone location of a short circuit in these detectors:

- Strut overheat detectors
- Wing duct leak detectors
- Body duct leak detectors.

When there is a short circuit, the DLODS control card measures the electrical resistance to the short. The card calculates the proportion that this resistance is to the total loop resistance. This proportion of the loop length identifies the location of the short. The central maintenance computer system (CMCS) shows this location as an airplane zone.

Isolation of an Open Circuit in an Overheat Detector

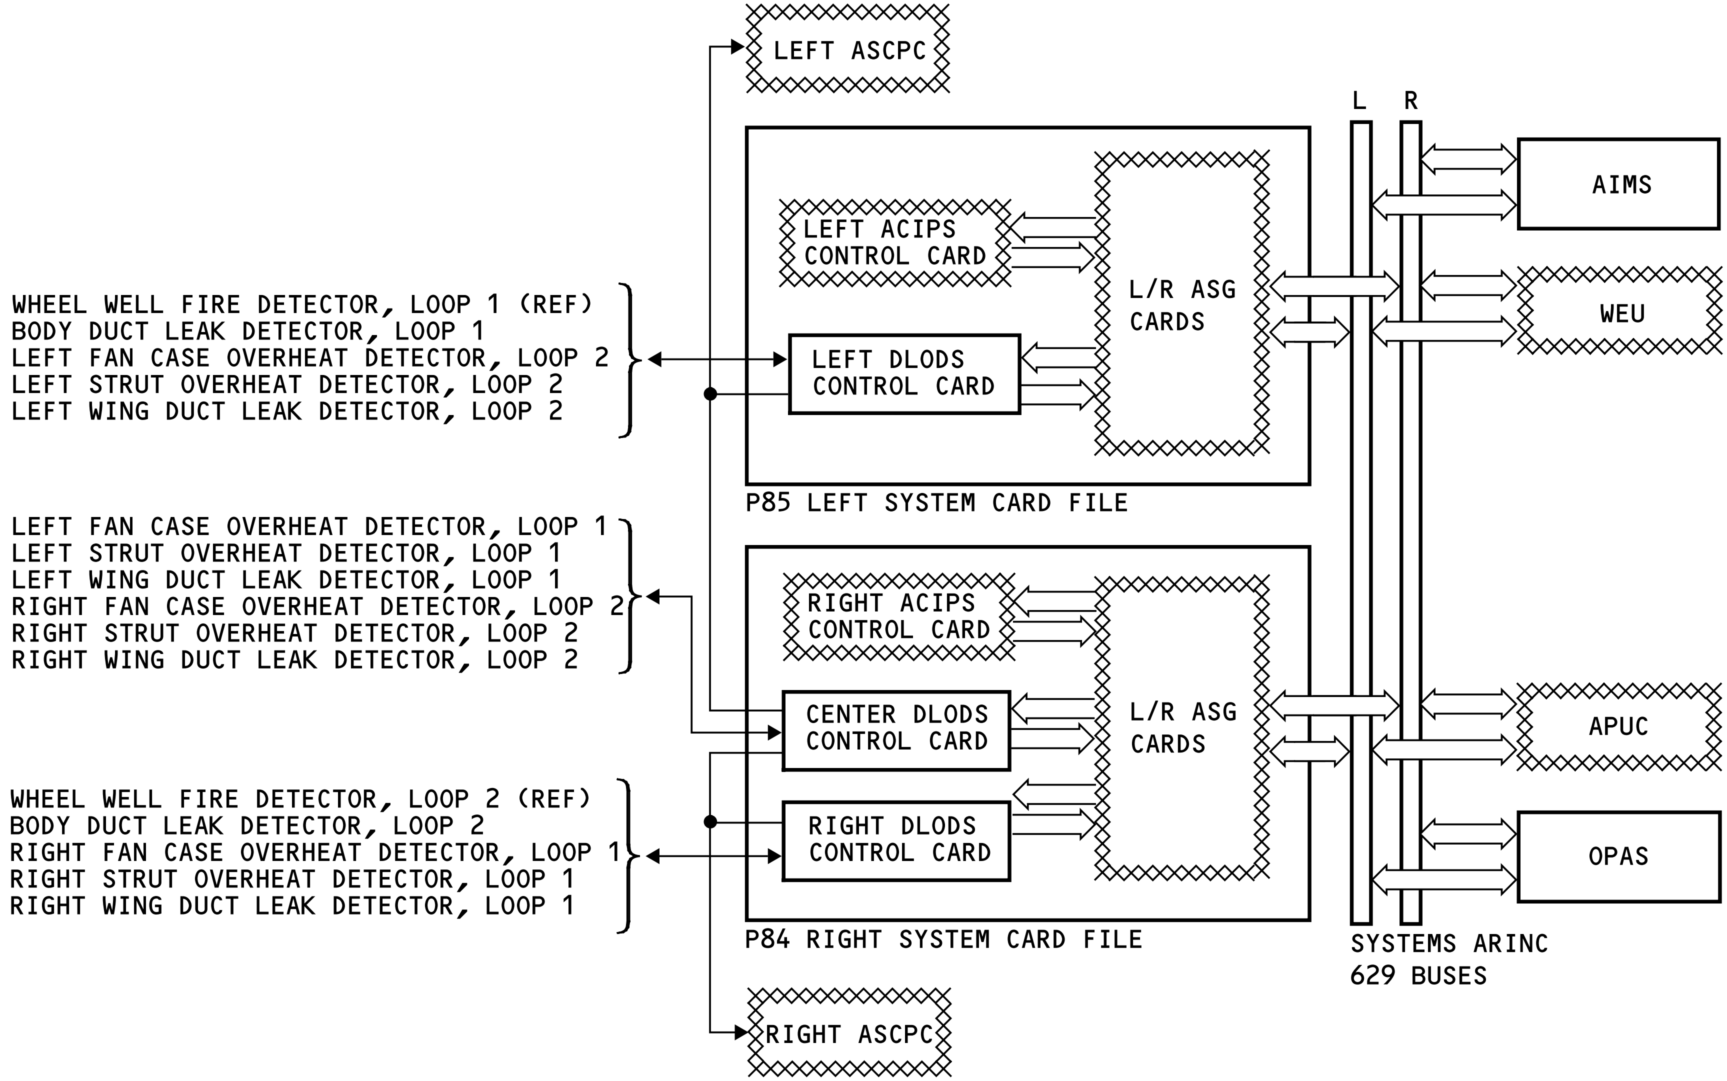
When loop resistance is greater than a specified level, A DLODS control card shows the loop as an open circuit. A DLODS control card isolates the zone location of an open circuit in these detectors:

- Wing duct leak detectors
- Body duct leak detectors.

When there is an open circuit, the DLODS control card measures the electrical capacitance to the open. The card calculates the proportion that this capacitance is to the total loop capacitance. This proportion of the loop length identifies the location of the open. The central maintenance computer system (CMCS) shows this location as an airplane zone.

DLODS Control Card Failure

If a DLODS control card has a failure, status messages show the loops for that card as failed. The serviceable cards use the related loop in a detector as the only source of fire/overheat detection.



26-18-00-009 Rev 0

DUCT LEAK AND OVERHEAT DETECTION (DLODS) - FUNCTIONAL DESCRIPTION

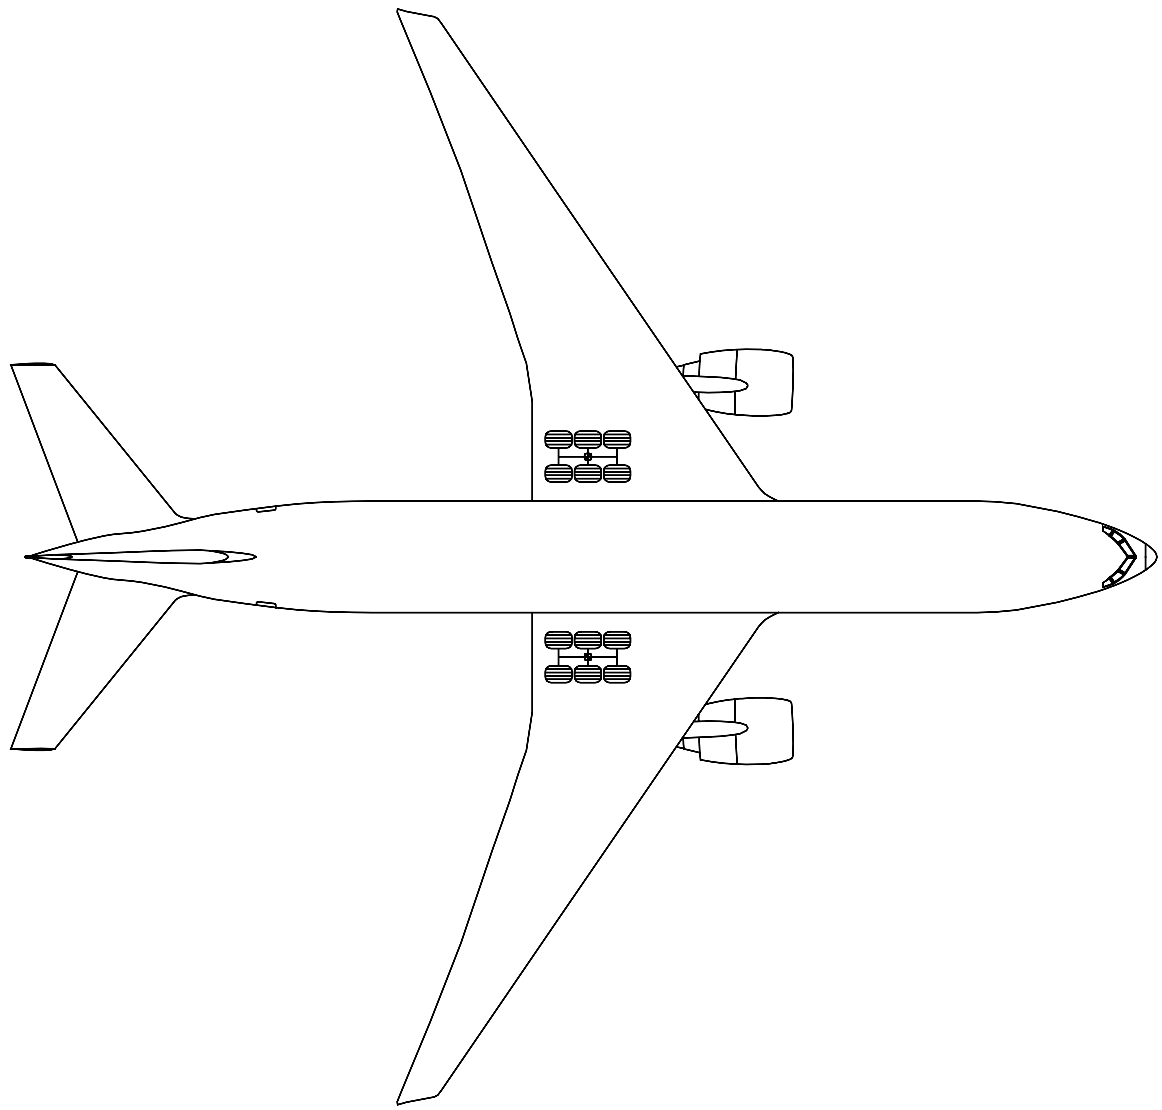
WHEEL WELL FIRE DETECTION - INTRODUCTION

Purpose

The wheel well fire detection system monitors the main wheel wells for a fire condition.

General

The wheel well fire detection system has an interface with the duct leak and overheat detection system. A fire in a wheel well causes an EICAS warning message in the flight deck.



WHEEL WELL FIRE DETECTION - INTRODUCTION

WHEEL WELL FIRE DETECTION - GENERAL DESCRIPTION

General

There are two adjacent fire detectors in each main wheel well. Each detector in the left wheel well connects to a detector in the right wheel. This makes two detector loops that operate independently.

Interfaces

The wheel well fire detection system has these interfaces:

- AIMS
- Warning electronics unit (WEU)
- Cargo fire/engine control panel
- Duct leak/overheat detection system (DLODS).

General Operation

Duct leak and overheat detection (DLODS) control cards in the left and right card files monitor the wheel well detectors. If both loops give an indication of a wheel well fire, the DLODS control cards send a signal to the AIMS. A fire warning message shows on EICAS.

Tests

The DLODS control cards continuously test the detector loops for open and short circuits. If the DLODS control cards find a failure, the cards send a signal to AIMS. A maintenance message shows if a single loop fails. A status message shows if both loops fail.

Use the fire/overheat test switch to manually test the wheel well fire detection system.

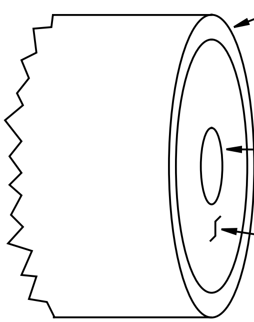
(RIGHT WHEEL WELL SIMILAR)



CROSS SECTION OF
DETECTOR ELEMENT

26-17-00-004 Rev 0

WHEEL WELL FIRE DETECTION - WHEEL WELL FIRE DETECTORS - INTRODUCTION

WHEEL WELL FIRE DETECTION - FUNCTIONAL DESCRIPTION

Fire Detection

The wheel well fire detection system has two detector loops that operate independently.

The left duct leak and overheat detection system (DLODS) control card monitors loop 1. The right (DLODS) control card monitors loop 2. Each card electrically excites its related loop at a specified voltage. The signal from the loop shows a high electrical resistance at temperatures less than the fire set point (575 F, 302 C). At the fire set point or higher, the signal from the loop shows a low electrical resistance.

If the DLODS control cards find low resistance in both loops of a wheel well, the cards send a signal to the AIMS to indicate a fire. A warning message shows on EICAS. The warning electronic unit (WEU) turns on the master warning lights and fire aural warning.

Loop Failure

The DLODS control cards continuously monitor the detector loops for open and short circuits. If a card finds a short circuit in only one loop of a wheel well, the cards send a signal to AIMS to show a short circuit failure of the detector.

If the signal from the loop shows an open circuit, The DLODS control cards send a signal to AIMS to show an open circuit failure of the detector.

A short or open circuit failure of one detector loop causes maintenance messages. A failure of the two loops causes a status message to show.

DLODS Control Card Failure

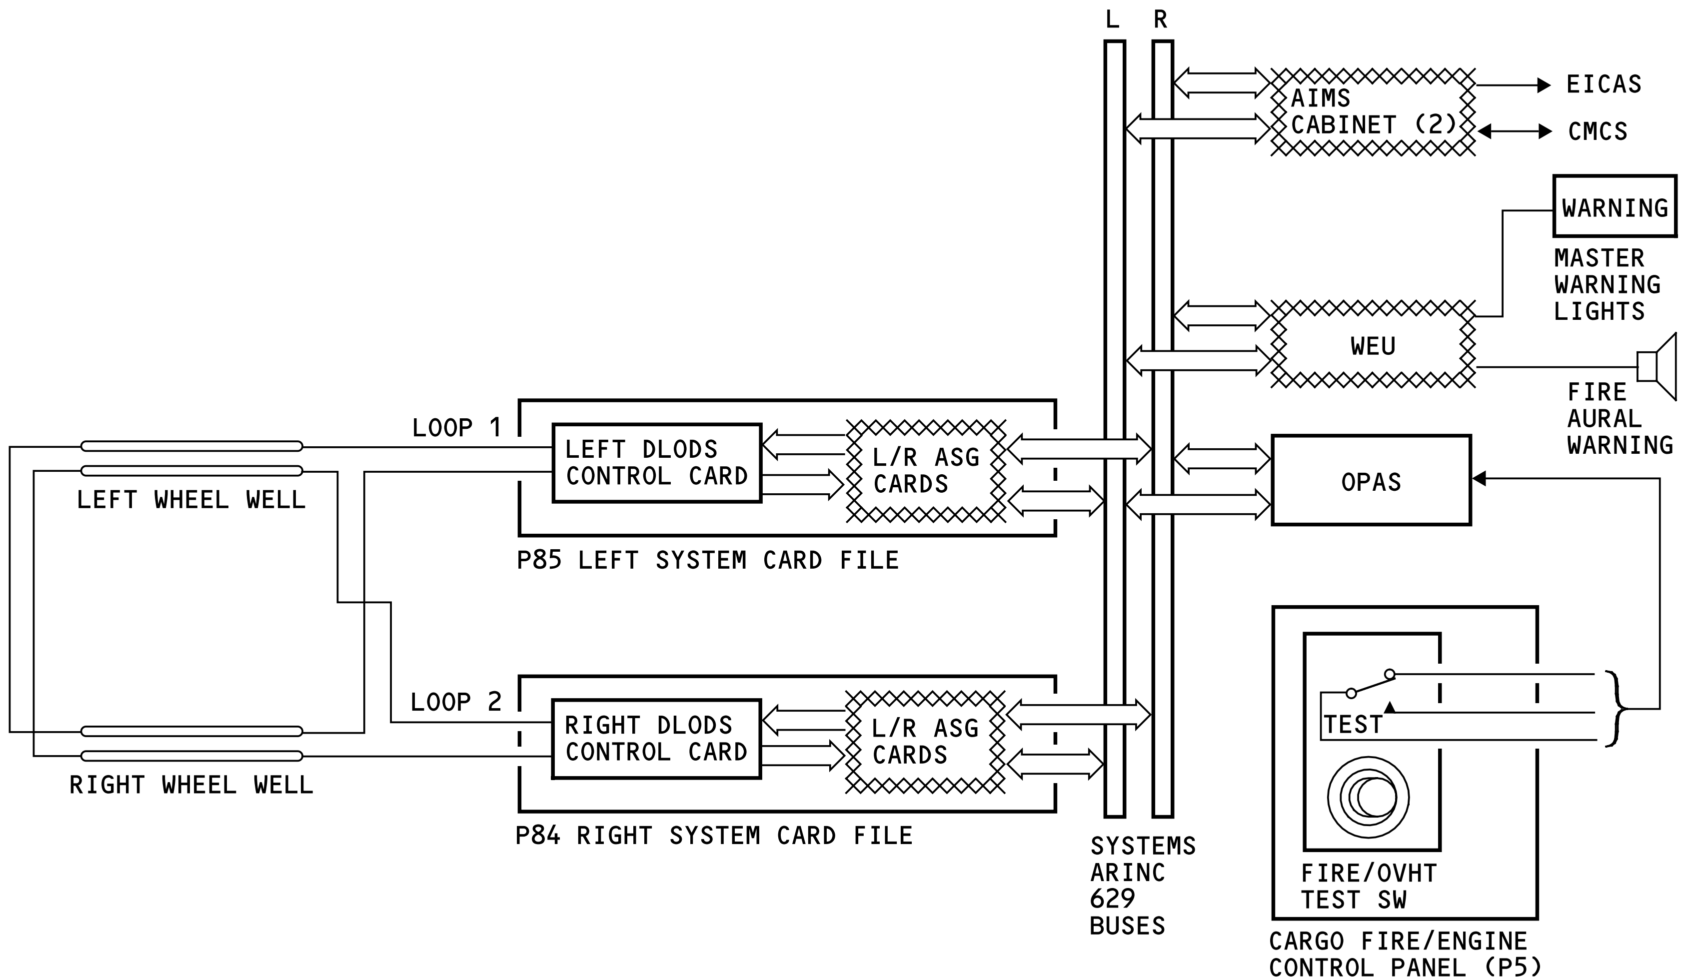
If a DLODS control card has a failure, a status message on EICAS show the loop monitored by that card as failed. The serviceable card then uses the other loop as the only source of fire detection.

Fire/Overheat Test

A fire/overheat test causes the DLODS control cards to do a test of the wheel well fire detectors. If the cards find an open or a short circuit in the loop, they send a signal to AIMS. EICAS messages report the results of the test. Failure of the two loops causes an advisory message to show.

Training Information Point

The advisory message that shows as a result of the fire/overheat test only shows for this manual test. If the DLODS control card finds a failure during continuous testing, there is no advisory message.



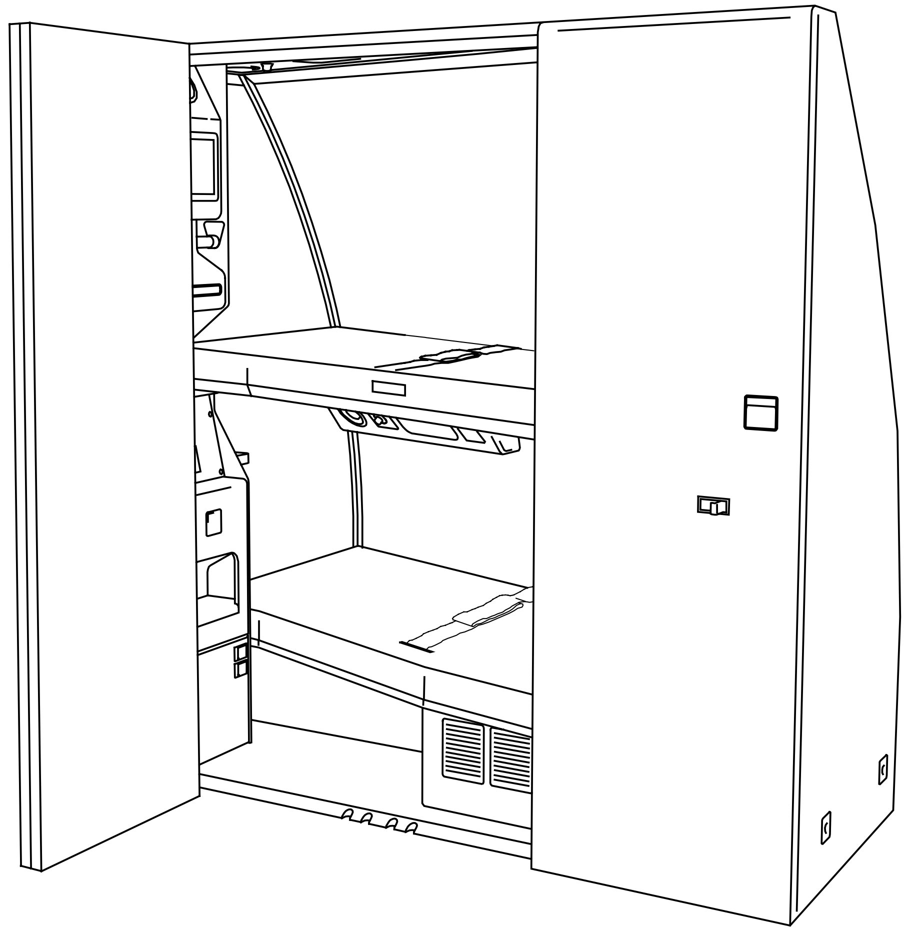
26-17-00-006 Rev 0

WHEEL WELL FIRE DETECTION - FUNCTIONAL DESCRIPTION

MISCELLANEOUS MODULE SMOKE DETECTION - INTRODUCTION

Purpose

The flight crew rest (FCR) smoke detection system monitors the flight crew rest area for smoke.



FLIGHT CREW REST AREA

MISCELLANEOUS MODULE SMOKE DETECTION - INTRODUCTION

MISCELLANEOUS MODULE SMOKE DETECTION - FLIGHT CREW REST - GENERAL DESCRIPTION

General

The smoke detection system gives indications to the flight crew and cabin attendants if there is smoke in the crew rest area. There is one smoke detector for each bunk and one for the common area.

Indications

CSS gives these smoke indications to the cabin attendants:

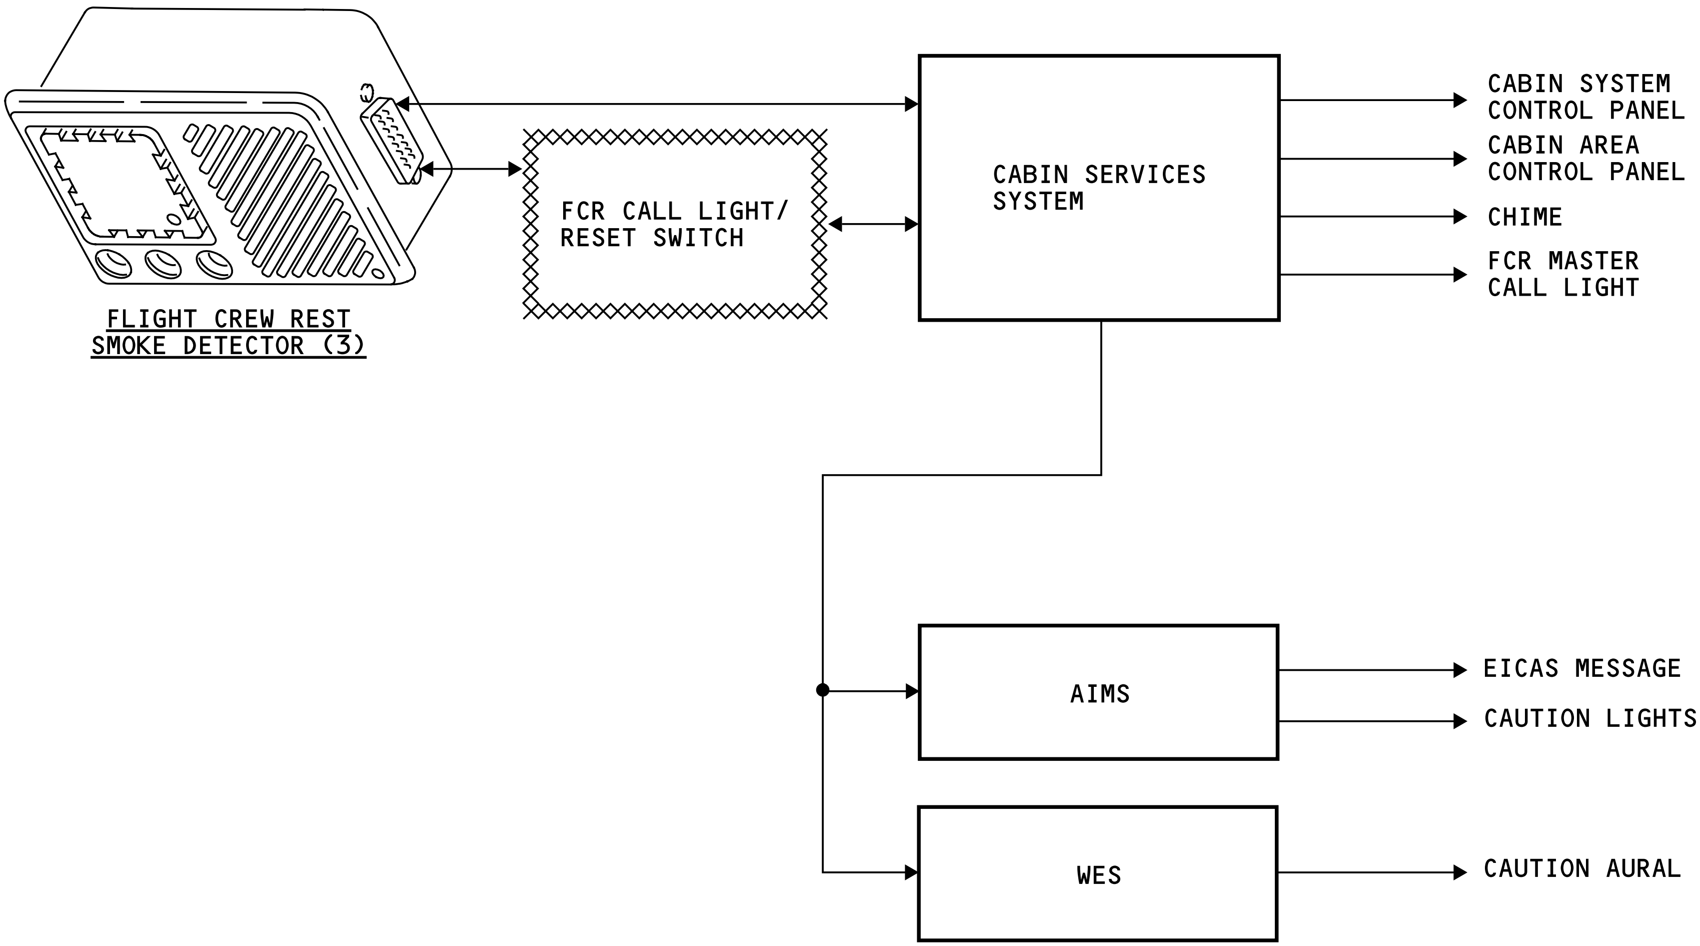
- CSCP/CACP crew rest smoke message shows
- Master call light
- Chime.

The AIMS causes an EICAS caution message and the caution lights to show in the flight deck. The warning electronic system (WES) causes the caution aural to sound.

The flight crew rest call light flashes and the warning horn in the smoke detector operates.

System Test

The cabin services system ALL TEST does a test of the flight crew rest smoke detection system. Each smoke detector also has a test switch you can use to do a test of the detector.



26-14-00-011 Rev 2 02/17/1997

MISCELLANEOUS MODULE SMOKE DETECTION - FLIGHT CREW REST - GENERAL DESCRIPTION

MISCELLANEOUS MODULE SMOKE DETECTION - CREW REST AREA SMOKE DETECTOR

Purpose

The smoke detector monitors the crew rest area for smoke and gives warnings if there is smoke.

Physical Description

The smoke detector has these parts:

- Electrical connector
- Mounting bracket
- Smoke sensor
- Filter
- Alarm LED (red)
- Power-on LED (green)
- Interrupt switch
- Test switch
- Alarm horn.

Operation

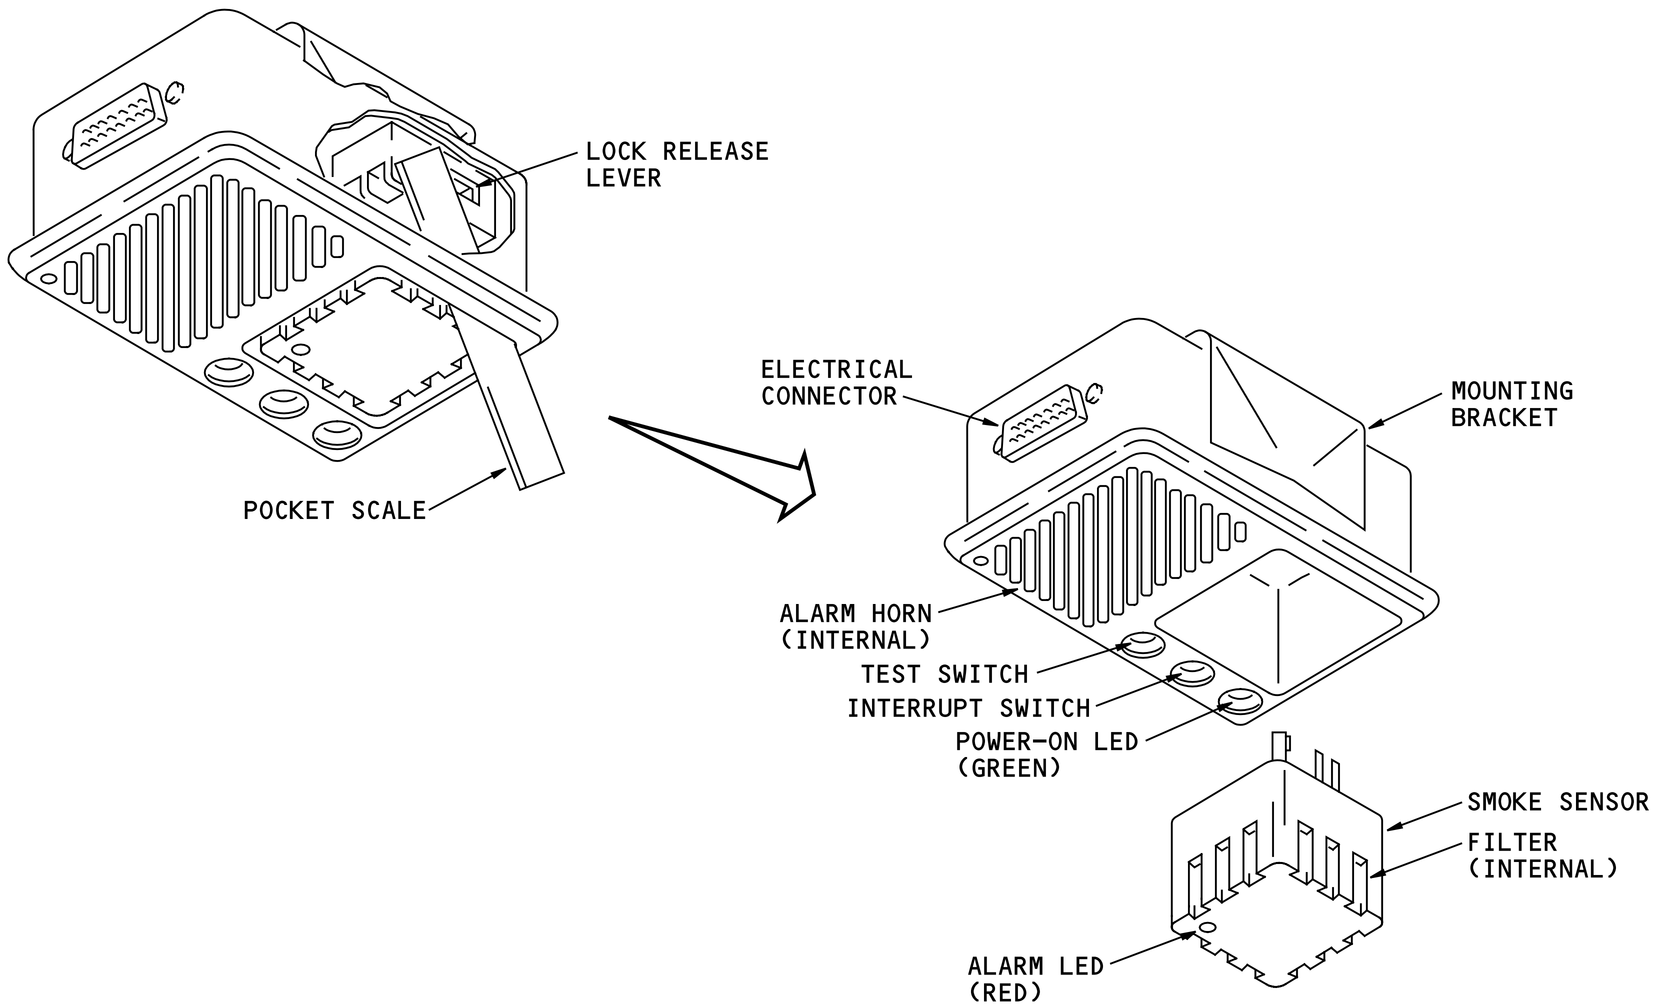
The power-on LED comes on when the smoke detector gets power. The alarm LED and horn come on when the detector senses smoke. Push the interrupt switch to make the horn stop. The alarm LED stays on until the smoke is gone.

Use the test switch to do a test of the smoke detector. The horn and alarm LED (red) come on during the test.

Training Information Point

The smoke sensor is an LRU. There is a filter inside the smoke sensor. It is necessary to clean the filter. It is not necessary to remove the smoke detector to remove the smoke sensor. To remove the smoke sensor, use a pocket scale to move the lock release lever. This lets the sensor come out of the smoke detector assembly.

CAUTION: DO NOT TOUCH THE ELECTRODE INSIDE OF THE SENSOR.



26-14-00-012 Rev 1 08/07/96

MISCELLANEOUS MODULE SMOKE DETECTION - CREW REST AREA SMOKE DETECTOR

MISCELLANEOUS MODULE SMOKE DETECTION - FLIGHT CREW REST - FUNCTIONAL DESCRIPTION

General

The left main dc bus supplies 28 volt electrical power to the flight crew rest smoke detectors. The power-on LED (green) shows that the smoke detector has power.

Smoke Detection

If there is smoke in the sensing chamber, the alarm LED (red) comes on. The timing circuit makes an intermittent ground and causes the warning horn to operate. The smoke detection circuit makes a ground for the relay. The energized relay makes a ground signal for these items:

- The ELMS electronic unit (EEU)
- The call light select relay
- The call light flasher relay
- The overhead electronics unit (OEU).

The EEU sends data about the alarm condition to the AIMS to cause the SMOKE CREW REST F/D advisory message to show.

The call light select relay and the call light flasher relay cause the flight crew rest call light to flash.

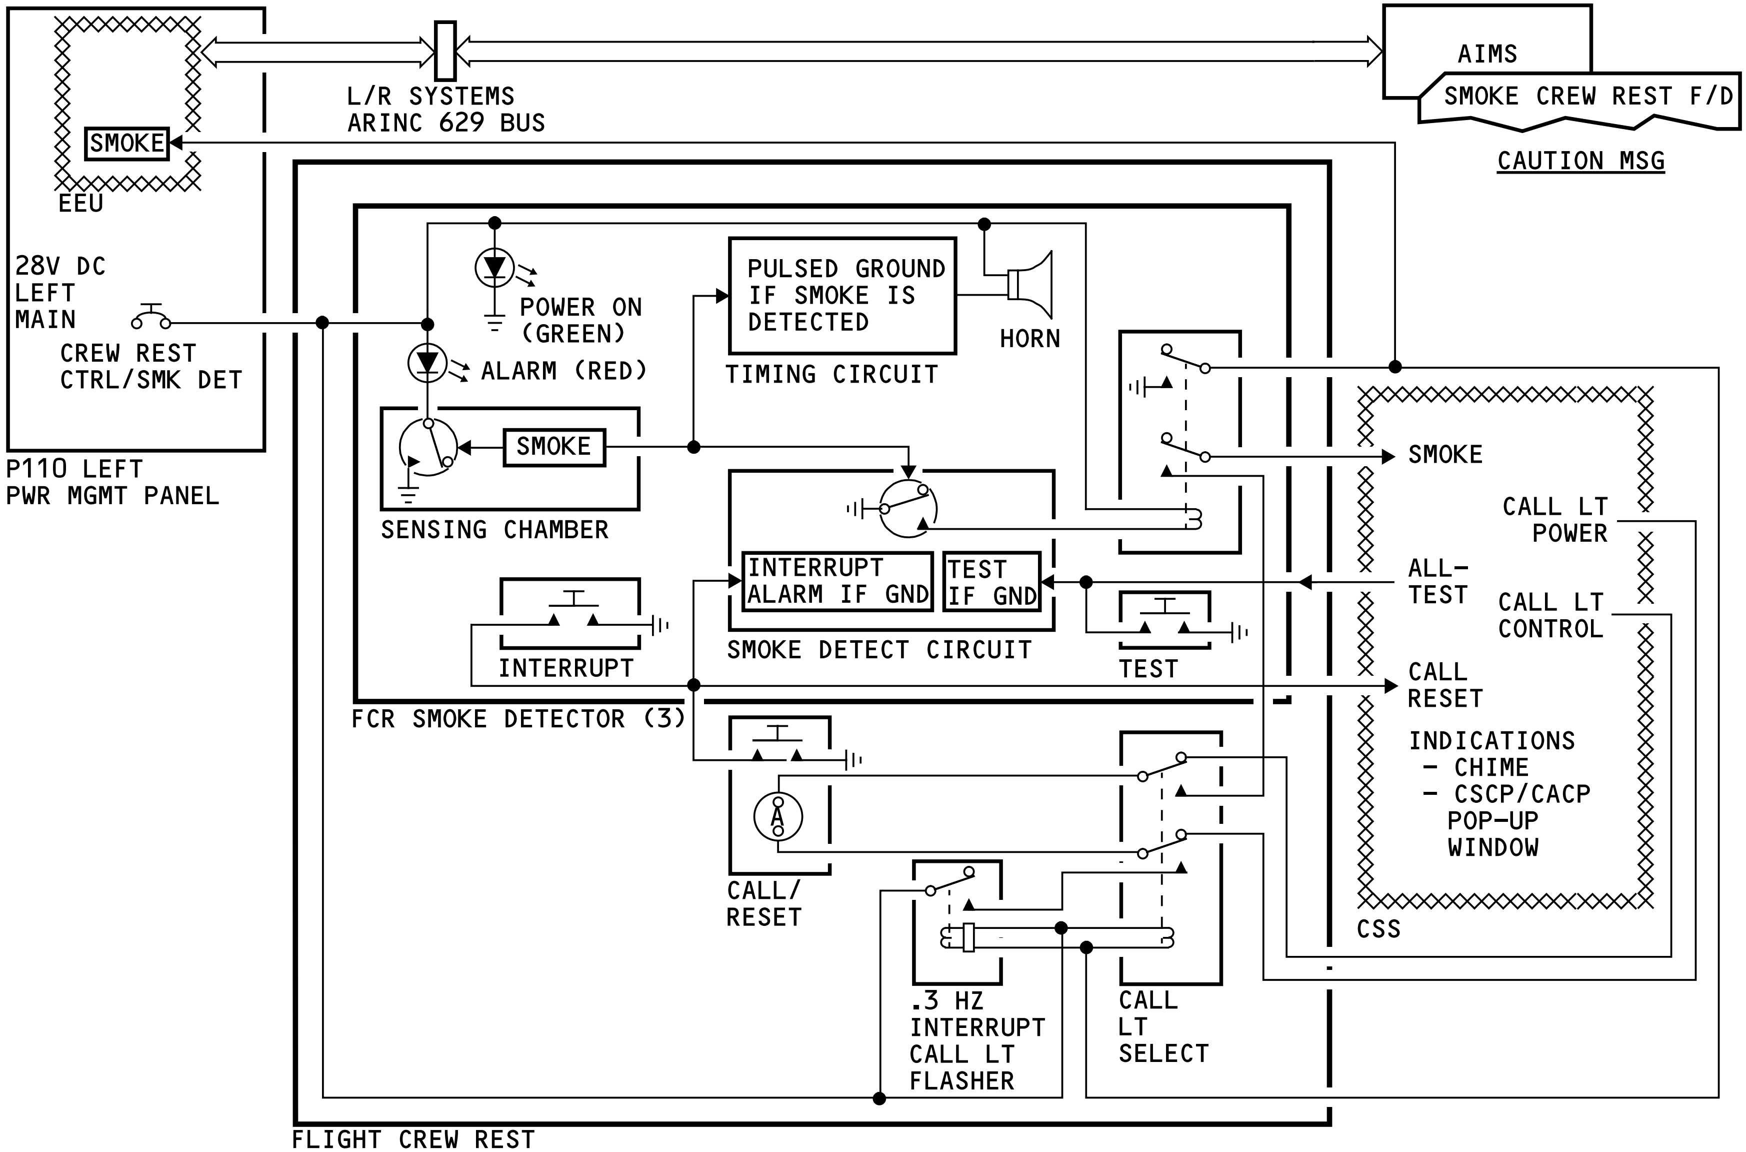
The OEU is the interface with the cabin services system. The CSS gives these indications:

- FCR master call light flashes
- CSCP/CACP pop-up windows show
- FCR call chime operates.

Push the call/reset switch or the smoke detector interrupt switch to cancel the smoke indications. If there is still smoke in the crew rest area, the alarm LED (red) stays on. All smoke indications go away automatically when the smoke is gone.

Training Information Point

You can do a test of the crew rest smoke detectors from the cabin system control panel. Use the cabin tests menu ALL TEST. During the ALL TEST, the OEUs make a ground for the test circuit in the smoke detectors. Test results show on the CSCP.



MISCELLANEOUS MODULE SMOKE DETECTION - FLIGHT CREW REST - FUNCTIONAL DESCRIPTION

MISCELLANEOUS MODULE SMOKE DETECTION - FLIGHT CREW REST - INDICATIONS

Smoke Indications

If there is smoke in the flight crew rest area, these are the indications:

- Flight crew rest call light flashes
- Master call light for the crew rest comes on
- Flight crew rest call chime sounds
- Crew rest smoke pop-up window shows at the CSCP and CACPs
- Smoke detector horn operates
- Smoke detector alarm LED comes on.

Push the flight crew rest call light/reset switch or the smoke detector interrupt switch to make the indications stop. All indications except the smoke detector alarm LED should go away. The alarm LED goes out when the smoke is gone.

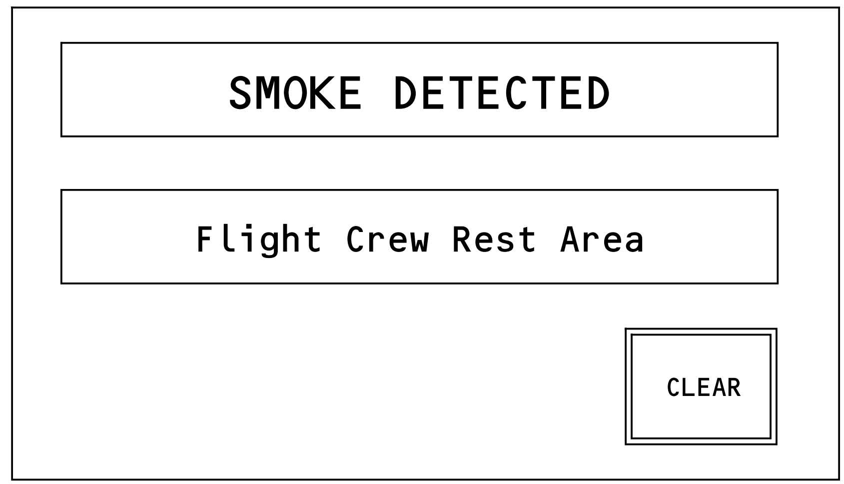
LIGHT MODULE (TYP)



CSCP/CACP POP-UP WINDOW

MISCELLANEOUS MODULE SMOKE DETECTION - FLIGHT CREW REST - INDICATIONS

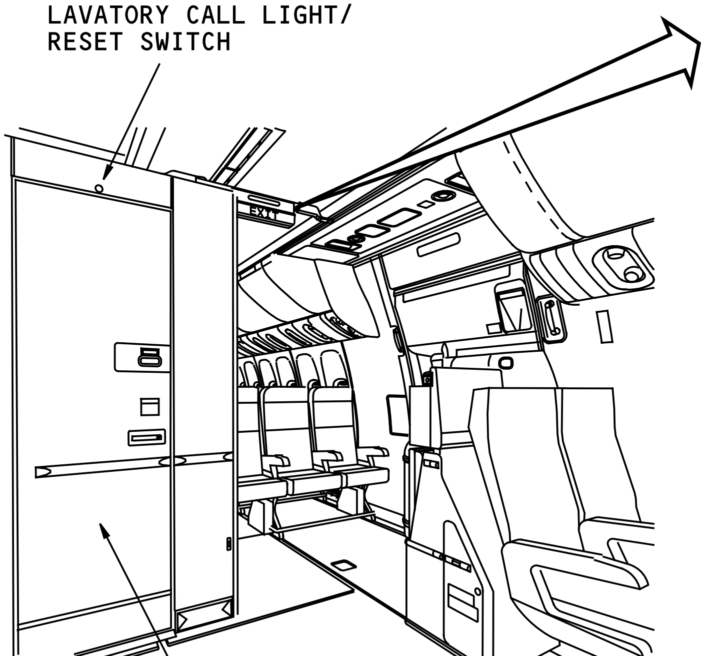
LAVATORY SMOKE DETECTION - OPERATION - INDICATIONS

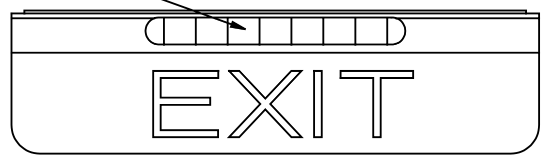
Smoke Indications

If there is smoke in a lavatory, these are the indications:

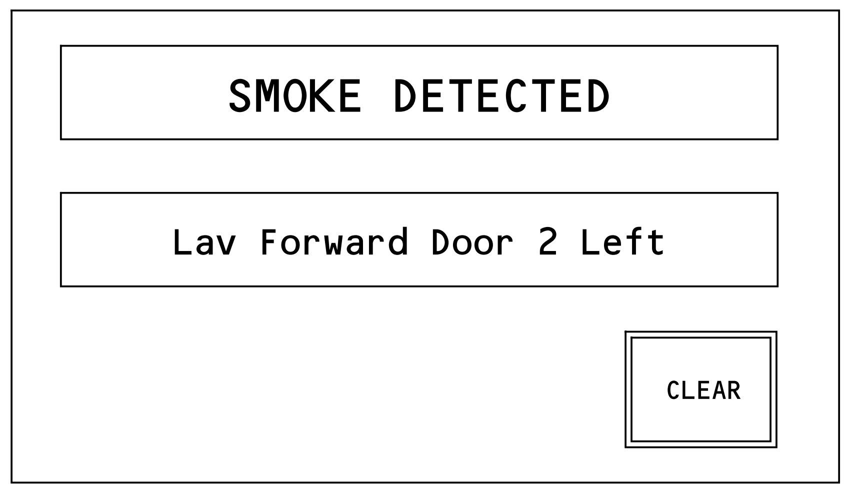
- Lavatory call light flashes
- Master call light for the lavatory comes on
- Lavatory call chime sounds
- Lavatory smoke pop-up window shows at the CSCP and CACPs
- Smoke detector horn operates
- Smoke detector alarm LED comes on.

Push the lavatory call light/reset switch or the smoke detector interrupt switch to make the indications stop. All indications except the smoke detector alarm LED should go away. The alarm LED goes out when the smoke is gone.





MASTER CALL
LIGHT MODULE (TYP)



CSCP/CACP POP-UP WINDOW

LAVATORY SMOKE DETECTION - OPERATION - INDICATIONS

LAVATORY WASTE COMPARTMENT FIRE EXTINGUISHING - FIRE EXTINGUISHER BOTTLE

Purpose

The lavatory waste compartment fire extinguisher extinguishes fires in the waste compartment.

Physical Description

The fire extinguisher is a bottle with two nozzles. The bottle contains pressurized halon 1301 fire extinguishing agent. The nozzles are sealed with a solder which melts at approximately 170 F (77 C).

Location

The fire extinguisher is above the waste container in the cabinet under the sink. The fire extinguisher nozzles point into the waste container. Open the cabinet for access.

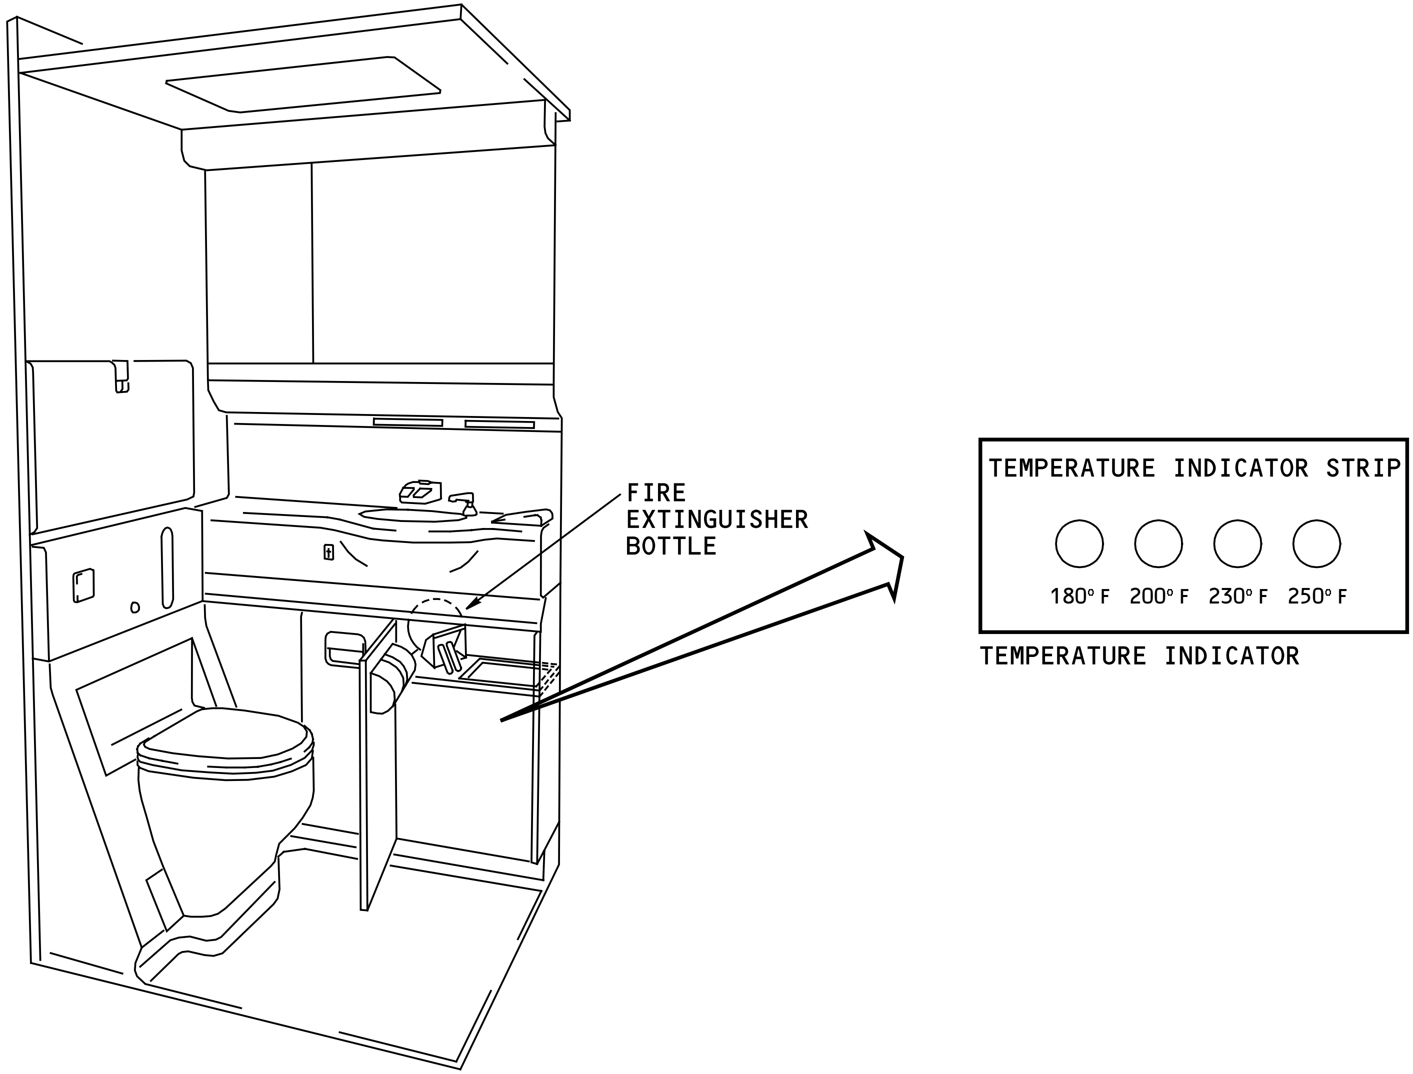
Functional Description

A fire in the waste container melts the solder on the nozzles. This releases halon from the bottle to put out the fire.

Training Information Point

A temperature indicator on the side of the waste container shows if there has been a fire. You can see the indicator without removing the container to look inside. The indicator circles are normally white. Black circles show a fire.

You can weigh the fire extinguisher to find out if it is empty. Replace an empty bottle; you cannot fill it again.



26-24-00-001 Rev 0

LAVATORY WASTE COMPARTMENT FIRE EXTINGUISHING - FIRE EXTINGUISHER BOTTLE

PORTABLE FIRE EXTINGUISHERS

General

The portable fire extinguishers extinguish fires. There are two types of extinguishers: water and Halon 1211. The Halon extinguishers are used on electrical and flammable liquid fires. The water extinguisher is used on non-electrical fires.

Location

There are extinguishers in these areas:

- Flight deck
- Galley stowage compartment
- Closet
- Underseat stowage
- Attendant seat bustle
- Seat track mounted storage.

Placards identify all the extinguisher locations.

Physical Description

The water extinguishers contain a water and anti-freeze mixture. Each water extinguisher has these parts:

- Trigger
- Cartridge (internal)
- Handle
- Quick-release mounting strap.

The fire extinguisher is held on a mounting bracket by a quick release strap.

Each Halon extinguisher has these parts:

- Pressure gage
- Handle lock pin
- Handle.

The fire extinguisher is held on a mounting pad by a quick release mounting strap.

Operation

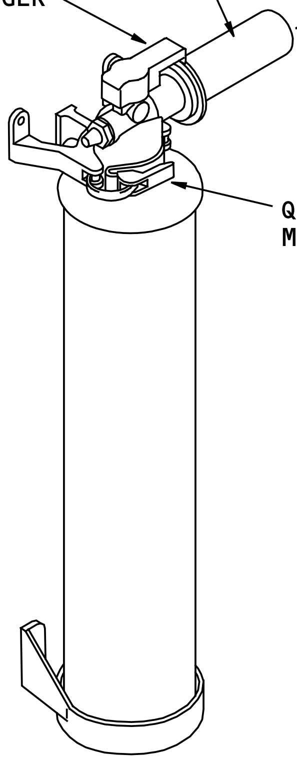
To operate the water extinguisher, turn the handle and push the trigger.

To operate the Halon extinguisher, remove the handle lock pin and push the handle.

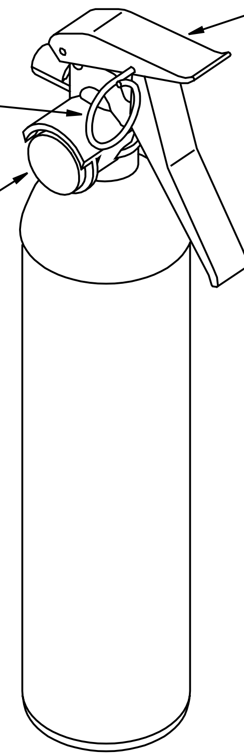
Training Information Point

After you use the water extinguisher, it must be refilled and you must replace the cartridge.

If the handle lock pin on the Halon extinguisher is not there, you must weigh the extinguisher to find out if it has been discharged. The pressure gage is not a satisfactory check of the extinguisher.



WATER FIRE EXTINGUISHER



HALON FIRE EXTINGUISHER

26-26-00-001 Rev 1 08/08/1996

PORTABLE FIRE EXTINGUISHERS

FIRE PROTECTION - SYSTEM TESTS

General

These are the system tests for the fire extinguishing system:

- Cargo squibs
- Engine and APU squibs.

Cargo Squibs

WARNING: KEEP PERSONS AWAY FROM THE CARGO COMPARTMENT DURING THIS TEST. IF A SQUIB FIRES ACCIDENTALLY, THE FIRE BOTTLE CAN RELEASE ITS CONTENTS AND CAUSE INJURIES.

This test supplies a small current to these squibs:

- Cargo compartment fire extinguishing bottles
- Cargo compartment fire extinguishing flow valves
- Engine fire extinguishing bottles
- APU fire extinguishing bottle.

The test makes sure that there are no open circuits in the cargo compartment fire extinguishing squibs and their related wiring.

Engine and APU Squibs

WARNING: KEEP PERSONS AWAY FROM THE ENGINE AND APU DURING THIS TEST. IF A SQUIB FIRES ACCIDENTALLY, THE FIRE BOTTLE CAN RELEASE ITS CONTENTS AND CAUSE INJURIES.

This test supplies a small current to these squibs:

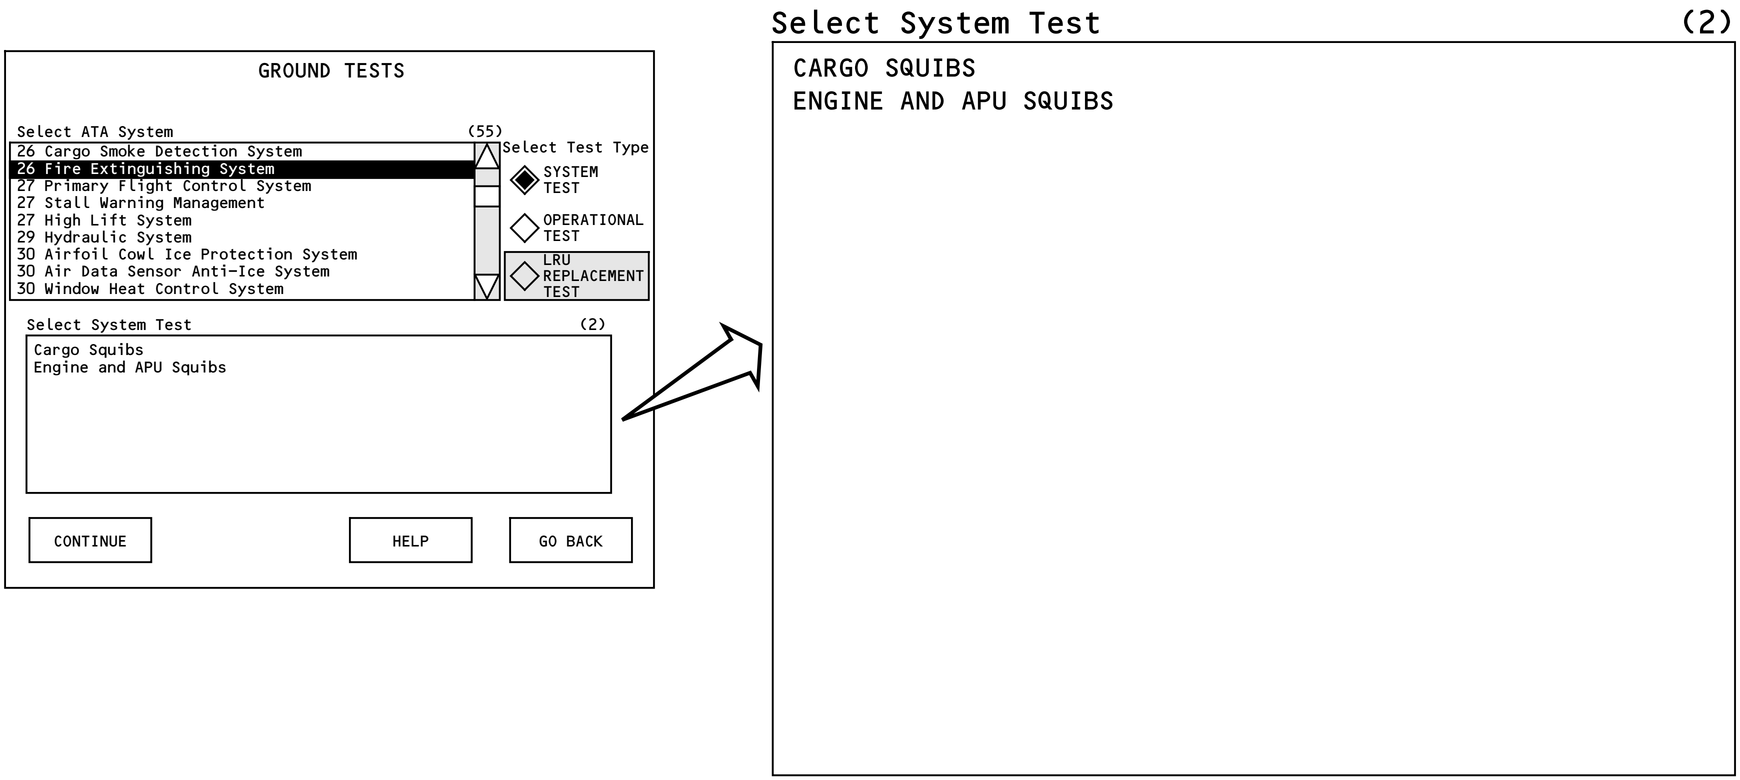
- Engine fire extinguishing bottles
- APU fire extinguishing bottle
- Cargo compartment fire extinguishing bottles
- Cargo compartment fire extinguishing flow valves.

The test makes sure that there are no open circuits in the engine and APU fire extinguishing squibs and their related wiring.

Training Information Point

NOTE: When you do either test, keep persons away from the cargo compartments, engines, and APU. Each test supplies power to all the squibs in the airplane.

When you do either test, the ELMS supplies a small current to all the squibs in the airplane. The MAT shows the test results only for the selected test. See Fire Protection - Squib Test - Functional Description in this section for more information.



26-00-00-002 Rev 3 07/31/95

FIRE PROTECTION - SYSTEM TESTS

FIRE PROTECTION - TRAINING INFORMATION POINT - FIRE/OVERHEAT TEST

General

The fire and overheat test switch (FIRE/OVHT TEST) does a test of these systems:

- Engine fire detection
- APU fire detection
- Lower cargo compartment smoke detection
- Wheel well fire detection.

Fire/Overheat Test

Push and hold the fire/overheat test switch. Make sure these indications come on:

- APU fire warning light
- Forward cargo fire warning light
- Aft cargo fire warning light
- Master warning lights
- Fire aural warning
- Engine fuel control switch fire warning lights
- Left and right engine fire warning lights
- FIRE TEST IN PROGRESS warning message.

Release the fire/overheat test switch when the test is complete. The test is complete when the warning message FIRE TEST PASS or FIRE TEST FAIL shows. All the test indications go away when you release the switch.

Fire Test Pass

This message shows that the systems are serviceable. The systems may have faults which do not prevent flight. An example is a single loop fault in the engine fire detection system. Status messages show these faults. Look in the Dispatch Deviation Guide book to see if these faults limit flight operations.

Fire Test Fail

This message shows that one or more systems are not serviceable. These advisory messages show which system has a failure:

- DET FIRE ENG L
- DET FIRE ENG R
- DET FIRE APU
- DET FIRE CARGO FWD
- DET FIRE CARGO AFT
- DET FIRE WHEEL WELL.

Status messages show the failed LRUs.

DOORS - INTRODUCTION

Purpose

Doors give access to compartments and service areas.

General Description

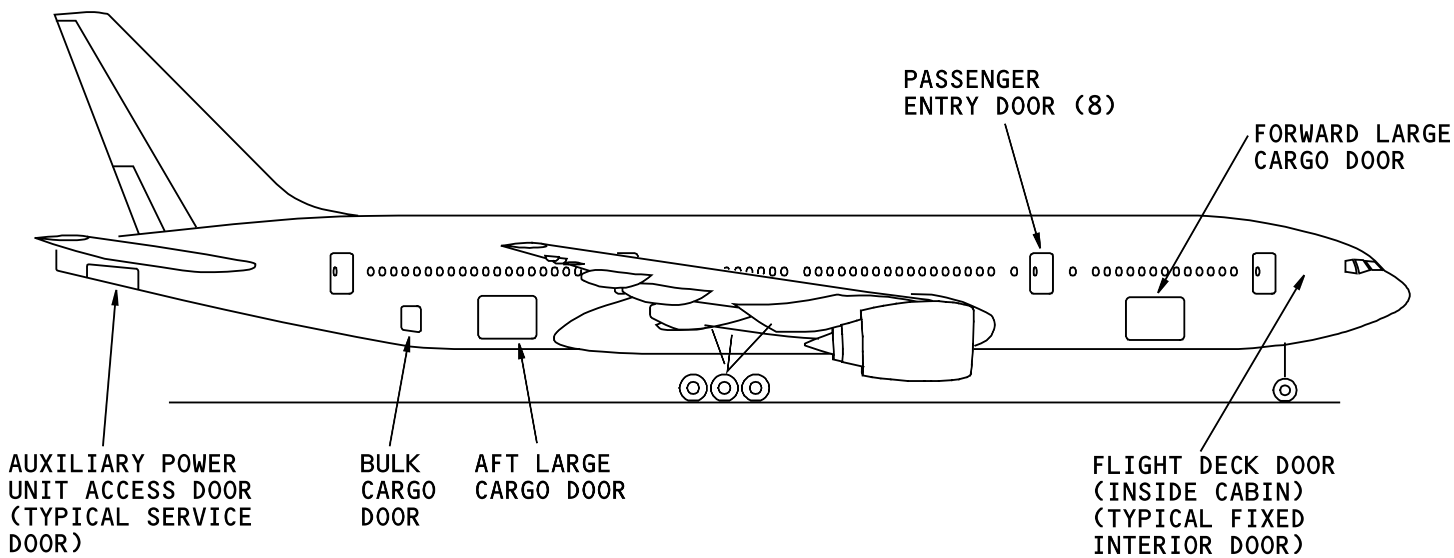
These are the types of doors:

- Passenger entry doors
- Cargo doors
- Service doors
- Fixed interior doors.

There is a door warning system that gives door status information to the flight crew.

Abbreviations and Acronyms

AC - alternating current
ADP - air-driven pump
AIMS - airplane information management system
APU - auxiliary power unit
ARINC - Aeronautical Radio, Inc.
aux - auxiliary
CACP - cabin area control panel
cm - centimeter
CSS - cabin services system
CSCP - cabin system control panel
DC - direct current
ECS - environmental control system
EICAS - engine indication and crew alerting system
E/E - electrical and electronic
EPAS - emergency power assist system
fwd - forward
gnd - ground
hdlg - handling
Hz - hertz
inbd - inboard
MAT - maintenance access terminal
MEC - main equipment center
outbd - outboard
PDU - power drive unit
pnl - panel
PSI - pounds per square inch
PSEU - proximity sensor electronics unit
pwr - power
ref - reference
RPM - revolutions per minute
V - volt



52-00-00-001 Rev 3 09/15/1997

DOORS - INTRODUCTION

PASSENGER ENTRY DOOR SYSTEM - INTRODUCTION

Purpose

Passenger entry doors give access to the passenger compartment.

General Description

There are four passenger entry doors on each side of the airplane.

Linings cover the hinge and upper part of the door. A bustle covers the escape/slide raft on the lower part of the door.

The doors are plug-type. They open and close on a single hinge arm. As a door opens, the first movement is upward out of its plug position. Then it translates forward. Translation means that the door does not turn in relation to the airplane. When open, the inside of the door is next to the outside of the fuselage.

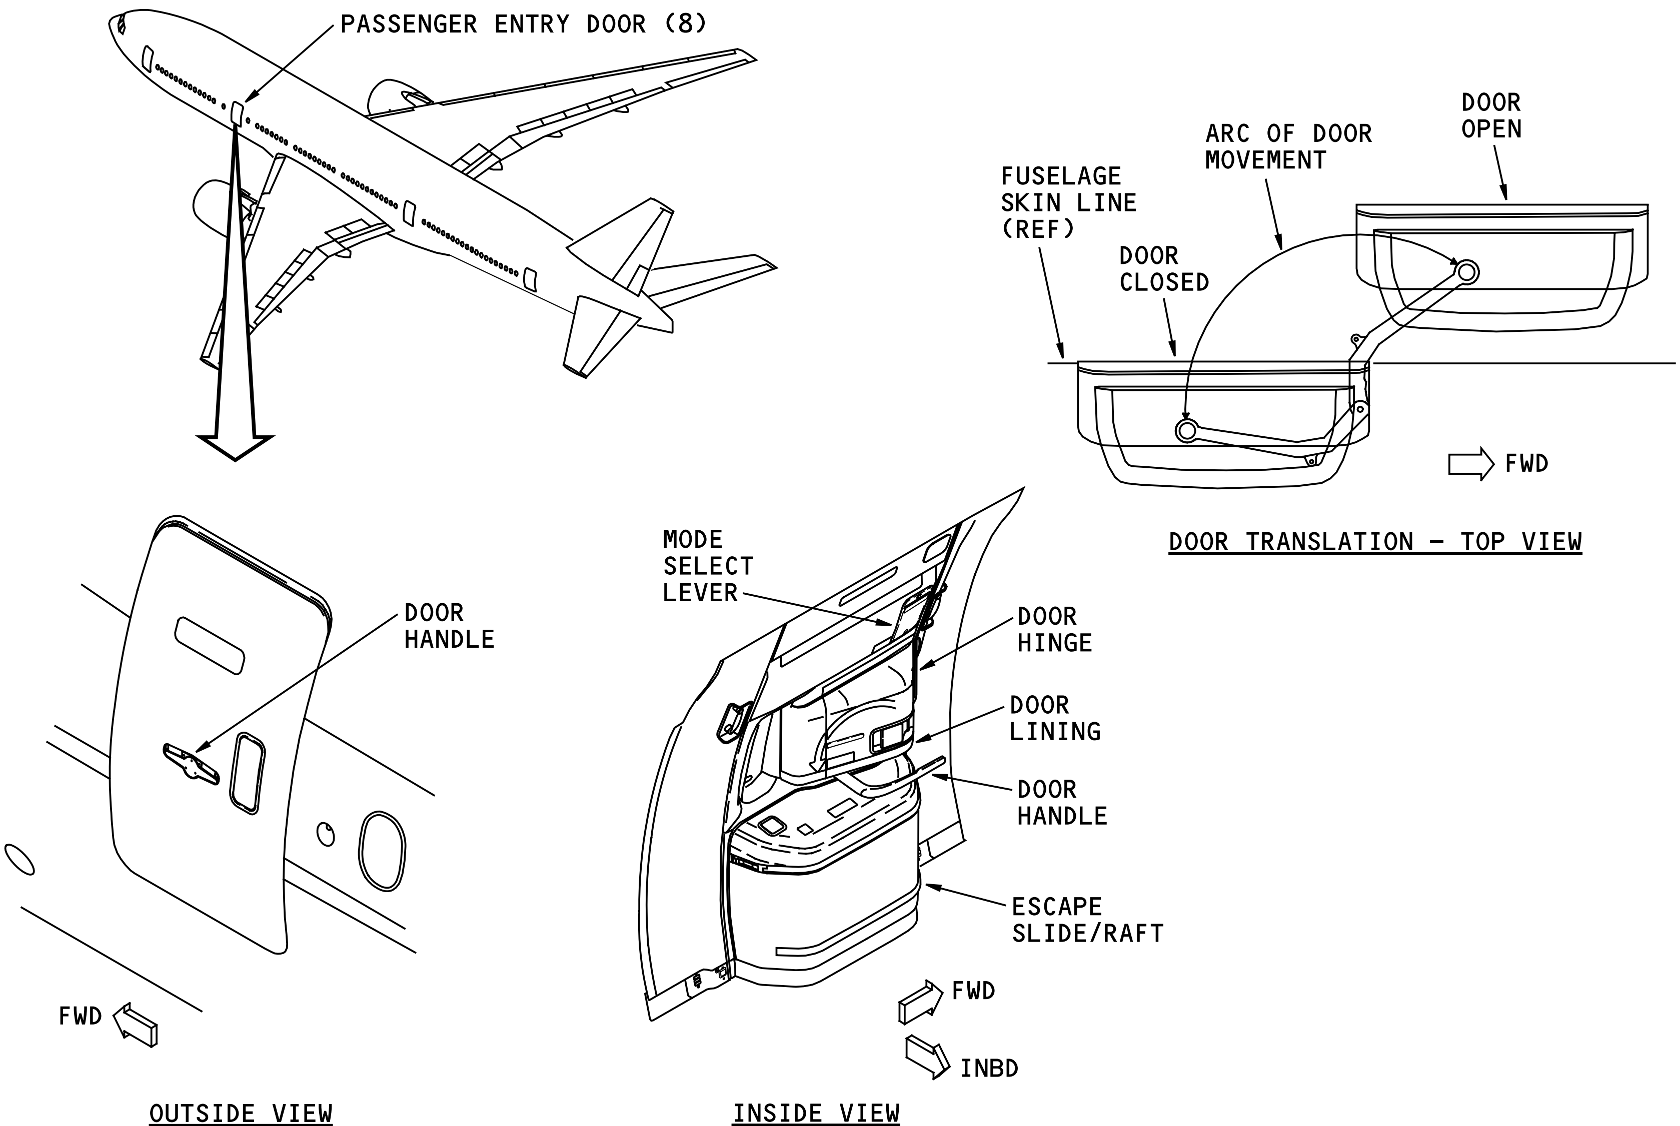
The door dimensions allow two people to move through the door at the same time.

Handles to open and close the door are on the inside and outside of the door.

The mode select lever for armed or disarmed operation is on the inside of the door.

In the armed mode operation, when you move the internal door handle to the open position:

- The emergency power assist system (EPAS) (not shown) moves the door to the open position
- The emergency escape slide/raft deploys.



52-11-00-001 Rev 3 07/30/1997

PASSENGER ENTRY DOOR SYSTEM - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

PASSENGER ENTRY DOOR SYSTEM - COMPONENT LOCATIONS

<u>Components on the Inside of the Door - Lining Removed</u>

The vent door mechanism is near the top of the door.

The mode select mechanism is on the forward, upper part of the door. The girt bar mechanism is on the bottom of door. The push/pull cable connects the mode select mechanism and the girt bar mechanism.

The door hinge connects the middle of the door to the forward side of the door cutout.

These components are on the door hinge:

- Programming chain mechanism
- Snubber
- Hold-open mechanism
- Emergency power assist system (EPAS) battery
- EPAS reservoir
- EPAS actuator.

The EPAS actuator does not show in this view. It is on the outboard side of the door hinge.

<u>Components Outboard of the Door Hinge</u>

The flight lock mechanism is near the forward edge of the door. It connects to the Latch mechanism.

The door handle mechanism is near the middle of the door. It connects to the latch mechanism and the vent door mechanism.

The latch mechanism goes across the middle of the door. It connects to the handle mechanism and the vent door mechanism.

<u>Proximity Sensors and Mechanical Switches</u>

The proximity sensors on the aft door latch and the vent door are components of the door warning system. See the door warning section for more information on the door warning system (AMM PART I 52-71). The proximity sensors (not shown) on the flight lock mechanism are components of the door system.

The EPAS uses these two mechanical switches:

- The mode select switch on the mode select mechanism
- The door open switch on the door handle mechanism.

<u>Door Open Sequence</u>

Movement of the lever on the mode select mechanism disarms the escape slide/raft and EPAS. The mode select switch on the mechanism is the component that disarms the EPAS. The push/pull cable transmits mode select lever movement to the girt bar mechanism.

The door handle mechanism lets you unlatch the passenger entry door. The mechanical switch on the mechanism starts the EPAS if the mode select mechanism is in the armed position.

PASSENGER ENTRY DOOR SYSTEM - COMPONENT LOCATIONS

The vent door mechanism releases pressurization before the passenger entry door can unlatch completely. It also locks the latch mechanism if pressurization is too high for safe passenger entry door operation.

The latch mechanism lifts and unlatches the door.

The door moves up past the stops on the cutout and translates open on the hinge.

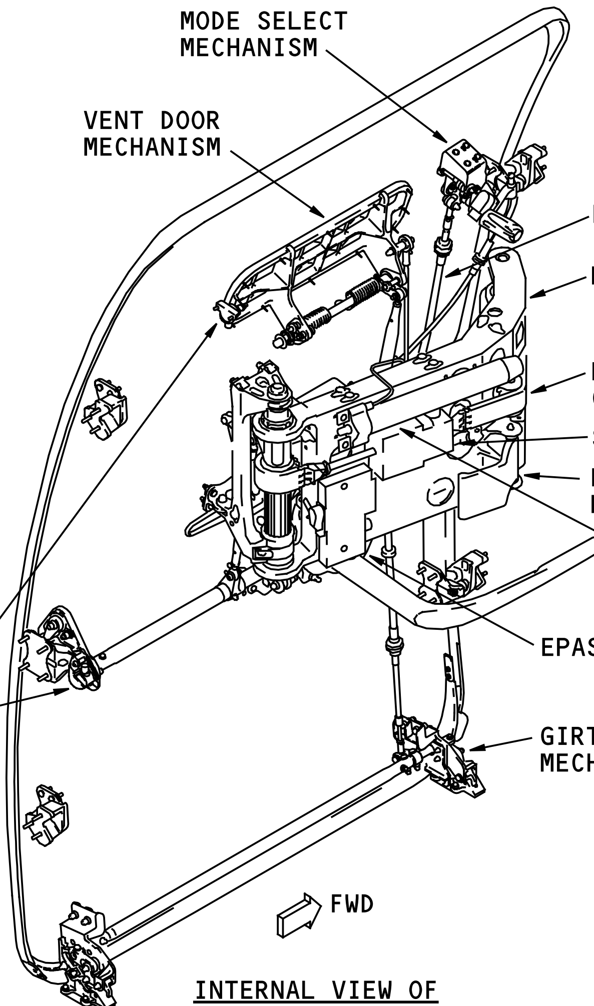
The programming chain mechanism keeps the inside of the door parallel to the airplanes longitudinal axis as the door opens.

The snubber controls the rate of movement of the door.

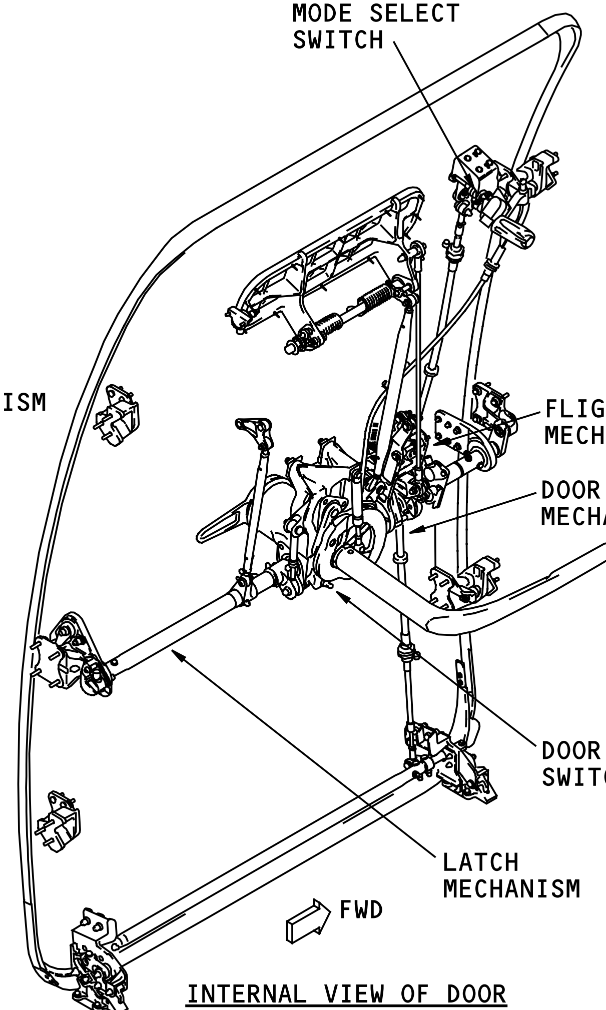
The hold-open mechanism holds the door in the completely open position.

The EPAS moves the door open in emergencies.

The girt bar mechanism locks the emergency escape slide/raft to the bottom of the door cutout when you open the door in emergencies.



INTERNAL VIEW OF DOOR MECHANISMS



INTERNAL VIEW OF DOOR MECHANISMS WITHOUT HINGE

PASSENGER ENTRY DOOR SYSTEM - COMPONENT LOCATIONS

PASSENGER ENTRY DOOR SYSTEM - DOORS AND SEALS

Purpose

The passenger entry doors and seals close and seal the external access to the passenger compartment.

Physical Description

The door has these components:

- Outer skin
- Acoustic seal
- Inner skin
- Frames
- Intercostals
- Beams
- Stops
- Pressure seal.

Part of the blade-type pressure seal attaches to the bottom edge and corners of the door. The other part of the seal attaches to the sides and top of the door cutout.

The tube-type acoustic door seal attaches to the top door beam.

Functional Description

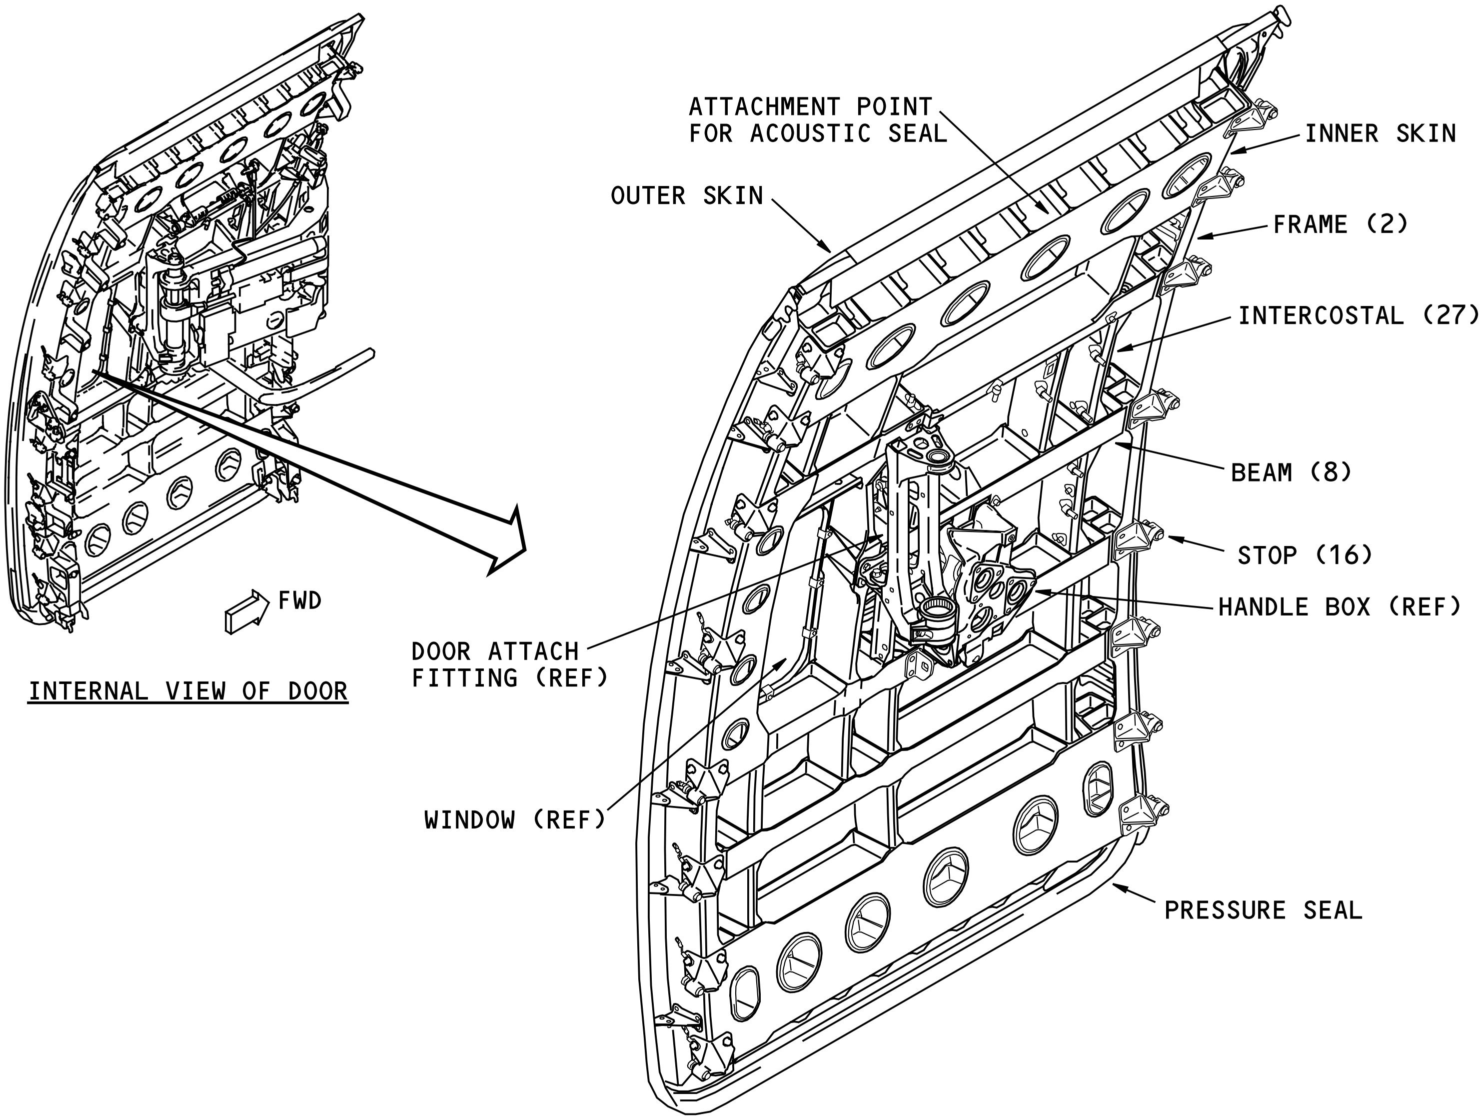
The door is a plug-type. The door stops fit against cutout stops. The stops prevent the outward movement of the door when the airplane is pressurized.

The pressure door seal prevents flow of cabin air to the outside.

The acoustic door seal reduces the outside noise that enters the cabin.

Training Information Point

The pressure seal depressor (not shown) on the forward side of doors one left and one right may have one or two holes in the area 40 to 50 inches above the cabin floor. These holes help control air noise. Do not block these holes. If a new depressor is installed, drill the same size holes in the same location on the new depressor.



52-11-00-003 Rev 1

PASSENGER ENTRY DOOR SYSTEM - DOORS AND SEALS

PASSENGER ENTRY DOOR SYSTEM - DOOR HINGE

Purpose

The hinge connects the door to the airplane and lets the door open and close.

Physical Description

The door hinge has these components:

- Hinge support fitting
- Hinge arm
- Lift sleeve
- Linear lift
- Door attach fitting

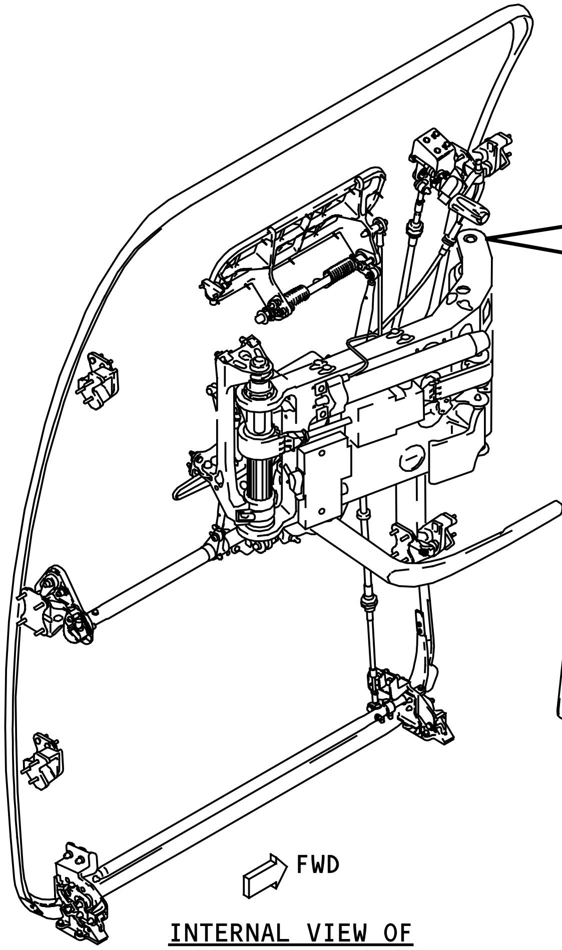
The hinge support fittings connect the hinge arm to the door cutout. The upper fitting has a sprocket for the programming chain.

The door attach fitting connects the door to the linear lift. The linear lift connects to the hinge arm. It has a sprocket for the programming chain. The programming chain is described later in this section.

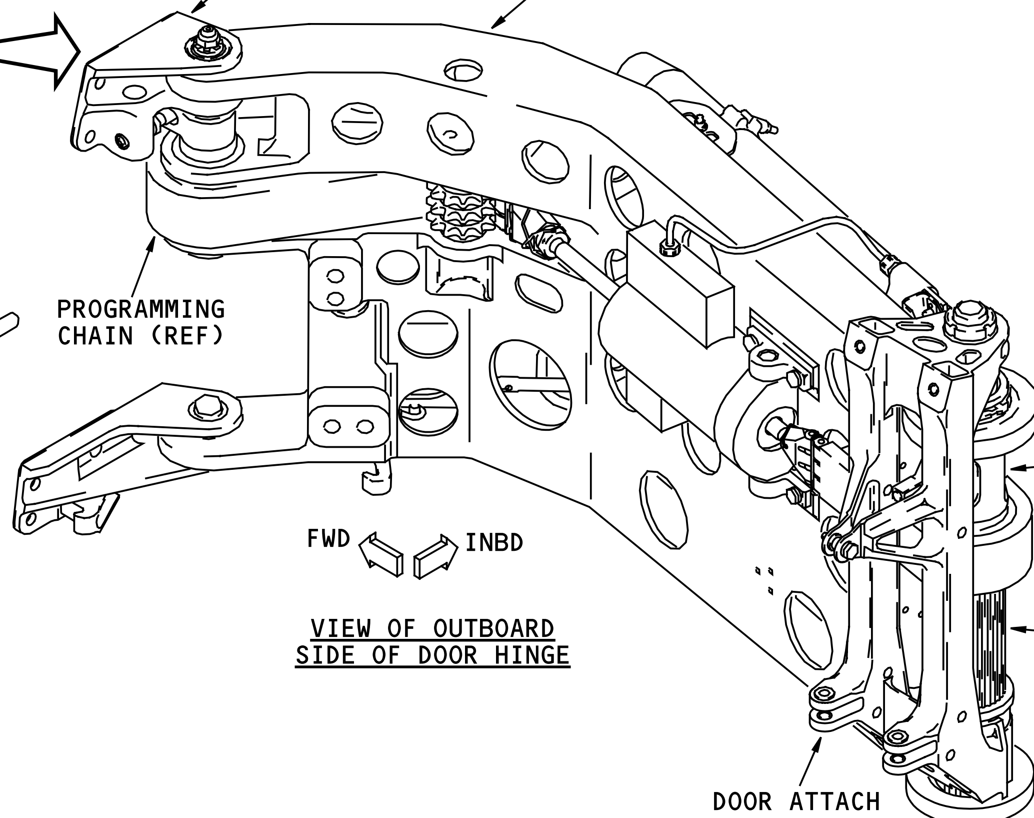
Functional Description

As the door opens or closes:

- The hinge arm turns on the hinge support fittings
- The door turns and moves up and down on the linear lift.



INTERNAL VIEW OF DOOR MECHANISMS



VIEW OF OUTBOARD SIDE OF DOOR HINGE

52-11-00-004 Rev 0

PASSENGER ENTRY DOOR SYSTEM - DOOR HINGE

PASSENGER ENTRY DOOR SYSTEM - DOOR HINGE - LINEAR LIFT FUNCTION

Linear Lift Functional Description

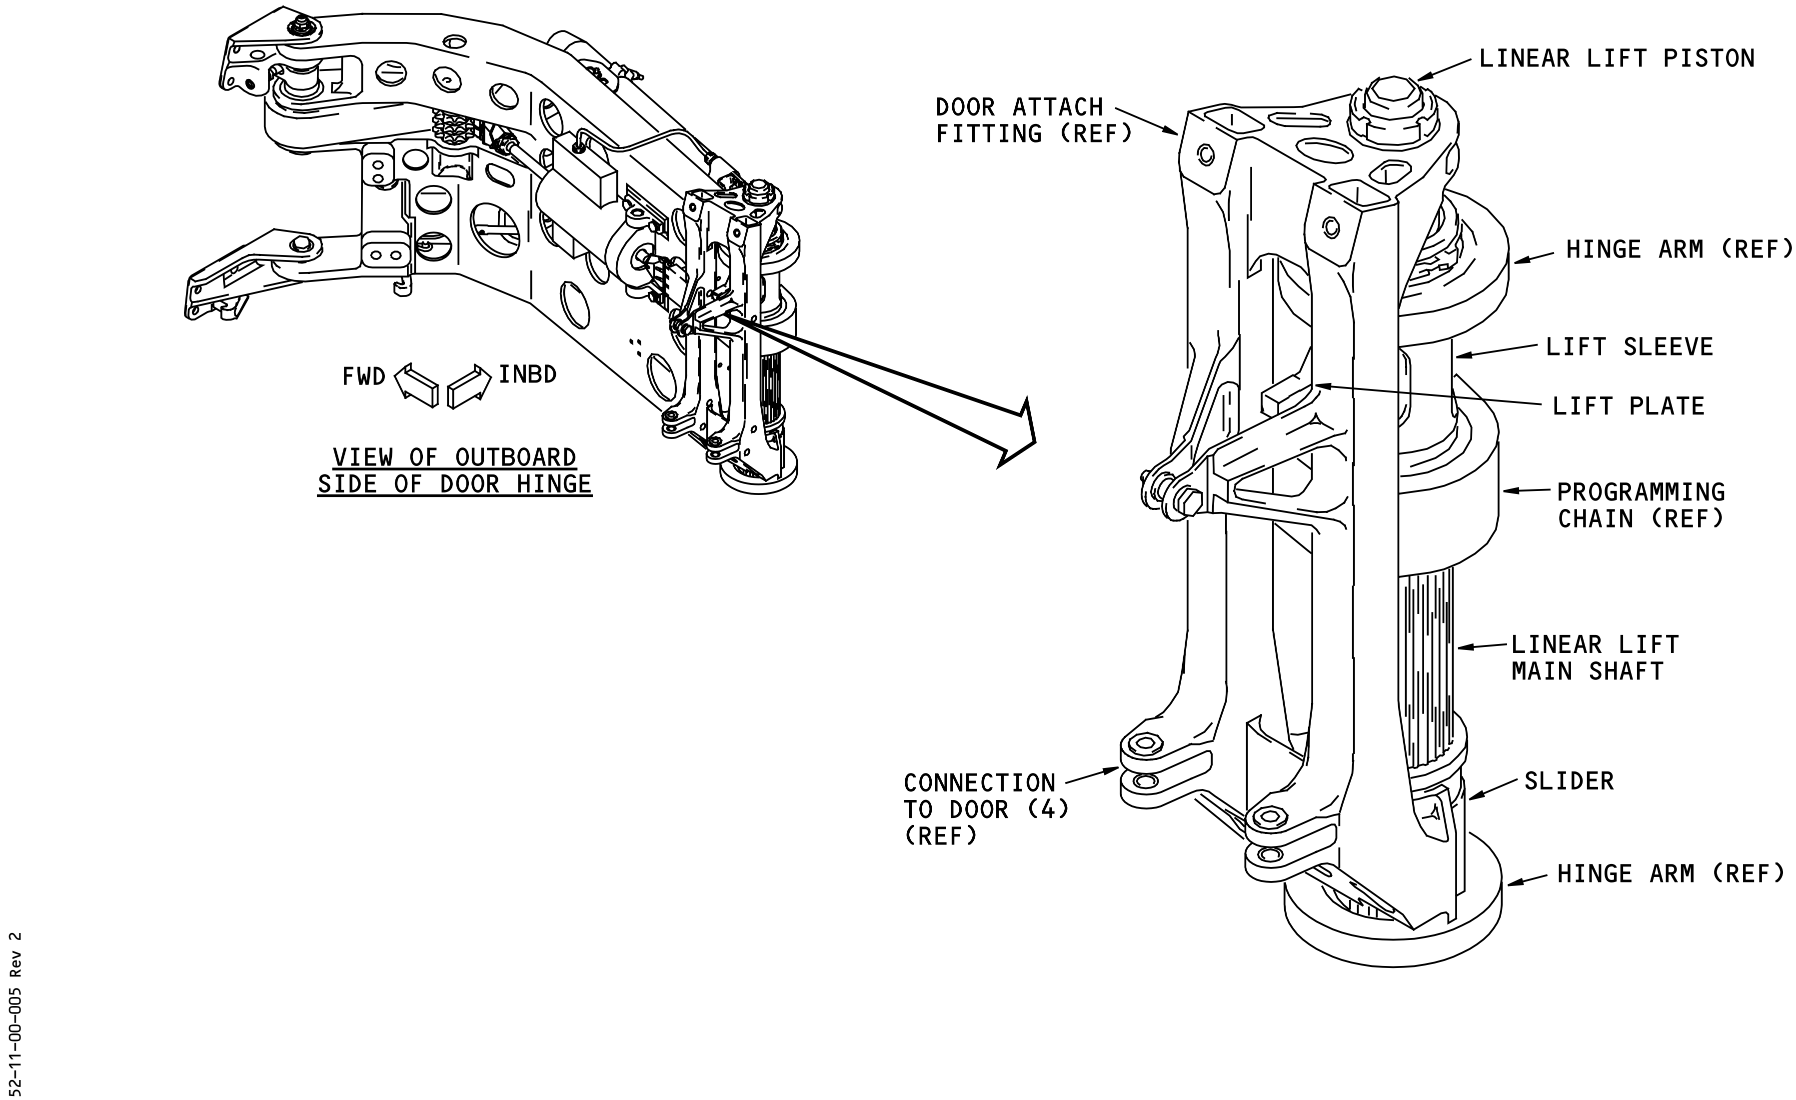
The linear lift piston moves up and down inside the main shaft. The door counterbalance spring is inside the main shaft. It pushes the piston up.

The top of the piston connects to the door attach fitting. A slider that moves up and down on the main shaft connects to the bottom of the door attach fitting.

The force of the counterbalance spring helps the latch mechanism lift the door. The movement of the piston inside the main shaft makes sure the door lift is vertical.

Training Information Point

Do not lubricate the linear lift. Its surface includes a dry lubricant. Liquid lubricants can collect dirt.



PASSENGER ENTRY DOOR SYSTEM - DOOR HINGE - LINEAR LIFT FUNCTION

PASSENGER ENTRY DOOR SYSTEM - PROGRAMMING MECHANISM CHAIN

Purpose

The programming mechanism chain has these functions:

- Correctly aligns the door to the airplane as the door opens and closes
- Lets he door emergency power assist system (EPAS) open the door in emergencies.

Physical Description

The chain goes completely around the hinge arm.

The chain has two parts. One part of the chain connects to the snubber piston. It goes around the sprocket on the linear lift and connects to the EPAS actuator piston. The second part of the chain connects to the other end of the actuator piston. It goes around a sprocket on the hinge pin and connects to the other end of the snubber piston.

Idler sprockets let the chain follow the shape of the hinge arm.

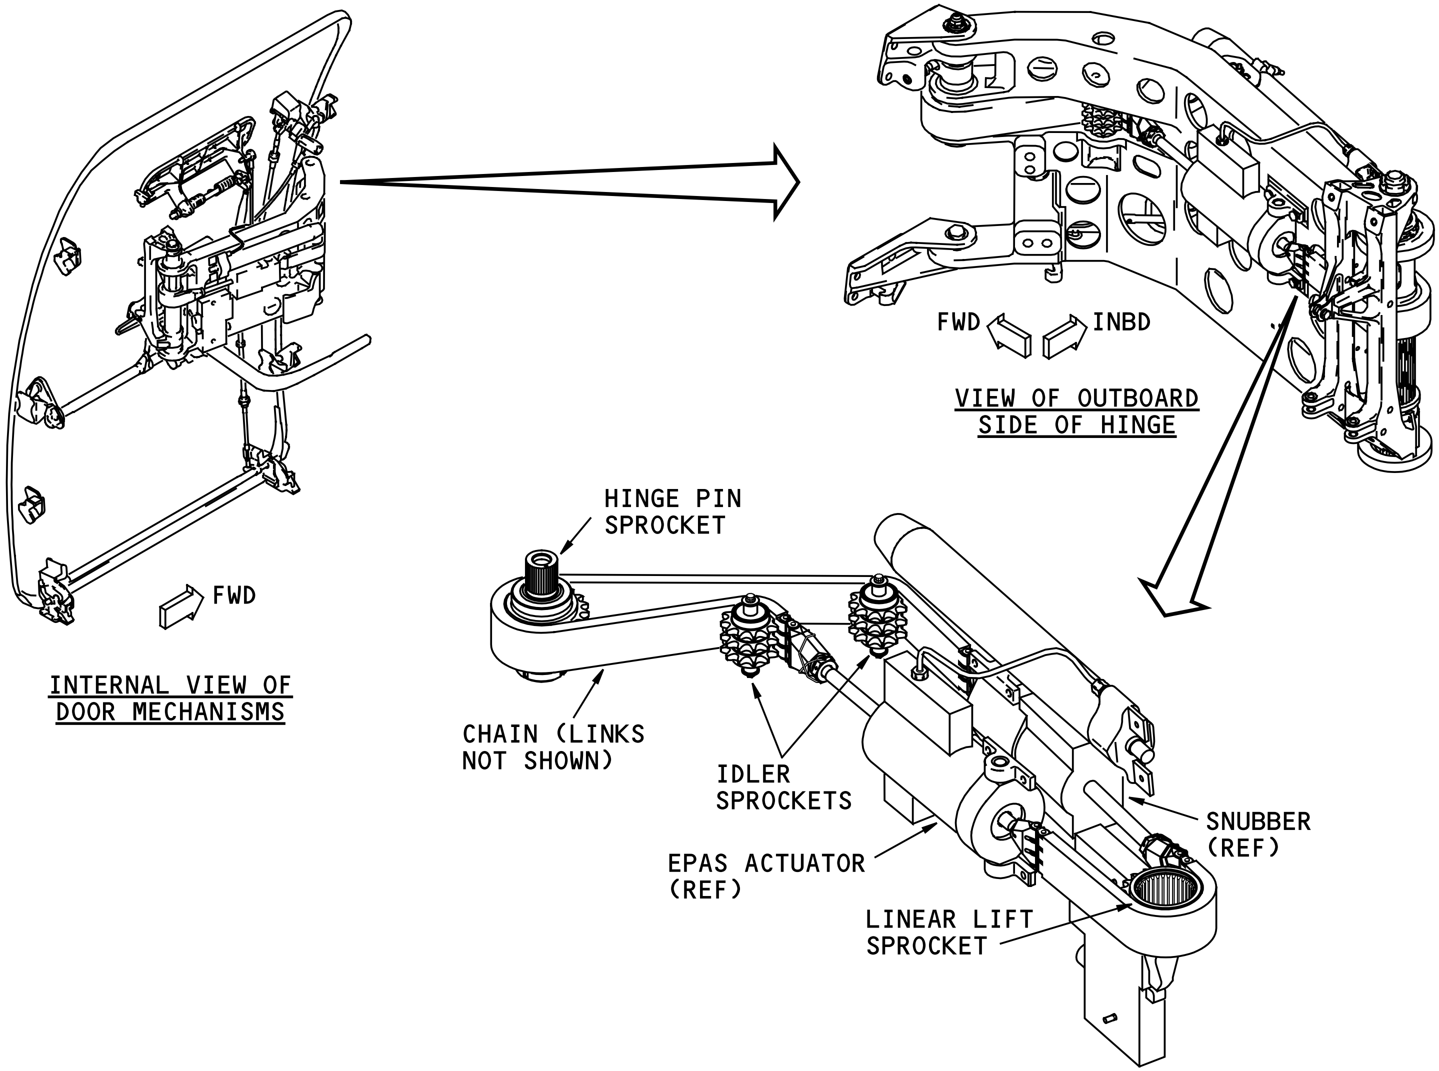
Functional Description

The hinge arm turns on the hinge pin as the door opens and closes. The sprocket on the hinge pin does not turn. This causes the chain to move in relation to the hinge arm. The pistons of the EPAS actuator and the snubber pass the movement through to the other part of the chain.

The sprocket on the linear lift does not turn in relation to the door. The movement of the chain around the sprocket causes the door to move in relation to the hinge arm. This lets the door move forward and aft but not turn in relation to the airplane.

Training Information Point

Do not lubricate the chain. Its surface includes a dry lubricant. Liquid lubricants can collect dirt.



52-11-00-006 Rev 1

PASSENGER ENTRY DOOR SYSTEM - PROGRAMMING MECHANISM CHAIN

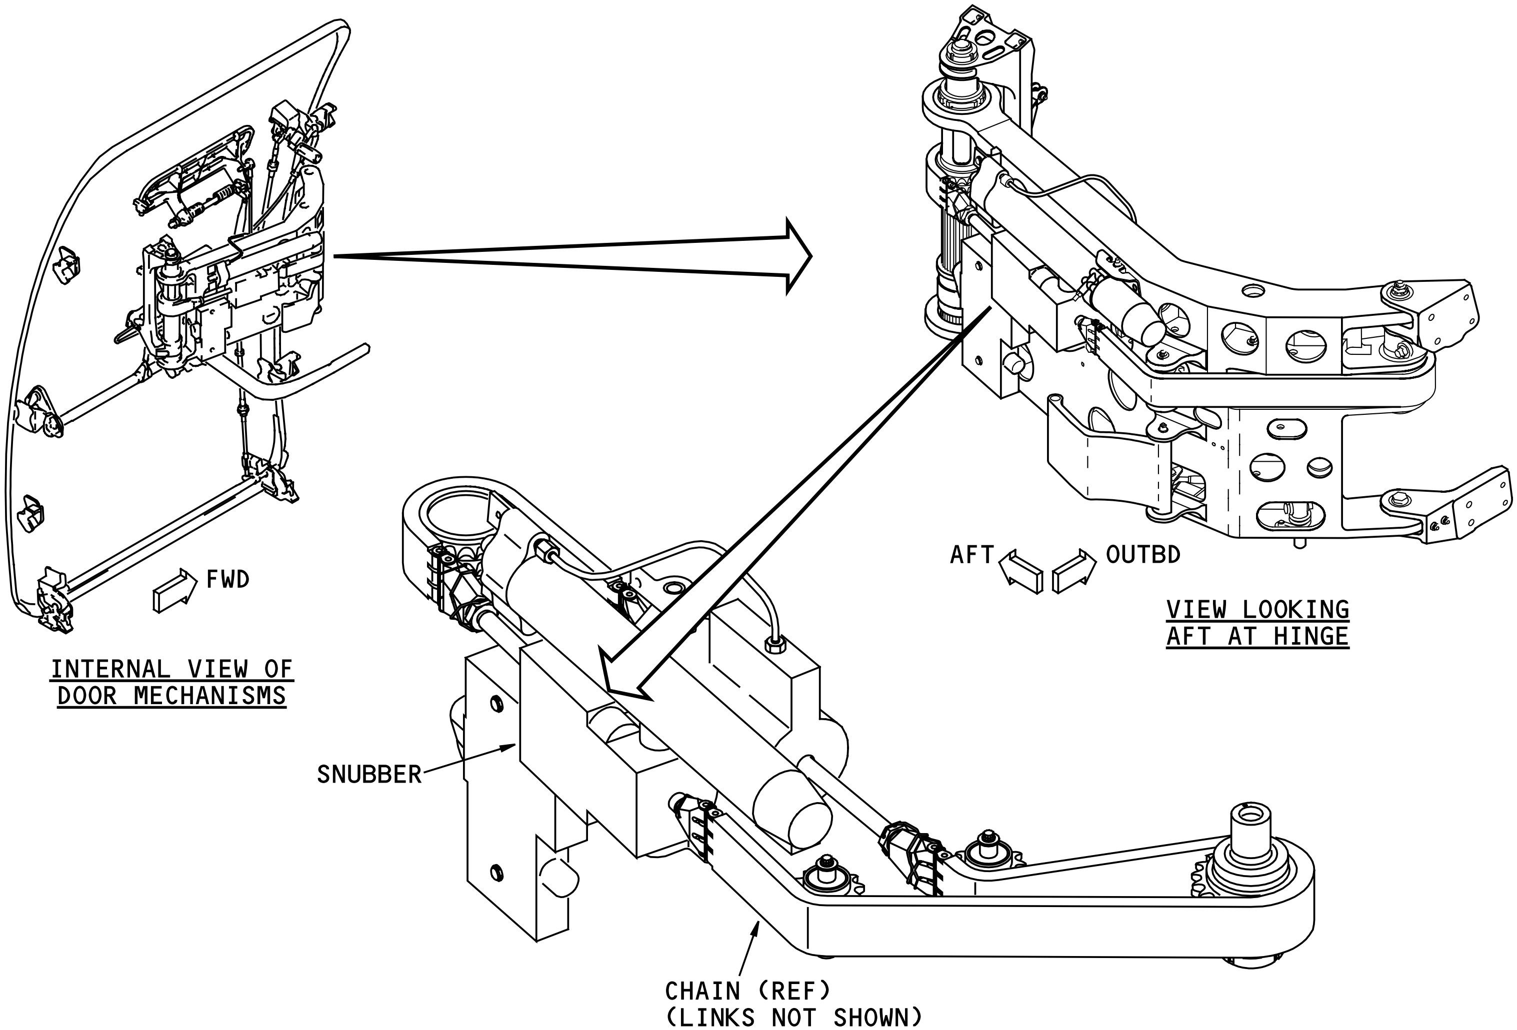
PASSENGER ENTRY DOOR SYSTEM - SNUBBER

Purpose

The snubber controls the rate at which the door opens or closes.

Physical Description

The snubber attaches to the inboard side of the hinge arm. It has a piston and hydraulic fluid. The ends of the piston attach to the programming chain.



52-11-00-007 Rev 0

PASSENGER ENTRY DOOR SYSTEM - SNUBBER

PASSENGER ENTRY DOOR SYSTEM - HOLD-OPEN MECHANISM

Purpose

The hold open mechanism holds the door in the full open position. You use the mechanism handle to pull the door closed.

Physical Description

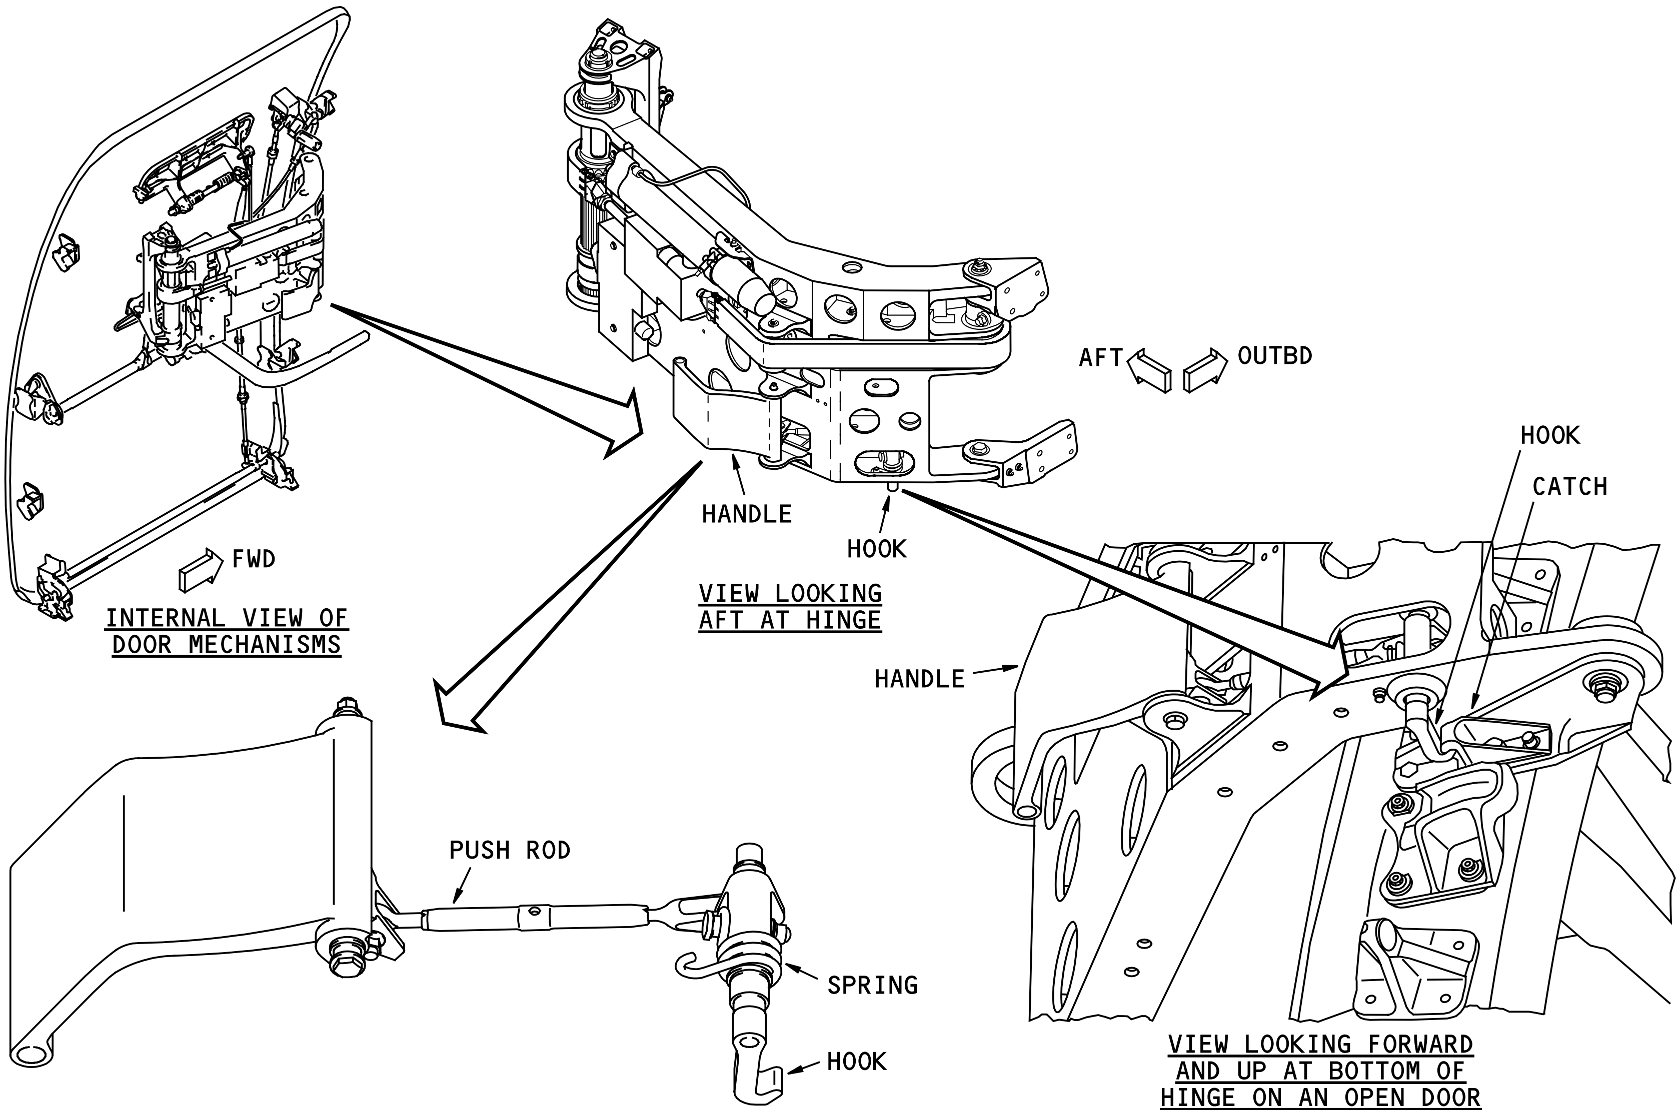
The mechanism is on the hinge arm and has these components:

- Handle
- Hook
- Catch
- Spring
- Push rod.

Functional Description

When the door is full open, the spring pushes the hook into the catch on the door cutout.

You pull on the handle to release the hook. The door closes if you continue to pull on the handle.



PASSENGER ENTRY DOOR SYSTEM - HOLD-OPEN MECHANISM

52-11-00-008 Rev 0

PASSENGER ENTRY DOOR SYSTEM - HANDLE MECHANISM AND MECHANICAL SWITCHES

Purpose

The door handle mechanism lets you open and close the door.

Physical Description

The door handle mechanism has these components:

- Internal handle
- Inner shaft
- Outer shaft
- External handle
- External handle return spring
- Disarm crank
- Handle box
- Gas spring
- Vent door crank
- Door open switch
- Handle cam
- Lift crank.

The door open switch is on the door handle mechanism.

Functional Description

The external handle connects to the outer shaft. The internal handle connects to the inner shaft. The outer shaft fits over the inner shaft.

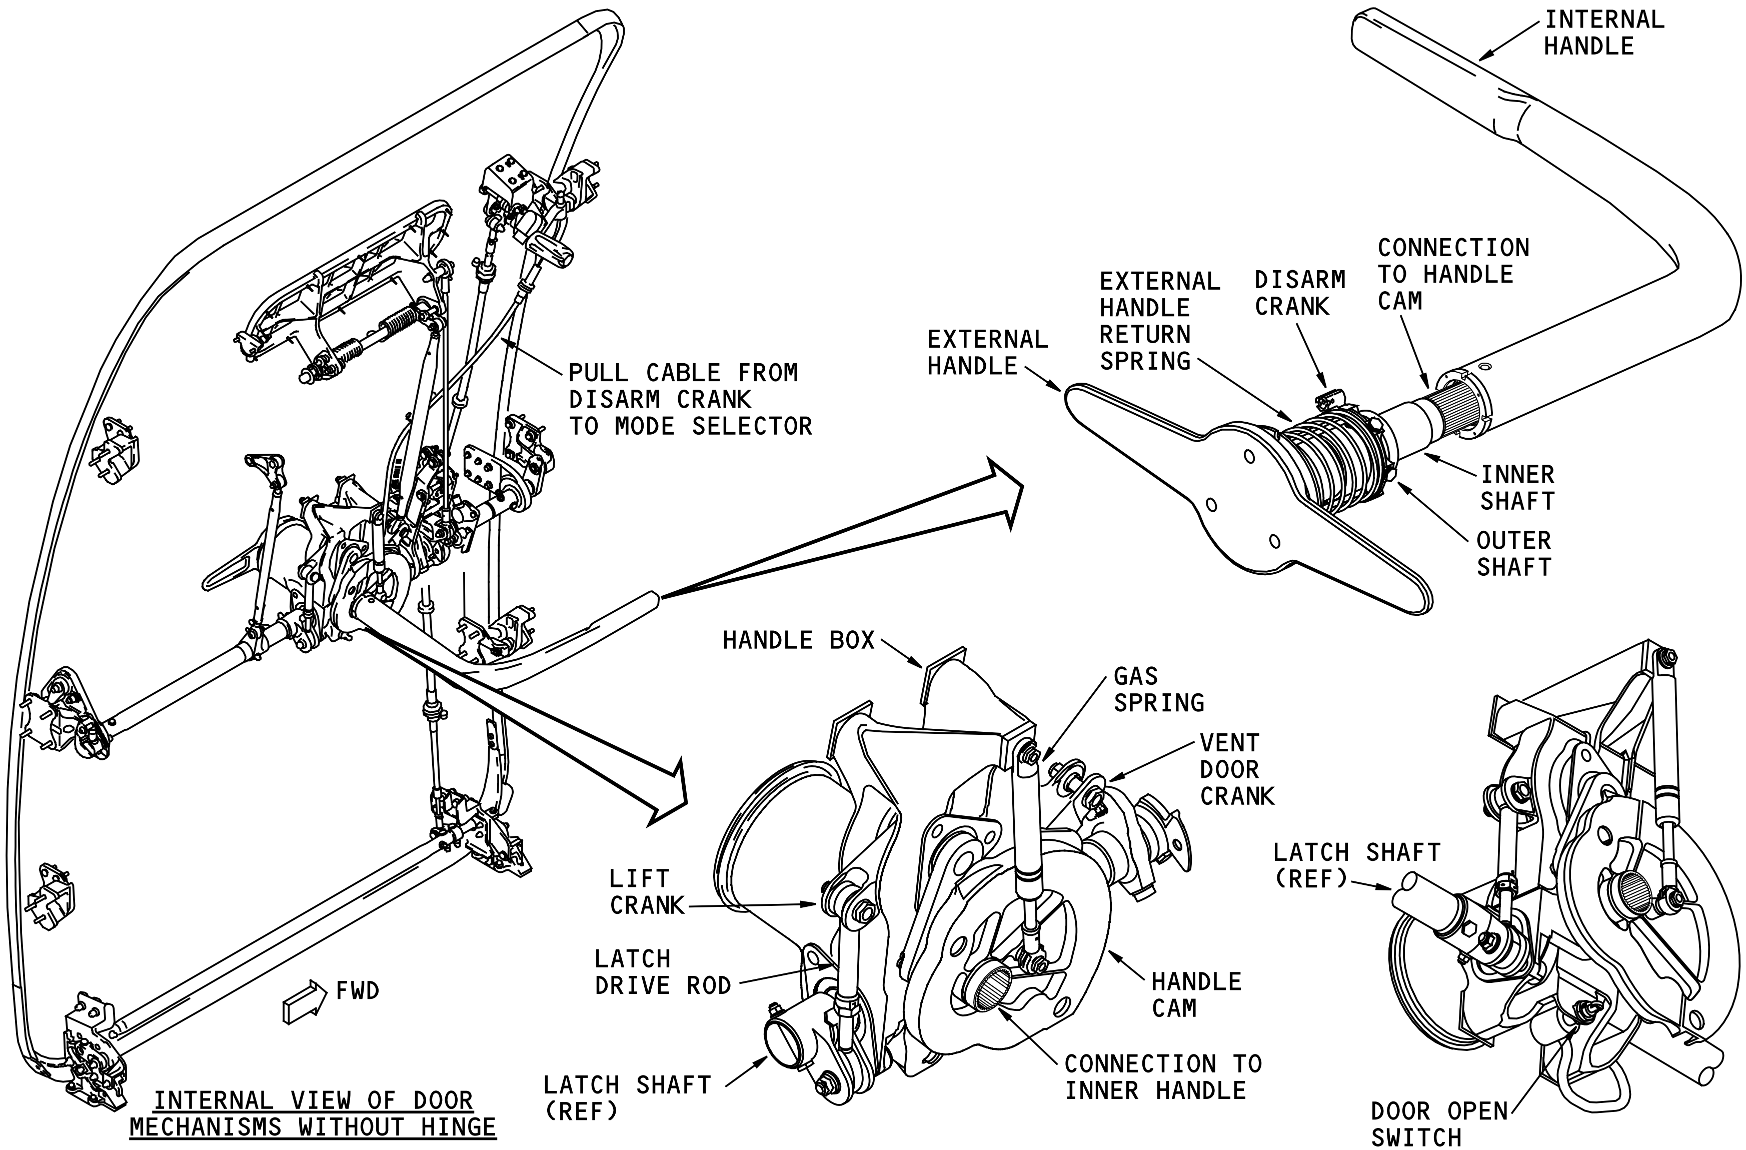
The external handle return spring holds the outer shaft over the inner shaft. When you pull outboard on the external handle, the outer and inner shafts lock together.

The inner shaft goes through the handle box which provides a bearing surface for the handle. The inner shaft connects to the handle cam. A lift drive crank and a latch drive rod connect the handle cam to the latch shaft. When you turn either handle, you move the latch shaft.

Pressure in the gas spring pushes down on the handle cam so the door handles are held in the full close position. Movement of either handle toward open compresses the gas in the spring. When the handle is past the center of movement, the compressed gas helps move the handle to full open.

A cable connects the disarm crank on the external handle to the mode select mechanism. When you pull the external handle out, you move the disarm crank. It pulls on the cable which moves the mode select mechanism to the disarm mode.

When the door is open, the handle cam will not transmit back drive forces from the latch shaft to the handles.



52-11-00-009 Rev 4

PASSENGER ENTRY DOOR SYSTEM - HANDLE MECHANISM AND MECHANICAL SWITCHES

PASSENGER ENTRY DOOR SYSTEM - LATCH MECHANISM - INTRODUCTION

Purpose

The latch mechanism does these functions:

- Unlatches and latches the door
- Lifts and lowers the door as it opens and closes so the door stops can move past the cutout stops.

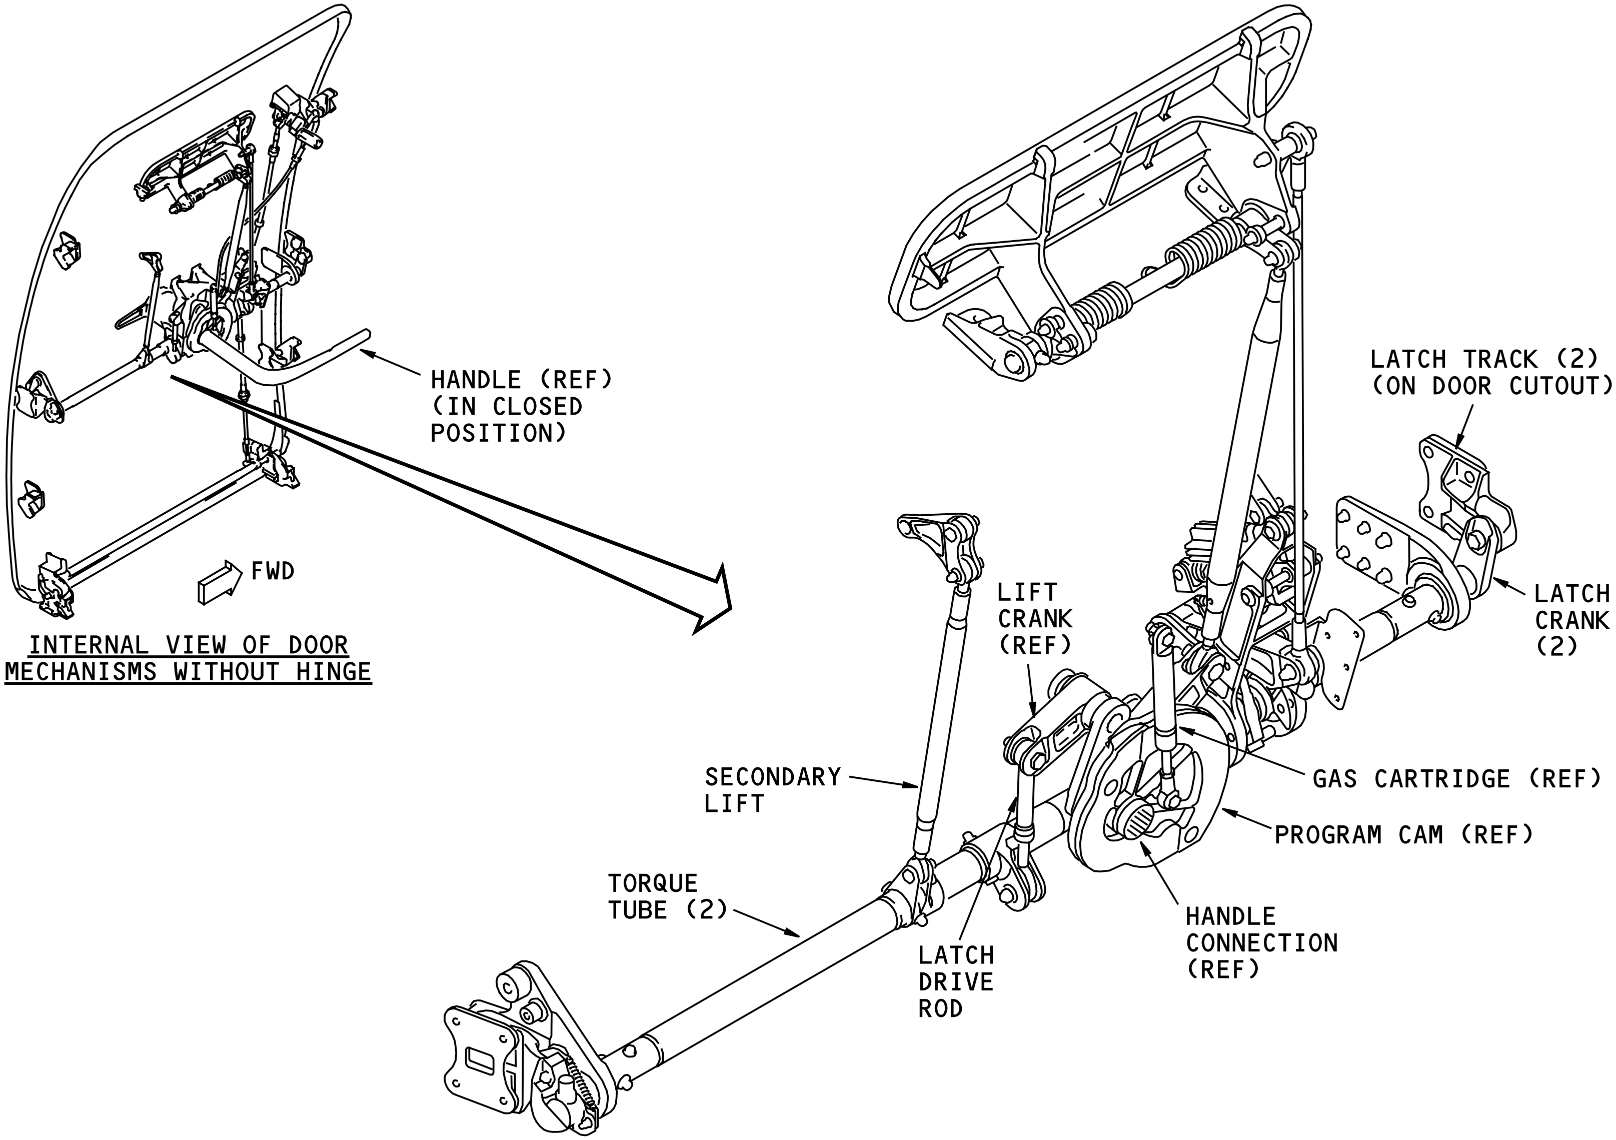
Physical Description

The mechanism has these components:

- Door locked proximity sensor
- Latch track (2)
- Latch crank (2)
- A latch drive rod
- Torque tube (2)
- A secondary lift.

Functional Description - Cam, Crank, and Torque Tube

The program cam moves the lift crank which pulls the latch drive rod up. This turns the torque tubes.



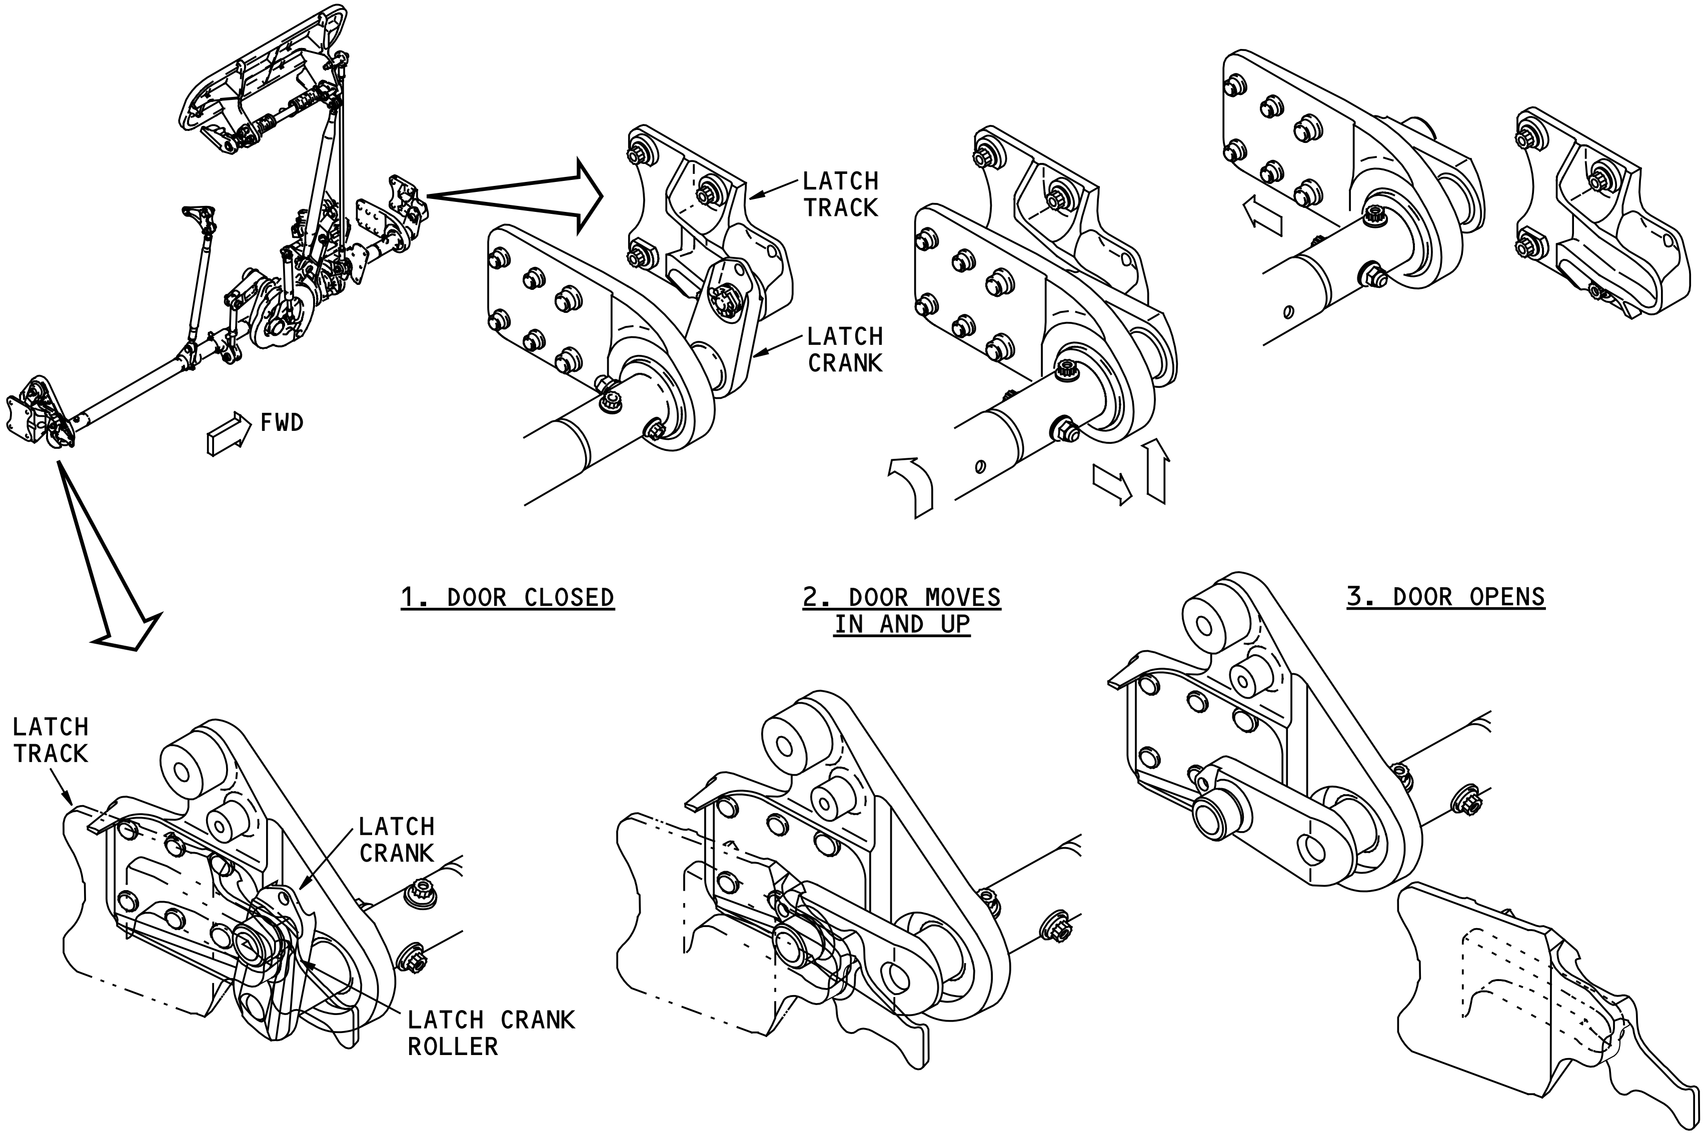
52-11-00-010 Rev 4 11/06/1997

PASSENGER ENTRY DOOR SYSTEM - LATCH MECHANISM - INTRODUCTION

PASSENGER ENTRY DOOR SYSTEM - LATCH MECHANISM - LATCH CRANK FUNCTION

Functional Description

The torque tubes turn the latch cranks. The latch crank rollers push down on the latch tracks when opening. This moves the door inboard and lifts the door. During closing they perform the opposite motions.



52-11-00-011 Rev 1 11/06/1997

PASSENGER ENTRY DOOR SYSTEM - LATCH MECHANISM - LATCH CRANK FUNCTION

PASSENGER ENTRY DOOR SYSTEM - LATCH MECHANISM - SECONDARY LIFT FUNCTION

Functional Description

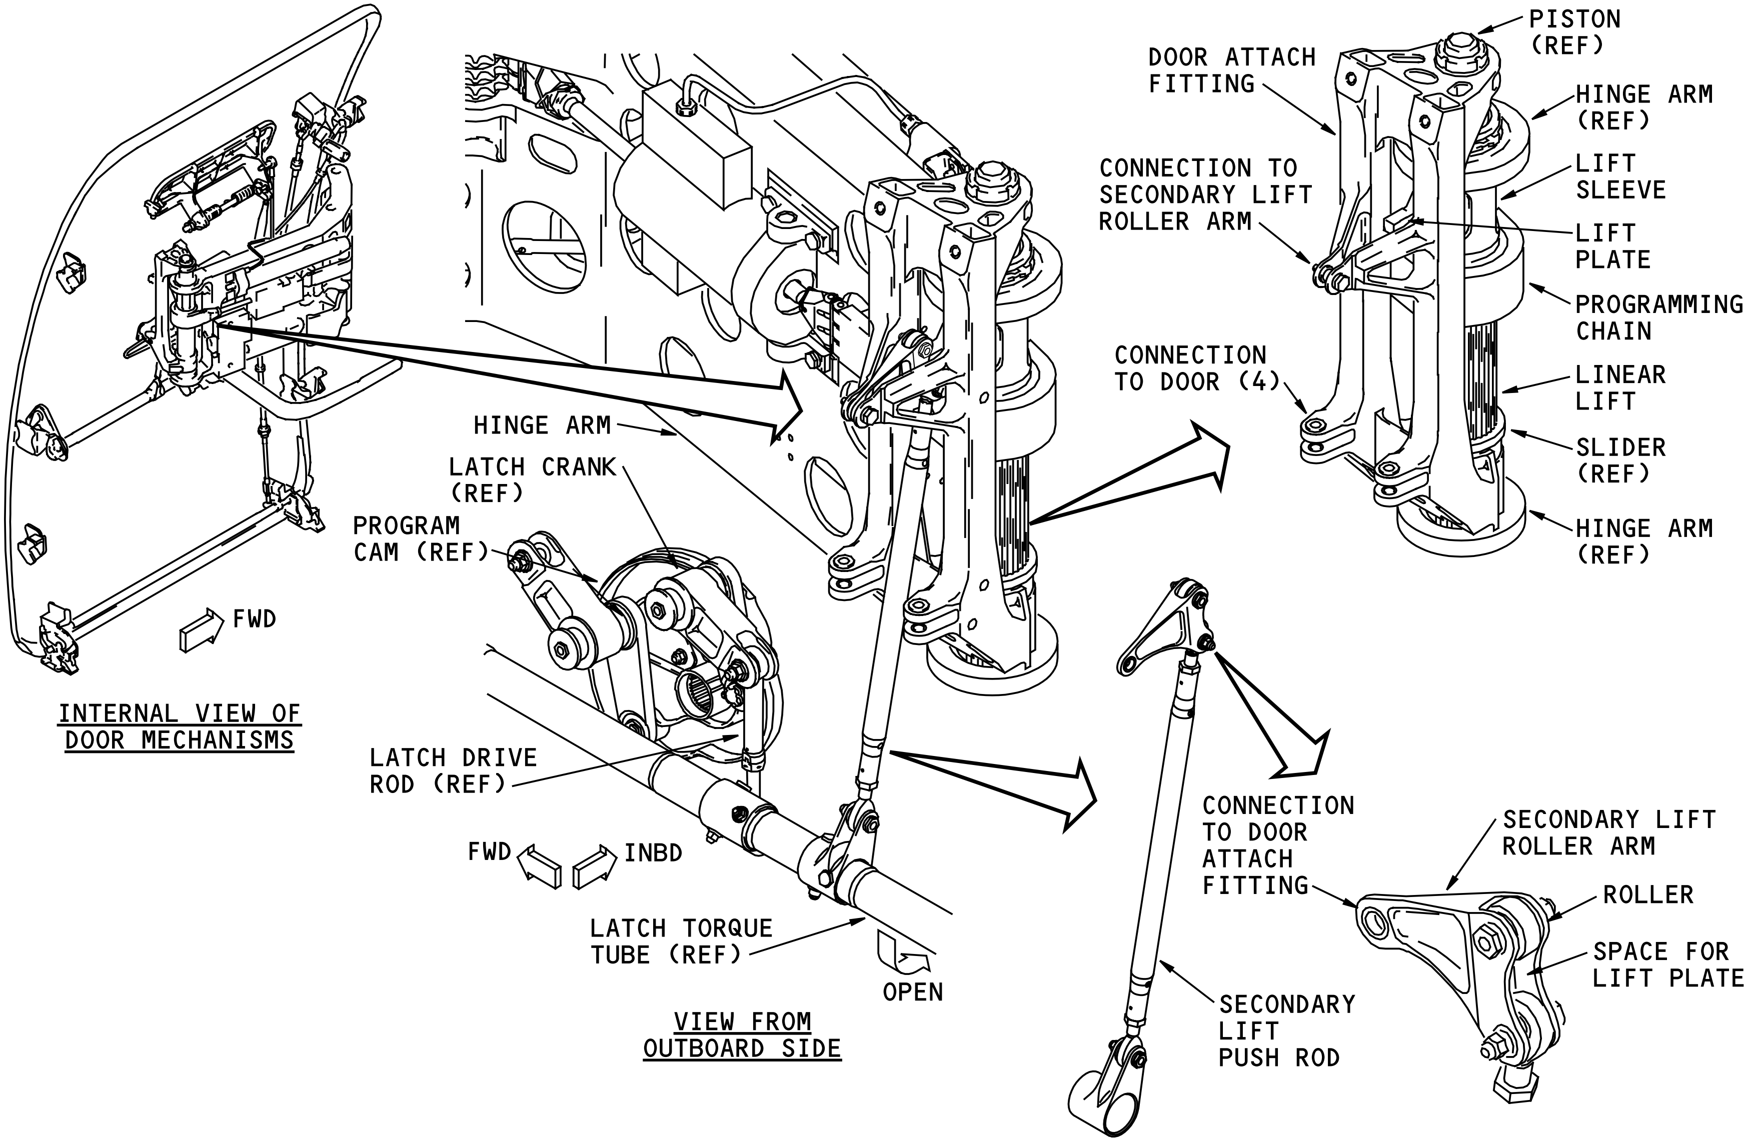
The secondary lift works with the door attach fitting and the lift sleeve.

The lift plate is part of the lift sleeve. The lift sleeve is held by the hinge arm. It can turn but cannot move up and down.

The secondary lift roller arm connects to the door attach fitting. The roller fits above the lift sleeve lift plate.

Rotation of the latch torque tube to open the door, pulls down on the secondary lift. The roller arm roller pushes down on the lift plate. This causes the outboard end of the roller arm to moves up. This lifts the door attach fitting which lifts the door.

When the door is closed, the secondary lift works against aerodynamic forces or airplane movement that try to lift the door. When the door lifts on the end of the roller arm, the roller arm pushes down on the push rod. The rod push on the torque tube rotates the tube in the door close direction.



52-11-00-012 Rev 1

PASSENGER ENTRY DOOR SYSTEM - LATCH MECHANISM - SECONDARY LIFT FUNCTION

PASSENGER ENTRY DOOR SYSTEM - VENT DOOR MECHANISM - INTRODUCTION

Purpose

The vent door mechanism:

- Releases pressurization to prevent damage when the passenger entry door opens
- Will not let the passenger entry door unlatch if differential pressurization is above 0.21 psi.

Physical Description

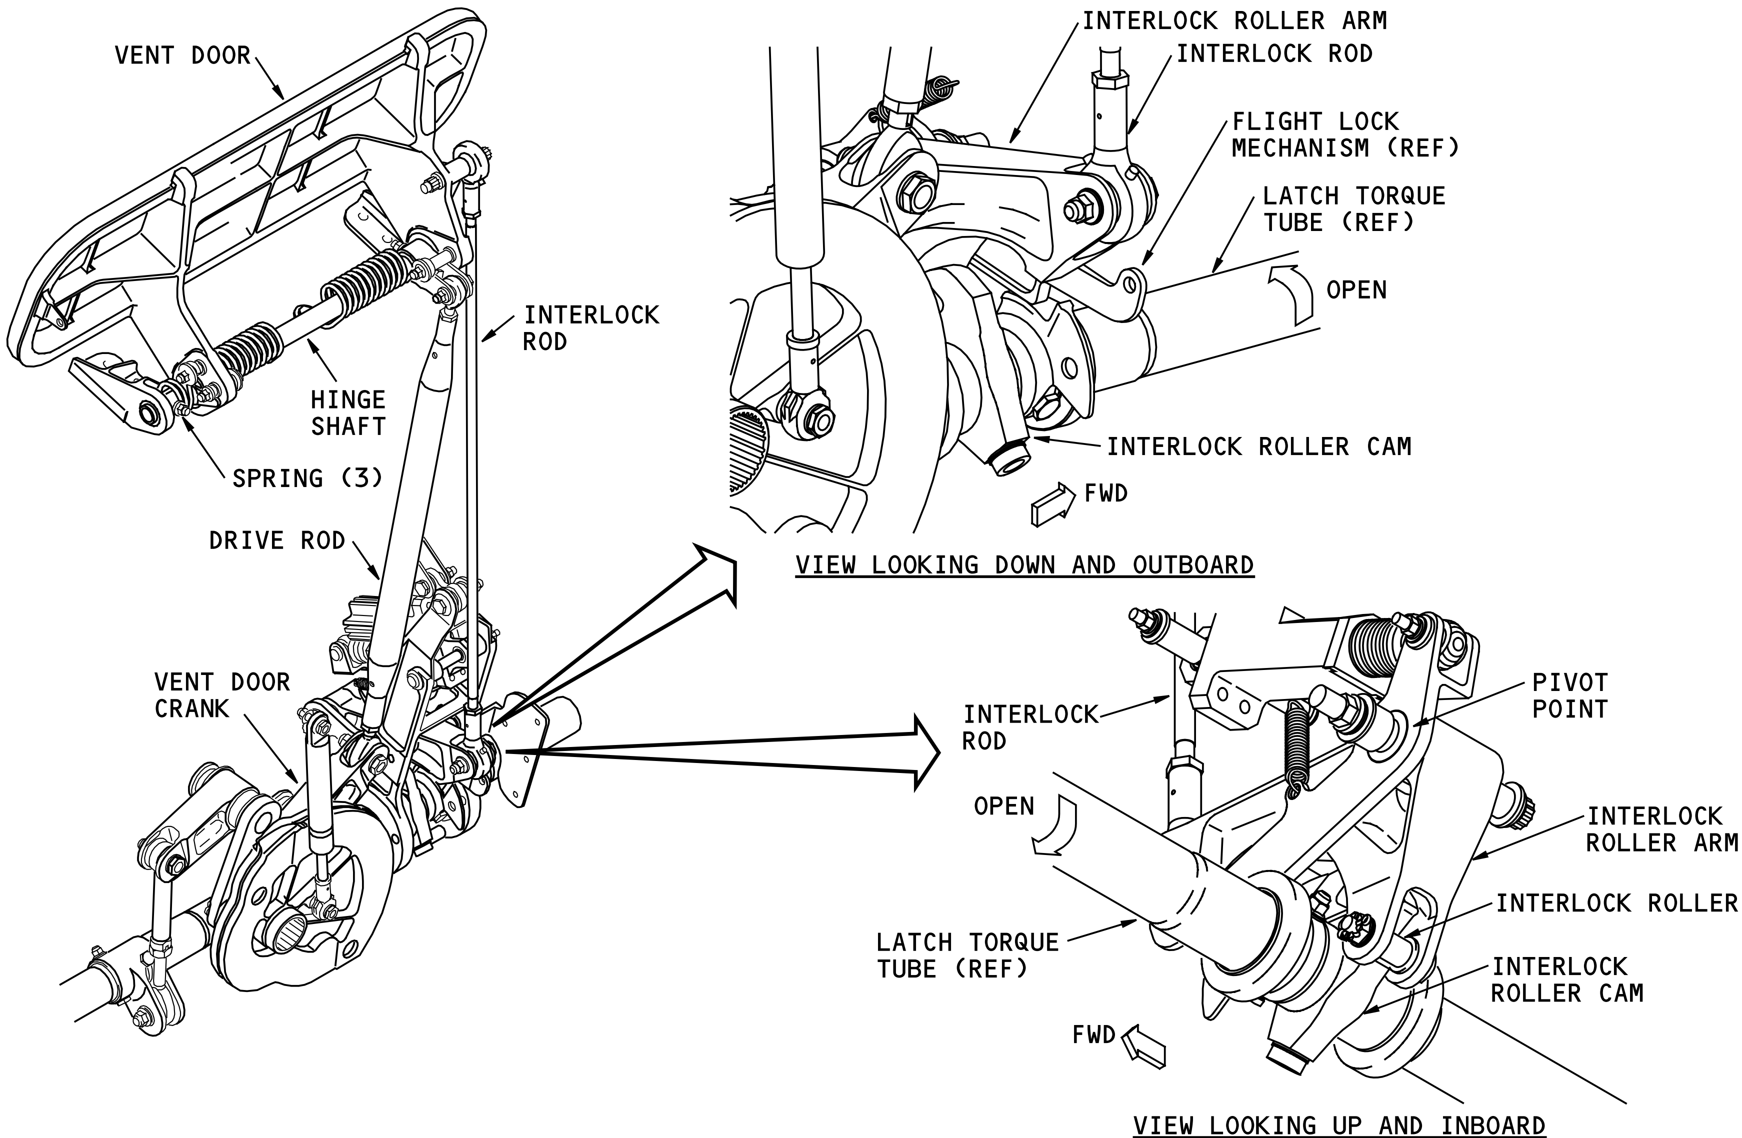
The vent door mechanism has these components:

- Vent door
- Interlock rod
- Interlock roller arm
- Interlock cam
- Drive rod
- Spring (3)
- Hinge shaft.

Functional Description - Vent Door

In the passenger entry door closed position, the drive rod holds the vent door closed. The initial movement of the door handle pulls down on the drive rod which releases the vent door. The springs open the vent door if differential pressurization is below 0.125 psi.

When the vent door opens the interlock rod pushes down on the roller arm. The roller arm moves the roller away from the interlock cam so the cam will let the latch torque tube turn.



52-11-00-013 Rev 2 10/13/96

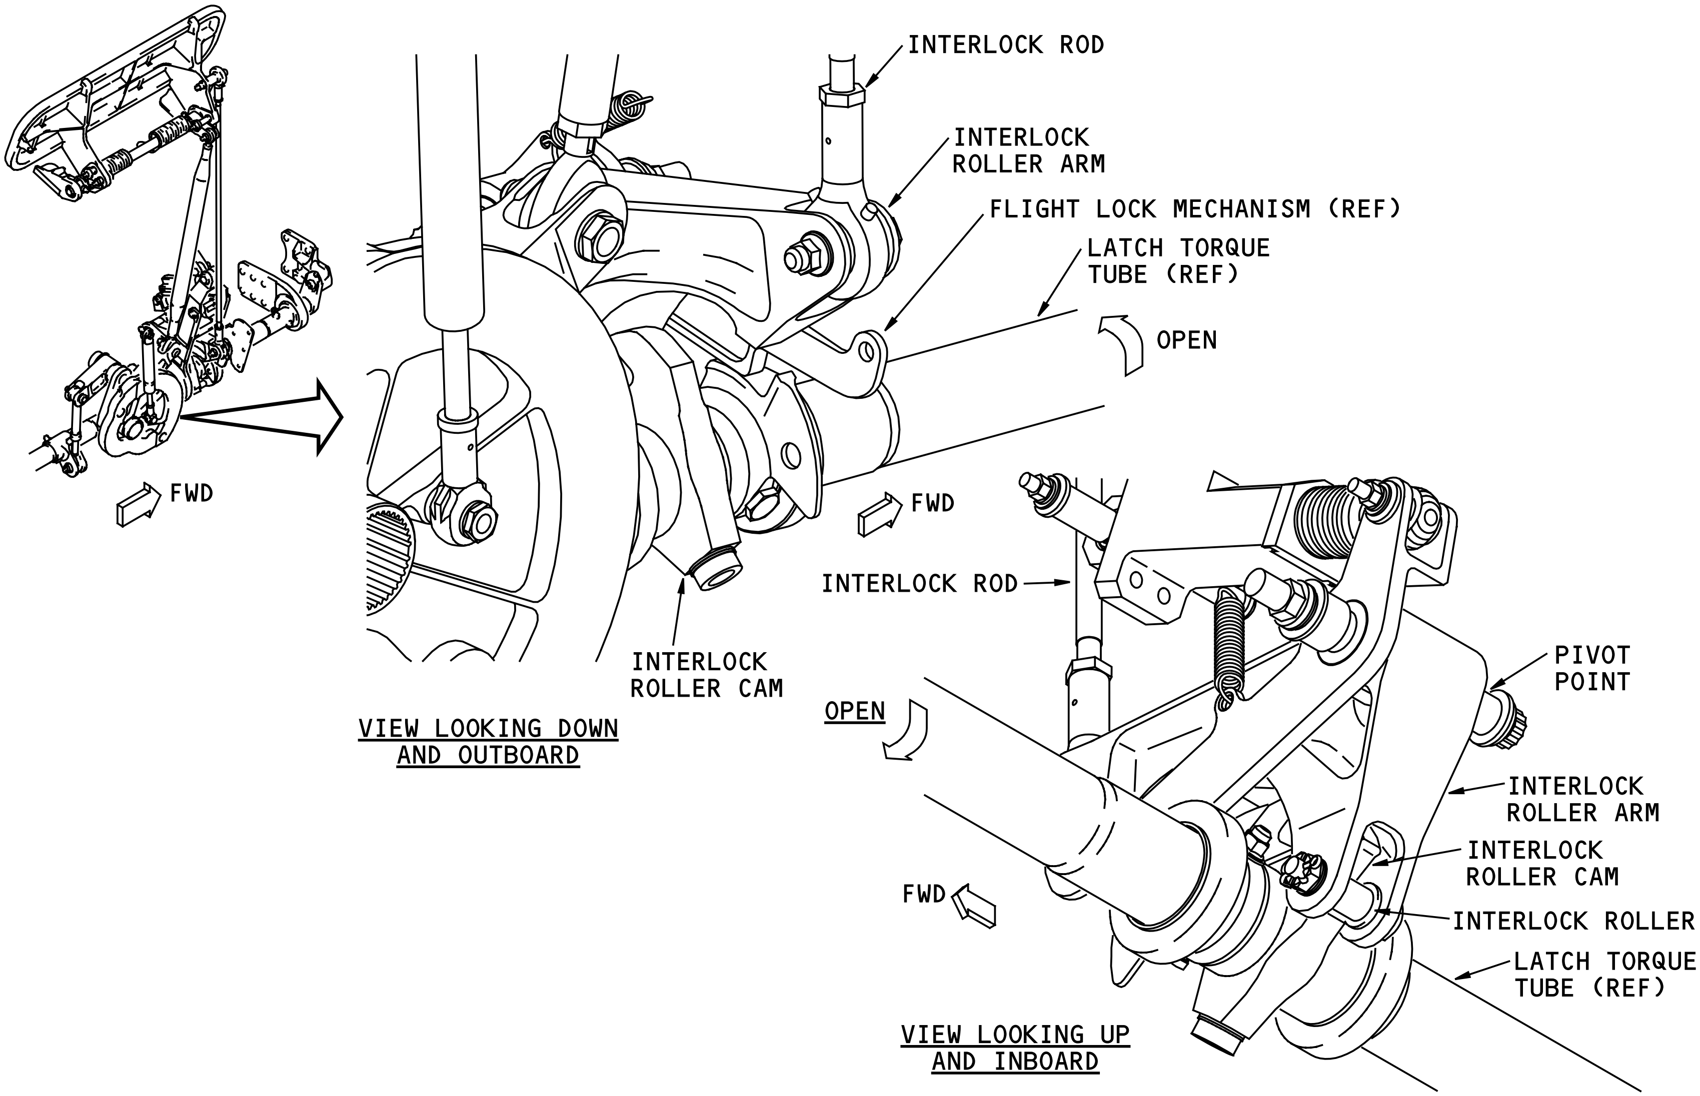
PASSENGER ENTRY DOOR SYSTEM - VENT DOOR MECHANISM - INTRODUCTION

Pressurization Lockout Function

The vent door mechanism will not let you open the passenger entry door when pressurization is too high for safe operation.

When the vent door opens, the interlock rod pushes down on the interlock roller arm. This moves the interlock roller out of the interlock cam. The latch torque tube can complete its rotation to open the door.

If too much pressurization remains, the vent door springs cannot open the vent door. The interlock rod continues to hold the interlock roller arm up. The interlock roller will not let the interlock cam turn. The latch torque tube cannot turn to unlatch the passenger entry door.



52-11-00-014 Rev 1

PASSENGER ENTRY DOOR SYSTEM - VENT DOOR MECHANISM - PRESSURIZATION LOCKOUT FUNCTION

PASSENGER ENTRY DOOR SYSTEM - VENT DOOR MECHANISM - INTERLOCK FUNCTION

Pressurization Lockout Function

When differential pressurization is above 0.125 psi, the vent door springs cannot open the vent door. The interlock rod continues to hold the interlock roller arm up. The interlock roller will not let the interlock cam turn. The latch torque tube cannot turn to unlatch the passenger entry door.

If differential pressurization is between 0.125 and 0.21 psi, and you continue to pull up on the door handle with sufficient force:

- The cam will force the roller to move outboard along the flat cam surface
- The roller arm to will pull down on the interlock rod
- The vent door will open
- The roller will move past the hook.

If differential pressurization is above 0.21 psi, and you continue to pull up on the door handle with sufficient force:

- The cam will force the roller to move outboard along the flat cam surface
- The roller arm to will pull down on the interlock rod sufficient to open the vent door 30 degrees
- The roller cannot move past the hook.

When the differential pressurization goes below 0.21 psi, upward force on the handle will move the vent door full open.

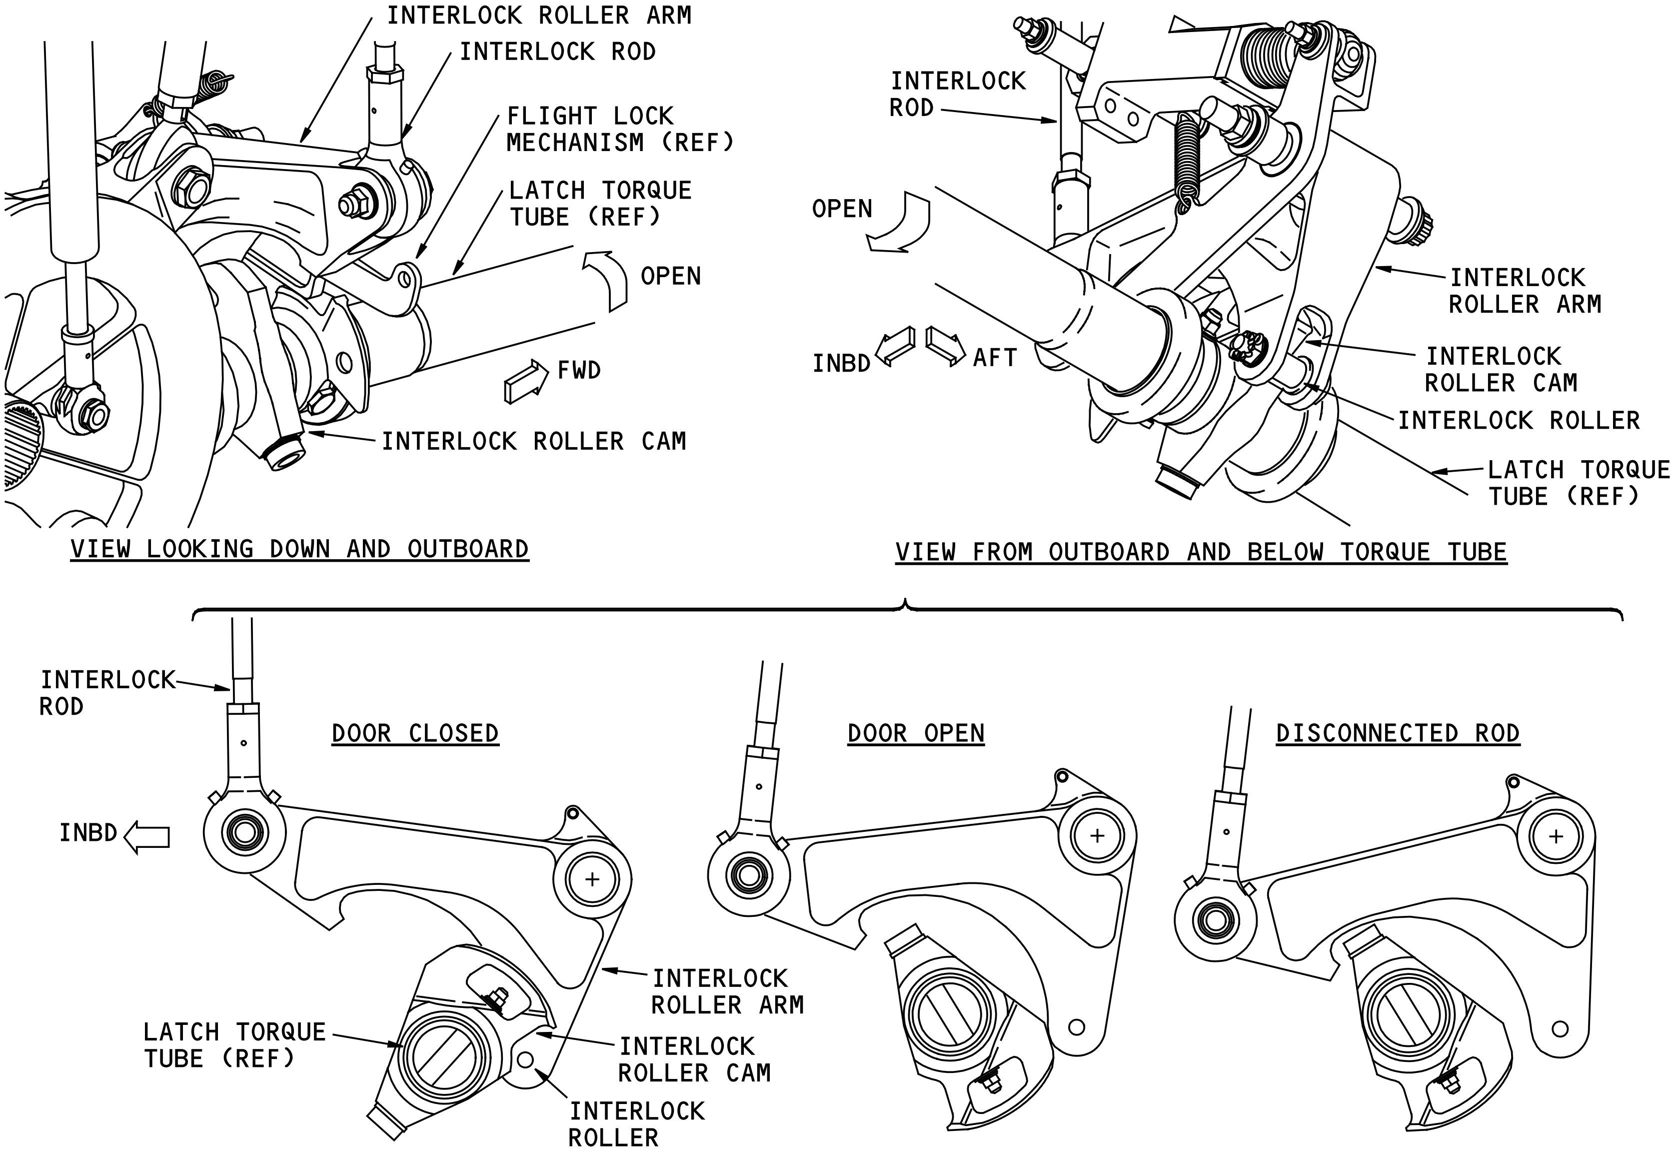
An example of sufficient force to open the vent door 30 degrees is approximately 200 pounds when differential pressurization is 1.0 psi.

Vent Door Mechanism Failure

If either rod fails or disconnects, the inboard end of the roller arm moves down. The rotation of the roller arm moves the roller away from the interlock cam so the interlock cam can turn. The cam can push the roller arm up to let you open the door. If you try to latch the door, the arm catches the cam. The cam cannot push the arm up to go back to the door close position.

Training Information Point

Do a check of the vent door mechanism if you cannot move either door handle to the close position when you try to close the door.



PASSENGER ENTRY DOOR SYSTEM - VENT DOOR MECHANISM - INTERLOCK FUNCTION

52-11-00-015 Rev 1 10/12/96

PASSENGER ENTRY DOOR SYSTEM - FLIGHT LOCK MECHANISM AND FLIGHT LOCK SENSORS

Purpose

The flight lock mechanism locks the latch mechanism closed when the airplane airspeed is 80 knots or more.

Physical Description

The flight lock mechanism has these components:

- Motor
- Flight lock disengaged sensor
- Flight lock engaged sensor
- Target
- Lock pawl lever
- Cam
- Spring (2)

Functional Description - Flight Lock Mechanism

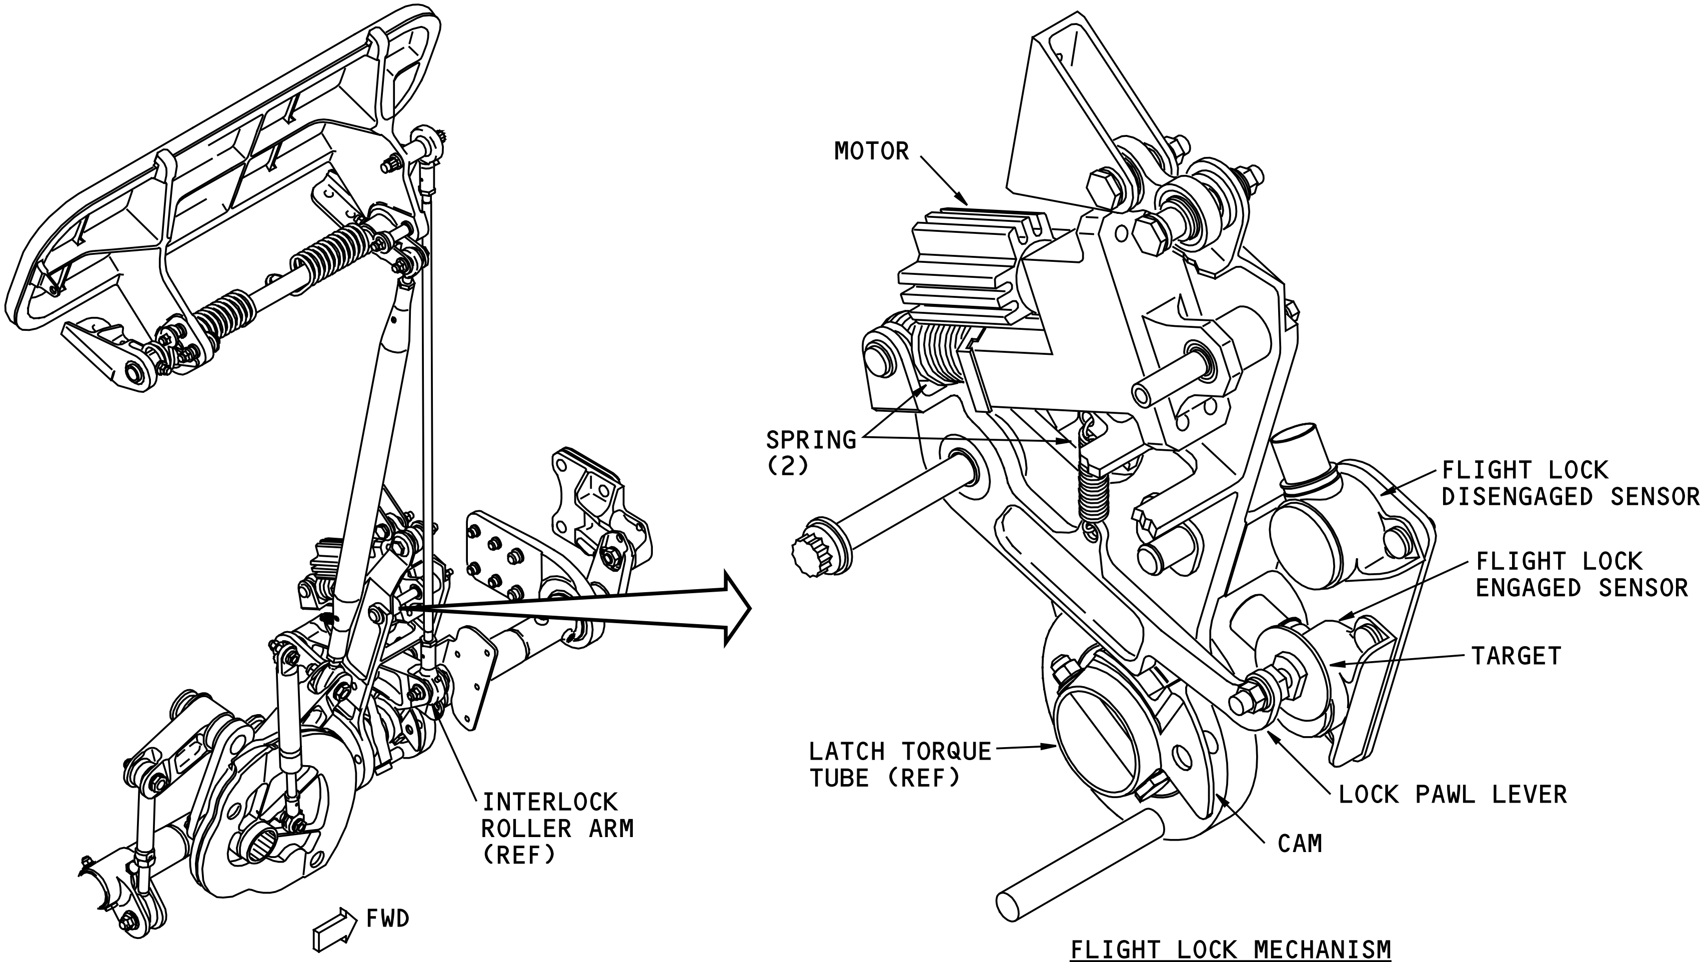
The air data inertial reference unit (ADIRU) and the secondary attitude and air data reference unit (SAARU) supply an airspeed signal when the airplane reaches 80 knots.

The PSEU and an ELMS electronics unit energize relays that send power to the flight lock motor. The motor moves the lock pawl lever to the locked position. The motor stalls and holds the lever in the locked position. The lever engages the cam on the latch torque tube. The latch torque tube cannot turn to unlatch the door.

When the airplane goes below 80 knots, the relays open to remove power from the motor. The springs move the lever to the unlocked position. The latch torque tube can turn to unlatch the door.

Functional Description - Flight Lock Sensors

Flight lock engaged and the flight lock disengaged sensor information goes from the proximity sensor electronics units (PSEU) to the airplane information management system (AIMS). Status and maintenance messages show when the lock pawl lever is not in its commanded position.



52-11-00-016 Rev 3 10/18/96

PASSENGER ENTRY DOOR SYSTEM - FLIGHT LOCK MECHANISM AND FLIGHT LOCK SENSORS

PASSENGER ENTRY DOOR SYSTEM - MODE SELECT MECHANISM AND MECHANICAL SWITCHES

Purpose

The mode select mechanism lets you set the operation mode for the emergency power assist system (EPAS), and the girt bar mechanism.

Physical Description

The mode select mechanism has these components:

- Mode select handle
- Cable crank
- Push/pull cable assembly
- Cam lever
- Spring.

The mode select switch is on the mode select mechanism.

Functional Description

When you move the mode select handle aft, you select the armed mode. Selection of the armed mode does these two things:

- Closes the mode select switch which arms the emergency power assist system (EPAS)
- Pushes down on the push/pull cable which arms the girt bar mechanism.

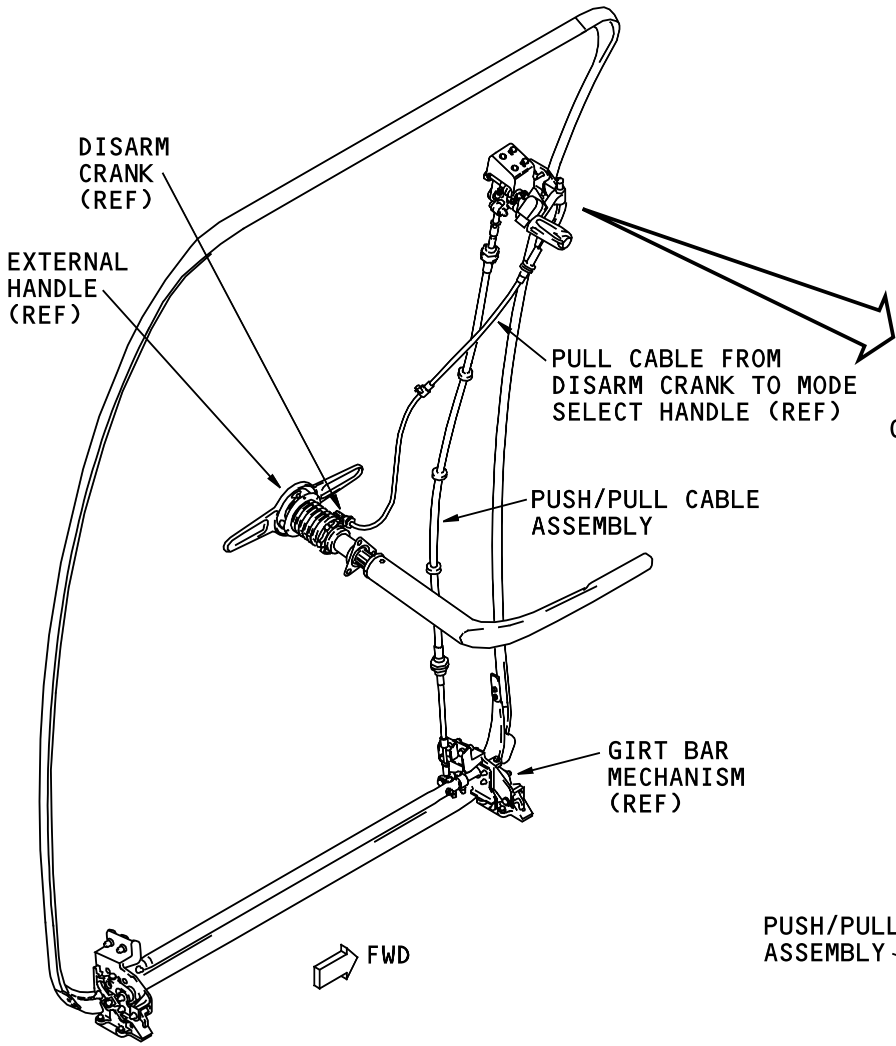
When you pull the external door handle outboard, the disarm crank pulls the cable that goes to the mode select handle. It moves the handle forward to the disarm position.

When you move the external door handle inboard, the disarm crank pushes the cable. The cable slides through the mode select handle. It does not move the handle. The lever stays in the disarm position.

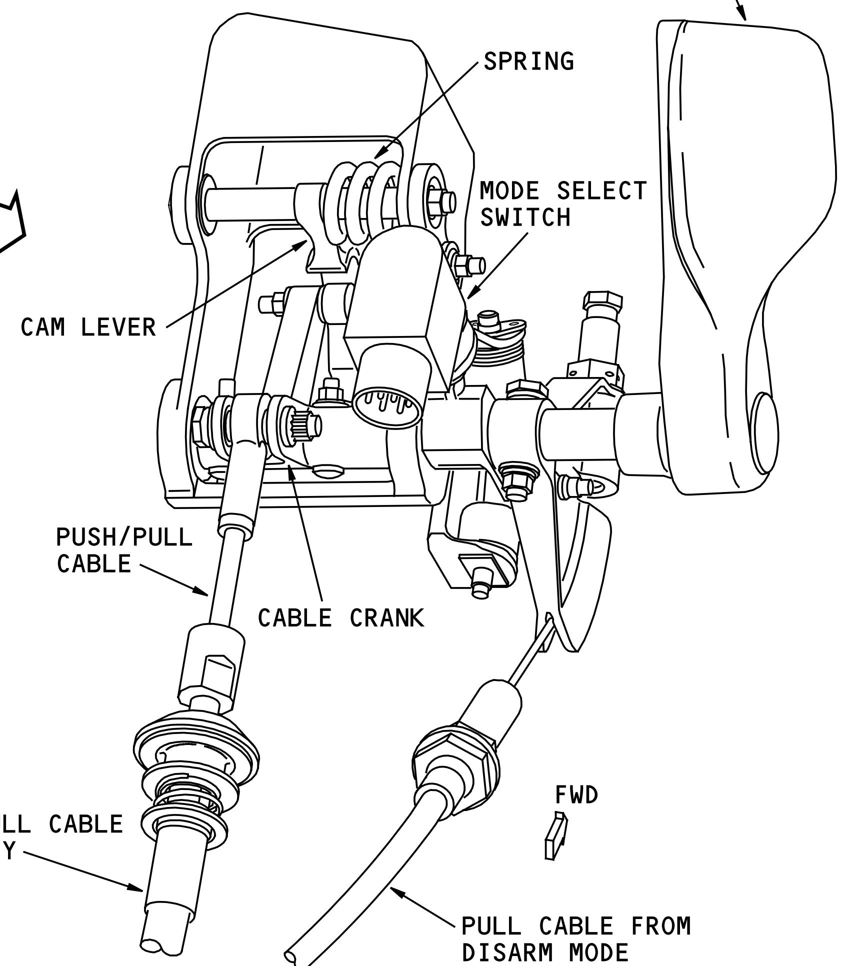
When you move the mode select handle forward, it does not push on the cable. The cable slides through the handle. It does not move the external door handle.

The spring and cam lever are an overcenter device for the mode select handle. When you move the handle the spring and cam push the handle completely to the position you select.

The mode select switch is one of two mechanical switches used in the emergency power assist system (EPAS) operation.



INTERNAL VIEW OF DOOR WITHOUT LATCH MECHANISM,
VENT DOOR MECHANISM AND HINGE



52-11-00-017 Rev 4 11/06/1997

PASSENGER ENTRY DOOR SYSTEM - MODE SELECT MECHANISM AND MECHANICAL SWITCHES

PASSENGER ENTRY DOOR SYSTEM - GIRT BAR MECHANISM AND GIRT BAR FLOOR FITTING - INTRODUCTION

Purpose

The girt bar mechanisms hold the emergency slide girt bar on the bottom of the door in the disarmed mode and releases it into the girt bar floor fittings in the armed mode.

The floor fittings hold the girt bar on the floor when you open the door in the armed mode.

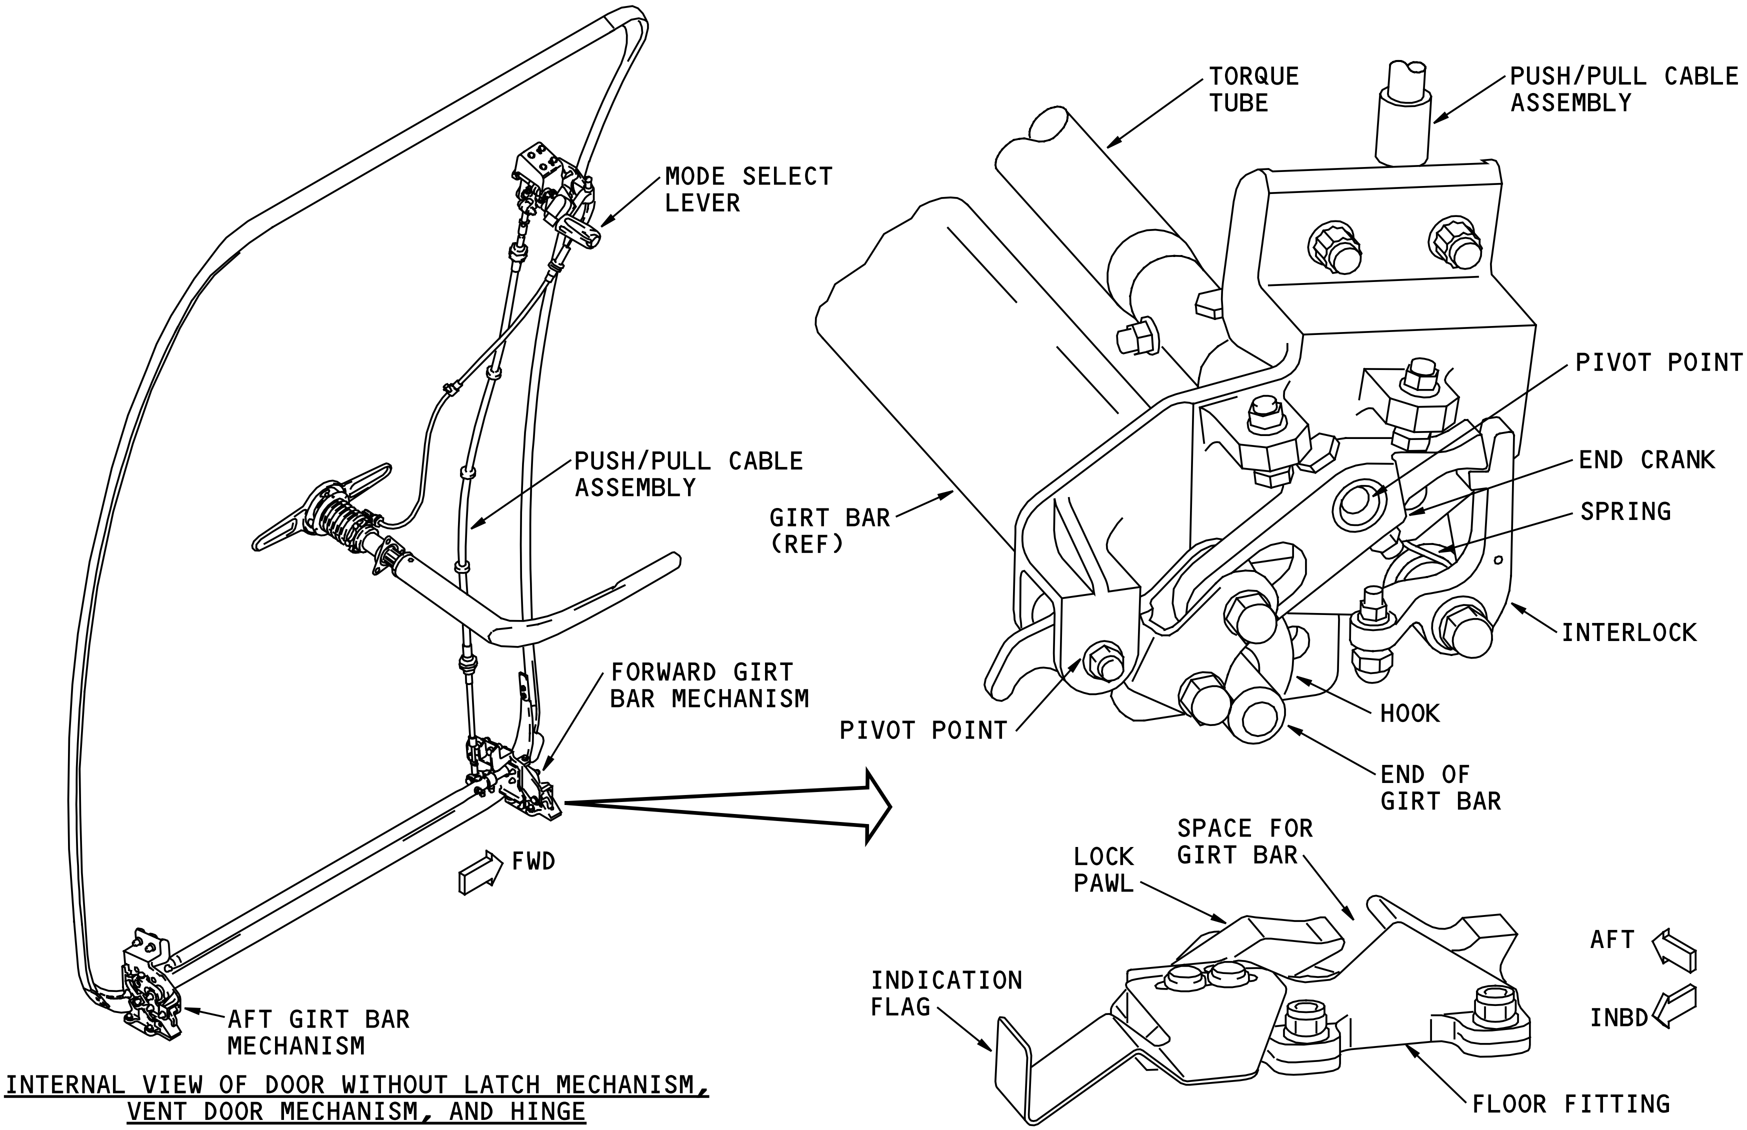
Physical Description

There are girt bar mechanisms on the lower forward and aft corners of the door. A torque tube connects the end crank of the two mechanisms to the push/pull cable assembly.

Each girt bar mechanism has these components:

- End crank
- Spring
- Interlock
- Hook
- Carrier fitting.

Each floor fitting assembly has a spring-loaded lock pawl. A yellow indication flag attaches to the lock pawl. The flag shows through a witness port on the sidewall. You see the witness port later in this section, in the door operation.



INTERNAL VIEW OF DOOR WITHOUT LATCH MECHANISM,
VENT DOOR MECHANISM, AND HINGE

52-11-00-018 Rev 4 11/06/1997

PASSENGER ENTRY DOOR SYSTEM - GIRT BAR MECHANISM AND GIRT BAR FLOOR FITTING - INTRODUCTION

PASSENGER ENTRY DOOR SYSTEM - GIRT BAR MECHANISM - FUNCTIONAL DESCRIPTION

Door Lifted, Escape Slide Not Armed

The girt bar mechanism holds the girt bar when the door is not latched and in the armed mode. The girt bar is held between the hook and the carrier fitting (not shown).

You cannot move the mode select lever when the door is open. The spring holds the interlock so the end crank cannot turn. The hook that holds the girt bar will not move to release the girt bar.

The indication flag is not lifted. You see the flag through the witness port in the sidewall.

Door Latched, Escape Slide Not Armed

When the door moves down to latch, these two things occur with the girt bar mechanism:

- The roller pushes down on the lock pawl and lifts the indication flag up out of the witness port
- The interlock pushes down on the floor fitting and turns to release the end crank.

Door Latched, Escape Slide Armed

When you move the mode select lever to the armed position, the push/pull cable turns the torque tube. The torque tube turns the end crank. The crank turns the hook.

When the hook turns, the outboard end moves up to releases the girt bar and releases the lock pawl. The spring in the lock pawl lifts the pawl and lowers the flag.

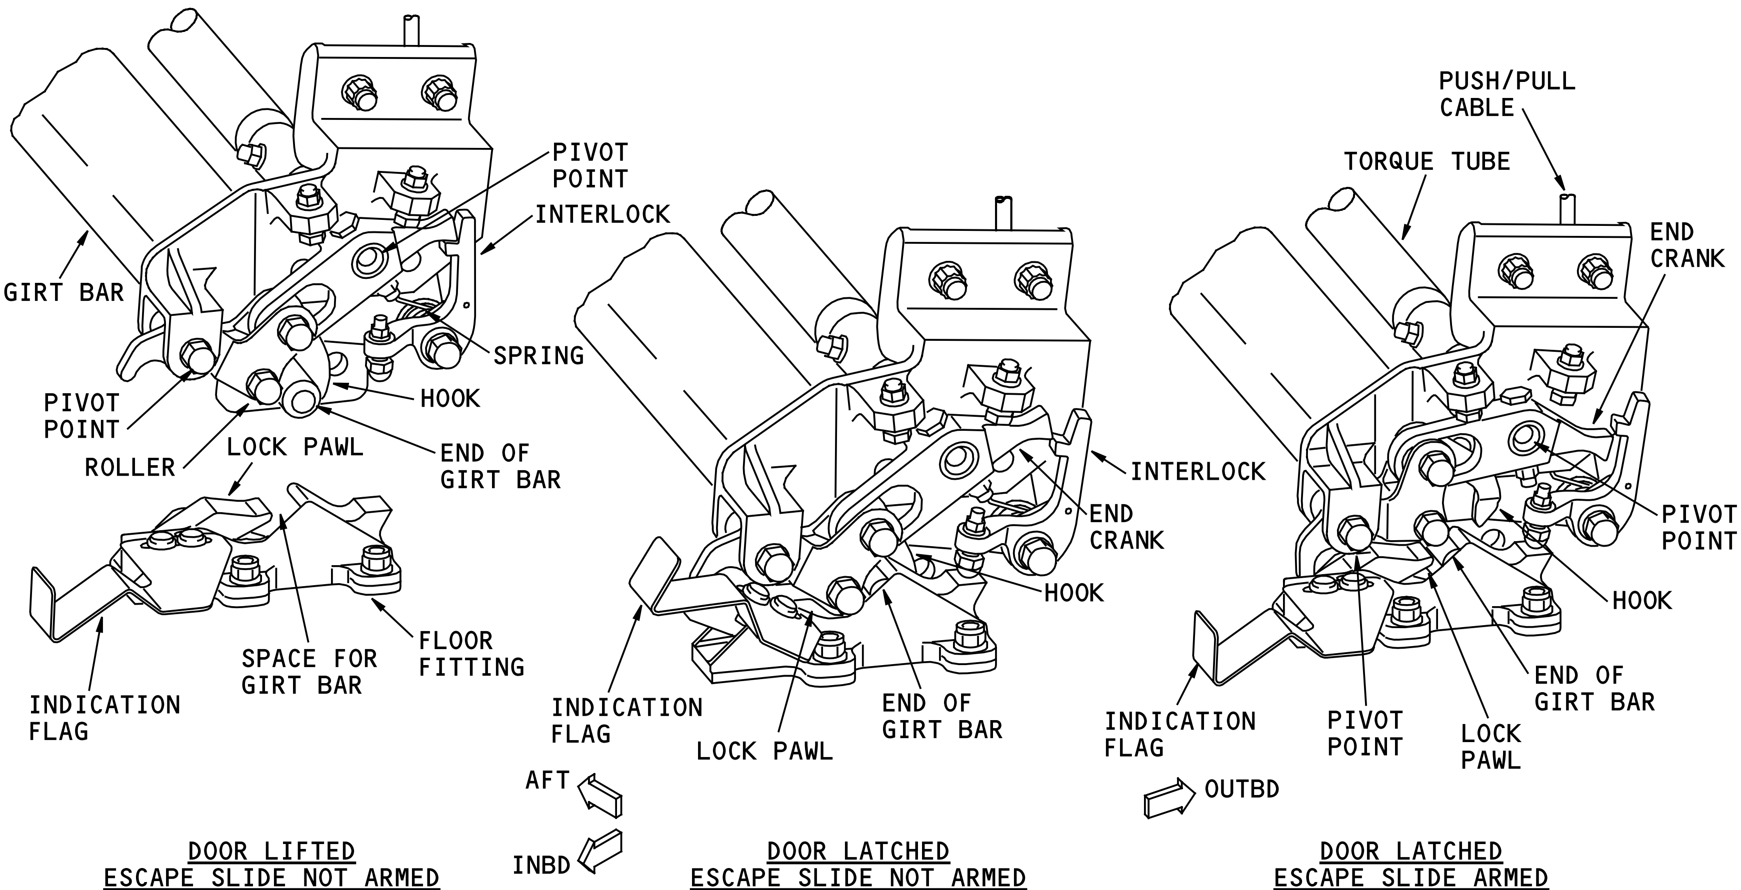
The lock pawl locks the girt bar to the floor. The door is in the armed mode. The flag in the witness port indicates the door is in the armed mode.

If you unlatch and open the door, the girt bar stays locked to the floor. The bar pulls the escape slide/ raft out of the door.

Training Information Point

The interlock must release the end crank before you can move the mode select lever to the arm position. If you cannot move the lever to the arm position, it may show a blockage problem.

Make sure there is no unwanted material around the door bottom that keeps the door from moving completely outboard as it closes. When the door is not completely outboard, the floor fitting will not push the interlock sufficiently to release the end crank.



52-11-00-019 Rev 4 11/06/1997

PASSENGER ENTRY DOOR SYSTEM - GIRT BAR MECHANISM - FUNCTIONAL DESCRIPTION

PASSENGER ENTRY DOOR SYSTEM - EMERGENCY POWER ASSIST SYSTEM (EPAS) - INTRODUCTION

Purpose

The emergency power assist system (EPAS) supplies mechanical power to open the passenger entry door in emergencies.

Physical Description

The EPAS has these components:

- Reservoir
- Actuator
- Battery pack.

Functional Description

Power from the EPAS battery ignites the squib on the reservoir when you move the internal door handle to open with the mode select handle in the armed mode. The squib breaks the rupture disc on the reservoir.

Compressed nitrogen gas from the reservoir goes through a tube to the actuator. Gas expansion in the actuator pushes on piston attached to the rod. This moves the chain. The chain pulls on the fixed sprockets to open the door open.

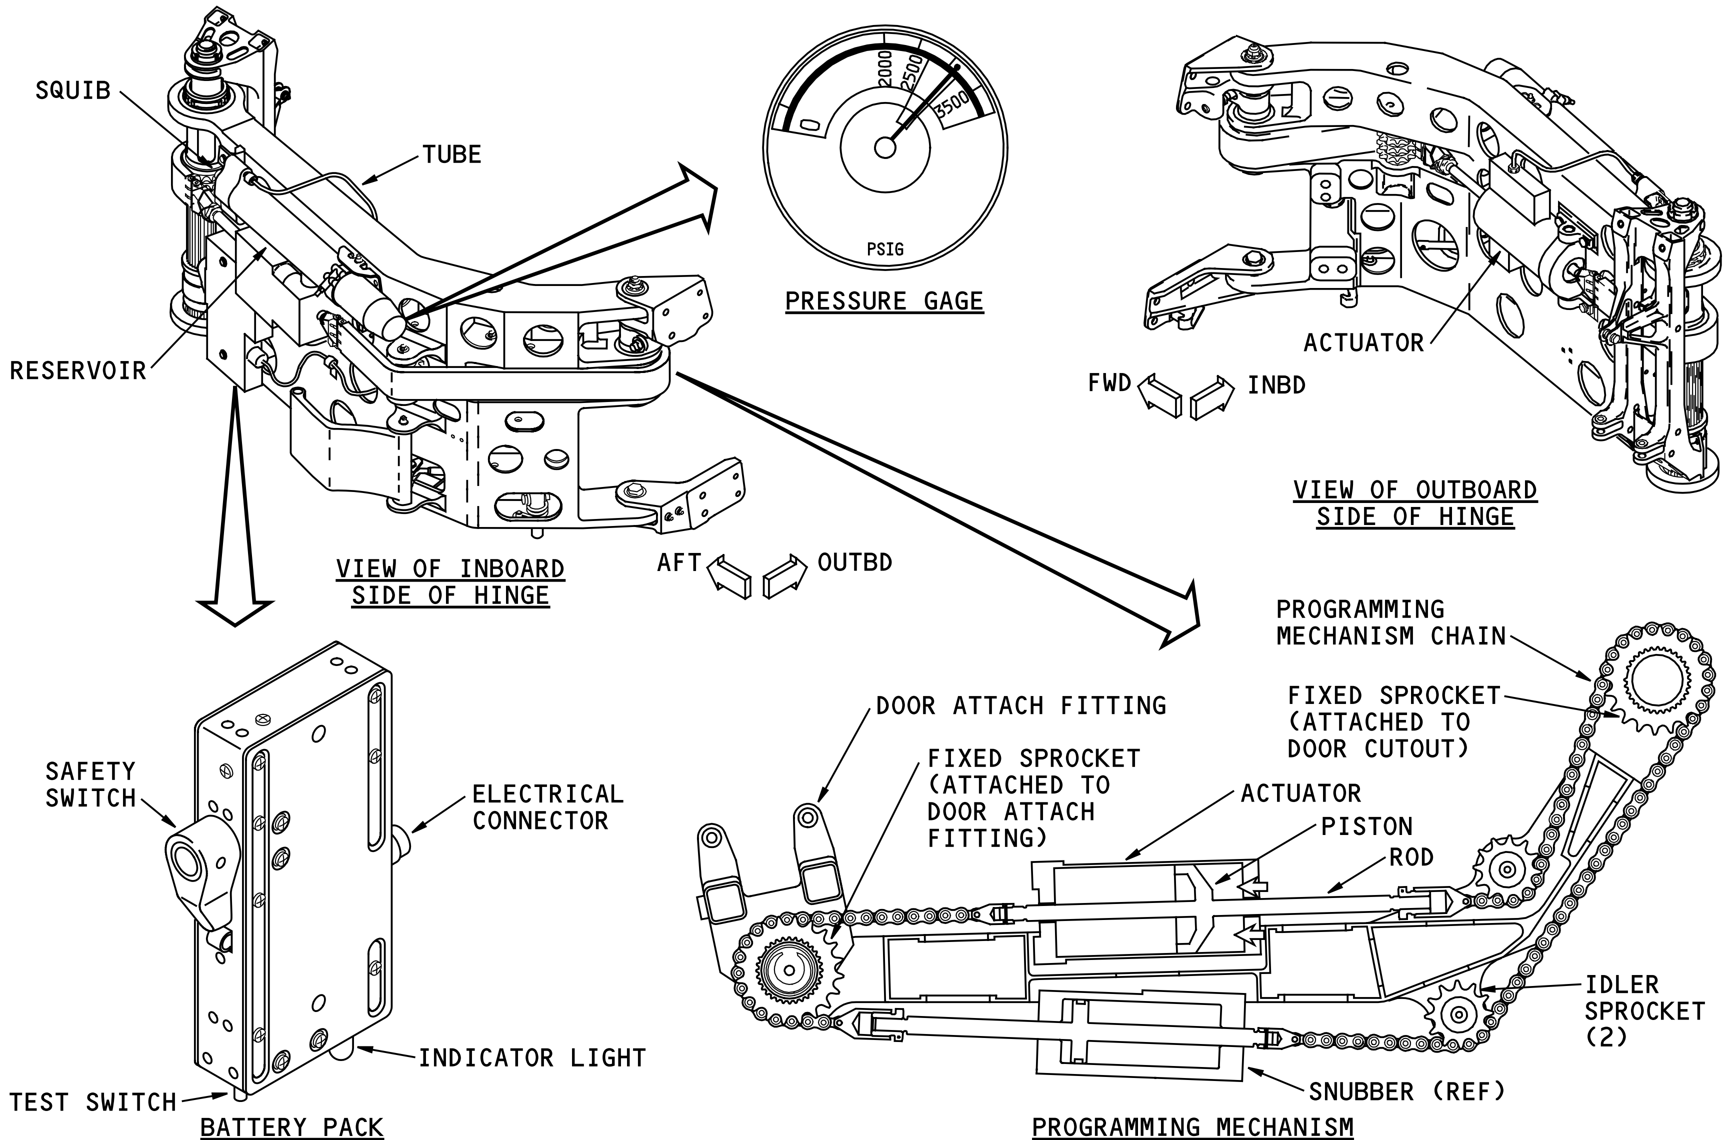
Training Information Point

A safety switch on the battery pack lets you stop the EPAS operation when you do door maintenance. You cannot close the hinge cover when the switch is in the safe position.

A test switch and a red test indicator light on the bottom of the battery let you do a test of the battery for a sufficient charge. You put your hand below the hinge cover to push the switch. You do not have to open the cover. If the battery has a sufficient charge, the red indicator light comes on. The light is red so you can see it reflect off of your hand. You do not have to look directly at the light.

A gage on the forward end of the reservoir lets you know if the pressure in the reservoir is sufficient. You can see the gage through a hole in the hinge cover.

You cannot close the door when there is pressure in the actuator. It takes five minutes for actuator pressure to bleed down after the EPAS has fired.



PASSENGER ENTRY DOOR SYSTEM - EMERGENCY POWER ASSIST SYSTEM (EPAS) - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

PASSENGER ENTRY DOOR SYSTEM - OPERATION

General

There are markers on the door that tell you the direction to move the handles for door operation.

External Open Operation

Pull the external handle outboard. This will move the mode select handle to the disarm position if it has not already been set to that position.

Turn the handle 180 degrees in the open direction. The vent door should open as you start to turn the handle. The door will move inboard and upward as you continue to turn the handle. The external handle will stay in the extended position while the door is open.

Pull the door outboard and push it forward until it stops. Do a check to see that the hold-open hook has engaged the hold-open catch.

External Close Operation

Do a check to see that the door area and girt bar floor fitting are not blocked.

If the external handle is not extended, pull it outboard and rotate it 180 degrees. It will remain extended outboard.

Pull the hold-open release handle on the inside of the door. This releases the door and start its close movement. Use the extended, external handle to push the door inboard into the cabin.

Turn the external handle 180 degrees in the close direction. The door will move downward and slightly outboard as it goes to the closed position. The vent door should close as you complete the door handle movement. The door is now closed, latched, and locked.

The handle is spring loaded and moves inboard to the faired position at the end of the rotation.

When you turn the external handle to close the door, it does not move the mode select handle to the armed position.

If the handle will not turn to the closed position, do a check of the door system.

Internal Open Operation

Move the mode select lever to the disarm position. Do a check of the two witness ports in the sidewall near the bottom of the door. The yellow door armed indication flags should not be visible.

If either flag is visible, do not use the door. Do a system check.

Move the handle to the open position. Push outboard and forward on the door. When the door stops, do a check to see that the hold-open hook has engaged the hold-open catch.

PASSENGER ENTRY DOOR SYSTEM - OPERATION

Internal Close Operation

Do a check to see that the door area and girt bar floor fitting are not blocked. Pull on the hold-open release handle to release the door and move the door into the cabin.

Turn the door handle in the close direction. If the handle will not turn to the closed position, do a check of the door system.

Training Information Point

A safety switch on the battery pack lets you stop the EPAS operation when you do door maintenance. You cannot close the hinge cover when the switch is in the safe position.

PASSENGER ENTRY DOOR SYSTEM - OPERATION

THIS PAGE INTENTIONALLY LEFT BLANK

PASSENGER ENTRY DOOR SYSTEM - FUNCTIONAL DESCRIPTION

Flight Lock Disengage

Airplane airspeed below 80 knots removes electric power from the flight lock. The flight lock releases the latch mechanism.

Disarm

Forward movement of the mode select lever opens the mode select switch so the emergency power assist system (EPAS) will not operate. It also pulls the push/pull cable. This unlocks the girt bar from the floor fitting and locks it to the girt bar mechanism on the door.

Unlatch

When you pull on the external handle, it connects to the internal handle. The external handle open movement pulls a cable that moves the mode select lever to the disarm position.

Initial movement of either door handle releases the vent door. The vent door opens if the airplane is sufficiently depressurized. The interlock rod pushes down on the interlock roller arm. The interlock roller releases the interlock cam on the latch torque tube.

The latch torque tube turns the latch cranks. The cranks push down on the latch tracks. The secondary lift pushes up on the door attach fitting and lifts the door. The girt bar mechanism interlock turns to stop mode select mechanism movement.

Open

The latch crank rollers move out of the latch tracks. The latch crank interlock locks the cranks.

The door translates open on the hinge. The programming chain keeps the door parallel to the fuselage. The snubber controls the rate of door movement.

When the door is completely open the hold open hook engages the hold open catch.

Close

When you pull on the hold open handle (not shown), the hold open hook releases and the door moves aft.

Either the external or internal handle closes the door. The secondary lift and latch cranks lower the door into the plug position inboard of the cutout stops. The drive rod pushes the vent door closed.

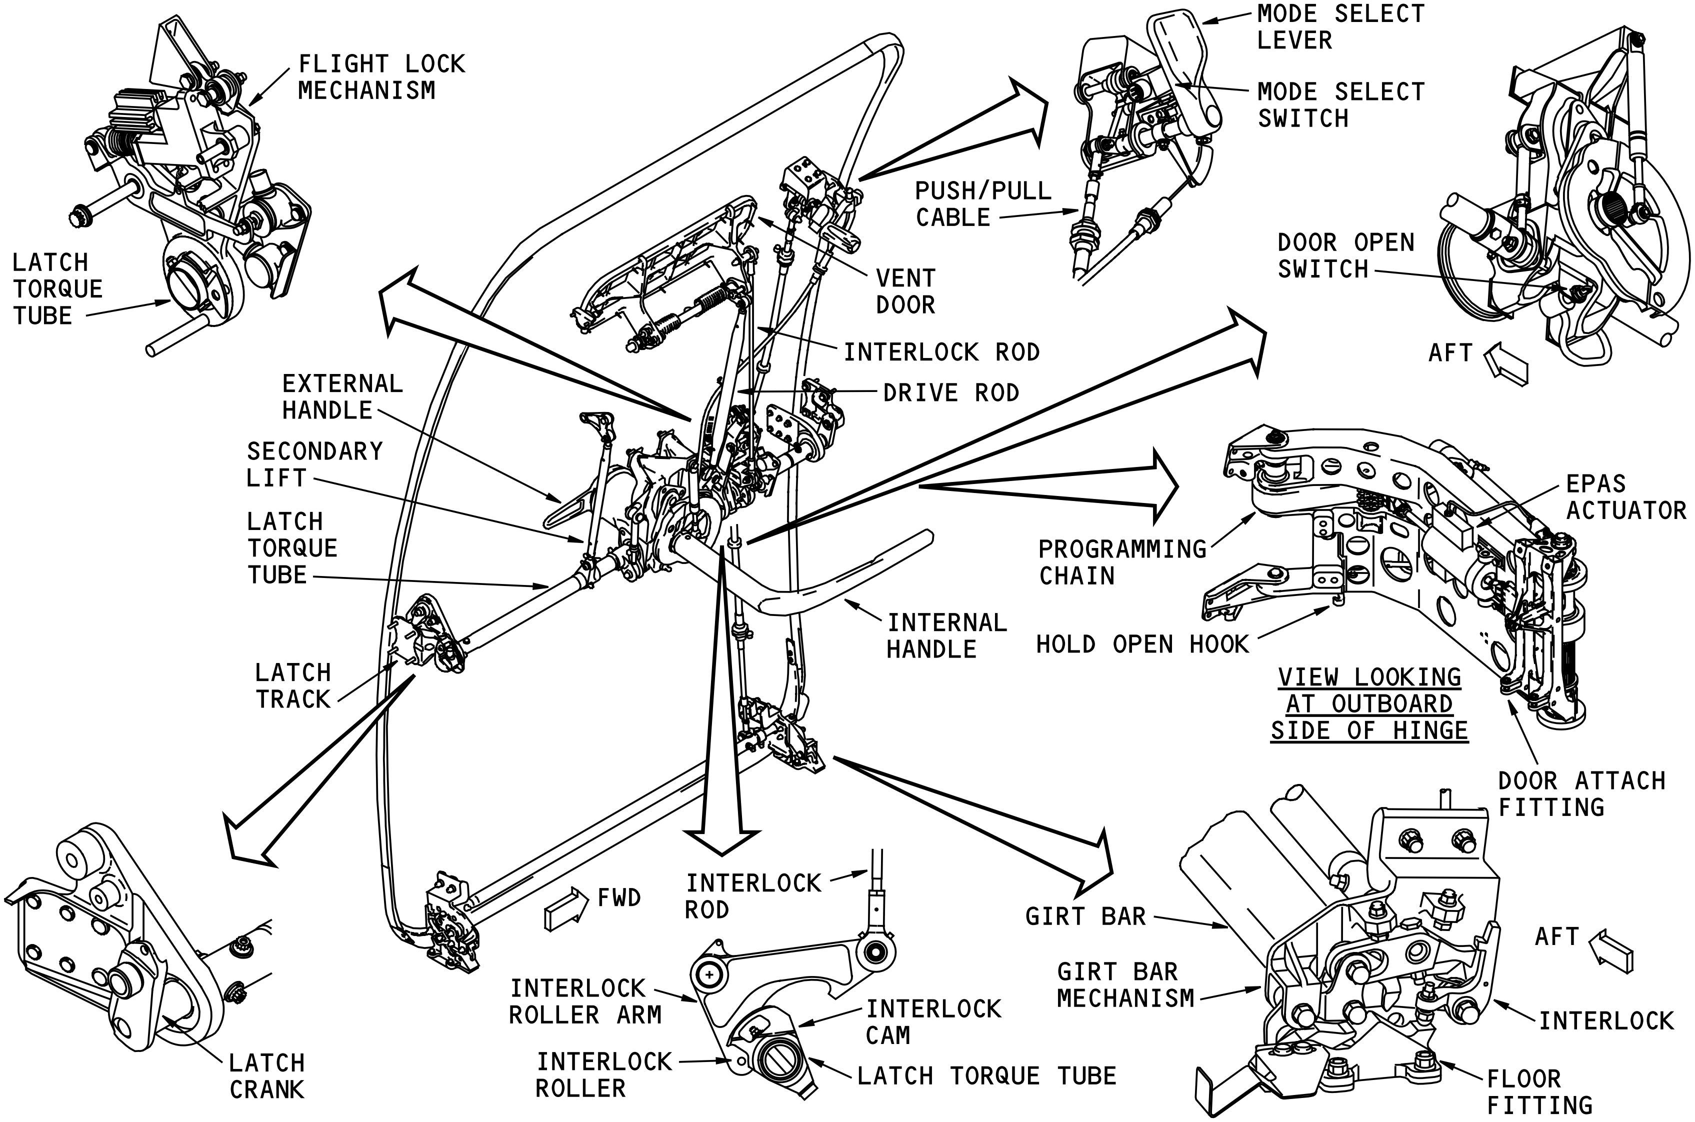
The girt bar mechanism interlock releases the end crank.

Either the external or internal handle closes the door. The secondary lift and latch cranks lower the door into the plug position inboard of the cutout stops. The drive rod pushes the vent door closed.

PASSENGER ENTRY DOOR SYSTEM - FUNCTIONAL DESCRIPTION

Arm

Aft movement of the mode select mechanism lever closes the mode select switch. This arms the EPAS electric power circuit. The movement also releases the girt bar from the girt bar mechanism. The floor fitting assembly locks the bar to the floor.



PASSENGER ENTRY DOOR SYSTEM - FUNCTIONAL DESCRIPTION

Functional Description

The emergency power assist system (EPAS) gets electrical power for its batteries from the same source as the emergency lights power supplies. See the emergency lights section for more information (AMM PART I 33-50).

The battery test circuit does a check of the battery and the position of the safety switch. When you hold the test switch in, the red test indicator light will come on if there is sufficient voltage to ignite the squib and the safety switch is set to ARM.

The safety switch is for maintenance. It disconnects the battery from the circuit to the squib.

The mode select switch is on the mode select handle on the door. When the handle is in the armed position, the switch is in the auto position. This arms the system.

The door open switch goes to the open position when the internal door handle moves to the door open position. Electrical power goes from the battery to the squib. The squib discharges when it gets power.

Use of the external door handle automatically moves the mode select handle to the disarm position.

The shunts in the door open switch and the mode select switch and the safety switch protect the squib from accidental ignition.

The position of the mode select switch goes to the AIMS to show on the door synoptic display. See the door warning system section for more information about indications (AMM PART I 52-71).

PASSENGER ENTRY DOOR - EMERGENCY POWER ASSIST SYSTEM (EPAS) - FUNCTIONAL DESCRIPTION

PASSENGER ENTRY DOOR SYSTEM - SYSTEM TESTS

General

ATA 52 Passenger Door Flight Locks has this systems test:

- Passenger entry doors, flight lock control test.

Passenger Entry Doors, Flight Lock Control Test

In this test, the proximity sensor electronics unit 1 (PSEU 1) sets the flight lock on all the passenger entry doors. See the proximity sensor system section for more information about proximity sensors (AMM PART I 32-08).

You must operate each passenger entry door to make sure that the flight lock is set. When you finish, you must select stop on the MAT or PMAT. No pass/fail shows for this test.

PASSENGER ENTRY DOOR SYSTEM - SYSTEM TESTS

DOOR-MOUNTED ESCAPE SYSTEM - GENERAL DESCRIPTION

Purpose

The door-mounted escape system helps passengers and crew get out of the airplane in an emergency. If the airplane lands in water, the slide/rafts disconnect from the airplane and used as life rafts.

General Description

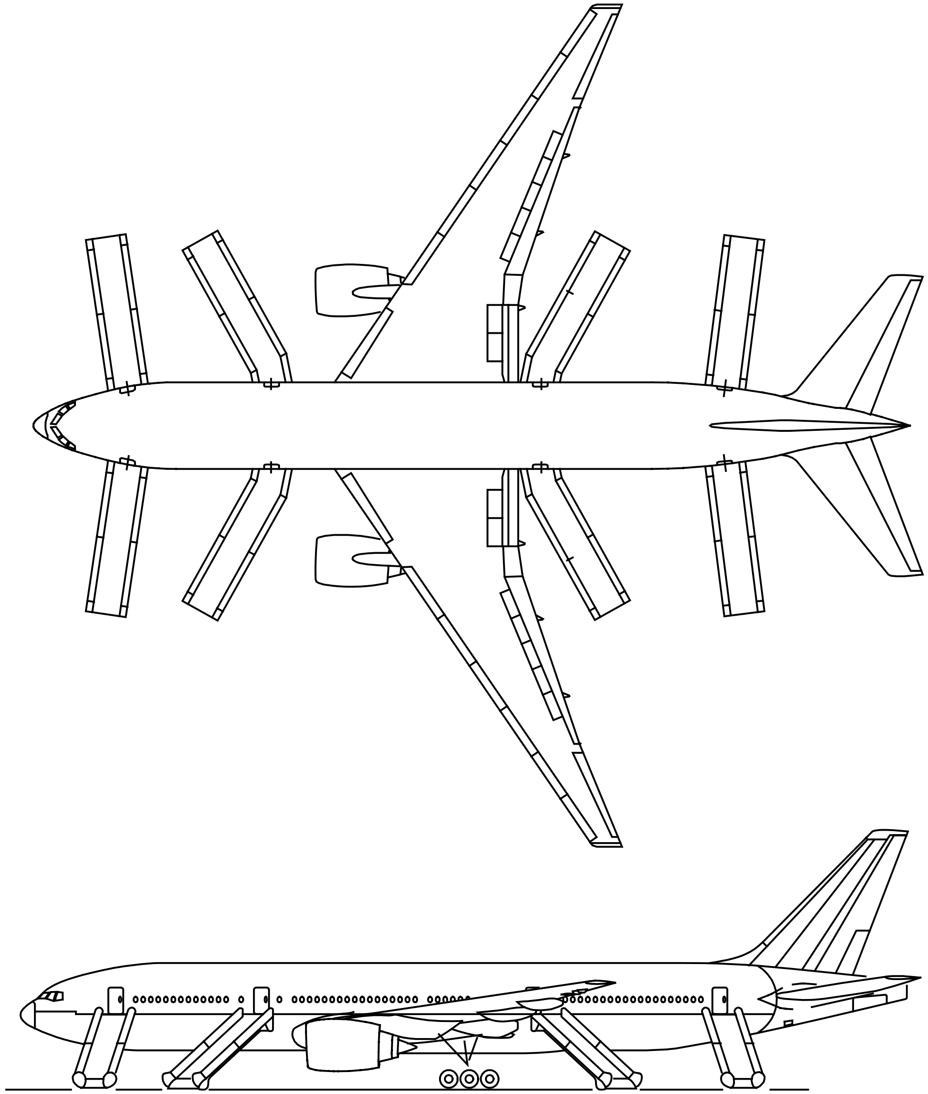
When you arm a door, the girt bar latches in the floor fittings (not shown). The girt bar and floor fittings attach one end of the slide/raft to the airplane floor. When you open the door, the bottom of the escape slide pack opens. The folded slide/raft falls through the door opening. The slide/raft unfolds and inflates automatically in six seconds or less.

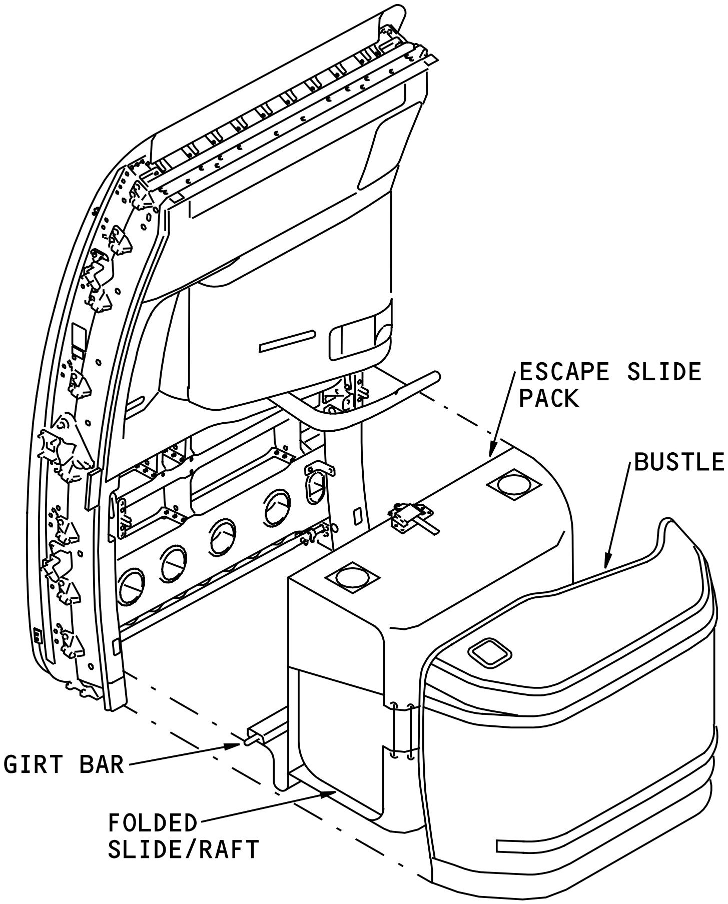
The slide/rafts operate correctly in wind as much as 25 knots. The slide/rafts are safe to use with different door heights caused by the failure of one or more landing gear. The slide/raft has two lanes; two people can use the slide at the same time.

The capacity of the life rafts is sufficient to hold all the passengers and crew, even if one raft is lost.

This equipment (not shown) can be included with each raft:

- Sea anchor
- Mooring line
- Hook knife
- Lighting systems
- Manual inflation pump
- Heaving ring and line
- Survival kit
- Raft canopy
- Emergency locator transmitter (if installed).





DOOR-MOUNTED ESCAPE SYSTEM

DOOR-MOUNTED ESCAPE SYSTEM - GENERAL DESCRIPTION

DOOR-MOUNTED ESCAPE SYSTEM - ESCAPE SLIDE PACK - INTRODUCTION

General

The escape slide pack has two primary parts: the packboard and the slide/raft.

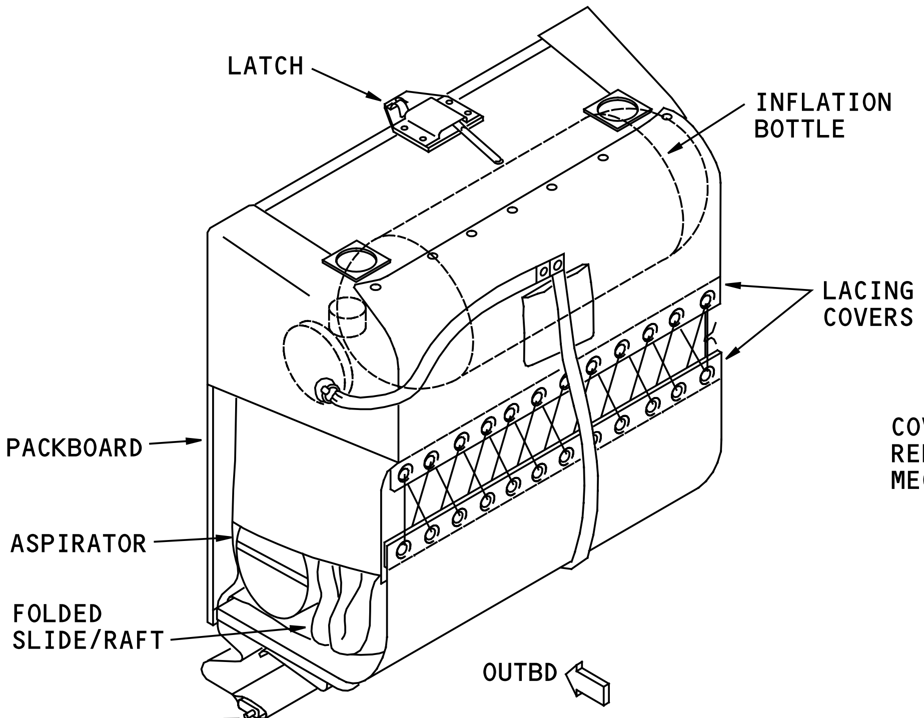
Packboard

The packboard is a composite tray (Kevlar honeycomb) which attaches to the door with two fittings and a latch. Fabric lacing covers hold the folded slide/raft in the packboard until released by the cover release mechanism. When the release mechanism opens, the folded slide/raft falls out of the packboard.

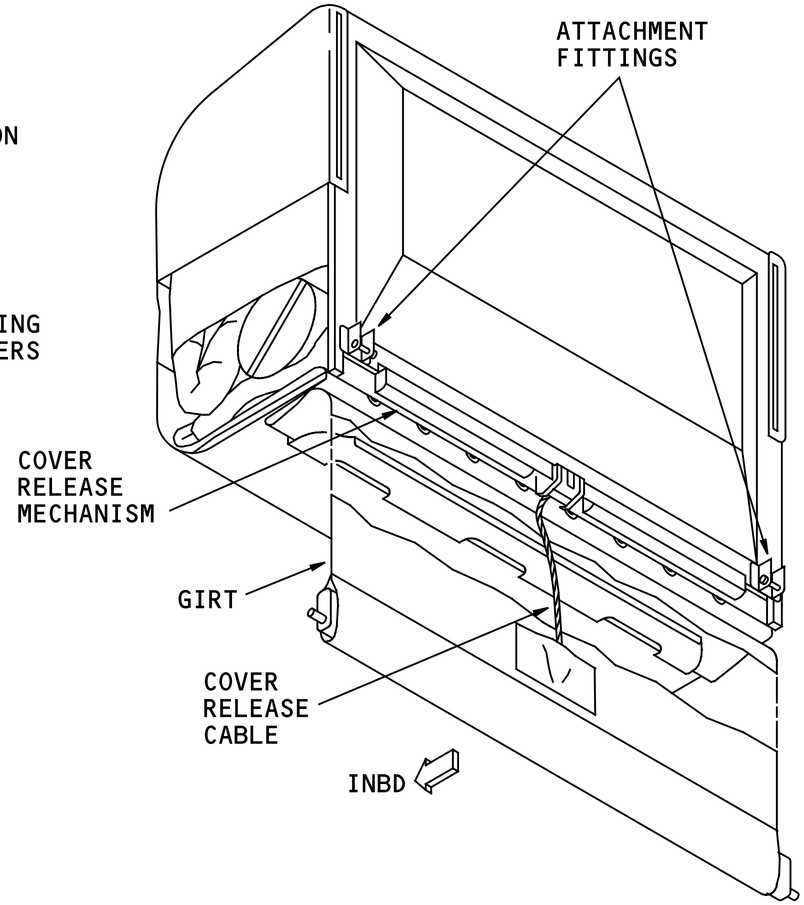
Slide/Raft

The slide/raft is an inflatable structure made of coated Nylon fabric. Upper and lower air chambers support the slide/raft floor. An inflation cylinder and two aspirators inflate the air chambers. A manual handle (not shown) operates the inflation mechanism if the slide/raft fails to inflate automatically. Relief valves (not shown) keep internal pressure to a limit.

The girt and girt bar attach the slide/raft to the airplane doorway. The girt is part of the escape slide. Speed-lacing attaches the girt to the girt bar. After ditching, remove the speed-lacing to release the inflated slide/raft from the airplane.



ESCAPE SLIDE PACK
(INBOARD SIDE)



ESCAPE SLIDE PACK
(OUTBOARD SIDE)

25-66-00-002 Rev 0

DOOR-MOUNTED ESCAPE SYSTEM - ESCAPE SLIDE PACK - INTRODUCTION

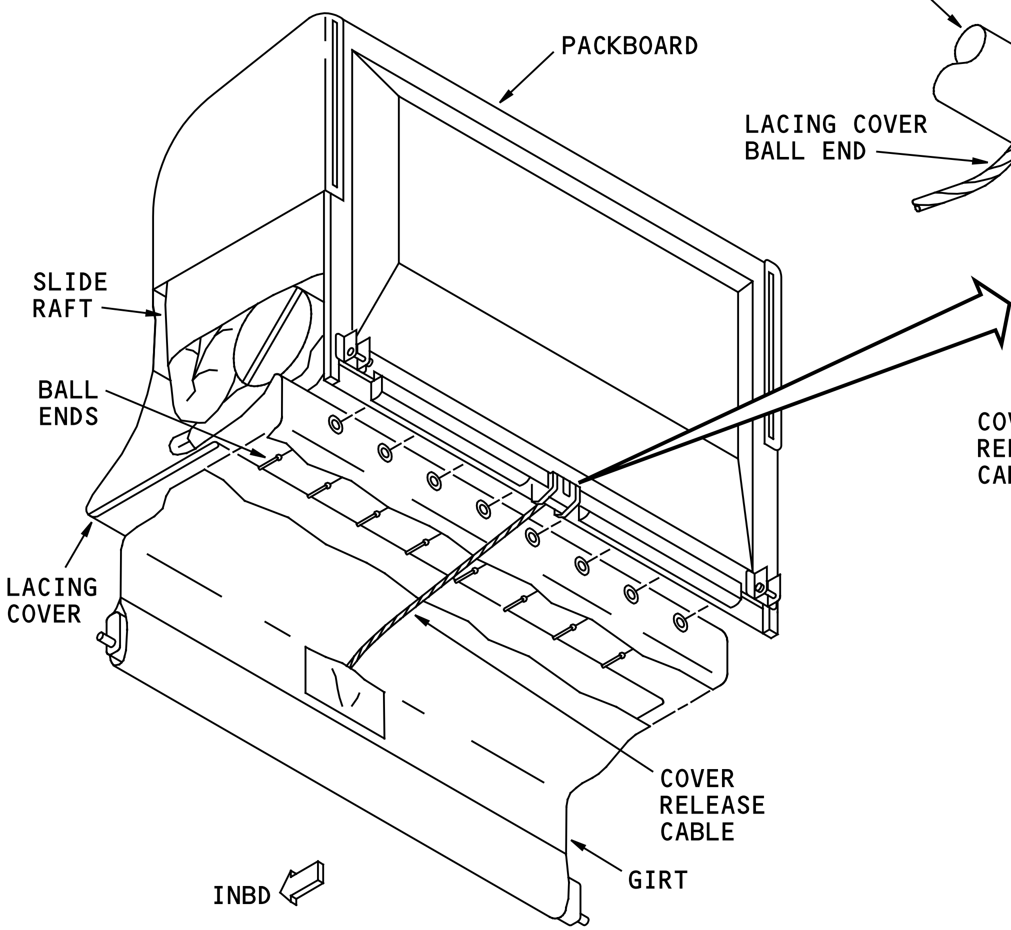
DOOR-MOUNTED ESCAPE SYSTEM - ESCAPE SLIDE PACK - PACKBOARD FUNCTIONAL DESCRIPTION

Cover Release

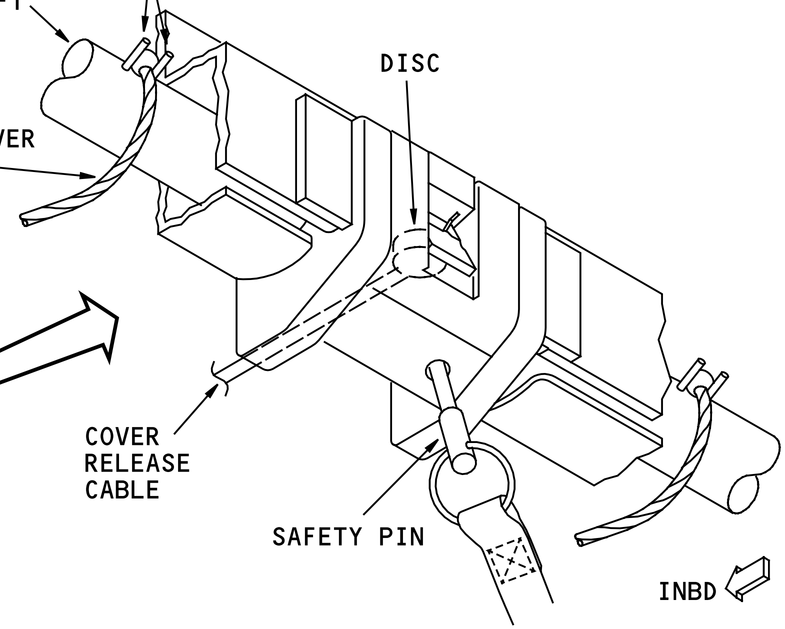
Tension on the girt pulls on the cover release cable. The cable disengages the disc from the release mechanism. The shaft rotates and causes the pins to release the lacing cover ball ends. With the bottom of the lacing cover released from the packboard, the folded slide/raft falls away from the packboard.

Training Information Point

A lanyard attaches a safety pin to the lacing cover. Install the pin to lock the release mechanism during removal or installation of the escape slide pack. When you return the airplane to its usual condition, be sure to remove the pin from the release mechanism. The inboard side of the lacing cover has a stowage pouch for the pin.



ESCAPE SLIDE PACK



LACING COVER RELEASE MECHANISM

25-66-00-003 Rev 0

DOOR-MOUNTED ESCAPE SYSTEM - ESCAPE SLIDE PACK - PACKBOARD FUNCTIONAL DESCRIPTION

DOOR-MOUNTED ESCAPE SYSTEM - ESCAPE SLIDE PACK - SLIDE/RAFT FUNCTIONAL DESCRIPTION

Slide/Raft Inflation

The inflation cylinder holds a mixture of carbon dioxide and nitrogen at 3000 psig. A gage shows how much pressure is in the cylinder. A pressure relief valve protects the cylinder from excessive pressure. The relief valve opens at 4500 psig. A fusible plug protects the inflation cylinder from high temperatures. The plug opens at 174F (79C).

Tension on the inflation cable rotates the inflation valve to the open position. The pressure regulator (internal) reduces the pressure to 550 psig. Gas flows through the hoses, check valves, aspirator nozzles, then into the slide raft air chambers.

The gas flow through the aspirator nozzle creates a venturi effect in the aspirator. The flapper valve opens and ambient air flows through the aspirator to help inflate the slide/raft.

When pressure inside the slide/raft reaches a specified value, the flapper valves close. Gas continues to flow from the cylinder into the slide raft. When the slide/raft is at the correct operating pressure (2.6 psig), relief valves open to prevent overpressurization.

Training Information Point

Hold the aspirator flapper valves open to deflate the slide/raft after an inflation test.

You must install the safety pin to lock the inflation valve during removal or installation of the escape slide pack. When you return the airplane to its usual condition, be sure to remove the pin from the valve. The slide pack lacing cover has a stowage pouch for the pin.

The pressure gage makes allowance for temperature changes. The pointer moves with pressure changes. The green band moves with temperature changes. If the pointer is within the green band, the cylinder pressure is correct for the cylinder temperature.

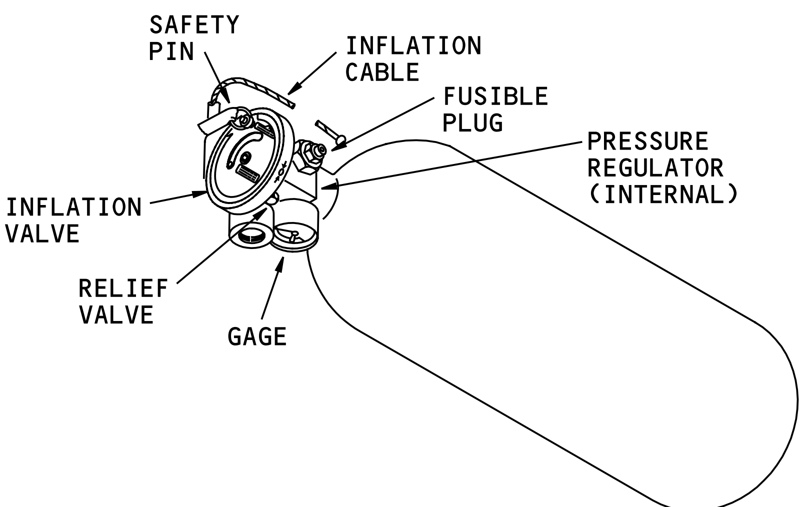
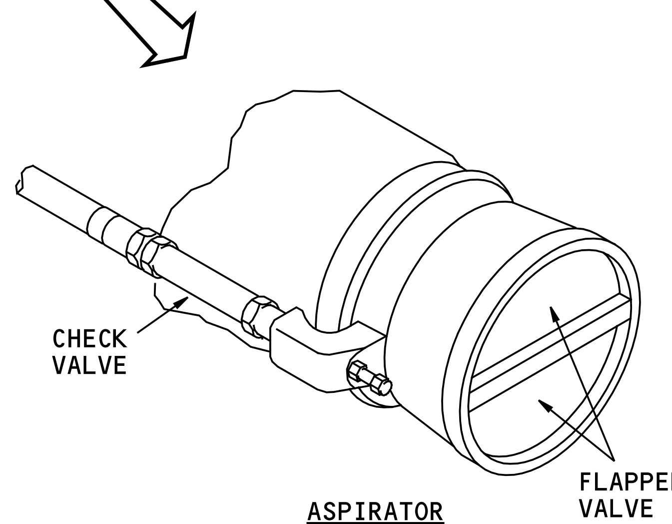
PRESSURE GAGE



INFLATION CYLINDER



ASPIRATOR

25-66-00-004 Rev 0

DOOR-MOUNTED ESCAPE SYSTEM - ESCAPE SLIDE PACK - SLIDE/RAFT FUNCTIONAL DESCRIPTION

DOOR-MOUNTED ESCAPE SYSTEM - BUSTLE

Purpose

The bustle is the door lower liner. It is a cover for the slide/raft and makes the installation look good.

Physical Description

The bustle is a crushed core shell covered on both sides with graphite composite. Tedlar laminate covers the inboard side. A window in the bustle lets you see the slid pack pressure gauge. Rubstrips protect the bustle from galley service carts.

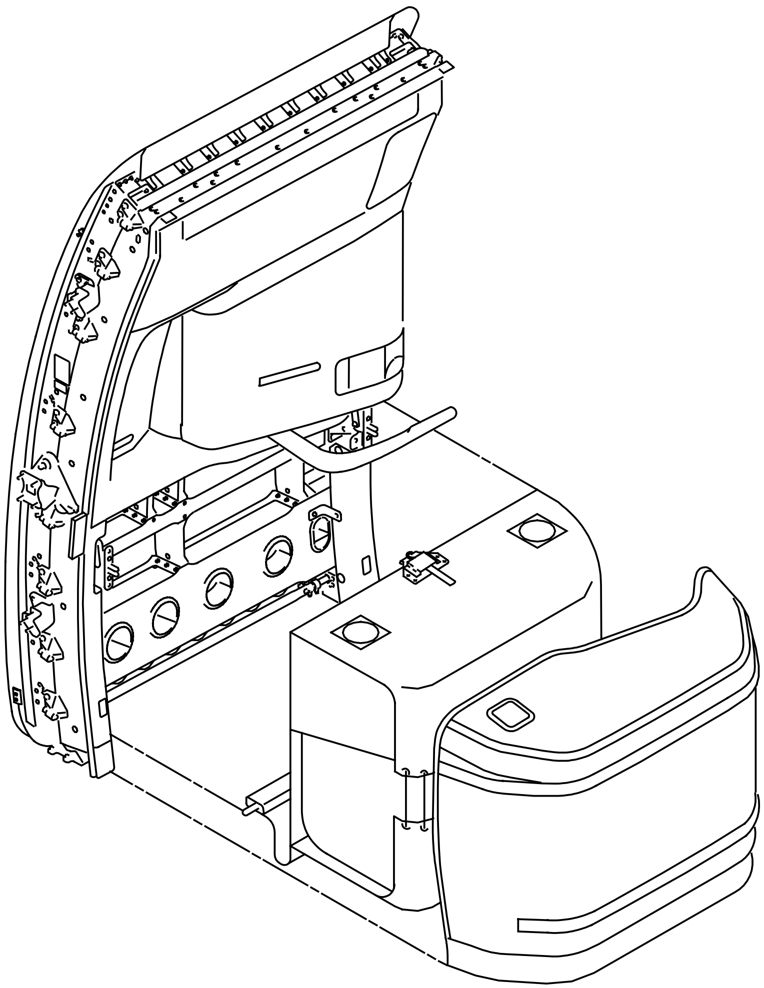
Two latches hold the top of the bustle to the door. The latches have a hinge which allows the bottom of the bustle to move inboard. Alignment fittings hold the bottom of the bustle in position against the door.

Functional Description

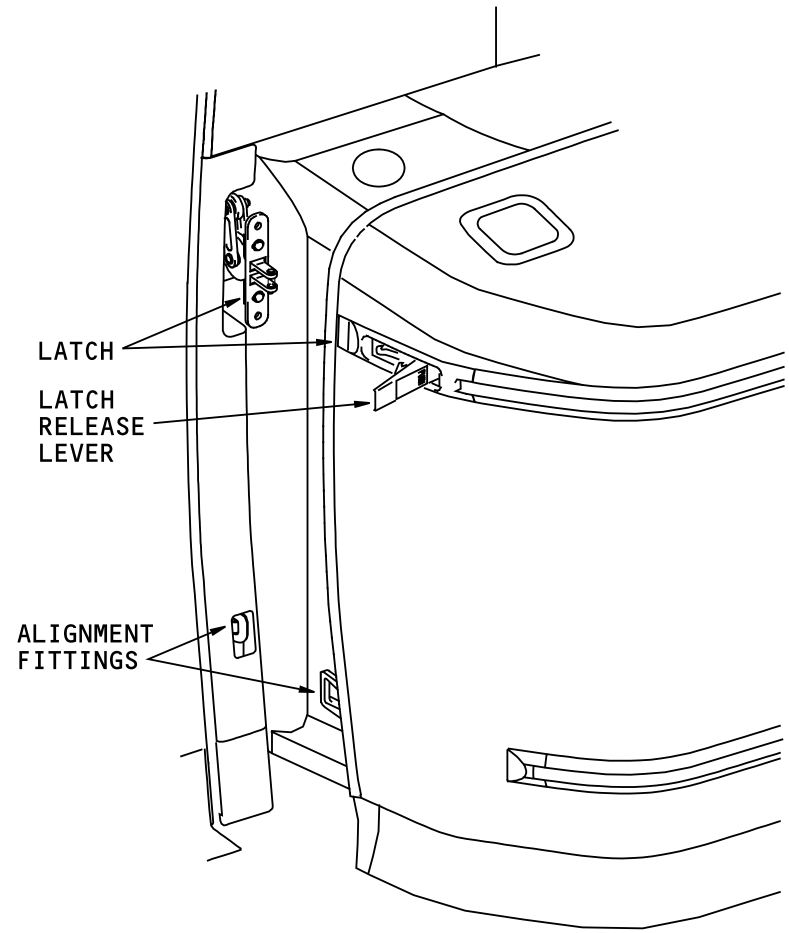
When the door opens in the armed mode, the escape slide girt puts pressure on the bottom edge of the bustle. The alignment fittings at the bottom of the bustle click open. This permits the door to continue opening while the escape slide drops.

Training Information Point

Release the alignment fittings and latches to remove the bustle from the door. Pull the bottom of the bustle inboard to release the alignment fittings. Open the levers to release the latches at the top of the bustle.



DOOR-MOUNTED ESCAPE SYSTEM



BUSTLE

25-66-00-005 Rev 0

DOOR-MOUNTED ESCAPE SYSTEM - BUSTLE

DOOR-MOUNTED ESCAPE SYSTEM - FUNCTIONAL DESCRIPTION - DEPLOYMENT

Door Handle Moved to the Open Position

When you put the door mode selector in the armed position, the girt bar locks in the floor fittings. When you move the door handle to the open position, the door unlatches. The emergency power assist system (EPAS) starts to open the door. See the passenger entry doors section for more information on the EPAS (AMM PART I 52-11).

Tension on the Cover Release Cable

When the door opens far enough to put tension on the cover release cable, this sequence occurs:

- Tension at the girt clicks the bustle open
- The door continues to move open
- The cover release cable pulls free of the release mechanism, so it can open
- The lower lacing cover releases from the packboard
- The escape slide pack falls from the packboard.

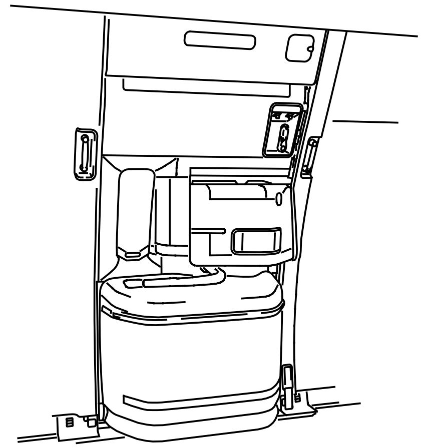
Tension on the Slide Inflation Cable

When the escape slide pack falls from the packboard, the weight of the pack applies tension to the slide inflation cable. This sequence occurs:

- Tension on the inflation cable opens the inflation cylinder valve
- The inflation cylinder uses air from the aspirators to inflate the slide.

Manual Inflation

Sometimes the slide pack hits the ground or water before it falls far enough to apply tension to the inflation cable. If that happens the slide does not inflate automatically. A handle on the girt end of the inflation cable lets you open the inflation valve manually. Pull the handle to inflate the slide.



DOOR HANDLE MOVED TO OPEN

DOOR-MOUNTED ESCAPE SYSTEM - FUNCTIONAL DESCRIPTION - DEPLOYMENT

DOOR-MOUNTED ESCAPE SYSTEM - FUNCTIONAL DESCRIPTION - SEPARATION

General

During ditching, when passengers and crew are aboard the rafts, the rafts must move away from the airplane.

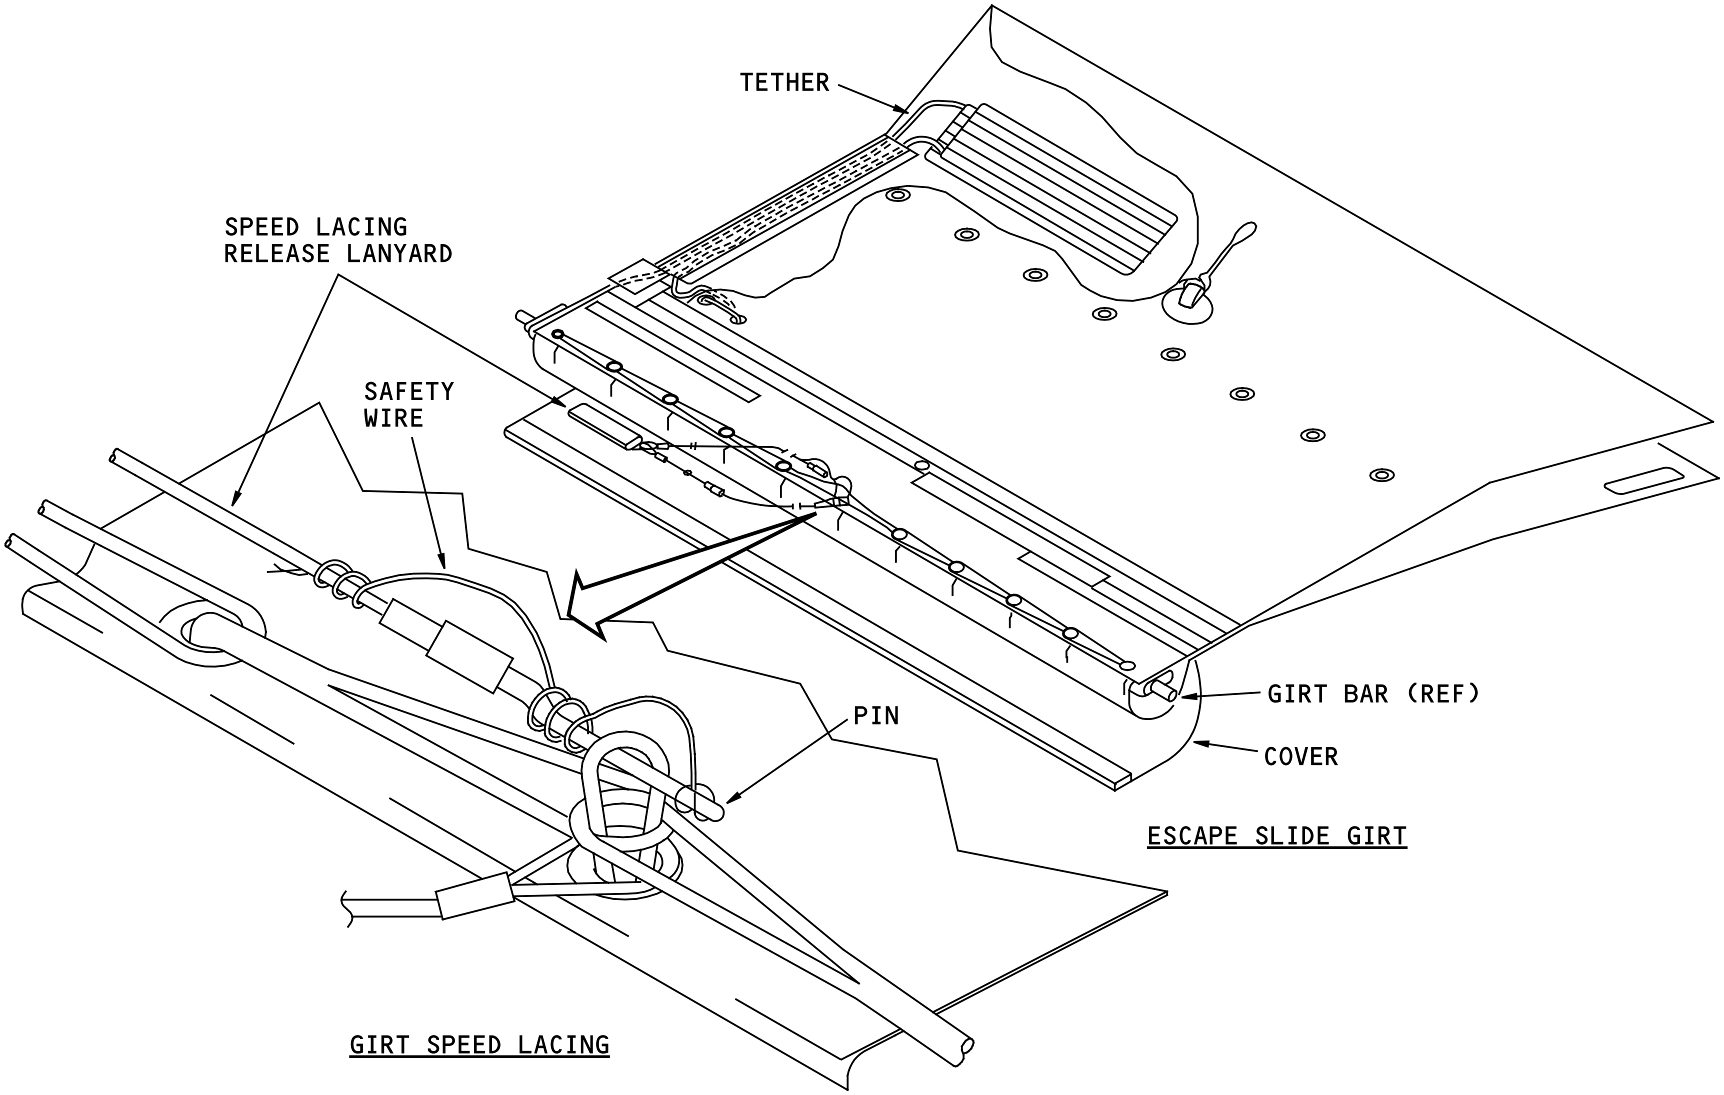
The slide raft girt attaches to the girt bar with speed lacing. Open the cover at the girt and pull the lanyard. This removes the pin and releases the speed lacing so the slide/raft can move away from the airplane. The girt bar stays attached to the airplane.

A tether stowed in the girt keeps the raft attached loosely to the airplane. A hook knife is in the raft to cut the tether when necessary.

Training Information Point

After an inflation test, remove the slide/raft from the airplane this way:

- Support the girt end of the slide/raft
- Remove the girt bar from the floor fittings
- Lower the girt end of the slide/raft to the floor.



25-66-00-007 Rev 0

DOOR-MOUNTED ESCAPE SYSTEM - FUNCTIONAL DESCRIPTION - SEPARATION

CARGO DOORS - INTRODUCTION

Purpose

Cargo doors give access to the forward, aft, and bulk cargo compartments.

Location

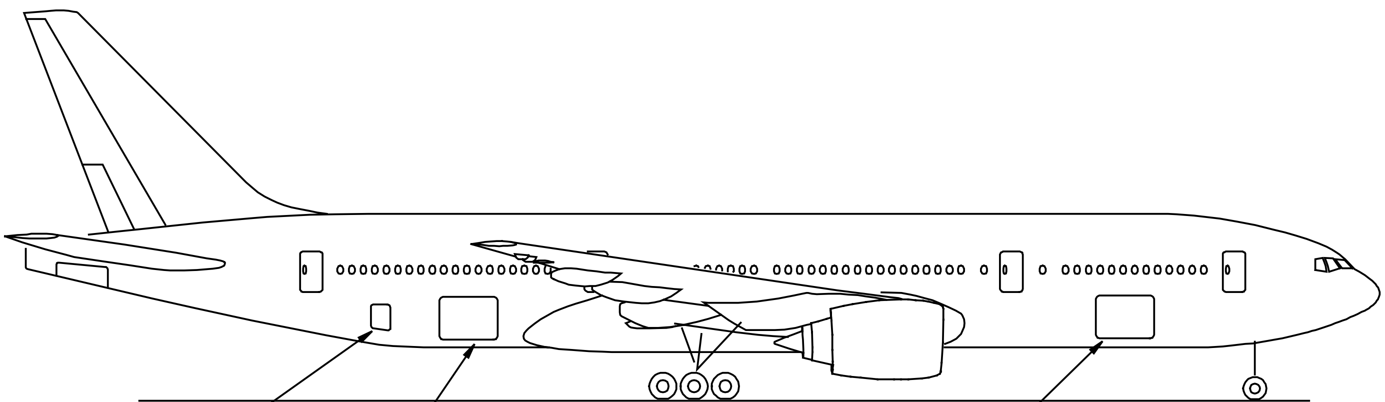
The cargo doors are on the right side of the airplane.

General Description

The forward and aft large cargo doors are the same.

The forward and aft cargo doors lets the crew load cargo on pallets and in containers.

The bulk cargo door lets the crew load smaller cargo that is not on pallets or in containers.



52-30-00-001 Rev 2 11/06/1997

CARGO DOORS - INTRODUCTION

FORWARD LARGE CARGO DOOR SYSTEM - INTRODUCTION

Purpose

The forward large cargo door system gives access to the forward cargo compartment.

Location

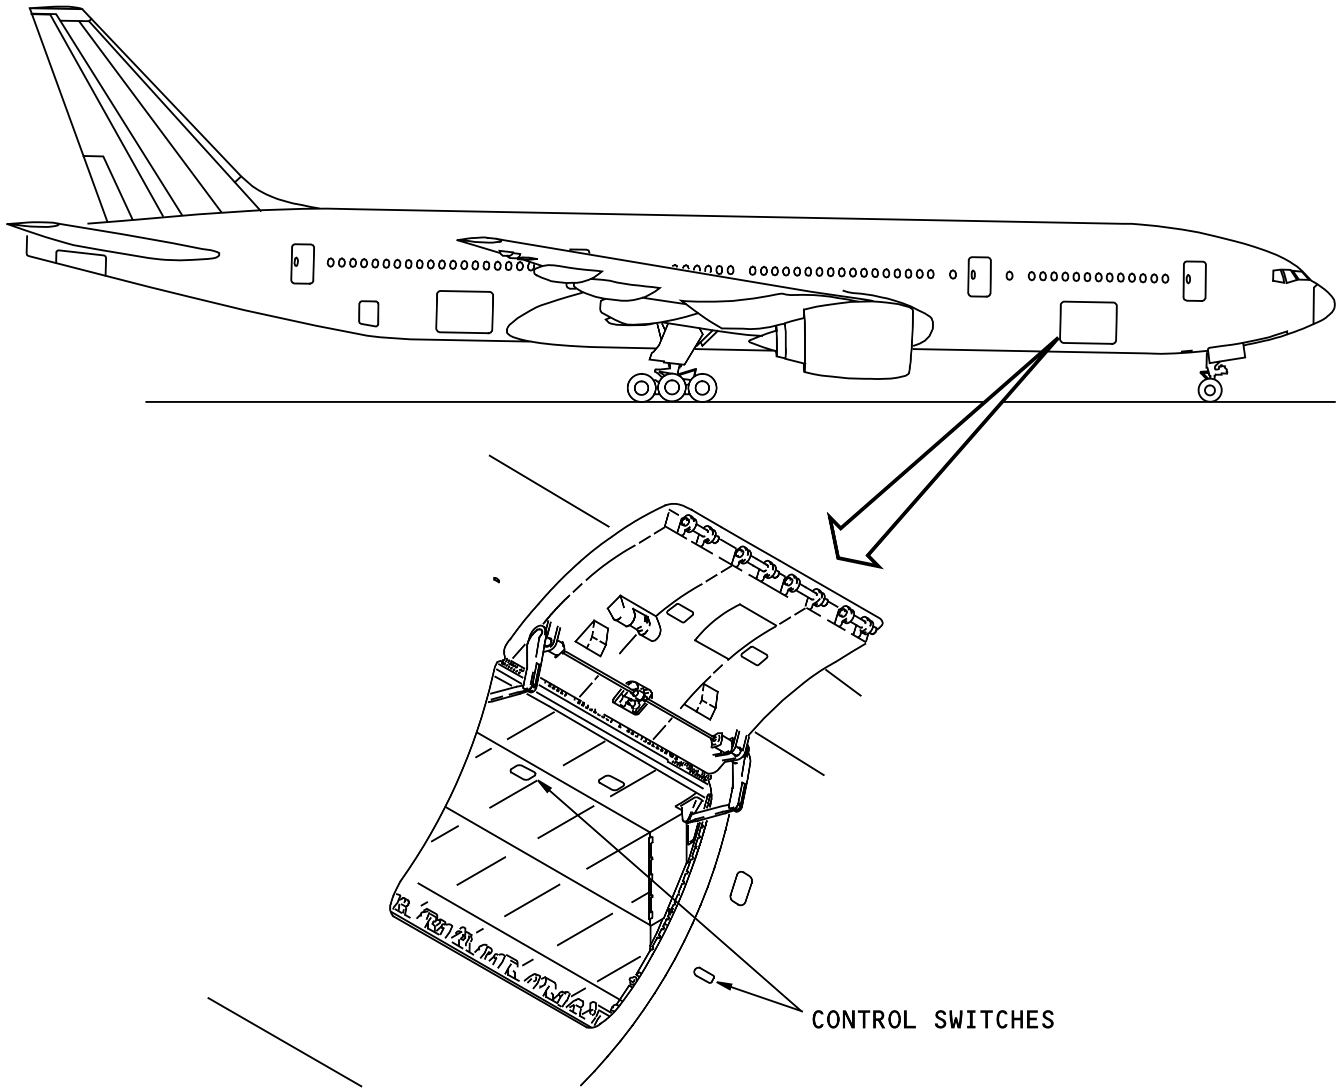
The door is forward of the wing on the right side of the airplane.

General Description

The large cargo door supplies a clear opening of 106 inches (269.2 cm) wide and 67 inches (170.2 cm) high. The dimensions of the door lets cargo handlers load and unload pallets and containers. The aft cargo door is the same.

The door is a non-plug type of door. Door latches hold the door closed against cabin pressure loads.

The door opens outward and upward. You can operate it electrically from inside or outside the cargo compartment. You can operate it manually from outside the cargo compartment.



FORWARD LARGE CARGO DOOR SYSTEM - INTRODUCTION

FORWARD LARGE CARGO DOOR SYSTEM - COMPONENT LOCATIONS - 1

Components on the Outside of the Door

The lift manual drive sockets are on the upper, forward corner of the door.

The lock handle is on the lower half of the door, near the center. You can see the latch manual drive socket when you release the handle to the open position.

There are eight witness ports along the bottom edge of the door.

There are three sling attach points.

There are seven component access panels.

Training Information Point

Use the lock handle to lock and unlock the door. It connects to the lock mechanism on the inside of the door. Also, you enable electrical operation of the door when you release the lock handle.

The latch manual drive socket is for manual operation of the latch cams and pull-in hooks. It connects to the latch manual drive on the inside of the door.

The lift manual drive sockets are for manual operation of the lift mechanism. They connect to the lift manual drive on the inside of the door.

The witness ports let you make sure the door is latched and locked.

The sling attach points let you sue a sling to lift the door for removal and replacement. It also lets you lift the door open if the lift mechanism fails.

The access panels give access to failed components if the cargo door is not open.

FORWARD LARGE CARGO DOOR SYSTEM - COMPONENT LOCATIONS - 1

FORWARD LARGE CARGO DOOR SYSTEM - COMPONENT LOCATIONS - 2

THIS PAGE INTENTIONALLY LEFT BLANK

52-34-00-003 Rev 1 11/06/1997

FORWARD LARGE CARGO DOOR SYSTEM - COMPONENT LOCATIONS - 2

Components on the Inside of the Door

The two lift mechanisms are near the upper forward and the upper aft corners of the cargo door.

The two rotary actuators are near the upper, forward and the upper, aft corners.

The lift manual drive is near the upper, forward corner.

The lift power unit is located near the top, center of the door.

The vent door is near the horizontal mid line of the cargo door, near the aft edge.

The two pull-in hooks are at the forward and aft edges.

The vent door mechanism goes from the vent door to the lock mechanism lock pawl on the aft latch cam.

The latch mechanism goes from the latch/hook power unit to the pull-in hooks and latch cams.

The latch power unit is on the lower part of the door, near the center.

Eight main latch cams are near the bottom of the door.

The lock mechanism goes from the lock handle to lock pawls on the eight main latch cams at the bottom of the door. The mechanism also goes to the vent door interlock.

The lock handle assembly is near the center of the cargo door.

The latch manual drive is goes from the lock handle assembly to the latch/hook power unit.

The graphic does not show the location of the proximity sensors that do control functions. Their locations are shown at the component level.

General Description

This section describes the function of the components on the inside of the door as the door goes from the fully open position to the closed, latched, and locked position.

The motor in the lift power unit supplies the torque to lower the door. Torque can also come from the lift manual drive. The torque goes to the rotary actuators. The torque goes from the rotary actuators to the lift mechanism. The lift mechanism lowers the door.

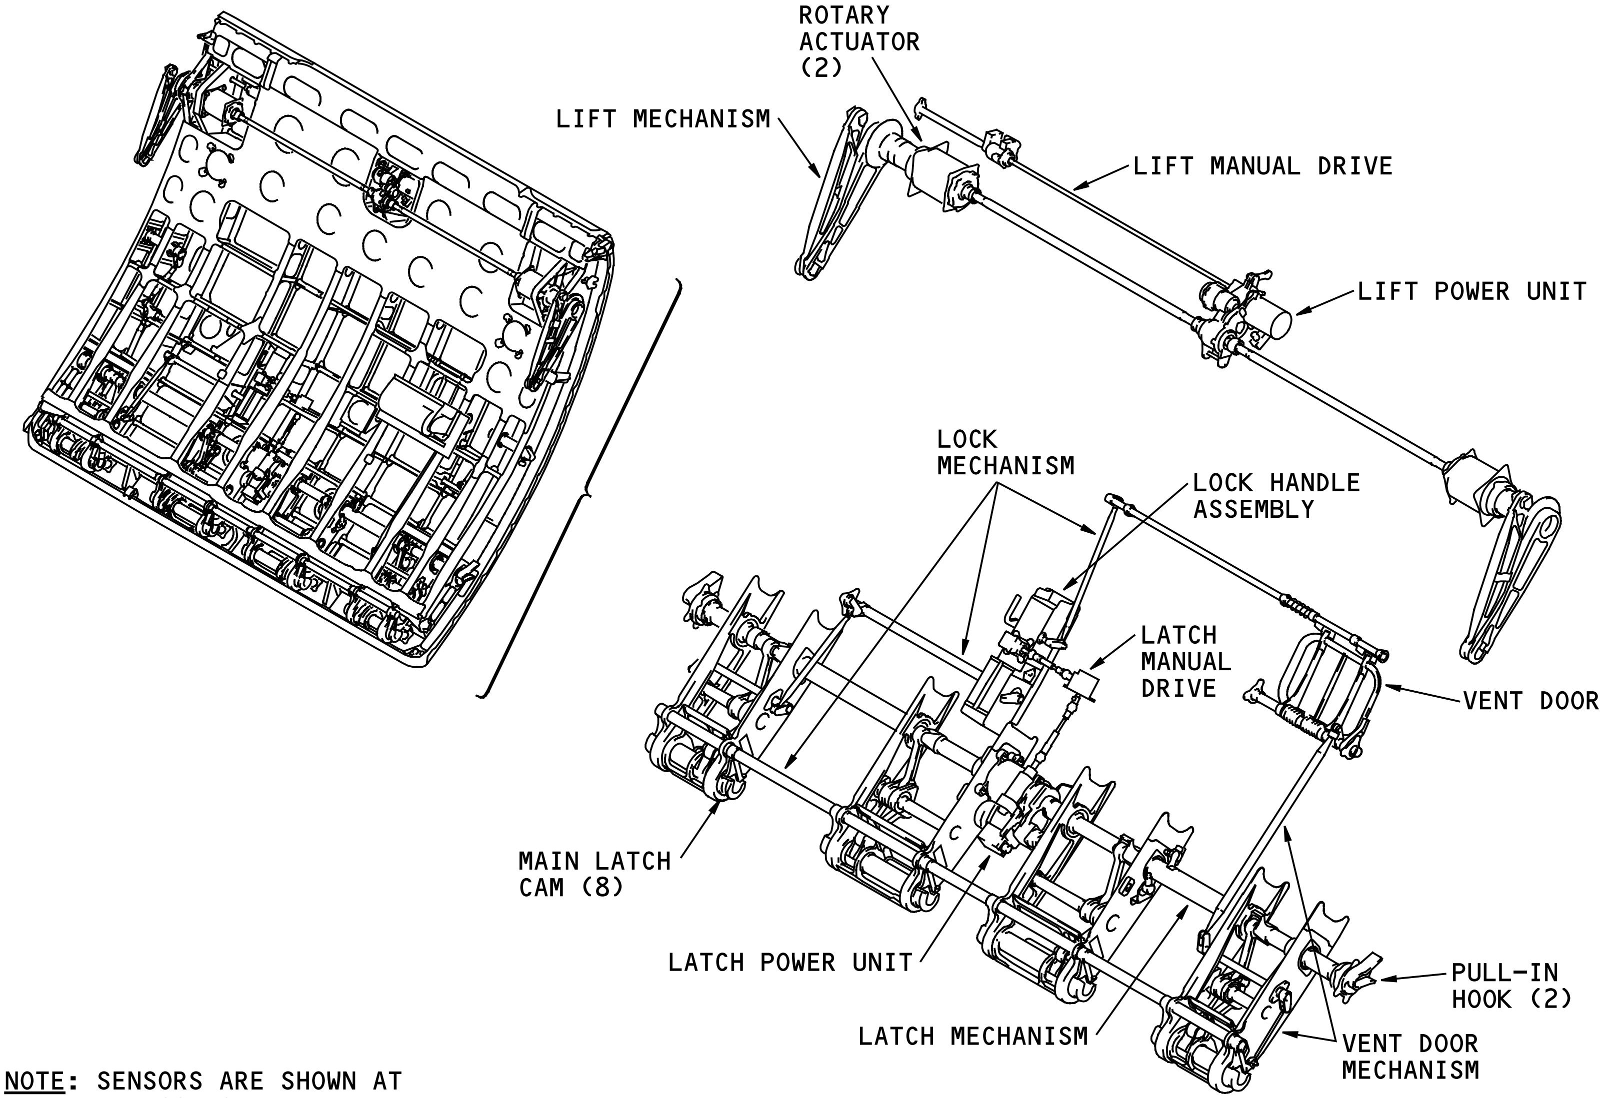
Electric power shifts from the lift power unit to the latch power unit when a proximity sensor senses the door is completely lowered. Torque goes from the latch power unit to the pull-in hooks. Movement of the pull-in hooks around the pull-in pins on the door cutout, pulls the door into the latch position.

FORWARD LARGE CARGO DOOR SYSTEM - COMPONENT LOCATIONS - 2

After the door is pulled in, torque goes from the latch power unit to all of the latch cams. The cams turn around the latch pins. This latches the door. When a proximity sensor senses the door is latched, electric power is removed from the power unit.

Movement of the lock handle on the outside of the door to the lock position, locks the door. The lock action causes these actions to occurs on the inside of the door:

- Proximity sensors cause electric door operation to be disabled
- The lock mechanism locks the main latch cams at the bottom of the door
- The lock mechanism holds the vent door closed.



NOTE: SENSORS ARE SHOWN AT THE COMPONENT LEVEL.

52-34-00-003 Rev 1 11/06/1997

FORWARD LARGE CARGO DOOR SYSTEM - COMPONENT LOCATIONS - 2

FORWARD LARGE CARGO DOOR SYSTEM - COMPONENT LOCATIONS - 3

Components on the Door Cutout

The hinge is along the top of the door cutout.

The two pull-in pins are on the forward and aft side of the door cutout.

Eight main latch pins are along the bottom of the door cutout.

Components near the Door Cutout

The internal door control switch is in the cargo compartment ceiling, near the forward end of the door cutout.

The P43, external cargo door control panel is forward of the door cutout.

General Description

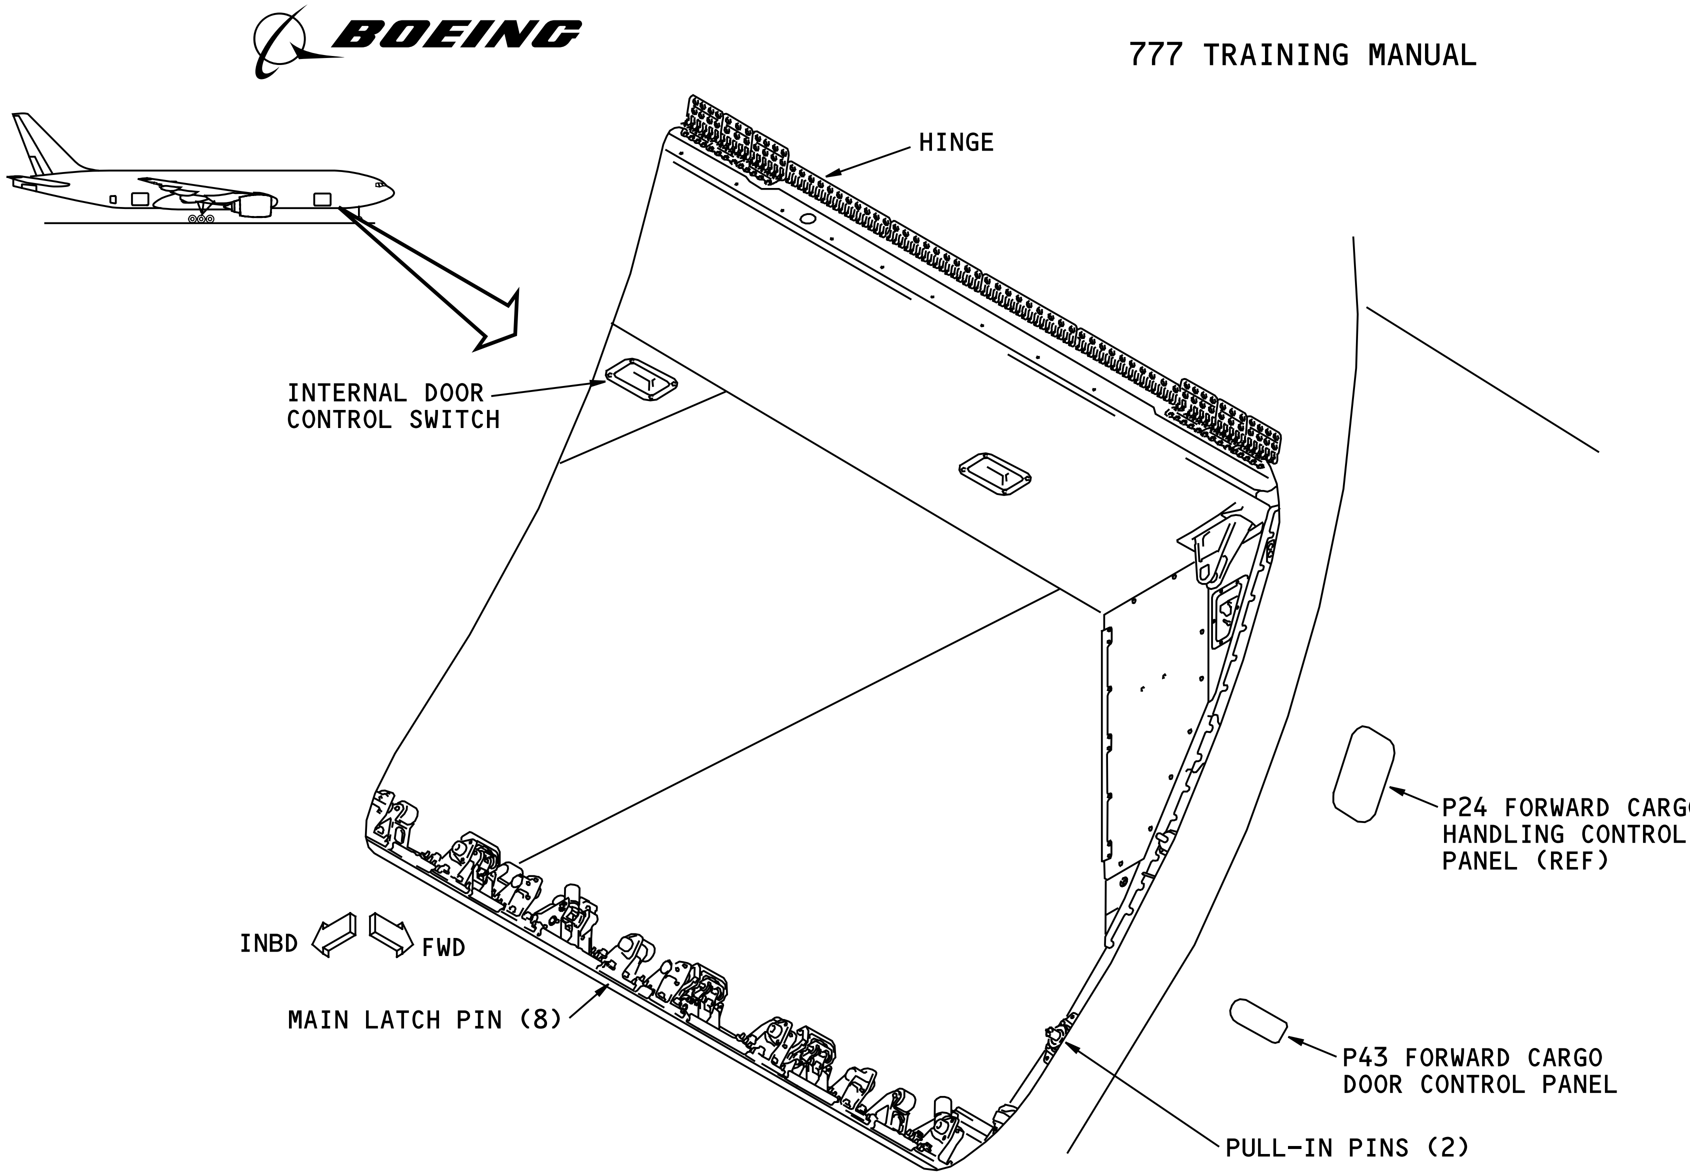
The door rotates on the hinge as it opens and closes.

The pull-in hooks on the door engage the pull-in pins to pull the door into position where it can be latched.

The latch cams on the side and bottom of the door turn around the latch pins to latch the door.

Training Information Point

The internal cargo door control switch and the door control switch on the P43, external cargo door control panel, let you operate the door electrically.



VIEW LOOKING INTO CARGO COMPARTMENT
(DOOR REMOVED)

FORWARD LARGE CARGO DOOR SYSTEM - COMPONENT LOCATIONS - 3

FORWARD LARGE CARGO DOOR SYSTEM - LIFT POWER UNIT

Purpose

The lift power unit supplies the power to open and close the door.

Physical Description

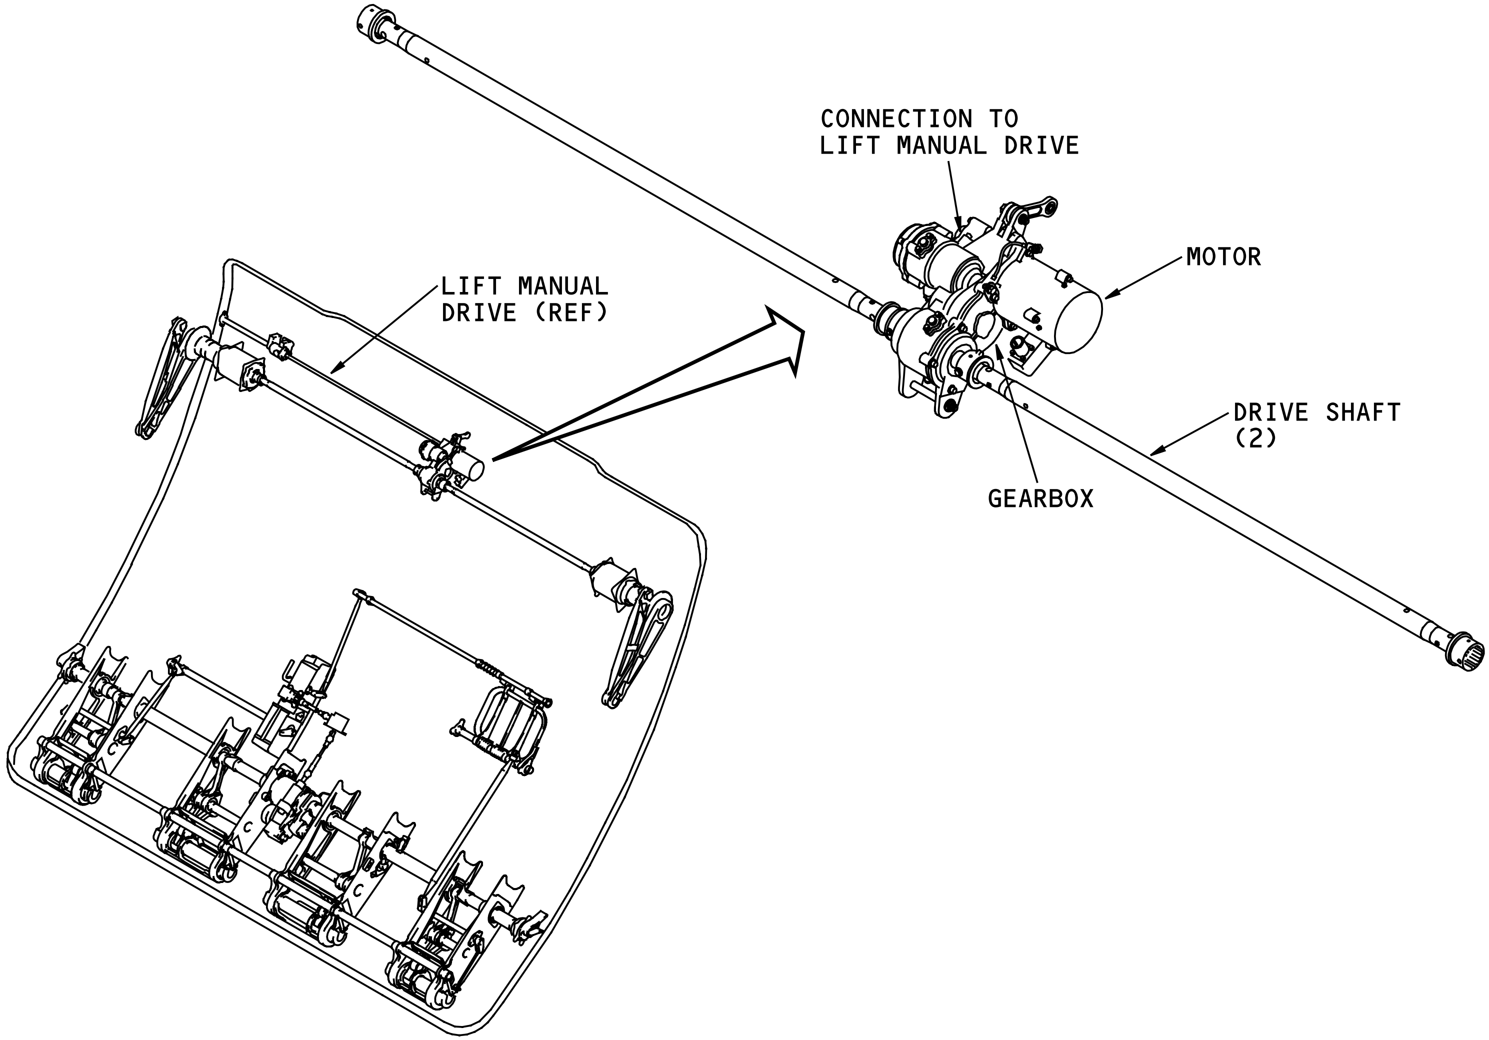
The unit has these components:

- Connection to the lift manual drive
- A three phase, 115/200v ac, 400 Hz motor with a brake
- A gear box
- Two drive shafts.

Functional Description

The motor supplies torque through the gearbox and torque tubes to rotary actuators.

The gearbox gets torque from the lift manual drive when you lift and lower the door manually.



52-34-00-006 Rev 1 11/06/1997

FORWARD LARGE CARGO DOOR SYSTEM - LIFT POWER UNIT

FORWARD LARGE CARGO DOOR SYSTEM - LIFT MANUAL DRIVE

Purpose

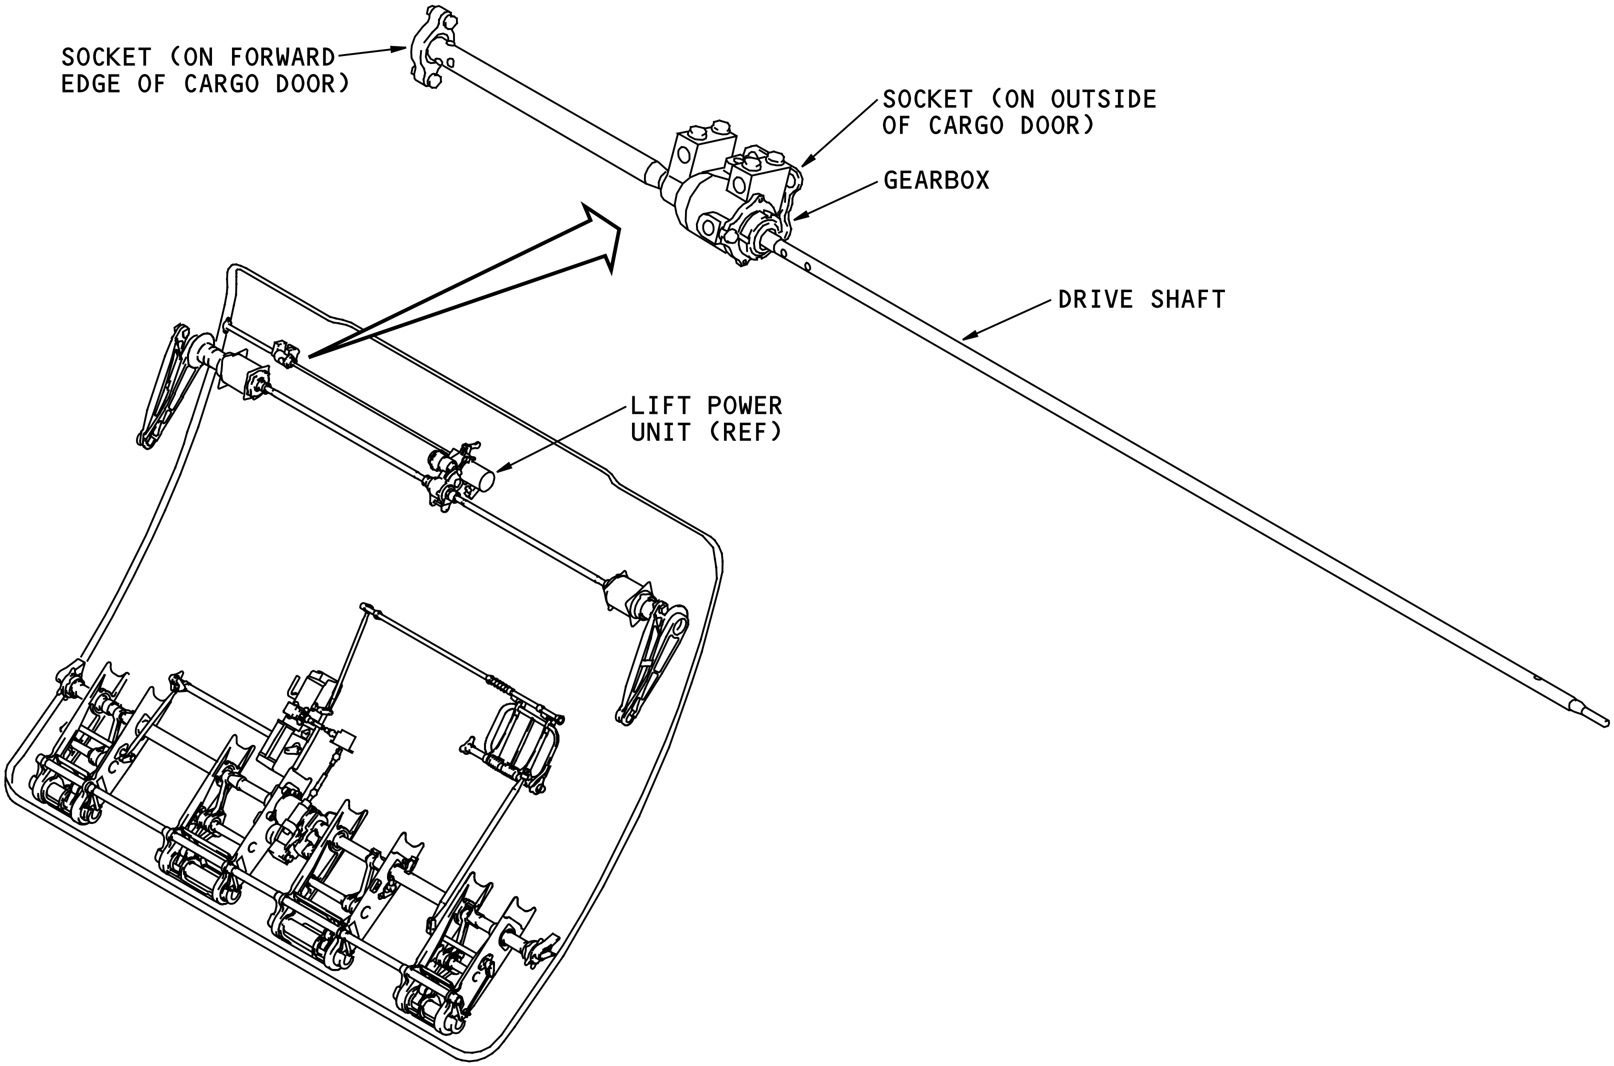
The lift manual drive lets you manually lift and lower the door.

Physical Description

The lift manual drive has two 3/8-inch square drive sockets. A drive shaft goes from the socket on the forward edge of the door, through a gear box, to the lift power unit. A short shaft connects the socket on the outside of the door to the gear box.

Functional Description

The lift manual drive receives torque through the sockets. The torque goes from the sockets, through the gear box and torque tubes, to the lift power unit.



52-34-00-007 Rev 1 11/06/1997

FORWARD LARGE CARGO DOOR SYSTEM - LIFT MANUAL DRIVE

FORWARD LARGE CARGO DOOR SYSTEM - ROTARY ACTUATOR

Purpose

The two rotary actuators transmit torque from the lift power unit torque tubes to the door lift mechanisms.

Physical Description

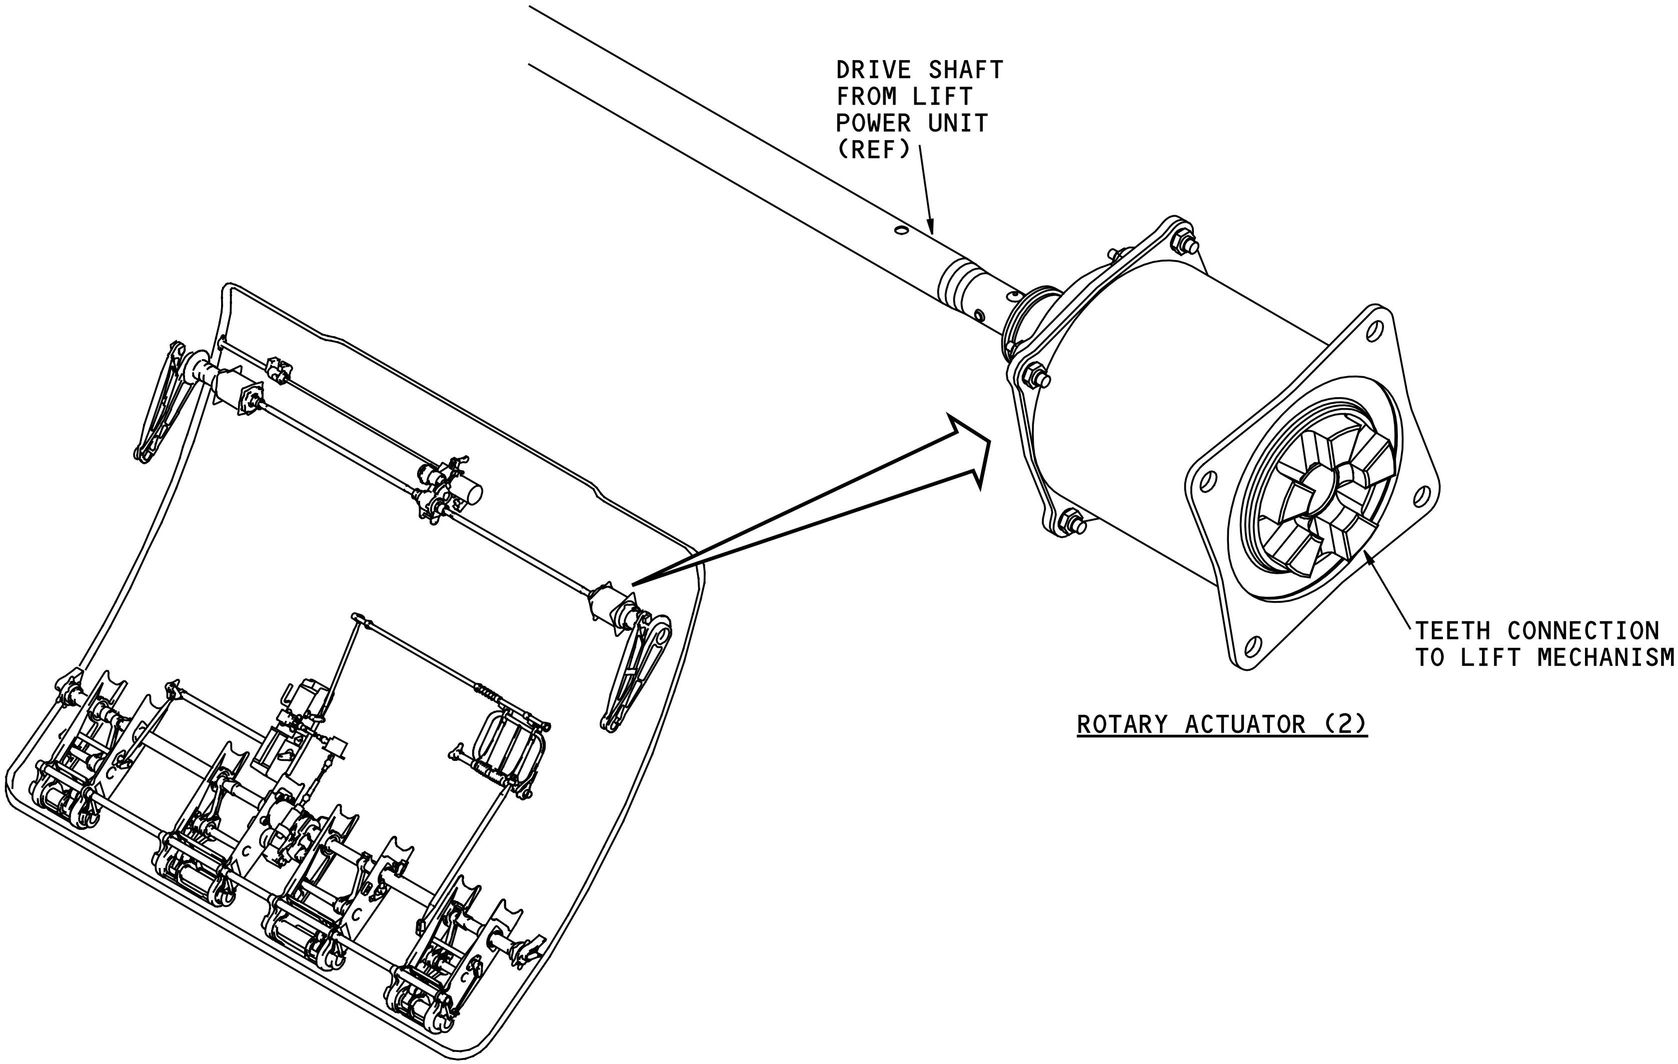
The actuator has these parts:

- A dog coupling to the lift drive mechanism
- Three planetary gear stages (internal)
- A no-back (internal).

Functional Description

The gears of the actuator reduce the rotation rate from the lift power unit. The teeth transmits torque into the lift mechanism. The free play in the teeth connection lets the door move a small amount without torque from the lift power unit. This lets the latch mechanism operate.

The no-back inside each actuator stops door movement toward closed when you remove power from the lift power unit.



FORWARD LARGE CARGO DOOR SYSTEM - ROTARY ACTUATOR

FORWARD LARGE CARGO DOOR SYSTEM - LIFT MECHANISM

Purpose

The lift mechanisms supply the motion that lifts and lowers the door.

Physical Description

Each lift mechanism has a drive arm and a drive link. One end of the drive arm has a short shaft with a teeth connection to the rotary actuator. The other end is a pivot connection to the drive link. The drive link connects to the door cutout structure.

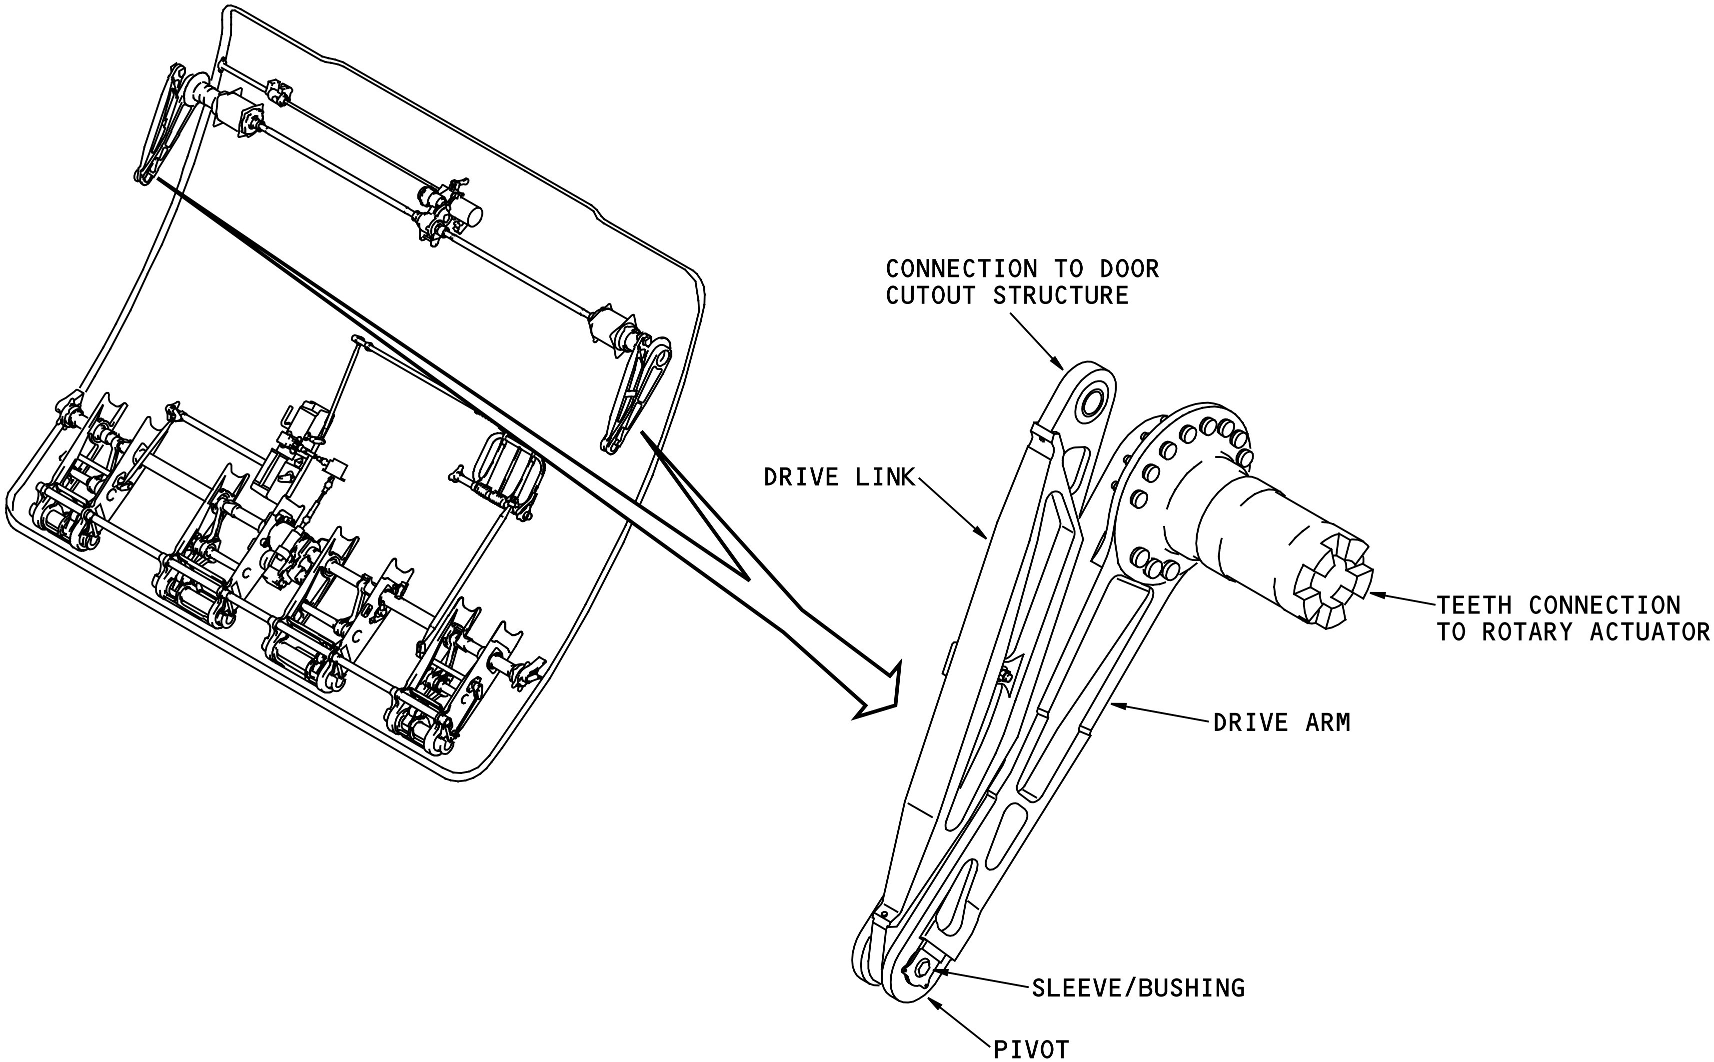
Functional Description

The lift mechanism takes the rotary motion of the rotary actuator and changes it into motion that lifts and lowers the door.

Training Information Point

If the door fails to open because of a problem with the lift mechanism, lift power drive unit, or rotory actuator, it may be necessary to remove the fasteners at the joint between the drive arm and the drive link at the forward and aft sides of the door. There are two panals (not shown) on the outside of the door that provide access to the fasteners.

WARNING: BLOCK THE DOOR AT THE LOWER EDGE. THE DOOR CAN OPEN SUDDENLY WITH GREAT FORCE AND INJURIES TO PERSONS OR DAMAGE TO EQUIPMENT CAN OCCUR.



LIFT MECHANISM

FORWARD LARGE CARGO DOOR SYSTEM - LIFT MECHANISM

FORWARD LARGE CARGO DOOR SYSTEM - LATCH POWER UNIT

Purpose

The latch power unit supplies torque to the latch cams and the pull-in hooks.

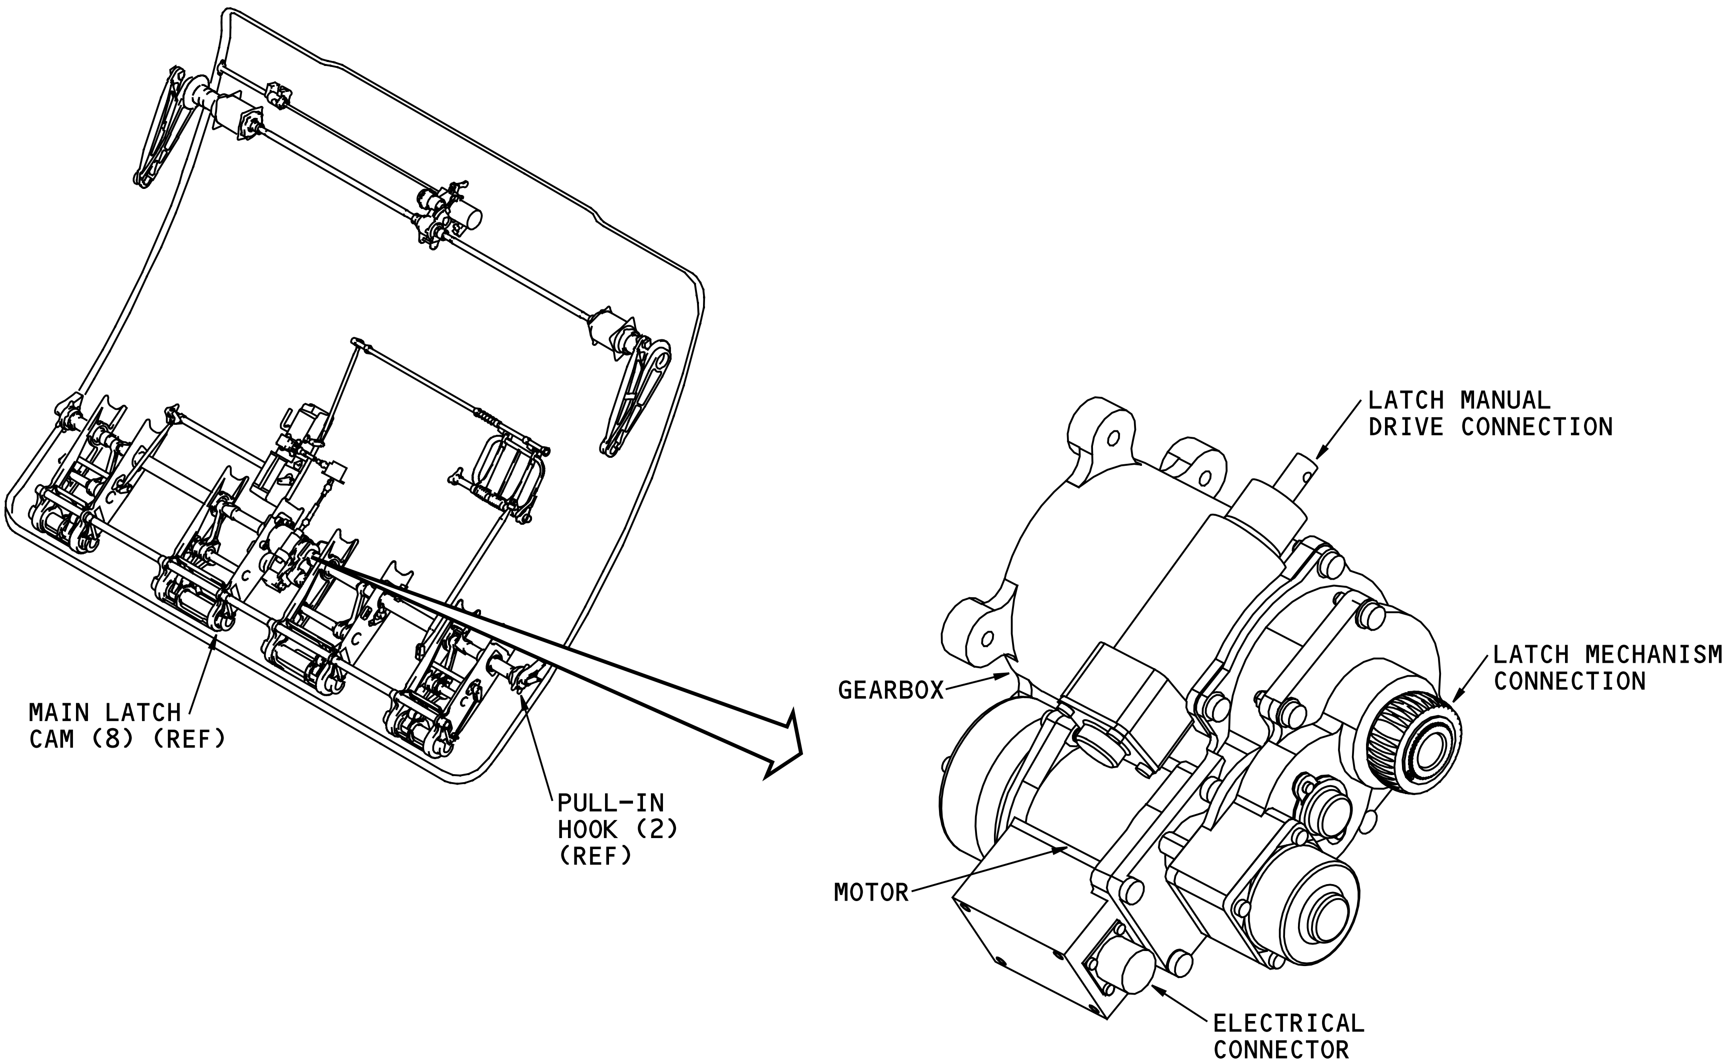
Physical Description

The latch power unit has these components:

- Latch manual drive connection
- Latch mechanism connection
- Electric power connection
- Three phase, 115/200v ac, 400 Hz motor
- Gear box
- Clutch (internal).

Functional Description

The motor supplies torque to the gearbox. The latch manual drive can also supply the torque. The clutch limits the torque supplied to the pull-in hooks and latch cams. This prevents damage when the latch cams or pull-in hooks are not able to move.



FORWARD LARGE CARGO DOOR SYSTEM - LATCH POWER UNIT

FORWARD LARGE CARGO DOOR SYSTEM - LATCH MANUAL DRIVE

Purpose

The latch manual drive lets you manually unlatch and latch the cargo door.

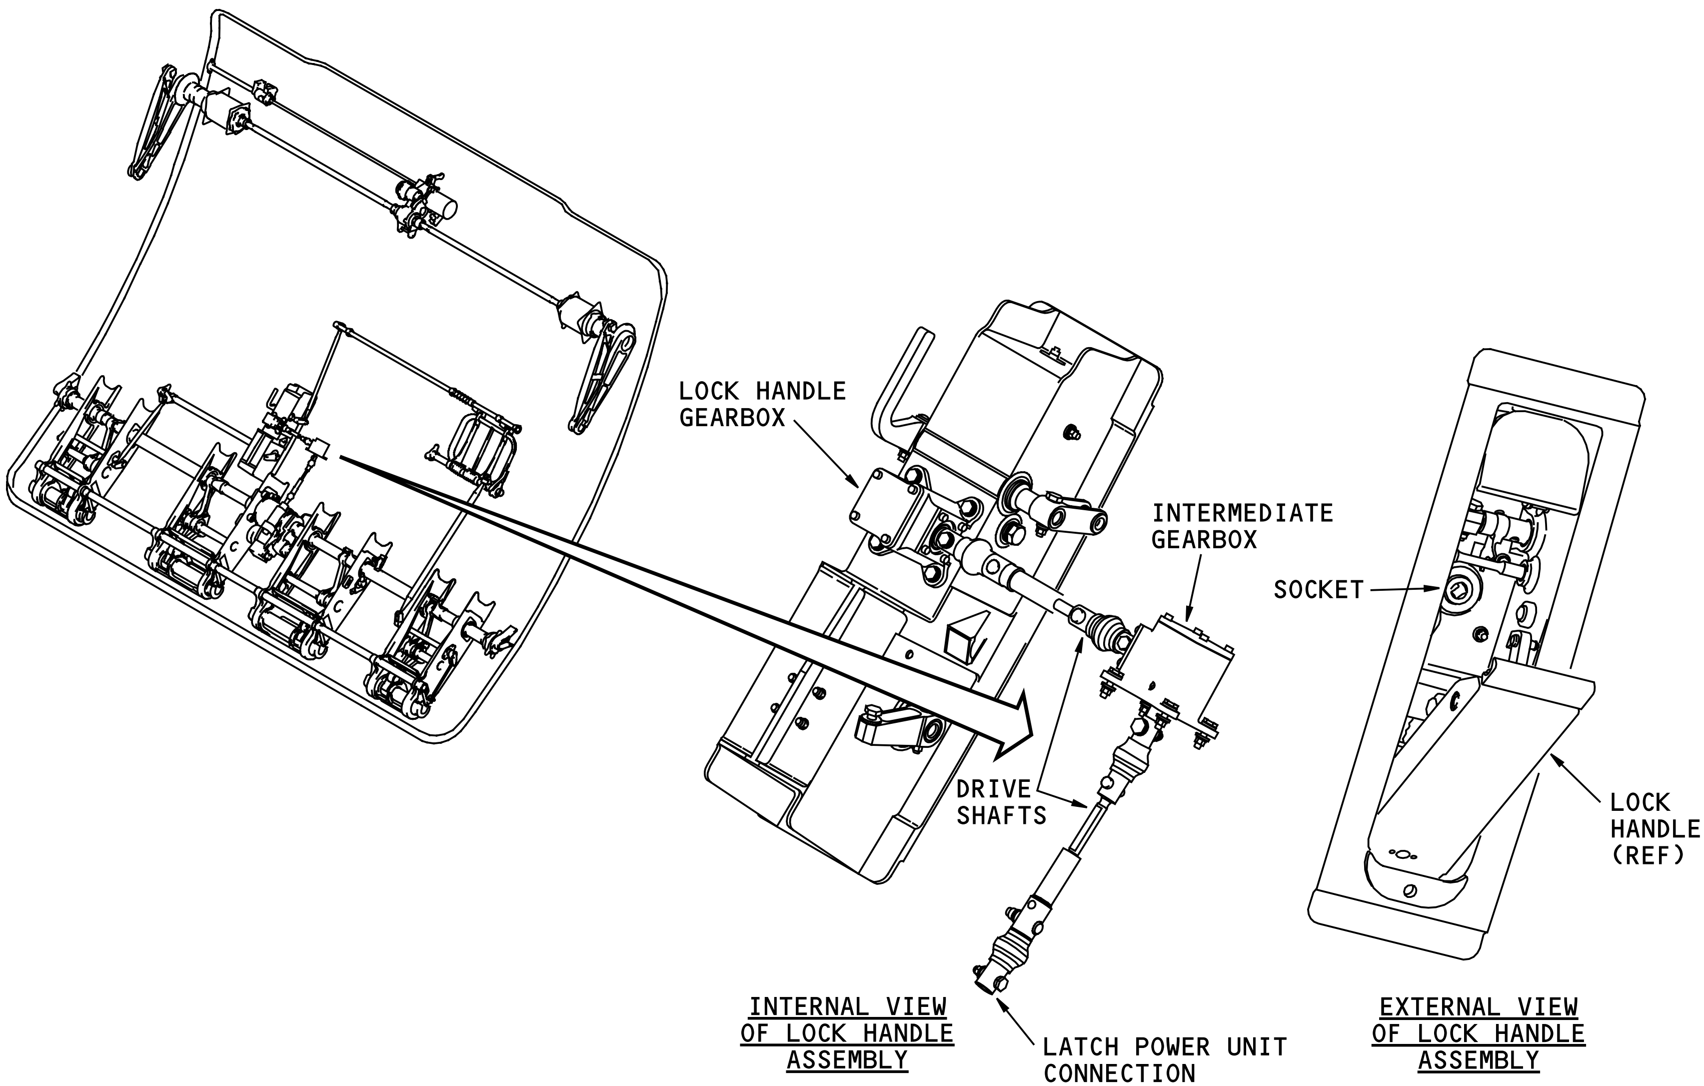
Physical Description

The manual drive has these components:

- Two gear boxes
- Two drive shafts
- A 3/8 inch drive socket
- A latch power unit connection.

Functional Description

The latch manual drive receives torque through the drive socket located in the lock handle housing. Torque goes from the sockets, through the gear boxes and shafts, to the latch power unit.



52-34-00-011 Rev 1 11/07/1997

FORWARD LARGE CARGO DOOR SYSTEM - LATCH MANUAL DRIVE

FORWARD LARGE CARGO DOOR SYSTEM - LATCH MECHANISM

Purpose

The latch mechanism transmits torque from the latch power unit to the latch cams and pull-in hooks.

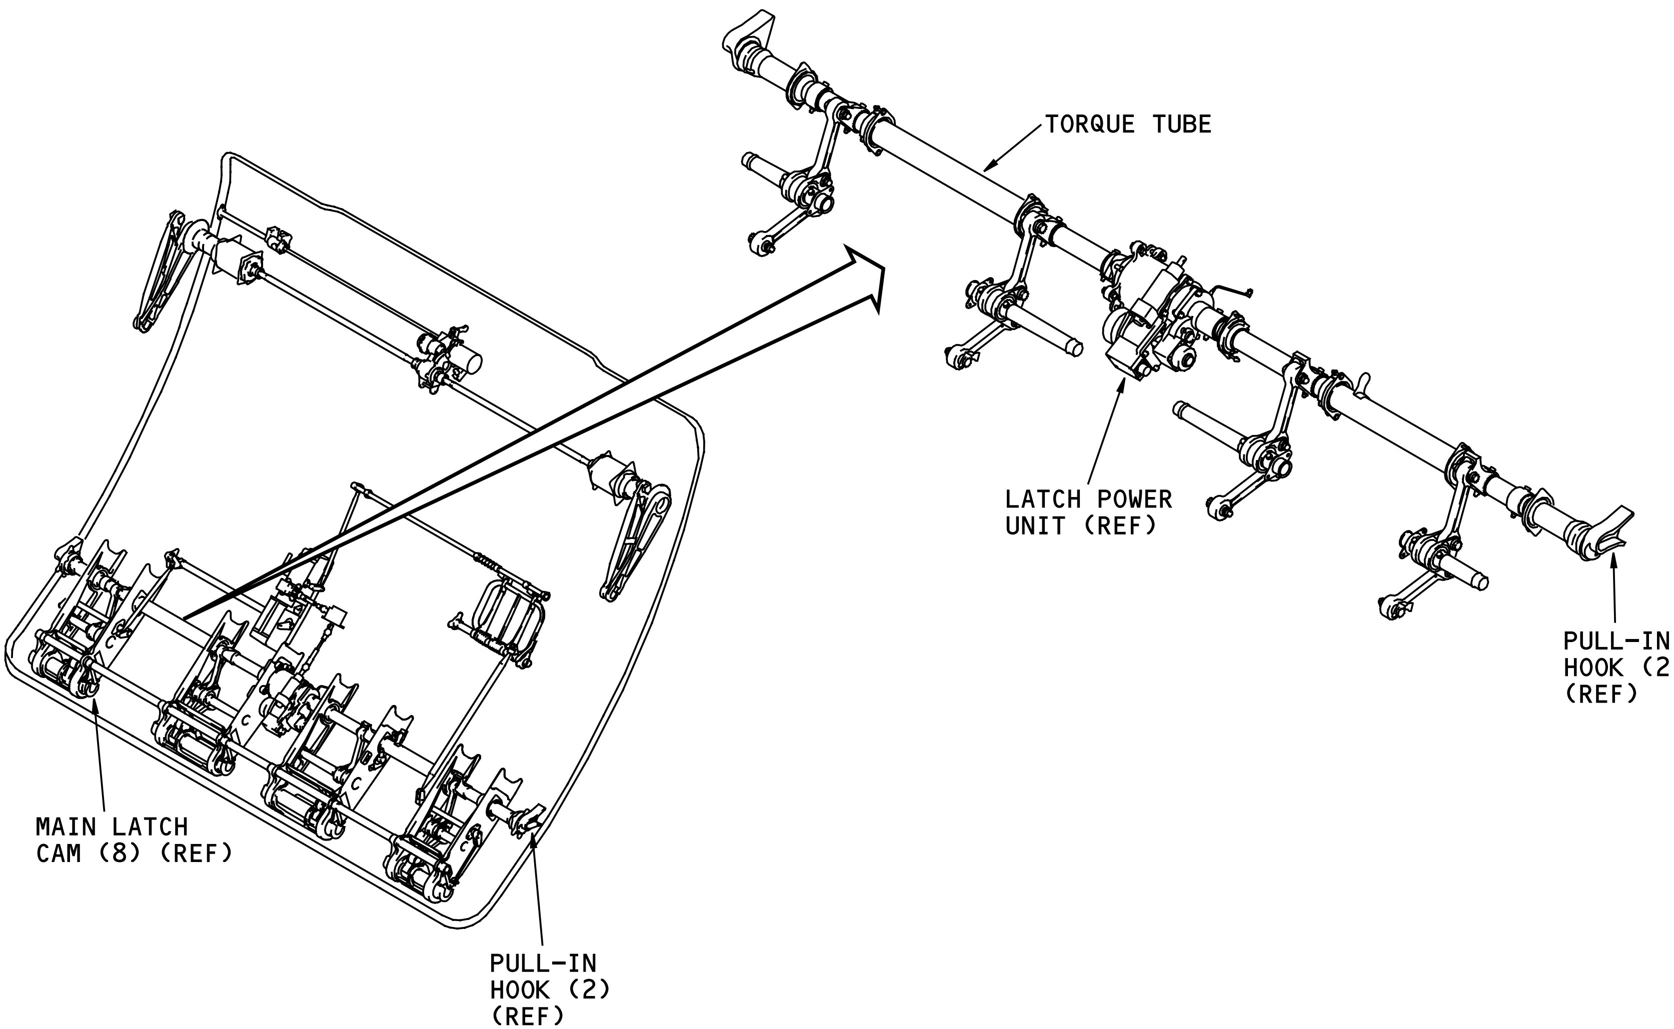
Physical Description

The mechanism has these components:

- Torque tubes
- Push rods
- Bellcranks
- Drive links
- Pull-in hooks
- Main latch cams.

Functional Description

The torque tubes transmit torque directly to the pull-in hooks. The push rods, bellcranks, and drive links transmits torque from the torque tube to the latch cams.



52-34-00-012 Rev 1 11/07/1997

FORWARD LARGE CARGO DOOR SYSTEM - LATCH MECHANISM

FORWARD LARGE CARGO DOOR SYSTEM - PULL-IN HOOKS AND PINS

Purpose

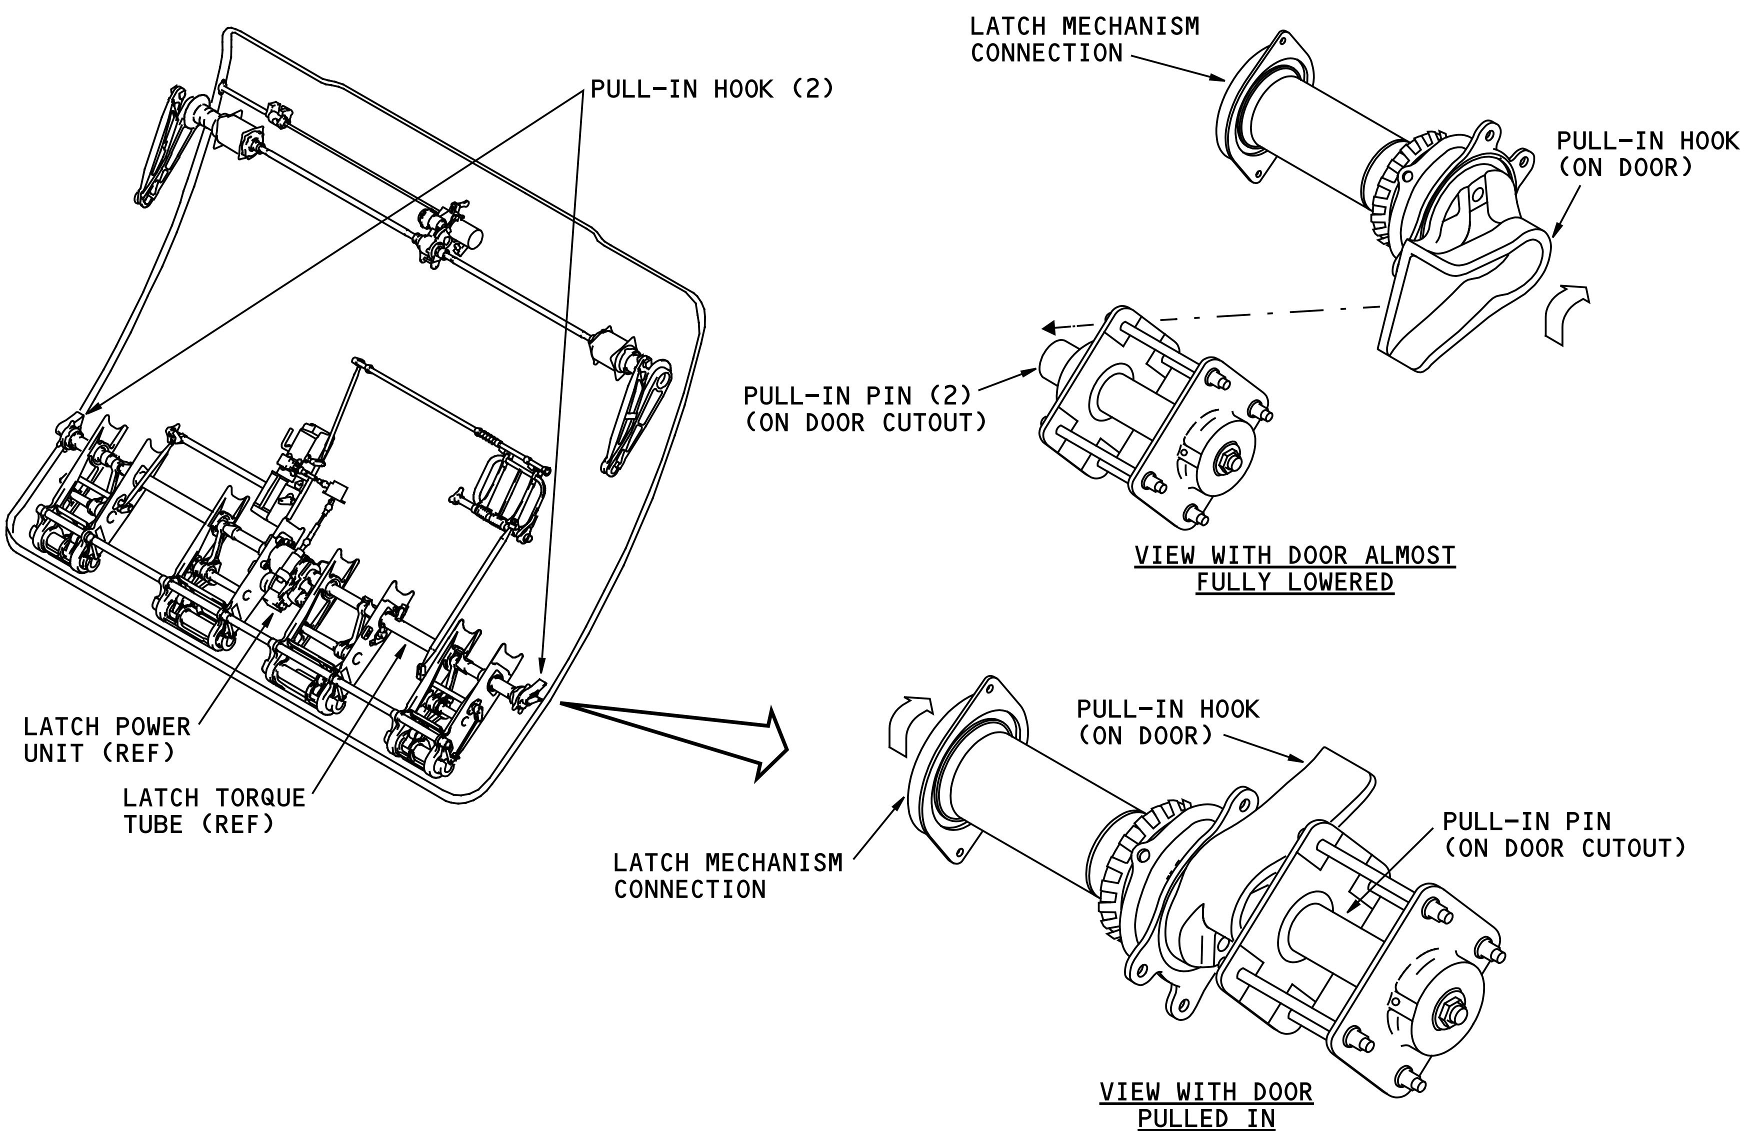
The pull-in hooks and pins pull the door into the position where the cargo door can latch.

Location

The pull-in hooks are on the ends of the latch torque tubes. The pins are on the forward and aft sides of the door cutout.

Functional Description

The pull-in function begins when the door is lowered fully. In this position, the open end of the hook is around the pin. The latch power unit turns the pull-in hooks. As the hook turns around the pin, it pulls the door into the position where the latch cams can turn around the latch pins.



52-34-00-013 Rev 1 11/07/1997

FORWARD LARGE CARGO DOOR SYSTEM - PULL-IN HOOKS AND PINS

FORWARD LARGE CARGO DOOR SYSTEM - LATCH CAMS AND LATCH PINS

Purpose

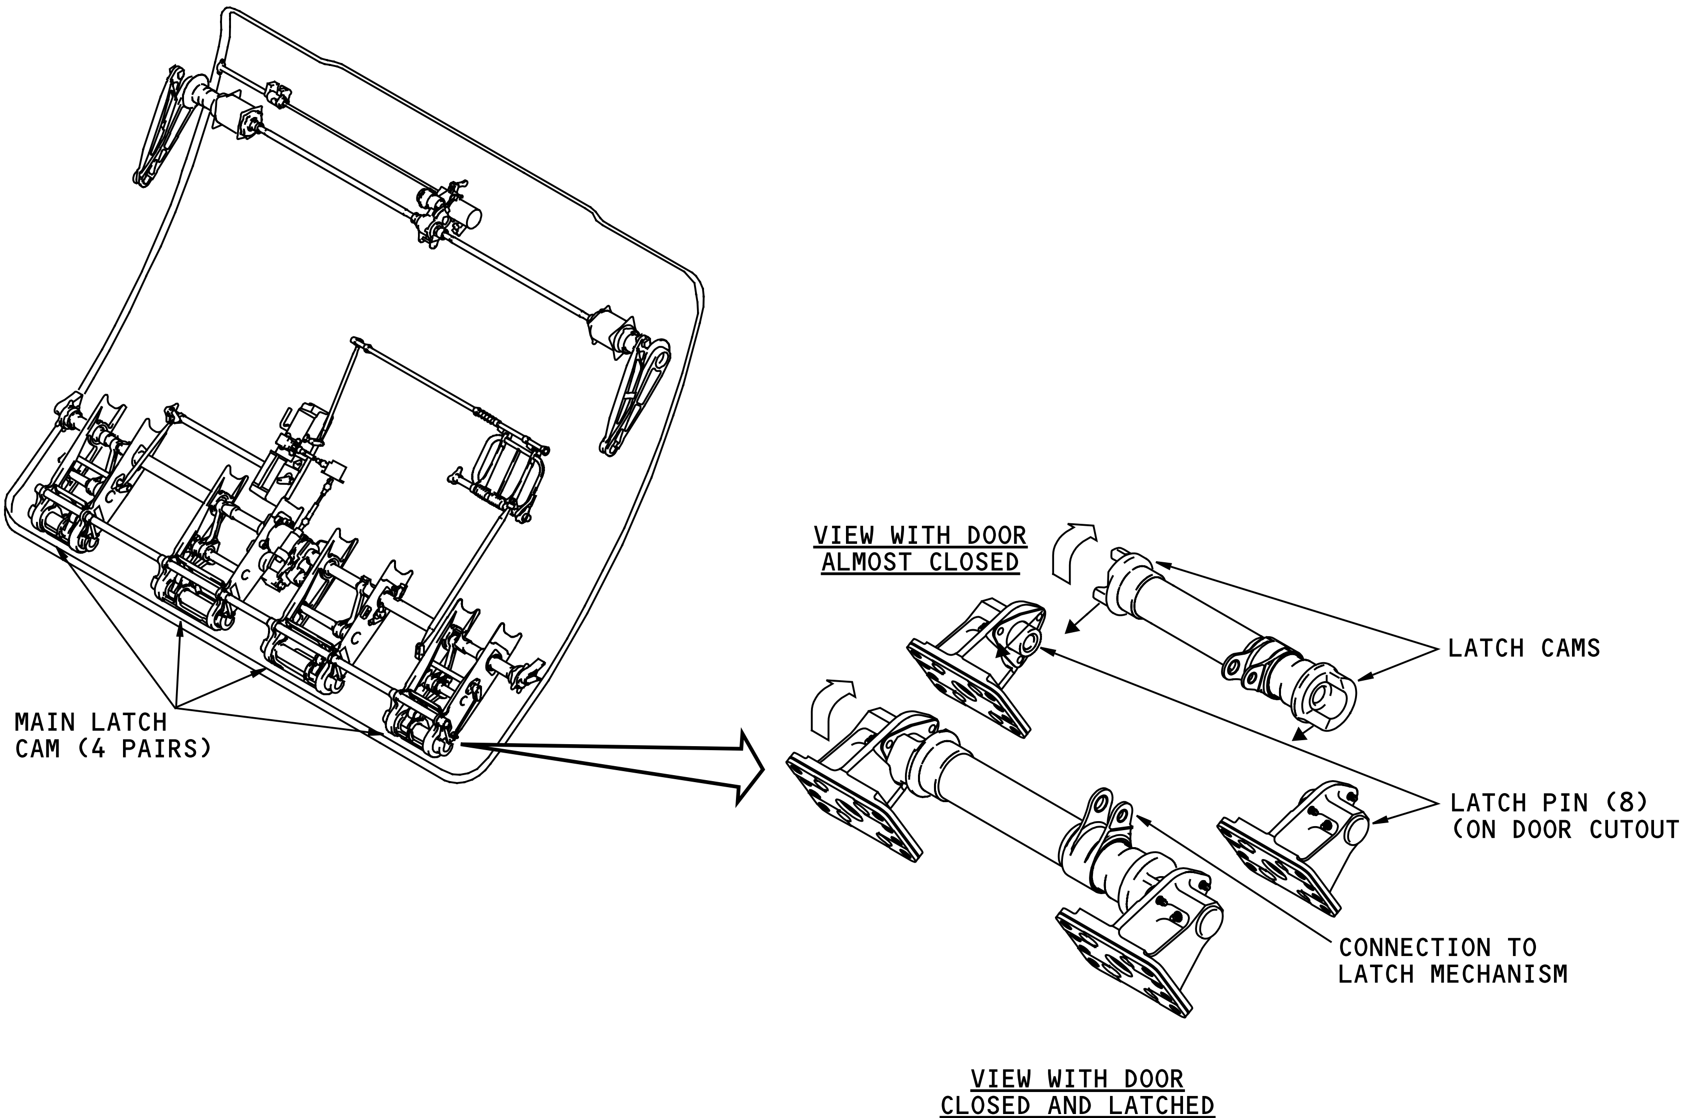
The latch cams and latch pins hold the cargo door closed.

Location

The eight main latch cams are in pairs along the bottom of the door. The eight main latch pins are along the bottom of the door cutout.

Functional Description

Linkage connects the latch cams to latch mechanism torque tubes. Torque from the power unit turns the latch cams around the latch pins. In the rotated position the cams cannot move away from the pins. This latches the door.



FORWARD LARGE CARGO DOOR SYSTEM - LATCH CAMS AND LATCH PINS

52-34-00-014 Rev 1 11/07/1997

FORWARD LARGE CARGO DOOR SYSTEM - LOCK MECHANISM

Purpose

The lock mechanism holds the large cargo door main latch cams in the latched position and the vent door closed.

Physical Description

The lock mechanism has these components:

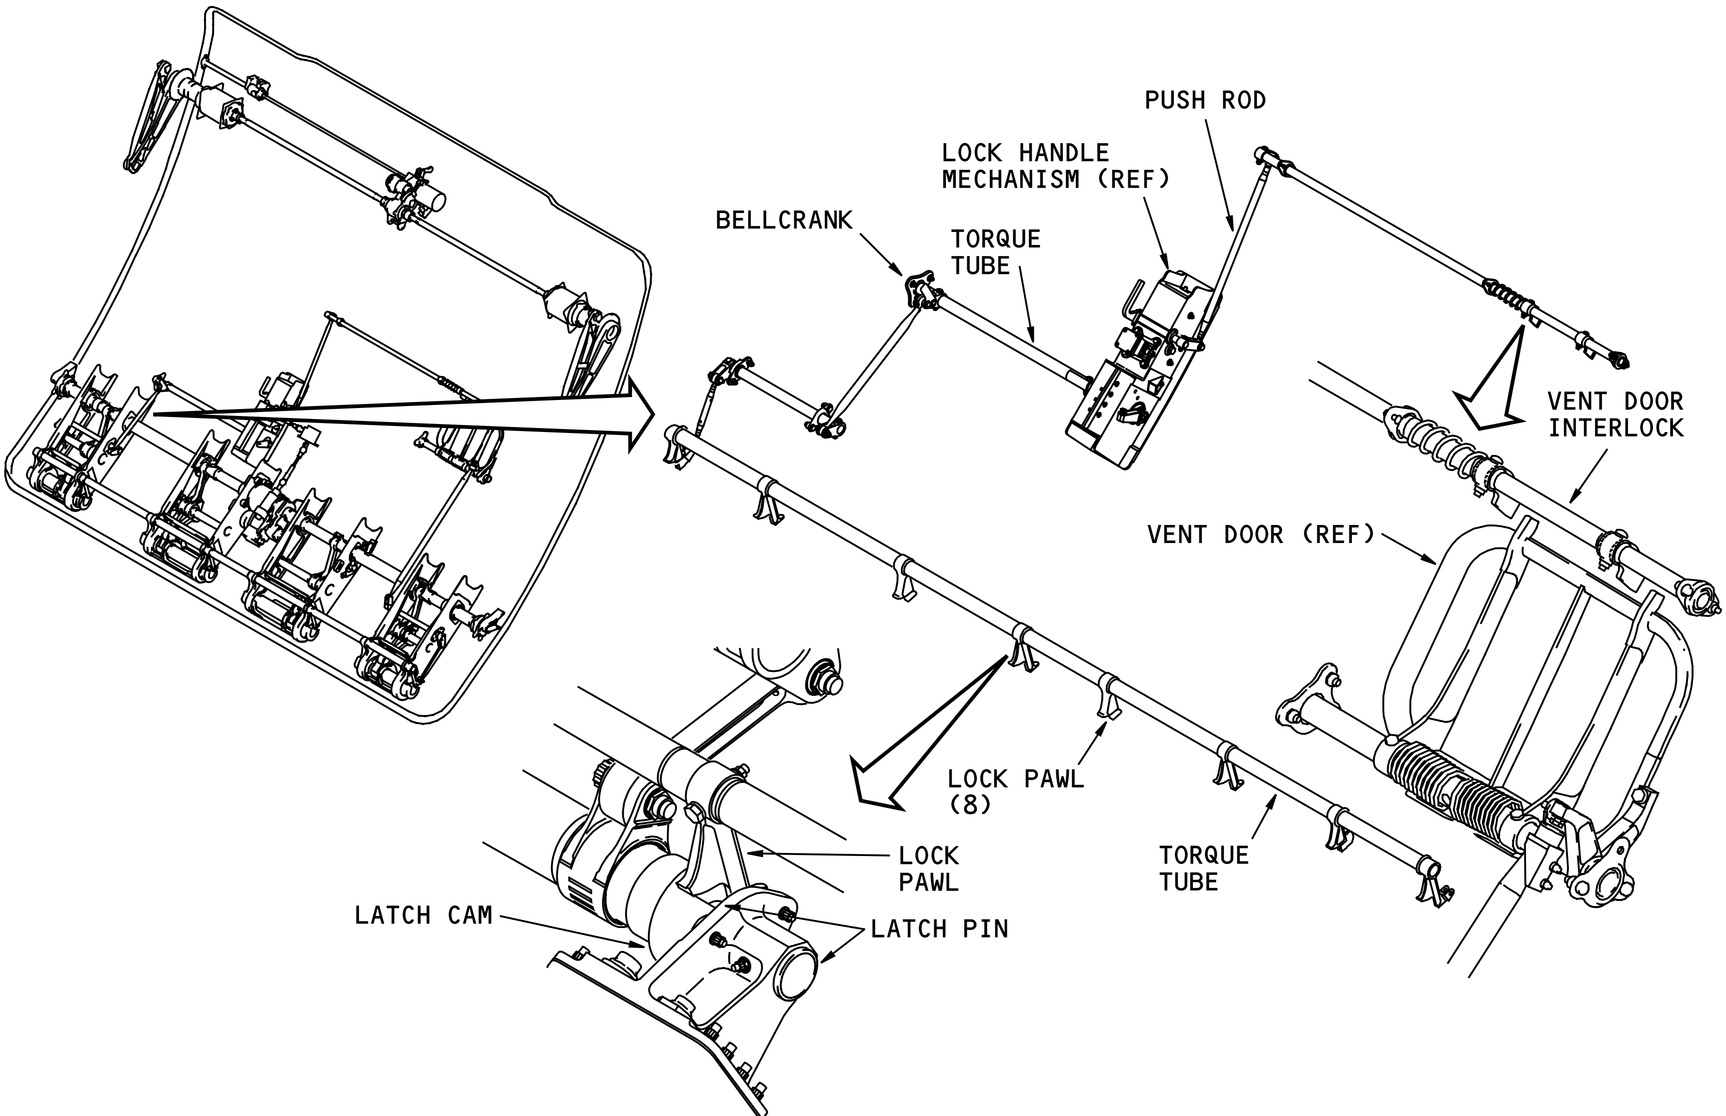
- Bellcranks
- Torque tubes
- Push rods
- Vent door interlock
- Torque tubes
- Lock pawls.

Functional Description

The lock mechanism does two things when you move the lock handle to the lock position.

The mechanism transmits the movement of the lock handle to the lock pawls. The lock pawls move to a position that will not let the main latch cams turn.

The mechanism also transmits the movement of the lock handle to the vent door interlock. The vent door interlock keeps the vent door closed if the airplane is ditched in water.



FORWARD LARGE CARGO DOOR SYSTEM - LOCK MECHANISM

FORWARD LARGE CARGO DOOR SYSTEM - VENT DOOR AND VENT DOOR MECHANISM

Purpose

The vent door and vent door mechanism prevent damage from pressurization when you open the cargo door.

Physical Description

The door has stops and connections to the torque shaft. The mechanism has these components:

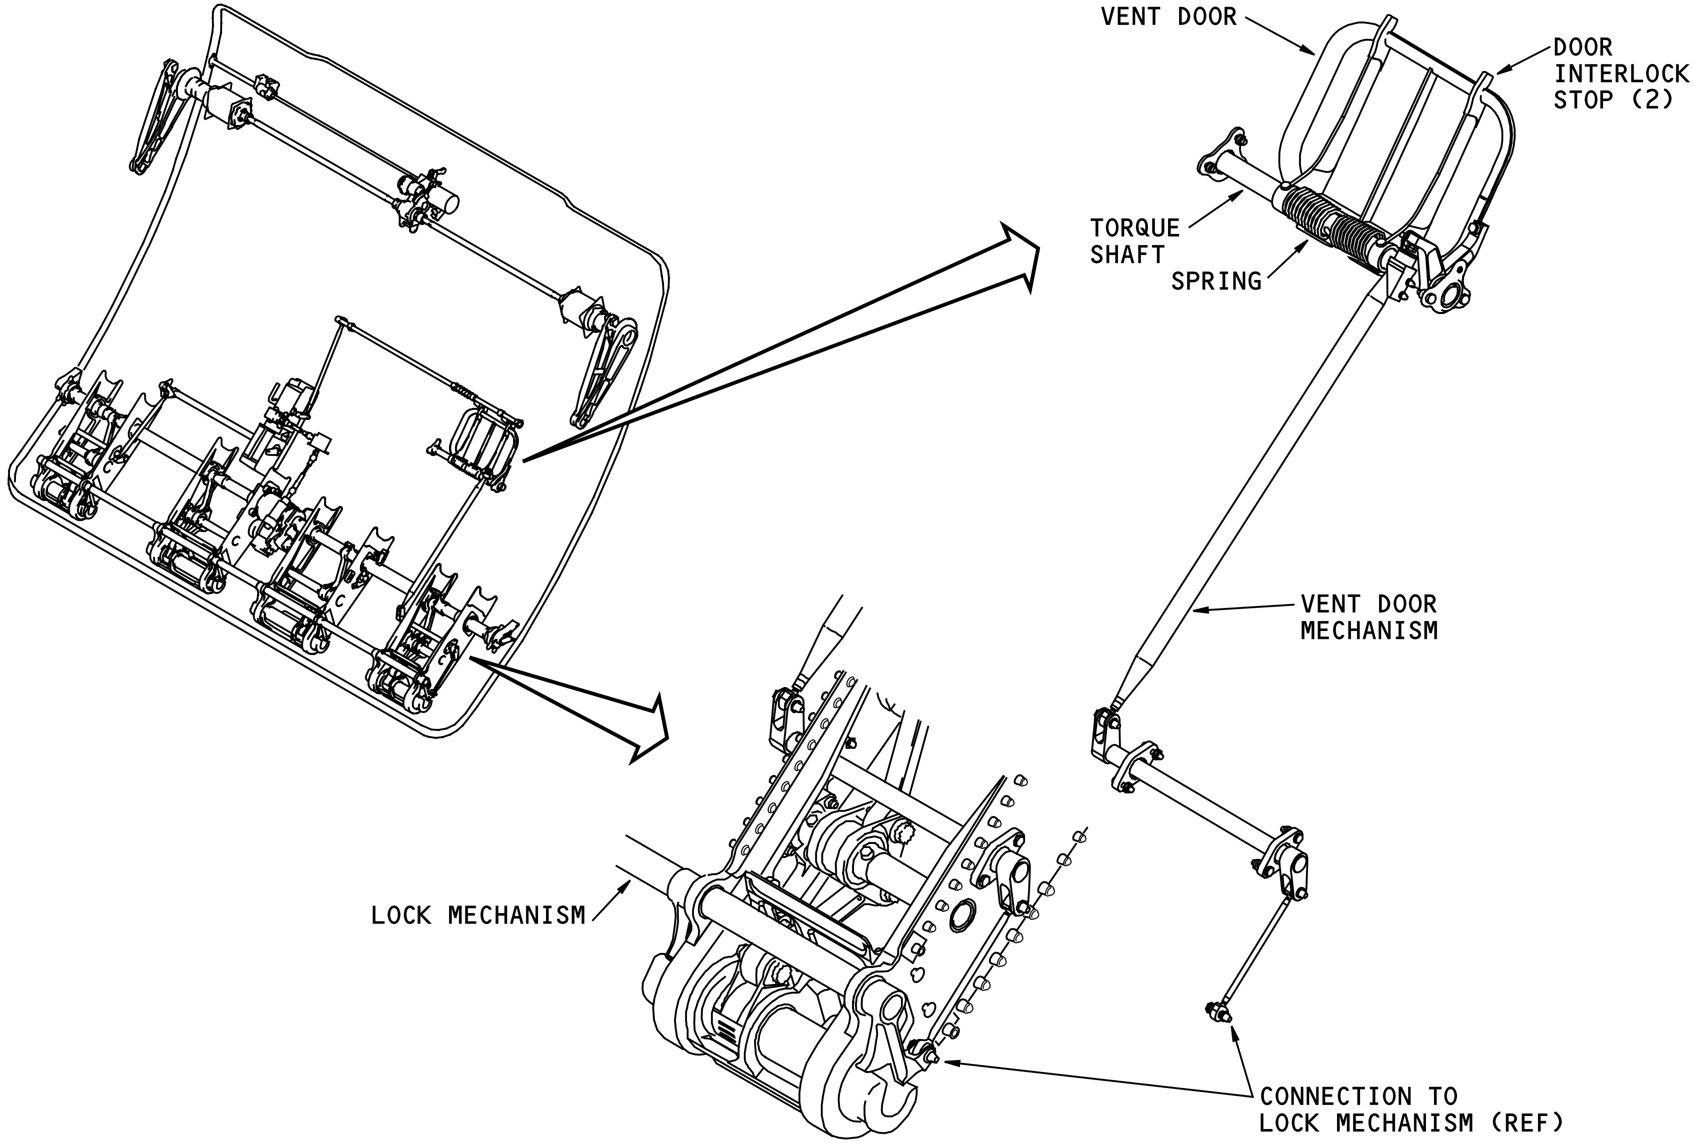
- A spring that pulls the vent door open
- A torque shaft
- Linkage that connects the vent door to the lock mechanism.

Functional Description

The door and vent door mechanism have two functions.

One function is to release air pressure from inside the airplane before you open the cargo door. When the lock mechanism moves to the unlock position, it causes the vent door mechanism to pull the vent door open. This releases any air pressure that remains.

The second function is to keep the cargo door locked if there is too much pressure to let you open the cargo door safely. Pressure on the vent door prevents movement of the vent door mechanism. This stops movement of the lock mechanism. You cannot unlock and open the cargo door.



FORWARD LARGE CARGO DOOR SYSTEM - VENT DOOR AND VENT DOOR MECHANISM

FORWARD LARGE CARGO DOOR SYSTEM - CONTROL SWITCHES

Purpose

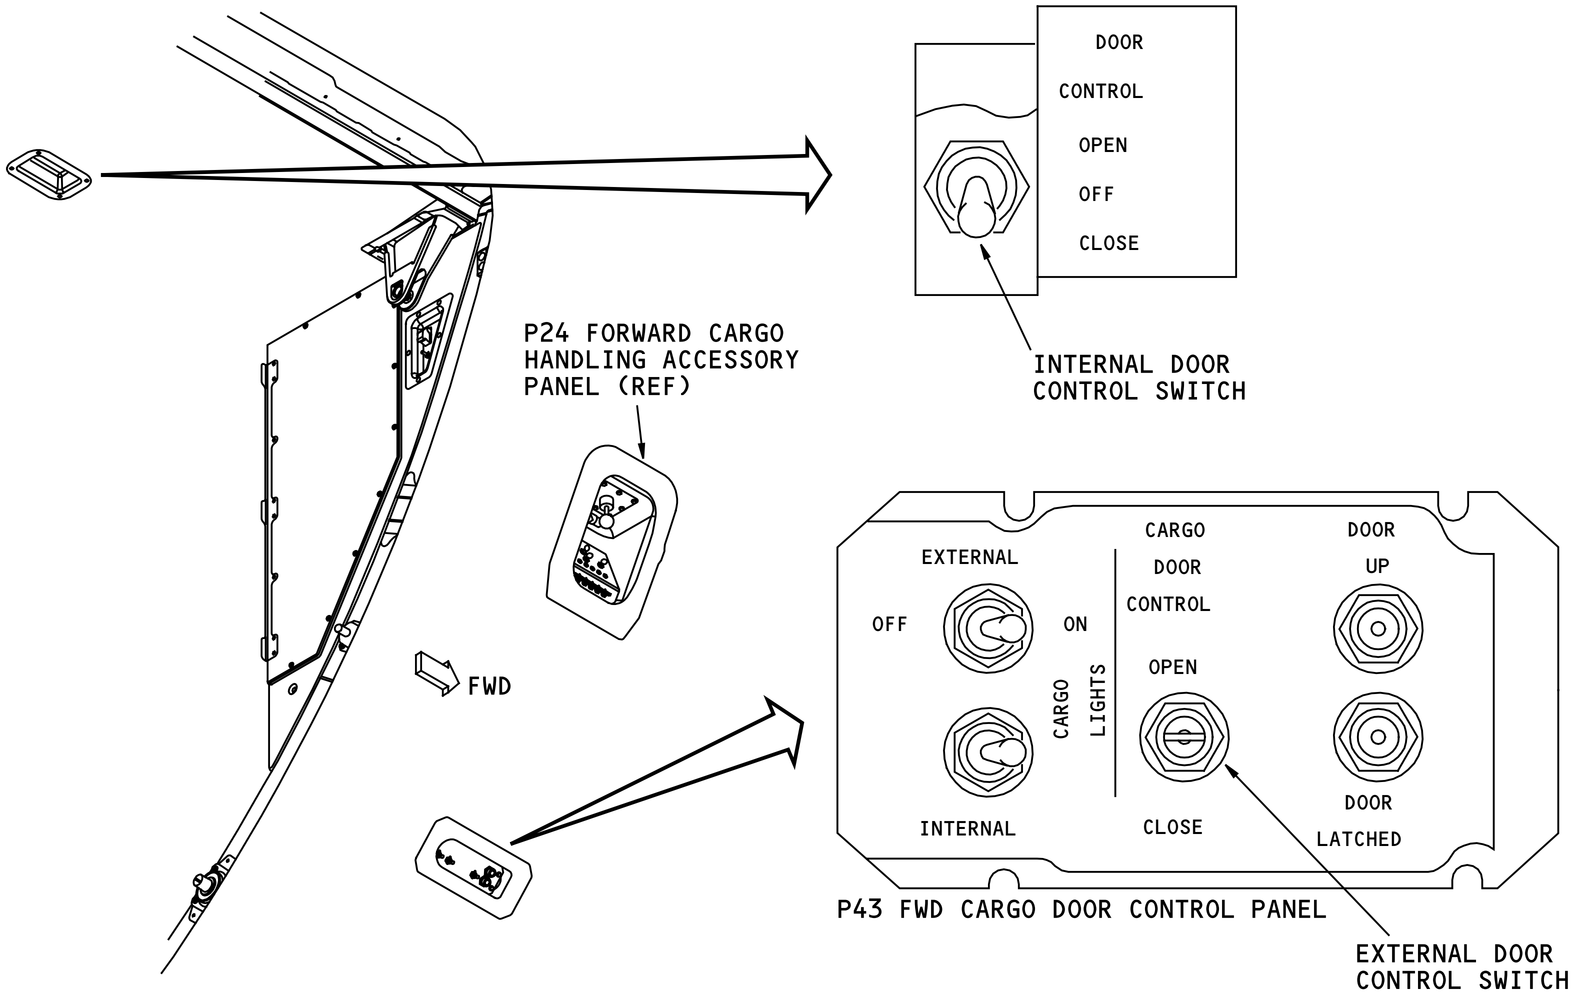
Control switches let you operate the door electrically.

Physical Description

The internal and external toggle type door control switches are spring-loaded.

Functional Description

The switches let you operate the door electrically, after the door is unlocked. You can use either switch. The internal switch has priority over the external switch.



52-34-00-018 Rev 0

FORWARD LARGE CARGO DOOR SYSTEM - CONTROL SWITCHES

FORWARD LARGE CARGO DOOR SYSTEM - PROXIMITY SENSORS

Purpose

Proximity sensors supply door and door mechanism position information to the proximity sensor electronics unit (PSEU) for door operational control and door status indications.

Physical Description

The sensors are electrical devices that work with metal targets.

Functional Description

These sensors are for door operation control:

- Door up
- Door latched
- Door unlatched
- Latch range
- Handle unlocked.

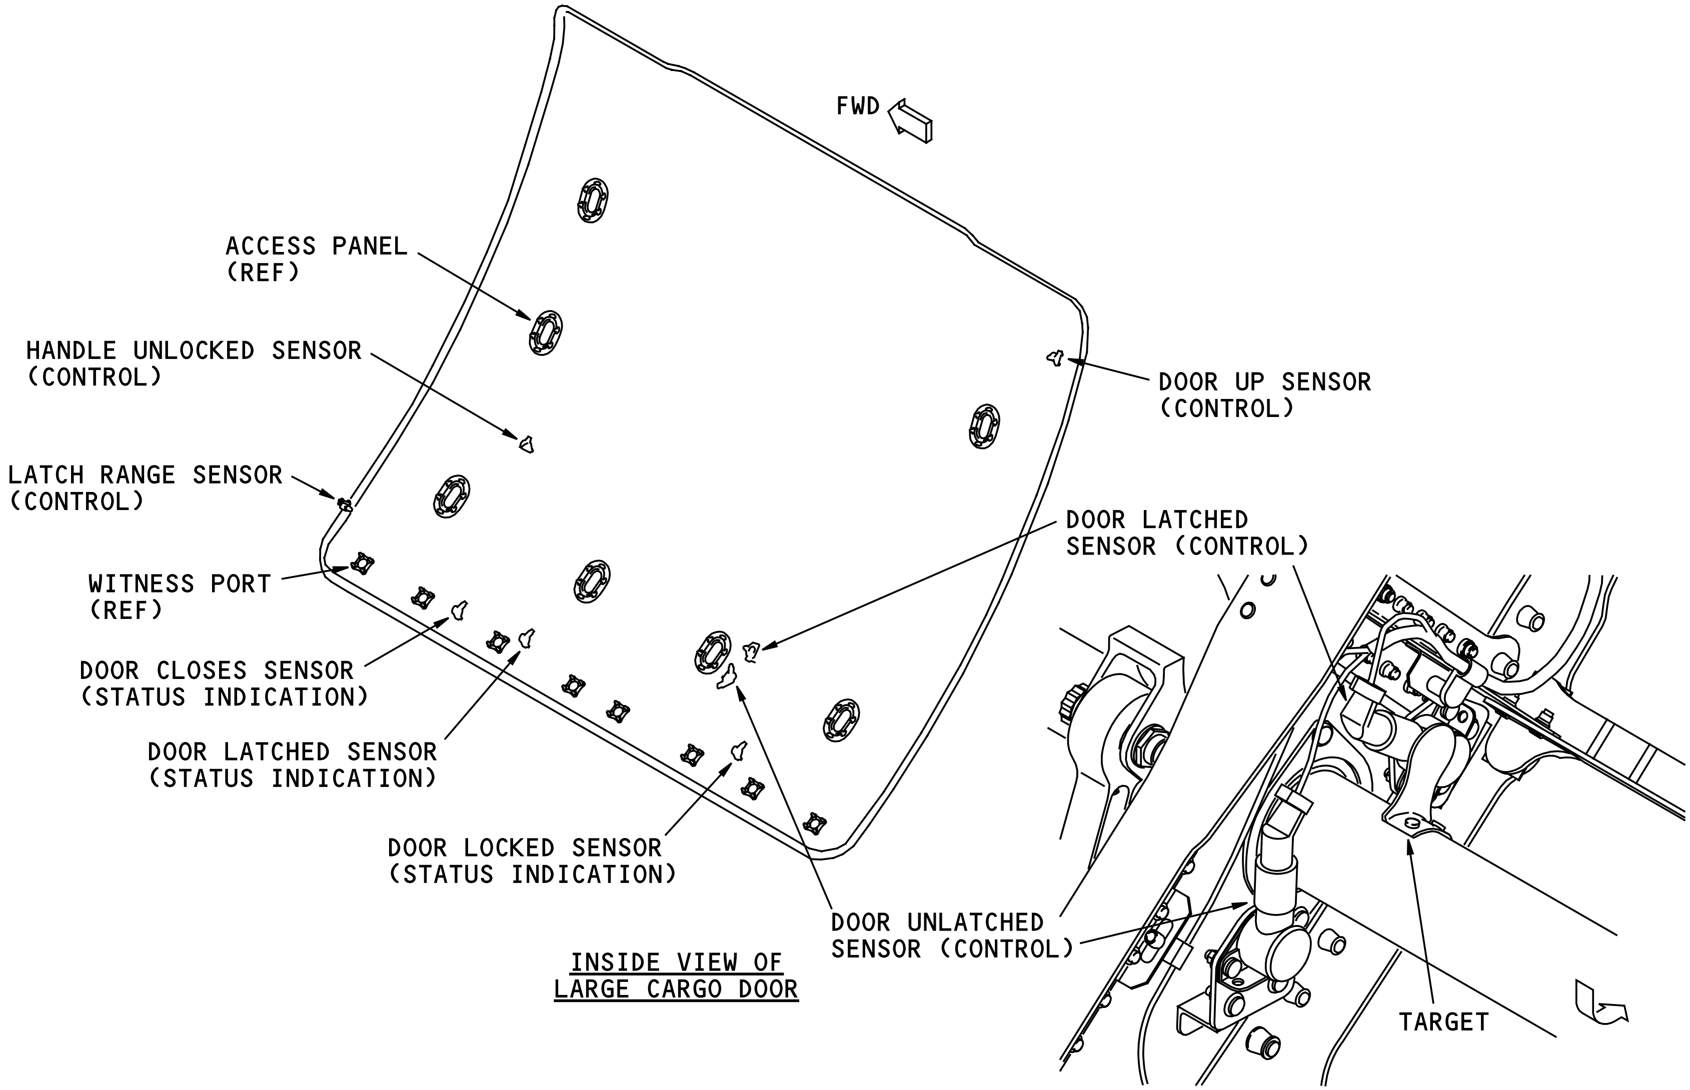
The door status indication sensors are:

- Door closed
- Door latched
- Door locked.

See the door warning system section for more information on the door status sensors (AMM PART I 52-71).

Each sensor has a related target. The sensor senses if the target is near or far. The position information goes to the PSEU.

The door operation control sensors tell the PSEU the position of the door and door mechanisms. The PSEU uses the information to control the cargo door operation and the door control panel indication lights.



INSIDE VIEW OF LARGE CARGO DOOR

TYPICAL SENSORS

52-34-00-019 Rev 3

FORWARD LARGE CARGO DOOR SYSTEM - PROXIMITY SENSORS

THIS PAGE INTENTIONALLY LEFT BLANK

FORWARD LARGE CARGO DOOR SYSTEM - ELECTRICAL OPERATION

General

The large cargo door uses power from the ground handling bus for electrical operation.

WARNING: DO NOT OPERATE THE DOOR IN WINDS MORE THAN 40 KNOTS. DO NOT LET THE DOOR STAY OPEN IN WINDS MORE THAN 65 KNOTS. INJURIES TO PERSONS OR DAMAGE TO EQUIPMENT CAN OCCUR.

WARNING: DO NOT OPEN THE DOOR WHEN THE AIRPLANE IS PRESSURIZED. INJURIES TO PERSONS OR DAMAGE TO EQUIPMENT CAN OCCUR.

Controls

The cargo door lock handle is on the outside of the door. There is an internal and an external release.

The external door control switch is on P43. The internal door control switch is in the cargo compartment ceiling.

Displays and Indications

Indication lights on the external control panel supply door operation information.

Witness ports on the door let you see the position of the door latches and locks.

Unlock Operation

WARNING: STAY AWAY FROM THE PATH OF THE LOCK HANDLE. THE LOCK HANDLE IS SPRING-LOADED TO OPEN WHEN YOU PULL THE CATCH RELEASE LEVER AND INJURIES TO PERSONS OR DAMAGE TO EQUIPMENT CAN OCCUR.

Release the lock handle to unlock the cargo door. If the vent door opens, the cargo door has unlocked. This enables cargo door electric operation.

Unlatch and Open Operation

WARNING: MAKE SURE ALL PERSONS AND EQUIPMENT ARE CLEAR OF THE PATH OF THE DOOR ON THE EXTERNAL SIDE. THE DOOR OPENS OUTBOARD AND UP. INITIALLY, THE DOOR MOVES DOWN BELOW THE DOOR CUTOUT. THE MOVEMENT OF THE DOOR CAN CAUSE INJURIES TO PERSONS OR DAMAGE TO EQUIPMENT.

CAUTION: DO NOT OPERATE THE DOOR ELECTRICALLY MORE THAN 2 FULL OPEN/CLOSE CYCLES WITHIN 5 MINUTES. DAMAGE TO THE LIFT MECHANISM CAN OCCUR.

Move either the external or the internal switch to the open position. The door unlatches.

Continue to hold the switch in the open position. The door moves to the full up position. When it stops. The amber door up light on the P43 comes on.

FORWARD LARGE CARGO DOOR SYSTEM - ELECTRICAL OPERATION

Close and Latch Operation

CAUTION: MAKE SURE THE E/E EQUIPMENT DOORS ARE CLOSED ON THE SIDES OF THE DOOR CUTOUT BEFORE YOU CLOSE THE DOOR. THE CARGO DOOR CAN CAUSE DAMAGE TO OPEN E/E EQUIPMENT DOORS WHEN IT CLOSES.

Move either the external or the internal switch to the close position. The amber door up light goes off when the door leaves the full up position.

Continue to hold the switch in the close position. The door goes to the full down position. Then it latches. The green door closed and latched light comes on.

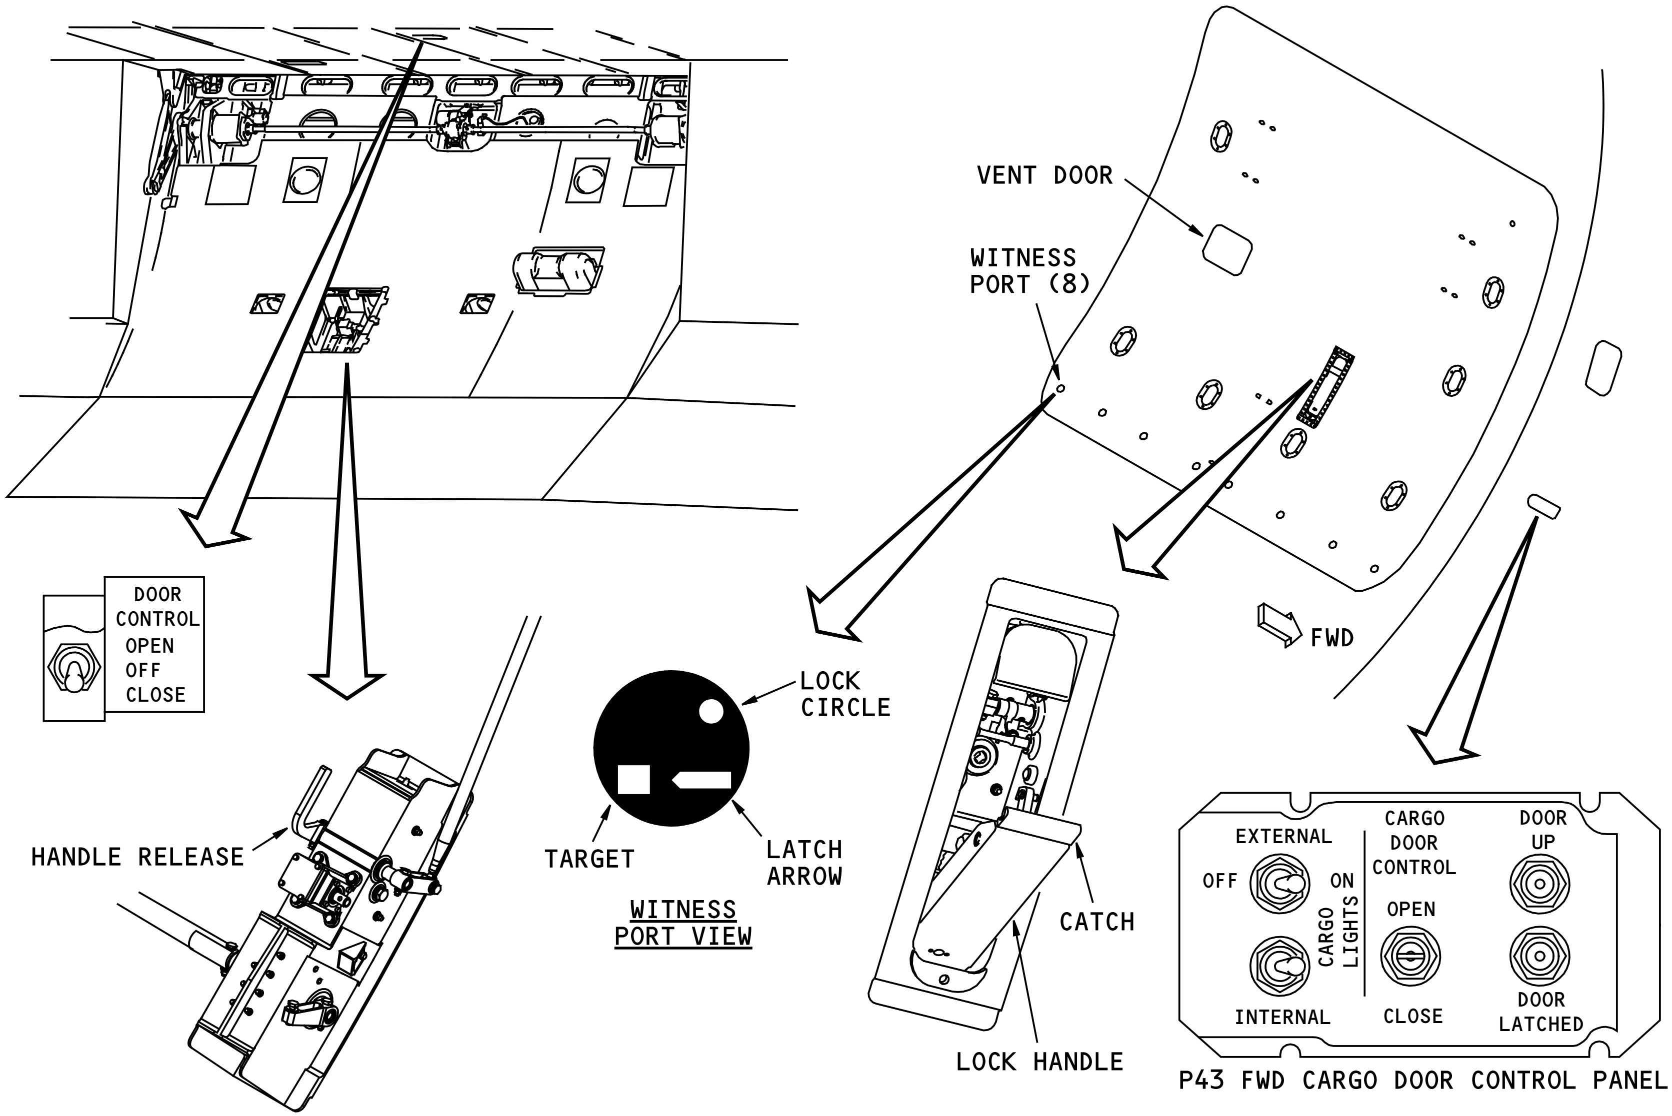
Lock Operation

Close the lock handle. Make sure that the vent door closes. The door is locked if the vent door is closed.

Training Information Point

Look through each witness port along the bottom edge of the door for latch and lock indications. The latch and lock components are black. The indications and target are yellow.

The door is latched if the indication arrow on each latch cam points to the target on each latch fitting. The door is locked if you see all of the door locked circle on each lock pawls.



FORWARD LARGE CARGO DOOR SYSTEM - ELECTRICAL OPERATION

52-34-00-020 Rev 1

THIS PAGE INTENTIONALLY LEFT BLANK

FORWARD LARGE CARGO DOOR SYSTEM - MANUAL OPERATION

General

Use a 3/8 inch drive tool for manual door operations.

WARNING: DO NOT OPERATE THE DOOR IN WINDS MORE THAN 40 KNOTS. DO NOT LET THE DOOR STAY OPEN IN WINDS MORE THAN 65 KNOTS. INJURIES TO PERSONS OR DAMAGE TO EQUIPMENT CAN OCCUR.

WARNING: DO NOT OPEN THE DOOR WHEN THE AIRPLANE IS PRESSURIZED. INJURIES TO PERSONS OR DAMAGE TO EQUIPMENT CAN OCCUR.

Controls

The cargo door lock handle covers the latch manual drive socket. Release lock handle to access the socket.

There are two lift manual drive sockets on the upper, forward corner of the cargo door.

Indications

Witness ports along the bottom edge of the door let you see if the door is latched and locked.

Unlock and Unlatch Operations

WARNING: STAY AWAY FROM THE PATH OF THE LOCK HANDLE. THE LOCK HANDLE IS SPRING-LOADED TO OPEN WHEN YOU PULL THE CATCH RELEASE LEVER AND INJURIES TO PERSONS OR DAMAGE TO EQUIPMENT CAN OCCUR.

Release the lock handle. If the vent door opens, the door is unlocked.

Insert the drive tool into the latch manual drive socket. Turn it in the unlatch direction. The door is unlatched when it moves outboard to where you can move it freely a small distance inboard and outboard, approximately 120 full turns.

NOTE: The lower edge of door will move 2-3 inches (5-8 cm) outboard.

Lift and Lower Operations

CAUTION: DO NOT LET THE POWER DRIVE UNIT OPERATE WITH TORQUE LIMITER SLIPPAGE FOR MORE THAN 5 SECONDS. DAMAGE TO THE POWER DRIVE UNIT CAN OCCUR.

DO NOT OPERATE THE MANUAL DRIVE AT A SPEED FASTER THAN 500 RPM OR A TORQUE OF MORE THAN 110 POUNDS-INCHES. DAMAGE TO THE MANUAL DRIVE CAN OCCUR.

Insert the drive tool in the lift manual drive socket on the outside of the door. Turn it in the open direction, approximately 320 full turns. When the door is open sufficiently, move the tool to the lift manual drive socket on the forward edge of the door. Turn it in the open direction until the door is in the full up position, approximately 1150 full turns.

FORWARD LARGE CARGO DOOR SYSTEM - MANUAL OPERATION

NOTE: It is usual for the door to stop at the low point of its travel.

CAUTION: MAKE SURE THE E/E EQUIPMENT DOORS ARE CLOSED ON THE SIDES OF THE DOOR CUTOUT BEFORE YOU CLOSE THE DOOR. THE CARGO DOOR CAN CAUSE DAMAGE TO OPEN E/E EQUIPMENT DOORS WHEN IT CLOSES.

Reverse the operations to lower the door.

latch and Lock Operations

Insert the drive tool in the latch manual drive socket. Turn it in the latch direction. The door latches.

Close the handle. Check that the vent door closes. The door is locked if the vent door is closed.

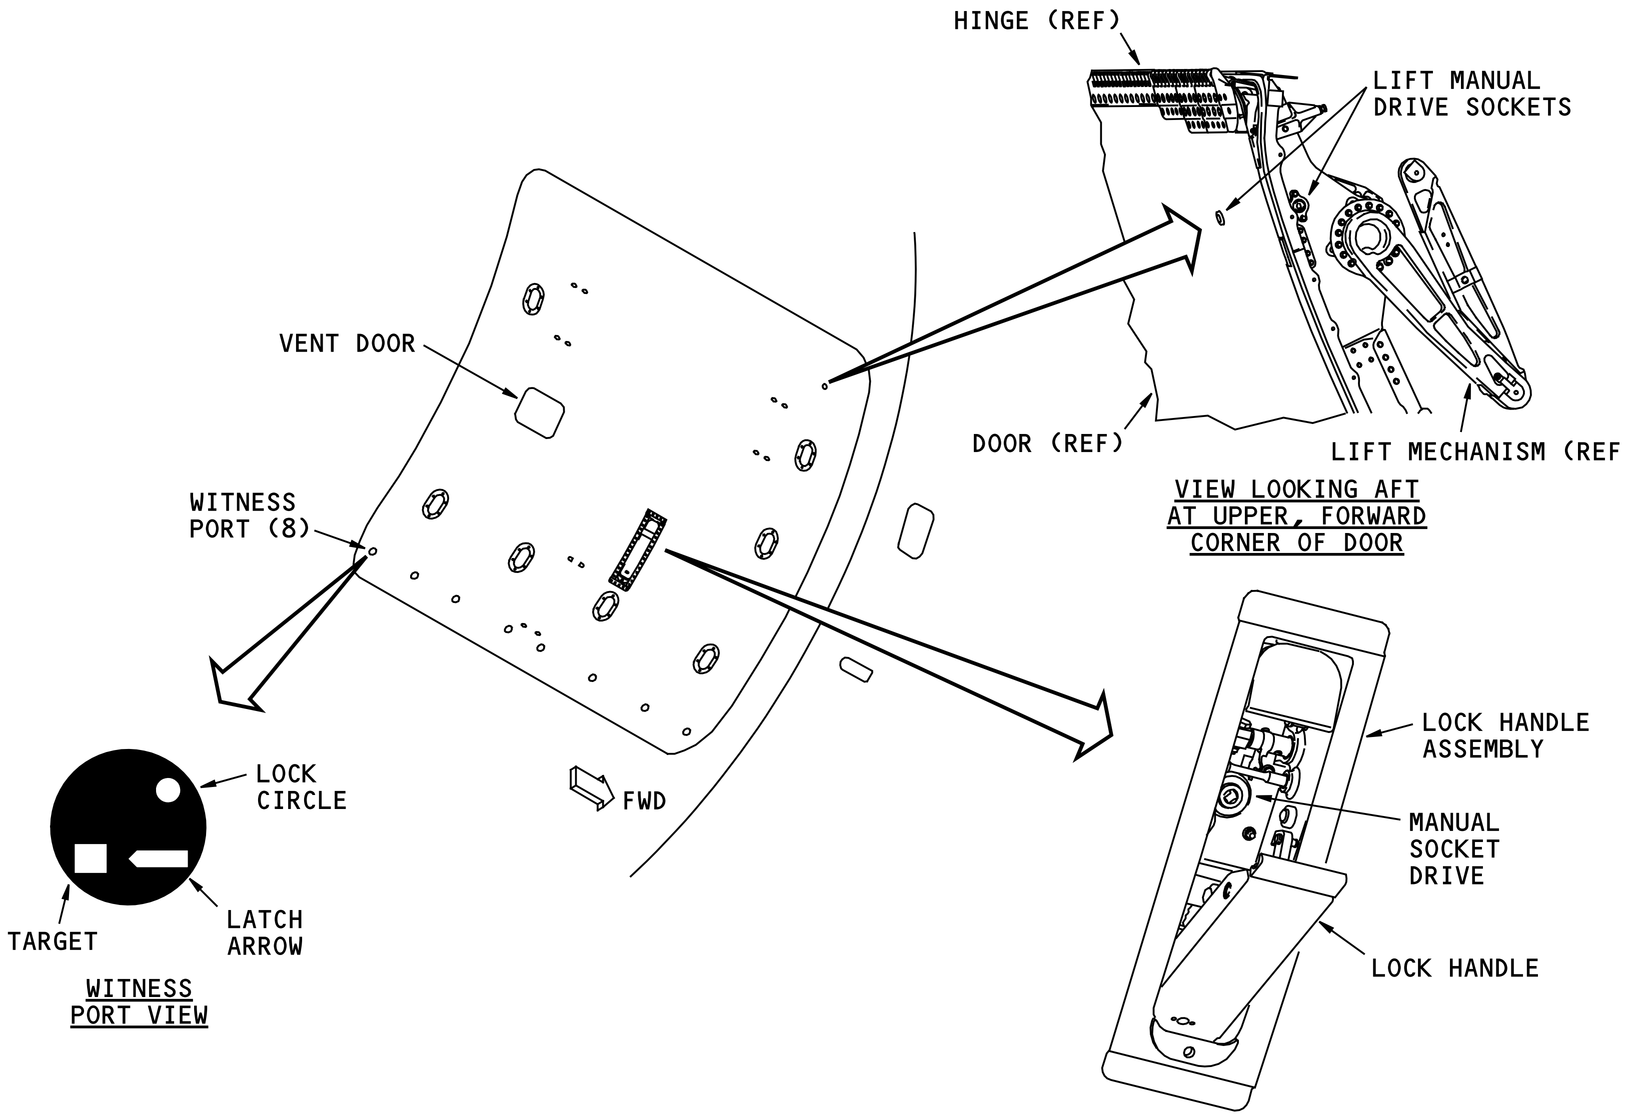
Training Information Point

The door must be unlatched before you lift the door with the lift manual drive.

The door must be full down before you can latch the door with the latch manual drive.

Look through each witness ports along the bottom edge of the door for latch and lock indications. The latch and lock components are black. The indications and target are yellow.

The door is latched if the indication arrow on each latch cam points to the target on each latch fitting. The door is locked if you see all of the door locked circle on each lock pawls.



52-34-00-021 Rev 1

FORWARD LARGE CARGO DOOR SYSTEM - MANUAL OPERATION

FORWARD LARGE CARGO DOOR SYSTEM - MECHANICAL FUNCTIONAL DESCRIPTION

Unlock

Release of the cargo door lock handle starts the unlock operation.

The lock handle connects to the lock mechanism. The lock mechanism has a vent door interlock. Open movement of the lock handle releases the vent door from the vent door interlock. The vent door spring moves the vent door open if the airplane is not pressurized.

The vent door connects to the vent door mechanism. The vent door mechanism connects to the lock mechanism. Movement of the vent door and the lock handle cause the lock mechanism to turn. It moves the lock pawls away from the latch cams. This unlocks the door.

Unlatch

With the door unlocked, the latch power unit or the latch manual drive can unlatch the door. The dog drive connection between the rotary actuator and the lift mechanism leaves free play sufficient to let the pull-in hooks move the door.

Torque goes through linkage to the latch cams and pull-in hooks. The latch cams turn from around the latch pins. The pull-in hooks turn from around the pull-in pins. The door is unlatched and can open.

Lift and Lower Movement

With the door unlatched, the hinge power unit or the lift manual drive supplies torque. Power goes through the rotary actuators and lift mechanism to move the door up and down.

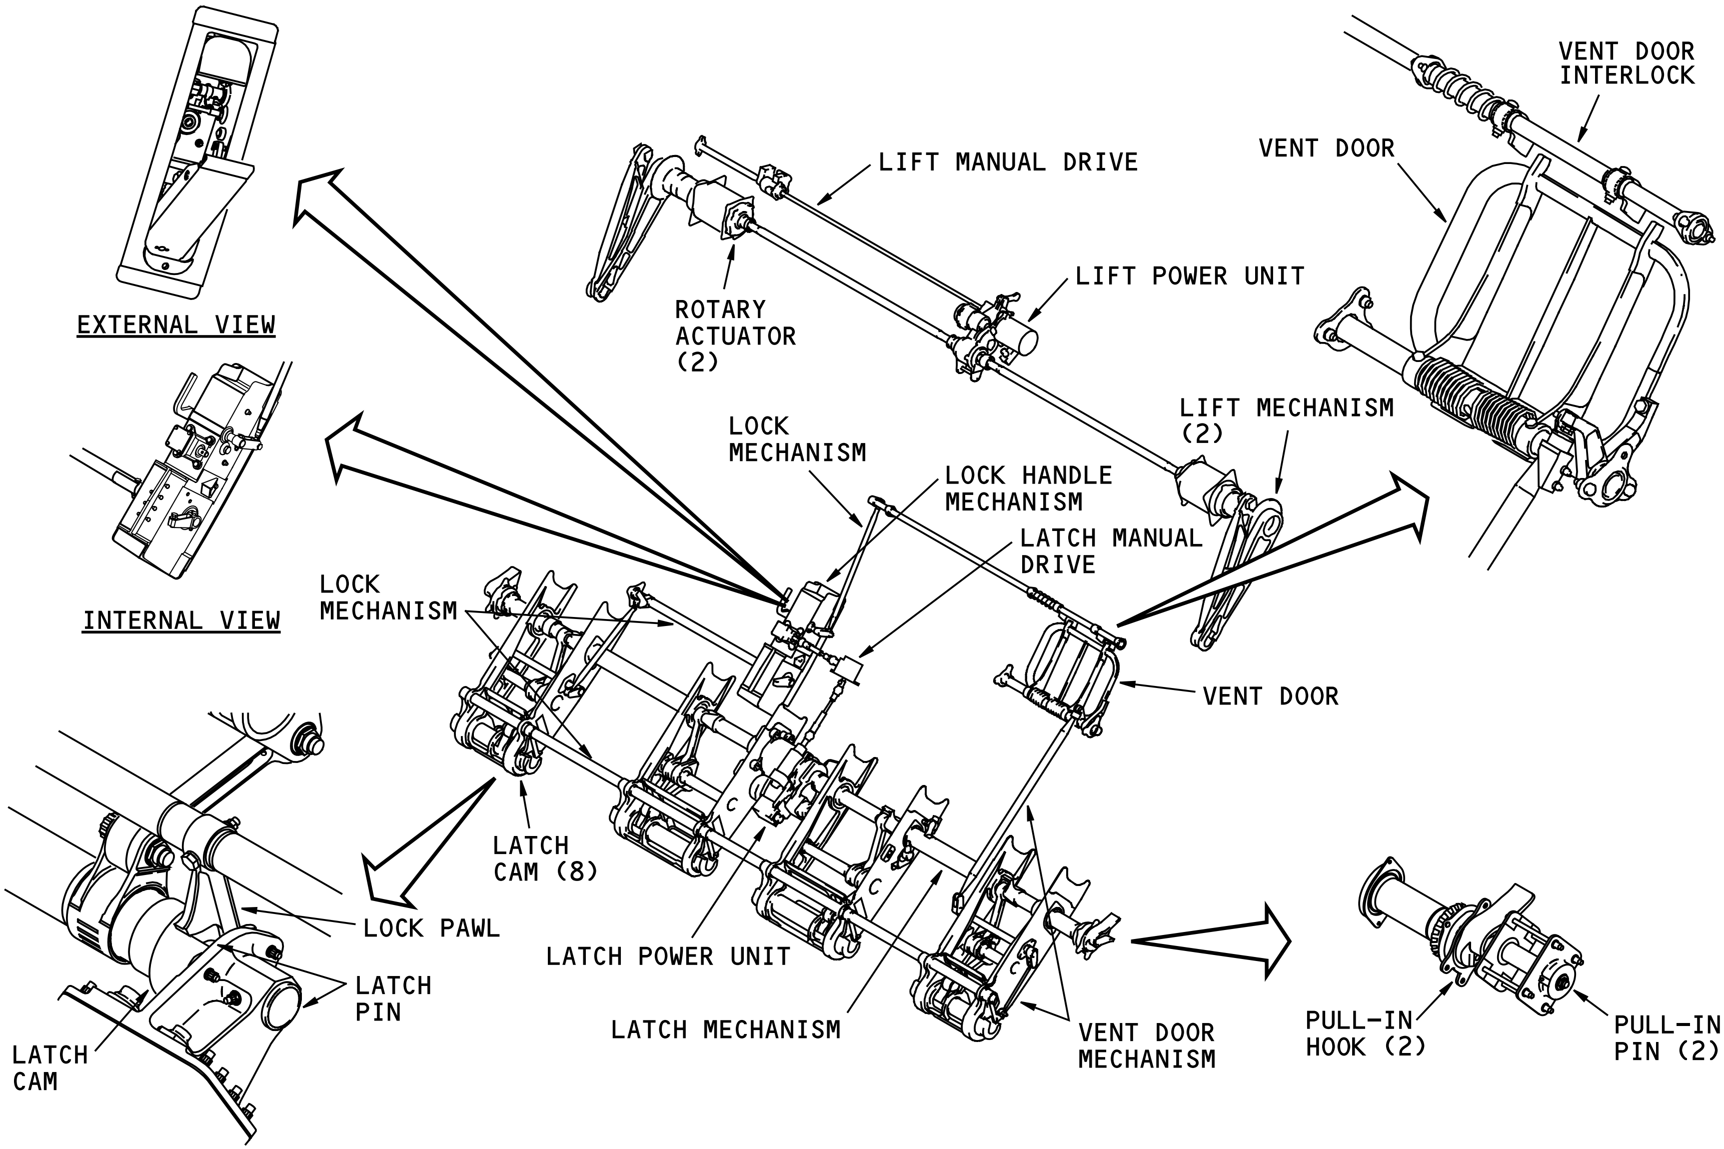
Latch

The latch power unit or the latch manual drive can latch the door when the door is fully down. The dog drive connection between the rotary actuator and the lift mechanism leaves free play sufficient to let the pull-in hooks move the door.

Torque goes through linkage to the pull-in hooks, and the latch cams. The pull-in hooks turn around the pull-in pins. This pulls the door in to where the latch cams can turn around the latch pins. The door latches.

Lock

Return of the lock handle to the close position locks the door. The movement of the handle moves the lock mechanism. The lock pawls move into a position that will not let the latch cams turn. Linkage from the lock mechanism to the vent door closes the vent door. Linkage from the lock handle moves the vent door interlock to a position that will not let the vent door open. The door is locked.



FORWARD LARGE CARGO DOOR SYSTEM - MECHANICAL FUNCTIONAL DESCRIPTION

FORWARD LARGE CARGO DOOR SYSTEM - ELECTRICAL FUNCTIONAL DESCRIPTION

General

Sensors on the door give inputs to the proximity sensor electronics unit (PSEU). The PSEU uses the inputs to turn on door position indication lights, and enable door control relays.

The relays supply three phase power in specified configurations to power units on the door. The phase configuration controls whether a power unit opens or closes the door.

There are internal and external control switches. The internal switch has priority over the external switch.

Unlock and Unlatch

A full open door lock handle enables door operation. The PSEU uses inputs from the handle unlocked sensor and door unlatched sensor to enable the door control relay. Either control switch in the OPEN position energizes the relay. The relay configures the power phases so the latch power unit unlatches the door.

Lift Movement

The PSEU uses input from the door unlatched sensor and door up sensor to enable the hinge up relay. Either control switch in the OPEN position energizes the relay. The relay configures the power phases so the lift power unit moves the door up. The PSEU uses input from the door up sensor to open the hinge up relay, and turn on the door up light.

Lower Movement

The PSEU uses input from the door unlatched sensor and latch range sensor to enable the hinge down relay. Either the external or internal control switch in the CLOSE position energizes the relay. The relay configures the power phases so the lift power unit lowers the door.

The PSEU uses input from the door up sensor to turn off the door up light.

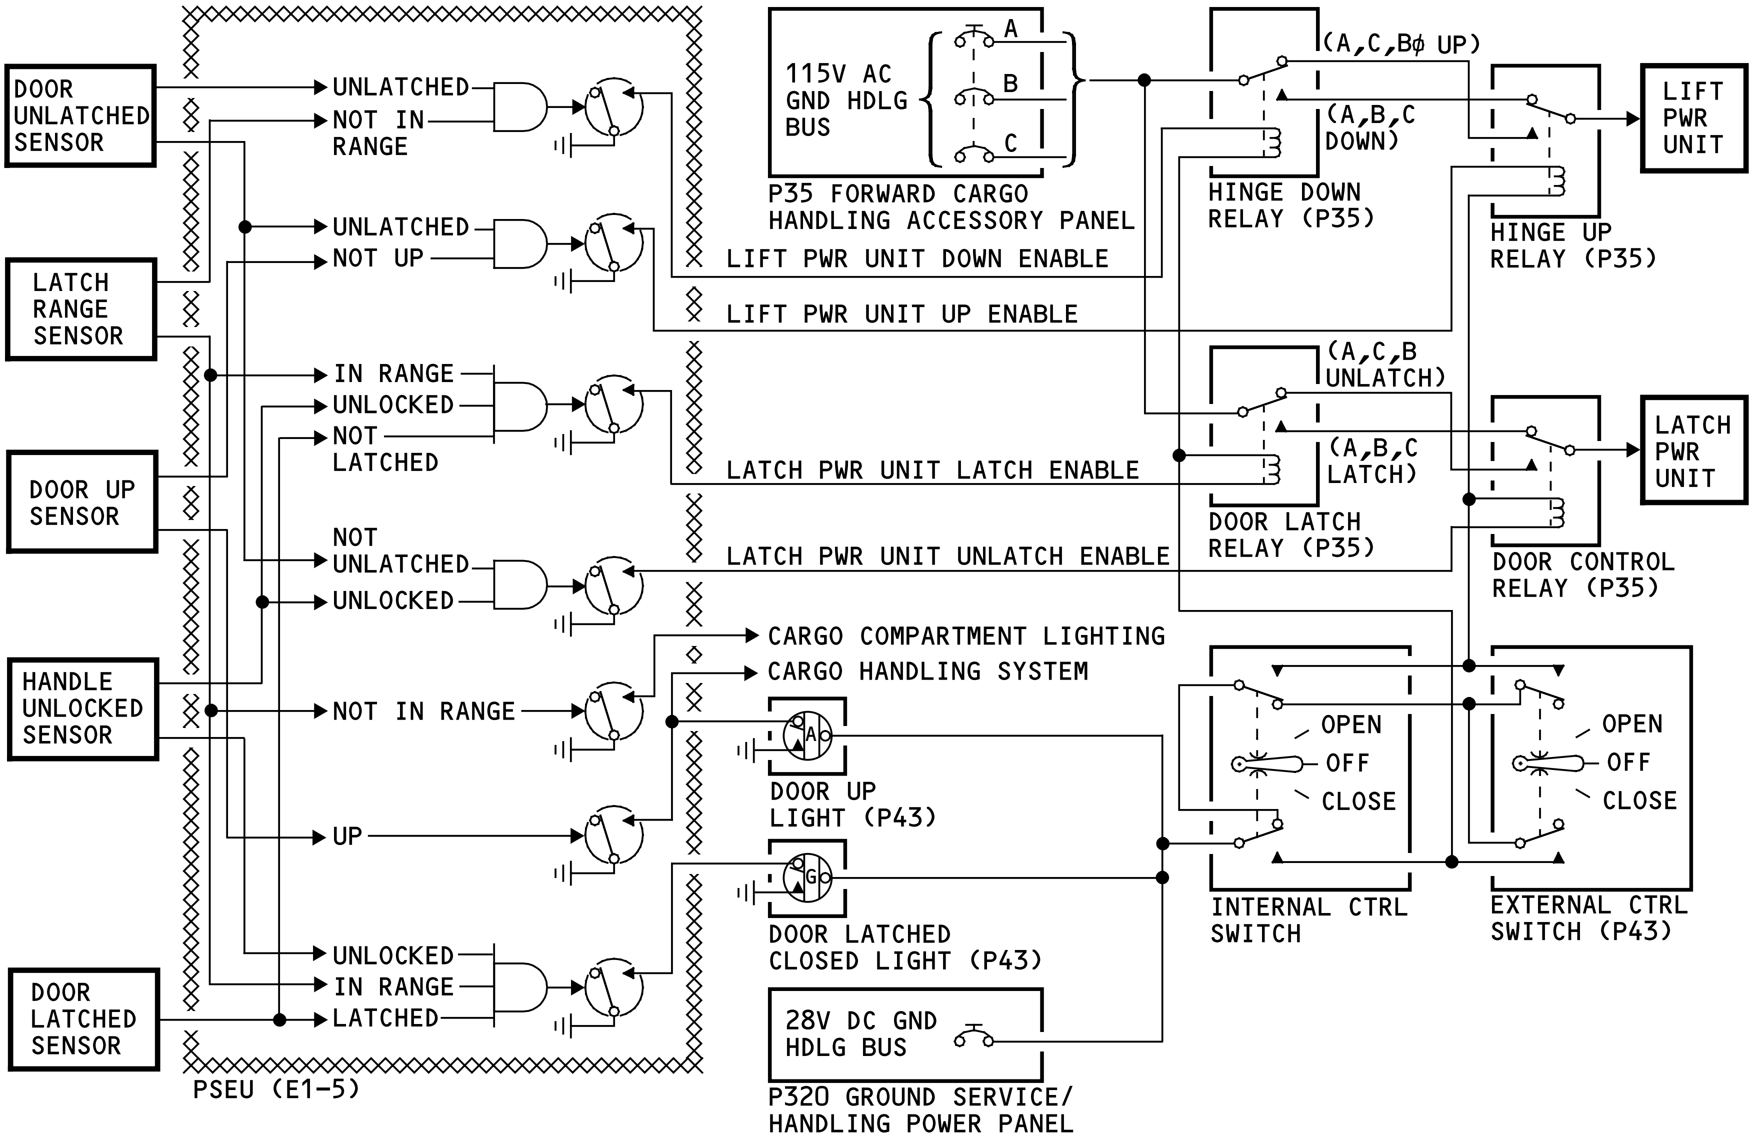
The PSEU uses input from the latch range sensor to open the hinge down relay.

Latch and lock

The PSEU uses input from the latch range sensor and handle unlocked sensor to enable the door latch relay. Either control switch in the CLOSE position energizes the relay. The relay configures the power phases so the latch power unit pulls in and latches the door. The PSEU uses input from the door latched sensor to open the door latch relay.

The PSEU uses input from the latch range sensor, door latched sensor, and handle unlocked sensor to turn on the door latched closed light.

When the lock handle is closed, the PSEU uses inputs from the handle unlocked sensor to turn off the door latched closed light.



52-34-00-023 Rev 1

FORWARD LARGE CARGO DOOR SYSTEM - ELECTRICAL FUNCTIONAL DESCRIPTION

AFT LARGE CARGO DOOR SYSTEM - INTRODUCTION

Purpose

The aft large cargo door system gives access to the aft cargo compartment.

Location

The door is on the right side of the air plane, aft of the wing.

General Description

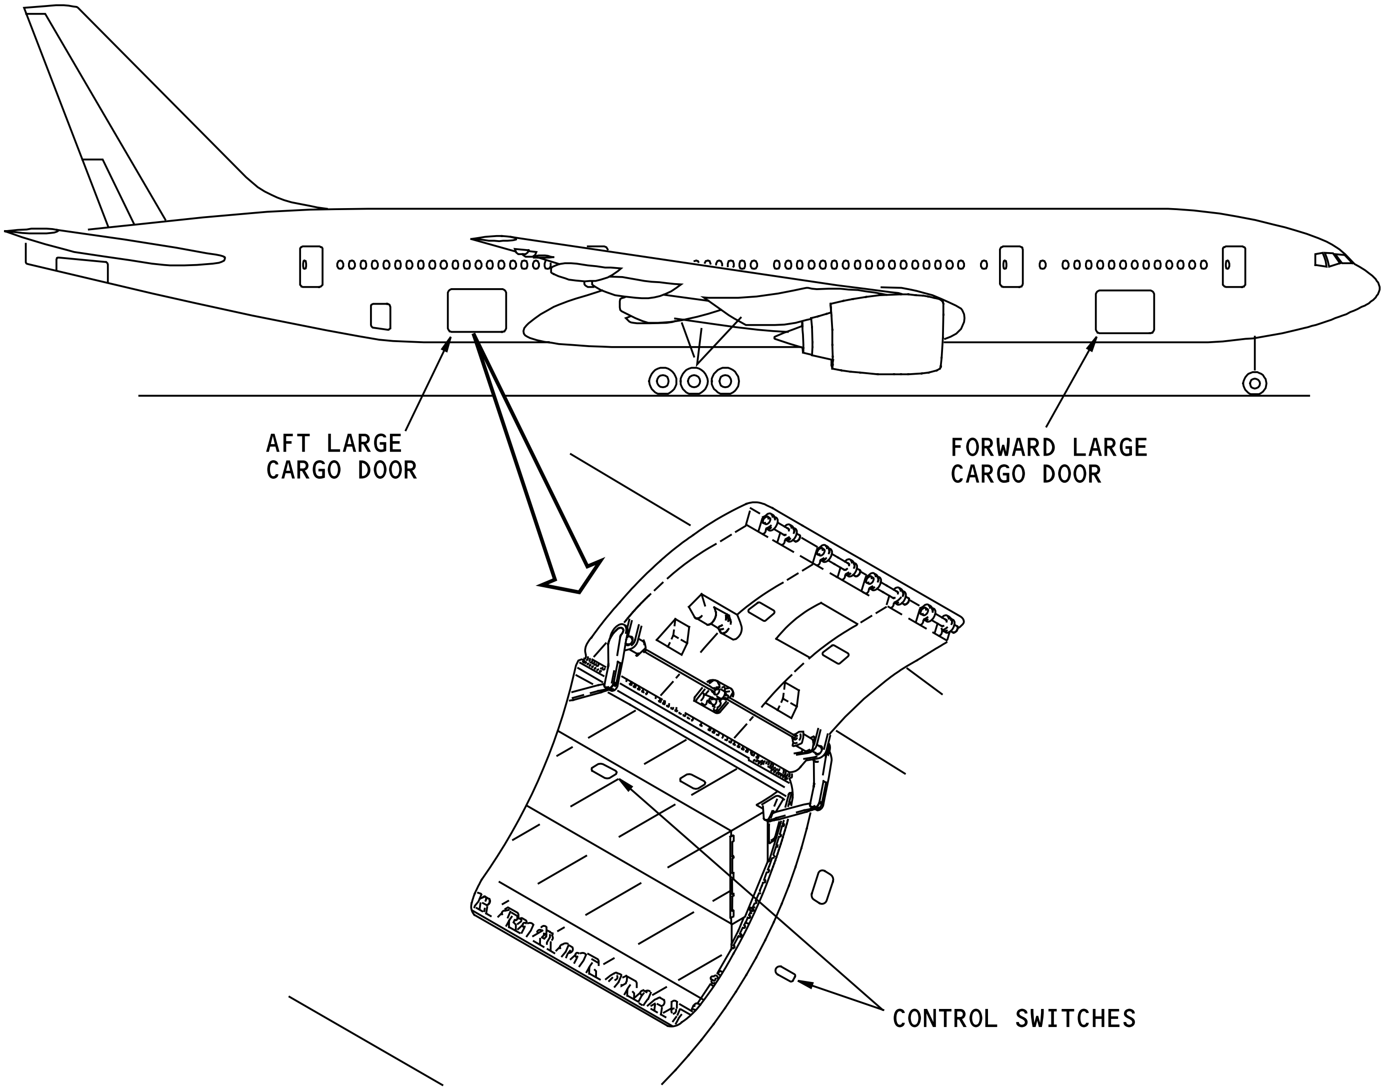
The large cargo door supplies a clear opening of 106 inches (269.2 cm) wide and 67 inches (170.2 cm) high. The dimensions of the door lets cargo handlers load and unload pallets and containers.

The door is a non-plug type of door. Door latches hold the door closed against cabin pressure loads.

The door opens outward and upward. You can operate it electrically from inside or outside the cargo compartment. You can operate it manually from outside the cargo compartment.

The forward and aft large cargo doors are the same in structure and operation.

See the forward large cargo door section for more information (AMM PART I 52-34).



AFT LARGE CARGO DOOR SYSTEM - INTRODUCTION

BULK CARGO DOOR SYSTEM - INTRODUCTION

Purpose

The bulk cargo door system gives access to the bulk cargo compartment.

Location

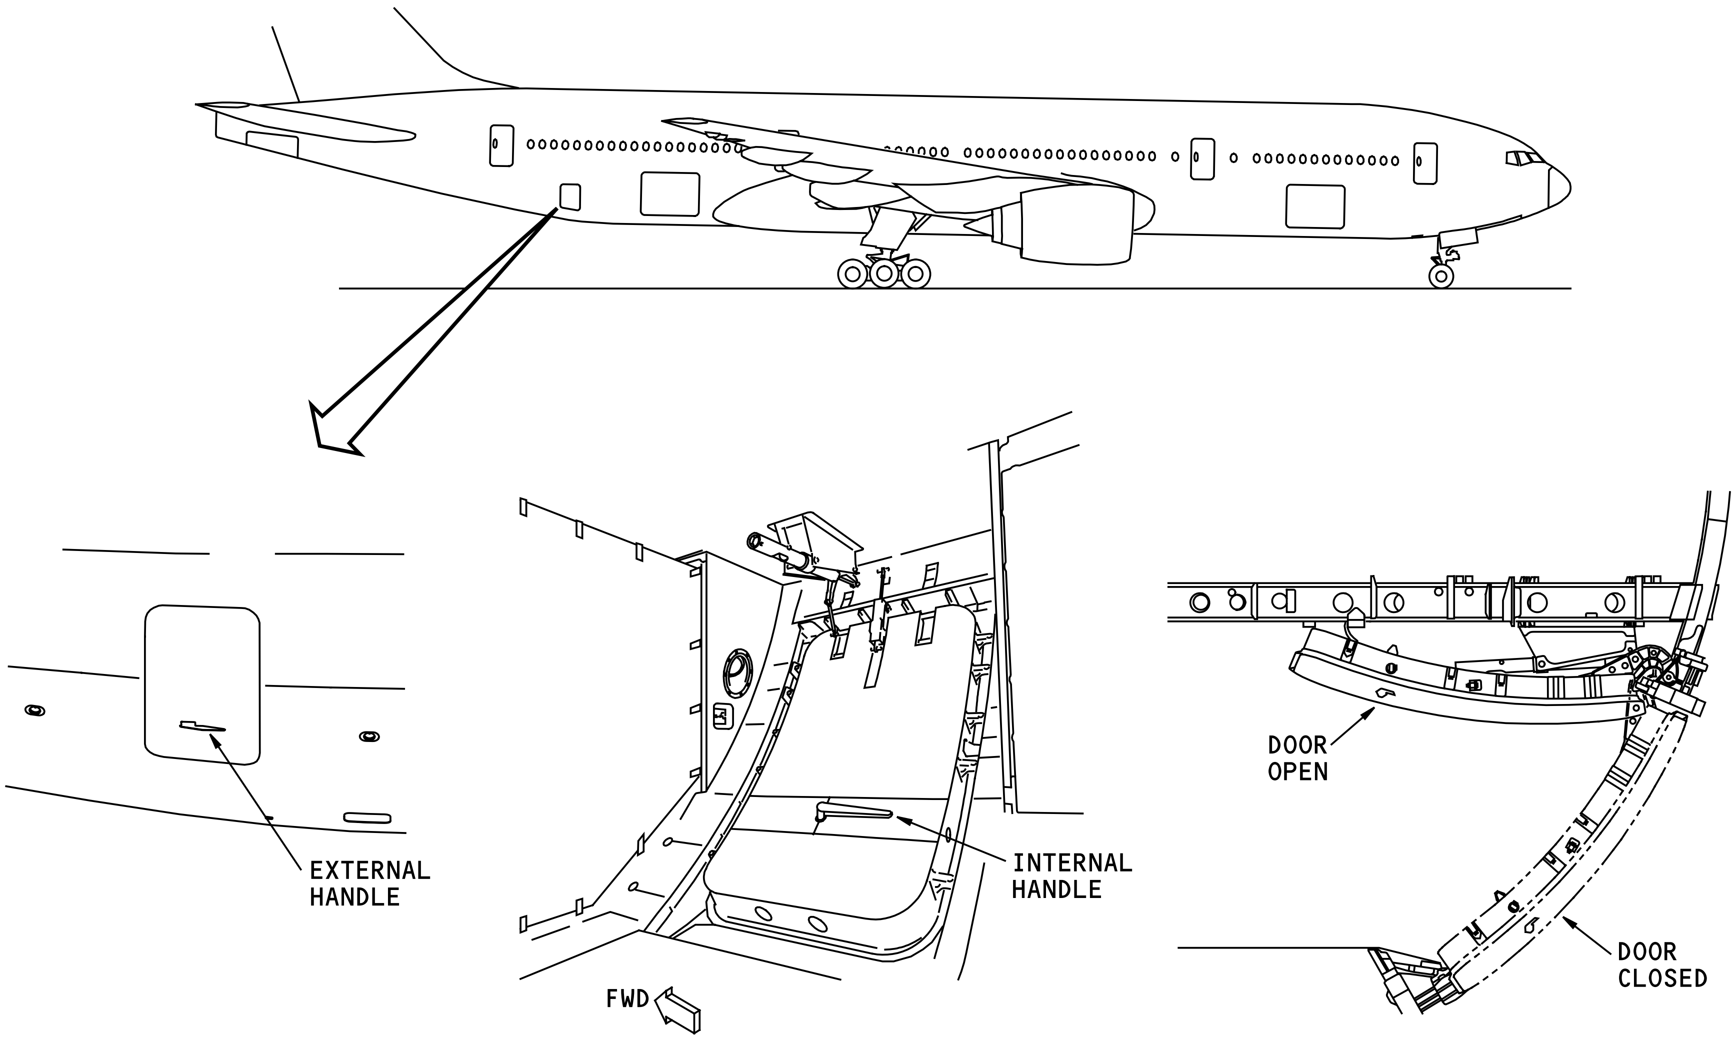
The bulk cargo door is on the right side of the airplane, aft of the aft cargo door.

General Description

The bulk cargo door supplies a clear opening of 36 inches (91.4 cm) wide and 45 inches (114.3 cm) high. Door dimensions let cargo handlers load and unload cargo that is not on pallets or in containers.

The door is a plug type. To open, it hinges along the top and moves into the bulk cargo compartment area.

You operate it manually from outside or inside the bulk cargo compartment.



INSIDE VIEW OF DOOR

VIEW LOOKING FORWARD

BULK CARGO DOOR SYSTEM - INTRODUCTION

52-36-00-001 Rev 3 03/02/1998

BULK CARGO DOOR SYSTEM - COMPONENT LOCATIONS

Component Locations

The counterbalance mechanism is on the cargo compartment ceiling structure, inboard of the bulk cargo door.

The snubber is at the top, center of the cargo door.

The two hinge arms are at the top of the cargo door.

The latch mechanism is across the door, near the bottom.

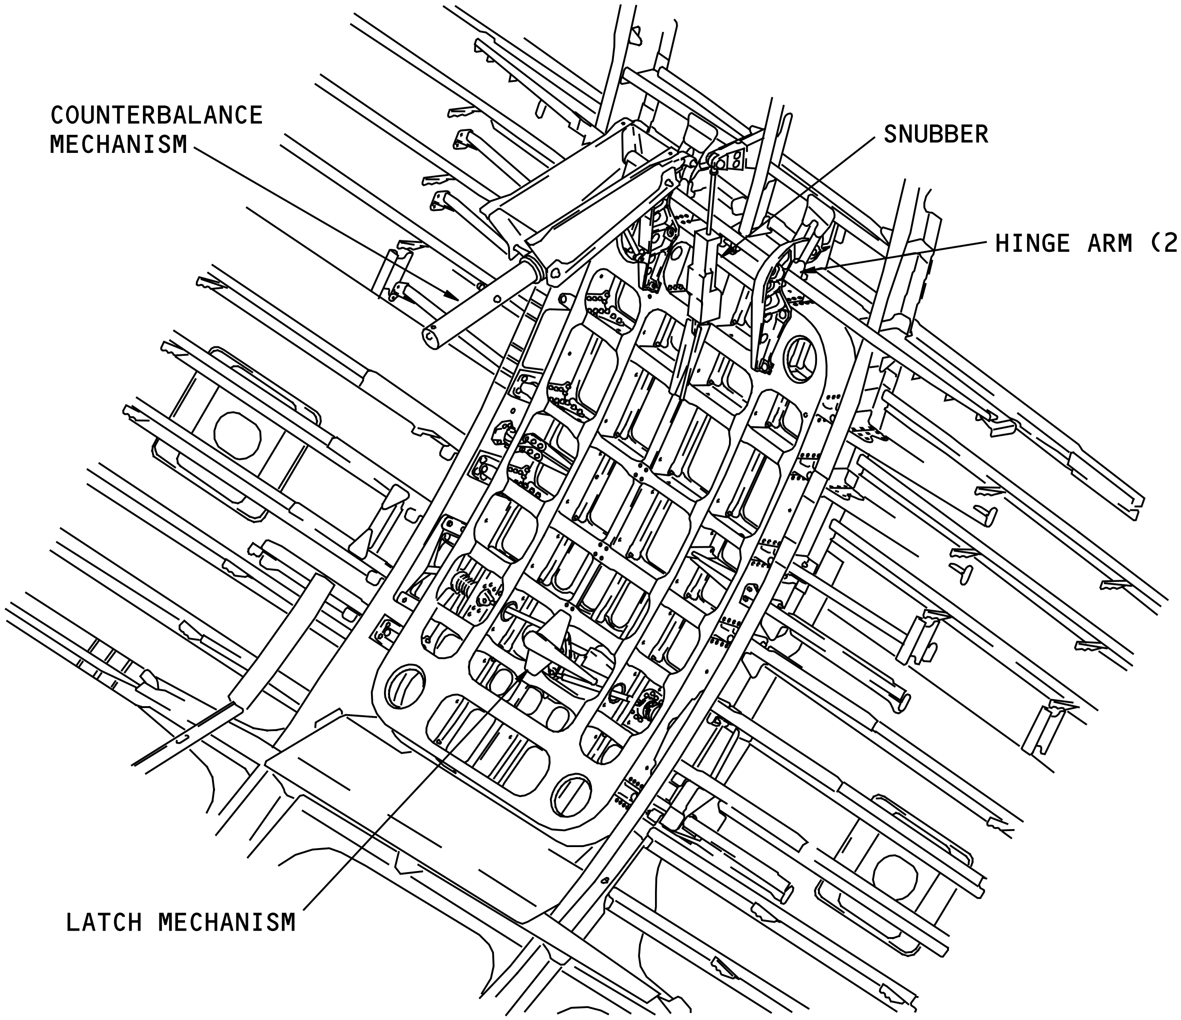
General Description

The latch mechanism lets you open and close the door. It also holds the door closed.

The hinge arms let the door rotate open and closed.

The counterbalance lifts the door open.

The snubber controls the movement rate of the door.



52-36-00-002 Rev 0

BULK CARGO DOOR SYSTEM - COMPONENT LOCATIONS

BULK CARGO DOOR SYSTEM - DOOR AND SEAL

Purpose

The door and seal close and seal the external access to the bulk cargo compartment.

Physical Description

The door is a plug-type. It has a skin, frames, beams, guide rollers, and stops.

The seal is a blade-type that goes completely around the edge of the door.

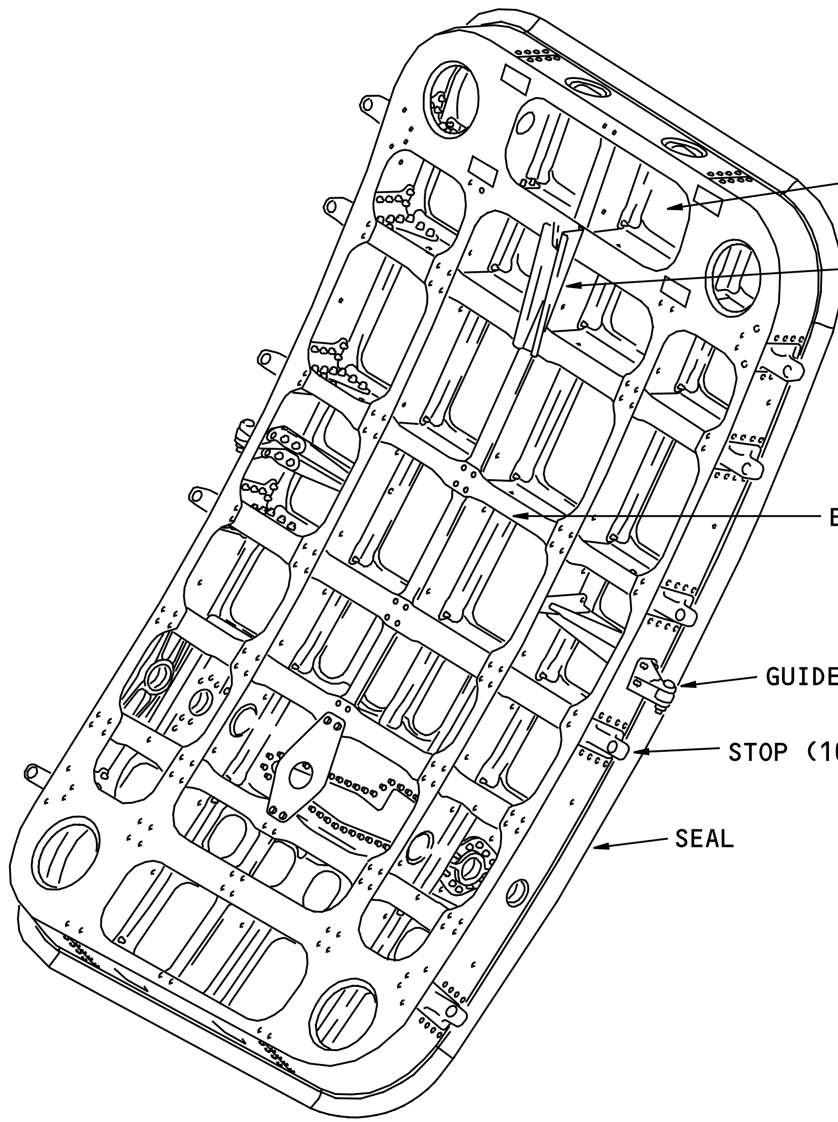
Functional Description

The five stops on each side of the door pass the pressurization load on the door to stops on the door cutout.

The guide rollers put the door in the correct position as it goes into the cutout.

Training Information Point

The door seal prevents air flow from the cargo compartment to the outside.



52-36-00-003 Rev 0

BULK CARGO DOOR SYSTEM - DOOR AND SEAL

BULK CARGO DOOR SYSTEM - COUNTERBALANCE MECHANISM

Purpose

The counterbalance mechanism lifts the bulk cargo door to the open position.

Physical Description

The counterbalance mechanism has these components:

- Tube that contains four springs
- Saddle fitting
- Piston rod
- Bellcrank
- Control rod.

Location

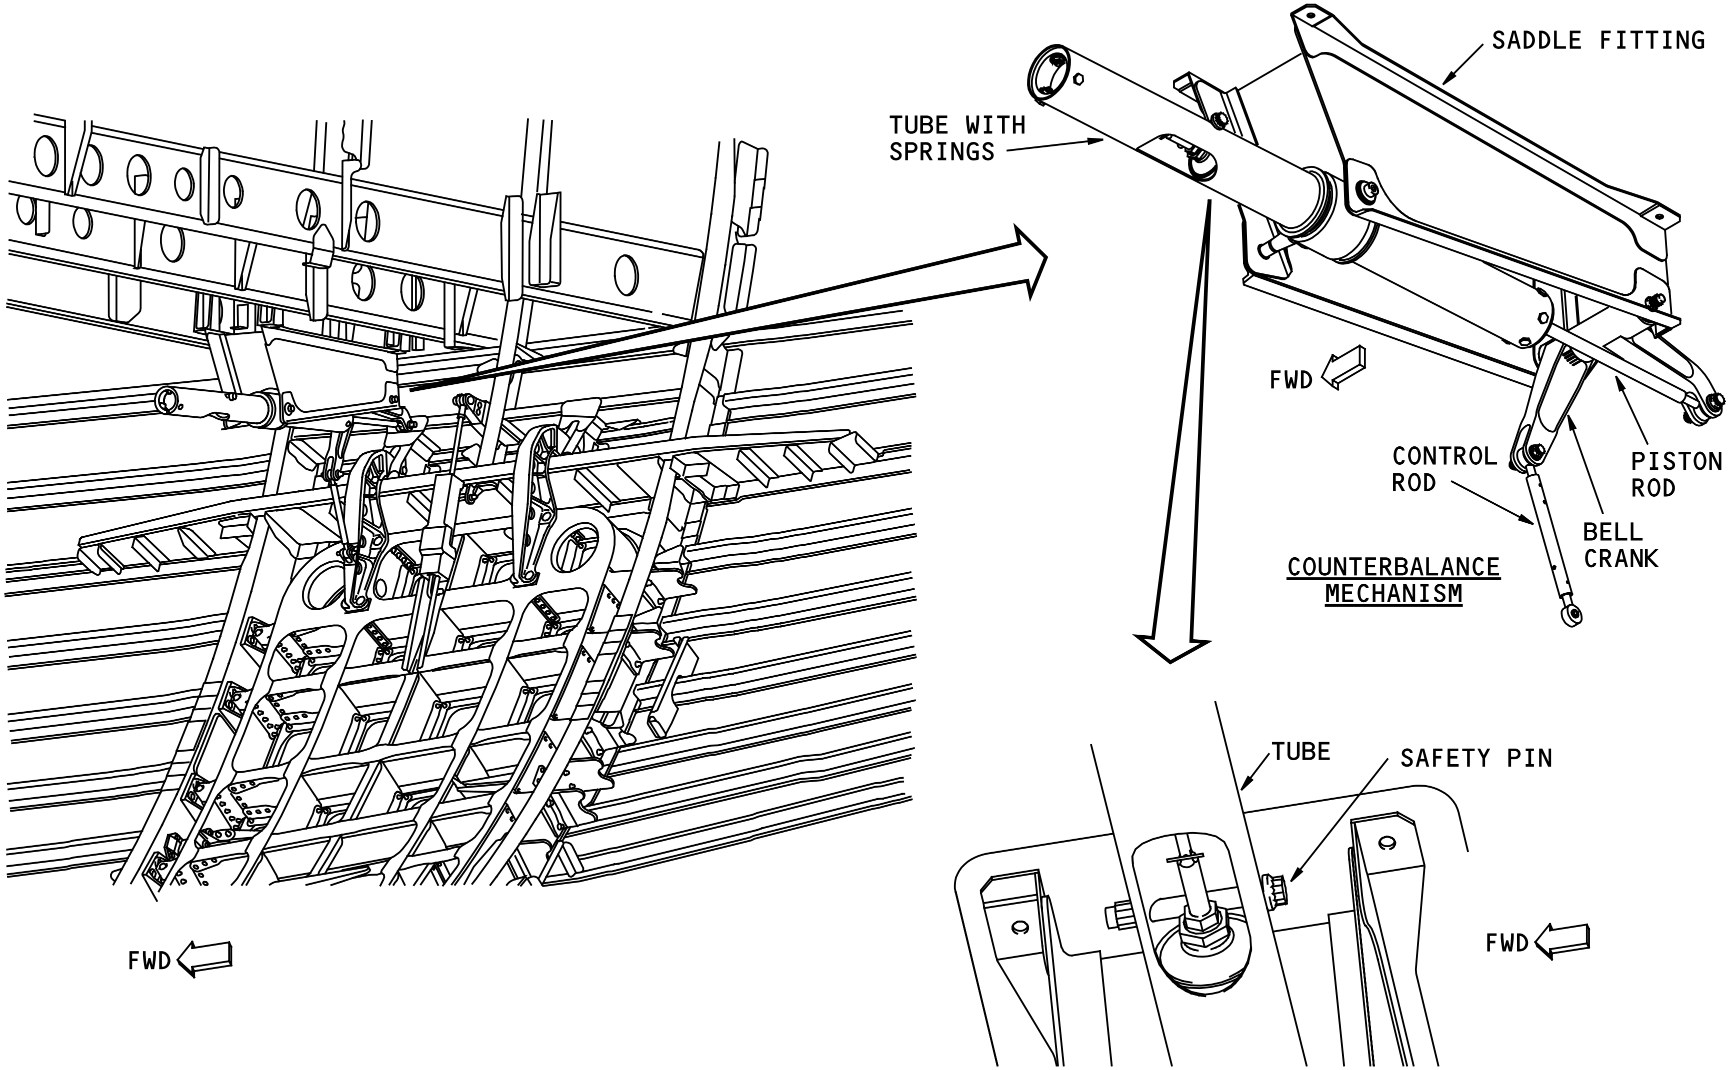
The tube has a pin in the middle that attaches to the saddle fitting. The saddle fitting attaches to airplane structure at the top of the bulk cargo compartment. The control rod attaches to the door.

Functional Description

The springs in the tube supply the force that opens the door. The piston rod, bellcrank, and control rod transmit the force that lifts the door.

Training Information Point

You can put a safety pin through the tube to keep the springs compressed when you disconnect linkage or remove the tube from the saddle fitting.



52-36-00-004 Rev 1 10/09/96

BULK CARGO DOOR SYSTEM - COUNTERBALANCE MECHANISM

BULK CARGO DOOR SYSTEM - SNUBBER

Purpose

The snubber controls the rate at which:

- The counterbalance opens the door
- You can close the door
- The door closes if the counterbalance fails.

Physical Description

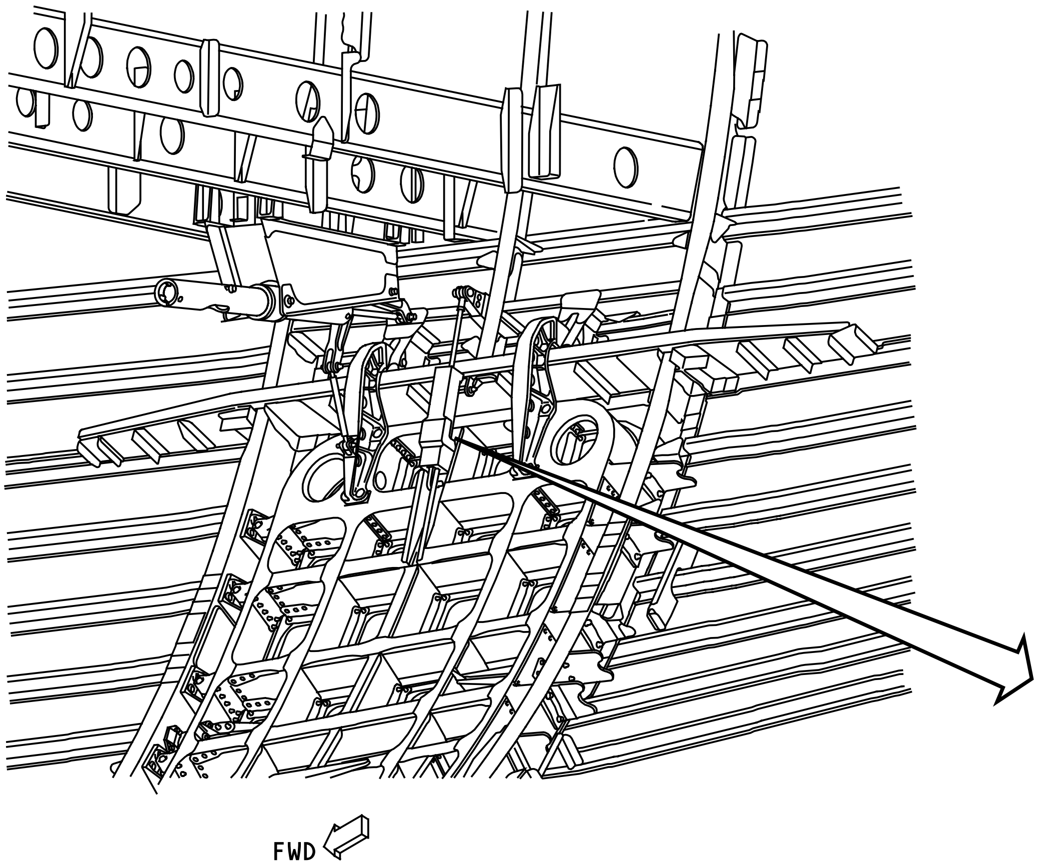
The snubber is a piston rod in a fluid-filled tube.

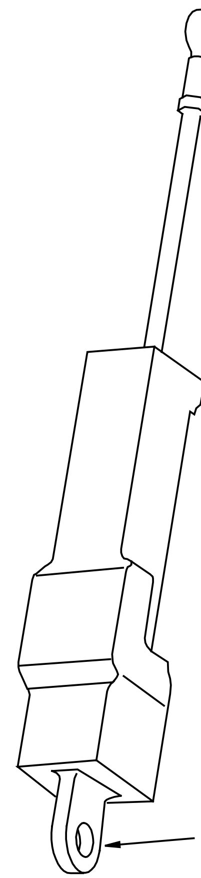
Location

The tube end of the snubber attaches to the airplane structure above the door cutout. The rod end attaches to the door.

Functional Description

Movement of the piston rod makes fluid flow through an orifice in the piston. This controls the rate at which the door moves.





SNUBBER

52-36-00-005 Rev 0

BULK CARGO DOOR SYSTEM - SNUBBER

BULK CARGO DOOR SYSTEM - LATCH MECHANISM

Purpose

The latch mechanism lets you latch and unlatch the door.

Physical Description

The mechanism is made up of these components:

- External handle
- Latch probes
- Springs
- Push/pull rods
- Internal handle.

Location

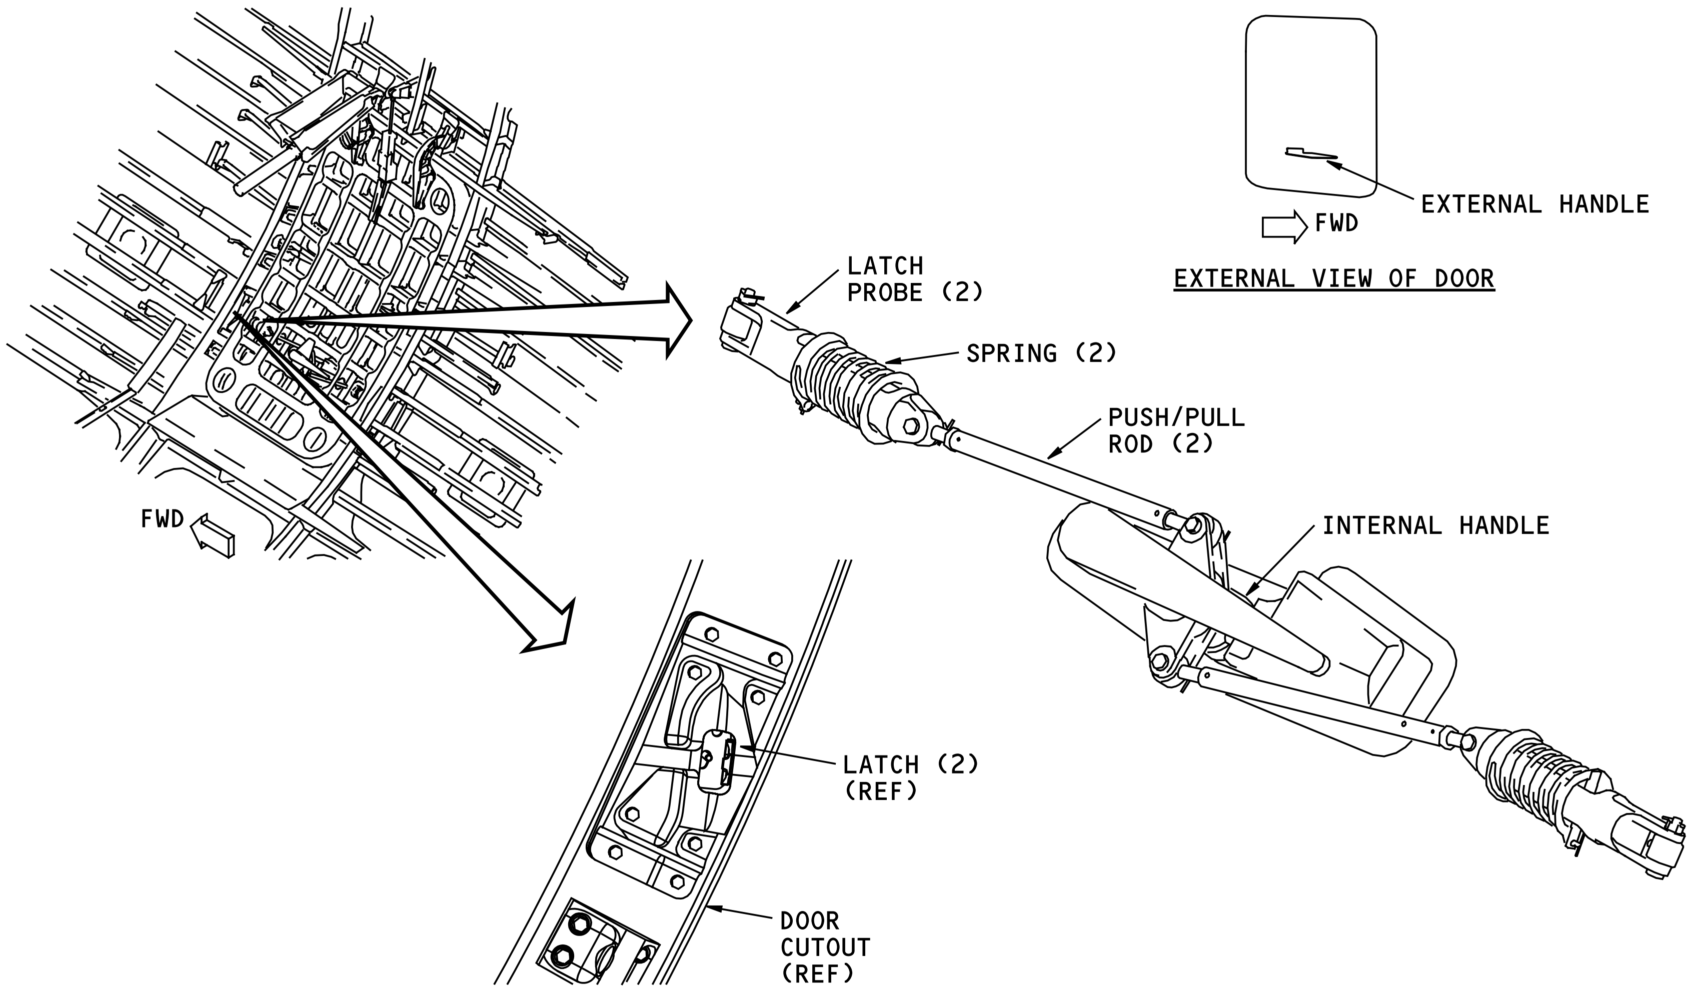
The latch mechanism goes across the door, near the bottom. The latches are on the door cutout.

Functional Description

When you pull outboard on the external handle, it connects to the internal handle. The internal handle connects to the push/pull rods.

When you turn either handle, the push/pull rods compress the springs and pull the probes out of the latches. When you release the handle, the springs push the latch probes outward.

A spring on the external handle pulls it inboard to the fair position when the door is latched.



EXTERNAL VIEW OF DOOR

VIEW LOOKING FORWARD AT THE
FORWARD SIDE OF THE DOOR CUTOUT

52-36-00-007 Rev 0

BULK CARGO DOOR SYSTEM - LATCH MECHANISM

BULK CARGO DOOR SYSTEM - OPERATION

Operation - Door Open

You can use either the internal or the external handle to unlatch door. To use the external handle, pull the handle outboard until you can turn it. To use the internal handle, you only need to turn it.

When the door is unlatched, the counterbalance supplies the force to open the door. The snubber controls the rate at which the door opens. The door rotates inward and upward on the hinge arms.

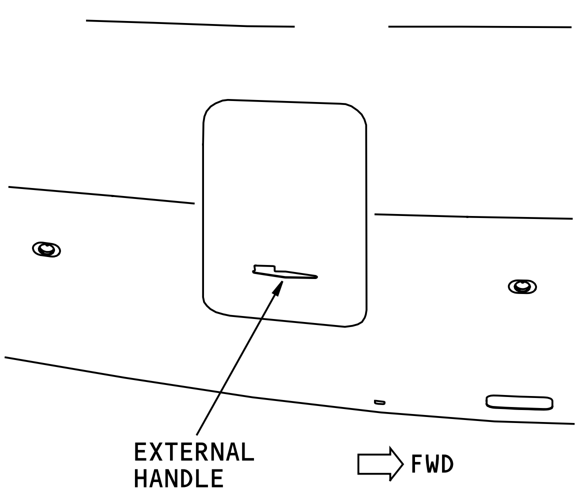
When the door is fully open, put the hold-open strap around the lower, aft door stop.

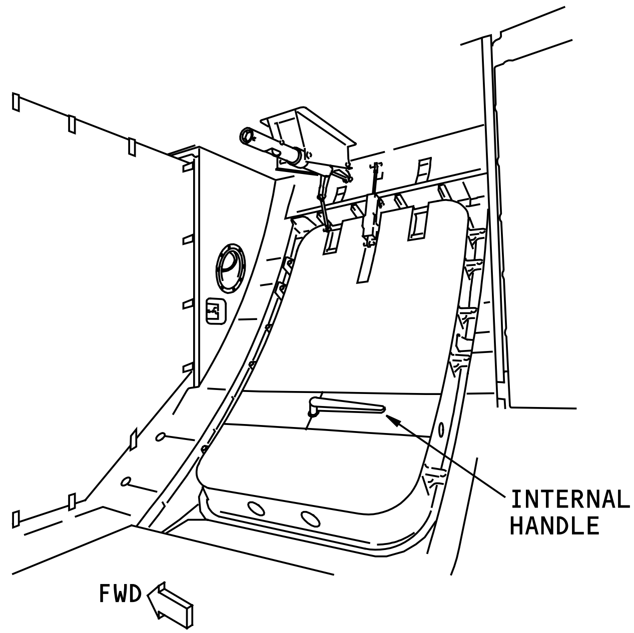
Operation - Door Close

To close the door, release the hold open strap. Pull or push the door down. Rotate the handle to the unlatch position. Close the door. Turn the handle to the latch position. The door is latched and locked.

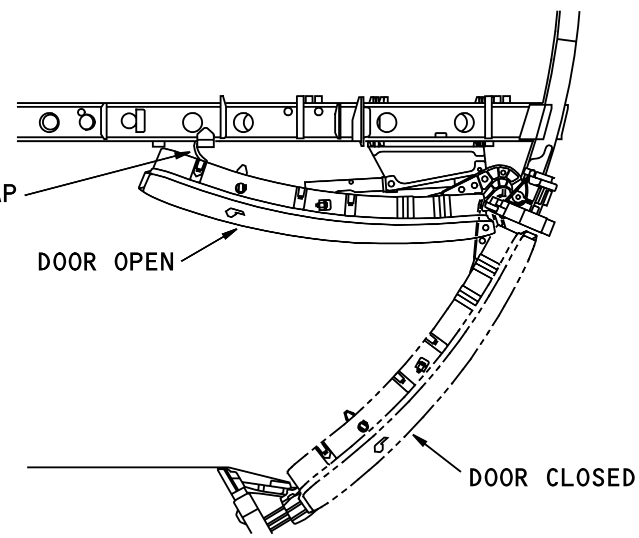
When the door is full open, use the hold open strap. It gives protection in case the counterbalance and snubber fail.

If you use the external handle, make sure the handle goes inboard to the fair position when you close the door.





INSIDE VIEW OF DOOR



VIEW LOOKING FORWARD

BULK CARGO DOOR SYSTEM - OPERATION

EQUIPMENT COMPARTMENT AND EQUIPMENT SERVICE DOORS - LEFT SIDE OF AIRPLANE

Purpose

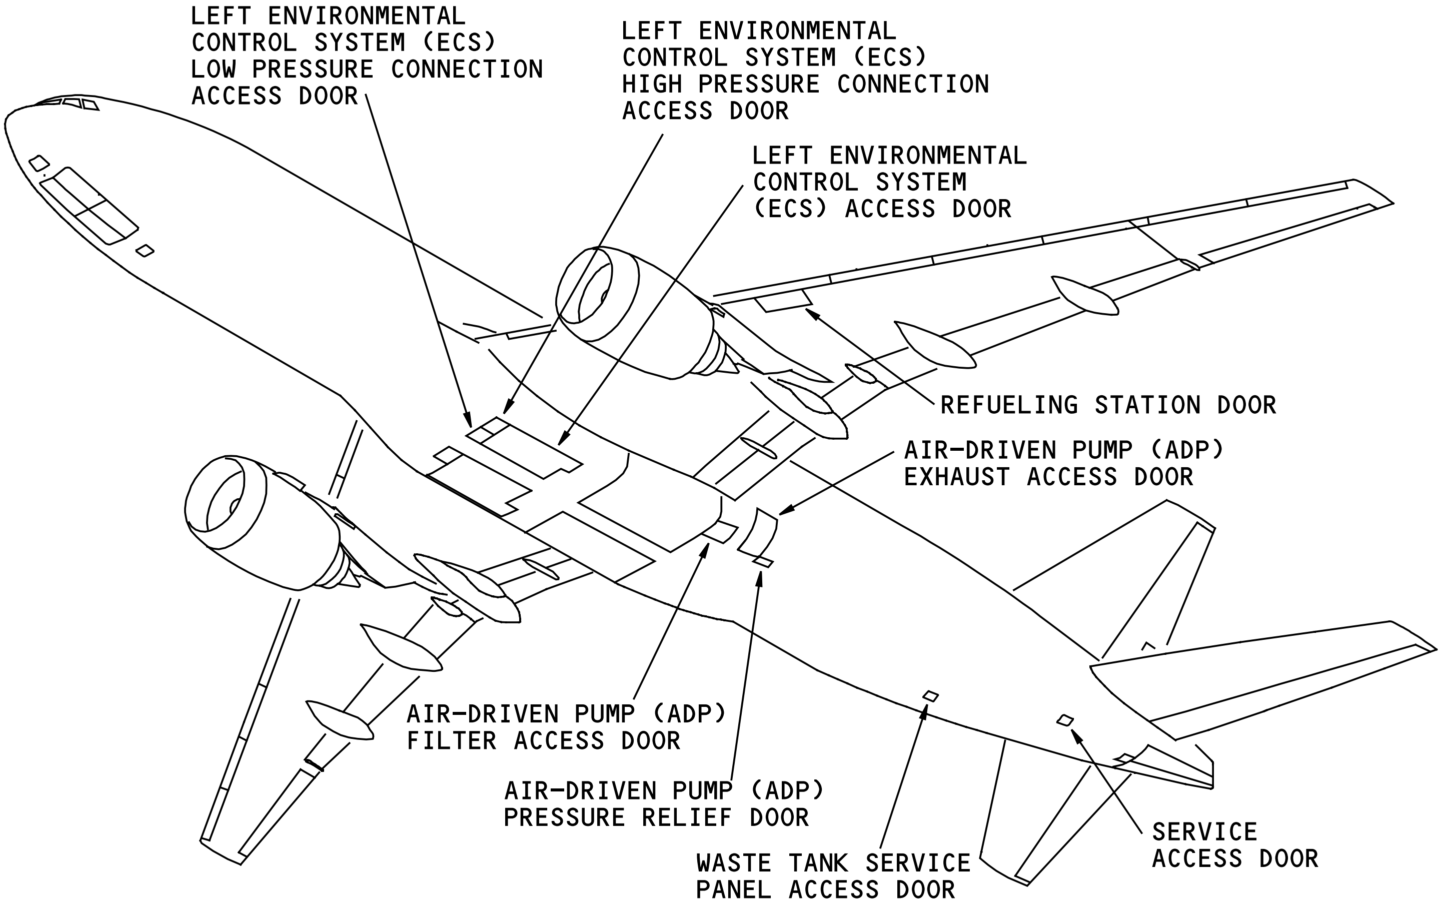
Equipment compartment doors give access to equipment on the airplane.

Equipment service doors give access to service airplane systems.

Location

These equipment compartment and equipment service doors are on the left side of the airplane:

- Left environmental control system (ECS) low pressure connection access door
- Left environmental control system (ECS) high pressure connection access door
- Left environmental control system (ECS) access door
- Refueling station door
- Air driven pump (ADP) exhaust door
- Service access door
- Waste tank service access door
- Air-driven pump (ADP) pressure relief door
- Air-driven pump (ADP) filter access door.



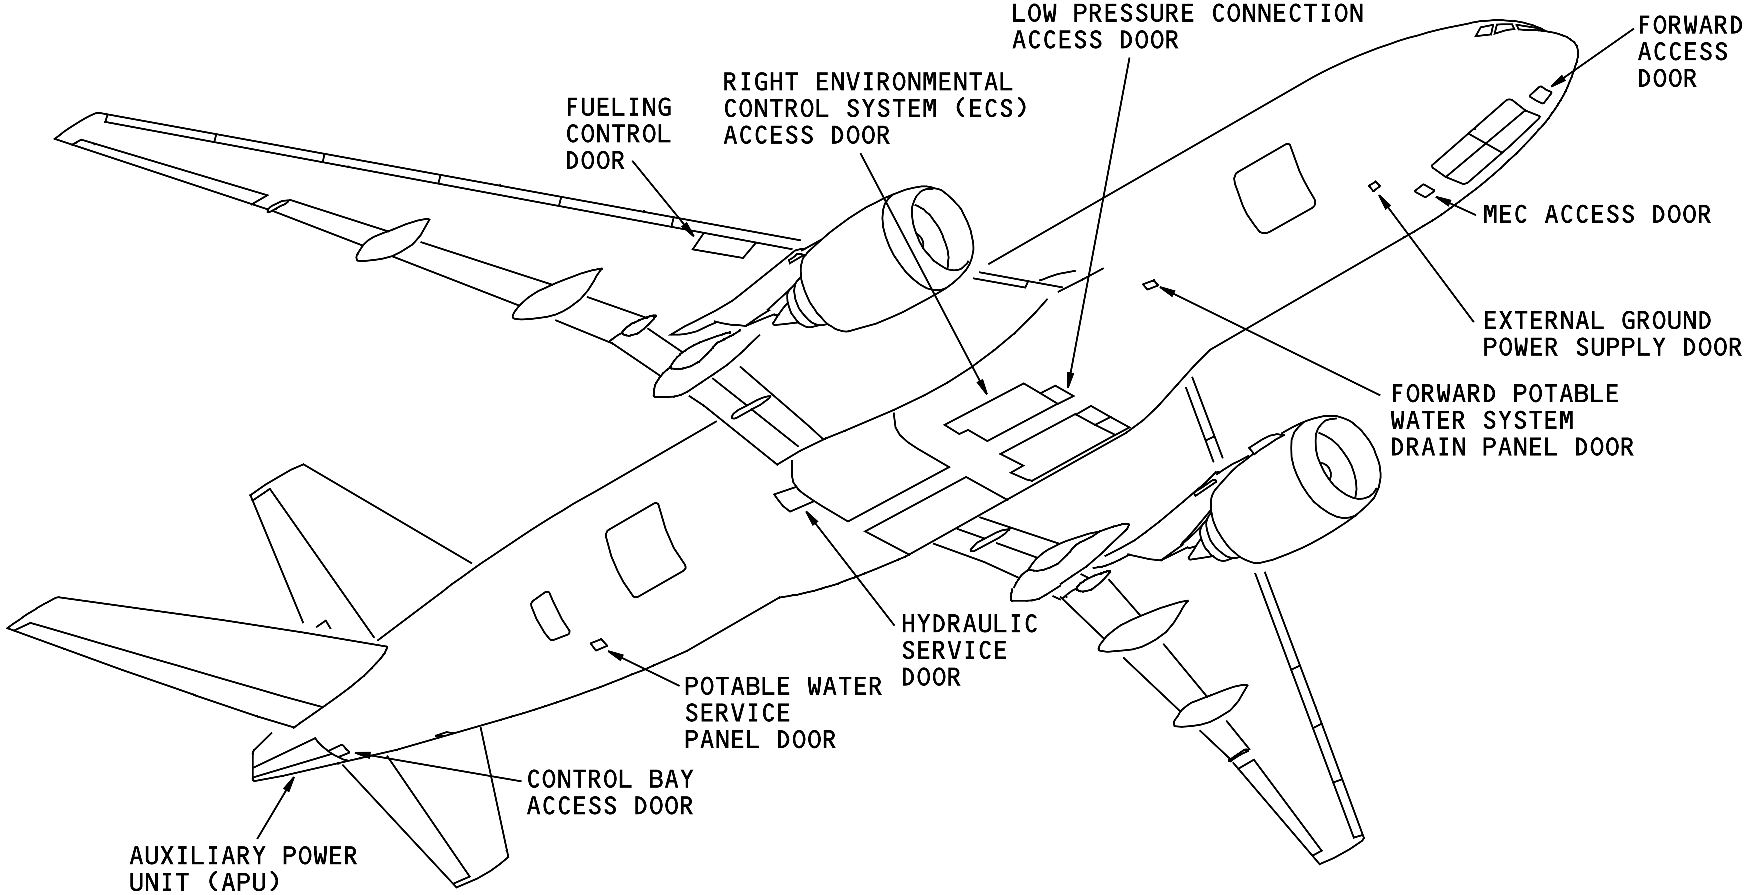
EQUIPMENT COMPARTMENT AND EQUIPMENT SERVICE DOORS - LEFT SIDE OF AIRPLANE

EQUIPMENT COMPARTMENT AND EQUIPMENT SERVICE DOORS - RIGHT SIDE AND BOTTOM OF AIRPLANE

Location

These equipment compartment doors and equipment service doors are on the right side and bottom of the airplane:

- Fueling control door
- Right environmental control system (ECS) access door
- Right environmental control system (ECS) low pressure connection access door
- MEC access door
- Forward access door
- External ground power supply access door
- Forward potable water system drain panel door
- Hydraulic service door
- Potable water service panel door
- Control bay access door
- Auxiliary power unit (APU) access door.



52-40-00-002 Rev 2 03/02/1998

EQUIPMENT COMPARTMENT AND EQUIPMENT SERVICE DOORS - RIGHT SIDE AND BOTTOM OF AIRPLANE

FIXED INTERIOR DOORS - INTRODUCTION

Purpose

Fixed interior doors give access from one compartment to another inside the airplane.

Location

These are the fixed interior doors:

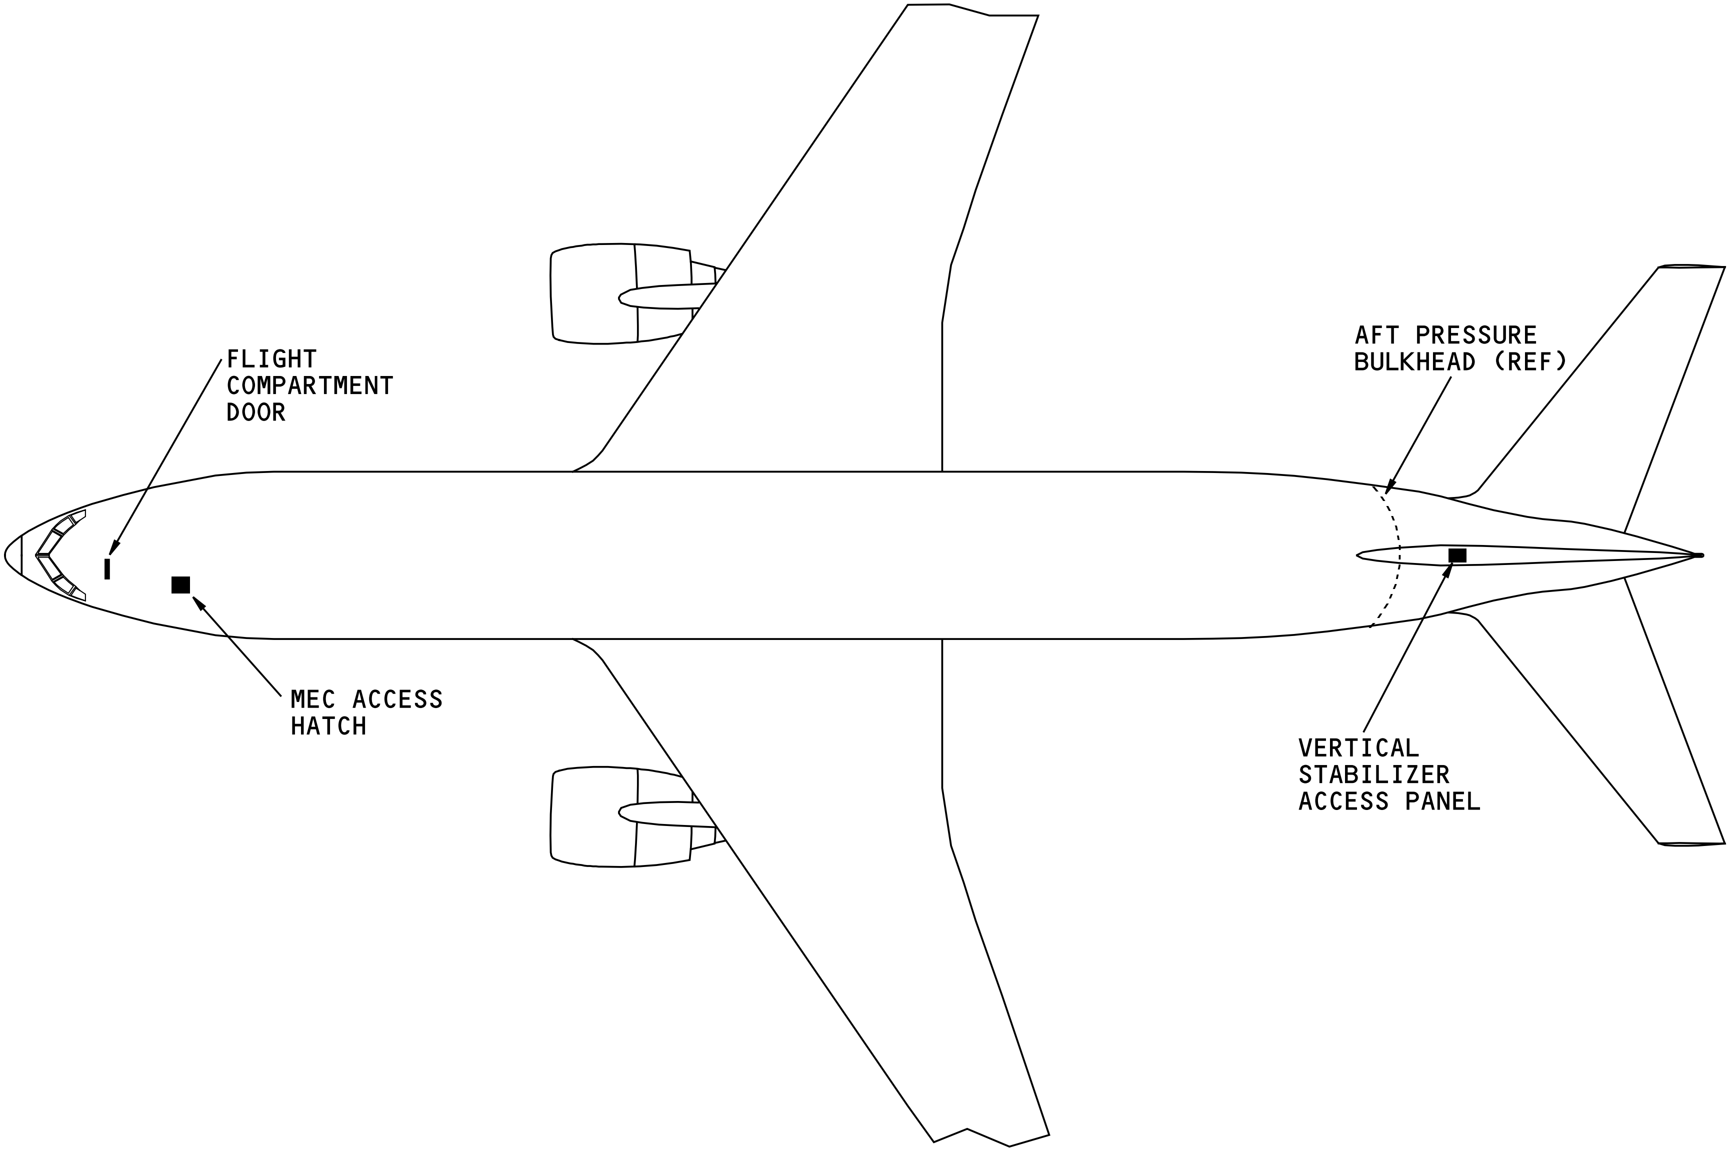
- Flight compartment door
- Main equipment center (MEC) access hatch
- Vertical stabilizer access panel.

The flight compartment door is on the left side of flight compartment aft bulkhead.

The main equipment center access hatch is in the forward end of the passenger compartment left aisle near the passenger entry door.

The vertical stabilizer access panel is in the top of the fuselage tail section. Access to the tail section is through the service access door.

See the equipment compartment and equipment service doors section for more information (AMM PART I 52-40).



FIXED INTERIOR DOORS - INTRODUCTION

FIXED INTERIOR DOORS - FLIGHT COMPARTMENT DOOR - FUNCTIONAL DESCRIPTION

Door Hinge

The door hinge is on the outboard side of the door cutout in the flight compartment aft bulkhead. The door turns forward on the hinge into the flight compartment. Three pins let you disconnect the door from the hinge.

Lock Unit and Handle

The door lock unit is on the inboard side of the door cutout in the door post. A door bolt (not shown) engages a spring-loaded catcher in the lock unit to hold the door closed.

The door handle on the flight compartment side of the door connects to the door bolt. When you turn the handle the door bolt pulls out of the catcher and you can open the door into the flight compartment.

The door handle on the passenger compartment side of the door does not connect to the door bolt. You push on the door to open it. The door bolt pushes on the catcher. The catcher turns against its spring until the bolt moves past. When you close the door, the bolt pushes on the catcher. The bolt moves into the door against its spring until it moves past the strike.

The catcher and the lock are on the same bolt in the lock unit. Two balls are in detents, between the catcher and the lock. A spring washer (not shown) on the bolt, pushes the catcher, balls, and lock together. The roller attaches to the lock. When you open the door normally, the catcher, balls, lock, and roller turn together.

A flight compartment door lock switch (not shown) on the P5 lets you lock the door. The solenoid moves a pin up. When you try to push the door open from the passenger side, the roller pushes against the pin. The lock and catcher cannot turn.

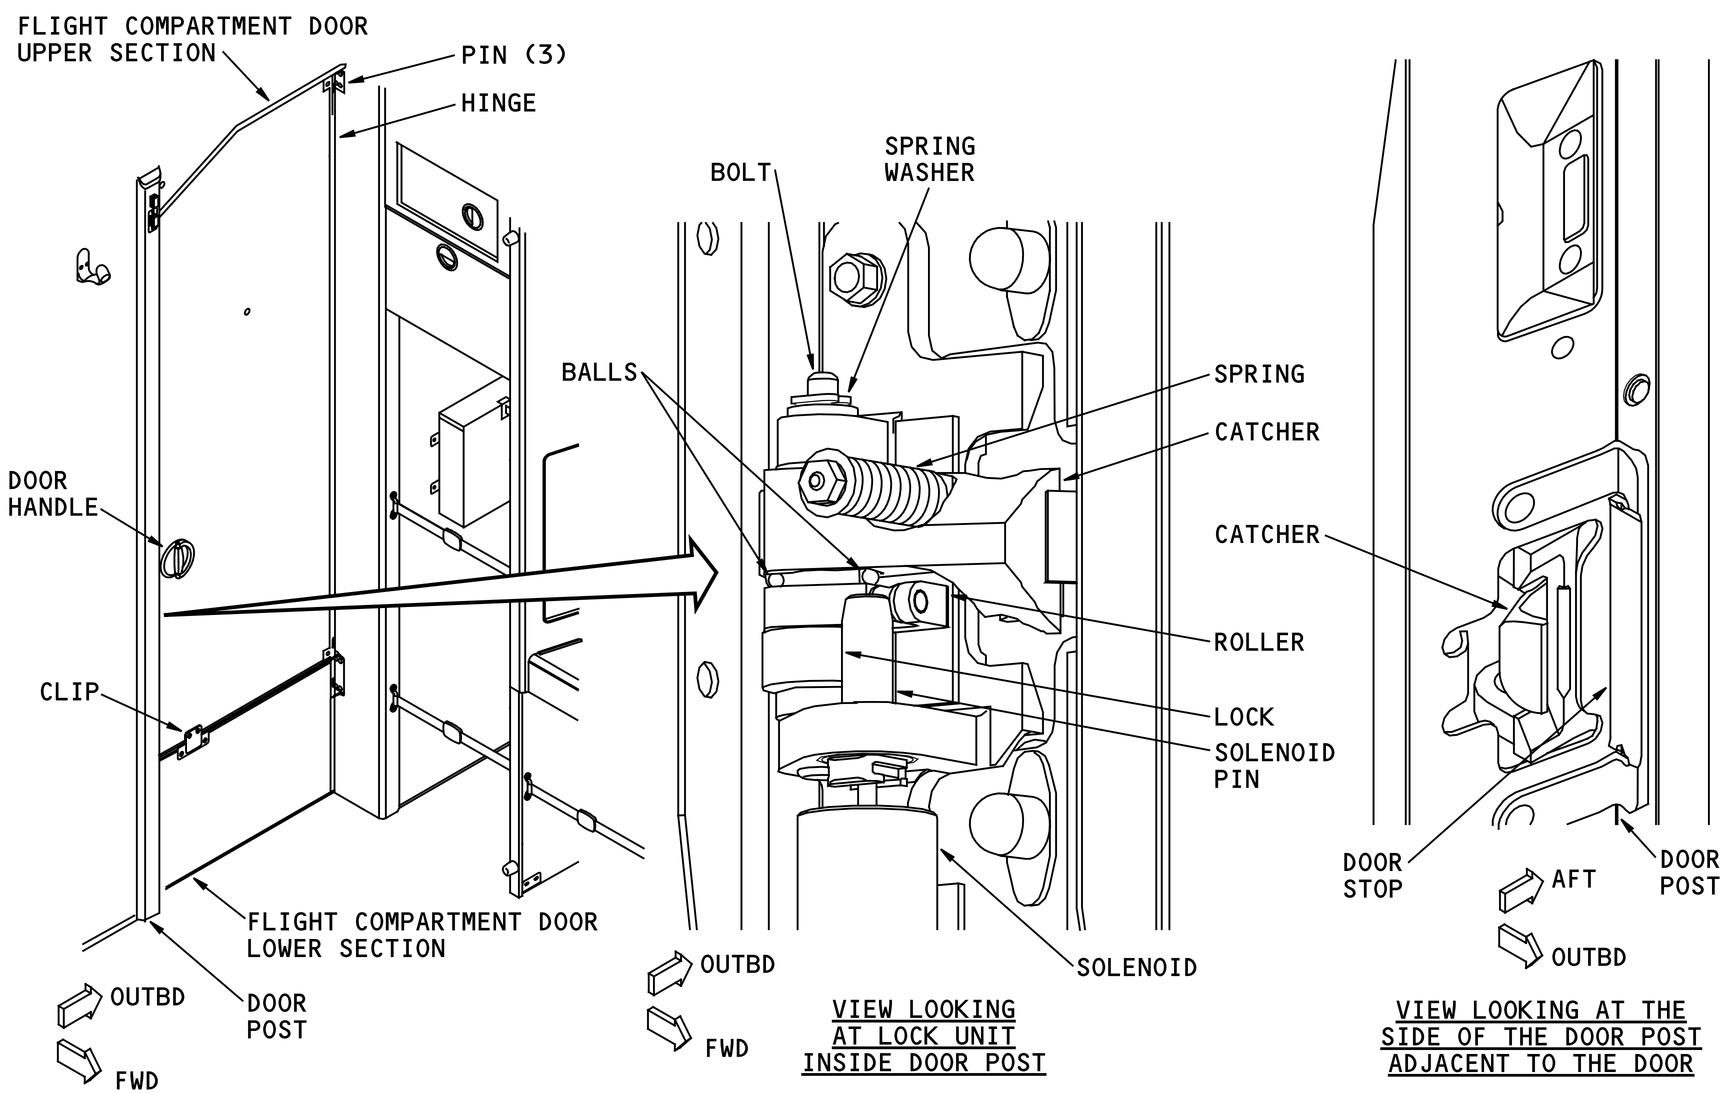
Decompression

If there is fast decompression in the flight deck, passenger compartment air pressure pushes against the door. A 120 pound force compresses the spring washer sufficiently to let the balls in the detents disconnect the catcher from the lock. The catcher can turn. This releases the door to move on its hinge into the flight compartment.

If there is fast decompression in the passenger compartment, air pressure pushes the door toward the passenger compartment. A 120 pounds force breaks the door stop. This releases the door to move on its hinge into the passenger compartment.

Door Sections

The door has upper and lower sections. They are held together by a clip and normally turn together. If a blockage on the floor will not let the door turn, the clip lets the sections disconnect. This releases the upper section to turn.



52-50-00-002 Rev 1 11/03/1997

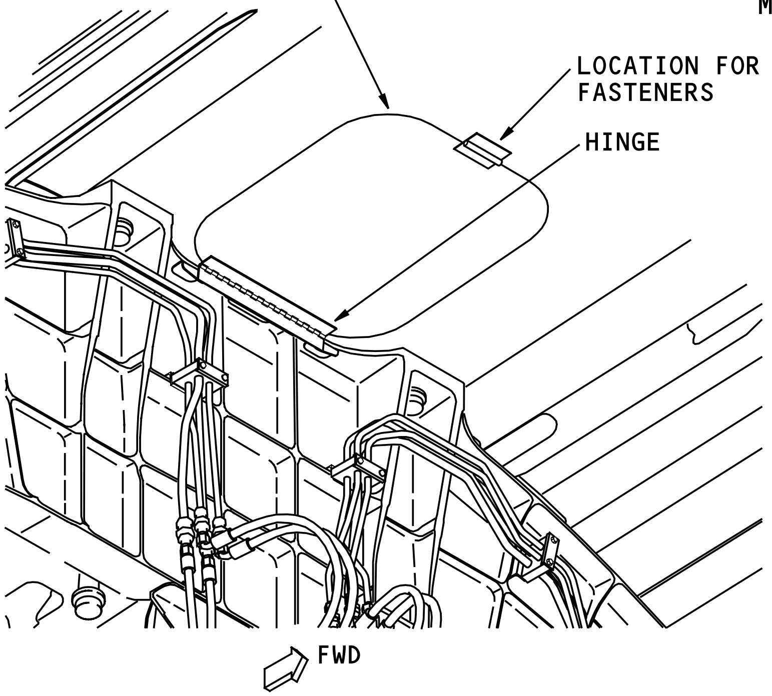
FIXED INTERIOR DOORS - FLIGHT COMPARTMENT DOOR - FUNCTIONAL DESCRIPTION

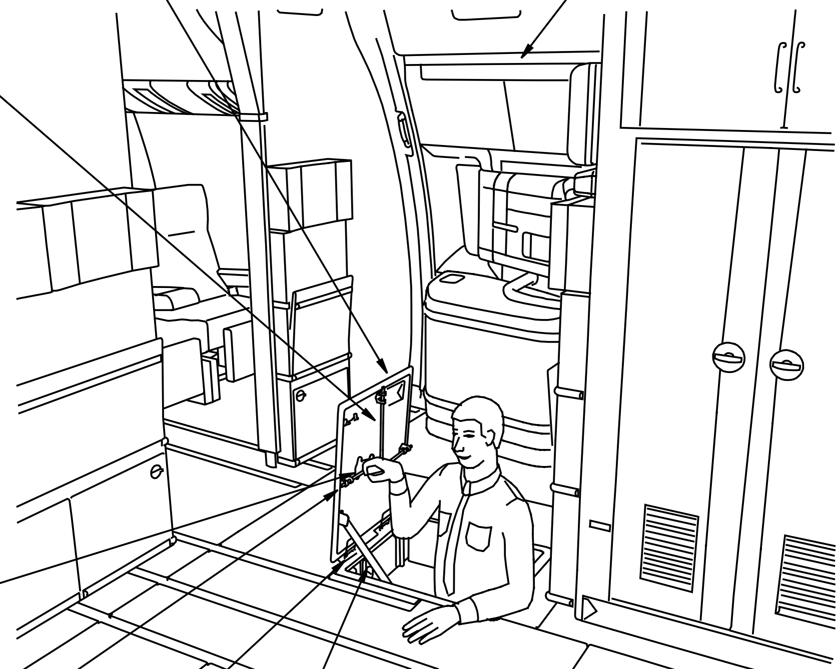
Vertical Stabilizer Access Panel Functional Description

The vertical stabilizer access panel is held closed by quarter turn fasteners (not shown) on the forward side of the panel. The panel opens downward on a hinge on the aft side of the panel.

Electrical/Electronic Access Hatch Functional Description

The electrical/electronics access hatch has handles on both sides that move the three pins of the latch mechanism. Hinges on the aft side of the hatch let it open upward. The restraint arm holds it in the open position.





52-50-00-003 Rev 1 08/13/96

FIXED INTERIOR DOORS - ELECTRICAL/ELECTRONICS ACCESS HATCH & VERTICAL STABILIZER ACCESS PANEL

DOOR WARNING SYSTEM - PASSENGER ENTRY DOOR SENSORS

Location

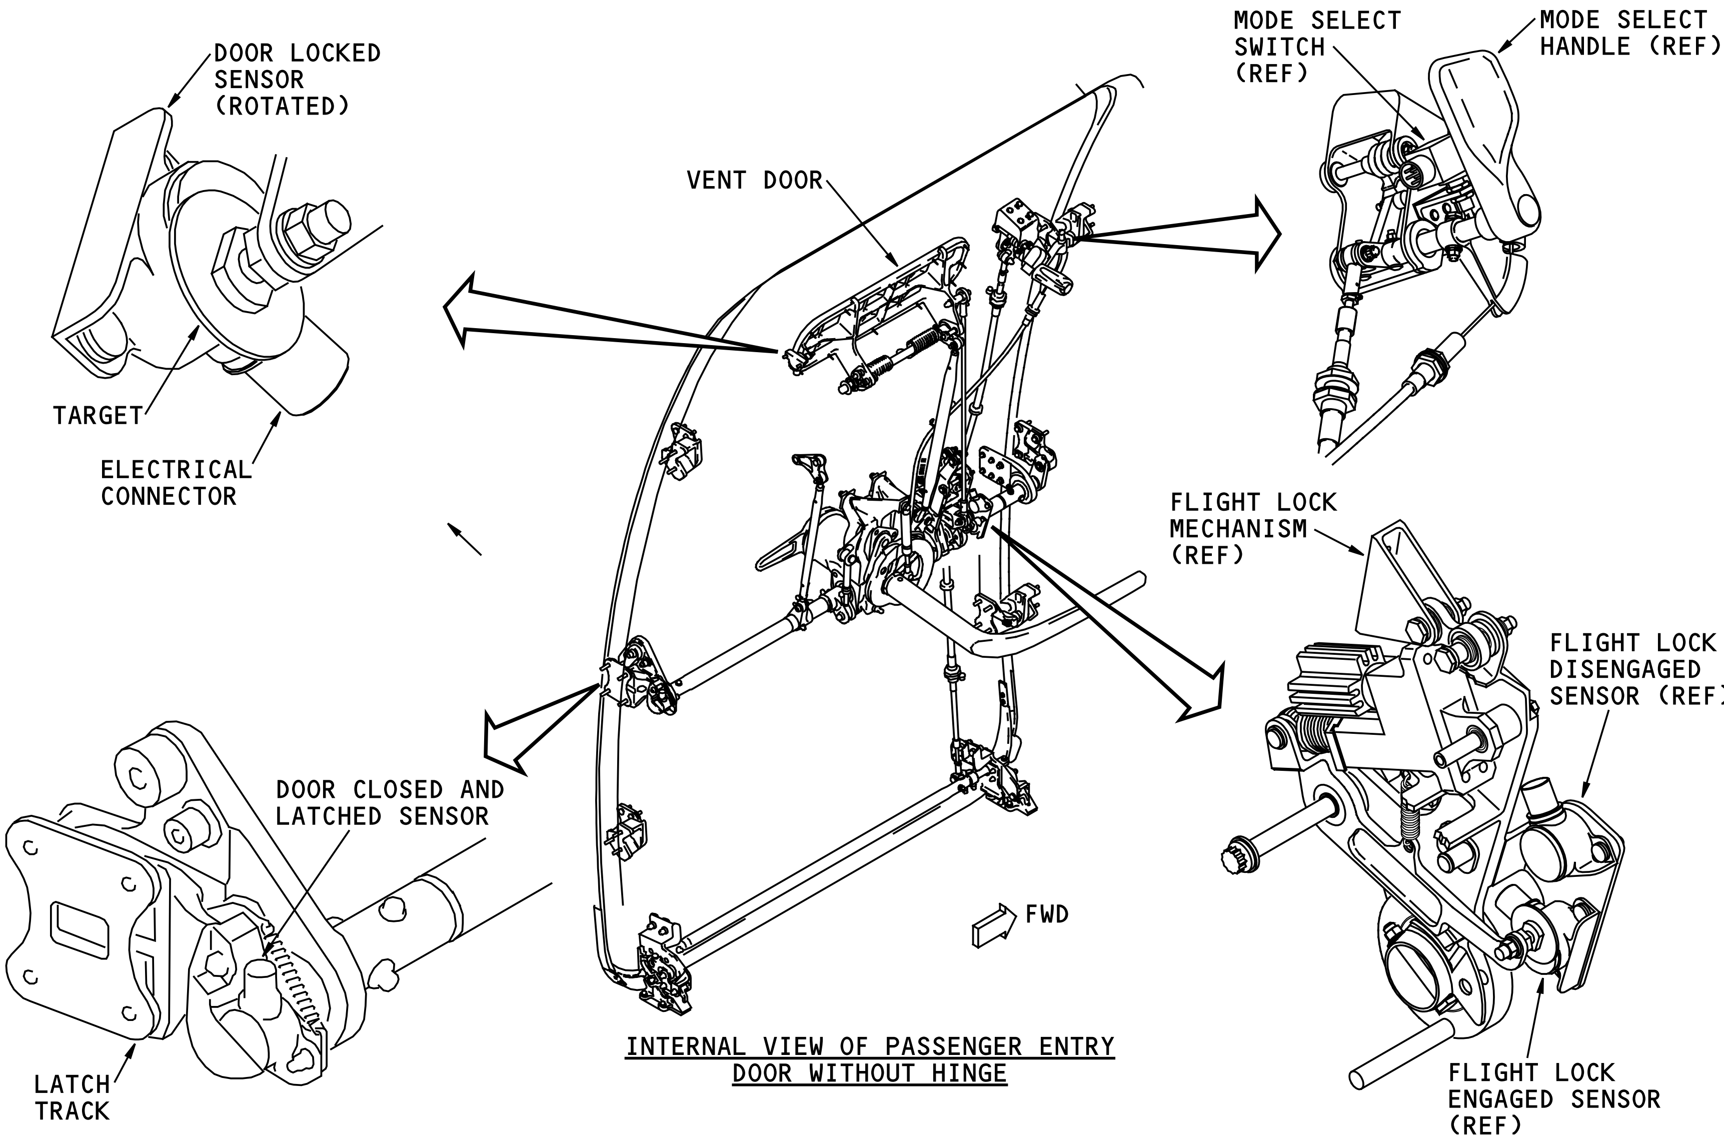
Each passenger entry door has two proximity sensors that are components of the door warning system. The door closed and latched sensor is on the aft latch track. The door locked sensor is on the vent door.

The mode select switch on the mode select handle is a door component. It is part of the emergency power assist system (EPAS). It also gives door warning information.

See passenger entry door section for more information on the mode select switch (AMM PART I 52-11).

The flight lock engaged and disengaged sensors are flight lock components. They give information for status and maintenance messages.

See passenger entry door section for more information on the flight lock sensors (AMM PART I 52-11).



DOOR WARNING SYSTEM - PASSENGER ENTRY DOOR SENSORS

DOOR WARNING SYSTEM - LARGE CARGO DOOR SENSORS

Location of Large Cargo Door Sensors

There are three proximity sensors on the large cargo door that supply information for door status indications along the bottom of the door. These are the large cargo door status sensors:

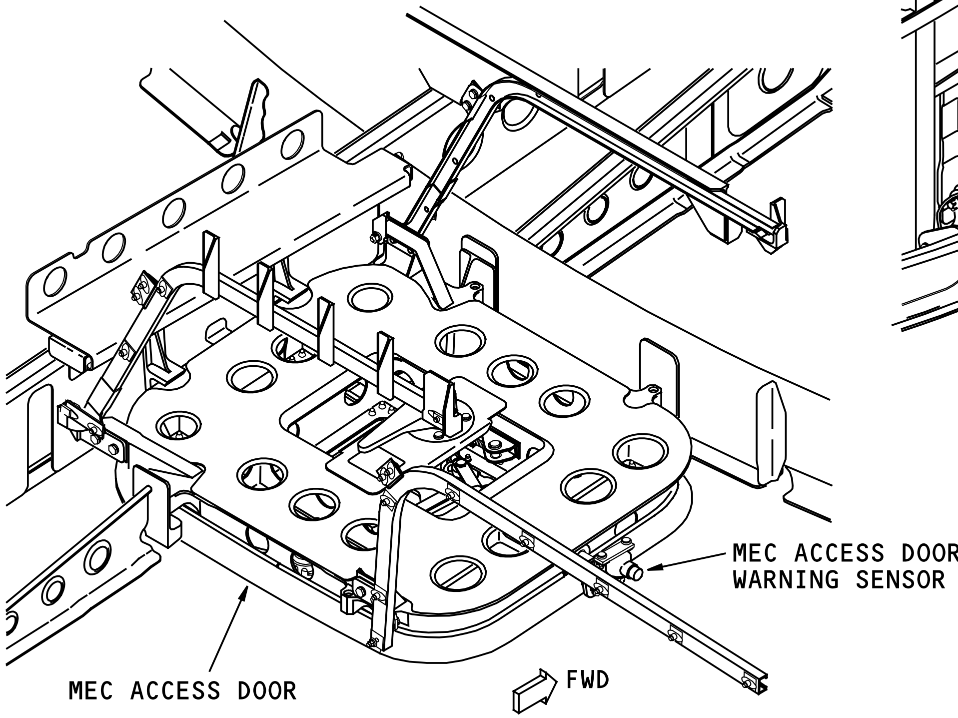
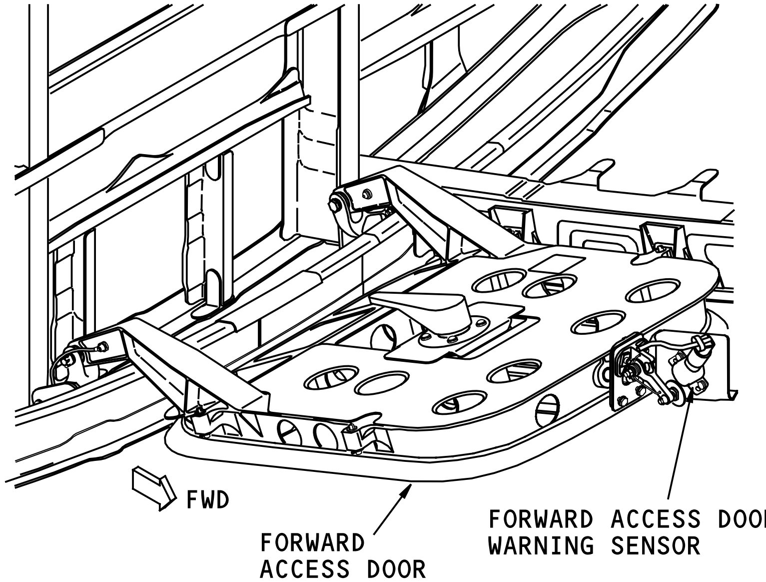
Location of Main Equipment Center (MEC) Access Door Warning Sensors

The electrical/electronics access door proximity sensor that supplies door status information is adjacent to the door latch in the cutout.





52-71-00-005 Rev 1

DOOR WARNING SYSTEM - ACCESS DOOR SENSORS

DOOR WARNING SYSTEM - FUNCTIONAL DESCRIPTION

Functional Description

These components give door status information to the PSEU:

- A switch on the bulk cargo door
- Proximity sensors on all of the other doors that go through the pressurized structure of the airplane.

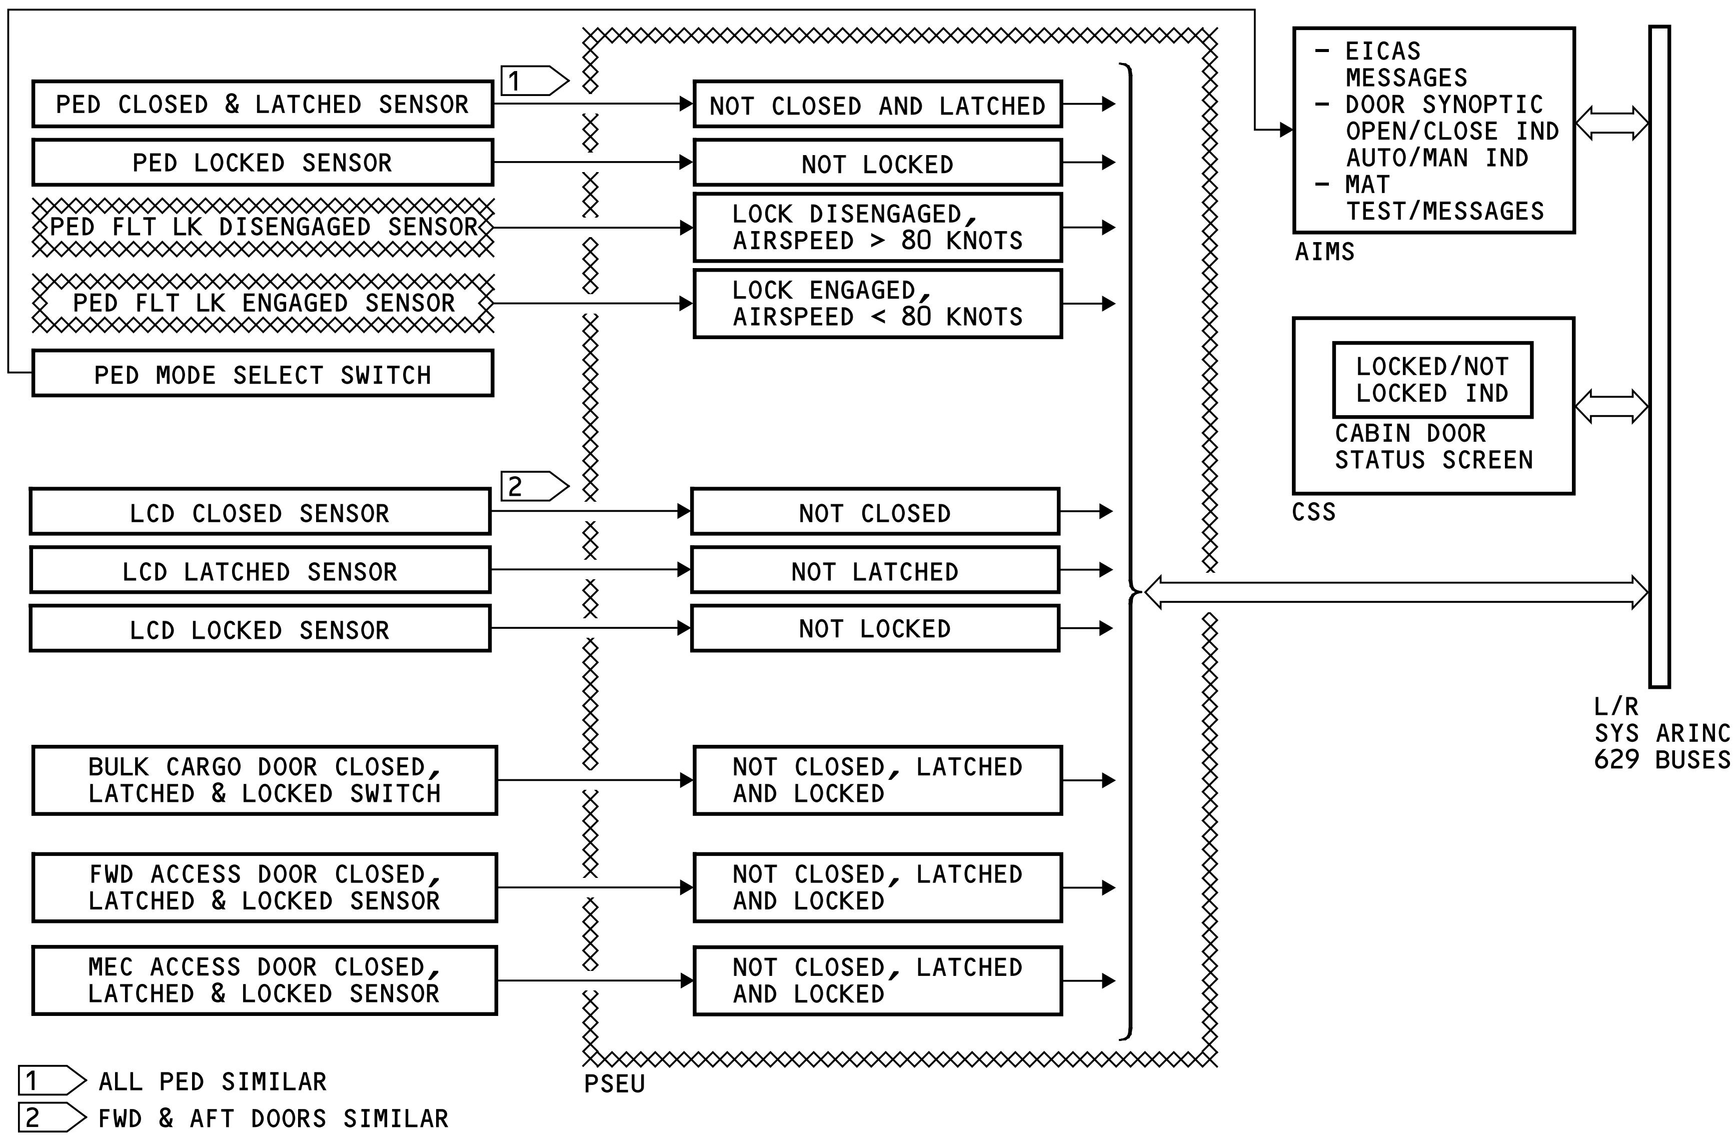
The PSEU monitors information about door positions and about the sensors/switches used to monitor door positions. The PSEU sends the information to the AIMS through the left and right ARINC 629 buses.

AIMS shows the information on these displays:

- EICAS
- STATUS
- DOOR SYNOPTIC
- MAT.

The AIMS supplies passenger entry door information from the PSEU to the cabin services system (CSS). The CSS shows door LOCKED/NOT LOCKED information on the cabin door status screen.

The passenger entry door mode select switch sends auto/manual position information directly to the AIMS. AIMS shows the position information on the door synoptic display.



DOOR WARNING SYSTEM - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

DOOR WARNING SYSTEM - INDICATIONS

General

The following displays show door indications:

- EICAS
- Door synoptic
- Status
- MAT.

EICAS Display

The following door information shows on the EICAS display:

- Configuration warning
- Caution
- Advisory
- Memo.

A configuration warning shows if an engine is put at takeoff power with one or more of these doors not in the closed, latched, and locked position.:

- Passenger entry
- Forward cargo
- Aft cargo.

Caution or advisory messages show for each door that is not in the closed, latched, and locked position. The large cargo door has a caution message. The other doors have advisory messages. For the doors that have advisory messages, a single message will show when these conditions are true:

- The airplane is on the ground
- Both engines are off
- More than one of the doors are not closed, latched and locked.

Memo messages show this passenger entry door mode information:

- AUTO when all of the doors are in the auto mode
- MANUAL when all of the doors are in the manual mode
- AUTO/MANUAL when some of the doors are in the auto mode and some are in the manual mode.

These memo messages do not show from the time takeoff power is applied to one minute after landing.

Door Synoptic Display

The door synoptic display shows the status of these doors:

- Equipment center access doors
- Passenger entry doors
- Cargo compartment doors.

The names of the doors always show. An amber door symbol shows when a door is not closed, latched, and locked. The symbol does not show when a door is closed, latched, and locked. Invalid sensor information shows as a white door symbol outline.

DOOR WARNING SYSTEM - INDICATIONS

When a passenger entry door is closed, latched, and locked, these letters (in color) show the position of the mode select handle:

- A - auto (green)
- M - manual (white).

Status and MAT Displays

DOOR WARNING SYSTEM - INDICATIONS

DOOR WARNING SYSTEM - INDICATIONS - CSCP/CACP - CABIN DOOR STATUS SCREEN

General

Attendants use the cabin door status screen to see if the doors are locked or not locked.

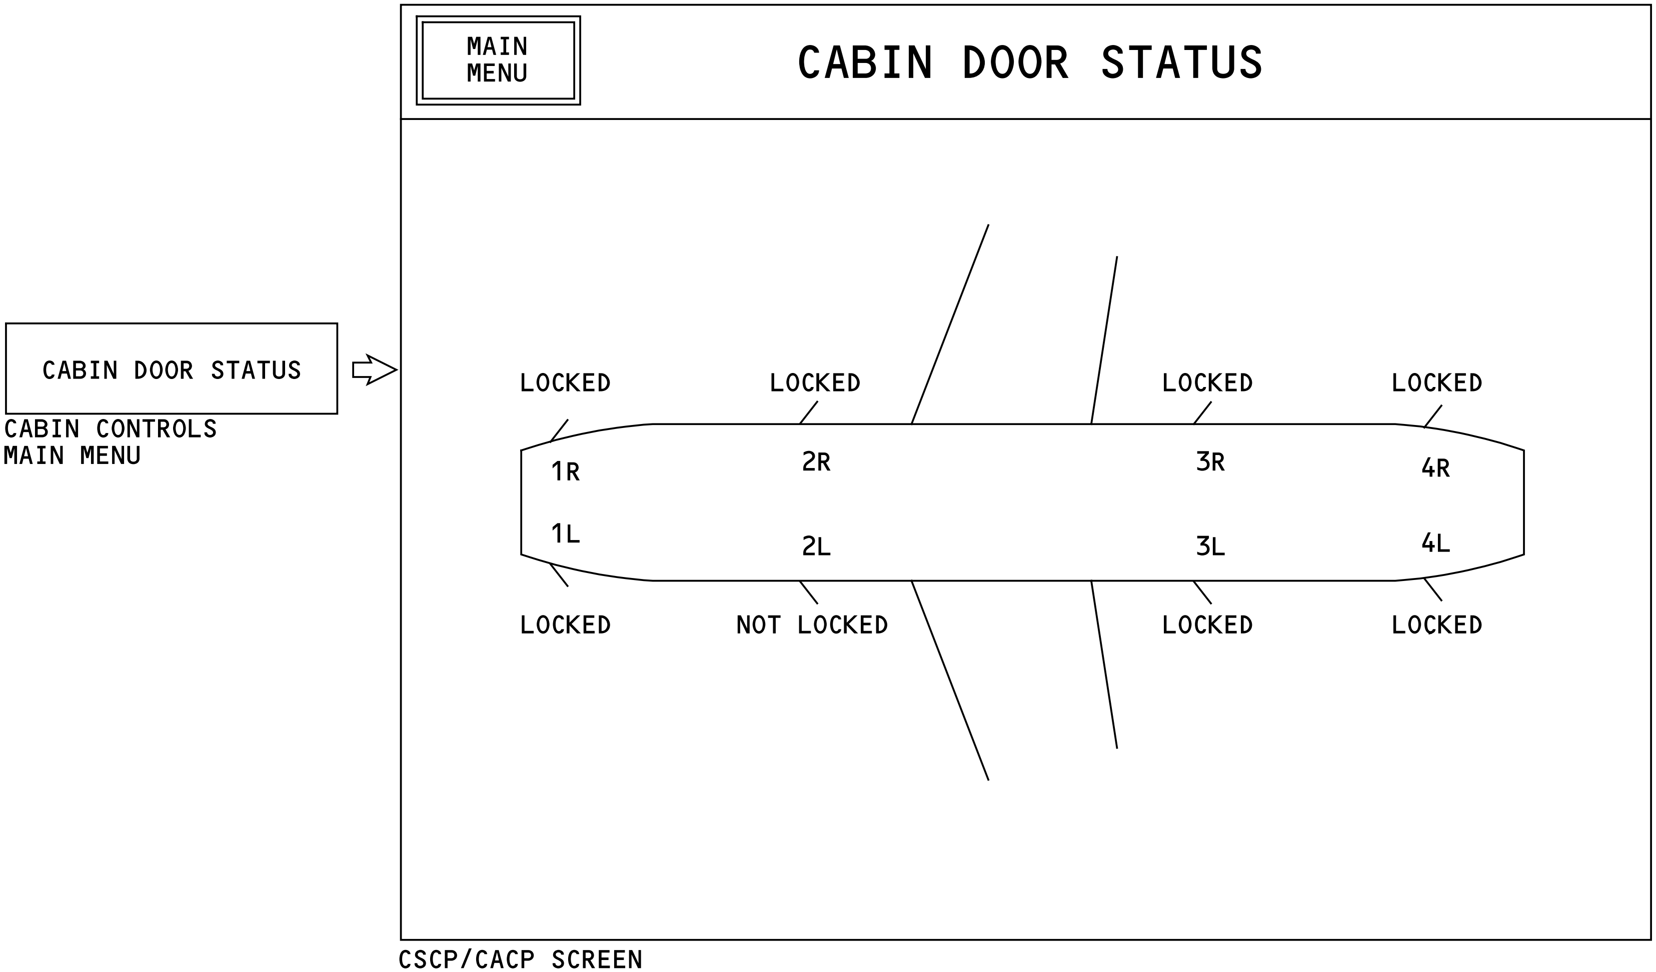
Access

You use the cabin system control panel (CSCP) or cabin area control panels (CACP) to get the status of the cabin doors. Touch CABIN DOOR STATUS on the cabin controls main menu to show this screen.

Indications

The cabin door status screen shows (in color) the status of the cabin doors:

- LOCKED (green)
- NOT LOCKED (red).



52-71-00-008 Rev 2 07/31/1997

TABLE OF CONTENTS

WINDOWS - INTRODUCTION

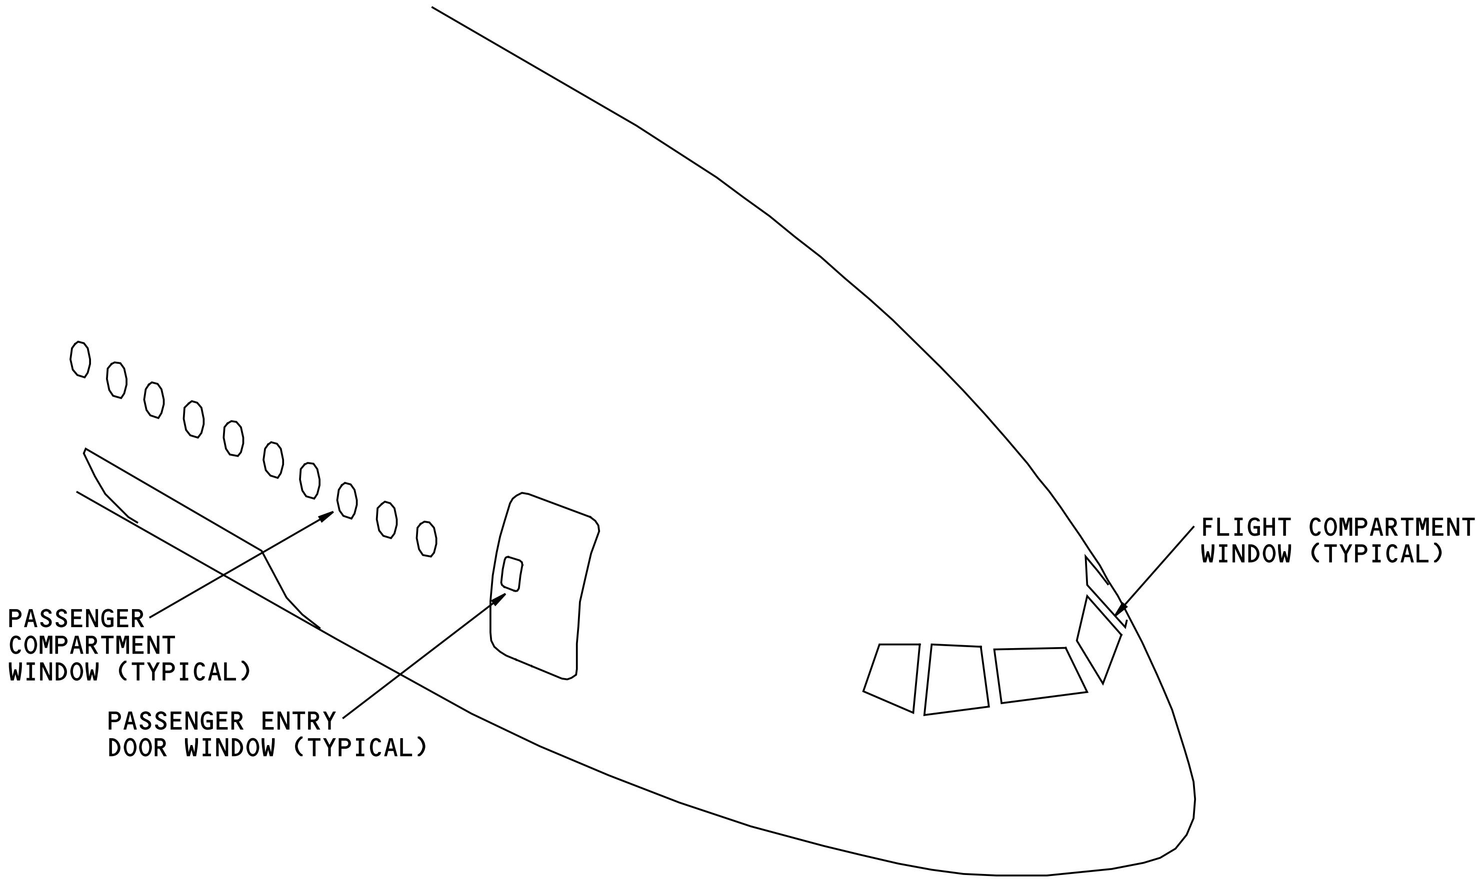
THIS PAGE INTENTIONALLY LEFT BLANK

WINDOWS - INTRODUCTION

Location

Windows are in these locations:

- Passenger compartment (126)
- Passenger entry doors (8)
- Flight compartment (6).



56-00-00-001 Rev 1 03/26/96

WINDOWS - INTRODUCTION

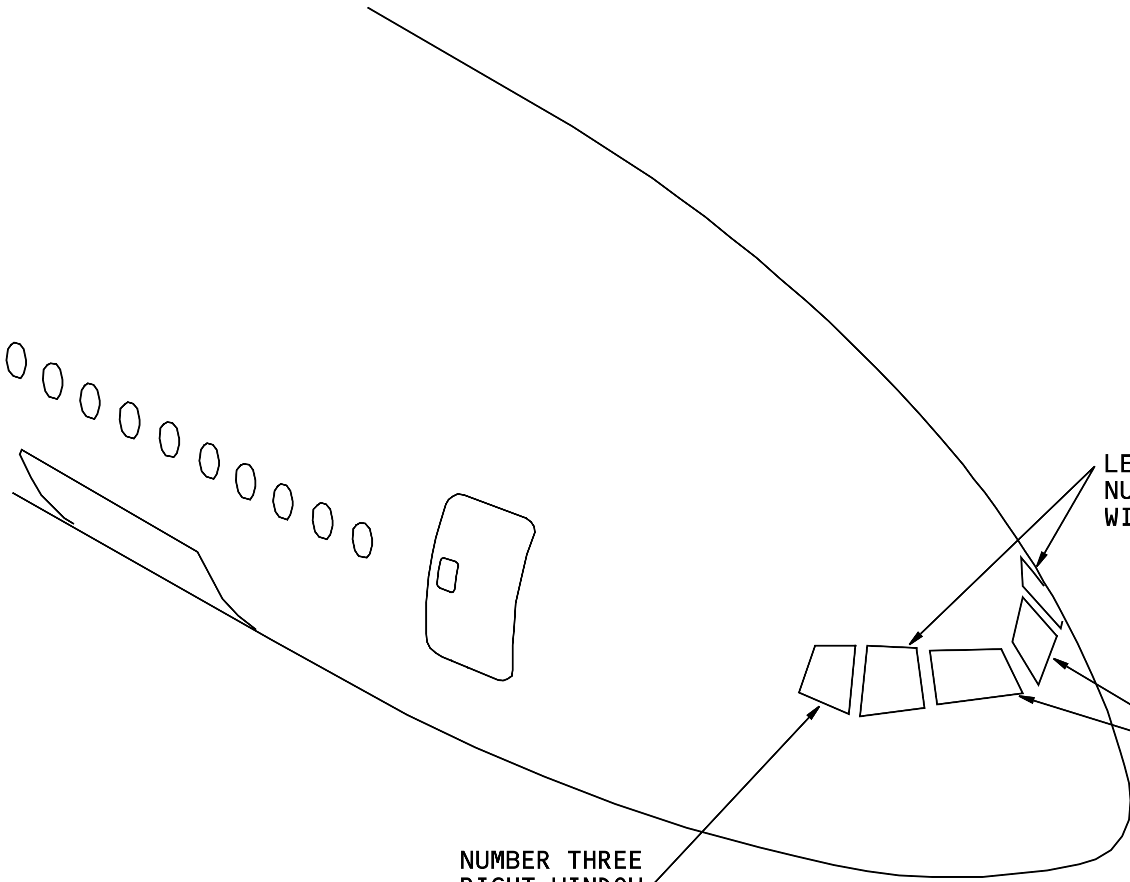
WINDOWS - FLIGHT COMPARTMENT WINDOWS - INTRODUCTION

Location

The left and right number one windows are in front of the captain and the first officer. The number two and three windows are aft of the number one windows.

Interface With Other Systems

The flight compartment windows get electric power from the window anti-ice system. See the flight deck window anti-ice section for more information (AMM PART I 30-41).



56-11-00-001 Rev 2

WINDOWS - FLIGHT COMPARTMENT WINDOWS - INTRODUCTION

Physical Description

Each number three window is a lamination of glass, plastic, and an anti-fog heating film. The external and internal window surfaces are glass.

Each number one window is a lamination of glass, plastic, anti-ice heating film, and anti-fog heating film. The external and internal window surfaces are glass. The external surface has a rain protection hydrophobic coating.

The windows have retainer rings, moisture seals, and pressure seals. Sealant holds the rings, seals, and window together as an assembly.

Screws go through the rings to attach the assembly to the airplane structure.

There are temperature sensors for the heating films. The heating film and sensors have electrical terminals. The bus bar connects the electric terminals for heat to the heating film.

The number three window has these terminals:

- Two sensor
- Two anti-fog electric.

The number one window has these terminals:

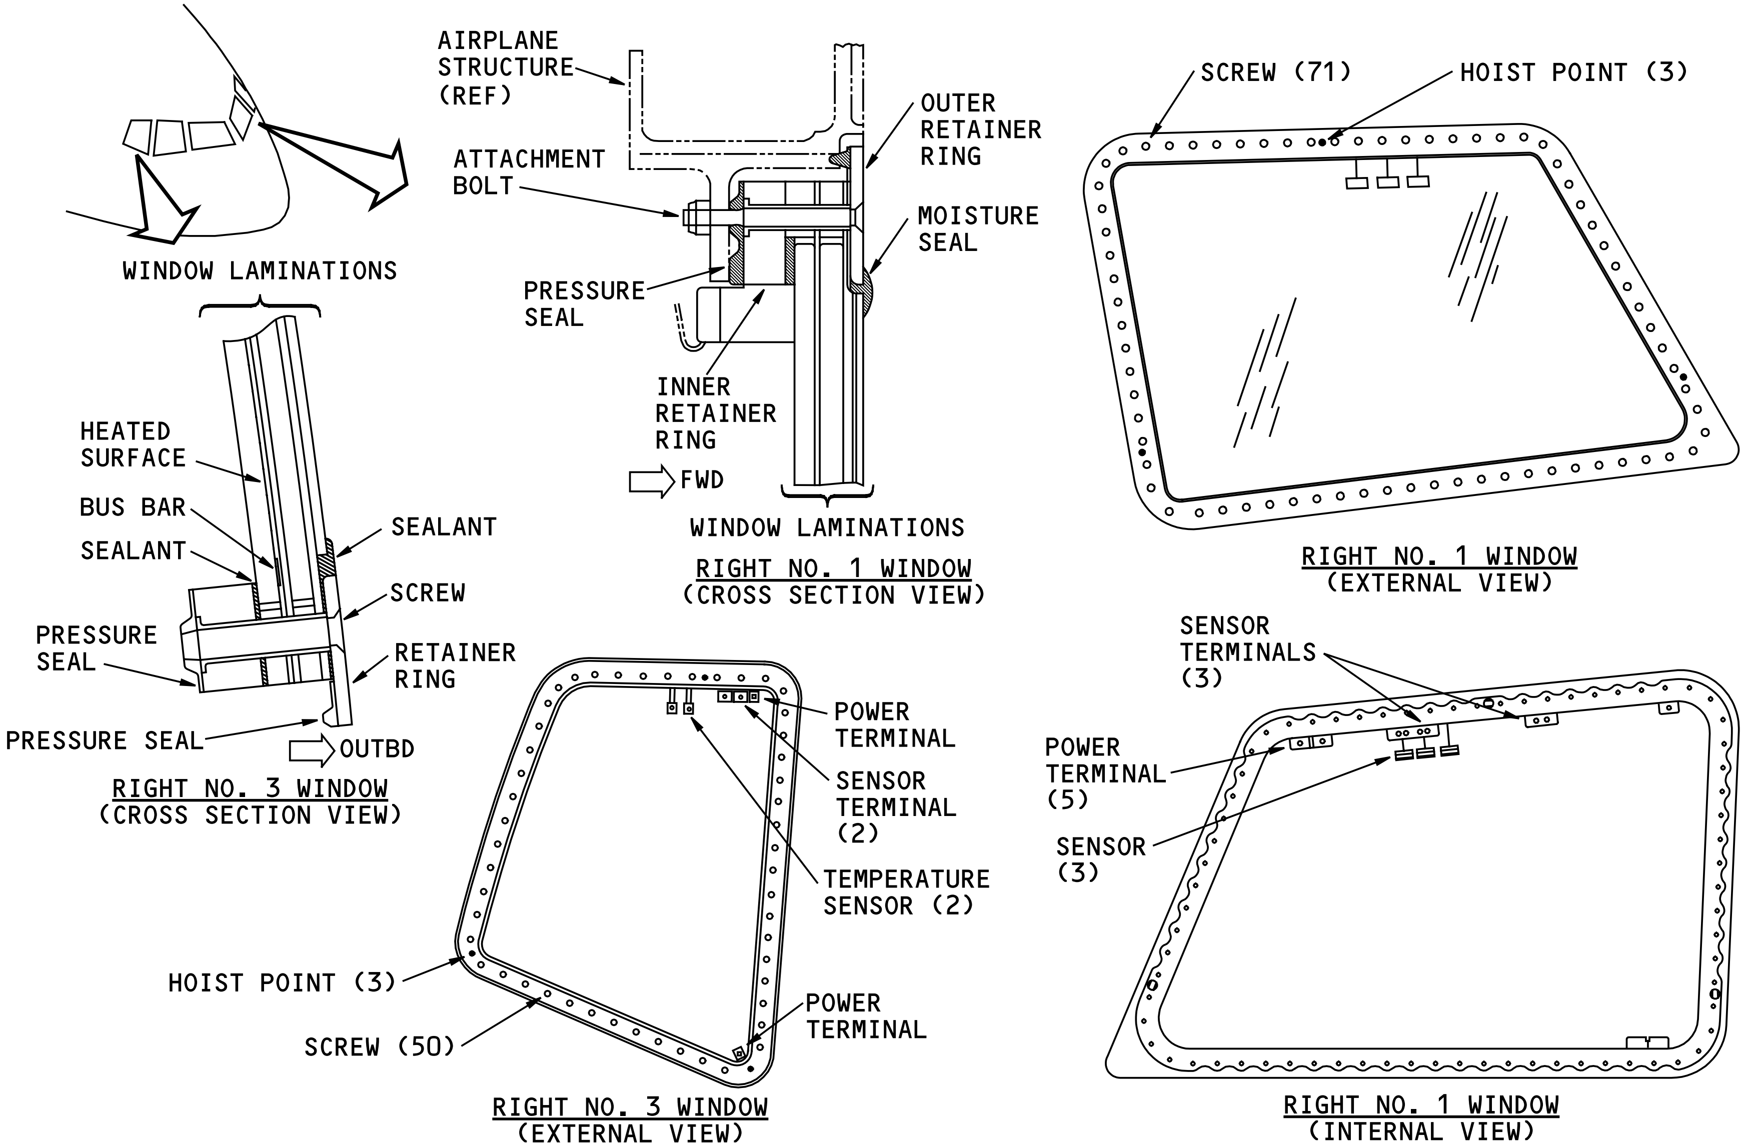
- Three sensor
- Three anti-ice electric power
- Two anti-fog electric.

Training Information Point

There are three hoist points to lift each number three and number one window for removal and installation.

Use proper methods when you clean the windows to prevent damage. On the external surface use an isopropanol and water mixture. On the internal surface use a mild soap and water mixture or an isopropanol and water mixture.

You can put a new hydrophobic coating on the number one windows on the airplane.



WINDOWS - FLIGHT COMPARTMENT WINDOWS - NUMBER ONE AND NUMBER THREE WINDOWS

WINDOWS - FLIGHT COMPARTMENT WINDOWS - NUMBER TWO OPENABLE WINDOW - INTRODUCTION

Purpose

The number two openable windows give emergency escape routing.

Physical Description

Each number two openable window has operating and latching mechanisms.

The operating mechanism has:

- Upper and lower tracks
- Drive cable
- Operating handle
- Drive screw (not shown) in lower aft track
- Rollers
- Carriage
- Link arm
- Torque tube.

The latching mechanism has:

- Latch handle
- Teleflex cable
- Latches.

There is an alert switch at the top of the window. It operates with a cam that attaches to the top latch.

The window is a lamination of glass, plastic, and an anti-fog heating film. The external and internal window surfaces are glass. The window has electrical terminals for the heating film and for heat control sensors. The bus bar connects the electric terminals for heat to the heating film. Coiled electrical wire connects the window terminals to terminals on the airplane.

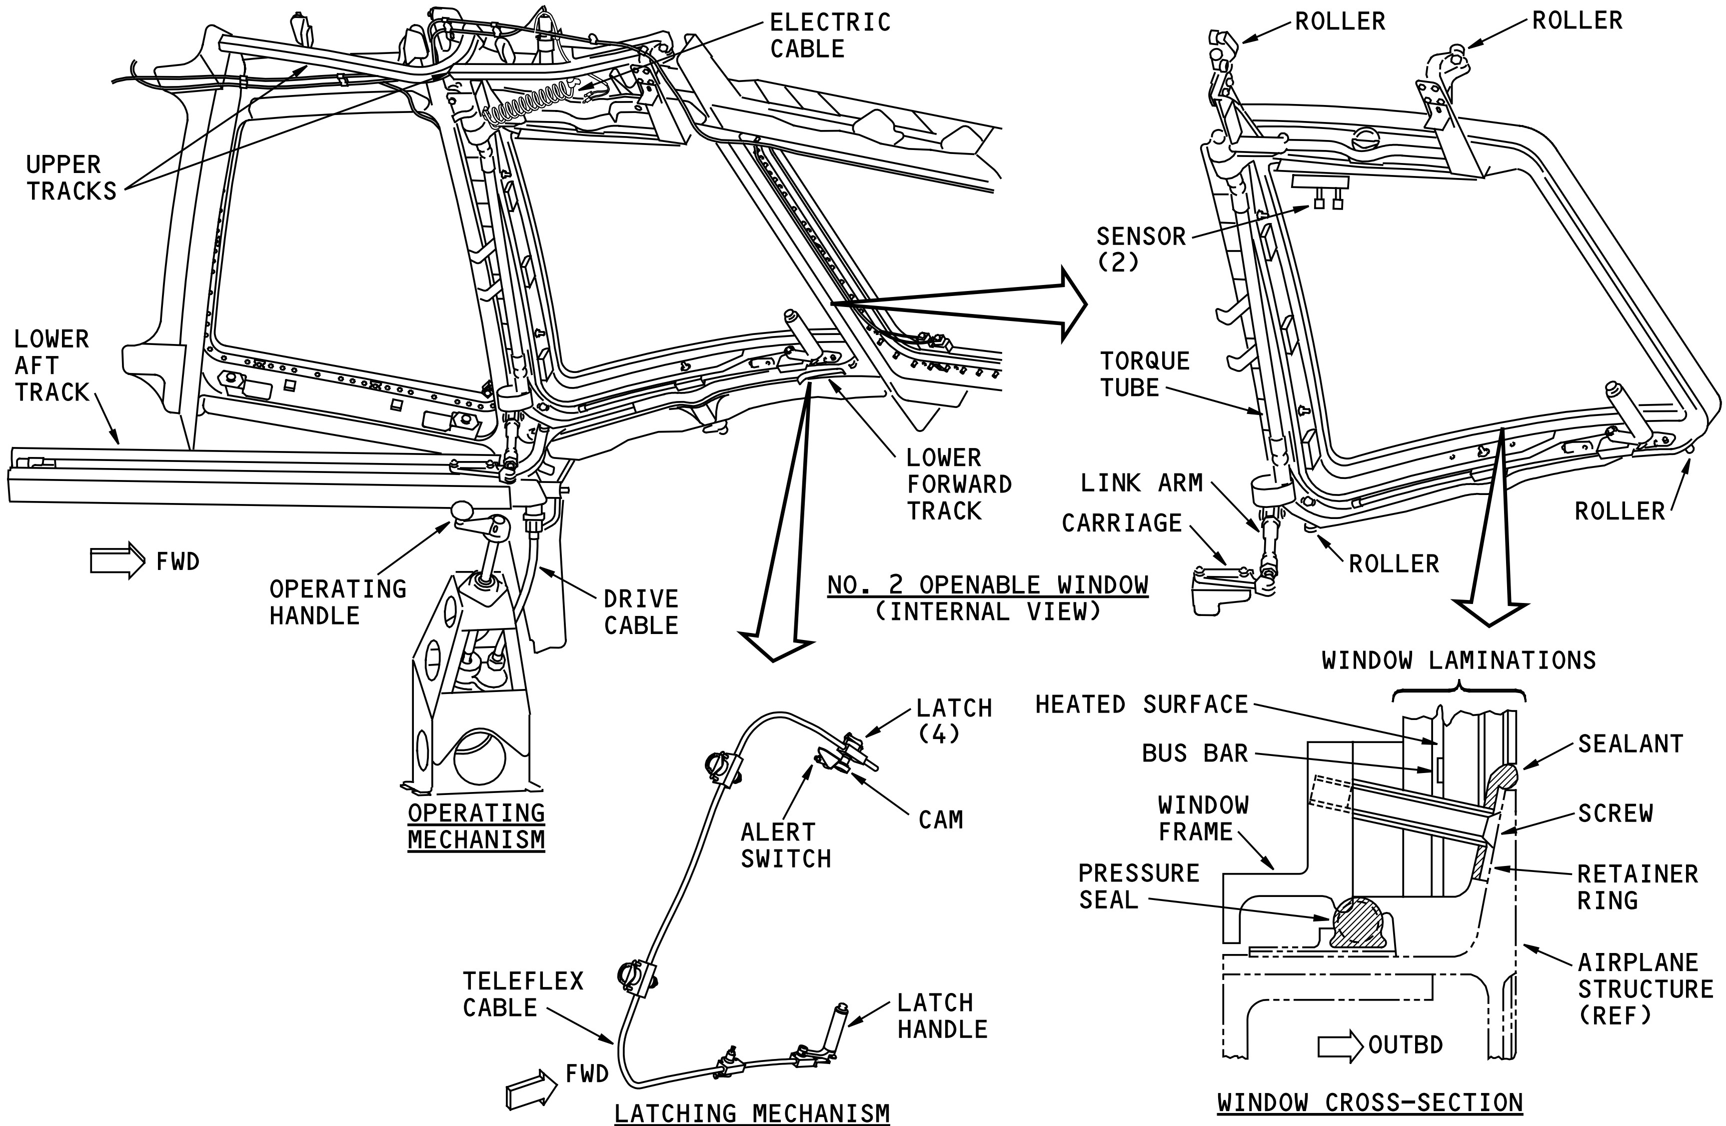
There is a retainer ring, sealant, and frame. Screws go through the ring and lamination, and into the frame to hold them together as an assembly.

The silicone bulb pressure seal between the window frame and fuselage attaches to the fuselage.

Training Information Point

Use proper methods when you clean the windows to prevent damage. Use a mild soap and water mixture or an isopropanol and water mixture.

Do not touch the silicone bulb pressure seal when you have the window open for maintenance activities. This can damage the seal and cause air leaks.



56-11-00-003 Rev 4 03/26/96

WINDOWS - FLIGHT COMPARTMENT WINDOWS - NUMBER TWO OPENABLE WINDOW - INTRODUCTION

WINDOWS - FLIGHT COMPARTMENT WINDOWS - NUMBER TWO OPENABLE WINDOW - ALERT SWITCH

Purpose

The alert switch supplies window status to the flight crew.

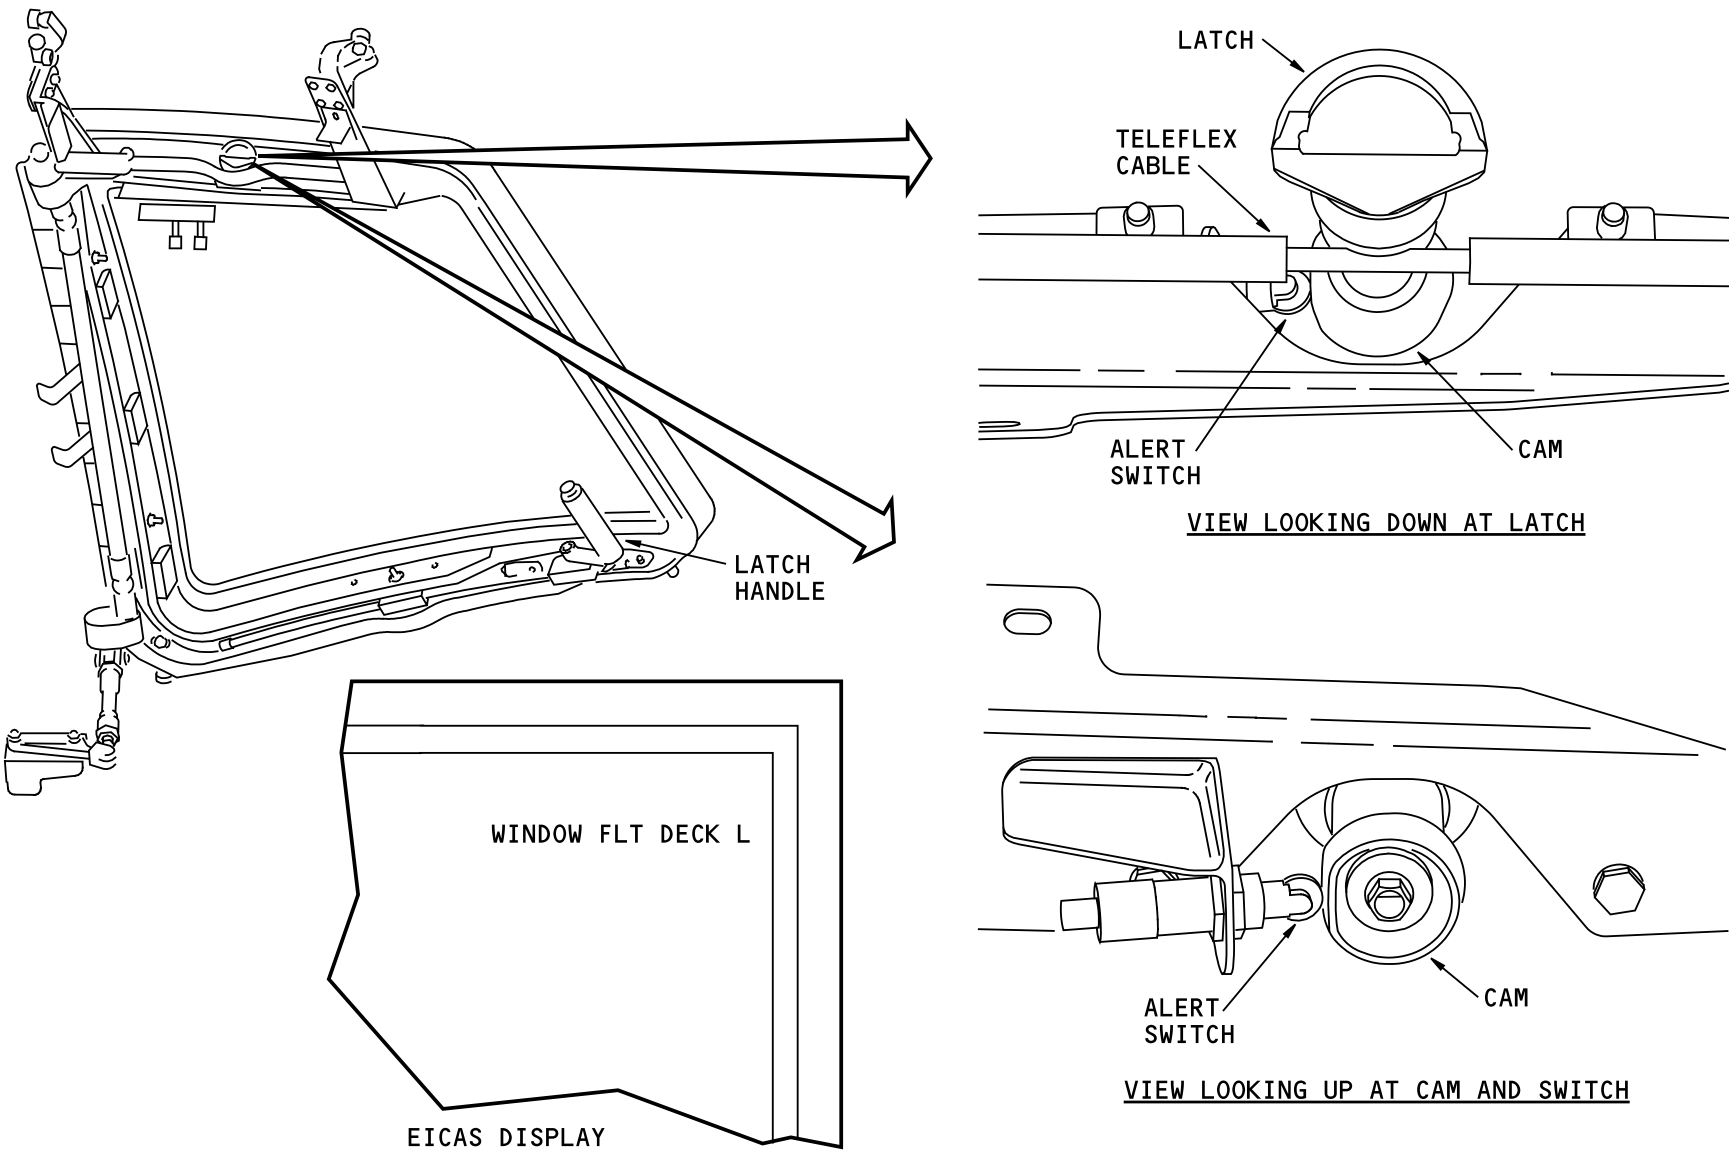
Physical Description

The switch is a plunger type that attaches to the window frame below the top window latch. The switch is adjacent to a cam that attaches to the upper latch.

Functional Description

Movement of the latch handle out of the latched position causes the teleflex cable to turn the latch and cam. The cam pushes the switch plunger in to close the switch.

When the switch closes, the WINDOW FLT DECK L(R) advisory message shows.



56-11-00-007 Rev 1 03/27/96

WINDOWS - FLIGHT COMPARTMENT WINDOWS - NUMBER TWO OPENABLE WINDOW - ALERT SWITCH

WINDOWS - FLIGHT COMPARTMENT WINDOWS - NUMBER TWO OPENABLE WINDOW - OPERATION

Unlatch/Latch Operation

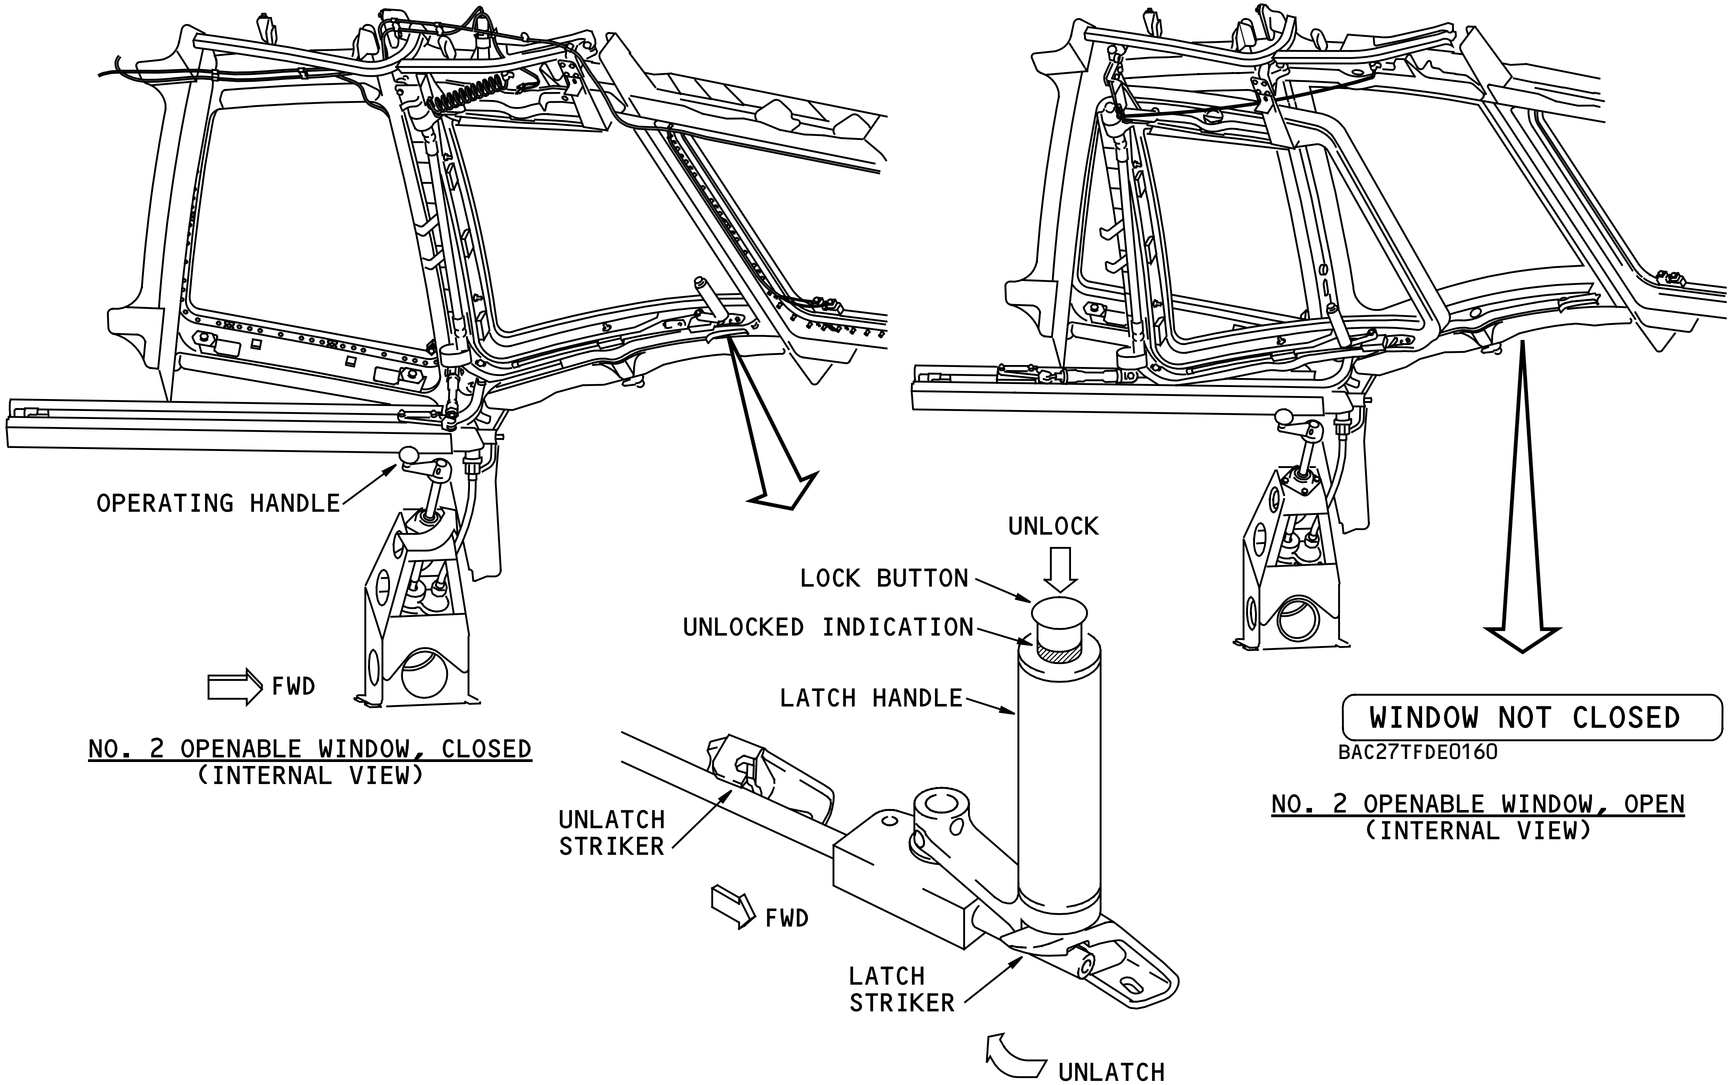
Push down on the latching handle lock button until the handle releases from the latch striker. Move the handle inboard and aft until it locks in the unlatch striker.

Reverse these operations to latch the window. The window is latched and the latching handle is locked when you cannot see the yellow indication stripe on the latch handle release.

Open/Close Operation

Turn the window operating handle to open the window. The left window handle turns counterclockwise. The right window handle turns clockwise.

Reverse these operations to close the window. The window is not closed if you see the WINDOW NOT CLOSED decal.



56-11-00-004 Rev 1

WINDOWS - FLIGHT COMPARTMENT WINDOWS - NUMBER TWO OPENABLE WINDOW - OPERATION

WINDOWS - NUMBER TWO OPENABLE WINDOW - FUNCTIONAL DESCRIPTION - CLOSE/OPEN

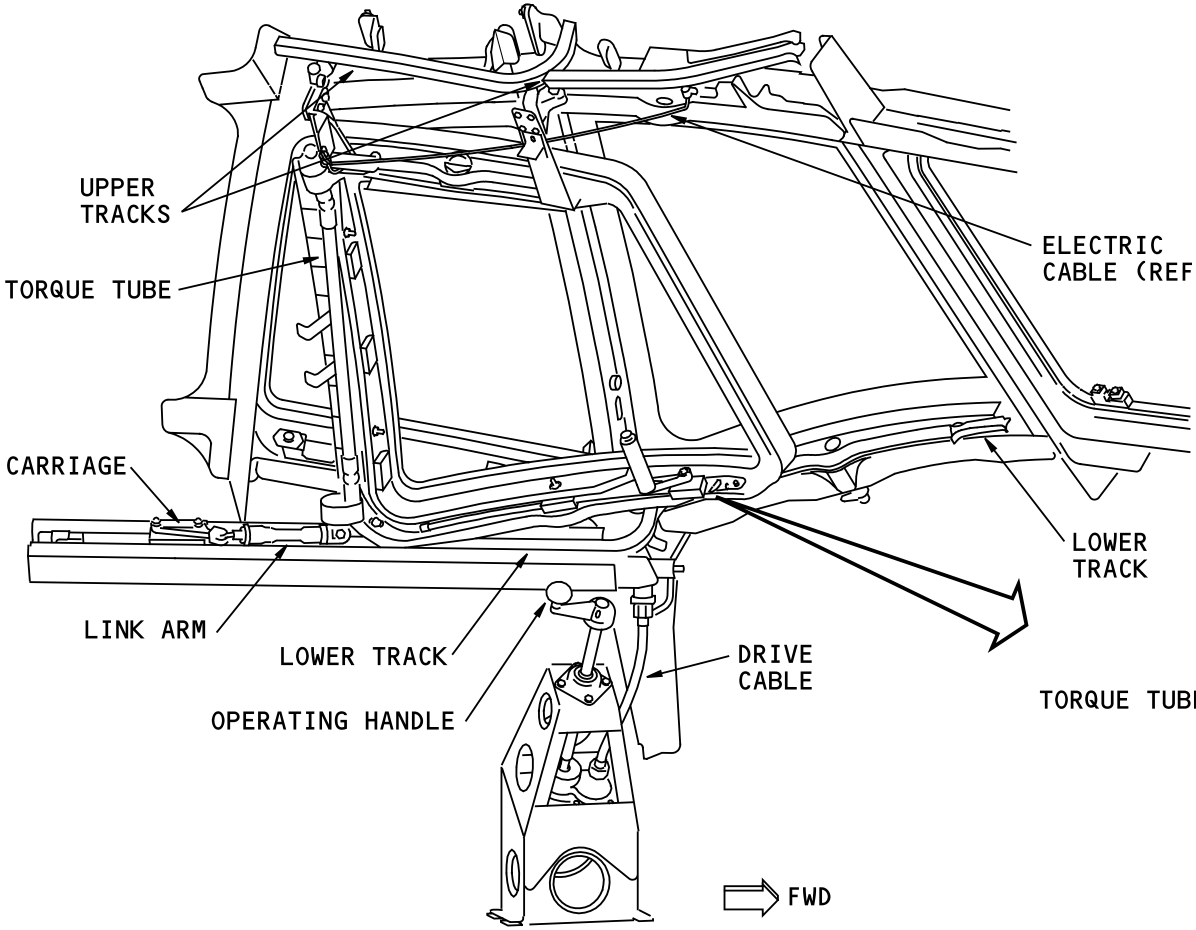
Close Functional Description

Clockwise rotation of the operating handle goes through the drive cable to the ball screw (not shown) in the lower latch track. The ball screw rotates. The carriage moves forward on the screw. The carriage pushes on the link arm. The link arm pushes on the torque tube on the window. The window moves forward on its rollers in the tracks.

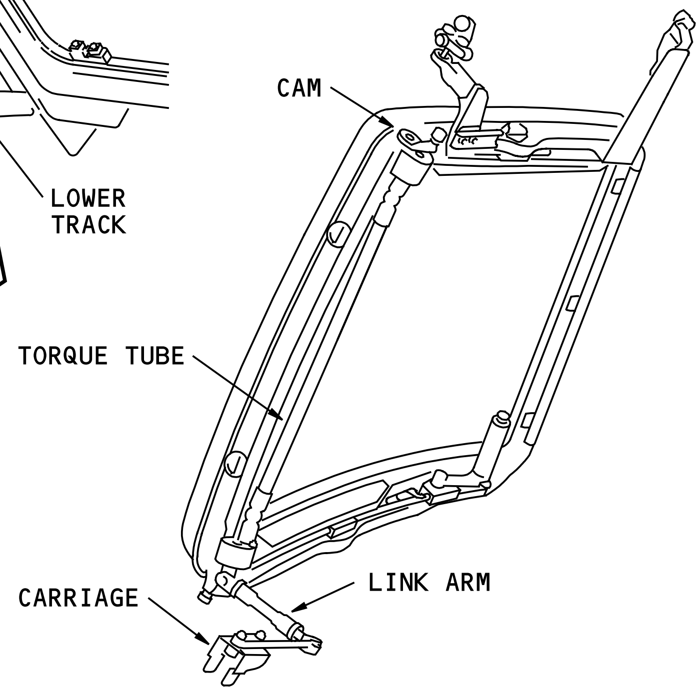
When the rollers gets to the curves in the tracks, the window moves outboard. The carriage and link arm push the bottom of the window to the completely closed position and turn the torque tube. A cam on the top of the torque tube push the top of the window outboard to the completely closed position.

Open Functional Description

Component movement to open the window is the reverse of the movement to close the window.



NO. 2 OPENABLE WINDOW
(INTERNAL VIEW)



VIEW OF WINDOW WITH MECHANISMS
IN CLOSED POSITION

56-11-00-005 Rev 0

WINDOWS - NUMBER TWO OPENABLE WINDOW - FUNCTIONAL DESCRIPTION - CLOSE/OPEN

WINDOWS - NUMBER TWO OPENABLE WINDOW - FUNCTIONAL DESCRIPTION - LATCH/UNLATCH

Latch Functional Description

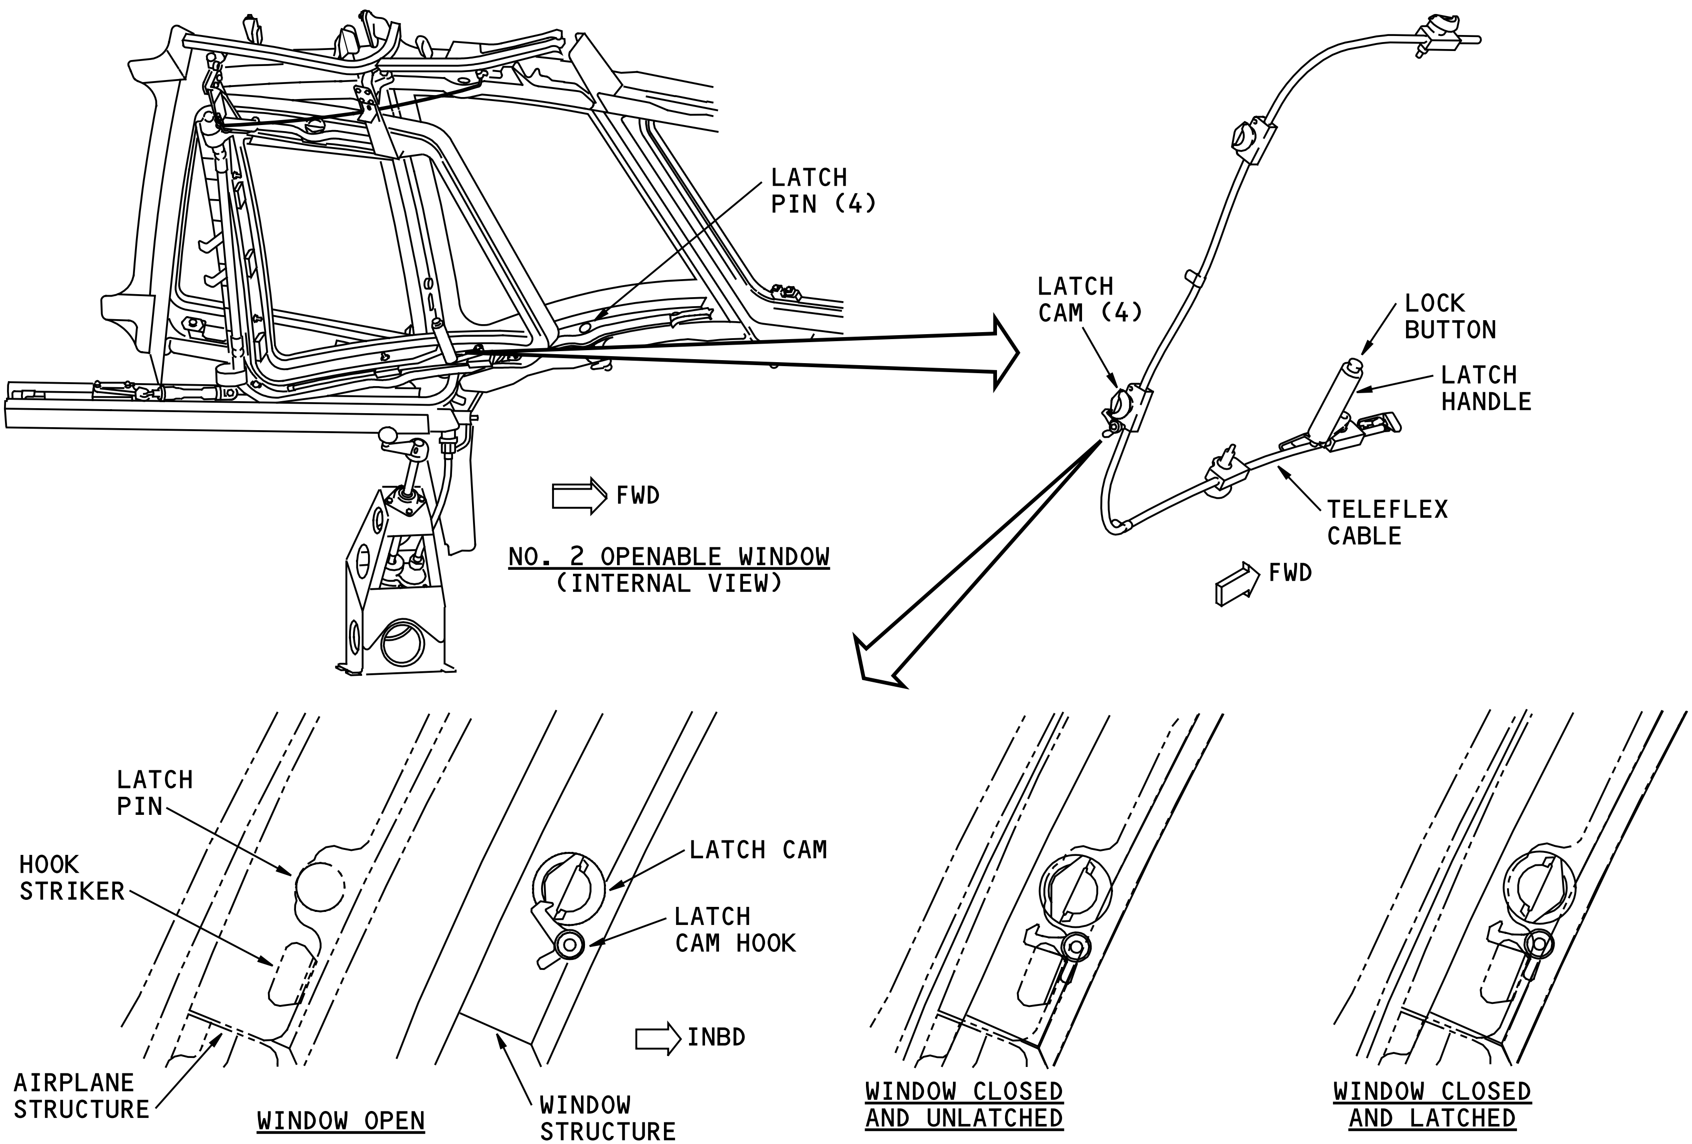
Four latch pins are on the airplane structure around the window opening. One is on the top, two are on the aft side, and one is on the bottom. The latch cams on the window use these latch pins to latch the window.

When the window is not completely closed, the spring-loaded latch cam hook will not let the latch cam turn. When the window moves to the closed position, the hook striker on the airplane structure moves the latch cam hook. The latch cam is free to turn.

Downward movement of the lock button on the latching handle releases the handle from the handle unlatched striker. Forward movement of the handle causes the teleflex cable to turn the latch cams to a position outboard of the latch pins. The window cannot move inboard. It is latched. The latch striker holds the latch handle.

Unlatch Functional Description

Component movement to unlatch the window is the reverse of the movement to latch the window.



56-11-00-006 Rev 0

WINDOWS - NUMBER TWO OPENABLE WINDOW - FUNCTIONAL DESCRIPTION - LATCH/UNLATCH

WINDOWS - PASSENGER COMPARTMENT WINDOWS

Location

There are passenger compartment windows along both sides of the passenger compartment.

Physical Description

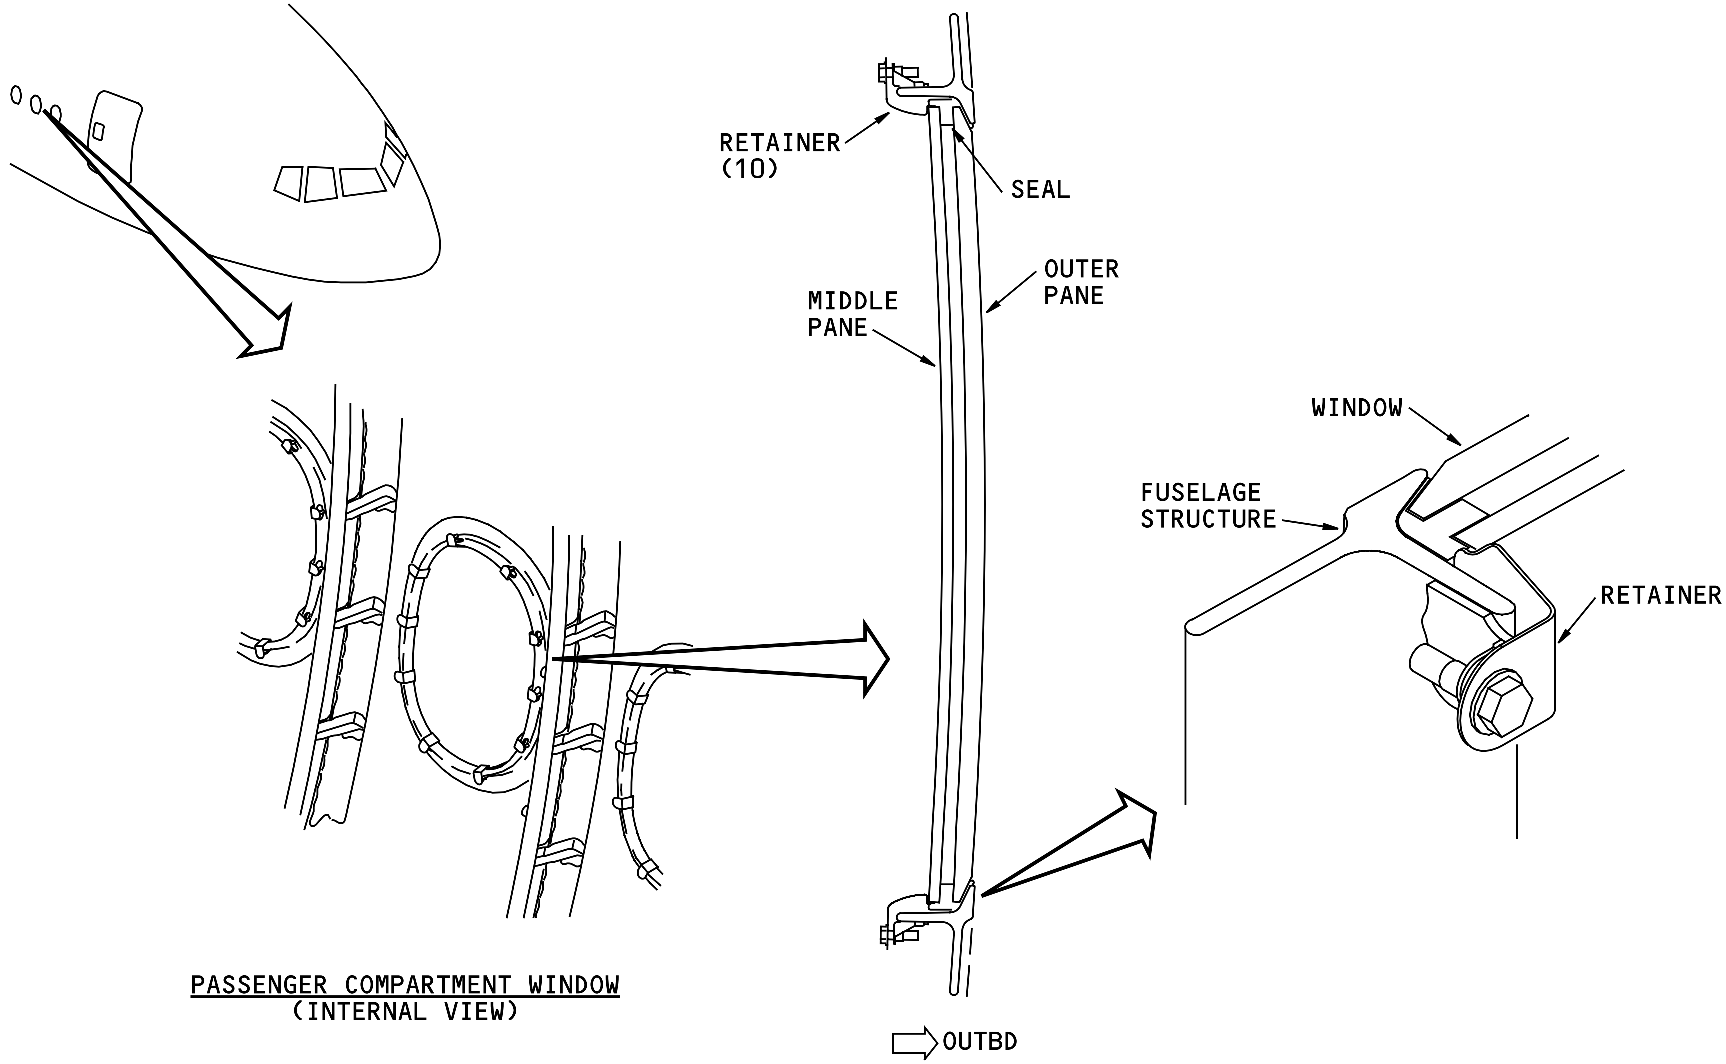
Each window has a plastic middle and outer pane. A seal holds the panes together in an assembly. Retainers hold the assembly to the fuselage.

The inner pane (not shown) is part of the passenger compartment sidewall lining. See the passenger compartment section for more information (AMM PART I 25-20).

Training Information Point

There are retainers with different grip lengths. The grip length depends on the location of the window in the fuselage. The retainers are a different color for each grip length.

Use proper methods when you clean the windows to prevent damage. Use a mild soap and water mixture or an isopropanol and water mixture.



PASSENGER COMPARTMENT WINDOW
(INTERNAL VIEW)

56-21-00-001 Rev 3 10/08/1996

WINDOWS - PASSENGER COMPARTMENT WINDOWS

WINDOWS - DOOR-MOUNTED WINDOWS

Purpose

The door-mounted windows let the cabin attendants see if the space outside the door is clear to open the door.

Location

There is a window in each of the passenger entry doors.

Physical Description

Each window has a plastic outer and a middle pane. A seal holds the panes together in an assembly. Retainers hold the assembly to the door.

The inner pane (not shown) is part of the door lining.

The retainers for the passenger entry door windows are all the same grip length and color.

Training Information Point

Use proper methods when you clean the windows to prevent damage. Use a mild soap and water mixture or an isopropanol and water mixture.

CARGO HANDLING SYSTEM - INTRODUCTION

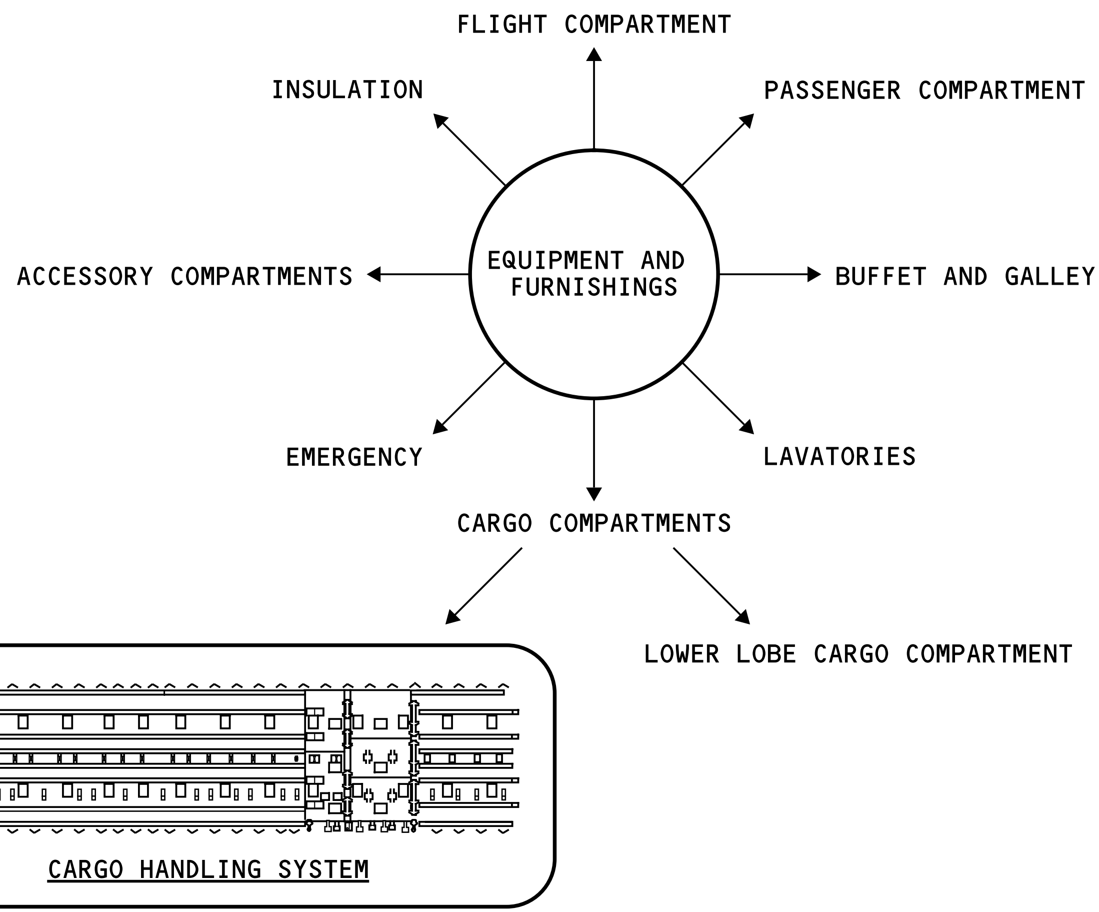
General

The cargo handling system lets a single operator safely load, unload, and lock cargo.

Cargo handling is a subsystem of equipment and furnishings.

Abbreviations and Acronyms

aux	- auxiliary
cmd	- command
CSC	- cargo system controller
ctr	- center
fwd	- forward
LBL	- left buttock line
LCD	- large cargo door
LD	- load device
LED	- light emitting diode
LRU	- line replaceable unit
MEC	- main equipment center
PSEU	- proximity sensor electronics unit
PDU	- powered drive unit
ref	- reference
ret	- retractable
RBL	- right buttock line
sta	- station line
typ	- typical
ULD	- unit load device



CARGO HANDLING SYSTEM - INTRODUCTION

CARGO HANDLING SYSTEM - GENERAL DESCRIPTION - INTRODUCTION

General

The forward and aft cargo compartments each have cargo handling systems. Operation of the two systems is similar. Both systems use electrically and manually operated components. The bulk cargo compartment does not have a cargo handling system.

Controls

The controls for the forward and aft cargo handling systems are similar. The controls are near the forward part of the cargo door openings. You operate and set the forward or aft cargo handling systems using these interior and exterior controls:

- Secondary joystick
- Cargo control joystick
- Cargo handling control panel.

The cargo system controller (CSC) uses inputs from the interior and exterior controls to position the electrically operated system components. The controller does not affect manually operated components.

The cargo handling accessory panels have system power relays and circuit breakers.

You can manually operate the components that are normally electrically operated if electrical power is not available.

Unit Load Devices

The cargo handling system lets the airplane carry different sizes of unit load devices (ULDs). The airplane can carry containers with profiles matching these sizes:

- LD-1
- LD-2
- LD-3
- LD-4
- LD-5
- LD-6
- LD-7
- LD-8
- LD-10
- LD-11.

Pallets matching these sizes can also be carried:

- A
- K
- L
- M
- N.

CARGO HANDLING SYSTEM - GENERAL DESCRIPTION - INTRODUCTION

CARGO HANDLING SYSTEM - FWD CARGO ELECTRICAL/MECHANICAL COMPONENT LOCATIONS

General

The forward cargo handling system has electrical/mechanical components that let you load and unload ULDs.

These are the electrical/mechanical components:

- Powered drive units (PDUs)
- Lateral guides.

You may operate the lateral guides manually.

Location

PDUs are in all areas of the cargo compartment.

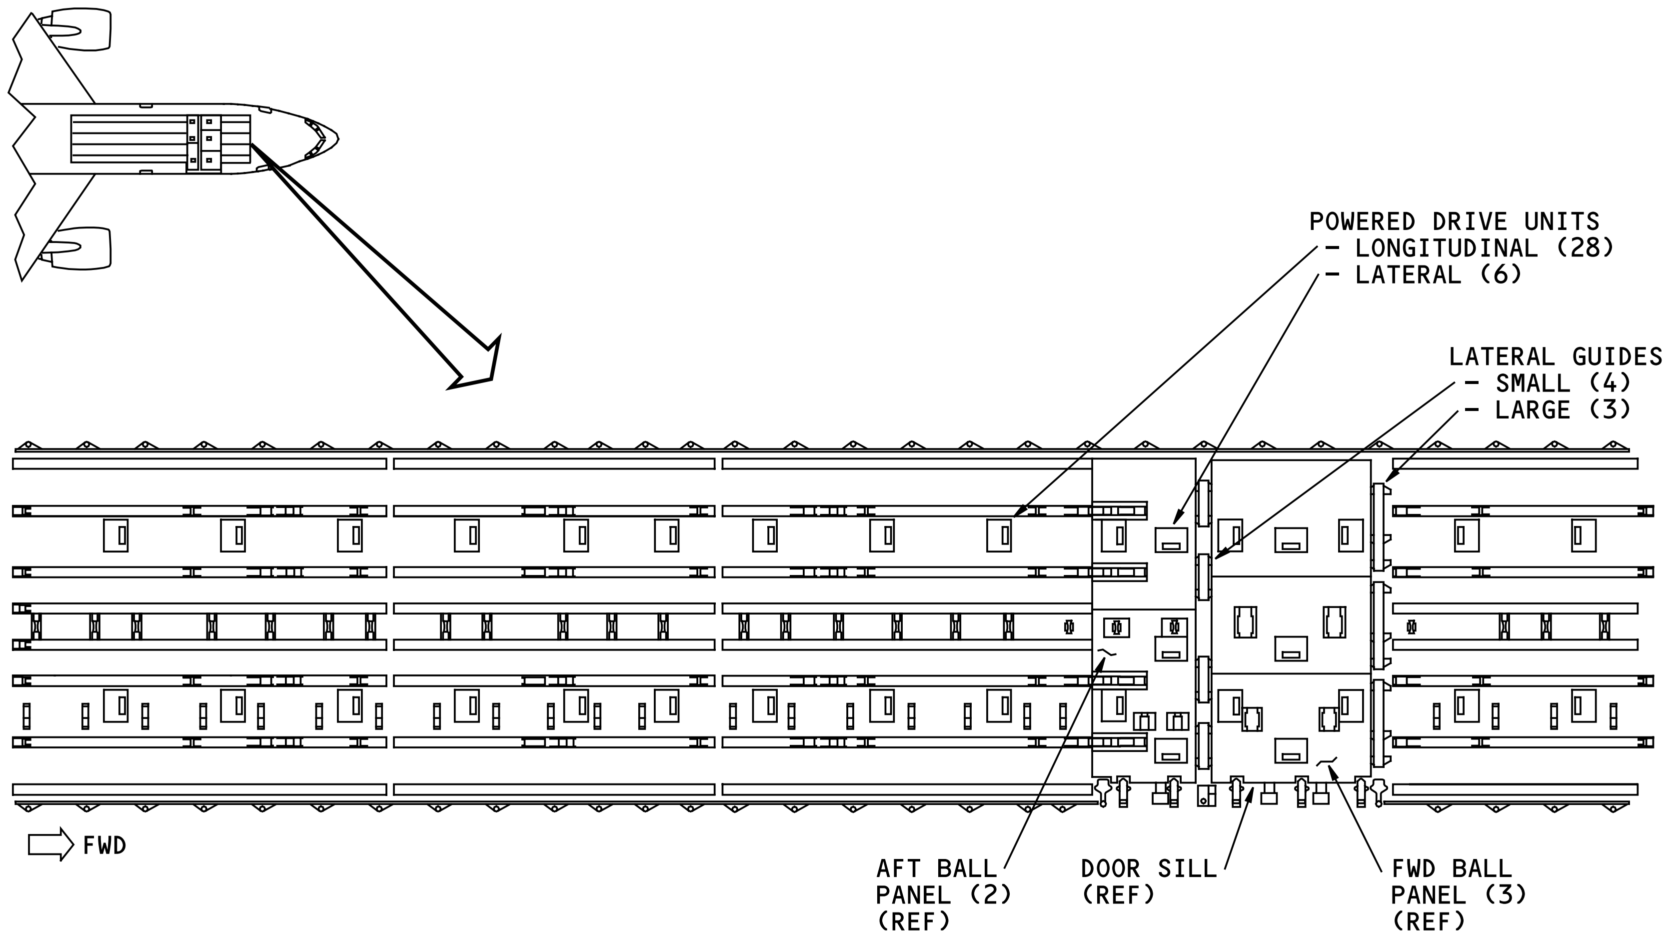
Lateral PDUs are in the same area as the ball panels. There are two rows of lateral PDUs. Each row has three PDUs.

Longitudinal PDUs are on the left and right sides of the compartment in rows. There are fourteen rows of longitudinal PDUs. Each row has two PDUs.

Lateral guides are in the ball panel area of the cargo compartment.

Small lateral guides are between the forward and aft ball panels.

Large lateral guides are forward of the forward ball panels.



FORWARD CARGO HANDLING SYSTEM

THIS PAGE INTENTIONALLY LEFT BLANK

CARGO HANDLING SYSTEM - FWD CARGO MECHANICAL COMPONENT LOCATIONS

General

The forward cargo handling system has mechanical components that let you load, unload, and lock ULDs. These are the mechanical components:

- End stops
- Side guide rails
- Stop/locks
- Roller trays
- Pallet locks
- Ball panels
- Center stop/locks
- Guide rollers
- Auxiliary stop/locks
- Rollout stop/locks
- Retractable guide roller/lock
- Sill rollers
- Auxiliary guides
- Center guides
- Partial load stops.

Location

End stops are in the forward and aft ends of the cargo compartment. There are six in the aft end and four in the forward end. All end stops are the same except for the middle two in the aft end of the compartment. These do not give vertical restraint.

Side guide rails are along the sides of the cargo compartment. There are five on the left side and four on the right side of the compartment.

Stop/locks are in the aft part of the compartment. All four stop/locks are in one row. The stop/locks attach to the roller trays.

Roller trays are forward and aft of the ball panels. There are eight columns of roller trays across the compartment. Each column has four trays each.

Pallet locks are throughout the cargo compartment. The locks attach in nine rows with four locks in each row. Twenty-eight of the pallet locks mount to the roller trays. Eight of the pallet locks attach to floor structure in the area of the aft ball panels.

Ball panels are to the left of the door sill. The panels are in two sets, forward and aft. The forward set is in the area used to load/unload containers and pallets. The aft set of panels are in the area used to load/unload pallets.

Center stop/locks are in the middle panel of the forward ball panels.

Guide rollers are in the door sill area, one roller forward and one aft.

Auxiliary stop/locks are in the right panel of the forward ball panels.

Rollout stop/locks are in the door sill area.

Retractable guide roller/lock is in the door sill area.

CARGO HANDLING SYSTEM - FWD CARGO MECHANICAL COMPONENT LOCATIONS

Sill rollers are in the cargo door sill area.

Auxiliary guides are along the right part of the cargo compartment.

Center guides are along the center of the cargo compartment.

Partial load stops are in all areas of the cargo compartment. There are six rows of stops with four in each row. All partial load stops attach to the roller trays.

FORWARD CARGO HANDLING SYSTEM
(LOOKING DOWN)
(TYPICAL)

CARGO HANDLING SYSTEM - FWD CARGO MECHANICAL COMPONENT LOCATIONS

CARGO HANDLING SYSTEM - AFT CARGO ELECTRICAL/MECHANICAL COMPONENT LOCATIONS

General

The aft cargo handling system has electrical/mechanical components that let you load and unload ULDs.

These are the electrical/mechanical components:

- Powered drive units (PDUs)
- Lateral guides.

You may operate the lateral guides manually.

Location

Powered drive units are in all areas of the cargo compartment.

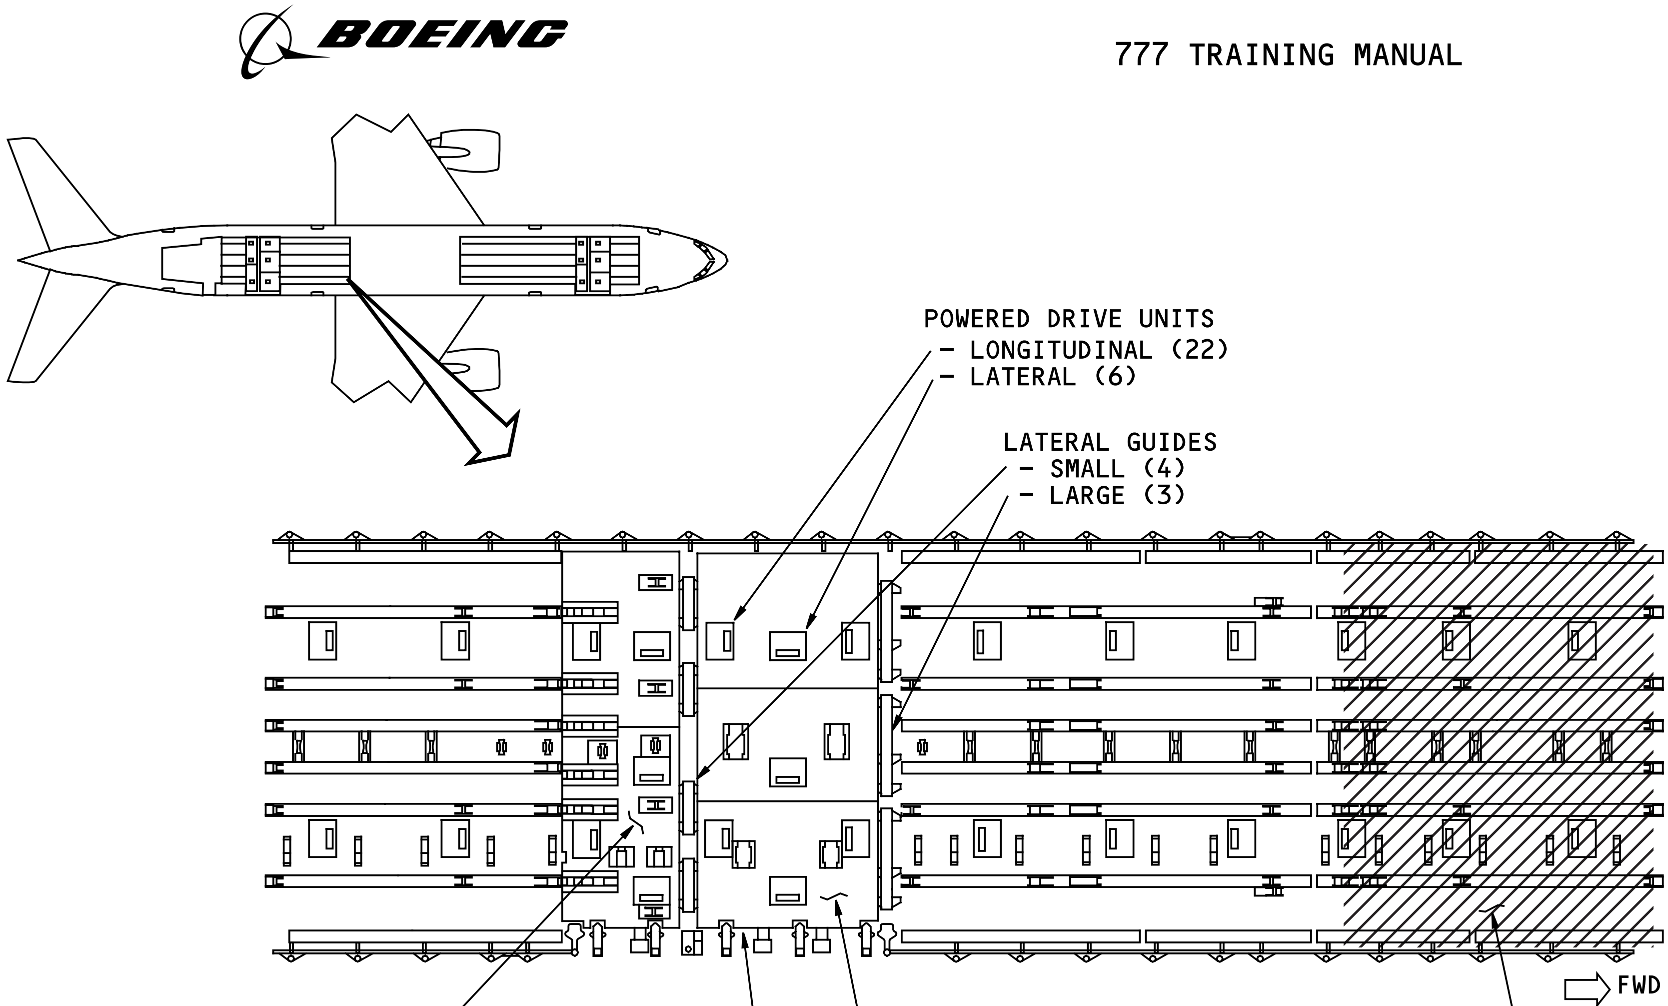
The longitudinal PDUs are on the left and right sides of the compartment in rows. There are eleven rows of PDUs with two PDUs in each row.

Lateral PDUs are in the same area as the ball panels. There are two rows of lateral PDUs, each row has three PDUs.

Lateral guides, small and large are next to the ball panels.

Small lateral guides are between the forward and aft ball panels. These guides are structurally different than the ones in the forward cargo handling system.

Large lateral guides are forward of the forward ball panels. These guides are different from the ones in the forward system because give vertical restraint for only one pallet while the ones in the forward system give vertical restraint for two pallets.



AFT CARGO HANDLING SYSTEM
(LOOKING DOWN)
(TYPICAL)

CARGO HANDLING SYSTEM - AFT CARGO ELECTRICAL/MECHANICAL COMPONENT LOCATIONS

CARGO HANDLING SYSTEM - AFT CARGO MECHANICAL COMPONENT LOCATIONS

THIS PAGE INTENTIONALLY LEFT BLANK

CARGO HANDLING SYSTEM - AFT CARGO MECHANICAL COMPONENT LOCATIONS

General

The aft cargo handling system has mechanical components that let you load, unload, and lock ULDs. You operate the mechanical components manually.

These are the mechanical components:

- Ball panels
- Center stop/locks
- Auxiliary stop/locks
- Rollout stop/locks
- Retractable guide roller/lock
- Side guide rails
- Roller trays
- Pallet locks
- End stops
- Stop/locks
- Guide rollers
- Sill Rollers
- Auxiliary guides
- Center guides
- Partial load stops.

Location

Ball panels are to the left of the door sill. The panels are in two sets: forward and aft. The forward set is in the area used for loading/unloading containers and pallets. The aft set of panels are in the area used for loading/unloading pallets. The aft ball panels have a different shape than the ones used in the forward cargo handling system.

Center stop/locks mount to structure in the area of the middle forward ball panel.

Auxiliary stop/locks mount to structure in the area of the forward right ball panel.

Rollout stop/locks mount to structure in the door sill area.

Retractable guide roller/lock mounts to structure in the area of the door sill.

Side guide rails are along the sides of the cargo compartment. There are six on the left side and five on the right side of the compartment. These guide rails are shorter than the ones used in the forward cargo handling system.

Roller trays are forward and aft of the ball panels. There are eight columns of roller trays across the compartment. The columns along the sides of the compartment have five trays each. The columns along the middle of the compartment have three trays each. These roller trays are a different length than the ones in the forward cargo handling system.

Pallet locks are all along the cargo compartment. The locks are installed in six rows with six locks in each row. Twelve of the pallet locks mount to the roller trays. Twelve of the pallet locks mount to structure in the area of the aft ball panels.

CARGO HANDLING SYSTEM - AFT CARGO MECHANICAL COMPONENT LOCATIONS

End stops are at the forward and aft ends of the cargo compartment in the roller trays. There are six in the aft end and six in the forward end. The aft cargo handling system uses one type of end stop, with vertical restraint. The forward system uses two types one without vertical restraint and one with vertical restraint.

Stop/locks are forward of the ball panels. All six stop/locks attach to roller trays. The aft cargo handling system uses stop/locks that are structurally different than the ones in the forward compartment.

Guide rollers are in the door sill area, one roller forward and one aft.

Sill rollers are in the door sill area. The aft cargo handling system uses cantilevered rollers for all of its sill rollers. The forward system uses both cantilevered and non-cantilevered.

Auxiliary guides are along the right part of the cargo compartment.

Center guides are along the center of the cargo compartment.

Partial load stops are all along the cargo compartment. Twenty stops attach to the roller trays in four rows. Another row of four stops attach to floor structure in the area of the aft ball panels. All rows except row two have four stops. Row two has eight stops, four that face aft and four that face forward.

AFT CARGO HANDLING SYSTEM
(LOOKING DOWN)
(TYPICAL)

CARGO HANDLING SYSTEM - AFT CARGO MECHANICAL COMPONENT LOCATIONS

25-53-00-006 Rev 4 08/21/1997

CARGO HANDLING SYSTEM - ELECTRICAL GENERAL DESCRIPTION

General

The cargo handling system gets power for control from the P320 ground service/handling power panel. The system gets operating power from the P300 auxiliary power panel.

PSEU number one supplies cargo door position information. The cargo system controller (CSC) lets the system operate only if the cargo door is full open.

CSC Inputs

The cargo system controller (CSC) gets inputs from these components:

- Cargo handling accessory panel (system power relays and circuit breakers)(P35 fwd, P39 aft)
- Secondary joystick
- Cargo control joystick
- Cargo handling control panel (Switches, P24, P27)
- Hard wired program pins give controller installation location and information about system options. (Fwd cargo compartment, LD-4/LD-8 option, aft large cargo door option, crew rest in place 1 option, crew rest in place 2 option, no gearmotor devices installed).

The CSC does not get inputs from the PDUs or the lateral guides. The CSC has no interface with the AIMS.

Operation

The CSC controls the position of these electrical/ mechanical components:

- Powered drive units
- Lateral guides.

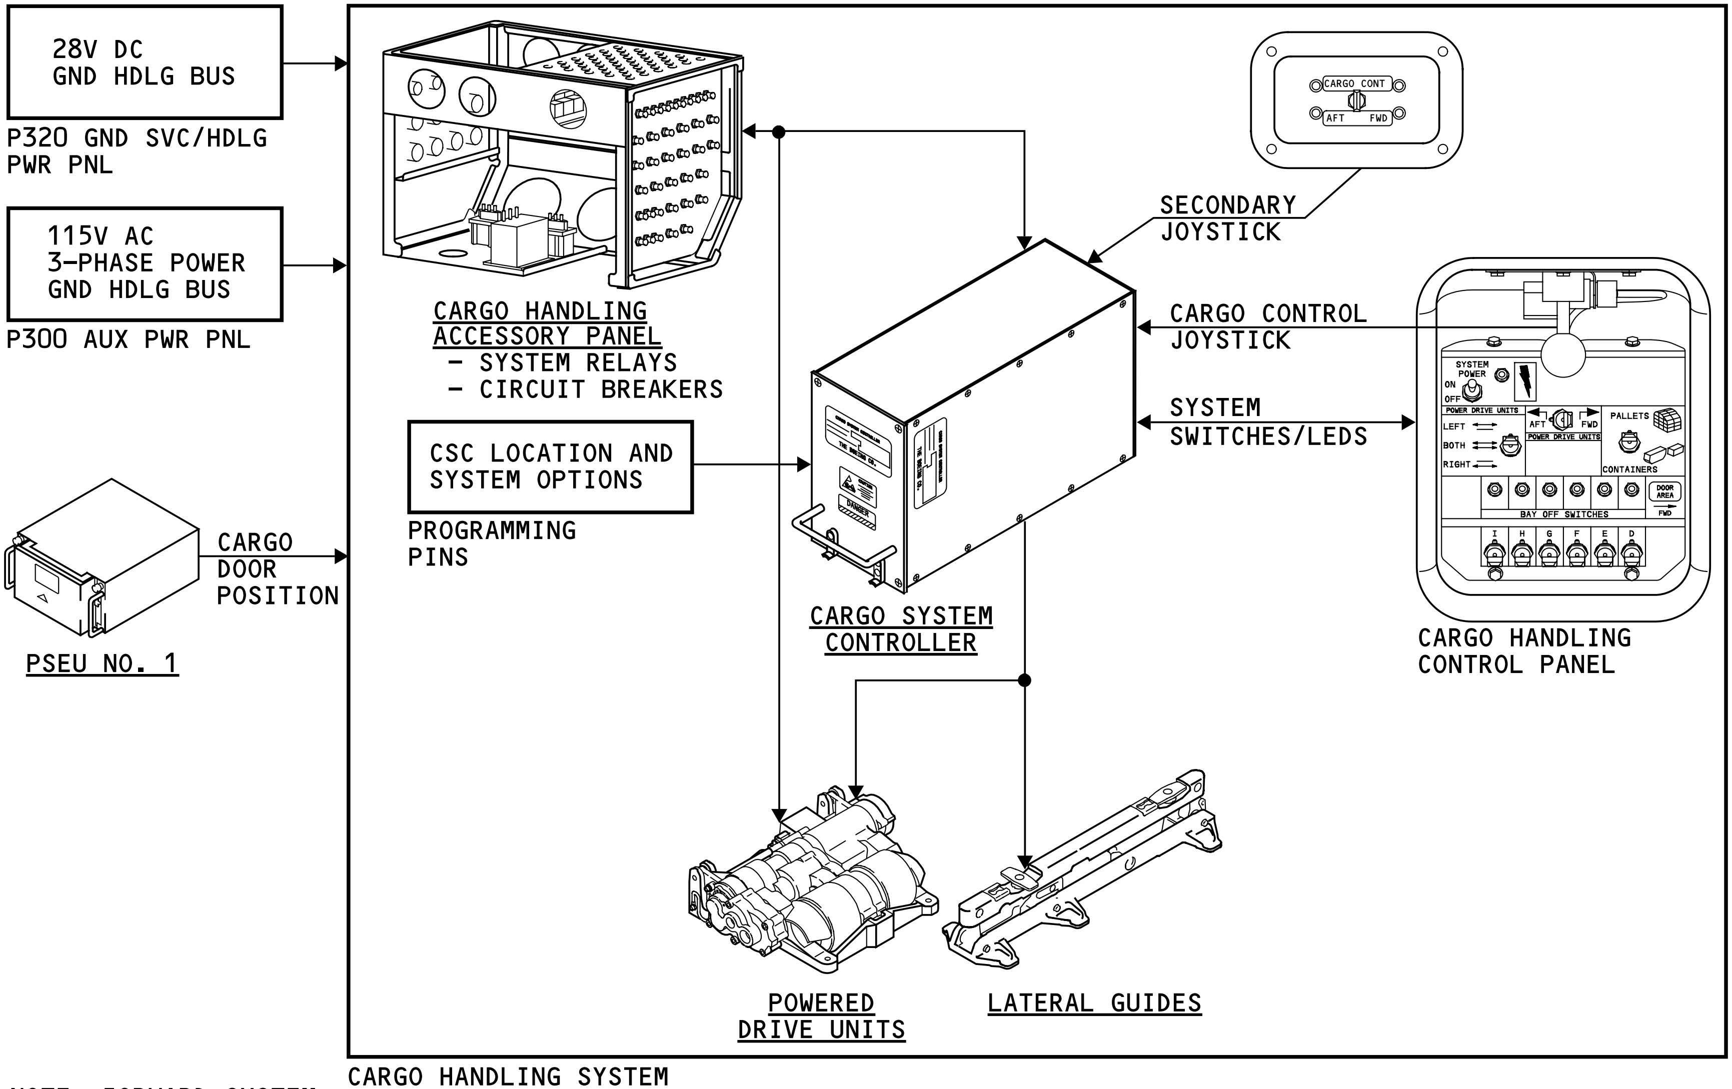
To supply power to the system these conditions must be true:

- the ground handling bus has power
- the cargo door is full open
- the SYSTEM POWER switch on the cargo handling control panel is in the ON position.

You can tell that power is on when the system power LED comes on.

Use the switches on the cargo handling control panel to configure the system. The switches let you set the system for the type of cargo you need to load or unload (CONTAINERS OR PALLETS). The switches also let you enable sets of power drive units (PDU FWD or AFT and PDU LEFT, CENTER OR RIGHT).

You use the cargo control joystick to move ULDs in all directions, FORWARD, AFT, IN or OUT. The secondary joystick lets you move ULDs in two directions, FORWARD or AFT. The secondary joystick does not let you move ULDs onto or off of the ball panels. The cargo system controller uses your inputs for system configuration and joystick position to operate the components.



NOTE: FORWARD SYSTEM
SHOWN, AFT SIMILAR

CARGO HANDLING SYSTEM - ELECTRICAL GENERAL DESCRIPTION

25-53-00-007 Rev 4 08/21/1997

CARGO HANDLING SYSTEM - MECHANICAL GENERAL DESCRIPTION

General

These are the mechanical components that you manually operate:

- Pallet locks
- Stop/locks
- Center stop/locks
- Center guides
- Auxiliary stop/locks
- Auxiliary guides
- Rollout stop/locks
- Retractable guide roller/lock
- Partial load stops.

Operation

A typical unloading/loading operation usually requires the use of both electrically and manually operated components. The type of ULDs (containers or pallets) and the amount of cargo (partial or full load) tell you which components to use.

Pallet locks and stop/locks let you lock pallets in place. The lock position gives vertical and longitudinal restraint for the pallets.

Center and auxiliary guides in the area of the ball panels can be locked down. You do this so pallets can be loaded and unload.

You use the center stop/locks for these functions:

- To give laterial seperation between containers
- To give laterial restraint for containers
- To give vertical restraint for containers.

You use the auxiliary stop/locks for these functions:

- To give laterial restraint for containers (LD-4 or LD-8)
- To give vertical restraint for containers (LD-4 or LD-8).

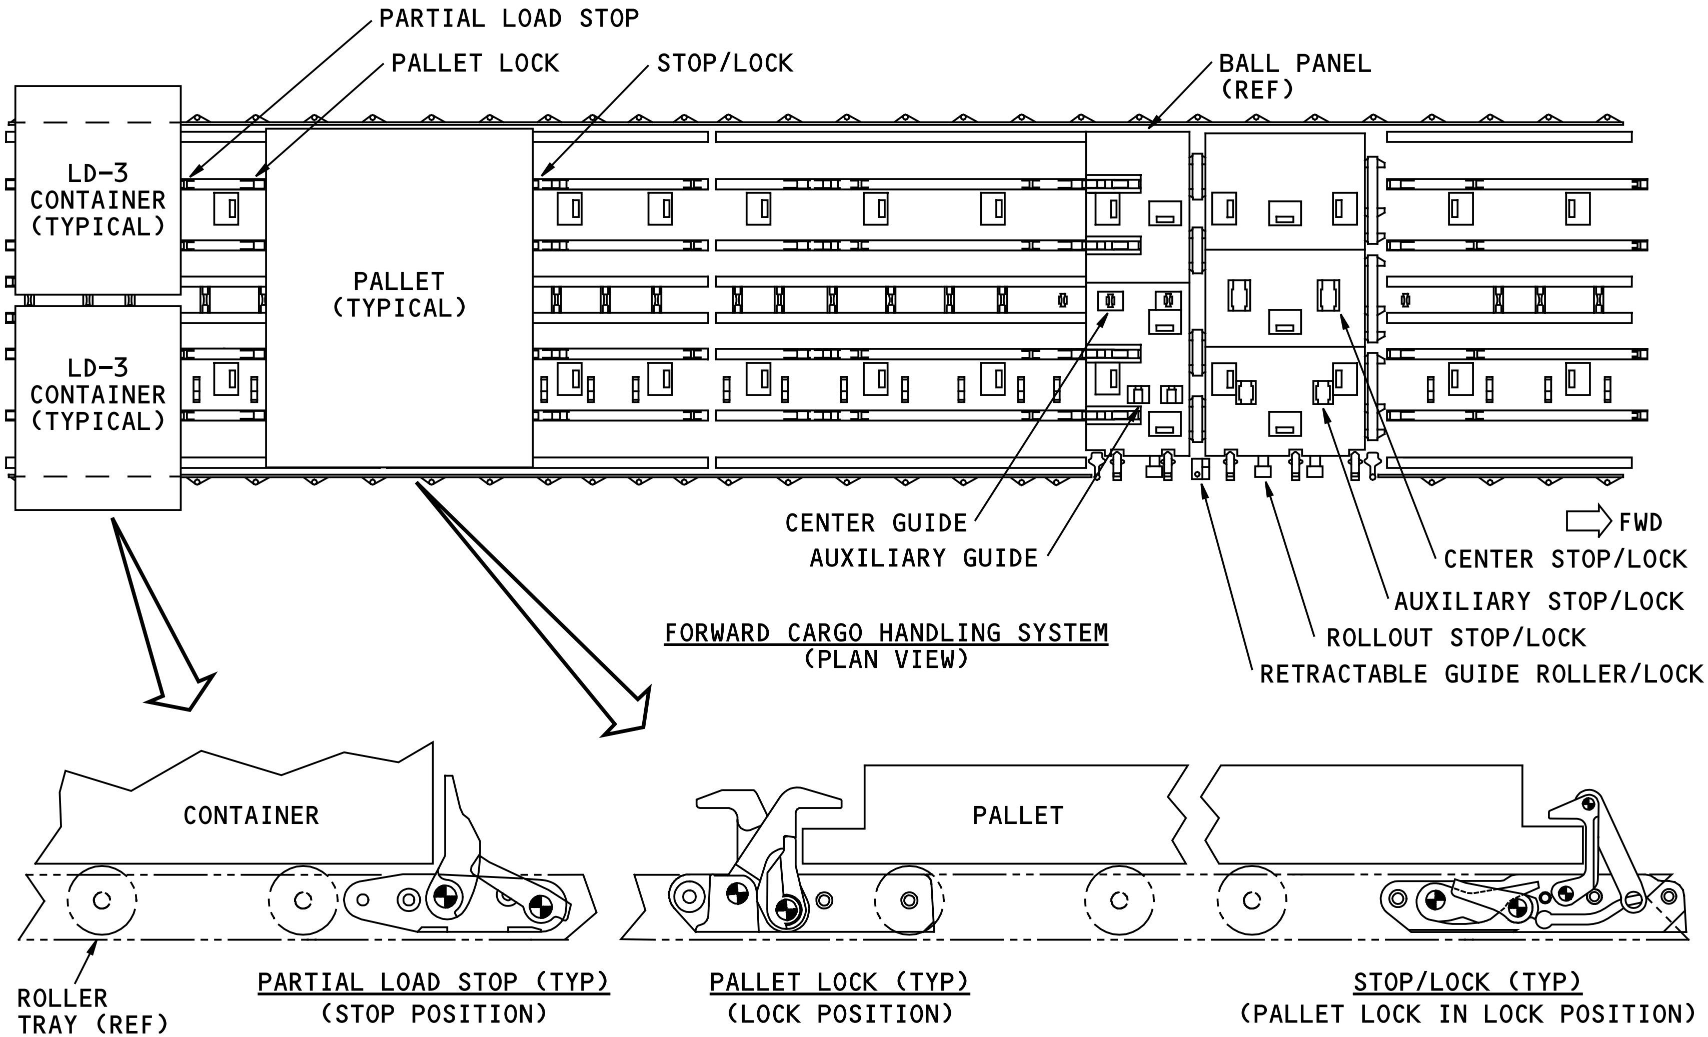
You use the rollout stop/locks for these functions:

- To give laterial restraint for containers and pallets
- To give vertical restraint for containers and pallets.

You use the retractable guide roller/lock for these functions:

- To guide contrainers into the compartment
- To give vertical restraint for containers and pallets.

You use the partial load stop to give longitudinal restraint for containers when another container is not adjacent to it.



NOTE: TYPICAL SYSTEM SHOWN

25-53-00-008 Rev 3 08/21/1997

CARGO HANDLING SYSTEM - MECHANICAL GENERAL DESCRIPTION

CARGO HANDLING SYSTEM - ROLLOUT STOP/LOCK - INTRODUCTION

Purpose

The rollout stop/lock gives lateral and vertical restraint for containers and pallets.

Physical Description

These units are spring-loaded mechanical units. They have these parts:

- Lateral restraint
- Vertical restraint
- Pedal
- Base.

Location

Each cargo compartment has three rollout stop/locks in the cargo door sill area.

Functional Description

Manual movement of the lateral restraint lets you set the restraint in the up or down position. Manual movement of the of the vertical restraint lets you set the restraint to the up position. Manual movement of the pedal lets you lower the vertical restraint.

Training Information Point

You remove the rollout stop/lock as a single unit.

CARGO HANDLING SYSTEM - ROLLOUT STOP/LOCK - INTRODUCTION

CARGO HANDLING SYSTEM - AUXILIARY STOP/LOCK - INTRODUCTION

Purpose

Auxiliary stop/locks supply lateral and vertical restraint for LD-4/LD-8 containers and longitudinal guidance for LD-4/LD-8 containers.

Physical Description

The auxiliary stop/locks are spring-loaded mechanical units. The units have these parts:

- Base
- Vertical restraint
- Lateral restraint
- Pedal.

The forward and aft auxiliary stop/locks are opposite of each other.

Location

There are two auxiliary stop/locks in the ball panel area of the forward and aft cargo compartments. They are on the right side of the compartments.

Functional Description

Manual movement of the lateral restraint lets you set the restraint in the up or down position. Manual movement of the of the vertical restraint lets you set the restraint to the up position. Manual movement of the pedal lets you lower the vertical restraint.

Training Information Point

You remove the auxiliary stop/locks as single units.

CARGO HANDLING SYSTEM - AUXILIARY STOP/LOCK - INTRODUCTION

CARGO HANDLING SYSTEM - CENTER STOP/LOCK - INTRODUCTION

Purpose

Center stop/locks have these functions:

- Supplies lateral and vertical restraint for LD-3/LD-1 containers, K and N size pallets
- Supplies lateral separation between LD-3 containers, K and N size pallets
- Supplies longitudinal guidance for LD-3/LD-1 containers, K and N size pallets.

Physical Description

Center stop/locks are spring-loaded mechanical units. The units have these parts:

- Vertical restraints
- Pawl
- Base
- Lateral restraint
- Lockdown pawl
- Retract lever
- Latch.

The center stop/locks are opposite of each other.

Location

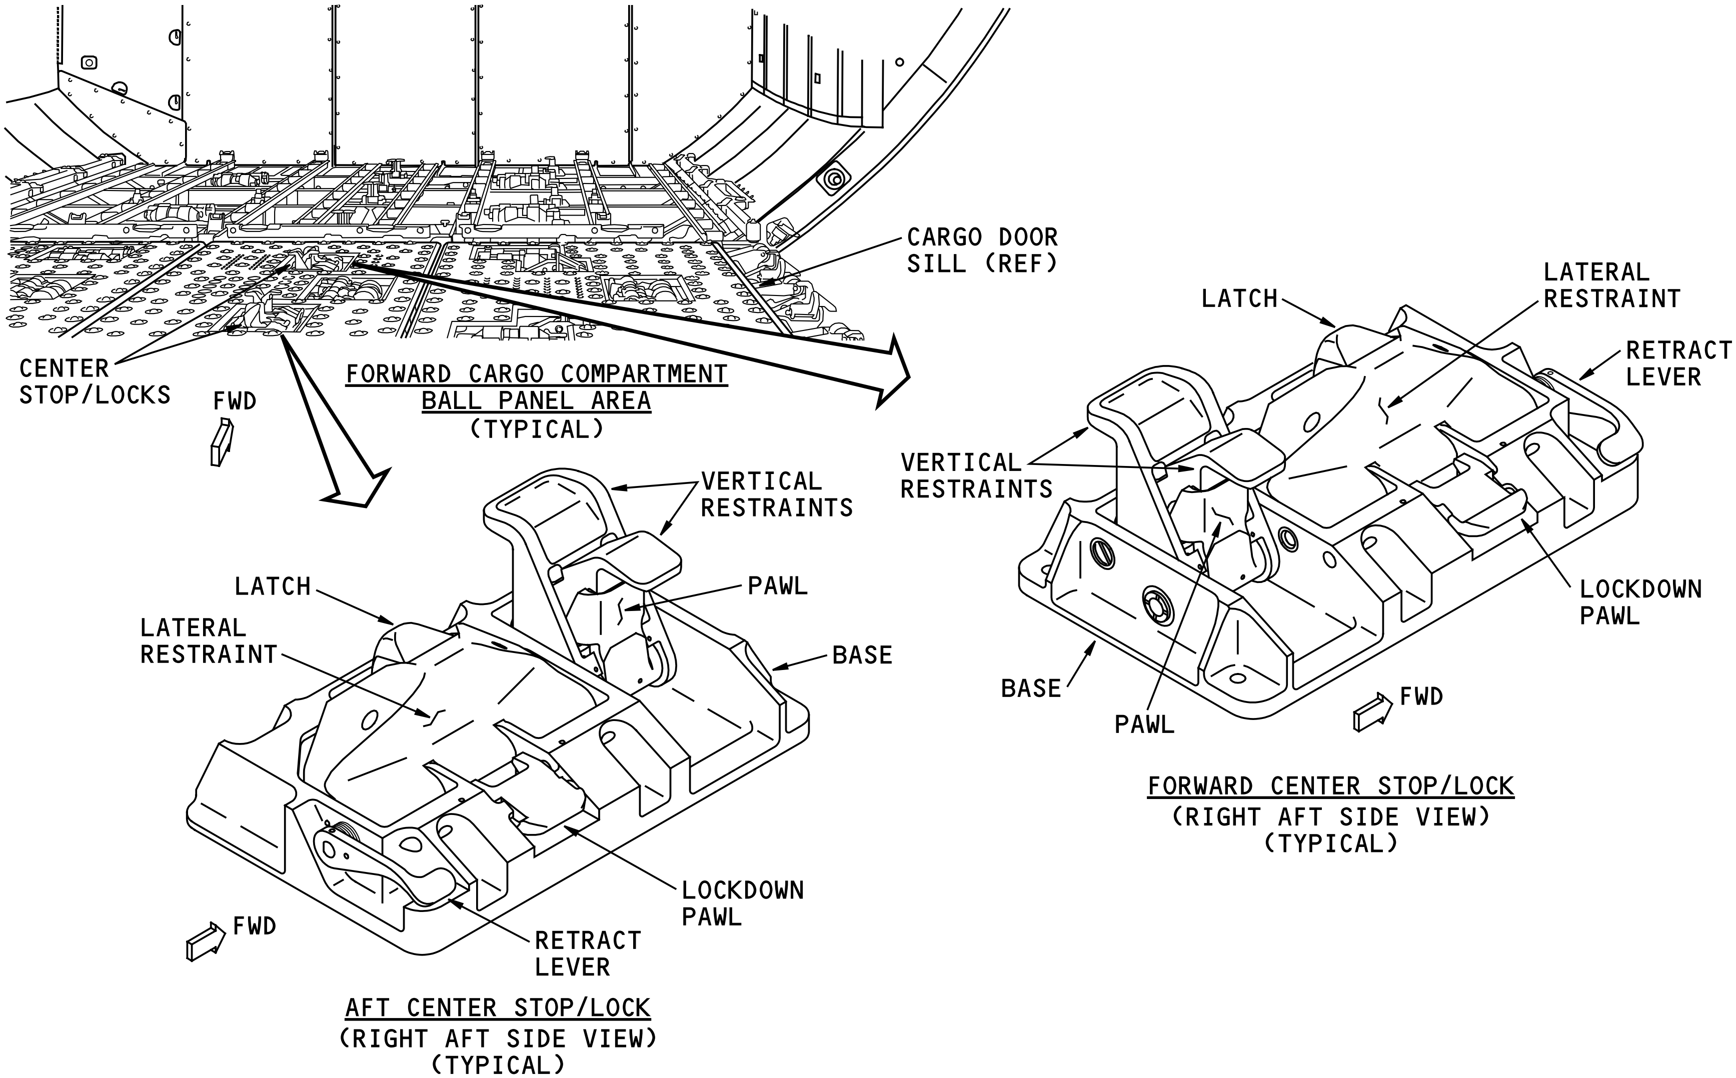
There are two center stop/locks in the ball panel area of the forward and aft cargo compartments. The center stop/locks are along the centerline of the compartments.

Functional Description

Manual movement of the lateral restraint lets you set the restraint in the up or down position. Manual movement of the of the vertical restraint lets you set the restraint to the up position. Manual movement of the pedal lets you lower the vertical restraint.

Training Information Point

You remove the center stop/locks as single units.



25-53-00-043 Rev 3 08/21/1997

NOTE: FORWARD CARGO HANDLING SYSTEM SHOWN, AFT SIMILAR

CARGO HANDLING SYSTEM - CENTER STOP/LOCK - INTRODUCTION

CARGO HANDLING SYSTEM - ROLLOUT, CENTER, AND AUXILIARY STOP/LOCKS - OPERATION

General

The rollout, center and auxiliary stop/locks operate almost the same. The shape and size of their restraints are different. You manually operate the stop/locks to set them to one of these positions:

- Lock, vertical and lateral restraints are up
- Load, vertical restraints are down, lateral restrains are up
- Unload, all restraints are down.

Manual Operation - Down

You use the pedals on the rollout and on the auxiliary stop/locks and the pawl on the center stop/lock to release a lock that holds the vertical restraint up. To move a vertical restraint down on a rollout or on an auxiliary stop/lock, push the pedal down. To move the vertical restraints down on a center stop/lock, pull the pawl down. This lets restraints move down over the pawl.

The lateral restraints are spring-loaded to the load (up) position. To lock a lateral restraint in the unload (down) position you push the restraint to the left (away from the cargo door) and at the same time push the restraint down. Hold the restraint down and let it move to the right (towards the door). This lets a lock hold the lateral restraint down.

Manual Operation - Up

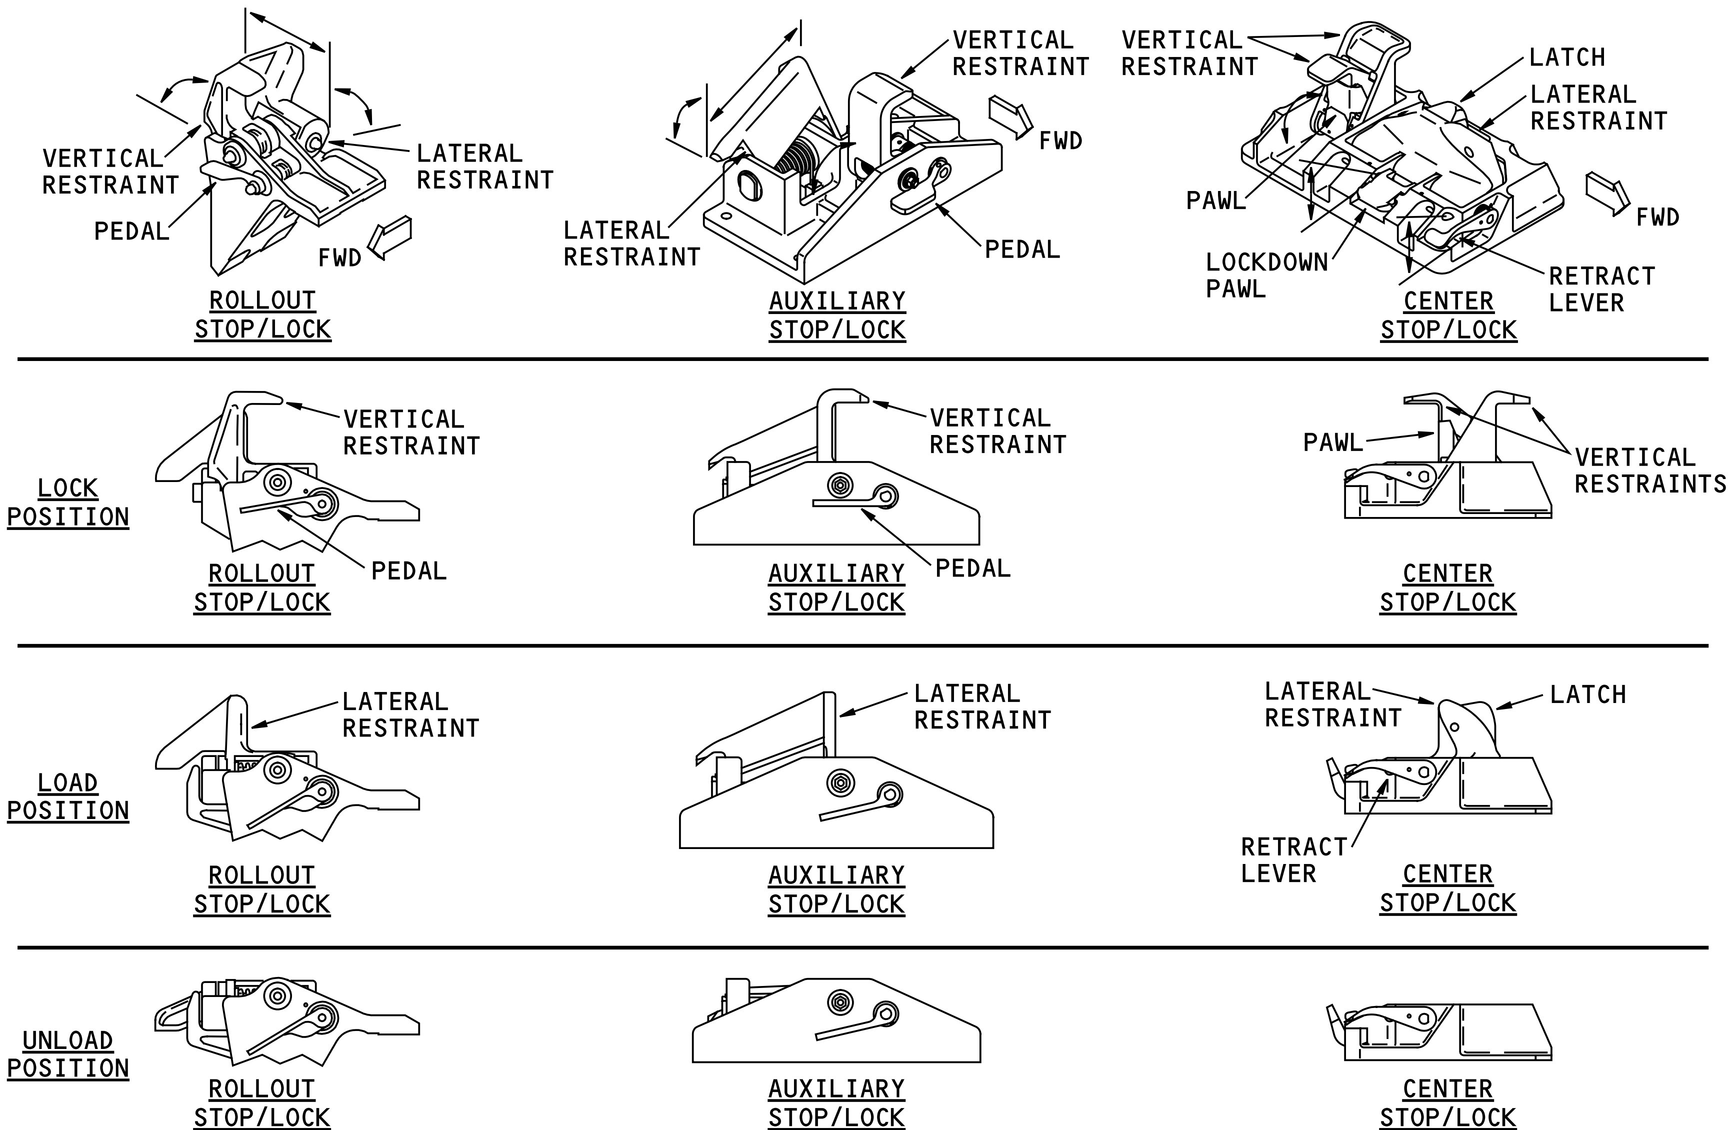
If the lateral restraint for a rollout or an auxiliary stop/lock is down, push the restraint to the left and let it move up. The lateral restraint is spring-loaded up. It will move up by itself to the load position.

If the lateral restraint for a center stop/lock is down, push down on the lockdown pawl. The pawl releases a lock that holds the restraint down. The lateral restraint is spring-loaded up. It will move up by itself to the load position.

If a vertical restraint is down, lift up the restraint to move it up to the lock position.

Lateral Restraint Operation

The lateral restraint is spring-loaded to the load position. During the load operation the restraint pivots down when a ULD pushes on it from the outboard side. When the ULD moves completely into the ball panel area, the lateral restraint pivots back up to the load position. ULDs cannot move outboard past the lateral restraint.



25-53-00-011 Rev 2 08/21/1997

CARGO HANDLING SYSTEM - ROLLOUT, CENTER, AND AUXILIARY STOP/LOCKS - OPERATION

CARGO HANDLING SYSTEM - RETRACTABLE GUIDE ROLLER/LOCK - INTRODUCTION

Purpose

The retractable guide roller/lock guides and aligns containers as they move through the cargo door opening. It also gives lateral and vertical restraint for containers and pallets.

Physical Description

The retractable guide roller/lock is a spring-loaded mechanical unit.

The unit has these parts:

- Fork
- Roller
- Restraint
- Pedal
- Bracket.

Location

There is one retractable guide roller/lock in each cargo compartment. It mounts to the middle part of the door sill.

Functional Description

You control the position of the restraint and the roller manually. Manual movement of the roller or of the vertical restraint lets you set them to the up position. The pedal and fork let you manually lower the restraint and the roller.

Training Information Point

The roller on the retractable guide roller/lock is a LRU.

(TYPICAL RETRACTABLE GUIDE ROLLER/LOCK)
(LOCK POSITION)

CARGO HANDLING SYSTEM - RETRACTABLE GUIDE ROLLER/LOCK - INTRODUCTION

CARGO HANDLING SYSTEM - RETRACTABLE GUIDE ROLLER/LOCK - OPERATION

Operation

The retractable guide roller/lock has these positions:

- Container load: The roller is up and the restraint is down to move containers into the cargo compartment.
- Pallet load and Contain/Pallet Unload: The roller and the restraint are down. Use this position to load pallets or unload containers and pallets.
- Lock: The roller is down and the restraint is up when cargo movement into or out of the cargo compartment is complete.

You use the pedal to lower the restraint. You use the fork to lower the roller. Push the pedal all the way down to move the restraint down. Push down on the inboard end of the fork to move the roller down.

You lift the roller or the restraint to put them up.

CARGO HANDLING SYSTEM - RETRACTABLE GUIDE ROLLER/LOCK - OPERATION

CARGO HANDLING SYSTEM - LATERAL GUIDE - INTRODUCTION

General

Lateral guides make sure containers stay straight on the forward ball panels for the load or unload operation. Some guides also give vertical restraint and more anchor fittings for pallets.

Seven lateral guides are in each cargo compartment. There are four different types of lateral guides:

- Large with forward and aft vertical restraints (forward cargo compartment)
- Large with aft vertical restraints only (aft cargo compartment)
- Small with heavy weight rail and base (forward cargo compartment)
- Small with light weight rail and base (aft cargo compartment).

Large Guides

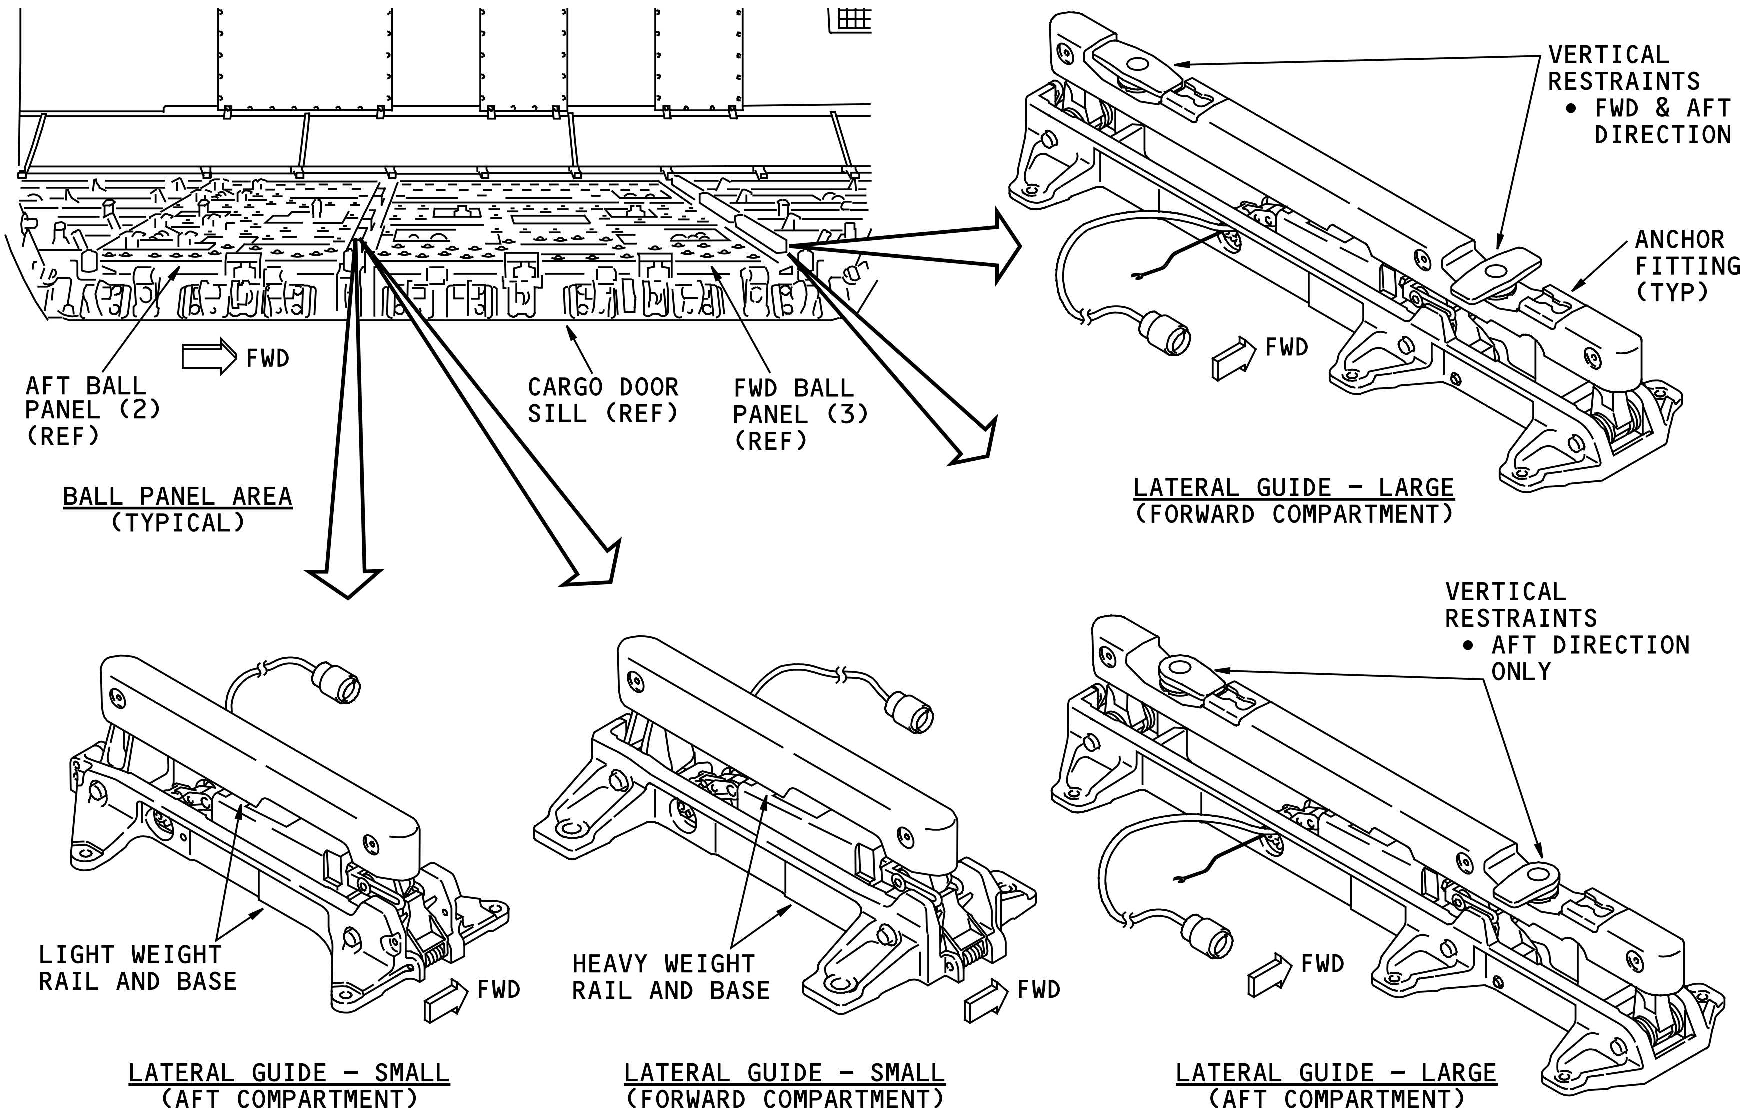
The large lateral guides in the forward cargo compartment give vertical restraint for pallets forward and aft of the guide. The large lateral guides in the aft compartment give vertical restraint for pallets aft of the guide only.

Small Guides

The small lateral guides in the forward cargo compartment are heavier in construction than the ones in the aft compartment. This makes them more resistant to the higher longitudinal loads in the forward compartment.

Location

Three large lateral guides are forward of the forward ball panels. Four small lateral guides are between the forward and aft ball panels.



25-53-00-015 Rev 3 12/11/1996

CARGO HANDLING SYSTEM - LATERAL GUIDE - INTRODUCTION

CARGO HANDLING SYSTEM - LATERAL GUIDE - PHYSICAL DESCRIPTION

Physical Description

Lateral guides are spring loaded electrical/mechanical units. The guides have these parts:

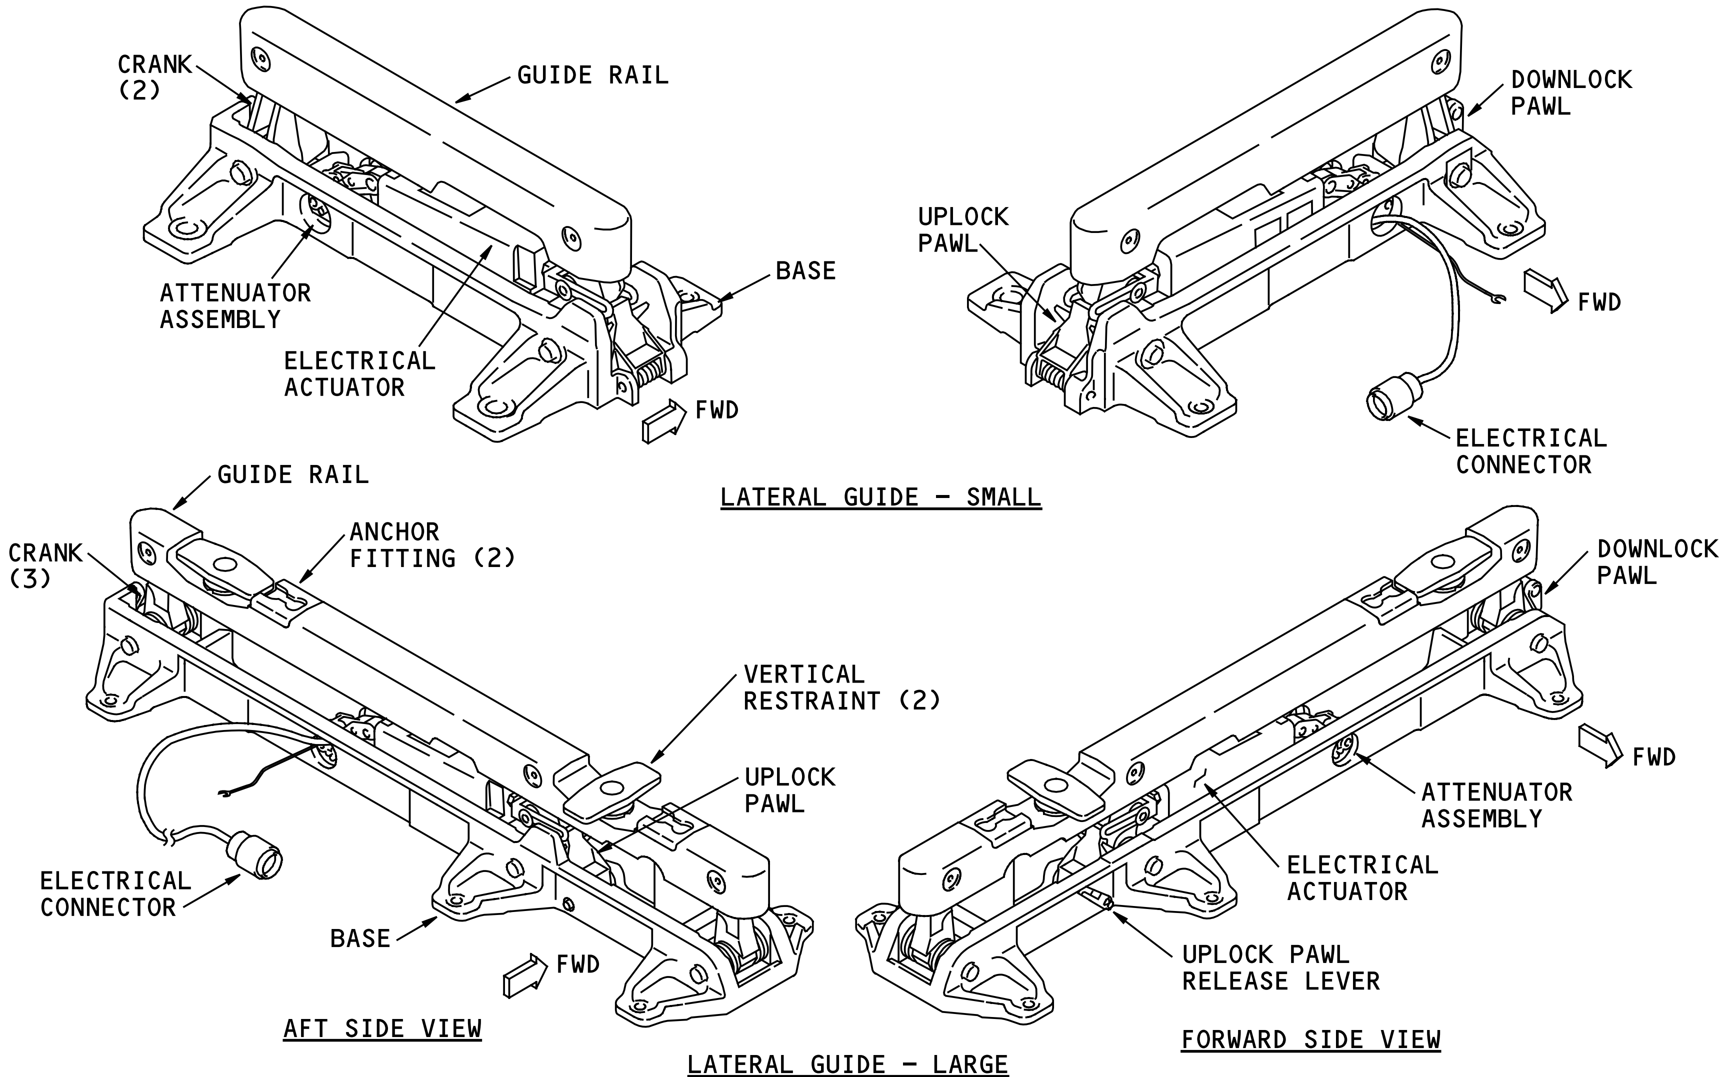
- Crank (2 for small guides, 3 for large guides)
- Guide rail
- Base
- Electrical actuator
- Attenuator assembly
- Downlock pawl
- Electrical connector
- Uplock pawl
- Anchor fitting (2) (large lateral guides only)
- Vertical restraint (2) (large lateral guides only)
- Uplock pawl release lever (large lateral guides only).

Functional Description

The electrical actuator controls the position of the guide rail. The pawls and pawl release lever manually operate the guide rail.

Training Information Point

You remove the lateral guides as a single unit.



NOTE: FORWARD CARGO LATERAL GUIDES SHOWN, AFT SIMILAR

25-53-00-016 Rev 0

CARGO HANDLING SYSTEM - LATERAL GUIDE - PHYSICAL DESCRIPTION

CARGO HANDLING SYSTEM - LATERAL GUIDE - OPERATION - LOCK DOWN

General

Normally the guide rail on the lateral guides moves electrically to down when you move cargo forward or aft. If the rail does not move electrically you can manually move and lock it down with these components:

- Uplock pawl (small guides only)
- Uplock pawl release lever (large guides only)
- Guide rail
- Down lock pawl.

Lock down

For small guides move the uplock pawl away from the crank. For large guides use the uplock pawl release lever to move the uplock pawl away from the crank. The uplock pawl is spring loaded. Hold the pawl or lever to keep the pawl away from the crank.

While you hold the pawl or the release lever push the guide rail down. The guide rail is spring loaded up.

As you hold the guide rail, move the downlock pawl to lock the guide rail down.

Release

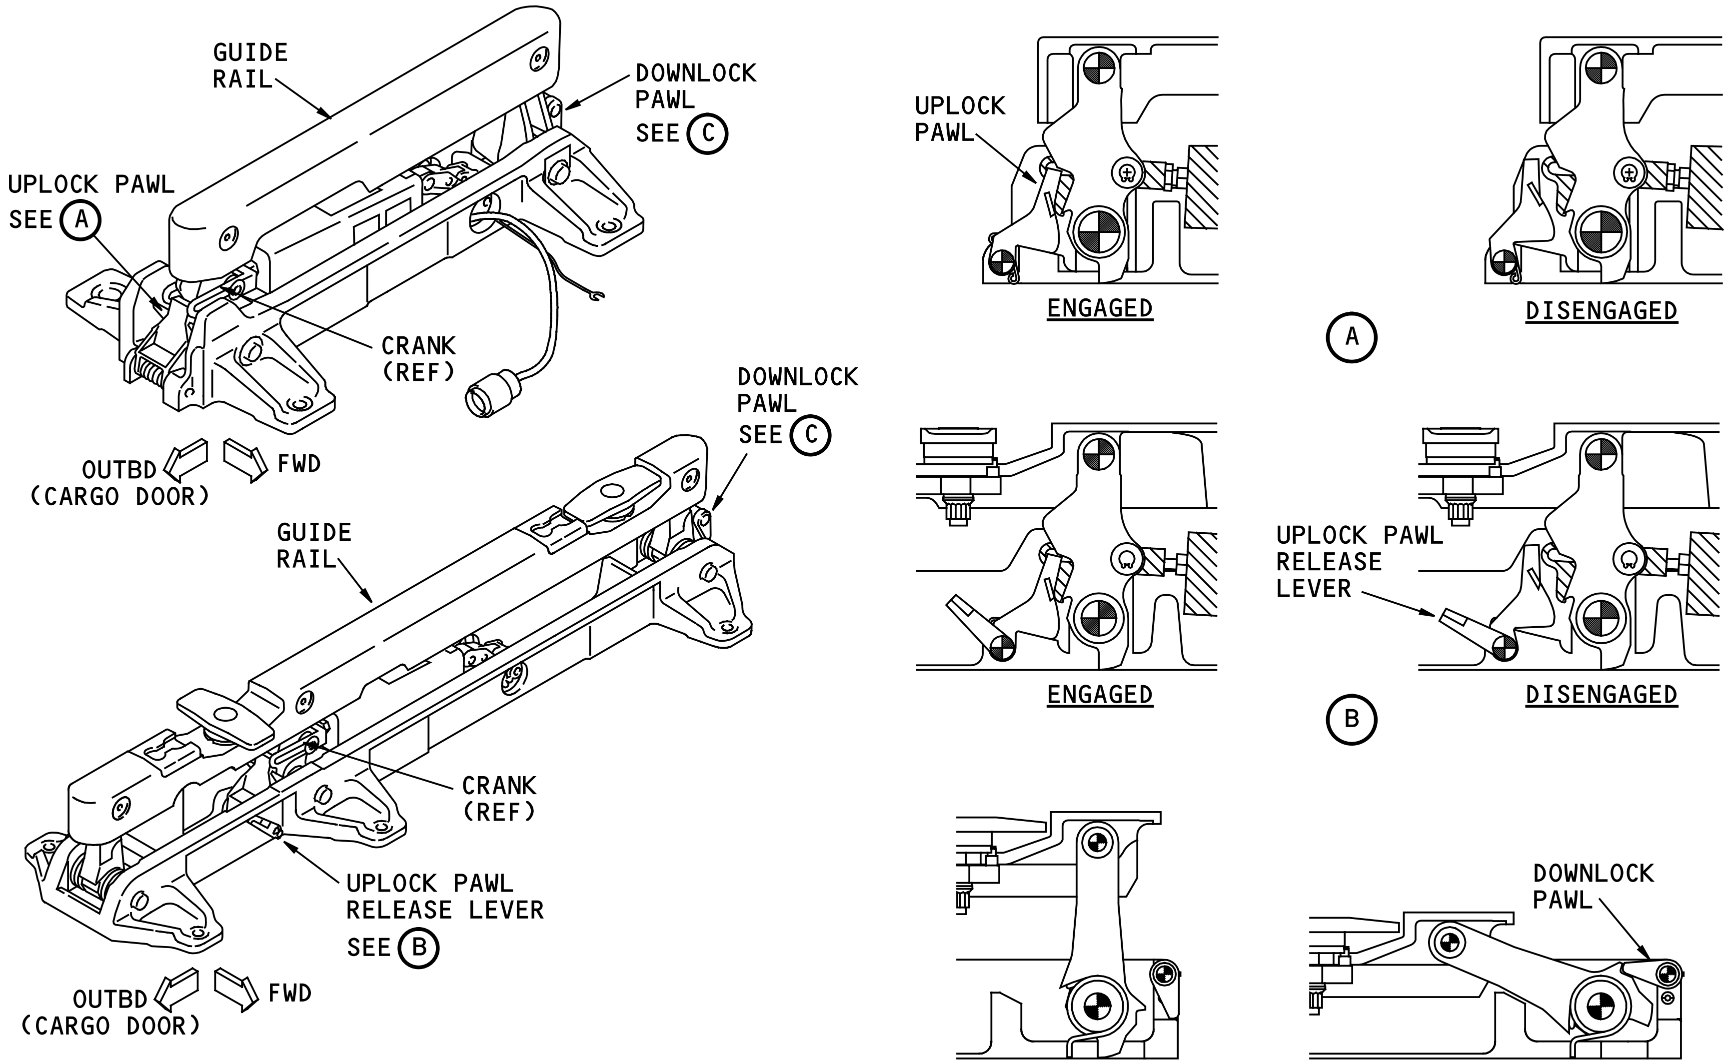
Push and hold down the guide rail. This removes pressure on the downlock pawl.

Move the downlock pawl to unlock the guide rail.

Release the guide rail. Springs automatically move it up.

Training Information Point

If you manually lower a lateral guide, you must manually release it before it will operate electrically.



NOTE: FORWARD CARGO LATERAL GUIDES SHOWN, AFT SIMILAR

25-53-00-017 Rev 0

CARGO HANDLING SYSTEM - LATERAL GUIDE - OPERATION - LOCK DOWN

CARGO HANDLING SYSTEM - LATERAL GUIDE - OPERATION - LIFT UP

General

To lift up a lateral guide when it does not move up electrically, you must manually operate the toggle link in the attenuator assembly.

Lift up

Use a common screwdriver or similar long, thin object to trip the toggle link on the attenuator assembly. Springs lift the guide rail automatically if the toggle link is tripped correctly.

The attenuator resets automatically when the guide rail is lowered manually.

Access

Access to the toggle link is different for large and small guides.

Large guides - you access the toggle link thought a side access hole in the base of the lateral guide. This hole is on the forward side of the guide.

Small guides - you access the toggle link from the top of the lateral guide. The tool you use to the trip the toggle link fits between the rail and the base of the guide.

Training Information Point

If you manually lift a lateral guide, you do not have to move it down before electrical operation. The lateral guide will reset itself when power is put on the system.

CARGO HANDLING SYSTEM - LATERAL GUIDE - OPERATION - LIFT UP

CARGO HANDLING SYSTEM - POWERED DRIVE UNIT - INTRODUCTION

General

Powered drive units (PDUs) move containers and pallets.

There are two types of PDUs:

- Lateral
- Longitudinal.

Lateral PDU

There are six lateral PDUs in each compartment. The lateral PDUs move containers and pallets into or out of the cargo compartment.

longitudinal PDU

There are 28 longitudinal PDUs in the forward cargo compartment and 22 in the aft cargo compartment. They move containers and pallets forward or aft in the compartment.

Location

Lateral PDUs are in the ball panel area, bays B and C forward compartment, bays E and F aft compartment (not shown).

Longitudinal PDUs are throughout the compartments.

Training Information Point

The lateral PDUs are interchangeable with the longitudinal PDUs.

You identify individual PDUs by PDU row location number and its location in the row, right, center or left. For one example, 5R is the PDU in the fifth row of PDUs from the front of the compartment on the right side. For another example, 4C in the forward compartment is the center PDU in the fourth row from the front of the compartment.

CARGO HANDLING SYSTEM - POWERED DRIVE UNIT - INTRODUCTION

CARGO HANDLING SYSTEM - POWERED DRIVE UNIT - FUNCTIONAL DESCRIPTION

General

The power drive unit (PDU) has these parts:

- Hinge
- Actuator
- Roller guards
- Rollers
- Mounting base
- Electrical connector
- Lift cams.

The actuator attaches to the mounting base at the hinge. The rollers are a hard rubber-like material. The lift cams are on the bottom side of the actuator.

Functional Description

The PDUs actuator has a reversible AC motor (not shown) that drives the rollers and lift cams through reduction gears (not shown). The actuator also has an internal erection coil (not shown) that locks the lift cams when the PDU is in the raised position. The motor has an electrically activated brake (not shown). It stops and holds the motor when the PDU is not in the drive condition. The lift cams move the PDU up the first time the motor is in the drive condition. The cams keep the PDU up until power is removed from the PDU. Power to the PDU is removed by any of these:

- System power switch
- Bay OFF switch
- Cargo system controller (CSC) control logic.

Training Information Point

When you replace a PDU you must clean and seal the PDU mounting base to the airframe. Then make sure electrical resistance between the PDU and airframe is acceptable. Make sure the wire bundle is clamped (not shown) to prevent fraying.

CARGO HANDLING SYSTEM - POWERED DRIVE UNIT - FUNCTIONAL DESCRIPTION

CARGO HANDLING SYSTEM - SILL ROLLER

Purpose

The sill rollers support cargo as it moves through the cargo door opening. The rollers make sure that the cargo is at same height of the balls in the ball panels. They also give a place to tie down cargo.

Physical Description

There are two types of sill rollers:

- Non-Cantilevered
- Cantilevered.

The forward cargo handling system uses both types. The aft system uses only the cantilevered type.

The sill rollers have these parts:

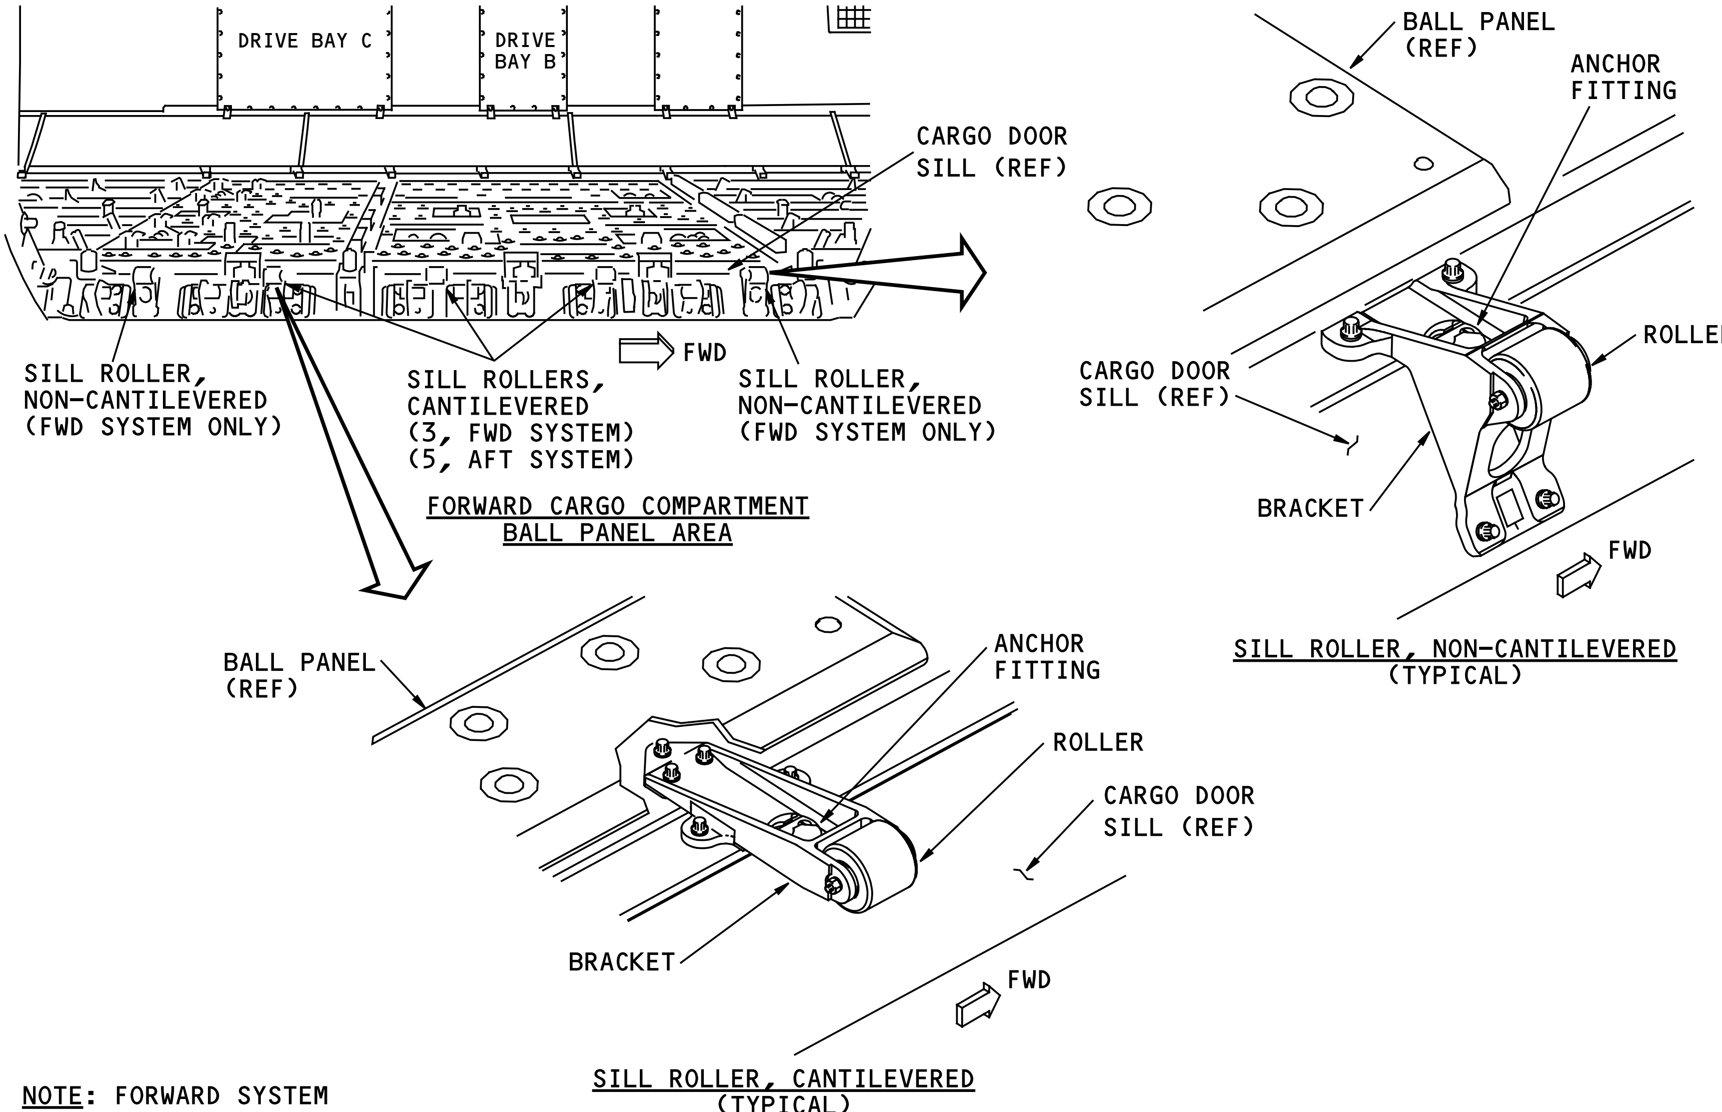
- Anchor fitting
- Roller
- Bracket.

Location

There are five sill rollers in each cargo compartment on the cargo door sill. The first and last sill rollers on the forward cargo door sill are the non-cantilevered type.

Training Information Point

The roller is a LRU.



NOTE: FORWARD SYSTEM SHOWN, AFT SIMILAR

25-53-00-021 Rev 1 06/02/1995

CARGO HANDLING SYSTEM - SILL ROLLER

CARGO HANDLING SYSTEM - GUIDE ROLLERS

Purpose

The guide rollers guide and align cargo as it moves through the cargo door opening.

Physical Description

The guide roller has a bracket and a roller. The guide rollers in the forward cargo compartment have a different bracket than the ones used in the aft cargo compartment. The side guide rail attaches to the bracket of the guide rollers.

Location

There are two guide rollers in each cargo compartment. The guide rollers mount to the door sill, one forward and one aft of the ball panel area.

Training Information Point

The roller is an lRU.

25-53-00-022 Rev 0 06/01/1995

CARGO HANDLING SYSTEM - GUIDE ROLLERS

CARGO HANDLING SYSTEM - BALL PANEL

Purpose

The ball panels do these functions:

- Make a low friction surface to help in the movement of cargo
- Supply a primary bearing surface to transmit cargo loads to the airframe
- Make a surface to walk on.

Physical Description

Airplanes with large forward and aft cargo doors have five ball panels in each cargo compartment, three forward panels and two aft panels.

The panels are two sheets of aluminum that are bonded and riveted to a corrugated inner core. The inner core is made of channels and doublers. Each ball panel has insert cups that let the ball transfer units (BTU) lock to the panel.

Each BTU locks into an insert cup with two latches.

Location

The panels are adjacent to the forward and aft cargo doors (not shown). The panels are in container bays B and C for the forward compartment.

The panels are in container bays E and F for the aft cargo compartment (not shown).

Training Information Point

BTUs are LRUs.

WARNING: BE CAREFUL WHEN YOU WALK ON THE BALL PANELS OR ALONG THE FLOOR PANELS IN THE CARGO COMPARTMENT. THE COMPONENTS IN THE CARGO COMPARTMENT CAN MOVE AND CAUSE YOU TO FALL.

CARGO HANDLING SYSTEM - BALL PANEL

CARGO HANDLING SYSTEM - ROLLER TRAY

Purpose

The roller trays do these functions:

- Make a low friction surface to help in the forward and aft movement of cargo
- Supply a primary cargo load bearing surface
- Supply a place to mount cargo handling system components.

Physical Description

The roller trays have rollers and a tray.

These cargo handling components mount to the trays:

- End stops
- Pallet locks
- Stop/locks
- Partial load stops.

Location

Roller trays are forward and aft of the ball panels in the forward and aft cargo compartments. There are eight columns of roller trays across each compartment. There are different tray lengths.

The aft cargo compartment has auxiliary roller trays (not shown) in the area forward of the ball panels. The trays give more places to mount equipment for the lower lobe attendant rest module.

In the forward cargo compartment each column has four trays. In the aft cargo compartment the columns along the sides of the compartment have five trays (not shown). The columns along the middle of the compartment have three trays (not shown).

CARGO HANDLING SYSTEM - SIDE GUIDE RAIL

Purpose

The side guide rail has these functions:

- Gives lateral alignment and longitudinal guidance to the cargo
- Gives the cargo lateral and vertical restraint
- Gives a place to tie down cargo.

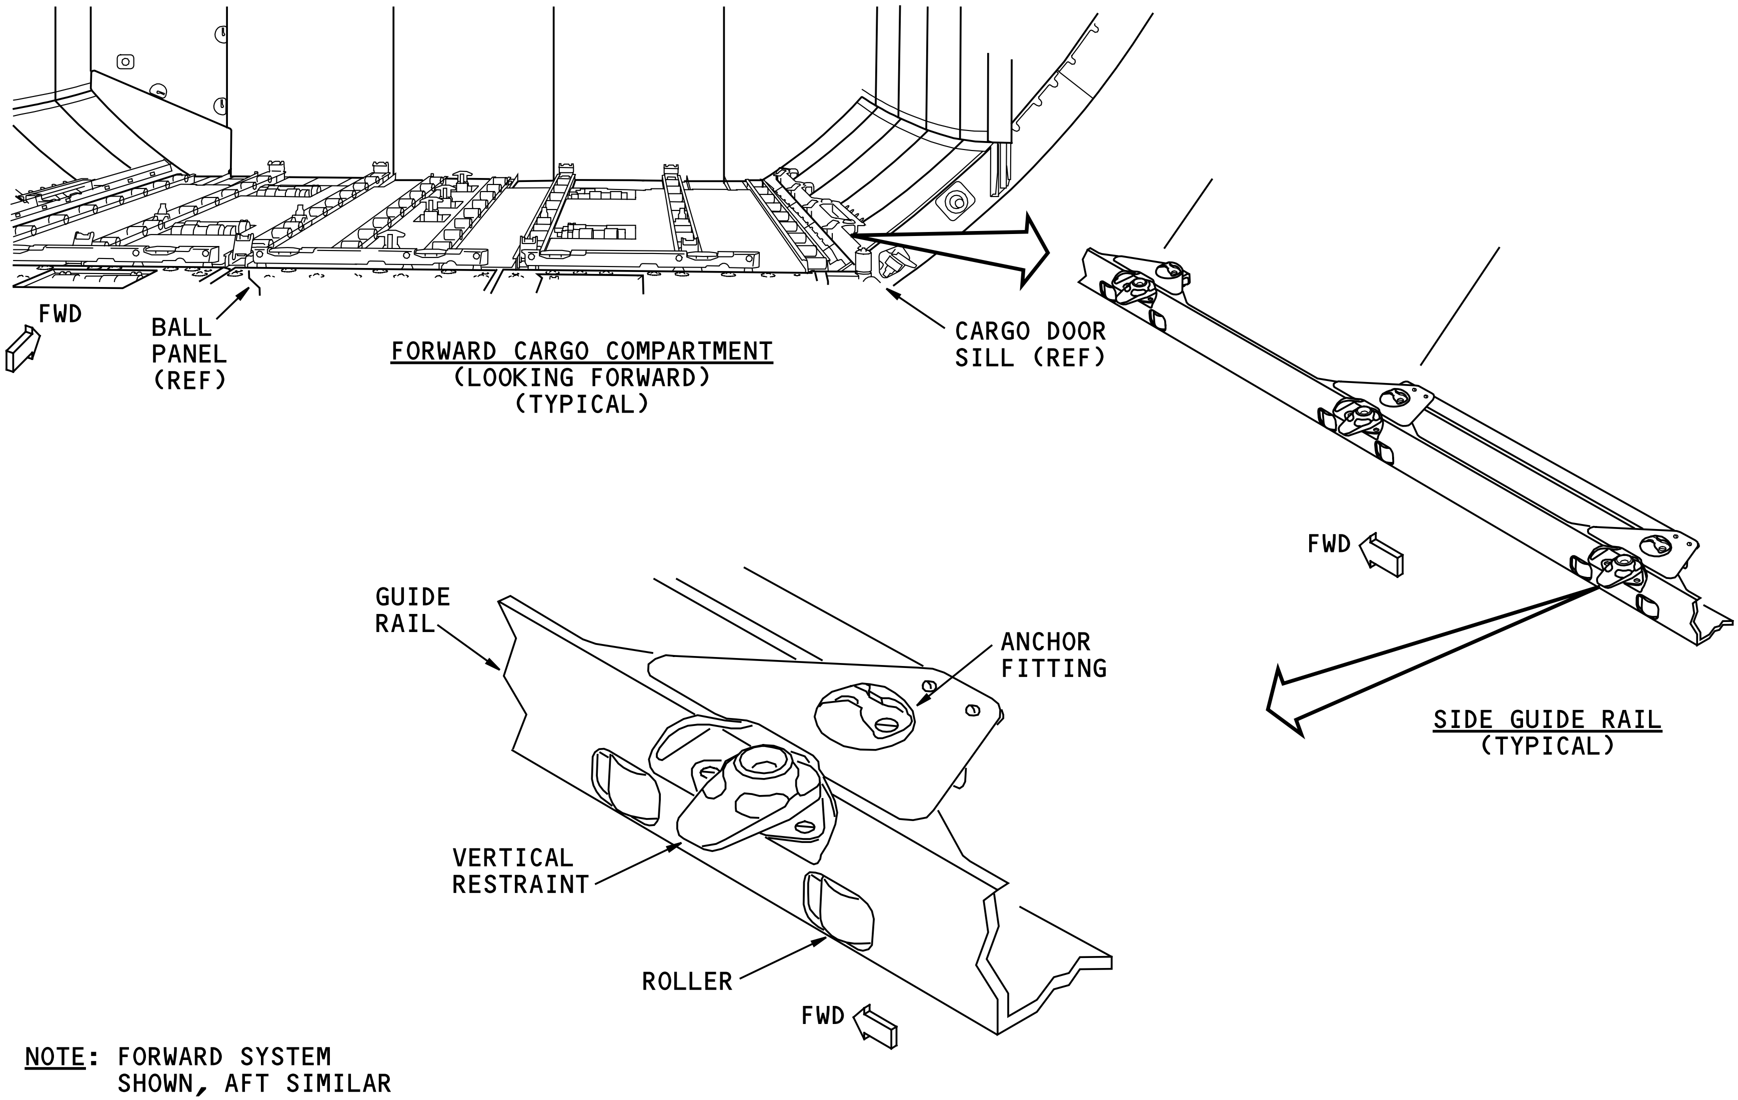
Physical Description

The side guide rail has these parts:

- Anchor fitting
- Roller
- Vertical restraint
- Guide rail.

Location

Side guide rails are along the sides of the cargo compartment, except in the cargo door sill area. In the forward cargo compartment there are five on the left side and four on the right side of the compartment. In the aft cargo compartment there are six on the left side and five on the right side of the compartment (not shown).



25-53-00-025 Rev 2 10/31/1997

CARGO HANDLING SYSTEM - SIDE GUIDE RAIL

CARGO HANDLING SYSTEM - AUXILIARY GUIDE - INTRODUCTION

General

There are two types of auxiliary guides: with-roller and without-roller.

With-roller guides are light-weight units forward and aft of the ball panels, away from the pallet loading area. Without-roller guides are heavier units near the ball panels, in the pallet loading area. Without-roller guides let you lock them down so pallets can be loaded.

Purpose

The auxiliary guides have these functions:

- Lateral and vertical restraint for LD-4/LD-8 containers
- Longitudinally guidance for LD-4/LD-8 containers
- A low friction surface to help in the movement of LD-4/LD-8 containers longitudinally.

Location

Auxiliary guides are on the right side of each cargo compartment. The without-roller auxiliary guides are in the area of the ball panels. The with-roller auxiliary guides are forward and aft of the ball panels.

CARGO HANDLING SYSTEM - AUXILIARY GUIDE - INTRODUCTION

CARGO HANDLING SYSTEM - CENTER GUIDE - INTRODUCTION

General

There is only one type of center guide. This type of guide is foot operated and can be locked down if necessary.

Purpose

The center guides have these functions:

- Supplies lateral and vertical restraint for LD-3/LD-1 containers, K and N size pallets
- Supplies lateral separation between LD-3 containers, K and N size pallets
- Supplies longitudinal guidance for LD-3/LD-1 containers, K and N size pallets.

Location

Center guides are along the center of each cargo compartment. The guides are in the area of the ball panels and in the areas forward and aft of the ball panels.

25-53-00-045 Rev 1 08/21/1997

CARGO HANDLING SYSTEM - CENTER GUIDE - INTRODUCTION

CARGO HANDLING SYSTEM - CENTER GUIDE - OPERATION

Physical Description

Center guides are spring-loaded mechanical devices. They have these parts:

- Vertical restraints (movable)
- Housing
- Base
- Spring
- Lock lever
- Lock cam
- Roller (2).

Functional Description

The spring in the base makes sure that the housing stays in the up position. The housing and the lock cam pivot together in the forward or aft direction. A lock lever spring (not shown) makes sure that the lock lever continues to touch the lock cam as it rotates.

The vertical restraints are spring-loaded devices. They are shown in there usual position.

Operation

You push the center guide all the way down (forward or aft) to lock it down. When the guide is all the way down, the lock lever engages one of two flats on the lock cam. This holds the center guide in the down position.

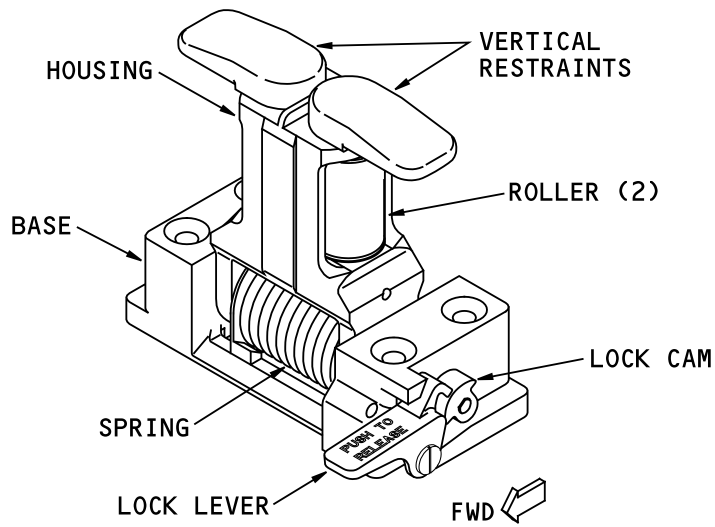
You push the lock lever to let the center guide move up.

Training Information Point

The center guides are for LD-3 and LD-1 containers. Other ULDs move over or to the sides of the center guides.

When you load pallets, they will hit the right side of the center guides in the ball panel area. You must lock the center guides down in the ball panel area when you load pallets.

The guide is spring-loaded to up. Thus, when you lock or unlock a center guide, it will come up quickly when the lock is disengaged.



CENTER GUIDE

(TYPICAL)

25-53-00-027 Rev 1 08/21/1997

CARGO HANDLING SYSTEM - CENTER GUIDE - OPERATION

CARGO HANDLING SYSTEM - AUXILIARY GUIDE - OPERATION

Physical Description

Auxiliary guides are spring loaded mechanical devices. They have these parts:

- Bolt
- Vertical restraint
- Vertical roller
- Shaft
- Horizontal roller (nonlocking guide only)
- Ball plunger (locking guide only)
- Lock (locking guide only)
- Spring
- Base
- Housing.

Functional Description

The vertical restraint pivots around a bolt in the housing. A spring (not shown) under the restraint keeps the restraint in the position shown. The spring in the base makes sure that the housing stays in the up position. The housing and the shaft pivot together. The housing and shaft pivot in the forward or aft direction. On locking guides only, the end of shaft next to the lock has two flats. These flats line up with a slot in the lock when the housing is all the way down. The lock pivots around a pin (not shown) in the base to engage or disengage with the flats. The ball plunger keeps pressure on the lock so it does not move by itself.

Operation

You use the lock to hold the auxiliary guide down. Push and hold the housing of the guide all of the way down in the aft direction. The auxiliary guide can not be locked down in the forward direction. Move the lock up so the slot in the lock fits over the flats on the shaft. The ball plunger holds the lock up.

Training Information Point

The auxiliary guides are designed for LD-4 and LD-8 containers. Other ULDs pass over or to the left of the auxiliary guides. Pallets hit the right side of the auxiliary guides in the ball panel area during loading. You must lock the auxiliary guides down in the ball panel area when you load pallets.

The guide is spring-loaded to up. Thus, when you lock or unlock a center guide, it will come up quickly when the lock is disengaged.

CARGO HANDLING SYSTEM - PARTIAL LOAD STOPS - INTRODUCTION

Purpose

Partial load stops give longitudinal restraint for containers when container loading is not continuous in the cargo compartment.

Location

Partial load stops are in many places in the forward and aft cargo compartments. In both cargo compartments, the stops attach to the four roller trays adjacent to the longitudinal PDUs.

The partial load stops are in rows. Each row has four stops.

The aft cargo compartment also has one row of four partial load stops that attach to structure. They are in the area of the aft ball panels (not shown).

● = PARTIAL LOAD STOP
= STOP/LOCK

CARGO HANDLING SYSTEM - PARTIAL LOAD STOPS - INTRODUCTION

25-53-00-029 Rev 4 03/09/1998

CARGO HANDLING SYSTEM - PARTIAL LOAD STOPS - OPERATION

Physical Description

Partial load stops are spring-loaded mechanical units. There are six types of partial load stops that are almost the same (not all shown). Most partial load stops are single units, but some may be part of a stop/lock unit (not shown).

Each partial load stop has these parts:

- Lockhead
- Base
- Fork
- Springs (not shown).

Operation

You manually put the lockhead up to the STOP position to restrain a partial load of containers. The lockhead is spring loaded to down so you must lift the lockhead until the fork locks the lockhead in the STOP position.

You manually put down the lockhead to load more containers or to unload a partial load of containers. The lockhead will go down by itself when you lift the fork.

Training Information Point

When you put the lockhead down, it is easier if you hold the lockhead as you lift the fork. This lets you get the fork up all the way and your fingers out of the way of the lockhead before the lockhead goes down.

CARGO HANDLING SYSTEM - PARTIAL LOAD STOPS - OPERATION

CARGO HANDLING SYSTEM - PALLET LOCK - INTRODUCTION

Purpose

Pallet locks give longitudinal and vertical restraint for pallets and pallet sized containers, LD-7 and LD-11.

Location

Pallet locks are in many places in the forward and aft cargo compartments.

Most pallet locks mount to the roller trays and some mount to floor structure. Some pallet locks may be part of a stop/lock unit.

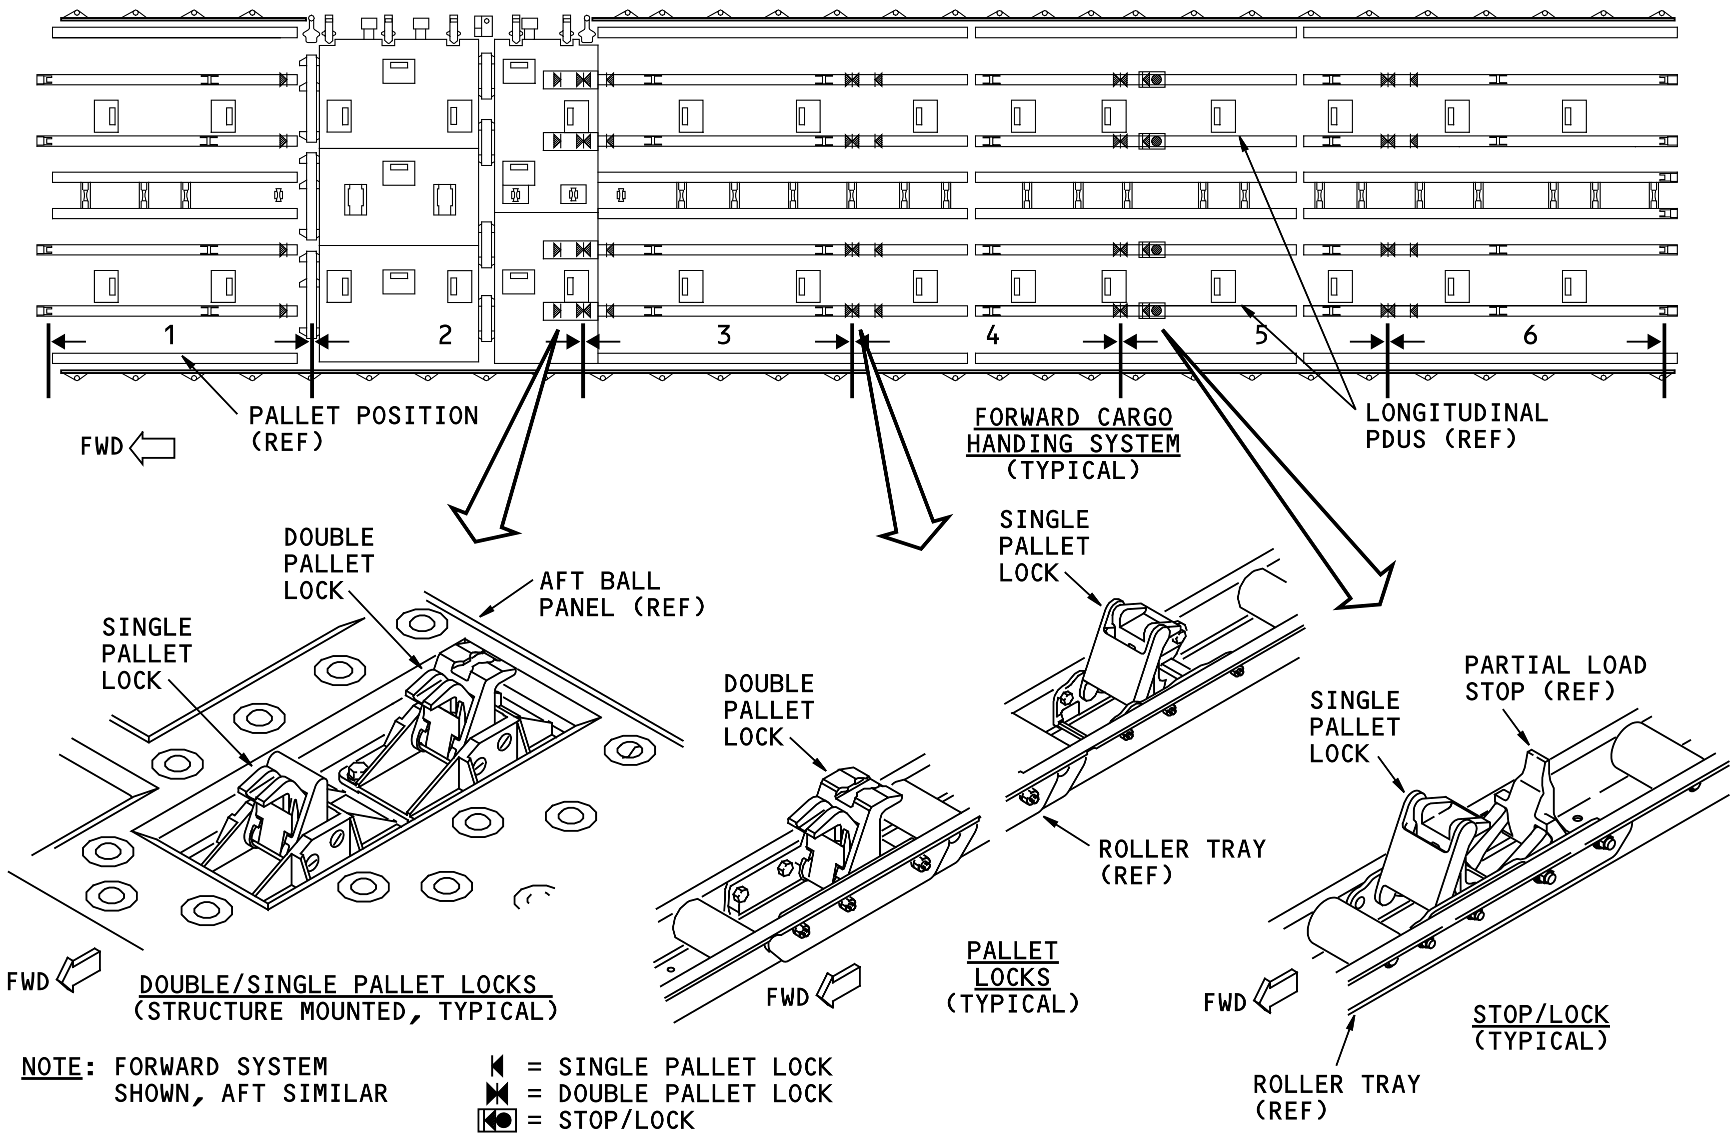
The locks mount to the four roller trays that parallel the longitudinal PDUs.

The aft cargo compartment also has pallet locks mounted in the two center most roller trays (not shown).

The floor structure mounted locks are in the area of the aft ball panels.

The locks are in rows, each row in the forward cargo compartment has four locks.

In the aft cargo compartment, each row has six locks. The additional locks are necessary to divide the weight of the cargo evenly to the airplane structure.



CARGO HANDLING SYSTEM - PALLET LOCK - INTRODUCTION

CARGO HANDLING SYSTEM - PALLET LOCK - OPERATION

Physical Description

All pallet locks are spring-loaded mechanical units. There are seven similar types of pallet locks (not all shown). More than one type is necessary because of mounting and space limits. Some pallet locks have parts that let them restrain only one pallet. Others have parts that let them restrain two pallets.

Pallet locks have these parts:

- Lockhead(s)
- Anchor fitting (not all locks)
- Base
- Pawl (double pallet locks)
- Link (single pallet locks)
- Springs (not shown).

Double Pallet Lock Operation

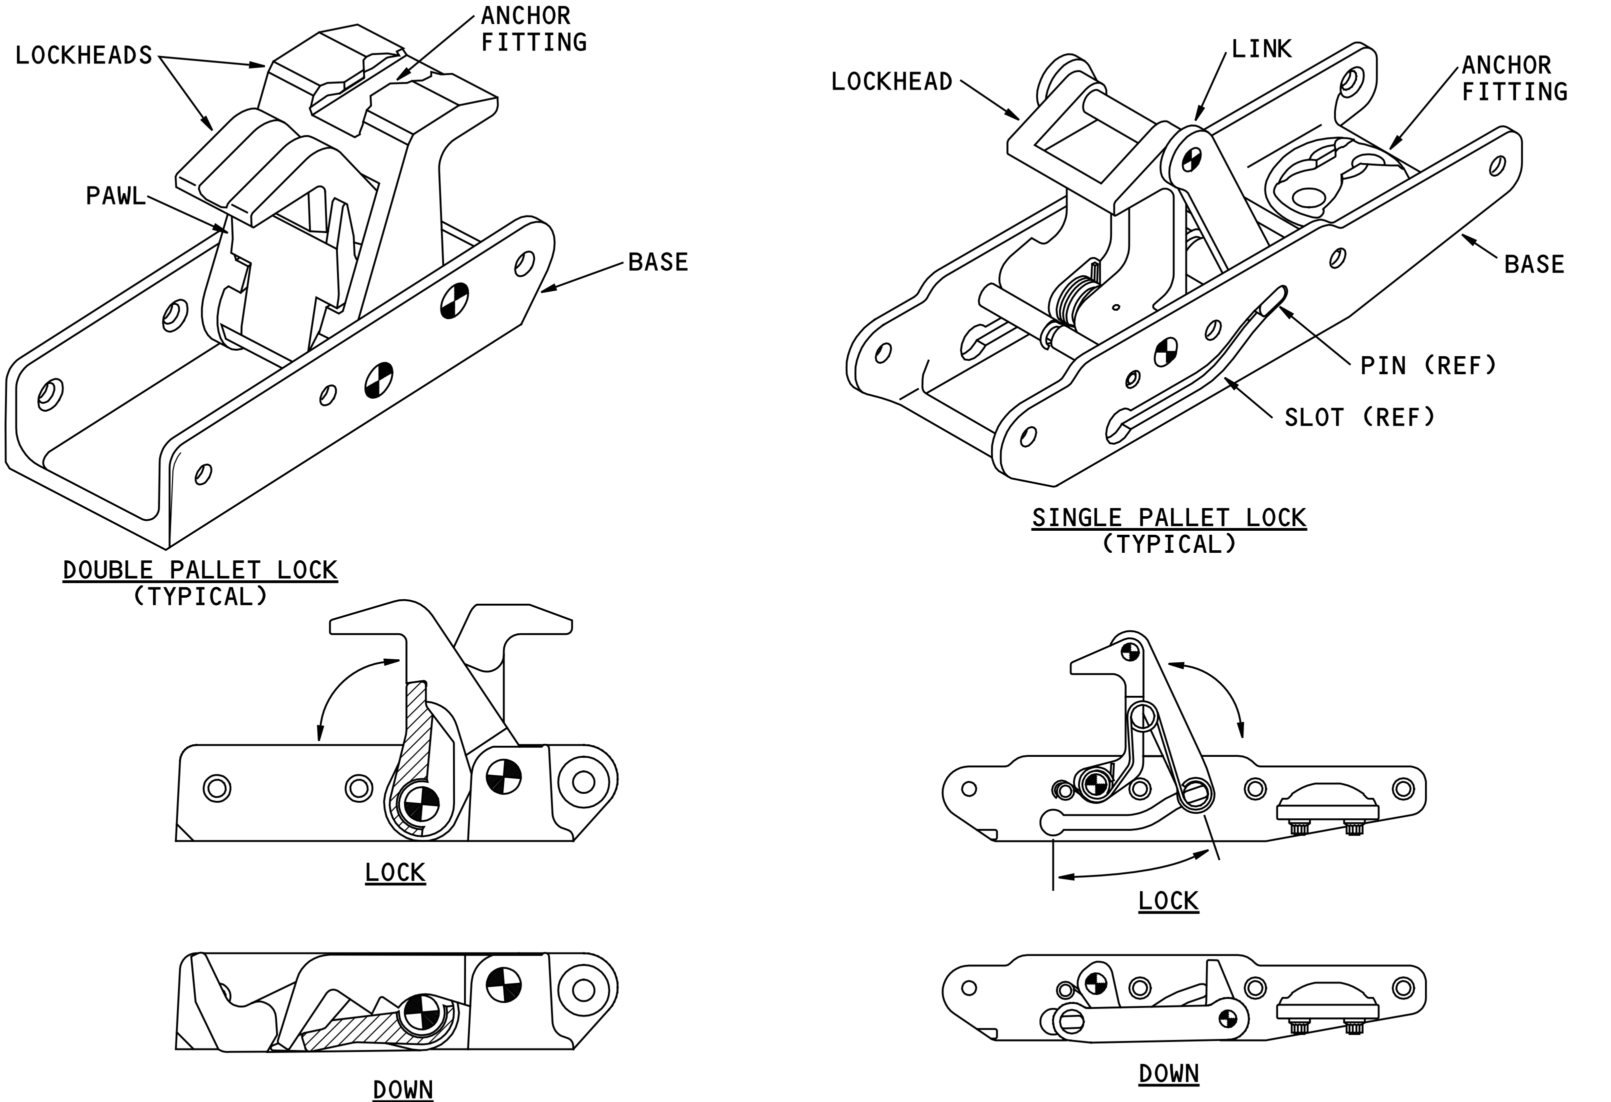
You manually put the lockhead up to restrain pallets. The lockhead is spring loaded to down so you must lift the lockheads until the pawl locks the lockheads in the LOCK position.

You manually put down the lockheads to unload cargo. The lockheads will go down on there own when you pull the upper part of the pawl away from them. It is easier to move the pawl if you hold the heads up then let them go down.

Single Pallet Lock Operation

You manually put the lockhead up to the LOCK position to restrain one pallet. The lockhead is spring-loaded down so you must lift the lockhead until the link locks the lockhead in the LOCK position.

You manually put down the lockhead to unload cargo. The lockhead will go down by itself when you push the lower part of the link towards it. The lower part of the link attaches to a pin. The pin follows slots in the base when you push on the lower part of the link.



CARGO HANDLING SYSTEM - PALLET LOCK - OPERATION

CARGO HANDLING SYSTEM - STOP/LOCK - INTRODUCTION

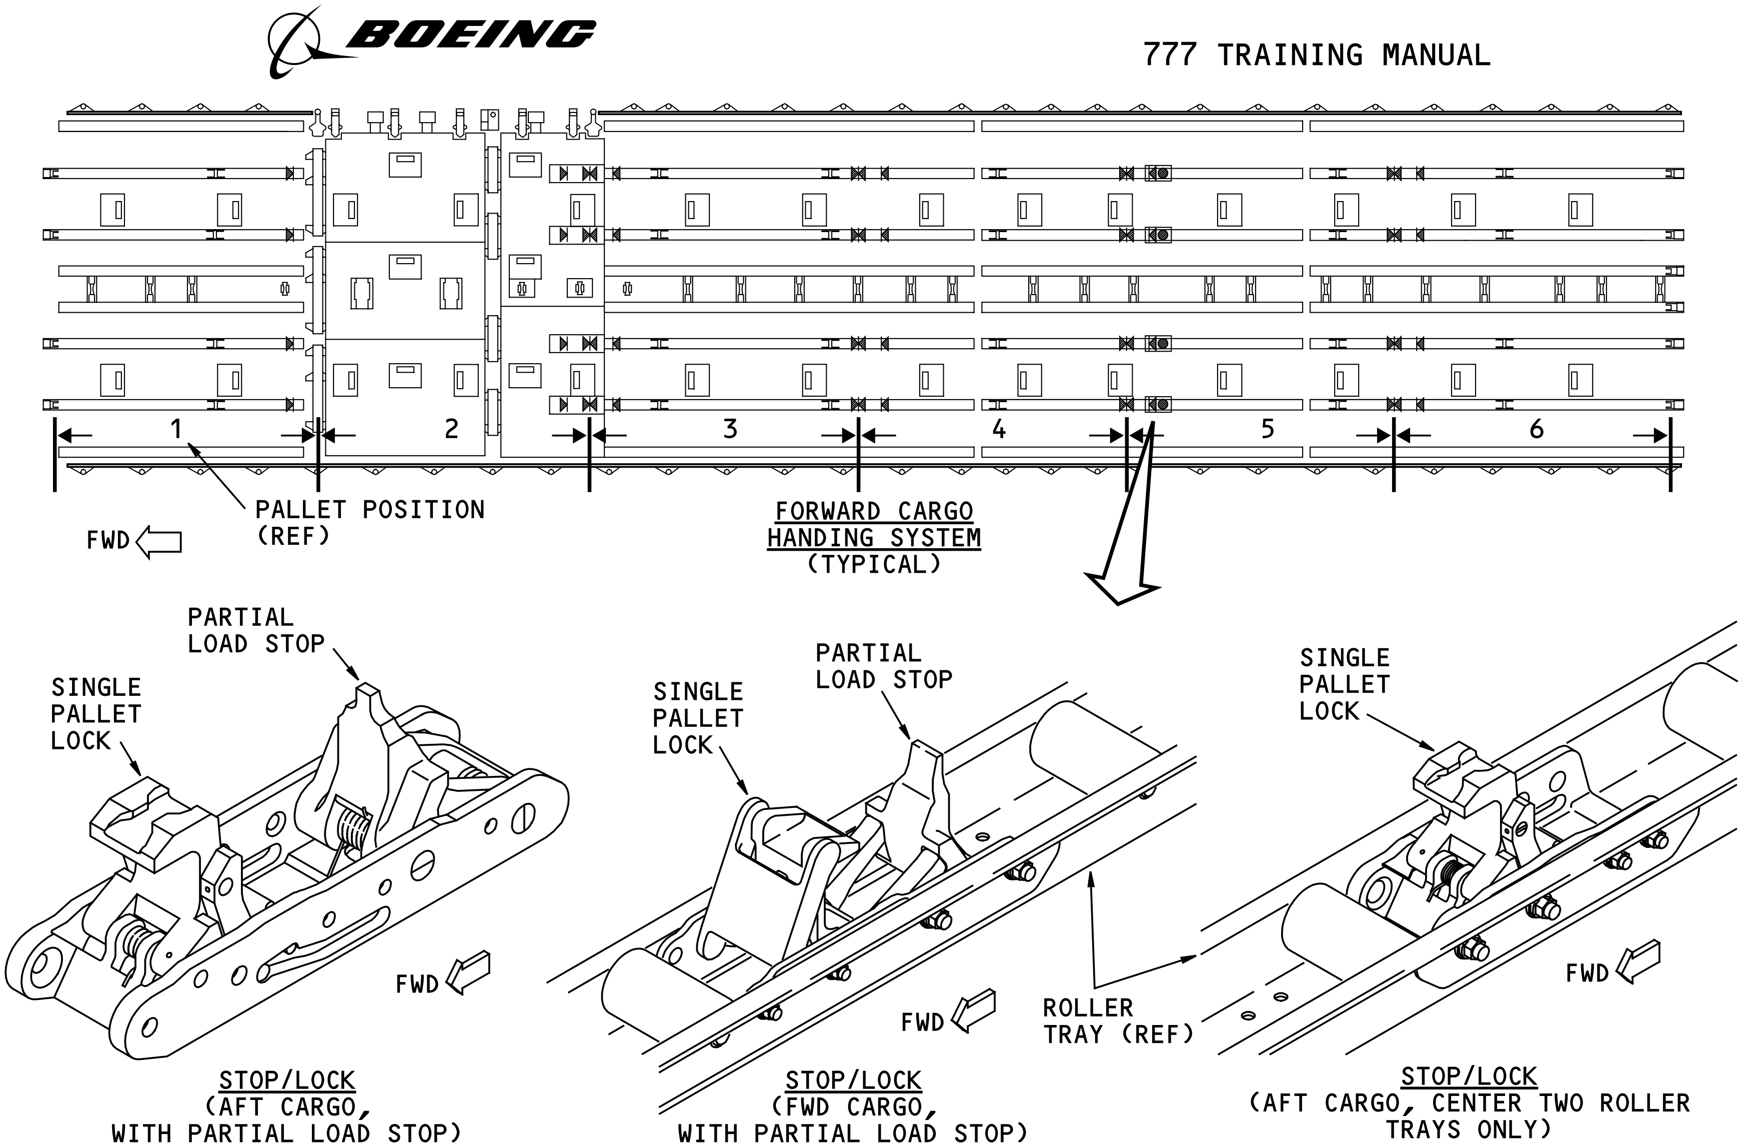
Purpose

Stop/locks give longitudinal and vertical restraint for pallets. Some locks also give longitudinal restraint for containers.

Location

Both cargo compartments have one row of stop/locks. In the forward cargo compartment the row is aft of the ball panels and in the aft compartment (not shown) the row is forward of ball panels.

Stop/locks with partial load stops mount to the roller trays that parallel the longitudinal PDUs in both compartments. Locks without partial load stops are in the two center most roller trays in the aft cargo compartment only (not shown).



NOTE: FORWARD SYSTEM SHOWN, AFT SIMILAR

= STOP/LOCK

25-53-00-033 Rev 4 10/31/1997

CARGO HANDLING SYSTEM - STOP/LOCK - INTRODUCTION

CARGO HANDLING SYSTEM - STOP/LOCK - OPERATION

Physical Description

The three types of stop/locks are almost the same:

- Stop/lock, with partial load stop and no anchor fitting (4, fwd cargo)
- Stop/lock, with partial load stop and with anchor fitting (4, aft cargo)
- Stop/lock, without partial load stop and with anchor fitting (2, aft cargo).

The stop locks are spring-loaded mechanical units with these parts:

- Anchor fitting (aft cargo stop/locks only)
- Lockhead(s)
- Base
- fork (not all locks)
- Pin
- Link
- Pawl (aft cargo stop/locks only)
- Springs (not shown).

Operation

If a stop/lock has two lockheads, you use only one at a time. The one you use depends on if the cargo is a container or a pallet.

You manually set the stop/locks to one of these positions:

- LOCK (for pallets)
- STOP (for containers)
- UNLOAD.

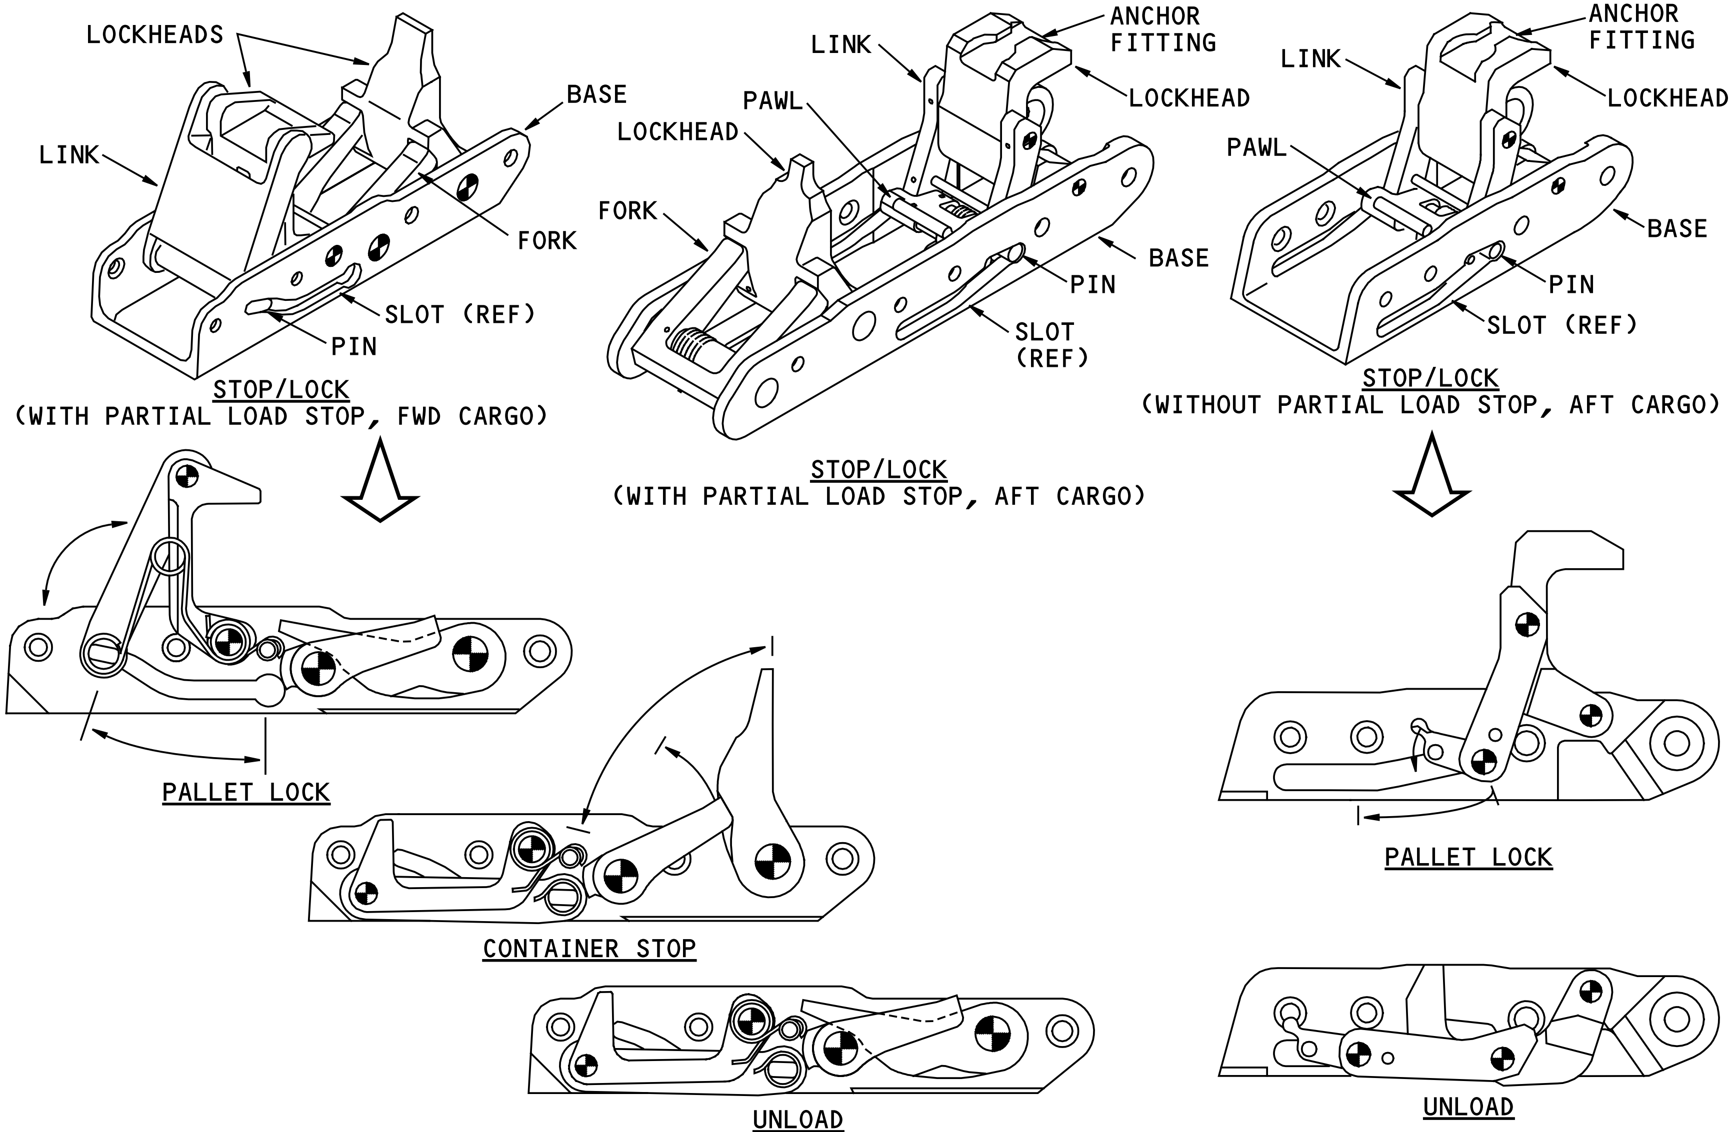
You manually put the lockheads up, LOCK or STOP position to restrain cargo. The lockheads are spring loaded to down so you must lift the lockheads until the fork or the link locks the heads up.

You manually put down the lockheads to unload cargo.

The container stop lockhead (fwd cargo) will go down by itself when you lift the fork. It is easier to lower the head if you hold the head up as you lift the fork.

The pallet lock lockhead (fwd cargo) will go down by itself when you push the lower part of the link towards it. The lower part of the link attaches to the pin. The pin follows the slots in the base when you push on the lower part of the link.

The pallet lock lockhead (aft cargo) will go down on its own when you push down on the pawl and pull it away from the head. The pawl attaches to the lower part of the link. The link attaches to the pin. The pin follows the slot in the base when you pull on the pawl.



CARGO HANDLING SYSTEM - STOP/LOCK - OPERATION

25-53-00-034 Rev 1 05/31/95

CARGO HANDLING SYSTEM - END STOP

General

There are two types of end stops:

- End stop with vertical restraint
- End stop without vertical restraint.

All end stops give longitudinal restraint for containers and pallets. End stops with vertical restraint give vertical restraint for pallets and pallet sized containers, LD-7 and LD-11.

Physical Description

The forward cargo compartment uses both types of end stops.

The aft cargo compartment uses end stops with vertical restraint only.

The stops are one piece, fixed (non-retractable) units. Stops with vertical restraint have an anchor fitting.

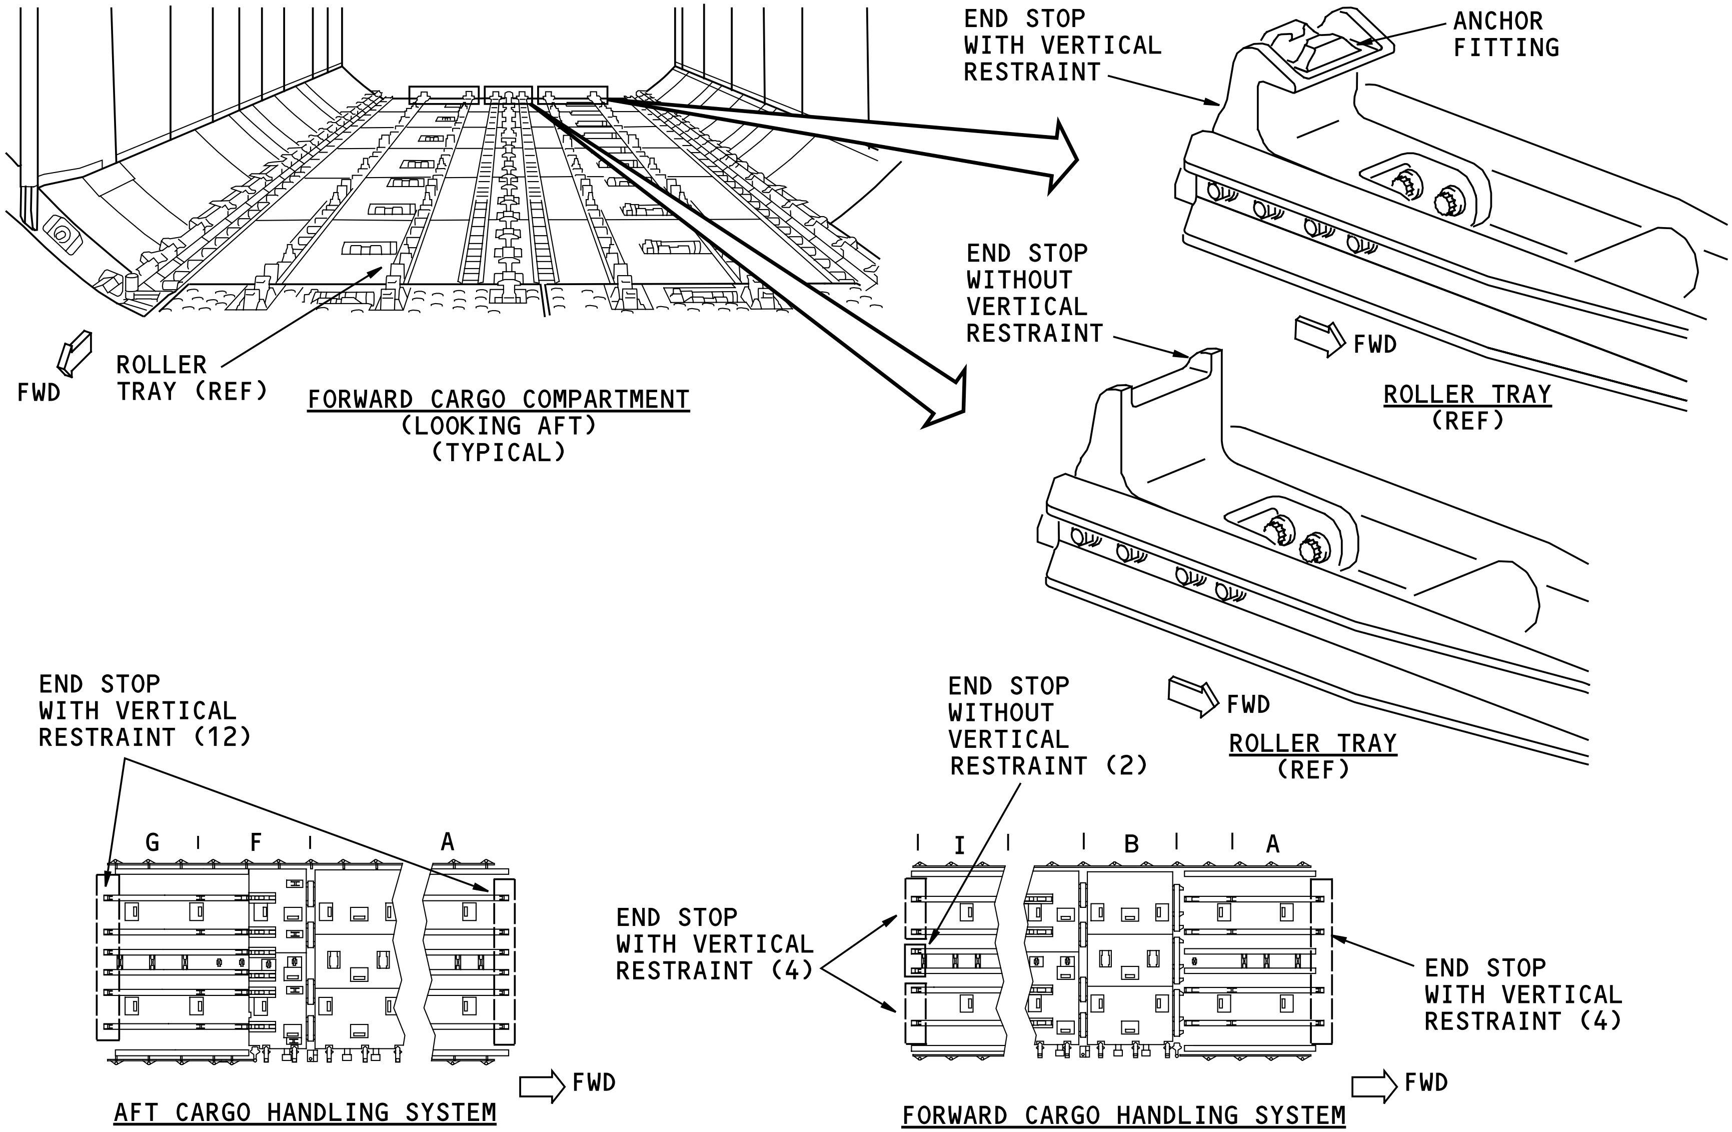
Location

The end stops mount to the roller trays at each end of the compartments.

The forward cargo compartment has four with vertical restraint at each end.

The forward cargo compartment also has two end stops without vertical restraint in the aft end of the compartment.

The aft cargo compartment has six with vertical restraint at each end.



CARGO HANDLING SYSTEM - END STOP

CARGO HANDLING SYSTEM - CARGO SYSTEM CONTROLLER

Purpose

The cargo system controllers (CSCs) give an interface between the cargo handling controls and the cargo handling electrical/mechanical units. The controllers control the operation and the sequence of operation for the units and give protection to prevent actuator/gear motor overheat and burnout.

Physical Description

The forward and aft CSCs are the same. The CSCs are passively cooled units.

Location

The forward cargo system controller is on the E16-2 shelf.

The aft cargo system controller is on the E17-1 shelf (not shown).

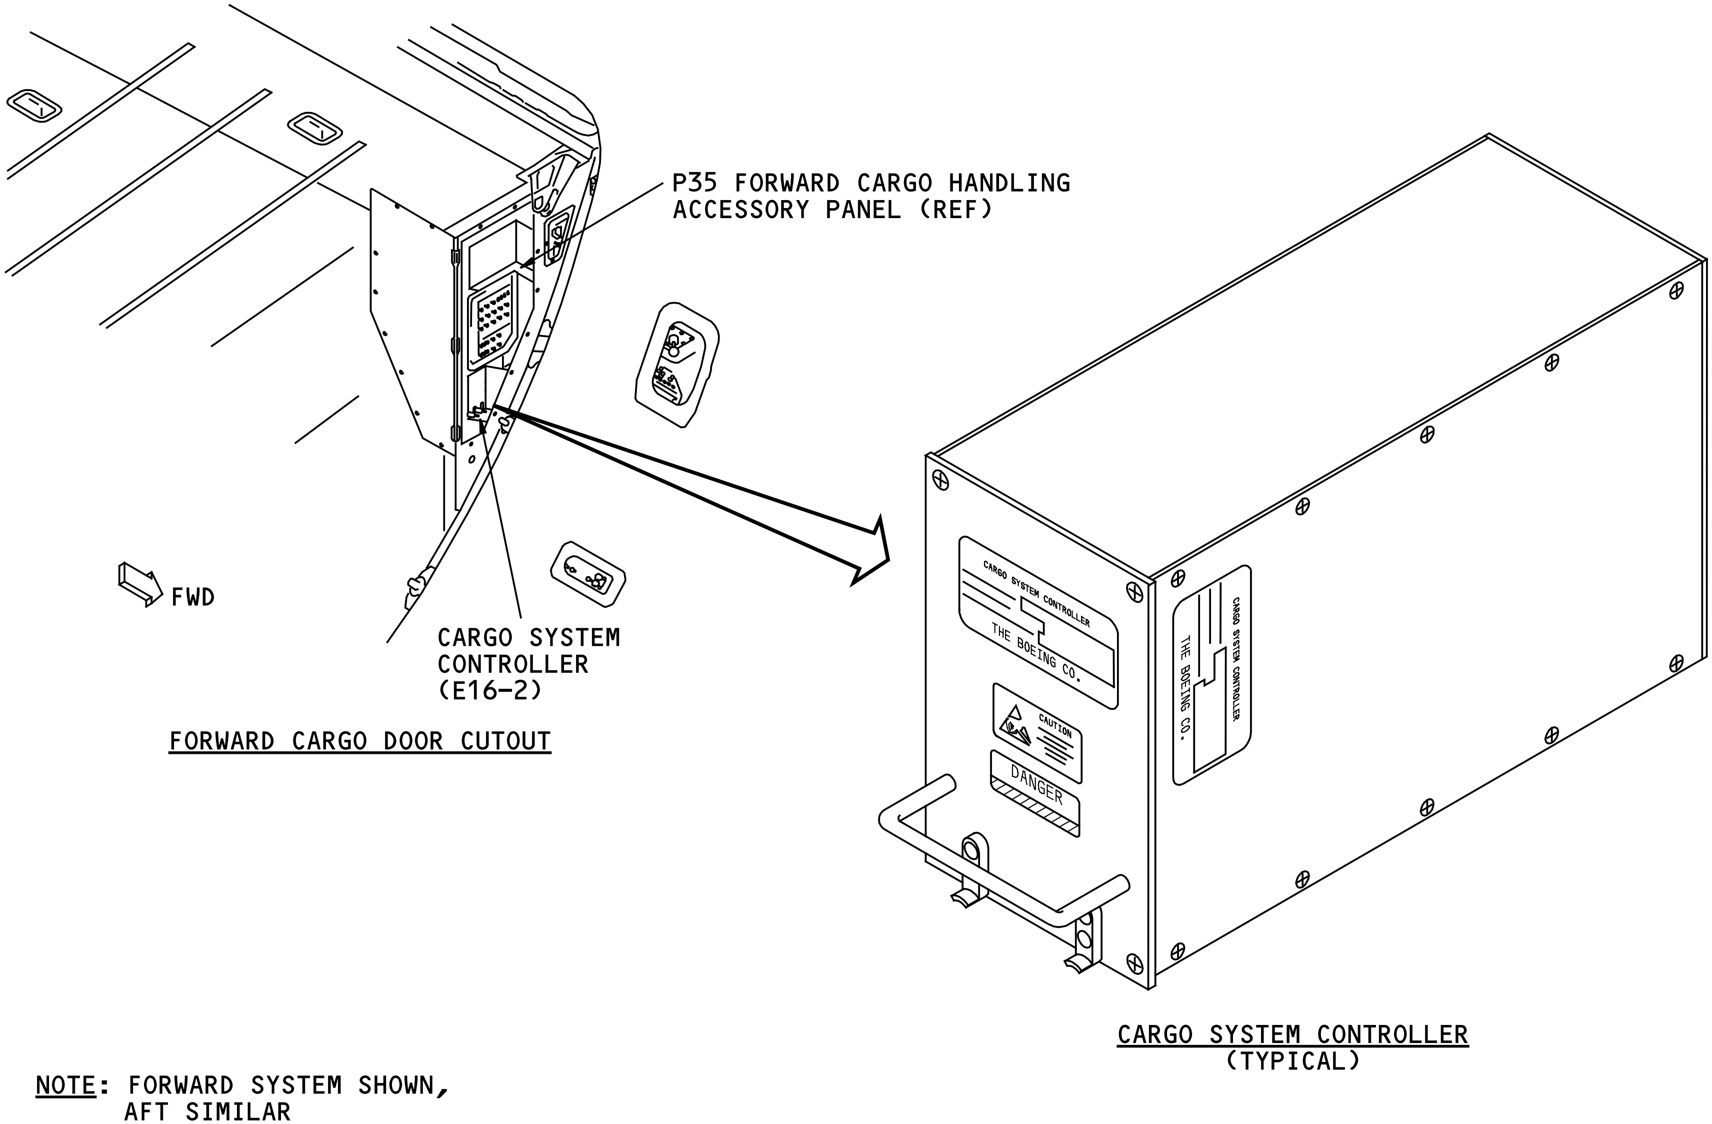
Operation

Controller logic changes with hard-wired programming pins. Pins in the electrical connector of the equipment rack (not shown), tell the controllers which cargo compartment they are in and which system options are active. This lets the controllers adjust for the difference between the forward and aft cargo compartments and for system options. For example, programming pins give this type of information:

- Forward or aft cargo compartment
- LD-4/LD-8 containers
- Aft large cargo door
- Crew rest in place 1
- Crew rest in place 2
- No gearmotor devices installed.

Training Information Point

The controllers do not have BITE. To do a test, you operate the system to see if it operates correctly. The controllers do not have an interface with the AIMS.



25-53-00-036 Rev 3

CARGO HANDLING SYSTEM - CARGO SYSTEM CONTROLLER

THIS PAGE INTENTIONALLY LEFT BLANK

CARGO HANDLING SYSTEM - OPERATION - CONTROLS

General

Controls for the cargo handling system let you operate the system. The controls for the forward and aft cargo handling systems are almost the same.

These are the controls that you use to operate the systems:

- Cargo control joystick
- P24 forward cargo handling control panel or P27 aft cargo handling control panel (not shown)
- Secondary joystick panel.

Location

Controls for the forward and aft cargo handling systems are near the forward part of the cargo cut out.

The cargo control joystick and the cargo handling control panel, P24 forward system and P27 aft system (not shown) are forward of the door cut out on the exterior.

The secondary joystick panel is in the ceiling of the cargo compartment between the interior cargo door control and cargo handling accessory panel (P35 forward or P39 aft, not shown).

P24 Cargo Handling Control Panels (P27 not shown)

The forward cargo handling control panel has these parts:

- SYSTEM POWER switch
- System power LED
- PDU AFT/FWD switch
- PDU LEFT/BOTH/RIGHT switch
- PALLETS/CONTAINERS switch
- Bay on LEDs
- BAY OFF switches.

The aft cargo handling control panel (not shown) has the same parts.

SYSTEM POWER switch: a two-position, ON/OFF switch. This switch lets you set system power to on/off.

System power ON LED: a yellow LED. This comes on when power is on the system. The CSC controls the LED.

PDU AFT/FWD switch: a two-position switch. This switch lets you set the area of the cargo compartment in which PDUs will be active.

PDU LEFT/BOTH/RIGHT switch: a three-position switch. This switch lets you set the side of the compartment in which PDUs will be active.

PALLETS/CONTAINERS switch: a two-position switch. This switch lets you set the system for the type of ULDs being loaded or unloaded.

Bay on LEDs: Yellow LEDs come on to let you know which bays have active PDUs.

CARGO HANDLING SYSTEM - OPERATION - CONTROLS

BAY OFF switches: These are three-position toggle switches spring-loaded to the center position. The up or down position lets you set the PDUs on or off. (Up or down for on, up or down again for off.) The P27 aft cargo handling control panel (not shown) only has four bay off switches: A, B, C, and G.

Lighting for the cargo handling control panel comes from an area light above the panel. The light shines down on the panel so you can see it when it is dark outside. The light also shows that power is available to the cargo handling system, because it is on anytime the ground handling bus has power.

The cargo control joystick is not part of the cargo handling control panel.

Cargo Control Joystick

The forward and aft (not shown) cargo control joysticks let you control the longitudinal and lateral movement of ULDs. The joystick has five positions: IN, OUT, FWD, AFT and neutral. It is spring loaded to the neutral position.

Secondary Joystick Panel

This panel has only the secondary joystick. This joystick is a three-position toggle switch that is spring-loaded to the middle position. The switch functions as a joystick because it lets you move cargo forward or aft but not on to the ball panel.

CARGO HANDLING SYSTEM - OPERATION - CONTROLS

CARGO HANDLING SYSTEM - FUNCTIONAL DESCRIPTION - POWER

General

The cargo handling system gets its power from the ground handling bus. It uses three phase 115v ac for operation and 28v dc for control.

Operation power loads go to two circuits: left system power and right system power. The CSC uses the left and right system relays to control system power.

System Power

The ground handling bus gives power directly to the cargo control panel area light. The light is on when the bus has power.

The CSC turns on system power if you open the cargo door to full open and set the cargo handling system power switch to the ON position. When power is on the system, the CSC turns on the system power ON LED.

CARGO HANDLING SYSTEM - FUNCTIONAL DESCRIPTION - LATERAL GUIDE

General

For control, the lateral guides have two major groups, forward and aft. Each major group has two minor groups, left and right. Guides in each major group have a number. The numbers increase from right to left.

These are the minor groups and the guides in them:

- Forward right: FWD 1 and FWD 2
- Forward left: FWD 2 and FWD 3
- Aft right: AFT 1 and AFT 2
- Aft left: AFT 3 and AFT 4.

Only the guides in a single major group operate at a time. Within a major group, the left and right minor groups of guides may operate independently or at the same time. The lateral guides have two positions, up and down.

The CSC uses inputs from these switches to set the position of the lateral guides:

- Cargo control joystick
- PDU forward/aft switch
- PDU left/both/right switch
- Pallet/container switch.

CSC Control

Power switching circuits in the CSC, get 115v ac single phase voltage from the ground handling bus. The switching circuits control the voltage and monitor for current flow to the lateral guides. The default value for CSC logic is to command (CMD) the guides to up. The down CMD is based on switch inputs.

The power switching circuits give voltage to move the guides up or down. Limit switches in the guides stop the current flow and apply a brake when the guide moves to the desired position. If a guide does not stop the current within three seconds after a up or down CMD is given, the power switching circuit removes the voltage. If no current draw is sensed within seventy-five milliseconds after a CMD is given, the voltage is removed.

Guides UP Position

All guides go to up when not commanded to down.

Forward Right Guides 1 and 2 Down Position

Forward guides 1 and 2 go to the down position when all of these events occur:

- Joystick to FWD or AFT
- System set to PDU RIGHT or to PDU BOTH
- System set to PDU FWD.

Forward Left Guides 2 and 3 Down Position

Forward guides 2 and 3 go to the down position when all of these events occur:

- Joystick to FWD or AFT

- System set to PDU LEFT or to PDU BOTH
- System set to PDU FWD.

Aft Right Guides 1 and 2 Down Position

Aft guides 1 and 2 go to the down position when the system is set to PALLETS or when all of these events occur:

- Joystick to FWD or AFT
- System set to PDU RIGHT or to PDU BOTH
- System set to PDU AFT.

Aft Left Guides 3 and 4 Down Position

Aft guides 3 and 4 go to the down position when the system is set to PALLETS or when all of these events occur:

- Joystick to FWD or AFT
- System set to PDU LEFT or to PDU BOTH
- System set to PDU AFT.

CARGO HANDLING SYSTEM - FUNCTIONAL DESCRIPTION - LATERAL GUIDE

THIS PAGE INTENTIONALLY LEFT BLANK

CARGO HANDLING SYSTEM - FUNCTIONAL DESCRIPTION - PDU

General

For control purposes, the powered drive units (PDUs) are in two major groups, longitudinal and lateral. The longitudinal group has two minor groups, left and right. All PDUs are also grouped by location in the compartment (bays). These are PDUs by group and location for the forward cargo handling system. The aft system is almost the same.

PDU Groups and Location		
Area	Major Group	PDUs by Row
Forward Bays	Longitudinal	1L/R, 2L/R
Ball Panel	Longitudinal	3L/R, 5L/R, 7L/R
	Lateral	4L/C/R, 6L/C/R
Aft Bays	Longitudinal	8L/R through 16L/R

Only the PDUs in a single major group operate at a given time. Within the longitudinal group, the left and right minor groups may operate independently or at the same time. You can operate all PDUs row by row. The PDUs have three conditions:

- Erect/drive
- Erect/brake
- Down.

All PDUs get 115v ac, three-phase voltage from the ground handling bus. They use this ac voltage for the erection coil, motor, brake and phase reversing relays.

The CSC uses inputs from these switches to set the position of the PDUs:

- Secondary joystick
- Cargo control joystick
- PDU forward/aft switch
- PDU left/both/right switch
- Pallet/container switch
- Bay off switches.

CSC Control

Control circuits within the CSC, use phase reversing relays in the PDUs to control when and how voltage is given to the PDU motor. The circuits also control the erection coils and brake for the PDUs in the ball panel area. PDUs forward and aft of the ball panels have their erection coils and brake active when system power is on and the PDU is not in the drive condition. CSC control circuits command PDUs to erect/drive one row at a time with a small delay between rows. This reduces inrush current demands.

The bay off switches stop the drive command for rows of PDUs. This prevents PDUs from scrubbing under ULDs that are in position. The PDU rows affected by the bay off switches are different for containers and pallets. These charts show the functions of the bay off switches for the forward cargo handling system. The aft system is almost the same.

Bay Off Switches (CONTAINER Mode)			
Action	Sw	Bay(s) Effected	PDU Rows Active
Toggle On	D	D	8, 9
Toggle On	E	D, E	8, 9, 10
Toggle On	F	D, E, F	8, 9, 10, 11, 12
Toggle On	G	D, E, F, G	8, 9, 10, 11, 12, 13
Toggle On	H	D, E, F, G, H	8, 9, 10, 11, 12, 13, 14, 15
Toggle On	I	D, E, F, G, H, I	8, 9, 10, 11, 12, 13, 14, 15, 16
Action	Sw	Bay(s) Effected	PDU Rows Not Active
Toggle Off	D	D, E, F, G, H, I	8, 9, 10, 11, 12, 13, 14, 15, 16
Toggle Off	E	E, F, G, H, I	10, 11, 12, 13, 14, 15, 16
Toggle Off	F	F, G, H, I	11, 12, 13, 14, 15, 16
Toggle Off	G	G, H, I	13, 14, 15, 16

Toggle Off	E	E, F, G, H, I	10, 11, 12, 13, 14, 15, 16
Toggle Off	F	E, F, G, H, I	10, 11, 12, 13, 14, 15, 16
Toggle Off	G	G, H, I	13, 14, 15, 16
Toggle Off	H	H, I	15, 16
Toggle Off	I	H, I	15, 16

The PDU erect command does not operate (ball panel area only) the longitudinal PDUs when the cargo control joystick is moved to IN or to OUT. Lateral PDUs erect command stops when the cargo control joystick is moved to FWD or AFT. The erect command for all PDUs stops when there is no system ac power.

Longitudinal PDUs - Ball Panel

The CSC uses almost the same logic to control longitudinal PDUs in the ball panel area as it uses for the PDUs in the forward and aft bays. The PDU forward/aft switch and the secondary joystick do not control the longitudinal PDUs in the ball panel area. The CSC also controls the erect/brake and down conditions for these PDUs. The PDUs go to the down condition when the cargo control joystick is set to IN or OUT.

Longitudinal PDUs - Ball Panel/Forward Bays

Longitudinal PDUs in the forward cargo bays stay in the erect/brake condition when system ac power is on and the PDUs are not commanded to the erect/drive condition.

PDUs in the ball panel and forward bays go to the erect/drive condition when all of these events occur:

- System set to PDU FWD

CARGO HANDLING SYSTEM - FUNCTIONAL DESCRIPTION - PDU

- Cargo control joystick to FWD or AFT or secondary joystick to FWD or AFT (secondary joystick affects only PDUs fwd or aft of ball panels)
- Forward lateral guides in the down position.

The position of the PDU left/both/right switch and the container/pallet switch controls which minor group of longitudinal PDUs go to the erect/drive condition when the cargo control joystick is set to FWD or AFT. If BOTH or PALLETS is set, then all PDUs in the area go to erect/drive condition. If CONTAINERS and LEFT or RIGHT is set, then only the PDUs in the area on the related side go to the erect/drive condition.

Longitudinal PDUs - Ball Panel/AFT Bays

Control for the longitudinal PDUs in the ball panel and aft bays is the same as the ones in the forward bays except for the following.

PDUs in the ball panel and aft bays go to the erect/drive condition when all of these events occur:

- System set to Bay ON for at least one bay
- System set to PDU AFT
- Cargo control joystick to FWD or AFT or secondary joystick to FWD or AFT (secondary joystick affects only PDUs fwd or aft of ball panels)
- Aft lateral guides in the down position
- Aft lateral guides in the down position.

Lateral PDUs

All lateral PDUs go to the erect/drive condition when all of these events occur:

- System set to PALLETS
- Cargo control joystick to IN or OUT.

The forward set of lateral PDUs go to the erect/drive condition when all of these events occur:

- System set to CONTAINERS
- Cargo control joystick to IN or OUT.
