TABLE OF CONTENTS

Introduction

The 777 is designed for ETOPS (extended range operations with two-engine airplanes). It is for medium and long range flights. The 777 size is between a 767-300 and a 747-400.

Features

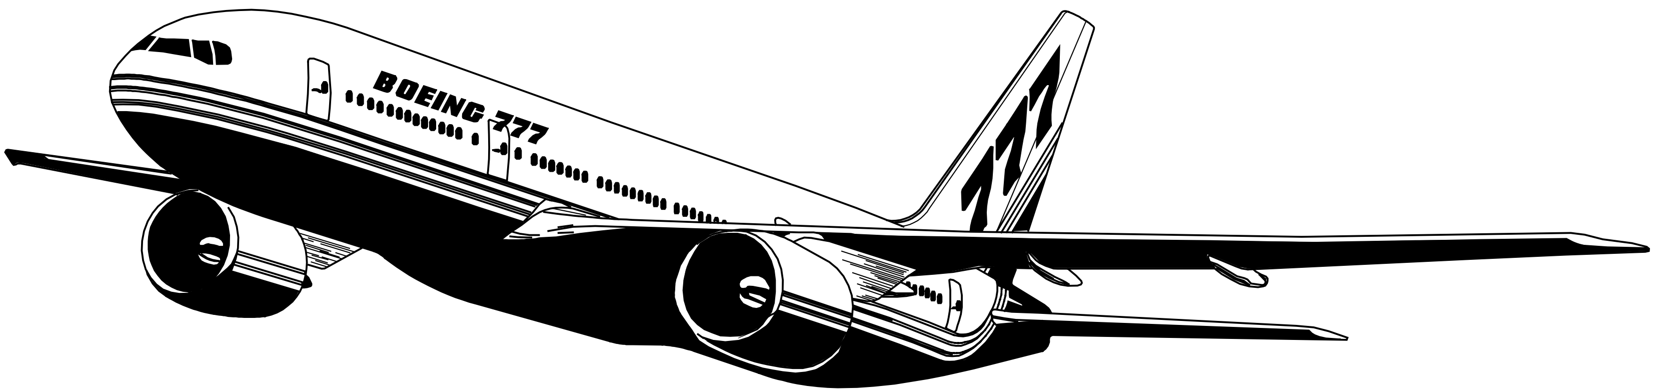
These are the major features of the 777:

- Two-crew flight deck
- Digital avionics
- Flat panel liquid crystal displays
- Fly-by-wire technology
- ARINC 629 data buses
- Ultrasonic fuel quantity measurement
- Six-wheel landing gear trucks with steering
- A combined air data inertial reference system
- Fiber optic technology
- Cabin management system
- Airplane information management system (AIMS) which combines many avionics functions.

Abbreviations and Acronyms

ACMP - AC motor pump
ACP - audio control panel
ADF - automatic direction finder
ADP - air-driven pump
ADIRS - air data inertial reference system
ADIRU - air data inertial reference unit
AFDS - autopilot flight director system
AIMS - airplane information management system
APU - auxiliary power unit
ARINC - Aeronautical Radio, Inc.
ASG - ARINC signal gateway
ATC - air traffic control
BPS - bits per second
BSU - bypass switch unit
CACP - cabin area control panel
CAH - cabin attendant handset
CCD - cursor control device
CDU - control display unit
CIS - cabin interphone system
CMCS - central maintenance computing system
CMS - cabin management system
CSCP - cabin system control panel
DME - distance measuring equipment
EDP - engine-driven pump
EFIS - electronic flight instrument system
EICAS - engine indication and crew alerting system
EPAS - emergency power assist system
ESDS - electrostatic discharge sensitive
ETOPS - extended range operations with two-engine airplanes
FCR - flight crew rest
FDH - flight deck handset
GPS - global positioning system
HF - high frequency

HLCS	-	high lift control system
IDG	-	integrated drive generator
IGW	-	increased gross weight
ILS	-	instrument landing system
KBPS	-	kilobits per second
LAN	-	local area network
LRU	-	line replaceable unit
MAT	-	maintenance access terminal
MBPS	-	megabits per second
MEC	-	main equipment center
mic	-	microphone
OLAN	-	onboard local area network
OPAS	-	overhead panel ARINC 629 system
OPBC	-	overhead panel bus controller
OPCF	-	overhead panel card file
PAX TEL	-	passenger telephone
PDCU	-	panel data concentrator unit
PES	-	passenger entertainment system
PFCS	-	primary flight control system
PMAT	-	portable MAT
RA	-	radio altitude
RAT	-	ram air turbine
RS	-	recommended standard
RTP	-	radio tuning panel
SAARU	-	secondary attitude air data reference unit
SATCOM	-	satellite communication
SCF	-	system card file
TAC	-	thrust asymetry compensation
TCAS	-	traffic alert and collision avoidance system
VHF	-	very high frequency
VOR	-	VHF omni range
WPS	-	words per second



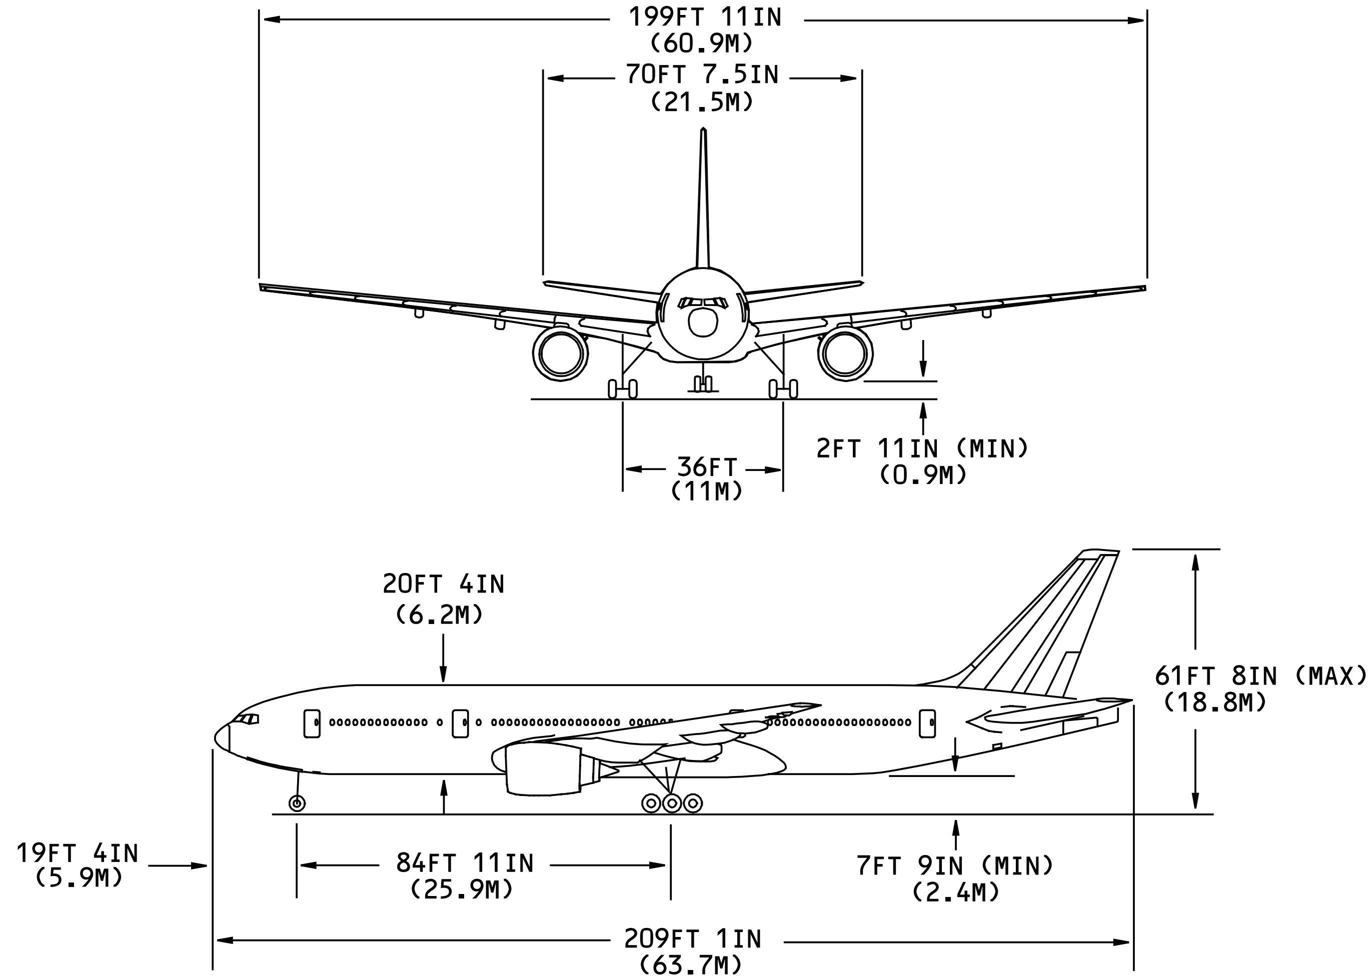
00-00-00-001 Rev 5

777 GENERAL - INTRODUCTION

777 GENERAL - PRINCIPAL DIMENSIONS

777 Principal Dimensions

These are the principal dimensions of the 777-200 increased gross weight (IGW) airplane on a front and side view.



777 GENERAL - PRINCIPAL DIMENSIONS

General Arrangement

The fuselage has these six manufacturing sections:

- Section 41
- Section 43
- Section 44
- Section 46
- Section 47
- Section 48

Section 41 (STA 92.5 - 655)

Section 41 contains these:

- Flight deck
- Radome
- Forward pressure bulkhead
- Forward equipment center
- Nose gear wheel well
- Main equipment center
- Forward entry doors (2)
- Forward cargo compartment.

Section 43 (STA 655 - 1035)

Section 43 contains these:

- Aft part of the forward cargo compartment
- Main entry doors (2).

Section 44 (STA1035 - 1434)

Section 44 is the center portion of the fuselage. It contains these:

- Keel beam
- Main gear wheel wells (2).

Section 46 (STA 1434 - 1832)

Section 46 contains these:

- Main entry doors (2)
- Aft cargo compartment.

Section 47 (STA 1832 - 2150)

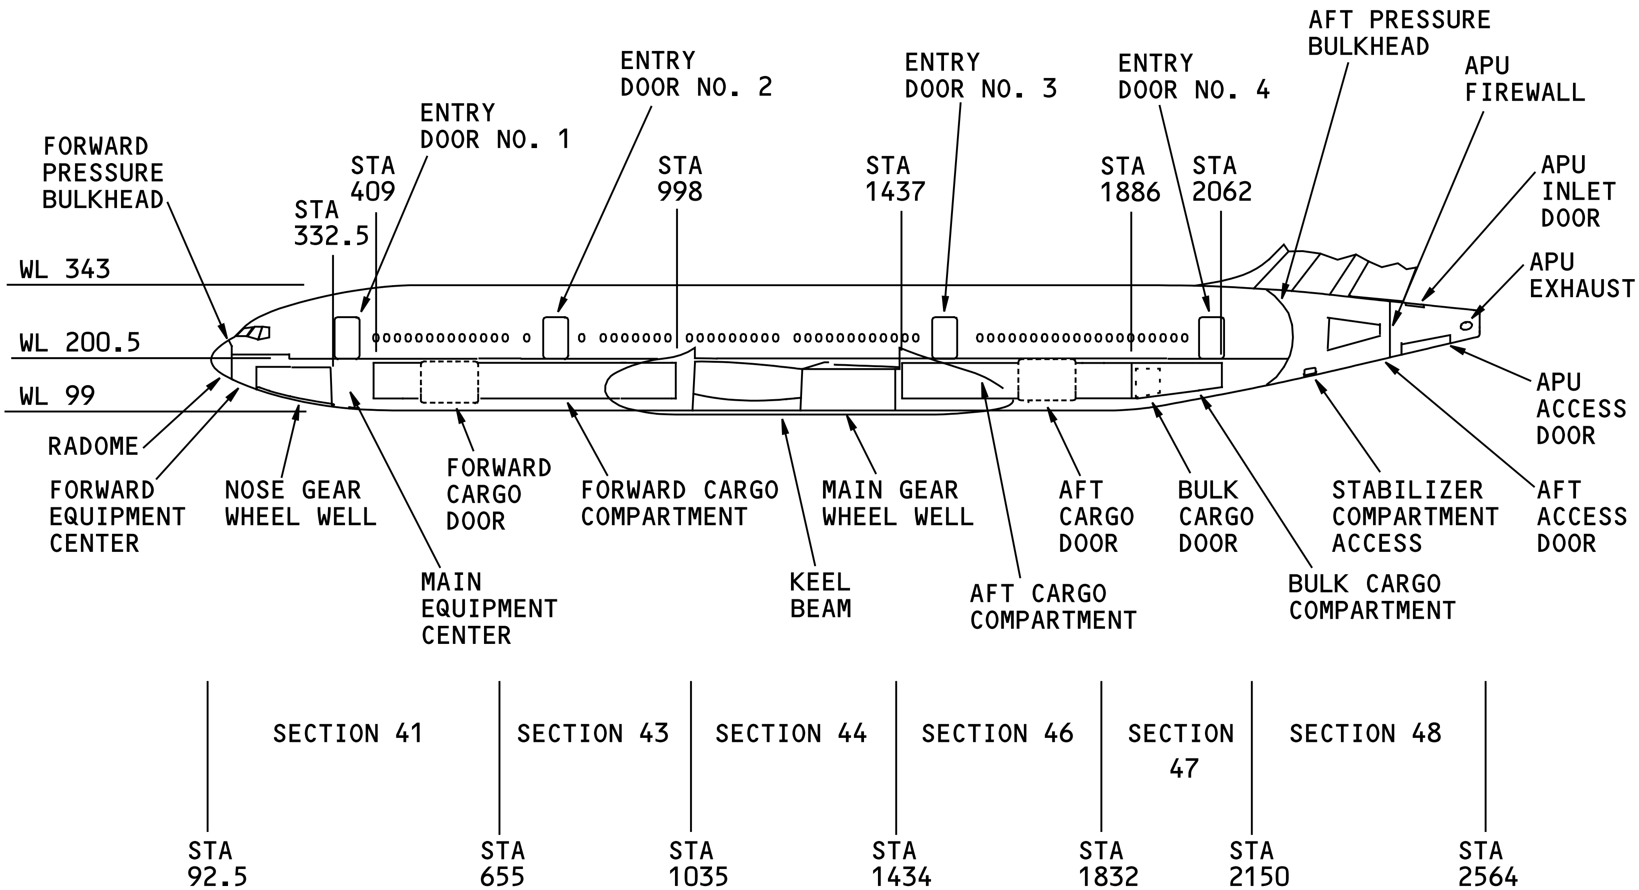
Section 47 contains these:

- Aft entry doors (2)
- Bulk cargo compartment.

Section 48 (STA 2150 - 2564)

Section 48 contains these:

- Aft pressure bulkhead
- Stabilizer compartment access door
- Auxiliary power unit (APU) firewall
- APU inlet and exhaust
- APU access doors
- Aft access door.

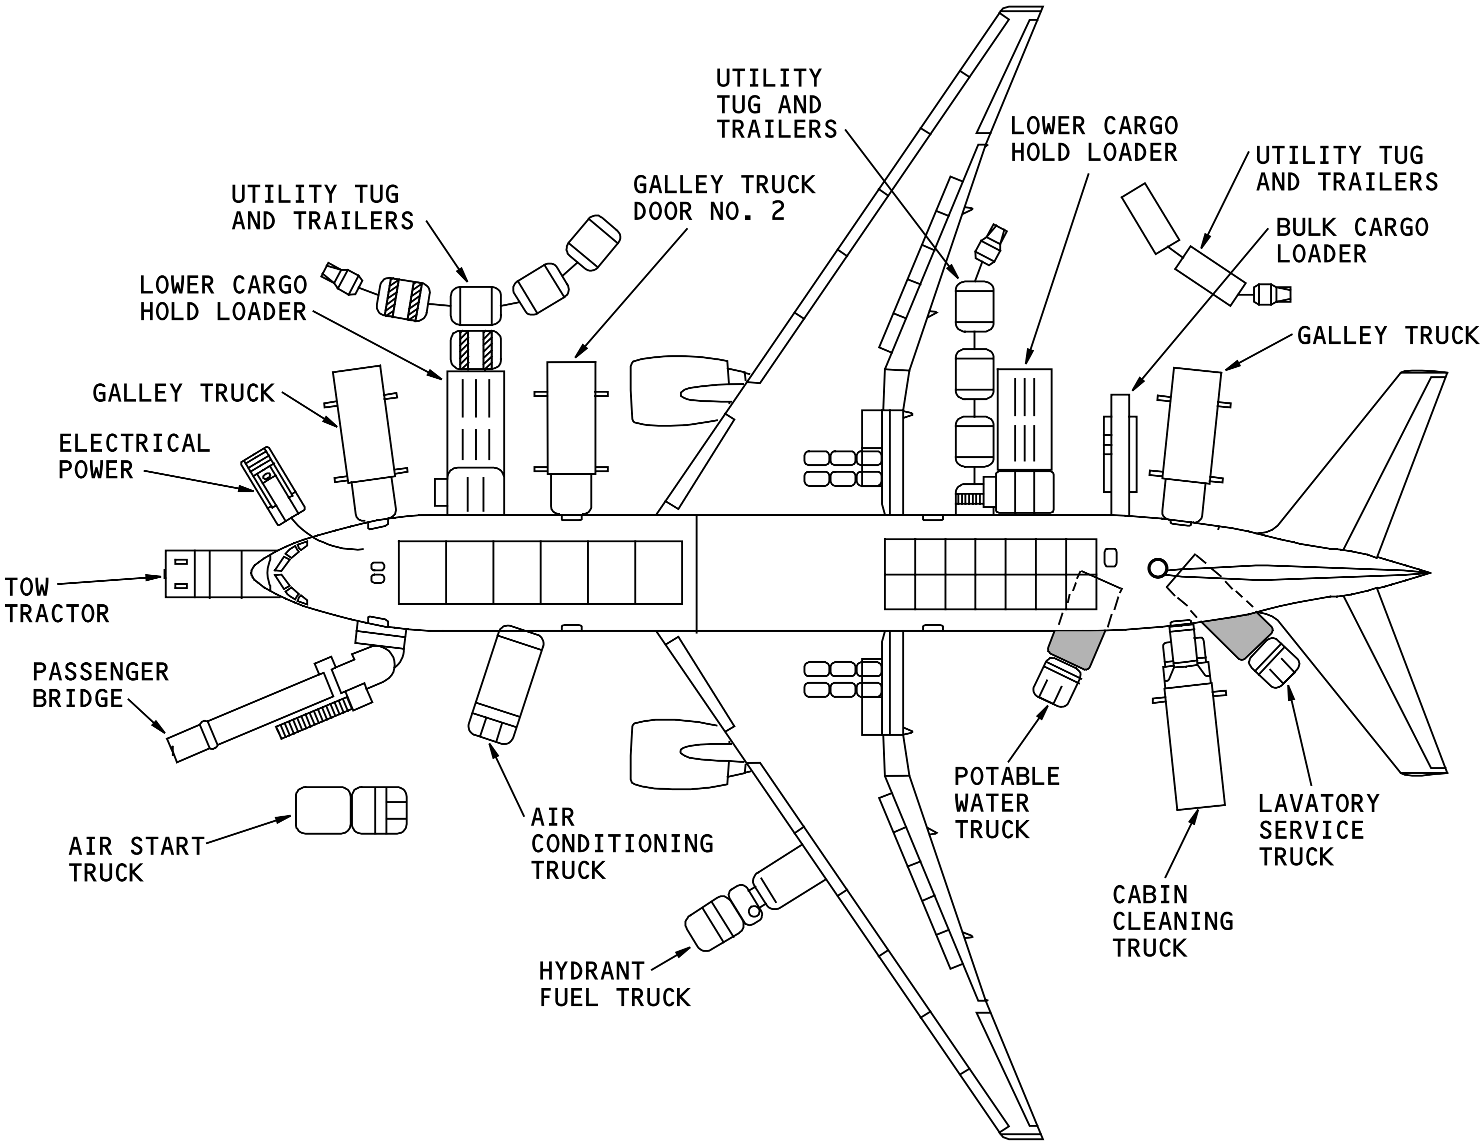


00-00-00-003 Rev 1

777 GENERAL - GENERAL ARRANGEMENT

General

The locations of doors, service connections, and access panels make it possible to do servicing of many systems at the same time.



777 GENERAL - AIRPLANE SERVICING

777 GENERAL - FLIGHT CONTROL SURFACES

General

There are two flight controls systems. They are the primary flight control system and the high lift control system.

Primary Flight Control System (PFCS)

The control surfaces of the PFCS are:

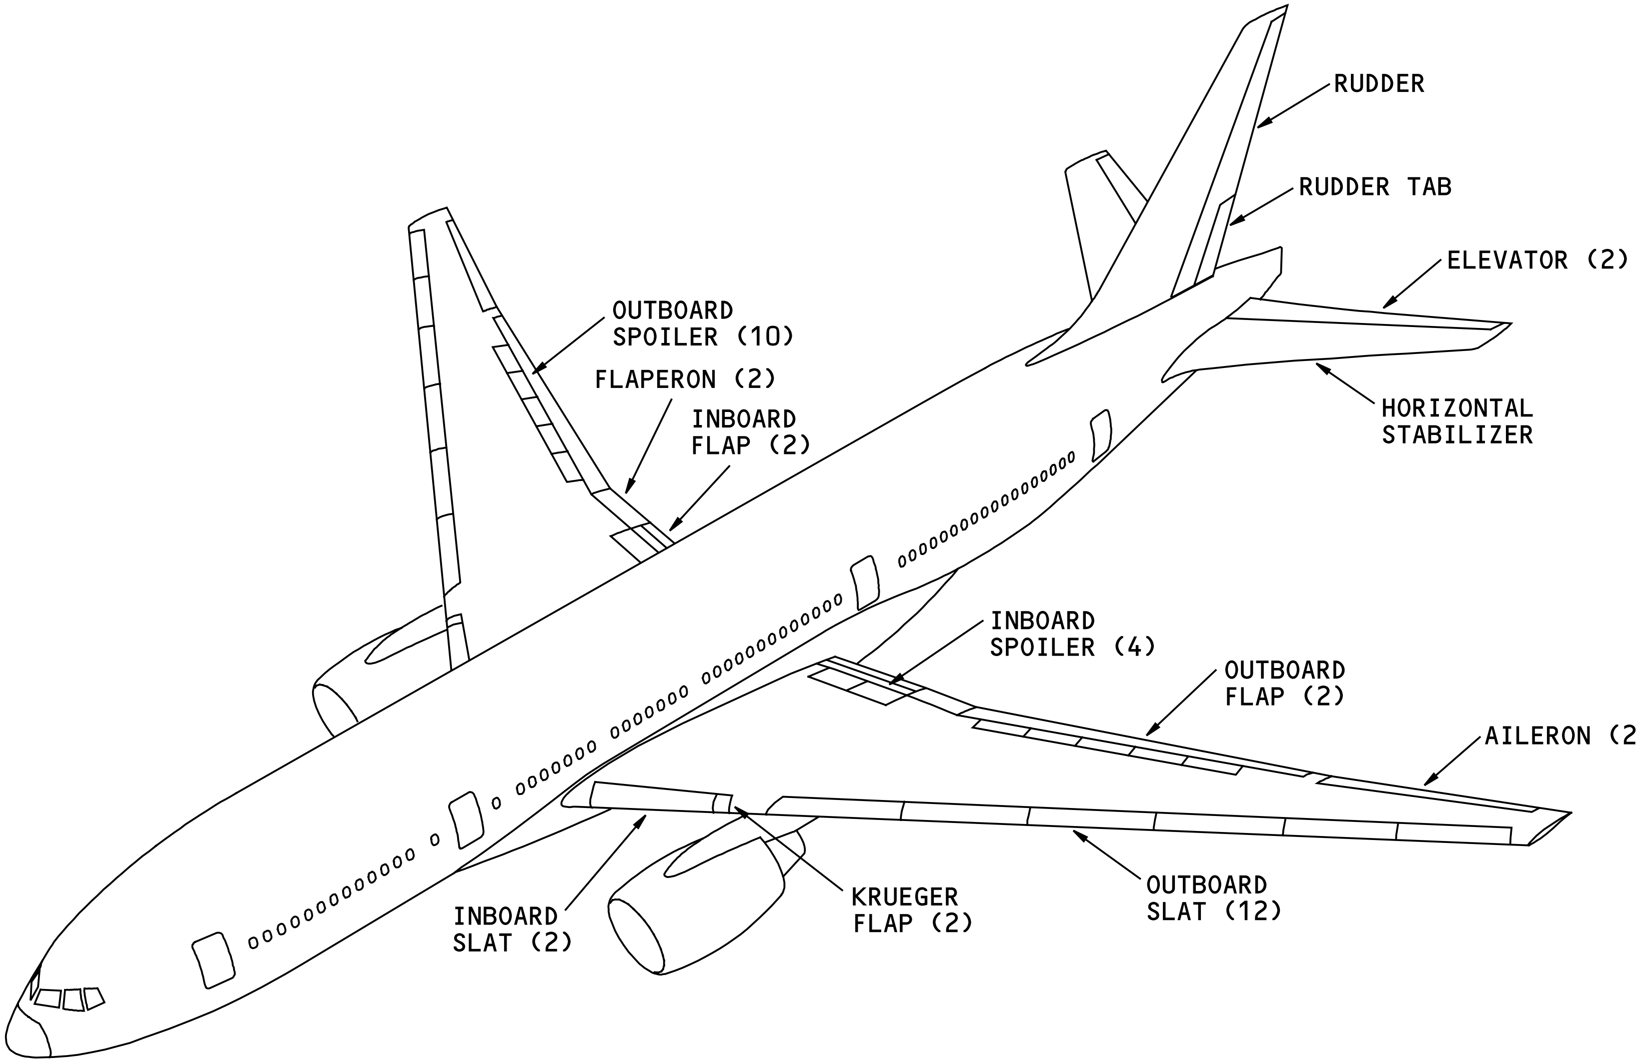
- One aileron on each wing
- One flaperon on each wing
- Seven spoilers on each wing
- One horizontal stabilizer
- One elevator on each side of the horizontal stabilizer
- One rudder (with tab).

High Lift Control System (HLCS)

The high lift devices of the HLCS are:

- Seven leading edge slats on each wing
- One Krueger flap on each wing
- One outboard flap on each wing
- One inboard flap on each wing.

Operation of the HLCS also causes the ailerons and the flaperons to move. They droop on both wings when the high lift devices extend.



00-00-00-005 Rev 1

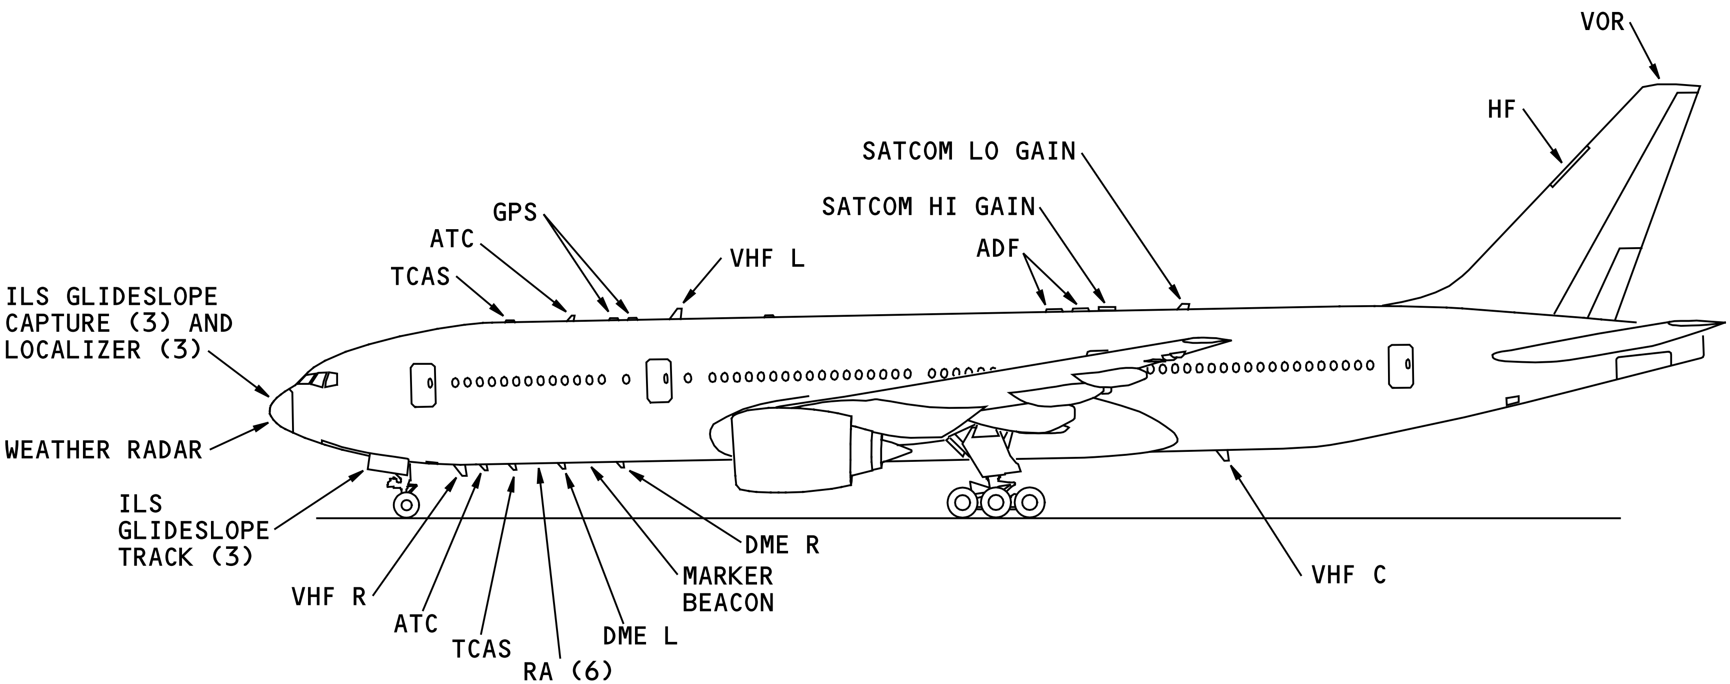
777 GENERAL - FLIGHT CONTROL SURFACES

777 GENERAL - ANTENNA LOCATIONS

Antenna Locations

These are the communication and navigation system antennas:

- Weather Radar
- TCAS (traffic alert and collision avoidance system)
- ATC (air traffic control)
- GPS (global positioning system)
- VHF (very high frequency) communication
- SATCOM (satellite communication)
- ADF (automatic direction finder)
- HF (high frequency) communication
- VOR (VHF omni range)
- Marker beacon
- RA (radar altimeter)
- DME (distance measuring equipment)
- ILS (instrument landing system).



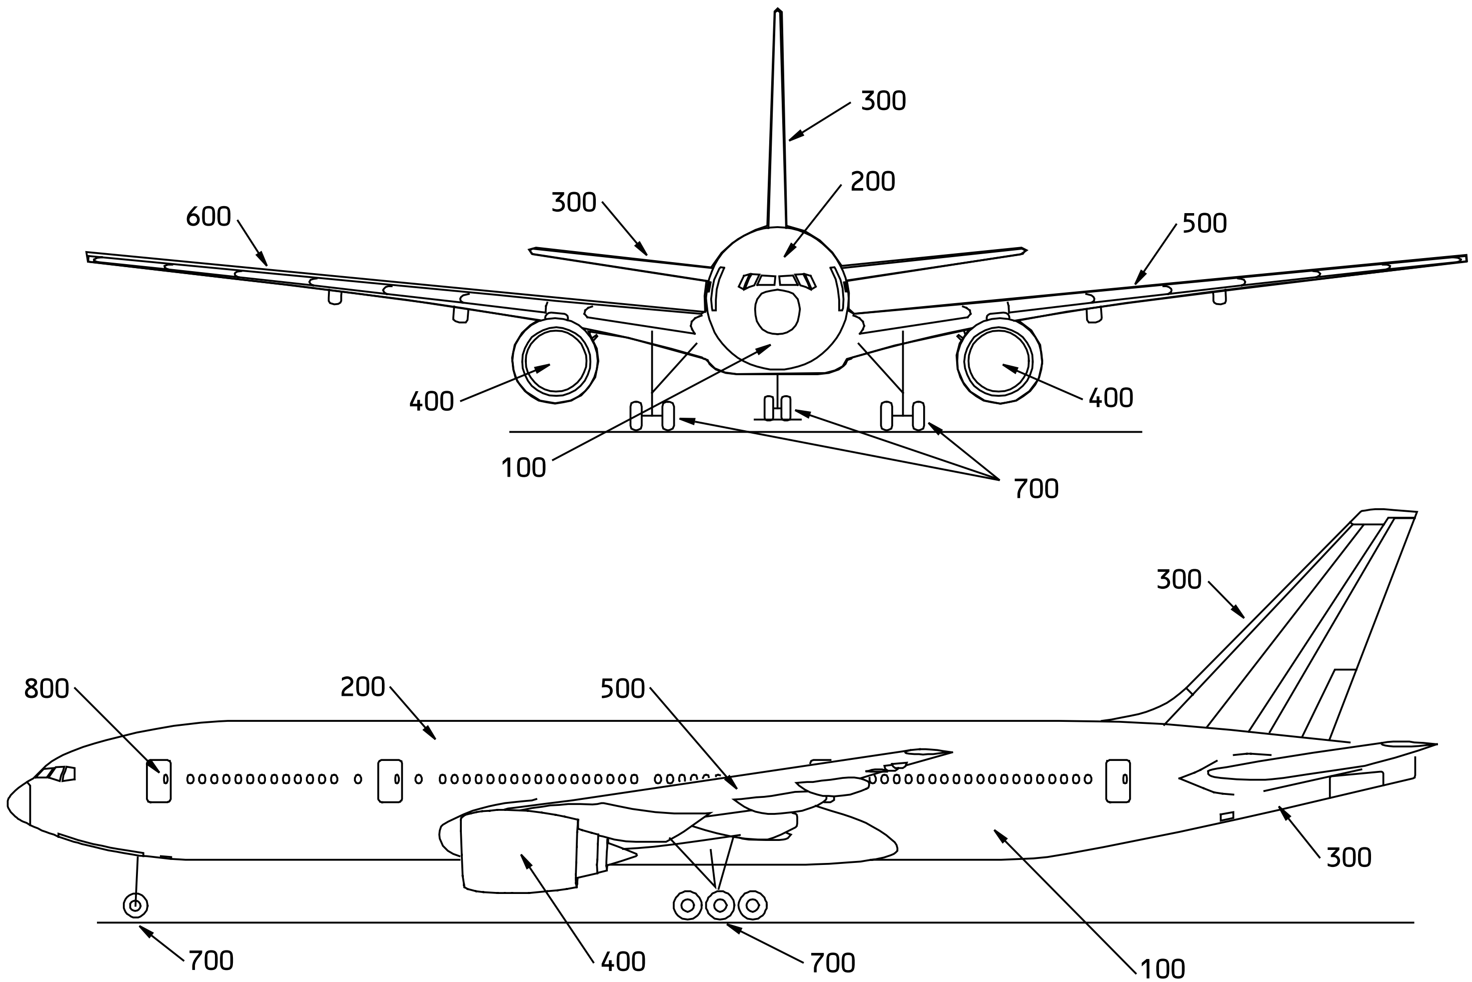
777 GENERAL - ANTENNA LOCATIONS

777 GENERAL - ZONE DIAGRAMS - AIRPLANE MAJOR ZONES

General

The 777 airplane has 8 major zones to help you find and identify airplane components and parts. These are the major zones:

- 100 - lower half of the fuselage
- 200 - upper half of the fuselage
- 300 - empennage and body section 48
- 400 - power plants and nacelle struts
- 500 - left wing
- 600 - right wing
- 700 - landing gear and landing gear doors
- 800 - passenger and cargo compartment doors.



00-00-00-007 Rev 0

777 GENERAL - ZONE DIAGRAMS - AIRPLANE MAJOR ZONES

777 GENERAL - ZONE DIAGRAMS - SUBZONES AND ZONES

General

The eight major zones have subzones and the subzones have zones. A three-digit number shows the major zone, subzones, and zones this way:

- Major zone - the first digit is a number from 1 to 8 with two zeros after
- Subzone - the first digit is the major zone number, the second digit is a number from 1 to 9, and the third digit is zero
- Zone - the first two digits are the subzone number and the third digit shows a component or group of components in the subzone.

This is the number sequence for the zones and subzones:

- Wings - inboard to outboard and front to back
- Horizontal stabilizer and elevator - inboard to outboard and front to back
- Vertical stabilizer and rudder - root to tip of vertical stabilizer
- Fuselage - front to back and away from the floor line.

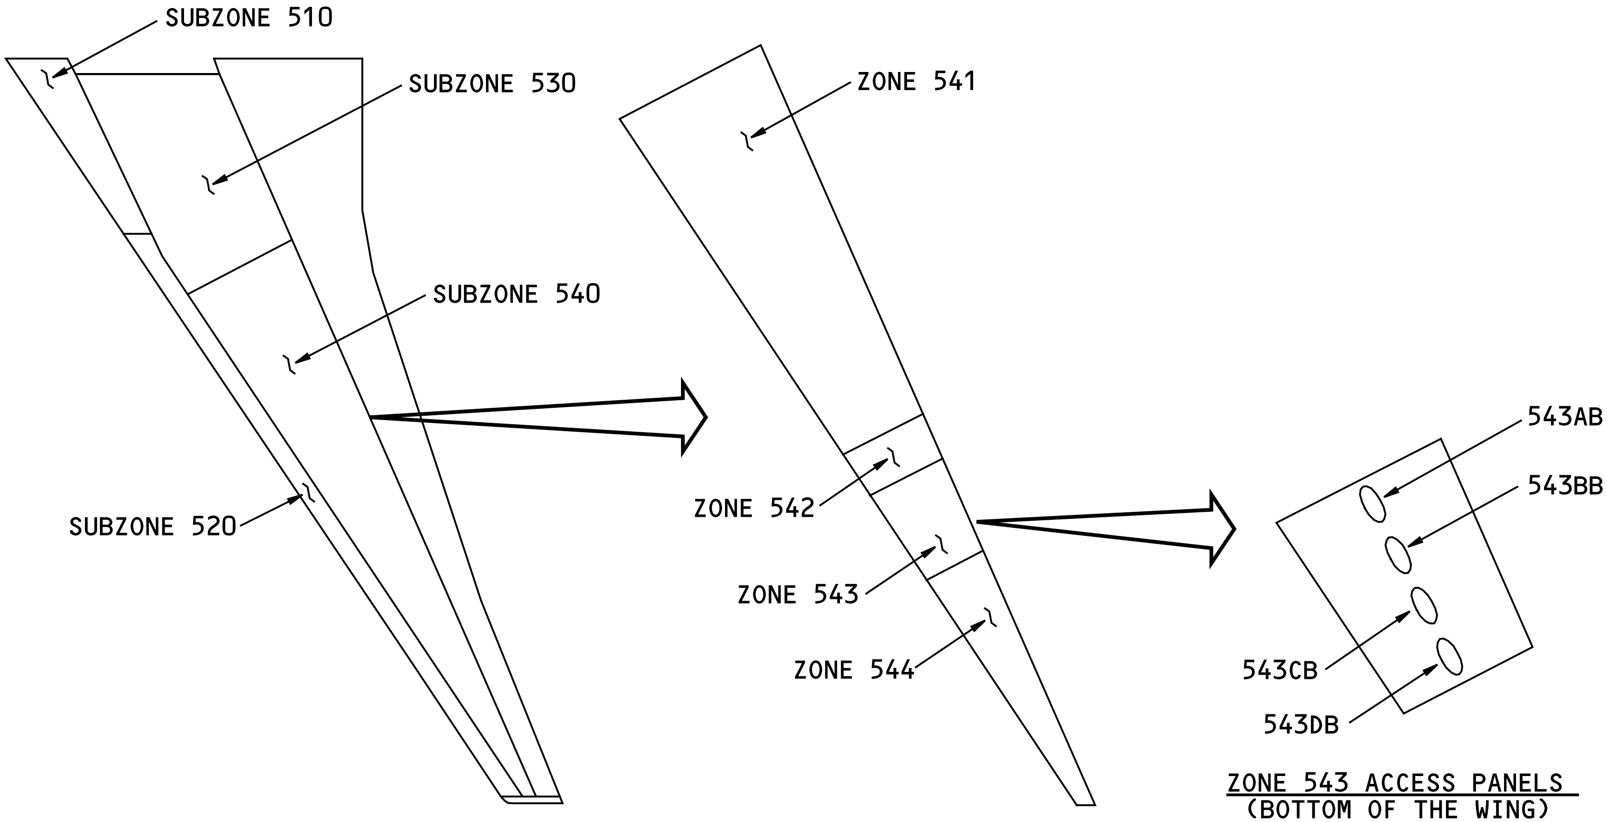
Access Panel Identification

Access doors or panel have five digit alpha-numeric codes. The codes have these parts:

- First three digits: airplane zone
- Fourth digit: a letter that identifies each access door or panel in a zone. If there are more than one access panels in a zone, they have letters (A, B, C, etc.). The letters increase inboard to outboard, bottom to top, and forward to aft.
- Fifth digit: a letter that gives additional location information if the access door or panel is on the top (T), bottom (B), left (L), right (R), internal (Z), ceiling (C), floor panels (F), floor panels (use G when F sequence designation is used), sloping sidewall (S), sidewall (W).

Training Information Point

A small number of access doors or panels have six digit codes. This occurs when a panel is added later in production. In this condition, the first three digits are the zone number. The fourth and fifth digits (letters) designate the panel. The sixth digit gives the additional location information.



SUBZONES OF MAJOR ZONE 500 - LEFT WING

ZONES OF SUBZONE 540

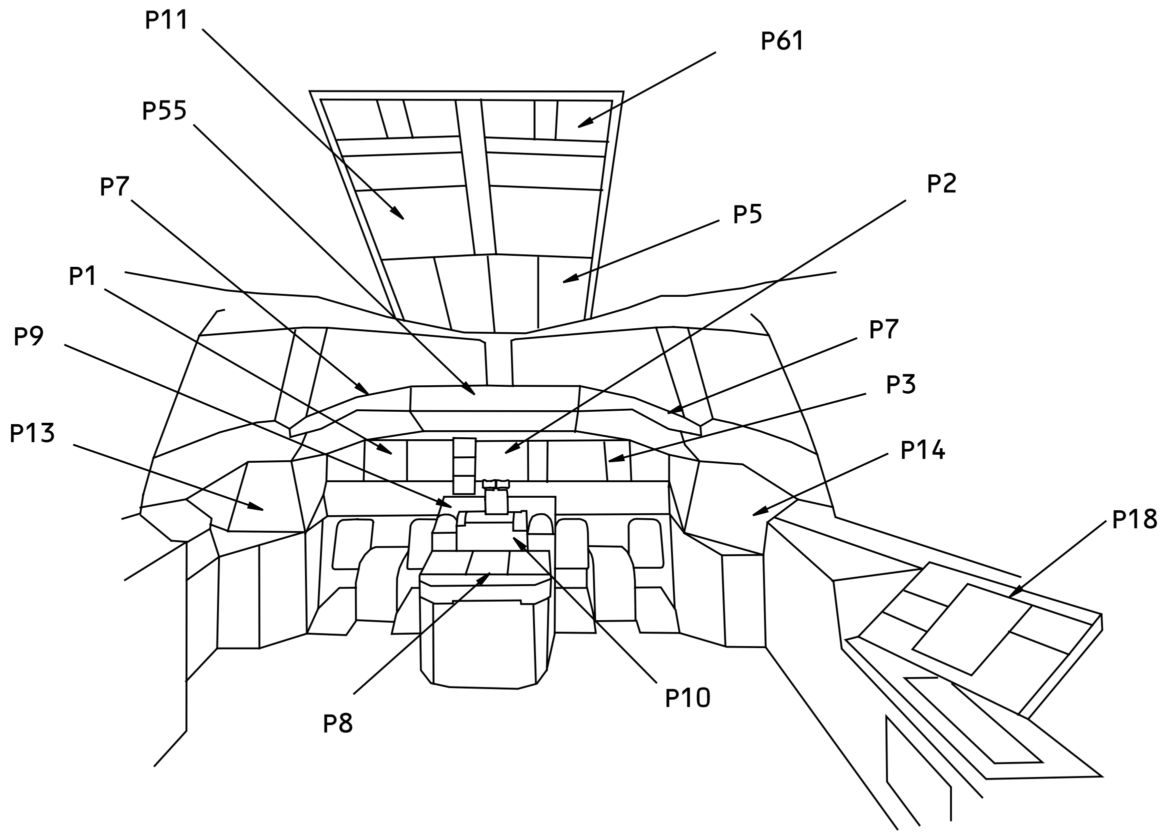
777 GENERAL - ZONE DIAGRAMS - SUBZONES AND ZONES

Flight Deck Major Panels

These are the major panels in the flight deck:

- P1 left forward panel
- P2 center forward panel
- P3 right forward panel
- P5 overhead panel
- P7 glareshield panel
- P8 aft aisle stand panel
- P9 forward aisle stand panel
- P10 control stand
- P11 overhead circuit breaker panel
- P13 left sidewall panel
- P14 right sidewall panel
- P18 MAT/second observer panel
- P55 glareshield center panel
- P61 overhead maintenance panel.



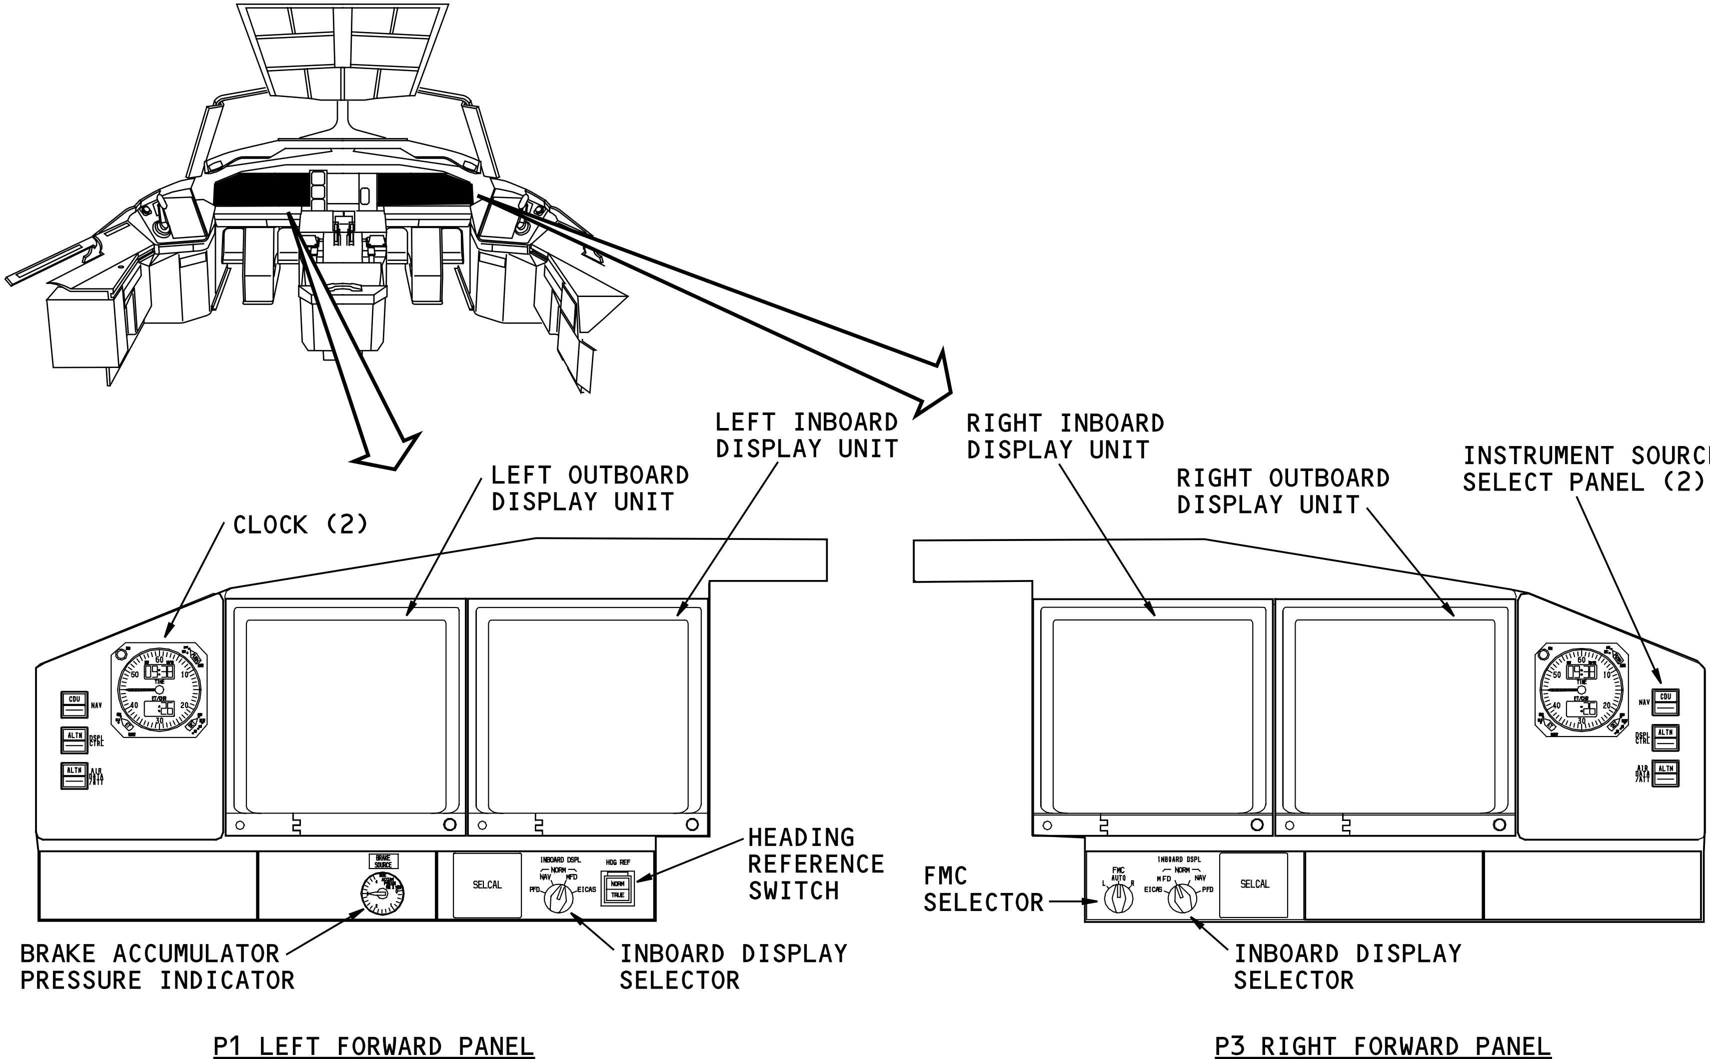
777 GENERAL - FLIGHT DECK

777 GENERAL - MAIN INSTRUMENT PANELS

General

The main instrument panels (P1 and P3) have these displays and controls:

- Display units (4)
- Instrument source select panels (2)
- Clocks (2)
- Inboard display selectors (2)
- FMC selector
- Heading reference switch
- Brake accumulator pressure indicator.



00-00-00-010 Rev 1 12/12/95

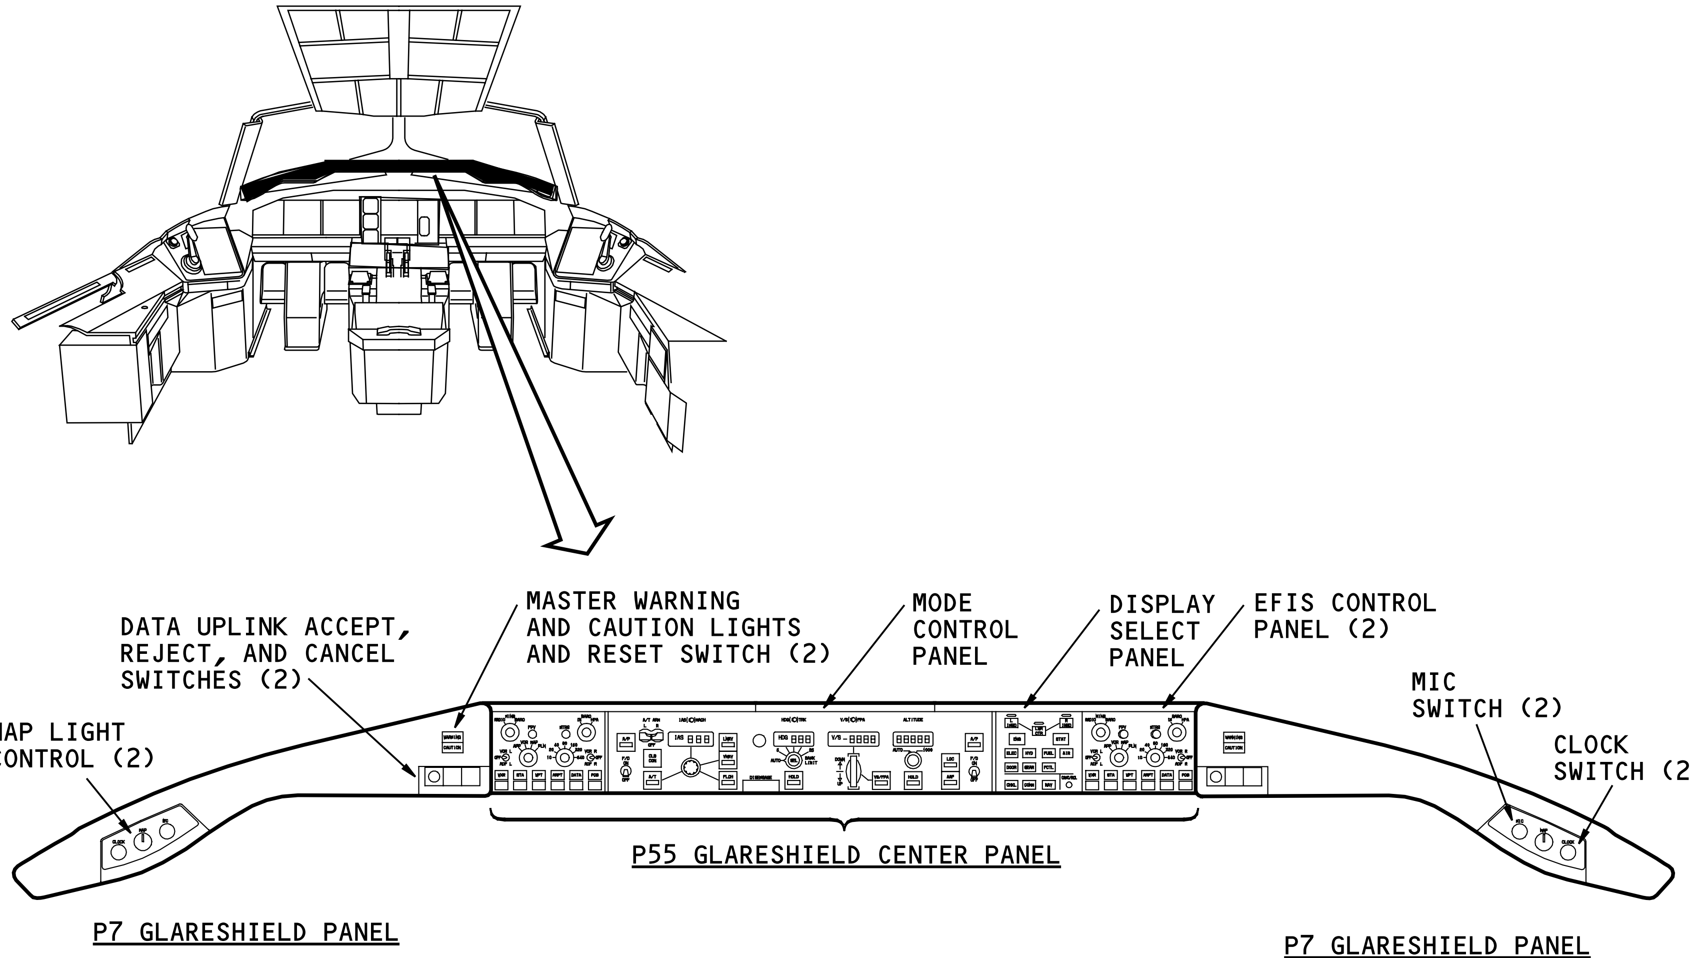
777 GENERAL - MAIN INSTRUMENT PANELS

777 GENERAL - GLARESHIELD PANELS

General

The glareshield panels have these controls:

- Master warning and caution lights (2)
- Master warning and caution reset switches (2)
- Mode control panel
- EFIS control panels (2)
- Display select panel
- Data uplink switches (2)
- Map light controls (2)
- MIC switches (2)
- Clock switches (2).



00-00-00-011 Rev 3 09/12/96

777 GENERAL - GLARESHIELD PANELS

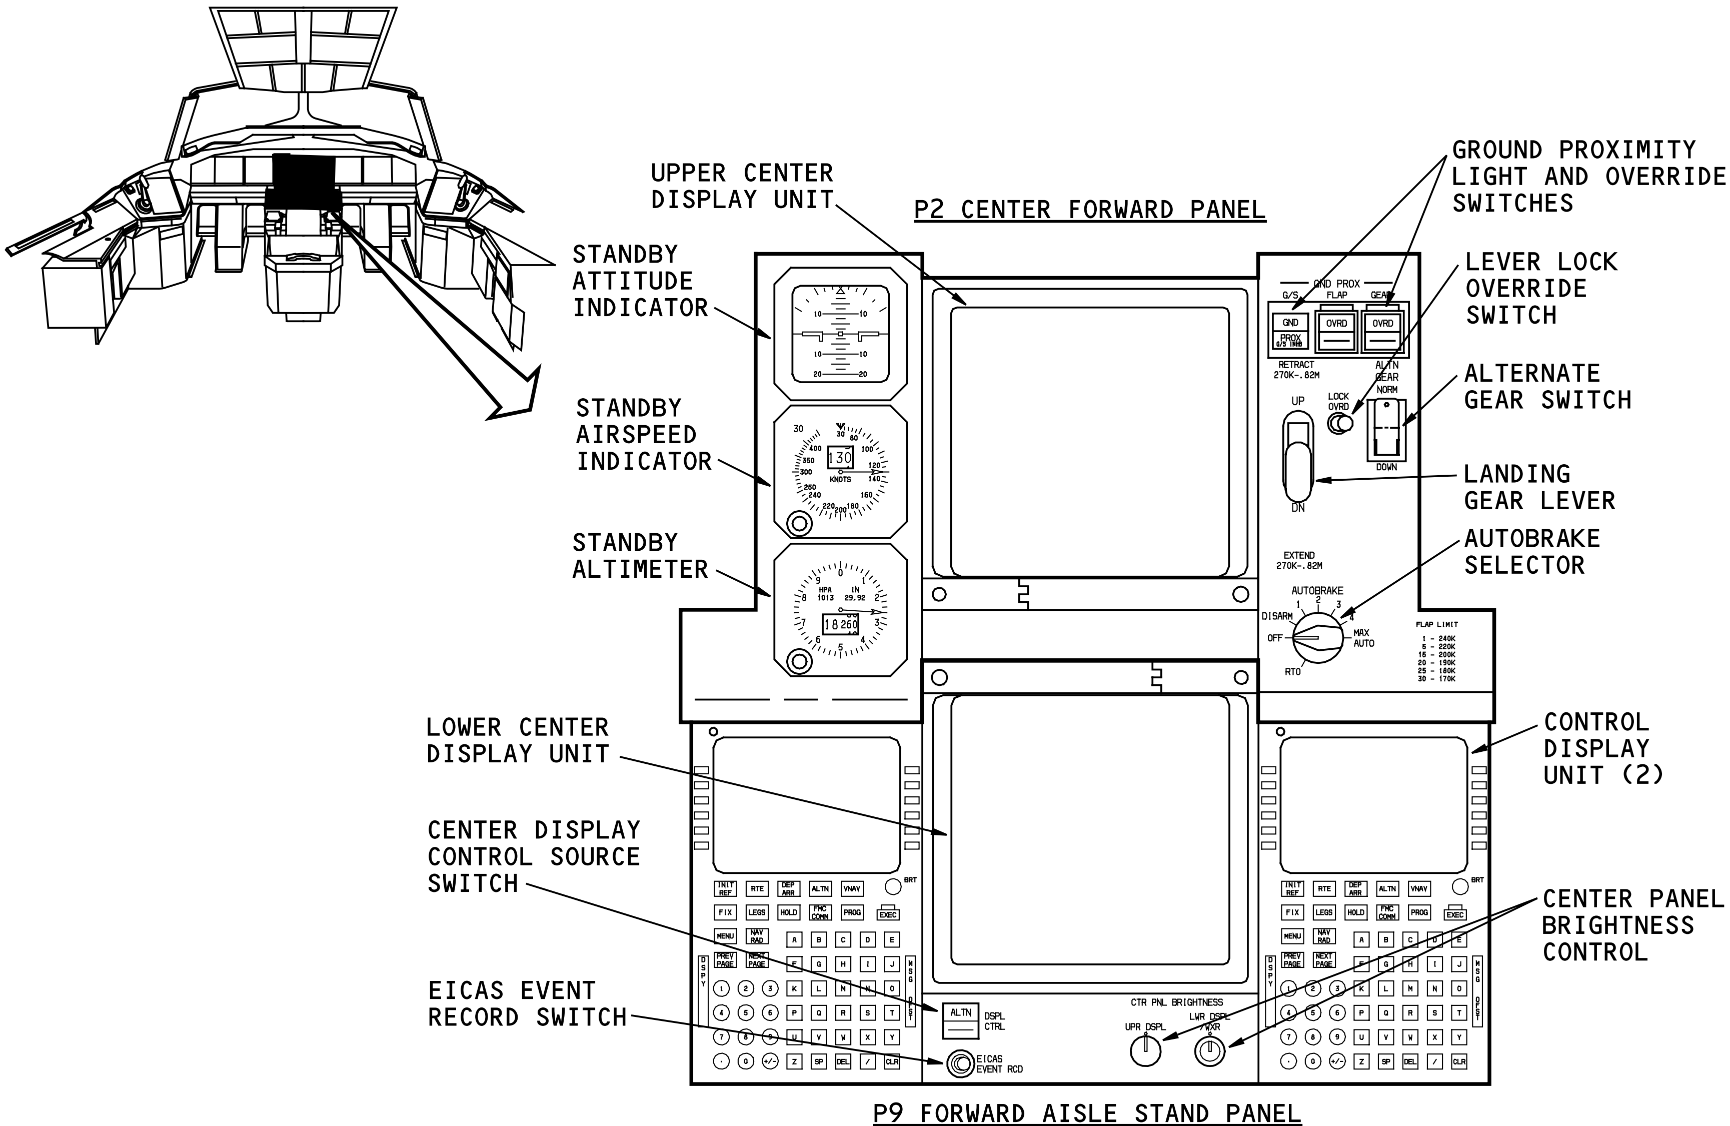
777 GENERAL - P2 CENTER FORWARD AND P9 FORWARD AISLE STAND PANELS

General

The P2 center forward and P9 forward aisle stand panels have these controls:

- Standby instruments (3)
- Display units (2)
- Ground proximity light and override switches
- Landing gear lever
- Autobrake selector
- Control display units (2)
- Center panel brightness control
- EICAS event record switch
- Center display control source switch.

Note that the lower center display unit is reversed (top to bottom) from the other five display units.



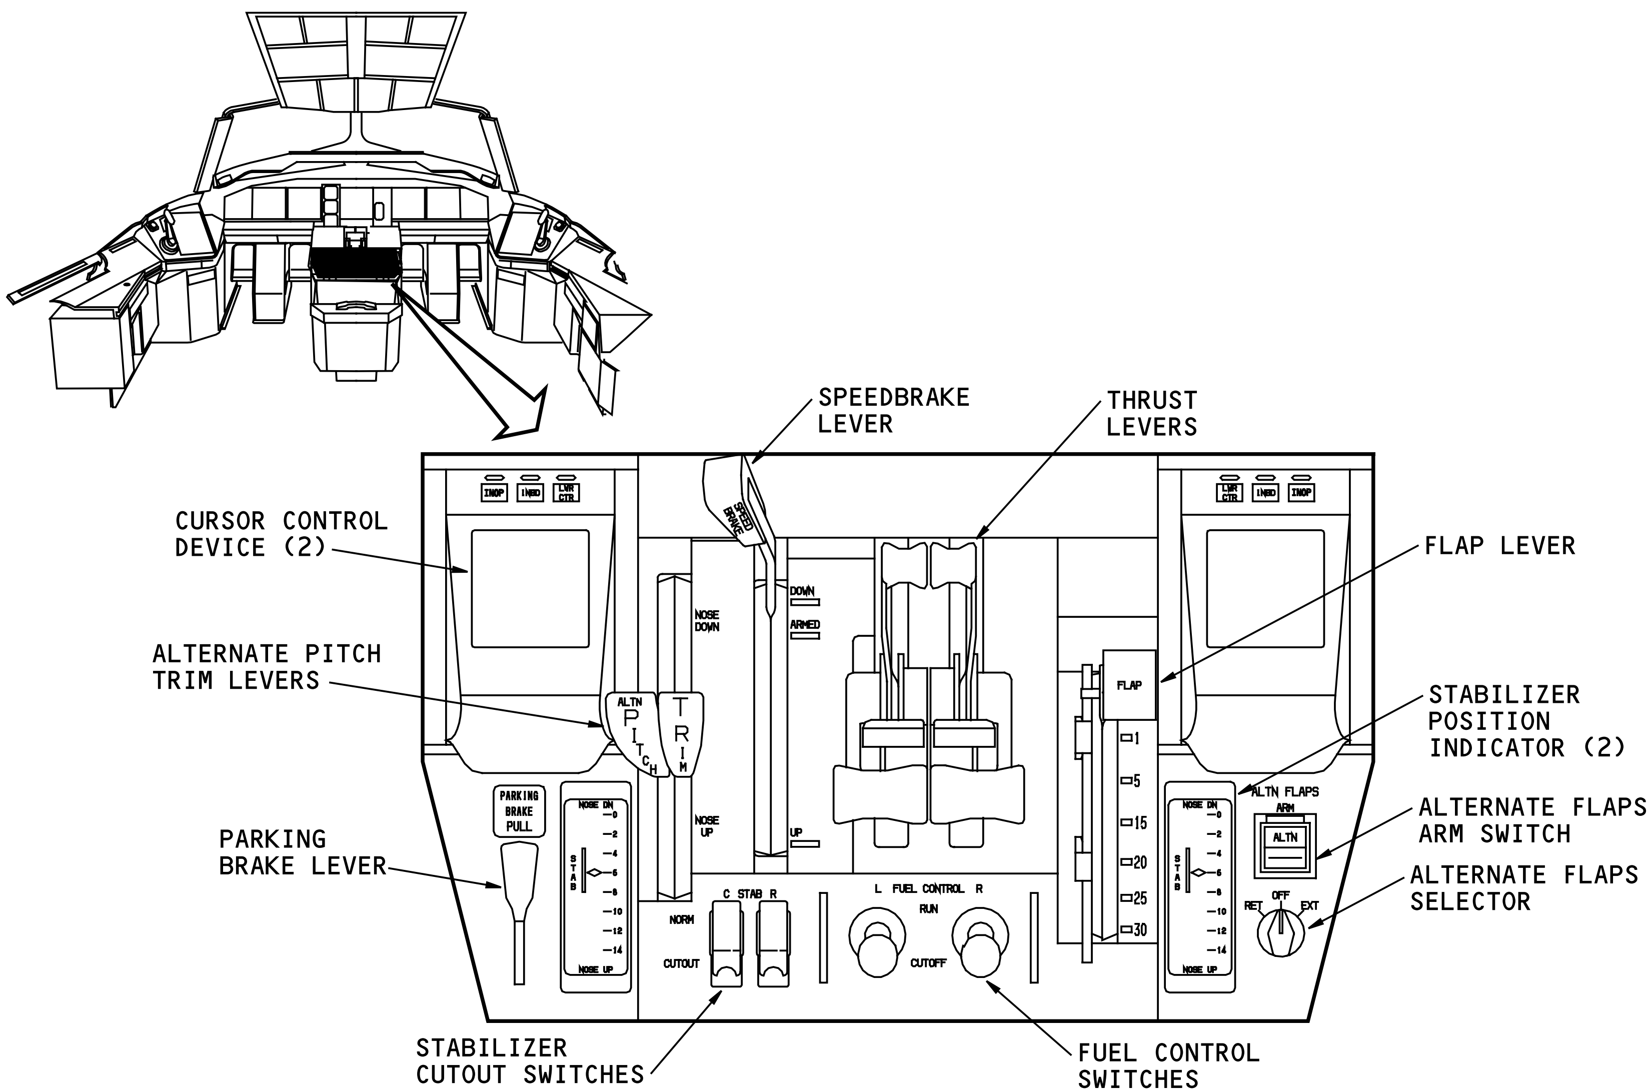
777 GENERAL - P2 CENTER FORWARD AND P9 FORWARD AISLE STAND PANELS

777 GENERAL - P10 CONTROL STAND

General

The P10 control stand has these controls and indications:

- Speedbrake lever
- Thrust levers(2)
- Stabilizer position indicators (2)
- Alternate flaps arm switch
- Alternate flaps selector
- Fuel control switches (2)
- Stabilizer cutout switches (2)
- Parking brake lever
- Alternate pitch trim levers
- Cursor control devices (2)
- Flap lever.



P10 CONTROL STAND

777 GENERAL - P10 CONTROL STAND

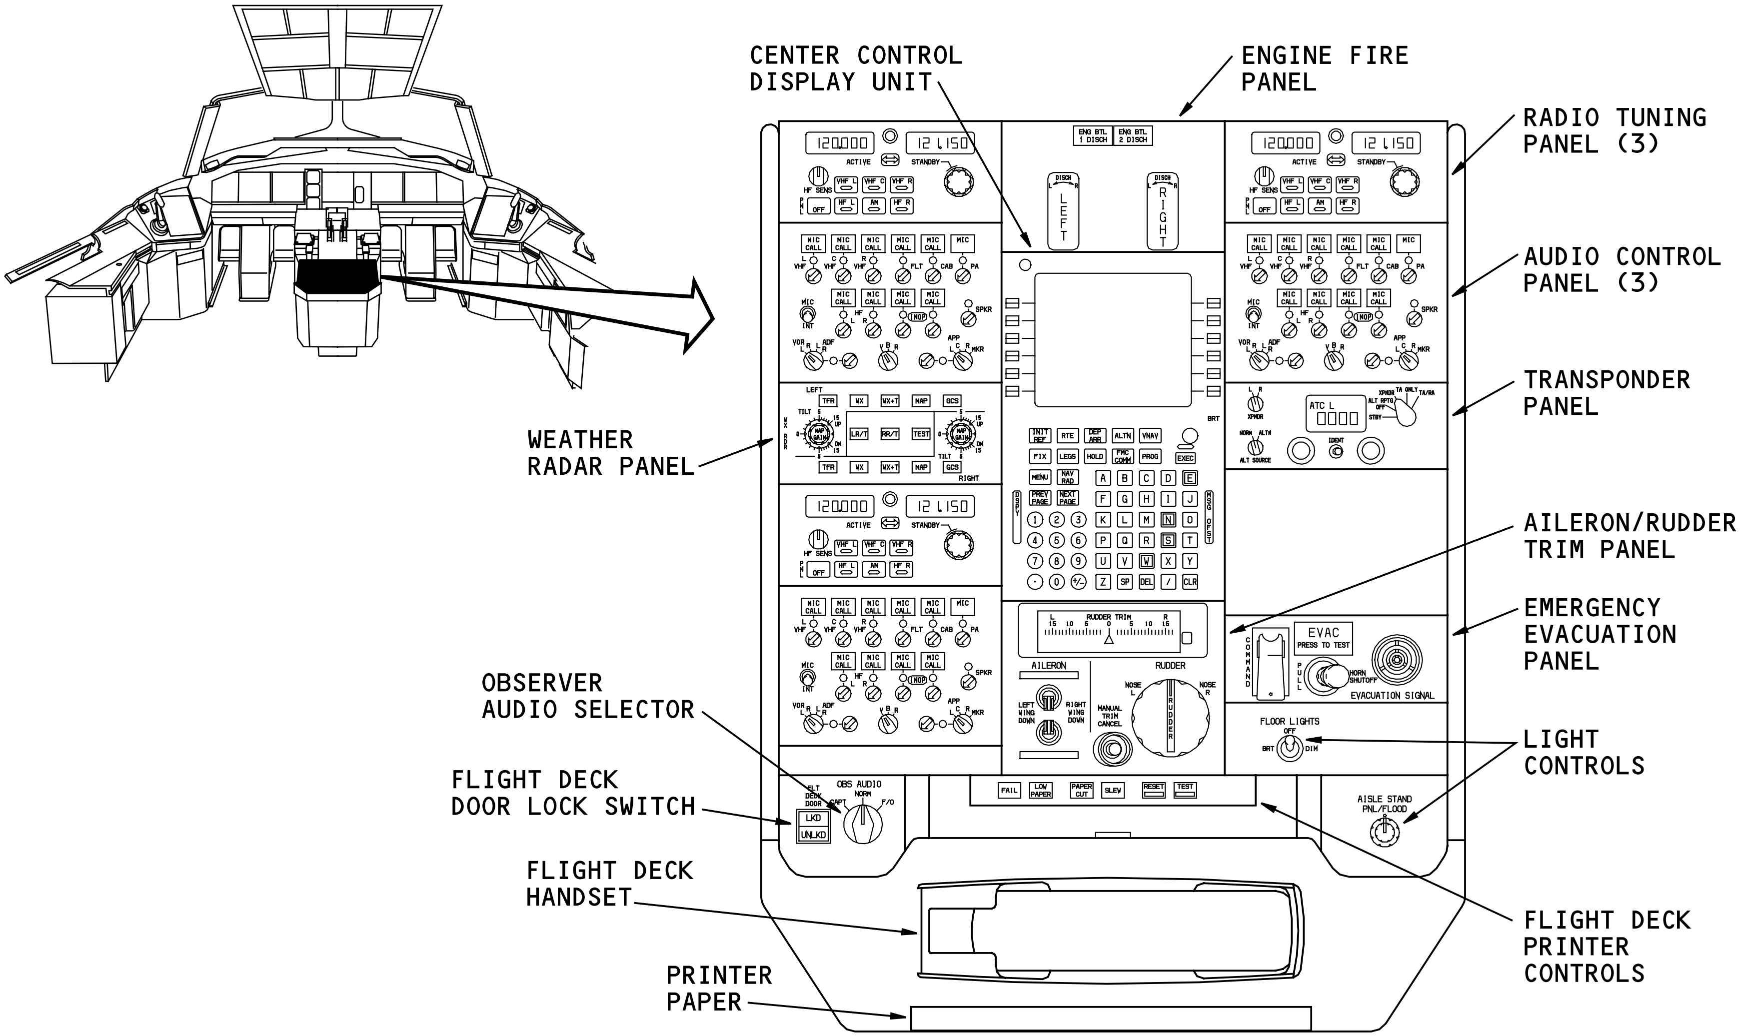
00-00-00-013 Rev 2 10/02/96

777 GENERAL - P8 AFT AISLE STAND PANEL

General

The P8 aft aisle stand panel has these controls:

- Control display unit
- Engine fire panel
- Radio tuning panels (3)
- Audio control panels (3)
- Transponder panel
- Aileron/rudder trim panel
- Light controls
- Flight deck printer
- Flight deck handset
- Observer audio selector
- Flight deck door lock switch
- Weather radar panel.



P8 AFT AISLE STAND PANEL

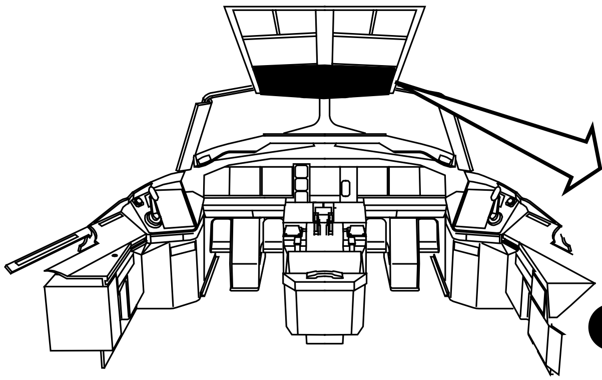
777 GENERAL - P8 AFT AISLE STAND PANEL

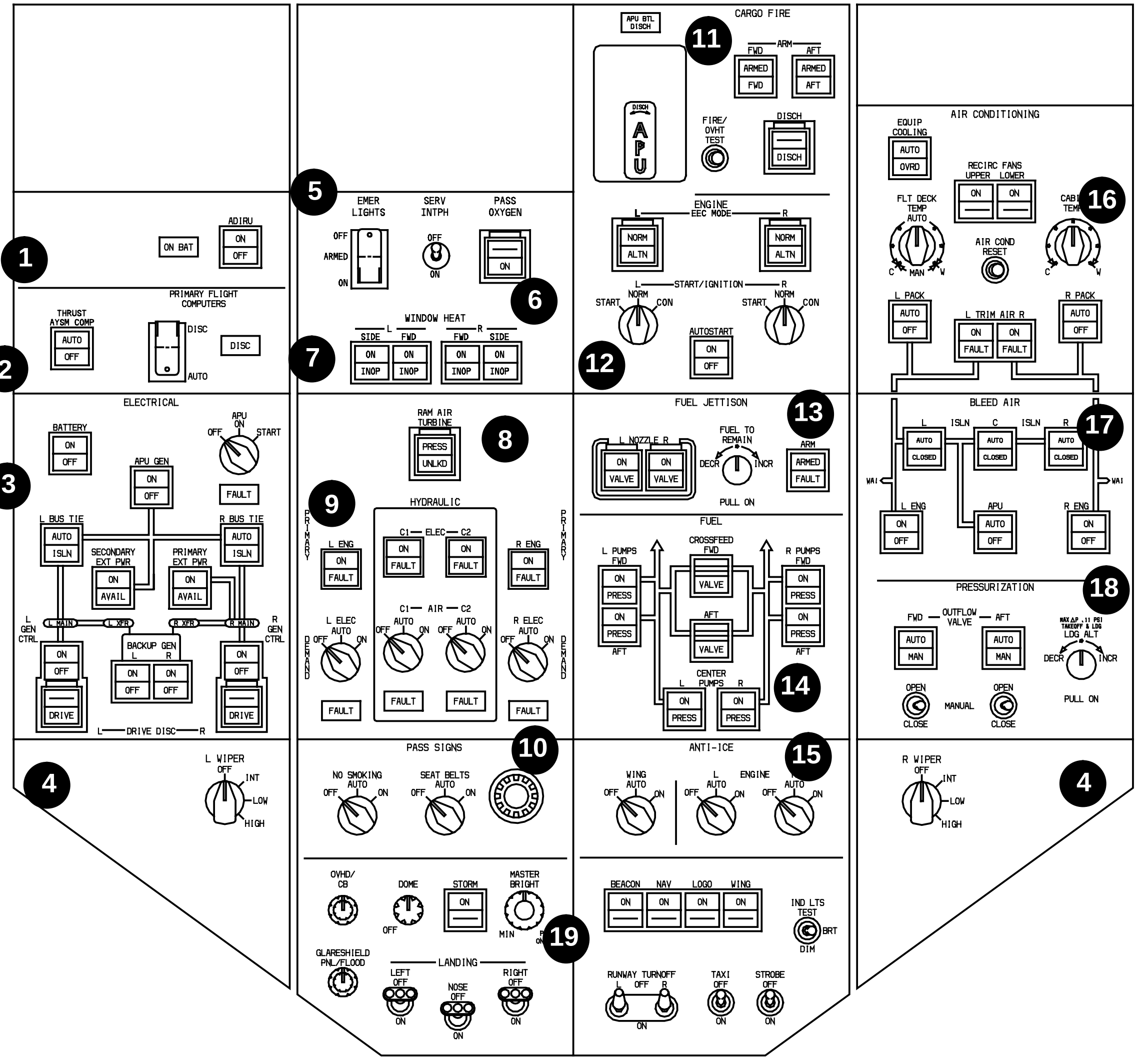
777 GENERAL - P5 OVERHEAD PANEL

General

The P5 overhead panel has controls for these functions (reference numbers on graphic):

- 1. Air data inertial reference system (ADIRS)
- 2. Primary flight computers
- 3. Electrical system/APU
- 4. Wiper control
- 5. Emergency lighting
- 6. Passenger oxygen
- 7. Window heat
- 8. Ram air turbine
- 9. Hydraulic system
- 10. Passenger signs
- 11. APU and cargo fire
- 12. Engine start
- 13. Fuel jettison
- 14. Fuel management
- 15. Anti-ice system
- 16. Air conditioning
- 17. Bleed air system
- 18. Pressurization control
- 19. Lighting





P5 OVERHEAD PANEL

777 GENERAL - P5 OVERHEAD PANEL

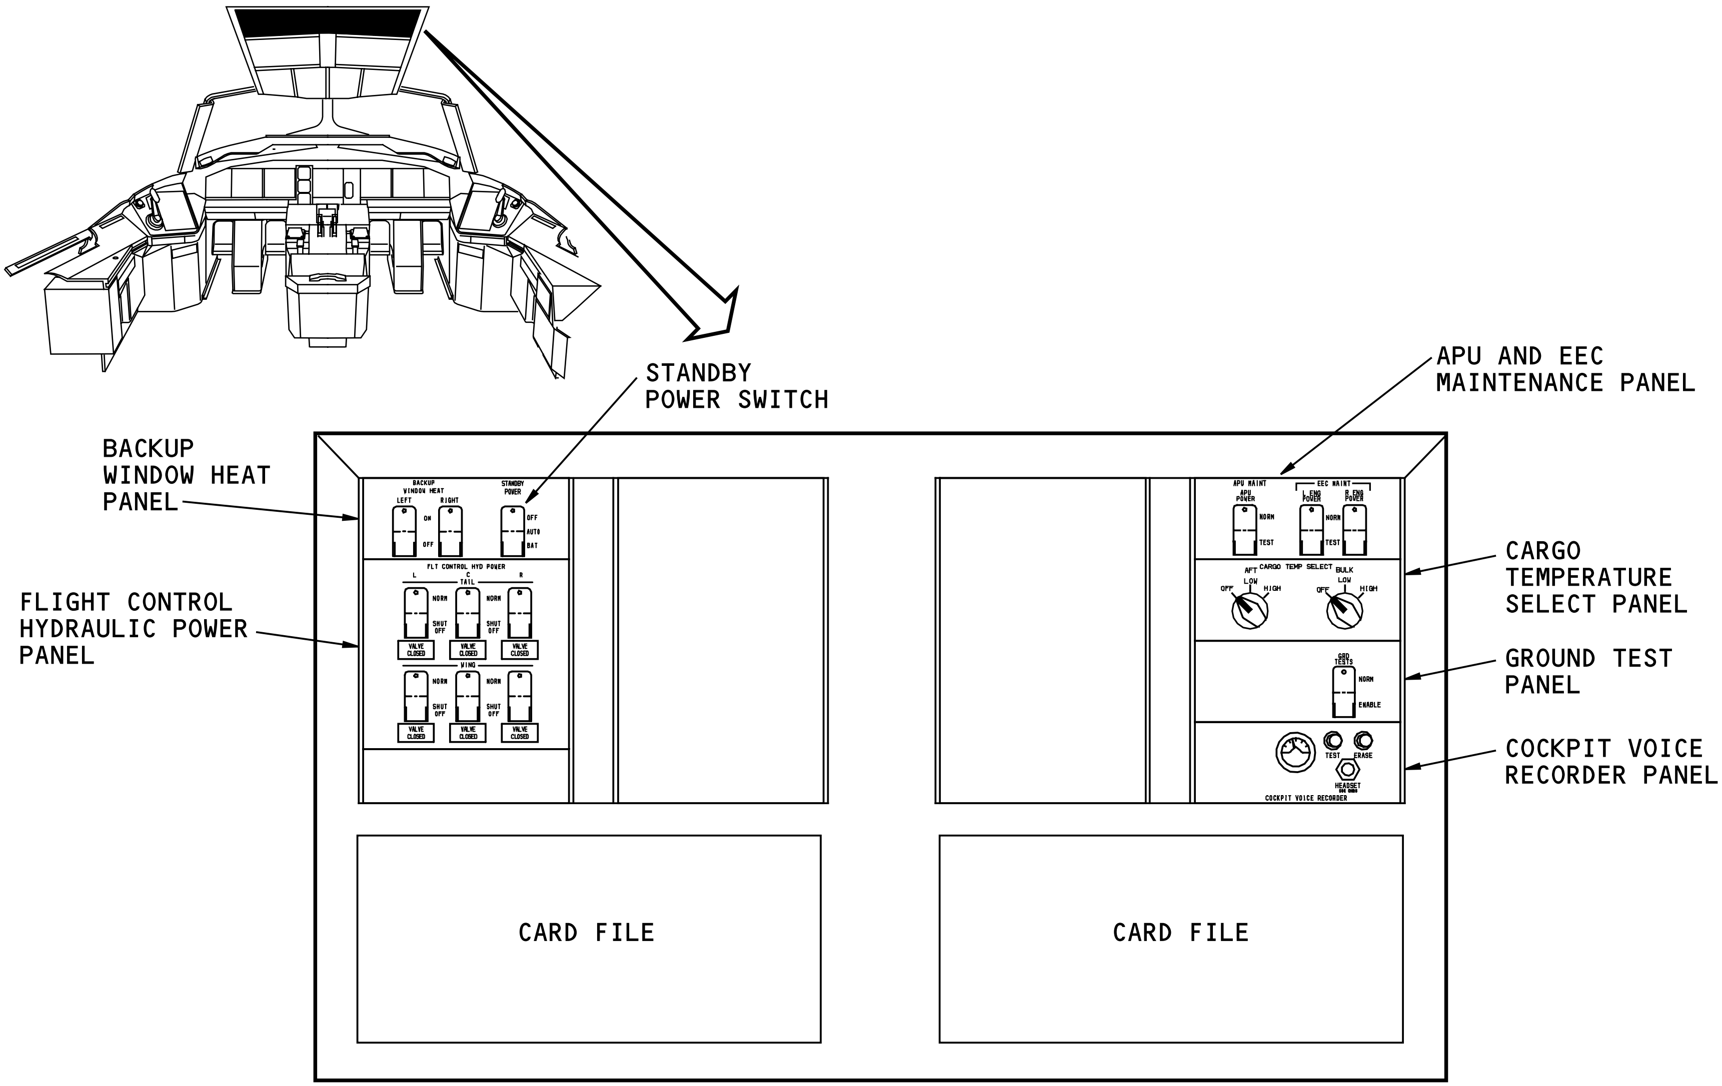
777 GENERAL - P61 OVERHEAD MAINTENANCE PANEL

General

The P61 overhead maintenance panel has control functions used normally only by maintenance personnel. The P61 overhead maintenance panel has these controls:

- Backup window heat switches
- Standby power switch
- Flight control shutoff switches
- APU and EEC maintenance panel
- Cargo temperature select panel
- Ground test switch
- Cockpit voice recorder panel.

The P61 panel also has the card files which contain the multiplexers for the overhead panel ARINC 629 system (OPAS).



P61 OVERHEAD MAINTENANCE PANEL

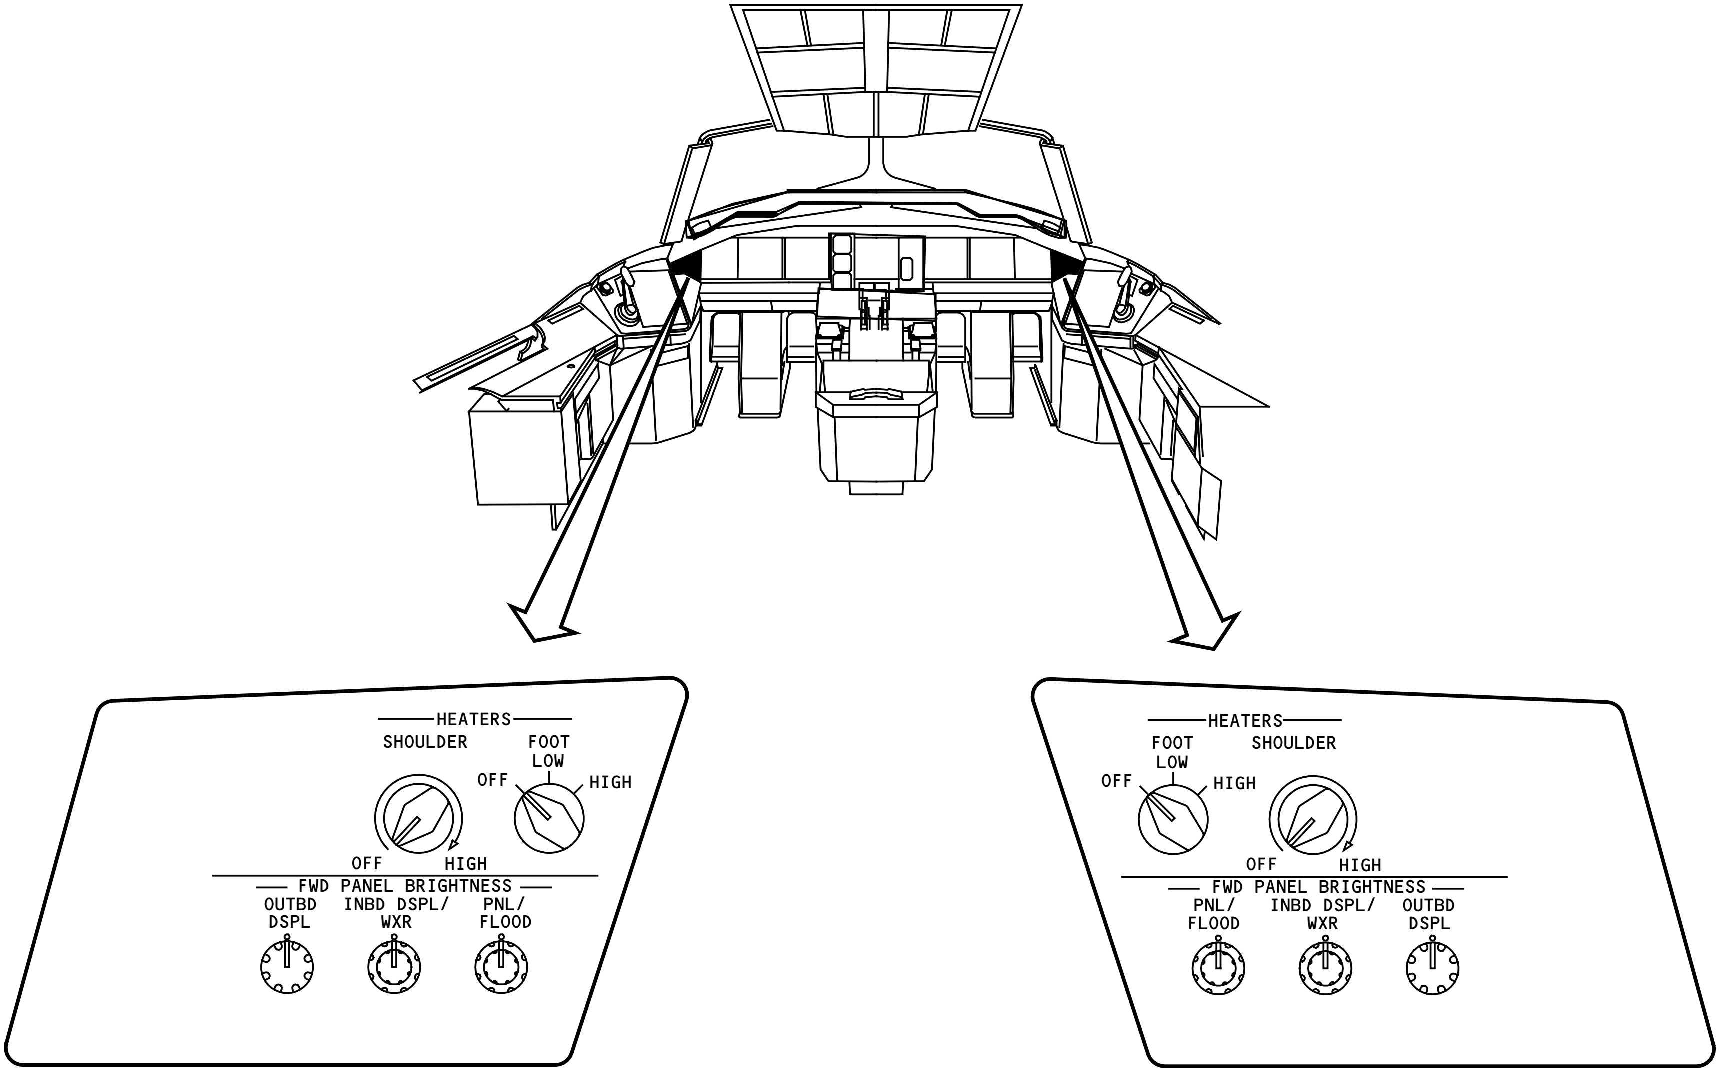
777 GENERAL – P61 OVERHEAD MAINTENANCE PANEL

777 GENERAL - P13 AND P14 SIDEWALL PANELS

General

The sidewall panels have these controls:

- Shoulder heater (2)
- Foot heater (2)
- Outboard display brightness (2)
- Inboard display weather radar (2)
- Panel flood light (2).



P13 LEFT SIDEWALL PANEL

P14 RIGHT SIDEWALL PANEL

777 GENERAL - P13 AND P14 SIDEWALL PANELS

00-00-00-061 Rev 2 05/30/96

777 GENERAL - P18 MAT/SECOND OBSERVER PANEL

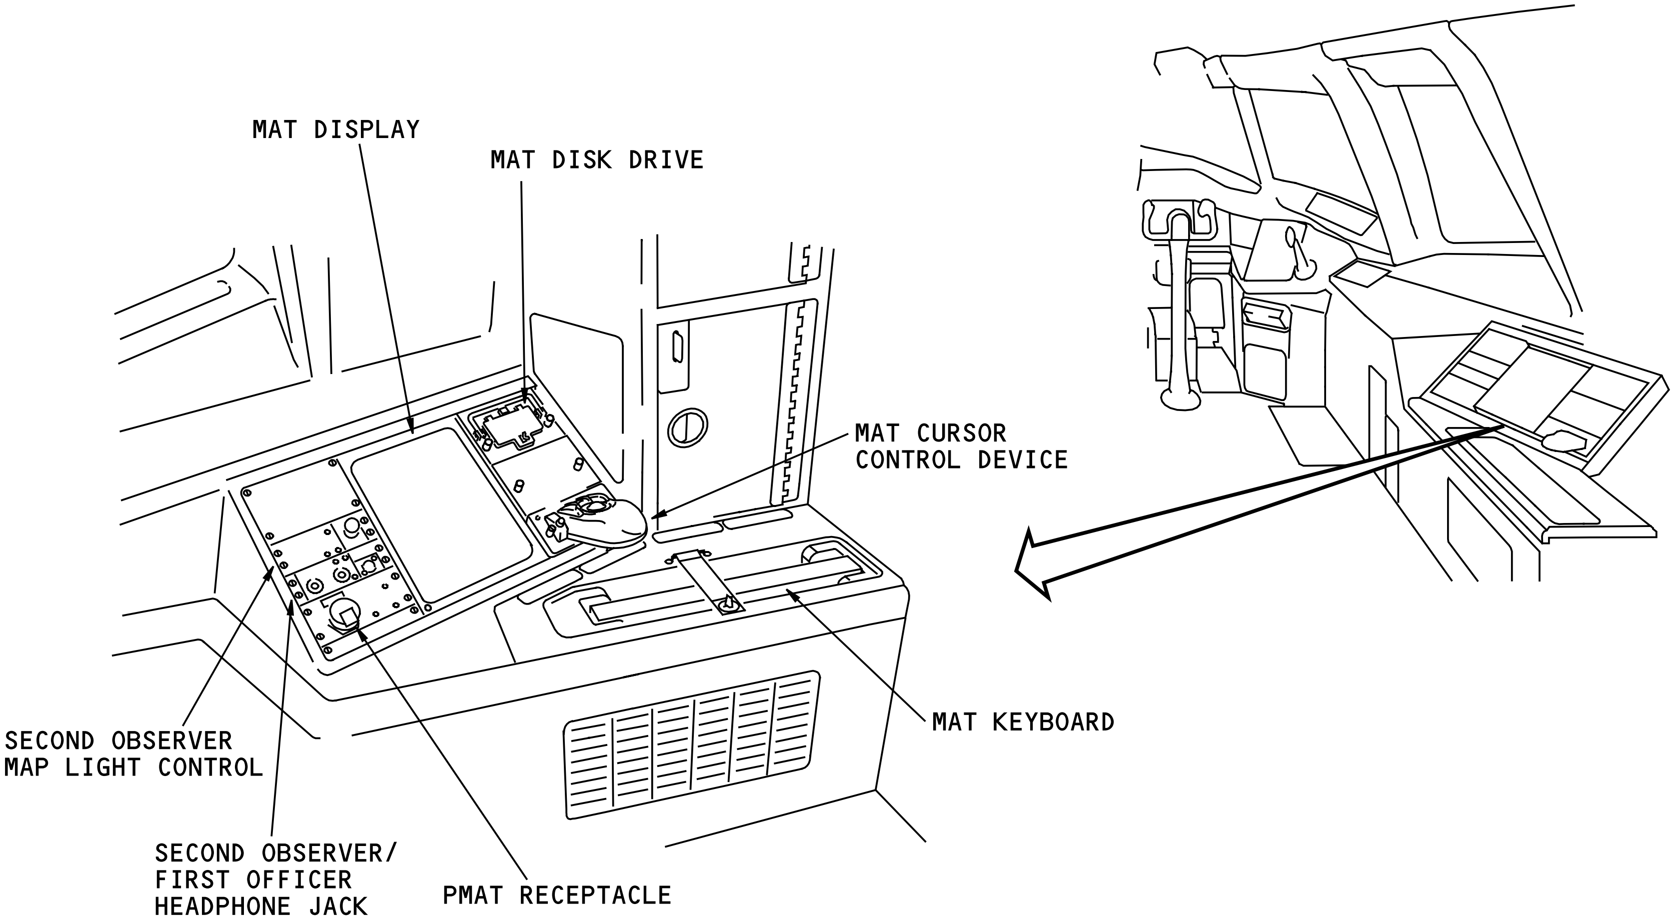
General

The MAT/second observer panel has these maintenance access terminal (MAT) items:

- MAT display
- MAT disk drive
- MAT cursor control device (CCD)
- MAT keyboard
- Portable MAT (PMAT) receptacle.

The panel also has these second observer controls:

- Map light control
- Headphone jack.



00-00-00-017 Rev 1

777 GENERAL - P18 MAT/SECOND OBSERVER PANEL

777 GENERAL - EQUIPMENT CENTER AND RACKS - INTRODUCTION

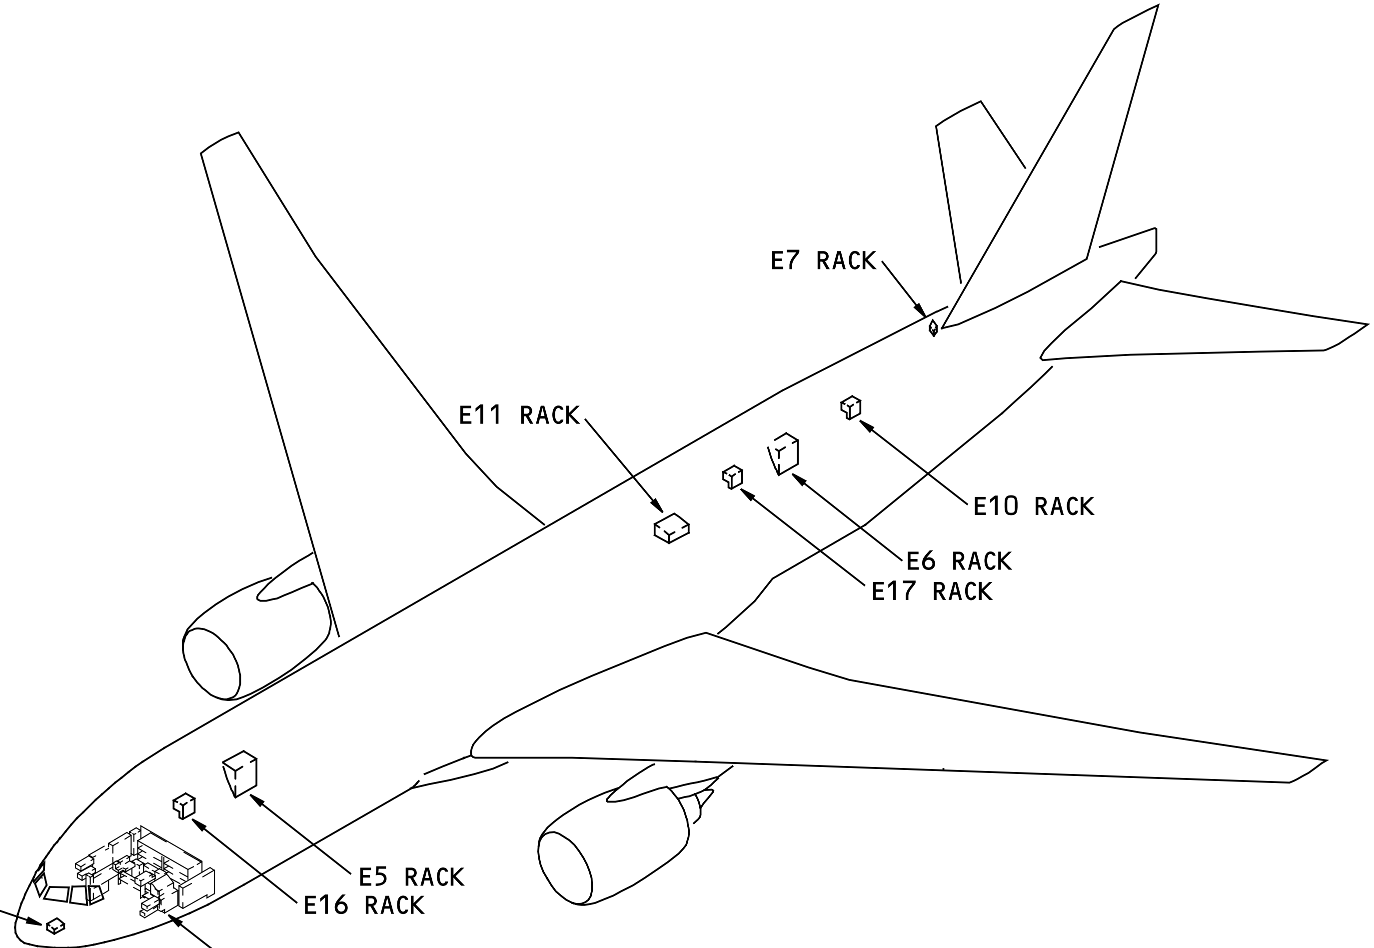
Equipment Centers

The main equipment center is aft of the nose wheel well. The forward equipment center is forward of the nose wheel well.

The E16 rack is forward and the E5 rack is aft of the forward cargo door. The E17 rack is forward and the E6 rack is aft of the aft cargo door.

The E11 and E7 racks are overhead in the passenger compartment.

The E10 rack is in the bulk cargo compartment aft of the bulk cargo door.



777 GENERAL - EQUIPMENT CENTER AND RACKS - INTRODUCTION

Main Equipment Center Electronics

The main equipment center (MEC) contains most of the electronics equipment on the airplane. The electronics equipment in the MEC is on the E1, E2, E3, and E4 racks. The equipment in the MEC includes electronics for these functions:

- Information management
- Generator control
- Transformer rectifier
- Flight control and autopilot
- Environmental control
- Recording
- Navigation
- Communication
- Cabin management
- Weight and balance
- Air data
- Inertial data
- Warning
- Proximity sensing
- Engine control.

Power Management

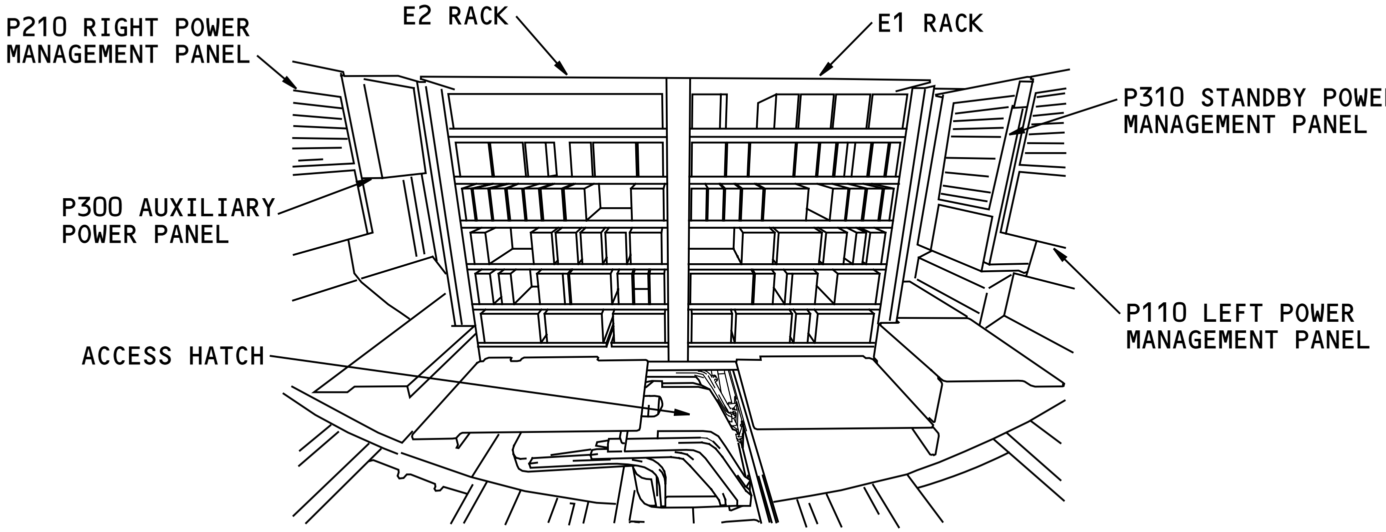
The MEC also contains these components for the electrical loads management system (ELMS):

- Power panels
- Power management panels.

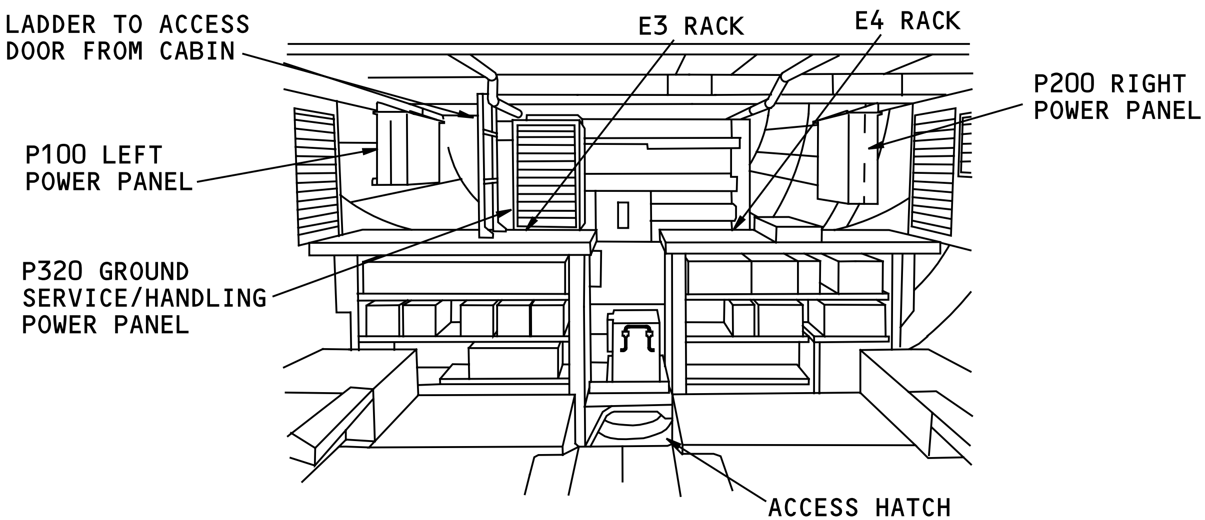
Access to the Main Equipment Center

Access to the MEC is through these:

- Access hatch in the bottom of the airplane
- Access hatch in the passenger compartment
- Door from the forward cargo compartment.



LOOKING AFT



LOOKING FORWARD

777 GENERAL - MAIN EQUIPMENT CENTER - 1

777 GENERAL - MAIN EQUIPMENT CENTER - 2

General

The systems card files hold interface cards for systems that use ARINC 429 buses.

These are the two systems card files in the main equipment center:

- P85 left systems card file (LSCF)
- P84 right systems card file (RSCF).

P85 Left Systems Card File

The LSCF has cards for these systems:

- Power supply units (PSUs)
- Hydraulic interface modules (HYDIMs)
- Duct leak and overheat detection system (DLODS)
- Airfoil and cowl ice protection system (ACIPS)
- APU fire/overheat detection
- Left engine fire/overheat detection
- ARINC 629 signal gateway (ASG)
- Environmental control system (ECS)
- Weight on wheels (WOW).

P84 Right Systems Card File

The RSCF has cards for these systems:

- Power supply units (PSUs)
- Hydraulic interface modules (HYDIMs)
- Duct leak and overheat detection system (DLODS)
- Airfoil and cowl ice protection system (ACIPS)
- Right engine fire/overheat detection
- ARINC 629 signal gateway (ASG)
- Environmental control system (ECS)
- Weight on wheels (WOW).

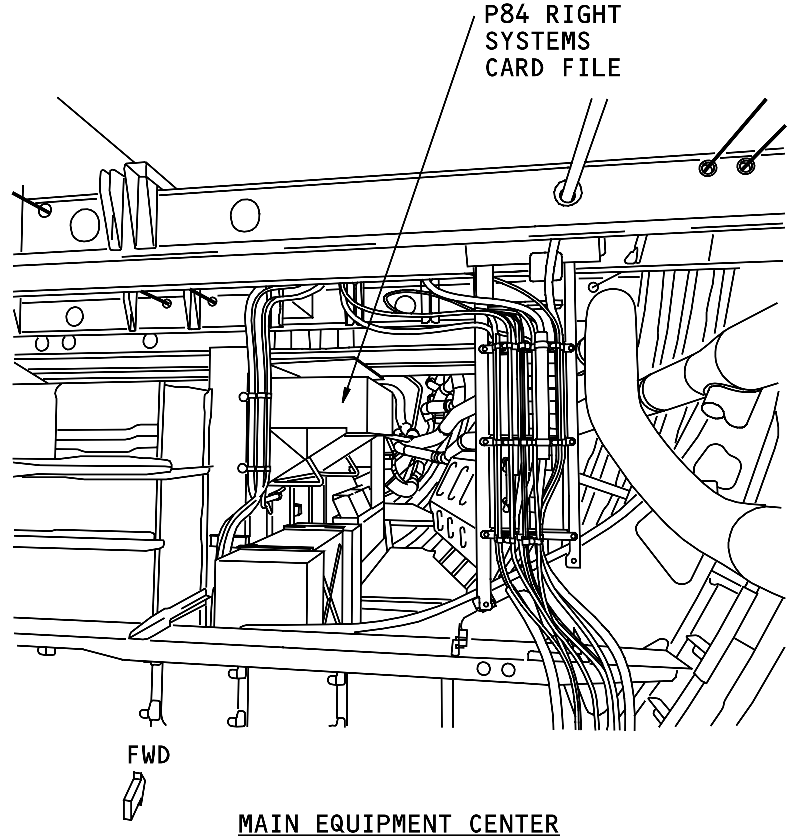
(LEFT SIDE, LOOKING FORWARD)



MAIN EQUIPMENT CENTER
(RIGHT SIDE, LOOKING FORWARD)

00-00-00-020 Rev 3 02/22/95

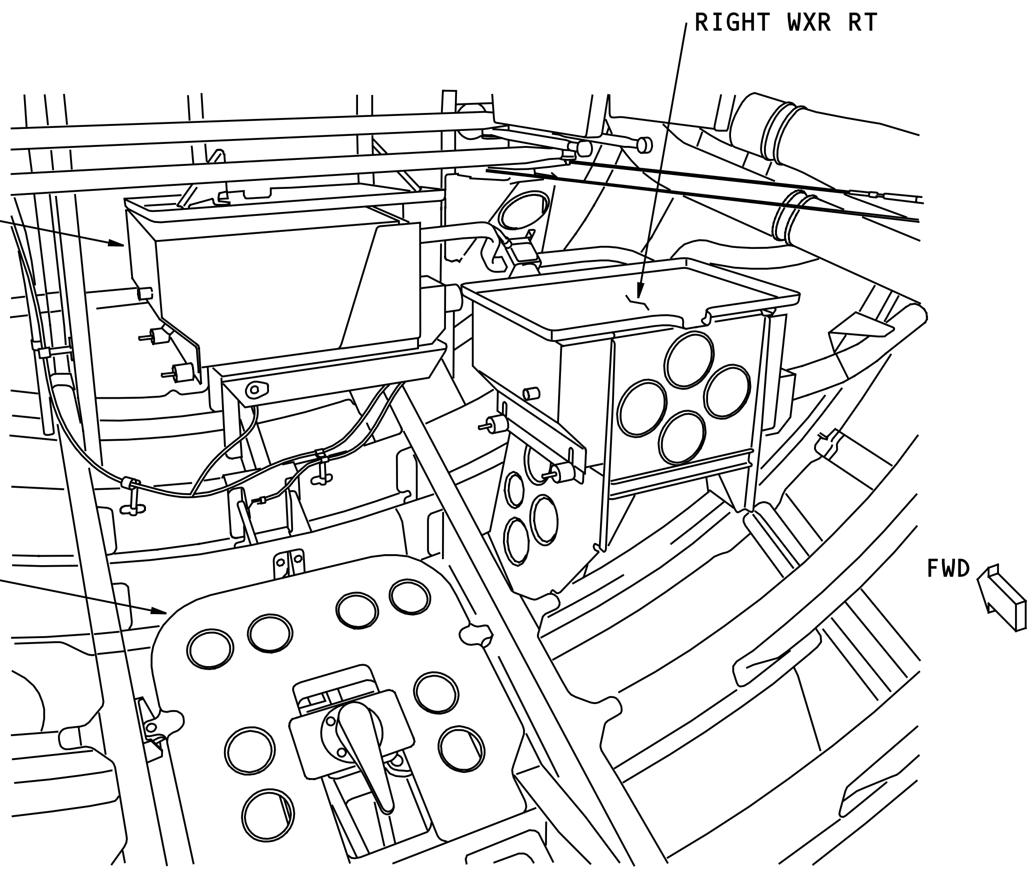
777 GENERAL - MAIN EQUIPMENT CENTER - 2

Forward Equipment Center Electronics

The forward equipment center contains the two weather radar receiver/transmitters.

Access to the Forward Equipment Center

Access to the forward equipment center is through the access door forward of the nose landing gear.



FORWARD EQUIPMENT CENTER
(LOOKING FORWARD)

777 GENERAL - FORWARD EQUIPMENT CENTER

777 GENERAL - CARGO DOOR EQUIPMENT RACKS

General

These four equipment racks are adjacent to the cargo doors:

- E16 rack and E5 rack (forward cargo door)
- E17 rack and E6 rack (aft cargo door).

E16 Rack

The E16 rack is at the forward cargo door at station 501. It contains components for these functions:

- Primary flight control
- Cargo handling.

E5 Rack

The E5 rack is at the forward cargo door at station 613. It contains components for these functions:

- Primary flight control power
- Actuator control electronics
- Radio altitude
- Fuel quantity.

E17 Rack

The E17 rack is at the aft cargo door at station 1678. It contains components for cargo handling.

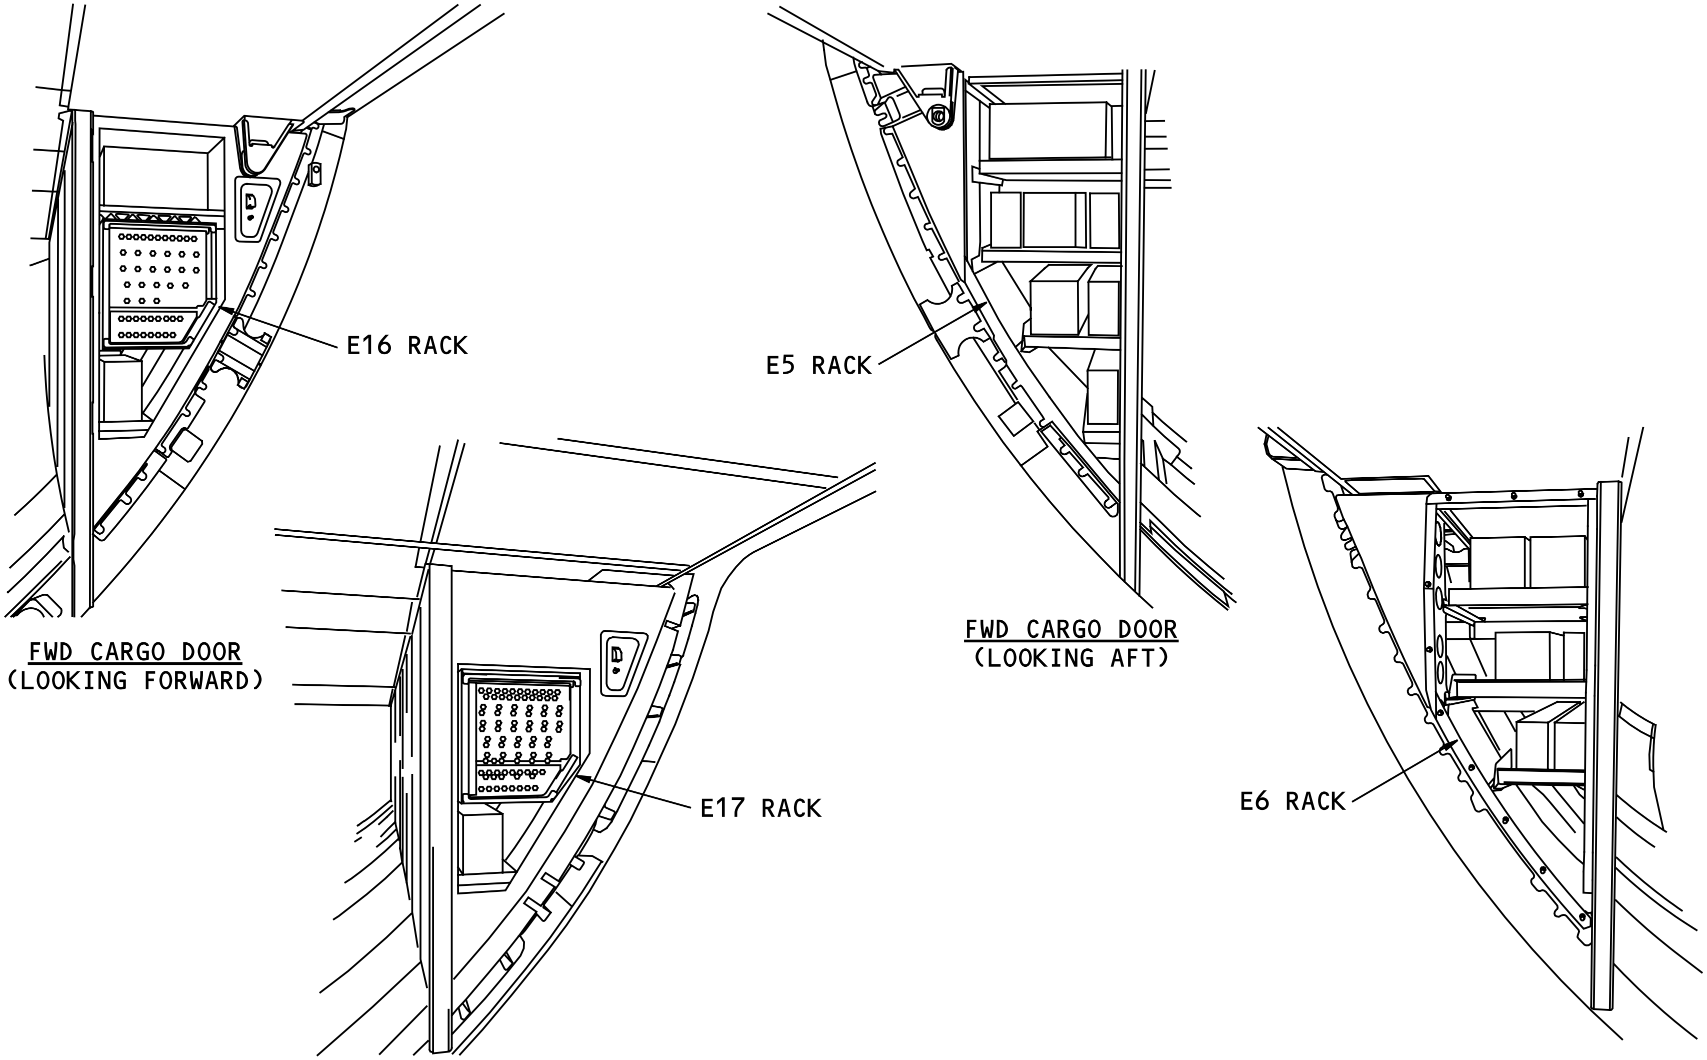
E6 Rack

The E6 rack is at the aft cargo door at station 1754. It contains components for these functions:

- HF communication
- Brake and tire system
- Main gear steering.

Access for Cargo Door Equipment Racks

Access for these equipment racks is at the cargo doors. You must open the cargo door to get access to the equipment rack. You then release and open a protective cover to get to the equipment on the rack.



FWD CARGO DOOR
(LOOKING FORWARD)

FWD CARGO DOOR
(LOOKING AFT)

AFT CARGO DOOR
(LOOKING FORWARD)

AFT CARGO DOOR
(LOOKING AFT)

00-00-00-021 Rev 0

777 GENERAL - CARGO DOOR EQUIPMENT RACKS

777 GENERAL - OTHER EQUIPMENT RACKS

General

In addition to the equipment racks in the main equipment center and at the forward and aft cargo doors, there are these other equipment racks in the airplane:

- E11 rack
- E7 rack
- E10 rack

E11 Rack

The E11 rack is in the passenger compartment above the door 3 cross-aisle at station 1530. It is on the left of airplane center. Access is through a ceiling panel.

The E11 rack contains satellite communication (SATCOM) equipment.

E7 Rack

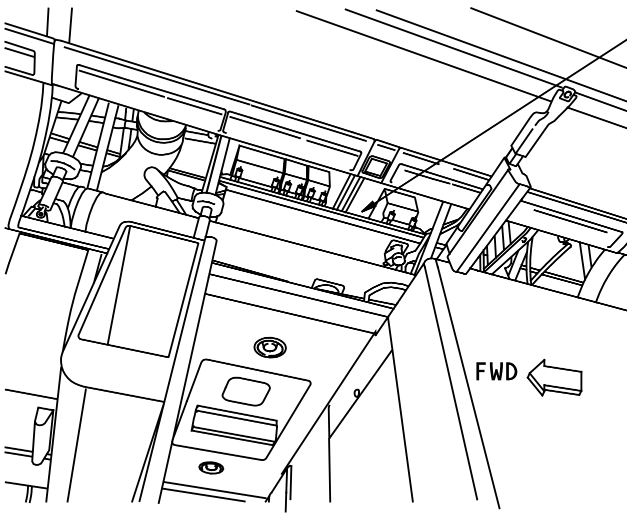
The E7 rack is in the passenger compartment above the aft galley at station 2100. It is on the right side of the airplane. Access is through a ceiling panel.

The E7 rack contains recorder equipment and the APU controller.

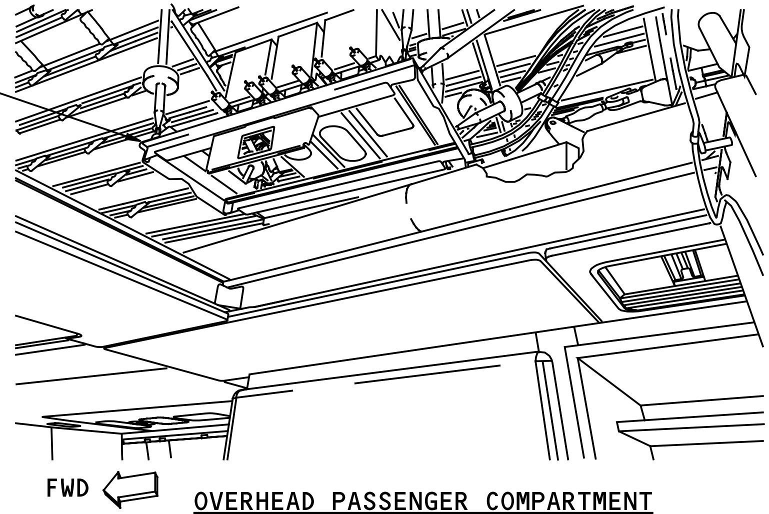
E10 Rack

The E10 rack is aft of the bulk cargo door on the right side of the lower lobe at station 1937. Access is through a door that faces inboard.

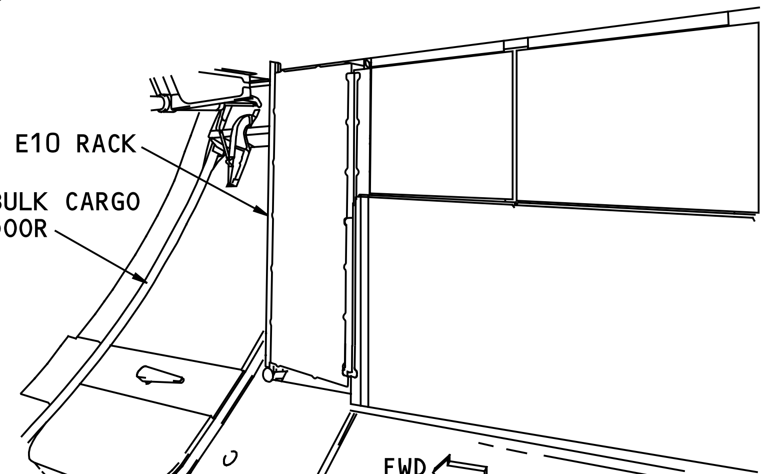
The E10 rack contains the APU battery and charger.



OVERHEAD PASSENGER COMPARTMENT
(LEFT SIDE LOOKING INBOARD)



OVERHEAD PASSENGER COMPARTMENT
(RIGHT SIDE LOOKING OUTBOARD)



BULK CARGO COMPARTMENT
(RIGHT SIDE LOOKING OUTBOARD)

777 GENERAL - OTHER EQUIPMENT RACKS

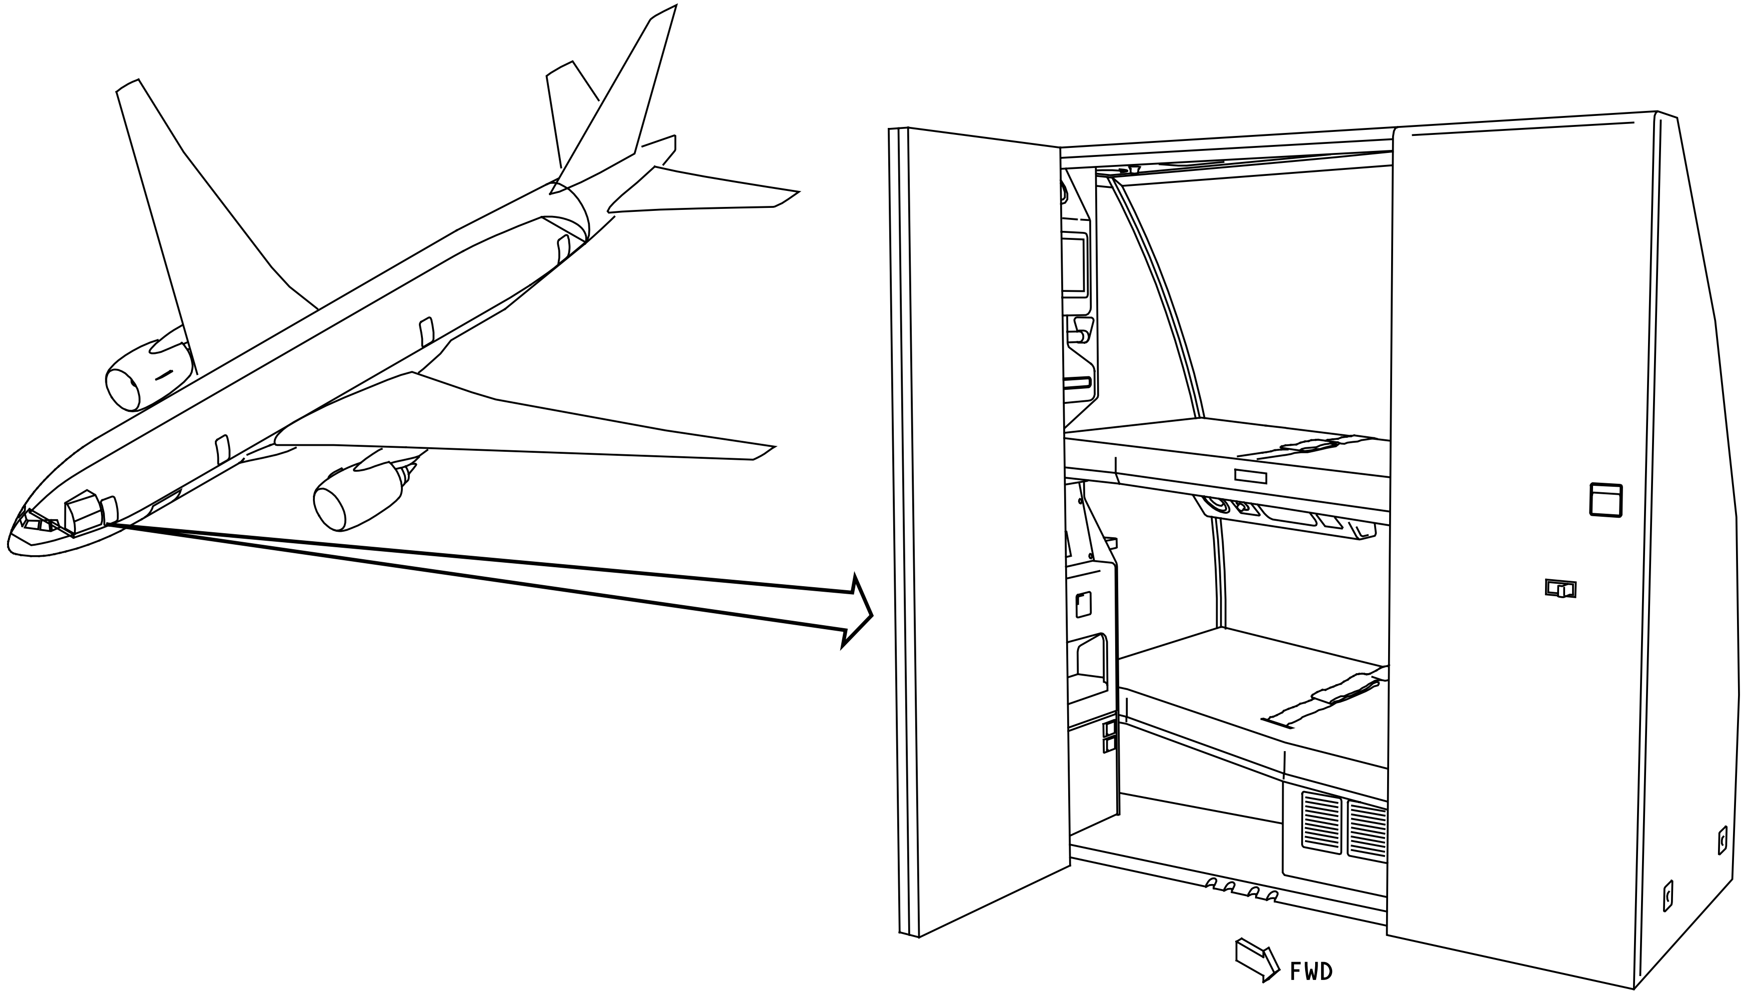
Flight Crew Rest (FCR) Module

The FCR module contains sleeping bunks for two crew members and storage compartments (not shown) for their belongings. The FCR module has these functions (not shown):

- Ventilation and heating
- Aural and visual fire/smoke indication
- Cabin interphone
- Passenger address
- Lighting
- Audio entertainment
- Attendant call
- Supplemental oxygen.

Access to Flight Crew Rest Module

Two doors give access to the FCR module. The primary access door latches open to block the adjacent aisle. This isolates the flight crew rest from the passenger compartment. The secondary access door gives access to the bunks. You can close and latch the two doors from the top or the bottom bunk. A step and handle (not shown) provide access the upper bunk.



FLIGHT CREW REST MODULE

00-00-00-064 Rev 5 02/24/1997

777 GENERAL - CREW REST MODULE(S)

777 GENERAL - ENGINE HAZARD AREAS

General

The hazards around jet engines in operation include:

- Inlet suction
- Heat
- Thrust
- Noise.

Inlet Suction

Suction at the inlet of an engine can pull objects, including a person, into the engine. At idle power, the hazard area is an 8 ft (2.4m) radius around the inlet. At takeoff thrust, the hazard area is a 16 ft (5m) radius around the inlet.

WARNING: IF SURFACE WIND IS GREATER THAN 25 KNOTS, INCREASE THE INLET HAZARD AREA BY 20%.

Engine damage can result when loose objects go into the inlet cowl. You must attach or remove any loose objects before you work around the engine.

Heat

High temperatures exist several hundred feet from the exhaust nozzle depending on wind conditions and thrust settings.

Thrust

The engine thrust makes high speed exhaust gases that can cause injury.

Noise

Engine noise can cause hearing loss. You must wear cup-type ear protection near an engine in operation.

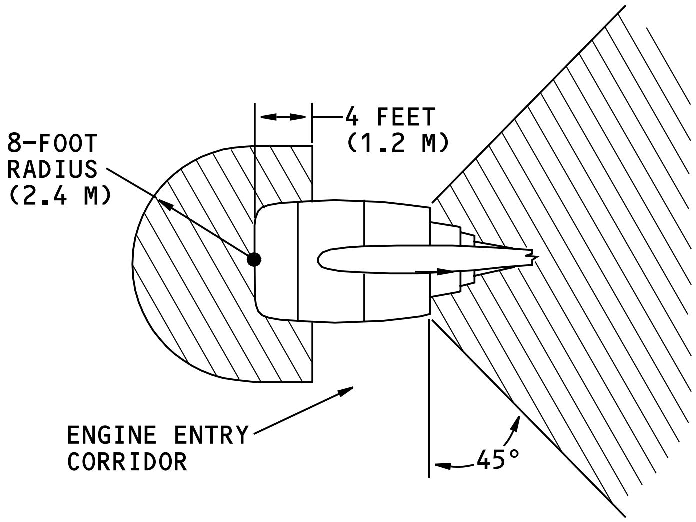
WARNING: LONG EXPOSURES TO JET ENGINE NOISE CAN CAUSE HEARING DAMAGE; EVEN WHEN YOU WEAR HEARING PROTECTION.

Engine Entry Corridors

Engine entry corridors are between the inlet hazard areas and the exhaust hazard areas. You should go near an engine in operation only when:

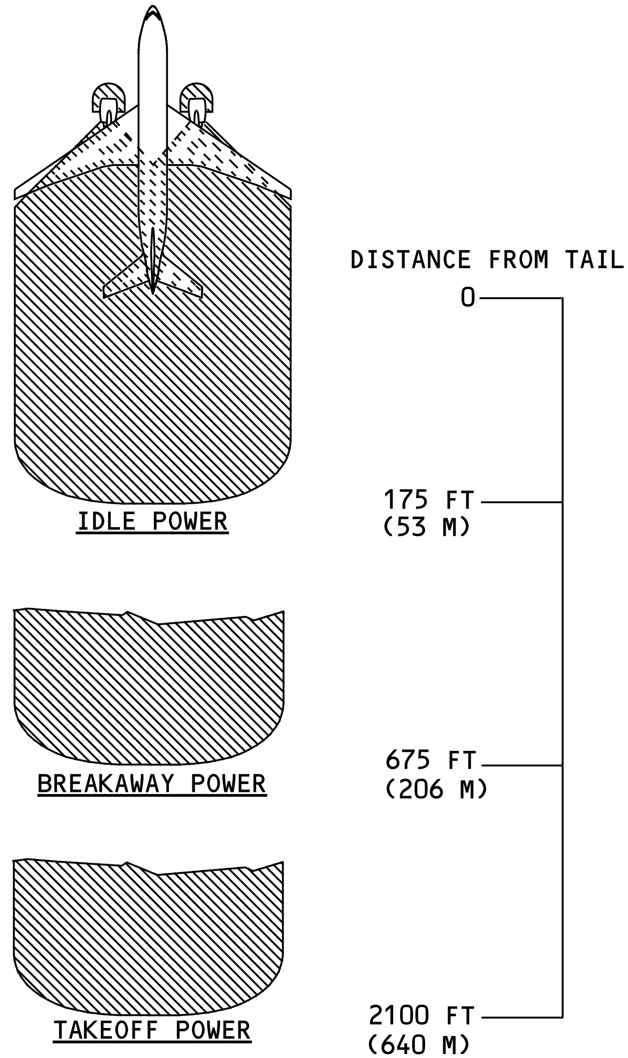
- The engine is at idle (forward thrust only)
- You have communication with the flight deck.

INLET HAZARD AREAS



IDLE POWER HAZARD AREA

EXHAUST HAZARD AREAS



00-00-00-036 Rev 3 12/12/95

777 GENERAL - ENGINE HAZARD AREAS

777 GENERAL - AIRPLANE TOWING

General

You can push or tow the airplane from the nose or main landing gear.

There is a forward tow fitting for a tow bar on the nose gear.

There is a forward and an aft (not shown) tow bar fitting on each main gear truck.

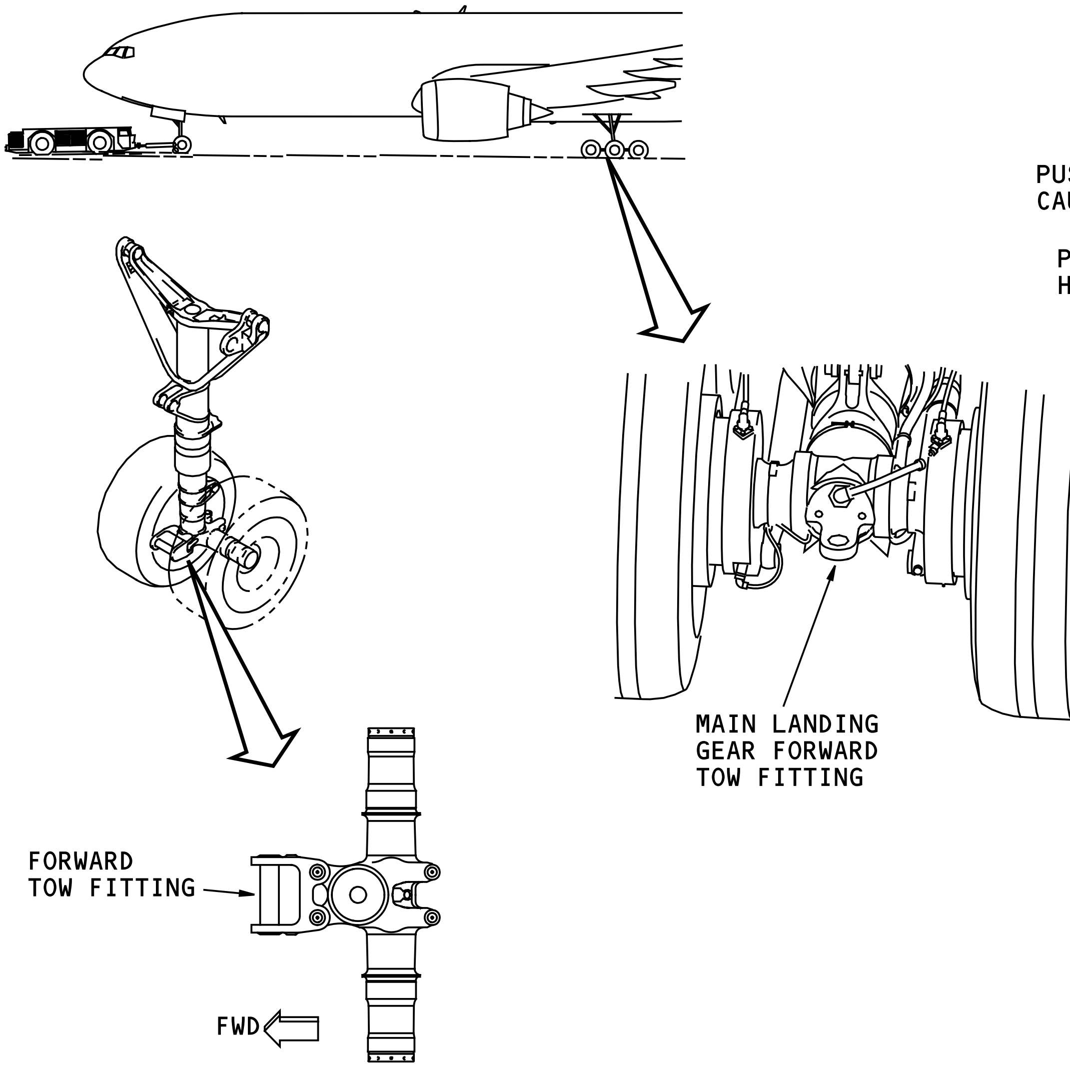
You can use towbarless equipment to push or pull the airplane.

For a fully loaded airplane, the minimum fuselage ground clearance is approximately 86 inches.

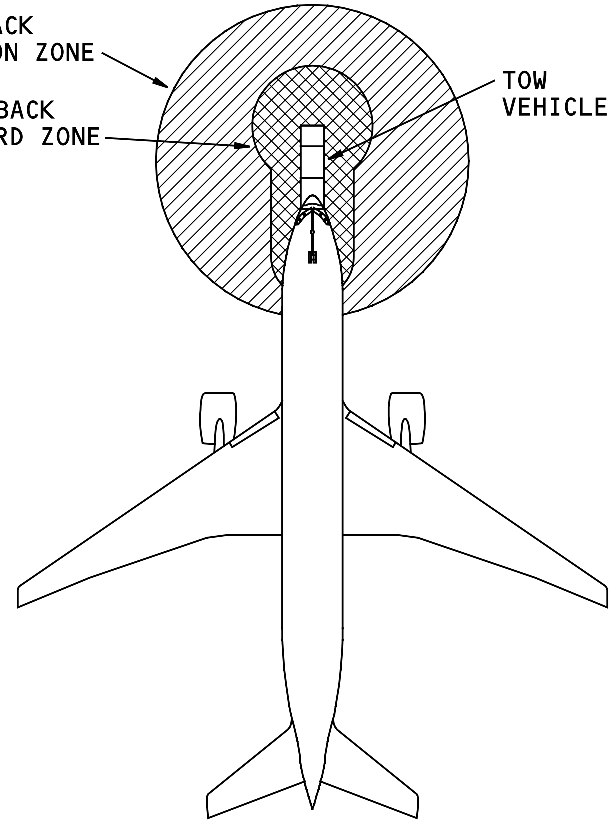
WARNING: WHEN YOU TOW THE AIRPLANE, ALL PERSONS MUST STAY OUT OF THE DANGEROUS AREAS AROUND THE TOW VEHICLE, TOW BAR, AND NOSE WHEELS. PERSONNEL ON THE GROUND MUST BE AWARE OF THE POSSIBILITY OF BEING RUN OVER BY THE NOSE WHEELS. THE TOW VEHICLE, TOW BAR, AND AIRPLANE WILL CHANGE POSITION DURING PUSHBACK AND TOWING. MAINTAIN A MINIMUM OF 10 FEET SEPARATION BETWEEN PERSONS ON THE GROUND AND THE EQUIPMENT THAT MOVES. A FATAL INJURY COULD OCCUR.

Training Information Point

You can tow the airplane when it has flat tires. Keep these operations to a minimum because flat tires can put too much load on the inflated tires.



NOSE GEAR TOW FITTINGS
(TOP VIEW)



TOWING HAZARD ZONES

00-00-00-037 Rev 2 03/01/96

777 GENERAL - AIRPLANE LEVELING

General

For some maintenance procedures, the airplane must be level. To do a check of the airplane attitude, the airplane has these components:

- Longitudinal inclinometer
- Lateral inclinometer
- Plumb bob fitting
- Plumb bob scale.

You can use either the inclinometers or the plumb bob scale to find the airplane pitch and roll attitudes.

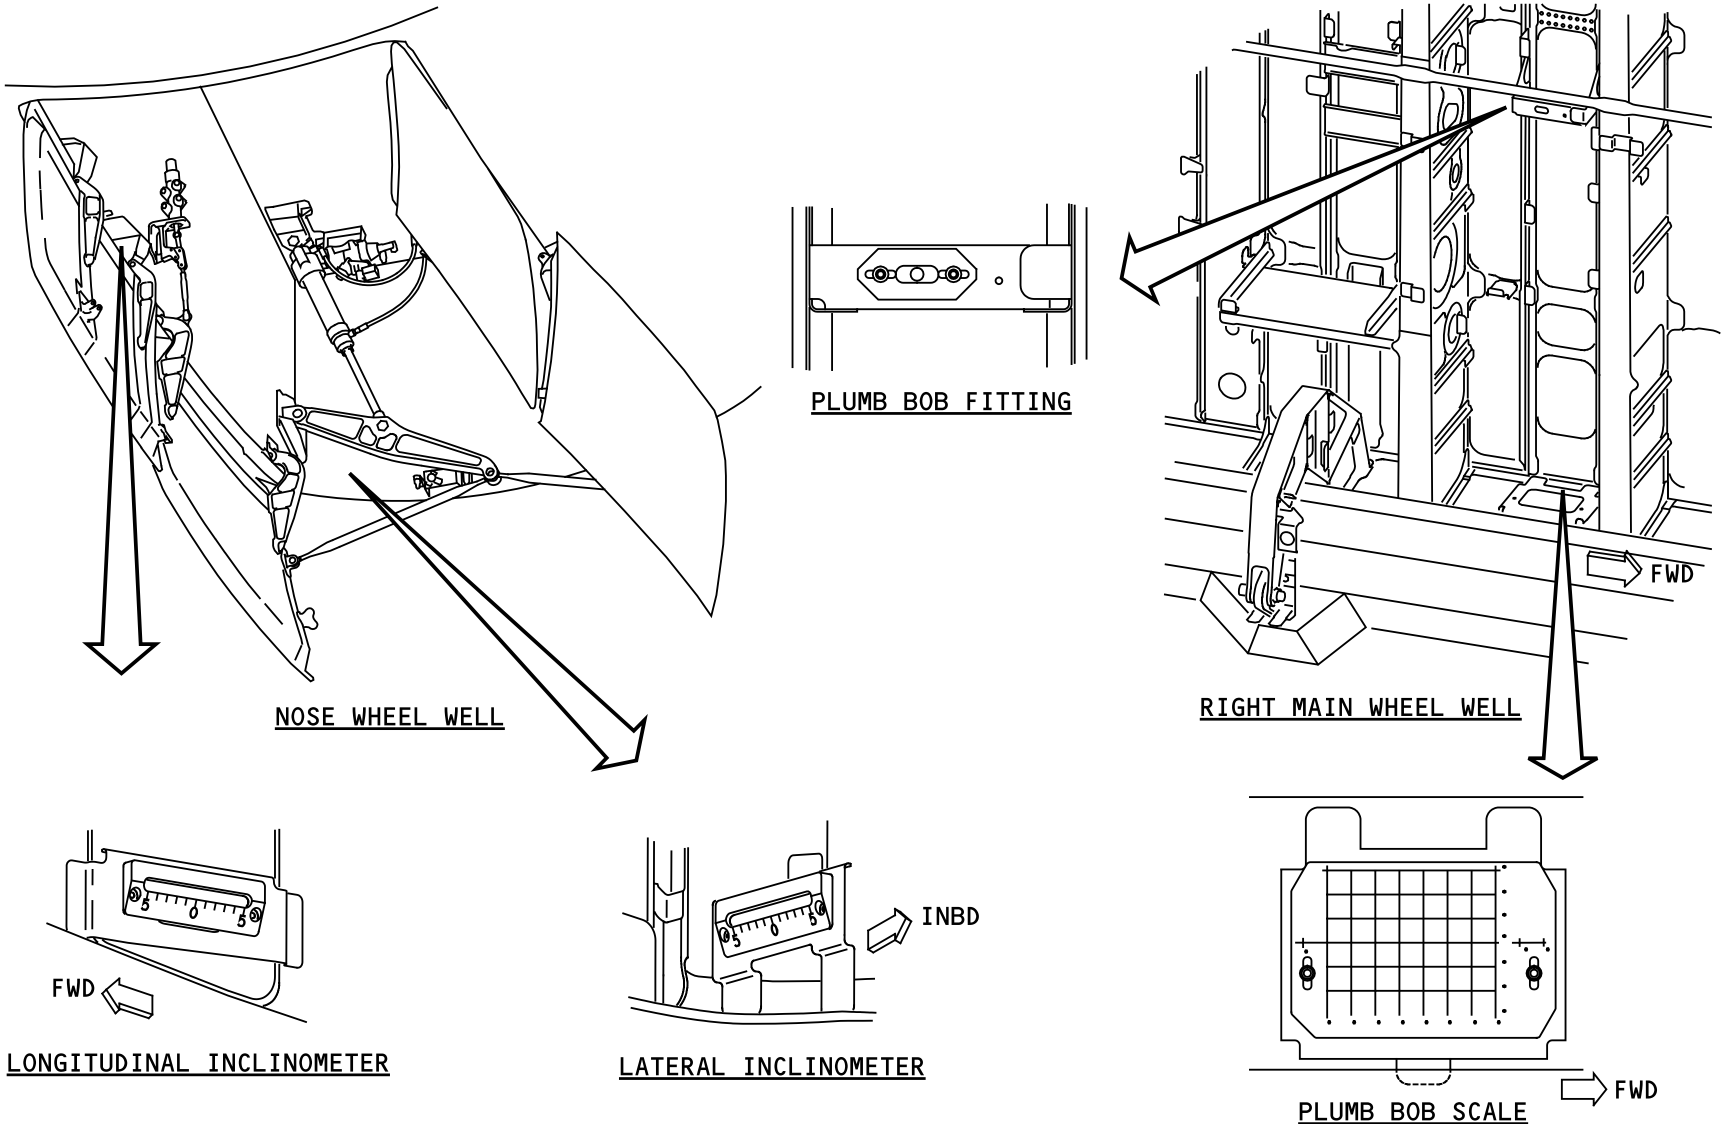
The longitudinal inclinometer tells you the pitch attitude of the airplane. The lateral inclinometer tells you the roll attitude.

You can hang a plumb bob on the plumb bob fitting. You then can read both the pitch and roll attitudes on the plumb bob scale.

Location

The inclinometers are in the nose wheel well.

The plumb bob fitting and plumb bob scale are in the right main wheel well.



777 GENERAL - AIRPLANE LEVELING

THIS PAGE INTENTIONALLY LEFT BLANK

General

You can lift all of the airplane on jacks, or lift only the airplane nose. You can also jack the airplane axles.

To lift the airplane, there are three primary jack points. There are five auxiliary jack points to make the airplane stable after the airplane is at the necessary height.

The airplane has seven axle jack points.

Airplane Jack Points, Pads, and Adapters

The three primary jack points are: A, B, and C. These jack points have jack pads which are part of the airplane body.

The auxiliary jack points are: D, E, F, G, and H. You must install adapters at these points before you put a jack there. You must remove bolts from the airplane body before you install the jack adapter at point D.

Airplane Jacking

Before you jack the airplane, you must make sure that the airplane gross weight and center of gravity are within specified limits.

Also, the loads on the jacks must be within limits. These loads are a function of airplane gross weight.

When you jack the airplane, the airplane must remain level within specified limits. One person must stay in the nose wheel well to monitor the airplane inclinometers.

Nose Jacking

You use jack point D to jack only the airplane nose.

CAUTION: DO NOT LIFT THE NOSE OF THE AIRPLANE TO MORE THAN SIX INCHES OF TIRE CLEARANCE. IF YOU LIFT THE NOSE HIGHER, SIDE LOADS THAT ARE MORE THAN DESIGN LOAD LIMITS CAN OCCUR. THIS CAN CAUSE DAMAGE TO THE JACK RAM AND JACK ADAPTER BECAUSE THEY WILL MOVE IN AN ARC.

Axle Jacking

There are three axle jack points on each main gear (not shown). There is one axle jack point on the nose gear. The pads of the axle jack points are all part of the landing gear.

You can lift the airplane on one axle or a combination of axles. If you use a jack on one axle, you can jack the airplane in winds up to 35 knots. When you use two or more axle jacks, you can jack the airplane in winds up to only 25 knots.

If you have two flat tires on an axle, you can use axle jacking bars to lift the axle enough to install the axle jack.

777 GENERAL - AIRPLANE JACKING

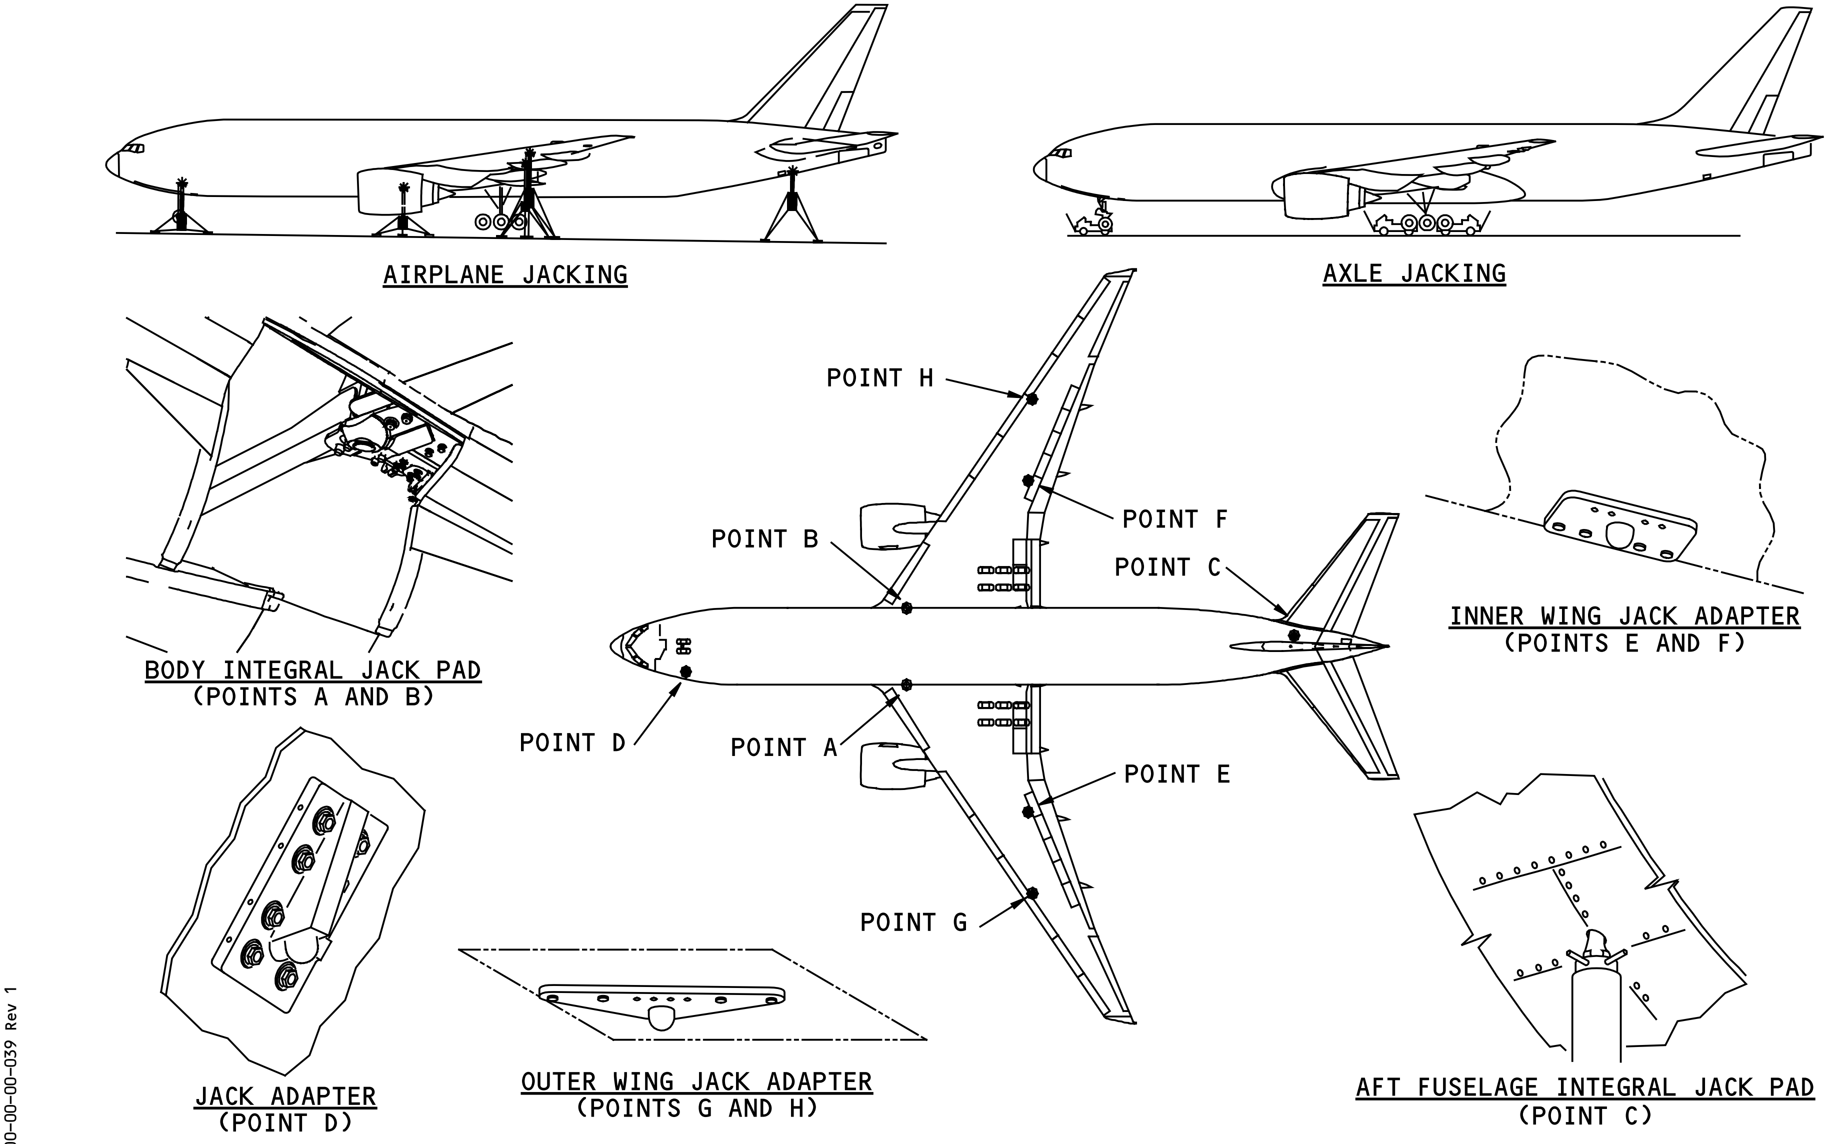
Training Information Point

If you supply electrical power to the airplane while it is on jacks, obey this warning:

WARNING: DO THE DEACTIVATION PROCEDURE FOR THE AIR MODE SIMULATION (AMM 32-09-01) BEFORE YOU LIFT THE AIRPLANE. IF YOU DO NOT OBEY THESE INSTRUCTIONS, INJURIES TO PERSONS OR DAMAGE TO EQUIPMENT CAN OCCUR.

CAUTION: DO NOT LIFT THE AIRPLANE ON JACKS IN WINDS MORE THAN 35 KNOTS. IF YOU DO NOT OBEY THESE INSTRUCTIONS, DAMAGE TO THE AIRPLANE CAN OCCUR.

NOTE: If you use jacks that have general specifications but are not designed for the 777, be careful. It is possible that the maximum wind speed limit (35 knots) will have to be decreased.



777 GENERAL - AIRPLANE JACKING

777 GENERAL - FLIGHT INTERPHONE SYSTEM - FLIGHT DECK COMPONENT LOCATIONS - 2

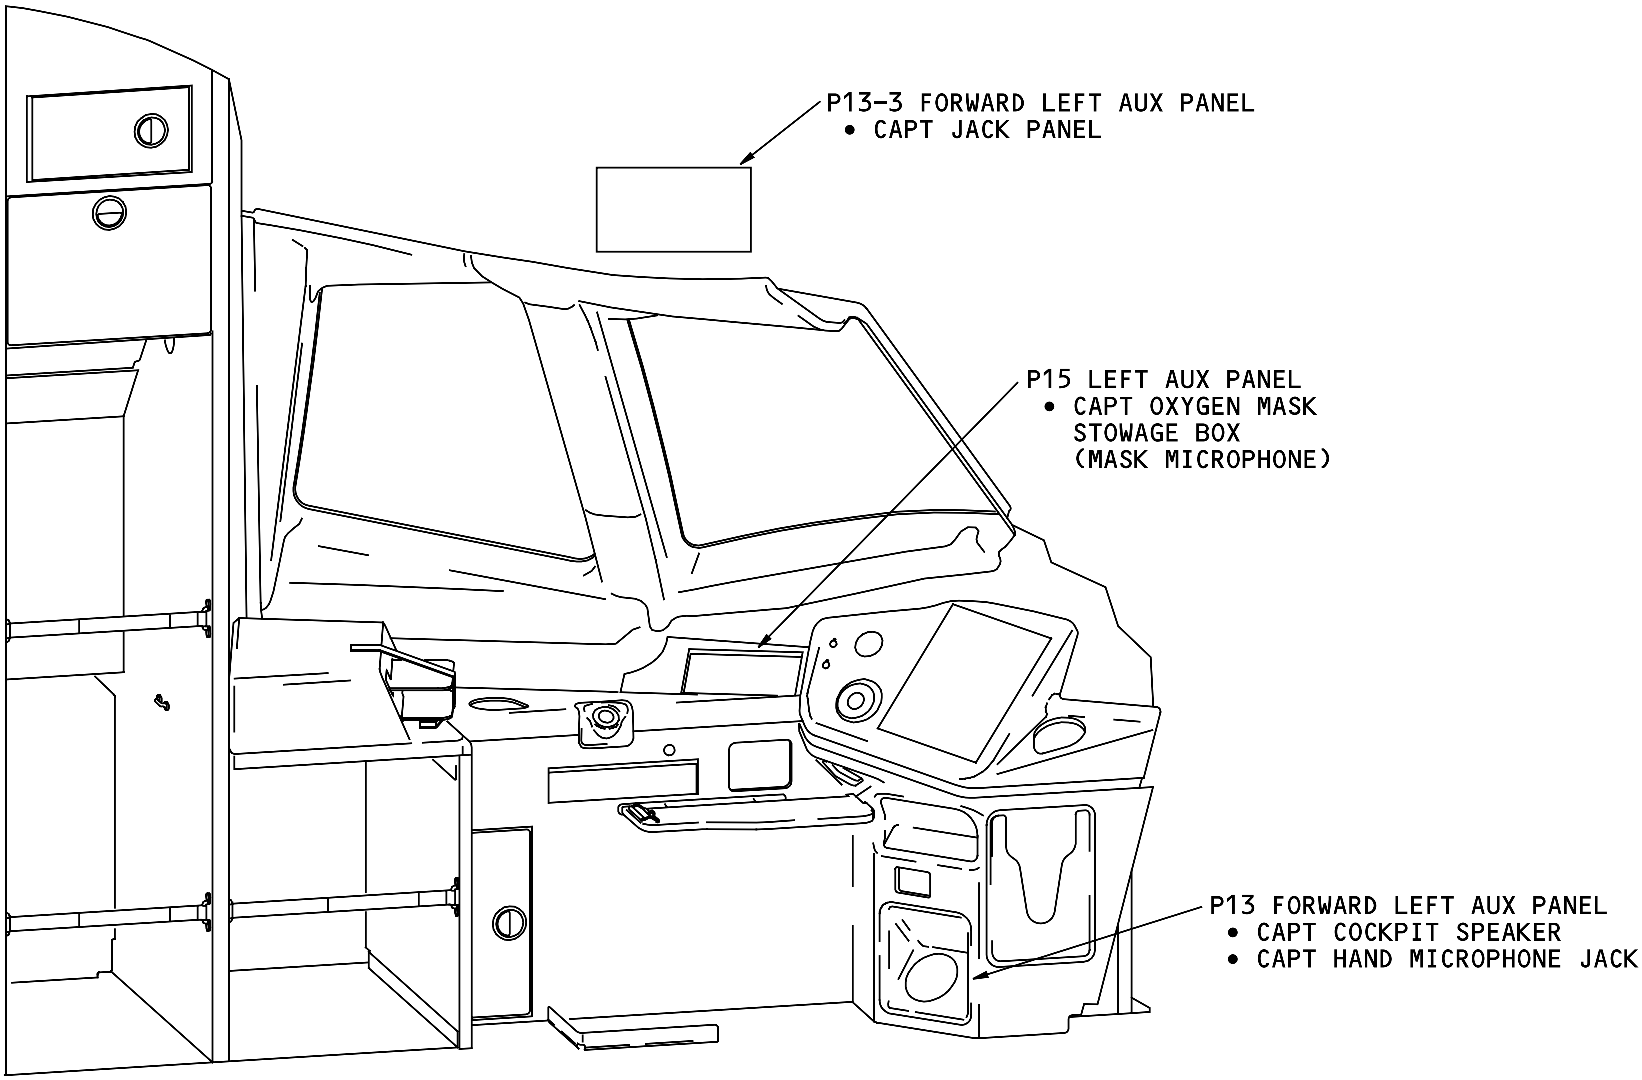
Flight Interphone Component Locations

The flight interphone system components on the left side of the flight deck include:

- Captain's jack panel
- Captain's cockpit speaker
- Captain's hand microphone jack.

Component locations on the right side of the flight deck are almost the same.

The captain's oxygen mask microphone connects with the flight interphone system.



00-00-00-045 Rev 0

777 GENERAL - FLIGHT INTERPHONE SYSTEM - FLIGHT DECK COMPONENT LOCATIONS - 2

777 GENERAL - ELECTROSTATIC DISCHARGE SENSITIVE (ESDS) DEVICES

General

Many electronic line replaceable units (LRUs) contain micro-circuits and other devices that electrostatic discharges can damage. These LRUs are electrostatic discharge sensitive (ESDS). There are placards on ESDS LRUs.

There are precautions that you must take when you touch ESDS LRUs. Some precautions apply only to ESDS printed circuit boards, and some precautions apply only to ESDS metal encased units.

ESDS Printed Circuit Boards

On the outer area of card files, there are placards that show which boards are ESDS printed circuit boards.

You must use a wrist strap when you touch one of the ESDS boards. The wrist strap is on the plenum between the E1 and E2 racks. Connect the wrist strap into an electrostatic ground jack. There are placards that show the jack locations.

Use the extractors on the card to remove it. Put the card in an ESDS conductive bag, and close the bag with ESDS or 100 percent cotton twine.

ESDS Metal Encased Units

On the equipment racks, there are ESDS placards and placards that show the procedure for the removal and installation of ESDS metal encased units.

Training Information Point

When you remove a unit, do not touch the pins in the electrical connectors. Install a conductive dust cover on the connectors.

NOTE: The conductive dust caps and the connector covers are black.

NOTE: You can use the conductive dust caps and the connector covers from the unit you install on the unit you remove.

777 GENERAL - ELECTROSTATIC DISCHARGE SENSITIVE (ESDS) DEVICES

THIS PAGE INTENTIONALLY LEFT BLANK

General

The 777 line replaceable units (LRUs) and line replaceable modules (LRMs) use different data buses.

An LRU/LRM may use one or more of these types of data buses:

- ARINC 629
- ARINC 429
- ARINC 453
- ARINC 717
- ARINC 618
- RS-422
- RS-232
- 10 base T
- RS-485
- 10 base 2
- ARINC 636.

LRUs/LRMs send data to their data bus(es) at different speeds.

ARINC 629

The ARINC 629 data bus is an unshielded, twisted pair of wires continuously bonded and terminated at both ends. Many LRU/LRMs connect to an ARINC 629 data bus with current mode couplers. The LRU/LRMs send data to the ARINC 629 data bus one at a time. All connected LRU/LRMs can receive data from the ARINC 629 data bus at the same time. Some LRU/LRMs only receive ARINC 629 data.

An ARINC 629 LRU/LRM sends and receives data on the ARINC 629 data bus at 2 megabits per second (MBPS).

ARINC 429, 453, 717, 618, and RS-422

The ARINC 429, 453, 717, 618, and RS-422 data buses are one-way buses that send data on a twisted, shielded pair of wires.

Each bus has only one transmitter that sends data to one or more receivers.

An ARINC 429 LRU/LRM sends and receives data at low and high speeds on the ARINC 429 data bus. Low speed data rate is between 12 kilobits per second (KBPS) and 14 KBPS. High speed data rate is 100 KBPS.

An ARINC 453 LRU/LRM sends data to the ARINC 453 data bus at 1 MBPS.

An ARINC 717 LRU/LRM sends and receives data on the ARINC 717 data bus at 128 words per second (WPS).

An ARINC 618 LRU/LRM sends and receives data on the ARINC 618 data bus at up to 2400 BPS.

An RS-422 LRU/LRM sends and receives data on the RS-422 data bus at 9600 BPS.

RS-232

The RS-232 data bus is a one-way bus that sends data on a coaxial wire.

An RS-232 LRU/LRM sends and receives data on the RS-232 data bus up to 20 KBPS.

10 Base T

The 10 base T data bus is a two-way bus that sends data on two twisted, shielded pairs of wires. One pair transmits and the other pair receives signals. The 10 base T bus operates between two LRU/LRMs only.

A 10 base T LRU/LRM sends and receives data at 10 MBPS on the 10 base T data bus.

RS-485

The RS-485 data bus is a two-way bus that sends data on a twisted, shielded pair of wires. The RS-485 bus operates between two LRU/LRMs only.

An RS-485 LRU/LRM sends and receives data at 10 MBPS on the RS-485 data bus.

10 Base 2

The 10 base 2 data bus is a two-way bus that uses a single coaxial wire connected to each LRU/LRM on the bus. The operation of the bus is similar to ARINC 629 but the LRU/LRMs connect to the 10 base 2 bus internally.

A 10 base 2 LRU/LRM sends and receives data at 10 MBPS on the 10 base 2 data bus.

ARINC 636

The ARINC 636 is a fiber optic data bus. One strand of optical fiber per bus. Two strands of optical fiber provide a primary (PRI) and secondary (SEC) bus.

The ARINC 636 fiber optic data bus connects to many LRU/LRMs. LRU/LRMs send and receive data in series on the ARINC 636 fiber optic data bus.

An ARINC 629 LRU/LRM sends and receives data at 100 MBPS on the ARINC 636 data bus.

777 GENERAL - DATA BUSES

THIS PAGE INTENTIONALLY LEFT BLANK

General

An ARINC 629 data bus is an electronic data movement system that connects many line replaceable units (LRUs) in a single communication loop. Data from any ARINC 629 LRU is available to all other LRUs on the ARINC 629 bus.

An ARINC 629 data bus is a twisted pair of wires with termination resistors at each end. As many as 120 LRUs can use one ARINC 629 data bus. On the 777 airplane, the maximum number of LRUs on one bus is 46.

Components

The ARINC 629 data bus system has these parts:

- Data bus cable
- Current-mode couplers
- Stub cables.

The ARINC 629 system also includes these components in the LRUs:

- Serial interface modules
- Terminal controllers.

Physical Description

The ARINC 629 data bus system has these characteristics:

- Many LRUs send data one at a time in sequence
- Many LRUs receive data at the same time
- Communication on ARINC 629 is bi-directional; LRUs may transmit and receive data on the same bus
- One LRU may connect to more than one data bus through separate couplers on each bus
- All data on the bus is available to all the LRUs on that bus.

ARINC 629 Data Buses Configuration

There are eleven ARINC 629 data buses. They are:

- Three flight controls buses
- Four systems buses
- Four airplane information management systems (AIMS) intercabinet buses.

The flight controls buses connect LRUs that have flight control functions.

The systems buses connect LRUs that have other airplane system functions. These buses work independently from the flight controls buses. The systems buses move data between these five areas:

- Avionics
- Propulsion
- Electrical
- Electro-mechanical
- Environmental control.

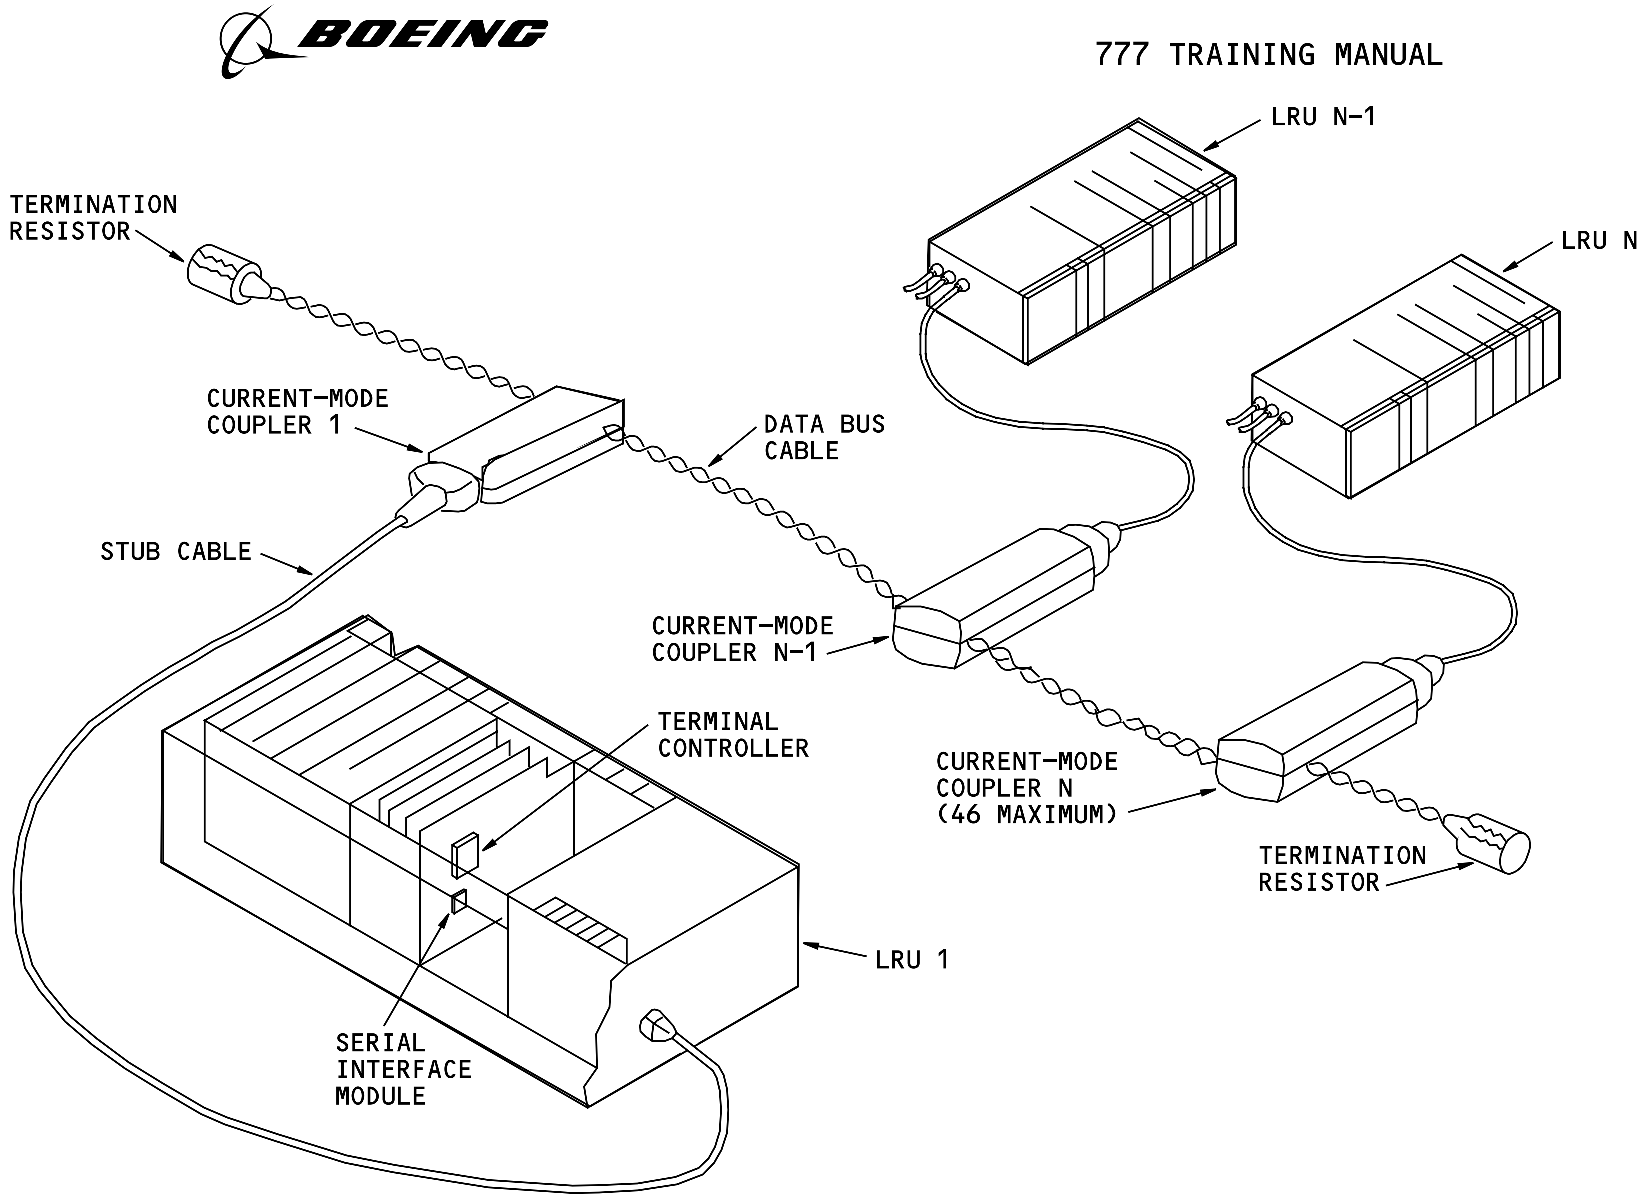
777 GENERAL - ARINC 629 - GENERAL DESCRIPTION

Four AIMS intercabinet buses move data between the two AIMS cabinets and the three control display units (CDUs).

Functional Description

Each LRU uses one or more current-mode couplers to connect to data buses.

A current mode coupler and its terminal (terminal controller and serial interface module) move data to and from the bus. Only one terminal on a bus transmits at a time. Each terminal listens to the bus and waits for a stop in data movement on the bus from other LRUs before it transmits.



777 GENERAL - ARINC 629 - GENERAL DESCRIPTION

777 GENERAL - ARINC 629 - MEC COMPONENT LOCATIONS

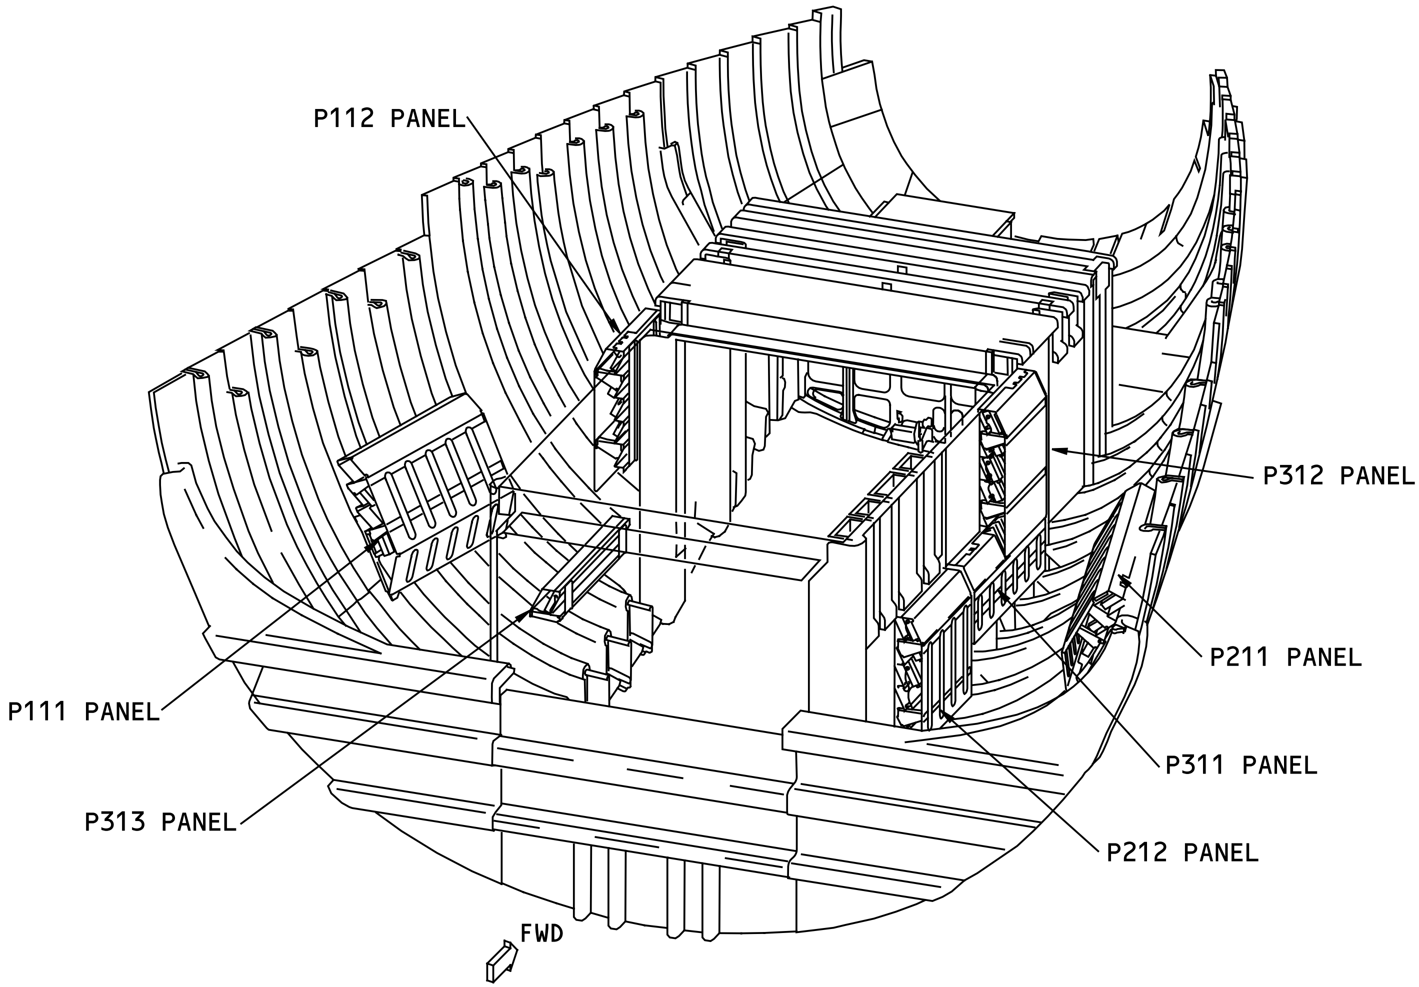
General

There are seven bus panels in the MEC on the left and right sides of the nose wheel well. Each bus panel contains the current-mode couplers and ARINC 629 buses.

Current-Mode Coupler Panels

These are the seven ARINC 629 bus panels:

- P111 (contains the AIMS intercabinet ARINC 629 bus 1 and the forward section of the left systems ARINC 629 bus)
- P112 (contains the left flight controls ARINC 629 bus)
- P211 (contains the AIMS intercabinet ARINC 629 bus 3 and the forward section of the right systems ARINC 629 bus)
- P212 (contains the right flight controls ARINC 629 bus)
- P311 (contains the AIMS intercabinet ARINC 629 bus 2, the AIMS intercabinet ARINC 629 bus 4 and the center 1 systems ARINC 629 bus)
- P312 (contains the center flight controls ARINC 629 bus)
- P313 (contains the center 2 systems ARINC 629 bus).



777 GENERAL - ARINC 629 - MEC COMPONENT LOCATIONS

777 GENERAL - ARINC 629 - BULK CARGO COMPARTMENT COMPONENT LOCATIONS

General

There are two bus panels in the aft section. Each panel contains current-mode couplers and ARINC 629 buses.

Current-Mode Coupler Panels

These are the bus panels in the aft sections:

- P115 (contains the aft section of the left systems ARINC 629 bus)
- P215 (contains the aft section of the right systems ARINC 629 bus).

VIEW LOOKING FORWARD

00-00-00-052 Rev 2

777 GENERAL - ARINC 629 - BULK CARGO COMPARTMENT COMPONENT LOCATIONS

777 GENERAL - ARINC 629 - CURRENT MODE COUPLER

Purpose

The current-mode coupler connects the data bus cable to the stub cable.

Physical Description

The current-mode coupler has these characteristics:

- Two part assembly for fast installation
- Cover with the electronics and the receptacle for the stub cable
- Base designed for easy installation on panel
- Waterproof housing
- Protective wire guide to install the data bus cable.

There are different suppliers for current-mode couplers. They all function in the same way. They are interchangeable.

E-Core Assembly

An E-core assembly is a part of the coupler base. E-core assemblies are electromagnetic components that couple the signals in the data bus cable in and out of the coupler. The wire guides are grooves that give a controlled routing and protection for the wires of the data bus cable as they go through the E-core assembly.

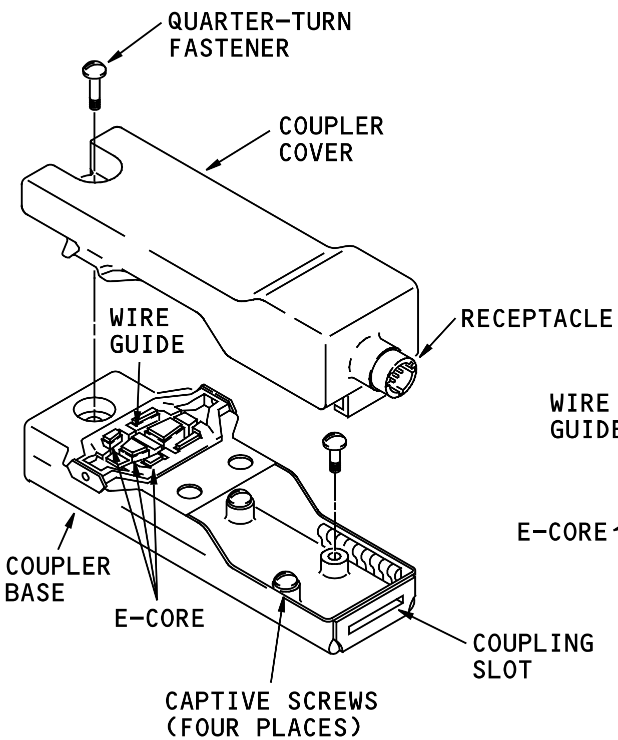
Location

All the current-mode couplers are on the current-mode coupler panels.

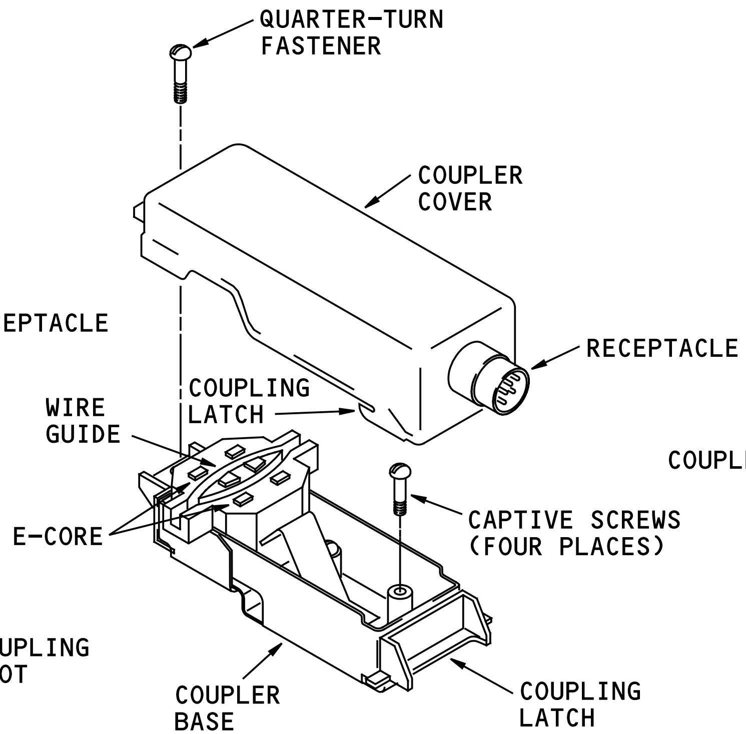
Training Information Point

Couplers are interchangeable units. Covers and bases from different suppliers are not interchangeable.

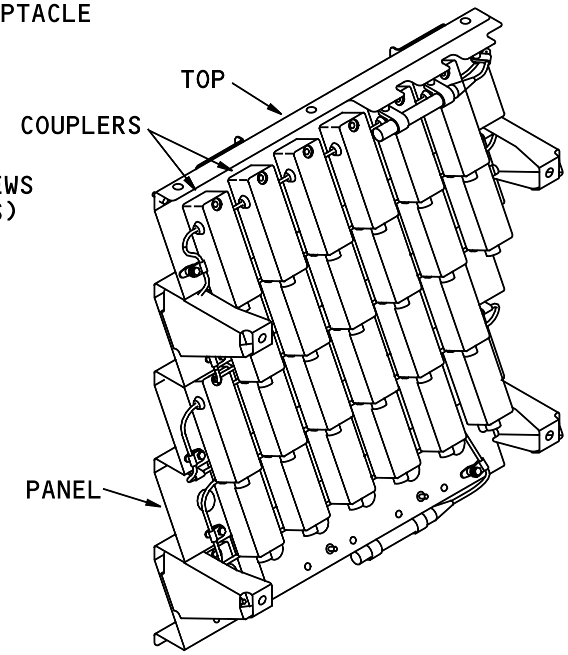
Remove power from the LRU before you replace couplers for that LRU.



COUPLER-AMPHENOL (TYPICAL)



COUPLER-SCI (TYPICAL)



BUS PANEL (COVER REMOVED)
(TYPICAL)

777 GENERAL - ARINC 629 - DATA BUS CABLE

Purpose

The data bus cable moves data between LRUs. A current-mode coupler and a stub cable attach each LRU terminal to the data bus cable.

Physical Description

A data bus cable is a pair of twisted wires with a termination resistor at each end.

The left and right systems ARINC 629 bus cables have production breaks with splices in the middle. The parts of the systems ARINC 629 bus cable that are external to the coupler panels have shielding.

A data bus cable in the 777 may be as long as 180 feet (47.5 m).

A data bus cable in the 777 connects as many as 46 current-mode couplers.

Location

All the data bus cables are fully inside the current-mode coupler panels except the left and right systems bus cables. The left systems ARINC 629 bus connects the P111 forward current-mode coupler panel to the P115 aft current-mode coupler panel. There is a production break in the bus between the panels.

The right systems ARINC 629 bus connects the P211 forward current-mode coupler panel to the P215 aft current-mode coupler panel. There is a production break in the bus between the panels.

Training Information Point

Be careful when you install the data bus cable on a panel. Do not cut or cause damage to the teflon skin of the data bus cable. Damage to the teflon skin can cause corrosion on the conductor or failure of the system.

There is a special wire separator tool for data bus cable installation on the coupler. The use of unapproved tools can cause damage to the data bus.

777 GENERAL - ARINC 629 - DATA BUS CABLE

777 GENERAL - ARINC 629 - STUB CABLE

Purpose

The stub cables are for bi-directional data movement between the LRU and the current-mode coupler. The stub cables also supply power from the LRUs to the current-mode couplers.

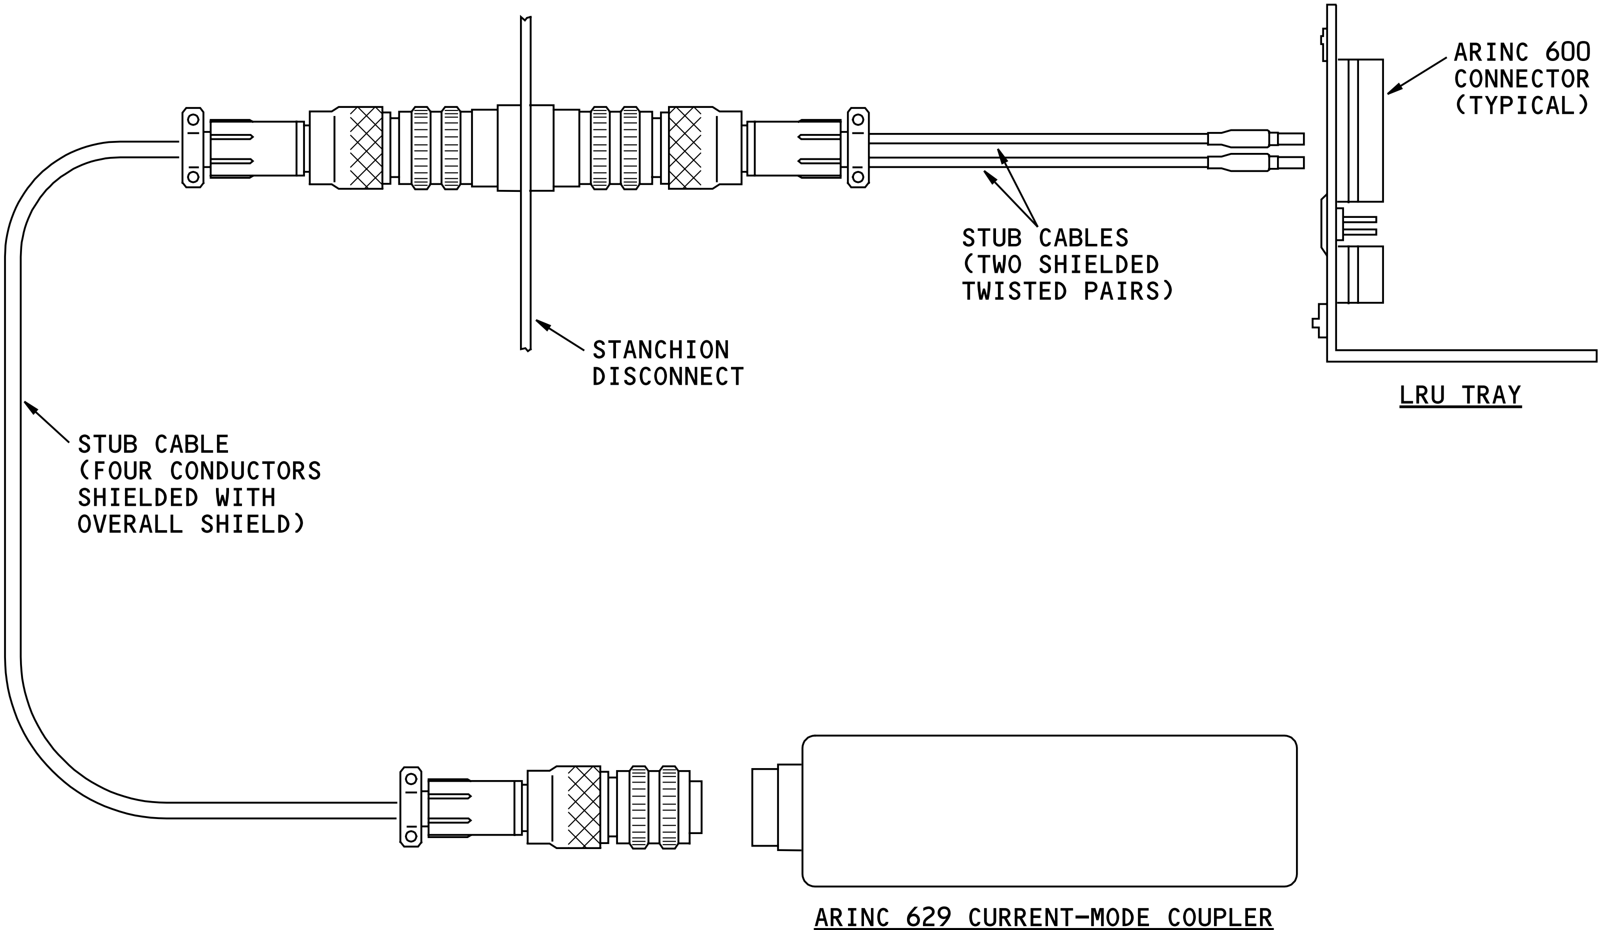
Physical Description

A stub cable has four wires, two to transmit and two to receive.

Stub cables can be as long as 57 feet for transmit and receive couplers and 75 feet for receive only couplers.

Location

The stub cables are in the airplane wiring bundles.



00-00-00-055 Rev 0

777 GENERAL - ARINC 629 - STUB CABLE

777 GENERAL - OVERHEAD PANEL ARINC 629 SYSTEM (OPAS)

General

The overhead panel ARINC 629 system (OPAS) moves data between many flight deck switches and lights and the ARINC 629 systems buses.

The OPAS moves data through overhead panel card files (OPCFs) and through panel data concentrator units (PDCUs).

The OPCFs send switch position data and signals to the lights on the P5 overhead panel and the P61 overhead maintenance panel.

The PDCUs send switch position data and signals to the lights on these panels:

- P1
- P3
- P7
- P8
- P9
- P10
- P55.

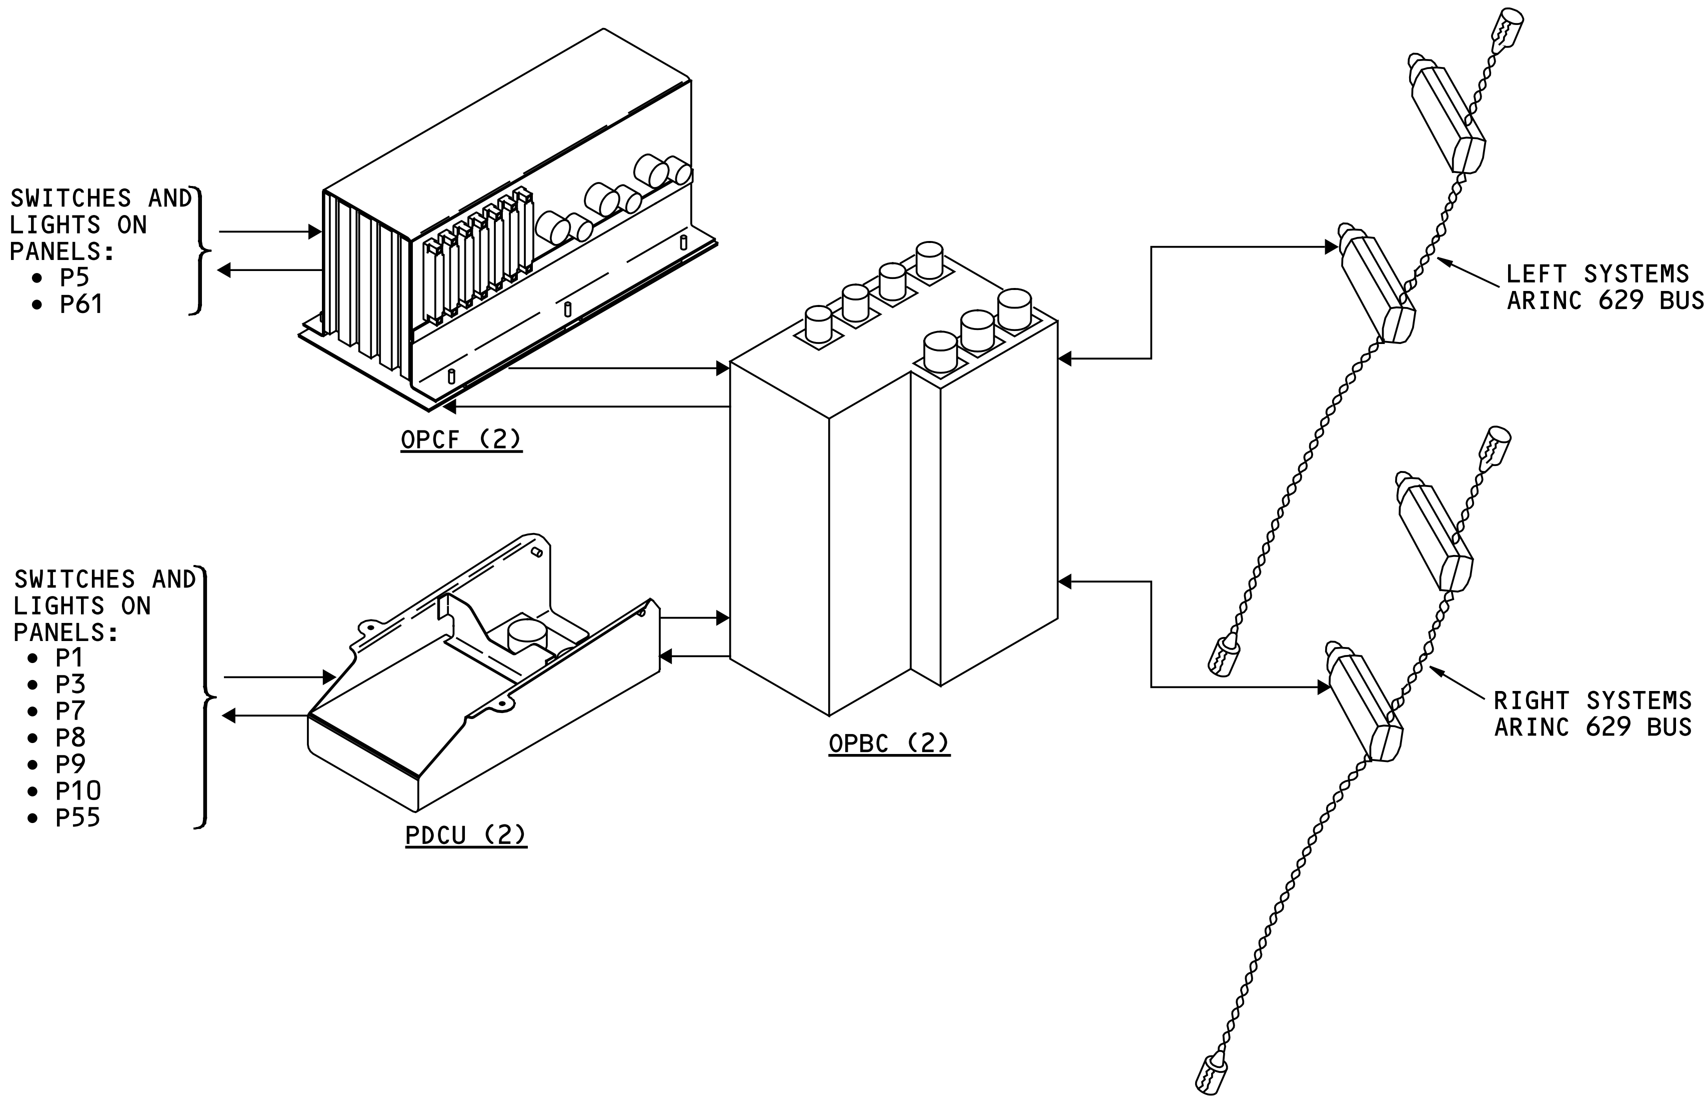
Two overhead panel bus controllers (OPBCs) are the interface units for the ARINC 629 buses.

The OPAS operates automatically. It continuously monitors switches, lights and ARINC 629 system buses. It sends system fault information to the central maintenance computing system (CMCS).

Physical Description

The OPAS has six parts:

- Left and right OPCFs
- Left and right PDCUs
- Left and right OPBCs.



00-00-00-056 Rev 1 11/06/95

777 GENERAL - OVERHEAD PANEL ARINC 629 SYSTEM (OPAS)

777 GENERAL - ARINC 629 SIGNAL GATEWAY (ASG) CARDS

General

The ARINC 629 signal gateway (ASG) cards change data format from ARINC 429 to ARINC 629, and from ARINC 629 to ARINC 429.

The cards move data between the interface cards in the systems card files and ARINC 629 system buses. The ASG cards also move data between the cargo smoke detection system and ARINC 629 system buses.

Components

These are the four ASG cards in two systems card files:

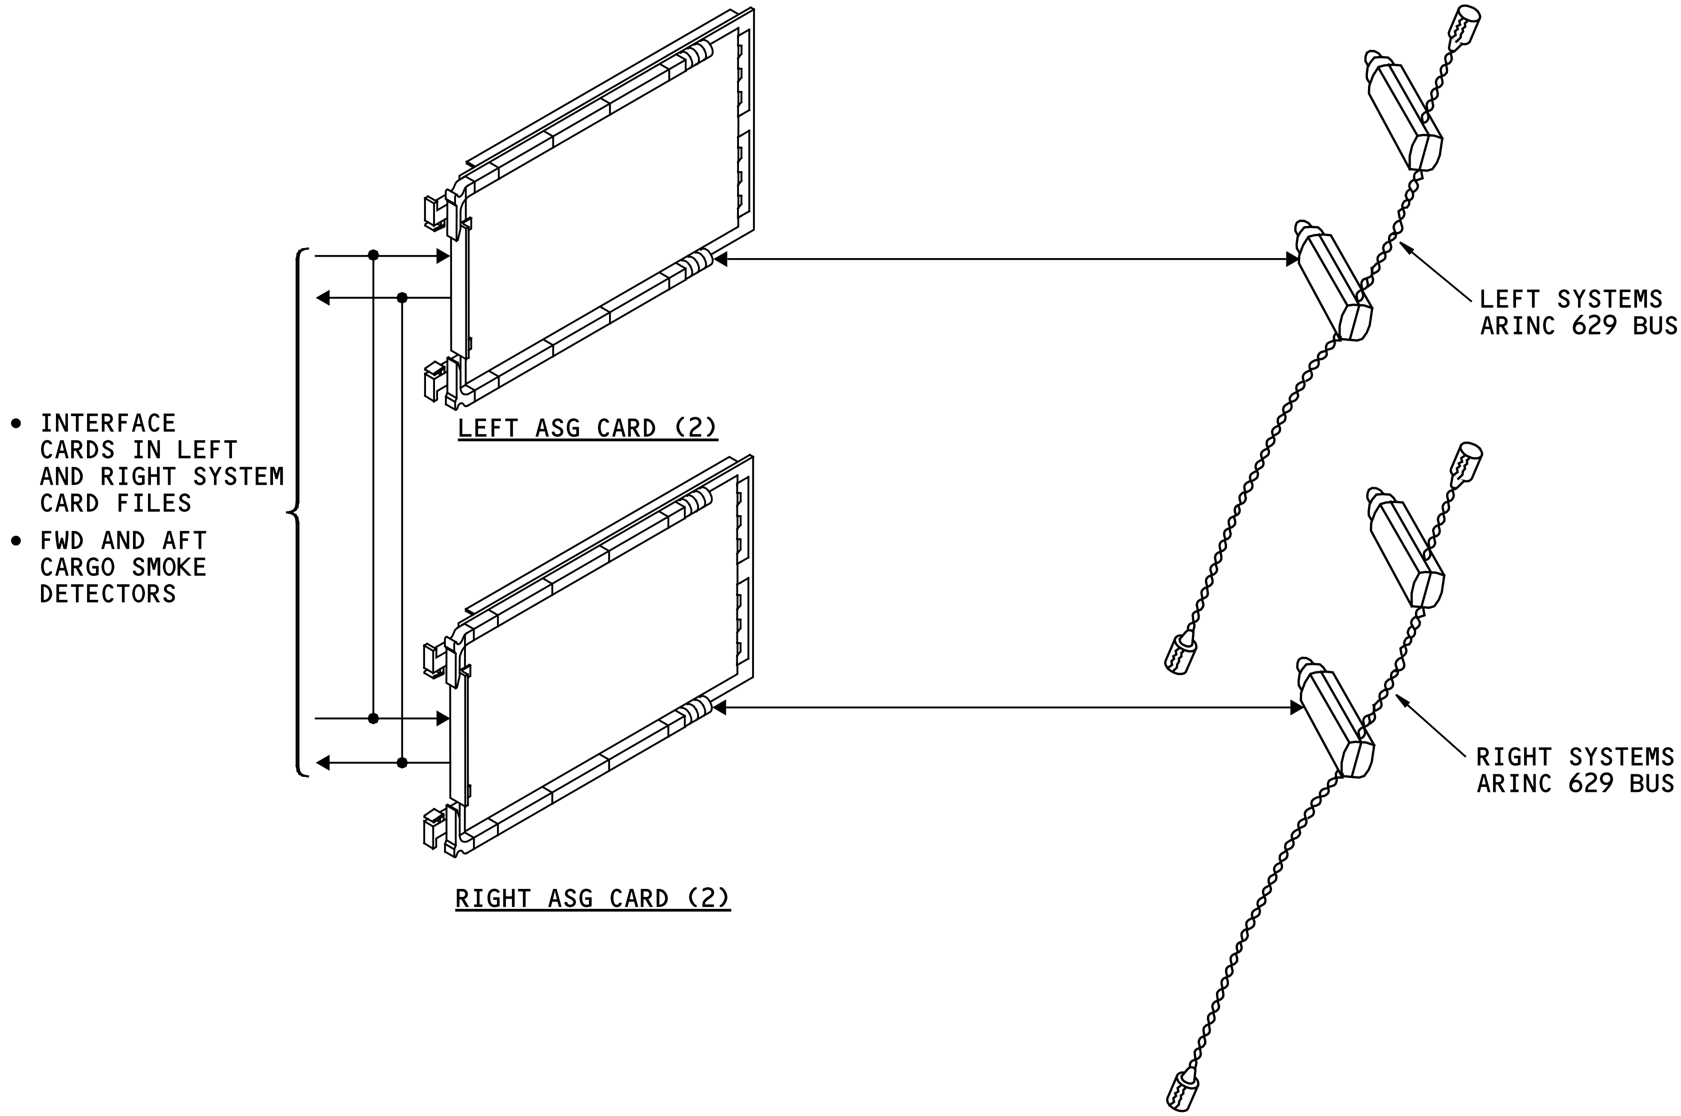
- Right ASG card in the P84 right systems card file (RSCF)
- Left ASG card in the RSCF
- Right ASG card in the P85 left systems card file (LSCF)
- Left ASG card in the LSCF.

Interfaces

The interface cards in a systems card file connect to both the right and left ASG cards in that card file.

Each of the cargo smoke detectors connects to the right and left ASG cards in one of the systems card files.

The left ASG cards connect to the left systems ARINC 629 bus and the right ASG cards connect to the right systems ARINC 629 bus.



777 GENERAL - ARINC 629 SIGNAL GATEWAY (ASG) CARDS

777 GENERAL - ONBOARD LOCAL AREA NETWORK (OLAN) - GENERAL DESCRIPTION

Purpose

The onboard local area network (OLAN) is a fiber optic communications network. It moves digital data between line replaceable units (LRUs). Fiber optic networks have these qualities:

- They are faster than wire
- They weigh less than wire buses
- Electromagnetic radiation has no effect on the data.

Physical Description

The LAN has these parts:

- A primary ring (PRI)
- A secondary ring (SEC)
- Two bypass switch units (BSUs).

The bypass switch units (BSUs) connect the primary and secondary rings with the LRUs. Line replaceable units (LRUs) connect to both rings of a LAN through a BSU.

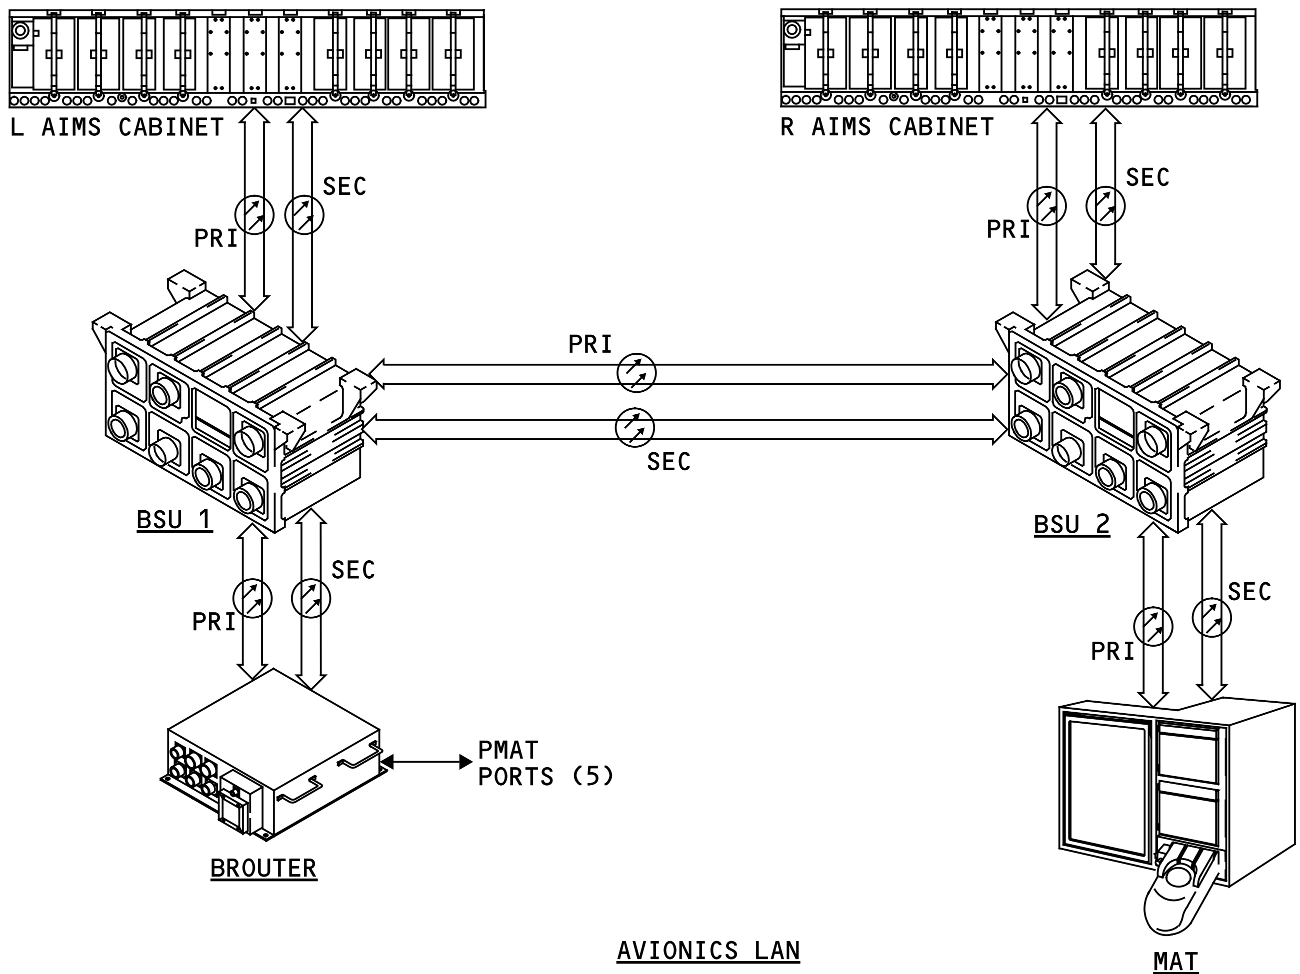
Avionics LAN

The avionics LAN connects these LRUs:

- Right AIMS cabinet
- Left AIMS cabinet
- Maintenance access terminal (MAT)
- Brouter.

The brouter gets fiber optic signals from the LRUs in the avionics LAN. It also sends fiber optic signals to the LRUs. The brouter controls the routing of the signals through the LAN.

The avionics LAN connects the portable maintenance access terminals (PMATs) to the AIMS cabinets through the brouter.



777 GENERAL - ONBOARD LOCAL AREA NETWORK (OLAN) - GENERAL DESCRIPTION

777 GENERAL - OLAN - FIBER OPTIC CABLE

General

Each cable has these items:

- Optical fiber strands
- Two filler strands
- Separator tape
- Aramid yarn strength member
- An outer jacket.

The cable is about 0.2 inches in diameter.

Optical Fiber Strands

The optical fiber strands are glass. Each optical fiber strand is .0055 inches (140 microns) in diameter.

A primary and secondary buffer covers each fiber strand. The primary buffer protects the glass fiber during manufacture.

The secondary buffer adds strength and increases the diameter of the fiber. The secondary buffers of the five optical fiber strands are these five colors:

- Blue
- Red
- Green
- Yellow
- White.

The colors permit you to identify the individual fiber strands at each end of the cable.

Each optical fiber strand with its buffers is .035 inches (900 microns) in diameter.

Cables have three or five optical fiber strands. Cables with three strands use two more filler strands. The example shows a cable with five optical fiber strands.

Filler Strands

The black filler strands are polyester and are .035 inches in diameter.

Separator Tape

A polyester separator tape covers the group of seven strands. The tape is low-friction polyester. It makes the cable more flexible.

Aramid Yarn

A strength member of woven Aramid (Kevlar) yarn protects the optical fibers from damage.

Outer Jacket

The outer jacket of the cable is purple thermoplastic.

Training Information Point

The optical fiber strands may break if the cable bend radius is less than 1.5 inches.

777 GENERAL - OLAN - FIBER OPTIC CABLE

THIS PAGE INTENTIONALLY LEFT BLANK

777 GENERAL - OLAN - CONNECTORS

General

OLAN uses two types of connectors: a type-A connector and a type-B connector.

The connectors have these parts:

- Alignment keys and grooves
- Guide pins and cavities
- Color bands
- Three start threads.

Type-A Connector

The type-A connector is for production breaks that are not regularly connected and disconnected.

The type-A connector is a multi-channel, in-line (butt-type) connector. This connector has very low light loss between optical fiber components.

The type-A connector has three fiber optic cables or five fiber optic cables.

Type-B Connector

The Type-B connector attaches a fiber optic cable to a line replaceable unit (LRU). The type-B connector is more frequently connected and disconnected than the type-A connector.

The type-B connector is a multi-channel, expanded beam (ball lens) connector. Light loss across this connector is low but not as low as in the type-A connector.

Alignment Keys and Grooves

Each connector has alignment keys on the plug and alignment grooves on the receptacle. These accurately align the connector optical components.

Guide Pins and Cavities

Guide pins in the plug fit into cavities in the receptacle when the plug and receptacle connect. The pins of the plug touch the bottom of the cavities in the receptacle. You can not overtighten the connector.

Color Bands

The coupling nut on the plug barrel has a yellow band. The receptacle barrel has a red and a yellow band. When the red band on the receptacle is at least 50 percent covered by the coupling nut, this shows a correct connection. With a correct connection, the optical fibers in the plug align end-to-end with the fibers in the receptacle.

Start Threads

Three start threads on the plug and receptacle make sure of a straight start when they join.

Type-A Connector/Fiber Optic Interface

The type-A plug and receptacle have ceramic contacts that touch when connected. The light signal goes through holes in the end of the ceramic contacts when they are in direct physical contact with each other.

Type-B Connector/Fiber Optic Interface

The connector has miniature ball lenses behind a protective window. Each lens is at the end of a fiber. The ball lenses expand and focus the light signal from the fiber. The light goes through the protective windows of the plug and receptacle to another ball lens. This ball lens narrows the light and sends it into a fiber.

Training Information Point

This training information point refers to both the type-A and type-B connectors.

WARNING: BEFORE YOU EXAMINE THE CONNECTOR FACE OR THE CERAMIC CONTACTS, DISCONNECT THE CABLE FROM THE EQUIPMENT AT BOTH ENDS OR SET THE EQUIPMENT TO OFF. THE LIGHT FROM THE OPTICAL FIBER THAT ATTACHES TO THE AVIONICS EQUIPMENT IS INVISIBLE AND CAN BE INTENSE ENOUGH TO CAUSE DAMAGE TO YOUR EYES.

Before you install a connector, examine it to make sure it is clean.

Use only approved procedures to clean the connectors and the fiber optic lenses.

ARINC 629 - GENERAL DESCRIPTION

General

An ARINC 629 data bus is a twisted pair of wires with termination resistors at each end. As many as 120 LRUs can use one ARINC 629 data bus. In 777 airplanes the maximum number of current-mode couplers per bus is 46.

Components

The ARINC 629 data bus system has these parts:

- Data bus cable
- Current-mode couplers
- Stub cables.

The ARINC 629 system also includes these components in the LRUs:

- Serial interface modules
- Terminal controllers.

Characteristics

The ARINC 629 data bus system has these characteristics:

- The LRUs send data one at a time in sequence
- The LRUs receive data at the same time
- Communication on ARINC 629 is bi-directional; LRUs may transmit and receive data on the same bus
- One LRU may connect to more than one data bus through separate couplers on each bus
- All data on the bus is available to all the LRUs on that bus.

ARINC 629 Data Bus Configuration

These are the eleven ARINC 629 data buses:

- Three flight control buses
- Four system buses
- Four airplane information management systems (AIMS) intercabinet buses.

The flight control buses connect LRUs that have flight control functions.

The system buses connect LRUs that have airplane system functions. These buses work independently from the flight control buses. The systems buses move data between these five areas:

- Avionics
- Propulsion
- Electrical
- Electro-mechanical
- Environmental control.

Four AIMS intercabinet buses move data between the two AIMS cabinets and the three control display units (CDUs).

ARINC 629 - GENERAL DESCRIPTION

Functional Description

Each LRU uses one or more current mode couplers to connect to data buses.

A current mode coupler and its terminal (terminal controller and serial interface module) move data to and from the bus. Only one terminal on a bus transmits at a time. Each terminal listens to the bus and waits for a stop in data movement on the bus from other LRUs before it transmits.

ARINC 629 - SYSTEMS BUS INTERFACES

General

These are the four systems ARINC 629 buses:

- Left systems bus
- Center 1 systems bus
- Center 2 systems bus
- Right systems bus.

left Systems ARINC 629 Bus

These LRUs transmit and receive on the left systems bus:

- Bus power control unit (BPCU)
- Generator control unit (GCU)
- Backup (BU) converter
- Left system card file (LSCF)
- Right system card file (RSCF)
- Electrical load management system (ELMS)
- Proximity switch electronics unit (PSEU)
- Fuel quantity indicating system (FQIS)
- Auxiliary power unit (APU)
- Airborne vibration monitor (AVM)
- Flap slat electronics unit (FSEU)
- Air supply control and cabin pressure controllers (ASCPC)
- Cabin temperature controllers (CTC)
- Overhead panel ARINC 629 system (OPAS)
- Audio management unit (AMU)
- Main wheel steering control unit (MWSCU)
- Brake temperature monitor unit (BTMU)
- Tire pressure monitor unit (TPMU)
- Brake system control unit (BSCU)
- Warning electronic system - left (WES-L)
- Autopilot flight director computer (AFDC)
- Engine data interface unit (EDIU)
- Passenger address/cabin interphone (PA/CI) controller
- Control display unit (CDU)
- Airplane information management system (AIMS).

One LRU also has a receive-only connection to the left systems bus:

- Warning electronic system - left (WES-L CH 2).

Center1 Systems ARINC 629 Bus

These LRUs transmit and receive on the center1 systems bus:

- Flap slat electronics unit (FSEU)
- Warning electronic system (WES)
- Autopilot flight director computer (AFDC)
- Engine data interface unit (EDIU)
- Airplane information management system (AIMS).

These LRUs also have a receive-only connection to the center1 systems bus:

- Flap slat electronics unit - 1 (FSEU-1)
- Flap slat electronics unit - 2 (FSEU-2)
- Warning electronic system - right channel 1 (WES-R CH 1).

ARINC 629 - SYSTEMS BUS INTERFACES

Center 2 Systems ARINC 629 Bus

These LRUs transmit and receive on the center 2 systems bus:

- Engine data interface unit (EDIU)
- Airplane information management system (AIMS).

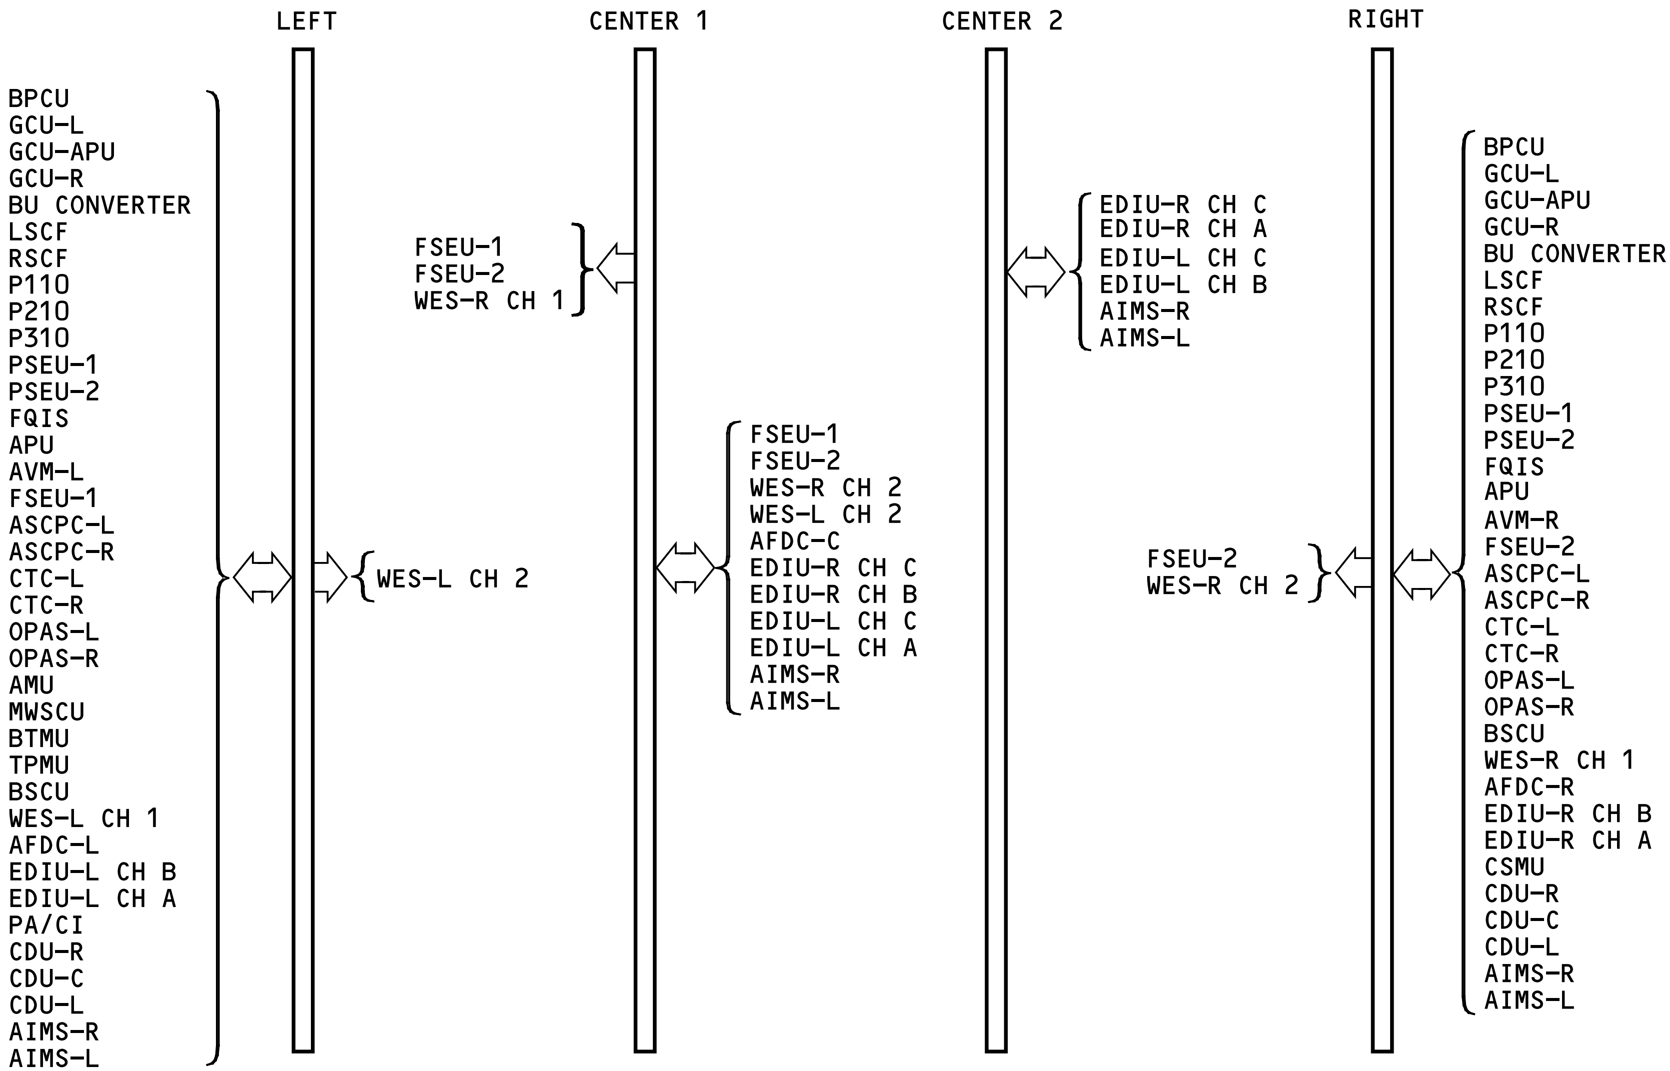
Right Systems ARINC 629 Bus

These LRUs transmit and receive on the right systems bus:

- Bus power control unit (BPCU)
- Generator control unit (GCU)
- Backup (BU) converter
- Left system card file (LSCF)
- Right system card file (RSCF)
- Electrical load management system (ELMS)
- Proximity switch electronics unit (PSEU)
- Fuel quantity indicating system (FQIS)
- Auxiliary power unit (APU)
- Airborne vibration monitor (AVM)
- Flap slat electronics unit (FSEU)
- Air supply control and cabin pressure controllers (ASCPC)
- Cabin temperature controllers (CTC)
- Overhead panel ARINC 629 system (OPAS)
- Brake system control unit (BSCU)
- Warning electronic system (WES)
- Autopilot flight director computer (AFDC)
- Engine data interface unit (EDIU)
- Cabin system management unit (CSMU)
- Control display unit (CDU)
- Airplane information management system (AIMS).

These LRUs also have a receive-only connection to the right systems bus:

- Flap slat electronics unit - 2 (FSEU-2)
- Warning electronic system - RIGHT (WES-R CH 2).



SYSTEMS ARINC 629 BUSES

ARINC 629 - SYSTEMS BUS INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

ARINC 629 - FLIGHT CONTROLS BUS INTERFACES

General

These are the three flight controls ARINC 629 buses:

- Left flight controls bus
- Center flight controls bus
- Right flight controls bus.

Left Flight Controls ARINC 629 Bus

These LRUs transmit and receive on the left flight controls bus:

- Air data inertial reference unit (ADIRU)
- Airplane information management system (AIMS)
- Air data module total pressure (ADM TP)
- Air data module static pressure (ADM SP)
- Autopilot flight director computer (AFDC)
- Power supply assembly (PSA)
- Primary flight computer (PFC)
- Actuator control electronics (ACE).

These LRUs also have a receive-only connection to the left flight controls bus:

- Secondary attitude air data reference unit (SAARU)
- Control display unit (CDU)
- Autopilot flight director computer (AFDC)
- Primary flight computer (PFC)
- Actuator control electronics (ACE).

Center Flight Controls ARINC 629 Bus

These LRUs transmit and receive on the center flight controls bus:

- Secondary attitude air data reference unit (SAARU)
- Air data module total pressure (ADM TP)
- Air data module static pressure (ADM SP)
- Autopilot flight director computer (AFDC)
- Power supply assembly (PSA)
- Primary flight computer (PFC)
- Actuator control electronics (ACE)
- Airplane information management system (AIMS).

These LRUs also have a receive-only connection to the center flight controls bus:

- Air data inertial reference unit (ADIRU)
- Autopilot flight director computer (AFDC)
- Primary flight computer (PFC)
- Actuator control electronics (ACE).

Right Flight Controls ARINC 629 Bus

These LRUs transmit and receive on the right flight controls bus:

- Air data inertial reference unit (ADIRU)
- Air data module total pressure (ADM TP)
- Air data module static pressure (ADM SP)
- Autopilot flight director computer (AFDC)
- Power supply assembly (PSA)
- Primary flight computer (PFC)

ARINC 629 - FLIGHT CONTROLS BUS INTERFACES

- Actuator control electronics (ACE).

These LRUs also have a receive-only connection to the right flight controls bus:

- Secondary attitude air data reference unit (SAARU)
- Airplane information management system (AIMS)
- Control display unit (CDU)
- Autopilot flight director computer (AFDC)
- Primary flight computer (PFC)
- Actuator control electronics (ACE).

ARINC 629 - FLIGHT CONTROLS BUS INTERFACES

ARINC 629 - AIMS INTERCABINET BUS INTERFACES

General

The AIMS intercabinet ARINC 629 buses move data between LRUs of the AIMS.

There are four AIMS ARINC 629 intercabinet buses:

- Airplane information management system (AIMS) intercabinet bus 1
- AIMS intercabinet bus 2
- AIMS intercabinet bus 3
- AIMS intercabinet bus 4.

AIMS Intercabinet Bus 1

These LRUs transmit and receive on the AIMS intercabinet bus 1:

- AIMS left
- AIMS right.

AIMS Intercabinet Bus 2

These LRUs transmit and receive on the AIMS intercabinet bus 2:

- AIMS left
- AIMS right
- Control display unit (CDU) center
- CDU right
- CDU left.

AIMS Intercabinet Bus 3

These LRUs transmit and receive on the AIMS intercabinet bus 3:

- AIMS left
- AIMS right.

AIMS Intercabinet Bus 4

These LRUs transmit and receive on the AIMS intercabinet bus 4:

- AIMS left
- AIMS right.

ARINC 629 - AIMS INTERCABINET BUS INTERFACES

23-91-00-008 Rev 1

ARINC 629 - CURRENT-MODE COUPLER

Purpose

The current-mode coupler connects the bus cable to the stub cable.

Physical Description

These are the physical characteristics of the current-mode coupler:

- It is a two part assembly for fast installation
- It has a cover with the electronics and the receptacle for the stub cable
- It has a base designed for easy installation on the panel
- It has a waterproof housing
- It has protective wire guides to install the data bus cable.

There are different suppliers for current-mode couplers. They all function in the same way. They are interchangeable.

E-Core Assembly

An E-core assembly is a part of the coupler base. E-core assemblies are electromagnetic components that couple the signals in the data bus cable in and out of the coupler. The wire guides are grooves that give a controlled routing and protection for the wires of the data bus cable as they go through the E-core assembly.

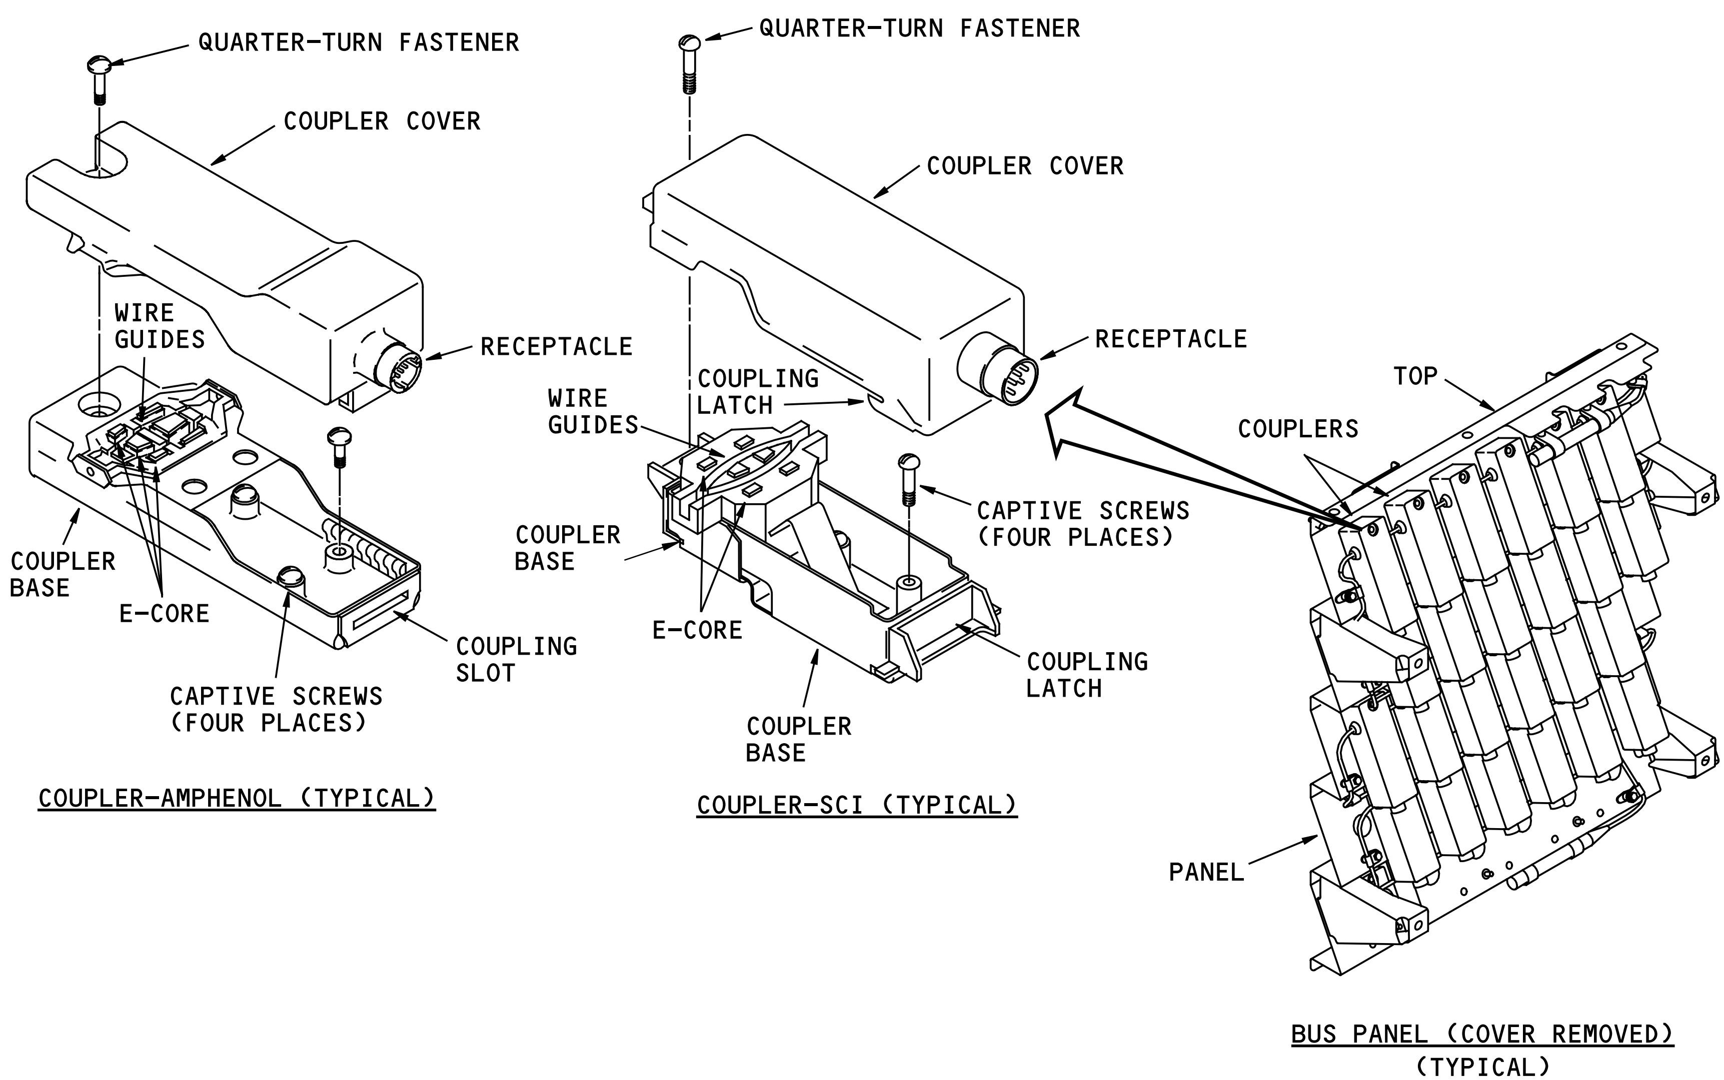
Location

All the current-mode couplers are on the bus panels.

Training Information Point

Couplers are interchangeable units. Covers and bases from different suppliers are not interchangeable.

Remove power from the LRU before you replace the coupler for that LRU.



23-91-00-009 Rev 3 12/06/1995

ARINC 629 - CURRENT-MODE COUPLER

ARINC 629 - BUS CABLE AND BUS PANEL

Purpose

The bus cable moves data between LRUs. A current-mode coupler and a stub cable attach each LRU terminal to the data bus cable.

Physical Description

A bus cable is a pair of twisted wires with a termination resistor at each end. Each resistor has a value of about 130 ohms.

The left and right systems bus cables have production break connectors in the middle for easy replacement. The parts of the system bus cable that are external to the coupler panels have shielding outside.

A bus cable in the 777 may be as long as 180 feet. It connects as many as 46 current-mode couplers.

The cable has a center conductor covered by a layer of foam. A Teflon skin covers the foam.

Location

All the bus cables except the left and right systems bus cables are fully inside the bus panels. The left system bus connects the forward bus panel (P111) to the aft bus panel (P115) with a production break in between. The right systems bus connects the forward bus panel (P211) to the aft bus panel (P215) with a production break in between.

Training Information Point

Be careful when you install the bus cable on a panel. Do not cut or cause damage to the Teflon skin of the bus cable. Damage to the Teflon skin can cause corrosion on the conductor or failure of the system.

There is a special wire separator tool (WST8139) for bus cable installation on the coupler. The use of unapproved tools can cause damage to the bus.

ARINC 629 - BUS CABLE AND BUS PANEL

ARINC 629 - STUB CABLE

Purpose

The stub cables are for bi-directional data movement between the LRU and the current-mode coupler. The stub cables also supply power from the LRUs to the current-mode couplers.

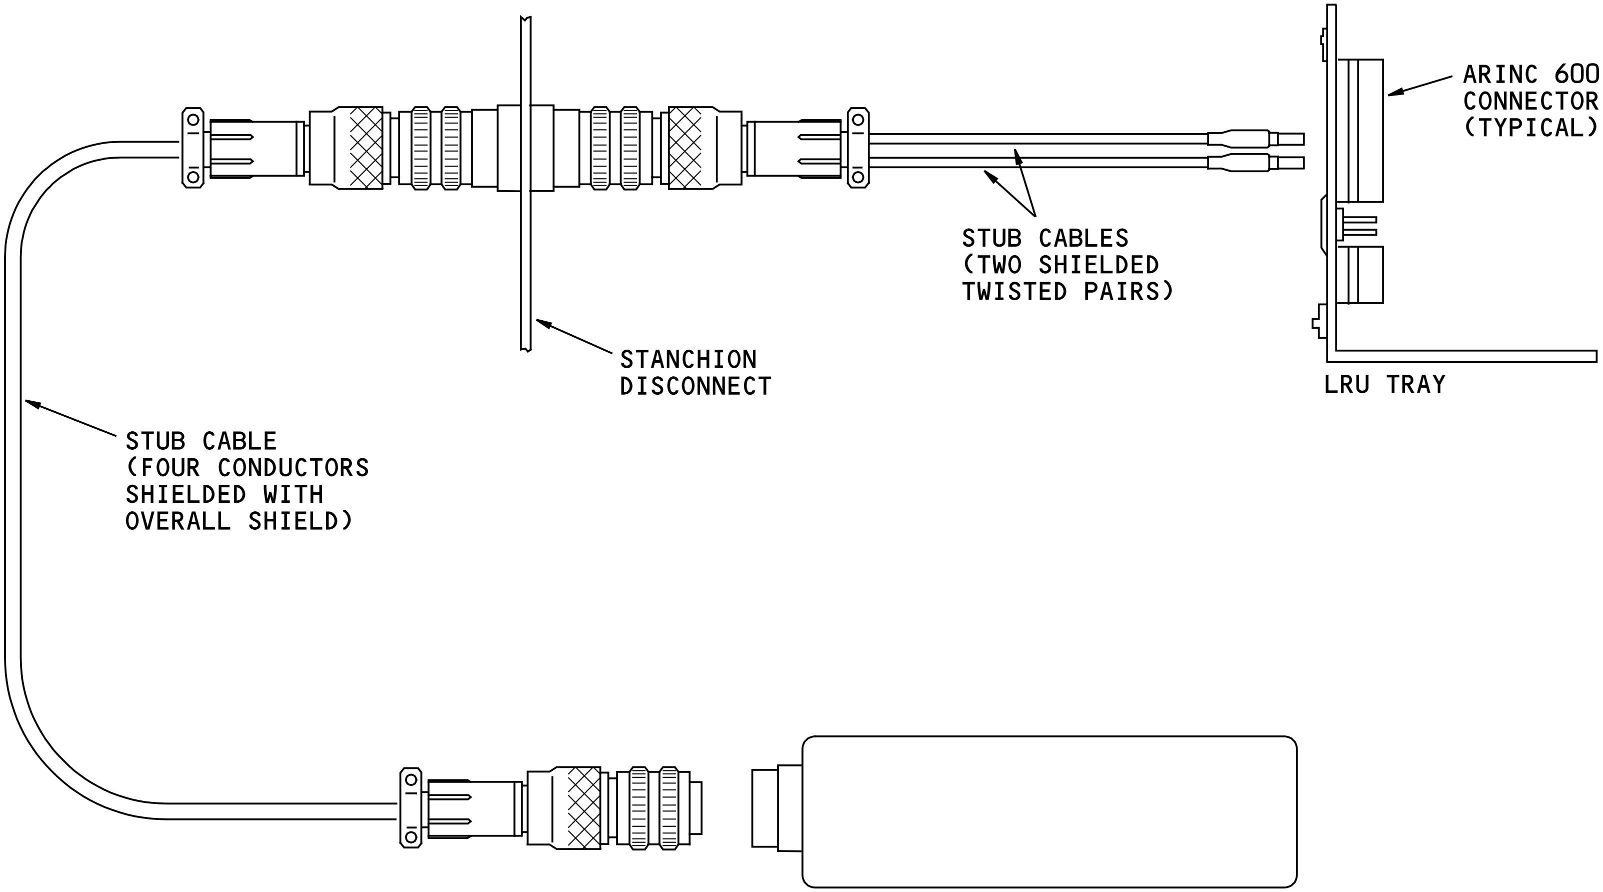
Physical Description

A stub cable has four wires; two to transmit and the other two to receive.

Stub cables can be as long as 57 feet for transmit/receive couplers and 75 feet for receive-only couplers couplers.

Location

The stub cables are in the airplane wiring bundles.



23-91-00-011 Rev 1

ARINC 629 - STUB CABLE

ARINC 629 - CURRENT-MODE COUPLER FUNCTIONAL DESCRIPTION

General

A current-mode coupler, together with a serial interface module (SIM) supplies the interface between the ARINC 629 data bus cable and an ARINC 629 terminal in the LRU. The current-mode coupler is a dual channel device in both transmit and receive operations. It has two transmit drivers and two receivers. The SIM makes the transmit and receive channel selection.

Normal Transmit Mode Operation

The current mode coupler transmit drivers put signals on the data bus. The current mode coupler receives the voltage signals from the SIM over the transmit stub of the stub cable. The current mode coupler puts the signals onto the data bus. Thus it changes voltage signals from the SIM to the current signals on the bus.

Normal Receive Mode Operation

The current mode coupler receives current mode signals from the bus. It changes them to voltage signals which go to the SIM over the receive stub of the stub cable.

Transmit Inhibit Mode Operation

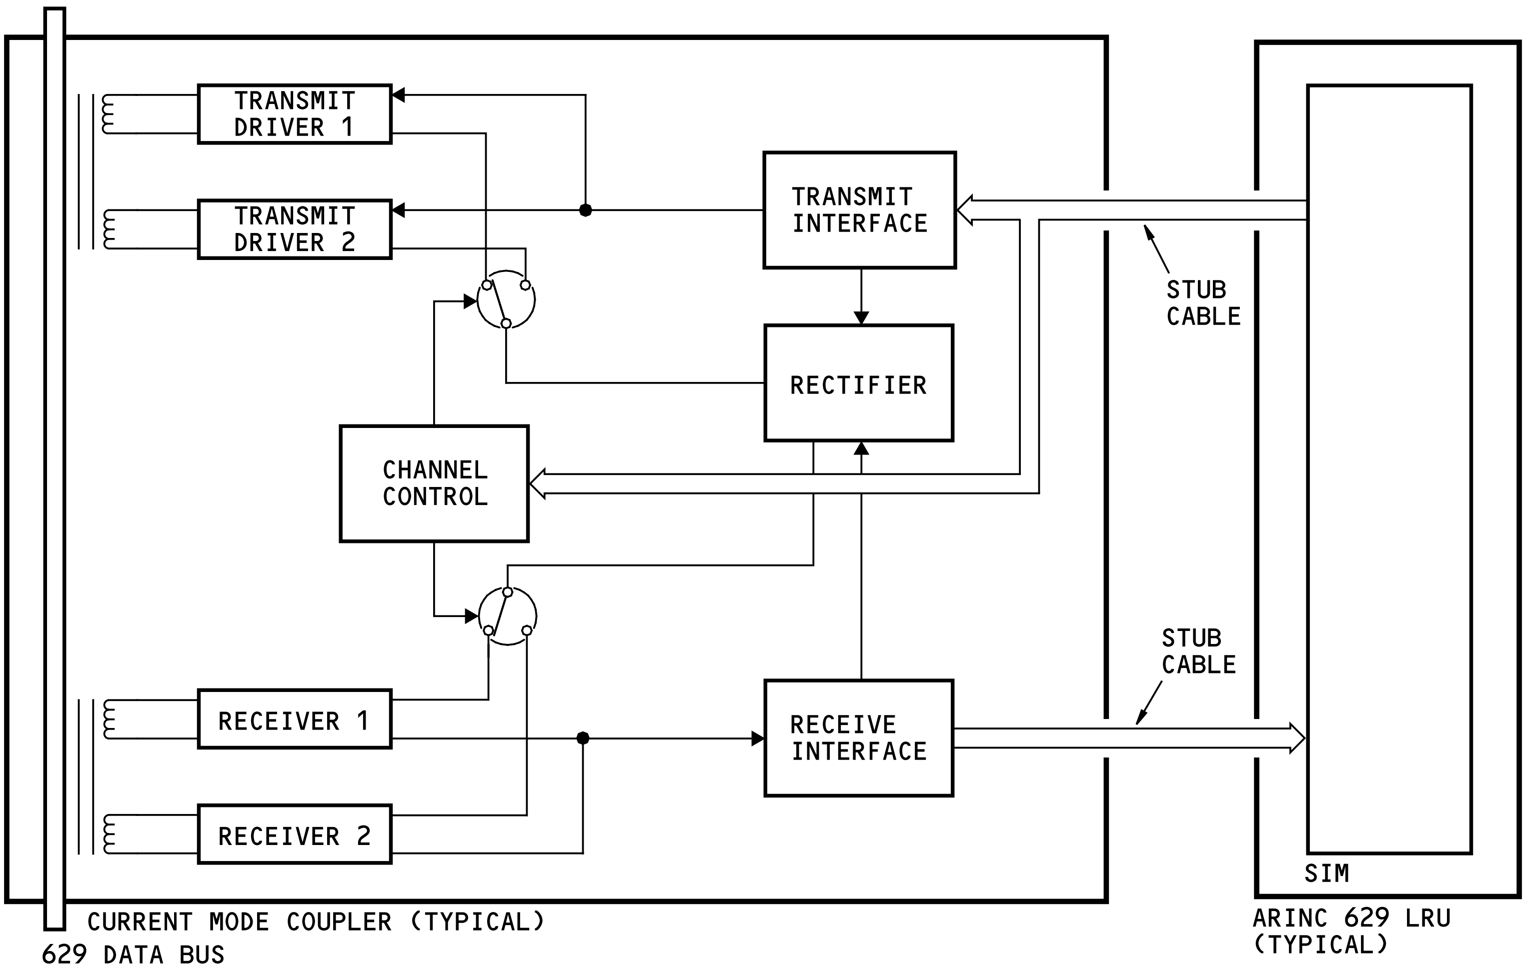
The SIM monitors the quality of the transmit signal from the LRU. If the signal is unsatisfactory, the SIM stops transmit operation. The LRU continues to receive data during the transmit inhibit mode of operation.

Power

The coupler rectifier receives power from the SIM through the transmit and receive interfaces.

Control

The SIM selects the active transmit driver and receiver for transmit and receive operations. The channel control logic selects the switch position in the coupler for the correct transmit driver and receiver.



23-91-00-012 Rev 1

ARINC 629 - CURRENT-MODE COUPLER FUNCTIONAL DESCRIPTION

ARINC 629 - LRU FUNCTIONAL DESCRIPTION

General

An ARINC 629 LRU contains a serial interface module (SIM) and a terminal controller. These move data between the LRU and the current-mode coupler. Each LRU has a personality that identifies its purpose and operation. The personality data is in two parts:

- Transmit personality PROM (XPP)
- Receive personality PROM (RPP).

The terminal controller uses the personality proms to control the flow of data between the LRU and the data bus.

SIM Functions

The SIM together with the current-mode coupler supplies the interface between the ARINC 629 data bus cable and the terminal controller in an LRU.

In transmit mode, the SIM changes transmit signals from the terminal controller into analog voltage signals. It moves these to the current-mode coupler over the transmit stub of the stub cable.

In receive mode, the SIM receives the voltage signals from the current-mode coupler after the current-mode coupler changes the current-mode signals to voltage signals. The SIM changes the received voltage signals into transition signals and moves them to the terminal controller.

The SIM monitors the quality of its own transmit signal and tells the terminal controller about any problem.

It does a check of the signal put on the data bus by the current-mode coupler. The SIM tells the terminal controller if the signal is not satisfactory.

The SIM also monitors the quality of signals received from other LRUs.

Terminal Controller Functions

The ARINC 629 terminal controller moves data to and from the LRU subsystem memory through the subsystem interface. The LRU transmit personality PROM (XPP) and receive personality PROM (RPP) control the flow of data.

The terminal controller gets its protocol access values from the XPP or the RPP.

Bus Protocol

The ARINC 629 uses a procedure to control access to the data bus. This procedure is the bus protocol.

Each LRU has a time period in which it may transmit.

After an LRU transmits, the control function measures the time and makes sure that it does not transmit again until all the other LRUs on the bus have an option to transmit.

ARINC 629 - LRU FUNCTIONAL DESCRIPTION

Transmitter Operation

In an ARINC 629 LRU, the terminal controller controls the schedule of messages on the data bus based on personality data stored in the transmit personality PROM (XPP).

The transmitter uses the XPP to put these details in each message on the data bus:

- Labels in the message
- Number of words in each word string in the message.

The transmitter gets transmit data from the subsystem memory. The protocol logic of the terminal controller monitors the operations and permits the transmitter to transmit. The transmitter sends one complete message each time it transmits.

Receiver Operation

In an LRU, the SIM receiver circuit gets the messages from the data bus through the coupler. It uses the received data based on personality data in the receive personality PROM (RPP).

The receive circuit monitors all signals on the data bus.

When it finds a message label on the bus, it knows if the message is good or is not based on the message structure. If it is good, the receiver uses the message.

Fault Monitor and Control Function

The fault monitor in the ARINC 629 system prevents faults that cause the bus to fail or that degrade the data on the bus. An ARINC 629 LRU monitors all signals on the bus including its own.

ARINC 629 messages contain data words. All received words must pass a receive data test which examines the word structure.

The SIM monitors the received word strings to make sure they are correct.

When a terminal transmits a message on the bus, the terminal receiver reads the message and the monitor circuit makes sure it is correct.

When in the monitor mode, the receiver uses the RPP based on the transmitted label in the same way as in the receive mode.

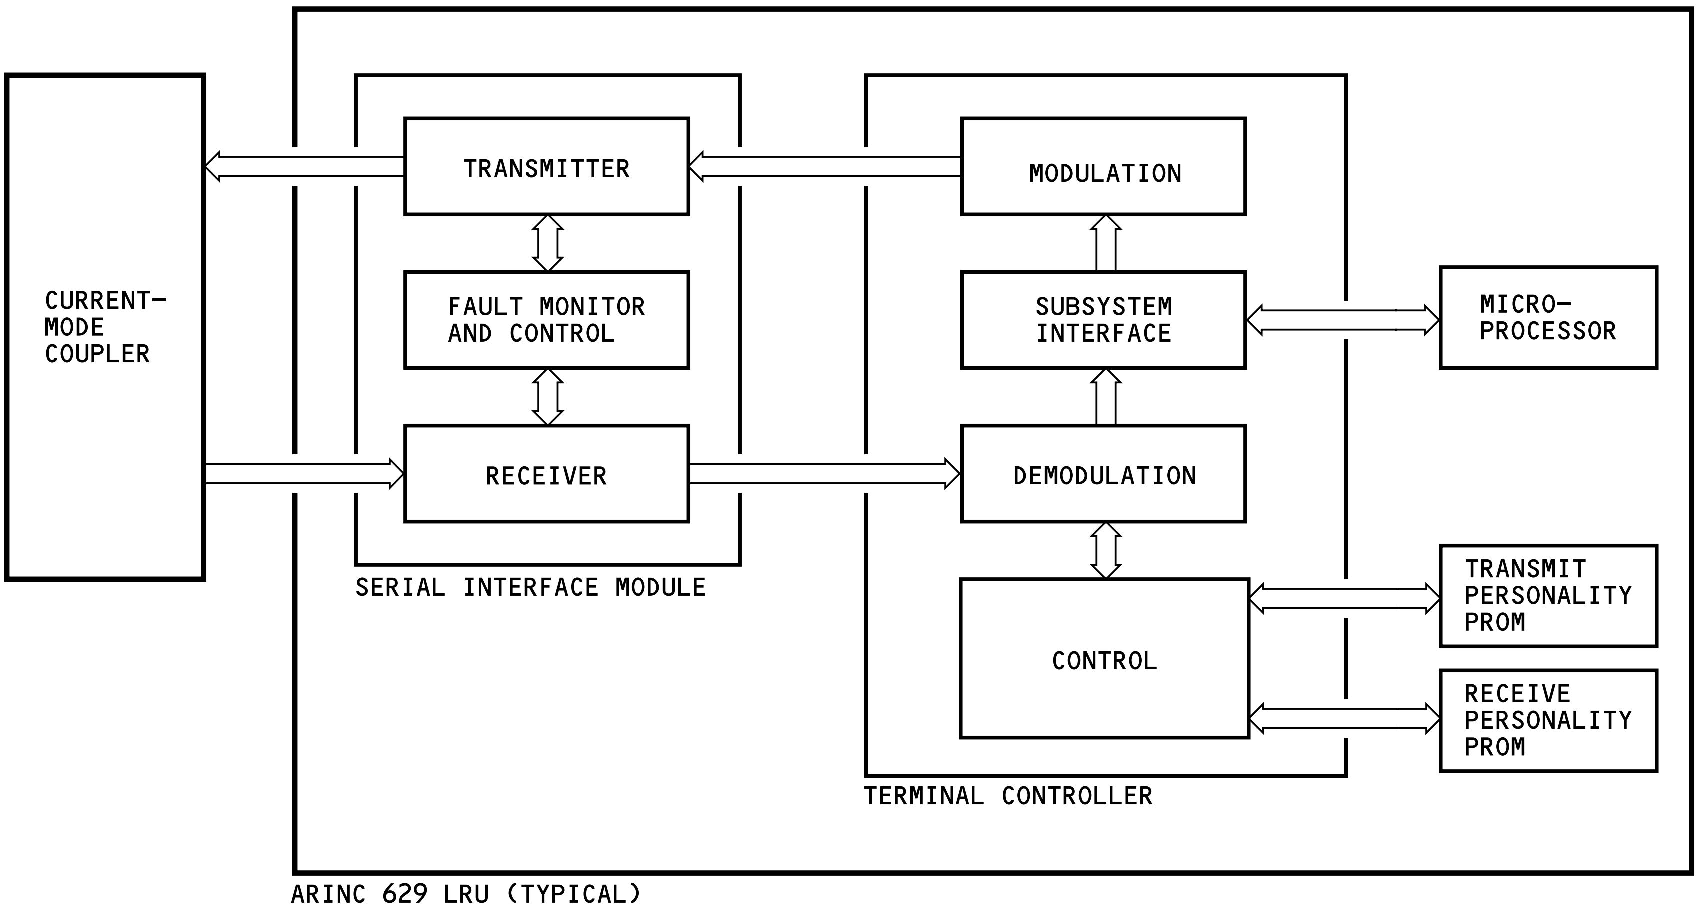
The receiver goes into the monitor mode when any of the following occurs:

- The transmitter gives a signal to the coupler when it starts to transmit
- The receiver finds a label that the terminal has authority to transmit.

ARINC 629 - LRU FUNCTIONAL DESCRIPTION

The transmitter stops operation if there are repeated transmit signal errors. You must reset power to the LRU to continue transmit operation.

If the monitor function does not operate, the transmitter will stop. This occurs if the LRU transmits but the monitor does not receive data.



23-91-00-013 Rev 2

ARINC 629 - LRU FUNCTIONAL DESCRIPTION

ARINC 629 - MESSAGE STRUCTURE FUNCTIONAL DESCRIPTION

General

Data in the ARINC 629 system moves through the data bus cable and other components as messages. Between each message is a terminal gap. A message is a group of word-strings. Each word string has a label word followed by data words. Each message has a special structure. The structure allows the LRUs to select and read the message.

Message Structure

A message has up to 31 word strings. There is a 4-bit time gap between each word string.

A word string begins with a label word. A word string has up to 256 data words. There is no gap between words in a word-string.

The minimum length message has 1 label and no data words. The maximum length message has 31 labels with 256 data words following each label, and 30 time gaps of 4 bits each.

Label Word Structure

A label word is a 20-bit word. It has:

- A 12-bit label field
- A 4-bit label extension field
- A single parity bit
- A 3-bit time hi lo sync pulse.

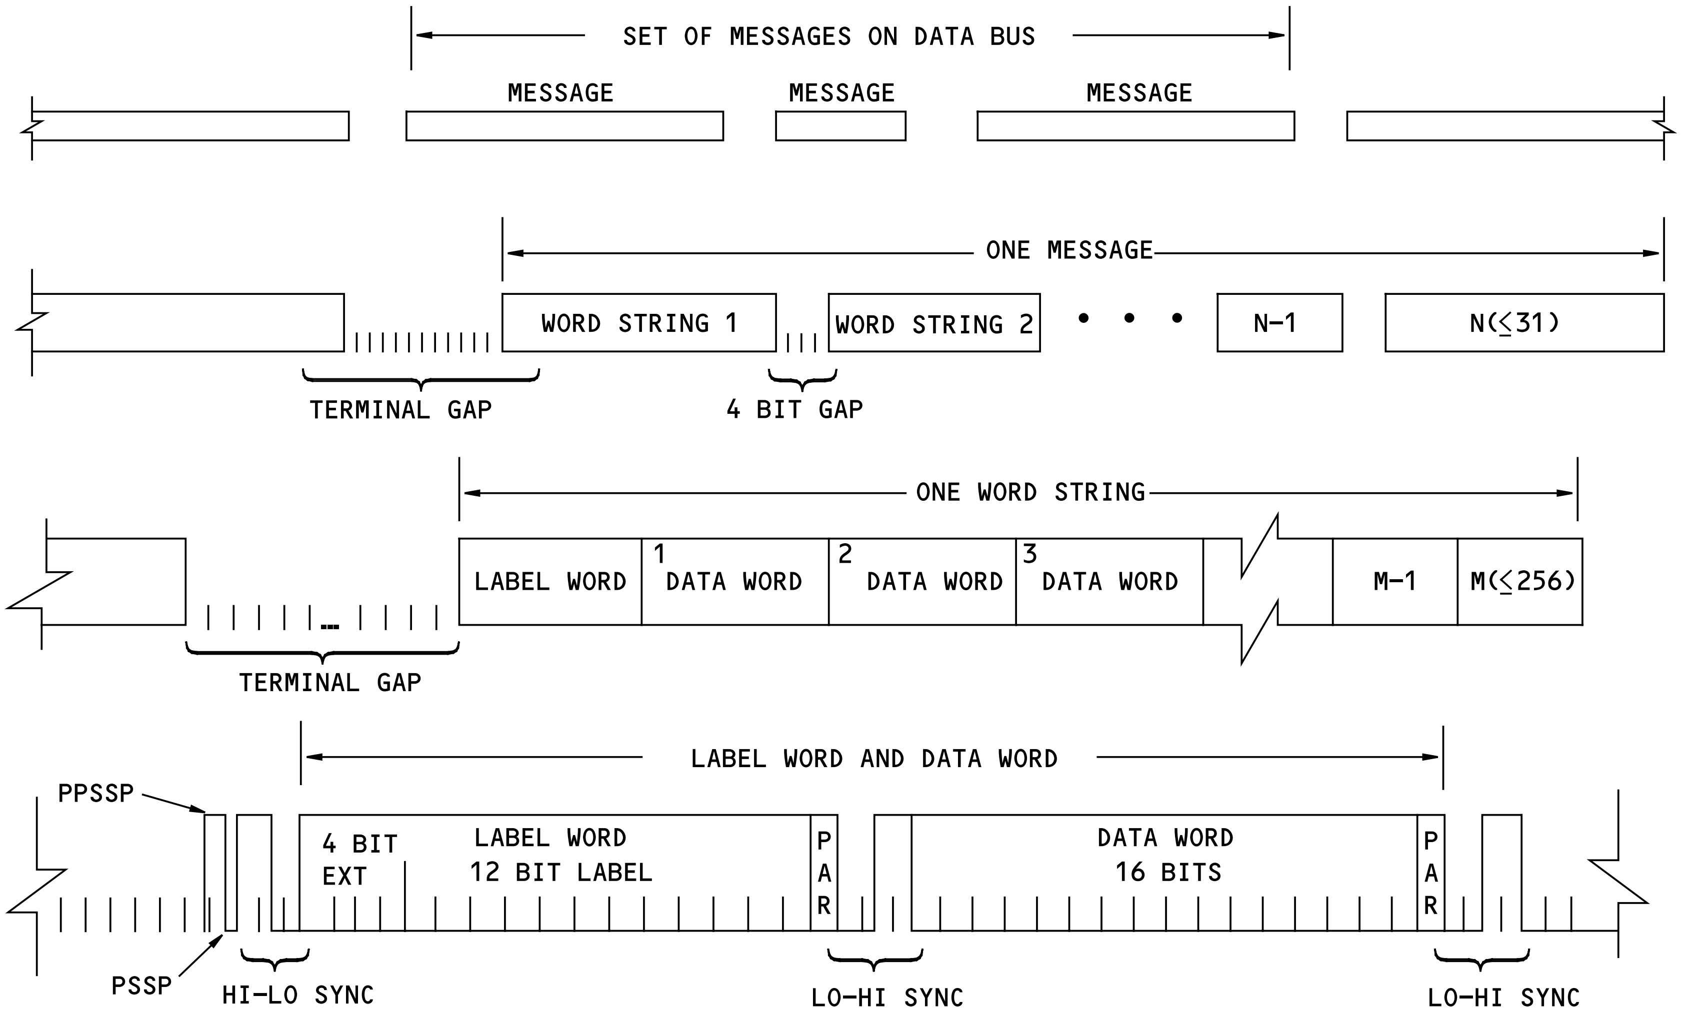
A pulse of one half-bit time, called the pre-sync sync pulse (PSSP), comes before the first label word of a message. An approximately one half-bit time pre-pre-sync sync pulse (PPSSP) comes before the PSSP.

The PPSSP and the PSSP occur prior to the 3-bit time hi lo sync pulse

Data Word Structure

A data word is also a 20-bit word. It has:

- A 16 bit data field
- A single parity bit
- A 3-bit time lo hi sync pulse.



23-91-00-014 Rev 1

ARINC 629 - MESSAGE STRUCTURE FUNCTIONAL DESCRIPTION

ARINC 629 - TIMING FUNCTIONAL DESCRIPTION

General

Because of the quantity of data that may be on the bus, ARINC 629 uses a time procedure to prevent accidental signal mixture. ARINC 629 uses three timers:

- Transmit interval (TI) timer
- Synchronization gap (SG) timer
- Terminal gap (TG) timer.

The timers are part of the LRU personality. Each LRU uses all three timers to isolate data messages.

Transmit Interval (TI)

The TI for any LRU begins the moment the terminal starts to transmit. After the terminal transmits a message, it must wait the length of time equal to TI before it transmits again.

All LRUs on a bus have the same TI.

Synchronization Gap (SG)

After the TI, the SG is the longest timer. The SG begins when there is no signal on the bus. The SG is the same for all LRUs. It has a value larger than the value of the longest terminal gap used on a given bus.

If a signal comes on the bus before the SG completes, the SG stops. When the SG completes, it stays reset until the LRU transmits again.

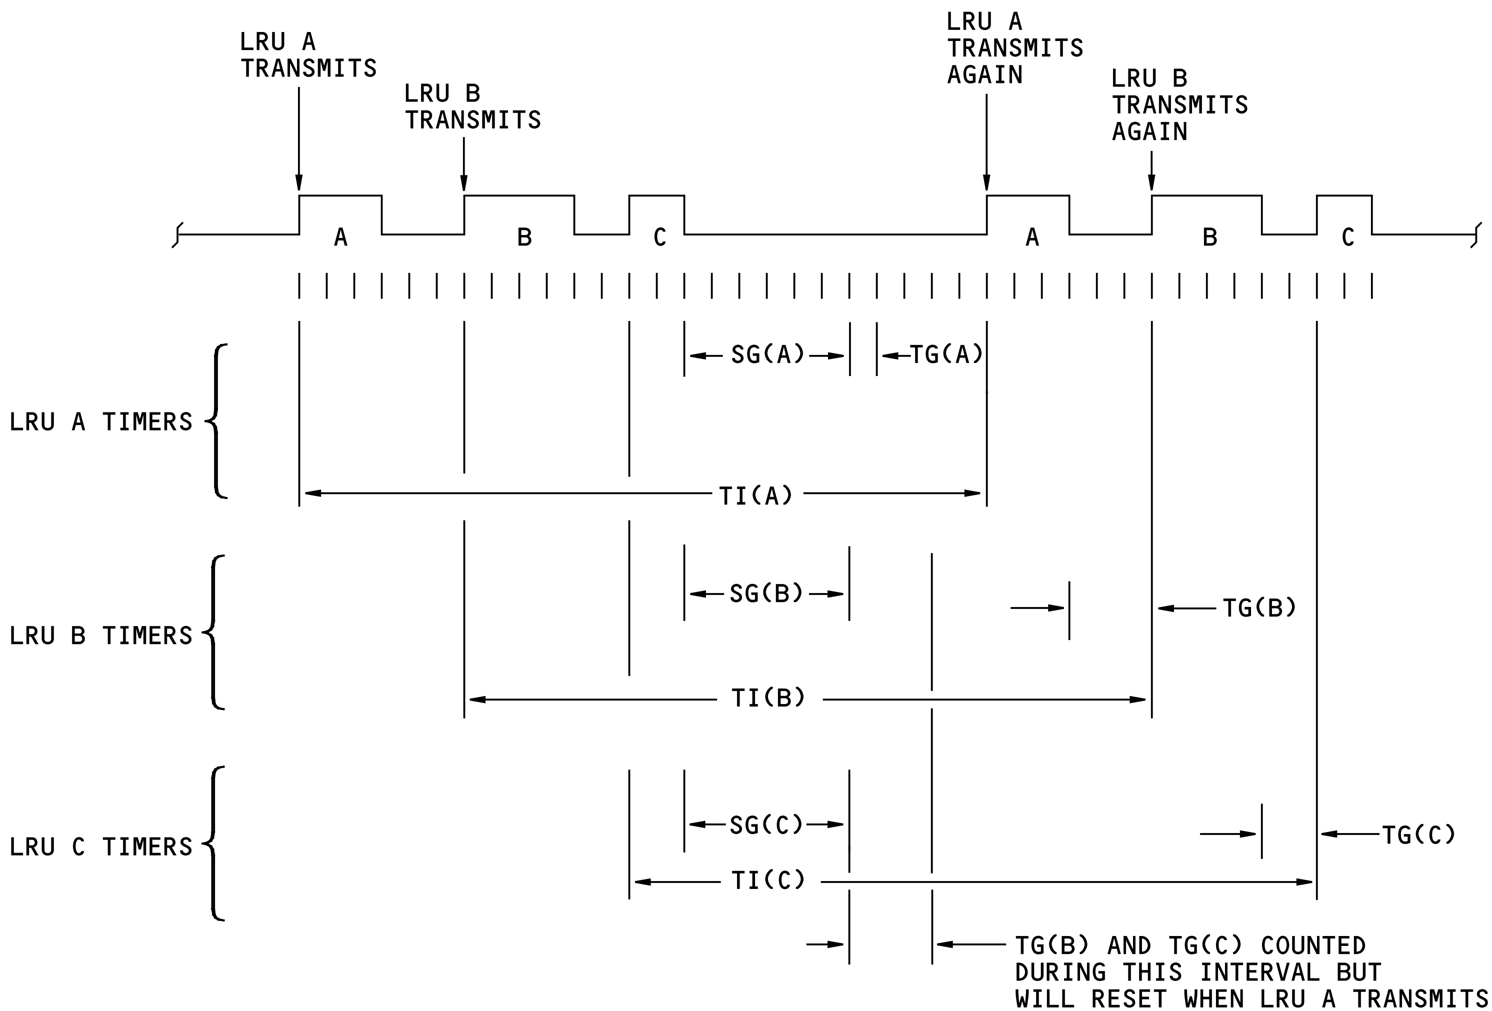
Terminal Gap (TG)

Each LRU on the bus has a special TG.

The TG begins after the SG is complete and no signal is on the bus.

If there is a signal on the bus before the TG completes, the TG stops. It starts again when there is no signal on the bus.

The TG and SG cannot overlap in time. They must occur in sequence.



23-91-00-015 Rev 1

ARINC 629 - TIMING FUNCTIONAL DESCRIPTION

ARINC 629 - PERIODIC MODE TIMING FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

ARINC 629 - PERIODIC MODE TIMING FUNCTIONAL DESCRIPTION

General

The ARINC 629 uses these three timers:

- Transmit interval (TI)
- Synchronization gap (SG)
- Terminal gap (TG).

The three timers operate in these two ways:

- Periodic mode
- Aperiodic mode.

The periodic mode makes sure that an LRU transmits at a regular time sequence, in their power-up order.

If an LRU message length increases because of a non-normal condition, the system changes to aperiodic operation. In aperiodic operation, the LRU transmits in a different time sequence. In the aperiodic mode, the LRUs transmit in order of shortest TG to longest TG.

Periodic Mode

The periodic mode is the normal mode of operation.

In the periodic mode, an LRU transmits one time every TI.

The examples show the timing diagram for three LRUs in the periodic mode.

At event 1, all three timers (TI, SG & TG) for LRU 1 are complete and LRU 1 starts to transmit a message (M). LRUs 2 and 3 stop their TGs when LRU 1 starts to transmit.

At event 2, LRU 1 no longer transmits, and LRU 2 and 3 start their TG timers.

At event 3, the TG timer for LRU 3 is complete, however TI still continues. LRU 3 does not transmit. The TG timer for LRU 2 continues.

At event 4, the TG timer for LRU 2 is complete. All three timers for LRU 2 (TI, SG and TG) are complete and the LRU starts to transmit a message, while LRU 3 waits for its TI to complete. LRU 3 stops its TG when LRU 2 starts to transmit.

At event 5, LRU 2 stops transmission and LRU 2 starts its TG timer.

At event 6, the TG timer for LRU 3 completes. For LRU 3, all three timers (TI, SG and TG) are complete and it starts to transmit a message.

At event 7, LRU 3 no longer transmits, and all three LRUs start their SG timers.

At event 8, all three SG timers are complete and the TG timers start.

At event 9, the TG for LRU 1 completes, TI continues, so it does not transmit.

ARINC 629 - PERIODIC MODE TIMING FUNCTIONAL DESCRIPTION

At event 10, TG for LRU 3 is complete, the TI continues, so the LRU does not transmit.

At event 11, the TG for LRU 2 completes, the TI continues, so the LRU does not transmit.

Back at event 1 when all three timers (TI, SG and TG) for LRU 1 are complete and it starts to transmit a message. LRU 2 and 3 stop their TGs when LRU 1 starts to transmit.

Aperiodic Mode

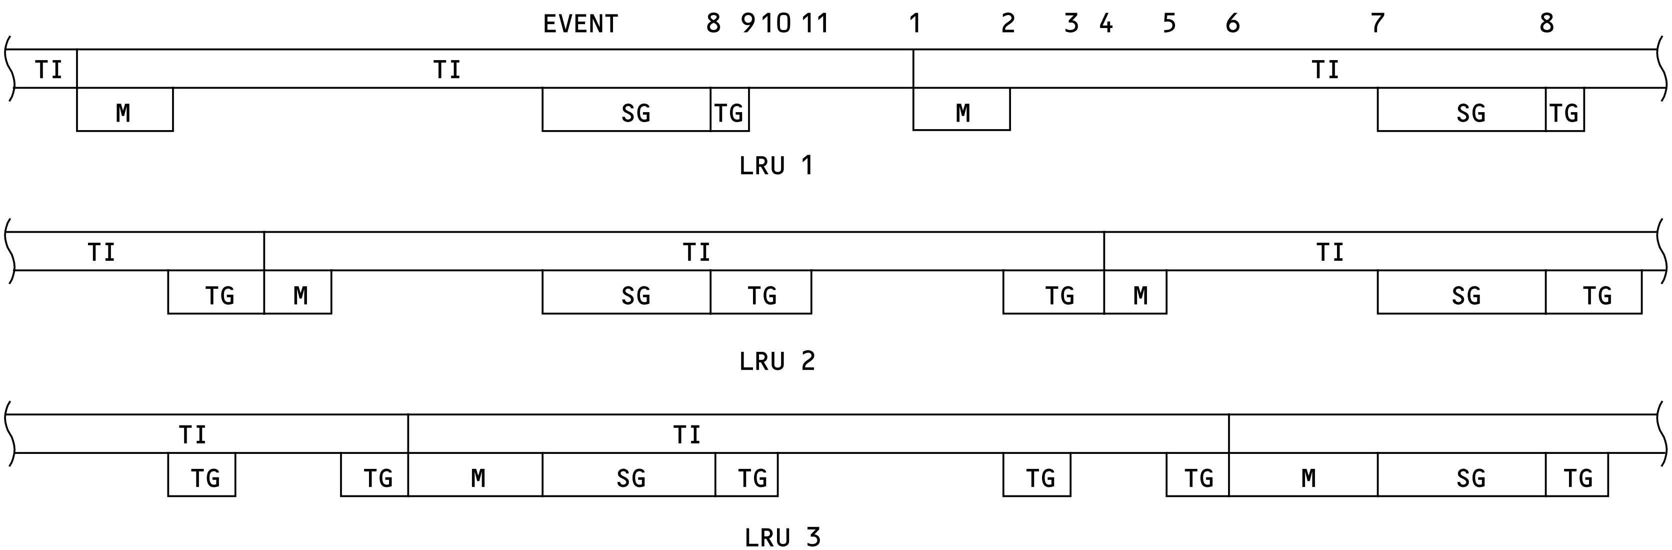
Aperiodic data is a direct result of a discrete event. It is data that is asynchronous and updated at a non-uniform rate. For example, aperiodic data can be a position report in landing gear systems.

Aperiodic data transfers data on events important to airplane operation. This data is in two classes:

- Data to control tasks such as landing gear sensors and flight deck switches
- Data for status information.

Aperiodic data also transmits large blocks of data for these functions:

- Data base loads
- Operational software
- BITE information.



NOTE: NOT TO SCALE

23-91-00-016 Rev 1

ARINC 629 - PERIODIC MODE TIMING FUNCTIONAL DESCRIPTION

ARINC 629 - TEST

Tests

You use the maintenance access terminal (MAT) to do the ARINC 629 coupler replacement test.

This test does not do a check of the AIMS intercabinet buses.

The central maintenance computing function (CMCF) does not have a specified ARINC 629 system test to check the entire system.

ARINC 629 Coupler Replacement Test

For this operational test, you do a check of the configuration of a system that connects to each of the buses. The data you see on the MAT tells you if the bus is operational.

Training Information Point

Use the ARINC 629 system test procedure if you can not do the operational test. This test does not use the MAT. You use an ARINC 629 data bus analyzer.

Use the standard wiring practices manual when you replace ARINC 629 stub or system cables.

TABLE OF CONTENTS

THIS PAGE INTENTIONALLY LEFT BLANK

OVERHEAD PANEL ARINC 629 SYSTEM - INTRODUCTION

General

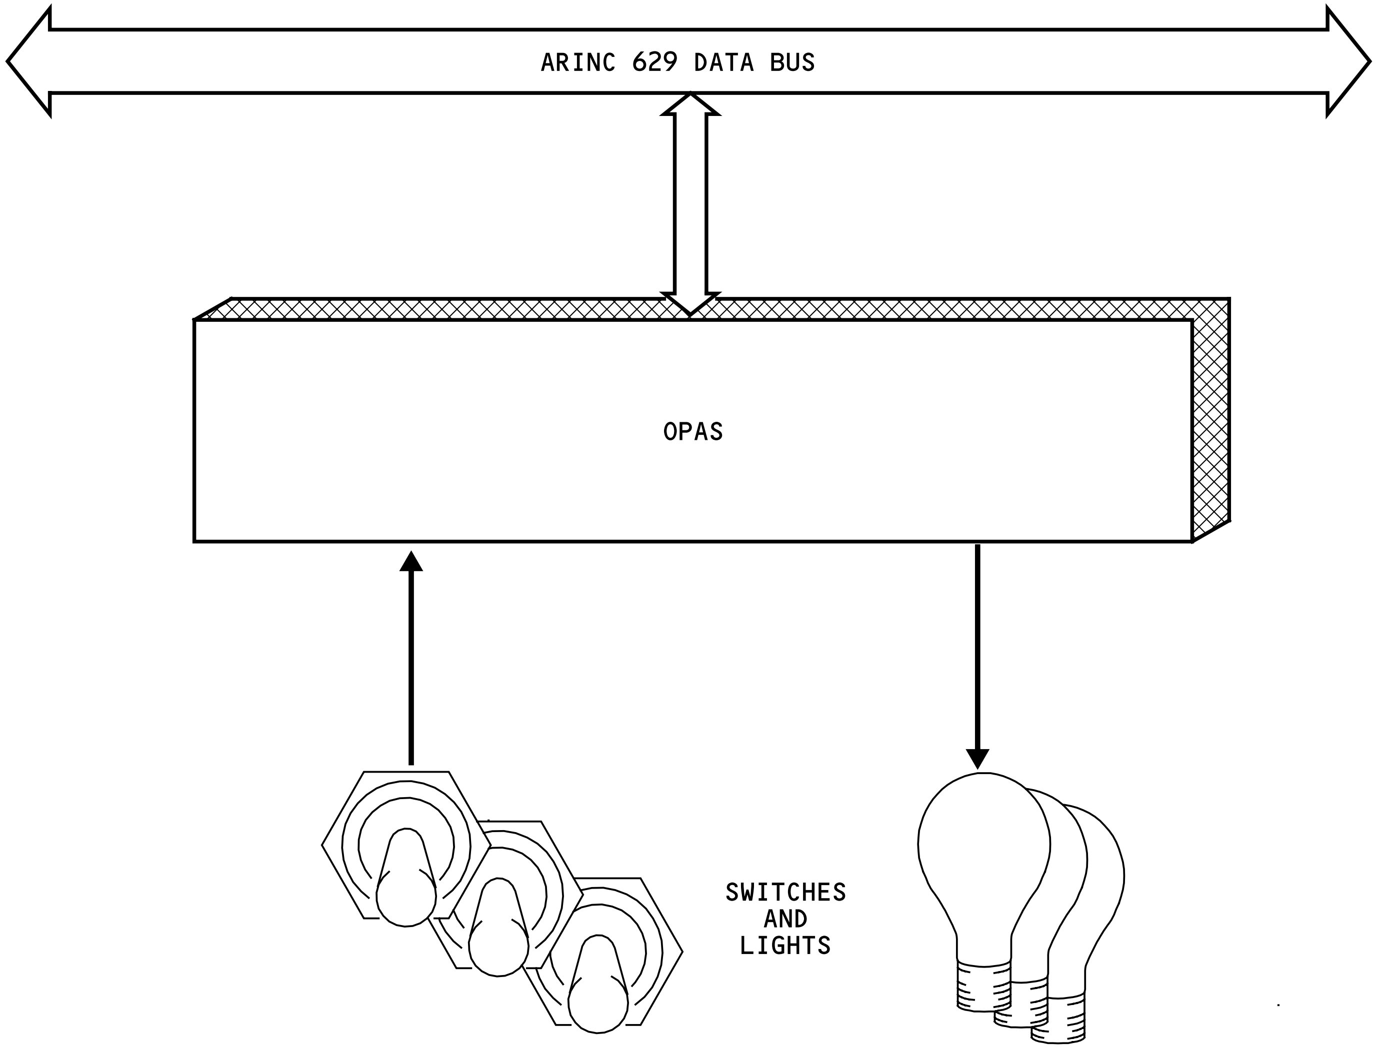
The overhead panel ARINC 629 system (OPAS) sends flight deck switch position data to the ARINC 629 systems buses. It also gets data from the ARINC 629 systems buses to turn on and off some flight deck panel lights.

The OPAS helps decrease the weight of the airplane. It uses less wires than direct connections between these units:

- Switches
- Lights
- Line replaceable units (LRUs)
- Line replaceable modules (LRMs).

Abbreviations and Acronyms

ARINC	- Aeronautical Radio, Inc.
CMCS	- central maintenance computer system
EICAS	- engine indication and crew alerting system
LED	- light emitting diode
LRM	- line replaceable module
LRU	- line replaceable unit
MAT	- maintenance access terminal
MD&T	- master dim and test
OPAS	- overhead panel ARINC 629 system
OPBC	- overhead panel bus controller
OPCF	- overhead panel card file
OPIC	- overhead panel interface card
PDCU	- panel data concentrator unit



23-93-00-001 Rev 0

OVERHEAD PANEL ARINC 629 SYSTEM - INTRODUCTION

OPAS - GENERAL DESCRIPTION

General

The OPAS moves flight deck switch and light data through the overhead panel card files (OPCFs) and panel data concentrator units (PDCUs).

The overhead panel bus controllers (OPBCs) are the interface units for the ARINC 629 buses.

Components

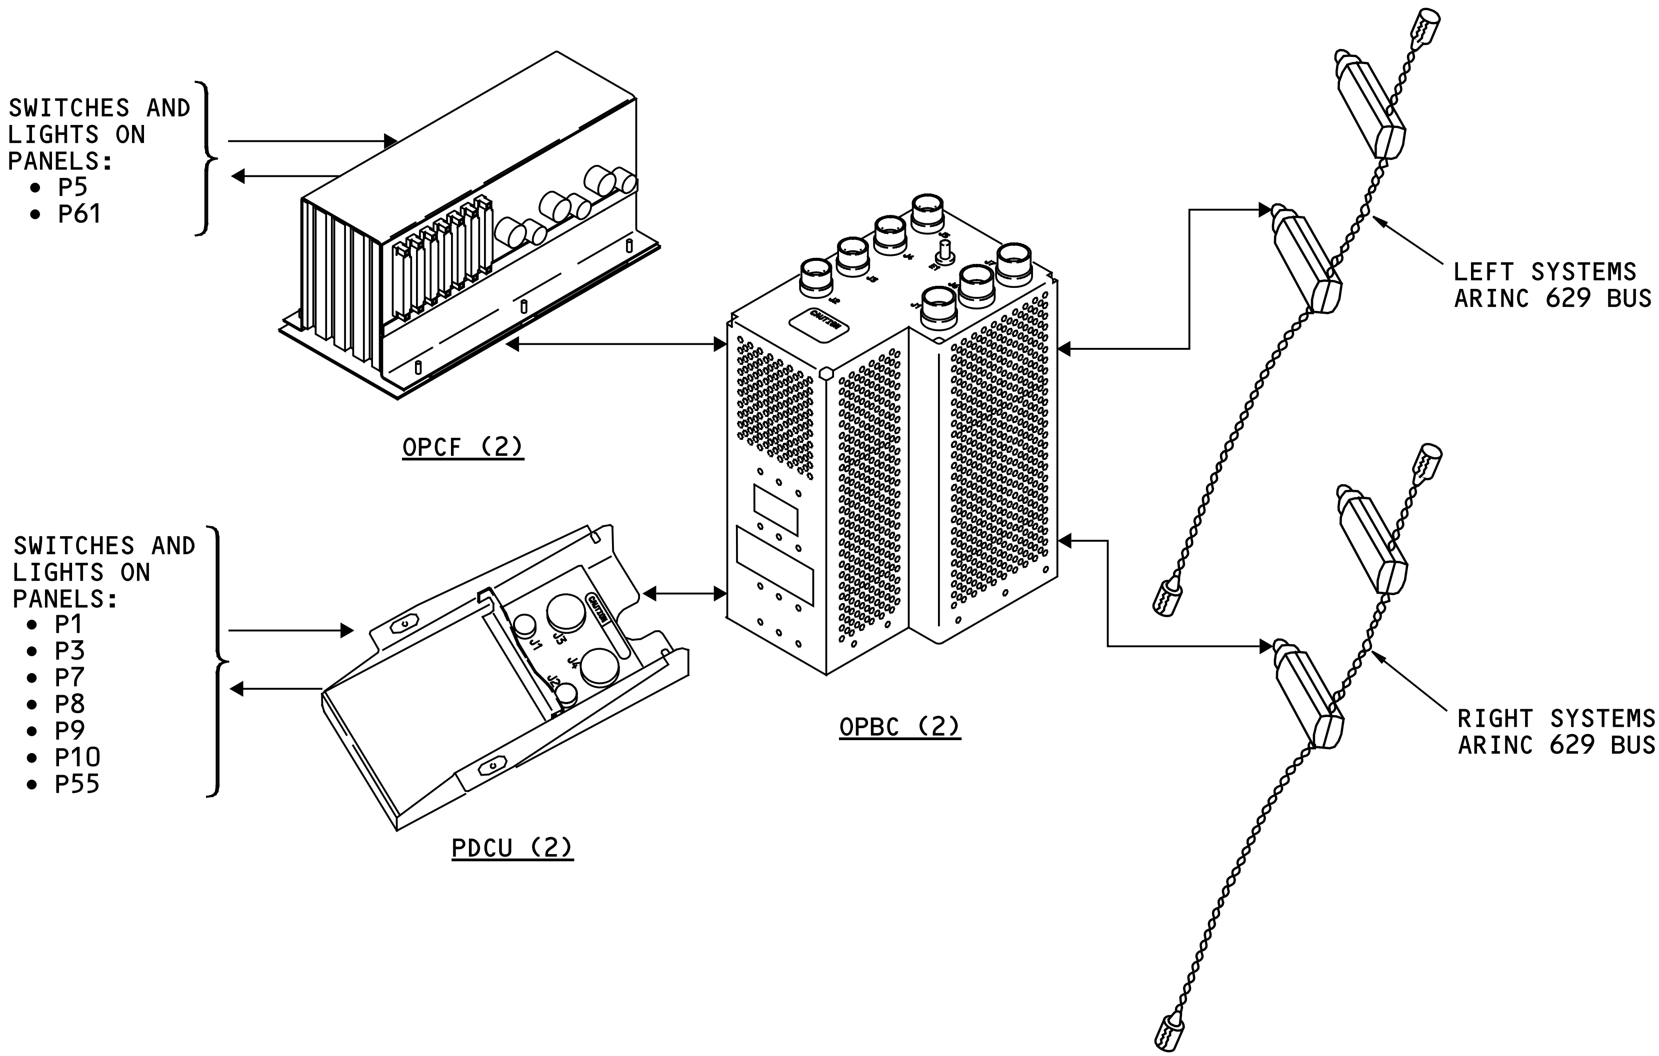
The OPAS has these six components:

- Left and right OPCFs
- Left and right PDCUs
- Left and right OPBCs.

Operation

These are the functions of OPAS:

- It sends flight deck switch position data to the systems ARINC 629 buses
- It gets data from the systems ARINC 629 buses to turn some flight deck panel lights on and off
- It reports system faults to the central maintenance computer system (CMCS)
- It reports OPAS failures to the flight crew by an EICAS status message.



23-93-00-002 Rev 0

OPAS - GENERAL DESCRIPTION

OPAS - COMPONENT LOCATIONS

General

These are the OPAS components in the flight deck:

- Left and right overhead panel card files (OPCFs)
- Left and right panel data concentrator units (PDCUs)
- Left and right overhead panel bus controllers (OPBCs).

Each OPCF has right and left overhead panel interface cards (OPICs).

Overhead Panel Card Files

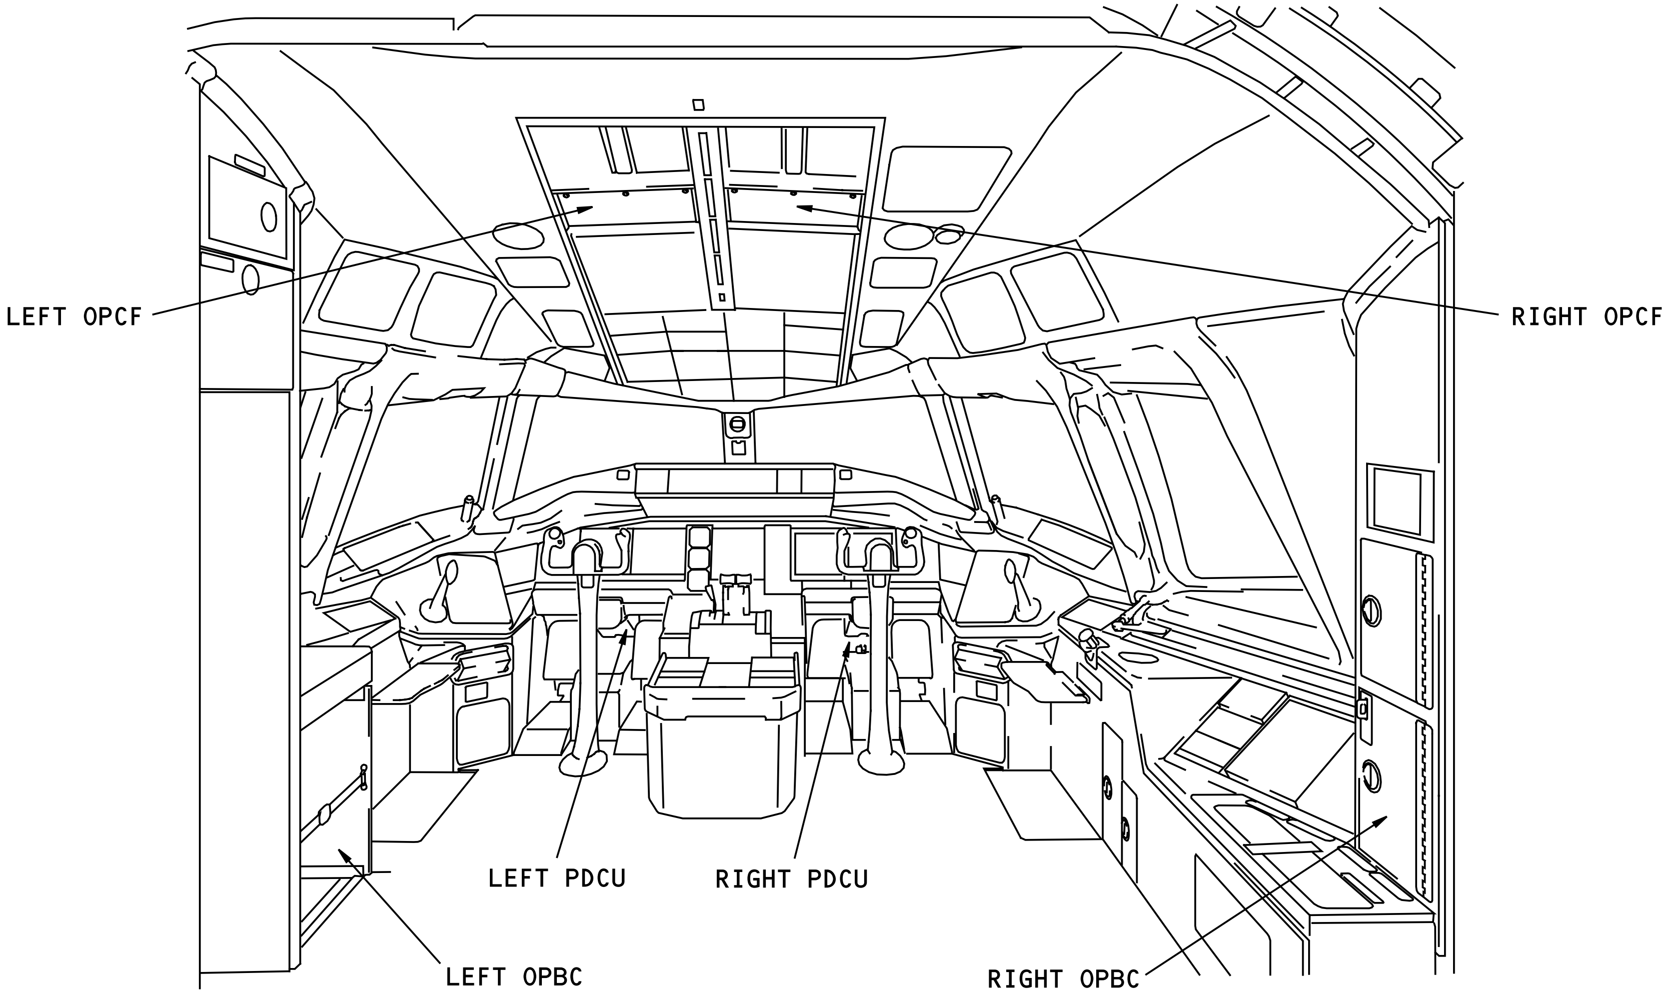
The OPCFs are in the P61 overhead maintenance panel. The left OPCF is in the left side of the panel. The right OPCF is in the right side of the panel.

Panel Data Concentrator Units

The PDCUs are near the floor in the forward part of the flight deck. The left PDCU is on the left side, forward of the captain's seat. The right PDCU is on the right side, forward the first officer's seat.

Overhead Panel Bus Controllers

The left OPBC is in the back of the storage area adjacent to the captain's seat. The right OPBC is in the storage area adjacent to the maintenance access terminal (MAT).



23-93-00-003 Rev 0

OPAS - COMPONENT LOCATIONS

OPAS - OVERHEAD PANEL CARD FILES INTERFACES

General

There are two overhead panel card files (OPCFs). Each OPCF has two interchangeable overhead panel interface cards (OPICs); A1 and A2.

The OPICs send data to the right and left overhead panel bus controllers (OPBCs) on RS 485 buses. Each RS 485 bus has a twisted shielded pair of wires. Data is moved at 10 mega-bits per second on the RS 485 bus. The OPBCs connect to the left and right systems ARINC 629 buses.

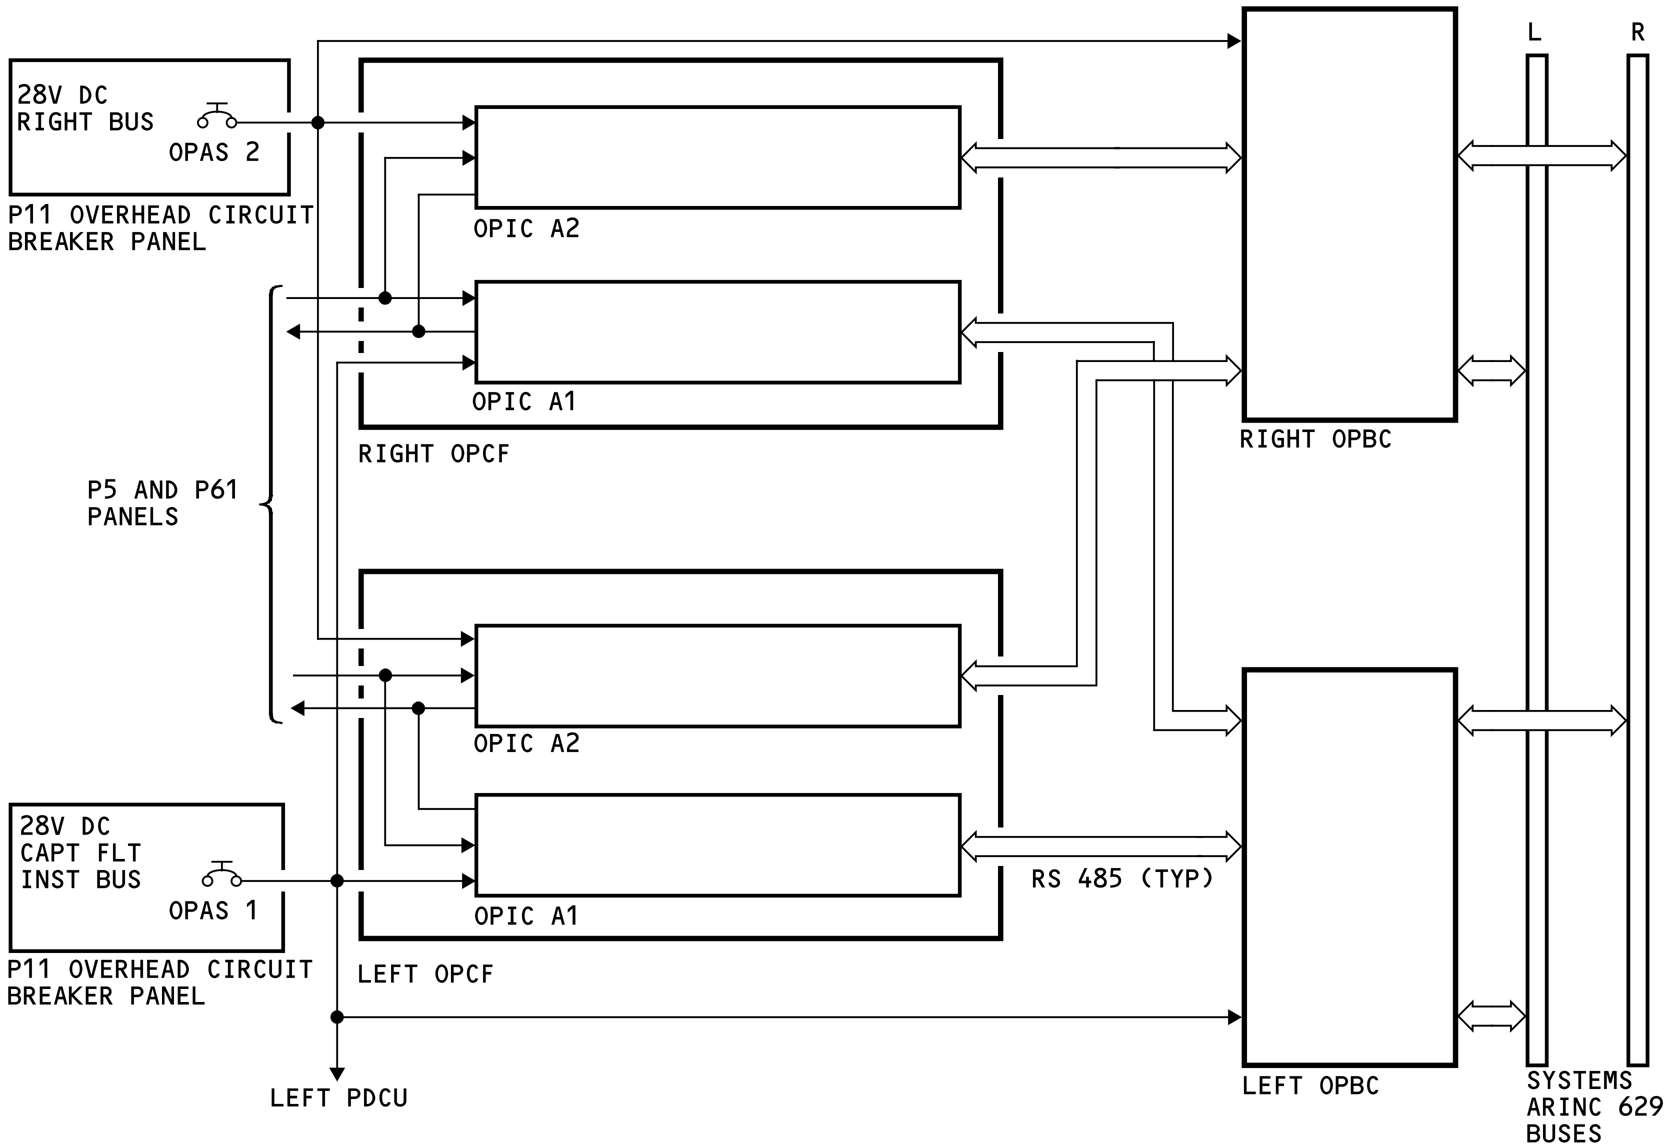
Power Interfaces

The OPAS 2 circuit breaker connects 28v dc to the OPIC A2 in each OPCF and to the right OPBC.

The OPAS 1 circuit breaker connects 28v dc to the OPIC A1 in each OPCF and to the left OPBC.

Right and Left OPCFs

Many switches and lights on the P5 and P61 panels connect to the OPICs in the right and left OPCFs. The OPIC A2s in both card files connect to the right OPBC. Both OPIC A1s connect to the left OPBC.



23-93-00-004 Rev 4 01/26/1998

OPAS - OVERHEAD PANEL CARD FILES INTERFACES

OPAS - PANEL DATA CONCENTRATOR UNITS INTERFACES

General

Switches and lights in the flight deck connect to right and left panel data concentrator units (PDCUs).

The PDCUs connect to the right and left overhead panel bus controllers (OPBCs). The OPBCs connect to the left and right systems ARINC 629 buses.

Power Interfaces

The OPAS 3 circuit breaker connects 28v dc to the right PDCU.

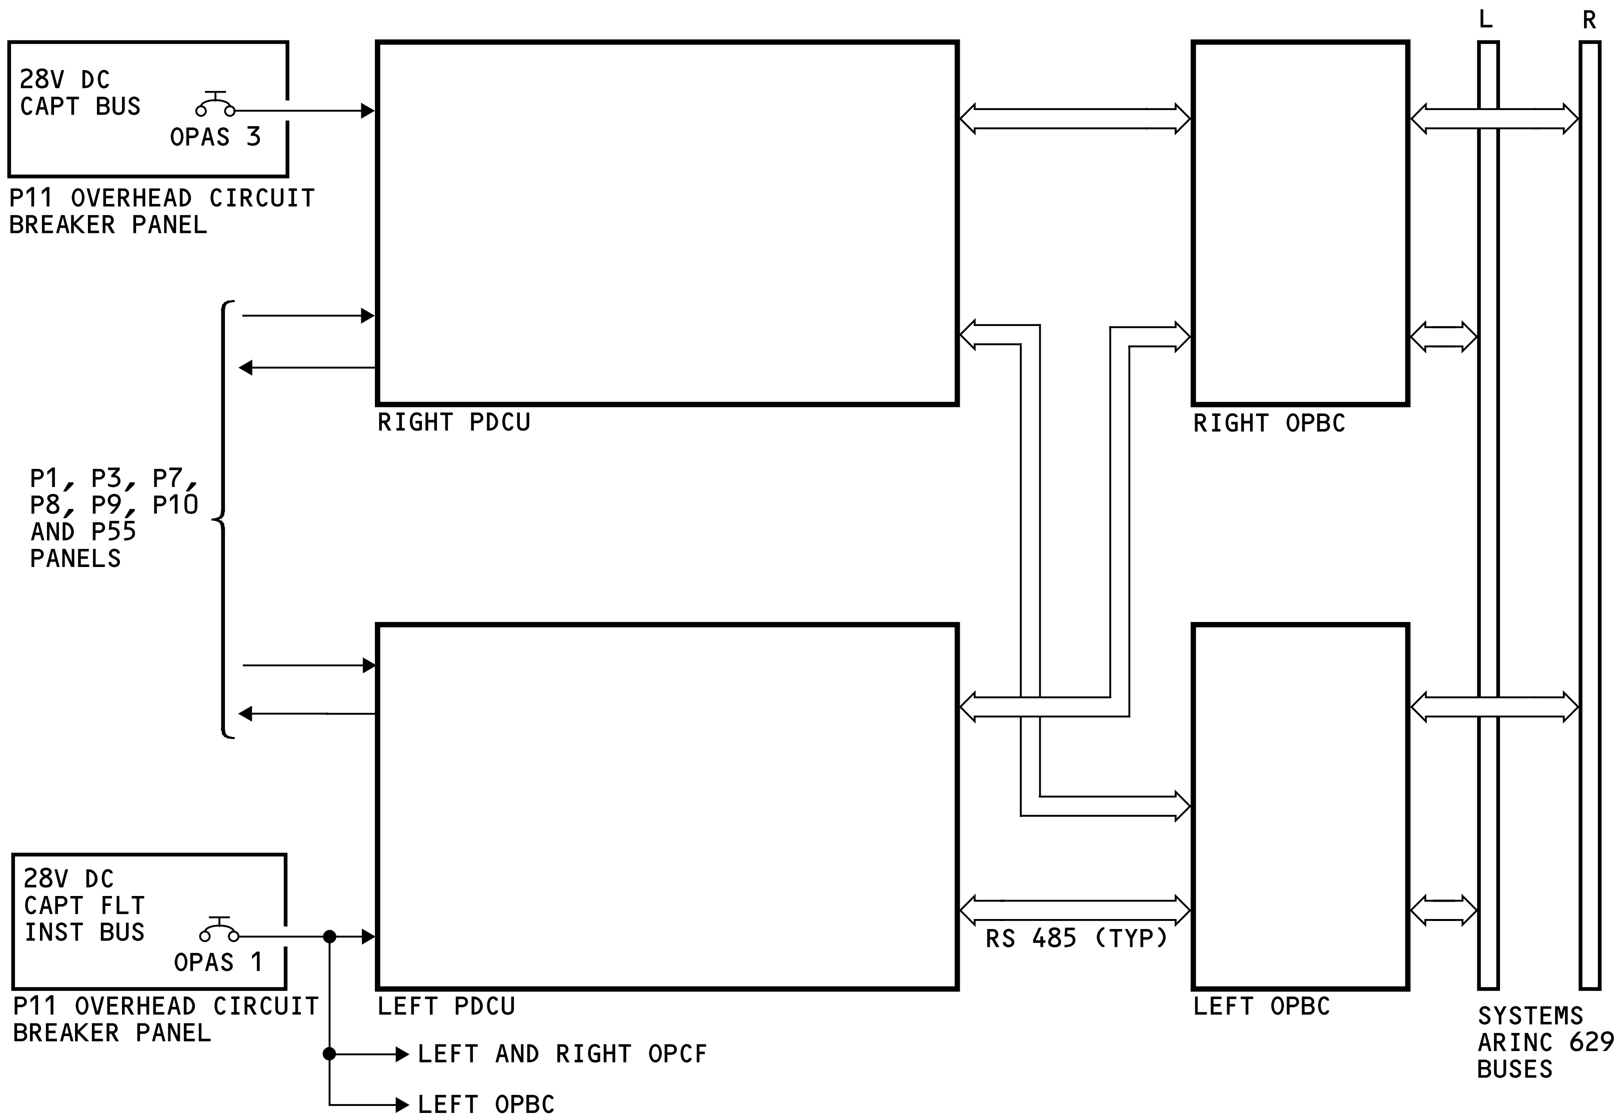
The OPAS 1 circuit breaker connects 28v dc to the left PDCU.

Right and Left PDCUs

Many switches and lights on these flight deck panels connect to the PDCUs:

- P1 left forward panel
- P3 right forward panel
- P7 glareshield panel
- P8 aft aisle stand panel
- P9 forward aisle stand panel
- P10 control stand
- P55 glareshield center panel.

The right and left PDCUs connect to both right and left OPBCs.



OPAS - PANEL DATA CONCENTRATOR UNITS INTERFACES

OPAS - OVERHEAD PANEL CARD FILES

Purpose

The overhead panel card files (OPCFs) send switch position data from the P5 and P61 panels to the overhead panel bus controllers (OPBCs). They also get data from the OPBCs to control some lights in the P5 and P61 panels.

Physical Description

Each OPCF has these parts:

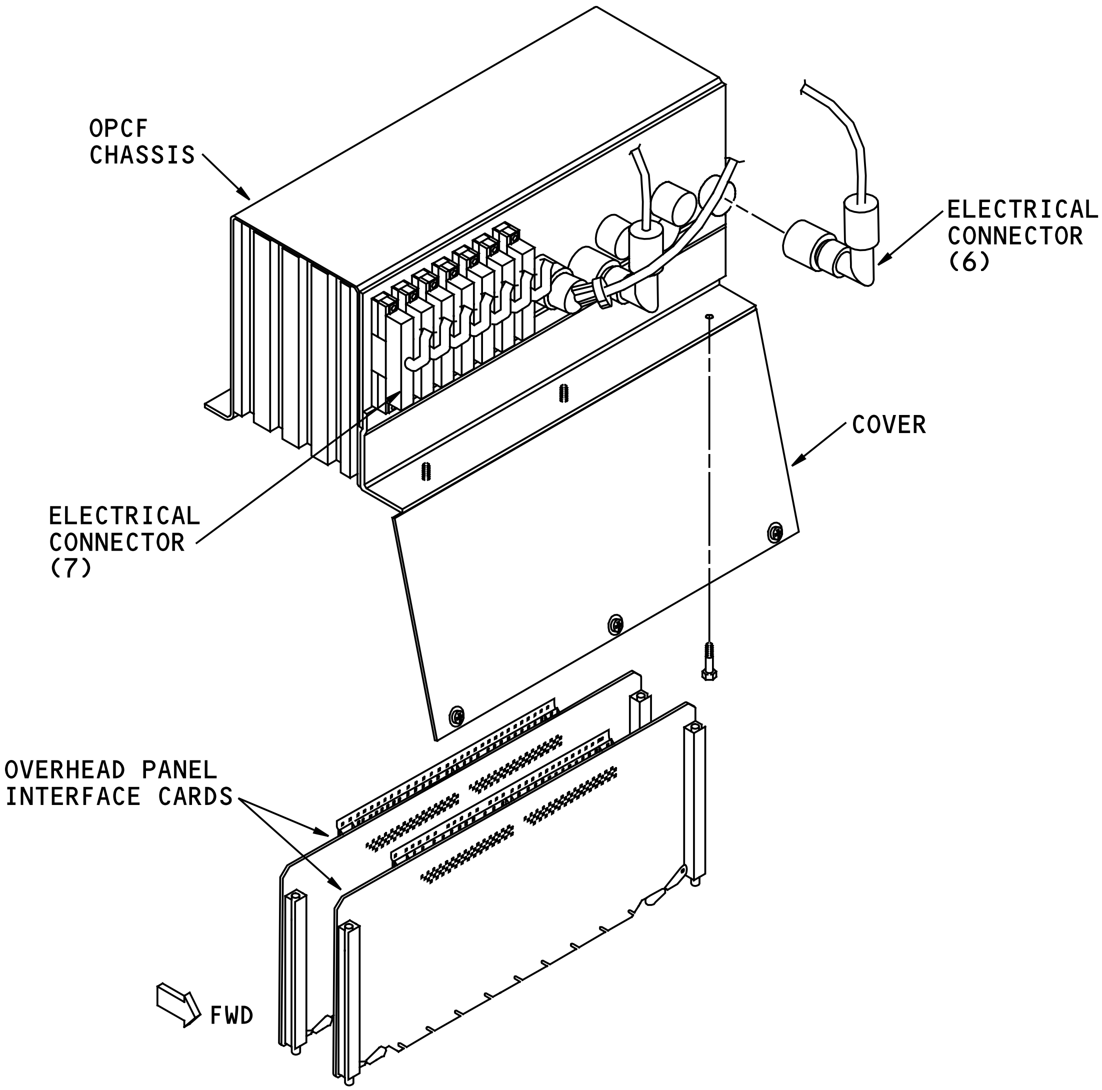
- A chassis
- A connector board
- A backplane board
- Two overhead panel interface cards (OPICs).

An OPCF with both OPICs weighs 9 pounds. Its dimensions are:

- Length - 13 inches
- Width - 6 inches
- Height - 4.5 inches.

Training Information Point

The OPCFs are interchangeable. The OPICs in each OPCF are also interchangeable.



23-93-00-006 Rev 3 04/29/95

OPAS - OVERHEAD PANEL CARD FILES

OPAS - OVERHEAD PANEL CARD FILES FUNCTIONAL DESCRIPTION

General

Each overhead panel card file (OPCF) has two overhead panel interface cards (OPICs); A1 and A2. The positions of many switches in the P5 and P61 panels go to the OPICs. The OPICs send the switch position data to the overhead panel bus controllers (OPBCs) on a serial bus.

The OPICs also get data from the OPBCs to turn on and off indicator lights on the P5 and P61 panels.

OPCF Description

Each OPCF has two OPICs. An OPCF contains connections to the OPICs for these signals:

- Switch inputs
- Light outputs
- Serial data inputs and outputs
- Channel identifications.

OPIC Description

Each OPIC has these circuits:

- A multiplexer for as many as 160 inputs
- A demultiplexer for as many as 36 light outputs
- A microprocessor
- A fault monitor
- One serial port communication bus
- A channel identification interface for program pins.

OPIC Operation

The multiplexer receives inputs from the panel switches. It selects a signal from one switch at a time and sends it to the microprocessor.

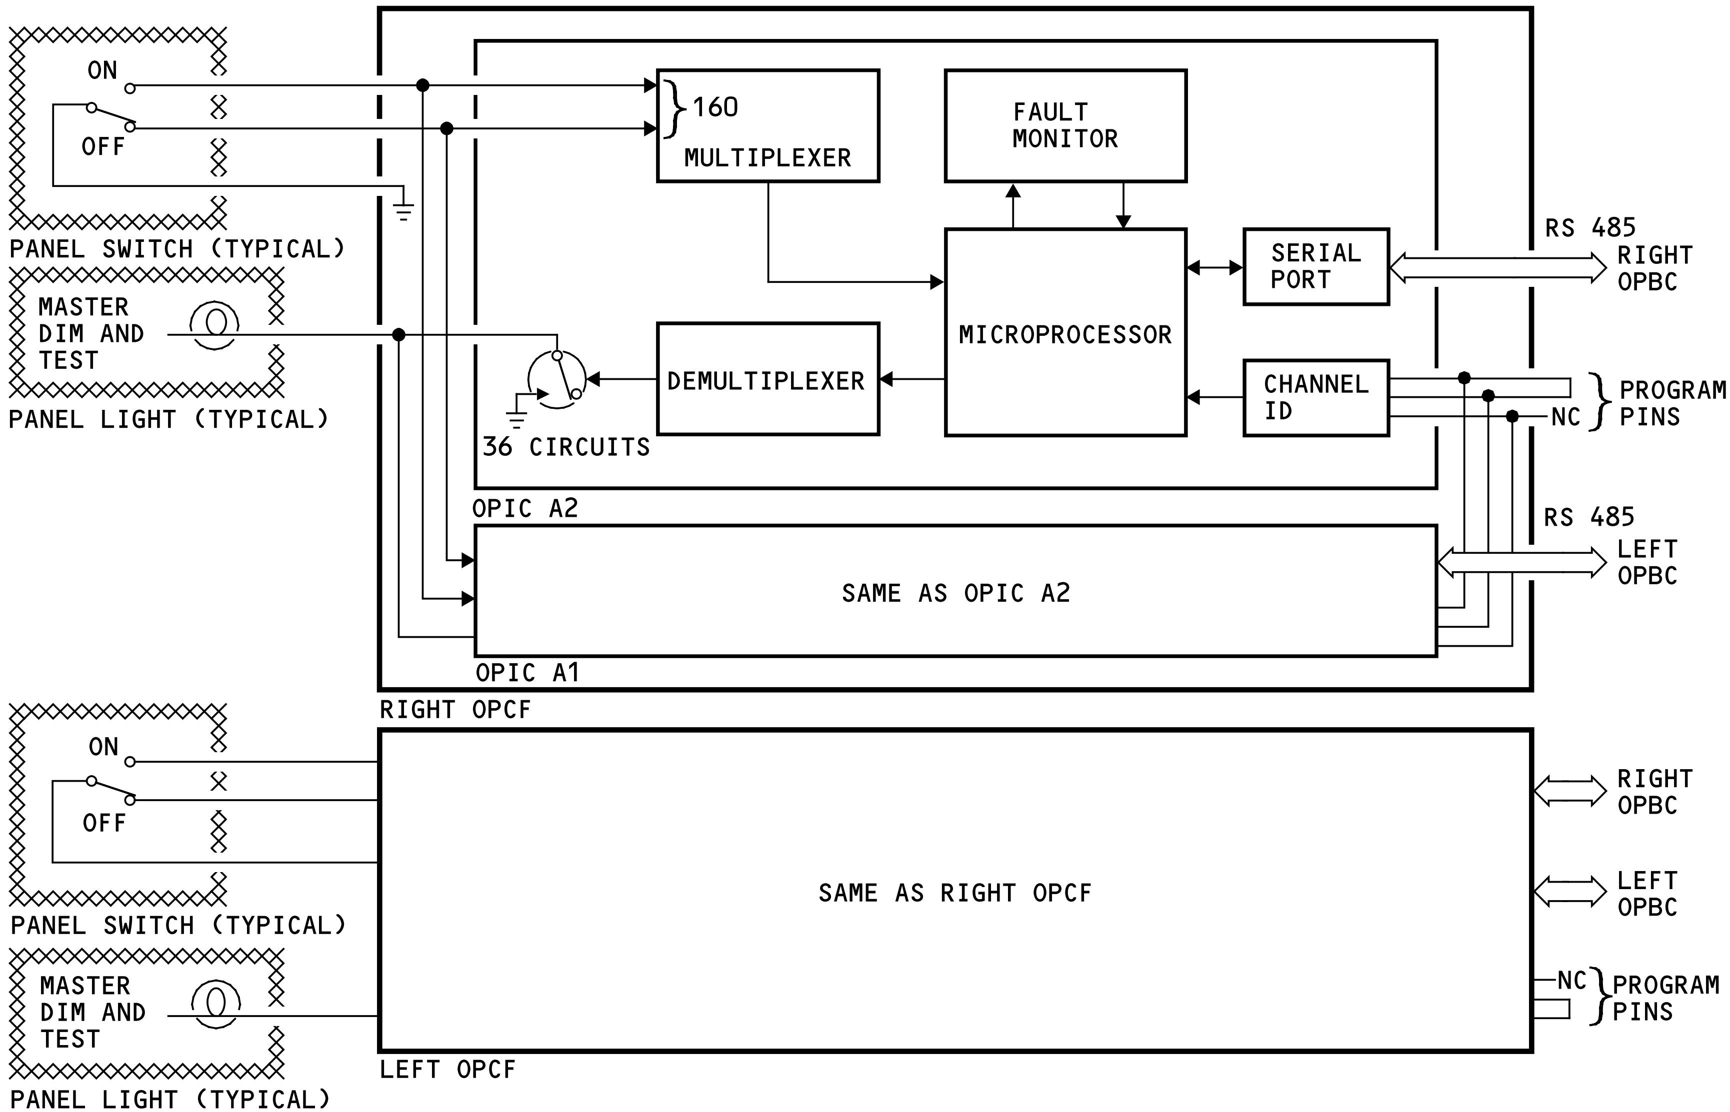
The microprocessor sends the switch position data to the serial port. The microprocessor also receives data from the serial port to control lights. It sends this data to the demultiplexer.

The demultiplexer controls the output to the lights.

The fault monitor circuit identifies OPAS faults to the microprocessor. The microprocessor sends the fault data to the OPBC. The OPBC then sends this data to the central maintenance computer system (CMCS).

The serial port permits the OPIC to send and get switch and light data from the OPBC.

The program pins connect to the channel identification circuit to tell the OPIC its location and functions.



23-93-00-007 Rev 3 01/26/1998

OPAS - OVERHEAD PANEL CARD FILES FUNCTIONAL DESCRIPTION

OPAS - PANEL DATA CONCENTRATOR UNIT

Purpose

The panel data concentrator units (PDCUs) send switch position data from some flight deck panels to the overhead panel bus controllers (OPBCs). They also get data from the OPBCs to turn on and off some panel lights.

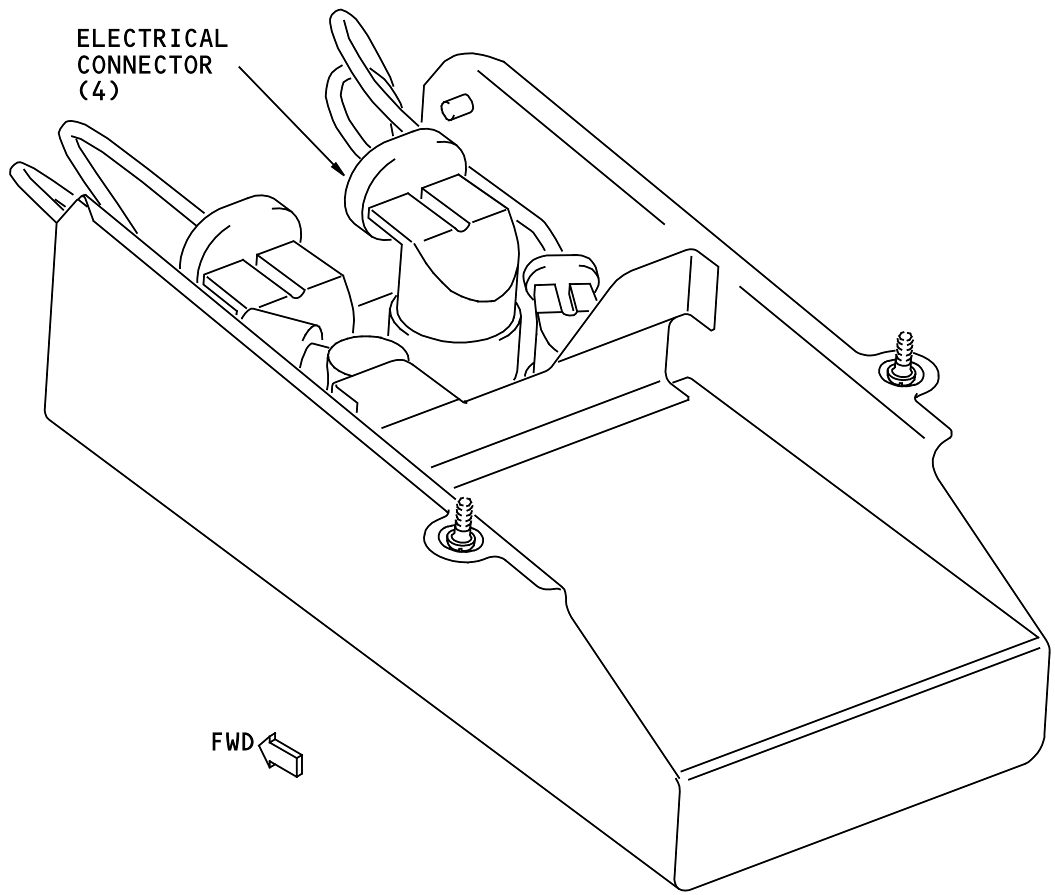
Physical Description

A PDCU weighs 3.5 pounds. Its dimensions are:

- Length - 14 inches
- Width - 8 inches
- Height - 3.5 inches.

Training Information Point

The PDCUs are interchangeable.



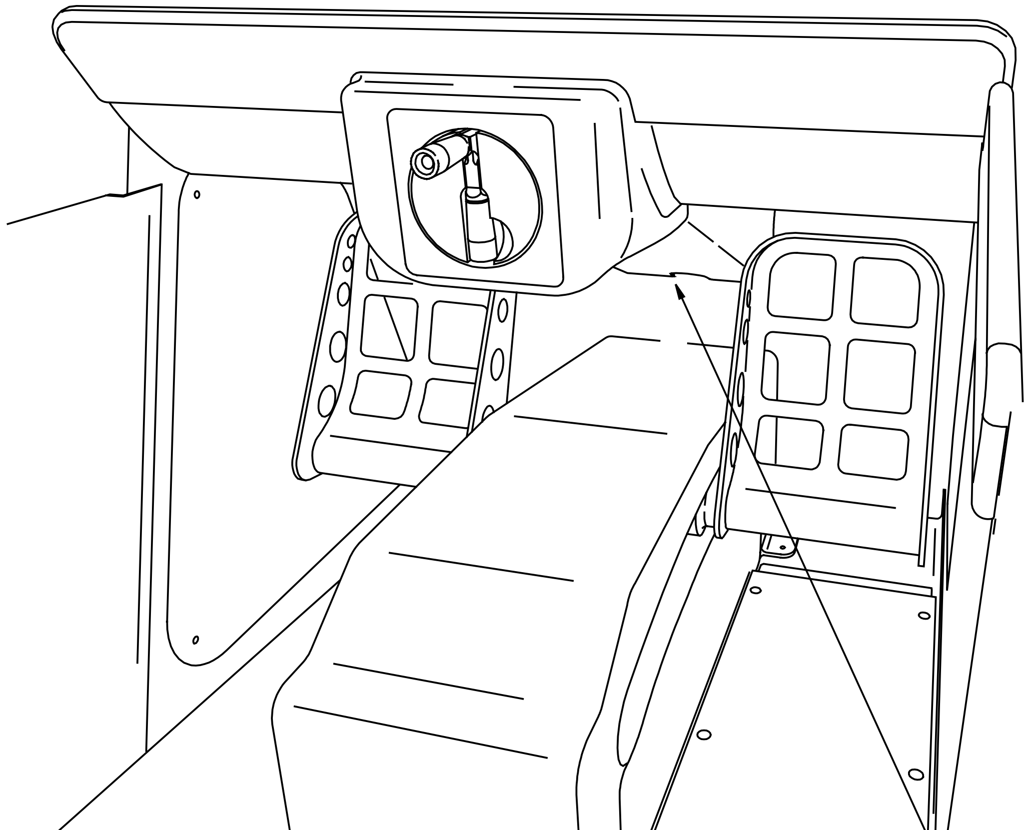
23-93-00-008 Rev 1 04/29/95

OPAS - PANEL DATA CONCENTRATOR UNIT

OPAS - PANEL DATA CONCENTRATOR UNIT INSTALLATION

General

The left panel data concentrator unit (PDCU) is in the flight deck, near the floor between the captain's rudder pedals. The right PDCU is in the same location between the first officer's rudder pedals.



CAPTAIN'S RUDDER PEDAL AREA

OPAS - PANEL DATA CONCENTRATOR UNIT INSTALLATION

OPAS - PANEL DATA CONCENTRATOR UNITS FUNCTIONAL DESCRIPTION

General

The panel data concentrator units (PDCUs) send serial switch position data to the overhead panel bus controllers (OPBCs). The PDCUs also get data from the OPBCs to turn on and off some panel lights.

PDCUs Functions

Each PDCU has these circuits:

- A multiplexer for 80 inputs
- A demultiplexer for 18 light outputs
- Two serial ports.

PDCUs Operation

Each PDCU gets inputs from switches on these panels:

- P1 left forward panel
- P3 right forward panel
- P7 glareshield panel
- P8 aft aisle stand panel
- P9 forward aisle stand panel
- P10 control stand
- P55 glareshield center panel.

The multiplexer receives inputs from the panel switches. It selects a signal from one switch at a time and sends it to the microprocessor.

The microprocessor sends the condition of the switch to the serial ports. The microprocessor receives data from the serial ports to control lights. It also sends data to the demultiplexer.

The demultiplexer controls the output to the lights.

The fault monitor circuit identifies OPAS faults to the microprocessor. The microprocessor sends the fault data to the central maintenance computer system (CMCS).

The serial ports permit the PDCUs to send and get switch and light data from the OBPCs.

OPAS - OVERHEAD PANEL BUS CONTROLLER INSTALLATION

OPAS - OVERHEAD PANEL BUS CONTROLLER FUNCTIONAL DESCRIPTION

General

There are two overhead panel bus controllers (OPBCs), one on each side of the flight deck. Each OPBC has these components:

- Four serial interface controllers
- Microprocessor
- Fault monitor
- Two ARINC 629 terminal controllers
- A channel identification interface for program pins.

Overhead Panel Bus Controller Functions

Each OPBC has these functions:

- It transmits flight deck switch position data to the ARINC 629 system buses
- It receives data for flight deck lights and LEDs from the ARINC 629 system buses
- It does a fault check of data.

Serial Interface Controllers

The microprocessor uses the serial interface controllers to send and get data through the overhead panel interface cards (OPICs) and panel data concentrator units (PDCUs).

Fault Monitor

The fault monitor circuit identifies OPAS faults to the microprocessor. The microprocessor sends the fault data to the central maintenance computer system (CMCS).

Microprocessor

The microprocessor sends data to and receives data from the ARINC 629 system buses, PDCUs, and OPICs.

It isolates and controls data inputs and outputs to prevent signal mixture.

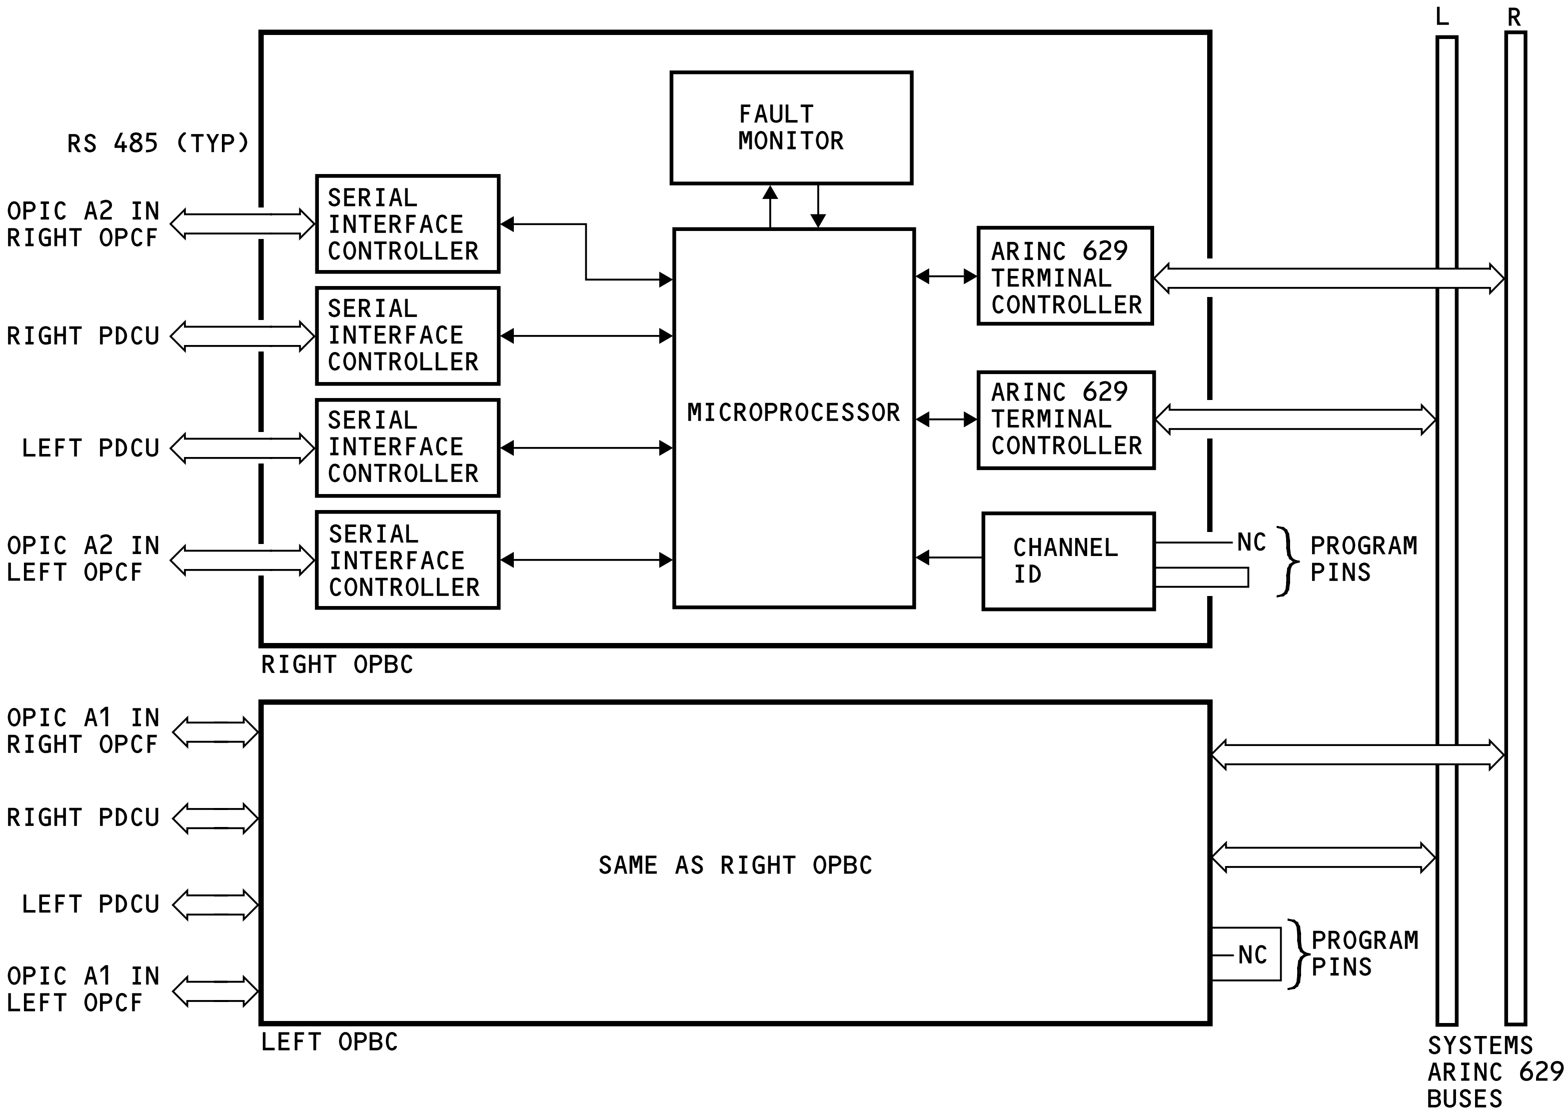
ARINC 629 Terminal Controllers

The ARINC 629 terminal controllers are the interfaces between the OPBCs and the ARINC 629 system buses.

The ARINC 629 terminal controllers monitor the data they transmit. If they find faults in the data, they stop operation.

Channel Identification

The program pins connect to the channel identification circuit to tell the OPBC its location and functions.



OPAS - OVERHEAD PANEL BUS CONTROLLER FUNCTIONAL DESCRIPTION

OPAS - TEST

General

These are the system tests for the OPAS:

- Left overhead panel ARINC 629 system
- Right overhead panel ARINC 629 system

OPAS System Test

Each system test makes sure the operation of that channel is fully functional.

Do both system tests to completely make sure the operation of the OPAS is correct.

Onboard Local Area Network

WB371

TABLE OF CONTENTS

THIS PAGE INTENTIONALLY LEFT BLANK

ONBOARD LOCAL AREA NETWORK - INTRODUCTION

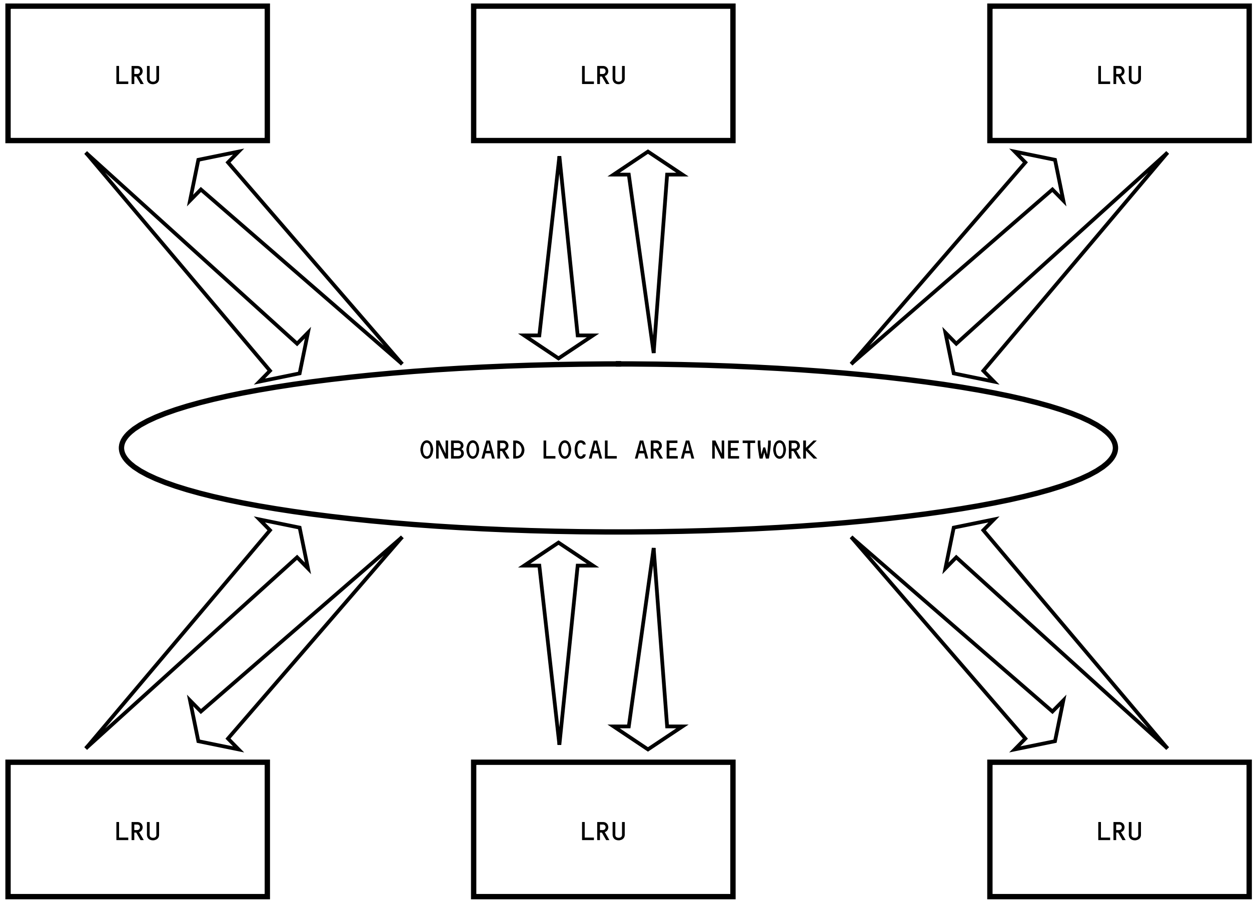
Purpose

The onboard local area network (OLAN) is a fiber optic communications network. It moves digital data between line replaceable units (LRUs). Fiber optic networks have these qualities:

- They carry more data than wire buses
- They weigh less than wire buses
- Electromagnetic radiation has no effect on the data.

Abbreviations and Acronyms

AIMS	- airplane information management system
BSU	- bypass switch unit
LAN	- local area network
LRU	- line replaceable unit
MAT	- maintenance access terminal
OLAN	- onboard local area network
PMAT	- portable maintenance access terminal
pri	- primary
rcvr	- receiver
sec	- secondary
xmtr	- transmitter
ZMU	- zone management unit



23-94-00-001 Rev 2

ONBOARD LOCAL AREA NETWORK - INTRODUCTION

ONBOARD LOCAL AREA NETWORK - GENERAL DESCRIPTION

General

The OLAN has the avionics local area network (LAN). The LAN has these parts:

- A primary ring (PRI)
- A secondary ring (SEC)
- Two bypass switch units (BSUs).

Line replaceable units (LRUs) connect to both rings of a LAN through a BSU.

Avionics LAN

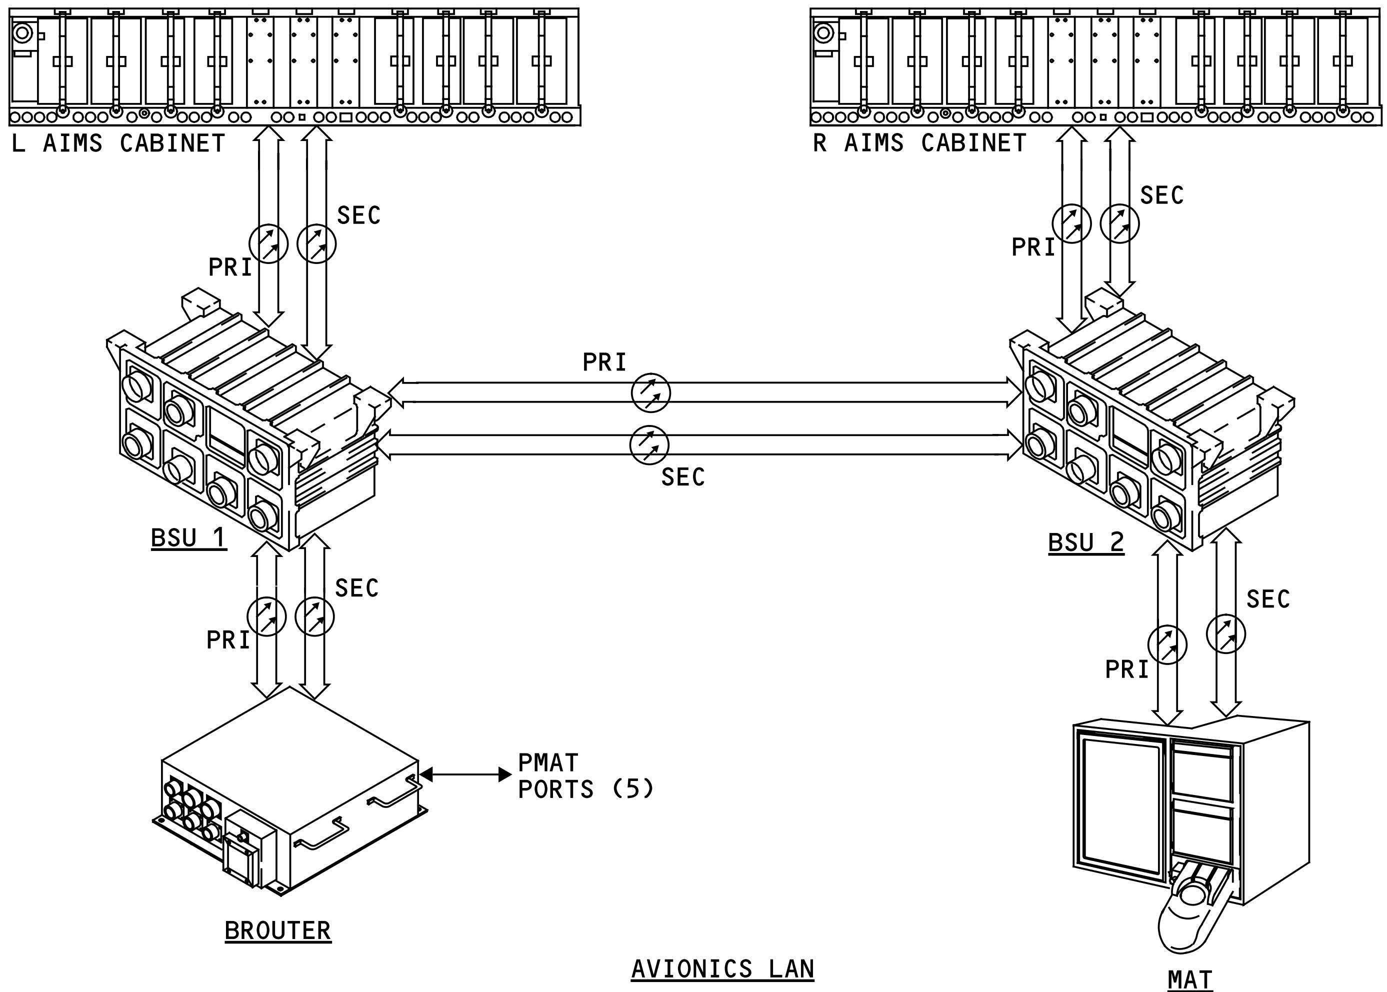
The avionics LAN connects these LRUs:

- Right AIMS cabinet
- Left AIMS cabinet
- Maintenance access terminal (MAT)
- Brouter.

These interfaces permit these functions:

- Data load
- Tests
- Fault isolation.

The avionics LAN connects the portable maintenance access terminals (PMATs) to the AIMS cabinets through the brouter.



AVIONICS LAN

ONBOARD LOCAL AREA NETWORK - GENERAL DESCRIPTION

ONBOARD LOCAL AREA NETWORK - COMPONENT LOCATION 1

General

The brouter and bypass switch unit (BSU) 1 are in the main equipment center on the left side.

BSU 2 is in the main equipment center on the right side.

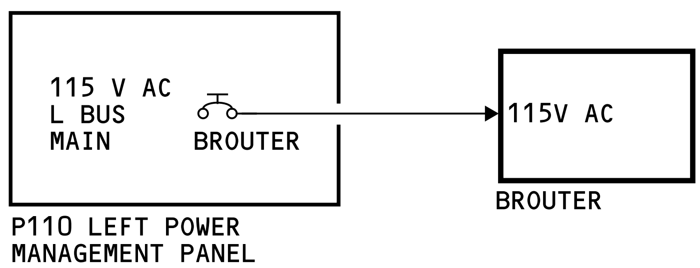
ONBOARD LOCAL AREA NETWORK - COMPONENT LOCATION 1

ONBOARD LOCAL AREA NETWORK - POWER INTERFACE

General

Power for the brouter comes through the P110 left power management panel.



23-94-00-005 Rev 1

ONBOARD LOCAL AREA NETWORK - POWER INTERFACE

ONBOARD LOCAL AREA NETWORK - AVIONICS LAN - INTERFACES

General

The avionics LAN connects these LRUs:

- Left AIMS cabinet
- Right AIMS cabinet
- Brouter
- Maintenance access terminal (MAT).

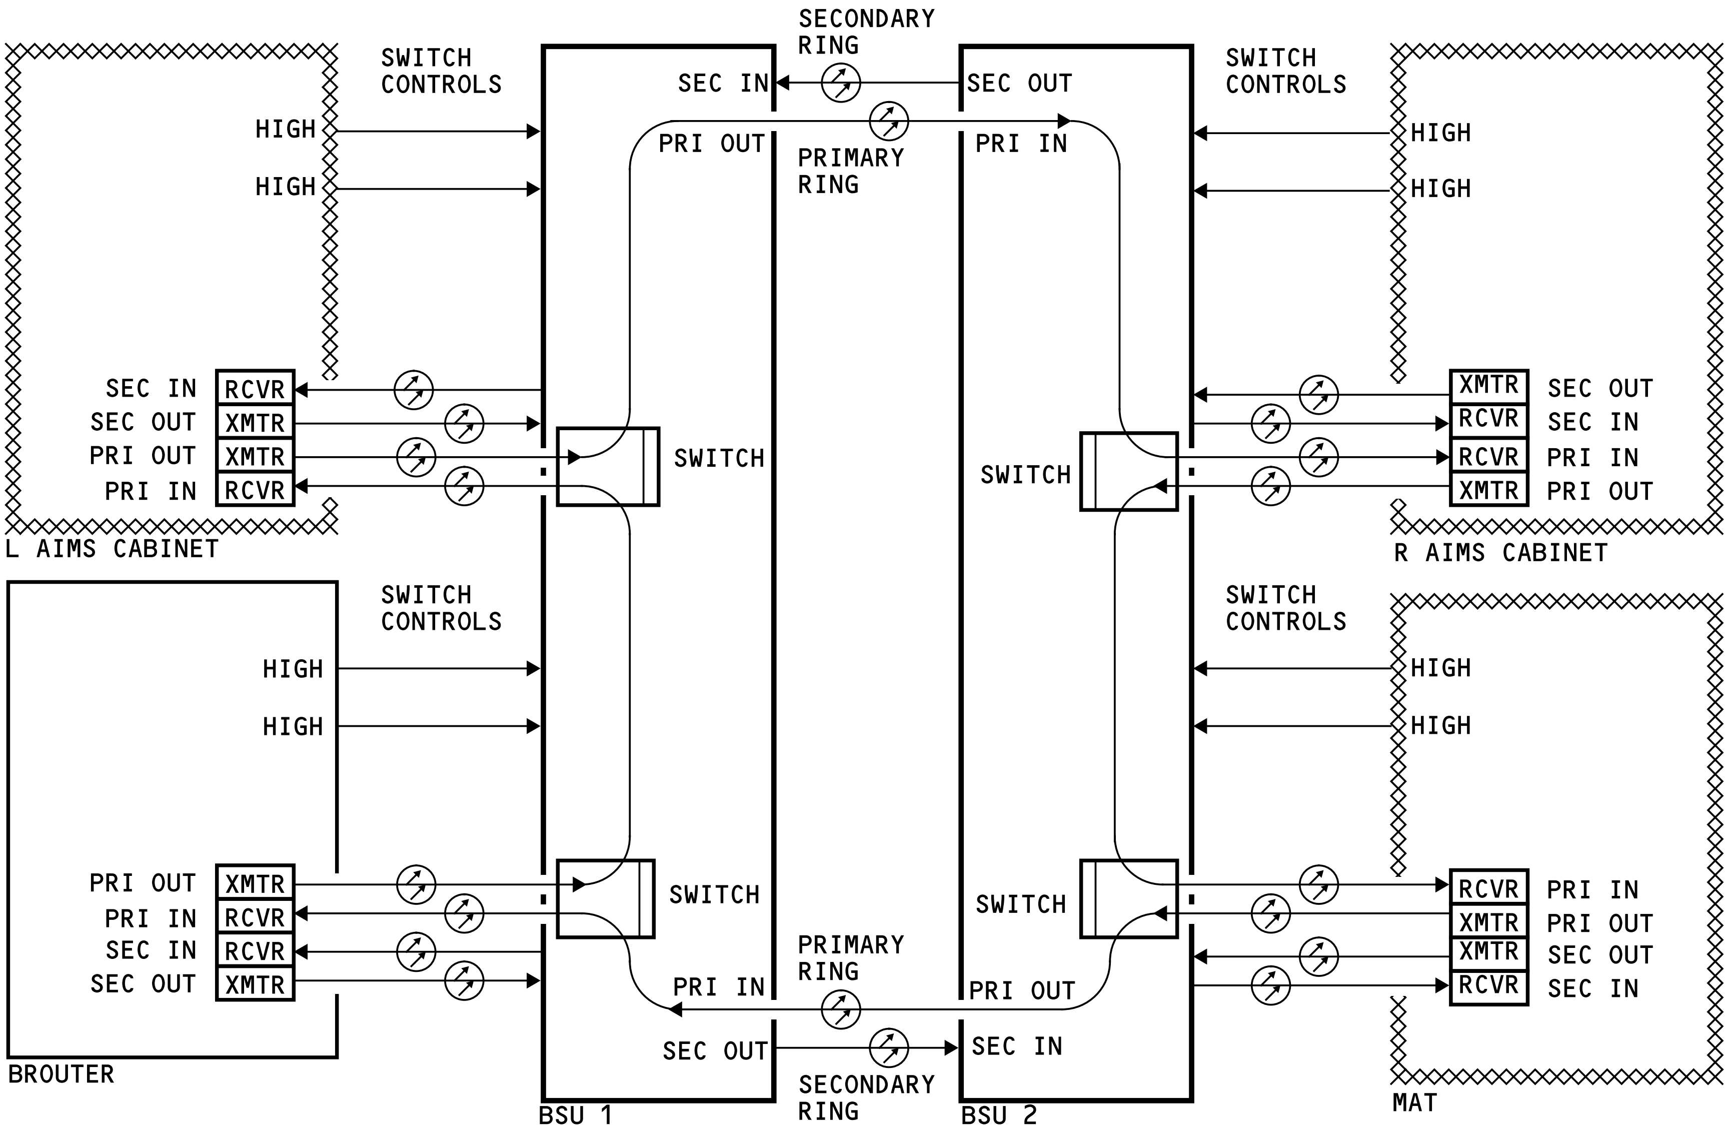
Line Replaceable Unit

Each LRU has two optical receivers and two optical transmitters. The LRUs change electronic data to optical data and transmit it on the primary and secondary rings. They also receive optical data from each ring and change it to electronic data.

Each LRU controls the position of two optical switches in a bypass switch unit (BSU). Electrical return and high signals supply this control.

Bypass Switch Unit

BSUs are the interfaces between the rings of the avionics LAN and the LRUs. Each BSU switch connects a ring to an LRU or bypasses the LRU. Each LRU controls primary and secondary BSU switches at the same time. The example shows the primary ring. The secondary ring operates in the same way.



23-94-00-006 Rev 3 05/30/96

ONBOARD LOCAL AREA NETWORK - AVIONICS LAN - INTERFACES

ONBOARD LOCAL AREA NETWORK - BROUTER

General

The brouter is a local area network (LAN) communication device. It is also a router of data between the avionics LAN components.

The brouter changes data between these formats:

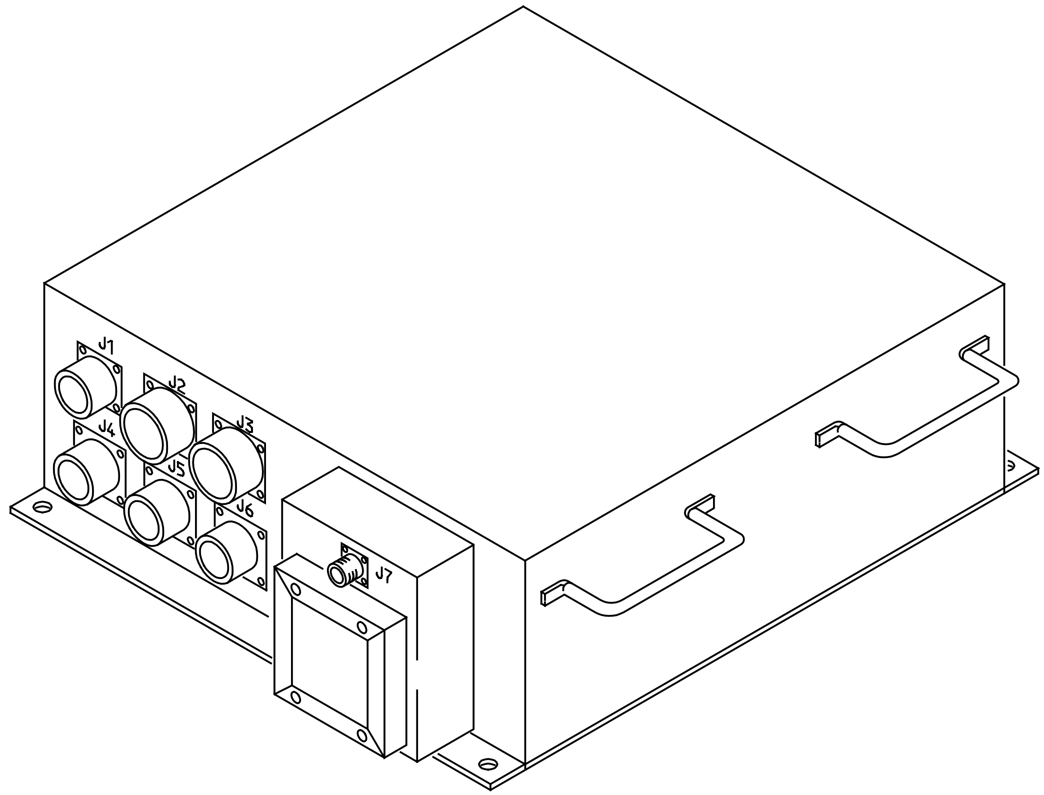
- Fiber optic data
- 10 Base T data.

The brouter sends data to and gets data from the portable maintenance access terminals (PMATs).

Physical Description

The brouter has these physical dimensions:

- Height - 5.5 inches
- Length - 11.6 inches
- Width - 6.2 inches.



23-94-00-008 Rev 1

ONBOARD LOCAL AREA NETWORK - BROUTER

ONBOARD LOCAL AREA NETWORK - BYPASS SWITCH UNIT

General

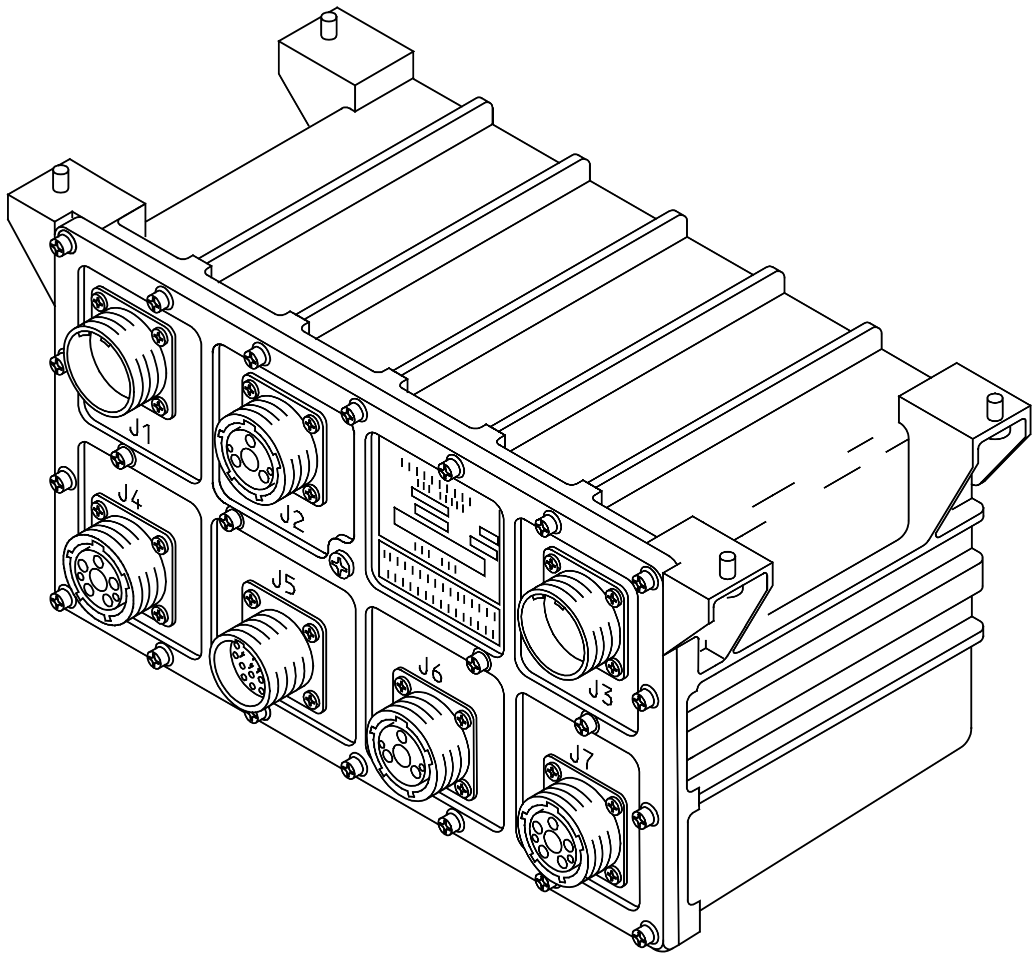
The bypass switch unit (BSU) connects the fiber optic rings to the LRUs. The BSUs receive control signals from the connected LRUs.

Each BSU has one switch for each LRU. Each switch connects an LRU to both fiber optic rings.

Physical Dimensions

The BSU has these properties:

- Length - 6.0 inches
- Width - 11.5 inches
- Height - 5.5 inches.



ONBOARD LOCAL AREA NETWORK - BYPASS SWITCH UNIT

ONBOARD LOCAL AREA NETWORK - FIBER OPTIC CABLE

Fiber Optic Cable Description

Each cable has these items:

- Five optical fibers
- Two filler strands
- Separator tape
- Aramid yarn strength member
- An outer jacket.

The cable is about 0.2 inches in diameter.

Optical Fiber

The optical fiber strands are glass. Each optical fiber strand is .0055 inches (140 microns) in diameter.

A primary and secondary buffer covers each fiber strand. The primary buffer protects the glass fiber during manufacture.

The secondary buffer adds strength and increases the diameter of the fiber. The secondary buffers of the five optical fiber strands are these five colors:

- Blue
- Red
- Green
- Yellow
- White.

The colors permit you to identify the individual fiber strands at each end of the cable.

Each optical fiber strand with its buffers is .035 inches (900 microns) in diameter.

Cables have three or five optical fibers. Cables with three fibers use two more filler strands. The example shows a cable with five optical fiber strands.

Filler Strands

The black filler strands are polyester and are .035 inches in diameter.

Separator Tape

A polyester separator tape covers the group of seven strands. The tape is low-friction polyester. It makes the cable more flexible.

Aramid Yarn

A strength member of woven Aramid (Kevlar) yarn protects the optical fibers from damage.

Outer Jacket

The outer jacket of the cable is purple thermoplastic.

Training Information Point

The optical fiber strands may break if the cable bend radius is less than 1.5 inches.

ONBOARD LOCAL AREA NETWORK - CONNECTORS

General

OLAN uses two types of connectors, a type-A connector and a type-B connector.

The connectors have these parts:

- Alignment keys and grooves
- Guide pins and cavities
- Color bands
- Three start threads.

Alignment Keys and Grooves

Each connector has alignment keys on the plug and alignment grooves on the receptacle. These accurately align the connector optical components.

Guide Pins and Cavities

Guide pins in the plug fit into cavities in the receptacle when the plug and receptacle connect. The pins of the plug touch the bottom of the cavities in the receptacle. You can not over tighten the connector.

Color Bands

The coupling nut on the plug barrel has a yellow band. The receptacle barrel has a red and a yellow band. When the red band on the receptacle is at least 50 percent covered by the coupling nut, this shows a correct connection. With a correct connection, the optical fibers in the plug align end-to-end with the fibers in the receptacle.

Start Threads

Three start threads on the plug and receptacle make sure of a straight start when they join. The recessed receptacle components prevent damage from the plug if it strikes the receptacle at an angle.

The plug and receptacle seal to prevent moisture or dust in the connector.

Type-A Connector

The type-A connector is for production breaks that are not regularly connected and disconnected.

The type-A connector is a multi-channel, in-line (butt-type) connector. This connector has very low light loss between optical fiber components.

The type-A connector has three fiber optic cables or five fiber optic cables.

Type-A Connector/Fiber Optic Interface

The plug and receptacle have ceramic contacts that touch when connected. The light signal goes through holes in the end of the ceramic contacts when they are in direct physical contact with each other.

ONBOARD LOCAL AREA NETWORK - CONNECTORS

Type-B Connector

The type-B connector attaches a fiber optic cable to a line replaceable unit (LRU). The type-B connector is more frequently connected and disconnected than the type-A connector.

The type-B connector is a multi-channel, expanded beam (ball lens) connector. Light loss across this connector is low but not as low as in the type-A connector.

Type-B Connector/Fiber Optic Interface

The connector has miniature ball lenses behind a protective window. Each lens is at the end of a fiber. The ball lenses expand and focus the light signal from the fiber. The light goes through the protective windows of the plug and receptacle to another ball lens. This ball lens narrows the light and sends it into a fiber.

Training Information Point

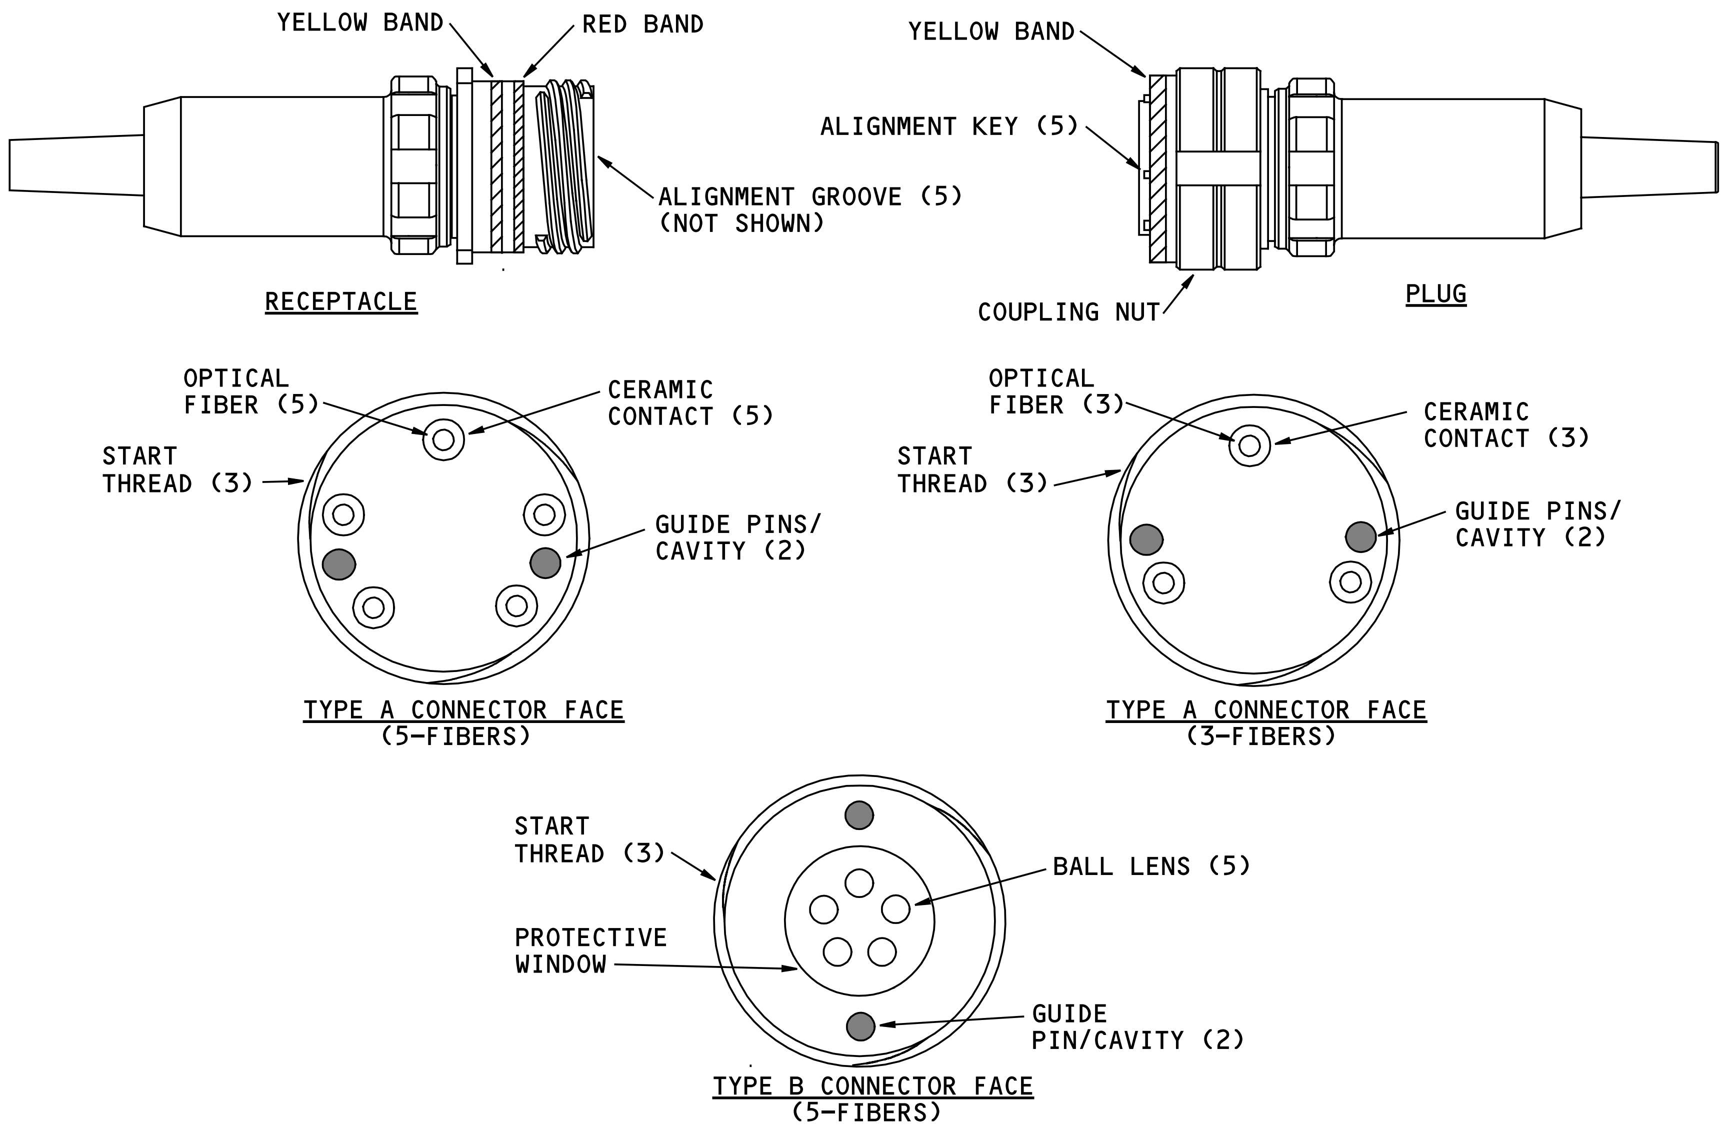
This training information point refers to both the type-A and type-B connectors.

WARNING: BEFORE YOU EXAMINE THE CONNECTOR FACE OR THE CERAMIC CONTACTS, DISCONNECT THE CABLE FROM THE EQUIPMENT AT BOTH ENDS OR SET THE EQUIPMENT TO OFF. THE LIGHT FROM THE OPTICAL FIBER THAT ATTACHES TO THE AVIONICS EQUIPMENT IS INVISIBLE AND CAN BE INTENSE ENOUGH TO CAUSE DAMAGE TO YOUR EYES.

Before you install a connector, examine it to make sure it is clean.

Use only approved procedures to clean the connectors and the fiber optic lenses.

Do not disconnect the connectors unless absolutely necessary.



23-94-00-011 Rev 2

ONBOARD LOCAL AREA NETWORK - CONNECTORS

THIS PAGE INTENTIONALLY LEFT BLANK

ONBOARD LOCAL AREA NETWORK - BROUTER - FUNCTIONAL DESCRIPTION

General

The brouter gets fiber optic signals from the LRUs in the avionics local area network (LAN). It also sends fiber optic signals to these LRUs. The brouter controls the routing of the signals through the avionics LAN.

Brouter Circuits

The brouter has these circuits:

- Bypass switch controller
- Fiber optic interface
- Router processor
- Ethernet control unit
- 10 Base T processors 1 and 2
- 10 Base T interfaces.

Bypass Switch Controller

The bypass switch controller uses bypass switch unit (BSU) control signals to control the BSU internal switches. The router processor sends control signals to the bypass switch controller.

The BSU control signals are:

- PRI HI
- PRI RTN
- SEC HI
- SEC RTN

A logic high on PRI HI or SEC HI connects the BSU to the fiber optic ring. A logic low on PRI HI or SEC HI disconnects the BSU from the fiber optic ring. The PRI RTN and SEC RTN control signals are grounds to the BSU switch relays.

Fiber Optic Interface

The fiber optic interface changes BSU fiber optic signals to electronic signals and electronic signals to BSU fiber optic signals. The router processor controls the fiber optic interface.

Router Processor

The router processor uses internal brouter buses to control all operations of the brouter.

Ethernet Control Unit

The Ethernet control unit controls the 10 base T processors 1 and 2.

The Ethernet control unit sends signals between these circuits:

- Router processor
- 10 Base T processors 1 and 2.

10 Base T Processors 1 and 2

The 10 base T processors control the 10 base T interfaces. They also sends and receive data from the

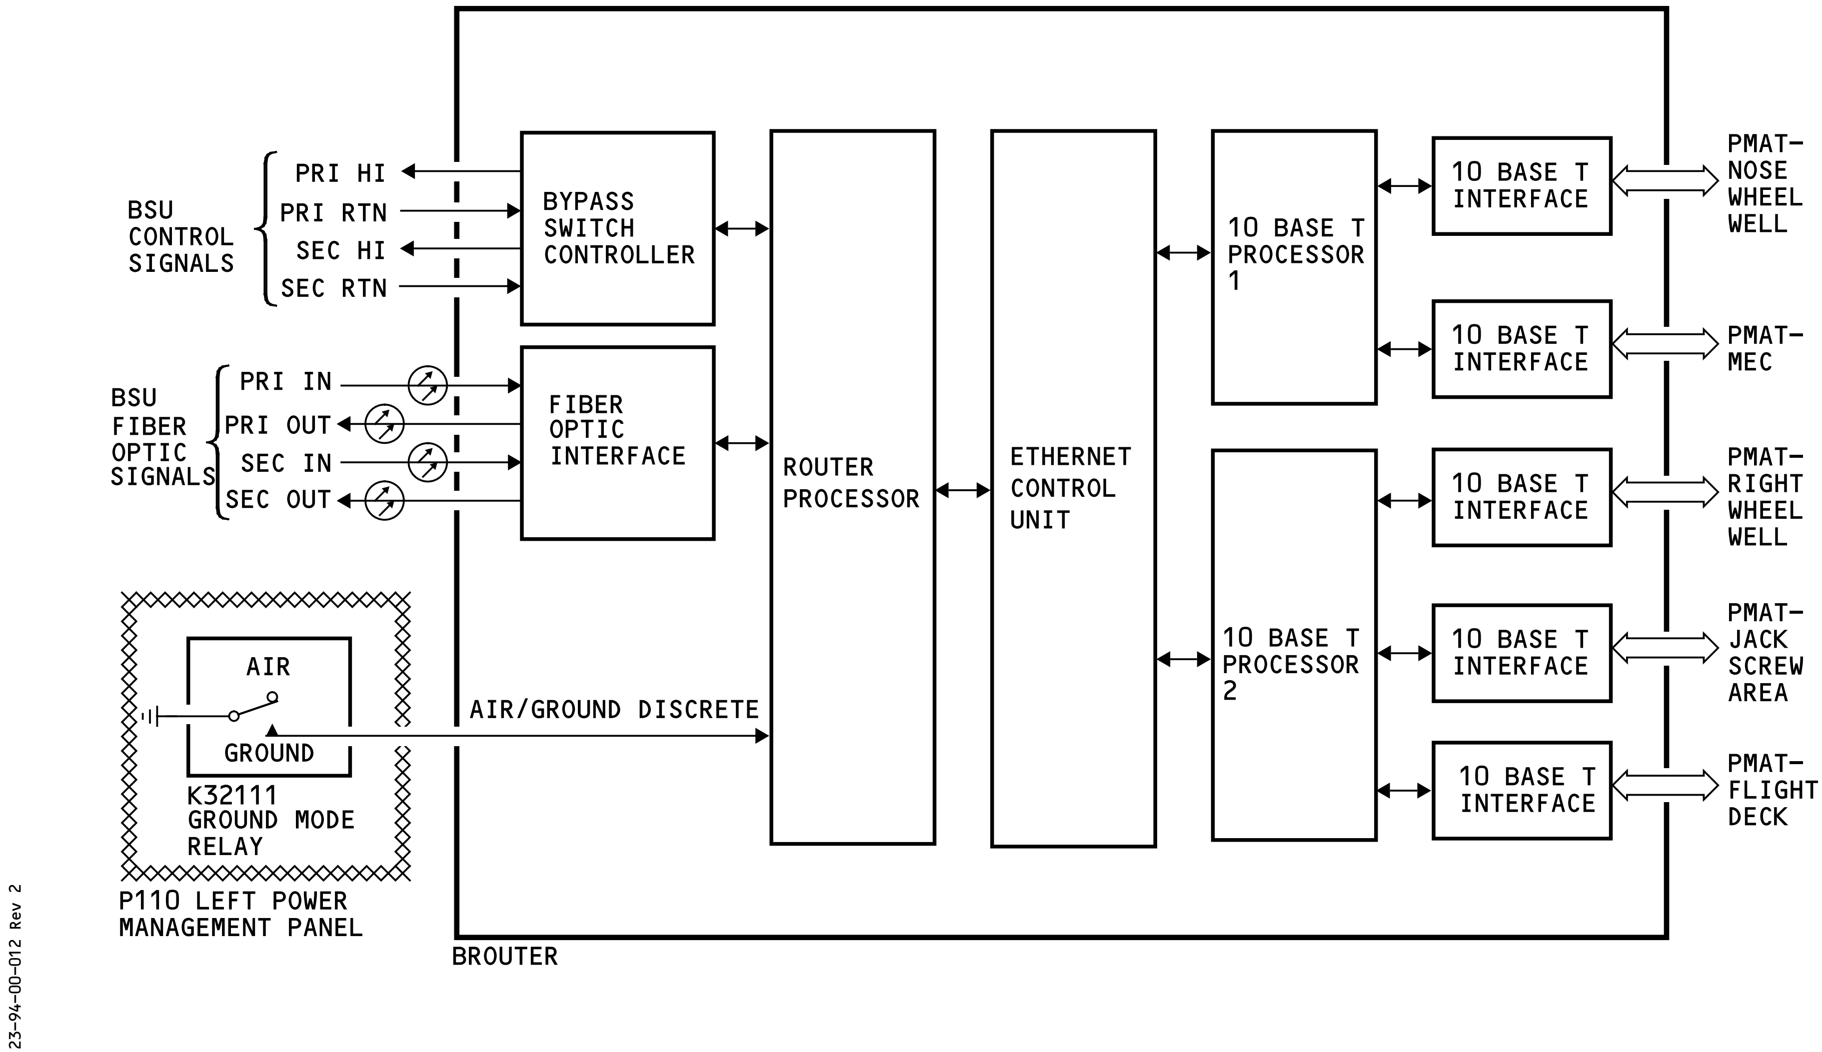
Ethernet control unit. The processors connect the portable maintenance access terminal (PMAT) ports to the Ethernet control unit.

10 Base T Interfaces

The brouter has a 10 base T interface with the PMAT ports to send and get MAT data. The 10 base T interfaces connect with the 10 base T processors 1 and 2.

Air/Ground Discrete

The ground mode relay in the P110 left power management panel sends an air/ground discrete to the brouter. In the air, an open signal from this relay goes to the brouter. This inhibits data loads and manually initiated tests of LRUs.



ONBOARD LOCAL AREA NETWORK - BROUTER - FUNCTIONAL DESCRIPTION

ONBOARD LOCAL AREA NETWORK - BYPASS SWITCH UNIT - FUNCTIONAL DESCRIPTION

General

The bypass switch units (BSUs) connect the primary and secondary rings with the LRUs. None of the components inside the BSU are line replaceable.

Switch Control

Each LRU controls one switch in a BSU. The switch connects the LRU to the primary and secondary rings. The logic high and return for each switch comes from the LRU.

Each BSU switch contains two mirrors and two solenoids. A logic high signal from an LRU causes both solenoids to energize. This moves the mirrors to the ring-connect position. The mirrors move to the bypass position when the LRU de-energizes the solenoids.

Ring-connect Position

In the ring-connect position, each mirror sends the light from its ring into the LRU. The LRU re-transmits the light back to the BSU. The mirrors send the light to the next switch or to the next BSU.

Bypass Position

In the bypass position, the mirrors reflect light from the LRU back to the LRU. Light from the rings passes through the switch and goes to the next switch or to the next BSU.

LRU Pre-connect Test

Before an LRU transmits data to the rings, it runs a pre-connect test. The LRU commands the BSU switch to the bypass position and transmits test data. The BSU returns the data. If the returned data is good, the LRU commands the BSU switch to the ring-connect position. All LRUs do this pre-connect test before they transmit on a ring.

SYSTEMS CARD FILES - INTRODUCTION

31-09-00-001 Rev 2 09/21/95

SYSTEMS CARD FILES - GENERAL DESCRIPTION

General

The systems card files hold cards for ARINC 429 systems. These cards calculate data for their systems.

Data moves between the cards in the card files and the left and right ARINC 629 systems buses. Two ARINC signal gateway (ASG) cards in each card file supply the interface to and from the 629 data buses.

Components

There are two systems card files in the airplane, left and right. The system card files contain:

- Power supply cards (4 in each)
- ARINC signal gateway (ASG) cards (2 in each)
- ARINC 429 system cards (8 in Left)
- ARINC 429 system cards (9 in Right).

Interfaces

The eight ARINC 429 cards in the left system card file (LSCF) connect to their systems and to the ASG cards. The forward cargo smoke detector connects directly to the ASG cards in the LSCF.

The nine ARINC 429 cards in the right system card file (RSCF) connect to their systems and to the ASG cards. The aft cargo smoke detector connects directly to the ASG cards in the RSCF.

The left and right ASG cards in each card file connect to the left and right systems ARINC 629 buses.

SYSTEMS CARD FILES - POWER INTERFACES

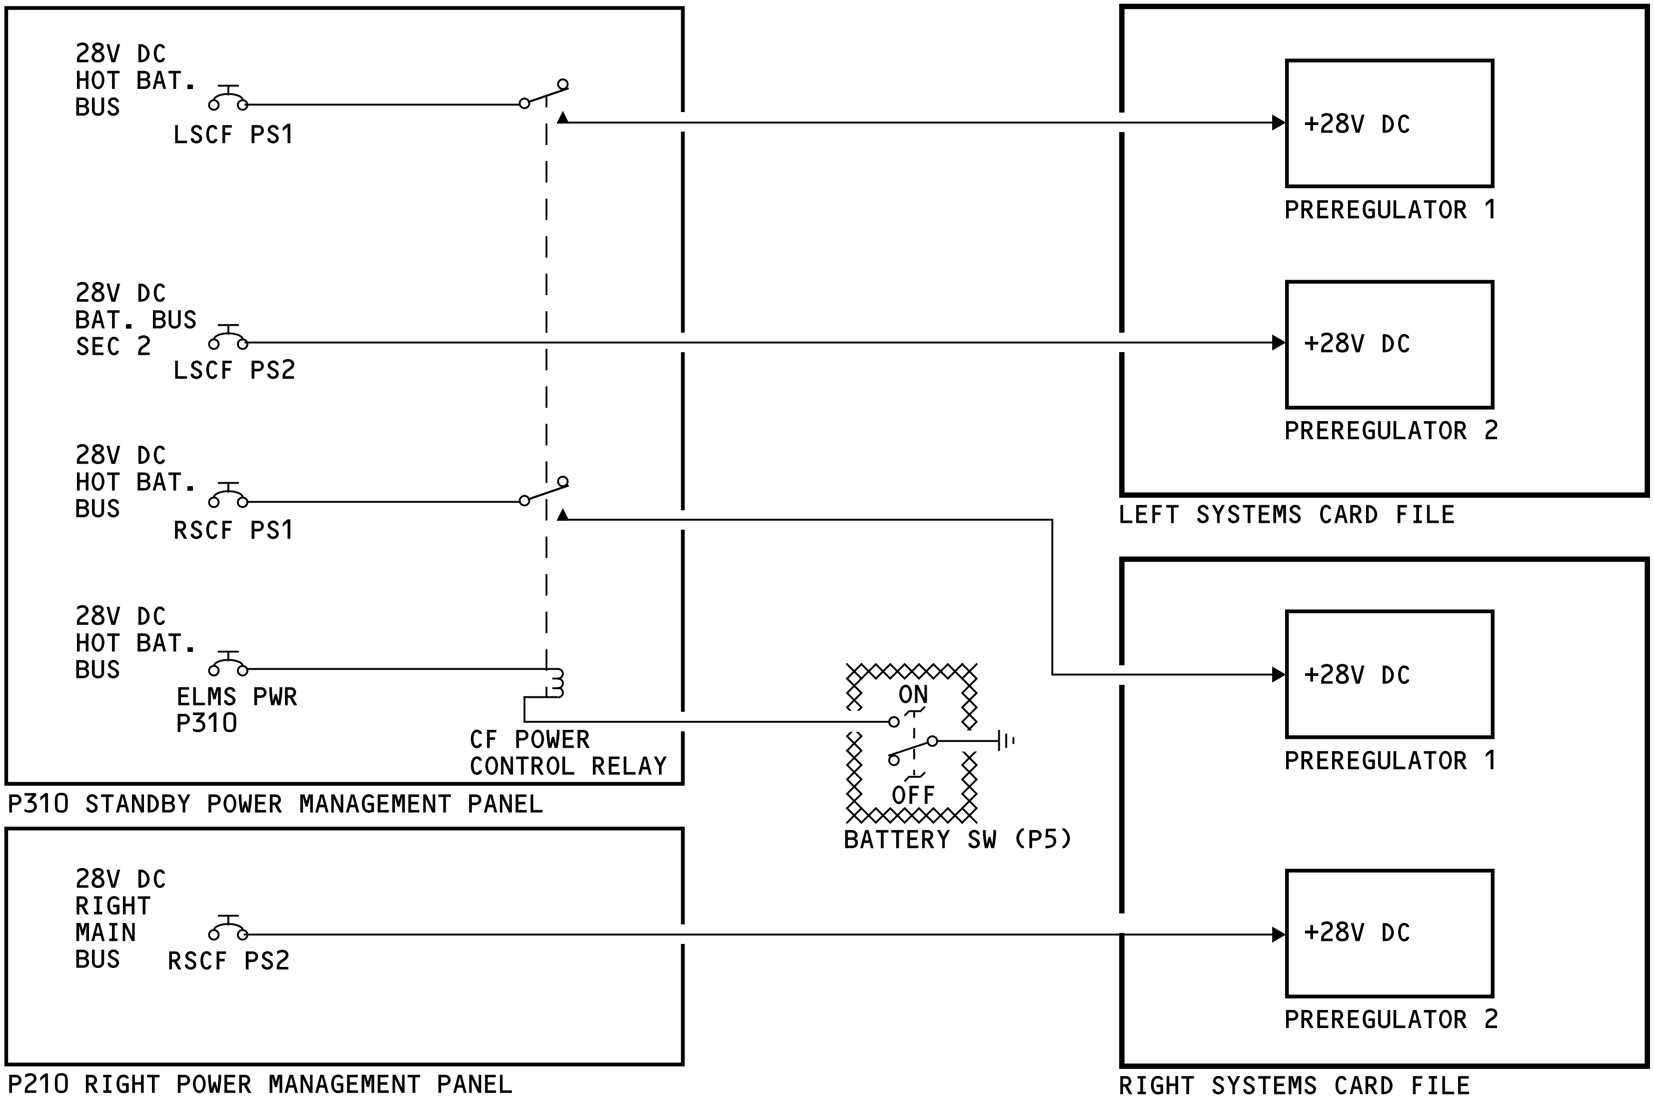
General

The LSCF PS1 circuit breaker in the P310 standby power management panel connects 28v dc to the preregulator 1 card in the LSCF. The LSCF PS2 circuit breaker connects 28v dc to the preregulator 2 card in the LSCF.

The RSCF PS1 circuit breaker in the P310 standby power management panel connects 28v dc to the preregulator 1 card in the RSCF.

The RSCF PS2 circuit breaker in the P210 left power management panel connects 28v dc to the preregulator 2 card in the RSCF.

The battery switch controls the 28v dc that goes to the PS1 power supplies in the left and right system card files.



31-09-00-006 Rev 2

SYSTEMS CARD FILES - POWER INTERFACES

SYSTEMS CARD FILES - LSCF POWER INTERFACES

General

The left system card file (LSCF) has two power supplies. Each power supply has these two cards:

- Preregulator
- linear monitor.

Preregulator Cards

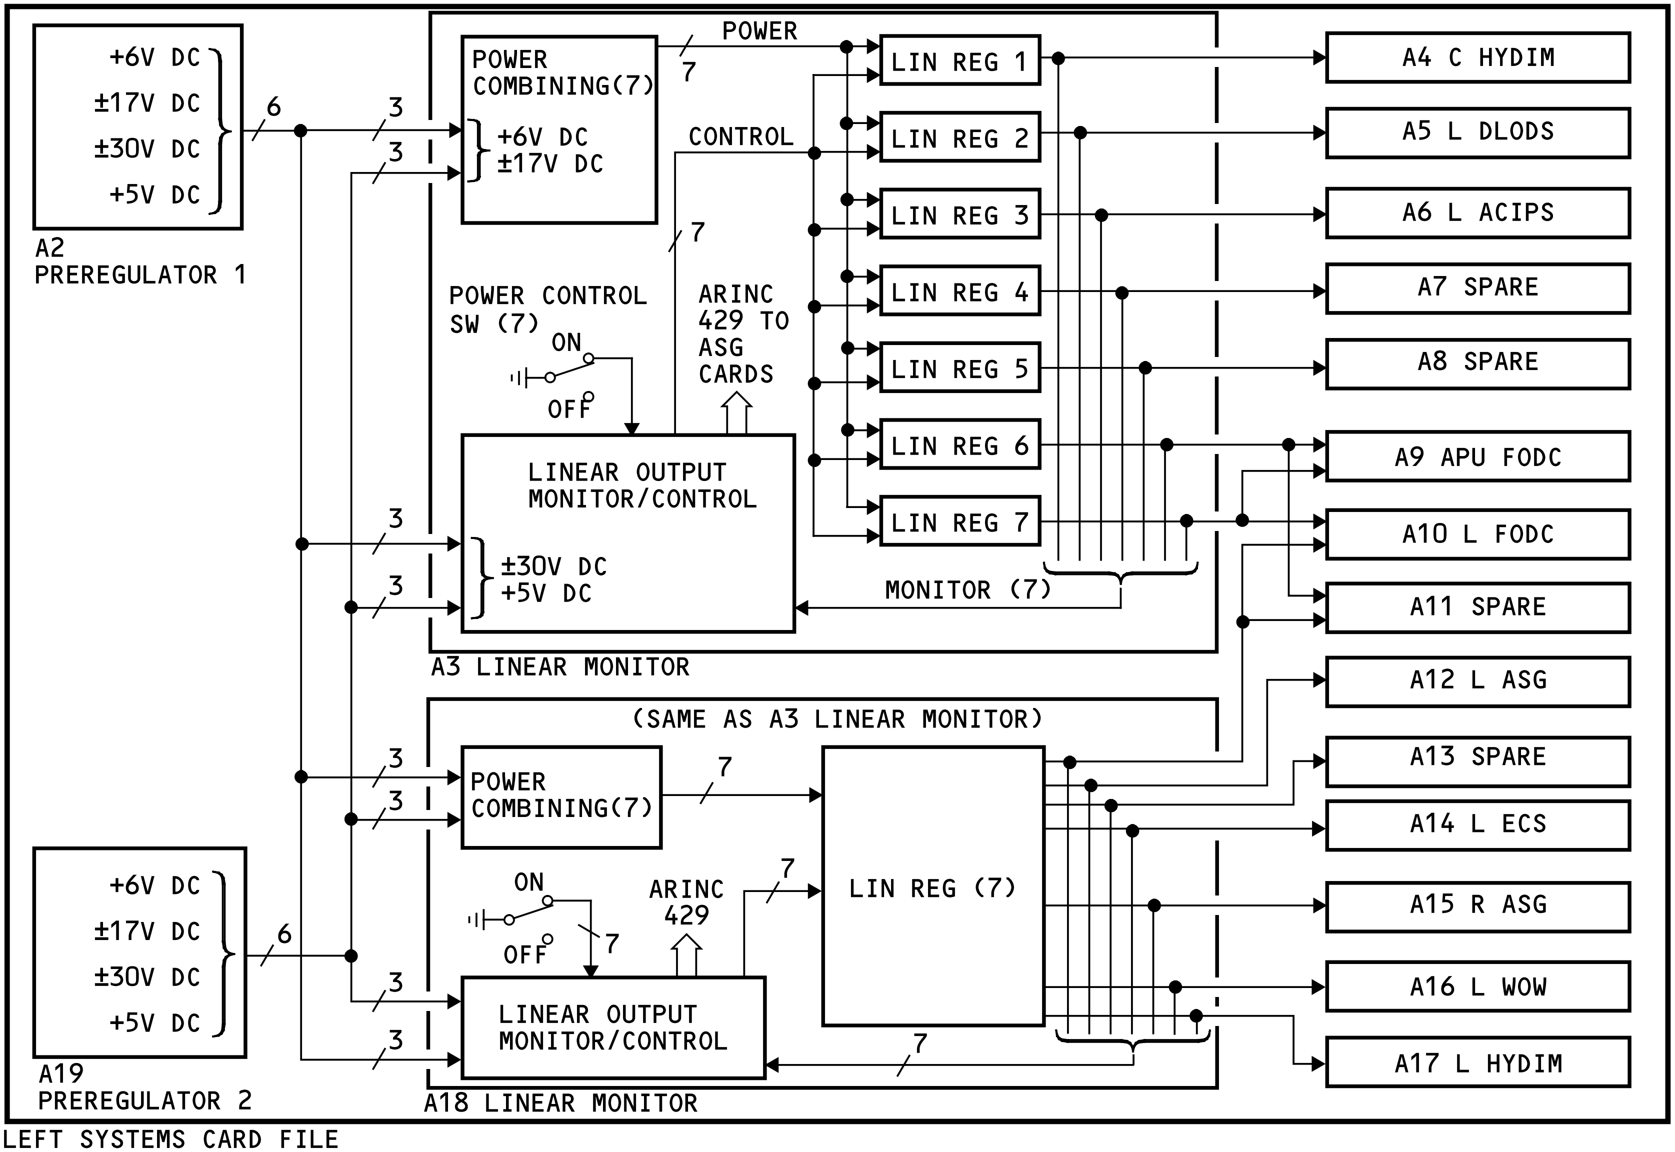
Each preregulator card supplies power to both linear monitor cards. Both linear monitor cards use the power from the preregulator 2 card. Preregulator 1 supplies backup power.

Linear Monitor Cards

Each linear monitor card sends power to seven linear regulators. The linear regulators are isolated from each other and send power to each member system card. The APU and left fire and overheat detection cards (FODC) receive two power inputs each.

The linear output monitor/control monitors the input and output power of the linear monitor. It sends power supply status to the ARINC signal gateway cards (ASG) on an ARINC 429 bus.

The linear output monitor/control also receives inputs from the power control switches. These switch inputs cause the linear regulators to be on or off.



SYSTEMS CARD FILES - LSCF POWER INTERFACES

31-09-00-007 Rev 2

SYSTEMS CARD FILES - RSCF POWER INTERFACES

General

The right system card file (RSCF) has two power supplies. Each power supply has these two cards:

- Preregulator
- linear monitor.

Preregulator Cards

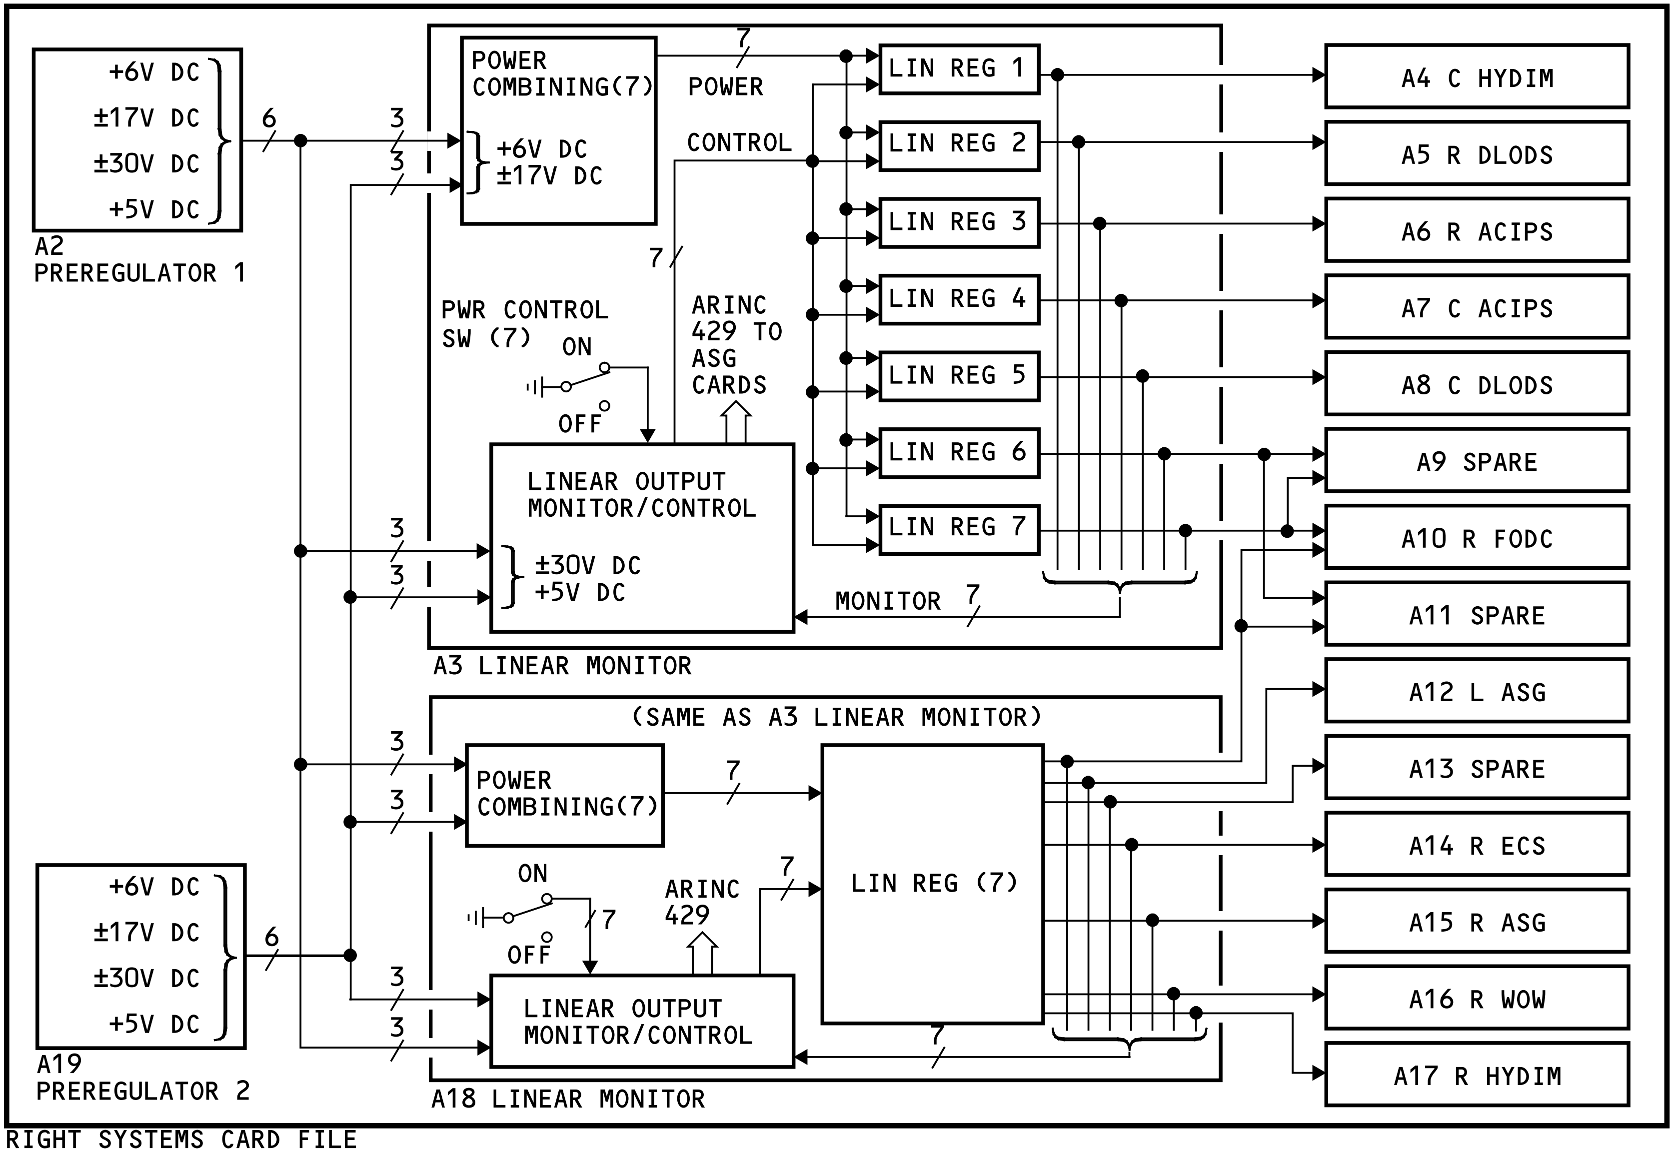
Each preregulator card supplies power to both linear monitor cards. Both linear monitor cards use the power from the preregulator 2 card. Preregulator 1 supplies backup power.

Linear Monitor Cards

Each linear monitor card sends power to seven linear regulators. The linear regulators are isolated from each other and send power to each member system card. The right fire and overheat detection card (FODC) receives two power inputs.

The linear output monitor/control monitors the input and output power of the linear monitor. It sends power supply status to the ARINC signal gateway cards (ASG) on an ARINC 429 bus.

The linear output monitor/control also receives switch inputs from the card file front panel. These switch inputs cause the linear regulators to be on or off.



SYSTEMS CARD FILES - RSCF POWER INTERFACES

SYSTEMS CARD FILES - ARINC 429 AND 629 INTERFACES

General

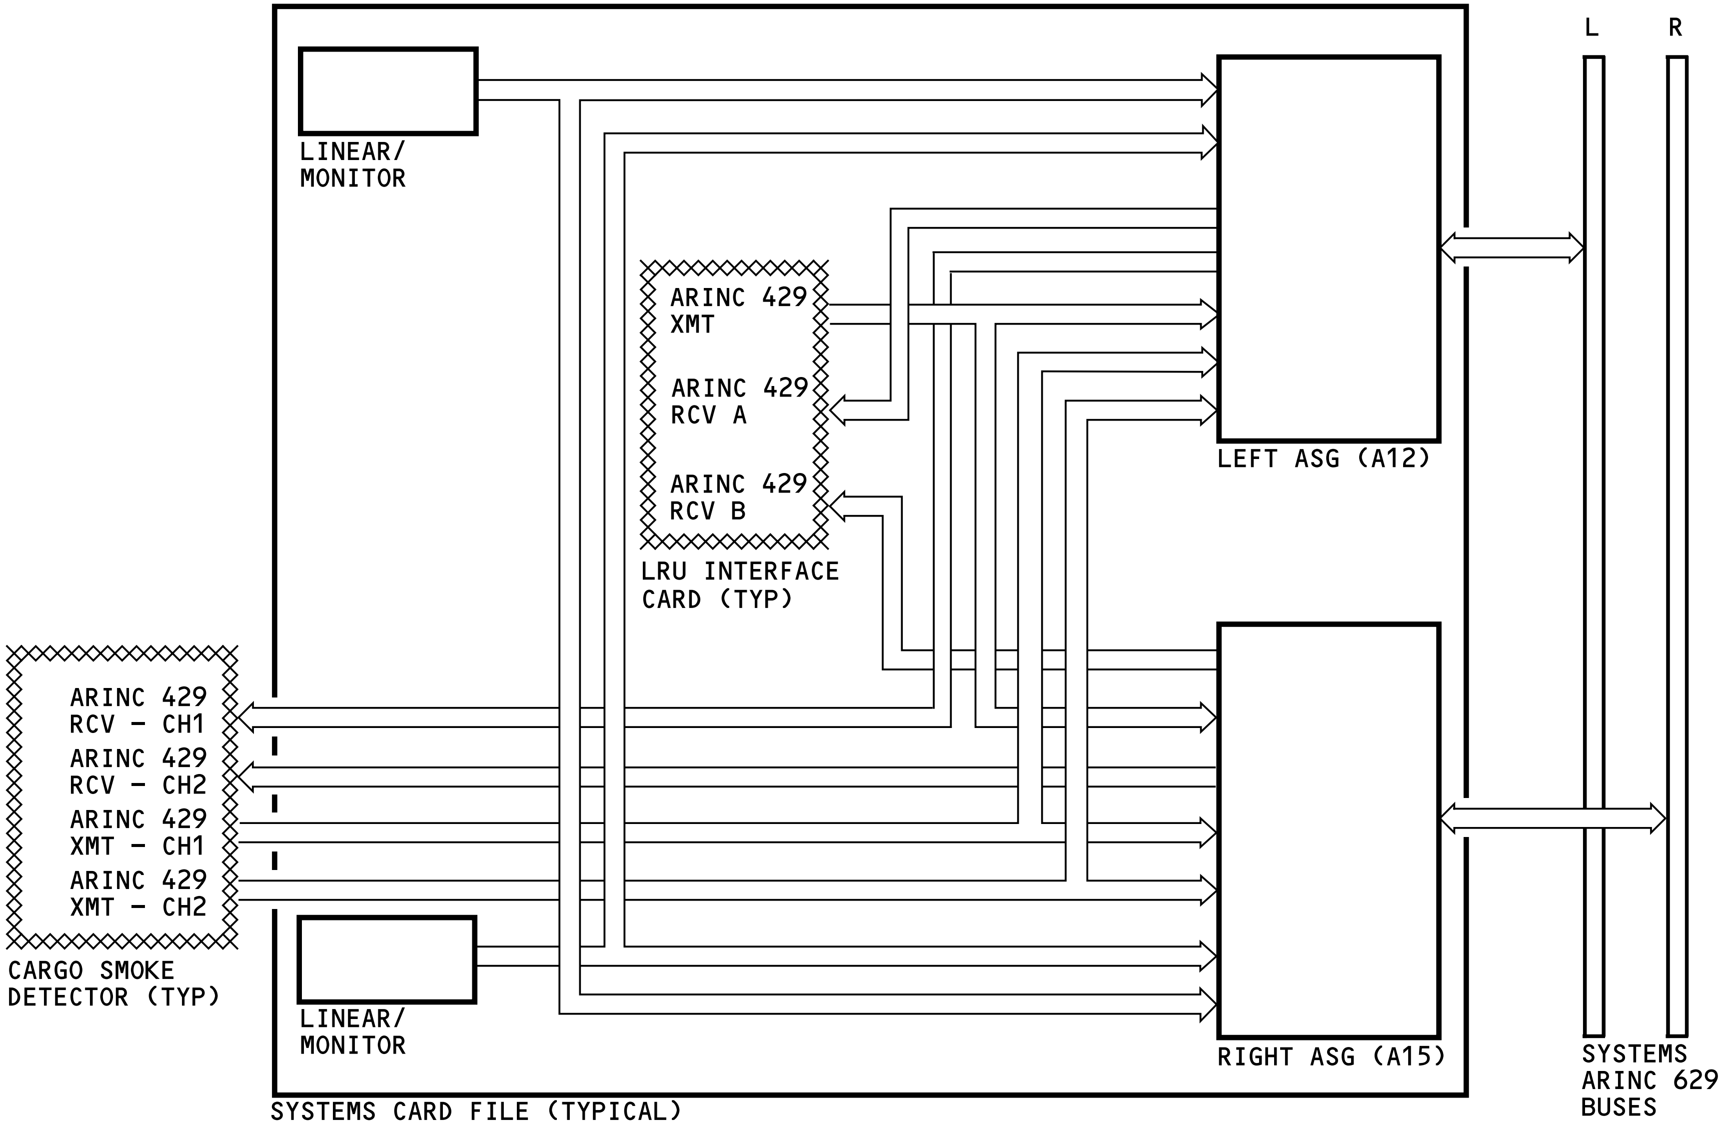
The interface cards in the system card files interface with their systems. They send and receive this type of information:

- ARINC 429 digital data
- Analog
- Analog discretes.

The interface cards also interface with other airplane systems. They send ARINC 429 data to and receive ARINC 429 data from the ASG cards.

The cargo smoke detectors also interface with other airplane systems. They send ARINC 429 data to and receive ARINC 429 data from the ASG cards. The cargo smoke detectors are not located in the system card files.

The ASG cards convert ARINC 429 data to ARINC 629 data and send it to the left and right systems ARINC 629 buses. They also receive ARINC 629 data from the left and right systems ARINC 629 buses. They convert this data to ARINC 429 data and send it to the interface cards and the cargo smoke detectors.



SYSTEMS CARD FILES - ARINC 429 AND 629 INTERFACES

SYSTEMS CARD FILES

Purpose

The left systems card file (LSCF) and right systems card file (RSCF) hold interface cards for the member systems LRUs. Each systems card file gives ARINC 429/629 and ARINC 629/429 communications and power supply connections.

Physical Description

The systems card files chassis have machined and sheetmetal parts.

A typical card file has these dimensions:

- Length 26.4 inches
- Height 17.85 inches
- Width 13.6 inches

Maximum weight of the systems cardfile chassis is 40 pounds.

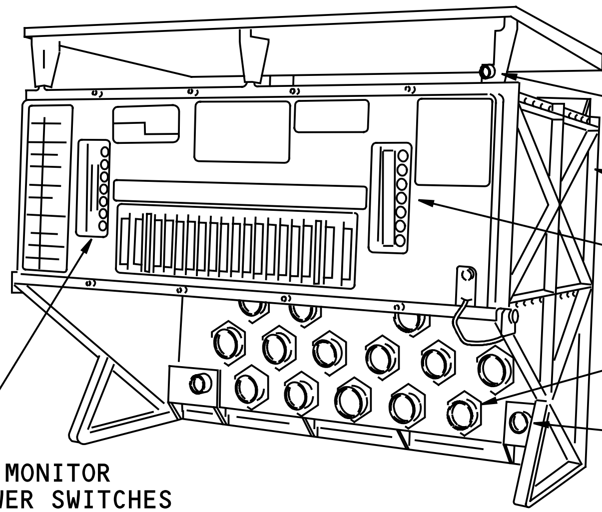
There are eighteen positions for interface cards in each of the two systems card files. Centralized power takes four of these positions in each systems card file.

The power switches on the A3 and A18 linear/monitor cards extend through the card file cover.

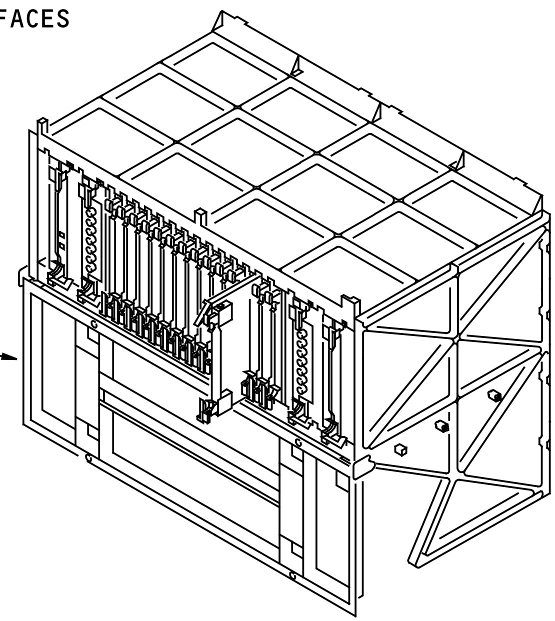
Training Information Point

The RSCF chassis is the same as the LSCF chassis except that it holds right airplane electrical systems or one channel of a dual redundant system. The RSCF chassis has a different part number than the LSCF chassis and different member system LRU slot assignments.

There is an ESDS jack located above each systems card file chassis.



SYSTEMS CARD FILE (TYPICAL)



SYSTEMS CARD FILE WITH COVER OPEN (TYPICAL)

31-09-00-008 Rev 2 09/21/95

SYSTEMS CARD FILES

SYSTEMS CARD FILES - ASG CARDS

Purpose

ARINC 629 signal gateway (ASG) cards change data format between ARINC 429 and ARINC 629. The ASG cards move data between the LRU interface cards in the left and right systems card files and the left and right systems ARINC 629 buses. The ASG cards also move data between the forward and aft cargo smoke detectors and the left and right systems ARINC 629 buses.

Physical Description

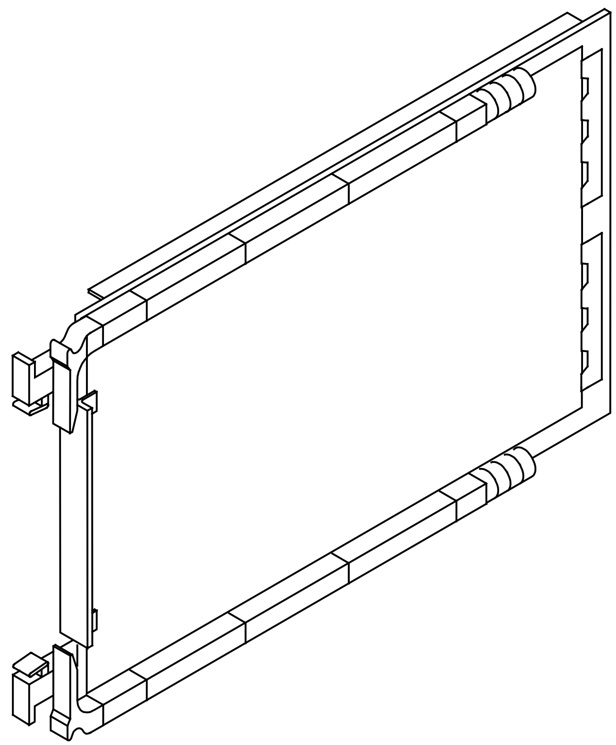
A typical card has these dimensions:

- Length 12 inches
- Height 7.43 inches
- Width 0.6 inch maximum with component protrusion

Maximum weight 1.9 pounds.

Training Information Point

The ASG cards are interchangeable.



ARINC 629 SIGNAL GATEWAY (ASG) CARD (TYPICAL)

31-09-00-009 Rev 1

SYSTEMS CARD FILES - ASG CARDS

SYSTEMS CARD FILES - ASG CARD FUNCTIONAL DESCRIPTION

General

An ARINC 629 signal gateway (ASG) card changes ARINC 429 data from LRU interface cards and cargo smoke detectors to ARINC 629 data. It sends this data to an ARINC 629 system bus.

The ASG card also gets data from an ARINC 629 system bus. It changes this data to ARINC 429 data and sends it to LRU interface cards and cargo smoke detectors.

Each ARINC 629 signal gateway (ASG) card has these components:

- ARINC 429 receiver
- ARINC 429 to ARINC 629 converter
- ARINC 629 terminal
- ARINC 629 to ARINC 429 converter
- ARINC 429 transmitter.

ARINC 429 Receiver

The ASG card receives ARINC 429 data at the ARINC 429 receiver from the LRU interface cards in the systems card files and the forward and aft cargo smoke detectors.

ARINC 429 to ARINC 629 Converter

The ARINC 429 to ARINC 629 converter in an ASG card changes the data from ARINC 429 to ARINC 629 format.

ARINC 629 Terminal

The ARINC 629 terminal transmits the data to an ARINC 629 systems bus.

The ARINC 629 terminal receives data from an ARINC 629 systems bus.

ARINC 629 to ARINC 429 Converter

The ARINC 629 to ARINC 429 converter changes the data from the ARINC 629 systems bus to ARINC 429.

ARINC 429 Transmitter

The ARINC 429 transmitter sends the data to the LRU interface cards in the systems card files and the forward and aft smoke detectors.

AIRPLANE INFORMATION MANAGEMENT SYSTEM - INTRODUCTION

Purpose

The airplane information management system (AIMS) collects and calculates large quantities of data. The AIMS manages this data for several integrated avionics systems. These systems are the:

- Primary display system (PDS)
- Central maintenance computing system (CMCS)
- Airplane condition monitoring system (ACMS)
- Flight data recorder system (FDRS)
- Data communication management system (DCMS)
- Flight management computing system (FMCS)
- Thrust management computing system (TMCS).

The AIMS has software functions that do the calculation for each of these avionics systems.

The AIMS supplies one other software function that many airplane systems use. It is the data conversion gateway function (DCGF).

Abbreviations and Acronyms

ACARS	- aircraft communications addressing and reporting system
ACE	- actuator control electronics
ACMF	- airplane condition monitoring function
ACMS	- airplane condition monitoring system
ADF	- automatic direction finder
ADIRS	- air data inertial reference system
ADIRU	- air data inertial reference unit
ADM	- air data module
AFDC	- autopilot flight director computer
AFDS	- autopilot flight director system
AIMS	- airplane information management system
ALDB	- airline loadable database
AMI	- airline modifiable information
AMU	- audio management unit

AIRPLANE INFORMATION MANAGEMENT SYSTEM - INTRODUCTION

AIMS - GENERAL DESCRIPTION - 1

AIMS Cabinets

The AIMS has two cabinets which do the calculations for other avionic systems. To do these calculations, each AIMS cabinet has these:

- A cabinet chassis
- Four Input/output modules (IOM)
- Four Core processor modules (CPM).

The IOMs and the CPMs are in the cabinet chassis. The chassis also has a backplane data bus and a backplane power bus to distribute data and power to the IOMs and CPMs.

The input/output module (IOM) transfers data between the software functions in the AIMS CPMs and external signal sources.

The CPMs supply the software and hardware to do the calculations for several avionic systems. The software is called functions. To keep a necessary separation between the functions, each function is partitioned. The partitions permit multiple functions to use the same hardware and be in the same CPM.

These are the four types of CPMs:

- CPM/Communication (CPM/Comm)
- CPM/Airplane condition monitoring function (CPM/ACMF) (left AIMS cabinet only)
- CPM/Basic (right AIMS cabinet only)
- CPM/Graphics generator (CPM/GG).

CPM Functions

These are the software functions in the CPM/Comm:

- Data conversion gateway function (DCGF)
- Central maintenance computing function (CMCF)
- Data communication management function (DCMF)
- Flight deck communication function (FDCF)
- Quick access recorder function (QARF)
- Digital flight data acquisition function (DFDAF).

These are the software functions in the CPM/ACMF:

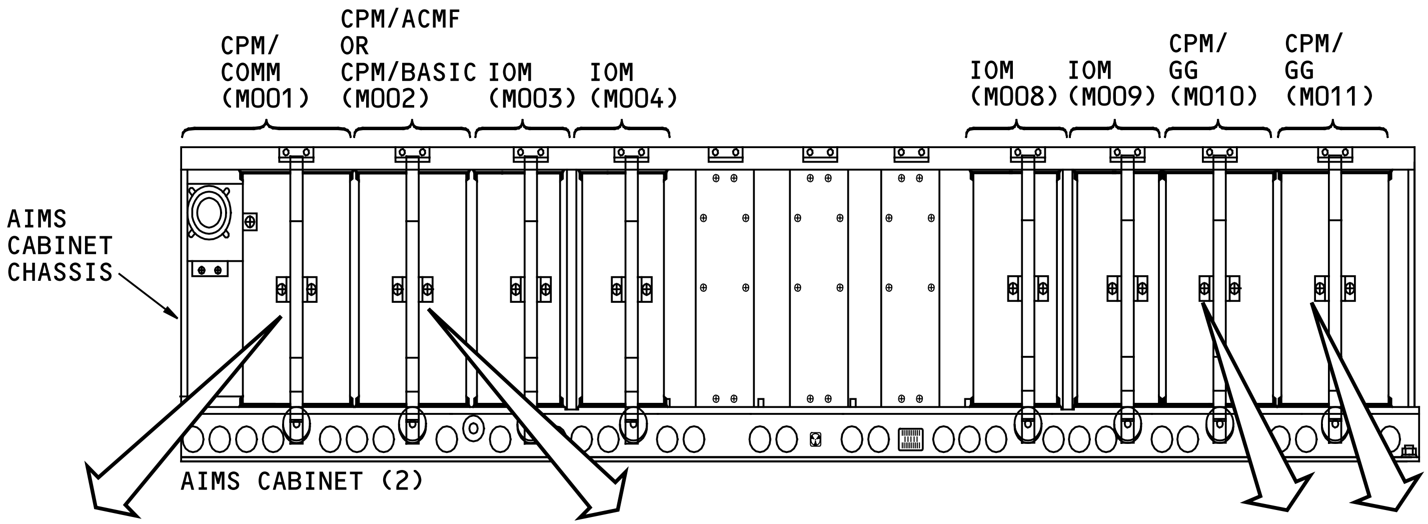
- Data conversion gateway function (DCGF)
- Flight management computing function (FMCF)
- Thrust management computing function (TMCF)
- Airplane condition monitoring function (ACMF).

These are the software functions in the CPM/Basic:

- Data conversion gateway function (DCGF)
- Flight management computing function (FMCF)
- Thrust management computing function (TMCF).

These are the software functions in the CPM/GG:

- Data conversion gateway function (DCGF)
- Primary display function (PDF).



- DATA CONVERSION GATEWAY FUNCTION

AIMS - GENERAL DESCRIPTION - 2

Avionics Systems Supported by AIMS

The AIMS cabinets do the calculations for several avionic systems. Because the cabinets do the calculations for these systems the systems are considered to be integrated. The systems are:

- Primary display system (PDS)
- Central maintenance computing system (CMCS)
- Airplane condition monitoring system (ACMS)
- Digital flight data recorder system (DFDRS)
- Data communication management system (DCMS)
- Flight management computing system (FMCS)
- Thrust management computing system (TMCS).

The system includes the software function in the AIMS cabinets plus their components that have an interface.

Primary Display System

The components of the primary display system are:

- Primary display function (PDF)
- Display unit (DU) (6)
- Display select panel (DSP)
- Cursor control device (CCD) (2)
- Captain display switching panel
- First officer display switching panel
- Center display control panel
- Instrument source select panel (2)
- EFIS control panel (EFIS CP) (2)
- Remote light sensor (RLS) (2).

Central Maintenance Computing System

These are the components of the central maintenance computing system:

- Central maintenance computing function (CMCF)
- Maintenance access terminal (MAT)
- Portable maintenance access terminal (PMAT).

Airplane Condition Monitoring System

These are the components of the airplane condition monitoring system:

- Airplane condition monitoring function (ACMF)
- Quick access recorder function (QARF).

Flight Data Recorder System

These are the components of the flight data recorder system:

- Digital flight data acquisition function (DFDAF)
- Flight data recorder (FDR).

Data Communication Management System

These are the components of the data communication management system:

- Data communication management function (DCMF)
- Flight deck communication function (FDCF)
- Accept/Cancel/Reject switches (2).

AIMS - GENERAL DESCRIPTION - 2

Flight Management Computing System

These are the components of the flight management computing system:

- Flight management computing function (FMCF)
- Control display unit (CDU) (3).

Thrust Management Computing System

These are the components of the thrust management computing system:

- Thrust management computing function (TMCF)
- Autothrottle servo motor (ASM) (2)
- TO/GA switch (2)
- Autothrottle disconnect switch (2).

AIMS - GENERAL DESCRIPTION - 3

General Interfaces

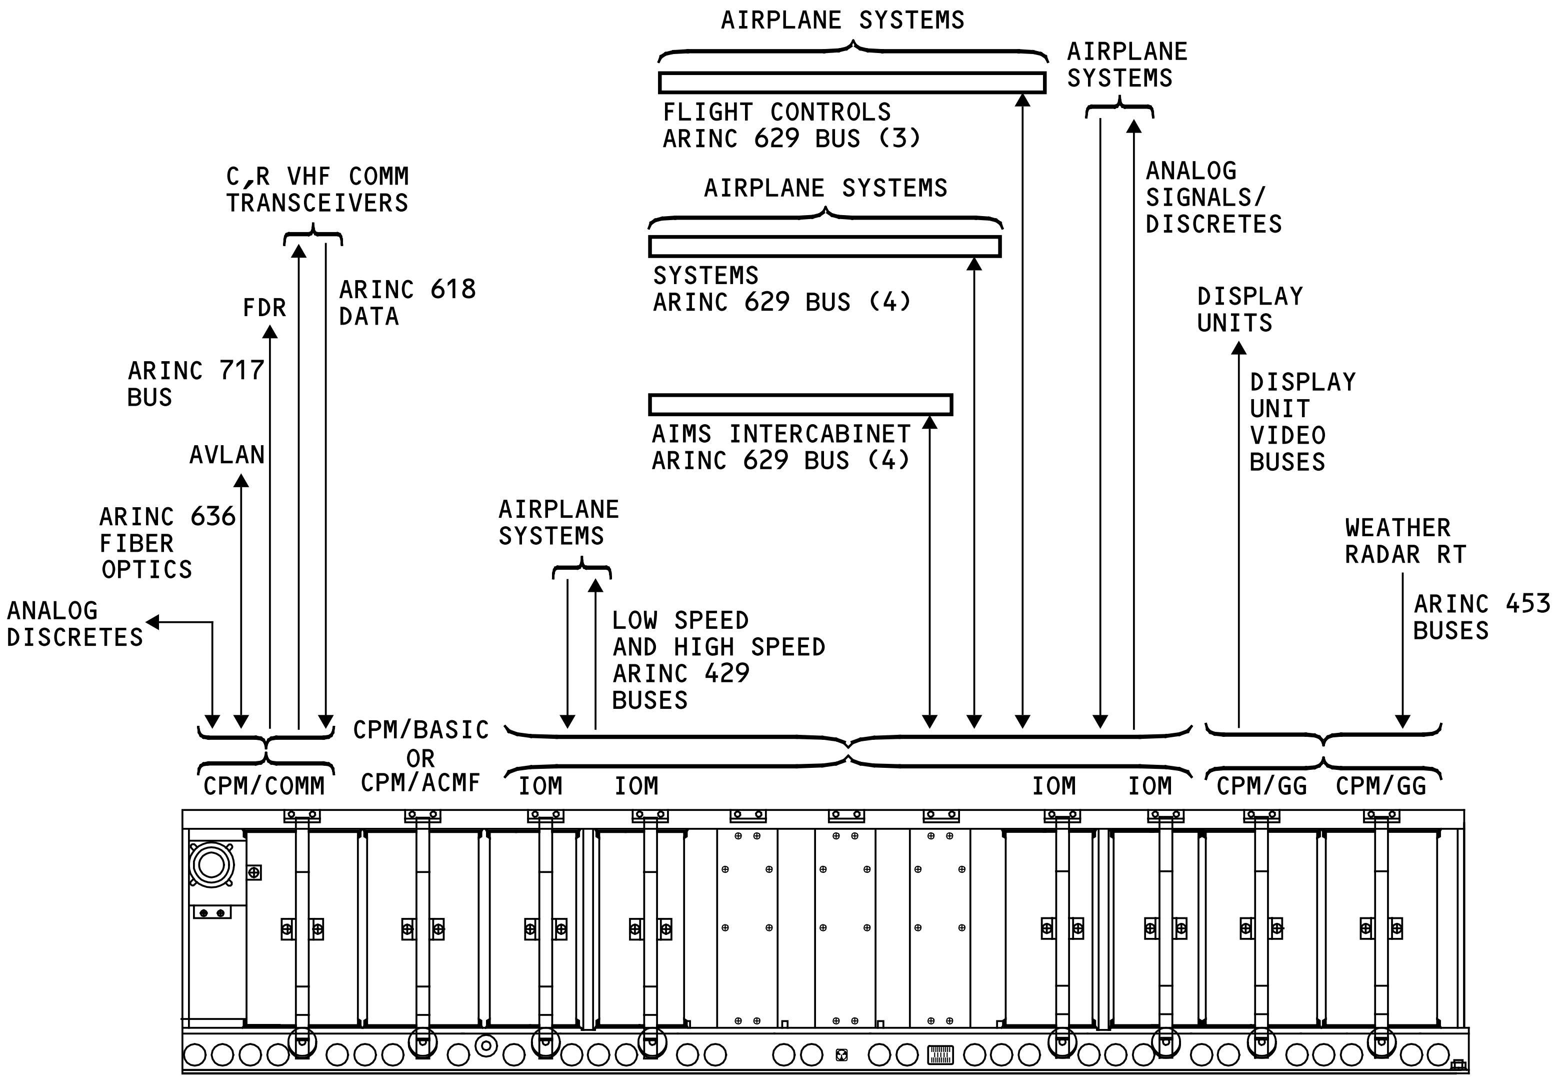
The AIMS has interface with all types of data communication formats. The two AIMS cabinets send data to and receive data from many:

- LRUs
- Sensors
- Switches
- Indicators.

These are the types of interfaces with the AIMS cabinets:

- Flight controls ARINC 629 buses (3)
- Systems ARINC 629 buses (4)
- AIMS intercabinet ARINC 629 buses (4)
- Low speed and high speed ARINC 429 data buses
- ARINC 453 buses
- ARINC 717 bus
- ARINC 618 data
- ARINC 636 Fiber optics
- Display units video buses
- Analog discretes
- Analogs.

The large quantity of interfaces lets the AIMS integrate information from a majority of the airplane systems.



AIMS - GENERAL DESCRIPTION - 3

AIMS - FLIGHT DECK COMPONENT LOCATIONS-1

Integrated Systems Component Locations

These are the integrated systems that have components in the flight deck:

- Primary display system (PDS)
- Data Communication management system (DCMS)
- Flight management computing system (FMCS)
- Thrust management computing system (TMCS).

These PDS components are on the P1, P2, and P3 panels:

- Left instrument source select panel (ISSP)
- Left outboard display unit (DU)
- Left inboard DU
- Captain display switching panel
- Center upper DU
- Right inboard DU
- Right outboard DU
- Right instrument source select panel (ISSP)
- First officer display switching panel.

These PDS components are on the P55 and P7 panels:

- Left EFIS control panel (CP)
- Display select panel (DSP)
- Right EFIS CP
- Left Remote Light Sensor (RLS)
- Right RLS.

These PDS components are on the P9 and P10 panels:

- Lower center DU
- Center display control panel
- Left cursor control device (CCD)
- Right CCD.

The DCMS components on the P7 panel are the data uplink control switches. The DCMS controls the flight compartment printer on the P8 panel.

These FMCS and TMCS components are on the P8 and P10 panels:

- Left control display unit (CDU)
- Right CDU
- Center CDU
- Left autothrottle servo motor (ASM)
- Right ASM
- Left TO/GA switch
- Right TO/GA switch
- Left autothrottle disconnect switch
- Right autothrottle disconnect switch.

AIMS - AIMS CABINET COMPONENT LOCATIONS

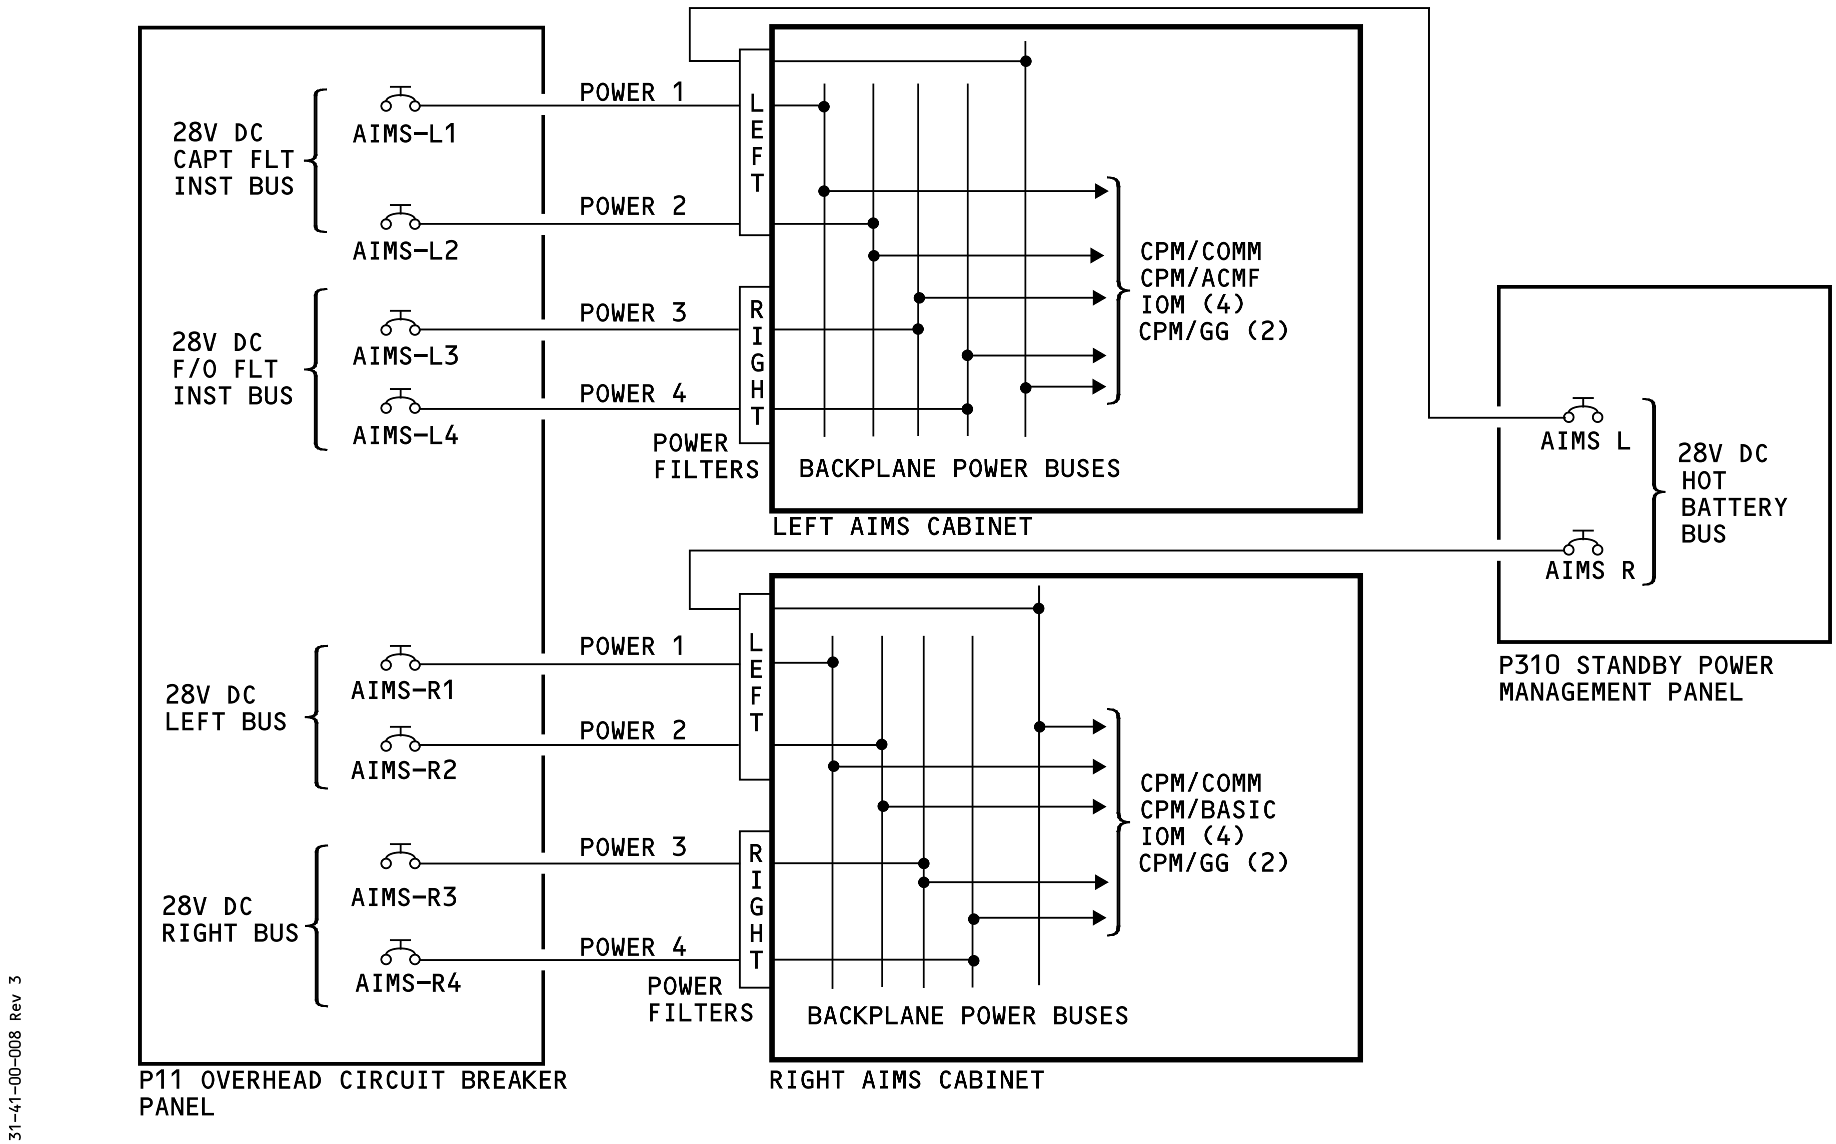
AIMS - INPUT POWER INTERFACES

General

Each AIMS cabinet receives power through four circuit breakers in the overhead circuit breaker panel. Each AIMS cabinet also receives power through one hot battery bus circuit breaker in the standby power management panel.

The left AIMS cabinet gets electrical power from the 28v dc capt flight instrument bus, the 28v dc f/o flight instrument bus, and the hot battery bus. The right AIMS cabinet gets electrical power from the 28v dc left bus, the 28v dc right bus and the hot battery bus.

The electrical power goes through a power filter on the back of the AIMS cabinet and then goes to the backplane power bus. The backplane power bus supplies power to the eight LRMs in the cabinet.



AIMS - INPUT POWER INTERFACES

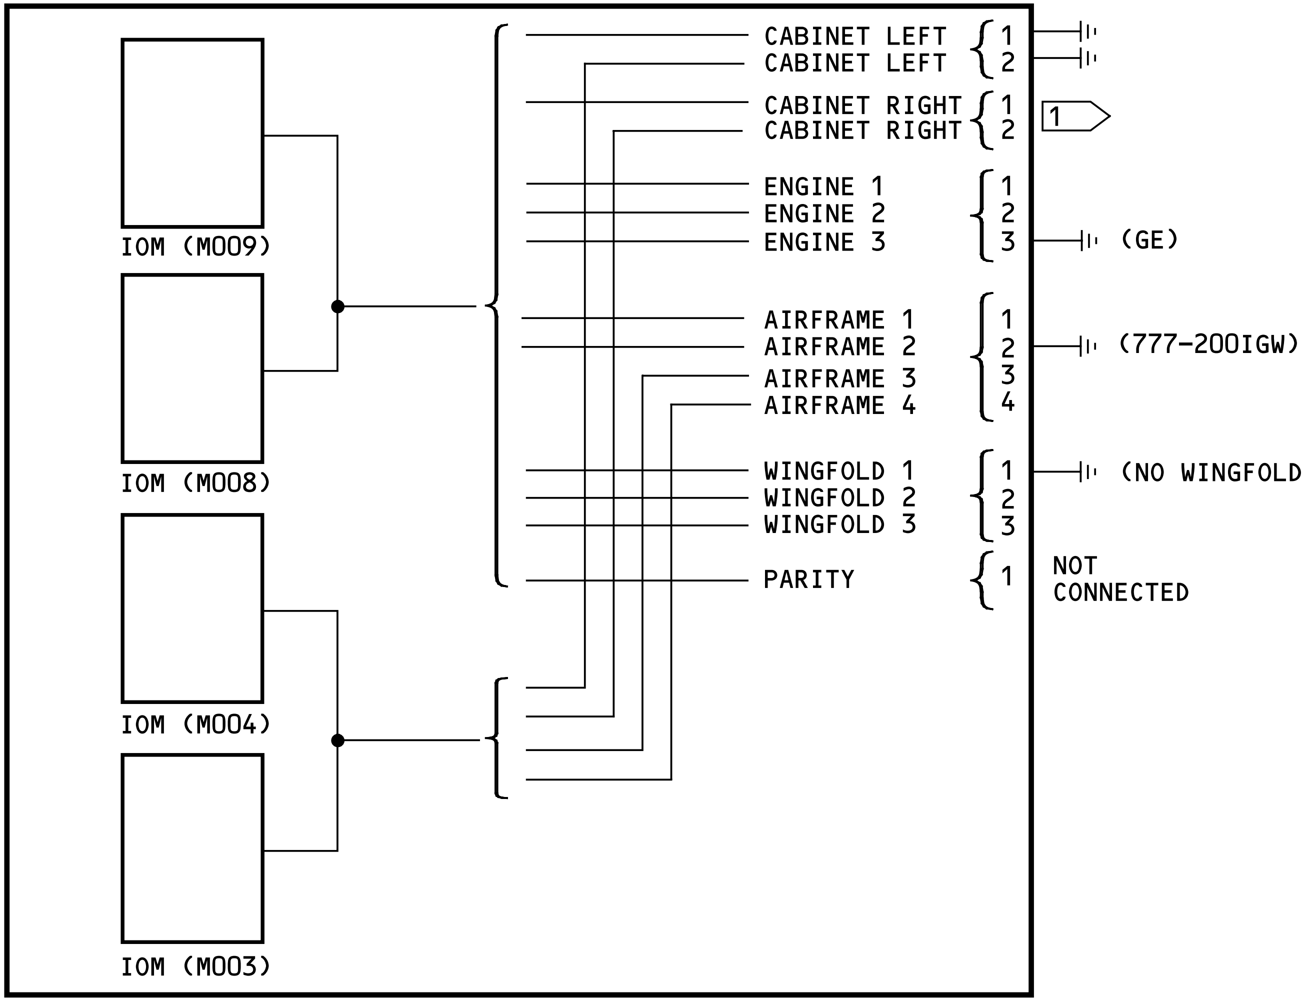
AIMS - CONFIGURATION PIN INTERFACES

Configuration Pins

The left and right AIMS cabinets have program pins that set the configuration of the:

- Cabinet position
- Engine manufacturer
- Airframe type
- Wingfold configuration
- Parity for the program pins.

The parity pin is grounded when an even number of program pins are grounded.



LEFT AIMS CABINET

1 THE RIGHT CABINET HAS THESE PINS GROUNDED AND THE LEFT CABINET PINS ARE NOT CONNECTED

THIS PAGE INTENTIONALLY LEFT BLANK

AIMS - FLIGHT CONTROLS ARINC 629 BUSES INTERFACES

General

The AIMS cabinets receive data on all three of the flight controls ARINC 629 buses and transmit data on the left and right buses. The AIMS cabinets also transmit data on the center flight controls ARINC 629 bus when the airplane is on the ground. The AIMS cabinets transmit data loading information and maintenance data on the center flight controls ARINC 629 bus.

The LRUs that have an interface with the AIMS cabinets on the flight controls ARINC 629 buses are the:

- Air data inertial reference unit (ADIRU)
- Secondary attitude air data reference unit (SAARU)
- Air data module (ADM), static (3)
- Air data module (ADM), pitot (3)
- Primary flight computer (PFC) (3)
- Actuator control electronics (ACE) (4)
- Flight control power supply assembly (FCPSA) (3).

The control display units (CDUs) and the autopilot flight director computers (AFDCs) connect to the flight controls ARINC 629 buses. However, the CDUs and AFDCs do not communicate with the AIMS cabinets on the flight controls ARINC 629 buses.

ADIRU

The AIMS cabinets receive inertial reference data and air data from the ADIRU on the left and right flight controls ARINC 629 buses. The AIMS cabinets transmit data to the ADIRU on the left and right flight controls ARINC 629 buses.

SAARU

The AIMS cabinets receive inertial reference data and air data from the SAARU on the center flight controls ARINC 629 bus. The AIMS cabinets transmit data to the SAARU on the left and right flight controls ARINC 629 buses.

ADM

The AIMS cabinets receive static pressure and total pressure data from the six ADMs on the three flight controls ARINC 629 data buses. The AIMS cabinets transmit data to the six ADMs on the left and right flight controls ARINC 629 data buses.

PFC

The AIMS cabinets receive flight control position data from the left, right and center PFCs on the left, center and right flight controls ARINC 629 buses. The AIMS cabinets transmit data to each PFC on the left and right flight controls ARINC 629 buses.

ACE

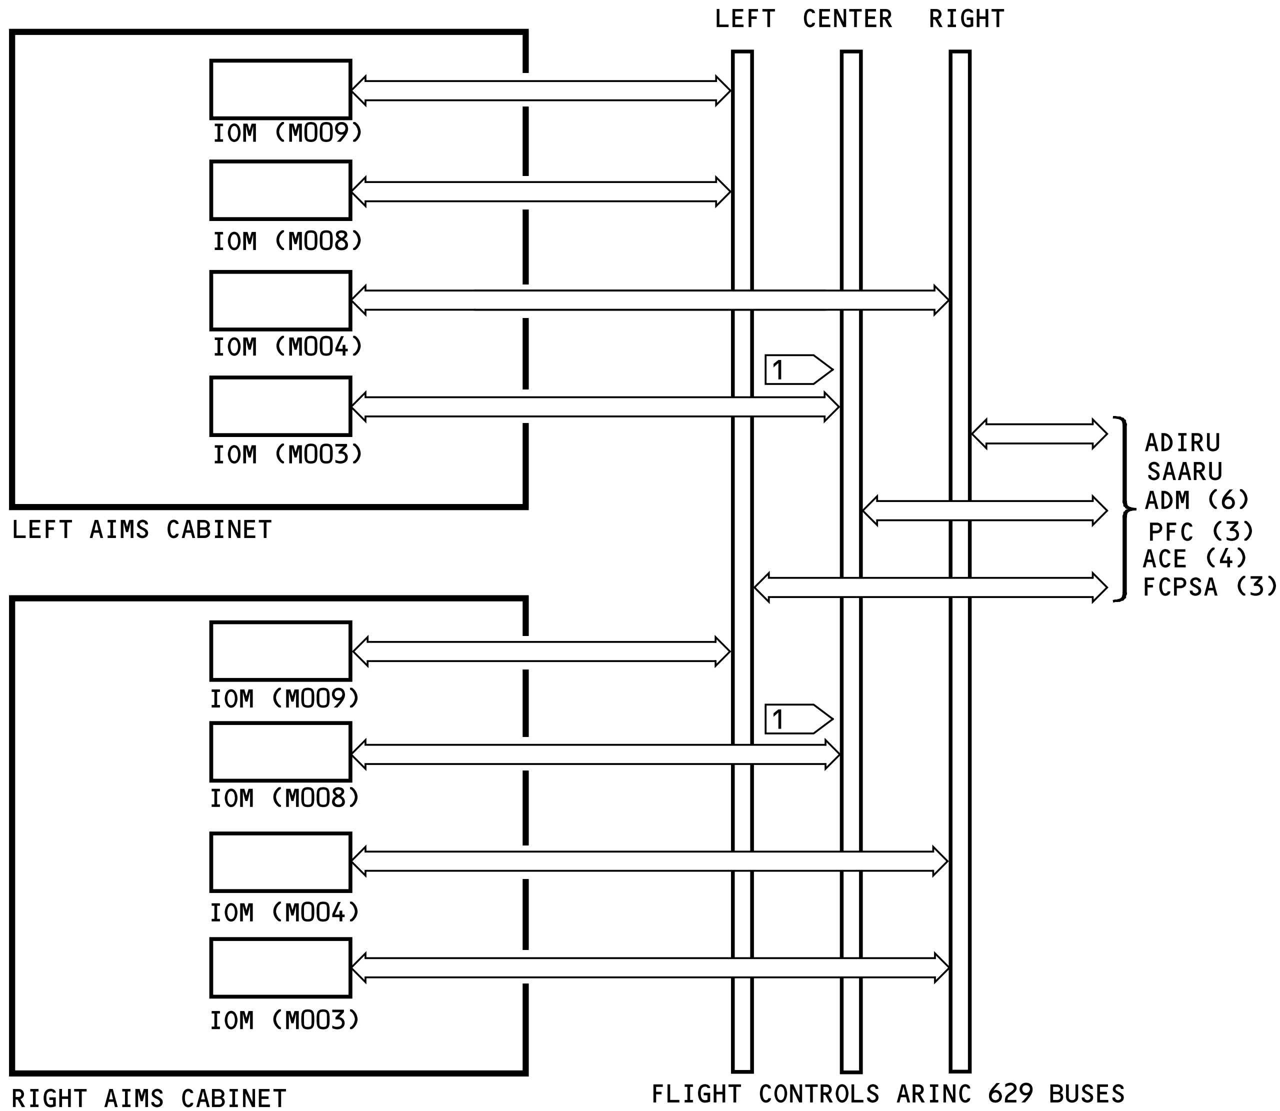
The AIMS cabinets receive power control unit data and position data from the four ACEs on the left, right, and center flight controls ARINC 629 buses. The AIMS

AIMS - FLIGHT CONTROLS ARINC 629 BUSES INTERFACES

cabinets do not transmit data to the ACEs. The AIMS cabinets receive ACE status data from the PFCs.

FCPSA

The AIMS cabinets receive voltage measurement data from the three FCPSAs on the three flight controls ARINC 629 buses. The AIMS cabinets transmit data to the FCPSAs on the left and right flight controls ARINC 629 buses.



1 THE AIMS CABINETS TRANSMIT TO THE CENTER FLIGHT CONTROLS ARINC 629 BUS ONLY WHEN THE AIRPLANE IS ON THE GROUND.

31-41-00-010 Rev 3 08/21/96

AIMS - FLIGHT CONTROLS ARINC 629 BUSES INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

AIMS - SYSTEMS ARINC 629 BUSES INTERFACES

General

The AIMS cabinets receive and transmit data on all four of the systems ARINC 629 buses. These LRUs have an interface with the AIMS cabinets on the systems ARINC 629 buses:

- ARINC signal gateway card (ASG)
- Warning electronic unit (WEU)
- Backup generator converter (BU gen conv)
- Proximity sensor electronics unit (PSEU)
- Bus power control unit (BPCU)
- Generator control unit (GCU)
- ELMS power management panel (ELMS pwr mgmt pnl)
- Passenger address/cabin interphone controller (PA/CI CONT)
- Cabin system management unit (CSMU)
- Overhead panel bus controller (OPBC)
- Flap slat electronics unit (FSEU)
- Brake system control unit (BSCU)
- Brake temperature monitor unit (BTMU)
- Main gear steering control unit (MGSCU)
- Tire pressure monitor unit (TPMU)
- Cabin temperature controller (CTC)
- Air supply-cabin pressure controller (ASCPC)
- Airborne vibration monitor signal conditioner (AVM signal conditioner)
- Engine data interface unit (EDIU)
- APU controller
- Fuel quantity processor unit (FQPU)
- Audio management unit (AMU)
- Control display unit (CDU)
- Autopilot flight director computer (AFDC).

ASG Card- System CardFile

A left and right system cardfile integrate many systems cards. The systems cardfiles have many data inputs and outputs. The left and right system cardfiles communicate on the left and right systems ARINC 629 buses.

Both systems cardfiles have two ARINC signal gateway (ASG) cards. One ASG card in each cardfile connects to the left ARINC 629 bus and one card in each cardfile connects to the right ARINC bus.

The other cards in the systems cardfiles are the:

- Engine fire detection card (2)
- Engine overheat detection card (2)
- APU fire detection card
- Airfoil and cowl ice protection system card (3)
- ECS card (2)
- HYDIM card (4)
- Weight on wheels (WOW) card (2)
- Duct leak overheat detection card (3)
- Cardfile power supply unit, monitor card (4).

The AIMS cabinets receive fire detection and fire handle position data from the:

- Left engine fire detection card
- Right engine fire detection card
- APU fire detection card.

AIMS - SYSTEMS ARINC 629 BUSES INTERFACES

The AIMS cabinets receive overheat detection data from the left engine overheat detection card and right engine overheat detection card.

The AIMS cabinets receive duct leak data from the left, right and center duct leak overheat detection cards.

The AIMS cabinets receive environmental system status data from the left and right ECS cards.

The AIMS cabinets receive hydraulic system status data from the HYDIM cards in each cardfile.

The AIMS cabinets receive weight on wheels data from the left and right WOW cards.

The AIMS cabinets receive wing and cowl TAI data, and ice detector status from the left, right and center airfoil and cowl ice protection system cards.

The AIMS cabinets receive cardfile power-supply-unit cards status-data from the monitor card in each of the cardfile power supply units. There are 2 cardfile power supply units in each of the systems cardfiles.

<u>WEU</u>

The AIMS cabinets receive warning system data from the left and right WEUs on the left, right and center 1 systems ARINC 629 buses. The left WEU communicates on the left and center 1 buses and the right WEU communicates on the right and center 1 buses.

The AIMS cabinets transmit data to the WEUs on the left, right and center 1 systems ARINC 629 buses.

<u>BU Generator Converter</u>

The AIMS cabinets receive backup electrical power system data from the BU generator convertor on the left and right systems ARINC 629 buses.

The AIMS cabinets transmit data to the BU generator convertor on the left and right systems ARINC 629 buses.

<u>PSEU</u>

The AIMS cabinets receive proximity sensor data from the left and right PSEUs on the left and right systems ARINC 629 buses.

The AIMS cabinets transmit data to each PSEU on the left and right systems ARINC 629 buses.

<u>BPCU</u>

The AIMS cabinets receive electrical power system data from the BPCU on the left and right systems ARINC 629 buses.

The AIMS cabinets transmit data to the BPCU on the left and right systems ARINC 629 buses.

AIMS - SYSTEMS ARINC 629 BUSES INTERFACES

GCU

The AIMS cabinets receive electrical power system data from the left GCU, right GCU and APU GCU on the left and right systems ARINC 629 buses.

The AIMS cabinets transmit data to the GCUs on the left and right systems ARINC 629 buses.

ELMS

The AIMS cabinets receive electrical power system data from the ELMS left power management panel, right power management panel, and standby power management panel on the left and right systems ARINC 629 buses.

The AIMS cabinets transmit data to the ELMS power management panels on the left and right systems ARINC 629 buses.

PA/CI CONT

The AIMS cabinets receive PA/CI CONT status data from the PA/CI CONT on the left systems ARINC 629 bus.

The AIMS cabinets transmit data to the PA/CI CONT on the left systems ARINC 629 bus.

CSMU

The AIMS cabinets receive cabin management system status data from the CSMU on the right systems ARINC 629 bus.

The AIMS cabinets transmit data to the CSMU on the right systems ARINC 629 bus.

OPBC

The AIMS cabinets receive switch position data from the overhead panel switches and other flight deck switches via the left and right OPBC on the left and right systems ARINC 629 buses.

The AIMS cabinets transmit flight deck indicator states data to the OPBCs on the left and right systems ARINC 629 buses.

FSEU

The AIMS cabinets receive flap position data and slat position data from the left and right FSEU on the left, right and center 1 systems ARINC 629 buses.

The left FSEU has two interfaces on the left bus and two interfaces on the center 1 bus. The right FSEU has two interfaces on the right bus and two interfaces on the center 1 bus.

The AIMS cabinets transmit data to the left and right FSEU on the left, right and center 1 systems ARINC 629 buses.

AIMS - SYSTEMS ARINC 629 BUSES INTERFACES

BSCU

The AIMS cabinets receive brake system control data, from the BSCU on the left and right systems ARINC 629 buses.

The AIMS cabinets transmit data to the BSCU on the left and right systems ARINC 629 buses.

BTMU

The AIMS cabinets receive brake temperature data from the BTMU on the left systems ARINC 629 bus.

The AIMS cabinets transmit data to the BTMU on the left systems ARINC 629 bus.

MGSCU

The AIMS cabinets receive aft axle steering locked status from the MGSCU on the left systems ARINC 629 bus.

The AIMS cabinets transmit data to the MGSCU on the left systems ARINC 629 bus.

TPMU

The AIMS cabinets receive tire pressure data from the TPMU on the left systems ARINC 629 bus.

The AIMS cabinets transmit data to the TPMU on the left systems ARINC 629 bus.

CTC

The AIMS cabinets receive air conditioning data and system status data from the left and right CTCs on the left and right systems ARINC 629 buses.

The AIMS cabinets transmit data to the CTCs on the left and right systems ARINC 629 buses.

ASCPC

The AIMS cabinets receive air supply data and cabin pressure data from the left and right ASCPCs on the left and right systems ARINC 629 buses.

The AIMS cabinets transmit data to the ASCPCs on the left and right systems ARINC 629 buses.

AVM Signal Conditioner

The AIMS cabinets receive engine vibration data and system status message data from the left and right AVM signal conditioners on the left and right systems ARINC 629 buses.

The AIMS cabinets transmit data to the AVM signal conditioners on the left and right systems ARINC 629 buses.

EDIU

The EDIUs receive ARINC 429 data from the A and B channels of the left and right electronic engine controls (EECs). The EDIUs convert the data to an ARINC 629 format. The left and right EDIUs transmit the ARINC 629 formatted data to the AIMS cabinets.

The AIMS cabinets receive engine data and system status message data from the channel A, the channel B, and the channel C EDIU interface cards in each EDIU. The EDIU channel interface cards and the systems ARINC 629 buses that connect to each are as follows:

- Channel A - left EDIU, left and C1 buses
- Channel B - left EDIU, left and C2 buses
- Channel C - left EDIU, C1 and C2 buses
- Channel A - right EDIU, right and C2 buses
- Channel B - right EDIU, right and C1 buses
- Channel C - right EDIU, C1 and C2 buses.

The AIMS cabinets transmit data to the channel A, the channel B, and the channel C EDIU interface cards, in each EDIU.

The AIMS cabinets transmit data to the EDIUs on the same systems ARINC 629 buses that they receive data from. The EDIUs then transmit the data received from the AIMS cabinets to the left and right EECs.

APU Controller

The AIMS cabinets receive APU data from the APUC controller on the left and right systems ARINC 629 buses.

The AIMS cabinets transmit data to the APU controller on the left and right systems ARINC 629 buses.

FQPU

The AIMS cabinets receive fuel data and system status data from the FQPU on the left and right systems ARINC 629 buses.

The AIMS cabinets transmit data to the FQPU on the left and right systems ARINC 629 buses.

AMU

The AIMS cabinets receive digital audio system status data from the AMU on the left systems ARINC 629 bus.

The AIMS cabinets transmit data to the AMU on the left systems ARINC 629 bus.

CDU

The AIMS cabinets receive keyboard selection data and map data from the left, right and center CDUs on the left and right systems ARINC 629 buses.

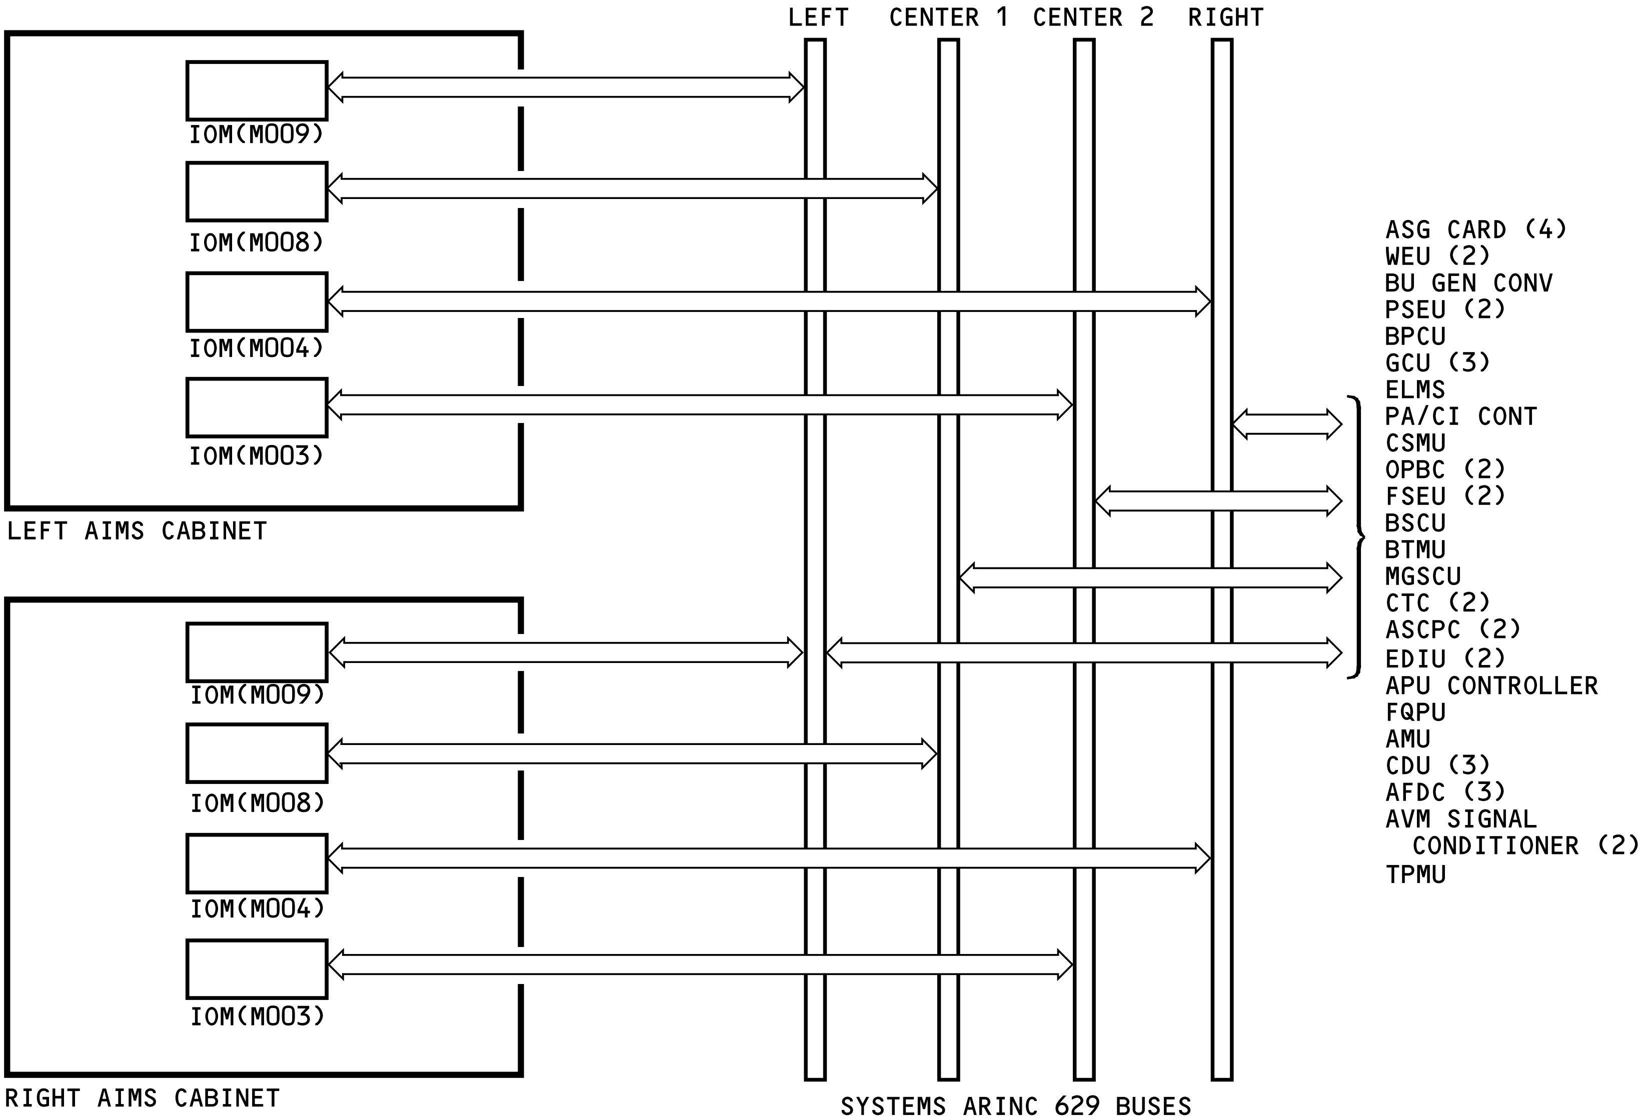
The AIMS cabinets transmit data to the CDUs on the left and right systems ARINC 629 buses.

AIMS - SYSTEMS ARINC 629 BUSES INTERFACES

AFDC

The AIMS cabinets receive autopilot status and guidance data from the left, right and center AFDCs on the left, right and center 1 systems ARINC 629 data buses.

The AIMS cabinets transmit data to the AFDCs on the left, right and center 1 systems ARINC 629 buses.



31-41-00-011 Rev 5

AIMS - SYSTEMS ARINC 629 BUSES INTERFACES

AIMS - AIMS INTERCABINET ARINC 629 BUSES INTERFACES

General

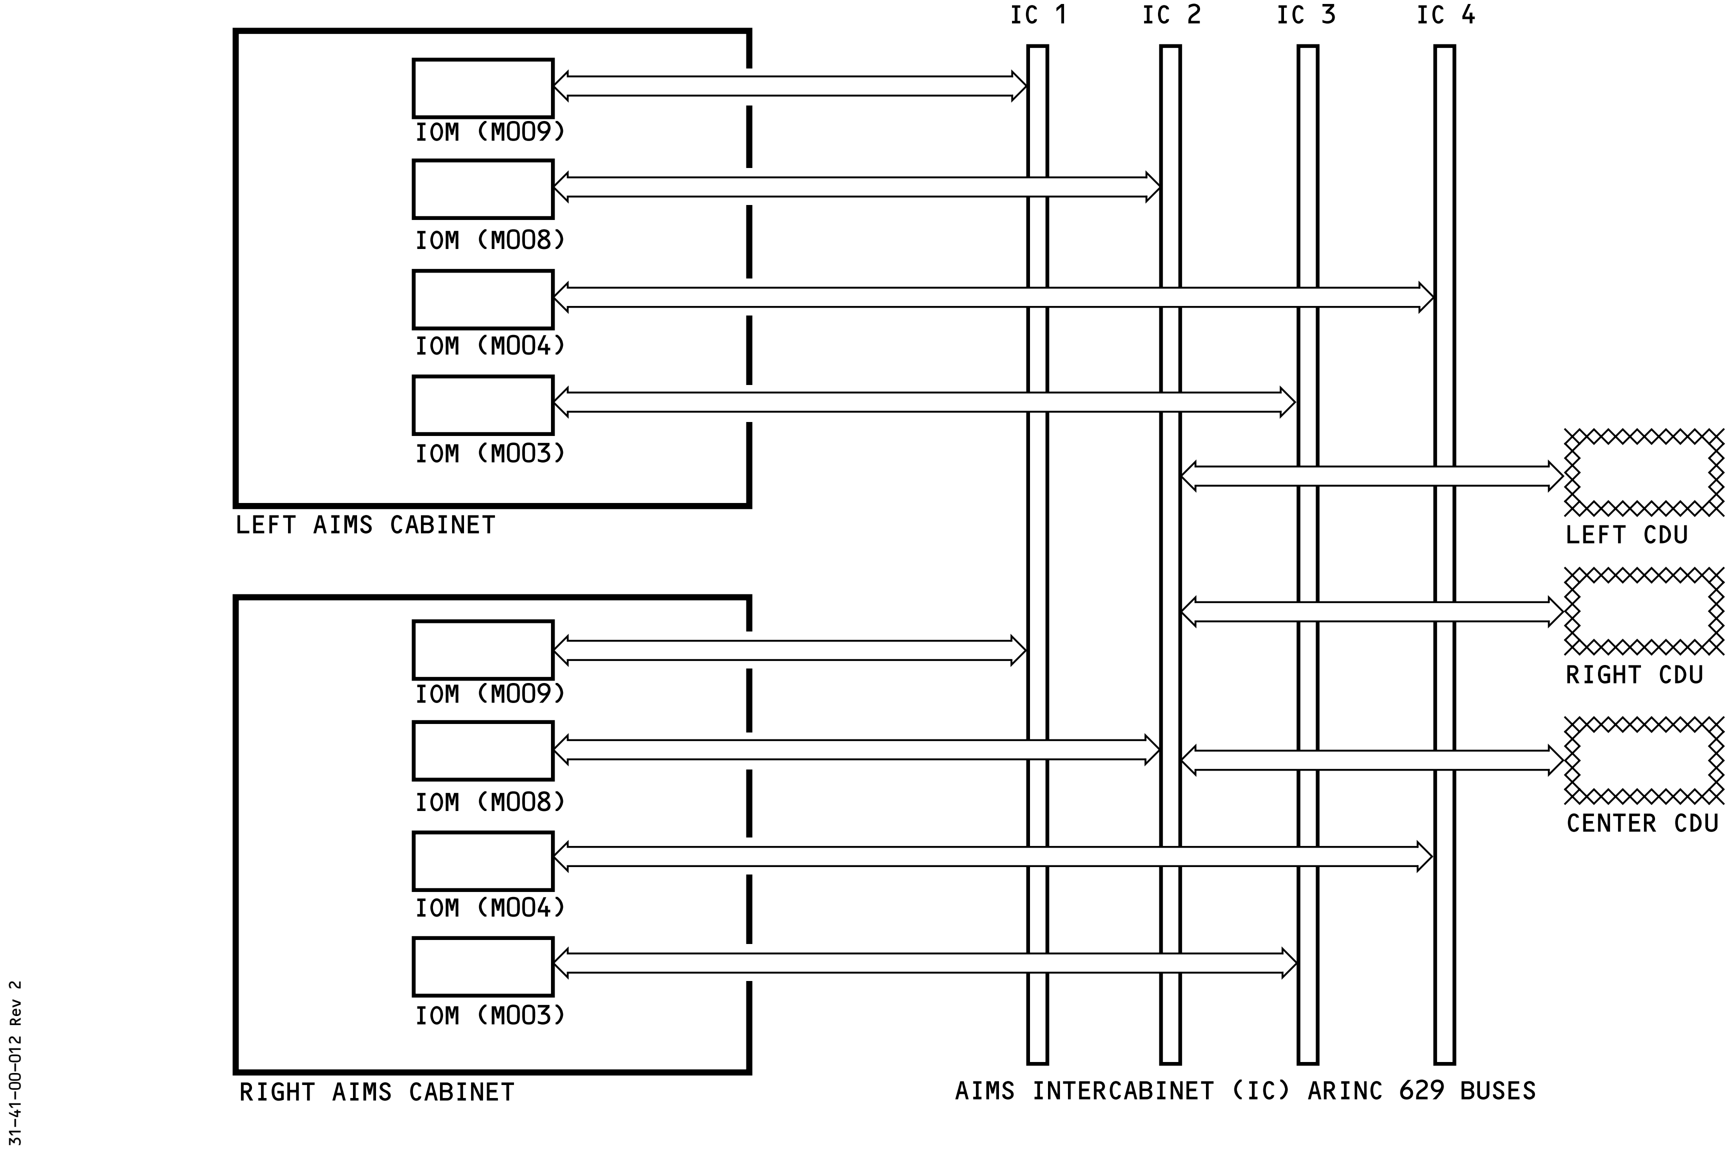
The left and right AIMS cabinets transmit and receive data on all four of the AIMS intercabinet (IC) buses. The CDUs communicate with the AIMS cabinets on the AIMS intercabinet (IC) 2 bus.

AIMS Cabinets

Data that goes between the two AIMS cabinets includes intra-function active-nonactive data and inter-function communication data.

CDU

If the systems ARINC 629 buses fail, the CDUs use the AIMS IC 2 bus. The AIMS cabinets receive keyboard selection data and map data from the left, right and center CDUs on the IC 2 bus.



AIMS - AIMS INTERCABINET ARINC 629 BUSES INTERFACES

AIMS - ARINC 429 INPUTS INTERFACES

General

These are the four ways the ARINC 429 input buses go to the input/output modules:

- ARINC 429 bus goes directly to one IOM
- ARINC 429 bus goes to two IOMs in the same AIMS cabinet
- ARINC 429 bus goes to one IOM in each AIMS cabinet.
- ARINC 429 bus goes to two IOMs in each AIMS cabinets.

More critical systems usually send their data to more that one IOM.

The ARINC 429 buses may be either low speed or high speed buses.

ARINC 429 inputs

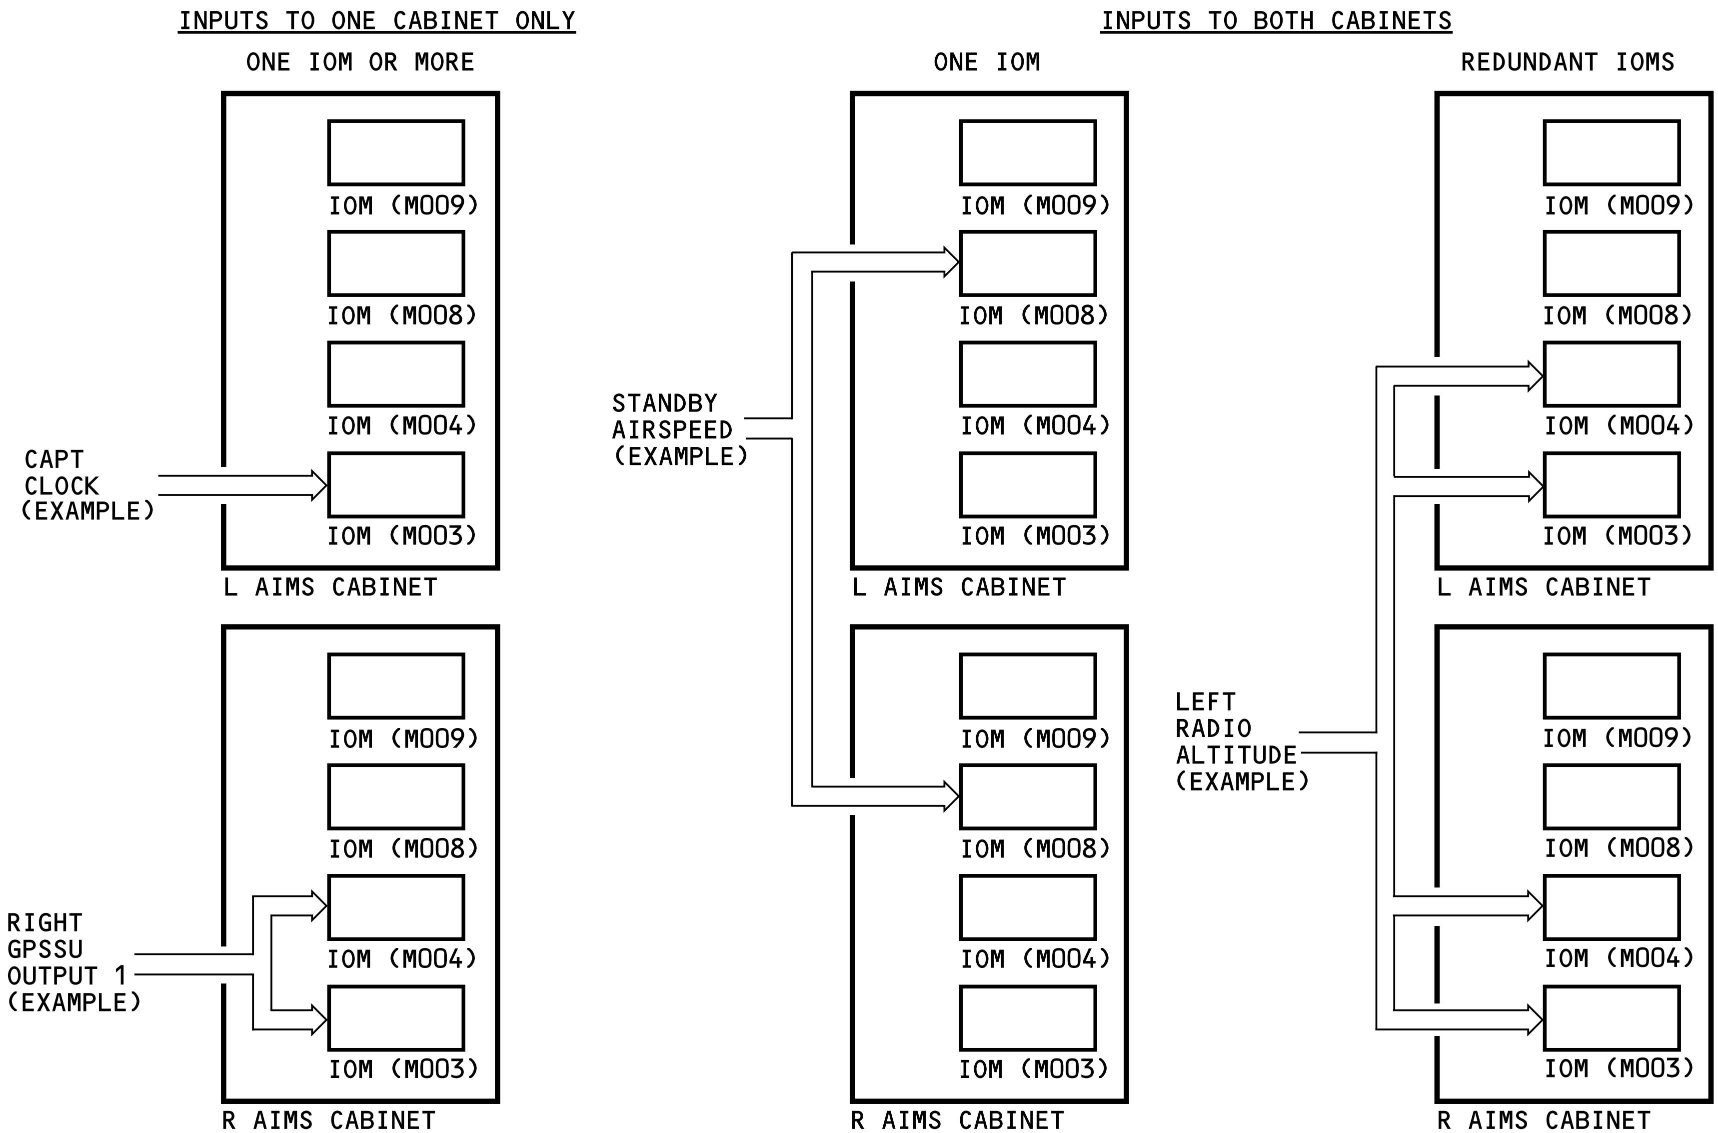
These LRUs send data to the AIMS cabinet on ARINC 429 buses:

- Autothrottle servo motors
- Mode control panel
- VHF communication transcievers
- HF communication transceivers
- Radio tuning panels
- Satellite data unit
- Clocks
- Cursor control devices (Capt and F/O)
- Display units
- EFIS control Panels
- Window heat control units
- Radio altimeter transcievers
- Weather radar receiver/transceivers
- TCAS computers
- ILS receivers
- VOR/MB receivers
- ADF receivers
- DME interrogators
- Global position system sensor units
- Cabin telecommunications unit
- Standby airspeed indication
- Standby altimeter
- Ground proximity warning computer
- Air traffic control mode S transponders.

Some of these LRUs have more than one ARINC 429 bus that go to the AIMS cabinet. Each bus sends different types of data.

Training Information Point

For details on the exact interfaces between the LRUs and the IOMs, refer to the wiring diagram manual.



AIMS - ARINC 429 INPUTS INTERFACES

31-41-00-013 Rev 3 04/29/95

AIMS - ARINC 429 OUTPUTS INTERFACES

General

The left and right AIMS cabinets transmit low speed and high speed ARINC 429 outputs in these three ways:

- There is a direct output
- There are two IOM sources in the same AIMS cabinet. A relay controls the output from one source.
- There is one IOM source in each AIMS cabinet. A relay controls the output from one source.

The different AIMS functions control the relays. For example, the FMCF controls the center nav tuning bus.

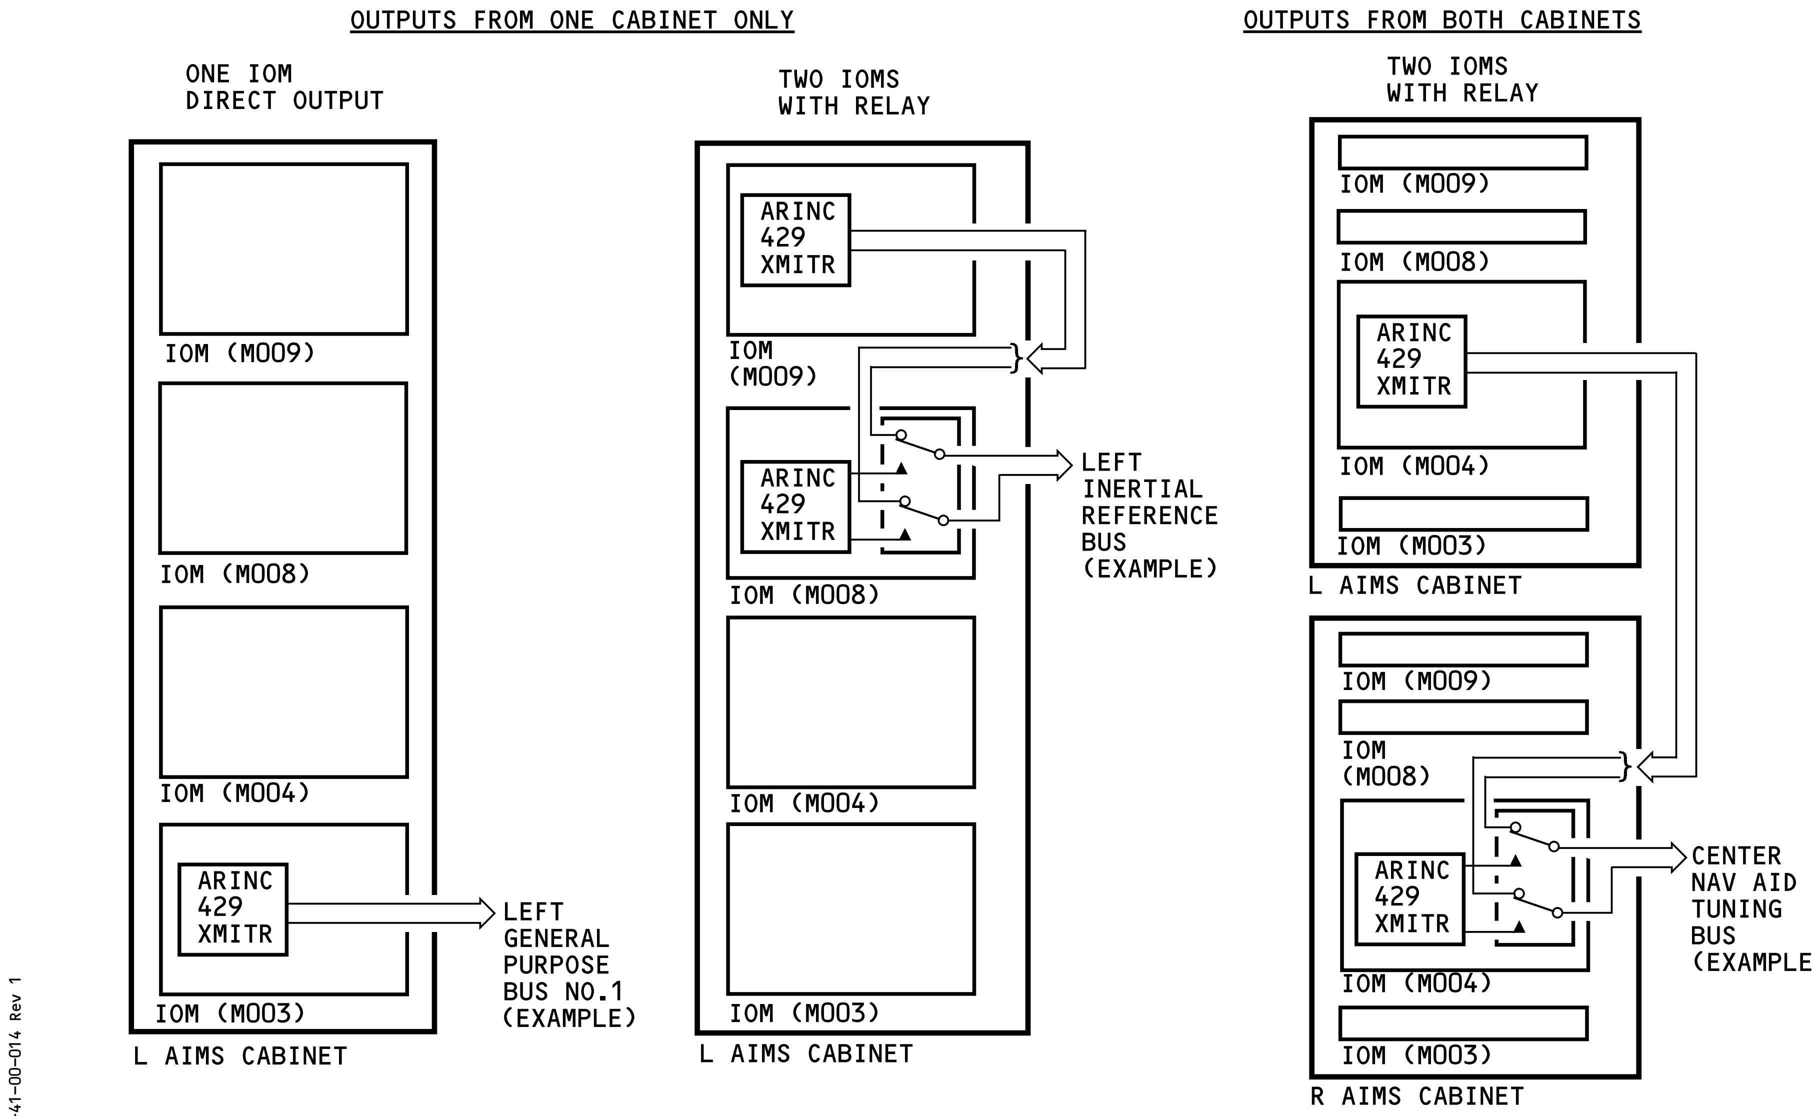
ARINC 429 outputs

There are eighteen 429 output buses. Each 429 bus transmits different types of data. These are the ARINC 429 output buses:

- Left general purpose bus #1
- Right general purpose bus #1
- Left general purpose bus #2
- Right general purpose bus #2
- Left general purpose bus #3
- Right general purpose bus #3
- Left DCMF data bus
- Right DCMF data bus
- Left inertial reference bus
- Right inertial reference bus
- Center nav tuning bus
- Left nav tuning bus
- Right nav tuning bus
- Center CMCF bus
- Left CMCF bus
- Right CMCF bus
- Left data load bus
- Right data load bus.

Training Information Point

For details on the exact interfaces between the IOMs and the LRUs, refer to the wiring diagram manual.



AIMS - ARINC 429 OUTPUTS INTERFACES

AIMS - ARINC 717 BUS INTERFACES

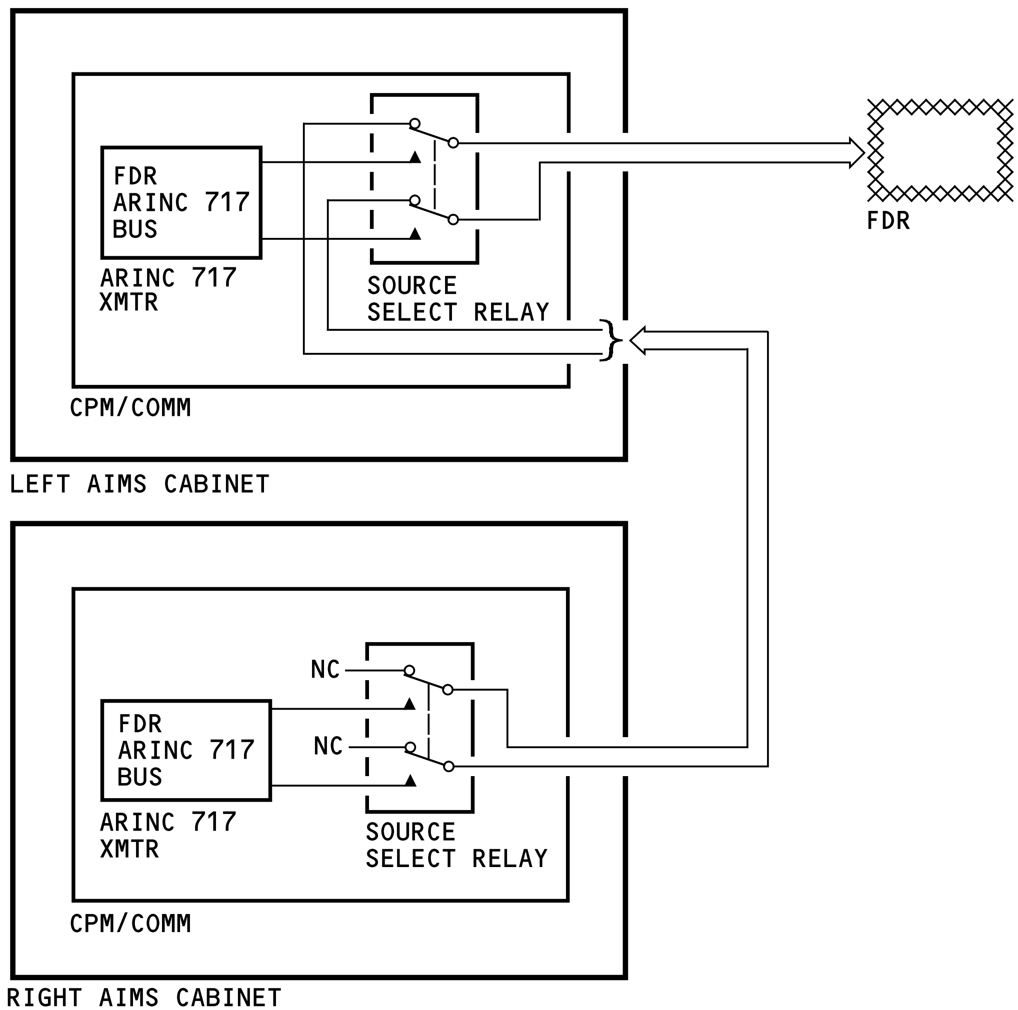
General

The CPM/Comm in the left and right AIMS cabinets supplies an ARINC 717 bus interface to the flight data recorder (FDR).

FDR ARINC 717 Buses

The CPM/Comm sends data to the flight data recorder (FDR) on an ARINC 717 bus. Each of the AIMS cabinets has an ARINC 717 transmitter and an ARINC 717 output bus for the FDR. The ARINC 717 transmitter receives data from the DFDAF and sends the data to the FDR.

The FDR ARINC 717 output from the right AIMS cabinet goes to a relay in the left AIMS cabinet. The relay sends the output from the left AIMS cabinet ARINC 717 transmitter or the right AIMS cabinet ARINC 717 transmitter to the FDR. The DFDAF in the left AIMS cabinet controls the state of the source select relay.



31-41-00-015 Rev 2

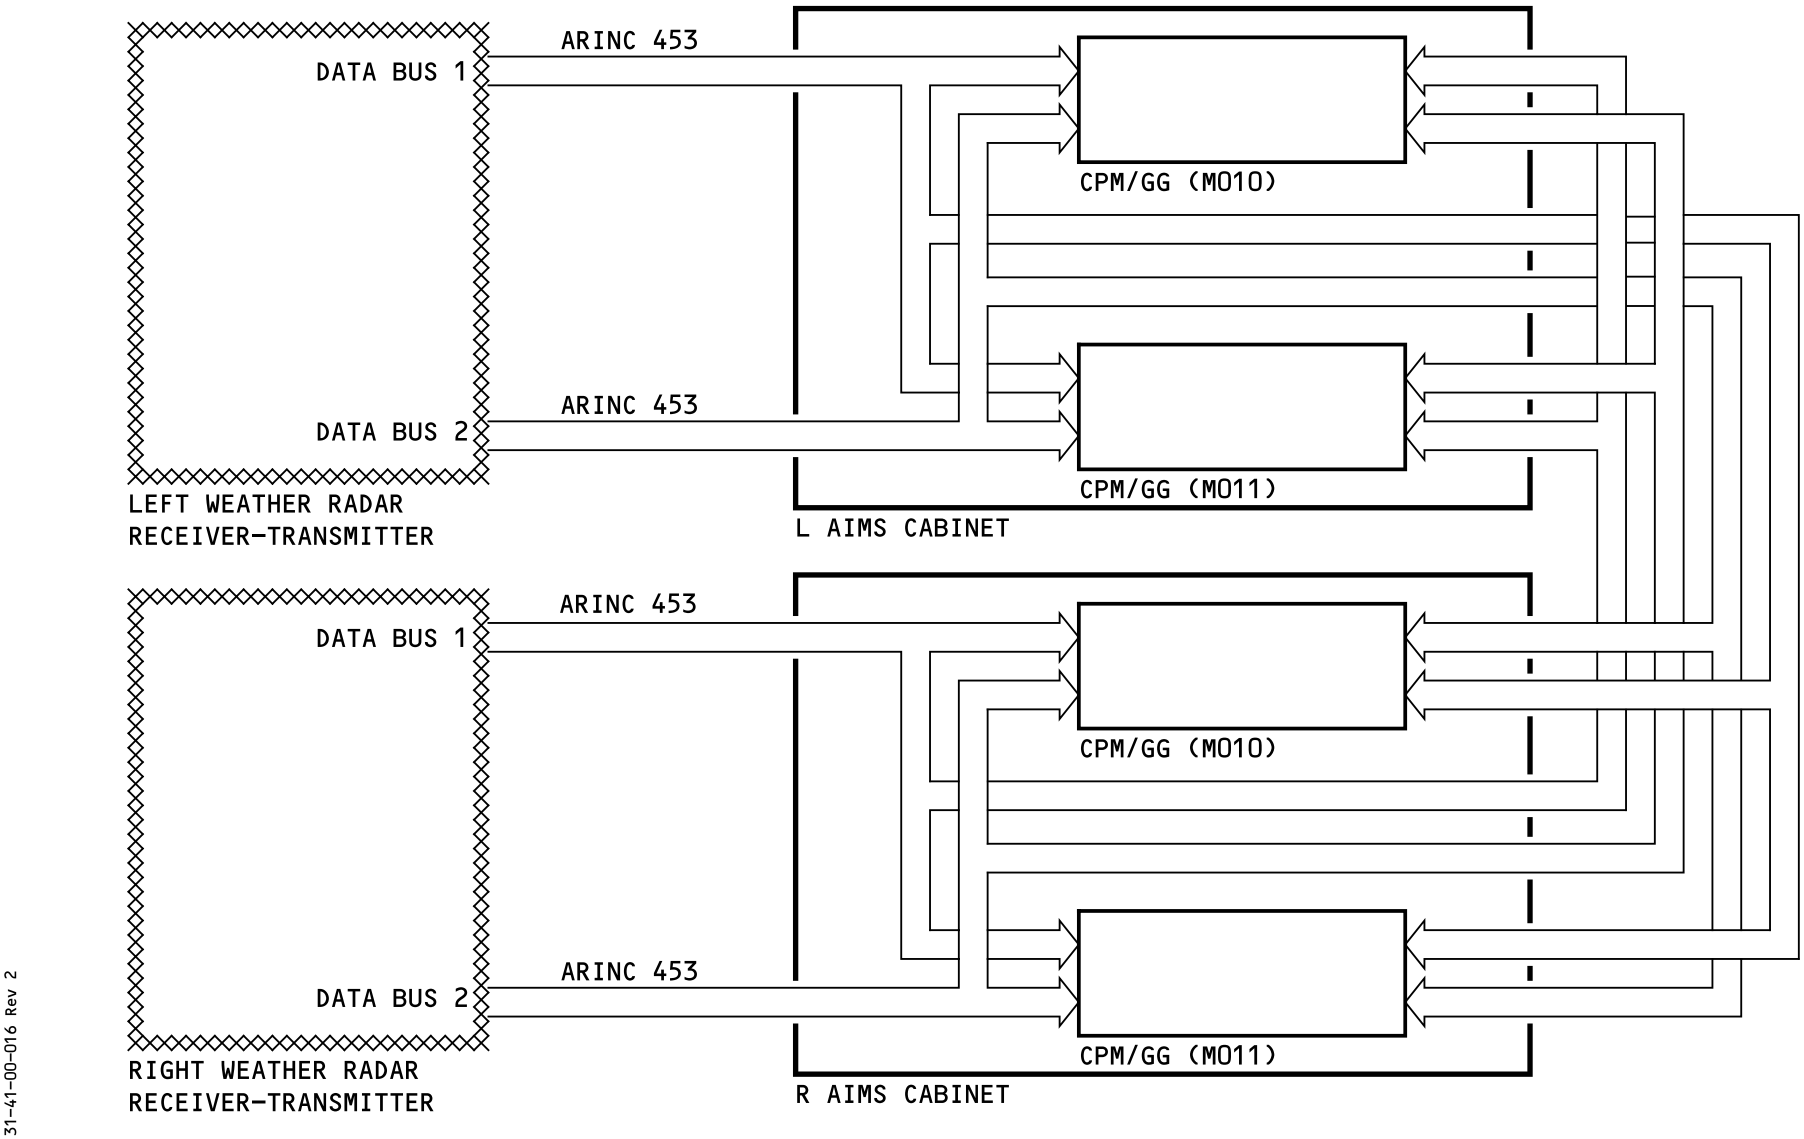
AIMS - ARINC 717 BUS INTERFACES

AIMS - WEATHER RADAR BUSES ARINC 453 INTERFACES

ARINC 453 Buses

The left and right weather radar receiver-transmitters (WXR RT) send weather data to both AIMS cabinets on high speed ARINC 453 buses. Each WXR RT transmits the data over two ARINC 453 buses. Each AIMS cabinet also sends the ARINC 453 weather radar bus inputs to the other AIMS cabinet.

Two load resistors terminate the ARINC 453 weather radar bus inputs at the rear connector in each AIMS cabinet.



AIMS - WEATHER RADAR BUSES ARINC 453 INTERFACES

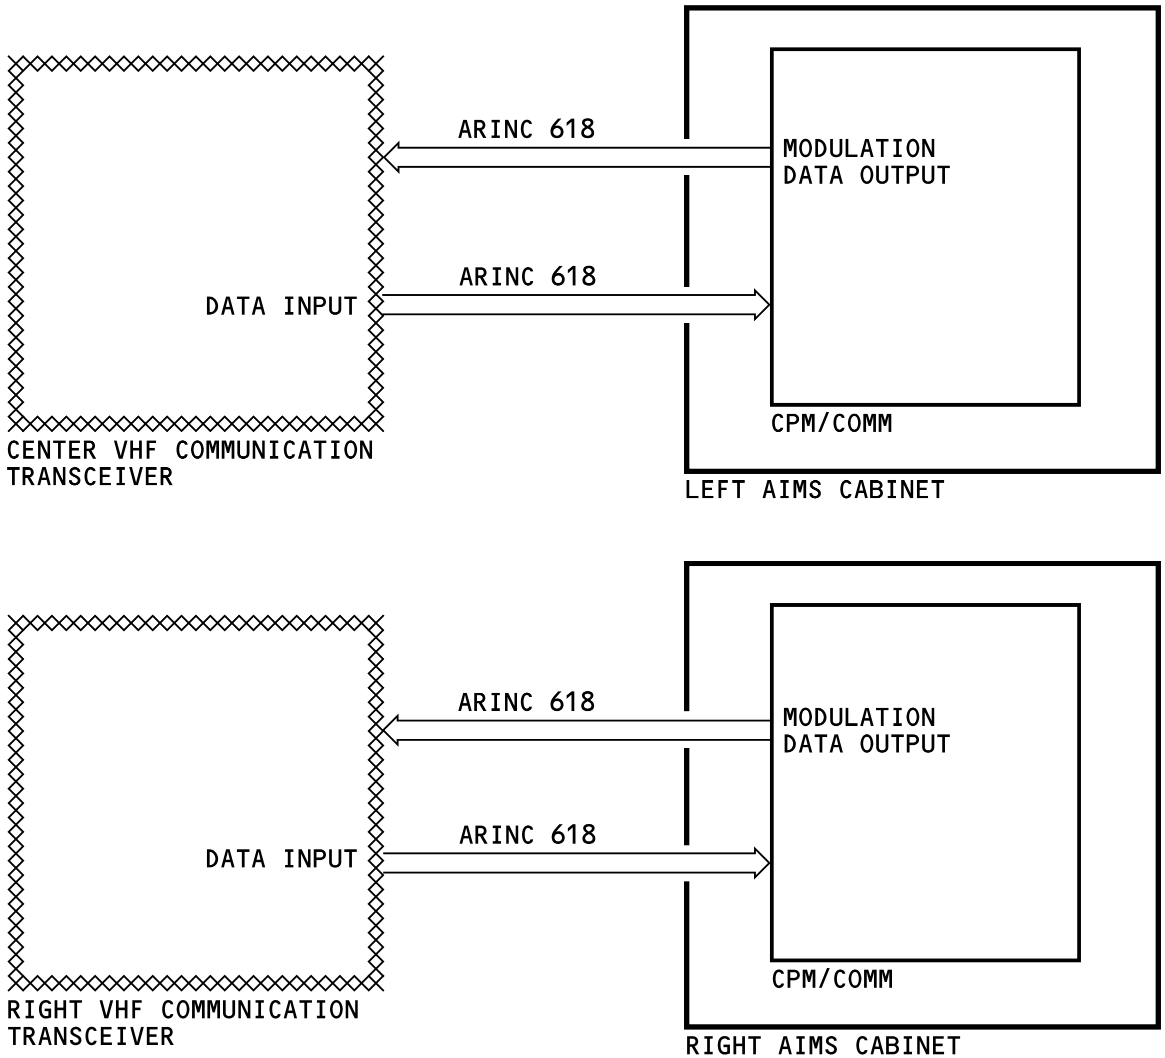
AIMS - DATALINK ARINC 618 INTERFACES

ARINC 618

Each AIMS cabinet receives uplink ARINC 618 signals from its VHF communication transceiver.

Each AIMS cabinet transmits downlink ARINC 618 signals to its VHF communication transceiver.

The CPM/Comm in each AIMS cabinet has a modem interface to receive and transmit the signals.



31-41-00-017 Rev 2 04/26/95

AIMS - DATALINK ARINC 618 INTERFACES

AIMS - AVIONICS LOCAL AREA NETWORK ARINC 636 INTERFACES

Avionics Local Area Network

The CPM/Comm in both AIMS cabinets has the fiber optics interface that supplies the connections to an avionics local area network (AVLAN). The AVLAN supplies a high speed communication path to the:

- Maintenance access terminal (MAT)
- Portable maintenance access terminal (PMAT)
- Four portable maintenance access terminal (PMAT) receptacles.

The AVLAN connects the AIMS cabinets to the MAT and a brouter through a bypass switch unit. The brouter supplies the connection to the PMAT and PMAT receptacles with a ten base T bus.

The DCMF in the CPM/Comm has the communication protocols that permit the AIMS functions to communicate with the AVLAN.

The CMCF and ACMF send their data to the DCMF to be formatted with the correct data format. The DCMF then transmits this data on the AVLAN.

AIMS - DISPLAY UNITS VIDEO BUSES INTERFACES

Display Units Video Buses

The two core processor module/graphics generators (CPM/GG) in both AIMS cabinets transmit video signals to the six display units. Each CPM/GG transmits on a dedicated display units video bus.

The display units video buses are coaxial cables that transfer high speed digitized compressed video signals. Each of the video buses is split by a coaxial coupler into six signals. The six signal then go to the six display units.

AIMS - DISPLAY UNITS VIDEO BUSES INTERFACES

AIMS - ANALOG DISCRETE INPUTS INTERFACES

General

There are two ways analog discrete inputs go to the input/output modules:

- The analog discrete input goes to two IOMs in the one AIMS cabinet
- The analog discrete input goes to two IOMs in both AIMS cabinets.

Analog Discrete Inputs

The AIMS cabinets receive these analog discretes:

- Autothrottle disconnect
- Autothrottle disconnect reset
- Takeoff go around
- Master caution warning light reset
- Key event from the VHF radios
- Program pins
- Air ground status from ELMS
- Maintenance/software load enable
- Trucks not tilted from the PSEU
- Flight data recorder status
- Flight data recorder maintenance status
- Fuel lever at cutoff position
- EEC GND test switch in ON position
- ACE in direct mode
- ACE power supply valid
- Alternate pitch trim - arm active
- Alternate pitch trim - arm down
- Alternate pitch trim - arm up
- Alternate pitch trim - control active

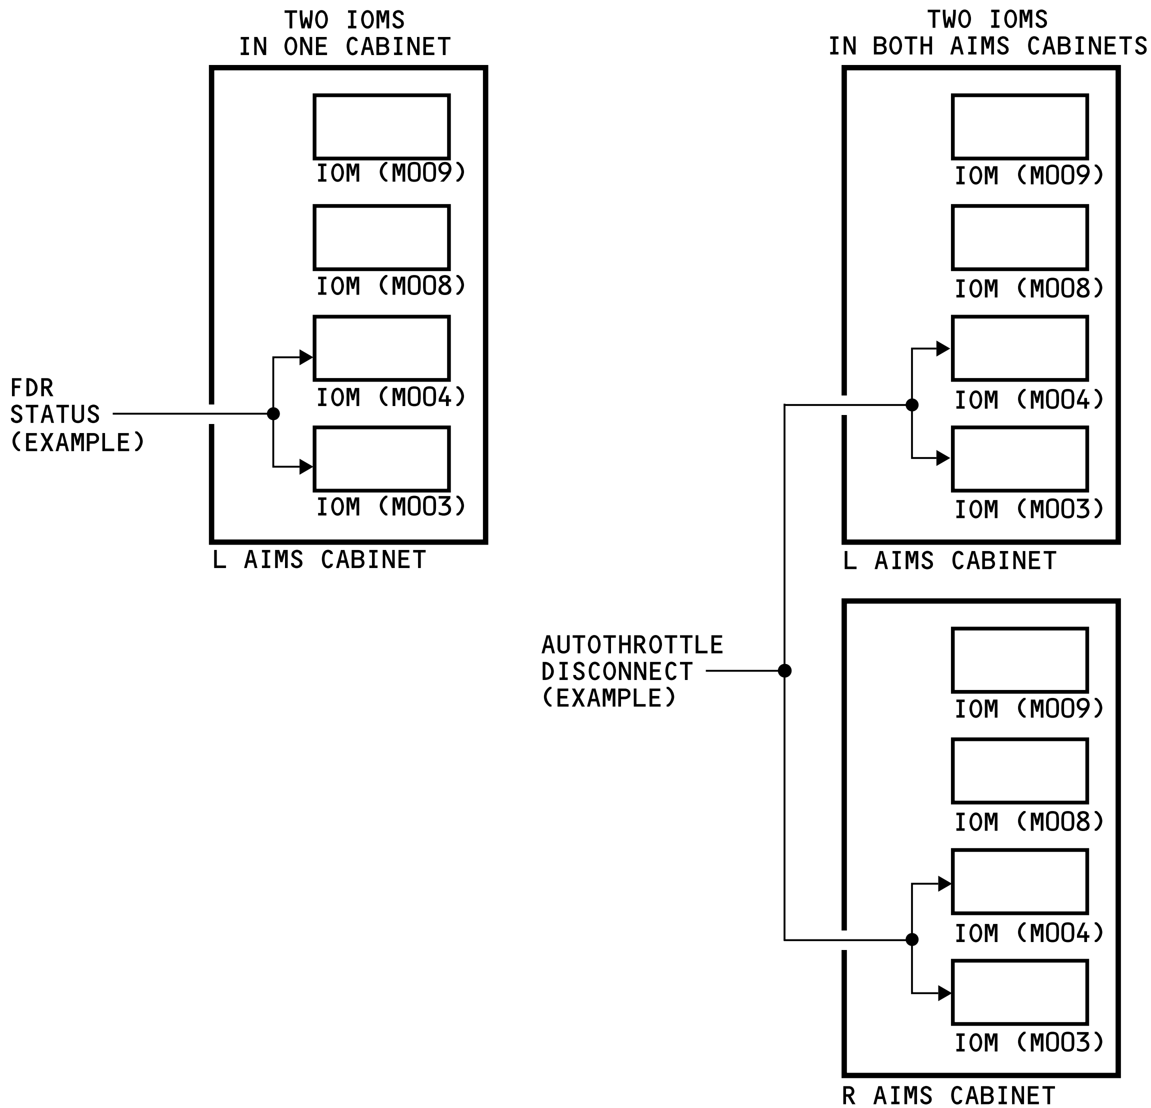
Training Information Point

For details of the exact interfaces between the LRUs and the IOMs, refer to the wiring diagram manual.



31-41-00-020 Rev 2

AIMS - ANALOG DISCRETE INPUTS INTERFACES

AIMS - ANALOG DISCRETES OUTPUTS INTERFACES

General

The AIMS cabinets transmit analog discretes in these three ways:

- The analog discrete output comes from one IOM in one AIMS cabinet
- The analog discrete comes from the outputs of two IOMs in the same AIMS cabinet. The outputs are wired together in that AIMS cabinet
- The analog discrete comes from the outputs of two IOMs in both AIMS cabinets. The outputs are wired together in each AIMS cabinet and in the airplane wiring outside the cabinet.

The CPM/Comm also has analog discrete outputs. They are all direct outputs.

Analog Discrete Outputs

The IOMs send these analog discretes:

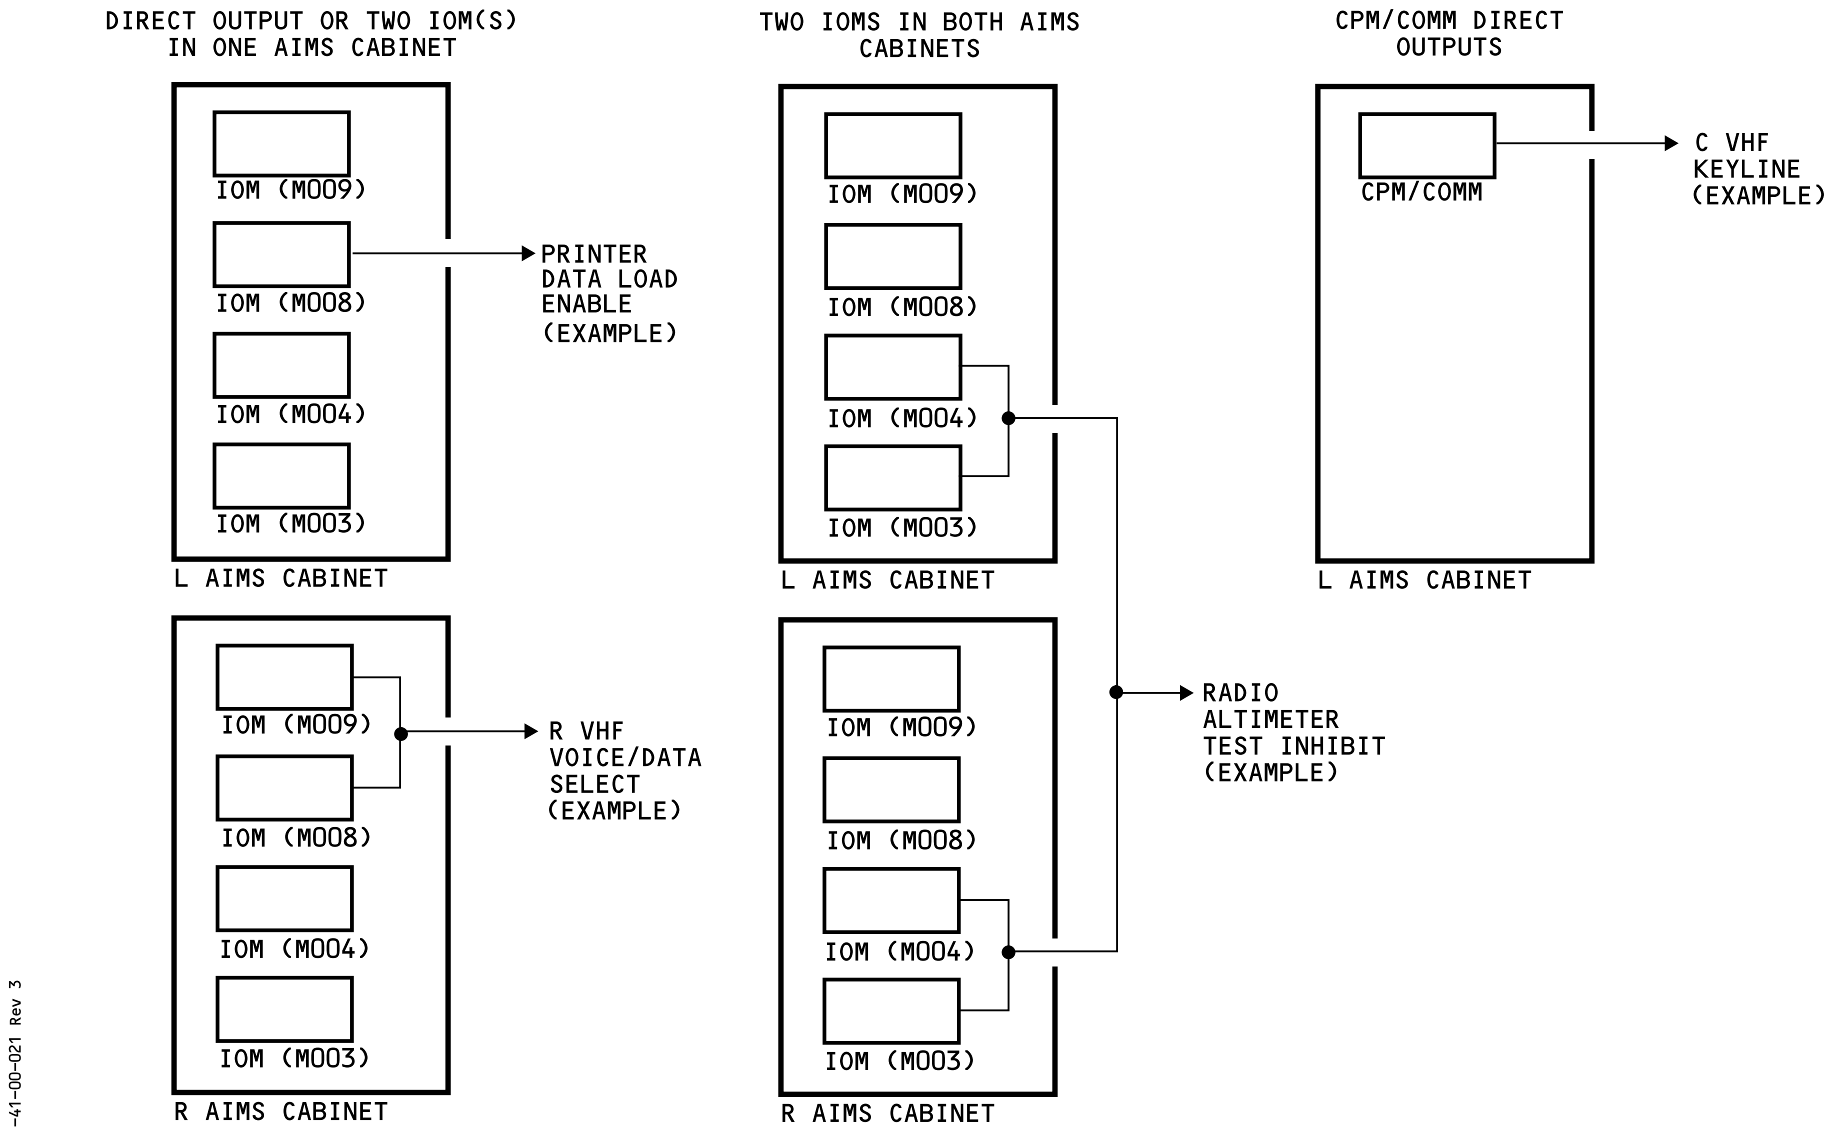
- Autothrottle servo inhibit
- Master caution lamp drive
- VHF voice data select
- VHF bite inhibit
- SDU data load enable
- Printer data load enable
- TCAS data load enable
- GPS data load enable
- ASCPC engine running
- Engine start solenoid
- PFC disconnect
- Radio altimeter test inhibit
- IRS 429 bus invalid
- WXR control on
- TCAS RA display status.

The CPM/Comm sends these analog discretes:

- VHF data keyline
- Bypass switch unit bypass control.

Training Information Point

For details of the exact interfaces between the IOMs or CPMs and the LRUs, refer to the wiring diagram manual.



AIMS - ANALOG DISCRETES OUTPUTS INTERFACES

AIMS - ANALOG INTERFACES

General

The input/output modules receive analog inputs in these three ways:

- The analog input goes to one IOM
- The analog input goes to two IOMs in the same AIMS cabinet
- The analog discrete input goes to two IOMs in each AIMS cabinets.

The input/output modules transmit analog outputs in these two ways:

- One IOM supplies the analog output
- One IOM in each AIMS cabinet supplies the analog output. The airplane wiring splices together the outputs.

Analog Inputs

The IOMs receive this analog data:

- Total air temperature
- Angle of attack
- Global positioning system time mark
- Crew oxygen pressure
- Passenger oxygen pressure
- Cabin pressure sensor
- N1 Tach
- N2 Tach
- Engine oil quantity sense.

Analog Outputs

IOMs send analog data to the engine oil quantity sensor. The AIMS cabinet sends a 6v dc oil quantity excitation voltage to the engine oil quantity sensor unit.

Training Information Point

For details of the exact interfaces between the IOMs and the LRUs, refer to the wiring diagram manual.

AIMS - ANALOG INTERFACES

AIMS - CABINET CHASSIS - 1

General

Each cabinet chassis is a rack enclosure. It can hold up to 11 LRMs. Currently, there are eight LRMs installed in the cabinet and three spare slots.

A printed wiring board called the backplane runs the width of the cabinet chassis. This backplane transfers the power and data to each LRMs.

Physical Description

The cabinet chassis has these dimensions:

- Width = 48 inches
- Depth = 24 inches
- Height = 12 inches.

The cabinet chassis weighs approximately 45 pounds.

With the eight LRMs installed, the AIMS cabinet weighs 146.4 pounds.

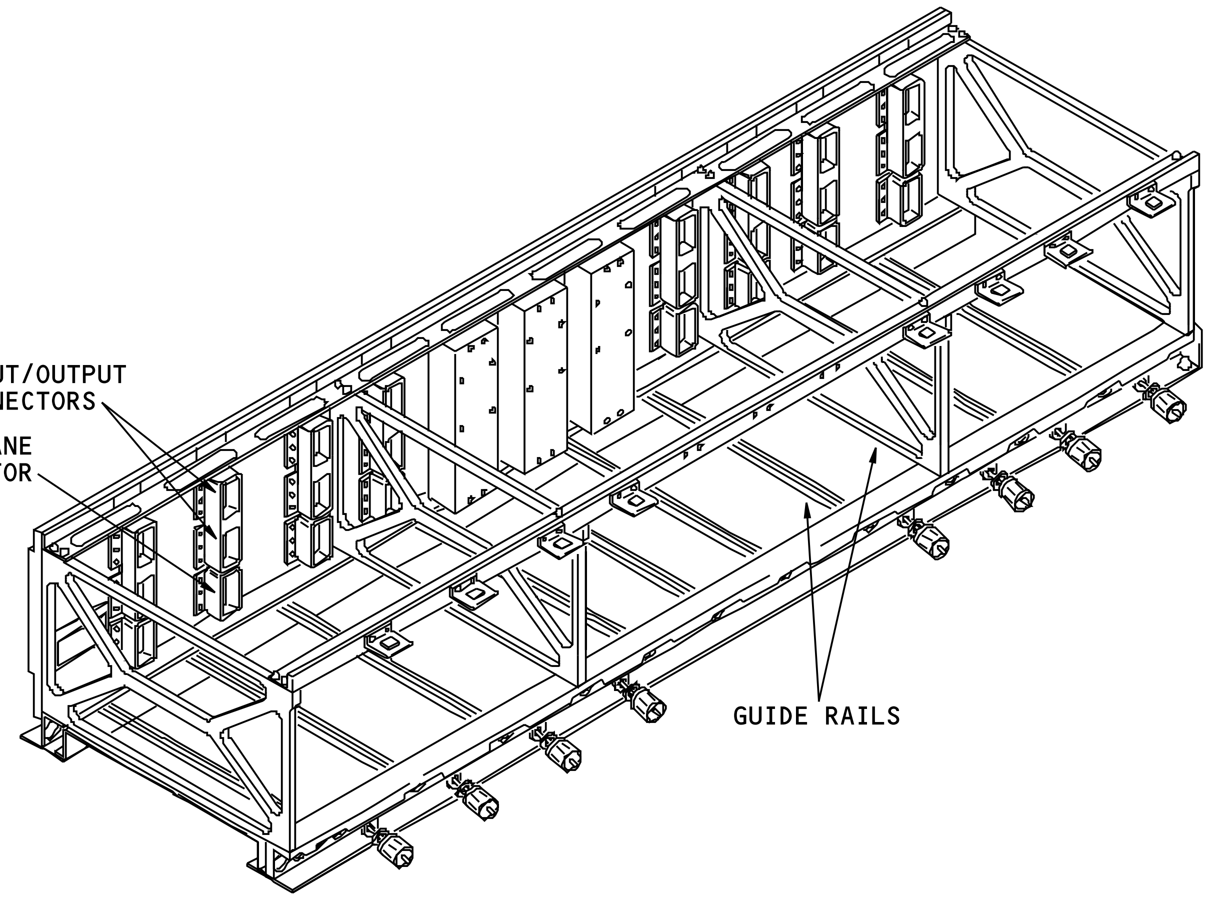
The Back of the Cabinet Chassis

In the back of the cabinet chassis, there are three ARINC 650 connectors for each slot. The top two connectors, A and B, are for input and output data. The bottom connector C, is for the interface to the backplane.

In the empty slot, there are load plugs on the bottom connector.

Installation

The cabinet has guide rails on the bottom surface and guide pins at the top and bottom of the rear connector to align the LRMs.



31-41-00-040 Rev 1

AIMS - CABINET CHASSIS - 1

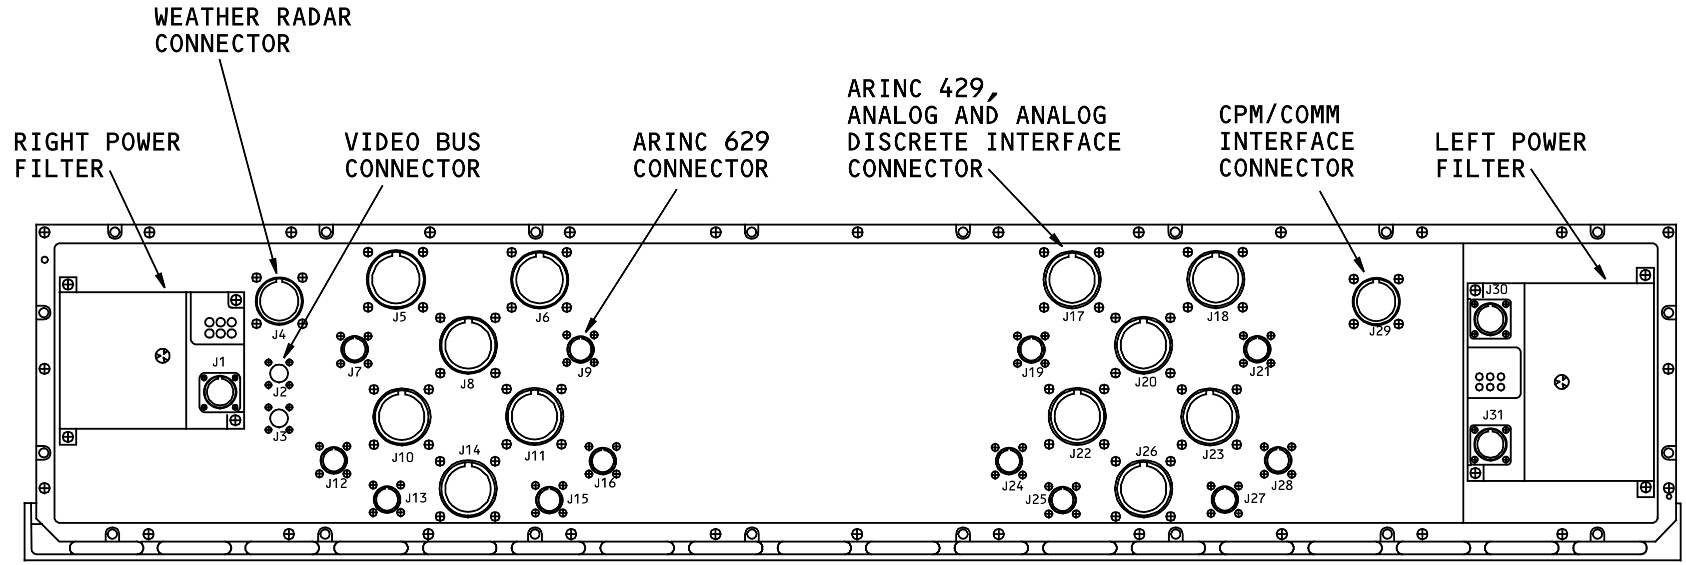
AIMS - CABINET CHASSIS - 2

The Rear of the Cabinet Chassis

These are the interface connectors on the rear of the cabinet:

- 12 connectors for ARINC 629 interface
- 2 connectors for video bus data output
- 12 connectors for ARINC 429, analog and analog discrete interface
- 3 connectors for power interface
- 1 connector for CPM/COMM interface
- 1 connector for ARINC 453, weather radar interface.

The airplane power comes into two power supply filters. These filter the power and distribute it on the backplane.



AIMS CABINET CHASSIS - REAR VIEW

31-41-00-023 Rev 4

AIMS - CABINET CHASSIS - 2

AIMS - INPUT/OUTPUT MODULE

General

The input/output module (IOM) supplies the interface between the software functions in the AIMS cabinet and external signal sources. The four IOMs supply most of the standard and shared interfaces necessary to operate the CPMs. The CPM/COMM and the CPM/GG supply some unique input and output interfaces.

Input/Output Modules

The IOM supplies these types of interfaces:

- 76 analog discrete inputs
- 16 analog discrete outputs
- 32 ARINC 429 data bus inputs
- 5 ARINC 429 data bus outputs
- 3 ARINC 629 data buses
- 12 analog inputs
- 2 analog outputs.

The IOMs also interface with the backplane data bus, and the backplane power bus to communicate with the software functions in the cabinet.

Physical Description

These are the dimensions of an IOM:

- 3.41 inches wide
- 15 inches deep (includes the handle assembly)
- 7.2 inches high.

The weight of an IOM is 10.6 pounds.

Installation

The IOMs have a hot insertion switch on the rear surface. This insertion switch keeps the cabinet +28v dc from the IOM until it makes positive contact between the IOM ARINC 650 connector and the backplane pins of the cabinet.

The four IOMs have the same keyed connectors. This makes the IOMs interchangeable.

31-41-00-024 Rev 2

AIMS - INPUT/OUTPUT MODULE

THIS PAGE INTENTIONALLY LEFT BLANK

AIMS - CORE PROCESSOR MODULES

General

The core processor modules (CPM) supplies the hardware and software for the AIMS functions. These are the four different CPMs:

- CPM/Communications (CPM/Comm)
- CPM/Basic
- CPM/Airplane condition monitoring function (CPM/ACMF)
- CPM/Graphics generator (CPM/GG).

Core Processor Modules

The CPM has internal slots for up to 7 circuit card assemblies (CCAs). The CPMs all have five basic CCAs. The remaining internal slots for CCAs contain unique CCAs to make each CPM different.

These are the five basic CCAs:

- Power supply CCA
- Backplane interface/power monitor (BIPM) CCA
- Processor CCA
- Instruction Memory CCA
- Data memory CCA.

The CPM/Comm has a sixth and a seventh CCA. These are the multifunction CCA and the fiber optics CCA. The purpose of the multifunction CCA is to:

- Transmit ARINC 717 formatted data
- Transmit and receive datalink data for the center and right VHF communication transceivers.

The fiber optics CCA transmits and receives data for the onboard local area network.

The CPM/Basic does not have any additional CCAs. It only has the 5 basic CCAs.

The CPM/ACMF has a sixth CCA. This CCA is the ACMF memory CCA. It supplies the static random access memory (SRAM) for the ACMF.

The CPM/GG has a sixth CCA. This CCA is the graphics generator CCA. This CCA has the weather radar and high speed coax interfaces necessary to support the displays.

Physical Description

The dimensions of the CPM/GG, CPM/Basic, and CPM/ACMF are:

- 4.18 inches wide
- 15 inches deep (includes the handle assembly)
- 7.2 inches high.

The CPM/Comm dimensions are the same except it is 6 inches wide. It is wider than the other CPM because it has the fiber optics connector.

The weight of the four CPM types is:

AIMS - CORE PROCESSOR MODULES

- CPM/Comm - 15.7 pounds
- CPM/ACMF - 13.5 pounds
- CPM/Basic - 12.3 pounds
- CPM/GG - 13.4 pounds.

Installation

The CPMs have a hot insertion switch on the rear surface. This insertion switch keeps the cabinet +28v dc from the CPM until it makes positive contact between the CPM ARINC 650 connector and the backplane pins of the cabinet.

Each CPM has a unique keyed connector, except for the CPM/basic and CPM/ACMF. Because the CPM/basic and CPM/ACMF are in the same cabinet position they have the same keyed connector. This allows the left and right cabinet to have the same part number.

Training Information Point

Although the CPM/Basic and CPM/ACMF have the same keyed connector, do not install a CPM/Basic in the left cabinet chassis. If you install the CPM/Basic in the left cabinet with the proper software, the CPM reports a hardware and software incompatibility to the central maintenance computing function.

AIMS - CORE PROCESSOR MODULES

THIS PAGE INTENTIONALLY LEFT BLANK

AIMS - CABINET CHASSIS POWER DISTRIBUTION FUNCTIONAL DESCRIPTION

General

A signal distribution area goes along the full width of the rear of the cabinet chassis. This area has a backplane power bus for power distribution.

Four power sources and the hot battery bus power source connect to an AIMS cabinet. The backplane power bus distributes the power inputs to each LRM. Power contacts on the LRM connector connect directly to the power backplane.

The steady state load is 700 W.

Input Power

Each cabinet receives four 28v dc inputs. The sources of 28v dc for the left AIMS cabinet are the 28v dc capt flight instrument bus and the 28v dc F/O flight instrument bus. The sources of 28v dc for the right AIMS cabinet are the 28v dc left bus and 28v dc right bus.

The four 28v dc bus inputs are power 1 through power 4. Power 1 and power 2 enter the cabinet through a connector on the left side of the cabinet. Therefore, power 1 and power 2 are left power.

Power 3 and power 4 enter the cabinet through a connector on the right side of the cabinet. Therefore, power 3 and power 4 are right power.

Each LRM receives power from four sources, two for main power and two for monitor power. The main circuitry uses the main power. Special circuits that monitor the condition of the power supply in the LRM use the monitor power. The two main and two monitor sources of power for each LRM come from different power sources.

Each LRM must have at least one main and one monitor power input to operate.

The loss of any one of the four power buses to the backplane power bus or to any one LRM has no effect on the function of the LRMs.

The loss of two power inputs from the same side of the cabinet, left or right, has no effect on the function of the LRMs. The loss of one power input from the left side and one power input from the right side results in the loss of function in four LRMs.

The loss of three or four of the power buses to the cabinet chassis power backplane results in the loss of function of all the LRMs.

Training Information Point

The status message AIMS shows when one or more of the power inputs has failed for one second.

Hot Battery Bus

Each LRM also receives one 28v dv power source from the hot battery bus.

AIMS - CABINET CHASSIS POWER DISTRIBUTION FUNCTIONAL DESCRIPTION

The connection to the hot battery bus keeps the LRMs internal memories active. The hot battery bus also makes the AIMS cabinet less likely to have faults due to power transients. The LRMs shut down after 500 msec of hot battery bus power operation.

Training Information Point

The hot battery bus holds the static random access memory (SRAM) with no other power on the airplane. If you remove the battery, you lose some data from the LRMs. The data you lose includes:

- ACMF report data stored on the ACMF CCA
- Fault history data collected by the CMCF.

Power Distribution

Each LRM changes the 28v dc from the backplane power buses into:

- Voltages required by the LRM
- 5v dc transceiver voltage
- 2v dc termination voltage.

Each LRM sends a 5v dc transceiver voltage to one of the four transceiver power backplanes. This power is used by the transceivers in the LRMs.

Each LRM sends a 2v dc termination voltage to one of the four termination power backplanes. Terminators on the ends of the backplane data buses use the power from the 2v termination power backplanes.

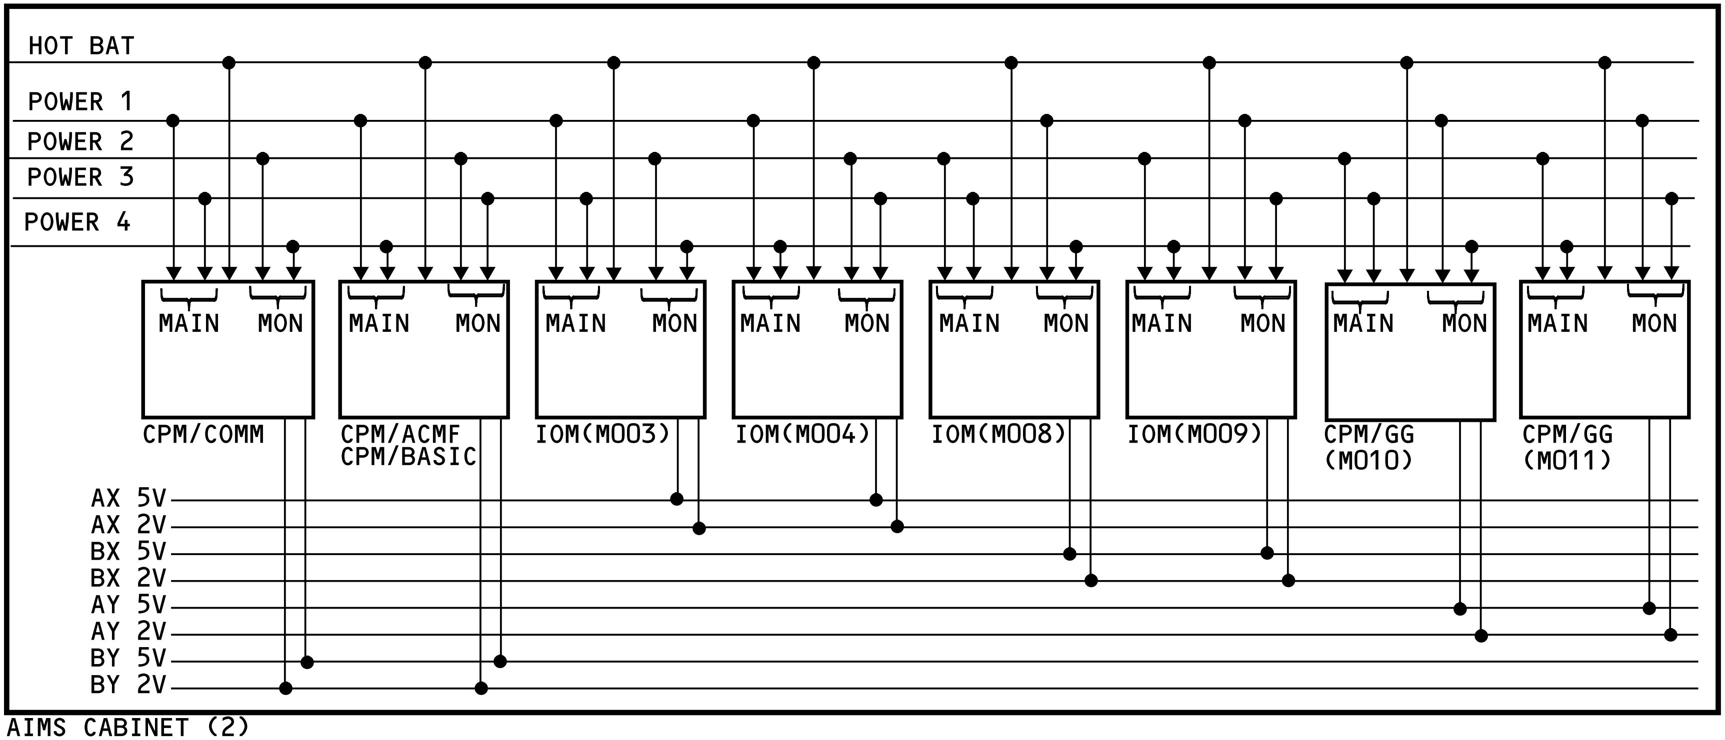
Training Information Point

Each LRM has a hot insertion switch. The switch makes sure that the LRM does not get power until it has positive contact between its connector pins and the backplane pins.

When you install an LRM into the cabinet, this sequence occurs:

- The ground, power, and signal pins in the connector make contact with the backplane ground, power, and signal pins
- The hot insertion switch engages. This lets the power from the backplane go to the power in the LRM.

When you remove an LRM from the cabinet, the reverse sequence occurs.



LOSS OF POWER INPUTS							
POWER 1 AND 3		POWER 2 AND 4		POWER 1 AND 4		POWER 2 AND 3	
MAIN	MONITOR	MAIN	MONITOR	MAIN	MONITOR	MAIN	MONITOR
CPM/COMM IOM(M003)	CPM/GG(M011) IOM(M009)	CPM/GG(M011) IOM(M009)	CPM/COMM IOM(M003)	CPM/ACMFORBASIC IOM(M004)	CPM/GG(M010) IOM(M008)	CPM/GG (M010) IOM(M008)	CPM/ACMFORBASIC IOM(M004)

NOTE: AN LRM MUST HAVE AT LEAST ONE MAIN AND ONE MONITOR POWER INPUT TO OPERATE. LOSS OF TWO POWER INPUTS, ONE FROM EACH SIDE (LEFT AND RIGHT) RESULTS IN THE LOSS OF LRMS ACCORDING TO ABOVE TABLES.

AIMS - CABINET CHASSIS POWER DISTRIBUTION FUNCTIONAL DESCRIPTION

31-41-00-026 Rev 5 03/28/95

AIMS - CABINET CHASSIS BACKPLANE DATA BUSES FUNCTIONAL DESCRIPTION

General

A signal distribution area goes along the entire width of the rear of the cabinet chassis. This area has four serial backplane data buses. These data buses distribute data between the LRMs.

The data on the backplane buses transfers at a rate of 60 million bits per second (Mbps).

Data Distribution

The serial buses are AX, BX, AY and BY. The buses all transmit the same information. The two serial buses AX and BX come from the X bus interface in the LRM, and are a bus pair. The two serial buses AY and BY come from the Y bus interface in the LRM and are a bus pair. With the dual redundant buses, the LRM can isolate failures in the module.

A serial bus consists of three signal lines. Two of the signal lines are data lines and the third signal line is a clock line. A terminator at each end of a serial bus terminates the three signal lines. The terminator gets power from the termination power backplane bus.

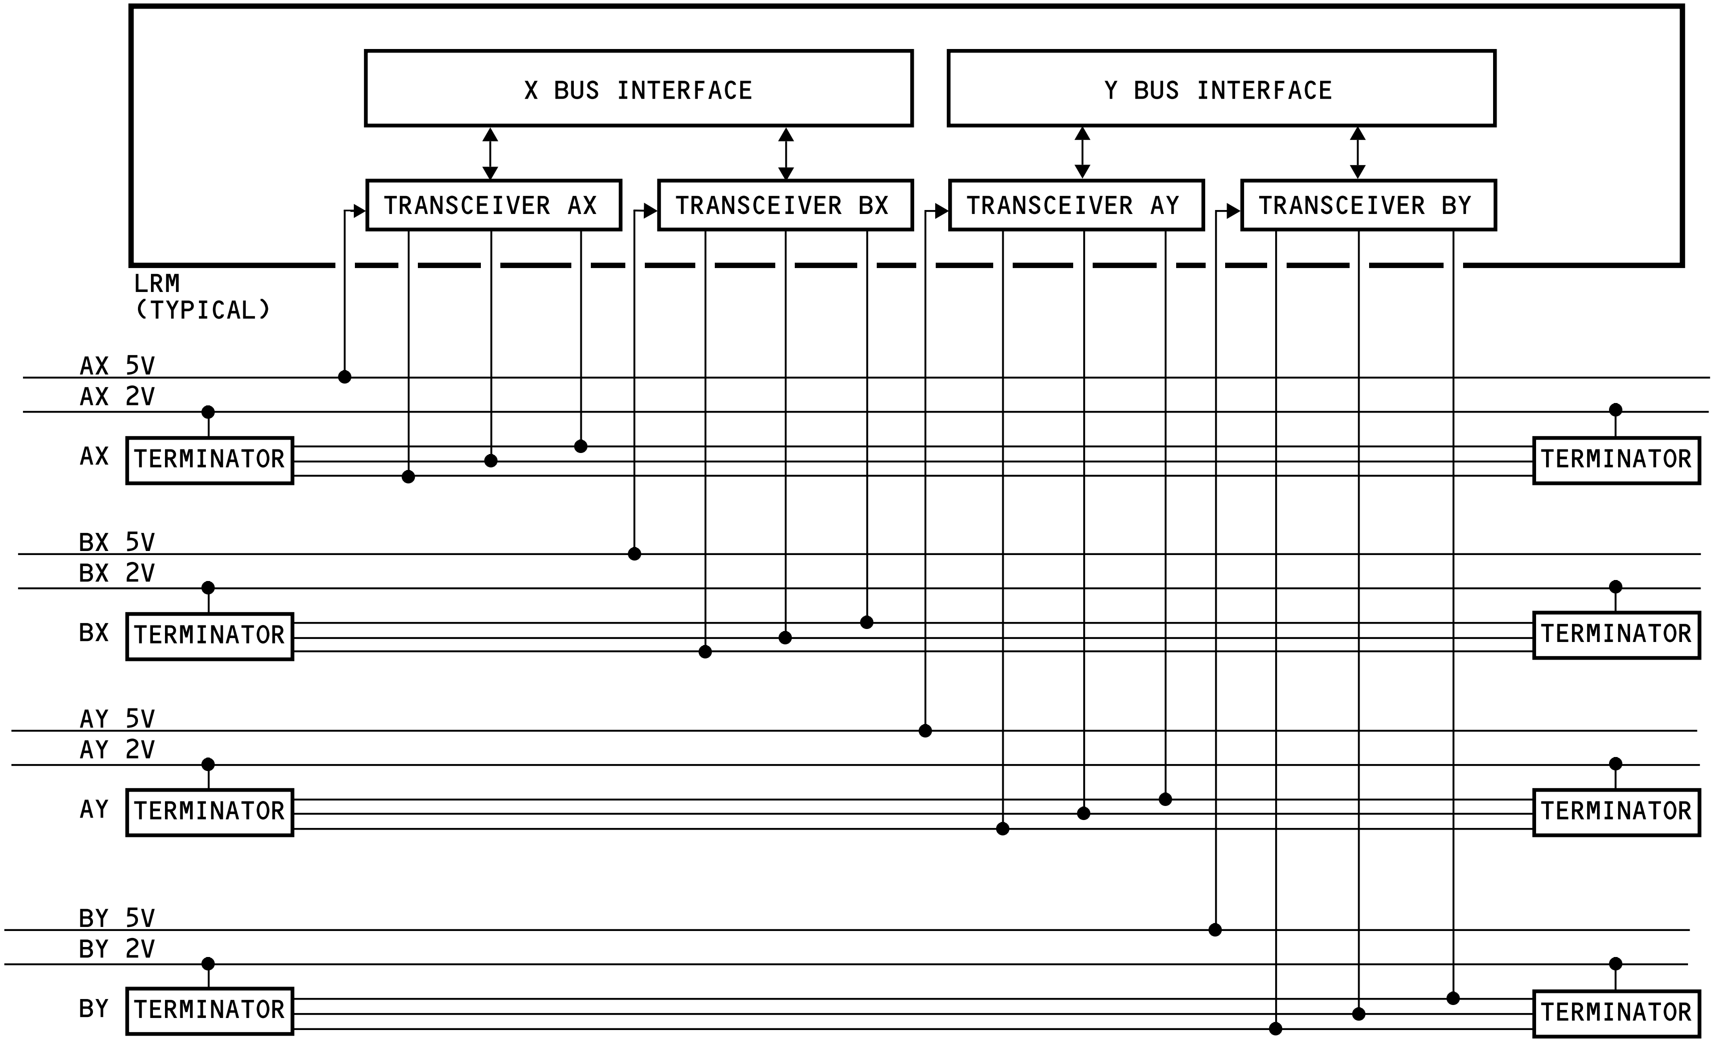
Transceivers in each LRM transmit data to and receive data from the backplane data buses. The LRM transmits data on all four of the serial buses at the same time. The transceivers get power from the transceiver power backplane bus.

The LRM compares the data it transmits on serial buses AX and BX with the data it transmits on serial buses AY and BY.

The duplicate bus pairs supply bit-for-bit identical information. The duplication supplies error detection, isolation, and containment.

Training Information Point

The status message AIMS shows when one or more of the serial backplane data buses fail for one second. All communication can be lost over a serial bus if a transceiver shorts out the serial bus or if power to the terminators fails.



31-41-00-027 Rev 5 07/10/95

AIMS - CABINET CHASSIS BACKPLANE DATA BUSES FUNCTIONAL DESCRIPTION

AIMS - INPUT/OUTPUT MODULE FUNCTIONAL DESCRIPTION

General

The input/output module (IOM) supplies the interface between the software functions in the AIMS cabinet and external signal sources. The four IOMs supply most of the standard and shared input and output interfaces necessary to operate the CPMs. Some unique input and output interfaces are supplied by the CPM/Comm and the CPM/GG.

The IOM does not monitor or interrogate any data that passes through it. The IOM is only a high-speed data mover.

IOM Hardware

The IOM has these four circuit card assemblies (CCAs):

- Power supply CCA
- Input/output controller/ backplane interface/power monitor (IOC/BIPM) CCA
- ARINC 629/429 CCA
- Analog and discrete/ARINC 629 CCA.

Power Supply CCA

The power supply CCA receives 28v dc from five sources on the power backplane. The power supply CCA supplies power for:

- IOM CCAs
- 5v dc transceiver power backplane
- 2v dc termination power backplane
- Different I/O interfaces.

I/O Controller/Backplane Interface/Power Monitor CCA

The I/O controller/backplane interface/power monitor (IOC/BIPM) CCA has:

- One single thread interface
- Two I/O controllers (IOC)
- Two backplane interface/power monitors (BIPM)
- Four transceivers.

The single thread interface receives data from the input and output interfaces and sends the data to the X IOC and the Y IOC. The single thread interface also receives data from the X IOC and sends the data to the input and output interfaces.

The I/O controllers (IOC) control the operation of the different IOM input and output interfaces. The IOCs receive data from the single thread interface and transmit the data to the BIPMs. Each IOC receives data from a BIPM and compares the data with the other IOC. IF the data is the same, the X IOC sends the data to the single thread interface.

The IOC also supplies the BITE for the IOM. The IOC BITE supplies an IOM BITE history log and an IOM fault history log. The IOC communicates with the four core processing modules to supply IOM BITE data. The functions in the CPMs use the BITE data to check for I/O interface faults.

AIMS - INPUT/OUTPUT MODULE FUNCTIONAL DESCRIPTION

The IOCs operate in a dual, self-monitoring configuration. The IOCs are identical. The self-monitoring operation allows both IOCs to execute the same instructions on a clock-for-clock basis. The IOCs cross-compare all signals during normal operation. This is called lock-step operation. If the data in each IOC is the same, the X IOC sends the data to the single thread interface. If the data in each IOC is different, the IOCs will not send any more data to the I/O interfaces.

The X BIPM sends data to and receives data from the AX and BX transceivers. The X BIPM also sends data to and receives data from the X IOC. The Y BIPM sends data to and receives data from the AY and BY transceivers. The Y BIPM also sends data to and receives data from the Y IOC.

The BIPM has an intermodule memory (IMM) array for data storage. The IMM array holds the data to be passed from one LRM to another LRM in the cabinet. The IMM array, in combination with the data bus interface, supplies an orderly flow of the data.

For input and output data, the functions in the CPMs need to know what place in the array in the IMM to write to for output data and what place in the array IMM to read from for input data.

The BIPMs also monitor power for the IOM. The BIPMs detect over voltage and under voltage conditions. The BIPMs prevent IOM operation during these conditions.

The monitor circuits use a different power source than the rest of the IOM for operation.

The four transceivers supply the interface between the backplane data buses and the BIPM. The four transceivers receive 5v dc from the transceiver power backplane.

ARINC 629 And ARINC 429 CCA

The ARINC 629 and ARINC 429 CCA supplies the interface between the IOC/BIPM CCA and the ARINC 629 and ARINC 429 buses.

The ARINC 629 interface transmits data to and receives data from the ARINC 629 buses. There are two ARINC 629 terminals in this CCA. There is another ARINC 629 terminal in the analog and discrete/ARINC 629 CCA. Each ARINC 629 terminal has one transmit bus and one receive bus.

The ARINC 429 interface transmits data to and receives data from the ARINC 429 buses. An IOM has 27 ARINC 429 receivers and five ARINC 429 transmitters. Each transmitter has a wrap around receiver that monitors the transmitted data. The five wrap around receivers make the total number of receivers equal to 32.

Two of the ARINC 429 transmit channels are sent out through relays. The other input into each relay is from the other AIMS cabinet or from another IOM in the same AIMS cabinet. The AIMS functions in the CPMs supply the relay control. The functions that supply the ARINC 429 source select logic are:

- Flight management computing function
- Central maintenance computing function
- Data conversion gateway function
- Data communication management function.

Analog and Discrete/ARINC 629 CCA

The analog and discrete/ARINC 629 CCA supplies the interface between the IOC/BIPM and the analog inputs and outputs, the discrete inputs and outputs and one ARINC 629 channel.

The analog and discrete interface supplies 76 discrete inputs. Sixteen of the inputs are wrap around discretes. The total number of discrete inputs available for other inputs is 60. The analog and discrete interface converts the discrete inputs to a digital format. The IOC/BIPM CCA transmits the digital data on the backplane data bus to the CPMs.

The analog and discrete interface supplies sixteen discrete outputs. Wrap around discrete inputs monitor the discrete outputs. The analog and discrete interface coverts the digital data from the IOC/BIPM CCA and sets the analog discrete outputs.

The analog and discrete interface supplies 11 analog inputs and converts the analog inputs to a digital format. The IOC/BIPM CCA transmits the digital data on the backplane data bus to the CPMs.

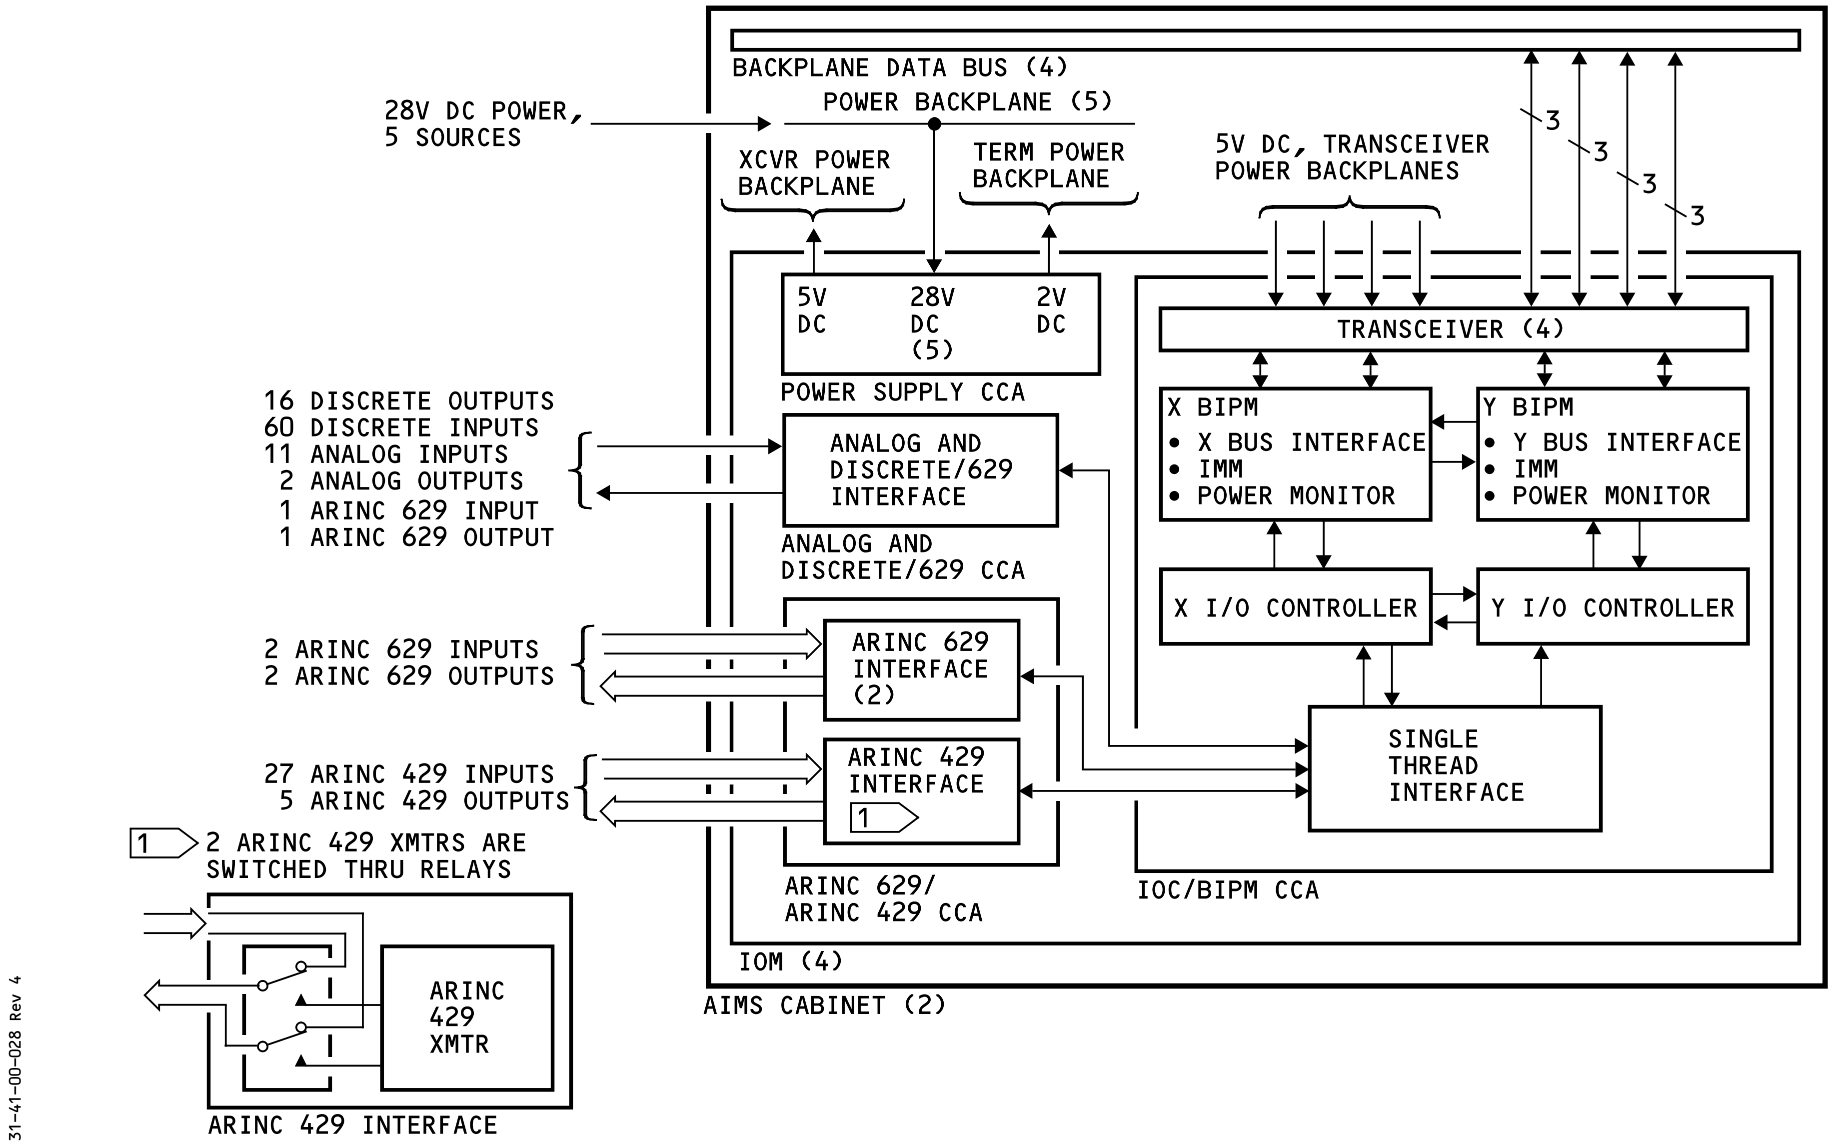
The analog and discrete interface supplies two analog outputs. It converts the digital data from the IOC/BIPM CCA and supplies the analog discrete outputs.

IOM Slot Position

The IOMs all have the same hardware and software. The IOM gets its slot identity from a ground that the cabinet supplies.

Training Information Point

At power up, the IOMs go through an initialization phase where they read their slot identity and configure themselves to the slot they are in. If you remove and install an IOM, when you reapply power to the cabinet, the IOM will go through the initialization phase.



AIMS - INPUT/OUTPUT MODULE FUNCTIONAL DESCRIPTION

AIMS - CORE PROCESSOR MODULE/BASIC FUNCTIONAL DESCRIPTION

General

These are the four types of core processor modules:

- CPM/Basic
- CPM/Graphics generator (CPM/GG)
- CPM/Airplane condition monitoring function (CPM/ACMF)
- CPM/Communication (CPM/Comm).

Each CPM has the same basic hardware and some unique hardware. Each of the CPMs have the same hardware as the CPM/Basic and then some unique hardware to make it different.

The CPM/Basic does the calculations for these systems:

- Flight management computing system
- Thrust management computing system.

CPM Hardware

The core processor modules have:

- lockstep processors
- Memory devices
- Application specific integrated circuits
- Support hardware.

All of this is mounted on circuit card assemblies in the CPM.

Circuit Card Assemblies

The CPMs have internal slots for up to 7 circuit card assemblies (CCAs). The CPMs all have five basic CCAs. The remaining internal slots for CCAs contain unique CCAs to make each CPM different.

These are the five basic CCAs:

- Power supply CCA
- Backplane interface/power monitor (BIPM) CCA
- Processor CCA
- Instruction Memory CCA
- Data memory CCA.

The sixth and seventh slots have a unique CCA in some CPMs. This makes each of the four types of CPMs different.

The CPM/Basic only has the five basic CCAs. The CPM/Basic is described here.

Power Supply CCA

The power supply CCA receives 28v dc from five sources on the power backplane. The power supply CCA supplies power for these functions:

- The other CCAs
- 5v dc transceiver power backplane
- 2v dc termination power backplane.

AIMS - CORE PROCESSOR MODULE/BASIC FUNCTIONAL DESCRIPTION

Backplane Interface/Power Monitor CCA

The backplane interface/power monitor (BIPM) CCA has two backplane interface/power monitors (BIPM) interface circuits and four transceivers.

The CPM uses the BIPMs for communication to the other CPMs and to the IOMs on the backplane data bus. The BIPM CCA also monitors the CPM power.

The X BIPM sends data to and receives data from the AX and BX transceivers. The Y BIPM sends data to and receives data from the AY and BY transceivers. The X BIPM and Y BIPM also sends data to and receives data from the processor CCA.

The BIPM has an intermodule memory (IMM) array for data storage. The IMM array holds the data to be passed from one LRM to another LRM in the cabinet. The IMM array, in combination with the bus interface, supplies an orderly flow of the data.

The BIPMs detect over voltage and under voltage conditions. The BIPMs prevent IOM operation during these conditions. The monitor circuits use a different power source than the rest of the CPM for operation.

The four transceivers supply the interface between the backplane buses and the backplane data bus/IMM interface circuits. The transceivers receive 5v dc from the transceiver power backplanes.

Processor CCA

There are two identical microprocessors on the processor CCA. The microprocessors do the same operations and use the same software from memory. The processor CCA has bus comparison circuits to compare the data and control the buses of the two microprocessors. The bus comparison circuits check that the microprocessors generate and receive identical information. The bus comparison circuits report a fault to BITE if the data is not identical.

Instruction Memory and Data Memory CCAs

The microprocessors access instruction memory from the instruction memory CCA through the bus comparison circuits. The microprocessors also access data memory from the data memory CCA through the bus comparison circuits. Both memories are software loadable. The memories use electrically erasable programmable read only memory (EEPROM) devices and battery-backed static random access memory (SRAM) devices.

The instruction memory stores operational (OPS) software. It includes this software:

- Core software
- BITE software
- Operational software for the AIMS functions.

Each microprocessor accesses this instruction software and does the instructions directly out of the instruction memory.

AIMS - CORE PROCESSOR MODULE/BASIC FUNCTIONAL DESCRIPTION

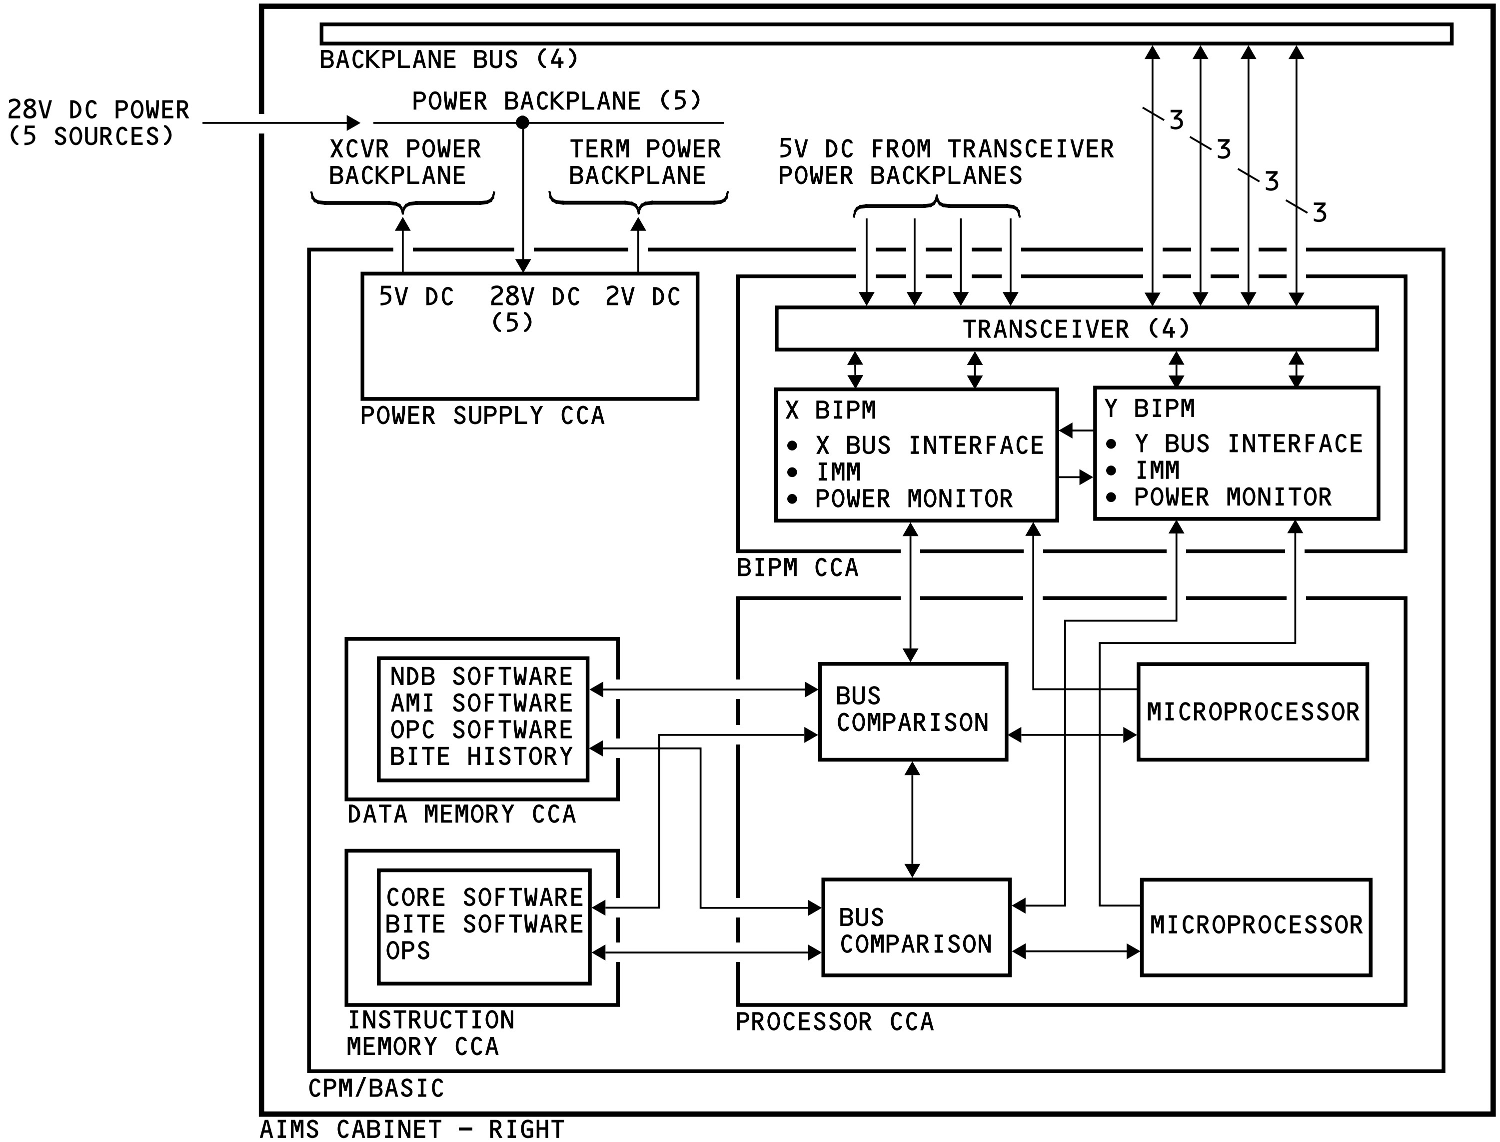
The data memory stores databases and program variables.

These are the databases:

- Navigation database (NDB) software
- Airline modifiable information (AMI) software
- Operational program configuration file (OPC) software
- BITE history data.

These are the program variables:

- FMCF CDU entered data
- CMCF existing faults
- CMCF fault histories.



AIMS - CORE PROCESSOR MODULE/BASIC FUNCTIONAL DESCRIPTION

31-41-00-029 Rev 4 02/20/95

AIMS - CORE PROCESSOR MODULE/AIRPLANE CONDITION MONITORING FUNCTION FUNCTIONAL DESCRIPTION

General

The core processor module/airplane condition monitoring function (CPM/ACMF) uses the same hardware as the CPM/Basic and additional hardware to supply memory to store reports and variables for the airplane condition monitoring system.

The CPM/ACMF does computations for these systems:

- Flight management computing system
- Thrust management computing system
- Airplane condition monitoring system.

CPM/ACMF Hardware

In addition to the five standard CCAs, the CPM/ACMF has a sixth CCA. The sixth CCA is the ACMF memory CCA. The ACMF memory CCA has 6 Mbytes of battery backed static random access memory (SRAM).

ACMF Memory CCA

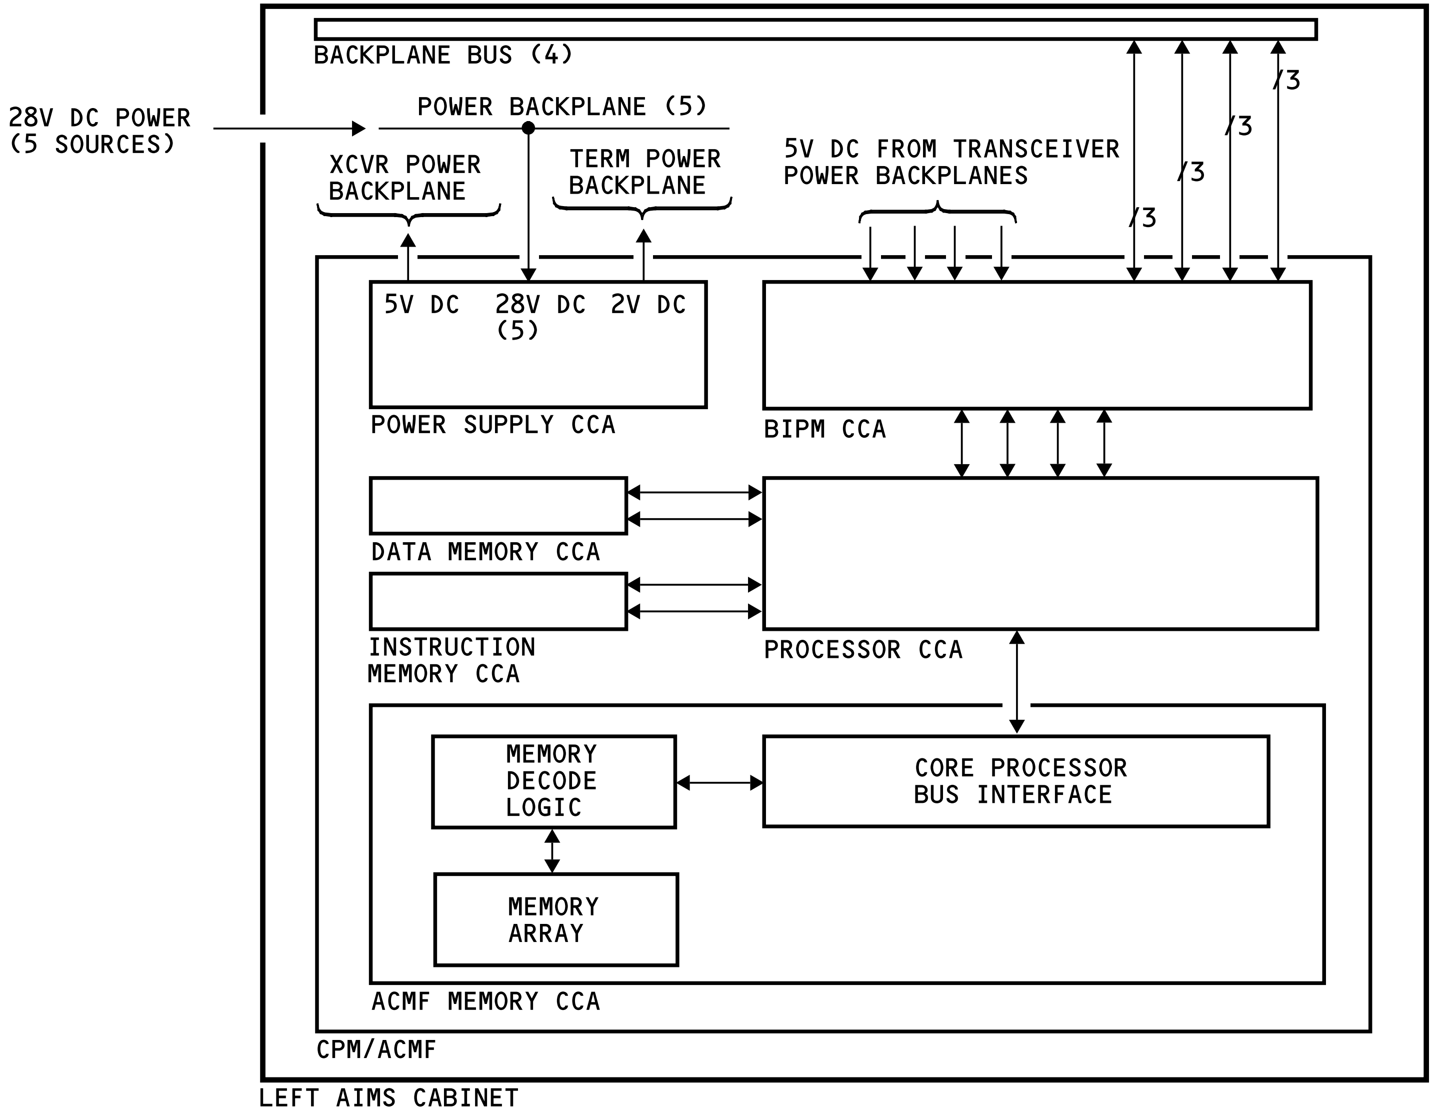
The ACMF memory CCA includes the:

- Core processor bus interface
- Memory array
- Memory decode logic.

The core processor bus interface communicates with the processor CCA. It supplies the protocol for the data transfers between the ACMF memory CCA and the processor CCA.

The memory array is 6 Mbytes of SRAM. The memory array stores reports and variables.

The memory decode logic supplies the control signals to the memory array. It is the interface between the core processor bus interface and the memory array.



31-41-00-030 Rev 2

AIMS - CORE PROCESSOR MODULE/AIRPLANE CONDITION MONITORING FUNCTION FUNCTIONAL DESCRIPTION

AIMS - CORE PROCESSOR MODULE/GRAPHICS GENERATOR FUNCTIONAL DESCRIPTION

General

The core processor module/graphics generator (CPM/GG) uses the same hardware as the CPM/Basic and additional hardware to generate image data for the six display units.

The CPM/GGs do the calculations for the primary display system.

CPM/GG Hardware

In addition to the five standard CCAs, the CPM/GG has a sixth CCA. This sixth CCA is the graphics generator (GG) CCA. The graphics generator CCA generates display formats and transmits this information to the display units.

GG CCA

The GG CCA includes these functions:

- Core processor bus interface
- Vector generation logic
- Weather radar logic
- Data compression/transmission.

The core processor bus interface communicates with the processor CCA. It supplies the protocol for the data transfers between the GG CCA and the processor CCA.

The vector generation logic creates these display functions:

- Lines
- Arcs
- Characters
- Background shading colors.

The vector generation logic receives graphics instructions from the core processor bus interface. The vector generation logic supplies the display format data to the data compression/transmission logic.

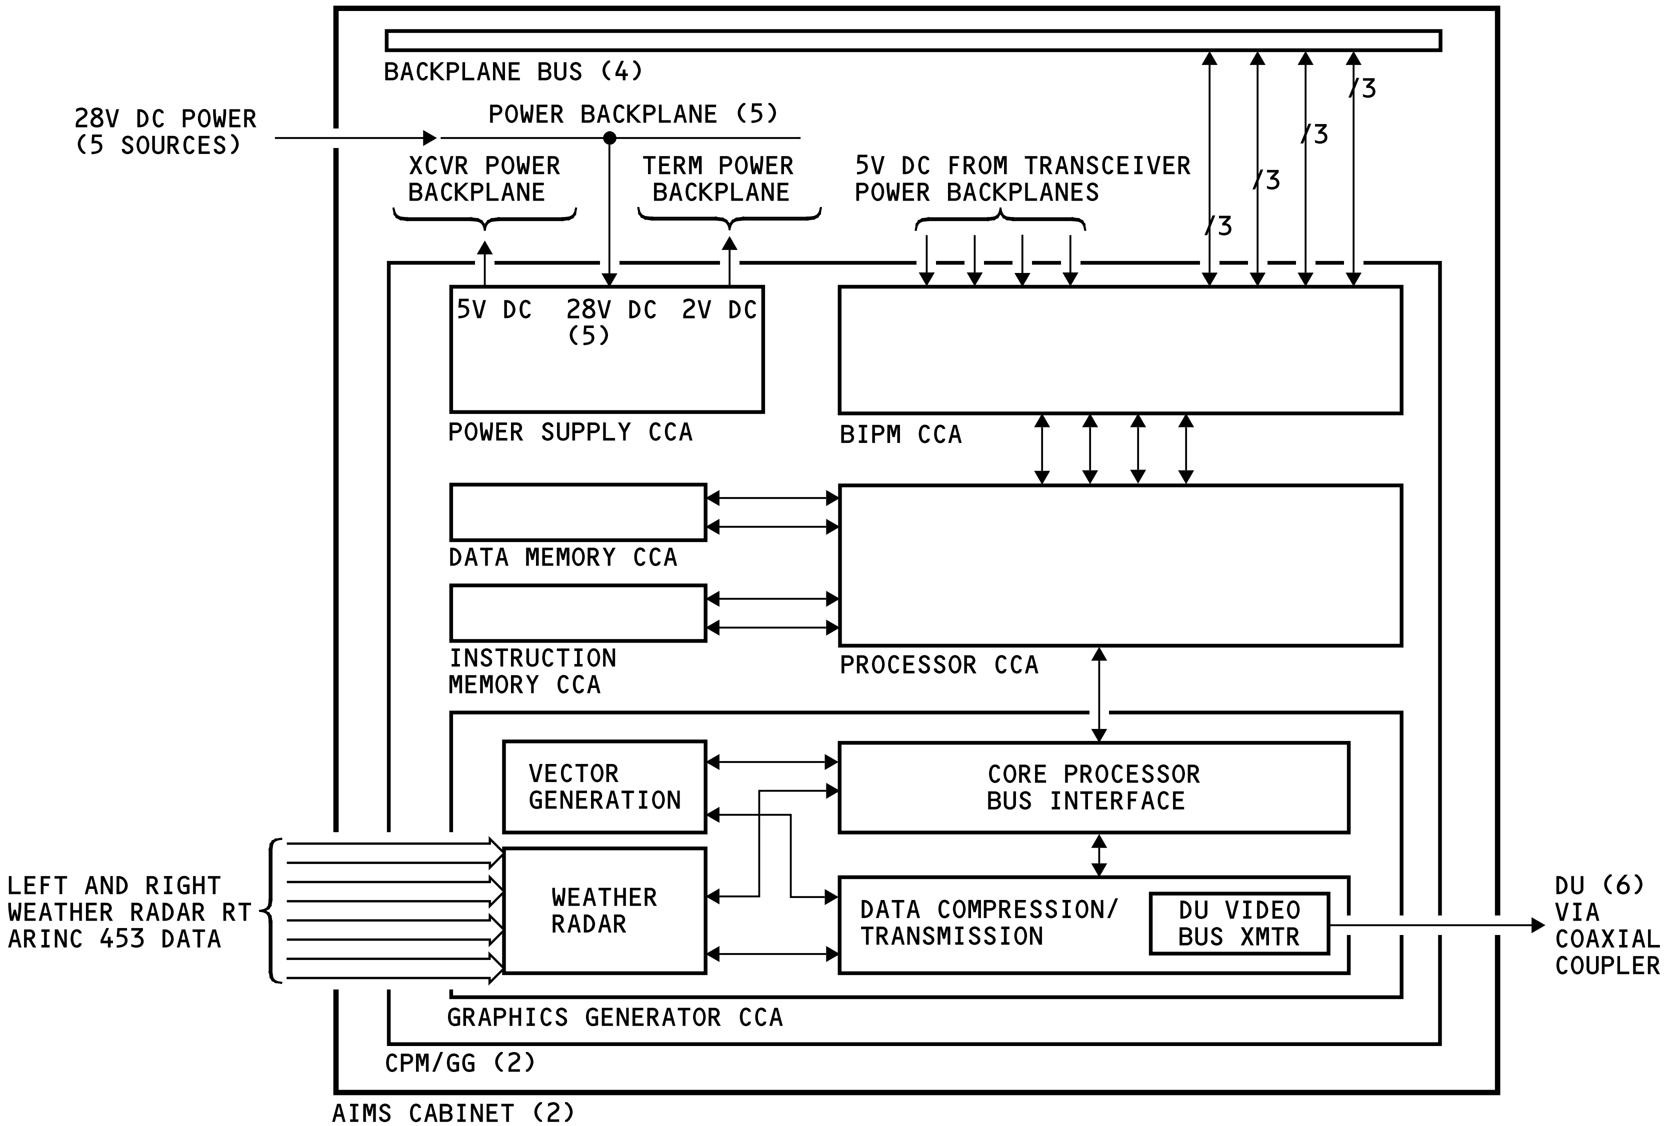
The weather radar logic does these functions:

- Receives weather radar ARINC 453 data from the left and right weather radar receiver-transmitters
- Creates raster type map image for display
- Calculates and adjusts the radar data to correct for airplane motion
- Supplies the weather radar data to the data compression/transmission logic.

The data compression/transmission logic:

- Combines data from the vector generation logic and the weather radar logic
- Compresses the data
- Transmits the data to the display units.

The data compression/transmission logic has a display unit video bus transmitter. The transmitter sends image data to the display units at a 125 Mbit per second rate. The data compression/transmission logic receives transmission instructions from the core processor bus interface.



AIMS - CORE PROCESSOR MODULE/GRAPHICS GENERATOR FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

AIMS - CORE PROCESSOR MODULE/COMMUNICATIONS FUNCTIONAL DESCRIPTION

General

The core processor module/communications (CPM/Comm) uses the same hardware as the CPM/Basic and additional hardware to supply unique interfaces not supplied by the IOMs.

The CPM/Comm does the calculations for these systems:

- Flight data recorder system
- Central maintenance computing system
- Data communication management system.

CPM/Comm Hardware

In addition to the five standard CCAs, the CPM/Comm has two additional CCAs. The two CCAs are the multifunction CCA and the fiber optics CCA.

Multi-Function CCA

The multifunction CCA has these interfaces:

- Core processor bus interface
- Datalink ARINC 618 interface
- FDR ARINC 717 interface
- QAR ARINC 717 interface
- QAR RS422 interface.

The core processor bus interface supplies the protocol for the data transfers between the processor CCA and the:

- Datalink ARINC 618 interface
- FDR ARINC 717 interface
- QAR ARINC 717 interface
- QAR RS422 interface
- Fiber optics interface in the fiber optics CCA.

The datalink ARINC 618 interface does these functions:

- Receives data modulated on tones from the center or right VHF communication transceiver
- Demodulates the tones and determines the message data
- Transmits the message data to the DCMF.

The datalink ARINC 618 interface also does these functions:

- Receives message data from the DCMF
- Modulates audio tones with the message data
- Transmits the data modulated on the audio tones to the center or right VHF radio.

The datalink ARINC 618 interface also transmits faults to the DCMF.

The center VHF communication transceiver interfaces with the CPM/Comm in the left AIMS cabinet. The right VHF communication transceiver interfaces with the CPM/Comm in the right AIMS cabinet.

The FDR ARINC 717 interface receives data from the DFDAF software. The FDR ARINC 717 interface in the right AIMS cabinet transmits the data to a relay in the left AIMS cabinet. The DFDAF software in the left AIMS cabinet controls the relay and selects between the data received from the DFDAF in the left AIMS cabinet and the data received from the right AIMS cabinet. The FDR ARINC 717 interface in the left AIMS cabinet transmits the selected source of data from this relay to the FDR.

The FDR ARINC 717 interface also transmits faults to the DFDAF.

The QAR ARINC 717 and RS422 interface are not used.

Fiber Optics CCA

The fiber optics CCA contains two optic transmitters and receivers. These transmitters and receivers are the interface to the avionics local area network bypass switch units. The left AIMS cabinet communicates with BSU 1. The right AIMS cabinet communicates with BSU 2. The DCMF software in the CPM/Comm transfers data to and receives data from the fiber optics.

AIMS - AIRLINE MODIFIABLE INFORMATION OVERVIEW

General

The airplane information management system (AIMS) must have several types of software loads. These are the types of software:

- Operational program software (OPS) in all CPMs and IOMs
- Operational configuration files (OPC) in all CPMs
- Navigation Data Base (NDB) software for the FMCF function
- Airline modifiable information (AMI) software for related functions.

The design of the 777 airplane gives the option to permit airlines to customize the operation of some of the functions in AIMS.

AMI software supplies this flexibility. Baseline AMI software and default values provides basic functionality for the related AIMS systems.

If you make the decision to modify or customize the basic functionality, you use the ground based software tool (GBST to develop the new AMI. You must have a Sun workstation to operate the software for the GBST.

Baseline AMIs

Baseline AMIs supply an initial level of functionality for several AIMS functions.These are the functions that use baseline AMIs:

- Airplane condition monitoring function (ACMF)
- Flight deck communication function (FDCF)
- Electronic checklist (ECL) portion of the primary display function (PDF)
- Central maintenance computing function (CMCF).

You load baseline AMIs software into the AIMS cabinet from a separate diskette. This software is in addition to the other software for the core processor module (CPM) that has the related function. A new or modified AMI load will replace any existing AMI software for that particular function.

Default Values

Default values also supply an initial level of functionality for several AIMS functions. These are the functions that use default values:

- Data communication management function (DCMF)
- Flight management computer function (FMCF).

Default values are hardcoded (non-modifiable) values found in the operational software of the CPM for the related functions. To cause the function to operate with new values you must develop a customized AMI and load that software into the CPM from a new diskette. These new values do not replace the default values but are used instead of the default values. If the AMI fails, the functions go back to the default values.

AIMS - AIRLINE MODIFIABLE INFORMATION OVERVIEW

Boeing initially installs a null AMI. A null AMI is a blank AMI that causes the related function to use the default values.

AIMS - AIRLINE MODIFIABLE INFORMATION OVERVIEW

AIMS - SOFTWARE FUNCTIONAL DESCRIPTION

General

These are the four different types of software in the AIMS cabinet:

- Operational program software (OPS)
- Operational configuration files (OPC)
- Airline modifiable information (AMI)
- Database.

These are the two different types of data stored by the LRMs:

- Bite history data
- Run-time data.

These are the three different types of memory that the LRMs use to store the software and the data:

- Flash which is nonvolatile
- EEPROM which is nonvolatile
- SRAM which is volatile.

Operation Program Software

The OPS is the core software and the application software for the avionic functions. There is a unique software part number for each type of LRM. Modules that are the same, like all the IOMs and the two CPM/GGs, have the same part number.

The OPS is stored in flash memory which is nonvolatile memory. If you remove the module from the cabinet, you do not lose the OPS software. The OPS software can be loaded into the module either in the shop or when it is installed on the airplane.

Operation Program Configuration Files

The OPCs set the configuration of the airplane. The OPCs replace hardware program pins used on older model airplanes. There is only one OPC part number for the cabinet. This one part number includes the OPCs for several avionic functions.

The OPCs are in flash memory.

Training Information Point

There is only one OPC software part number for the cabinet. When you remove and replace one LRM, you can load the OPC into that LRM. When you load the OPC into the LRM, it will do a check to make sure it is the same OPC software that is in the other LRMs in the cabinet. This is to make sure that you can not load an OPC with a different part number into any LRM.

If the OPC software part number changes, you need to load the new OPC into all the LRMs in the cabinet. During a data load, you will get a dialog box that shows that the software is incompatible with the old OPC part number in the other LRMs. You can override and force the software to load into the LRM.

Airline Modifiable Information

The AMIs set the configuration of the airplane. This software, developed with the ground based software tool, gives the airlines more flexibility to define their configuration. Several avionic functions have an AMI. There is a separate software part number for each AMI.

The AMIs are in flash memory.

Database

There is one database for AIMS, the navigation database. The flight management computing function uses this database. There is only one part number for this database.

The database is in flash memory.

BITE History Data

Each LRM stores BITE history in EEPROM. EEPROM is nonvolatile memory. If you remove the LRM this BITE history is saved.

Run-Time Data

The run-time data is data that is generated by the operation of the cabinet. This run-time data is in SRAM. If you remove the module you will lose this data.

The hot battery bus power holds the data in SRAM, so that when you power down the airplane you do not lose this data.

Training Information Point

If you remove the LRM or if you remove the battery without primary power, you lose this run time data. Specific data that you lose includes:

- ACMF report data stored in the ACMF CCA
- Fault history data collected by the CMCF.

LRMs software

This is the software loaded into the CPM/Comm:

- CPM/Comm OPS (includes core software and DCGF, CMCF, DCMF, DFDAF, FDCF, QARF)
- AIMS OPC
- AMI for CMCF
- AMI for DCMF
- AMI for FDCF.

This is the software loaded into the CPM/ACMF:

- CPM/ACMF OPS (includes core software and DCGF, ACMF, FMCF, TMCF, and performance database)
- AIMS OPC
- AMI for FMCF
- AMI for ACMF
- Nav database.

AIMS - SOFTWARE FUNCTIONAL DESCRIPTION

This is the software loaded into the CPM/Basic:

- CPM/Basic OPS (includes core software and DCGF, FMCF, TMCF, and performance database.)
- AIMS OPC
- AMI for FMCF
- Nav database.

This is the software loaded into the CPM/GGs:

- CPM/GG OPS (includes core software, DCGF and PDF)
- AMI for PDF
- AIMS OPC.

The software loaded into the IOMs is IOM OPS (includes core software).

<u>Training Information Point</u>

The status message AIMS shows when there is a difference between the OPCs or program pins of the left and right AIMS cabinets. This is monitored at power up or when this software is loaded.

AIMS - SOFTWARE FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

AIMS - DATA CONVERSION GATEWAY FUNCTION FUNCTIONAL DESCRIPTION

General

The data conversion gateway function (DCGF) has these five primary purposes:

- Transfer data between the flight control ARINC 629 buses and analog, analog discrete and ARINC 429 buses
- Transfer data between the systems ARINC 629 buses and analog, analog discrete and ARINC 429 buses
- Transfer data between the systems ARINC 629 buses and the flight control ARINC 629 buses
- Isolate transfer of engine data between the flight control ARINC 629 buses and the systems ARINC 629 buses
- Isolate transfer of engine data between the systems ARINC 629 buses and analog, analog discrete and ARINC 429 buses.

All DCGF data transfers follow the same basic data flow. The IOMs receive the data. The data then moves to the CPMs over the backplane data bus. The CPMs reformat the data and send the data back to the IOMs. The IOMs then transmit the data.

DCGF Types

There are seven different types of data transfer.

DCGF Type 1: The AIMS cabinets receive ARINC 429, analog discrete signals, and analog signals and transmit the data to the flight controls ARINC 629 buses.

DCGF Type 2: The AIMS cabinets receive ARINC 429 and analog discrete signals and transmit the data to the systems ARINC 629 buses.

DCGF Type 3: The AIMS cabinets receive data from the flight controls ARINC 629 buses and transmit the data to the systems ARINC 629 buses.

DCGF Type 4: The AIMS cabinets receive data from the systems ARINC 629 buses and transmit the data to the flight controls ARINC 629 buses.

DCGF Type 5: The AIMS cabinets receive data from the flight controls ARINC 629 buses and transmit ARINC 429 data and analog discrete signals.

DCGF Type 6: The AIMS cabinets receive data from the systems ARINC 629 buses and transmit ARINC 429 data and analog discrete signals.

DCGF Type 7: The AIMS cabinets receive data from a systems ARINC 629 bus and transmit the data to another systems ARINC 629 bus.

DCGF Software

Each AIMS cabinet has two DCGFs. Each DCGF has a master and a shadow. The master is in control unless the CPM fails. Then the shadow takes over. DCGF1 is in the two CPM/GGs. CPM/GG M0010 is the master and CPM/GG M0011 is the shadow. DCGF2 is in the CPM/COMM and the CPM/Basic or CPM/ACMF. The CPM/Basic or CPM/ACMF is the master

AIMS - DATA CONVERSION GATEWAY FUNCTION FUNCTIONAL DESCRIPTION

and the CPM/COMM is the shadow. DCGF1 and DCGF2 operate independently.

DCGF1 processes left engine data, data transfers and AOA and TAT calculations. DCGF2 processes right engine data and data transfers.

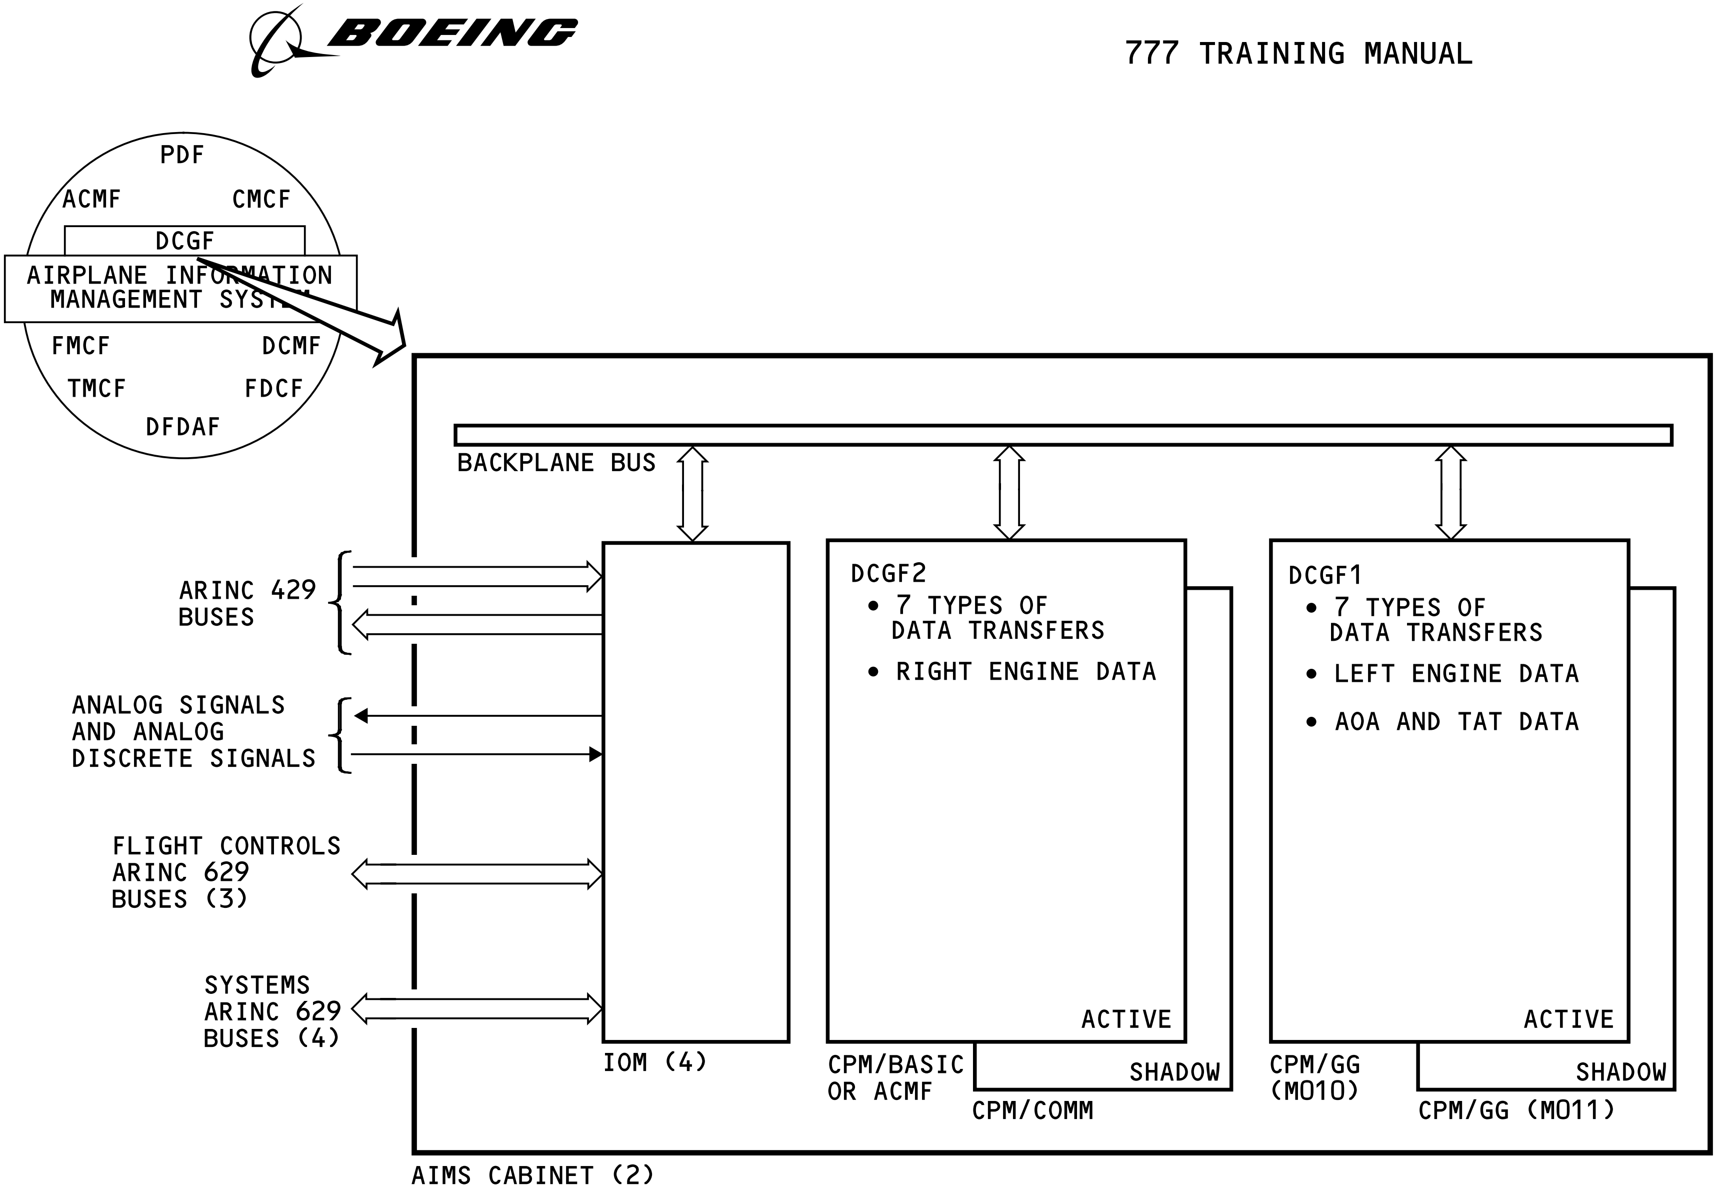
The engine data is data that goes to and from both engines for control and indication. This data goes to the EECs via the engine data interface units:

- ADIRU and SAARU data
- Autothrottle trim commands
- Condition of various engine related flight deck controls and switches.

Training Information Point

The status message AIMS shows when the DCGF fails in more than one of the CPMs or there is insufficient input/output resources for more than one second.

When only one of the DCGFs fail, a scheduled maintenance task (SMT) message AIMS CABINET LRM shows. It is a requirement that you do a check for this SMT message every 30 days. If the SMT message shows, you must do the corrective action for the DCGF. The SMT messages are on the maintenance task maintenance page.



31-41-00-034 Rev 3 04/26/95

AIMS - DATA CONVERSION GATEWAY FUNCTION FUNCTIONAL DESCRIPTION

AIMS - UNIVERSAL TIME (COORDINATED) FUNCTION FUNCTIONAL DESCRIPTION

General

The core processor modules (CPMs) each perform the universal time (coordinated) function (UTCF) in addition to their other major functions.

Each CPM has a UTCF that supplies universal time (coordinated) (UTC) and date to all the functions in that CPM. One of the CPMs in each cabinet also sends UTC and date to the other airplane systems.

Time and Date Calculation

The AIMS cabinets receive time and date data from the global positioning system sensor units (GPSSUs). The GPSSUs also send an analog time mark once per second. The UTCF uses the time mark signal and the time data to calculate the UTC.

CPM Interface

The UTCF in each CPM computes the UTC and provides the UTC and date to the functions on that CPM. The UTCF uses the left GPSSU data if it is valid. Otherwise, the UTCF uses the right GPSSU data.

If GPSSU data is not available, the UTCF maintains the UTC and the date. It does this based on the last valid data received from the GPSSU and its own internal clock.

The hot battery bus power permits the CPM clocks to continue to keep time when no other sources of power is available to the CPMs.

User System Interface

Each AIMS cabinet transmits UTC and date data to other airplane systems on these ARINC 429 data buses:

- General purpose #1 bus
- General purpose #2 bus
- Inertial reference bus
- Central maintenance buses (L/C/R).

Each AIMS cabinet transmits UTC and date data to other airplane systems on these ARINC 629 data buses:

- Flight controls buses
- Systems buses.

Only one of the four CPMs in a cabinet sends time and date data to other airplane systems. The priority for the CPM that sends the data is:

- CPM/Comm
- CPM/GG (M010)
- CPM/GG (M011)
- CPM/ACMF or CPM/Basic.

AIMS - UNIVERSAL TIME (COORDINATED) FUNCTION FUNCTIONAL DESCRIPTION

AIMS - SYSTEM GROUND TESTS

General

These are the two different types of systems tests:

- IOM module reset test
- CPM reset test.

IOM Module Reset Test

Each of the four IOMs have an individual module reset test.

This test makes sure that the IOM operates correctly. The approximate time to run the test is less than one minute. After the test starts, you can not stop it.

This test may show failures of fault tolerant components which may not have an effect on airworthiness. Use EICAS messages with the proper documentation to find airworthiness.

CPM Module Reset Test

Each of the four CPMs have an individual module reset test.

This test makes sure that the CPM operates correctly. The approximate time to run the test is less than one minute. After the test starts, you can not stop it.

This test may show failures of fault tolerant components which may not have an effect on airworthiness. Use EICAS messages with the proper documentation to find airworthiness.

PRIMARY DISPLAY SYSTEM - INTRODUCTION

General

The primary display system (PDS) is part of the airplane information management system (AIMS). The PDS shows information in many different formats on six display units (DUs) in the flight deck. The information includes:

- Airplane status
- Navigation data
- Flight plan data
- Engine indicating and crew alerting data
- Communication data
- Checklists
- Maintenance data.

Abbreviations and Acronyms

ACARS	- aircraft communications addressing and reporting system
ACE	- actuator control electronics
acpt	- accept
ADIRS	- air data inertial reference system
ADIRU	- air data inertial reference unit
AFDS	- autopilot flight director system
ail	- aileron
AIMS	- airplane information management system
ALDB	- airline loadable database
alt	- altitude
altn	- alternate
app	- approach
ARINC	- Aeronautical Radio, Inc.
arpt	- airport
att	- attitude
baro	- barometric
BLS	- bezel light sensor
brks	- brakes
canc	- cancel
capt	- captain
CAS	- calibrated airspeed
CCD	- cursor control device
CDU	- control display unit
chkl	- checklist
CMCF	- central maintenance computing function
comm	- communication
CPM/GG	- core processor module/graphics generator
crz	- cruise
DH	- decision height
DSP	- display select panel
dspl	- display
DU	- display unit
EFIS CP	- electronic flight instrument system control panel
EGT	- exhaust gas temperature
EICAS	- engine indication and crew alerting system
elev	- elevator
eng	- engine
EPCS	- electronic propulsion control system
ESI	- engine start inhibit

excd - exceedance
ext - external
fctl - flight control
F/D - flight director
FDCF - flight deck communication function
FF - fuel flow
flprn - flaperon
flt - flight
FMA - flight mode annunciation
FMCF - flight management computing function
FMCS - flight management computing system
F/O - first officer
FPV - flight path vector
FPA - flight path angle
FSEU - flap slat electronics unit
fwd - forward
GPWS - ground proximity warning system
GS - glide slope
G/S - ground speed
hdg - heading
hPa - hectopascal
hyd - hydraulic
IDG - integrated drive generator
ILS - instrument landing system
IM - inner marker
inbd - inboard
IOM - input/output module
isln - isolation
ISSP - instrument source select panel
lim - limit
LNAV - lateral navigation
lo - low
loc - localizer
LRU - line replaceable unit
LRM - line replaceable module
LSK - line select key
mag - magnetic
MAT - maintenance access terminal
MCP - mode control panel
MDA - minimum descent altitude
MFD - multi-function display
MINS - minimums
MLW - maximum landing weight
MM - middle marker
MMEL - master minimum equipment list
MMO - maximum operating mach number
MTRS - meters
nav - navigation
NCD - no computed data
ND - navigation display
NVM - nonvolatile memory
N1 - low pressure rotor speed
N2 - high pressure compressor RPM
OF - overfull
OM - outer marker
OPAS - overhead panel ARINC 629 system
outbd - outboard
ovht - overheat

PDS	- primary display system
PFD	- primary flight display
pln	- plan
pos	- position
QFE	- altimeter setting to indicate height above reference airfield
QNH	- altimeter setting to indicate height above mean sea level

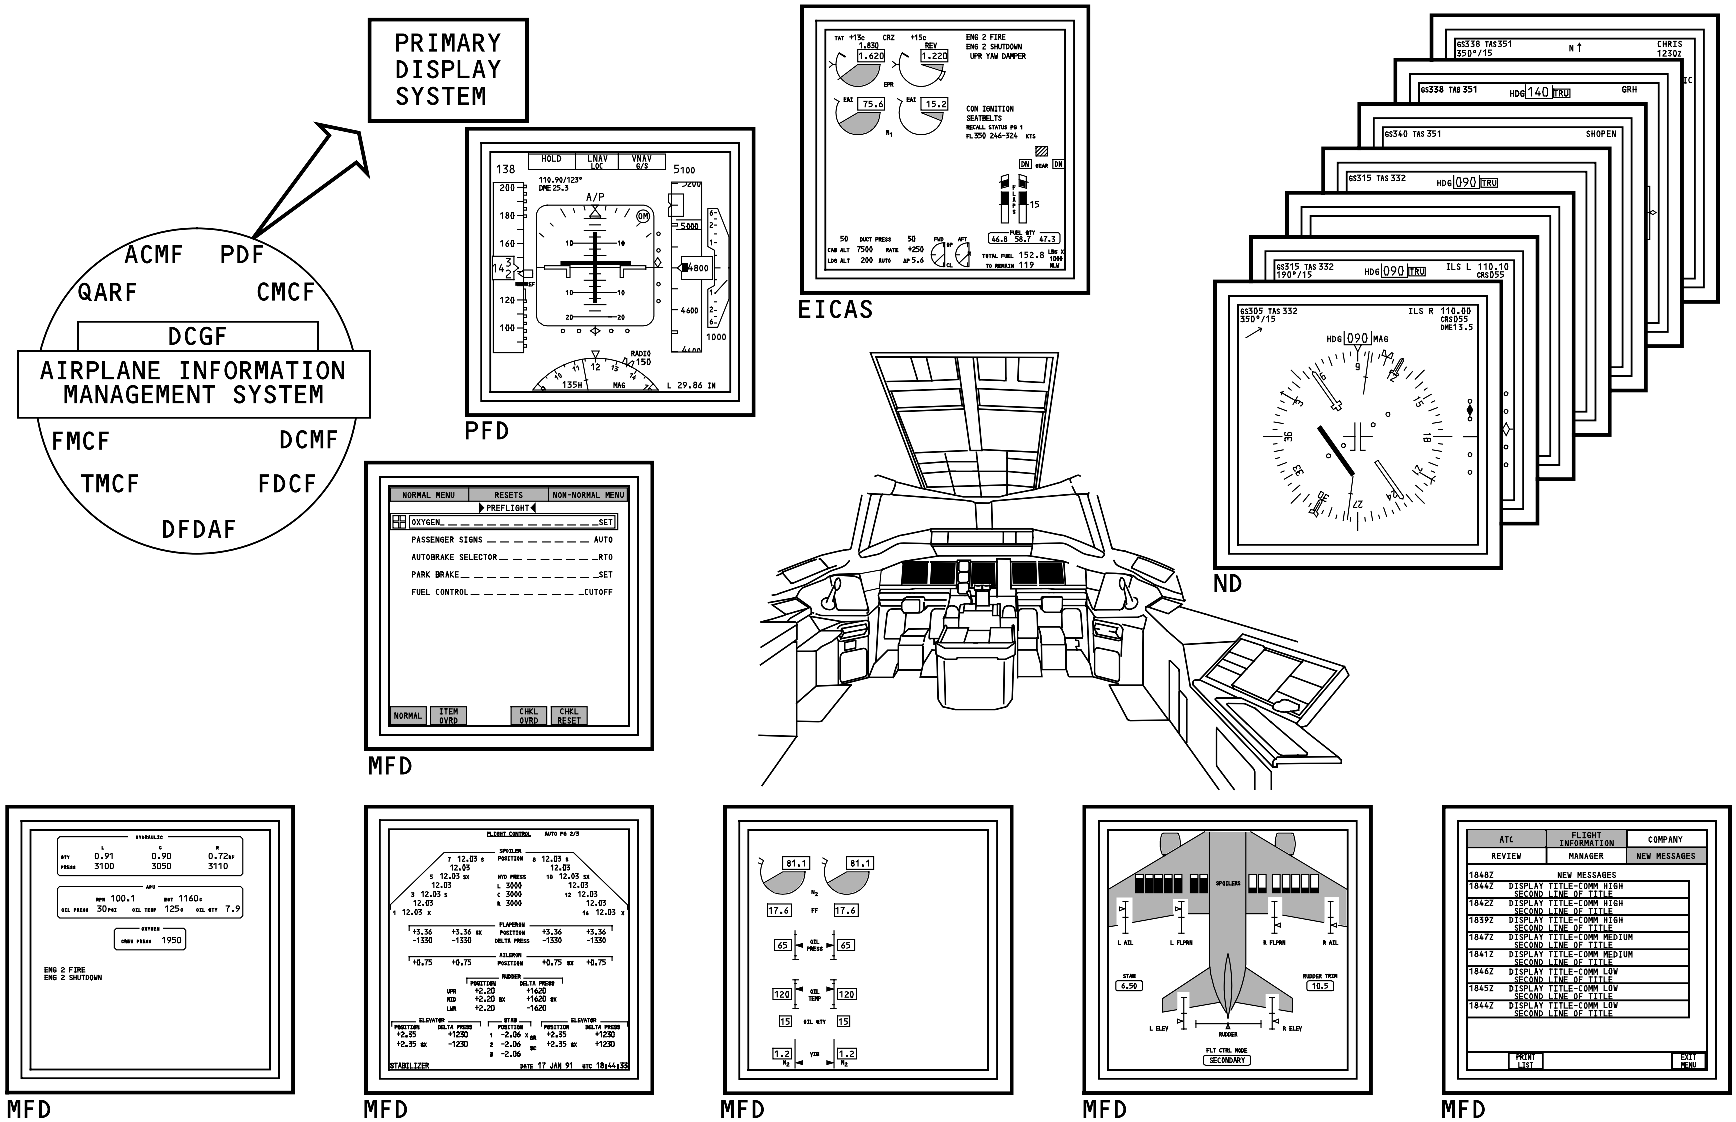
VMO	- maximum operating limit speed
VNAV	- vertical navigation
VR	- rotation speed
VREF	- landing reference speed
VSI	- vertical speed indicator
VS	- stall speed
VTK	- vertical track
VTO	- volumetric topoff
V1	- takeoff decision speed
V2	- takeoff safety speed
WAI	- wing anti-ice
WES	- warning electronics system
wpt	- waypoint
WXR	- weather radar
X-BLD	- cross bleed



PRIMARY DISPLAY SYSTEM - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - GENERAL DESCRIPTION

General

The AIMS PDS provides dynamic and static information to the flight and ground crews. The PDS also provides crew interface with other avionics systems. These are the major components of the AIMS PDS:

- Six display units (DUs)
- Two EFIS control panels (EFIS CPs)
- Display select panel (DSP)
- Two cursor control devices (CCDs)
- Two remote light sensors (RLSs)
- Two instrument source select panels (ISSPs)
- Two display switching panels
- Center display control panel.

Three control display units (CDU) give alternate EFIS CP functions and alternate DSP functions.

Overhead Panel ARINC 629 System (OPAS) Interface

These are the control panels that interface with the OPAS:

- DSP
- Two CCDs
- Two ISSPs
- Two display switching panels
- Center display control panel.

OPAS multiplexes the signals and sends the data to the systems ARINC 629 data buses.

OPAS also sends control information to each control panel.

AIMS Cabinet Interfaces

The AIMS cabinets get airplane information on the ARINC 629 flight controls and system buses and the ARINC 429 buses. The AIMS cabinets also get analog and analog discrete data.

The AIMS cabinets get control information from the two EFIS CPs and the two CCDs on ARINC 429 data buses. Additional control information comes from the three CDUs on the systems ARINC 629 buses.

The AIMS cabinets send information to the display units on high speed coax lines through four coax couplers.

Two remote light sensors supply inputs to the two outboard display units. Other flight deck controls supply additional brightness and contrast controls for the display units.

Each display unit sends information to the AIMS cabinets on ARINC 429 data buses. This data is for fault reporting and brightness controls.

DU Location and Formats

Location determines which types of display format shows. These are the display locations:

- Left outboard DU

PRIMARY DISPLAY SYSTEM - GENERAL DESCRIPTION

- Left inboard DU
- Upper center DU
- Lower center DU
- Right inboard DU
- Right outboard DU.

The format that each DU shows depends on its location. DU status, location, and switch inputs determine the format a DU shows. These are the formats a DU can show:

- Primary flight display (PFD)
- Navigation display (ND)
- EICAS
- Multifunction display (MFD).

The left and right outboard DUs show only a PFD format.

The left and right inboard DUs normally show the ND format. They can show these formats:

- PFD
- EICAS
- MFD.

The upper center DU shows only the EICAS format. The lower center DU normally shows the MFD format. It can show these formats:

- EICAS
- ND
- MFD.

Each format has one or more modes. Flight deck control inputs and other system inputs determine which mode shows.

The PFD has only one mode.

The ND has these seven modes:

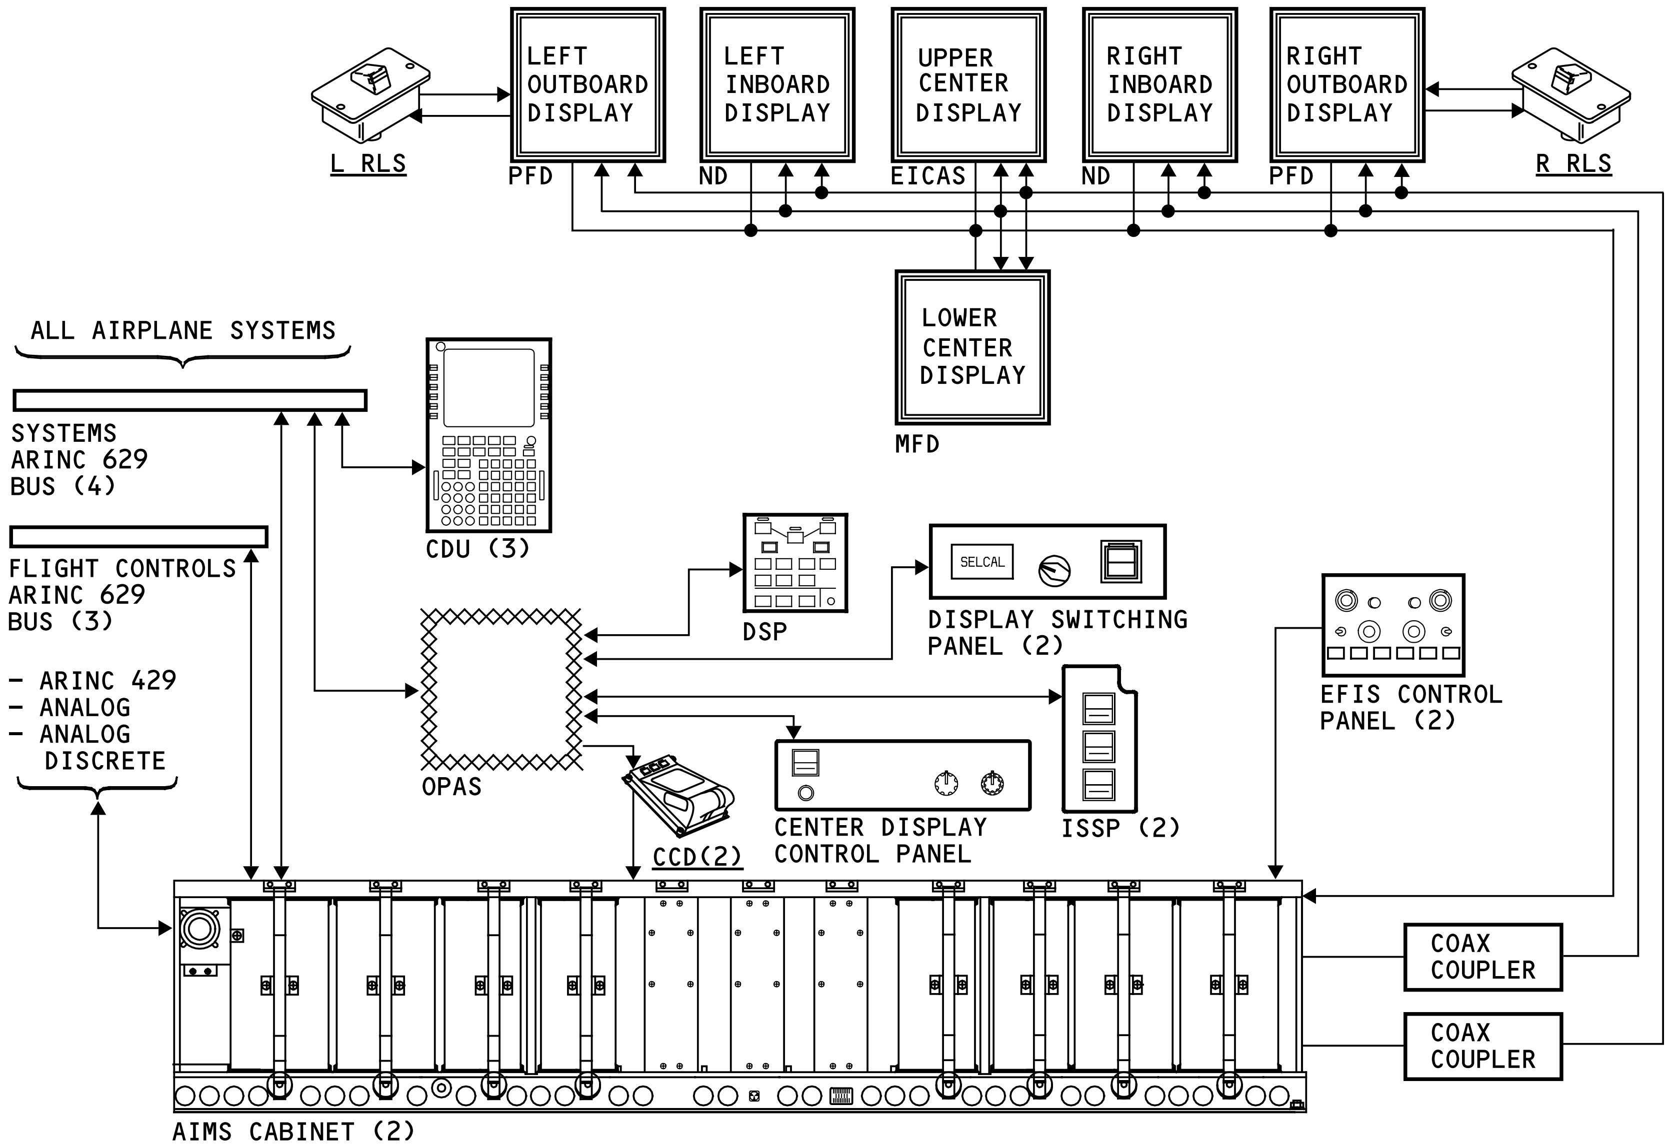
- Centered approach mode
- Expanded approach mode
- Centered VOR mode
- Expanded VOR mode
- Centered map mode
- Expanded map mode
- Plan mode.

The EICAS display can show the normal display or a compacted format.

The MFD can show these formats:

- Secondary engine display
- Status display
- Synoptic display (7)
- Maintenance page (19)
- Checklists display
- Communication display.

The PFD, EICAS and secondary engine formats are critical formats. The ND and other MFD formats are essential formats.



PRIMARY DISPLAY SYSTEM - GENERAL DESCRIPTION

PRIMARY DISPLAY SYSTEM - COMPONENT LOCATIONS - 1

Major Components

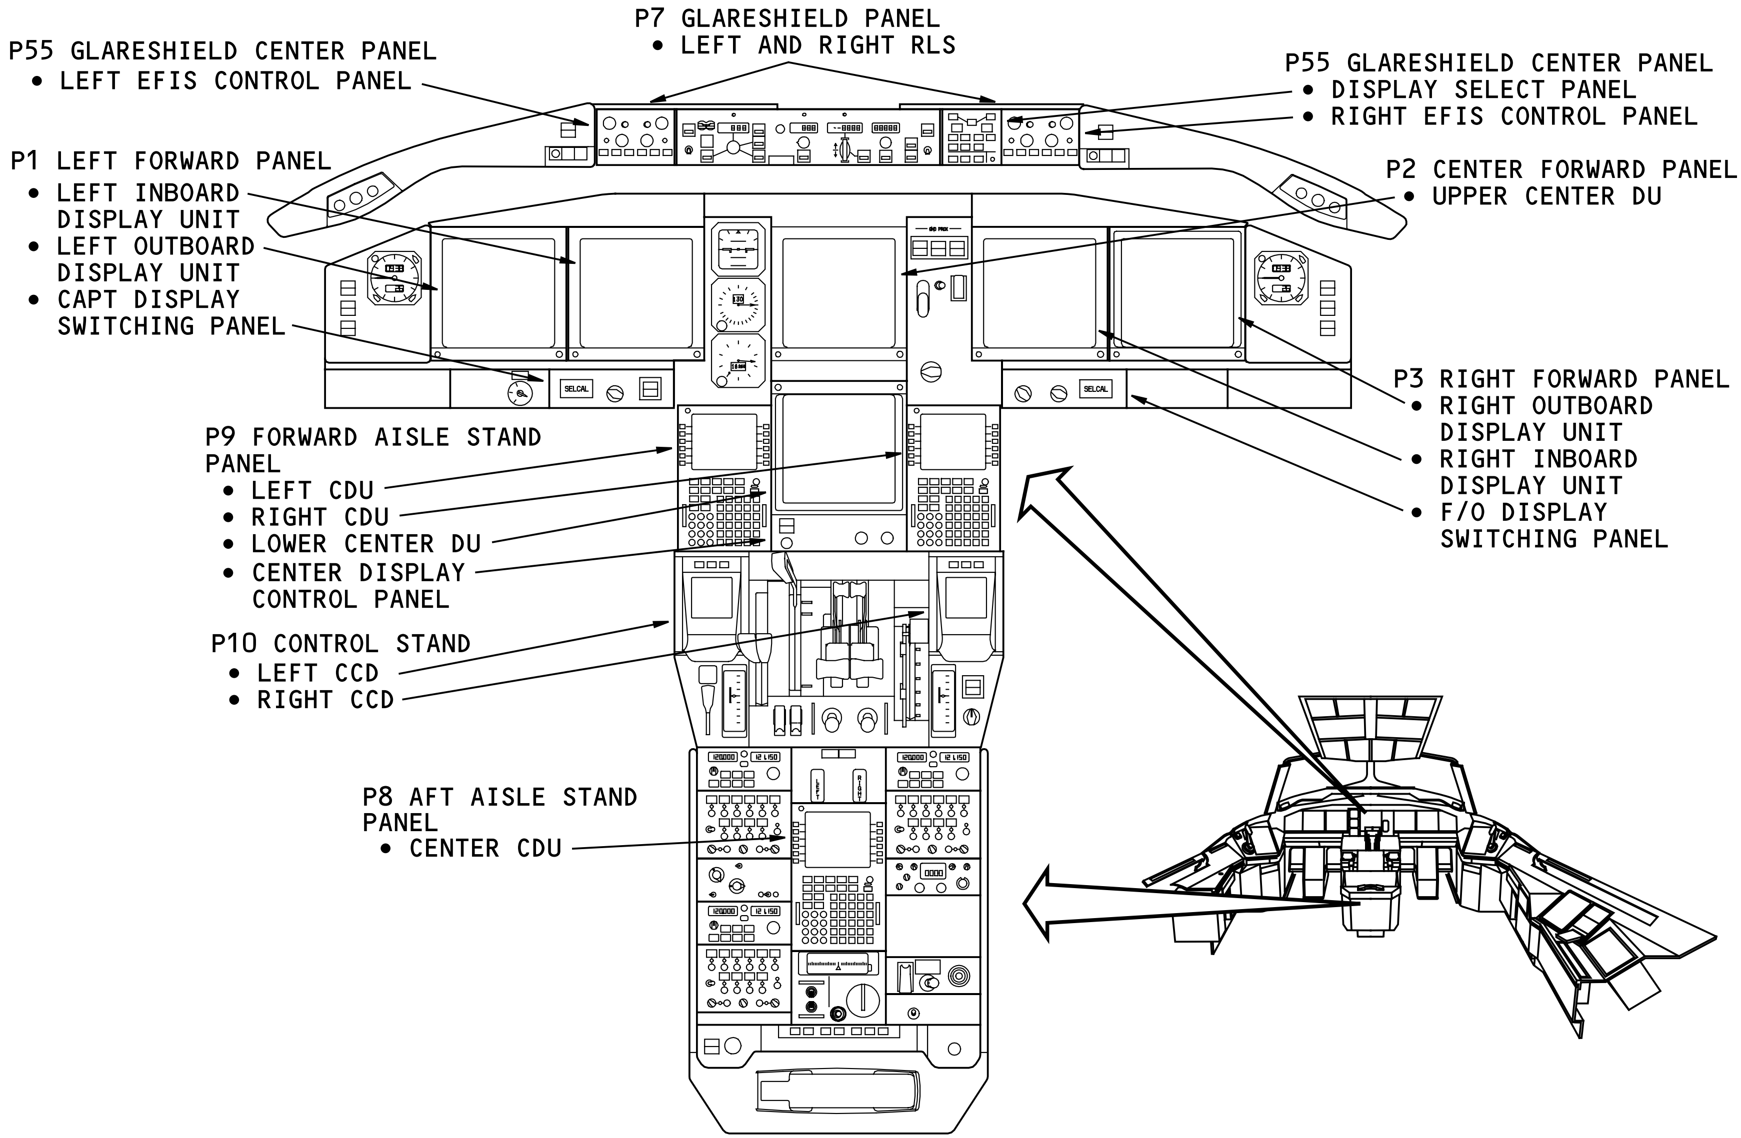
The primary display system major components in the flight deck are:

- Left outboard display unit (DU)
- Left inboard DU
- Right outboard DU
- Right inboard DU
- Upper center DU
- Lower center DU
- Left EFIS control panel (CP)
- Right EFIS CP
- Display select panel
- Left cursor control device (CCD)
- Right CCD
- Left Remote Light Sensor (RLS)
- Right RLS
- Captain's display switching panel
- F/O display switching panel
- Center display control panel.

Miscellaneous Components

Other controls and switches in the flight deck are:

- Left control display unit (CDU)
- Right CDU
- Center CDU.



PRIMARY DISPLAY SYSTEM - COMPONENT LOCATIONS - 1

PRIMARY DISPLAY SYSTEM - COMPONENT LOCATIONS - 2

Miscellaneous Components

There are these control panels and switches in the flight deck:

- Left instrument source select panel (ISSP)
- Right ISSP
- Captain's data uplink control switches
- F/O data uplink control switches
- Captain's master warning and caution light
- F/O master warning and caution light
- Captain's forward panel brightness controls
- F/O forward panel brightness controls.

These are the data uplink control switches:

- Accept switch
- Cancel switch
- Reject switch.

These are the forward panel brightness controls:

- Outboard display brightness control
- Inboard display brightness control
- Inboard display weather radar brightness control.

PDS Components

The left AIMS cabinet is on the E3-1 rack in the main equipment center.

The right aims cabinet is on the E2-1 rack in the main equipment center.

PRIMARY DISPLAY SYSTEM - COMPONENT LOCATIONS - 2

PRIMARY DISPLAY SYSTEM - SYSTEM INTERFACE

OPAS Interface

The overhead panel ARINC 629 system (OPAS) receives control panel and switch input data from the flight deck. OPAS multiplexes the analog and discrete data and sends it to AIMS on the systems ARINC 629 bus. OPAS sends control signals to each of the control panels. These components interface with OPAS:

- Display select panel (DSP)
- Two cursor control devices (CCD)
- Two display switching panels
- Two instrument source select panels (ISSP)
- Center display control panel.

Primary Display Function (PDF) of AIMS Interface

The PDF of AIMS gets control information from the two EFIS CPs and the two CCDs on ARINC 429 data buses and from the overhead panel ARINC system (OPAS) on the systems ARINC 629 data buses. Additional control information comes from the three CDUs on the systems ARINC 629 buses.

The PDF of AIMS gets airplane information on these buses for display:

- Flight controls ARINC 629 buses (3)
- Systems ARINC 629 buses (4)
- ARINC 429 buses.

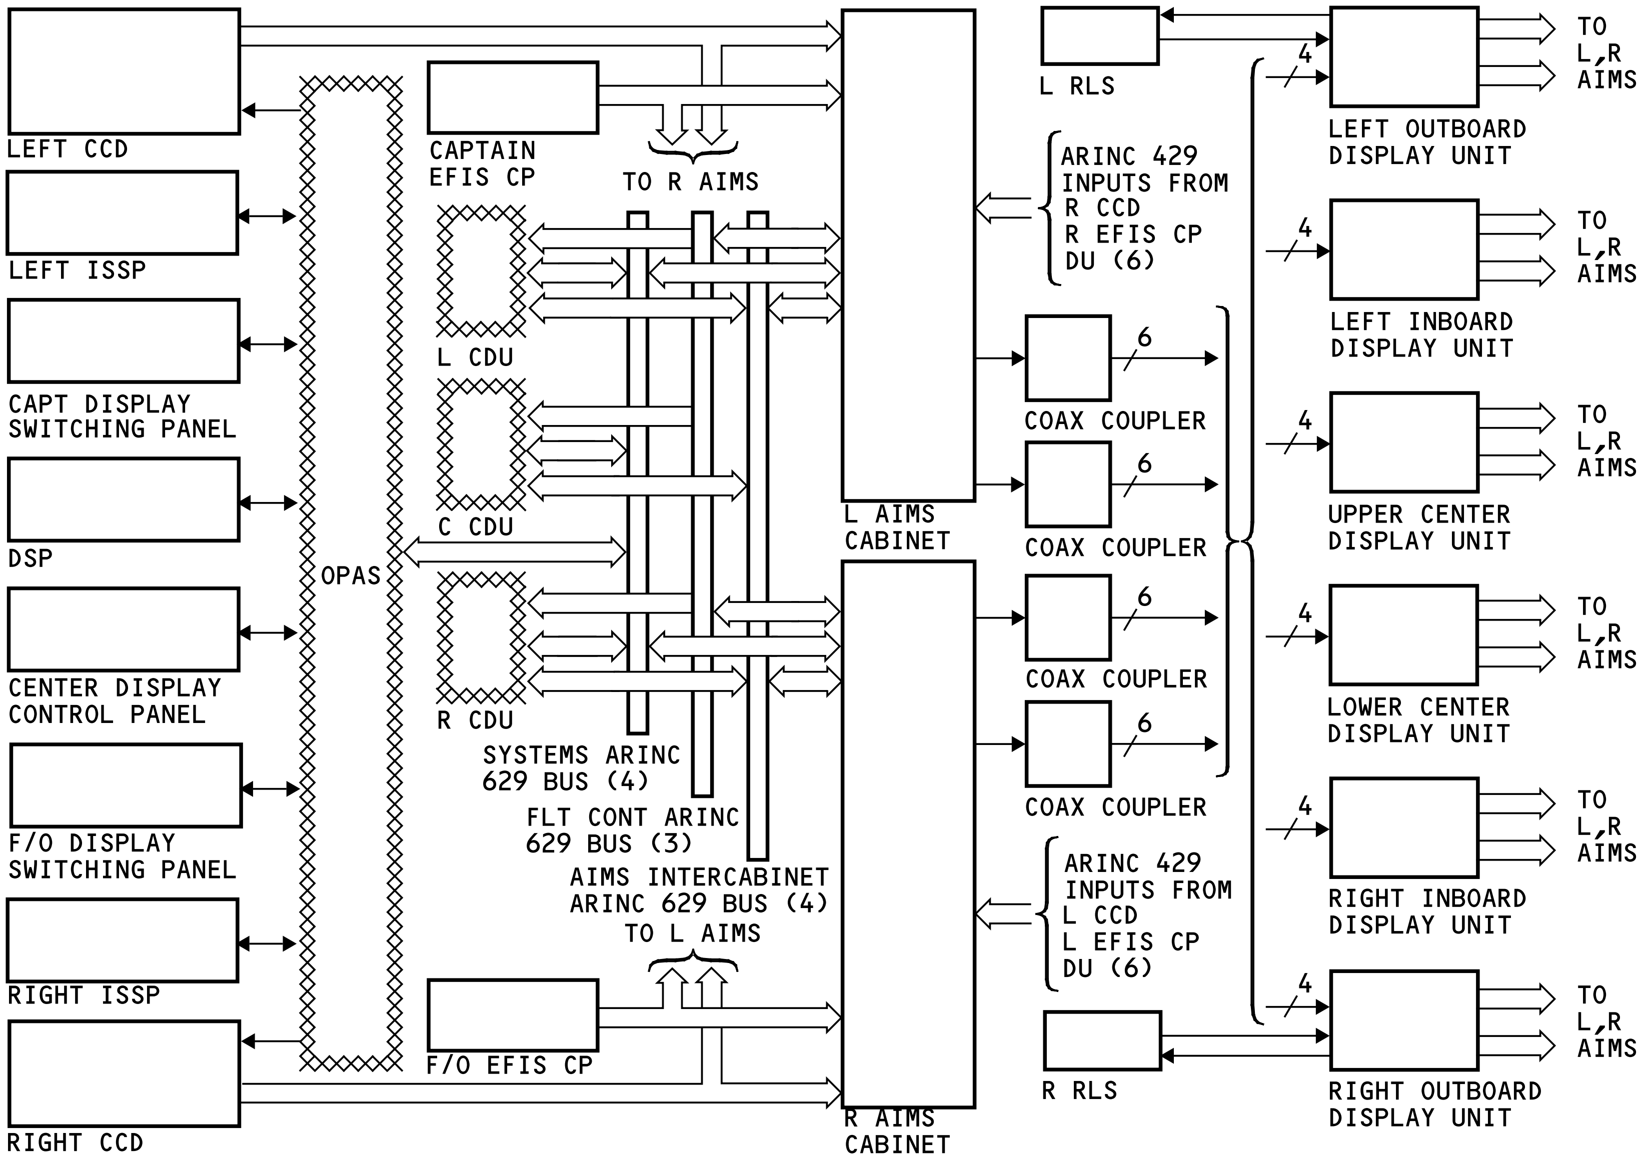
The interface between the two AIMS cabinets is on four ARINC 629 intercabinet buses. The PDF of AIMS shares data for redundancy and configuration management.

Display Unit (DU) Interface

The AIMS cabinets send information to the DUs on high speed coaxial-lines through four coaxial couplers. Each coaxial coupler sends data to each DU.

Two remote light sensors (RLS) supply inputs to the two outboard DUs, left RLS to left inboard DU and right RLS to right outboard DU. Other flight deck controls supply additional brightness and contrast controls for the display units.

Each display unit sends information to the AIMS cabinets on ARINC 429 data buses. This data is for fault reporting.



PRIMARY DISPLAY SYSTEM - SYSTEM INTERFACE

31-61-00-005 Rev 1

PRIMARY DISPLAY SYSTEM - POWER INTERFACES

Power

The captain's flight instrument 28v dc bus supplies power to these components:

- Left outboard display unit
- Left inboard display unit
- Upper center display unit
- Left cursor control device
- Left EFIS control panel.

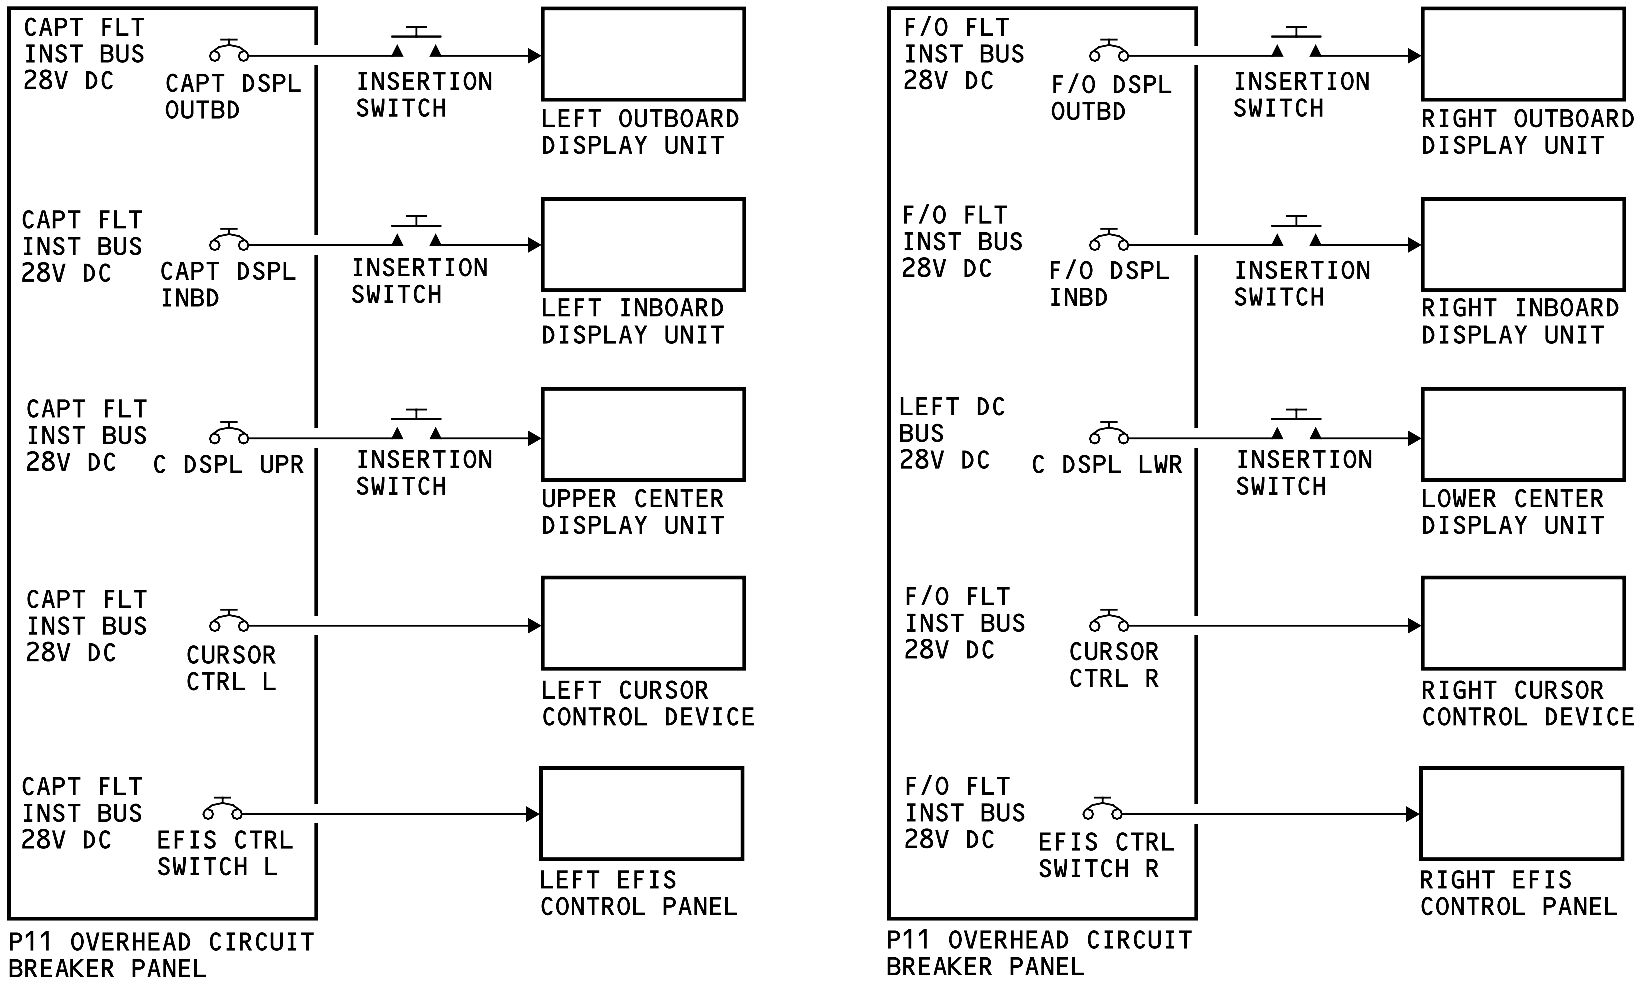
The first officers's flight instrument 28v dc bus supplies these components:

- Right outboard display unit
- Right inboard display unit
- Right cursor control device
- Right EFIS control panel.

The left dc bus supplies the lower center display unit with 28v dc.

Switches

An insertion switch is on the inside of each display unit (DU) rack. As the technician installs the DU, the switch closes and completes the circuit for the power input.



31-61-00-006 Rev 2

PRIMARY DISPLAY SYSTEM - POWER INTERFACES

PRIMARY DISPLAY SYSTEM - BRIGHTNESS CONTROL INTERFACES

General

The display units (DUs) get brightness control inputs manually and automatically. Each display unit has a built-in bezel light sensor (BLS) for automatic brightness control. A remote light sensor (RLS) on the glareshield also supplies automatic brightness control to the onside outboard DU. The passenger sign module also sends automatic brightness control inputs to the outboard DUs.

Control panels in the flight deck have individual manual brightness controls for each display unit. Additional manual brightness controls are available for the display units (DUs) that show weather radar (WXR).

Automatic Brightness Control

Each display unit has a BLS on the front of the unit that measures ambient light. The automatic brightness control calculation uses two BLSs and an RLS input to adjust the DU brightness of the six DUs.

The brightness of a DU pair changes automatically based on the calculation of the brightest value the pair gets from their BLSs.

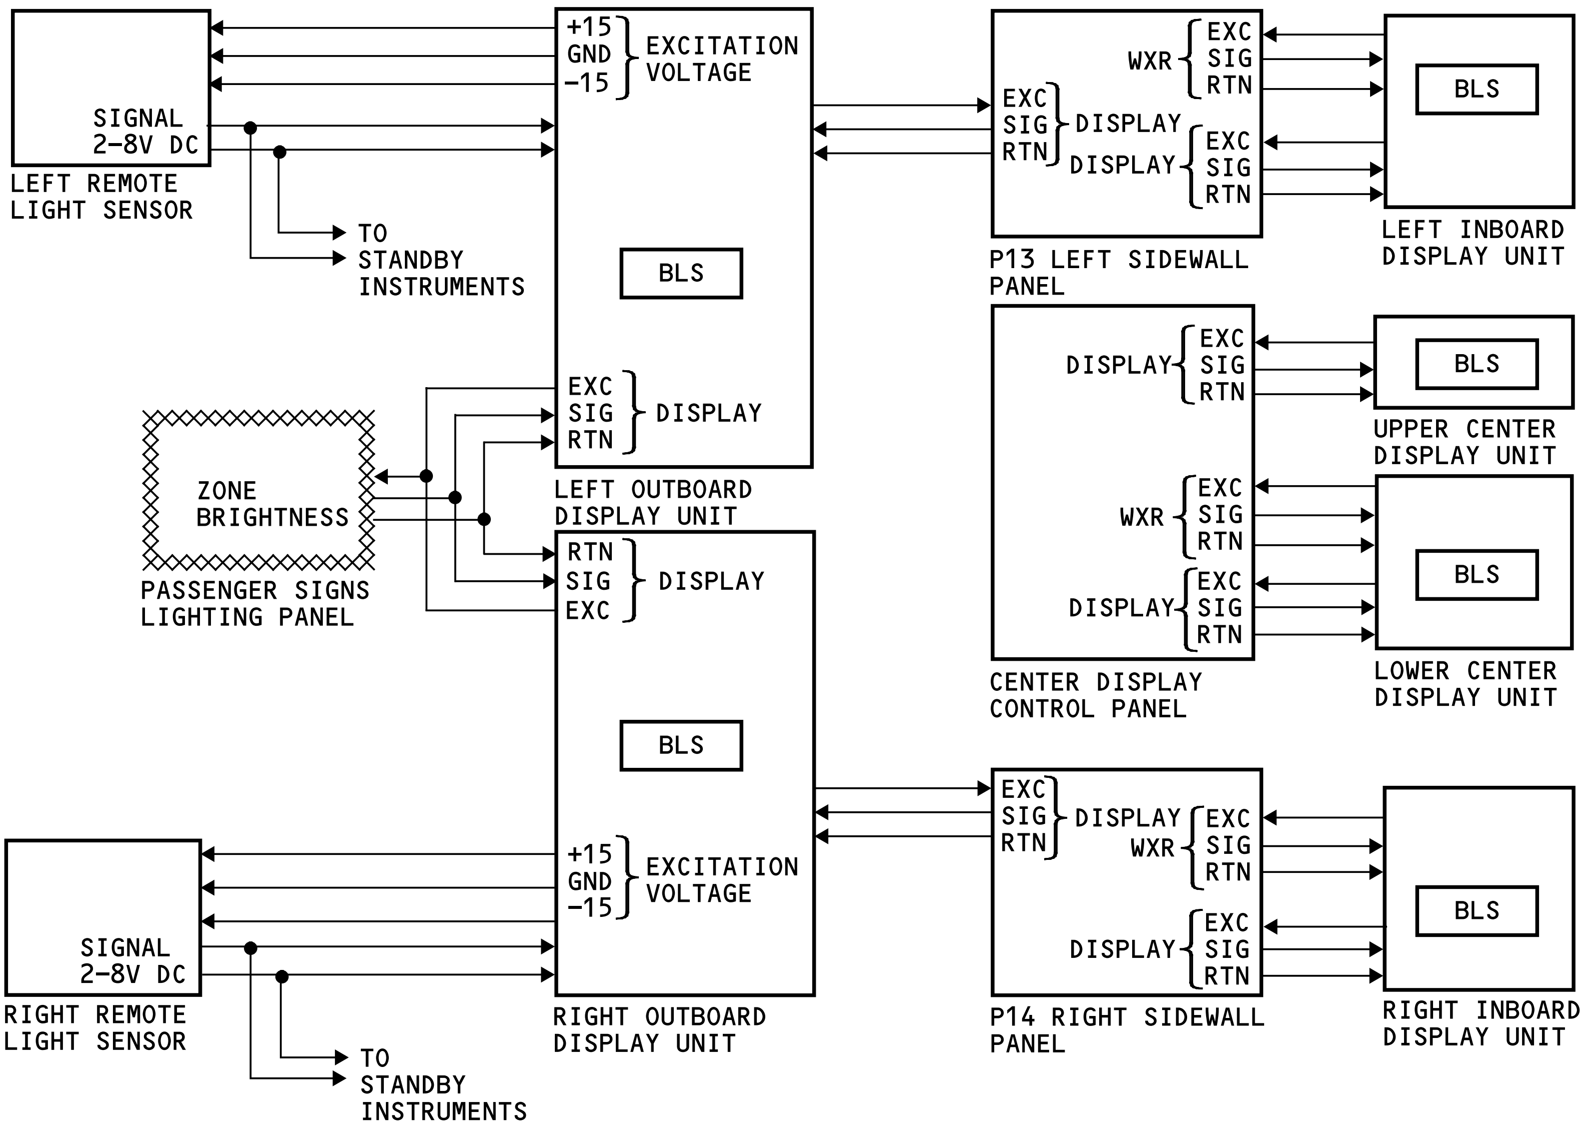
Each outboard DU sends an excitation voltage to its respective RLS. The RLS sends a signal back to its DU. The signal changes with the amount of light in the forward part of the flight deck.

Manual Brightness Control

The master brightness control on the passenger sign module sends a zone brightness input to the left and right outboard display units.

The captain's and first officer's forward panel brightness controls have controls for their outboard and inboard display units. These controls are on the sidewall panels. There is a single control for the outboard display units. There is a dual control knob for the inboard display units. The outer knob controls display brightness and the inner knob controls WXR brightness.

The center display control panel has a single knob to control the brightness of the upper center display unit. There is a dual control knob for the lower center display unit. The outer knob controls display brightness and the inner knob controls weather radar brightness when weather radar information shows on the lower center display unit.



PRIMARY DISPLAY SYSTEM - BRIGHTNESS CONTROL INTERFACES

31-61-00-007 Rev 3 05/30/96

PRIMARY DISPLAY SYSTEM - ARINC 429 DATA BUS INTERFACES

General

These components send data to the input/output modules (IOMs) in the two AIMS cabinets on ARINC 429 data buses:

- Six display units
- Two EFIS control panels
- Two cursor control devices (CCDs).

Display Unit Interface

The display units send:

- Fault monitoring data
- Brightness sensor values
- Remote light sensor values
- Manual brightness values.

EFIS Control Panel Interface

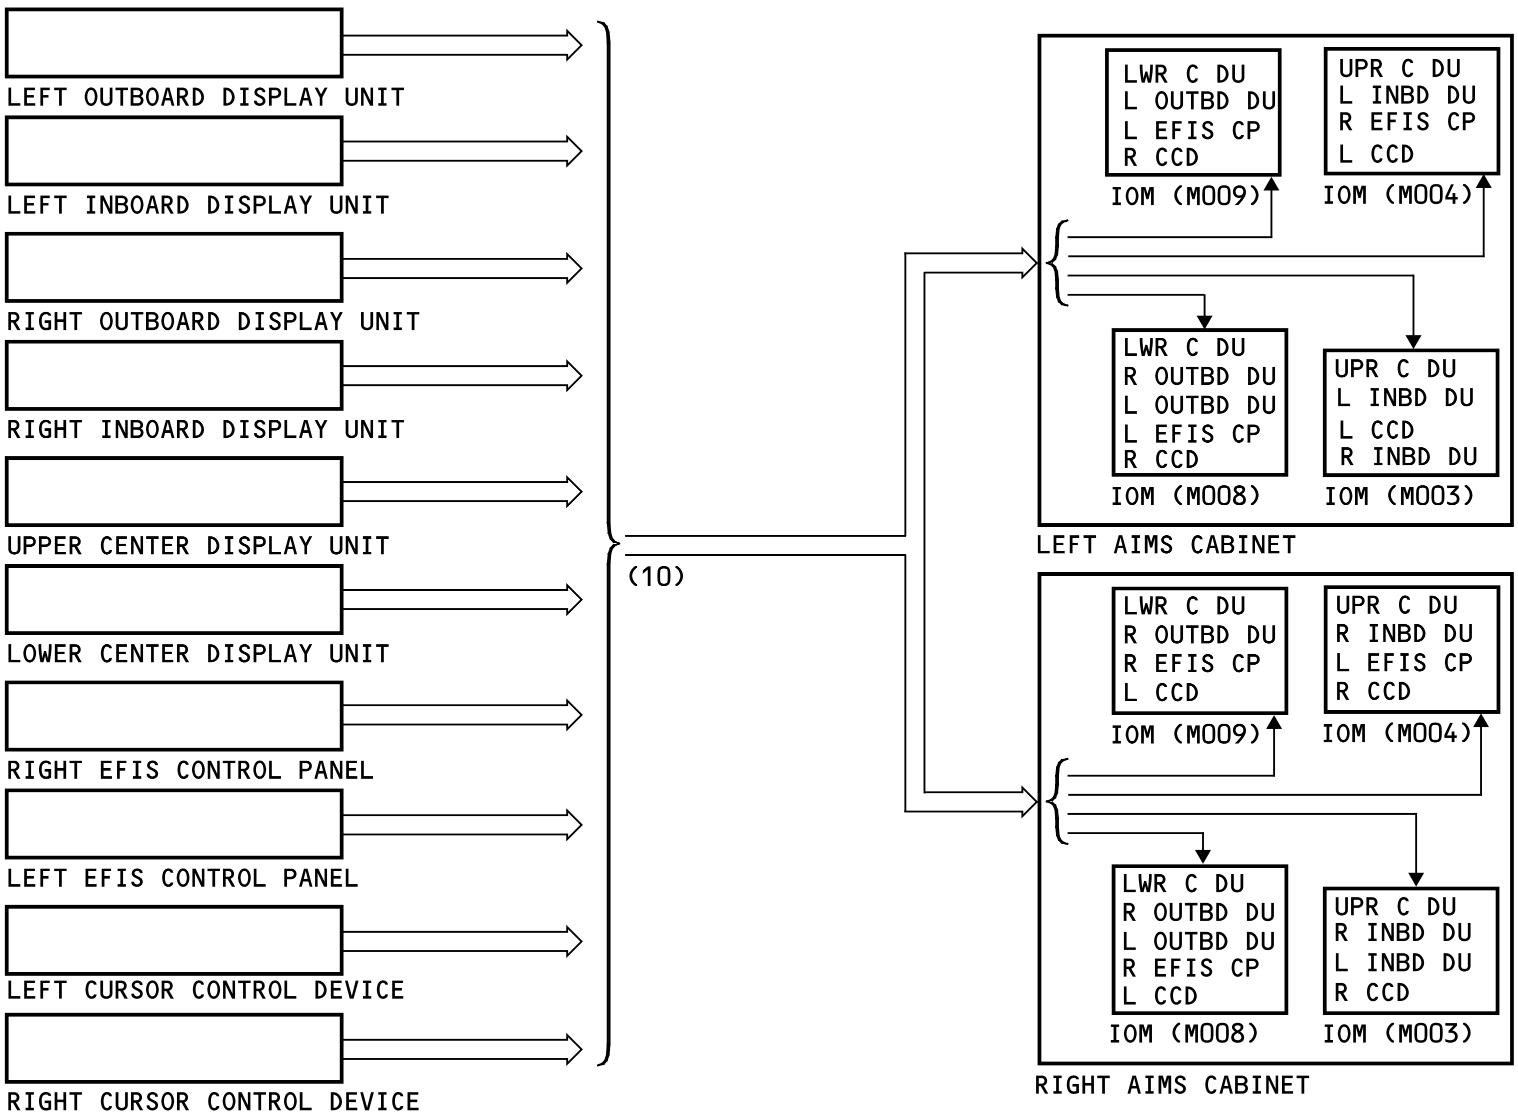
The EFIS control panels send switch position data to control the operation of the related primary flight display and navigation display.

Cursor Control Device Interface

The cursor control devices send:

- Cursor position data
- Display cursor position switch discretes
- Cursor activation switch discrete
- CCD status
- Program pin data
- CCD version number.

The inputs go to multiple IOMs in both cabinets. The multiple inputs provide for redundancy.



31-61-00-008 Rev 5 05/30/96

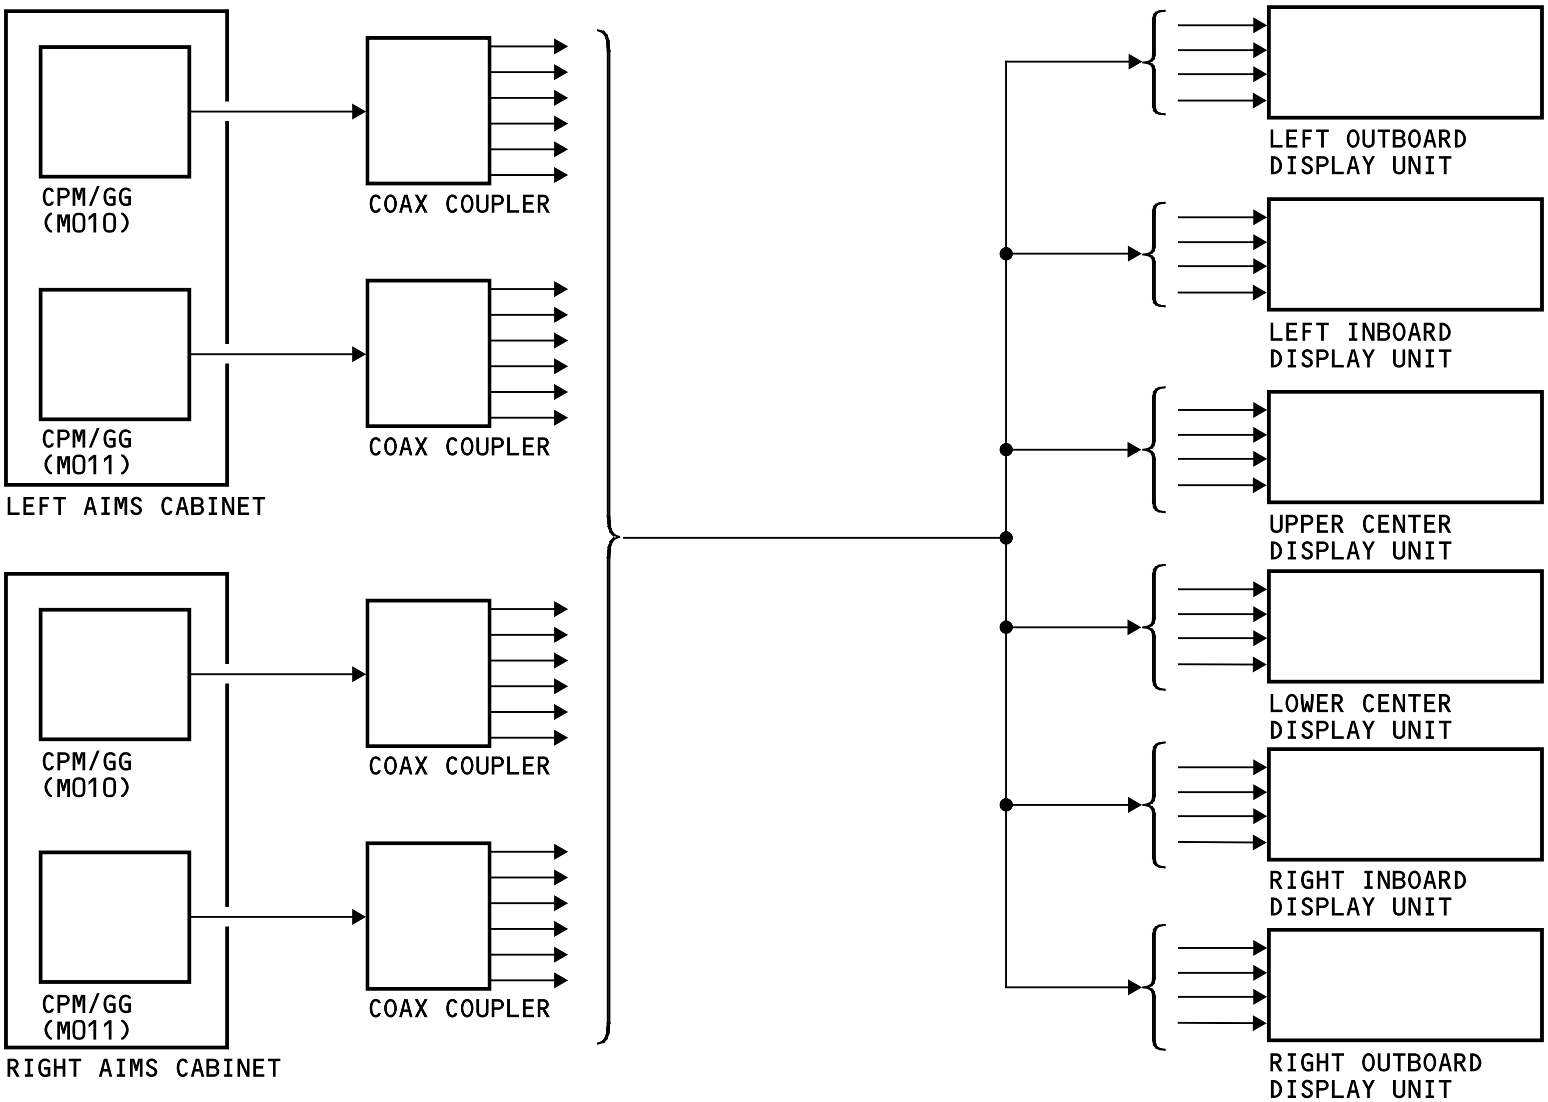
PRIMARY DISPLAY SYSTEM - ARINC 429 DATA BUS INTERFACES

PRIMARY DISPLAY SYSTEM - DISPLAY UNIT COAX INTERFACES

General

The display units get data from the AIMS graphic generators through coax buses. Each AIMS cabinet has two graphics generators, each with a bus output. Each bus output is split six ways and goes to each DU.

The data from the graphics generators contains instructions that make the symbols on the DUs.



31-61-00-009 Rev 1 01/06/1998

PRIMARY DISPLAY SYSTEM - DISPLAY UNIT COAX INTERFACES

PRIMARY DISPLAY SYSTEM - OPAS INTERFACE

General

The overhead panel ARINC 629 system (OPAS) continuously receives and monitors flight deck switches and lights, processes and formats the data, and transmits the data. OPAS uses the left and right systems ARINC 629 data buses. OPAS supplies two outputs to each of the primary display functions of AIMS.

Primary Display System OPAS Interface

OPAS monitors these panels and switches of the primary display system. They include:

- All the switches on the CAPT and F/O instrument source select panels
- CAPT display switching panel
- F/O display switching panel
- CAPT and F/O accept/reject switches
- EICAS display select panel
- Center display control panel
- CCDs.

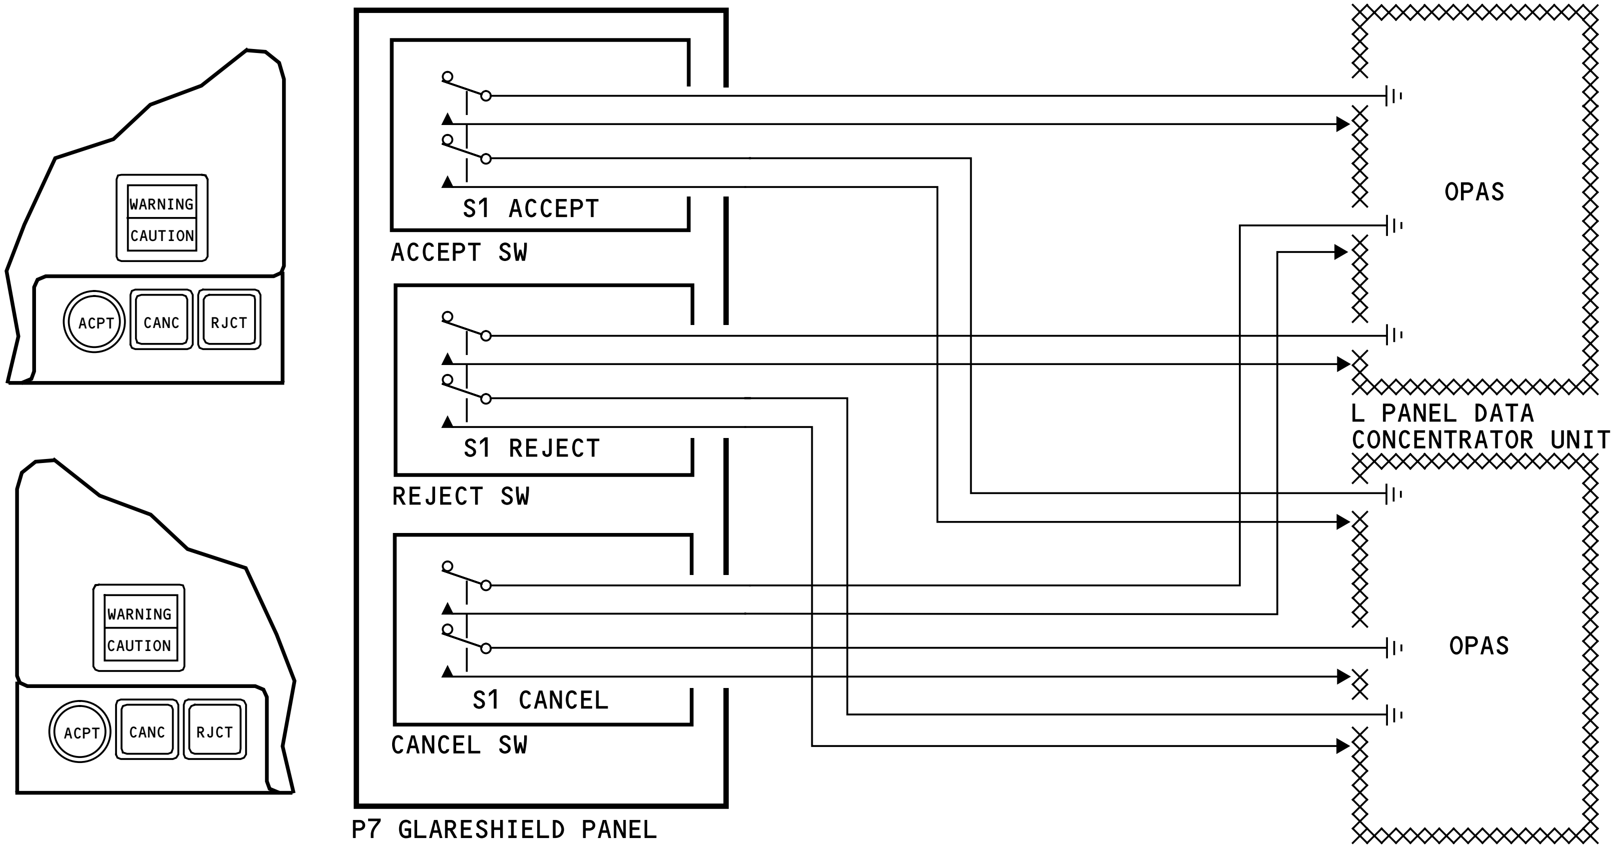
PRIMARY DISPLAY SYSTEM - OPAS INTERFACE

31-61-00-010 Rev 6 03/26/1998

PRIMARY DISPLAY SYSTEM - ACCEPT, REJECT AND CANCEL SWITCH INTERFACE

General

The ACCEPT/REJECT/CANCEL switches on the captain's and first officer's glareshields give the flight crew control of uplink and downlink messages. The OPAS panel data concentrator units (PDCUs) receive requests as analog discretes and process them.



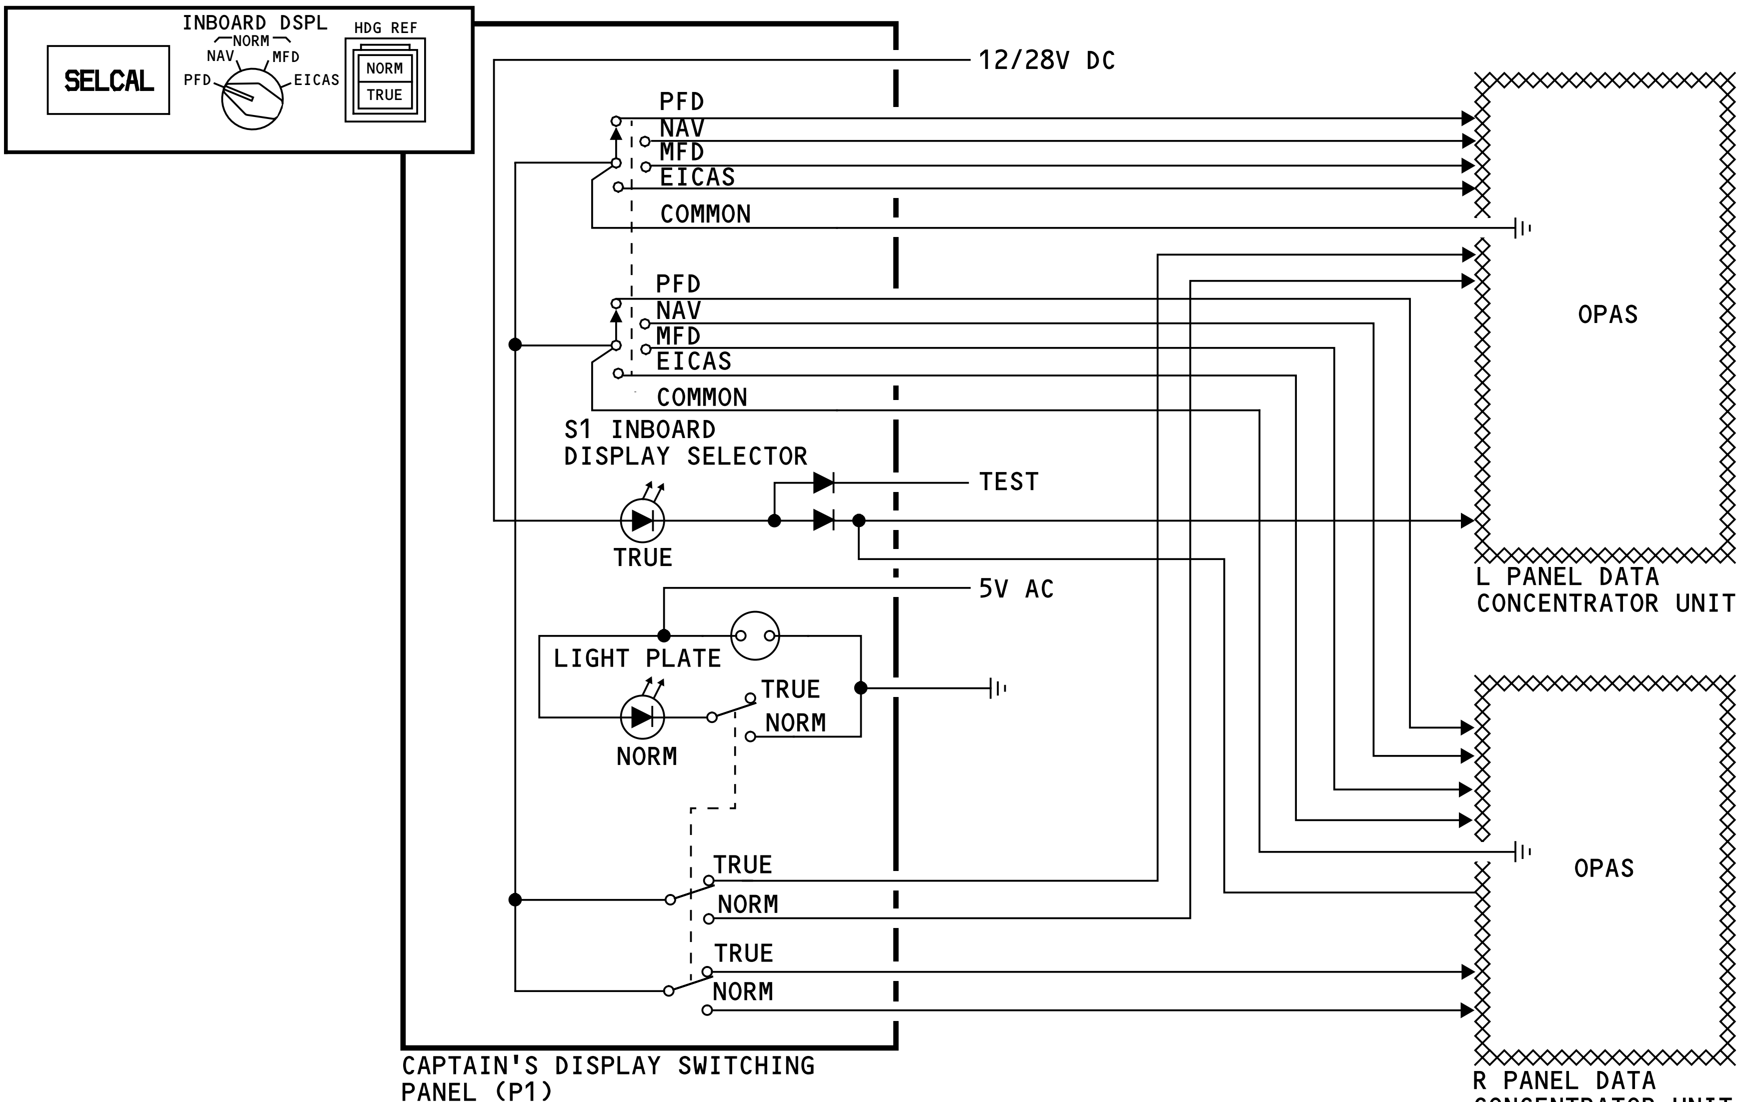
31-61-00-011 Rev 0

PRIMARY DISPLAY SYSTEM - ACCEPT, REJECT AND CANCEL SWITCH INTERFACE

PRIMARY DISPLAY SYSTEM - CAPTAIN DISPLAY SWITCHING PANEL INTERFACES

General

An inboard display (INBOARD DSPL) selector and a heading reference (HDG REF) switch send analog discretes to the OPAS panel data concentrator units (PDCUs). The inboard display selector gives the flight crew control of the inboard display format. The heading reference switch gives the flight crew control of the compass heading reference on both the captain's and first officer's displays.



31-61-00-012 Rev 2 03/28/95

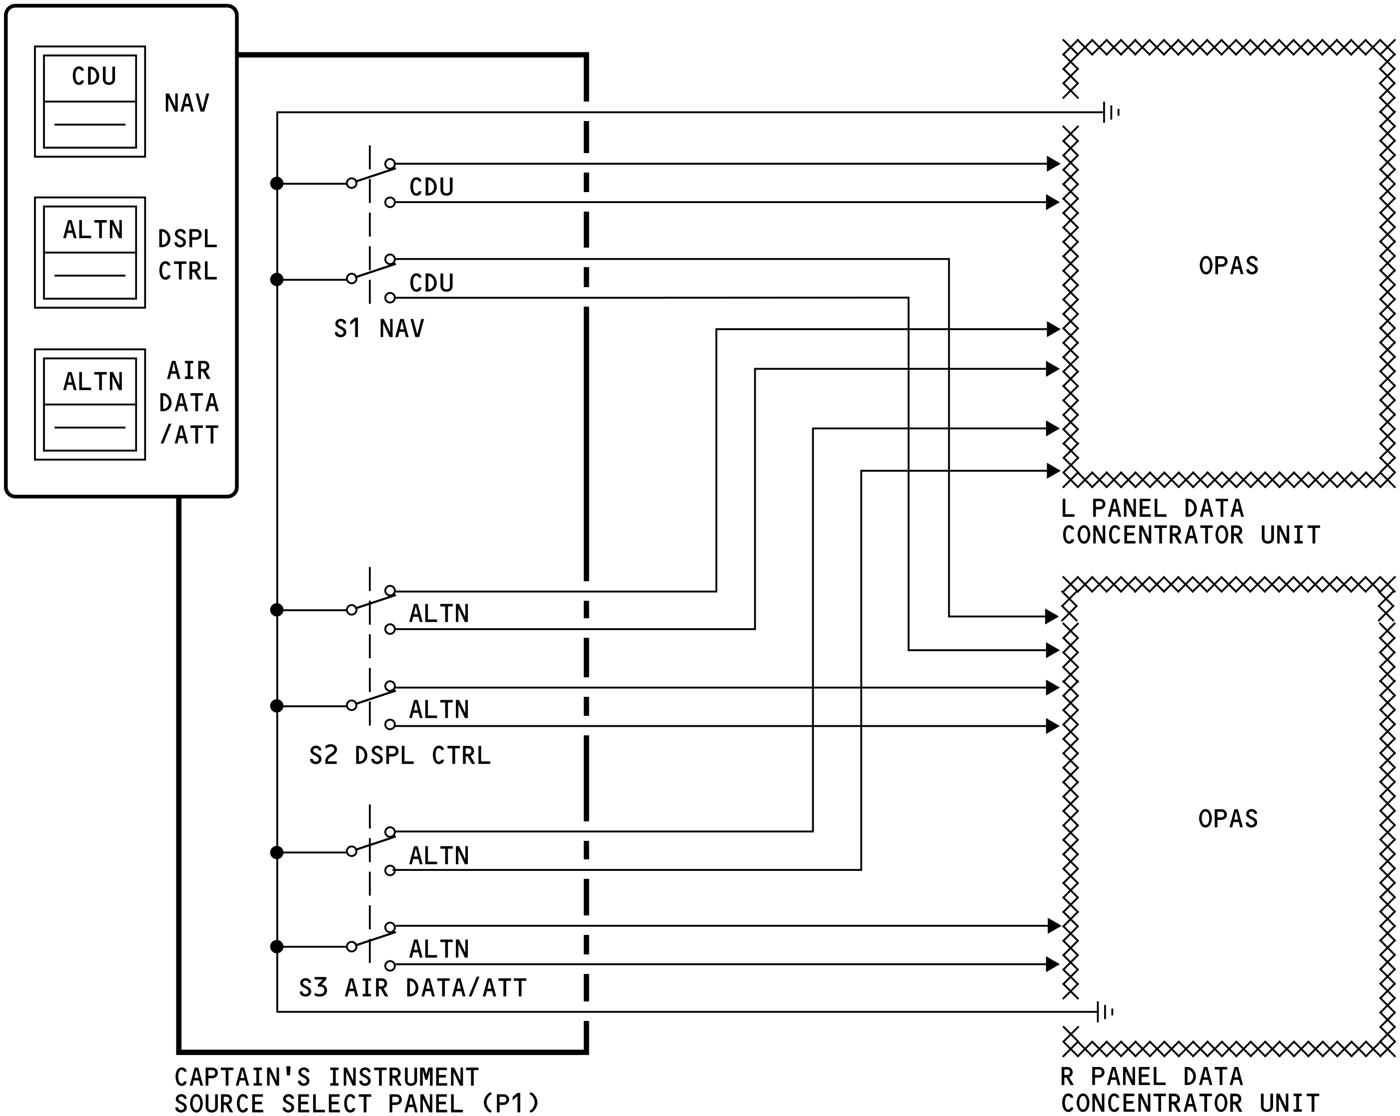
PRIMARY DISPLAY SYSTEM - CAPTAIN DISPLAY SWITCHING PANEL INTERFACES

PRIMARY DISPLAY SYSTEM - INSTRUMENT SOURCE SELECT PANELS INTERFACE

General

The captain's and first officer's instrument source select panels (ISSPs) send analog discretes to the OPAS panel data concentrator units (PDCUs) to process. Each ISSP switch gives onside flight crew control for an alternate source display.

The PDS has automatic control when the ISSP switches are in the normal position.



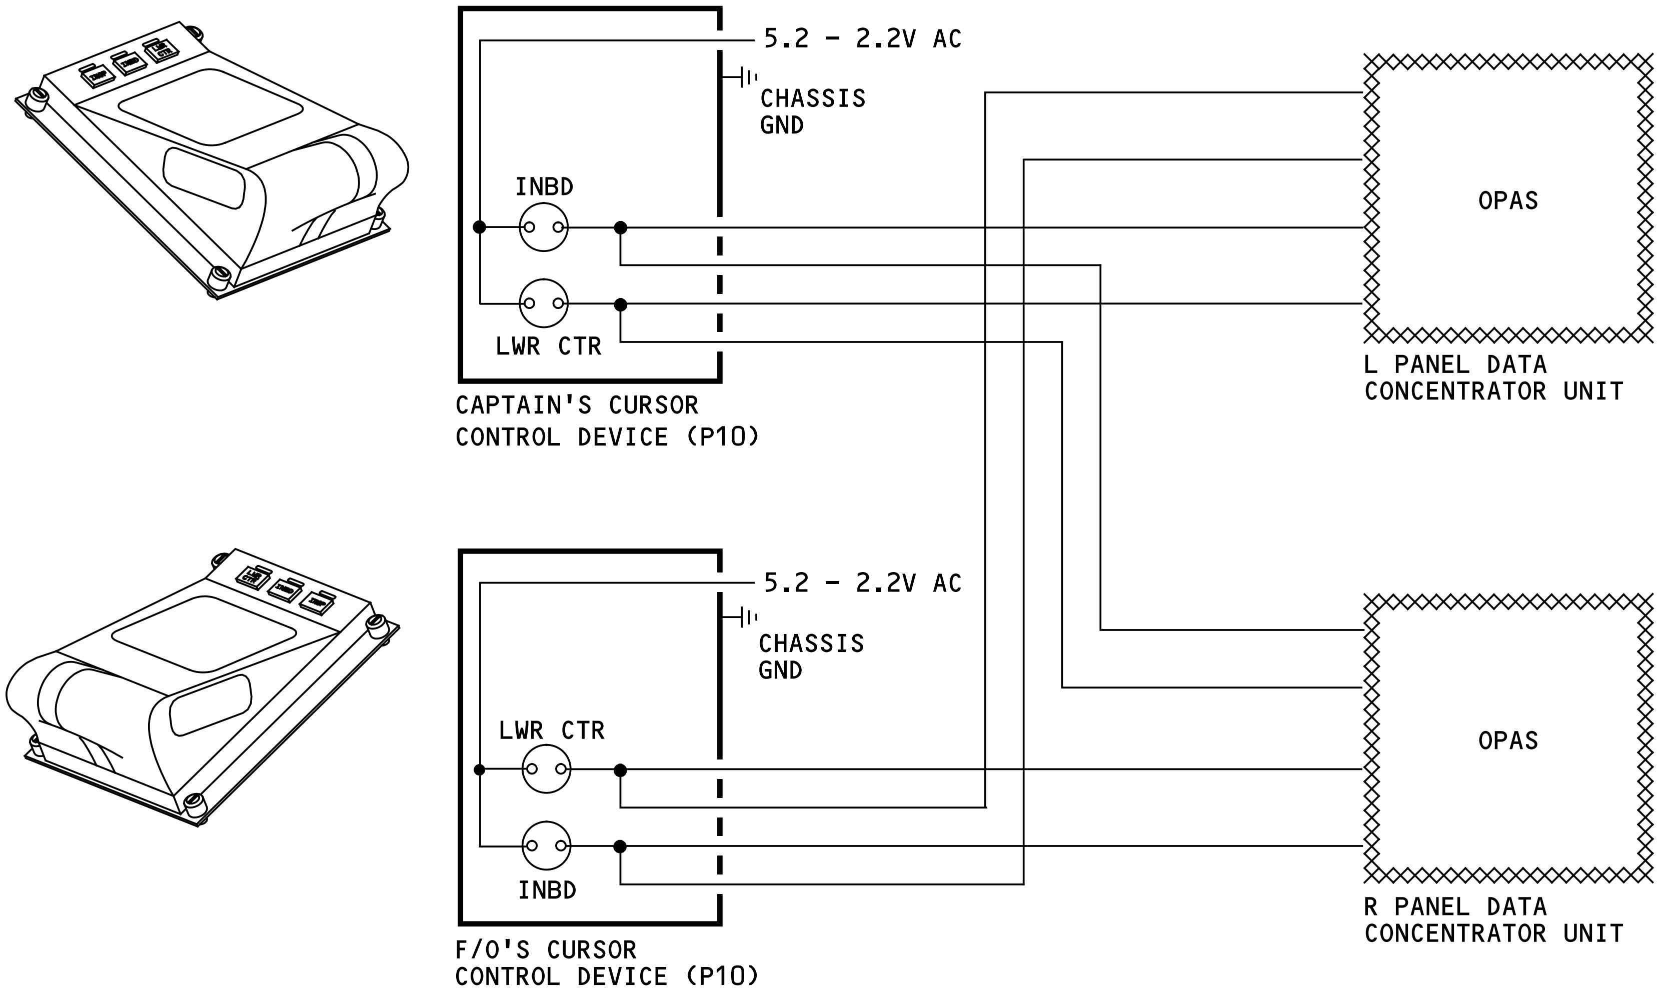
31-61-00-013 Rev 0

PRIMARY DISPLAY SYSTEM - INSTRUMENT SOURCE SELECT PANELS INTERFACE

PRIMARY DISPLAY SYSTEM - CURSOR CONTROL DEVICE INTERFACES

General

The cursor control devise (CCD) gets grounds from the panel data concentrator units. The grounds turn on lights to indicate which display the operator selected.



31-61-00-014 Rev 2 05/30/96

PRIMARY DISPLAY SYSTEM - CURSOR CONTROL DEVICE INTERFACES

PRIMARY DISPLAY SYSTEM - DISPLAY SELECT PANEL INTERFACES

General

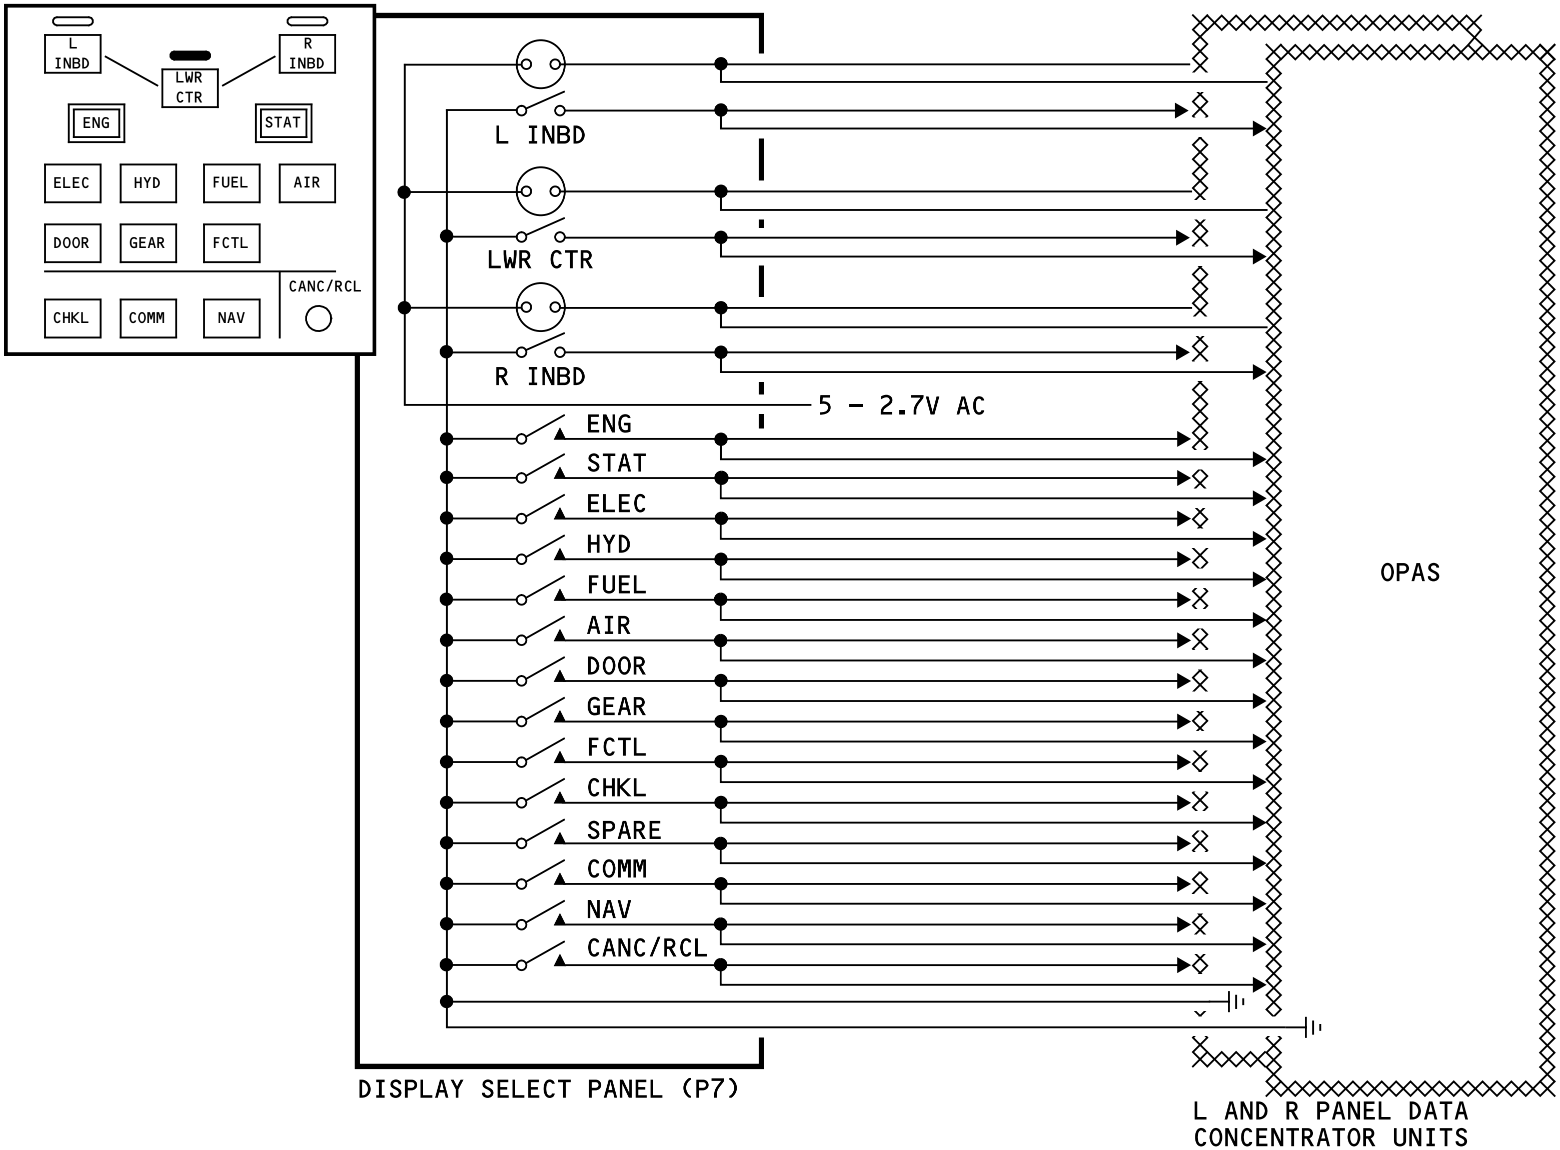
The display select panel (DSP) receives analog discrete data from the overhead panel ARINC 629 system (OPAS). The DSP sends analog discrete data to OPAS.

Inputs

The DSP receives a ground analog discrete from each OPAS panel data concentrator unit (PDCU). The DSP receives power from -2.7 to 5 vac.

Outputs

The DSP sends an analog discrete(s) to each OPAS PDCU when you make a mode and/or a display request.



PRIMARY DISPLAY SYSTEM - DISPLAY SELECT PANEL INTERFACES

31-61-00-015 Rev 4 01/16/1998

PRIMARY DISPLAY SYSTEM - CENTER DISPLAY CONTROL PANEL INTERFACES

General

The center display control panel receives analog discretes from and sends analog discretes to OPAS.

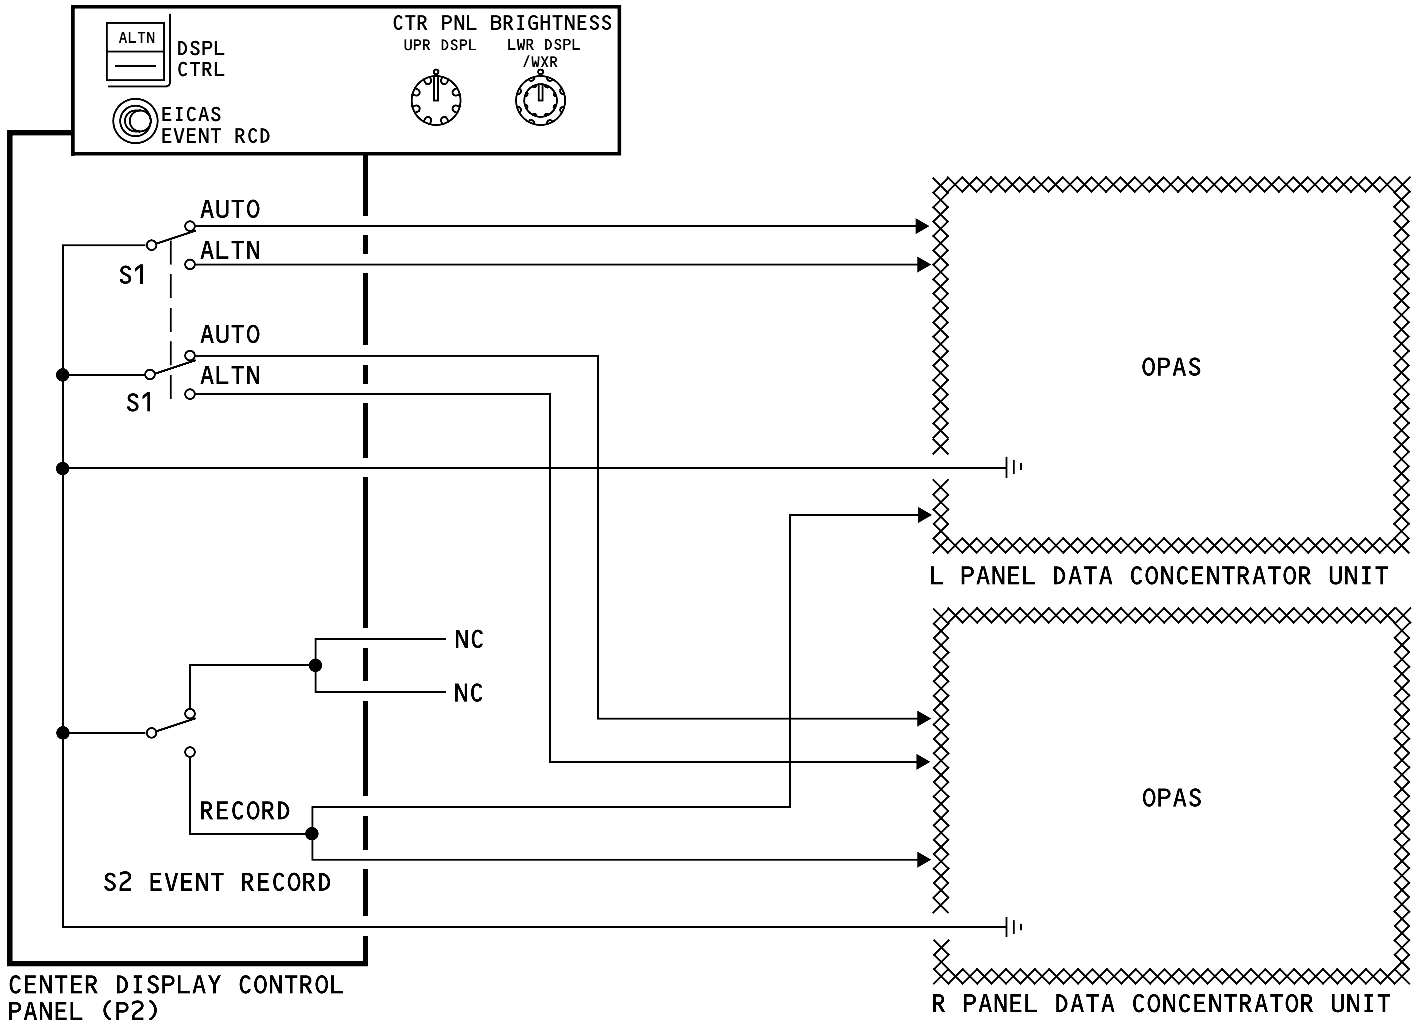
Inputs

OPAS sends two analog discrete grounds to the center display control panel.

Outputs

The center display control panel sends an analog discrete when the DSPL CTRL switch is in the AUTO and ALTN position to OPAS.

The center display control panel also sends an analog discrete to OPAS when the operator uses the event record switch.



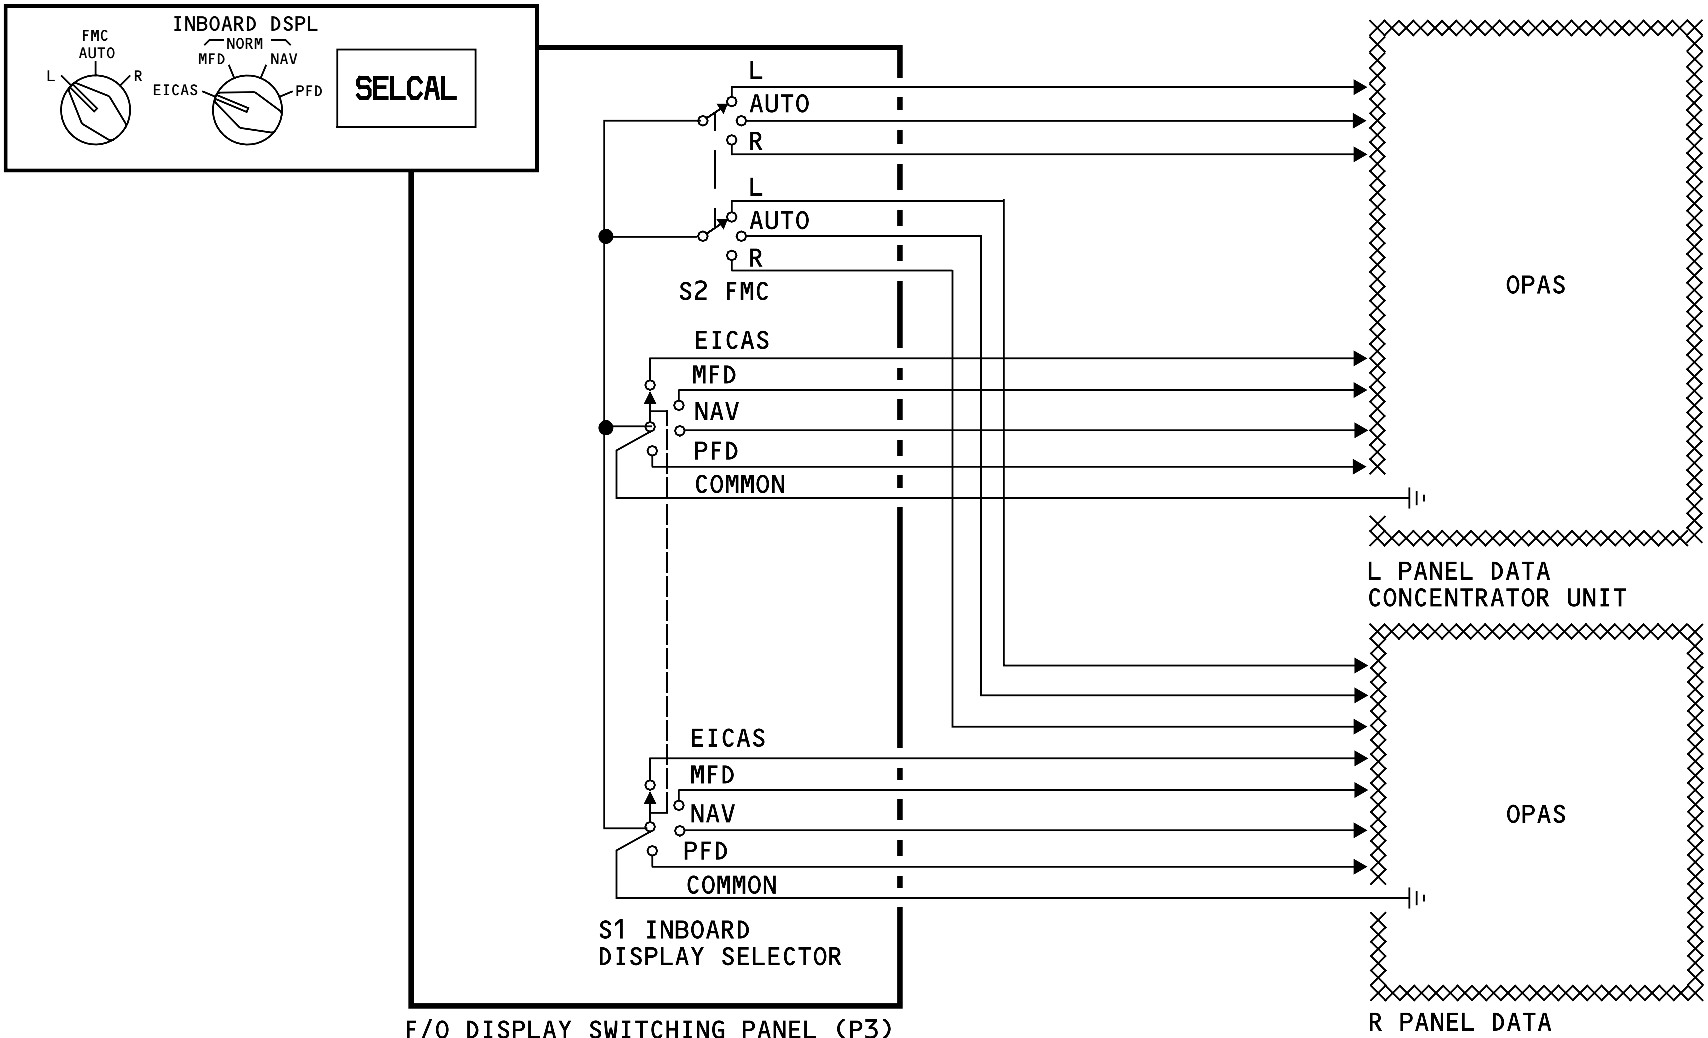
31-61-00-016 Rev 1

PRIMARY DISPLAY SYSTEM - CENTER DISPLAY CONTROL PANEL INTERFACES

PRIMARY DISPLAY SYSTEM - F/O DISPLAY SWITCHING PANEL INTERFACES

General

An inboard display (INBOARD DSPL) selector and an FMC selector send analog discretes to the OPAS panel data concentrator units (PDCUs). The display selector gives the flight crew control of the inboard display format. The FMC selector gives the flight crew manual or automatic control of the FMCF source on both the captain and first officer's displays.



31-61-00-017 Rev 1

PRIMARY DISPLAY SYSTEM - F/O DISPLAY SWITCHING PANEL INTERFACES

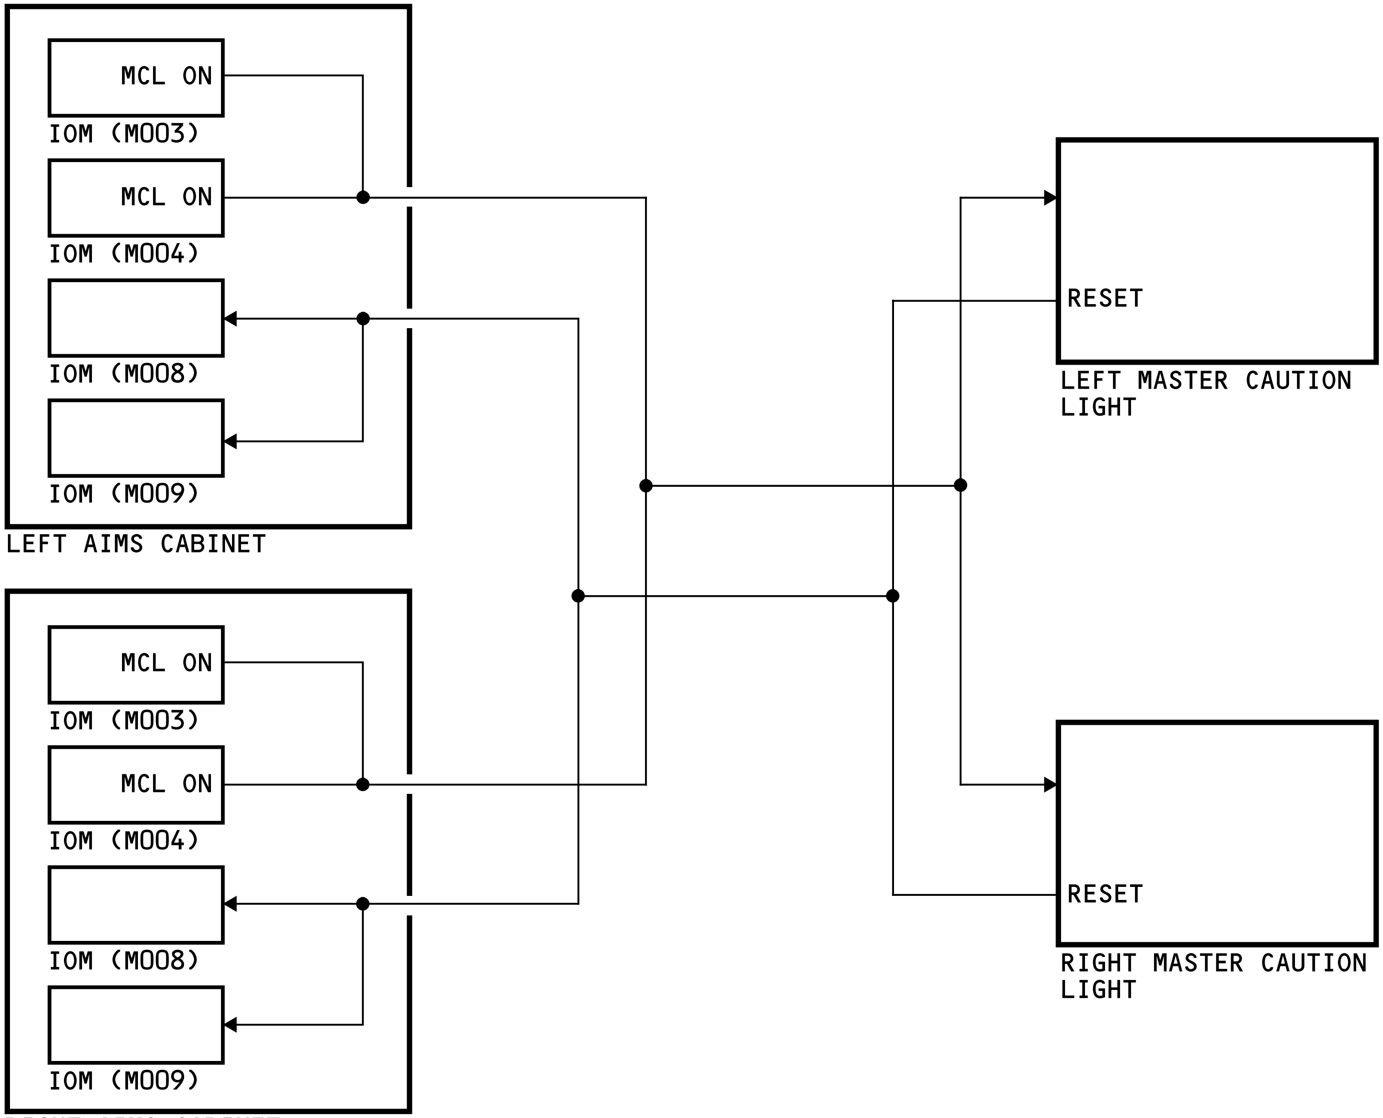
PRIMARY DISPLAY SYSTEM - MASTER CAUTION LIGHTS INTERFACES

Master Caution Light On Signal

IOMs M004 and M003 in each AIMS cabinet supply a master caution light on signal to both master caution lights.

Reset

When you push a master caution light, IOMs M008 and M009 in each AIMS cabinet receive a master caution light reset signal. This makes both master caution lights go out.



31-61-00-132 Rev 0 03/07/96

PRIMARY DISPLAY SYSTEM - MASTER CAUTION LIGHTS INTERFACES

PRIMARY DISPLAY SYSTEM - DISPLAY UNIT

Purpose

The primary display system uses six identical ARINC D flat panel liquid crystal display (LCD) units. These display units (DUs) show:

- Primary flight information
- Navigation information
- Engine information
- Crew alerting information
- Airplane systems data.

Physical Description

The DUs are in a rack. The DUs are 8 inches by 8 inches and are 8.75 inches deep. Each DU weighs 18 pounds.

There is a bezel light sensor (BLS) at the bottom edge of the face plate.

Operation

The DUs have two internal temperature detectors. The power supply has a detector that causes the DU to shutdown when the internal temperature reaches 110 degrees centigrade. The backlight assembly has a detector that causes the DU to shutdown when the internal temperature reaches 95 degrees centigrade. The detectors automatically turn the DUs off during an overtemperature condition. The DUs come on when the temperature returns to normal. The DUs use forced air cooling.

Training Information Point

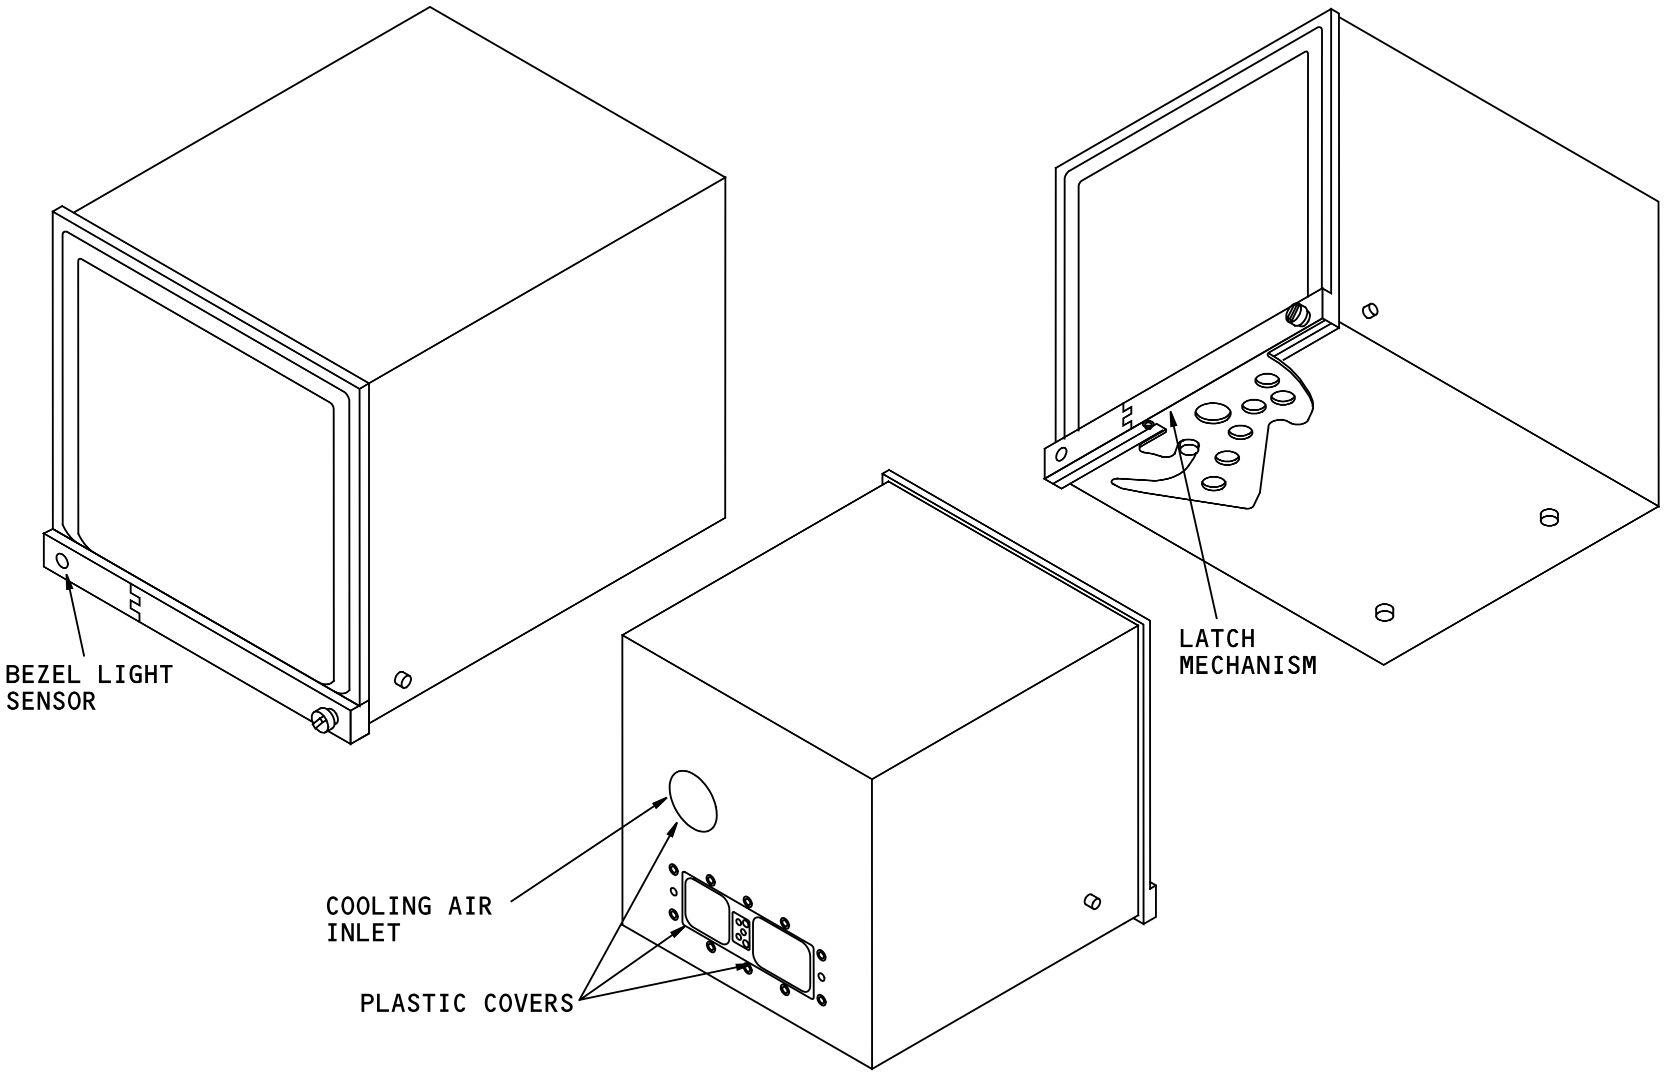
The six DUs are interchangeable. Due to the viewing angle limitations of LCD technology, the installation of the lower center DU is 180 degrees (handle at the top) from the other DUs. For the lower center DU, the handle is opposite to the handle of the other DUs.

Training Information Point

During the removal or installation of the inboard and outboard DUs, you must move the control column.

CAUTION: MOVEMENT OF THE CONTROL COLUMN MAY CAUSE FLIGHT SURFACE MOVEMENT.

NOTE: Remove plastic covers from the connectors before you install a DU.



31-61-00-018 Rev 3

PRIMARY DISPLAY SYSTEM - DISPLAY UNIT

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - EFIS CONTROL PANEL

Purpose

Two identical EFIS control panels (EFIS CP) control data on the PFD and ND formats.

Description

The EFIS CP is 4.8 inches by 3.45 inches and 6 inches deep. The panel weighs approximately 4 pounds.

PFD Controls

Use these controls to manage data on the PFD:

- Minimums reference selector
- Flight path vector (FPV) switch
- Meters (MTRS) switch
- Barometric (BARO) reference selector.

The minimums reference selector selects and sets altitude minimums. The minimums reference outer selector selects either RADIO or BARO minimums. The inner selector sets the altitude. The reset (RST) push-button switch cancels the RADIO or BARO alert annunciation.

The FPV switch enables or disables the display of the FPV vector symbol.

The meters (MTRS) switch is an alternate action switch that controls the display of actual and selected altitude in meters. This is in addition to the display of these parameters in feet.

The barometric reference selector selects and sets the barometric reference. This selector has three controls, outer, middle, and inner. The baro reference outer selector selects either inches of mercury (IN) or hectopascals (hPa) as the barometric reference on the related PFD. The barometric middle selector sets the barometric correction. The inner push-button switch selects the standard baro setting 29.92 inches of Hg or 1013 hpa.

ND Controls

The ND mode selector enables either the approach (APP), VOR, MAP, or PLAN modes. Use the center (CTR) push-button to toggle between an expanded display that covers 90 degrees and a centered display that covers 360 degrees in all modes except PLAN.

The ND range selector controls the map range or display range in the MAP or PLAN mode. This selector also controls weather radar range and TCAS intruder symbol range in the expanded APP mode, expanded VOR mode and MAP modes.

The traffic switch selects or cancels TCAS traffic data.

The VOR/ADF switches show radio navigation aid data in all modes except PLAN. The OFF position causes the VOR and ADF information to go out of view. Bearing information shows on the compass rose when you set either switch to VOR or ADF. VOR/ADF identification or frequency data also shows in the lower corner or the display. Co-located DME distance shows when the switches are in the VOR position.

These ND map switches cause data to show on the NDs or cause data on the NDs to go out of view:

- Weather radar (WXR)
- Station (STA)
- Waypoint (WPT)
- Airport (ARPT)
- DATA
- Position (POS).

The weather map switch causes weather radar (WXR) data to show.

The station map switch causes navigation aids not in the flight plan to show.

The waypoint map switch causes waypoints and ground reference points to show.

The airport map switch causes airports not in the flight plan to show.

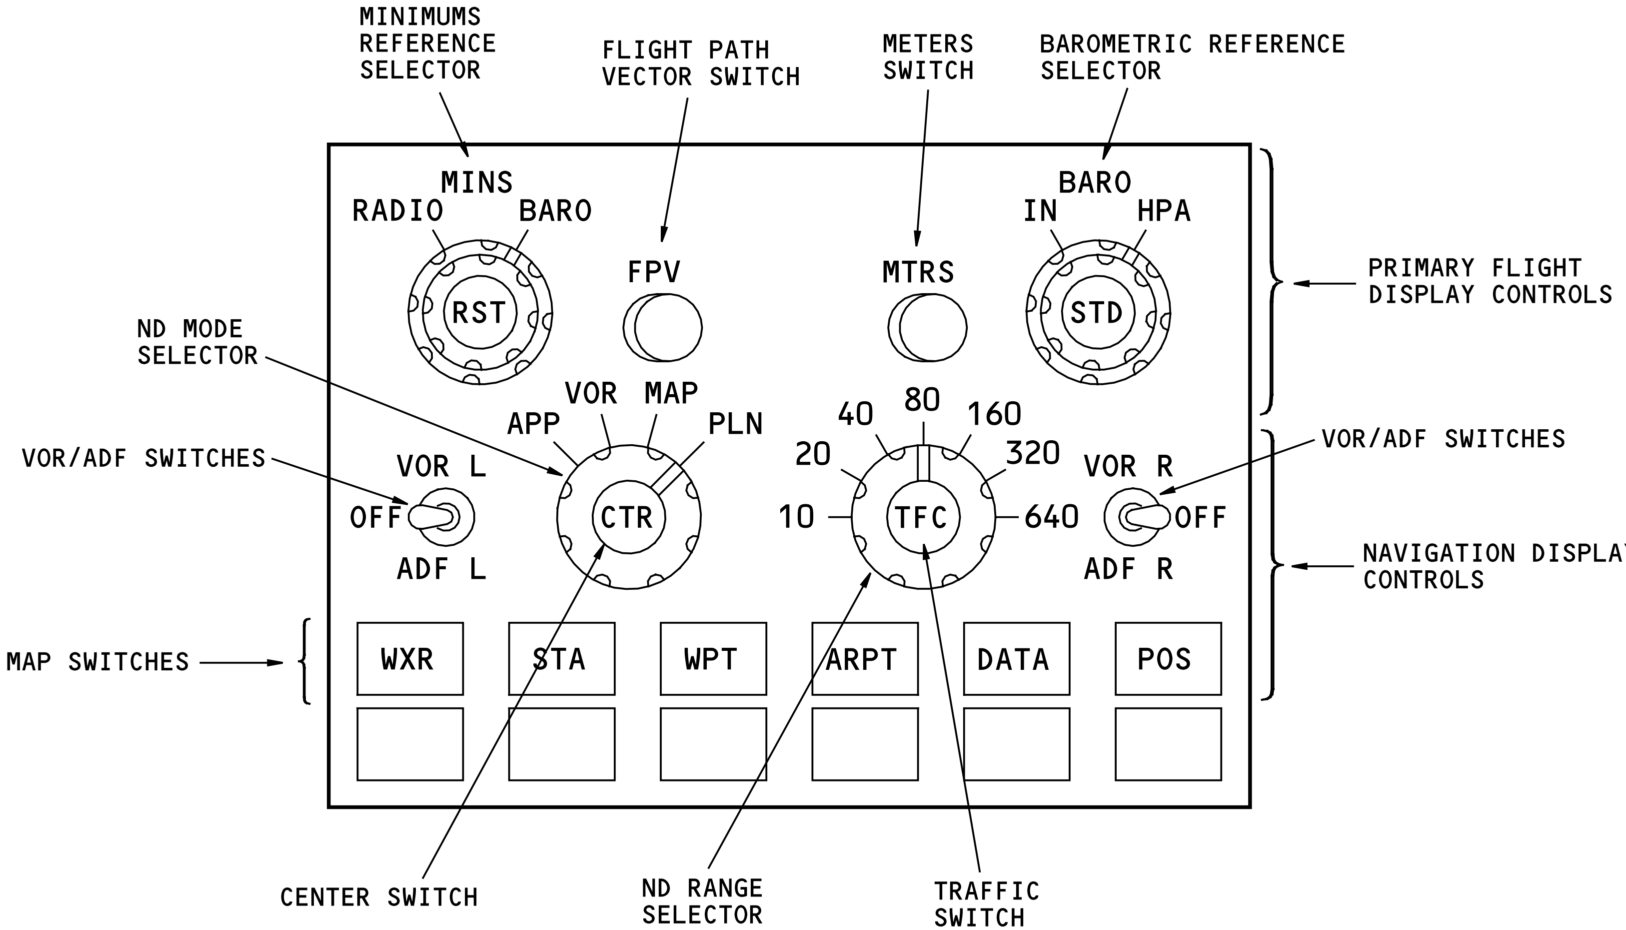
The DATA map switch causes route data to show.

The STA, WPT, ARPT and DATA switches affect the map background display.

The position map switch causes VOR/DME and air data inertial reference system (ADIRS) position data to show on the map display.

Alternate Control Panel Functions

The left and right control display units (CDUs) provide alternative EFIS CP functions. CDU menu selections enable the alternate EFIS CP functions.



31-61-00-019 Rev 1

PRIMARY DISPLAY SYSTEM - EFIS CONTROL PANEL

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - DISPLAY SELECT PANEL

Purpose

The display select panel (DSP) controls the formats on the two inboard and the center lower display units.

Physical Description

The DSP is 3.5 inches by 3.45 inches and 3 inches deep. It weighs 4 pounds.

DU Selection Controls

There are three switches at the top of the panel. The labels on the switches are L INBD, R INBD, and LWR CTR. Each switch has a light that comes on when you set the switch. The switches select which display unit (left inboard, right inboard, or lower center) responds to the mode select switches. The three select switches are latched electronically, only one switch is active at a time.

Mode Controls

The mode select switches are alternate action switches that control the display of these formats:

- ENG: Engine secondary
- STAT: Status page
- ELEC: Electrical synoptic
- HYD: Hydraulic synoptic
- FUEL: Fuel synoptic
- AIR: Air synoptic
- DOOR: Door synoptic
- GEAR: Gear synoptic
- FCTL: Flight controls synoptic
- CHKL: Checklists
- COMM: Communication function
- NAV: Navigation display.

On an inboard DU, if you select the same display that shows, the navigation display format will show. On the lower center DU, if you select the same display that shows, the DU blanks.

The status format is an exception. When the status format shows and you select the STAT switch, the next status page shows. When the last page shows and you select the STAT switch, the inboard DU shows the navigation display format and the lower center DU blanks.

The ENG, FUEL, and AIR switches also control information on the EICAS and compacted engine displays when EICAS is in the limited mode.

Cancel/Recall Switch

The cancel/recall (CANC/RCL) switch cancels and recalls EICAS caution and advisory messages.

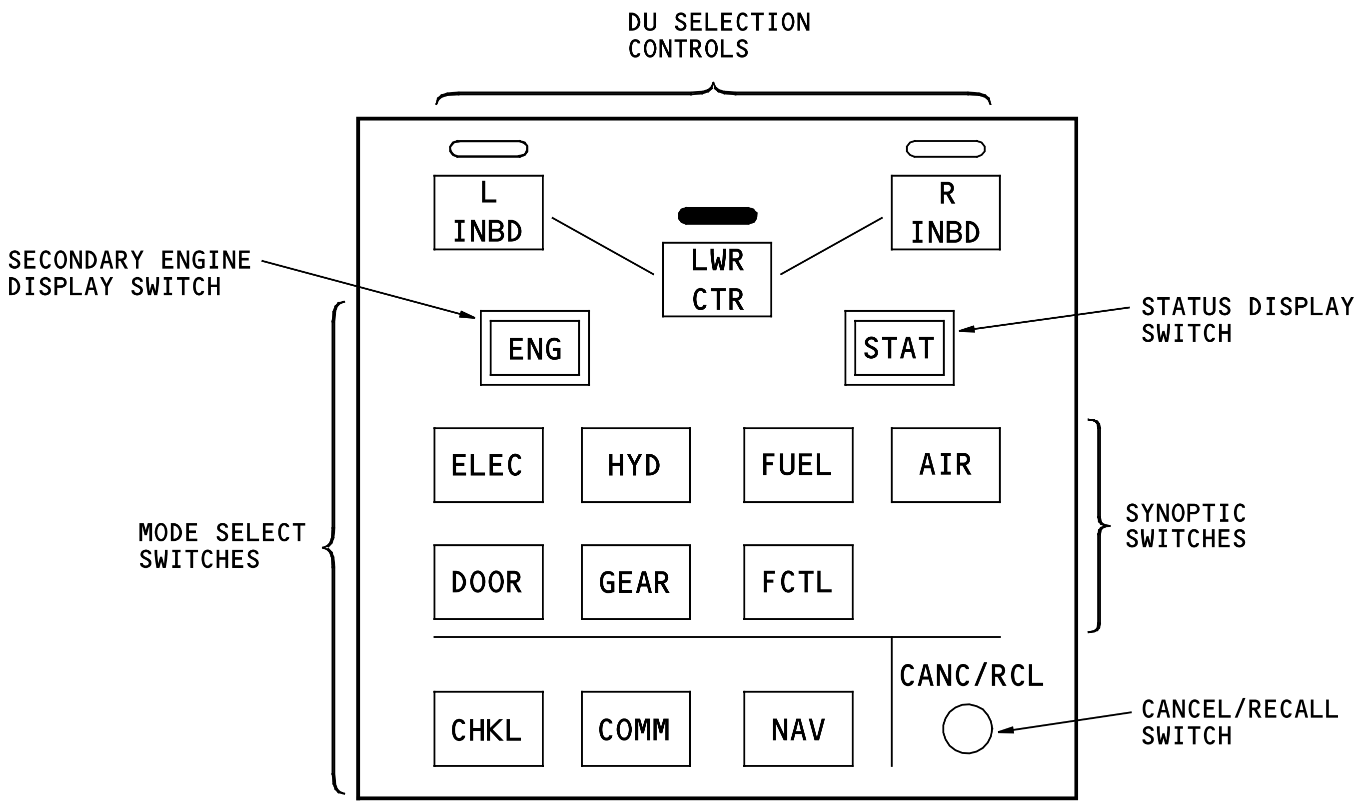
When caution and advisory messages show, selection of this switch causes the first page of messages to go out of view and causes the next page of messages to show if additional pages exist. Warning, memo, and COMM messages remain. This switch also cancels red latched exceedance boxes.

PRIMARY DISPLAY SYSTEM - DISPLAY SELECT PANEL

You can recall caution and advisory messages when you select the CANC/RCL switch again. Previous messages return if the conditions that cause them to show still exist. Red exceedance boxes that you cancelled also show.

Alternate DSP Functions

The three control display units (CDU) supply an alternate way to select the DSP functions. CDU menu selections enable the DSP functions.



31-61-00-020 Rev 5 05/19/1997

PRIMARY DISPLAY SYSTEM - DISPLAY SELECT PANEL

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - CONTROL DISPLAY UNIT MENUS

Purpose

The control display units (CDUs) provide menu selections for:

- Maintenance page selections
- Alternate EFIS control panel functions
- Alternate display select panel (DSP) functions

Maintenance Page Selection

Use Line select key (LSK) five right (5R) on the CDU MENU page to show the maintenance page menu on the selected display unit. Then use the cursor control device to make other selections.

The maintenance page selection is available on all three CDUs.

You can select and see maintenance pages any time the airplane is on the ground or any time the airplane is above ten thousand feet.

EFIS Control Panel Functions

The onside CDU provides a menu selection for the EFIS control panel. The selection of the EFIS function on a CDU disables the onside EFIS control panel.

The center CDU is a backup for the left or right CDU for the EFIS control panel functions. IF both CDUs fail, the center CDU is a backup for the CDU that fails first.

The CDU remembers the last valid settings of the EFIS CPs.

Use LSK 1R on the CDU MENU page, then LSK 2R to show the EFIS CONTROL page.

Use the OPTIONS key (LSK 6R) on the EFIS CONTROL page to show the EFIS OPTIONS page.

Use the CONTROL key (LSK 6R) on the EFIS OPTIONS page to show the EFIS CONTROL page.

These two pages supply most of the functions of the EFIS CP.

Display Select Panel Functions

The DSP menu selection is available on all three CDUs.

The CDU remembers the last valid DSP selection.

The selection of the DSP function on a CDU disables the DSP and the DSP lights go out. It also disables the DSP menu selections on the other two CDUs.

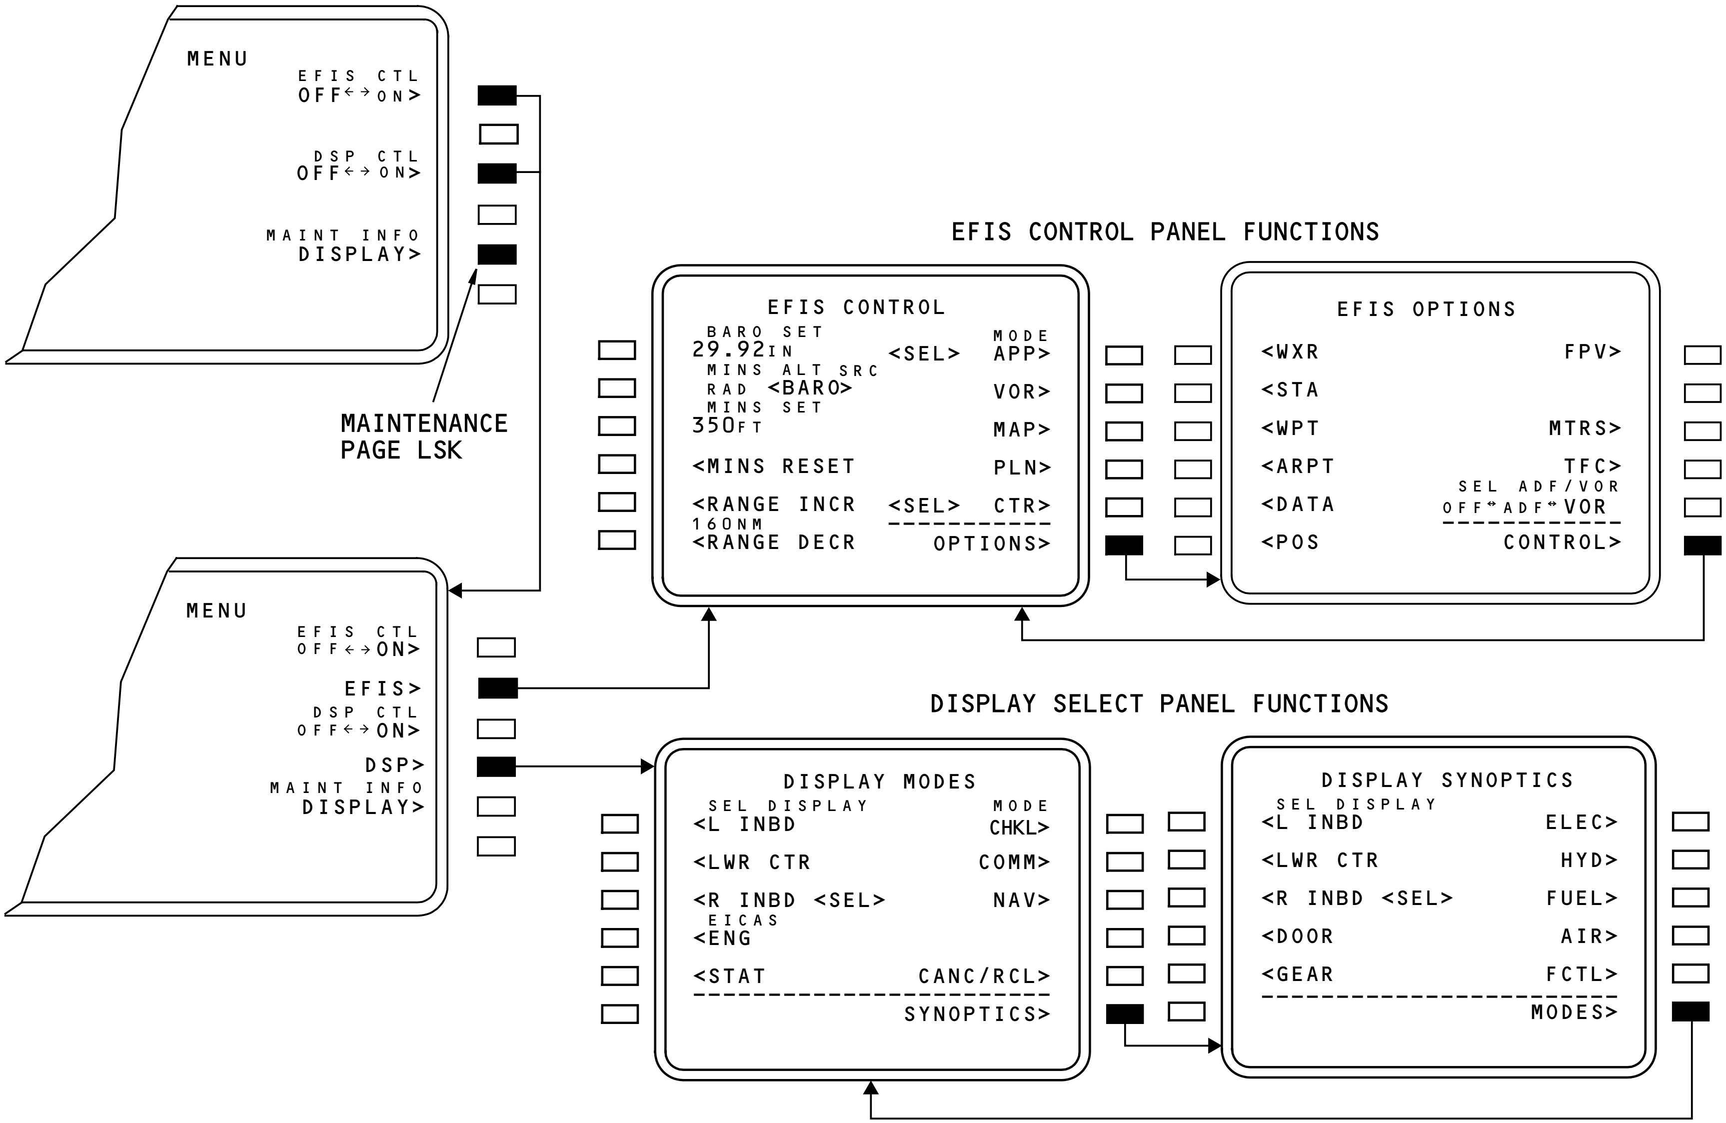
Use DSP CTL (LSK 3R), then DSP (LSK 4R) to show the DSP DISPLAY MODES page.

Use the SYNOPTICS key (LSK 6R) on the DISPLAY MODES page to show the DISPLAY SYNOPTICS page.

Use the MODES key (LSK 6R) on the DISPLAY SYNOPTICS page to show the DISPLAY MODES page.

PRIMARY DISPLAY SYSTEM - CONTROL DISPLAY UNIT MENUS

The CDU keys for the DSP functions operate the same as the switches on the DSP. The two pages supply all the functions of the DSP.



31-61-00-021 Rev 5 05/19/1997

PRIMARY DISPLAY SYSTEM - CONTROL DISPLAY UNIT MENUS

PRIMARY DISPLAY SYSTEM - CURSOR CONTROL DEVICES

Purpose

Flight crews and maintenance personnel use the cursor control devices (CCD) for the data communication management function and to control the maintenance page format selections.

You also use the CCDs to control the electronic checklists.

Description

The CCD weighs four pounds. The CCD has its own power supply. The CCD has two electrical connectors, one for power and one for control. The CCD has three control switches and a touch pad.

Controls

The CCD has two momentary cursor location switches for display selection, one cursor select switch on the side for selection, and a touch pad.

The cursor location switches are:

- LWR CTR: This switch connects the CCD to the lower center display
- INBD: This switch connects the CCD to the inboard display.

Each cursor location switch has a cursor location light (green LED) that comes on when you select the switch.

Use the cursor select switch to make a selection when the cursor on the display is in an active area. You operate the switch with the thumb. This switch gives a tactile feedback.

Touch Pad

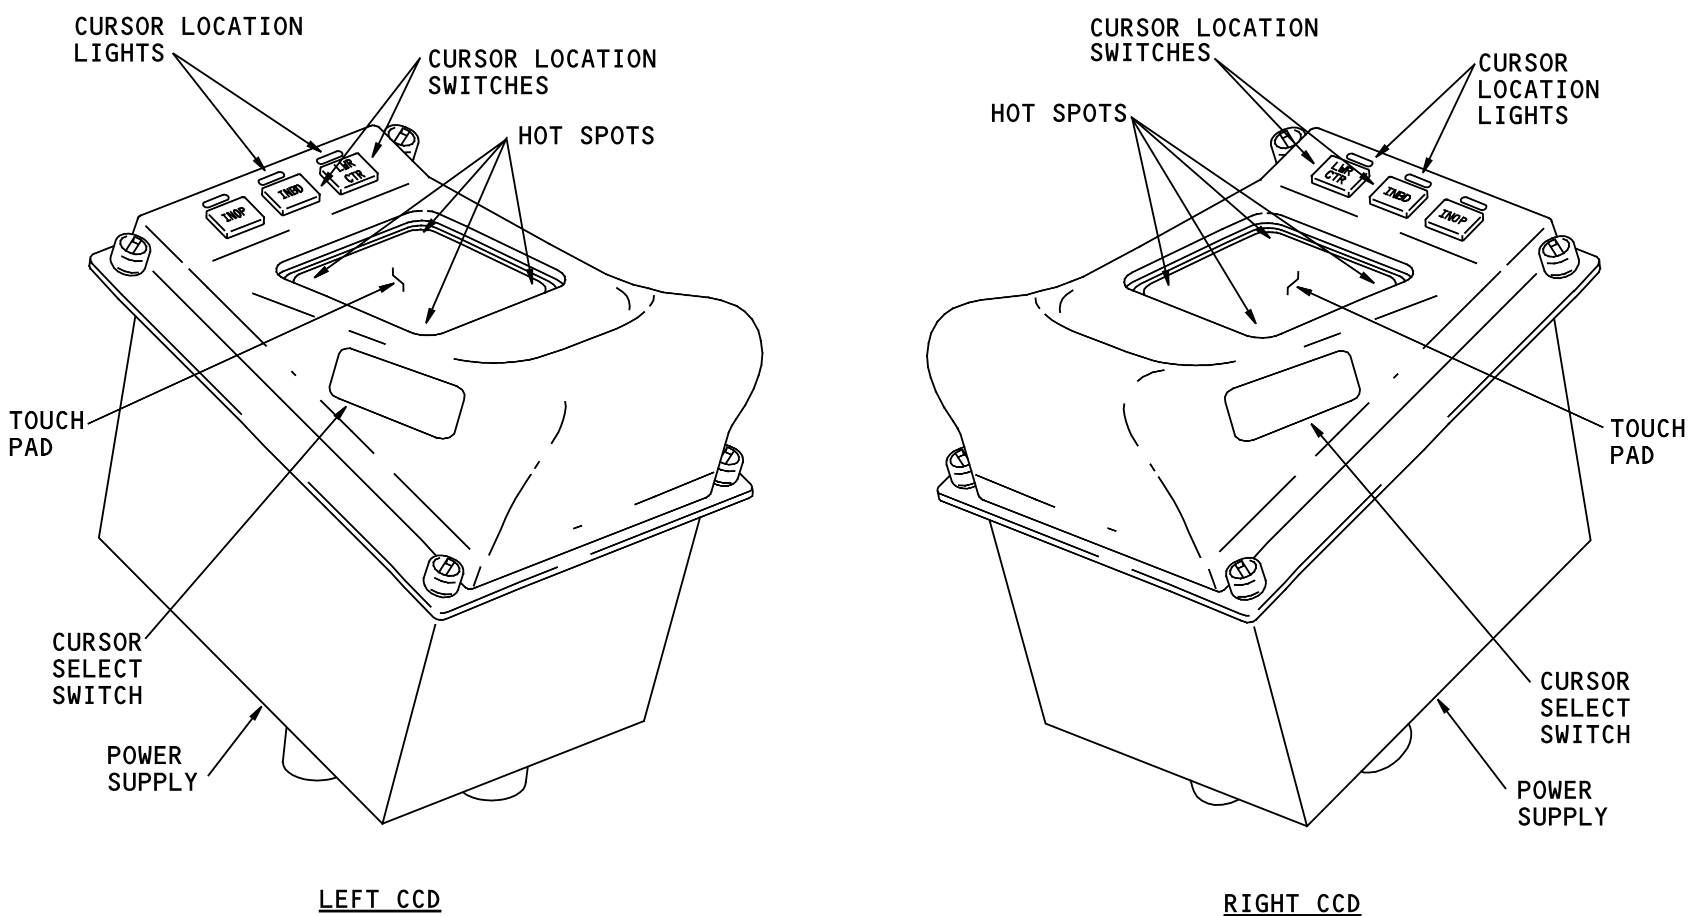
The cursor follows your finger on the display when you move a finger across the touch pad. Each touch pad has hot spots. These hot spots are at each corner of the touch pad. The cursor goes to the corner of the active display when you touch a corner of the touch pad. This gives the operator quick access to frequently used menu selections. In some instances, the cursor automatically moves to the next selection.

Training Information Point

The two CCDs are not interchangeable because the cursor select and cursor location switches are not in the same position.

The manufacturer seals the CCD touch pad to prevent damage from liquid spills.

A glass faceplate over the touch pad prevents damage to the touch pad. The touch pads are impact resistant up to a force of 5 pounds.



31-61-00-022 Rev 4 05/30/96

PRIMARY DISPLAY SYSTEM - CURSOR CONTROL DEVICES

PRIMARY DISPLAY SYSTEM - REMOTE LIGHT SENSOR

Purpose

Two remote light sensors (RLSs) are on the forward part of the glareshield. The sensors face forward. The RLSs measure ambient light with a photodiode sensor and supply an analog signal proportional to the ambient light. The left and right RLS sends data to the respective outboard display unit. The display units use the analog signals for automatic brightness control.

Description

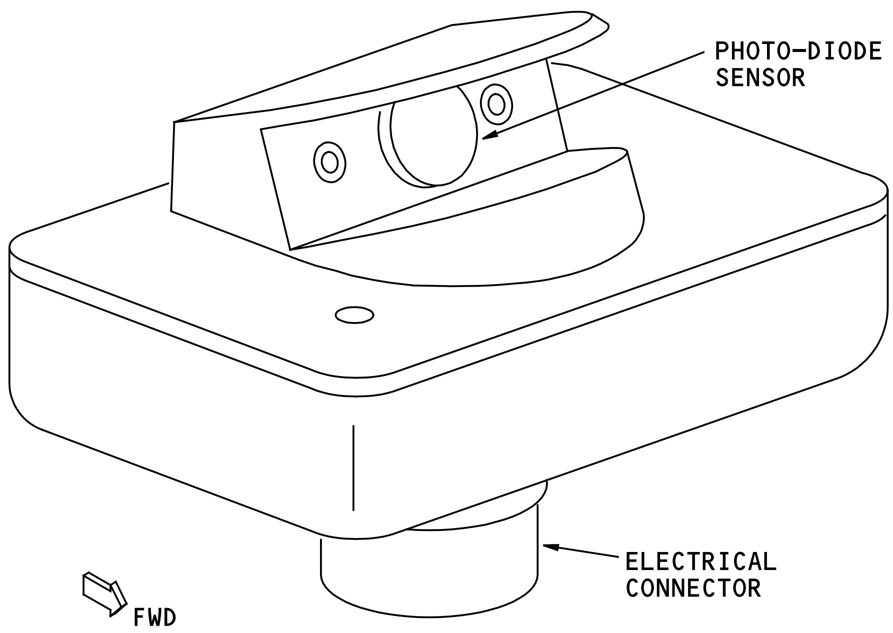
Each sensor weighs less than 1/2 pound. Each has a cable that has all the wires required for electrical power and signal interface. The cable is 84 inches long.

Each RLS has a field-of-view of 60 degrees left, 60 degrees right, 35 degrees up, and 35 degrees down.

Each RLS gets ±15v dc from the onside display unit.

Training Information Point

The remote light sensors are interchangeable.



REMOTE LIGHT SENSOR

31-61-00-023 Rev 1

PRIMARY DISPLAY SYSTEM - REMOTE LIGHT SENSOR

PRIMARY DISPLAY SYSTEM - BRIGHTNESS CONTROLS

Purpose

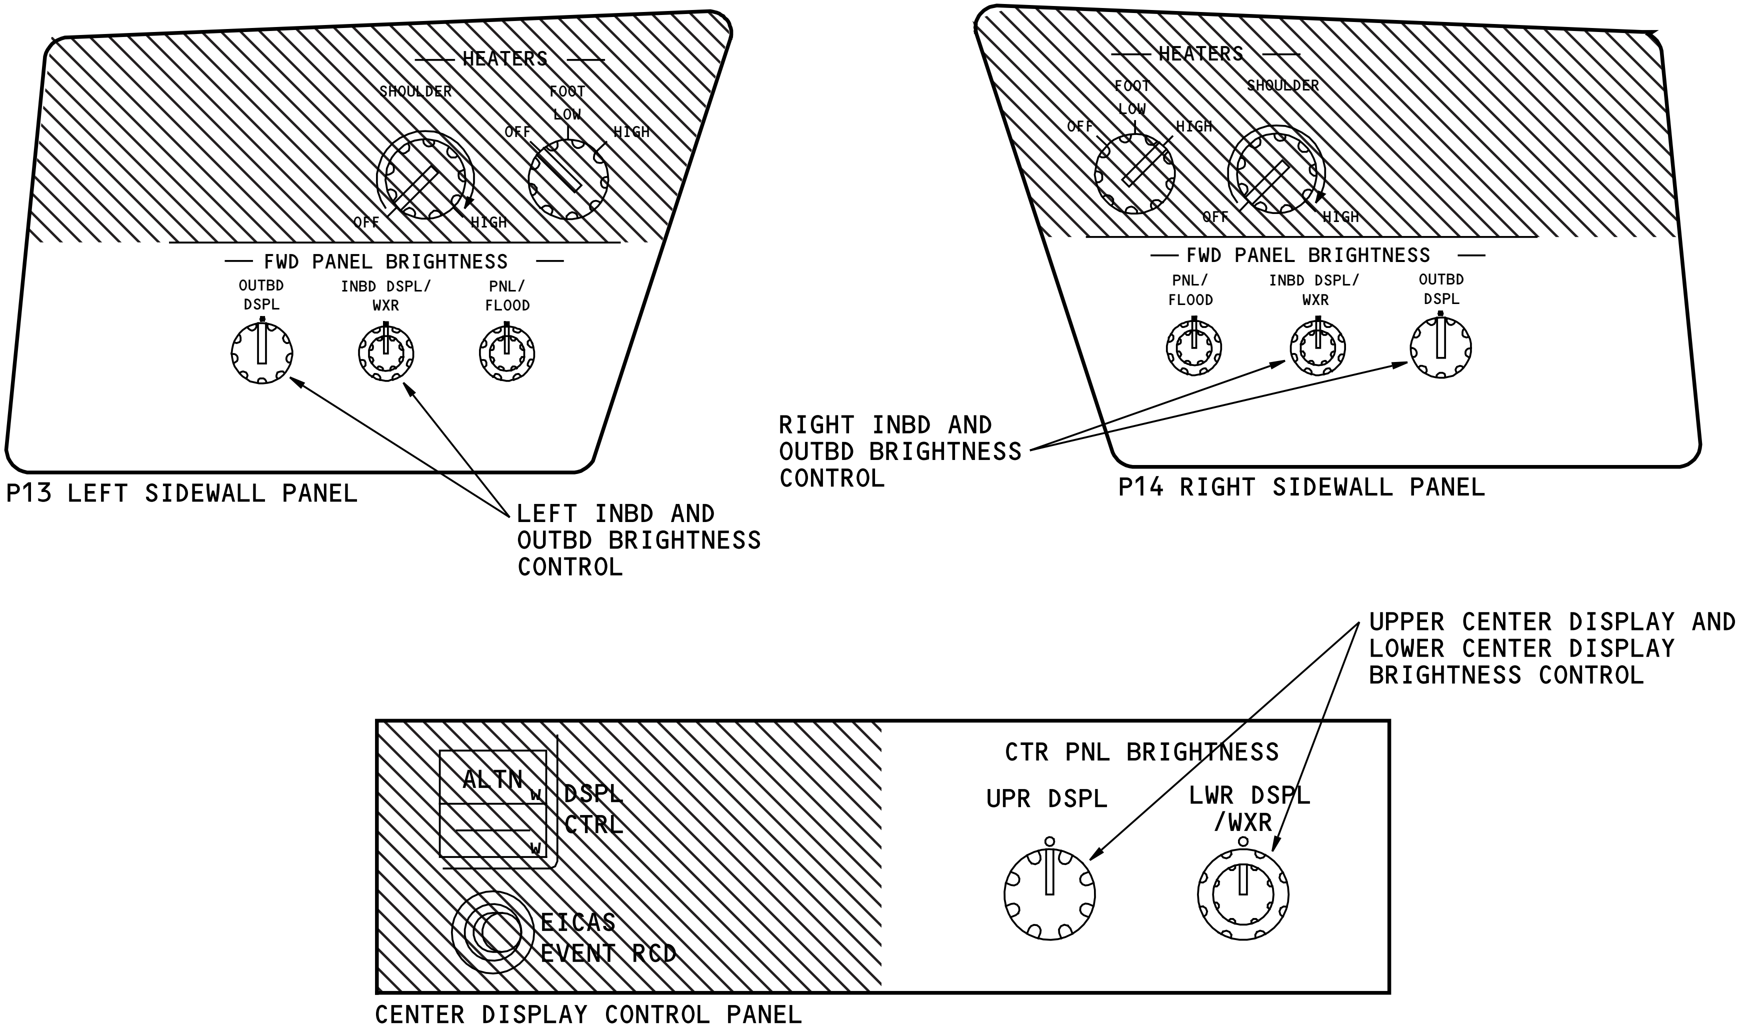
The brightness controls permit manual brightness control by the flight crew for the display units.

Forward Panel Brightness/Heater Controls

The flight crew forward panel brightness controls, control the brightness on the inboard and outboard DUs. There is a single control for the outboard display units. There are two controls for the inboard display units. The outer knob controls brightness and the inner knob controls the weather radar brightness.

Center Display Control Panel

The center display control panel has two brightness controls. The UPR DSPL control adjusts the brightness of the upper center display unit. The LWR DSPL/WXR has an outer knob and an inner knob. The outer knob adjusts the brightness of the center lower display. The inner knob adjusts the weather radar brightness.



31-61-00-024 Rev 3 08/08/96

PRIMARY DISPLAY SYSTEM - BRIGHTNESS CONTROLS

PRIMARY DISPLAY SYSTEM - DISPLAY SWITCHING PANELS

Purpose

Use the display switching panels to select alternate positions for display formats.

Operation

The NORM position has two selections. The MFD position causes the inboard DU to respond to the selections of the display select panel (DSP). The NAV position forces the inboard DU to show the ND format. In the NAV position, the inboard DU does not respond to DSP inputs.

The PFD position causes the inboard DU to show the PFD format.

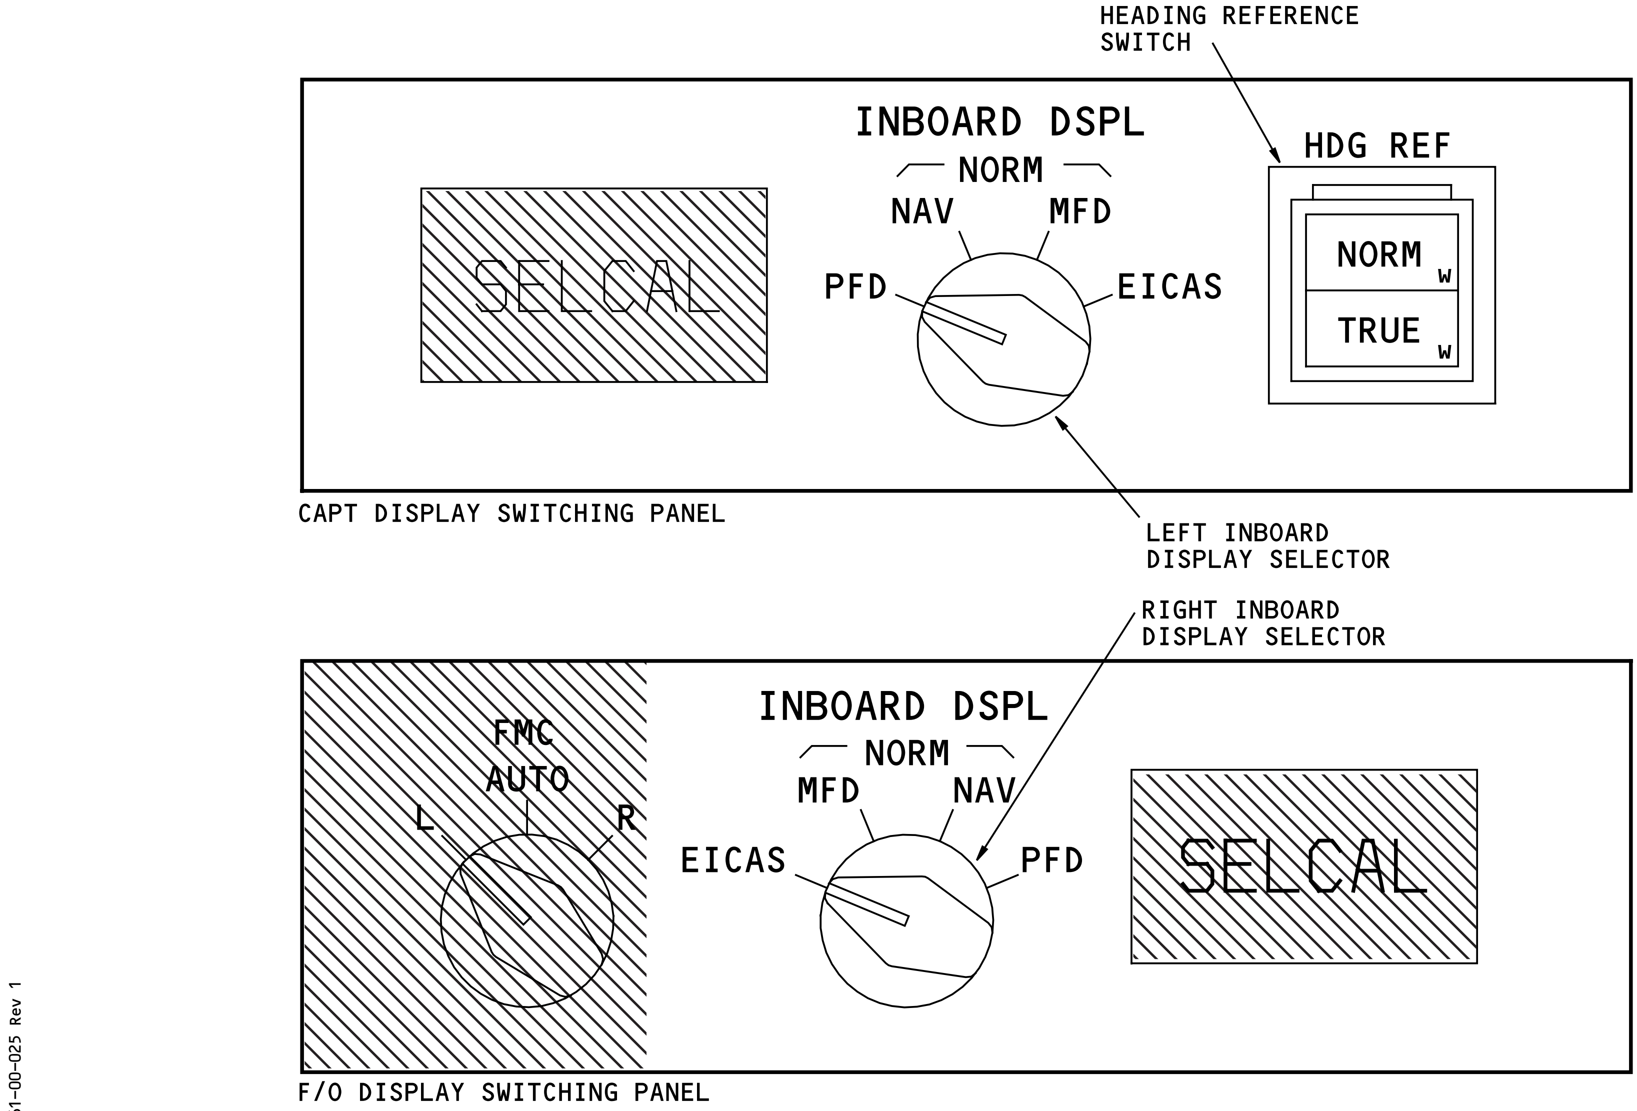
The EICAS position causes the inboard DU to show the EICAS display format.

The INBD DSPL switch has no effect on the inboard display unit(s) (DU) when the associated outboard DU finds a failure and the PFD switches automatically to the inboard DU. You cannot use the display selector for manual display selection.

Heading Reference Switch

The heading reference switch sets the reference for the PFD and ND formats. The NORM position sets the reference to magnetic heading and turns the NORM light on. The TRUE position sets the reference to true heading and turns the TRUE light on.

The switch has a plastic guard.



PRIMARY DISPLAY SYSTEM - DISPLAY SWITCHING PANELS

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - MISCELLANEOUS CONTROLS - 1

General

The left and right instrument source select panels (ISSPs) and the center display control panel supply additional controls for the primary display system. Each source switch permits alternate display source for the flight crew member. These are the alternate source display control switches:

- Navigation source switch
- Display control source switch
- Air data/attitude source switch
- Center display control source switch
- Event record switch.

The three display source control (DSPL CTRL) switches in the flight deck supply manual control for the display channel outputs from the two graphics generators in each AIMS cabinet.

Instrument Source Select Panel (ISSP) Switches

The captain and first officer use the ISSP switches to select an alternate display source.

Use the navigation source switch (NAV) to select the CDU as an alternate map source.

Use the display control source switch (DSPL CTRL) on the ISSP to control the display channels source for the respective inboard and outboard display units. During normal operation, the captain's DUs use graphics generator M010 in the left AIMS cabinet and the first officer's DUs use graphics generator M011 in the right AIMS cabinet.

Use the air data/attitude source switch (AIR DATA/ATT) to select an alternate attitude and other ADIRU source inputs.

The center display control source switch (DSPL CTRL) is on the center display control panel. This switch controls the display source for the two center display units. During normal operation, these DUs use graphics generator M011 in the Left AIMS cabinet.

In the normal configuration, the switches are in the out position and no legend shows. A failure of a display channel causes the DUs to automatically switch to an alternate source. No legend shows in this case.

The selection of any of the switches, causes the display system to assume a failure and automatically change display channels. The NAV switch legend shows CDU when you select the NAV switch for alternate navigation source. In this case, the onside CDU or closest valid CDU. All other switches show ALTN when you select them.

If the display system has lost input sources, you can not cause the entire system to fail through the selection of manual overrides. The system ignores the switch(es) with only one display channel left.

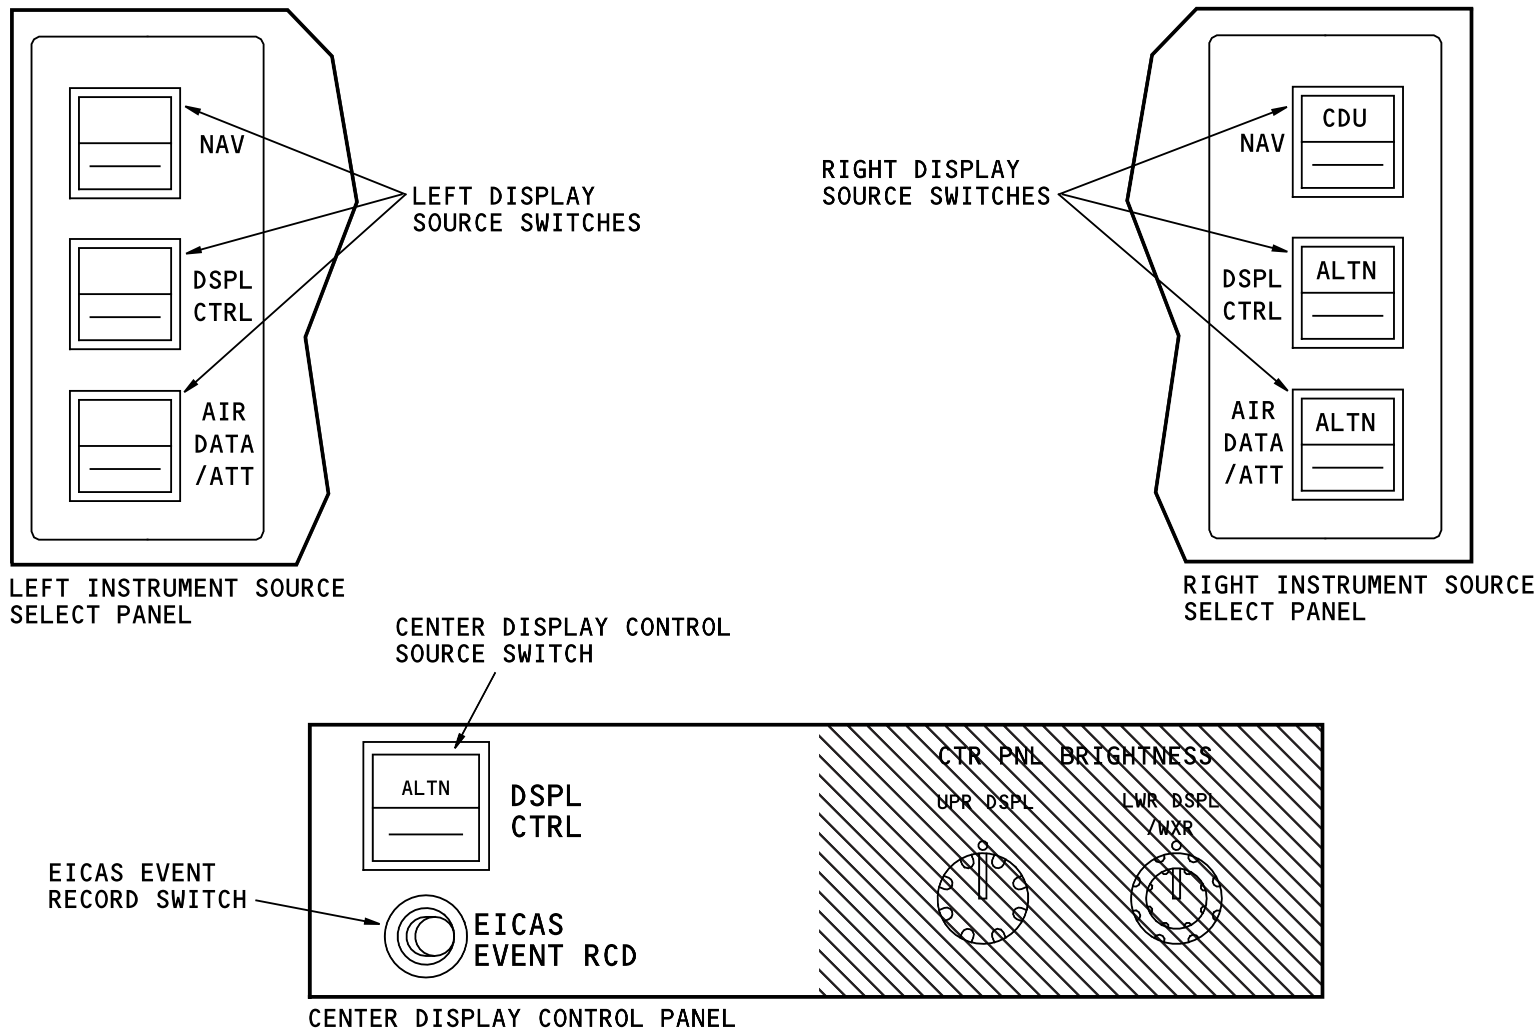
PRIMARY DISPLAY SYSTEM - MISCELLANEOUS CONTROLS - 1

EICAS Event Record Switch

The EICAS event record switch is an additional primary display system control on the center display control panel. Push the this switch to store a snapshot for each maintenance page.

Training Information Point

All display control source switches are line replaceable.



31-61-00-026 Rev 3

PRIMARY DISPLAY SYSTEM - MISCELLANEOUS CONTROLS - 1

PRIMARY DISPLAY SYSTEM - MISCELLANEOUS CONTROLS - 2

Purpose

The master caution lights alert the flight crew visually of a condition(s) that require crew awareness. You use the master warning/caution reset switch to reset the caution annunciation.

The master caution lights come on when a caution message shows on the EICAS display.

Training Information Point

When the master caution lights come on and there is a caution message on the EICAS display, you also hear a caution aural. The warning electronic system (WES) makes the caution aural. For all caution messages except ALTITUDE ALERT and SPEEDBRAKES EXT, AIMS sends a digital request to the WES to make the caution aural. WES makes the aural request for the caution messages ALTITUDE ALERT and SPEEDBRAKES EXT.

Master Caution Lights and Master Warning/Caution Reset Switch

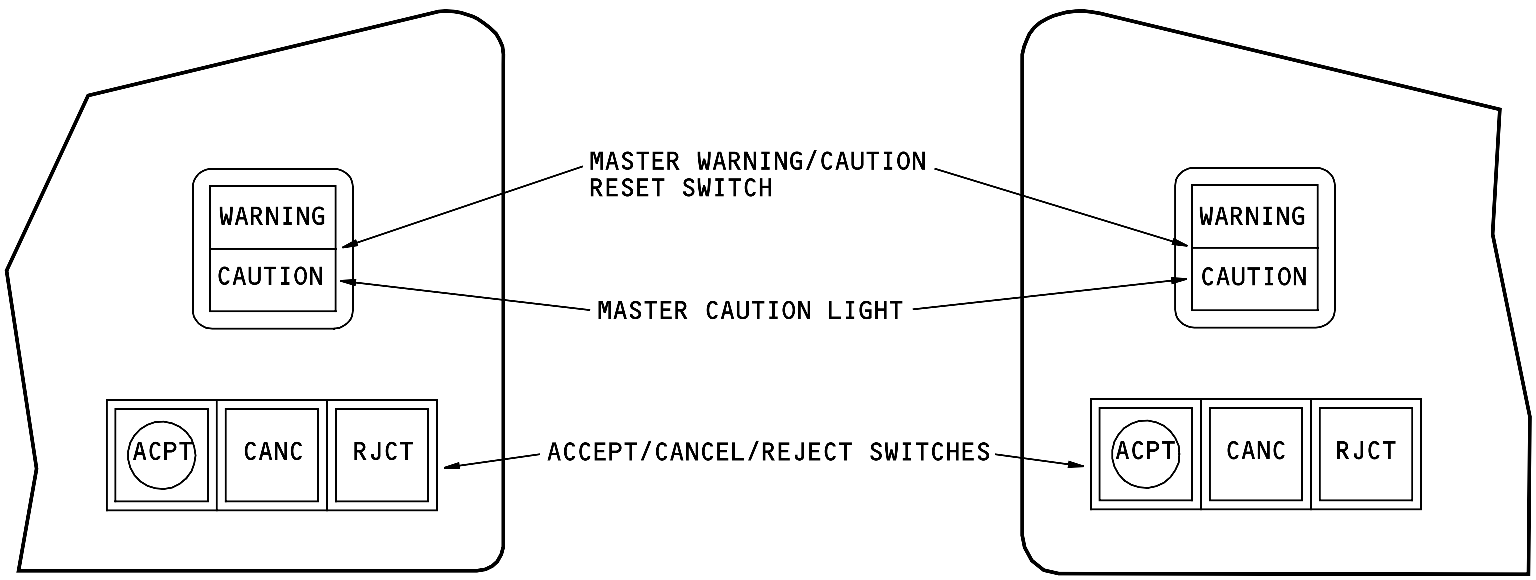
The master caution lights come on whenever the system finds a new active caution message. The lights go out when you push the switch or when the condition that caused the message goes away. The master caution lights are amber.

Training Information Point

The master warning lights are part of the warning electronic system (WES). WES controls the master warning lights. The master warning lights are red. The master warning lights come on when there is a warning message on the EICAS display. The master warning lights also come on when there is a time critical warning (TCW) message on the PFD.

Accept (ACPT), Cancel (CANC), and Reject (RJCT) Switches

You use these switches with the flight deck communication function when you receive uplink messages.



31-61-00-027 Rev 4 03/07/96

PRIMARY DISPLAY SYSTEM - MISCELLANEOUS CONTROLS - 2

PRIMARY DISPLAY SYSTEM - PRIMARY FLIGHT DISPLAY OVERVIEW

Purpose

The primary flight display (PFD) gives the crew this information:

- Attitude
- Critical parameters cross comparison
- Airspeed
- Altitude
- Marker beacon
- Vertical speed
- Heading
- Localizer and glide slope deviation
- Autopilot and autothrottle mode annunciations
- Autopilot status annunciations
- Radio altitude and decision height
- Time critical warning (TCW) messages.

Attitude

The attitude area supplies the flight crew with pitch and roll information from the air data inertial reference system (ADIRS). This data shows as sky/ground shading, a horizon line and a fixed airplane symbol. Additional information in this area includes this:

- Flight director (F/D) bars
- Flight path vector (FPV)
- Flight path angle (FPA)
- TCAS commands
- Slip/skid information
- Pitch limit indications.

Critical Parameter Cross Comparison

Each PFD graphic generator compares this data with the data for the other PFD:

- Track
- Heading
- Pitch attitude
- Roll attitude.

When the difference between pitch or roll attitude exceeds three degrees, heading exceeds four degrees, or track exceeds six degrees, the system makes an EICAS ATTITUDE message.

Airspeed

The airspeed indication is to the left of the attitude area. Digital readouts show computed air speed (CAS) and MACH values. Reference speeds, maximum and minimum limit speeds, and speed trend data also show.

Altitude

The barometric altitude indication shows as a digital readout and a moving tape to the right of the attitude area.

Marker beacon

The marker beacon indication shows in the upper right area of the attitude display. Inner marker (IM) white, middle marker (MM) amber, or outer marker (OM) blue, show as the airplane flies over a marker beacon.

Vertical Speed

The vertical speed indication shows on a fixed scale with a pointer. It is to the right of the barometric altitude indication.

Heading

Heading and track data show on a partial compass rose at the bottom of the PFD.

ILS Data

ILS data shows when the ILS receiver tunes to a valid frequency. This data includes:

- localizer and glide slope deviation
- ILS frequency
- ILS identifier
- DME distance and
- Selected runway course.

The identifier and selected runway course show at the upper left corner of the attitude area. Co-located DME distance shows just below the identifier.

Localizer and glide slope deviation show as pointers against fixed scales at the bottom and right sides of the attitude area. The scales go away when the ILS receivers are not tuned or invalid.

Flight Mode Annunciations

Autopilot and autothrottle flight mode annunciations show at the top of the PFD. The top lines show autothrottle, AFDS roll, and AFDS pitch active modes in large green letters. The lower line shows AFDS roll and pitch armed modes in the center and right areas in small white letters.

AFDS Status

The AFDS status shows at the top center of the attitude area. These annunciations show for a flight director (F/D) only or an autopilot and F/D engaged:

- FLT DIR - F/D only
- A/P - autopilot only or autopilot and F/D.

These are the autoland status annunciations:

- NO AUTOLAND
- >LAND 2<
- LAND 3.

Radio Altitude and Minimums

Radio altitude shows as a digital readout in the bottom center portion of the attitude area when the radio altitude is at or below 2500 feet. A highlight box shows for ten seconds as the altitude goes below 2500 feet.

PRIMARY DISPLAY SYSTEM - PRIMARY FLIGHT DISPLAY OVERVIEW

Radio minimums (decision height-DH) shows as a digital readout near the lower left side of the altitude tape. The operator sets the RADIO value on the onside EFIS control panel. An amber alert shows as the radio altitude goes below the RADIO value.

Time Critical Warning (TCW) Messages

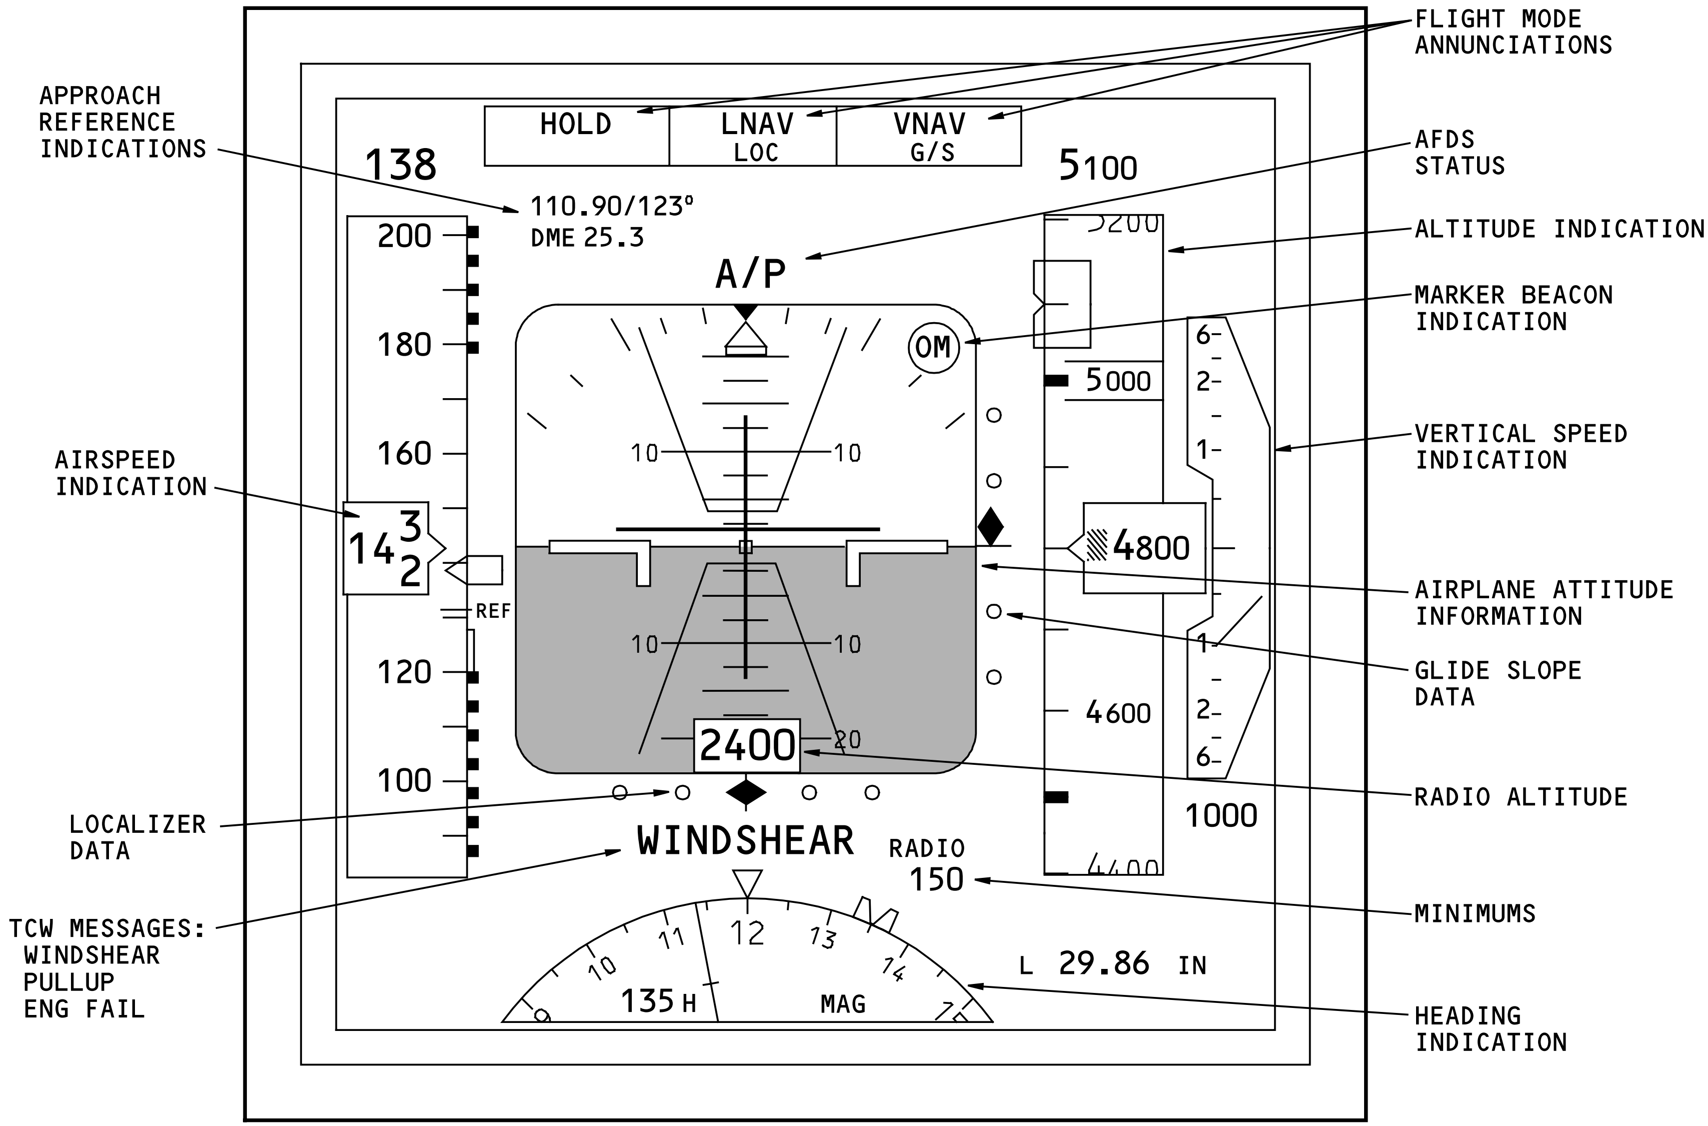
There are three time-critical warning messages. The two ground proximity warning system (GPWS) and one engine messages show on the PFD at the bottom center of the attitude area. These messages are the highest priority messages in the flight deck. Immediate flight crew intervention must follow to keep the airplane in a safe operating environment.

The GPWS message WINDSHEAR shows red during a windshear alert condition.

The GPWS message PULL UP shows red during a pull up alert condition.

The message ENG FAIL shows red during a failed engine condition.

If more than one condition exists, only one message shows in the priority above.



PRIMARY DISPLAY SYSTEM - PRIMARY FLIGHT DISPLAY OVERVIEW

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - PFD ATTITUDE AREA

General

The attitude area has a pitch scale with a horizon line, bank pointer and scale, sky and ground shading, and a fixed airplane symbol. The dynamic symbols of the display move in response to the air data inertial reference system (ADIRS) pitch and roll outputs.

Roll Attitude

The bank pointer moves to show roll against the fixed bank scale. The bank scale shows ±60 degrees of bank and the indices are at 10, 20, 30, 45, and 60 degrees. The bank pointer and slip/skid indicator turn amber when the bank is equal to or greater than ±35 degrees.

Pitch Attitude

The pitch scale moves against the fixed airplane symbol. The pitch lines are every 2.5 degrees from -90 degrees to +90 degrees. The sky/ground shading shows airplane attitude at a quick glance.

Flight Director Bars

Flight director bars show in the sky/ground area as a cross-pointer. The pitch command is a horizontal magenta bar. The roll command is the vertical magenta bar. The two bars move independently.

Flight Path Vector (FPV) and Flight Path Angle (FPA)

The FPV symbol shows the flight path angle and drift angle. The FPA is relative to the horizon line. Drift angle is the difference between airplane track and airplane heading. You use the FPV switch on the onside EFIS control panel to show the symbol. The symbol shows when there are valid pitch and bank commands from the AFDS, and valid pitch and roll information from the ADIRS.

The selected flight path angle shows the FPA selected on the mode control panel (MCP).

Traffic Alert and Collision Avoidance System (TCAS) Resolution Advisory Commands

TCAS resolution advisory commands show on the attitude display as three red bands. This makes a symbol similar to a rising runway. Pilots must avoid this area(s) inside the lines during a traffic encounter.

Slip/Skid Indication

The slip/skid indication shows the lateral acceleration of the airplane by the displacement of the lower portion of the bank pointer. With no lateral acceleration, the pointer and rectangular section align.

PRIMARY DISPLAY SYSTEM - PFD ATTITUDE AREA

Pitch Limit Indication

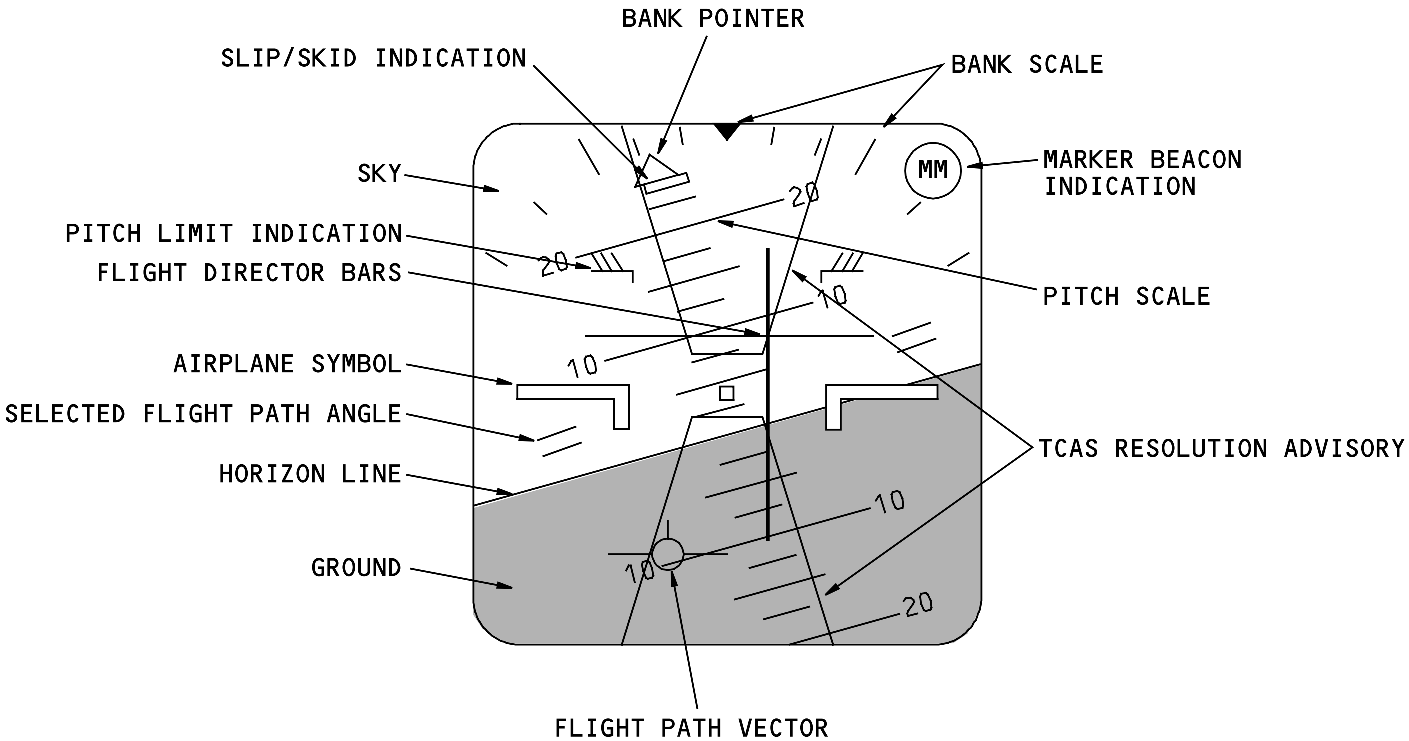
The pitch limit indication shows the remaining pitch angle to stick shaker activation for the current conditions. They show as amber eyelash symbols. They show during flap extension.

Marker Beacon Indication

The marker beacon indication shows in the upper right area of the attitude display. These are the indications that may show:

- IM (inner marker) white
- MM (middle marker) amber
- OM (outer marker) blue.

The indication shows as the airplane flies over a marker beacon. During a marker beacon functional test, the symbol FT shows. A circle encloses the symbols. The beacon displays flash at the rate normal for each beacon, IM-high, MM-medium, or OM-low.



31-61-00-029 Rev 3 10/28/1996

PRIMARY DISPLAY SYSTEM - PFD ATTITUDE AREA

THIS PAGE INTENTIONALLY LEFT BLANK

General

The airspeed indication is a display that moves against a fixed pointer. The indication has a visible range of 121 knots. Lines show at 10 knot intervals from 30 knots to 990 knots. Numbers show every 20 knots from 40 knots to 980 knots. Airspeed indication limits cause the display to show 30 knots for computed airspeed inputs of 30 knots or less (airspeed NCD).

Airspeed and MACH Number

A digital readout in the center of the tape shows the current computed airspeed (CAS) from the ADIRS. As the value changes, the digits move to simulate a drum type readout. The tape moves so that the current CAS shows by the point of the readout box. Current MACH shows below the speed tape for MACH values greater than 0.4. The information goes away when MACH goes below 0.38 or when MACH fails.

Selected Speed

Selected speed or MACH show as a pointer against the speed tape. The pointer is magenta and is rectangular with a point on one end that shows the selected speed. A numeric readout of the selected speed or MACH shows above the airspeed indication.

Takeoff Reference Speeds

The takeoff reference speeds have of three symbols that show against the speed tape before and during takeoff roll. The bugs show as a green dash followed by V1, VR, or V2. V1 is the decision speed for takeoff abort. VR is the recommended rotation speed. V2 is the takeoff safety speed. The FMCF calculates these speeds. The pilots use the CDU to accept or change the speeds. V1 and VR go away after lift-off. V2 goes away after lift-off when the flaps begin to raise. VR changes to R when GS is less than four knots.

Landing reference speed shows as a green dash and the letters REF.

Flap Maneuver Speeds

Two flap maneuver speeds show. The speeds agree with the current flap selection and the next retracted flap selection. The speeds show as tick marks on the airspeed tape with labels for the flap selections.

Limit Speeds

Maximum speed shows as a red and black barber pole that extends from the top of the speed tape. The barber pole extends to either VMO, MMO, flap placard or gear placard, whichever is smaller. The maneuver margin shows as a hollow amber bar that extends down from the bottom of the maximum speed barber pole. It represents the highest speed before the start of high speed buffet.

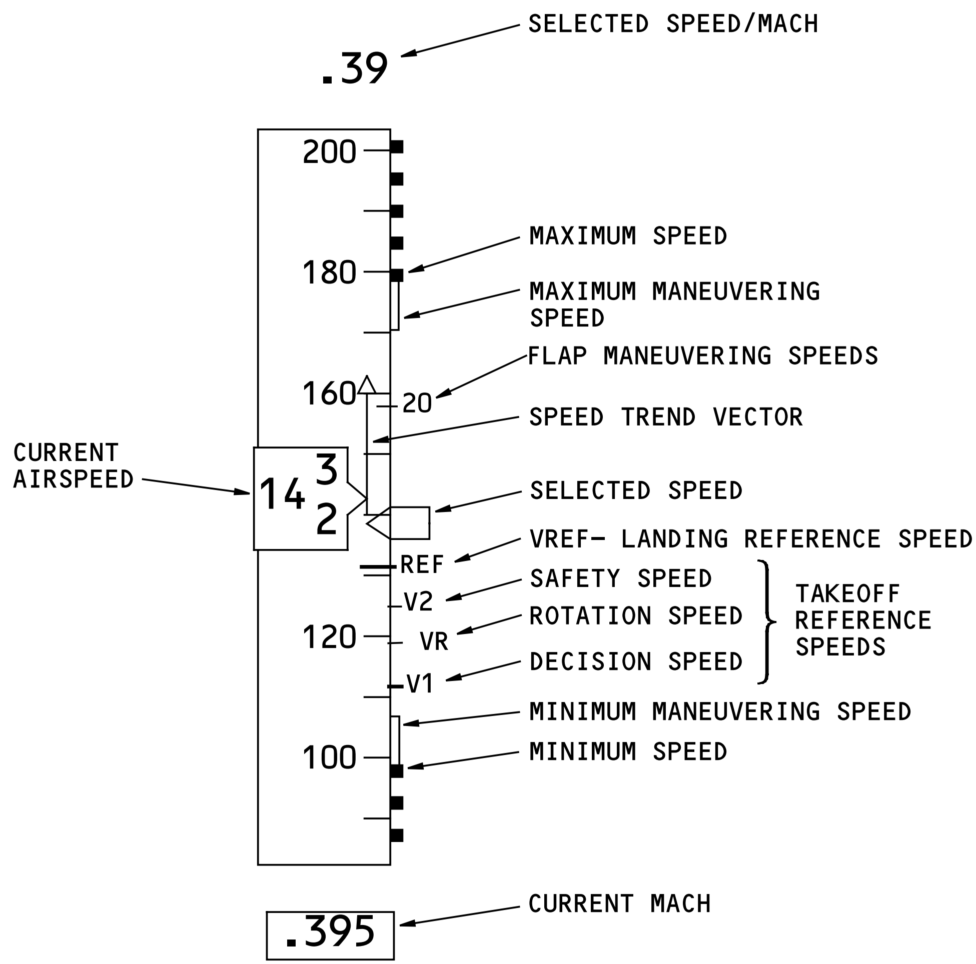
Minimum speed shows as a red and black barber pole that extends from the bottom of the speed tape to the Minimum speed.

PRIMARY DISPLAY SYSTEM - PFD AIRSPEED INDICATION

The maneuver margin shows as a hollow amber bar above the minimum speed barber pole. It shows the minimum maneuvering speed of the aircraft. This speed depends on flap/slat settings.

Speed Trend Vector

The length and direction of the green speed trend vector shows the airspeed in ten second intervals based on current acceleration.



31-61-00-030 Rev 2

PRIMARY DISPLAY SYSTEM - PFD AIRSPEED INDICATION

PRIMARY DISPLAY SYSTEM - BAROMETRIC ALTITUDE AND VERTICAL SPEED

General

Barometric altitude shows as a digital readout on a moving tape. As altitude changes, the tape moves against a fixed readout box that contains a drum type readout. The baro altitude tape goes from a -9900 feet to 99900 feet. Lines show every 100 feet with numbers every 200 feet.

Selected Altitude

A selected altitude bug shows the selected altitude from the mode control panel (MCP). The bug rests at the top or the bottom of the scale with only half the bug visible when the selected/target altitude is off the scale. The meters (MTRS) switch on the onside EFIS control panel adds the actual altitude and selected altitude show in meters.

Baro Minimums (MDA)

The baro minimums show as a pointer and a digital readout. A knob on the EFIS CP lets the operator set the value. Baro minimums or MDA has a range that starts at -1000 feet. For values less than -1000 feet, the pointer and readout go away.

Barometric Reference

Barometric reference data includes:

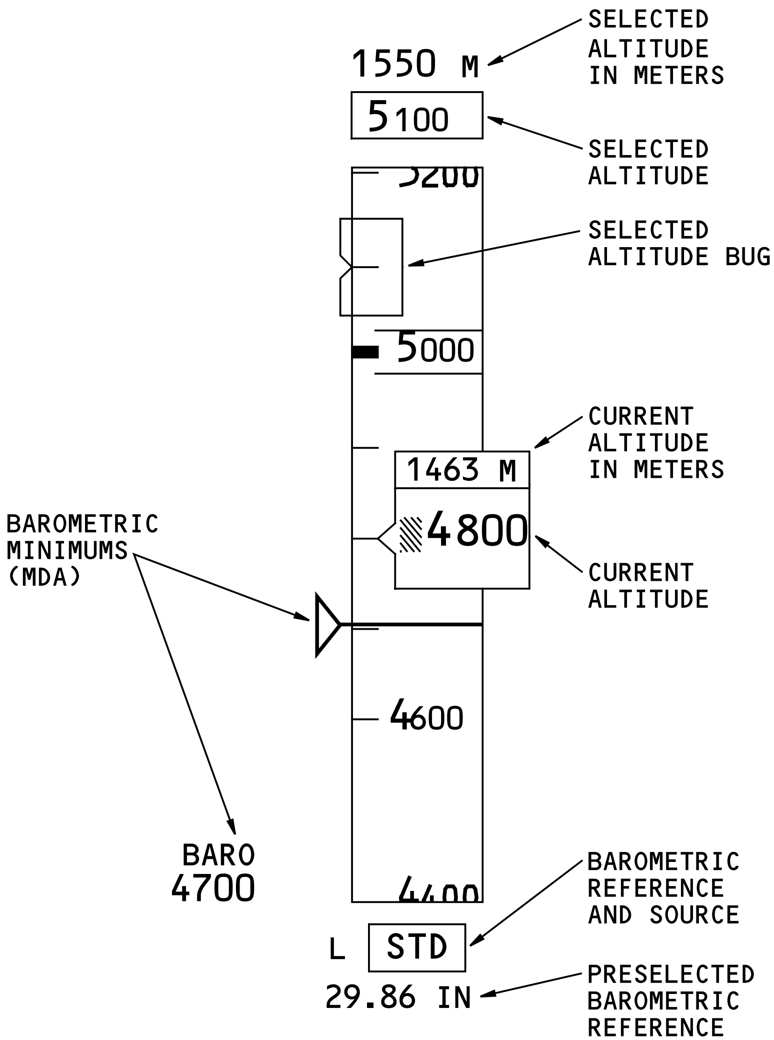
- Actual barometric reference
- Barometric reference source (L or R)
- Preselected barometric reference
- Barometric correction reference (QNH or QFE).

An amber box shows around the reference readout for a barometric transfer warning.

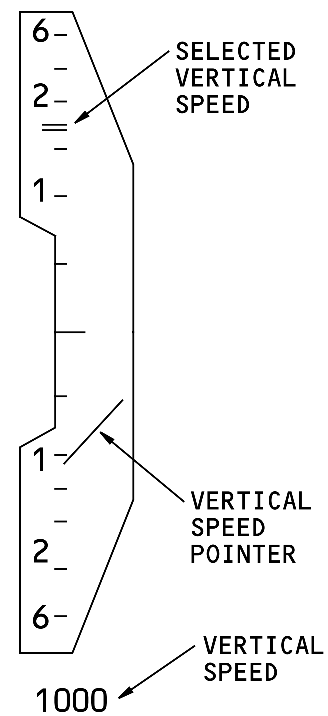
Vertical Speed (V/S)

Vertical speed shows as amoving pointer against a fixed scale. The display range of the scale is ± 6000 feet/minute. The top half of the scale shows a positive V/S and the bottom half shows a negative V/S. A V/S in excess of 400 feet per minute causes a digital readout to show. With a positive rate of climb, a digital readout shows at the top of the VS scale. With a negative rate of climb, a digital readout shows at the bottom of the VS scale.

Selected V/S shows as a magenta double line against the numerical scale. You can select the V/S value from the MCP.



ALTITUDE INDICATION



VERTICAL SPEED INDICATION

PRIMARY DISPLAY SYSTEM - BAROMETRIC ALTITUDE AND VERTICAL SPEED

PRIMARY DISPLAY SYSTEM - PFD HEADING AND TRACK

General

A partial compass rose of approximately 80 degrees shows at the bottom of the PFD. The compass rose shows this data:

- Heading and track
- Heading reference
- Selected heading or track.

Heading and Track

The current heading shows as a white (W) triangular pointer above the compass rose. The track line shows as a white (W) line that extends up from the center of the compass rose (off screen) and moves in response to track data.

Heading Reference

The heading reference shows automatic or manual selections in the bottom right part of the compass rose. MAG in green (G) shows when the heading reference switch is in the NORM position. TRU (G) shows in a white box when the switch is in the TRUE position. When the reference switches from TRUE to MAG, a green highlight box appears around MAG for 10 seconds.

Selected Heading or Track

A selected heading or selected track shows magenta (M) both digitally and by a bug that shows the value on the compass rose. The digital readout shows in the lower portion just left of center. An H follows the value for selected heading and a T follows the value for selected track. The selected heading bug is in the shape of an M (bow tie). The bug is on the outer portion of the compass rose. The selected track bug is in the shape of a V and is in the inner portion of the compass rose. Use the heading/track selector on the mode control panel (MCP) to select a heading or track.

PRIMARY DISPLAY SYSTEM - PFD NCD AND FAIL CONDITIONS -4

PRIMARY DISPLAY SYSTEM - NAVIGATION DISPLAY OVERVIEW

General

The navigation display (ND) has seven modes of operation. The modes are:

- Expanded approach mode
- Centered Approach mode
- Expanded VOR mode
- Centered VOR mode
- Expanded map mode
- Centered map mode
- Plan mode.

Flight planning, different flight phases, and flight changes require the use the various modes.

The plan mode has a north-up orientation.

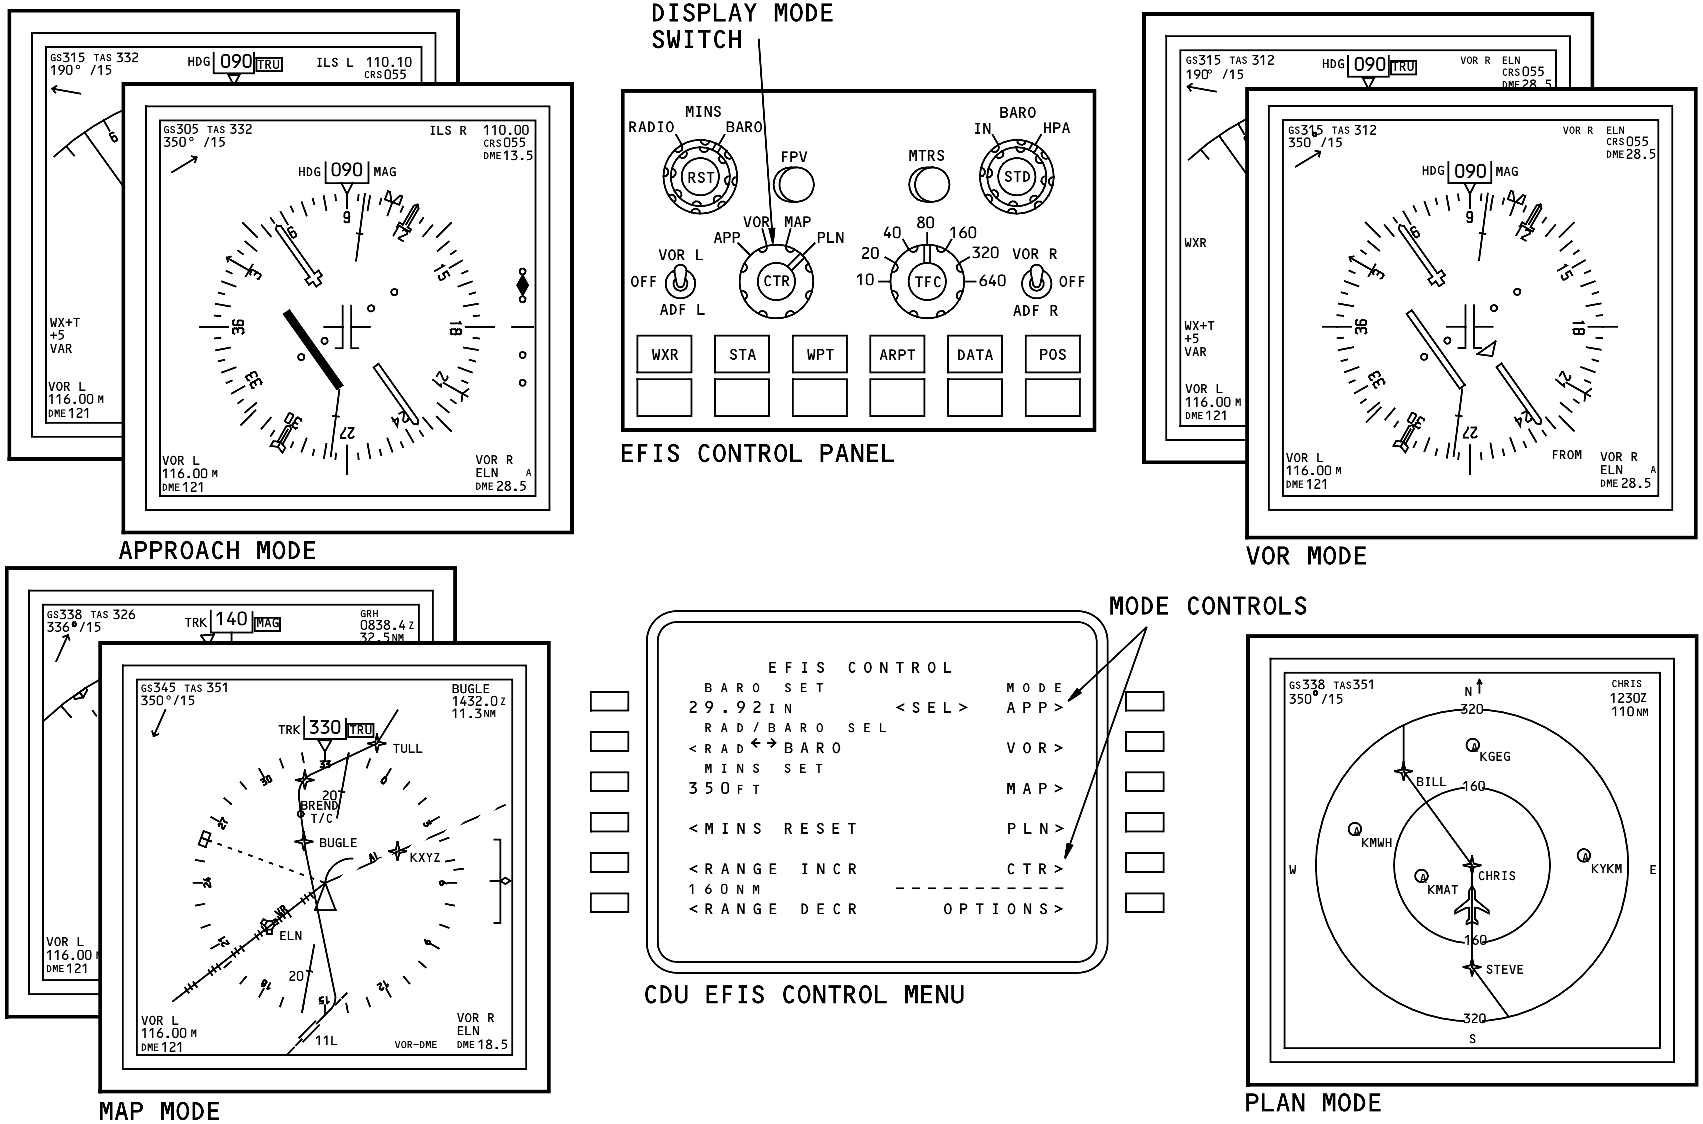
The centered modes show 360 degrees of the compass rose. The expanded modes show 90 degrees of the compass rose.

Use the EFIS control panel (CP) to change the modes of operation.

Controls

Use the onside EFIS CP or the onside CDU to control the mode of operation.

Use the CTR push-button on the EFIS CP or the CTR selection on the CDU EFIS page to toggle the ND between the centered and the expanded display in the approach, VOR and MAP modes.



31-61-00-038 Rev 1

PRIMARY DISPLAY SYSTEM - NAVIGATION DISPLAY OVERVIEW

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - CENTERED APPROACH MODE

General

The centered approach mode display shows ILS course deviation, and navigation information over a full 360 degree compass rose. The centered approach mode is a heading-up display. The airplane symbol in the center of the display shows the airplane position along the flight path.

Display Data

The heading box at the upper center of the display shows digital heading in 1 degree increments. The compass rose also rotates to show airplane heading. The digital heading readout is green. MAG or TRU annunciation shows in green to indicate the heading reference.

A white track pointer on the compass rose shows track angle.

Selected course shows as a magenta pointer that rotates around the fixed airplane symbol. The selected course also shows digitally in the upper right corner of the display.

The localizer deviation indication contains a deviation bar on a dot scale. The localizer deviation indicator rotates around the airplane symbol with the pointer.

Glide slope deviation shows as a deviation bar on a vertical dot scale on the right side of the display.

This data shows in the upper right corner for a tuned ILS station when the receiver gets a valid identifier from the ground station:

- Frequency
- Station (STA) identifier
- DME distance.

With no valid identifier, the tuned frequency shows. Below the frequency/identifier field is the selected course. DME distance to a co-located DME station shows below the selected course when available.

The ILS radio source shows at the upper right, near the frequency or STA identifier.

VOR or ADF bearing pointers show on the compass rose. VOR and ADF pointers move clockwise. The VOR pointer movement equals the difference between the received omni-bearing signal and the airplane heading. VOR pointers are green and ADF pointers are cyan. The left pointer is thin and the right pointer is thick for both radios. ADF pointer movement from the airplane heading is the received ADF bearing.

Use the VOR/ADF switches on the EFIS CP to show the applicable data in the lower left and/or right corners of the display. The switch position shows as well as the identifier/frequency of the tuned navigation aids. ADF data shows in cyan and VOR data shows in green. DME distance shows below the frequency/identifier for VOR stations with a co-located DME.

PRIMARY DISPLAY SYSTEM - CENTERED APPROACH MODE

Selected heading shows as M shaped box on the outer edge of the compass rose. When selected heading and actual heading are equal, the box fits around the heading pointer. Selected track shows as a cursor on the inner edge of the compass rose.

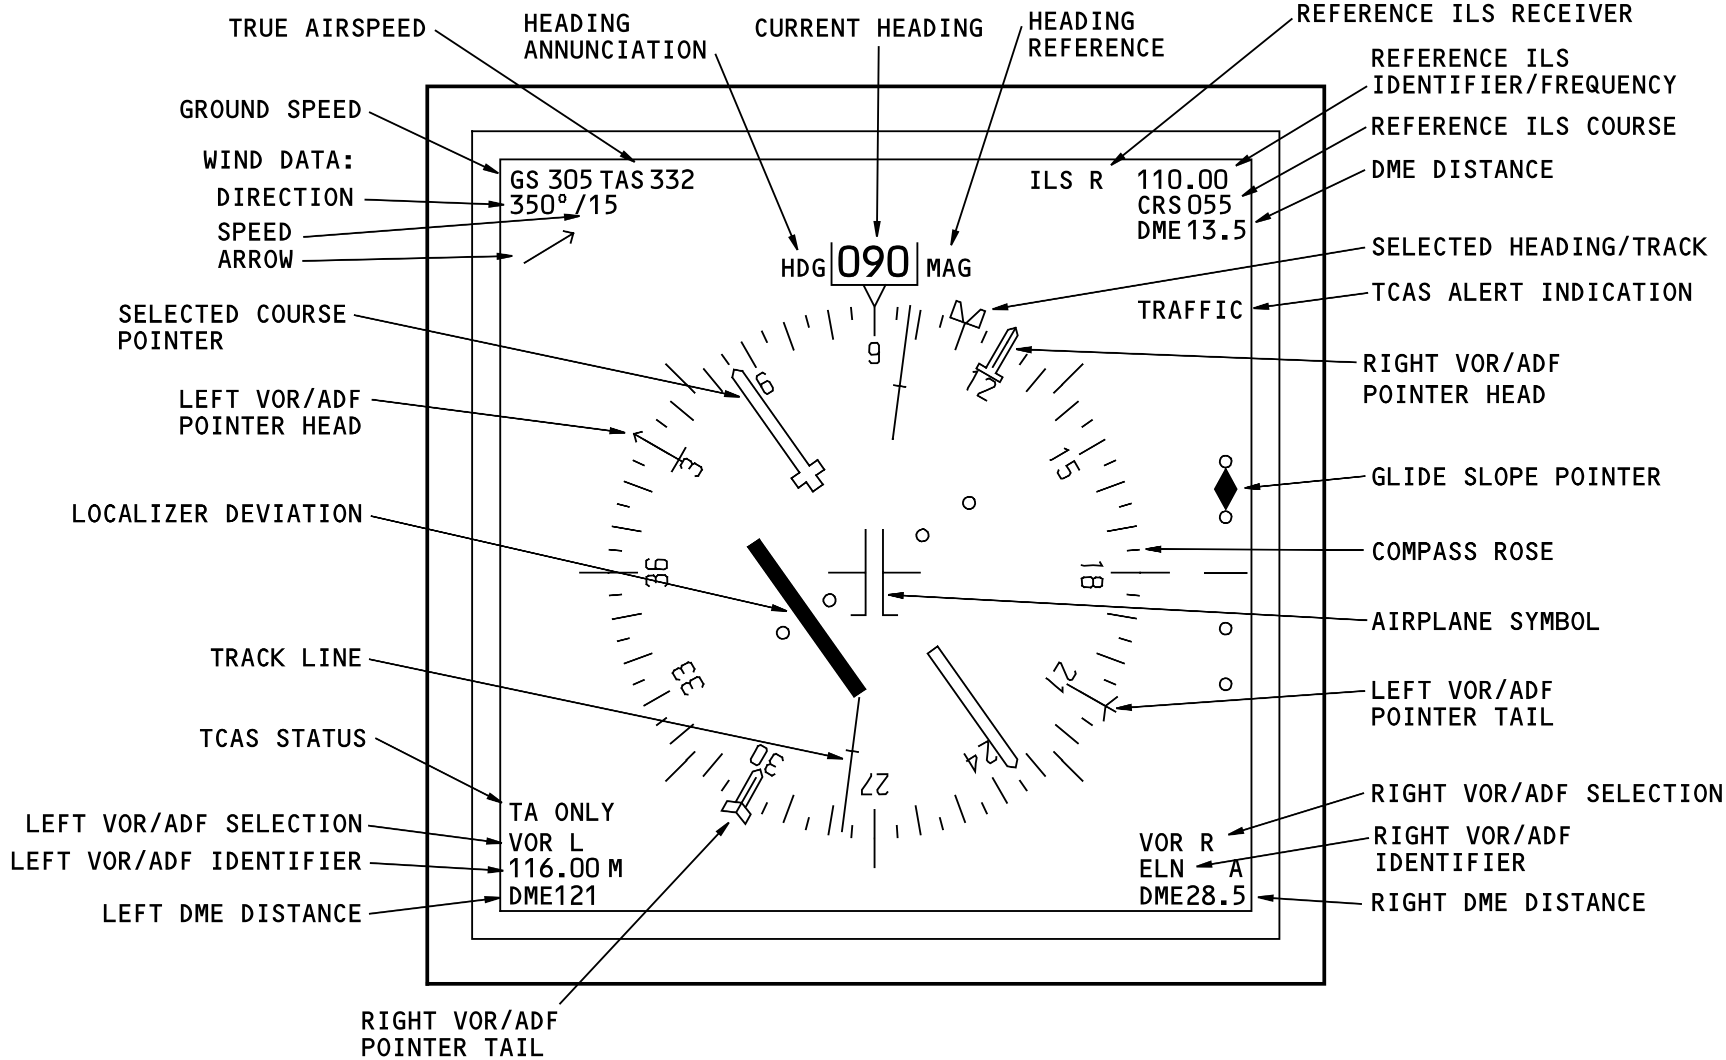
This data shows in the upper left corner:

- Ground speed
- True airspeed
- Wind data.

Ground speed and true airspeed shows as digital readouts. Wind data shows as digital readouts and a rotating arrow.

TCAS information shows as a message below the DME distance in the upper right corner.

TCAS status information shows below the WXR data field to indicate TCAS selection, TA ONLY (TCAS is not computing RAs) or TCAS TEST (TCAS is in the test mode).



PRIMARY DISPLAY SYSTEM - CENTERED APPROACH MODE

PRIMARY DISPLAY SYSTEM - EXPANDED APPROACH MODE

General

The expanded approach mode shows ILS course and course deviation and navigation information. The display shows 90 degrees of the compass rose. The airplane symbol is at the bottom of the display and the point of the symbol represents the present position of the airplane along the flight path.

Display Data

The expanded approach mode shows data that does not show or is different on the full rose approach mode.

Heading and track, the airplane heading shows as digits on top of a 90 degree arc and is the same as the full approach mode. The track line extends from the tip of the airplane symbol to the compass rose.

Selected runway course shows as a magenta pointer.

Localizer and glide slope deviation scales and symbology are slightly different in appearance. The function is the same as the centered approach mode.

VOR/ADF bearing pointers head or the tail of the applicable pointer shows.

Selected heading or track show as a magenta dashed line that extends from the selected heading or track pointer to the apex of the airplane symbol.

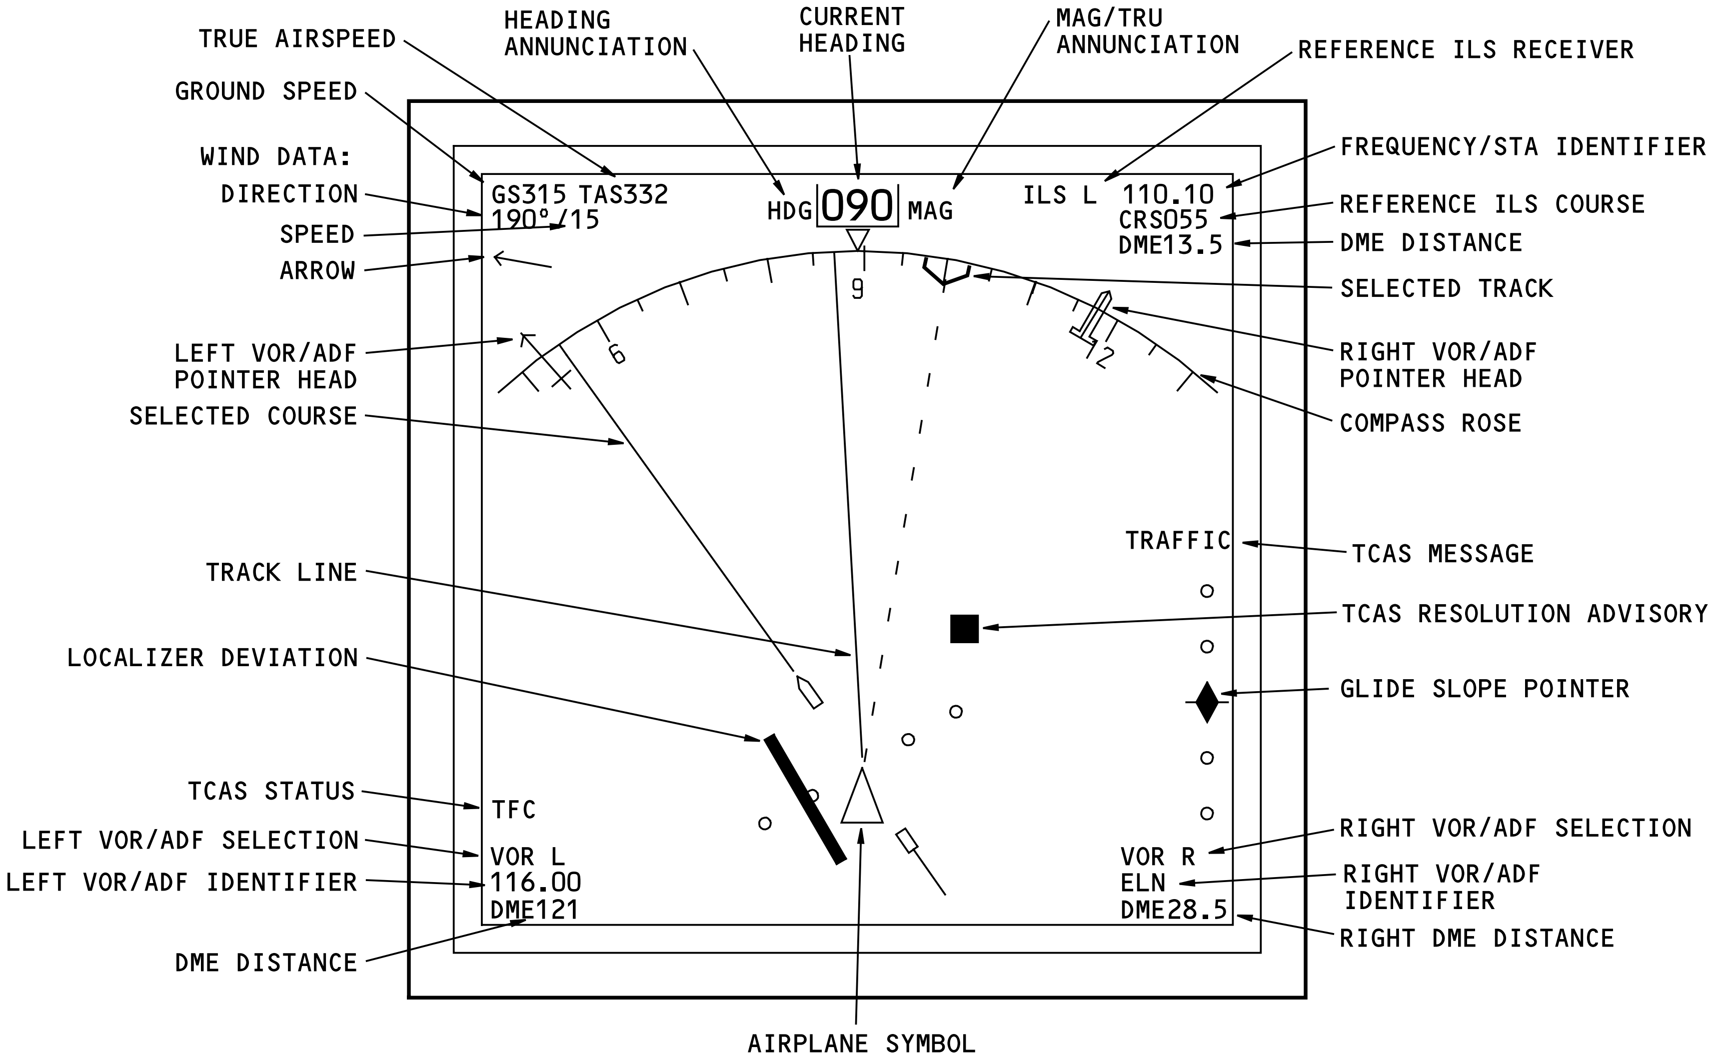
TCAS information shows as messages in the right center of the display and as symbols.

TCAS status and mode information shows below the WXR data field to show this TCAS selection (TFC) and mode data:

- TA ONLY (TCAS is not computing RAs)
- TCAS TEST (TCAS is in the test mode)
- TCAS OFF
- TCAS FAIL (a fault exist in TCAS).

Data that does not change includes:

- Identifier, frequency and DME distance
- The radio source
- ADF/VOR switch position, frequency and DME distance
- Ground speed, wind data and true airspeed.



31-61-00-040 Rev 1

PRIMARY DISPLAY SYSTEM - EXPANDED APPROACH MODE

PRIMARY DISPLAY SYSTEM - APPROACH MODE FAILURE FLAGS

General

Failures of input sources cause data to go away from the display and failure flags to show.

All the flags are amber.

The captain's and first officer's NDs operate independently.

Failure Flags

A heading (HDG) input failure to the ND causes HDG to show.

The DME co-located with the ILS, or left or right VOR failure causes DMEL or DMER to show on the ND. To see the flag for DMEs co-located with the VOR stations, put the applicable VOR switch on the EFIS CP in the VOR position.

The localizer (LOC) input failure causes the LOC to show on the ND. The localizer flag is independent of the glideslope flag.

A glide slope (G/S) failure causes G/S to show on the ND. The glide slope flag is independent of the localizer flag.

A left or right ADF failure causes ADFL or ADFR to show on the ND. To see the flag, put the applicable switch on the EFIS control panel in the ADF position.

A left or right VOR failure causes VORL or VORR to show on the ND. To see the flag, put the applicable switch on the EFIS control panel in the VOR position.

DME DISTANCE	FAIL	AN AMBER DME FLAG SHOWS	ON-SIDE DME CO-LOCATED WITH VOR FAILS
HEADING	NCD	TAPE NUMERICS GO AWAY	NCD HEADING
HEADING	FAIL	TAPE NUMERICS, TICKS, AND HEADING INDEX GO AWAY. AN AMBER HDG FLAG SHOWS	FAILED HEADING

31-61-00-042 Rev 0

PRIMARY DISPLAY SYSTEM - APPROACH MODE NCD AND FAIL CONDITIONS

PRIMARY DISPLAY SYSTEM - CENTERED VOR MODE

General

The centered VOR mode shows selected VOR course and course deviation. The display shows the full 360 degrees of the compass rose. The centered VOR mode has a heading up display.

Display Data

There is some data that is the same as the data on the centered approach mode. Other data is unique to the VOR mode.

Heading and track is the same as the approach mode.

Selected VOR course shows as a magenta pointer that rotates around a fixed airplane symbol. The selected VOR course also shows digitally in the upper right corner.

VOR course deviation shows as a deviation bar on a dot scale. The dot scale rotates around the airplane symbol.

TO shows airplane direction to the tuned station. FROM shows airplane direction from the tuned station. A pointer and the TO or FROM indication shows this data.

The decoded VOR station identifier shows in the upper right corner for a tuned VOR station when the receiver gets a valid identifier from the ground station. With no valid identifier, the tuned frequency shows. Below the frequency/identifier field is the selected course.

DME distance to the co-located DME station shows below the selected VOR course.

The radio source shows at the upper right between the heading readout and the frequency/identifier.

ADF/VOR bearing information is the same as the approach mode.

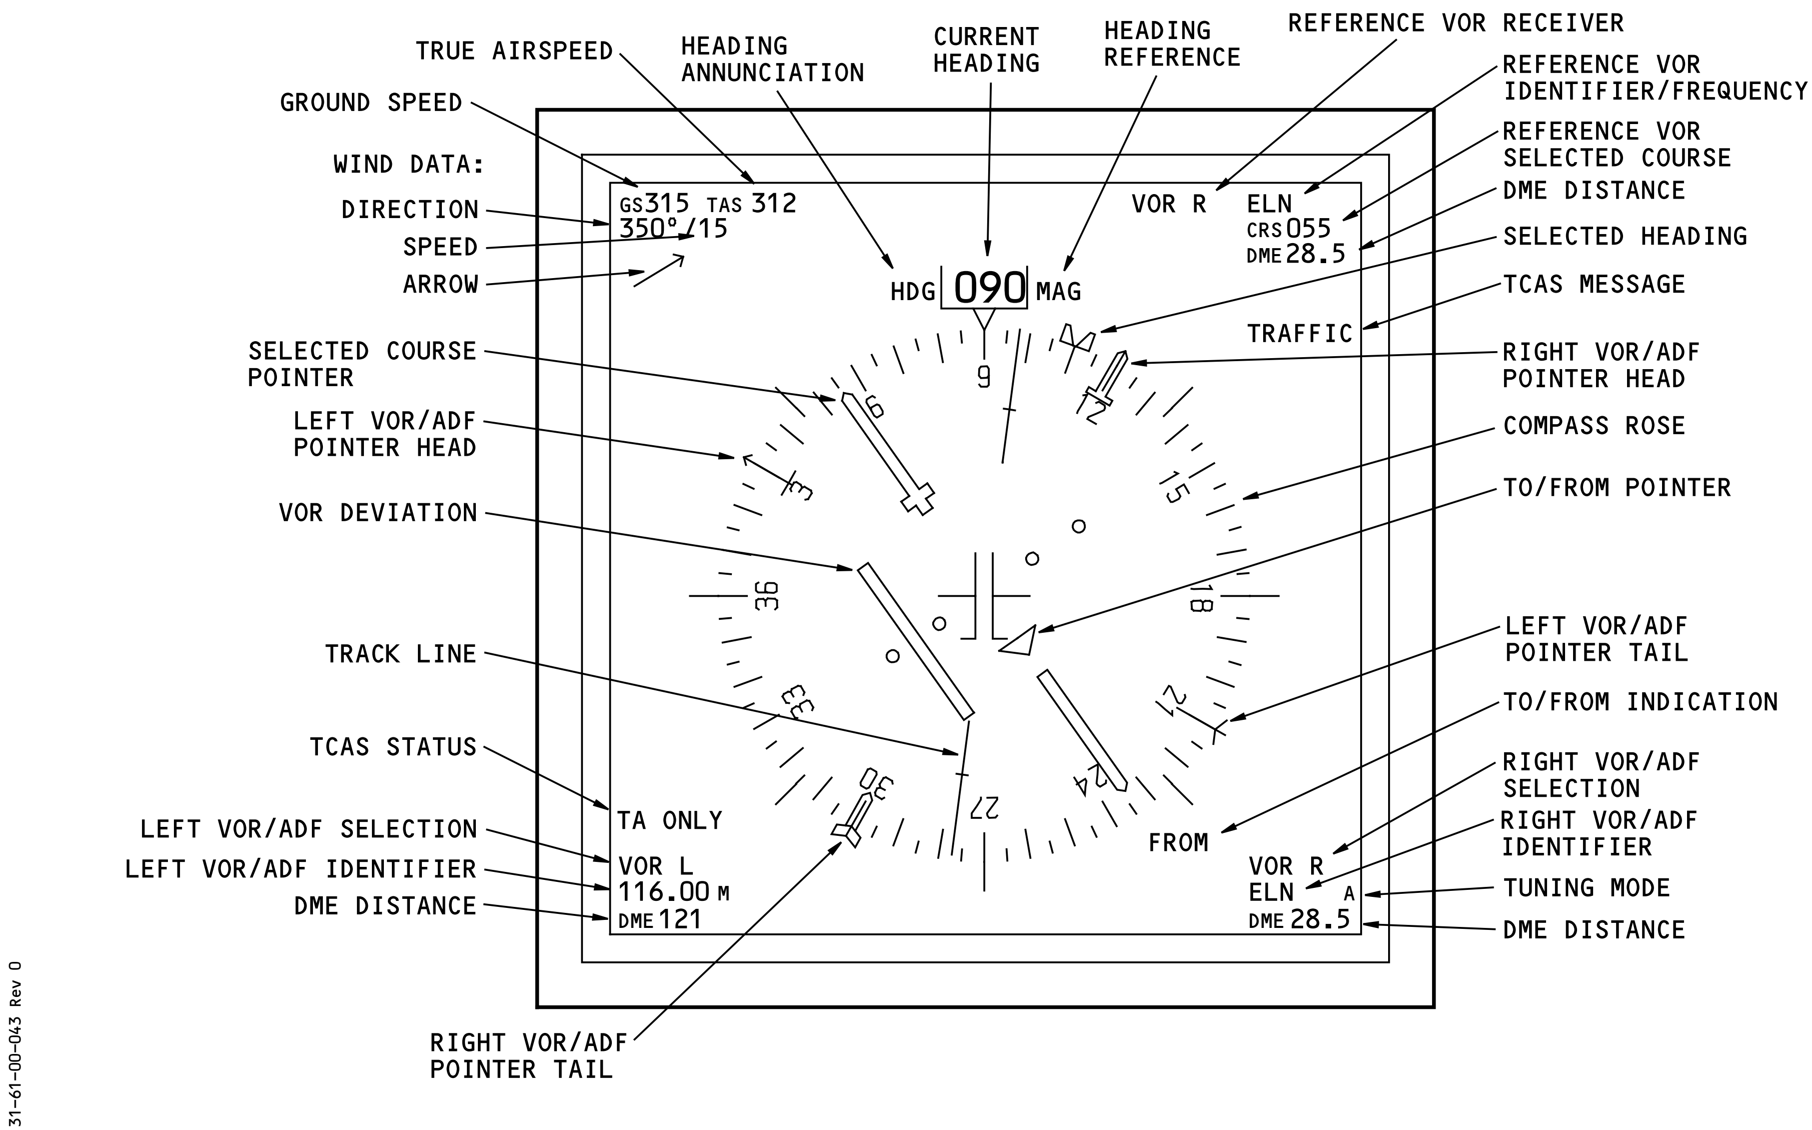
ADF/VOR switch position, frequency, and DME distance is the same as the approach mode.

Selected heading or track is the same as the approach mode.

Ground speed, wind data and true airspeed is the same as the approach mode.

TCAS information shows as a message below the DME distance in the upper right corner. Set the TFC switch on the EFIS CP to see the data.

TCAS status information shows below the WXR data field to indicate TCAS selection; TA ONLY (TCAS is not computing RA) or TCAS TEST (TCAS is in the test mode).



PRIMARY DISPLAY SYSTEM - CENTERED VOR MODE

PRIMARY DISPLAY SYSTEM - EXPANDED VOR MODE

General

The expanded VOR mode shows the selected VOR course and course deviation. The display shows 90 degrees of the compass rose. The airplane symbol is at the bottom of the display and the apex of the symbol represents the present position of the airplane.

Display Data

The expanded VOR mode shows data that does not show or is different on the centered VOR mode.

The airplane heading shows as digits on top of a 90 degree arc and is the same as the centered VOR mode. The track line extends from the tip of the airplane symbol to the compass rose.

Selected course shows as a magenta line.

VOR course deviation scales and symbols look slightly different. They function the same as the centered VOR mode.

Only the head or the tail of the VOR/ADF bearing pointers shows.

Selected heading or track shows as a magenta dashed line that extends from the apex of the airplane symbol to the selected heading or track pointer.

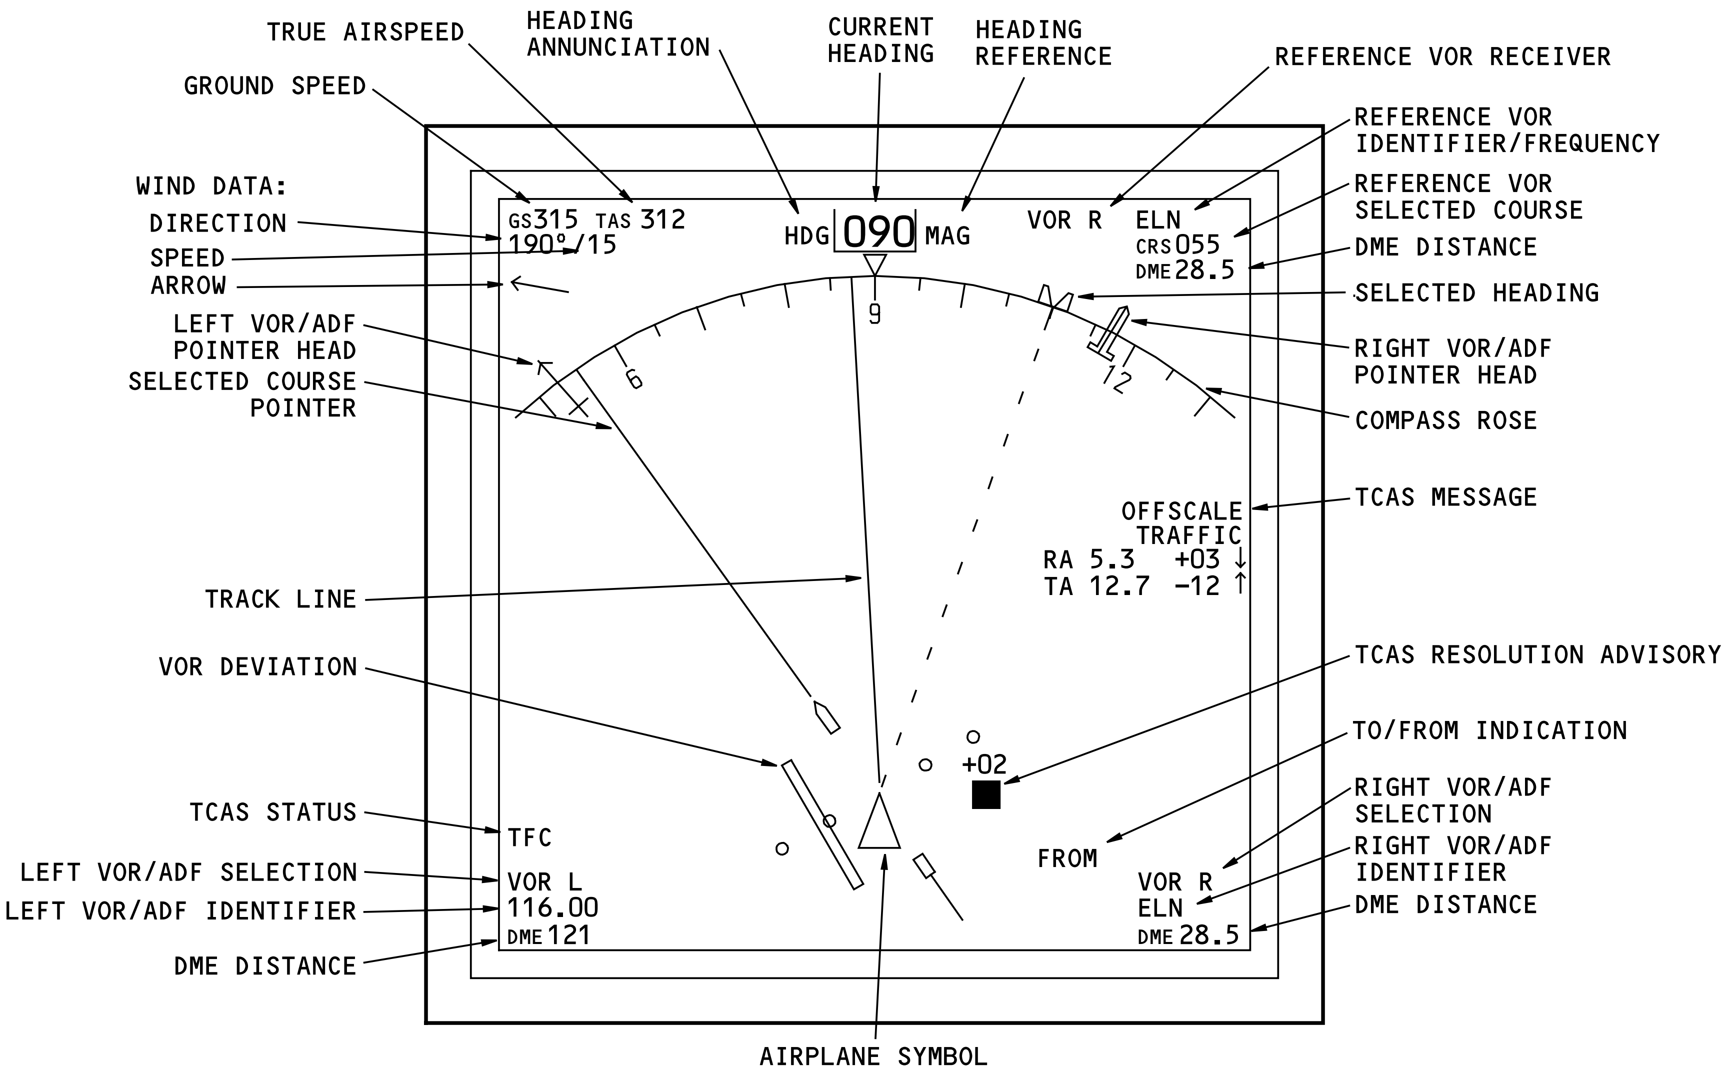
TCAS information shows as messages in the right center of the display and as symbols on the display. Set the TFC switch on the EFIS CP to see the information.

TCAS status and mode information shows below the WXR data field to show:

- TCAS selection
- TFC and mode data
- TA ONLY (TCAS is not computing RA)
- TCAS TEST (TCAS is in the test mode)
- TCAS OFF
- TCAS FAIL (a fault exist in TCAS).

Data that does not change includes:

- Identifier, frequency and DME distance
- The radio source
- ADF/VOR switch position, frequency and DME distance
- Ground speed, wind data and true airspeed.



31-61-00-044 Rev 1

PRIMARY DISPLAY SYSTEM - EXPANDED VOR MODE

PRIMARY DISPLAY SYSTEM - VOR MODE FAILURE FLAGS

General

Failures of input sources cause data to go away from the display and failure flags to show.

All the flags are amber in color.

The captain's and first officer's NDs operate independently.

Failure Flags

The heading (HDG) flag shows when the input to the applicable ND fails

DMEL or DMER (top corner information) flag shows when the DME co-located with the left or right VOR input fails to the ND

VORL or VORR (mode information) flag shows when the left or right VOR input fails to the ND

DMEL or DMER (bottom corner information) shows when the DME co-located with the left or right VOR input fails to the ND. To see the flag, put the applicable VOR switch on the EFIS CP in the VOR position.

VORL or VORR (bottom corner information) shows when the left or right VOR input fails to the ND. To see the flag, put the applicable switch on the EFIS control panel in the VOR position.

ADFL or ADFR shows when the left or right ADF input fails to the ND. To see the flag, put the applicable switch on the EFIS control panel in the ADF position.

PRIMARY DISPLAY SYSTEM - VOR MODE NCD AND FAIL CONDITIONS

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - CENTERED MAP MODE

General

The centered map mode shows the airplane flight plan on a full 360 degree display. The centered map mode has a track up reference. The point of the airplane symbol (a triangle) is the present position of the airplane.

The same basic data shows in both the centered and the expanded map modes.

Display Data

The current track value shows digitally in the readout box. The compass rose rotates and the readout changes in one degree increments. TRK shows on the left and MAG or TRU shows on the right. A track line shows from the bottom of the display through the tip of the airplane symbol to the readout box. Current heading shows as a triangular pointer on the outer edge of the compass rose.

Selected heading shows as a magenta (M) cursor (bow tie) on the outer edge of the compass rose. The selected heading cursor and the heading cursor (W) fit together when their values are equal. A dotted magenta vector shows full time except when the AFDS roll mode is LOC, ROLLOUT or LNAV. For these modes, the vector shows for ten seconds after selected heading changes, then goes away. Selected track shows as a magenta cursor on the inner edge of the compass rose. The vector is the same as the selected heading vector.

VOR/ADF bearing information is the same as approach and VOR modes.

VOR/ADF selection is the same as approach and VOR modes.

Ground speed, wind data, and true airspeed are the same as approach and VOR modes.

A curved position trend vector (W) shows from the tip of the airplane symbol. The vector shows the airplanes predicted position in 30, 60, or 90 second intervals. The map range controls the number of segments. The tip of each segment shows the future airplane position in 30 seconds. The ground speed determines the length of the line. Cross track acceleration from the ADIRU controls the curve.

This data shows in the upper right corner:

- Active waypoint identifier
- Estimated time of arrival (ETA) to the waypoint
- Distance to the waypoint.

The active (next) waypoint on the flight path is magenta.

The FMCF navigation mode shows in the lower right corner next to the navigation aid information. The update method shows as:

- VOR-DME
- DME-DME

PRIMARY DISPLAY SYSTEM - CENTERED MAP MODE

- GPS
- LOC
- INERTIAL.

TCAS traffic messages and TCAS traffic symbols show in the centered map mode.

TCAS status and mode information shows below the WXR data field to indicate TCAS selection (TFC) and mode data; TA ONLY (TCAS is not computing RA), TCAS TEST (TCAS is in the test mode), TCAS OFF, or TCAS FAIL (a fault exist in TCAS).

Vertical deviation from the FMCF flight plan descent path shows on the VNAV path scale. The information shows when the descent phase becomes active. Deviation greater than 420 feet above the path causes a numerical readout to show above the vertical scale. Deviation greater than 420 feet below the path causes a numerical readout to show below the vertical scale.

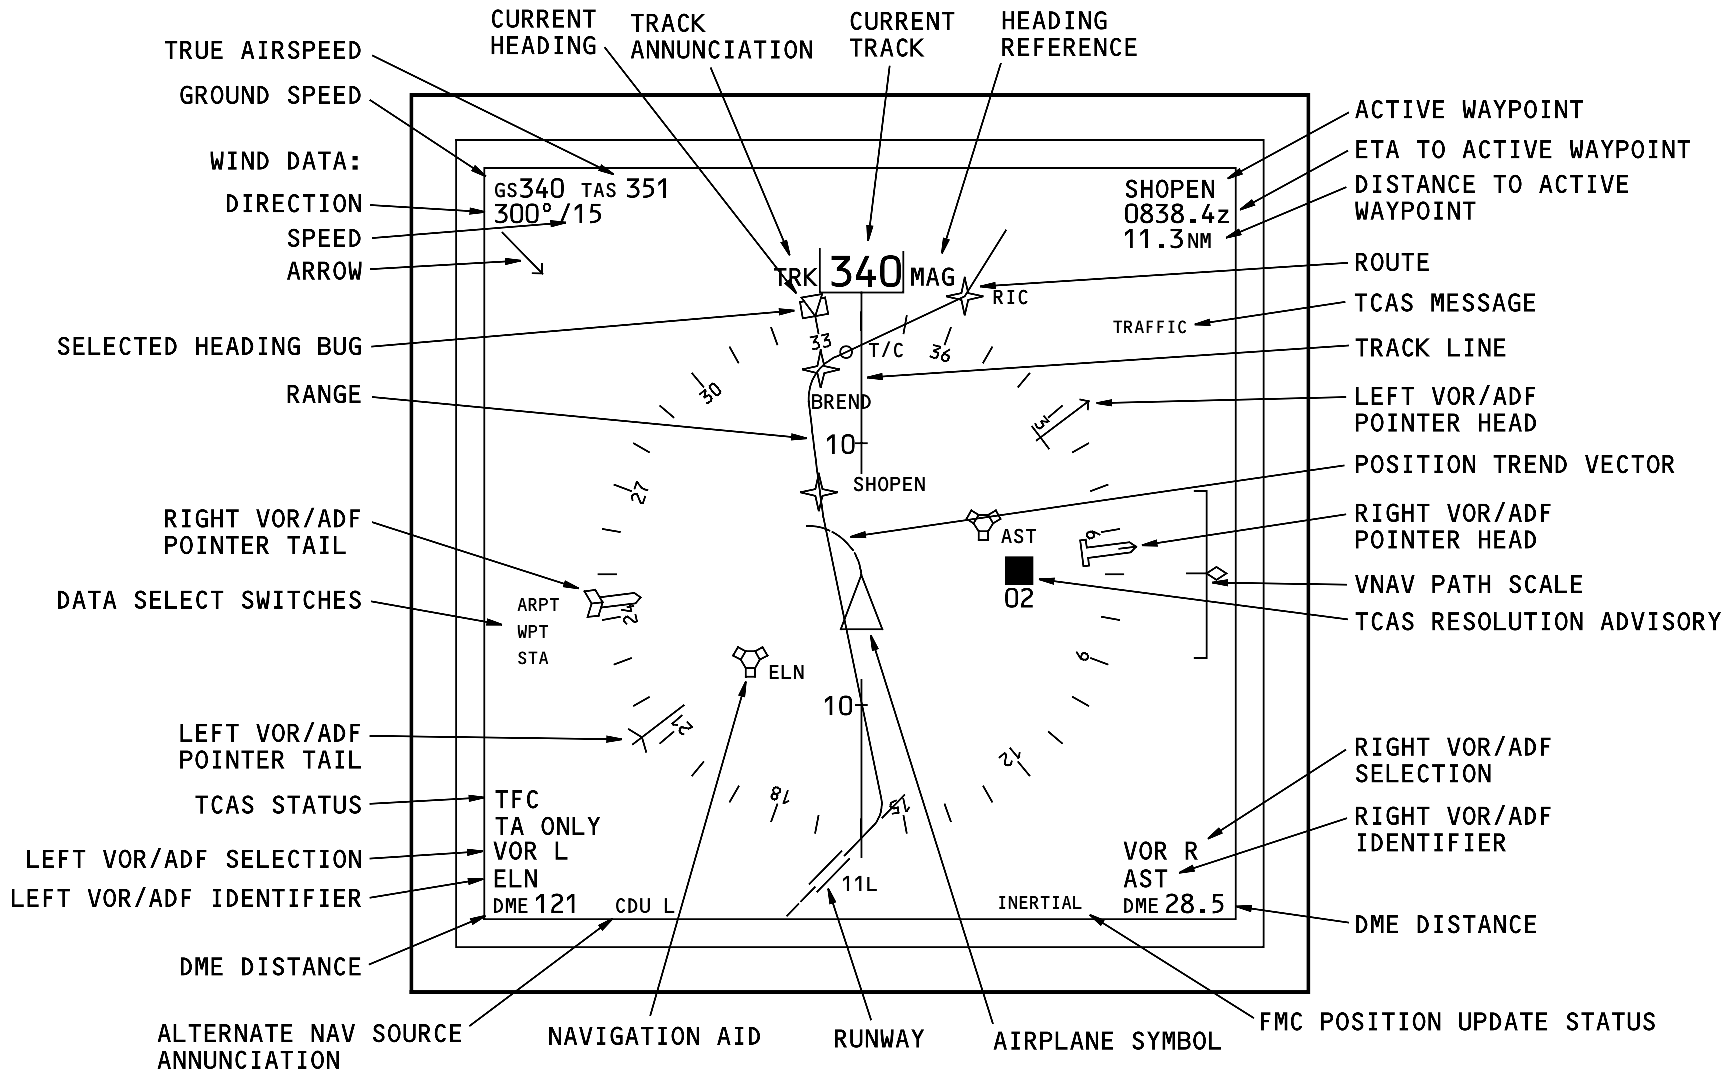
Weather radar shows in this mode when the crew turns weather radar on.

Map background data contains many types of symbols and data. This data includes:

- Active, inactive and modified flight plans
- Flight plan waypoints
- Holding patterns
- Airports
- Runways
- Navigation aids
- Airway segments
- Radio navigation aid raw data.

The ND data select switches on the EFIS control panels control much of the data.

The alternate navigation source shows if the FMCF fails in the lower left corner next to the navigation aid information. For CDU map changes, the CDU can only do straight or direct to calculations.



PRIMARY DISPLAY SYSTEM - CENTERED MAP MODE

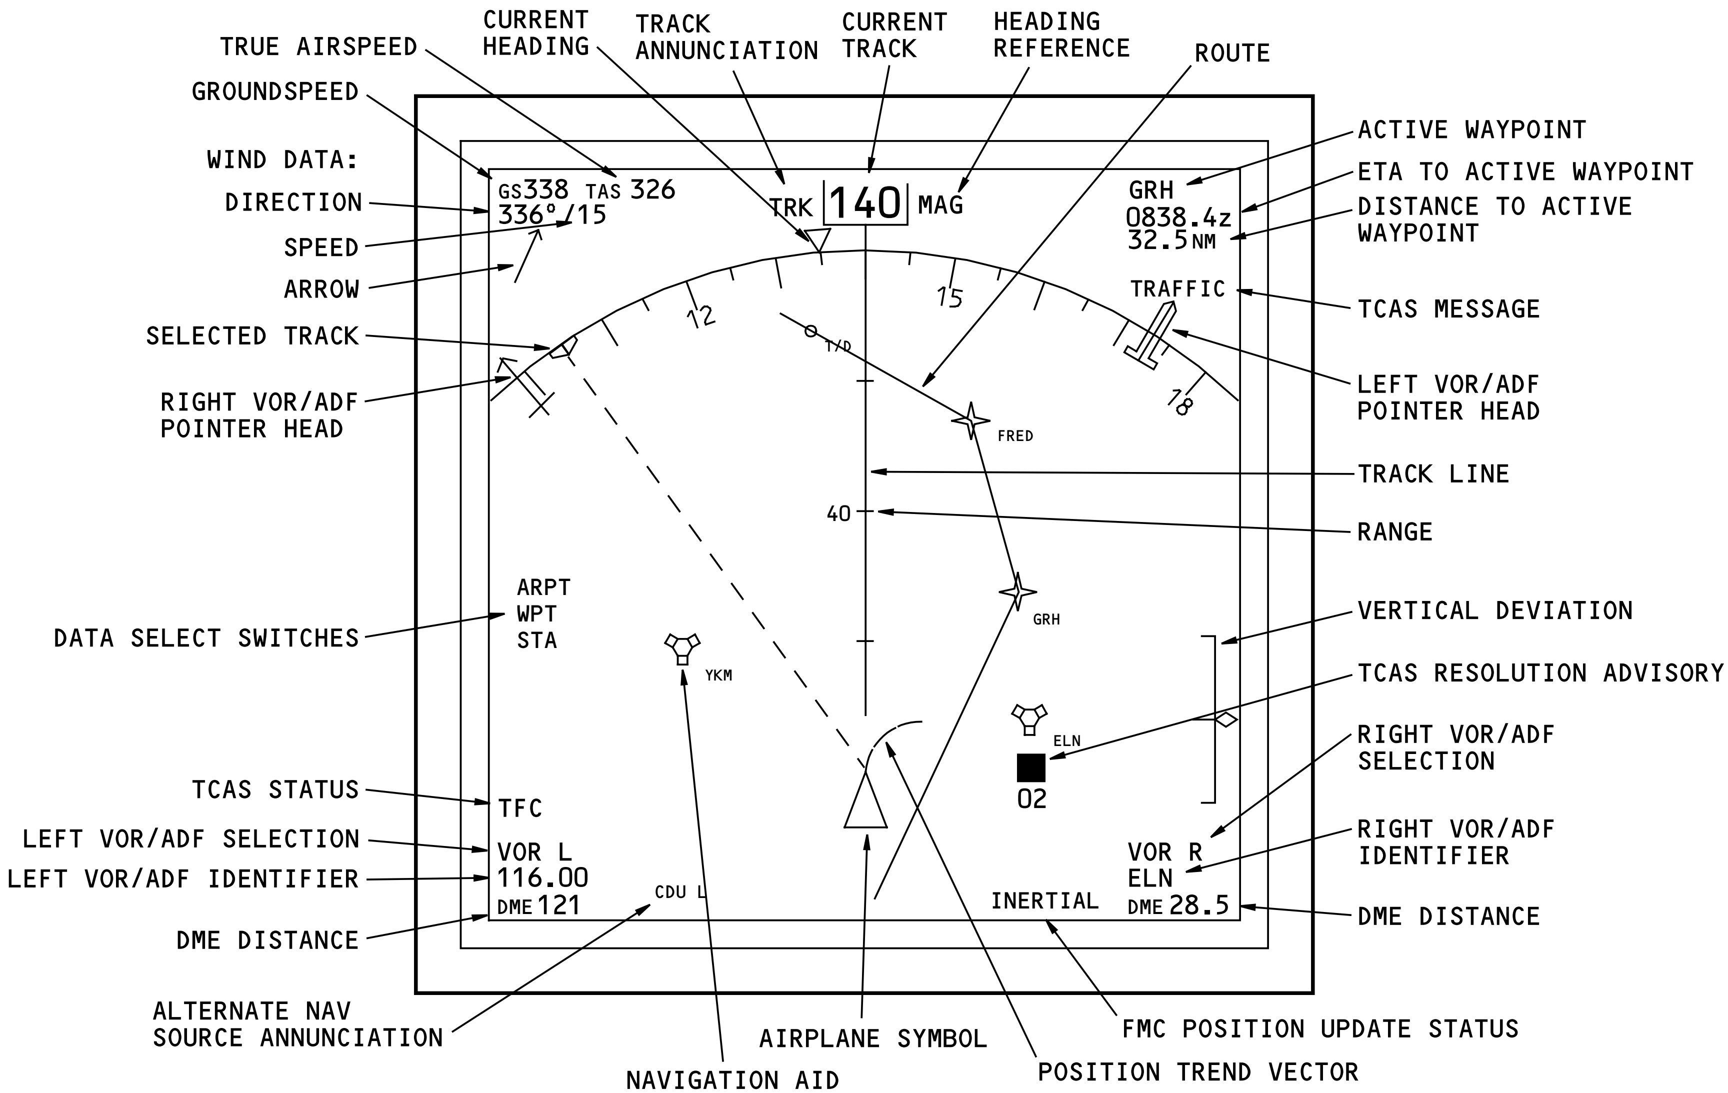
31-61-00-047 Rev 1

PRIMARY DISPLAY SYSTEM - EXPANDED MAP MODE

General

The expanded map mode shows the same basic data as the centered map mode. The airplane symbol is identical. The top of the symbol shows the present position of the airplane.

The single range numeric shows one half of the full scale map range from the range control on the EFIS control panel or the CDU.



PRIMARY DISPLAY SYSTEM - EXPANDED MAP MODE

31-61-00-048 Rev 1

PRIMARY DISPLAY SYSTEM - MAP MODE FAILURE FLAGS

General

Failures of input sources cause data to go away from the display and failure flags to show.

All the flags are amber in color.

The captain's and first officer's NDs operate independently.

Failure Flags

The TRK flag shows when the ADIRU track input fails.

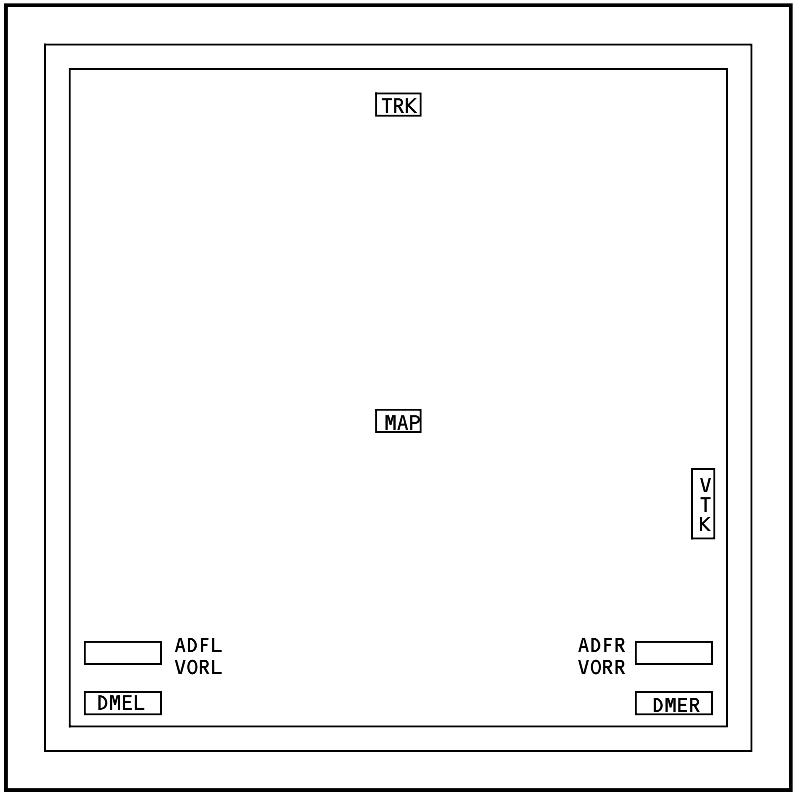
The MAP flag shows when the FMCF latitude or longitude is invalid or when the MAP dynamic or background data is invalid.

The VTK (vertical track) flag shows if the map dynamic or background data is invalid or the FMC altitude error rate is invalid.

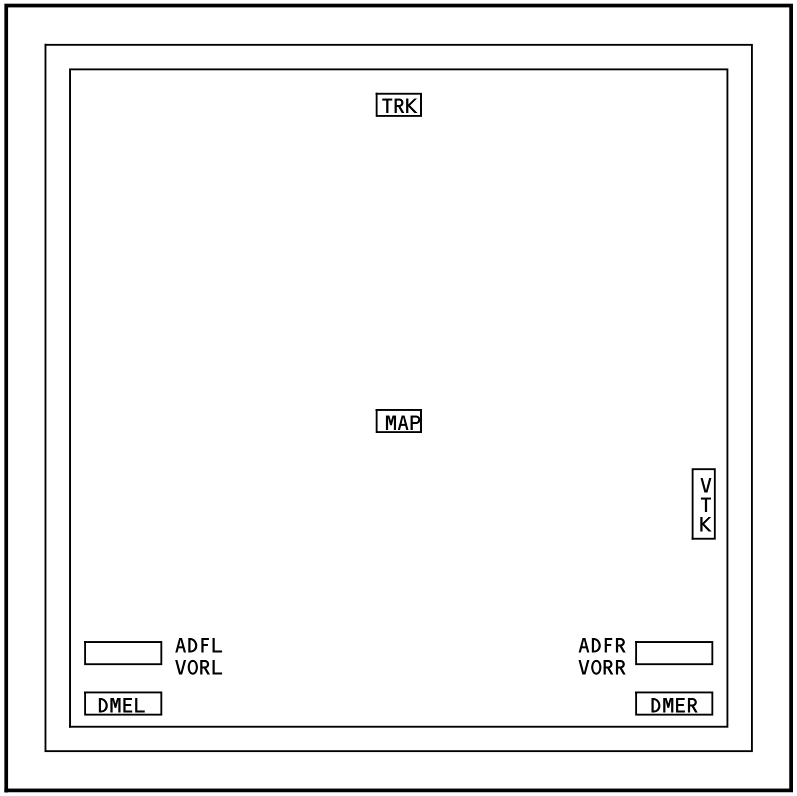
The VORL or VORR flag shows when the left or right VOR input fails. To see the flag, put the applicable switch on the EFIS control panel in the VOR position.

The ADFL or ADFR flag shows when the left or right ADF fails. To see the flag, put the applicable switch on the EFIS control panel in the ADF position.

The DMEL or DMER flag shows when the DME co-located with the ILS, or left or right VOR fails. To see the flag for DMEs co-located with the VOR stations, put the applicable VOR switch on the EFIS CP must in the VOR position.



CENTERED MODE



EXPANDED MODE

PRIMARY DISPLAY SYSTEM - MAP MODE FAILURE FLAGS

PRIMARY DISPLAY SYSTEM - MAP MODES NCD AND FAIL CONDITIONS

General

The display function in the AIMS cabinets evaluates inputs from the airplane systems.

A no computed data (NCD) status causes information on the display to go away.

A fail status causes information on the display to go away and a fail flag to show.

MAP Modes NCD and Failure Conditions

The chart shows the NCD and fail conditions for the MAP modes.

PARAMETER	CONDITION	RESULT	REMARKS
TRACK	NCD	TAPE NUMERICS GO AWAY, CURVED TREND VECTOR GOES AWAY	NCD TRACK
TRACK	FAIL	TAPE NUMERICS, TICKS, AND TRACK INDEX GO AWAY. CURVED TREND VECTOR GOES AWAY, AN AMBER TRK FLAG SHOWS	FAILED TRACK
MAP BACKGROUND	FAIL	ALL MAP DISPLAY DATA GOES AWAY AND AN AMBER MAP FLAG SHOWS	INVALID MAP DATA FROM FMCF
VERTICAL DEVIATION	NCD	VERTICAL DEVIATION SCALE GOES AWAY. AMBER VTK SHOWS	MAP BACKGROUND NCD OR FMC ALTITUDE ERROR RATE NCD
VERTICAL DEVIATION	FAIL	VERTICAL DEVIATION SCALE GOES AWAY	MAP BACKGROUND NCD OR FMC ALTITUDE ERROR RATE NCD

31-61-00-050 Rev 1

PRIMARY DISPLAY SYSTEM - MAP MODES NCD AND FAIL CONDITIONS

PRIMARY DISPLAY SYSTEM - ND MAP SYMBOLOGY - 1

General

The ND map has dynamic and background data and may include a combination of the symbols or data in the chart. Dynamic data changes as a function of time. Background data is stationary data that does not move as a function of time.

The latitude and longitude of the symbol determines its location on the map display.

The EFIS control panel STA, WPT, ARPT, DATA and POS switches control some data.

The flight management computer function (FMCF) of AIMS supplies the map flight plan data.

The mode control panel (MCP) supplies selected heading (HDG) and track (TRK) data.

These symbology colors show on the ND:

- Green (G) - shows an engaged mode condition, dynamic conditions
- White (W) - shows present status, scales, armed flight mode displays
- Magenta (M) - shows command information, pointers, symbols, fly to condition
- Cyan (B) - shows nonactive or background information
- Red (R) - shows warnings
- Amber (A)- shows caution information, faults, flags.

SYMBOL	NAME	MODE(S)	REMARKS
1. GS310	GROUND SPEED INDICATION (W)	ALL	CURRENT GROUND SPEED
2. TAS312	TRUE AIRSPEED INDICATION (W)	ALL	CURRENT TRUE AIRSPEED SHOWS ABOVE 100 KTS
3. 350° /15 ↙	WIND BEARING/SPEED (W) DIRECTION (W)	ALL	WIND DATA SHOWS IN RESPECT TO DISPLAY ORIENTATION AND HDG/TRK REFERENCE. ARROW DOES NOT SHOW IN THE PLAN MODE.
4. AAAAA	ACTIVE WAYPOINT IDENTIFIER	MAP, MAP CTR AND PLAN	SHOWS THE GO TO WAYPOINT IN THE ACTIVE FLIGHT PLAN.
5. VOR L,R ILS L,C,R	RECEIVER REFERENCE (G)	VOR, VOR CTR APP, APP CTR	SHOWS RECEIVER REFERENCE FOR THE DISPLAY.
6. 116.80 OR SEA	ILS (W)/VOR (G) FREQUENCY OR IDENTIFIER DISPLAY	VOR, VOR CTR APP, APP CTR	FREQUENCY SHOWS BEFORE THE IDENT IS DECODED. DECODED IDENT REPLACES THE FREQUENCY. MED FONT VOR, SMALL FONT DME ONLY.
7. 124NM	DISTANCE DISPLAY (W)	MAP, MAP CTR AND PLAN	SHOWS DISTANCE TO THE ACTIVE WAYPOINT.
8. DME 24.6	DME DISTANCE DISPLAY (W)	VOR, VOR CTR APP, APP CTR	SHOWS DME DISTANCE TO THE REFERENCE NAVAID.
9. 0835.4Z	ETA DISPLAY (W)	MAP, MAP CTR AND PLAN	SHOWS FMCF CALCULATED ETA FOR THE ACTIVE WAYPOINT.
10. CRS135	COURSE DISPLAY (W)	VOR, VOR CTR APP, APP CTR	SHOWS VOR COURSE OR LOCALIZER COURSE.

59. OFFSCALE	TCAS OFFSCALE MESSAGE (RA-R, TA-A)	MAP, MAP CTR APP, VOR	SHOWS RA OR TA TRAFFIC IS OUTSIDE THE TRAFFIC AREA OF THE ND RANGE. TFC SWITCH NEEDS TO BE ON.
60. TFC	TCAS MODE (B)		SHOWS TRAFFIC MODE IS ON.
61. TA ONLY	TCAS MODE (B)	ALL	SHOWS WHEN TCAS COMPUTER IS NOT COMPUTING RAS.
62. TCAS TEST			TCAS COMPUTER IS OPERATING IN THE TEST MODE. TFC IS ON (EFIS CP).
63. TCAS OFF	TCAS MODE (A)	MAP, MAP CTR APP, VOR	SHOWS A TCAS CONDITION EXISTS WHEN TFC IS ON FROM THE EFIS CP.
64. TCAS FAIL			SHOWS A FAULT IS PRESENT IN TCAS DATA WHEN TFC IS ON FROM THE EFIS CP.

1 THE TCAS SYMBOLS ABOVE THE ARROW SHOWS THAT THE TRAFFIC IS CLIMBING OR DESCENDING; NO ARROW INDICATES ALTITUDE OF TRAFFIC IN HUNDREDS OF FEET RELATIVE TO AIRPLANE POSITION. FOR ABSOLUTE ALTITUDE SYMBOLS, THE NUMERICS SHOW ALTITUDE OF TRAFFIC IN HUNDREDS AND THOUSANDS OF FEET. RELATIVE VERSUS ABSOLUTE ALTITUDE DISPLAY IS SELECTED BY A SWITCH ON THE TCAS CONTROL PANEL. FOR BOTH RELATIVE AND ABSOLUTE ALTITUDE, THE NUMERIC SHOWS BELOW THE TRAFFIC SYMBOL WHEN THE TRAFFIC IS BELOW THE AIRPLANE AND ABOVE THE TRAFFIC SYMBOL WHEN THE TRAFFIC IS ABOVE THE AIRPLANE. NO NUMERICS IN BOTH CASES SHOW ALTITUDE IS UNKNOWN. TCAS DATA SHOWS WHEN TRAFFIC (TFC) IS SELECTED ON THE EFIS CP.

31-61-00-058 Rev 0

PRIMARY DISPLAY SYSTEM - ND MAP SYMBOLOGY - 8

PRIMARY DISPLAY SYSTEM - PLAN MODE

General

The flight crew uses the plan mode for flight planning purposes.

The plan mode is a north-up presentation. The plan mode shows the entered route from the FMCS.

Range information shows as circles around the reference point in the middle of the display.

An airplane symbol shows current position and track, if the airplane is within the range and portion of the flight plan shown.

Display Data

Ground speed, wind data, and true airspeed is the same as approach, VOR and map modes except that the wind direction arrow does not show.

This data shows in the upper right corner:

- Active waypoint identifier
- Estimated time of arrival (ETA) to the waypoint
- Distance to the waypoint.

The active waypoint on the route is magenta.

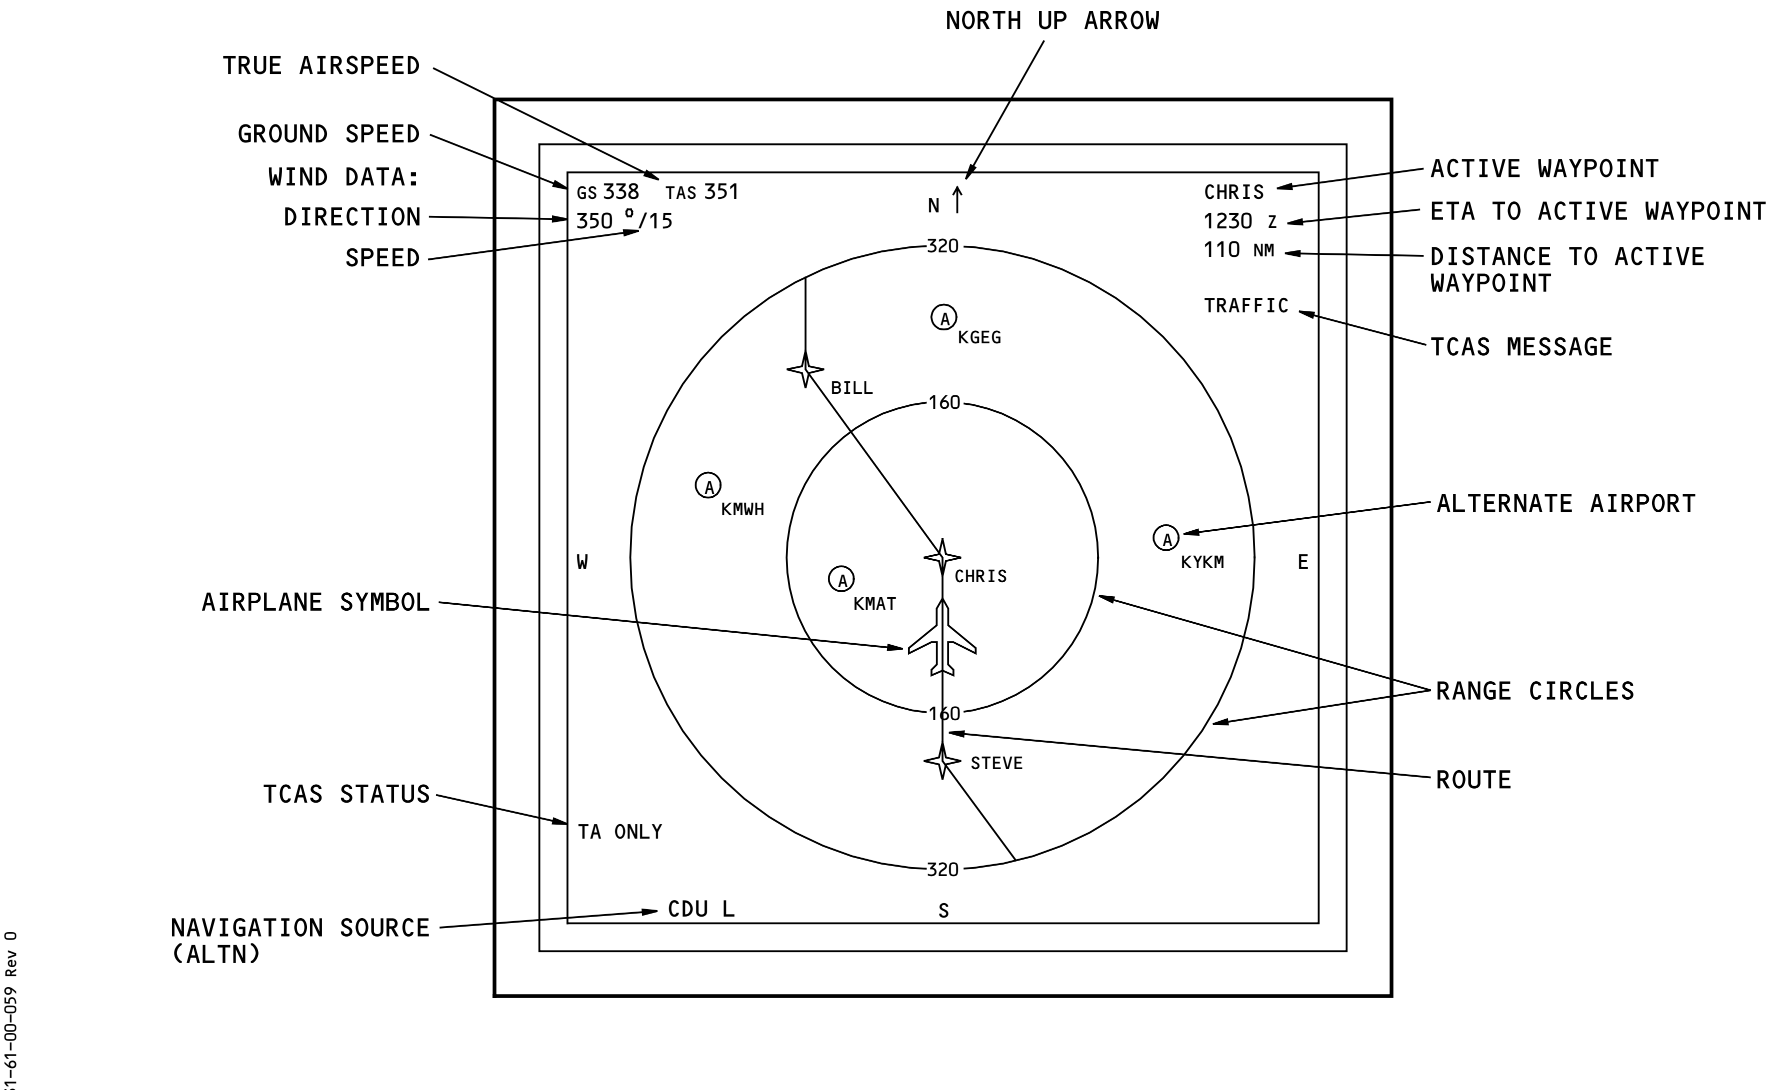
Only TCAS traffic data messages show in the plan mode.

TCAS status information shows below the WXR data field to indicate TCAS selection. Information is TA ONLY (TCAS is not computing RA) or TCAS TEST (TCAS is in the test mode).

The alternate navigation source, CDU L, CDU C, or CDU R shows if the active FMCF(s) fail(s) in the lower left corner next to the navigation aid information

Alternate airports for the origin and destination airports on the flight plan show as a circle around the letter A.

The MAP fail flag shows in the plan mode when the FMCS fails. TCAS status is the same as the map mode.



PRIMARY DISPLAY SYSTEM - PLAN MODE

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - PFD AND ND DISPLAY FUNCTIONAL DESCRIPTION

General

Each AIMS cabinet has four input/output modules (IOMs) and two core processor/graphic generators (CPM/GGs). Each graphic generator has an output to the display units (DUs). The PFD and ND functions in the CPM/GGs independently process their formats. The PFD function has these sub-functions:

- Display format processing
- Display resource management
- PFD display generator
- Graphics generator.

The ND function shares the display format processing and display resource management sub-function. The ND function has these sub-functions:

- ND generator
- Graphics generator.

Both functions send data to the graphic generator sub-function. The graphic generator reformats and sends this data to the DUs.

IOM

Each IOM does these functions:

- Presence and validity checks
- Source select and filtering.

The IOM modules do presence and validity checks on all display input parameters. Data updates ensure that the information the flight crew sees is current.

Each IOM removes bad data, replaces it with a good source, and filters the change from bad to a good data source. For critical data, the IOM sends messages to alert the flight crew of a failure. The IOMs send the valid and message data to the EICAS and MFD functions through the backplane bus.

CPM/GG

Each CPM/GG also has a PFD and ND function with sub-functions. Each AIMS cabinet has a redundant pair (CPM/GGs) for a total of four on the aircraft. Each CPM/GG can drive any three display units or three out of four display formats (PFD, ND, EICAS, or MFD). The EICAS and MFD functions configure and format the EICAS and MFD displays. The outboard DU location is for PFD display only. This redundant system supplies fail operational capability and allows deferred airplane maintenance.

The sub-functions in the CPM/GGs decode switch inputs and make the appropriate displays. Additional switch positions determine format location. If the outboard DU fails, the inboard DU automatically changes to the outboard format. The IOMs send display and switch input data to the display processing sub-function for the PFD and ND functions.

PRIMARY DISPLAY SYSTEM - PFD AND ND DISPLAY FUNCTIONAL DESCRIPTION

PFD/ND Function- Display Format Processing

The display format processing sub-function receives display and switch input data from the IOMs. It receives status data from the display system resource management sub-function for CPM/GG redundancy management. The display format processing sub-function formats the data and sends PFD and ND format data to the PFD and ND generator sub-functions. It also sends status data to the other CPM/GGs.

PFD/ND Function- PFD and ND Generators

The PFD and ND display generator sub-functions reformat the display data for the graphics generator.

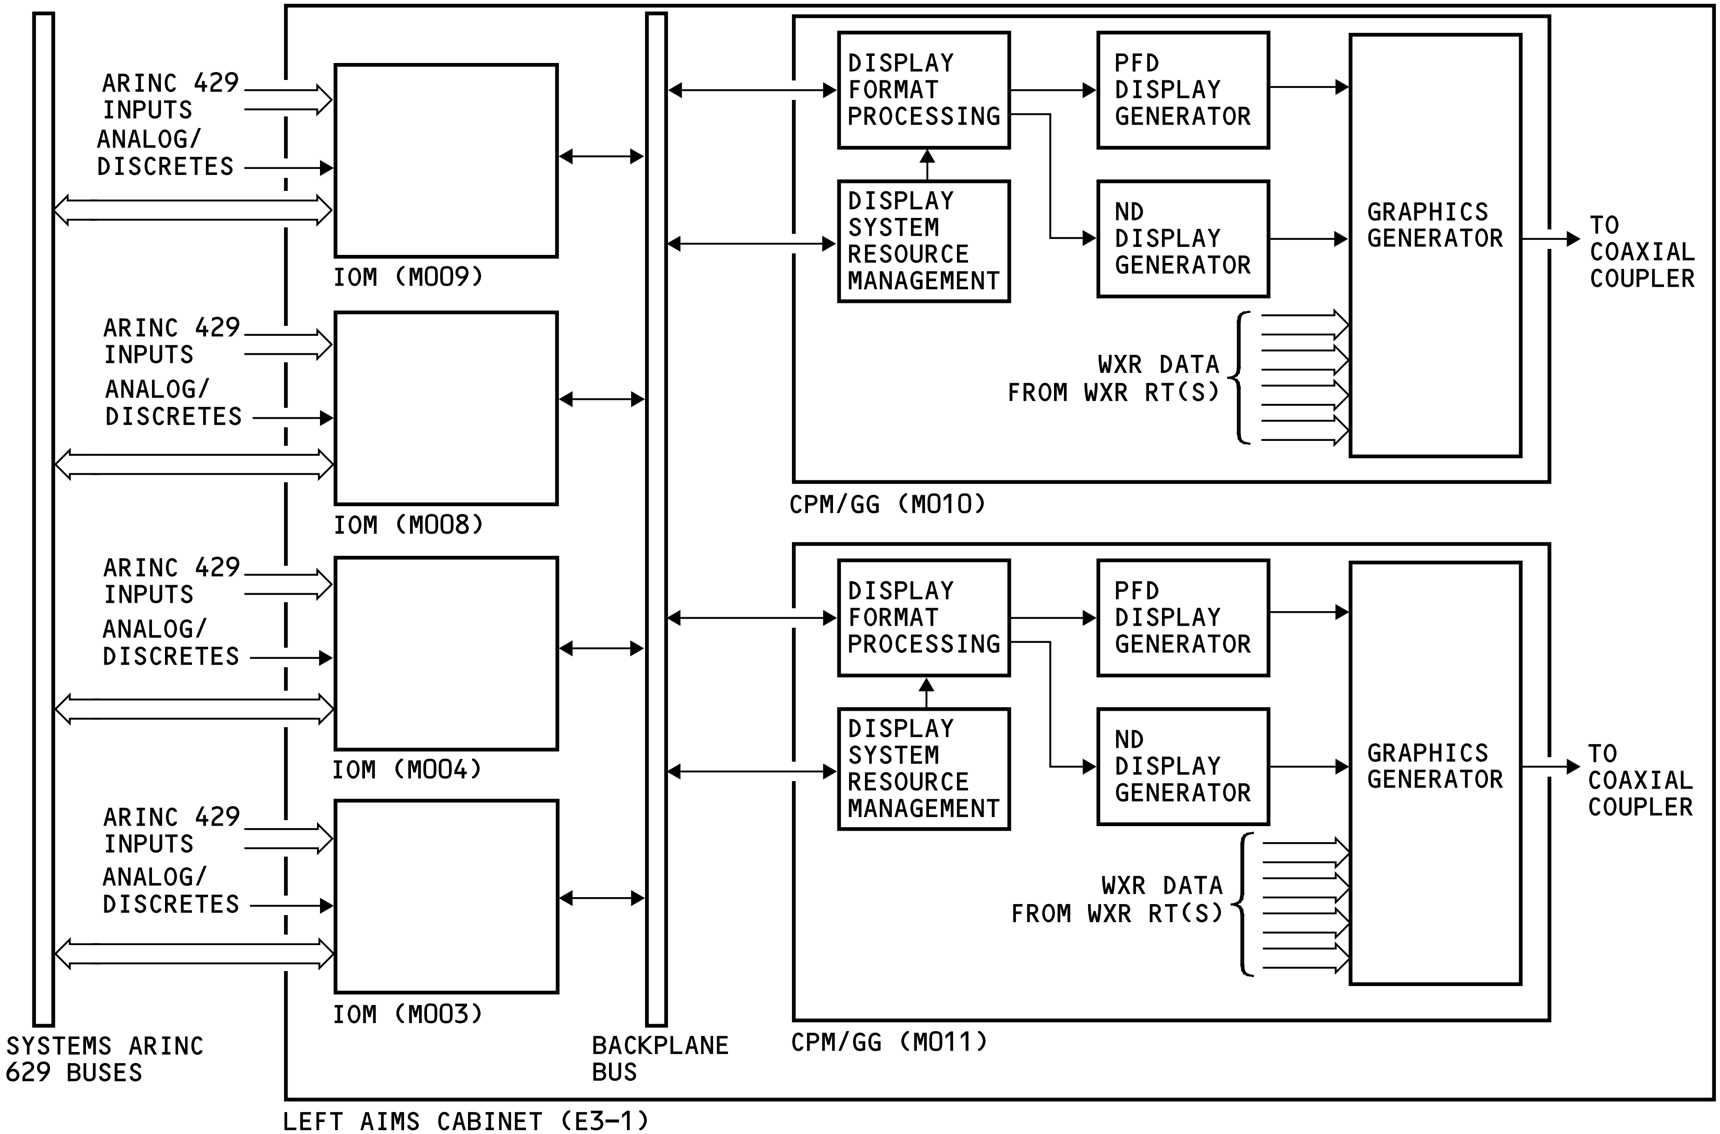
PFD/ND Function- Graphics Generator

The graphics generator sub-functions use switch inputs and output device selection data to determine display location and correct format. The PFD has one format. The ND has these seven formats

- Approach (2)
- VOR (2)
- Map (2)
- Plan.

The switch inputs permit automatic switch over of the PFD (outboard) to the ND (inboard) location in case of a PFD failure. The switch inputs also permit a ND in two locations.

The graphics generator receives the PFD and ND reformatted data from the PFD and ND generators. It converts this data to a video format and sends it to the DUs through a coaxial cable.



PRIMARY DISPLAY SYSTEM - PFD AND ND DISPLAY FUNCTIONAL DESCRIPTION

31-61-00-060 Rev 3 05/12/1995

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - DU FUNCTIONAL DESCRIPTION

General

Each display unit (DU) receives this from the AIMS cabinets:

- Graphics data
- Display format commands.

AIMS data goes to the DUs through coaxial cables. The DUs also receive brightness control data from internal and external sources. The DUs use this data to show flight information and status data to the flight crews during normal and non-normal conditions.

The input/output (I/O) controller also gets DU address information from five identification pins.

Input/Output Controller

The I/O controller receives, converts, and transmits data to the AIMS cabinet and the DU functions. The I/O controller sends graphics data to the beamformer and brightness control data to brightness control circuit. It sends command and BITE data to the DU controller.

A ground on an identification pin is a logic one. Address numbers on each DU set the standard configuration.

DU Controller

The DU controller uses a dedicated bus to receive and send data to the I/O controller. The DU controller is a programmable logic device. The DU controller has built in test (BITE) and fault logic circuits. BITE and fault circuits collect status data from the functions in the DU. The DU controller formats the data and sends it to the I/O controller. The DU controller also sends a DU reset signal and processes the DU identification (ID).

Beamformer

The beamformer receives the digital data and changes it to a CRT-like image. The beamformer splits the image data and sends it to the liquid crystal display (LCD). The beamformer also responds to BITE.

LCD Interface Register and LCD

The LCD interface register changes the two data images from the beamformer into a single image and loads the values into the LCD source drivers. The LCD interface register applies voltages to compensate for data that changes. This improves LCD response times. The interface also supplies timing and control signals to the LCD drivers. The LCD circuit responds to BITE.

Brightness Control

The brightness control circuit uses a combination of these inputs to adjust the LCD brightness:

- Bezel light sensor (BLS), internal
- Paired DUs, WXR, and RLS from the brightness controls and sensors table, external.

The brightness control circuit responds to the BITE.

PRIMARY DISPLAY SYSTEM - DU FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - EICAS DISPLAY FORMAT

General

The EICAS display normally shows on the upper center display unit (DU). When the upper center DU fails, the display automatically shows on the lower center DU. The display shows primary engine parameters and other data which require continuous display for flight safety. The EICAS display shows:

- Total air temperature (TAT) and assumed temperature
- Thrust reference mode
- Thrust reverser indication
- Primary engine parameters
- Anti-ice indication
- Pressurization indications
- Alerting and other annunciation messages
- Engine in-flight start envelope
- Gear position
- Flap position
- Fuel data.

TAT and Assumed Temperature

TAT shows above the N1 scales in white. Assumed temperature shows above the N1 scale in green when a request is made from the CDU thrust limit page. Assumed temperature is for reduced thrust takeoffs.

Thrust Limit Mode Annunciations

The thrust limit mode annunciation shows in green above and between the N1 scales.

Thrust Reverser Indication

REV shows above each engine N1 actual readout when the thrust reverser is in transit or the extended position. The indication temporarily overrides the primary thrust reference readout. The REV readout is amber when the thrust reverser is in transit and is green when the thrust reverser is fully extended.

Engine Parameters

The engine parameters show in a round dial format in a vertical column. N1 shows first, then EGT. Each parameter has a digital readout and an analog round dial.

N1

The N1 scale starts at an N1 minimum (3 o'clock position). N1 maximum shows at the 210 degree position. A pointer and the gray shading behind the pointer shows the actual N1. An amber bar at the upper end of the scale shows N1 maximum. Digital readouts for N1 show above the round dials. N1 command shows as a white sector that moves around the N1 scale. The reference N1 shows as a green digital readout above the actual N1 box.

Anti-Ice Indication

A green engine anti-ice (EAI) indication shows next to the N1 scale when the engine anti-ice valve is open. The wing anti-ice (WAI) indication shows near the bottom of the N1 scale when the wing anti-ice valve is open.

EGT

EGT also shows in a round dial format. A pointer and a gray scale show the actual values. Redline limits, amber band and amber band limits show on the scales. Digital readouts for EGT show above the analog dial.

When an engine exceedance occurs, this data changes from white to red or amber:

- Scale
- Digital readout
- Digital readout box
- Fill area.

For redline exceedances, the box around the digital readout stays red after the exceedance goes away.

The CANC/RCL switch removes or shows the exceedance indication.

The engine exceedance maintenance page shows the exceedance information and controls the data. Both N1 and EGT show exceedances when they occur.

ATC Datalink Message Field

An ATC message shows in the communication message field at the bottom left corner of EICAS when there is an ATC uplink.

If ECS information shows the ATC text shows above it.

If the EICAS display is not in the compacted format, ATC message text shows in the ATC datalink message field.

The ATC datalink message field has a maximum of 30 characters across. It also has:

- A maximum of 5 lines of text
- 1 line for accept, reject, cancel, and time information.

Pressurization Indications

Pressurization indications show below the EGT scales when an associated crew alert message shows or a parameter exceedance occurs. The data shows for the length of the condition when no AIR synoptic shows. The data includes:

- Duct pressure
- Cabin altitude
- Cabin rate
- Cabin differential pressure
- Outflow valves
- Landing altitude.

Any non-normal condition shows in red or amber.

Alerting and Other Annunciation Messages

These crew alerting and annunciation messages show on the right side of the display:

- Warning
- Caution
- Advisory
- Communication
- Memo.

The messages show by priority and in chronological order. The message field shows eleven messages. When more than eleven messages exist, a white page number shows.

A small box shows adjacent to these messages when there is a non-normal checklist with the message:

- Warning
- Caution
- Advisory.

The small box goes away when electronic checklists are on and the checklist for the message is complete.

STATUS Cue and RECALL Annunciation

The STATUS cue shows when the PDS makes a new status message and the status page is not showing. The STATUS cue goes away when the operator selects the status page or when the condition that causes the status message goes away. The STATUS cue is cyan.

The RECALL annunciation shows for one second each time the operator uses the recall switch. The RECALL annunciation is white.

In-flight Start Envelope

The range of airspeed for an in-flight start shows below the crew alerting message field. This occurs during flight if any engine is shut down and its fire switch is on.

The flight level shows in hundreds of feet and is to the nearest 1,000 feet of actual airplane altitude. If the airplane is above the maximum flight level for in-flight start, the maximum and current flight level show.

Gear Position Indication

A single landing gear indication shows the condition of the nose, left, and right main gear during normal operation. A white UP shows when all gear are up and locked. A green DOWN shows when all gear are down and locked. When the gear are in transit, a series of white diagonal lines show. The gear display goes blank after the gear UP shows for ten seconds.

During non-normal conditions, a multiple gear indication shows all individual gear positions.

Flap Position Indication

During normal flap operation, a single thermometer style indicator shows for all flap segments. The indicator shows the flap lever detents of 0, 1, 5, 10, 20, 25, and 30 degrees along the scale. Zero is at the top. A horizontal bar and a digital readout show the commanded flap position. The digital readout shows when the flap handle is in detent. The bar and readout are green when the flaps/slats are in the commanded position. Otherwise they are magenta.

The flap position indication goes blank ten seconds after the commanded flap position is 0 and both the flap handle and the flaps are in the 0 detent.

During non-normal conditions, a multiple flap indication shows. The multiple indication shows all individual flap/slat segments for each wing.

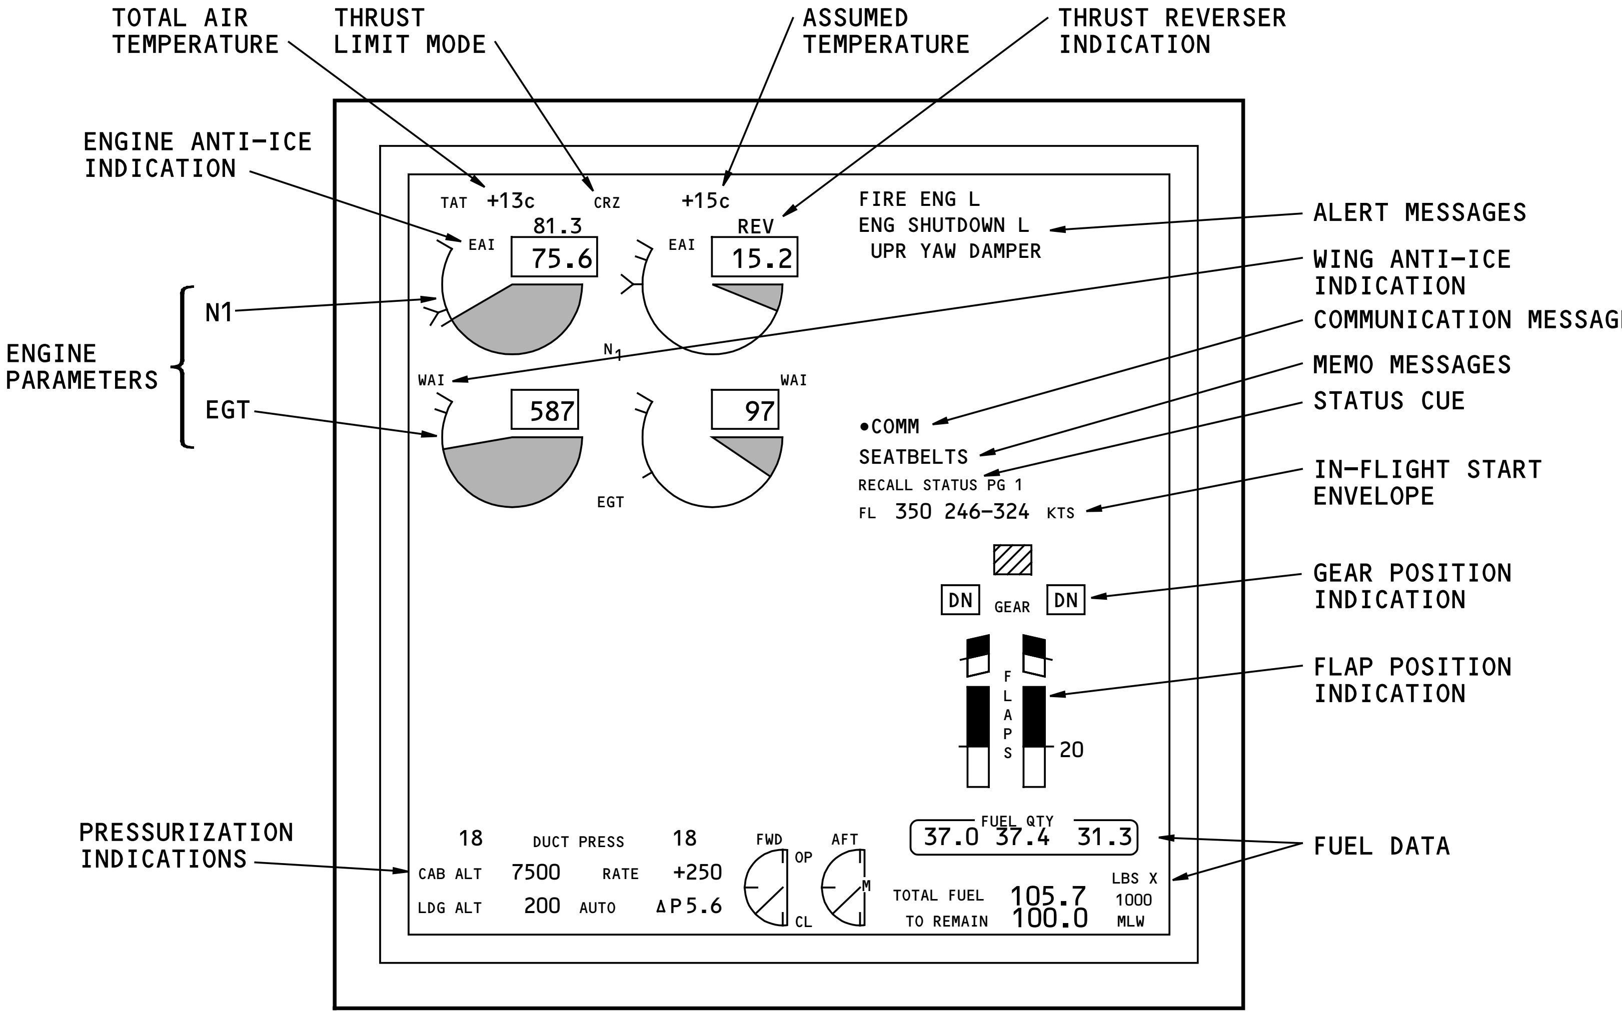
Fuel Data

Total fuel quantity and fuel temperature show as white numerical readouts in the lower right corner of the display. TOTAL FUEL and TEMP show in cyan.

During a fuel imbalance condition, a fuel quantity block shows to help the crew balance the fuel in the main tanks.

A low fuel temperature condition causes the fuel temperature readout to change to amber.

During fuel jettison, the fuel temperature readout changes to fuel-to-remain indication.



31-61-00-062 Rev 9 11/10/1997

PRIMARY DISPLAY SYSTEM - EICAS DISPLAY FORMAT

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - SECONDARY ENGINE DISPLAY FORMAT

General

The secondary engine display format shows on the center lower display unit (DU) at power-up. The format shows secondary engine parameters not required for continuous display. The ENG switch on the EICAS display select panel controls the display.

The display shows this information:

- High pressure rotor speed (N2)
- Fuel flow
- Oil pressure
- Oil temperature
- Oil quantity
- Engine vibration
- In-flight start data.

N2

N2 shows as a digital readout and a round analog scale. The display units are percent RPM. Red lines and color code for exceedance are the same as the N1 display on the EICAS display format.

Fuel Flow

A digital readout shows fuel flow in units of thousands of pounds per hour for each engine just below the N2 scale. There are no exceedance indications for fuel flow.

Oil Pressure, Temperature, Quantity

Oil pressure shows as a digital readout and filled, moving pointers on a vertical analog scale. Oil pressure has a lower red line limit and an upper and lower amber band limit.

Oil temperature shows as a digital readout in degrees C and filled, moving pointers on a vertical analog scale. Oil temperature has an upper and lower red line limit and a high and low amber band limit.

For both oil pressure and oil temperature, these change colors (white to amber to red) as the parameter exceeds applicable high or low limits:

- Digital readouts
- Readout boxes
- Pointers.

Oil quantity shows as a digital readout in quarts. For a low oil quantity condition, the digital readout changes to reverse video and a LO message shows next to the readout.

Engine Vibration

Engine vibration shows at the bottom of the page as a digital readout and a moving pointer on an analog scale. Vibration shows in normalized units from zero to five. The scale is white. A message shows below each digital readout. The message shows the rotor with the highest vibration level. The messages are N1, N2, or BB

PRIMARY DISPLAY SYSTEM - SECONDARY ENGINE DISPLAY FORMAT

(broadband). During a high vibration condition, the vibration indication goes to reverse video.

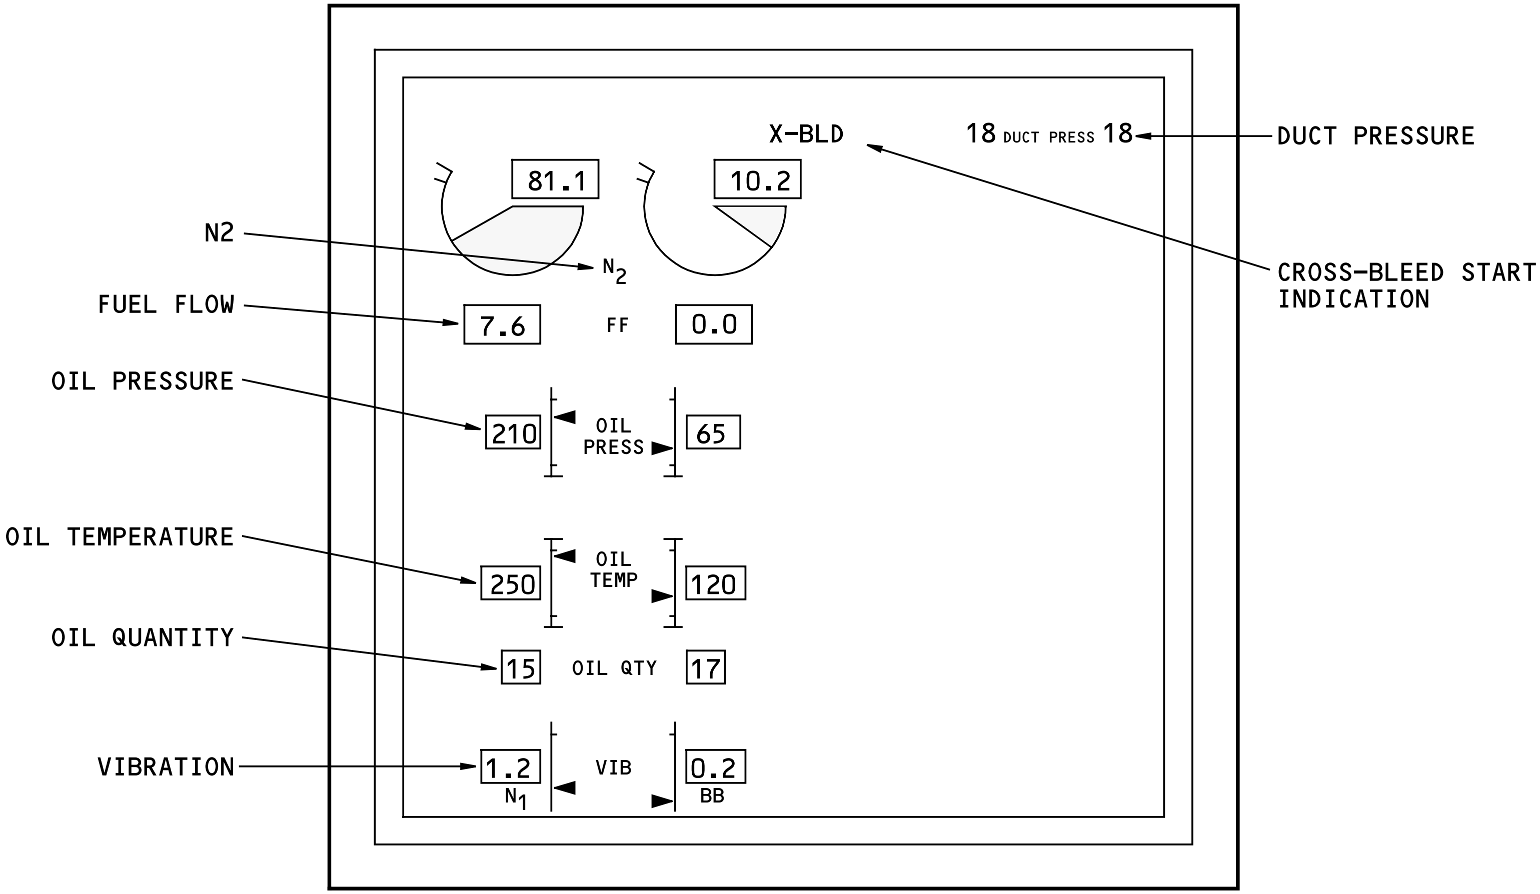
In-Flight Start Data

During in-flight start conditions, if airspeed and altitude conditions require cross-bleed, then a X-BLD message shows. A fuel-on line shows the RPM level where the crew applies fuel. The message and indication are magenta. The fuel-on line shows when an engine shuts down in the air.

During an in-flight engine shutdown, the secondary engine display format automatically shows.

Duct Pressure

The duct pressure legend and readout show when one of the engines is not running and the fire handle is not pulled.



31-61-00-063 Rev 4 09/26/1995

PRIMARY DISPLAY SYSTEM - SECONDARY ENGINE DISPLAY FORMAT

PRIMARY DISPLAY SYSTEM - EICAS ENGINE COMPACTED DISPLAY FORMAT

General

When either the upper center or lower center is not available for engine data, engine parameters from the EICAS display and secondary engine display formats show in a compacted format. With only one DU available, EICAS is in the limited mode of operation.

When the above conditions exist, the ENG switch on the display select panel (DSP) controls the compacted format. The ENG switch changes the compacted format to the EICAS display format or the EICAS display format to the engine compacted format.

The FUEL switch controls the display of the fuel data block when EICAS is in the limited mode of operation.

The AIR switch controls the display of the ECS data block when EICAS is in the limited mode of operation.

The compacted format also shows when a maintenance page shows on the lower center DU.

Compacted Format Features

N1 and EGT are the same as the EICAS display format.

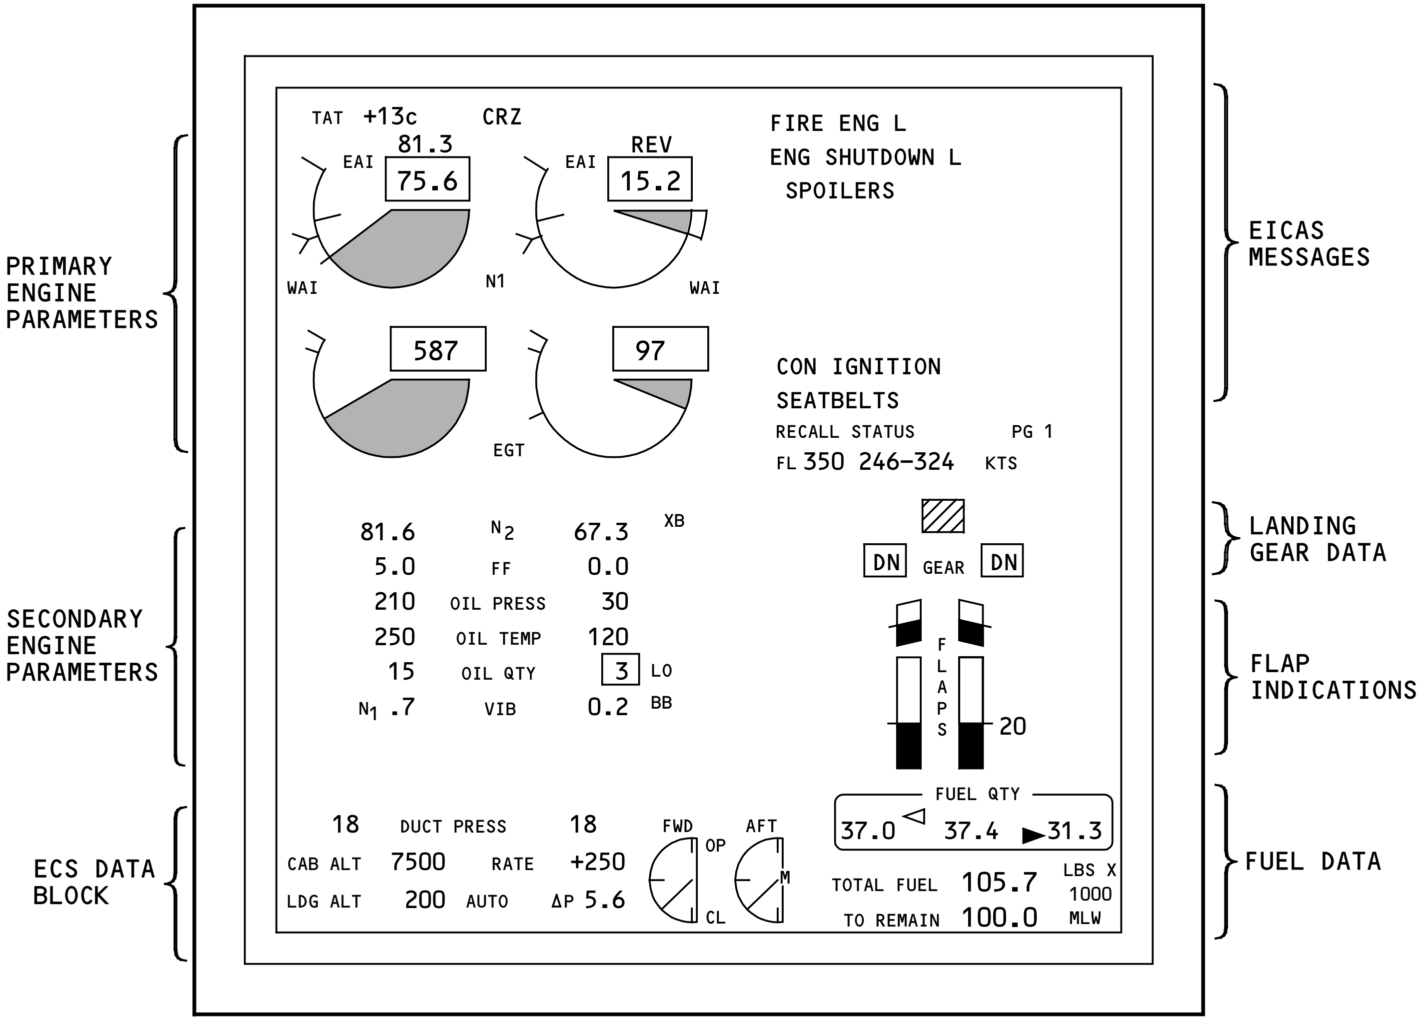
N2 shows as a numerical readout only. Cross-bleed (XB) shows next to N2.

Fuel flow and oil quantity are the same as the secondary engine display format except that the readout box goes away.

Oil pressure, oil temperature, and vibration show digitally only. The readout box and the analog scale go away.

This data shows in the same way as the EICAS display format:

- Alert and annunciation messages
- Gear information
- Flap/slat information
- Cabin pressure data
- Fuel quantity and temperature.



PRIMARY DISPLAY SYSTEM - EICAS ENGINE COMPACTED DISPLAY FORMAT

PRIMARY DISPLAY SYSTEM - CREW ALERT MESSAGES

General

The EICAS display and engine compacted formats show these types of messages:

- Warnings
- Cautions
- Advisory
- Comm
- Memo
- In-flight start.

Warning, caution, and advisory messages are crew alerting messages. Comm messages tell the crew of communication requests. Memo messages are crew reminders of the current state of manually selected normal conditions.

The most important messages in sequence are:

- Warnings
- Cautions
- Advisory
- Comm and FMC medium
- Comm low
- Memo.

Warning, caution, and advisory messages show from the top down with the most recent message at the top of its category.

Comm and memo messages start on line eleven and work up. The most recent message shows at the bottom of its group.

There are eleven messages available on each page. The CANCEL/RECALL switch controls message paging when an overflow condition exists. A page number shows when an overflow condition exists. A bullet next to a message identifies a comm message.

Warning Messages

Warning messages have a relation to operational or airplane system conditions that require immediate crew action. Warning messages are red and have an associated aural and dedicated master warning lights.

The most recent warning message shows at the top of the message field. You cannot cancel warning messages with the cancel/recall switch.

The master warning light reset switch cancels aurals and master warning light indications. The message stays on the display until the condition that caused the message goes away.

Warning messages are left justified and have a maximum of 20 characters.

Caution Messages

Caution messages have a relation to an operational or airplane condition that requires immediate crew awareness and possible action. Caution messages are amber and have an associated aural and dedicated master caution lights.

The most recent caution message shows at the top of the caution messages and below any existing warning messages.

The first push of the cancel/recall switch removes caution messages from the display. The second push returns the messages to the display if they are still active.

The master caution light reset switch cancels the master caution light and the caution aural. The message remains on the display until the condition that caused the message goes away.

Caution messages are left justified and have a maximum of 20 characters.

<u>Advisory Messages</u>

Advisory messages have a relation to an operational or airplane condition that requires crew awareness. Advisory messages are amber.

The most recent advisory message shows at the top of any advisory messages and below any existing warning or caution messages.

The first push of the cancel/recall switch removes advisory messages from the display. The second push returns the messages to the display if they are still active.

Advisory messages are left justified with the first space blank. They have a maximum of 19 characters.

<u>Comm Messages</u>

Comm messages alert the flight crew to new messages. The messages may affect the FMCS functions and advise the crew to check the CDU scratch pad. They may also affect the flight deck communication function (FDCF) and alert the crew to check the FDCF displays. Comm messages may also affect the cabin management system (CMS).

There are two levels of comm messages:

- Comm medium
- Comm low.

Comm medium messages identify an incoming communication request which requires immediate crew awareness and prompt crew acknowledgment. Comm medium messages are white and are associated with a hi-lo chime.

Comm medium messages are left justified, 20 characters long and the first character is a bullet.

Comm low messages identify an incoming communication request which requires timely crew awareness and timely crew acknowledgment. Comm low messages are white.

PRIMARY DISPLAY SYSTEM - CREW ALERT MESSAGES

Comm low messages are left justified, 19 characters long and the first character is blank. The second character is a bullet.

To cancel a comm or FMC message, use the accept switch on the glareshield panel. Or use the appropriate datalink page of the CDU or MFD to accept the uplink.

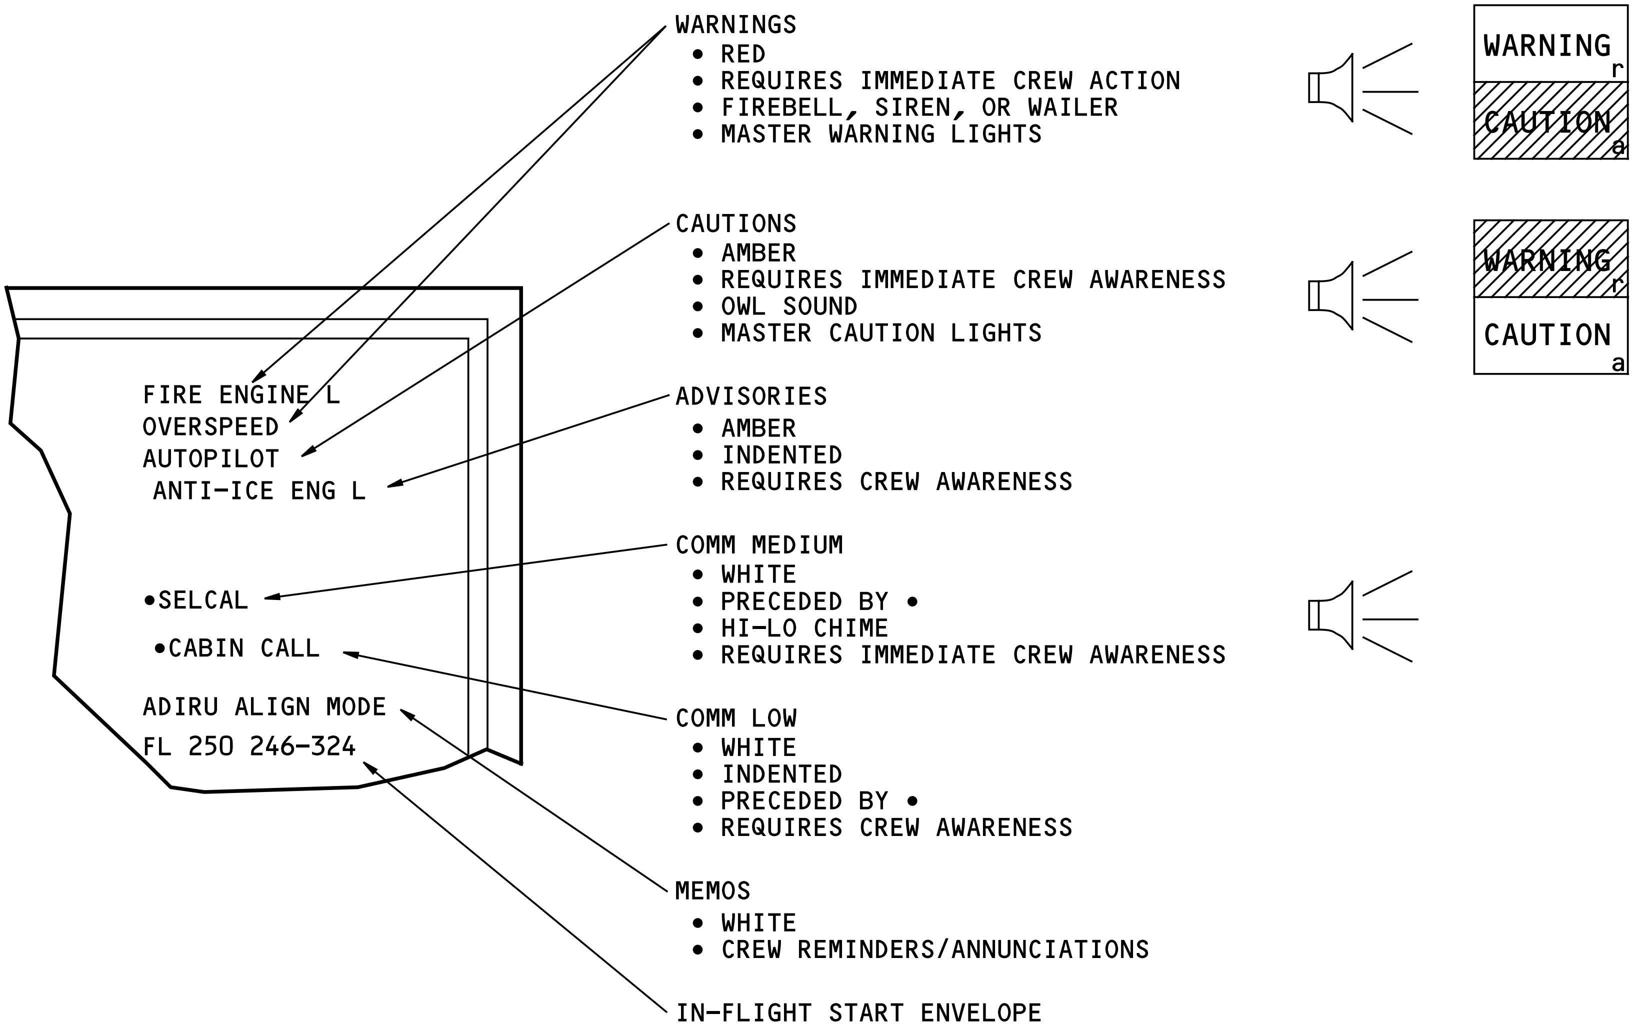
Memo Messages

Memo messages remind the crew of certain manually selected normal conditions. Memo messages are white.

Memo messages are left justified and 20 characters long.

To cancel a memo message remove the condition to cause it to show.

The highest priority memo message shows at the bottom of the display below any existing comm messages.



31-61-00-065 Rev 5 02/08/1997

PRIMARY DISPLAY SYSTEM - CREW ALERT MESSAGES

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - EICAS INHIBITS SUMMARY

General

EICAS inhibits remove invalid messages and also remove the caution visuals and aural tones during the maintenance period and during certain airplane and flight conditions.

Message Inhibits

These are the six types of EICAS message and caution inhibits:

- Engine start inhibit (ESI)
- Starter cutout inhibit
- Message inhibit
- General inhibit
- Flight phase inhibits
- Master caution and caution aural tone inhibits.

Engine Start Inhibit

The engine start inhibit prevents some of these messages and alerts during an engine start sequence:

- Caution
- Advisory
- Memo
- Status.

The engine start inhibit prevents automatic electrical bus load shedding and bus transient annunciations that may occur due to generator switching during an engine start.

Starter Cutout Inhibit

When a starter cutout condition occurs, the STARTER CUTOUT caution message replaces these existing messages:

- Caution
- Advisory
- Comm
- Memo.

During the inhibit, message processing continues but the messages do not show.

The starter cutout inhibit stops when one of these happens:

- The starter cutout condition goes away
- A new caution message occurs that is not subject to ESI inhibits
- 20 seconds after it starts
- You push the CANCL/RCL switch.

Message Inhibit

Some messages cause other messages not to show. As an example, the caution message ENG R SHUTDOWN inhibits the advisory message ENG CONTROL R.

PRIMARY DISPLAY SYSTEM - EICAS INHIBITS SUMMARY

General Inhibit

Some airplane conditions cause certain messages not to show. As an example, airplane-on-the-ground inhibits the advisory message ICING WING.

Flight Phase Inhibits

There are several flight phase inhibits.

The advisory message takeoff inhibit prevents the display of all advisory messages during takeoff.

The comm message takeoff inhibit prevents the display of comm messages during takeoff except CABIN ALERT.

The status cue inhibit prevents the display from first engine start to top of climb or 30 minutes after liftoff.

The comm message landing inhibit prevents the display of comm messages during landing except CABIN ALERT.

The caution/advisory landing inhibit prevents the display of caution and advisory messages during landing. These are the exceptions:

- AUTOPILOT
- NO AUTOLAND
- SPEEDBRAKE EXTENDED
- AUTOTHROTTLE DISC.

Master Caution Light and Caution Aural Tone Inhibits

There are two master caution lights and aural tone inhibits. They are the:

- Airplane takeoff inhibit
- All engine shutdown inhibit.

The airplane takeoff inhibit prevents the lights and tone during takeoff. The inhibit starts as the airplane accelerates through 80 knots and ends when one of these happens:

- The airplane reaches 400 feet of radio altitude
- 20 seconds after it starts
- The airplane slows to less than 75 knots.

The all engine shutdown inhibit prevents the lights and tones when the airplane is on the ground and both engines are shut down.

INHIBIT	RESULTS	CONDITIONS
ENGINE START INHIBIT	CERTAIN CAUTION, ADVISORY, MEMO, STATUS & ASSOCIATED ALERTS	EITHER ENGINE STARTER VALVE OPEN TO ENGINE IDLE RPM OR FUEL SWITCH IN CUTOFF
STARTER CUTOUT INHIBIT	CAUTION, ADVISORY, COMM, MEMO PROCESSED BUT DO NOT SHOW. REPLACES WITH STARTER CUTOUT CAUTION MESSAGE	AIRPLANE ON THE GROUND AND L OR R STARTER PROBLEM. ENDS WHEN ABOVE NOT TRUE OR 20 SECONDS OR NEW CAUTION OR CANCEL/RECALL PRESSED.
ADVISORY MESSAGE TAKEOFF INHIBIT	NO ADVISORY MESSAGES SHOW	STARTS WITH AIRPLANE ON GROUND AND TRANSITION FROM BELOW TO ABOVE 80 KNOTS. ENDS AT CLIMB THROUGH 400 FT RA OR 20 SECONDS OR ON GROUND AND TAKEOFF THRUST NOT SELECTED ON BOTH ENGINES.
COMM MESSAGE TAKEOFF INHIBIT	CERTAIN COMM MESSAGES DO NOT SHOW	STARTS WHEN T/O THRUST ON EITHER ENGINE AND AIRPLANE ON THE GROUND. ENDS AT CLIMB THROUGH 400 FT RA OR 20 SEC AFTER ROTATION OR T/O THRUST NOT SELECTED ON BOTH ENGINES
STATUS CUE INHIBIT	STATUS CUE DISPLAY DOES NOT SHOW	STARTS WITH FIRST ENGINE START. ENDS AT TOP OF CLIMB OR 30 MINUTES AFTER LIFTOFF.
COMM MESSAGE LANDING INHIBIT	CERTAIN COMM MESSAGES DO NOT SHOW	STARTS AT DESCENT THROUGH 800 FT RA. ENDS AT TRANSITION FROM AIR TO GROUND AND GS<80 KNOTS OR LOSS OF RA OR CLIMB THROUGH 800 FEET RA.
CAUTION/ADVISORY LANDING INHIBIT	CERTAIN CAUTION/ADVISORY MESSAGES NOT DISPLAYABLE. MASTER CAUTION LIGHT AND CAUTION AURAL TONE INHIBITED	STARTS AT DESCENT THROUGH 800 FT RA. ENDS AT TRANSITION FROM AIR TO GROUND AND GS<75 KNOTS OR 40 SEC OR ASCENT THROUGH 800 FEET RA.
AIRPLANE TAKEOFF INHIBIT	MASTER CAUTION LIGHT AND CAUTION AURAL TONE INHIBITED	STARTS WHEN CAS>80 KNOTS AND CAS NOT PREVIOUSLY >80 KNOTS. ENDS WHEN RA > 400 FT OR 20 SEC OR CAS<75 KNOTS
ALL ENGINE SHUTDOWN INHIBIT	MASTER CAUTION LIGHT AND CAUTION AURAL TONE INHIBITED	ENABLED WHEN AIRPLANE IS ON THE GROUND AND BOTH ENGINES SHUT DOWN

31-61-00-066 Rev 2

PRIMARY DISPLAY SYSTEM - EICAS INHIBITS SUMMARY

PRIMARY DISPLAY SYSTEM - EICAS MESSAGE PROCESSING

General

EICAS shows messages when certain conditions are met. Each type of message goes through several possible conditions before it shows on the display. Each message condition needs certain logic to be true.

Crew Alert Messages

Crew alert messages have these three possible conditions:

- ENABLED
- ACTIVE
- DISPLAYABLE.

A message is ENABLED when the logic is true and configuration requirements are true.

A message is ACTIVE when it is ENABLED and there are no inhibits.

A message is DISPLAYABLE when it is ACTIVE and it is not cancelled.

ACTIVE crew alerting messages that are inhibited by the starter cutout inhibit or that go away because of an overflow condition are DISPLAYABLE. Use the CNCL/RCL switch on the display select panel (DSP) to review the starter cutout inhibit messages. Also use the CNCL/RCL switch to go to the next page to review the overflow messages.

Status Messages

Status messages have these four possible conditions:

- ENABLED
- CURRENT
- ACTIVE
- DISPLAYABLE.

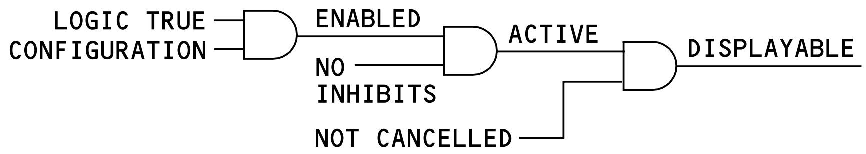
A message is ENABLED when the logic is true and configuration requirements are true.

A message is CURRENT when it is ENABLED and there are no inhibits. (ESI must be false or ESI became true after the message was ACTIVE.)

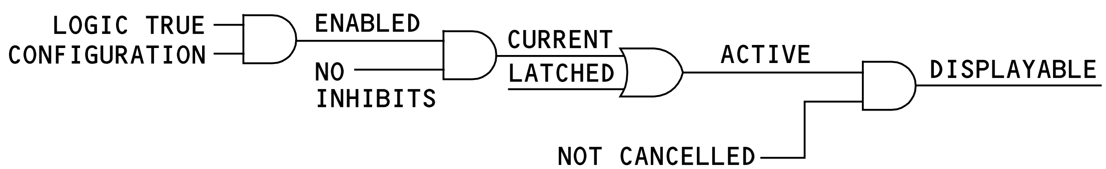
A message is ACTIVE when it becomes current or when it is latched.

A message is DISPLAYABLE when it is ACTIVE and it is not cancelled.

ACTIVE status messages that go away because of an overflow condition are DISPLAYABLE. Use the STAT switch on the DSP to go to the next page of messages.



CREW ALERT MESSAGE CONDITIONS



STATUS MESSAGE CONDITIONS

31-61-00-067 Rev 2

PRIMARY DISPLAY SYSTEM - EICAS MESSAGE PROCESSING

PRIMARY DISPLAY SYSTEM - STATUS PAGE FORMAT

General

The status display shows information that helps the technician make a decision on the dispatch status of the airplane.

The status display shows:

- Hydraulic system information
- APU information
- Crew oxygen information
- Status messages.

You use the status display switch on the display select panel (DSP) to select the status display on the multifunction display (MFD).

Hydraulic System Information

Digital display of hydraulic fluid quantity shows as a percentage; 1.00 equals full. Hydraulic fluid pressure shows for each of the three hydraulic systems.

These messages show next to the quantity readouts when the condition exists:

- LO (low)
- RF (refill)
- OF (overfill).

The LO message is amber and the RF and OF messages are white.

APU Information

APU information shows below the hydraulic information. The APU information includes:

- APU exhaust gas temperature (EGT), in centigrade
- APU rotor speed
- APU oil quantity
- APU oil pressure
- APU oil temperature.

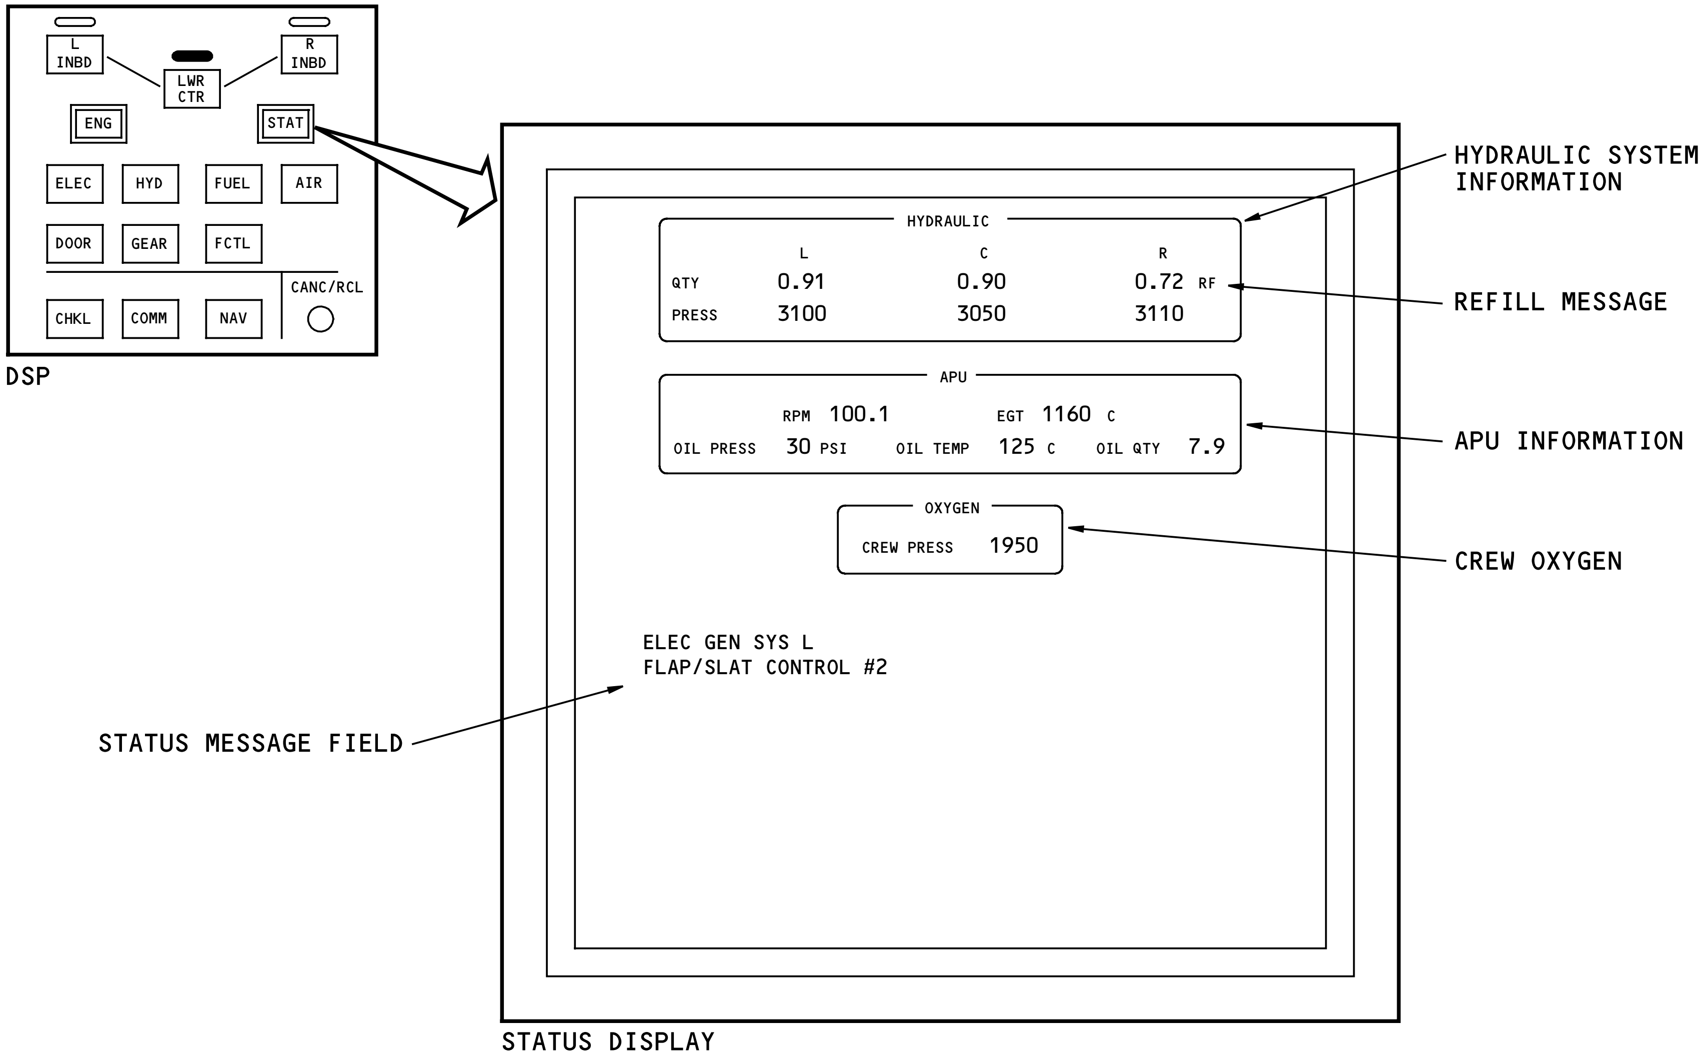
Crew Oxygen

Crew oxygen status shows below the APU information.

Status Messages

Status messages have a relation to conditions that affect dispatch. The technician uses applicable publications to make a decision on the dispatch status of the airplane.

The status message field holds eleven messages on each page. Use the status display switch on the DSP to page through multiple pages of status messages. When the last page of status messages shows, a push of the status display switch causes the display to go away.



31-61-00-068 Rev 4 05/19/1997

PRIMARY DISPLAY SYSTEM - STATUS PAGE FORMAT

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - STATUS MESSAGE FIELD AND STATUS CUE

General

The status message field shows in the lower left corner on the status display (MFD). Status messages show the dispatch status of the airplane in the status message field. A status message is based on the requirements of the master minimum equipment list (MMEL). The most recent message shows at the top of the list.

The STATUS cue field shows on the EICAS display when the status display does not show and a new status message occurs. The STATUS cue shows below the memo message field.

These are the two types of status messages:

- Non-latched
- Latched.

Non-Latched

Non-latched status messages show on the status display when some malfunctions occur in the systems monitored by AIMS. The newest message shows first. When the condition that causes the message goes away, the message on the status page format goes away.

If more than eleven messages exist, they overflow to additional pages and a page number shows below the status message field. Use the status display switch on the display select panel (DSP) to page through multiple pages of status messages. When the last page of status messages shows, a push of the status display switch causes the display to go away.

Latched

Latched status messages also show on the status display when malfunctions occur in systems monitored by AIMS. They have the same priority as non-latched status messages. The most recent message of either type shows at the top of the list.

These are the three types of latched status messages:

- Ground only
- Air only
- Either air or ground.

AIMS stores latched status messages in memory. The messages go to the central maintenance computing function (CMCF) for flight deck effect correlation.

Latched messages allow the maintenance technicians to look at failures that occur in specific flight phases and may not be present or active all the time.

Latched status messages do not go away when the condition that causes the message goes away. Some latched status messages require the technician to do the necessary repair and then use the ERASE function on the MAINTENANCE TASK maintenance page to erase the messages. Other latched status messages require the technician to do the necessary repair and then do a ground test of the system to erase the message.

PRIMARY DISPLAY SYSTEM - STATUS MESSAGE FIELD AND STATUS CUE

Status Cue

A STATUS cue shows on the EICAS display any time a new status message becomes current and the status page format does not show. The STATUS cue is cyan.

There is a fifteen second time delay before the STATUS cue shows. This prevents transient messages.

The STATUS cue goes away when one of these occurs:

- The status page format shows
- The condition that causes the status message goes away.

Status Cue Inhibit

A status cue inhibit does not let the STATUS cue show. During takeoff, the inhibit starts when both of these occur:

- The airplane is on the ground
- First engine start.

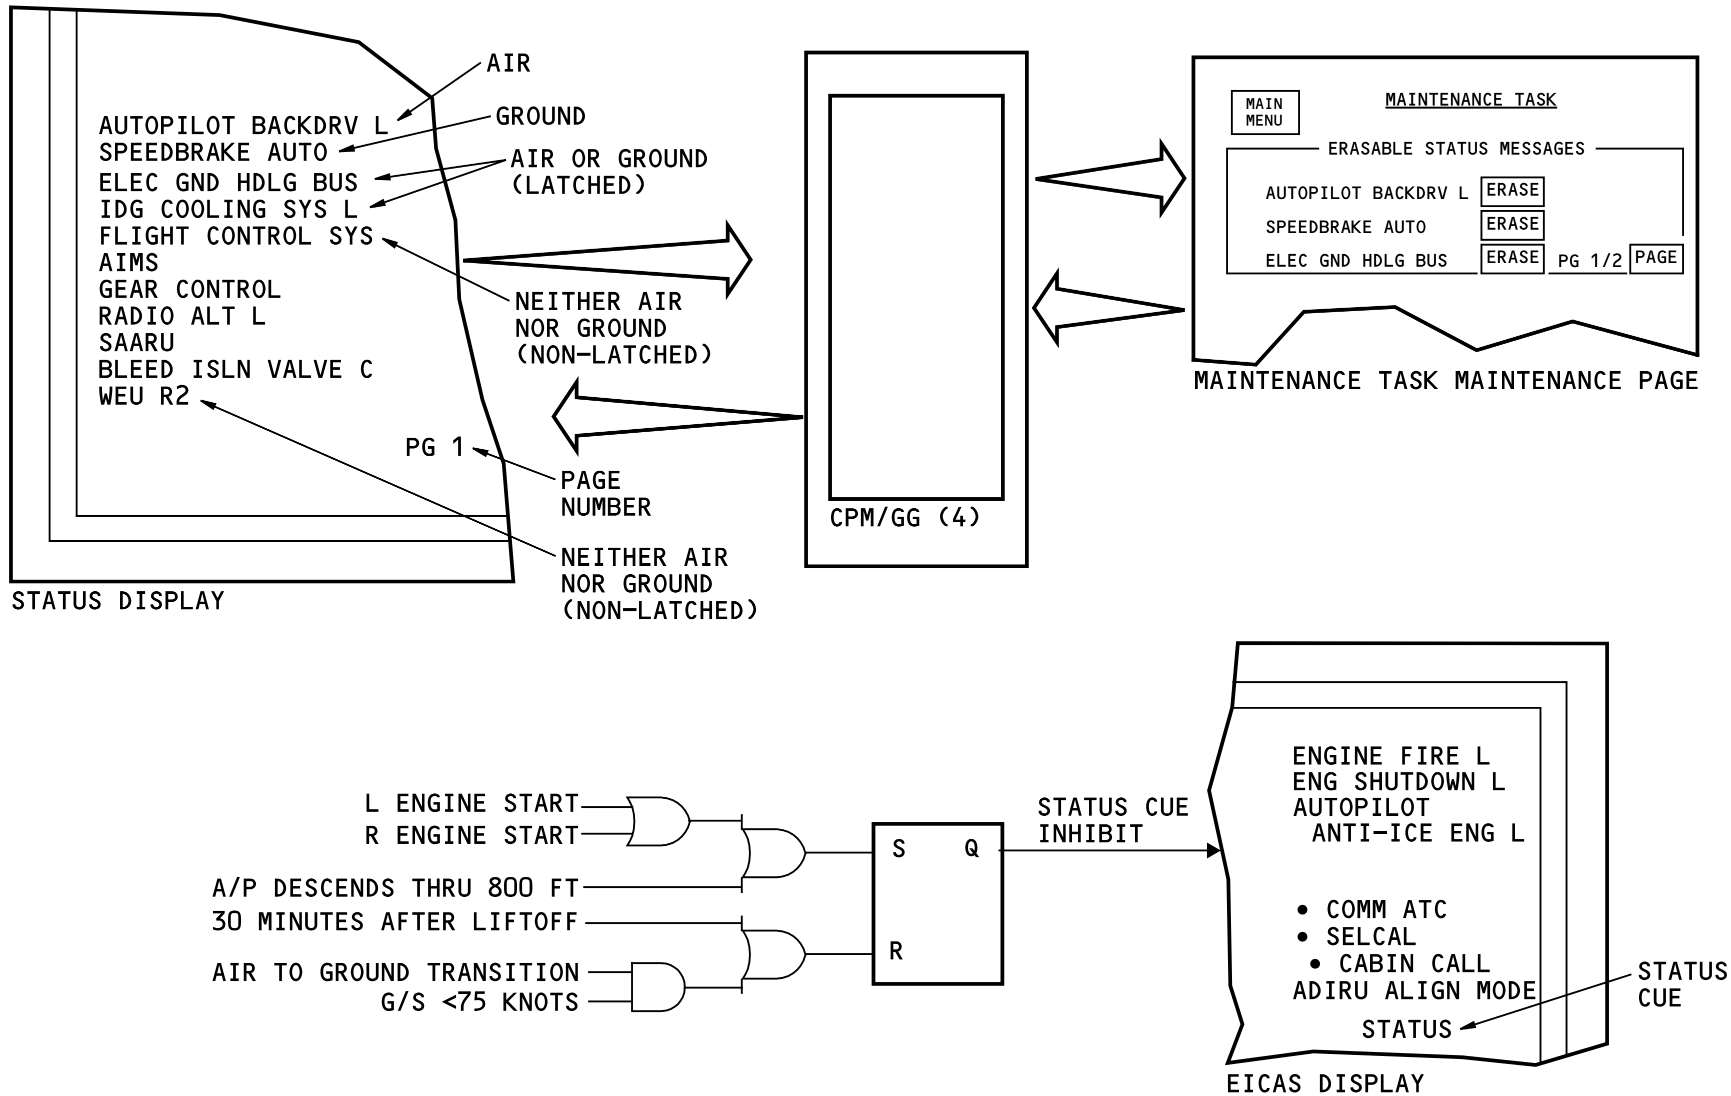
During landing, the inhibit starts when the airplane descends through 800 feet of altitude.

The inhibit stops 30 minutes after liftoff.

After landing, the inhibit stops when the airplane ground speed is less than 75 knots.

If a STATUS cue shows before the start of the inhibit, it continues to show.

If a status message becomes active during the inhibit and is still active when the inhibit ends, the STATUS cue shows.



PRIMARY DISPLAY SYSTEM - STATUS MESSAGE FIELD AND STATUS CUE

31-61-00-069 Rev 7 11/15/95

PRIMARY DISPLAY SYSTEM - SYNOPTIC FORMATS OVERVIEW

General

Synoptic formats give a graphic representation of airplane systems. The word SYNOPTIC combines the words synopsis (summary) and optic (visual). Synoptics are dynamic displays in color of real-time data. The synoptic displays are available for these systems:

- Flight controls (FCTL)
- Landing gear (GEAR)
- Doors (DOOR)
- Environmental control system (AIR)
- Fuel (FUEL)
- Hydraulic (HYD)
- Electrical (ELEC).

Push the applicable switch on the display select panel (DSP) to show a synoptic. Push the same switch a second time and the display goes away.

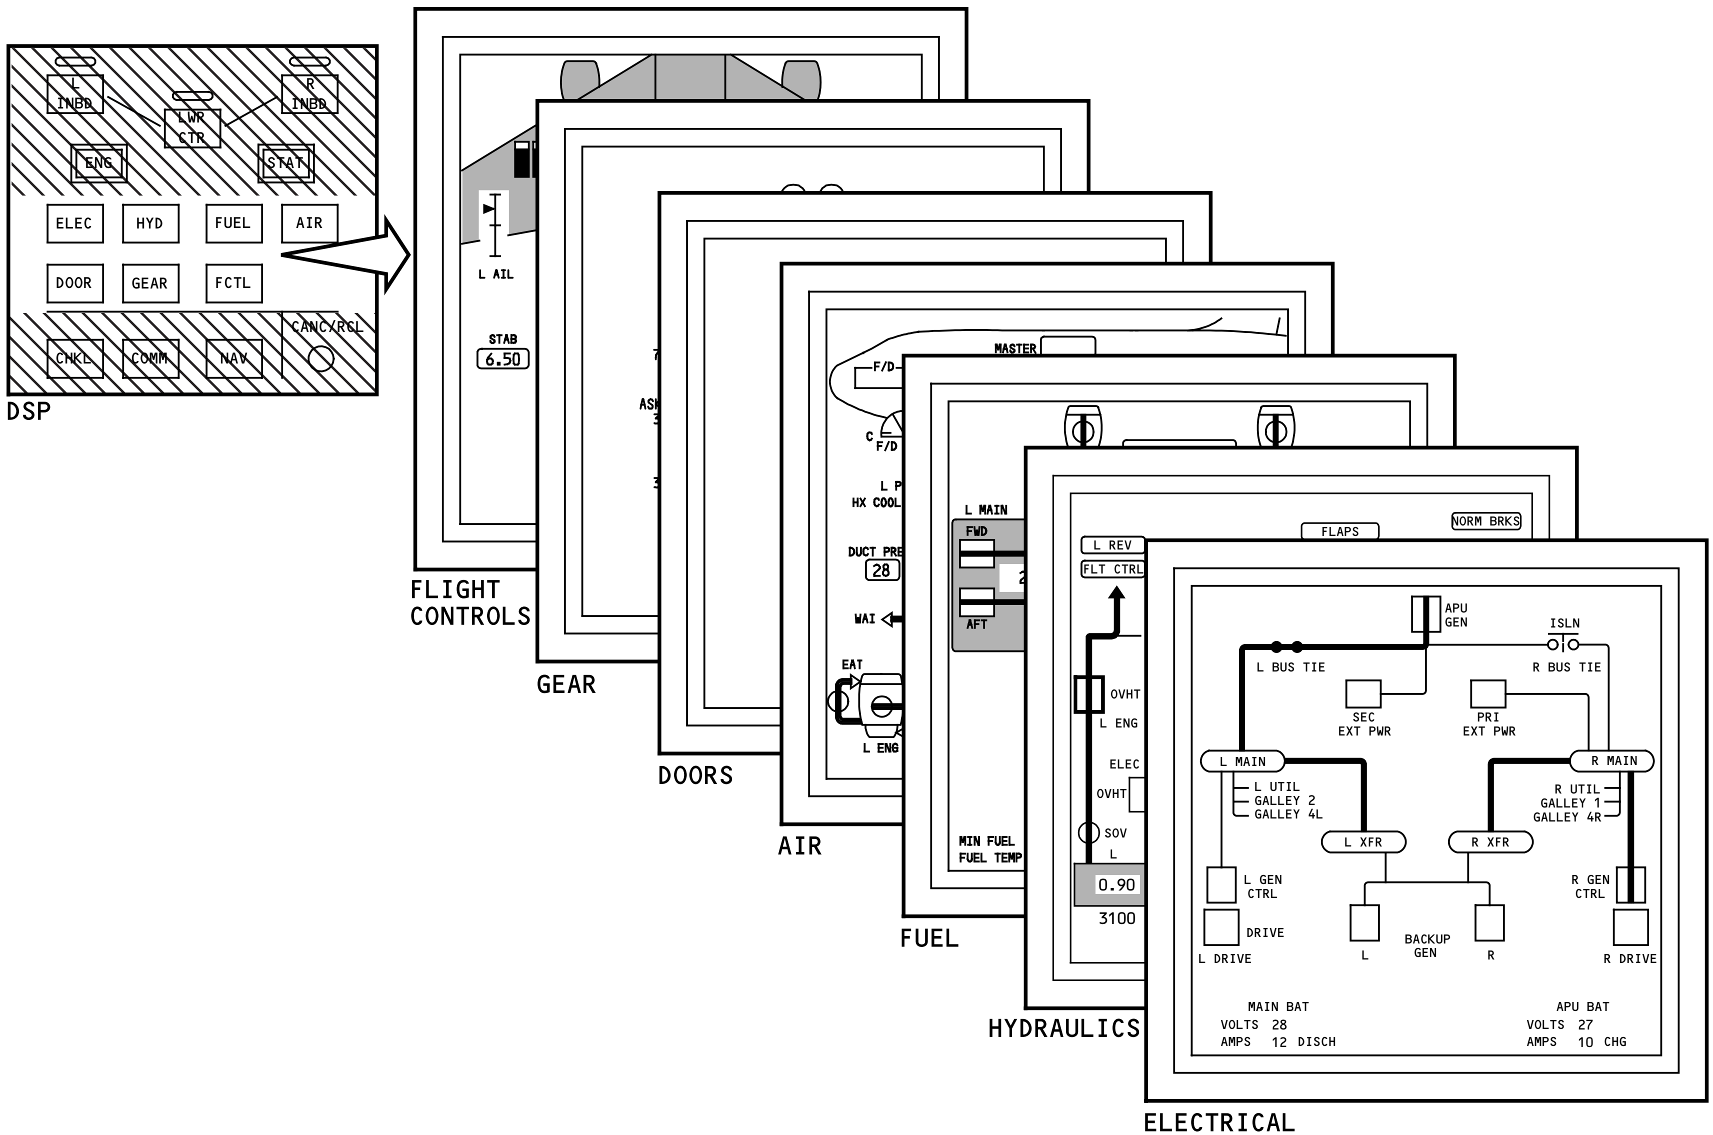
Synoptic formats can show as a multi functional display (MFD) on any or all of these DUs:

- Lower center DU
- Left inboard DU
- Right inboard DU.

Colors

Colors show on synoptic pages to help identify conditions and states. These colors show on the synoptic pages:

- Red, warning/limit/exceedance
- Amber, caution/limit/exceedance/failed
- Magenta, commands/targets
- Cyan, arm state
- Green, on/flow
- Grey, actual airplane condition
- White, off/invalid data.



PRIMARY DISPLAY SYSTEM - SYNOPTIC FORMATS OVERVIEW

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - FLIGHT CONTROLS SYNOPTIC

General

The flight controls synoptic display shows the status of the external flight control surfaces on an airplane outline.

The synoptic shows this information:

- Spoiler position
- Flaperon position
- Aileron position
- Elevator position
- Stabilizer position
- Rudder trim position
- Rudder position
- Flight control mode
- Hydraulic system status
- Actuator control electronics (ACE) status.

Spoiler Position

Spoiler positions show as a thermometer. The full up position shows as a filled thermometer and the full down position has no fill. For invalid conditions the spoiler symbol goes away. For fail conditions an amber X shows.

Flaperon, Aileron, and Elevator Position

The flaperon, aileron and elevator surface position shows as a pointer that moves along a vertical scale. The ends of the scales show full range deflection and the tick mark at the center shows zero deflection. For invalid conditions, the triangular pointer goes away. For fail conditions, an amber X shows.

Stabilizer Position

Stabilizer position shows as a digital readout in units of trim. For invalid conditions, the digital readout goes away. For fail conditions, an amber X shows.

Rudder Trim Position

Rudder trim position shows as a digital readout in units of trim. The letters L or R show trim direction. For invalid conditions, the digital readout and the L and R goes away. For fail conditions, an amber X shows.

Rudder Position

The rudder position shows as a pointer that moves along a horizontal scale. The ends of the scales show full range deflection and the tick mark at the center shows zero deflection. For invalid conditions, the triangular pointer goes away. For fail conditions, an amber X shows.

Flight Control Mode

NORMAL, SECONDARY, or DIRECT shows for the applicable flight control mode. NORMAL is white and SECONDARY and DIRECT are amber. The box and message goes away when no data is available.

PRIMARY DISPLAY SYSTEM - FLIGHT CONTROLS SYNOPTIC

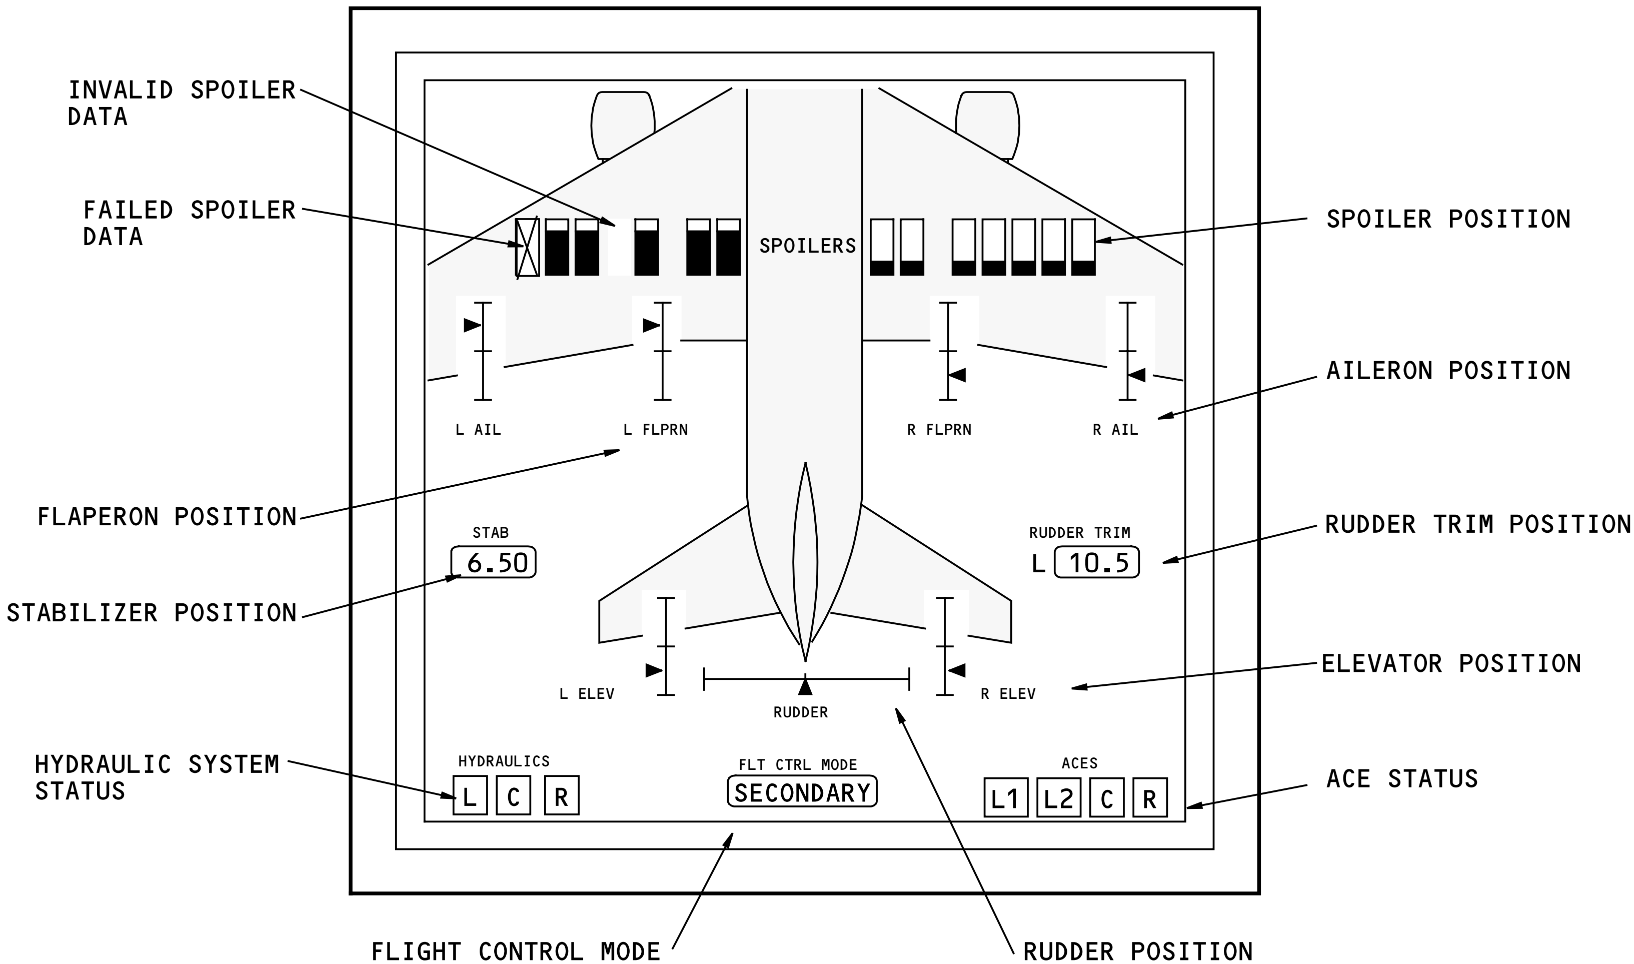
Hydraulic System Status

The hydraulic system status blocks show when there is low pressure in any of the three systems. L, C or R show for the applicable system. The system with low pressure shows as an amber letter and box. The normal systems show as green letters and boxes.

When all three systems are normal, the display goes away.

Actuator Control Electronics (ACE) Status

The ACE status blocks show when there is a failure. L1, L2, C, or R show for the applicable system. The box and label for the failed system shows in amber. The normal systems show as green letters and boxes.



PRIMARY DISPLAY SYSTEM - FLIGHT CONTROLS SYNOPTIC

PRIMARY DISPLAY SYSTEM - GEAR SYNOPTIC

General

The Gear synoptic shows this information:

- Tire pressure
- Gear door information
- Brake temperature
- Brake symbols
- Brake deactivation/antiskid status.

Tire Pressure

Tire pressure shows in each tire symbol. Normal pressures show in white. Non-normal tire pressure shows in amber. Invalid tire pressure information shows blank.

Gear Doors

The message CLOSED shows in the door symbol when the nose gear doors or the main landing gear doors close. When the doors are in transit, diagonal lines show in the door symbol. For invalid conditions, the door symbols go away.

Brake Temperature

Brake temperature shows as a digital readout next to the wheel symbol. Temperatures show as numbers on a scale that relates to actual brake temperatures. Normal temperatures are white readouts. Non-normal temperatures are amber readouts. Invalid brake temperature information shows blank.

Brake Status and Symbols

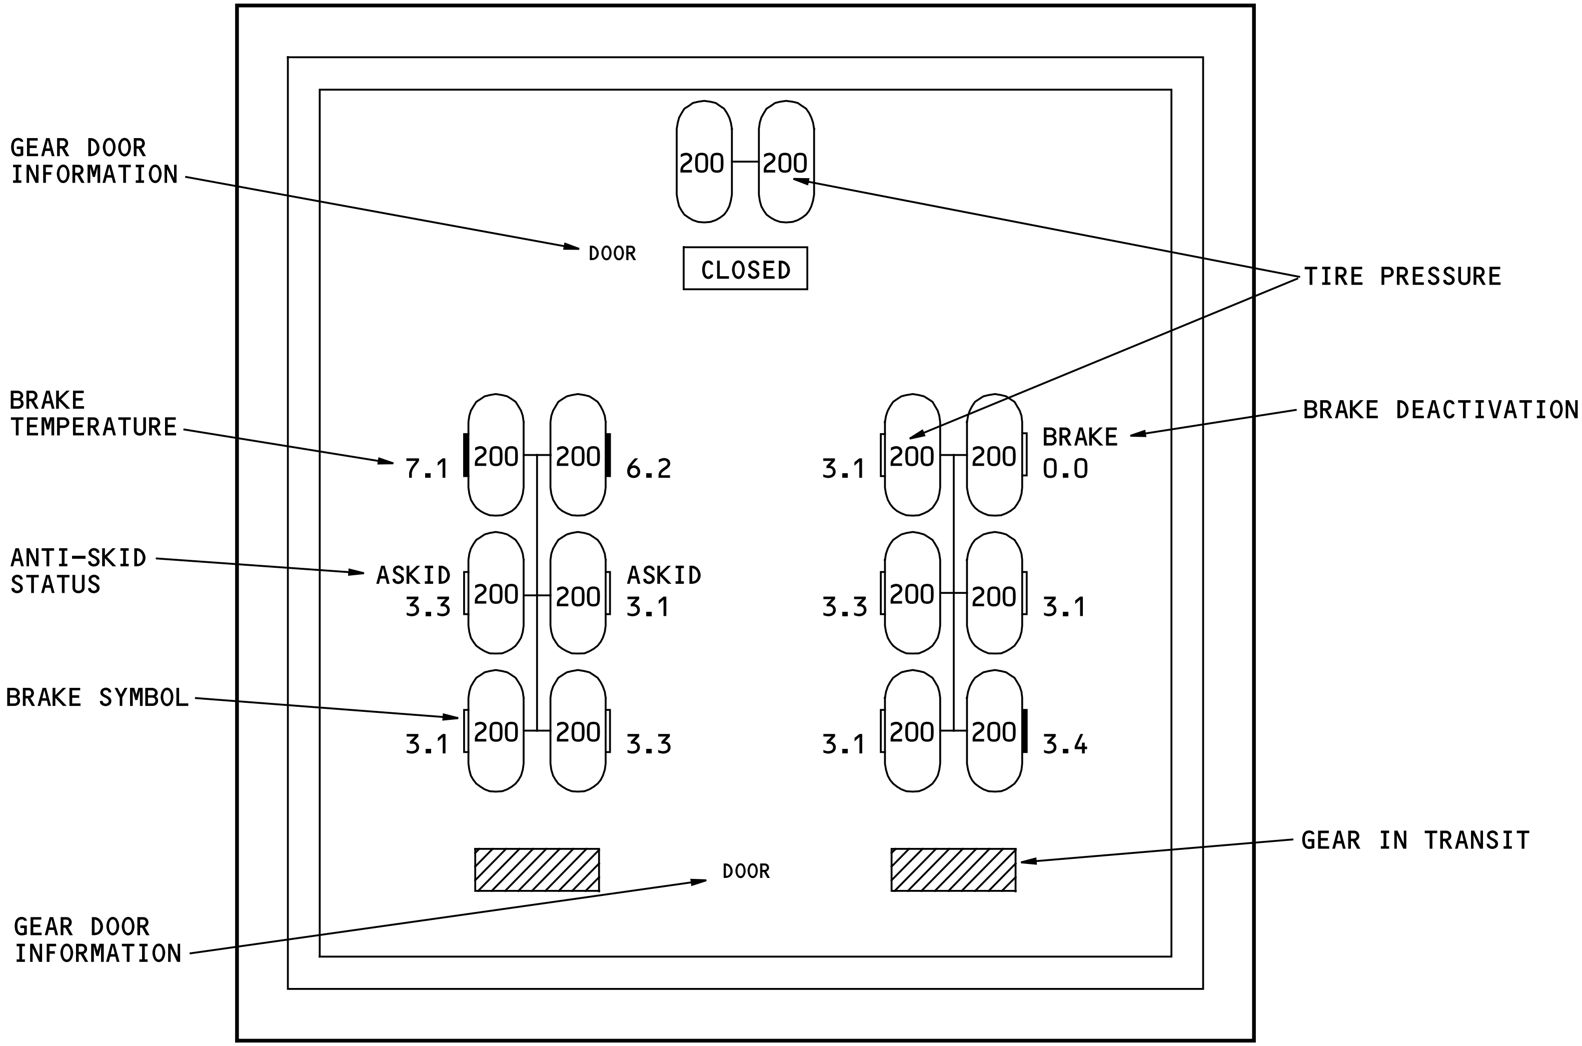
The brake symbol is a vertical bar next to the wheel symbol.

These are the four conditions and displays for the brakes:

- Brake invalid - a white symbol and blank digital temperature readout
- Brake normal - a white brake symbol and digital temperature readout
- Brake hottest - a solid white brake symbol shows on each truck for the hottest brake. The temperature readout remains white
- Brake overheat - the brake symbol and digital temperature readout change to amber. This cancels the brake hottest indication for that truck.

Brake Deactivation/Antiskid

The message BRAKE or ASKID shows next to the applicable wheel when there is a brake deactivation or an antiskid condition.



31-61-00-072 Rev 2

PRIMARY DISPLAY SYSTEM - GEAR SYNOPTIC

PRIMARY DISPLAY SYSTEM - DOOR SYNOPTIC

General

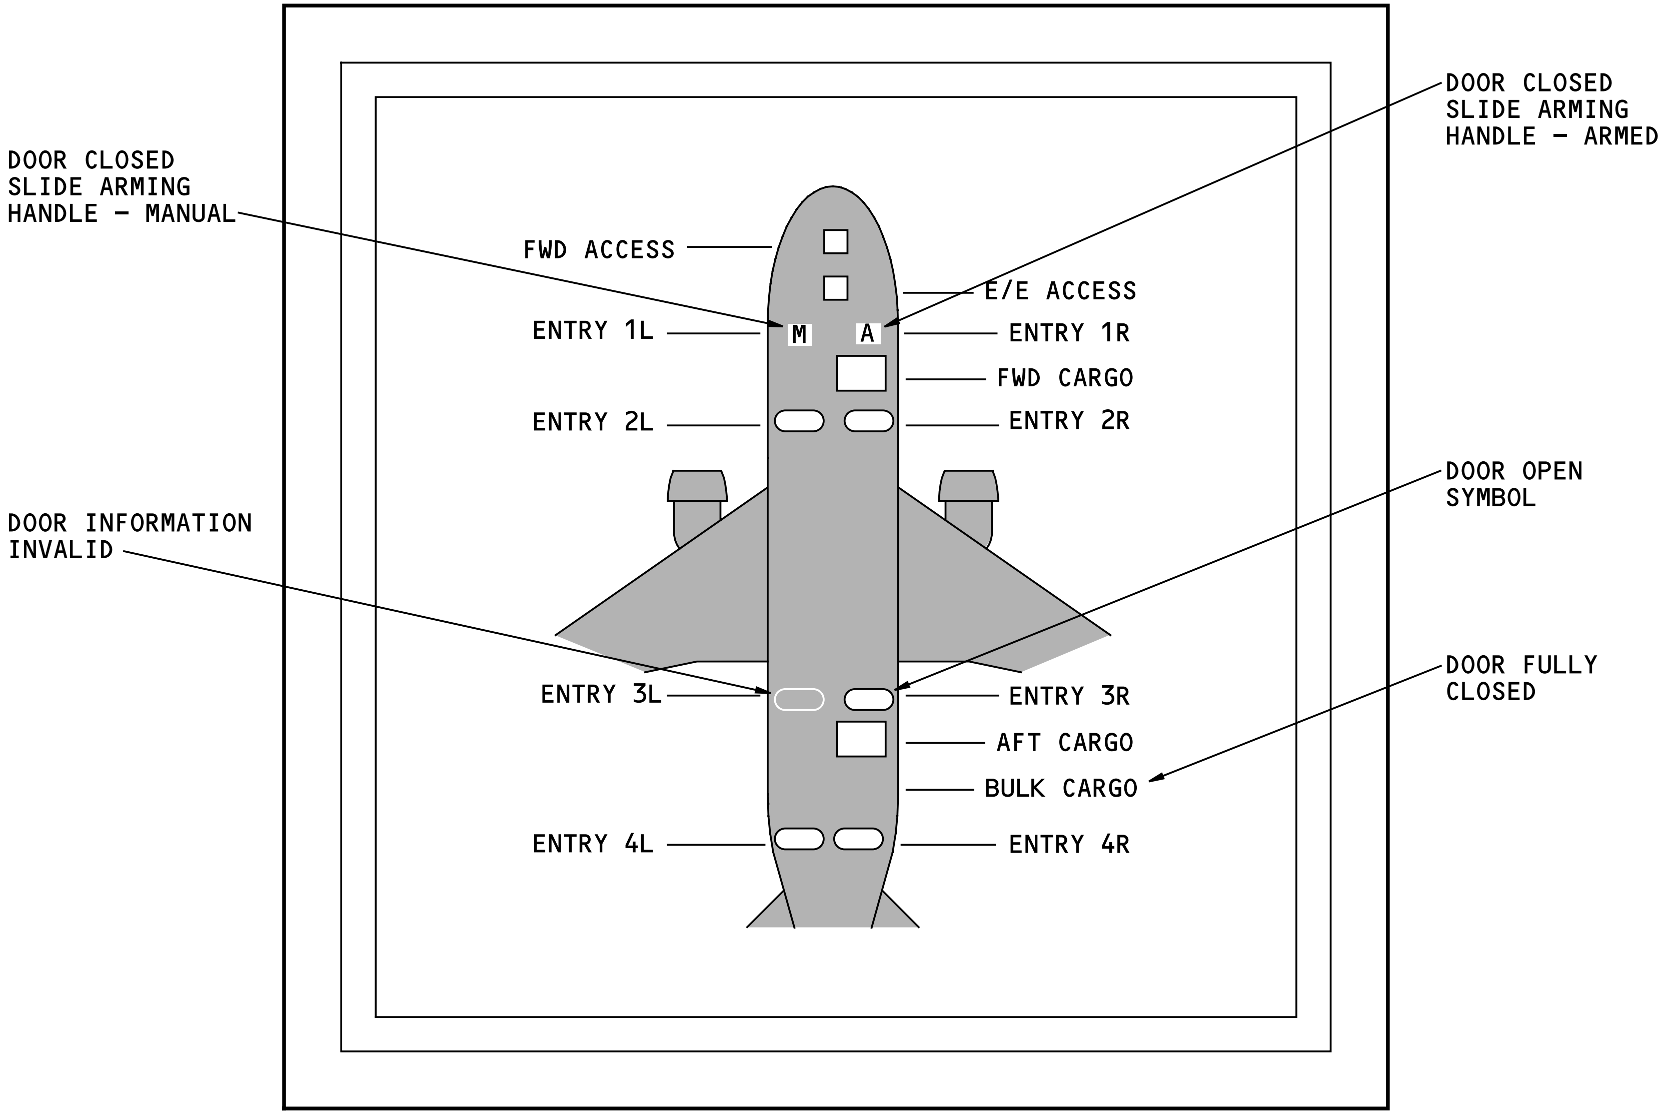
The door synoptic shows the status of these doors:

- Access doors
- Passenger entry doors
- Cargo doors.

The names of the doors always show. An amber symbol shows when a door is open or not completely closed. Cargo and access doors show nothing when they are fully closed. Invalid door information shows a white door symbol outline.

The slide arming handle position shows when the entry doors are fully closed. The symbol shows:

- A - for handle armed
- M - for handle in manual.



PRIMARY DISPLAY SYSTEM - DOOR SYNOPTIC

31-61-00-073 Rev 3 03/03/1998

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - FUEL SYNOPTIC

General

The fuel synoptic shows APU and ENG normal and non-normal pump status. The fuel synoptic also shows other ENG normal and non-normal fuel data. The fuel synoptic shows:

- APU pump status
- ENG pump status
- Total fuel
- Fuel quantity
- Fuel temperature and minimum fuel temperature
- Cross feed valve position
- Flow indications
- Fuel jettison.

APU Pump Status

The APU dc pump status shows as:

- Pump on (green)
- Pump off (white)
- Pump invalid (white).

ENG Pumps Status

The ENG ac pumps status show as:

- Pump on (green)
- Pump off (white)
- Pump invalid (white)
- Pump failed (amber with an X).

Total Fuel, Fuel Quantities, and Fuel Temperatures

The fuel synoptic shows this fuel information in the same way as the information on the EICAS display.

The legends are cyan and the readouts are white. For invalid or fail conditions, the readouts go away.

Fuel Balanced Message

A FUEL BALANCED message shows below total fuel when the left and right tanks disagree.

Cross Feed Valve Position

The valves show as one of these conditions:

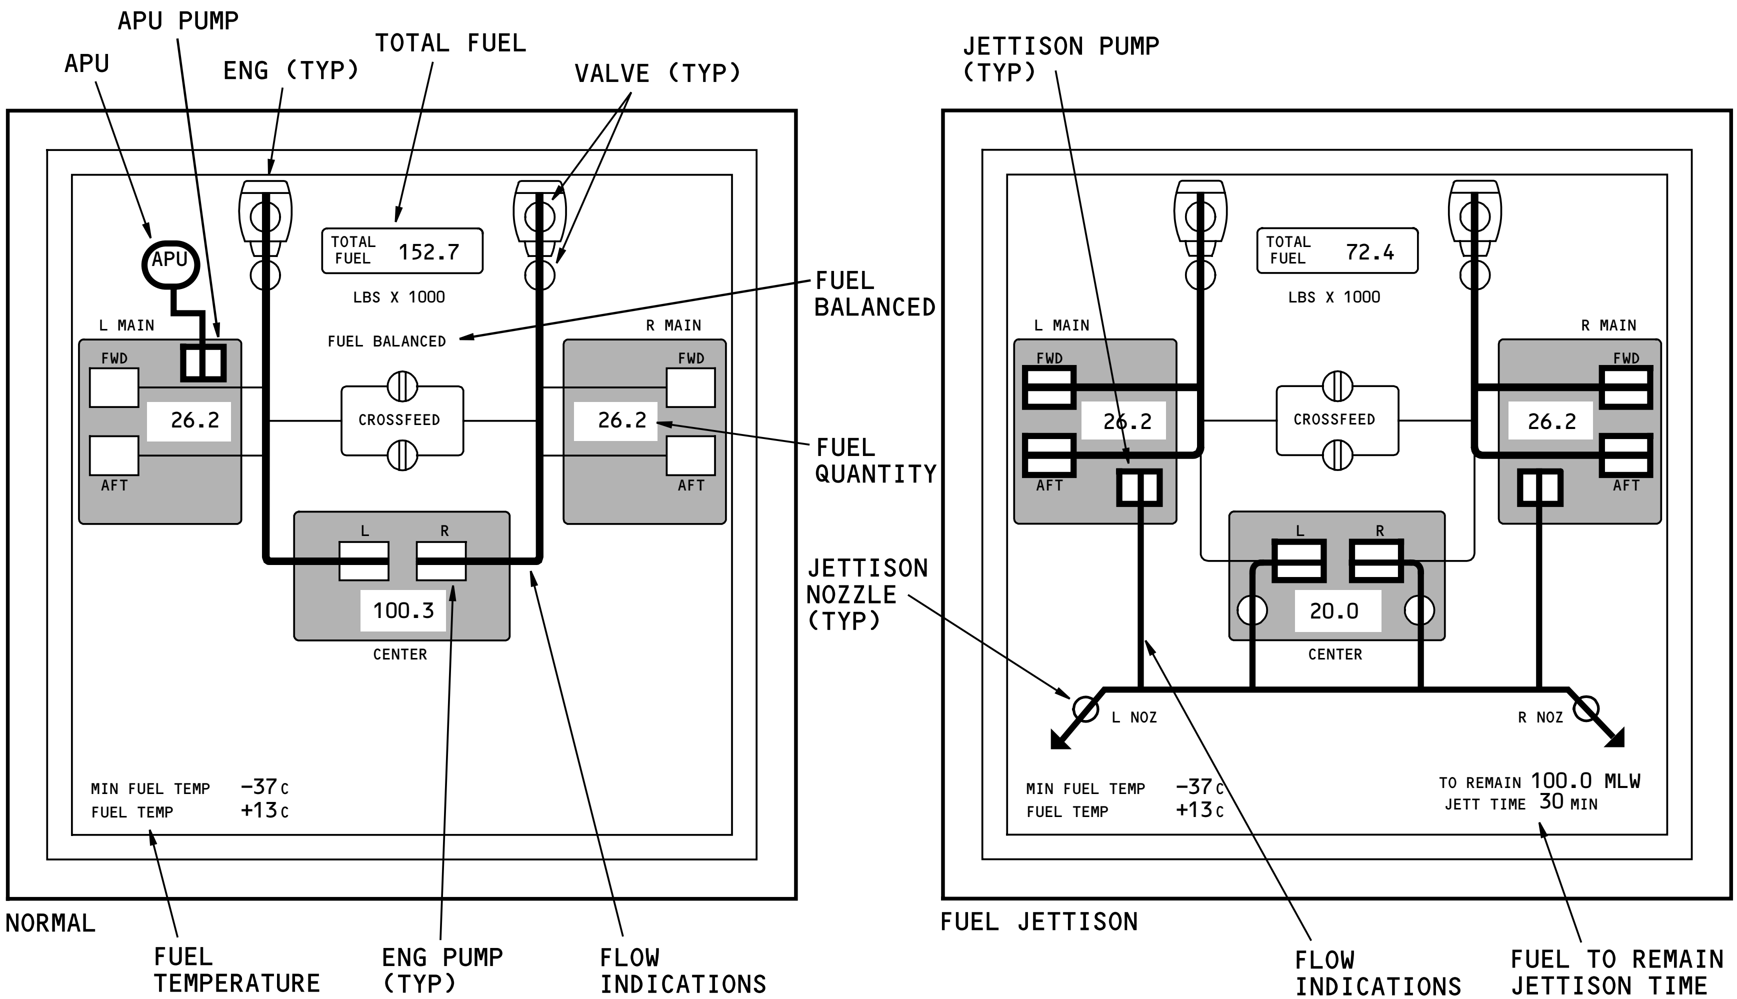
- Open
- Closed
- Failed open
- Failed closed
- Invalid.

Flow Indications

Automatic overrides and pressures cause fuel flow segments to show. Normal flow indications are green. When the engines use fuel with the pumps off, the flow indications are amber.

Fuel Jettison

During a fuel jettison condition, the fuel synoptic shows more information. The flow indications are magenta. The jettison pumps show. Fuel to remain and fuel jettison time also show.



31-61-00-074 Rev 1

PRIMARY DISPLAY SYSTEM - FUEL SYNOPTIC

PRIMARY DISPLAY SYSTEM - AIR SYNOPTIC

General

The air synoptic shows this information:

- Master temperature
- Zone temperature
- Flight deck trim valve position
- Bleed isolation valve status
- Anti-ice valve positions
- APU isolation valve status
- Engine bleed valve status
- Engine start valve status
- Pack status
- Duct pressure and ground air supply
- APU running status
- Air flow indications.

Temperatures

The master temperature shows as a magenta digital readout. Zone temperatures, target and actual, also show as magenta and white digital readouts.

Target and actual zone temperatures show for these areas:

- Flight deck
- Zones A through F
- Aft cargo
- Bulk cargo.

The target temperature is magenta. The actual temperature is white.

Valves

The trim valves show in several possible conditions.

An open valve is green with a horizontal bar. A closed valve is white with a vertical bar.

A failed open valve is amber with an X. A failed closed valve is amber with an X.

Pack Status

Pack status shows as a symbol. The symbol is green for a pack on condition. The symbol is white for a pack off or invalid condition. The symbol is amber with an X for a failed pack condition.

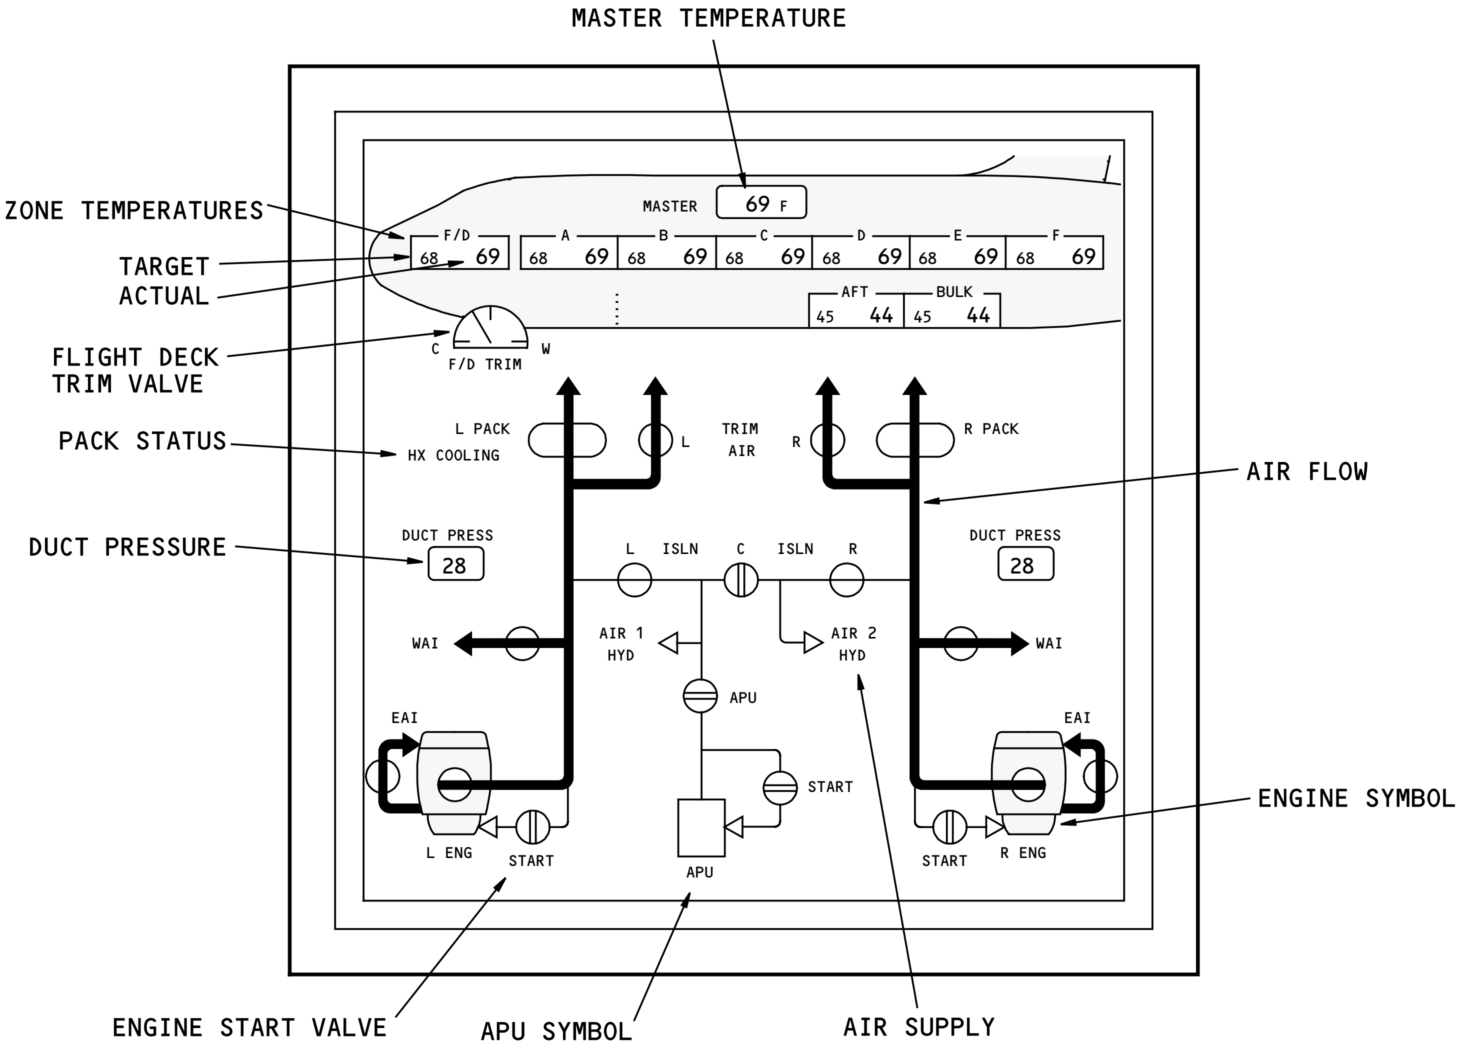
Duct Pressure and Ground Air Supply

Duct pressure shows as a digital readout.

The air source, either ground-air or an air-driven pump, shows as a cyan message.

APU Status

The APU symbol is green when the APU is running. The APU symbol is white when the APU is not running.



PRIMARY DISPLAY SYSTEM - AIR SYNOPTIC

31-61-00-075 Rev 1

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - HYDRAULIC SYNOPTIC

General

The hydraulic synoptic shows this information:

- User systems
- Flow indications
- Pump status
- Valve information
- Reservoir quantity and status
- System pressure.

User Systems

The systems that use hydraulic power show at the top of the display.

Flow Segments

Flow segments are green. Pressure causes a segment to show.

Pump Status

A pump on symbol is green. A pump off symbol is white. A pump invalid symbol is white. A pump failed symbol is amber with an X.

An overheat message (OVHT) shows for the primary engine pump, primary electrical pump, demand electrical pump, and the demand air pump.

Valve Information

The shutoff valve and reserve supply valve have four possible conditions. A valve open symbol is green with a vertical line. A valve closed symbol is white with a horizontal line. A valve invalid symbol is white with no line. A valve failed symbol is amber with an X.

The reserve isolation valve has four possible conditions. A valve normal symbol is green with a horizontal line. A valve isolation symbol is white with a wedge shaped horizontal line. A valve invalid symbol is white with no line. A valve failed symbol is amber with an X.

The nose gear and steering isolation valve has four possible conditions. A valve normal symbol is green with a horizontal line. A valve isolation symbol is white with a horizontal line. A valve invalid symbol is white with no line. A valve failed symbol is amber with an X.

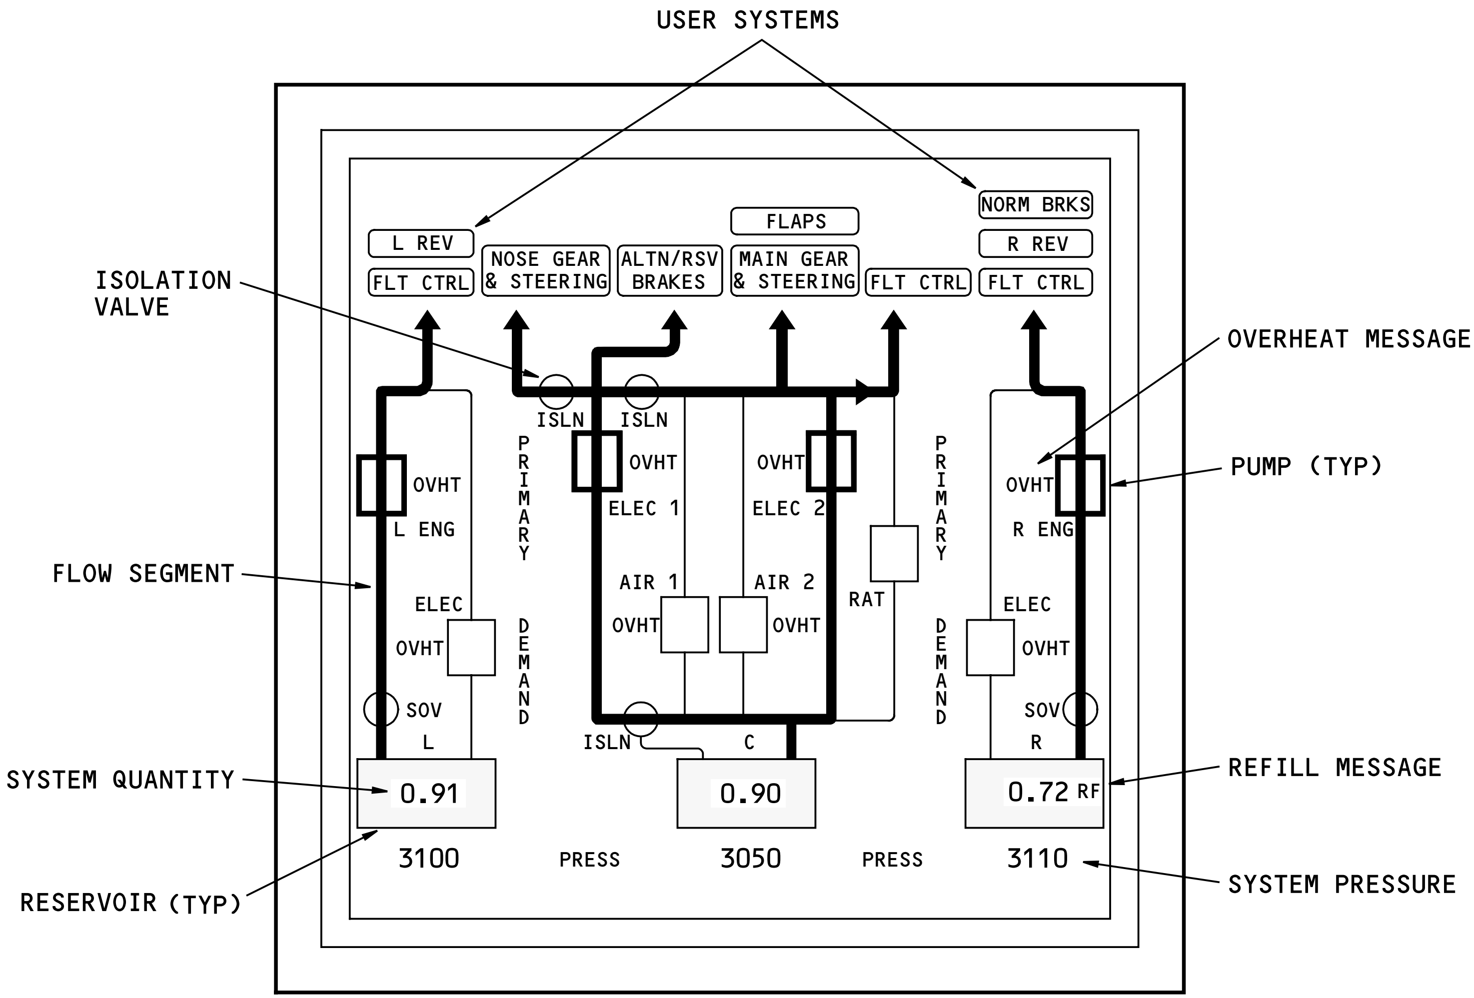
Reservoir Quantity and Status

Reservoir quantity for each tank shows as a digital readout. The readout values go from 0.0 to 1.20. A readout of 1.0 means the reservoir is full. When the airplane is on the ground, messages show for low quantity (LO), overfill (OF) or refill (RF). The quantity readout is normally white. The OF and RF messages are white. During a low condition, both the quantity readout and the LO message are amber.

PRIMARY DISPLAY SYSTEM - HYDRAULIC SYNOPTIC

System Pressure

System pressures show as digital readouts at the bottom the display.



31-61-00-076 Rev 1

PRIMARY DISPLAY SYSTEM - HYDRAULIC SYNOPTIC

PRIMARY DISPLAY SYSTEM - ELECTRICAL SYNOPTIC

General

The electrical synoptic shows:

- Bus information
- Bus tie breakers position
- Power flow
- Generator drive status and control
- Backup generator status
- Battery information.

Bus information

Buses show as a legend in an oval symbol. For invalid conditions, the symbols and legends are white. For unpowered conditions, the symbols and legends are amber. With power applied, the symbols and legends are green.

Bus Tie Breakers

The bus tie breaker symbol is circuit breaker with two circular contacts. During normal operation the symbol is white when the breaker is open and green when the breaker is closed. When the breaker is isolated and the bus tie is commanded closed or tripped, the symbol is amber. During these conditions an amber isolation message (ISLN) shows also.

Power Flow

Power flow shows as green segments.

Power sources show as green boxes when power is available and as white boxes when power is not available. Logic equations determine which flow segments show.

Generator Drive and Control

The generator symbols have four conditions. The drive on symbol is a green box. The drive off and drive invalid symbols are white boxes. The drive failed symbol is an amber box with an X.

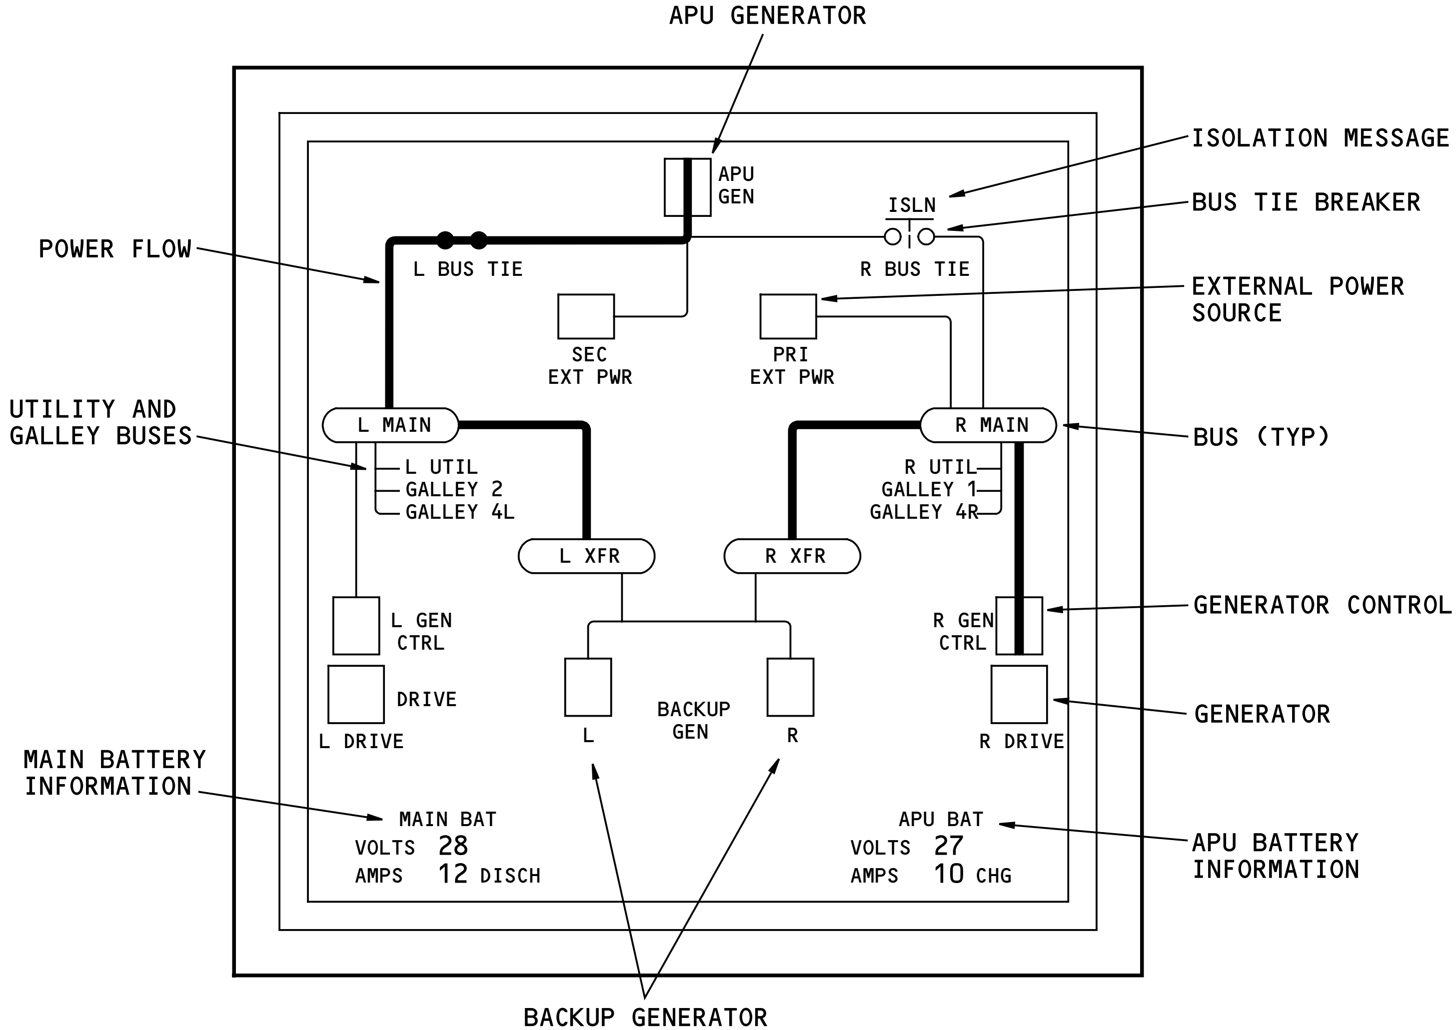
The generator control symbols have four conditions. The generator control breaker open and breaker invalid symbols are white boxes. The breaker closed symbol is a green box. The breaker failed symbol is an amber box with an X.

Backup Generator

The symbols for the backup generators are the same as the left and right generators.

Battery Information

Voltage, current, and battery charge status show for the main battery, and the APU battery.



31-61-00-077 Rev 0

PRIMARY DISPLAY SYSTEM - ELECTRICAL SYNOPTIC

PRIMARY DISPLAY SYSTEM - MAINTENANCE PAGES OVERVIEW

General

There are 18 system maintenance pages. The maintenance pages supply information that is useful in the analysis and repair of airplane systems.

You can select and see maintenance pages any time the airplane is on the ground or any time the airplane is above ten thousand feet.

The information shows in real time or as a snapshot (manual event or auto event). Snapshots occur automatically when individual systems exceed established parameters. The operator can print or downlink the maintenance pages to ground stations.

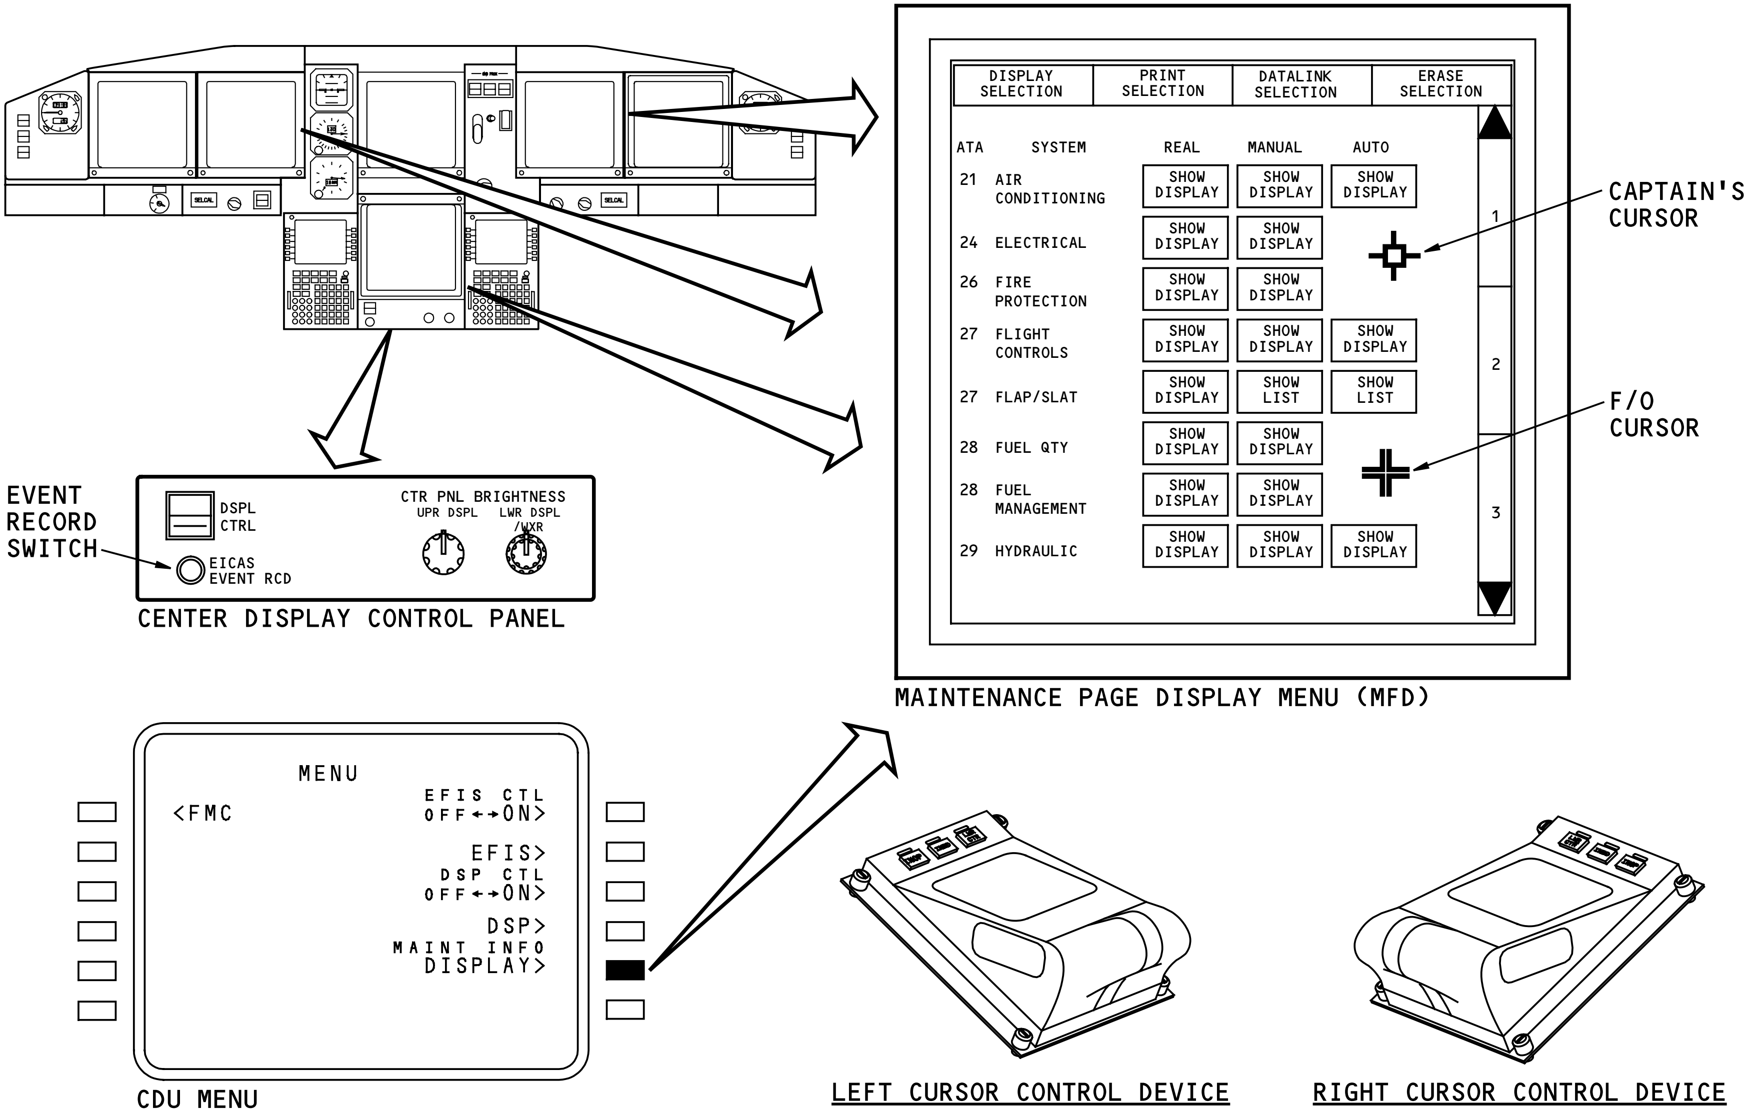
You can also take a manual snapshot of all the maintenance pages or of individual maintenance pages.

Maintenance Page Controls

The MAINT INFO prompt on the left, center, or right CDU gives access to the maintenance pages on the multifunction display (MFD). You use the display select panel and the display switching panels to show the maintenance page display selection menu on the lower center, left inboard, or right inboard display units.

The EICAS event record switch on the center display control panel lets the operator take a manual snapshot of all the applicable maintenance pages at the same time. A snapshot is a picture of a maintenance page frozen in time.

You use the cursor control device to control more menu selections. Move your finger on the CCD touchpad to move the cursor symbol on the display. When the cursor is over the desired selection, use the cursor activation switch to make the selection. Each corner of the CCD touchpad has a "hot spot". This causes the cursor to go the related corner of the display. This gives you quick access to frequently used menu selections.



PRIMARY DISPLAY SYSTEM - MAINTENANCE PAGES OVERVIEW

31-61-00-078 Rev 5 03/31/95

PRIMARY DISPLAY SYSTEM - MAINTENANCE PAGE MAIN MENU BAR SELECTIONS

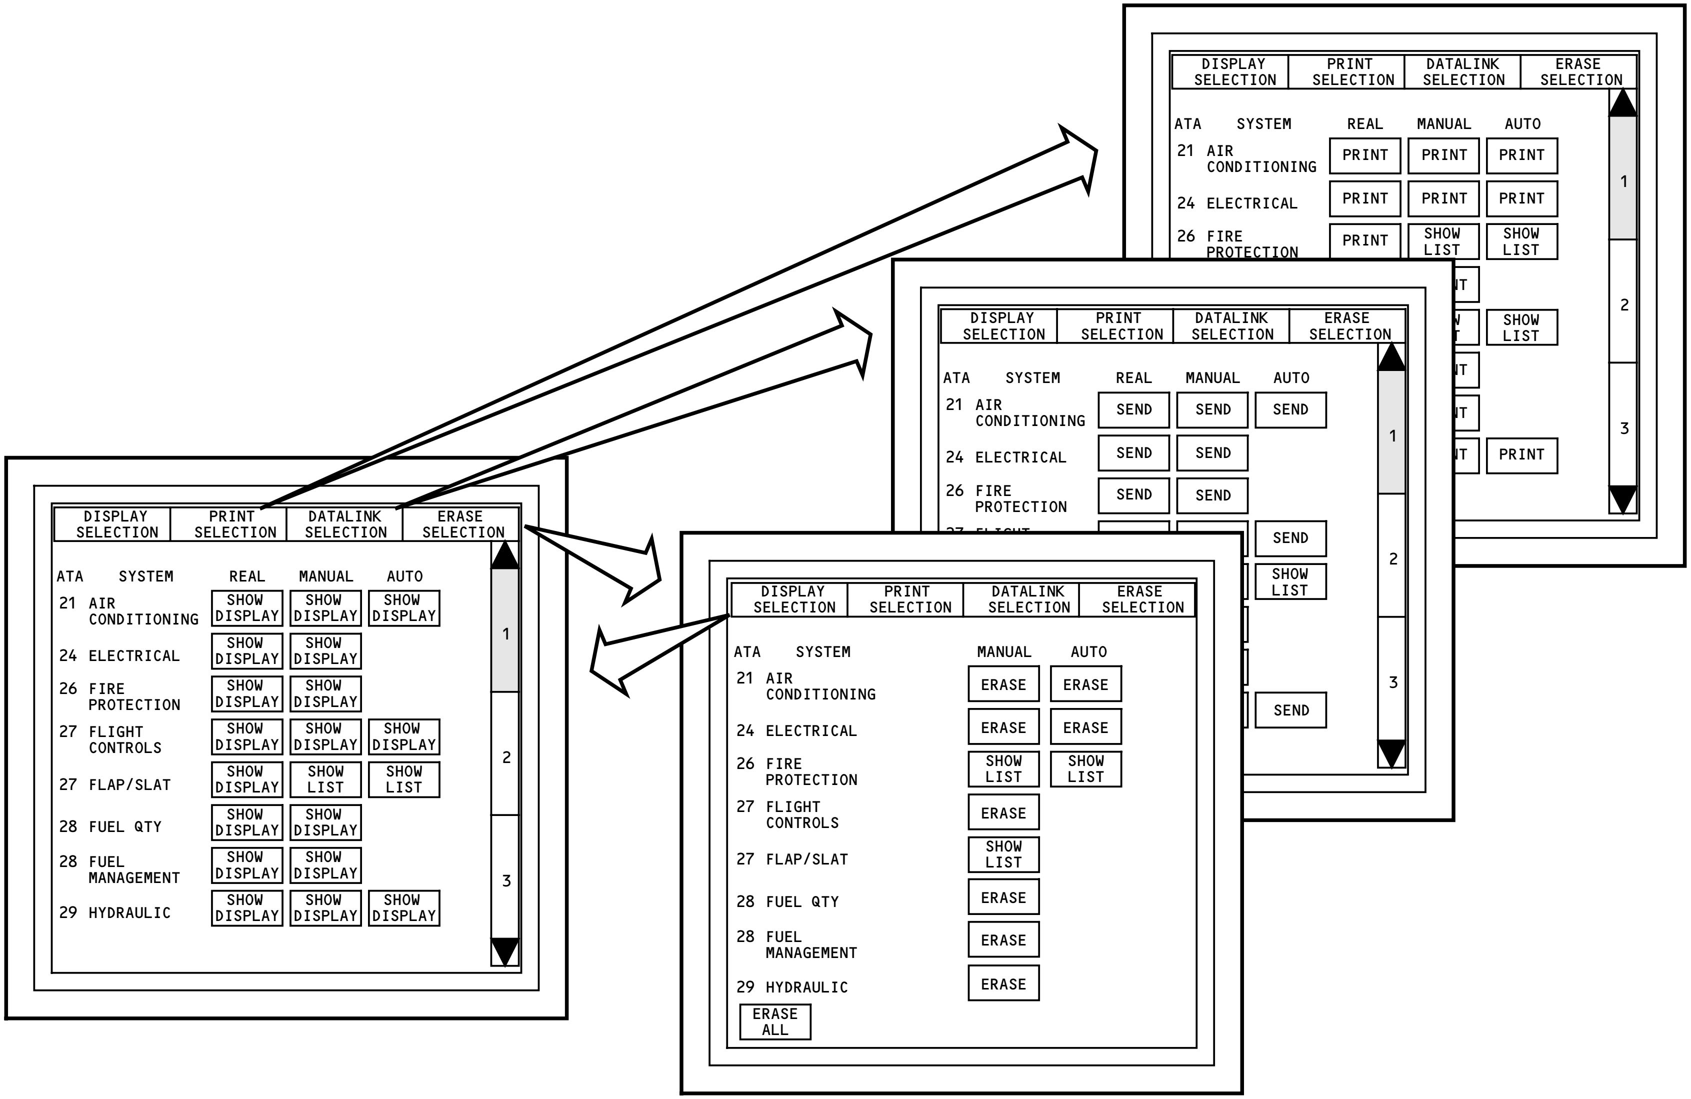
General

The main menu bar lets the operator choose a specific function and move from one function to another. The functions available are:

- DISPLAY SELECTION - This prompt lets the operator show real time or existing, manual snapshots, or auto snapshots of maintenance pages.
- PRINT SELECTION - This prompt lets the operator print real time or existing, manual snapshots, or auto snapshots of maintenance pages.
- DATA LINK SELECTION - This prompt lets the operator downlink real time or existing, manual snapshots, or auto snapshots of maintenance pages.
- ERASE SELECTION - This prompt lets the operator erase manual or auto snapshots of maintenance pages.

After a selection, the main menu function highlights.

The maintenance pages are in ATA sequence on all the menu pages. For the ERASE function, only those ATAs with manual or auto snapshots in memory show.



31-61-00-079 Rev 1 02/25/95

PRIMARY DISPLAY SYSTEM - MAINTENANCE PAGE MAIN MENU BAR SELECTIONS

PRIMARY DISPLAY SYSTEM - MAINTENANCE PAGE DISPLAY SELECTION MENUS

General

The DISPLAY menu gives access when you select a maintenance page to real time information, auto snapshots, and manual snapshots. These are the display selections:

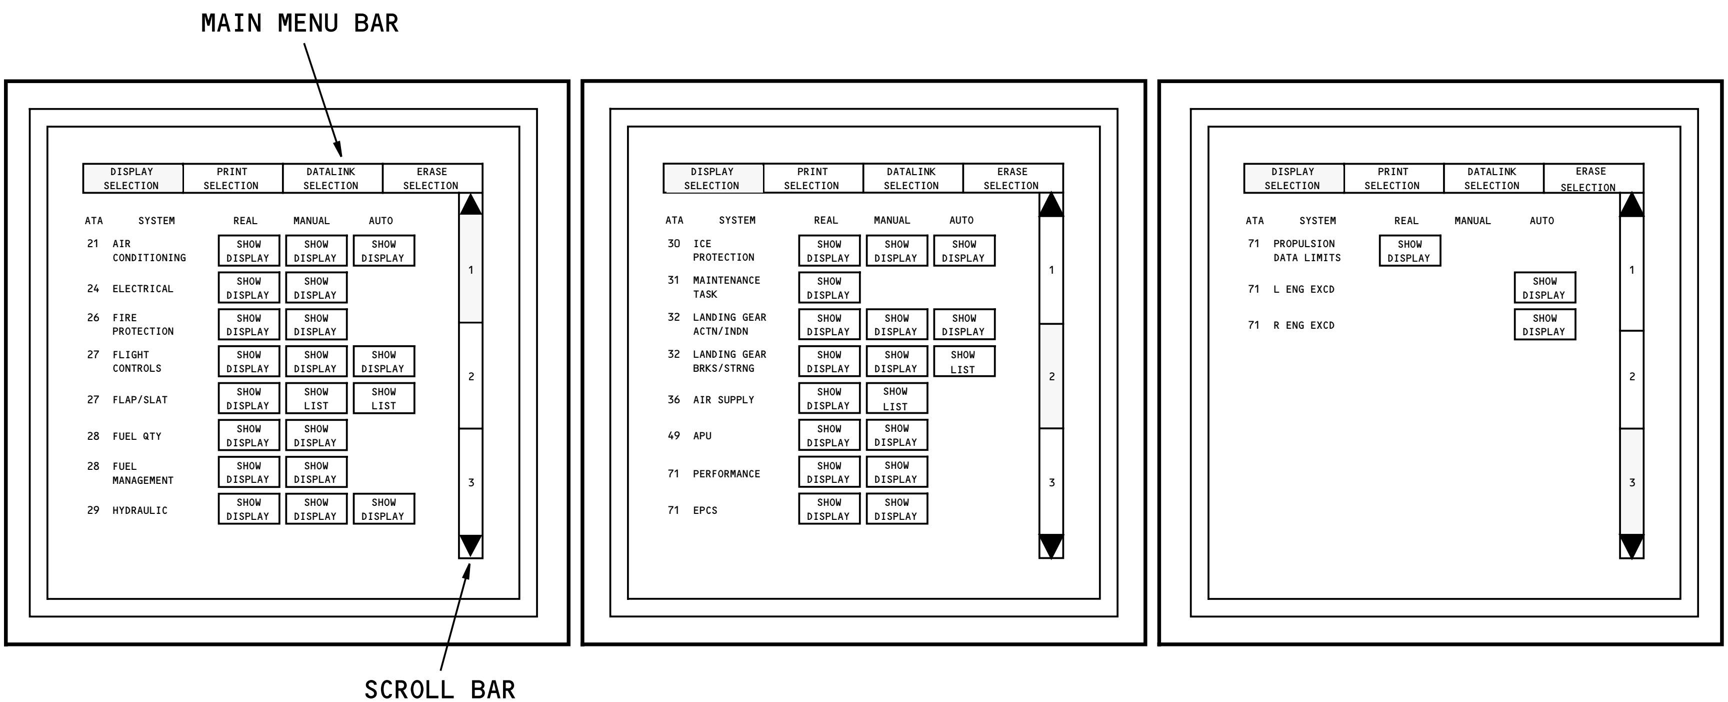
- SHOW DISPLAY - This selection shows the real time display of the maintenance page. It also shows a single auto or manual snapshot in memory
- SHOW LIST - This selection shows if there is more than one auto or manual snapshot in memory.

A blank area next to any selection means there are no selections for that maintenance page.

Maintenance Page Selections

There are three pages of maintenance page selections. They show in ATA sequence. A scroll bar at the right of the display lets the operator select the appropriate menu page. A highlight shows around the applicable page number. These are the selections:

- 21 AIR CONDITIONING
- 24 ELECTRICAL
- 26 FIRE PROTECTION
- 27 FLIGHT CONTROLS
- 27 FLAP/SLAT
- 28 FUEL QUANTITY
- 28 FUEL MANAGEMENT
- 29 HYDRAULIC
- 30 ICE PROTECTION
- 31 MAINTENANCE TASK
- 32 LANDING GEAR ACTUATION/INDICATION
- 32 LANDING GEAR BRAKES/STEERING
- 36 AIR SUPPLY
- 49 APU
- 71 PERFORMANCE
- 71 EPCS
- 71 PROPULSION DATA LIMITS
- 71 LEFT ENGINE EXCEEDANCE
- 71 RIGHT ENGINE EXCEEDANCE.



31-61-00-080 Rev 0

PRIMARY DISPLAY SYSTEM - MAINTENANCE PAGE DISPLAY SELECTION MENUS

PRIMARY DISPLAY SYSTEM - MAINTENANCE PAGE AUTO AND MANUAL EVENT MENU PAGES

General

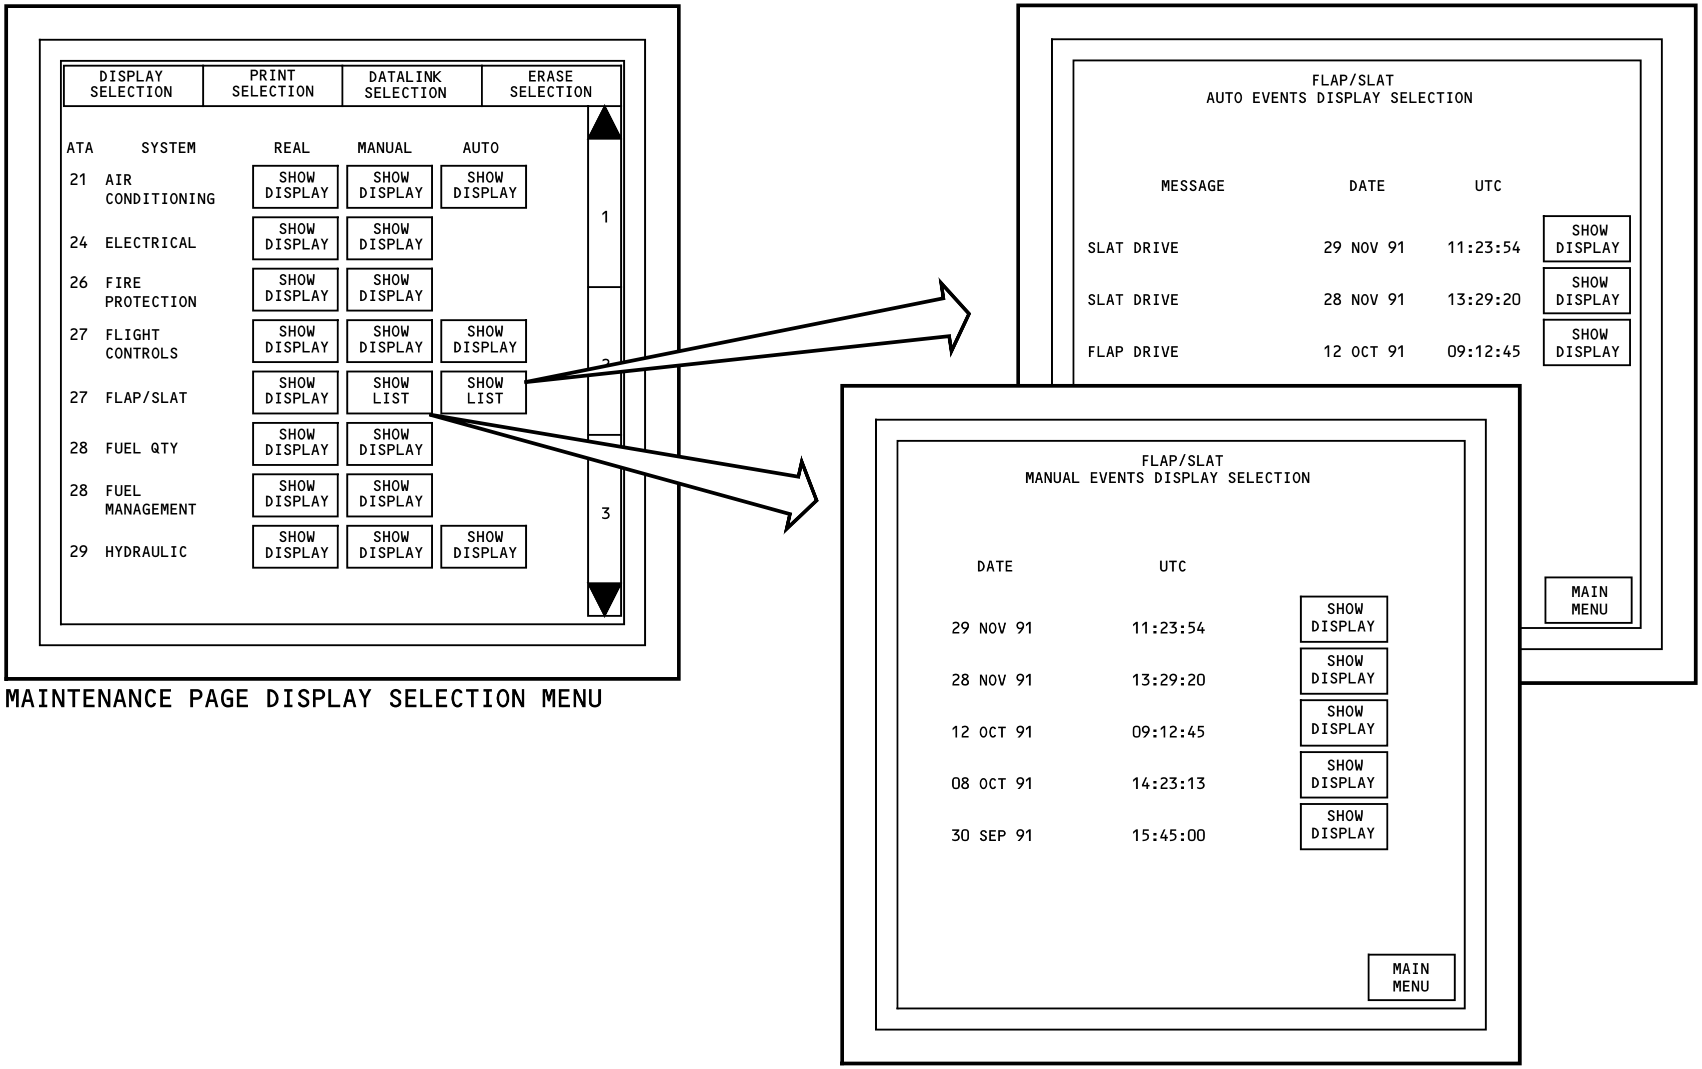
The SHOW DISPLAY prompt shows next to the maintenance page in the applicable column when one manual or auto snapshot is in memory.

The SHOW LIST prompt shows next to the maintenance page when there is more than one manual or auto snapshots for that system.

The selection of the SHOW LIST prompt causes a menu to show that lists the snapshots that are in memory. AIMS stores up to five manual snapshots and five auto snapshots for each system. The menu page shows the maintenance page category at the top and the date and time of each snapshot. The auto event menu page also shows the associated auto event message.

The SHOW DISPLAY prompt causes the maintenance page in memory to show on the display unit.

The MAIN MENU prompt at the bottom-right returns the operator to the DISPLAY SELECTION menu.



31-61-00-081 Rev 2 03/31/95

PRIMARY DISPLAY SYSTEM - MAINTENANCE PAGE AUTO AND MANUAL EVENT MENU PAGES

PRIMARY DISPLAY SYSTEM - MAINTENANCE PAGE PRINT MENUS

General

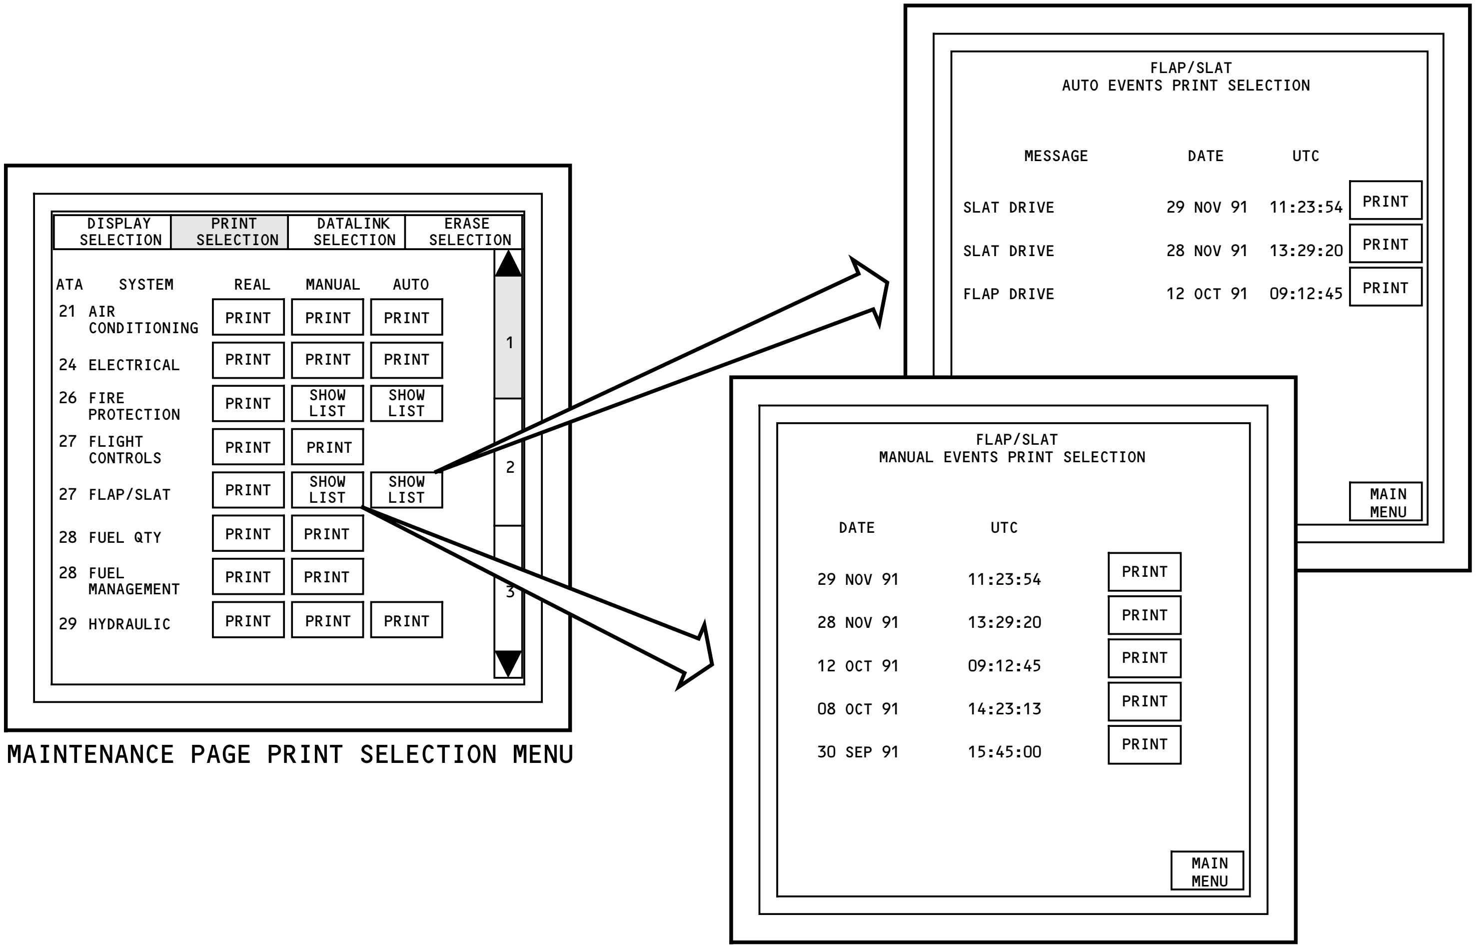
The PRINT SELECTION menu lets the operator print real time displays, manual snapshots, or auto snapshots of the maintenance pages.

A PRINT prompt shows for the real time displays. A PRINT prompt also shows for manual or auto snapshots when one snapshot is in memory.

A SHOW LIST prompt shows when more than one auto or manual snapshot is in memory.

Selection of the SHOW LIST prompt causes a menu page to show that lists the maintenance pages in memory. The PRINT prompt lets the operator print the individual pages.

The MAIN MENU prompt returns the operator to the PRINT SELECTION menu page.



MAINTENANCE PAGE PRINT SELECTION MENU

31-61-00-082 Rev 1 09/22/1995

PRIMARY DISPLAY SYSTEM - MAINTENANCE PAGE PRINT MENUS

PRIMARY DISPLAY SYSTEM - MAINTENANCE PAGE DATALINK MENUS

General

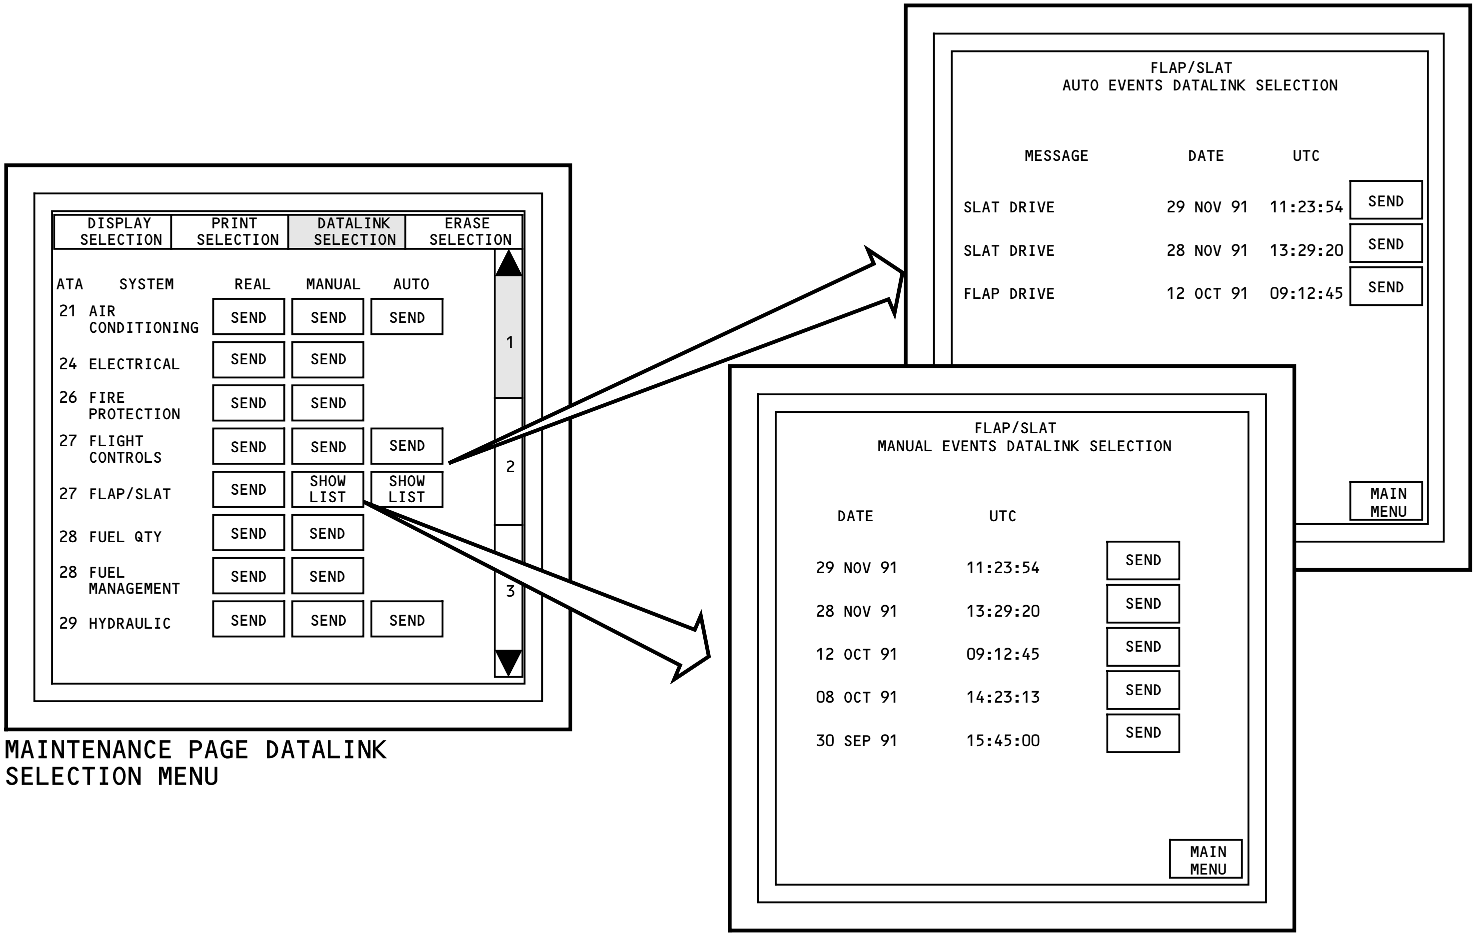
The DATALINK SELECTION menu lets the operator downlink real time displays, manual snapshots or auto snapshots of the maintenance pages.

A SEND prompt shows for the real time displays. A SEND prompt also shows for manual or auto snapshots when one snapshot is in memory.

A SHOW LIST prompt shows when more than one auto or manual snapshot is in memory.

Selection of the SHOW LIST prompt causes a menu page to show that lists the maintenance pages in memory. The SEND prompt lets the operator downlink the individual pages.

The MAIN MENU prompt returns the operator to the DATALINK SELECTION menu page.



31-61-00-083 Rev 1 09/22/1995

PRIMARY DISPLAY SYSTEM - MAINTENANCE PAGE DATALINK MENUS

PRIMARY DISPLAY SYSTEM - MAINTENANCE PAGE ERASE MENUS

General

The ERASE SELECTION menu lets the operator erase manual and auto snapshots of the maintenance pages. You cannot erase snapshots when the airplane is in the air.

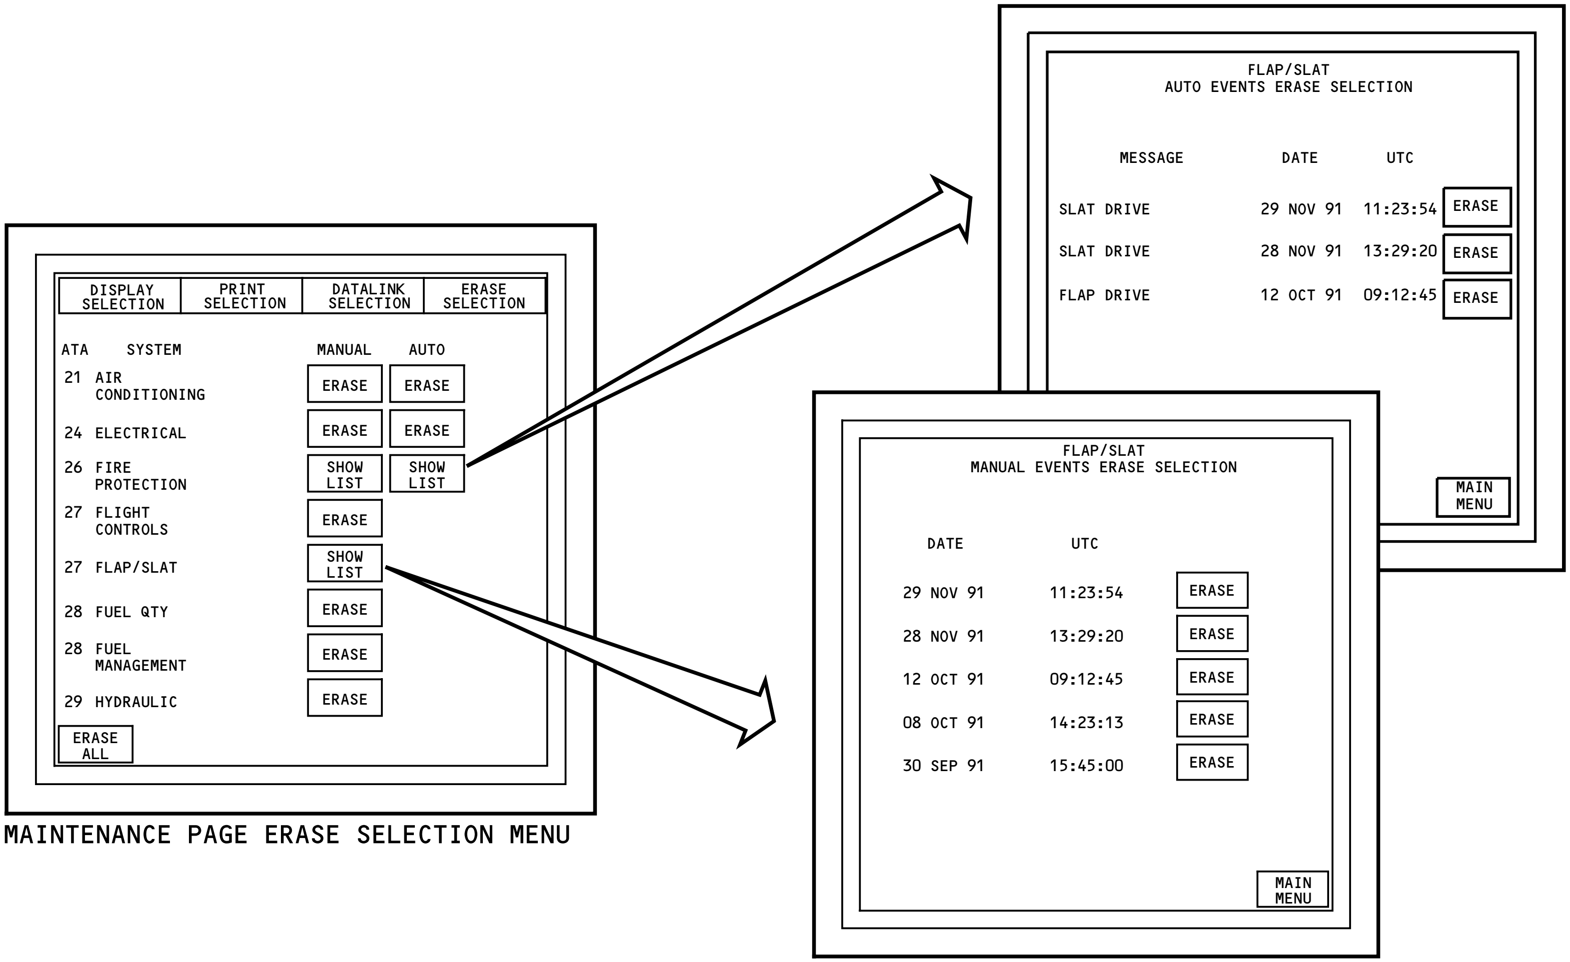
An ERASE prompt shows for maintenance pages when only one manual or one auto snapshot is in memory.

A SHOW LIST prompt shows when more than one auto or manual snapshot is in memory.

Selection of the ERASE ALL prompt erases all manual and auto events (snapshots) stored in non volatile memory.

Selection of the SHOW LIST prompt causes a menu page to show that lists the maintenance pages in memory. The ERASE prompt lets the operator erase the individual pages.

The MAIN MENU prompt returns the operator to the ERASE SELECTION menu page.



31-61-00-084 Rev 3 10/23/95

PRIMARY DISPLAY SYSTEM - MAINTENANCE PAGE ERASE MENUS

PRIMARY DISPLAY SYSTEM - INDIVIDUAL MAINTENANCE PAGE MENUS

General

Each maintenance page format except for the maintenance task maintenance page has several possible menu selections. The SHOW PG MENU or the CANCEL PAGE MENU shows in the top left corner of each maintenance page.

The SHOW PG MENU causes several menu selections to show across the bottom of the maintenance page and causes the CANCEL PAGE MENU selection to show at the top left of the display.

The CANCEL PAGE MENU causes the menu selections across the bottom of the maintenance page to go away and causes the SHOW PG MENU selection to show at the top left of the display.

The menu functions are available for real time, auto, or manual snapshot displays.

These are the commands that show across the bottom of the display:

- SEND - This selection lets the operator downlink the maintenance page that shows
- PRINT - This selection lets the operator print the maintenance page that shows
- ERASE - This selection lets the operator erase the manual or auto event for maintenance page that shows. This selection does not show for a real time format
- RECORD - This selection lets the operator take a manual snapshot of the maintenance page that shows (real time only)
- NEXT PAGE and PREV PAGE - This selection lets the operator page through a sequence of pages for systems that have more than one page format
- PREV MENU - This selection lets the operator return to MANUAL (AUTO) EVENT SELECTION page for the maintenance page that shows if they were accessed by the MANUAL (AUTO) EVENT SELECTION menu pages
- MAIN MENU - The selection lets the operator return to the DISPLAY SELECTION menu page. This selection is available on the maintenance task maintenance page.

Training Information Point

The ATA that shows can have more than one page. These command buttons will cause the selected action on all pages of the ATA:

- SEND
- PRINT
- ERASE
- RECORD.

PRIMARY DISPLAY SYSTEM - INDIVIDUAL MAINTENANCE PAGE MENUS

PRIMARY DISPLAY SYSTEM - AIR CONDITIONING MAINTENANCE PAGE

General

The air conditioning maintenance page is available in these three display modes:

- Real time
- Manual event
- Auto event.

Title

The title shows the display mode. The title shows as:

- AIR CONDITIONING for the real time mode
- AIR CONDITIONING MAN for the manual event mode
- AIR CONDITIONING AUTO for the auto event mode.

Auto Event Message

In the real time mode, the auto event message shows for the most recent auto event in memory. If there are no auto events in memory, the message field is blank.

In the auto event mode, the message for the incident shows.

There is no message in the manual event mode.

Date and Time

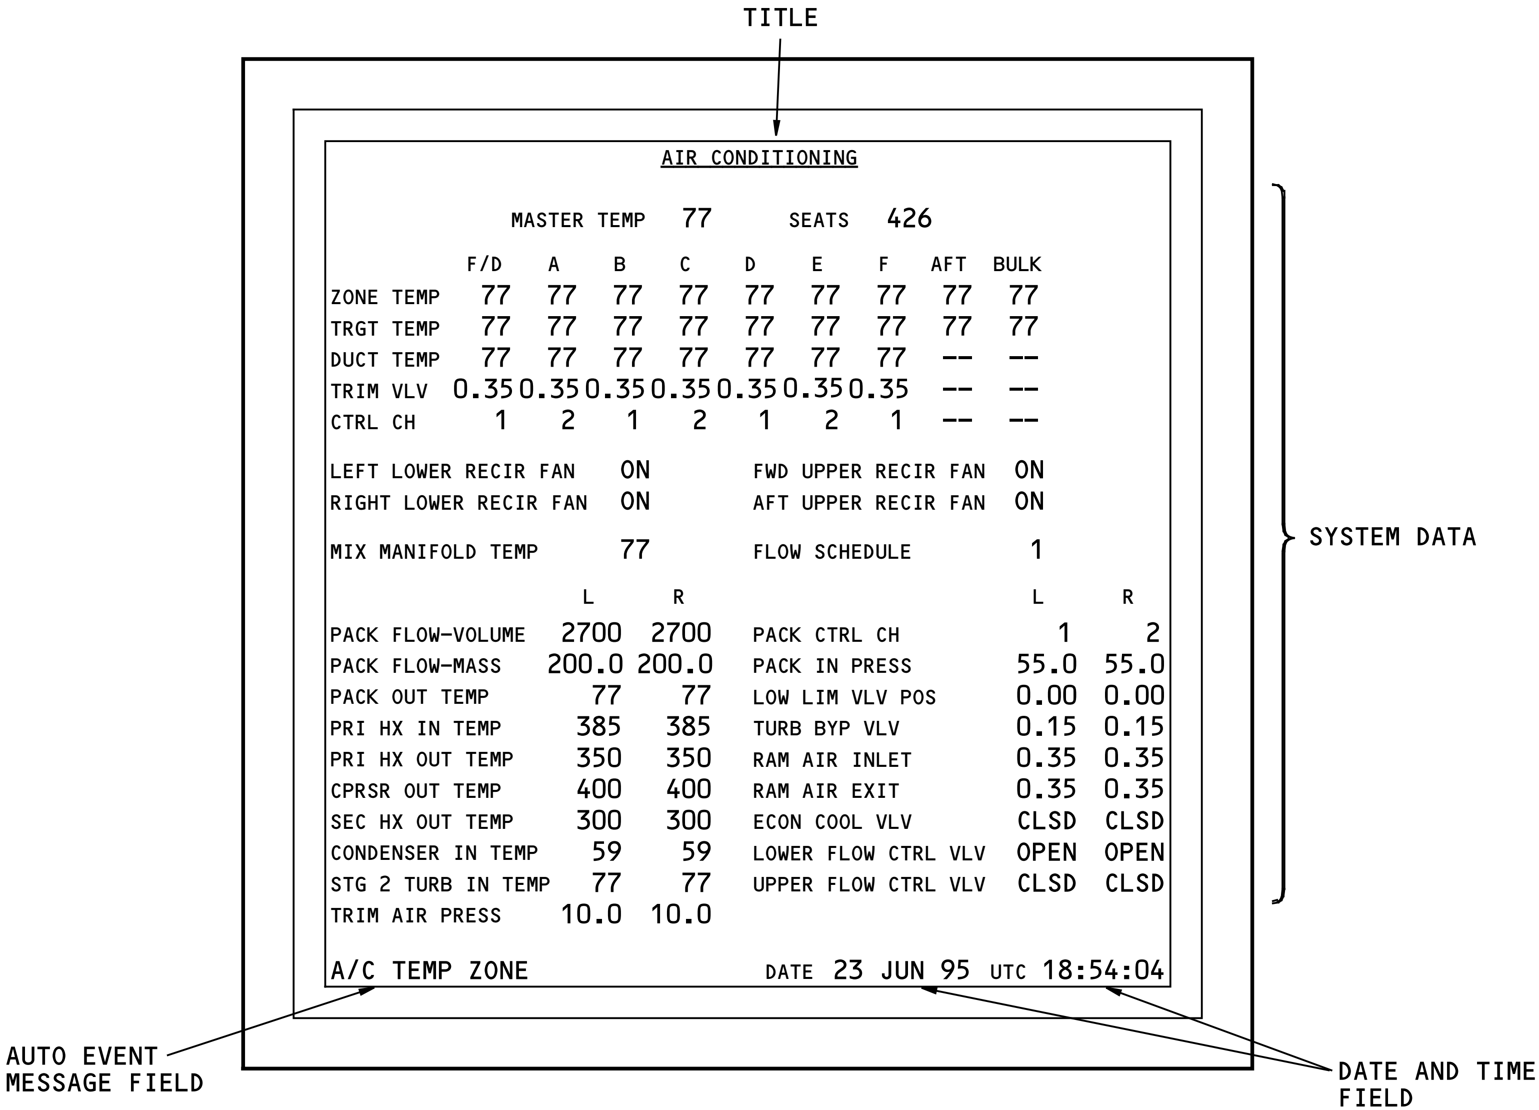
In the real time mode, the date field shows the current date and universal coordinated time (UTC).

In the manual event mode and the auto event mode, the date field shows the date and UTC of the incident.

System Data

The air conditioning maintenance page shows environmental control system information. The information includes:

- Zone temperature
- Target temperature
- Duct temperature
- Trim valve position
- Recirculation fan status
- Trim air pressure
- Pack outlet temperature
- Pack flow
- Turbine bypass valve position
- Ram air inlet/exit positions
- Compressor outlet temperature
- Cabin temperature controller channel in control.



31-61-00-086 Rev 1

PRIMARY DISPLAY SYSTEM - AIR CONDITIONING MAINTENANCE PAGE

PRIMARY DISPLAY SYSTEM - ELECTRICAL MAINTENANCE PAGES

General

There are two electrical maintenance pages. They are available in these three display modes:

- Real time
- Manual event
- Auto event.

Title

The titles show the display mode and page number. The titles show as:

- ELECTRICAL PG 1/2 for the real time mode
- ELECTRICAL PG 2/2 for the real time mode
- ELECTRICAL MAN 1/2 for the manual event mode
- ELECTRICAL MAN 2/2 for the manual event mode
- ELECTRICAL AUTO 1/2 for the auto event mode
- ELECTRICAL AUTO 2/2 for the auto event mode.

Auto Event Message

In the real time mode, the auto event message shows for the most recent auto event in memory. If there are no auto events in memory, the message field is blank. The message shows on both pages.

In the auto event mode, the message for the incident shows. The message shows on both pages.

There is no message in the manual event mode.

Date and Time

In the real time mode, the date field shows the current date and universal coordinated time (UTC).

In the manual event mode and the auto event mode, the date field shows the date and UTC of the incident.

System Data

The information on electrical maintenance page 1/2 includes:

- AC voltage
- AC frequency
- AC load
- DC voltage
- DC amperage
- IDG outlet/rise temperature
- IDG oil and oil filter information
- Fly by wire (FBW) DC system information.

The electrical maintenance page 2/2 has bus status information for the:

- AC buses
- AC standby bus
- DC buses
- DC standby bus
- Ground service bus
- Ground handling bus.

There are three flight control maintenance pages. They are available in three display modes. They are:

- Real time
- Manual event
- Auto event.

Title

The titles show the display mode and page number. The titles show as:

- FLIGHT CONTROL PG 1/3 for the real time mode
- FLIGHT CONTROL PG 2/3 for the real time mode
- FLIGHT CONTROL PG 3/3 for the real time mode
- FLIGHT CONTROL MAN PG 1/3 for the manual event mode
- FLIGHT CONTROL MAN PG 2/3 for the manual event mode
- FLIGHT CONTROL MAN PG 3/3 for the manual event mode
- FLIGHT CONTROL AUTO 1/3 for the auto event mode
- FLIGHT CONTROL AUTO 2/3 for the auto event mode
- FLIGHT CONTROL AUTO 3/3 for the auto event mode.

Auto Event Message

In the real time mode, the auto event message shows for the most recent auto event in memory. If there are no auto events in memory, the message field is blank. The message shows on all pages.

In the auto event mode, the message for the incident shows. The message shows on all pages.

There is no message in the manual event mode.

Date and Time

In the real time mode, the date field shows the current date and universal coordinated time (UTC).

In the manual event mode and the auto event mode, the date field shows the date and UTC of the incident.

System Data

The information on the flight controls maintenance page 1/3 includes:

- Airplane state information (roll, pitch, yaw etc.)
- Column information
- Wheel information
- Pedal information
- Speed brake handle information
- Rudder trim position data
- Column feel data
- Gust suppression data
- Flight mode information.

The information on the flight controls maintenance page 2/3 includes:

- Spoiler position data
- Hydraulic pressure data

PRIMARY DISPLAY SYSTEM - FLIGHT CONTROLS MAINTENANCE PAGES

- Flaperon position data
- Aileron position data
- Rudder position data
- Elevator position data
- Stab position data.

The information on the flight controls maintenance page 3/3 includes:

- Manual event
- Auto event.

Title

The titles show the display mode and page number. The titles show as:

- FUEL QTY PG 1/2 for the real time mode
- FUEL QTY PG 2/2 for the real time mode
- FUEL QTY MAN 1/2 for the manual event mode
- FUEL QTY MAN 2/2 for the manual event mode
- FUEL QTY AUTO 1/2 for the auto event mode
- FUEL QTY AUTO 2/2 for the auto event mode.

Auto Event Message

In the real time mode, the auto event message shows for the most recent auto event in memory. If there are no auto events in memory, the message field is blank. The message shows on both pages.

In the auto event mode, the message for the incident shows. The message shows on both pages.

There is no message in the manual event mode.

Date and Time

In the real time mode, the date field shows the current date and universal coordinated time (UTC).

In the manual event mode and the auto event mode, the date field shows the date and UTC of the incident.

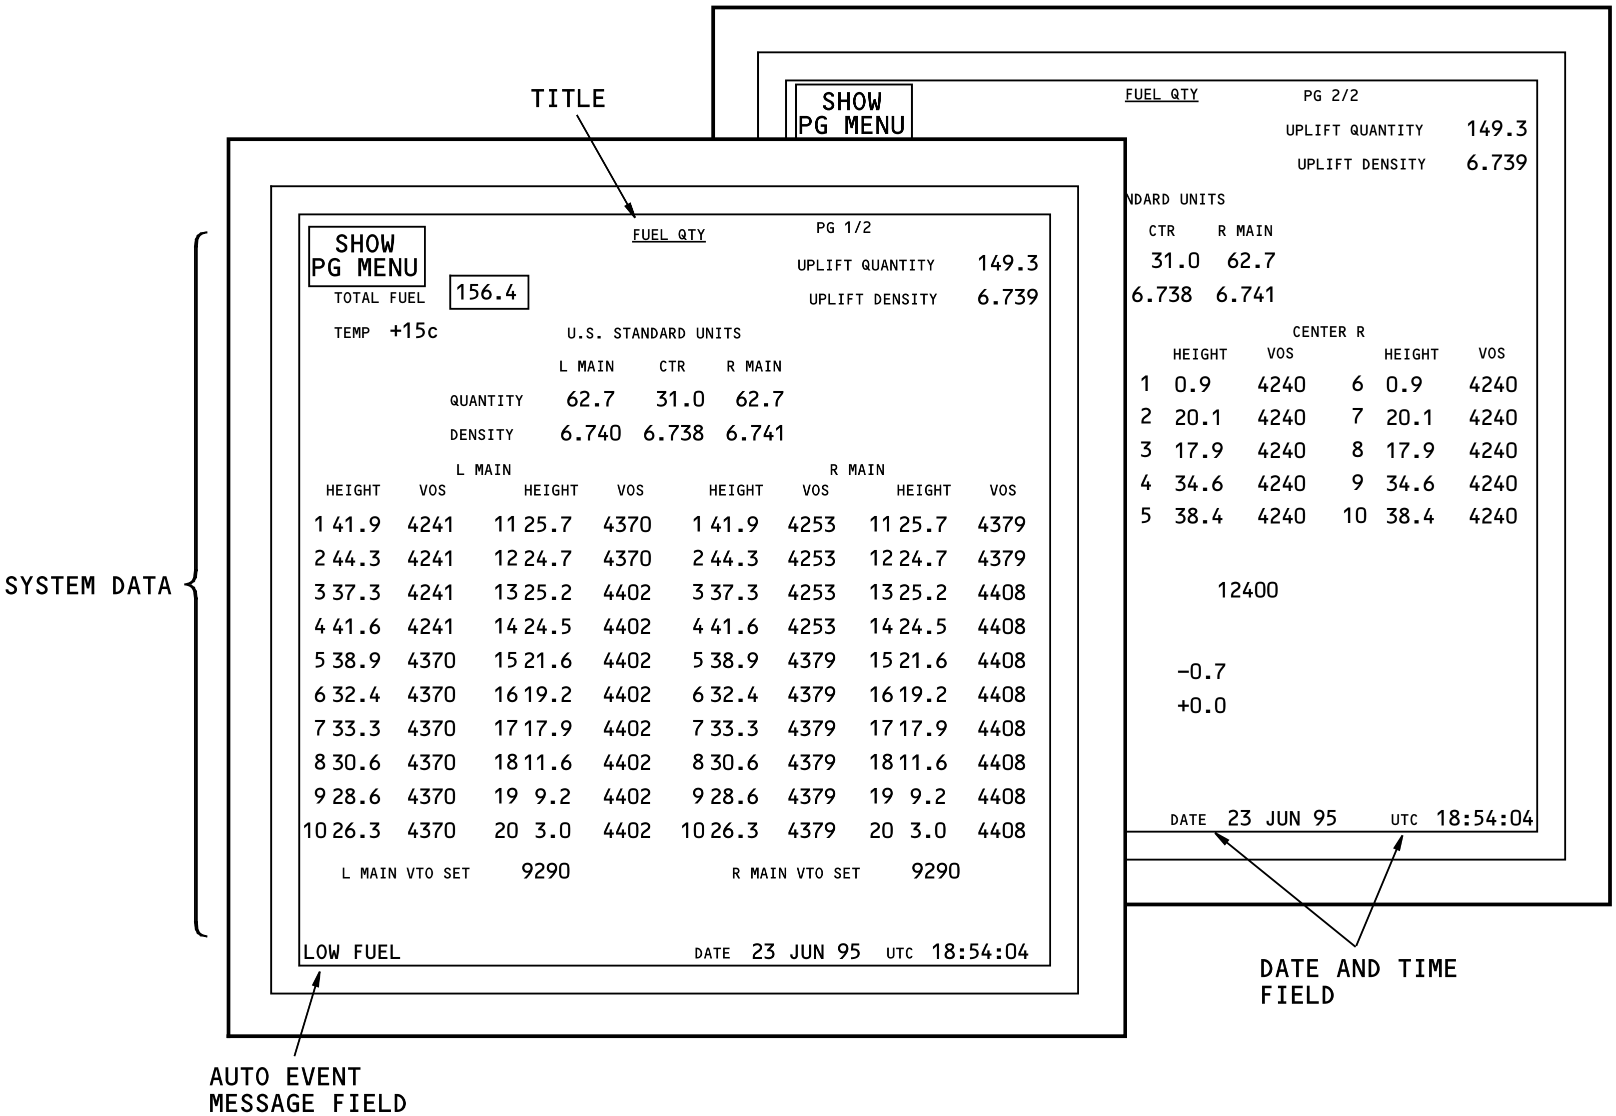
System Data

The information on fuel quantity maintenance page 1/2 includes:

- Total fuel quantity
- Total fuel density
- Main tank ultrasonic probe velocity of sound
- Main tank fuel height
- Main tank volume top-off data.

The information on fuel quantity maintenance page 2/2 includes:

- Total fuel quantity
- Total fuel density
- Center tank ultrasonic probe velocity of sound
- Center tank fuel height
- Center tank volume top-off data
- Pitch and roll data.



PRIMARY DISPLAY SYSTEM – FUEL QUANTITY MAINTENANCE PAGES

PRIMARY DISPLAY SYSTEM - FUEL MANAGEMENT MAINTENANCE PAGE

There is no message in the manual event mode.

Date and Time

In the real time mode, the date field shows the current date and universal coordinated time (UTC).

In the manual event mode and the auto event mode, the date field shows the date and UTC of the incident.

System Data

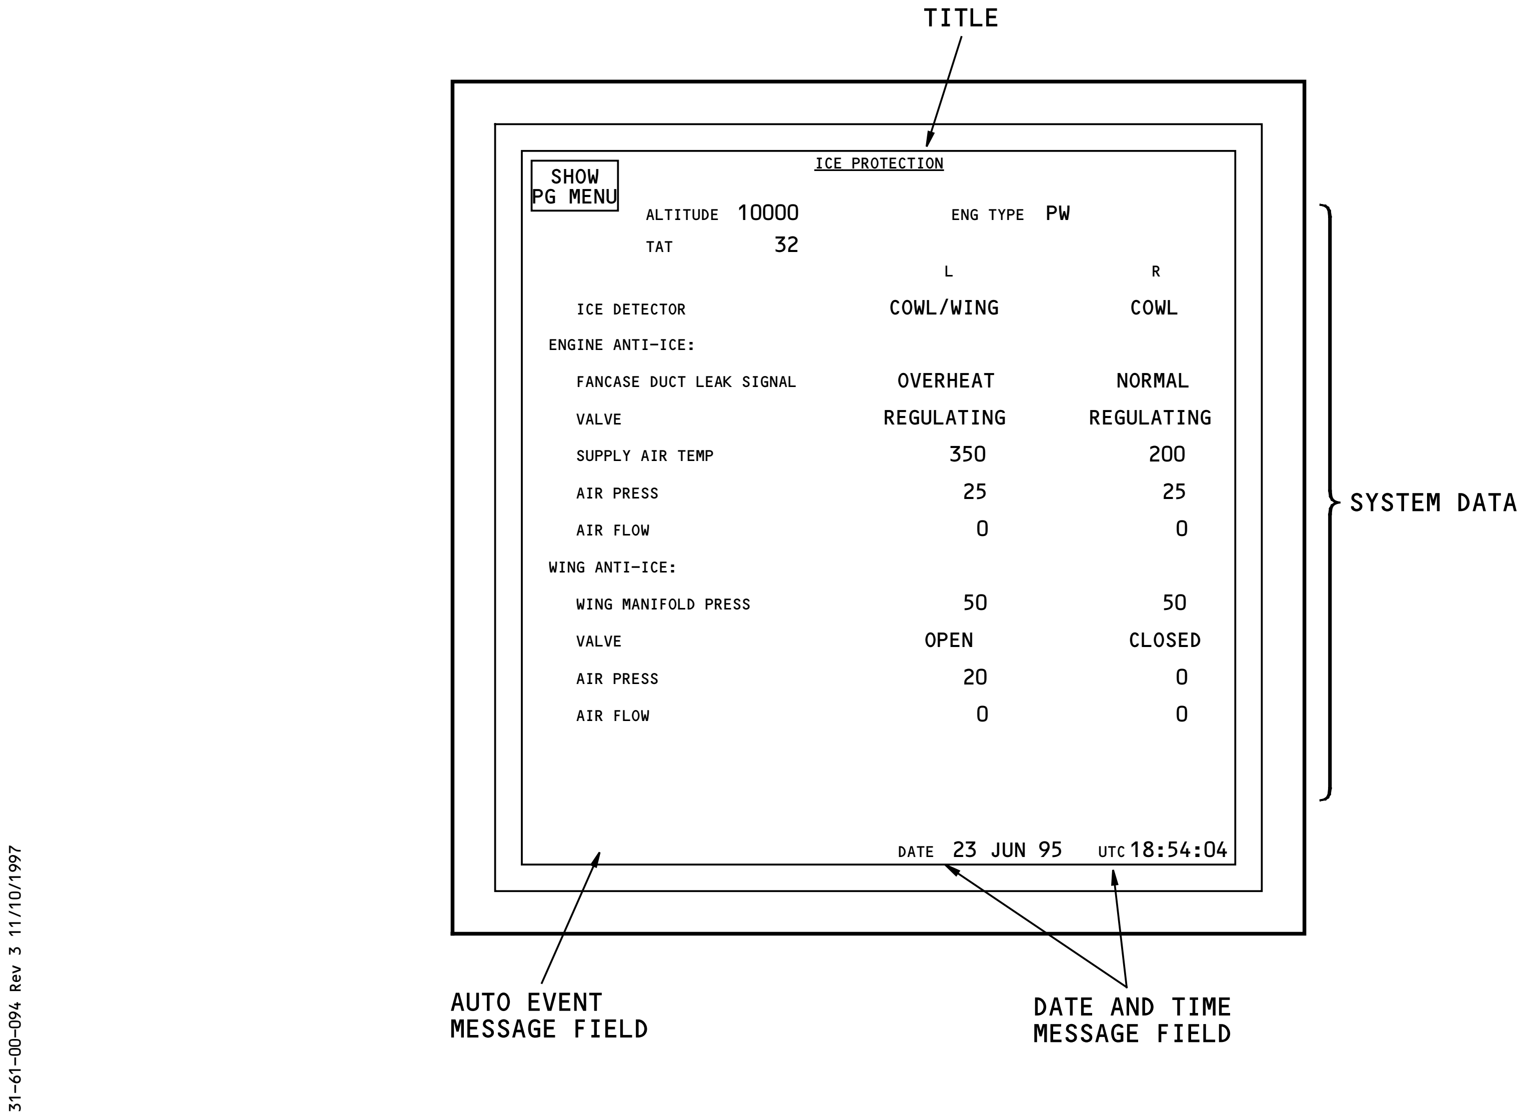
The ice protection maintenance page shows engine and wing anti-ice system information. The information includes:

- Airplane altitude
- Total air temperature
- Engine type
- Engine anti-ice system valve positions, pressure, and flow
- Wing anti-ice system valve positions, pressure, and flow.



PRIMARY DISPLAY SYSTEM - ICE PROTECTION MAINTENANCE PAGE

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - MAINTENANCE TASK MAINTENANCE PAGE

General

The maintenance task maintenance page is unique. The page has these functions:

- Erase latched status messages
- View and erase scheduled maintenance task (SMT) messages
- Control the electronic checklist.

Use the cursor control device to clear, enable or disable any of the functions.

The MAIN MENU command at the top left causes the maintenance page DISPLAY SELECTION menu to show.

Erasable Latched Status Messages

This window shows status messages whose activation conditions are no longer true but are latched in AIMS nonvolatile memory (NVM). The messages show in the order in which they were latched in NVM. The window shows a maximum of three messages. When three messages or less show, the page number shows 1/1. When more than one page of messages exist, the PAGE command shows. The page number then shows the total number of pages. Use the PAGE command to get to the other pages of messages. The messages page in a circular way. When you return to the first page of messages from the last pages of messages, the messages update and the page number updates. The initial selection of this maintenance page always causes the first page of messages to show.

The ERASE command clears the message from NVM and removes the message from the display.

The ERASE function does not operate when the airplane is in the air.

SMT Message Functions

This window shows the active SMT messages whose activation conditions are true or are latched in NVM. The messages show in the order they were latched in NVM. The window shows a maximum of three messages. Use the PAGE command when more than three messages exist. (PAGE operation identical to latched status message function).

The ERASE command shows to the right of messages latched in NVM. Activation of the command clears the message from NVM and removes the message from the display. Not all SMT messages latch in NVM.

The ERASE function does not operate when the airplane is in the air.

Checklist Function

Each selection of the ENABLE/DISABLE button causes the message to toggle between [ENABLE] and [DISABLE]. This selection enables or disables the electronic checklist function. The current checklist condition shows next to the STATUS prompt. The system stores the message in non-volatile memory so that the condition remains when you put power back on the airplane.

PRIMARY DISPLAY SYSTEM - MAINTENANCE TASK MAINTENANCE PAGE

The initial software load in the graphics generators cause the function to be ENABLED.

The toggle does not operate when the airplane is in the air.

PRIMARY DISPLAY SYSTEM - LANDING GEAR BRAKE/STEERING MAINTENANCE PAGE

PRIMARY DISPLAY SYSTEM - AIR SUPPLY MAINTENANCE PAGE

General

The air supply maintenance page is available in these three display modes:

- Real time
- Manual event
- Auto event.

Title

The title shows the display mode. The title shows as:

- AIR SUPPLY for the real time mode
- AIR SUPPLY MAN for the manual event mode
- AIR SUPPLY AUTO for the auto event mode.

Auto Event Message

In the real time mode, the auto event message shows for the most recent auto event in memory. If there are no auto events in memory, the message field is blank.

In the auto event mode, the message for the incident shows.

There is no message in the manual event mode.

Date and Time

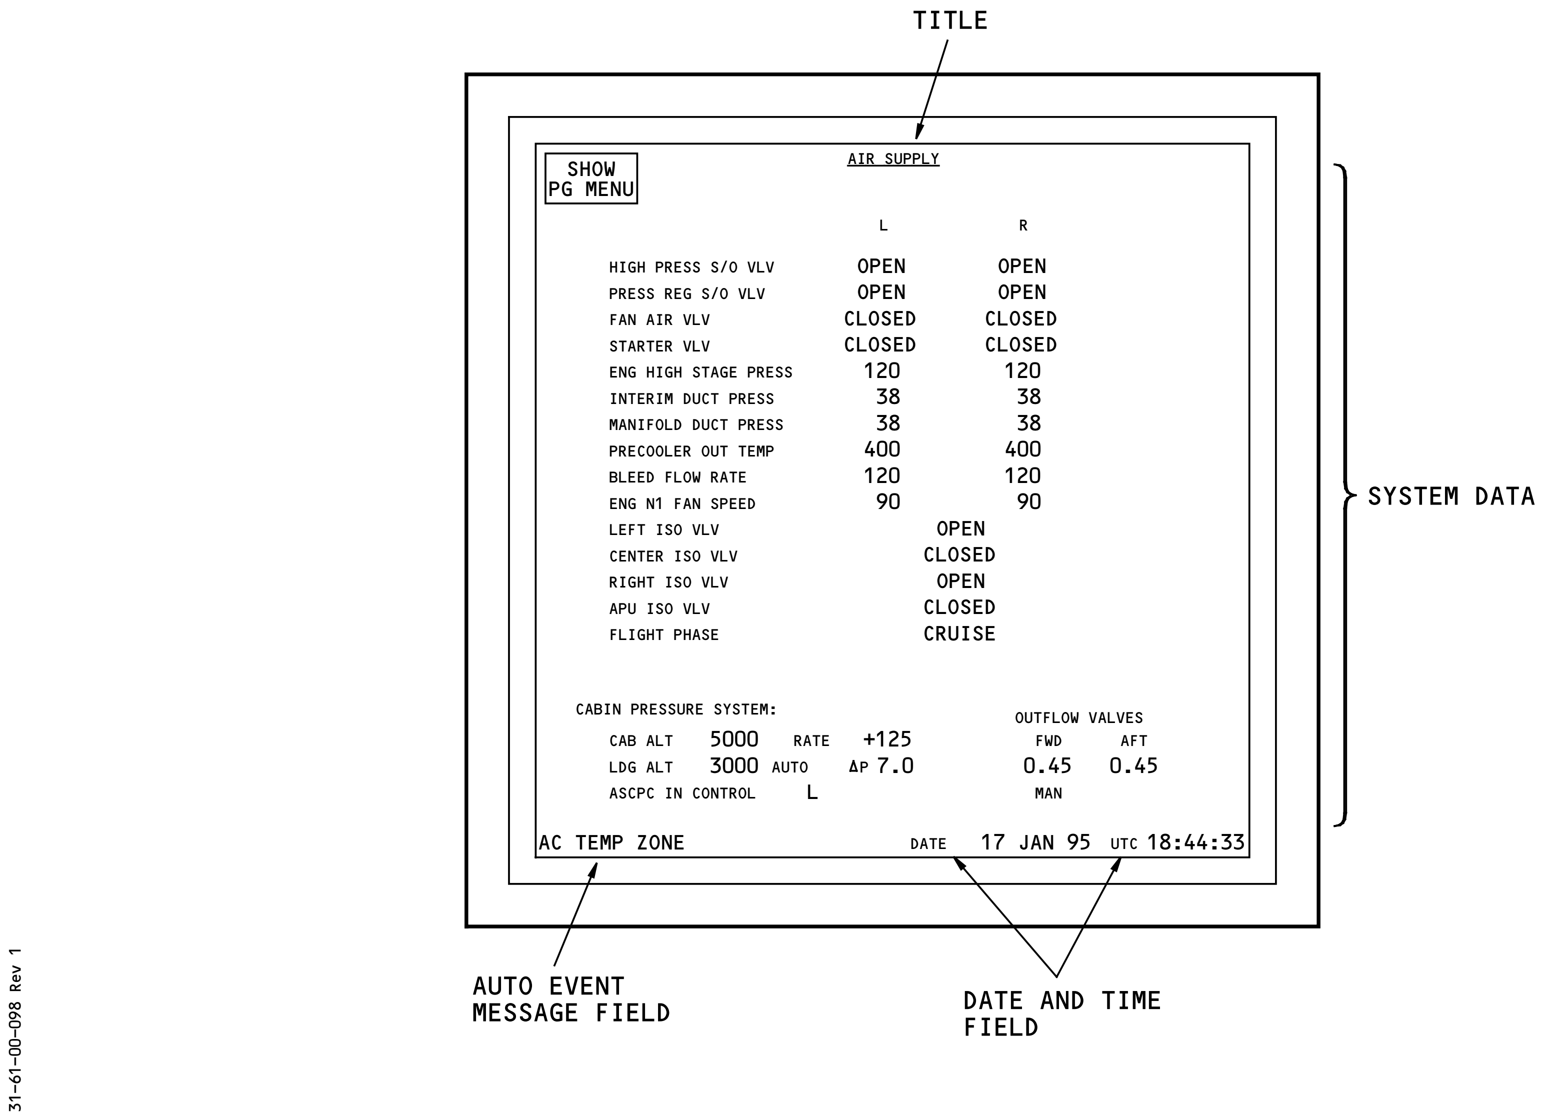
In the real time mode, the date field shows the current date and universal coordinated time (UTC).

In the manual event mode and the auto event mode, the date field shows the date and UTC of the incident.

System Data

The air supply maintenance page shows environmental control system information. The information includes:

- Air supply valve positions
- Air supply miscellaneous data
- Flight phase
- Cabin pressure system data
- Outflow valve data
- Cabin pressure controller channel in control.



PRIMARY DISPLAY SYSTEM - AIR SUPPLY MAINTENANCE PAGE

PRIMARY DISPLAY SYSTEM - APU MAINTENANCE PAGE

General

The APU maintenance page is available in these three display modes:

- Real time
- Manual event
- Auto event.

Title

The title shows the display mode. The title shows as:

- APU for the real time mode
- APU MAN for the manual event mode
- APU AUTO for the auto event mode.

Auto Event Message

In the real time mode, the auto event message shows for the most recent auto event in memory. If there are no auto events in memory, the message field is blank.

In the auto event mode, the message for the incident shows.

There is no message in the manual event mode.

Date and Time

In the real time mode, the date field shows the current date and universal coordinated time (UTC).

In the manual event mode and the auto event mode, the date field shows the date and UTC of the incident.

System Data

The APU maintenance page shows:

- APU mode
- Rotor speed
- EGT
- Oil information
- Starter voltage
- Pressure data
- Valve positions
- Door positions
- Battery, starter, and generator status
- Status code, APU unique maintenance codes (six maximum), hexadecimal
- APU operating hours and starts
- Other APU status data.

PRIMARY DISPLAY SYSTEM - APU MAINTENANCE PAGE

PRIMARY DISPLAY SYSTEM - PERFORMANCE MAINTENANCE PAGE

General

The performance maintenance page is available in these three display modes:

- Real time
- Manual event
- Auto event.

Title

The title shows the display mode. The title shows as:

- PERFORMANCE for the real time mode
- PERFORMANCE MAN for the manual event mode
- PERFORMANCE AUTO for the auto event mode.

Auto Event Message

In the real time mode, the auto event message shows for the most recent auto event in memory. If there are no auto events in memory, the message field is blank.

In the auto event mode, the message for the incident shows.

There is no message in the manual event mode.

Date and Time

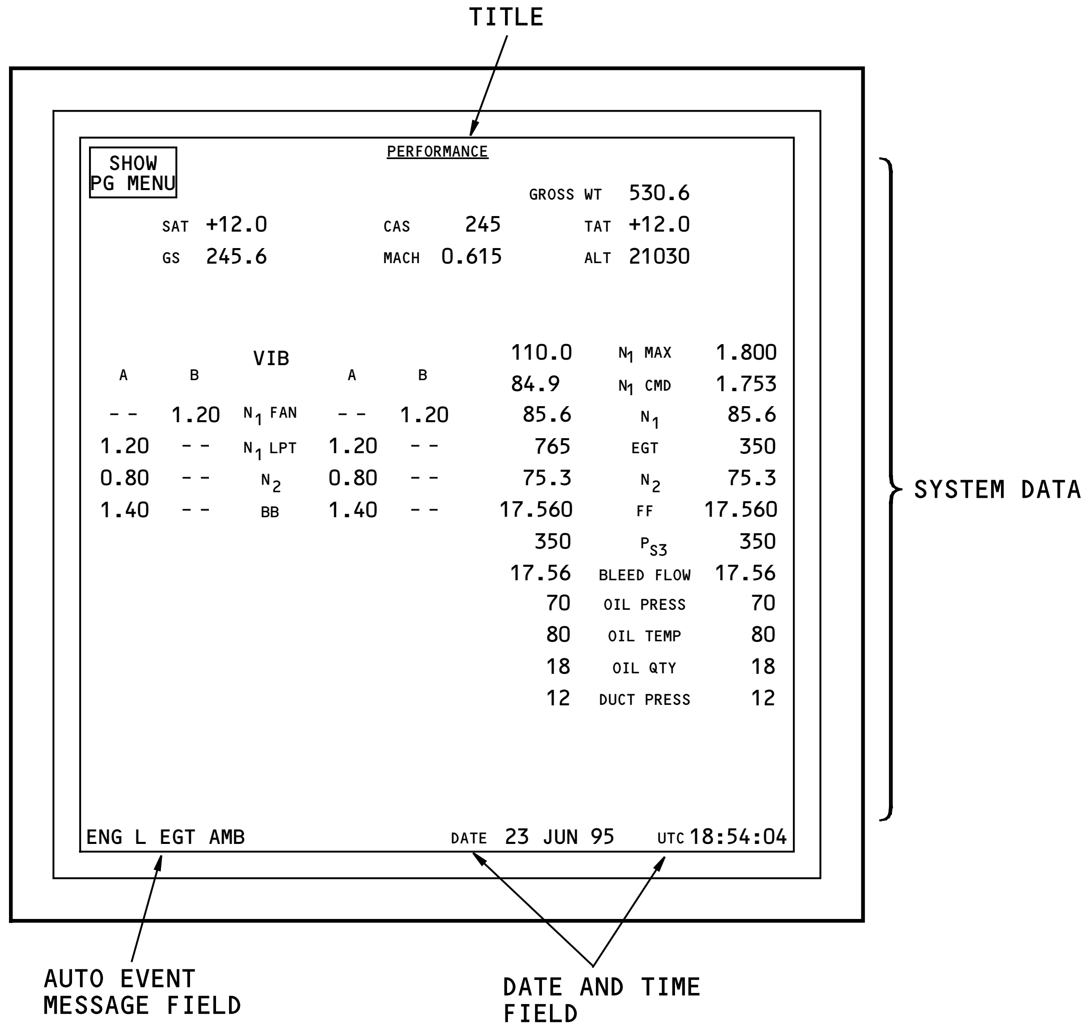
In the real time mode, the date field shows the current date and universal coordinated time (UTC).

In the manual event mode and the auto event mode, the date field shows the date and UTC of the incident.

System Data

The performance maintenance page shows:

- Airplane state data
- Engine parameters
- Engine vibration
- Engine oil parameters.



31-61-00-100 Rev 3 09/18/96

PRIMARY DISPLAY SYSTEM - PERFORMANCE MAINTENANCE PAGE

PRIMARY DISPLAY SYSTEM - EPCS MAINTENANCE PAGES

General

There are two electronic propulsion control system (EPCS) maintenance pages. They are available in these three display modes:

- Real time
- Manual event
- Auto event.

Title

The titles show the display mode and page number. The titles show as:

- EPCS PG 1/2 for the real time mode
- EPCS PG 2/2 for the real time mode
- EPCS MAN 1/2 for the manual event mode
- EPCS MAN 2/2 for the manual event mode
- EPCS AUTO 1/2 for the auto event mode
- EPCS AUTO 2/2 for the auto event mode.

Auto Event Message

In the real time mode, the auto event message shows for the most recent auto event in memory. If there are no auto events in memory, the message field is blank. The message shows on both pages.

In the auto event mode, the message for the incident shows. The message shows on both pages.

There is no message in the manual event mode.

Date and Time

In the real time mode, the date field shows the current date and universal coordinated time (UTC).

In the manual event mode and the auto event mode, the date field shows the date and UTC of the incident.

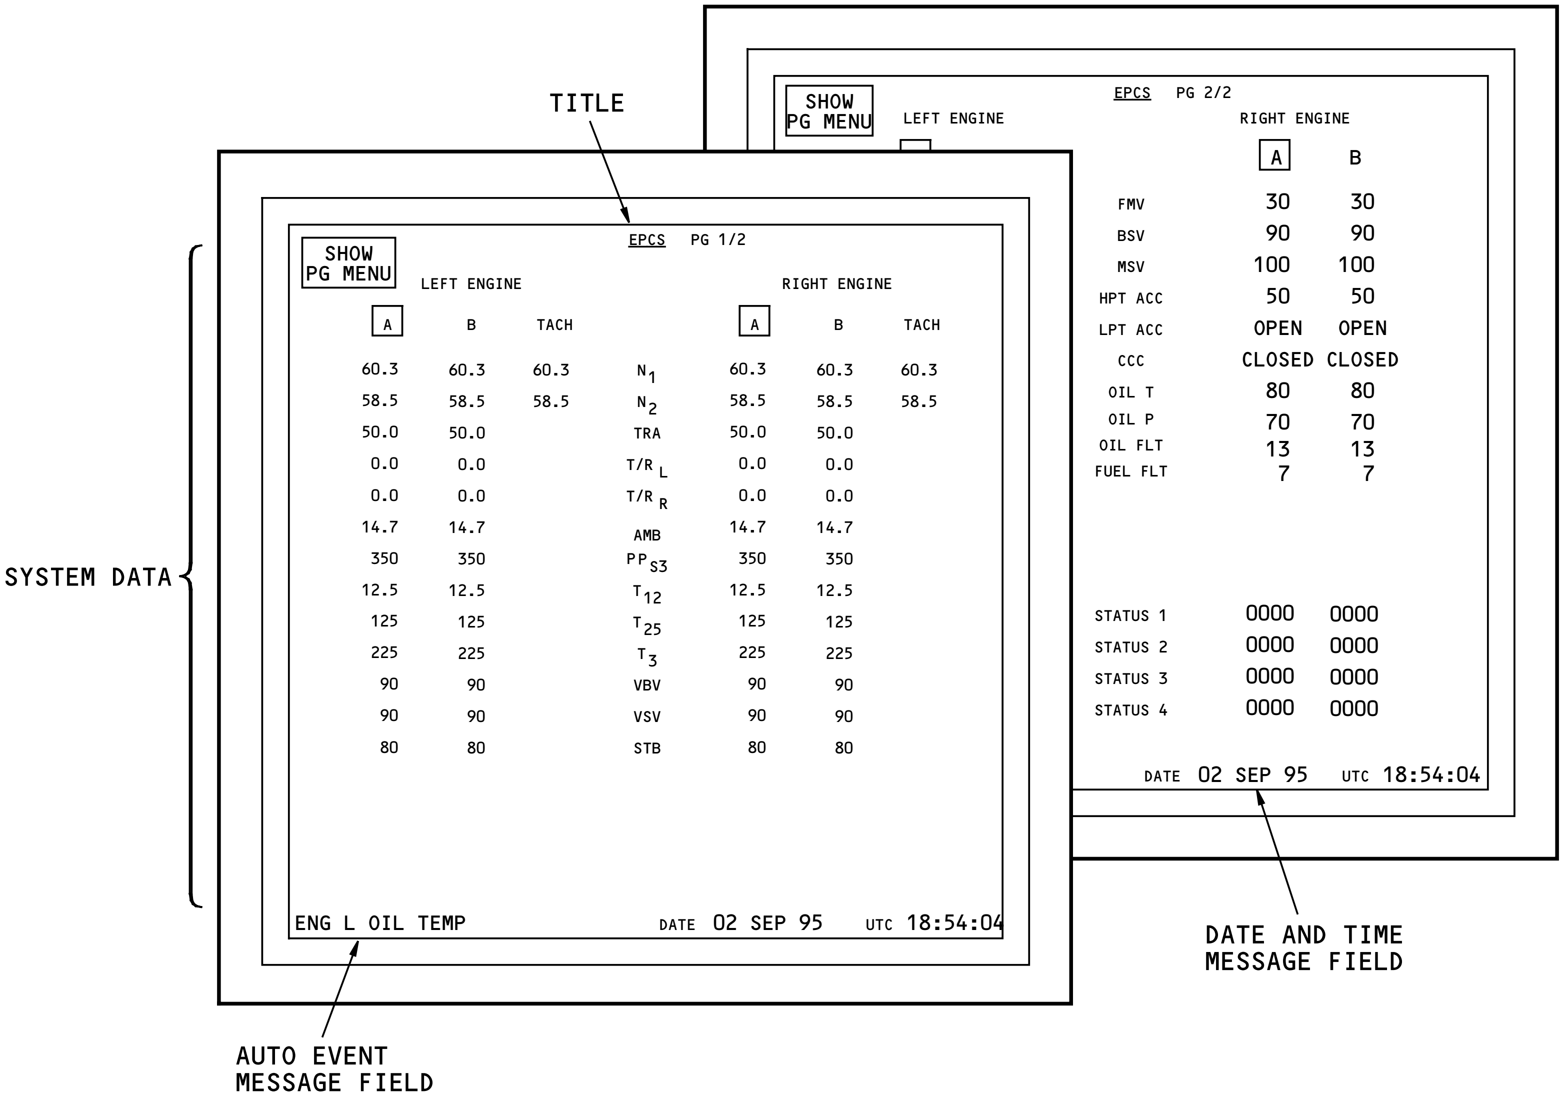
System Data

The information on EPCS maintenance page 1/2 includes:

- Channel in control
- Rotor speed information
- Thrust reverser information
- Engine temperature and pressure data.

The information on EPCS maintenance page 2/2 includes:

- Channel in control
- Oil pressure and temperature
- Status message codes (hexadecimal).



PRIMARY DISPLAY SYSTEM - EPCS MAINTENANCE PAGES

PRIMARY DISPLAY SYSTEM - PROPULSION DATA LIMITS MAINTENANCE PAGES

General

There are two maintenance pages for propulsion data limits. They are available in the real time display mode only.

Title

The title shows the page. The titles show as:

- PROPULSION DATA LIMITS PG 1/2
- PROPULSION DATA LIMITS PG 2/2.

System Data

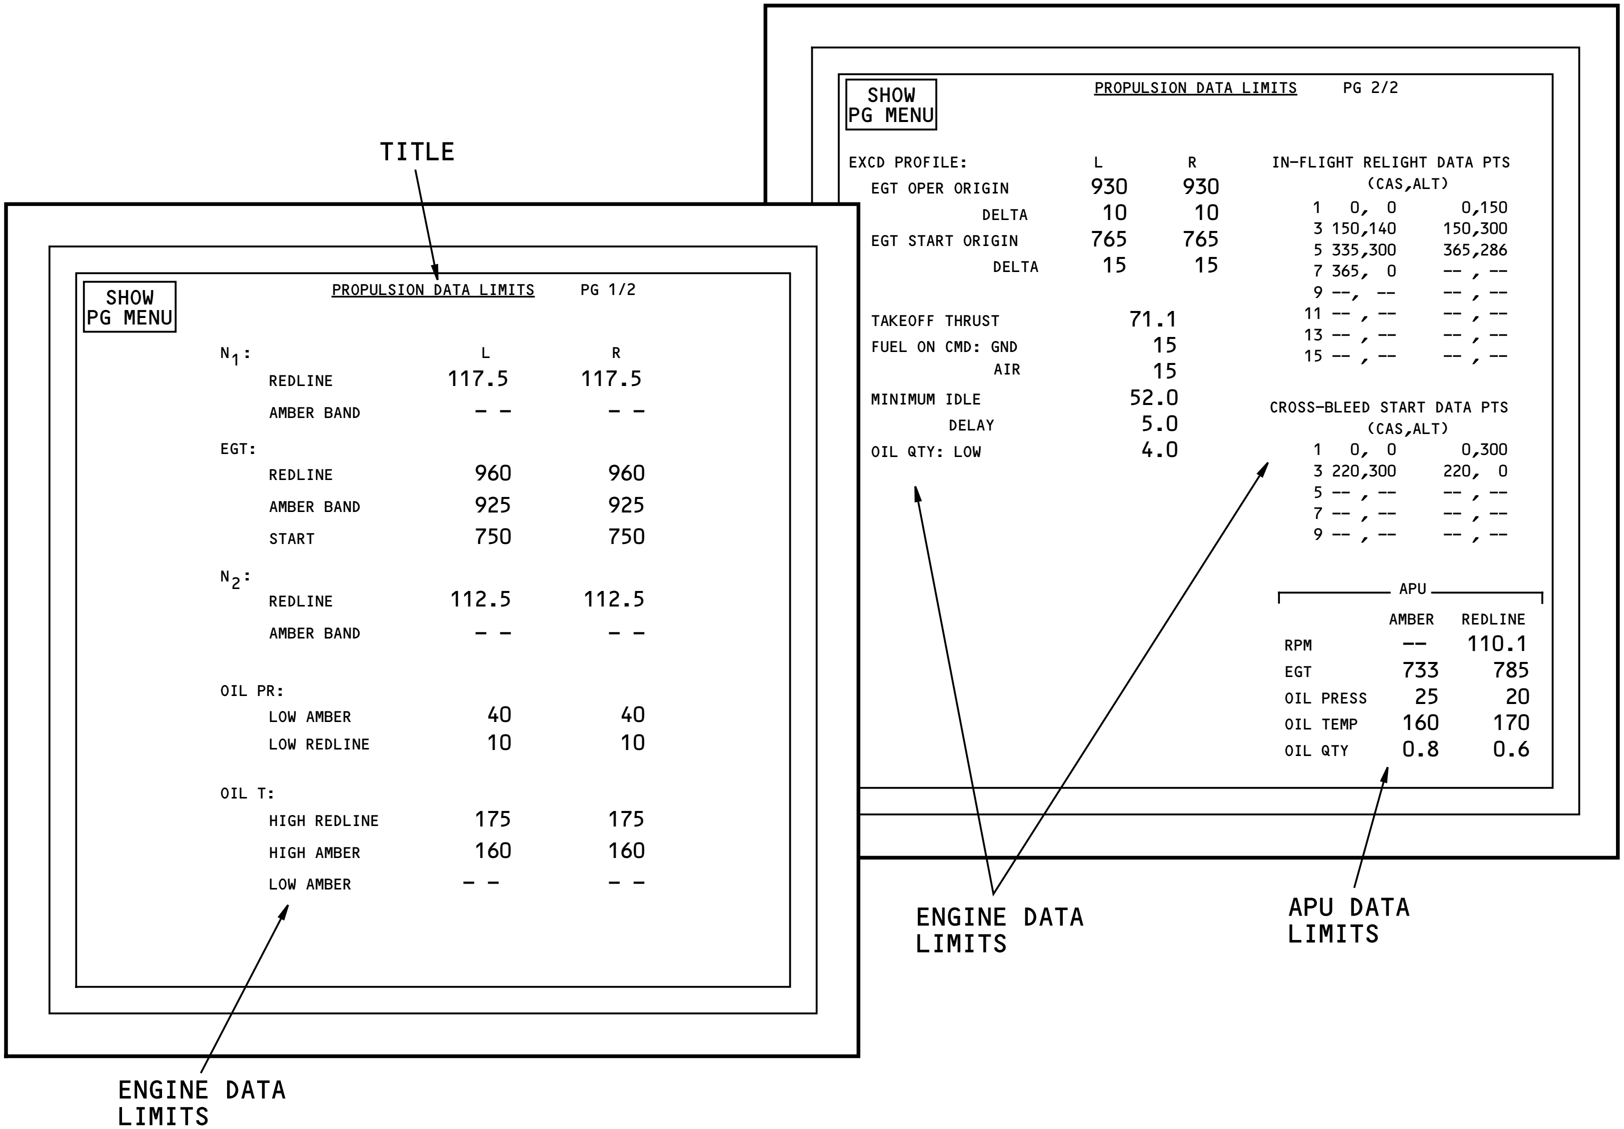
The propulsion data limits maintenance pages show engine red-line and amber-line exceedance limits. The information shows on two pages.

The information on the limits maintenance page 1/2 for propulsion data includes:

- Rotor speeds
- EGT
- Oil pressure
- Oil temperature
- Oil pressure data points.

The information on the limits maintenance page 2/2 for propulsion data includes:

- Takeoff thrust
- Fuel on command
- Minimum idle
- Oil quantity
- Engine vibration
- Exceedance profile
- In-flight relight data points
- Cross-bleed start data points
- APU data limits.



31-61-00-102 Rev 2

PRIMARY DISPLAY SYSTEM - PROPULSION DATA LIMITS MAINTENANCE PAGES

PRIMARY DISPLAY SYSTEM - ENGINE EXCEEDANCE MAINTENANCE PAGES

General

There are two separate engine exceedance maintenance pages, one for the left engine and one for the right engine. They are available in the auto event display mode only.

Title

The title shows the engine. The titles show as:

- L ENG EXCD
- R ENG EXCD.

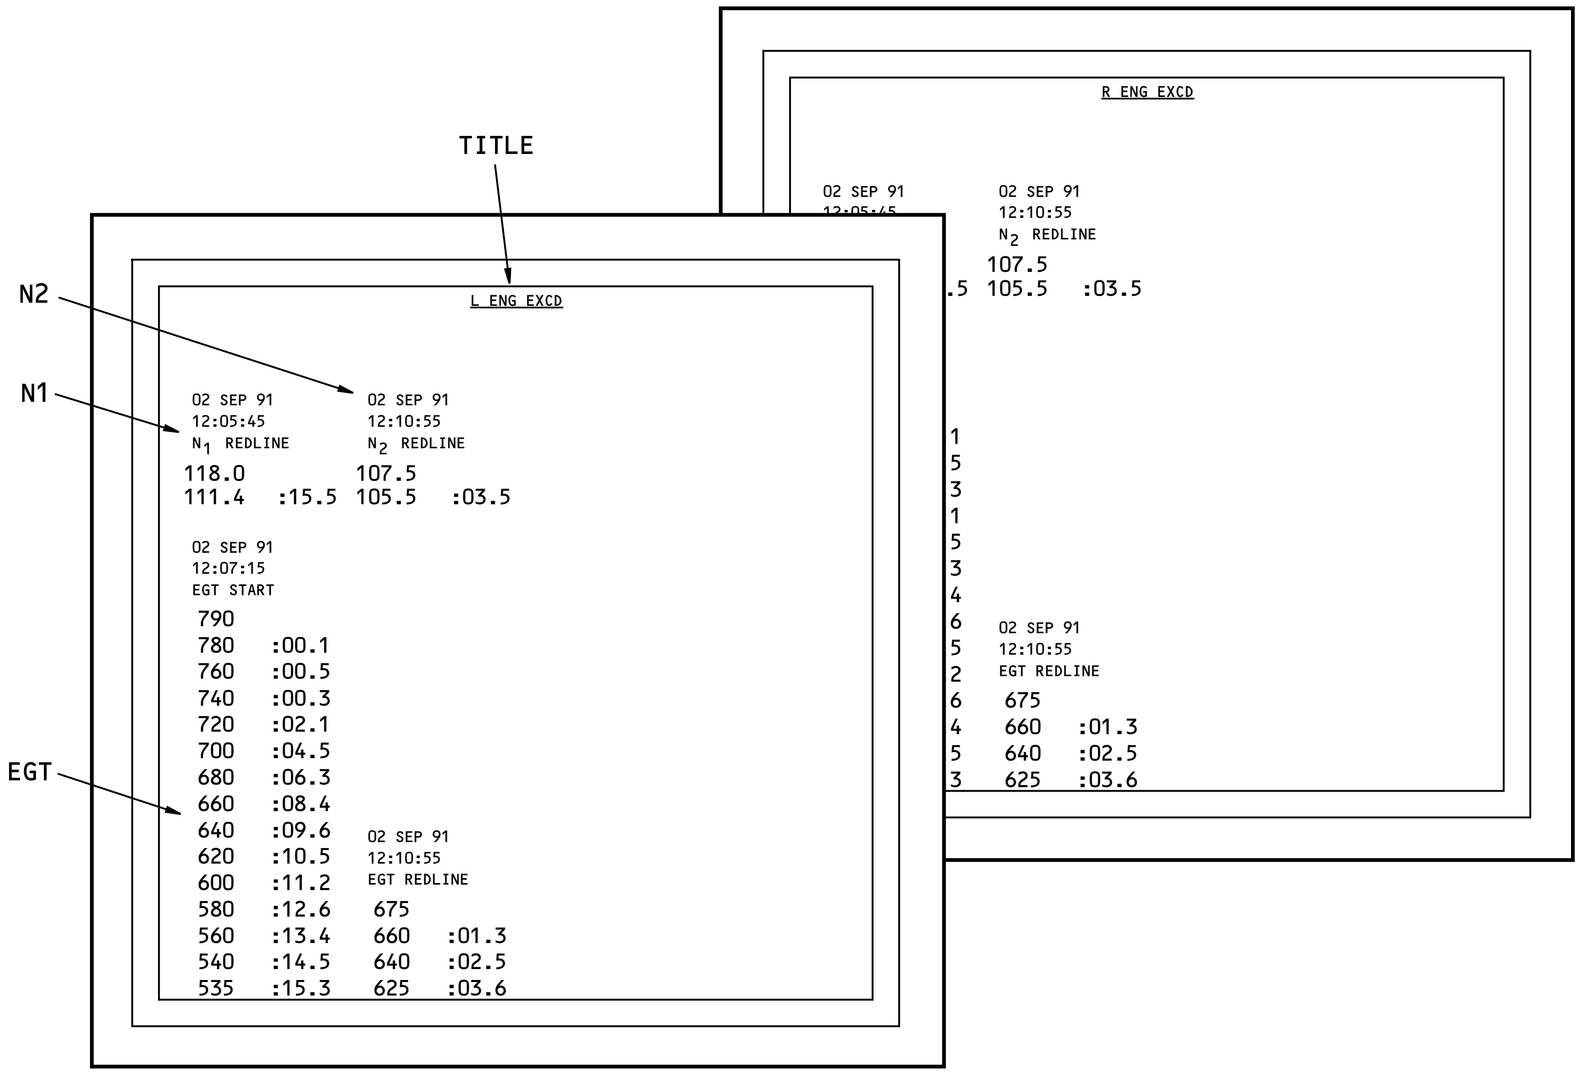
System Data

The engine exceedance maintenance pages show engine red line and amber line exceedance profiles. Profiles show for:

- N1 amber band/red line exceedance mini-profile
- N2 amber band/red line exceedance mini-profile
- EGT start limit exceedance profile
- EGT amber band/red line exceedance profile.

Each profile area stores up to four exceedances in nonvolatile memory (NVM). The date and time of each exceedance shows at the top of the profile. The parameter message follows the date. The profile data follows the message.

The exceedances show in order of occurrence with the most recent exceedance in the right hand column.



31-61-00-103 Rev 1

PRIMARY DISPLAY SYSTEM - ENGINE EXCEEDANCE MAINTENANCE PAGES

PRIMARY DISPLAY SYSTEM - MAINTENANCE PAGES SUMMARY

General

These are the four main selection pages:

- Display selection page
- Print selection page
- Datalink selection page
- Erase selection page.

These are the eight sub-page selections:

- Manual events display selection sub-page
- Auto events display selection sub-page
- Manual events print selection sub-page
- Auto events print selection sub-page
- Manual events datalink selection sub-page
- Auto events datalink selection sub-page
- Manual events erase selection sub-page
- Auto events erase selection sub-page.

Also, individual menu selections show on each maintenance page.

Each maintenance page shows the available menu selections.

These menu selections for the maintenance pages show in the summary chart:

- Real time
- Manual event
- Auto event
- Number of pages.

PRIMARY DISPLAY SYSTEM - MAINTENANCE PAGES SUMMARY

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - DISPLAY CONTROL FUNCTIONAL DESCRIPTION

General

There are four display channels in the primary display system. Each channel has a graphics generator, a coax coupler, and six coax cables.

Each AIMS cabinet has a left (M010) and a right (M011) graphics generator (GG). During normal operation, three of the GGs each send data to two DUs. The fourth GG is a spare. The GGs normally drive the displays at a 20 Hz rate.

Display control (DSPL CTRL) switches on the left instrument source select panel (L ISSP), center display control panel (CDCP), and right instrument source select panel (R ISSP) change the source of display data for the six display units (DUs).

Each switch has two positions, AUTO and alternate (ALTN). Normally, the switches are in the AUTO position. With the switches in the AUTO position, the AIMS cabinets automatically switch sources when a GG fails.

System software determines the switching sequence. For example, if the left GG in the left AIMS cabinet fails, the right GG in the left AIMS cabinet takes over.

Each graphics generator has the capability to drive a maximum of two critical formats and one essential format. The critical formats are the PFD, EICAS and secondary engine displays. The essential formats are the ND and the other MFD formats.

AUTO Position Operation

The AUTO position of the DSPL CTRL switch on the L ISSP causes the CPM/GG (M010) in the left AIMS cabinet to send data to the left outboard DU and left inboard DU.

The AUTO position of the DSPL CTRL switch on the CDCP causes the CPM/GG (M011) in the left AIMS cabinet to send data to the upper center DU and the lower center DU.

the AUTO position of the DSPL CTRL switch on the R ISSP causes the CPM/GG (M011) in the right AIMS cabinet to send data to the right outboard DU and right inboard DU.

The CPM/GG (M010) in the right AIMS cabinet is the spare.

ALTN Switch Operation or One Channel Failure

The ALTN position of the switches changes the source of display data.

With the display control switches in AUTO, failures also cause the source of display data to change.

When you put the DSPL CTRL switch on the L ISSP in the ALTN position, or the CPM/GG (M010) in the left AIMS cabinet fails, the CPM/GG (M011) in the left AIMS cabinet sends data to the captain DUs.

PRIMARY DISPLAY SYSTEM - DISPLAY CONTROL FUNCTIONAL DESCRIPTION

When you put the DSPL CTRL switch on the CDCP in the ALTN position, or CPM/GG M011 in the left AIMS cabinet fails, the CPM/GG (M010) in the right AIMS cabinet sends data to the upper center and lower center DUs.

When you put the DSPL CTRL switch on the R ISSP in the ALTN position, or the CPM/GG (M0011) in the right AIMS cabinet fails, CPM/GG M010 in the left AIMS cabinet sends data to the first officer's DUs.

For any of the above conditions all display functions are available and there is no reduction in system capability and functionality. There are no flight deck effects set.

ALTN Switch Operation and One Channel Failure

Alternate switch operation and one channel failure together cause the display system to go to a limited format operation. The total display system has the capability to show four critical and two essential formats.

With all other conditions normal, the outboard display units will show PFDs. The inboard display units will show NDs. The upper center DU will show EICAS and the lower center DU will show the secondary engine display.

If the CPM/GG (M010) in the left AIMS cabinet fails and the captain display control switch is in the alternate position, CPM/GG (M010)in the right AIMS cabinet sends data to the left outboard (LOB), left inboard (LIB), and upper center DUs. CPM/GG (M011) in the right AIMS cabinet sends data to the right outboard (ROB), right inboard (RIB) and lower center DUs. This causes the display system to go to the limited format mode. For this condition there are no flight deck effects and no dispatch limitations.

If the CPM/GG (M011) in the left AIMS cabinet fails and the center display control switch is in the alternate position, CPM/GG (M010)in the left AIMS cabinet sends data to the LOB, LIB, and upper center DUs. CPM/GG (M011) in the right AIMS cabinet sends data to the ROB, RIB and lower center DUs. This causes the display system to go to the limited format mode. For this condition there are no flight deck effects and no dispatch limitations.

If the CPM/GG (M010) in the right AIMS cabinet fails and the first officer display control switch is in the alternate position, CPM/GG (M010)in the left AIMS cabinet sends data to the LOB, LIB, and upper center DUs. CPM/GG (M011) in the left AIMS cabinet sends data to the ROB, RIB and lower center DUs. This causes the display system to go to the limited format mode. For this condition there are no flight deck effects and no dispatch limitations.

If the CPM/GG (M011) in the right AIMS cabinet fails and the first officer display control switch is in the alternate position, CPM/GG (M010)in the left AIMS cabinet sends data to the LOB, LIB, and upper center DUs. CPM/GG (M011) in the left AIMS cabinet sends data to the ROB, RIB and lower center DUs. This causes the display system to go to the limited format mode. For this condition there are no flight deck effects and no dispatch limitations.

Two Display Channel Failures

Two failures cause the display system to go limited format operation. The total display system has the capability to show four critical and two essential formats.

With two failures, the system has the capability for:

- Separate captain and first officer PFDs.
- EICAS and secondary engine displays
- At least one ND to be controlled by either pilot
- Crew warnings, alerts, and cautions
- MFD availability (not required full time)
- Displays at a 10 Hz rate.

Two failures also cause the status message DISPLAY RESOURCES to show. There is no master minimum equipment list (MMEL) relief for this condition.

Three Display Channel Failures

If three failures occur, the last channel can fully support three display units.

This channel can send data to all display formats. In this condition, the GG sends data to three displays and then echoes or duplicates displays on other DUs.

After the third channel failure, the system has the capability for:

- Single PFD and single ND generation
- EICAS and secondary engine displays with warnings and alerts on EICAS (compacted EICAS)
- MFD availability in place of the ND.

This condition causes the status message DISPLAY PROCESSING and the caution message SGL SOURCE DISPLAYS to show. There is no MMEL relief for this condition.

Graphics Generator to Display Unit Interfaces Summary

There are many possible combinations of display channel failures and switch positions. The above text and chart that follows summarizes several of these conditions.

CONDITION	LOB DU	LIB DU	CU DU	CL DU	RIB DU	ROB DU
NORMAL GGs	L10	L10	L11	L11	R11	R11

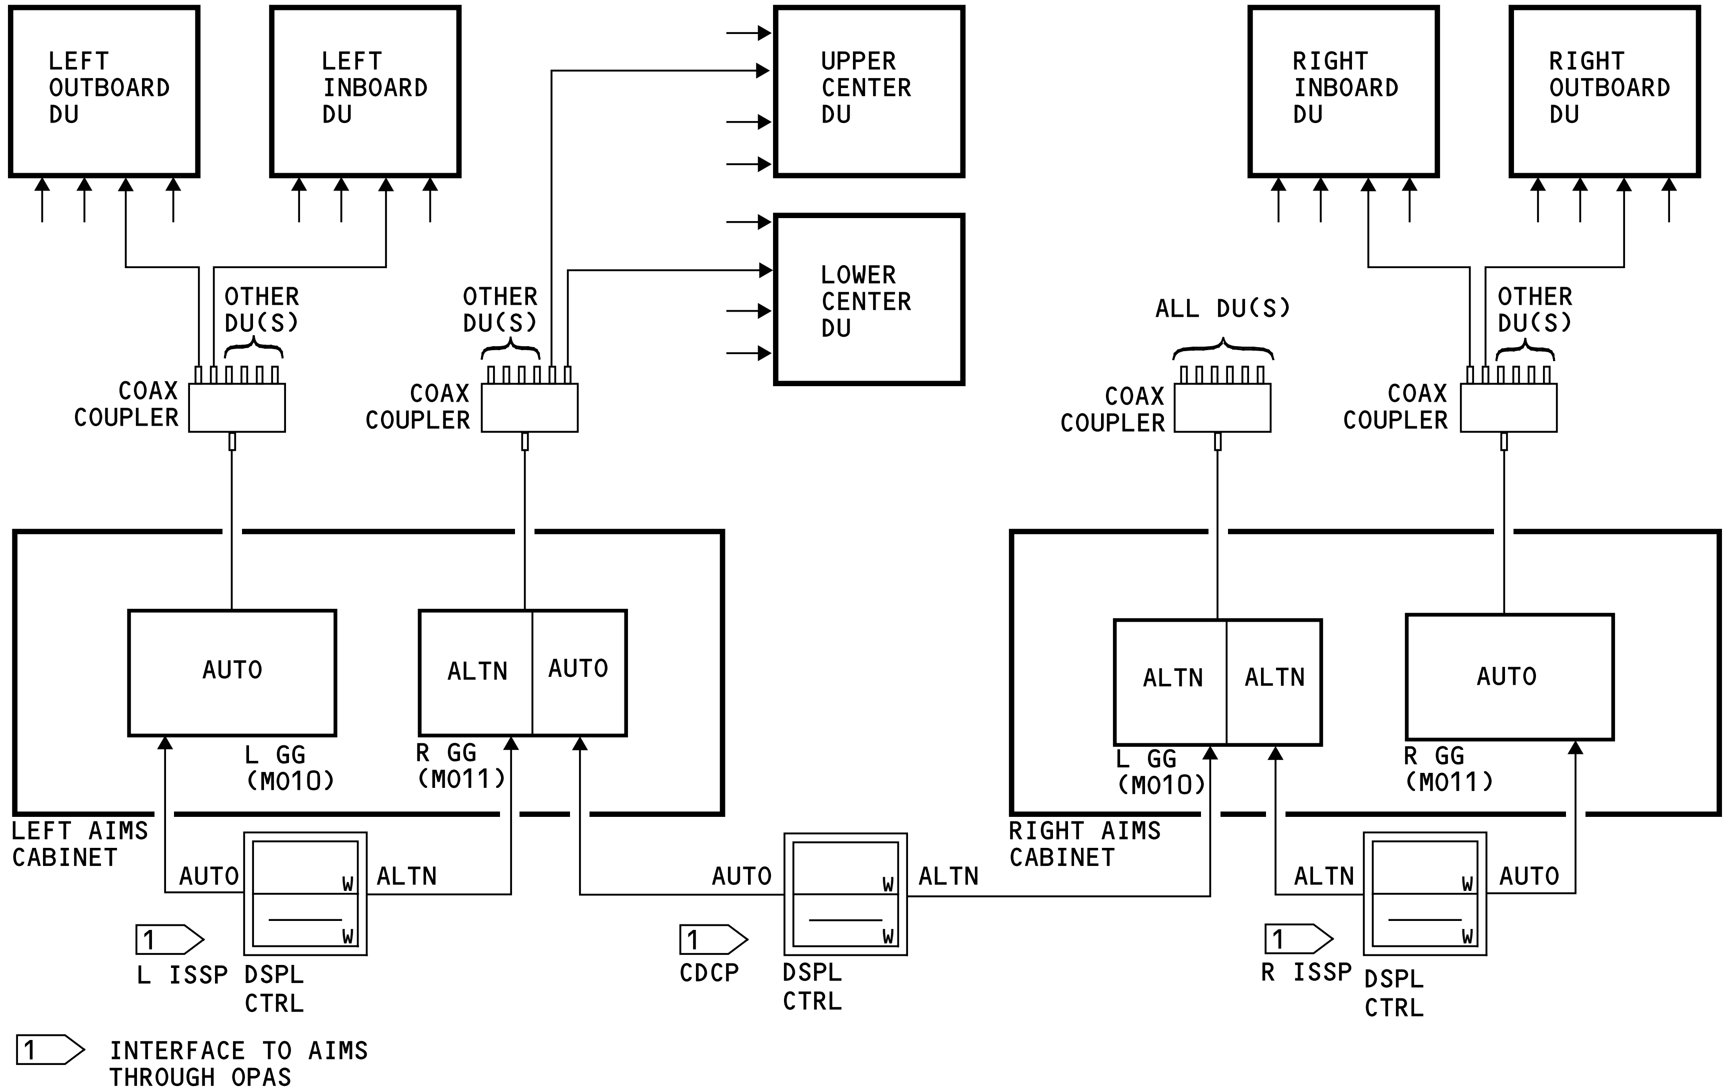
	C = Captain					

Training Information Point

On the ground, the display system will try to switch back to a previously failed graphics generator. This will cause the display unit to blink on and off. This condition lets the maintenance personnel troubleshoot an intermittent GG or wiring problem. There is no limit to the number of times the display system will try to switch.

In the air, the display system will try to switch back to a bad GG up to four times. After four tries, redundancy logic takes effect and the blinking stops.



31-61-00-120 Rev 10 10/07/1997

PRIMARY DISPLAY SYSTEM - DISPLAY CONTROL FUNCTIONAL DESCRIPTION

PRIMARY DISPLAY SYSTEM - ELECTRONIC CHECKLIST OVERVIEW

General

Checklists contain data necessary for the flight crew to operate the airplane in normal conditions and to help with non-normal conditions.

The flight crew completes the electronic checklist item by item on a READ and DO basis. These are the three types of checklists:

- Normal checklists (for example, PREFLIGHT and BEFORE START)
- Non-normal checklists related to an EICAS message (for example, ENG FAIL L and FIRE APU)
- Non-normal checklists not related to an EICAS message (for example, GEAR LEVER LOCKED DN and VOLCANIC ASH).

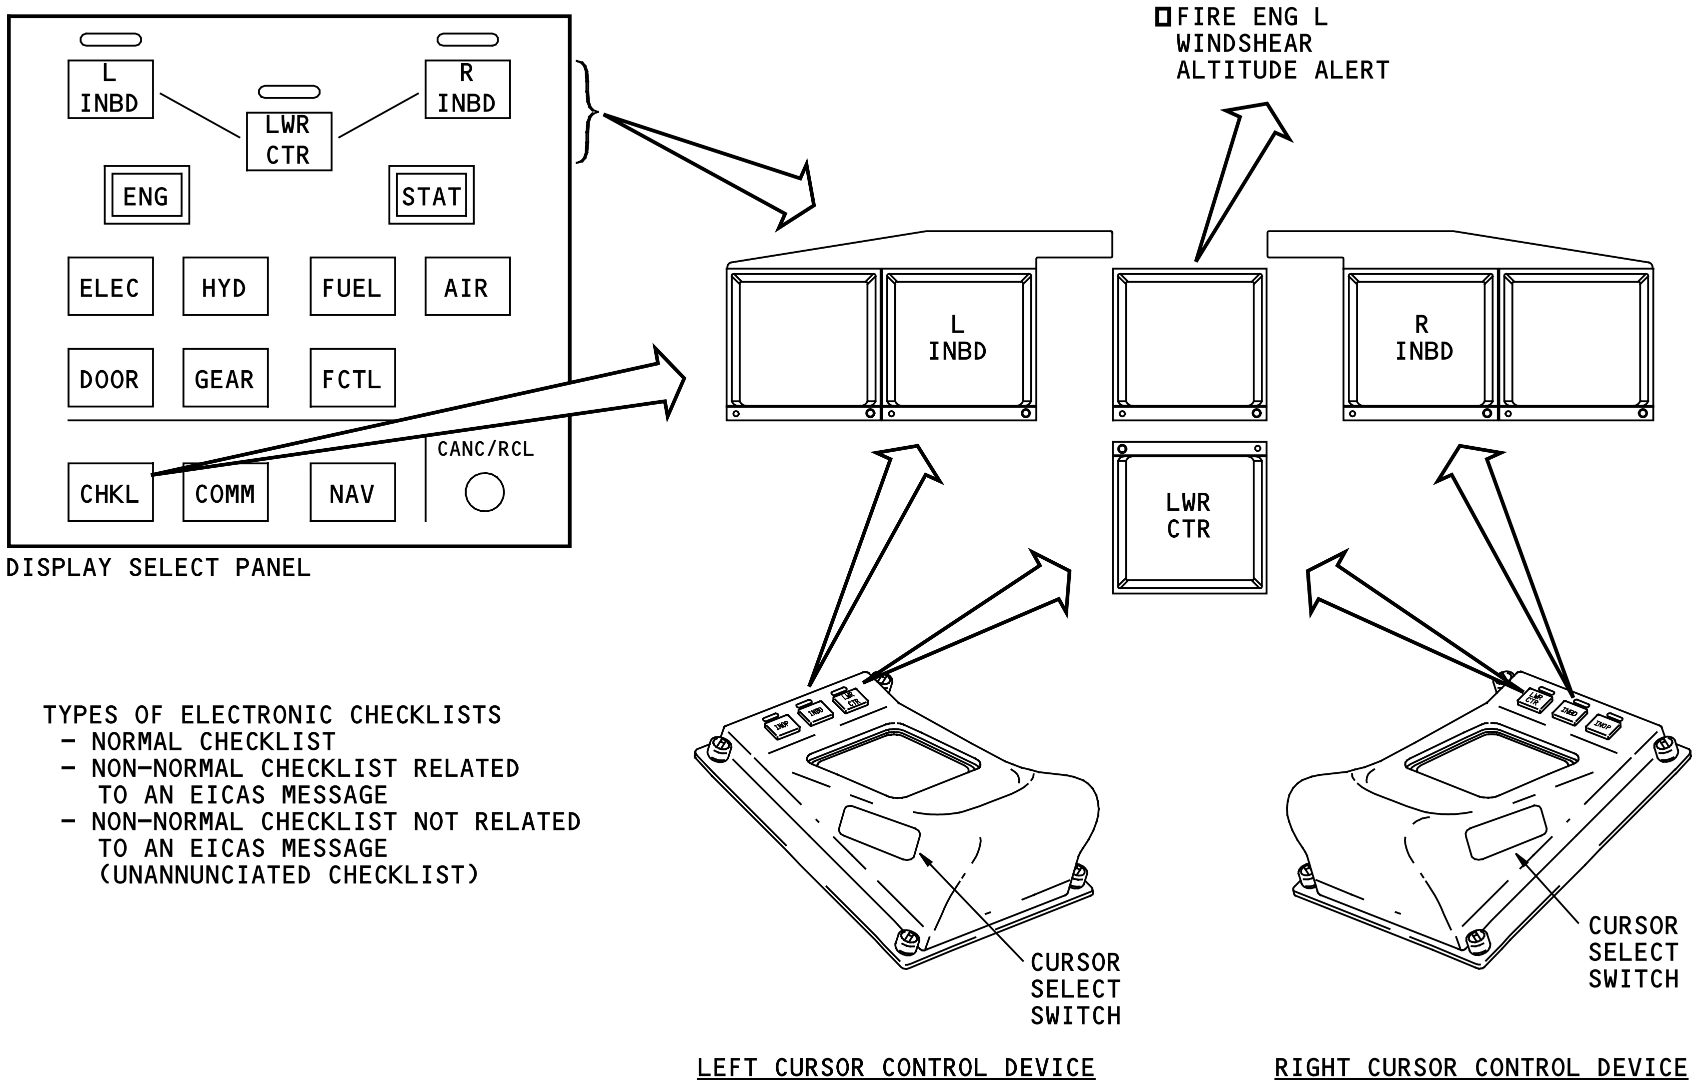
Normal checklist are organized by phase of flight. The flight crew uses them to verify that important procedural steps have been done.

Non-normal checklists contain steps to correct a condition. A square box shows in front of an EICAS message when the message is related to a non-normal checklist and the checklist is not complete. There are also non-normal checklists not related to an EICAS message. These are called unannunciated checklists.

Electronic Checklist Operation

Normal and non-normal electronic checklists show on any multifunction display (MFD). Push the CHKL switch on the display select panel (DSP) to show a checklist.

Only one checklist shows at a time. This checklist can show on more than one display unit, but only one cursor control device (CCD) can control the checklist.



TYPES OF ELECTRONIC CHECKLISTS
- NORMAL CHECKLIST
- NON-NORMAL CHECKLIST RELATED TO AN EICAS MESSAGE
- NON-NORMAL CHECKLIST NOT RELATED TO AN EICAS MESSAGE (UNANNUNCIATED CHECKLIST)

PRIMARY DISPLAY SYSTEM - ELECTRONIC CHECKLIST OVERVIEW

PRIMARY DISPLAY SYSTEM - CHECKLIST DISPLAY PRIORITY

Automatic Display of Checklists

Push the CHKL switch on the display select panel (DSP) to show a checklist on the selected MFD. The primary display system monitors the air/ground phase and EICAS message level and makes an automatic checklist selection.

When the airplane is in the ground phase (on the ground and engines off), this is the checklist priority:

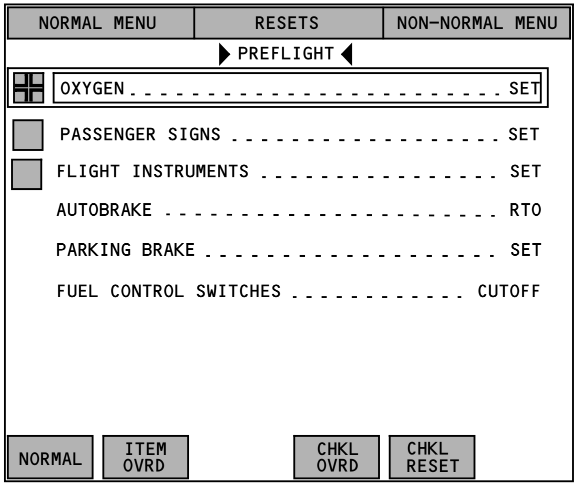
- Warning message checklist (not completed or not accessed)
- Normal checklist (not completed or not accessed)
- Caution message checklist (not completed or not accessed)
- Advisory message checklist (not completed or not accessed)
- Unannunciated checklist (not completed).

When the airplane is in the air phase (engines running), this is the priority:

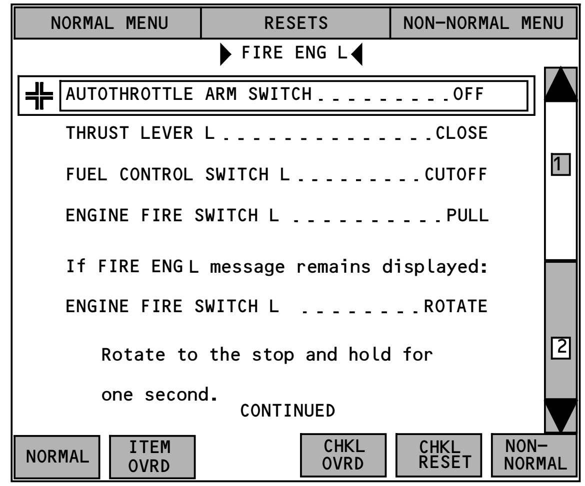
- Warning message checklist (not completed or not accessed)
- Caution message checklist (not completed or not accessed)
- Advisory message checklist (not completed or not accessed)
- Unannunciated checklist (not completed)
- Normal checklist (not completed or not accessed).

Manual Display of Checklists

Push the CHKL switch on the DSP to show a checklist. If the primary display system makes a decision that no checklists needs to show (all checklists are complete), only the menu bar at the top of the display shows. This permits selection of the normal and non-normal menus. These menus show a list of all the normal and non-normal checklists available for manual selection.

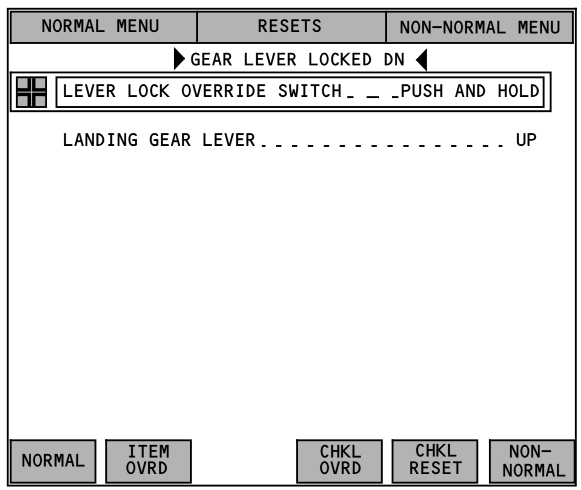


NORMAL CHECKLIST



NON-NORMAL CHECKLIST CONNECTED TO AN EICAS MESSAGE

DISPLAY PRIORITY – GROUND PHASE
- WARNING MESSAGE CHECKLISTS
- NORMAL CHECKLISTS
- CAUTION MESSAGE CHECKLISTS
- ADVISORY MESSAGE CHECKLISTS
- UNANNUNCIATED CHECKLISTS



NON-NORMAL CHECKLIST NOT CONNECTED TO AN EICAS MESSAGE

DISPLAY PRIORITY – AIR PHASE
- WARNING MESSAGE CHECKLISTS
- CAUTION MESSAGE CHECKLISTS
- ADVISORY MESSAGE CHECKLISTS
- UNANNUNCIATED CHECKLISTS
- NORMAL CHECKLISTS

31-61-00-122 Rev 1 11/15/1995

PRIMARY DISPLAY SYSTEM – CHECKLIST DISPLAY PRIORITY

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - CHECKLIST CONTROL

General

Use the active cursor control device (CCD) to control the checklist.

Checklist Menu Bar

Use the NORMAL and NON-NORMAL menu selection on the checklist menu bar to show a list of all normal or non-normal checklists.

Use the RESETS menu selection to show a list of checklist reset options and the airline modifiable information (AMI) software part numbers.

Command Keys

These are the six command keys that control the checklists:

- NORMAL shows the next normal checklist
- ITEM OVRD overrides the highlighted checklist item. An overridden item changes color to cyan
- NOTES key shows if the checklist has more information for the flight crew
- CHKL OVRD allows the flight crew to override the current checklist so they can go on to the next one
- CHKL RESET resets the current checklist
- NON-NORMAL shows the next non-normal checklist.

Closed Loop and Open Loop Items

The checklist function monitors the position of switches, controls and other data in the flight deck. Checklist items that are monitored by the checklist function are called closed loop items. Checklist items that are not monitored are called open loop items.

Closed loop (monitored) items are checklist items that automatically show complete when the boolean state of the applicable line item goes true. Closed loop items show as checkmarks with no gray checkboxes.

Open loop (not monitored) items show as a gray checkbox. Use the CCD cursor activation switch to set open loop items complete.

Line Item and Active Area Highlight Boxes

After the flight crew makes a checklist selection, a line item highlight box shows on the first line item that is not complete. The line item highlight box has a thin line width which goes around the text of the checklist line item. When the cursor is on a line item, an active area highlight box goes around the line item highlight box and open loop check box. When line items are marked complete, the cursor and the line item highlight box move to the next line item.

Cursor Movement

The flight crew moves the cursor as necessary. When all checklist items on a page are complete, the cursor moves to the next page selection on the scroll bar (the scroll bar shows if the checklist has more than one page).

Completed Line Items and Checklists

Checklist line items show in white and change color to green when the flight crew does the required action. When the flight crew completes all items (green) or overrides all items (cyan), one of these messages show at the bottom of the checklist:

- CHECKLIST COMPLETE
- CHECKLIST COMPLETE EXCEPT DEFERRED ITEMS
- CHECKLIST OVERRIDDEN.

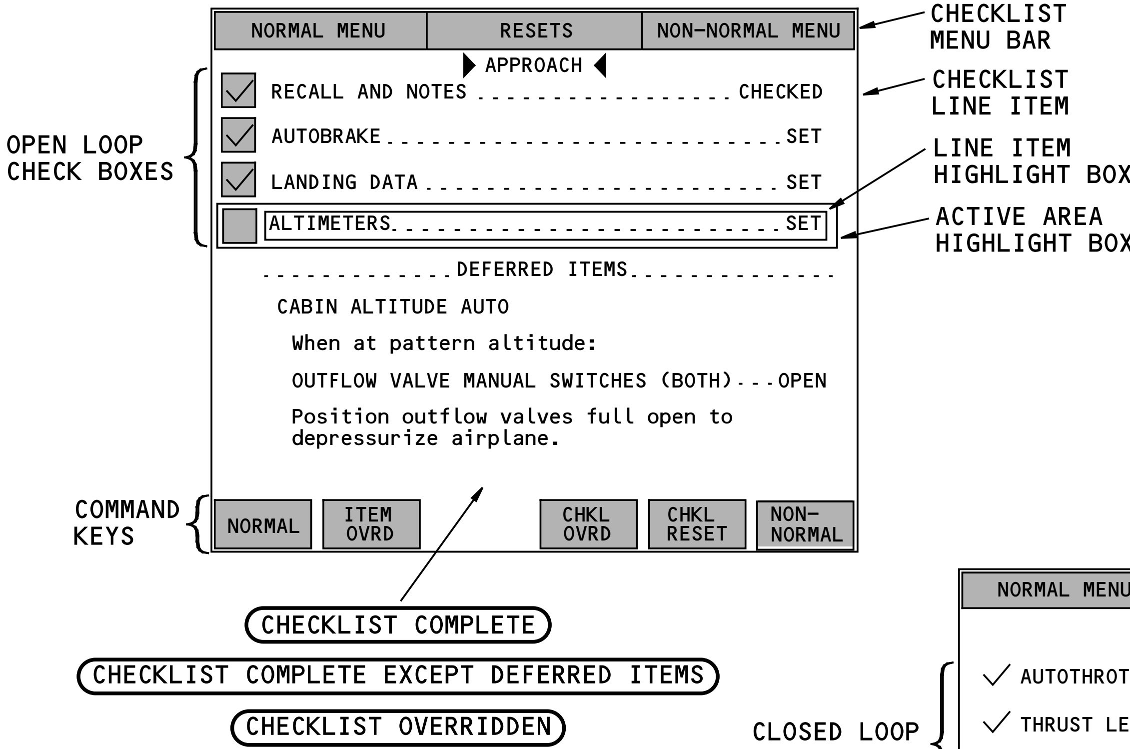
If the flight crew does not complete one checklist before they go to another, the NORMAL or NON-NORMAL command key changes color to amber to show that one or more checklists are not complete. Selection of the amber command key returns the system to the first line item not complete in the first incomplete checklist.

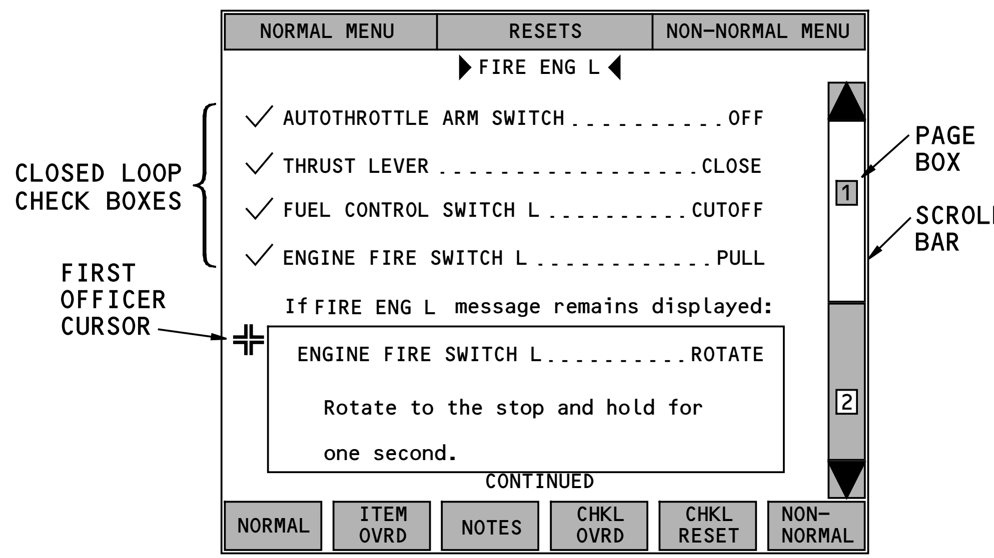
Scroll Bar

Checklists with more than one page have a scroll bar to give access to different pages. A page box and highlight indicates the page that shows on the display unit. Each page box shows the status of that page:

- White - At least one line item is not complete, or the page has not been accessed
- Green - All line items on the page are complete.

A page indicator shows a maximum of nine page numbers. Selection of a page number shows that page. A down arrow symbol replaces page number nine if the checklist is larger than nine pages. Selection of this arrow shows a page indicator that starts with an up arrow. Immediately below the up arrow is the selection of page nine and subsequent pages. This allows for a maximum of 99 pages in a checklist.





31-61-00-123 Rev 1 11/15/1995

PRIMARY DISPLAY SYSTEM - CHECKLIST CONTROL

PRIMARY DISPLAY SYSTEM - NORMAL CHECKLIST OPERATION

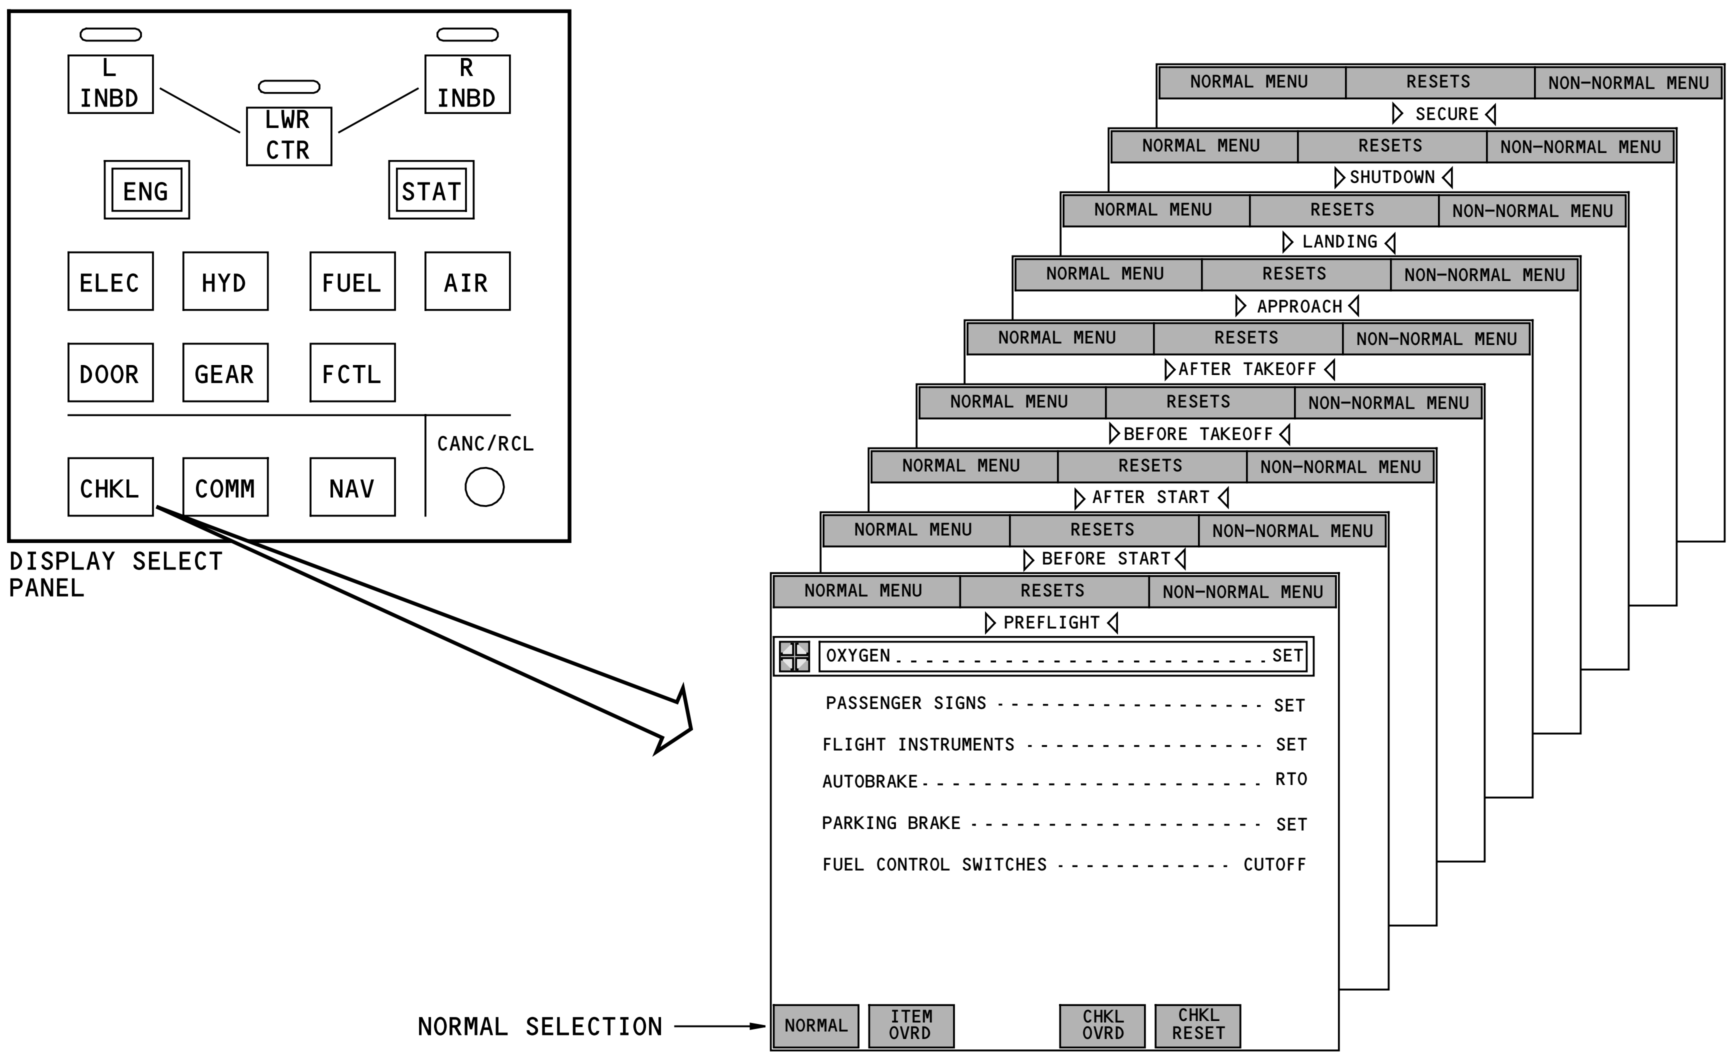
Checklist Access

To show a normal checklist, push the CHKL button on the display select panel (DSP). The first normal checklist that is not complete shows (unless a checklist with a higher priority exists). The normal checklist order directly relates to the different flight phases. The checklist changes after each flight phase. At the end of each normal checklist, select CHKL on the DSP or NORMAL in the lower left corner of the display to show the next checklist in order.

This is the order of the normal checklists:

- PREFLIGHT
- BEFORE START
- AFTER START
- BEFORE TAKEOFF
- AFTER TAKEOFF
- APPROACH
- LANDING
- SHUTDOWN
- SECURE.

To remove the checklist from the display unit (after all checklists are complete), push CHKL on the DSP a second time.



31-61-00-124 Rev 1 05/19/1997

PRIMARY DISPLAY SYSTEM - NORMAL CHECKLIST OPERATION

PRIMARY DISPLAY SYSTEM - NON-NORMAL CHECKLIST OPERATION

Checklist Access

To show a non-normal checklist, push the CHKL button on the display select panel (DSP). The first non-normal checklist that is not complete shows (unless a checklist with a higher priority exists).

If an EICAS message shows with a white empty box next to it, select CHKL to access the non-normal checklist for that condition. If more than one EICAS message shows, a CHKL selection causes a list box of non-normal checklists to show.

List Box

The list box shows non-normal checklists in this order:

- Warning message checklists
- Caution message checklists
- Advisory message checklists
- Unannunciated checklists.

The list box contains a list of incomplete checklists that have a relation to an EICAS message. Use the cursor control device to select a checklist from the list box. When the checklist is complete, the checklist title goes away from the list box. If there are more than nine non-normal checklists, a scroll bar shows adjacent to the list box.

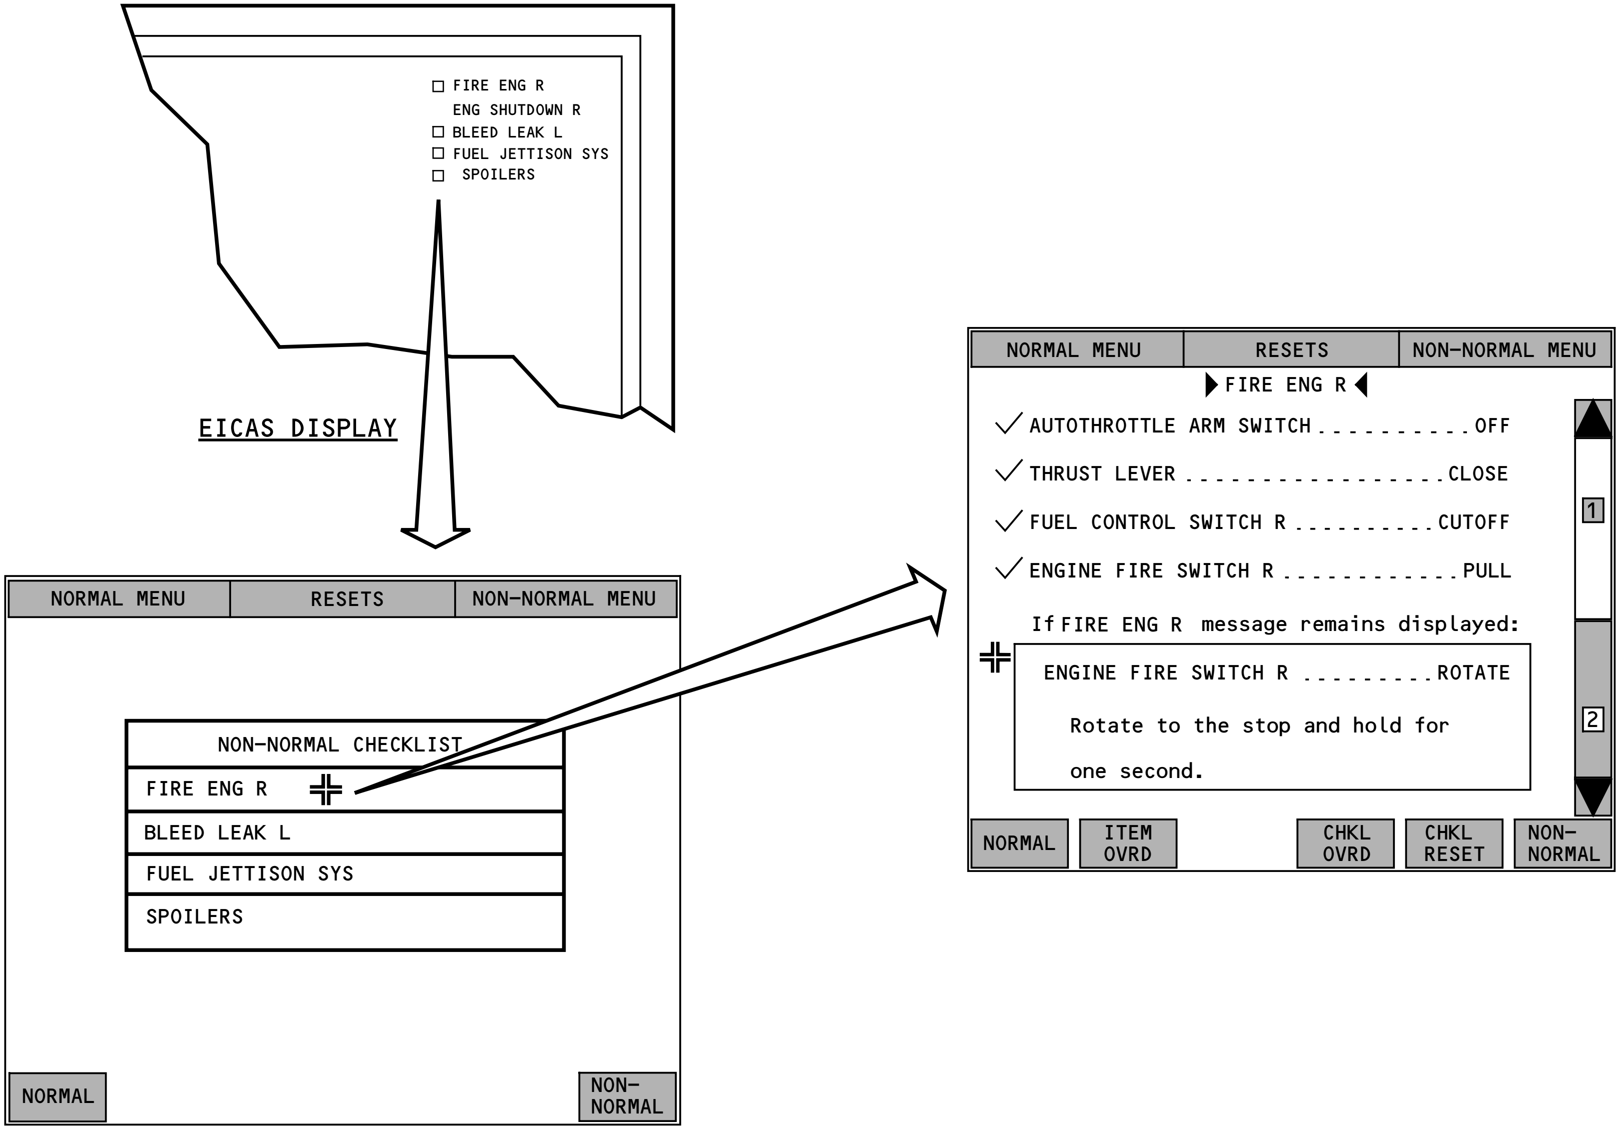
Un-annunciated Non-normal Checklists

Non-normal checklists that do not have a relation with an EICAS message are called unannunciated checklists. Select the NON-NORMAL MENU to show the non-normal checklist menu. Unannunciated checklists are the first sub-menu under the non-normal menu.

Non-normal Checklist Status Indicator

The condition of a non-normal checklist that has a relation to an EICAS message shows on the display unit (engine primary format) as a box adjacent to the related EICAS message. The checklist status shows as one of these:

- White empty box - The checklist for the message has not been accessed or the checklist has been accessed but not complete
- No box - The checklist for the message is complete or no checklist procedure exists for the message.



31-61-00-125 Rev 2 11/15/1995

PRIMARY DISPLAY SYSTEM - NON-NORMAL CHECKLIST OPERATION

PRIMARY DISPLAY SYSTEM - CHECKLIST OPERATIONAL NOTES

General

Operational notes give information about the effects of failures that occur during the flight. Operational notes include:

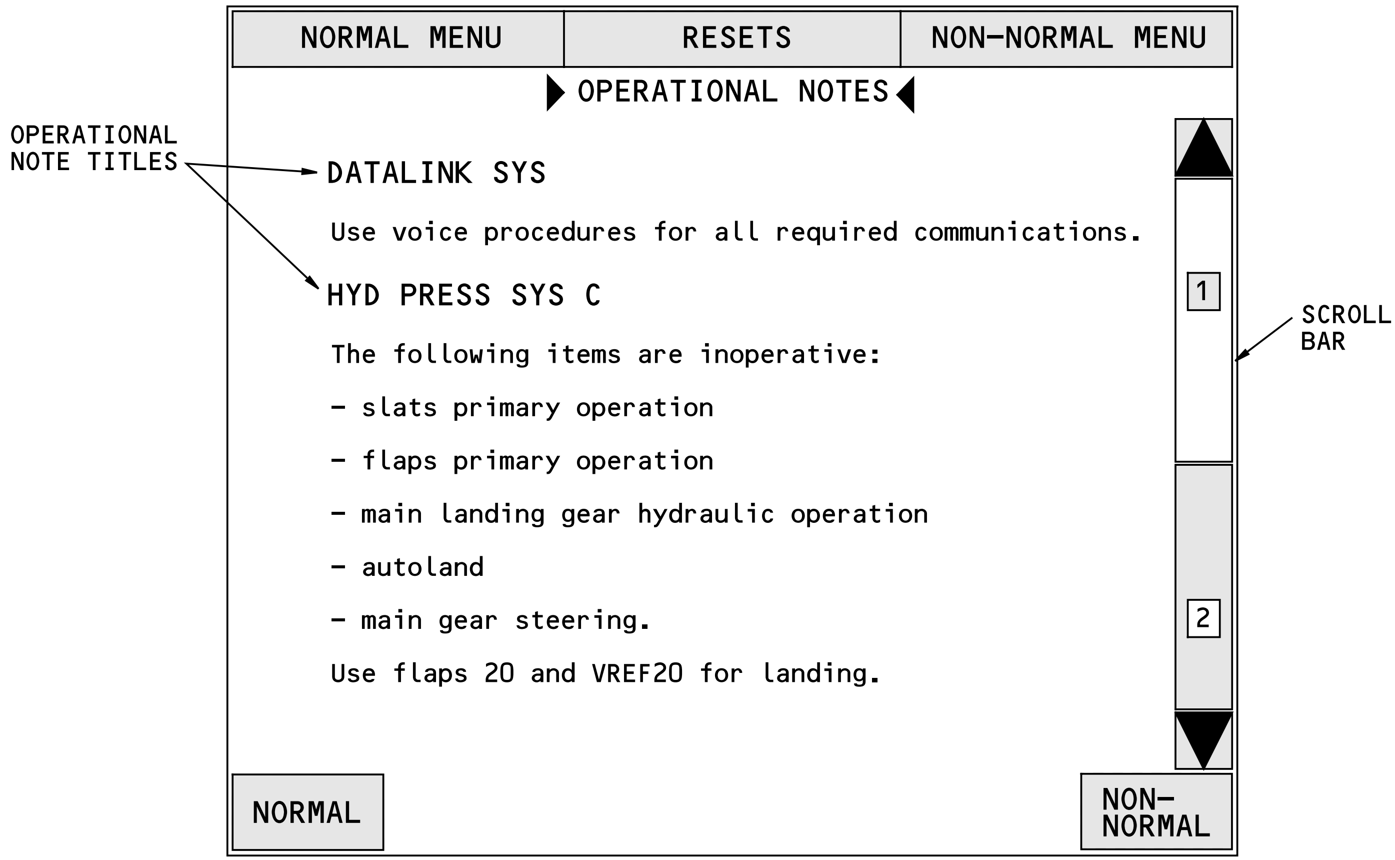
- Inoperative equipment
- Limitations
- Notes.

To access operational notes, select the NOTES command key. The NOTES selection shows on the lower part of the display unit when information that has a relation to a non-normal condition is important. Operational notes are available throughout the rest of that flight.

Each operational note includes a title which is the same as the EICAS message.

A paging panel shows if the operational notes have more than one page.

Operational notes latch to the state of the non-normal condition. When the condition and EICAS message goes away, the operational note goes away.



31-61-00-126 Rev 0

PRIMARY DISPLAY SYSTEM - CHECKLIST OPERATIONAL NOTES

PRIMARY DISPLAY SYSTEM - CHECKLIST LANDING PREPARATION FEATURE

Landing Preparation Functions

Many non-normal checklists contain landing preparation line items also known as deferred line items. These items have a relation to the approach and landing phases of flight. The landing preparation information includes:

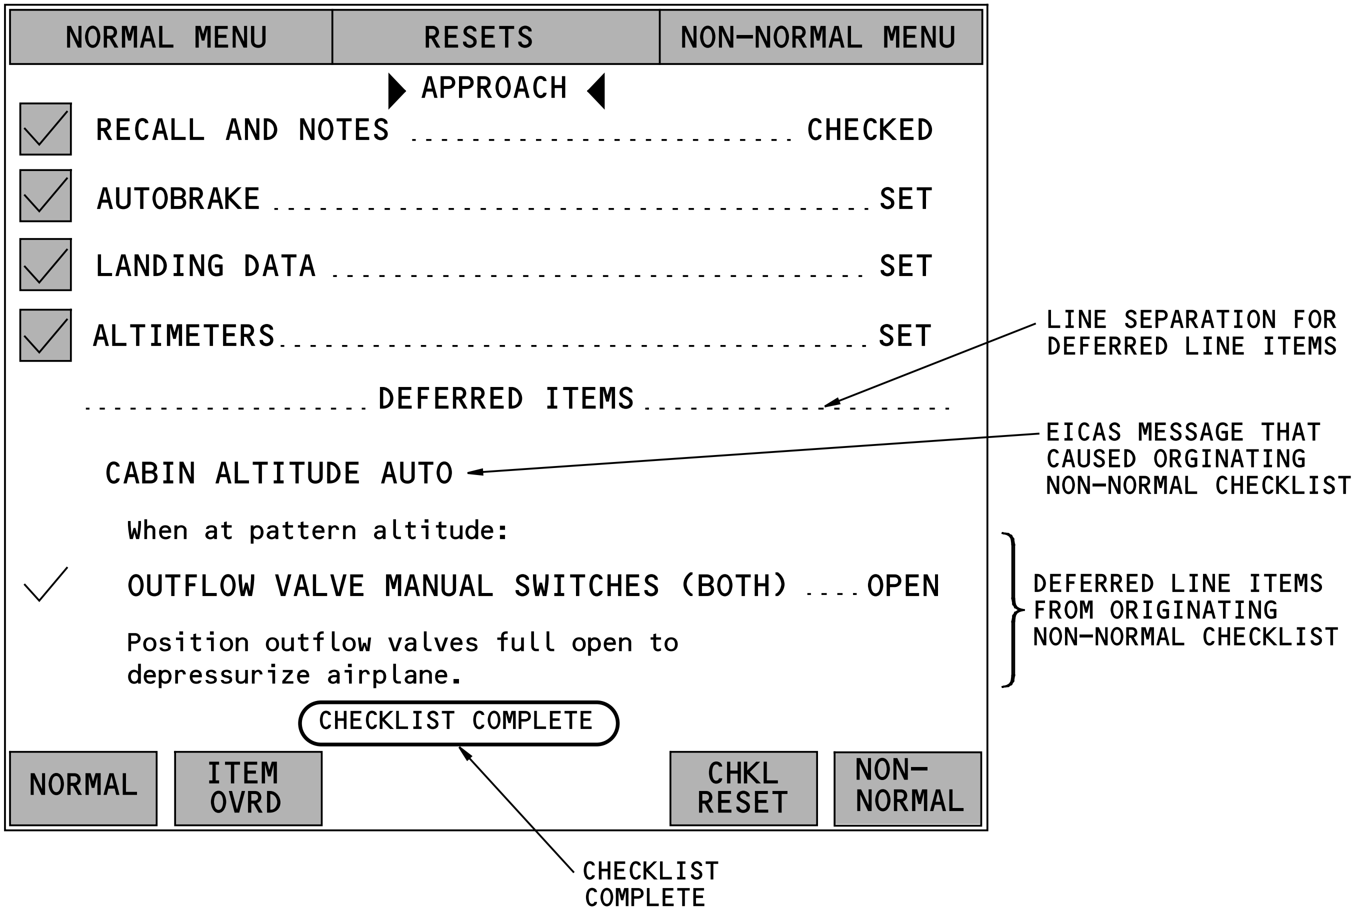
- Inoperative equipment
- Limitations
- Landing preparation procedures
- Conditional statements
- Notes.

If a non-normal checklist has deferred items, they show on a subsequent normal checklist.

A non-normal checklist that contains deferred items is complete when all line items before the deferred items are complete. The message CHECKLIST COMPLETE EXCEPT DEFERRED ITEMS shows on the bottom of the checklist.

On the normal checklists, each set of deferred items refers to the EICAS message that caused the original non-normal checklist. A line makes a separation of the deferred items from both the originating non-normal checklist and the approach or landing normal checklist.

If a non-normal condition occurs after the normal checklist is complete, the non-normal checklist is not complete until all items including the deferred items are complete.



31-61-00-127 Rev 2 03/02/95

PRIMARY DISPLAY SYSTEM - CHECKLIST LANDING PREPARATION FEATURE

PRIMARY DISPLAY SYSTEM - NON-NORMAL CHECKLIST CONDITIONAL STATEMENTS

General

These are the two different types of conditional statements for non-normal checklists:

- Closed loop (automatic switch and system input)
- Open loop (manual input from the pilot).

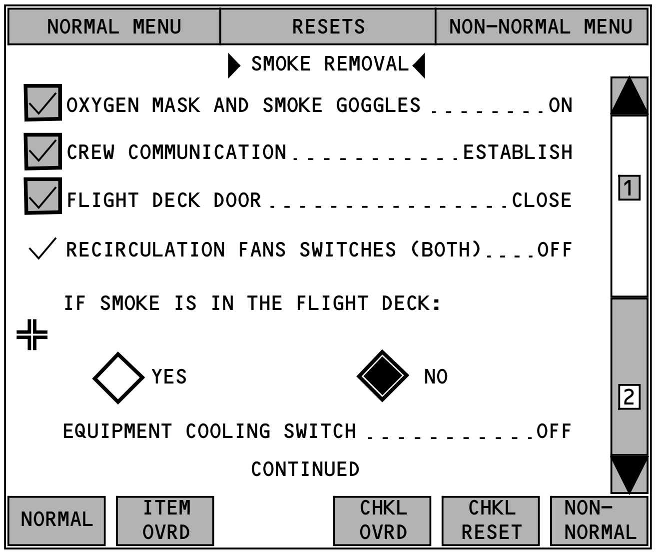
Conditional statements have an IF-THEN structure.

Open Loop If Statement

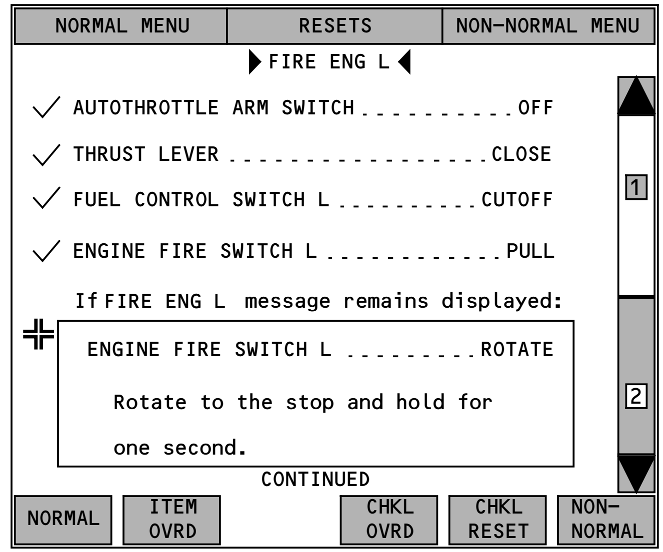
Open loop IF statements include the selections YES and NO. Use the CCD to place the cursor adjacent to the YES/NO line and make a selection to answer the statement. If the answer to the IF statement is yes, the cursor moves to the first line item within the IF statement to be completed. If the answer to the IF statement is no, the line item turns cyan to show that the item is not applicable.

Closed Loop If Statement

Closed loop IF statements are similar to open loop IF statements with one difference. In closed loop IF statements, the YES and NO decision is made automatically by the checklist function which monitors airplane system status. If the condition is yes, the cursor moves to the first line item within the IF statement to be completed. If the condition is no, the IF statement is satisfied and turns cyan to show that the item is not applicable.



OPEN LOOP IF STATEMENT



CLOSED LOOP IF STATEMENT

31-61-00-128 Rev 1 11/15/1995

PRIMARY DISPLAY SYSTEM - NON-NORMAL CHECKLIST CONDITIONAL STATEMENTS

PRIMARY DISPLAY SYSTEM - CHECKLIST OVERRIDE FUNCTION/CHECKLIST TIMERS

General

These are the two types of override functions:

- Checklist item overrides
- Checklist overrides.

Checklist Item Override

The ITEM OVRD selection is available on all checklists. Selection of the ITEM OVRD command key turns the highlighted step to cyan. This shows that the step has been overridden. Both closed loop and open loop steps can be overridden.

A checklist is complete if all steps, except landing preparation steps, are green or cyan.

Conditional statements (both closed and open loop) cannot be overridden. Steps within conditional statements can be overridden.

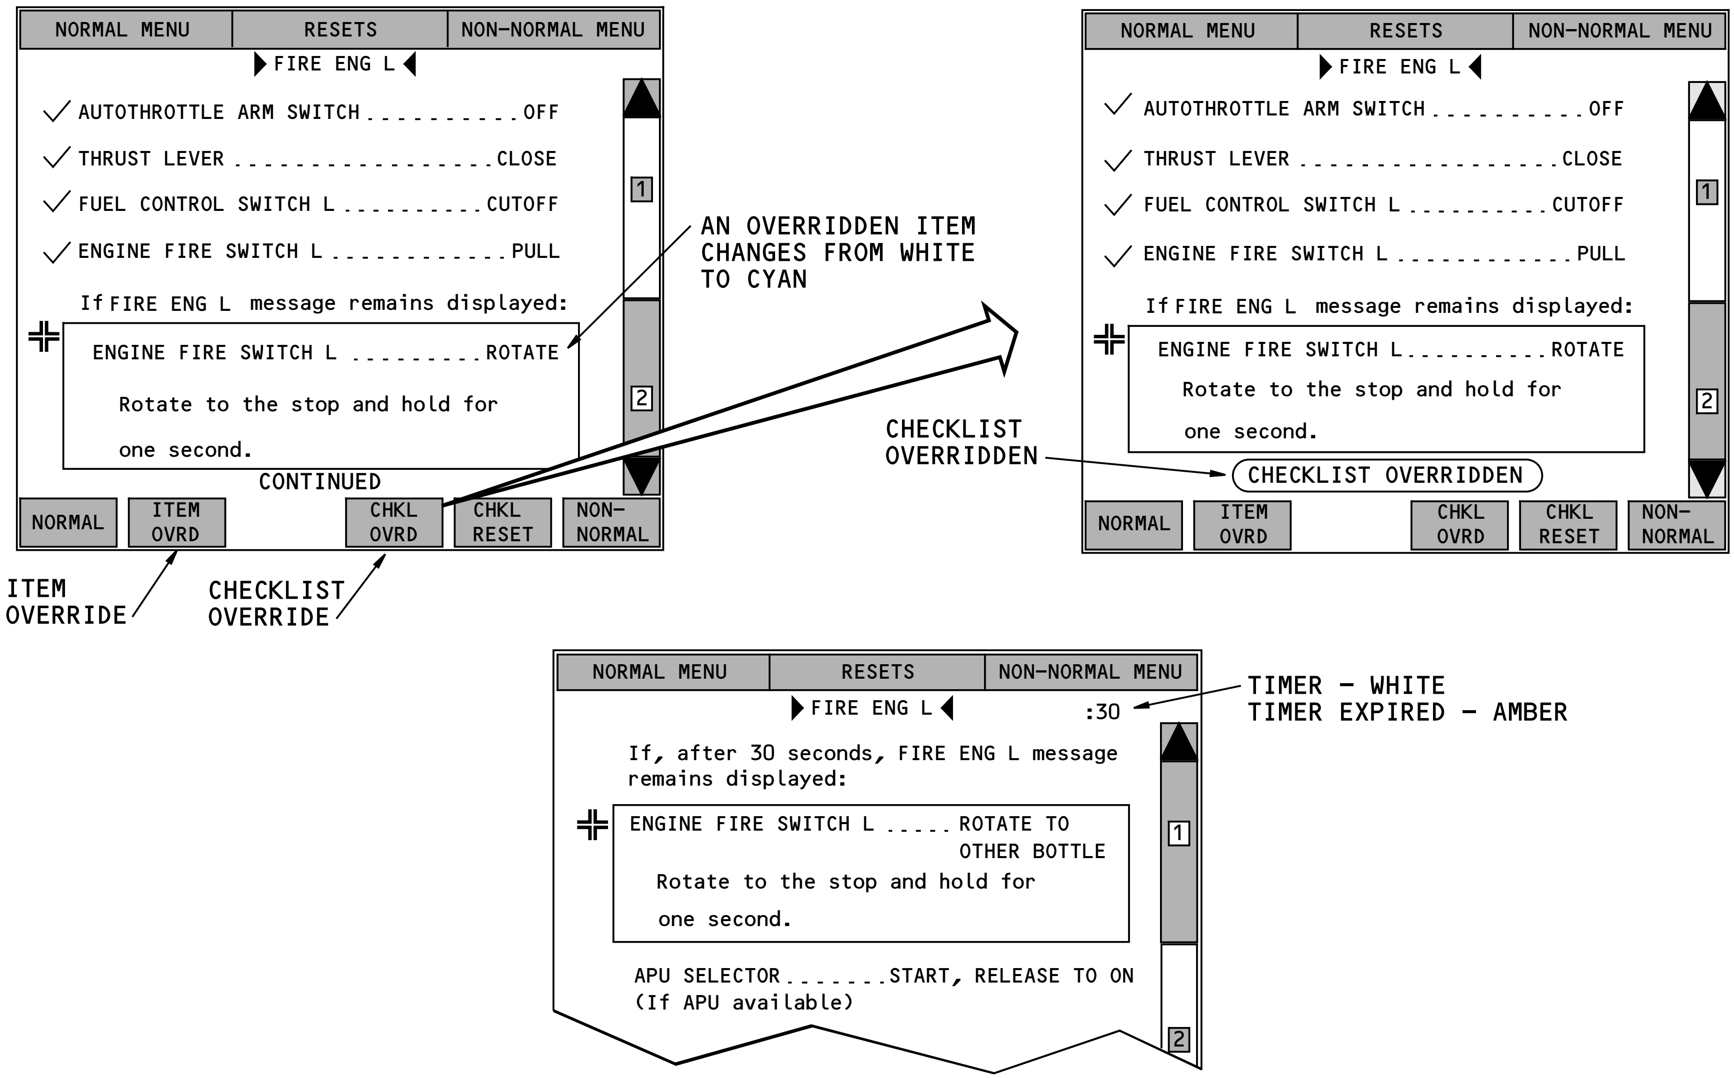
Checklist Override

Full checklists can be overridden. Select the CHKL OVRD command key to override a checklist. The checklist turns cyan when it is overridden. All related operational notes and landing preparation items go away and conditional statements cancel. The message CHECKLIST OVERRIDDEN shows at the bottom of the page.

Checklist Timers

Where necessary, an automatic timer shows in the upper right corner of the checklist. This helps complete checklist items where time delays are necessary. Maximum time is 99 minutes and 59 seconds. All timers are countdown timers. Timers usually go with conditional IF statements. When the line item highlight box shows on a line item, the timer starts to count down.

Timers continue to operate when the checklist does not show. This lets the flight crew do other tasks and then return to the checklist. Timers show in white. An expired timer shows :00 and the color is amber. As soon as the operator completes the next line item, the expired timer goes away.



PRIMARY DISPLAY SYSTEM - CHECKLIST OVERRIDE FUNCTION/CHECKLIST TIMERS

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - CHECKLIST RESETS

General

When a checklist is complete, to do the checklist again, the checklist must be reset. Some conditions require resets to prepare the checklist for the next phase of flight.

There are manual resets and automatic resets.

The resets menu page also has the software part numbers for the checklist databases.

Normal Checklist - Manual Reset Conditions

These are the normal manual checklist reset conditions:

- RESETS FUNCTION. The flight crew selects the RESETS function from the menu bar and then selects RESET NORMAL. This resets all normal checklists. If the flight crew selects RESET ALL, then all normal and non-normal checklists are reset.
- INDIVIDUAL CHECKLIST RESET. Select the CHKL RESET command key to reset any displayed checklist.

Normal Checklist - Automatic Reset Conditions

These are the automatic normal checklist reset conditions:

- GO-AROUND. If the airplane is in the air, the landing gear is not up, and TO/GA is selected, or takeoff thrust is set on either engine, then all specified normal checklists automatically reset.
- TOUCH AND GO. If the airplane changes from air to ground, and takeoff thrust is set with groundspeed greater than 80 KIAS, and the thrust reversers not deployed, then all specified normal checklists are reset.
- RESET ALL. The airplane changes from air to ground, and both engines are shut down, and at least one passenger door is open (conditions must be set for 10 minutes). All normal checklists are reset.
- If a completed checklist is selected from the menu, it is automatically reset.

Non-Normal Checklist Manual Reset Conditions

These are the non-normal manual checklist reset conditions:

- RESETS FUNCTION. During preflight, the flight crew selects the RESETS menu and then selects RESET NON-NORMAL. This resets all non-normal checklists. If the flight crew selects RESET ALL, then all normal and non-normal checklists are reset.
- INDIVIDUAL CHECKLIST RESET. Select the CHKL RESET command key to reset any displayed checklist.

Non-Normal Checklist - Automatic Reset Conditions

These are the automatic non-normal checklist reset conditions:

- The non-normal conditions no longer exist.

PRIMARY DISPLAY SYSTEM - CHECKLIST RESETS

- RESET ALL. The airplane changes from air to ground, and both engines are shut down, and at least one passenger door is open (conditions must be set for 10 minutes). All checklists are reset.

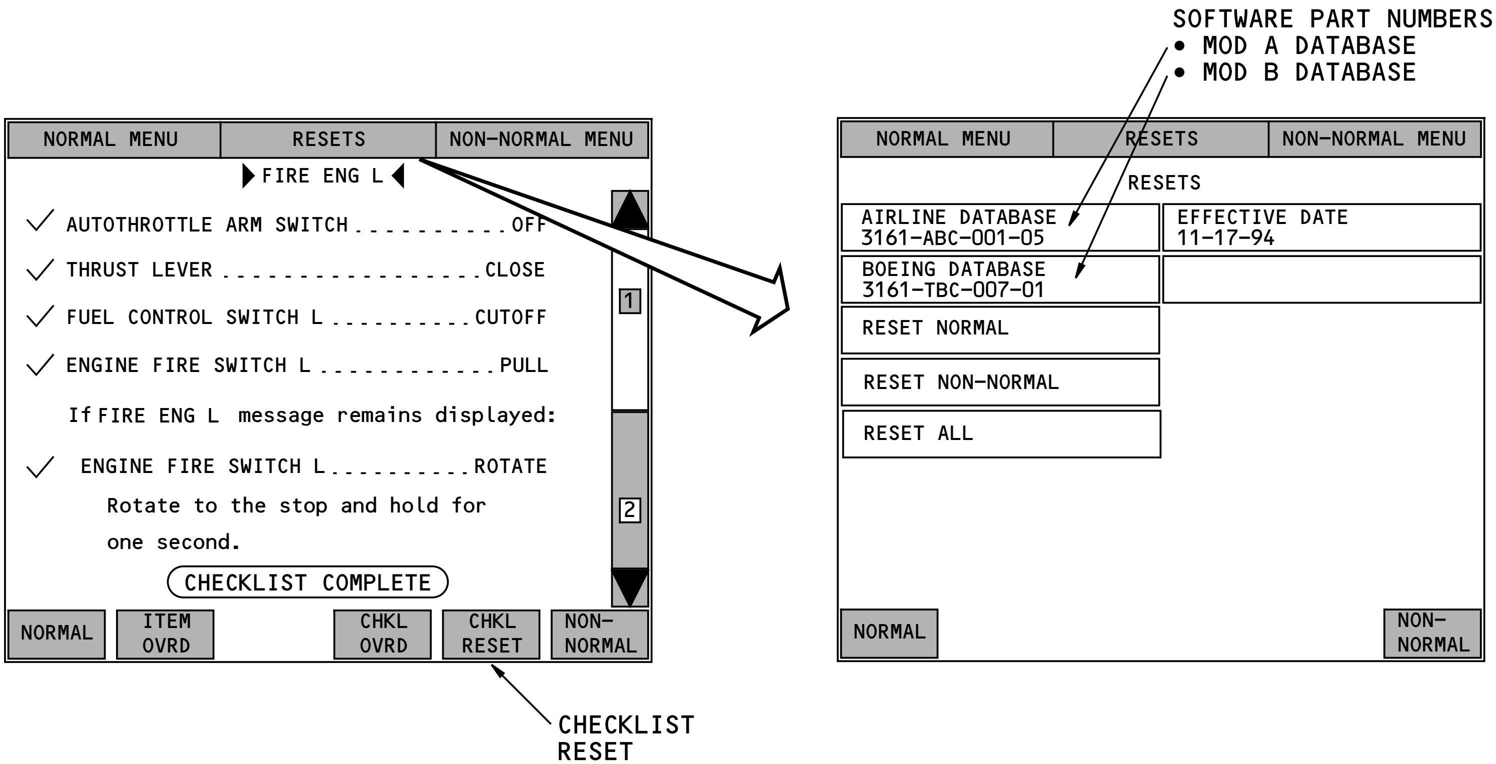
Checklist Databases

The checklist database has two parts, the MOD B database and the MOD A database.

The MOD B database has the Boeing baseline checklist and the specific rules and global rule flags for the particular airplane configuration.

The MOD A database has the Boeing baseline checklist (without the specific rules) and all the airline modifications (AMI).

Together, the two databases make an operational checklist.



31-61-00-130 Rev 1 11/15/1995

PRIMARY DISPLAY SYSTEM - CHECKLIST RESETS

PRIMARY DISPLAY SYSTEM - AIRLINE MODIFIABLE INFORMATION

General

Boeing provides an initial customized normal and non-normal checklist for each airline.

Boeing will also provide electronic checklist revision information along with operations manual updates.

The airline may use the ground based software tool to make any other desired changes to the baseline AMI.

BASELINE AMI	MODIFIABLE INFORMATION
CUSTOMIZED NORMAL AND NON-NORMAL CHECKLIST	ANY ELEMENT OF THE CHECKLIST THAT THE AIRLINE FINDS TO BE NECESSARY

31-61-00-131 Rev 1 03/02/95

PRIMARY DISPLAY SYSTEM - AIRLINE MODIFIABLE INFORMATION

PRIMARY DISPLAY SYSTEM - EICAS AND MFD FUNCTIONAL DESCRIPTION

General

Each AIMS cabinet has four input/output modules (IOMs) and two core processor/graphic generators (CPM/GGs). Each graphic generator has an output to the display units (DUs). The EICAS and MFD functions in the CPM/GGs independently process their formats. The EICAS function has these sub-functions:

- Solution logic
- EICAS display generator.

The MFD function has these sub-functions:

- System fault reports
- Determine dispatch status
- MFD display generator.

Both functions send data to the graphic generator sub-function. The graphic generator reformats and sends this data to the DUs.

IOMs

Each IOM does these functions:

- Presence and validity checks
- Source select and filtering.

The IOM modules do presence and validity checks on all display input parameters. Data updates at specified frequencies make sure that the information the flight crews see is current.

Each IOM removes bad data, replaces it with a good source, and filters the change from bad to a good data source. The IOM sends, in critical cases, messages to alert the flight crew of a failure. The IOMs send the valid and message data to the EICAS and MFD functions through the backplane bus.

CPM/GGs

Each CPM/GG also has an EICAS and MFD function with sub-functions. Each AIMS cabinet has two CPM/GGs for a total of four on the aircraft. Each CPM/GG can drive any three display units or three out of four display formats (EICAS, MFD, PFD, or ND). The PFD and ND functions configure and format the PFD and ND displays. The outboard DU location is for PFD display only. This redundant system supplies fail operational capability and allows deferred airplane maintenance.

The sub-functions in the CPM/GGs decode switch inputs and make the appropriate displays. Additional switch positions determine format location. If the upper center DU fails, the lower center DU changes to the upper center DU format.

EICAS Function- Solution logic

The solution logic sub-function receives display and switch input data from the IOMs. The solution logic sub-function determines which of these formats to select:

- EICAS display

- Compacted engine
- Secondary engine.

The solution logic use the DSP DU and ENGINE push-button selection along with DU failure status to change between the EICAS display and compacted engine formats. A second push of the DSP ENGINE switch causes the MFD to show the secondary engine format.

The solution logic sub-function sends the display data to the EICAS display function. A failure of the lower DU also causes the solution logic to send compacted engine set logic along with display outputs to the EICAS display sub-function.

EICAS Function- EICAS Display

The EICAS display sub-function use the solution logic inputs and display data to select the correct format(s) and display data. The EICAS and/or secondary formats go to the EICAS display generation block.

EICAS Function- EICAS Display Generation

The EICAS display generation sub-function reformats the display data for the graphics generator.

EICAS/ Function - MFD Graphics Generator

The graphics generator sub-function changes the EICAS display data to graphics on a vector format and sends it to the displays through a coaxial-cable. DU switch inputs from the display switching panels determine when an EICAS display shows in more than one location.

MFD Function - System Fault Reports

The system fault reports sub-function receive faults, sort and order the faults by time of occurrence. It sends this data to the determine dispatch status sub-function.

MFD Function - Determine Dispatch Status

The determine dispatch status sub-function use the fault report data and an airworthiness table to determine the airplane dispatch status. It sends this data to the MFD display generator.

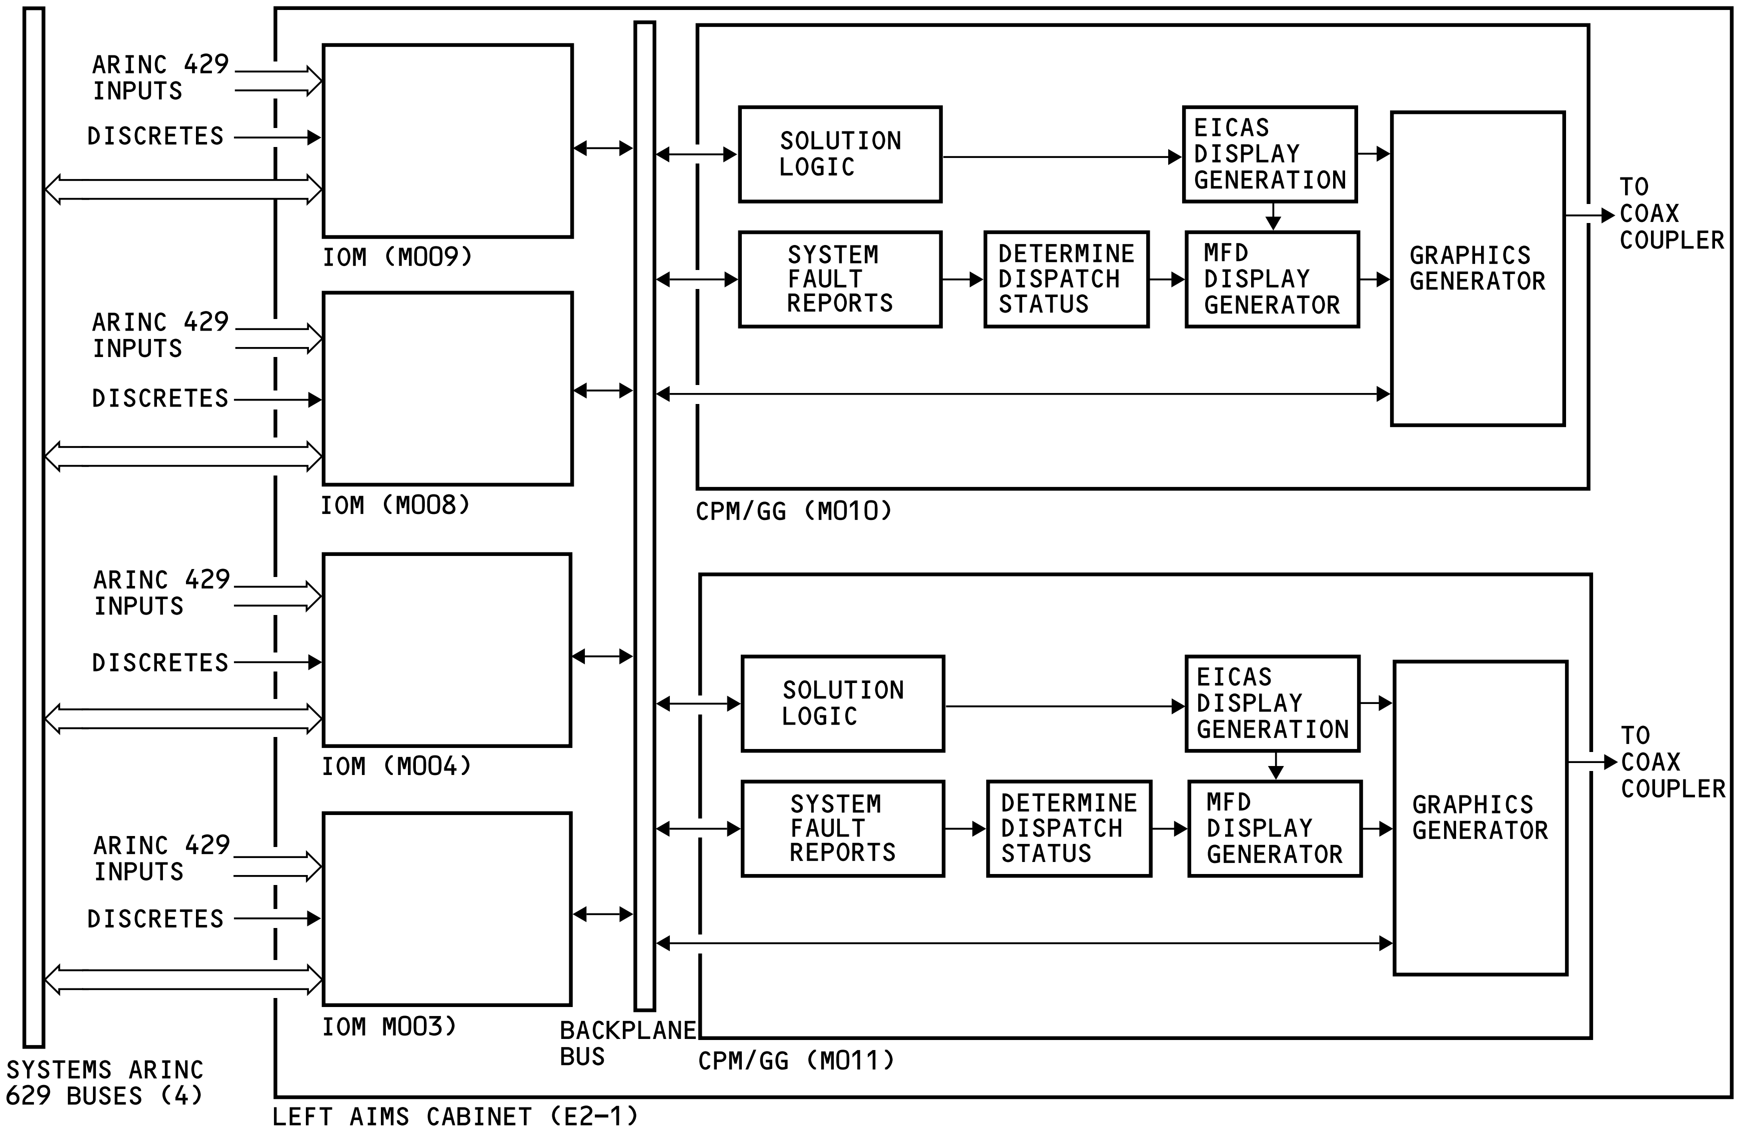
MFD Function - MFD Display Generator

The MFD display generator sub-function use the airplane status data, display selection, and real time status inputs to properly format displays. The display generator use this data along with the maintenance page control and output device selection inputs for proper page display and correct DU location. These inputs permit the MFD display to show synoptics and maintenance formats.

It also use the switch data for automatic lower DU selection to an EICAS format in case the upper DU fails.

PRIMARY DISPLAY SYSTEM - EICAS AND MFD FUNCTIONAL DESCRIPTION

The graphics generator sub-function changes the display data to a video format and sends it to the DUs through a coaxial-cable. DU switch inputs from the display switching panels determine when a MFD display shows in more than one location.



31-61-00-105 Rev 1

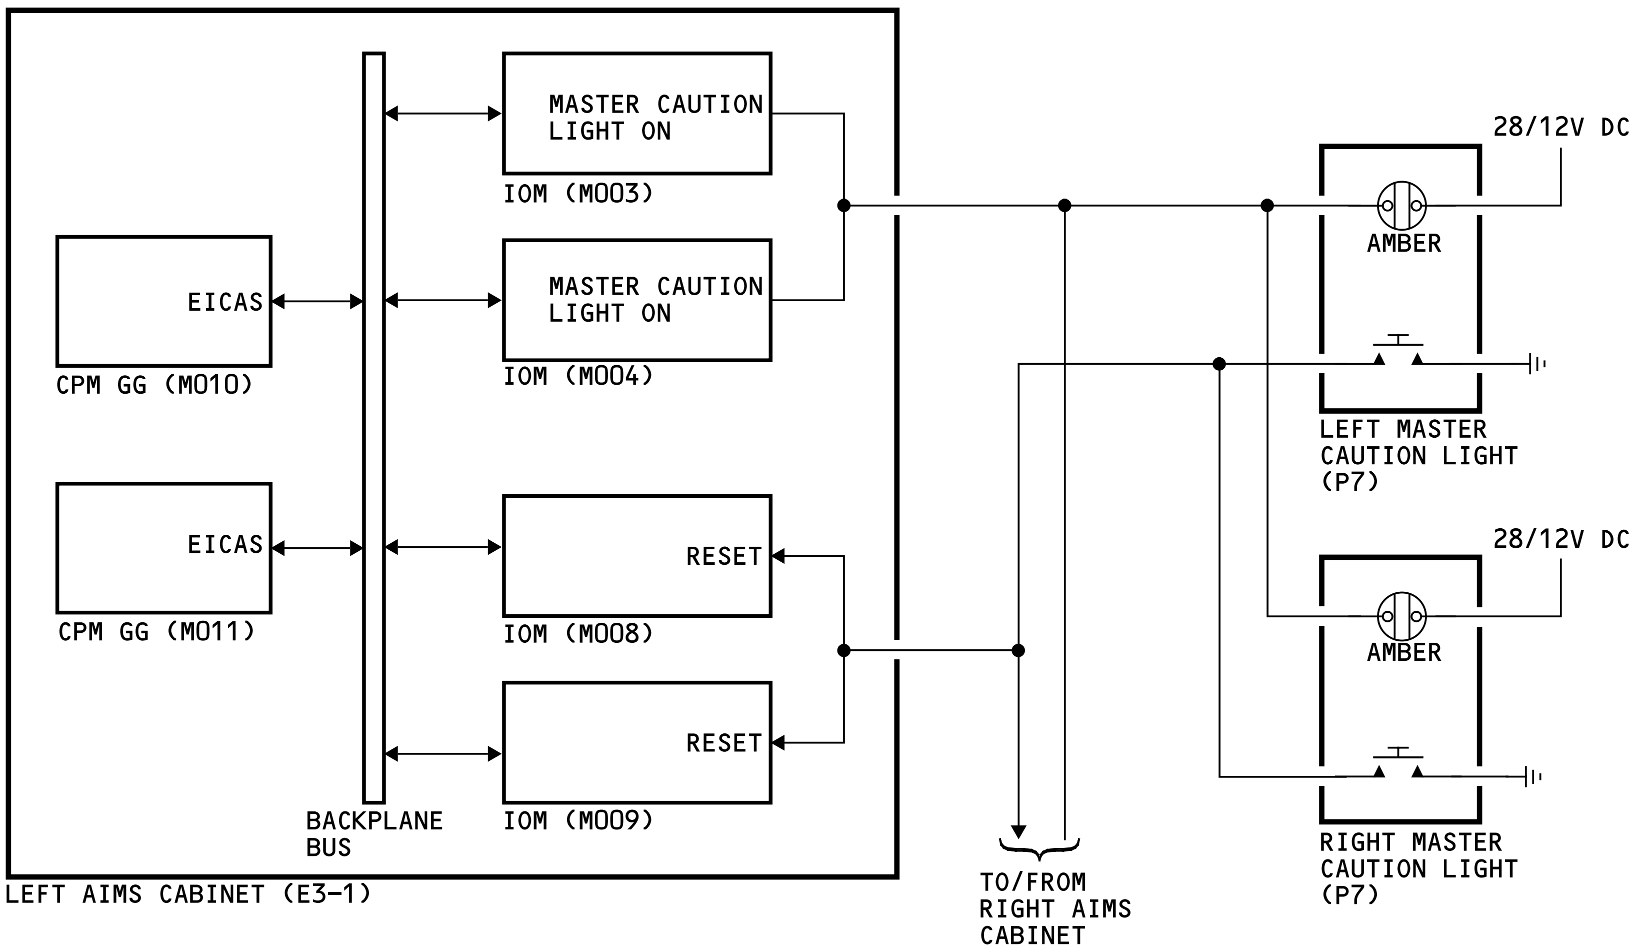
PRIMARY DISPLAY SYSTEM - EICAS AND MFD FUNCTIONAL DESCRIPTION

PRIMARY DISPLAY SYSTEM - MASTER CAUTION LIGHTS FUNCTIONAL DESCRIPTION

General

When a caution message shows on the EICAS display, the EICAS function in the CPM GGs make master caution light on signals. The IOMs supply the master caution light on signals to the master caution lights. The master caution lights come on.

When you push the master caution lights, a momentary reset signal goes to the IOMs. The IOMs send the reset signal to the EICAS function in the CPM GGs. The EICAS function then makes the master caution lights go out.



31-61-00-133 Rev 0 03/07/96

PRIMARY DISPLAY SYSTEM - MASTER CAUTION LIGHTS FUNCTIONAL DESCRIPTION

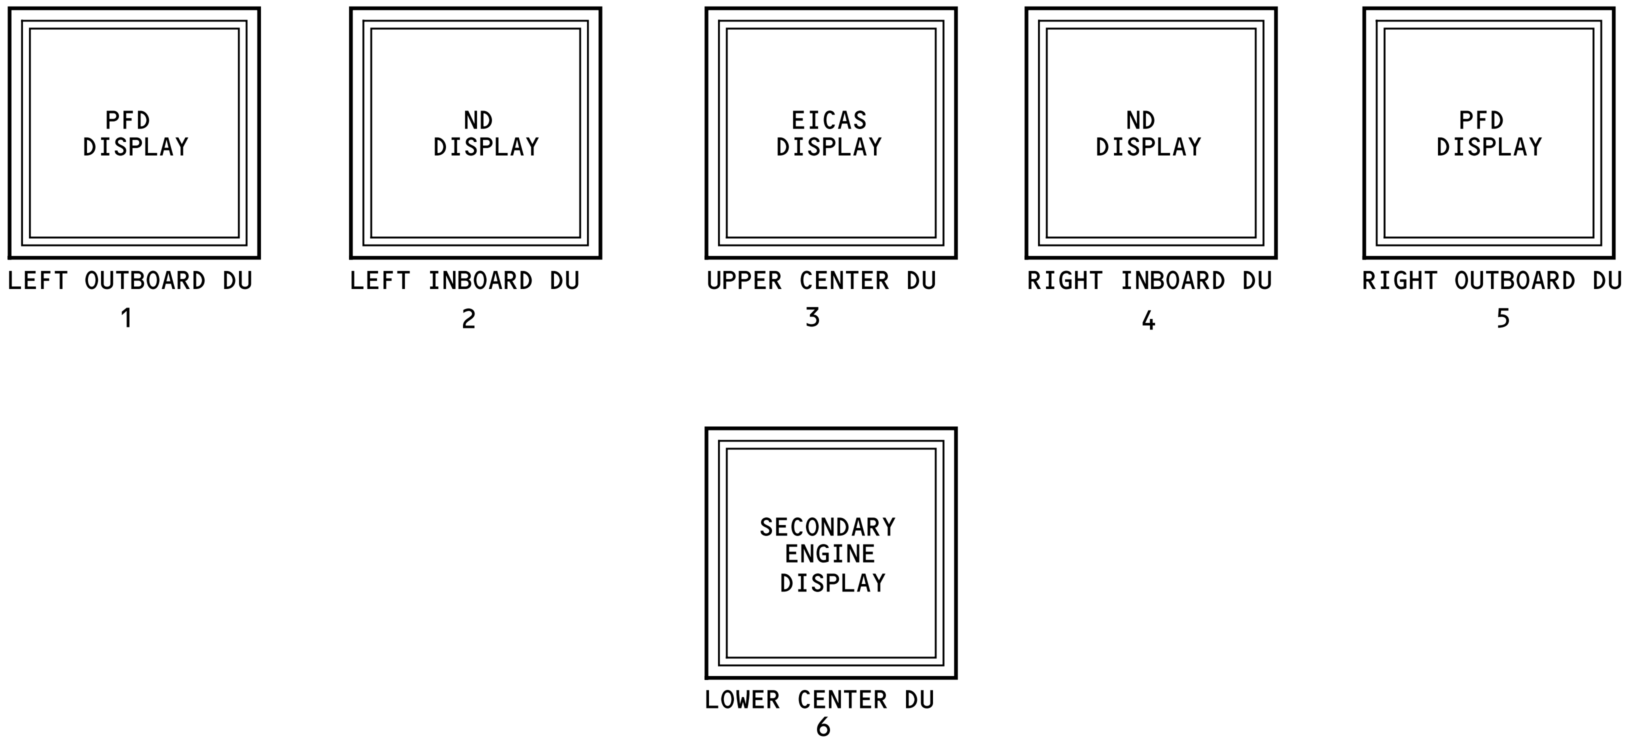
PRIMARY DISPLAY SYSTEM - DISPLAY FORMAT ALLOCATIONS - 1

General

Hardware position pins for display units (DU) determine normal display configuration. A position number identifies each DU location and its normal format. These are the position numbers, normal display format, and location:

- Position 1 - Captain's PFD (left outboard)
- Position 2 - Captain's ND (left inboard)
- Position 3 - EICAS display (upper center)
- Position 4 - First officer's ND (right inboard)
- Position 5 - First officer's PFD (right outboard)
- Position 6 - Secondary engine (lower center).

Each DU reports its operational status at power-up on the ground or at power-up after a long term power interrupt (5 seconds). The display function latches the configuration in memory. Subsequent in-flight failures of a position pin configuration does not cause format changes or failure indications.



31-61-00-106 Rev 1

PRIMARY DISPLAY SYSTEM - DISPLAY FORMAT ALLOCATIONS - 1

PRIMARY DISPLAY SYSTEM - DISPLAY FORMAT ALLOCATIONS - 2

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - DISPLAY FORMAT ALLOCATIONS - 2

General

Display unit failures or unique requirements cause the need to move displays to alternate DU locations. Some displays move automatically. Controls on the display select panel and the display switching panels enable the operator to move displays manually.

Display Unit Display Format Allocations

Each DU location has the capability to show specific formats.

The left outboard DU shows the captain PFD format only.

The right outboard DU shows the first officer PFD format only.

The center upper DU shows the EICAS display or compacted engine formats.

The left inboard DU shows these displays:

- Captain ND
- Captain PFD
- EICAS display
- Compacted engine display
- MFD formats.

The right inboard DU shows these displays:

- First officer ND
- First officer PFD
- EICAS display
- MFD formats.

The center lower DU shows these displays:

- MFD formats
- EICAS display
- Captain ND display
- First officer ND display.

The left, right inboard and lower center DUs can show the MFD formats. The MFD formats are:

- Secondary engine display
- Status display
- Synoptic displays
- Maintenance pages
- Checklists
- Communication displays.

Inboard Display Selectors

The inboard display selectors control onside movement of display formats to and from the inboard DUs.

The NORM position of the selector has two settings. The ND position causes the inboard DU to show the ND format. The MFD position works with the display select panel (DSP) L or R INBD switch and the other DSP display switches to show one of these displays on an inboard DU:

- Secondary engine display

PRIMARY DISPLAY SYSTEM - DISPLAY FORMAT ALLOCATIONS - 2

- Status display
- Synoptic displays
- Flight deck communication function display.

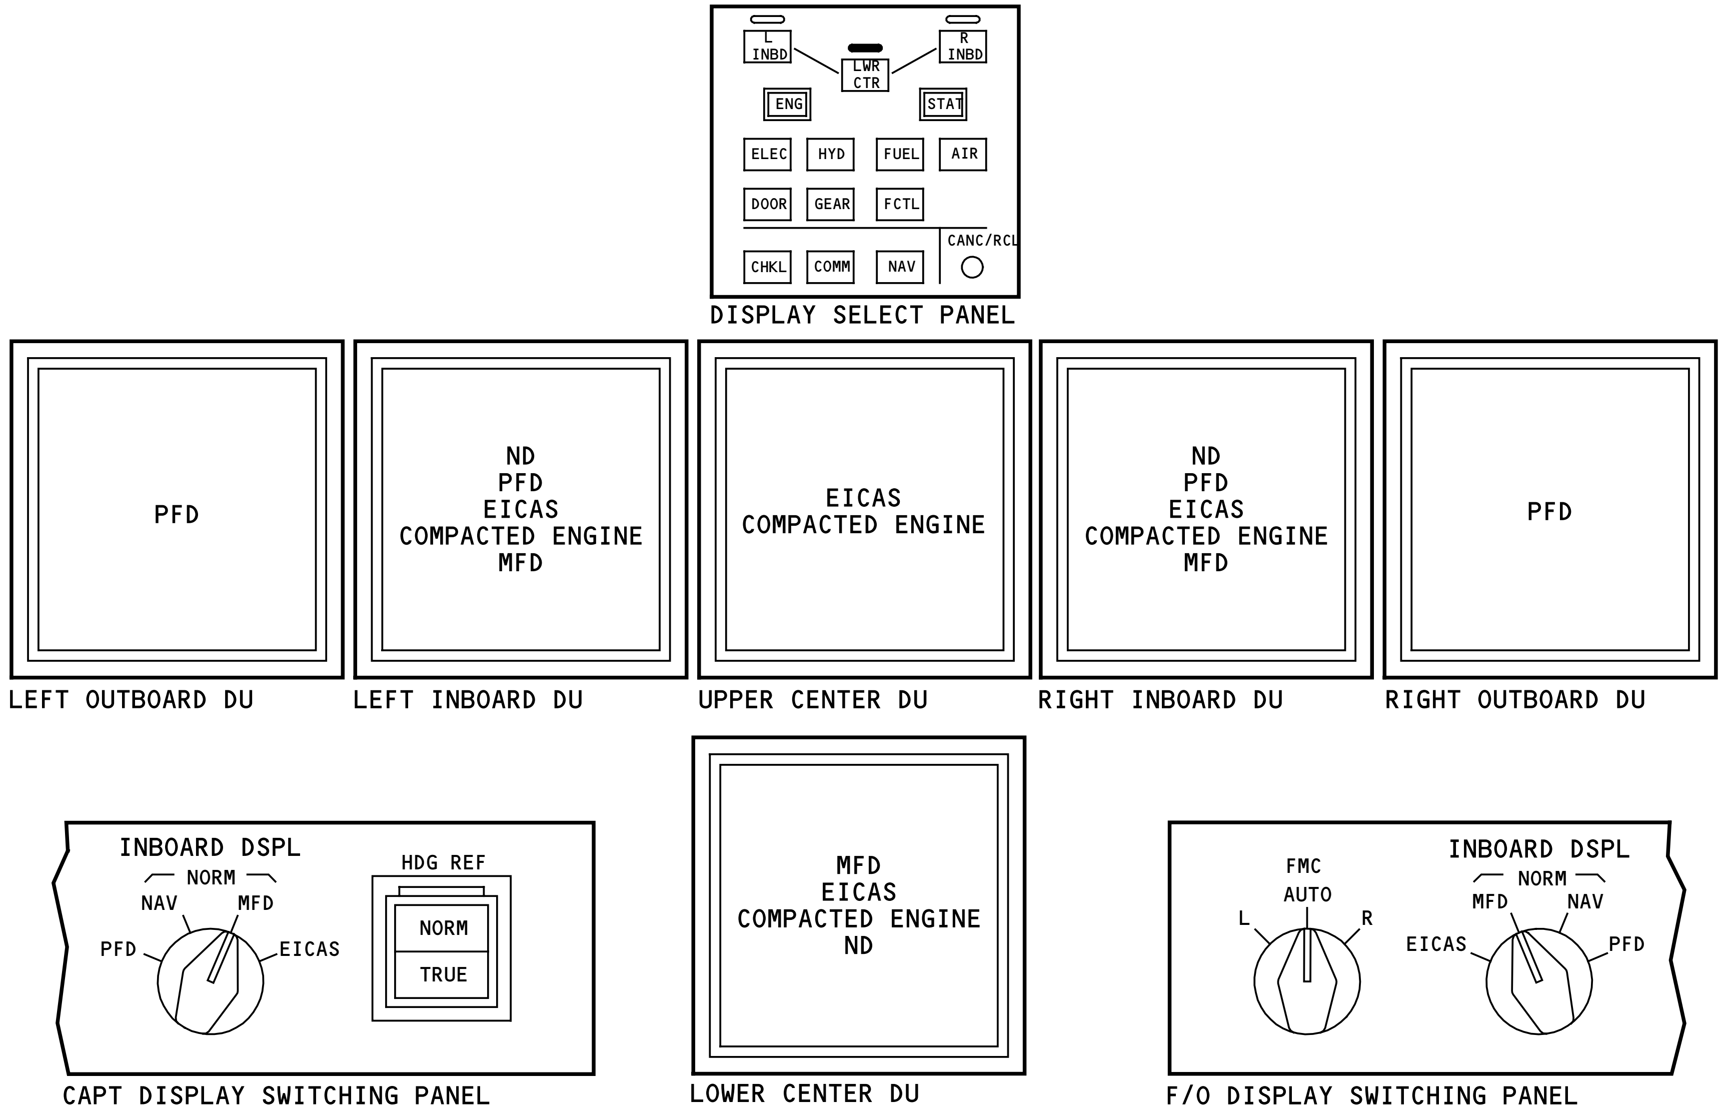
The L or R INBD switch on the DSP and the MFD position of the selector cause maintenance pages to show on an inboard DU after selection on a CDU.

PFD position causes the PFD display to show on the inboard DU.

The EICAS position causes the EICAS display to show in the normal mode or the compacted engine display to show in the limited mode. The limited mode exists when only one DU is available for EICAS display and secondary engine display.

Movement of the inboard display selector from the PFD position or from the EICAS position to the NORM position (ND or MFD) causes the ND format to show on the inboard DU.

A failure of the inboard display selector causes the display format that shows to latch.



PRIMARY DISPLAY SYSTEM – DISPLAY FORMAT ALLOCATIONS – 2

31-61-00-107 Rev 5 10/20/1997

PRIMARY DISPLAY SYSTEM - AUTOMATIC DISPLAY SWITCHING

General

The PFD display on the outboard DUs and the EICAS display on the upper center DU automatically move to alternate locations when a DU failure occurs.

When only one DU shows the EICAS display, EICAS is in the limited mode. In the limited mode, only these three switches on the DSP have a function:

- ENG switch
- AIR switch
- FUEL switch.

Outboard DU Failures

The PFD display automatically moves to the onside inboard location when a detected failure of the outboard DU occurs.

After the PFD display moves automatically, the inboard display selector on the display switching panel has no effect on the inboard DU.

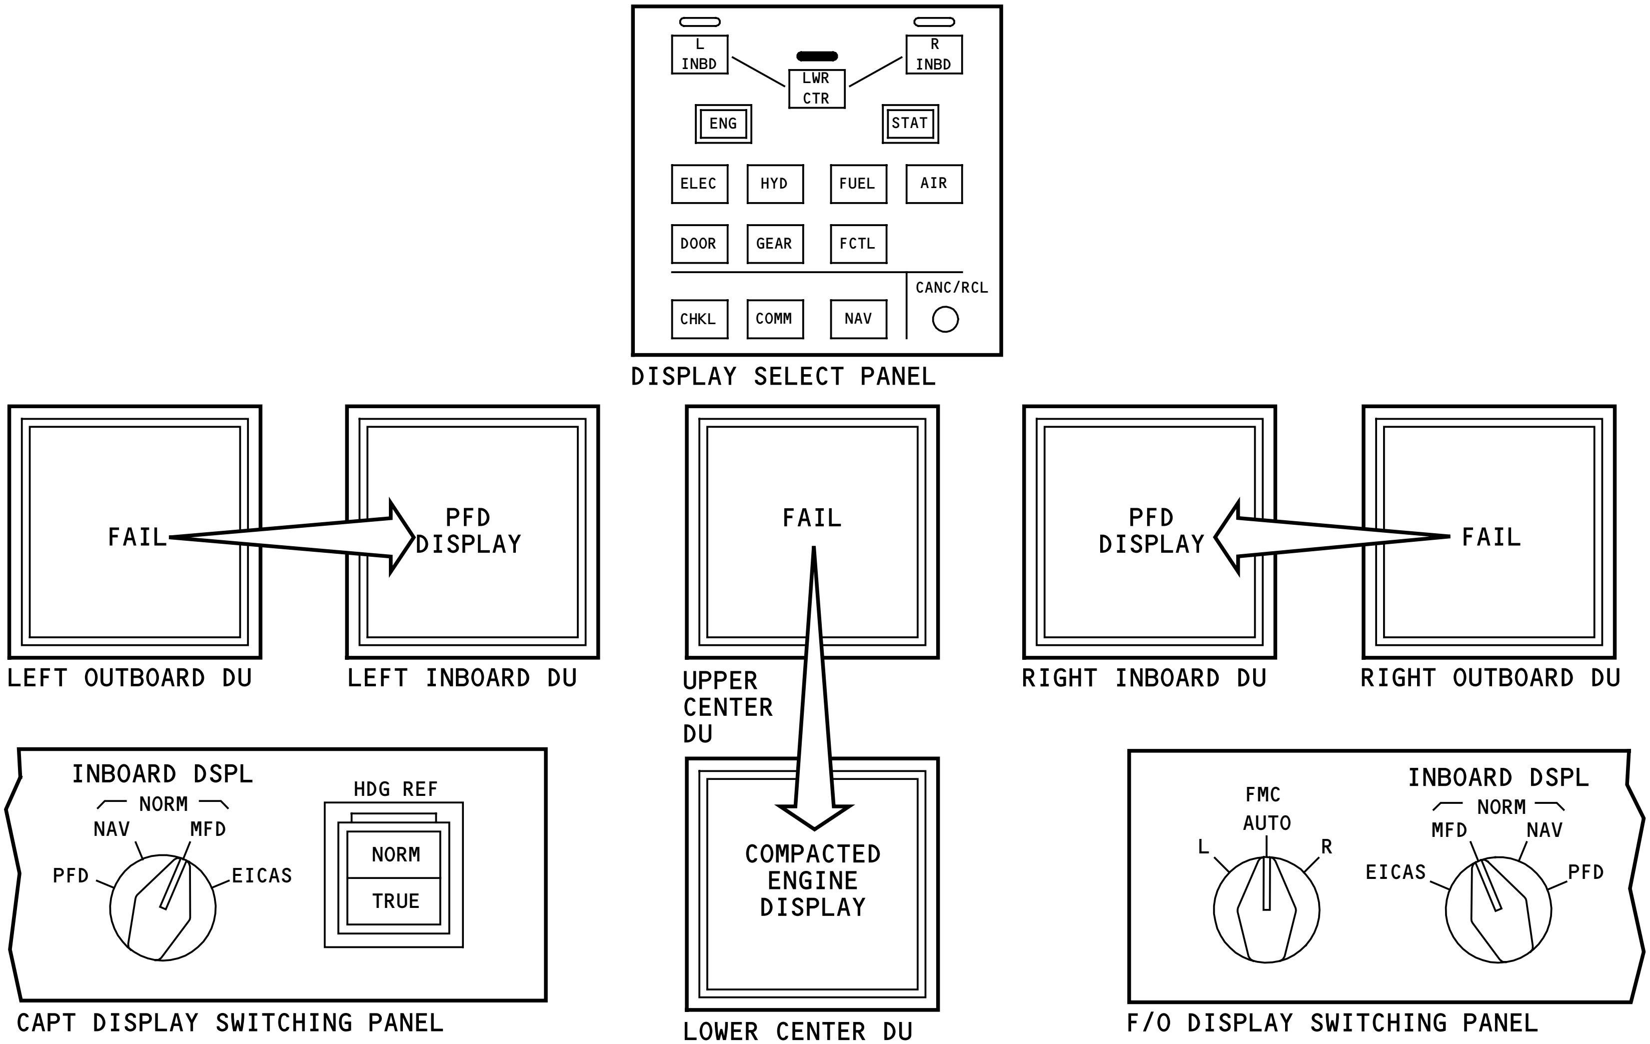
Upper Center DU failures

The EICAS display automatically moves to the lower center DU when a detected failure of the center upper DU occurs. The lower DU then shows the compacted engine display.

The ENG switch on the DSP causes the display to change between EICAS display and compacted engine display.

The AIR switch controls the ECS data block.

The FUEL switch controls the fuel quantity and fuel imbalance display.



31-61-00-108 Rev 2 05/19/1997

PRIMARY DISPLAY SYSTEM - AUTOMATIC DISPLAY SWITCHING

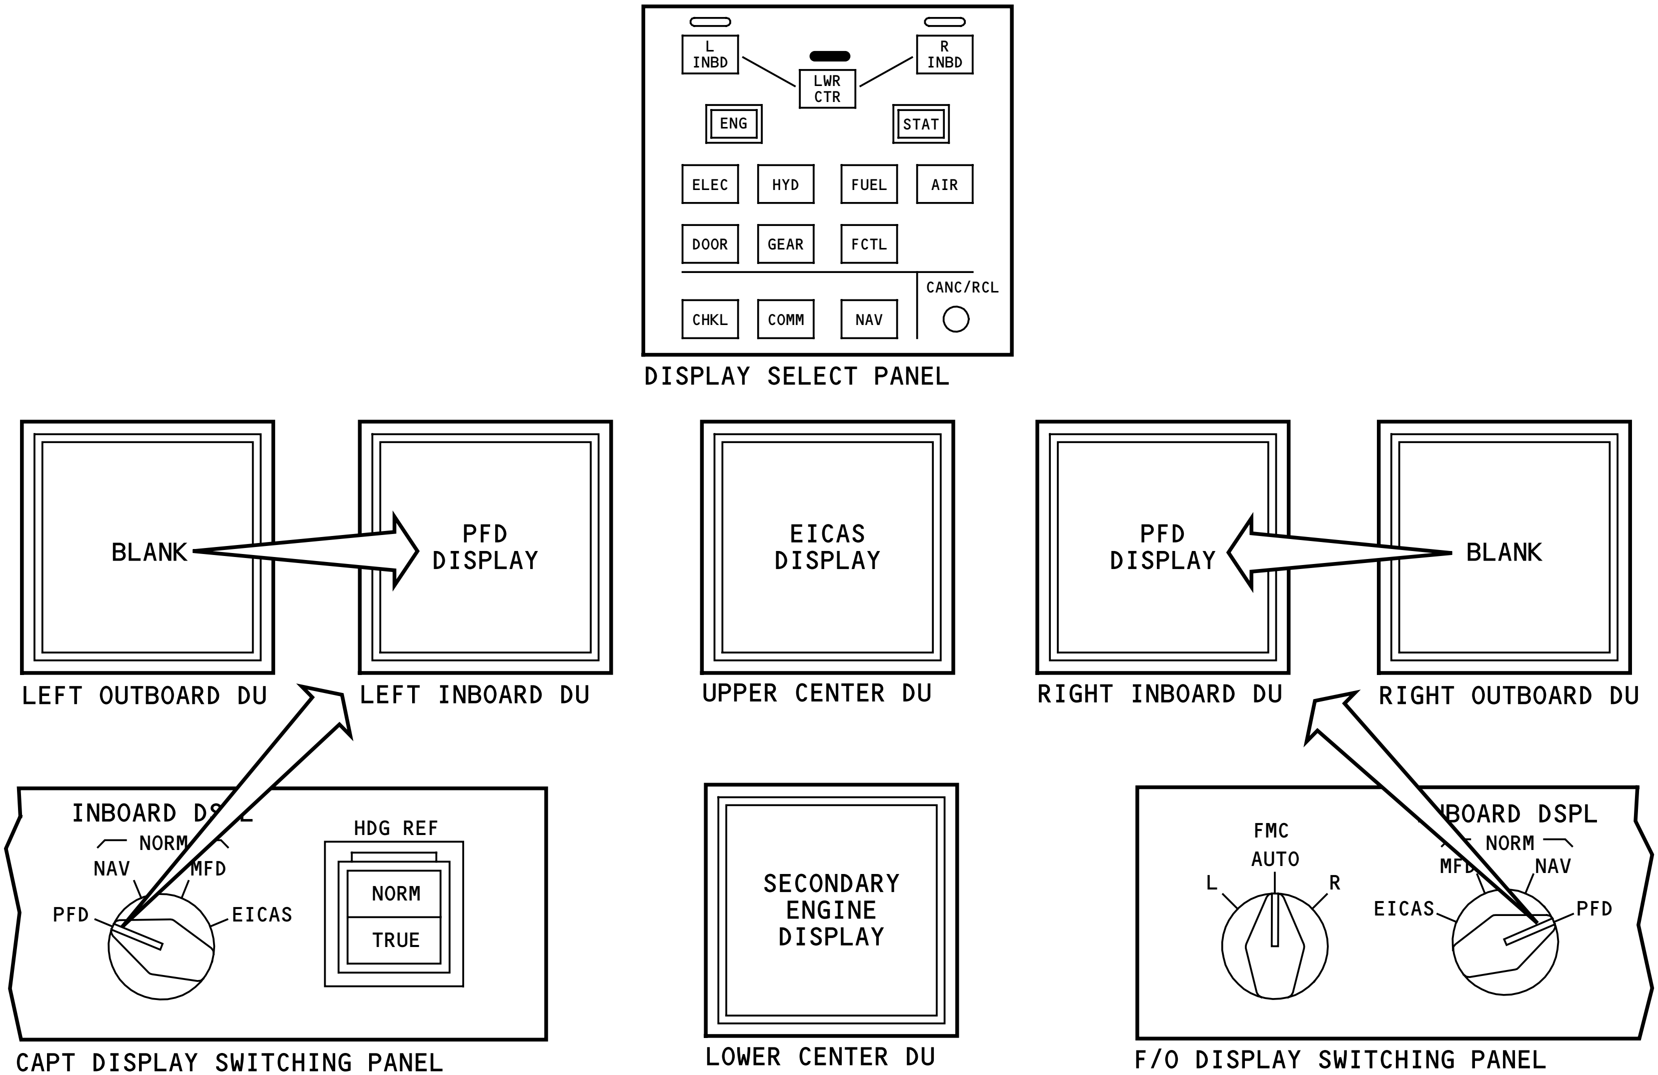
PRIMARY DISPLAY SYSTEM - PFD MANUAL SWITCHING

General

The PFD position of the inboard display selector on the display switching panel lets the operator move the PFD format to the inboard DU.

The outboard DU blanks when the selector is in the PFD position.

Return the inboard display selector to NORM (ND or MFD) to cause the PFD to show on the outboard DU and to cause the ND format to show on the inboard DU.



PRIMARY DISPLAY SYSTEM - PFD MANUAL SWITCHING

31-61-00-109 Rev 1 05/19/1997

PRIMARY DISPLAY SYSTEM - MANUAL EICAS SWITCHING

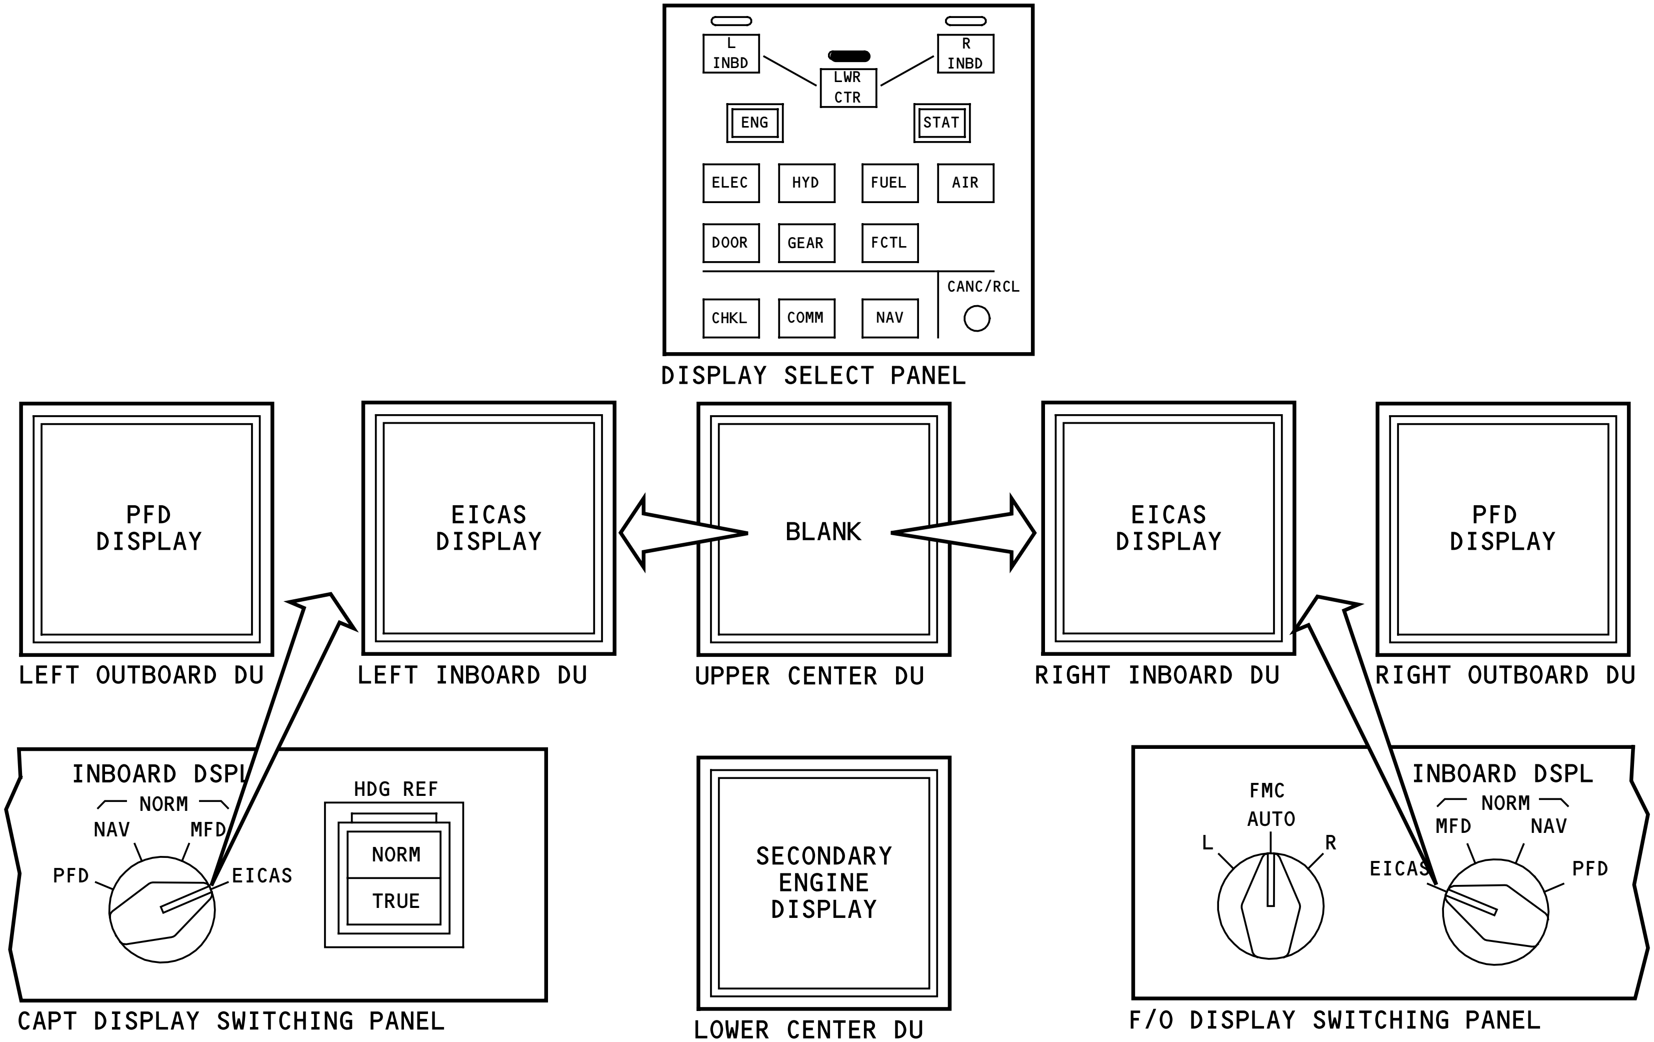
General

The EICAS position of the inboard display selector on the display switching panel lets the operator move the EICAS display format to the inboard DU.

Both inboard DUs can show the EICAS display format at the same time. Both displays will be identical. One DU cannot show EICAS display and the other show compacted engine.

The upper center DU blanks when the inboard display selector is in the EICAS position.

Return the inboard display selector to NORM (ND or MFD) to cause the engine EICAS display to show on the upper center DU and to cause the ND format to show on the inboard DU.



PRIMARY DISPLAY SYSTEM - MANUAL EICAS SWITCHING

PRIMARY DISPLAY SYSTEM - MULTIPLE DU FAILURES

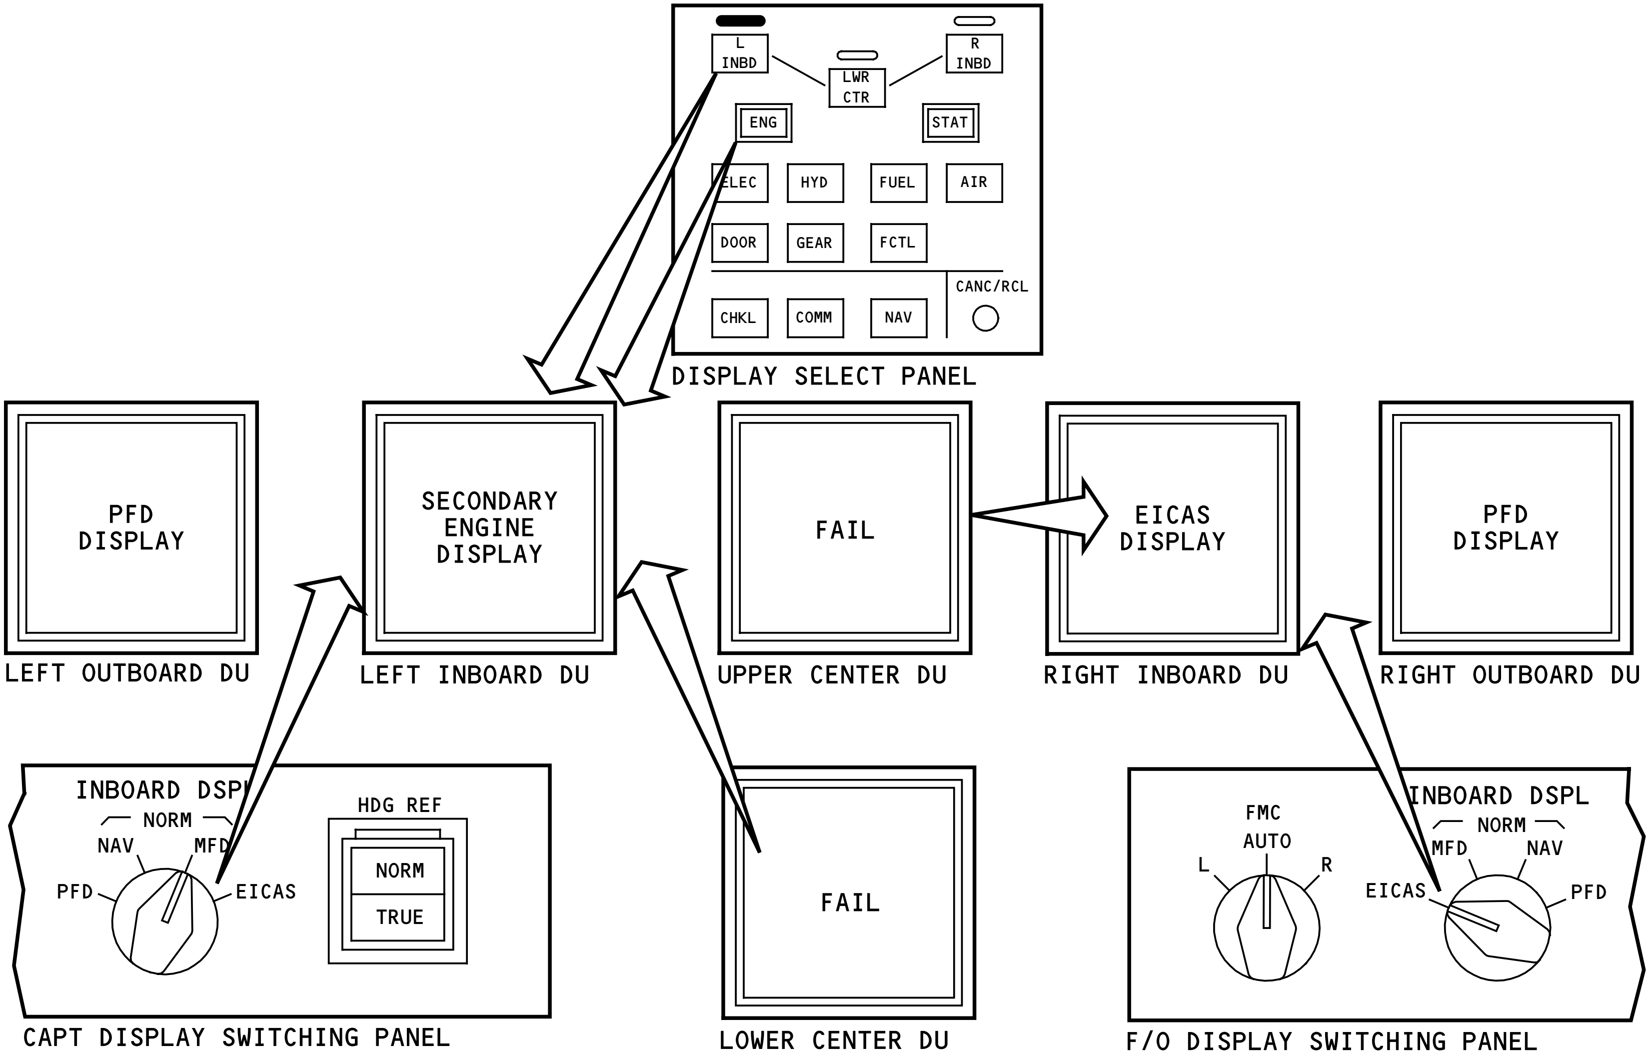
General

The display select panel (DSP) switches and the inboard display selectors on the display switching panel provide system redundancy when multiple DU failures occur.

The EICAS position of the inboard display selector causes the EICAS display format to show on an inboard DU.

The L INBD or R INBD switch on the DSP causes other EICAS formats to show on an inboard DU. The inboard display selector must be in the MFD position before the DSP L INBD or R INBD switch will have effect.

The L INBD or R INBD switch also has no effect if an outboard DU fails and the PFD automatically switches to an inboard DU.



31-61-00-111 Rev 1 05/19/1997

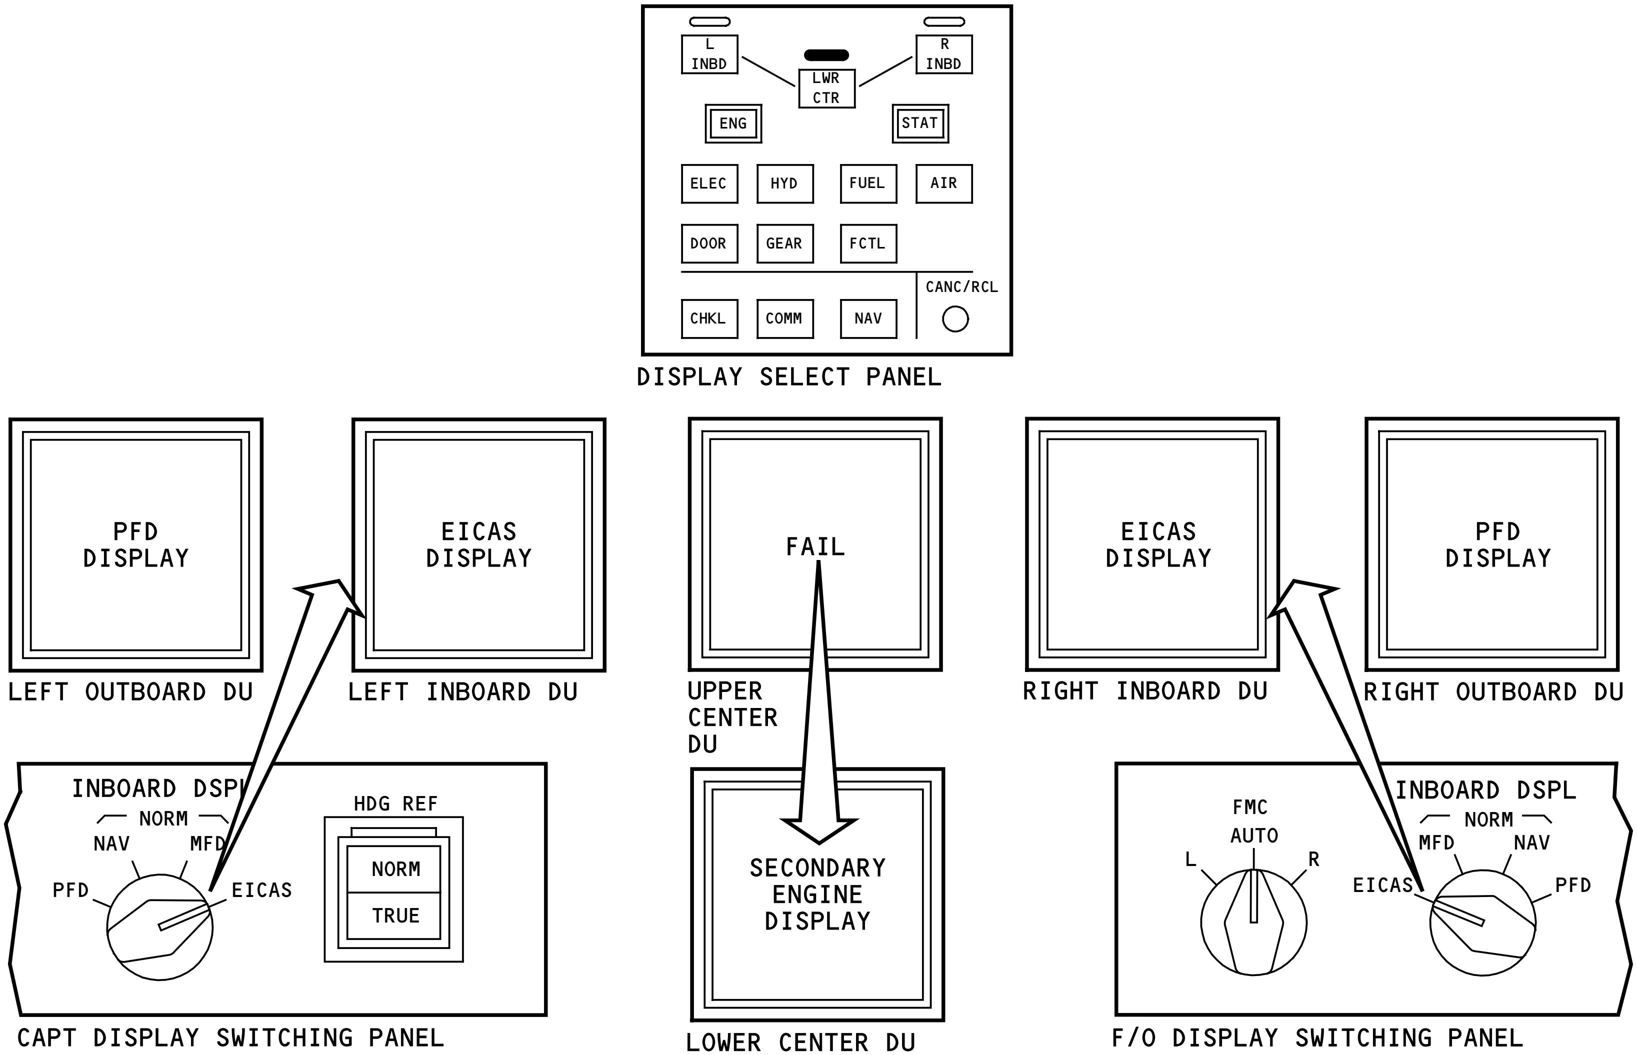
PRIMARY DISPLAY SYSTEM - MULTIPLE DU FAILURES

PRIMARY DISPLAY SYSTEM - EICAS LIMITED MODE RECOVERY

General

After the EICAS display automatically switches, the selection of EICAS on either inboard display selector causes the lower center DU to show the secondary engine format. The EICAS display shows on the inboard DU.

The EICAS display shows on both inboard DUs when the inboard display selectors are in the EICAS position.



31-61-00-112 Rev 2 05/19/1997

PRIMARY DISPLAY SYSTEM - EICAS LIMITED MODE RECOVERY

PRIMARY DISPLAY SYSTEM - MULTIPLE DISPLAY FORMATS

General

The primary display system has the capability to show multiple formats at the same time. To do this, the DSP works with the inboard display selectors on the display switching panels. The system has the capability to show any combination of display formats.

As an example, to show the AIR synoptic on the F/O's inboard DU, do this:

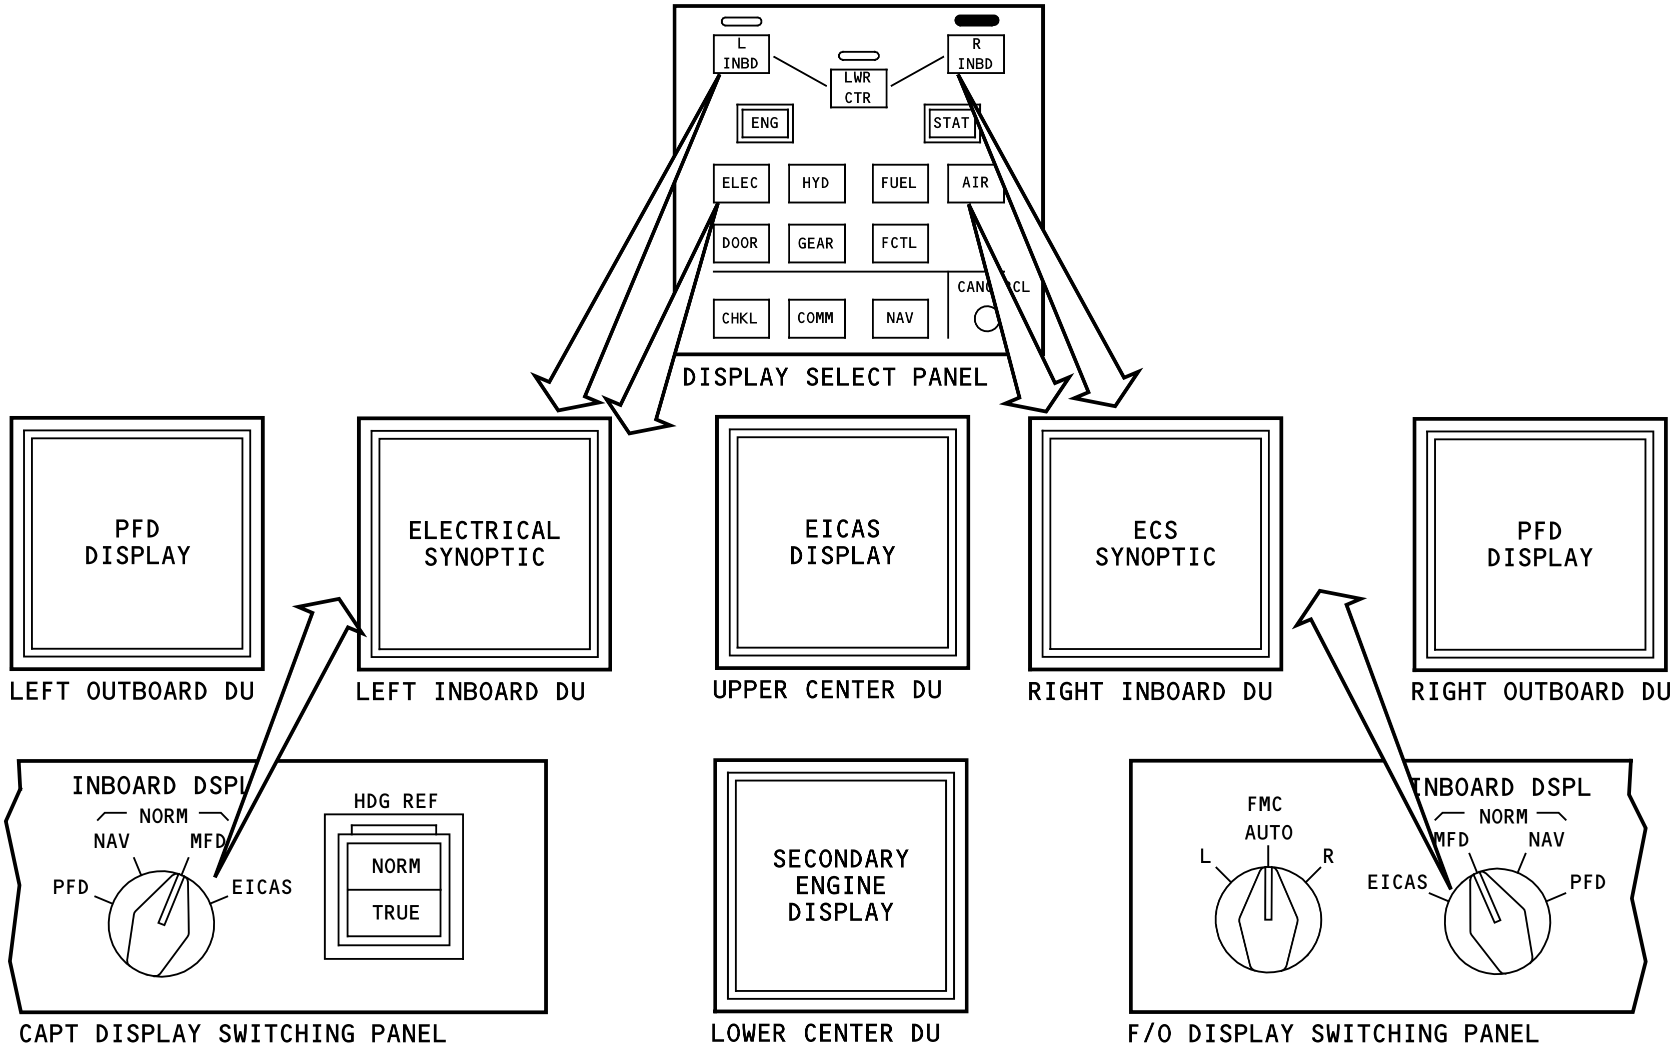
- Put the right inboard display selector in the MFD position
- Select R INBD on the DSP
- Select AIR on the DSP.

To show the electrical synoptic on the captain's inboard DU, do this:

- Put the left inboard display selector in the MFD position
- Select L INBD on the DSP
- Select ELEC on the DSP.

The inboard DUs return to the ND display when you put the inboard display selector in the ND position or when you select the NAV switch on the DSP.

The inboard DU also returns to the ND display when you select a synoptic that already shows on that ND.



PRIMARY DISPLAY SYSTEM - MULTIPLE DISPLAY FORMATS

31-61-00-113 Rev 3 05/19/1997

PRIMARY DISPLAY SYSTEM - NAVIGATION DISPLAY PRIORITIES

Center Lower DU

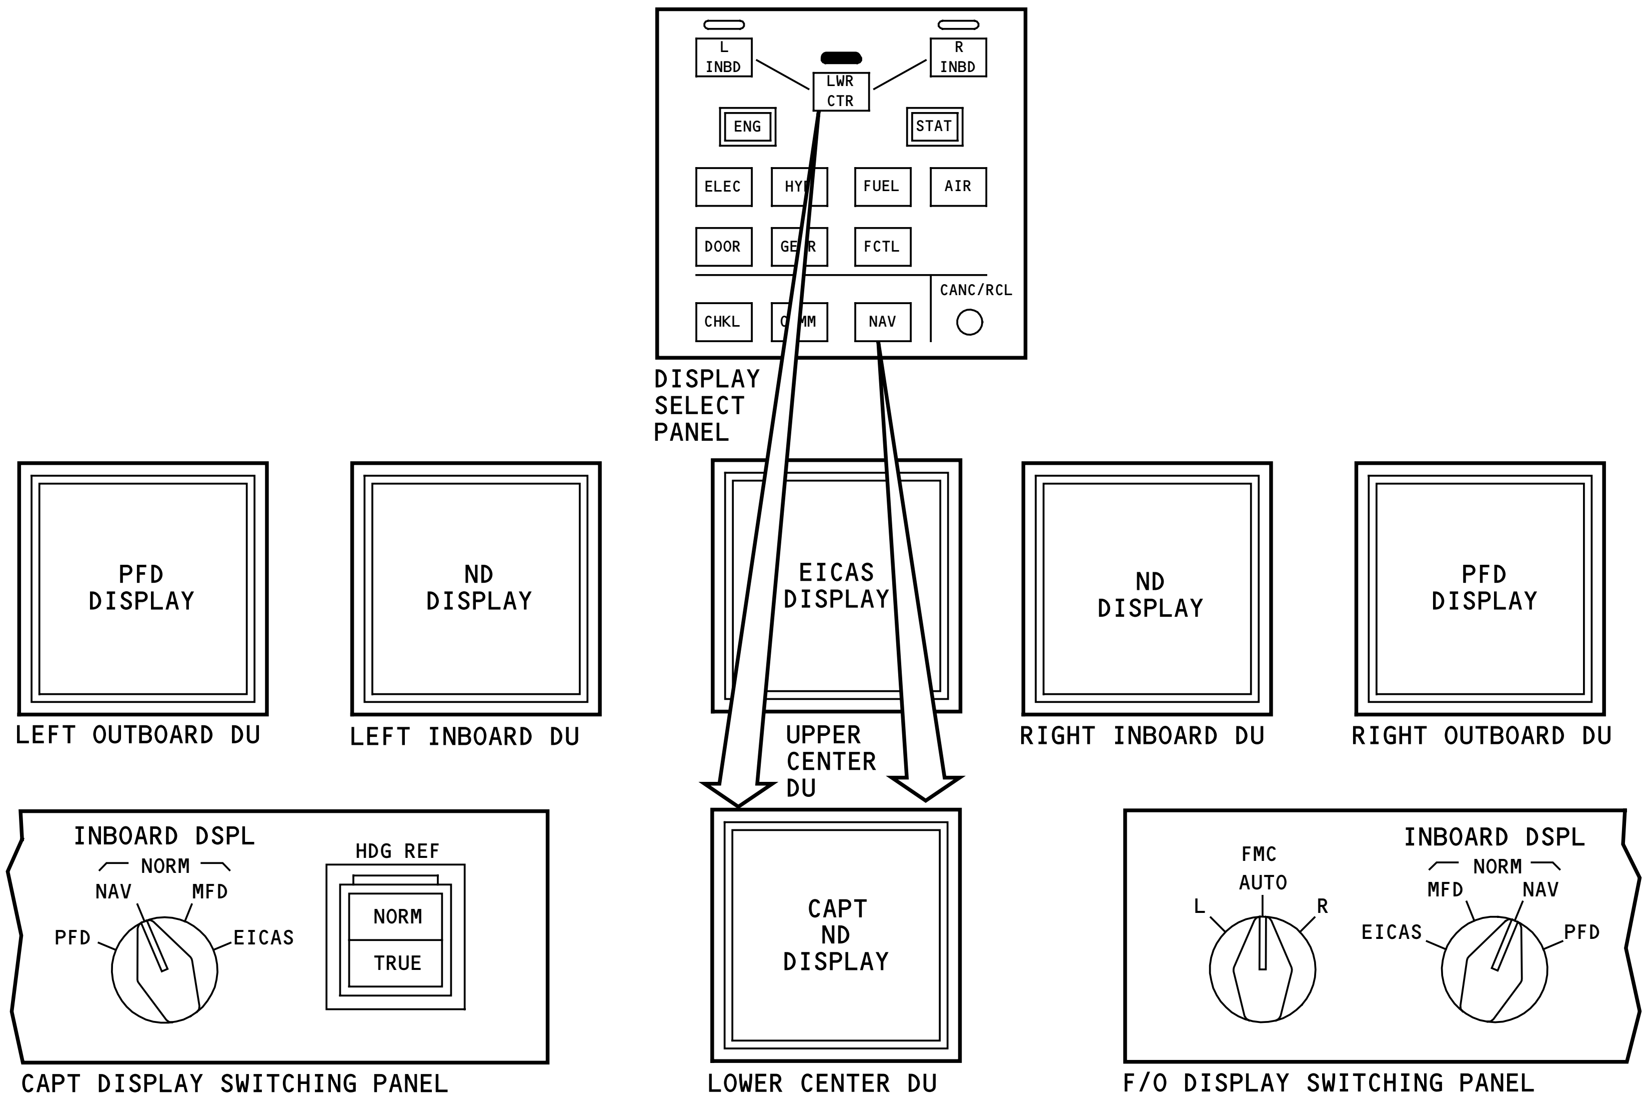
Select the NAV switch and the LWR CRT switch on the DSP to cause an ND display to show on the lower center DU.

If only one ND (capt or F/O) shows on an inboard DU, the other ND (capt or F/O) shows on the lower center DU.

If both the captain's and the F/O's inboard DUs show the ND display or neither show the ND display, the lower center DU shows the captain's ND.

Inboard DU

If the left or right inboard display selector on the display switching panels is in the NAV or MFD position and the NAV switch on the DSP is set, the left or right inboard DU shows the associated captain's or first officer's ND display unless that ND display already shows, then the inboard DU blanks.



PRIMARY DISPLAY SYSTEM - NAVIGATION DISPLAY PRIORITIES

PRIMARY DISPLAY SYSTEM - SECONDARY ENGINE EXCEEDANCE

General

The EICAS display format and MFD show different formats when a secondary exceedance latches or an exceedance clear occurs. This occurs during normal and limited operation.

Secondary Engine Exceedance Latches

When a secondary engine exceedance latches in memory, the upper center DU and lower center DU change formats. The new formats depend on the formats that show before the exceedance occurs.

During normal operation one of these will occur:

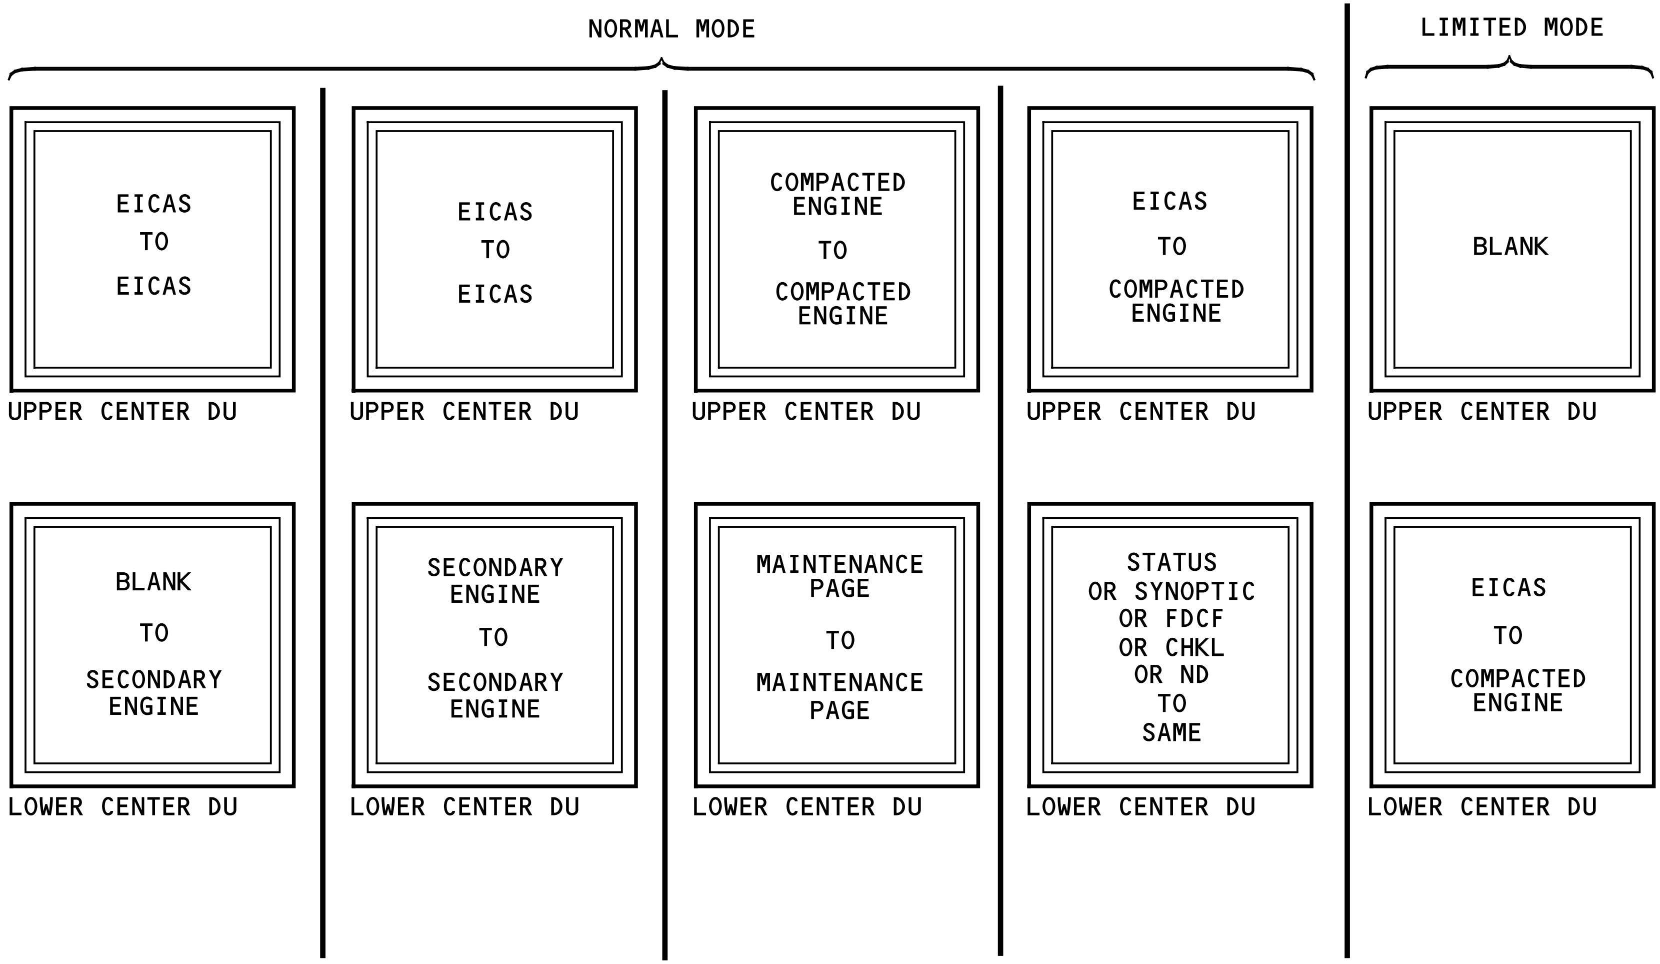
- If the lower center DU is blank, then it shows the secondary engine format and the upper center DU shows the EICAS display format.
- If the lower center DU shows the secondary engine format, it remains the same and the upper center DU shows the EICAS display format.
- If the lower center DU shows a maintenance page while the airplane is on the ground, it remains the same and the upper center DU shows the compacted engine format.
- If the lower center DU shows a status page format, a synoptic, flight deck communication function format, checklist format or a navigation display, it remains the same and the upper center DU shows the compacted engine format.

During limited operation, if the upper center DU is blank and the lower center DU shows the EICAS display format, the lower center DU shows the compacted engine format.

Secondary Engine Exceedance Clears

During normal operation, when the secondary engine exceedance clears, the upper center DU shows the EICAS display format for all conditions except when the lower center DU shows a maintenance page while the airplane is on the ground, then the upper center DU shows the compacted engine format. The center lower DU remains the same.

During limited operation, when the exceedance clears, the lower center DU remains the same.



31-61-00-115 Rev 1 03/20/95

PRIMARY DISPLAY SYSTEM - SECONDARY ENGINE EXCEEDANCE

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - SPECIAL FUNCTIONS

General

The AIMS primary display system (PDS) special functions make sure the interfaces of the displays to their hardware are correct. PDS hardware includes:

- CPM/GGs
- Display units (DU)
- Coaxial couplers
- Control panels and switches
- Remote light sensors
- Cursor control devices (CCD).

These are the special functions for PDS hardware:

- Display Switches
- Display screens (5)
- CPM/GG to WXR interface checks (4)
- Brightness control and display units
- CPM/GG to DU interface checks (4).

Display Switches

The display unit special functions supports functional testing of interfaces and verifies correct operation. The DUs show a test format to do this.

Display Screens (5)

Select the display screen special functions on the MAT. Examine the DU liquid crystal display (LCD). The DU BITE circuits do not monitor the DU LCD and electronic driver circuits. These are the failures to look for:

- Line defects
- Element defects
- Full-field gray scale characteristics.

For the full red screen test (the red, blue, and green screen tests are similar), all six DUs show a solid red screen. Use the MAT to cycle through the seven red gray scales. All six DUs show the same red gray scale level. This occurs with the brightness controls on all six DUs set to maximum and all six DUs should appear equal. A DU with a weak backlight or electronic driver failure stands out from the other DUs at one or more of the gray scale levels.

For the full white/black screen test, all DUs show a solid white screen. Use the MAT to cycle through the seven gray scales plus black. This test detects intermittent dot failures and hard failures. A DU with a weak backlight or electronic driver failure stands out from the other DUs at one or more of the gray scale levels.

For the striped pattern test, all six DUs show a screen with diagonal white and black stripes. This format allows detection of electrically floating line failures. These lines may not be visible on a solid color screen.

CPM/GG to WXR Interface Check (4)

The CPM/GG to WXR interface check verifies the validity to the WXR ARINC 453 inputs to the GGs in each AIMS cabinet.

PRIMARY DISPLAY SYSTEM - SPECIAL FUNCTIONS

Brightness Control and Display Units

This special function supports functional tests of hardware interfaces and makes sure operation is correct. The six DUs show a test display to do this.

CPM/GG to DU Interface Checks (4)

The graphic generator special functions supports functional tests of airplane interfaces and verifies correct interface of the CPM/GGs to the DUs. The CPM/GGs do a test one at a time. The DUs are grouped in two sets of three for this test. All four combinations of CPM/GG to DU groups are tested. The DUs show the test format to make sure that each DU receives each CPM/GG input.

PRIMARY DISPLAY SYSTEM - SPECIAL FUNCTIONS

THIS PAGE INTENTIONALLY LEFT BLANK

PRIMARY DISPLAY SYSTEM - BRIGHTNESS CONTROLS AND DISPLAY UNITS TEST DISPLAY

General

The brightness controls and display units test is a special purpose test that does a test of the primary display system hardware. You use the MAT or PMAT to start the test and the test display shows on all six DUs.

The test display shows these:

- DU location
- ARINC 429 loop
- Graphic generator (GG) source
- DU input activity
- Status of brightness inputs.

The background of the test format is black. Text titles are cyan. Test values are white except for FAIL, N (for no) and BAD which are red. PASS and Y (for yes) are green.

DU Location

The DU location information shows the location ID pins of the DU that the GG is addressing. The readouts show as:

- RIB - right inboard DU
- ROB - right outboard DU
- CU - center upper DU
- CL - center lower DU
- LIB - left inboard DU
- LOB - left outboard DU.

An invalid DU location ID shows as BAD.

ARINC 429 Loop

The ARINC 429 loop shows the status of the ARINC 429 bus from the DUs to the AIMS cabinets.

A PASS or FAIL indication shows on the DU.

GG Source

The GG source shows the GG that is driving the display. The readouts show as:

- L10 for the left GG in the left AIMS cabinet
- L11 for the right GG in the Left AIMS cabinet
- R10 for the left GG in the right AIMS cabinet
- R11 for the right GG in the right AIMS cabinet.

Input Activity

The input activity area shows the status of the four DU coaxial cable inputs. The specific input for each DU shows with a white highlight box.

A Y or N shows for each of the four coaxial inputs.

Brightness Inputs

The value of both automatic and manual brightness control inputs show as a percentage of maximum value.

PRIMARY DISPLAY SYSTEM - BRIGHTNESS CONTROLS AND DISPLAY UNITS TEST DISPLAY

The range of each of the inputs is from 0 to 100. BAD shows if the input is bad. These are the inputs for automatic brightness controls:

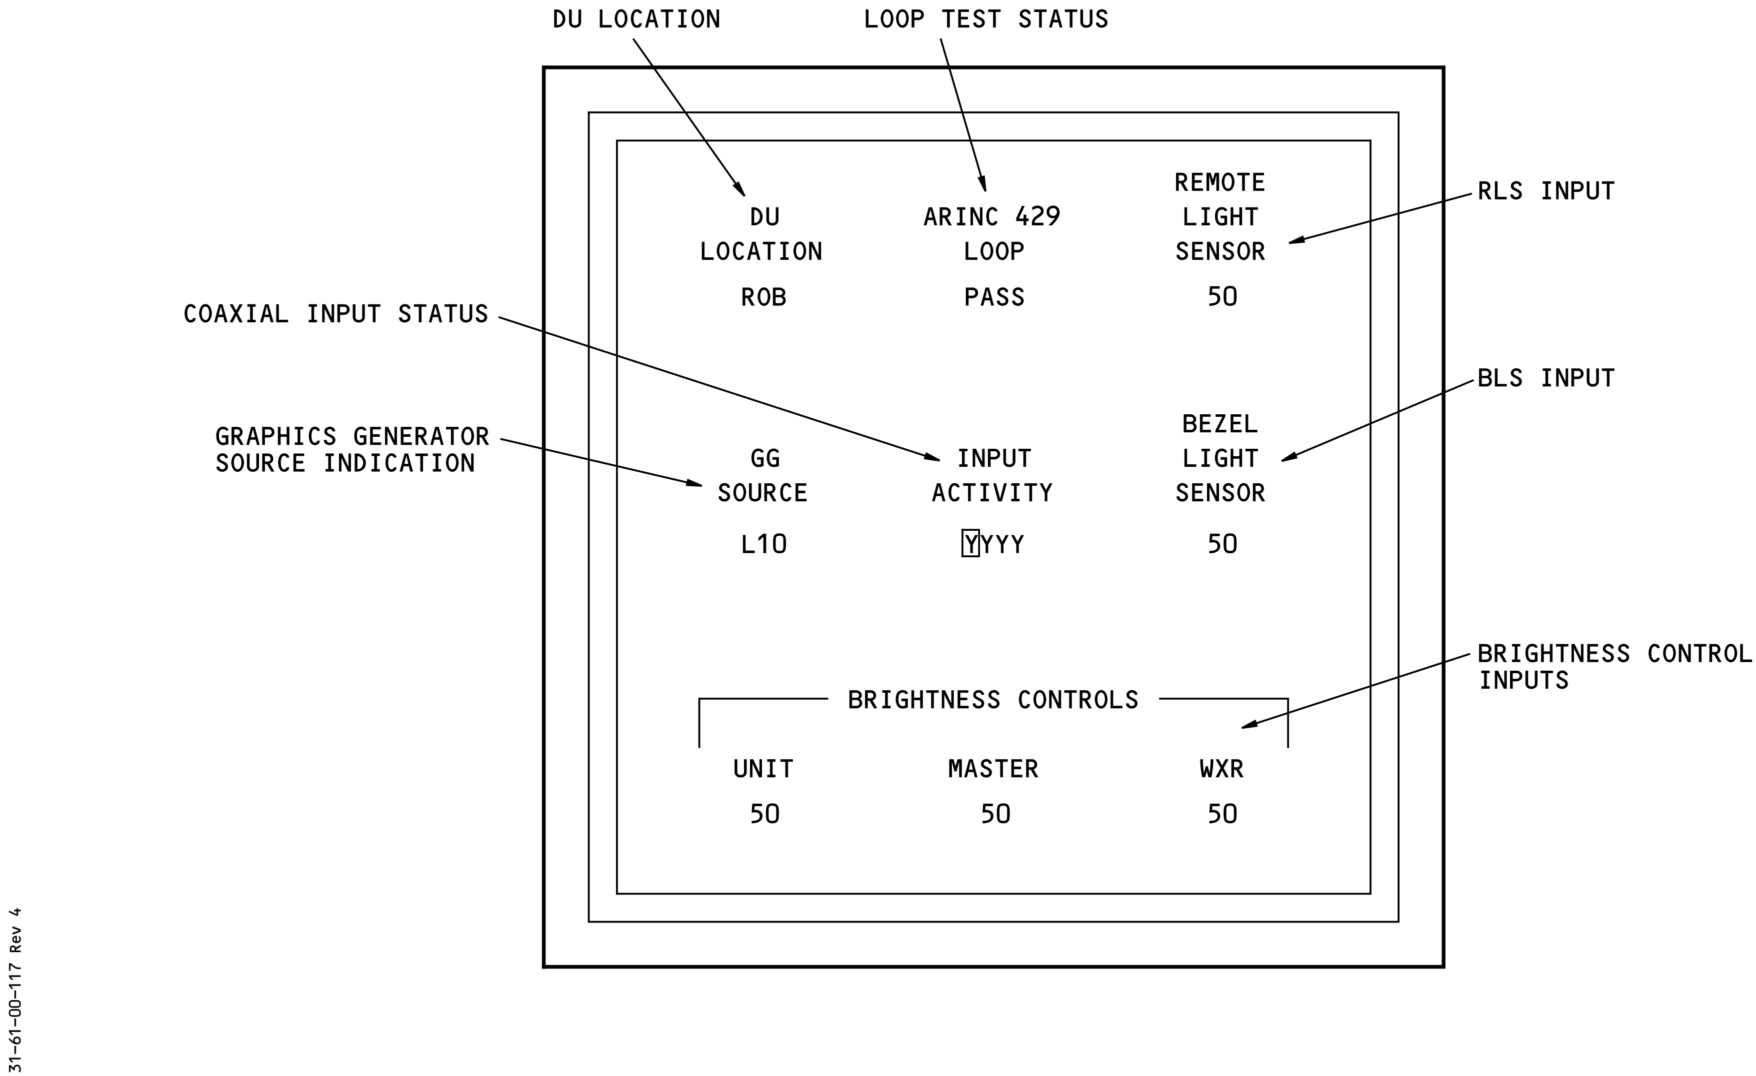
- Remote light sensor (RLS)
- Bezel light sensor (BLS).

During the test, automatic brightness control of the DUs is disabled.

These are the manual inputs:

- Unit brightness from the individual brightness control knob
- Master brightness from the zone brightness control
- WXR from the shading brightness control knob.

As you adjust a knob, the value on the DU should change.



PRIMARY DISPLAY SYSTEM - BRIGHTNESS CONTROLS AND DISPLAY UNITS TEST DISPLAY

PRIMARY DISPLAY SYSTEM - DISPLAY SWITCHES TEST DISPLAY

General

The display switches test display is a special purpose test that shows the status of switches that effect the primary display system. You use the MAT or the PMAT to select the test and a test display shows on all six DUs. As you change the position of any of the switches, the display changes.

The display shows the condition of these switches:

- Display select panel (DSP) switches
- Accept (ACPT), cancel (CANC), reject (RJCT) switches.

The display also shows the position of switches and selectors on the:

- Instrument source select panels (ISSPs)
- Display switching panels
- CDCP.

DSP Switches

There is an indication for all the switches on the DSP. A filled white box shows when you select a switch. The fill goes away when you deselect the switch.

Accept, Cancel, Reject Switches

A filled white box shows when you select a switch. The fill goes away when you deselect the switch.

ISSPs

The position of each of the switches on the captain's and first officer's ISSPs show.

The display control (DSPL CTRL) switch positions show as AUTO or ALT.

The navigation source switch positions show as AUTO or CDU.

The air data/attitude source switch positions show as NORM or ALT.

Display Switching Panels

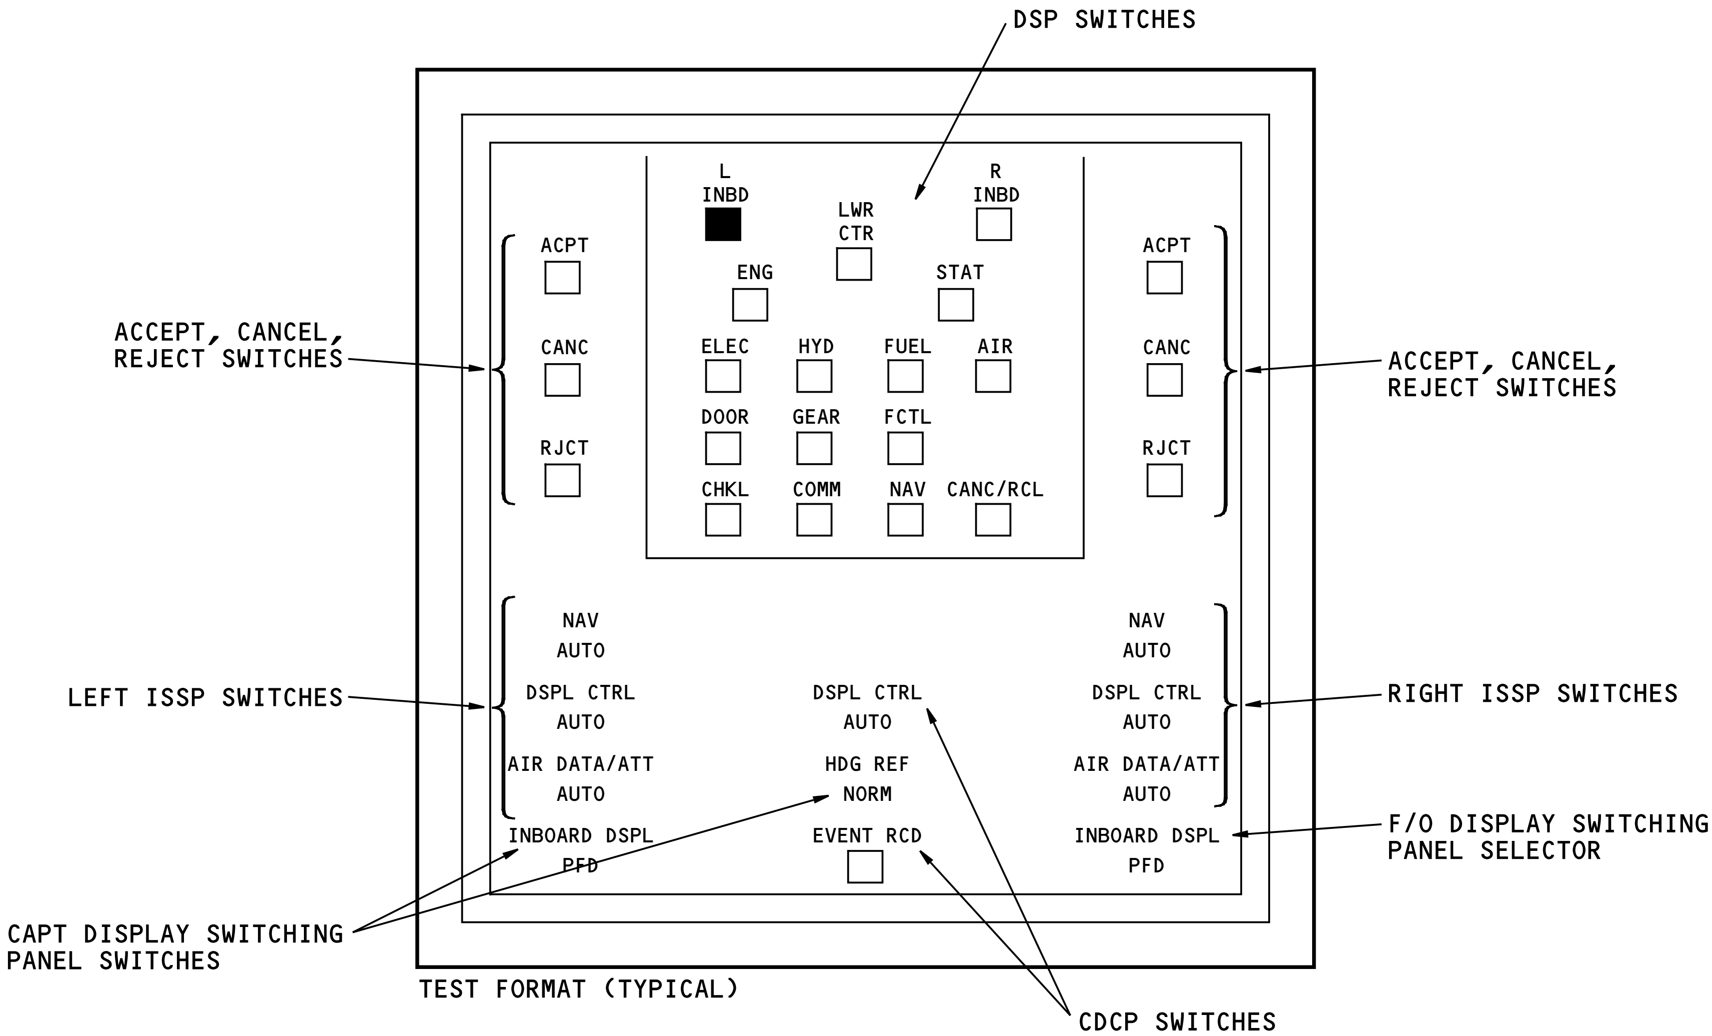
The captain's and first officer's inboard display selector positions show as PFD, ND, MFD or EICAS.

The heading reference switch position shows as NORM or MAG.

CDCP

The display control (DSPL CTRL) switch position shows as AUTO or ALT.

The event record switch shows a white box shows when you select the switch. The white box goes away when you deselect the switch.



31-61-00-118 Rev 1 01/16/1998

PRIMARY DISPLAY SYSTEM - DISPLAY SWITCHES TEST DISPLAY

PRIMARY DISPLAY SYSTEM - COAXIAL COUPLER

General

There are four coaxial couplers on the airplane. Each graphics generator sends a video output to a coaxial coupler. The coaxial coupler splits the signal and sends an output to each of the six display units.

Location

The coaxial couplers are on disconnect brackets outboard of the captain's and first officer's outboard rudder pedals. There are two coaxial couplers on the outboard side of each disconnect bracket.

THIS PAGE INTENTIONALLY LEFT BLANK

General

The central maintenance computing system (CMCS) collects and stores maintenance data for most of the airplane systems. The maintenance access terminal (MAT) or portable maintenance access terminal (PMAT) shows the data. Menu selections on the MAT give access to maintenance functions based on type of task. The CMCS primary functions include:

- Fault processing
- Testing
- Data loading.

The CMCS also does these functions:

- Fault history
- Input monitoring
- Configuration reporting
- Shop faults
- Engine balancing
- PSEU and air/ground rigging
- Report generation.

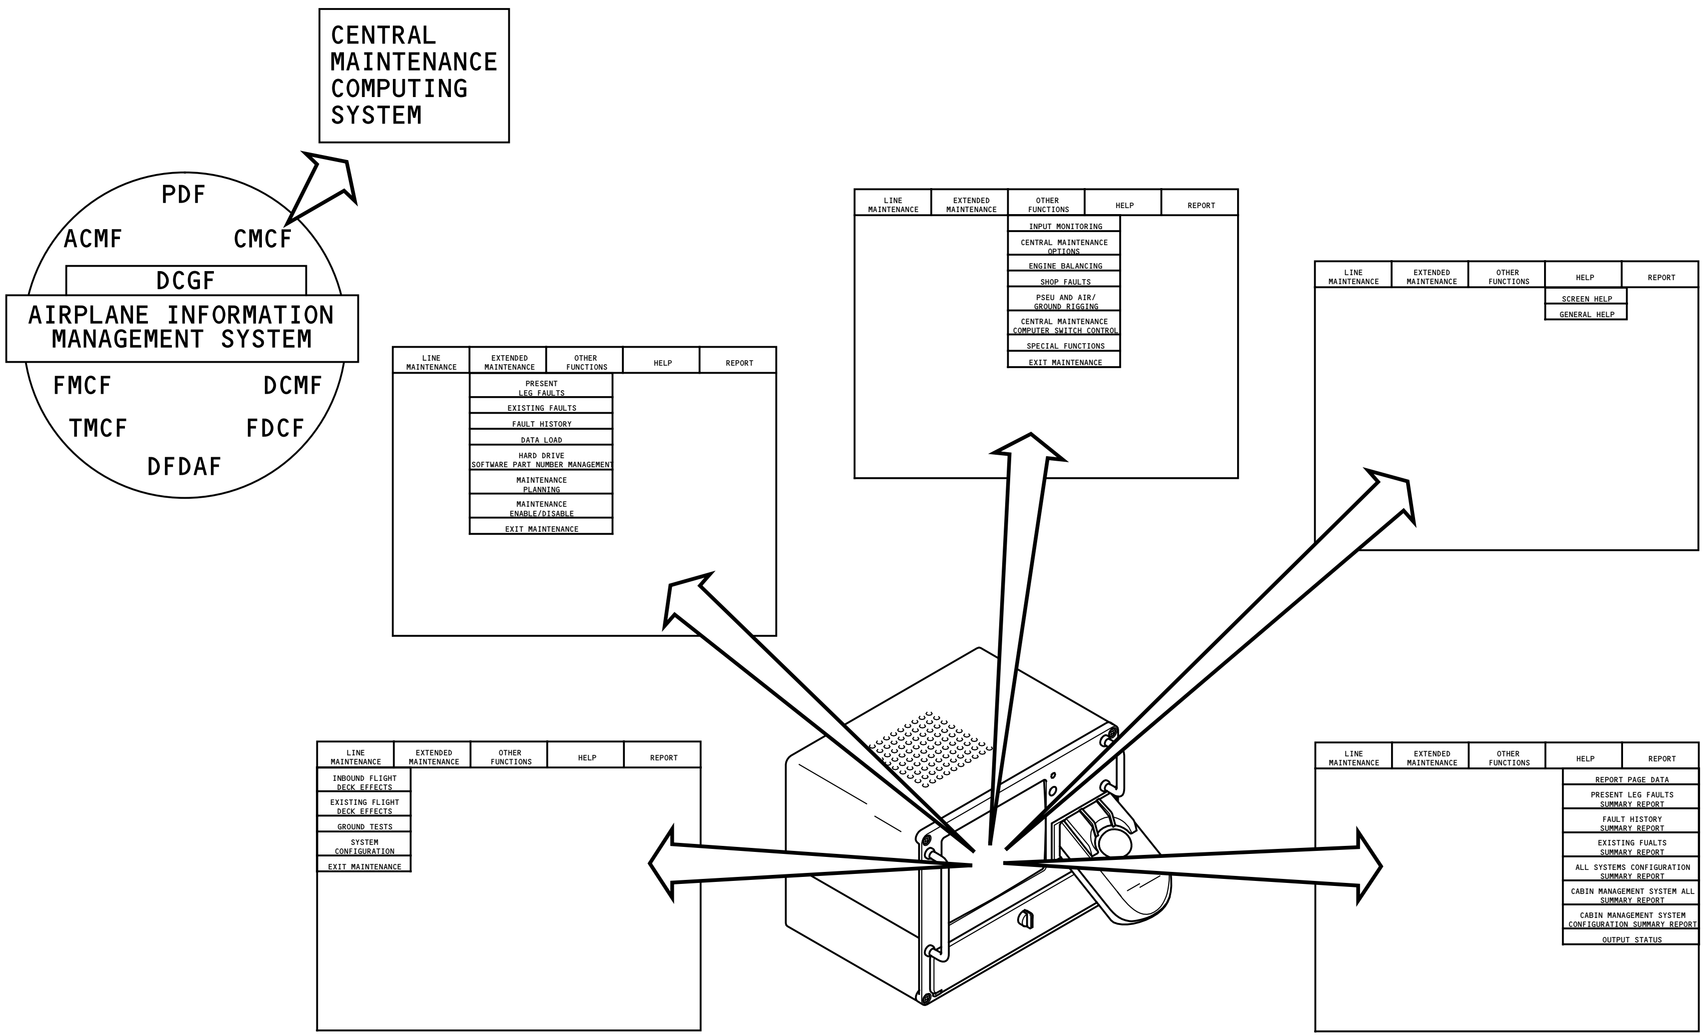
The MAT also supplies access to on-line help.

Abbreviations and Acronyms

ACARS	- aircraft communications addressing and reporting system
ACIPS	- airfoil and cowl ice protection system
ACMF	- airplane condition monitoring function
ACMS	- airplane condition monitoring system
ADF	- automatic direction finder
ADIRU	- air data inertial reference unit
ADM	- air data module
AFDC	- autopilot flight director computer
AIMS	- airplane information management system
AMI	- airline modifiable information
AMM	- airplane maintenance manual
APU	- auxiliary power unit
APUC	- auxiliary power unit controller
ARINC	- Aeronautical Radio, Inc.
ASCPC	- air supply cabin pressure controller
ASG	- ARINC 629 signal gateway
ATC	- air traffic control
AVLAN	- avionics local area network
AVM	- airborne vibration monitoring
BPCU	- bus power control unit
BEPS	- backup electrical power system
BSCU	- brake system control unit
BS	- bypass switch
BSU	- bypass switch unit
CCD	- cursor control device
CMCF	- central maintenance computing function
CMCS	- central maintenance computing system
CMR	- certification maintenance requirement
comm	- communication
CPM	- core processor module
CTC	- cabin temperature controller
CTU	- cabin telecommunication unit
DCGF	- data conversion gateway function

DCMF - data communication management function
DFDAF - digital flight data acquisition function
DTD - data terminal display
EEC - electronic engine control
EICAS - engine indication and crew alerting system
ELMS - electrical load management system
FDCF - flight deck communication function
FDE - flight deck effect
FIM - fault isolation manual
FMCF - flight management computing function
FSEU - flap/ slat electronics unit
GBST - ground based software tool
GCU - generator control unit
GPSSU - global positioning system sensor unit
GPWC - ground proximity warning computer
HYDIM - hydraulic interface module
ICAO - international civil aviation organization
IMM - intermodule memory
IOM - input/output module
ISO - International Standards Organization
LAN - local area network
LCD - liquid crystal display
LDI - loadable diagnostic information
LPT - low pressure turbine
LRM - line replaceable module
LRU - line replaceable unit
MAT - maintenance access terminal
MEC - main equipment center
MFD - multi-function display
MO - maintenance memo
MPS - maintenance page snapshot
MTF - maintenance terminal function
ND - navigation display
NVM - non-volatile memory
OEBS - onboard engine balancing system
OLAN - onboard local area network
OMS - onboard maintenance system
OPC - operational program configuration
OPS - operational program software
PDF - primary display function
PDS - primary display system
PFC - primary flight computer
PFD - primary flight display
PMAT - portable maintenance access terminal
PSEU - proximity sensor electronics unit
RAM - random access memory
RMM - ramp maintenance manual
SAARU - secondary attitude air data reference unit
SCSI - small computer system interface
SD - side display
SDI - source destination indicator
SDU - satellite data unit
SMT - scheduled maintenance task
TCAS - traffic alert and collision avoidance system

TMCF	- thrust management computing function
UTC	- universal time (coordinated)
UTCF	- universal time (coordinated) function
WHCU	- window heat control unit
WXR	- weather radar



MAINTENANCE ACCESS TERMINAL

CENTRAL MAINTENANCE COMPUTING SYSTEM - INTRODUCTION

CMCS - FAULT PROCESSING CONCEPT

General

The central maintenance computing system (CMCS) does these things:

- Monitors airplane systems for faults
- Processes fault information
- Supplies maintenance messages.

The CMCS also monitors flight deck effect (FDE) activity. The CMCS matches, or correlates, applicable FDEs and maintenance messages.

Flight deck effects (FDEs) tell the flight and ground crews of conditions related to safe operation. The ground crew must find the cause of an FDE to find the corrective action. You use this information along with these manuals to isolate airplane faults

- Fault isolation manual (FIM)
- Airplane maintenance manual (AMM)
- Ramp maintenance manual (RMM).

Flight Deck Effects

The airplane systems monitor conditions related to loss of a system or function. If a condition exists that requires repair or deferral, the airplane system sends FDE data to the AIMS primary display system (PDS). The PDS shows the FDE.

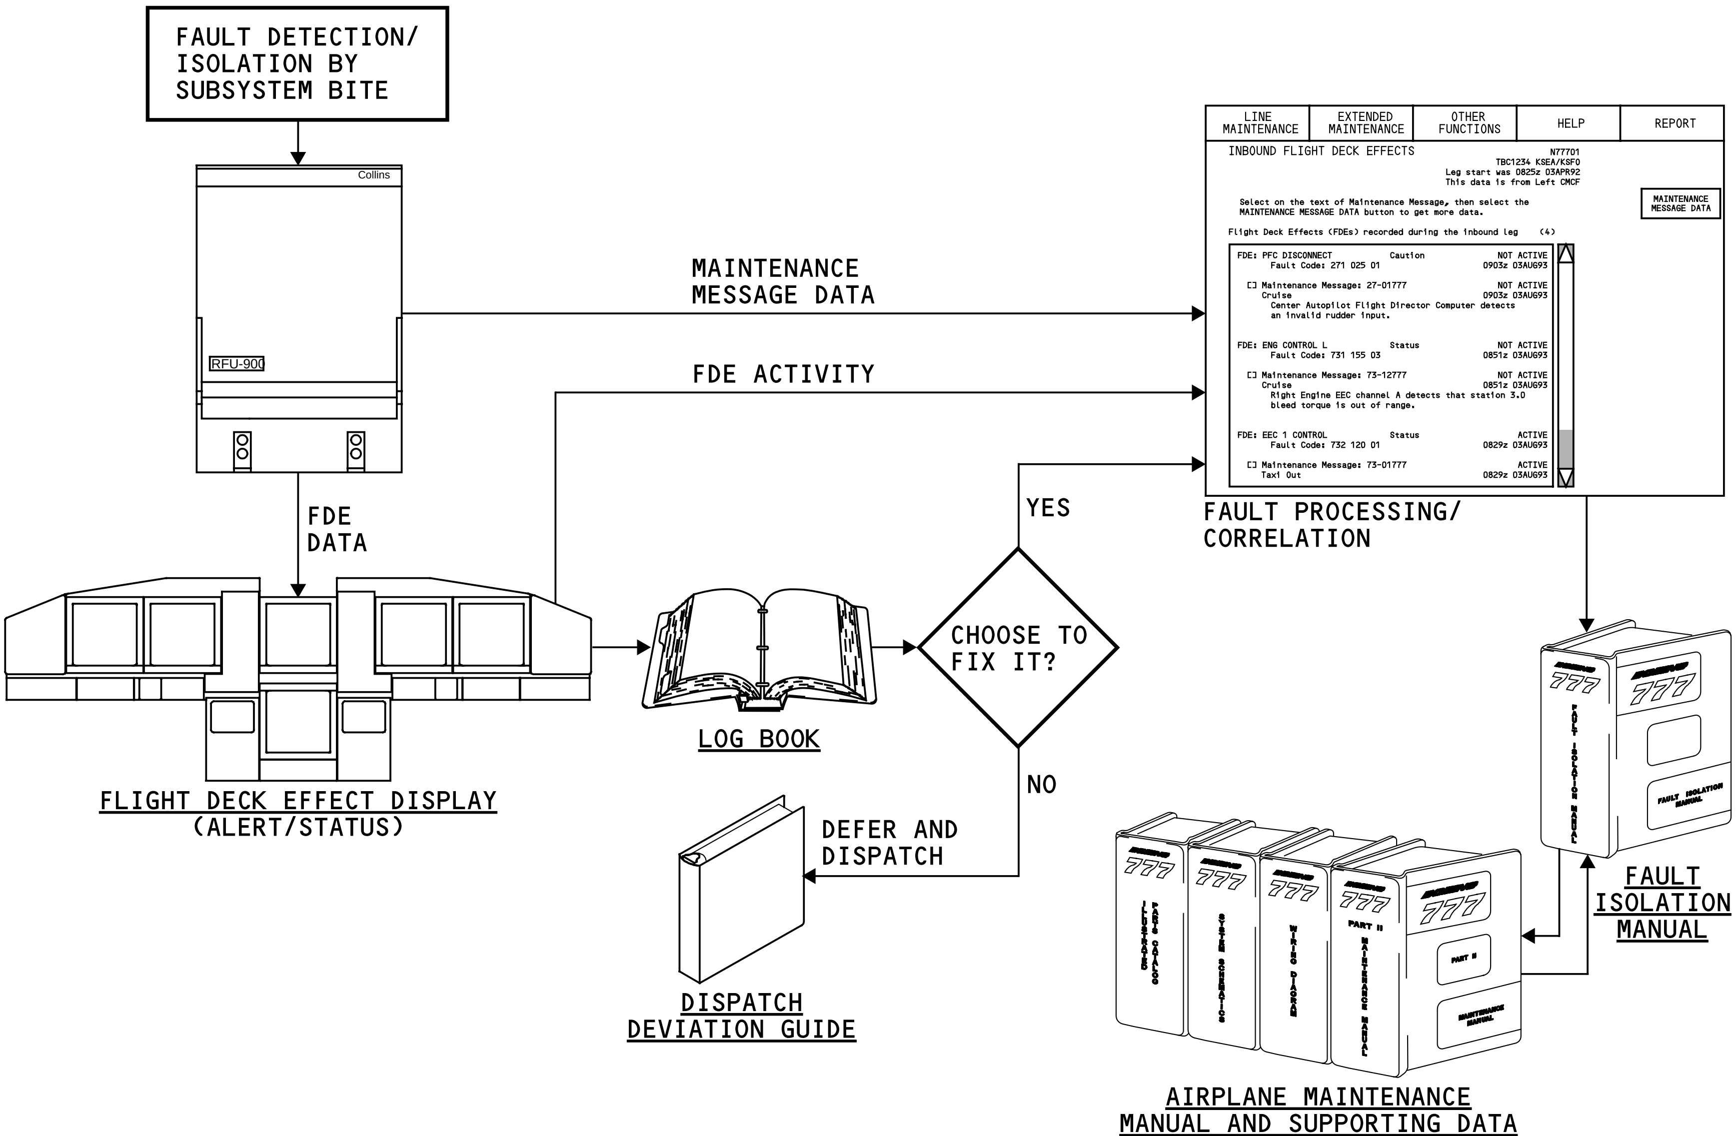
Many flight log entries have an FDE. The ground crew examines and makes an analysis of additional FDEs before they release the airplane.

Maintenance Messages

Maintenance messages supply the ground crew with detailed fault information to help in troubleshooting. Airplane systems monitor for system faults. If an airplane system finds a fault, it sends maintenance message data to the CMCS. The CMCS processes the data and shows a maintenance message so the maintenance crew can examine it and find a corrective action.

FDE/Maintenance Message Correlation

The CMCS has logic that makes a relation between maintenance messages and FDEs. When an FDE occurs and the CMCS receives a maintenance message that has a relation to the FDE, the CMCS correlates the FDE to the message.



CMCS - FAULT PROCESSING CONCEPT

THIS PAGE INTENTIONALLY LEFT BLANK

CMCS - GENERAL DESCRIPTION

General

The central maintenance computing system (CMCS) supports both line maintenance and extended maintenance functions through menu selections on the maintenance access terminal (MAT). Other menu selections support special maintenance functions, supply on-line help, and make reports.

There is a central maintenance computing function (CMCF) in each AIMS cabinet. Only one CMCF operates at a time, the other is a backup.

CMCS Components

The components of the CMCS are the:

- Central maintenance computing function (CMCF) in the AIMS cabinets
- MAT
- MAT keyboard
- Portable maintenance access terminal (PMAT) in the main equipment center (MEC)
- PMAT receptacles (4)
- Ground test switch.

Use the MAT in the flight deck or a PMAT to operate the CMCS.

The PMAT receptacles permit the use of another PMAT. These are the four other locations on the airplane that have PMAT receptacles:

- On the right side of the P40 panel at the nose wheel well
- On the P56 main wheel well electrical service panel
- Inside of the stabilizer jack screw service access door
- On the P18 panel in the flight deck.

Fiber Optic Interfaces

The MAT communicates with the CMCF in the AIMS cabinets through two fiber optic interfaces. The fiber optics interfaces supply a dual connection to the avionics local area network (AVLAN). These interfaces and the AVLAN are part of the onboard local area network (OLAN). The MAT connects directly to the AVLAN. The PMAT and the PMAT receptacles connect to a brouter. The brouter performs a network bridging function.

Primary Display System Interface

The CMCF gets fault reports from systems and records this information in a fault history. The primary display system (PDS) shows failure conditions in the form of flight deck effects (FDEs). The primary display function in the AIMS cabinets sends FDEs to the CMCF. The CMCF correlates faults to PDS failure indications.

These are the types of FDEs:

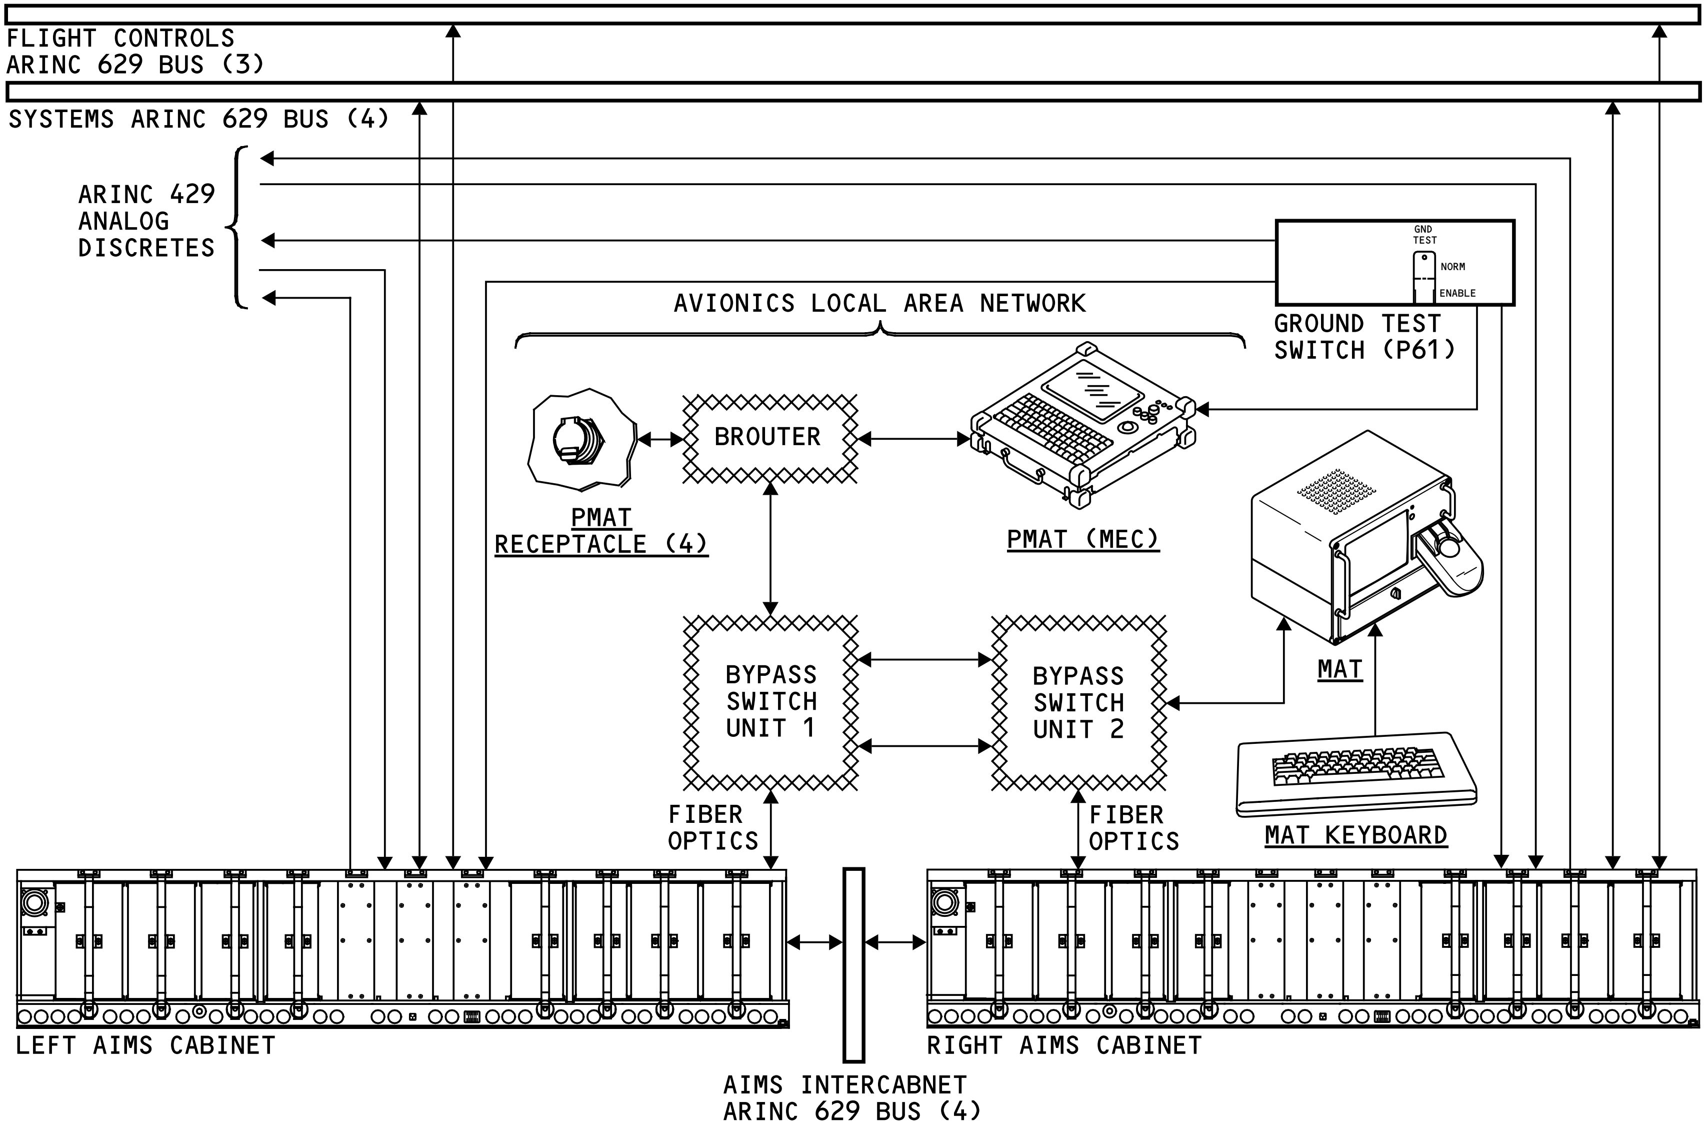
- EICAS messages
- PFD flags
- ND flags

- EIICAS snapshots
- Scheduled maintenance tasks
- Other display features.

The CMCS lets the maintenance personnel look at faults and correlated FDEs based on flight phases and flight legs.

<u>Ground Test Switch Interface</u>

The GROUND TEST switch on the ground test panel permits certain CMCS ground tests, data loads and special functions. It also provides power to the PMAT in the MEC.



45-10-00-003 Rev 3 11/06/1997

CMCS - GENERAL DESCRIPTION

CMCS - COMPONENT LOCATIONS

Flight Deck

The maintenance access terminal (MAT) is on the P18 panel.

The MAT keyboard is on the P18 panel in front of the MAT.

The portable maintenance access terminaL (PMAT) receptacle is on the left side of the MAT on the P18 panel.

The GROUND TEST switch is on the P61 overhead maintenance panel.

Main Equipment Center

The left AIMS cabinet is on the E3-1 shelf. The right AIMS cabinet is on the E2-1 shelf.

The PMAT is on top of the E-4 rack.

The PMAT receptacle is between the E-3 and E-4 racks.

CMCS - PMAT RECEPTACLE LOCATIONS - 2

CMCS - MAT INTERFACES

Power

The MAT receives 115v ac from the MAINT ACCESS TERM circuit breaker on the P11 overhead circuit breaker panel. The MAT cursor control power supply module receives the 115v ac and sends the power to the other components in the MAT.

Air Ground Discrete

A ground mode relay in the right power management panel supplies an air ground discrete to the MAT display module. The maintenance terminal function in the MAT display module uses the air ground discrete.

MAT Keyboard

The MAT keyboard transmits data to and receives data from the MAT display module. Certain pages that show on the MAT require entries from the keyboard.

Bypass Switch Unit

The MAT has a fiber optics interface which connects the MAT to the avionics local area network (AVLAN). The interface and the avionics LAN are parts of the onboard local area network (OLAN). The AVLAN supplies a high speed communication path with the:

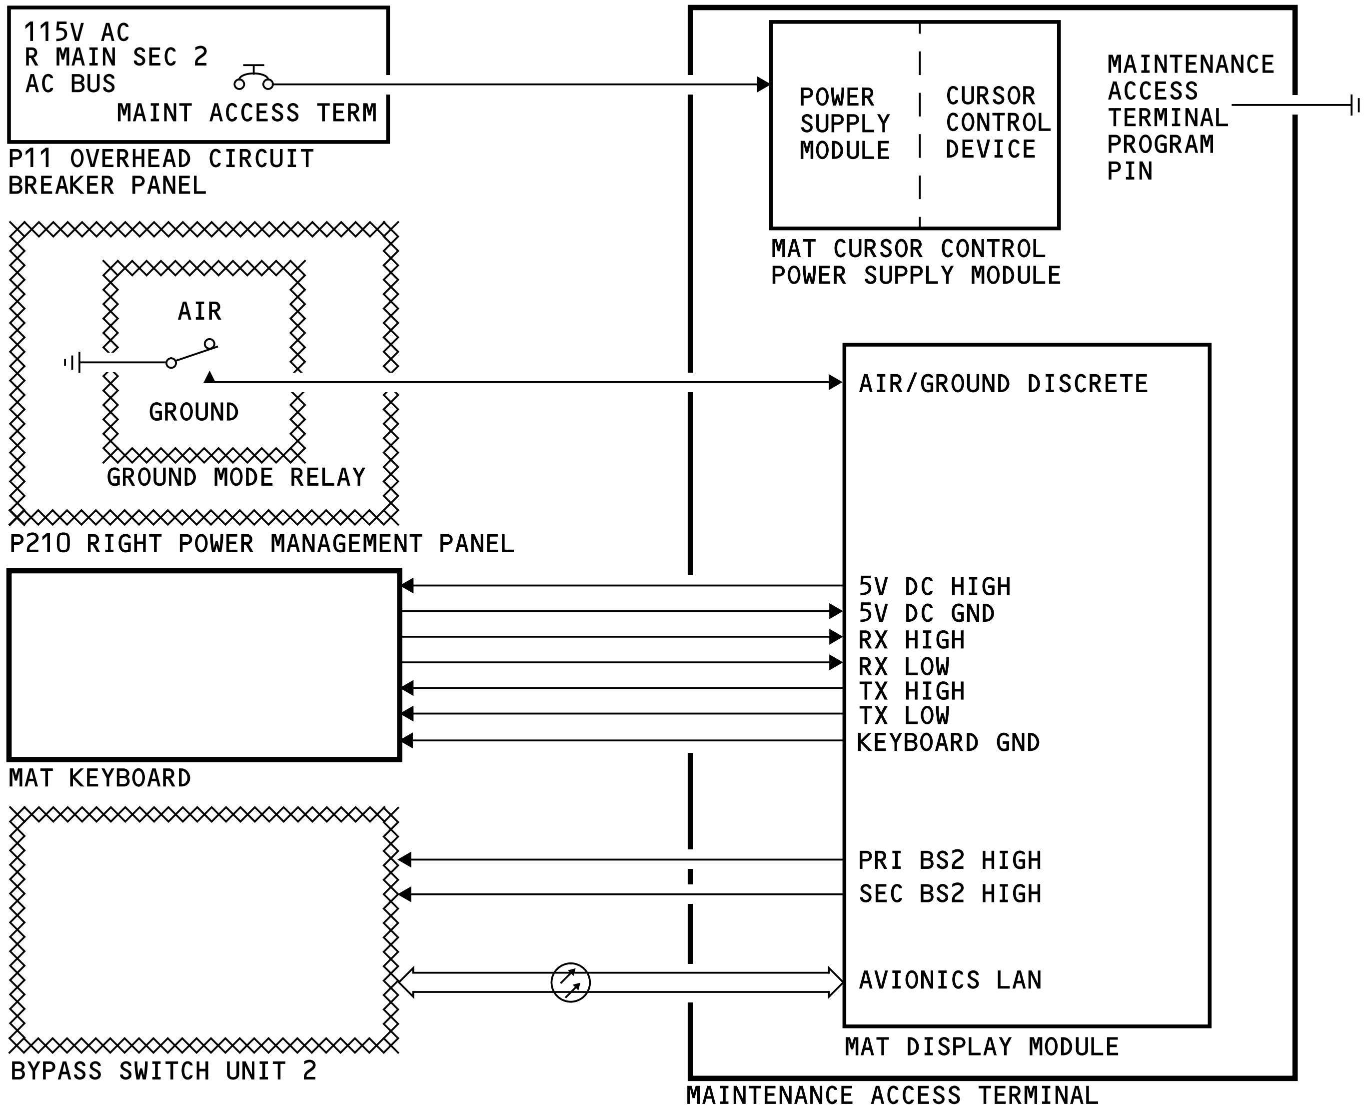
- AIMS cabinets
- MAT
- PMAT
- PMAT receptacles.

The MAT receives data from and transmits data to the avionics LAN through bypass switch unit (BSU) 2.

The MAT controls switches in the BSU to connect the MAT to the avionics LAN. The bypass switch control in the MAT display module sends two discretes to the BSU.

Program Pin

A program pin identifies this unit as the maintenance access terminal.



CMCS - MAT INTERFACES

CMCS - MAT INTERNAL INTERFACES

Power

The MAT cursor control power supply module receives 115v ac power from the R MAIN SEC 2 AC BUS. The MAT cursor control power supply module supplies 115v ac power to the:

- MAT dual disk drive module
- MAT display module.

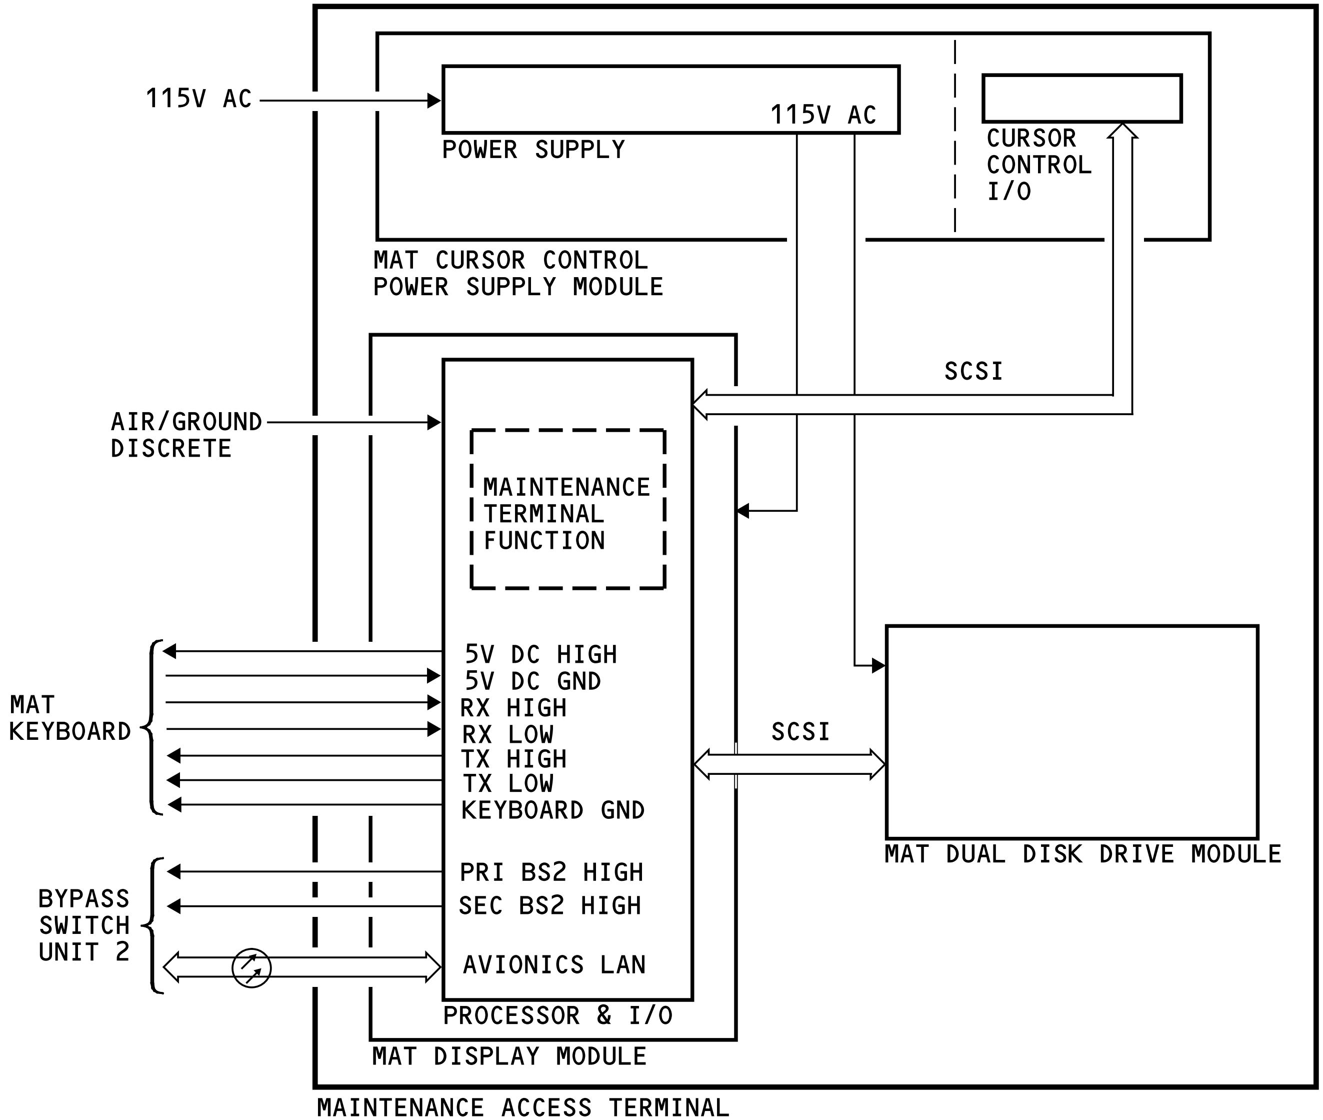
Small Computer System Interface

The MAT display module supplies a small computer system interface (SCSI) connection to the:

- MAT cursor control power supply module
- MAT dual disk drive module.

Maintenance Terminal Function

The MAT display module contains the maintenance terminal function (MTF) software that operates the MAT. You can load the MTF software.



45-10-00-006 Rev 1 07/27/1995

CMCS - MAT INTERNAL INTERFACES

CMCS - GROUND TEST SWITCH INTERFACE

General

The ground test switch:

- Permits some ground tests to run
- Permits some software to load into some LRUs
- Provides power to the portable maintenance access terminal (PMAT) in the main equipment center.

The ground test switch sends discrete signals to the:

- Left and right AIMS cabinets
- PSEU 1 and 2
- Left and right systems card files.

PMAT Interface

The ground test switch sends 115v ac from the left power management panel to the portable maintenance access terminal in the main equipment center.

AIMS Interface

The ground test switch discrete signals go to IOM (M004) and IOM (M003) in both the left and right AIMS cabinets.

The AIMS uses the data conversion gateway function (DCGF) and converts the switch discretes to ARINC 629 formatted signals. The DCGF puts the signals on the systems ARINC 629 buses and the flight controls ARINC 629 buses.

LRUs that connect to the ARINC 629 buses use the data to permit critical tests.

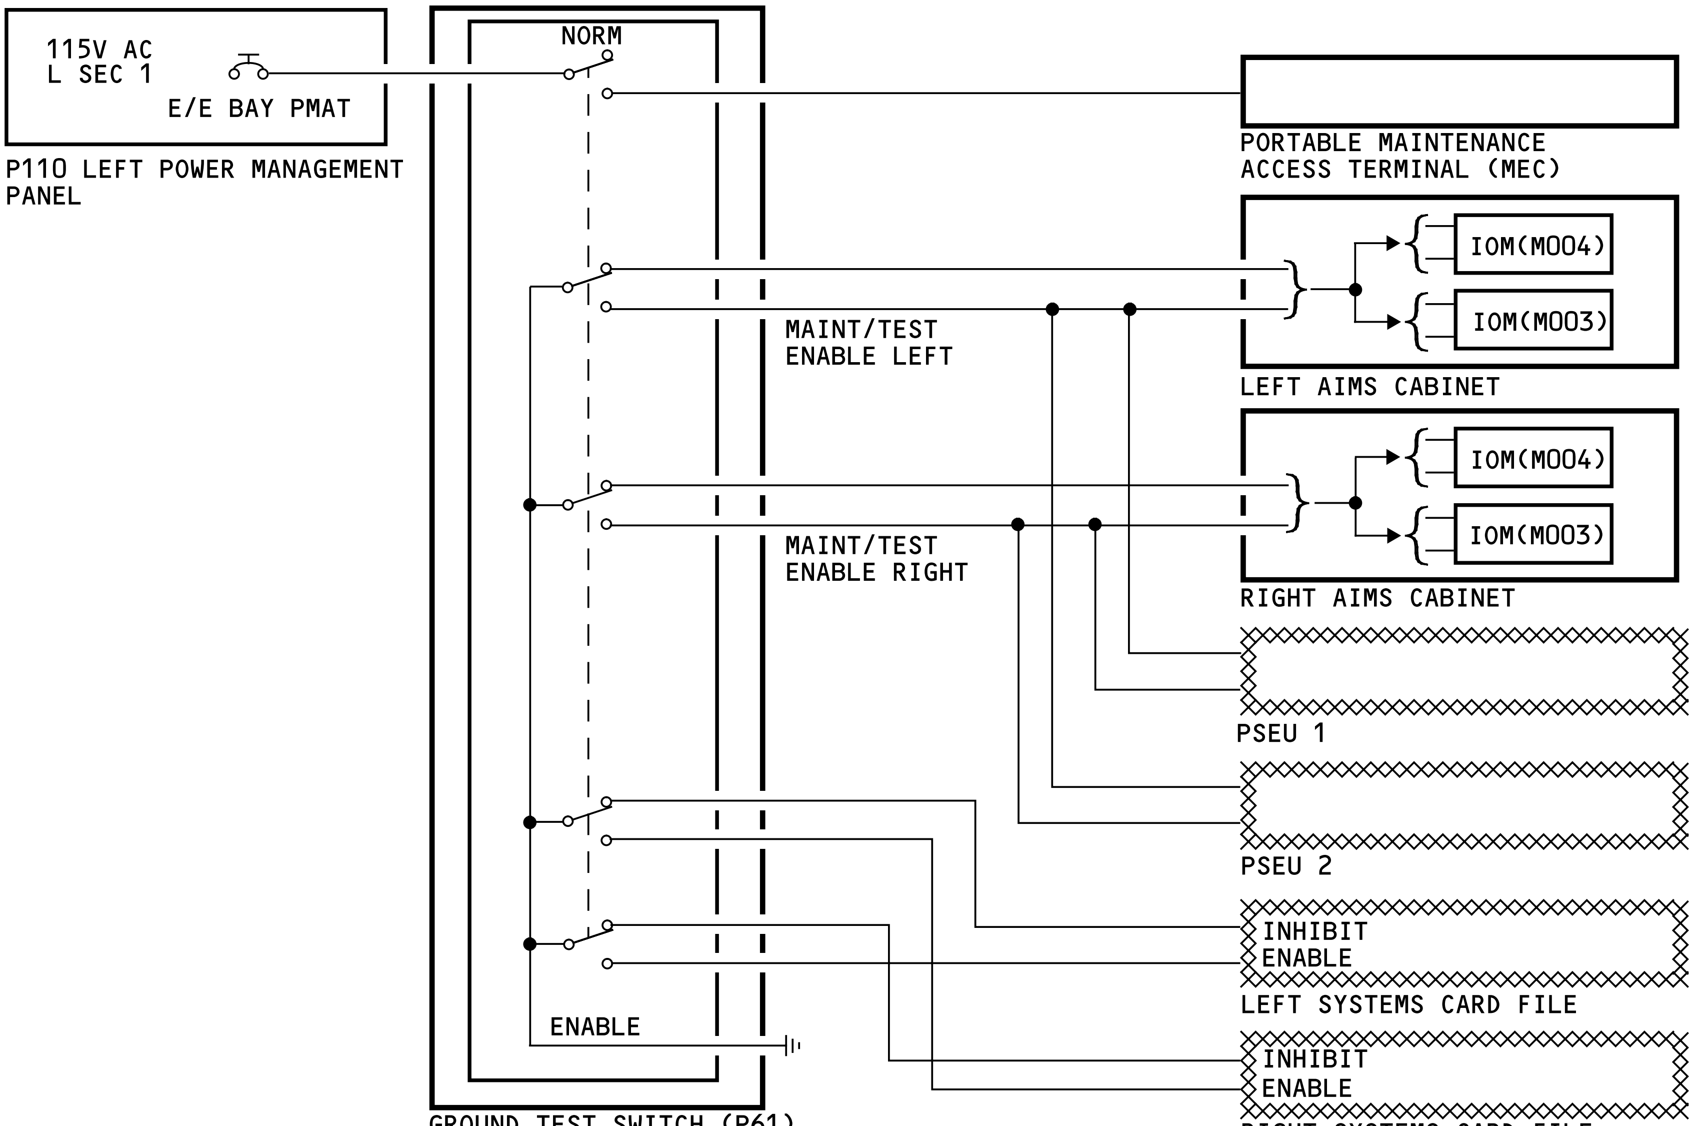
PSEU Interface

The proximity sensor electronics units (PSEU) get a direct input from the switch. The PSEUs use the signal for ground test control.

Systems Card File Interface

The left and right systems card files get switch discretes that show the position of the ground test switch. These are the systems that use the signal to permit ground tests:

- Fire/overheat detection system
- Airfoil and cowl ice protection system
- Duct leak detection system
- Air/ground system
- Hydraulic system
- Environmental control system
- Cargo smoke detection system.



CMCS - GROUND TEST SWITCH INTERFACE

CMCS - PMAT INTERFACES

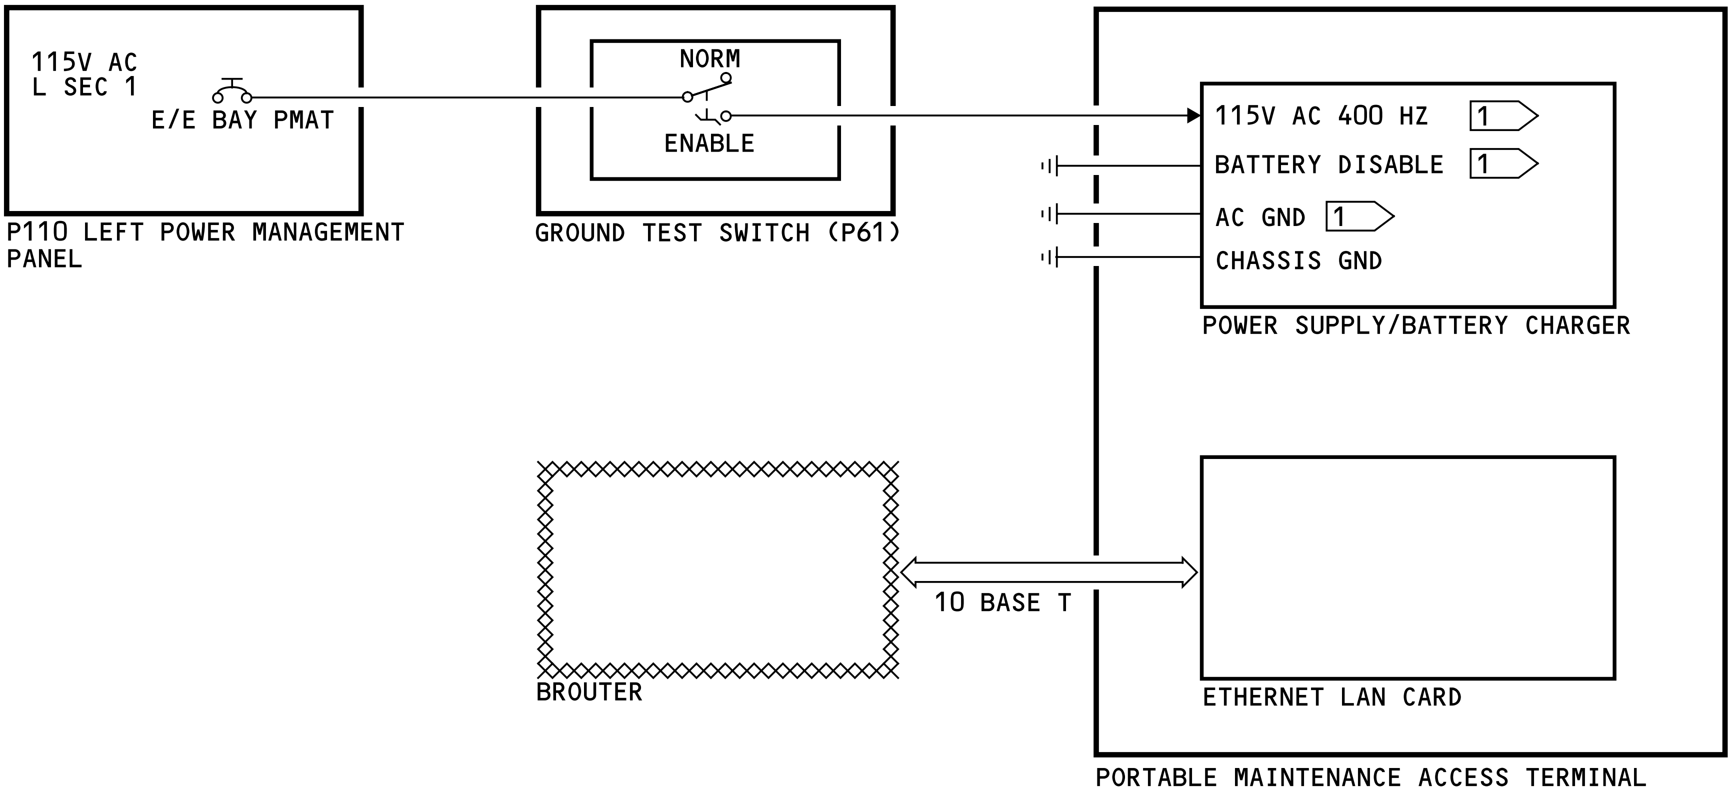
Power

The portable maintenance access terminal (PMAT) in the main equipment center (MEC) receives 115v ac 400 hz from the E/E BAY PMAT circuit breaker on the P110 left power management panel. The PMAT receives power when the ground test switch is in the enable position.

The PMAT in the MEC has a battery disable discrete to disable the battery.

Brouter

The brouter transmits data to and receives data from the ethernet local area network card in all PMATs. The PMATs use a 10 base T interface.



45-10-00-129 Rev 0

1 MAIN EQUIPMENT CENTER PMAT ONLY

CMCS - PMAT INTERFACES

CMCS - FIBER OPTICS INTERFACE

Avionics Local Area Network

The left and right AIMS cabinets have a fiber optics interface which supplies two connections to an avionics local area network (AVLAN). The MAT and a brouter also have fiber optics connections to the avionics LAN. The avionics LAN is part of an onboard local area network (OLAN). The AVLAN supplies a high speed communication path between the AIMS cabinets and the:

- Maintenance access terminal (MAT)
- Portable maintenance access terminal (PMAT)
- Four portable maintenance access terminal (PMAT) receptacles.

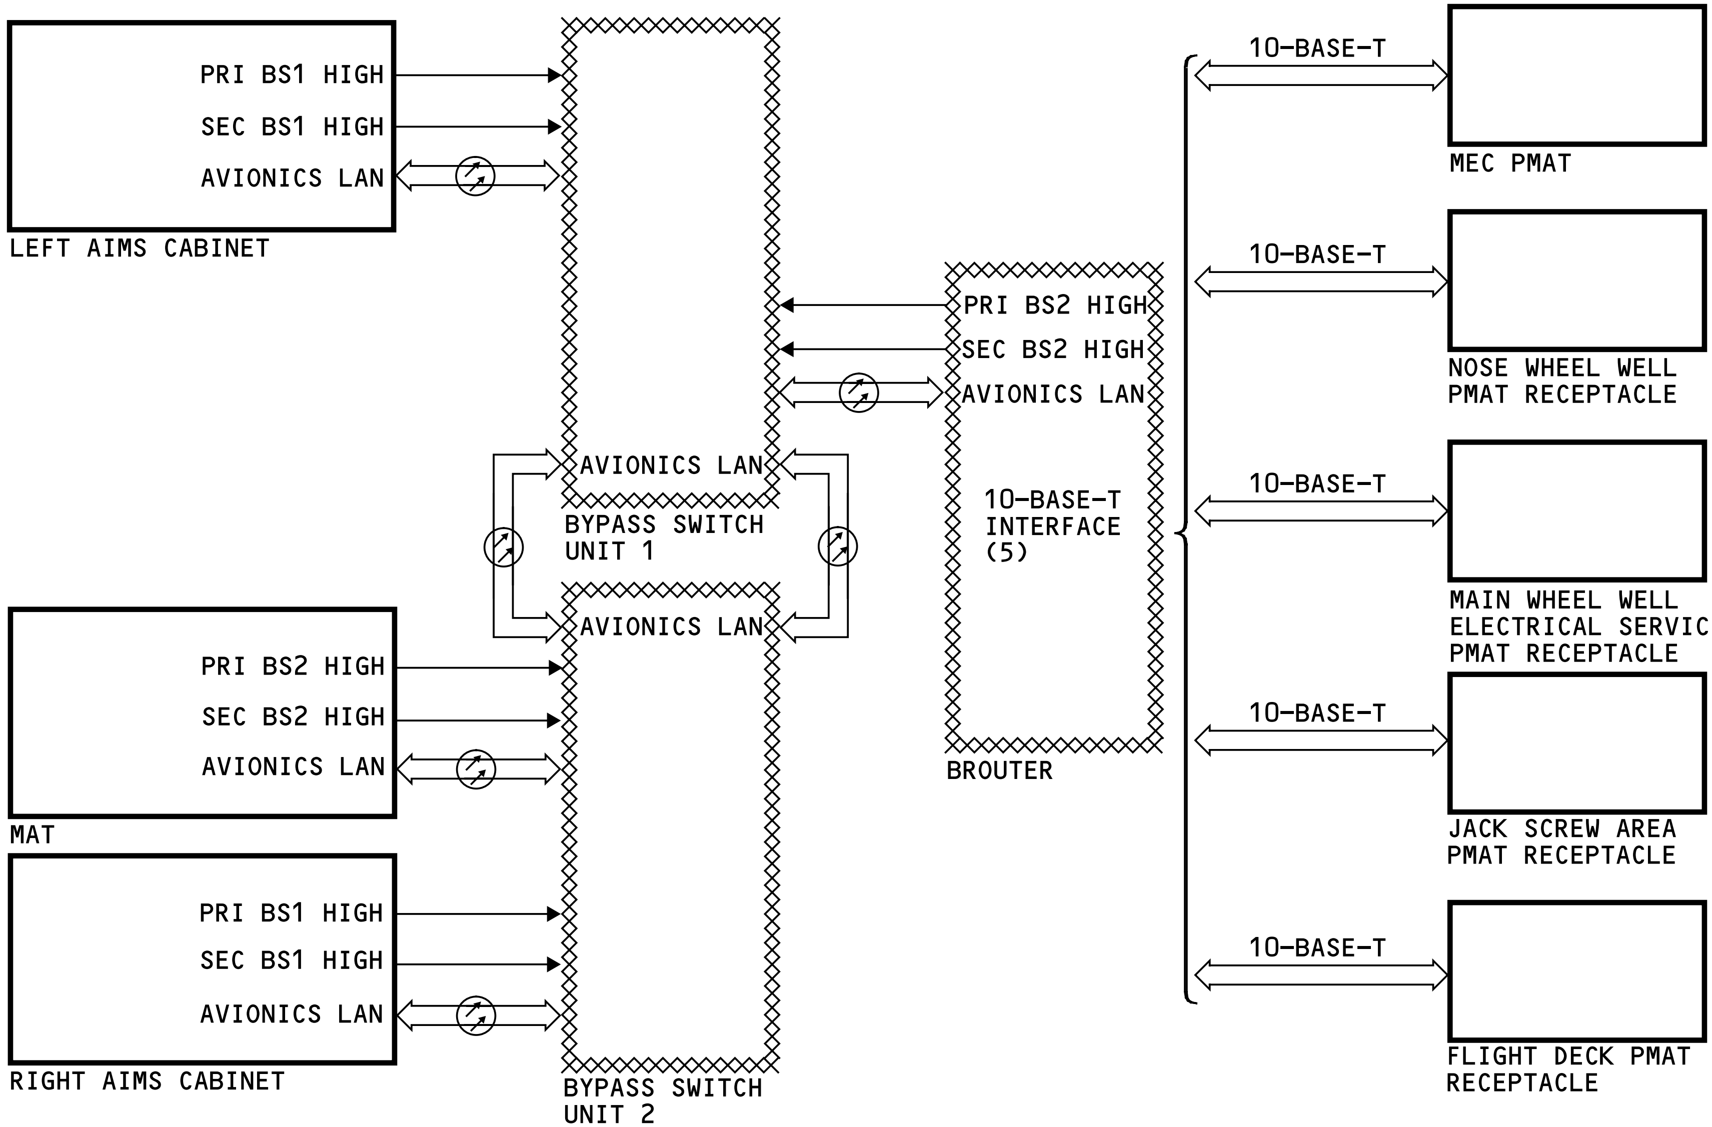
The MAT receives data from and transmits data to the avionics LAN through a bypass switch unit (BSU). The MAT controls switches in BSU 2 to connect the MAT to the AVLAN. The MAT uses two discretes, primary bypass switch (BS) 2 high and secondary BS 2 high, to control the switches in BSU 2.

A brouter supplies the connection to the PMAT and PMAT receptacles. The brouter has a network bridging function. The network bridging function supplies the brouter connection to the avionics LAN. The brouter also uses two discretes, primary bypass switch (BS) 2 high and secondary BS 2 high, to control the switches in BSU 1.

The data communication management function (DCMF) in the left and right AIMS cabinets has the communication protocols that permit the AIMS functions to communicate with the OLAN.

The AIMS functions that use the DCMF communication services are the:

- CMCF for software data loading from the MAT and PMAT
- CMCF and ACMF for communications with the maintenance terminal function (MTF) in the MAT and PMAT
- CMCF to record OLAN faults.



CMCS - FIBER OPTICS INTERFACE

45-10-00-008 Rev 4 05/30/96

CMCS - ARINC 429 DATA LOAD INTERFACE

General

The central maintenance computing function (CMCF) in the AIMS cabinets supplies data load display formats that appear on the MAT display unit. The data load display formats let the maintenance crew select the source of the data and the destination of the data.

The source of the data is a data file on the hard drive or on a disk in the disk drive. The destination is one of these:

- An ARINC 429 LRU
- An LRU on a systems ARINC 629 bus
- An LRU on a flight controls ARINC 629 bus
- An LRM in the AIMS cabinet.

When the crew selects the source and the destination, the MAT sends the data through the fiber optics interface to the CPM/COMM in the AIMS cabinets. The CMCF sends the data to the correct LRU or LRM on a designated data load port through an IOM.

ARINC 429

The data goes out on the ARINC 429 data load bus.

Along with the data, load enable discretes go to the ARINC 429 LRUs.

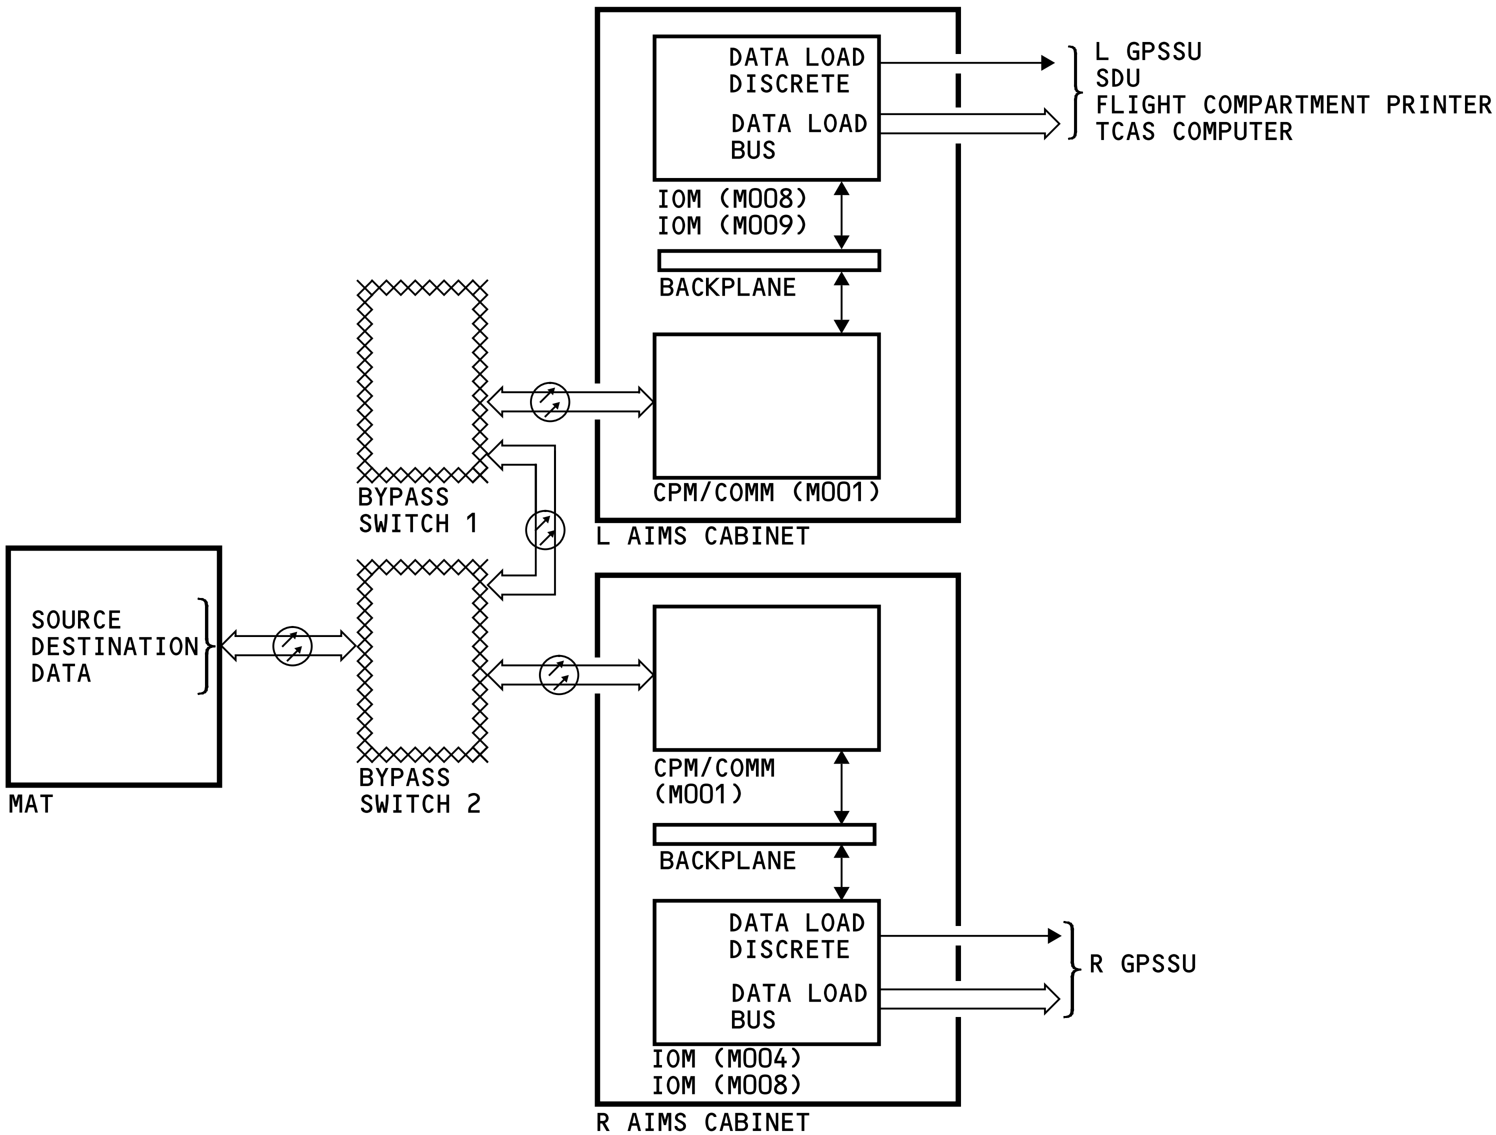
Data and status information comes in from the ARINC 429 LRUs on the 429 data input buses.

Training Information Point

These are the times when you must switch the active CMCF to do a data load:

- To load some LRUs on the flight controls ARINC 629 buses
- To load a 429 LRU connected to the right AIMS cabinet when the left CMCF is active.
- To load a 429 LRU connected to the left AIMS cabinet when the right CMCF is active.

Use the central maintenance computer switch control from the other functions menu to switch the active CMCF.

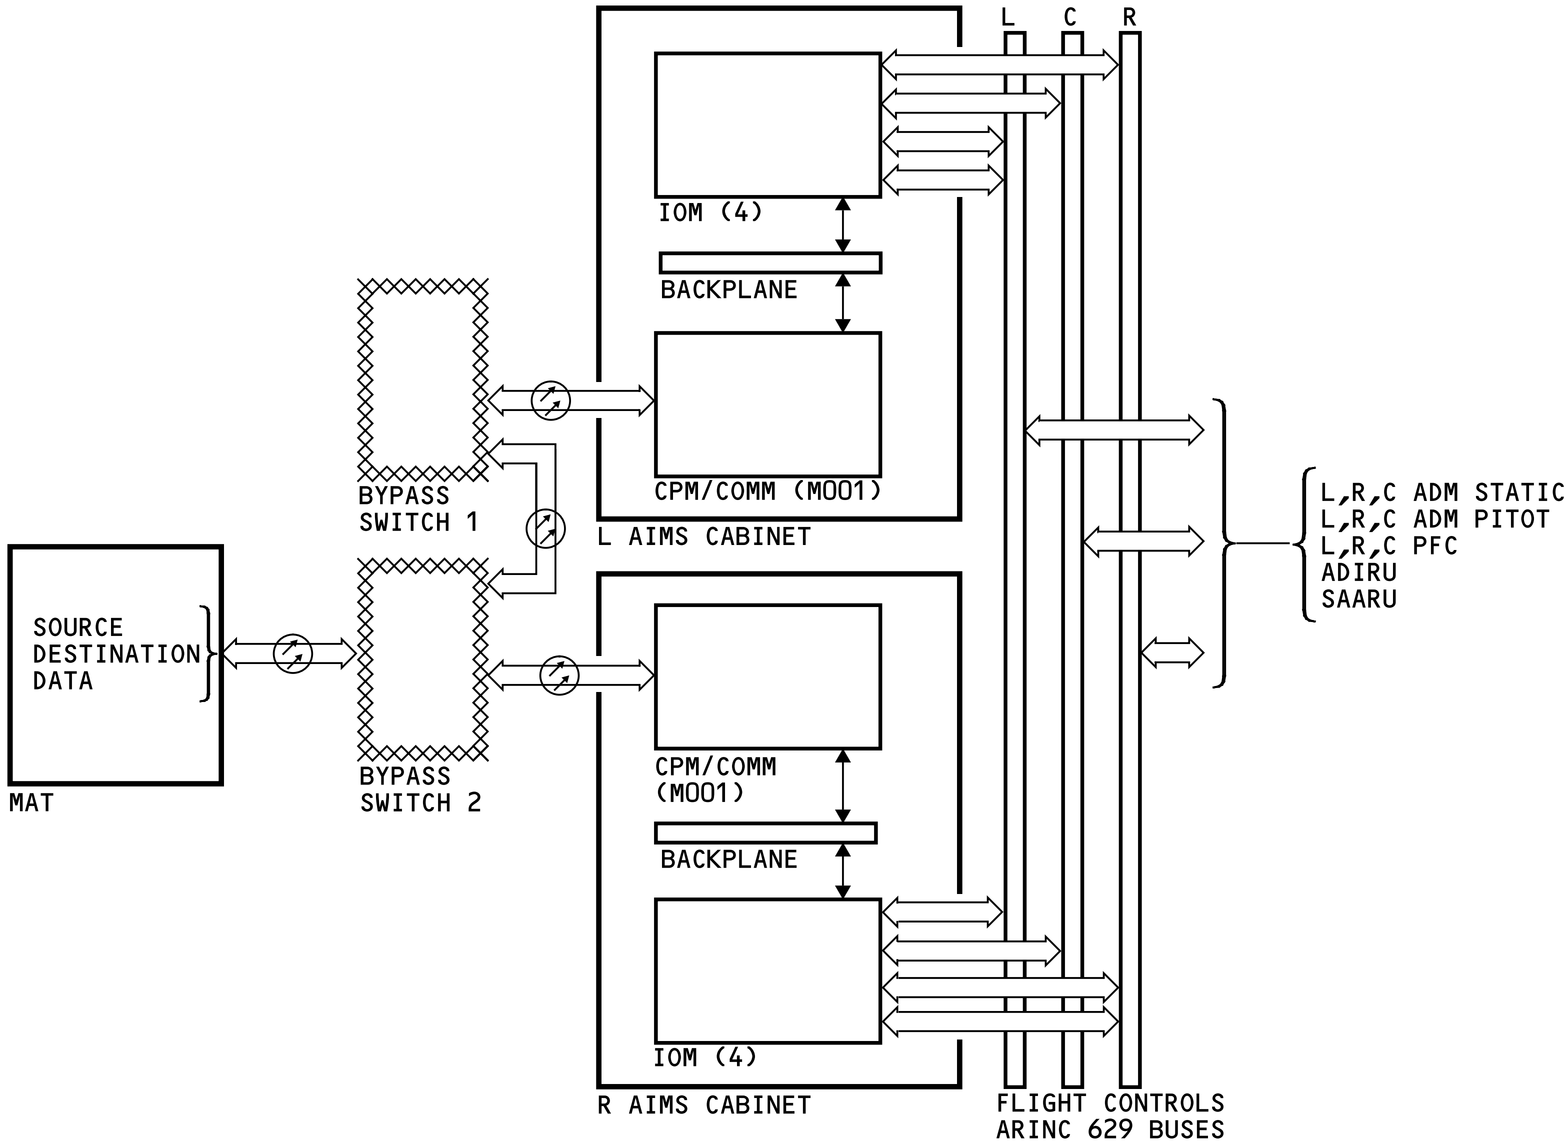


CMCS - ARINC 429 DATA LOAD INTERFACE

CMCS - FLIGHT CONTROLS ARINC 629 BUS DATA LOAD INTERFACE

Flight Controls ARINC 629 Data Buses

The data load information goes to the flight controls system LRUs on the left, center, or right flight controls ARINC 629 data buses.

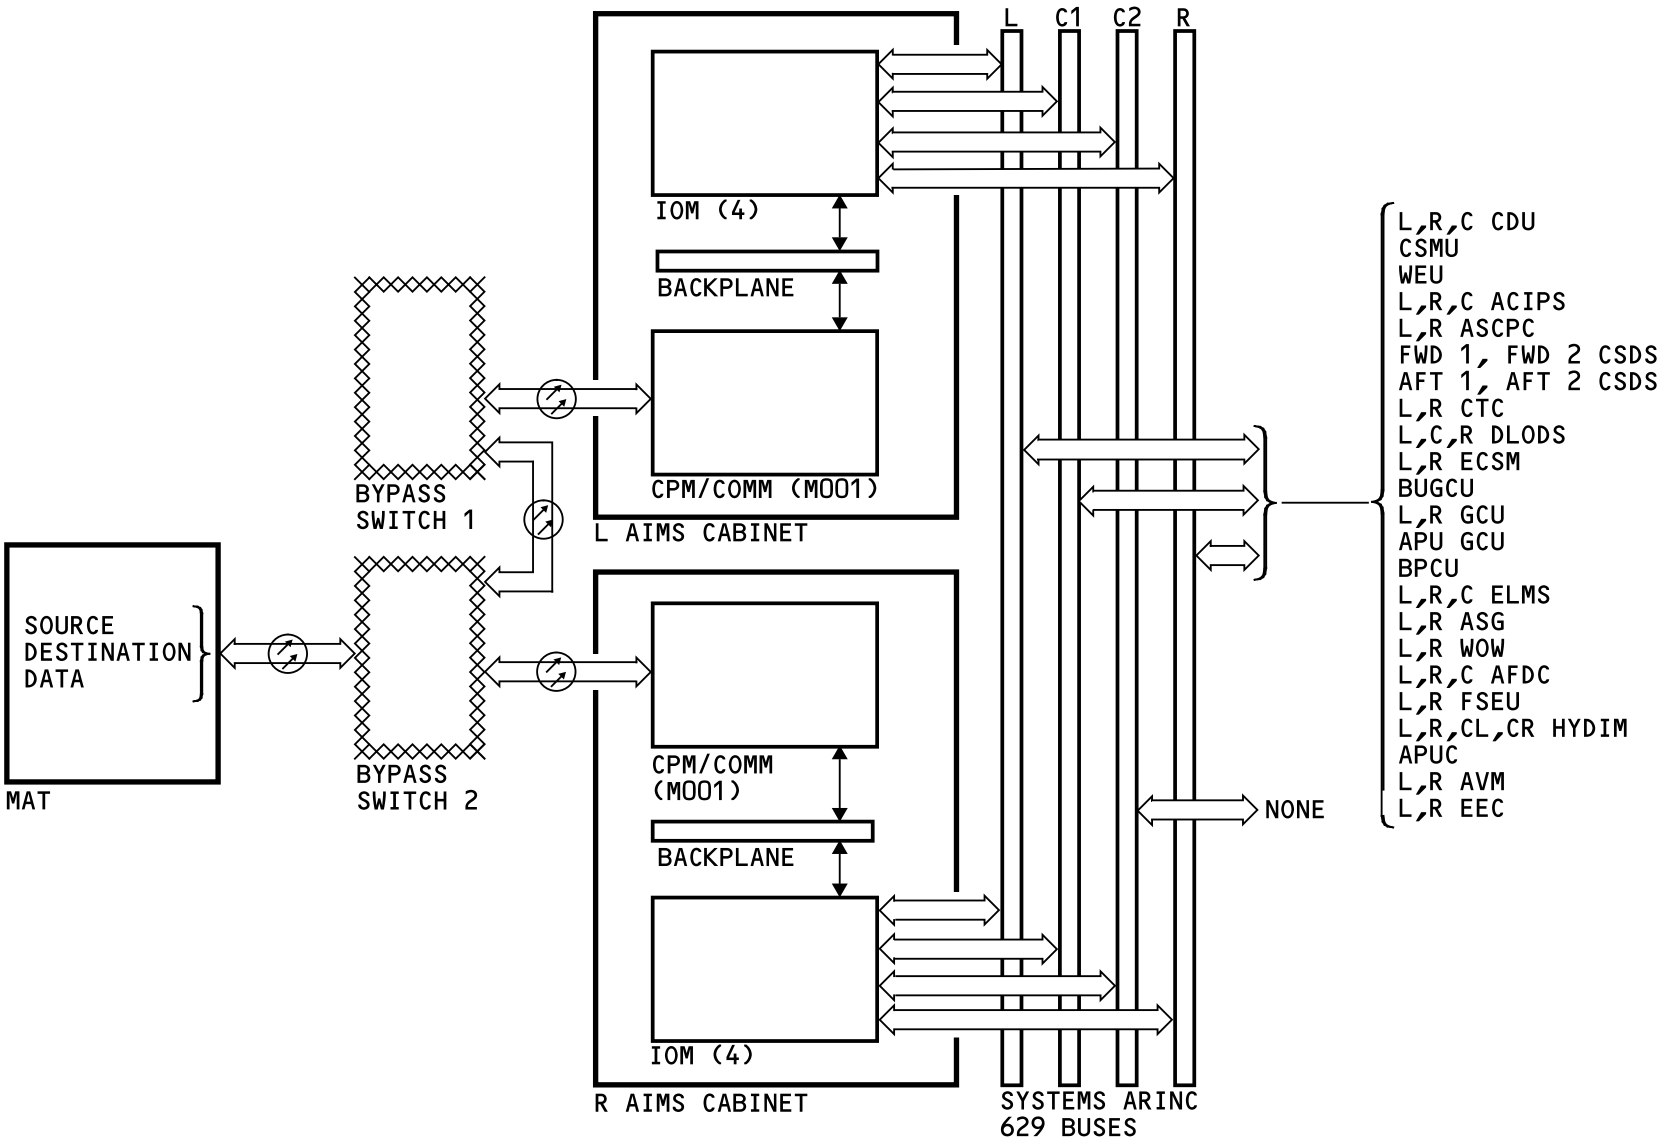


CMCS - FLIGHT CONTROLS ARINC 629 BUS DATA LOAD INTERFACE

CMCS - SYSTEMS ARINC 629 BUS DATA LOAD INTERFACE

Systems ARINC 629 Buses

The data goes to the airplane system LRUs on the left, center 1, or right systems ARINC 629 data bus. No data goes out on the center 2 systems ARINC 629 data bus.



CMCS - SYSTEMS ARINC 629 BUS DATA LOAD INTERFACE

45-10-00-011 Rev 2

CMCS - ARINC 429 INTERFACES

CMCS ARINC 429 Bus Control

The central maintenance computing system (CMCS) buses connect the left and right AIMS cabinets with LRUs that use the ARINC 429 standard for digital data transfer. The CMCF supplies data to three low speed ARINC 429 transmitters in each AIMS cabinet. Three source select relays in the left AIMS cabinet select between the left and right AIMS cabinets as the data source to the LRUs.

The left CMCF controls the source select relays. If the left CMCF is the primary CMCF, the relays are energized and the left CMCF supplies the outputs on the CMCS buses.

If an IOM fails in the left AIMS cabinet, the relay relaxes in that IOM and the data comes from the right CMCF.

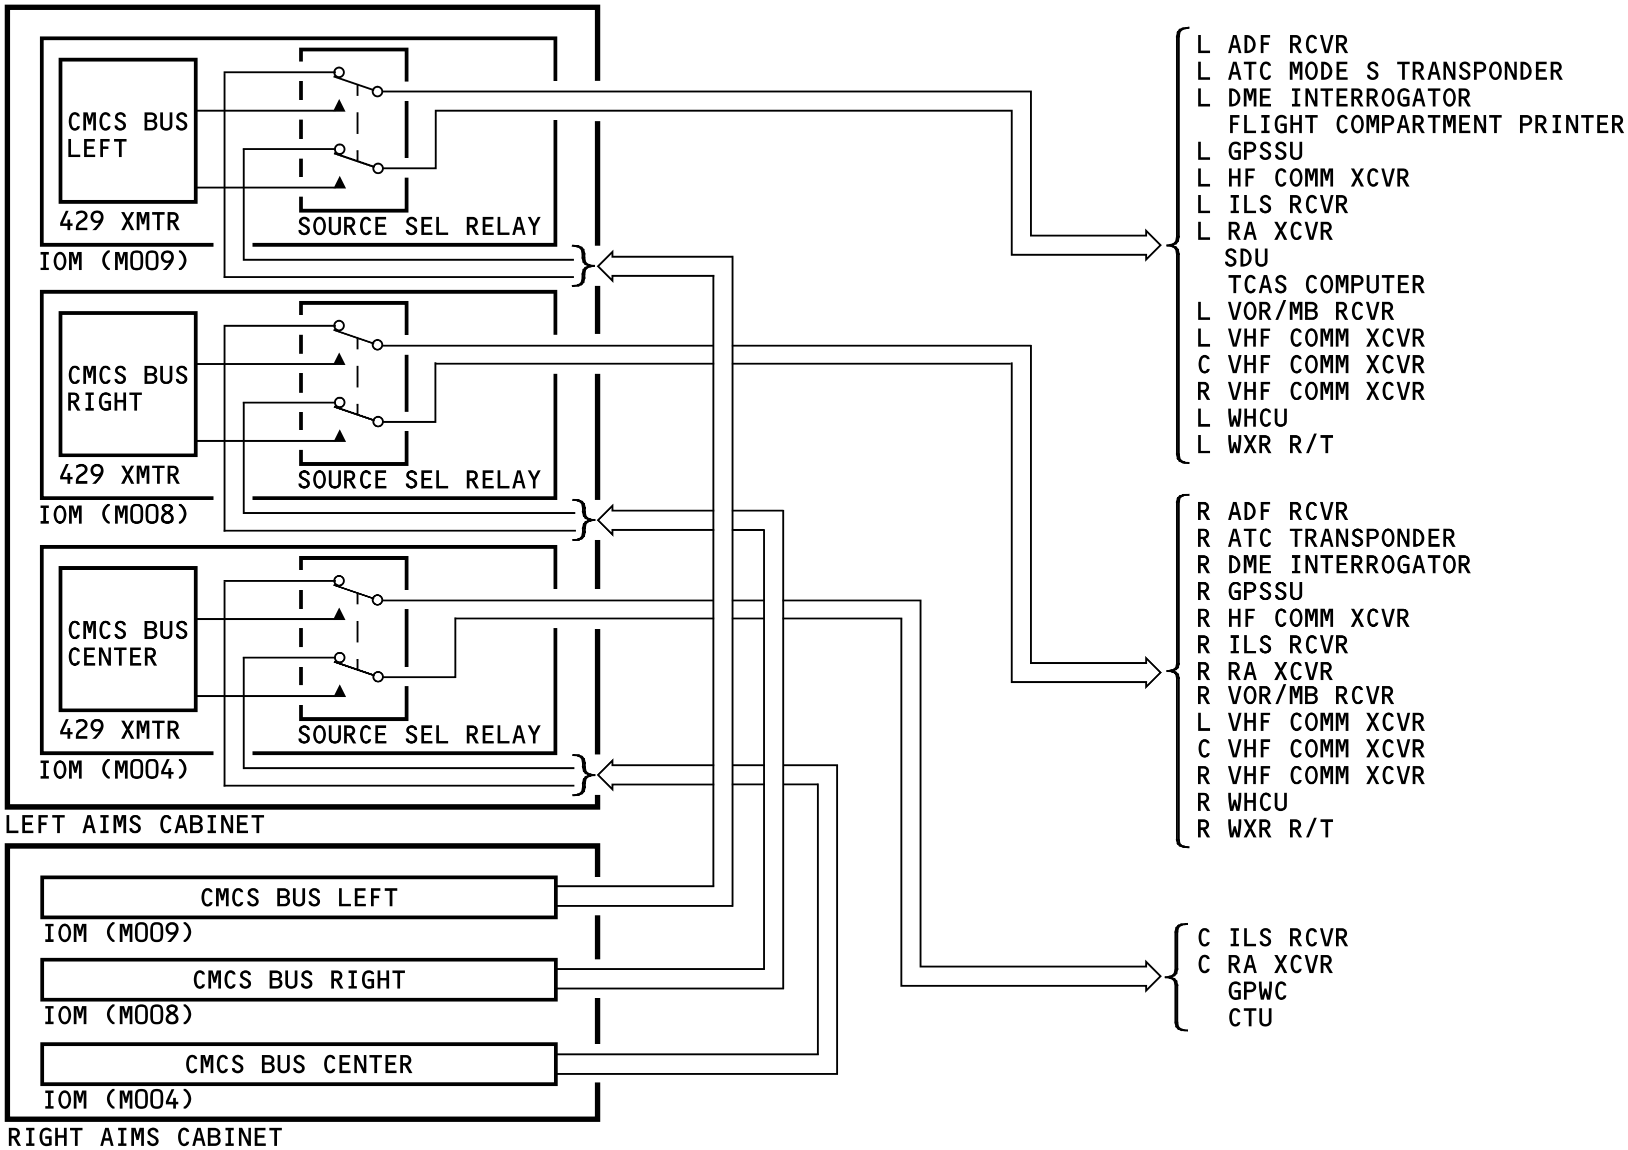
If the left CMCF fails, all three relays relax and the data on the CMCS buses comes from the right CMCF.

CMCS ARINC 429 Outputs

The LRUs that receive data on the CMCS buses are the:

- ATC mode S transponder; left and right
- ADF receiver; left and right
- Cabin telecommunications unit (CTU)
- DME interrogator; left and right
- Flight compartment printer
- GPSSU; left and right
- GPWC
- HF communication transceiver; left and right
- ILS receiver; left, right and center
- Radio altimeter receiver/transmitter; left, right and center
- Satellite data unit
- TCAS computer
- VHF communication transceiver; left, right and center
- VOR/MB receiver; left and right
- Weather radar receiver/transmitter; left and right
- Window heat control unit; left and right.

The CMCS data includes maintenance test command data and flight phase data.



CMCS - ARINC 429 INTERFACES

CMCS - MAINTENANCE ACCESS TERMINAL

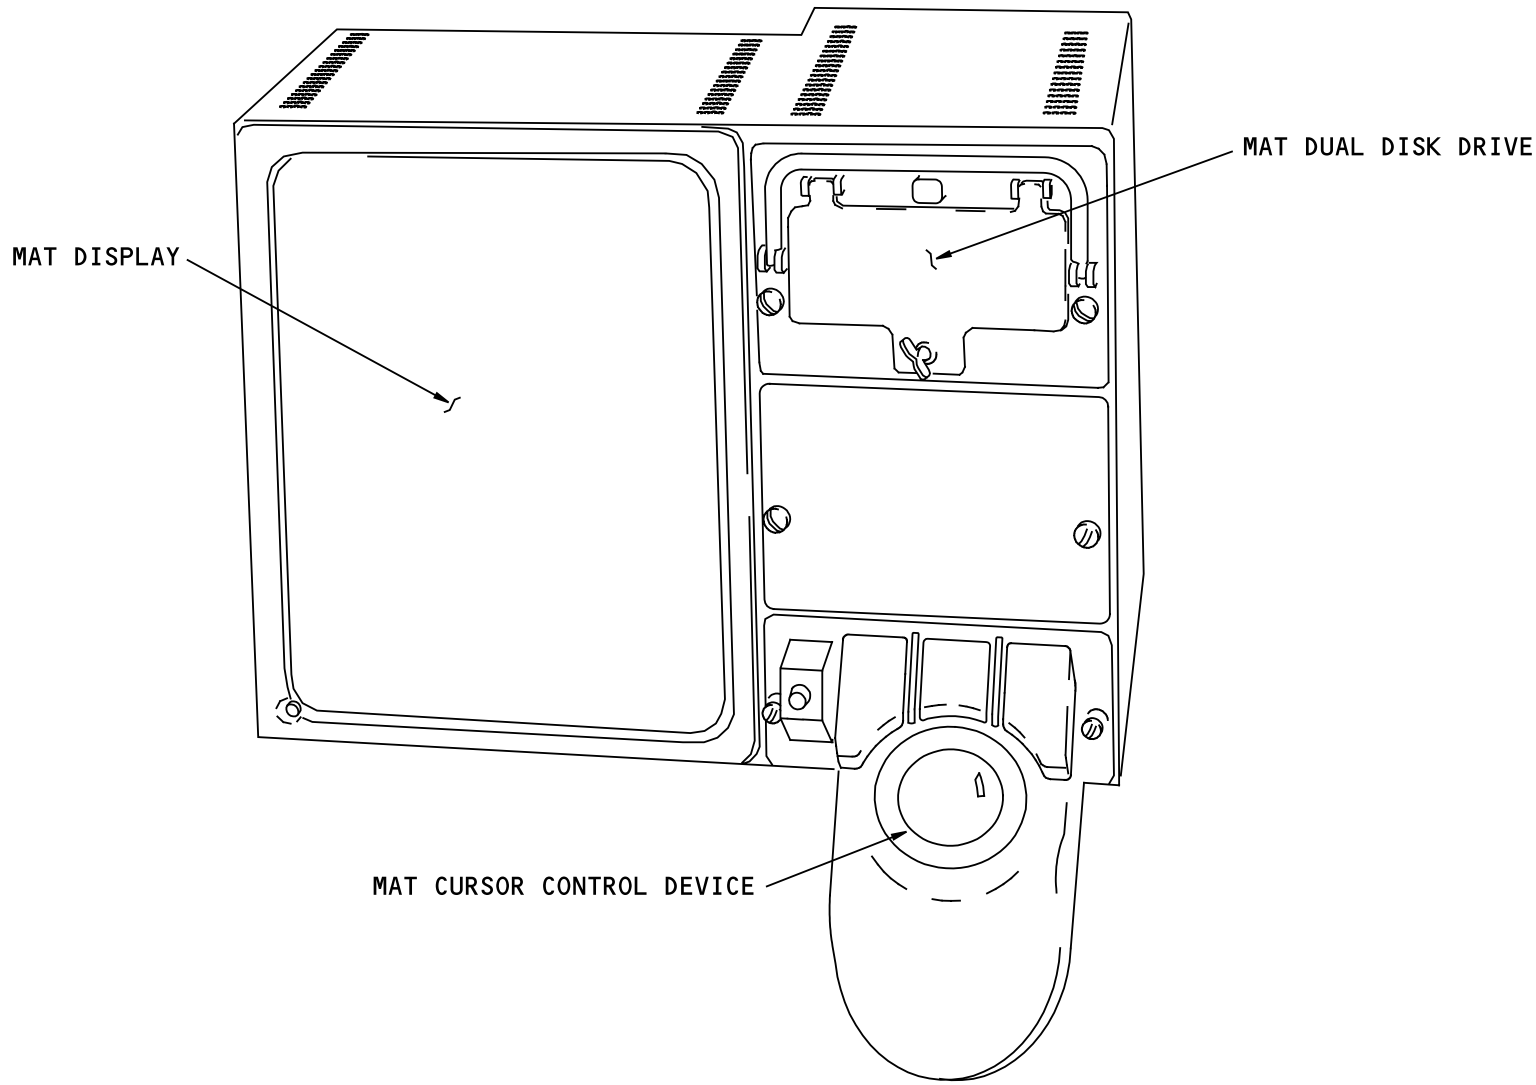
Purpose

The maintenance access terminal (MAT) gives access to the central maintenance computing system (CMCS) and the airplane condition monitoring system (ACMS).

General Description

The MAT has these four line replaceable units (LRUs):

- MAT chassis
- MAT display
- MAT dual disk drive module
- MAT cursor control device.



CMCS - MAINTENANCE ACCESS TERMINAL

CMCS - MAINTENANCE ACCESS TERMINAL KEYBOARD

Purpose

The MAT keyboard supplies:

- Standard keyboard functions
- Alternate cursor control capability.

Physical Description

The keyboard is 15 inches wide, 5.7 inches deep, and 2 inches high.

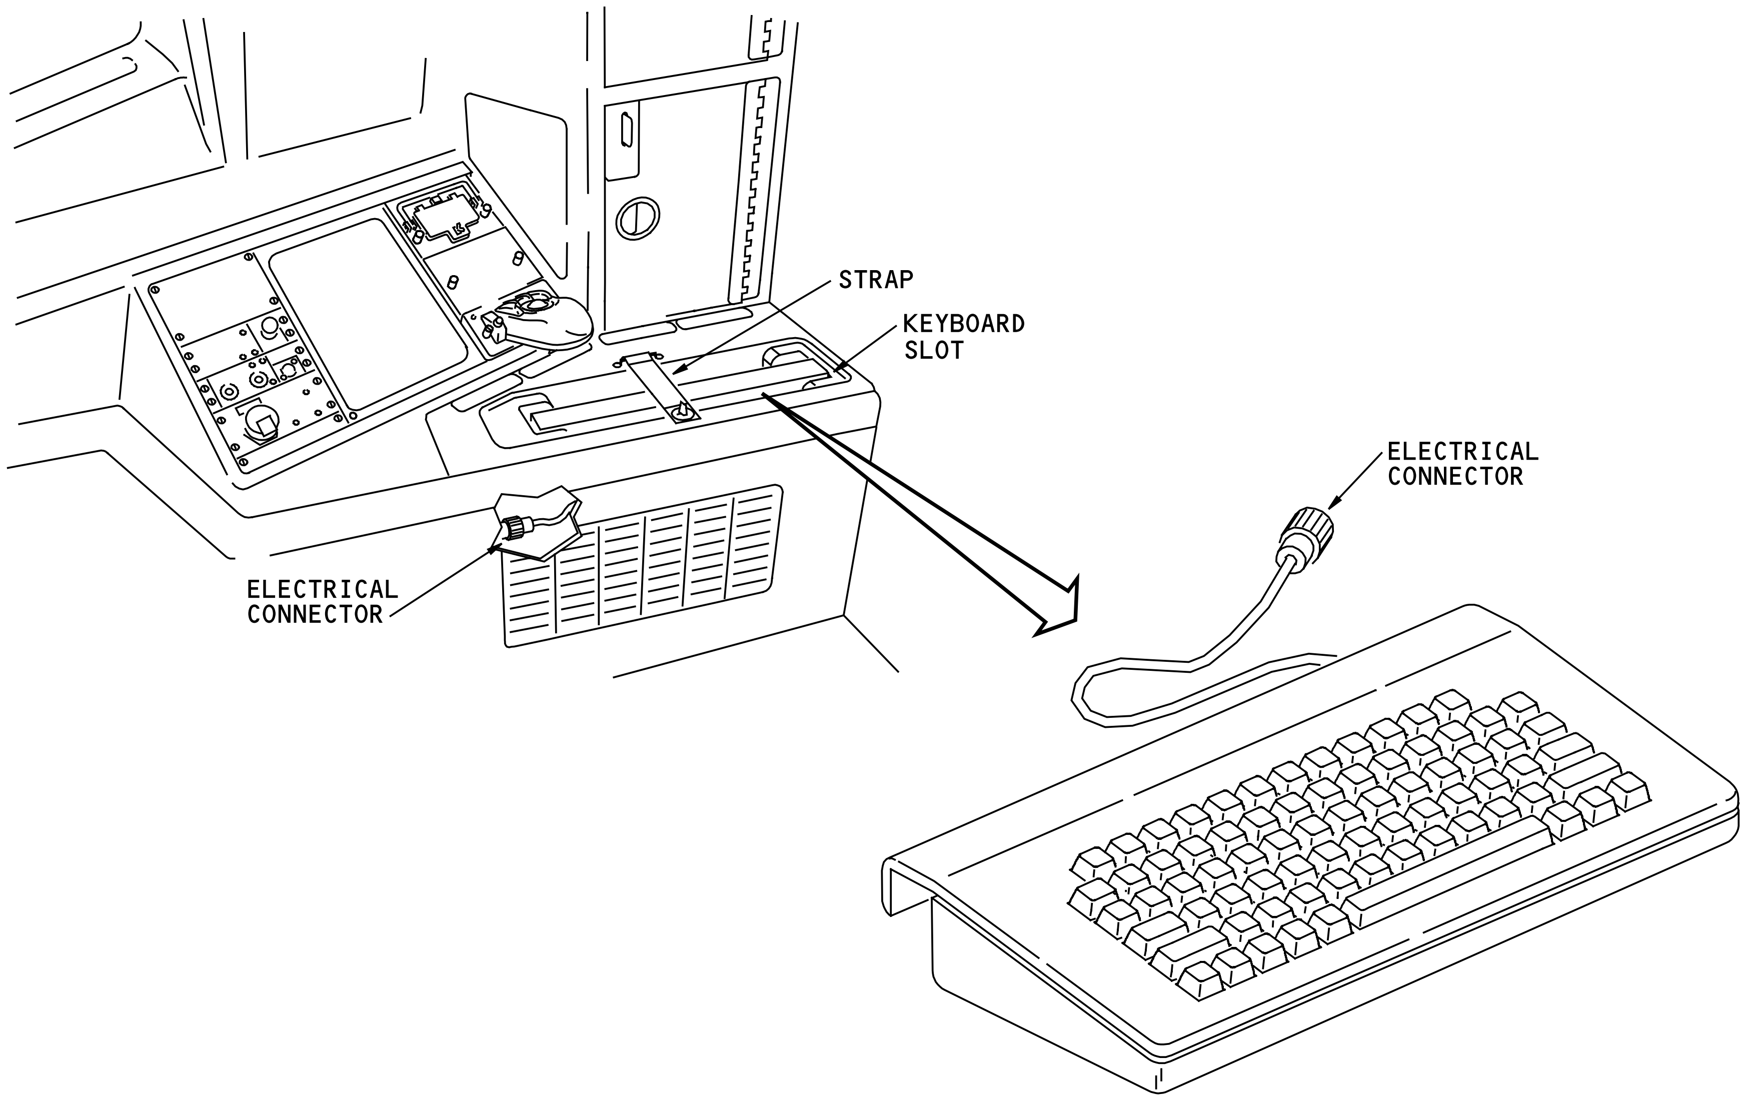
The MAT keyboard weighs approximately 4.5 pounds.

The keyboard stows on edge in the built-in stowage slot.

The keyboard has a non-removable cable at the back that connects to airplane wiring inside the keyboard slot. The keyboard cable is 48 inches long.

Training Information Point

Store the keyboard so the keyboard cable does not touch the keyboard keys. If the keyboard cable, or anything else, pushes the keyboard keys, the MAT may not operate.



CMCS - MAINTENANCE ACCESS TERMINAL KEYBOARD

CMCS - PORTABLE MAINTENANCE ACCESS TERMINAL

Purpose

The portable maintenance access terminal (PMAT) lets the operator access the CMCS and the airplane condition monitoring system (ACMS) from various locations on the airplane. All functions available on the maintenance access terminal are available on the PMAT. The locations are:

- Flight deck
- Main equipment center
- Nose wheel well
- Right main wheel well
- Jack screw area.

The PMAT in the main equipment center is permanently mounted on top of the E4 rack.

Physical Description

The PMAT is 14.00 inches wide, 14.70 inches deep, and 4.75 inches high.

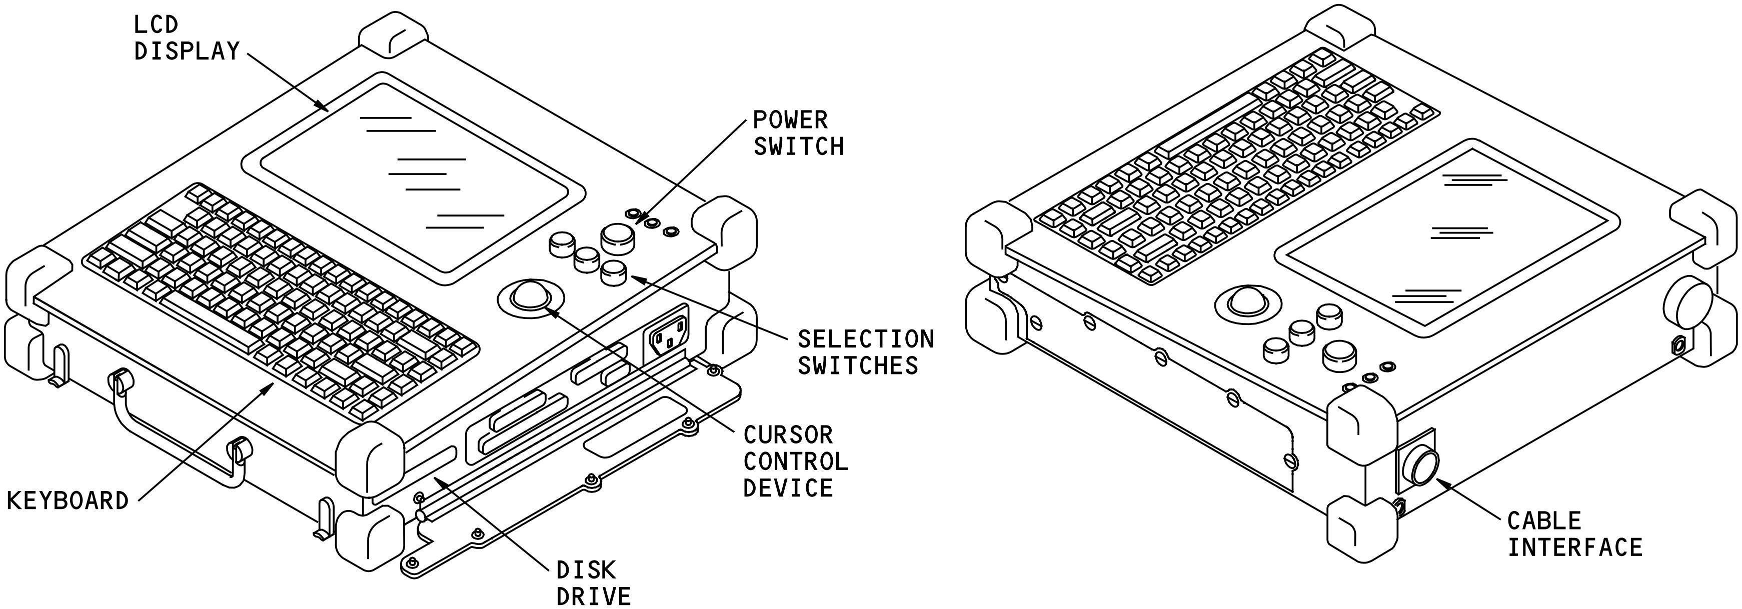
The PMAT weighs approximately 16 pounds.

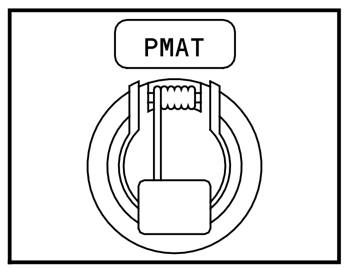
An interface cable connects to the back of the PMAT and supplies and interface to the airplane.

The PMAT receptacle has a dust cover for protection against dust and fluids.

PMAT Receptacle

The PMAT receptacle supplies an interface between a PMAT and the avionics local area network (AVLAN). The PMAT receptacle in the main equipment center also supplies power to the PMAT.





PMAT RECEPTACLE

45-10-00-019 Rev 1

CMCS - PORTABLE MAINTENANCE ACCESS TERMINAL

CMCS - FUNCTIONAL DESCRIPTION

General

The CMCF is software in the CPM/Comm that does many operations. The CMCF divides the software into many sub-functions. The software sub-functions supply these:

- Redundancy management
- BITE
- Power-up configuration checks
- Power-up hardware failure detection
- Fault data processing
- Fault and FDE correlation
- Data tables
- Flight leg and flight phase calculations
- Ground tests
- Input monitoring
- Special functions
- PSEU and air/ground rigging/calibration
- On-board engine balancing
- System configuration
- Software controlled options
- Shop faults processing
- Airline database
- Report generation
- Data load gateway
- Interface protocol.

There is CMCF software in each CPM/Comm.

Redundancy Management

Each CMCF supplies a redundancy management sub-function which does:

- Dual CMCF configuration checks
- CMCF fault history database synchronization
- Central maintenance source switching
- Offside CMCF data access.

After power-up, if both the CMCFs are operational then the primary CMCF is the left CMCF. The secondary CMCF is the right CMCF. The primary CMCF controls all the CMCF outputs to the airplane systems. The right CMCF becomes the primary CMCF if the left CMCF fails or if changed by the central maintenance source switching selection on the MAT.

The CMCFs do configuration checks continuously after a power-up. During dual operation, the CMCFs do configuration checks for these:

- Operational program configuration files (OPC)
- Operational program software (OPS)
- Airline modifiable information (AMI)
- Fault history databases
- Manual flight leg enabled/disabled condition.

In case of a configuration check difference between the two CMCFs, the CMCF shows a warning dialog box on the MAT.

For different AMIs between the two CMCFs, the CMCFs:

- Record a shop fault message
- Generate a fault report
- Continue to operate normally.

CMCS - FUNCTIONAL DESCRIPTION

The primary CMCF automatically cross loads the flight leg enabled/disabled condition to the secondary CMCF when the two CMCFs manual flight leg enable/disable conditions are different.

The CMCF supplies an automatic way to maintain an identical fault history database in both CMCFs at all times. The primary CMCF cross loads the fault history database to the secondary CMCF automatically whenever the two databases are different. The primary CMCF cross loads the fault history database in 1 minute.

The primary CMCF can be switched from one CMCF to the other CMCF. The MAT supplies the central maintenance source switching operation. The central maintenance source switching is inhibited during these conditions:

- Ground tests operation
- Data load operation
- One CMCF failure
- Onboard engine balancing system operation.

Each CMCF gets data from the other CMCF for input monitoring and reports from the AIMS intercabinet buses.

CMCF BITE

Each CMCF has BITE which detects any CMCF software partition failures. A CMCF fails if the CMCF BITE detects one of these:

- Bad data tables
- Loss of maintenance message correlation to flight deck effects (FDEs)
- Bad stored fault history database
- Loss of MAT and PMAT communications.

The CMCF BITE records a shop fault message when a failure occurs. After a CMCF failure, the failed CMCF if in control, loses control to the offside CMCF. The offside CMCF becomes the primary CMCF.

Single CMCF Power-up Configuration Checks

Each CMCF does configuration checks during power-up or after the software load of an OPS, OPC, data table, or airline database. The CMCF does configuration checks for an:

- Invalid or missing OPC
- Invalid or missing OPS
- OPC that is incompatible with the OPS
- Invalid or missing AMI
- AMI that is incompatible with the OPS.

If a configuration check finds a failure the CMCF records a shop fault message. The CMCF also shows a warning dialog box for each failure.

Single and Dual Hardware Power-up Failures

The CMCFs check for hardware failures at power-up. A failure indication, R CMCF or L CMCF Initialization Failed, shows on the MAT if one of the CMCFs has a hardware failure at power-up. The CMCF also records a shop fault message. The CMCF with no failures is the primary CMCF and supplies the CMCF outputs.

If both CMCFs have hardware failures at power up, Initialization Failed shows on the MAT. The CMCFs record a shop fault message.

Fault Data Processing

The CMCF fault processing sub-function:

- Processes inputs
- Inhibits invalid fault reports
- Creates limited fault reports
- Removes cascaded effects of failures
- Correlates FDEs and maintenance messages
- Stores FDEs and maintenance messages.

Loadable Diagnostic Information

The CMCF requests data from the loadable diagnostic information (LDI) to operate. The LDI contains:

- Fault data
- FDEs data
- MOs data
- Maintenance page snapshots (MPSs) data
- Fault correlation algorithms
- LRUs that the CMCF has access to for shop faults information
- Options
- LRU/LRM installation data.

Flight Leg and Flight Phase Calculations

The CMCF calculates the airplane flight legs. The flight legs are calculated as:

- Present leg = leg 0
- Last leg = leg -1
- Previous legs = legs -2, -3, -4, etc. to -99.

The CMCF calculates the airplane flight phases, which are:

- Power on
- Engine start
- Taxi out
- Takeoff roll
- Initial climb
- Climb
- Cruise
- Descent
- Approach
- Go around
- Flare
- Rollout
- Taxi in
- Shutdown
- Maintenance.

Ground Tests

The CMCF controls ground tests for the airplane systems. These are the three types of ground tests:

- System test
- Operational test
- LRU replacement test.

System tests make sure the system meets all tolerances and specifications for in-service use.

Operational tests are short tests that find if the system is operational.

LRU replacement tests make sure that you installed an LRU correctly and it does a check of airplane system interfaces.

Some of the grounds tests are interactive tests. Interactive tests require interaction on the MAT to complete the test.

The CMCF transmits test commands and receives test replies from the airplane systems on the:

- ARINC 629 buses
- ARINC 429 buses
- Onboard local area network (OLAN).

System Configuration

The CMCF supplies equipment and software identification (ID) data from many LRUs and LRMs to show on the MAT. The CMCF transmits ID data to and receives system configuration data from LRUs and LRMs connected to the:

- ARINC 629 buses
- ARINC 429 buses
- OLAN.

Input Monitoring

The CMCF has an input monitoring sub-function which receives input signals and supplies the signals for display on the MAT. The CMCF monitors these five signal input types:

- ARINC 629
- ARINC 429
- Analog variable
- Analog discrete
- AIMS intermodule memory (IMM).

Onboard Engine Balancing

The CMCF, with the left and right airborne vibration monitoring units, supplies the onboard engine balancing system (OEBS). The airbone vibration monitoring units transmit data to the CMCF for the OEBS.

The CMCF starts and controls the engine balancing procedure. The CMCF also supplies the displays for the engine balancing procedure.

PSEU and Air/Ground Rigging/Calibration

Rigging is a procedure where a mechanic uses information shown on the PSEU and air/ground rigging/ calibration display to make sure a sensor installation is correct. The manual mechanical rerigging of a sensor installation is also possible with the information shown on the display.

Rigging calibration permits the mechanic to change the sensor operation range from the MAT. This feature permits compensation for small differences in sensor installations.

The PSEU and air/ground rigging/calibration sub-function receives data from the:

- Left proximity sensor electronics unit (PSEU)
- Right PSEU
- Left weight on wheels (WOW) card
- Right WOW card.

You can rig or calibrate only one sensor at a time per PSEU or WOW card.

The CMCF supplies rigging and rigging calibration information for:

- Air/ground sensors
- Nose gear sensors
- Left and right main gear sensors
- Tail strike sensors
- Left and right thrust reversers indication sensors
- Forward and aft cargo doors control sensors
- Forward and aft cargo doors indication sensors
- Passenger entry doors flight lock sensors
- Passenger doors indication sensors
- Forward access door sensor
- Electrical/electronic access door sensor.

Special Functions

The CMCF supplies special functions for certain LRUs and LRMs. The protocols for special functions is the same as the protocols for ground tests. The CMCF transmits data to and receives data from the LRUs and the LRMs to show special function displays on the MAT.

Data Load Gateway

The data load gateway sub-function supplies the transfer of data between a data loader and an LRU or LRM. The data load gateway sub-function permits only one software data loading or recording session at a time.

The data load gateway sub-function moves the data between a source and a destination. The sources and destinations are LRUs and LRMs.

The sources of data for data loading are the:

- MAT
- PMAT.

The data load gateway sub-function can update a destination software configuration or record data from an LRU.

The data load gateway sub-function permits data transfers when weight is on the wheels for 5 minutes and computed airspeed is less than 40 knots.

The data load gateway sub-function supplies data to show that a destination LRU is being loaded by the data load gateway sub-function. This permits the fault processing sub-function not to show that the destination LRU has failed due to lack of response or incorrect output due to the load process. The data load gateway sub-function sends control and status data, and receives control and status data from the:

- ARINC 629 buses
- ARINC 429 buses
- Avionics local area network (AVLAN).

Software Controlled Options

The CMCF identifies software controlled options by the:

- Operational program configuration (OPC) file
- Airline modifiable information (AMI)
- CMCF options display on the MAT
- Fault table software inhibits in the data tables.

Shop Faults

The CMCF shop faults sub-function supplies a way for maintenance personnel to show and to report shop fault data stored in LRUs and LRMs, including the AIMS functions.

Shop fault data is a combination of LRU maintenance information and failure information that the LRU detects by BITE. The LRU stores the maintenance and failure information in non-volatile memory (NVM) for use during shop maintenance.

The CMCF supplies access to the shop faults data on the MAT.

Airline Modifiable Information

These are the types of data which the airline modifiable information (AMI) supplies for the CMCF:

- Notes text for maintenance messages, ground test displays, and configuration displays
- Help text for CMCF dialog boxes and displays
- The types of reports available
- Event triggers for automatically generated reports
- Tail number cross reference table which gets the specific tail number associated with the received international civil aviation organization (ICAO) number from the ATC transponder.

Report Generation

The CMCF report generation sub-function processes requests for CMCF reports from:

- The MAT dialog boxes or displays
- The PMAT dialog boxes or displays
- A ground station via datalink
- The flight deck communication function (FDCF)
- The MAT disk drive.

The CMCF also generates event triggered reports. The CMCF generates reports of the requested data and transmits the data to:

- The flight compartment printer
- A ground station
- The MAT disk drive
- The PMAT disk drive.

The print driver sub-function in the data communication management function (DCMF) receives the CMCF report data for the flight deck printer. The ACARS datalink sub-function in the DCMF receives the CMCF report data for transmission to a ground station. The OLAN sub-function in the DCMF receives the CMCF report data for transmission to the MAT and PMAT over the AVLAN.

The CMCF supplies one report at a time. The CMCF generates reports automatically at selected CMCF flight events. The flight events are program selectable and deselectable on the GBST. The CMCF transmits the flight event data to ground stations via datalink.

CMCF Interface Protocol

The CMCF interface protocol supplies the communications with the:

- DCMF
- PDF EICAS sub-function
- FMCF
- ARINC 629 buses
- ARINC 429 buses
- AVLAN.

The CMCF transmits data to and receives data from the DCMF. The data is used for:

- Downlink and uplink communications
- AVLAN communications
- Flight deck printer communications.

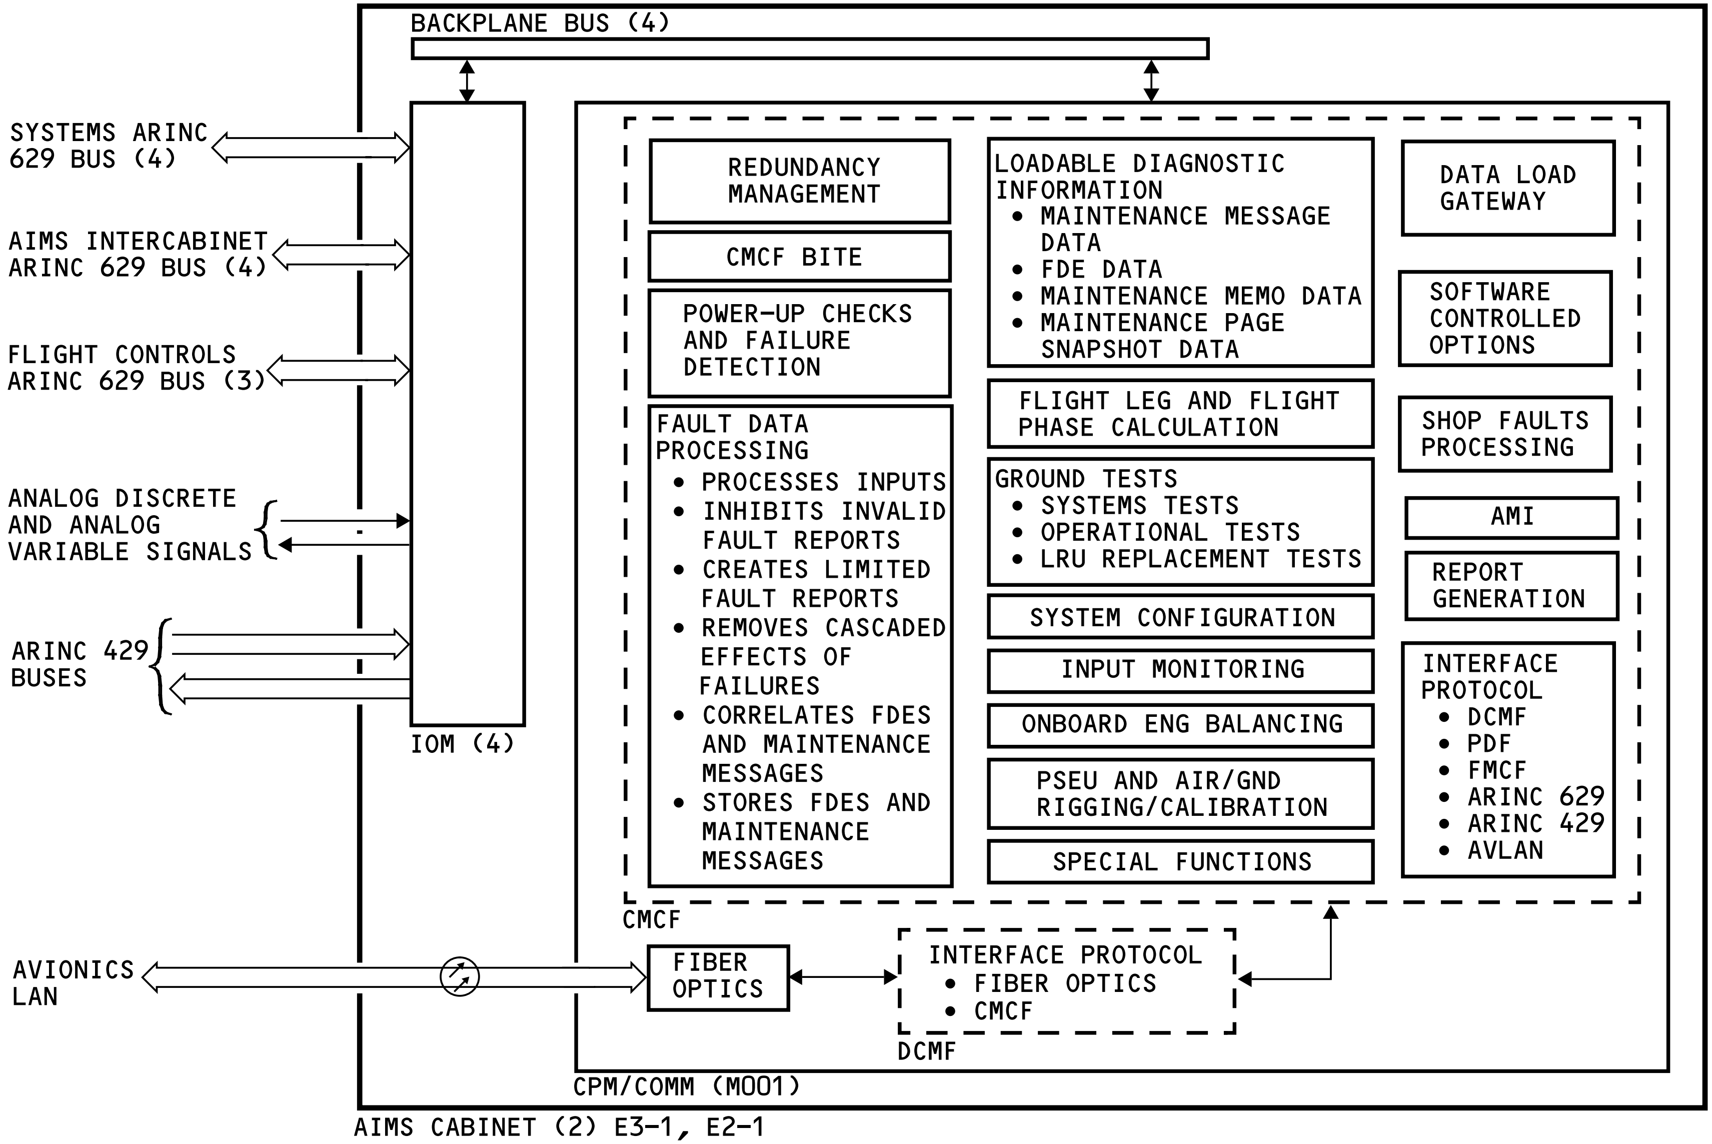
The PDF EICAS sub-function supplies FDE status data to the CMCF, which indicates the active, inactive and latched states of the FDEs.

The FMCF transmits data to the CMCF. The CMCF receives:

- Flight phase
- Flight number
- City pair
- Top of descent.

The CMCF transmits data to and receives data from many LRUs and LRMs. The CMCF supplies three interface protocols for communications with the LRUs and LRMs:

- ARINC 629 protocol
- ARINC 429 protocol
- AVLAN protocol.



CMCS - FUNCTIONAL DESCRIPTION

CMCS - AIRLINE MODIFIABLE INFORMATION

General

The design of the 777 airplane lets the airlines customize certain functions in the central maintenance computing system (CMCS). You customize these functions through airline modifiable information (AMI). You use the ground based software tool (GBST) to make the modifications.

The CMCS system comes with a baseline AMI. The baseline AMI for this system has HELP pages only.

The total memory available for the CMCS AMI is one megabyte. This total includes the baseline AMI and any modifications you make using the GBST.

You use the GBST to modify these:

- Notes
- Help
- Reports selections
- Tail number cross reference table.

Baseline Help

The baseline AMI provides help screens for displays and dialog boxes.

Modifiable Functions

You can use the GBST to specify notes for any maintenance message, ground test, or system configuration. When you select them, notes show in dialog boxes.

You can modify the baseline AMI and show help for most displays and most dialog boxes.

You can use the GBST to specify a selection for an automatic downlink of CMCF reports. You can specify these:

- Type of report to downlink
- Trigger for the report
- Destination (VHF or SATCOM)
- Downlink label and sublabel.

You can have a table to define the airplane tail identification. This table correlates to the ICAO addresses with tail numbers to allow proper identification for downlinked messages. This table has all the tail numbers for the airplanes in your 777 fleet.

Training Information Point

The CMCS AMI supplies the airplane tail identification to the data communication management system (DCMS). The DCMS aircraft communication addressing and reporting system (ACARS) sub-function must have this information to operate.

BASELINE AMI

CMCS - AIRLINE MODIFIABLE INFORMATION

CMCS - FLIGHT LEG LOGIC

General

You can review fault data on the MAT by flight legs. The CMCF computes the flight legs.

The flight leg logic defines the flight leg period. There are no time gaps between flight legs. When one flight leg ends, the next flight leg begins.

Flight Leg Transition Logic

The CMCF transitions or increments the flight leg when all of these conditions are true:

- The airplane is on the ground
- Either one of the engines is running after both have been shut down or one or both engines are running and the last door transitions from open to closed
- The flight leg transition is enabled.

Flight Leg Enable Logic

The flight leg enable logic prevents nuisance flight legs because of engine starts and shutdowns or doors open and closed.

A flight leg enable occurs when either of these are true:

- You manually enable the flight leg on the MAT
- The CMCF detects parking brakes off, engine at takeoff thrust, and a ground speed of more than 80 knots.

After the enable occurs, The CMCF stores it until the next flight leg transition logic becomes true.

When the CMCF uses the enable, a new flight leg enable must occur before the next flight leg can transition.

When the flight leg transition occurs, the CMCF generates a transition inhibit. This inhibit resets the enable logic. You can also manually set the transition inhibit on the MAT.

The next flight leg enable causes the inhibit to go away.

Flight Leg Calculations

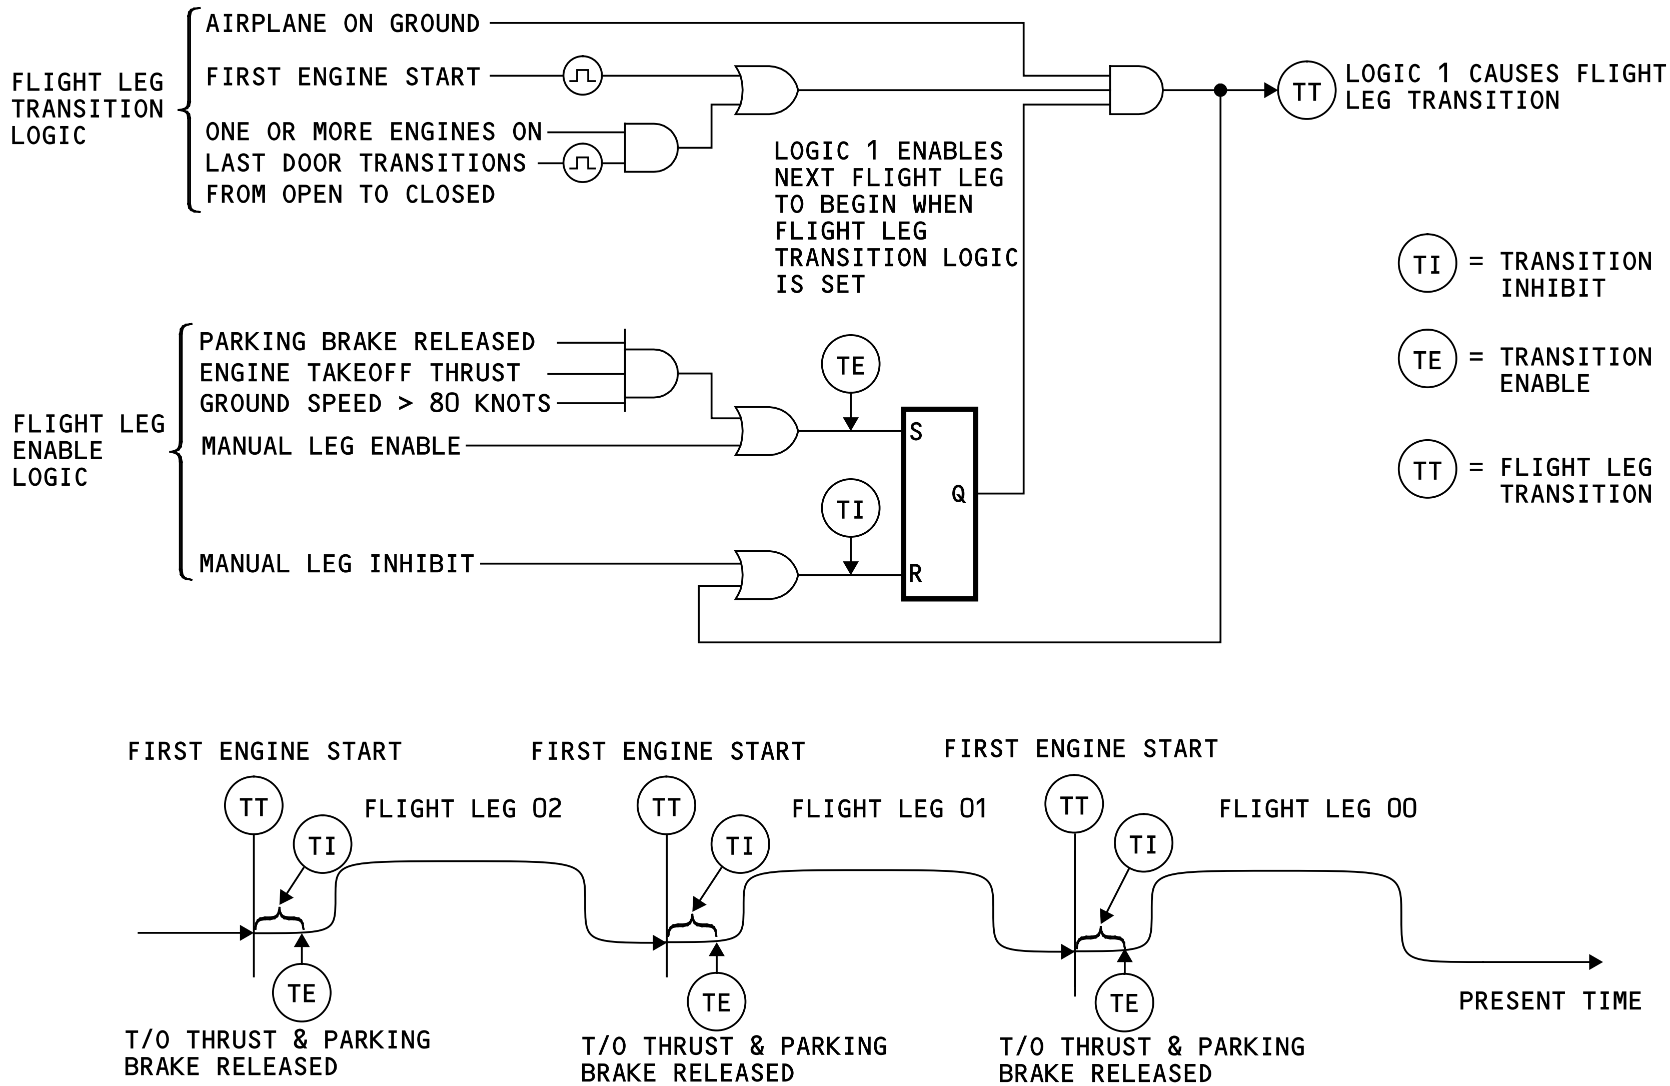
The current flight leg shows as flight leg 00.

The previous flight leg shows as flight leg 01.

Other flight legs show as 02, 03, 04,...99. The CMCF stores the most recent 100 flight legs.

Flight legs help identify faults stored for these:

- Inbound flight deck effects
- Present leg faults
- Fault history.



CMCS - FLIGHT LEG LOGIC

45-10-00-022 Rev 3 06/22/95

THIS PAGE INTENTIONALLY LEFT BLANK

CMCS - FLIGHT PHASES - 1

Flight Phase Logic

The CMCF in AIMS calculates flight phases. A flight leg has several flight phases. The CMCF uses specific logic for these calculations. The logic includes:

- Only one flight phase is active at any time
- A flight phase remains active until conditions for a new flight phase exist
- The maintenance (MT) flight phase has priority over all other flight phases
- The engine start (ES) flight phase has priority over all flight phases except MT
- The shutdown (SD) flight phase has priority over all flight phases except ES and MT
- The go around (GA) flight phase has priority over all flight phases except MT, ES, SD and climb (CL)
- The approach (AP) and flare (FL) flight phases have priority over descent (DC).

Flight Phase Calculations

The CMCF uses specific inputs to calculate and transition flight phases. There are fifteen flight phases.

Flight phases show on various CMCS displays to show the part of the flight that a fault first becomes active.

Power On (PO) Flight Phase

PO is the CMCF default flight phase. The CMCF transitions to PO when both of these are true:

- There is power on the airplane
- No other flight phase conditions are true.

Engine Start (ES) Flight Phase

The CMCF transitions to ES when these are true:

- The airplane is on the ground
- An engine's starter air valve transitions from closed to open.
- The engines fuel switch is in the RUN position
- N2 is less than idle.

Taxi Out (TA) Flight Phase

The CMCF transitions to TA when all of these are true:

- At least one engine has N2 equal to or greater than idle
- The airplane is on the ground
- The airplanes ground speed (GS) is less than 80 knots
- The flight leg transition is disabled.

Takeoff Roll (TO) Flight Phase

The CMCF transitions to TO when all of these are true:

- Both engines are running
- The airplane is on the ground
- The throttle resolver angle (TRA) for both engines is at takeoff
- Flaps/slats are set for takeoff

- GS is greater than 80 knots.

Initial Climb (IC) Flight Phase

The CMCF transitions to IC when all of these are true:

- The airplane is in the air
- Flaps/slats are set for takeoff
- Mode control panel (MCP) altitude is above the airplane's current altitude.

Climb (CL) Flight Phase

The availability of FMCF flight phase data determines how the CMCF transitions to CL.

When FMCF flight phase data is available, the CMCF transitions to CL when the FMCF flight phase transitions to CL.

When FMCF flight phase data is not available, the CMCF transitions to CL when all of these are true:

- The airplane is in the air
- The airplane climbs at more than 400 feet per minute.
- Radio altitude (RA) data shows that RA is greater than 1500 feet or RA data is not available and IC or go around (GA) has been active for two minutes.

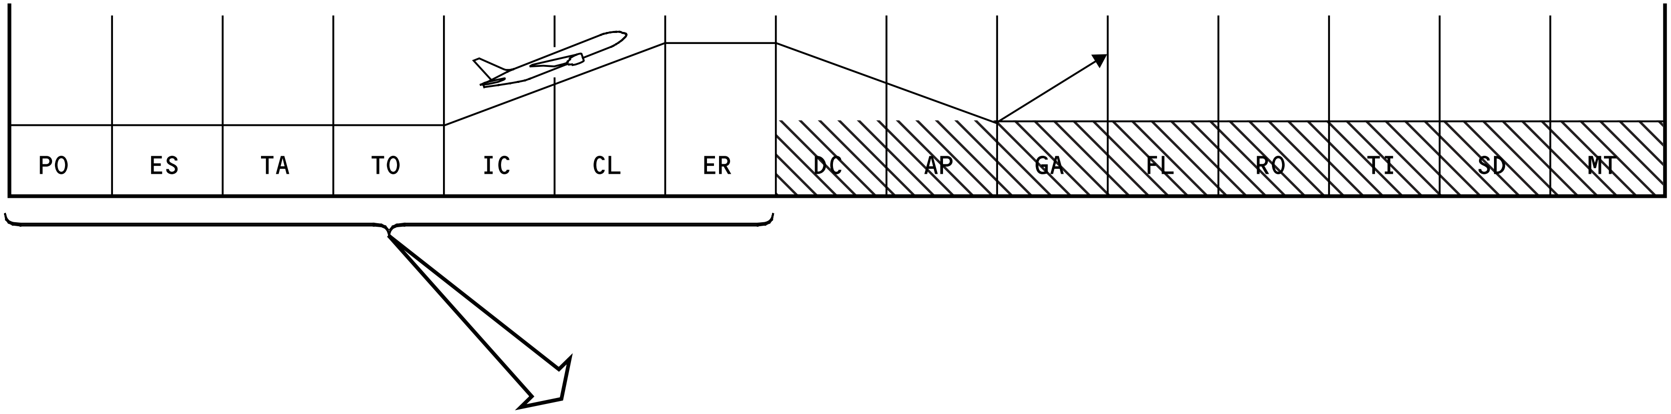
Cruise (ER) Flight Phase

The availability of FMCF flight phase data determines how the CMCF transitions to ER.

When FMCF flight phase data is available, the CMCF transitions to ER when the FMCF flight phase transitions to cruise.

When FMCF flight phase data is not available, the CMCF transitions to ER when both of these are true:

- The airplane is in the air
- The airplane either climbs or descends at a rate less than 400 feet per minute.



FLIGHT PHASE	CONDITION
PO (POWER ON)	POWER TO AIRPLANE AND NO OTHER FLIGHT PHASE
ES (ENGINE START)	AIRPLANE ON GROUND AND STARTER VALVE FROM CLOSED TO OPEN AND FUEL SWITCH IN RUN AND N2 IS LESS THAN IDLE
TA (TAXI OUT)	ONE ENGINE RUNNING (N2 > IDLE) AND AIRPLANE ON GROUND AND GS < 80 KNOTS AND FLIGHT LEG TRANSITION DISABLED
TO (TAKEOFF ROLL)	BOTH ENGINES RUNNING AND AIRPLANE ON GROUND AND TRA SET TO TAKEOFF AND FLAPS/SLATS IN TAKEOFF AND GS > 80 KNOTS
IC (INITIAL CLIMB)	AIRPLANE IN AIR AND FLAPS/SLATS AT TAKEOFF AND MCP ALTITUDE IS ABOVE CURRENT ALTITUDE
CL (CLIMB)	FMCF FLIGHT PHASE TRANSITIONS TO CLIMB OR FMCF FLIGHT PHASE DATA NOT AVAILABLE AND AIRPLANE IN AIR AND AIRPLANE CLIMBS AT MORE THAN 400 FEET/MINUTE AND RA > 1500 FEET OR IC OR GA FOR TWO MINUTES
ER (CRUISE)	FMCF FLIGHT PHASE DATA AVAILABLE AND FMCF TRANSITIONS TO CRUISE OR FMCF FLIGHT PHASE DATA NOT AVAILABLE AND AIRPLANE IN AIR AND AIRPLANE CLIMBS OR DESCENDS AT A RATE LESS THAN 400 PER MINUTE.

CMCS - FLIGHT PHASES - 1

45-10-00-023 Rev 5 11/06/1997

CMCS - FLIGHT PHASES - 2

THIS PAGE INTENTIONALLY LEFT BLANK

CMCS - FLIGHT PHASES - 2

Descent (DC) Flight Phase

The availability of FMCF flight phase data determines how the CMCF changes to DC.

With FMCF flight phase data available, the CMCF changes to DC when the FMCF flight phase changes to descent.

With FMCF flight phase data not available, the CMCF changes to DC when both of these conditions are true:

- The airplane is in the air
- The airplane descends at more than 400 feet per minute.

Approach (AP) Flight Phase

The CMCF changes to AP when all of these are true:

- The airplane is in the air
- The flaps are set for landing
- The landing gear is down.

Go-Around (GA) Flight Phase

There are two conditions that cause the CMCF to change to GA.

For the first condition, the CMCF changes to GA when both of these are true:

- The airplane is in the air
- The TOGA switch is set.

For the second condition, the CMCF changes to GA when all these are true:

- The airplane is in the air
- The flaps have changed from landing to takeoff
- The TRA for both engines is set for takeoff.

Flare (FL) Flight Phase

The CMCF changes to FL when all of these are true:

- The airplane is in the air
- The flaps are set for landing
- Radio altitude is less than 50 feet.

Rollout (RO) Flight Phase

The CMCF changes to RO when all of these are true:

- The airplane is on the ground
- Ground speed is more than 80 knots.

Taxi In (TI) Flight Phase

The CMCF changes to TI when all of these are true:

- The airplane is on the ground
- At least one engine is running
- Ground speed is less than 80 knots
- The flight leg transition is enabled.

CMCS - FLIGHT PHASES - 2

Shutdown (SD) Flight Phase

The CMCF changes to SD when all of these are true:

- The airplane is on the ground
- The starter air valve is closed
- Either engine fuel switch changes from RUN to CUTOFF and the EEC is active.

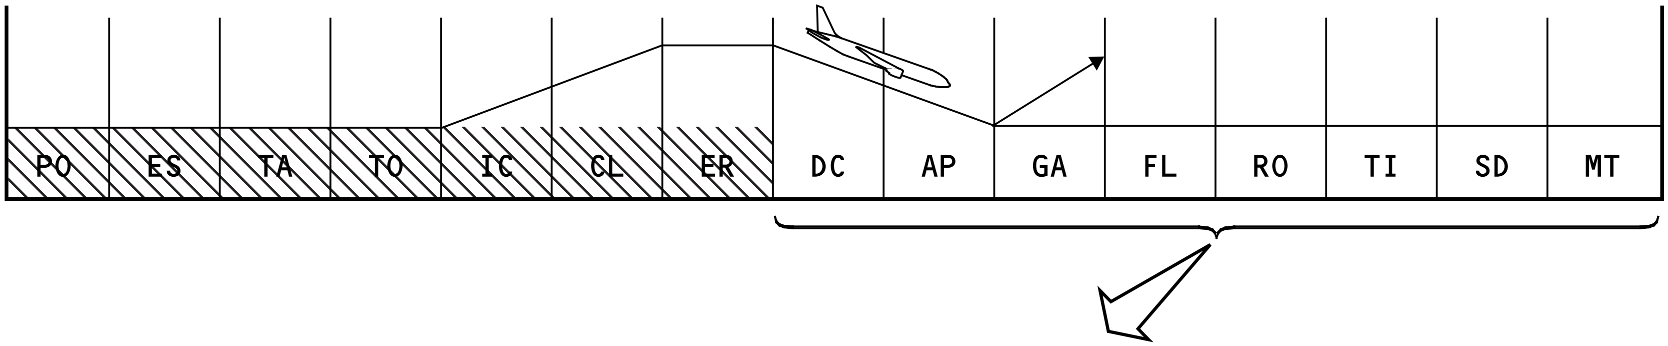
Maintenance (MT) Flight Phase

There are two conditions that cause the CMCF to change to MT.

For the first condition, the CMCF changes to MT when both of these are true:

- Aircraft vibration monitoring (AVM) onboard engine balancing system (OEBS) on the MAT is in test
- The airplane is on the ground.

For the second condition, the CMCF changes to MT when the maintenance phase is selected on the maintenance enable/disable dialog box on the MAT.



FLIGHT PHASE	CONDITION
DC (DESCENT)	FMCF FLIGHT PHASE CHANGES TO DESCENT OR FMCF FLIGHT PHASE DATA NOT AVAILABLE AND AIRPLANE IN AIR AND AIRPLANE DESCENDS AT MORE THAN 400 FEET/MINUTE
AP (APPROACH)	AIRPLANE IN AIR AND FLAPS SET FOR LANDING AND LANDING GEAR DOWN
GA (GO AROUND)	AIRPLANE IN AIR AND TOGA SWITCH IS ENABLED OR AIRPLANE IN AIR AND FLAPS SET FOR LANDING AND TRA SET TO TAKEOFF
FL (FLARE)	AIRPLANE IN AIR AND FLAPS SET FOR LANDING AND RADIO ALTITUDE < 50 FT
RO (ROLLOUT)	AIRPLANE ON GROUND AND GROUND SPEED > 80 KNOTS
TI (TAXI IN)	AIRPLANE ON GROUND AND AT LEAST ONE ENGINE RUNNING AND GROUND SPEED < 80 KNOTS AND FLIGHT LEG TRANSITION ENABLED
SD (SHUTDOWN)	AIRPLANE ON GROUND AND THE STARTER AIR VALVE CLOSED AND EITHER FUEL SWITCH CHANGES FROM RUN TO CUTOFF/EEC ACTIVE
MT (MAINTENANCE)	AVM OEBS SELECTED ON MAT AND AIRPLANE ON GROUND OR MAINTENANCE ENABLE MODE IS SELECTED ON MAT

45-10-00-024 Rev 4 10/29/1997

CMCS - FLIGHT PHASES - 2

CMCS - CMCF CORRELATION

General

The central maintenance computing function (CMCF) in the AIMS cabinets monitors systems for failures and reports these failures as maintenance messages.

The primary display function (PDF) in the AIMS cabinets also monitors systems for faults that show on these displays:

- PFD
- ND
- EICAS
- MFD.

These faults show as failure flags, messages, or non-normal displays. The PDF groups these indications and calls them flight deck effects (FDEs). The flight crews report these FDEs as log book entries. The PDF sends the FDEs to the CMCF.

The CMCF correlates or associates these maintenance messages with an FDE and makes displays that show on the MAT.

Correlated maintenance messages also relate to and cause maintenance memos.

The CMCF also generates non-correlated maintenance messages. These messages do not relate to an FDE but provide useful maintenance data.

Correlated Maintenance Messages

Correlated maintenance messages are those messages that are directly linked to a FDE or a maintenance memo (MO). These are the requirements to correlate a message to an FDE:

- They must both be active or latched at the same time
- The FDE and maintenance message must match on a CMCS correlation list.

Flight Deck Effects

These are the nine categories of flight deck effects:

- EICAS warning messages
- EICAS caution messages
- EICAS advisory messages
- EICAS status messages
- PFD flags
- ND flags
- EICAS snapshots
- Displays (exceedances, etc.)
- Scheduled maintenance tasks.

The primary display function (PDF) sends the flight deck effects to the CMCF. The CMCF then correlates the FDE to a maintenance message.

CMCS - CMCF CORRELATION

Scheduled Maintenance Tasks

Scheduled maintenance task messages relate to certification maintenance requirement items (CMR) or maintenance review board (MRB) items with time exposure limits.

These messages relate to those that show on the maintenance task maintenance page on the MFD.

These messages are available in the maintenance planning function as:

- Inbound scheduled maintenance tasks (from maintenance planning menu)
- Existing scheduled maintenance tasks (from maintenance planning menu).

One or more correlated maintenance messages cause a scheduled maintenance task. There is no requirement to check these messages prior to flight.

Maintenance Memos

Maintenance memos (MO) are a special category of CMCS messages. The purpose of these messages is to report failures in fault tolerant parts of systems. If another failure in that system occurs, it may affect function of the system. They let maintenance organizations plan appropriate actions before a system or component becomes not airworthy.

These messages are available in the maintenance planning function as:

- Inbound maintenance memos (from maintenance planning menu)
- Existing maintenance memos (from maintenance planning menu).

One or more correlated maintenance messages cause a maintenance memo. There is no requirement to check these messages prior to flight.

Maintenance Message Storage

The CMCF stores maintenance messages differently for the different flight phases. This is called flight phase screening. If the maintenance message occurred during a storable flight phase, it is kept in static random access memory (SRAM). The maintenance messages may show on one of these:

- Inbound flight deck effects
- Present leg faults
- Fault history
- Inbound scheduled maintenance tasks (from maintenance planning menu)
- Inbound maintenance memos (from maintenance planning menu).

Maintenance messages that do not occur during a storable flight phase are also kept in SRAM. But, these messages are erased when they become not active or unlatched. They show on these:

CMCS - CMCF CORRELATION

- Existing flight deck effects
- Existing faults
- Existing scheduled maintenance tasks (from maintenance planning menu)
- Existing maintenance memos (from maintenance planning menu).

Training Information Point

More than one maintenance message may correlate to an FDE or MO. Find the corrective action for the maintenance message nearest in time to the FDE or MO. If the display does not show the time of the maintenance message, find the corrective action for the maintenance message that shows first below the FDE or MO.

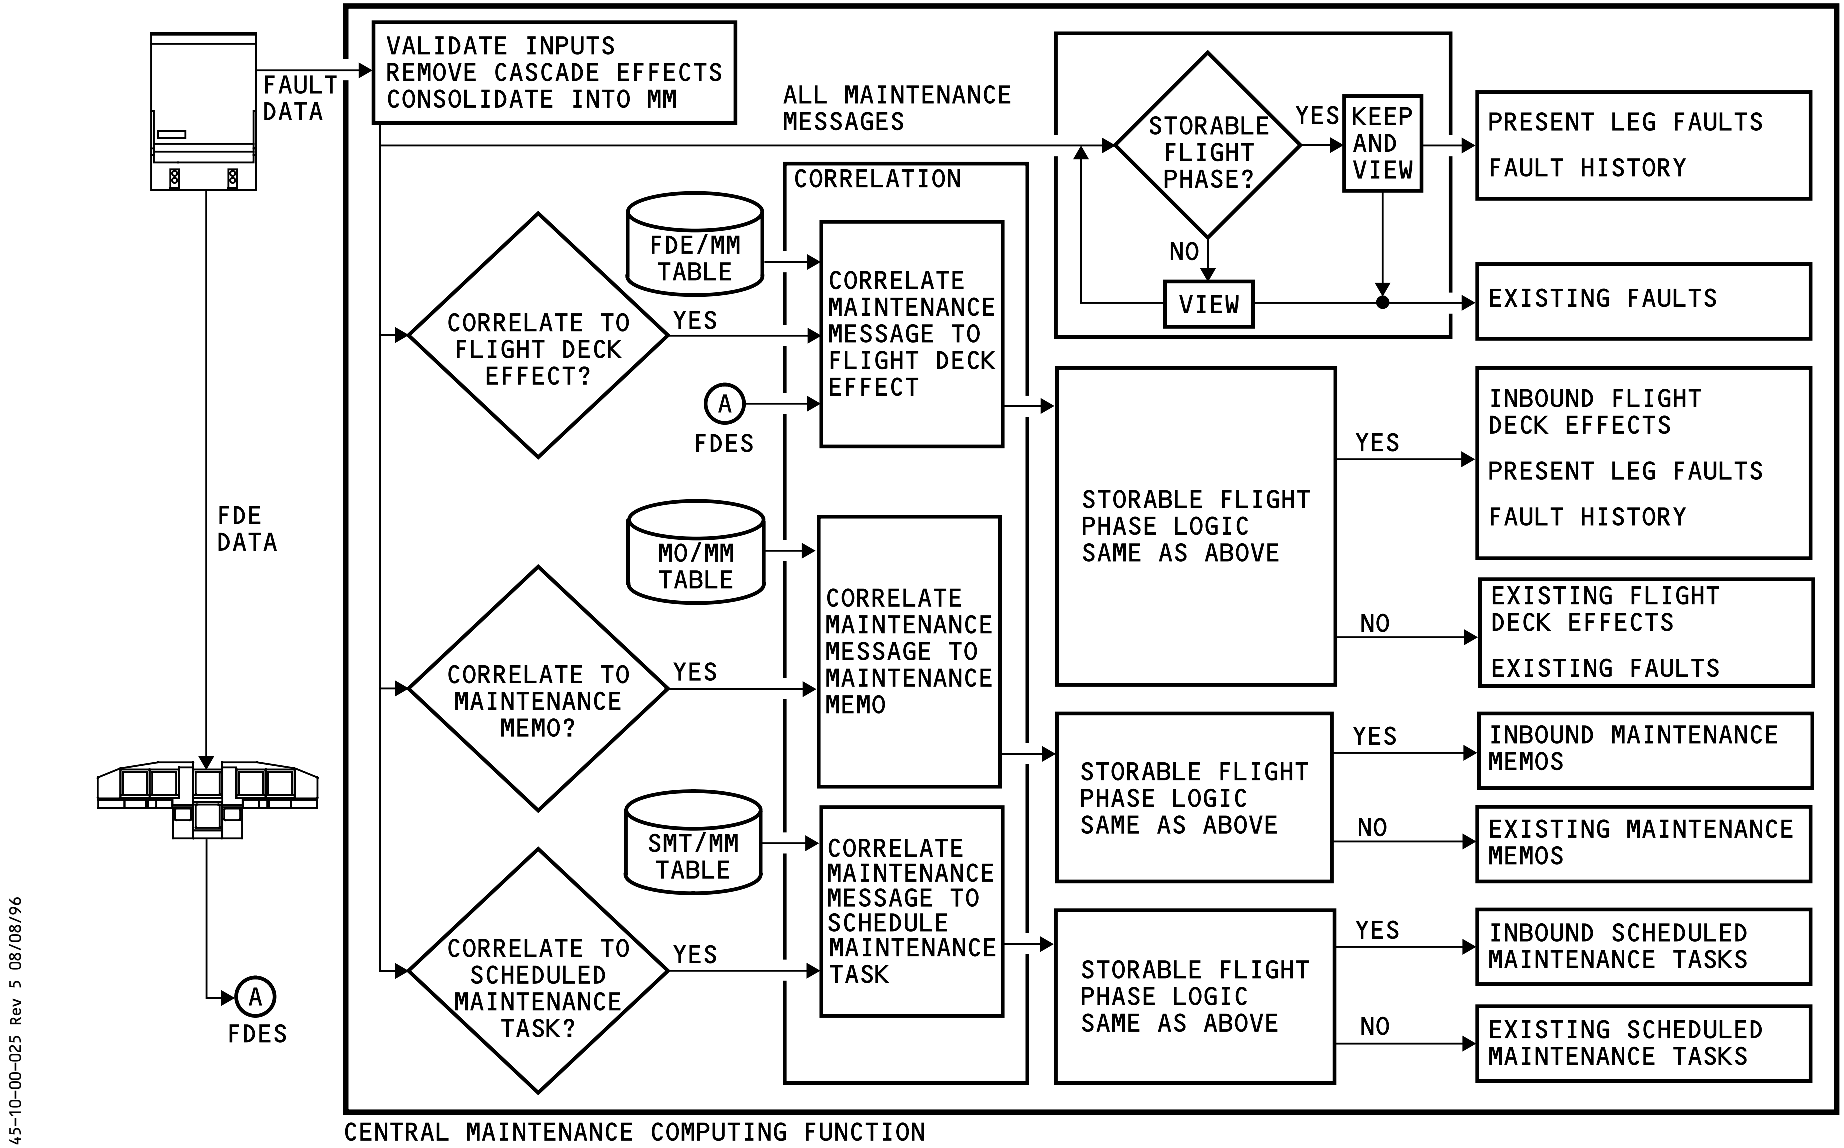
The CPM/COMM SRAM is kept by the hot battery bus. Use the move fault history function from the fault history summary display to move the fault history to diskettes if you are going to disconnect the hot battery bus.

Non-Correlated Maintenance Messages

Non-correlated maintenance messages are those messages that do not relate to a FDE but provide useful diagnostic information. The MAT reports these messages as non-FDE messages.

These messages show in these areas:

- Present leg faults
- Existing faults
- Fault history.



CMCS - CMCF CORRELATION

THIS PAGE INTENTIONALLY LEFT BLANK

CMCS - CMCF FLIGHT PHASE SCREENING

General

The CMCF uses the flight phase to make a decision about where to store maintenance messages and where to show them on the MAT. This is called flight phase screening.

Flight phase screening prevents the CMCF from storing nuisance or false maintenance messages. Every maintenance message is storable during some flight phases.

Maintenance Message Correlation

The CMCF receives active or latched fault data and changes it to a maintenance message. The CMCF may correlate a maintenance message to one or more of these flight deck effects (FDEs):

- EICAS warning message
- EICAS caution message
- EICAS advisory message
- EICAS status message
- PFD Flag
- ND FLag
- EICAS auto snapshot
- Display (exceedance, etc.)
- Scheduled maintenance task (SMT).

The CMCF may also correlate a maintenance message to a maintenance memo (MO).

Storable Flight Phase Logic

The CMCF stores the active or latched maintenance message and correlation in temporary memory. The CMCF calculates the flight phase. If the maintenance message is active or latched during a storable flight phase, the CMCF also stores the maintenance message and correlation in fault history memory.

Maintenance Message Display - Temporary Memory

The CMCF will always show an active or latched maintenance message on the MAT. This chart shows which MAT displays show the maintenance message when it is active or latched and stored in temporary memory:

Maintenance message is active or latched and correlates to:	Shows on display(s):
None	Existing Faults
FDE	Existing Flight Deck Effects
	Existing Faults
Maintenance Memo (MO)	Existing Maintenance Memos
	Existing Faults
Scheduled Maintenance Task (SMT)	Existing Scheduled Maintenance Tasks
	Existing Faults

If a maintenance message becomes not active, the CMCF removes the maintenance message and correlation from temporary memory. It no longer shows on the above displays.

Maintenance Message Display - Fault History Memory

If the maintenance message is active or latched during a storable flight phase, the maintenance message and correlation is also in fault history memory. The maintenance message and correlation shows on the above displays when it is active or latched. This chart shows which other MAT displays show the maintenance message when it is stored in fault history memory:

Maintenance message is active or latched during a storable flight phase and correlates to:	Shows on display(s):
None	Present Leg Faults
	Fault History
FDE	Inbound Flight Deck Effects
	Fault History
Maintenance Memo	Inbound Maintenance Memos
	Present Leg Faults
	Fault History
Scheduled Maintenance Task	Inbound Scheduled Maintenance Tasks
	Present Leg Faults
	Fault History

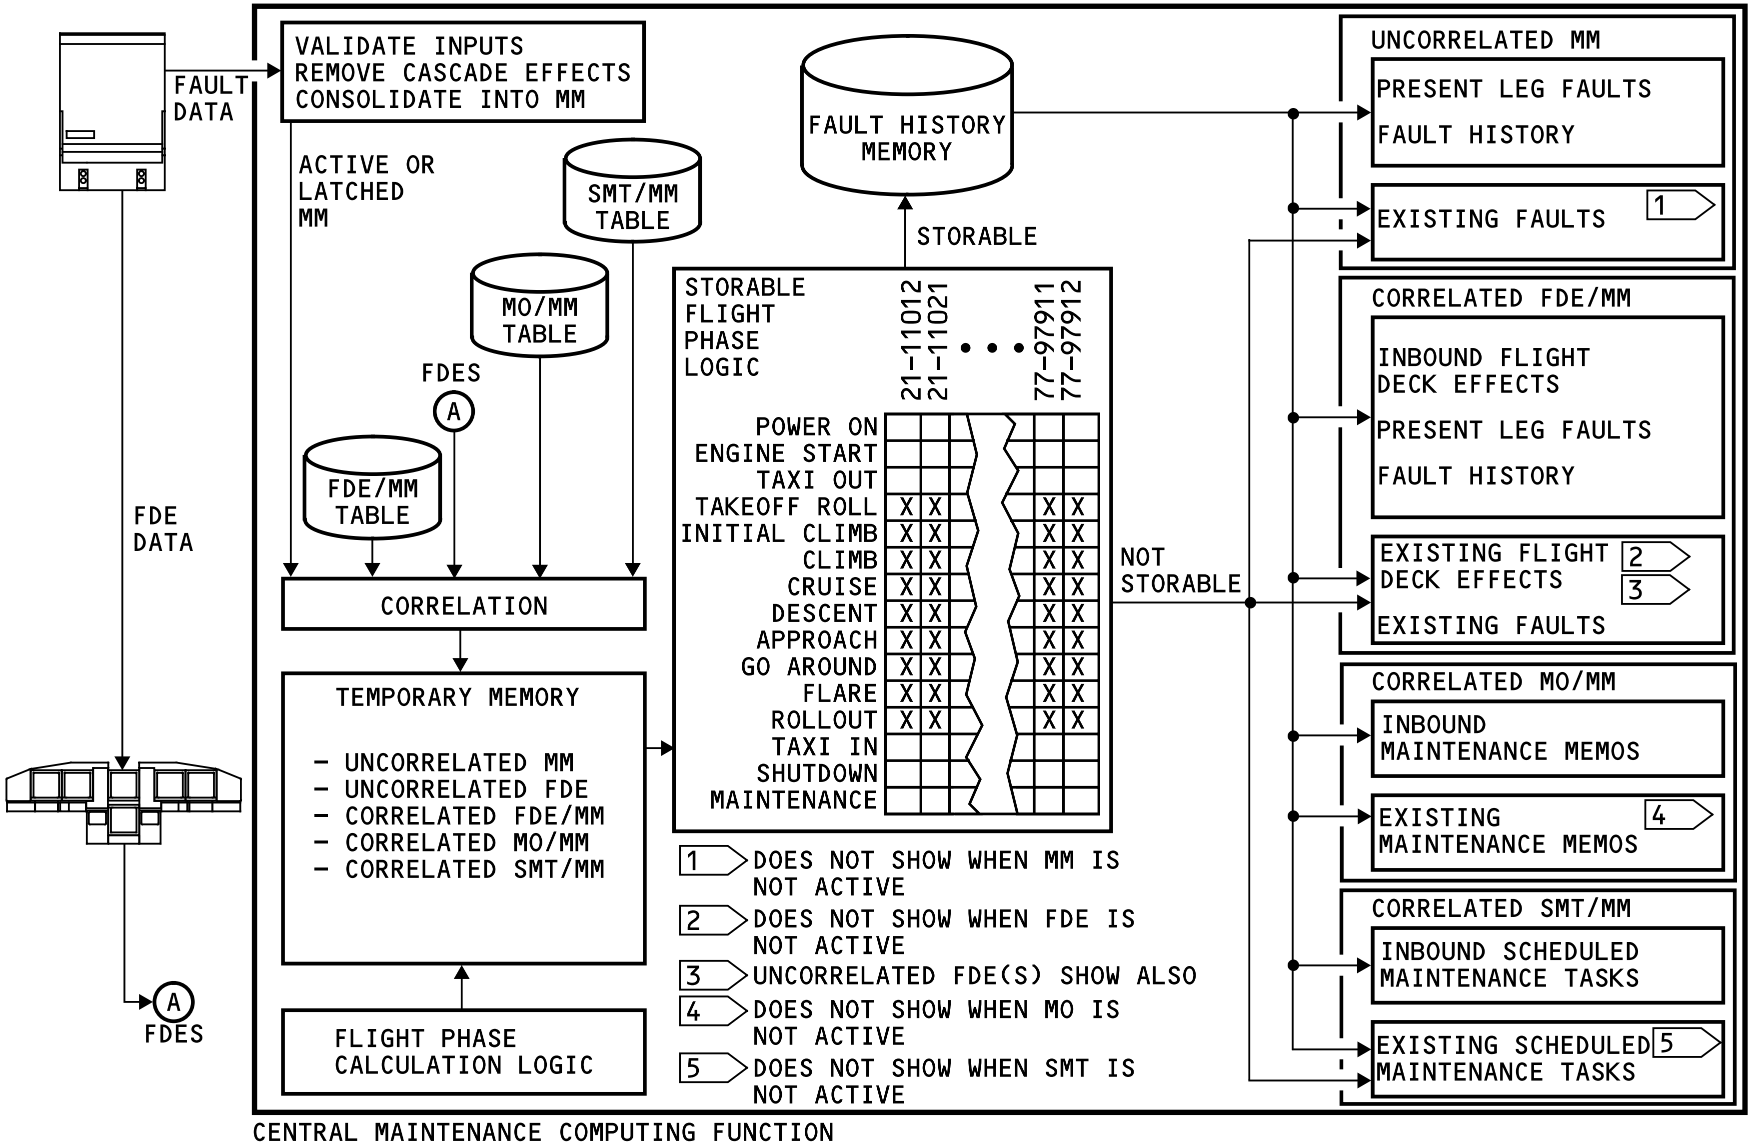
If a maintenance message becomes not active, the CMCF keeps the maintenance message and correlation in fault history memory. It changes the maintenance message activity to not active.

Training Information Point

Some FDEs with no correlated maintenance messages show on the existing flight deck effects display. Normal conditions on the ground, such as engine shutdown, usually cause these FDEs.

Latched EICAS status messages stay on the inbound and existing flight deck effects display after the correlated maintenance message becomes not active. When you erase the status message from the maintenance task maintenance page:

- The CMCF changes the status message activity to not active on the inbound flight deck effects display.
- The CMCF removes the status message from the existing flight deck effects display.



CMCS - CMCF FLIGHT PHASE SCREENING

CMCS - FAULT DISPLAY SUMMARY

General

You can see flight deck effects (FDEs) and maintenance message (fault) data on many different CMCS displays.

You use the different displays for different work on the airplane. You use the fault isolation manual (FIM) to find the cause of maintenance messages.

These displays show FDEs and their correlated maintenance messages:

- Inbound flight deck effects
- Existing flight deck effects.

These displays show maintenance messages and their correlated FDEs:

- Present leg faults
- Existing faults
- Fault history.

These displays show maintenance memos (MOs) and their correlated maintenance messages:

- Inbound maintenance memos
- Existing maintenance memos.

These displays show scheduled maintenance tasks (SMTs) and their correlated maintenance messages:

- Inbound scheduled maintenance tasks
- Existing scheduled maintenance tasks.

Ground test displays show maintenance messages when a ground test fails.

Inbound Flight Deck Effects Display

The inbound flight deck effects display shows the flight deck effects and correlated maintenance messages from the last flight. Flight phase screening occurs, so maintenance messages must have been active or latched during a storable flight phase to show on this display. The CMCF shows the FDEs by time. The most recent FDE shows first.

Existing Flight Deck Effects Display

The existing flight deck effects display shows all active and latched flight deck effects. There is no flight phase screening. Flight deck effects that show because of airplane system problems have correlated maintenance messages. Some EICAS messages which are not failure related or which show a pilot selected condition do not have correlated maintenance messages. Many EICAS messages which are not failure related show when the airplane is parked on the ground. These are examples of EICAS messages which are not failure related:

- FUEL PUMP R AFT
- HYD PRESS SYS C
- ENG SHUTDOWN
- ICING WING.

CMCS - FAULT DISPLAY SUMMARY

These are examples of EICAS messages which show a pilot selected condition:

- PARKING BRAKE SET
- APU RUNNING
- AUTOBRAKE 3.

The CMCF shows the FDEs by time. The most recent FDE shows first.

Present Leg Faults Display

The present leg faults display shows the maintenance messages from the last flight. Flight phase screening occurs so maintenance messages must have been active or latched during a storable flight phase to show on this display. Maintenance messages with correlated flight deck effects show on the display. Maintenance messages which are not correlated to flight deck effects show in a separate group on the display. These are for airplane system problems which are not critical. These are called non-correlated maintenance messages.

The CMCF shows the maintenance messages and correlated FDEs by time. The maintenance message with the most recent FDE shows first. The group of non-correlated maintenance messages shows last. In this group, the most recent non-correlated maintenance message shows first. You can also select the maintenance messages by ATA chapter.

Existing Faults Display

The existing faults display shows active and latched maintenance messages. There is no flight phase screening. You select the maintenance messages by ATA chapter. You can also show the maintenance messages and FDEs by time. The maintenance message with the most recent FDE shows first. The group of non-correlated maintenance messages shows last. In this group, the most recent non-correlated maintenance message shows first.

Fault History Display

The fault history display shows the maintenance messages from the last 100 flight legs. Flight phase screening occurs so maintenance messages must have been active or latched during a storable flight phase to show on this display. You select the maintenance messages by ATA chapter. You can also show the maintenance messages and FDEs by flight leg. The maintenance message with the most recent FDE of the flight leg shows first. The group of non-correlated maintenance messages shows last. In this group, the most recent non-correlated maintenance message shows first.

Inbound Maintenance Memos Display

The inbound maintenance memo display shows the maintenance memos and correlated maintenance messages from the last flight. Maintenance memos and their correlated maintenance messages give data about the condition of redundant LRUs and systems. Flight phase screening occurs so maintenance messages must have been active or latched during a storable flight phase to show on this display. The CMCF shows the maintenance memos by time. The most recent maintenance memo shows first.

Existing Maintenance Memos Display

The existing maintenance memos display shows all active and latched maintenance memos. There is no flight phase screening. Maintenance memos and their correlated maintenance messages give data about the conditions of redundant LRUs and systems. The CMCF shows the maintenance memos by time. The most recent maintenance memo shows first.

Inbound Scheduled Maintenance Tasks Display

The inbound scheduled maintenance tasks display shows the scheduled maintenance tasks and correlated maintenance messages from the last flight. Scheduled maintenance tasks and their correlated maintenance messages relate to certification maintenance requirement (CMR) items or maintenance review board (MRB) items. These items have time exposure limits. Flight phase screening occurs so maintenance messages must have been active or latched during a storable flight phase to show on this display. Some inbound scheduled maintenance tasks which are not failure related do not have correlated maintenance messages. The CMCF shows the scheduled maintenance tasks by time. The most recent scheduled maintenance task shows first.

Existing Scheduled Maintenance Tasks Display

The existing scheduled maintenance tasks display shows all active scheduled maintenance tasks. There are no latched scheduled maintenance tasks. There is no flight phase screening. Scheduled maintenance tasks and their correlated maintenance messages relate to certification maintenance requirement (CMR) items or maintenance review board (MRB) items with time exposure limits. Some existing scheduled maintenance tasks which are not failure related do not have correlated maintenance messages. The CMCF sorts the scheduled maintenance tasks by time. The most recent scheduled maintenance task shows first.

Ground Tests Display

Maintenance messages that cause a ground test to fail show on the ground test tests display. The CMCF shows the maintenance messages by ATA chapter.

CMCS - FAULT DISPLAY SUMMARY

CMCS - MAT MAIN MENU DISPLAY

Initial Power-Up

At initial power-up of the airplane, the maintenance access terminal (MAT) shows a MAT main menu display. The MAT main menu display supplies access to these functions:

- Central maintenance computing system (CMCS)
- Airplane conditioning monitoring system (ACMS)
- MAT status
- Self load.

Software Requirements

The operational software for the MAT supplies the displays on the MAT display module. It is in the memory of the MAT display module. This software is called the maintenance terminal function (MTF). Select SELF LOAD from the MAT main menu display to load the MTF.

The operational software for the central maintenance computing function (CMCF) is in memory in the AIMS cabinets.

Screen Saver

The MAT has a screen saver. If you do not use the MAT for 30 minutes, the MAT display becomes dim. Use one of these controls to make the MAT display bright again:

- MAT cursor control device
- MAT keyboard
- MAT brightness control.

The master brightness control does not make the MAT display bright again.

Buttons

Select ONBOARD MAINTENANCE to send a request for CMCS information from the CMCF in the AIMS cabinets. The CMCF sends the data to the MAT and the CMCF main menu shows.

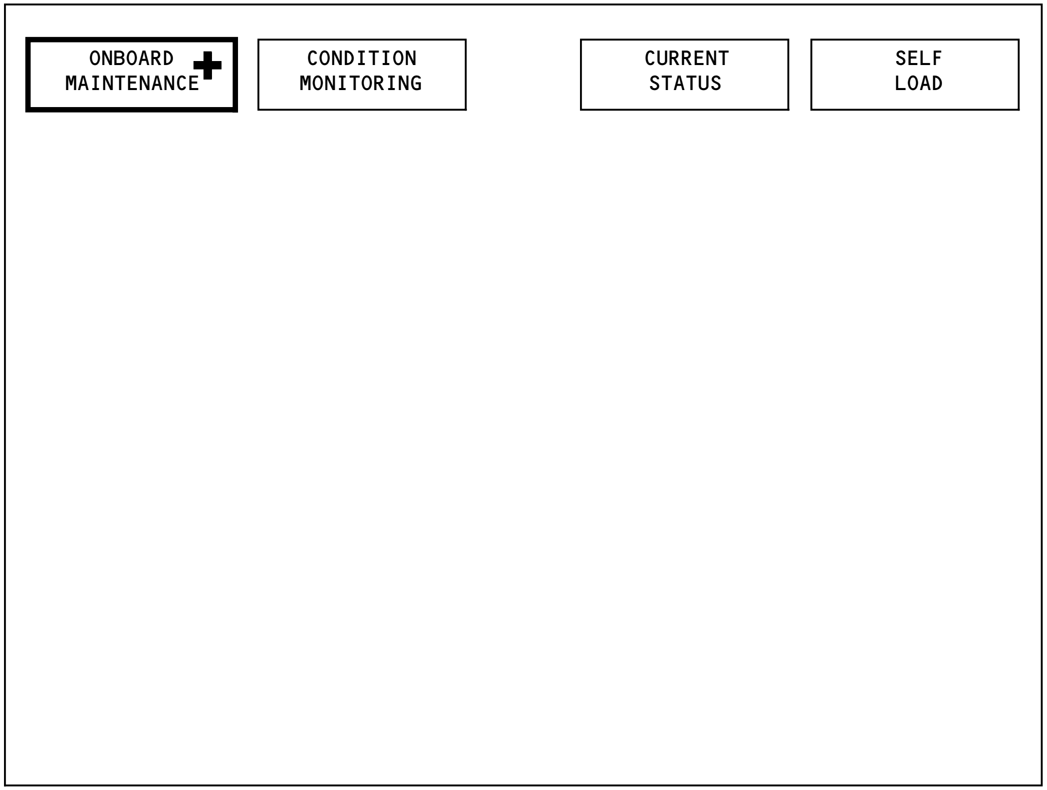
Select CONDITION MONITORING to send a request for ACMS data from the airplane condition monitoring function (ACMF) in the left AIMS cabinet. The ACMF sends the data to the MAT and the ACMF main menu shows.

Select CURRENT STATUS to see the condition of the MAT. A dialog box shows any hardware or software failures.

Select SELF LOAD to load the MTF into the MAT. Use the MAT disk drive or MAT hard drive as the source of the software.

Training Information Point

As many as three technicians can use the CMCS at the same time. Only one technician can use the ACMS at a time. You can also use a portable maintenance access terminal (PMAT) to use the CMCS and ACMS.



45-10-00-026 Rev 6 11/06/1997

CMCS - MAT MAIN MENU DISPLAY

THIS PAGE INTENTIONALLY LEFT BLANK

CMCS - MAIN MENU SELECTIONS

General

The CMCF menus supply access to functions that are task oriented. The menus also supply access to functions based on when and how often technicians do certain tasks. As many as three technicians can use the CMCS at the same time.

Main Menu Bar

Select ONBOARD MAINTENANCE from the MAT main menu display to cause the CMCS main menu bar to show at the top of the MAT display. ONBOARD MAINTENANCE and the CMCF in control shows in the center of the MAT. All the menu items are available for selection except when a dialog box shows on the display.

You can use the CMCS from three maintenance access terminals at the same time. These are the maintenance access terminals:

- the maintenance access terminal in the flight compartment
- the portable maintenance access terminal (PMAT) in the main equipment center
- a PMAT at one of the PMAT receptacles.

These are the main menu selections:

- LINE MAINTENANCE
- EXTENDED MAINTENANCE
- OTHER FUNCTIONS
- HELP
- REPORT.

LINE MAINTENANCE Selection

Select LINE MAINTENANCE to get access to maintenance functions generally done during quick turnarounds at the gate.

Select LINE MAINTENANCE to cause another menu to show. These are the selections available on this menu:

- INBOUND FLIGHT DECK EFFECTS
- EXISTING FLIGHT DECK EFFECTS
- GROUND TESTS
- SYSTEM CONFIGURATION
- EXIT MAINTENANCE.

INBOUND FLIGHT DECK EFFECTS gives a summary of the faults correlated to flight deck effects (FDEs) for the present flight leg (0). The CMCF shows the FDEs in the reverse order of occurrence.

EXISTING FLIGHT DECK EFFECTS shows all currently active and latched FDEs. The CMCF shows the FDEs in the reverse order of when the FDEs occurred.

GROUND TESTS supplies access to:

- System tests
- Operational tests
- LRU replacement tests.

CMCS - MAIN MENU SELECTIONS

SYSTEM CONFIGURATION gives access to configuration data for system LRUs. This data includes hardware and software part numbers.

EXIT MAINTENANCE ends the CMCF session on the MAT and shows the MAT main menu display.

EXTENDED MAINTENANCE Selection

The EXTENDED MAINTENANCE selection supplies access to functions performed when more time is needed such as during overnight maintenance.

Select EXTENDED MAINTENANCE to cause another menu to show. These are the selections available on this menu:

- PRESENT LEG FAULTS
- EXISTING FAULTS
- FAULT HISTORY
- DATA LOAD
- HARD DRIVE SOFTWARE PART NUMBER MANAGEMENT
- MAINTENANCE PLANNING
- MAINTENANCE ENABLE/DISABLE
- EXIT MAINTENANCE.

PRESENT LEG FAULTS shows maintenance messages for the current flight leg. These maintenance messages are grouped by FDE and the most recent maintenance messages shows first. Non-correlated maintenance messages show at the end of the FDEs. The present leg faults display also shows the faults by ATA chapter number and ATA name.

EXISTING FAULTS show maintenance messages for each ATA chapter that has active and latched faults in memory. The user can also group the faults by FDE.

FAULT HISTORY supplies access to faults by ATA chapter or by flight leg. Also, you can use FAULT HISTORY to erase single faults, all faults for an ATA or all faults from the fault history database.

Use DATA LOAD to load LRU software. Menu selections permit the selection of the source of the software and the destination LRU.

HARD DRIVE SOFTWARE PART NUMBER MANAGEMENT lets you change, examine, and do a check of LRU software on the maintenance access terminal hard drive.

MAINTENANCE PLANNING supplies access to inbound maintenance memos, existing maintenance memos, inbound scheduled maintenance tasks (SMT), and existing scheduled maintenance task messages.

MAINTENANCE ENABLE/DISABLE permits the selections to enable or to disable the flight leg or the maintenance phase.

EXIT MAINTENANCE ends the CMCF session on the MAT and shows the MAT main menu display.

OTHER FUNCTIONS Selection

The OTHER FUNCTIONS selection supplies access to more complex maintenance functions. Special training is necessary to do these complex functions.

Select OTHER FUNCTIONS to cause another menu to show. These are the selections available on this menu:

- INPUT MONITORING
- CENTRAL MAINTENANCE OPTIONS
- ENGINE BALANCING
- SHOP FAULTS
- PSEU AND AIR/GROUND RIGGING
- CENTRAL MAINTENANCE COMPUTER SWITCH CONTROL
- SPECIAL FUNCTIONS
- EXIT MAINTENANCE.

INPUT MONITORING lets you analyze specific interface signals. The types of signals available for analysis include analog discretes, analog variables, ARINC 429 words and ARINC 629 words.

CENTRAL MAINTENANCE OPTIONS supplies access to user interface controlled options. The central maintenance options display permits the selections to activate or to deactivate up to fifty CMCF options.

ENGINE BALANCING supplies access to the onboard engine balancing system (OEBS) menus. Use the OEBS menus to do in-depth engine maintenance and to show engine data stored in memory.

Use SHOP FAULTS to show internal LRU faults. Data is available by ATA and by LRU.

Use PSEU AND AIR/GROUND RIGGING to rig and to calibrate sensors for the PSEU and air/ground functions.

Use CENTRAL MAINTENANCE COMPUTER SWITCH CONTROL to set the control source of CMCF data.

SPECIAL FUNCTIONS supplies access to unique functions within certain ATA chapters. Use special functions to set conditions that aid in specific maintenance tasks.

EXIT MAINTENANCE ends the CMCF session on the MAT and shows the MAT main menu display.

HELP Selection

The HELP selection supplies access to SCREEN HELP or GENERAL HELP. The help that is available is defined in the airline modifiable information (AMI) using the ground based software tool (GBST).

REPORT Selection

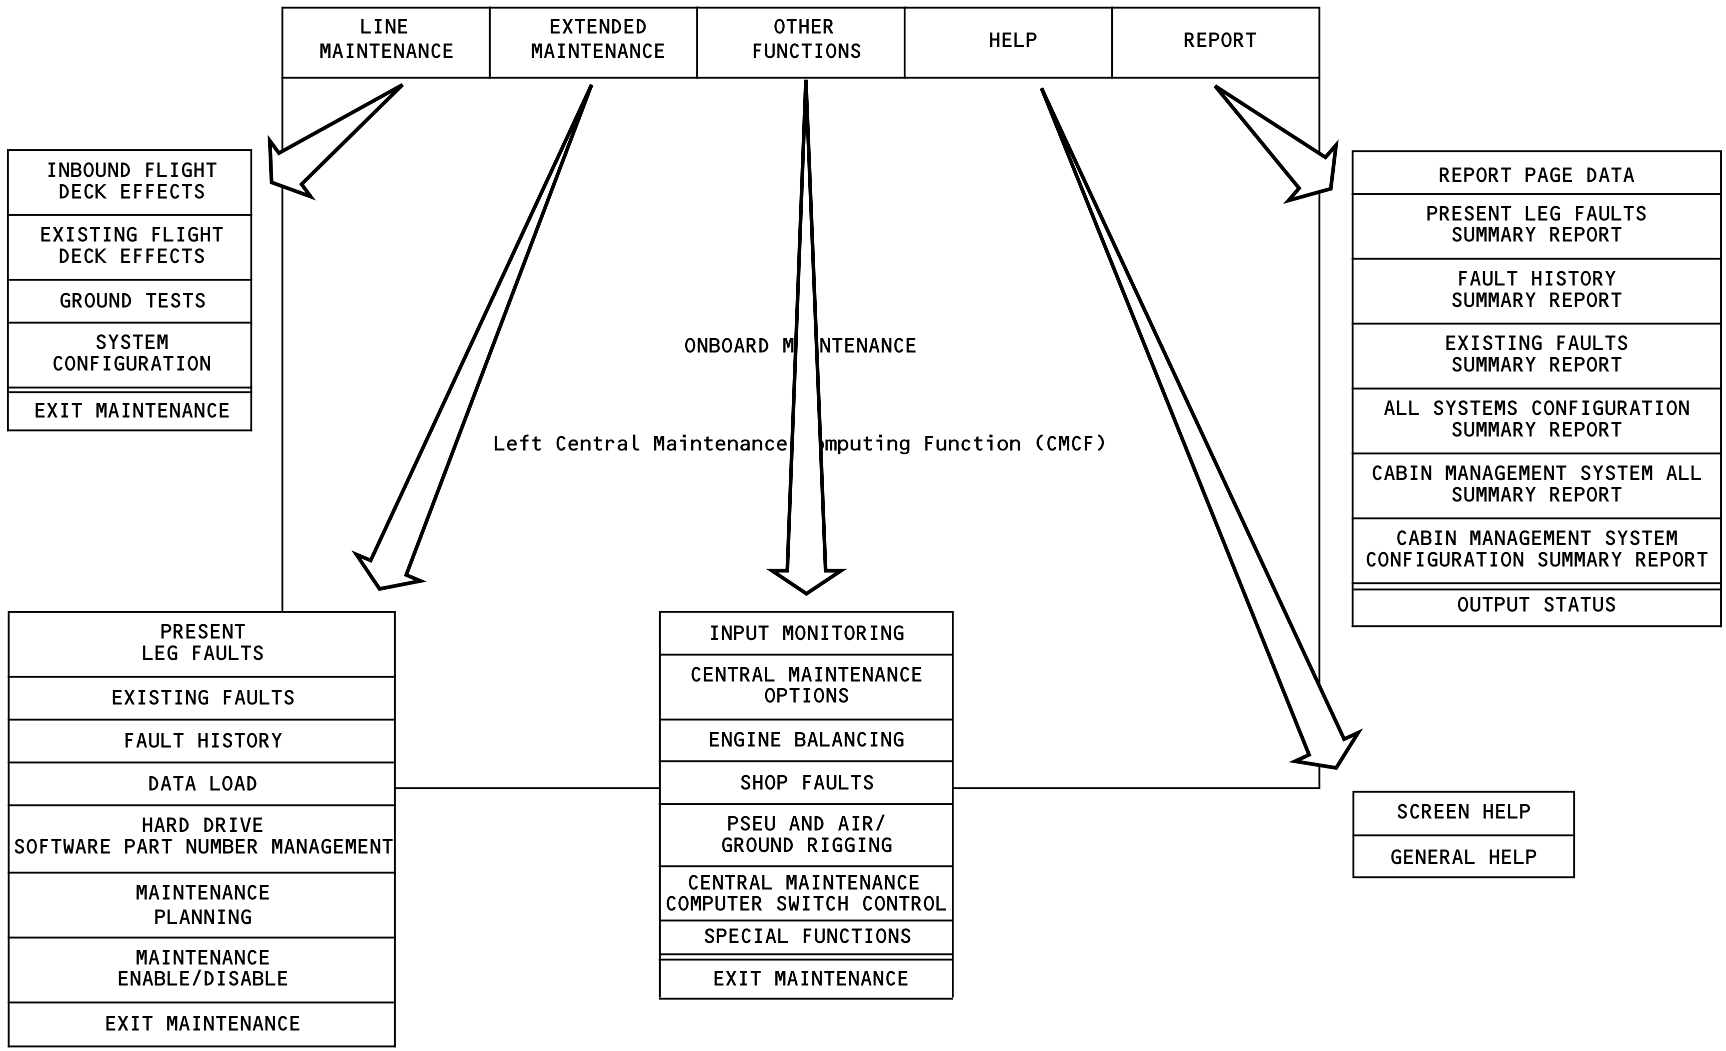
The REPORT selection lets the user send predefined reports to the printer, to the disk drive, or by datalink to a ground station.

These are the selections available on the REPORT menu:

- REPORT PAGE DATA
- PRESENT LEG FAULTS SUMMARY REPORT

CMCS - MAIN MENU SELECTIONS

- FAULT HISTORY SUMMARY REPORT
- EXISTING FAULTS SUMMARY REPORT
- ALL SYSTEMS CONFIGURATION SUMMARY REPORT
- CABIN MANAGEMENT SYSTEM ALL SUMMARY REPORT
- CABIN MANAGEMENT SYSTEM CONFIGURATION SUMMARY REPORT
- OUTPUT STATUS.



45-10-00-027 Rev 7 10/29/1997

CMCS - MAIN MENU SELECTIONS

THIS PAGE INTENTIONALLY LEFT BLANK

General

To do specific functions, several categories of controls show on the MAT. These categories are:

- MAT menu functions
- Cursor functions
- Dialog boxes
- Buttons
- Selection options
- Scroll bar.

Basic MAT Menu Functions

All the text on the displays is white. When the cursor is in an area, a white solid border highlights the area. Other colors, such as blue and green show on the MAT displays.

The main menu bar normally shows on the display at all times. In some cases, a dialog box can hide it. The selection of an item on the main menu bar causes a pull-down menu to show. This pull-down menu supplies additional selections within the main menu category.

The selection of an item on the pull-down menu causes a new display to appear. If the new display is a dialog box, the dialog box shows on top of the display. Portions of the original display remain visible but the data does not update.

Make main menu selections at any time except when dialog boxes show. Dialog box functions must be completed before access to the main menu returns.

When the dialog box goes away, the data on the original display continues to update.

Cursor Functions

The cursor on the display shows as one of three symbols. The symbols are:

- A plus (+) symbol for the normal cursor
- A wrist watch symbol for the wait cursor
- An I-beam symbol for the text entry cursor.

Cursor control device selections and keyboard selections have no effect when the wait cursor is active.

To highlight or make a selection, use the cursor control device. Place the cursor over any part of a message or command selection and select using any of the activation switches on top of the cursor control device. This highlights a message or chooses the command.

Dialog Boxes

There are several types of dialog boxes. In general, dialog boxes supply additional instructions or information about the current function. Dialog boxes show on top of the previous display.

The list box is a special type of dialog box. It is a list of scrollable items in a text box. Use the cursor control device to select an item. When you select an item, it highlights.

If a dialog box has only one possible choice, that choice is automatically made.

Command Buttons

Select a command button (button) to start a process or change a display or dialog box on the MAT. Most buttons are located at the bottom of displays and dialog boxes. A button dims when selection is not possible. Deactivated buttons do not highlight when the cursor goes over them.

Selection Options

Selection options show as a group of possible label selections. These selections are exclusive or non-exclusive.

Exclusive selections have a diamond symbol that comes before the selections.

Non-exclusive selections have a square symbol that comes before the selections.

When a selection is made, the square or diamond shows the selected state. You can select only one exclusive selection at a time. You can select none, one, or more than one non-exclusive selection at a time.

A crosshatch covers selections that are not active. Deactivated selections do not highlight as the cursor passes over them.

Scroll Bar

The scroll bar has a triangle that represents an arrow that points away from the center of the scroll bar.

The activation of the cursor over the triangle causes the visible area to move one increment in the direction of the arrow.

The slider is a variable length box that shows on the scroll bar. The position of the slider represents the position of the visible area in the entire data field. The length of the slider represents how much of the text is visible in the text box.

The slider moves along the scroll bar. The activation of the cursor in the scroll bar above the slider causes the visible area to move up one length of the visible area. The activation of the cursor in the scroll bar below the slider causes the visible area to move down one length of the visible area.

CMCS - GENERAL FEATURES AND CONTROLS

CMCS - NOTES AND HELP DIALOG BOXES

Notes Dialog Box

The notes dialog box is available for these functions:

- Maintenance messages
- Ground tests
- Configuration.

The central maintenance computing function (CMCF) airline modifiable information (AMI) must be loaded with the notes. If the CMCF AMI is not loaded in the CMCF, the notes selection does not show.

A scroll bar shows on the notes dialog box if there is more text than can fit in the visible area.

Notes Buttons

Select GO BACK to remove the dialog box and return to the previous page.

Select REPORT DATA to show the report dialog box.

Select HELP to show the help dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Help Dialog Box

The help dialog box is available from the main menu at the top of the MAT display or from HELP buttons on these dialog boxes or displays:

- Notes dialog box
- ATA chapter selection dialog box
- Ground test selection dialog box
- Test inhibit dialog box
- Test interference dialog box
- Precondition dialog box
- Configuration selection dialog box
- System configuration dialog box
- Existing faults dialog box
- Fault history erase dialog box
- Fault history erase confirmation dialog box
- Fault history ATA dialog box
- Fault history leg dialog box
- Move fault history dialog box
- Source selection dialog box
- Destination selection dialog box
- Load message dialog box
- Destination LRU not enabled dialog box
- Change diskette dialog box
- Wrong diskette in disk drive dialog box
- Diskette access error dialog box
- Load in progress activity indication dialog box
- Destination LRU incompatibility dialog box
- Data storage error dialog box
- Data transfer completion dialog box
- Data load completion and verification dialog box
- Are you sure dialog box
- Data load function not enabled dialog box
- Check disk dialog box
- Data load function already in use dialog box
- Hard drive main menu
- Cannot get disk drive connection
- Hard drive in air

- No hard drive
- Hard drive partially updated
- Hard drive unknown configuration

CMCS - NOTES AND HELP DIALOG BOXES

CMCS - ATA CHAPTER SELECTION DIALOG BOX

THIS PAGE INTENTIONALLY LEFT BLANK

CMCS - ATA CHAPTER SELECTION DIALOG BOX

General

The ATA CHAPTER selection dialog box permits the selection of an ATA system. Select the ATA system to show the maintenance message summary groups or system configuration information for that system.

The ATA chapter selection dialog box is available from these displays:

- Present leg faults
- Existing faults
- Fault history.

The ATA chapter selection dialog box also shows when you make these CMCS main menu selections:

- System configuration
- Existing faults
- Fault history.

The ATA chapter selection dialog box shows:

- Dialog box title
- List box
- Number of items
- Buttons.

Dialog Box Title

The dialog box title shows the main display title of the display that the SORT BY ATA command selection was made from.

List Box

The list box shows the ATA systems that have faults in memory when you select these displays:

- Present leg faults
- Existing faults
- Fault history.

The list box shows the ATA systems that can show hardware and software part numbers when you select system configuration.

Number of Items

The number of items that show in the list box shows at the top of the list box.

Buttons

Select an ATA system and then select CONTINUE to show fault information about that system.

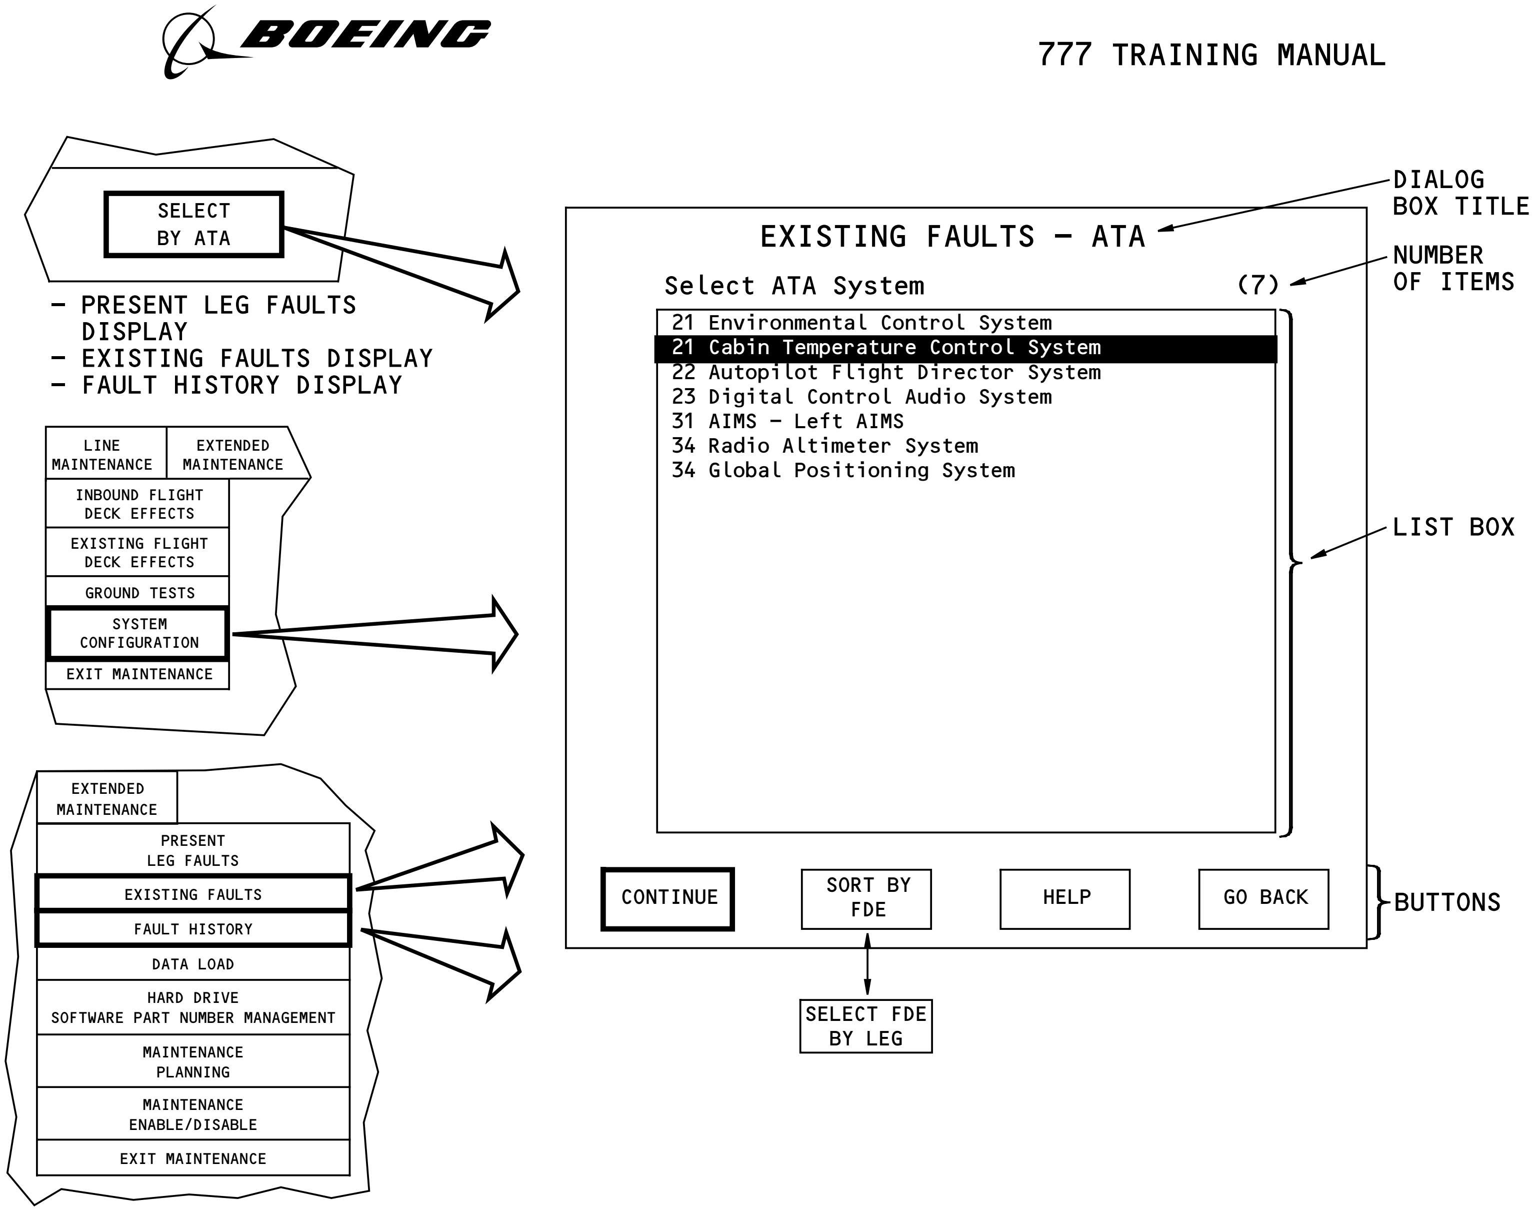
Select SORT BY FDE to show all selected faults by FDE summary groups and maintenance message summary groups. This button shows when you select present leg faults or existing faults.

Select SELECT FDE BY LEG to show all selected faults by FDE summary groups and maintenance message summary groups for one leg from fault history. This button shows when you select fault history.

CMCS - ATA CHAPTER SELECTION DIALOG BOX

Select HELP to show the HELP dialog box for the ATA CHAPTER selection dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to remove the ATA CHAPTER selection dialog box and return to the previous display.



45-10-00-030 Rev 5 10/29/1997

CMCS - ATA CHAPTER SELECTION DIALOG BOX

CMCS - INBOUND FLIGHT DECK EFFECTS DISPLAY

General

The purpose of inbound flight deck effects is to help the line maintenance technician repair the airplane during quick turnarounds at the gate.

Use inbound flight deck effects (FDEs) to look at FDEs and their correlated maintenance messages for the current flight leg (0).

The CMCF sorts the FDEs and any correlated maintenance messages by time. The most recent FDE shows first.

Use the maintenance message data button to show the single maintenance message display for a maintenance message summary group.

This shows on the inbound flight deck effects summary display:

- Header information
- Instructions field
- Fault summary field title
- Number of items
- Fault summary field
- Buttons.

Header Information

This data shows under the main menu bar on the right side:

- Tail identification
- Flight number from the FMCF
- Leg ID, departure airport and arrival airport identifiers from the FMCF
- Leg start time and date from the CMCF
- CMCF source field.

Fault Summary Field Title

The number of flight deck effects in the fault summary field shows at the top of the scroll bar.

The fault summary field has the FDE summary groups.

Each FDE summary group includes this data:

- Flight deck effect
- FDE and maintenance message activity
- Fault code
- FDE time and date
- Maintenance message summary groups.

FDE and Maintenance Message Activity

The activity of an FDE shows as one of these:

- Active
- Latched
- Not Active.

An active FDE is an FDE that currently shows in the flight deck.

A latched FDE can only be a status message or a scheduled maintenance task. Scheduled maintenance tasks are discussed elsewhere in this section.

A failure that causes a status message may impact dispatch and may be intermittent or detectable only under certain conditions. The PDS holds a status message to make sure that you see it on the ground. You must do a task to clear a latched FDE.

An FDE is not active if it can not currently show on the flight deck.

The activity of a maintenance message also shows as one of these:

- Active
- Latched
- Not Active.

A maintenance message is active if a system can continuously monitor for a fault condition, and the fault exists.

A maintenance message is latched for these reasons:

- If a system detects a fault and no longer uses the related equipment as part of its operational function
- To ensure correlation with an FDE
- If a system can not always detect if the fault exists.

You must do something to clear a latched maintenance message.

A maintenance message is not active if a system can continuously monitor for a fault condition, and the fault does not exist.

Maintenance Message Summary Groups

Each maintenance message summary group includes this data:

- Maintenance message number
- Maintenance message activity
- Flight phase
- Fault time and date
- Maintenance message symptom.

One or more maintenance messages may be correlated to each FDE and shows with an FDE summary group.

Button

Highlight and select a maintenance message summary group. Next, select MAINTENANCE MESSAGE DATA to show the single maintenance message display.

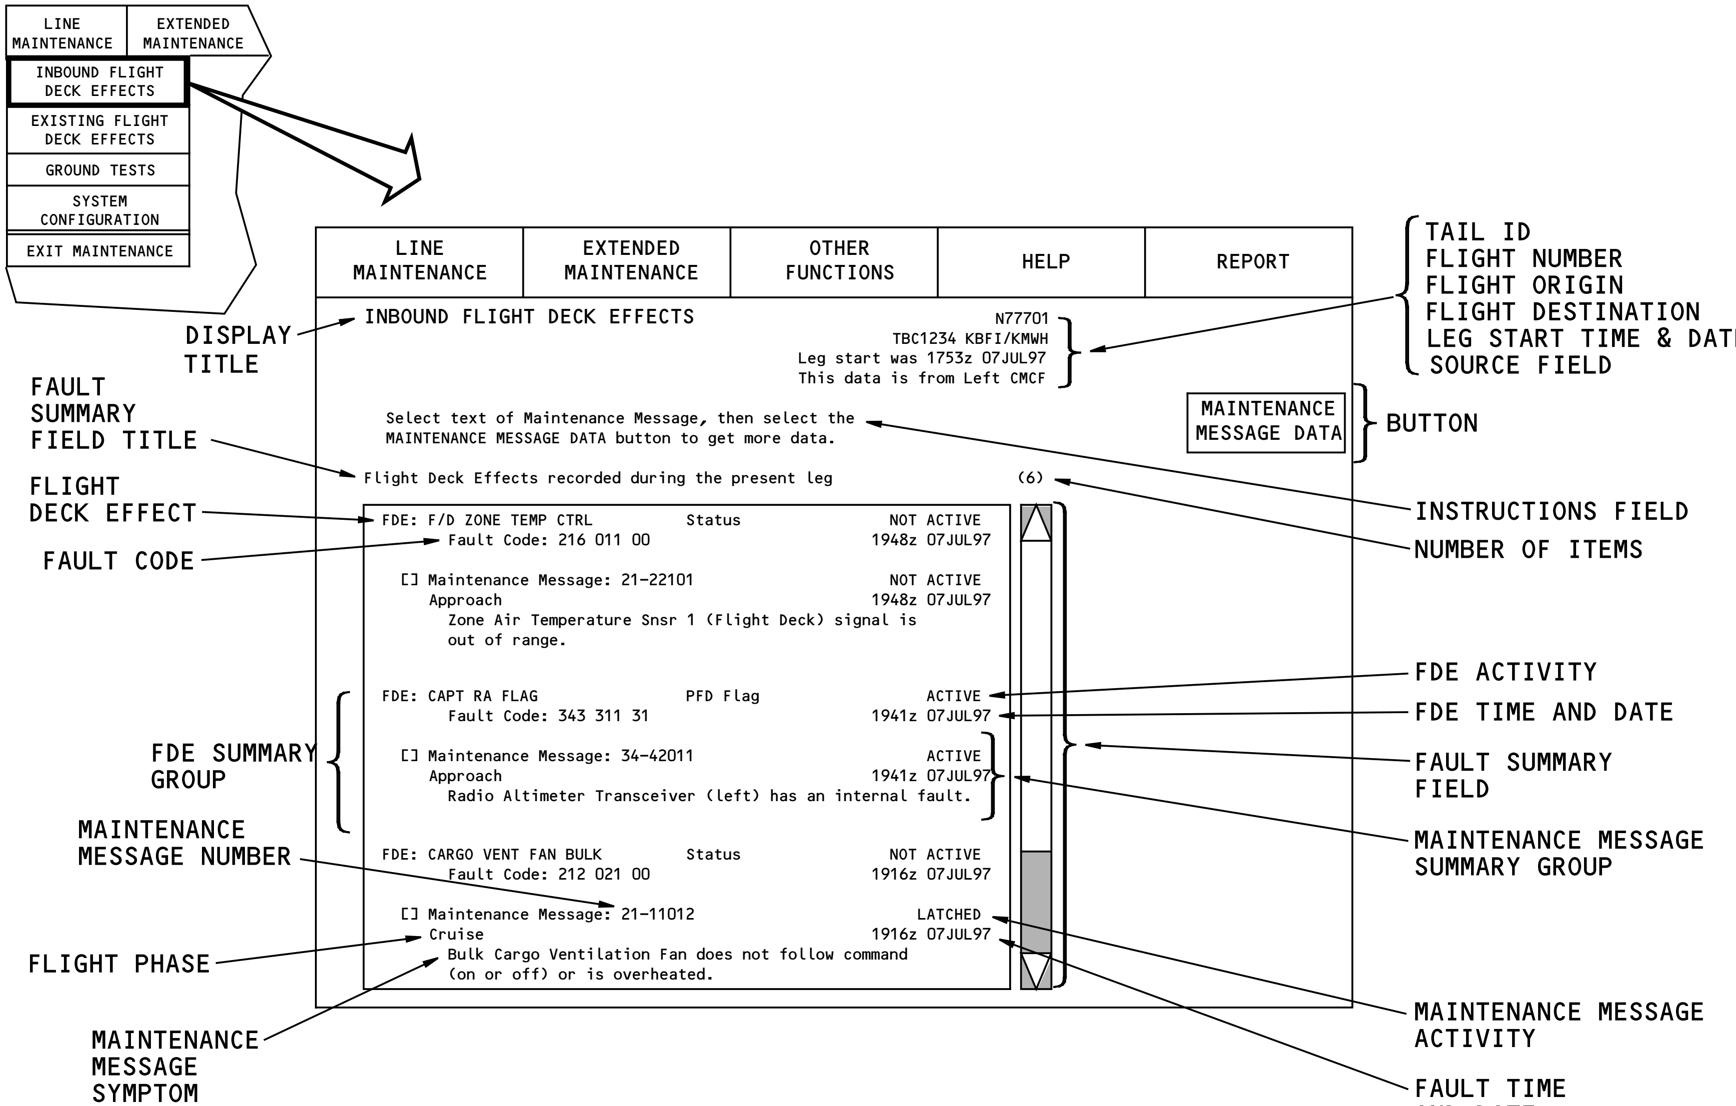
Training Information Point

If a flight leg transition occurs while the inbound flight deck effect display shows, this happens:

- If a fault summary field shows, it goes away

CMCS - INBOUND FLIGHT DECK EFFECTS DISPLAY

- A text dialog box shows with Flight Leg Has Changed. To See Data from Before, Go to Fault History Leg-1.
- Select CONTINUE on the text box to remove the text box and to show the Inbound Flight Deck Effects display again.



CMCS - INBOUND FLIGHT DECK EFFECTS DISPLAY

THIS PAGE INTENTIONALLY LEFT BLANK

CMCS - SINGLE MAINTENANCE MESSAGE DATA DISPLAY

General

The single maintenance message data display shows this data on one page:

- Title
- Fault information
- Maintenance message information
- Activity
- Occurrence field
- Leg information
- Recommended maintenance actions
- Correlated flight deck effects
- Buttons.

The single maintenance message data display is available from one of these displays:

- Inbound flight deck effects display
- Existing flight deck effects display
- Ground tests display
- Present leg faults display
- Existing faults display
- Fault history display
- Maintenance planning displays.

Within these displays, the single maintenance message data display supplies data for a maintenance message summary group from a one of these:

- FDE summary group
- Maintenance message summary group
- Non-FDE summary group.

Title

The title shows the original source of the message and previous display title of the page that showed the maintenance message.

Fault Information

The fault information field shows specific fault data and shows the source of the data.

Maintenance Message Information

The maintenance message number field contains the unique number associated with that specific maintenance message.

FDE, Maintenance Message, or Maintenance Memo Activity

The CMCF receives LRU fault information for display on the single maintenance message display that refers to these:

- FDEs
- Maintenance messages
- Maintenance memos.

The CMCF stores the information in the fault database.

The condition of an FDE shows as one of these:

- Active
- Latched

- Not Active.

An active FDE is an FDE that currently shows in the flight deck.

A latched FDE can only be a status message or a scheduled maintenance task. A failure that causes a status message may impact dispatch and may be intermittent or detectable only under certain conditions. The PDS holds a status message to make sure that you can see it on the ground.

An FDE is not active if it can not currently show on the flight deck

The activity of a maintenance message and maintenance memo also shows as one of these:

- Active
- Latched
- Not Active.

A maintenance message or maintenance memo is active if a system can continuously monitor for a fault condition, and the fault exists.

A maintenance message or maintenance memo is latched for one of these reasons:

- If a system detects a fault and no longer uses the related equipment as part of its operational function
- To ensure correlation with an FDE (maintenance message only)
- If a system can not always detect if the fault exists.

You must do something to clear a latched maintenance message.

A maintenance message or maintenance memo is not active if a system can continuously monitor for a fault condition, and the fault does not exist.

Occurrence Field

The occurrence field tells where the fault occurred, the time of the occurrence and the flight phase.

The occurrence field also tells if the fault is one of these:

- Hard
- Intermittent
- Message is ACTIVE only during operational mode shown in FIM.

A fault shows as hard if a system can currently monitor the fault condition, the fault exists, and it has not become not active.

A fault shows intermittent if a system can currently monitor the fault condition and the fault condition has gone away at least once. The fault condition may or may not currently exist. The number of times the fault has become active also appears.

A fault shows as "Message is ACTIVE only during operational mode shown in FIM" if the system has modes in which it can not tell if the fault is active. Use the initial evaluation paragraph of the fault isolation task in the FIM to see if it is active.

The occurrence field only shows when you select the maintenance message display from one of these displays:

- Inbound flight deck effects display
- Present leg faults display
- Fault history display.

Leg Information

The leg field shows information about the message and tells if the message occurred in a previous leg.

Recommended Maintenance Action Field

The recommended maintenance action field shows possible causes for the maintenance message.

The cause number shows in the order of probability. Causes with the same number have the same probability.

Training Information Point

The fault isolation manual (FIM) may show the fault isolation steps in a different order than the items in the recommended maintenance action field. The FIM considers ease of access and cost of component replacement in addition to probability.

Correlated Flight Deck Effects Field

The correlated flight deck effects field shows all the FDEs correlated to the message. This field updates as FDEs change.

Buttons

Select NEXT MESSAGE to show the next maintenance message in the FDE summary group. NEXT MESSAGE shows when viewing a maintenance messages selected from an FDE summary group.

Select PREVIOUS MESSAGE to show the previous maintenance message in the FDE summary group. PREVIOUS MESSAGE shows when viewing a maintenance messages selected from an FDE summary group.

FAULT HISTORY shows only when you access the single maintenance message display through one of these displays:

- INBOUND FLIGHT DECK EFFECTS
- PRESENT LEG FAULTS
- INBOUND MAINTENANCE MEMOS
- INBOUND SCHEDULED MAINTENANCE TASKS.

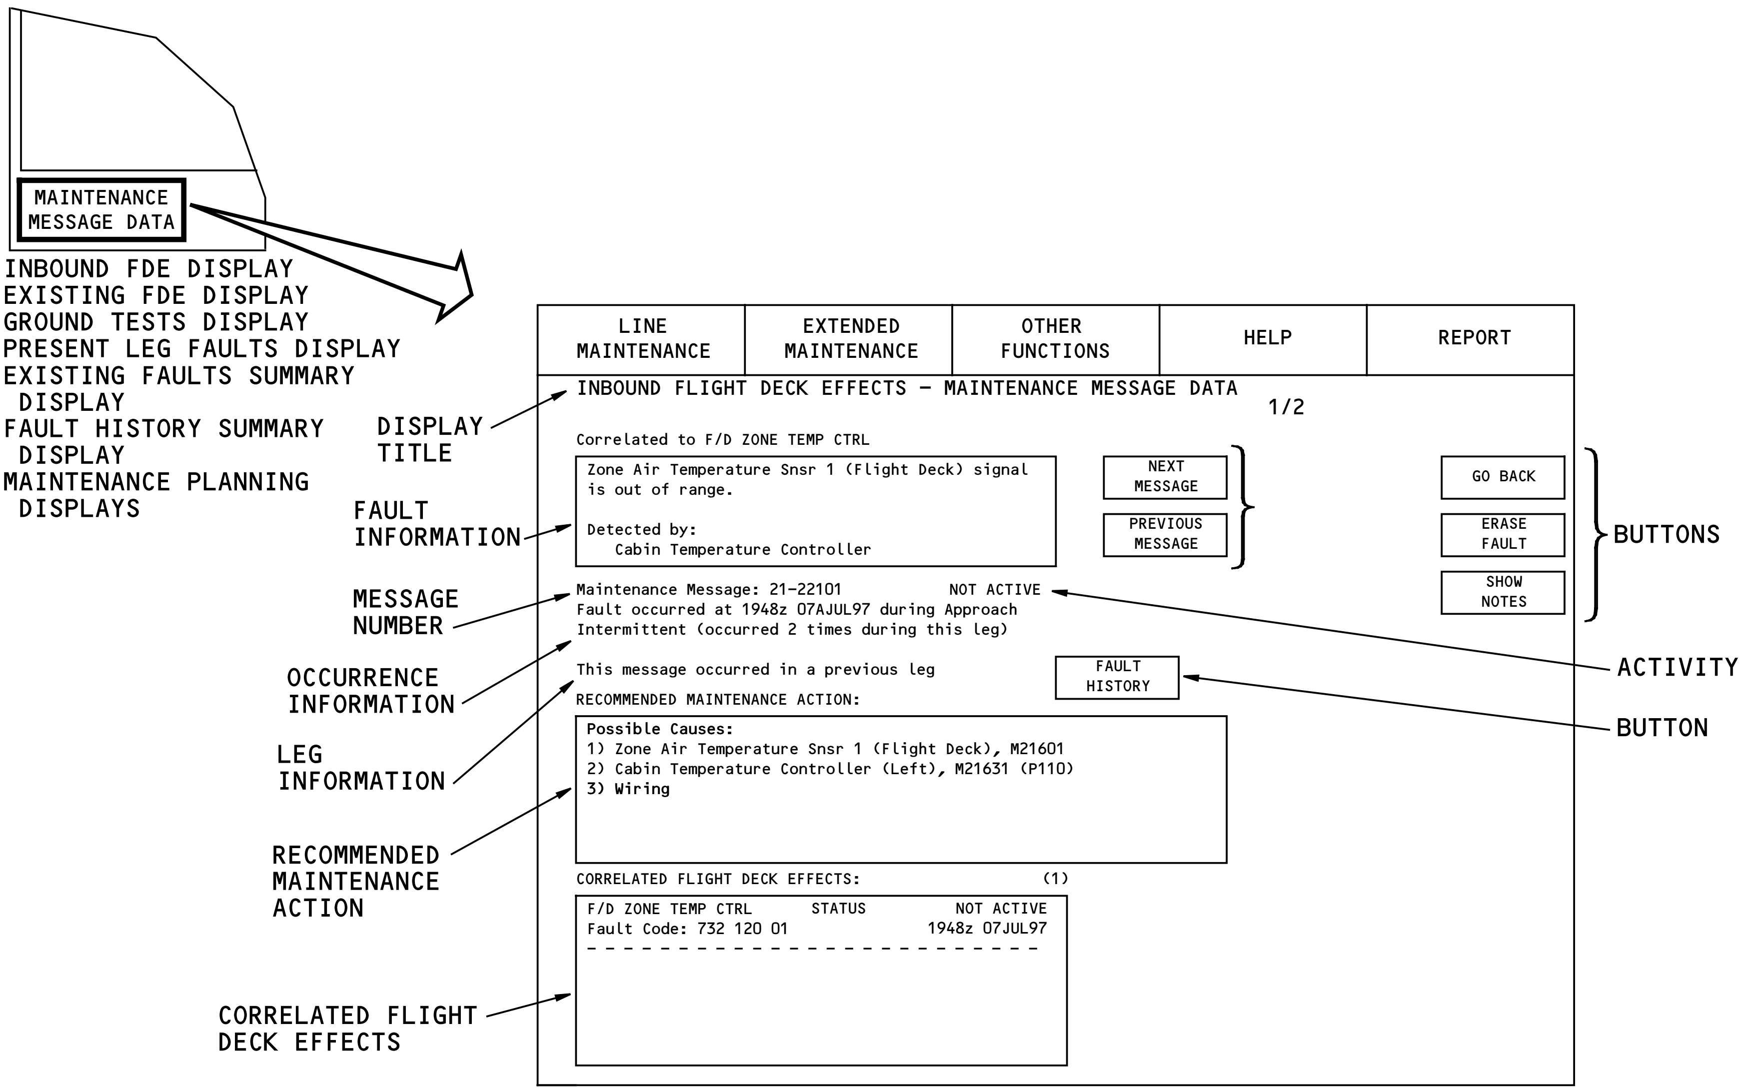
Select FAULT HISTORY to show the fault history summary display for the applicable maintenance message.

CMCS - SINGLE MAINTENANCE MESSAGE DATA DISPLAY

Select GO BACK to return to the page from which the single maintenance message display was selected.

ERASE FAULT shows only when you access the single maintenance message page through fault history. Select ERASE FAULT to show the fault history erase confirmation dialog box.

Select SHOW NOTES to show the notes dialog box.



CMCS - SINGLE MAINTENANCE MESSAGE DATA DISPLAY

45-10-00-032 Rev 6 11/06/1997

THIS PAGE INTENTIONALLY LEFT BLANK

CMCS - EXISTING FLIGHT DECK EFFECTS DISPLAY

General

The purpose of the existing flight deck effects display is to help the line maintenance technician repair the airplane during quick turnarounds at the gate.

Use the existing flight deck effects display to get access to any existing FDEs and their correlated maintenance messages. The FDEs may be active or latched.

The CMCF sorts the FDEs and any correlated maintenance messages by time and the most recent FDE shows first.

The user has the option to show the single maintenance message display.

The existing flight deck effects display shows this data:

- Header information
- Instructions field
- Fault summary field title
- Number of items
- Fault summary field
- Buttons.

Header Information

The data under the main menu bar on the right side shows this data:

- Tail identification
- Time and date from the CMCF
- CMCF source field.

Fault Summary Field

The number of flight deck effects in the fault summary field shows at the top of the scroll bar.

The fault summary field has the FDE summary groups.

Each FDE summary group includes this data:

- Flight deck effect
- Flight deck effect activity
- Fault code
- Maintenance message summary groups.

FDE and Maintenance Message Activity

The CMCF receives LRU fault information for display on the existing flight deck effects display that refers to:

- FDEs
- Maintenance messages.

The CMCF stores the information in the fault database. The information shows in FDE summary groups.

The condition of an FDE shows as one of these:

- Active
- Latched.

CMCS - EXISTING FLIGHT DECK EFFECTS DISPLAY

An active FDE is an FDE that currently shows in the flight deck.

A latched FDE can only be a status message or a scheduled maintenance task. A failure that caused a status message may impact dispatch and may be intermittent or detectable only under certain conditions. The PDS holds a status message to make sure it can be seen on the ground.

The condition of a maintenance message shows as one of these:

- Active
- Latched
- Not Active.

A maintenance message is active if a system can continuously monitor for a fault condition, and the fault exists.

A maintenance message is latched for one of these reasons:

- If a system detects a fault and no longer uses the related equipment as part of its operational function
- To ensure correlation with an FDE
- If a system can not always detect if the fault exists.

You must do something to clear a latched maintenance message.

A maintenance message is not active if a system can continuously monitor for a fault condition, and the fault does not exist.

Maintenance Message Summary Group

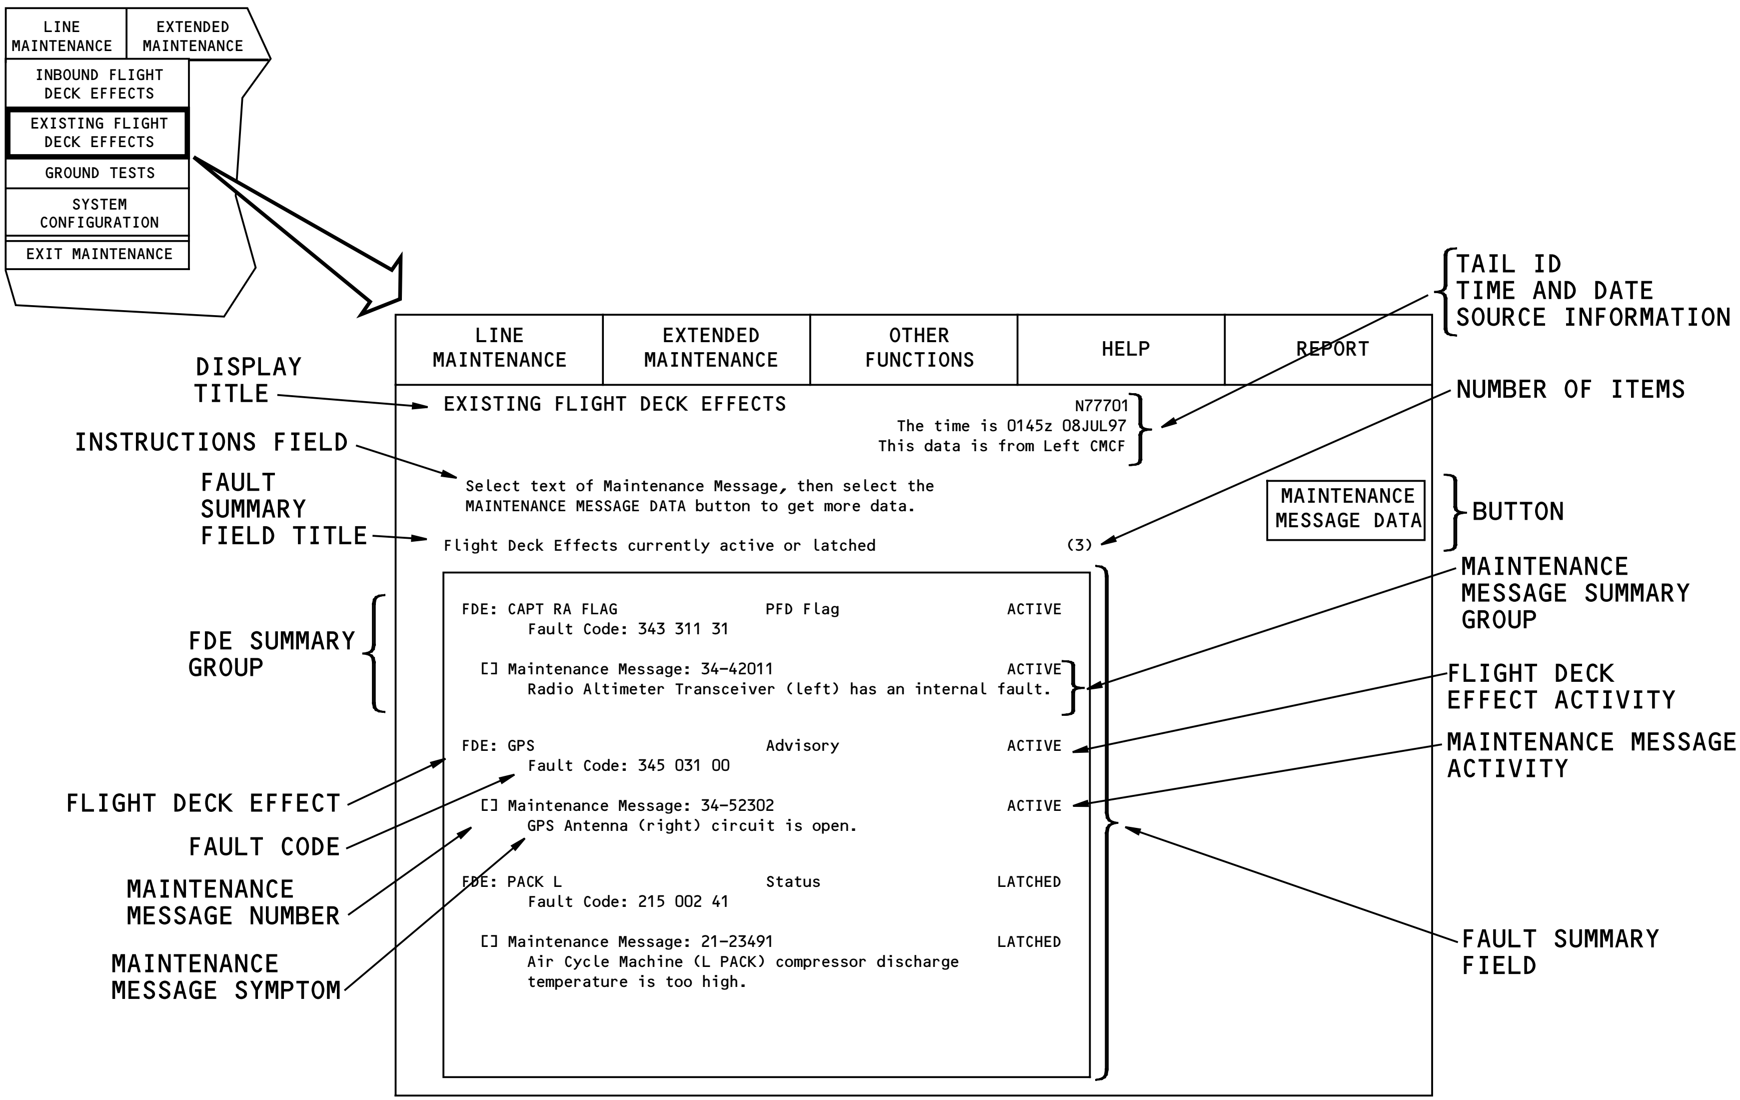
Each maintenance message summary group includes:

- Maintenance message symptom
- Maintenance message number
- Maintenance message activity.

One or more maintenance messages may be correlated to each FDE.

Button

Select MAINTENANCE MESSAGE DATA to show the single maintenance message display for the selected maintenance message.



45-10-00-033 Rev 5 11/06/1997

CMCS - EXISTING FLIGHT DECK EFFECTS DISPLAY

CMCS - GROUND TESTS SELECTION DIALOG BOX

THIS PAGE INTENTIONALLY LEFT BLANK

CMCS - GROUND TESTS SELECTION DIALOG BOX

General

The GROUND TESTS selection supplies access to airplane systems with ground tests. In this ground test selection dialog box, you select this data:

- ATA system
- Type of test
- LRU in that system.

Many ATA systems and LRU have unique requirements that cause additional dialog boxes to show before the test actually starts. The types of dialog boxes include these:

- Precondition dialog boxes
- Inhibit dialog boxes
- Interference dialog boxes
- Interactive dialog boxes
- Menu abort dialog boxes.

When all requirements are met, the ground tests display shows the status and instructions for the test.

Buttons on the ground tests display and the dialog boxes supply:

- Specific instructions
- Help
- Report capability
- Access to the single maintenance message page.

The ground test selection dialog box shows this data:

- Dialog box title
- List box titles
- ATA system list box
- Test type exclusive selections
- Test list box
- Buttons.

ATA System List Box

The ATA System list box lists the airplane systems in ATA order. Select an ATA system first. This highlights the selection. This selection causes the test types for that ATA to become available. Those test types that are not available show dim or gray.

Test Type Exclusive Selections

These are the test types that are exclusive selections:

- SYSTEM TEST
- OPERATIONAL TEST
- LRU REPLACEMENT TEST.

A system test contains all adjustment specifications and tolerances to maintain systems or units at maximum efficiency. It is self-contained and may duplicate other tests.

An operational test determines only that a system or unit is operational. These tests require no special test equipment.

CMCS - GROUND TESTS SELECTION DIALOG BOX

An LRU replacement test determines only that the interfaces to the LRU are operational.

The selection of a test type causes the test list box to show.

Test List Box

The title of the test list box matches the test type. The test list box shows all LRUs in the ATA that have the appropriate test available. The selection of an LRU in the test list box causes that LRU to highlight.

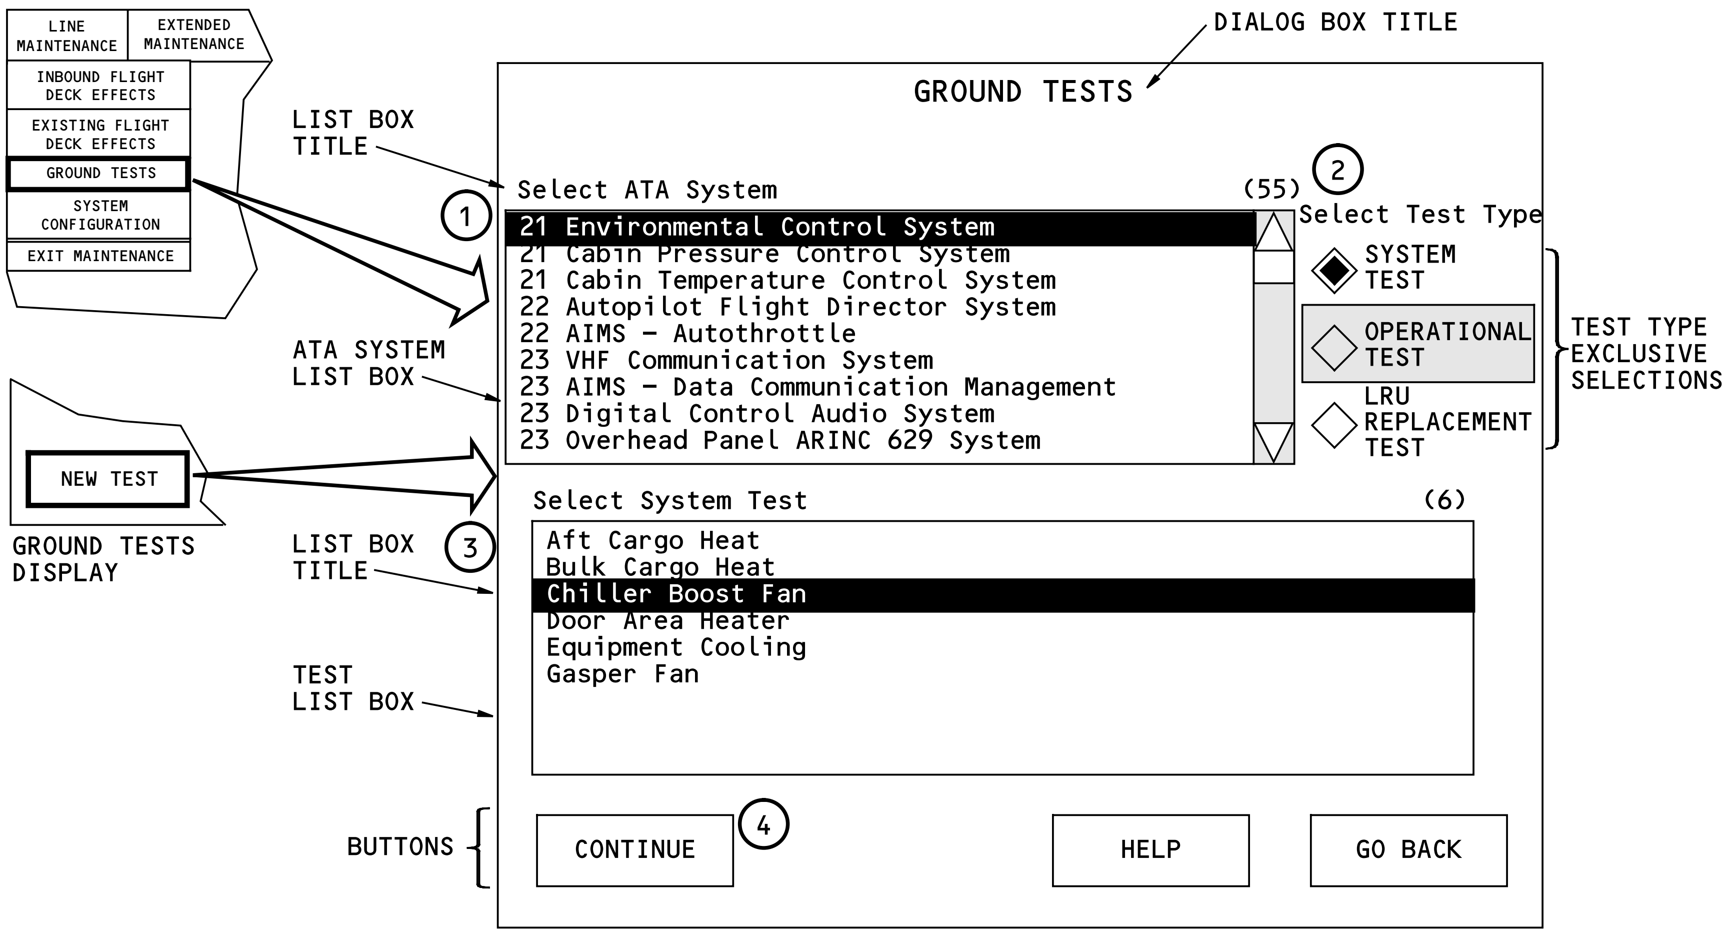
The selection of the LRU also makes the CONTINUE command available.

Buttons

Select CONTINUE to show the precondition dialog box on top of the ground test selection dialog box for the selected test.

Select HELP to show the help dialog box for the ground tests selection dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to remove the ground test selection dialog box and to show the previous display.



1 - 4 TEST SELECTION SEQUENCE

45-10-00-034 Rev 2

CMCS - GROUND TESTS SELECTION DIALOG BOX

CMCS - GROUND TESTS PRECONDITION DIALOG BOX

General

The precondition dialog box has a description for each test and special instructions for each test (if required).

The precondition dialog box shows this data:

- Display title
- Test title
- Test description
- Precondition list
- Buttons.

Test Title

The test title shows the test name from the selection you make on the ground test selection dialog box.

Test Description

The test description briefly tells you about the test.

Precondition List

The precondition list gives instructions for you to follow before the test is run.

The precondition display database stores the test description and the precondition list.

Buttons

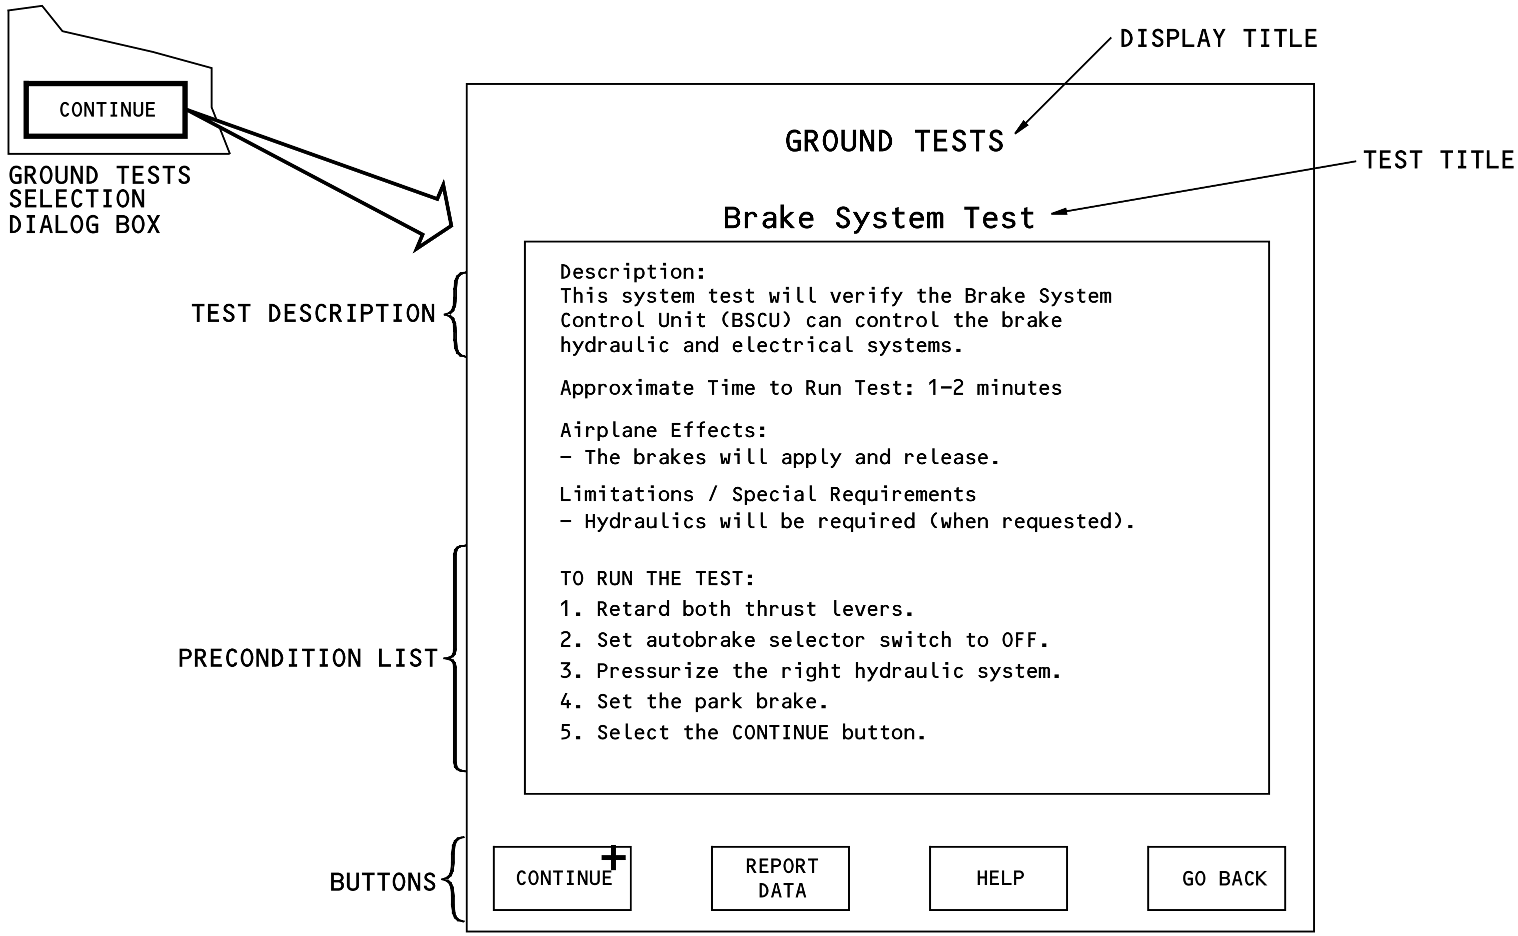
The precondition dialog box shows four buttons.

Select CONTINUE to close the ground test selection dialog box (if open), to close the precondition dialog box, and to cause the test display to show.

Select REPORT DATA to show the report dialog box.

Select HELP to show the help dialog box for the precondition dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to remove the precondition dialog box to show the previous display.



45-10-00-035 Rev 1

CMCS - GROUND TESTS PRECONDITION DIALOG BOX

THIS PAGE INTENTIONALLY LEFT BLANK

45-10-00-036 Rev 4

CMCS - GROUND TESTS TEST DISPLAY

General

The ground tests test display supplies status information and control for ground tests.

The ground tests test display shows:

- Display title
- ATA chapter and name
- Test type title
- Test title
- Test condition messages
- Test control buttons
- Text field
- Text field title
- Buttons.

ATA Chapter and Name

This field shows the ATA chapter and system name from the initial selection on the ground tests selection dialog box.

Test Type Title

This field shows the test type title from the initial selection on the ground tests selection dialog box.

Test Title

This field shows the test title from the initial selection on the ground tests selection dialog box.

Test Condition Messages and Test Control Buttons

The TEST CONDITION messages field can show these messages:

- READY
- INHIBITED
- CAN NOT OPERATE
- OPERATING
- PASSED
- FAILED
- STOPPED.

These are the possible test control buttons:

- START TEST
- STOP TEST
- OPERATE TEST AGAIN
- TO TEST.

READY shows when no inhibit conditions or no interference conditions exist. START TEST shows next to the READY message.

START TEST causes the CMCF to begin the test. OPERATING shows as the message.

When OPERATING shows, the button changes to STOP TEST.

The selection of STOP TEST causes the message STOPPED to show.

At the completion of the test, PASSED or FAILED shows.

CMCS - GROUND TESTS TEST DISPLAY

With STOPPED, PASSED or FAILED as the message, OPERATE TEST AGAIN shows as the button.

OPERATE TEST AGAIN causes the precondition to show.

INHIBITED shows when a test inhibit condition exists. The TO TEST control selection shows next to the message. Select TO TEST to show the test inhibit dialog box.

CAN NOT OPERATE shows as the message if a test interference condition exists. The TO TEST control selection shows next to the message. Select TO TEST to show the test interference dialog box.

Text Field

The text field shows the maintenance message summary group and reported test results when a test fails.

If the message STOPPED shows in the test condition field, and you stop the test, or the system in test stops the test, then the text field shows one of these messages:

- Test stopped due to user request
- Test stopped due to member system request.

Text Field Title

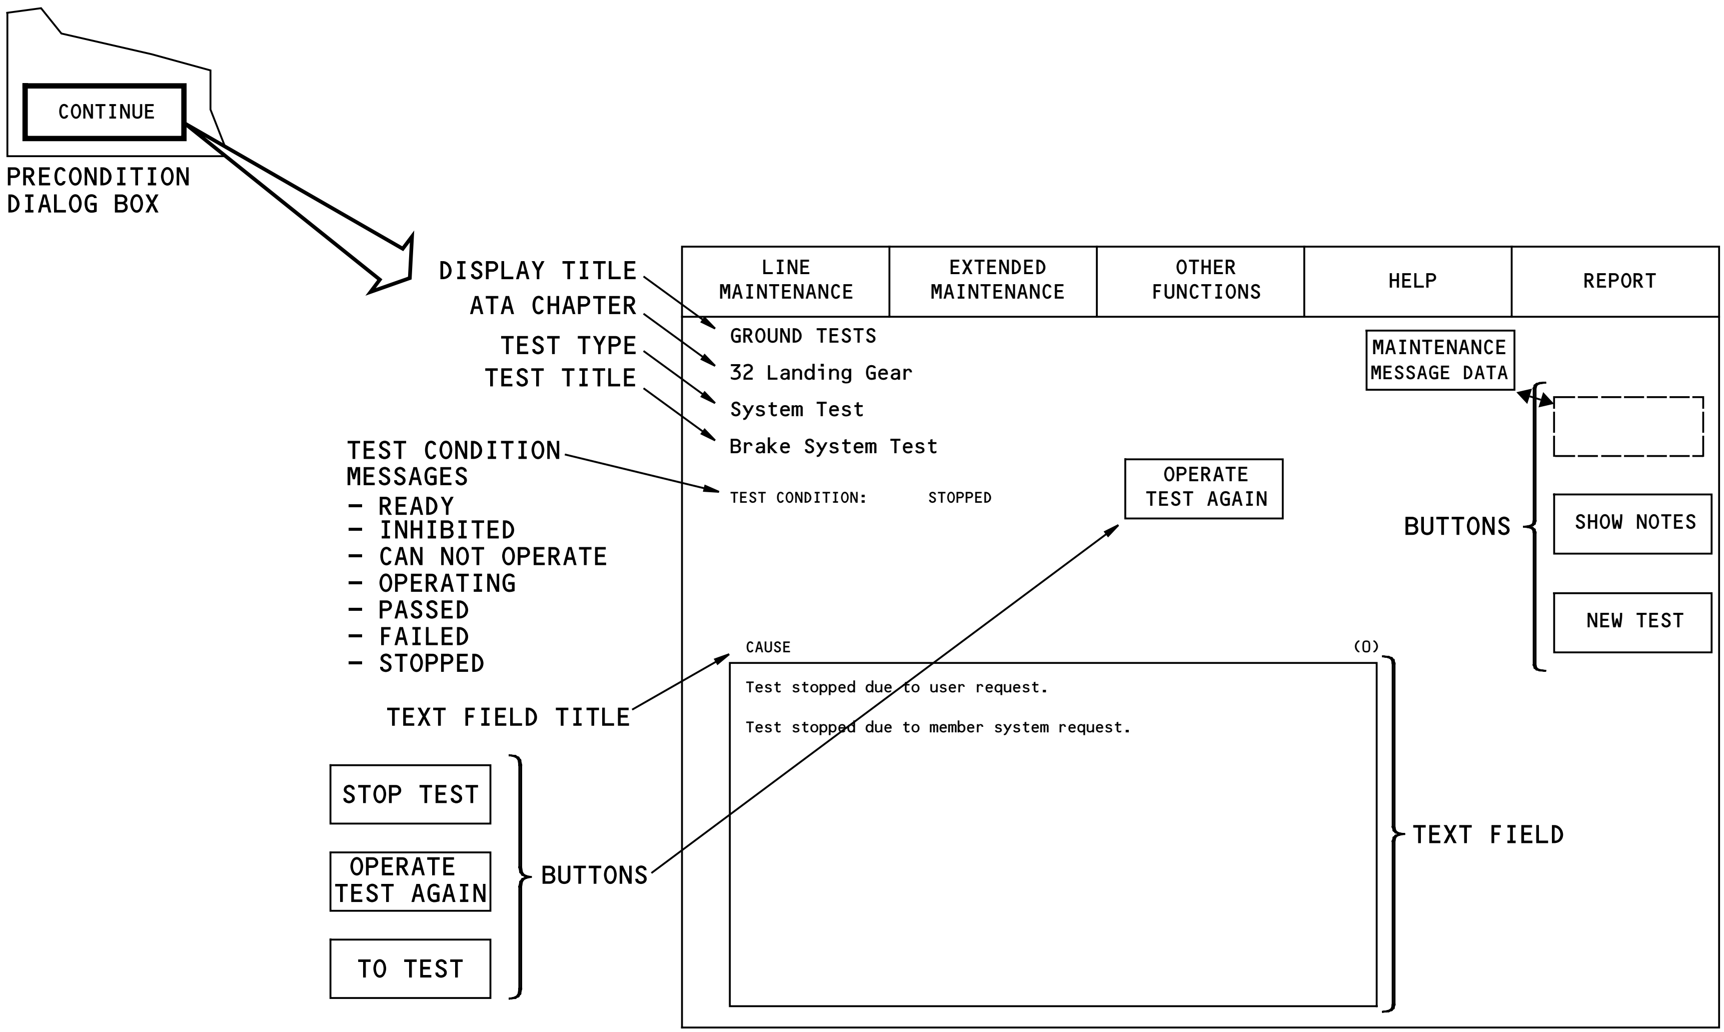
When FAILED or STOPPED shows in the test condition field, the title of the text field is CAUSE.

Buttons

The MAINTENANCE MESSAGE DATA button is available when a maintenance message summary group shows for a failed test.

Select SHOW NOTES to show the notes dialog box selected ground test. Notes text for the dialog box must be in the CMCF AMI for SHOW NOTES to show.

Select NEW TEST to show the ground tests selection dialog box.



45-10-00-036 Rev 4 11/06/1997

CMCS - GROUND TESTS TEST DISPLAY

CMCS - GROUND TESTS DISPLAYS - 2

General

The test condition messages and the test control button show the current status of the test and give the next control selection.

These are the two possible displays that show:

- Test failed display
- Test stopped display.

Test Failed Display

The test failed display shows the test condition message FAILED and gives the operator the control command to OPERATE TEST AGAIN.

The title of the variable text field is CAUSE and the variable text field shows the maintenance message groups or messages associated with the failure.

The MAINTENANCE MESSAGE DATA button lets you see a single maintenance message after the selection of that maintenance message.

NEW TEST and SHOW NOTES functions remain the same.

Test Stopped Display

After a tests starts, the test condition message changes to OPERATING and the control command changes to STOP TEST.

The test can be stopped by you or by the system.

When you stop the test, the test condition message changes to STOPPED and the button changes to OPERATE TEST AGAIN. The variable text field title is CAUSE and the variable text field shows the message:

- Test stopped due to user request.

When the system stops the test, the test condition message changes to STOPPED and the button changes to OPERATE TEST AGAIN. The variable text field title is CAUSE and the variable text field shows the message:

- Test stopped due to member system request.

The MAINTENANCE MESSAGE DATA button is not available from this display.

NEW TEST and SHOW NOTES functions remain the same.

CMCS - GROUND TESTS DISPLAYS - 2

CMCS - GROUND TEST INTERACTIVE DIALOG BOX

General

The ground test interactive dialog boxes show only if your interaction is necessary to complete the test.

The member systems control the interactive displays. LRUs in the member systems send a control signal that tells the CMCF to show the interactive displays as necessary. When the CMCF gets the control signal, it removes the current interactive display that shows.

Each interactive dialog box shows:

- Dialog box title
- Test title
- Messages
- Exclusive selections
- Buttons.

Test Title

The test title shows the title of the test from the initial selection on the Ground Tests selection dialog box.

Messages

The messages area shows directions to successfully run and complete the test.

The message area also shows any warnings for the test.

If there is more text to show than can fit in the message area, a scroll bar shows.

Exclusive Selections

The member systems define the exclusive selections. The selections permit communication between you and the LRU under test.

Each interactive dialog box can show a maximum of ten exclusive selections.

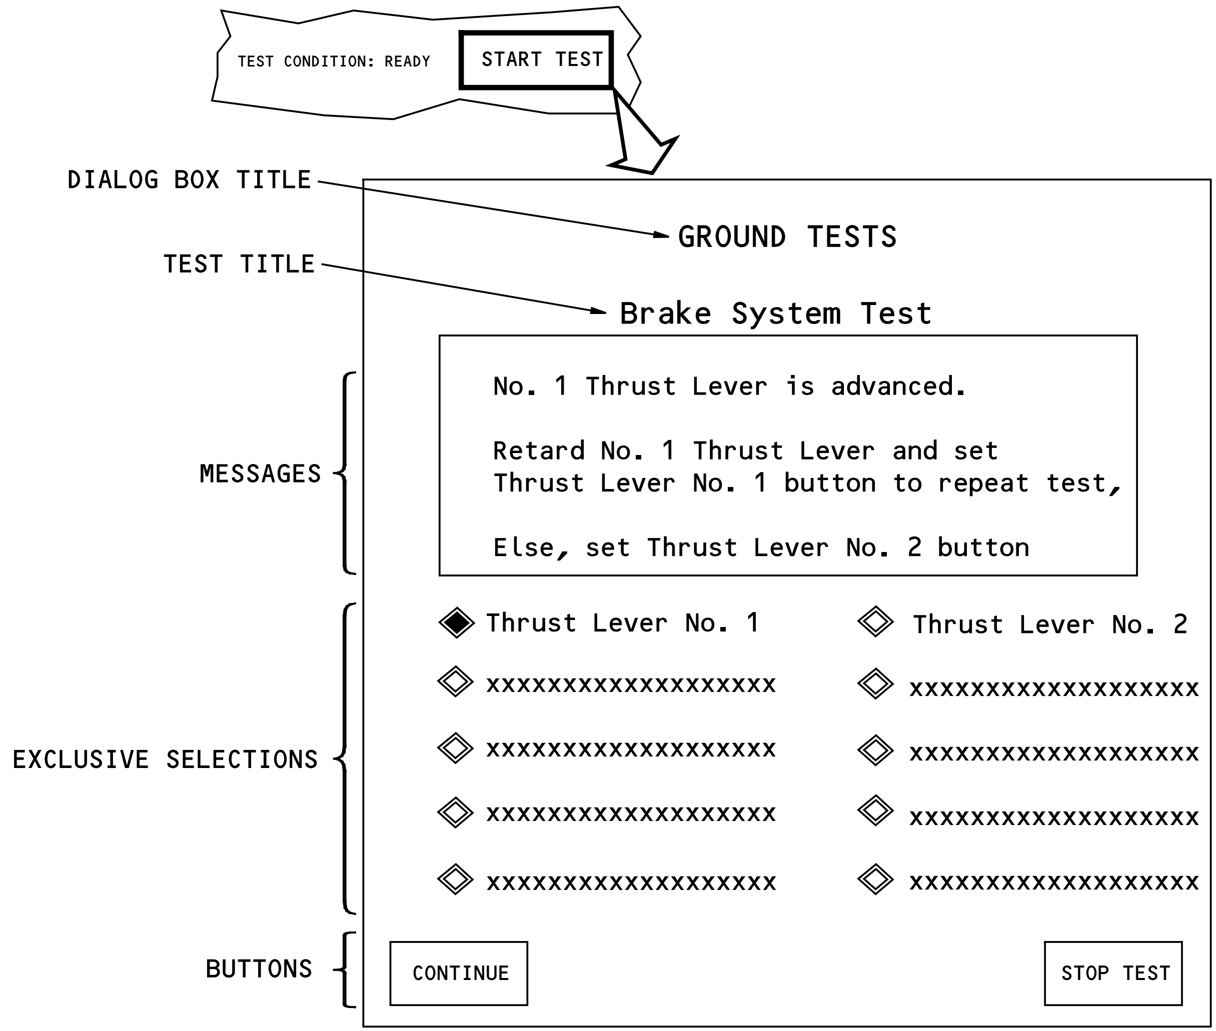
Only the required number of exclusive selections show for each test. The ground test interactive dialog box grows to fit the buttons.

Buttons

The CONTINUE button shows dim or is not available if exclusive selections are not available or until you make an exclusive selection.

After you make an exclusive selection, select CONTINUE to cause that selection to go to the LRU. The CMCF removes the interactive dialog box. The CMCF then starts the test.

Select STOP TEST to remove the interactive dialog box and cause the TEST CONDITION message on the system test screen to show STOPPED. The control selection shows OPERATE TEST AGAIN.



45-10-00-038 Rev 0

CMCS - GROUND TEST INTERACTIVE DIALOG BOX

CMCS - GROUND TESTS INHIBIT AND INTERFERENCE DIALOG BOXES

Test Inhibit Dialog Box

When the TEST CONDITION message shows INHIBITED, the control button changes to TO TEST.

Select TO TEST to show the ground tests test inhibit dialog box.

The ground tests test inhibit dialog box shows:

- Dialog box title
- Test title
- Instructions to continue the test
- Buttons.

The test title shows the title from the original selection on the ground test selection dialog box.

The instructions tell why the test is inhibited and how to enable the test.

After the inhibit condition goes away, select CONTINUE to remove the dialog box and permit the test to continue.

Select REPORT DATA to show the report dialog box.

Select HELP to show the help dialog box for the dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to remove the test inhibit dialog box.

Test Interference Dialog Box

When the TEST CONDITION message shows CAN NOT OPERATE, the control button changes to TO TEST.

Select TO TEST to show the ground tests test interference dialog box.

The ground tests test interference dialog box shows:

- Dialog Box title
- Test title
- Test interference information
- Buttons.

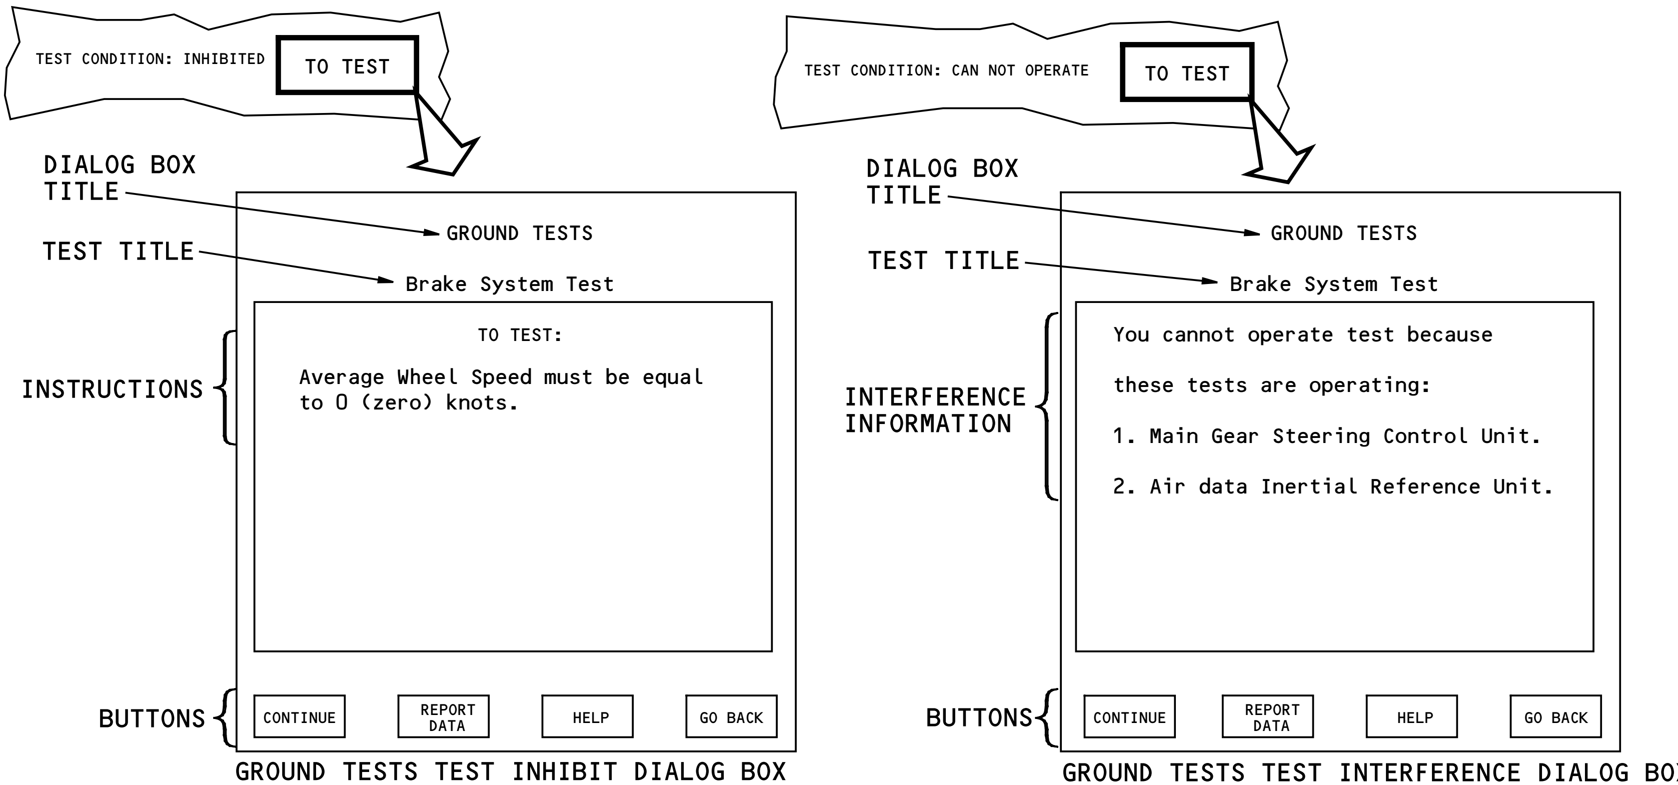
The test title shows the title from the original selection on the ground test selection dialog box.

The test interference information has the header "You cannot operate this test because these tests are operating" and a numbered list of the causes of the interference. After the interference condition goes away, select CONTINUE to remove the dialog box and permit the test to continue.

Select REPORT DATA to show the report dialog box.

Select HELP to show the help dialog box for the dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to close the test interference dialog box.



45-10-00-039 Rev 1

CMCS - GROUND TESTS INHIBIT AND INTERFERENCE DIALOG BOXES

CMCS - GROUND TESTS MENU ABORT AND NO TEST ABORT DIALOG BOXES

Ground Tests Menu Abort Dialog Box

The ground tests menu abort dialog box shows when a selection other than HELP is made from the main menu bar or the user selects NEW TEST with a test in progress.

The menu abort dialog box shows:

- Dialog box title
- Message text
- Buttons.

The message text shows:

- Do you wish to STOP the Test?

Select YES to do these:

- Stop the test
- Remove the menu abort dialog box
- Show the main menu bar selection or the NEW TEST button.

Select GO BACK to remove the menu abort dialog box.

Ground Tests No Menu Abort Dialog Box

The ground tests no menu abort dialog box shows when a selection other than help is made from the main menu bar or the user selects NEW TEST with a test in progress.

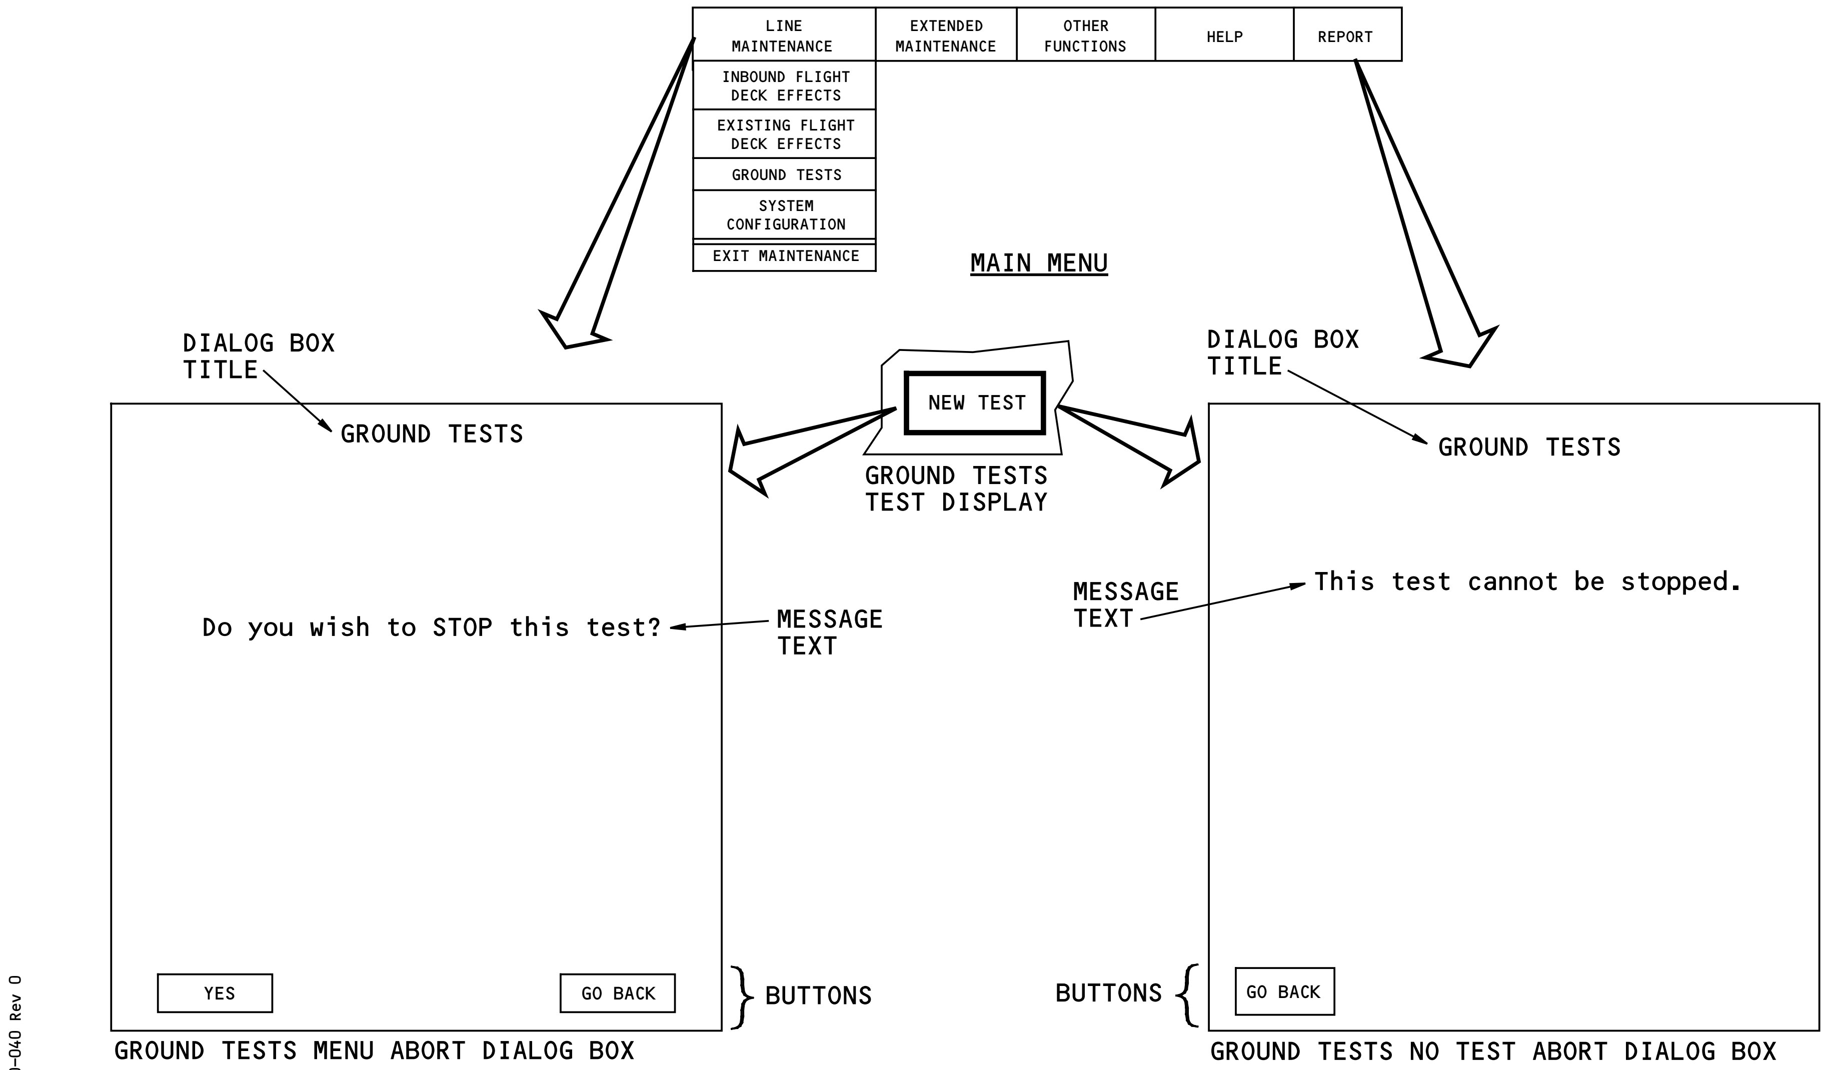
The no menu abort dialog box has:

- Dialog box title
- Message text
- Buttons.

The message text shows:

- This test cannot be stopped.

Select GO BACK to remove the no menu abort dialog box and return to the previous display.



CMCS - GROUND TESTS MENU ABORT AND NO TEST ABORT DIALOG BOXES

CMCS - SYSTEM CONFIGURATION SELECTION DIALOG BOX

General

The system configuration selection dialog box shows ATA chapters and ATA system names for access to hardware and software configuration information for different LRUs and LRMs in the ATA systems.

The system configuration selection dialog box shows:

- Dialog box title
- List box title
- Number of items
- List box
- Buttons.

The list box shows a list of ATA chapter numbers and ATA chapter names. The list box shows the ATA systems sorted in order of ATA chapter number.

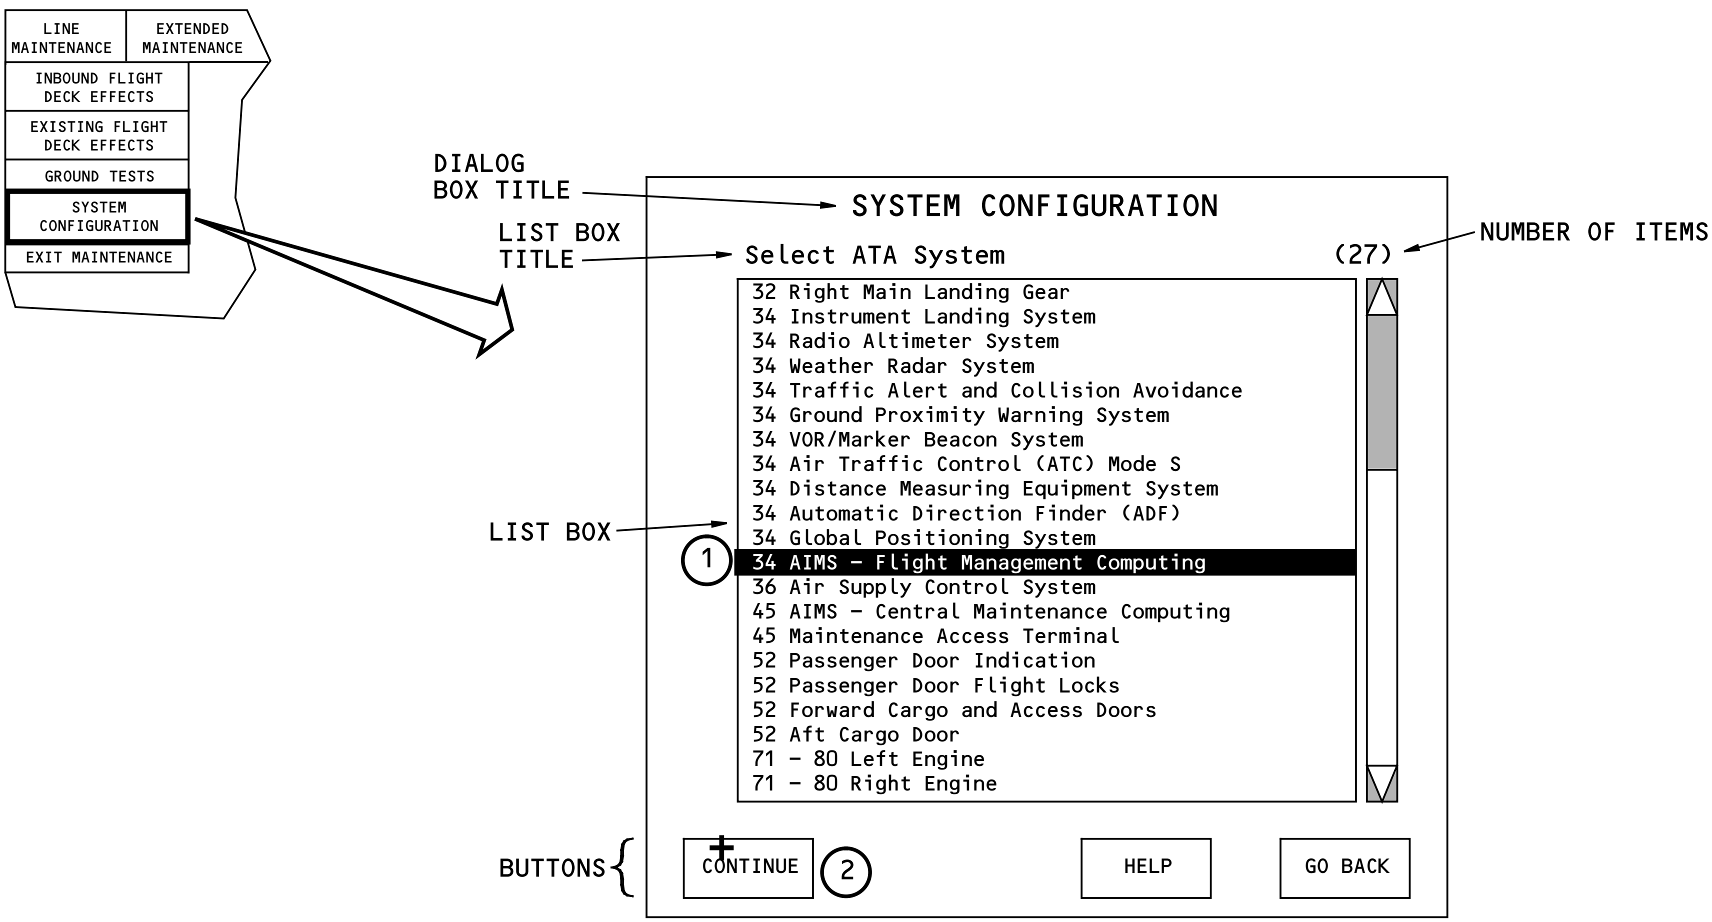
The selected item highlights. The total number of ATA chapter numbers and systems items shows at the top of the list box.

Buttons

Select CONTINUE to remove the system configuration selection dialog box and show the system configuration dialog box. The CONTINUE selection is not available until an ATA system is highlighted.

Select GO BACK to close the system configuration selection dialog box and return to the previous display.

Select HELP to show the help dialog box for the system configuration selection dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.



SYSTEM CONFIGURATION SELECTION DIALOG BOX

1 - 2 SELECTION SEQUENCE

45-10-00-041 Rev 3 11/06/1997

CMCS - SYSTEM CONFIGURATION SELECTION DIALOG BOX

CMCS - SYSTEM CONFIGURATION DIALOG BOX

THIS PAGE INTENTIONALLY LEFT BLANK

CMCS - SYSTEM CONFIGURATION DIALOG BOX

General

The system configuration dialog box shows hardware and software configuration information for different ATA systems.

The system configuration dialog box shows:

- Dialog box title
- List box title
- Number of items
- List box
- Buttons.

The title of the list box is the ATA chapter number and system selected from the system configuration selection dialog box.

The total number of LRM/LRU items shows at the top of the list box.

List Box

The list box shows the:

- System identifiers
- LRU/LRM identifiers for the system
- Configuration data identifiers
- Configuration data
- Configuration data not available text.

The system identifiers and the LRU/LRM identifiers show for the ATA chapter number and system that shows on top of the list box.

Configuration Data

The configuration data identifiers are:

- Hardware Part Number
- Software #n Part Number
- LRU Part Number
- Serial Number
- Options
- Other Item.

Configuration data shows to the right of the configuration data identifiers.

If an LRU/LRM cannot supply configuration data to the CMCF, the configuration data identifiers and configuration data do not show. The list box shows one of four text blocks in the place of the configuration data identifiers and configuration data.

If there is no response from an LRU/LRM the text block shows:

- CONFIGURATION DATA NOT AVAILABLE.
  CANNOT CONNECT TO THIS SYSTEM. THIS SYSTEM DOES NOT GIVE A REPLY.

CMCS - SYSTEM CONFIGURATION DIALOG BOX

If the CMCF receives data from an LRU/LRM, but no configuration information is in the data received, the text block shows:

- CONFIGURATION DATA NOT AVAILABLE.

If an LRU/LRM is inactive, the text block shows:

- CONFIGURATION DATA NOT AVAILABLE. CANNOT CONNECT TO THIS SYSTEM. THIS SYSTEM IS INACTIVE/FAULTED.

An LRU/LRM can only do one system configuration request at a time. If the CMCF receives a second request to show a system configuration dialog box for the same LRU/LRM the text block shows:

- CONFIGURATION DATA NOT AVAILABLE. CANNOT CONNECT TO XXXX. SYSTEM CONFIGURATION IS ALREADY CONNECTED TO XXXX.

The XXXX is the LRU/LRM that system configuration information was requested for. For example:

- CONFIGURATION DATA NOT AVAILABLE. CANNOT CONNECT TO AIR DATA SYSTEM. SYSTEM CONFIGURATION IS ALREADY CONNECTED TO AIR DATA SYSTEM.

Buttons

Select SELECT NEW ATA to show the system configuration selection dialog box on top of the system configuration dialog box. The configuration data that shows on the system configuration dialog box remains the same and shows below the system configuration selection dialog box.

Select REPORT DATA to show the report dialog box.

Select SHOW NOTES to show the notes dialog box for the system configuration dialog box. Notes text for the dialog box must be in the CMCF AMI for SHOW NOTES to show.

Select HELP to show the help dialog box for the system configuration dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to remove the system configuration dialog box and show the previous display.

CMCS - SYSTEM CONFIGURATION DIALOG BOX

THIS PAGE INTENTIONALLY LEFT BLANK

CMCS - PRESENT LEG FAULTS DISPLAY

General

The present leg faults display shows FDE and non-FDE summary groups. The FDE summary group shows FDEs and their correlated maintenance message summary groups which the CMCF stores in fault history leg 0. The non-FDE summary group shows non-correlated maintenance message summary groups which the CMCF stores in fault history leg 0.

FDEs and their correlated maintenance message summary groups show in time order of occurrence, with the most recent FDE and correlated maintenance message summary groups at the top of the list. The non-FDE summary groups show at the bottom of the list.

The present leg faults display also shows maintenance message summary groups for a single ATA chapter, which the CMCF stores in fault history leg 0.

The present leg faults display shows:

- Header Information
- Instructions field
- Fault summary field title
- Number of items
- Fault summary field
- Buttons.

Header Information

The data under the main menu bar on the right side shows:

- Tail identification
- Flight number from the FMCF
- Leg ID, departure airport and arrival airport identifiers from the FMCF
- Leg start time and date from the CMCF
- CMCF source field.

Fault Summary Field Title

The fault summary field title shows above the fault summary field on the left side. The fault summary title shows:

- Data Recorded During the Present Leg - shows when the present leg faults display shows FDE and non-FDE summary groups
- Maintenance Messages Recorded During the Present Leg for XXXXX; (XXXXX is the ATA system that has faults) - shows when the present leg faults display shows maintenance message summary groups sorted by a single ATA chapter.

Number of Items

The number of items shows above the fault summary field on the right side. The number in the parentheses shows the total number of:

- FDE summary groups plus one for the non-FDE summary group, when the fault summary field shows FDE and non-FDE summary groups

CMCS - PRESENT LEG FAULTS DISPLAY

- Maintenance message summary groups, when the fault summary field shows maintenance message summary groups for a single ATA chapter.

Fault Summary Field

A fault summary field has:

- FDE summary groups
- Non-FDE summary group
- Maintenance message summary groups for a single ATA chapter.

The summary groups are faults and FDEs which the CMCF stores in the current leg. The fault summary field border highlights when the cursor is within the area of the fault summary field and there is one or more summary groups within the field.

Select the cursor control device button while the cursor is within the area of the fault summary field to highlight the text of a maintenance message summary group or the text of a FDE summary group header. Select a button to show more data for the highlighted maintenance message summary group or the highlighted FDE summary group header.

FDE Summary Group

A FDE summary group shows the:

- Flight deck effect EICAS message and level
- Flight deck effect activity
- Fault code for the FDE
- Time and date the FDE occurred
- One or more maintenance message summary groups.

FDE and Maintenance Message Activity

The activity of an FDE shows as one of these:

- Active
- Latched
- Not Active.

An active FDE is an FDE that currently shows in the flight deck.

A latched FDE can only be a status message or a scheduled maintenance task. Scheduled maintenance tasks are discussed elsewhere in this section.

A failure that caused a status message may impact dispatch and may be intermittent or detectable only under certain conditions. The PDS holds a status message to make sure you can see it on the ground. You must do something to clear a latched FDE.

An FDE is not active if it can not currently be seen on the flight deck.

The activity of a maintenance message also shows as one of these:

- Active
- Latched

- Not Active.

A maintenance message is active if a system can continuously monitor for a fault condition, and the fault exists.

A maintenance message is latched for one of these reasons:

- If a system detected a fault and is no longer using the related equipment as part of its operational function
- To ensure correlation with an FDE
- If a system can not always detect if the fault exists.

You must do something to clear a latched maintenance message.

A maintenance message is not active if a system can continuously monitor for a fault condition, and the fault does not exist.

Maintenance Message Summary Groups

Each maintenance message summary group includes:

- Maintenance message number
- Maintenance message activity
- Flight phase
- Fault time and date
- Maintenance message symptom.

One or more maintenance messages may be correlated to each FDE and shows with an FDE summary group.

Buttons

Select MAINTENANCE MESSAGE DATA to show the single maintenance message display for the highlighted maintenance message.

Select SELECT BY ATA to show the ATA chapter selection dialog box. If the fault summary field shows maintenance message summary groups for a single ATA chapter, then the button shows SORT BY FDE.

Select SORT BY FDE to show all the present leg, leg 0, FDE and non-FDE summary groups. If the fault summary field shows FDE and non-FDE summary groups, then the button shows SELECT BY ATA.

Select SELECT NEW ATA to show the ATA chapter selection dialog box. The SELECT NEW ATA button shows only if the fault summary field shows maintenance message summary groups for a single ATA chapter.

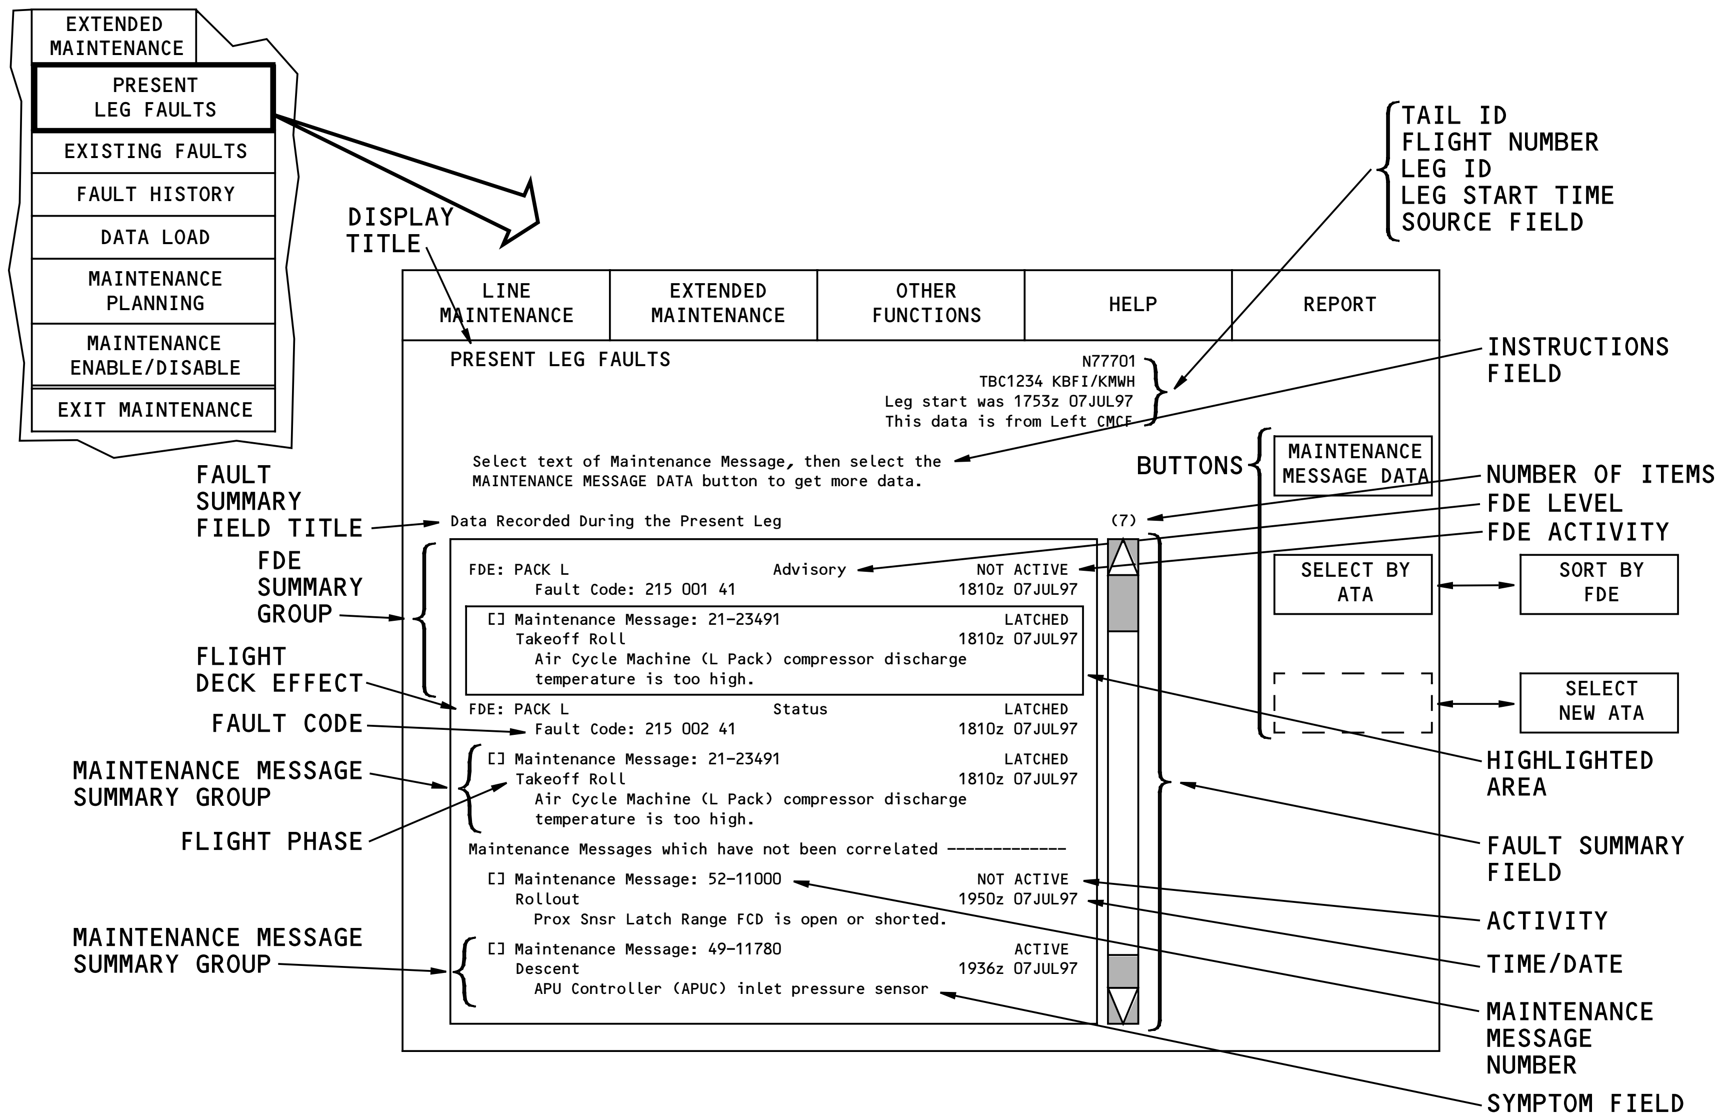
Training Information Point

If a flight leg transition occurs while any present leg faults display or dialog box shows this happens:

- The dialog box goes away
- The fault summary field goes away

CMCS - PRESENT LEG FAULTS DISPLAY

- A dialog box shows with the text: Flight Leg Has Changed. To See Data from Before, Go to Fault History Leg-1.
- Cancel the text dialog box to show the Present Leg Faults ATA chapter selection dialog box.



CMCS - PRESENT LEG FAULTS DISPLAY

CMCS - EXISTING FAULTS DIALOG BOX

General

The existing faults dialog box lets you select an ATA system that currently has faults. Select an ATA system to show the maintenance message summary groups for that system on the existing faults summary display.

The existing faults dialog box shows:

- Dialog box title
- Number of items
- List box
- Buttons.

The list box shows all the ATA systems that have active or latched maintenance messages.

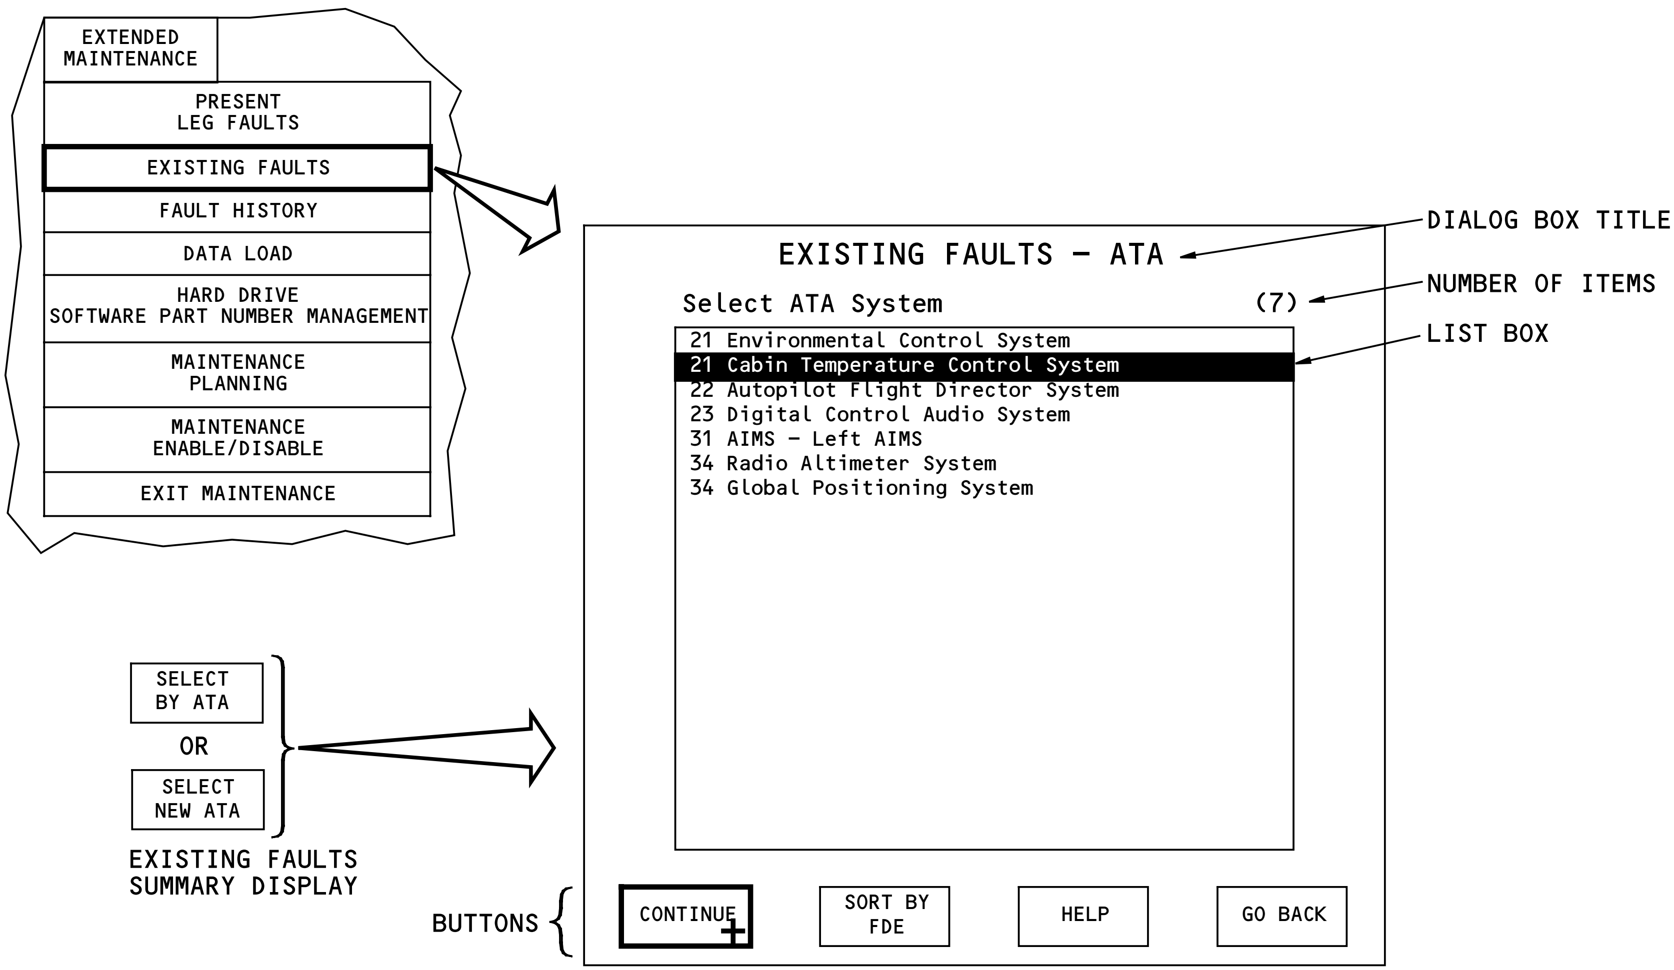
Buttons

Select an ATA system and then select CONTINUE to show the maintenance message summary groups for that ATA system on the existing faults summary display.

Select SORT BY FDE to show the existing faults summary display with all of the FDE and non-FDE summary groups which have active and latched maintenance messages.

Select the HELP button to show the help dialog box for the existing faults dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select the GO BACK button to close the existing faults dialog box and return to the previous display.



45-10-00-044 Rev 4 11/06/1997

CMCS - EXISTING FAULTS DIALOG BOX

CMCS - EXISTING FAULTS SUMMARY DISPLAY

General

The existing faults summary display shows maintenance message summary groups of all active and latched maintenance messages for a single ATA system. Maintenance message summary groups show in time order of occurrence with the newest at the top.

The existing faults summary display also shows FDE and non-FDE summary groups. A FDE summary group shows the currently active or latched FDE, and the active or latched maintenance message summary groups correlated to the FDE. The non-FDE summary group shows the currently active and latched non-correlated maintenance message summary groups.

FDEs and their correlated maintenance message summary groups show in time order of occurrence, with the most recent FDE and correlated maintenance message summary groups at the top of the list. The non-FDE summary groups show at the bottom of the list.

The existing faults summary display shows:

- Header Information
- Instructions field
- Fault summary field title
- Number of items
- Fault summary field
- Buttons.

Header Information

The data under the main menu bar on the right side shows:

- Tail identification
- Time and date from the CMCF
- CMCF source field.

Fault Summary Field Title

The fault summary field title shows above the fault summary field on the left side. The fault summary title shows:

- ATA ZZZZZ; shown when the existing faults summary display shows maintenance message summary groups for a single ATA system. (ZZZZZ is the ATA system that has faults)
- Faults Active or Latched; shown when the existing faults summary display shows FDE and non-FDE summary groups.

Number of Items

The number of items shows above the fault summary field on the right side. The number in the parentheses shows the total number of:

- Maintenance message summary groups, when the fault summary field shows maintenance message summary groups for a single ATA chapter

- FDE summary groups plus one for the non-FDE summary group, when the fault summary field shows FDE and non-FDE summary groups.

Fault Summary Field

The fault summary field has:

- Maintenance message summary groups for a single ATA chapter
- FDE summary groups
- Non-FDE summary group.

The fault summary field border highlights when the cursor is in the area of the fault summary field and there is one or more summary groups within the field.

FDE Summary Group

A FDE summary group shows the:

- FDE EICAS message and level
- FDE activity
- Fault code for the FDE
- Time and date the FDE occurred
- One or more maintenance message summary groups.

A non-FDE summary group shows a description field followed by one or more maintenance message summary groups. The description field shows the text:

- Maintenance Messages which have not been correlated.

Select the cursor control device button while the cursor is in the area of the fault summary field to highlight the text of a maintenance message summary group or the text of a FDE summary group header. Select the MAINTENANCE MESSAGE DATA button to show more data for the highlighted maintenance message summary group.

Maintenance Message Summary Group

A maintenance message summary group shows:

- Maintenance message number
- Maintenance message activity
- Symptom field.

FDE and Maintenance Message Activity

The activity of an FDE shows as one of these:

- Active
- Latched.

An active FDE is an FDE that currently shows in the flight deck.

A latched FDE can only be a status message or a scheduled maintenance task. Scheduled maintenance tasks are discussed in another section.

A failure that caused a status message may impact dispatch and may be intermittent or detectable only under certain conditions. The PDS holds a status

CMCS - EXISTING FAULTS SUMMARY DISPLAY

message to make sure you can see it on the ground. You must do something to clear a latched FDE.

The activity of a maintenance message also shows as one of these:

- Active
- Latched
- Not Active.

A maintenance message is active if a system can continuously monitor for a fault condition, and the fault exists.

A maintenance message is latched for one of these reasons:

- If a system detected a fault and is no longer using the related equipment as part of its operational function
- To ensure correlation with an FDE
- If a system can not always detect if the fault exists.

You must do something to clear a latched maintenance message.

A maintenance message is not active if a system can continuously monitor for a fault condition, and the fault does not exist.

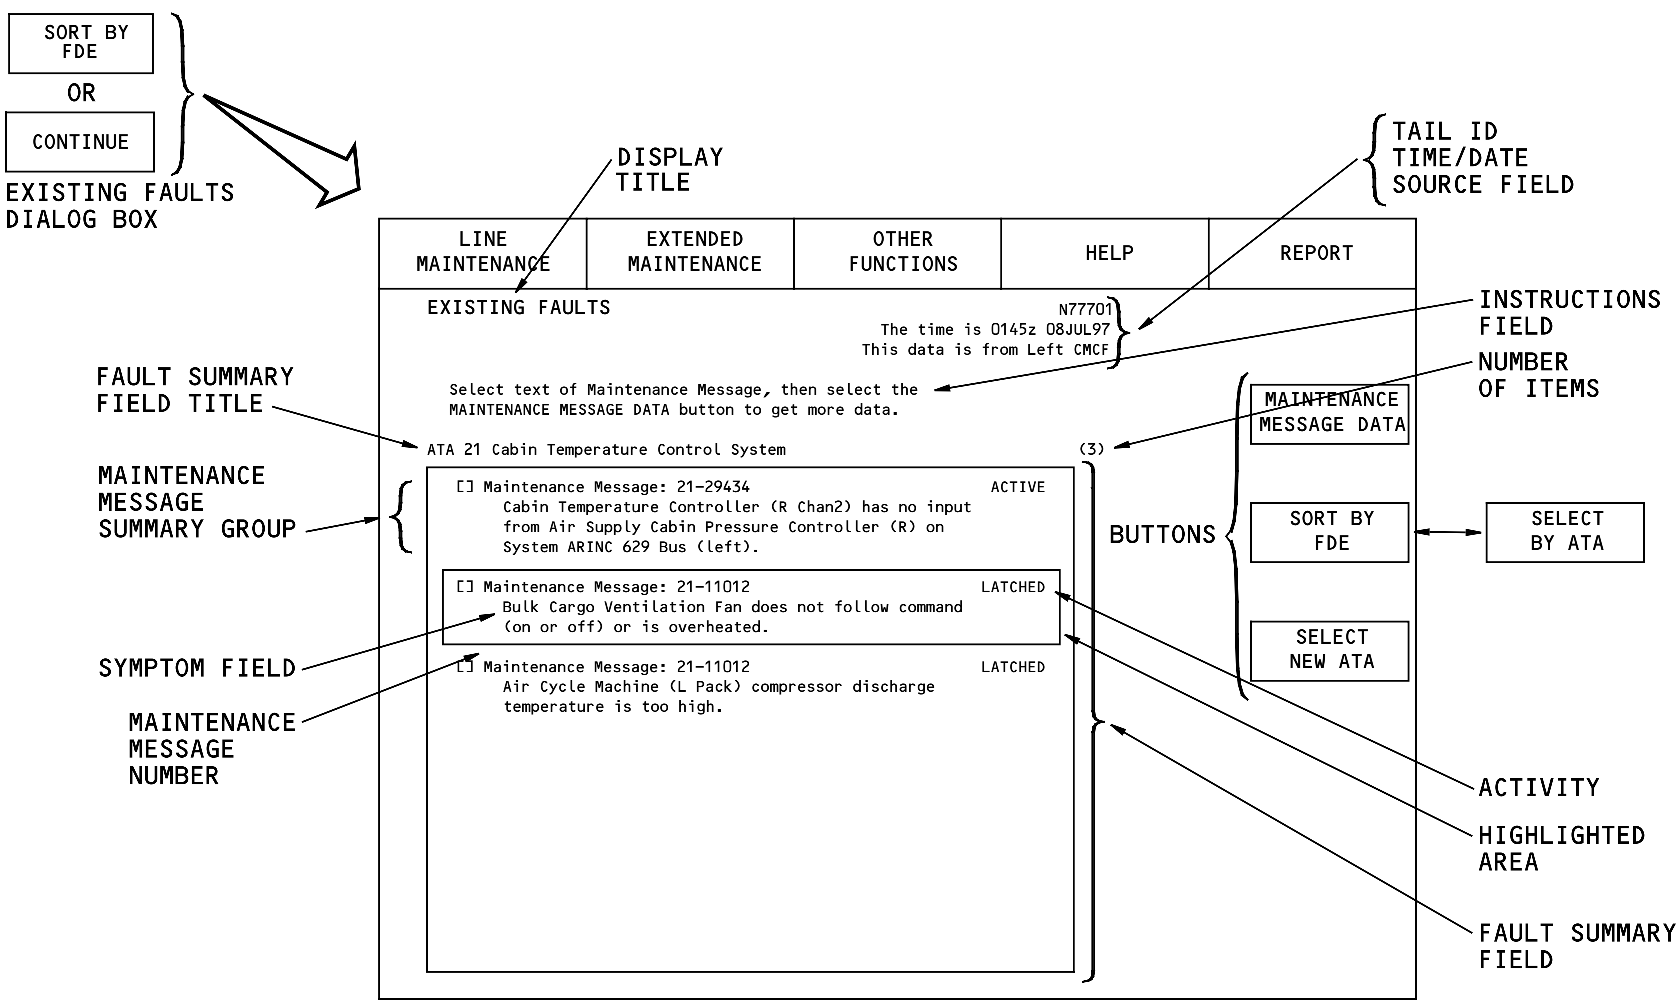
<u>Buttons</u>

Select MAINTENANCE MESSAGE DATA to show the single maintenance message display for the highlighted maintenance message.

Select SELECT BY ATA to show the existing faults dialog box. If the fault summary field shows maintenance message summary groups for a single ATA chapter, then the button shows SORT BY FDE.

Select SORT BY FDE to show all the existing FDE and non-FDE summary groups. If the fault summary field shows FDE and non-FDE summary groups, then the button shows SELECT BY ATA.

Select SELECT NEW ATA to show the existing faults dialog box. The SELECT NEW ATA button shows only if the fault summary field shows maintenance message summary groups for a single ATA chapter.



45-10-00-045 Rev 4 11/06/1997

CMCS - EXISTING FAULTS SUMMARY DISPLAY

CMCS - FAULT HISTORY - ATA DIALOG BOX

General

The fault history-ATA dialog box permits the selection of an ATA chapter that has failures in the CMCF fault history memory. Select an ATA chapter to show the fault summary groups of the failures in the CMCF fault history memory. They show on the fault history summary display.

If there are no failures in the CMCF fault history memory, the selection of FAULT HISTORY on the menu title bar shows the fault history summary display.

The fault history ATA dialog box shows:

- Dialog box title
- Number of items
- List box
- Buttons.

The list box shows all the ATA chapters that have failures in the CMCF fault history memory.

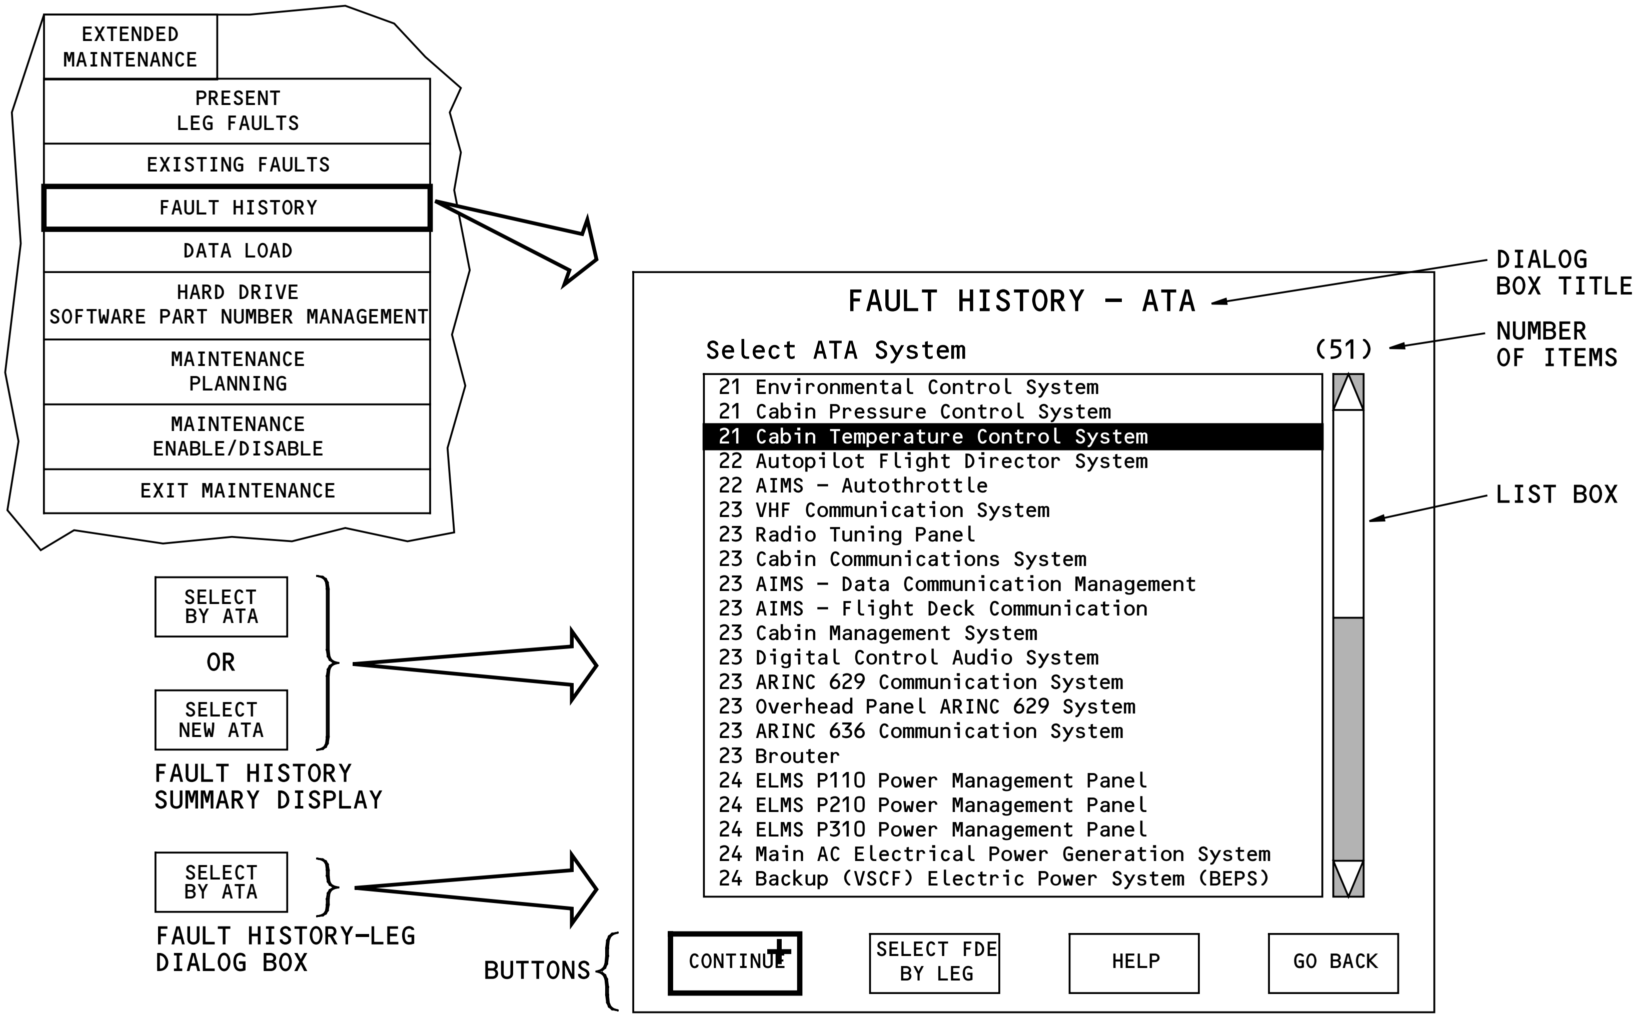
Buttons

Select an ATA system and then select CONTINUE to show the fault summary groups for that ATA system on the fault history summary display.

Select SELECT FDE BY LEG to show the fault history-Leg dialog box.

Select HELP to show the help dialog box for the fault history-ATA dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select the GO BACK button to remove the fault history-ATA dialog box and return to the previous display.



45-10-00-046 Rev 4 11/06/1997

CMCS - FAULT HISTORY - ATA DIALOG BOX

THIS PAGE INTENTIONALLY LEFT BLANK

CMCS - FAULT HISTORY SUMMARY DISPLAY

General

The fault history summary display shows the failures in the CMCF fault history memory. The fault history summary display shows failures for a single ATA chapter or sorted by FDE summary groups for a specific flight leg.

The fault history summary display shows:

- Header information
- Instructions field
- Fault summary field title
- Number of items
- Fault summary field
- Buttons.

Header Information

The header information shows:

- Display title
- Tail identification
- Flight number, only when fault history for a specific flight leg shows
- Leg ID, only when fault history for a specific flight leg shows
- Leg start time, only when fault history for a specific flight leg shows
- Current time and date from the universal time (coordinated) function (UTCF), when fault history does not show a specific flight leg
- CMCF source field.

Fault Summary Field Title

The fault summary field title shows above the fault summary field on the left side. The fault summary title shows:

- Faults recorded during leg NN; shown when fault history for a specific flight leg shows. (NN is the flight leg)
- Fault History for ATA ZZZZZ; shown when the Fault History Summary display shows fault history summary groups for a single ATA chapter. (ZZZZZ is the ATA chapter that has faults)
- Fault History for Maintenance Message XX; shown when fault history for a single maintenance message shows. (XX is the maintenance message number).

Number of Items

The number of items shows above the fault summary field on the right side. The number in the parentheses shows the total number of:

- Fault summary groups, when the fault summary field shows fault summary groups for a single ATA chapter
- FDE summary groups plus one for the non-FDE summary group, when the fault summary field shows FDE and non-FDE summary groups.

CMCS - FAULT HISTORY SUMMARY DISPLAY

Fault Summary Field for a Specific ATA Chapter

The fault summary field shows fault summary groups for a specific ATA chapter. The fault summary groups show all the failures for a specific ATA chapter. The fault summary groups show:

- Maintenance message symptom
- Maintenance message number
- One or more fault occurrence records.

A fault occurrence record shows the leg that had a failure. Each fault occurrence record has a:

- Leg number
- Flight phase
- Time and date
- Hard or intermittent if the CMCS can always monitor for a fault.

Fault Summary Field for a Specific Leg

The fault summary field also shows FDE summary groups and a non-FDE summary group for a specific leg. The FDE summary groups and the non-FDE summary group show all the failures for a specific leg.

A FDE summary group shows the:

- Flight deck effect EICAS message and level
- Flight deck effect activity
- Fault code for the FDE
- Time and date the FDE occurred
- One or more maintenance message summary groups.

A non-FDE summary group shows a description field followed by one or more maintenance message summary groups. The description field shows the text:

- Maintenance Messages which have not been correlated.

A maintenance message summary group shows:

- Maintenance message number
- Maintenance message activity
- Symptom field.

Fault Summary Field for a Single Maintenance Message

The fault summary field also shows the fault summary group for a single maintenance message. Select FAULT HISTORY from the single maintenance message display to show the fault summary group for a single maintenance message.

The fault summary group shows:

- Maintenance message symptom
- Maintenance message number
- One or more fault occurrence records.

A fault occurrence record shows the leg in which a specific failure occurred. Each fault occurrence record has a:

CMCS - FAULT HISTORY SUMMARY DISPLAY

- Leg number
- Flight phase
- Time and date
- Hard or intermittent indication.

Fault Summary Field Control

The fault summary field border highlights when the cursor is in the area of the fault summary field and there is one or more summary groups in the field.

Select the cursor control device switch while the cursor is in the area of the fault summary field to highlight the text of a maintenance message summary group or the text of a FDE summary group header. Selection of a button shows more data for the highlighted maintenance message summary group or the highlighted FDE summary group header.

Select the cursor control device switch while the cursor is in the area of the fault summary field to highlight the text of a fault occurrence record. Selection of a command selection shows more data for the highlighted fault occurrence record.

Buttons

Select GO BACK to close the fault history summary page and return to the single maintenance message display from which FAULT HISTORY was selected. The GO BACK button shows only if the you select the FAULT HISTORY button from the single maintenance message display.

Select MAINTENANCE MESSAGE DATA to show the single maintenance message display for the highlighted maintenance message summary group or the highlighted fault occurrence record.

Select SELECT FDE BY LEG to show the fault history-leg dialog box. The SELECT FDE BY LEG button shows when the fault summary field shows fault summary groups.

Select SELECT BY ATA to show the fault history-ATA dialog box. The SELECT BY ATA button shows when the fault summary field shows FDE summary groups.

Select SELECT NEW ATA to show the fault history-ATA dialog box. The SELECT NEW ATA button shows when the fault summary field shows fault summary groups.

Select SELECT NEW LEG to show the fault history-Leg dialog box. The SELECT NEW LEG button shows when the fault summary field shows FDE summary groups.

Select ERASE BY ATA to show the fault history-erase dialog box.

Select MOVE FAULT HISTORY to show the fault history-move dialog box.

Some of the buttons do not show when the fault history summary page is selected from the FAULT HISTORY button on the single maintenance message page. The buttons that do not show are:

- MAINTENANCE MESSAGE DATA

CMCS - FAULT HISTORY SUMMARY DISPLAY

- SELECT FDE BY LEG
- SELECT BY ATA
- SELECT NEW ATA
- SELECT NEW LEG
- ERASE BY ATA
- MOVE FAULT HISTORY.

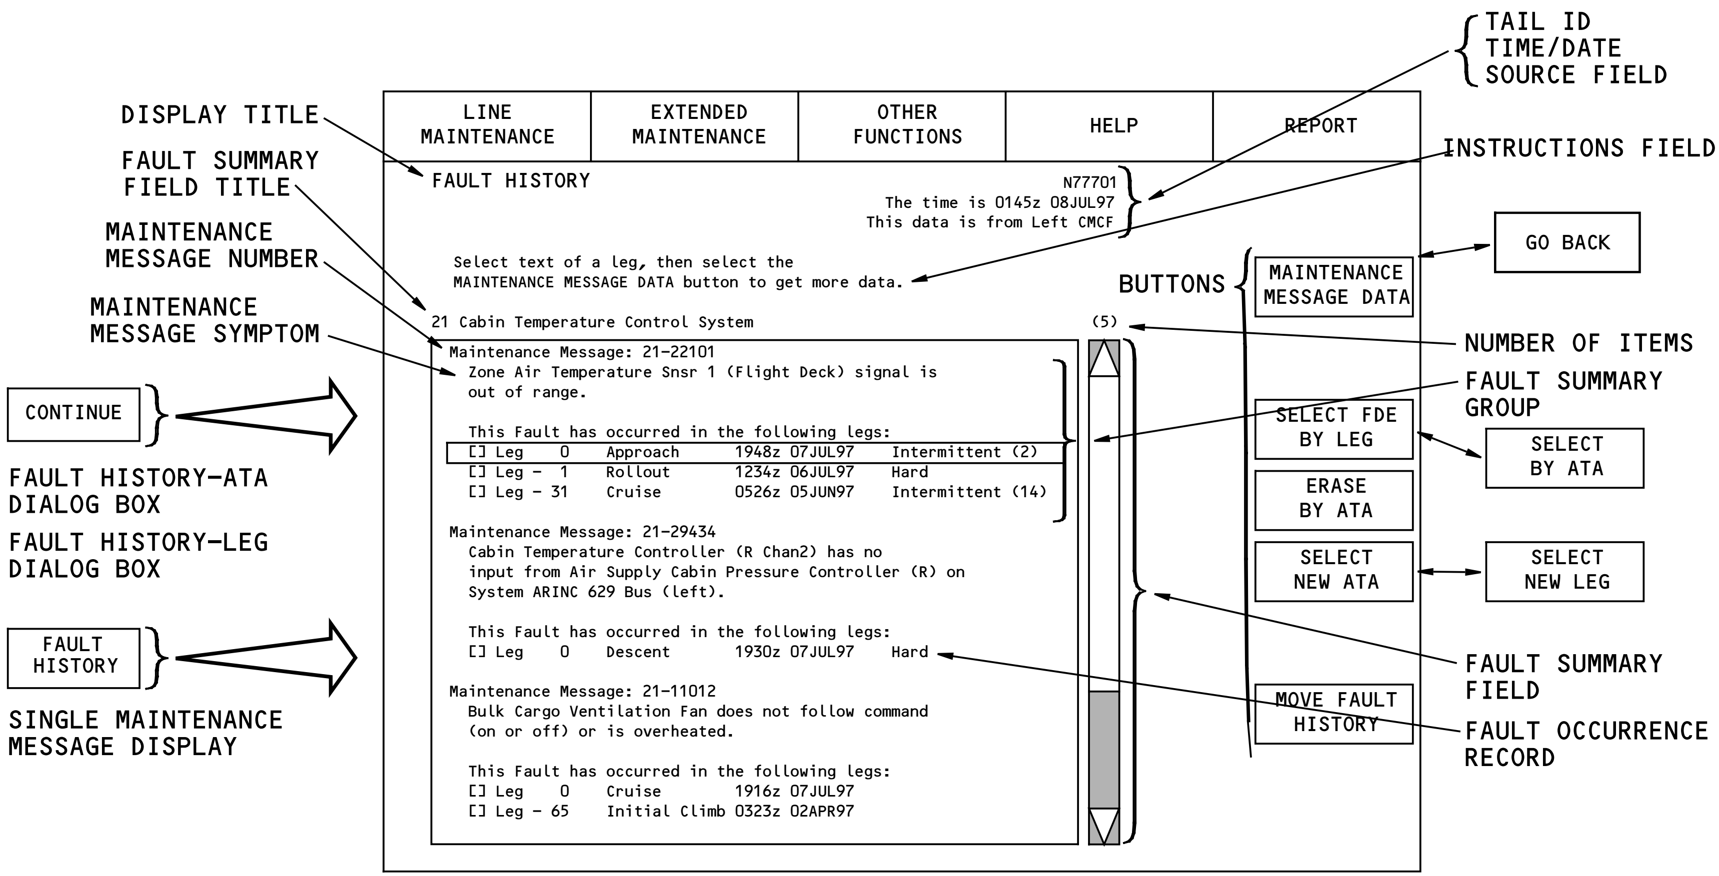
Training Information Point

If a flight leg transition occurs while any fault history display that is sorted by flight leg shows:

- Any open dialog boxes go away
- The fault summary field, if shown, blanks
- A text dialog box shows: Flight Leg has Changed. To See Data from before, Go to Fault History Leg-1.
- Cancel the text dialog box to show the Fault History-Leg dialog box which shows selections based on the new flight leg data.

If a flight leg transition occurs while any fault history display that is sorted by ATA chapter shows:

- Any open dialog box is removed
- The fault summary field, if shown, blanks
- A text dialog box shows: The Flight Leg has Changed. All Flight Leg Numbers are Increased by-1.
- Cancel the text dialog box to show the Fault History-ATA dialog box which shows selections based on the new flight leg data.



45-10-00-047 Rev 7 11/06/1997

CMCS - FAULT HISTORY SUMMARY DISPLAY

CMCS - FAULT HISTORY - LEG DIALOG BOX

General

The fault history-leg dialog box permits the selection of a flight leg that has failures in the CMCF fault history memory. Select a flight leg to show the FDE summary groups and the non-FDE summary group, of the maintenance messages that have failures in the CMCF fault history memory, on the fault history summary display.

The fault history-leg dialog box shows:

- Dialog box title
- Number of items
- List box
- Buttons.

The list box shows all the flight legs that have failures in the CMCF fault history memory.

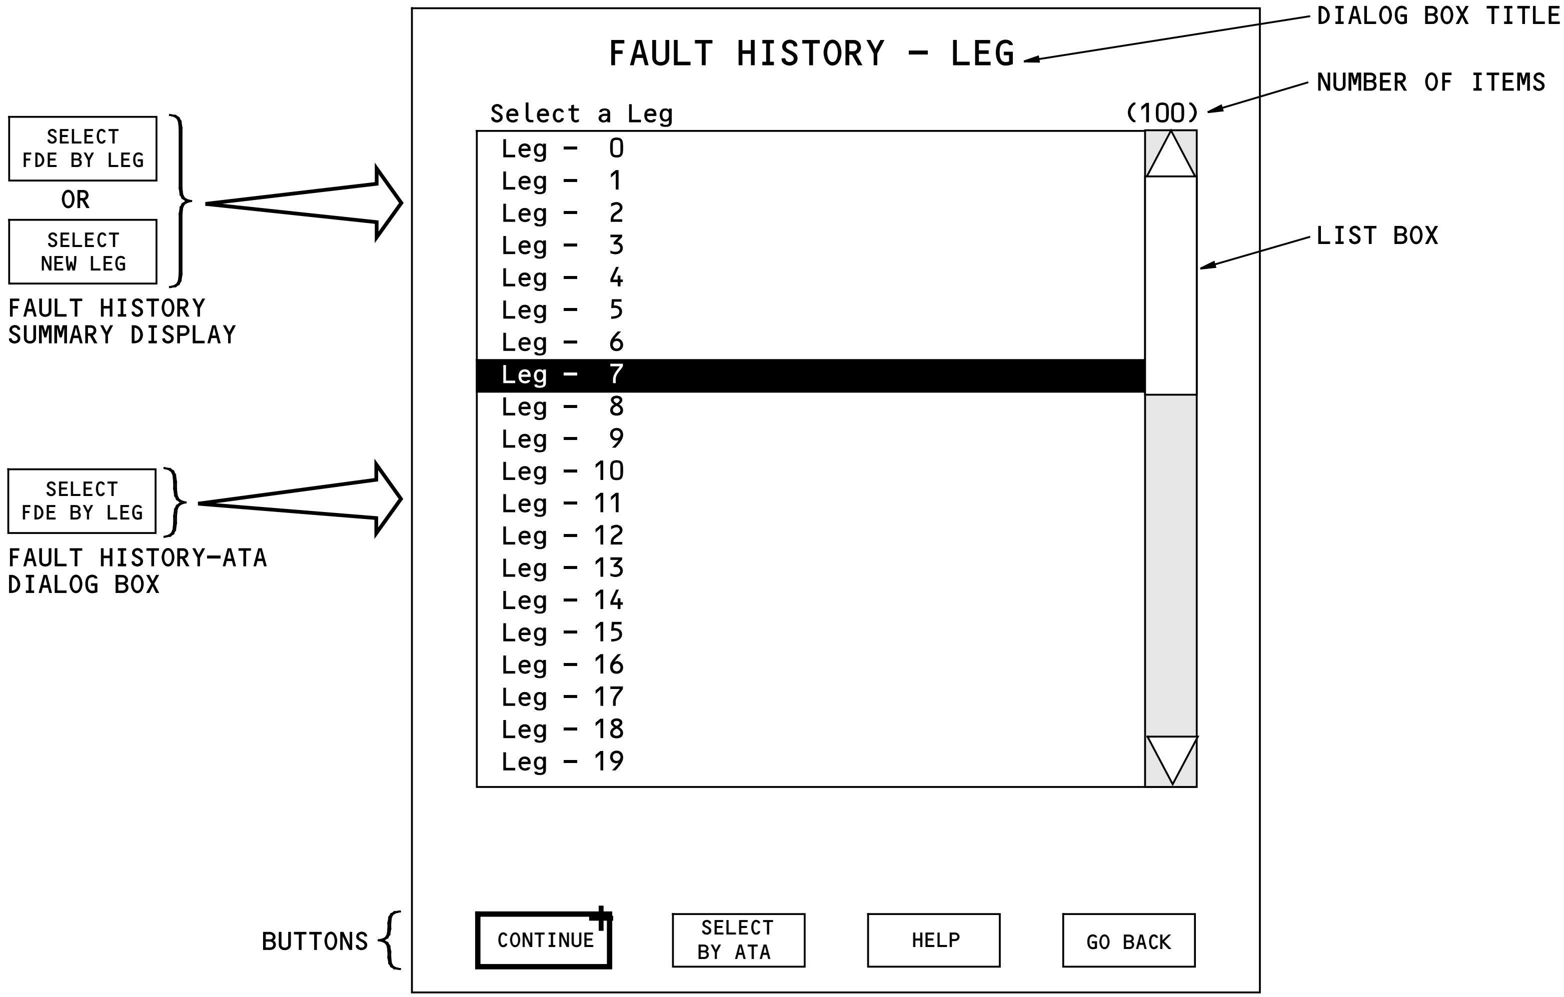
Buttons

Select a flight leg and then select CONTINUE to show the FDE summary groups and the non-FDE summary group for that flight leg on the fault history summary display.

Select SELECT BY ATA to show the fault history-ATA dialog box.

Select HELP to show the help dialog box for the fault history-leg dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to remove the fault history-Leg dialog box and return to the previous display.



45-10-00-048 Rev 2

CMCS - FAULT HISTORY - LEG DIALOG BOX

CMCS - FAULT HISTORY - ERASE DIALOG BOX

General

Fault history erase selections permit the removal of failures from the CMCF fault history memory. Fault history erase selections permit the removal of these:

- All occurrences of a single failure
- All failures for an ATA chapter
- All failures in the CMCF fault history memory.

The fault history-erase dialog box shows these:

- Dialog box title
- Number of items
- List box
- All Fault History selection
- Buttons.

The list box shows all the ATA chapters that have failures in the CMCF fault history memory.

Erase All Occurrences of a Single Failure

Select MAINTENANCE MESSAGE DATA on the fault history summary display to show the single maintenance message display. Select ERASE FAULT on the single maintenance message display to erase all occurrences of the single maintenance message. Then select ERASE on the fault history-erase confirmation dialog box.

Erase All Failures for an ATA Chapter

Use the fault history-erase dialog box to erase all maintenance messages from an ATA chapter. Select an ATA chapter that has failures in the CMCF fault history memory and select ERASE to erase the failures. Then select ERASE on the fault history-erase confirmation dialog box.

Erase All Failures

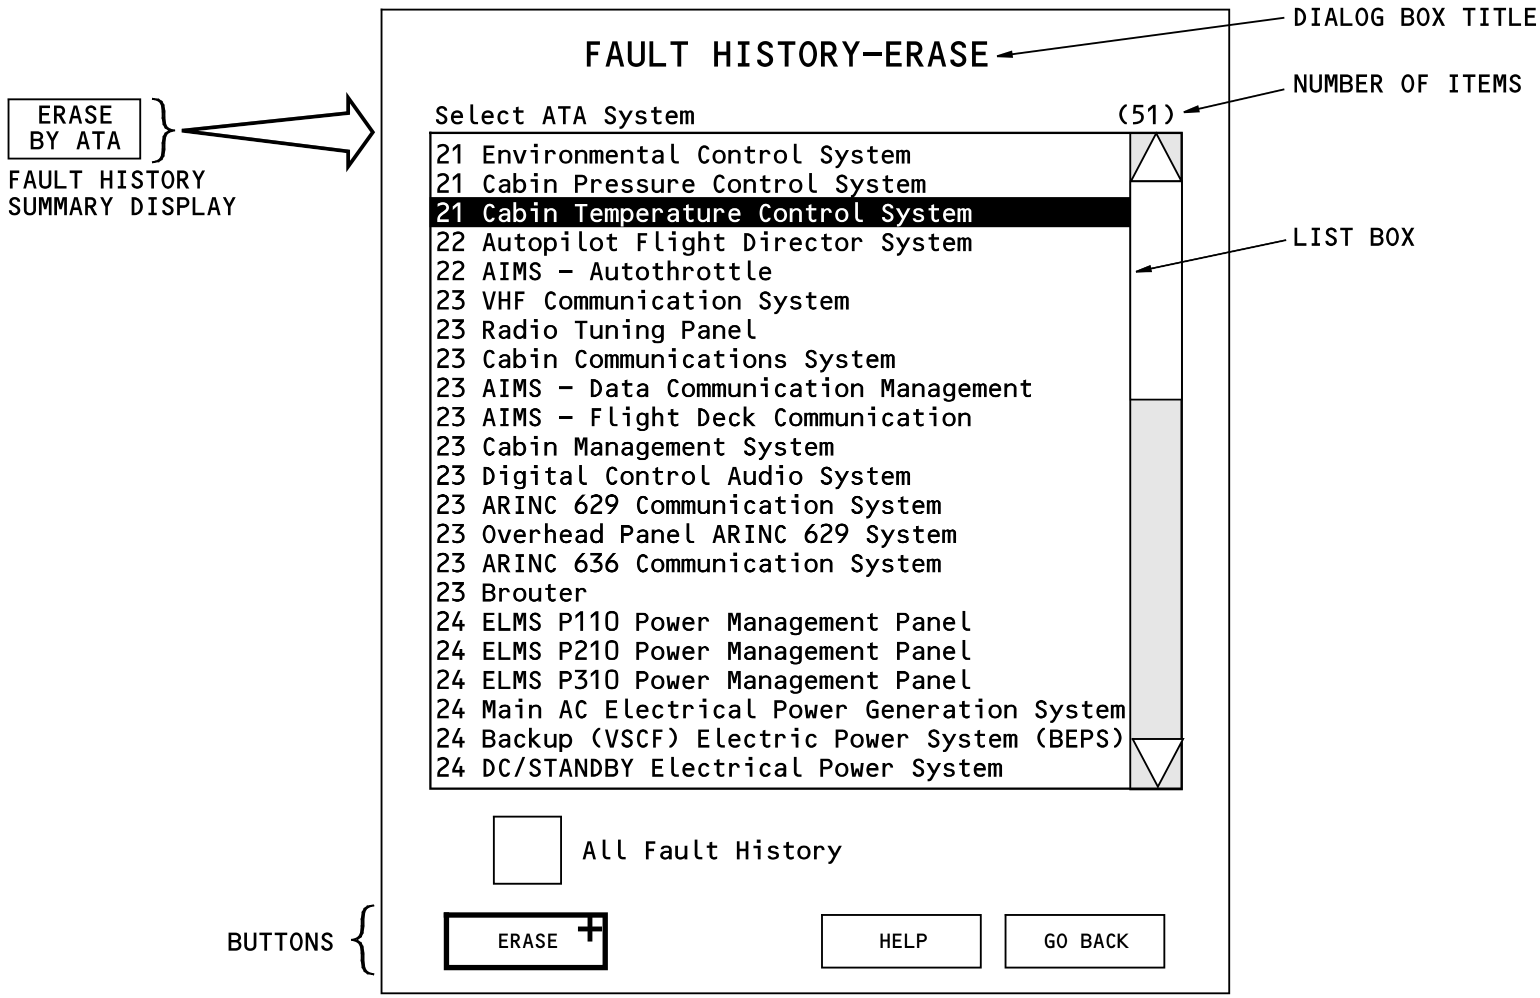
Use the fault history-erase dialog box to erase all maintenance messages in fault history. Select the All Fault History selection to indicate that all maintenances messages in the fault history should be erased. Then select ERASE to show the fault history-erase confirmation dialog box. Then select ERASE on the fault history-erase confirmation dialog box.

Buttons

Select an ATA system and then select ERASE to show the fault history-erase confirmation dialog box.

Select HELP to show the help dialog box for the fault history-erase dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to remove the fault history-erase dialog box and return to the previous display.



45-10-00-049 Rev 3

CMCS - FAULT HISTORY - ERASE DIALOG BOX

CMCS - FAULT HISTORY - ERASE CONFIRMATION DIALOG BOX

General

The fault history-erase confirmation dialog box permits the confirmation or cancellation to erase maintenance messages from fault history.

The text in the fault history-erase confirmation dialog box shows:

- If you select the ERASE button, xx Maintenance Message Occurrences will be erased from the Fault History database. Are you sure that you want to permanently remove these maintenance messages?

XX is the number of maintenance messages that will erase.

Buttons

Select ERASE to remove the maintenance messages from the CMCF fault history memory. The selection of ERASE removes the fault history-erase confirmation dialog box. The selection of ERASE also removes the fault history-erase dialog box. If the fault history-erase confirmation dialog box shows from the single maintenance message display, then the selection of ERASE removes the single maintenance message display, and the fault history summary display shows.

Select HELP to show the help dialog box for the fault history-erase confirmation dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to close the fault history-erase confirmation dialog box and return to the previous display.

CMCS - FAULT HISTORY - ERASE CONFIRMATION DIALOG BOX

CMCS - FAULT HISTORY - MOVE DIALOG BOX

General

The fault history-move dialog box permits an upload of the fault history data from the disk drive. The fault history-move dialog box also permits a download of the fault history data to the disk drive.

The fault history-move dialog box shows:

- Dialog box title
- Exclusive selections
- Buttons.

Training Information Point

Move the fault history data to diskettes before you disconnect the main battery. When there is no other power on the airplane, the hot battery bus provides power to the static random access memory (SRAM) that holds the fault history data.

Exclusive Selections

These are the two exclusive selections:

- Load from Disk Drive
- Report to Disk Drive.

Select Load from Disk Drive and then select CONTINUE to upload a fault history.

Select Report to Disk Drive and then select CONTINUE to download the fault history. Select CONTINUE to remove the fault history-move dialog box.

Buttons

Select HELP to show the help dialog box for the fault history-move dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to close the fault history-move dialog box and return to the previous display.

CMCS - FAULT HISTORY - MOVE DIALOG BOX

CMCS - FAULT HISTORY UPLOAD DIALOG BOXES - 1

THIS PAGE INTENTIONALLY LEFT BLANK

CMCS - FAULT HISTORY UPLOAD DIALOG BOXES - 1

General

The fault history upload procedure permits an upload of a fault history database from a diskette into the selected CMCF. This procedure overwrites the fault history database currently in the CMCF.

Certain dialog boxes show as a normal part of the upload procedure. Other dialog boxes show non-normal conditions and require other steps to complete the upload procedure.

The fault history upload dialog boxes are:

- Text
- In-progress
- Fault history advisory
- Load completion
- Next disk
- Loading error
- Incompatibility.

Each dialog box has these:

- Title
- Message field
- Buttons.

The message field shows messages or directions for each type of dialog box.

There is a maximum of four buttons at the bottom of each dialog box. The buttons may be different for each type of dialog box.

Text Dialog Box

If the tail identification of a diskette is the same as the tail ID of the CMCF fault history database, a text dialog box shows that says If continue is selected, the fault history database will be replaced.

Select CONTINUE to upload the fault history database on the diskette into the selected CMCF.

The selection of CONTINUE on the text dialog box also does these:

- Causes a fault history advisory dialog box to show on the MAT and PMATs that show fault history information, except on the MAT or PMAT that starts the fault history upload procedure
- Causes an in-progress dialog box to show on the MAT or PMAT that starts the fault history upload procedure
- Closes the text dialog box.

Select GO BACK to remove the text dialog box and to show the fault history-move dialog box.

In-Progress Dialog Box

The in-progress dialog box shows the progress of the fault history database upload procedure. The in-progress dialog box shows what percent of the fault history database has been transferred to the CMCF.

Select STOP to end the fault history database upload and to close the in-progress dialog box.

Select HELP to show the help dialog box.

Fault History Advisory Dialog Box

The fault history advisory dialog box shows that the fault history database is about to change on the MAT or PMATS that show fault history information, except on the MAT or PMAT that starts the fault history upload procedure.

Select CONTINUE to show the new summary groups based on the new fault history database.

Select HELP to show the help dialog box for the fault history advisory dialog box. Help text for the dialog box must be in the CMCF AMI for help to show.

Next Disk Dialog Box

The next disk dialog box shows that the part of the fault history database on the diskette in the disk drive was loaded. Remove the diskette and install the diskette with the next part of the fault history database.

Install the next diskette to remove the dialog box.

Select STOP to end the fault history database upload and to close the next disk dialog box.

Load Completion Dialog Box

The load completion dialog box shows that the fault history database upload procedure was successful.

Select CONTINUE to remove the dialog box.

Select HELP to show the help dialog box for the Load Completion dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

CMCS - FAULT HISTORY UPLOAD DIALOG BOXES - 2

General

The fault history upload procedure permits an upload of a fault history database from diskettes into the selected CMCF. This procedure overwrites the fault history database currently in the CMCF.

Certain dialog boxes show as a normal part of the upload procedure. Other dialog boxes show non-normal conditions and require other steps to complete the upload procedure.

The fault history upload dialog boxes are:

- Text dialog box
- In-progress dialog box
- Fault history advisory dialog box
- Load completion dialog box
- Next disk dialog box
- Loading error dialog box
- Incompatibility dialog box.

Each dialog box has these:

- Title
- Message field
- Buttons.

The message field shows messages or directions for each type of dialog box.

There are a maximum of four buttons at the bottom of each dialog box. The selections may be different for each type of dialog box.

Loading Error Dialog Box

If a data transfer error occurs while the fault history database is being uploaded, then the fault history database upload procedure stops and the loading error dialog box shows. The CMCF clears any partially loaded fault history database.

Select STOP to remove the loading error dialog box.

Select HELP to show the help dialog box for the Loading Error dialog box. Help text for the dialog box must be in the CMCF AMI for help to show.

Incompatibility Dialog Box

The fault history database on the diskette does not load into the CMCF and an incompatibility dialog box shows if one of these occurs:

- Tail ID of the database on the diskette is different than the tail ID of the CMCF fault history database
- CMCF cannot read the diskette
- Disk drive is not available.

Select GO BACK to remove the incompatibility dialog box and show the fault history-move dialog box.

CMCS - FAULT HISTORY UPLOAD DIALOG BOXES - 2

Select HELP to show the help dialog box for the Incompatibility dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

CMCS - FAULT HISTORY UPLOAD DIALOG BOXES - 2

CMCS - FAULT HISTORY DOWNLOAD DIALOG BOXES - 1

General

The fault history download procedure permits the transfer of the CMCF fault history to diskettes.

Certain dialog boxes show as a normal part of the download procedure. Other dialog boxes show non-normal conditions and show other steps to complete the download procedure.

These are the fault history download dialog boxes:

- Download in-progress dialog box
- Download completion dialog box
- Download interference dialog boxes
- Downloading error dialog box.

Each dialog box has these:

- Title
- Message field
- Buttons.

The message field shows messages or directions for each type of dialog box.

There is a maximum of four buttons at the bottom of each dialog box. The selections may be different for each type of dialog box.

Download In-Progress Dialog Box

The download in-progress dialog box shows the progress of the fault history database download procedure. The download in-progress dialog box shows what percent of the CMCF fault history database has been transferred to the diskette.

Select STOP to end the CMCF fault history database download procedure and to remove the download in-progress dialog box.

Select HELP to show the help dialog box for the Download In-Progress. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Download Completion Dialog Box

The download completion dialog box shows that the fault history database download procedure successfully completed.

Select CONTINUE to remove the download completion dialog box.

Select HELP to show the help dialog box for the download completion dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

CMCS - FAULT HISTORY DOWNLOAD DIALOG BOXES - 1

CMCS - FAULT HISTORY DOWNLOAD DIALOG BOXES - 2

General

The fault history download procedure lets the transfer of the CMCF fault history to diskettes.

Certain dialog boxes show as a normal part of the download procedure. Other dialog boxes show non-normal conditions and show other steps to complete the download procedure.

These are the fault history download dialog boxes:

- Download in-progress dialog box
- Download completion dialog box
- Download interference dialog boxes
- Downloading error dialog box.

Each dialog box has these:

- Title
- Message field
- Buttons.

The message field shows messages or directions for each type of dialog box.

There are a maximum of four buttons at the bottom of each dialog box. The selections may be different for each type of dialog box.

Download Interference Dialog Boxes

The download interference dialog boxes show that the CMCF fault history database cannot be transferred to a disk. A download interference dialog box shows if the:

- Disk drive is not available
- Disk drive does not have a diskette in it
- Diskette is write protected
- Diskette does not have sufficient memory space or runs out of memory space.

Select GO BACK to remove the download interference dialog box and show the Fault History-Move dialog box.

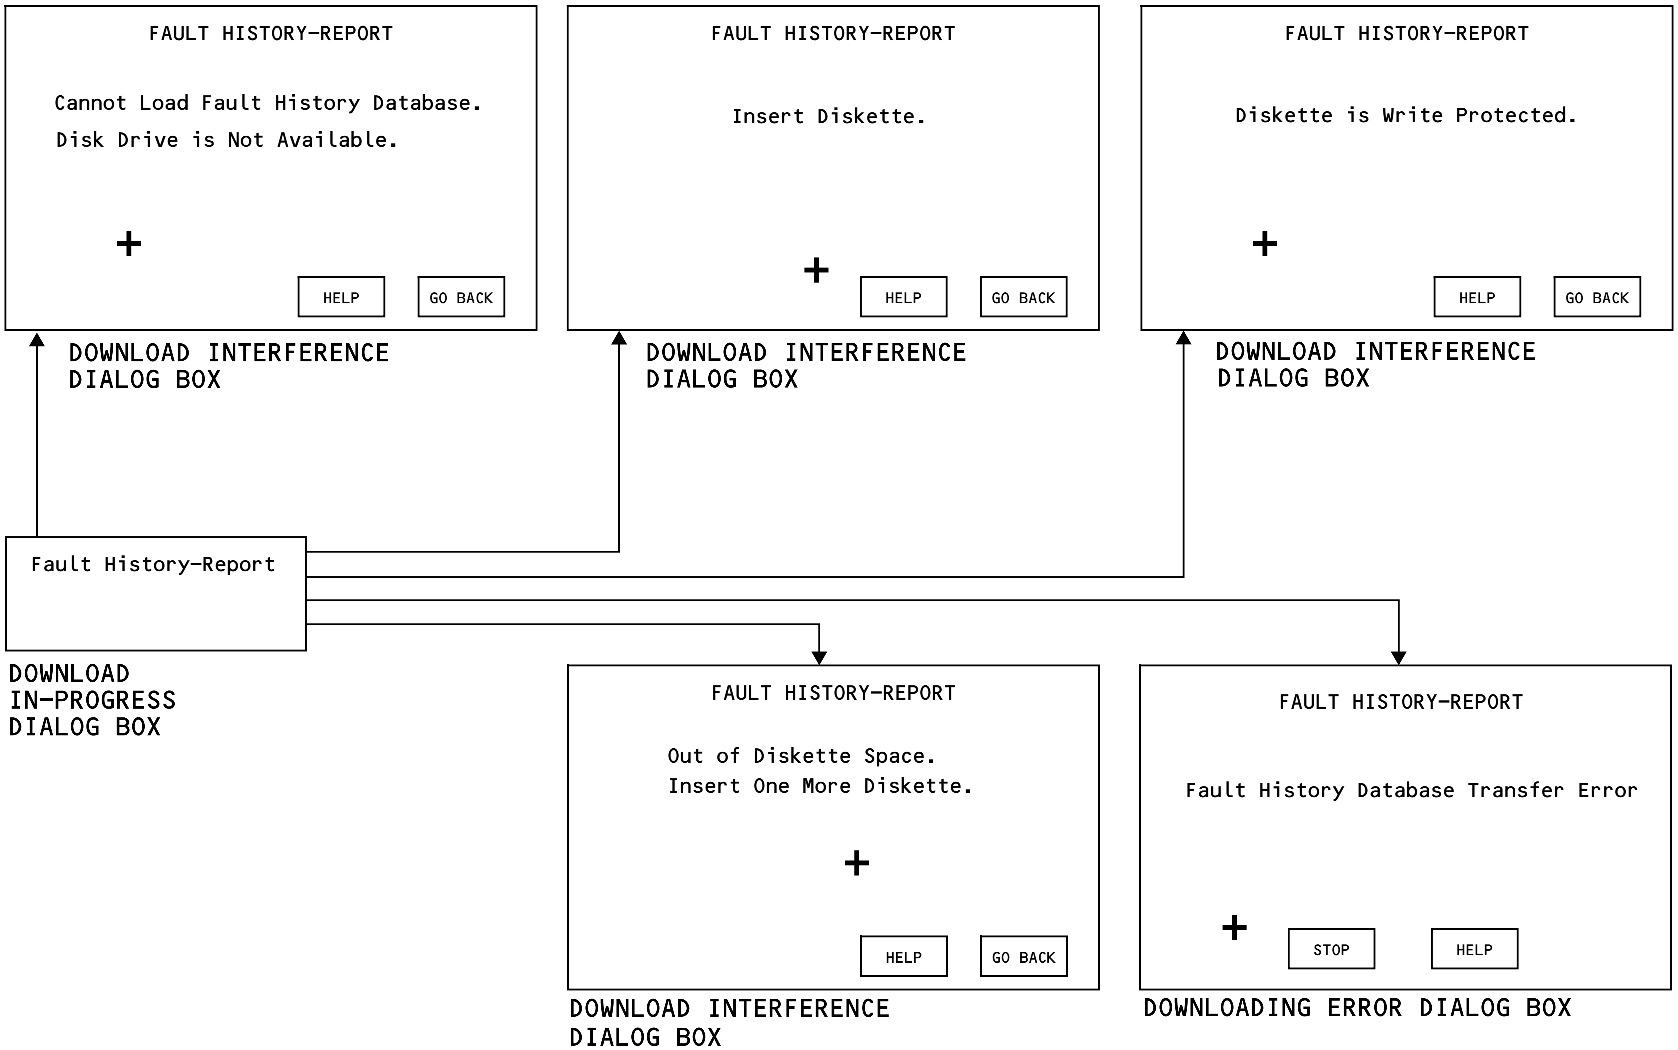
Select HELP to show the help dialog box for the download interference dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Downloading Error Dialog Box

If a data transfer error occurs while the CMCF fault history database is being downloaded, then the CMCF fault history database download procedure stops and the downloading error dialog box shows.

Select STOP to remove the downloading error dialog box.

Select HELP to show the help dialog box for the Downloading Error dialog box Help text for the dialog box must be in the CMCF AMI for HELP to show.



45-10-00-055 Rev 1

CMCS - FAULT HISTORY DOWNLOAD DIALOG BOXES - 2

CMCS - DATA LOAD MAIN DISPLAY

General

The data load main display format lets you start and monitor the data load process.

The data load main display shows this information:

- Header data
- Source indication field
- Destination indication field
- Data load Status field
- System configuration list box
- Buttons.

Header Data

The header data includes the:

- Title
- Tail ID
- Time field.

The tail ID field has the airplane tail ID.

The time field shows the current time in UTC. The format is: DDMMMYY HHMMz.

Source Indication Field

The source indication field has two labels and two data fields.

The first label is Data Source. The associated data field shows the data source from the source selection dialog box.

The other label is Load Part Number. The related data field shows the load part number from the source selection dialog box.

With no selection, the labels and data fields are blank.

Destination Indication Field

The destination indication field has one label and one data field.

The label is Data Destination. The associated data field shows the LRU/LRM identifier from the destination selection dialog box.

With no selection, the label and data field is blank.

Data Load Status Field

The data load status field is a message field.

The message field shows the status of the data load process. The message field shows these messages:

- Select the SOURCE or the DESTINATION
- Select the DESTINATION
- Select the SOURCE.

CMCS - DATA LOAD MAIN DISPLAY

- The data loader is prepared for operation. Select START.
- The data load is in progress.
- The data load is stopped.
- The data load is complete.

Select the DESTINATION shows when both the source indication and destination data fields are blank.

Select the SOURCE shows when the source indication and data field is blank.

When the data load process is ready to start, this shows:

- The data loader is prepared for operation. Select START.

When data transfer starts between the CMCF and the destination LRU/LRM, this shows:

- The data load is in progress.

When the data load process stops, this shows:

- The data load is stopped.

When the data load process is successful, this shows:

- The data load is complete. Select another source or another destination.

System Configuration List Box

The system configuration list box and box title shows information based on the system selection on the destination selection dialog box. The box shows:

- LRU/LRM identifier
- Hardware part number
- LRU serial number
- Software part number(s).

When the destination indication field is empty, the system configuration list box is empty.

Buttons

These are the three buttons that show on the data load main display:

- SELECT SOURCE
- SELECT DESTINATION
- START.

SELECT SOURCE shows next to the source indication field.

Select SELECT SOURCE to show the source selection dialog box.

The selection is not available during the data load process.

CMCS - DATA LOAD MAIN DISPLAY

SELECT DESTINATION shows next to the destination indication data field.

Select SELECT DESTINATION to show the destination selection dialog box.

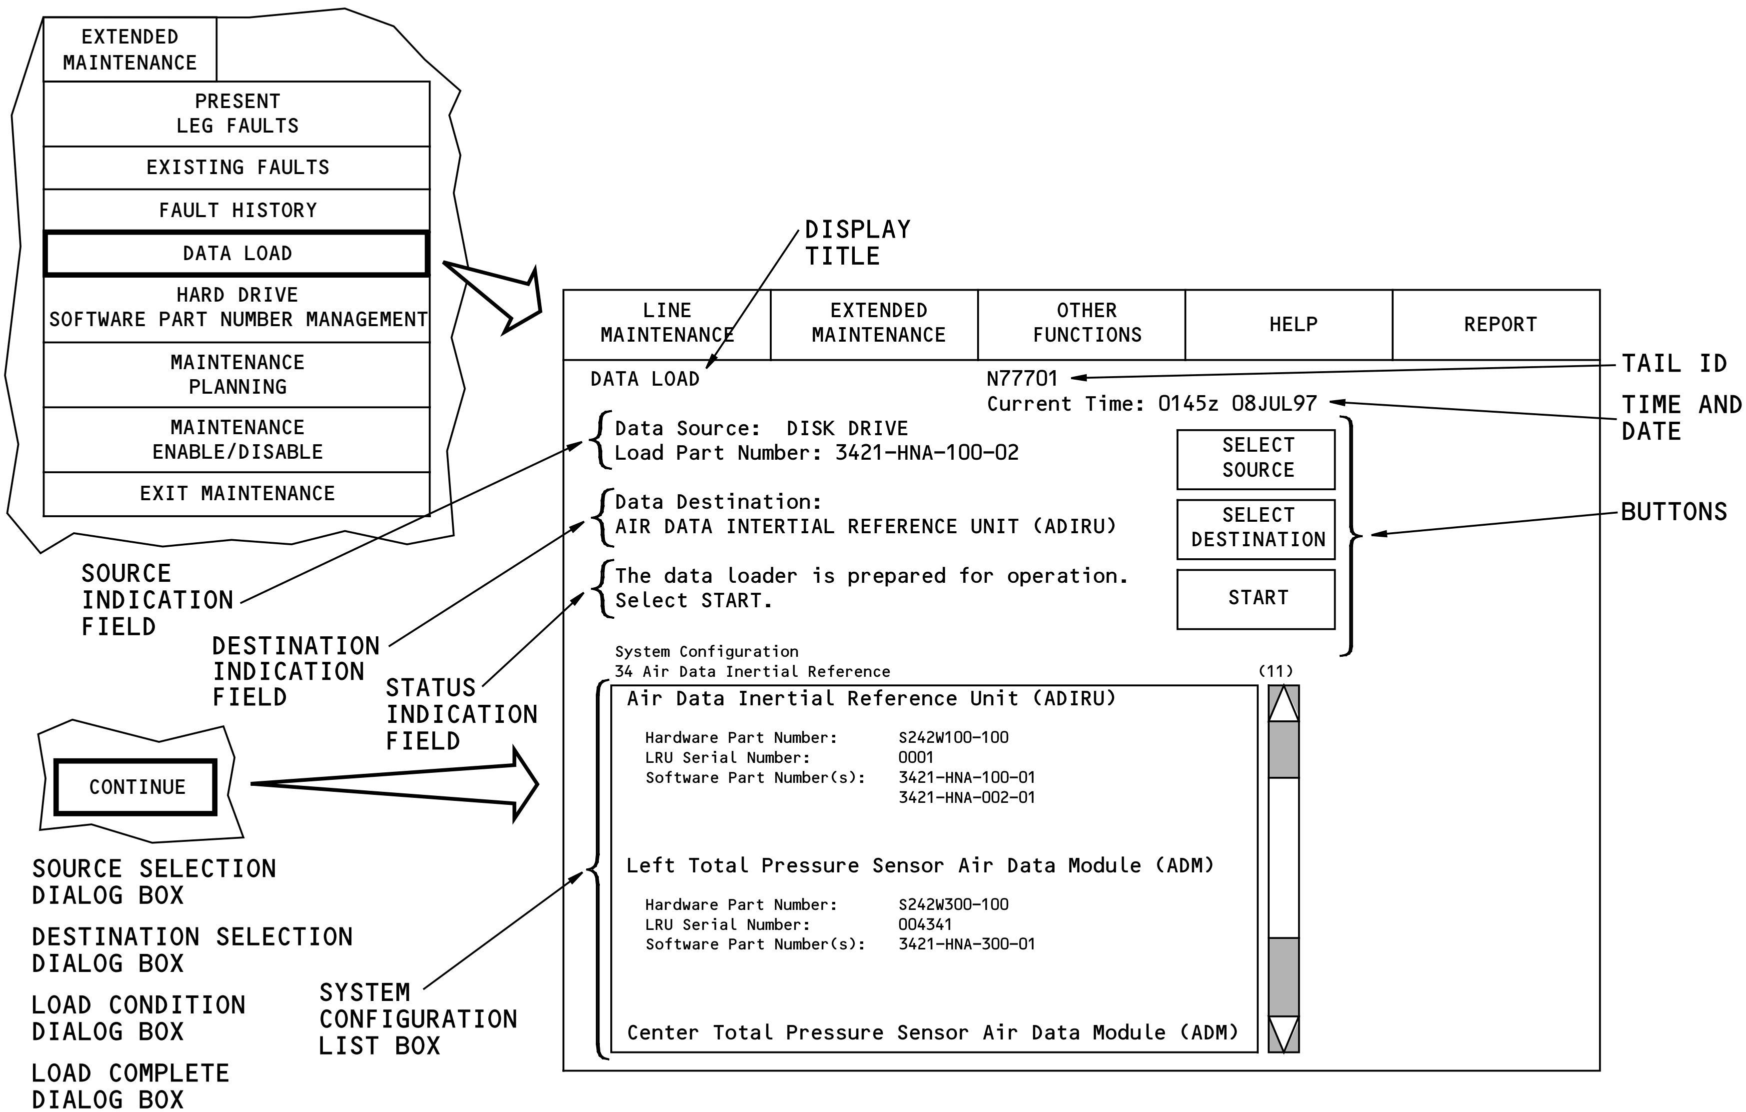
The selection is not available during the data load process.

START shows next to the data load status field.

Select START to begin the data load process.

At initial power-up, the START selection is not available. The START selection becomes available when this load status indication shows:

- The data loader is prepared for operation. Select START.



45-10-00-056 Rev 3 11/06/1997

CMCS - DATA LOAD MAIN DISPLAY

CMCS - DATA LOAD SOURCE SELECTION DIALOG BOX

THIS PAGE INTENTIONALLY LEFT BLANK

CMCS - DATA LOAD SOURCE SELECTION DIALOG BOX

General

The source selection dialog box lets you select a specific data source and a load part number for software data loading.

The source selection dialog box shows:

- Title
- Source selection list box
- Load part number list box
- Buttons.

Title

The first line of the title always shows DATA LOAD. The second line of the title shows Set Source.

Source Selection List Box

The title of the source selection list box is Select the Data Source.

The source selection list box shows the list of sources for the software. The source is one of these:

- MAT hard drive
- MAT disk drive
- PMAT disk drive.

Select the source first. Data does not show in the load part number list box until a selection is made.

The selection of a source causes that source to show on the data load main display in the source indication field.

Load Part Number List Box

The title of the load part number list box is Select the Load Part Number.

The load part number list box shows the list of software part numbers as they appear in the directory of the source.

If the source does not have any valid software numbers, the message No Software Load Part Numbers shows.

The list shows all software part numbers in the source or software for a specified LRU/LRM.

Buttons

The buttons that show at the bottom of the dialog box are:

- CONTINUE
- HELP
- SHOW MORE DATA/SHOW LESS DATA
- GO BACK.

CONTINUE is not available for selection until you make a selection for both a source and a software part number.

CMCS - DATA LOAD SOURCE SELECTION DIALOG BOX

Select CONTINUE to:

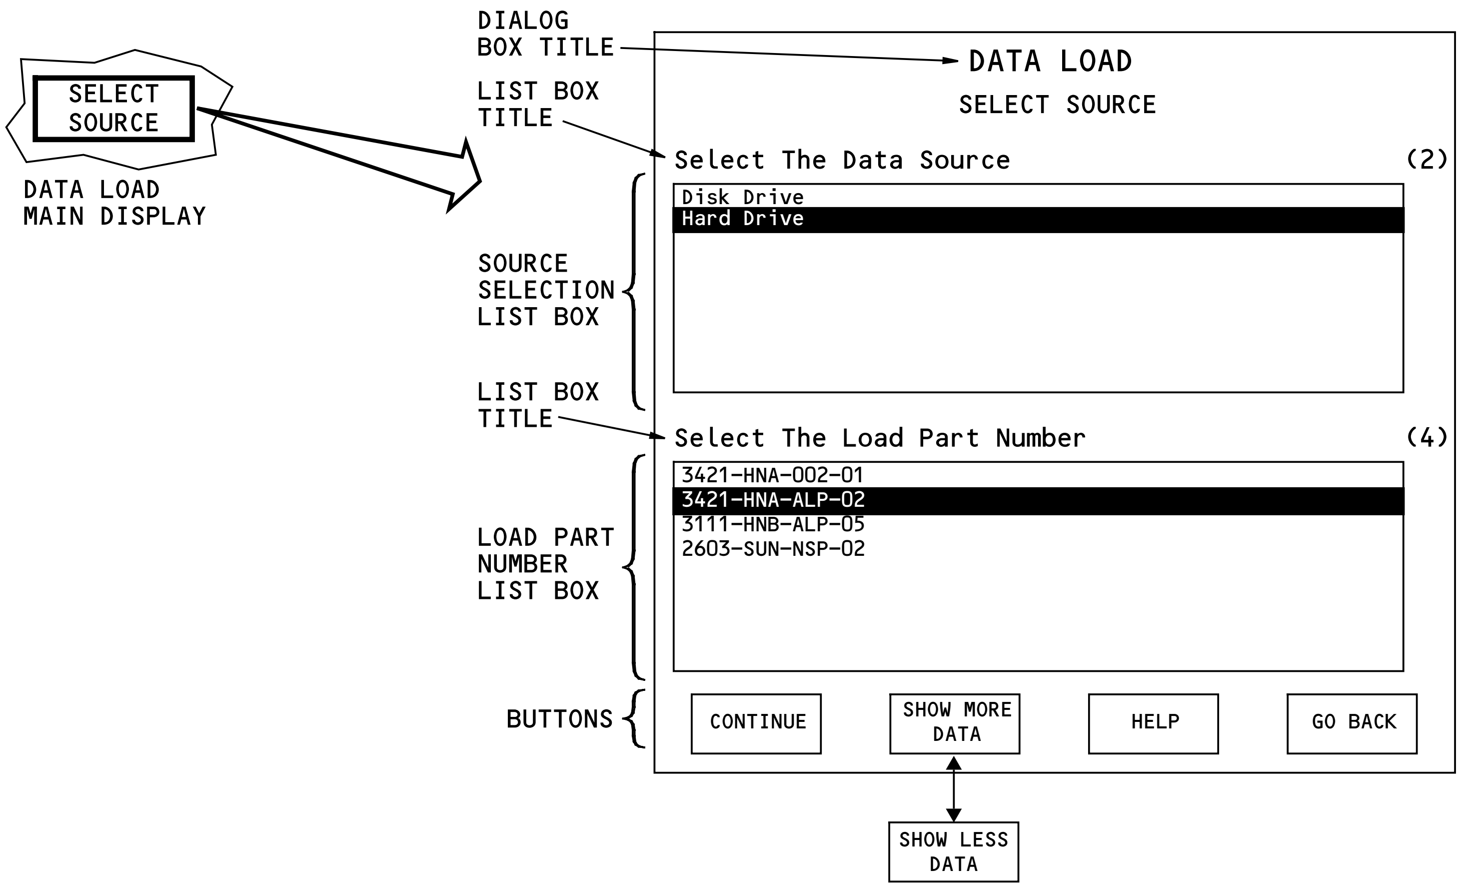
- Choose the source
- Choose the software part number
- Close the dialog box and return the user to the data load main display.

Select HELP to show the help dialog box for the source selection dialog box. Help text for the dialog box must exist in the CMCF AMI for HELP to show.

SHOW MORE DATA/SHOW LESS DATA are toggles. When the user chooses either a source or a destination, SHOW MORE DATA becomes available and a limit is applied to the destination selections and the software part number selections. This limits the number of possible choices to those choices that are compatible with the selected software or those choices that are compatible with the selected ATA and LRU.

Select SHOW MORE DATA to remove the limit. This selection causes all possible destination choices and software choices to show. The command selection toggles to SHOW LESS DATA.

Select GO BACK to remove the dialog box and return to the data load main display. The GO BACK selection does not affect any source selections already made.



45-10-00-057 Rev 4 11/06/1997

CMCS - DATA LOAD SOURCE SELECTION DIALOG BOX

CMCS - DATA LOAD DESTINATION SELECTION DIALOG BOX

THIS PAGE INTENTIONALLY LEFT BLANK

CMCS - DATA LOAD DESTINATION SELECTION DIALOG BOX

General

The destination selection dialog box lets you select a specific destination for software data loading.

The destination selection dialog box shows this:

- Title
- System selection list box
- LRU/LRM selection list box
- Buttons.

Title

The first line of the title always shows DATA LOAD. The second line of the title always shows Set Destination.

System Selection List Box

The title of the system selection list box is Select the ATA System.

The system selection list box shows the list of ATA system choices. The number of choices depends on the state of the SHOW MORE DATA/SHOW LESS DATA command selection.

Select the system first. The selected system becomes the title of the LRU/LRM selection list box.

If only one choice is available, that selection is automatically made.

LRU/LRM Selection List Box

The LRU/LRM selection list box shows the list of identifiers based on the ATA system selection.

The number of choices depends on the state of the SHOW MORE DATA/SHOW LESS DATA command selection.

If no ATA system choice is made, the list box is blank.

Buttons

These are the buttons that show at the bottom of the dialog box:

- CONTINUE
- HELP
- SHOW MORE DATA/SHOW LESS DATA
- GO BACK.

If you go to the destination selection dialog box before you select the source, CONTINUE is available for selection when the selection for both a system and a LRU/LRM is made.

Select CONTINUE to do this:

- Choose the destination
- Close the dialog box and return the user to the data load main display.

If you go to the destination selection dialog box after the source selection dialog box and a source selection

CMCS - DATA LOAD DESTINATION SELECTION DIALOG BOX

and a software part number selection is made, then the CONTINUE button is available.

The CONTINUE button does this:

- Chooses the ATA system
- Chooses the LRU for data load
- Closes the dialog box and returns the user to the data load main display.

Select HELP to show the help dialog box for the destination selection dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

SHOW MORE DATA/SHOW LESS DATA are toggles. When you choose either a source or a destination, SHOW MORE DATA becomes available and a limit is applied to the destination selections and the software part number selections. This limits the number of possible choices to those choices that are compatible with the selected software or those choices that are compatible with the selected ATA and LRU/LRM.

Select SHOW MORE DATA to remove the limit. This selection causes all possible destination choices and software choices to show. The command selection toggles to SHOW LESS DATA.

Select GO BACK to remove the dialog box and return to the data load main display. The GO BACK selection does not affect any destination selections already made.

45-10-00-059 Rev 1

CMCS - DATA LOAD MESSAGE DIALOG BOXES - 1

General

Message dialog boxes show as overlays on the data load main display. The dialog boxes are in a position that lets the source indication field and the destination indication field show.

Certain message dialog boxes show as a normal part of the data load process. Other message dialog boxes show non-normal conditions and require user involvement to complete the data load process.

Each dialog box has:

- Title
- Message field
- Buttons.

The title of each message dialog box changes to indicate the purpose of the dialog box.

The message field shows messages or directions for each type of dialog box. If the message exceeds the size of the dialog box, a scroll bar shows to allow the user to access the entire text field.

There is a maximum of four buttons at the bottom of each dialog box. The buttons may be different for each type of dialog box.

The types of message dialog boxes are:

- Load condition
- Destination LRU not enabled
- Change diskette
- Wrong diskette in disk drive
- Diskette access error
- Load in progress activity indication
- Destination LRU incompatibility
- Data transfer error
- Data storage error
- Data transfer completion
- Data load completion and configuration verification
- Are you sure?
- Data load function not enabled
- Check disk
- Data load function already in use
- Switch source CMCF
- Data loader not working.

Load Condition Dialog Box

The load condition dialog box gives indications of conditions that have to exist in member systems before the load process can begin.

The message shows:

- Put the airplane in this configuration

It is followed by specific instructions that relate to the LRU/LRM.

The buttons are:

CMCS - DATA LOAD MESSAGE DIALOG BOXES - 1

- CONTINUE
- REPORT DATA
- HELP
- GO BACK.

Select CONTINUE to close the dialog box and return to the data load main display.

Select REPORT DATA to show the report dialog box. This enables the user to get a hard copy of the dialog box.

Select HELP to show the help dialog box for the Load Condition dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to close the dialog box and return to the previous display.

<u>Destination LRU Not Enabled Dialog Box</u>

The destination LRU not enabled dialog box shows when the destination LRU/LRM is not available or when the CMCF cannot communicate with the destination LRU/LRM.

The message shows:

- The destination LRU cannot receive the data load.

The message also shows:

- The airplane configuration is not correct; or
- No signal came back from the destination LRU.

The buttons are:

- HELP
- GO BACK.

Select HELP to show the help dialog box for the destination LRU not available dialog box. Help must exist in the CMCF AMI for the HELP selection to show.

Select GO BACK to close the dialog box and return to the previous display.

<u>Change Diskette Dialog Box</u>

The change diskette dialog box instructs the user to insert a specific disk into the disk drive.

The message shows:

- Change the disk.

The message also shows:

- Put disk sequence number x of disk set number NNNNNNNNNNNNNNN into the disk drive.

The letter x stands for the specific disk sequence number of the disk set and NNNNNNNNNNNNNNN is the 15 character disk set part number.

The buttons are:

- STOP

CMCS - DATA LOAD MESSAGE DIALOG BOXES - 1

- HELP
- GO BACK.

Select STOP to end the data load process, close the dialog box and return to the data load main display.

The STOP selection is only available during data transfer.

Select HELP to show the help dialog box for the Change Diskette dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to close the dialog box and return to the previous display.

GO BACK is not available for selection during data transfer.

Wrong Diskette in Disk Drive Dialog Box

The wrong diskette in disk drive dialog box shows after the change diskette dialog box when the user inserts the wrong disk in the disk drive.

The message field shows:

- The incorrect disk in the disk drive.

The message also shows:

- Put disk sequence number x of disk set number NNNNNNNNNNNNNNN into the disk drive.

The letter x stands for the specific disk sequence number of the disk set and NNNNNNNNNNNNNNN is the 15 character disk set part number.

The buttons are:

- STOP
- HELP
- GO BACK.

Select STOP to end the data load process, close the dialog box and return to the data load main display.

The STOP selection is only available during data transfer.

Select HELP to show the help dialog box for the Wrong Diskette in disk drive dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to close the dialog box and return to the previous display.

GO BACK is not available for selection during data transfer.

Diskette Access Error Dialog Box

The diskette access error dialog box tells you that the CMCF is not receiving data from the disk drive.

The message shows:

CMCS - DATA LOAD MESSAGE DIALOG BOXES - 1

- The data loader cannot read the disk drive.
- If there is no disk in the disk drive, you must put the disk in the disk drive.
- If there is a disk in the disk drive, you must make sure it is put in the disk drive correctly, and the disk must have a valid load part number.

The command selections are:

- STOP
- HELP
- GO BACK.

Select STOP to end the data load process, close the dialog box and return to the data load main display.

The STOP selection is only available during data transfer.

Select HELP to show the help dialog box for the diskette access error dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to close the dialog box and return to the previous display.

GO BACK is not available for selection during data transfer.

Load in Progress Activity Indication Dialog Box

The Load In Progress Activity Indication dialog box shows the of the data load transfer process.

The message field shows:

- Load in Progress
- Wait...
- The percent of data that has transferred.

The buttons are:

- STOP
- HELP.

Select STOP to end the data load process, close the dialog box and return to the data load main display.

Select HELP to show the help dialog box for the load in progress activity indication dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

CMCS - DATA LOAD MESSAGE DIALOG BOXES - 2

Destination LRU Incompatibility Dialog Box

The destination LRU incompatibility dialog box shows when the destination LRU/LRM detects an incompatibility with the current data load. The text also shows the override capabilities for the incompatibility.

If the destination does not allow the software load, but can be overwritten, this message shows:

- The destination LRU does not allow this load part number, but you may continue.

If the destination does not allow the software load, and can not be overwritten, this message shows:

- The destination LRU does not allow this load part number.

If the LRU tells the CMCF the software is not compatible with other software loaded in the LRU, the message shows:

- The load part number is not compatible with the software of the destination LRU.

If the LRU tells the CMCF the software is not compatible with other LRU software in the system, the message shows:

- The load part number is not compatible with software loaded in the other LRUs in this system.

If the LRU tells the CMCF the software is not compatible with LRU, the message shows:

- The load part number is not compatible with the hardware of the destination LRU.

If the LRU tells the CMCF the software is not compatible with airplane, the message shows:

- The load part number is not compatible with the airplane.

The buttons are:

- OVERRIDE
- STOP
- HELP

The OVERRIDE selection shows if an override capability exists. Select OVERRIDE to continue the load process.

Select STOP to end the data load process, close the dialog box and return to the data load main display.

Select HELP to show the help dialog box for the destination LRU incompatibility dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Data Transfer Error Dialog Box

The data transfer error dialog box shows when the load transfer process ends because of a data transfer error.

CMCS - DATA LOAD MESSAGE DIALOG BOXES - 2

The message field shows:

- The data load stopped.
- The signal became incorrect.
- Usually, the destination LRU cannot operate.

The buttons show:

- STOP
- HELP.

Select STOP to close the dialog box and return to the data load main display.

Select HELP to show the help dialog box for the data transfer error dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Data Storage Error Dialog Box

The data storage error dialog box shows when the destination LRU/LRM cannot validate the data load.

The message field shows:

- The destination cannot make sure the new load part number is loaded correctly.
- If this is the first time that the data load has stopped, select TRY AGAIN.
- If this is the second time the data load has stopped, select CHECK DISK. The select TRY AGAIN if the load part number is good.

The command selections are:

- TRY AGAIN
- STOP
- HELP
- CHECK DISK.

Select TRY AGAIN to start the full load process for the same source and destination selections.

Select STOP to close the dialog box and return to the data load main display.

Select HELP to show the help dialog box for the data storage error dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select CHECK DISK to start the disk validation procedure.

Data Transfer Completion Dialog Box

The data transfer completion dialog box shows that the transfer of data is complete for the current load process.

The message field shows:

- Wait for the destination LRU to start.
- If you wait more than fifteen minutes, select STOP.

The buttons are:

CMCS - DATA LOAD MESSAGE DIALOG BOXES - 2

- STOP
- HELP.

Initially, the STOP selection does not show. The STOP selection shows if the destination LRU/LRM does not respond within ten minutes.

Select STOP to close the dialog box and return to the data load main display.

Select HELP to show the help dialog box for the data transfer completion dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Data Load Completion and Configuration Verification

The data load completion and configuration verification dialog box shows that the load process is complete and successful.

The message field has several items. These items are:

- The data load is complete. The current LRU configuration is shown below.
- LRU Part Number:
- Hardware Part Number:
- Serial Number:

If necessary, a scroll bar may show to enable the user to scroll through the text.

The buttons are:

- CONTINUE
- HELP.

Select CONTINUE to close the dialog box and return to the data load main display.

Select HELP to show the help dialog box for the data load completion and configuration verification dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Are You Sure? Dialog Box

The Are You Sure? dialog box shows when you select a button which you can not undo. The dialog box gives the user a chance to undo the selection.

There is no dialog box title.

The message text shows:

- If you stop now, usually the destination LRU cannot operate.
- You must complete a data load to make the destination LRU serviceable with the new load part number.

The buttons are:

- STOP
- HELP
- GO BACK.

CMCS - DATA LOAD MESSAGE DIALOG BOXES - 2

Select STOP to continue with the previous command selection and close the dialog box.

Select HELP to show the help dialog box for the are you sure? dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to undo the previous command selection and close the dialog box.

DATA LOAD

The destination LRU does not allow this load part number, but you may continue.

The load part number is not compatible with the software of the destination LRU.

CMCS - DATA LOAD MESSAGE DIALOG BOXES - 3

Data Load Function Not Enabled Dialog Box

The data load function not enabled dialog box shows when the use of the CMCF is not available because the enable logic is not set.

If this dialog box shows after you start a data load the message shows:

- The data loader cannot start.

If the data load cannot finish, the message shows:

- The data loader has stopped.
- Usually the destination LRU cannot operate.

This message also shows:

- To start and complete a data load, you must make sure the airplane is in this configuration:
- 1. Airplane is on the ground
- 2. Engines are off.

The buttons are:

- GO BACK
- STOP
- HELP.

Select GO BACK to remove the dialog box and return to the previous display.

Select STOP to end the data load and remove the dialog box.

Select HELP to show the help dialog box for the data load not enabled dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Check Disk Dialog Box

The check disk dialog box shows when the CMCF does a load integrity check.

The check disk dialog box follows the selection of the CHECK DISK command selection on the data storage error dialog box.

The message field shows:

- The data loader will make sure load part number AACC-MMM-SSS-SS is serviceable.
- Wait...

If the load part number is valid, the message shows:

- Load part number AACC-MMM-SSS-SS is serviceable.

If the load part number is not valid, the message shows:

- Load part number AACC-MMM-SSS-SS is not serviceable.

CMCS - DATA LOAD MESSAGE DIALOG BOXES - 3

You must get a serviceable disk to complete the data load of this load part number.

The buttons are:

- CONTINUE
- STOP
- HELP.

CONTINUE is not available for selection while the CMCF is verifying the disk.

Select CONTINUE to close the dialog box.

STOP is not available while the message field shows Usable or Not Usable.

Select STOP to end the CMCF disk verification and to remove the dialog box.

Select HELP to show the help dialog box for the check disk dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Data Load Function Already in Use Dialog Box

The data load function already in use dialog box shows that the data load sub-function of the CMCF is already in use.

The message field shows:

- The data loader is already in use.
- Only one person can use the data loader at a time.

The buttons are:

- GO BACK
- HELP.

Select GO BACK to remove the dialog box and return to the previous display.

Select HELP to show the help dialog box for the data load function already in use dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Switch Source CMCF Dialog Box

The switch source CMCF dialog box shows when there is no data bus connection in the AIMS cabinet with the active CMCF to the destination LRU. This will occur with some 429 destination LRUs.

The message field shows:

- The Data Loader cannot data load the destination from the current Central Maintenance Computing Function source.
- You must switch to the other Central Maintenance Computing Function to complete this data load. Do the following steps:
- 1. Select GO BACK
- 2. Select the OTHER FUNCTIONS menu and CENTRAL MAINTENACE SOURCE SWITCHING

CMCS - DATA LOAD MESSAGE DIALOG BOXES - 3

- 3. After you switch source, select DATA LOAD and start again.

The buttons are:

- GO BACK
- HELP.

Select GO BACK to remove the dialog box and return to the previous display.

Select HELP to show the help dialog box for the switch source CMCF dialog box dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Data Loader Not Working Dialog Box

The data loader not working dialog box shows when the CMCF detects a fault with the data load gateway sub-function.

The message field shows:

- The data loader finds and internal failure and cannot operate.
- You may select CONTINUE to data load the AIMS CMCF/Comm destination LRU. This may make the data loader serviceable.
- NOTE: If you select CONTINUE, all functions of the connected Central Maintenance Computing Function will stop.
- If a new load is necessary in the CPM/Comm, select CONTINUE.

The buttons are:

- CONTINUE
- HELP
- GO BACK.

Select CONTINUE to start a data load of the CPM/Comm LRM.

Select HELP to show the help dialog box for the data loader not working dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to remove the dialog box and return to the previous display.

DATA LOAD

CMCS - HARD DRIVE MAIN MENU DIALOG BOX

General

The hard drive main menu dialog box gives access to functions that let you do these:

- Add a new part number to the hard drive
- Remove an existing part number from the hard drive
- Show stored part numbers
- Check a part number.

The software part numbers are on the maintenance access terminal (MAT) hard drive.

The hard drive main menu dialog box shows:

- Exclusive selectors
- Buttons.

Exclusive Selections

These are the four exclusive selections:

- ADD A NEW PART NUMBER TO THE HARD DRIVE
- REMOVE AN EXISTING PART NUMBER FROM THE HARD DRIVE
- SHOW STORED PART NUMBERS
- CHECK PART NUMBER.

Select ADD A NEW PART NUMBER TO THE HARD DRIVE to add LRU software part numbers to the hard drive.

Select REMOVE AN EXISTING PART NUMBER FROM THE HARD DRIVE to show the remove part number dialog box. Select the LRU software part number you want to remove from the remove part number dialog box.

Select SHOW STORED PART NUMBERS to show the show part numbers dialog box. The show part numbers dialog box shows:

- Hard drive configuration name
- Hard drive configuration index
- Hard drive capacity
- LRU software part numbers on the hard drive.

Select CHECK PART NUMBER to show the check part number dialog box. The check part number function checks that an LRU software part number is stored correctly on the hard disk. Select the LRU software part number you want to check from this dialog box.

Buttons

When you select an exclusive selection, the CONTINUE button is available. Select CONTINUE to go to one of the four hard drive software part number management functions.

Select HELP to show the help for this dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to remove the dialog box and return to the previous display.

CMCS - HARD DRIVE MAIN MENU DIALOG BOX

CMCS - MAINTENANCE PLANNING DIALOG BOX

General

The maintenance planning dialog box gives access to information that the airline maintenance organizations can use to plan maintenance.

The information available is in the form of maintenance memo messages and scheduled maintenance tasks.

Maintenance memos relate to faults in fault tolerant systems. These memos let the maintenance organizations monitor the deterioration of a component/system. They also let the maintenance organizations plan the appropriate maintenance actions before a system or component becomes not airworthy. Maintenance memos correlate to maintenance messages.

Scheduled maintenance task messages relate to certification maintenance requirement items (CMR) or maintenance review board (MRB) items with time exposure limits. They are stored and reported by the airplane systems and correlate to maintenance messages.

The maintenance planning dialog box shows:

- Exclusive selections
- Buttons.

Exclusive Selections

These are the four exclusive selections:

- Inbound Maintenance Memos
- Existing Maintenance Memos
- Inbound Scheduled Maintenance Tasks
- Existing Scheduled Maintenance Tasks.

Select one of the exclusive selections and CONTINUE to show that display.

Select HELP to show the help dialog box for the maintenance planning dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to remove the dialog box and return to the previous display.

CMCS - MAINTENANCE PLANNING - INBOUND MAINTENANCE MEMO SUMMARY DISPLAY

General

The inbound maintenance memo summary display shows all maintenance messages that are correlated to maintenance memos that occurred in present flight leg.

Maintenance memos are a group of maintenance messages that give information about the condition of redundant LRU/systems.

These memos let the maintenance organizations monitor the deterioration of a component/system. They also let the maintenance organizations plan the appropriate maintenance actions before a system or component becomes not airworthy.

A maintenance memo normally shows one fault away from a fault that will cause a status message.

Maintenance memos are either active, latched, or not active. Latched messages are those that occur in a particular flight phase and are in the memory of the LRU.

Maintenance memos are correlated to one or more maintenance messages.

The inbound maintenance memo summary display shows the maintenance memos by time (the newest memo shows first) or by ATA.

The inbound maintenance memo summary display shows this:

- Header information
- Fault summary field
- Buttons.

Header Information

The header information includes:

- Display title
- Instructions to access the single maintenance message summary display
- Tail identification
- Flight leg ID with origin and destination airports
- Flight leg start time and date
- Source of information.

Fault Summary Field

The fault summary field includes:

- Fault summary field title
- Number of items
- Maintenance memo summary groups.

The fault summary field title shows above the fault summary on the left side. The title is Maintenance Memos recorded during the Inbound Leg.

The number of items shows above the scroll bar. The number shows the total number of memo summary groups.

CMCS - MAINTENANCE PLANNING - INBOUND MAINTENANCE MEMO SUMMARY DISPLAY

Buttons

CMCS - MAINTENANCE PLANNING - EXISTING MAINTENANCE MEMO SUMMARY DISPLAY

General

The existing maintenance memo summary display shows all maintenance memos that are currently active or latched.

Maintenance memos are a group of maintenance messages that give information about the condition of redundant LRU/systems.

These memos let the maintenance organizations monitor the deterioration of a component/system. They also let the maintenance organizations plan the appropriate maintenance actions before a system or component becomes not airworthy.

A maintenance memo normally shows one fault away from a fault that will cause a status message.

Maintenance memos are either active or latched. Latched messages are those that occur in a particular flight phase and are in the memory of the LRU.

Maintenance memos are correlated to one or more maintenance messages.

The existing maintenance memo summary display shows the maintenance memos by time (the newest memo shows first) or by ATA.

The existing maintenance memo summary display shows:

- Header information
- Fault summary field
- Buttons.

Header Information

The header information includes:

- Display title
- Instructions to access the single maintenance message summary display
- Tail identification
- Time and date
- Source of information.

Fault Summary Field

The fault summary field includes:

- Fault summary field title
- Number of items
- Maintenance memo summary groups

The fault summary field title shows above the fault summary on the left side. The title is Maintenance Memos currently ACTIVE or LATCHED.

The number of items shows above the scroll bar. The number shows the total number of memo summary groups.

Buttons

Select MAINTENANCE MESSAGE DATA to show the single maintenance message display.

CMCS - MAINTENANCE PLANNING - EXISTING MAINTENANCE MEMO SUMMARY DISPLAY

CMCS - MAINTENANCE PLANNING - INBOUND SCHEDULED MAINTENANCE TASKS MESSAGE SUMMARY DISPLAY

General

The inbound scheduled maintenance tasks message summary display shows all maintenance messages that are correlated to scheduled maintenance task messages that occurred in present flight leg.

Scheduled maintenance task messages relate to certification maintenance requirement items (CMR) or maintenance review board (MRB) items with time exposure limits.

These messages relate to those that show on the maintenance task maintenance page on the MFD.

There is no requirement to check these messages prior to flight.

The inbound scheduled maintenance task message summary display shows:

- Header information
- Fault summary field
- Buttons.

Header Information

The header information includes:

- Display title
- Instructions to access the single maintenance message summary display
- Tail identification
- Flight leg ID with origin and destination airports
- Flight leg start time and date
- Source of information.

Fault Summary Field

The fault summary field includes:

- Fault summary field title
- Number of items
- Scheduled maintenance task summary groups.

The fault summary field title shows above the fault summary on the left side. The title is Scheduled Maintenance Tasks recorded during the Inbound Leg.

The number of items shows above the scroll bar. The number shows the total number of scheduled maintenance task message summary groups.

CMCS - MAINTENANCE PLANNING - EXISTING SCHEDULED MAINTENANCE TASKS MESSAGE SUMMARY DISPLAY

CMCS - MAINTENANCE ENABLE/DISABLE DIALOG BOX

General

The maintenance enable/disable dialog box lets the user enable or disable flight legs and the maintenance phase.

The maintenance enable/disable dialog box shows:

- Dialog box title
- Text box titles
- Two text boxes
- buttons.

Text Box Titles

The title of the upper text box is FLIGHT LEG TRANSITION ENABLE/DISABLE.

The title of the lower test box is MAINTENANCE PHASE ENABLE/DISABLE.

Text Boxes

The upper text box shows the status of the flight leg transition. Two possible messages show in the box.

The lower text box shows the status of the maintenance phase. This text box has two messages.

Buttons

Two buttons control the status of the flight leg transition.

Select LEG ENABLE to enable the flight leg transition. This selection is available only when the flight leg transition is disabled.

Select LEG DISABLE to disable the flight leg transition. This selection is available only when the flight leg transition is enabled.

Two buttons control the status of the maintenance phase.

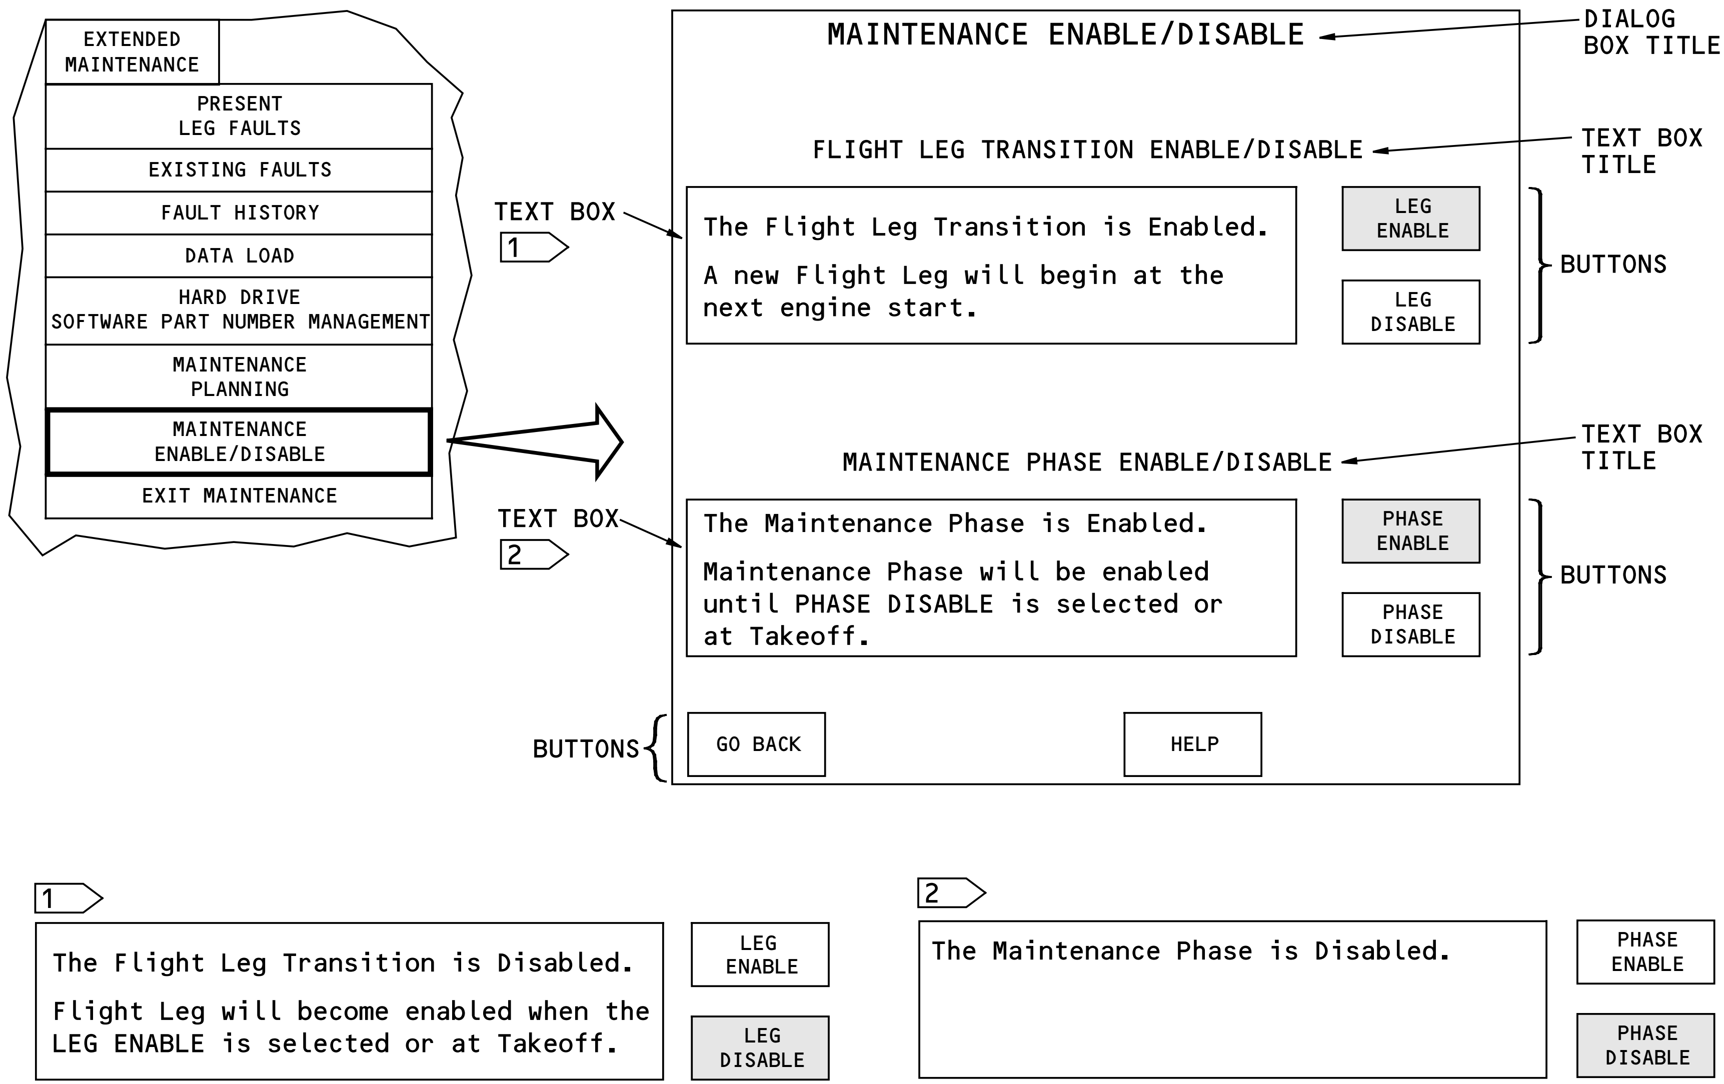
Select PHASE ENABLE to enable the maintenance phase. This selection is available only when the maintenance phase is disabled.

Select PHASE DISABLE to disable the maintenance phase. This selection is available only when the maintenance phase is enabled.

Two buttons show at the bottom of the dialog box.

Select GO BACK to remove the dialog box and return to the previous screen.

Select HELP to show the help dialog box for the maintenance enable/disable dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.



45-10-00-067 Rev 2 07/27/1995

CMCS - MAINTENANCE ENABLE/DISABLE DIALOG BOX

CMCS - INPUT MONITORING MAIN MENU DIALOG BOX

General

Input monitoring is a tool which specially trained personnel use to check signals to the AIMS cabinets. These signals are:

- 32 bit ARINC 429 word
- 16 bit or 32 bit ARINC 629 word
- Hard wired AIMS analog variable input
- Hard wired AIMS analog discrete input
- AIMS partition IMM signal of one, two, or four bytes.

The CMCF shows these two types of input monitoring displays on the MAT:

- General input displays
- Special input displays.

You use the general input displays to select and monitor up to eight input signals.

You use these special input displays to select four types of input monitoring displays:

- Analog discrete display
- Analog variable display
- ARINC 629 full word string display
- Input monitoring aliases display.

Input Monitoring Main Menu Dialog Box

The INPUT MONITORING MAIN MENU dialog box has:

- Dialog box title
- Exclusive selections
- Buttons.

Exclusive Selections

Use an exclusive selection and the CONTINUE command selection to monitor one of these signal types:

- General inputs
- Analog discretes
- Analog variables
- ARINC 629 full word strings.

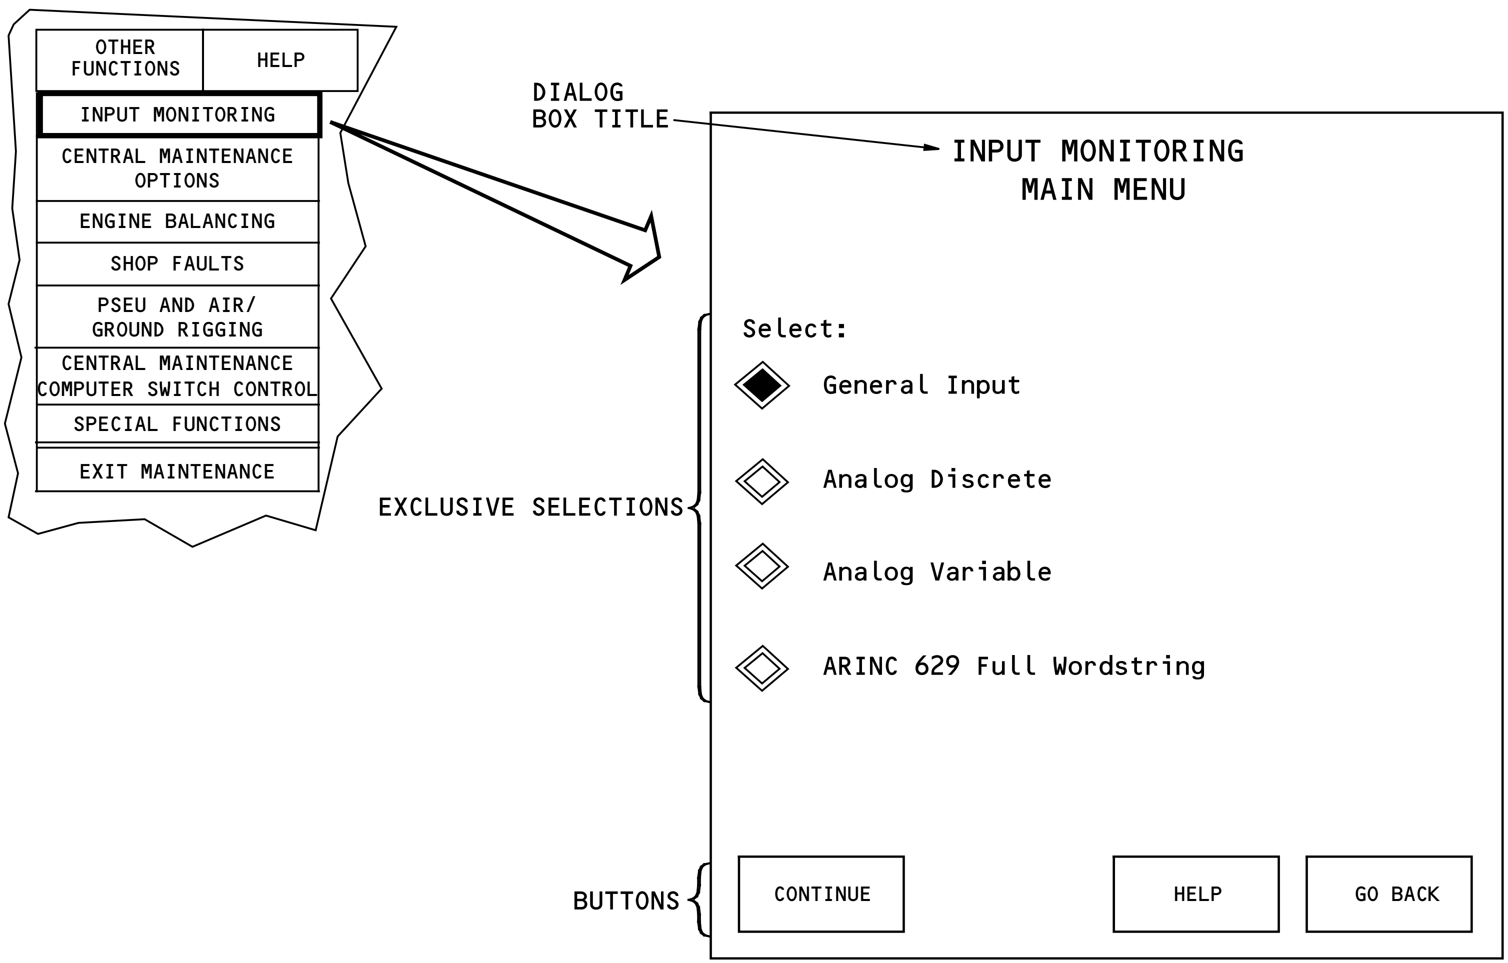
Buttons

The CONTINUE button becomes available when you make an exclusive selection.

Select CONTINUE to show the display for the exclusive selection.

Select GO BACK to remove the dialog box and return to the previous display.

Select HELP to show the help dialog box for the INPUT MONITORING MAIN MENU dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.



45-10-00-068 Rev 1

CMCS - INPUT MONITORING MAIN MENU DIALOG BOX

CMCS - CENTRAL MAINTENANCE COMPUTER SWITCH CONTROL DIALOG BOX

General

The central maintenance computer switch control dialog box lets the user switch the source of CMCF data to the left or right CMCF.

Display Characteristics

The dialog box has:

- Title
- Message field
- Buttons.

Message Field

The CMCF shows these messages that identifies the CMCF currently in control.

Buttons

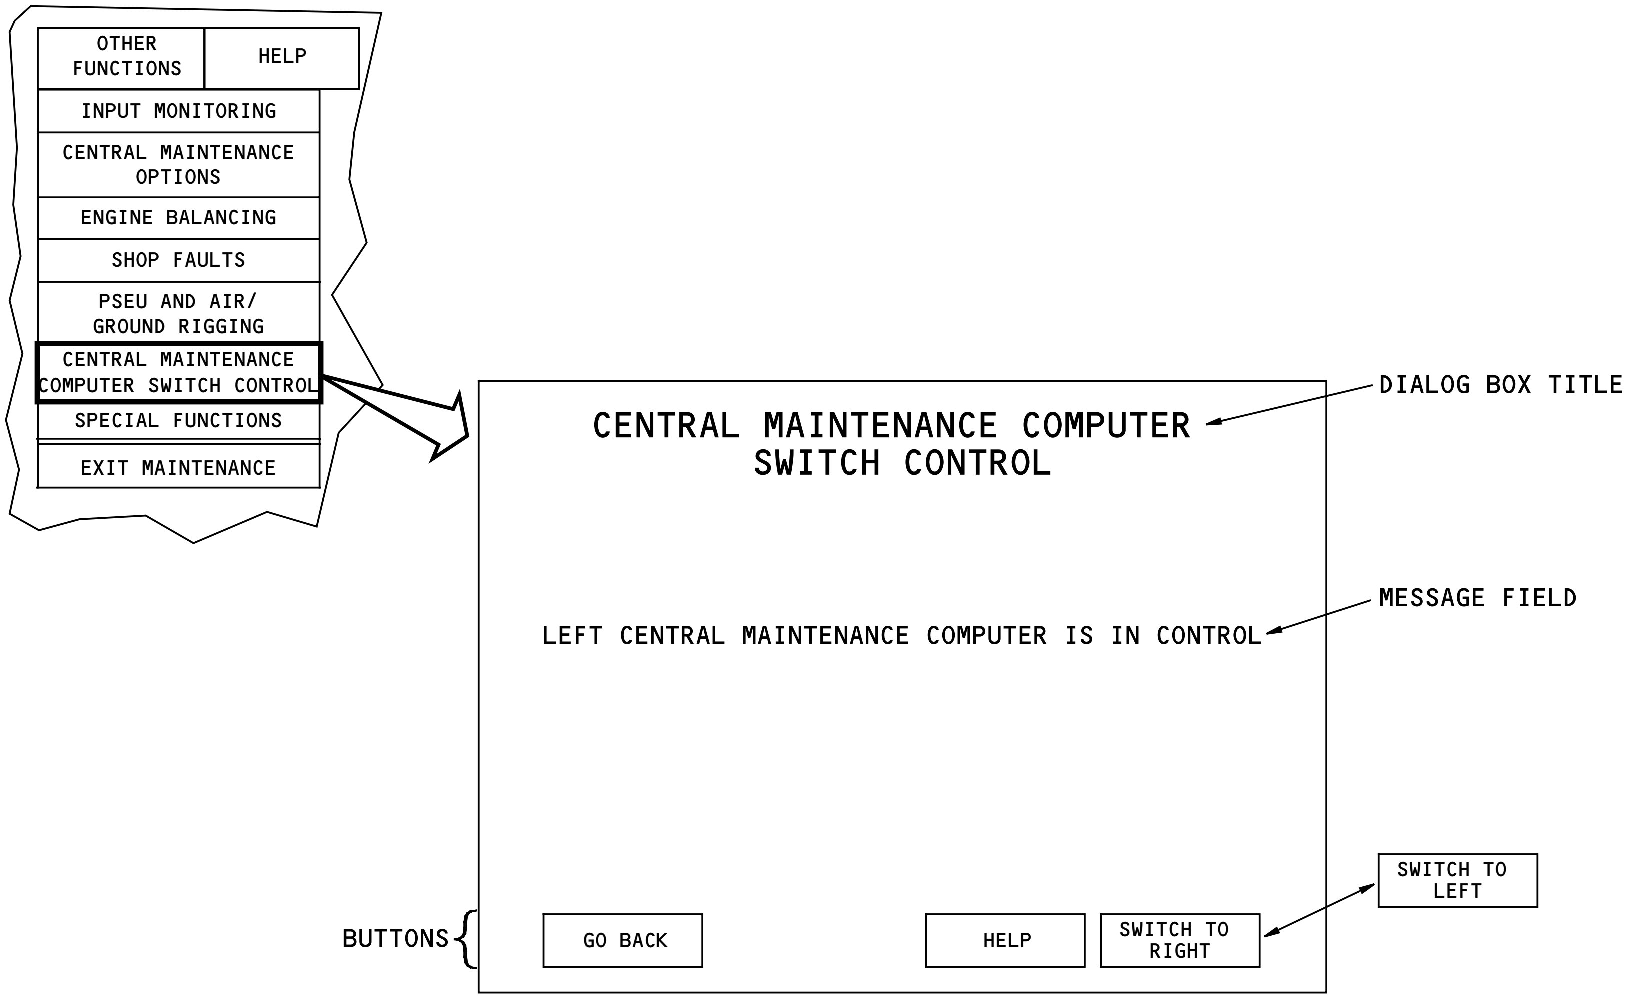
Select HELP to show the help dialog box for the shop faults shop faults status dialog box. Help must exist in the CMCF AMI for the HELP selection to show.

Select GO BACK to show all messages except Request Is In Progress. Select GO BACK to remove the shop faults status dialog box and to return to the previous screen.

SWITCH TO LEFT and SWITCH TO RIGHT are toggles. If the left CMCF is in control then the button shows SWITCH TO RIGHT.

If the right CMCF is in control then the button shows SWITCH TO LEFT.

Select SWITCH TO LEFT or SWITCH TO RIGHT to remove the dialog box and to show an inhibit dialog box or a confirmation dialog box.



45-10-00-111 Rev 0

CMCS - CENTRAL MAINTENANCE COMPUTER SWITCH CONTROL DIALOG BOX

CMCS - CENTRAL MAINTENANCE COMPUTER SWITCH CONTROL INHIBIT DIALOG BOX

General

The central maintenance computer switch control inhibit dialog box shows if a condition exists that affects the ability of the CMCF to switch sources.

Display Characteristics

The dialog box has:

- Title
- Message field
- Buttons.

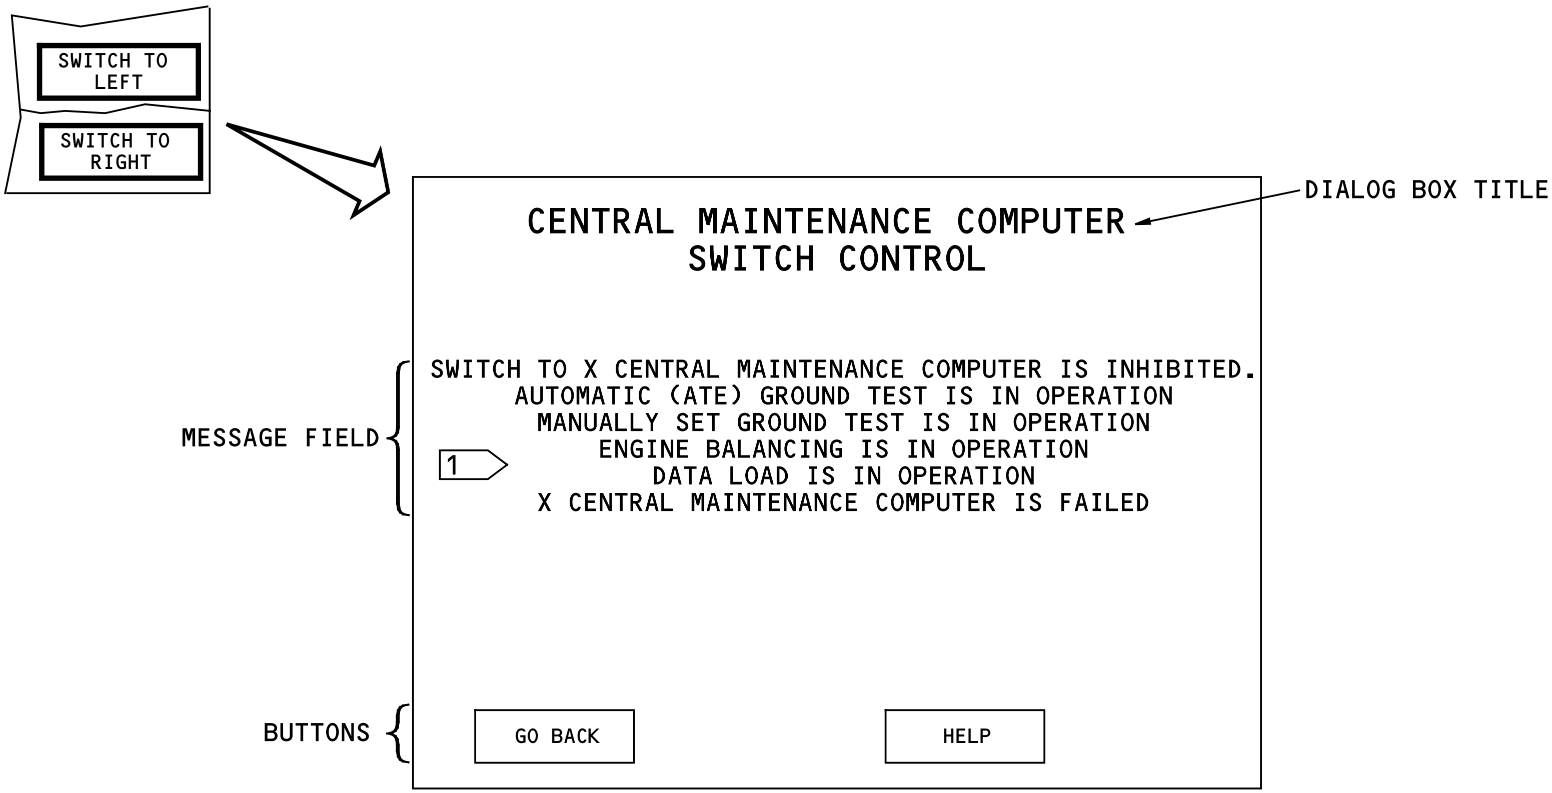
Message Field

The CMCF shows one or more messages that identify the specific inhibits.

Buttons

Select HELP to show the help dialog box for the central maintenance computer switch control dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to remove the dialog box to return to the previous display.



1 X = LEFT OR RIGHT

45-10-00-112 Rev 1

CMCS - CENTRAL MAINTENANCE COMPUTER SWITCH CONTROL INHIBIT DIALOG BOX

CMCS - CENTRAL MAINTENANCE COMPUTER SWITCH CONTROL CONFIRMATION DIALOG BOXES

General

If there are no inhibits, the selection of SWITCH TO LEFT or SWITCH TO RIGHT causes a confirmation dialog box to show.

A YES selection on the confirmation dialog box causes another dialog box to show while the CMCF switches sources.

Dialog Box Characteristics

Each dialog box has:

- Title
- Message Field
- Buttons.

Message Field

The message field on each dialog identifies the current condition of the CMCF and provides instructions.

Buttons

The first dialog box has three buttons.

Select YES to show the second dialog box.

Select HELP on both to show the help dialog box for the central maintenance computer switch control dialog box. Help must exist in the CMCF AMI for the HELP selection to show.

Select GO BACK on the dialog box to remove all dialog boxes and to return to the previous display.

45-10-00-113 Rev 0

CMCS - CENTRAL MAINTENANCE COMPUTER SWITCH CONTROL CONFIRMATION DIALOG BOXES

CMCS - SPECIAL FUNCTIONS DIALOG BOX

General

The SPECIAL FUNCTIONS selection supplies you with access to airplane systems that have unique maintenance functions.

Many ATA systems and LRUs have unique requirements that cause additional dialog boxes to show before the function starts. The types of dialog boxes include:

- Precondition dialog box
- Inhibit dialog box
- Interference dialog box
- Interactive dialog box
- Menu abort dialog box.

When you meet all unique requirements, the special function display shows with status and instructions for the special function.

Special Functions Selection Dialog Box

The special functions selection dialog box has:

- Title
- Select ATA list box
- Select function list box
- Button area.

Select ATA List Box

The select ATA list box shows the airplane systems in ATA order. You must choose an ATA system first. This selection causes the functions for that ATA to become available.

Select Function List Box

The select function area list box has all the LRUs in the ATA that have a special function available.

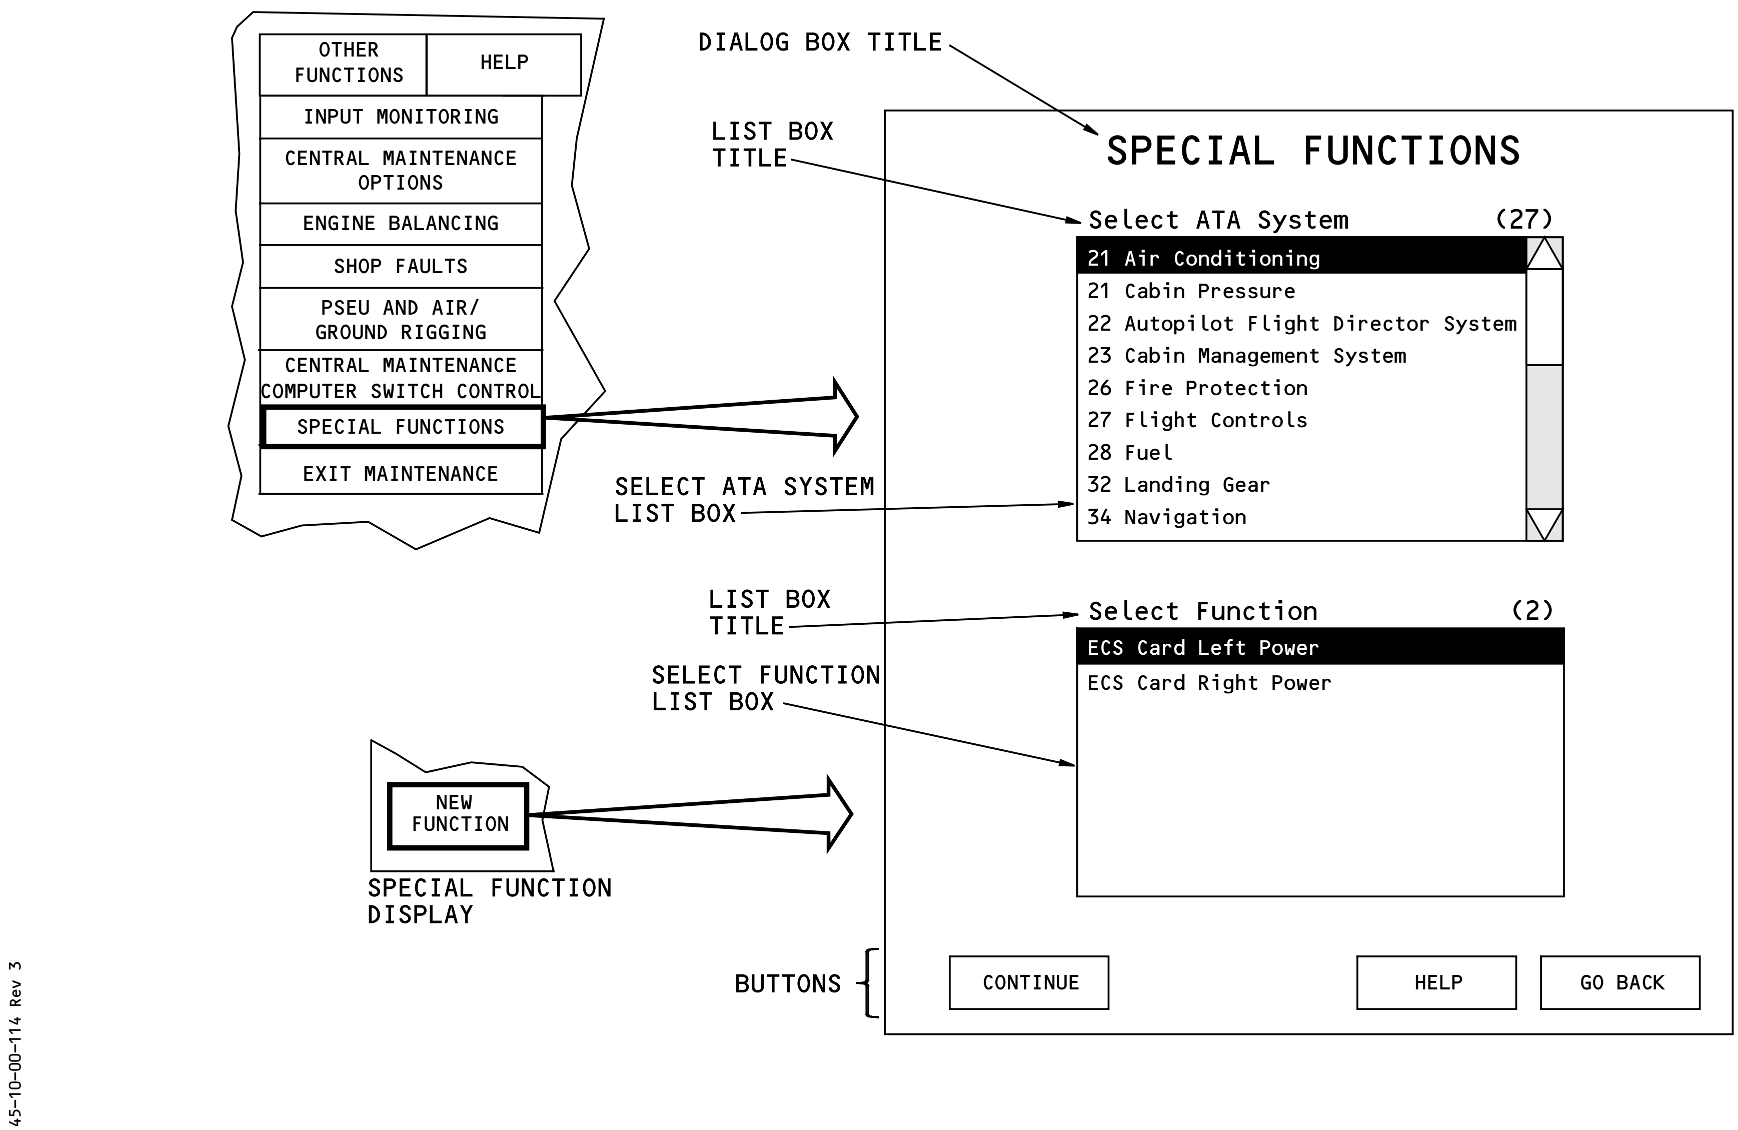
The selection of the LRU with a special function makes the CONTINUE command available.

Button

Select CONTINUE to show the precondition dialog box on top of the ground test selection dialog box for the selected special function.

Select HELP to show the help dialog box for the special function dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to remove the special function selection dialog box and to return to the previous display.



CMCS - SPECIAL FUNCTIONS DIALOG BOX

CMCS - SPECIAL FUNCTIONS PRECONDITION DIALOG BOX

General

The special functions precondition dialog box is similar to the ground test precondition dialog box. The special functions precondition dialog box contains:

- Title
- Special function title
- Special function description
- Precondition list
- Buttons.

Special Function Title

The special function title shows the name from the selection made on the special function selection dialog box.

Special Function Description

The test description is a brief description about the special function.

Precondition List

The precondition list gives instructions to follow before you run the special function.

The precondition display database stores the special function description and the precondition list.

Buttons

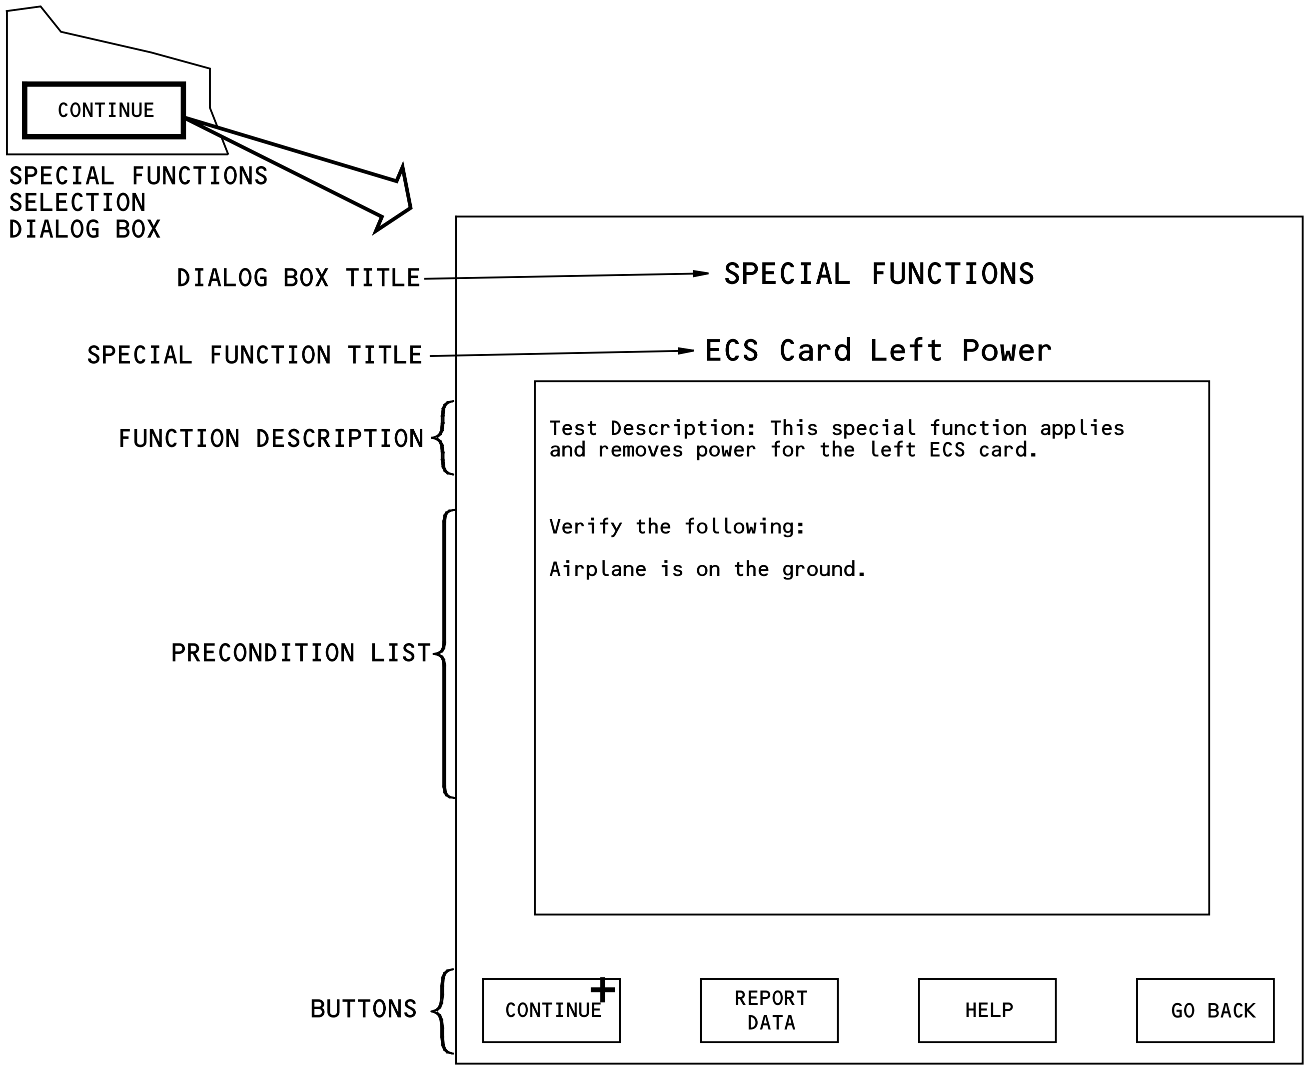
The precondition dialog box shows four buttons.

Select CONTINUE to close the special function selection dialog box (if open), the precondition dialog box, and to show the special function display.

Select REPORT DATA to show the report dialog box.

Select HELP to show the help dialog box for the special function precondition dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to remove the precondition dialog box and to return to the previous display.



45-10-00-115 Rev 1

CMCS - SPECIAL FUNCTIONS PRECONDITION DIALOG BOX

THIS PAGE INTENTIONALLY LEFT BLANK

CMCS - SPECIAL FUNCTION MAIN DISPLAY

General

The SPECIAL FUNCTION main display supplies status information and control for the special functions.

The SPECIAL FUNCTION display shows:

- Display title
- ATA chapter and name
- Special function title
- FUNCTION CONDITION messages
- Function control selections
- Text field
- Text field title
- Buttons.

ATA Chapter and Name

This field shows the ATA chapter and system name from the initial selection on the special functions selection dialog box.

Special Function Title

This field shows the system function title from the initial selection on the special function selection dialog box.

Function Condition Messages and Control Selections

The function condition messages field can show these messages:

- READY
- INHIBITED
- CAN NOT OPERATE
- OPERATING
- STOPPED
- COMPLETE.

The possible function control buttons are:

- START FUNCTION
- STOP FUNCTION
- OPERATE FUNCTION AGAIN
- TO START FUNCTION.

READY shows when no inhibits or no interference conditions exist. The START FUNCTION button shows next to the READY message.

Select START FUNCTION to begin the function. OPERATING shows as the message.

When OPERATING shows, the button changes to STOP FUNCTION.

Select STOP FUNCTION to stop the function and show the STOPPED message.

At the completion of the function, COMPLETE shows.

With STOPPED, or COMPLETE as the message, OPERATE FUNCTION AGAIN shows as the button.

CMCS - SPECIAL FUNCTION MAIN DISPLAY

Select OPERATE FUNCTION AGAIN to show the precondition dialog box.

INHIBITED shows when a test inhibit condition exists. The TO START FUNCTION control selection shows next to the message.

The TO START FUNCTION selection in this case causes the function inhibit dialog box to show.

CAN NOT OPERATE shows as the message if a function interference condition exists. The TO START FUNCTION control selection shows next to the message.

The TO START FUNCTION selection in this case causes the function interference dialog box to show.

If the LRU stops the special function, STOPPED shows as the message and TO START FUNCTION shows as the control selection.

<u>Text Field</u>

If the message STOPPED shows in the function condition field, and the user stops the function, or the member system stops the function, then the text field shows one of these messages:

- User Stopped the Function
- Member System Stopped the Function.

<u>Text Field Title</u>

When STOPPED shows in the function condition field, the title of the text field is CAUSE.

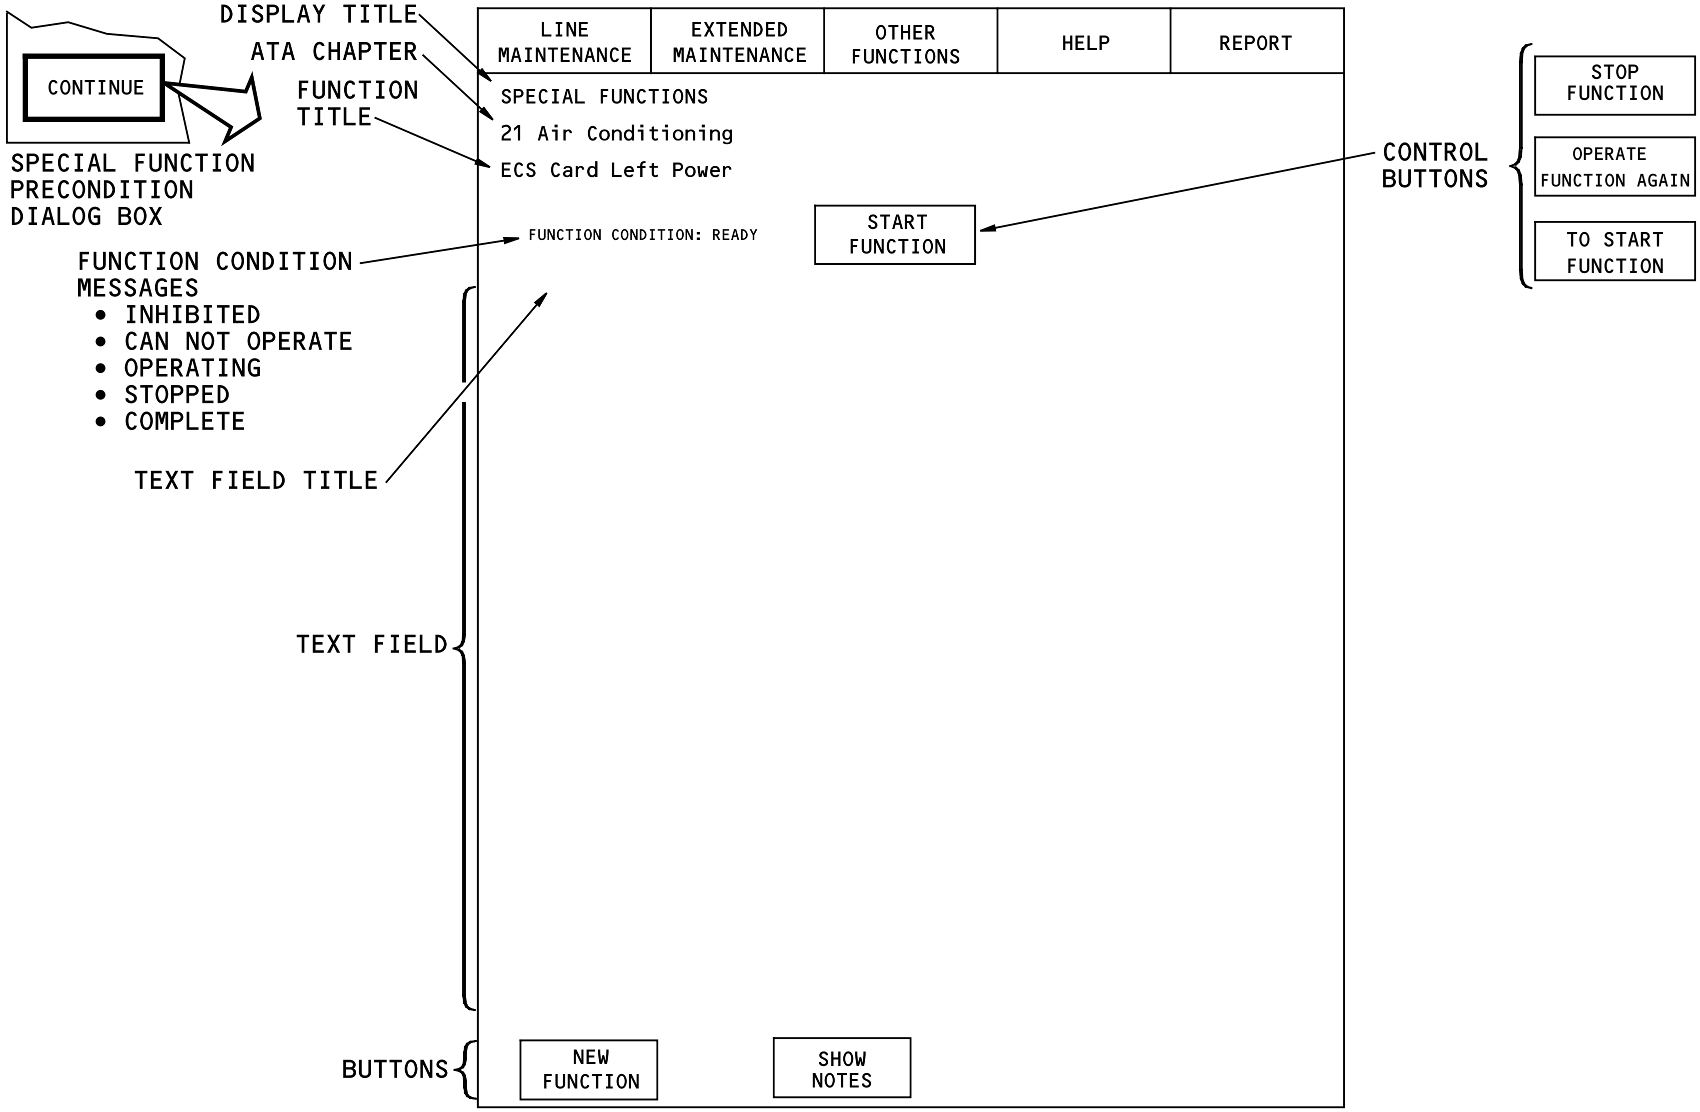
<u>Buttons</u>

Select NEW FUNCTION to show the special function selection dialog box.

Select SHOW NOTES to show the notes dialog box for the selected special function. Notes text for the dialog box must be in the CMCF AMI for SHOW NOTES to show.

<u>Button</u>

Select NEW FUNCTION to show the special function selection dialog box.



45-10-00-116 Rev 2 12/08/95

CMCS - SPECIAL FUNCTION MAIN DISPLAY

CMCS - SPECIAL FUNCTION INTERACTIVE DIALOG BOX

General

Interactive dialog boxes show when interaction by the user is necessary to complete the function.

The member systems control the interactive displays. LRUs in the member systems send a control signal that tells the CMCF to show the interactive displays as necessary. When the CMCF gets the control signal, any existing interactive displays close.

Each interactive dialog box has:

- Dialog box title
- Function title
- Messages
- Buttons

Function Title

The function title shows the title of the function from the initial selection on the special functions selection dialog box.

Messages

The messages area shows directions to complete the function.

The message area also shows any warnings associated with the function.

Buttons

Select CONTINUE to remove the interactive dialog box and the to start the function.

Select STOP FUNCTION to remove the interactive dialog box and to show STOPPED as the FUNCTION CONDITION message on the special function display. The control selection shows OPERATE FUNCTION AGAIN.

Select REPORT DATA to show the report dialog box.

Select HELP to show the help dialog box for the interactive dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Function Inhibit Dialog Box

When the FUNCTION CONDITION message shows INHIBITED, the control command changes to TO START FUNCTION.

Select TO START FUNCTION to show the function inhibit dialog box.

The dialog box has:

- Box title
- Function title
- Instructions to continue the function
- Buttons.

The function title shows the title from the original selection on the special function selection dialog box.

The instructions tell why the function is inhibited and how to enable the function.

After the inhibit condition goes away, select CONTINUE to remove the dialog box to enable the function to continue.

Select REPORT DATA to show the report dialog box.

Select HELP to show the help dialog box for the function inhibit dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to remove the function inhibit dialog box and to return to the previous display.

Function Interference Dialog Box

When the FUNCTION CONDITION message shows CAN NOT OPERATE, the control command changes to TO START FUNCTION.

Select TO START FUNCTION to show the function interference dialog box .

The dialog box has:

- Box title
- Function title
- Function interference information
- Buttons.

The box title always shows SPECIAL FUNCTIONS.

The function title shows the title from the original selection on the special function selection dialog box.

The function interference information has the header (You cannot operate this function because these functions are operating) and a numbered list of the tests that cause the interference.

After the interference condition goes away, select CONTINUE to remove the dialog box to enable the function to continue.

Select REPORT DATA to show the report dialog box.

CMCS - SPECIAL FUNCTION INHIBIT AND INTERFERENCE DIALOG BOXES

Select HELP to show the help dialog box help for the interference dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

CMCS - SPECIAL FUNCTION MENU ABORT DIALOG BOX

General

The menu abort dialog box shows when a selection other than HELP is made from the main menu title bar or the user selects NEW FUNCTION and a function is in progress.

The dialog box has:

- Dialog box title
- Message text
- Buttons.

Message Field

The message text provides instructions to stop or continue the function.

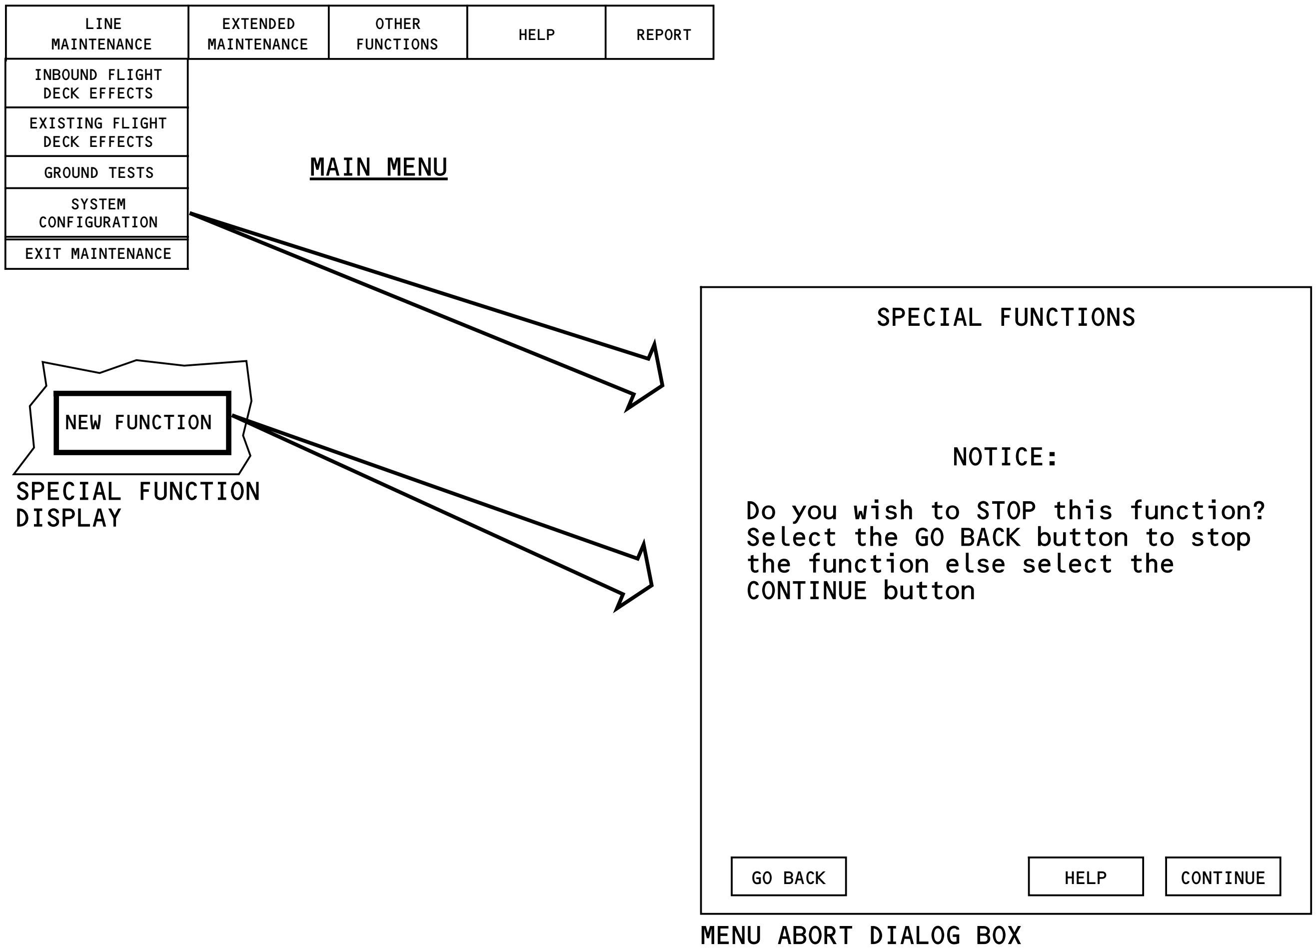
Buttons

Select GO BACK to do this:

- Stop the function
- Close the menu abort dialog box
- Process the main menu selection or the NEW FUNCTION selection.

Select HELP to show the help dialog box for menu abort dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select CONTINUE to remove the menu abort dialog box.



45-10-00-119 Rev 1

CMCS - SPECIAL FUNCTION MENU ABORT DIALOG BOX

CMCS - HELP FUNCTION

General

The main menu HELP selection is available on every CMCF display. The selection of HELP causes the menu with SCREEN HELP and GENERAL HELP to show.

A HELP button also shows on many of the CMCF dialog boxes.

The information on the help dialog boxes comes from data in the CMCF airline modifiable information (AMI).

SCREEN HELP

Select SCREEN HELP to get information about the present display.

If the CMCF does not have AMI data, this message shows:

- NO HELP, Maintenance Airline Modifiable Information (AMI) is not loaded.

If the AMIis loaded but no help is available for the present screen, this message shows:

- NO HELP, help is not assigned in the Maintenance Airline Modifiable Information (AMI).

If there is help data, a dialog box with a display title and a scrollable text field shows with the specific help for the present display.

Each dialog box has two command selections. Select REPORT DATA to show the report dialog box. Select GO BACK to remove the dialog box and return to the previous display.

GENERAL HELP

Select GENERAL HELP to get general help information in the CMCF AMI. If there is no CMCF AMI or if general help is not available, the dialog boxes with the applicable message show.

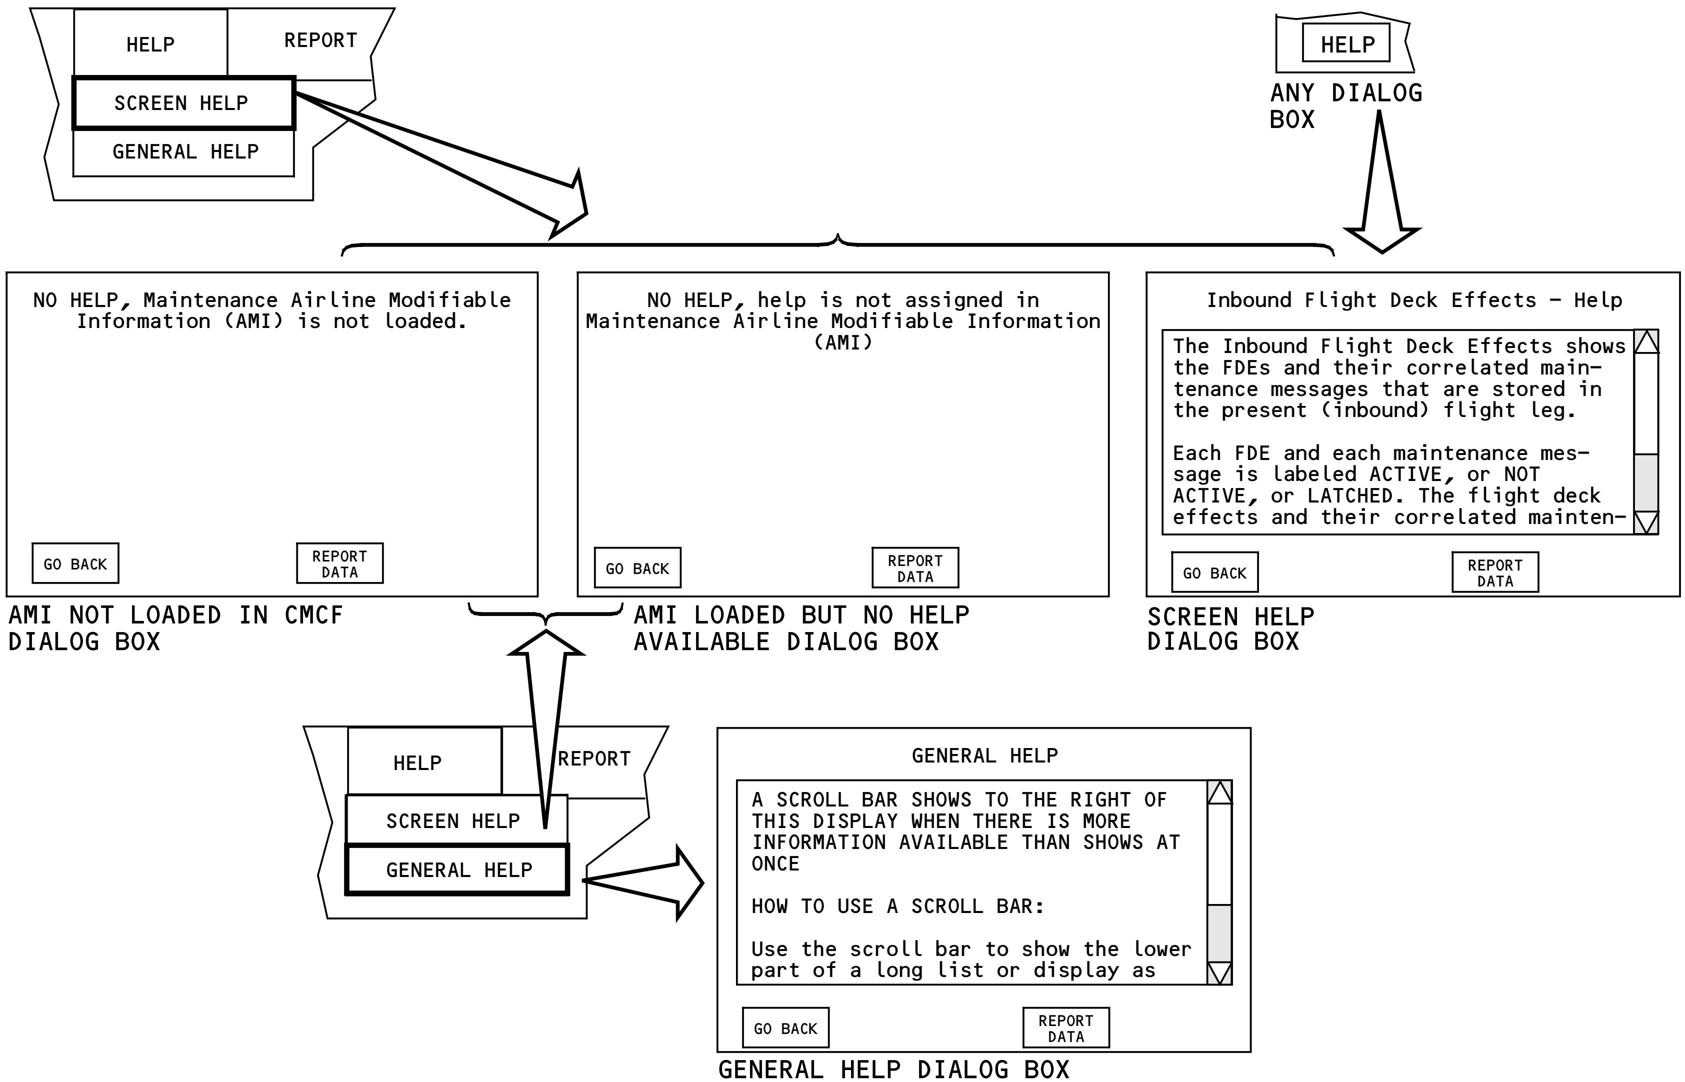
If general help is available, a scrollable dialog box shows and has the title GENERAL HELP.

The GENERAL HELP dialog box has the same two command selections as the screen help dialog box.

Dialog Box Help

If help for specific dialog boxes is available, the HELP command selection on that dialog box shows.

Select HELP on the dialog box to show the help dialog box. The dialog box has a display title and a scrollable text field with the help information for the present display.



45-10-00-120 Rev 1 06/02/1995

CMCS - HELP FUNCTION

CMCS - REPORT OUTPUT DEVICE DIALOG BOX

General

The CMCF can generate reports from user inputs, from a ground station request or when events cause an automatic report.

The CMCF sends a print image of the reports to the flight compartment printer and the disk drive. The CMCF sends reports to a ground station are in a compressed format.

The CMCF can complete one report at a time. You may send another report after the CMCF completes the first report.

Automatic CMCF Event Triggered Reports

The CMCF can automatically generate reports at certain flight events. Use the ground based software tool (GBST) to select the flight events. When selected, the events that trigger an automatic report are:

- Top of descent
- Roll out
- Engine shutdown
- Present flight leg flight deck effects, maintenance page snapshots, and maintenance messages.

Ground Station Report Requests

The CMCF can respond to ground station requests for these reports:

- Inbound flight deck effects summary
- Present leg fault summary
- Fault history summary
- Existing faults summary
- Airplane configuration summary
- Cabin management fault summary
- Maintenance planning summary.

Report Menu Selections

When you select any item on the report menu bar or select REPORT DATA on any dialog box, the output device dialog box shows.

Select REPORT PAGE DATA to cause a report to go to the output device for the information that shows on the display.

Dialog Box Characteristics

The dialog box has:

- Title
- Exclusive source selections
- Printer output device selection
- Disk drive output device selection
- Data link output device selection
- Buttons.

Title

The title shows REPORT: followed by the item from the menu selection or the dialog box.

CMCS - REPORT OUTPUT DEVICE DIALOG BOX

Printer Output Device Selection

The printer area has:

- Title
- Buttons
- Text area.

The buttons are SEND and STOP. When you select SEND the CMCF sends the report to that device. The SEND button is not available during these times:

- When the output device is not available
- During the transmission of a report to that device
- After the selection of OUTPUT STATUS on the menu bar.

Select STOP to abort the report in progress.

The text area shows the status of the transmission to the printer. These are the possible messages:

- Transmission in Operation
- Door Open/Printer out of Paper
- Printer Busy
- Cannot Connect to the Printer. The Printer is Inactive/Faulted
- Cannot Connect to the Printer. The Printer Does not Give a Reply
- Transmission Completed.

Disk Drive Output Device Selection

The disk drive area has:

- Title
- Buttons
- Text area.

The buttons are SEND and STOP. Their function here is the same as the printer area.

The text area shows the status of the transmission sent to the disk drive. These are the possible messages:

- Transmission in Progress
- Insert Disk
- Change Disk
- Disk Write Protected
- Cannot Connect to the Disk Drive. The Disk Drive is Inactive/Faulty
- Cannot Connect to the Disk Drive. The Disk Drive Does not Give a Reply
- Transmission Completed to Disk Drive.

Datalink Output Device Selection

The datalink area has:

- Title
- Buttons
- Text area.

CMCS - REPORT OUTPUT DEVICE DIALOG BOX

The buttons are SEND and STOP. Their function here is the same as the printer area.

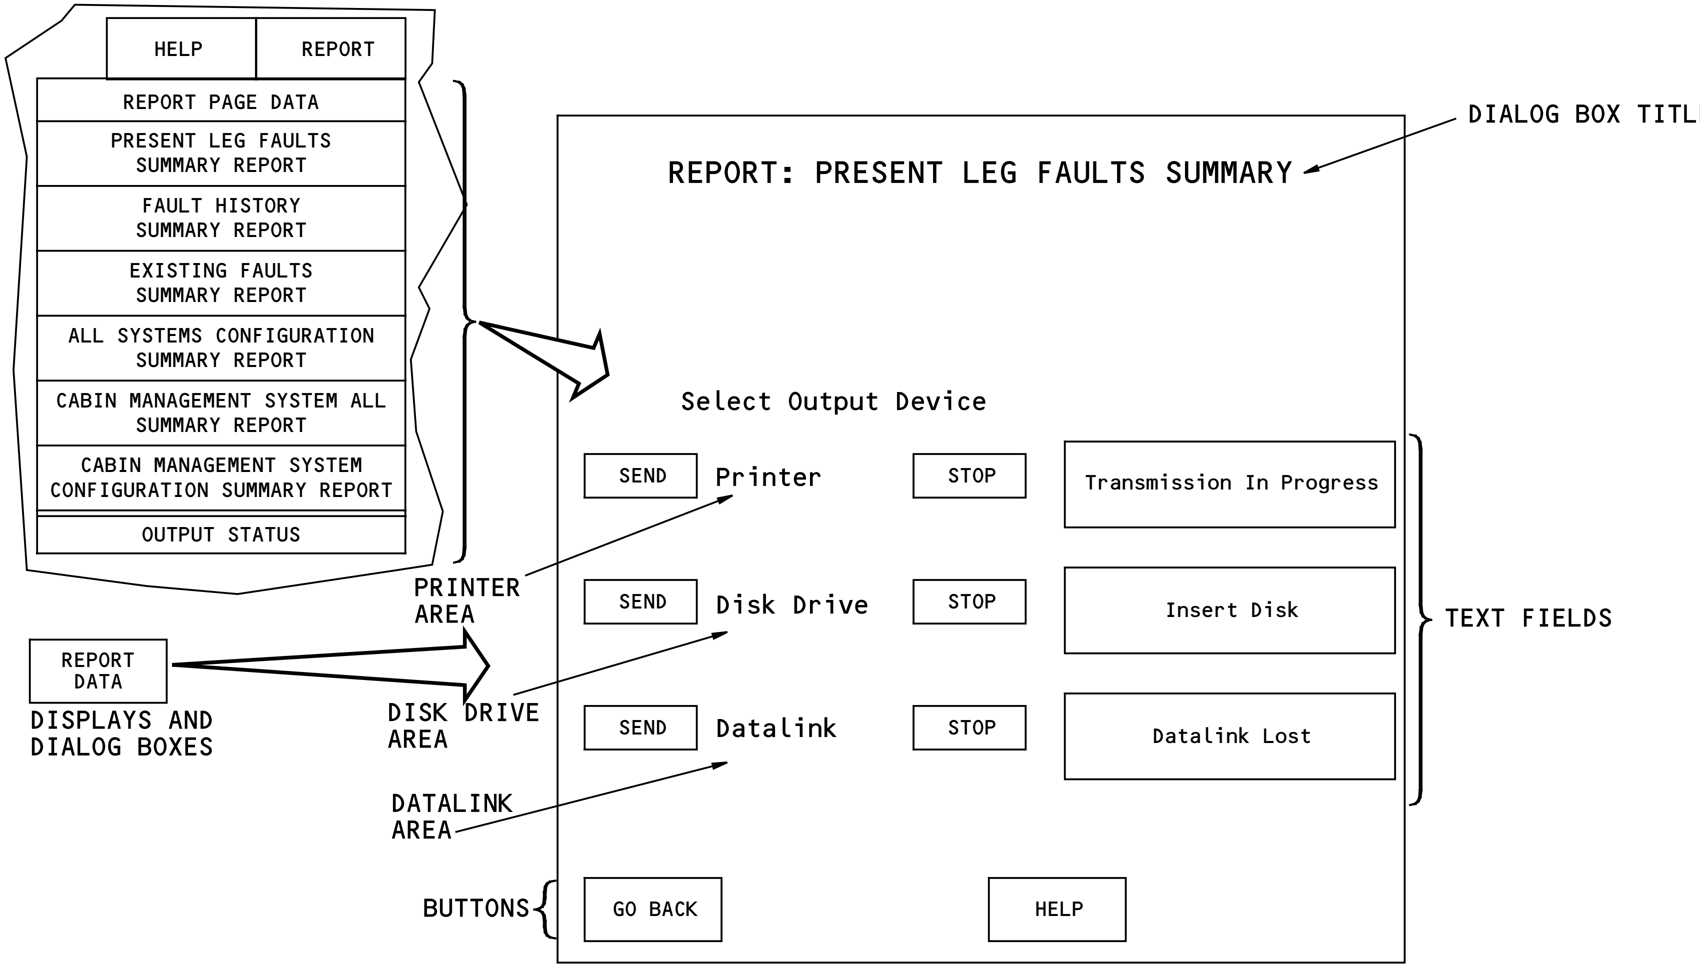
The text area shows the status of the transmission sent to datalink. These are the possible messages:

- Transmission in Progress
- Datalink SYS Faulted
- Datalink Lost
- Disk Write Protected
- Transmission Completed to Ground.

<u>Buttons</u>

Select HELP to show the help dialog box for the report output device dialog box. Help text for the dialog box must be in the CMCF AMI for HELP to show.

Select GO BACK to remove the dialog box and return to the previous display.



45-10-00-121 Rev 3 02/12/96

CMCS - REPORT OUTPUT DEVICE DIALOG BOX

THIS PAGE INTENTIONALLY LEFT BLANK

General

Datalink reports are changed into short codes to lower the cost of using a satellite or ground station.

The reports have header information and can show data for FDE summary groups and maintenance message summary groups. Correlated FDEs and maintenance messages also show.

Report Header

Each report has header information that describes:

- Report type
- Report number
- Date and time sent
- Airplane tail number
- Flight number
- Flight origin and destination
- CPM/COMM OPS part number
- Active CMCF.

These are the codes for report type:

- IFDE: Inbound FDE summary report
- EFDE; Existing FDE summary report
- TEST; Ground test report
- CFG; System configuration summary report
- PLF; Present leg fault summary report
- EF; Existing faults summary report
- DL; Data load reports
- IMM; Inbound maintenance memo summary report
- EMM; Existing maintenance memo summary report
- ISMT; Inbound scheduled maintenance task summary report
- ESMT; Existing scheduled maintenance task summary report
- IMON; Input monitoring report
- OPT; Central maintenance options report
- ENG; Engine balancing report
- SFLIST; Shop fault list of contents report
- SFDATA; Shop fault data report
- PSEU; PSEU rigging/calibration report
- AGRIG; Air/ground rigging report
- SPEC; Special function report
- MSG; Single maintenance message report
- NOTES; Notes report
- HELP; Help report.

The report number is the number of reports sent to the ground during the present flight leg.

The active CMCF shows as L for left and R for right.

FDE Summary Groups

Flight deck effect (FDE) summary groups start with the code FDE. They also have the:

- Fault code
- FDE activity
- Time and date the FDE first occurred.

The codes for FDE activity are:

- A; active
- I; not active
- L; latched
- N; no activity.

Maintenance Message Summary Groups

Maintenance message summary groups start with the code MSG. They also have the:

- Maintenance message number
- Maintenance message activity
- Time and date the maintenance message first occurred
- Flight phase
- Intermittence
- Intermittence number
- Previous leg identifier
- Detected by identifier.

The codes for maintenance message activity are the same as for FDE activity.

These are the codes for flight phase activity:

- PO; Power on
- ES; Engine start
- TA; Taxi out
- TO; Take off
- IC; Initial climb
- CL; Climb
- ER; Cruise
- DC; Descent
- AP; Approach
- GA; Go around
- FL; Flare
- RO; Rollout
- TI; Taxi in
- SD; Shutdown
- MT; Maintenance.

These are the codes for intermittence:

- H; Hard
- I; Intermittent
- M; Mode dependent.

If the fault occurred in a previous leg, PL will show.

The LRU that detects the fault shows after the code DB.

Correlated FDEs and Maintenance Messages

The summary groups for maintenance messages correlated to FDEs show after the FDE summary groups.

THIS PAGE INTENTIONALLY LEFT BLANK

CMCS - MAINTENANCE ACCESS TERMINAL - SYSTEM TESTS

General

These are the six system tests for the maintenance access terminal (MAT):

- MAT Display Unit System Test
- MAT Display Brightness System Test
- MAT Display Unit Graphical Pattern System Test
- MAT Cursor Control Unit System Test
- MAT Standard Disk Drive System Test
- MAT AVLAN System Test.

MAT Display Unit System Test

This test makes sure the power-on self-tests run correctly. The approximate time to run the test is one to three minutes.

You must do this test from a portable maintenance access terminal.

MAT Display Brightness System Test

This test makes sure the brightness control analog inputs operate correctly. The approximate time to do the test changes based on the operator.

You must do this test from a portable maintenance access terminal.

MAT Display Unit Graphical Pattern System Test

This test makes sure the graphics capability of the display operates correctly. The approximate time to do the test changes based on the operator.

You must do this test from a portable maintenance access terminal.

MAT Cursor Control Unit System Test

This test makes sure the maintenance access terminal cursor controller operates correctly. The approximate time to do the test changes based on the operator.

For this test, you will move the cursor control and look at the results on the display.

MAT Standard Disk Drive System Test

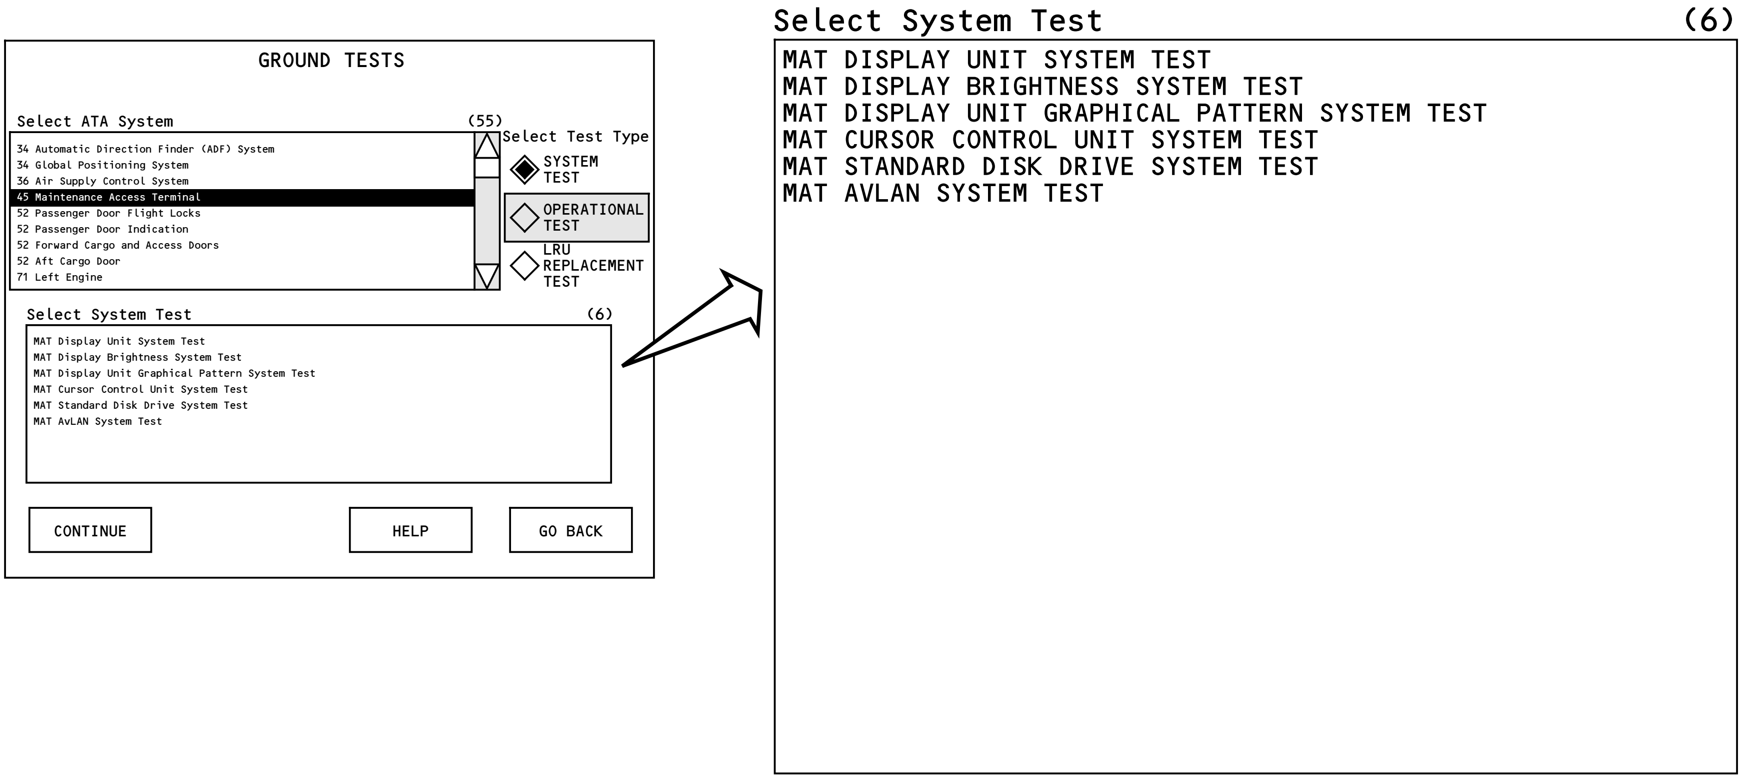
This test makes sure the standard disk drive operates correctly by writing to a diskette and reading back the results. The approximate time to do the test is less than one minute.

For this test, you will insert a formatted, writable diskette into the standard disk drive.

MAT AVLAN System Test

This test makes sure the avionics local area network (AVLAN) interface to the MAT display unit functions correctly. The approximate time to do the test is less than one minute.

You must do this test from a portable maintenance access terminal.



45-10-00-123 Rev 4 07/27/1995

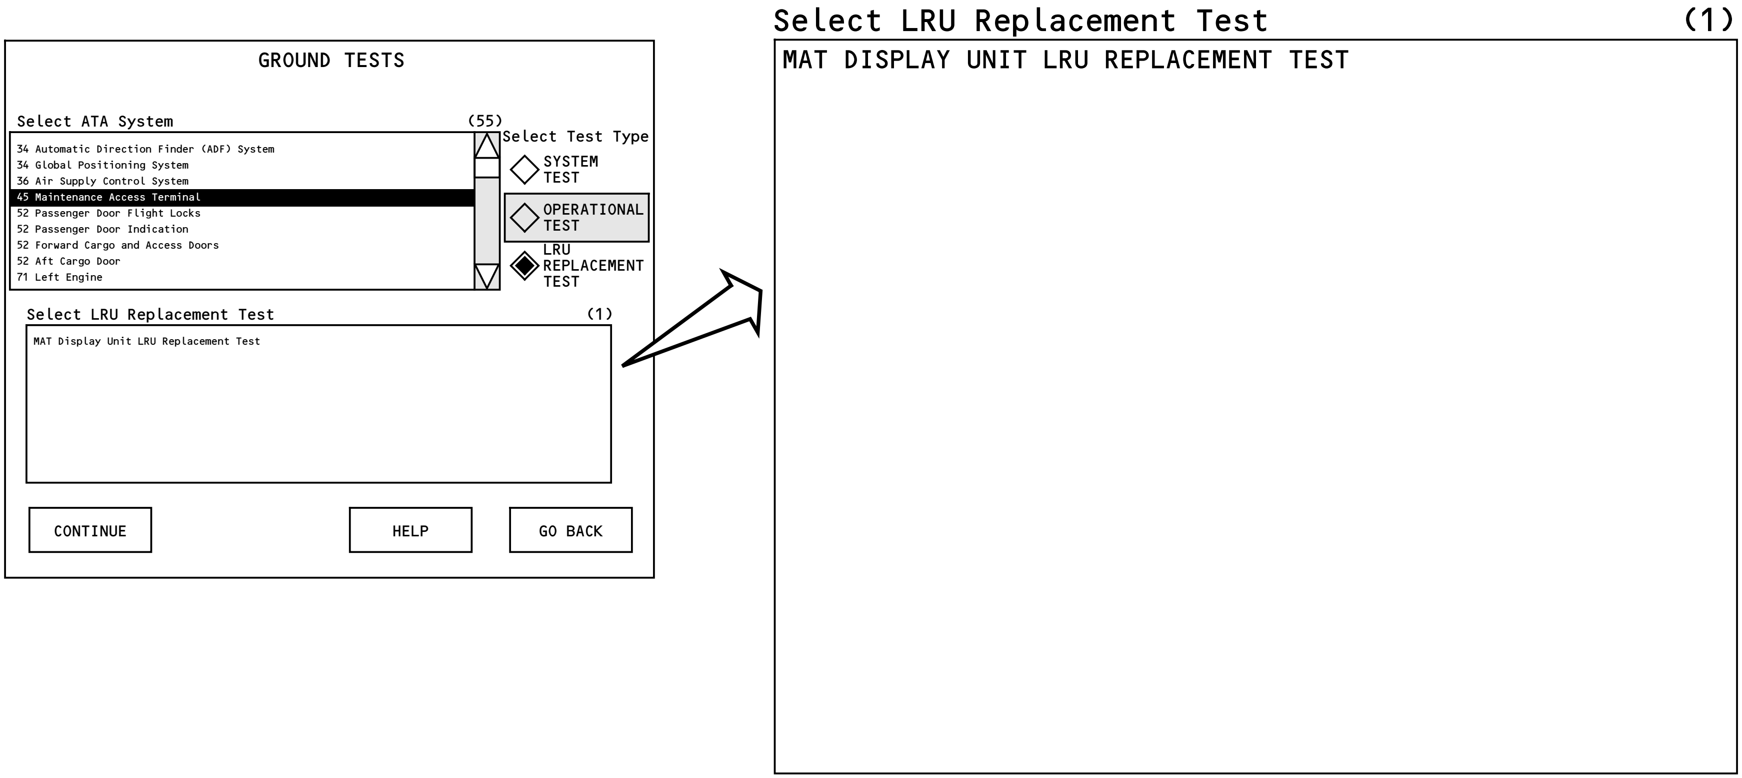
CMCS - MAINTENANCE ACCESS TERMINAL - SYSTEM TESTS

General

There is one LRU replacement test for the maintenance access terminal (MAT). It is the MAT display unit LRU replacement test.

MAT Display Unit LRU Replacement Test

The MAT display unit LRU replacement test does a check of the fiber optics interface between the display unit and the avionics local area network (AVLAN). It also does a check of the interface between the display unit and other MAT functions.



45-10-00-124 Rev 3 07/27/1995

Continental Airlines, Inc

777 Manuals

WB371

TABLE OF CONTENTS

777 MAINTENANCE DOCUMENTS - INTRODUCTION

General

The maintenance documents for the 777 supply help for all maintenance activities. You use many different documents to do scheduled and unscheduled maintenance.

Scheduled Maintenance

These are examples of scheduled maintenance work:

- Through stop checks
- Airplane turn around
- Daily checks
- Planned checks.

You use these documents to do scheduled maintenance:

- Maintenance Planning Data (MPD) Document
- Airplane Maintenance Manual (AMM).

Unscheduled Maintenance

These are examples of unscheduled maintenance work:

- Flight faults
- Ground faults
- Service problems
- Structural damage.

You use these documents to do unscheduled maintenance:

- Fault Reporting Manual (FRM)
- Maintenance Tips
- Fault Isolation Manual (FIM)
- Structural Repair Manual (SRM)
- Dispatch Deviations Guide (DDG)
- Airplane Maintenance Manual.

Supporting data

These documents supply supporting data to do scheduled and unscheduled maintenance:

- System Schematics Manual (SSM)
- Wiring Diagram Manual (WDM)
- Illustrated Parts Catalog (IPC)
- Standard Wiring Practices Manual.

Maintenance Planning Data (MPD) Document

The MPD defines the tasks for each type of scheduled maintenance check. Most airlines use the MPD to make a set of task cards that the technician uses during the checks.

Airplane Maintenance Manual (AMM)

The AMM has two parts. Part I is the Systems Description Section (SDS). This section replaces the Description And Operation (D and O) section of airplane models before the 777. Part II is maintenance practices and procedures.

The practices and procedures has data related to these functions:

- Removal and installation of components
- Component Location
- Maintenance practices
- Servicing
- Adjustment/test
- Inspection/check
- Cleaning/painting
- Repair.

Fault Reporting Manual (FRM)

The flight crew uses the FRM to improve communication with maintenance personnel. The flight crew uses the FRM to get fault codes for airplane faults. These faults can be flight deck effects or other faults. The FRM has standard log book write-ups for each fault code.

The flight crew can send the fault code to ground personnel. This permits faster maintenance when the airplane lands.

FRM fault codes refer you to the FIM.

Maintenance Tips

Maintenance tips give information that help the mechanic with specified procedures. The information is short and simple so it is easy to understand. The maintenance tip gives mechanics information to make repairs quickly and easily. It has these sections:

- Subject
- Applicability
- Condition
- Recommended action
- Background (optional)
- Maintenance manual action.

Fault Isolation Manual (FIM)

You use the FIM to repair airplane faults. You start the fault isolation process with FRM fault codes or other fault data. You use the fault data and the FIM to identify the maintenance action(s) to correct the fault.

Structural Repair Manual (SRM)

The SRM supplies data and specific instructions to help in field repair of airplane structure. The SRM is not customized. It has data related to these areas:

- Allowable damage evaluation
- Typical repairs
- Material identification
- Material substitution
- Fastener installation
- Alignment check
- Planning.

Dispatch Deviation Guide (DDG)

The DDG supplies Boeing's recommended minimum equipment necessary for dispatch in the master minimum equipment list (MMEL). It also supplies the procedures and references to AMM procedures to dispatch the airplane with a fault.

The DDG also has an EICAS message section that has a relation to the MMEL.

System Schematics Manual (SSM)

The SSM gives the user an understanding of system operation and helps in the fault isolation process. It supplies the interconnection of all LRUs of a system or subsystem. It also supplies data for a general knowledge about system operation.

Wiring Diagram Manual (WDM)

The WDM supplies details of the point-to-point wiring on the airplane.

Illustrated Parts Catalog (IPC)

The IPC supplies part replacement data. This data includes:

- Hardware and software part number replacement
- Part illustrations
- Supplier data
- Specification numbers
- Recommended spares
- Service bulletin activity.

Standard Wiring Practices Manual

The Standard Wiring Practices Manual has instructions for maintenance and repair of the wiring of all Boeing airplanes. It is not customized.

Training Information Point

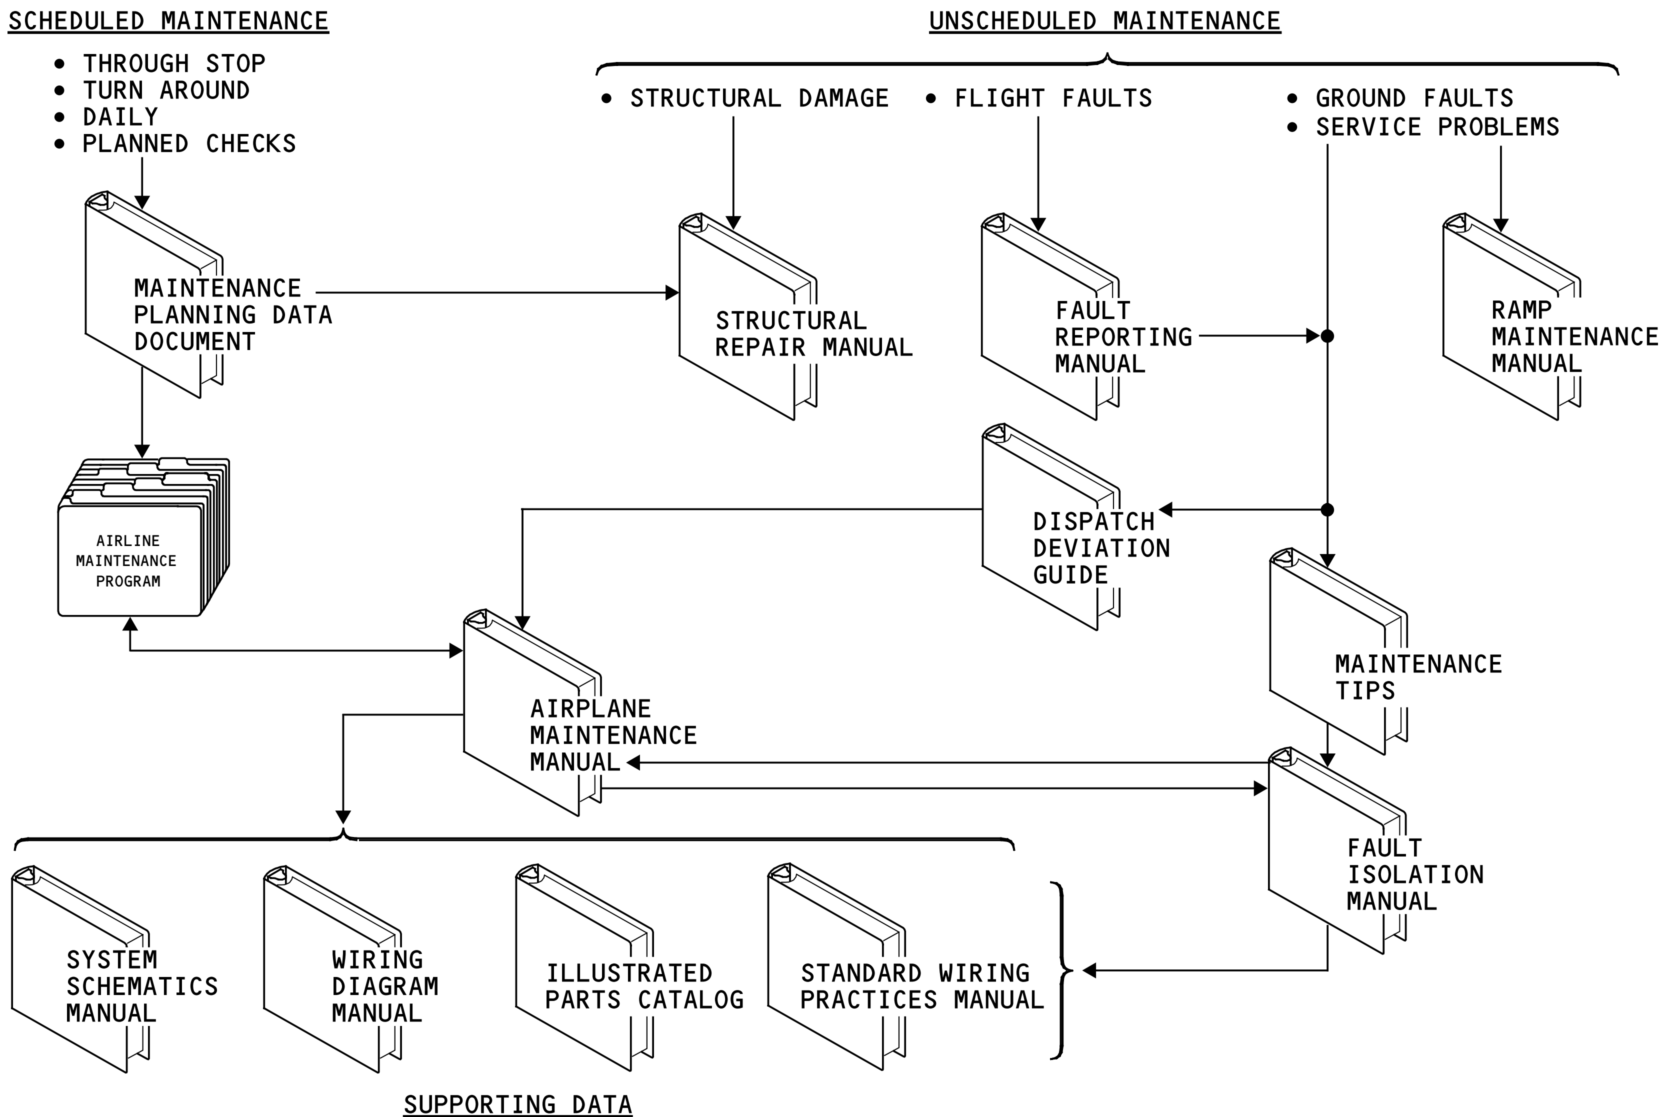
Each maintenance document has an introduction to show you how to use that document.

Abbreviations and Acronyms

AMM	- Airplane Maintenance Manual
AR	- airplane repair
ASN	- assigned subject number
A/T	- adjustment/test
ATA	- Air Transport Association
CL	- component location
CMCS	- central maintenance computing system
C/P	- cleaning/painting
DDG	- Dispatch Deviation Guide
FIM	- Fault Isolation Manual
FRM	- Fault Reporting Manual
I/C	- inspection/check
IPC	- Illustrated Parts Catalog
LRU	- line replaceable unit
MAT	- maintenance access terminal
MMEL	- Master Minimum Equipment List
MP	- maintenance practices
MPD	- Maintenance Planning Data

777 MAINTENANCE DOCUMENTS - INTRODUCTION

R/I	- removal/installation
SDS	- Systems Description Section
SRM	- Structural Repair Manual
svce	- service
SSM	- System Schematics Manual
WDM	- Wiring Diagram Manual



777 MAINTENANCE DOCUMENTS - INTRODUCTION

General

The airplane maintenance manual (AMM) Part I is the first of the two parts of the 777 AMM. It is called the systems description section (SDS). This section replaces the description and operation (D and O) section of earlier model Boeing airplanes. Both Part I and Part II of the AMM show the configuration of the airplanes in an operator's fleet. They have frequent revisions for improvements and for configuration changes.

Purpose

The SDS gives descriptions of the interfaces, function, and operation of the airplane systems and subsystems. You use these descriptions to become familiar with the airplane systems so that you can do fault isolation and system maintenance.

The SDS content and format is such that it can be a training manual.

Organization

The SDS uses text/graphic paravisuals (pagesets). Each graphic has one or more pages of text that describe the information on the graphic. The graphic has the primary information and the associated text page(s) have the support information or explanations.

The SDS uses a horizontal (sometimes called landscape) format. All pages (graphic and text) are 8-1/2 by 11 inches. The graphic page is always on the bottom (odd numbered page) of the text/graphic paravisual. The text pages have a double galley (two column) format.

Divisions

The SDS organization is by ATA chapter (system) or chapter/section (subsystem). Each ATA chapter/section usually defines an airplane system or subsystem. Several volumes (or binders) are used to cover all the airplane systems.

Each subject of the SDS has this information:

- Purpose/introduction
- General description
- Component location
- Interface
- Operation
- Functional description
- Training information points (TIPs).

TEXT PAGE

BOEING 777-200

MAINTENANCE MANUAL

777 AIR CONDITIONING - PACK FLOW CONTROL - OPERATION

Operation

When the pack switch on the P5 overhead panel is in the AUTO position, the CTC automatically controls the pack.

The CTC controls the operation of the two flow control and shutoff valves for the related pack. When the pack switch is in the OFF position, the CTC closes both valves. In this position, the OFF light on the pack switch comes on.

Functional Description

The CTC and air supply-cabin pressure controller (ASCPC) control the flow of air to the pack by adjustment of the flow control and shutoff valves. The ASCPC controls the valves for system shutdown and emergency flow control if the CTC loses electrical power.

The CTC closes the upper valve to permit flow through the lower valve and ozone converter at higher altitudes. The CTC closes the lower valve to permit flow through the upper valve and bypass the ozone converter at lower altitudes.

These sensors supply related inputs to the CTC:

- Flow sensor
- Primary heat exchanger inlet temperature sensor.

The flow sensor also supplies an input directly to AIMS.

These conditions cause the flow control and shutoff valves to adjust air flow to the packs:

- Cabin pressure
- Altitude
- Airplane operation
- Faults.

THIS PAGE INTENTIONALLY LEFT BLANK

777 MAINTENANCE DOCUMENTS - AMM PART II - INTRODUCTION

General

Part II of the AMM has the maintenances practices and procedures to do maintenance on the airplane.

Chapter Numbering System

The manual has a tab section for each ATA chapter. Within each tab section, the manual has more divisions that use the assigned subject number (ASN) list number XX-YY-ZZ, where:

- XX is the ATA chapter
- YY is the subsystem or sub-subsystem
- ZZ is the unit (component).

The table of contents for each chapter lists the maintenance procedures in numerical order for each subsystem and sub-subsystem. For each subsystem or sub-subsystem, the maintenance tasks are in alphabetical order based on the page numbers described below.

Page Numbering System

Each page has two numbers in the lower right corner: the ASN and a topic page number. Each topic is made up of a page block. Each page block is for a special type of information. These are the page blocks:

Type of Information	Page Block
COMPONENT LOCATION (CL)	101-199
MAINTENANCE PRACTICES (MP)	201-299
SERVICING (SRV)	301-399
REMOVAL/INSTALLATION (R/I)	401-499
ADJUSTMENT/TEST (A/T)	501-599
INSPECTION/CHECK (I/C)	601-699
CLEANING/PAINTING (C/P)	701-799
REPAIRS (AR)	801-899
DISPATCH DEVIATIONS GUIDE (DDG)	901-999

The dispatch deviations guide page block is new with the 777. It has procedures with maintenance tasks that prepare the airplane for flight with certain systems/ components inoperative. It also has tasks that put the airplane back to its usual condition.

If all the topics for an ATA chapter, subsystem, or sub-subsystem are brief, all the topics are in a single MAINTENANCE PRACTICES page block.

Component Locations

The COMPONENT LOCATION topic has a component index and component location illustrations.

The component index is an alphabetical list of all components for the system, subsystem, or sub-subsystem. There is a reference to the figure and sheet for each component.

777 MAINTENANCE DOCUMENTS - AMM PART II - INTRODUCTION

Components from different systems that have an operational relationship to the system, are also in the index. These components have a cross-reference to the chapter to which they are assigned.

Circuit breakers and other electrical components that do not have specific maintenance manual procedures have references to the wiring diagram manual (WDM).

Training Information Point

Each chapter of part II of the AMM has a list of effective pages at the beginning of each chapter.

Chapter 12 of the AMM has the title SERVICING. This chapter has procedures to fill and drain items such as:

- Fuel
- Oil
- Hydraulic fluid
- Water
- Tire pressure.

777 MAINTENANCE DOCUMENTS - AMM PART II - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

777 MAINTENANCE DOCUMENTS - AMM PART II - MAINTENANCE TASK STRUCTURE

General

The maintenance tasks are procedures for specific maintenance requirements. For example, R/I page blocks normally contain two tasks: removal of the LRU and installation of the LRU.

Each procedure has some or all of these paragraphs:

- General
- Access
- Prepare for removal
- Equipment
- Consumable materials
- References.

General Paragraph

The general paragraph is an introduction that gives the purpose and limitations of the task. There may be a general paragraph for the page block, or for each task.

References Paragraph

The references paragraph is a list that supplies all references. References may be made to other AMM procedures or other manuals.

Access Paragraph

The access paragraph is a summary of all location zones and access panel information to do the task. See chapter six of the maintenance manual for more information on the zone and access panel numbering systems.

Prepare for Removal Paragraph (Not Shown)

The prepare for removal paragraph is for tasks in the R/I page block. The paragraph gives all the things you must do before you start the task. This includes any doors, panels, or circuit breakers that you must open.

Equipment Paragraph

The equipment paragraph is a summary of all tools and test equipment to do the task. Each piece of equipment also has its part number.

Consumable Materials Paragraph

The consumable materials paragraph is a summary of all consumable materials necessary to complete the task. The Boeing Spares Department gives each airline a list of all consumable materials that you need to do all the tasks in the maintenance manual.

Procedure Paragraph

The procedure paragraph has the steps to complete the task.

Training Information Point

Each page has a section that gives the effectivity of the page. It may say ALL or it may give specified airplane identification numbers.

POWER DOOR OPENING SYSTEM (PDOS) - SERVICING

GENERAL PARAGRAPH

1. General
   A. This procedure has one task:
      (1) Fill the power door opening system (PDOS) pump (referred to as the PDOS pump) with oil.

   TASK 12-12-02-610-801

2. Fill the PDOS Pump with Oil (Fig. 301)
   A. General
      (1) The PDOS pump is installed in the brackets on the fan cowl support assembly. The fan cowl support assemble is on the forward side of the strut. You must remove the No. 1 forward fairing from the strut to get access to the PDOS pump.
      (2) You need to use the fall arrest lifeline procedure or other safety equipment to do this task.
      (3) After the oil servicing, you must do a bleed air check on the PDOS system.

777 MAINTENANCE DOCUMENTS - AMM PART II - MAINTENANCE TASK STRUCTURE

THIS PAGE INTENTIONALLY LEFT BLANK

777 MAINTENANCE DOCUMENTS - MAINTENANCE TIPS

General

The maintenance tip gives information that helps the mechanic in a procedure. The information is short and simple so it is easy to understand. It is published and mailed within 10 days by Boeing Service Engineering. The maintenance tip gives mechanics information to make repairs quickly and easily. It has these sections:

- Number
- Release date
- Subject
- Applicability
- Condition
- Recommended Action
- Background (optional)
- Maintenance Manual Action
- Reason For Cancellation (optional)
- Reference Message Number (#) (optional).

Number

The maintenance tip number has five digits. The first two digits are the ATA chapter. The last three digits are the sequence number for the ATA.

Release Date

This is the publication date for the maintenance tip.

Subject

The subject shows the topic of the procedure.

Applicability

The applicability gives line numbers, airplanes, or part numbers and software if necessary.

Condition

The condition section gives a brief description of the condition.

Recommended Action

This section gives the actions necessary to dispatch the airplane. This section may include a sketch if applicable.

Background (optional)

The background section gives the probable cause of the condition. It may tell how to prevent the condition.

Maintenance Manual Action

This section shows which manuals have updates.

Reason For Cancellation (optional)

This section shows why this maintenance tip is no longer in effect. CANCELLED also shows across the first page of the maintenance tip.

Reference Message Number (#) (optional)

This section has the central maintenance computing system maintenance messages shown in this tip.

RELEASE DATE

21 JUNE 1996

SUBJECT

SUBJECT GPS STATUS MESSAGES

APPLICABILITY

APPLICABILITY All 777-200 airplanes equipped with P/NS242T104-201 (XYZ Corp P/N XG2021GP01) Global Positioning System (GPS) sensor units.

CONDITION

CONDITION "GPS L" or "GPS R" status message displayed.

RECOMMENDED ACTION

RECOMMENDED ACTION If the status message "GPS L" or "GPS R" is displayed after a flight, accomplish the following:

1. View the PRESENT LEG FAULT information for the flight where the "GPS L,R" status message was displayed.
2. Check for the following maintenance messages:

   34-52801 = GPS sensor unit (left) has no output on any bus
   34-52802 = GPS sensor unit (right) has no output on any bus

3. If either of these maintenance messages are correlated to the "GPS L" or "GPS R" status message, then cycle the circuit breaker for the applicable GPS sensor unit:

GRID LOCATION	NOMENCLATURE	
11G5	GLOBAL POS L	for left GPS sensor unit
11G18	GLOBAL POS R	for right GPS sensor unit

If cycling power to the GPS sensor unit does not clear the status message, then the GPS sensor unit should be replaced.

BACKGROUND

BACKGROUND Boeing is currently investigating a condition experienced during flight where the XYZ Corp. GPS sensor unit detects a critical fault and shuts down. The result is display of the "GPS L" or "GPS R" status message. Cycling electrical power to the GPS sensor clears the status message and restores normal operation of the sensor unit. Subsequent shop testing of GPS sensor units removed from the airplane due to this condition results in the unit testing ok with no faults found. Since this is a potential nuisance message condition, this maintenance tip is being issued to advise maintenance crews to first cycle power to the GPS sensor unit when the aforementioned maintenance messages are displayed.

MAINTENANCE MANUAL ACTION

MAINTENANCE MANUAL ACTION The 5 September 1996 revision to the 777 Fault Isolation Manual will include the troubleshooting information in this maintenance tip.

REFERENCE MAINTENANCE MESSAGE NUMBER

REFERENCE MSG # 34-52801
34-52802

777 MAINTENANCE DOCUMENTS - MAINTENANCE TIPS

01-00-00-023 Rev 0 11/04/1996

777 MAINTENANCE DOCUMENTS - SYSTEM SCHEMATICS MANUAL (SSM)

Purpose

The system schematics manual gives the user an understanding of system operation and helps in the fault isolation process. To do this, the manual includes this kind of information on the schematics:

- Component locations
- Component identification (drawings)
- Controls
- Displays
- Logic for system/subsystem operation
- Logic for messages.

Organization

The system schematics manual organization is by ATA chapter, then chapter/section (subsystem). Each ATA chapter/section usually defines an airplane system or subsystem. Within an ATA chapter, the schematics show in increasing depth or complexity.

The schematic numbers follow this order:

- ATA chapter/section (four-digit number)
- Schematic number (two-digit number)
- Page number
- Sheet number.

Page numbers (Page 101, 102, etc.) show configurations of a schematic for different airplanes in a customer's fleet.

There is a sheet number only if the schematic cannot show on one sheet.

General Chapter

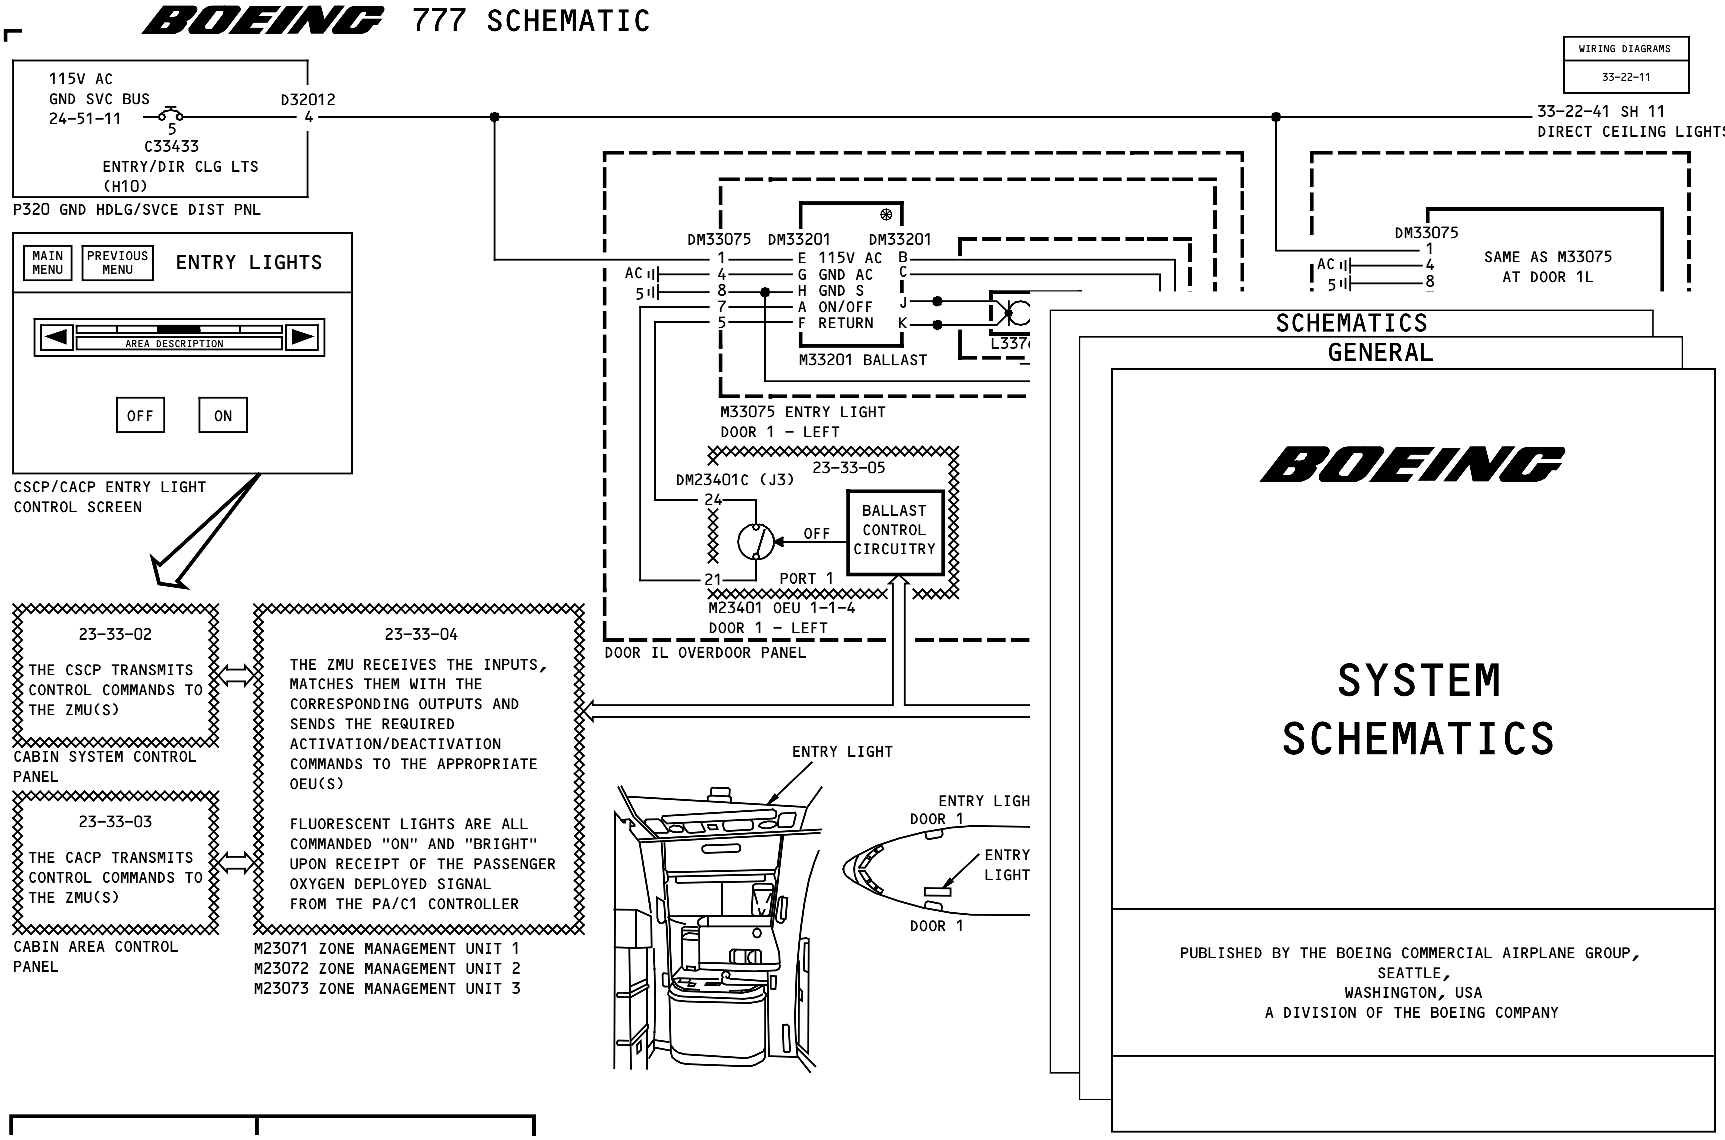
There is a general chapter. It has chapter number 00. The general chapter has this customized data:

- 00-00-00-00; Airplane principal dimensions
- 00-00-00-10; Ground service access panels
- 00-00-00-20; Airplane stations
- 00-00-00-30; Panel locations (including circuit breaker panel configurations)
- 00-00-00-40; Equipment center locations and configurations.

Training Information Point

Schematics and wiring diagrams show two important improvements that affect the maintenance technician. First, the equipment number of an LRU on the 777 has the ATA chapter of the LRU as the first two numbers. These numbers are after the letter that shows the kind of LRU (M, K, L, etc.).

Second, the connector numbers for an LRU are the same as the equipment numbers with the letter "D" in front. For example, the connector for the M33075 entry light is DM33075. The exception to this is for connectors on power panels which have numerous connectors. In this case, the connector number has the panel number and a two-digit connector number. For example, a connector on the P320 panel is D32012.



01-00-00-005 Rev 2

777 MAINTENANCE DOCUMENTS - SYSTEM SCHEMATICS MANUAL (SSM)

777 MAINTENANCE DOCUMENTS - WIRING DIAGRAM MANUAL (WDM)

Purpose

The wiring diagram manual gives details of the point-to-point wiring on the airplane. It shows all connectors including breakout and shelf connectors.

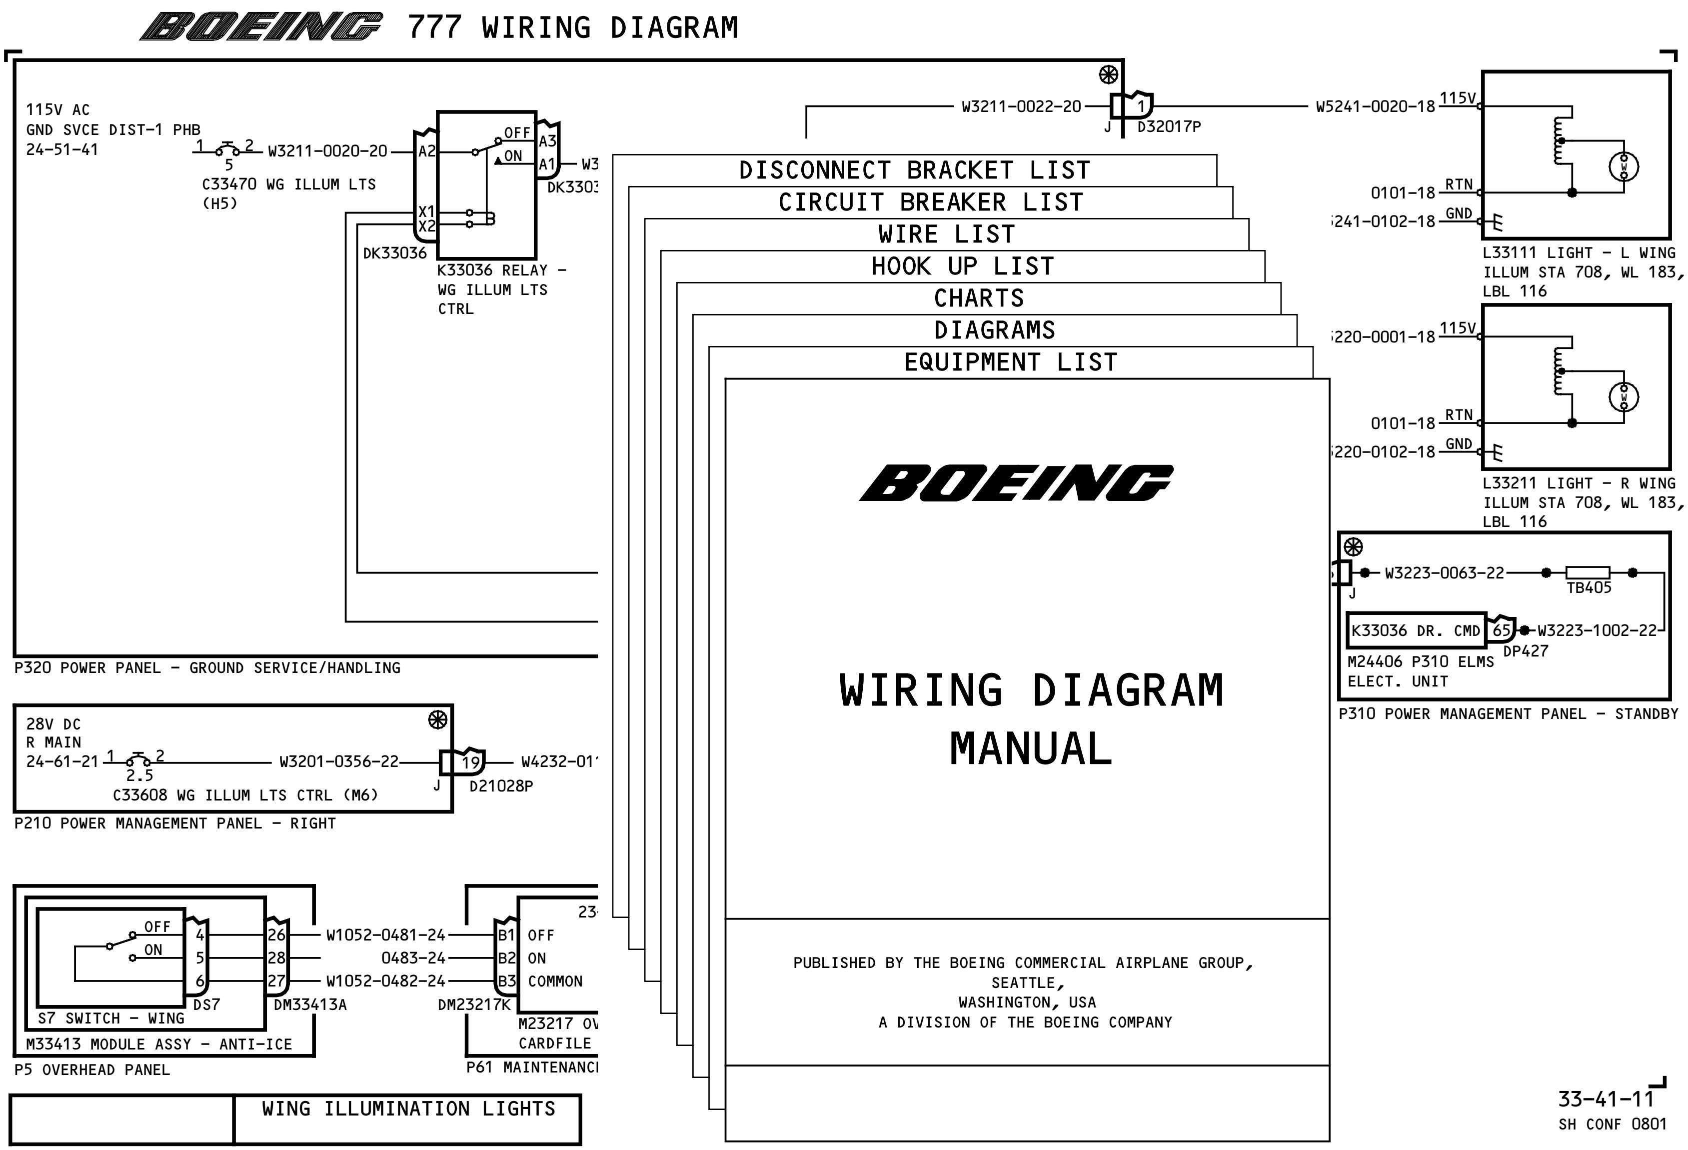
The wiring diagram shows simple internal components of LRUs so the user may better understand the signal flow and purpose of the wiring. Internal components do not show if they are complex or if the signal(s) comes from or goes to software.

Organization

The organization of the wiring diagram manual is similar to the system schematic manual. It uses the ATA chapter/section organization.

These are the sections of the wiring diagram manual:

- Equipment list
- Diagrams
- Charts
- Hook up list
- Wire list
- Circuit breaker list
- Disconnect bracket list.



777 MAINTENANCE DOCUMENTS - WIRING DIAGRAM MANUAL (WDM)

General

The dispatch deviations guide (DDG) helps the airline operations and maintenance organizations. It helps these organizations develop the procedures to operate their airplane in non-standard configurations. This manual shows the Federal Aviation Administration's (FAA) permitted non-standard configurations. It has these sections:

- Introduction
- EICAS Messages
- Minimum Equipment List Items
- Configuration Deviation List Items
- Ferry Items
- Miscellaneous Items.

Introduction

The introduction section gives the purpose, background, contents, and organization of the DDG.

EICAS Messages

The DDG has an EICAS message list with a cross reference to the minimum equipment list items. Use the EICAS message list to find the minimum equipment list (MEL) item for possible dispatch relief. The EICAS message is in alphabetical order by EICAS message text.

The EICAS message list has these parts:

- Message text
- Level
- Notes
- Condition
- MMEL item.

The message text shows the text of the EICAS message as it shows on the airplane.

These are the EICAS message levels:

- Warning
- Caution
- Advisory
- Comm
- Memo
- Status.

The notes show if the EICAS message is basic, optional, or provisional.

The condition gives a description of what causes this EICAS message.

Use the MEL item to find the necessary procedures to operate the aircraft in a non-standard configuration.

Minimum Equipment List Items

The FAA publishes a master minimum equipment list (MMEL). The operator can add to the MMEL. Then it is the MEL. The MEL has the minimum equipment and the procedures necessary to operate the aircraft. The company MEL cannot be less restrictive than the master minimum equipment list.

The MEL has an ATA index of MEL items and a list of definitions.

The MEL items are in ATA sequence. There is a general system schematic at the start of each ATA chapter.

These are the parts of the minimum equipment list items:

- Item
- Repair Interval
- Number Installed
- Number Required For Dispatch
- Remarks Or Exceptions
- EICAS Status Messages
- Placard
- Maintenance Procedure (optional)
- Operations Procedure (optional).

The Item is the equipment, system, or function installed in the airplane.

The Repair Interval shows when you must repair the item. Repair intervals are specified in the front section of the MEL. These letter codes show the time interval:

- A; as shown in the remarks or exceptions column
- B; within 3 consecutive calendar days
- C; within 10 consecutive calendar days
- D; within 120 consecutive calendar days.

The Number Installed is the quantity usually installed in the airplane. A dash "-" shows if the quantity can change.

The Number Required For Dispatch is the minimum quantity necessary for operation if you meet the conditions in the remarks of exceptions column. The MMEL may show a dash "-" in this column. The MEL must show actual quantity required.

The Remarks Or Exceptions column shows what you must do to release the airplane. It may also show operations notes and limits.

The EICAS Status Message section lists the EICAS status messages that show when this item does not operate.

The Placard section shows the placard and where you must put it when this item does not operate.

Some MEL items have a Maintenance Procedure that you must do to release the airplane. The maintenance procedure is listed in the MEL if it is simple. A reference to the procedure in the 900 page block of the airplane maintenance manual (AMM) is listed if the procedure is more complex.

Some MEL items have an Operations Procedure. The flight crew must do this procedure if your airline operates the airplane when this item does not operate.

Configuration Deviation List Items

The Configuration Deviation List (CDL) is an appendix to the FAA approved aircraft flight manual (AFM). It includes secondary airframe and engine parts which you do not have to have for dispatch.

Ferry Items

A ferry flight occurs when it is necessary to fly the aircraft back to a maintenance base for repairs. Your airline makes a ferry flight when the MMEL or the CDL does not permit dispatch with revenue passengers. The Ferry Items section contains information you must have for dispatch with a configuration deviation for a ferry flight.

Miscellaneous Items

The Miscellaneous Items section contains a list of items that are unique and do fit in the other deviation lists.

DISPATCH DEVIATIONS GUIDE

ATA 27
Flight Controls

ITEM		REPAIR INTERVAL	NUMBER INSTALLED	NUMBER REQUIRED FOR DISPATCH	REMARKS OR EXCEPTIONS
27-62-1	Automatic Speedbrake Function	C	1	0	(M)(O) May be inoperative deactivated provided: a) Landing gear truck tilt pressure is verified to be normal before each flight, and b) Landing performance is based on manual speedbrakes.

EICAS STATUS MESSAGES

AUTO SPEEDBRAKE

PLACARD

Speedbrake lever ARMED detent on control stand -AUTO INOP

MAINTENANCE (M)

Deactivate the automatic speedbrake (AMM27-00-00/900).

1. AUTO SPDBRK (L,R) on the left power supply assembly (PSA-L) located in the E1-6 rack in the Main Equipment Center.
2. AUTO SPDBRK (L,R) on the right power supply assembly (PSA-R) located in the E5-1 rack aft of the forward cargo door.

Verify truck tilt pressure is normal.

1. Ensure landing gear lever is in the DOWN position.
2. Pressurize the center hydraulic system.
3. After 2 minutes, verify pressure readings for the L TRUCK TILT and R TRUCK TILT hydraulic lines are 2750 to 3050 psi on the LANDING GEAR ACTN/INDN EICAS Maintenance Page.
4. If low pressure is detected in one or both truck tilt lines, the landing gear may not fully retract. The airplane may be dispatched under this item, provided the Landing Gear Actuation System is considered inoperative and dispatch is also made under item 32-30-1, Landing Gear Actuation System.

OPERATIONS (O)

Speedbrake must be manually controlled for landing or rejected takeoff. Base landing performance on manual speedbrakes.

D630W003 Oct 12/95

DISPATCH DEVIATION GUIDE - MINIMUM EQUIPMENT LIST ITEM

THIS PAGE INTENTIONALLY LEFT BLANK

General

The fault reporting manual (FRM) gives the flight crew a simple list of fault descriptions. Each fault description has a fault code.

When the flight crew finds a problem on the airplane, they look for the description of the fault indication in the FRM. They write the fault description and the fault code in the log book. They can also send the information to a ground station so maintenance personnel can prepare before the airplane arrives.

The FRM has these sections:

- EICAS alert messages
- Observed faults
- EICAS status messages
- Cabin faults.

EICAS Alert Messages

The EICAS ALERT MESSAGES section is an alphabetical list of all EICAS warning, caution, and advisory messages. With each message is the message level (warning, caution, or advisory) and a fault code.

This information is the same as the information in the fault isolation manual (FIM). The FIM also has a brief description of the message. See the section on the FIM for more information.

Observed Faults

The OBSERVED FAULTS section is an alphabetical list of fault descriptions for malfunctions that the flight crew or ground service crew can see. These are some examples of observed faults:

- Flap lever difficult to operate
- Tire number 6 is worn.

This information is also in the FIM. The FIM also has a FIM task number. See the section on the FIM for more information.

EICAS Status Messages

The EICAS STATUS MESSAGES section is an alphabetical list of all EICAS status messages. Status messages are in a separate section because it is not necessary for the flight crew to monitor status messages during flight.

With each message is a brief description and a fault code.

This information is also in the FIM. See the section on the FIM for more information.

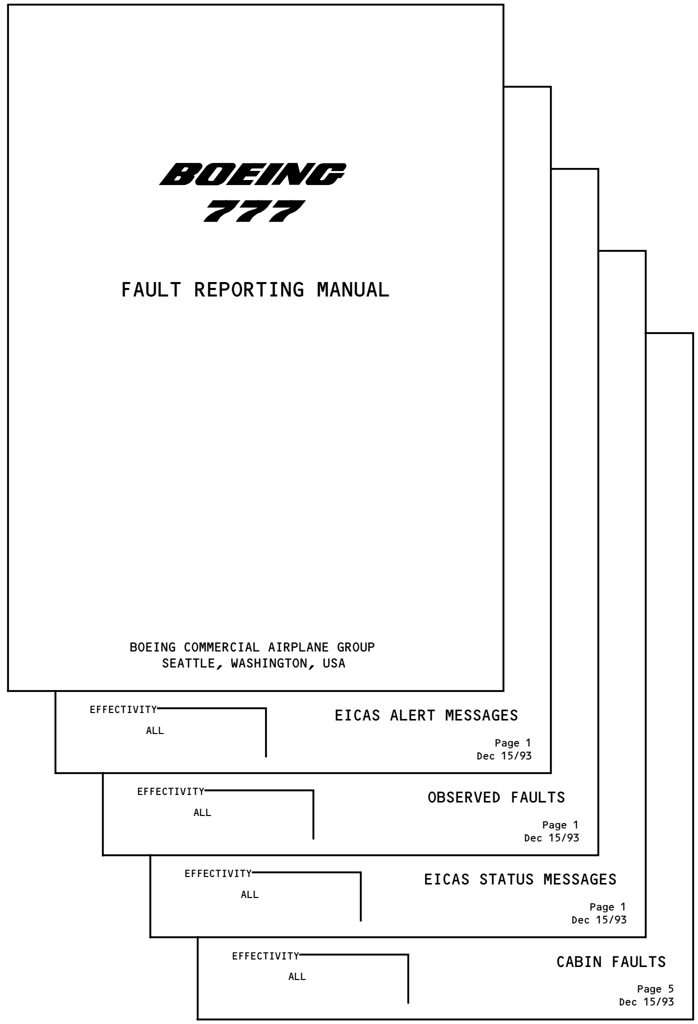
Cabin Faults

The CABIN FAULTS section is a list of fault descriptions for malfunctions that the cabin crew can see. The faults are in groups based on system function.

777 MAINTENANCE DOCUMENTS - FAULT REPORTING MANUAL (FRM)

With each description is a fault code. An example of a cabin fault is: GALLEYS - OVEN - DOES NOT HEAT.

This information is the same as the information in the FIM. The FIM also has a FIM task number. See the section on the FIM for more information.



777 MAINTENANCE DOCUMENTS - FAULT REPORTING MANUAL (FRM)

General

You use the fault isolation manual (FIM) to isolate and correct airplane faults.

To isolate a fault, you must get a FIM task number. You use different sections of the FIM along with airplane data to identify the correct task number.

The FIM has front subjects and chapter subjects.

FIM Front Subjects

You use the front subjects to find a fault code or a task number. With the fault code, you can find which tasks in the FIM you must do to correct the fault. These are the front subjects:

- EICAS message list
- Observed fault list
- Cabin fault list
- Cabin fault code index.

FIM Chapter Subjects

The chapter subjects have two types of information. The subjects have the fault isolation tasks. They also have information that help you identify the correct task. These are the chapter subjects:

- Fault code index
- Maintenance message index
- Fault isolation tasks
- Task support pages.

Training Information Point

If the flight crew does not supply a fault code, you can use the front subjects of the FIM to find the fault code.

777 MAINTENANCE DOCUMENTS - FIM - INTRODUCTION

777 MAINTENANCE DOCUMENTS - FIM - EICAS MESSAGE LIST

General

The EICAS MESSAGE LIST is an alphabetical list of all EICAS messages. Each message in the list has this information:

- Message level (warning, caution, advisory, status, communication, or memo)
- Brief description of the problem that causes the message
- Fault code.

See the primary display system section for information on EICAS message levels (AMM PART I 31-61).

Training Information Point

See the section on the FAULT CODE INDEX for information on the meaning of the digits of the fault code.

777 MAINTENANCE DOCUMENTS - FIM - EICAS MESSAGE LIST

777 MAINTENANCE DOCUMENTS - FIM - OBSERVED FAULT LIST

General

The OBSERVED FAULT LIST is an alphabetical list of fault descriptions for malfunctions that the flight crew or ground service crew can see.

These are the items in the list:

- Fault description
- Fault code
- FIM task number.

Training Information Point

When you use the list, select the fault that best describes the malfunction.

The same fault may have more than one description. For example, the fault code is the same for these descriptions:

- Glareshield panel light(s) do not come on
- Light(s), glareshield panel, do not come on.

777 MAINTENANCE DOCUMENTS - FIM - OBSERVED FAULT LIST

General

The CABIN FAULT LIST is a list of fault descriptions for malfunctions that the cabin crew finds. The faults are in groups based on system function.

These are the items in the list:

- Fault description
- Fault code
- FIM task number.

Cabin Fault Code Structure

Each cabin fault code starts with a letter. This tells you that the fault is not in a flight-related system. It shows the general cabin function. For example, G is the letter for galley faults.

The second and third digits show the type of component. For example, 01 is the code for a galley.

The fourth and fifth digits show the type of problem. For example, 33 is the code for an inoperative component.

The last three digits are not specified. The cabin crew uses these digits to enter a location identifier such as a seat number or galley location.

Training Information Point

When you use the cabin fault from the list, select the fault that best describes the malfunction.

Digits three, four, and five of the fault code are described in air transport association (ATA) specification 100.

777 MAINTENANCE DOCUMENTS - FIM - CABIN FAULT CODE INDEX

General

The CABIN FAULT CODE INDEX is an alphabetical list of fault codes for malfunctions that the cabin crew can see. You use the index when you have a cabin fault code.

The index has these items:

- Fault code
- Brief description
- FIM task number.

Training Information Point

The CABIN FAULT CODE INDEX has the same information as the CABIN FAULT LIST. The only difference is the faults are in alpha-numerical order of the fault codes. They are not grouped by system function.

777 MAINTENANCE DOCUMENTS - FIM - CABIN FAULT CODE INDEX

777 MAINTENANCE DOCUMENTS - FIM - FAULT CODE INDEX

General

The FAULT CODE INDEX is a numerical list of all fault codes for a chapter. With each fault code, there is a fault description and a minimum of one FIM task number.

If the fault description is an EICAS message, a list of maintenance messages shows next to the description. Each maintenance message has a specific task number reference on the same line. You must use the maintenance access terminal (MAT) to find the unique maintenance message for the fault.

See the central maintenance computing system section for more information on the MAT (AMM PART I 45-10).

Fault codes that are not for EICAS messages have one task number.

Fault Code Structure

All fault codes have eight digits. The codes have two blank spaces to make them easier to read.

The first three digits of the fault code are the ATA chapter plus the subsystem. For example, 213 is chapter 21 (air conditioning), subsystem 30 (pressurization).

The middle three digits are a unique number for the fault.

The last two digits are a location identifier, or an engine identifier. These location identifiers are described in air transport association (ATA) specification 100.

777 MAINTENANCE DOCUMENTS - FIM - FAULT CODE INDEX

777 MAINTENANCE DOCUMENTS - FIM - MAINTENANCE MESSAGE INDEX

General

The MAINTENANCE MESSAGE INDEX is a list in numerical order of maintenance message numbers for a chapter. With each message number is the symptom text for the message and a FIM task number.

You get maintenance messages from the MAT and the cabin system control panel (CSCP).

See the cabin services system section for more information on the CSCP (AMM PART I 23-39).

The maintenance message index has the task number references for all maintenance messages, even for messages which do not correlate to EICAS messages.

Each maintenance message has the problem that causes the message (MESSAGE SYMPTOM) and the FIM task number for the message.

Maintenance Message Structure

All maintenance messages have seven digits. The codes have a dash to make them easier to read.

The first two digits of the fault code are the ATA chapter.

The last five digits are a unique number for the fault.

777 MAINTENANCE DOCUMENTS - FIM - MAINTENANCE MESSAGE INDEX

777 MAINTENANCE DOCUMENTS - FIM - FIM TASKS

General

FIM tasks have the procedures to find and correct faults. The tasks are grouped at the sub-subsystem level. For example, all sub-subsystem 27-31 tasks are in a group. These tasks are in numerical order by task number.

The task identifier is the sub-subsystem number, the word TASK, and a three digit number.

Each FIM task assumes that the cause of the fault is a single component failure.

FIM Task Structure

Each FIM task has these parts:

- Task number and description
- Maintenance message
- Initial evaluation
- Fault isolation steps.

These are the assumed conditions at the start of the task:

- External electrical power is on
- Hydraulic power and pneumatic power are off
- Engines are shut down
- Circuit breakers for the system are closed.

The task has an initial evaluation paragraph that tells you if the fault is intermittent.

After the initial evaluation paragraph, the task has several steps. The steps may use several different paths. When you are at the end of a path, that task says that you corrected the fault.

Training Information Point

When a step in a FIM task says to do a wiring check, these are the types of checks you must do for the specified pins:

- Continuity from contact to contact
- Shorts between the contacts
- Shorts from each contact to ground.

A step in a FIM task may ask you to do a task in the AMM. After you do the AMM task, you must go back to the FIM and complete the FIM task.

BOEING 777
FAULT ISOLATION MANUAL

TASK NUMBER AND DESCRIPTION

805. Left Column Position Transducer 1 Problems - Fault Isolation

MAINTENANCE MESSAGE

A. This task is for maintenance message: 27-12000.

INITIAL EVALUATION PARAGRAPH

B. Initial Evaluation
   (1) If the MAT shows ACTIVE with the maintenance message, then do the Fault Isolation Procedure below.
   (2) If the MAT shows LATCHED with the maintenance message, then do the 27-Primary Flight Controls, Column Position Transducer test on the MAT.
   (3) If the MAT shows PASSED, then no corrective action is necessary.
   (4) If the MAT shows FAILED, do the Fault Isolation Procedure below.

FAULT ISOLATION STEPS

C. Fault Isolation Procedure
   (1) Make sure that the control column is at the neutral position.
   (2) Disconnect connector DM27134 from the left 1 column position transducer, M27134.
   (3) Do a check for 7 VAC between pins 8 and 9 of connector DM27134.
   (4) If there is 7 VAC between pins 8 and 9 of DM27134, do this check:
      (a) Measure the resistances between these pairs of pins of the connector on the transducer, M27134:
         1) Pin 1 to pin 5, specified resistance AA-BB ohms
         2) Pin 1 to pin 6, specified resistance CC-DD ohms
         3) Pin 8 to pin 9, specified resistance EE-FF ohms
      (b) If the resistance is not in the range specified for each pair of pins, replace the left 1 column position transducer, M27134 (AMM 27-31-04/401).
      (c) If the resistance is in the range specified for each pair of pins, do this check:
         1) Open these circuit breakers on the left PSA, M24101:
            a) A1 ACE PWR
            b) A3 AIL PCU
            c) A5 FLPRN PCU
            d) A7 ELEV PCU
            e) A9 RUD PCU
            f) B2 STAB TRIM
            g) B4 AUTOSPDBRK (L, R)
            h) B6 ELEV FEEL C
            i) B8 RUD TRIM ACTR (L)
         2) Remove the left 1 ACE, M27121 from the E1-5 shelf.
         3) Do a continuity check between these pins of connector DM27134 at the E1-5 shelf and connector D4474J at the E1-5 shelf (WDM 27-31-11):

WIRING CHECK

DM27134		D4474J
pin 1	-------------------------	pin 12
pin 5	-------------------------	pin 10
pin 6	-------------------------	pin 11

         4) If you find a problem in the wiring, do these steps:

777 MAINTENANCE DOCUMENTS - FIM - USE - 1

General

The FIM has an introduction section that gives you the procedure to do fault isolation. The introduction has these four figures:

- Figure one: basic fault isolation process
- Figure two: getting information from the MAT
- Figure three: find the fault isolation task in the FIM
- Figure four: Doing the fault isolation task.

Figure One: Basic Fault Isolation Process

The basic fault isolation process starts with some fault data that you have. Figure one tells you that after you get the fault data, you follow this sequence of steps:

- If necessary, use the MAT to get more information
- Go to the FIM task
- Do the FIM task.

Figure Two: Getting Information from the MAT

There are many locations in the MAT to get fault data. Figure two has a process to make sure you get the necessary data to complete the basic fault isolation process.

Figure Three: Find the Fault Isolation Task in the FIM

There are many locations in the FIM that help you find the FIM task number. For example, you can use the OBSERVED FAULT LIST or the MAINTENANCE MESSAGE INDEX to find a FIM task number. Figure three tells you where to find the task number if you have any of this data:

- Fault code
- EICAS message
- Observed or cabin fault description
- Maintenance message number (with no correlated EICAS message).

Figure Four: Doing the Fault Isolation Task.

Figure four tells you about the information that is in each FIM task. It also tells you how to do some of the steps in the task, such as a wiring check.

BOEING 777

FIGURE 3

BOEING 777
FAULT ISOLATION MANUAL

NOTE: Each task assumes that a single component failure caused the fault.

ASSUMED CONDITIONS AT START OF TASK
1. External electrical power is ON
2. Hydraulic power and pneumatic power are OFF
3. Engines are shut down
4. Circuit breakers for the system are closed
5. No equipment in the system is deactivated

INITIAL EVALUATION PARAGRAPH

The Initial Evaluation paragraph at the start of the task helps you determine whether you can detect the fault right now.

If you cannot detect the fault right now, then the task cannot isolate the fault and the Initial Evaluation paragraph will say that there was intermittent fault.

If you have an intermittent fault, you must use your judgement (and follow your airline's policy) to decide which components to replace. Then monitor the airplane to see if the fault happens again on subsequent flights.

FAULT ISOLATION STEPS

Follow the steps of the task in the order given. The "If...then" statements that you see will guide you along the correct path.

When you are at the endpoint of the path, the task says "You corrected the fault." Complete the step you are in and exit the procedure.

WIRING CHECKS

When a step says "Do a wiring check", do these three types of electrical checks for the specified contacts (pins):
- continuity from contact to contact
- shorts between the contacts
- shorts from each contact to ground

777 MAINTENANCE DOCUMENTS - FIM - USE - 1

THIS PAGE INTENTIONALLY LEFT BLANK

777 MAINTENANCE DOCUMENTS - FIM - USE - 2

General

You use the FIM, the other maintenance documents, and the MAT to isolate and correct faults. Because you can start fault isolation with different types of failure data, there are different paths to find the correct FIM task. As shown in figure one of the FIM introduction, you can start to isolate a fault with any of this data:

- EICAS message
- Observed fault
- Cabin fault
- Non-correlated maintenance message.

Start with an EICAS message

If you have an EICAS message, use the MAT to find the fault code and the maintenance message. You must do this because it is possible to have more than one maintenance message for an EICAS message. The MAT will tell you which maintenance message applies to the message.

If you have the fault code and a maintenance message, do these steps:

- Go to the fault code index for the applicable ATA chapter
- Find the fault code
- Record the FIM task that is next to the applicable maintenance message
- Go to the FIM task section for that ATA chapter
- Find the task.

Start with an Observed Fault

An observed fault is a fault that is not in the cabin and does not have an EICAS message. If you start with an observed fault, do these steps:

- Go to the observed fault list section
- Find the best match that describes the fault condition
- Record the FIM task
- Go to the FIM task section for the ATA chapter
- Find the task.

Start With A Cabin Fault

The cabin fault list has cabin faults in groups based on system function. The cabin fault code index has cabin faults in fault code order. Do these steps after you have the cabin fault code:

- Go to the cabin fault code index
- Find the fault code
- Record the FIM task
- Go to the FIM task section for the ATA chapter
- Find the task.

Start with a Non-Correlated Maintenance Message

A non-correlated maintenance message is a maintenance message that has no related EICAS message. If you start with a non-correlated maintenance message, do these steps:

777 MAINTENANCE DOCUMENTS - FIM - USE - 2

- Go to the maintenance message index section
- Find the maintenance message
- Record the FIM task
- Go to the FIM Task section for the ATA chapter
- Find the task.

The FIM also has task support pages. These pages have information to help you do specified fault isolation tasks. This may include simplified wiring diagrams or component access illustrations.

777 MAINTENANCE DOCUMENTS - FIM - USE - 2

THIS PAGE INTENTIONALLY LEFT BLANK

777 MAINTENANCE DOCUMENTS - AMM PART II - AMTOSS NUMBERS

General

All maintenance tasks and sub-tasks have an aircraft maintenance task oriented support system (AMTOSS) number. These are the reference numbers that you use to find a specified task. AMTOSS numbers show before each task and sub-task in the aircraft maintenance manual (AMM). These are examples of AMTOSS task numbers:

- TASK 29-11-05-000-801
- TASK 31-61-00-800-806
- TASK 71-11-04-010-804-G00.

These are examples of AMTOSS sub-task numbers:

- SUBTASK 870-001-002
- SUBTASK 710-001.

AMTOSS task numbers can have as many as six parts:

- ATA chapter
- ATA section
- ATA subject
- Function code
- Sequence number
- Configuration.

This is an example of the parts of an AMTOSS task:

AMTOSS TASK 71-11-04-010-804-N00	
71	ATA chapter
11	ATA section
04	ATA subject
010	Function code
804	Sequence number
G00	Configuration

ATA Chapter, Section, and Subject

These parts identify the airplane part for this task. Each has two digits.

Sub-Task Numbers

AMTOSS sub-task numbers can have as many as three parts:

- Function code
- Sequence number
- Configuration.

This is an example of the parts of the AMTOSS sub-task:

SUBTASK 870-001-002	
870	Function code
001	Sequence number
002	Configuration

Function Code

The function code defines the maintenance task. It has three alpha-numeric digits. The full definition of the function codes is in ATA Specification 100. The first two digits define the type of task. The third digit is not used by Boeing and is always zero. This is a list of the first two digits of the function codes:

Function Codes 0x0: Removal	
010	Remove, open for access
020	Remove, disconnect, loosen, remove unit, component, or item
040	Deactivate
070	Erase/delete software or data
080	Remove test or support equipment

Function Codes 1x0: Cleaning	
110	Chemical
120	Abrasive
130	Ultrasonic
140	Mechanical
150	Stripping
160	Miscellaneous cleaning
170	Flushing

Function Codes 2x0: Inspection, Checks	
210	General visual
220	Detailed dimensional
230	Penetrant
240	Magnetic
250	Eddy current
260	X-ray holographic
270	Ultrasonic
280	Special or specific
290	Borescope

Function Codes 3x0: Repair	
310	Welding or brazing
320	Machining, reaming, or blending
330	Composite
340	Fiberglass, plastic, honeycomb, or epoxy
350	Miscellaneous repair
360	Leakage repair
370	Painting
380	Plating
390	Sealing

Function Codes 4x0: Installation	
410	Install, close items removed, opened for access
420	Install, reconnect unit, tighten safety component or item
440	Reactivate
470	Install/load data or software
480	Install test or support equipment

Function Codes 5x0: Material and Aircraft Handling	
510	Shipping
520	Receiving
530	Packing
540	Unpacking
550	Storage or return to service
560	Marshaling or positioning
570	Engine ferry or pod maintenance
580	Aircraft handling

Function Codes 6x0: Servicing, Preserving, and Lubricating	
610	Servicing
620	Preserving
630	De-preserving
640	Lubricating
650	Fueling or defueling
660	Deicing or anti-icing
670	Disinfect or sanitize
680	Drain fluid

Function Codes 7x0: Testing and Checking	
710	Operational
720	Functional
730	System
740	BITE
750	Special
760	Electrical
780	Pressure
790	Leak

Function Codes 8x0 and 9x0: Miscellaneous	
810	Fault isolation
820	Adjusting, aligning, calibrating, or rigging
840	Preparing for maintenance or restoring to normal
850	Operator modification incorporation
860	Aircraft or system configuration
870	Bleeding
880	Heating or cooling
890	Airline maintenance program
900	Change (remove and install)
910	Standard practices
930	Marking
940	Job set up or close up
950	Masking
960	Replace
970	Data recording or calculating
980	Manual operation or positioning
990	Illustrations or tables

Sequence Number

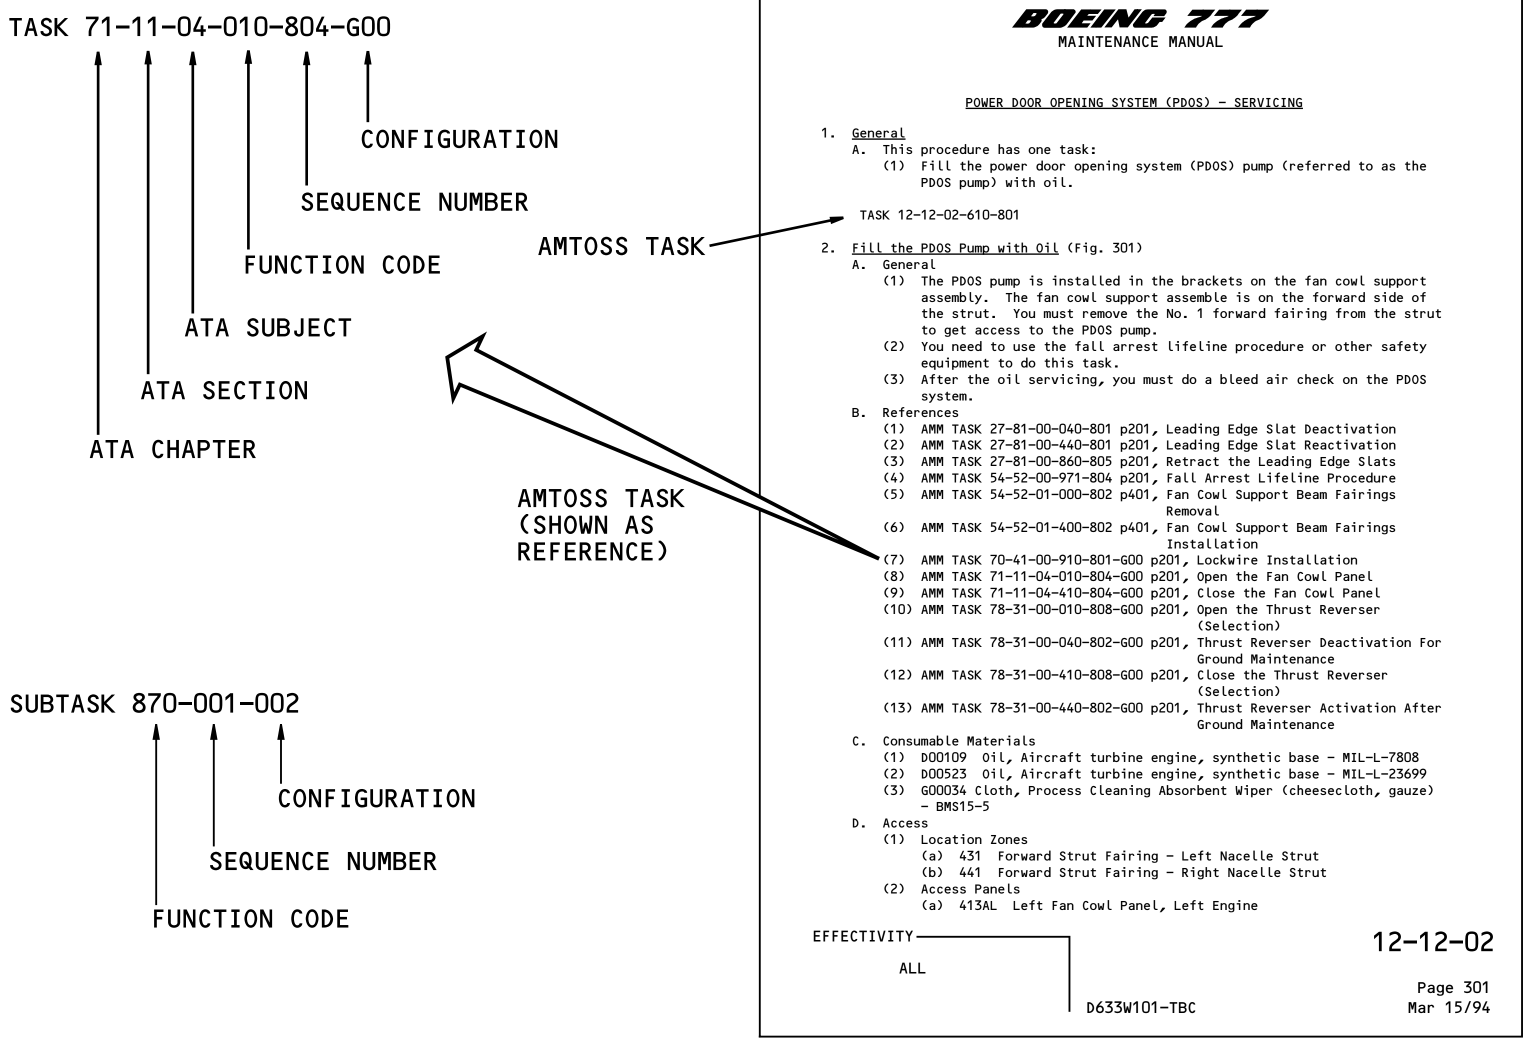
The sequence number makes sure there is a unique number for all tasks and sub-tasks which have the same ATA and function code. Tasks are numbered 801 through 999. If all task numbers are used, the third digit uses alphabetic characters. Sub-tasks are numbered 001 through 800.

Configuration

The configuration is a three digit alpha-numeric code that identifies the maintenance task for these items:

- Configuration
- Methods or techniques
- Variations of standard practices.

This data is blank or has zeroes if there is no data.



BOEING 777
MAINTENANCE MANUAL

POWER DOOR OPENING SYSTEM (PDOS) - SERVICING

1. General
   A. This procedure has one task:
      (1) Fill the power door opening system (PDOS) pump (referred to as the PDOS pump) with oil.

TASK 12-12-02-610-801

2. Fill the PDOS Pump with Oil (Fig. 301)
   A. General
      (1) The PDOS pump is installed in the brackets on the fan cowl support assembly. The fan cowl support assemble is on the forward side of the strut. You must remove the No. 1 forward fairing from the strut to get access to the PDOS pump.
      (2) You need to use the fall arrest lifeline procedure or other safety equipment to do this task.
      (3) After the oil servicing, you must do a bleed air check on the PDOS system.

AIRPLANE CONDITION MONITORING SYSTEM - INTRODUCTION

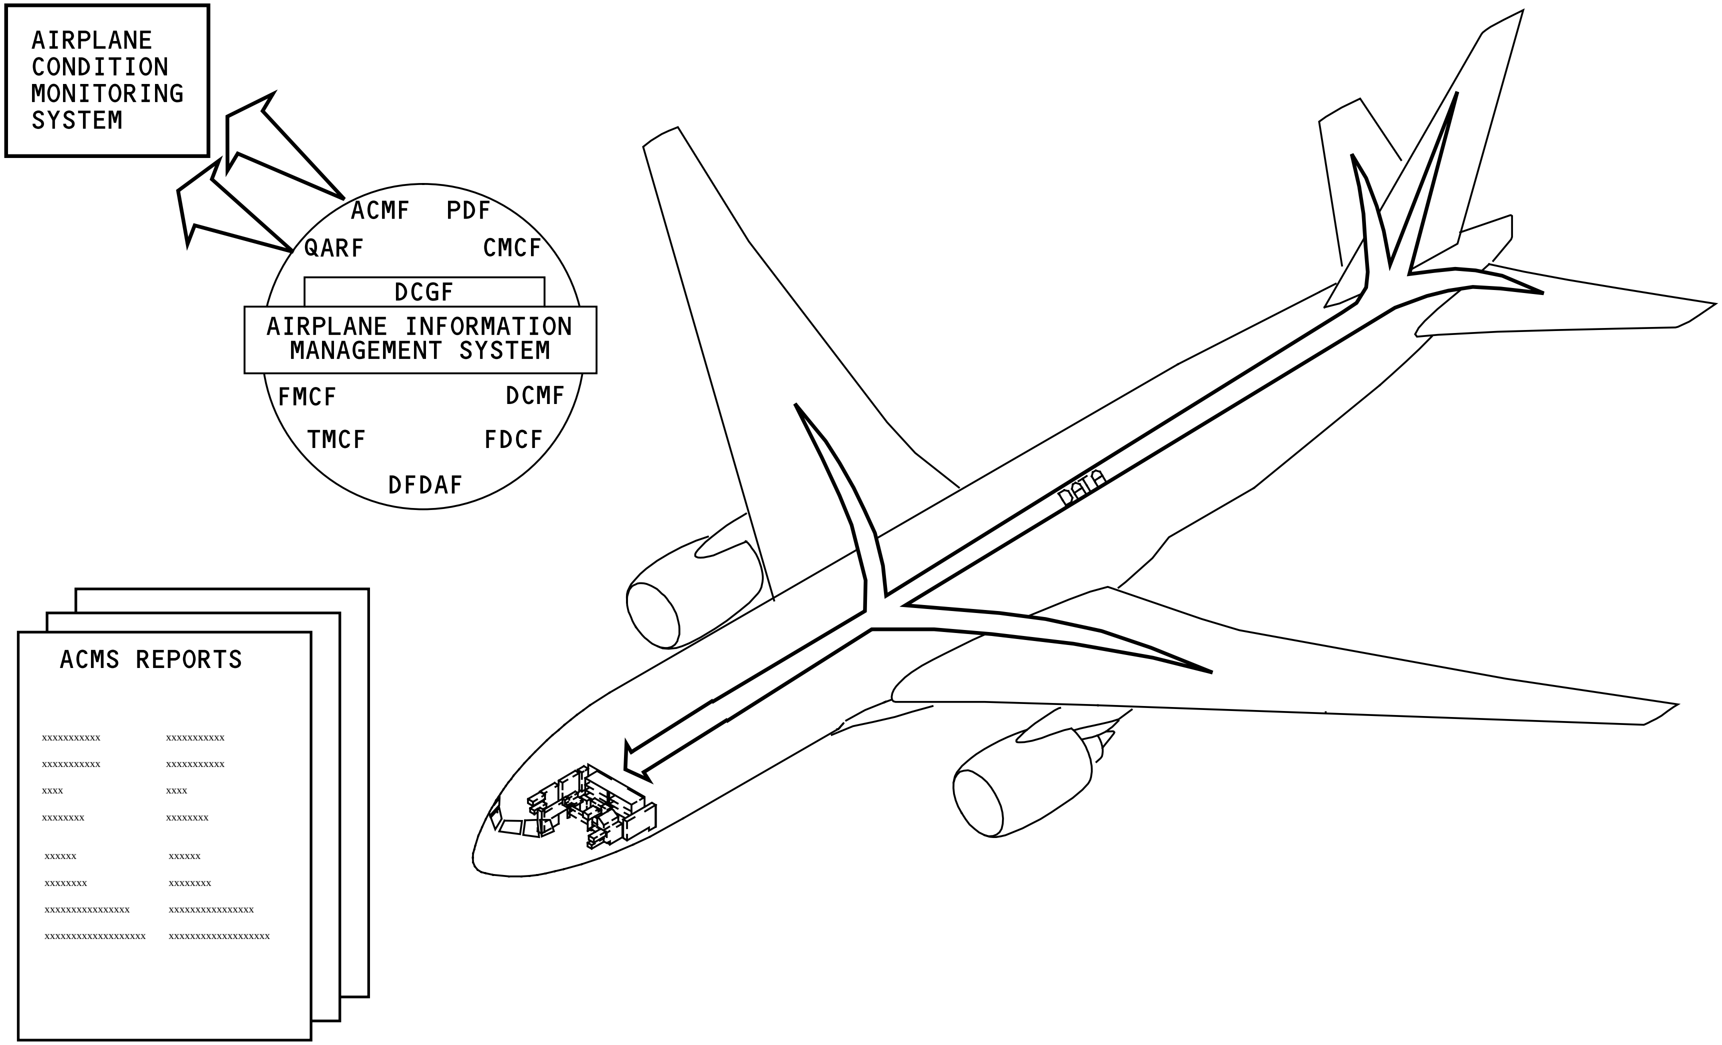
General

The airplane condition monitoring system (ACMS) collects, monitors, and records data from airplane systems. This data causes reports. The purpose of the reports are to:

- Analyze airplane performance
- Analyze trends
- Report significant events
- Troubleshoot faults.

Abbreviations and Acronyms

ACMF - airplane condition monitoring function
ACMS - airplane condition monitoring system
AIMS - airplane information management system
AMI - airline modifiable information
ARINC - Aeronautical Radio, Inc.
ATE - automatic test equipment
CPM/Comm - core processor module/communications
CPM/ACMF - core processor module/airplane condition monitoring function
CPU - central processing unit
DCMF - data communication management function
EEPROM - electrically erasable programmable read only memory
GBST - ground based software tool
IOM - input/output module
MAT - maintenance access terminal
OPC - operational program configuration
OPS - operational program software
SDU - satellite data unit
SRAM - static random access memory
VHF - very high frequency



31-35-00-001 Rev 5 02/12/1996

AIRPLANE CONDITION MONITORING SYSTEM - INTRODUCTION

ACMS - GENERAL DESCRIPTION

General

The ACMS has the airplane condition monitoring function (ACMF) in the left AIMS cabinet.

ACMS user interface is through formats on the maintenance access terminal (MAT) or portable maintenance access terminal (PMAT) displays.

The airline uses a ground based software tool (GBST) to program the ACMS with custom features.

ACMF

The ACMF is only in the left cabinet. The ACMF is a combination of standard and custom software. The software that the airline customizes sets these functions:

- Report format
- Report content
- Triggers.

Triggers are logic equations that detect conditions and cause data to record. An example of a trigger is an engine exceedance or a flight phase.

The ACMF sends the data to the:

- MAT
- PMAT
- MAT or PMAT disk drive to record on a diskette
- Data communication management function (DCMF).

The DCMF controls the interface to:

- The printer
- The satellite data unit (SDU)
- The VHF transceivers.

MAT

The ACMS main menu shows on the MAT. The standard ACMS menu lets the user do these:

- Modify constants
- Set triggers for manual reports
- See reports
- Set the destination for reports
- See real-time data.

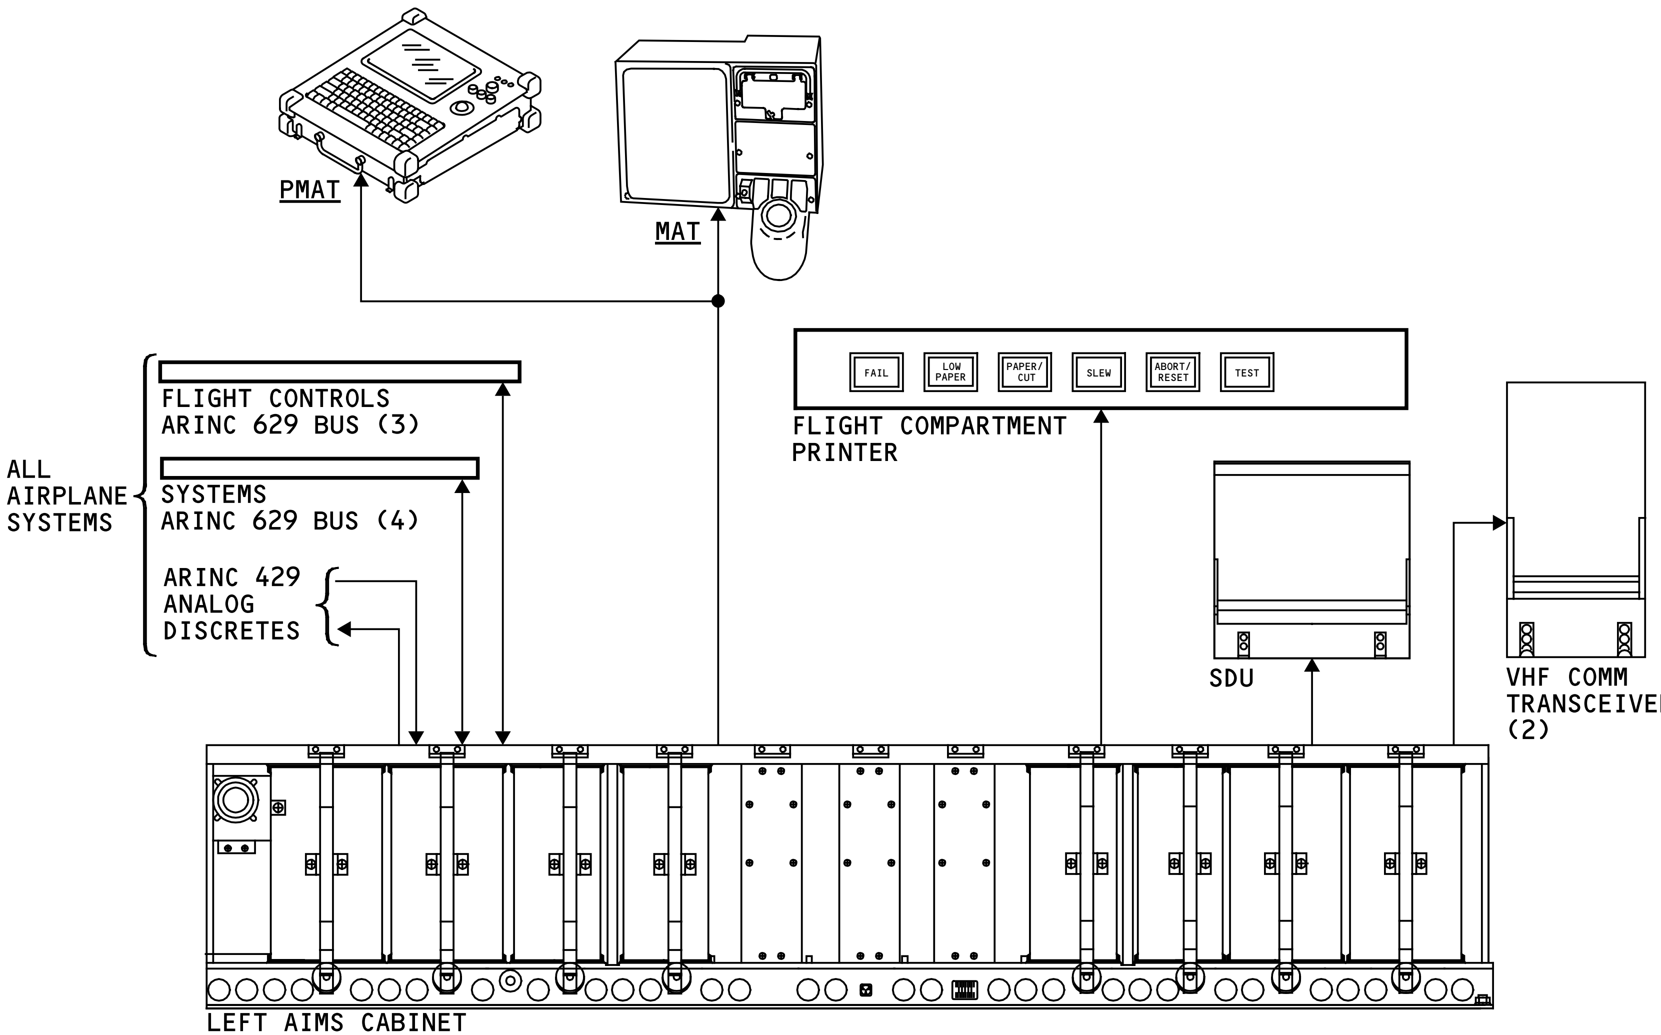
There are five ACMS menus that the airline can customize with the GBST.

Ground Based Software Tool

The airline uses the GBST to do these:

- Create custom MAT menus and displays
- Create specific reports
- Set triggers
- Set report types.

To load information from a diskette into the ACMF memory, use the disk drive on the MAT.



ACMS - GENERAL DESCRIPTION

31-35-00-002 Rev 17 03/11/1998

ACMS - COMPONENT LOCATIONS

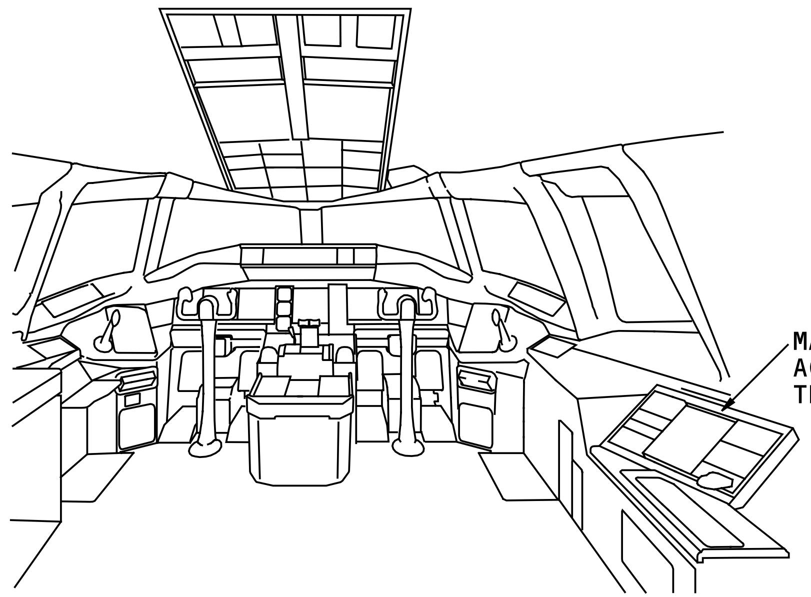
ACMS Component Locations

The airplane condition monitoring function (ACMF) is in the left AIMS cabinet.

Other System Component Locations

The user interface for the ACMS menus is through a maintenance access terminal (MAT) or portable maintenance access terminal (PMAT).

MAIN EQUIPMENT CENTER
(LOOKING FORWARD)



31-35-00-003 Rev 6 01/15/1997

ACMS - COMPONENT LOCATIONS

ACMS - INTERFACES

General

The ACMS collects data to record and sends reports to many output devices. The MAT and PMATs let you see ACMS data and control ACMS functions.

Data Collection

Airplane systems send data into the left AIMS cabinet input/output modules (IOMs) on:

- Flight controls ARINC 629 buses
- Systems ARINC 629 buses
- ARINC 429 buses
- Analog inputs
- Discrete inputs.

Some airplane system data only goes to the right AIMS cabinet. The data comes from the:

- Right angle of attack vane
- Left total air temperature probe, element two.

The data conversion gateway function in the right AIMS cabinet converts this data to ARINC 629. It then transmits the data to the left AIMS cabinet over the right flight controls ARINC 629 bus.

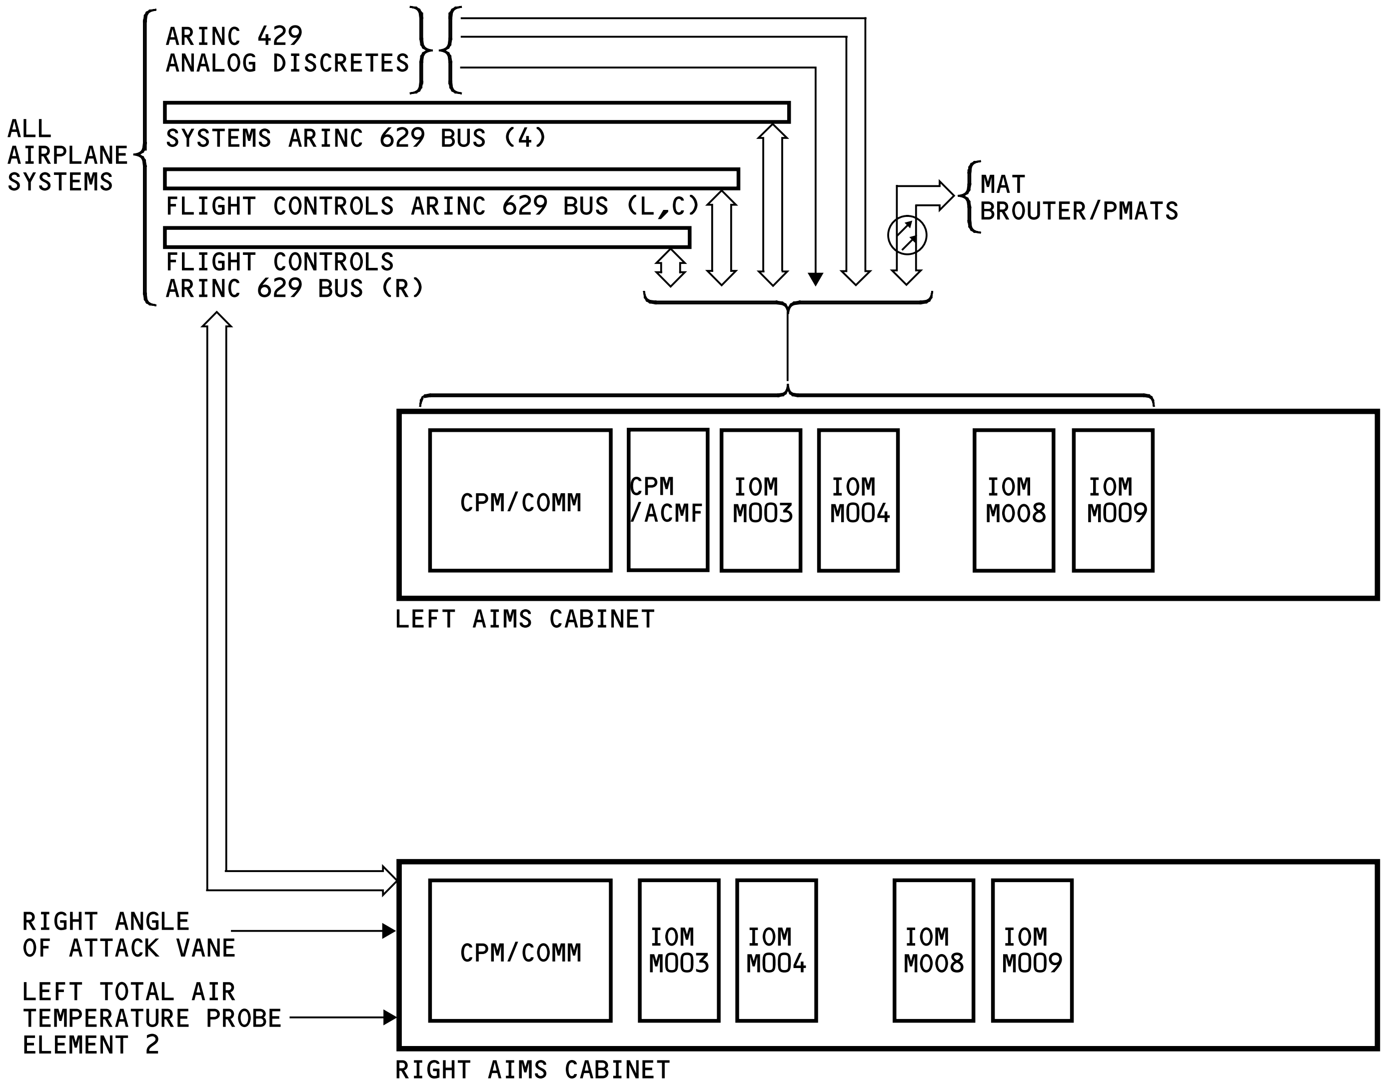
Control

The user requests information with the MAT or PMAT. The MAT/PMAT has ACMS menus and display formats. Also, ACMF airline modifiable information loads from the disk drive on the MAT or PMAT.

Output

ACMS reports can go to these:

- Data communication management system to transmit to a ground station
- Printer to print
- MAT or PMATs to see on the display or to record on a floppy disk.



ACMS - INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

ACMS - ACMF FUNCTIONAL DESCRIPTION

General

The ACMF gets airplane system data, records the data, and creates reports.

Data Collection

The ACMF can process:

- ARINC 429 or ARINC 629 data received by the left AIMS cabinet
- ARINC 429 data received by only the right AIMS cabinet
- Analog and discrete input data to the left and right AIMS cabinets
- Data that communicates between the AIMS software partitions
- Data that goes from the left AIMS cabinet to ARINC 429 buses and ARINC 629 buses.

From the four IOMs or the other CPMs, this data transmits through the backplane bus to the ACMF.

CPM/ACMF

Only the left AIMS cabinet has a CPM/ACMF. The CPM/ACMF has 6 megabytes of volatile RAM to store reports.

The CPM/ACMF contains the ACMF software. There are different parts of the software. The parts include these:

- ACMF operational program software (OPS)
- AIMS operational program configuration file (OPC)
- ACMF airline modifiable information (AMI).

The ACMF operational program software is standard and the airlines can not customize it. It does these things:

- Evaluates the triggers
- Gets the data
- Compresses the data
- Prepares the reports.

The ACMF AMI sets the:

- Report formats
- Triggers to record data
- Customized menus, display formats, and MAT ACMS features.

The ACMF AMI also contains the onboard signal database. This database has all the available signals to the ACMF.

CPM/Comm

The ACMF sends data to these functions in the CPM/Comm:

- Data communication management function (DCMF)
- Central maintenance computing function (CMCF).

The DCMF controls these interfaces:

- Onboard local area netework (OLAN) for MAT/PMAT

ACMS - ACMF FUNCTIONAL DESCRIPTION

- Printer
- Satellite communications system (SATCOM)
- VHF communication system.

The CMCF records and shows the status of ACMS components. It also lets you load this software:

- The ACMF AMI
- The AIMS OPC
- The ACMF OPS.

<u>Training Information Point</u>

When you load a new OPS or AMI, the ACMS data that is stored in the CPM/ACMF memory goes away. If you need data for a report, be sure that you download the data to the flight compartment printer or to a diskette before you load the new OPS or AMI. When you load an OPC, the ACMS data that is stored in the CPM/ACMF memory does not go away.

ACMS - ACMF FUNCTIONAL DESCRIPTION

ACMS - AIRLINE MODIFIABLE INFORMATION

General

The design of the 777 airplane lets the airlines customize certain functions in the airplane condition monitoring system (ACMS). You customize these functions through airline modifiable information (AMI). You use the ground based software tool (GBST) to make the modifications.

The ACMS system comes with a baseline AMI. This baseline AMI provides functionality to meet most airline requirements. The baseline AMI for the ACMS system has these types of reports and controls:

- Engine
- Airplane
- APU
- Environmental control system (ECS)
- Autoland
- Other report controls.

You use the GBST to modify:

- Report features
- ACMF features on the MAT
- Onboard parameter databases.

Engine Reports

The engine stable report collects data during stable cruise periods. It has these submenu items:

- REPORT SUMMARY
- MANNUALLY ITITIATED.

The engine takeoff report collects key data for EGT parameters and takeoff derate data.

The engine climb report collects EGT data and climb derate data.

The normal engine start report collects key data during engine start. It has these submenu items:

- LEFT ENGINE
- RIGHT ENGINE.

The abnormal engine start report collects historical and real time data when an engine start is aborted or a fault condition occurs in the start sequence. It has these submenu items:

- LEFT ENGINE
- RIGHT ENGINE.

The engine oil monitoring report collects oil quantity during taxi in and taxi out. This report also computes oil consumption for each flight leg and keeps oil consumption information for the last ten flight legs.

The EGT divergence report computes EGT divergence between the left and right engine during stable cruise conditions and generates a report when the divergence exceeds a specified delta value.

ACMS - AIRLINE MODIFIABLE INFORMATION

The engine data report collects information during engine runup and engine operation. It has these submenu items:

- REPORT SUMMARY
- MANUALLY ITITIATED.

The engine exceedance report collects historical and real time data during engine exceedances. It has these submenu items:

- LIMIT
- HISTORY-LEFT A
- HISTORY-LEFT B
- HISTORY-RIGHT A
- HISTORY-RIGHT B.

Airplane Reports

The airplane performance monitoring report collects airplane and engine data for the Boeing performance group for input into the Boeing supplied airplane performance analysis program. It has these submenu items:

- REPORT SUMMARY
- MANUALLY INITIATED.

APU Reports

The APU report collects airplane, engine, and APU data when an auto shutdown of the APU occurs. It also collects airplane, engine, and APU data at APU start, main engine start, defined duct pressure conditions, and at ECS demand limits. It has these submenu items:

- APU AUTO SHUTDOWN
- APU PERFORMANCE
- ALL APU REPORTS.

ECS Report

The ECS performance report collects airplane, engine, and ECS data at APU start, main engine start, defined duct pressure conditions, and at ECS demand limits.

Autoland Report

The autoland report collects aircraft systems data about an automatic landing sequence.

Other Report Controls

The all reports selection gives you access to these items:

- BASELINE
- ENGINE
- CURRENT FLIGHT LEG.

Modifiable Parameters

You can use the GBST to change the control logic that defines data collection. You can also change the content and format of reports.

ACMS - AIRLINE MODIFIABLE INFORMATION

You can change the structure and display formats of the ACMS screens on the MAT. You can also add security features to control access to the ACMS functions on the MAT.

You can also modify the onboard data bases in the ACMS memory.

BASELINE AMI
ENGINE STABLE
ENGINE TAKEOFF

ACMS - AIRLINE MODIFIABLE INFORMATION

ACMS - OPERATION - ENGINE REPORTS MENU

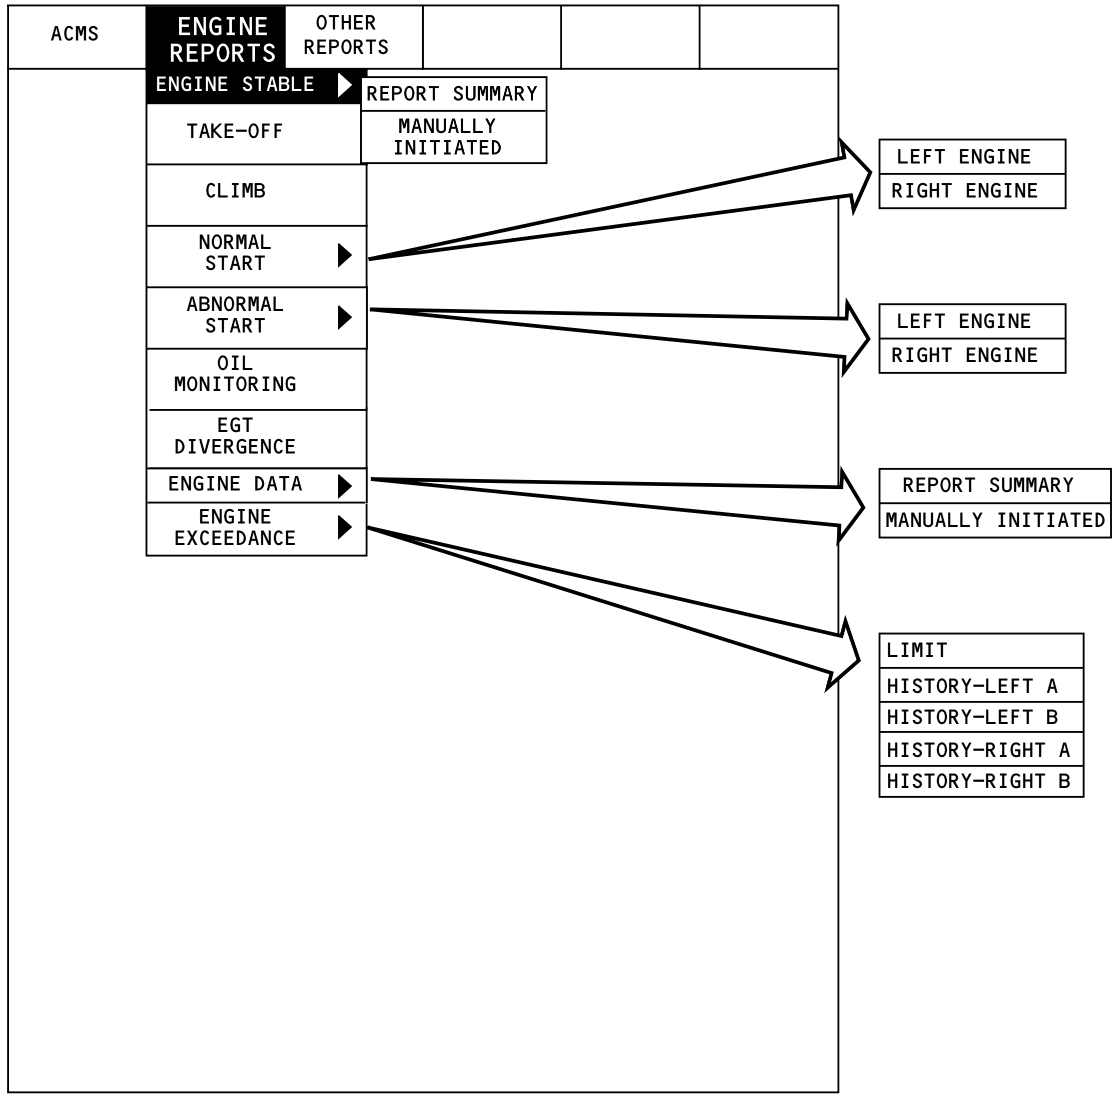
General

You get access to the ACMS main menu through the MAT main menu. Select ENGINE REPORTS to show the list of available engine reports.

Engine Reports Menu

The engine reports menu provides access to these menu items:

- ENGINE STABLE
- TAKE-OFF
- CLIMB
- NORMAL START
- ABNORMAL START
- OIL MONITORING
- EGT DIVERGENCE
- ENGINE DATA
- ENGINE EXCEEDANCE.



ENGINE REPORTS MENU

ACMS - OPERATION - ENGINE REPORTS MENU

ACMS - OPERATION - OTHER REPORTS MENU

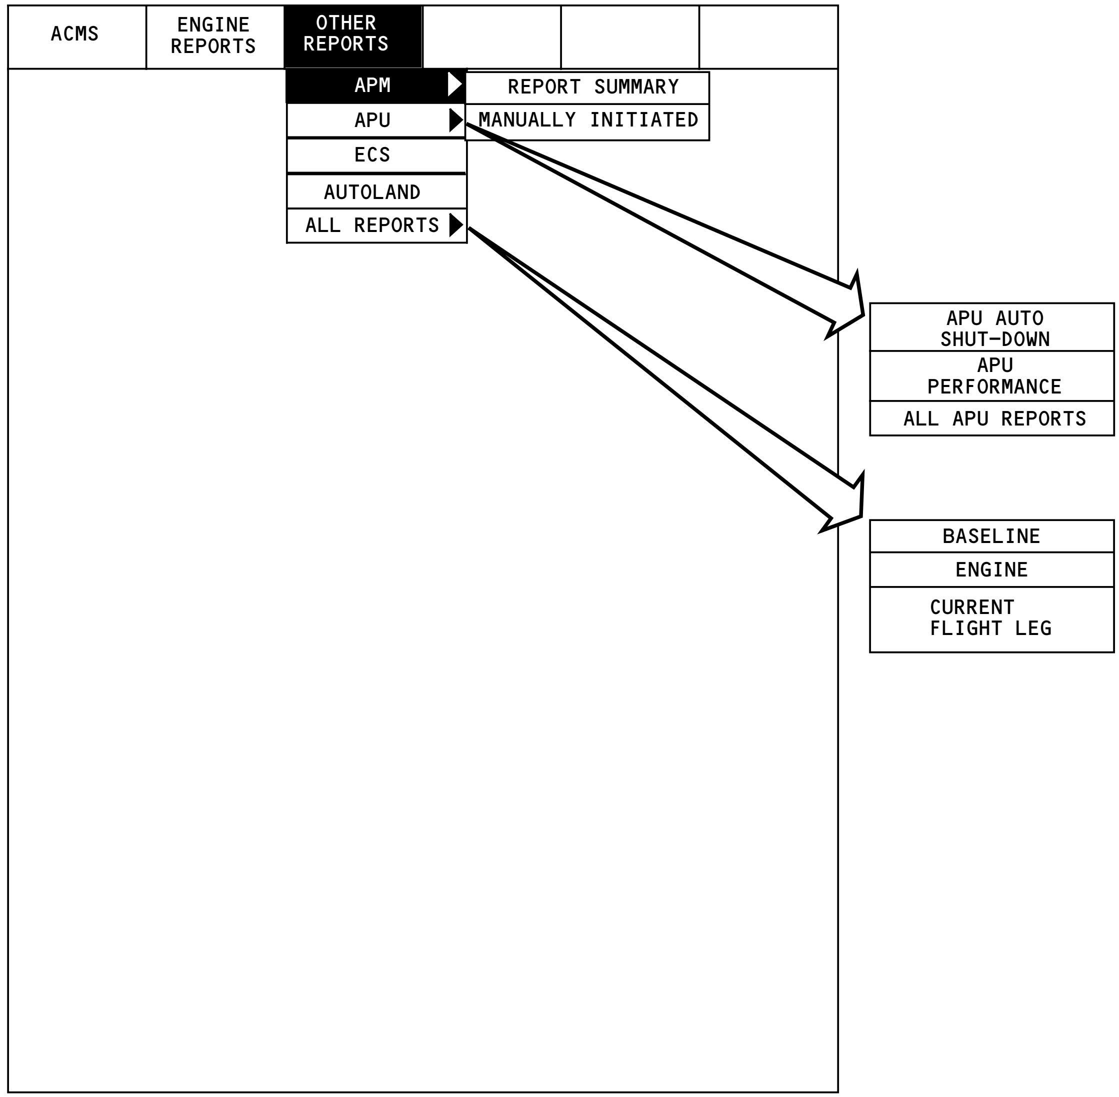
General

You get access to the ACMS main menu through the MAT main menu. Select OTHER REPORTS to show the available reports.

Other Reports Menu

The OTHER REPORTS menu provides access to these menu items:

- APM
- APU
- ECS
- AUTOLAND
- ALL REPORTS.



OTHER REPORTS MENU

ACMS - OPERATION - OTHER REPORTS MENU

ACMS - OPERATION - MAIN MENU

General

You get access to the ACMS main menu through the MAT main menu. Select ACMS to show the ACMS title display.

Menu Bar

The menu bar has the ACMS standard menu and five user defined menus. Airline modifiable information (AMI) software provides two of the user defined menus, engine reports and other reports.This manual does not describe the other three user-defined menus.

ACMS Standard Menu

The ACMS standard menu provides access to these menu items:

- PASSWORD
- TITLE SCREEN
- MNEMONIC DATA
- MODIFIABLE CONSTANTS
- PROGRAMMABLE REPORT 1
- PROGRAMMABLE REPORT 2
- PROGRAMMABLE REPORT 3
- QUICK REPORT
- TRACE LOG
- EXIT ACMS.

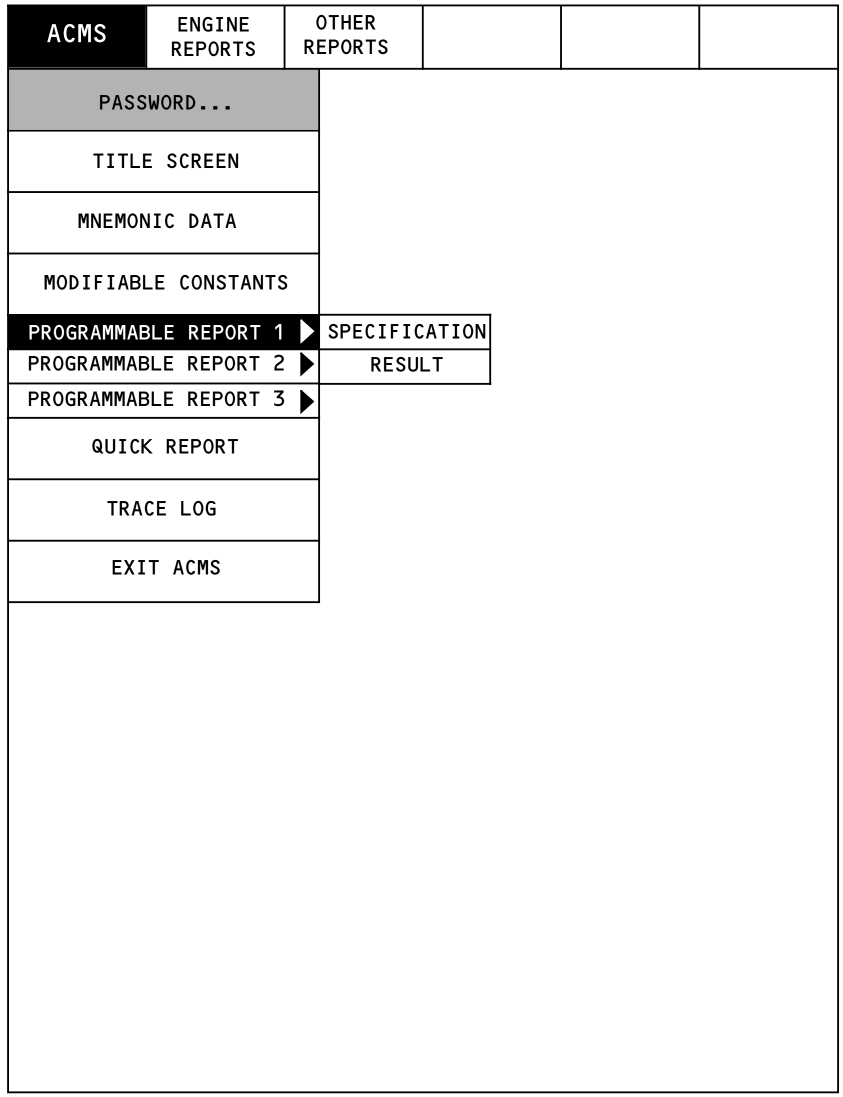
Programmable Reports

Each programmable report menu item supplies access to these cascaded menu options:

- SPECIFICATION
- RESULT.

Exit ACMS

The Exit ACMS menu item permits the user to return to the MAT main menu.



MAIN MENU

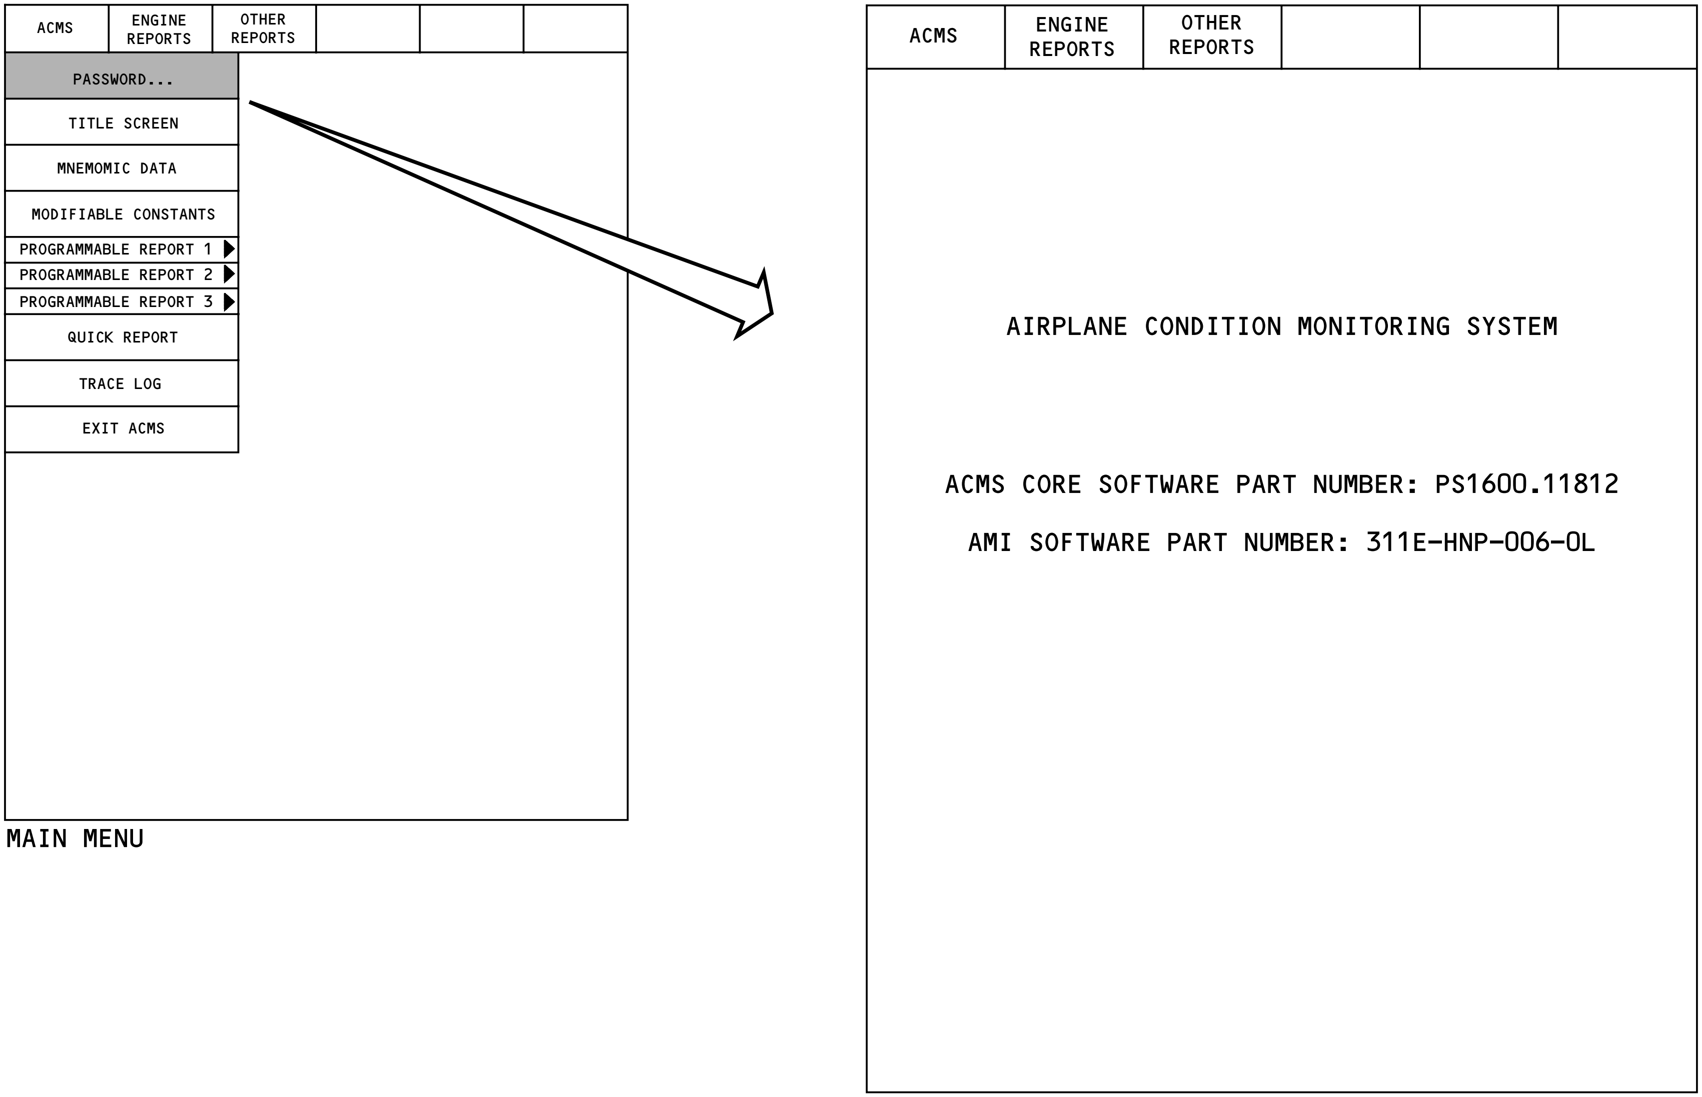
ACMS - OPERATION - MAIN MENU

ACMS - OPERATION - TITLE SCREEN

Title Screen

The ACMS menu has a title screen menu item. You select this menu item to show the title screen page.

The title screen page shows the ACMS core and airline modifiable information (AMI) software part numbers.



MAIN MENU

TITLE SCREEN PAGE

31-35-00-007 Rev 1 02/22/95

ACMS - OPERATION - TITLE SCREEN

ACMS - OPERATION - MNEMONICS

General

The mnemonic data page shows real time data. You use this page to monitor a specific signal parameter for troubleshooting.

The mnemonic data page shows this information for each mnemonic:

- Source LRU
- If applicable, left, center or right position
- Parameter value
- Engineering units of measure.

The mnemonic data page has command buttons at the bottom of the display.

Search Parameter

To show a parameter, select SEARCH PARAMETER and the parameter search dialog box shows.

Delete Parameter

To delete a parameter, select the parameter then select DELETE PARAMETER.

Start and Stop

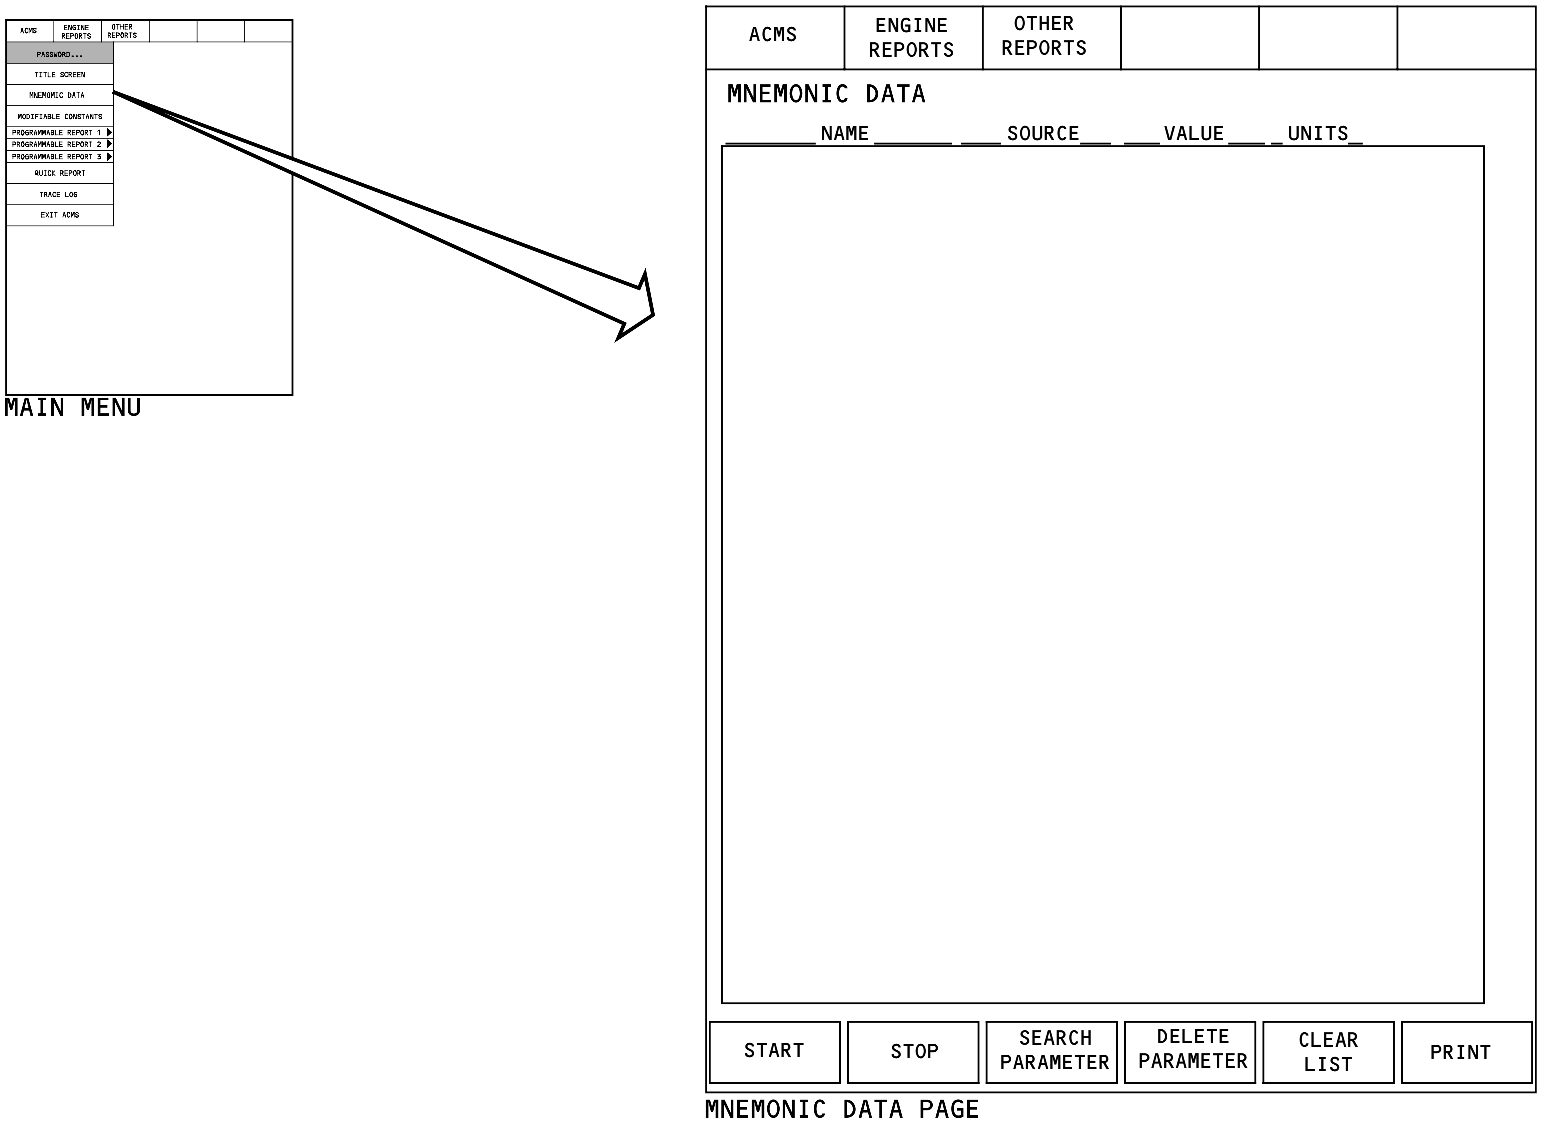
Select START and the mnemonic data page updates the parameters at a 1Hz rate. Select STOP and the parameters do not update.

Clear List

Select CLEAR LIST and the mnemonic list on the mnemonic data page goes away.

Print

The PRINT selection causes the list to go to the printer.



ACMS - OPERATION - MNEMONICS

31-35-00-008 Rev 1 01/06/95

ACMS - OPERATION - SIGNAL SOURCE DIALOG BOX

General

The mnemonic data page uses the parameter search dialog box. The parameter search dialog box finds any signal in the ACMS database. You enter a signal name in the SIGNAL NAME field and/or enter an LRU in the SOURCE field. You can use an asterisk (*) as a wild card in the SIGNAL NAME field.

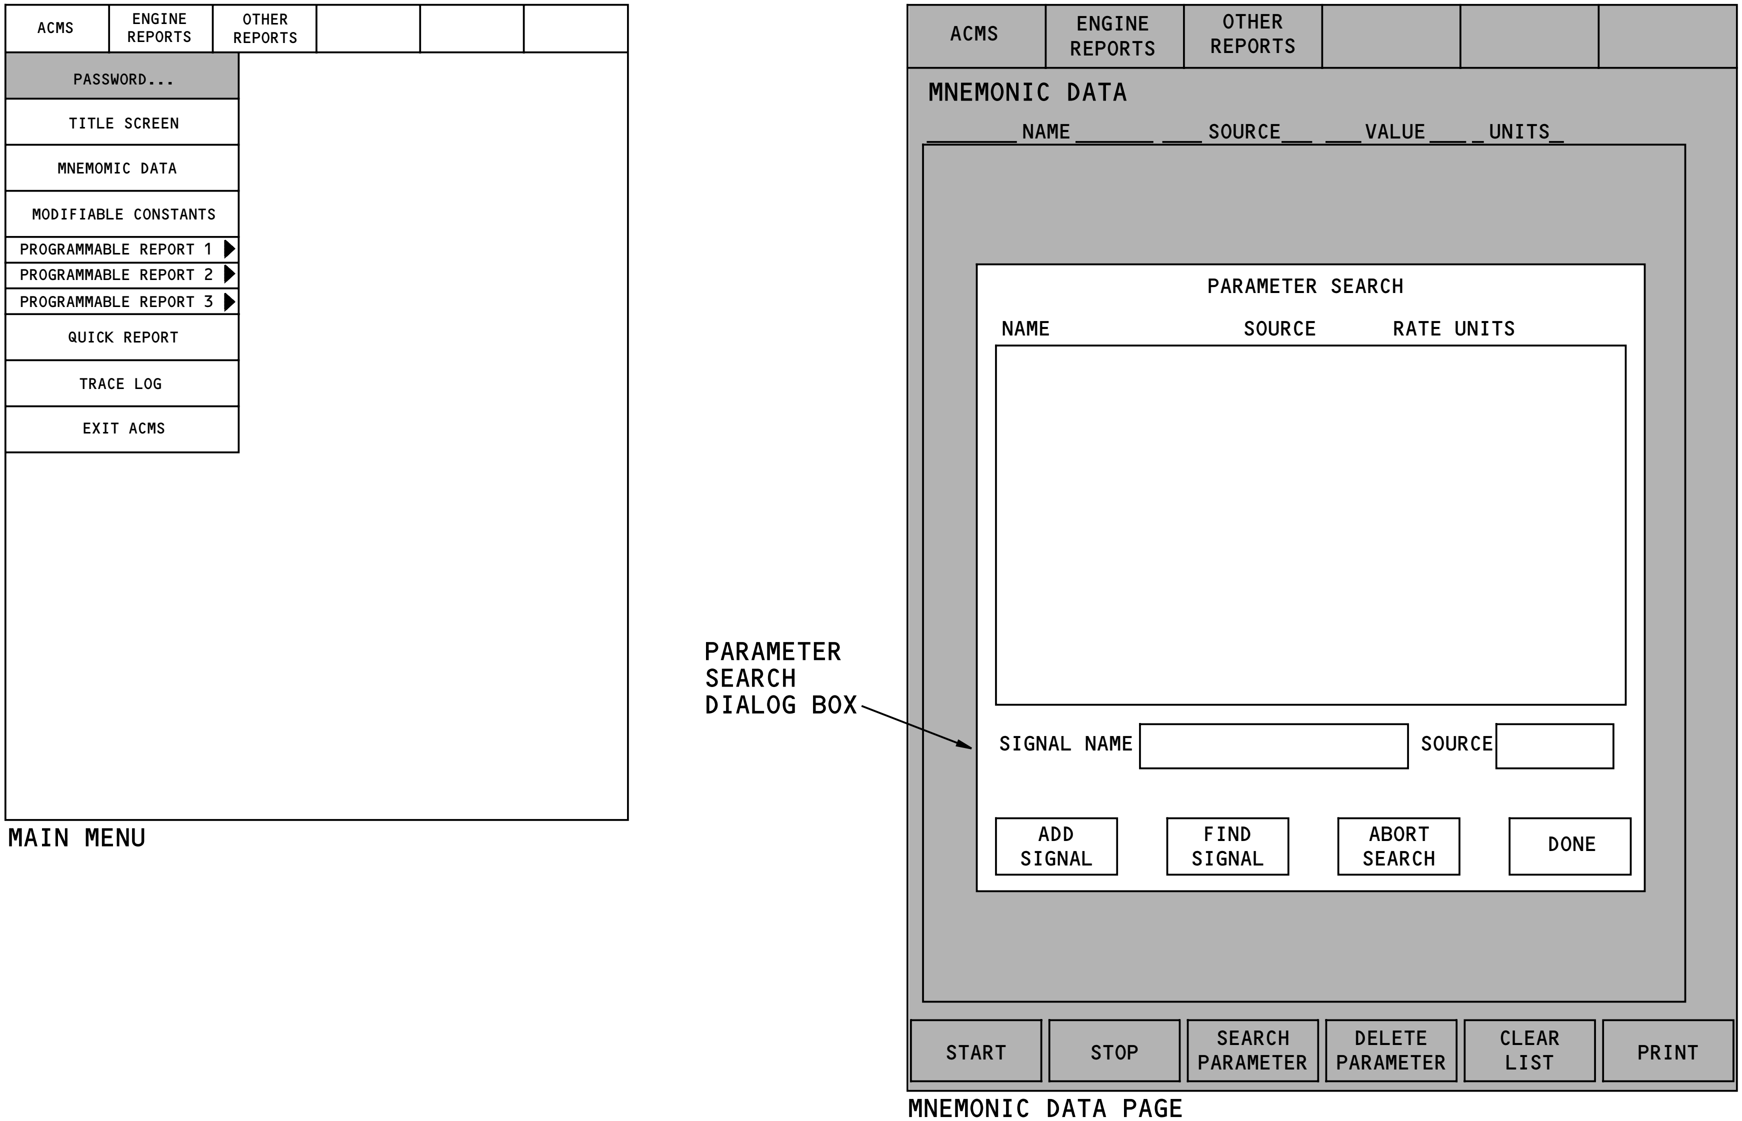
Select FIND SIGNAL to show a list of signals in the dialog box window.

Select the desired signal from the list and then select ADD SIGNAL.

Select DONE to close the parameter search dialog box. The selected signal then shows on the mnemonic data page.

Select ABORT SEARCH to stop a search.

The programmable report specification page also uses this dialog box.



ACMS – OPERATION – SIGNAL SOURCE DIALOG BOX

31-35-00-009 Rev 1 02/22/95

ACMS - OPERATION - MODIFIABLE CONSTANTS

General

The modifiable constants function lets you change a constant with the MAT rather than with the GBST.

The modifiable constants show on the modifiable constants page. Scroll through the display to view all the modifiable constants.

For each modifiable constant, the page shows this information:

- Name
- Default value
- Current value.

Two command buttons show at the bottom of the display.

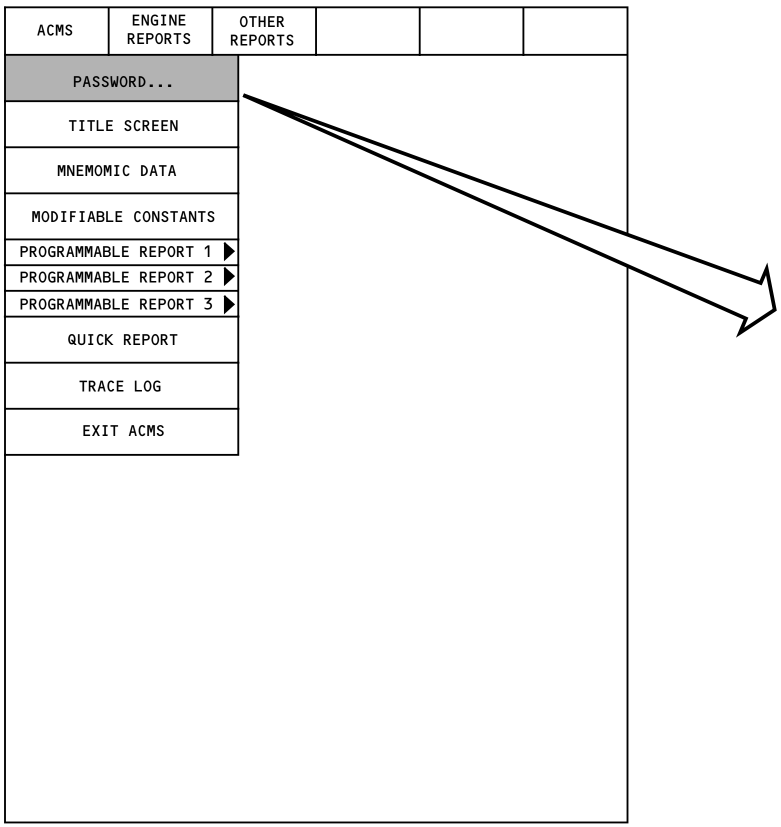
Modify Constant

To change a modifiable constant, select MODIFY CONSTANT and the modify value dialog box shows.

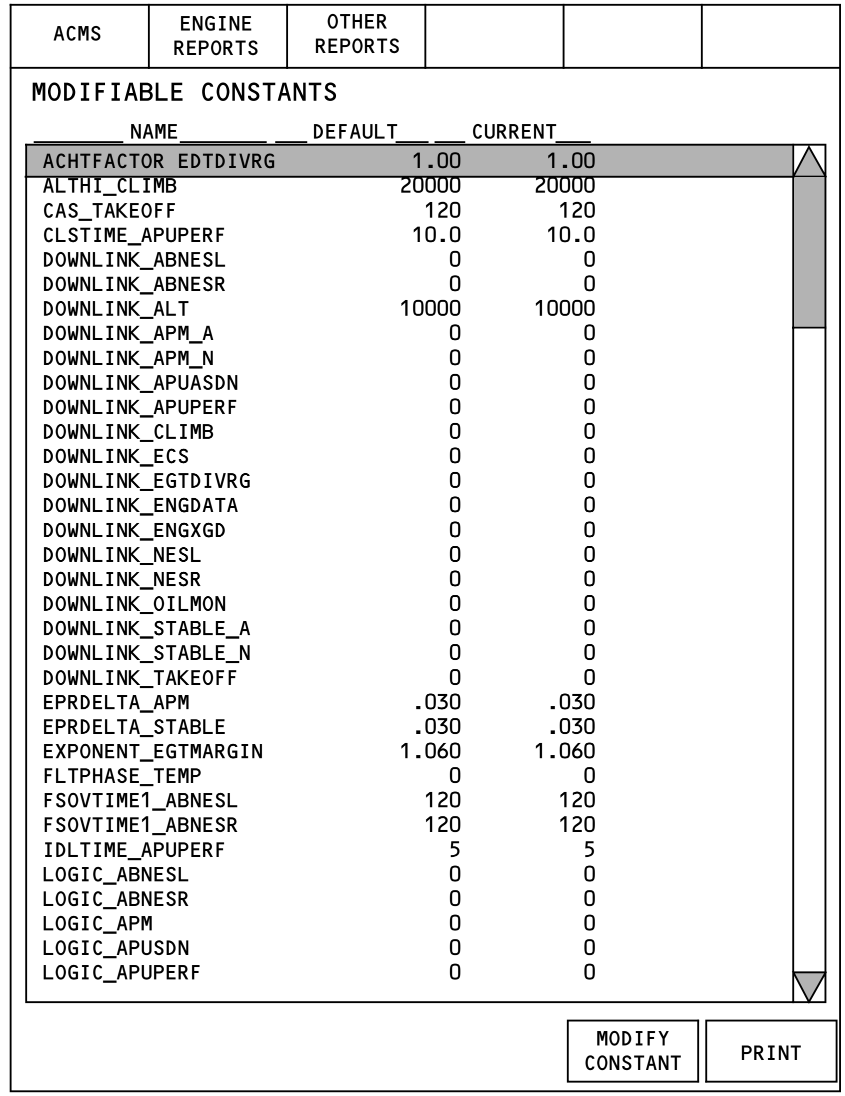
Print

Select PRINT, and a minimum of the last twenty modified constants show on the report. The printout contains these fields:

- Modified constant name
- Previous value
- New value
- Default value
- Time of change
- Date of change.



MAIN MENU



MODIFIABLE CONSTANTS PAGE (TYPICAL)

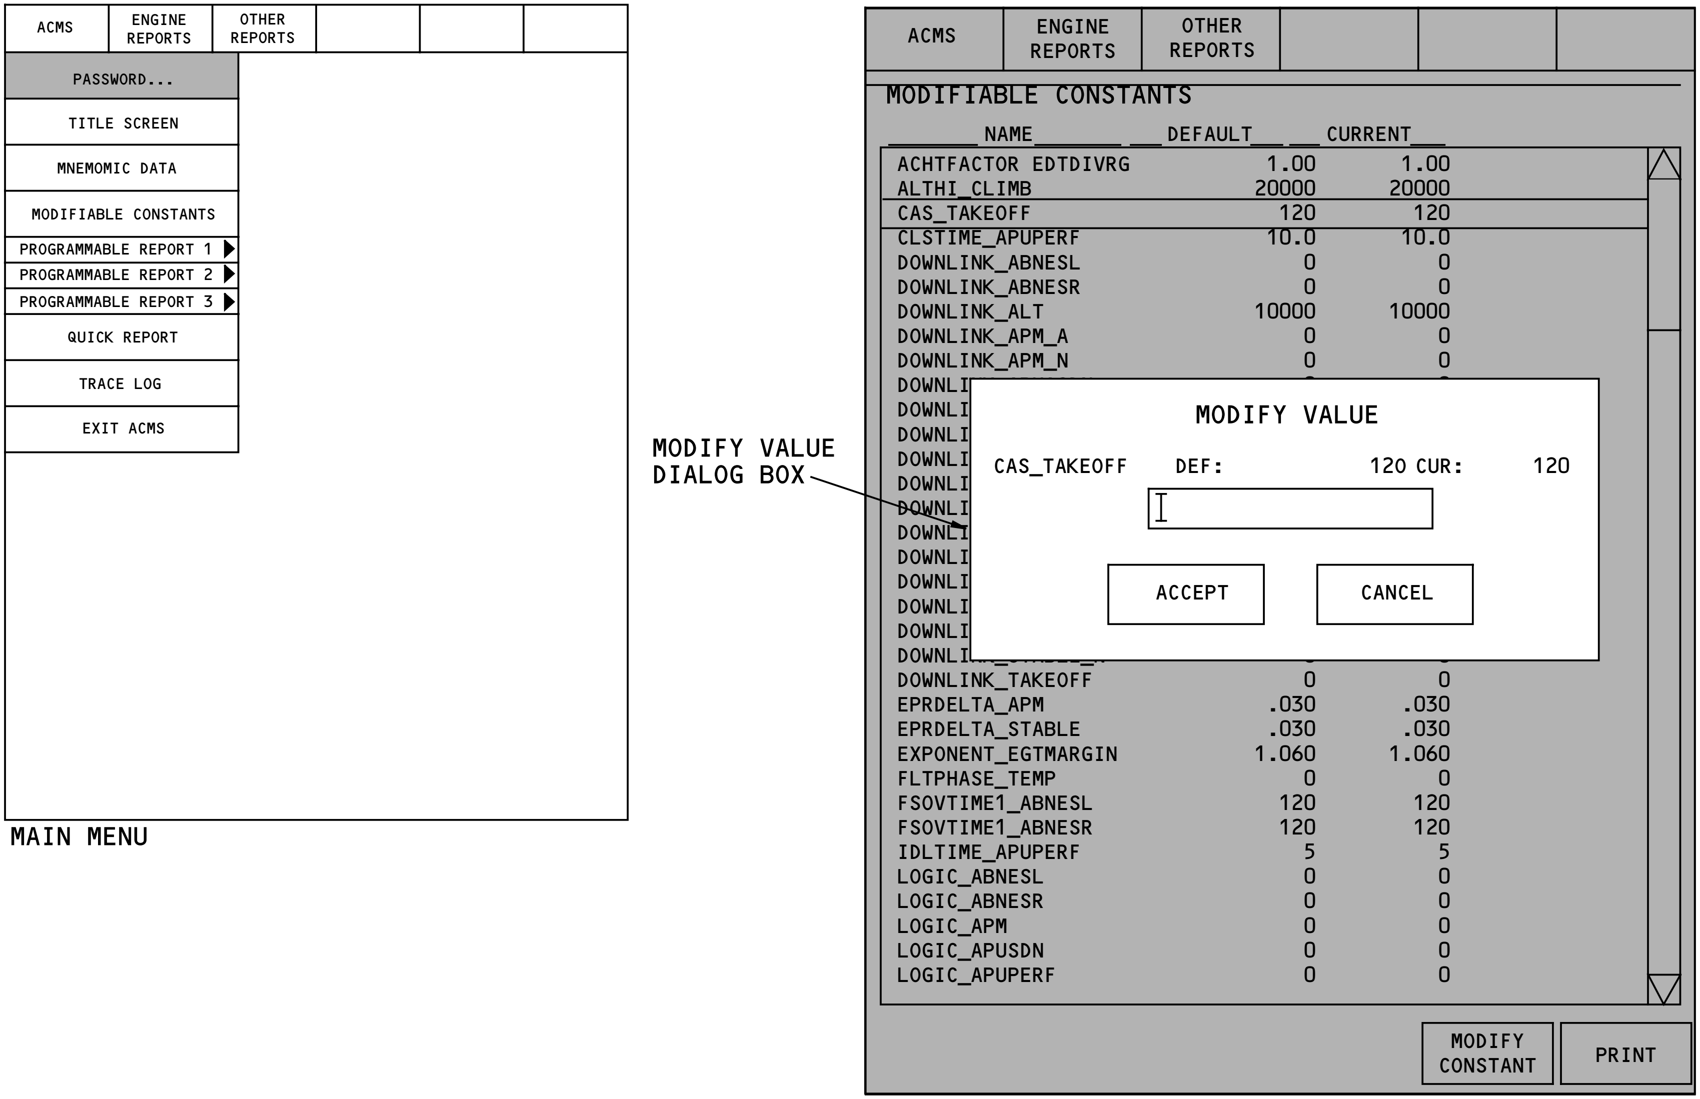
ACMS - OPERATION - MODIFIABLE CONSTANTS

ACMS - OPERATION - MODIFY VALUE DIALOG BOX

General

The modifiable constants page uses the modify value dialog box. The modify value dialog box lets you enter a new value in the value field. Select ACCEPT to return to the modifiable constants page. The new value then shows on the modifiable constants page.

The programmable reports specification page also uses this dialog box.



MAIN MENU

MODIFIABLE CONSTANTS PAGE

ACMS - OPERATION - MODIFY VALUE DIALOG BOX

ACMS - OPERATION - PROGRAMMABLE REPORT - SPECIFICATION

General

The ACMS menu has three programmable report menu items. The programmable reports let you create a limited logic unit and record airplane parameters onboard the airplane. Each programmable report menu item cascades into two selections, SPECIFICATION or RESULT. Select SPECIFICATION to see the report specification page. Select RESULT to see the report results page.

Report Specification Page

The report specification page lets you select these:

- A report title
- The report trigger parameters
- The data collection specifications
- Automatic datalink
- The report collection parameters.

You use text fields, selection boxes and cascading menu selections to define and control the report trigger parameters.

Select SEARCH PARAMETER and the parameter search dialog box shows. Use this to choose the collection parameters.

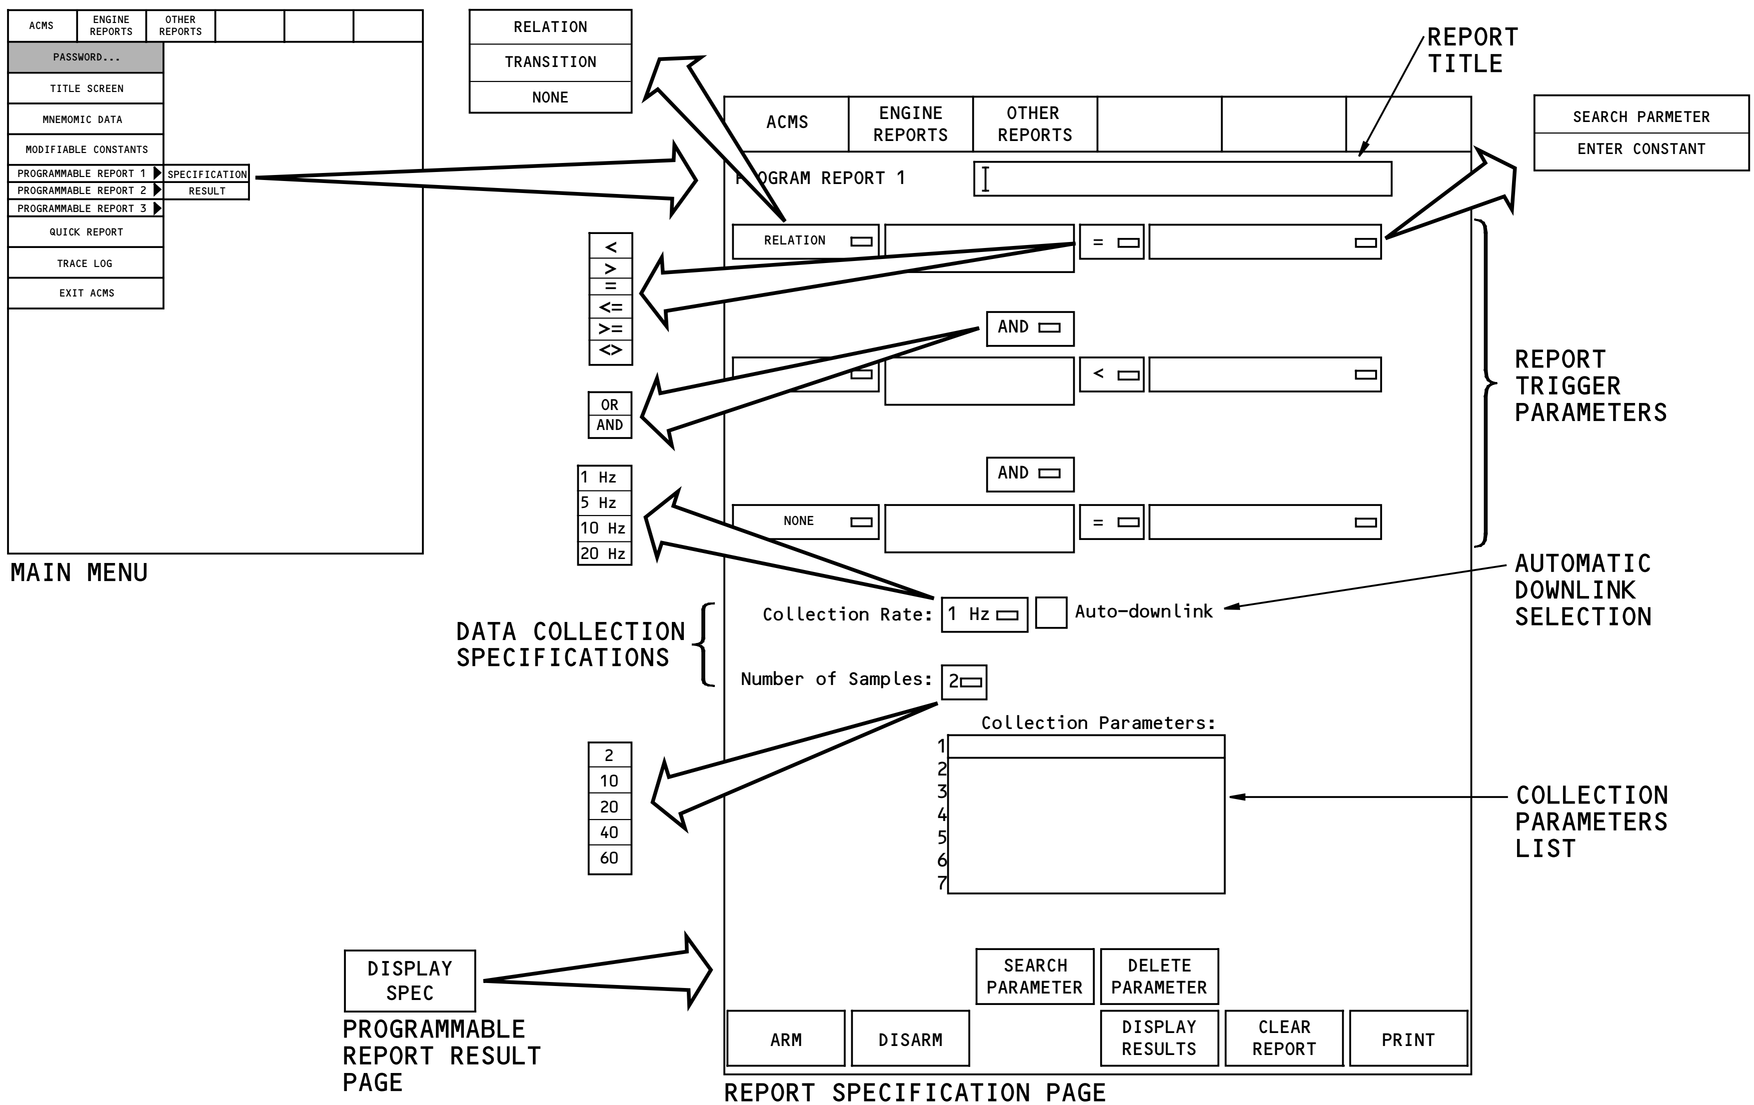
Select DELETE PARAMETER to remove a collection parameter from the list.

Select ARM to enable the report. The defined report trigger then causes collection of the report data. Select DISARM to disable the report.

Select DISPLAY RESULTS to see the report results page.

Select CLEAR REPORT to clear the current report specifications.

Select PRINT to print a copy of the programmable report specification page.



31-35-00-012 Rev 1 02/22/95

ACMS - OPERATION - PROGRAMMABLE REPORT - SPECIFICATION

ACMS - OPERATION - PROGRAMMABLE REPORT - RESULTS

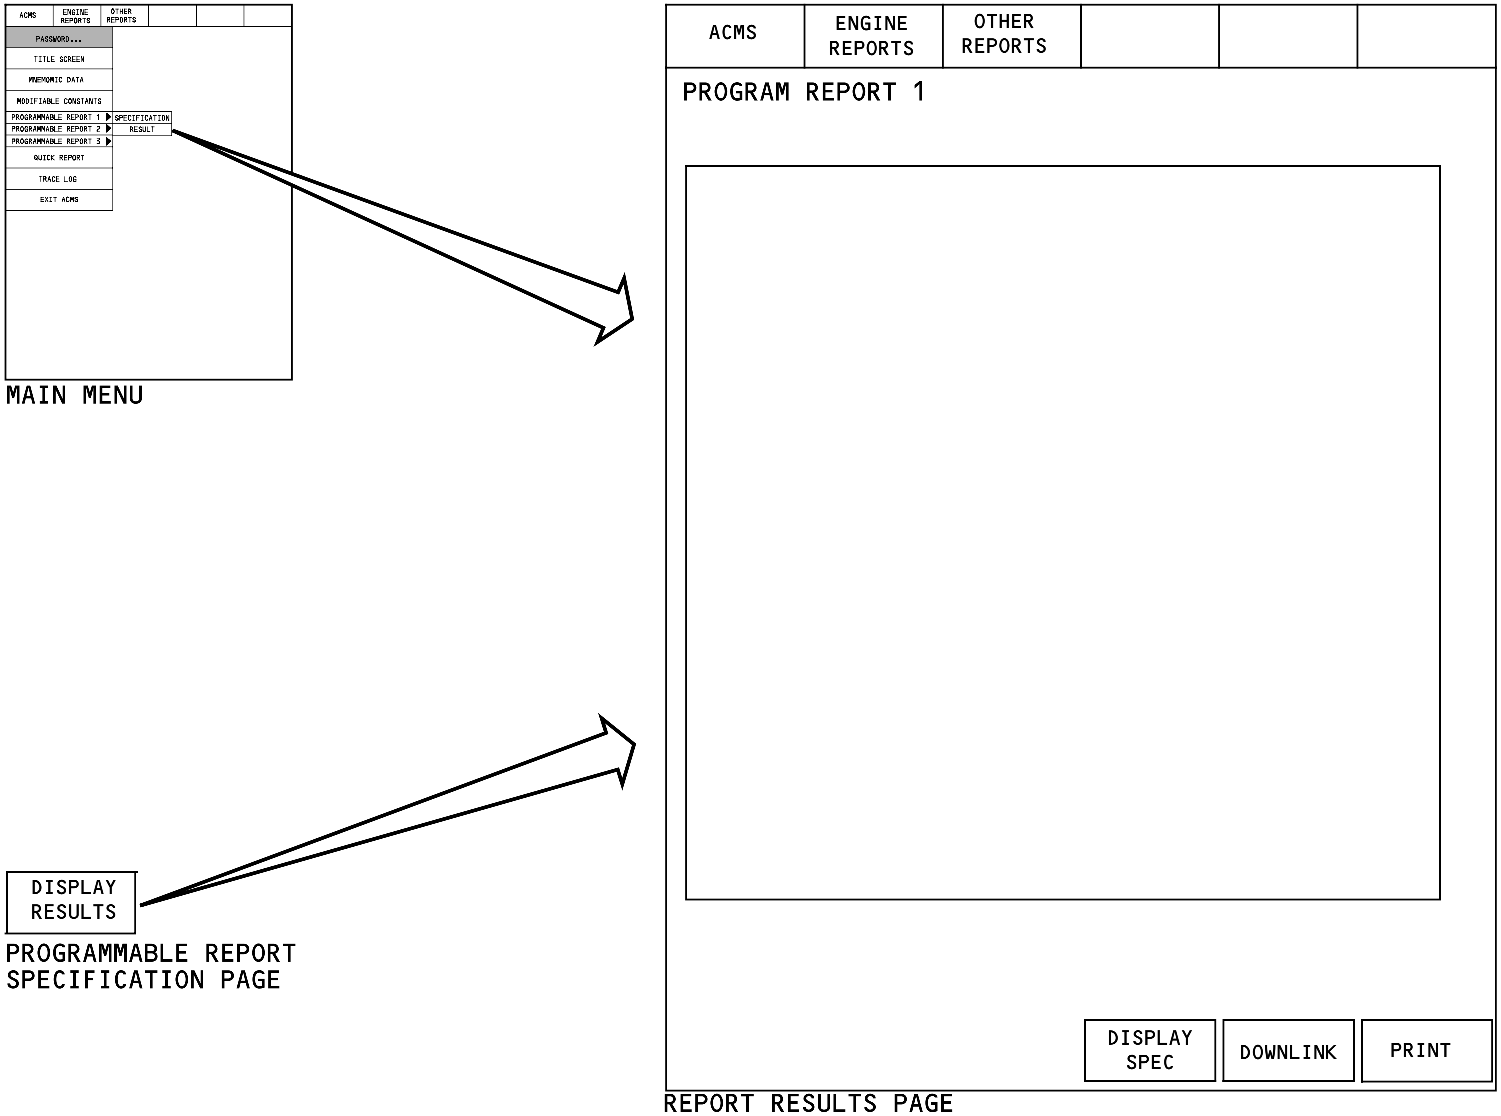
General

The programmable report result page shows the data for a report specification. Each report has header information that contains all the information captured in the report specification.

Select DISPLAY SPEC to return to the programmable report specification page.

Select DOWNLINK to transmit the report to a ground station.

Select PRINT to send the report to the flight compartment printer.



ACMS - OPERATION - PROGRAMMABLE REPORT - RESULTS

31-35-00-013 Rev 1 01/06/95

ACMS - OPERATION - QUICK REPORTS

General

The quick report page gives you a time history for a group of signals. The quick report results show on the MAT during data collection.

You can select the:

- Report title
- Signal collection rate
- Collection signals.

You can identify up to seven collection signals for data collection.

The date and time will show when the report results are displayed.

Command buttons show at the bottom of the display.

Start and Stop

Select START to start the quick report data collection. The report collects and shows 60 values for each collection signal. Select STOP to stop the data collection before all 60 values are collected.

Search and Delete Parameters

Select SEARCH PARAMETER to add a collection signal to the list.

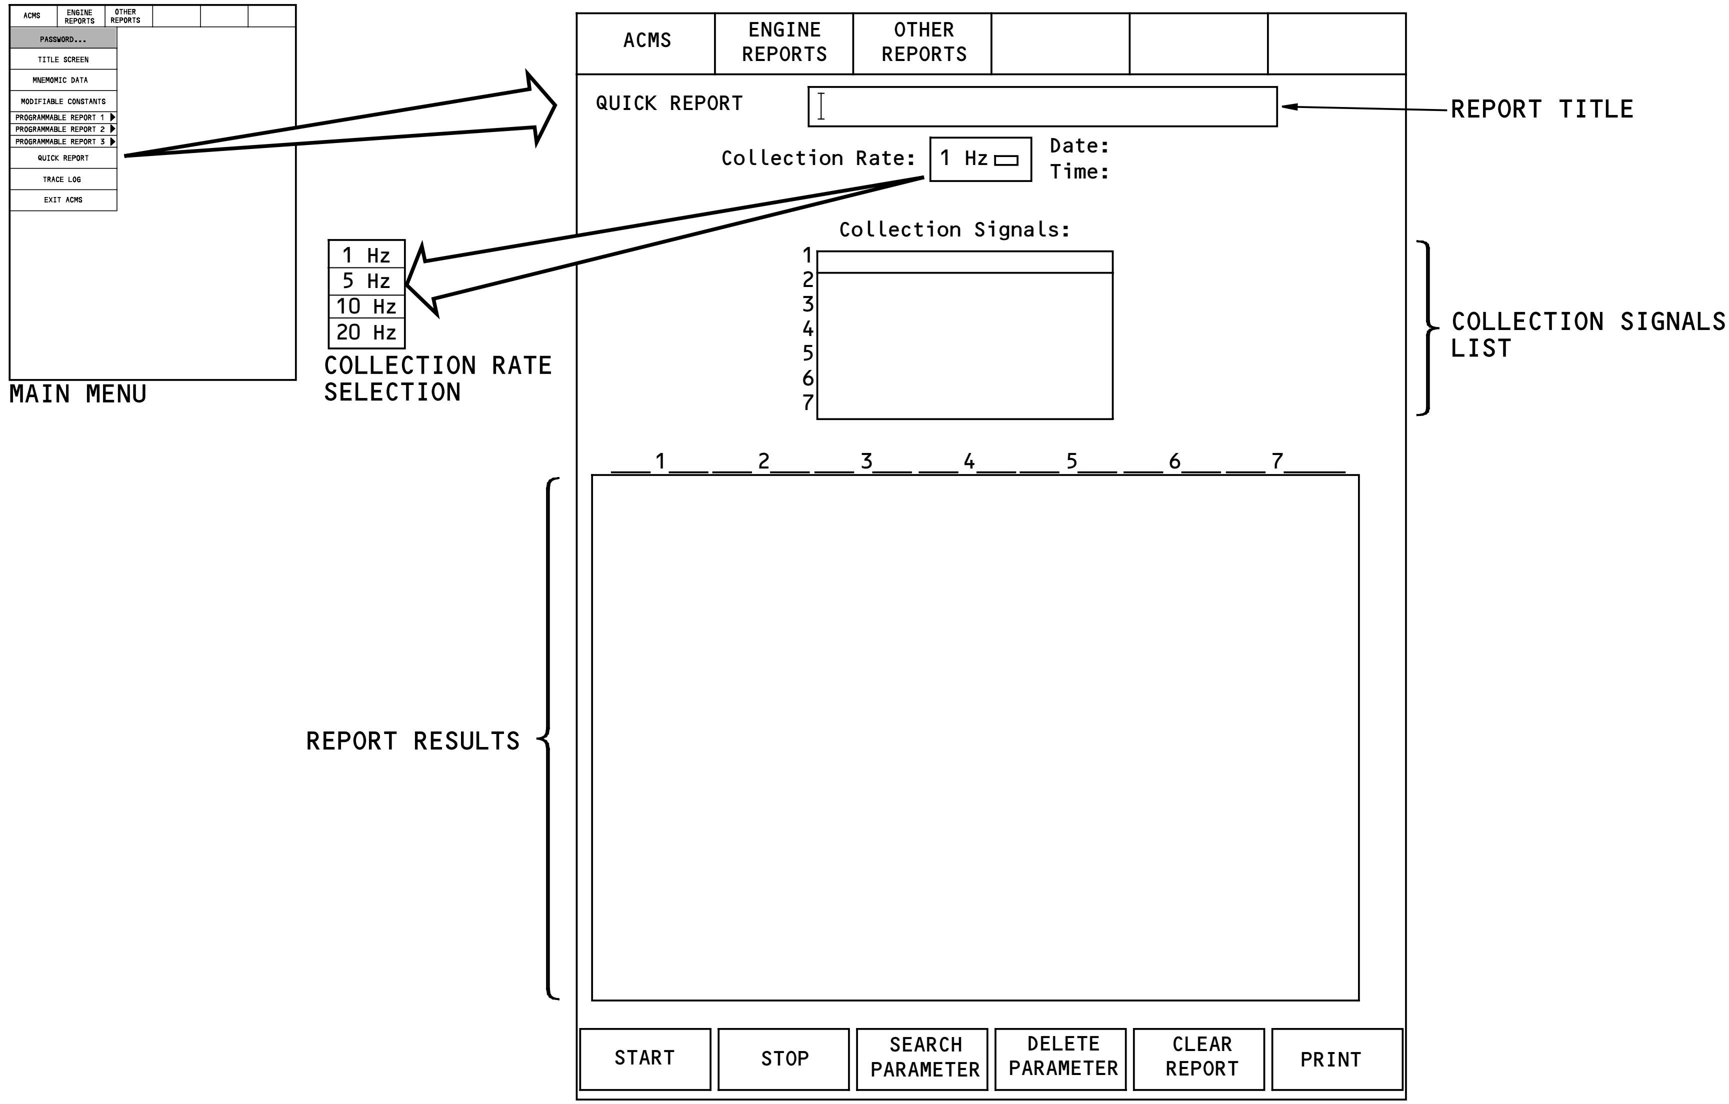
Select DELETE PARAMETER to delete a collection signal from the list.

Clear report

Select CLEAR REPORT to clear the current quick report specifications.

Print

Select PRINT to send the quick report to the flight compartment printer.

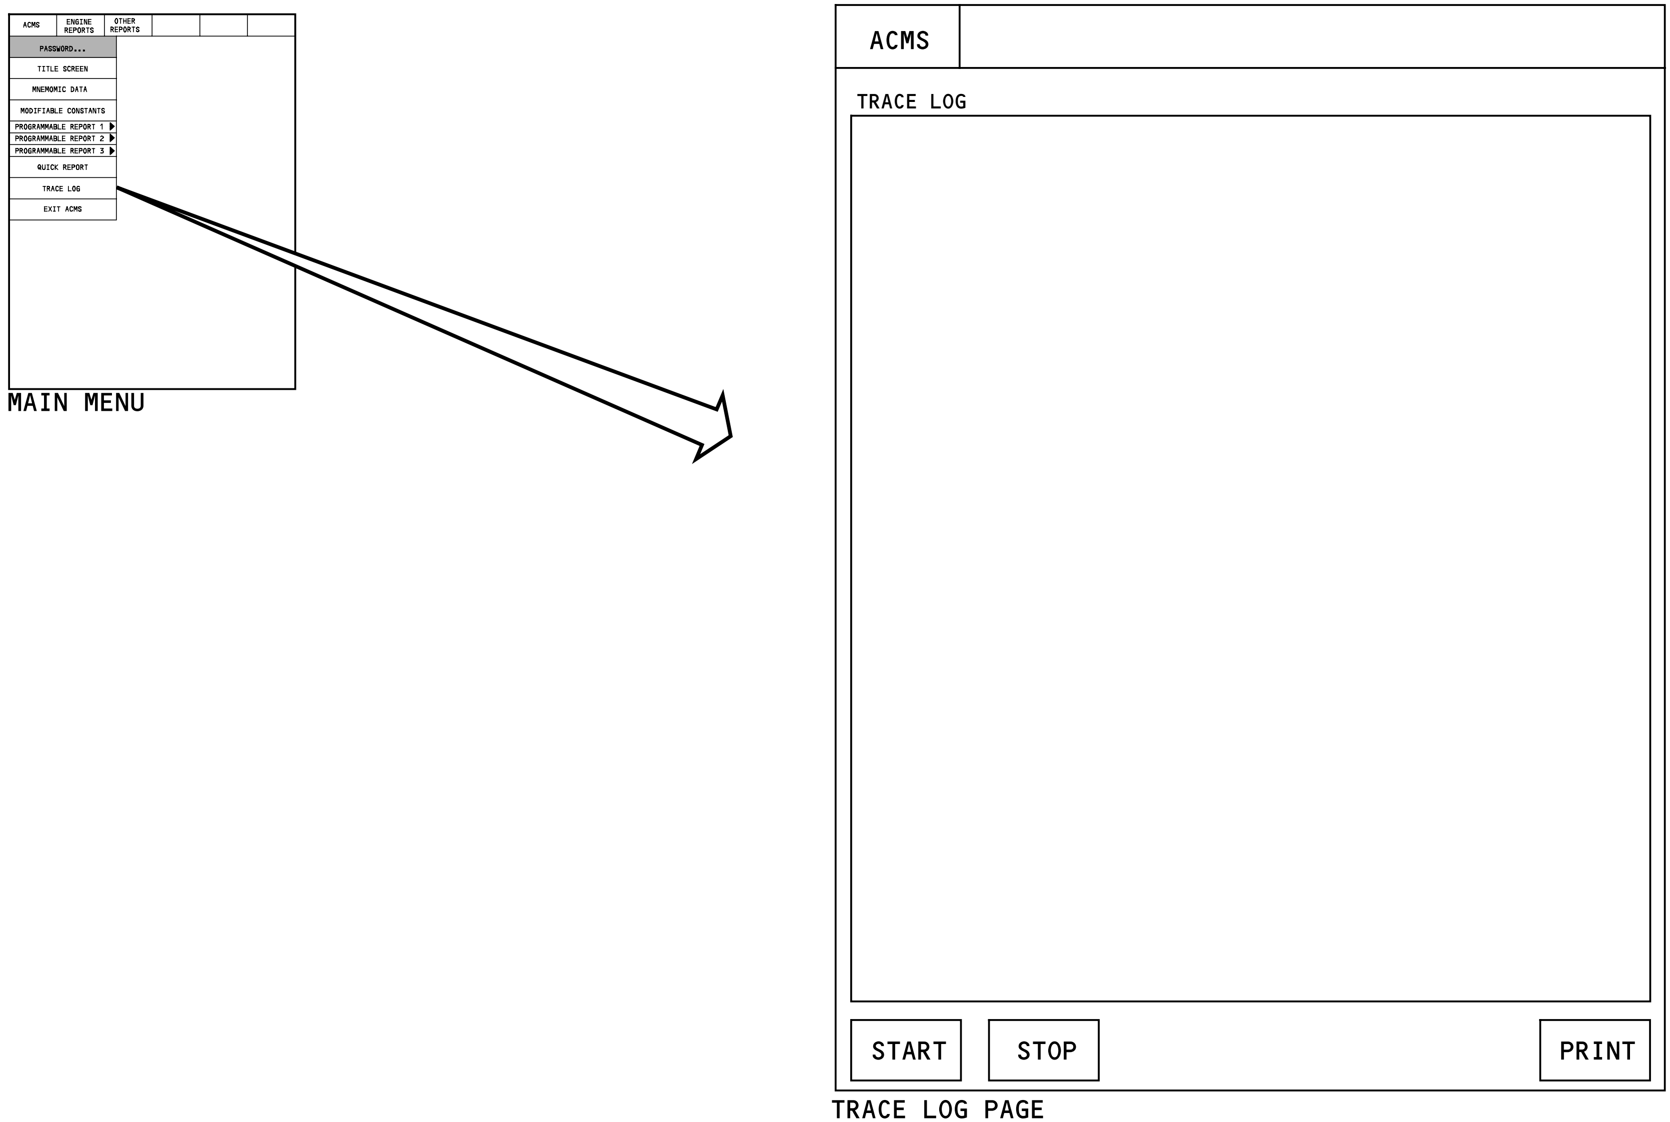


ACMS - OPERATION - QUICK REPORTS

ACMS - OPERATION - TRACE LOG

Trace Log

Software engineers use the trace log page to make sure the AMI software operates correctly.



31-35-00-015 Rev 1

ACMS - OPERATION - TRACE LOG

ACMS - SYSTEM TEST

General

There is one system test for the ACMS. It is the left ACMF software reset test.

Left ACMF Software Reset Test

This test makes sure that the ACMF software in the CPM/ ACMF operates correctly. The test erases all ACMF reports. This test may reveal failures of fault tolerant components which may not impact airworthiness. EICAS message indications are the final determinant.

The test takes about one minute.

ELECTRICAL POWER - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

ELECTRICAL POWER - GENERAL DESCRIPTION - POWER & CONTROL

Power Sources

The electrical power system has five main power sources, two backup power sources, and two standby power sources. These are the main power sources and their continuous supply capacity:

- Left integrated drive generator (IDG) (120 kva)
- Right IDG (120 kva)
- APU generator (120 kva)
- Primary external power (90 kva)
- Secondary external power (90 kva).

The backup power sources are the two backup generators. Each backup generator can continuously supply 20 kva. The standby power sources are the ram air turbine (RAT) generator and the main battery. The RAT generator can continuously supply 7.5 kva. The battery is a 47 amp-hour battery.

Control

These six electronic units control the ac power sources:

- Left generator control unit (GCU) - left IDG power
- Right GCU - right IDG power
- Backup generator converter - backup generator power
- APU GCU - APU generator power
- Bus power control unit (BPCU) - external power
- RAT GCU - RAT generator power.

The electrical load management system (ELMS) controls the main battery power.

ELMS

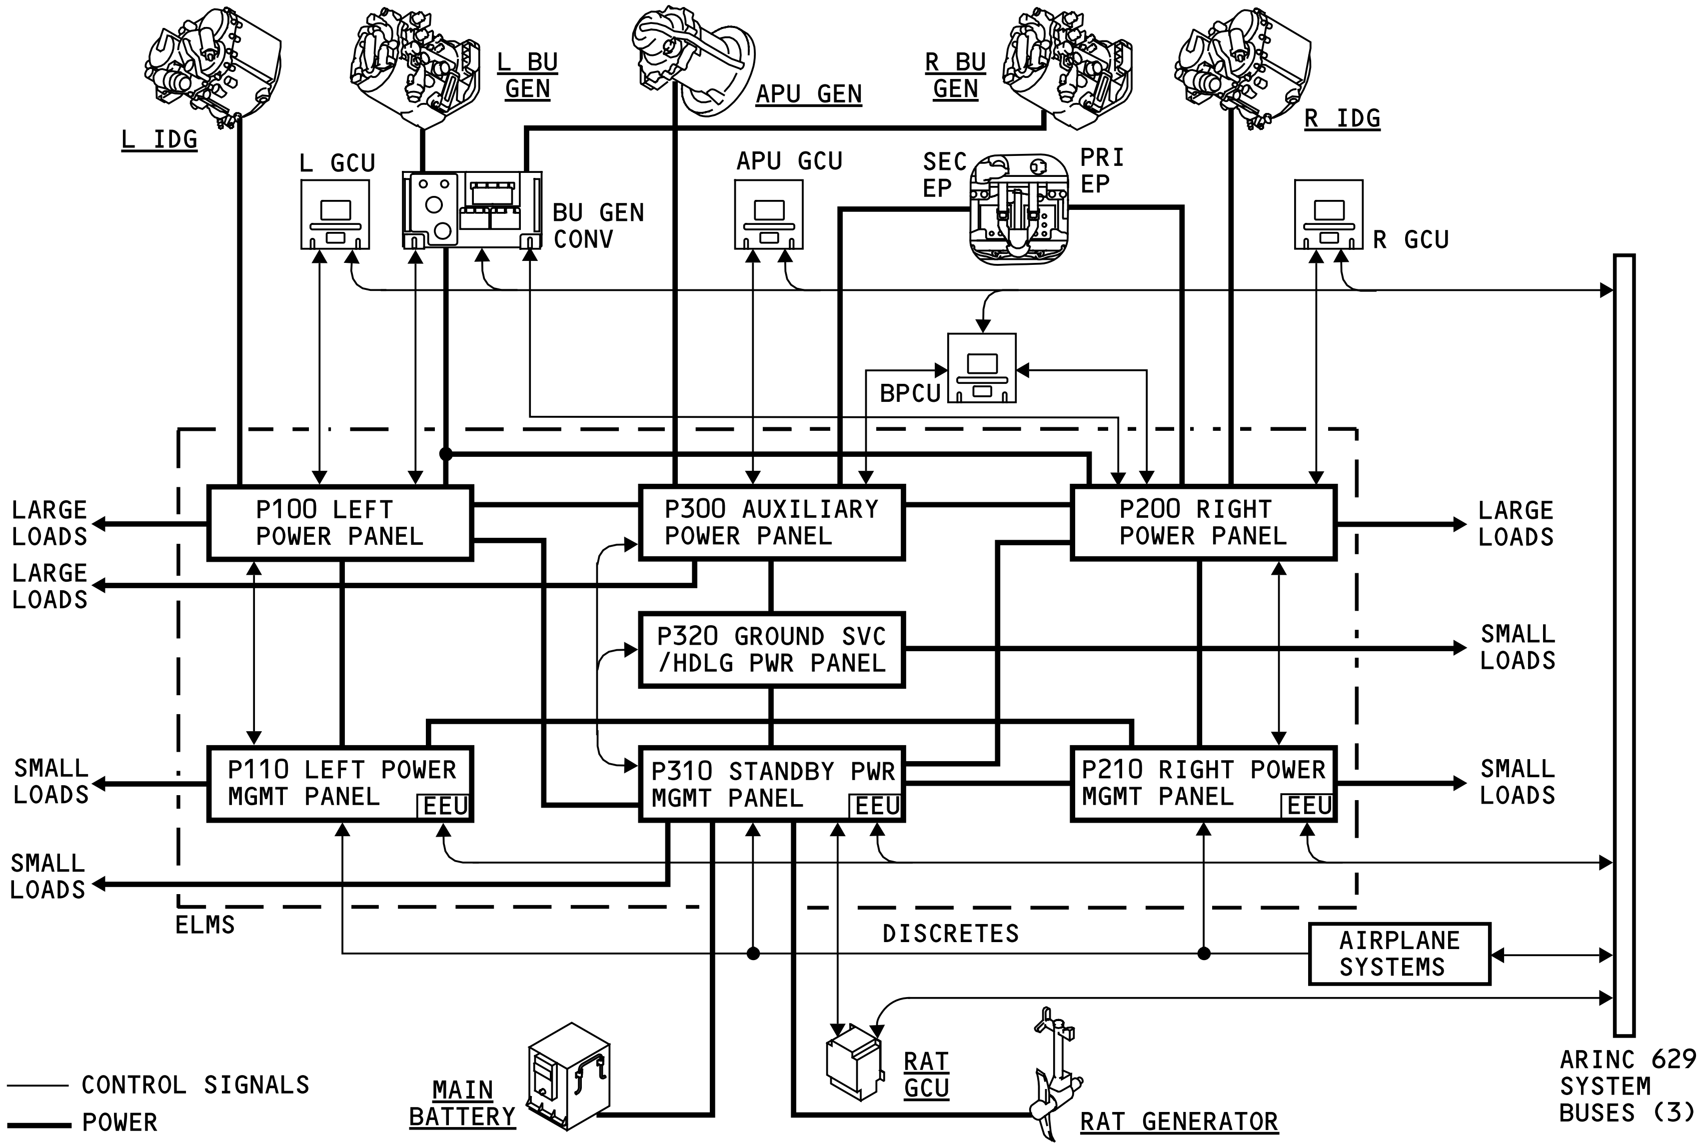
All airplane electrical power goes through the ELMS panels for distribution. The ELMS panels contain the load-switching devices that distribute this power. The ELMS also controls most of the devices. These are the ELMS panels:

- P100 Left power panel
- P200 Right power panel
- P300 Auxiliary power panel
- P110 Left power management panel
- P210 Right power management panel
- P310 Standby power management panel
- P320 Ground service/handling power panel.

Main and backup power go to the left, right, or auxiliary power panels. These power panels supply power to large loads (25 amps or more). They also supply power to the power management panels and the ground service/handling power panel. From these panels, electrical power goes to small loads (less than 25 amps).

The ELMS power management panels contain electronic units. These control and monitor the load-switching devices in their related ELMS panels. However, the ELMS electronic units (EEU) do not control all of the large load-switching devices in the power panels. The GCUs, BPCU, and backup generator converter directly control some of the large load-switching devices.

The EEUs get data from the other electrical power control units and airplane systems either directly or from the ARINC 629 system buses. They use this data to manage the loads of the electrical power system.



ELECTRICAL POWER - GENERAL DESCRIPTION - POWER & CONTROL

THIS PAGE INTENTIONALLY LEFT BLANK

ELECTRICAL POWER - GENERAL DESCRIPTION - DISTRIBUTION

General

The electrical power system normally operates as two independent power channels: left and right. These buses are on the left channel:

- Left main ac
- Left utility
- Left transfer
- Left dc
- Standby ac
- Captain's flight instrument
- Battery
- Battery #2.

The left channel also supplies power to the left and center flight controls dc power supply assemblies (FCDC PSA).

These buses are on the right channel:

- Right main ac
- Right utility
- Right transfer
- Right dc
- First officer's flight instrument
- Ground service
- APU battery
- Hot battery.

The right channel also supplies power to the right FCDC PSA.

Power Configurations

The buses may connect to different power sources and to each other. This depends upon which power sources are available, the flight phase of the airplane, and the configuration of the flight deck electrical panel. Breakers, contactors, and relays connect the buses to the power sources and to each other.

Ground Power

Primary external power automatically supplies power to the ground handling buses. You can also use a switch to connect primary external power to the ground service bus. When you turn primary external power on at the electrical panel, the power connects to the right main ac bus. From there, it supplies power to the rest of the electrical system.

If you need more ground power capacity, connect the secondary external power. The right bus tie breaker (BTB) opens so that the secondary external power supplies power to the left side of the electrical system while the primary supplies power to the right side.

APU Power

The APU generator can supply power to the airplane on the ground or in flight. On the ground, it can supply power to the ground handling bus. The APU generator can also supply all of the airplane power or share the load with an IDG, backup generator, or the primary external power source.

IDG Power

The IDGs normally supply the electrical power when the engines are operating. They each supply power to one side of the electrical system. If an IDG fails, the APU generator can supply power to the failed side.

Backup Generator Power

The backup generators are a variable-speed, variable-frequency type. They operate when the engines are running. They connect to the backup generator converter. The converter makes the backup generator output into satisfactory ac power. A backup generator supplies power to a transfer bus under non-normal conditions and during autoland.

Each backup generator also contains permanent magnet generators (PMGs). Two of these PMGs in each backup generator are the primary power sources for the FCDC PSAs.

Standby Power

If all normal power is lost, the RAT generator can supply the flight instrument buses with power. It does this through the two center transformer rectifier units (TRU). The captain's flight instrument bus then supplies power to the battery and standby ac buses.

If the RAT generator does not operate, the main battery supplies power to the battery buses, captain's flight instrument bus, and the standby ac bus.

Battery Power

The electrical system has these four battery buses:

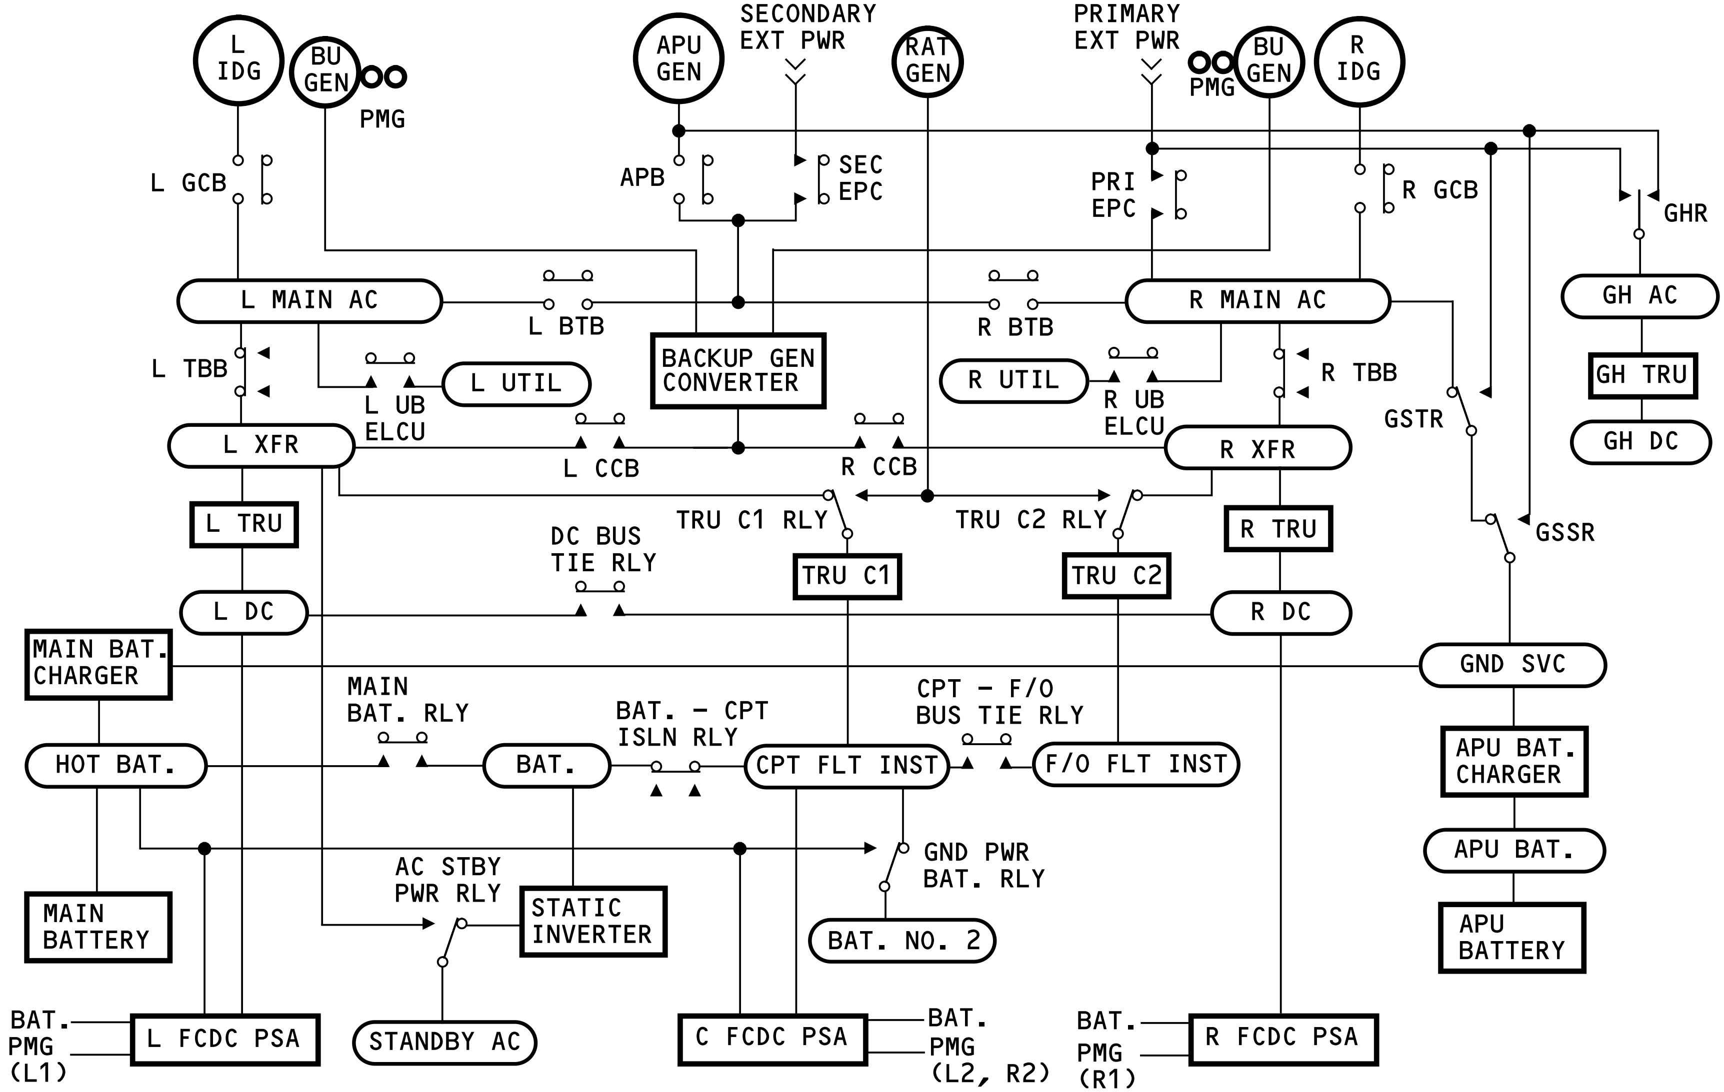
- Hot battery
- Battery
- Battery #2
- APU battery.

The ground service bus normally supplies power to the hot battery and APU battery buses through their related battery chargers.

The captain's flight instrument bus normally supplies power to the battery and battery #2 buses.

Flight Control Power

Three FCDC PSAs supply power to the flight control system. The PSAs have more than one power source. Each PSA has a small battery to prevent power interruptions during power transfers.



ELECTRICAL POWER - GENERAL DESCRIPTION - DISTRIBUTION

ELECTRICAL POWER - COMPONENT LOCATIONS - AIRPLANE

THIS PAGE INTENTIONALLY LEFT BLANK

ELECTRICAL POWER - COMPONENT LOCATIONS - AIRPLANE

General

There are electrical power components in these areas:

- Flight deck
- E5 rack
- Wing-to-body fairing
- APU gearbox
- E10 rack
- Engine accessory gearbox
- Engine fan hub/compressor case
- Door 2 left
- Main equipment center
- Right-forward fuselage.

Flight Deck

The electrical power system control switches are on the P5 overhead panel and the P61 overhead maintenance panel.

E5 Rack

Some of the FCDC components are in the E5 rack just aft of the forward cargo door.

Wing-to-Body Fairing

The RAT generator is in the wing-to-body fairing aft of the right main gear.

APU Gearbox

The APU generator attaches to the APU gearbox.

E10 Rack

The APU battery and battery charger are in the E10 rack just aft of the bulk cargo door.

Engine Accessory Gearbox

A backup generator attaches to the forward side of the main gearbox on each engine. The IDG attaches to the aft side.

The IDG fuel/oil heat exchanger attaches to the right forward side of the accessory gearbox. a

Engine Fan Hub / Compressor Case

The oil/oil heat exchanger is on the fan hub frame. The backup generator/IDG air/oil heat exchanger attaches to the high compressor case.

Door 2 Left

The ground service switch is on the flight attendant's panel by door 2 left.

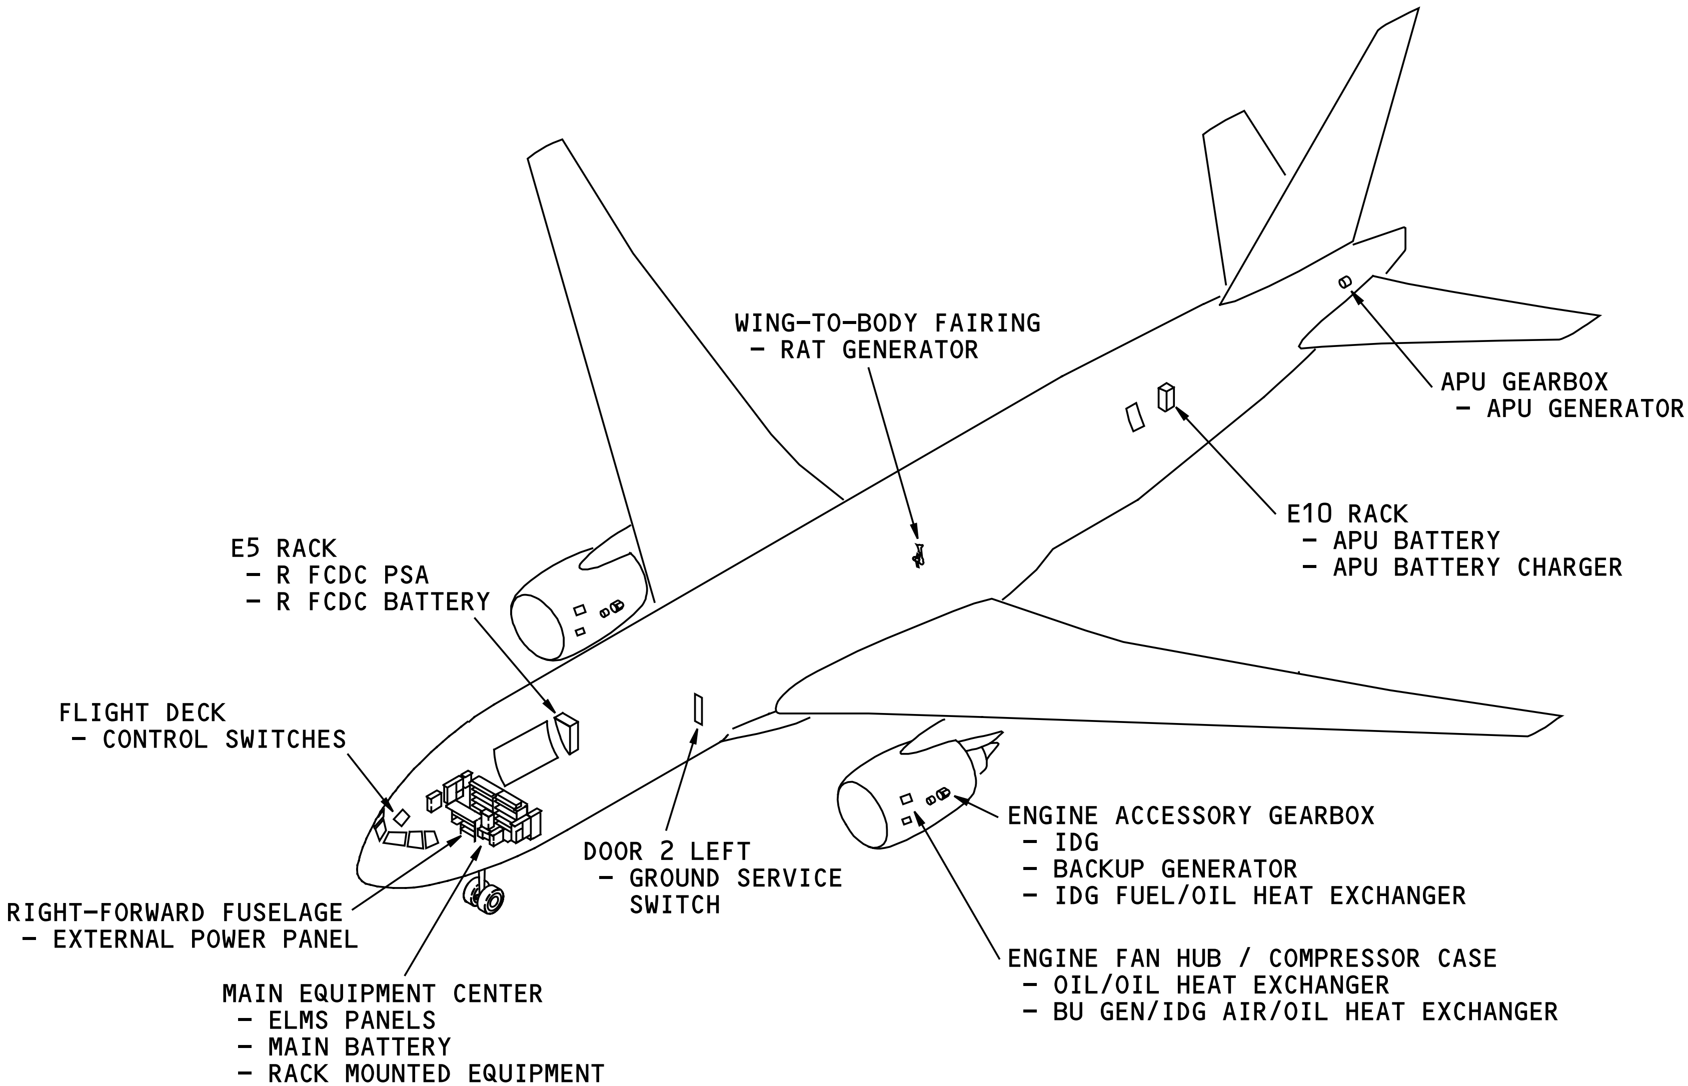
ELECTRICAL POWER - COMPONENT LOCATIONS - AIRPLANE

Main Equipment Center

Most of the electrical system components are in the main equipment center. The main battery is there. The rest are in equipment racks or the ELMS panels.

Right-Forward Fuselage

The external power panel is to the right of the main equipment center access door.



24-00-00-004 Rev 5 04/15/1997

ELECTRICAL POWER - COMPONENT LOCATIONS - AIRPLANE

ELECTRICAL POWER - GENERAL COMPONENT LOCATIONS - MAIN EQUIPMENT CENTER

General

Most of the electrical system components are in equipment racks or the ELMS panels.

The specific locations of components are in their related sections.

The ELMS section shows the specific location of components inside the ELMS panels.

Panels

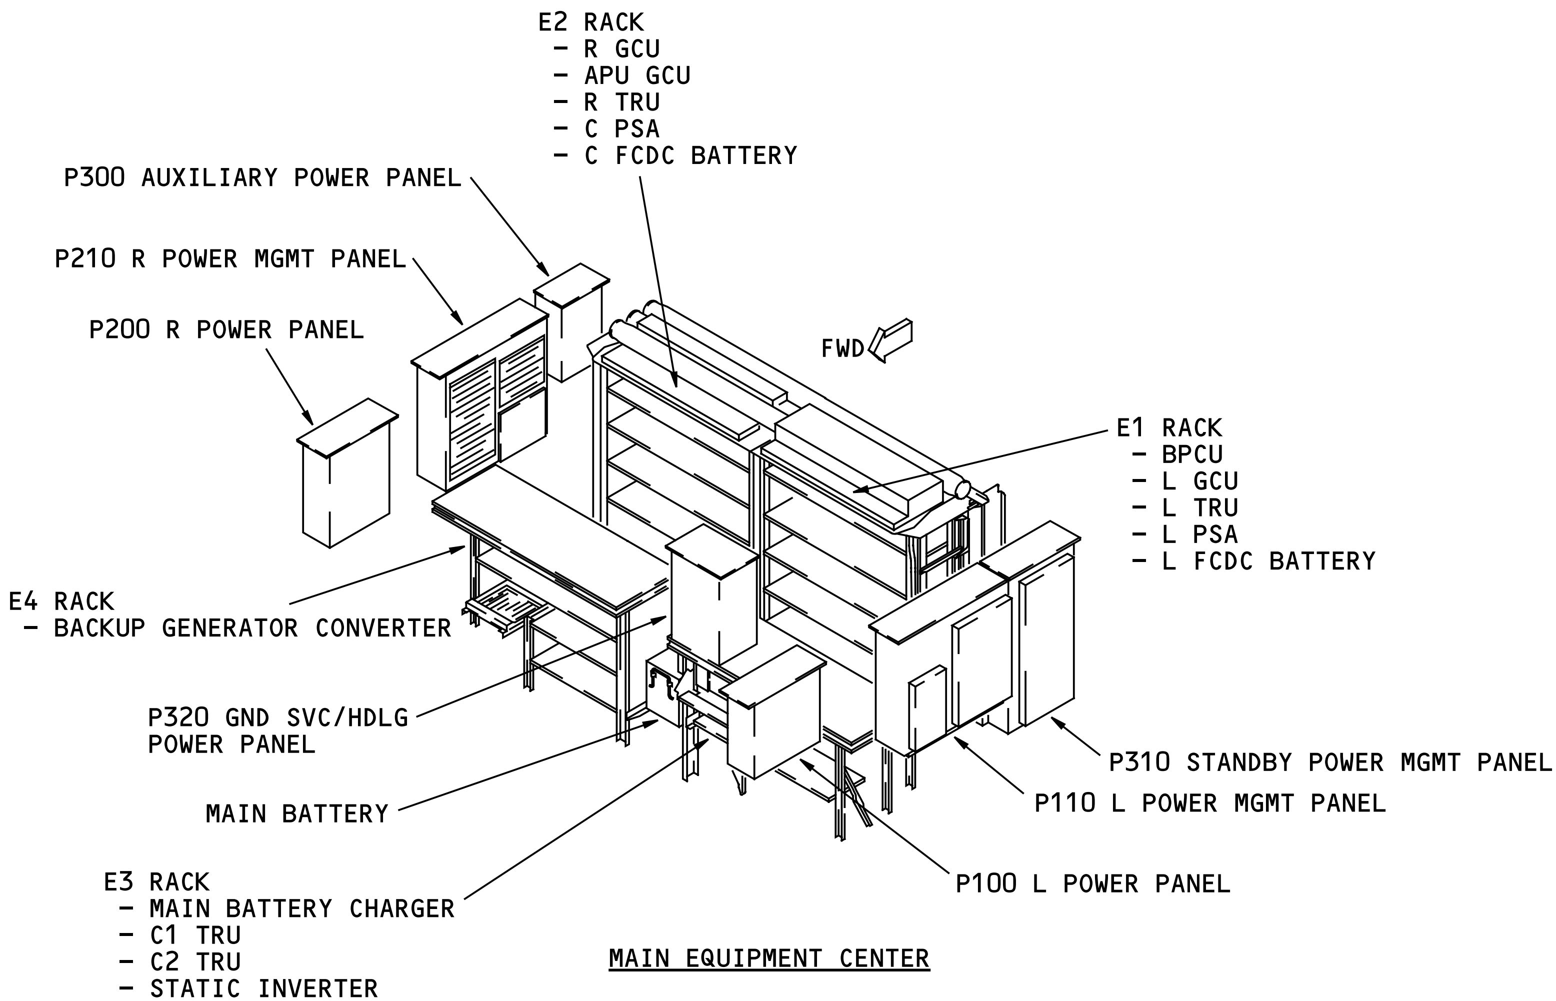
All the ELMS panels contain electrical system components. These are the ELMS panels:

- P200 right power panel
- P210 right power management panel
- P300 auxiliary power panel
- P100 left power panel
- P110 left power management panel
- P310 standby power management panel
- P320 ground service/handling power panel.

Racks

These main equipment center racks contain electrical system components:

- E1
- E2
- E3
- E4.



MAIN EQUIPMENT CENTER

24-00-00-005 Rev 3 04/15/1997

ELECTRICAL POWER - GENERAL COMPONENT LOCATIONS - MAIN EQUIPMENT CENTER

THIS PAGE INTENTIONALLY LEFT BLANK

General

The electrical panel is on the P5 overhead panel. The panel has four momentary-action switches and eight alternate-action switches. You use these to operate most of the electrical system. These are the momentary-action switches:

- External power (2)
- Drive disconnect (2).

These are the alternate-action switches:

- Battery
- APU generator
- Bus tie (2)
- Generator control (2)
- Backup generator (2).

The standby power switch is on the P61 overhead maintenance panel. It is a guarded, toggle switch. You use it to manually control standby power.

Battery Switch

The battery switch connects the hot battery bus to the battery #2 bus. ON is a mechanical indication that shows the switch is in its latched-in position. OFF is an amber light that shows when the switch is out and the airplane has ac power.

APU Generator Switch

The APU generator switch arms the APU GCU to automatically control APU generator electrical power. ON is a mechanical indication that shows the switch is in its latched-in position. OFF is an amber light that shows when the switch is out. If the APU is running, the light also comes on when the auxiliary power breaker (APB) opens for any reason other than when you apply secondary external power to the airplane. The switch is normally left on.

Bus Tie Switches

Each bus tie switch controls the operation of its related BTB. AUTO is a mechanical indication that shows the switch is in its latched-in position. ISLN is an amber light that shows when the switch is out and the BTB is open. The isolation (ISLN) light also comes on if the switch is in AUTO and the GCU opens the BTB for a fault. The switches are normally left in AUTO.

External Power Switches

Each external power switch controls the operation of its related external power contactor (EPC). AVAIL is a white light that shows good power quality at the ground power source. ON is a white light that shows a closed EPC. The available (AVAIL) light goes out when the EPC closes.

Generator Control Switches

Each generator control switch arms its GCU to automatically control IDG electrical power. ON is a mechanical indication that shows the switch is in its latched-in position. OFF is an amber light that shows when the related generator circuit breaker (GCB) is open. The switches are normally left on.

Backup Generator Switches

Each backup generator control switch arms the backup generator converter to control backup electrical power. ON is a mechanical indication that shows the switch is in its latched-in position. OFF is an amber light that comes on for these conditions:

- Generator control relay (GCR) opens for a fault
- Engine is shut down
- Related engine fire switch is pulled out
- Switch is out.

The switches are normally left on.

Drive Disconnect Switches

The drive disconnect (DISC) switch removes engine gearbox power from the IDG. When you press the switch, the two-piece IDG input shaft moves apart. DRIVE is an amber light that shows that the related IDG has low oil pressure. Plastic guards cover the drive disconnect switches to prevent accidental operation.

Standby Power Switch

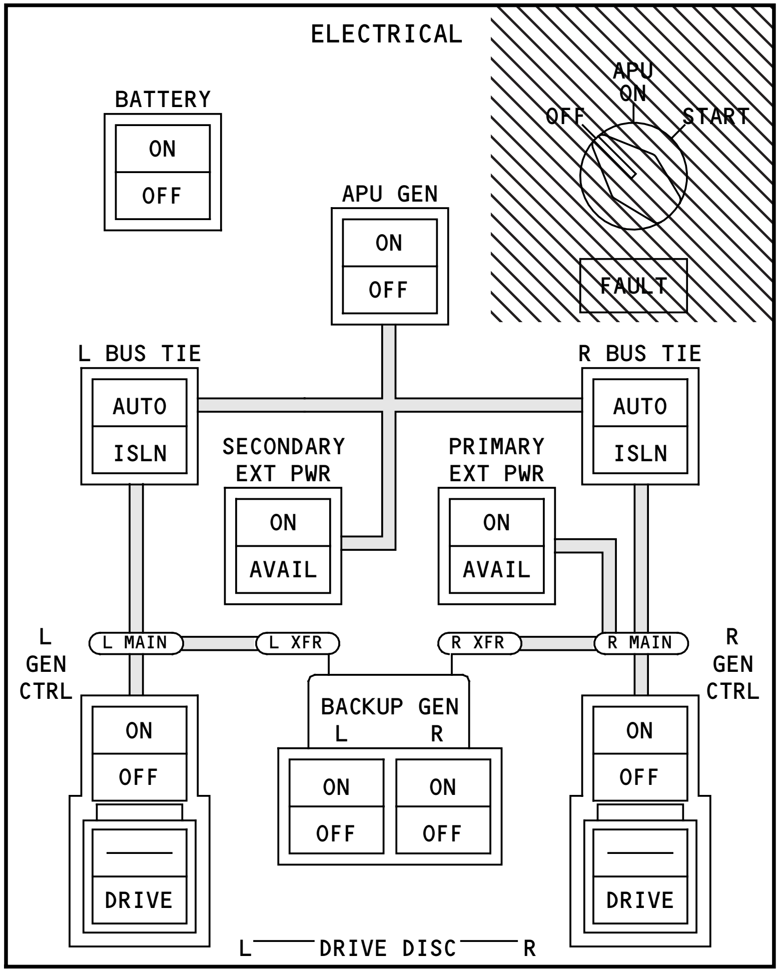
The standby power switch has these three positions:

- OFF
- AUTO
- BAT (momentary).

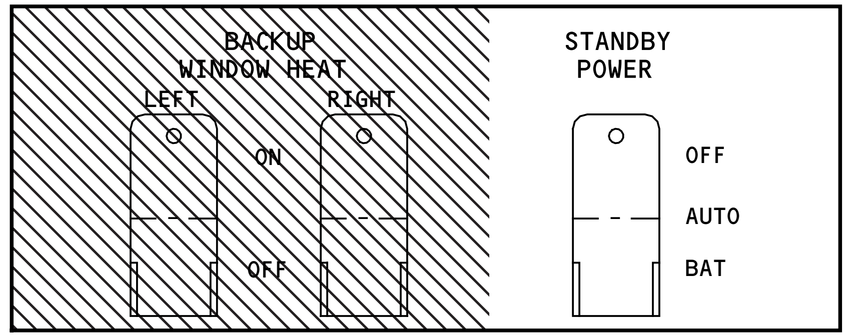
On the ground, the off position makes the static inverter stay off. In the air, the off position has no effect.

The automatic (AUTO) position puts the standby electrical power system under the ELMS control. A guard over the switch moves it to AUTO. The switch is normally left in AUTO.

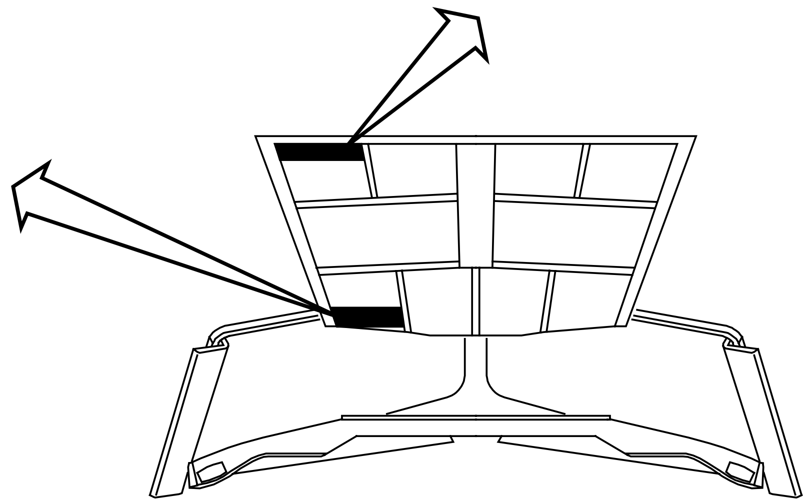
To use the battery position (BAT), you must first push the battery switch on. With no ac power on the airplane, the switch in BAT turns the static inverter on and makes it power the standby ac bus. With ac power on the airplane, the switch in BAT starts a dc/standby self check test.



ELECTRICAL PANEL (P5)



OVERHEAD MAINTENANCE PANEL (P61)



FLIGHT DECK OVERHEAD PANELS

24-00-00-006 Rev 6 05/16/95

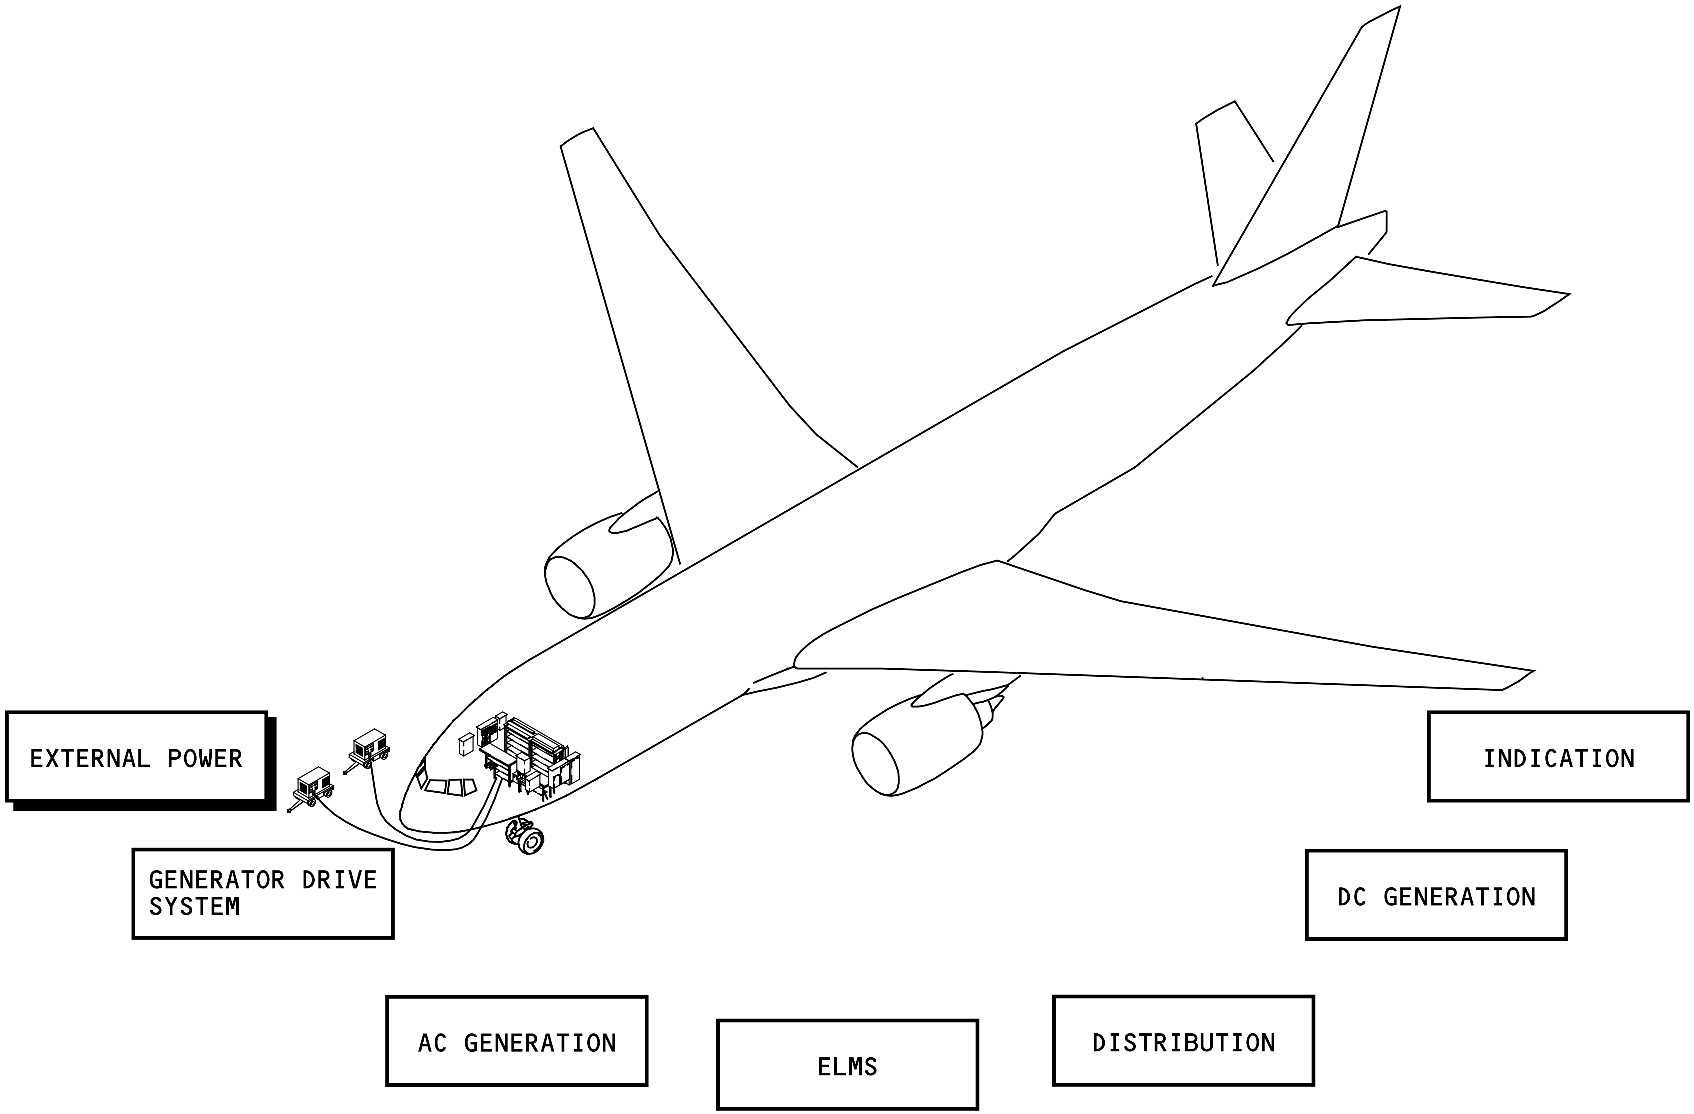
ELECTRICAL POWER - OPERATION - GENERAL

EXTERNAL POWER - INTRODUCTION

General

The external power system controls the electrical power on the airplane from ground power sources. The external power system has these electrical power system functions:

- Bus power control
- Ground handling power
- Ground service power
- Primary external power
- Secondary external power.



24-40-00-001 Rev 0

EXTERNAL POWER - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

EXTERNAL POWER - GENERAL DESCRIPTION

General

You use external power to supply the airplane with electrical power from a ground power source. You can supply the power directly to these electrical buses:

- Ground Handling
- Ground Service
- Main ac.

External Power Panel

The external power panel has two external power receptacles that have a continuous supply capacity of 90 kva each. The forward receptacle is for primary external power. The aft receptacle is for secondary external power.

Control

The BPCU controls these electrical switching devices that connect external power to the airplane:

- Secondary EPC
- Primary EPC
- Ground handling relay
- Ground service transfer relay
- Ground service select relay.

The GCUs control the BTBs to connect power between the main ac buses.

Ground Handling Power

When you supply power to the primary external power receptacle, the BPCU energizes the ground handling relay. This connects primary external power to the ground handling ac bus. The ground handling TRU supplies dc power to the ground handling dc bus.

The APU generator can also supply power to the ground handling ac bus, but secondary external power cannot. If both primary external power and the APU generator are available, the BPCU selects primary external power for the ground handling ac bus.

Ground Service Power

The BPCU selects the power source for the ground service bus in this order:

- Right main ac bus
- Primary external
- APU generator.

If the right main ac bus has no power, you can use the ground service switch. When you push the switch, the BPCU connects primary external power or APU generator power directly to the ground service bus.

Primary External Power

When you push the primary external power switch, you connect primary external power to the main ac buses.

EXTERNAL POWER - GENERAL DESCRIPTION

The BPCU closes the primary EPC and the GCUs close the BTBs to connect the power.

Secondary External Power

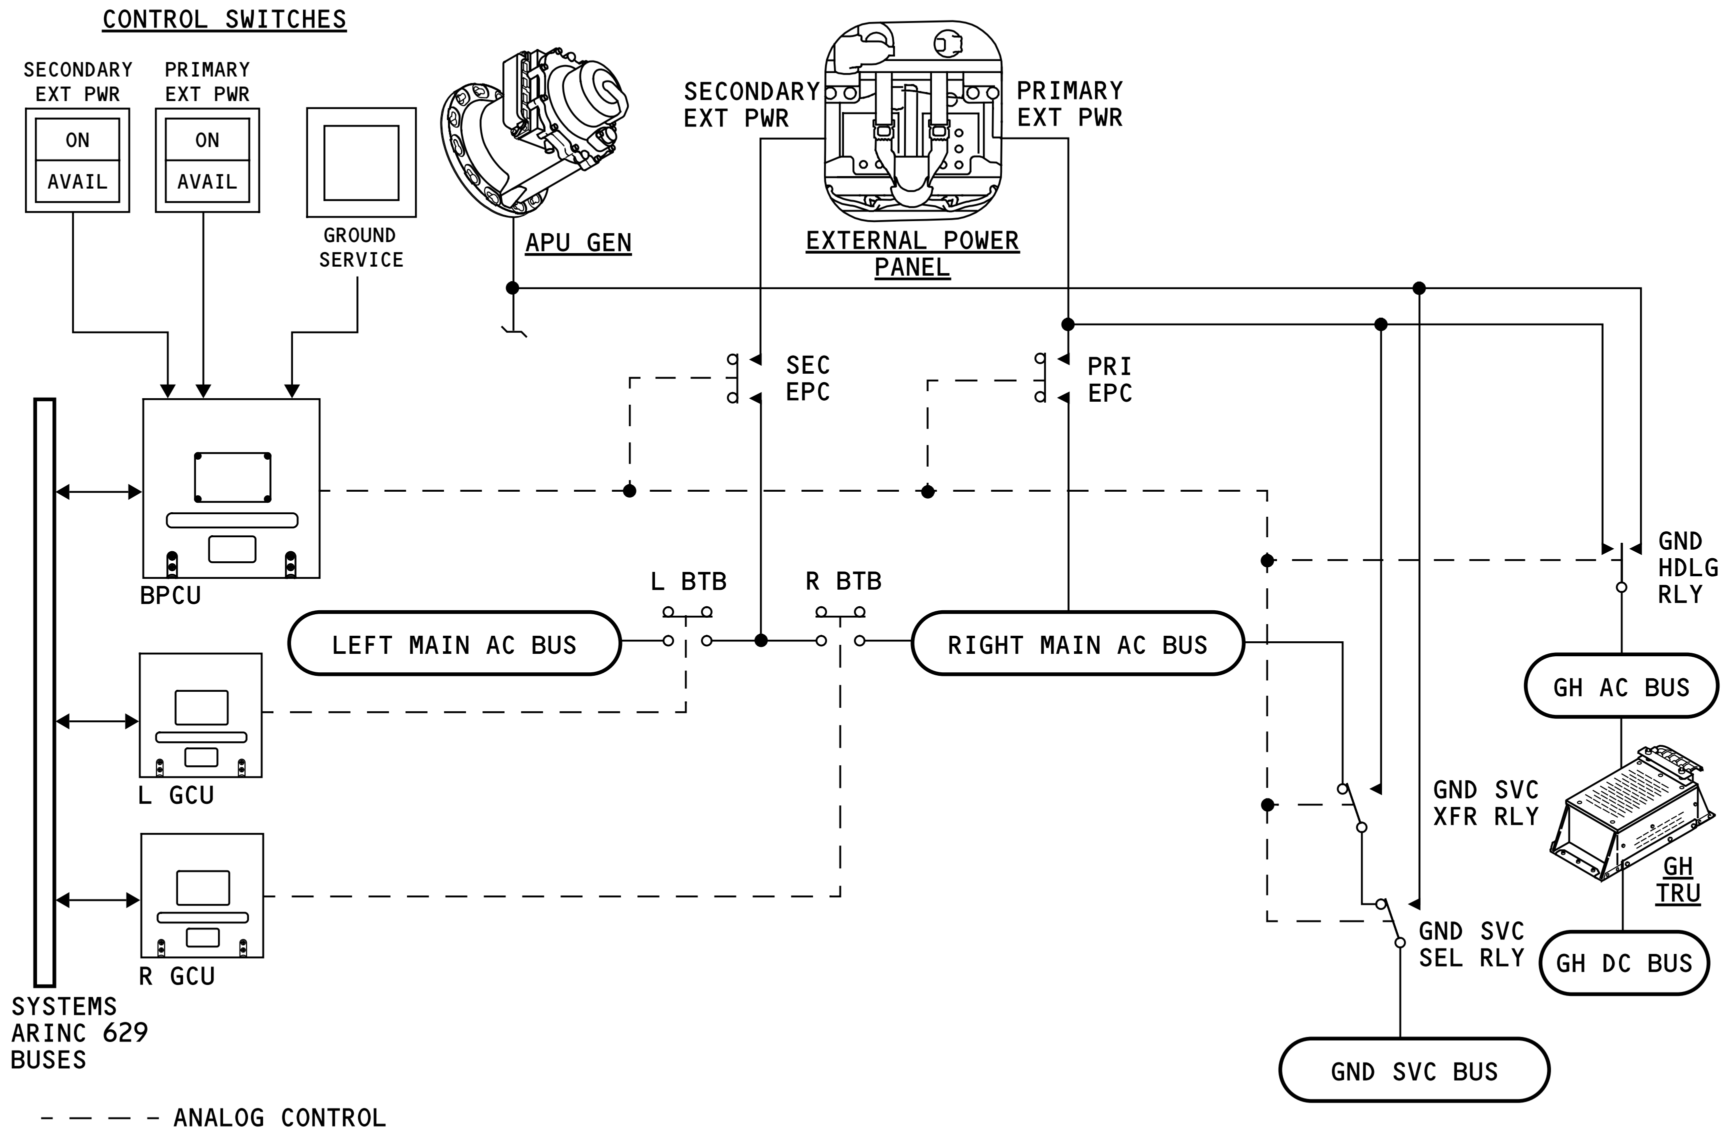
When you push the secondary external power switch, you connect secondary external power to the main ac buses. The BPCU closes the secondary EPC and the GCUs close the BTBs to connect the power. If primary external power was on the right main ac bus, the right GCU opens the right BTB first to perform a break-power transfer.

No-Break Power Transfers

The BPCU coordinates power transfers between the external power sources and the IDGs or APU generator. The BPCU and GCUs communicate on the systems ARINC 629 buses.

When the ac system changes from an external power source to another power source, it does no-break power transfers. The system momentarily connects the two power sources to one bus so there is no interruption in power. A GCU electronically adjusts an IDG speed to match the power of the external power source to do a no-break power transfer. For transfers between external power and the APU, the APU controller adjusts the APU speed to do the no-break power transfer.

The BPCU always does a break-power transfer between primary external power and secondary external power.



EXTERNAL POWER - GENERAL DESCRIPTION

24-40-00-002 Rev 4 08/08/96

EXTERNAL POWER - COMPONENT LOCATIONS

General

These are the components of the external power system:

- Primary EPC
- Ground service transfer relay
- Secondary EPC
- Ground service select relay
- Ground handling relay
- BPCU
- Ground handling TRU.

Main Equipment Center

Most of the external power components are in the ELMS panels in the main equipment center. See the electrical load management system section for more information on component locations (AMM PART I 24-09).

These are the components in the P200 right power panel:

- Primary EPC
- Ground service transfer relay.

These are the components in the P300 auxiliary power panel:

- Secondary EPC
- Ground service select relay
- Ground handling relay.

The ground handling TRU is in the P320 ground service/ handling power panel.

The BPCU is on the E1-1 shelf.

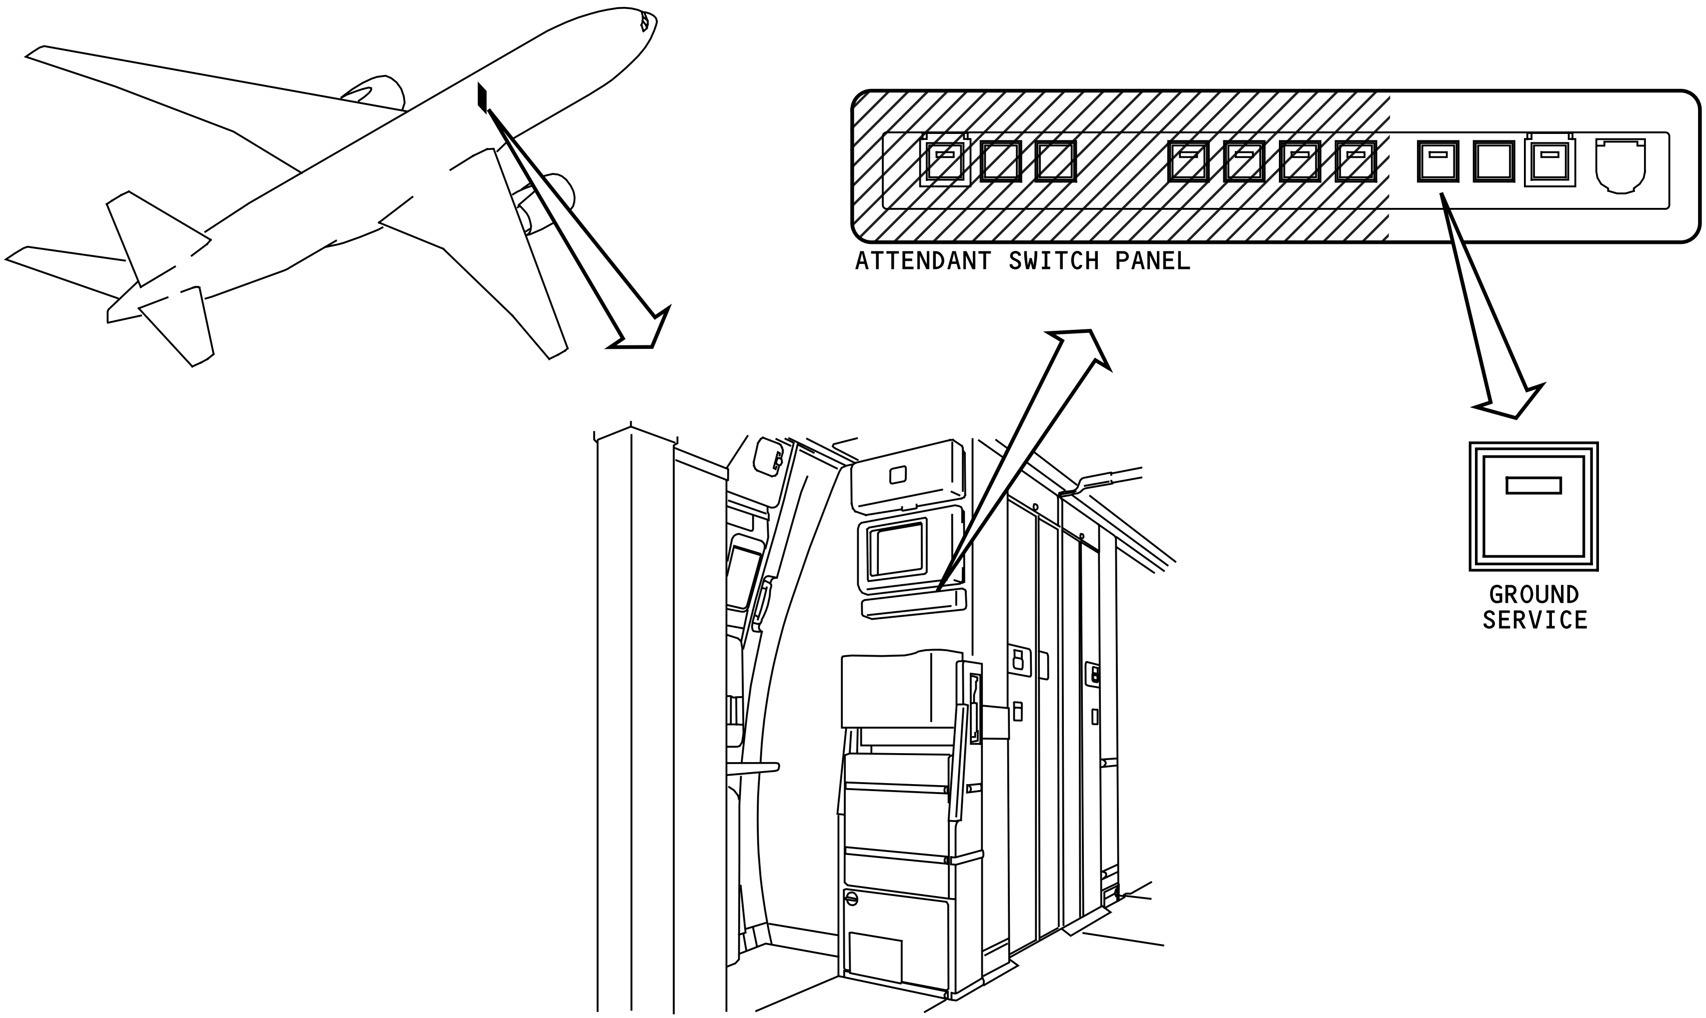
EXTERNAL POWER - COMPONENT LOCATIONS

EXTERNAL POWER - GROUND SERVICE SWITCH

General

The ground service switch arms the BPCU to connect either primary external power or the APU generator directly to the ground service bus. The switch is on the right side of the attendant switch panel at door 2 left.



ATTENDANT SWITCH PANEL - DOOR 2L
(LOOKING FWD)

EXTERNAL POWER - GROUND SERVICE SWITCH

24-40-00-004 Rev 4 04/26/96

EXTERNAL POWER - EXTERNAL POWER PANEL

General

You use the external power panel to connect ground power sources to the airplane electrical system. The panel is immediately to the right of the main equipment center access door approximately 10 ft (3 m) above the ground.

Physical Description

The panel contains two power receptacles and their related power cord restraining straps. The forward receptacle is for primary power. The aft receptacle is for secondary power.

Each receptacle has four large pins for ac power and two small ones for the interlock. Above each receptacle are two indication lights; CONNECTED and NOT IN USE.

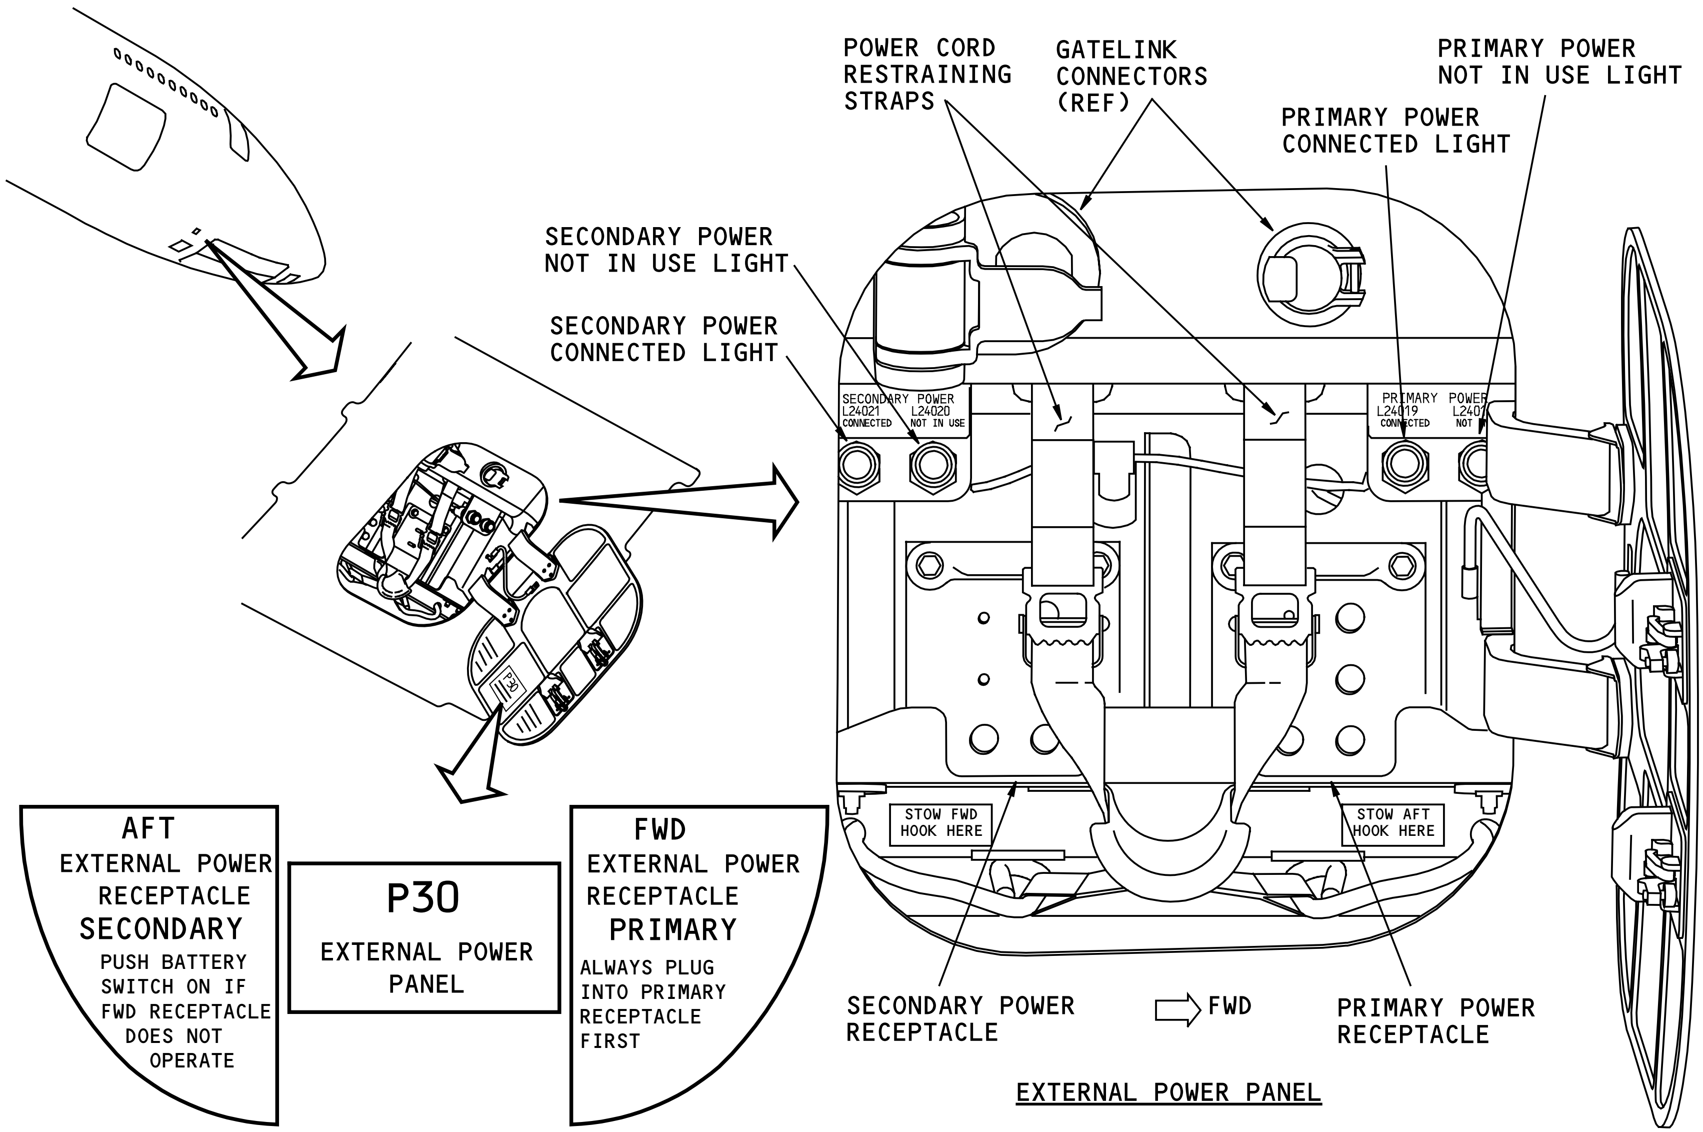
Above the lights are gatelink connectors. You find details on the gatelink connectors in chapter 23.

The power cord restraining straps are hook-type with adjustable straps. They hold the weight of the power cords to keep the plugs connected to the receptacles. The aft hook, which stows forward, is for the aft receptacle. The forward hook, which stows aft, is for the forward receptacle.

Placards inside the panel access door list specific information about connecting external power.

Training Information Point

When you stow the hooks, make sure the straps are tight.



EXTERNAL POWER - EXTERNAL POWER PANEL

THIS PAGE INTENTIONALLY LEFT BLANK

EXTERNAL POWER - FUNCTIONAL DESCRIPTION - BPCU

General

The BPCU controls external power on the airplane. It also controls ground handling and ground service power.

The BPCU sends data to the GCUs and the ELMS across the ARINC 629 systems data buses for power management. It also sends data to the AIMS for indications.

Switch Controls

These three switches supply control signals to the BPCU:

- Primary external power
- Secondary external power
- Ground service.

The BPCU supplies power to the switches and controls the lights in the switches.

Contactor and Relay Control

The BPCU controls these five electrical switching devices:

- Primary external power contactor (EPC)
- Secondary EPC
- Ground handling relay
- Ground service transfer relay
- Ground service select relay.

Power Transfer Control

The BPCU controls bus transfers between power sources. A reference frequency circuit in the BPCU permits no-break-power-transfers (NBPT) between external, APU, and IDG power sources on the ground. A NBPT is when two power sources momentarily parallel during a transfer. The power transfer circuit prevents any paralleling in the air and during takeoff and landing.

Protection

The BPCU protects the airplane electrical system from these external power problems:

- Over/under-voltage
- Over/under-frequency
- Over-current
- Unbalanced current
- Open phase
- Sustained parallel source (SPS)
- BPCU processor failure.

BPCU Power

The BPCU has these three power sources:

- Primary external power
- Battery bus #2
- Right dc bus.

A rectifier in the BPCU power supply changes the primary external ac power to dc. Battery bus #2 power

EXTERNAL POWER - FUNCTIONAL DESCRIPTION - BPCU

connects to the BPCU when you push the battery switch on.

Power Quality

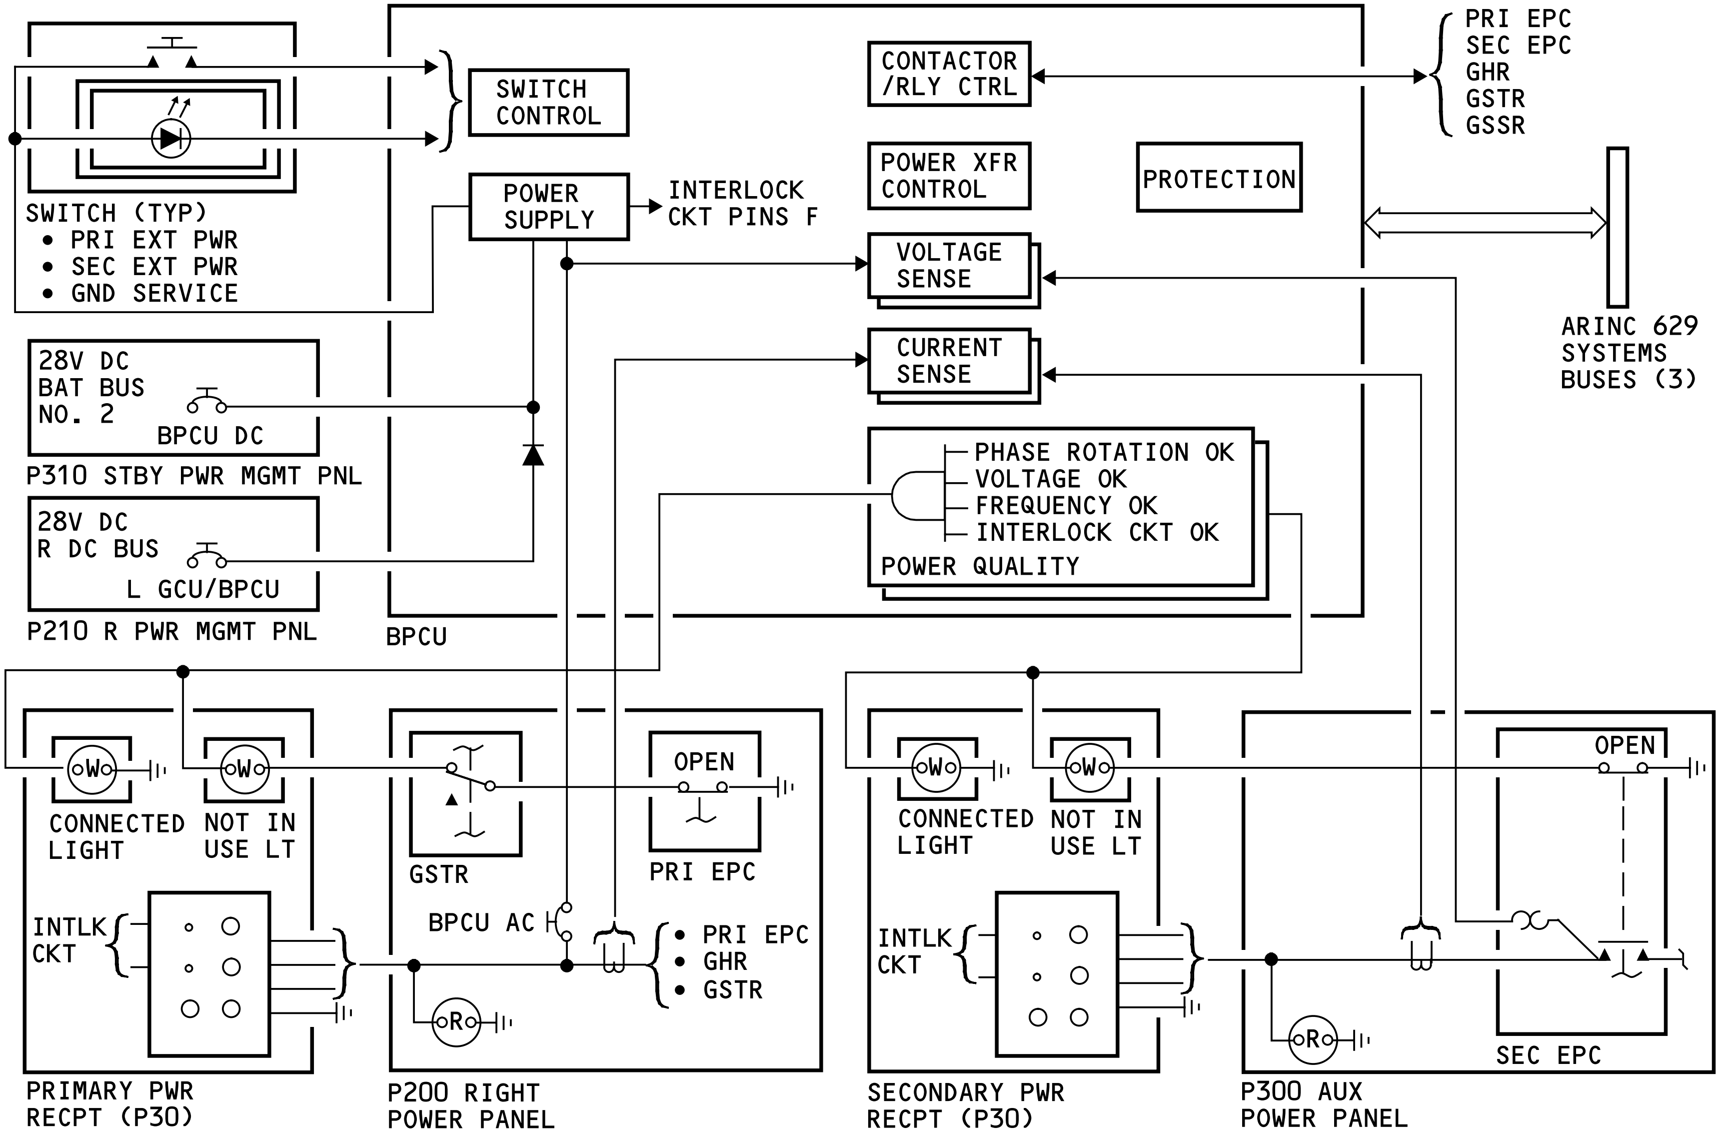
The BPCU checks the quality of the external power sources for:

- Phase rotation
- Voltage
- Frequency
- Interlock circuit.

If the power is good, the BPCU supplies power to turn on the related CONNECTED and NOT IN USE lights. When you select primary external power or ground service power, the primary NOT IN USE light goes off. When you select secondary external power, the secondary NOT IN USE light goes off.

Training Information Point

The secondary external power source does not supply power to the BPCU. To use secondary external power, you must connect the primary external power or push the battery switch on.



EXTERNAL POWER - FUNCTIONAL DESCRIPTION - BPCU

EXTERNAL POWER - GROUND HANDLING/GROUND SERVICE POWER - FUNCTIONAL DESCRIPTION

General

The BPCU controls the power to the ground handling bus and the ground service bus. Ground handling power is available only on the ground. Ground service power is available on the ground and in flight.

Ground Handling Power

When you apply good power to the primary power receptacle, the BPCU energizes one coil of the ground handling relay. This connects the primary external power to the ground handling bus.

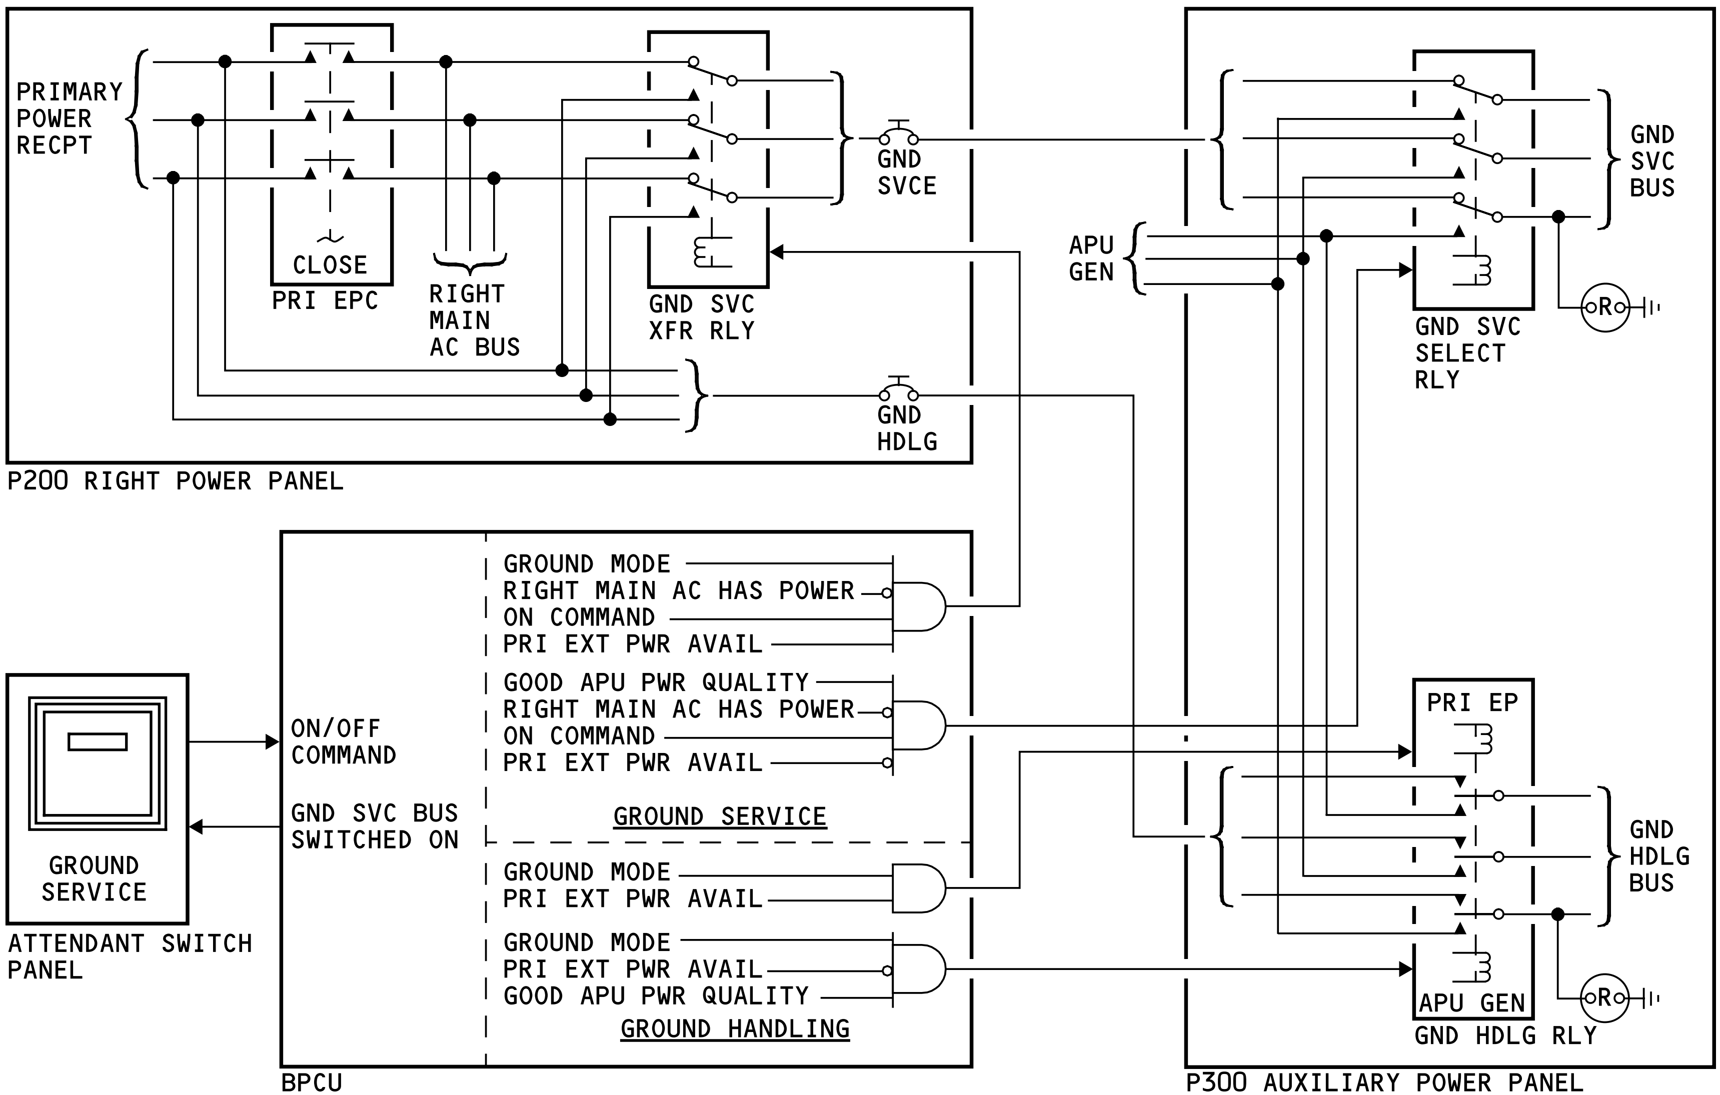
If no primary external power is available, but the APU generator power quality is good, the BPCU energizes the other coil of the ground handling relay. This connects the APU generator to the ground handling bus.

Ground Service Power

When you apply good power to the primary power receptacle, power is available at the ground service transfer relay. When you push the ground service switch, the BPCU energizes the ground service transfer relay. This connects primary external power to the ground service bus. With primary external power on the ground service bus, the BPCU turns on the light in the ground service switch.

When you push the ground service switch with no primary external power available, but the APU generator power quality is good, the BPCU energizes the ground service select relay. This connects the APU generator to the ground service bus. With APU power on the ground service bus, the BPCU turns on the light in the ground service switch.

When the right main ac bus has power, it automatically supplies the power to the ground service bus. In this case, the ground service switch has no effect on the ground service bus. The light in the switch does not come on or it goes out if it was on.



EXTERNAL POWER - GROUND HANDLING/GROUND SERVICE POWER - FUNCTIONAL DESCRIPTION

EXTERNAL POWER - FUNCTIONAL DESCRIPTION - PRIMARY/SECONDARY POWER

General

The BPCU controls external power on the airplane. You use the external power switches on the electrical panel to supply command signals to the BPCU.

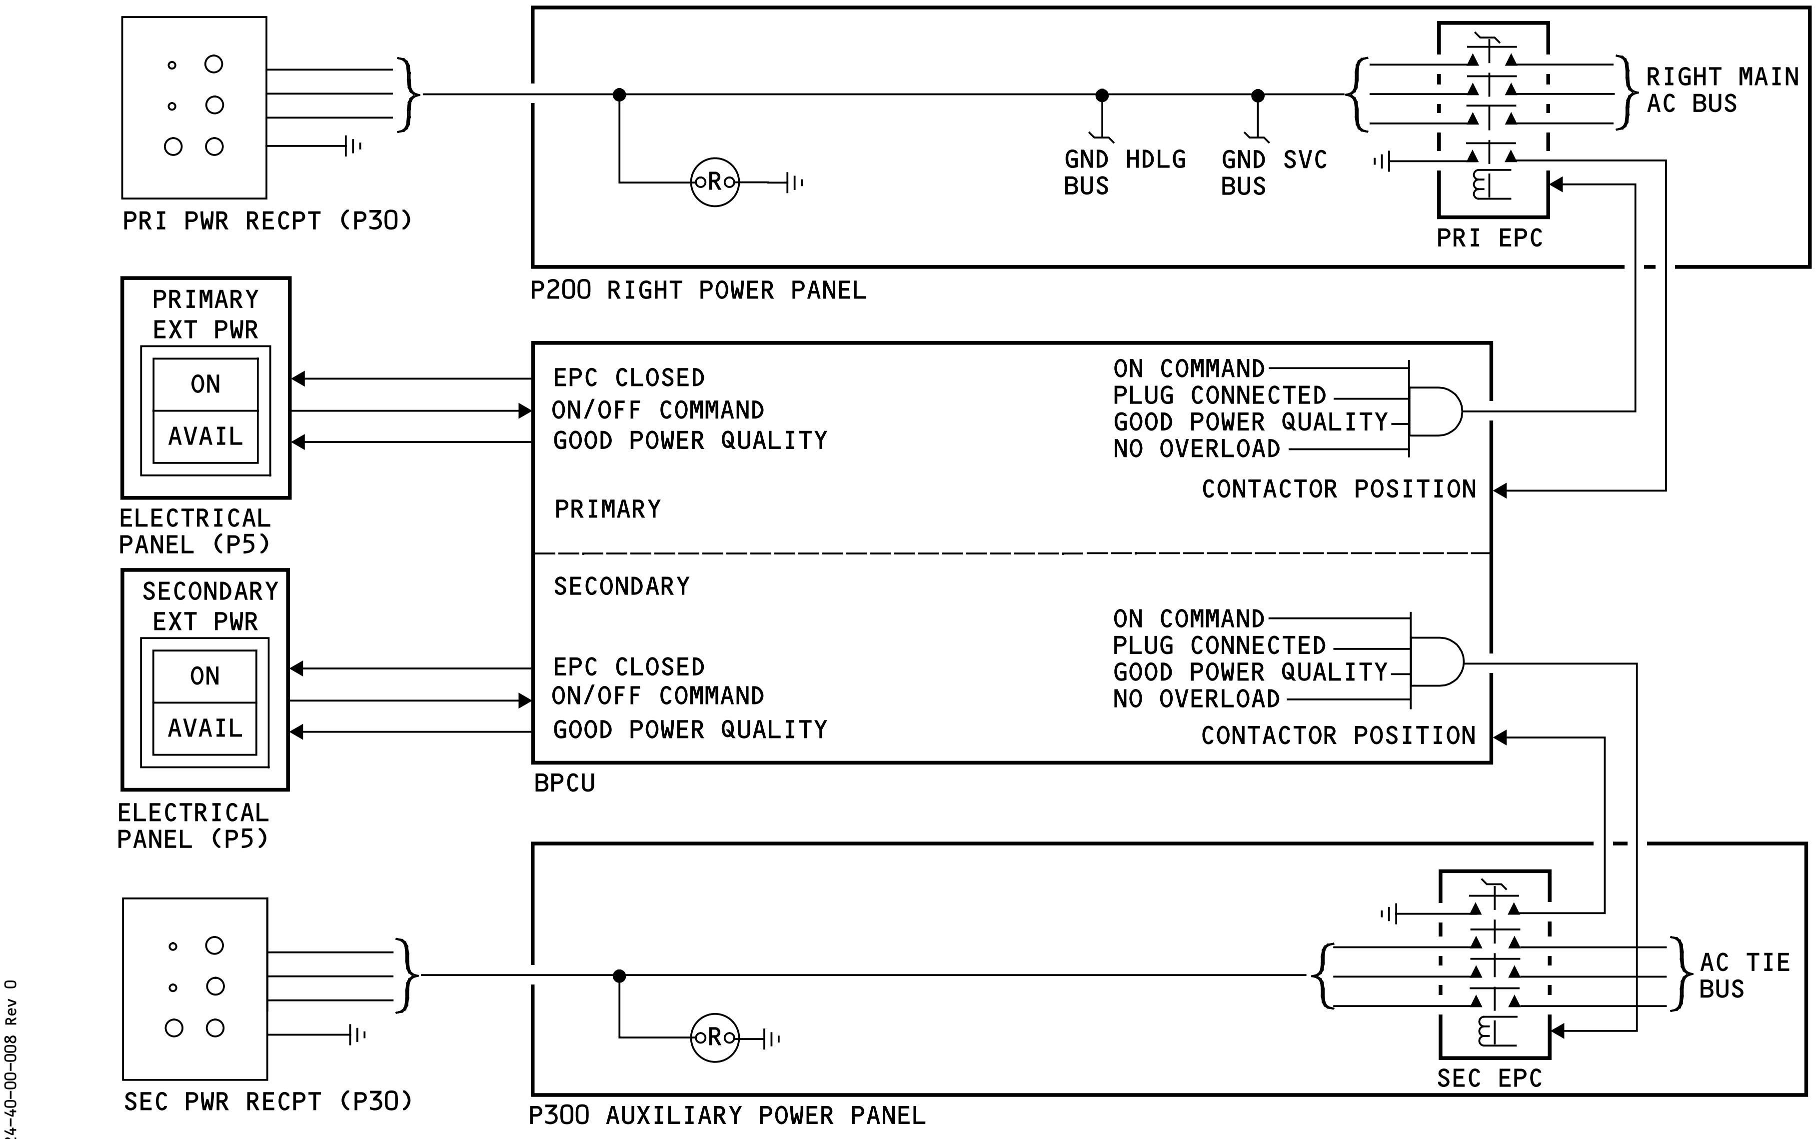
Primary External Power

When you apply power to the primary power receptacle, power is available at the primary EPC. With good power quality, the BPCU turns on the AVAIL light in the primary external power switch. When you push the primary external power switch, the BPCU energizes the primary EPC. This connects primary external power to the right main ac bus. When the EPC closes, the BPCU turns off the AVAIL light and turns on the ON light.

The BPCU must keep control power on the EPC to keep it closed. If you push the primary external power switch again, the on command in the BPCU goes away. This removes power to the EPC and it opens. The ON light goes off and the AVAIL light comes on again.

Secondary External Power

Secondary external power works the same as primary external power except the secondary external power connects to the ac tie bus through the secondary EPC.



EXTERNAL POWER - FUNCTIONAL DESCRIPTION - PRIMARY/SECONDARY POWER

THIS PAGE INTENTIONALLY LEFT BLANK

EXTERNAL POWER - OPERATION

General

To apply external power to the airplane electrical system, do these steps:

- Connect ground power plugs
- Observe indications
- Operate control switches.

Placards inside the external power panel access door give specific information about connecting external power.

Connect Ground Power Plugs

To connect to the power receptacles, you must loosen the restraining straps and remove the hooks from their stow points.

You should always use the primary receptacle. If you need more power, you can use the secondary receptacle.

Insert the ground power plug. Place the correct hook around the power cord behind the plug and tighten the restraining strap. Turn on power at the power source.

Observe Indications

If the quality of the power to the primary receptacle is good, the two lights above the receptacle come on. When the lights above the primary receptacle are on, the ground handling buses have power.

When you supply power to the secondary receptacle, the two lights above the receptacle come on if the power quality is good and one of these conditions exist:

- The primary receptacle has power
- The battery switch is on.

Operate Control Switches

You push the ground service switch to apply power to the ground service bus. The light in the switch comes on when the ground service bus has power. The NOT IN USE light above the primary receptacle goes out when the ground service bus gets power.

The AVAIL light in the primary external power switch comes on if the power quality is good.

The AVAIL light in the secondary external power switch comes on if the power quality is good and one of these conditions exist:

- The primary receptacle has power
- The battery switch is on.

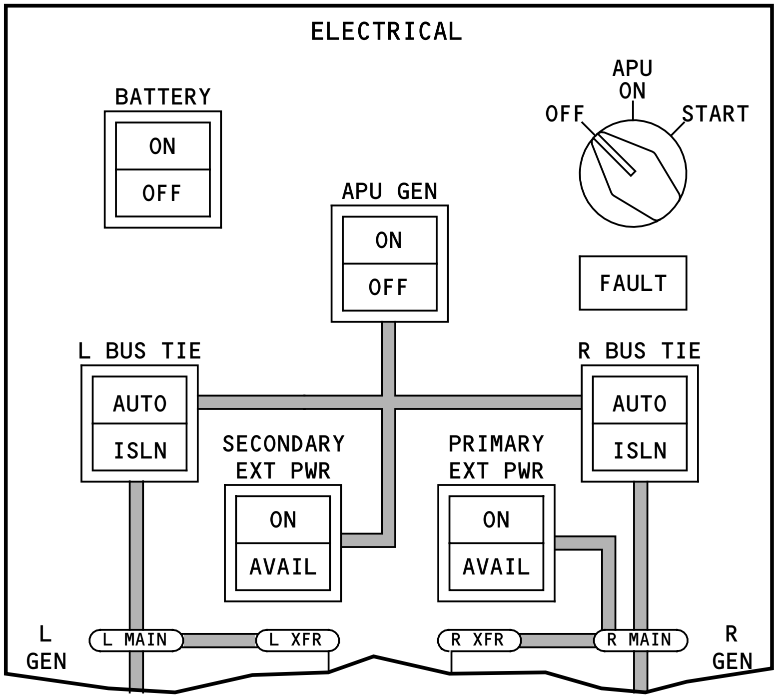
Push the battery switch on. Push the primary external power switch to apply primary ground power to the airplane electrical system. Push the secondary external power switch to apply secondary ground power to the airplane electrical system. When you supply power, the AVAIL lights go off and the ON lights come on.

EXTERNAL POWER - OPERATION

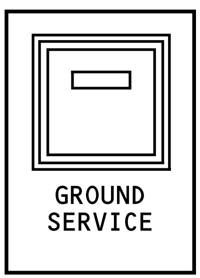
If the airplane will be left unattended, push the battery switch off. This prevents the automatic operation of the standby power system if you lose all ground power to the airplane.

Training Information Point

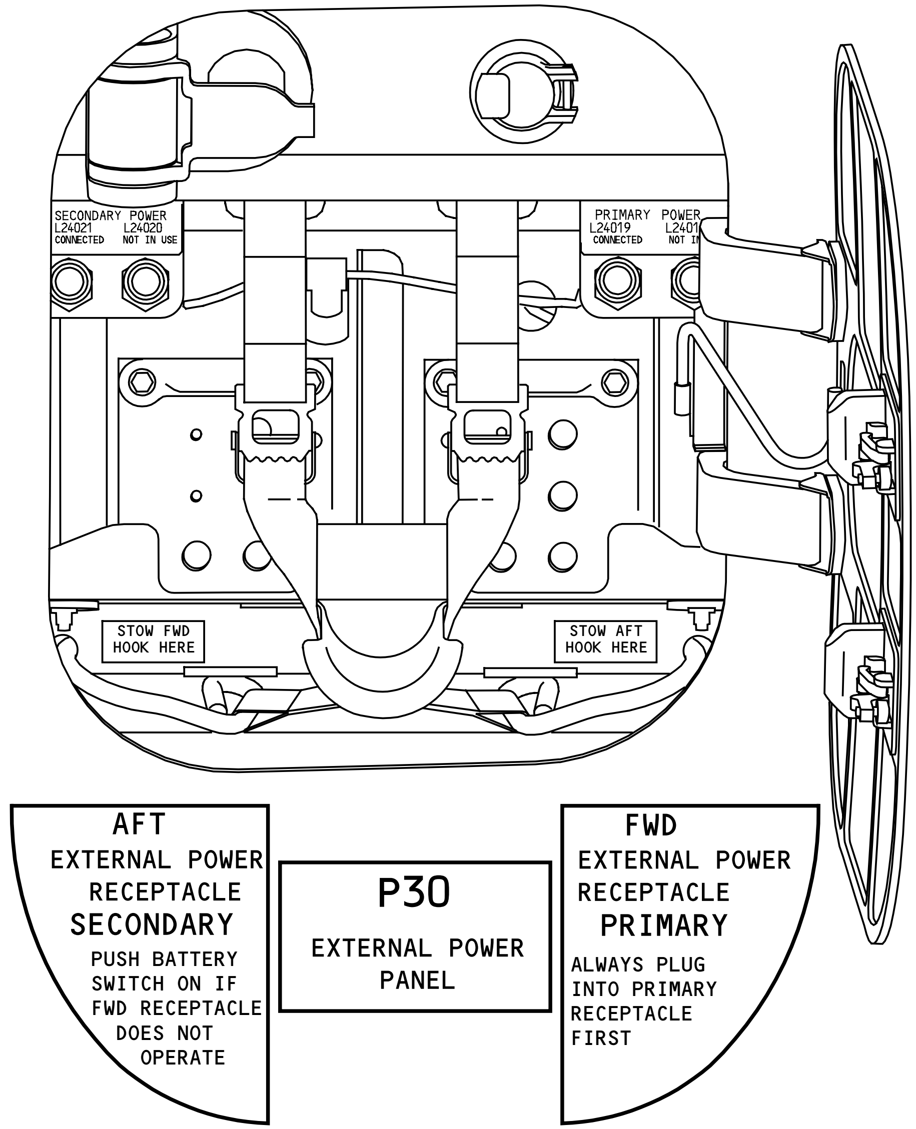
For each power receptacle, you should only use external power sources that have a power capacity of 90 kva or more. If you do not, it is possible that the ELMS will shed all the loads it controls or the BPCU will open the external power contactor(s). See the electrical load management system section for more information on load shedding (AMM PART I 24-09).



ELECTRICAL PANEL (P5)



ATTENDANT'S PANEL



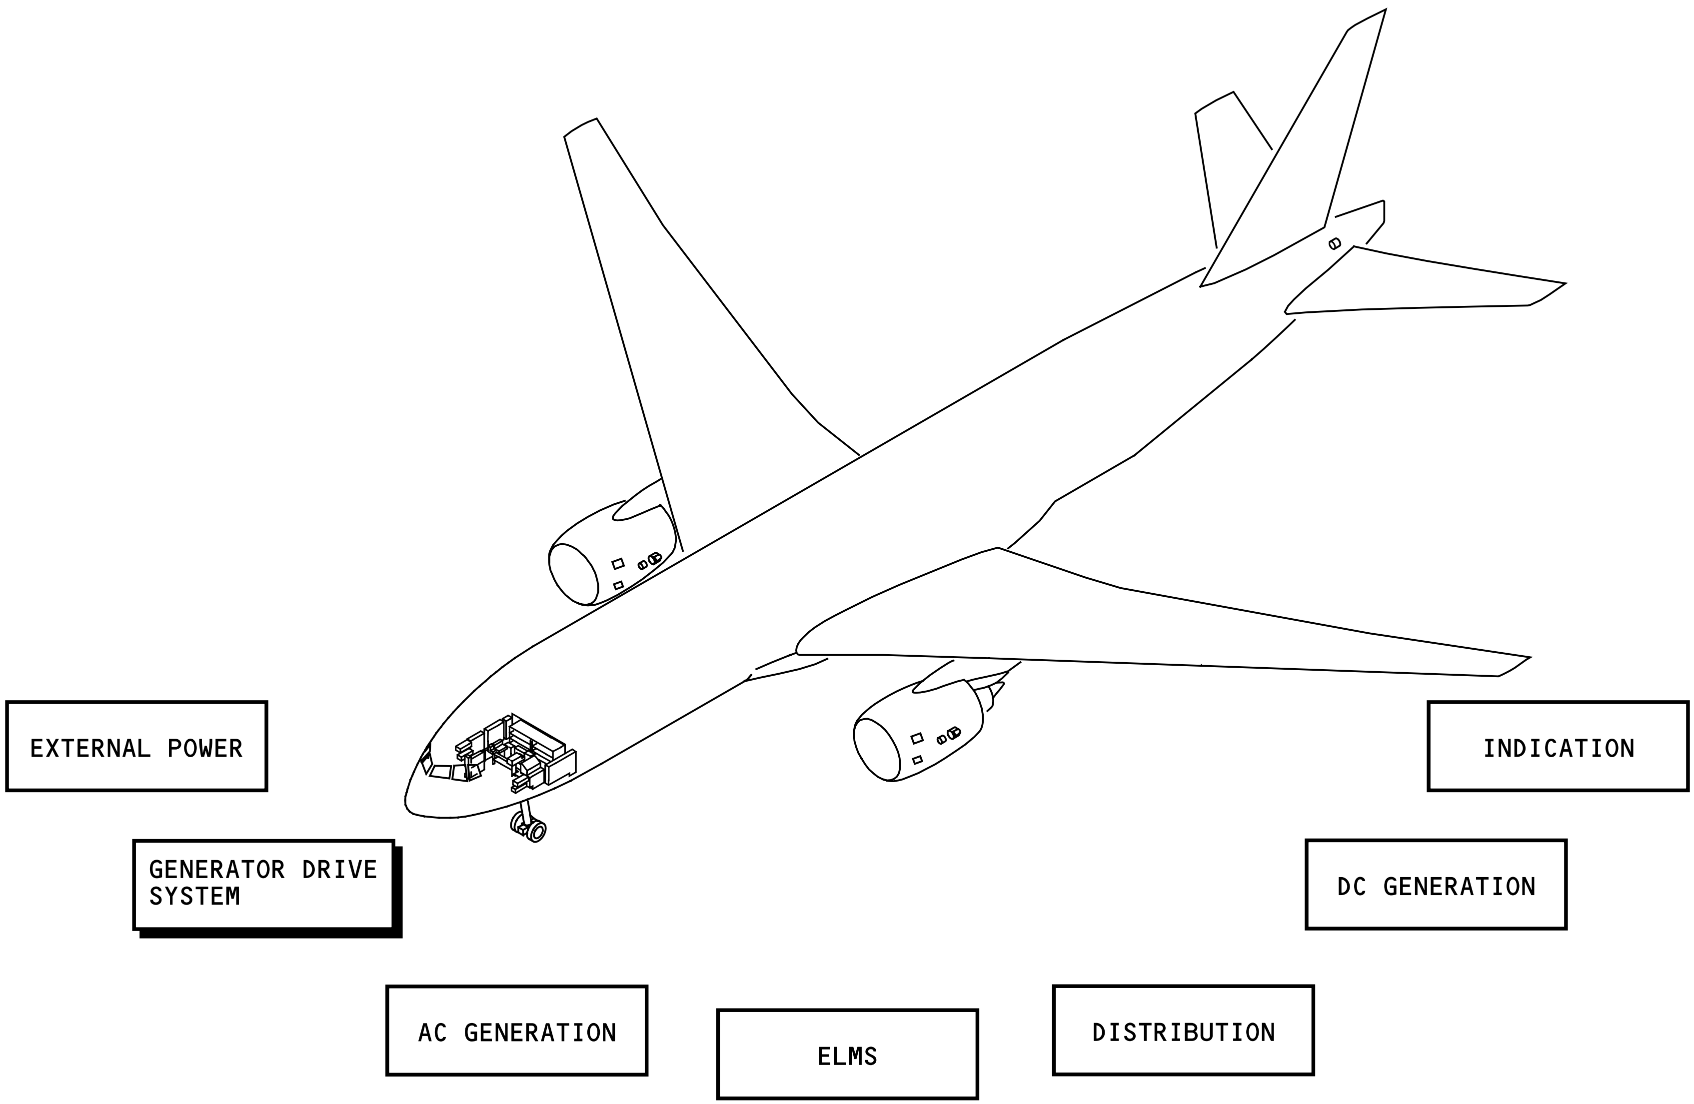
24-40-00-009 Rev 8 04/30/96

EXTERNAL POWER - OPERATION

GENERATOR DRIVE - INTRODUCTION

General

The generator drive system normally supplies electrical power to all of the electrical loads while the engines operate. The integrated drive generators (IDGs) are the primary sources of electrical power. The APU generator and the backup generators are secondary sources of electrical power.



GENERATOR DRIVE - INTRODUCTION

GENERATOR DRIVE - GENERAL DESCRIPTION

General

Two IDGs are primary power sources. The APU generator, and two backup generators are secondary power sources.

Heat exchangers remove heat from the generators.

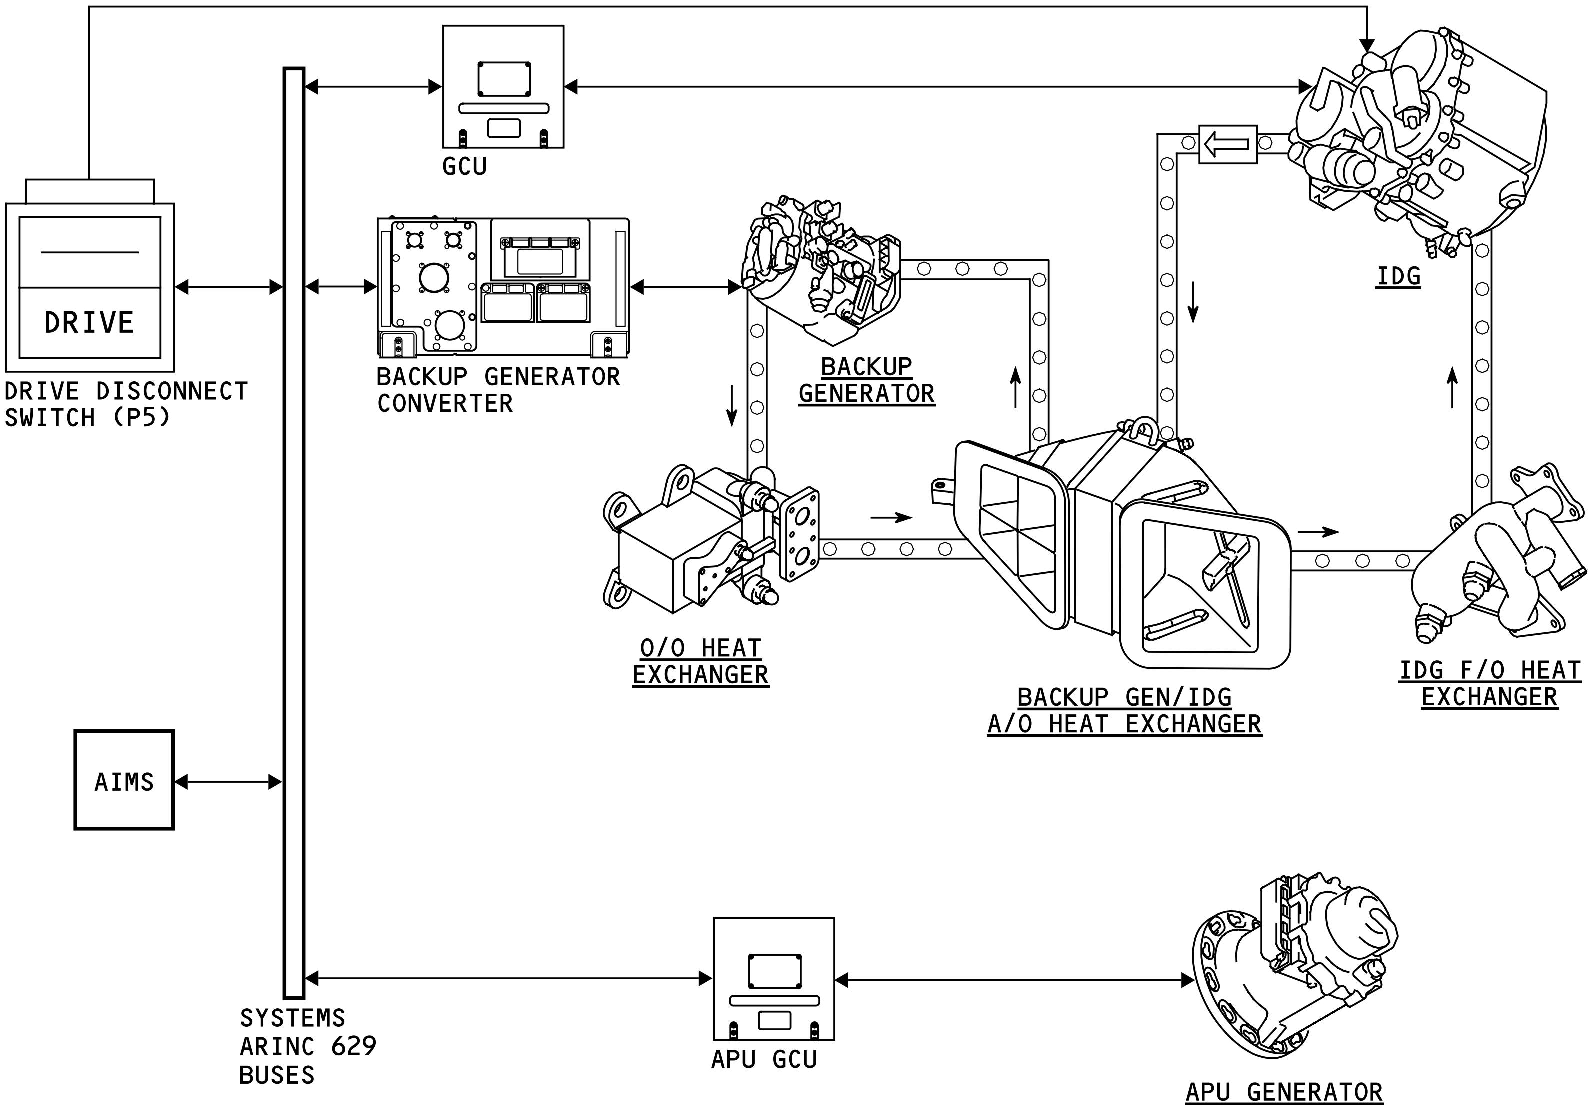
Electrical Interfaces

Switches on the electrical panel control the IDG disconnect operations. GCUs control the IDGs and the APU generator. One backup generator convertor controls the two backup generators. Lights on the electrical panel and EICAS messages show generator drive system information.

Mechanical Interfaces

Each engine mechanically turns an IDG and a backup generator. The IDGs change the mechanical power to constant-frequency ac electrical power. The backup generators change the mechanical power to variable-frequency ac electrical power. The backup generator converter changes the variable-frequency ac power to constant frequency ac power.

A continuous flow of fuel through the IDG fuel/oil heat exchanger cools the IDG oil. A continuous flow of fan air through the backup generator/IDG air/oil heat exchanger cools the oil for the backup generator and the IDG. The oil/oil heat exchanger heats the backup generator oil with engine oil.



GENERATOR DRIVE - GENERAL DESCRIPTION

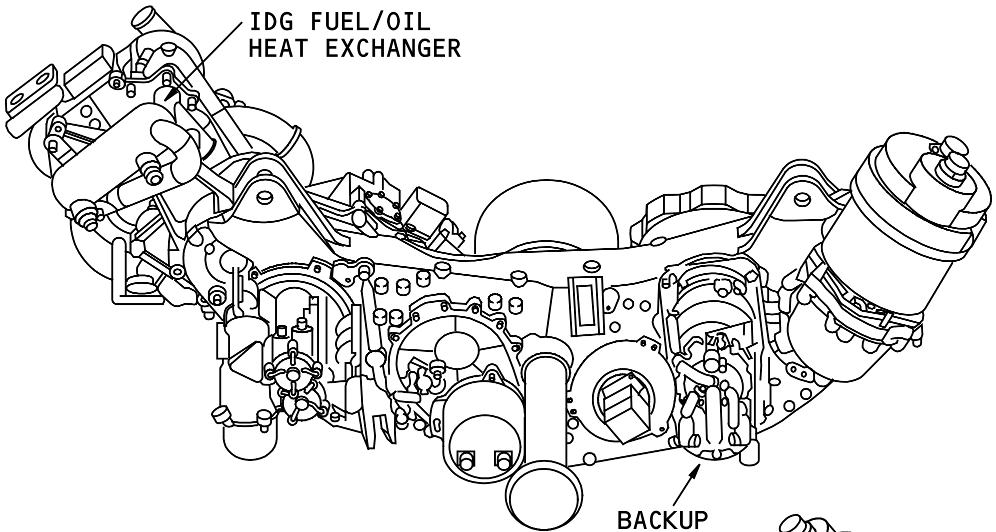
GENERATOR DRIVE - COMPONENT LOCATIONS - GEARBOX

General

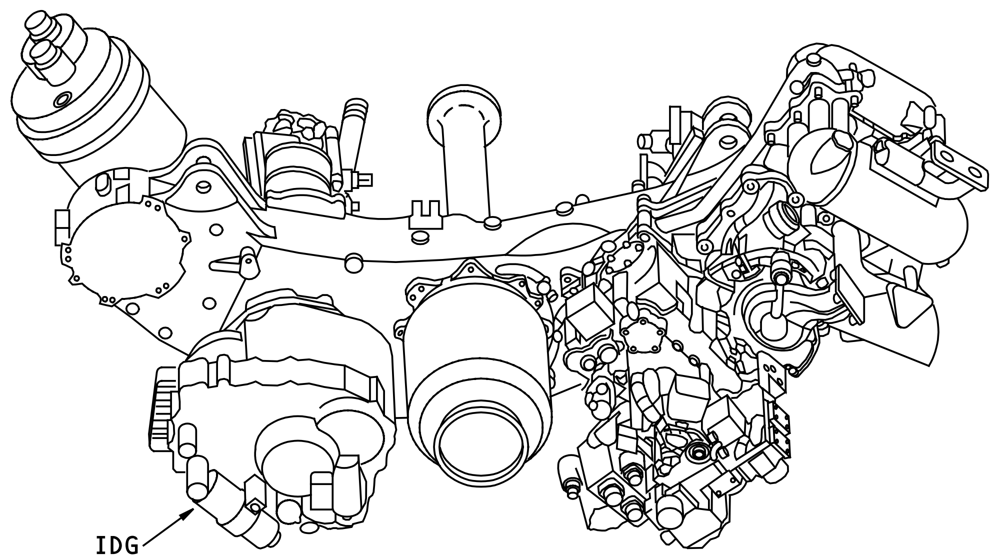
These are the generator drive components that attach to the accessory gearbox of each engine:

- IDG fuel/oil heat exchanger
- Backup generator
- IDG.

The IDG fuel/oil heat exchanger attaches to the front of the gearbox at the 4:30 position. The backup generator attaches to the front of the gearbox at the 6:30 position. The IDG attaches to the aft side of the gearbox at the 6:30 position.



ACCESSORY GEARBOX
(LOOKING AFT)



ACCESSORY GEARBOX
(LOOKING FORWARD)

GENERATOR DRIVE - COMPONENT LOCATIONS - GEARBOX

GENERATOR DRIVE - COMPONENT LOCATIONS - ENGINE

General

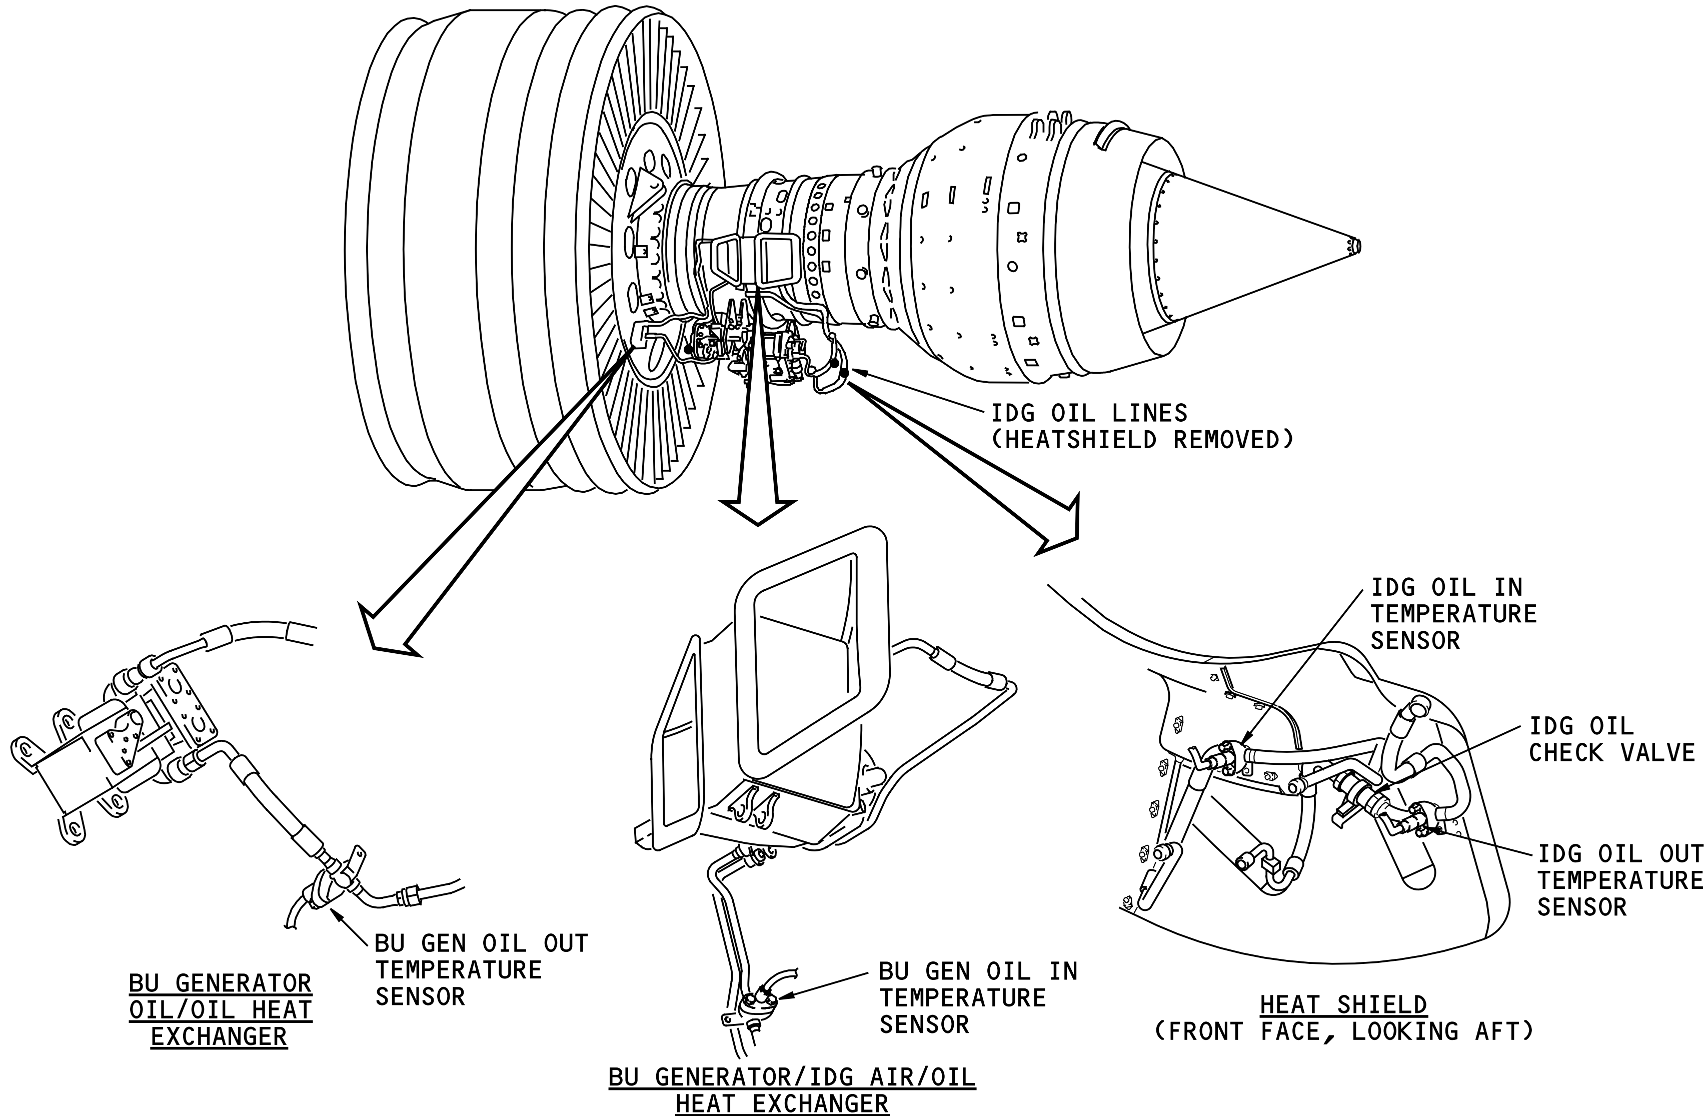
Each engine has these generator system components:

- Backup generator oil/oil heat exchanger
- Backup generator oil in and oil out temperature sensors
- Backup generator/IDG air/oil heat exchanger
- IDG oil in and oil out temperature sensors.

Component Locations

The backup generator oil/oil heat exchanger attaches to the fan hub frame at the 7:30 position. The backup generator oil out temperature sensor is in an oil line to the right of the oil/oil heat exchanger in the fan hub frame area. It is just in front of the BU generator (not shown). The oil in sensor is in an oil line forward and below the air/oil heat exchanger. It is just above and behind the left variable stator vane actuator (not shown).

The backup generator/IDG air/oil heat exchanger attaches to the high pressure compressor case at the 9:00 position. The IDG oil temperature sensors and the IDG oil check valve are aft of the IDG on the front face of the heat shield.



GENERATOR DRIVE - COMPONENT LOCATIONS - ENGINE

THIS PAGE INTENTIONALLY LEFT BLANK

GENERATOR DRIVE - INTEGRATED DRIVE GENERATOR

General

The IDG supplies electrical power to the airplane. It is a combination of a constant speed drive (CSD) and an ac generator. The CSD turns the generator at a constant speed to make constant frequency electrical power. Oil lubricates the IDG and makes it cool.

Electrical Connections

These are the four electrical connections on the IDG:

- Terminal block
- Electrical connector A
- Electrical connector B
- Electrical connector C.

The terminal block connects the power feeder cables to the IDG. The other connectors transmit control and monitoring inputs and outputs. They also transmit the PMG output.

Mechanical Items

You can get access to these mechanical items on the IDG:

- Input shaft (with aneroid valve)
- Aspirator
- Check valve
- Disconnect solenoid with thermal plug
- Case relief valve
- Oil out port
- Oil filter
- Oil in port
- Case drain
- Charge relief valve.

The aneroid valve, aspirator, and check valve keep a positive pressure inside the IDG when it operates. The aspirator pulls air in through the check valve. The air goes out through the aneroid valve. This prevents the collection of moisture in the IDG.

The case relief valve prevents the rupture of the IDG case if the IDG fuel/oil heat exchanger leaks.

The charge relief valve regulates the oil pressure of the IDG.

Maintenance Items

You use these items to maintain the IDG:

- Disconnect reset ring
- Oil level sightglass
- Overfill drain port
- Pressure fill port.

The disconnect reset ring lets you reset the drive disconnect mechanism. A solenoid operates the disconnect mechanism. You pull on the ring while the engine is shutdown to connect the drive shaft halves.

GENERATOR DRIVE - INTEGRATED DRIVE GENERATOR

NOTE: The IDG can automatically disconnect if the IDG oil gets too hot. A thermal plug melts and operates the disconnect mechanism. If the IDG disconnects automatically with the thermal plug, the reset ring cannot connect the drive shaft halves. The IDG must be reset at the repair shop.

You use the sightglass, fill port, and drain port to service the IDG oil.

Indication Items

These items supply data you use to make a check of the operational status of the IDG:

- Differential pressure switch (internal)
- Differential pressure indicator
- Remote oil level sensor
- Charge pressure switch (internal).

The differential pressure switch monitors the oil pressure upstream and downstream of the oil filter. The switch sends a signal that tells if the oil filter is clogged.

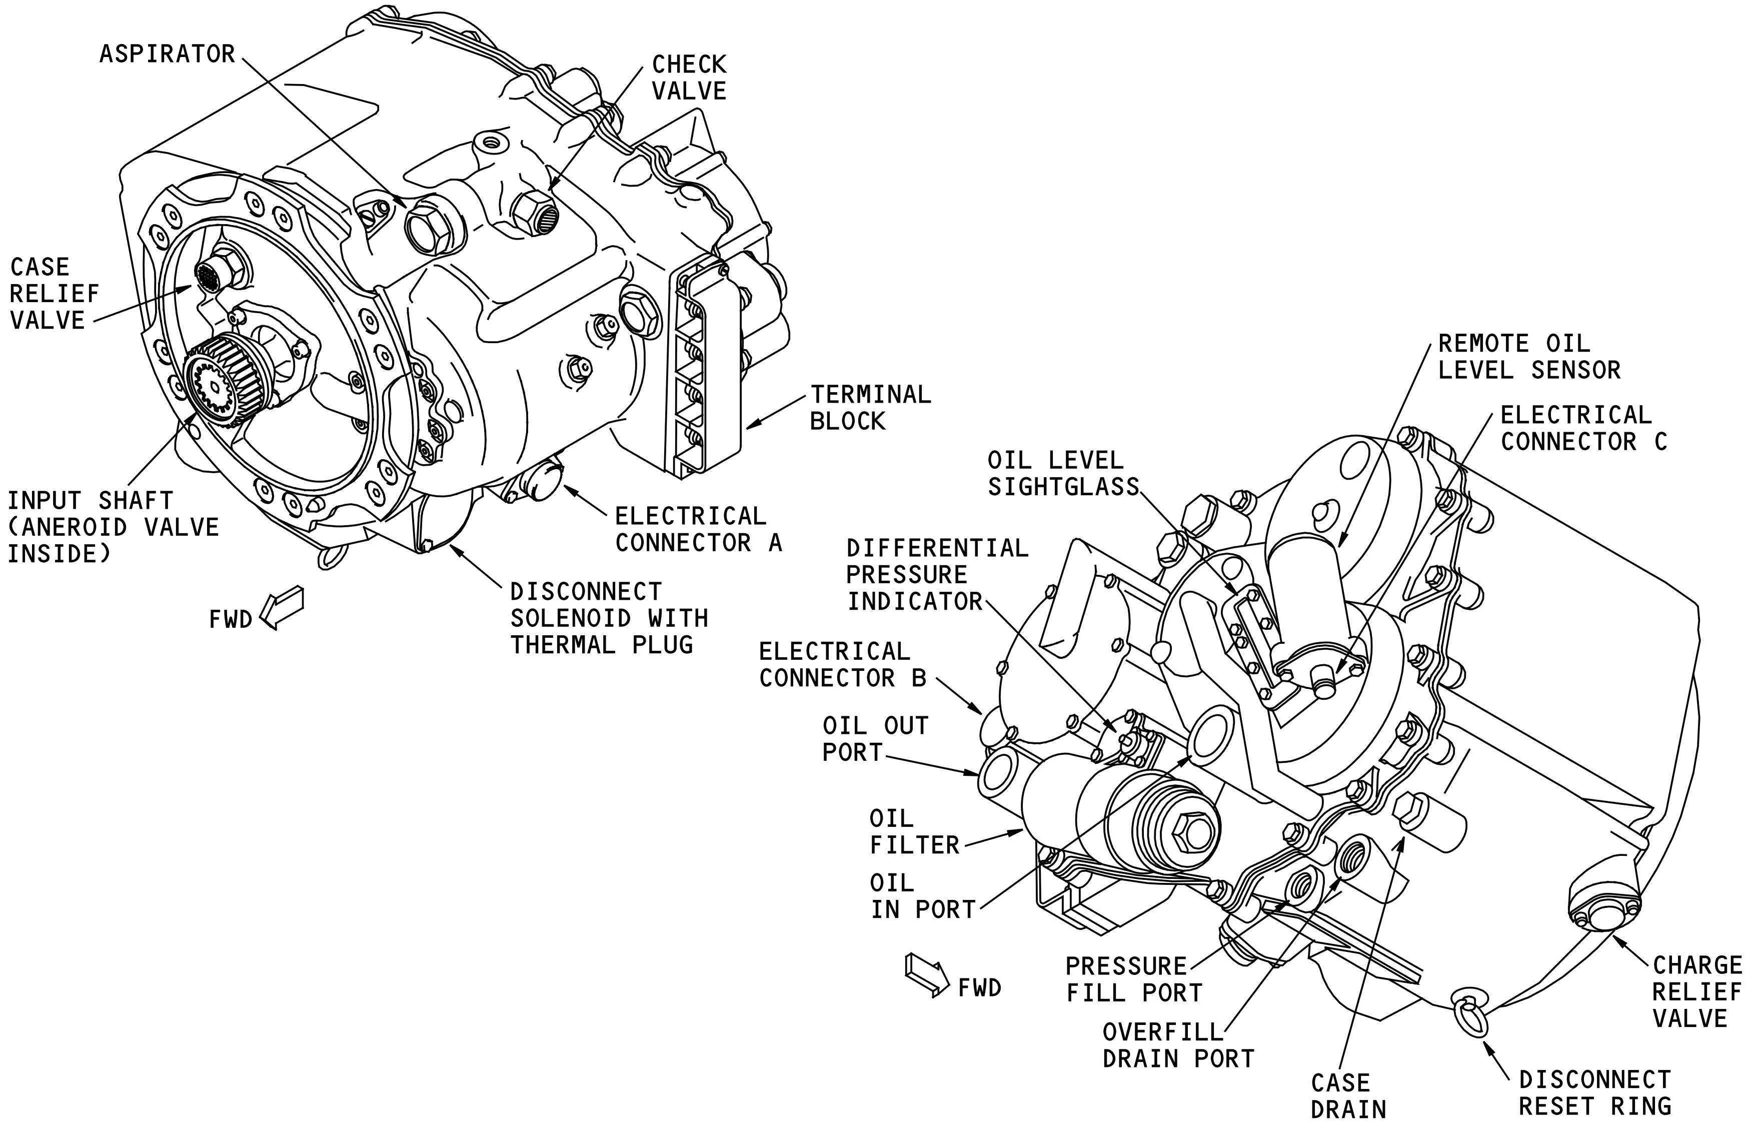
The differential pressure indicator has a red button. The red button moves out when the oil filter is clogged.

The remote oil level sensor sends the IDG oil level status to the GCU. The GCU supplies the primary display system with this data.

The charge pressure switch connects to the GCU. The switch monitors the oil pressure inside the IDG.

Training Information Point

The only LRMs on the IDG are the oil filter and the remote oil level sensor.



GENERATOR DRIVE - INTEGRATED DRIVE GENERATOR

GENERATOR DRIVE - IDG QAD COUPLING

General

The QAD coupling attaches the IDG to the gearbox. It has an adapter plate, a ring, index marks, and a tension bolt. You turn the tension bolt to turn the ring. When the ring releases the IDG, the ring index mark aligns with the adapter plate index mark and the IDG index mark.

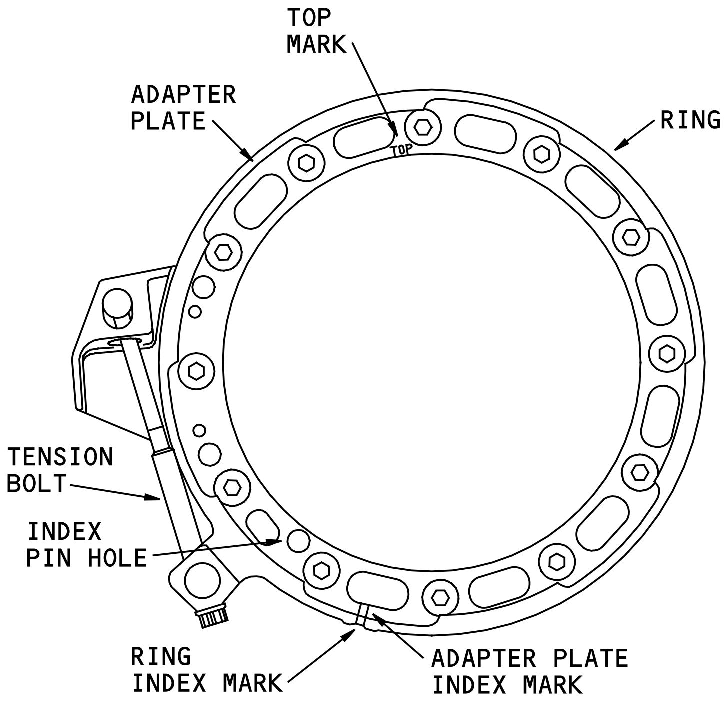
Training Information Point

There is a TOP mark that shows you how to put a new QAD coupling on the gearbox. You put the TOP mark at the 12:00 position.

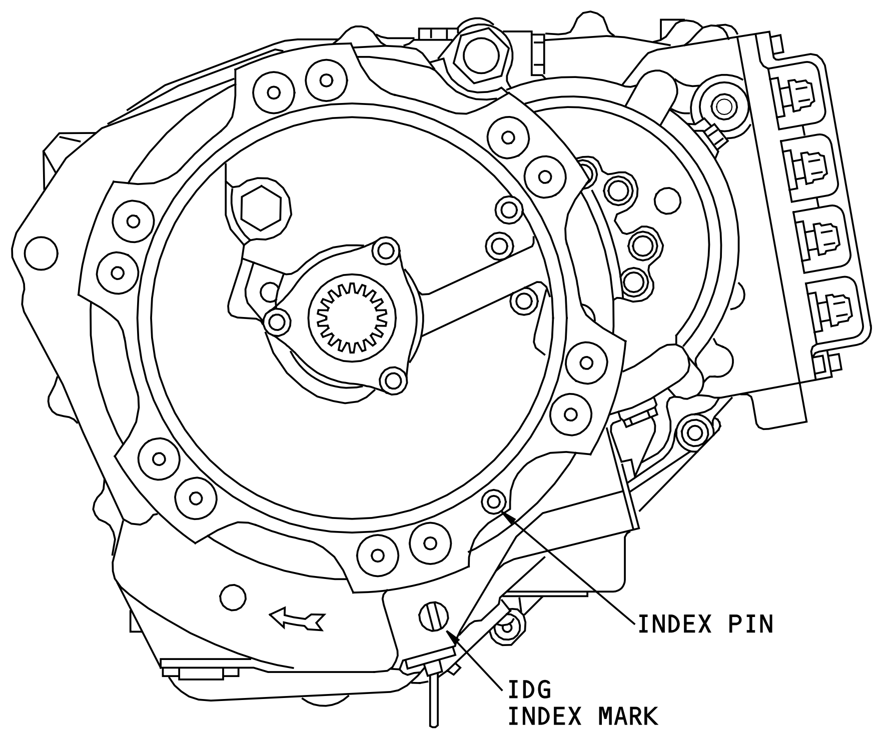
When you install a new QAD coupling, align the ring index mark and the adapter index mark so the IDG can go in. When you install an IDG, turn it so that the IDG index mark aligns with the ring index mark. This should align the IDG index pin with the QAD coupling index pin hole.

The IDG is very heavy. It weighs approximately 140 lbs (63 kgs). You must get the correct torque on the ring to prevent damage to the mating surfaces of the QAD coupling and the IDG.

At regular times, you must make a check of the QAD coupling. You must make sure that the IDG is locked in the QAD ring. You must make sure the tension bolt torque is correct. If the IDG is loose in the QAD coupling, vibration can cause damage to the QAD ring, the IDG mounting flange, and the IDG input seal.



QAD COUPLING
(LOOKING FORWARD)



IDG
(LOOKING AFT)

24-10-00-006 Rev 2

GENERATOR DRIVE - IDG QAD COUPLING

THIS PAGE INTENTIONALLY LEFT BLANK

GENERATOR DRIVE - IDG - FUNCTIONAL DESCRIPTION

General

The GCU and the drive disconnect switch control the IDG. The GCU sends information about the IDG to the systems ARINC 629 buses. The EEC sends oil temperature and oil filter data to the systems ARINC 629 buses. This permits the AIMS to show EICAS messages and maintenance data.

Generator Drive Light

The GCU controls the DRIVE light in the disconnect switch. The GCU sends a signal that causes the DRIVE light to come on when the IDG charge pressure is low. If the engine is running, the low oil pressure also causes the ELEC GEN DRIVE advisory message to show. When you see the ELEC GEN DRIVE message, you should immediately disconnect the IDG. This protects the IDG from damage. The drive disconnect switch on the P5 panel controls the IDG drive disconnect solenoid.

Drive Disconnect

The EEC reset/IDG disconnect relay arms the disconnect switch while the related engine fuel cutoff switch is in the RUN position. If the disconnect switch is in, the IDG disconnect solenoid energizes. This causes the spring-loaded disconnect mechanism to disconnect the IDG from the drive shaft.

The IDG can automatically disconnect if the IDG oil gets too hot. A thermal plug in the disconnect mechanism melts. This causes the spring-loaded disconnect mechanism to disconnect the IDG from the drive shaft.

Oil Level Sensing

The remote oil level sensor sends an oil level signal to the GCU. The sensor sends data only when the IDG charge pressure is low (IDG is shutdown). The electrical maintenance page shows the oil level data of the IDG. The oil level data shows two dashes when the IDG operates.

If oil does not cover the underfill sensor for the related IDG, the IDG oil level is too low. The maintenance page will show SERVICE when the IDG is shutdown.

If oil covers the underfill sensor, but not the overfill sensor, the IDG has sufficient oil. The maintenance page will show NORMAL when the IDG is shutdown.

If oil covers the overfill sensor and the related underfill sensor, the IDG oil level is too high. The maintenance page will show SERVICE when the IDG is shutdown.

Frequency Trim Control

The GCU controls the trim coil to increase or reduce the speed of the IDG drive. The speed change changes the frequency of the power output. The GCU uses the trim coil to match the IDG power frequency to the

GENERATOR DRIVE - IDG - FUNCTIONAL DESCRIPTION

frequency of an other power source during no-break power transfers.

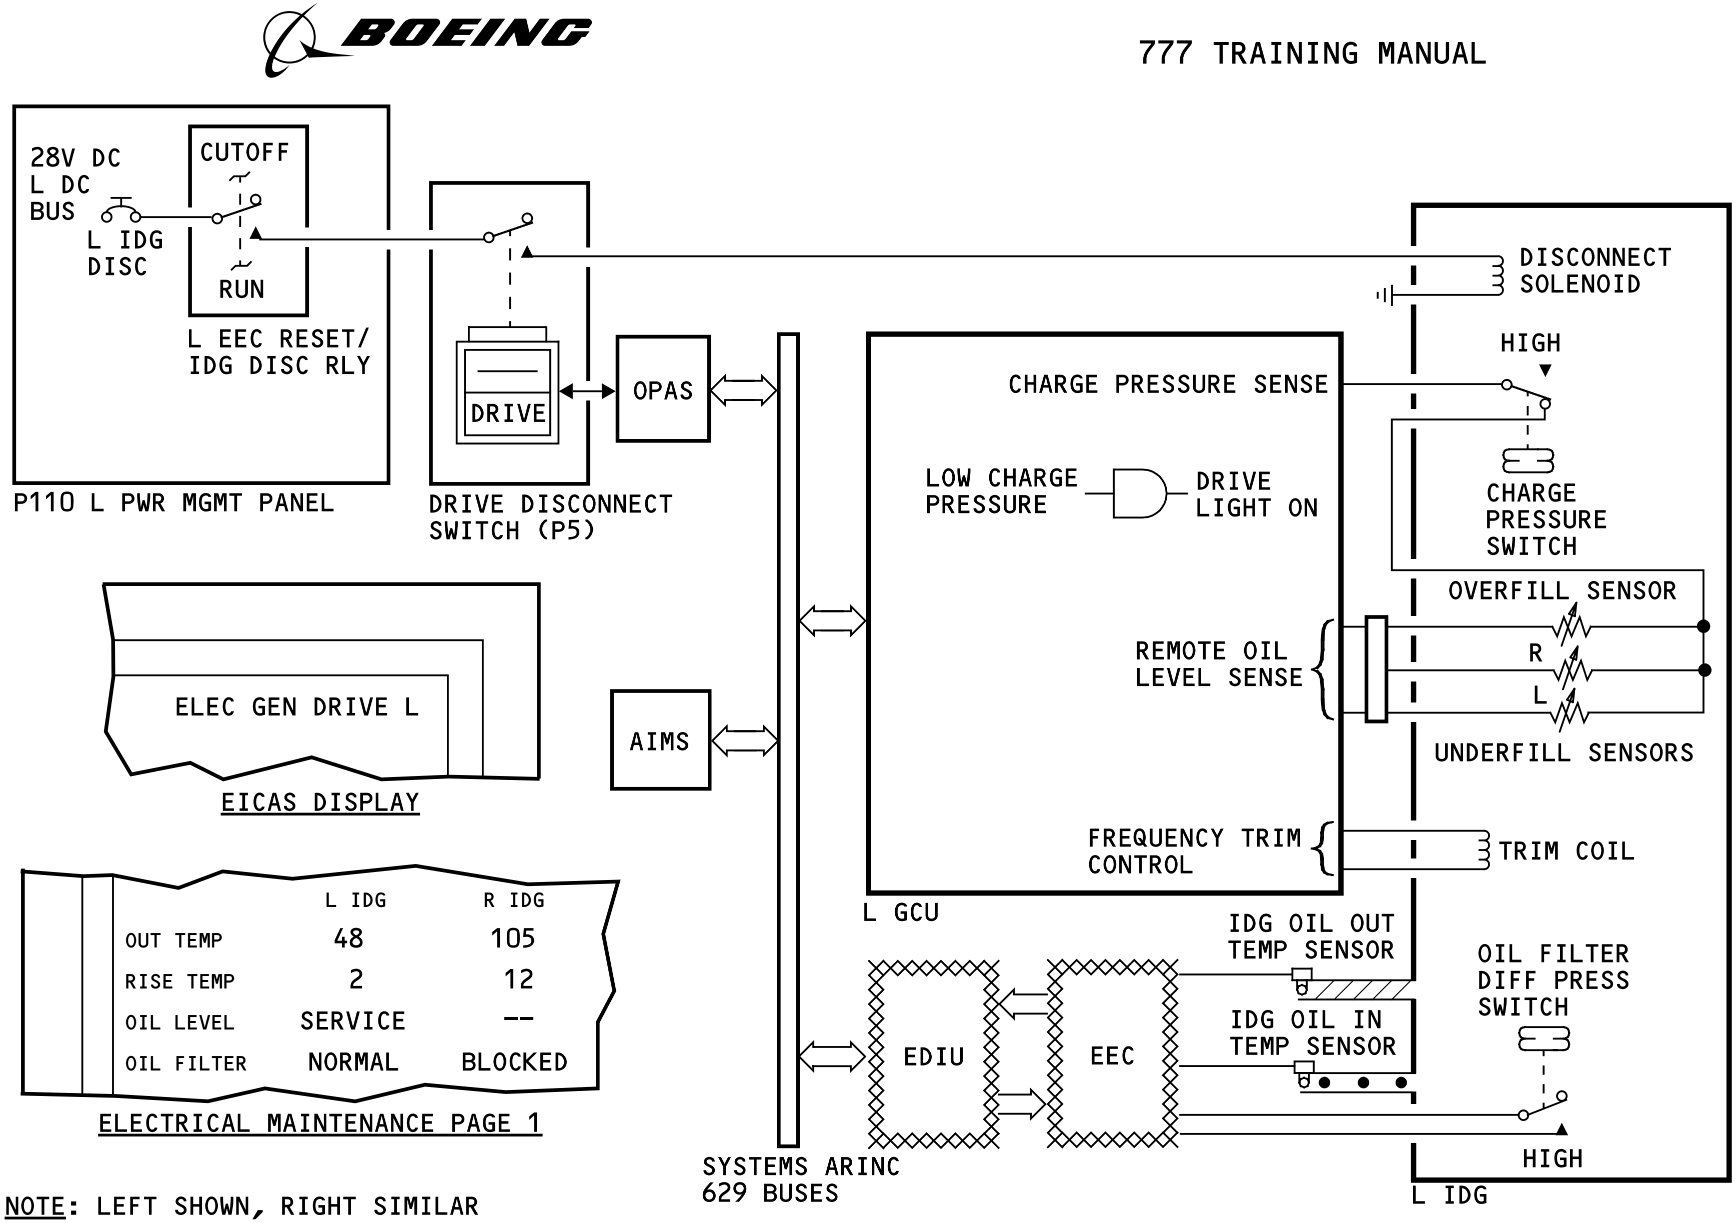
Oil Filter Status

The differential pressure switch monitors the difference between the pressures upstream and downstream of the oil filter. The switch sends a filter status signal through the EEC and the systems ARINC 629 buses to the GCU. The GCU causes the electrical maintenance page to show the status of the oil filter. The usual status on the maintenance page is NORMAL.

When the oil filter is clogged, the differential pressure switch closes. The GCU causes the electrical maintenance page to change the filter status to BLOCKED. The GCU inhibits the filter status signal when the oil out temperature is colder than 145F (62C).

Temperature Data

Oil temperature sensors in the inlet and outlet tubing send data to the EEC. The EEC sends the data to AIMS. The electrical maintenance page shows OUT TEMP, the temperature of the oil at the IDG outlet. And, it shows RISE TEMP, the difference between the inlet and the outlet temperatures. The data are in degrees C.



NOTE: LEFT SHOWN, RIGHT SIMILAR

GENERATOR DRIVE - IDG - FUNCTIONAL DESCRIPTION

GENERATOR DRIVE - IDG - OIL SERVICING

Oil Level Indication

The signal from the remote oil level sensor causes the IDG oil level data to show on the electrical maintenance page. The maintenance page shows the oil level data as NORMAL or SERVICE.

The IDG sightglass shows the oil level. You must open the left thrust reverser cowl to see the sightglass.

If the oil level is in the silver area of the sightglass, the IDG oil level is satisfactory. The black zone at the bottom of the sightglass is the low oil zone. The low oil zone is different for the left and right engine. You must add oil to the IDG if the oil level is in the low oil zone.

Add Oil to the IDG

You can add oil to the IDG through the IDG pressure fill valve. It is above an access door in the thrust reverser at the 6:00 position.

When you add oil, you must attach a drain hose to the IDG overflow drain valve. Add oil until at least one quart (liter) of oil comes out of the drain valve hose then stop. When the flow out of the overflow hose is within limits, disconnect the pressure fill hose and the drain valve hose.

CAUTION: MAKE SURE THE DRAIN VALVE HOSE IS CONNECTED TO LET THE OIL DRAIN TO THE CORRECT LEVEL IN THE IDG. TOO MUCH HEAT CAN OCCUR IF THE IDG IS FILLED WITH TOO MUCH OIL.

Training Information Point

The sightglass indication of the IDG oil level is not accurate until the engine is cold (a minimum of 30 minutes after engine shutdown).

When the IDG operates, the electrical maintenance page does not get new oil level data. The oil level data shows as two dashes.

The oil level data is blank for any of these conditions:

- Engine shutdown (blank for approximately 10 minutes)
- Initial GCU power-up (blank for approximately 10 minutes)
- Data is invalid due to a fault.

GENERATOR DRIVE - IDG - OIL SERVICING

THIS PAGE INTENTIONALLY LEFT BLANK

GENERATOR DRIVE - BACKUP GENERATOR

General

The backup generator is an alternative power source. It can supply 115v ac, 400 Hz, electrical power to the transfer buses.

The backup generator also has permanent magnet generators (PMGs). One PMG supplies the field power for the backup generator. Two PMGs are power sources for the flight control power supply assemblies (PSAs).

Electrical Connections

These are the four electrical connections on the backup generator:

- Terminal block
- Electrical connector J1
- Electrical connector J2
- Electrical connector J3.

The terminal block connects the power feeder cables to the backup generator. Electrical connector J1 transmits the control inputs and the data outputs of the backup generator. Electrical connectors J2 and J3 connect the backup generator PMG power to the PSAs.

Mechanical Items

You can get access to these mechanical items on the backup generator:

- Oil in port
- Oil out port
- Overtemperature dump valve port
- Case drain plug
- Oil filter.

The overtemperature dump valve opens when the generator gets too hot. Generator oil drains through the open valve to the accessory drain.

Maintenance Items

You use these items to maintain the backup generator:

- Oil level sightglass
- Overfill drain port
- Pressure fill port.

Indication Items

These items supply data you use to make a check of the operational status of the backup generator:

- Differential pressure indicator
- Differential pressure switch (internal)
- Charge pressure switch (internal)
- Remote oil level sensor (internal).

The differential pressure indicator has a red button. The red button moves out when the filter is clogged.

The differential pressure switch monitors the oil pressure upstream and downstream of the oil filter. The

GENERATOR DRIVE - BACKUP GENERATOR

switch sends a signal that tells if the oil filter is clogged.

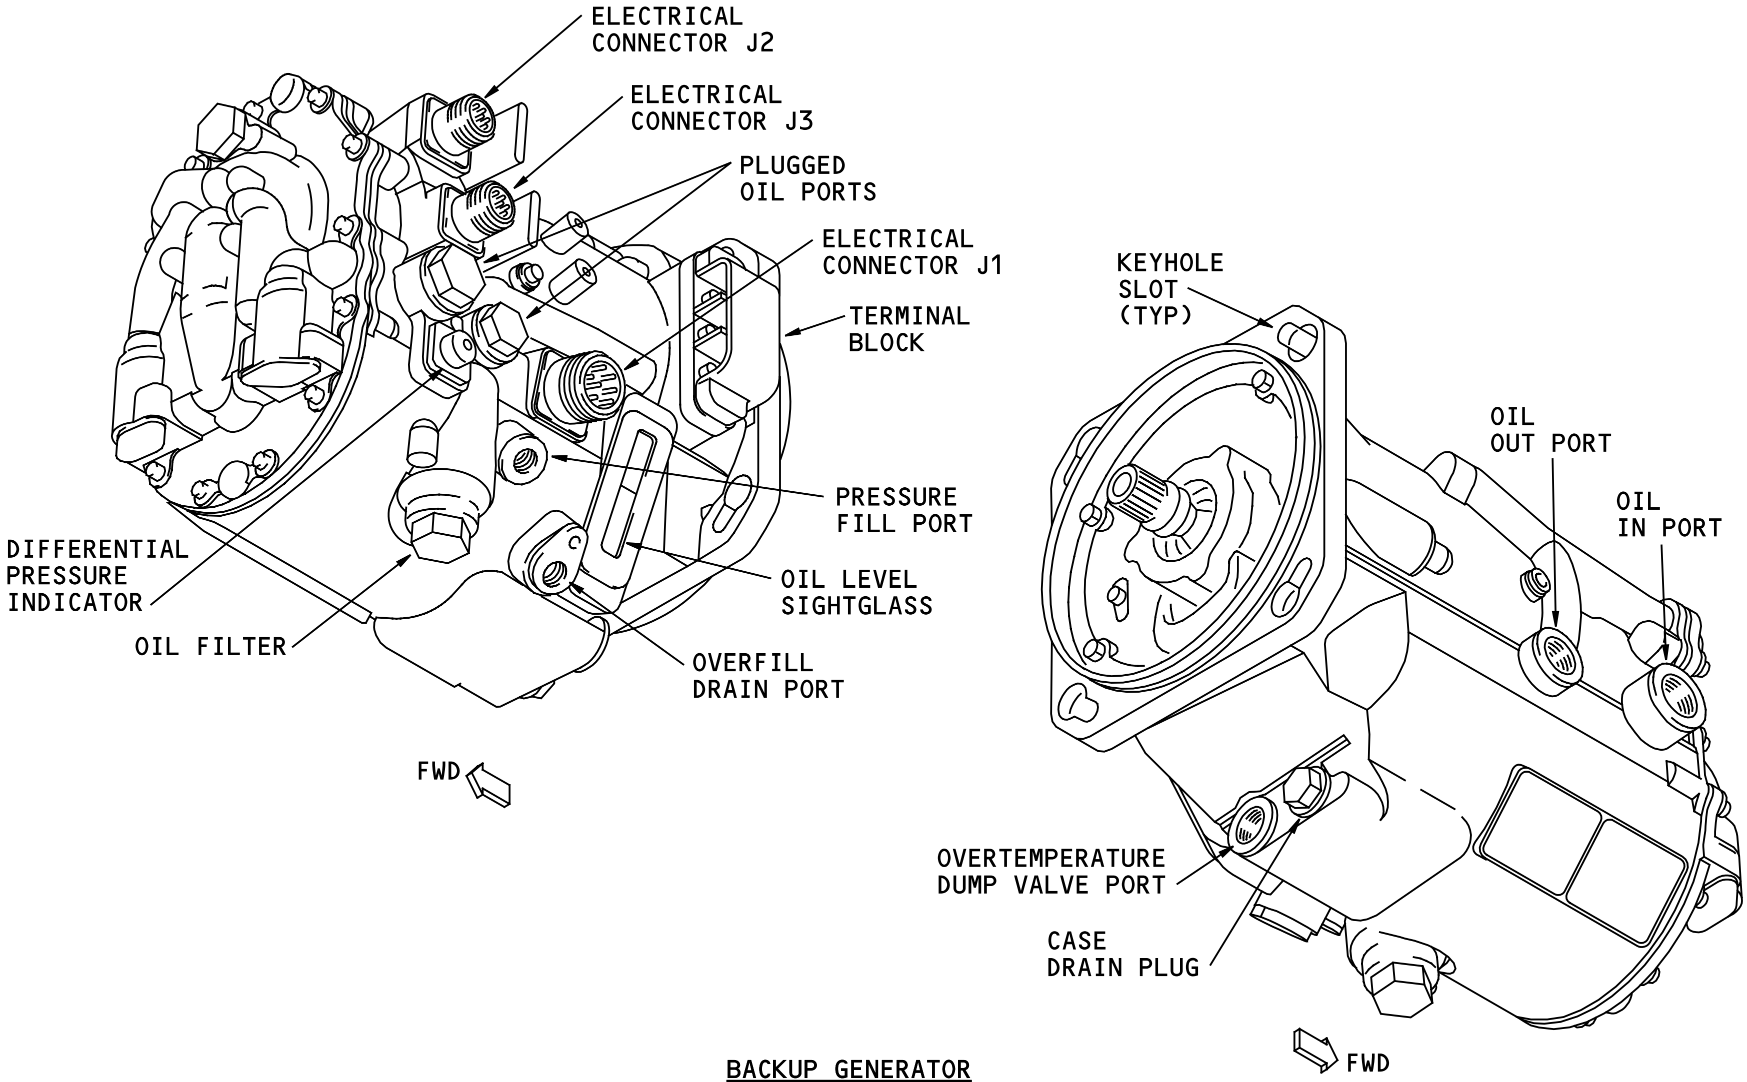
The charge pressure switch connects to the backup generator converter. The switch monitors the oil pressure inside the backup generator.

Two probes in the remote oil level sensor send the backup generator oil level status to the backup generator converter. The electrical maintenance page shows the oil level status from the remote oil level sensor.

Training Information Point

The generator has keyhole mounting holes in its mounting flange. This lets you leave the nuts and washers on the mounting bolts while you remove or install a generator.

The only LRM on the backup generator is the oil filter.



BACKUP GENERATOR

24-10-00-010 Rev 6

GENERATOR DRIVE - BACKUP GENERATOR

THIS PAGE INTENTIONALLY LEFT BLANK

GENERATOR DRIVE - BACKUP GENERATOR - FUNCTIONAL DESCRIPTION

General

The backup generator converter sends data from backup generator components to the systems ARINC 629 buses. The EEC puts oil temperature and oil filter data on the systems ARINC 629 buses. This permits AIMS to show EICAS messages and maintenance data.

Charge Pressure Switch

If the backup generator has low oil pressure, the charge pressure switch closes. If the charge pressure switch closes while the related engine is running and the backup generator oil temperature is above 20C, the backup converter trips the generator field. This causes the BACKUP GEN OFF light to come on. Low oil pressure also causes the ELEC BACKUP GEN message.

Oil Level Sensing

The remote oil level sensors send an oil level signal to the backup generator converter. The sensors send data only when the oil pressure is low (generator is shutdown). The electrical maintenance page shows the oil level data of the backup generator. The oil level data shows two dashes when the backup generator operates.

If oil does not cover the underfill sensor, the backup generator oil level is too low. The maintenance page will show SERVICE when the backup generator is shutdown.

If oil covers the underfill sensor, but not the overfill sensor, the backup generator has sufficient oil. The maintenance page will show NORMAL when the backup generator is shutdown.

If oil covers the two oil level sensors, the backup generator oil level is too high. The maintenance page will show SERVICE when the backup generator is shutdown.

The oil level data is blank for any of these conditions:

- Engine shutdown (blank for approximately 10 minutes)
- Initial converter power-up (blank for approximately 10 minutes)
- Data is invalid due to a fault.

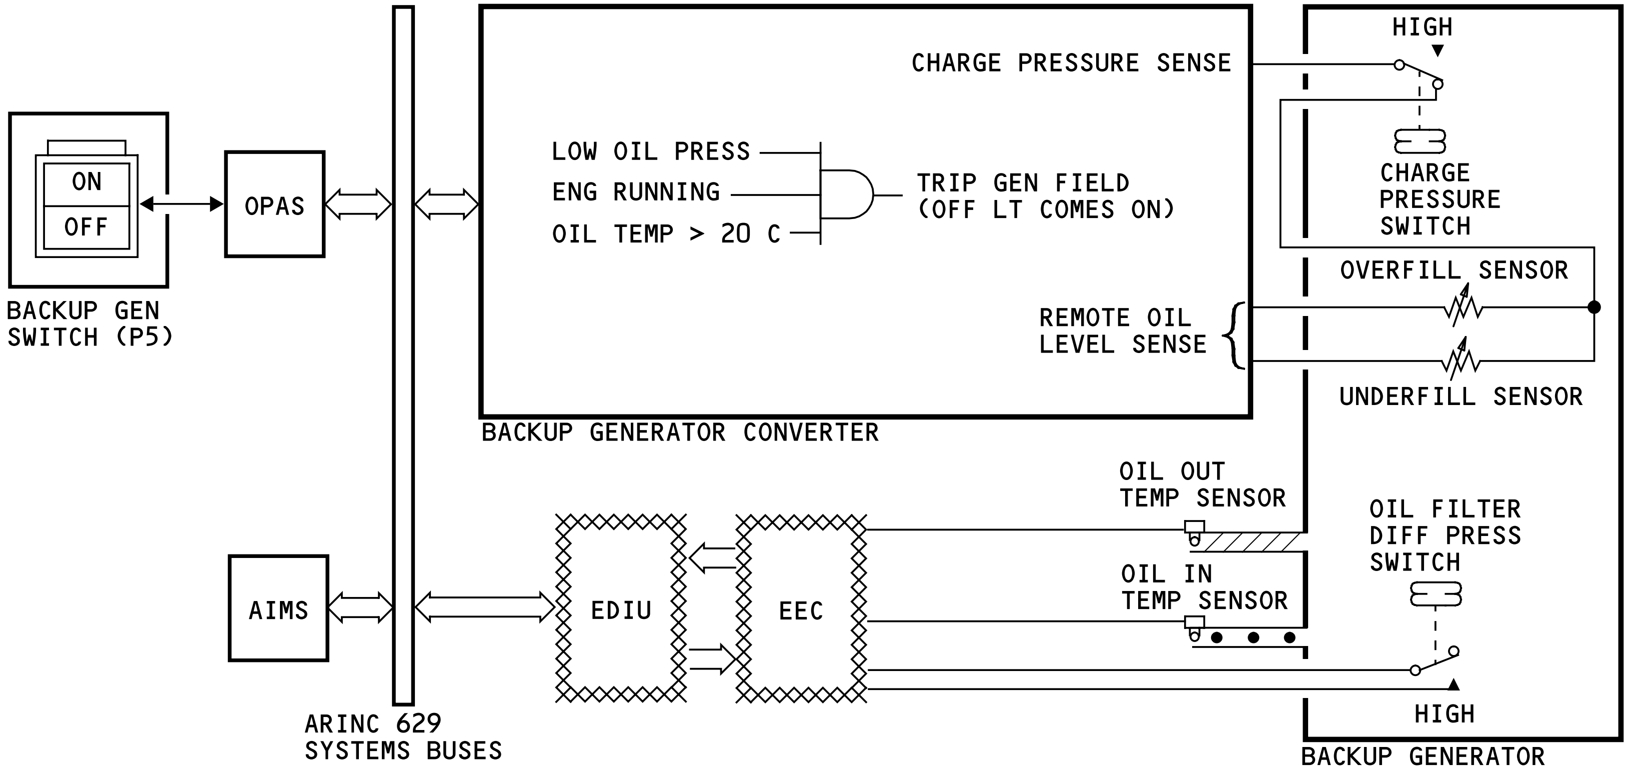
Oil Filter Status

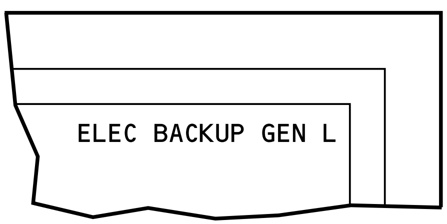
The differential pressure switch monitors the difference between the pressures upstream and downstream of the oil filter. The switch sends a filter status signal through the EEC and the systems ARINC 629 buses to the backup generator converter. The backup generator converter causes the electrical maintenance page to show the status of the oil filter. The usual status on the maintenance page is NORMAL.

When the oil filter is clogged, the differential pressure switch closes. The backup generator converter causes the electrical maintenance page to change the filter status to BLOCKED. The backup generator converter inhibits the filter status signal when the oil out temperature is less than 145F (62C).

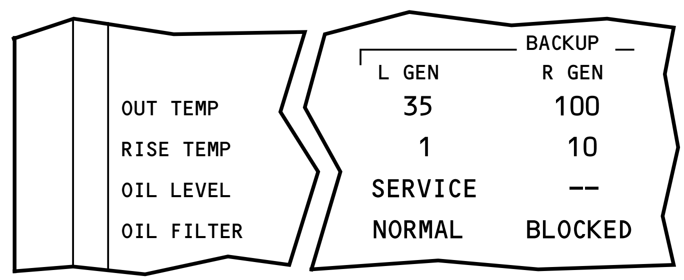
Temperature Data

Oil temperature sensors in the inlet and outlet tubing send data to the EEC. The EEC sends the data to AIMS. The electrical maintenance page shows OUT TEMP, the temperature of the oil at the backup generator outlet. It also shows RISE TEMP, the difference between the inlet and the outlet temperatures.





EICAS DISPLAY



ELECTRICAL MAINTENANCE PAGE 1

24-10-00-012 Rev 7 03/21/96

GENERATOR DRIVE - BACKUP GENERATOR - FUNCTIONAL DESCRIPTION

GENERATOR DRIVE - BACKUP GENERATOR - OIL SERVICING

Oil Level Indication

The signal from the remote oil level sensor causes the electrical maintenance page to show the backup generator oil level data. The maintenance page shows the oil level data as NORMAL or SERVICE.

The sightglass on the backup generator shows the oil level also. You must open the left thrust reverser cowl to see the sightglass.

The sightglass has two sets of oil level zones. You use one set when the generator is on the left engine. You use the other set when the generator is on the right engine.

The related center area of the sightglass is the normal zone. If the oil level is in the normal zone, the backup generator oil quantity is satisfactory. The related black zone at the top of the sightglass is the overfull zone. You must drain some oil from the generator if the level is in the overfull zone. The black zone at the bottom of the sightglass is the low oil zone. You must add oil to the generator if the oil level is in the low oil zone.

Add Oil to the Generator

You add oil to the generator through the backup generator pressure fill valve. It is above an access door in the thrust reverser at the 6:00 position.

When you add oil, you must attach a drain hose to the backup generator overflow drain valve. Add oil until at least one quart (liter) of oil comes out of the drain valve hose, then stop. When the flow out of the overflow hose is within limits, disconnect the pressure fill hose and the drain valve hose.

CAUTION: MAKE SURE THE DRAIN VALVE HOSE IS CONNECTED TO LET THE OIL DRAIN TO THE CORRECT LEVEL IN THE BACKUP GENERATOR. TOO MUCH HEAT CAN OCCUR IF THE BACKUP GENERATOR IS FILLED WITH TOO MUCH OIL.

Training Information Point

When the backup generator operates, the maintenance page does not get new oil level data. The oil level data shows as two dashes.

The oil level data shows blank for any of these conditions:

- Engine shutdown (blank for approximately 10 minutes)
- Initial converter power-up (blank for approximately 10 minutes)
- Data is invalid due to a fault.

24-10-00-013 Rev 11 04/10/1997

GENERATOR DRIVE - APU GENERATOR

Purpose

The APU generator is a secondary source of electrical power for airplane systems. It can supply electrical power when the airplane is on the ground or during flight. It can supply 120 kva of ac power.

Location

The APU generator is in the APU compartment. It attaches to the accessory pad of the APU gearbox. A seal plate is between the APU generator and the APU gearbox.

Interfaces

The APU GCU controls the APU generator.

The APU gearbox turns the APU generator. The APU oil system lubricates the APU generator and keeps it cool.

The APU generator has a terminal block and two electrical connectors. The oil ports are part of the mounting flange to the accessory pad. The seal plate prevents oil leakage at the mounting flange.

Training Information Point

The APU generator has keyhole slots in the mounting flange. You do not remove the fasteners to remove or replace the generator.

An indexing pin (not shown) on the APU generator helps you align it with the APU gearbox when you install it.

GENERATOR DRIVE - FUNCTIONAL DESCRIPTION

General

The gearbox of each engine turns an IDG and a backup generator. The related GCU controls the IDG. The backup generator converter controls the backup generators on both engines. Oil goes through the generators to make them cool. Heat exchangers take the heat from the oil. The IDG oil subsystem operates independently of the backup generator oil subsystem.

IDG Operation

The GCU causes the flight deck effects for the IDG. If the IDG has low pressure during operation, the GCU turns on the DRIVE light and makes an EICAS message. The drive disconnect switch on the electrical panel controls the disconnect solenoid.

The pumps in the IDG move the IDG oil. The oil filter removes unwanted particles from the oil. The differential pressure indicator and the MFD electrical maintenance page tell you if the filter is clogged. The GCU causes the maintenance page to show the oil level status.

Backup Generator Operation

The backup generator converter causes the flight deck effects for the backup generator. The supply pump in the backup generator moves the backup generator oil. The oil filter removes unwanted particles from the oil. The differential pressure indicator and the MFD electrical maintenance page tell you if the filter is clogged. The backup generator converter causes the maintenance page to show the oil level status.

APU Generator Operation

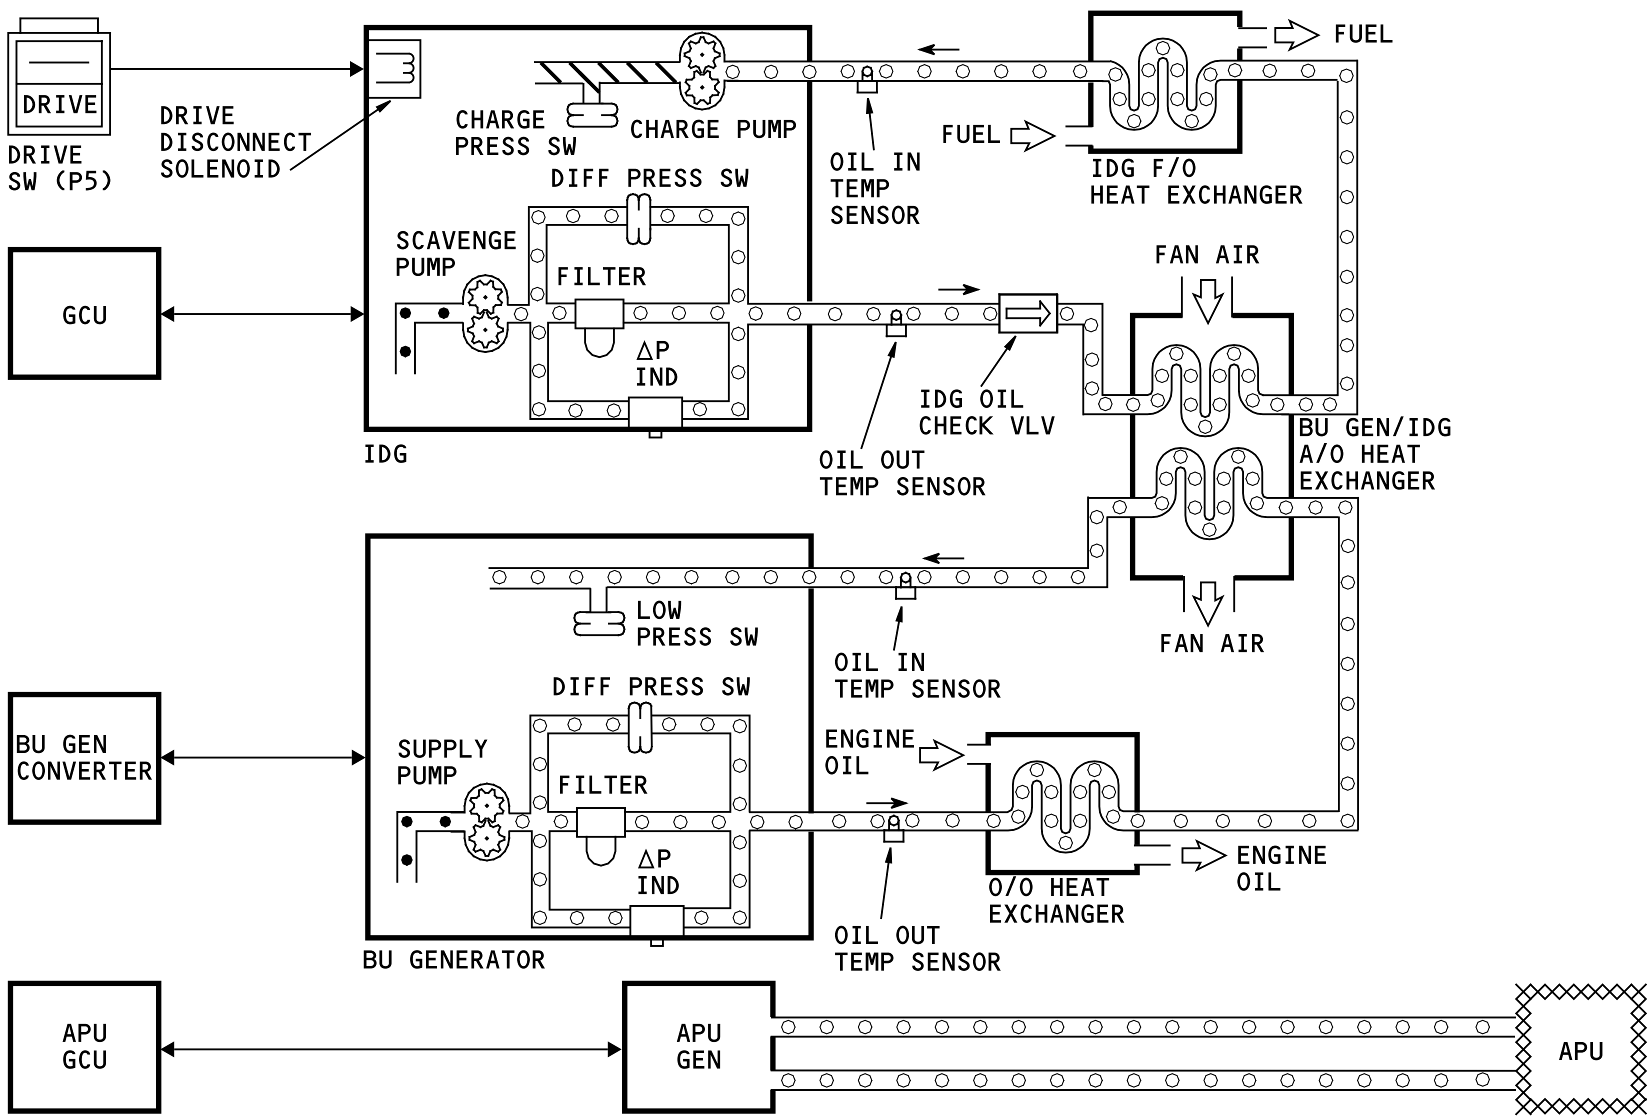
The APU gearbox turns the APU generator. The APU GCU controls and monitors the operation of the APU generator.

Generator Cooling

The IDG oil goes through the backup generator/IDG air/oil heat exchanger first. Then it goes through the IDG fuel/oil heat exchanger.

The backup generator oil goes through the oil/oil heat exchanger first. Then it goes through the backup generator/IDG air/oil heat exchanger.

The APU oil cools the APU generator. See the APU and generator lubrication system section for more information (AMM PART I 49-27).



GENERATOR DRIVE - FUNCTIONAL DESCRIPTION

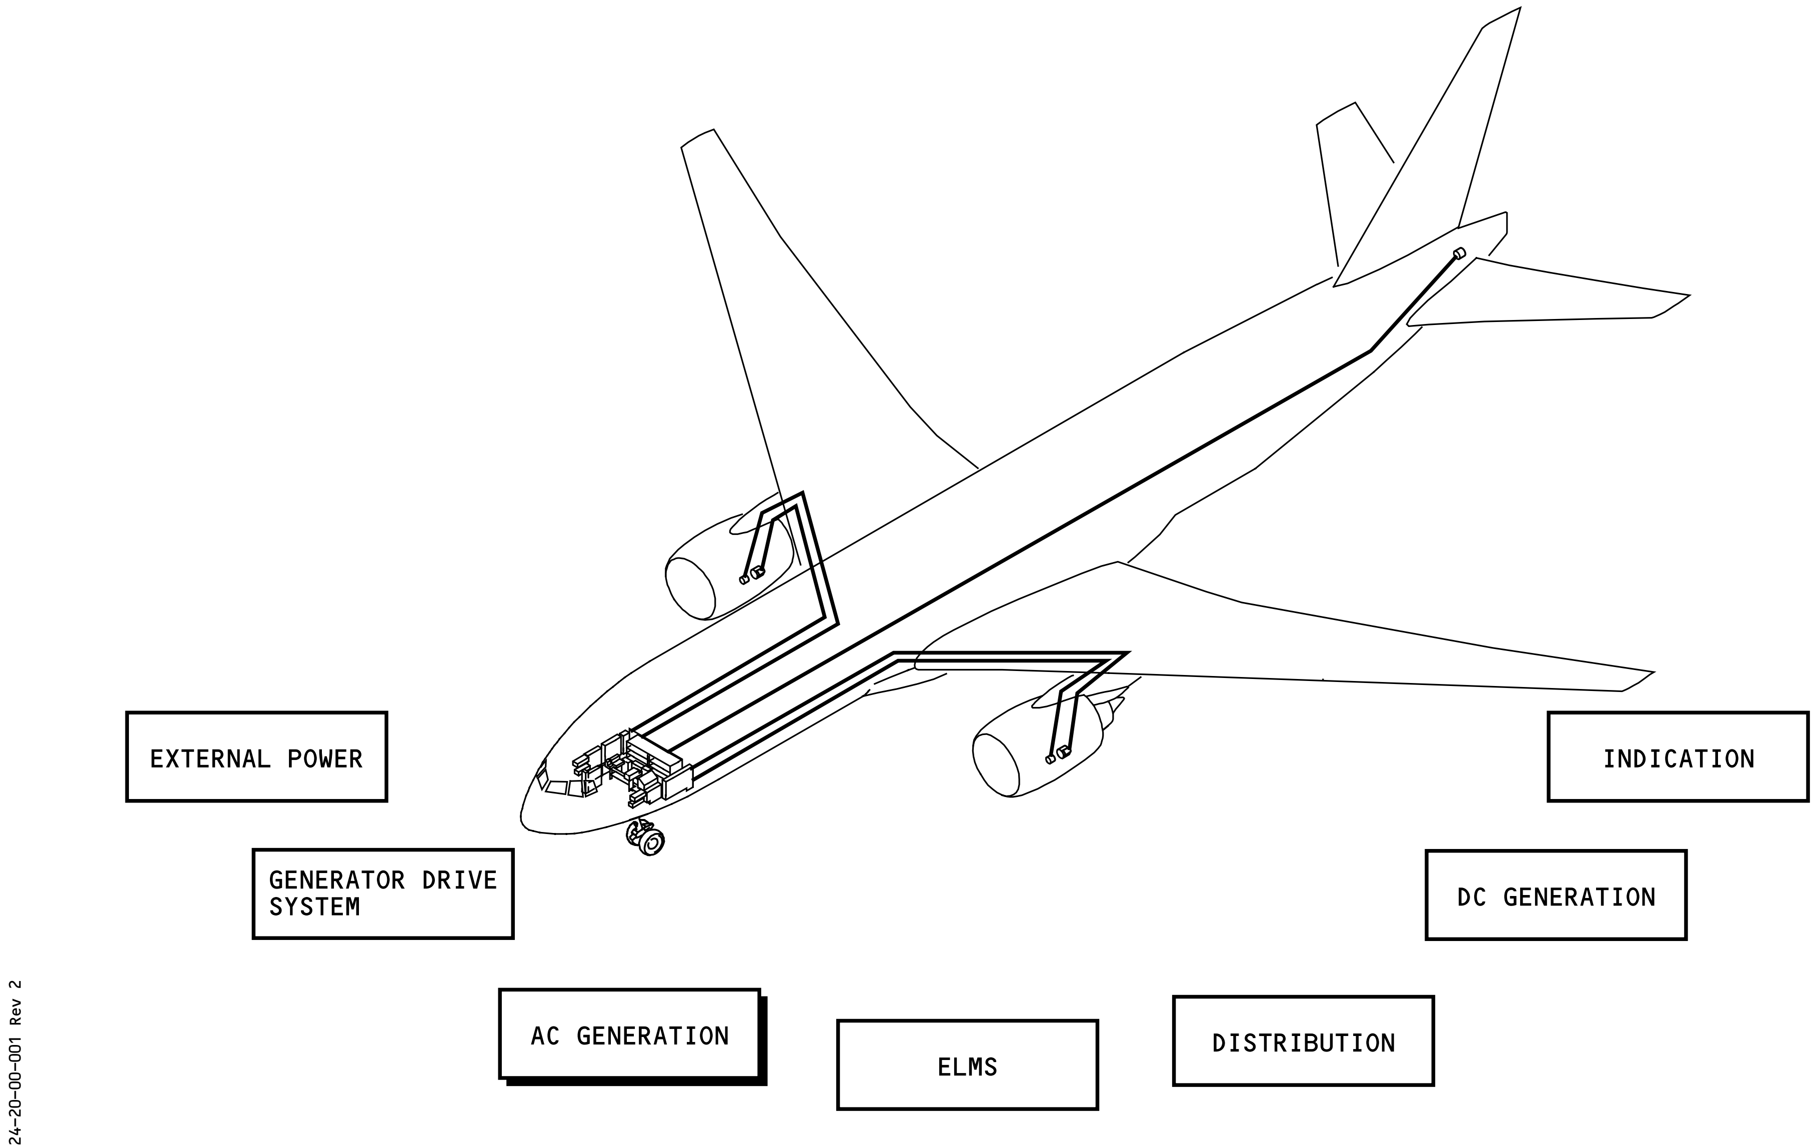
24-10-00-015 Rev 4

AC GENERATION - INTRODUCTION

General

The AC generation system supplies 115v ac power to the airplane. The ac generation system has these sub-systems:

- IDG power
- APU generator power
- Backup generator power.



AC GENERATION - INTRODUCTION

AC GENERATION - APU GENERATOR AND IDG POWER SYSTEMS - GENERAL DESCRIPTION

General

The IDGs and APU generator supply 115v ac, 400 Hz power to the left and right main ac buses. See the generator drive section for more inforation about the APU generator and the IDGs (AMM PART I 24-10).

APU Power

The APU generator supplies power through the APB to the tie bus. Power goes from the tie bus, through the BTBs, to one or both main ac buses.

The APU generator supplies power through the GSSR to the ground service bus. The APU generator also supplies power through the GHR to the ground handling bus.

The APU generator has a GCU that controls, monitors, and protects the APU power system. The APU GCU gets an input from the APU generator (APU GEN) switch. When the switch is in, the GCU automatically controls the APB. When the switch is out, the GCU opens the APB and trips the field of the generator. The OFF light comes on when the switch is out, or when the APB is open because of a fault.

IDG Power

The left IDG supplies power to the left main ac bus. The right IDG supplies power to the right main ac bus. Power goes through the GCBs.

There is a GCU for each IDG. The left and right GCUs control, monitor, and protect the IDG power system. Each GCU gets inputs from a generator control (GEN CTRL) switch and a BUS TIE switch.

When the GEN CTRL switch is in, the GCU automatically controls the GCB. When the switch is out, the GCU opens the GCB and trips the field of the generator.

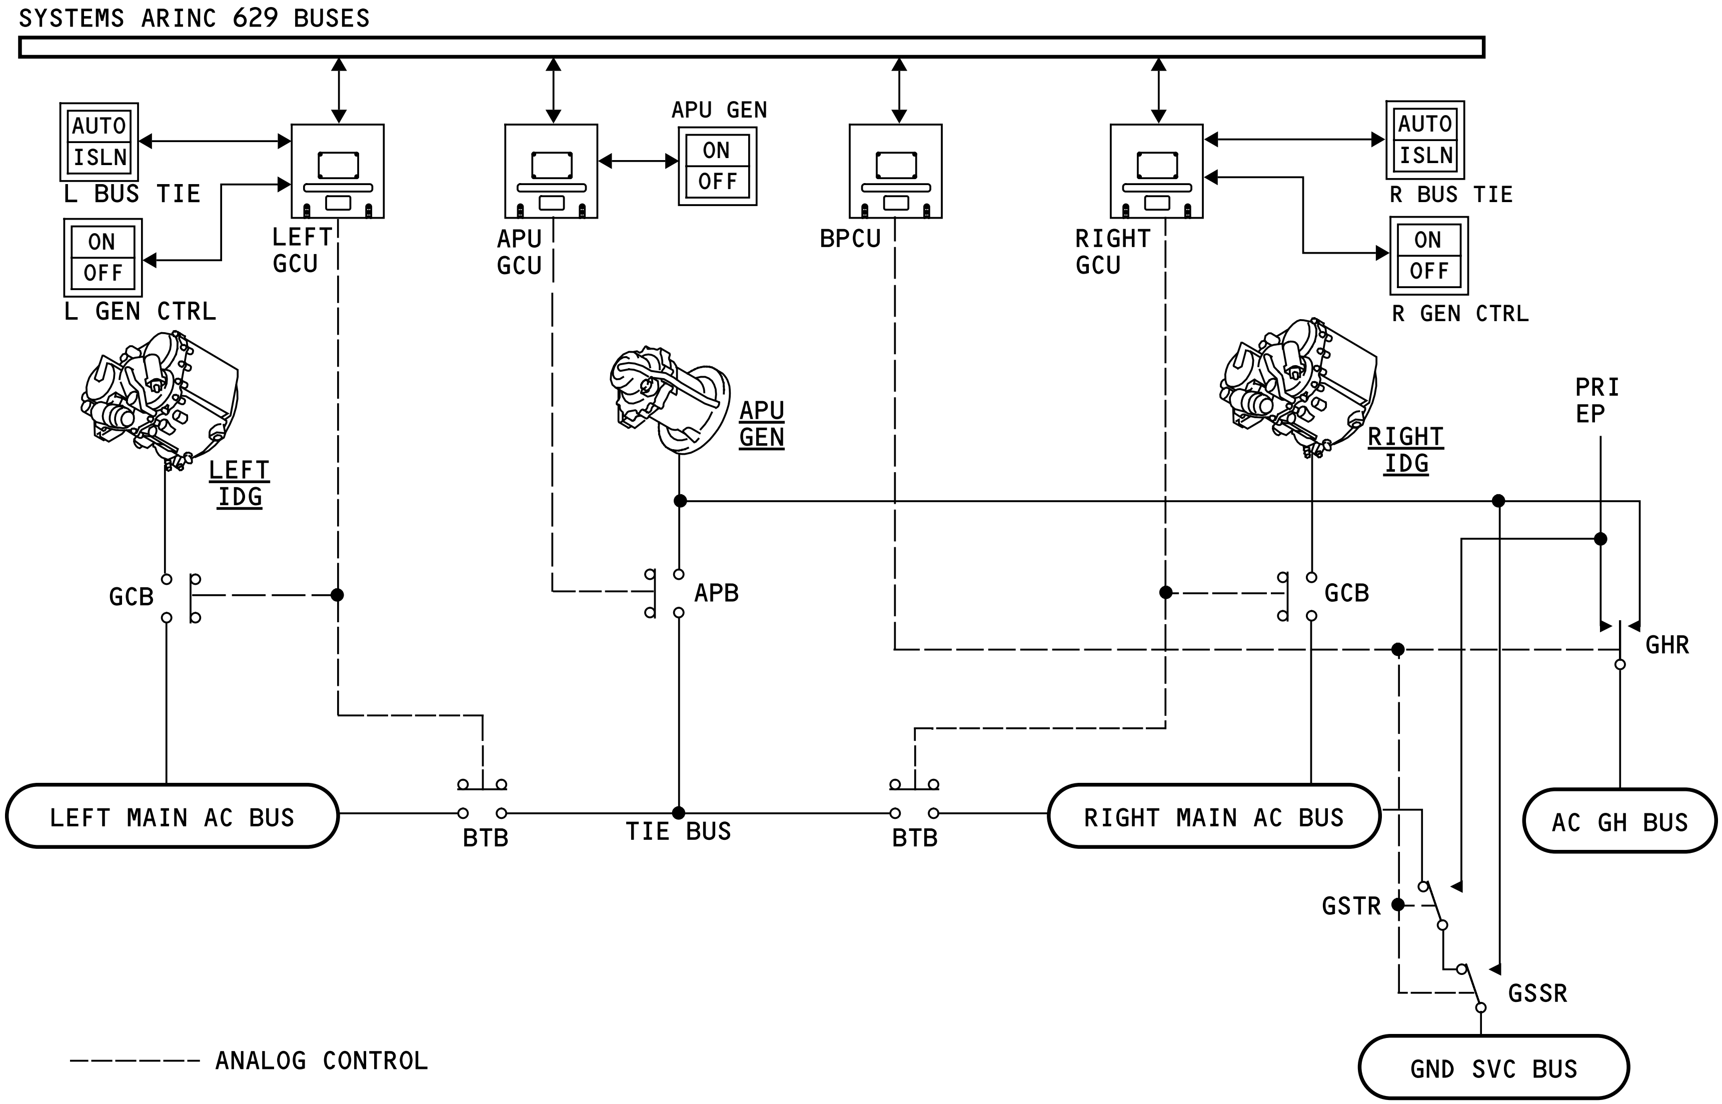
When the BUS TIE switch is in, the GCU automatically controls the BTB. When the switch is out, the GCU opens the BTB.

The GCU turns the switch light (ISLN or OFF) on for each switch when the switch is out, or the breaker is open because of a fault.

No-Break Power Transfers

The BPCU coordinates power transfers between the APU generator and IDGs. The BPCU and GCUs communicate on the systems ARINC 629 buses.

When the ac system changes from one power source to another in the air, it does break power transfers. On the ground, it does no-break power transfers. The system momentarily connects two power sources to one bus so there is no interruption in power. A GCU electronically adjusts an IDG speed to match the power of the two sources to do a no-break power transfer. For transfers between external power and the APU, the APU controller adjusts the APU speed to do the no-break power transfer.



24-20-00-002 Rev 6 03/11/1997

AC GENERATION - APU GENERATOR AND IDG POWER SYSTEMS - GENERAL DESCRIPTION

AC GENERATION - BACKUP GENERATOR POWER SYSTEM - GENERAL DESCRIPTION

General

The backup power system supplies 115v ac, 400 Hz power to the left, right, or both transfer buses. The transfer buses usually get power from the main ac buses. If a main ac bus loses power, the backup power system supplies power to the related transfer bus.

The backup power system also supplies power during autoland operations.

The backup power system has two backup generators and a backup generator converter. The system is independent of other airplane systems. There is no time limit for backup power system operation.

Backup Generator Power

The backup generators supply variable frequency ac power to the backup generator converter. The converter changes the variable frequency power to 115v, 400 Hz ac power and sends it to the transfer buses. Power goes through the converter circuit breakers (CCB).

Only one backup generator supplies power at a time. Normally, the left backup generator supplies power to the left transfer bus and the right backup generator supplies power to the right transfer bus. If the left and right transfer buses need power, the right backup generator supplies the power if it is available.

The backup generator converter also controls, monitors, and protects the backup power system. The converter gets an input from each backup generator (BACKUP GEN) switch. When the switch is in, the converter controls the related CCB and transfer bus breaker (TBB) automatically. When the switch is out, the converter opens the CCB, closes the TBB, and trips the field of the generator. The converter causes the OFF light to come on for each switch for any of these conditions:

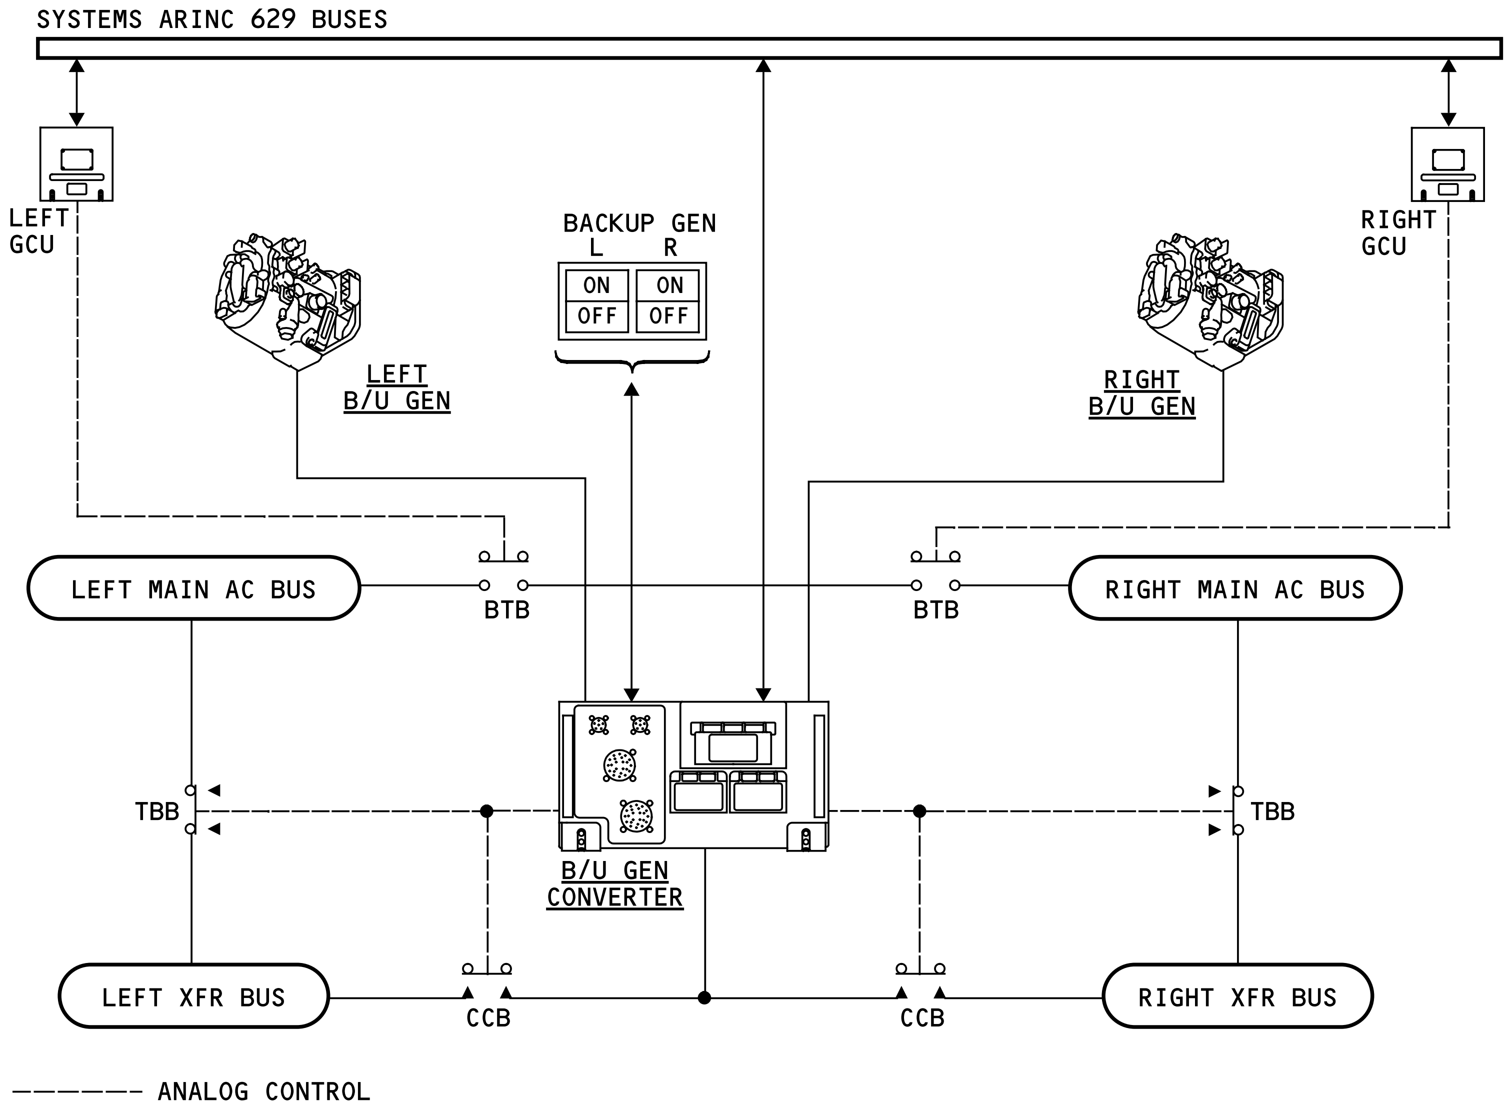
- Switch is out
- Backup generator field relay opens because of a fault
- Engine fire switch is pulled out
- Engine is shutdown.

No-Break Power Transfers

The backup generator converter controls the CCB and TBB to do no-break power transfers to the transfer buses. When a main ac bus loses power, the BTBs close to permit the opposite main ac bus to supply power to the main ac bus that lost power and its related transfer bus. The backup generator power system then momentarily connects the main ac bus power and the backup generator converter power on the transfer bus so there is no interruption in power. The backup generator converter electronically matches the power on the transfer bus to do a no-break power transfer.

Engine Start Test

After an engine starts, the backup generator supplies power to its transfer bus for approximately 15 seconds. This makes sure the system operates before each flight.



24-20-00-003 Rev 5

AC GENERATION - BACKUP GENERATOR POWER SYSTEM - GENERAL DESCRIPTION

AC GENERATION - COMPONENT LOCATIONS - GENERATORS

General

The ac generation system has these five generators:

- IDG (2)
- Backup generator (2)
- APU generator.

IDG

There is one IDG on each engine. The IDG attaches to the aft face of the gearbox.

Each IDG supplies a maximum of 120 kva of power.

Backup Generator

There is one backup generator on each engine. The backup generator attaches to the forward face of the gearbox.

Each backup generator supplies a maximum of 20 kva of power.

APU Generator

The APU generator is in the APU compartment. It attaches to the APU gearbox.

The APU generator supplies a maximum of 120 kva of power.

AC GENERATION - CONVERTER SUPPLEMENT COOLING FAN - COMPONENT LOCATION

AC GENERATION - BACKUP POWER - BACKUP GENERATOR CONVERTER & SUPPLEMENT COOLING FAN

Backup Generator Converter

The backup generator converter gets variable frequency ac power from both backup generators. It changes the variable frequency power into 115v, 400 hz, ac power. The converter supplies power to one or both transfer buses.

The converter also controls, monitors, and protects the backup electrical power system. The converter does an automatic test of the backup system immediately after an engine start. These are some of the protective functions of the converter:

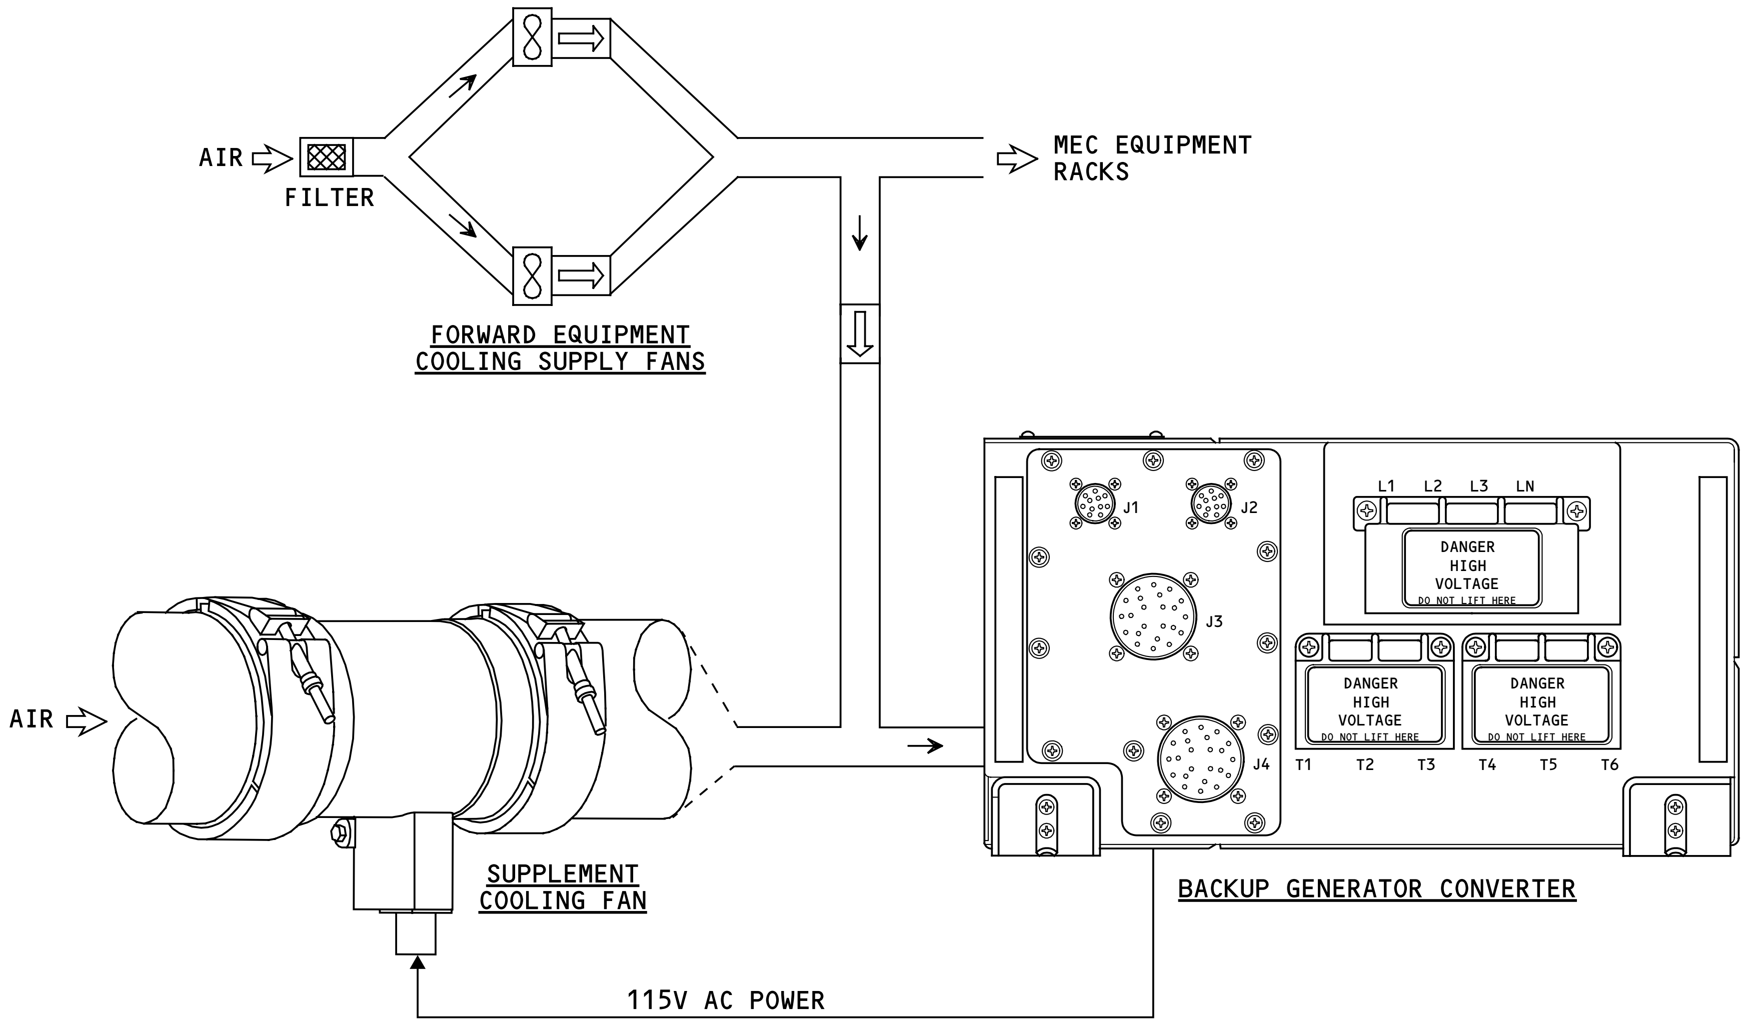
- Over/undervoltage
- Over/underfrequency
- Overcurrent
- Differential protection
- Converter fault.

Supplement Cooling Fan

The backup generator converter gets cooling air from the forward equipment cooling supply fans. It also gets cooling air from the supplement cooling fan.

The supplement cooling fan is an axial flow blower with an integral discharge check valve. The backup generator converter turns the fan on when it supplies it with 115v ac power during these conditions:

- Backup system test after an engine start
- Backup system supplies power to both transfer buses
- High temperature difference across the converter
- Inlet air temperature is greater than 40 degrees C and the backup system supplies power to one transfer bus
- Forward equipment cooling failure.



24-20-00-008 Rev 1

AC GENERATION - BACKUP POWER - BACKUP GENERATOR CONVERTER & SUPPLEMENT COOLING FAN

AC GENERATION - APU GENERATOR POWER - GENERATOR CONTROL

General

The APU GCU controls, protects, and monitors the APU power.

The forward equipment cooling system actively cools the GCU.

GCU Power

The APU GCU power supply gets power from two different sources. One source is the PMG in the APU generator. The other source is the captain's flight instrument bus.

Generator Excitation

The voltage regulator controls the power level to the exciter field in the generator. The voltage regulator rectifies ac power from the PMG to make dc current for the exciter field. Power to the voltage regulator goes through the generator control relay (GCR).

The generator uses the exciter field current to make the ac current in the power feeders. The feeder cables go to the APB, the ground handling relay, and the ground service select relay in the auxiliary power panel.

The voltage regulator monitors the generator output voltage. This is called the point-of-regulation (POR) voltage. POR voltage is on the generator side of the APB. The voltage regulator adjusts the dc current to the exciter field to keep the POR voltage at 115 volts.

Protection

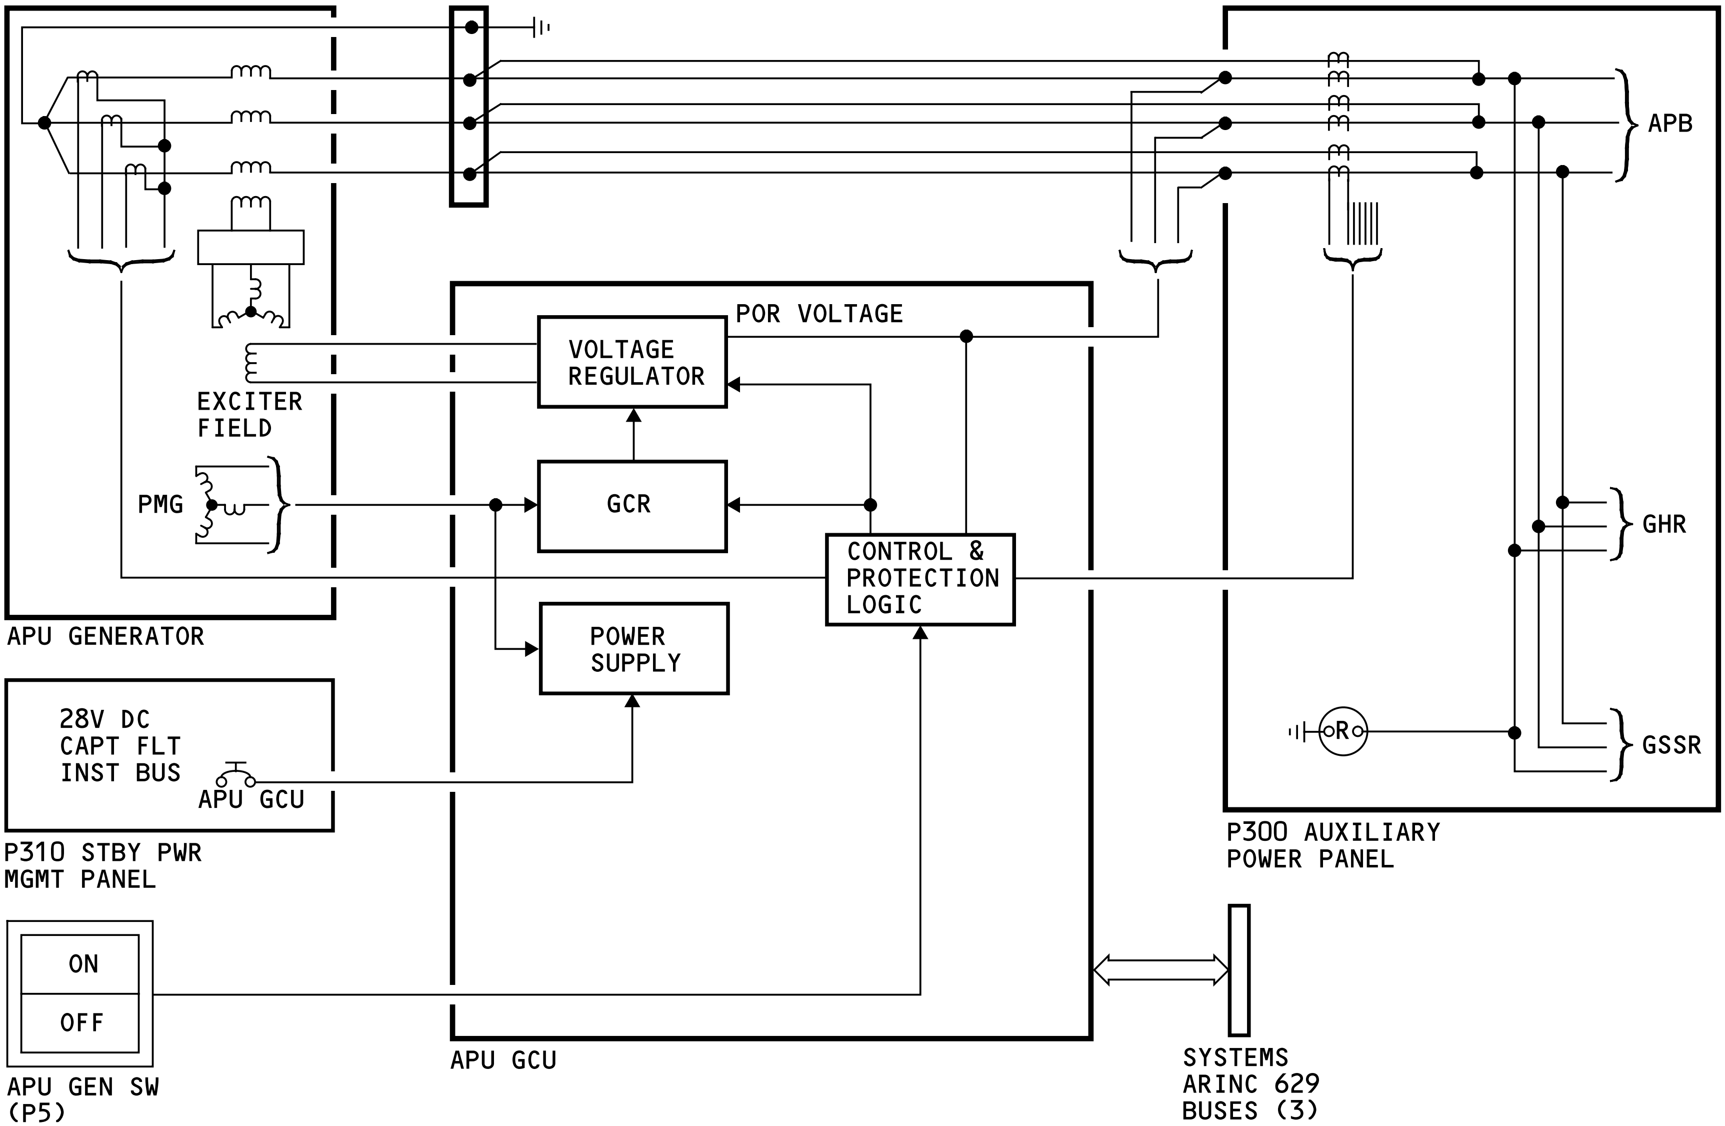
The GCU monitors the APU generator power and control inputs. It opens the GCR for any of these causes:

- Control switch off
- Fire switch pulled
- Over/under voltage
- Over/under frequency
- Differential fault
- Open phase
- Generator diode failure
- Parallel feeder open
- Unbalanced current
- Computer failure.

A protective trip is reset when you push the control switch off and then on.

Power Feeders

Copper feeders go from the APU to a terminal block at the aft stabilizer pivot bulkhead. From there, double-wire aluminum feeders go to the auxiliary power panel. The feeders reconnect in the power panel.



24-20-00-009 Rev 3

AC GENERATION - APU GENERATOR POWER - GENERATOR CONTROL

AC GENERATION - APU GENERATOR POWER - APB CONTROL

APB Control

The APU GCU controls the automatic operation of the APB. The GCU gets a switch position signal from the APU generator (APU GEN) switch.

When the switch is in, the GCU operates the APB automatically. The GCU uses power transfer logic to make a decision when to close the APB. In the air, with a single IDG operating, the APB closes if the APU is running (a break-power transfer). On the ground, the APB closes for no-break power transfers.

The GCU opens the APB for any these conditions:

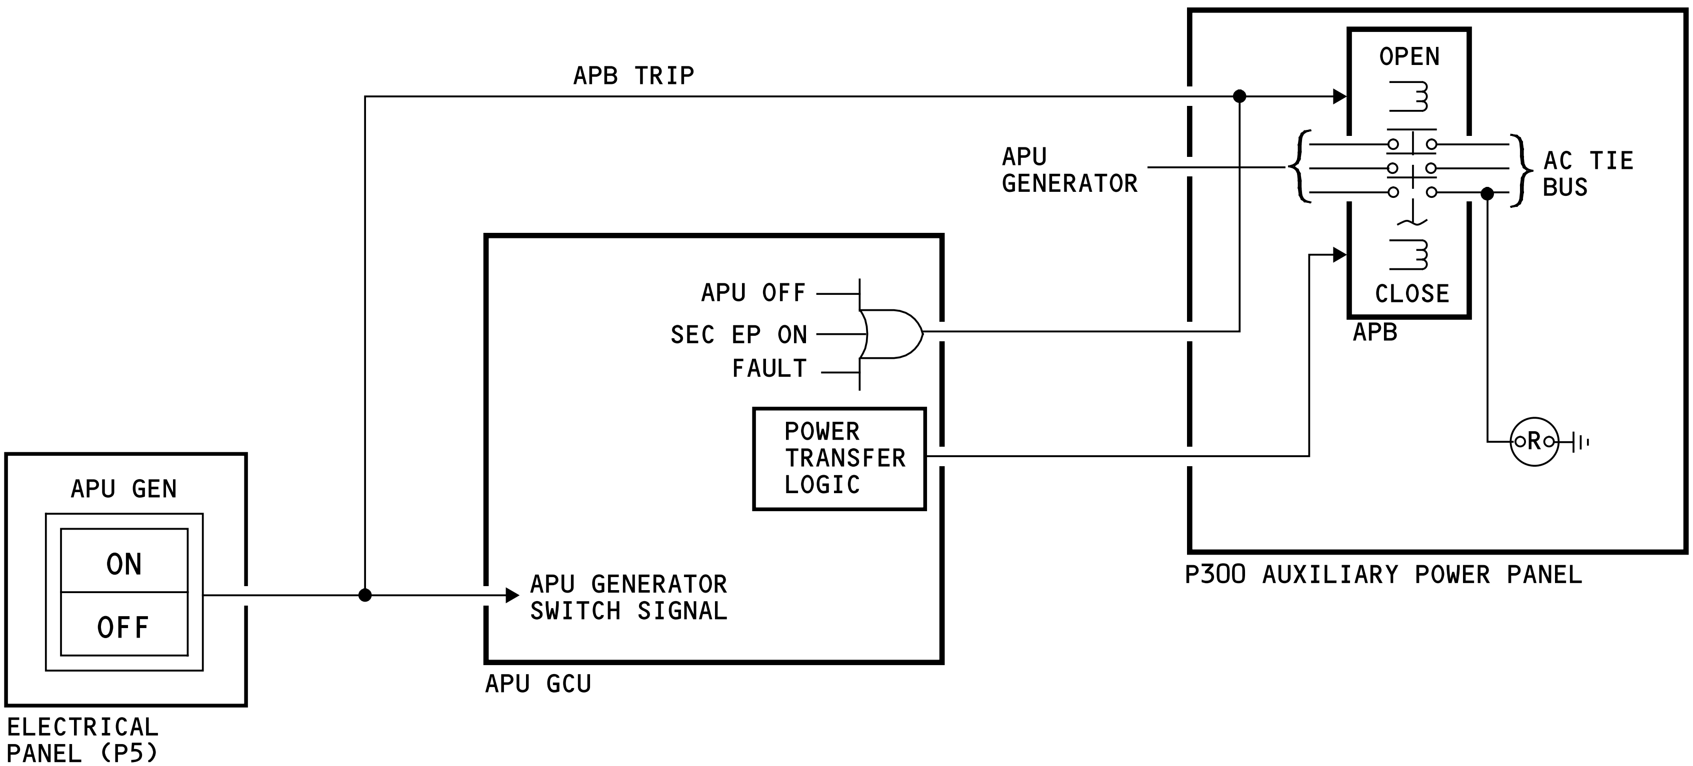
- The APU is off
- Secondary external power is on
- An APU power system fault occurs.

When the switch is out, a direct wire to the APB supplies power to open the breaker.

Switch Light

The OFF light on the APU GEN switch comes on for any of these conditions:

- The switch is out and the APB is open
- The APU is running and the GCU opens the APB because of a fault.



24-20-00-010 Rev 2 01/09/95

AC GENERATION - APU GENERATOR POWER - APB CONTROL

AC GENERATION - IDG POWER - GENERATOR CONTROL

General

The IDG GCU controls, protects, and monitors the IDG power.

The forward equipment cooling system actively cools the GCU.

GCU Power

The GCU gets power for control, protection, and BITE functions from these sources:

- IDG PMG
- Battery bus #2
- Right dc bus.

Generator Excitation

The voltage regulator controls the power level to the exciter field in the IDG. The voltage regulator rectifies ac power from the PMG to make dc current for the exciter field. Power to the voltage regulator goes through the generator control relay (GCR).

The generator uses the exciter field current to make the ac current in the power feeders. The power feeders go to the GCB in the power panel.

Point-of-Regulation (POR) Voltage

The voltage regulator monitors the voltage at the POR. POR is on the generator side of the GCB. The voltage regulator adjusts the dc current to the exciter field to keep the POR voltage at 115 volts.

Protection

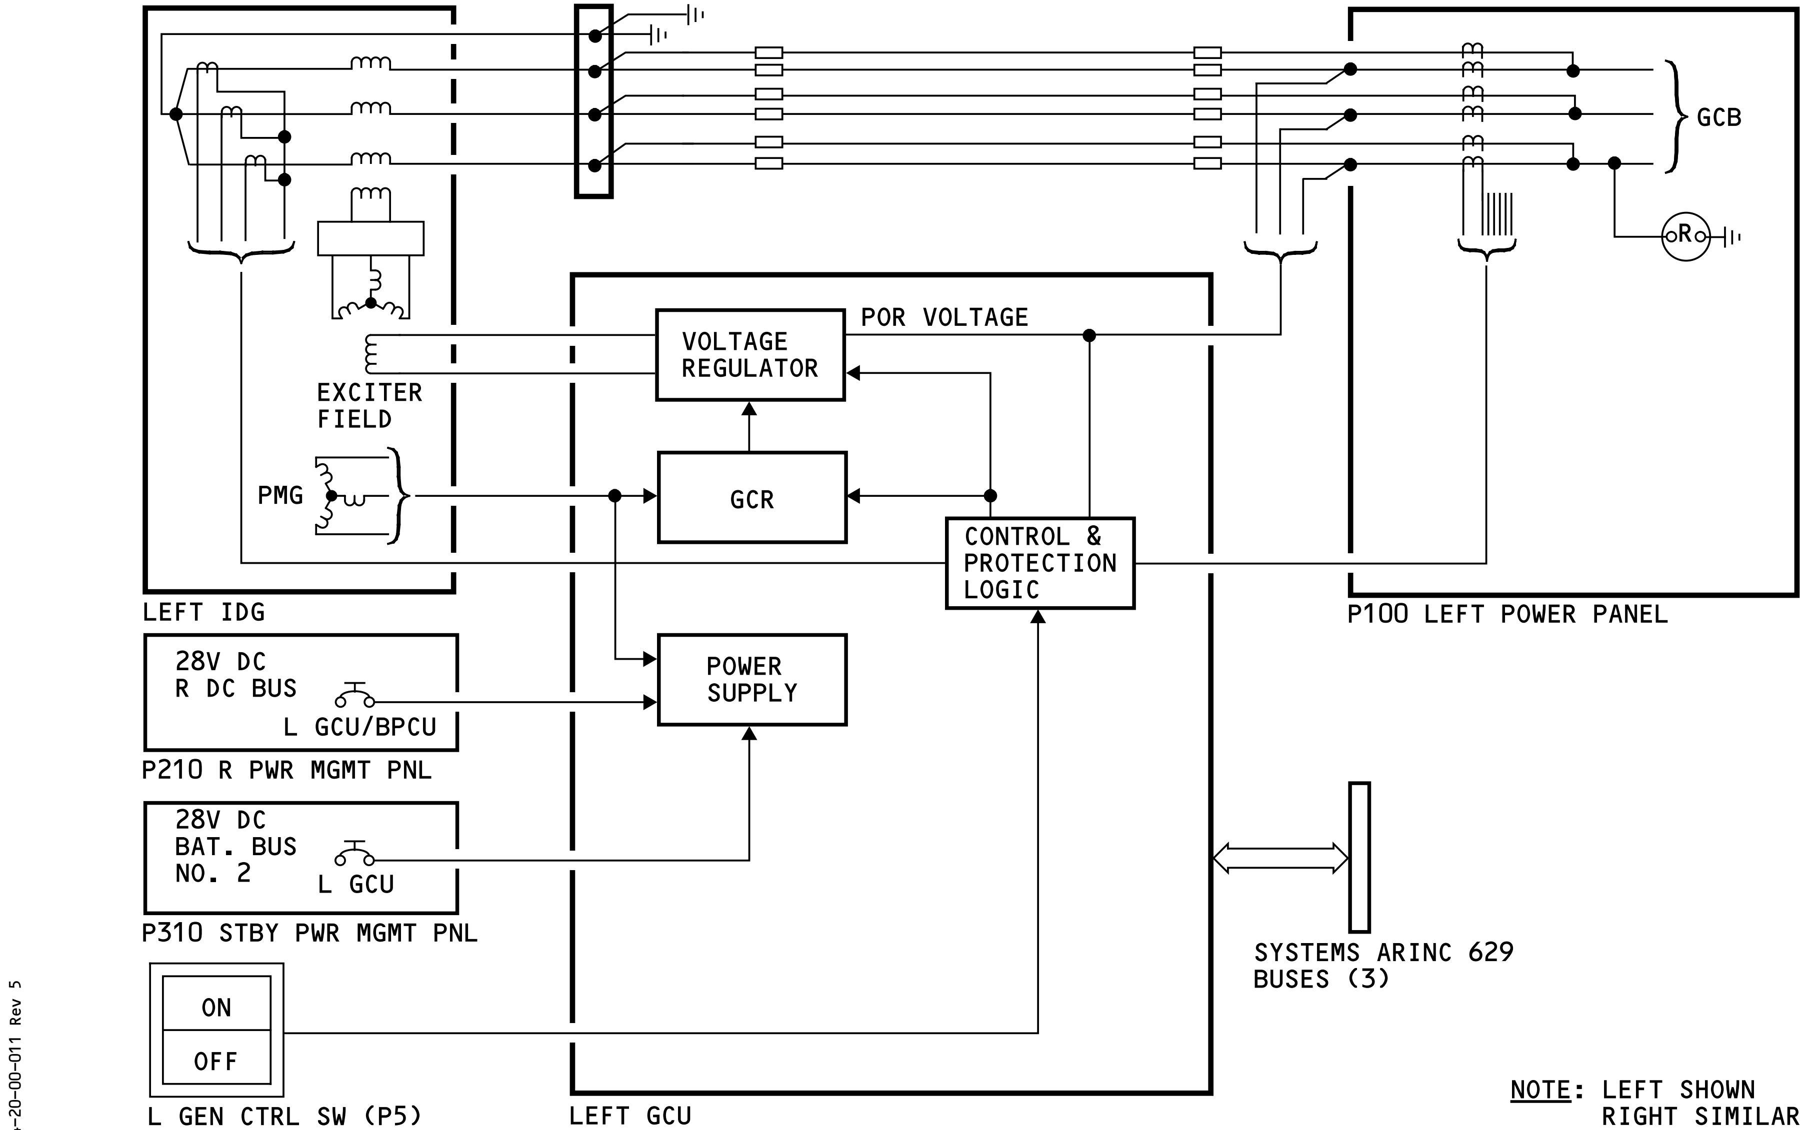
The GCU monitors the IDG generator power and control inputs. It opens the GCR for any of these causes:

- Control switch off
- Fire switch pulled
- IDG disconnect switch pushed
- Over/under voltage
- Over/under frequency
- Differential fault
- Open phase
- Generator diode failure
- Parallel feeder open
- Unbalanced current
- Computer failure.

A protective trip is reset when you push the control switch off and then on.

Power Feeders

Copper feeders go from the IDG to a terminal block under the strut. From there, double-wire copper feeders go through the strut to a splice in the wing leading edge. At the splice, the feeders change from copper to aluminum. Another splice is at the wing-to-body join. The feeders reconnect in the power panel.



AC GENERATION - IDG POWER - GENERATOR CONTROL

AC GENERATION - IDG POWER - BREAKER CONTROL

General

The GCU controls the GCB and BTB. When the GCB closes, the IDG connects to the main ac bus. When the BTB closes, the tie bus connects to the main ac bus.

The GCU gets switch position signals from the generator control (GEN CTRL) and BUS TIE switches.

GCB Control

When the GEN CTRL switch is in, the GCU operates the GCB automatically. The GCU closes the GCB when the IDG is available. This permits the left main ac bus to get power from the IDG. The GCU opens the GCB for any of these conditions:

- Secondary external power is on
- A fault occurs
- The IDG is not available.

When the GEN CTRL switch is out, a direct wire to the GCB open coil supplies power to open the GCB.

The OFF light on the GEN CTRL switch comes on when the GCB is open.

BTB Control

When the BUS TIE switch is in, the GCU operates the BTB automatically. The GCU closes the BTB to permit either of these conditions:

- The main ac bus gets power from the tie bus
- The main ac bus supplies power to the tie bus.

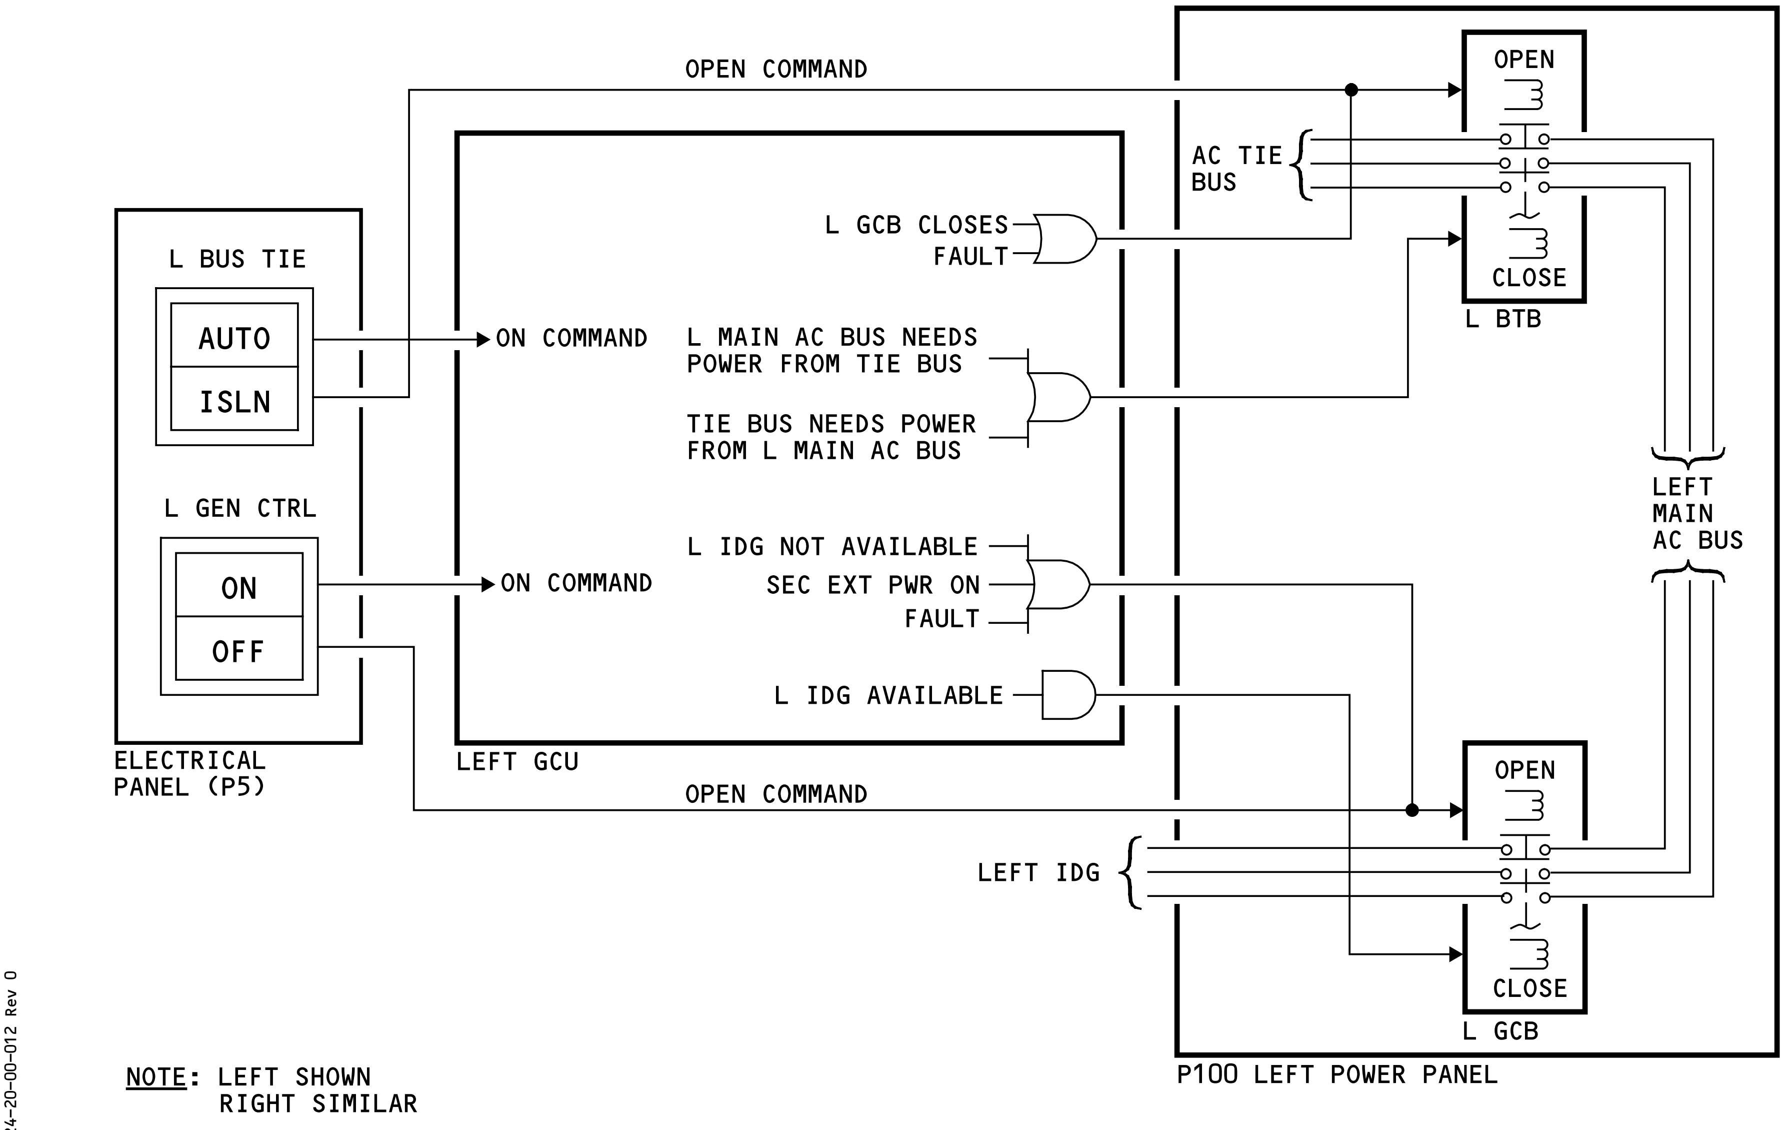
The GCU opens the BTB for either one of these conditions:

- The left GCB closes
- A fault occurs.

When the BUS TIE switch is out, a direct wire to the BTB open coil supplies power to open the BTB.

The ISLN light on the BUS TIE switch comes on for either of these conditions:

- The switch is out and the BTB is open
- The GCU opens the BTB because of a fault.



NOTE: LEFT SHOWN
RIGHT SIMILAR

AC GENERATION - IDG POWER - BREAKER CONTROL

Converter Power

The converter power supply gets power from a PMG in the backup generator or from the captain's flight instrument bus.

Generator Excitation

The voltage regulator controls power to the exciter field in the backup generator. The voltage regulator rectifies ac power from the PMG to make dc power for the exciter field. It sends power through the GCR to the exciter field. The generator uses the exciter field current to make variable frequency ac power. The generator sends variable frequency ac power to the converter.

Main Feeder Power

The rectifier changes the variable frequency ac power to dc power. The inverter changes dc power to constant frequency 115v ac power. The inverter sends the 115v ac power through the power feeders to the CCB.

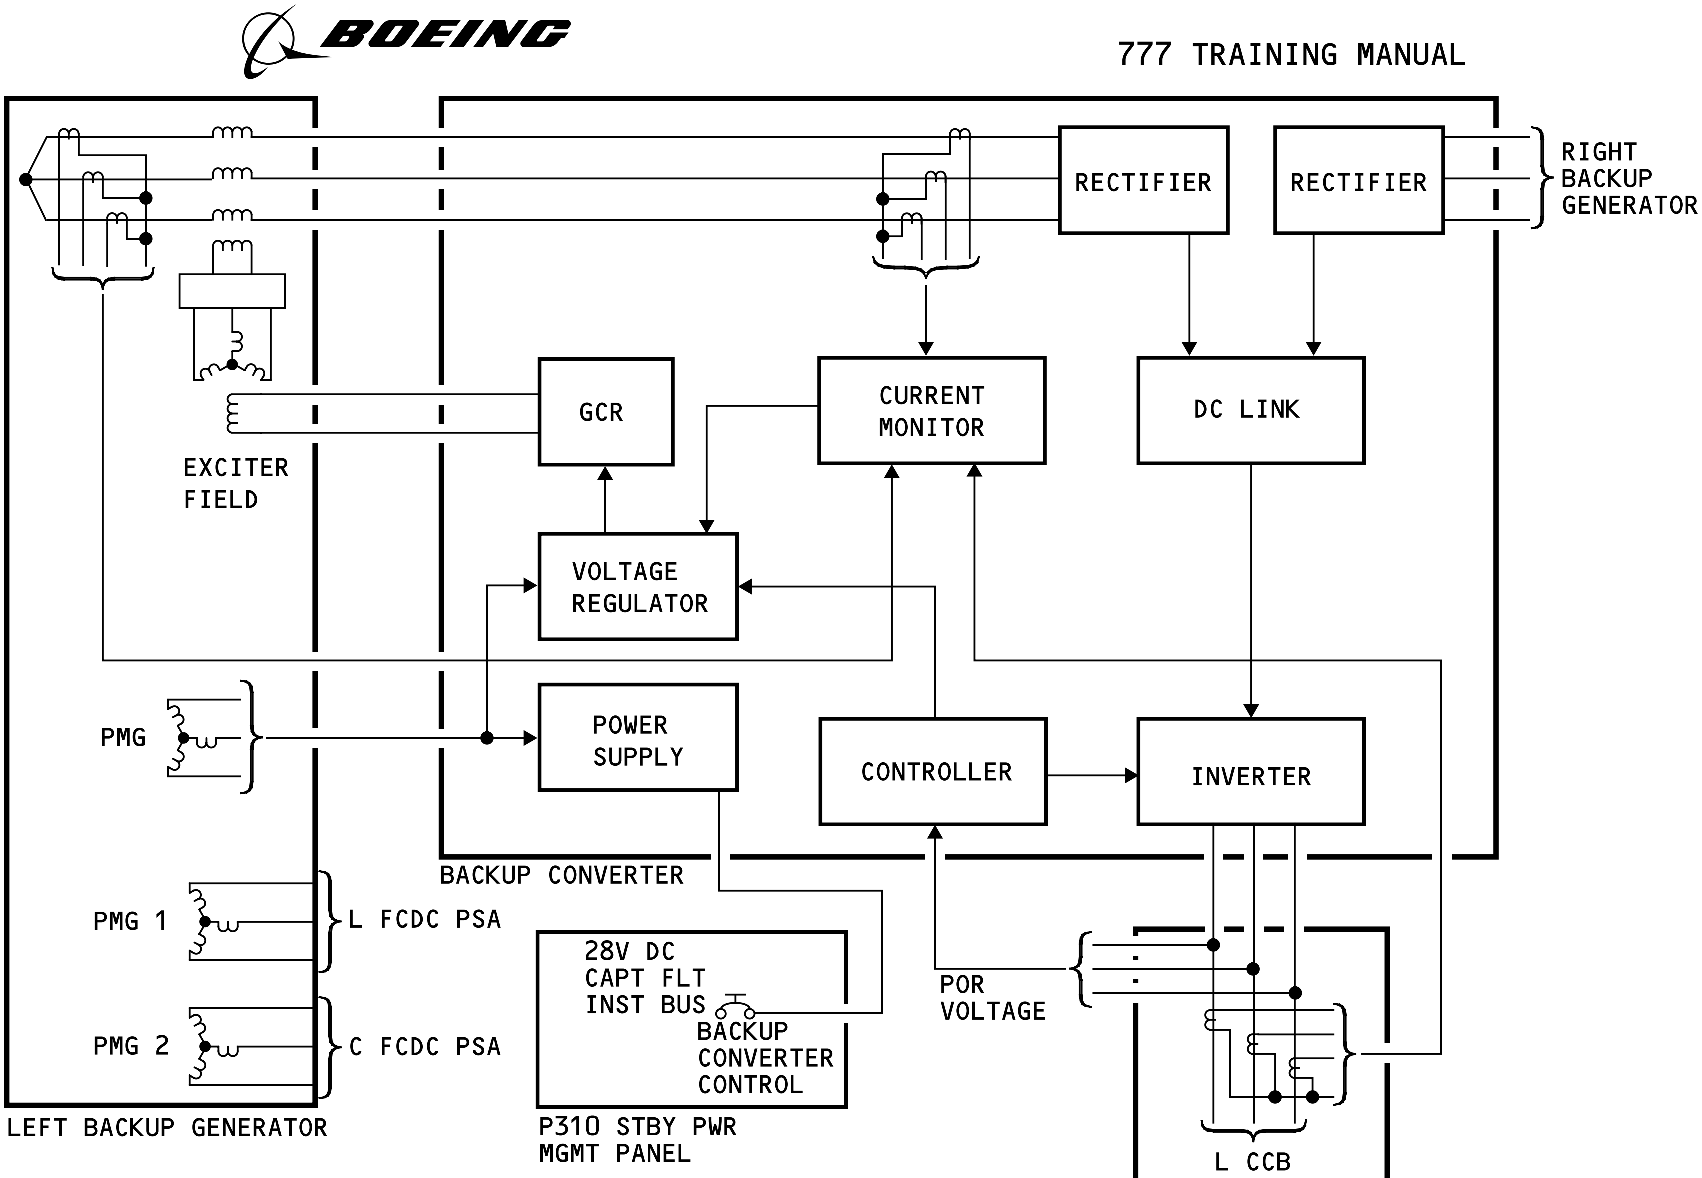
The controller monitors the POR voltage. The POR is on the generator side of the CCB. The controller adjusts the output from the inverter to keep the POR voltage at 115v.

Protection

The backup generator converter monitors the backup generator power and control inputs. It opens the GCR for the related backup generator for any of these causes:

- Control switch off
- Fire switch pulled
- Over/under-voltage
- Over/under-frequency
- Differential fault
- Computer failure
- Converter fault
- Generator over-temperature
- Low oil pressure
- DC link over-voltage
- Converter harmonic output distortion
- DC content out of range
- Converter over-current.

Under certain conditions the converter over-current fault does not trip the GCR.



NOTE: LEFT SHOWN
RIGHT SIMILAR

AC GENERATION - BACKUP POWER - GENERATOR CONTROL

24-20-00-013 Rev 3 03/19/96

AC GENERATION - BACKUP POWER - BREAKER CONTROL

TBB and CCB Control

The backup generator converter controls the automatic operation of the TBB and CCB. The converter gets a switch position signal from the backup generator (BACKUP GEN) switch.

When the switch is in, the converter controls the TBB and CCB. The TBB and CCB are normally not energized. A spring holds the TBB closed when it is not energized. A spring holds the CCB open when it is not energized.

The converter energizes the TBB and CCB to permit the backup system to supply power to the transfer buses. The TBB opens when it energizes. The CCB closes when it energizes.

When the switch is out, the TBB and CCB are relaxed.

Power Transfer

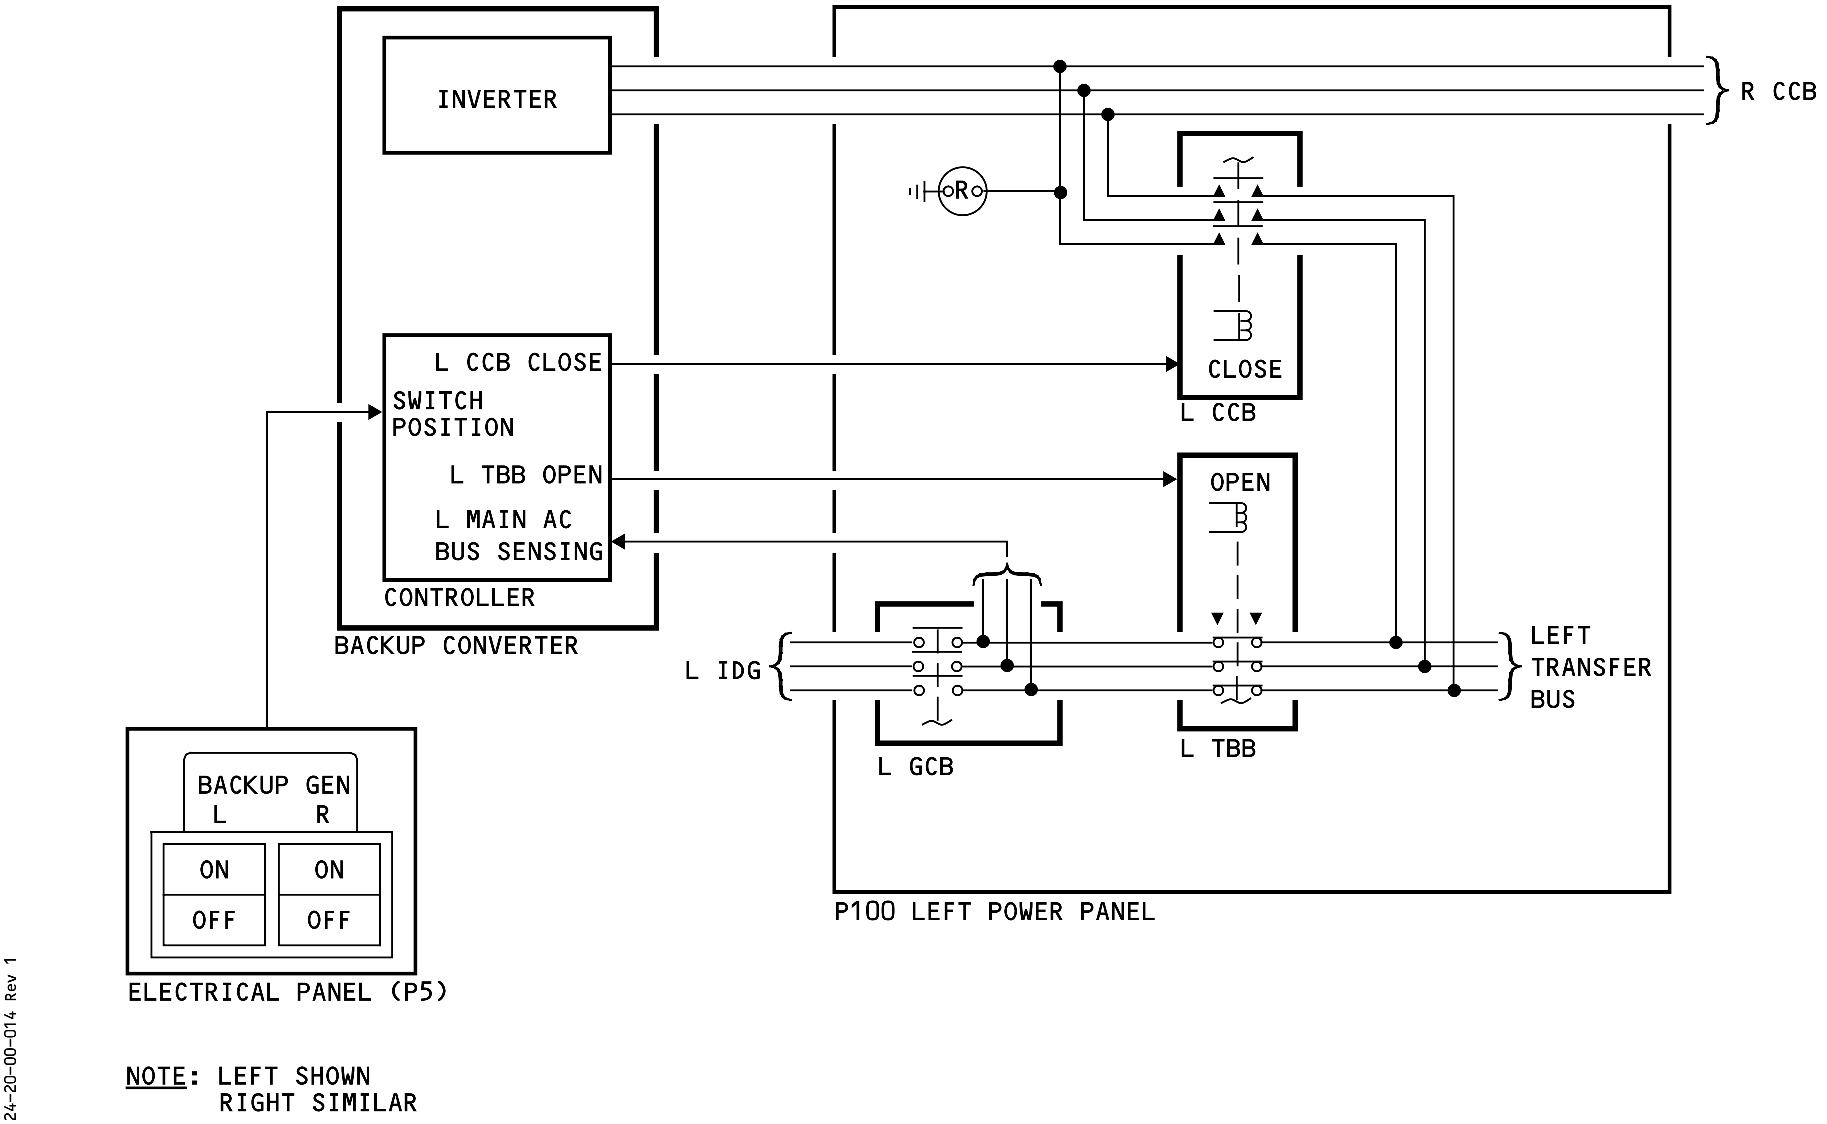
The left transfer bus normally gets power from the left IDG, through the left GCB and left TBB. When the converter senses no power at the left main ac bus, it opens the left TBB and closes the left CCB. This permits power to go from the converter to the left transfer bus.

If necessary, the converter supplies power to the right transfer bus through the right CCB.

Indication

The OFF light on the BACKUP GEN switch comes on for these conditions:

- Switch is out
- Backup generator field relay opens because of a fault
- Engine fire switch is pulled out
- Engine is shutdown.



NOTE: LEFT SHOWN
RIGHT SIMILAR

AC GENERATION - BACKUP POWER - BREAKER CONTROL

THIS PAGE INTENTIONALLY LEFT BLANK

AC GENERATION - FUNCTIONAL DESCRIPTION

General

The BPCU and GCUs automatically control the power source selection for each main ac bus. The power sources for a main ac bus have this priority:

- Related IDG
- APU generator
- Opposite IDG.

External power has priority over other sources when you manually choose it with the external power switch.

APB Control

When the APU is running, the APU GCU closes the APB. This permits the APU to supply power to the tie bus. If the left main ac bus has no power, the left GCU closes the left BTB. This connects the tie bus to the left main ac bus.

If the right main ac bus has no power, the right GCU closes the right BTB. This connects the tie bus to the right main ac bus.

GCB Control

When the left IDG operates, the left GCU closes the left GCB. This permits the IDG to supply power to the left main ac bus.

When the right IDG operates, the right GCU closes the right GCB. This permits the IDG to supply power to the right main ac bus.

BTB Control

One IDG can supply power to both main ac buses at the same time. For example, if the right IDG fails, the right GCU opens the right GCB and closes the right BTB. The left GCU closes the left BTB. This connects the left main ac bus to the right main ac bus.

Ground Service and Ground Handling Buses

When the right main ac bus has power, it supplies power to the ground service bus. When the right main ac bus has no power, the BPCU selects primary external power or the APU generator as the power source.

Primary external power or the APU generator also supply power to the ground handling bus through the ground handling relay.

If both the APU generator and primary external power are available, primary external power has priority.

Backup Generator Power

The backup power system supplies power to one or both transfer buses during these conditions:

- Loss of all main ac power
- Single main generator operation

AC GENERATION - FUNCTIONAL DESCRIPTION

- Autoland
- Backup system test after engine start.

The backup generator converter controls the TBBs and CCBs. For example, if the left main ac bus has no power, the converter opens the left TBB and closes the left CCB. This permits the converter to supply power to the left transfer bus.

BITE

The GCUs and backup converter protect and monitor the ac power systems for faults. They perform three kinds of tests:

- Continuous
- Power-up/manually-initiated
- Fault-initiated.

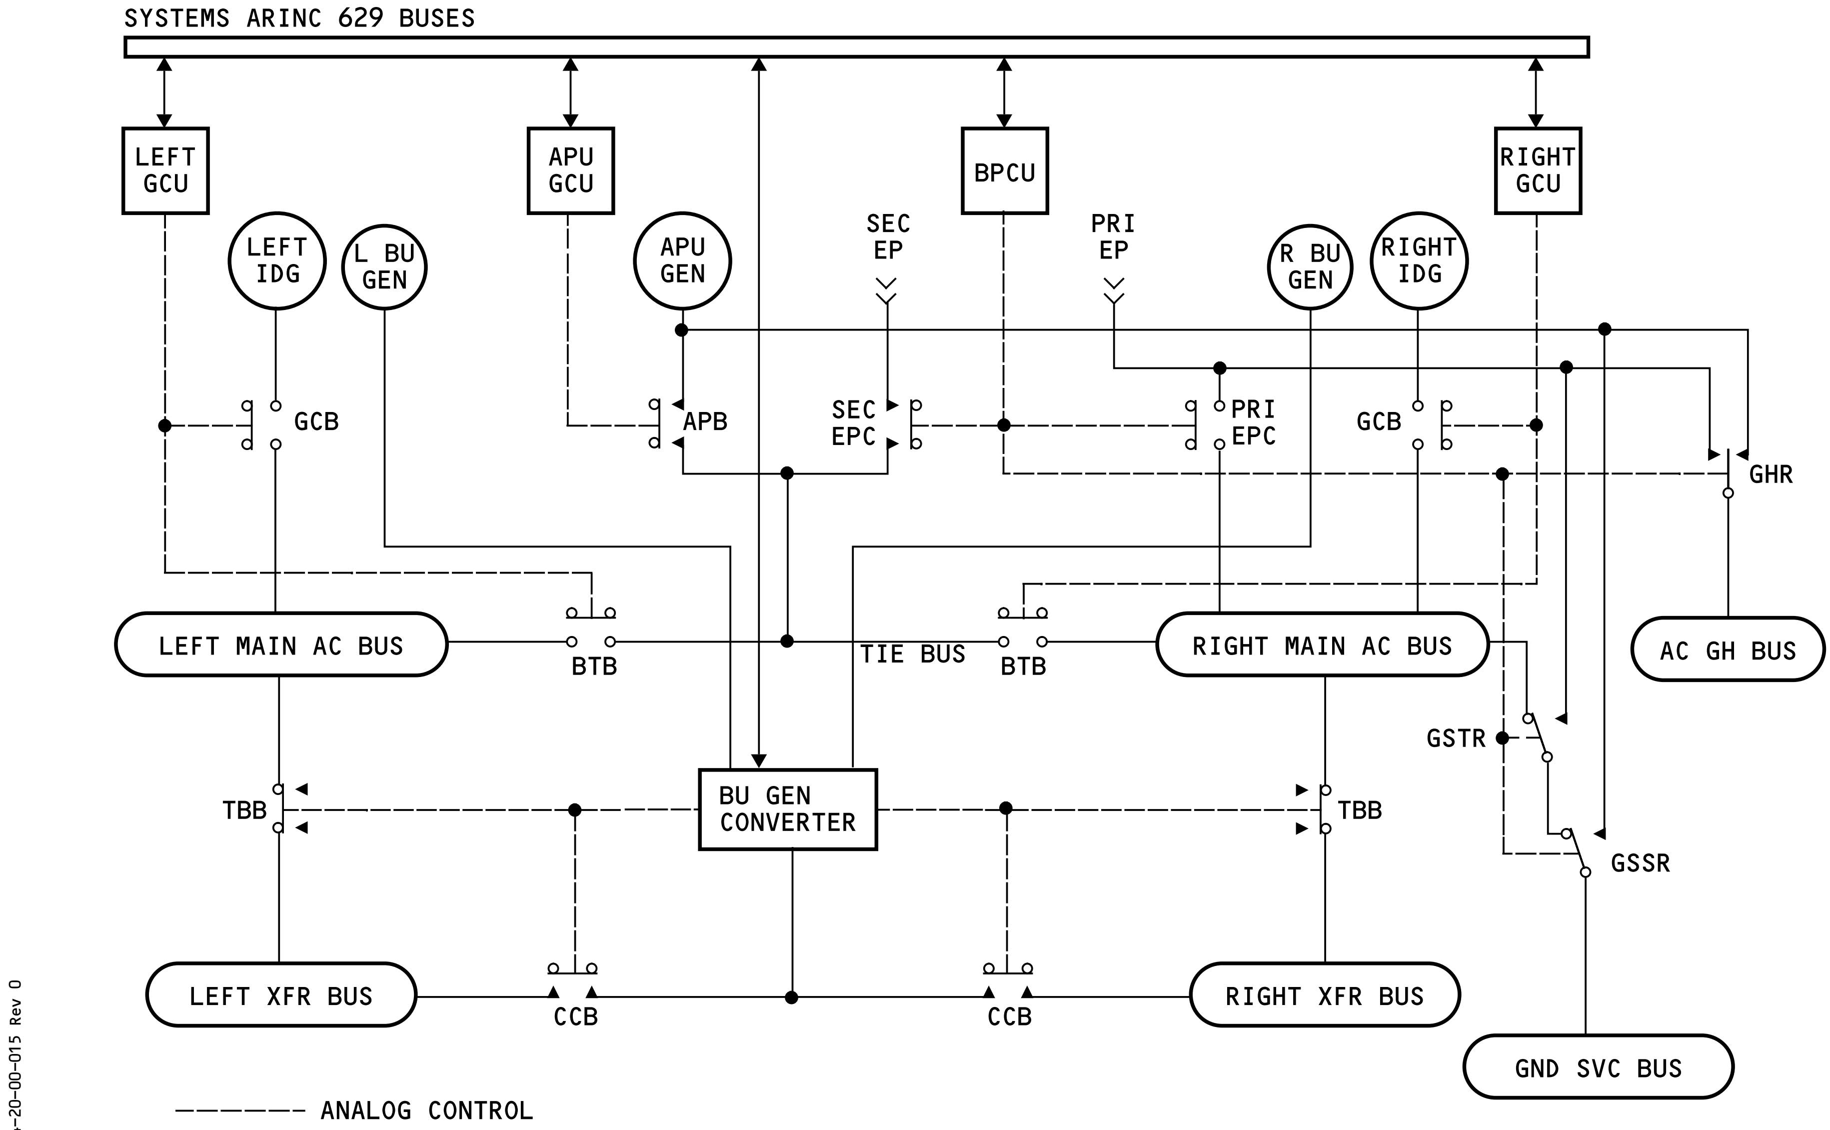
The GCUs and the converter send the test fault data to the AIMS.

Training Information Point

There is a short time delay between when the engine reaches idle and when the IDG starts to supply power. The length of the time delay depends on engine idle speed data from the engine data interface unit (EDIU).

On the ground, if the GCU gets a satisfactory engine idle speed signal from the EDIU, the IDG starts to supply power in 6 seconds. If there is not a satisfactory engine idle speed signal from the EDIU, the GCU gets a different engine speed signal from its own PMG. In this case, the IDG starts to supply power in 16 seconds.

In the air, if the GCU gets a satisfactory engine idle speed signal from the EDIU, the IDG starts to supply power in 10 seconds. If it must get an engine speed signal from the PMG, the IDG starts to supply power in 20 seconds.



AC GENERATION - FUNCTIONAL DESCRIPTION

AC GENERATION - IDG AND APU POWER CMCS GROUND TESTS

General

There are three operational tests for the main ac electrical power generation system:

- Unlatch Sustained Parallel Fault (AGCU)
- Unlatch Sustained Parallel Fault (LGCU)
- Unlatch Sustained Parallel Fault (RGCU).

There are four replacement tests for the main ac electrical power generation system:

- Auxiliary Generator Control Unit
- Bus Power Control Unit
- Left Generator Control Unit
- Right Generator Control Unit.

Unlatch Sustained Parallel Fault (AGCU)

When the APU generator control unit detects a fault in its sustained-parallel-source protection circuits, it latches a related fault message. You run this test to clear the latched fault message.

Unlatch Sustained Parallel Fault (LGCU)

When the left generator control unit detects a fault in its sustained-parallel-source protection circuits, it latches a related fault message. You run this test to clear the latched fault message.

Unlatch Sustained Parallel Fault (RGCU)

When the right generator control unit detects a fault in its sustained-parallel-source protection circuits, it latches a related fault message. You run this test to clear the latched fault message.

Auxiliary Generator Control Unit

This test makes the APU GCU do a BITE test of its internal circuits. The test is almost equivalent to the power-up test of the APU GCU.

Bus Power Control Unit

This test makes the BPCU do a BITE test of its internal circuits. The test is almost equivalent to the power-up test of the BPCU.

Left Generator Control Unit

This test makes the left GCU do a BITE test of its internal circuits. The test is almost equivalent to the power-up test of the left GCU.

Right Generator Control Unit

This test makes the right GCU do a BITE test of its internal circuits. The test is almost equivalent to the power-up test of the right GCU.

AC GENERATION - BACKUP POWER CMCS GROUND TESTS

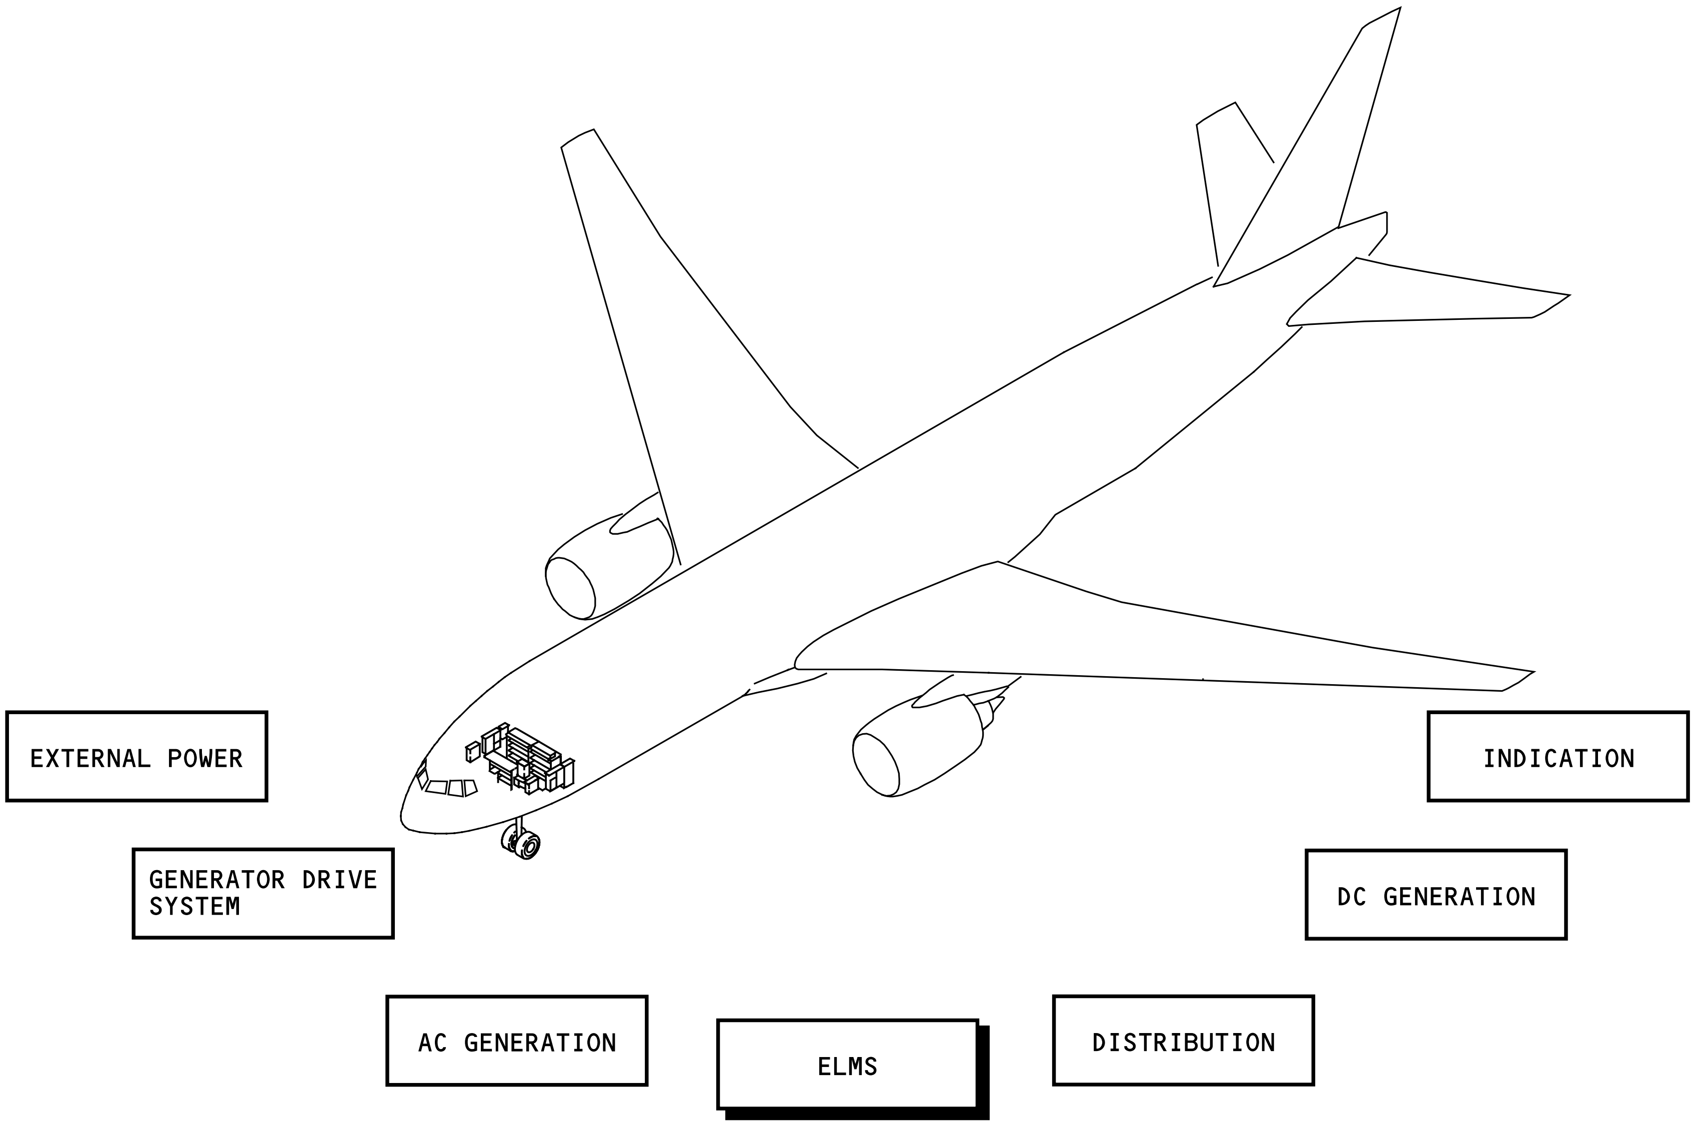
ELMS - INTRODUCTION

General

The electrical load management system (ELMS) has two basic functions that are independent of each other. First, the ELMS is a physical container for electrical equipment that it may or may not control. Second, the ELMS is a control system for many electrical components.



ELMS - INTRODUCTION

ELMS - GENERAL DESCRIPTION

General

The ELMS has seven panels that contain components to distribute electrical power. The ELMS also protects the electrical power system and controls many load-switching devices.

Distribution

All airplane electrical power goes through the ELMS panels for distribution. These are the ELMS panels:

- P100 Left power panel
- P200 Right power panel
- P300 Auxiliary power panel
- P320 Ground service/handling power panel
- P110 Left power management panel
- P210 Right power management panel
- P310 Standby power management panel.

Main and backup power go to the left, right, or auxiliary power panels. These power panels supply power to large loads (usually 25 amps or more). They also supply power to the power management panels and the ground service/handling power panel. The power management panels and the ground service/handling power panel supply power to small loads (usually less than 25 amps).

Load Switching

The power management panels contain ELMS electronic units (EEU). The EEUs control and monitor load-switching devices in their related ELMS panels. However, the EEUs do not control all of the load-switching devices. The GCUs, BPCU, and backup generator converter directly control some of the large load-switching devices in the power panels. Airplane systems directly control some load switching in the power management panels.

The EEUs get data from the other electrical power control units and airplane systems. This data comes directly or from the ARINC 629 system buses. The EEUs use this data to manage the loads of the electrical power system.

General

The P110 left power management panel contains switching devices and circuit breakers for smaller electrical loads. An EEU is also in P110.

Physical Description

You open the panel doors to get access to these components in the P110:

- Relays
- Relay panels
- EEU
- Signal conditioning modules (SCM).

Circuit breakers are in the doors of the panel.

A special section of P110 contains the EEU. This section shields the EEU circuit cards from electro-magnetic interference (EMI). You open the EEU cover door to get access to these EEU circuit cards:

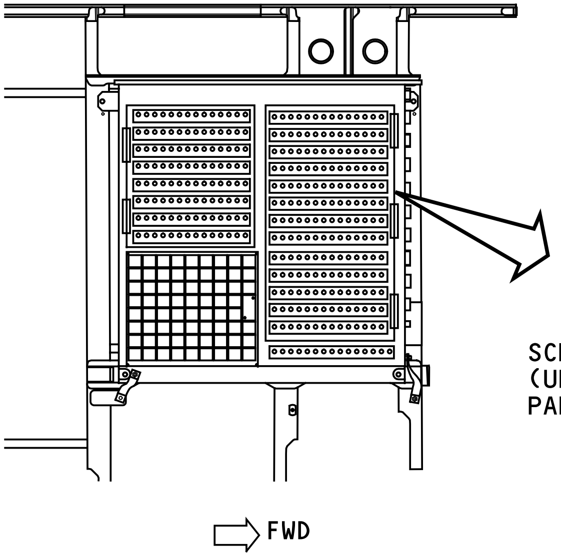
- Power supply unit (PSU) (2)
- ARINC 629 (2)
- I/O (6)
- CPU (2)
- Filter (3).

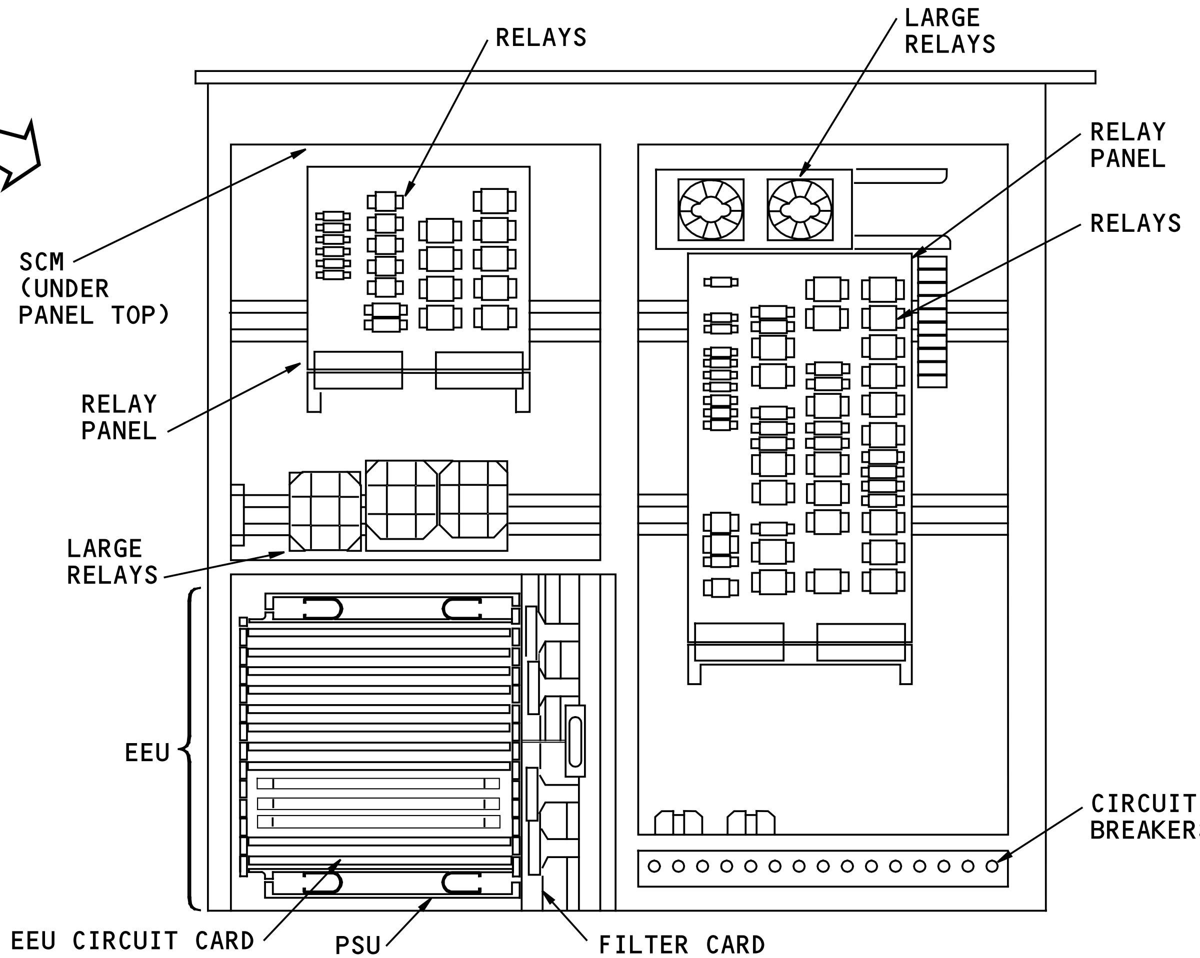
Labels on the ends of the EEU circuit cards identify them.

Training Information Point

You can remove the EEU circuit cards. Exposed connector pins make the cards electrostatic discharge sensitive (ESDS) components.

The CPU cards have software that is data-loadable.





P110 LEFT POWER MANAGEMENT PANEL

24-09-00-006 Rev 2

ELMS - P110 LEFT POWER MANAGEMENT PANEL

ELMS - P210 RIGHT POWER MANAGEMENT PANEL

General

The P210 right power management panel contains switching devices and circuit breakers for smaller electrical loads. An EEU is also in P210.

Physical Description

You open the panel doors to get access to these components in P210:

- Transformer
- SCMs
- Relays
- Relay panels
- EEU
- DC tie relay.

Circuit breakers are in the doors of the panel.

A special section of P210 contains the EEU. This section shields the EEU circuit cards from EMI. You open the EEU cover door to get access to these EEU circuit cards:

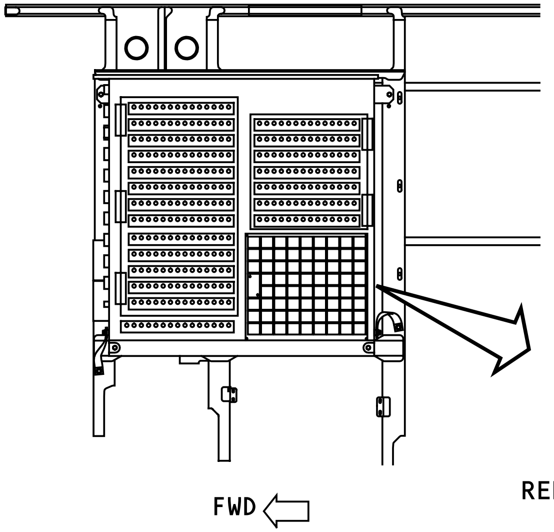
- PSUs (2)
- ARINC 629 (2)
- I/O (6)
- CPU (2)
- Filter (3).

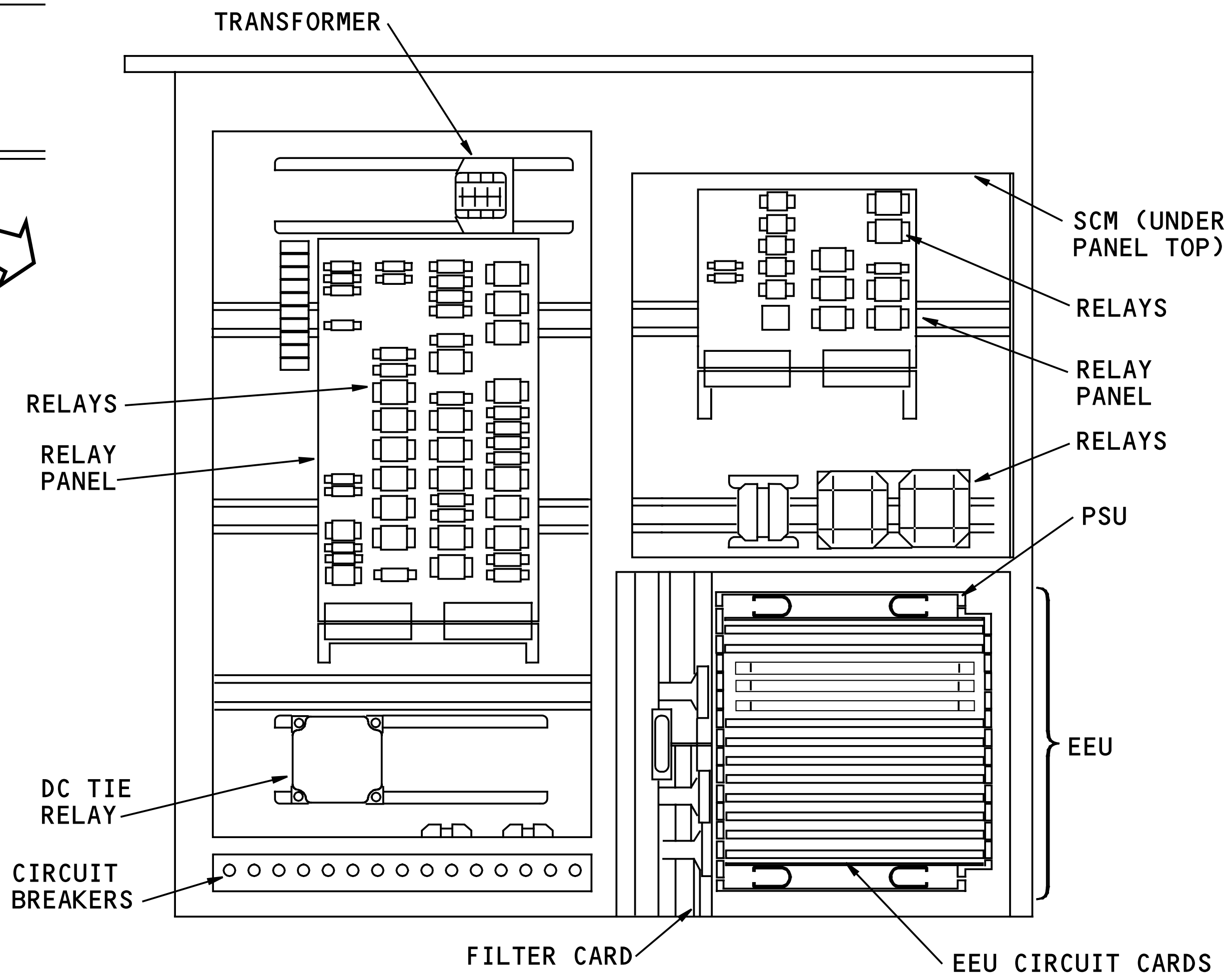
Labels on the ends of the EEU circuit cards identify them.

Training Information Point

You can remove the EEU circuit cards. Exposed connector pins make the cards ESDS components.

The CPU cards have software that is data-loadable.





P210 RIGHT POWER MANAGEMENT PANEL

ELMS - P210 RIGHT POWER MANAGEMENT PANEL

ELMS - P310 STANDBY POWER MANAGEMENT PANEL

General

The P310 standby power management panel contains switching devices and circuit breakers for smaller electrical loads. An EEU is also in P310.

Physical Description

You open the panel door to get access to these components in P310:

- SCMs
- Relay panel
- Relays
- EEU.

A special section of P310 contains the EEU. This section shields the EEU circuit cards from EMI. You open the EEU cover door to get access to these EEU circuit cards:

- PSUs (2)
- ARINC 629 (2)
- I/O (6)
- CPU (2)
- Filter (4)
- DC subsystem
- Special function.

Labels on the ends of the EEU circuit cards identify them.

Training Information Point

You can remove the EEU circuit cards. Exposed connector pins make the cards ESDS components.

The CPU cards have software that is data-loadable. The dc subsystem card is for dc power control and cannot be programmed. The special function card is for unusual input/output data handling and cannot be programmed.

ELMS - P310 STANDBY POWER MANAGEMENT PANEL

THIS PAGE INTENTIONALLY LEFT BLANK

ELMS - FUNCTIONAL DESCRIPTION - PANELS

General

Each of the ELMS panels has self-contained wiring. All of the airplane wiring connects to the panels with external connectors. Line replaceable modules (LRMs) are inside the ELMS panels.

Power Panels

The power panels contain the large electrical load switching devices. One side of each panel has connecting studs for the large power cables. The other side has electrical connectors for smaller circuits. Bus power lights show when buses in the panel have power.

Inside each power panel is a backplane. Panel wiring and current transformers are behind the backplane. LRM mounting bases are part of the backplane. No wire connections are in front of the backplane.

LRMs plug into the mounting bases. The LRM power contacts are spring-loaded to ensure good contact with the mounting bases. Screws hold the LRMs in position. Plates cover any mounting bases that are not used.

Power Management Panels

The power management panels contain the smaller electrical load switching devices and the EEUs. These LRMs are in the panels:

- SCMs
- Current monitors
- Relays
- Circuit breakers
- EEU circuit cards
- Breaker.

The SCMs change input signals into a type that is satisfactory for the EEUs.

Relays are inside the panels. Smaller relays attach to relay panels that rotate down to expose the back of the relay panel. Larger relays attach to rails.

Circuit breakers are in the doors of the panels. Those monitored by the ELMS have a small circuit card attached to their base on the back of the panel door. One row of high ampere dc circuit breakers attach to the bottom face of the panels.

The EEU circuit cards are in a special section of the power management panels. You open a door to get access to the cards. Labels on the cards identify them.

Training Information Point

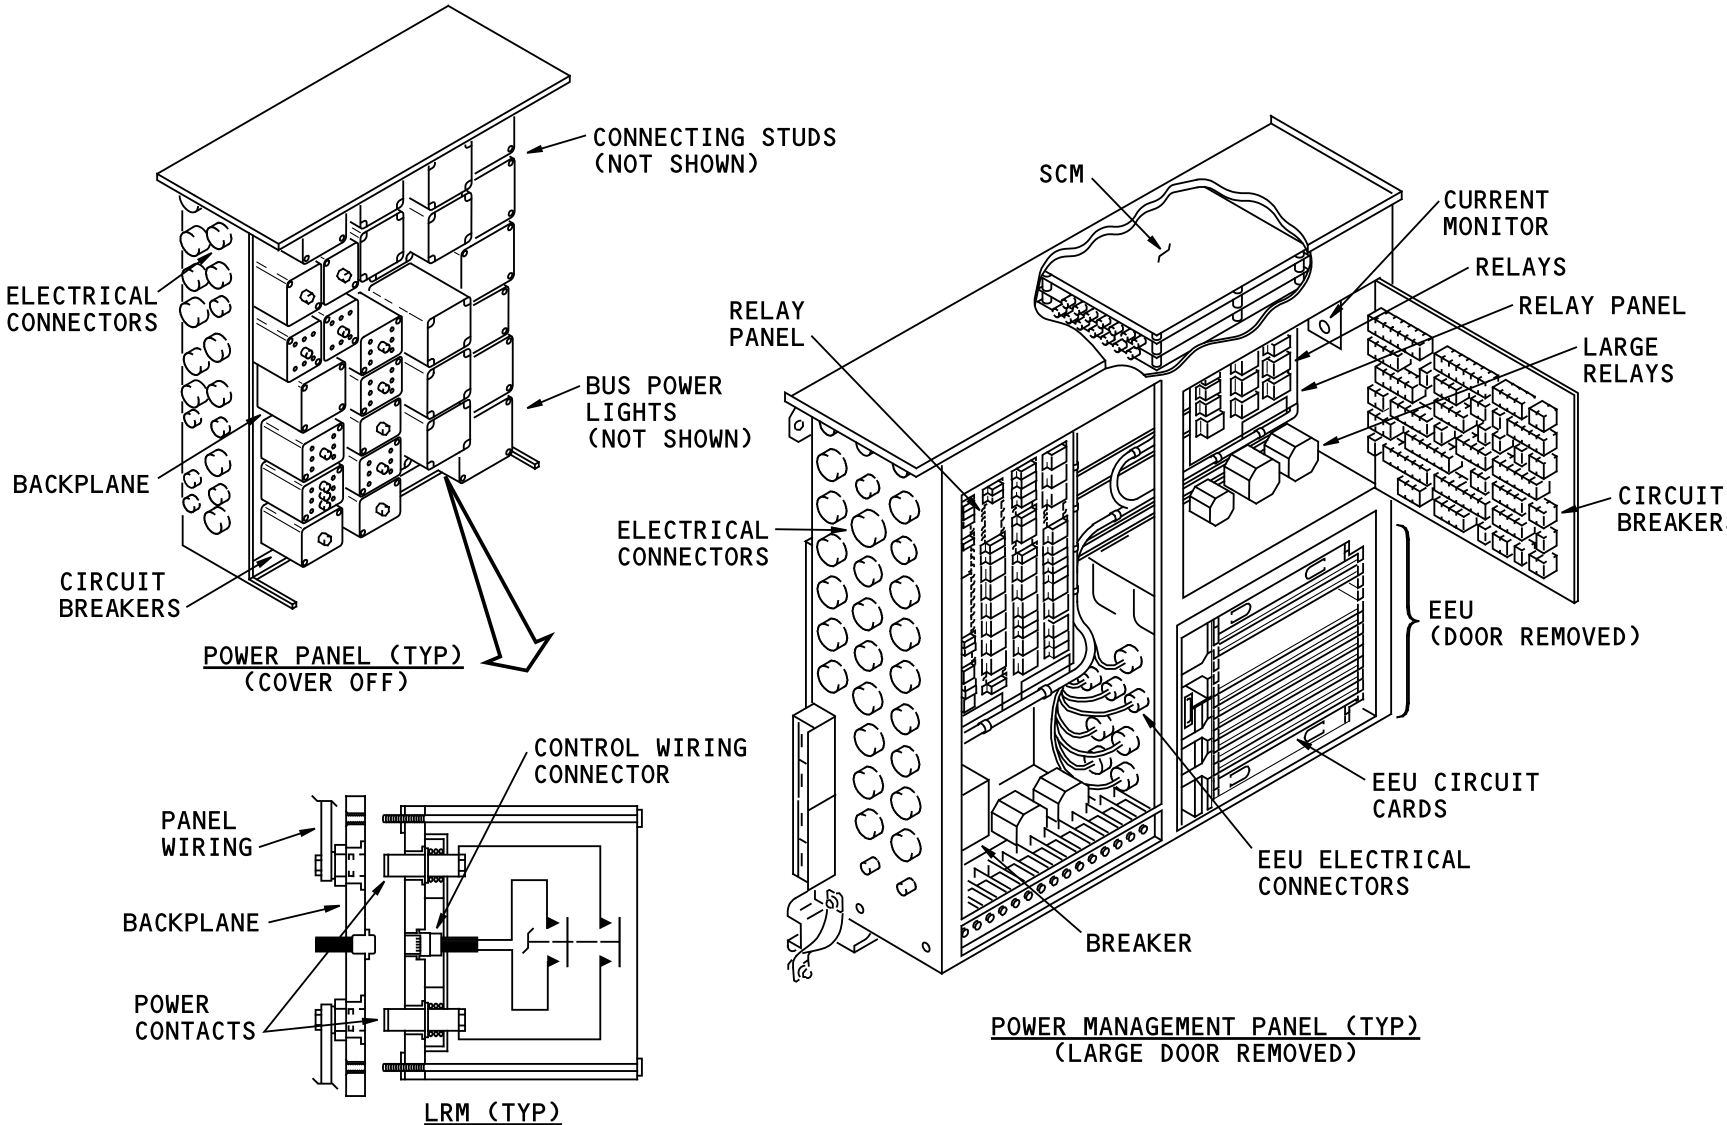
The screws of the power panel LRMs are captive (stay with the LRM).

Exposed connector pins on the EEU circuit cards make them ESDS components.

Circuit breakers for the ELMS panels are below the surface of the panel cover or are in a recess in the

ELMS - FUNCTIONAL DESCRIPTION - PANELS

panel doors. This prevents accidental damage to the circuit breakers, but you cannot easily see when a circuit breaker is open. Attach circuit breaker clips when you manually pull a circuit breaker to clearly show that it is open. Also supply power through the circuit breaker after you reset it to make sure it stays in.



24-09-00-009 Rev 3

ELMS - FUNCTIONAL DESCRIPTION - PANELS

THIS PAGE INTENTIONALLY LEFT BLANK

ELMS - FUNCTIONAL DESCRIPTION - EEU

General

The power management panels contain ELMS electronic units (EEU). The EEUs are two-channel computers that control and monitor load-switching devices in their related ELMS panels. Each EEU is an LRU that contains several circuit cards that are line replaceable modules (LRM). These are the circuit cards in the P310 EEU:

- Power supply
- CPU
- ARINC 629
- DC subsystem
- Special function
- I/O-1
- Filters A, B, and C.

P110 and P210 do not contain a dc subsystem, special function, or filter B circuit card. They also use an I/O-2 card instead of an I/O-1 card.

Physical Description

The EEU is in a special section of the power management panel that is shielded against EMI. You can remove the EEU from the panel. To remove the EEU from the panel, you have to disconnect the electrical connectors on the side of the EEU and remove it from the panel.

The circuit cards are in slots in the EEU. All of the cards, except the filter cards, are color-coded and labeled on the front of the card. There is also a label on the door of the EEU that shows the equipment number for each card slot. Card locks hold the cards in place. To remove a card, you loosen two card locks to release the card. To remove a filter card, you must first disconnect the electrical connector on the front of the card.

NOTE: The orientation of the P110 EEU is 180 degrees different from P210 and P310 (channel A is on top and the filter cards are to the right as you face the unit).

Power Supply

There are two power supply cards in each EEU. One is for channel A and the other for channel B. The power supplies convert the airplane dc power into acceptable power for the EEU LRMs. The power supply cards are brown.

CPU

There are two central processing unit (CPU) cards in each EEU. One is for channel A and the other for channel B. The CPUs contain the software that controls and monitors the ELMS functions. The CPU cards have a red removal handle.

The CPU channel that is the most healthy is the channel in control. The circuitry that decides which channel is the most healthy is split evenly between the two CPUs. If both CPUs have the same health, the channel that was in control when power to the EEU was removed, is the channel in control. The channel in control changes when the engines are shutdown at the end of a flight leg.

The channel in control can receive and transmit data to the ARINC 629, I/O, dc subsystem, and special function cards. The other channel is in a standby mode and can only receive data from the cards.

ARINC 629

There are two ARINC 629 cards in each EEU. The ARINC 629 cards transmit and receive data across the airplane systems ARINC 629 buses. One card is for the left systems bus and the other for the right systems bus. The ARINC 629 cards have a blue removal handle.

DC Subsystem

There is one dc subsystem card. It is in the P310 EEU. The dc subsystem card controls and monitors the airplane dc system. The dc subsystem card has a green removal handle.

Special Function

There is one special function card. It is in the P310 EEU. The special function card controls the interface between special external signals and the CPUs such as the battery and TRU current sensors and the cabin pressure sensor. The special function card has a black removal handle.

Input/Output (I/O)

There are six I/O cards in each EEU. There are expansion slots for additional I/O cards if they become necessary. P310 uses I/O-1 cards. P110 and P210 use I/O-2 cards. The I/O cards control the interface between external signals and the CPUs. The I/O-2 cards have a special loadshed function for the hydraulic ac motor pumps that the I/O-1 cards do not. All the I/O cards have yellow removal handles.

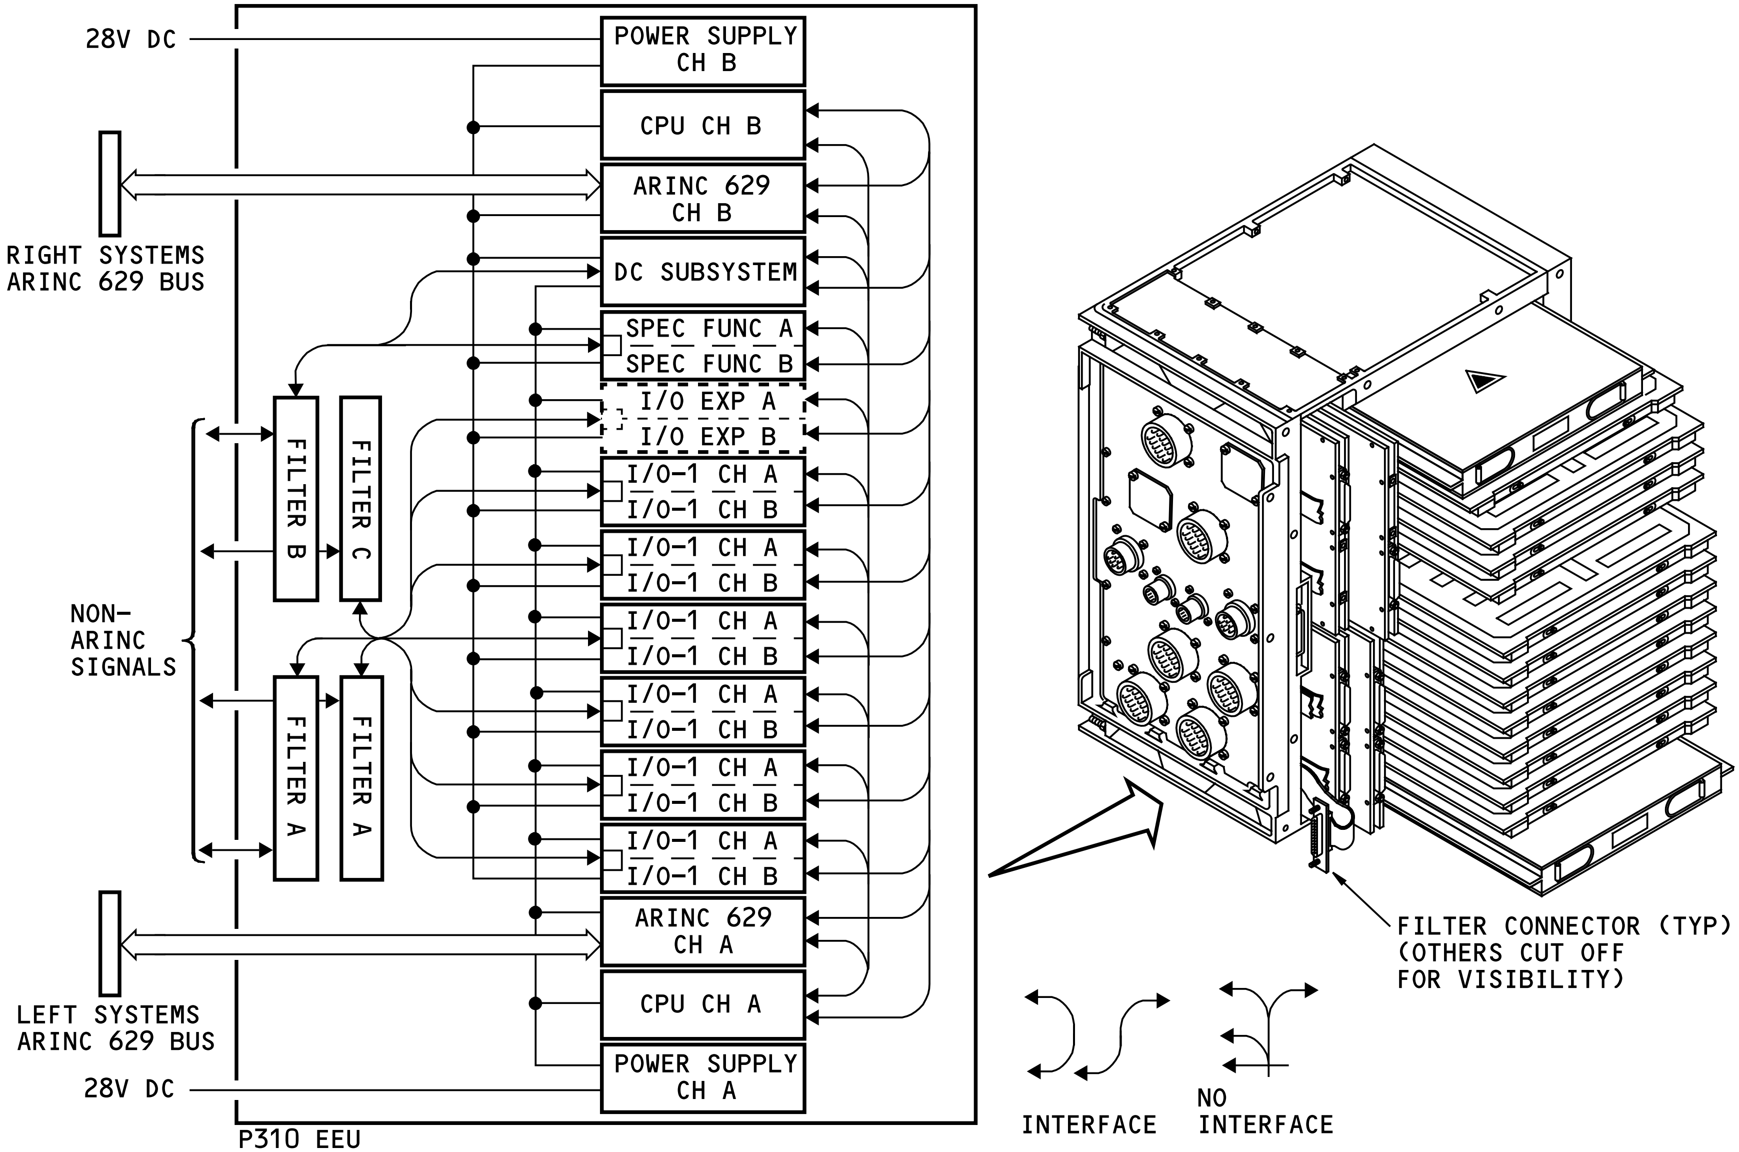
Filters

There are three filter cards in each EEU; filter A (2) and filter C. P310 has an additional fourth card; filter B. The filter cards remove noise from the signals to and from the EEU circuit cards. The filter cards have no colored removal handle.

The filter A and filter C cards remove noise from the signals to and from the I/O cards. The filter B card removes noise from the signals to and from the dc subsystem and special function cards.

Training Information Point

The EEU and its circuit cards are ESDS components. You must use a wrist strap to remove an EEU or any of its circuit cards.



ELMS - FUNCTIONAL DESCRIPTION - EEU

ELMS - FUNCTIONAL DESCRIPTION - EEU POWER

General

The ELMS power management panels operate with 28v dc power. Each power management panel has two power supply units (PSU) to control the power. The PSUs are circuit cards in the EEU. Two different dc power sources supply power to each PSU.

P110

The left power management panel gets power from the left and right dc buses.

P210

The right power management panel gets power from the left and right dc buses.

P310

The standby power management panel gets power from the battery #2 bus and the hot battery bus. The hot battery bus can supply power to P310 when any of these conditions occur:

- Battery switch is on
- Airplane is in the air
- RAT is deployed
- Refuel panel door is open.

The hot battery bus supplies control power to all of the relays that connect hot battery bus power to the P310 EEU.

Start Power Control

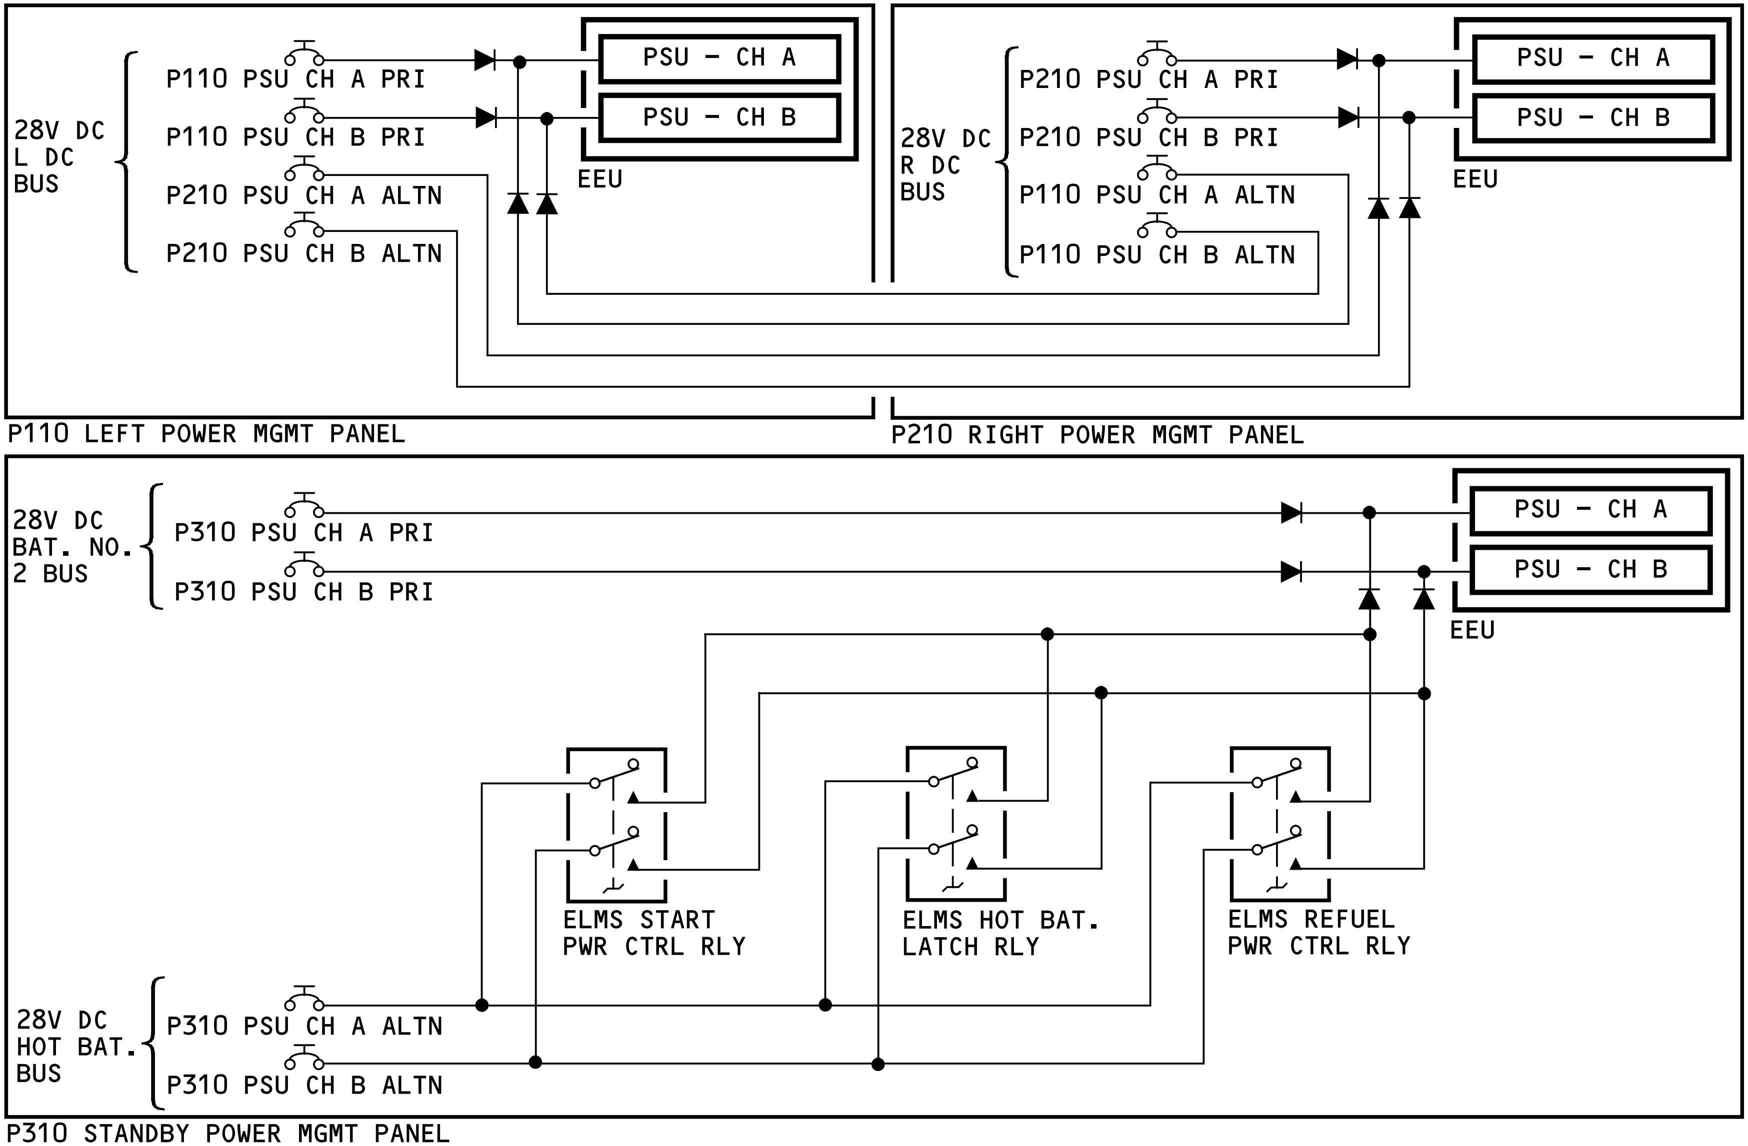
When the airplane has no power and you push the battery switch on, the ELMS start power control relay energizes. This supplies power to the P310 EEU so that it can energize the ground power battery relay. The ground power battery relay connects the hot battery bus to the battery No. 2 bus.

Hot Battery Latch

When the airplane is in the air or the RAT deploys, the hot battery latch relay energizes. This makes sure that the P310 EEU has power to control standby power operations even if the battery switch receives damage.

Refuel Power Control

When the integrated refuel panel door is open, the refuel power control relay energizes. This supplies power to the P310 EEU so that it can control the refuel valves.



ELMS - FUNCTIONAL DESCRIPTION - EEU POWER

ELMS - FUNCTIONAL DESCRIPTION - CONTROL

General

In addition to the distribution of electrical power, the ELMS also controls the switching of many electrical loads.

Control

Switching devices control the flow of electrical power to electrical loads. The ELMS controls these devices in one of these three ways:

- EEU control
- External control
- Remote control.

For EEU control, the EEUs receive control signal inputs. EEU software decides when the switching device should operate. The EEUs then directly control the power switching device.

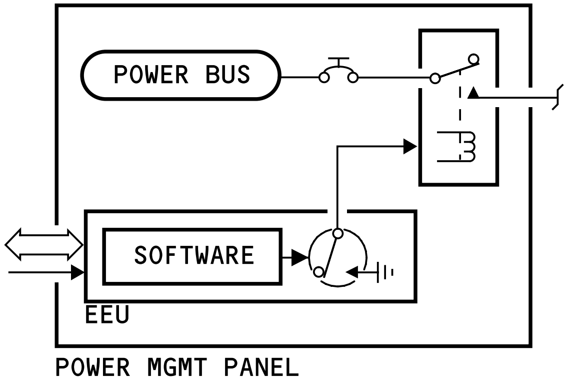
Other systems, external to the ELMS, also control switching devices in the ELMS panels. In these cases the ELMS has no control over the switching device.

For remote control, the EEUs control switching devices that are not in the power management panels. The EEUs supply a control signal that is either a ground for a remote relay or a logic discrete for a control unit.

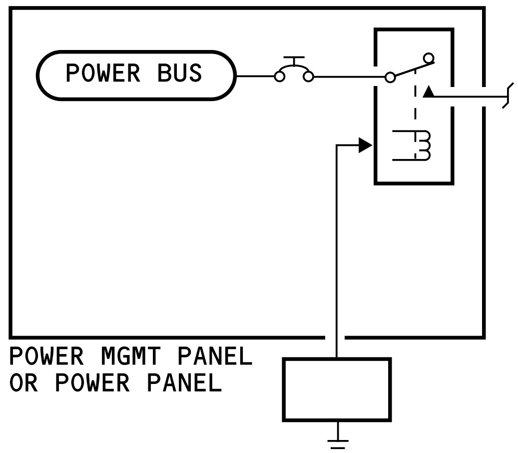
Software

The EEU control software for a switching device can be simple or complex. For some devices, the software just repeats a command input with no processing. For other devices, the software requires many inputs and does much processing.

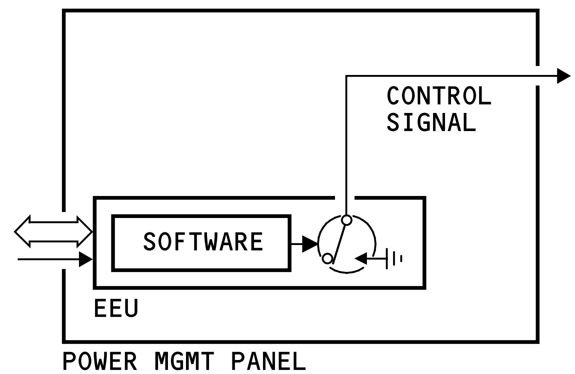
The software of the EEUs is data loadable.



EEU CONTROL



EXTERNAL CONTROL



REMOTE CONTROL

24-09-00-011 Rev 2 03/18/96

ELMS - FUNCTIONAL DESCRIPTION - CONTROL

ELMS - FUNCTIONAL DESCRIPTION - MONITORING

General

In addition to the distribution of electrical power, the ELMS also monitors the status of the power to many electrical loads for control purposes.

Monitor

The EEUs monitor electrical loads in several different ways. The EEUs can use different combinations of these ways to monitor the electrical loads:

- Bus voltage
- Circuit breaker position
- Relay position by voltage (option A)
- Relay position by ground (option B)
- Load current
- Analog discrete signal.

The EEUs use this load data to control the loads and to report faults. The EEUs also supply external control units with load data.

Bus Status

The EEUs monitor the power on buses by sensing the bus voltage. This is done with a voltage sensor (V SEN).

Bus/CB Status

The EEUs monitor the position of circuit breakers by sensing the voltage downstream of the circuit breaker. This is done with a circuit breaker monitor (CB MON).

Bus/CB/Relay Status - Opt A

Additionally, the EEUs can monitor the position of relays by sensing the voltage downstream of the relay contact. The signal conditioning module (SCM) makes the signal satisfactory for the EEU.

Bus/CB/Relay Status - Opt B

The EEUs sometime use an alternative to option A by sensing a ground (or power) through one contact of the relay. The SCM makes the signal satisfactory for the EEU.

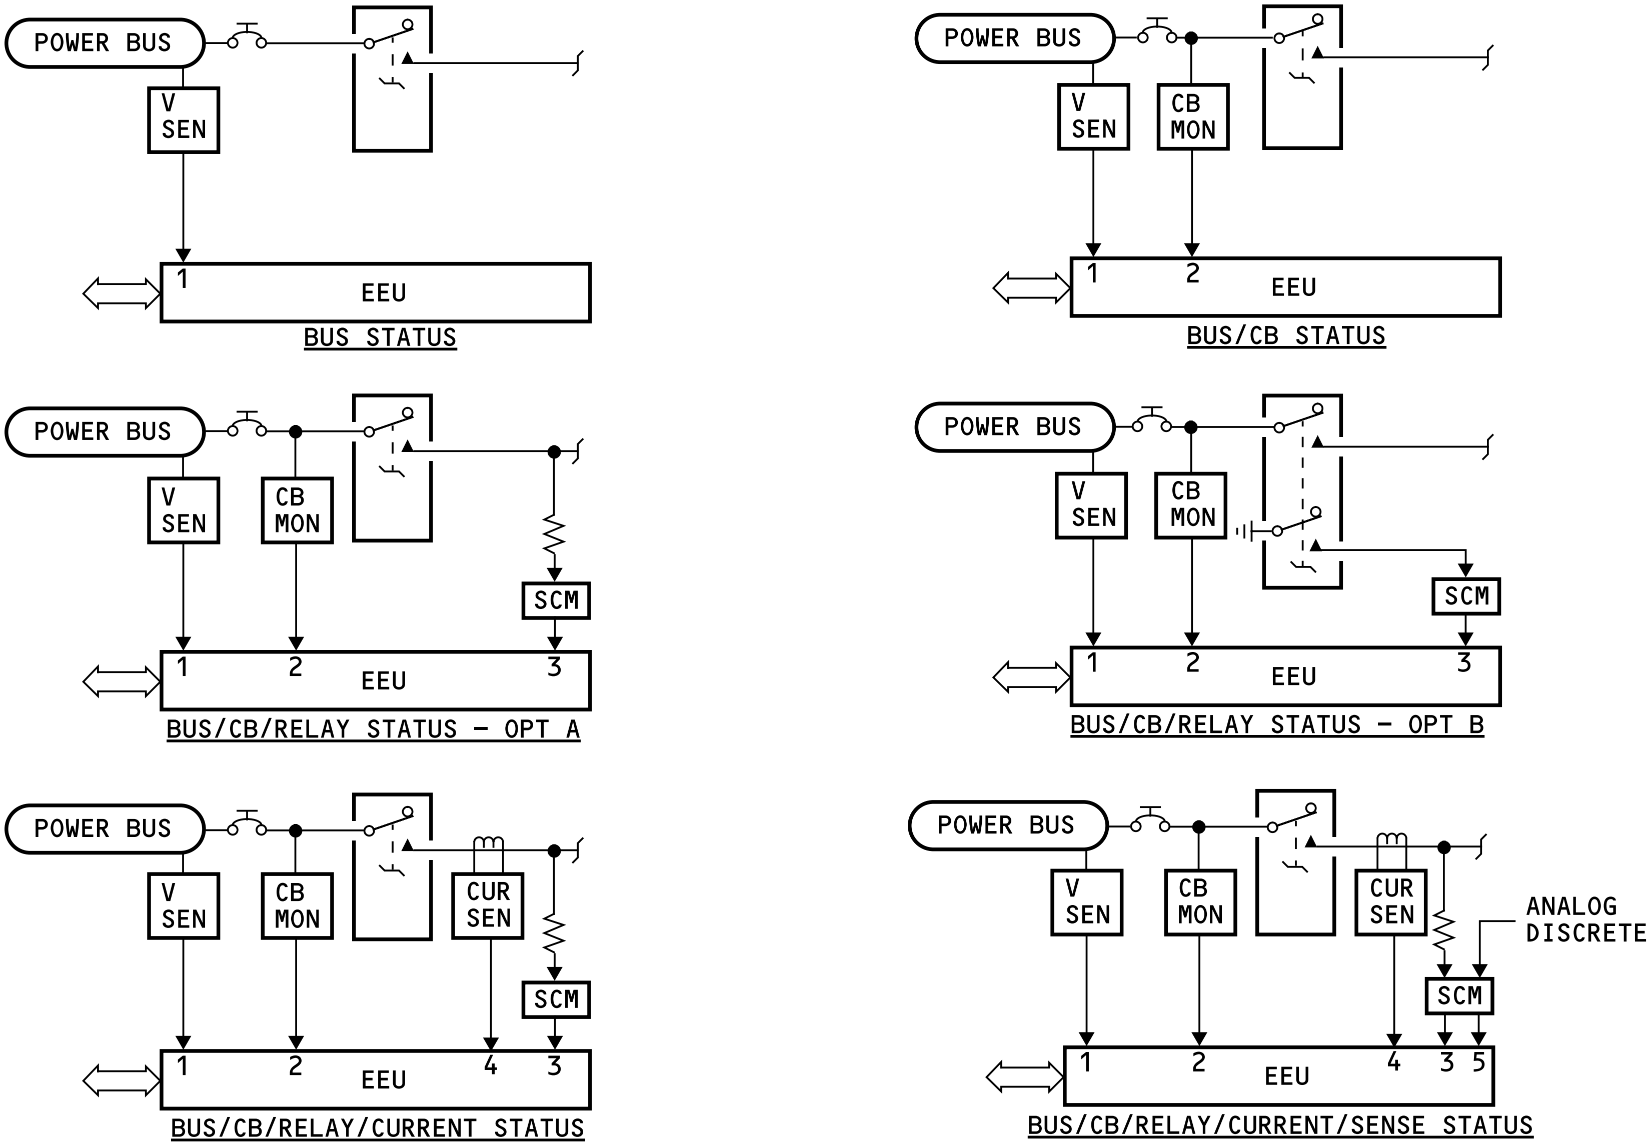
Bus/CB/Relay/Current Status

The EEUs can also monitor load current with a current sensor (CUR SEN).

Bus/CB/Relay/Current/Sense Status

In addition to the above, the EEUs can monitor load status with an analog discrete supplied by the load. The SCM makes the signal satisfactory for the EEU.

NOTE: These are examples. They only show, in increasing complexity, ways the ELMS can monitor electrical loads. The ELMS may not use some of these combinations.



ELMS - FUNCTIONAL DESCRIPTION - MONITORING

ELMS - FUNCTIONAL DESCRIPTION - LOAD SHEDDING - 1

THIS PAGE INTENTIONALLY LEFT BLANK

ELMS - FUNCTIONAL DESCRIPTION - LOAD SHEDDING - 1

General

The ELMS protects the electrical power system. It sheds (disconnects) electrical loads to keep the load levels below the power supply levels.

Power Sources

The ELMs monitors the status of these five power sources for load shed control:

- Left IDG (120 kva)
- APU generator (120 kva)
- Secondary external power (90 kva)
- Primary external power (90 kva)
- Right IDG (120 kva).

The ELMS does not monitor the backup generators for load shed control.

The GCUs and the BPCU digitally supply the ELMS with the power source status information. The ELMS also monitors the status of the power sources with hard-wired signals (configuration load shed signals). These signals come from circuits that go through the auxiliary contacts of the breakers and contactors in the power panels.

Load Shed Control

The EEUs in the P110 left power management panel and the P210 right power management panel control load shedding. P110 and P210 can shed loads independently or operate together (interpanel operation). If two power sources supply power to the airplane, the panels operate independently. If only one power source supplies power to the airplane, the panels operate together.

Independent Operation

If two power sources supply power to the airplane, P110 controls left side load shedding, and P210 controls right side load shedding. These are the loads that the ELMS can shed and the general sequence it sheds them:

- Galley loads
- Utility buses
- Equipment cooling vent fan
- Galley chillers
- Recirculation fans
- Lavatory/galley fans
- Electronic seat equipment
- Hydraulic pumps.

During independent operation, more important loads on one side can be shed while less important loads on the other side remain.

When you use external power, the ELMS reverses the load shed sequence for hydraulic pumps and electronic seat equipment.

ELMS - FUNCTIONAL DESCRIPTION - LOAD SHEDDING - 1

Interpanel Operation

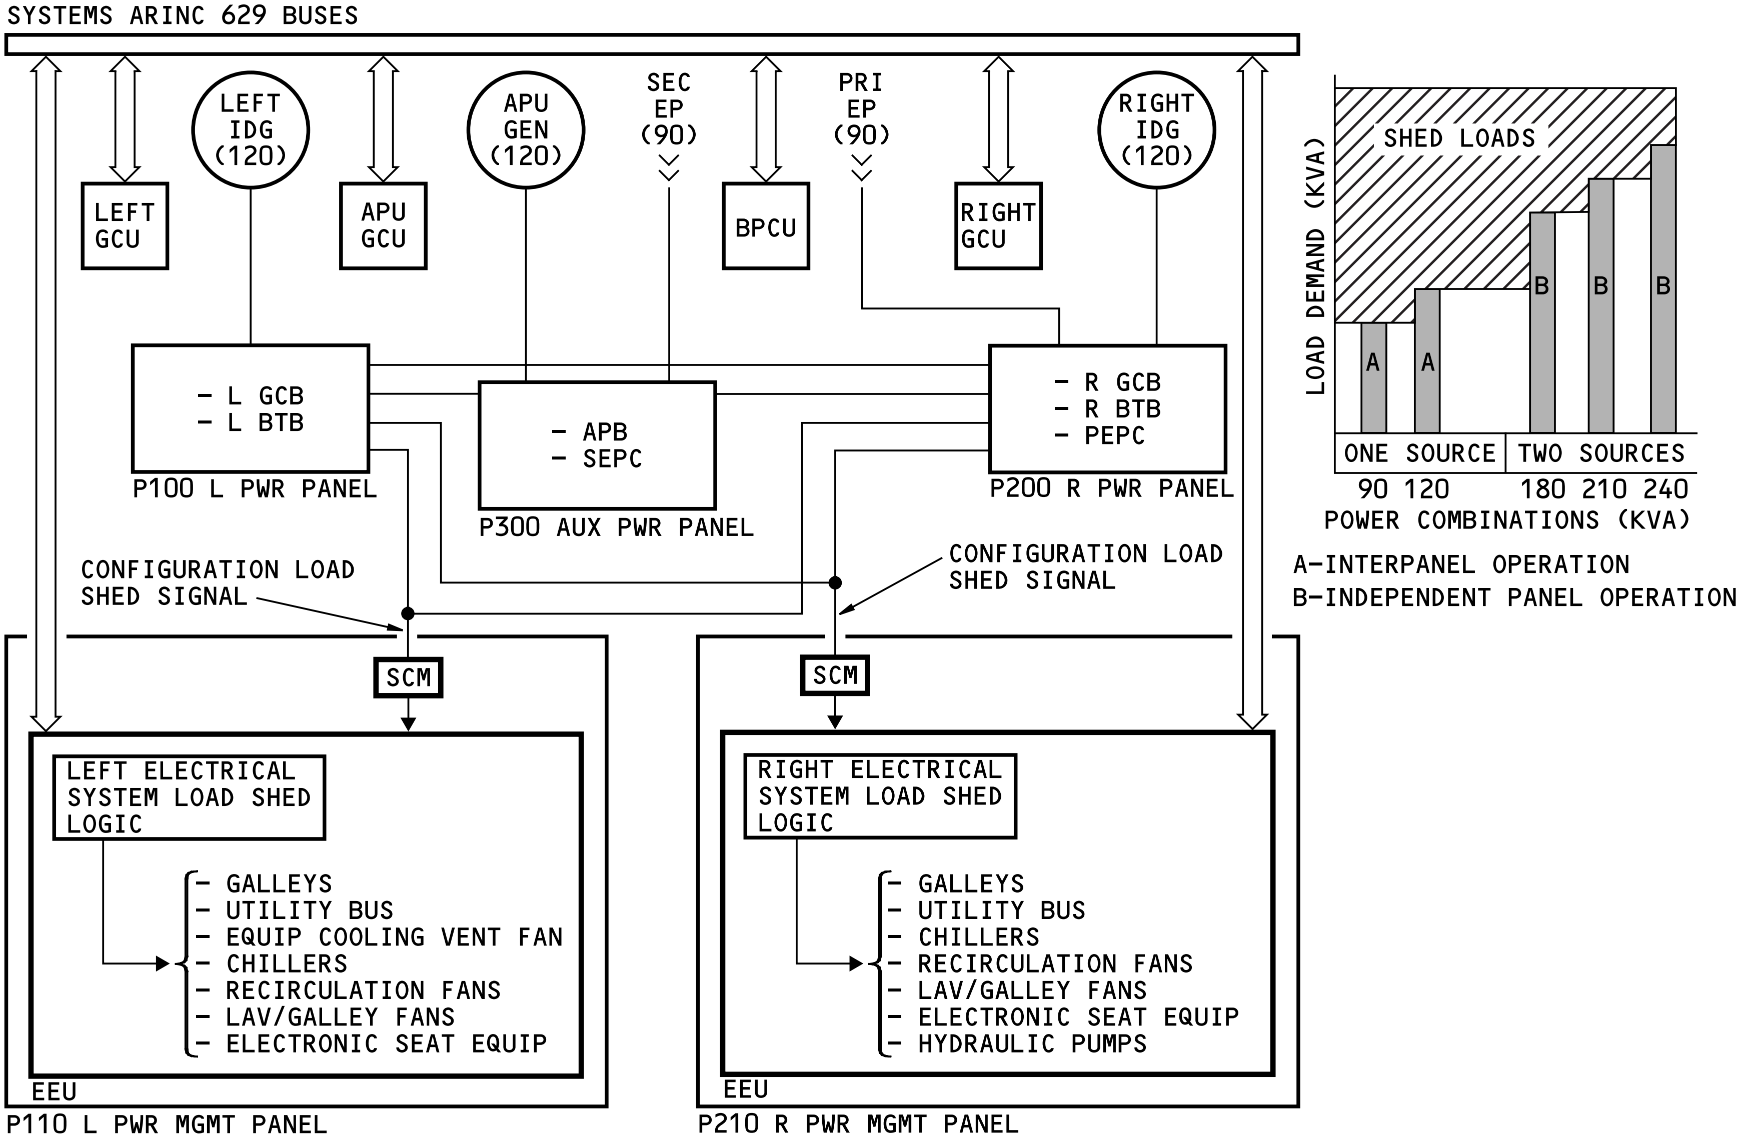
If only one power source supplies power to the airplane, P110 and P210 control load shedding together. They use a combined load shed sequence so that all the less important loads shed first and all the most important loads shed last.

Load Shed Limits

Since the power sources can supply different levels of power, there are several load shed limits. These are the conditions that define the load shed limits:

- Power source configuration
- Value of the overload
- Sustained time of the overload.

The ELMS gets load level data from the GCUs and BPCU across the systems ARINC 629 data buses.



ELMS - FUNCTIONAL DESCRIPTION - LOAD SHEDDING - 1

ELMS - FUNCTIONAL DESCRIPTION - LOAD SHEDDING - 2

Configuration Load Shed

A change in the source(s) of power for the airplane is called a change in the power source configuration. If the configuration change will result in a lower power supply capacity, the ELMS quickly sheds specified loads. This protects the new power source from overloading. The normal computer processing time does not occur fast enough to adequately do this function. Configuration load shed logic uses a hard-wired signal from the power management panel through auxiliary contacts in the BTBs, GCBs, APB, and EPCs to quickly detect a power source configuration change.

Configuration load shed logic sheds loads in groups. If the ELMS needs to shed more loads, it uses its normal computer processing.

Sequential Load Shed

If there is a large overload not due to a power source change , the ELMS sheds loads in groups like a configuration load shed.

If an overload is not large, the ELMS sheds individual loads until the electrical load demand level is below the available power supply level.

The ELMS sheds all loads on a main bus for these conditions:

- There is no power on the bus for over 2.5 seconds
- A failure of interpanel operations
- Loss of load level data from the GCUs and BPCU.

Load Restoration

After a load shed occurs, the ELMS adds loads in the reverse sequence they were shed. The ELMS continues to add loads until the electrical load demand level would exceed the available power supply level.

The ELMS staggers the starting of the hydraulic ac motor pumps.

After a configuration load shed, loads do not come back on for approximately 3 seconds.

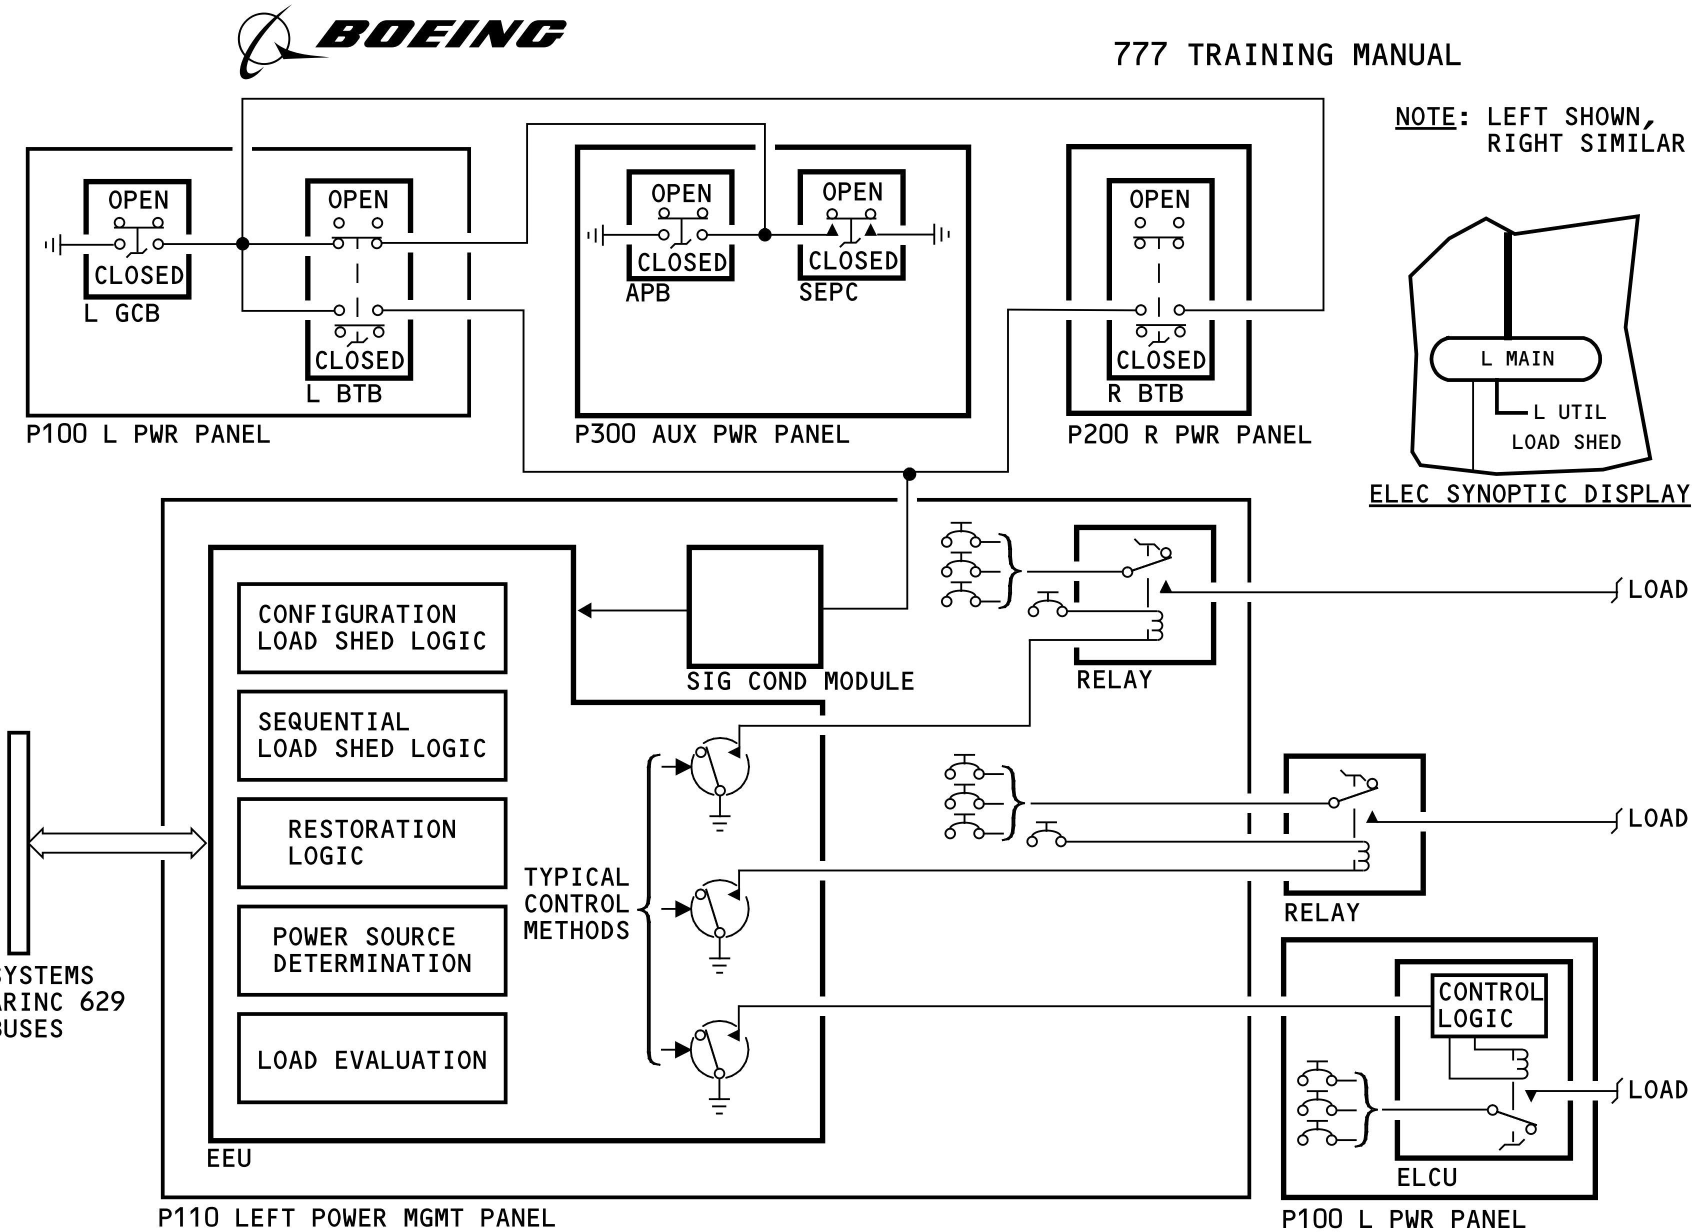
Failure of interpanel operations, prevents any load restoration.

Indication

When the ELMS does a load shed, the message LOAD SHED shows on the electrical power synoptic display below the utility bus indication for the related channel.

Training Information Point

If you use an external power source with less than a 90 kva capacity at an external power receptacle, the ELMS can possibly shed and restore all loads four times in about one minute. It then sheds all loads until you supply more power to the airplane.



ELMS - FUNCTIONAL DESCRIPTION - LOAD SHEDDING - 2

ELMS - SPECIAL FUNCTION TESTS

General

There is one special function test for each power management panel. These are the special function tests:

- Initiate P110 EU self test
- Initiate P210 EU self test
- Initiate P310 EU self test.

Initiate P110 EU Self Test

This test makes sure that all circuit cards in the P110 electronics unit operate correctly.

Initiate P210 EU Self Test

This test makes sure that all circuit cards in the P210 electronics unit operate correctly.

Initiate P310 EU Self Test

This test makes sure that all circuit cards in the P310 electronics unit operate correctly.

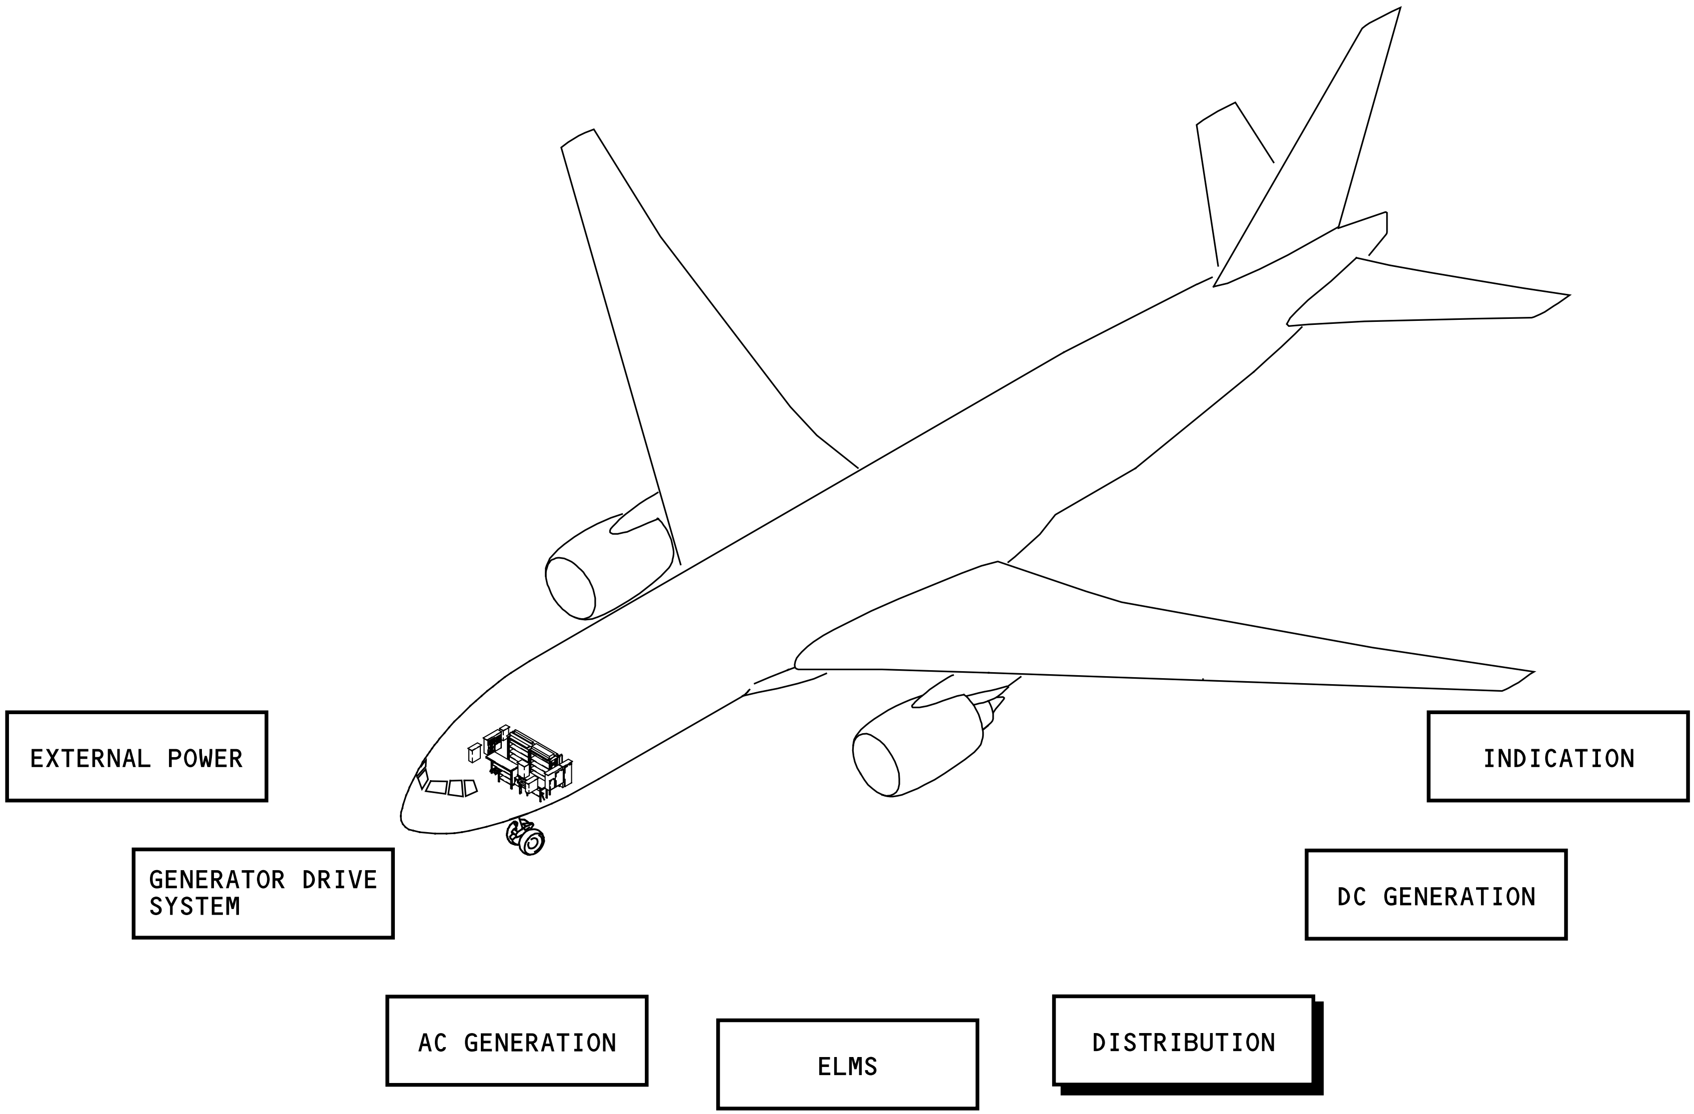
ELMS - SPECIAL FUNCTION TESTS

AC DISTRIBUTION - INTRODUCTION

General

The distribution section of electrical power includes both ac and dc power distribution.



AC DISTRIBUTION - INTRODUCTION

AC DISTRIBUTION - GENERAL DESCRIPTION

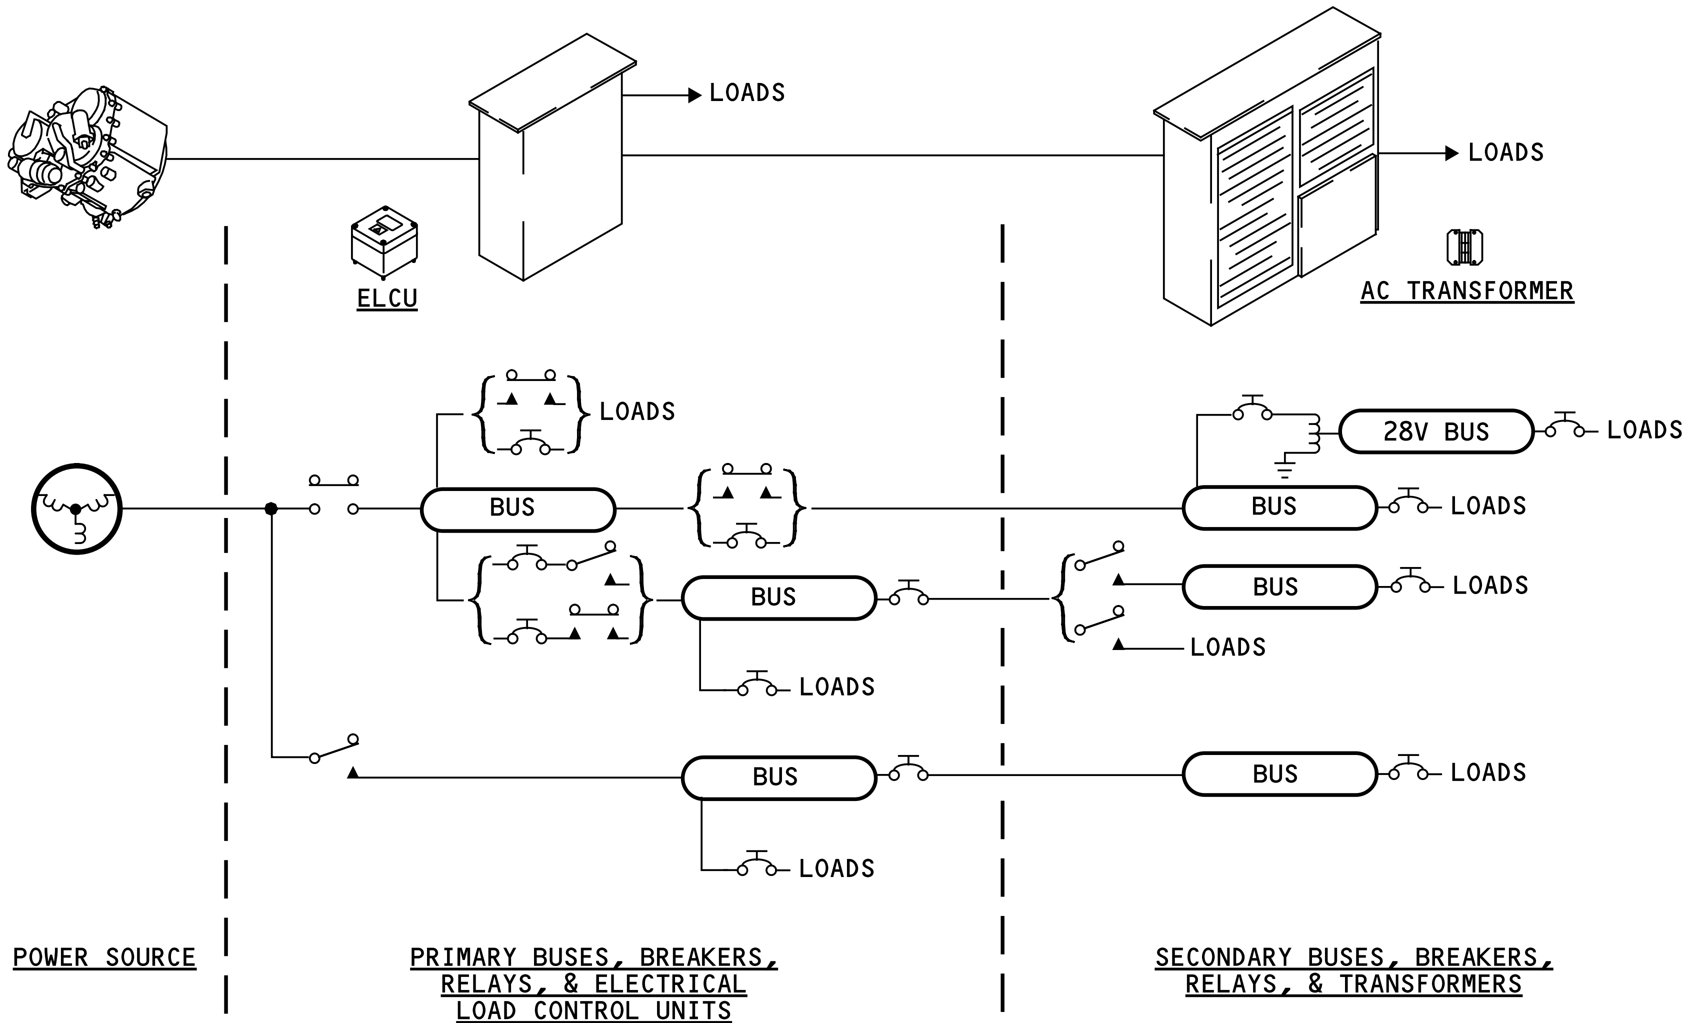
General

The ac distribution system divides the electrical power ac buses into sections. This permits better control over small groups of electrical loads. It also protects against a severe loss of power due to a single electrical power failure.

These are the only components in the ac distribution system:

- Electrical load control units (ELCU)
- 28v ac transformers.

A primary function of the ac distribution system is autoland bus isolation.



24-50-00-002 Rev 1

AC DISTRIBUTION - GENERAL DESCRIPTION

AC DISTRIBUTION - ELECTRICAL LOAD CONTROL UNIT

General

The ELCUs control and protect the electrical power supplied to large ac loads. There are several ELCUs in the P100 and P200 power panels.

Physical Description

The ELCUs are LRMs of the ELMS power panels. The ELCUs contain these parts:

- Current transformers
- Contactor
- Power supply
- Control logic.

The ELCUs are ESDS components because of the wiring connections to the control logic.

Control

The ELCUs use these things to control their contactors:

- Current transformers
- Rating jumper
- Input command.

The ELCU current transformers supply signals to the control logic for overcurrent and differential fault protection. The load current transformer signal supplies the second current signal necessary for differential fault protection. The control logic does not use the differential fault protection function if there is no load current transformer connected to the ELCU.

A rating jumper (external wiring) across pins of galley ELCU power panel wiring connectors sets the current capacity of the ELCUs.

A control signal to the ELCU causes it to open or close. The control signal comes from the ELMS or other airplane systems.

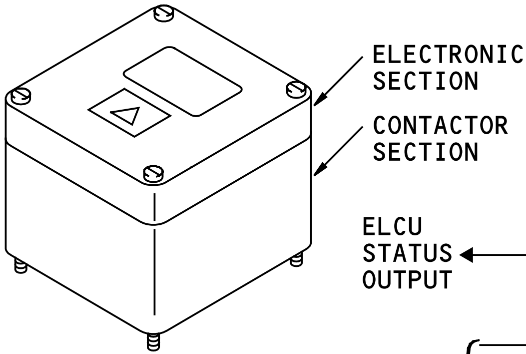
Operation

The ELCU contactor connects ac power to the load when the control inputs satisfy the control logic.

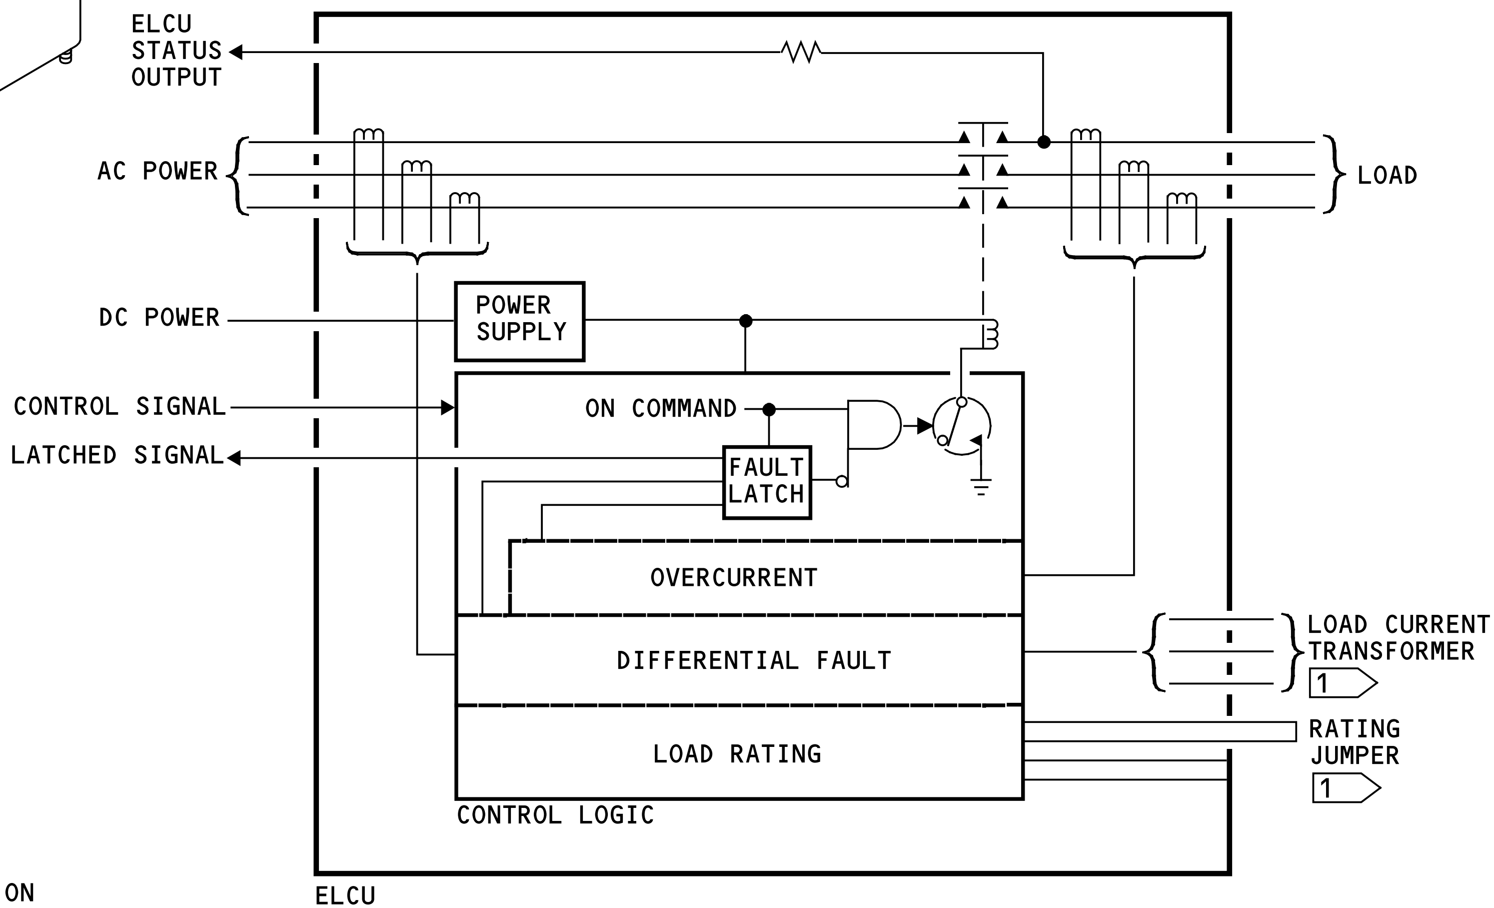
When the ELCU closes, a voltage signal goes to the ELMS for ELCU status monitoring. If the ELCU opens due to a fault, it latches open and sends a latched open signal to the ELMS. The ELCU is reset when the control signal goes off and then back on or when you remove dc power to the ELCU.

Training Information Point

Each ELCU is a two-piece unit. Do not disassemble it. The mounting screws are captive, but can be unscrewed from the ELCU housing. With the screws removed the electronic section can move apart from the contactor section for shop repair.



ELCU



1 NOT USED ON ALL ELCUS

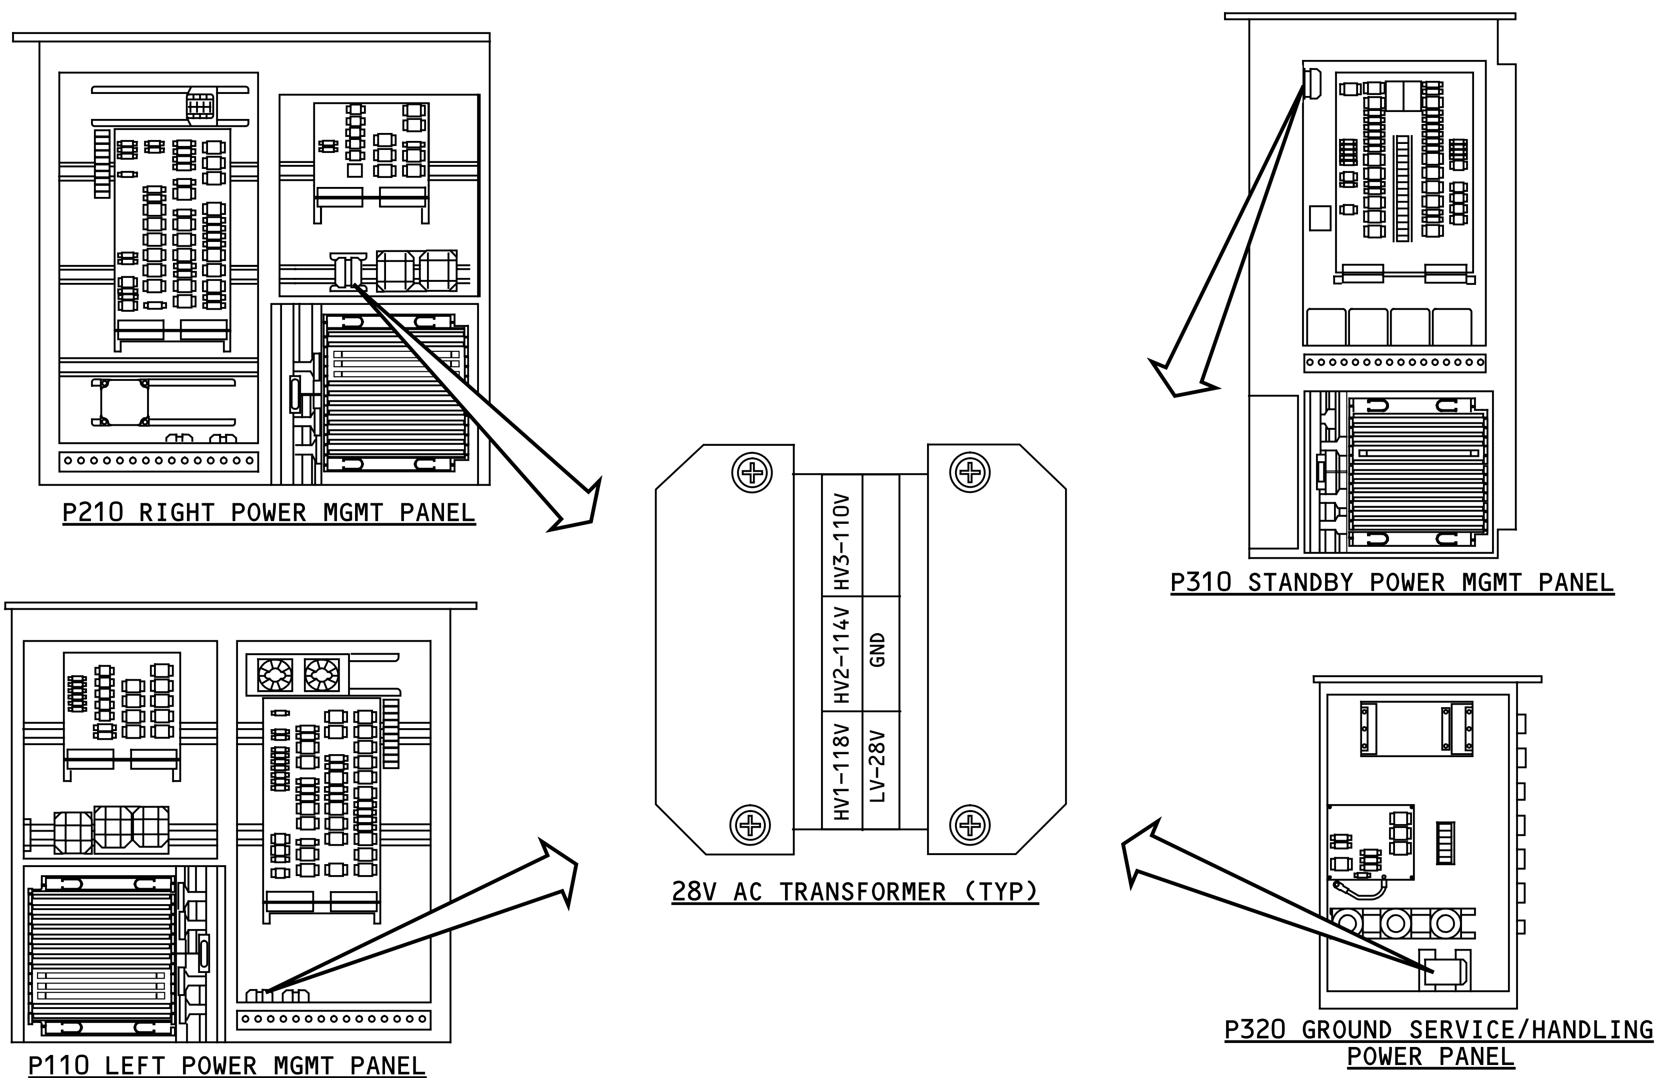
AC DISTRIBUTION - ELECTRICAL LOAD CONTROL UNIT

AC DISTRIBUTION - 28V AC TRANSFORMERS

General

The 28v ac transformers convert 115v ac power into 28v ac power. There are four transformers. They are in the ELMS power management panels and ground service/ handling power panel. These are typical loads for the 28v ac power:

- Signal conditioning card power supply
- Resolver excitation
- Sensor excitation
- Service lights.



24-50-00-004 Rev 1

AC DISTRIBUTION - 28V AC TRANSFORMERS

THIS PAGE INTENTIONALLY LEFT BLANK

AC DISTRIBUTION - FUNCTIONAL DESCRIPTION - POWER DISTRIBUTION

General

The ac distribution divides the electrical power buses into sections. The primary buses are in the ELMS power panels P100, P200, and P300. These are the primary buses of the electrical power ac system:

- Left main ac
- Left transfer
- Right main ac
- Right transfer
- Ground handling ac
- Ground service.

Left Main AC Bus

The left main ac bus divides into these buses:

- Left transfer
- Left utility
- Left section 1
- Left section 2.

The left section 1 bus supplies power to an ac transformer for the left 28v ac bus. The left section 2 bus is a P11 power source.

Left Transfer Bus

The left transfer bus divides into these:

- P11 supply
- Left transfer distribution bus
- Standby ac bus.

The standby ac bus supplies power to an ac transformer for the 28v ac standby bus.

Right Main AC Bus

The right main ac bus divides into these buses:

- Right transfer
- Right utility
- Right section 1
- Right section 2.

The right section 1 bus supplies power to an ac transformer for the right 28v ac bus. The right section 2 bus is a P11 power source.

Right Transfer Bus

The right transfer bus divides into these:

- P11 supply
- Right transfer distribution bus.

Ground Handling AC Bus

The ground handling ac bus supplies power to the ground handling distribution bus.

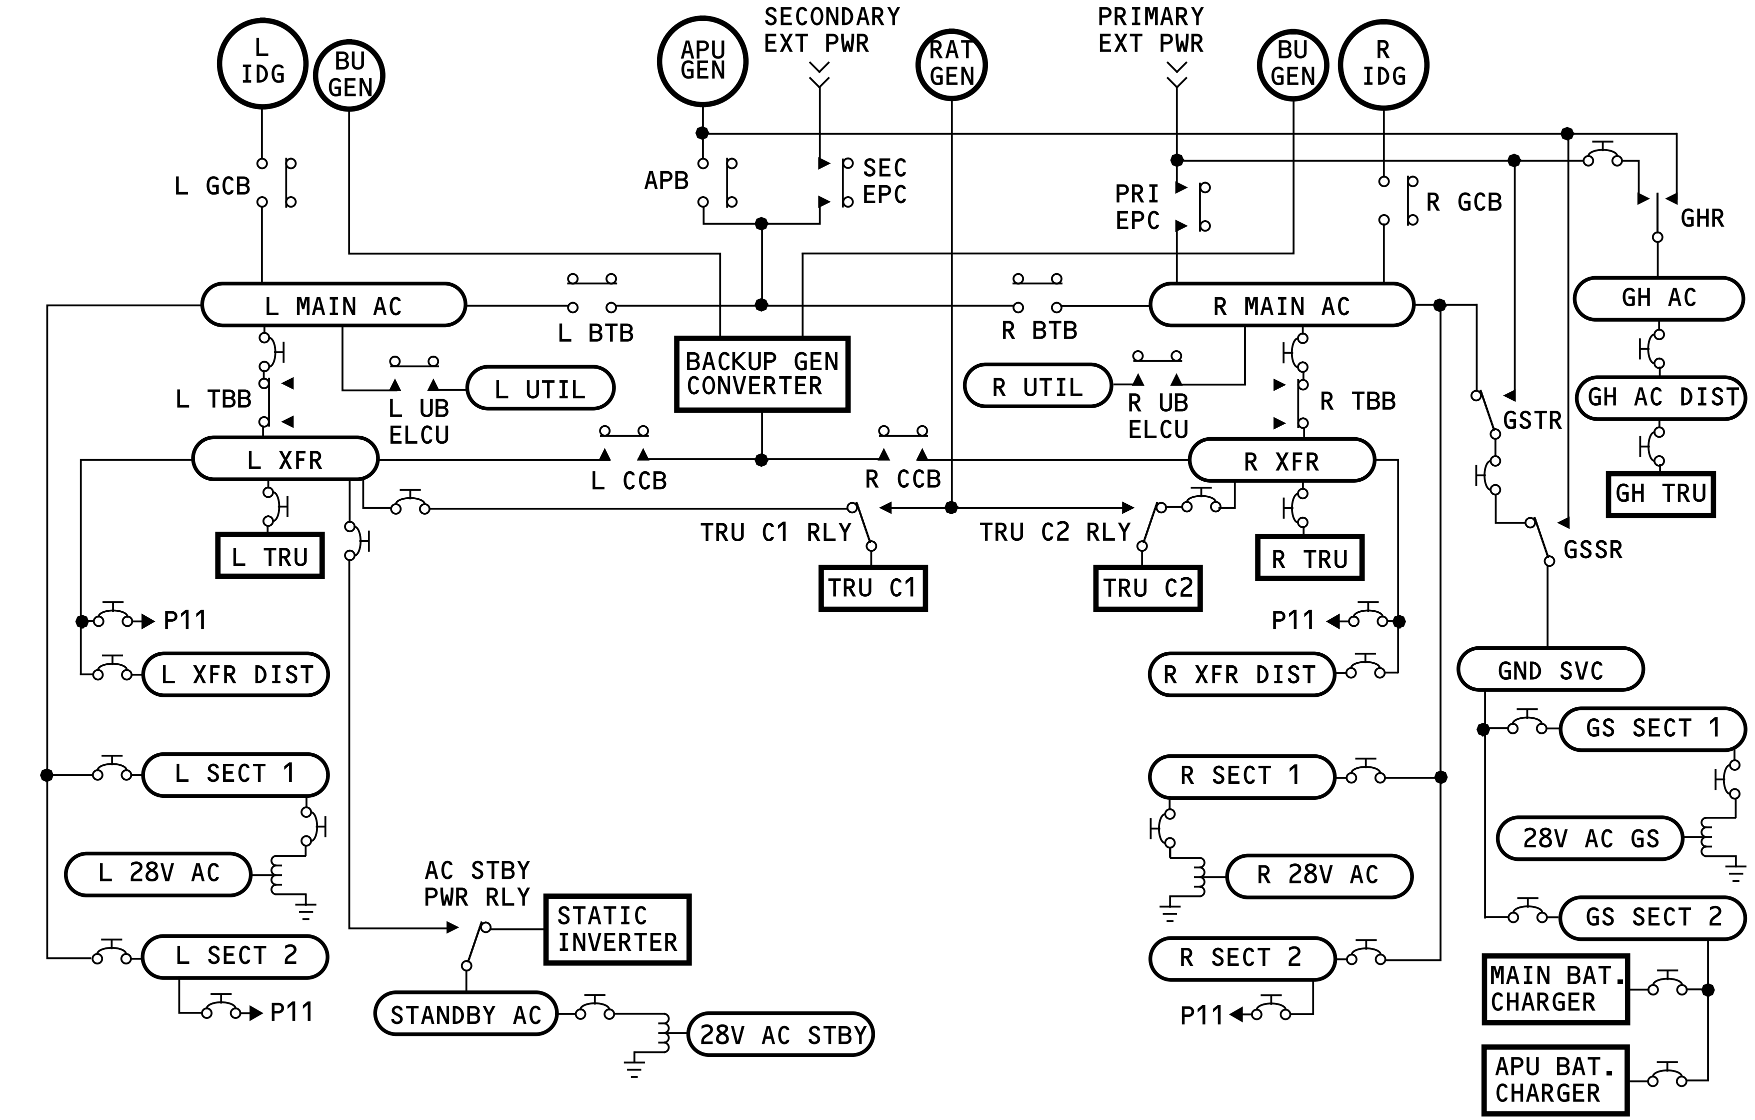
Ground Service Bus

The ground service bus divides into these buses:

AC DISTRIBUTION - FUNCTIONAL DESCRIPTION - POWER DISTRIBUTION

- Ground service section 1
- Ground service section 2.

The ground service section 1 bus supplies power to an ac transformer for the 28v ac ground service bus.



AC DISTRIBUTION - FUNCTIONAL DESCRIPTION - POWER DISTRIBUTION

AC DISTRIBUTION - FUNCTIONAL DESCRIPTION - AUTOLAND BUS ISOLATION INTERFACES

General

Autoland is an automatic flight director system (AFDS) mode. In this mode, the AFDS automatically lands the airplane.

During autoland, the electrical system divides into three different channels (bus isolation). This is to ensure that a single electrical power problem does not endanger the automatic landing.

Bus Isolation Process

The automatic flight director computers (AFDC) get an autoland request from pilot input. They send a bus isolation request signal on the systems ARINC 629 buses to these electrical power system components:

- ELMS
- BU generator converter
- GCUs.

Under normal conditions, the ELMS and the B/U generator converter divide the electrical system. The ELMS operates these components:

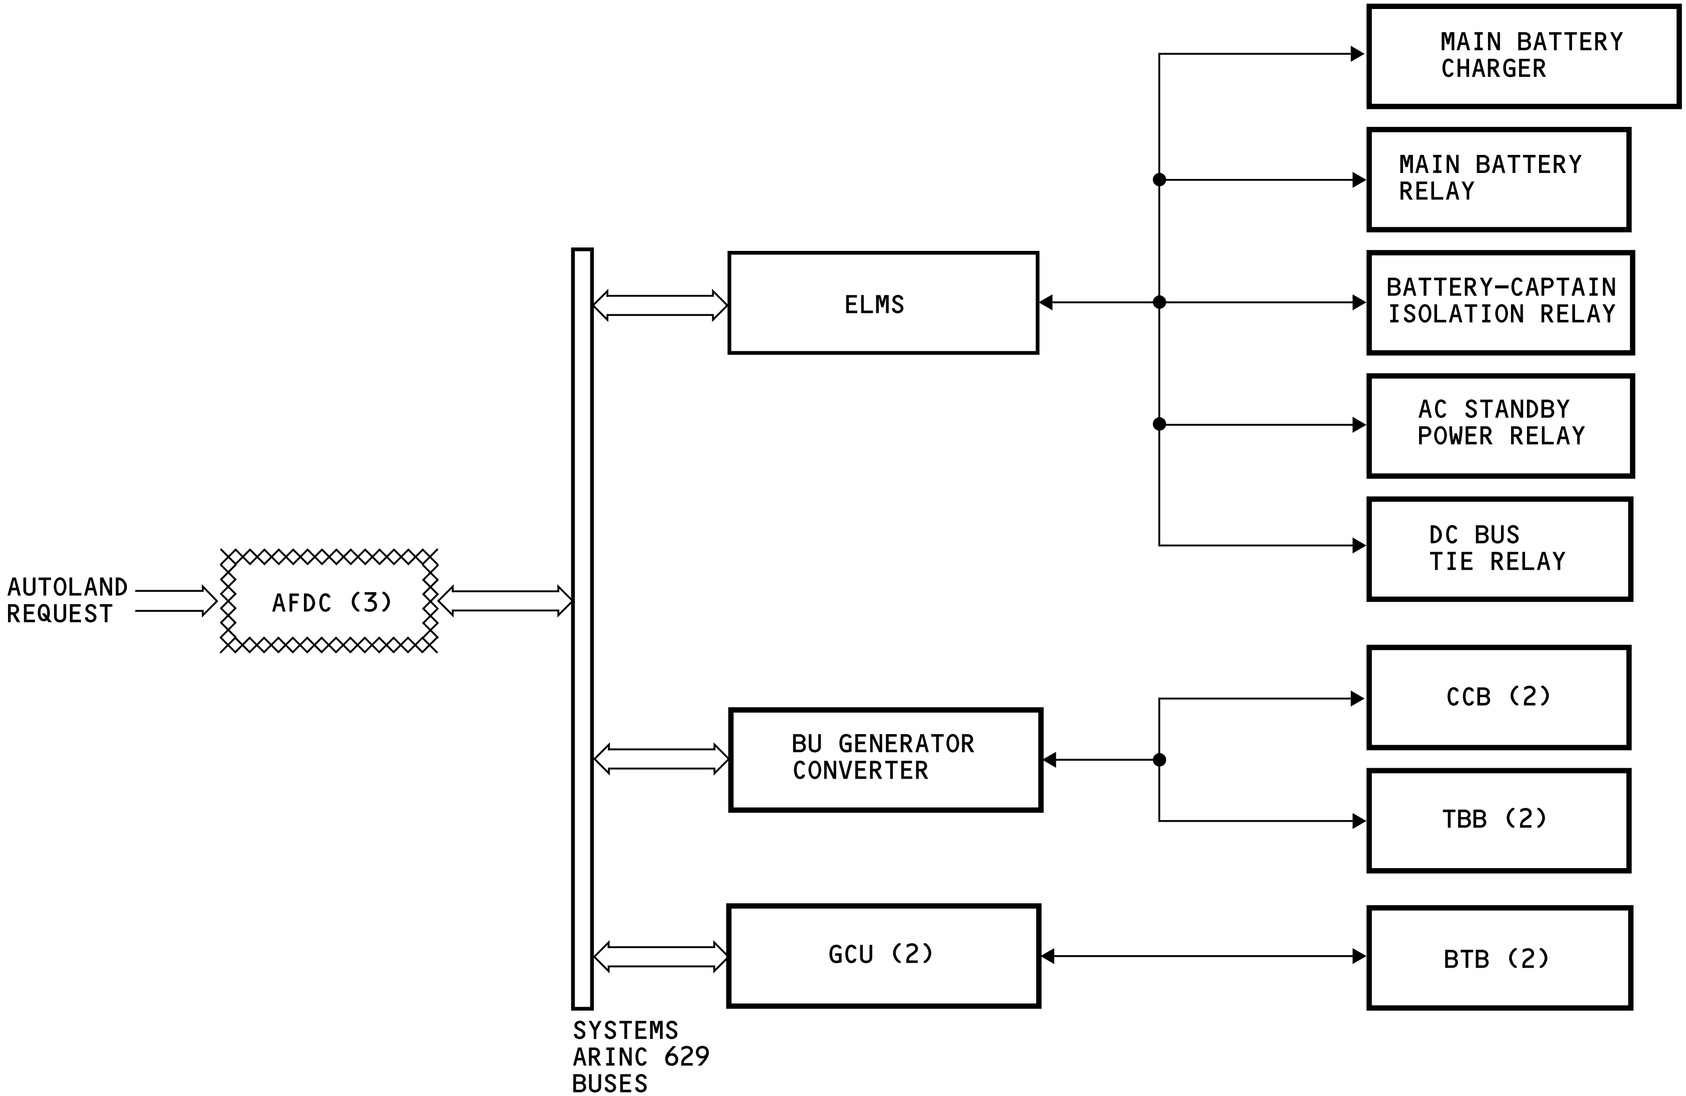
- Main battery charger
- Main battery relay
- Battery-captain isolation relay
- AC standby power relay
- DC bus tie relay.

The B/U generator converter operates the CCBs and TBBs.

When the bus isolation is complete, the B/U converter and the ELMS send autoland confirm signals to the AFDCs.

If the electrical power system is in a non-normal configuration before an autoland, other power configurations support the bus isolation. The GCUs then control part of the bus isolation.

If the electrical system cannot divide to support an autoland, the electrical control components send cannot-support-autoland signals to the AFDCs. The primary display system then shows a NO LAND 3 advisory message.



24-50-00-006 Rev 1

AC DISTRIBUTION - FUNCTIONAL DESCRIPTION - AUTOLAND BUS ISOLATION INTERFACES

AC DISTRIBUTION - FUNCTIONAL DESCRIPTION - NORMAL AUTOLAND BUS ISOLATION

General

When the electrical power system receives a bus isolation request signal from the AFDS, it divides into three different channels. This is to supply power to critical autoland components from different power sources. For normal autoland operations, these are the power sources for the three electrical power channels:

- Left IDG
- Right B/U generator
- Right IDG.

B/U Generator Converter Control

The B/U generator converter closes the right CCB to perform a no-break power transfer between the right B/U generator and the right transfer bus. The converter then opens the right TBB. The converter also prevents any operation of the left TBB and left CCB during autoland.

ELMS Control

The ELMS does these operations:

- Sends a signal to put the main battery charger into a TRU mode
- Closes the main battery relay
- Opens the battery-captain isolation relay
- De-energizes the ac standby power relay to connect the standby ac bus to the static inverter
- Prevents operation of the dc bus tie relay.

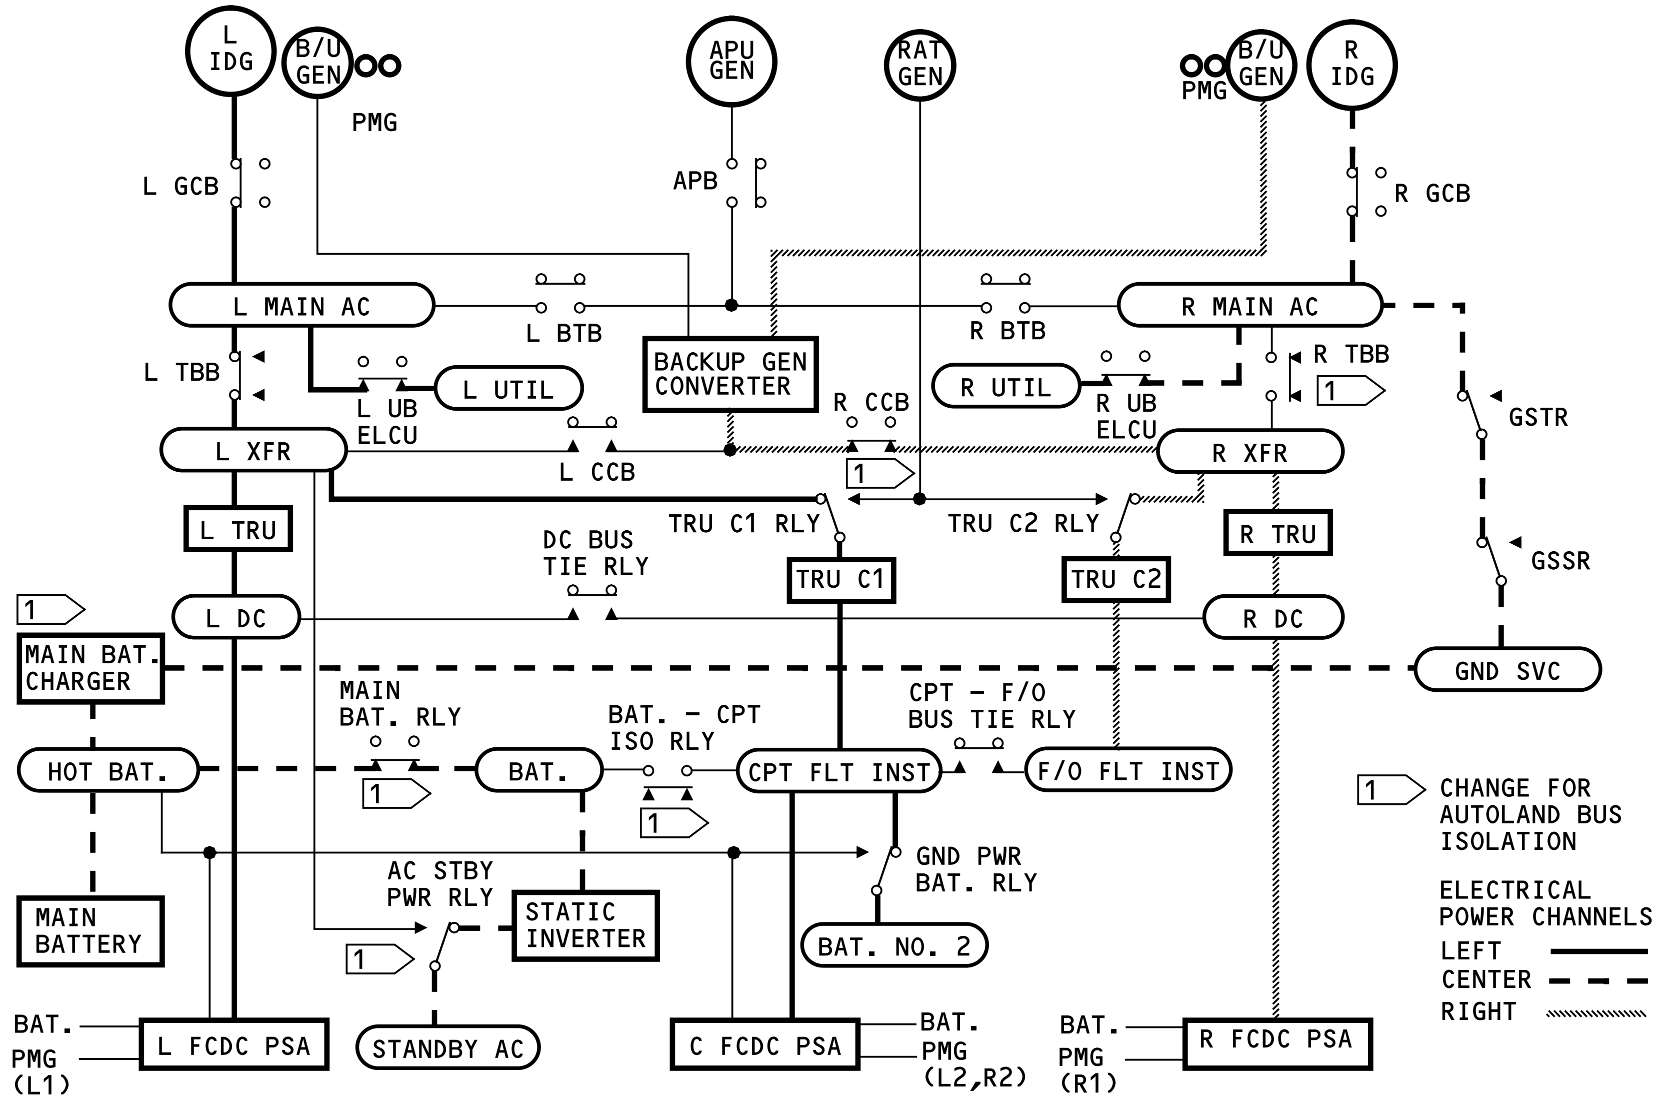
Autoland Components

There are three sets of critical autoland components; left, center, and right. These are the components in each set and their power requirements:

- Instrument landing system (ILS) (115v ac)
- Radio altimeter (115v ac)
- AFDC (28v dc)
- ILS antenna switch (28v dc).

During autoland bus isolation, the left set gets power from the left transfer bus and the left dc bus. The center gets power from the standby ac bus and the battery bus. The right set gets power from the right transfer bus and the right dc bus.

For more details on autoland, go to chapter 22.



24-50-00-007 Rev 0

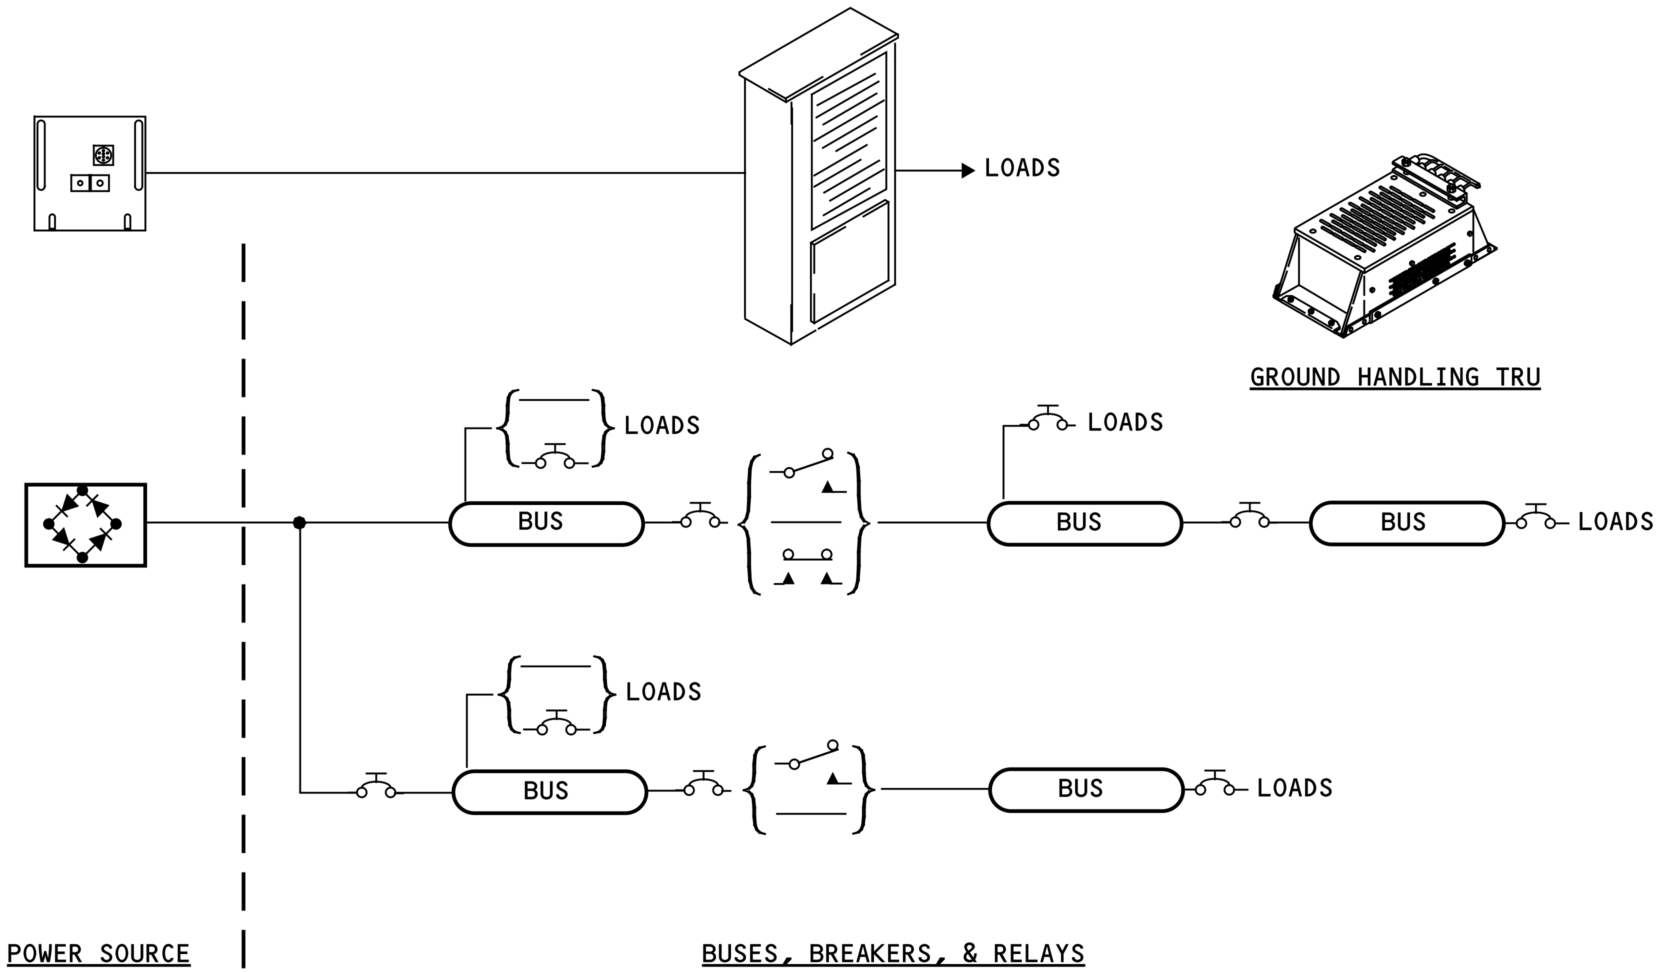
AC DISTRIBUTION - FUNCTIONAL DESCRIPTION - NORMAL AUTOLAND BUS ISOLATION

DC DISTRIBUTION - GENERAL DESCRIPTION

General

The dc distribution system divides the electrical power dc buses into sections. This permits better control over small groups of electrical loads. It also protects against a severe loss of power due to a single electrical power failure.

The ground handling TRU is the only component in the dc distribution system.



24-60-00-001 Rev 1

DC DISTRIBUTION - GENERAL DESCRIPTION

DC DISTRIBUTION - GROUND HANDLING TRU

General

The ground handling TRU is in the P320 ground service/ handling power panel. It converts ac power into 28v dc power. These are typical loads for the ground handling 28v dc power:

- Cargo handling
- Refuel valves
- Refuel quantity control/indication
- Service interphone
- Powered door opening system (engine cowls).

24-60-00-002 Rev 1 12/18/1995

GROUND HANDLING TRU

24-60-00-002 Rev 1

DC DISTRIBUTION - GROUND HANDLING TRU

DC DISTRIBUTION - FUNCTIONAL DESCRIPTION - POWER DISTRIBUTION

General

The dc distribution divides the electrical power dc buses into sections. The primary buses are in the ELMS power management panels P110, P210, and P310. These are the primary buses of the electrical power dc system:

- Hot battery
- Left dc
- Right dc
- Captain's flight instrument
- First officer's flight instrument.

The ground handling bus is in the P320 ground service/handling power panel. The APU battery bus is in the P49 APU panel.

Hot Battery Bus

The hot battery bus divides into these:

- P11 supply
- Hot battery distribution bus.

Left and Right DC Buses

The left and right dc buses do not divide. They do supply power to P11.

Captain's Flight Instrument Bus

The captain's flight instrument bus divides into these buses:

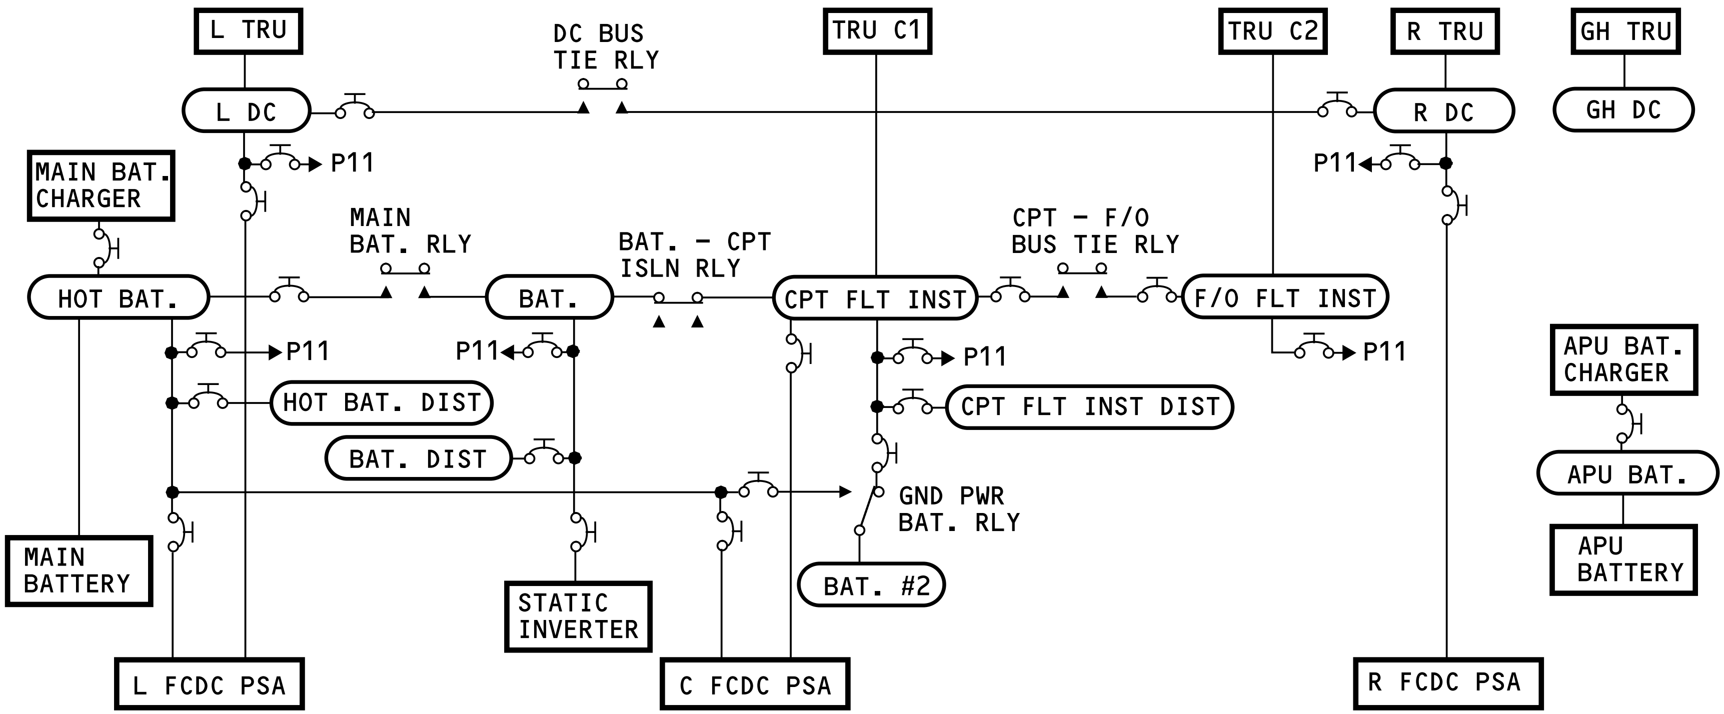
- Battery bus
- P11 supply
- Captain's flight instrument distribution bus
- Battery #2 bus.

The battery bus further divides into these:

- P11 supply
- Battery distribution bus.

First Officer's Flight Instrument Bus

The first officer's flight instrument bus does not divide. It does supply power to the P11.



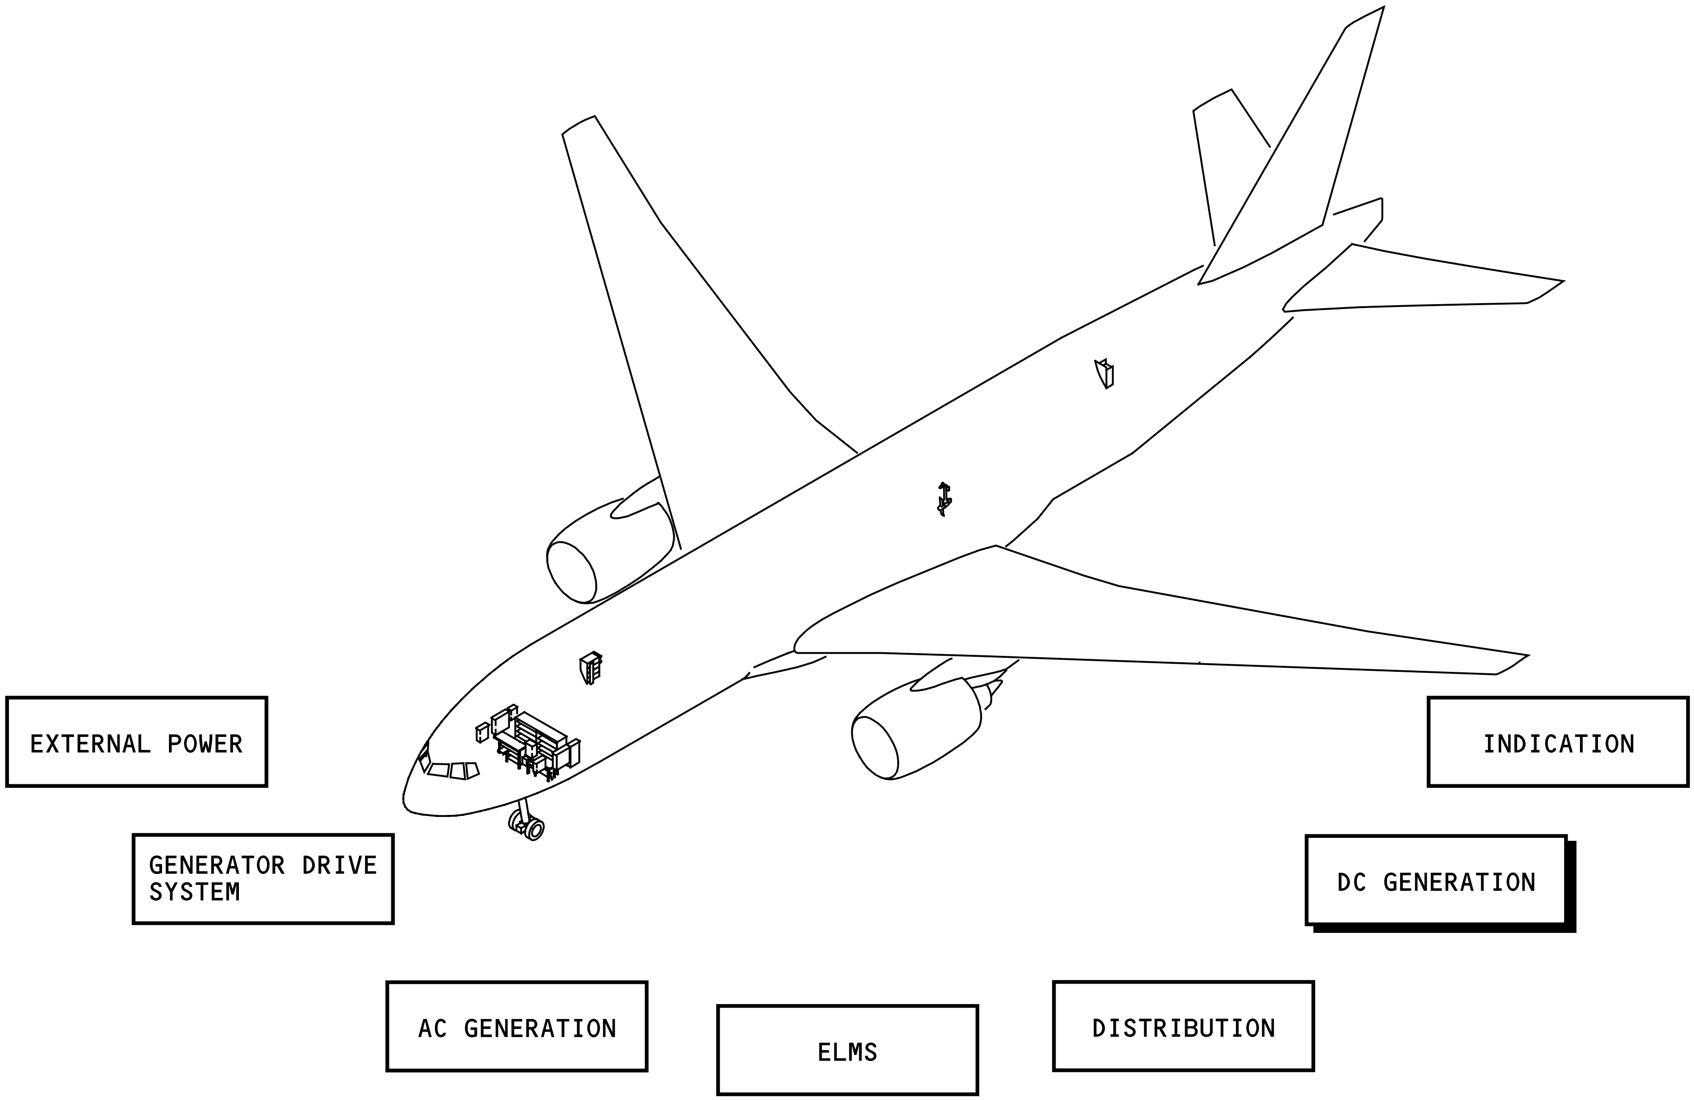
24-60-00-003 Rev 1 04/10/1997

DC DISTRIBUTION – FUNCTIONAL DESCRIPTION – POWER DISTRIBUTION

DC GENERATION - INTRODUCTION

General

The dc generation system changes ac power from the generators into dc power. It supplies power for dc loads and to charge the batteries. The batteries are an alternative power source for some loads when the generators do not operate.



DC GENERATION - INTRODUCTION

DC GENERATION - SUBSYSTEMS INTRODUCTION

General

The dc power system has these subsystems:

- Transformer rectifier units (TRUs)
- Batteries
- Standby power
- Flight controls dc (FCDC) power.

Transformer Rectifier Units (TRUs)

TRUs change ac power to dc power. There are four TRUs in the dc power system:

- Left
- Center 1 (C1)
- Center 2 (C2)
- Right.

Batteries

Batteries supply dc power to loads that require power when no ac power source is available.

Standby Power

Standby power supplies ac power and dc power to important systems when all normal ac power is lost. The RAT generator and the main battery are the sources of standby power.

TRUs change the RAT ac power to dc power. The static inverter changes dc power to ac power.

Flight Controls DC (FCDC) Power

Power supply assemblies (PSAs) supply power to the flight controls system. The related FCDC battery protects the PSA from power interruptions during power transfers.

Training Information Point

The external power system also has a TRU. The ground handling TRU supplies power to the ground handling bus. See the external power system section for more information (AMM PART I 24-40).

The right TRU is on the E2-2 shelf. The center FCDC battery is on the E2-5 shelf. The center PSA is on the E2-6 shelf.

E1 Rack

The left TRU is on the E1-1 shelf. The left FCDC battery and the left PSA are on the E1-6 shelf.

Standby Power Management Panel

These relays are in the P310 standby power management panel:

- TRU C1 relay
- TRU C2 relay
- Capt-F/O bus tie relay
- Main battery relay
- Bat-capt isolation relay
- Ground power relay
- AC standby control relay
- AC standby power relay
- RAT deploy relay.

RAT GCU

The RAT GCU is below the P310 standby power management panel.

DC GENERATION - COMPONENT LOCATIONS - RAT

TRU - GENERAL DESCRIPTION

General

Four TRUs change 115v ac power into 28v dc power to supply the main dc buses. The TRUs normally get power from the transfer buses. If the transfer buses have no power, the RAT generator supplies power to the two center TRUs.

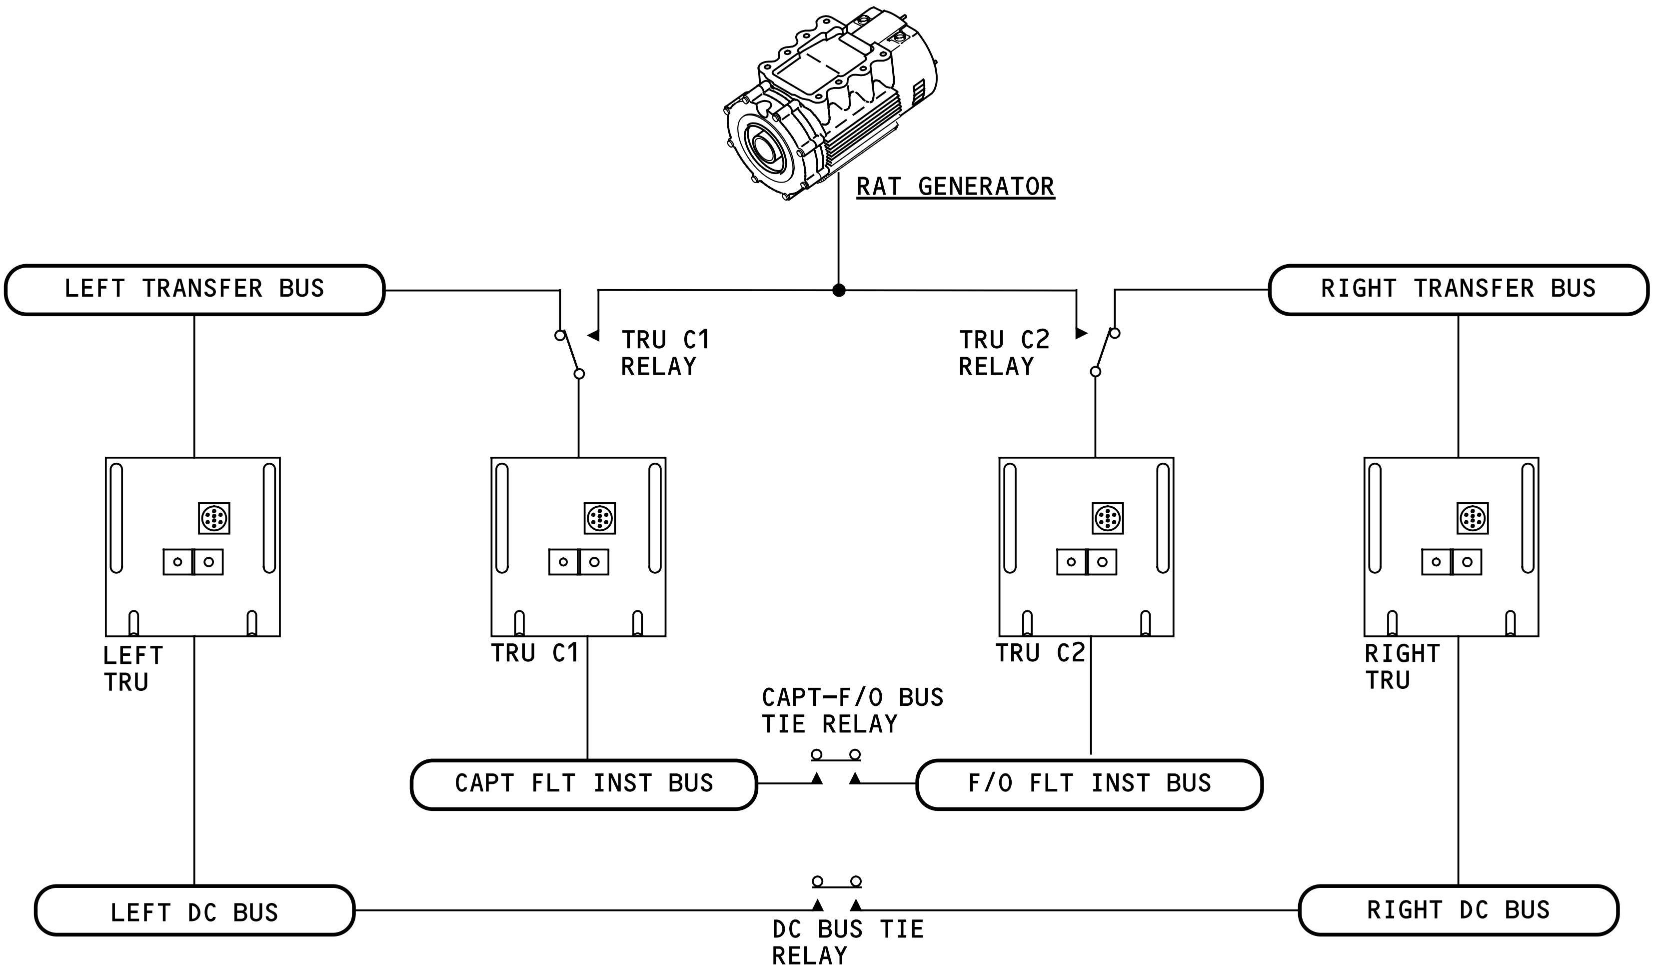
The dc subsystem card controls all the relays. The card is in the EEU in the P310 standby power management panel.

General Description - Left and Right DC Buses

During normal operation, the left TRU supplies power to the left dc bus, and the right TRU supplies power to the right dc bus. If a TRU fails, the dc bus tie relay closes to let the other TRU supply power to the two buses.

General Description - Flight Instrument DC Buses

During normal operation, TRU C1 supplies power to the captain's flight instrument bus, and TRU C2 supplies power to the first officer's flight instrument bus. If a TRU fails, the capt-F/O bus tie relay closes to let the other TRU supply power to the two buses.



24-32-00-001 Rev 1 03/21/96

TRU - GENERAL DESCRIPTION

TRU - FUNCTIONAL DESCRIPTION - LEFT AND RIGHT DC BUS

General

Normally the right TRU supplies power to the right dc bus, and the left TRU supplies power to the left dc bus. If one TRU does not operate, the other TRU can supply power to both buses through the dc tie relay.

The EEU in the standby power management panel has a dc subsystem card that controls the dc tie relay. The card gets voltage inputs from the left and right dc buses. The card also monitors the output current from each TRU.

DC Tie Relay - Normal Control

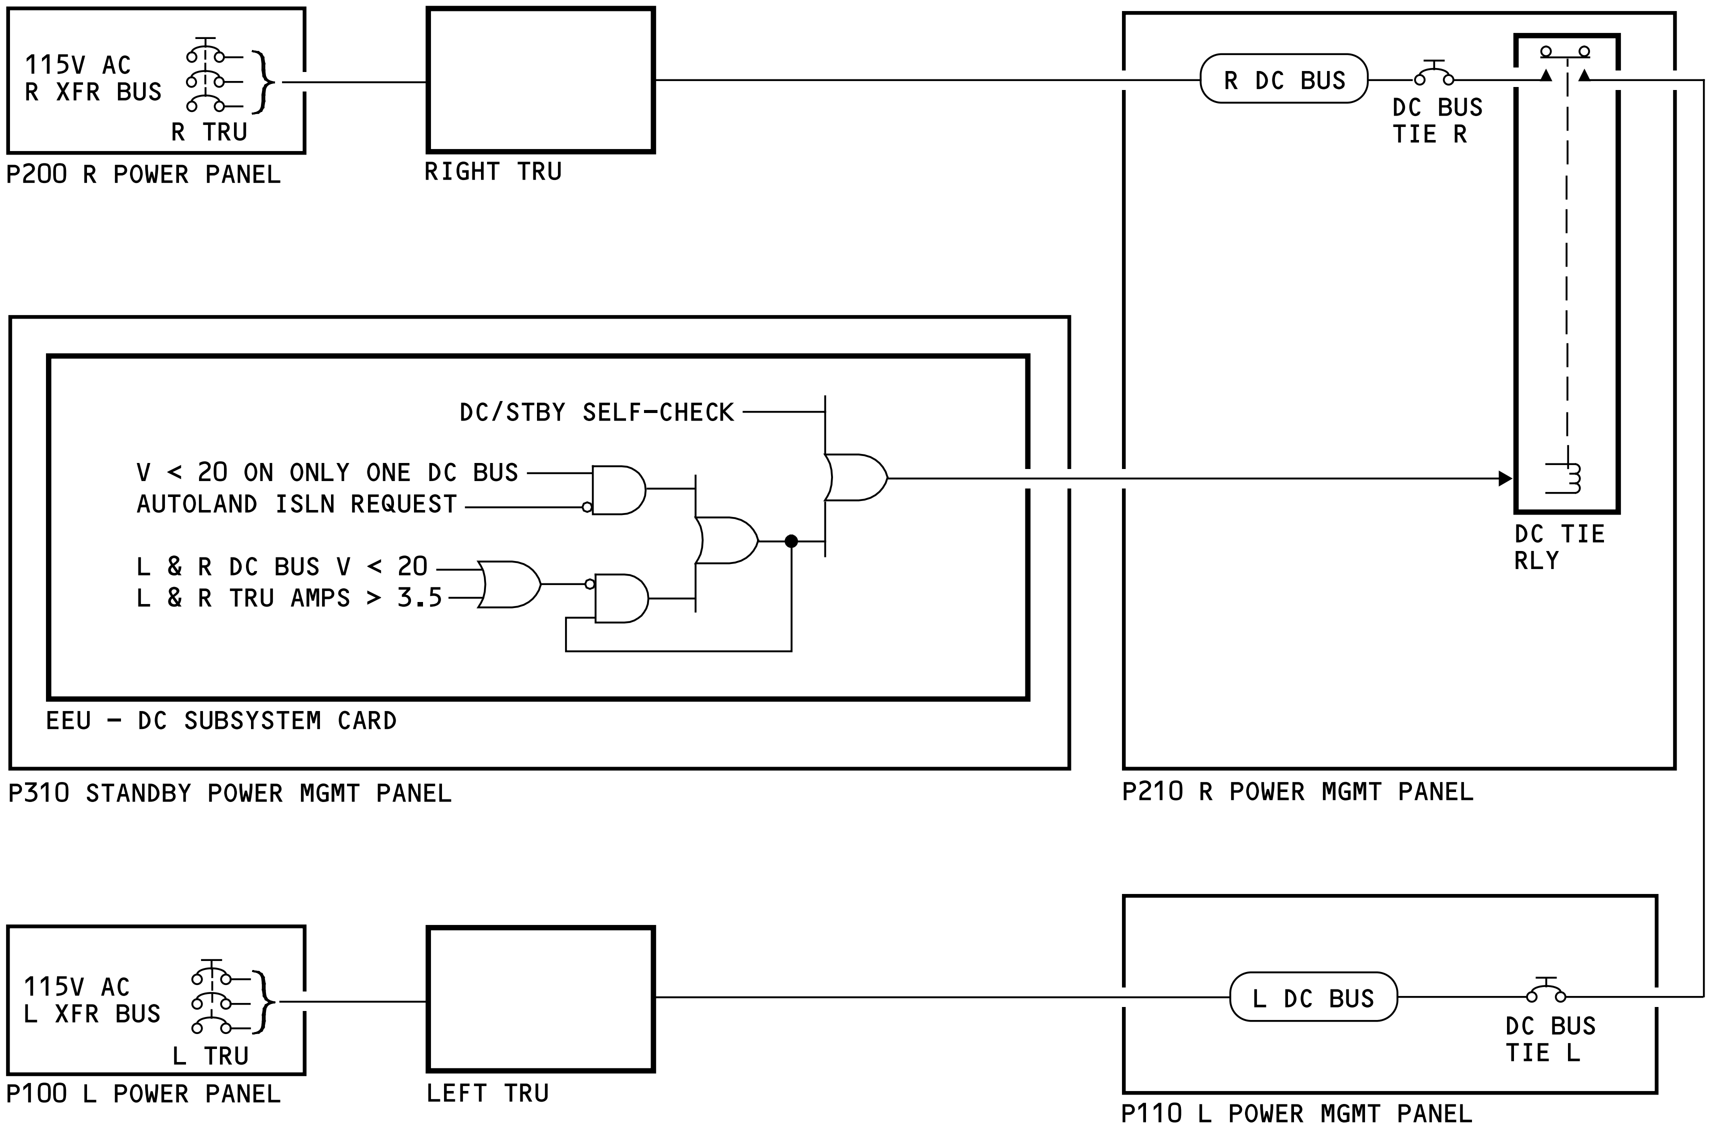
The dc tie relay is normally open to isolate the left and right dc buses. If one of the two dc buses has low voltage, the dc subsystem card closes the dc tie relay. This connects the left and right dc buses. The dc tie relay stays closed until the card senses output current from both TRUs.

If the tie relay closes and the card senses low voltage on the two dc buses, the card opens the relay. This is typical of a bus fault.

DC Tie Relay - Autoland Control

When the dc tie relay is open during autoland, the dc subsystem card keeps it open. This continues to isolate the left and right dc buses.

If the relay is closed before autoland, it stays closed. ELMS rejects the autoland request to isolate the buses.



TRU - FUNCTIONAL DESCRIPTION - LEFT AND RIGHT DC BUS

TRU - FUNCTIONAL DESCRIPTION - CAPT & F/O FLIGHT INSTRUMENT DC BUSES

General

Normally the TRU C1 supplies power to the captain's flight instrument bus, and the TRU C2 supplies power to the first officer's flight instrument bus. If TRU C1 does not operate, TRU C2 supplies power to the two buses through the captain-F/O bus tie relay. If TRU C2 does not operate, TRU C1 supplies power to the two buses through the captain-F/O bus tie relay.

During standby power operation, the RAT generator supplies power to the two flight instrument buses through the TRU C1 and C2 relays.

The EEU in the standby power management panel has a dc subsystem card that controls the captain-F/O bus tie and TRU C2 relays. The card and the RAT GCU control the TRU C1 relay.

Standby Power Control

When the RAT deploys, the RAT GCU sends a RAT power ready signal to the dc subsystem card. The RAT GCU also energizes the TRU C1 relay. This permits the RAT generator to supply power to the captain's flight instrument bus through the TRU C1. The dc subsystem card supplies a backup signal to energize the TRU C1 relay.

If the right transfer bus has no power the card energizes the TRU C2 relay. This permits the RAT generator to supply power to the F/O flight instrument bus through the TRU C2. Energizing the TRU C2 relay also causes the dc subsystem card to energize the captain-F/O bus tie relay.

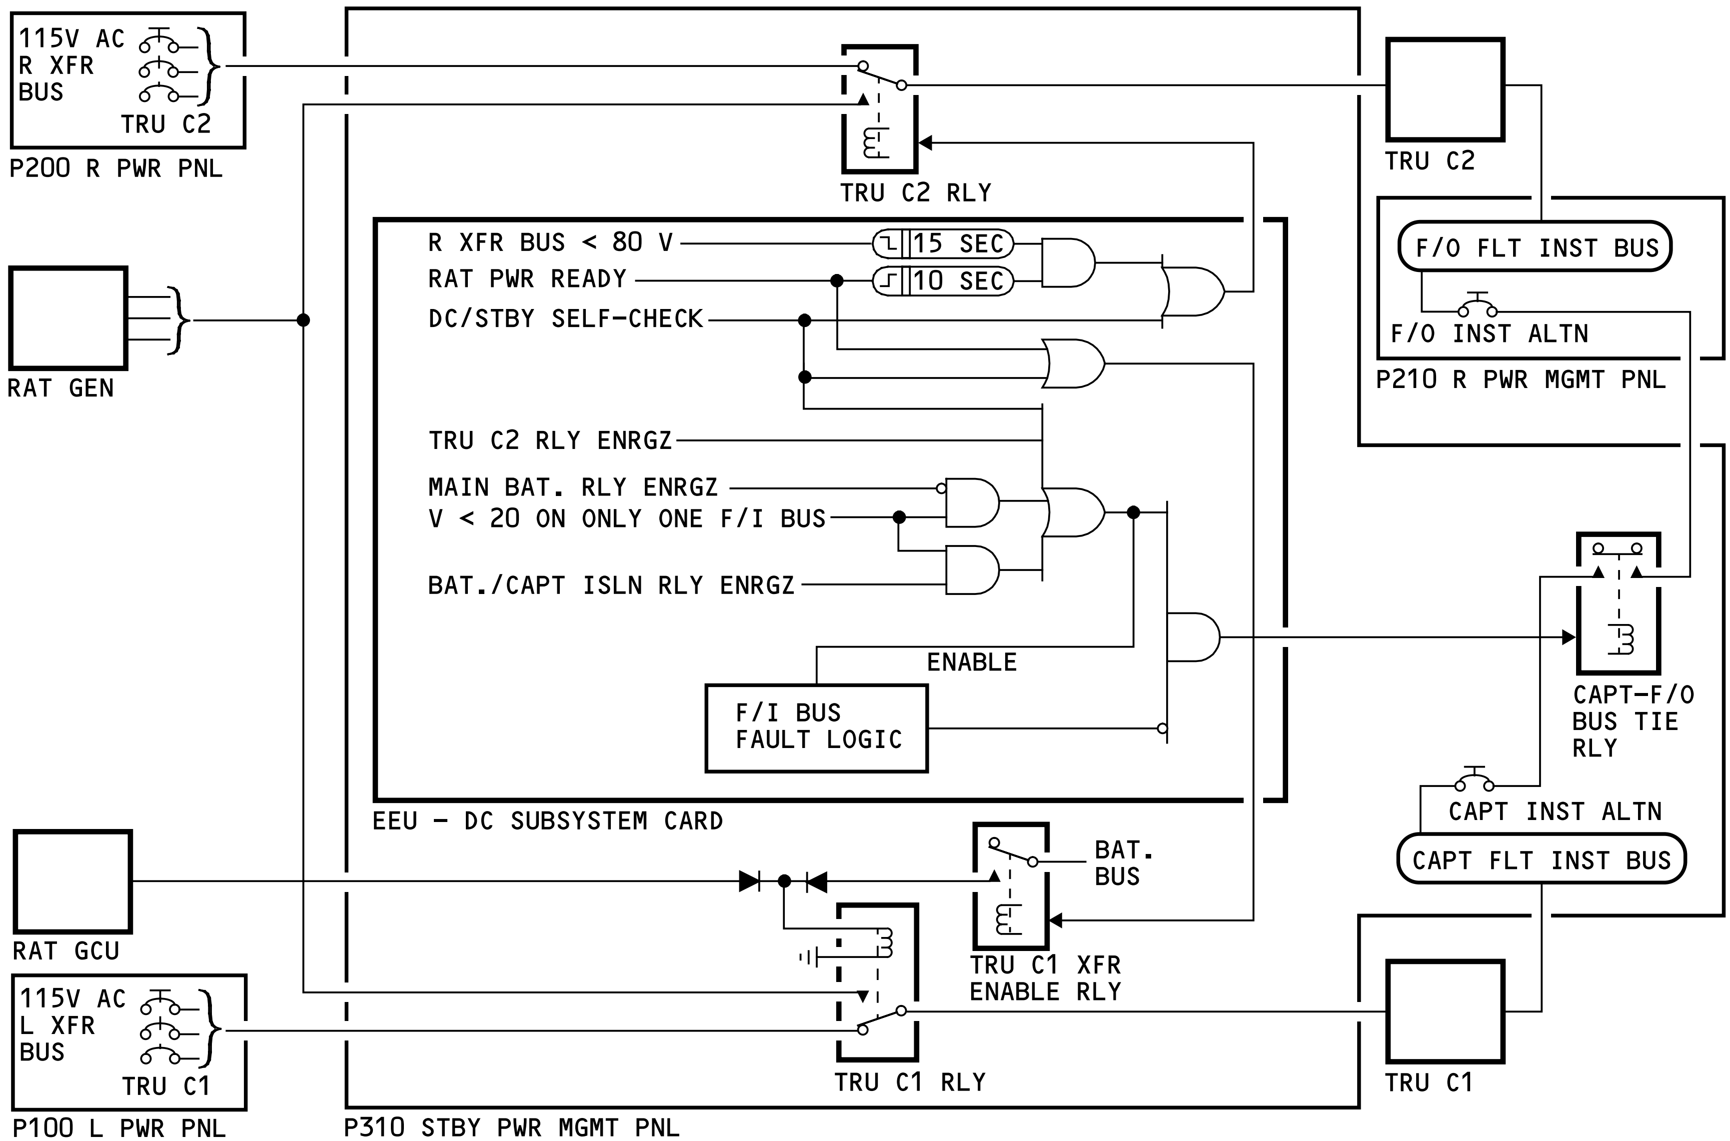
Captain-F/O Bus Tie Relay Control

The captain-F/O bus tie relay is normally open to isolate the captain's and first officer's flight instrument buses. If one of the flight instrument buses has no power and the main battery relay is not energized, the dc subsystem card energizes the captain-F/O bus tie relay. If one of the flight instrument buses has no power, the card also energizes the relay during autoland when the battery/captain isolation relay energizes. The relay connects the two flight instrument buses.

The control outputs of these two conditions latch to keep the relay energized. The latch releases if any of these occur:

- The left and right transfer buses lose power
- TRU C1 & C2 supply power
- The two flight instrument buses lose power.

All of the conditions that energize the captain-F/O bus tie relay also enable the flight instrument bus fault logic. The dc subsystem card monitors TRU current and bus voltage to detect a bus fault. If the card detects a fault, the relay is de-energized and the fault logic latches. The logic is reset at system power-up or with the MAT special function test: INITIATE P310 EU SELF TEST.



TRU - FUNCTIONAL DESCRIPTION - CAPT & F/O FLIGHT INSTRUMENT DC BUSES

THIS PAGE INTENTIONALLY LEFT BLANK

BATTERIES - GENERAL DESCRIPTION

General

There are two equivalent sets of battery equipment for main battery power and APU battery power. Each set has these components:

- Battery
- Battery charger
- Current sensor.

The main battery components supply dc power to important equipment when other power sources are not available.

The APU battery components supply power to start the APU.

The battery switch on the electrical panel supplies a control signal to ELMS. This permits you to supply main battery power to the battery #2 bus when the airplane is on the ground and has no ac power.

Batteries

The main battery supplies power to these buses:

- Hot battery bus
- Battery bus
- Captain's flight instrument bus
- Battery bus #2.

These relays select the buses to get power from the main battery:

- Main battery relay
- Battery-captain's bus isolation relay
- Ground power battery relay.

The APU battery supplies power directly to the APU battery bus. The APU battery bus supplies power to the APU electric starter through the APU crank contactor. The ELMS energizes the APU crank contactor when the APU controller starts the APU.

The APU battery bus is also an alternate power source for the APU controller and the RAT deploy relay.

Battery Chargers

The battery chargers do these functions:

- Change the ac power to dc power for the related dc buses
- Charge the batteries
- Send fault signals to the ELMS.

The ground service bus supplies 115v ac power to the main battery charger and the APU battery charger. The main battery charger charges the main battery through the hot battery bus. The APU battery charger charges the APU battery through the APU battery bus.

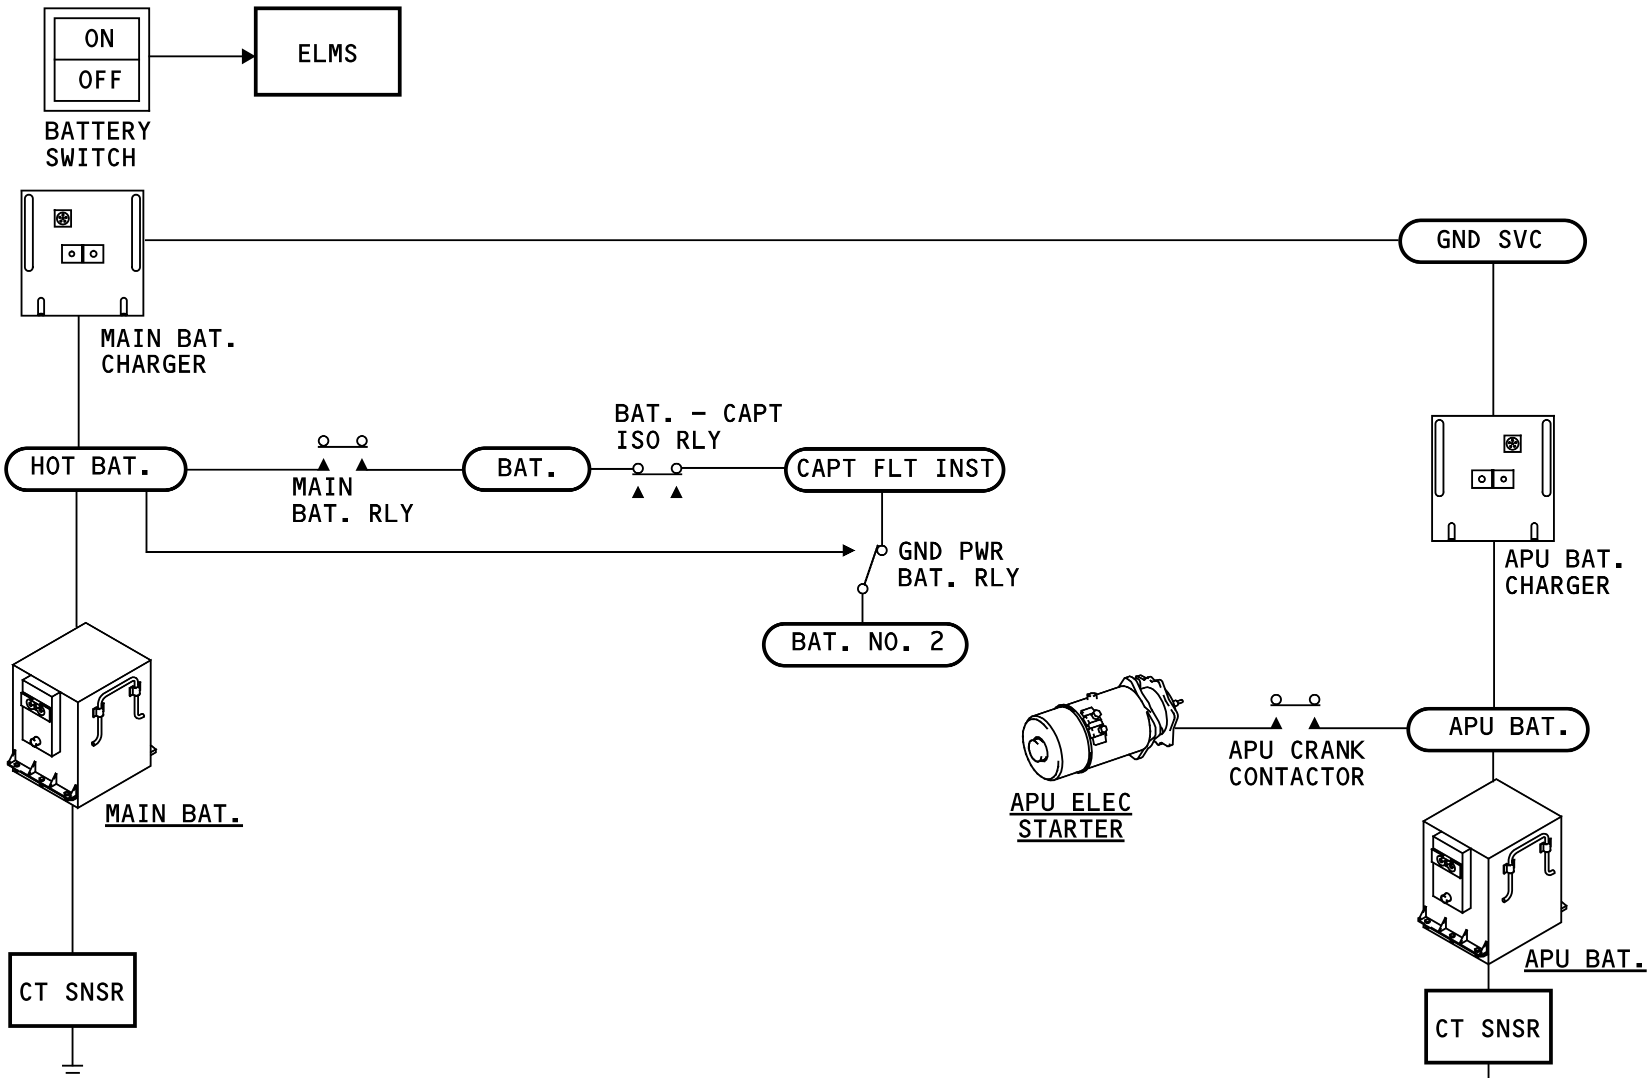
Current Sensors

Current sensors measure the current through the related battery. The ELMS EEU uses the current sensor output to calculate these data:

BATTERIES - GENERAL DESCRIPTION

- Amount of current
- Direction of current (charge or discharge).

The battery current data shows on page 1 of the MFD electrical maintenance page.



24-31-00-001 Rev 2

BATTERIES - GENERAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

BATTERIES - MAIN AND APU BATTERIES

Purpose

When ac power is not available, the main battery does these functions:

- Supplies power to dc loads that are necessary for ground operation
- Supplies power to all the components that deploy the RAT
- Supplies standby system power until the RAT generator starts to supply power.

The main battery can supply standby system power for at least five minutes.

The APU battery supplies electrical power to start the APU.

Physical Description

The main battery and the APU batteries are rechargeable. They are fiber nickel-cadmium (FNC) batteries. Each battery weighs 106 lb (48 kg).

Each battery has two sets of ten FNC cells. The battery case is green. The case has two mounting flanges and two lifting handles. Bolts attach the mounting flanges to the airplane. The lifting handles help you connect ground support equipment (GSE) to the battery when you move it.

The battery has a terminal block and an electrical connector. The terminal block connects the high power output. The electrical connector connects control and status signals.

The battery has a temperature sensor and an overheat switch (not shown).

Training Information Point

WARNING: BE CAREFUL WHEN YOU MOVE THE BATTERY. BECAUSE THE BATTERY WEIGHS 106 POUNDS (48 KG), INJURY TO PERSONS CAN OCCUR.

Use ground support equipment to lift the main battery. You install a rack and pulley between the floor beams above the battery to help you lift it.

The APU battery attaches to a tray that you can pull out to easily remove and install the battery. Once you push the tray in, there are two captive screws you must tighten to prevent the tray from moving.

CAUTION: DO NOT CHARGE THIS BATTERY WITH BATTERY CHARGERS WHICH ARE NOT APPROVED FOR THIS TYPE OF FNC BATTERY. OVER-CHARGING CAN OCCUR AND SERIOUSLY DAMAGE OR DESTROY BATTERY CELLS.

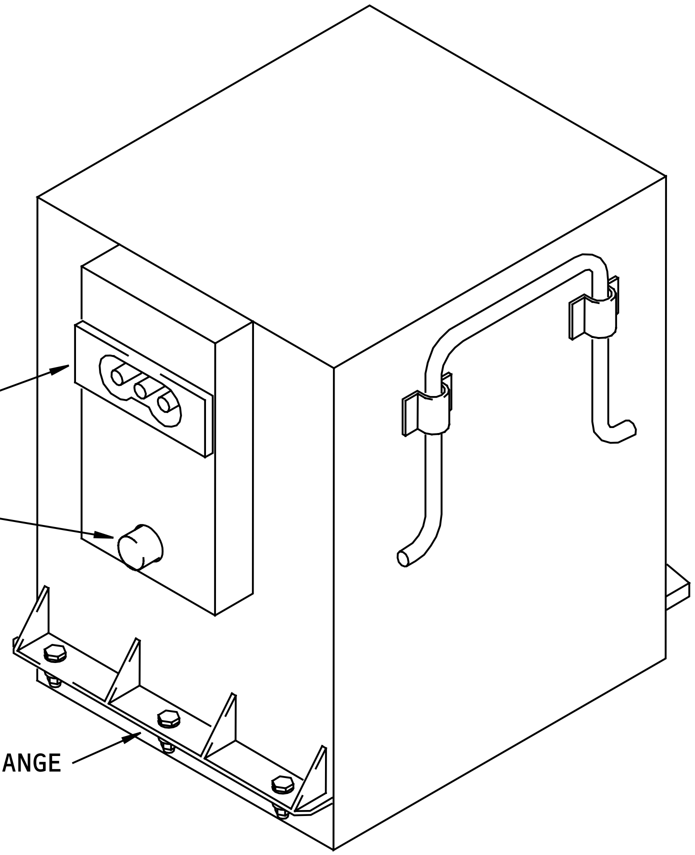
The capacity of each battery is 47 amp-hours. The main battery can supply the hot battery bus loads for 10 days.

The main battery and the APU battery are interchangeable.

BATTERIES - MAIN AND APU BATTERIES

No maintenance is necessary for FNC batteries.

When no other power is on the airplane, the hot battery bus supplies power to the static random access memory (SRAM) of the AIMS. If you disconnect the main battery with no power to the AIMS cabinets, you lose some data. See the AIMS section for more information (AMM PART I 31-41).



BATTERY
(TYPICAL)

24-31-00-002 Rev 3

BATTERIES - MAIN AND APU BATTERIES

BATTERIES - MAIN AND APU BATTERY CHARGERS

Purpose

The battery chargers change ac power to dc power for the related dc buses. The battery chargers keep the related batteries charged.

Physical Description

The battery chargers are ARINC 600-style LRUs. Each battery charger has these components on the front cover:

- Terminal block
- Electrical connector
- Handles.

The terminal block connects the high power output. The electrical connector connects ac power, control signals, and status signals to the battery charger.

Functional Description

The input power to each battery charger is 3-phase, 115v ac, 400 Hz. power.

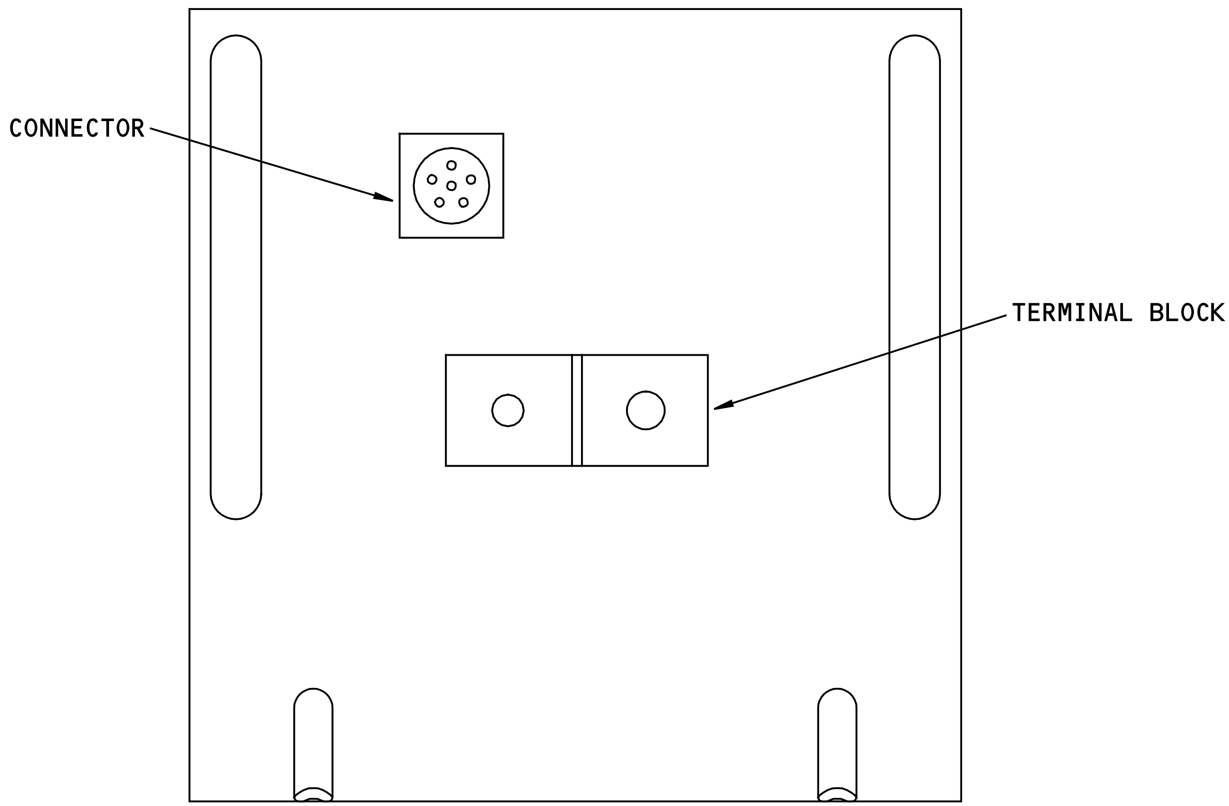
The battery charger has four modes of operation. Three of these are charge modes; the other is transformer-rectifier (TR) mode.

In the TR mode, the battery charger supplies dc power up to 65 amps. The voltage of this power is very tightly regulated.

Training Information Point

The main battery charger and the APU battery charger are interchangeable.

CAUTION: DO NOT TOUCH THE BATTERY CHARGER BEFORE YOU DO THE PROCEDURE FOR DEVICES THAT ARE SENSITIVE TO ELECTROSTATIC DISCHARGE. ELECTROSTATIC DISCHARGE CAN CAUSE DAMAGE TO THE BATTERY CHARGER.



BATTERY CHARGER

24-31-00-003 Rev 1

BATTERIES - MAIN AND APU BATTERY CHARGERS

THIS PAGE INTENTIONALLY LEFT BLANK

BATTERIES - FUNCTIONAL DESCRIPTION

General

This is how the main battery subsystem works. The APU subsystem is similar.

The battery charger supplies power to dc buses and keeps the battery charged. It operates in four modes:

- Main
- Topping
- Float
- TR.

Main Mode

The battery charger starts main mode operation when one of these conditions occurs:

- Power turns on the battery charger
- Battery has low voltage during float mode
- Battery charger stops TR mode operation.

Main mode is the fastest charge mode. The battery charger uses the increase in battery temperature to make a decision that the battery is almost fully charged. The temperature sensor in the battery gives the temperature data to the battery charger. The charger stops main mode when the battery temperature increases approximately 7F (4C).

Topping Mode

The battery charger automatically starts topping mode at the end of main mode. Topping mode supplies less current than main mode. The battery charger uses topping mode to make sure that the battery is fully charged. The battery charger operates in topping mode for 11 minutes.

Float Mode

The battery charger automatically starts float mode at the end of topping mode. The battery charger operates in float mode when the battery is fully charged. It can supply 65 amperes to the dc bus while it is in float mode.

Usually, the battery charger continues to operate in float mode.

TR Mode

In TR mode, the battery charger operates as a TRU and can supply up to 65 amperes to the dc bus. The output voltage of the TR mode is more closely regulated than the output voltage of the float mode.

The battery charger goes into the TR mode when there is a hot battery condition, or when it receives a TR mode signal from the ELMS. The TR mode overrides all other modes. The hot battery condition occurs when the battery is 145F (63C) or hotter. The ELMS supplies the TR mode signal when any of these conditions occur:

BATTERIES - FUNCTIONAL DESCRIPTION

- Main battery relay energizes
- Ground power battery relay energizes
- Autoland system sends an isolation request.

There is no ELMS TR mode signal for the APU battery charger.

Fault Protection

The battery charger monitors the battery for these conditions:

- Overheat switch closed (154F (68C))
- Colder than -40F (-40C)
- Cell imbalance
- Temperature sensor failure.

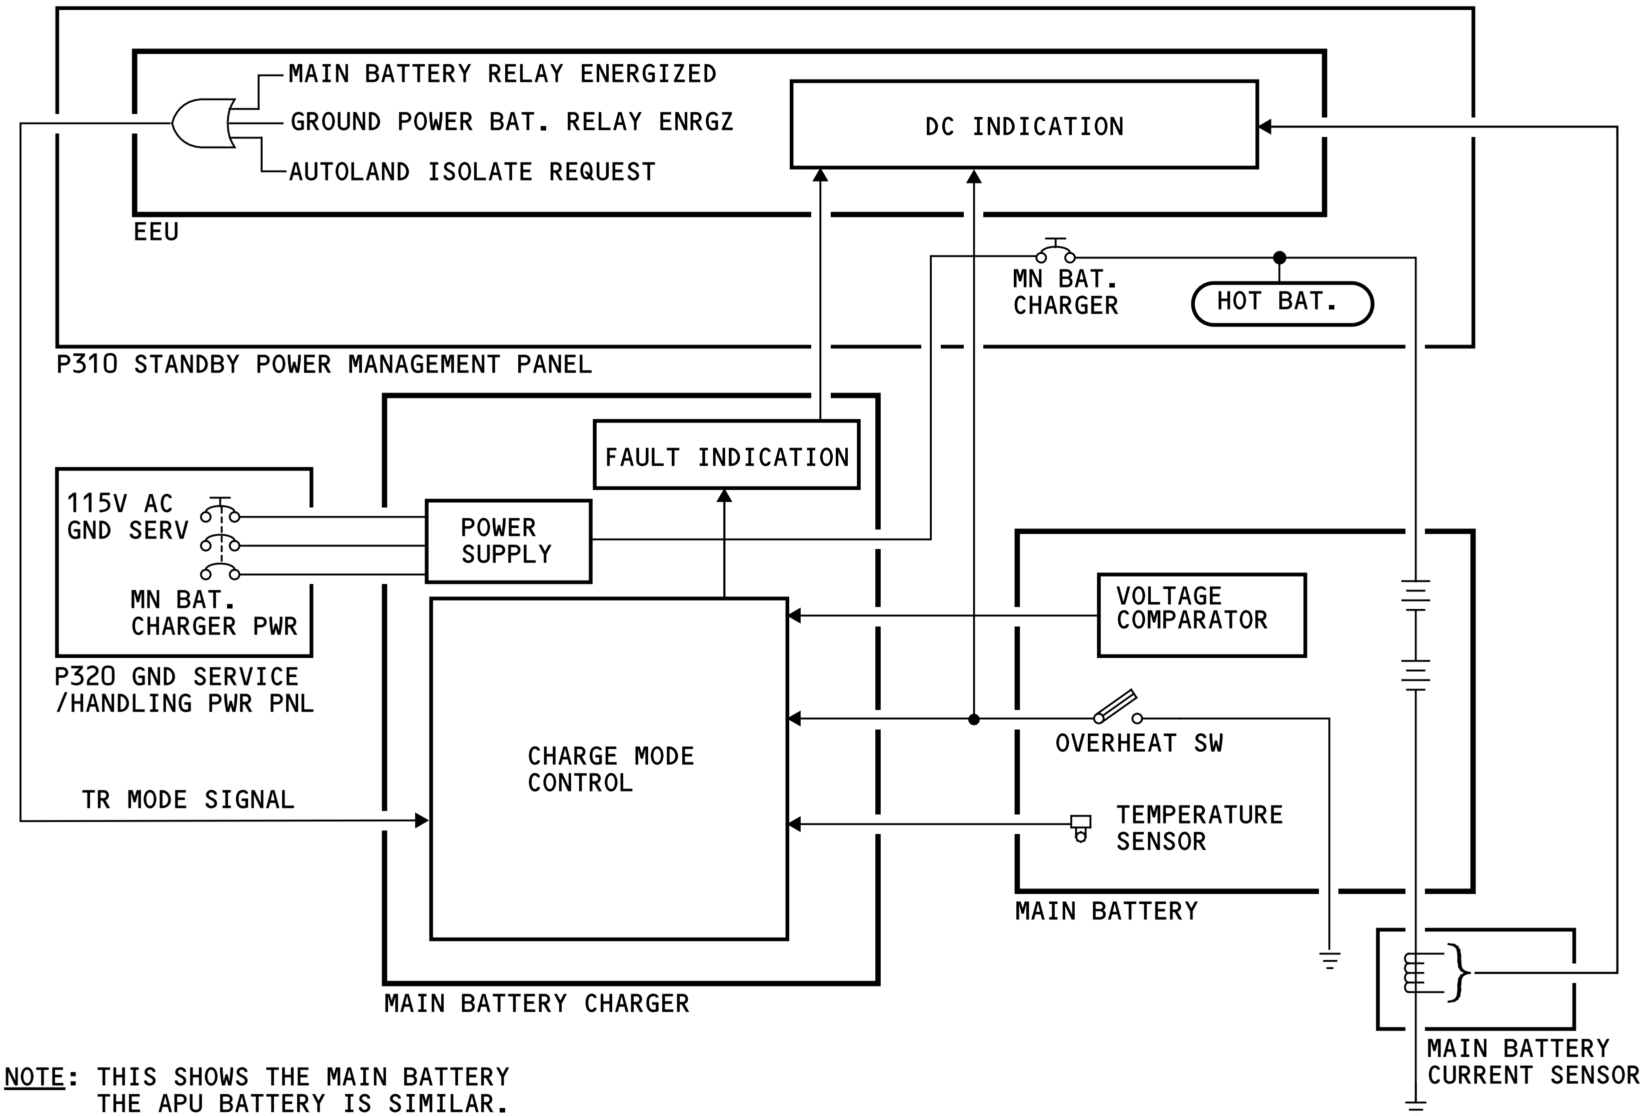
The cell imbalance condition occurs when the voltage of the first 10 battery cells is different from one half of the battery voltage. The battery charger monitors the voltage comparator in the battery to find this condition.

If the battery charger finds a fault, it turns off and sends a fault signal to the ELMS.

Current Indication

The current sensor sends current data to the EEU in the P310 panel.

The ELMS sends indication data to the AIMS.



NOTE: THIS SHOWS THE MAIN BATTERY
THE APU BATTERY IS SIMILAR.

24-31-00-004 Rev 4

BATTERIES - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

STANDBY POWER - GENERAL DESCRIPTION

General

The standby power system operates when the normal electrical power sources do not supply power to the left and right transfer buses. Standby power goes to these buses:

- Captain's flight instrument bus
- First officer's flight instrument bus
- Battery bus
- Battery bus #2
- Hot battery bus
- AC standby bus.

Standby power comes from either the RAT generator or the main battery. ELMS controls the standby system relays. The battery switch and the standby power switch send control signals to the ELMS.

Rat Generator

The RAT generator supplies 7.5 kva of ac power to the two center TRUs. The RAT GCU monitors and controls the output of the RAT. The TRUs change the ac power into 28v dc power and supply it to the captain's and first officer's flight instrument buses.

The captain's flight instrument bus supplies power to the battery bus and battery bus #2.

The battery bus supplies power to the hot battery bus and the ac standby bus. Power to the ac standby bus goes through the static inverter. The static inverter changes 28v dc power into one phase of 115v, 400 Hz, ac power.

Main Battery

The main battery supplies 28v dc power to the standby system if the RAT generator does not.

To supply power to the standby system, the main battery supplies power to the hot battery bus. The hot battery bus supplies power to the battery bus.

The battery bus supplies power to the captain's flight instrument bus. The captain's flight instrument bus supplies power to battery bus #2.

The battery bus supplies power to the static inverter, so that the ac standby bus has power.

Operation

The standby power switch on the P61 overhead maintenance panel has three positions:

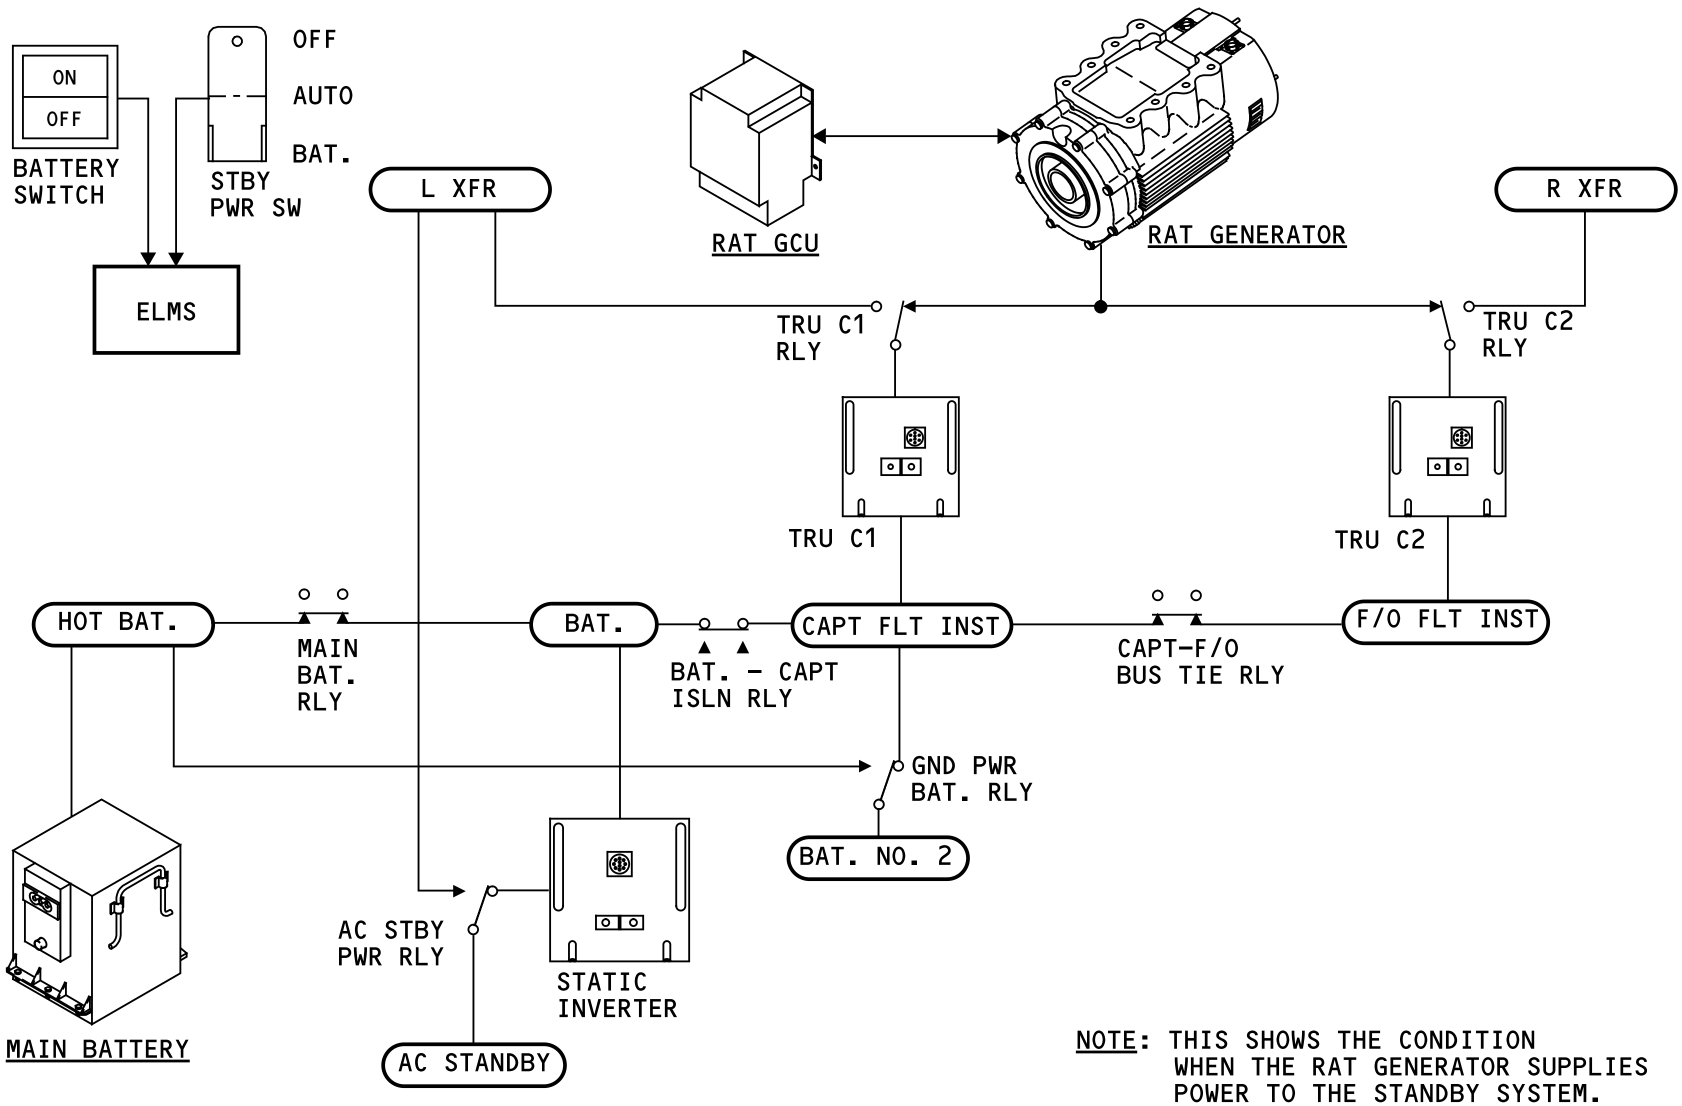
- OFF
- AUTO
- BAT.

The BAT position is a momentary position. The standby power switch permits you to do these functions on the ground only:

- De-energize the ac standby bus (OFF position)

STANDBY POWER - GENERAL DESCRIPTION

- Arm the standby system for automatic operation (AUTO position)
- Energize the standby buses when ac power is not available (BAT position, when the battery switch is in the ON position)
- Start a self-check of the dc/standby system (BAT position, when ac power is available).



STANDBY POWER - GENERAL DESCRIPTION

STANDBY POWER - RAT GENERATOR

General

The RAT generator supplies ac power when normal power sources are not available. The RAT generator supplies power to TRU C1 and TRU C2 for the standby system buses.

Physical Description

The generator capacity is 7.5 kva. It has two electrical connectors. One connector carries RAT GCU signals and power. The other carries the generator output to TRU C1 and TRU C2.

The generator contains these parts:

- Permanent magnet generator (2)
- Exciter
- Main generator
- Heater (2).

The main generator makes three-phase ac power. The voltage is 115 volts. The frequency is the result of the rotational speed of the of the RAT propeller/ governor unit. The frequency range is from 392 Hz to 510 Hz.

There are two heaters in the RAT generator that prevent ice. The hydraulic interface module (HYDIM) cards control the heaters through the ELMS. See the ram air turbine system section for more information on the heaters (AMM PART I 29-20).

Location

Eight bolts attach the RAT generator to the RAT strut. The RAT propeller/governor unit attaches to the front side of the generator. The hydraulic pump attaches to the aft side of the generator. See the ram air turbine system section for more information on the RAT (AMM PART I 29-20).

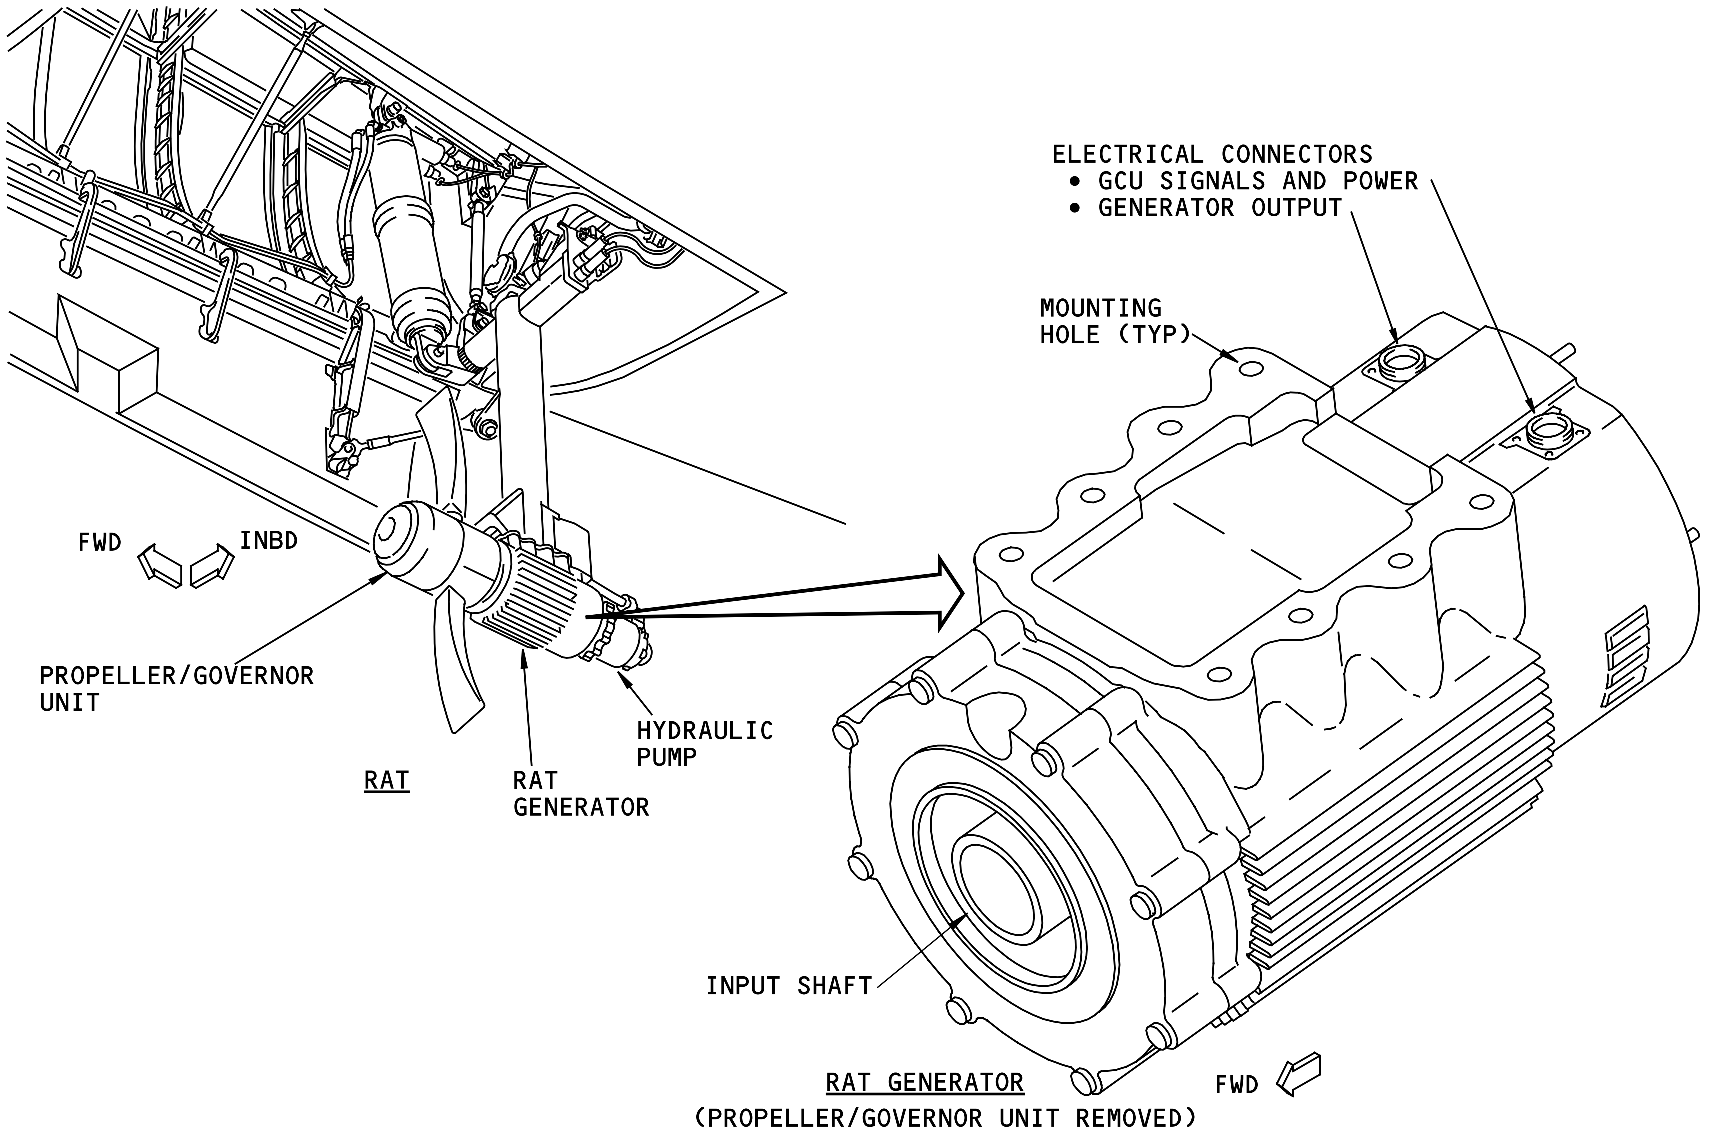
Functional Description

When the RAT deploys, the propeller/governor unit turns the input shaft of the generator and hydraulic pump. The generator changes the energy of the turning shaft into ac power.

Training Information Point

You remove and install the RAT generator and propeller/ governor unit as an assembly. More work on the assembly must be done in a shop.

You must do a test of the RAT at specified times. See the ram air turbine system section for more information on the test (AMM PART I 29-20).



STANDBY POWER - RAT GENERATOR

STANDBY POWER - FUNCTIONAL DESCRIPTION - AC CONTROL

General

The ac standby bus uses single phase, 115v ac power. The left transfer bus is the usual power source for the ac standby bus. The static inverter is an alternative power source for the ac standby bus. These components control power switching to the ac standby bus:

- AC standby power relay
- AC standby control relay
- Static inverter
- P310 EEU.

Power to energize the ac standby bus goes through the ac standby power relay. The ac standby control relay controls the ac standby power relay. The EEU controls the ac standby control relay.

Standby Power Control

The left transfer bus normally supplies power to the ac standby bus. The static inverter supplies the power when any of these conditions are true:

- Left transfer bus voltage is below 80 volts
- There is an autoland bus isolation request
- There is a dc/standby self-check in progress.

Static Inverter

The static inverter gets 28v dc power from the battery bus. The static inverter has a converter that increases the dc voltage, and an inverter that changes the dc power into single phase, 115v ac power.

The static inverter turns off for either of these conditions:

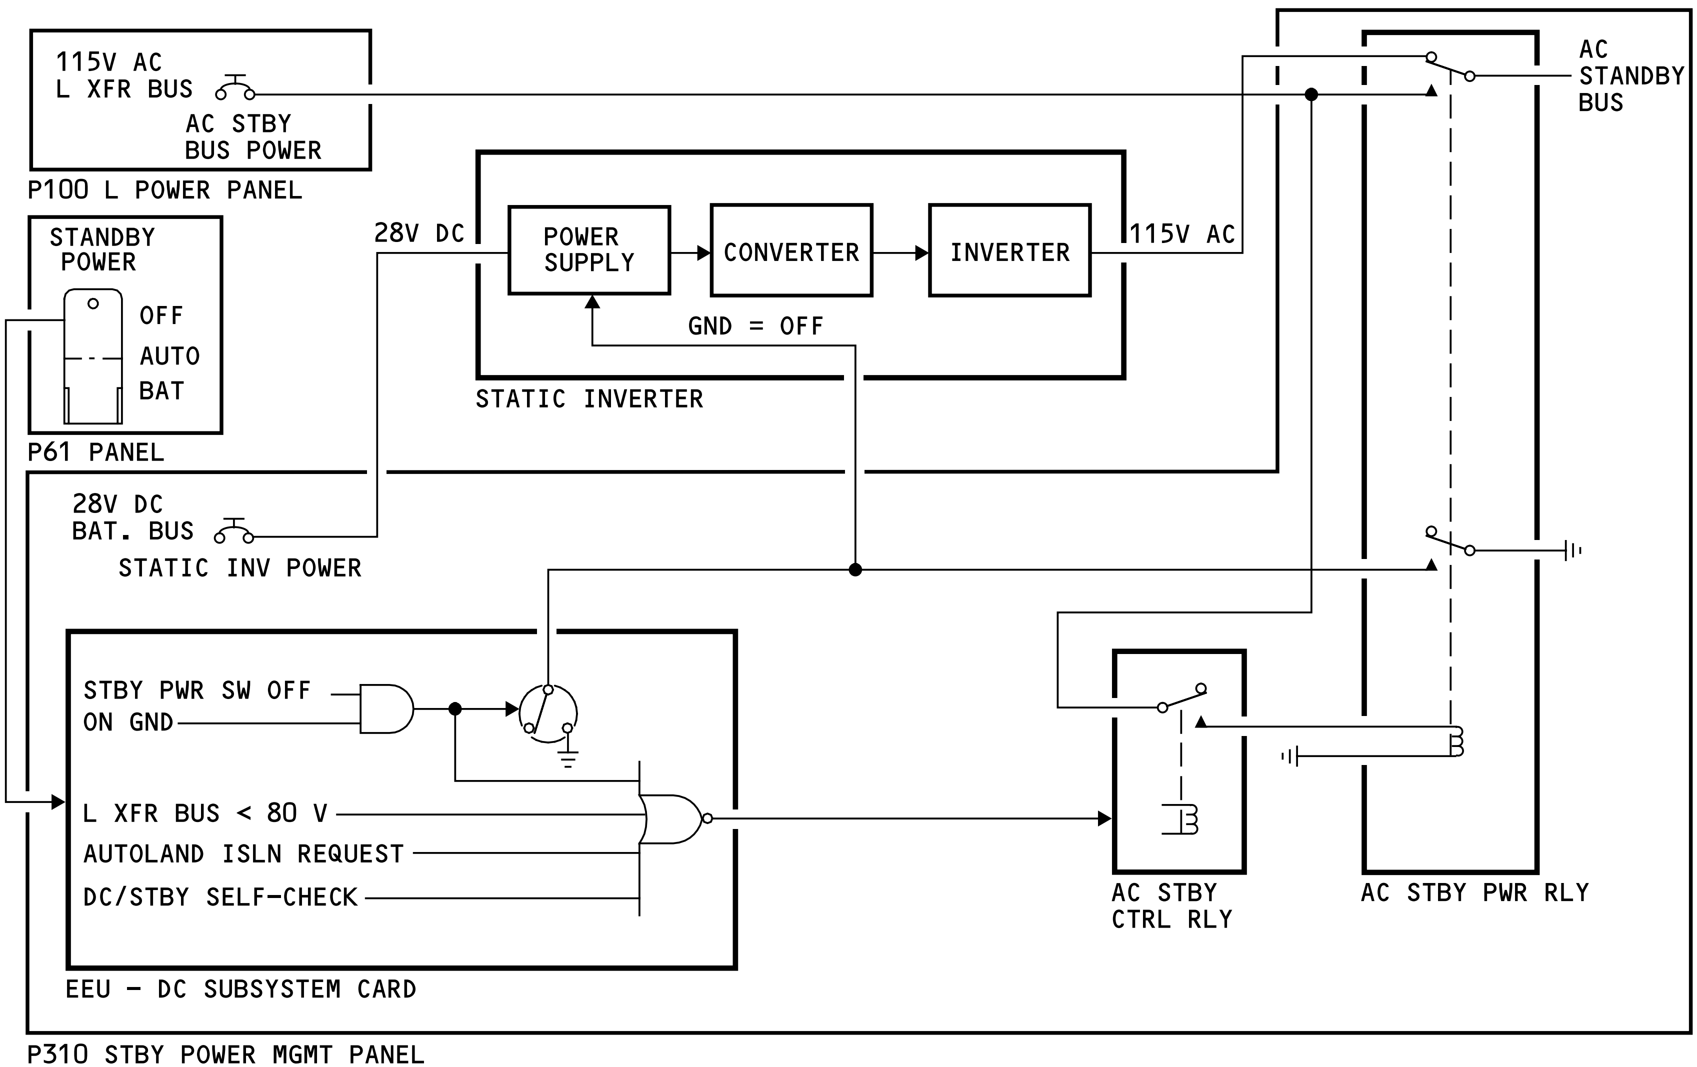
- Standby power switch is in the OFF position and the airplane is on the ground
- AC standby power relay is energized.

DC/Standby Self-Check

The dc subsystem card does a test of the dc system with a dc/standby self-check.

The self-check can start either manually or automatically. You manually start the self-check when you set these conditions:

- The airplane is on the ground
- Left and right ac transfer buses have power
- The battery switch is in the ON position
- The standby power switch is in the BAT position (momentary).



24-33-00-003 Rev 4

STANDBY POWER - FUNCTIONAL DESCRIPTION - AC CONTROL

STANDBY POWER - FUNCTIONAL DESCRIPTION - RAT GENERATOR CONTROL

General

The RAT deploys manually or automatically. The RAT switch controls manual deployment of the RAT. The P310 EEU and the hydraulic interface modules (HYDIM) (not shown) control the automatic deployment of the RAT. When one or two RAT actuator solenoids energize, the RAT deploys. Then, the RAT GCU controls and monitors the RAT generator power.

RAT Deployment

To deploy the RAT manually, you put the RAT manual switch in the DEPLOY position. This energizes the two RAT actuator solenoids.

The P310 EEU can deploy the RAT automatically. When the airplane is in the air and the two transfer buses do not have power for more than 15 seconds, the EEU energizes the RAT deploy relay for five seconds. The energized RAT deploy relay supplies power to the M29002 RAT actuator solenoid.

See the ram air turbine system section for more information on the hydraulic interface module card control of the M29001 RAT actuator solenoid (AMM PART I 29-20).

Power

The RAT GCU gets power from a PMG in the RAT generator. The PMG also supplies power to the voltage regulator.

The voltage regulator rectifies the power to make dc current for the exciter field.

The generator uses the exciter field current to make ac current. The ac current goes through two relays to the two center TRUs.

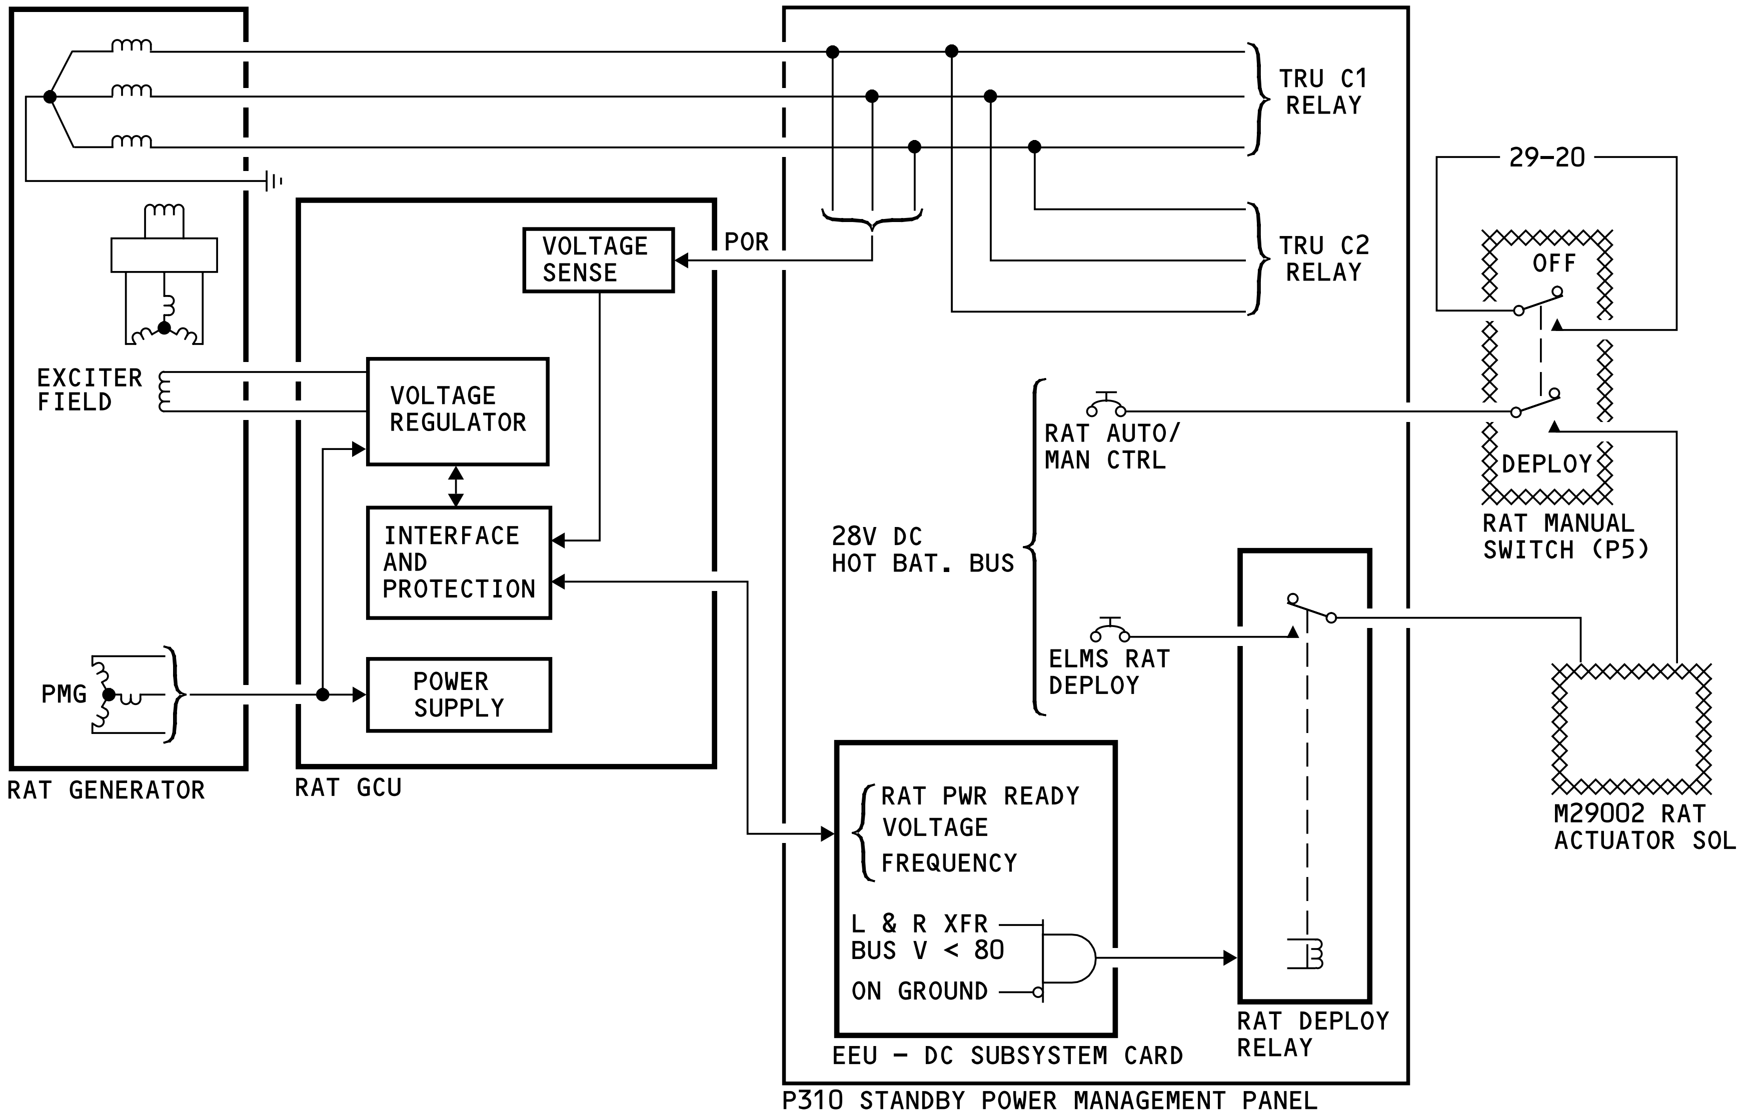
Control

The GCU monitors the voltage at the point of regulation (POR). The POR is between the generator and the TRU relays. The voltage regulator adjusts the dc current to the exciter field to keep the POR voltage at 115 volts.

The GCU sends these signals to the EEU in the standby power management panel:

- RAT generator power ready signal
- RAT generator voltage
- RAT generator frequency.

The ELMS uses the power ready signal for control logic. The voltage and frequency signals are for indication.



24-33-00-004 Rev 5

STANDBY POWER - FUNCTIONAL DESCRIPTION - RAT GENERATOR CONTROL

STANDBY POWER - FUNCTIONAL DESCRIPTION - DC CONTROL

General

The standby power system operates to control power from the hot battery bus to these buses:

- Battery bus
- Captain's flight instrument bus
- Battery bus #2.

The EEU controls these relays to control power from the hot battery bus:

- Main battery relay
- Battery-captain isolation relay
- Ground power battery relay.

Main Battery Relay

When the main battery relay energizes, the hot battery bus can supply power to the battery bus. In general, the main battery relay energizes for these conditions:

- Transfer bus power was available, but was lost (in the air, the EEU keeps the relay energized)
- You manually select standby power on
- The two center TRUs fail
- TRU C1 fails and the captain-F/O bus tie relay energizes to restore power
- Autoland bus isolation request
- DC/standby self-check.

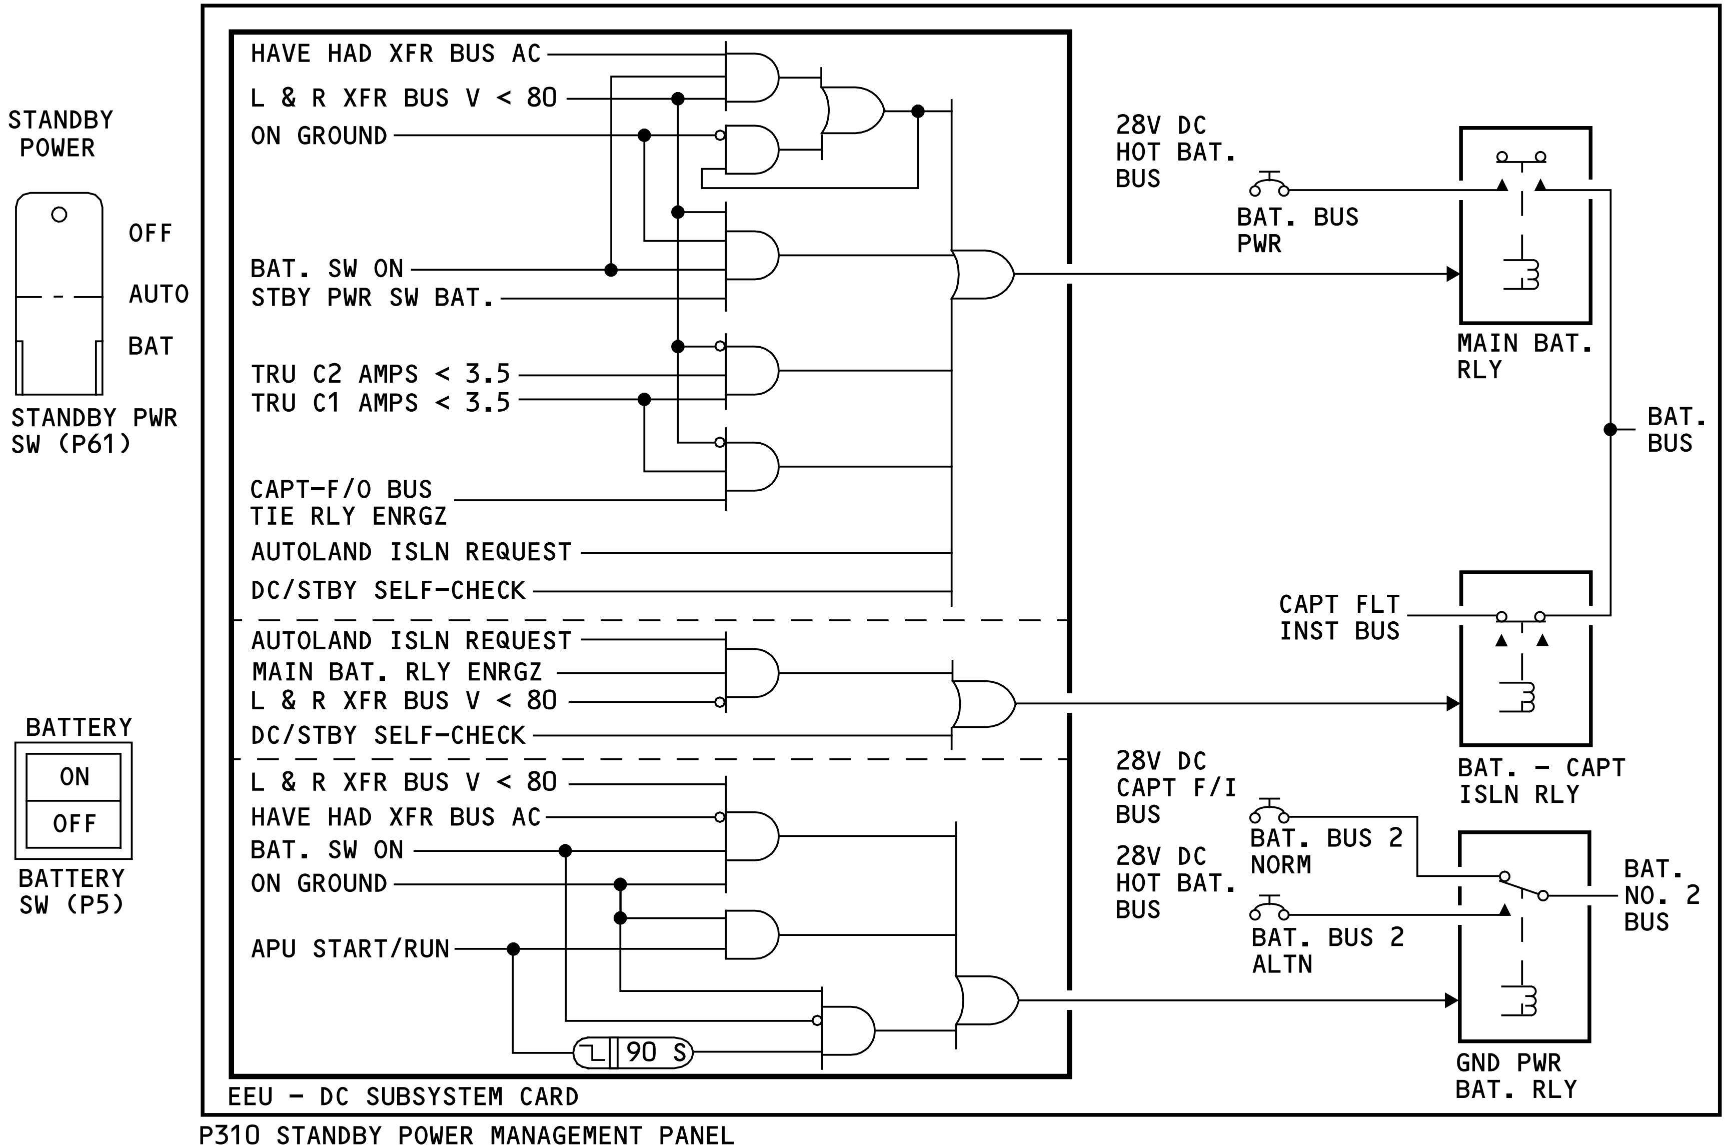
Battery-Captain Isolation Relay

The battery-captain isolation relay energizes to isolate the captain's flight instrument bus from the hot battery bus (through the battery bus). This occurs when there is an autoland bus isolation request or for a dc/standby self-check.

Ground Power Battery Relay

When the ground power battery relay energizes, the hot battery bus can supply power to the battery bus #2. The ground power battery relay energizes for these conditions:

- You push the battery switch on as part of initial power application
- APU starting/running on the ground
- When APU shuts down and the battery switch is off, the relay stays energized for 90 seconds. This makes sure the battery bus #2 has power to close the APU inlet door.



STANDBY POWER - FUNCTIONAL DESCRIPTION - DC CONTROL

24-33-00-005 Rev 3

FLIGHT CONTROLS DC POWER - GENERAL DESCRIPTION

Purpose

The flight controls dc (FCDC) power system supplies power to the flight controls system.

General Description

There are three FCDC power supply assemblies (PSA):

- Left
- Center
- Right.

These PSAs supply power to their related flight control buses.

Power Sources

Each PSA gets power from many different sources. The PSA automatically selects which power source to use. Each PSA has a battery to supply power during power interruptions.

The left PSA gets power from these sources:

- PMG L1
- Left dc bus
- Hot battery bus.

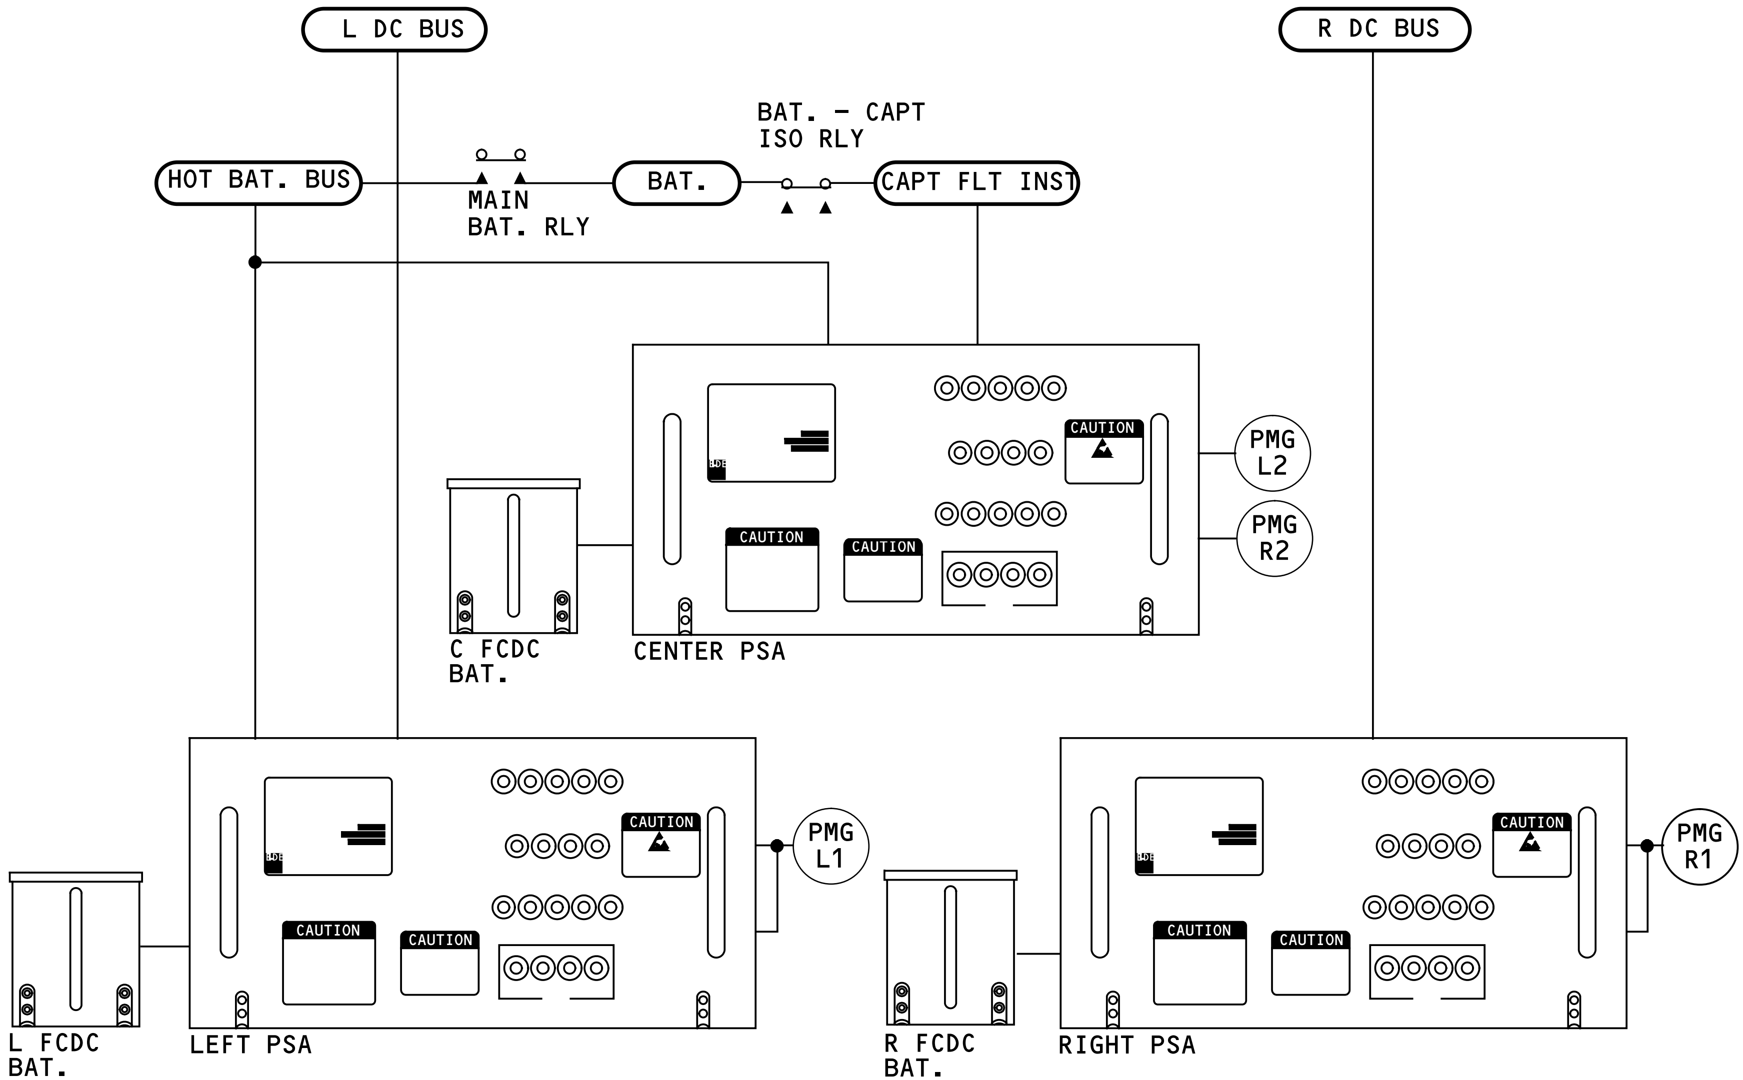
The center PSA gets power from these sources:

- PMG L2
- PMG R2
- Captain's flight instrument bus
- Hot battery bus.

The right PSA gets power from these sources:

- PMG R1
- Right dc bus.

The PMGs are permanent magnet generators in the backup generator housing. Each backup generator has two PMGs that supply power to the PSAs. The PSA changes variable frequency ac power from the PMGs into 28v dc power.



24-35-00-001 Rev 3

FLIGHT CONTROLS DC POWER - GENERAL DESCRIPTION

FLIGHT CONTROLS DC POWER - POWER SUPPLY ASSEMBLY

General

The PSA supplies power to the flight control systems.

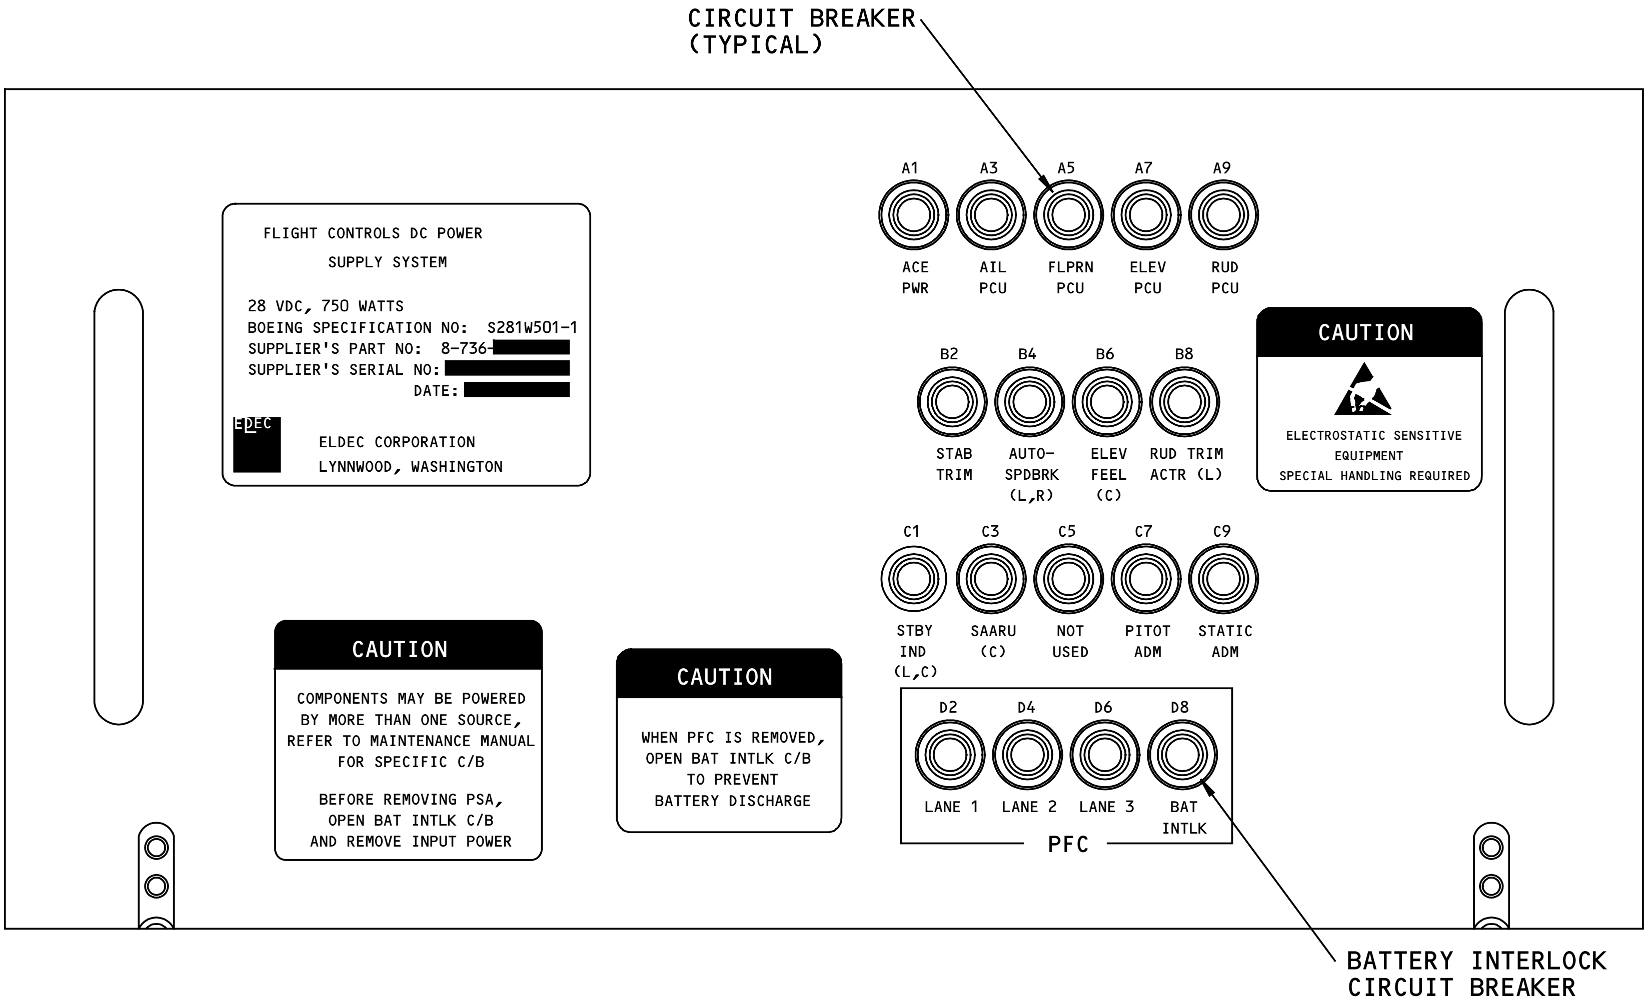
The PSA contains the FCDC bus. The FCDC bus supplies power to flight control LRUs. Power to each LRU goes through circuit breakers on the front of the PSA. You can remove power from an LRU when you open its related circuit breakers.

Training Information Point

Be sure to obey all of the cautions on the front of the PSA.

The left, center, and right PSAs are interchangeable.

The parentheses below a circuit breaker tells the PSA position in which that circuit breaker is active. For example, circuit breaker AUTO-SPDBRK (L,R) is only active when the PSA is in the left or right position.



24-35-00-002 Rev 2

FLIGHT CONTROLS DC POWER - POWER SUPPLY ASSEMBLY

FLIGHT CONTROLS DC POWER - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

FLIGHT CONTROLS DC POWER - FUNCTIONAL DESCRIPTION

General

The center PSA can get power from these sources:

- PMG L2
- PMG R2
- Captain's flight instrument bus
- Hot battery bus.

The PSA has a controller that selects which power source to use. The controller supplies grounds to relays in the PSA to select the different power sources.

PSA Operation Modes

The PSA has three modes of operation:

- Primary
- Secondary
- Backup.

Primary mode is the normal mode when the engines are running. The PSA uses power from one or both PMGs when it is in primary mode. The PMGs send ac power to a power converter. The power converter changes the ac power to 28v dc power.

When there is no power from either PMG, the PSA goes into secondary mode. Secondary mode is the normal mode when the airplane is on the ground and the engines are off. The K2 relay relaxes when the PSA is in secondary mode. This permits the PSA to use power from the captain's flight instrument bus.

When there is no power from either PMG or from the captain's flight instrument bus, the PSA goes into backup mode. The K1 relay energizes when the PSA is in backup mode. This permits the PSA to use power from the hot battery bus.

NOTE: The right PSA does not use backup mode because it does not connect to the hot battery bus.

FCDC Battery

Normally, the controller energizes the K3 relay to connect the FCDC battery to the FCDC bus. A diode prevents uncontrolled charging of the battery from the bus. When the bus loses power, the battery supplies power until the controller connects another power source.

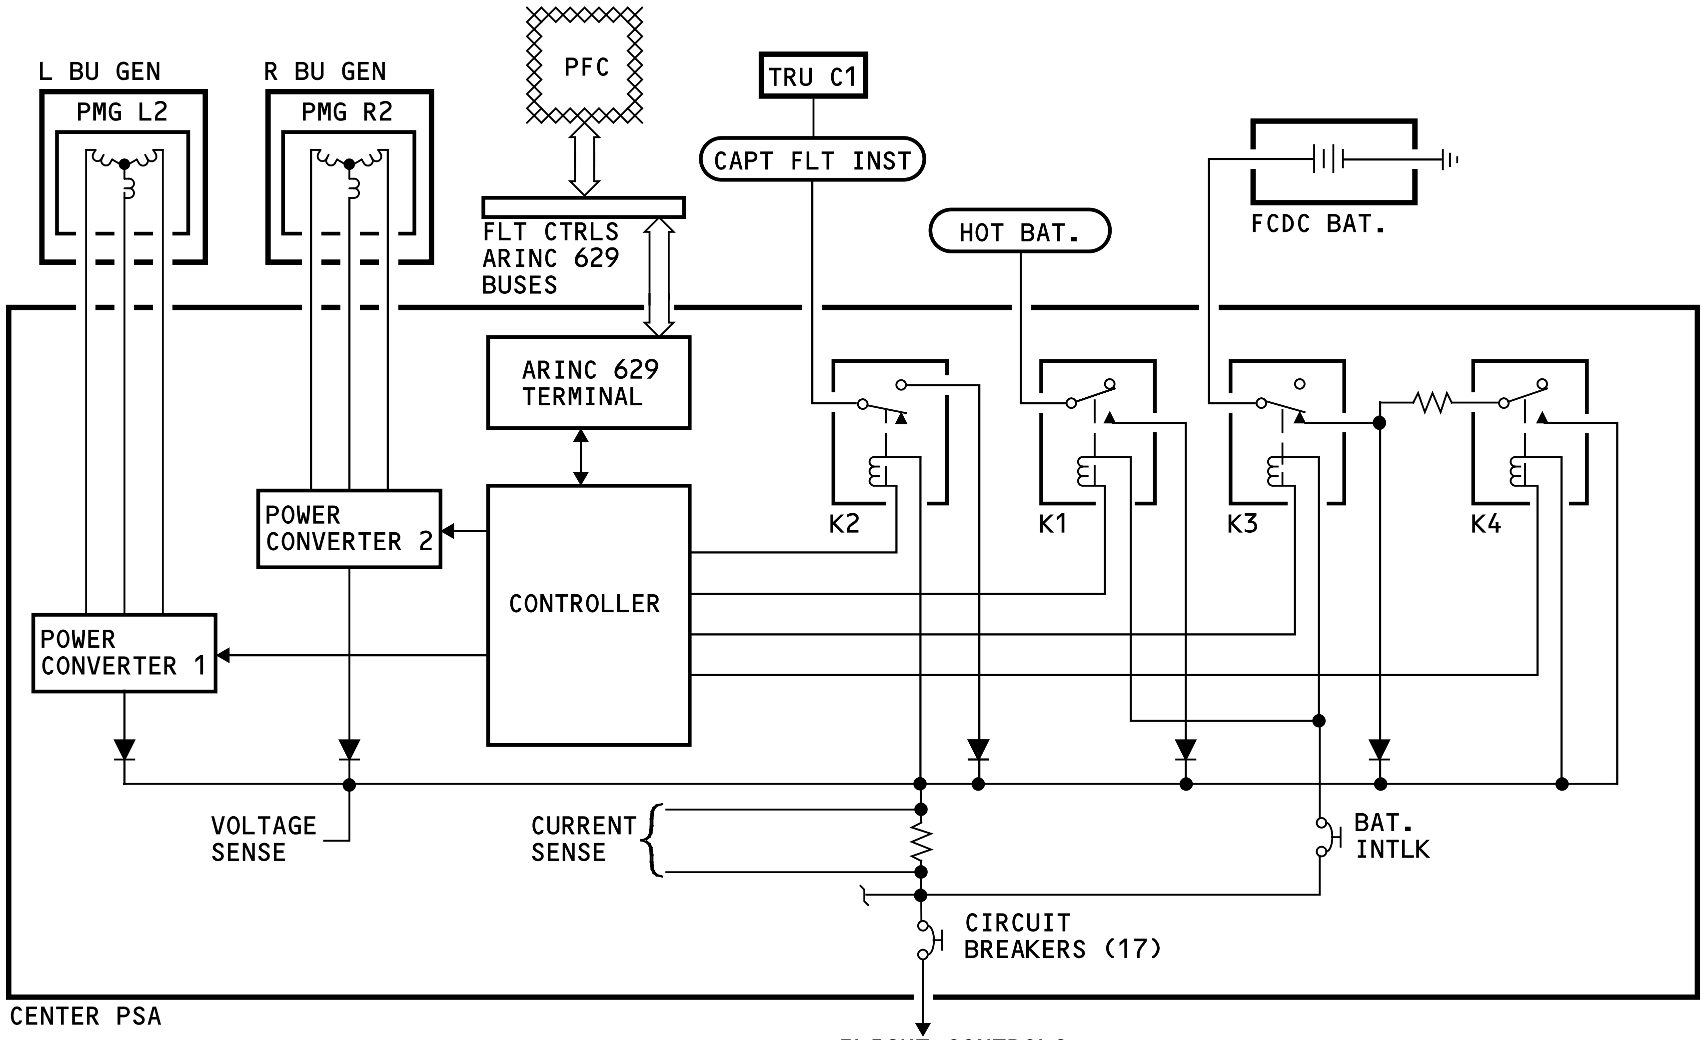
The PSA monitors the voltage of the FCDC battery. When the battery voltage is below 25 volts, the PSA energizes the K4 relay. This permits the FCDC bus to charge the battery. The battery charge cycle lasts for 300 minutes.

The PSA will not charge the battery if the battery voltage is below 21 volts or if the PSA is in backup mode.

FLIGHT CONTROLS DC POWER - FUNCTIONAL DESCRIPTION

Training Information Point

If you replace a primary flight computer (PFC), you must open the battery interlock circuit breaker of the related PSA before you remove power from the airplane. The battery interlock circuit breaker removes power from the K1 and the K3 relays. This prevents the FCDC loads from draining the main battery and the related FCDC battery. But, the PSA does automatically open K1 and K3 if the FCDC bus voltage drops below 17.5.



NOTE: CENTER PSA SHOWN WITH ENGINES RUNNING - LEFT AND RIGHT SIMILAR

24-35-00-003 Rev 3

FLIGHT CONTROLS DC POWER - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

DC GENERATION - FUNCTIONAL DESCRIPTION

Normal Power

The dc generation system normally receives power from these ac power sources:

- Left transfer bus
- Right transfer bus
- Ground service bus
- Backup generator PMGs.

Four TRUs change the ac power from the transfer buses to dc power. Most of the dc loads on the airplane use this power.

The standby ac bus uses power directly from the left transfer bus.

Two battery chargers change the ac power from the ground service bus to dc power. This dc power charges the main and APU batteries. It also supplies power to the hot battery bus loads.

Three PSAs change the ac power from the backup generator PMGs to dc power. Flight control components use this dc power.

Standby Power

When all ac power is lost, the main battery supplies power to the standby loads of the dc generation system until the RAT deploys (except those on the first officer's flight instrument bus). The standby loads are on these buses:

- Hot battery
- Battery
- Battery No. 2
- Captain's flight instrument
- First officer's flight instrument
- Standby ac.

After the RAT deploys, its generator supplies all of the power for the standby loads through the two center TRUs.

Control

The ELMS controls all the dc power system relays. (The RAT GCU can also control the TRU C1 relay.) The battery switch and the standby power switch supply manual control inputs to the ELMS.

The ELMS decreases the effect of faults in the dc generation system by normally keeping dc buses isolated. But, if there is a power loss to a dc bus, the ELMS can supply power to that bus from another dc bus. It does this by connecting the two buses. The ELMS uses these relays to connect dc buses:

- DC bus tie
- Main battery
- Battery-captain's isolation
- Captain's-first officer's bus tie
- Ground power battery.

DC GENERATION - FUNCTIONAL DESCRIPTION

Fault Isolation - DC/Standby Self-Check

The dc subsystem card does a check of the dc system. This is called a dc/standby self-check. It does these tests:

- Makes sure all dc/standby system relays operate correctly
- Makes sure the ac standby bus has power (this does a check of the static inverter).

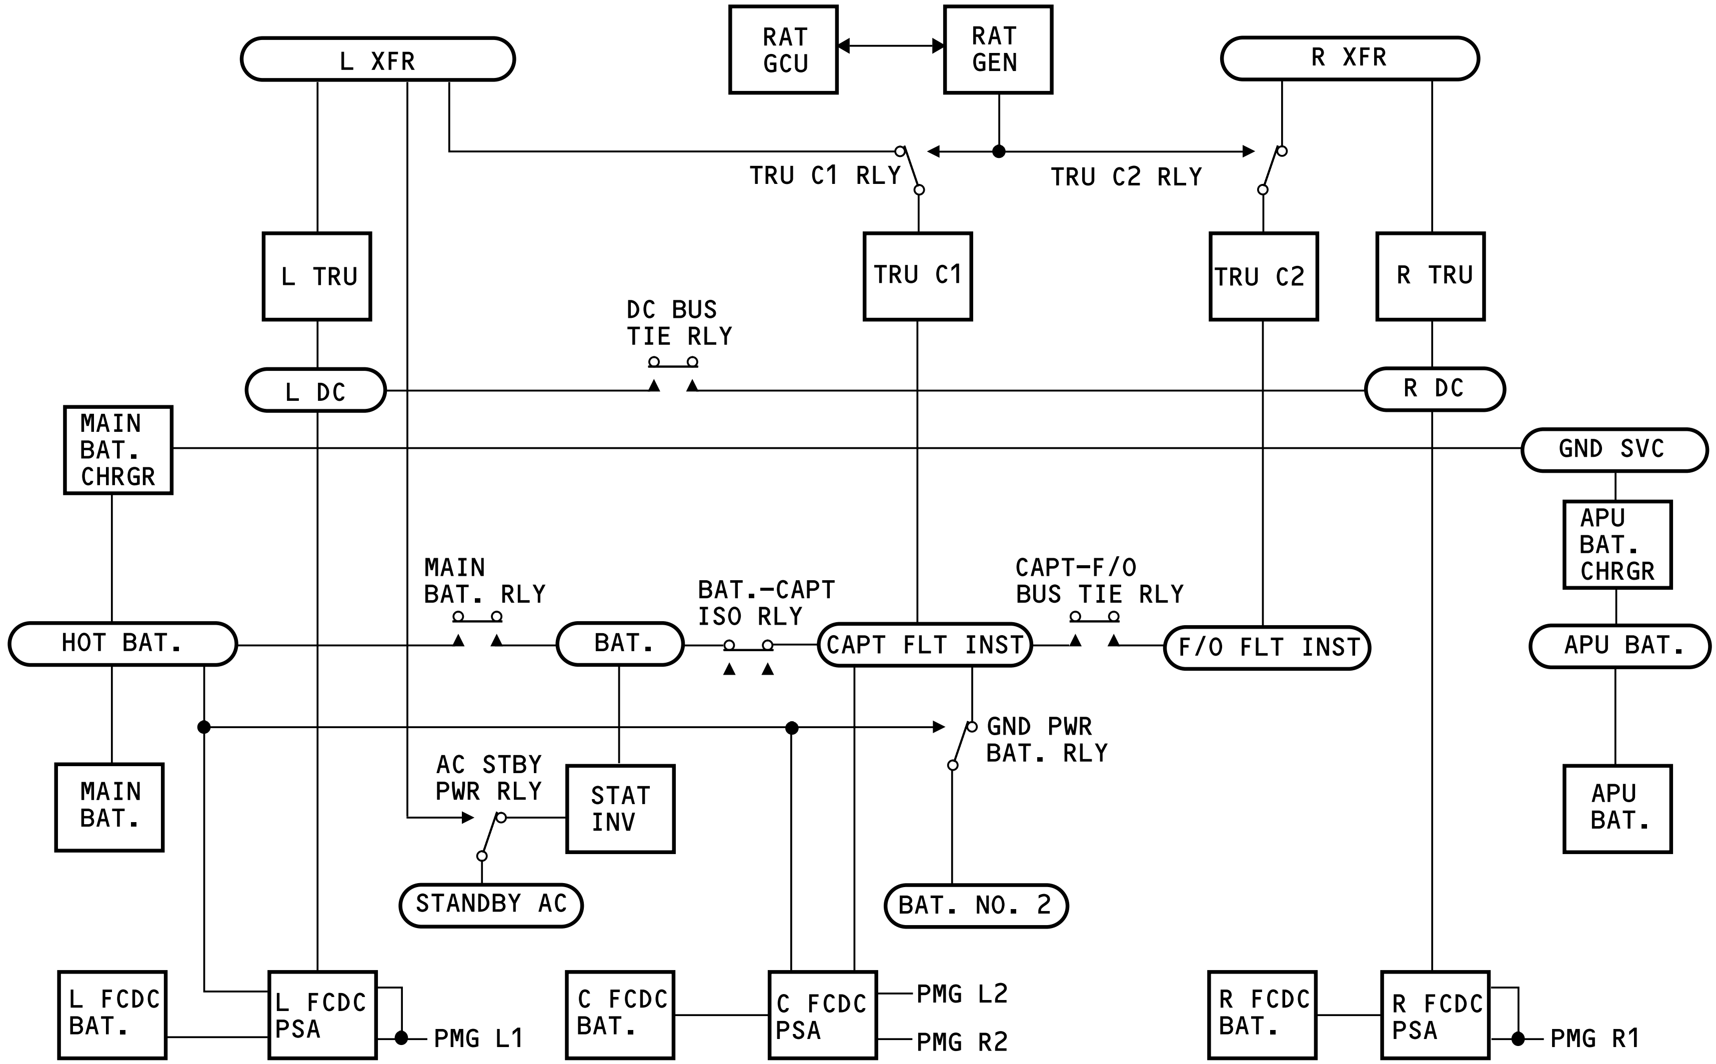
A dc/standby self-check can start either manually or automatically. You manually start the self-check when you set these conditions:

- The airplane is on the ground
- Left and right ac transfer buses have power
- The battery switch is in the ON position
- The standby power switch is in the BAT position (momentary).

The self-check starts automatically when these conditions occur:

- There are more than 72 hours since the last dc system test occurred
- The airplane is on the ground
- Left and right ac transfer buses have power.

The test takes less than ten seconds. If the system passes the test, no message shows on the EICAS display. If the system fails the test, the advisory message ELEC STANDBY SYS shows.



NOTE: ELMS CONTROLS ALL RELAYS SHOWN.
RAT GCU ALSO CONTROLS TRU C1 RELAY.

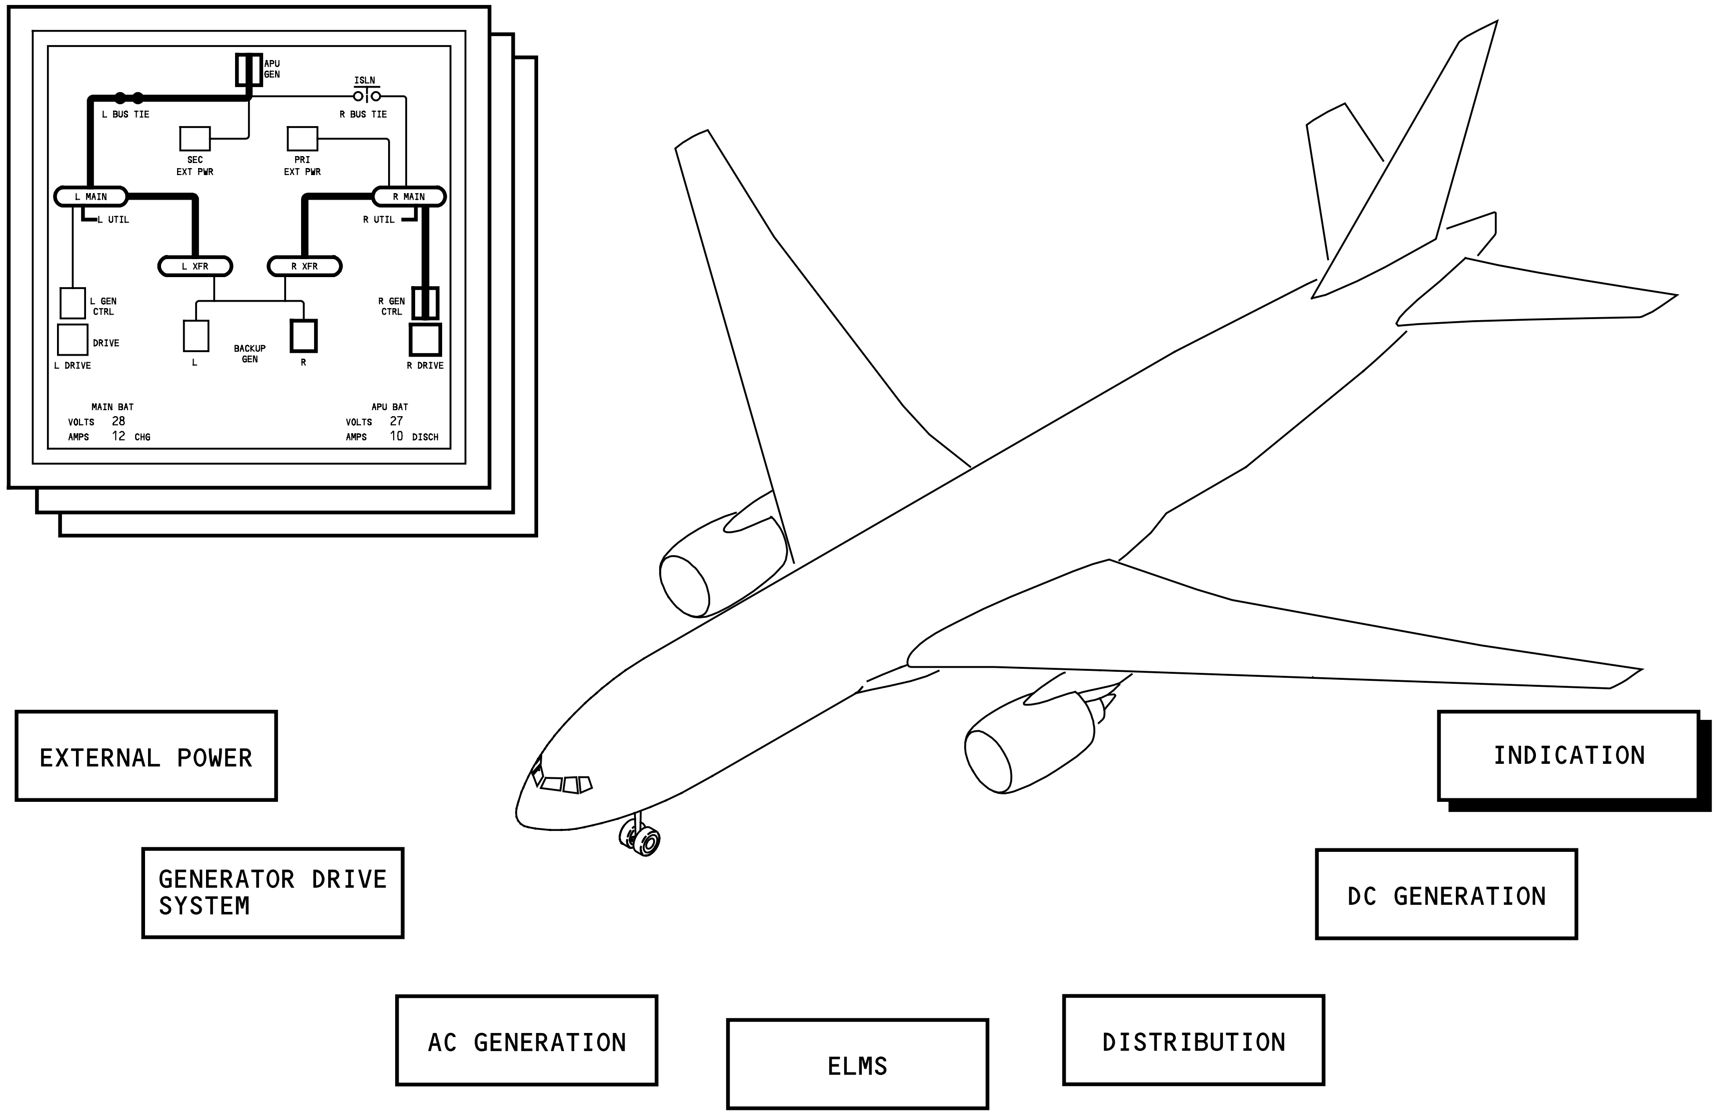
- Electrical maintenance page 1
- Electrical maintenance page 2.



ELECTRICAL POWER - INDICATION - INTRODUCTION

ELECTRICAL POWER - INDICATION - ELECTRICAL SYNOPTIC DISPLAY

General

The electrical synoptic display is a simplified schematic of the electrical system. It shows the system configuration for these parts of the ac and dc generation systems:

- Power sources
- Buses
- BTBs
- Generator drives
- Main and APU batteries.

Green flow segments show electrical power flow from power sources to buses.

Power Sources

The electrical synoptic shows power flow from these power sources:

- IDG
- APU generator
- Backup generator
- Primary and secondary external power.

It also shows the position of the breakers for the power sources.

A white box shows when the power source is off or the breaker is open. A green box shows when the power source is on or the breaker is closed. In general, an amber box and X show when there is a fault with the power source or a fault with the breaker.

Buses

The electrical synoptic shows when these buses receive power:

- Main ac buses
- Transfer buses
- Utility buses.

When the ELMS does a load shed, the message LOAD SHED shows below the utility bus indication for the related channel.

BTB Status

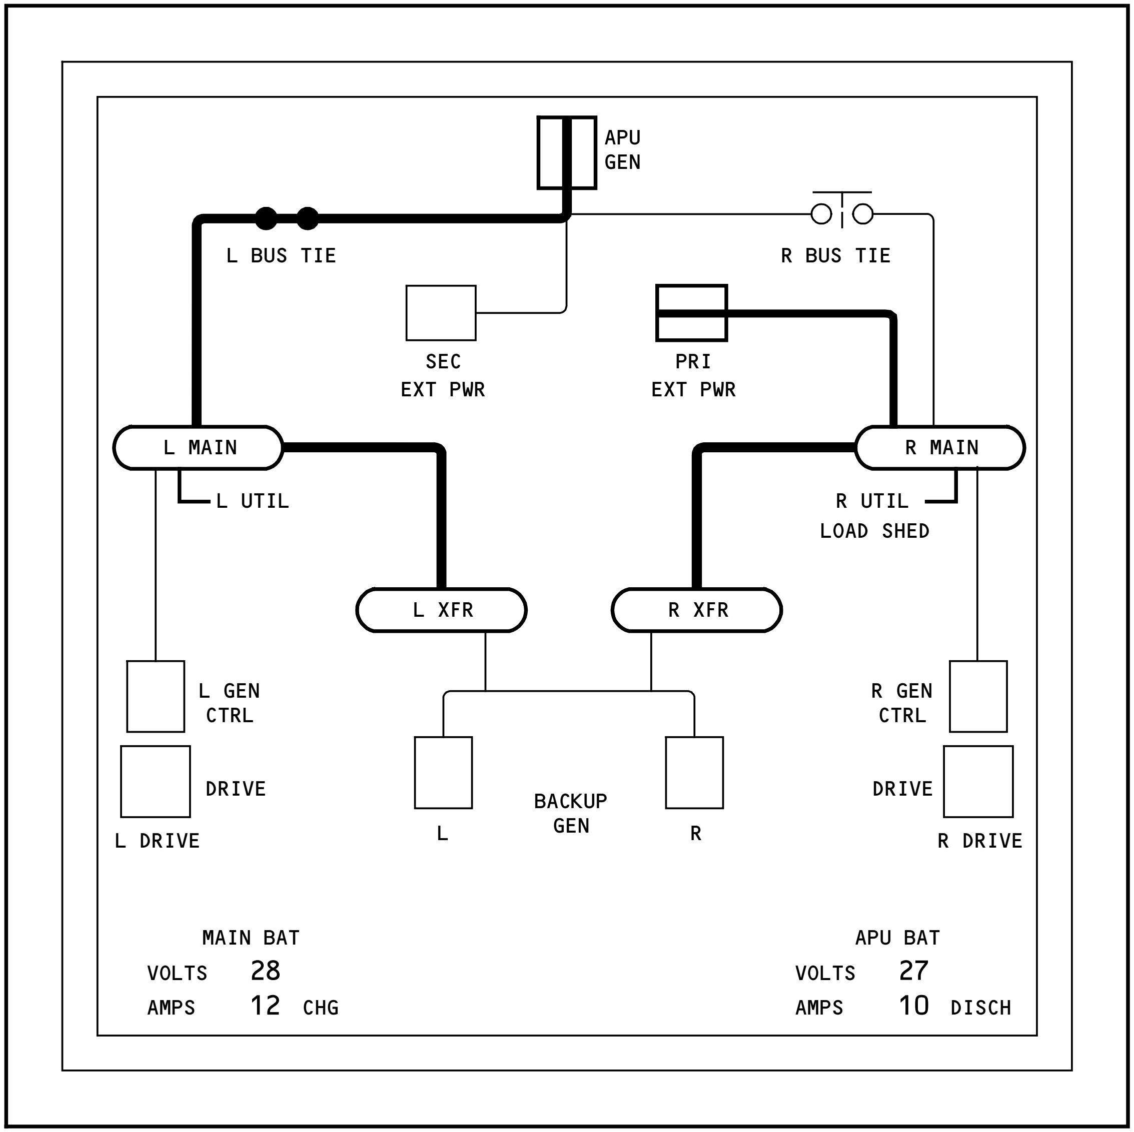
The electrical synoptic shows the BTB positions. An amber ISLN shows when a BTB is open because of a fault.

Drive Status

The electrical synoptic shows the IDG drive condition. The amber word DRIVE shows when the IDG has low oil pressure. An amber box and X show if the IDG is disconnected and the engine is running.

Main and APU Battery Output

The electrical synoptic shows the voltage and amperage output for the main and APU batteries. It also shows when a battery is charging or discharging.



ELECTRICAL POWER - INDICATION - ELECTRICAL SYNOPTIC DISPLAY

ELECTRICAL POWER - INDICATION - ELECTRICAL MAINTENANCE PAGE 1

General

The electrical system has two maintenance pages. Page 1 has information on these items:

- AC generation
- DC generation
- Generator oil information
- Fly-by-wire (FBW) output
- Auto-event messages.

AC Generation

The maintenance page shows these indications for the ac generation system power sources:

- Voltage
- Frequency
- Load.

The load is a percent of maximum output.

DC Generation

The maintenance page shows the voltage, and the load in amps, for the dc generation system power sources. Charge (CHG) and discharge (DIS) also show for the batteries.

Generator Oil Information

The maintenance page shows these indications for the IDGs and backup generators:

- Oil outlet temperature
- Oil rise temperature
- Oil level
- Oil filter message.

See the generator drive section for more information about generator oil indications (AMM PART I 24-10).

FBW Output

The maintenance page shows the voltage, and load in amps, for the FCDC buses.

FLIGHT DATA RECORDER SYSTEM - INTRODUCTION

FDRS - GENERAL DESCRIPTION

General

The flight data recorder (FDR) receives and stores selected airplane parameters from various airplane systems and sensors in a crash-protected solid state memory. The digital flight data acquisition function (DFDAF) of the airplane information management system (AIMS) receives all the flight recorder data. The DFDAF then processes the data and sends it to the FDR, where it is stored. The DFDAF is in the CPM/Comm module of both AIMS cabinets.

The flight data recorder system (FDRS) operates during any engine start, while any engine is running, during test or when the airplane is in the air.

The FDR records the most recent 25 hours of flight.

In addition to the data recording function, the FDR also has monitor circuits which send fault data to the DFDAF within AIMS.

DFDAF

The DFDAF receives all flight parameters to record. The DFDAF converts these parameters to a digital format and sends them to the FDR.

Analog Signals and Analog Discretes

The DFDAF processes and the FDR stores analog signals and analog discretes.

The FDR sends discrete signals to the DFDAF. The discretes show fault status.

Data Bus Interfaces

AIMS gets power control data from several airplane systems. Power goes to the FDR when the logic is valid. The power control data includes:

- Engine start
- Engine running
- Air/ground logic
- Test.

The FDR gets airplane parameters from the DFDAF in AIMS. Data goes on ARINC 717 buses. Each ARINC 717 bus has a shielded twisted pair of wires.

FDRS - SYSTEM INTERFACE

THIS PAGE INTENTIONALLY LEFT BLANK

FDRS - SYSTEM INTERFACE

General

The flight data recorder system (FDRS) gets digital data and digital discrete data on ARINC 629 and ARINC 429 data buses. The FDRS also receives analog inputs from some of the airplane systems and sensors. The FDR receives power from the power management panel. The FDR sends analog data to the digital flight data acquisition functions (DFDAF) of AIMS.

The left AIMS cabinet sends DFDAF data on an ARINC 717 data bus to the FDR. If the left AIMS cabinet DFDAF fails, the right AIMS cabinet sends DFDAF data to the FDR. The DFDAF sends fault data, status and test result data to the CMCF and the display system functions within the AIMS cabinets.

Power

The FDR receives power from the P210 right power management panel. DFDAF uses engine, air/ground, and ground test logic to determine when to turn on the FDR.

Analog Data

The DFDAFs receive status and maintenance flag data from the FDR. The DFDAFs receive key events from the VHF and HF LRUs and variable analog data from TAT, AOA and engine RPM sensors.

Digital Data

The systems ARINC 629 buses provides engine, airframe data, and air/ground logic. This is the engine data:

- Engine parameters, normal and exceedances
- Commands
- Actual thrust.

This is the airframe data:

- Flight deck switch position
- Flight controls positions
- Mode selections on control panels in the flight deck.

The DFDRS receives status from the engine and airframe sensors. The DFDRS also receives data and status from the electrical power system.

The flight controls ARINC 629 buses provide flight data and navigation data. This is the flight data:

- Flight control position
- Commands
- Status.

This is the navigation data from the ADIRU and SAARU:

- Pitch, roll and yaw attitude
- Acceleration data
- Status.

FDRS - SYSTEM INTERFACE

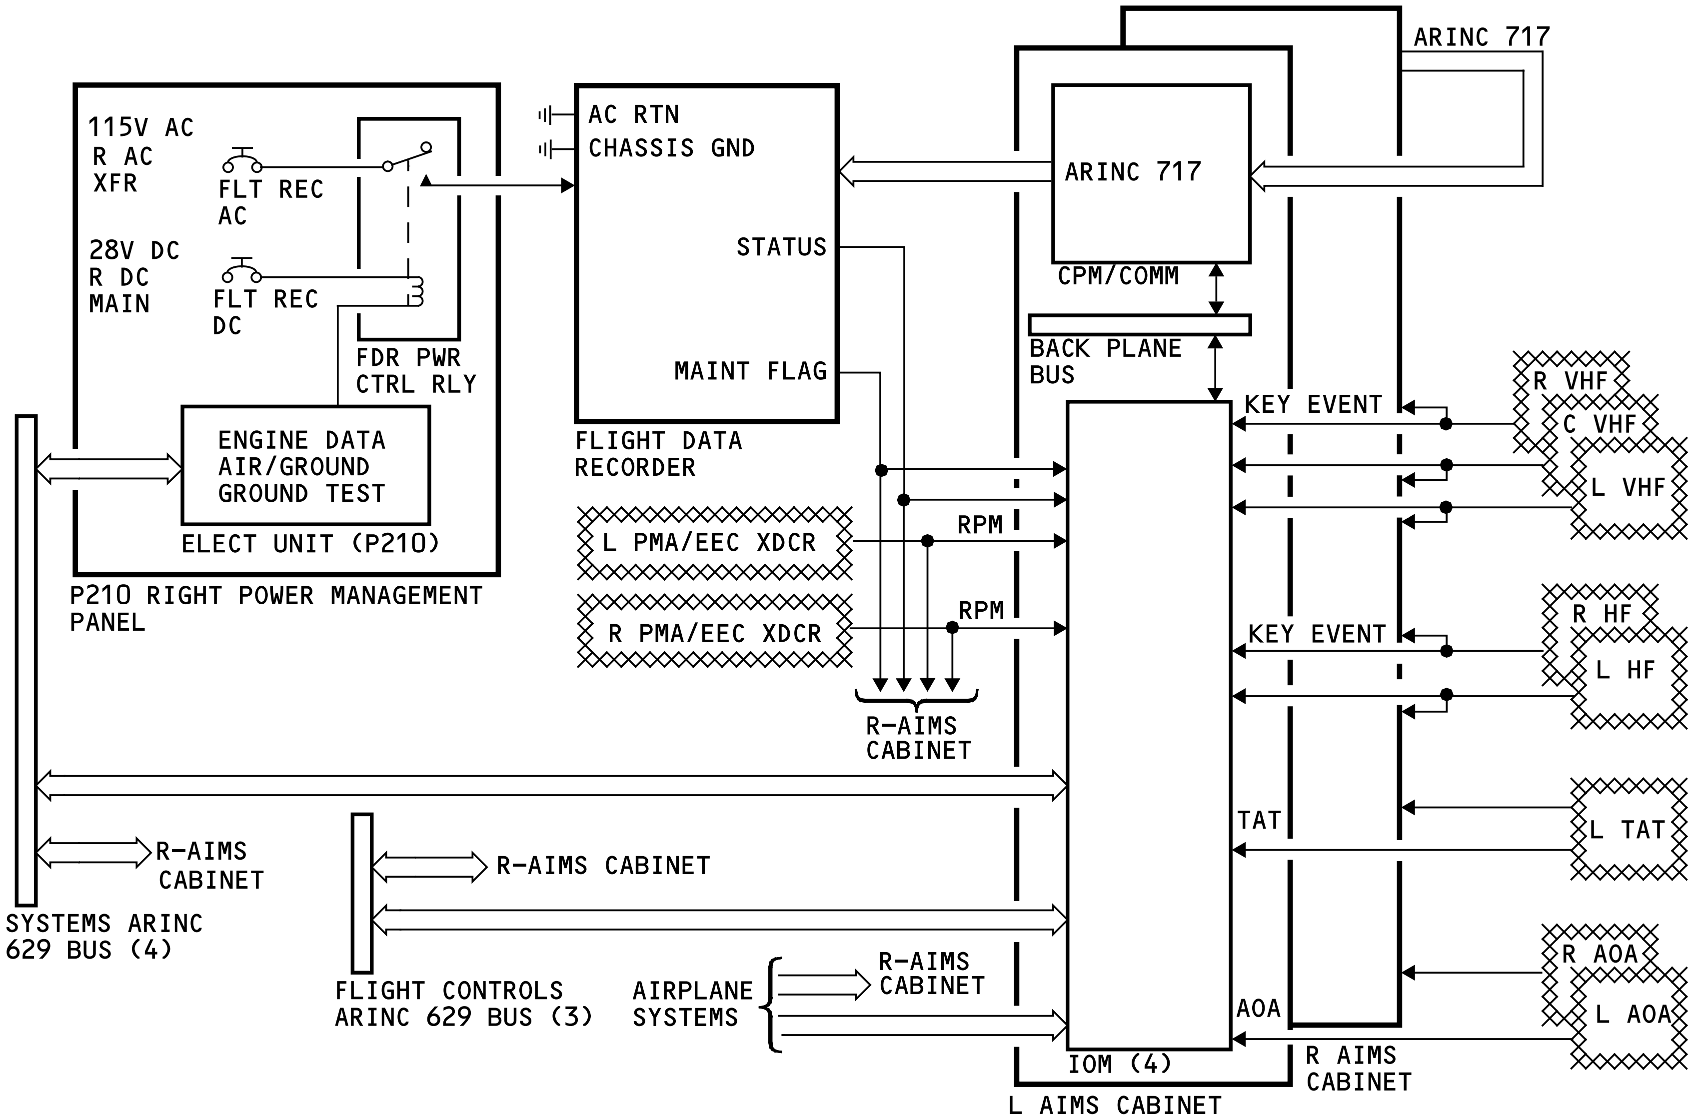
ARINC 429 provides navigation (NAV) radio/NAV data and communication (COMM) radio data. This is the NAV radio data:

- Radio frequencies
- Mode
- Parameters
- Status.

NAV data is aircraft position (LAT/LONG) and sensor status. COMM data is radio control panel frequencies and sensor status.

The left AIMS cabinet sends left or right DFDAF data on an ARINC 717 bus to the FDR.

The DFDAF sends fault data, status data and ground test results to the CMCF.



FDRS - SYSTEM INTERFACE

31-31-00-005 Rev 4 10/31/1997

FDRS - FLIGHT DATA RECORDER

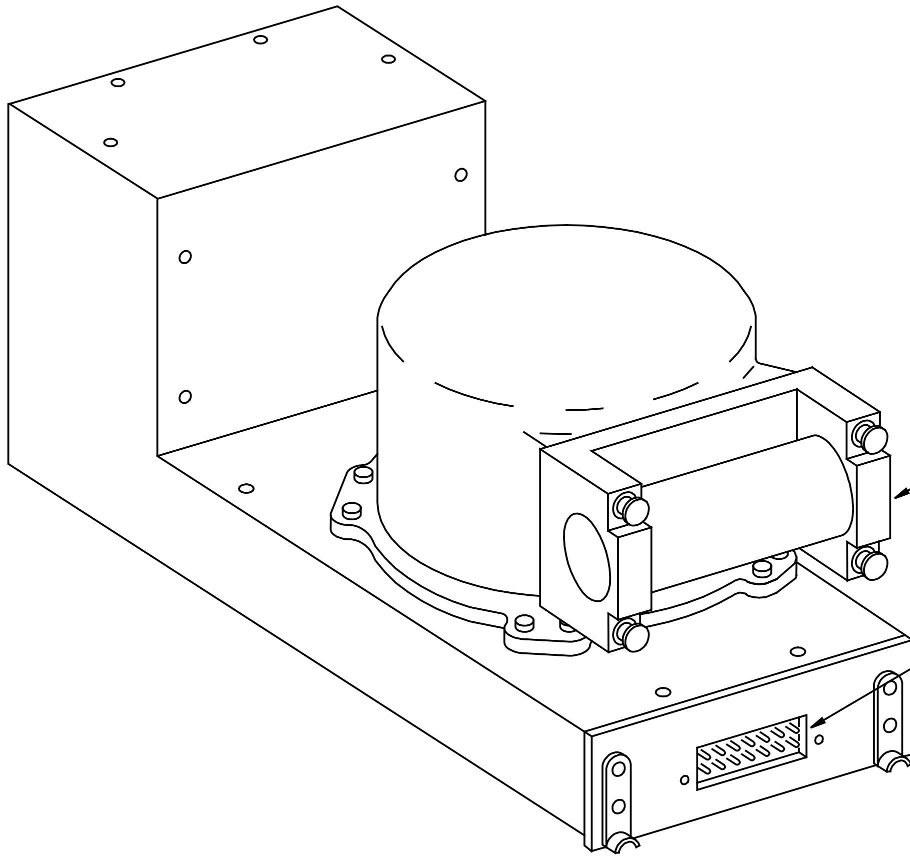
Purpose

The flight data recorder (FDR) records flight data in a protected solid-state memory.

Physical Description

The FDR is made of stainless steel. It weighs approximately 18 pounds. The memory storage assembly in the FDR is crush-proof up to 5000 pounds. The FDR case also supplies protection for up to 3400 g's of impact, deep sea pressures to 20,000 feet, and fire protection up to a temperature of 1100C for 1/2 hour.

An underwater locating device (ULD) is on the front panel. An automatic test equipment (ATE) connector is on the front of the unit.



31-31-00-006 Rev 3 03/17/1998

FDRS - FLIGHT DATA RECORDER

FDRS - UNDERWATER LOCATING DEVICE

Purpose

The underwater locating device (ULD) is an ultrasonic beacon. It makes the flight data recorder (FDR) easier to find if it is underwater.

Physical Description

The ULD is a line replaceable unit that is 1.3 inches in diameter and 4 inches long. It weighs less than 12 ounces.

Power

The ULD receives power from a 9.6 volt DUKANE model DK100 battery.

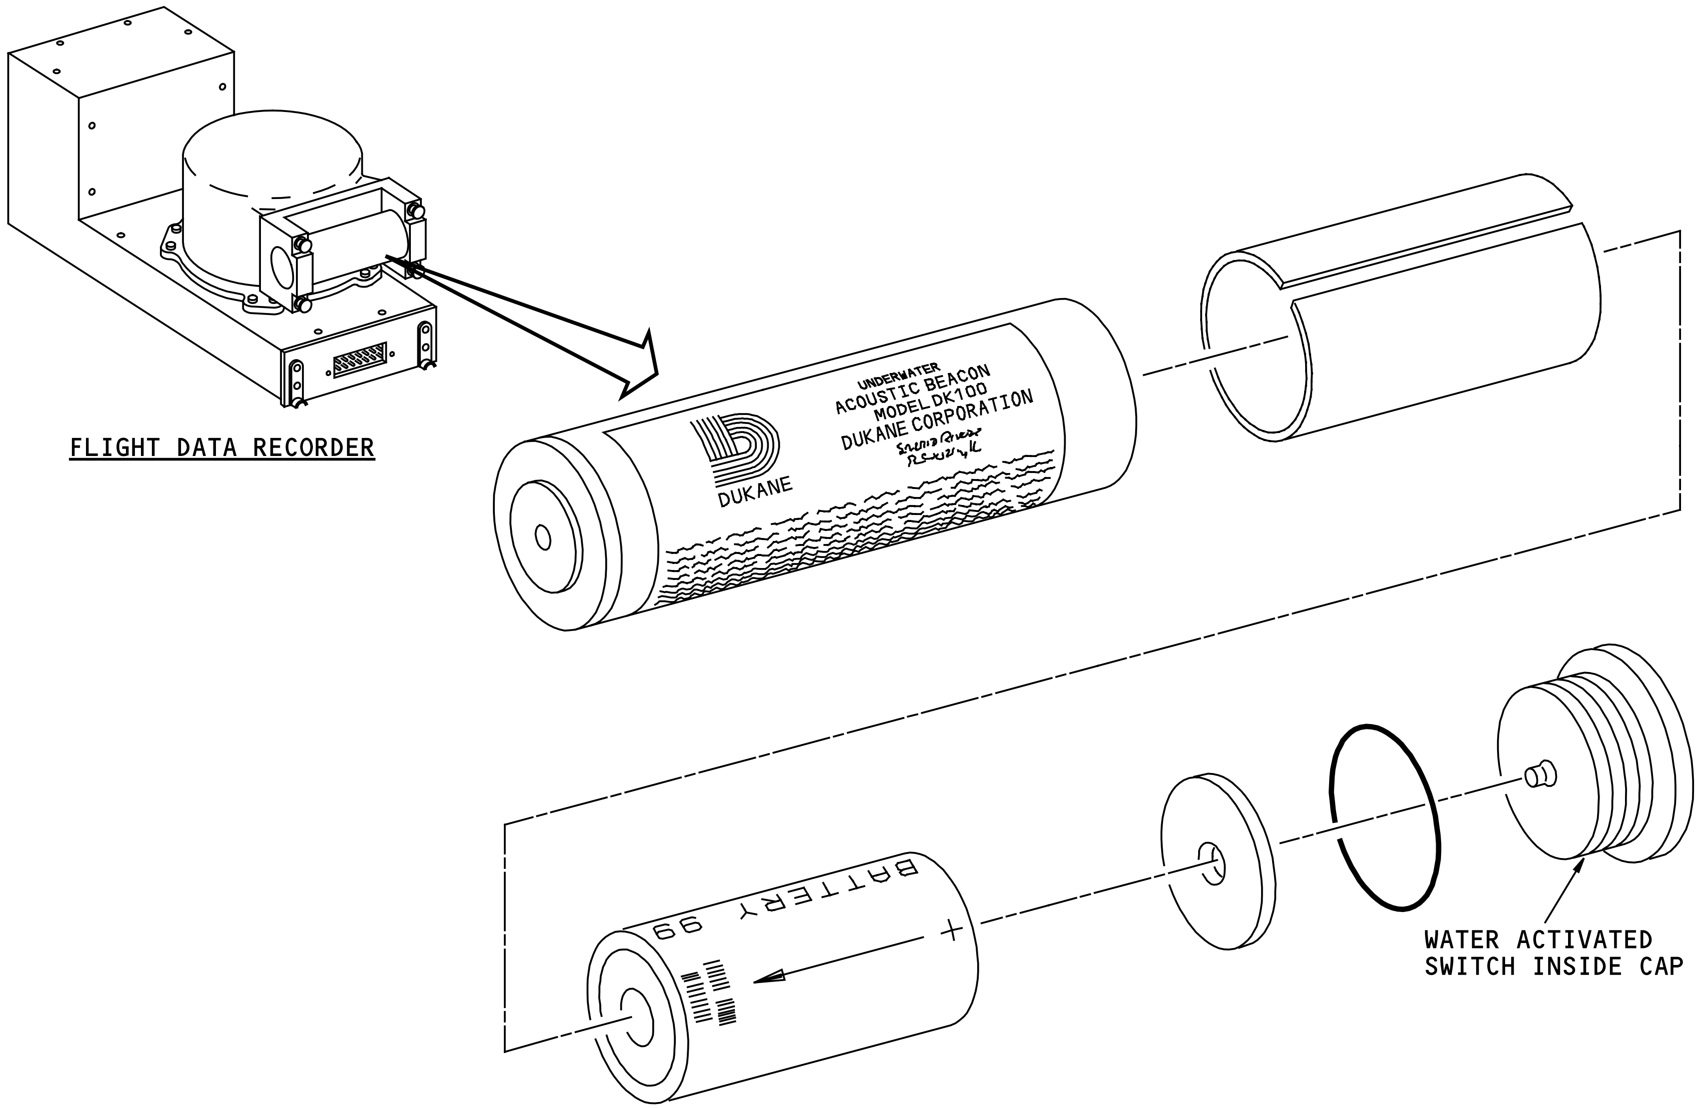
Functional Description

The ULD has these operational characteristics:

- Operates when it is put into water
- Operates to a maximum depth of 20,000 feet
- Has a detection range of 7,000 to 12,000 feet
- Has an operational life of 30 days underwater
- Sends out an acoustic pulse tone of 37.5 kHz at a rate of one pulse-per-second.

Training Information Point

The DK100 ULD uses a lithium battery. If not activated, it has a life of six years. It is important to keep the water switch contacts clean. The battery is not a line replaceable unit.



FDRS - UNDERWATER LOCATING DEVICE

THIS PAGE INTENTIONALLY LEFT BLANK

General

The digital flight data acquisition function (DFDAF) is software in each AIMS cabinet. The DFDAF collects data from:

- ARINC 629 buses
- ARINC 429 buses
- Analog discrete inputs
- Analog inputs.

The DFDAF reformats, organizes, and transmits this data to the FDR.

The DFDAF controls power to the FDR. The FDR records and monitors the fault status of the FDR system when it receives power. The FDR sends fault information to the central maintenance computing function (CMCF) and the primary display function (PDF) in AIMS.

ARINC 717 Interfaces

The AIMS core processor module/communication module (CPM/Comm) supplies ARINC 717 interfaces to the DFDAF. The AIMS DFDAF interfaces with the FDR via ARINC 717. Each of the AIMS cabinets has an ARINC 717 transmitter and a ARINC 717 bus for the FDR.

The output from the right AIMS cabinet goes to a source select relay in the left AIMS cabinet. The source select relay uses the output from the left or right DFDAF for the FDR. Software in the left AIMS cabinet controls the position of the source select relay. When the source select relay energizes, the left AIMS cabinet ARINC 717 output goes to the FDR.

DFDAF

Normal operation of the FDRS is automatic. The DFDAF is in both the left and right AIMS cabinets. The normal source of the data sent to the FDR is from the DFDAF in the left AIMS cabinet. If the left DFDAF fails, the DFDAF in the right AIMS cabinet automatically sends data to the FDR. In this case, the source select relay de-energizes. The DFDAF automatically collects, reformats and transmits data to the FDR shortly after the AIMS cabinets receive power.

The DFDAF continuously monitors airplane status to determine when to turn on the FDR and when to transmit data to the FDR. The DFDAF turns on the FDR when any one of these occur:

- Any engine is in start mode (starter air valve switch in START position or fuel cutoff lever not in CUTOFF position)
- Any engine is in the RUN mode (N1 RPM>20% or N2 RPM>20%)
- The airplane is airborne (from weight on wheels card in systems cardfile).

To supply power to the FDR, the DFDAF sends a digital discrete to the electrical load management system (ELMS) power management panel. The power management panel sends a ground to energize a relay in the panel and pass power to the FDR.

FDRS - DFDAF FUNCTIONAL DESCRIPTION

The DFDAF receives these two discrete inputs from the FDR:

- Maintenance flag
- System status flag.

The maintenance flag discrete shows a FDR internal failure. A system status flag shows a system level failure such as:

- No FDR power
- No data input to the FDR
- A power control relay failure in the power management panel.

The DFDAF reports system status to the CMCF within the AIMS cabinet.

CMCF

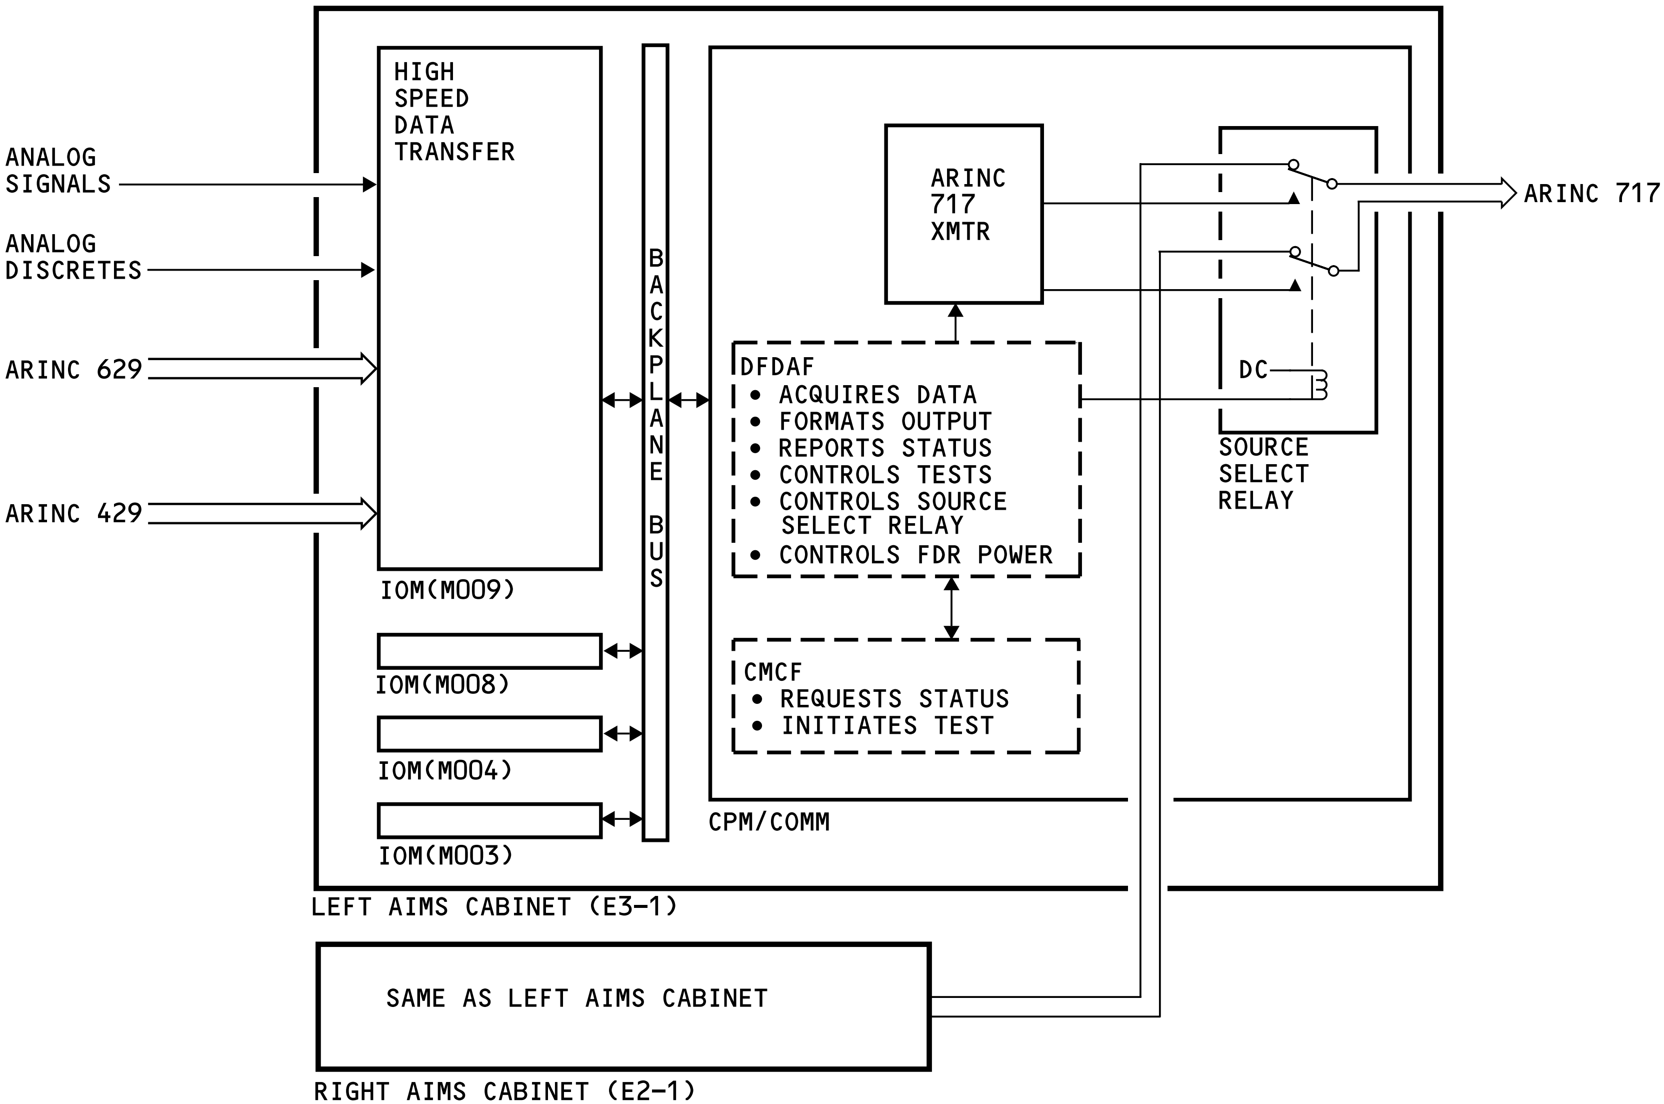
The DFDAF receives fault and status information from the FDR. DFDAF sends fault reports and status data to the CMCF. The CMCF determines pass/fail. For each fault message sent to the CMCF, the DFDAF records this information:

- Which message was sent
- The specified data
- Diagnostic data
- Date, time, and flight number
- Software part number.

Use the MAT to request the DFDAF to start the FDRS ground test. The MAT interfaces with the CMCF which sends the test command to the DFDAF. The DFDAF transmits two frames of data to the FDR to verify the operational status of the FDRS and responds back to the CMCF with a pass/fail message. You see the test results and fault status on the MAT and the EICAS display format.

The DFDAF in the right AIMS cabinet sends data to the FDR first during the ground test. After the ground test for the DFDAF in the right AIMS cabinet, the DFDAF in the left AIMS cabinet sends data to the FDR to do the second half of the ground test.

A manual POWER ON command causes the FDR to transfer data to an ARINC 615 portable data loader. A manual POWER OFF command is available from the MAT to remove power to the FDR. The FDRS normal mode of operation inhibits the manual commands.



31-31-00-008 Rev 2

FDRS - DFDAF FUNCTIONAL DESCRIPTION

FDRS - FDR FUNCTIONAL DESCRIPTION

General

The flight data recorder (FDR) receives and records the last 25 hours of data. The FDR receives the data from the DFDAF. The FDR records the data in a solid-state memory. The memory is in a crash-proof, fire-resistant container. The FDR also monitors and sends fault data to the DFDAF.

Recording Data

The AIMS digital flight data acquisition function (DFDAF) sends data on a high speed data bus (ARINC 717) to the FDR. In the FDR, the receiver processes and sends the data to the microprocessor. The microprocessor receives, processes and stores the data in a crash survival solid-state memory. Data is recorded at 128 words/second.

Data Downloading

The front mounted automatic test equipment (ATE) connector on the FDR provides a connection for:

- ATE or ramp test equipment for recorder checkouts on or off the aircraft
- Data download to a portable data unit while on or off the airplane.

Non-normal Conditions

The FDR microprocessor sends these two discretes to the AIMS DFDAF:

- System status flag
- Maintenance flag.

The system status flag discrete causes a system level alert. A maintenance flag discrete causes a FDR internal failure. When a FDR fails, the FDR sends both discretes. When the AIMS DFDAF receives either discrete, EICAS (PDF) shows a FLT RCDR SYS status message. The AIMS DFDAF also sends the fault data to the AIMS CMCF.

DATA COMMUNICATION MANAGEMENT SYSTEM - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

DCMS - GENERAL DESCRIPTION

General

The data communication management system (DCMS) manages analog and digital data in many different formats. It divides the work into these two functions:

- Data communication management function (DCMF)
- Flight deck communication function (FDCF).

The DCMF manages the radio hardware interfaces and internal processing. The FDCF controls the flight deck interface and passes it on to the DCMF.

DCMF

The DCMF supplies the protocols and manages data for these sub-functions:

- ACARS datalink sub-function
- Onboard local area network (OLAN) interface sub-function
- Print driver sub-function.

The aircraft communications addressing and reporting system (ACARS) datalink sub-function manages flight plan and maintenance data between the airplane and the ground service provider (GSP). The ACARS datalink sub-function connects to these components of other systems:

- Satellite data unit (SDU)
- Center and right VHF communication transceivers
- Left, center and right radio tuning panels (RTPs).

The OLAN interface sub-function manages the data exchange between the DCMF and the components on the avionics local area network (AVLAN). The AVLAN is part of the OLAN. The AVLAN includes these components:

- Maintenance access terminal (MAT)
- Brouter.

The brouter connects to the portable maintenance access terminals (PMATs).

The print driver sub-function manages all print requests for the DCMS. It sends data from the DCMS to the flight compartment printer, and sends print job status and any fault data back to the DCMS.

FDCF

The FDCF supplies an operator interface for the DCMS. You use these components to make inputs to the FDCF:

- The display select panel (DSP)
- The multi-function display (MFD)
- The control display units (CDU)
- The cursor control devices (CCD)
- Accept/reject/cancel switches.

The DSP controls which display unit shows the MFD. You use the DSP to select the COMM MFD display.

When you select the COMM display on the DSP, the MFD shows the FDCF main menu.

DCMS - GENERAL DESCRIPTION

You use the CDUs to enter text to the FDCF displays. After you type text in the CDU scratch pad you use the CCD select switch to move it to the FDCF display.

You also use the CCDs to select menu items, buttons, and text boxes on the FDCF displays.

You use the accept/reject/cancel switches to accept, reject, or cancel messages that show on the FDCF displays.

DCMS - COMPONENT LOCATIONS - MAIN EQUIPMENT CENTER

DCMS - ARINC 429 INPUTS AND ARINC 618 INTERFACES

General

The data communication management function (DCMF) receives data on low speed and high speed ARINC 429 buses. It also receives and sends data on ARINC 618 buses.

Input Components

These components exchange data with the DCMF:

- Satellite data unit (SDU)
- Flight deck printer
- Inflight entertainment system
- left, center, and right radio tuning panels (RTP)
- Center and right VHF communication transceivers (VHF).

Satellite Data Unit

The SDU sends ground service provider (GSP) data to the DCMF on a high speed ARINC 429 bus.

The SDU data goes to IOM (M003) and IOM (M004) in the left AIMS cabinet, and IOM (M008) and IOM (M009) in the right AIMS cabinet.

Flight Compartment Printer

The flight compartment printer sends status and error data to the DCMF on a high speed ARINC 429 bus.

Printer data goes to IOM (M009) in both AIMS cabinets.

Inflight Entertainment System

The inflight entertainment system sends data to the DCMF on a high speed ARINC 429 bus. The DCMF sends this data to the GSP. The data is downlink data.

Inflight entertainment system data goes to IOM (M009) in both AIMS cabinets.

Radio Tuning Panels

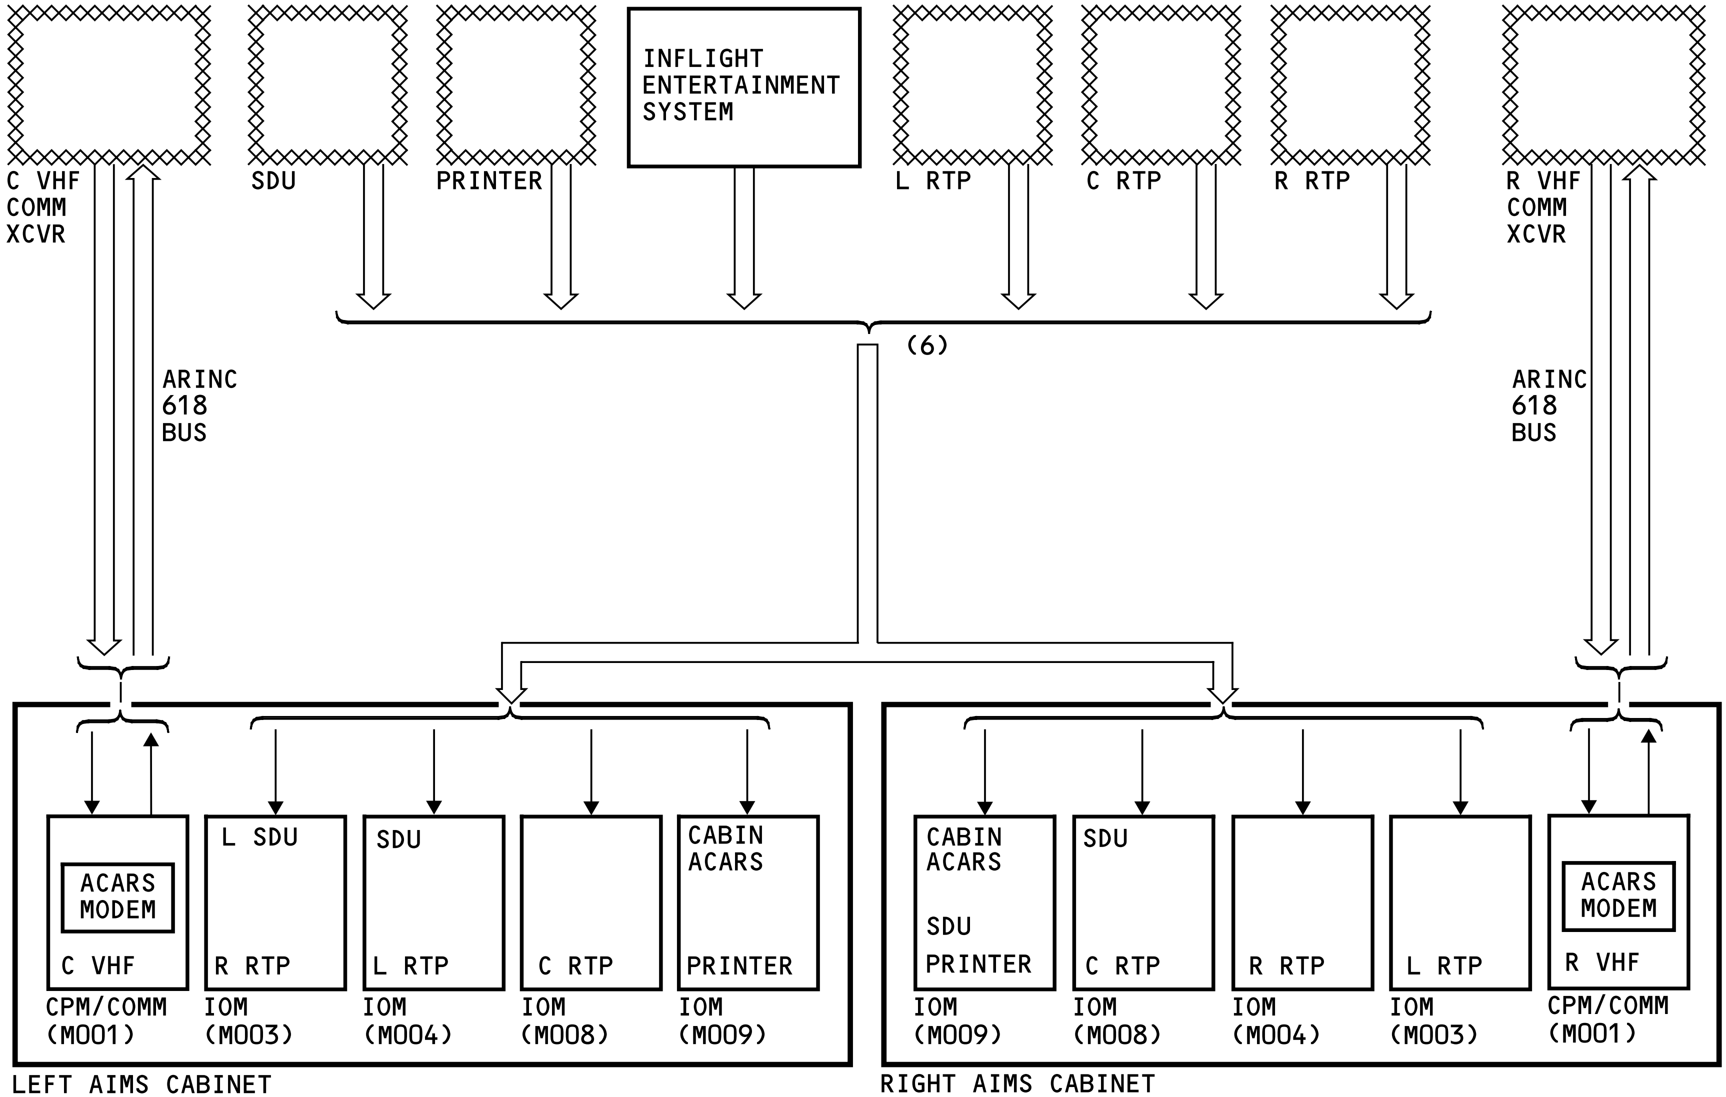
The RTPs send tuning data and broadcast status data to the DCMF and the flight deck communication (FDCF) on low speed ARINC 429 buses.

Left RTP data goes to IOM (M004) in the left AIMS cabinet and IOM (M003) in the right AIMS cabinet. Center RTP data goes to IOM (M008) in both cabinets. Right RTP data goes to IOM (M003) in the left AIMS cabinet and IOM (M004) in the right AIMS cabinet.

VHF Communication Transceivers

The DCMF receives and sends GSP data to the VHF transceivers on ARINC 618 data buses.

The center VHF exchanges data with the ACARS modem in the left CPM/Comm. The right VHF exchanges data with the ACARS modem in the right CPM/Comm. The DCMF does not interface with the left VHF transceiver.



DCMS - ARINC 429 INPUTS AND ARINC 618 INTERFACES

DCMS - ARINC 429 INTERFACES - OUTPUTS

General

The data communication management function (DCMF) uses the DCMF bus and the general purpose bus 2 to send data.

Each bus takes data from one of two IOMs in each cabinet. Each bus uses a source select relay to get data from one of two IOMs in each cabinet if necessary.

DCMF Bus

The source select relay for the DCMF bus energizes when the DCMF sends a signal. This causes data to come from IOM (M009). When the DCMF causes the source select relay to relax, data comes from IOM (M003).

The DCMF bus is a high speed ARINC 429 bus. It sends data from the left and right AIMS cabinets to the:

- Satellite data unit (SDU)
- Inflight entertainment system
- Flight compartment printer.

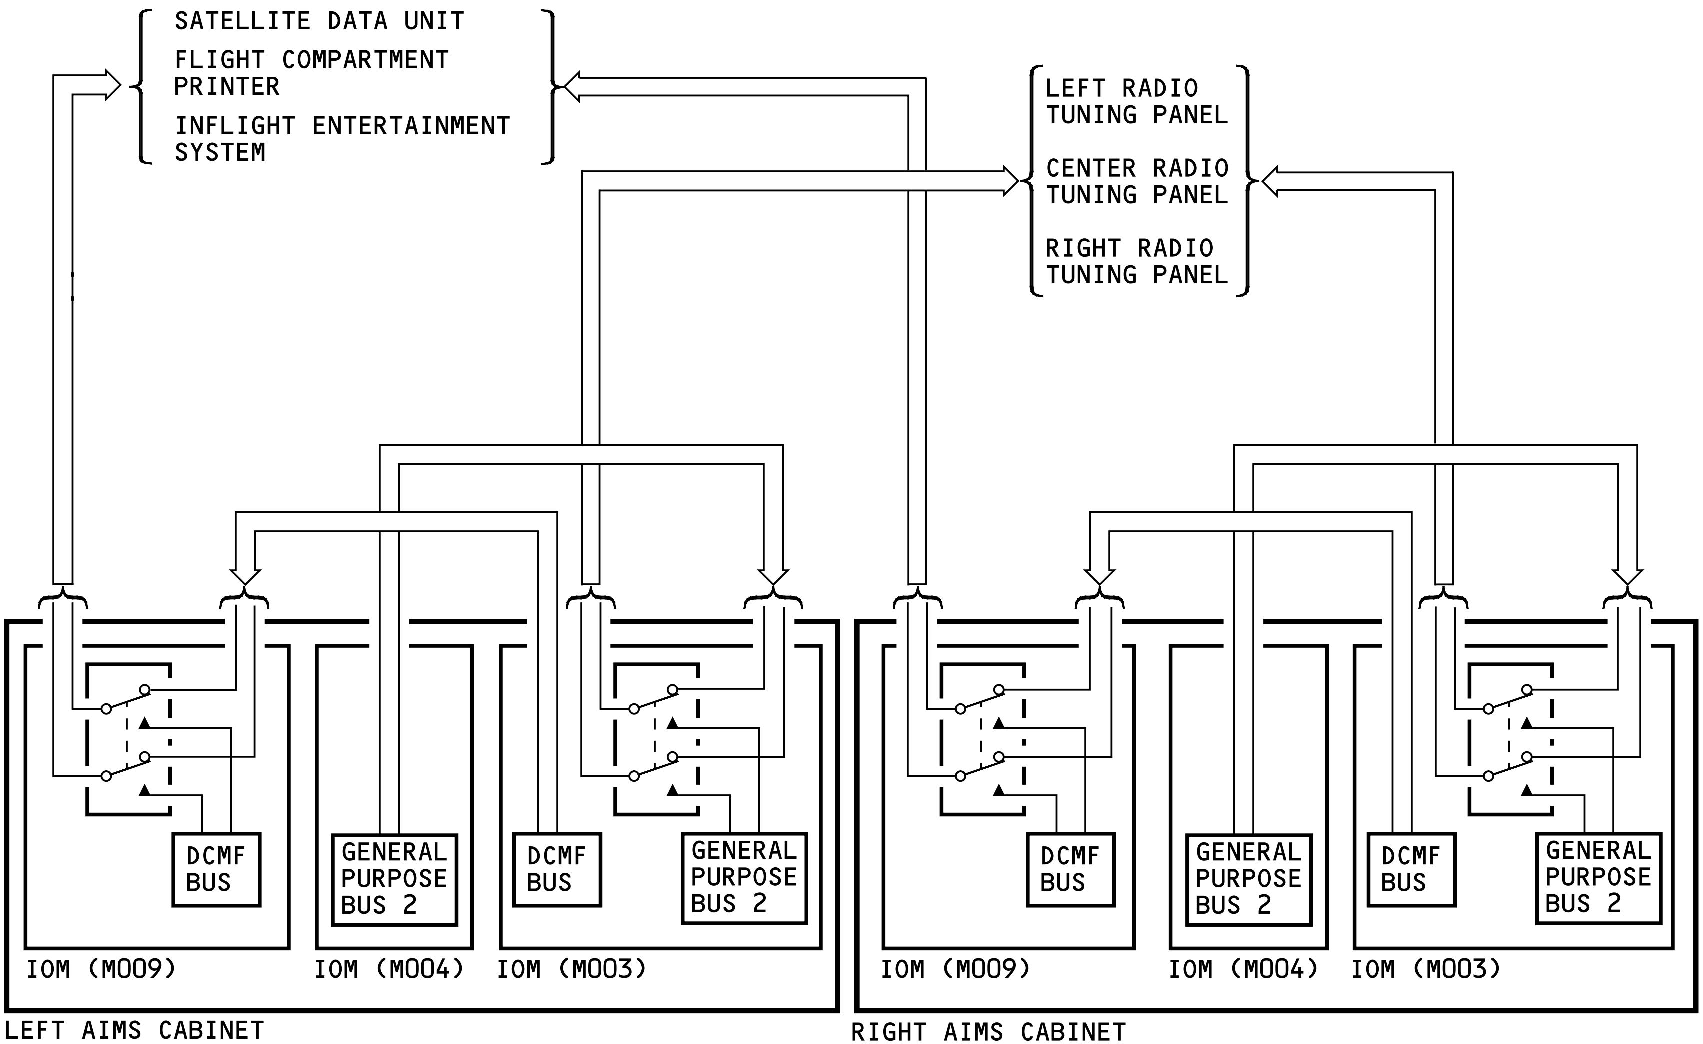
The DCMF sends downlink data through the SDU to the ground service provider (GSP).

The DCMF controls the print requests it receives from other AIMS functions. It sends print controls and data to the printer.

General Purpose Bus 2

Fault detection and switch logic in IOM (M003) energizes the source select relay. This causes the source select relay to use general purpose bus 2 data from IOM (M003). When the fault detection and switch logic causes the source select relay to relax, data comes from IOM (M004).

The general purpose bus 2 is a low speed ARINC 429 bus. It sends tuning data and broadcast status data to the RTPs.



23-27-00-006 Rev 6 02/24/1997

DCMS - ARINC 429 INTERFACES - OUTPUTS

DCMS - INTERCABINET ARINC 629 INTERFACES

Intercabinet Interface

The DCMFs and FDCF exchange data across AIMS intercabinet ARINC 629 buses. The DCMFs use buses 3 and 4. The FDCFs use buses 1 and 2.

The DCMF data includes the:

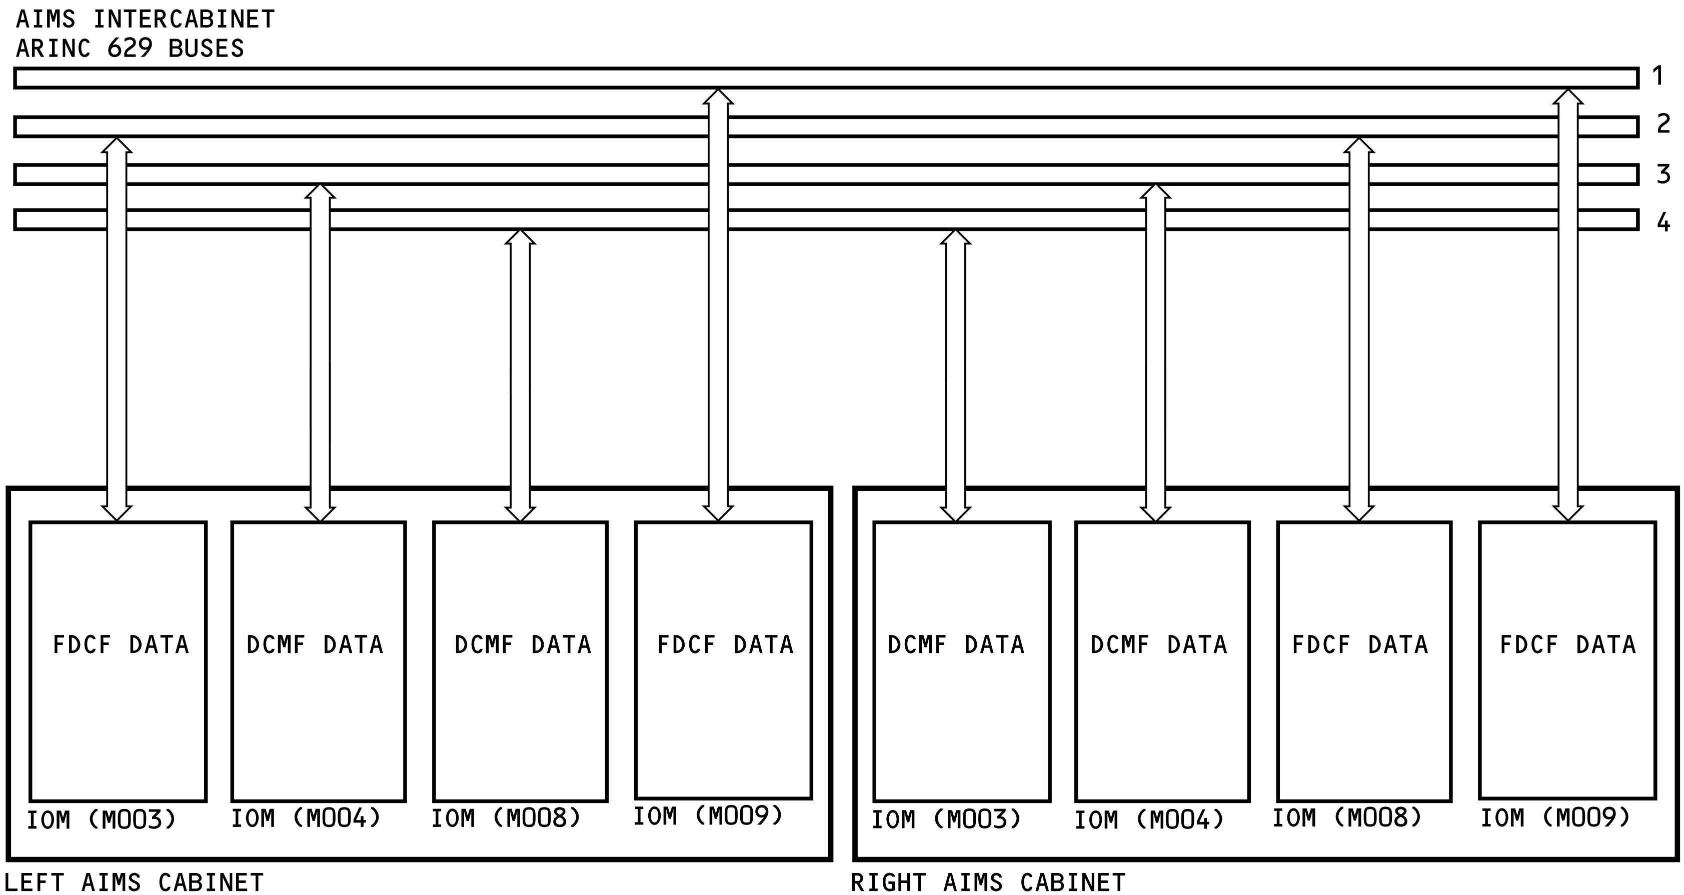
- Inputs to each DCMF
- Status and control information from each DCMF.

The DCMFs use this data to keep synchronized and to monitor their operation.

The FDCF data includes:

- FDCF-related display information
- FDCF-related central maintenance information
- FDCF-related DCMF information
- FDCF-redundancy information.

The FDCFs use this data to keep synchronized and to monitor their operation.



23-27-00-007 Rev 1

DCMS - INTERCABINET ARINC 629 INTERFACES

DCMS - OLAN AND DISCRETE INTERFACES

OLAN Interfaces

The avionics local area network (AVLAN) is part of the onboard local area network (OLAN) fiber distributed data interface (FDDI). The AVLAN uses a primary (PRI) network loop with a secondary (SEC) network loop as an alternative. The avionics LAN uses the ARINC 636 standard. The DCMF supplies the communications protocols that permit AIMS to exchange data with the:

- Maintenance access terminal (MAT)
- Brouter.

The brouter supplies the interface to the PMATs.

PRI BS1 is a 15v dc power discrete. It causes the bypass switch unit (BSU) to connect the left or right AIMS cabinet to the primary loop of the avionics LAN.

SEC BS1 is also a 15v dc power discrete. It causes the BSU to connect the left or right AIMS cabinet to the secondary loop of the avionics LAN.

Discrete Interfaces

The DCMF uses the data key line to key the VHF communication transceiver. When the DCMF keys the transceiver, the DCMF sends the downlink message to the VHF communication transceiver.

The DCMF uses the voice/data select to set the VHF communication transceiver to the data signal mode. At power-up, the DCMF sets the center VHF communication transceiver to the data signal mode. If the center VHF communication transceiver fails the DCMF selects satcom for data transmissions. If satcom fails, the DCMF selects the right VHF communication transceiver for data transmissions.

The left VHF communication transceiver is voice only.

DCMS - OLAN AND DISCRETE INTERFACES

DCMS - FDCF DISPLAY OVERVIEW

General

The FDCF displays show on a multifunction display (MFD). The FDCF receives messages from the airline's ground station and sends them to the PDS to show on the MFD. The flight crew can also send messages to the airline's ground station.

To show the FDCF main menu bar, select COMM on the display select panel (DSP).

These are the six menu selections that show on the FDCF main menu bar:

- ATC
- FLIGHT INFORMATION
- COMPANY
- REVIEW
- MANAGER
- NEW MESSAGES.

Buttons show at the bottom of the display to give the flight crew control.

ATC

The air traffic control (ATC) menu shows all of the displays the flight crew uses to communicate with the ATC system.

Flight Information

The FLIGHT INFORMATION selection is not available now. There is no response when the crew puts the CCD cursor in this menu selection.

COMPANY

The COMPANY menu shows all customer configured downlink messages.

REVIEW

The flight crew uses the REVIEW menu to look at uplink or downlink messages. Uplink messages show here after the crew accepts or rejects them. Messages that do not require an accept or reject also show here.

MANAGER

The MANAGER menu shows status information and supplies controls for flight deck communication external support devices. In the MANAGER menu, pages show for:

- The radios
- The flight compartment printer
- Message configuration
- Datalink configuration.

NEW MESSAGES

The NEW MESSAGES menu shows the new messages that require flight crew review. The new messages usually come from the airline ground station. They may also be messages that the flight crew enters.

Buttons

The flight crew uses the buttons to control the flight deck communication function (FDCF) displays. Each FDCF display causes different buttons to show.

The ACCEPT, REJECT, and CANCEL buttons on the FDCF display do the same functions as the ACCEPT, REJECT, and CANCEL switches on the P7 glareshield panel.

These buttons can show on the FDCF displays:

- ACCEPT
- SEND
- LOAD FMC
- PRINT
- PRINT LIST
- RESET
- STANDBY
- RETURN
- APPEND
- REJECT REASONS
- REJECT
- CANCEL
- EXIT
- EXIT MENU.

The ACCEPT button shows when a received message requires an accept or reject response and all pages of the message have been displayed.

The SEND button shows when all required data for the message has been entered and all pages have been displayed.

The LOAD FMC button shows when the air traffic control (ATC) system sends a flight plan modification. The flight crew uses this button to send the modified flight plan to the flight management computing function (FMCF).

The PRINT button shows when a page has the capability to be printed and the printer is available.

The PRINT LIST button is available for the REVIEW or NEW MESSAGES pages when a list shows. This lets the flight crew print multiple messages.

The RESET button shows when a downlink message is displayed. This clears the message text.

The STANDBY button lets the flight crew tell the ATC that the ATC message is in review.

The RETURN button shows when a review message page, a downlink message page, or a manager page shows. This returns you to the previous list box page or menu.

The APPEND button shows if the received message has the capability for the crew to add information and downlink a response message. The APPEND button shows only if all pages have been shown.

DCMS - FDCF DISPLAY OVERVIEW

The REJECT REASONS button shows when a received message requires an accept or reject response and all pages of the message have been shown. A list of reject reasons shows when you select this button.

The REJECT button shows when a received message requires an accept or reject response and all pages of the message have been shown. The message is rejected when the flight crew selects this button.

The CANCEL button shows when a received message does not require a response or the received message has been accepted or rejected.

The EXIT button shows when the downlink page or manager page shows.

The EXIT MENU button shows when a menu shows. The EXIT MENU button takes you back to the FDCF main menu screen.

DCMS - FDCF INFORMATION MESSAGES

General

During the uplink or downlink mode, information messages show on the display. The information box and the button show at the bottom of the display and hides other data. Information messages show in the box as the flight crew looks at the uplink or downlink message text. Information messages occur either as a result of flight crew action or automatically.

Uplink Information Messages

When you select the ACCEPT button on the MFD or the glareshield, one of these information messages show:

- ACCEPTING
- ACCEPTED
- NO ACCEPT.

ACCEPTING shows after crew selects ACCEPT and until the ACCEPT uplink is successful or the flight crew selects EXIT INFO.

ACCEPTED shows that the uplink is successful and shows when the flight crew selects EXIT INFO.

NO ACCEPT shows when the uplink queue is full or the crew selects EXIT INFO.

When you select the REJECT button on the MFD or the glareshield, one these information messages show:

- REJECTING
- REJECTED
- NO REJECT.

REJECTING shows after the crew selects REJECT and until the REJECT uplink is successful or the flight crew selects EXIT INFO.

REJECTED shows that the uplink is successful and shows when the flight crew selects EXIT INFO.

NO REJECT shows when the uplink queue is full or the crew selects EXIT INFO.

When you select the PRINT button on the MFD, one of these information messages show:

- MESSAGE TO PRINTER 1
- NO PRINT.

MESSAGE TO PRINTER 1 shows when the print format goes to the primary flight compartment printer. It shows until the flight crew selects EXIT INFO or until NO PRINT occurs.

NO PRINT shows when the print format cannot be sent to the flight compartment printer. It shows until the flight crew selects EXIT INFO.

INVALID DATA shows when the uplink has invalid data.

DATALINK LOST FOR THIS MESSAGE tells the flight crew that the datalink to respond to this message is not available. This type of information message requires a flight crew response. It shows until the flight crew makes a response. EXIT INFO then causes the message to go away.

INCOMPLETE MESSAGE shows when the flight crew receives an uplink with mandatory data fields blank. The message shows until the flight crew selects EXIT INFO.

Downlink Information Messages

When you select the PRINT button on the MFD, one of these information messages show:

- MESSAGE TO PRINTER 1
- NO PRINT.

MESSAGE TO PRINTER 1 shows when the print format goes to the flight compartment printer. It shows until the flight crew selects EXIT INFO or NO PRINT occurs.

NO PRINT shows when the print format cannot be sent to the flight compartment printer. It shows until the flight crew selects EXIT INFO.

When you select the SEND button on the MFD, one of these information messages show:

- SENDING
- SENT
- NO SEND.

SENDING shows until the downlink is successful or the flight crew removes the response from the downlink list or the flight crew selects EXIT INFO.

SENT shows that the downlink is successful. It shows until the flight crew selects EXIT INFO.

NO SEND shows when the flight crew deletes the response from the downlink list. It shows until the crew selects EXIT INFO.

DCMS - FDCF COMPANY MENU

General

The COMPANY menu gives you access to company format displays and sub-menus to downlink. You can transmit messages and data from a display. you can select the company menu anytime.

These are the displays you can select from the company menu:

- Flight initialization
- Diversion
- Estimated time of arrival (ETA)
- Flight times
- Departure report
- Position report
- Arrival report
- Message to ground
- Voice contact request
- Weather requests
- Maintenance report
- Miscellaneous codes
- Situation.

These are the sub-menus you can select from the company menu:

- Delay reports
- Crew requests.

Use the cursor control device to highlight and select a display or sub-menu.

Flight Initialization Display

The flight crew can initialize flight plan data from a single location on this display.

Diversion Report Display

The flight crew uses the diversion report display to tell the airline the ETA at the diversion destination.

Estimated Time of Arrival Display

The flight crew uses the estimated time of arrival display to tell the airline the planned ETA at the destination airport.

Flight Times Display

The flight crew uses the flight times display to show the OUT, OFF, ON, and IN times. This shows the fuel on board and boarded fuel for the current and previous flights.

Departure Report Display

The flight crew uses the departure report display to send information that shows on the flight times display and additional information that relates to a departure.

Position Report Display

The flight crew uses the position report display to send this information:

DCMS - FDCF COMPANY MENU

- Position information
- Current position
- Flight level
- Next position
- Other performance data.

Arrival Report Display

The flight crew uses the arrival report display to send information that shows on the flight times display and additional information that relates to an arrival.

Message To Ground Display

The flight crew uses the message to ground display to send free text messages to a selected ground station.

Voice Contact Request Display

The flight crew uses the voice contact request display to start voice contact with a selected ground station.

Weather Requests Display

The flight crew uses the weather request display to request weather information from the airline host or ground service provider.

Maintenance Report Display

The flight crew uses the maintenance report display to enter codes and/or free text about maintenance problems for transmissions to the ground.

Miscellaneous Codes Display

The airline uses the miscellaneous codes display to support new display functions.

Situation Display

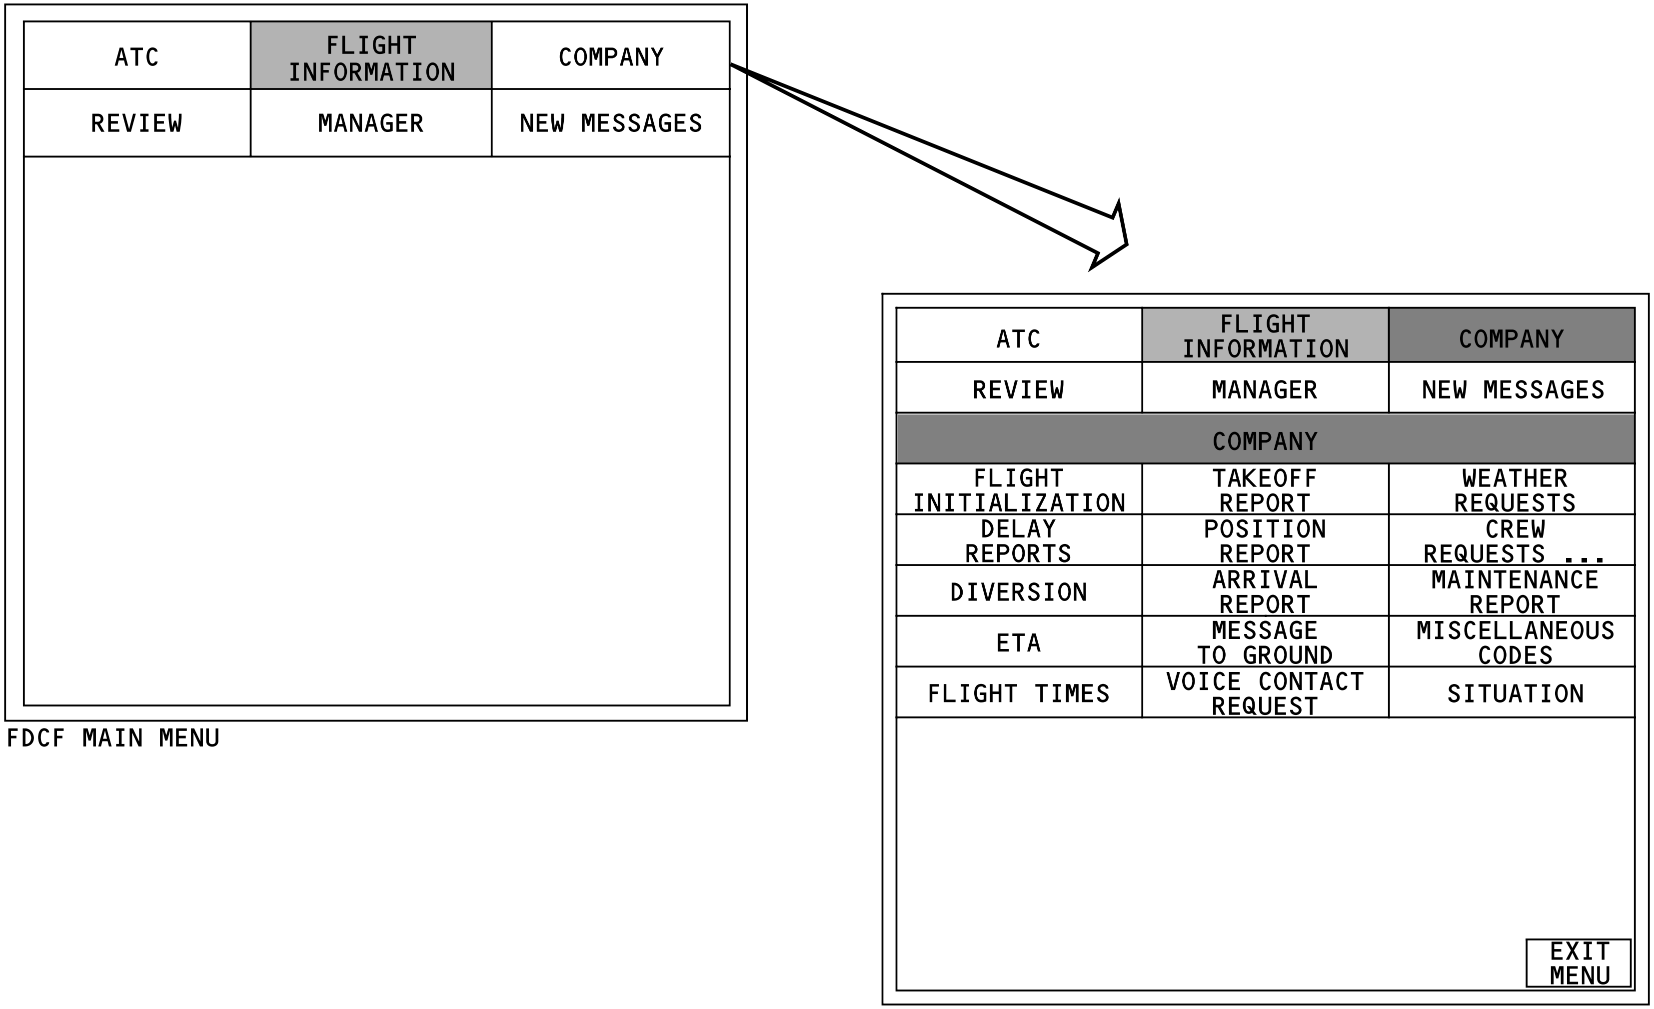
The flight crew uses the situation display to tell the ground station of an emergency situation.

Delay Reports Sub-menu

The flight crew uses the delay reports sub-menu to tell the airline of a departure, takeoff, or enroute delay.

Crew Requests Sub-Menu

When you select the crew requests box, the crew requests sub-menu shows. The crew requests sub-menu shows more display selections.



FDCF MAIN MENU

FDCF COMPANY MENU

23-27-00-013 Rev 2 03/05/96

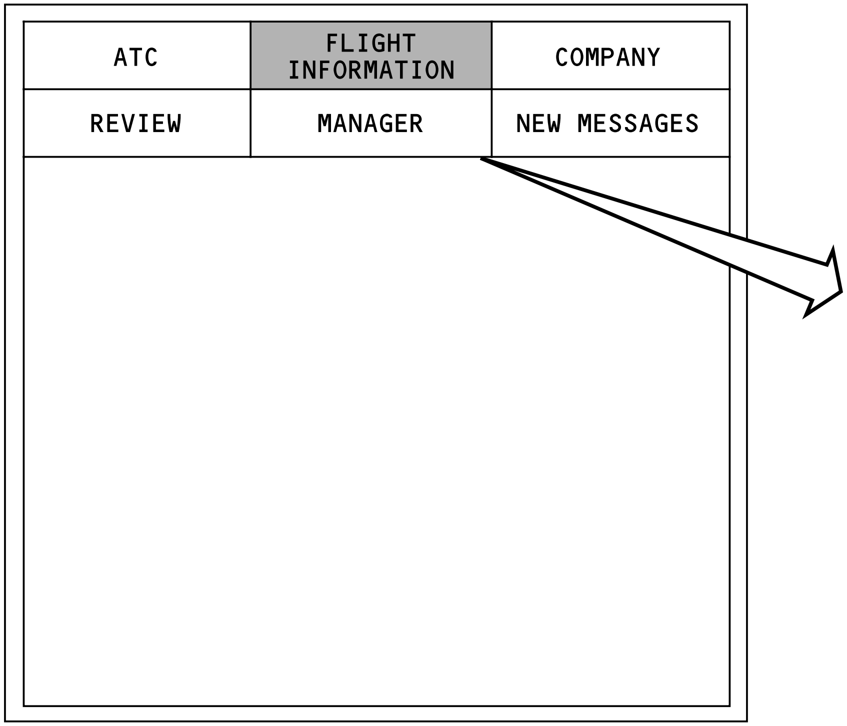
DCMS - FDCF COMPANY MENU

DCMS - FDCF MANAGER MENU

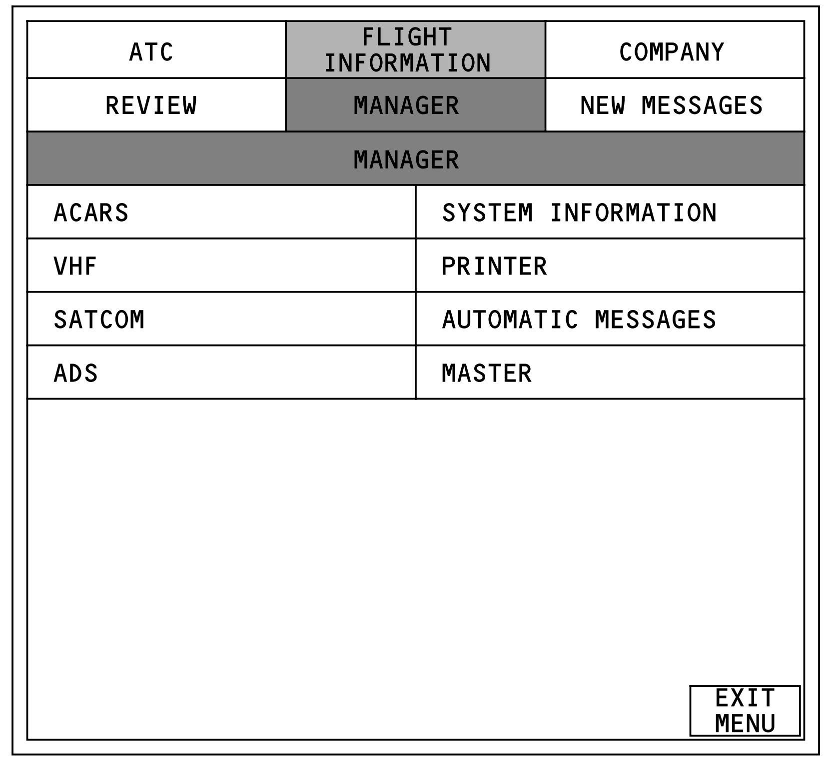
General

The MANAGER menu selection gives the flight crew access to these manager sub-menus:

- ACARS
- VHF
- SATCOM
- Automatic dependent surveillance (ADS)
- System information
- Printer
- Automatic messages
- Master.



FDCF MAIN MENU



FDCF MANAGER MENU

23-27-00-017 Rev 3 03/07/96

DCMS - FDCF MANAGER MENU

DCMS - FDCF ACARS SUB-MENU

ACARS Sub-menu Page One

Page one of the ACARS sub-menu lets the flight crew select the ACARS frequency and scan rate. It also lets the flight crew set the secondary frequency. To do this, type the frequency into the CDU scratch pad. Use the cursor control device (CCD) to highlight the box prompts. Use the CCD cursor select switch to select the secondary frequency.

The RETURN and EXIT buttons show on the display.

ACARS Sub-menu Page Two

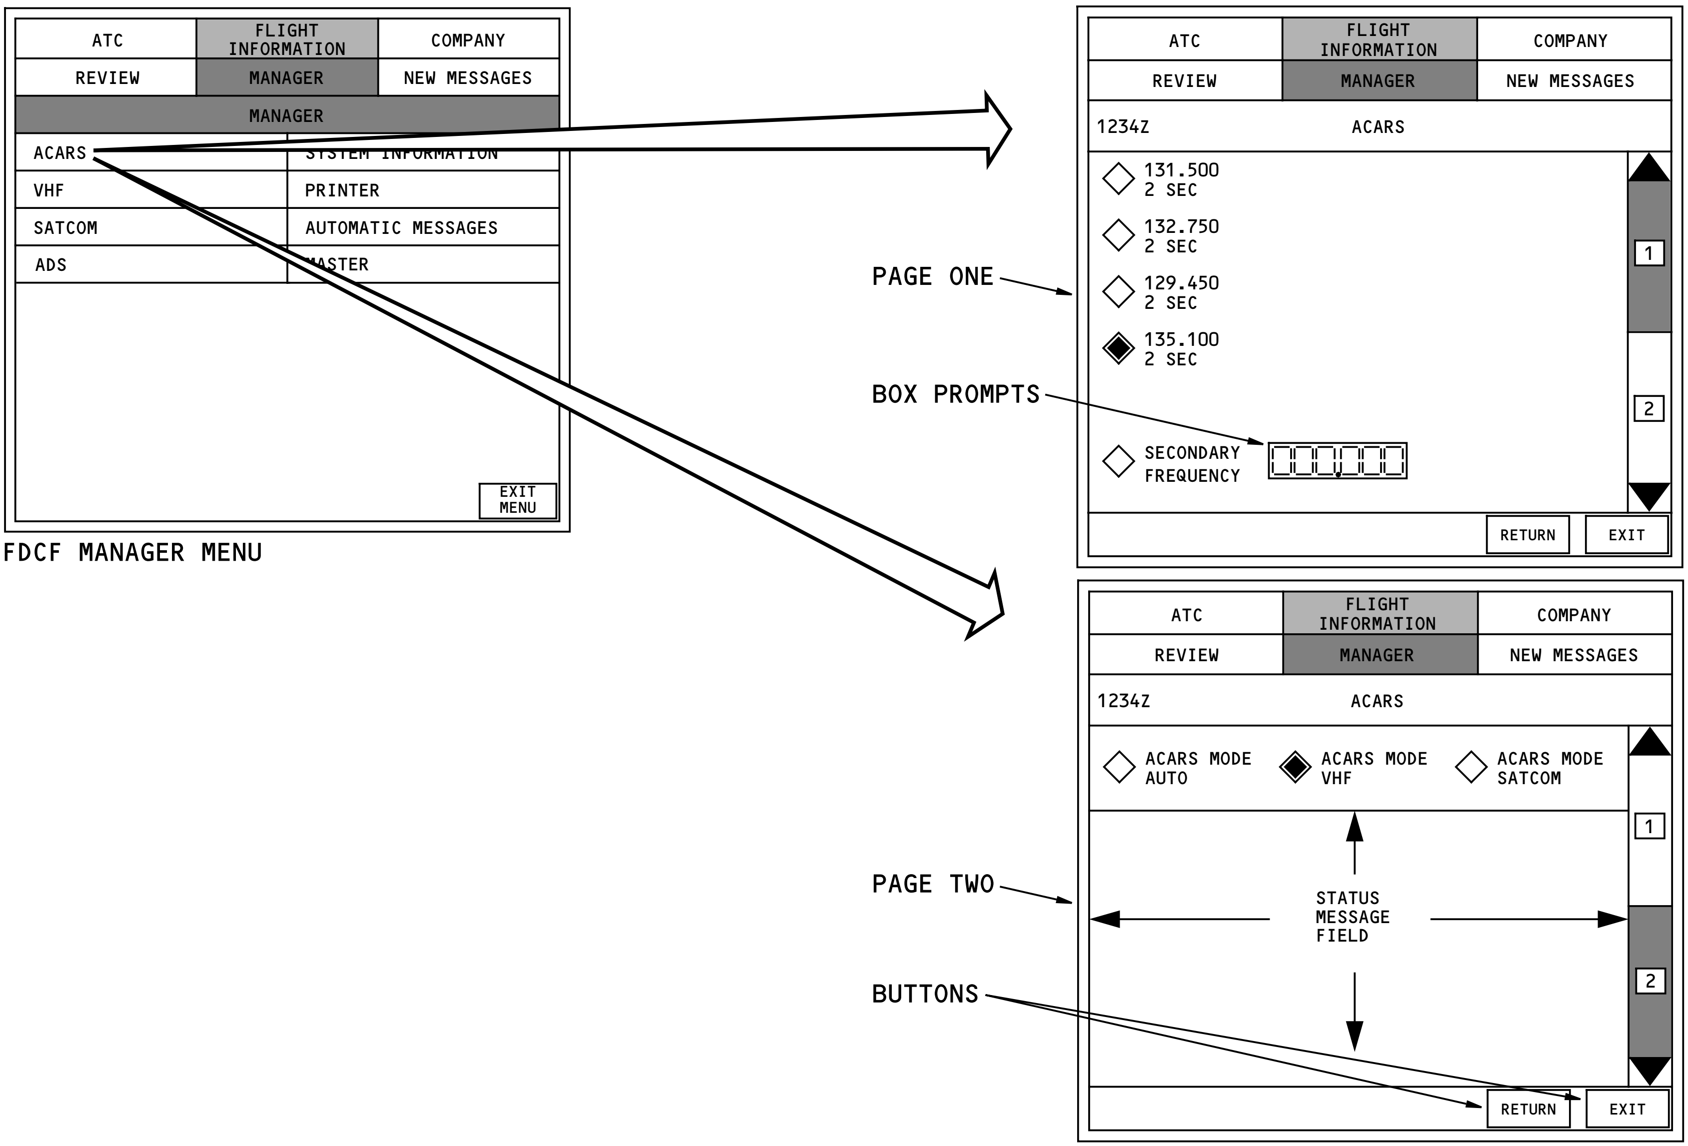
Page two of the ACARS sub-menu lets the flight crew select the ACARS mode of transmission. The selections are:

- AUTO
- SATCOM mode only
- VHF mode only.

Page two of the ACARS sub-menu also shows ACARS status messages. The status message field holds the 25 most recent messages. The newest messages show first. The possible ACARS messages are:

- NO ACARS LINK
- ACARS SATCOM MODE
- ACARS LINK ESTABLISHED
- ACARS VHF MODE.

The RETURN and EXIT buttons show on the display.



DCMS - FDCF ACARS SUB-MENU

DCMS - FDCF COMMUNICATION SUB-MENUS

SATCOM Sub-menu

The SATCOM sub-menu lets the flight crew see the SATCOM STATUS messages. The status message field holds the 25 most recent messages. The newest messages show first. These are the possible SATCOM messages:

- NO SATCOM LINK
- SATCOM LINK ESTABLISHED
- SATCOM FAILURE
- SATCOM NORMAL.

The RETURN and EXIT buttons show on the display.

VHF Sub-menu

The VHF sub-menu lets the flight crew set the radio transmission mode and select the VHF radio as the default data radio (right or center only). The graphic shows the power up default selections.

The sub-menu also shows VHF status messages. The status message field holds the 25 most recent messages. The newest messages show first. These are the possible VHF messages:

- NO VHF LINK
- VHF LINK ESTABLISHED
- VHF RADIO FAILURE
- VHF RADIO NORMAL.

The RETURN and EXIT buttons show on the display.

DCMS - FDCF COMMUNICATION SUB-MENUS

DCMS - DCMF FUNCTIONAL DESCRIPTION

General

The DCMF manages the internal and external communication of data. It supplies the many communication protocols and it routes data that AIMS needs to process data messages. Communication protocols are the rules and standards that the DCMF use for data communications.

The primary sub-functions of the DCMF are:

- ACARS datalink
- OLAN interface
- Print driver.

Other sub-functions of the DCMF are:

- Communications program interface (CPI)
- Initialization
- BITE
- Redundancy management.

ACARS Datalink Sub-function

The aircraft communications and reporting system (ACARS) permits communication of data between airplane systems and ground systems. The ACARS has airborne subsystems and ground station networks. The ground network is made up of subscriber airlines, aviation authorities, and other users.

The DCMF supplies the airplane part of ACARS. The ACARS sub-function controls air/ground file transfers and onboard message routing. The message routing process supplies uplink message routing to onboard systems. It downlinks message routing to the ACARS ground service providers (GSP) through VHF or SATCOM. The ACARS datalink sub-function uses information within each uplink to send the message to the applicable system. The ACARS datalink sub-function also routes downlinks to the path set by the flight deck crew and airplane systems.

The flight crew sets the datalink path through the MANAGER menu of the AIMS flight deck communications function (FDCF). The path preferences are:

- VHF
- SATCOM
- Auto.

The power-up default selection is auto. When the auto path is set, the ACARS sub-function uses a preference table for internal downlink routing to select a communications transceiver.

OLAN Interface Sub-function

The OLAN interface sub-function supplies the communications protocols that permit AIMS functions to send data to and receive data from member systems on the avionics local area network (AVLAN). AVLAN systems include the:

- Left and right AIMS cabinets
- Maintenance access terminal (MAT)

- Brouter.

These AIMS functions use the DCMF to exchange data through the AVLAN:

- Central maintenance computing function (CMCF)
- Maintenance terminal function (MTF).

The DCMF has redundancy management that sends data to the CMCFs in both AIMS cabinets. The CMCF also gives data load access and control to install LRU/LRM software for DCMF normal operation.

MTF provides communications between CMCF or ACMF and the AVLAN systems.

The BITE for AVLAN systems also uses the DCMF to report faults to the CMCF.

Print Driver Sub-function

The print driver sub-function transfers AIMS data to the flight compartment printer. The print driver sub-function sends data to and receives data from AIMS functions to:

- Spool a print job
- Send data to the flight compartment printer
- Send printer and job status and fault data back to the AIMS function.

Communications Program Interface (CPI) Sub-function

The communications program interface sub-function of the DCMF supplies a common interface for data communications between other AIMS functions and these DCMF sub-functions:

- ACARS datalink
- OLAN interface
- Printer driver.

The CPI supplies a common protocol across the AIMS backplane bus for data transfer.

Initialization Sub-function

The initialization sub-function of the DCMF has these two parts:

- Software installation checks
- Power interrupt processing.

The initialization sub-function does software installation checks on the DCMF software components during initialization. These components are the:

- Operational program configuration (OPC)
- Operational program software (OPS)
- Airline modifiable information (AMI).

Power interrupt processing reacts to primary power system interrupts in different ways. The reaction depends on the length of the interrupt and if the airplane is on the ground or in the air. The power interrupt groups are:

- Short term power interrupt (<500 ms)
- Warm start (>= 500 ms and < 5 s)
- Cold start (>= 5 s and airplane in air)
- Complete power loss.

BITE Sub-function

The DCMF BITE sub-function monitors the DCMF in the left and right CPM/Comm and the related hardware units use that the DCMFs use. The related hardware units that the DCMFs use are, the OLAN circuit card assembly (CCA) and the VHF modem in each CPM/Comm module. When the system first gets power, the power-up BITE test makes sure that the DCMF works correctly. During normal operation, the BITE continuously monitors the condition of the DCMF for redundancy management.

Redundancy Management Sub-function

The redundancy management sub-function of the DCMF does these four things:

- DCMF selection as primary at power-up
- Primary to secondary DCMF transfer
- External hardware monitors
- Datalink monitors.

The redundancy management function makes sure that one of the two DCMFs is primary and one is secondary. The primary DCMF does:

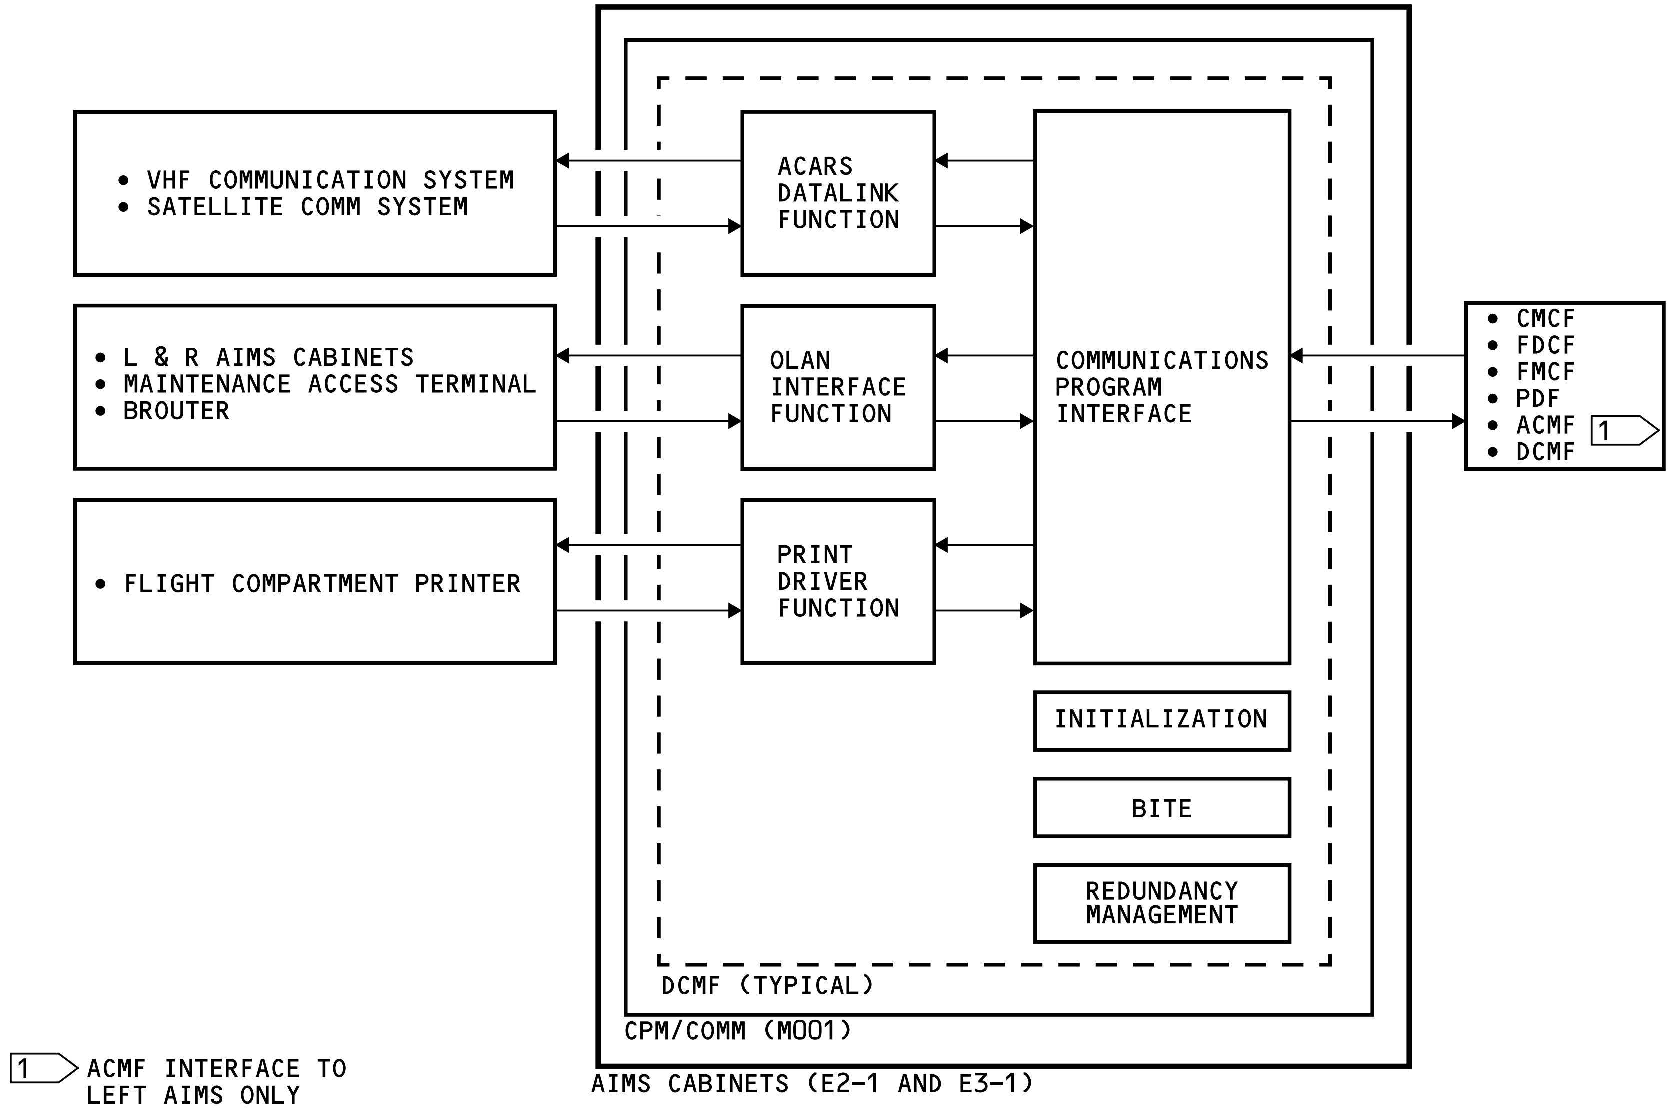
- All air/ground communications
- Maintenance of AVLAN connections to AIMS functions within its cabinet
- Monitors condition and status of the secondary DCMF.

The secondary DCMF does the same functions as the primary, but it does not handle air/ground communications.

The secondary DCMF takes over for the primary DCMF if it fails or if the flight crew changes the default VHF communications transceiver. The secondary DCMF monitors the intercabinet status messages from the primary DCMF. The primary DCMF uses the results of the monitors and other conditions to change to the secondary DCMF. The DCMF monitors this hardware for correct operation:

- Left, center, and right RTPs
- Center and right VHF comm xcvrs
- The SDU
- Flight compartment printer.

The DCMF monitors the condition of the VHF and SATCOM datalinks. The DCMF sends messages to the PDF for flight crew notification when the condition of the VHF or SATCOM systems change.



23-27-00-022 Rev 4 05/30/96

DCMS - DCMF FUNCTIONAL DESCRIPTION

DCMS - FDCF FUNCTIONAL DESCRIPTION

General

The flight deck communication function (FDCF) gives the flight crew access to data communication menus and their displays. The FDCF uses instructions in software and hardware to do this. The flight crew uses the menus and displays to do these tasks:

- Downlink messages
- Uplink messages
- Review messages
- Select a medium to transmit/receive and print messages.

The FDCF has inputs, outputs, and these sub-functions to give the flight crew access to the FDCF menus and to control the displays:

- Inputs
- Display/switch interface
- FDCF main sub-functions
- Redundancy management
- BITE
- Airline modifiable information (AMI)
- Communications program interface (CPI) input/ output (I/O).

Inputs

The FDCF uses inputs and the DCMF interfaces to do the FDCF sub-functions. These components send input data:

- CDU'S
- DSP
- CCD'S
- ACCEPT switch
- REJECT switch
- CANCEL switch
- RTP'S.

Display/Switch Interfaces

The display/switch interfaces convert the inputs to a format that the FDCF can use. Inputs show in order of time. The new format goes to the main FDCF sub-functions.

Main FDCF

The main FDCF lets the flight crew make menu selections. These are the main FDCF sub-functions:

- Main menus
- Sub-menus
- Up/downlink displays on a multifunctional display (MFD)
- Decode uplink and downlink messages
- Logic units
- Communication alerts.

The main menus sub-function uses the DSP COMM selection to show the FDCF main menu. This gives access to the sub-menus. The FDCF main menu has four sub-menus:

- Review
- Manager

- Company
- New messages.

The sub-menus sub-function uses the CCD selection to show a sub-menu. This gives access to a display for flight crew control and entry.

The up/downlink sub-function gives the flight crew control to receive, send messages, and make entries on a display. The flight crew uses the CCD to make selections on a display. To make an entry on a display, the flight crew uses the CDU scratch pad to type the message. They use the CCD to transfer the scratch pad data to a data field in the selected MFD. Data transfer occurs when you select box prompts or a line with dashes on the the MFD.

The decoding sub-function decodes the uplink messages and codes the downlink messages. This process is necessary to support these display features:

- Buttons that show in the display
- Data fields for entry
- Information that shows in the information display box.

The logic unit sub-function uses CDU, panel, and switch inputs to support display formats. It also uses the decoding sub-function to make sure that certain buttons and fields are active or not active on a display.

The communications alerts sub-function receives inputs from the decoding sub-function. It uses a look up table to send communication alerts to the PDF for visual and aural flight deck alerts.

<u>Redundancy Management</u>

The redundancy management of the FDCF does these tasks:

- Selects a primary FDCF at power-up
- Transfers a primary FDCF to secondary
- Monitors the datalink interface.

The redundancy management makes sure that one of the two FDCFs is primary and one is secondary at power-up. To do this, the primary FDCF:

- Remembers which FDCF was primary at last power-on
- Monitors the condition and status of the secondary FDCF.

The secondary FDCF does the same functions as the primary.

The primary-to-secondary FDCF transfer occurs when the primary FDCF fails. The secondary FDCF monitors the intercabinet status messages from the primary FDCF during normal operation. The primary FDCF uses the results of the monitors and power conditions to change to the secondary FDCF.

The secondary FDCF also takes over when a datalink interface is lost.

DCMS - FDCF FUNCTIONAL DESCRIPTION

BITE

The FDCF BITE monitors the hardware and software of the FDCF in the left and right CPM/Comm. When the system first gets power, the power up BITE test makes sure that the FDCF works correctly. During normal operation, the BITE monitors the condition of the FDCF for redundancy management.

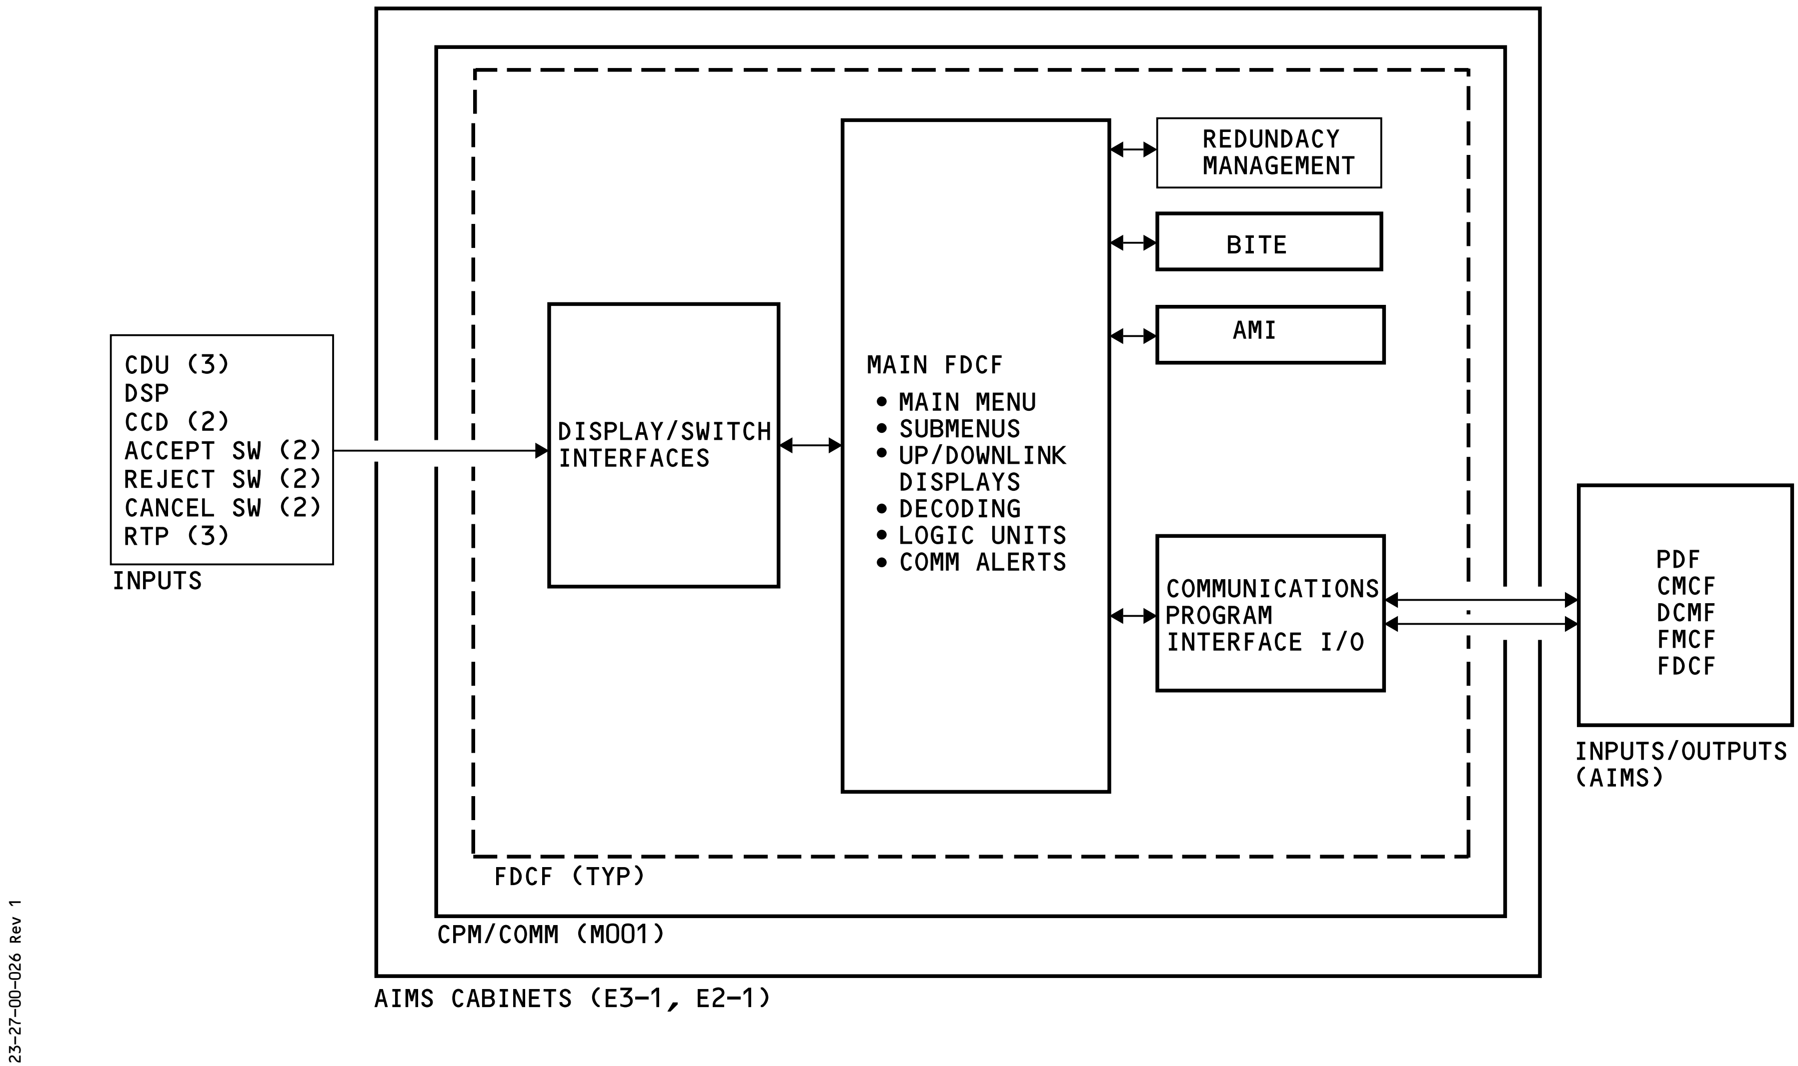
Airline Modifiable Information (AMI)

The airline can use a ground base software tool (GBST) to re-configure the FDCFs.

Communications Program Interfaces (CPI) I/O

The communications program interfaces of the FDCF supplies a common interface for data communications in the AIMS cabinets. To do this, the CPI supplies a common protocol for the AIMS backplane bus for data transfer. This supports the FDCF intracabinet data exchanges.

The CPI I/O of the FDCF supplies a common interface for data communications to the other AIMS cabinet. The primary and secondary FDCFs exchange data for redundancy management. To do this, the CPI supplies a common protocol for the intercabinet buses 1 and 2.



DCMS - FDCF FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

DCMS - DCMF AND FDCF AIRLINE MODIFIABLE INFORMATION

General

The data communication management system (DCMS) has a data communication management function (DCMF) and a flight deck communication function (FDCF). Together the two make up the functionality of ACARS. The design of the 777 airplane lets the airlines customize certain functions in the DCMS. You customize these functions through airline modifiable information (AMI). You use the ground based software tool (GBST) to make the modifications.

The DCMF comes with a default values AMI. The default values AMI has values that determine these:

- VHF data frequencies
- ACARS reject message formats
- Uplink message routing.

The FDCF comes with a baseline AMI. The baseline AMI defines these:

- Baseline flight deck communication display formats
- Basic screen reports
- Downlink messages and formats
- Uplink messages and formats
- Logic units and parameter definitions.

DCMF VHF Data Frequency Selection Tables

The default VHF data frequency selection table includes this information:

- Frequencies
- Scan times
- A prekey length
- An enable/disable trigger.

These are the default frequencies:

- 131.550 (ARINC and Australia)
- 131.725 (SITA)
- 131.475 (Canada)
- 131.450 (Japan).

You can enter up to 15 total frequencies in the table. The valid frequency range is 118.000 to 136.975 megahertz.

The default scan time for all frequencies is 126 seconds. You can change the scan time to any rate between 10 and 600 seconds.

The default prekey length is 75 milliseconds. The valid prekey lengths are 53 to 190 milliseconds in increments of one millisecond.

The default setting for the trigger is enable. You can set this to disable.

ACARS Reject Message

The ACARS reject message format has 69 characters and an HX label that identifies the reject message. Characters 1-10 contain a standard header. Character 11 has the slash character. Characters 12-18 contain the

DCMS - DCMF AND FDCF AIRLINE MODIFIABLE INFORMATION

ATA/IATA address. Character 19 has a period. You can not modify these characters.

Characters 20-69 contain the first 50 characters of the uplink message and label HX identifies the downlink as a reject. You can modify these characters.

DCMF Uplink Routing Tables

The default values are a table of predefined labels and sublabels that control the destination of uplink messages. These are the valid destinations:

- FDCF
- CMCF
- ACMF
- FMCF.

The DCMF routes the message according to the default table. This table is not modifiable. An uplink message routes to a destination defined in the modifiable AMI file only if it is not already defined by the hardcoded table.

This is the hardcoded table:

Label/Sublabel	Destination
51/none	FDCF
52/none	FDCF
54/none	FDCF
C1/none	FDCF
H1/CF	CMCF
H1/HF	ACMF
H1/W0	FMCF
H1/W1	FMCF
H1/W2	FMCF
A1/none	FDCF
A7/none	FDCF
RA/-1	FDCF
RA/-2	FDCF
RA/-3	FDCF
RA/-4	FDCF
RA/-5	FDCF
RA/-6	FDCF
RA/-7	FDCF

FDCF Display Formats

The FDCF baseline AMI provides a generic display menu structure. This structure meets the needs of most airlines. You can modify the basic structure or develop a custom AMI to meet specific needs.

DCMS - DCMF AND FDCF AIRLINE MODIFIABLE INFORMATION

FDCF Screen Reports

The FDCF baseline AMI provides generic screen reports. These reports meet the needs of most airlines. You can modify the basic screen reports or develop a custom AMI to meet specific needs.

Downlink Messages and Formats

The baseline AMI contains the Company Menu which you use to select the downlink formats. This section provides the downlink display, encoding, and print format definitions required to show, send, and print specific messages.

These are the downlink messages available in the baseline AMI:

- Flight initialization display
- Flight auto-Initialization request display and downlink message
- Delay report display and downlink message
- Diversion report display and downlink message
- Estimated time of arrival display and downlink message
- Departure report display and downlink message
- Position report display and downlink message
- Arrival report display and downlink message
- Message to ground display and downlink message
- Voice contact request display and downlink message
- Weather request display and downlink message
- Weight and balance request display and downlink message
- Clearance request display and downlink message
- Re-clearance request display and downlink message
- Flight plan request display and downlink message
- Flight release request display and downlink message
- Gate assignment request display and downlink message
- ATIS request display and downlink message
- NOTAMS request display and downlink message
- Maintenance deport display and downlink message
- Miscellaneous codes report display and downlink message
- Situation report display and downlink message
- Invalid reject message
- Unable to process reject message
- Unknown reject message
- Flight times display (OOOI).

You can modify the AMI to add or delete existing messages.

FDCF Uplink Messages and Formats

These are the uplink messages and formats available with the baseline AMI:

- Flight initialization uplink
- Free text uplink
- Crew advisory uplink
- Weather report uplink
- Weight and balance uplink
- Clearance uplink
- Re-clearance uplink

DCMS - DCMF AND FDCF AIRLINE MODIFIABLE INFORMATION

- Flight plan uplink
- Flight release uplink
- Gate assignment uplink
- VHF voice contact uplink
- Display command uplink
- Standard printer with Alert uplink
- Command/response uplink
- Acknowledgment of rejected uplink message.

You can modify the AMI to add or delete existing messages.

FDCF Logic Units and Airplane Parameters

The baseline AMI provides these logic units:

- OOOI initialization and state logic
- OUT event
- OFF event
- ON event
- IN event
- Return to gate event
- Diversion report logic
- End of flight.

Also, there is a list of airplane parameters available in the baseline AMI. The baseline AMI makes use of only a few of these parameters. You can modify the logic units and the airplane parameters.

FLIGHT COMPARTMENT PRINTING SYSTEM - GENERAL DESCRIPTION

General

The flight compartment printer supplies high-speed hard copy of text for these systems:

- Primary display system (PDS)
- Airplane condition monitoring system (ACMS)
- Central maintenance computing system (CMCS).

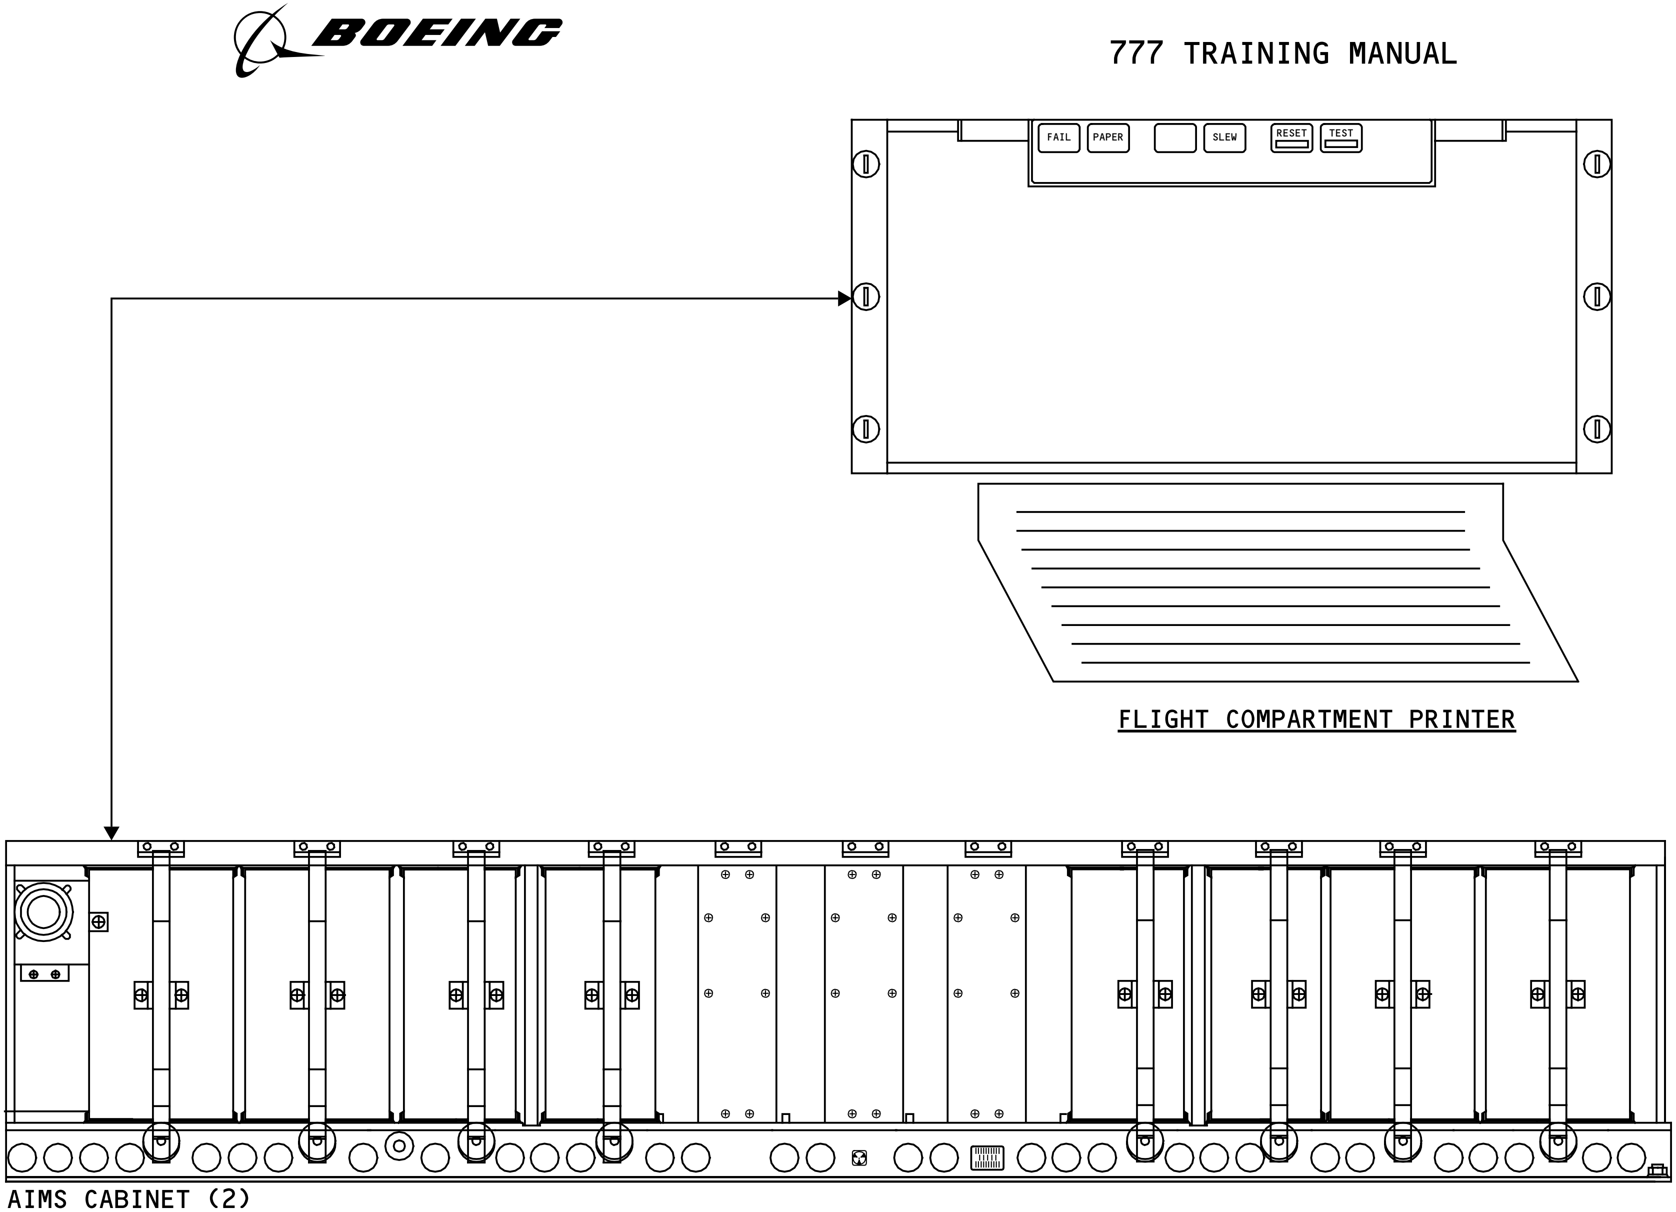
The flight compartment printer receives data from the print driver partition of the data communication management function (DCMF). The DCMF is part of the airplane information management system (AIMS). The printer sends status and error information back to the DCMF.

The DCMF prioritizes data sent to the printer in this order:

- Flight deck communication function (FDCF) of the DCMS
- Central maintenance computing function of the CMCS
- Airplane condition monitoring function of the ACMS
- Multifunction display (MFD).

Abbreviations and Acronyms

ac	- alternating current
ACMS	- airplane condition monitoring system
AIMS	- airplane information management system
CMCS	- central maintenance computing system
CPM	- core processor module
DCMF	- data communication management function
DCMS	- data communication management system
FDCF	- flight deck communication function
LAN	- local area network
MFD	- multifunction display
OPC	- operational program configuration file
OPS	- operational program software
PDF	- primary display function
PDS	- primary display system



FLIGHT COMPARTMENT PRINTING SYSTEM - GENERAL DESCRIPTION

FLIGHT COMPARTMENT PRINTING SYSTEM - COMPONENT LOCATIONS - FLIGHT COMPARTMENT

Flight Compartment Component locations

The flight compartment printer is on the P8 aft aisle stand panel. It is in front of the cabin interphone handset.

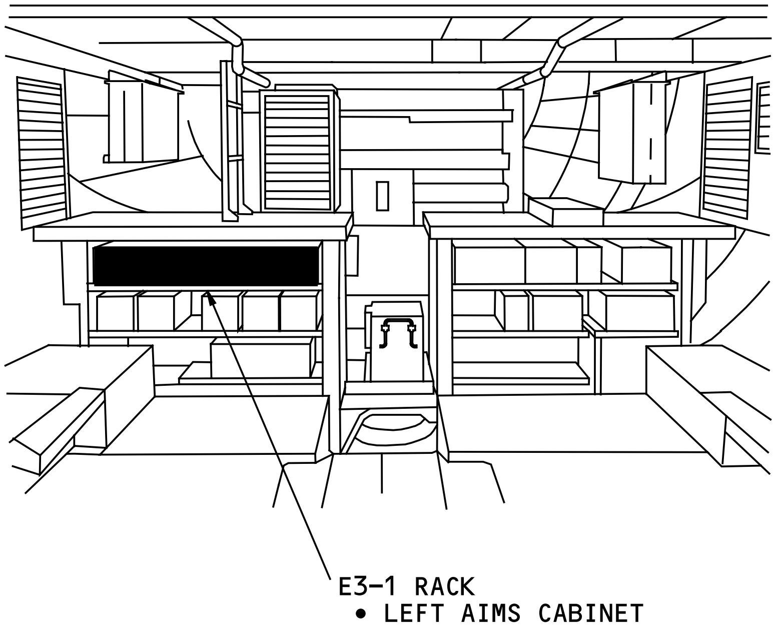
FLIGHT COMPARTMENT PRINTING SYSTEM - COMPONENT LOCATIONS - FLIGHT COMPARTMENT

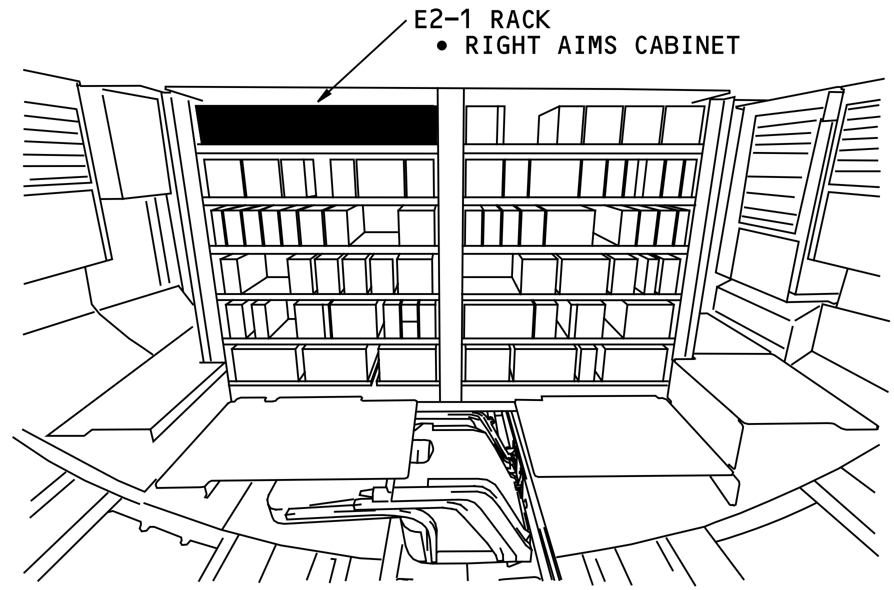
FLIGHT COMPARTMENT PRINTING SYSTEM - COMPONENT LOCATIONS - MEC

Other System Component Locations

The print driver is a software partition in the data communication management function (DCMF). The DCMF is in the AIMS core processor module/communications (CPM/Comm) in both the left and right AIMS cabinets. Both AIMS cabinets are in the main equipment center.



(LOOKING FORWARD)



(LOOKING AFT)

FLIGHT COMPARTMENT PRINTING SYSTEM - COMPONENT LOCATIONS - MEC

31-33-00-003 Rev 1

FLIGHT COMPARTMENT PRINTING SYSTEM - INTERFACES

Power

The right main ac bus supplies power to the flight compartment printer.

Discretes

The left AIMS cabinet sends an enable discrete before it sends the printer data load.

ARINC 429

The flight compartment printer receives new operational program software (OPS) on the data load bus from the left AIMS cabinet.

The DCMF in both AIMS cabinets sends print data to the printer on the DCMF data bus.

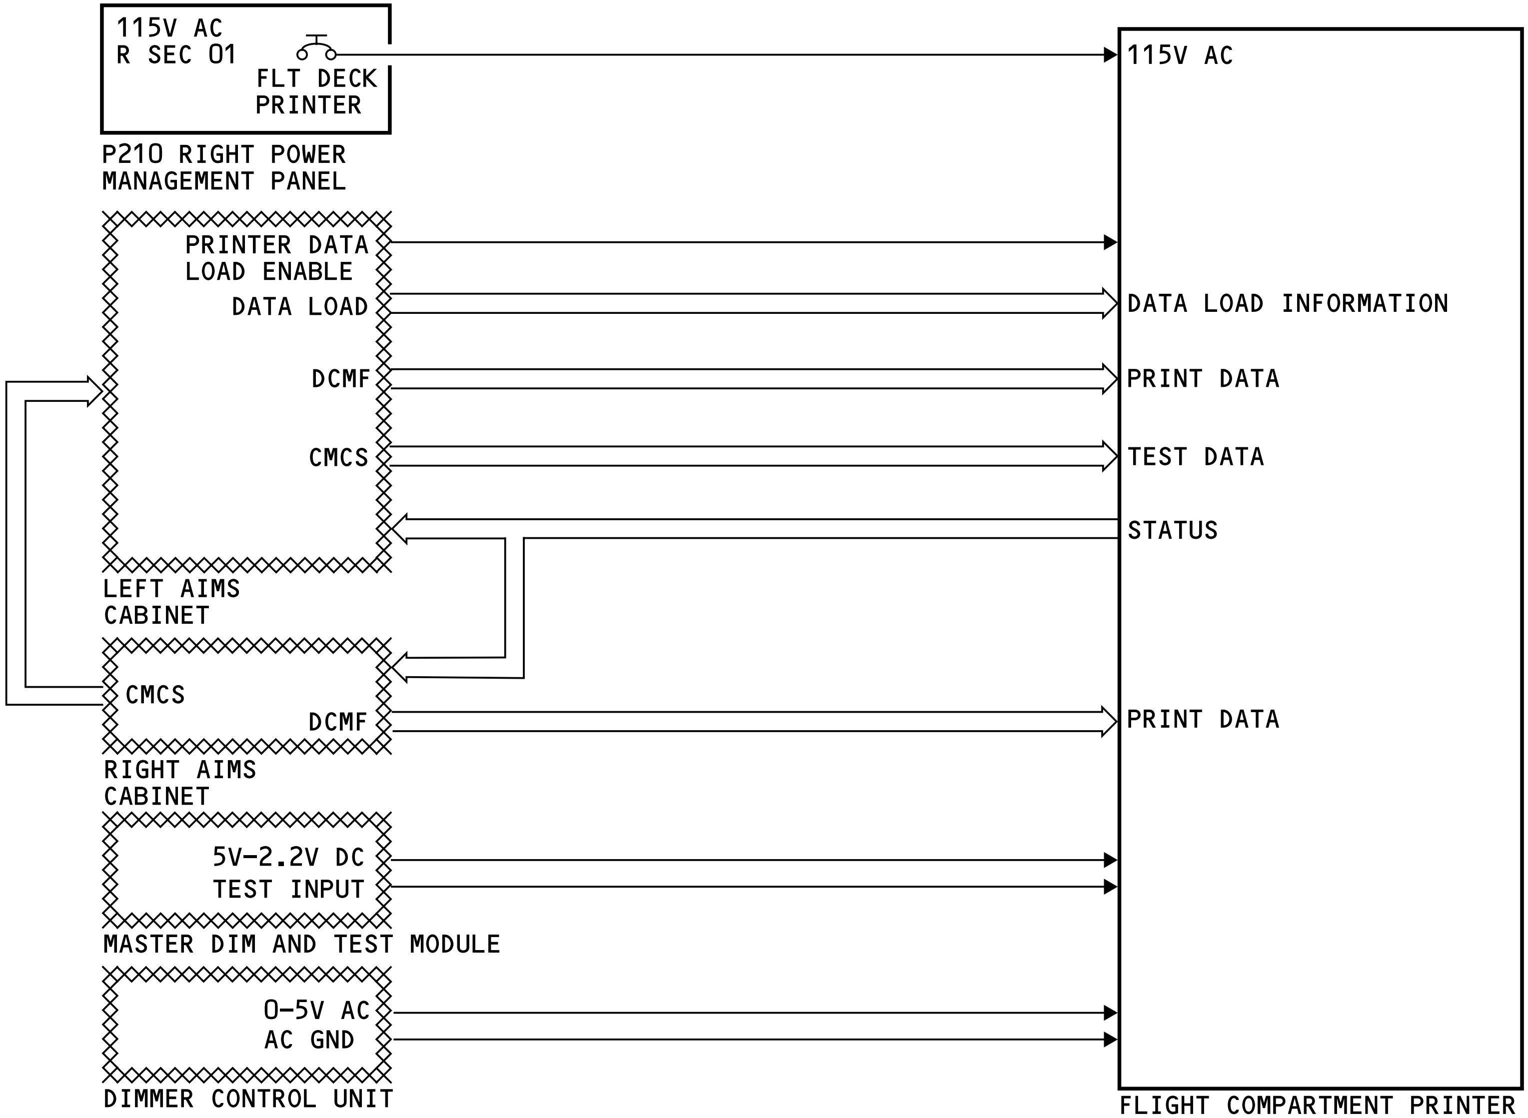
The central maintenance computing system (CMCS) in the left AIMS cabinet sends test data to the printer on the CMCS bus. If the left AIMS cannot send CMCS information, it will send the information from the right AIMS cabinet.

The flight compartment printer sends status and error messages to the DCMS in both AIMS cabinets over the status bus.

Analog

The master dim and test module supplies the power for the indication lights on the front panel. The master dim and test module also sends a test input to the printer.

The dimmer control unit sends lighting control for the integral lighting for the printer.



31-33-00-004 Rev 2 03/05/96

FLIGHT COMPARTMENT PRINTING SYSTEM - INTERFACES

FLIGHT COMPARTMENT PRINTING SYSTEM - FLIGHT COMPARTMENT PRINTER

General

The printer can print an 8.5 inch page. The printer resolution is 300 dots per inch. You can load a full paper roll of 125 linear feet into the printer. The printer uses the U.S. standard 8.5 inch roll or the A4 European Air standard paper.

Physical Description

The printer weighs approximately 12.2 lbs without a paper roll.

These are the dimensions of the printer:

- 5 inches high
- 10.75 inches wide
- 10.25 inches deep.

The printer contains all the mechanical components and electronics necessary for printer operation.

The mechanical components include:

- Printer head
- Rollers to move the paper
- Motor and drive system.

The electronic components include:

- Power supply
- Processor board
- Controller board
- Interconnection board
- 2 connectors.

FLIGHT COMPARTMENT PRINTING SYSTEM - FLIGHT COMPARTMENT PRINTER

FLIGHT COMPARTMENT PRINTING SYSTEM - OPERATION

General

There are five functional buttons on the printer. Two of the push buttons show printer status. Three of the push buttons control the printer.

Indications

The amber FAIL light comes on when a failure occurs that you can not repair on the line.

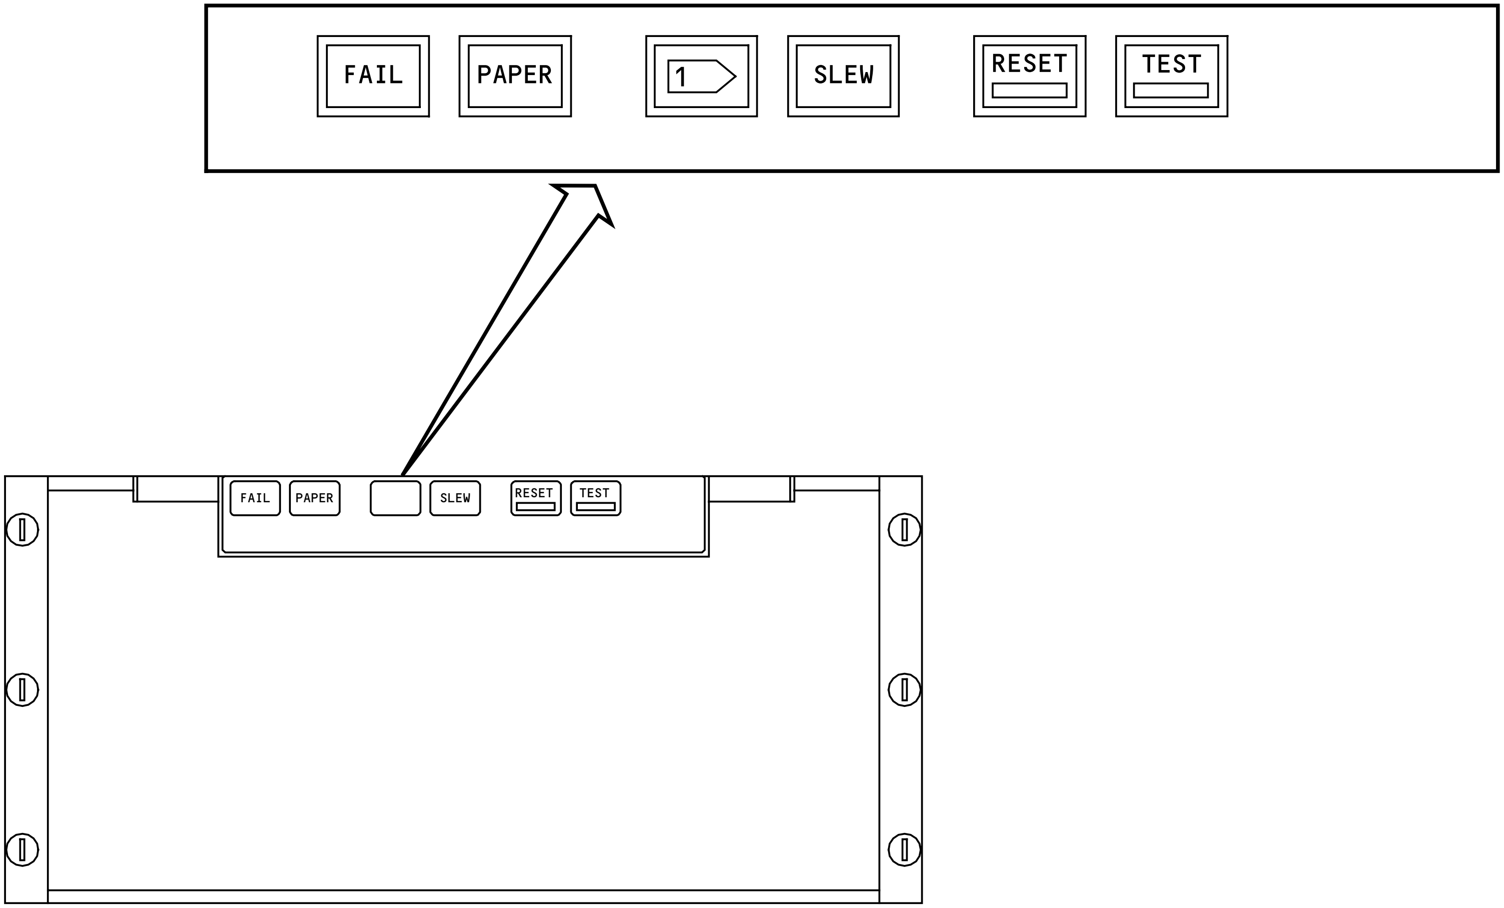
The amber PAPER light comes on when the printer is out of paper and when there is a paper jam.

Controls

Push the SLEW switch to move the paper out of the printer. Release the SLEW switch to stop the paper.

Push the RESET switch to cause a power-up reset of the electronic circuitry of the printer. Printing will stop. Messages in the printer memory are kept in memory. A green bar on the switch shows during the reset.

Push the TEST switch to do a test of the printer. During the test, a test pattern for text prints. The test pattern shows all the text characters the printer can print. A 300 dots per inch test pattern for graphics follows the test pattern for text. A green bar on the switch shows during the printer test.



1 THIS BUTTON NOT CONNECTED

FLIGHT COMPARTMENT PRINTING SYSTEM - OPERATION

FLIGHT COMPARTMENT PRINTING SYSTEM - OPERATIONAL GROUND TESTS

General

You can do a test of the flight compartment printer with the MAT. The MAT has one test for the printer, it is an operational ground test.

Flight Compartment Printer

During this test, the printer does an internal test. If the printer has no problem, it makes a printout of a page of characters. The lights on the printer come on during the test.

FLIGHT MANAGEMENT COMPUTING SYSTEM - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

FMCS - GENERAL DESCRIPTION

General

The flight management computing system shares data with the:

- Air data inertial reference system
- Global positioning system
- Navigation radios
- Engine sensors
- Fuel sensors
- FMCF internal databases
- Key entries into the control display units (CDUs).

The FMCS uses the data from the airplane systems to do these functions:

- Navigation
- Flight planning
- Performance management
- Guidance and control
- Thrust management
- Display and system control
- Datalink interface.

FMCS Components

The FMCS has these components:

- Flight management computing function (FMCF) (2) one in each AIMS cabinet
- CDUs (3)
- FMC selector
- Instrument source select panel (ISSP) navigation source switches (2).

Also, the mode control panel (MCP) has an interface with the FMCS, but is not an FMCS component.

Flight Management Computing Function

Each FMCF has these two software partitions:

- Flight management function (FMF) partition
- Navigation function partition.

The FMF partition supplies:

- Flight planning
- Lateral navigation (LNAV) guidance commands
- Vertical navigation (VNAV) guidance commands
- Thrust guidance commands
- Performance data
- Display control
- ND MAP display
- Manual, route, and procedure selection of navigation radios
- Required time of arrival (RTA) calculation
- Automatic dependent surveillance function (ADSF)
- BITE and fault monitoring.

The navigation function partition supplies:

- Position calculation
- Navaid selection for radio position calculation
- Navigation radio tuning command outputs.

FMCS - GENERAL DESCRIPTION

The FMCFs use performance and navigation data bases and sensor inputs to calculate guidance commands. When the flight crew uses the MCP to select the LNAV and VNAV modes, the FMCF sends:

- LNAV and VNAV guidance commands to the autopilot flight director computers (AFDCs)
- Thrust guidance commands and thrust limit data to the thrust management computing function (TMCF)
- Display and fault data to the primary display and central maintenance computing functions in the AIMS cabinets.

Automatic Dependent Surveillance Function

The automatic dependent surveillance function (ADSF) is a sub-function of the FMCF. The purpose of the ADSF is to permit air traffic control (ATC) to monitor the airplane in the air.

ATC sends automatic dependent surveillance (ADS) requests from the ground to the airplane. The ADSF in the airplane sends airplane position, heading, airspeed, and other data to the ground. ATC uses this data to manage air traffic. The ADSF is automatic and does not require flight crew action.

CDU - General

There are three CDUs in the flight deck. The CDUs are the primary control and display interface unit for the FMCF. The flight crew uses the left and right CDUs to enter flight plan data and interface with the FMCF and other systems. If the left or right CDU fails, the center CDU is the backup.

All CDUs can select a maintenance page format on a multifunction display (MFD) in the primary display system (PDS).

All CDUs can control the satellite communication (SATCOM) system.

The center CDU is the interface for the passenger address/cabin interphone (PA/CI) controller.

The CDU supplies these functions when the FMCFs fail:

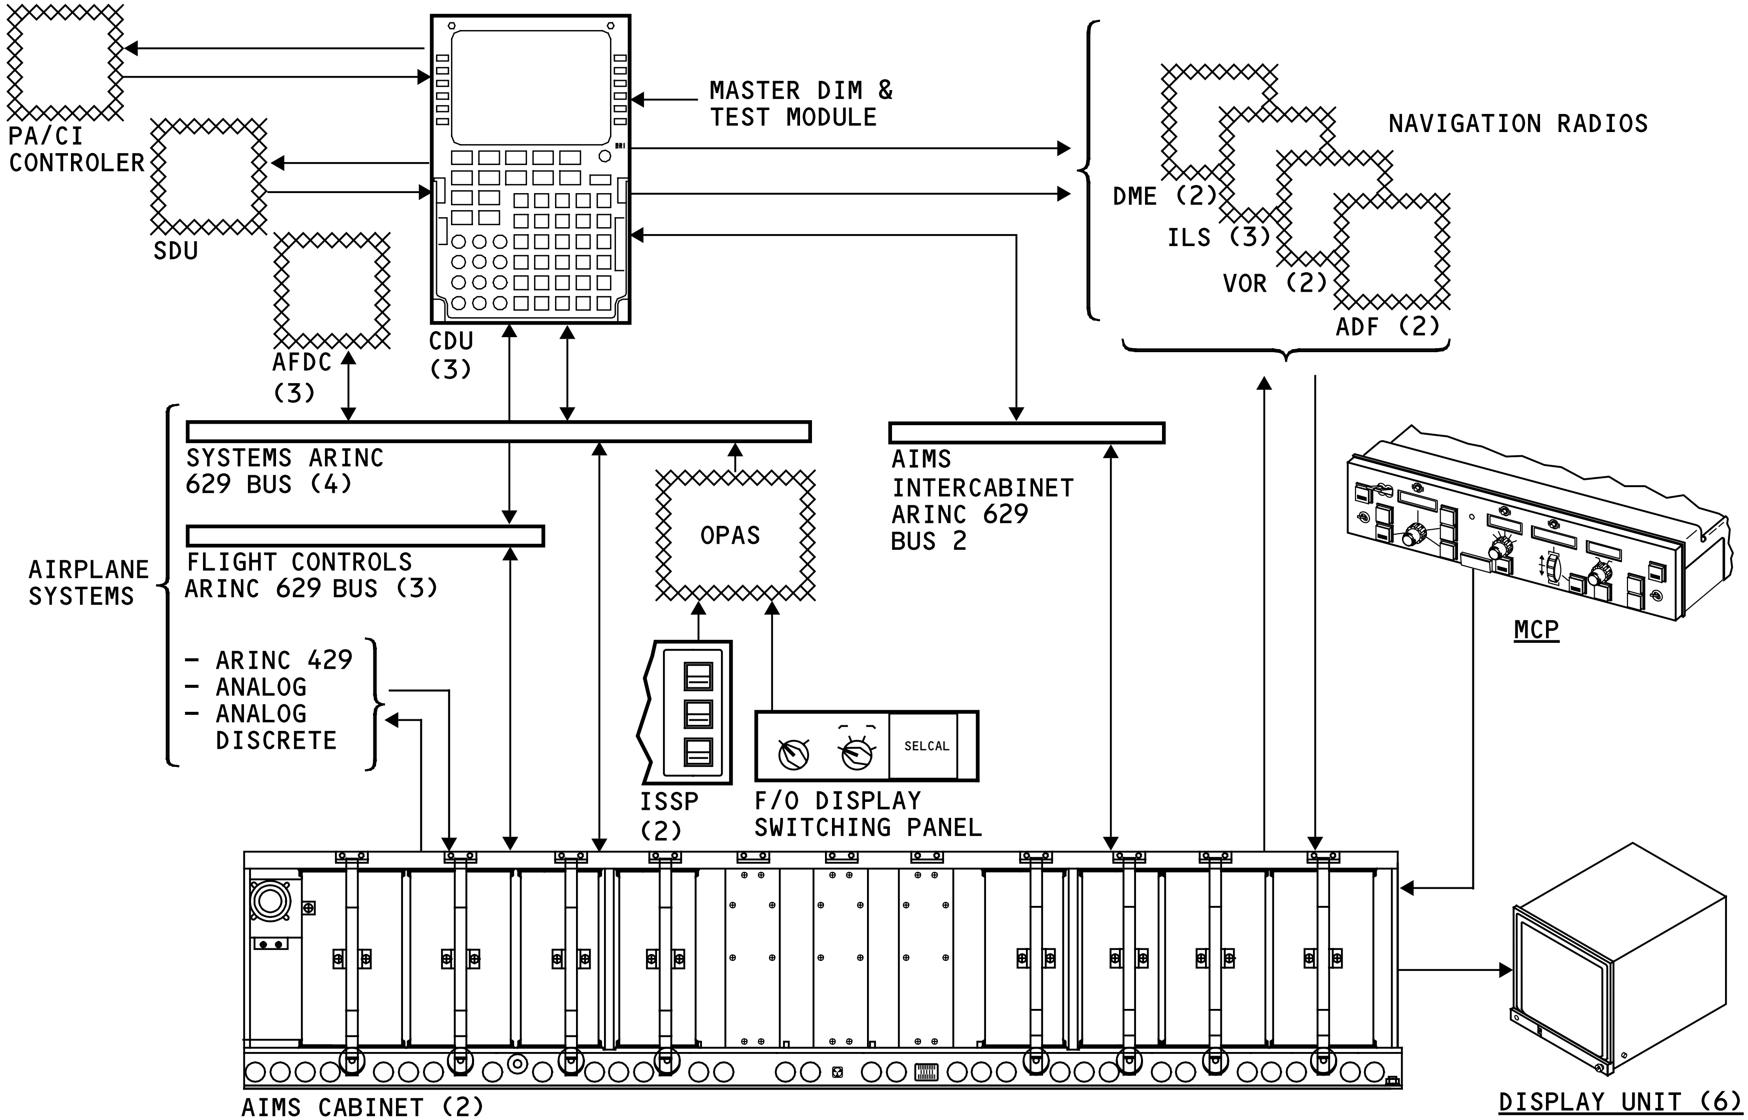
- Backup navigation radio tuning
- Calculates LNAV guidance commands
- Backup map data.

FMC Selector and Instrument Source Select Panel

The FMC selector is on the first officer's display switching panel. It determines the active FMCF.

The FMC selector and ISSP switches supply analog inputs to the overhead panel ARINC 629 system (OPAS). The OPAS converts these inputs and sends them to the AIMS cabinet on the systems ARINC 629 buses.

The NAV ISSP switch determines the source of navigation display data.



FMCS - GENERAL DESCRIPTION

FMCS - FLIGHT DECK COMPONENT LOCATIONS

FMCS Component Locations - P8 and P9 Panels

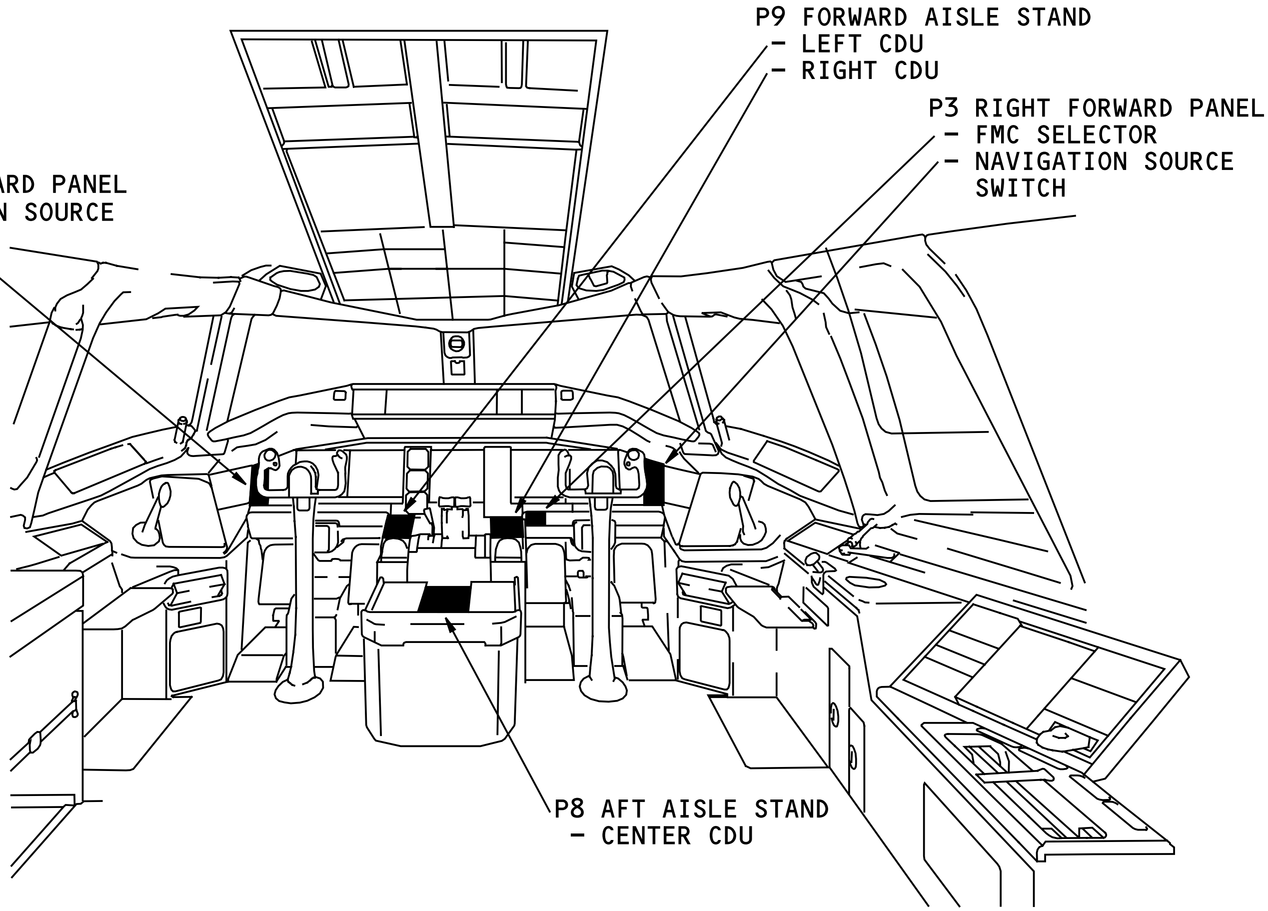
The FMCS components on the P9 forward aisle stand and P8 aft aisle stand panels are:

- Left control display unit (CDU)
- Right CDU
- Center CDU.

FMCS component Locations - P1 and P3 Panels

The FMCS components on the P1 left forward panel and P3 right forward panel are:

- Left and right navigation source switch (P1/P3)
- FMC selector (P3).



34-61-00-003 Rev 2 09/22/1997

FMCS - FLIGHT DECK COMPONENT LOCATIONS

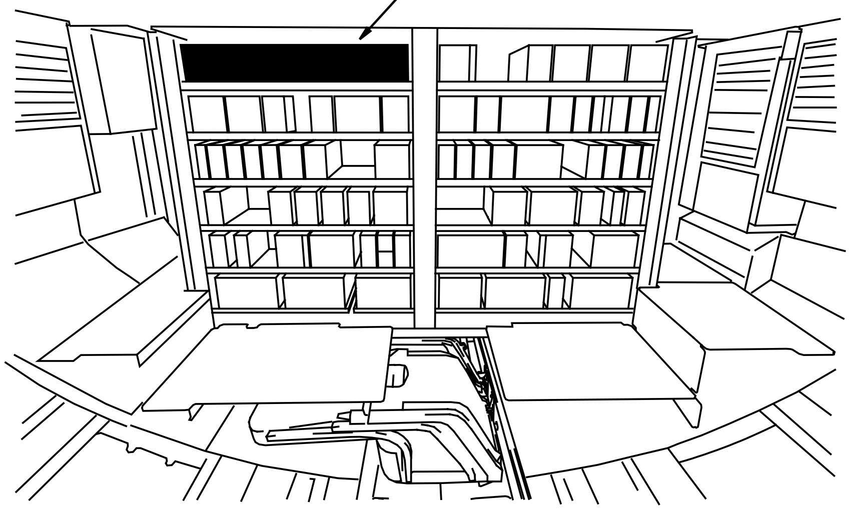
FMCS - MAIN EQUIPMENT CENTER COMPONENT LOCATIONS

General

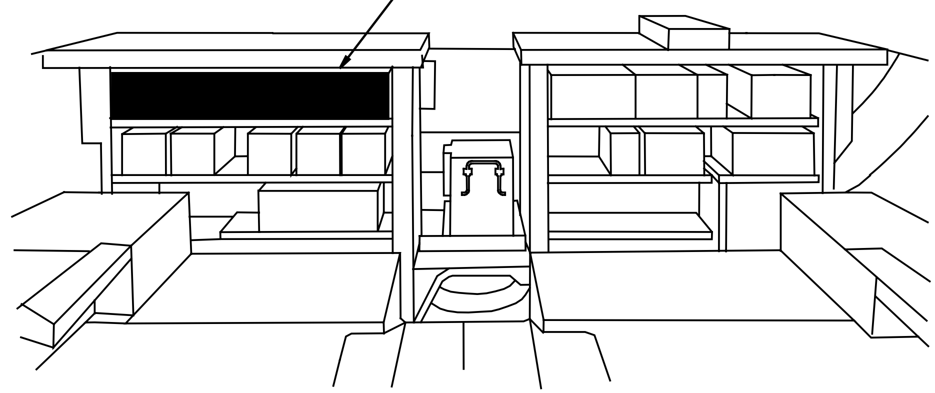
Each AIMS cabinet has an FMCF. The left AIMS cabinet has the FMCF in the core processor module/airplane condition monitoring function (CPM/ACMF). The right AIMS cabinet has the FMCF in the CPM/Basic.

Main Equipment Center Component Location

The left AIMS cabinet is on the E3-1 shelf. The right AIMS cabinet is on the E2-1 shelf.



MAIN EQUIPMENT CENTER
(LOOKING AFT)



MAIN EQUIPMENT CENTER
(LOOKING FORWARD)

FMCS - MAIN EQUIPMENT CENTER COMPONENT LOCATIONS

FMCS - CDU POWER INTERFACE

General

These power buses supply 28v dc power to a CDU through an insertion switch:

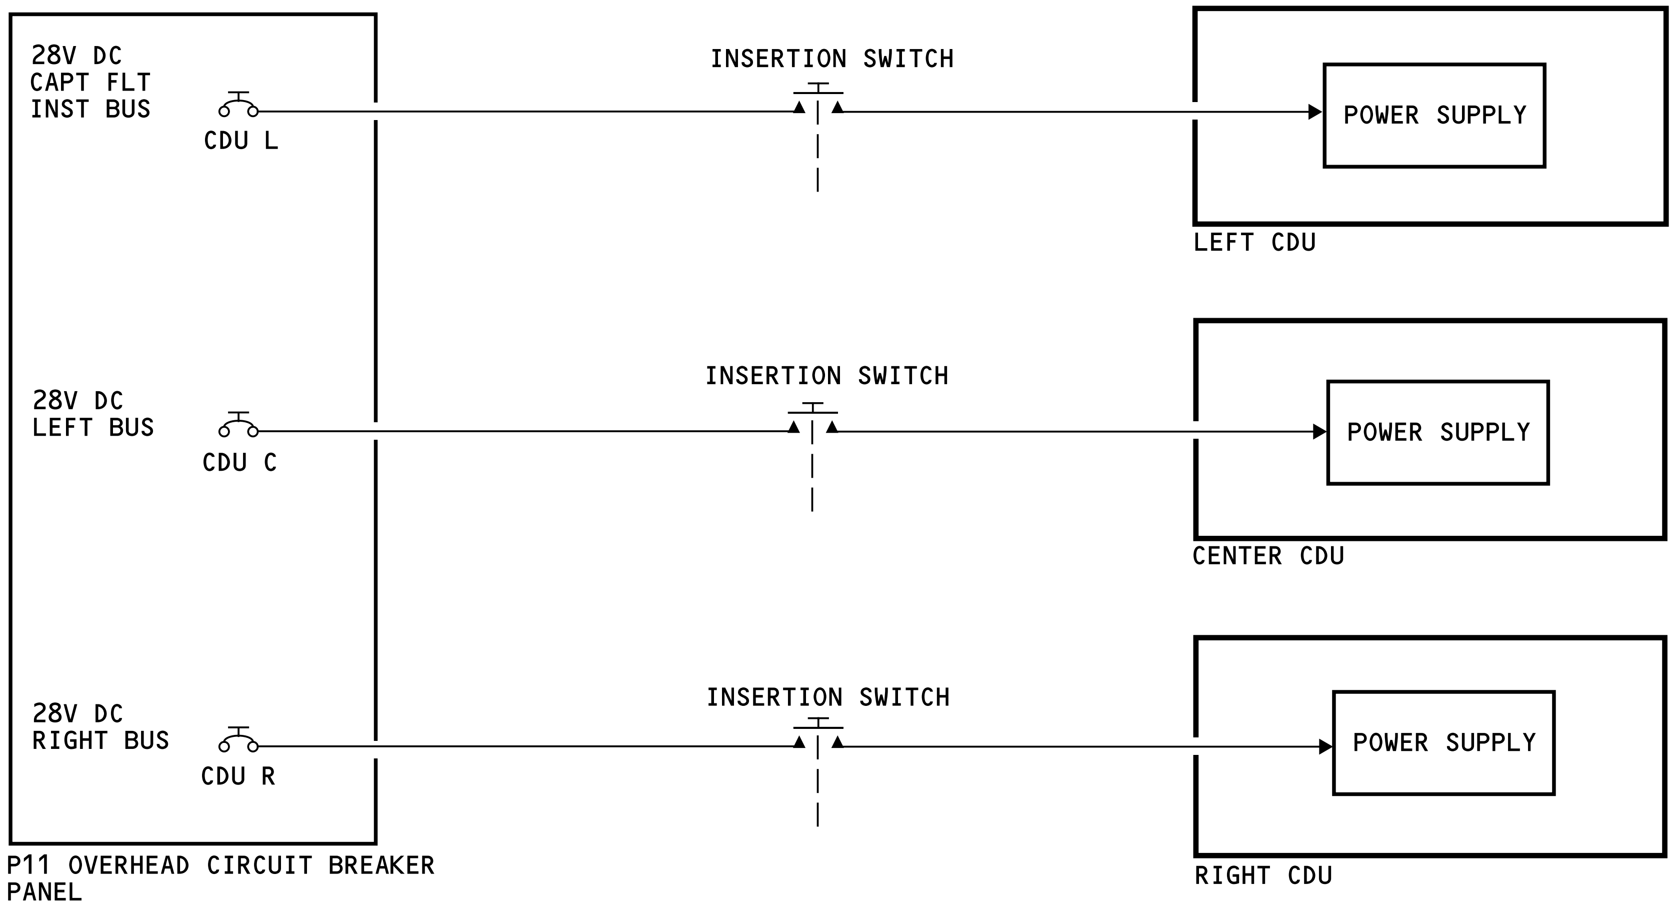
- Captain's flight instrument bus (L CDU)
- Left bus (C CDU)
- Right bus (R CDU).

Insertion Switch

When you remove the CDU from the CDU mount, the insertion switch opens and removes power from the CDU.

When you put the CDU into the CDU mount, the insertion switch closes and supplies power to the CDU.

The insertion switch is a spring loaded switch near the connector on the CDU mount.



34-61-00-005 Rev 3

FMCS - CDU POWER INTERFACE

FMCS - FMCF INTERFACES - 1

General

The FMCF in the AIMS cabinets receives digital and analog discrete inputs from components, sensors, and switches on these buses:

- Flight controls ARINC 629 buses
- Systems ARINC 629 buses
- ARINC 429 buses
- AIMS intercabinet ARINC 629 buses
- Analog discretes.

The FMCF in the AIMS cabinets sends digital data on these buses:

- Flight controls ARINC 629 buses
- Systems ARINC 629 buses
- ARINC 429 buses
- AIMS intercabinet ARINC 629 bus 2.

Input Overview

These are the components that have an interface on the flight controls ARINC 629 buses:

- Primary flight computer (PFC) (3)
- Air data inertial reference unit (ADIRU)
- Secondary attitude air data reference unit (SAARU).

These are the components that have an interface on the systems ARINC 629 buses:

- Autopilot flight director computers (AFDCs) (3)
- Warning electronic unit (WEU) (2)
- Air supply cabin pressure controller (ASCPC (2)
- Cabin temperature controller (CTC) (2)
- Engine data interface units (EDIU) (2)
- Flap slat electronic unit (FSEU) (2)
- Proximity switch electronic units (PSEU) (2)
- Electrical load management system (ELMS) (3)
- Fuel quantity processing unit (FQPU) (2)
- Overhead panel ARINC 629 system (OPAS)
- Audio management unit (AMU)
- Card files (2)
- ARINC signal gateway (ASG).

These are the components that have an interface on the AIMS intercabinet ARINC 629 bus 2:

- L AIMS cabinet
- R AIMS cabinet.

These are the components that have an interface on the ARINC 429 buses:

- Multi-mode receiver (MMR) (2)
- Ground proximity warning computer (GPWC)
- Passenger inflight information computer (PIIC)
- EFIS control panel (2).

The FMCFs receive analog discretes from these:

- VHF communication transceivers (3)
- HF communication transceivers (2)
- TO/GA switches (3).

FMCS - FMCF INTERFACES - 1

Input Details

The FMCFs get data from these interfaces:

- Flight control ARINC 629 buses
- Systems ARINC 629 buses
- AIMS inter-cabinet bus 2
- ARINC 429 buses
- Analog discretes.

PFC Inputs - Flight Control ARINC 629 Bus (L, R, & C)

The PFCs send bank angle protection data to the FMCFs. The FMCFs use this data to calculate the lateral guidance command.

ADIRU Inputs - Flight Control ARINC 629 Bus (L & R)

The ADIRU sends air data and inertial data to the FMCFs. The FMCFs use this data to calculate guidance and display commands.

SAARU Inputs - Flight Control ARINC 629 Bus (C)

The SAARU sends back-up air data and inertial data when the ADIRU fails.

AFDS Inputs - Systems Bus ARINC 629 (L, R, & C1)

The AFDCs send the ILS tune inhibit discrete and the arm/operational mode discretes to the FMCFs. The FMCFs use the ILS discrete to inhibit all ILS tune requests when the AFDS is in the approach mode. The arm/operational mode discretes tell the FMCF when to send its LNAV/VNAV guidance commands to the AFDS.

WEU Inputs - Systems ARINC 629 Bus (L, R, & C1)

The WEUs send this data to the FMCFs:

- Maximum operating speed
- Minimum operating speed
- Maximum placard speed.

The FMCFs use this data to compare with its maximum and minimum speed calculations. The active FMCF sends the safe maximum and minimum speeds to the WEUs for aural annunciations.

ASCPC and CTC Inputs - Systems ARINC 629 Bus (L & R)

The ASCPCs and CTCs send bleed air data to the FMCFs. The FMCFs use this data to calculate thrust and display commands when VNAV engages.

EDIU Inputs - Systems ARINC 629 Bus (L, R, C1, & C2)

The data the EDIUs send to the FMCFs includes this:

- Low speed compressor RPM (N1)
- Fuel flow for each engine.

The FMCFs use this data to calculate thrust commands and thrust limits.

FSEU Inputs - Systems ARINC 629 Bus (L, R, & C1)

The FSEUs send flap position and flap lever position to the FMCFs. The FMCF uses this data in its maximum speed and minimum speed calculations.

PSEU Inputs - Systems Bus ARINC 629 (L & R)

The PSEUs send landing gear position to the FMCFs. The FMCFs use this data to calculate speed limits.

FQPU Inputs - Systems Bus ARINC 629 (L & R)

The FQPUs send total fuel to the FMCFs. The FMCFs use this data to calculate performance data.

OPAS Inputs - Systems ARINC 629 Bus (L & R)

The OPAS send this data to the FMCFs:

- FMC selector position (Left, right or AUTO)
- Navigation source switch position
- Display select panel (DSP) switch position.

Card Files Inputs - Systems ARINC 629 Bus (L & R)

The FMCFs receive air/ground discretes and airfoil and cowl ice protection system (ACIPS) bleed air data from the card files. The FMCFs use the air/ground data to start and stop radio position calculation. The FMCFs use ACIPS data to help calculate performance commands.

FMCF Inputs - AIMS Intercabinet ARINC 629 Bus 2

The active FMCF receives intercabinet data, such as flight plan and map data, from the other FMCF. It does a comparison check with the other data. The active FMCF starts a resync to the other FMCF when the comparison check does not agree.

GPS Inputs - ARINC 429 Bus

The GPS sends this data to the FMCFs:

- Altitude
- Latitude
- Longitude
- East/north/vertical velocities
- Horizontal figure of merit (HFOM).

The FMCFs use GPS altitude, position (LAT and LON), and velocity data with ADIRU and radio data to calculate present position and ground speed. The FMCFs use the HFOM to reject the GPS data when the data is not within the necessary limits.

EFIS Control Panel Inputs - ARINC 429 Bus

The EFIS CPs send map data requests to the active FMCF to process. The active FMCF sends this map data to the PDF for display:

- Map mode
- Map range
- Navaid and waypoint data.

FMCS - FMCF INTERFACES - 1

Analog Discrete Inputs - HF (2), VHF (3) Communication Transceivers, and TO/GA Switches (3)

When the flight crew pushes the microphone switch on the HF or VHF communication transceivers or pushes the TO/GA switches, an analog discrete signal goes to the FMCFs. The FMCFs use the analog discretes with other entry inputs from these components to monitor crew work:

- MCP
- EFIS CP (2)
- DSP (2)
- CDU (3).

If the flight crew does not do any work over a period of time, the FMCF makes these alerts occur in cruise and descent:

- Warning
- Caution
- Advisory.

Output Overview

The active FMCF sends digital data to these components on the flight controls ARINC 629 buses:

- ADIRU
- SAARU.

The active FMCF sends digital data to these components on the system ARINC 629 buses:

- AFDS (3)
- ELMS (3)
- AMU
- ASG (2).

The active FMCF sends digital data to the other AIMS cabinet on the ICB ARINC 629 buses.

The active FMCF sends digital data to these components on the ARINC 429 buses:

- Passenger inflight information computer (PIIC)
- GPWC.

Output Details

The FMCFs send data to these interfaces:

- Flight controls ARINC 629 buses
- Systems ARINC 629 buses
- AIMS intercabinet ARINC 629 bus 2
- ARINC 429 buses.

SAARU/ADIRU Outputs - Flight Controls ARINC 629 Bus (3)

The active FMCF sends CDU heading requests to the SAARU when the SAARU is the active navigation source.

The active FMCF sends CDU LAT and LON entries to the ADIRU for initialization.

FMCS - FMCF INTERFACES - 1

AFDS Outputs - Systems ARINC 629 Bus (L, R, & C1)

The active FMCF sends the AFDS lateral and vertical steering guidance commands after the FMCFs receive an arm/operational mode discrete from the AFDS.

ELMS Outputs - Systems ARINC 629 Bus (L & R)

The active FMCF sends zero fuel weight to the ELMS.

AMU Outputs - Systems ARINC 629 Bus (L)

The FMCF sends a VOR/DME or ILS/DME pair discrete to the AMU. This pair discrete lets you hear the DME audio identifier with the co-located VOR or ILS audio identifier. Selections on the EFIS control panel and the audio control panel defines the audio pair.

ASG Outputs - Systems ARINC 629 Bus (L & R)

The active FMCF sends this data to the ASG:

- Airframe configuration
- Engine configuration
- Wing configuration.

FMCF Outputs - AIMS Intercabinet ARINC 629 Bus 2

The active FMCF sends resync data, such as flight plan and map data, to the other FMCF. This happens when a comparison check of the data between the two FMCFs fails.

Passenger Inflight Information Computer (PIIC) Outputs - ARINC 429 Bus

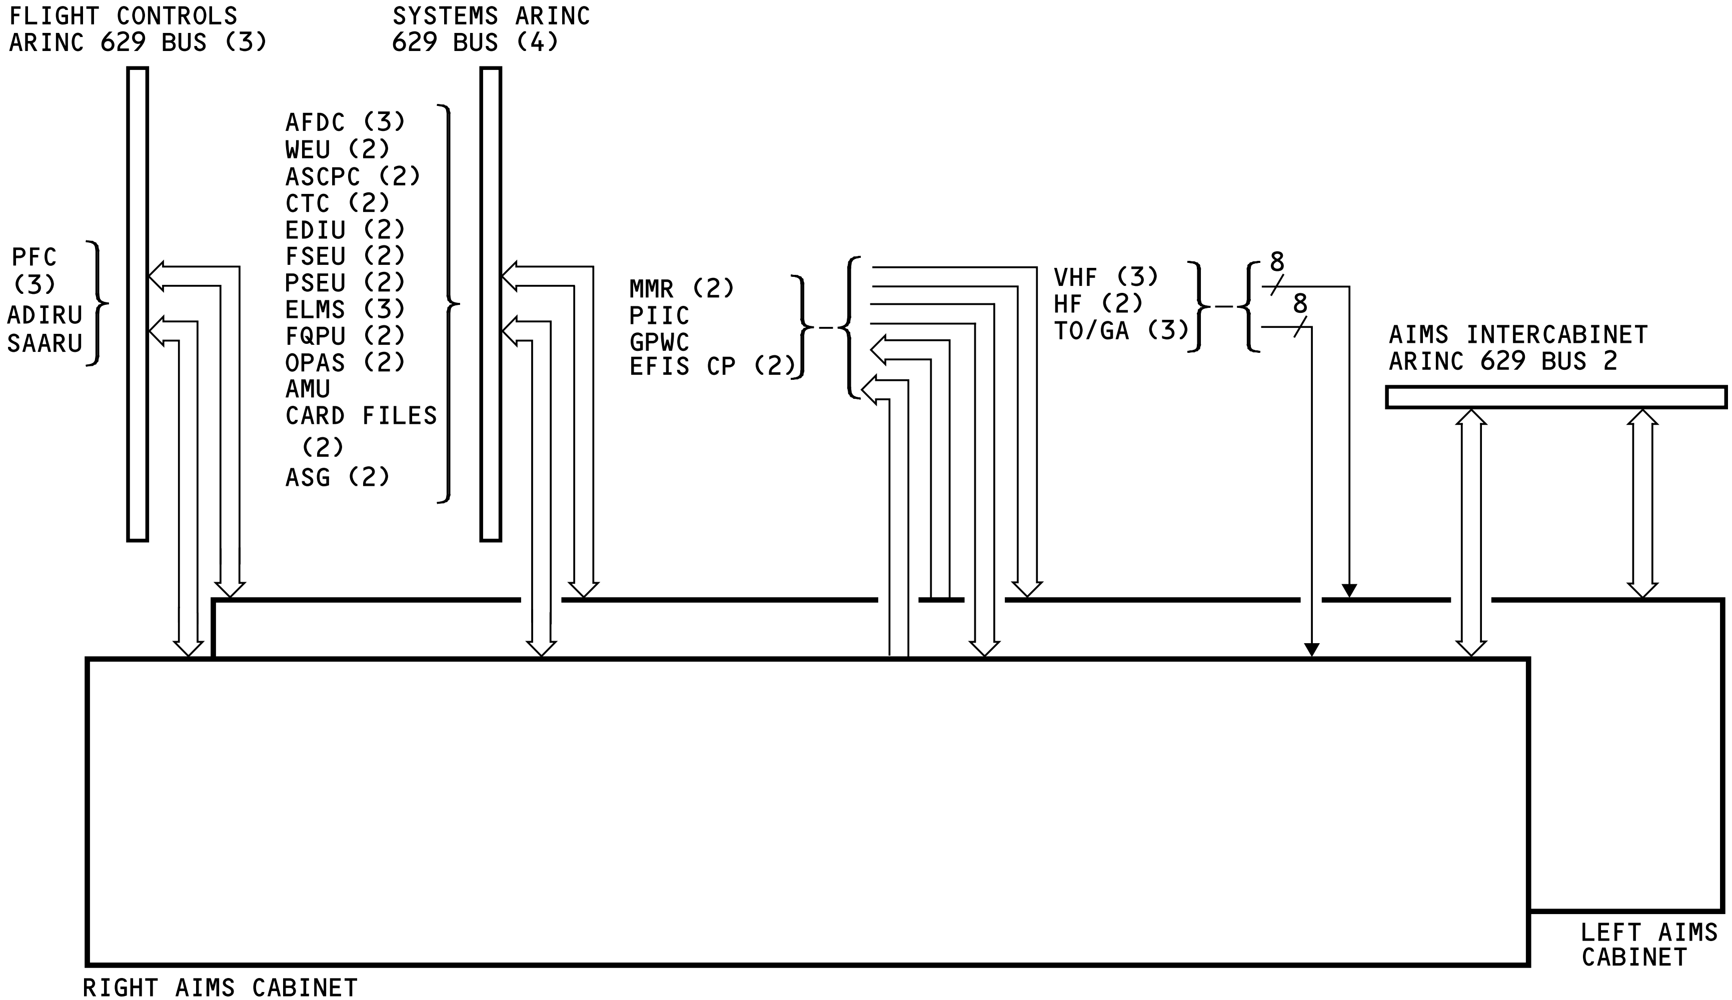
The active FMCF sends this data to the PIIC on a low speed 429 data bus:

- Distance and time to waypoint
- Distance and time to destination.

GPWC Outputs - ARINC 429 Bus

The active FMCF sends this data to the GPWC on a low speed ARINC 429 data bus:

- Air data and inertial data
- Magnetic track angle
- Position (latitude and longitude).



34-61-00-006 Rev 5

FMCS - FMCF INTERFACES - 1

FMCS - FMCF INTERFACES - 2

General

The FMCFs receive mode and status data from the mode control panel (MCP).

The FMCFs receive inputs from these navigation radios:

- MMR
- VOR
- DME
- ADF.

The navigation radio inputs go to the input/output modules (IOMs) in the left and right AIMS cabinets.

The FMCFs use DME distance, ILS deviation and VOR bearing for position update.

MCP Inputs - ARINC 429 Bus

The MCP sends this data to the FMCFs on two 429 buses:

- Altitude and altitude intervention
- Speed and speed intervention
- Mach and mach intervention
- LNAV and VNAV mode requests.

Navigation Radio Inputs - ARINC 429 Buses

The multi-mode receivers (MMR) send ILS deviation data to the FMCF navigation partition. The FMCF can use this data to calculate a position. The MMRs also send frequency data to the FMCF navigation partition so the FMCF can verify valid ILS tuning.

The VOR receivers send bearing, frequency, and status data.

The DME interrogators send distance, frequency, and status data.

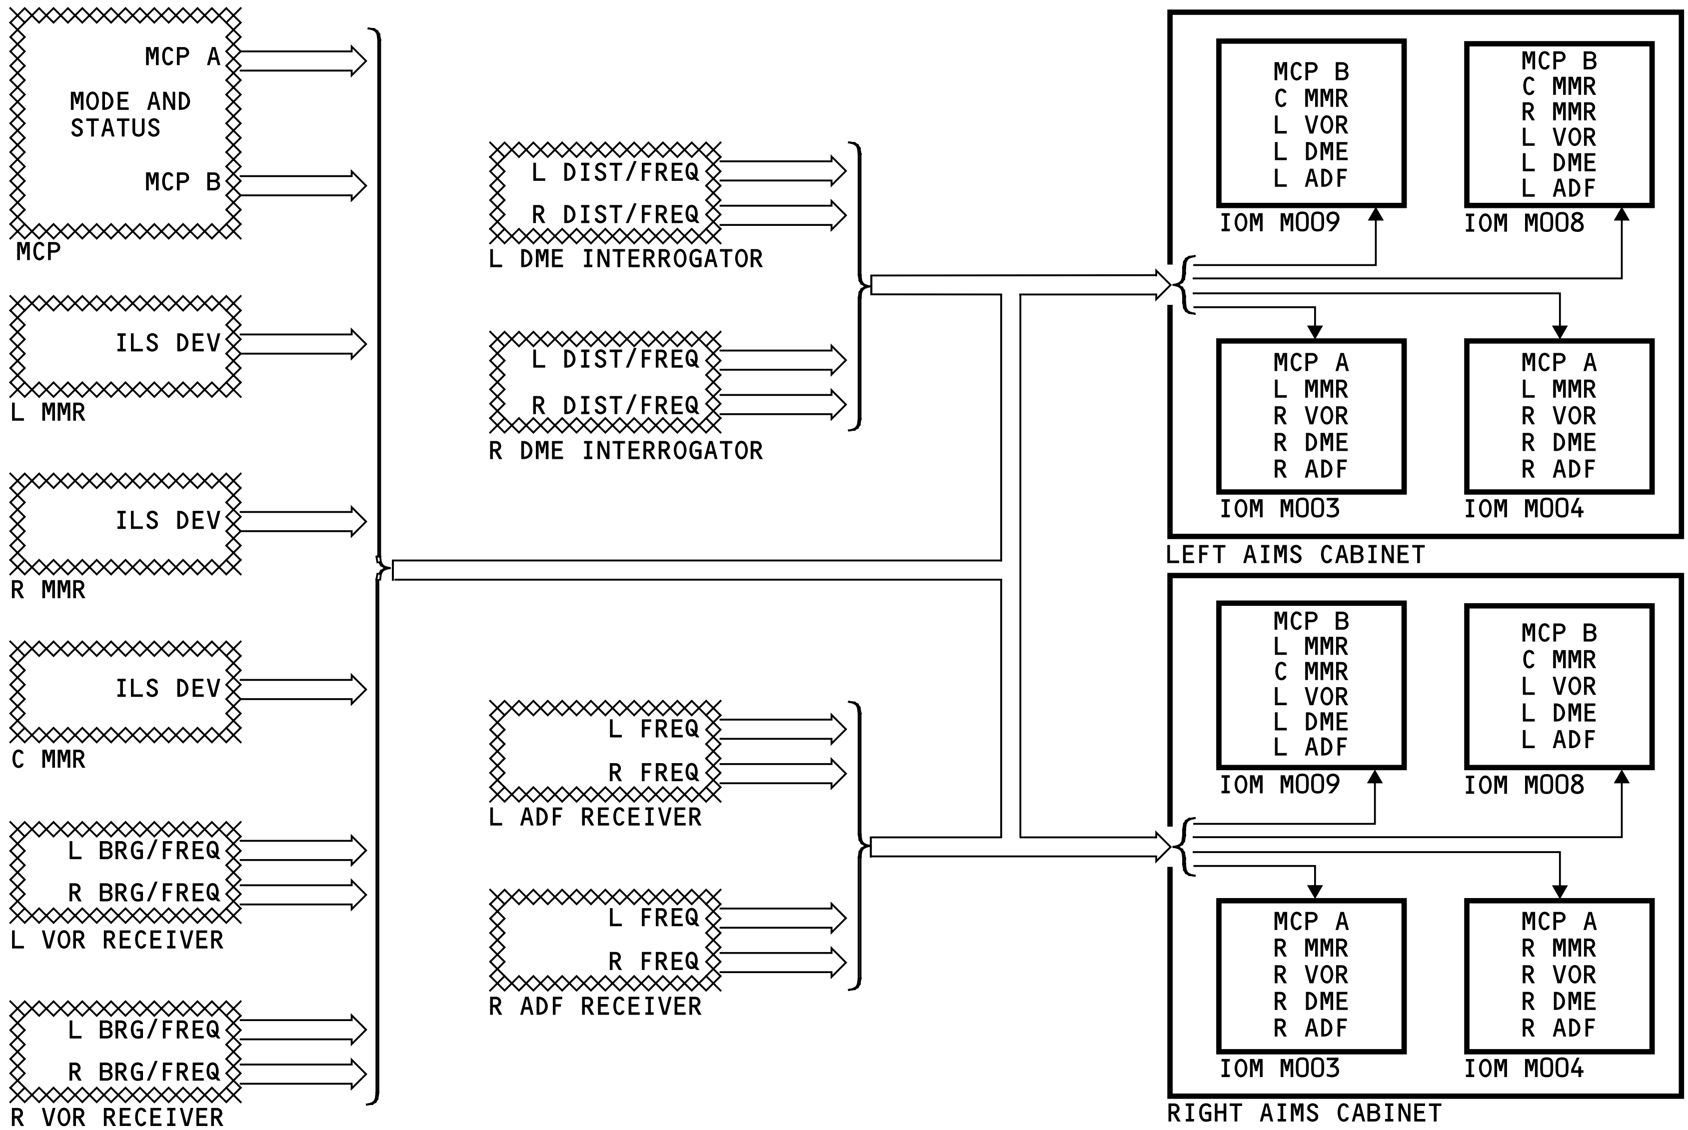
The ADF receivers send frequency and status data.

The navigation radios send the tuned frequencies back to the FMCFs. The FMCFs use these frequencies as a wrap around tests. The FMCFs use status data to blank or show dashes instead of the normal display.

The FMCFs use the navigation radios for position update in this order:

- ILS/DME in approach and ILS active
- DME/DME
- DME/VOR.

The FMCFs do not use ADF bearing in their position calculations.



FMCS - FMCF INTERFACES - 2

34-61-00-007 Rev 4 03/03/1998

THIS PAGE INTENTIONALLY LEFT BLANK

FMCS - FMCF INTERFACES - 3

General

These are the three types of procedures to tune navigation radio:

- Automatic
- Manual
- Alternate.

For the automatic procedure, the FMCFs send tune data to the ILS, VOR and DME navigation radios automatically. The ADF navigation radios are not tuned automatically.

For the manual tune procedure, you use the left or right CDU to manually tune all of the navigation radios through the FMCFs. You use the center CDU to manually tune the navigation radios only when the left or right CDU fails.

When both FMCFs fail, you use the CDUs and the alternate procedure to tune all of the navigation radios. The tune data goes from the on-side CDU directly to the on-side navigation radio. The center multi-mode receiver (MMR) gets the alternate tune data from the left CDU.

FMCF Radio Tune Outputs

Both FMCFs in the AIMS cabinets generate radio tune data. The left AIMS cabinet sends radio tune data to the right AIMS cabinet on ARINC 429 data buses.

The right AIMS FMCF radio tune sub-function normally tunes the navigation radios. The right AIMS cabinet has the radio tune relays. The radio tune relays energize when the right navigation radio tune sub-function and the input/output modules (IOMs) are valid.

Both AIMS FMCF radio tune sub-functions process radio input data and make radio tune output data. When the right radio tune sub-function fails, the right radio tune relays de-energize. This allows the left AIMS radio tune sub-function to tune the radios through the relaxed position of the relays in the right AIMS cabinet.

The right AIMS cabinet IOM M004 sends radio tune data to input port B in these radios:

- Right MMR receiver
- Right VOR receiver
- Right DME interrogator
- Right ADF receiver, manual tune only.

The right AIMS cabinet IOM M009 sends radio tune data to input port B in these radios:

- Left MMR
- Left VOR receiver
- Left DME interrogator
- Left ADF receiver, manual tune only.

The right AIMS cabinet IOM M008 sends radio tune data to input port B in the center ILS receiver.

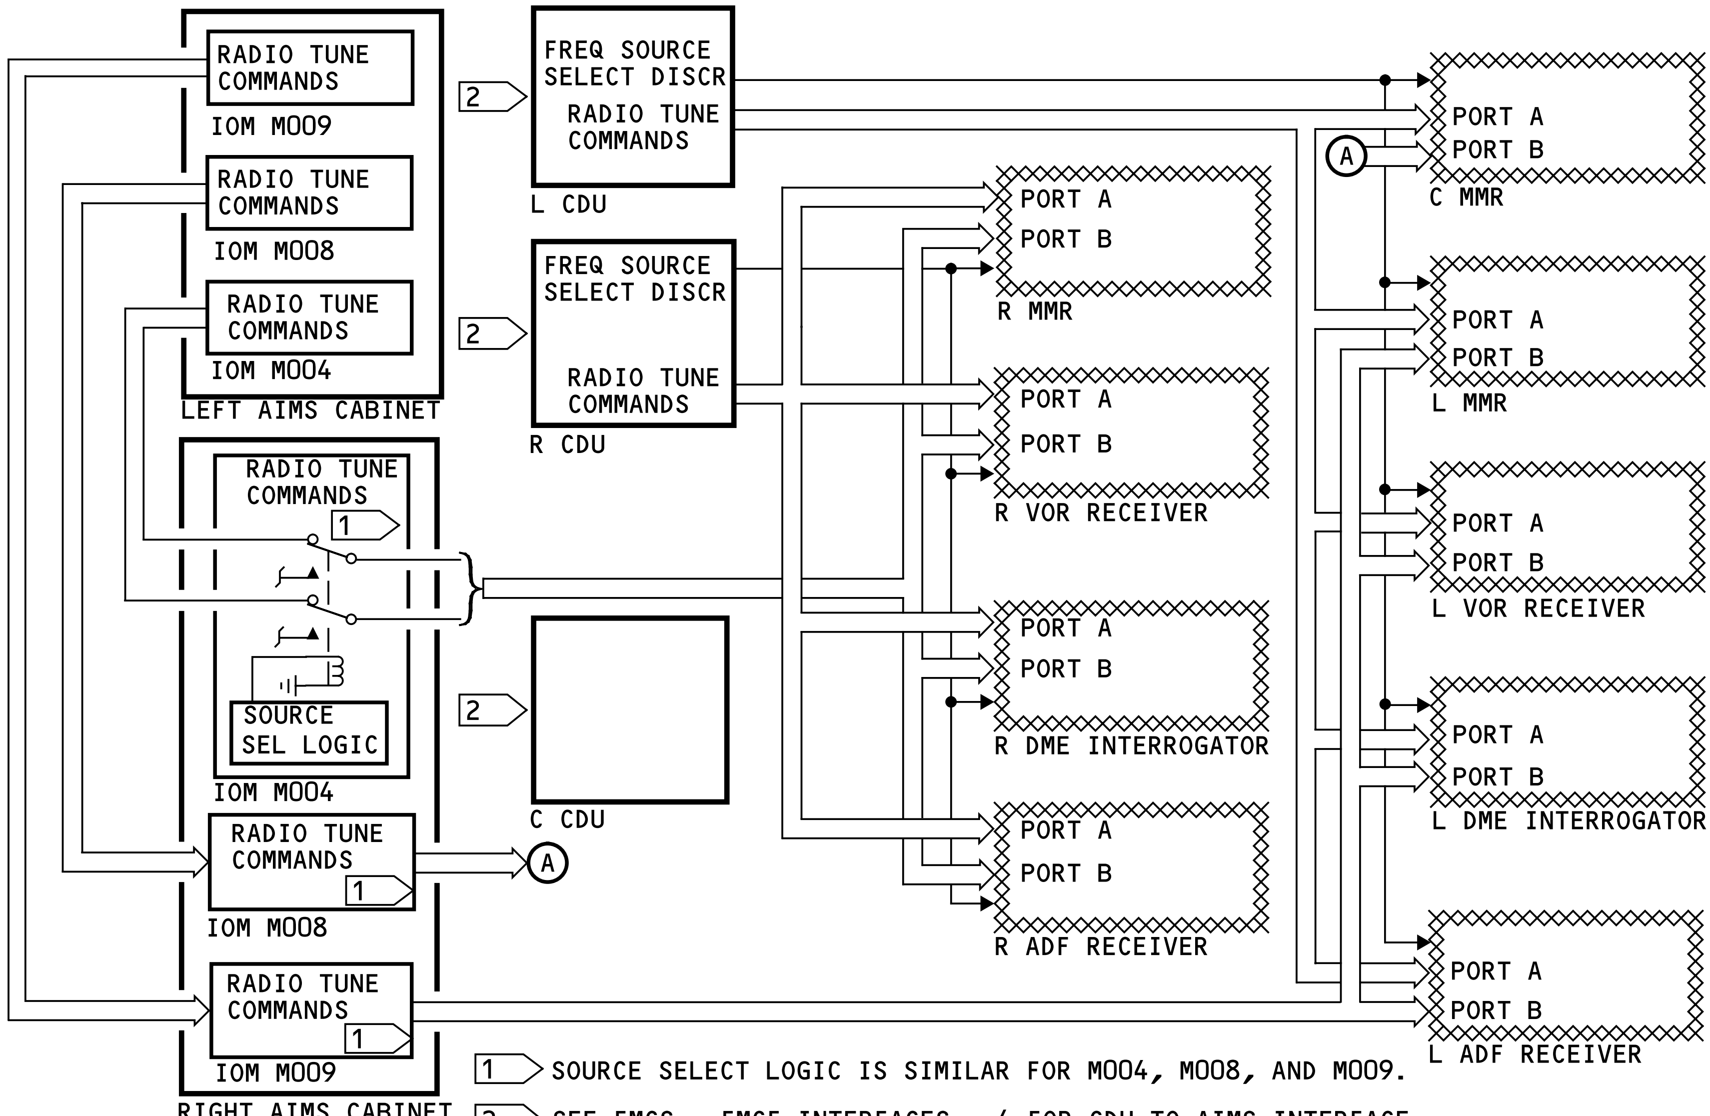
FMCS - FMCF INTERFACES - 3

CDU Navigation Radio Outputs - ARINC 429 Bus

When the FMCFs fail, the CDUs send a frequency source select discrete to the navigation radios. This discrete causes the navigation radios to select the input port A. Input port A receives the tune frequency directly from the ARINC 429 bus of the on-side CDU.

The FMCF or the on-side CDU for the alterenate tune procedure send this data to the NAV radios:

- ILS frequency and runway heading
- DME frequency
- VOR frequency and course
- ADF frequency, tune mode.



1 SOURCE SELECT LOGIC IS SIMILAR FOR M004, M008, AND M009.

2 SEE FMCS - FMCF INTERFACES - 4 FOR CDU TO AIMS INTERFACE

FMCS - FMCF INTERFACES - 3

FMCS - FMCF INTERFACES - 4

THIS PAGE INTENTIONALLY LEFT BLANK

FMCS - FMCF INTERFACES - 4

General

The CDU is the primary interface for the FMCF and other systems. The CDU also processes inputs from external sensors to supply alternate commands when the active FMCF fails. The CDUs receive some of the same inputs as the FMCFs.

The CDU also supplies:

- Alternate lateral navigation steering commands and map display data (LNAV)
- The interface with SATCOM
- The interface with the passenger address/cabin interphone (PA/CI) controller on the center CDU
- Alternate radio tuning (L and R)
- Alternate electronic flight instrument system control panel (EFIS CP)
- Alternate display select panel (DSP) control
- Alternate map display and control
- BITE and fault monitoring
- Maintenance page access.

CDU - Inputs Overview

The CDUs receive air data inertial reference unit (ADIRU) data on the flight controls ARINC 629 buses.

The CDUs receive digital data on the systems ARINC 629 buses from these components:

- Audio management unit (AMU)
- CDU (2)
- ARINC signal gateway (ASG) (2)
- Bus power control unit (BPCU)
- Overhead panel ARINC system (OPAS) (2)
- Autopilot flight director computer (AFDC) (3)
- AIMS Intercabinet ARINC 629 Bus 2
- AIMS FMCF data.

The CDUs receive digital data on the ARINC 429 bus from the satellite communication data unit (SDU).

The center CDU also gets data from the passenger address/cabin interphone (PA/CI) controller.

The CDUs receive analog discretes from the master dim and test module.

The CDUs receive digital flight plan data on the AIMS intercabinet bus (ICB) 2 from the active FMCF.

ADIRU Inputs - Flight Controls ARINC 629 Bus (L and R)

The ADIRU sends inertial data to the CDUs. The CDUs use this data to calculate LNAV commands when the active FMCF fails. The CDUs receive this data from the ADIRU:

- Position, latitude and longitude (lat/long)
- Heading (hdg)
- Roll angle
- Altitude data.

FMCS - FMCF INTERFACES - 4

CDU Inputs - Systems ARINC 629 Buses (L & R)

Each CDU receives flight plan synchronization data and brightness control data from the other CDUs. If both FMCFs failed, the flight plan synchronization data prevents flight plan map shifts when a CDU fails and the next CDU takes over. The brightness control input is fromthe local light sensors from each of the other CDUs (2) and the PDS light sensors.

ASG Inputs - Systems ARINC 629 Bus (L and R)

The ASG function sends weight-on-wheels data to the CDUs. The CDUs use this data for the air/ground logic.

BPCU Inputs - Systems ARINC 629 Bus (L and R)

The BPCU sends a discrete to the CDUs. This is air/ ground status.

OPAS Inputs - Systems ARINC 629 Bus (L and R)

The OPAS send the CDUs the navigation source select switch position (AUTO or CDU).

AFDC Inputs - Systems ARINC 629 Buses (L and R)

The AFDS sends LNAV arm/operate data to the CDUs during the alternate LNAV guidance mode. The AFDS also sends an ILS tune inhibit to the left and right CDUs to stop manual tune requests to the ILS radios in approach.

AIMS Cabinet Inputs - Systems ARINC 629 Bus (L and R)

These functions in AIMS send data to the CDUs on the left and right systems ARINC 629 buses:

- Central maintenance computing function (CMCF)
- Primary display function (PDF)
- Flight deck communication function (FDCF)
- Flight management computing function (FMCF).

The CMCF sends this data to the CDUs:

- Airplane identification
- Flight leg
- Flight phase
- Date and time
- Directed message commands
- Operational software
- Load commands
- Engine switch data for air/ground logic.

The PDF sends this data to the CDUs:

- Brightness command
- Display select panel (DSP) data
- EFIS CP data.

The FDCF sends a command to clear the scratchpad for the multi-functional display (MFD) text entry to the CDUs.

The FMCF sends this data to the left and right CDUs on the left and right system ARINC 629 buses:

FMCS - FMCF INTERFACES - 4

- Flight plan download
- Radio tune download
- Page displays.

The FMCF sends the same data on the left and right system buses to the center CDU when the left or right CDU fails.

SDU Inputs - ARINC 429 Bus

The SDU sends communications data to the CDUs on a high speed ARINC 429 data bus.

PA/CI Controller Inputs - ARINC 429 Bus

The PA/CI controller sends passenger address and cabin interphone data to the center CDU for flight deck and cabin interface.

Analog Inputs

The CDUs receive lamp test and bright/dim inputs from the master/dim and test module.

AIMS Intercabinet ARINC 629 Bus 2 Inputs

The AIMS ICB bus 2 supplies the data from the active FMCF when the left and right system ARINC 629 buses failed.

CDU Outputs Overview

The CDU sends digital and analog data to components and systems on these buses:

- Systems ARINC 629 buses
- ICB 2.

AMU Outputs - Systems ARINC 629 Bus (L)

This discrete causes the DME identifier audio to be paired with either VOR in the EFIS VOR mode or ILS audio in the EFIS approach mode.

AFDS Outputs - Systems ARINC 629 Bus (L and R)

When both FMCFs fail, the left CDU sends LNAV guidance commands to the AFDS. If the left CDU fails then the center CDU supplies the LNAV guidance commands. If the center CDU fails then the right CDU supplies the LNAV guidance data.

AIMS Outputs - Systems ARINC 629 Bus (L and R)

The CDUs send data to these AIMS functions on the left and right system buses:

- CMCF
- Primary display function (PDF)
- FDCF
- FMCF.

FMCS - FMCF INTERFACES - 4

The CDUs send fault reports and directed messages to the CMCF in the AIMS cabinets on the L and R systems ARINC 629 buses.

The CMCF in AIMS receives operational program load status data from the CDUs during data load operation.

The PDF in AIMS receives this data from the CDUs on the L and R systems ARINC 629 buses:

- Map background data
- Dynamic map data
- EFIS CP data
- DSP data
- Maintenance display discrete.

The CDUs supply on-side map display. The center CDU acts as a back-up CDU for the left or right CDU if a CDU failure occurs.

The FMCFs receives scratchpad contents from the CDUs on the L and R system ARINC 629 buses.

The FMCFs get button push and protocol data from the CDUs through the left and right system ARINC 629 buses.

SDU Outputs - ARINC 429 Bus

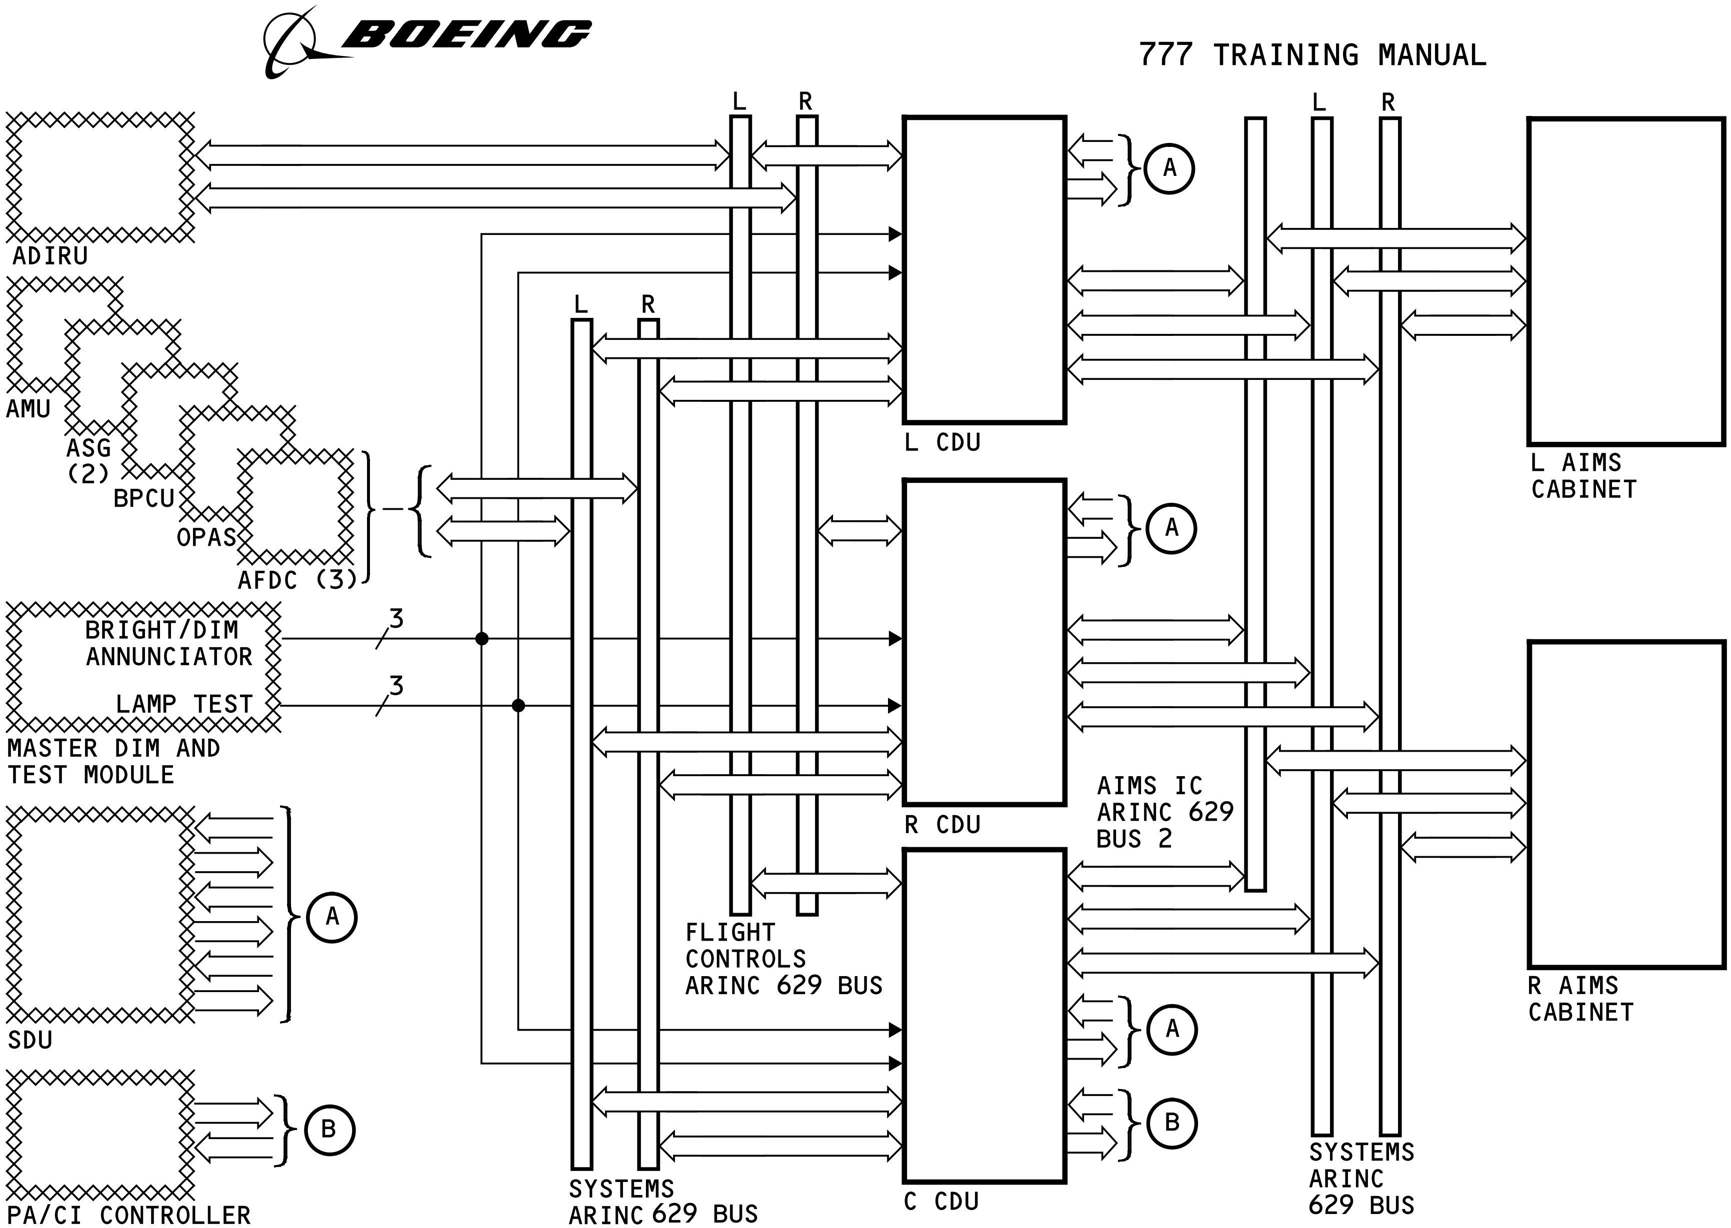
Each CDU sends communication data to the SDU on a high speed ARINC 429 data bus.

PA/CI Controller Outputs - ARINC 429 Bus

The center CDU sends passenger address and cabin interphone data to the PA/CI controller on a high speed ARINC 429 bus.

CDU Outputs - AIMS Intercabinet Bus 2

If the left and right system ARINC 629 buses fail, then the CDUs send data to the FMCFs on the ICB 2.



FMCS - FMCF INTERFACES - 4

34-61-00-009 Rev 5 10/13/95

THIS PAGE INTENTIONALLY LEFT BLANK

FMCS - CONTROL DISPLAY UNIT

Purpose

The CDU is the primary control and display interface for the FMCF. You use the CDU to enter flight plan data and performance data. Also, you use the CDU to manually tune the navigation radios and access maintenance pages. In the event of a EFIS control panel failure or display select panel (DSP) failure, you use the on-side CDU as a back-up EFIS control panel and any CDU as a back-up DSP.

Physical Features

The CDU weighs approximately 16 pounds. It is 9 inches tall, 10.5 inches deep and 5.75 inches wide. The LCD of the CDU shows the flight modes and data in color. The CDU needs 28v dc input power for normal operation. The CDUs use forced air through inlet and exhaust ports for cooling. The CDU shuts down at temperatures above 77C. It restarts when the temperature is below 77C. The CDU has these physical features:

- LCD
- CDU controls
- Annunciators
- Light sensor
- Manual brightness control.

LCD Display Format

The LCD shows 14 lines of data in various colors. Each line is 24 characters long. The top line is the page title field. The title field shows the function of the page and the current page number and the total number of pages for the page display. Lines 1L to 6L and 1R to 6R have title fields and data fields. The scratchpad area is below line 6L and 6R.

To enter or transfer data use the scratchpad. Alert and advisory messages also show in the scratchpad.

Some data fields can show box prompts or dashes. When the box prompts show, you must enter data into that data field. When the dashes show, data entry into that data field is optional.

Color

The LCD uses different colors to show flight activity and modes. Information shows in these colors:

- Black - background
- White - default color for text
- Magenta - next active waypoint in the flight plan
- Green - multiple state data fields with large font (ON) and VOR tuned navigational aids
- Cyan - ADF tuned navigational aids
- Shaded white - data that modifies the flight plan.

The CDU shows this data in white:

- Text
- Alert and advisory messages
- Multiple state data fields with small font (off)
- Tuned ILS navigational aids
- Line titles

- Dashes, except when the dash is an integral part of the data field
- Slashes, except when the slash has data on both sides.

CDU Controls

These are the primary controls for the CDU:

- Line select keys
- Function keys
- Mode keys
- Alpha-numeric keys
- Special keys.

Line Select Keys

Line select keys 1L to 6L and 1R to 6R, permit the operator to do these things:

- Transfer data from the scratchpad to a data field
- Copy data from a data field to the scratchpad
- Delete data from a data field
- Select an operation. (This occurs when the CDU operates as a control panel in the alternate mode, EFIS or DSP control panel. In this case, the line select key acts as a toggle switch to select between two states (OFF or ON))
- Select another page. This occurs when a caret (prompt) and a page title show next to a line select key.

Not all keys permit all actions. Keys can have different functions on other pages.

Function Keys

These are the three function keys:

- Execute (EXEC)
- NEXT PAGE
- Previous page (PREV PAGE).
- Use the EXEC key to execute (make active) or to modify a page with data entry when the EXEC light comes on.
- Use the NEXT PAGE key to go to the next page when the page count shows more than one page (1/X, 2/X ...).
- Use the PREV PAGE key to go back one page when the page count shows more than one page (1/X, 2/X ...).

Mode Keys

The mode keys select the page for the current airplane condition. These are the mode keys:

- Initialization/reference (INIT/REF)
- Route (RTE) page
- Departure/arrival (DEP/ARR) page
- Alternate (ALTN) page
- Vertical navigation (VNAV) pages
- FIX page
- LEGS page
- HOLD page

- FMC COMM page
- Progress (PROG) pages
- MENU page
- Navigation radio page (NAV/RAD).

Alpha-numeric Keys

The alpha-numeric keys permit the operator to type alpha-numeric data into the scratchpad. The operator can use the line select key to enter scratchpad data into a data field. Some data fields do not let the operator enter data.

Special keys

The keyboard has some special keys in addition to the alpha-numeric keys. These are the special keys:

- Change sign (+/-)
- Space (SP)
- Slash (/)
- Clear (CLR)
- Delete (DEL).

The change sign (+/-), SP keys and slash (/) keys are standard keys on a keyboard.

Use the CLR key to remove a single alpha-numeric character in the scratchpad or an alert or advisory message from the scratchpad with one push. Hold the CLR key down for one second to remove all scratchpad data.

A push of the DEL key puts the word DELETE in the CDU scratchpad and this permits the operator to delete a data field with the line select key next to the data field. The DEL key does not work when the scratchpad contains data. Some data fields do not permit the DEL key function. In this case, the INVALID DELETE message shows in the CDU sratchpad.

Annunciators

The annunciators come on to show status. These are the annunciators:

- Display (DSPY)
- Message (MSG)
- Offset (OFST).

DSPY shows when the current page does not relate to the active flight plan or present active mode or function. The DSPY comes on, as an example, when the route page 2 of 3 (2/3) shows on the LCD and the airplane is at the departure gate.

The MSG annunciator comes on whenever an alert or an advisory message shows in the scratchpad. The CDU or the FMCF can cause this to occur.

The OFST annunciator comes on when the airplane is in the air and an offset route is active. An offset route is a route parallel (left or right) to the active route.

Light Sensor

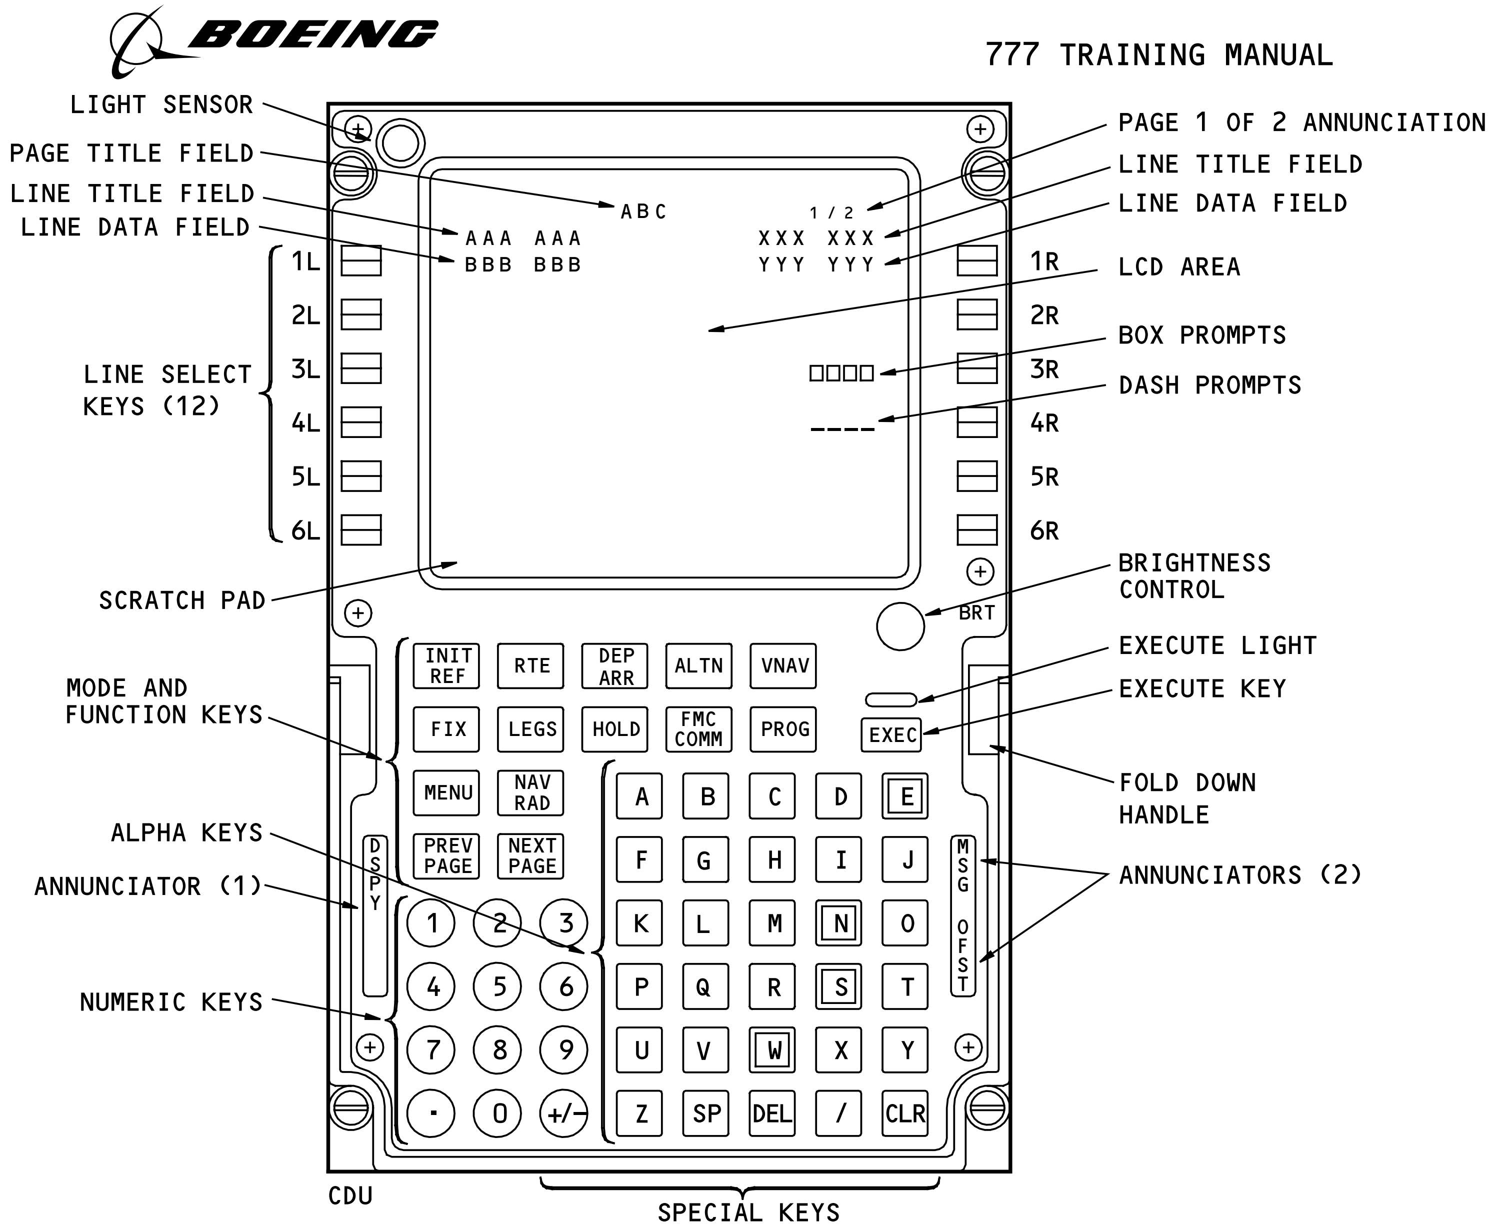
The light sensor on the CDU is one of four light sensor inputs the CDU uses to set the LCD brightness level. The others are the light sensors from the other CDUs and the PDS light sensors.

Manual Brightness Control

The manual brightness control adjusts the brightness level above or below the automatic brightness level set by the CDU. To do this, rotate the manual brightness knob left or right.

Training Information Point

The CDU has no line replaceable parts. The CDU is a line replaceable unit (LRU).



FMCS - CONTROL DISPLAY UNIT

FMCS - INSTRUMENT SOURCE SELECT PANELS AND F/O DISPLAY SWITCHING PANEL

General

The FMCS has an interface with these controls:

- Captain's NAV source switch on the instrument source select panel (ISSP)
- First officer's NAV source switch on the ISSP
- FMC selector on the first officer's display switching panel
- LNAV and VNAV mode switches on the mode control panel (MCP)

Operation - NAV Source Switch

The NAV source switch selects the source of NAV data that shows on the on-side ND and PFD. In the AUTO position, the active FMCF is the source of NAV data for the PFDs and NDs. The on-side CDU supplies map data to the on-side ND when both FMCFs fail and the FMC selector is in the AUTO position. The on-side CDU also supplies map data when the FMC selector is in the left or right FMCF position and the related FMCF fails.

The NAV source switches in the CDU position causes the on-side CDU to supply NAV data to the on-side ND. This position permits the flight and maintenance crews to do a check of the CDU alternate navigation capability. The CDU uses the active FMCF flight plan/map data, reformats it, and sends it to the on-side ND.

Operation - FMC Selector

The FMC selector has these three positions:

- Left (L)
- AUTO
- Right (R).

In the left position, the left FMCF and TMCF are active. If the left FMCF fails, there is no active FMCF.

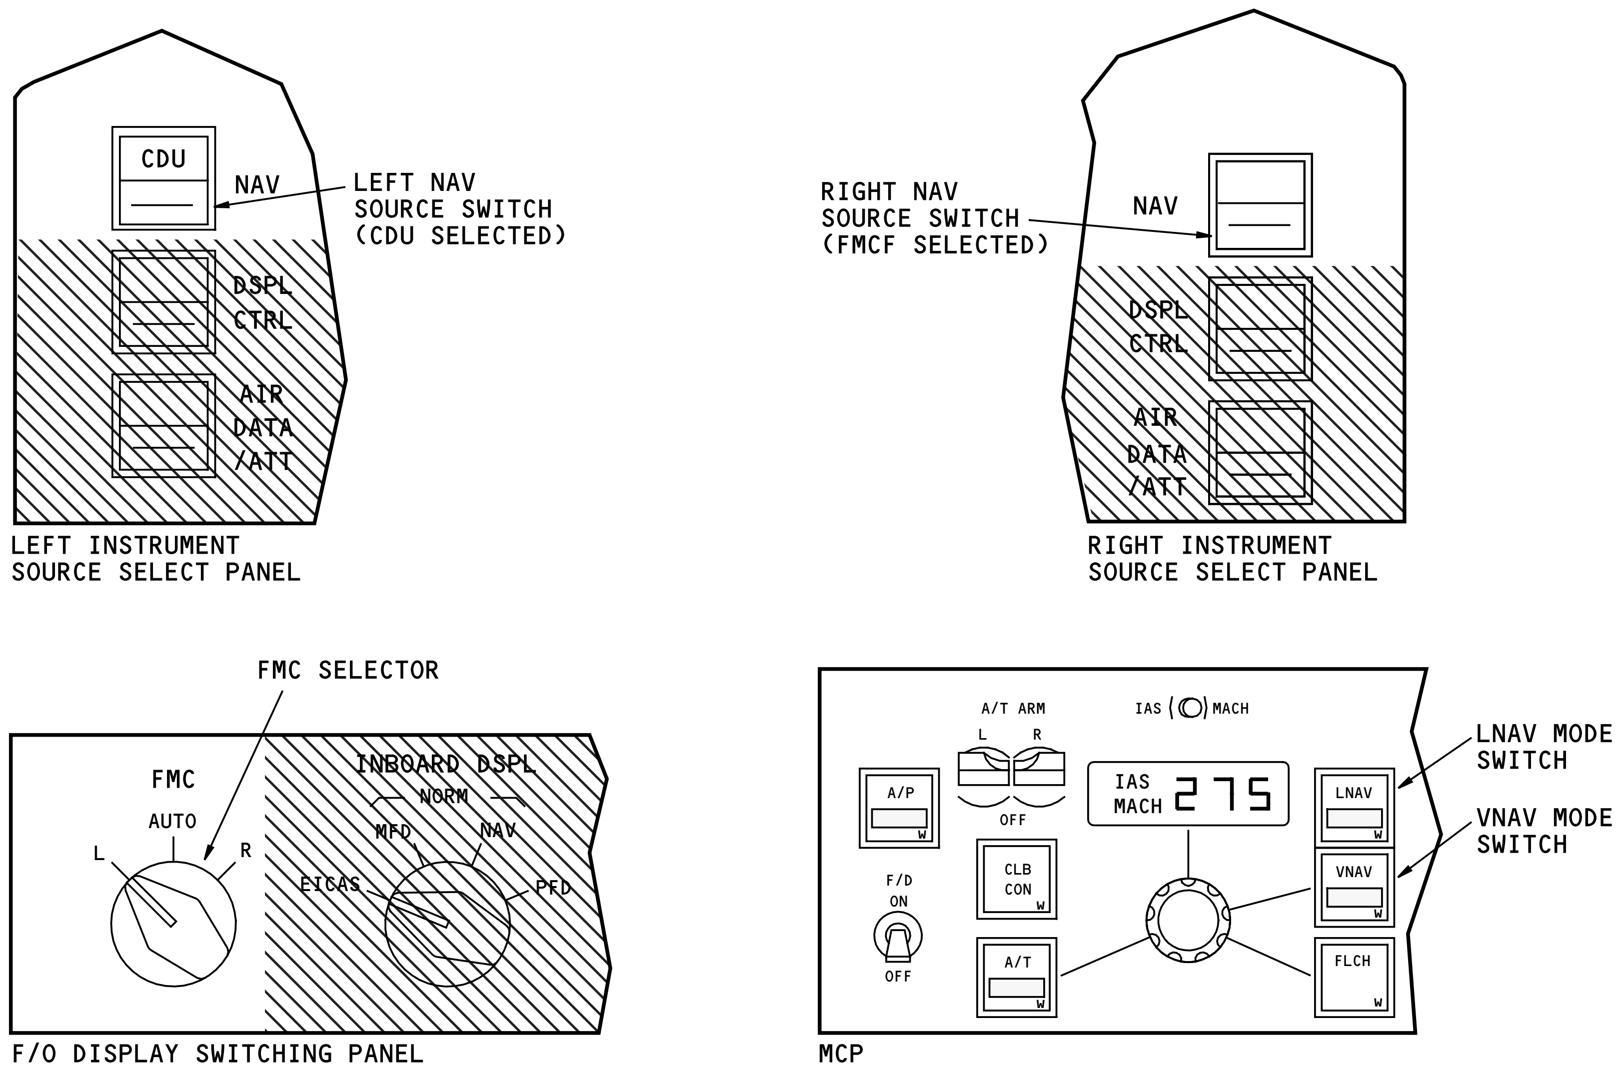
In the AUTO position, a random selection of the active FMCF and TMCF occurs after power is supplied. If the active FMCF fails, the other FMCF becomes active.

In the right position, the right FMCF and TMCF are active. If the right FMCF fails, there is no active FMCF.

Mode Switches (LNAV and VNAV)

The LNAV mode switch on the MCP sends mode requests to the FMCFs and the CDUs. Normally, the active FMCF uses the mode request to send lateral steering commands to the autopilot flight director system (AFDS) when the airplane is in the air. The CDU sends lateral steering commands to the AFDS when both FMCFs fail.

The VNAV mode switch on the MCP sends mode requests to the FMCFs. Normally, the active FMCF uses the mode request to send vertical steering commands to the AFDS when the airplane is in the air. The CDU does not calculate VNAV steering commands.



FMCS - INSTRUMENT SOURCE SELECT PANELS AND F/O DISPLAY SWITCHING PANEL

34-61-00-011 Rev 4

THIS PAGE INTENTIONALLY LEFT BLANK

FMCS - PRIMARY FLIGHT DISPLAY (PFD)

General

The flight management computing function (FMCF) sends speed and compass data to the primary display system to show on the primary flight display (PFD).

Speed Data

When the flight crew completes the FMCF pre-flight, the active FMCF sends this speed data to the primary display system to show on the PFDs:

- Selected target speed/mach and target cursor
- High SPD buffet
- Takeoff safety speed (V2)
- Rotation speed (VR)
- Takeoff decision speed (V1)
- Landing reference speed (VREF)
- Flap maneuver speed (extend or retract)
- Minimum speed limit (VMIN).

As part of the pre-flight, the flight crew can enter target speed/mach into the FMCF. When the vertical navigation (VNAV) mode is active, the FMCF selected target speed/mach shows above the speed tape on the PFD. Also, the selected target speed cursor points to the same target speed on the speed tape. If VNAV is not active, the MCP selected speed/mach shows.

High speed buffet is the maximum maneuver speed. The high speed buffet shows as a hollow yellow bar. The bar extends from the bottom of the maximum operating speed symbol. The maximum operating speed symbol is the red and black barber pole symbol which comes from the warning electronic system (WES).

V2 is the takeoff safety speed. V2 shows in green next to the climb out speed tick on the airspeed tape. V2 goes away when the flaps begin to retract.

VR is the takeoff rotation speed. VR shows in green next to the rotation speed tick on the airspeed tape. VR goes away after takeoff.

V1 is the takeoff decision speed. V1 shows in green next to the decision speed tick on the airspeed tape. V1 goes away after takeoff.

VREF is the landing approach speed when the flaps are extended. A green REF and a bar shows next to the airspeed tape.

Flap maneuver speeds show the flight crew the necessary flap selection for the current takeoff or cruise/ approach speed. The retract or extend speed shows as a tick mark on the airspeed tape with labels for the flap selections.

VMIN is the minimum speed limit of the airplane when the flaps/slats extend. VMIN shows as a hollow yellow bar that extends up from the top of the stick shaker symbol. The stick shaker symbol is a red and black barber pole symbol. The stick shaker symbol comes from the WES.

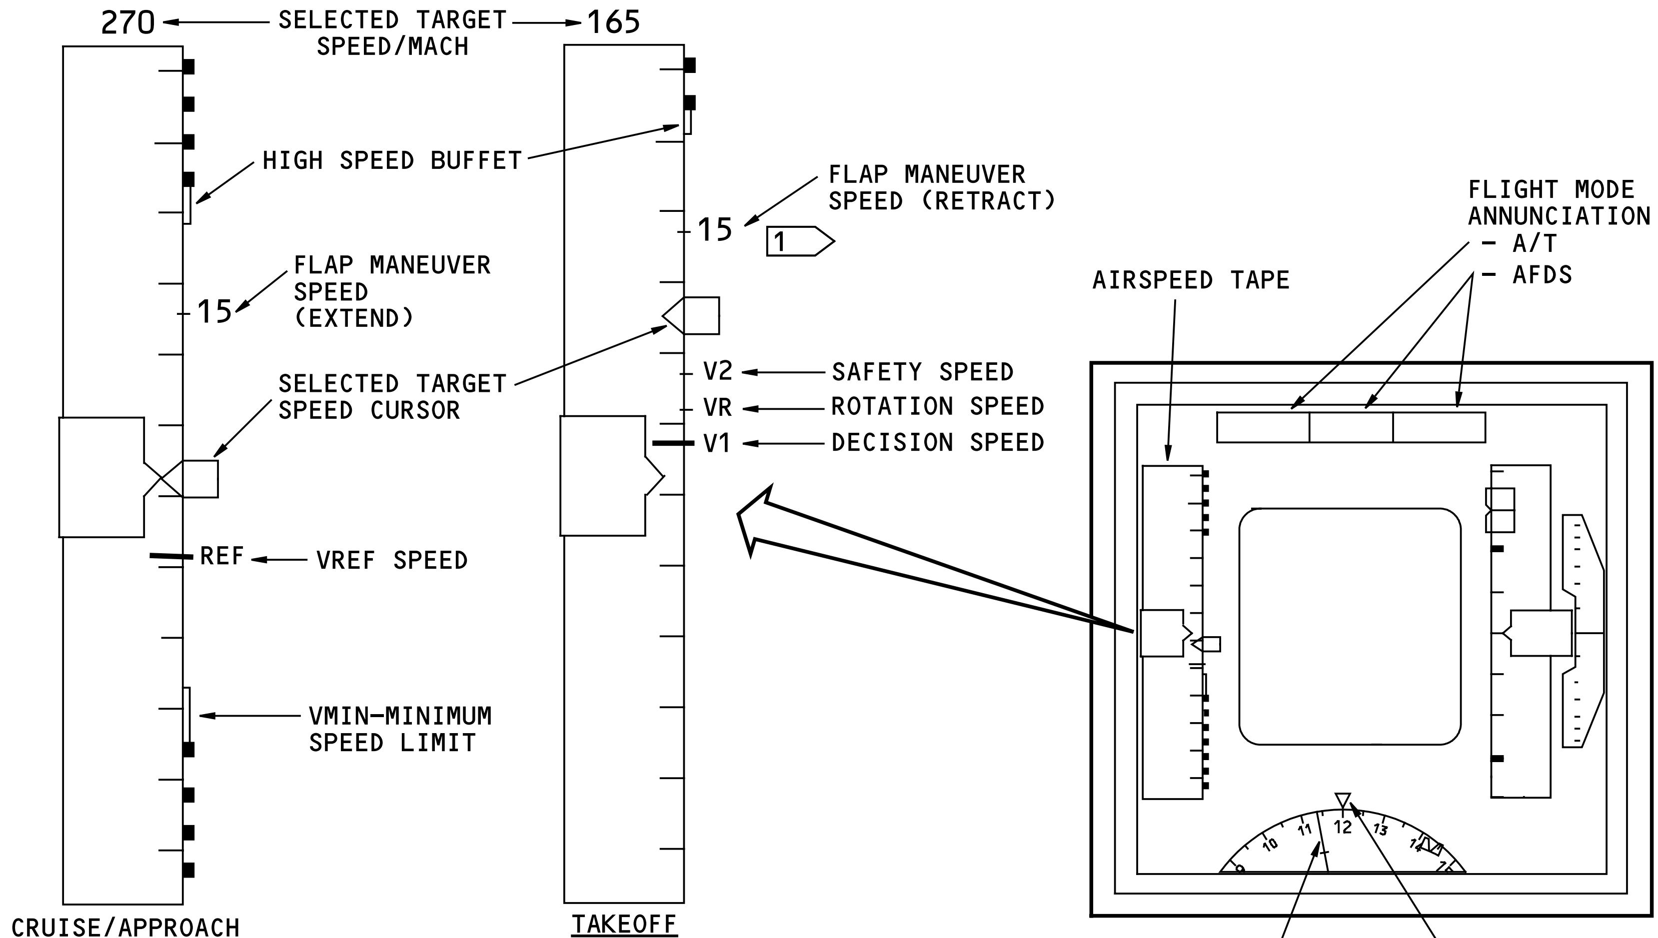
FMCS - PRIMARY FLIGHT DISPLAY (PFD)

Compass Data

The active FMCF sends this compass data to the primary display system to show on the PFD:

- Heading
- Track.

The air data inertial reference unit (ADIRU) sends heading and track data to the PFDs when the active FMCF fails.



1 UP, SHOWS WHEN FLAPS ARE RETRACTED

FMCS - PRIMARY FLIGHT DISPLAY (PFD)

THIS PAGE INTENTIONALLY LEFT BLANK

FMCS - NAVIGATION DISPLAY (ND)

General

The flight management computing function (FMCF) sends navigation display data to the primary display system (PDS) to show on the navigation display (ND).

Display Data

The active FMCF sends navigation data to the NDs for all display modes. If both FMCFs fail, the on-side CDU sends the navigation data.

There are two types of navigation data, dynamic data and background data. Dynamic data changes as a function of time. Background data is stationary data that does not move as a function of time. The active FMCF sends this dynamic data to show on the NDs via the PDF:

- Track (TRK)
- Heading (HDG)
- Ground speed (GS)
- Wind data - direction, speed, and angle. This shows when true airspeed is greater than 100 knots and wind speed is greater than 5 knots
- Active waypoint (magenta). This is the fly to waypoint. When the airplane crosses it, the waypoint color goes to white and the next fly to waypoint becomes magenta
- Altitude range arc. This shows the range to the mode control panel (MCP) altitude
- VNAV path deviation. This shows as a vertical scale and magenta pointer when the airplane goes through the top of descent profile point. The scale range is +/- 420 feet in 50 foot increments to a maximum of 9999 feet
- Estimated time of arrival (ETA) - FMCF or time to go (TTG) - CDU
- Distance to go (DTG). DTG to the active waypoint shows in nautical miles (nm) when greater than 100 nm and in tenths at less than 100 nm
- Altitude profile points. These are along the flight plan to show flight mode or vertical flight path changes, top of climb (T/C), top of descent (T/D), step climb (S/C), end of descent (E/D)
- Route. The route shows magenta when active, cyan when inactive, and white dash lines for modifications
- Airplane position
- FMC position update mode. This shows the data the FMCFs use for position update (GPS, lOC, DME/DME, VOR-DME, INERTIAL)
- Tuning mode. This shows as an A (auto tune) or M (manual tune).

The active FMCF sends this dynamic data in the approach and VOR ND modes via the PDF:

- Track
- Heading
- Ground speed
- Wind data.

FMCS - NAVIGATION DISPLAY (ND)

The air data inertial reference unit (ADIRU) sends wind data, ground speed, track, and heading data to the ND when the active FMCF fails.

If both FMCFs fail, the on-side CDU sends this dynamic data to the ND in the map and plan modes:

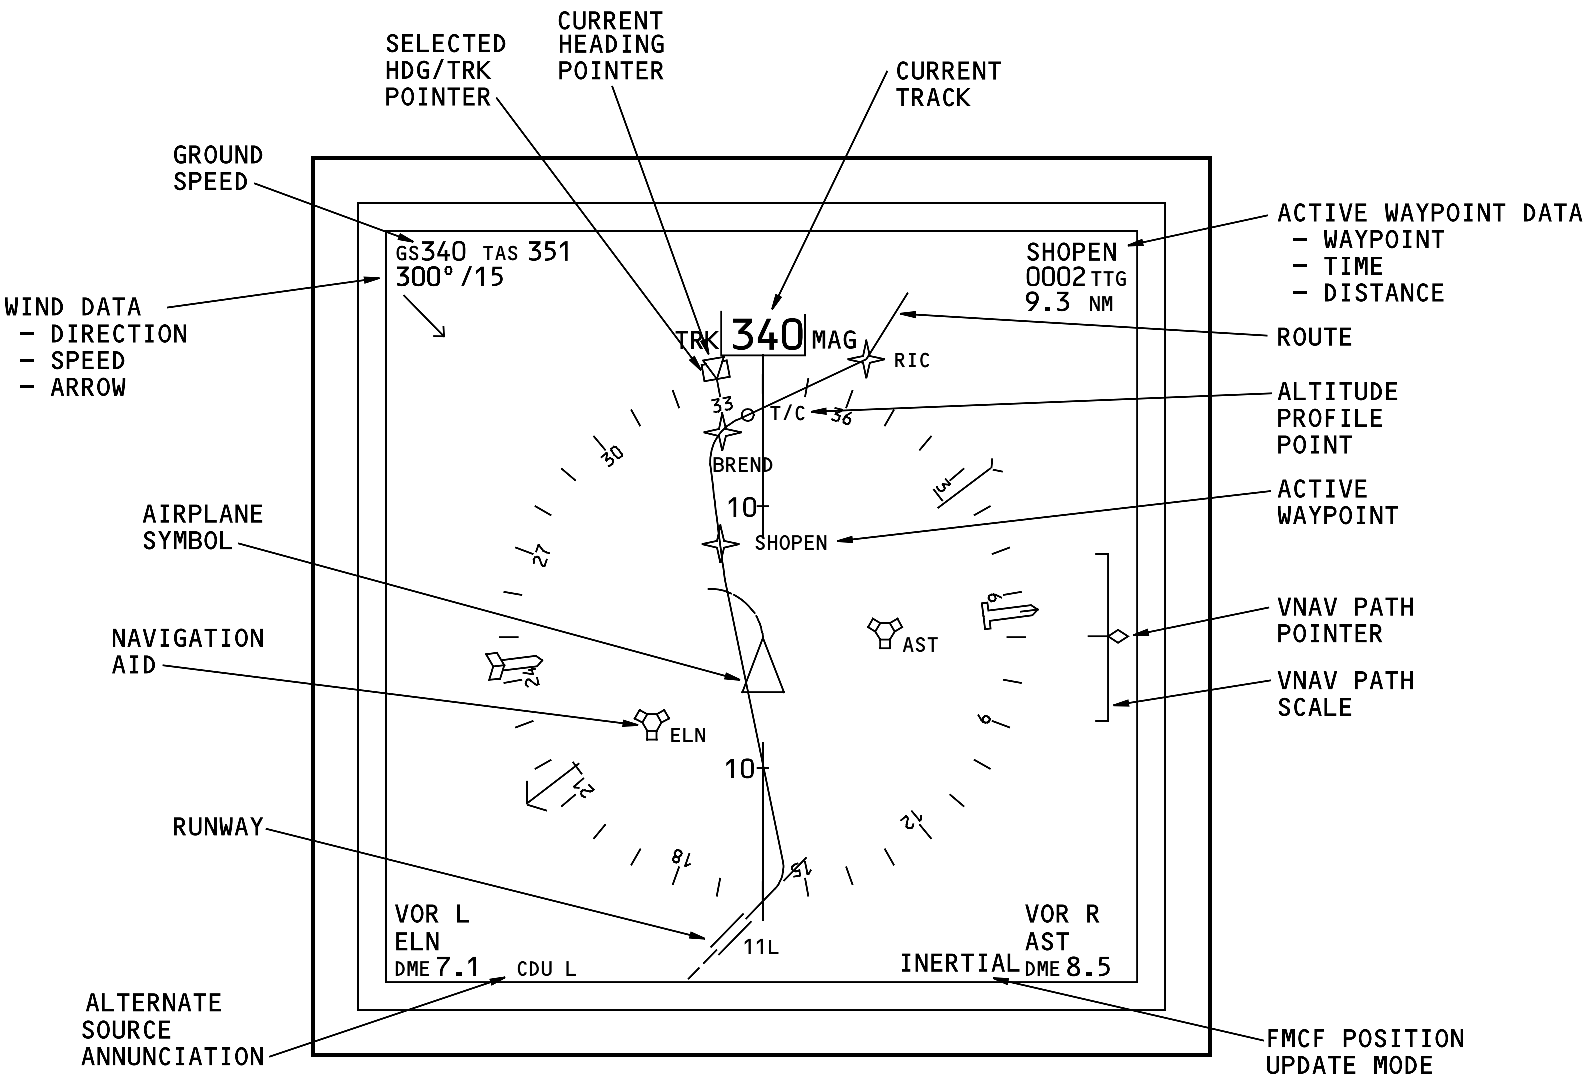
- Active waypoint
- Time to go (TTG)
- Distance to go (DTG)
- Route
- CDU position
- CDU (L, C or R) source for display.

The active FMCF sends this background data to the NDs in the map and plan modes:

- Runways
- Airports
- Waypoints, flight plan and off route waypoints
- Navaids (VOR, DME, etc.)
- Beacons, marker and non-directional
- Procedure turns
- Holding patterns
- Energy management circles.

If both FMCFs fail, the on-side CDU sends this background data to the NDs via the PDF in the back-up navigation mode:

- Waypoints (LAT/LON)
- Navaids (VOR, DME, etc.)
- Beacons, marker and non-directional.



FMCS - NAVIGATION DISPLAY (ND)

THIS PAGE INTENTIONALLY LEFT BLANK

FMCS - FMCF/CDU MESSAGES

General

The FMCS sends messages to the CDUs and the primary display system. The FMCS messages alert and advise the flight crew with:

- Information that relates to airplane system level of operation
- Airplane flight phase of operation
- Entry errors.

The CDUs show the FMCS message content in the scratchpad and the CDU MSG annunciator comes on. The FMCF sends an alert discrete that causes the advisory message (FMC MESAGE) to show on the EICAS display. The alert message content shows in the CDU scratchpad.

The CDUs show messages when they operate as the alternate navigation source.

Message, Priority, and Reset

The CDUs show these three message types in this priority:

- Entry error advisory
- Alert
- Advisory.

The CDUs store messages in stacks with a maximum of ten in each stack. The entry error advisory message has priority over the alert and advisory message that show in the CDU scratchpad. Alert messages have priority over advisory messages.

When a CDU scratchpad message occurs, it goes to the top of the related stack. A new message pushes down any other messages in the stack. A maximum of ten messages may enter a stack. If the stack is full and another message occurs, the message at the bottom of the stack exits the stack.

The CDU scratchpad message clears out of the scratchpad in one of these ways:

- A push of the CLR key - one push removes one message
- A new message occurrs at the same level or higher
- The condition that causes the message resets.

All CDU scratchpad messages are white.

Entry Error Advisory Messages

Entry error advisory messages relate to any crew entries on a CDU. Each CDU responds to entries from its keyboard. These are examples of entry error advisory messages:

- NOT IN DATA BASE
- INVALID ENTRY
- STANDBY ONE
- BUSY.

FMCS - FMCF/CDU MESSAGES

The CDU that is in use for entry shows the entry error advisory message in its scratchpad. The MSG annunciator comes on for all CDUs. The CDUs can supply the entry error advisory messages when the FMCFs fail.

Alert Messages

Alert messages tell the flight crew a flight phase or flight mode limitation. These are examples of alert messages:

- END OF ROUTE
- NO ACTIVE ROUTE
- UNABLE NEXT ALTITUDE
- INSUFFICIENT FUEL.

Alert messages set the CDU output discrete to show the advisory FMC MESSAGE on the EICAS display. The left and right CDU scratchpad shows the alert message.

The CDU annunciator MSG comes on for all CDUs.

Scratchpad display priority does not override the alert message indication on the EICAS display and MSG annunciator on the CDUs.

The approach flight phase and below 500 feet above ground level (AGL) inhibits the display of the alert messages when the arrival runway is part of the active route. The alert messages that occur in this flight phase show at flight completion or after the airplane climbs through 1000 feet AGL.

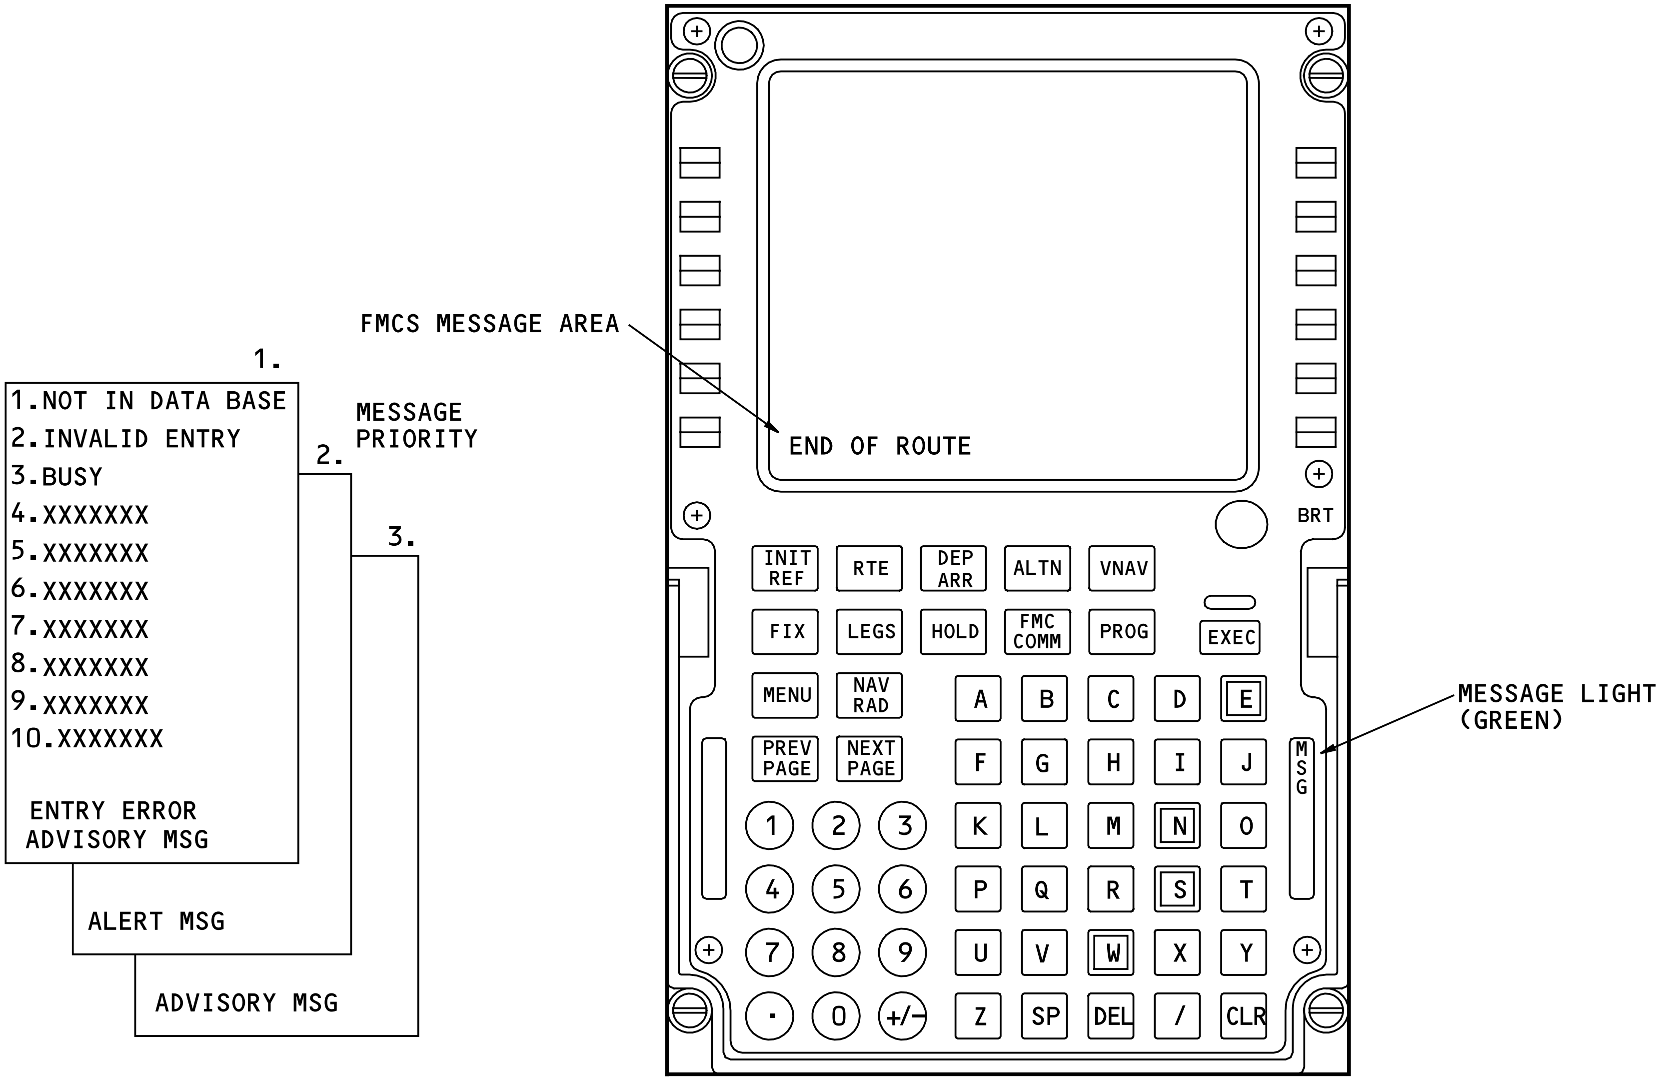
Advisory Messages

Advisory messages tell the crew flight activity they should perform to make their flight go smoothly. These are examples of advisory messages:

- NOT ON INTERCEPT HEADING
- RWY/ILS COURSE ERROR
- TIMEOUT - RESELECT.

The left and right CDU scratchpad shows the advisory message. The CDU annunciator MSG comes on for all CDUs.

The CDUs can supply the advisory messages when the FMCFs fail.



FMCS - FMCF/CDU MESSAGES

THIS PAGE INTENTIONALLY LEFT BLANK

FMCS - MENU PAGE

General

The MENU page gives a list of selections for systems that use the CDU. These are the systems that use the CDU:

- Flight management computing system (FMCS)
- Satellite communication (SATCOM) system
- Cabin services system (CSS)
- Primary display system (PDS).

The CDUs can operate as alternate control panels for the EFIS control panels and the display select panel (DSP).

The CDU has a selection that lets you get access to maintenance pages on an MFD.

Page Access

The MENU page shows at CDU power-up or push the MENU mode key to show the menu page.

Color

All text on the MENU page is white except for the OFF/ ON indications for the alternate EFIS CP and DSP functions. OFF is green when an EFIS CP or DSP has failed and should be selected. ON is green when the EFIS CP or DSP function on the CDU is in use.

Operation

The left line select keys select which system communicates with the CDU. Only one of these systems can control the CDU at a time. <ACT> shows on the MENU page for the system that is active. If a system requests control of the CDU, there is a <REQ> after the system name.

Push 1L <FMC for the FMCF to communicate with the CDU. The INIT/REF INDEX page shows.

Push 2L <SAT for the satellite data unit (SDU) to communicate with the CDU. The associated CDU page shows.

Push 4L <CAB INT for the passenger address/cabin interphone controller to communicate with the CDU. The associated CDU pages show. The <CAB INT prompt is only available on the center CDU.

Push 5R MAINT INFO DISPLAY> to show the PDS maintenance pages CDU on the MFD.

The left and right CDUs normally show the prompts for the alternate on-side EFIS CP function. If the left or right CDU fails, the EFIS CP function shows on the center CDU.

Do this to operate the alternate EFIS controls:

- Push 1R EFIS CTL OFF on> and EFIS> shows on line 2R
- Push 2R to go to the EFIS control selections page.

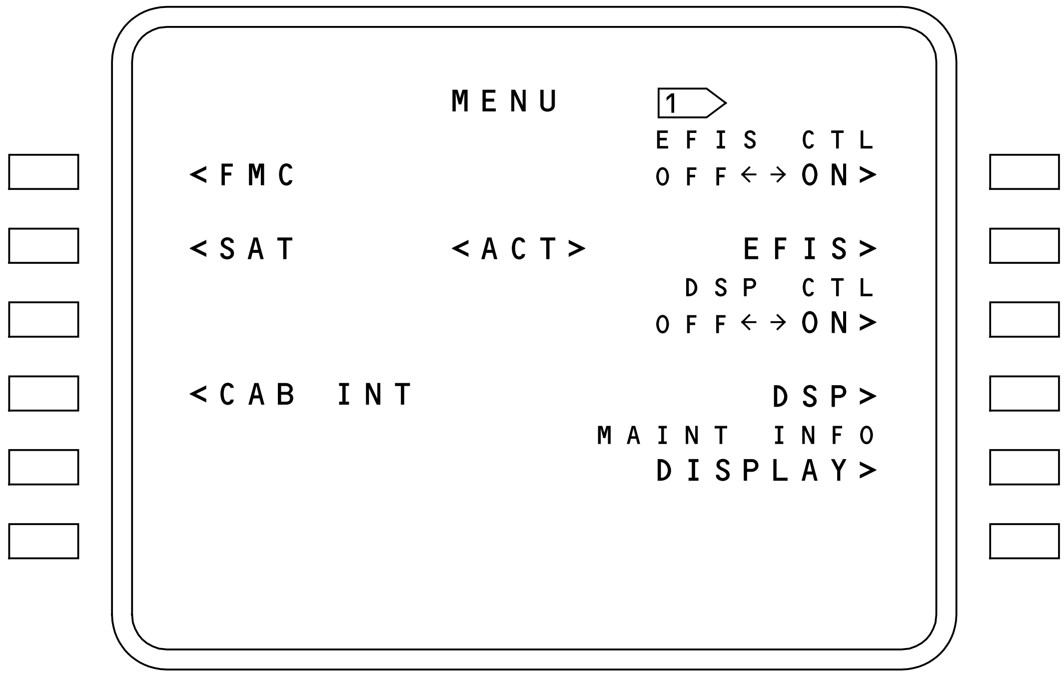
FMCS - MENU PAGE

All three CDUs show the alternate DSP prompt.

Do this to operate the alternate display select panel (DSP) controls:

- Push 3R DSP CTL OFF on> and DSP> shows on line 4R
- Push 4R, DSP> to go to the DSP control selections page.

You must cancel the alternate DSP function from the same CDU you used to enable the alternate DSP function.



C-CDU

1 THE EFIS CTL FUNCTION IS AVAILABLE ON THE C-CDU WHEN IT ACTS AS A LEFT OR RIGHT CDU.

FMCS - MENU PAGE

34-61-00-015 Rev 3 03/28/95

FMCS - INIT/REF INDEX PAGE

General

The initialization reference (INIT/REF) INDEX page is a menu of the pre-flight pages. You select these pages to initialize the FMCS and the ADIRU and enter other kinds of reference data.

The INIT/REF INDEX page also shows some inflight pages and the maintenance page prompt.

Page Access

To get access to the INIT REF INDEX page, do one of these steps:

- Push the INIT REF mode key to show a preflight page
- Push 6L <INDEX on a preflight page.

Color

All text on this page is white.

Page Selections

Use the active line select keys on the INIT/REF INDEX page to select additional pages.

Push 1L <IDENT to show the identification page.

Push 2L <POS to show the position initialization page.

Push 3L <PERF to show the performance initialization page.

Push 4L <THRUST LIM to show the thrust limits page.

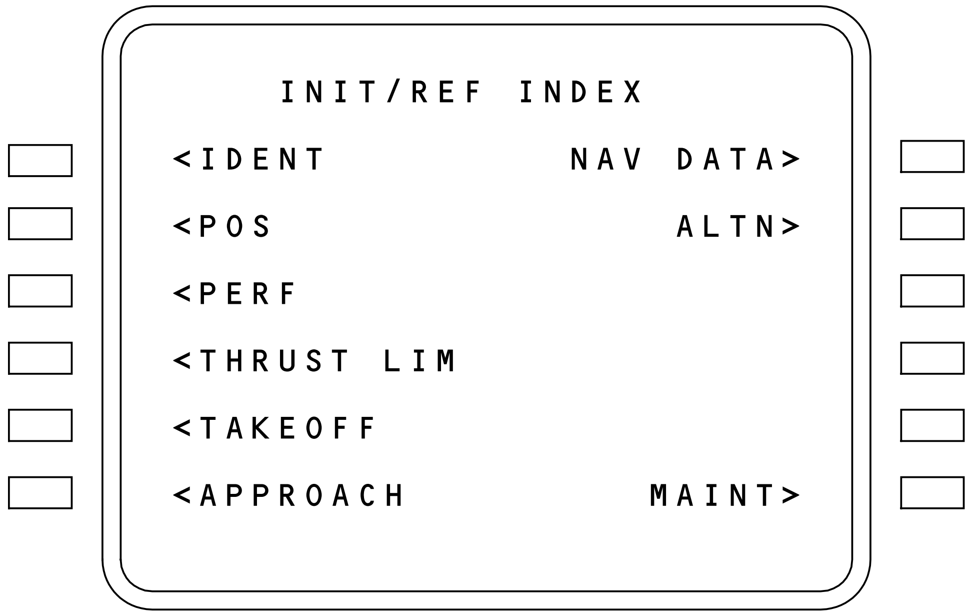
Push 5L <TAKEOFF to show the takeoff reference page.

Push 6L <APPROACH to show the approach reference page.

Push 1R NAV DATA> to show the navigation data reference page.

Push 2R ALTN> and the alternate page shows. The alternate page shows alternate route structures. Fuel and ETA also shows for the alternates route structures.

Push 5R MAINT> to show the maintenance index page. The MAINT> prompt only shows when the airplane is on the ground.



34-61-00-016 Rev 1

FMCS - INIT/REF INDEX PAGE

THIS PAGE INTENTIONALLY LEFT BLANK

FMCS - IDENT PAGE

Purpose

The identification (IDENT) page shows this information:

- Airplane model number
- Navigation database configuration
- Operational program
- Engine identification
- Drag factors
- Fuel flow factors.

Page Access

To get access to the IDENT page, select IDENT from the INIT/REF index page.

This page also shows when the self test is not satisfactory at power-up.

Color

All text on this page is white.

Information

Line 1L shows the model number. This number is the aircraft model from the airframe/engine program pins. Blanks show if the program pins do not match the performance database.

Line 2L shows the navigation data base number. Blanks show if there is a bad database load.

Line 4L shows the operational program part number.

Line 1R shows the engine identification. This line shows the engine identification number from the EECs and the airframe/engine program pin. Blanks show if the program pins do not match the performance database.

Line 2R shows the active navigational database.

Line 3R shows the navigational database that is not active.

Line 5R shows the drag factor followed by a fuel flow factor.

Operations

To change the navigation database:

- Push 3R, the inactive navigational database to copy the dates into the scratchpad
- Push 2R to transfer the navigational database that is not active to the active position.

Page Selections

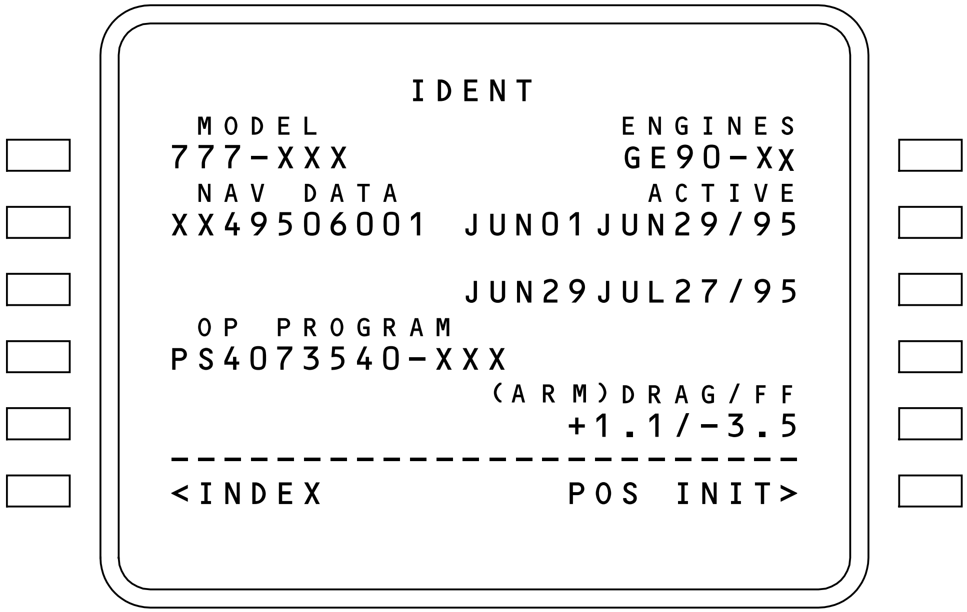
Push 6L <INDEX to show the INIT REF INDEX page.

Push 6R POS INIT> to show the POS INIT page.

FMCS - IDENT PAGE

Training Information Point

Refer to the Flight Operations Manual for more information related to the IDENT page.



34-61-00-017 Rev 2

FMCS - IDENT PAGE

FMCS - POS INIT 1/3 PAGE

THIS PAGE INTENTIONALLY LEFT BLANK

FMCS - POS INIT 1/3 PAGE

Purpose

The position initialization (POS INIT) 1/3 page lets the user enter a reference position for the air data inertial reference unit (ADIRU) alignment. The page also shows the FMCS time reference.

Page Access

To get access to the POS INIT 1/3 page, do one of these steps:

- Push POS INIT from the INIT/REF 1/3 page
- Push POS INIT from the IDENT page
- Push POS INIT from the TAKEOFF REF page
- On the ground with the ADIRU position not initialized, push the INIT/REF mode key.

Color

All text on this page is white.

Information

Line 4L shows the UTC time.

Line 1R shows the FMCF last calculated position. If the FMCF position is not valid, the last valid FMCF position shows.

Line 2R shows the reference airport position. This position shows when an airport identification is in line 2L.

Line 3R shows the reference gate position. This position shows with a gate entry in line 3L.

Line 4R shows the global positioning system (GPS) position.

Entries

This page permits entries of airports and gate identifiers in order to get the latitude and longitude from the navigation database. These latitudes and longitudes are available to initialize the ADIRU.

Do this to get the latitude and longitude of an airport:

- Type a valid airport identifier into the scratchpad
- Enter into 2L
- The latitude and longitude of the airport shows in 2R.

Do this to get the latitude and longitude of a gate at an airport:

- Type a valid gate identifier into the scratchpad
- Enter into 3L
- The latitude and longitude of the gate shows in 3R.

To initialize the ADIRU, there are two steps. First, enter a latitude and longitude into the scratchpad with one of these steps:

FMCS - POS INIT 1/3 PAGE

- Manually type the data with the keypad
- Push 1R, the last position
- Push 2R, the reference airport position
- Push 3R, the reference airport gate position
- Push 4R, the GPS position.

Then line select this data into 5R.

This page also permits the entry of a manual heading.

When the ADIRU has failed and the SAARU navigation parameters are valid, SET HDG shows above line 5L.

Page Selections

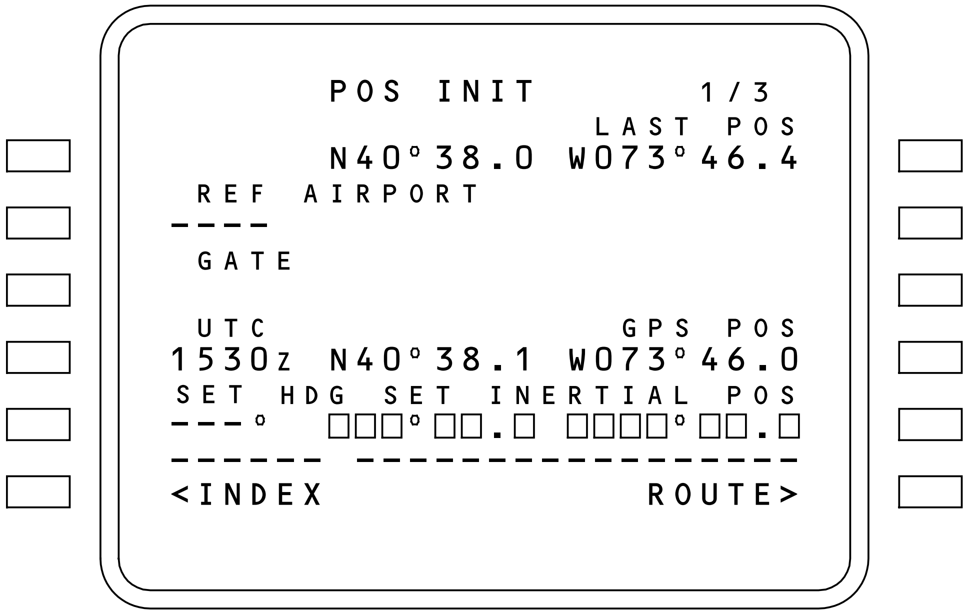
Push 6L <INDEX to show the INIT/REF INDEX.

Push 6R <ROUTE to show the appropriate RTE page.

Push the NEXT PAGE or PREV PAGE mode keys to go to the other POS INIT pages.

Training Information Point

Refer to the Flight Operations Manual for more information related to the this page.



34-61-00-018 Rev 3

FMCS - POS INIT 1/3 PAGE

FMCS - POS REF 2/3 and 3/3 PAGES

Purpose - POS REF Page 2/3 and 3/3

There are two additional POS REF pages. The POS REF page 2/3 shows this position information:

- FMCF position calculation
- Inertial position
- Global positioning system (GPS) position
- Radio position.

You can use these pages to update the FMCF position calculation so it to matches either the inertial, GPS, or radio position.

The POS REF page 3/3 shows the left and right GPS positions and the left and right FMCF positions.

This page lets the operator remove the GPS position update from the FMCFs at 5R.

The POS REF pages also permits the flight crew to show the relative bearing and distance from the FMCF position at 6R.

Page 2/3 access

To get access to the POS REF 2/3 page, do one of these steps:

- Push the NEXT PAGE function key while on the POS INIT page
- Push POS REF on the PROGRESS page.

Color - POS REF Page 2/3

All text on this page is white.

Information - POS REF 2/3 Page

Line 1L shows the FMCF position. The header shows if the inertial, GPS or radio is the primary source for update of the current FMCF position. The header shows one of these:

- GPS
- RADIO
- INERTIAL
- LOC-GPS
- LOC-RADIO
- LOC.

Line 2L shows the inertial position from the ADIRU.

Line 3L shows the GPS position.

Line 4L shows the radio position.

Line 5L shows the FMCF required navigation precision (RNP) and the FMCF actual position accuracy in nautical miles (NM). The RNP or actual position accuracy shows to the nearest 1/10NM if the accuracy is more than or equal to 10NM. The RNP or actual position accuracy shows to the nearest 1/100NM if the inaccuracy is less than 10NM. The active FMCF automatically sets the RNP for each flight phase. You can also manually update the RNP.

FMCS - POS REF 2/3 and 3/3 PAGES

Line 5R shows the three or four letter identifiers of the navigation stations that the FMCF uses in the radio navigation solution. The header shows the active radio update mode as one of these:

- DME/DME
- LOC/LOC
- VOR/DME.

Operations - POS REF Page 2/3

To update the computed FMCF position so it matches the inertial, GPS or radio position, first push 1R, ARM>. This arms the FMCF position update function and the line changes to ARMED. Then do one of these:

- Push either 2R, NOW> to update the FMCF position to match the inertial position
- Push 3R, NOW> to update the FMCF position to match the GPS position
- Push 4R, NOW> to update the FMCF position to match the radio position.

Page Selections

Push 6L <INDEX to show the INIT/REF INDEX page.

Page 3/3 Access

To get access to the POS REF 3/3 page, do one of these steps:

- Push 6R BRG/DIST> while on the POS REF page 2/3
- Push NEXT PAGE function key while on the POS REF page 2/3
- Push PREV PAGE function key while on the POS INIT page.

Color - POS REF 3/3 Page

All text on this page is white except the GPS NAV ON/OFF indication. The active condition is green and the not active condition is white.

Information - POS REF 3/3 Page

Line 1l shows the left GPS sensor unit position.

Line 2l shows the right GPS sensor unit position.

Line 3L shows the position from the left FMCF.

Line 4L shows the position from the right FMCF.

Operations - POS REF 3/3 Page

To toggle the GPS position update of the FMCF ON/OFF, do one of these:

- Push 5R when ON shows and the GPS data is inhibited from the FMCF navigation solution
- Push 5R when OFF shows and the GPS data is included in the FMCF navigation solution.

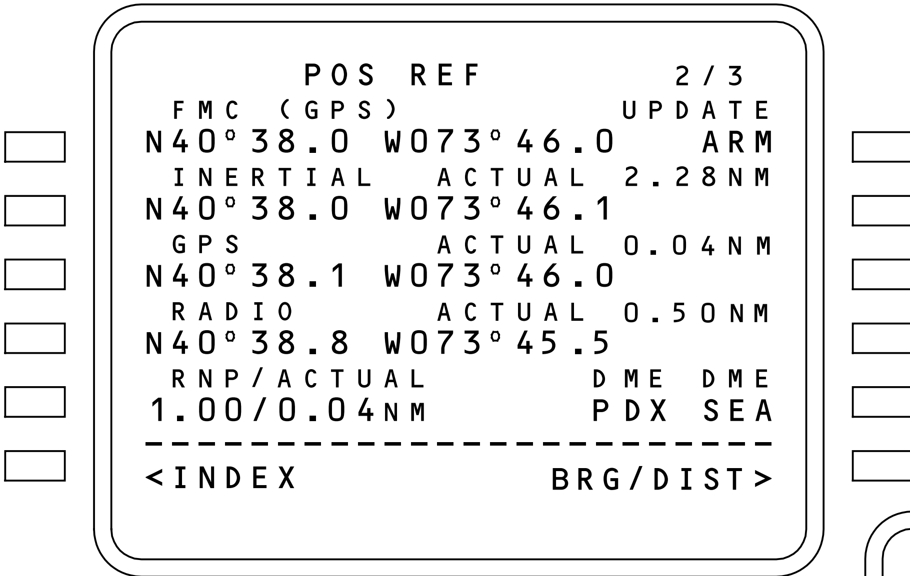
FMCS - POS REF 2/3 and 3/3 PAGES

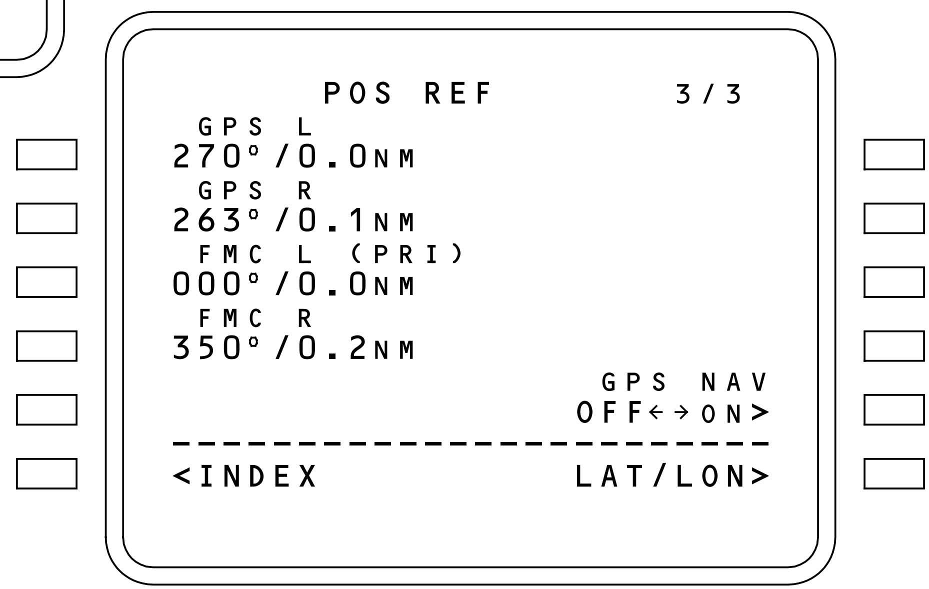
To toggle the display of the GPS and FMCF positions between latitude and longitude format and bearing distance format, do one of these:

- Push 6R, LAT/LON>, to show positions latitude and longitude
- Push 6R, BRG/DIST>, to show positions bearing and distance.

Training Information Point

Refer to the Flight Operations Manual for more information related to this page.





34-61-00-019 Rev 3 07/09/1997

FMCS - POS REF 2/3 and 3/3 PAGES

FMCS - MAINTENANCE INDEX PAGE

Purpose

Use the MAINTENANCE INDEX page to access several pages of data. These pages let maintenance personnel examine and change FMCF policy data and monitor ADIRU inertial position data.

Page Access

To get access to the MAINTENANCE INDEX page the airplane must be on the ground. Select MAINT> from the INIT/REF INDEX page.

Color

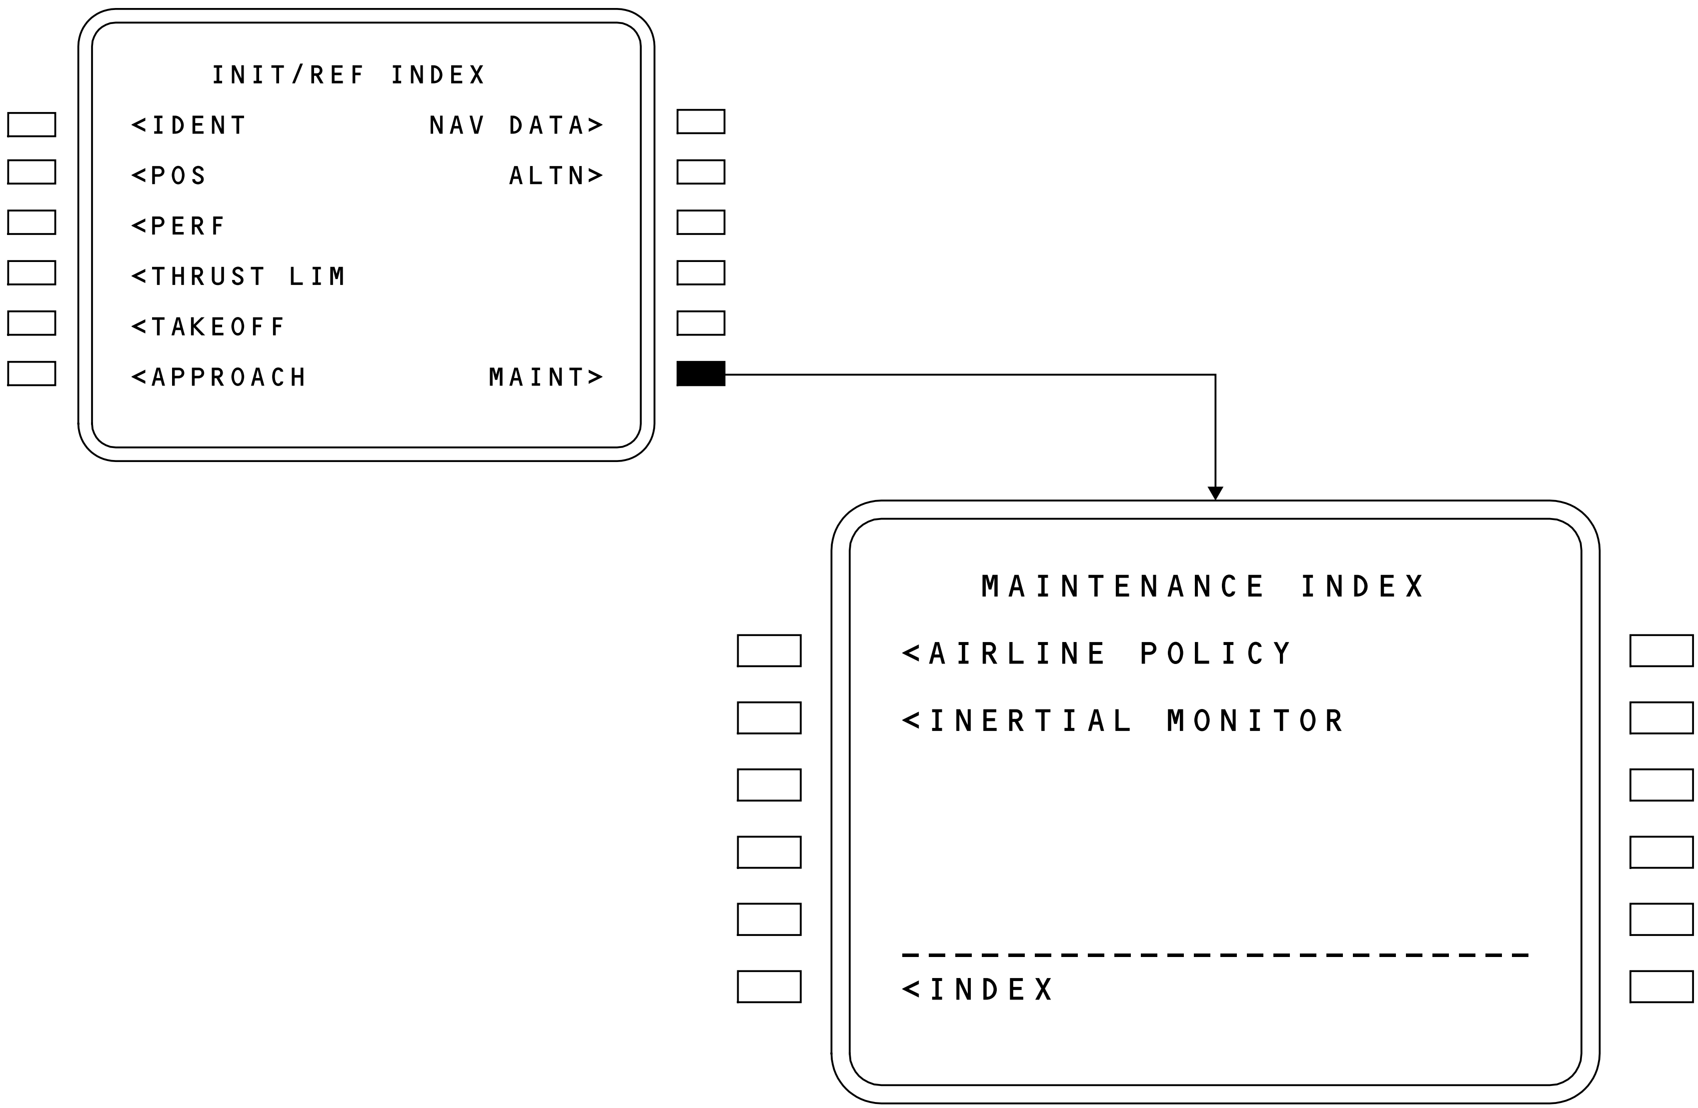
All text on this page is white.

Page Selections

Select 1L, <AIRLINE POLICY, to show the AIRLINE POLICY pages.

Select 2L, <INERTIAL MONITOR, to show the INERTIAL MONITOR page.

Select 6L, <INDEX, to show the INIT/REF INDEX page.



FMCS - MAINTENANCE INDEX PAGE

FMCS - AIRLINE POLICY 1/2 PAGE

THIS PAGE INTENTIONALLY LEFT BLANK

FMCS - AIRLINE POLICY 1/2 PAGE

Purpose

Use the AIRLINE POLICY 1/2 page to see some values from the airline modifiable information (AMI) file and the operational program configuration (OPC) file.

Page Access

To get access to the AIRLINE POLICY 1/2 page, select <AIRLINE POLICY from the MAINTENANCE INDEX page.

Color

All text on this page is white.

Information

Line 3L is the maneuver margin. This number is from the AMI. If the AMI is invalid or not loaded, the FMCF default value shows.

Line 4L is the minimum cruise time. This number is from the AMI. If the AMI is invalid or not loaded, the FMCF default value shows.

Line 5L is the fuel freeze temperature. This number is from the AMI. If the AMI is invalid or not loaded, the FMCF default value shows.

Line 1R is the option code. This option code is from the OPC.

Line 2R is the minimum rate of climb margin in climb. This number is from the AMI. If the AMI is invalid or not loaded, the FMCF default value shows.

Line 3R is the default thrust rating in cruise and minimum rate of climb margin in cruise. This number is from the AMI. If the AMI is invalid or not loaded, the FMCF default value shows.

Line 4R is the default thrust reduction height or the thrust reduction flap setting. Thrust reduction values show in feet for the altitude or show as FLAPS1 and FLAPS5. This number is from the AMI. If the AMI is invalid or not loaded, the FMCF default value shows.

Line 5R is the default all engine acceleration height and the default engine out acceleration height. This number is from the AMI. If the AMI is invalid or not loaded, the FMCF default value shows.

Line 6R is the AMI software part number. If no AMI is loaded, the field is blank.

Entries

To enter a takeoff derate percentage:

- Type a number between 0 and 30% and, if you enter two percentages separate them by a /, into the scratchpad
- Enter this into 2L.

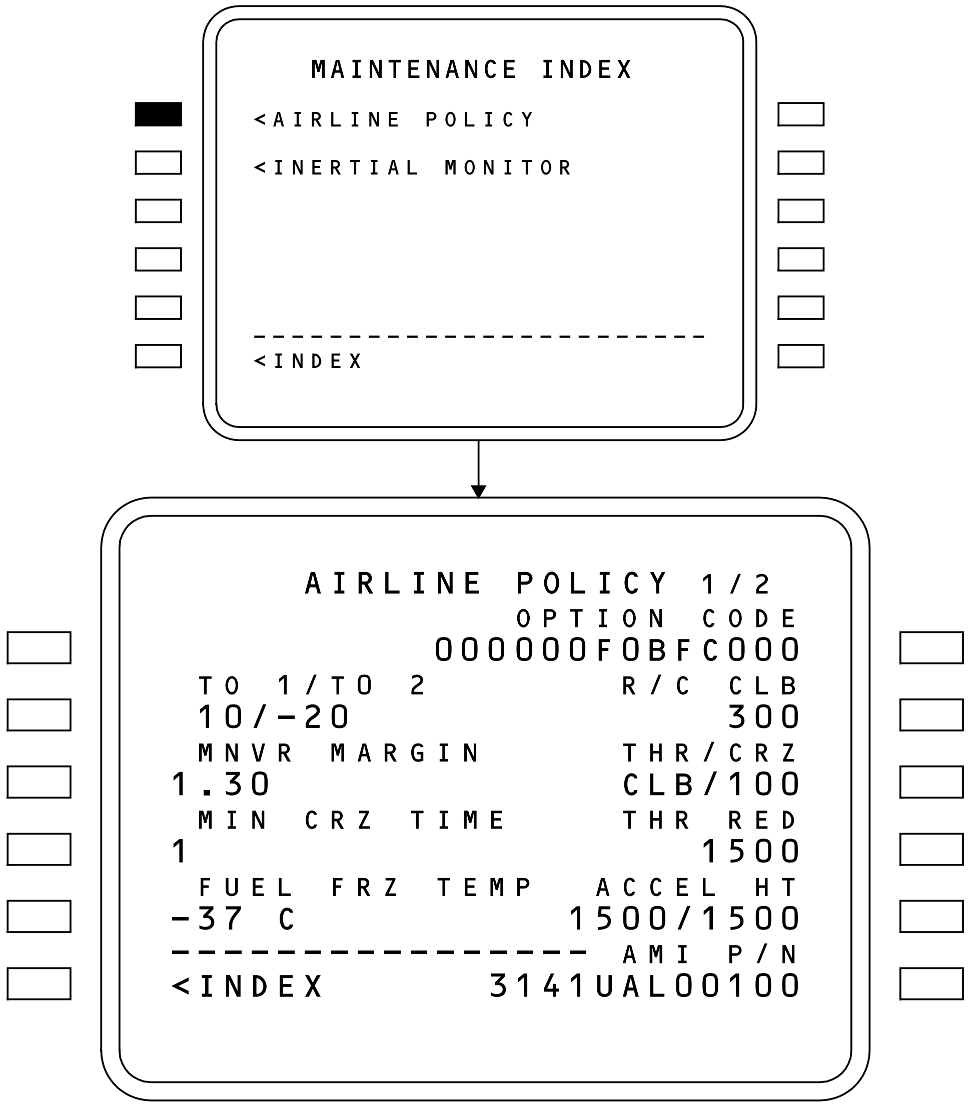
FMCS - AIRLINE POLICY 1/2 PAGE

You can also delete this value. When you delete an entered value, the takeoff derate percentage that shows returns to the FMCF default value.

Page Selections

Select 6L, <INDEX, to show the MAINTENANCE INDEX page.

Select the NEXT PAGE / PREV PAGE mode key to see AIRLINE POLICY page 2/2.



34-61-00-031 Rev 1

FMCS - AIRLINE POLICY 1/2 PAGE

FMCS - AIRLINE POLICY 2/2 PAGE

THIS PAGE INTENTIONALLY LEFT BLANK

FMCS - AIRLINE POLICY 2/2 PAGE

Purpose

Use the AIRLINE POLICY 2/2 page to see values from the airline modifiable information (AMI) file.

Page Access

To get access to the AIRLINE POLICY 2/2 page, do these steps:

- Select <AIRLINE POLICY from the MAINTENANCE INDEX page
- Push the NEXT PAGE function key.

Color

All text on this page is white.

Information

Line 1L is the default speed transition computed airspeed and the default speed transition altitude. The data is from the AMI. If the AMI is invalid or not loaded, the FMCF default value shows. The default value is the customer's baseline or delivered configuration without the AMI.

Line 2L is the alternate minimum runway length. The data is from the AMI. If the AMI is invalid or not loaded, the FMCF default value shows.

Line 3L is the alternate default speed mode. The data is from the AMI. If the AMI is invalid or not loaded, the FMCF default value shows.

Line 4L is the company speed thrust rating. The data is from the AMI. If the AMI is invalid or not loaded, the FMCF default value shows.

Line 5L is the company speed. The data is from the AMI. If the AMI is invalid or not loaded, the FMCF default value shows.

Line 1R is the default speed restriction computed airspeed and default speed restriction altitude. The data is from the AMI. If there is no AMI loaded, this field is blank.

Line 2R is the alternate altitude. The data is from the AMI. If there is no AMI loaded, this field is blank.

Line 3R is the data link option code. The data is from the AMI. If the AMI is invalid or not loaded, the FMCF default value shows.

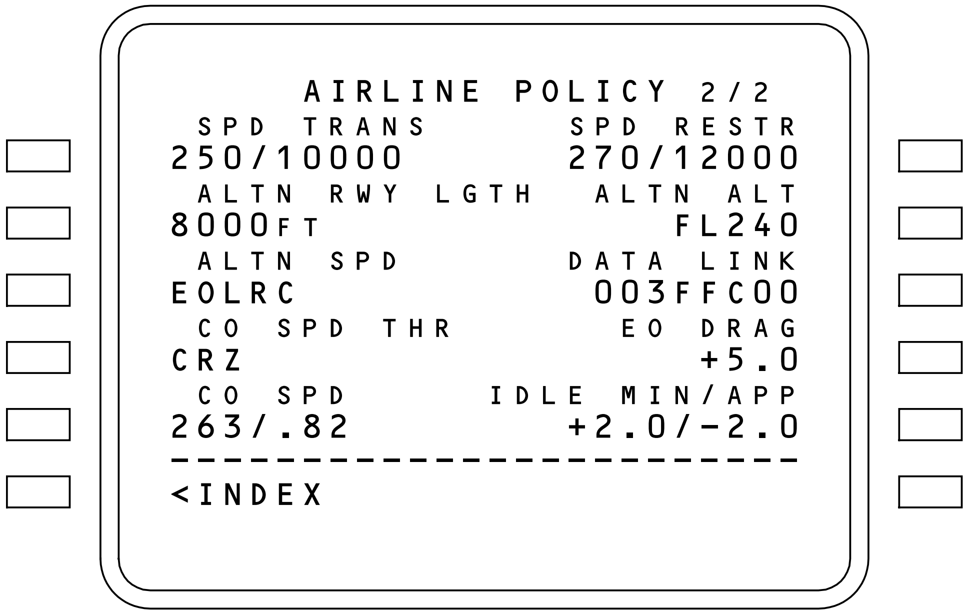
Line 4R is the engine out drag factor. The data is from the Boeing navigation database. If a non-Boeing database is loaded, it is blank.

Line 5R is the minimum idle thrust descent factor and approach idle thrust descent factor. The data is from the Boeing navigation database. If a non-Boeing database is loaded, it is blank.

FMCS - AIRLINE POLICY 2/2 PAGE

Page Selections

Select 6L, <INDEX to show the MAINTENANCE INDEX page.



34-61-00-032 Rev 1

FMCS - AIRLINE POLICY 2/2 PAGE

FMCS - INERTIAL MONITOR PAGE

Purpose

The inertial monitor page shows the position error rate for the ADIRU.

Page Access

To get access to the INERTIAL MONITOR page, select <INERTIAL MONITOR from the MAINTENANCE INDEX page.

Color

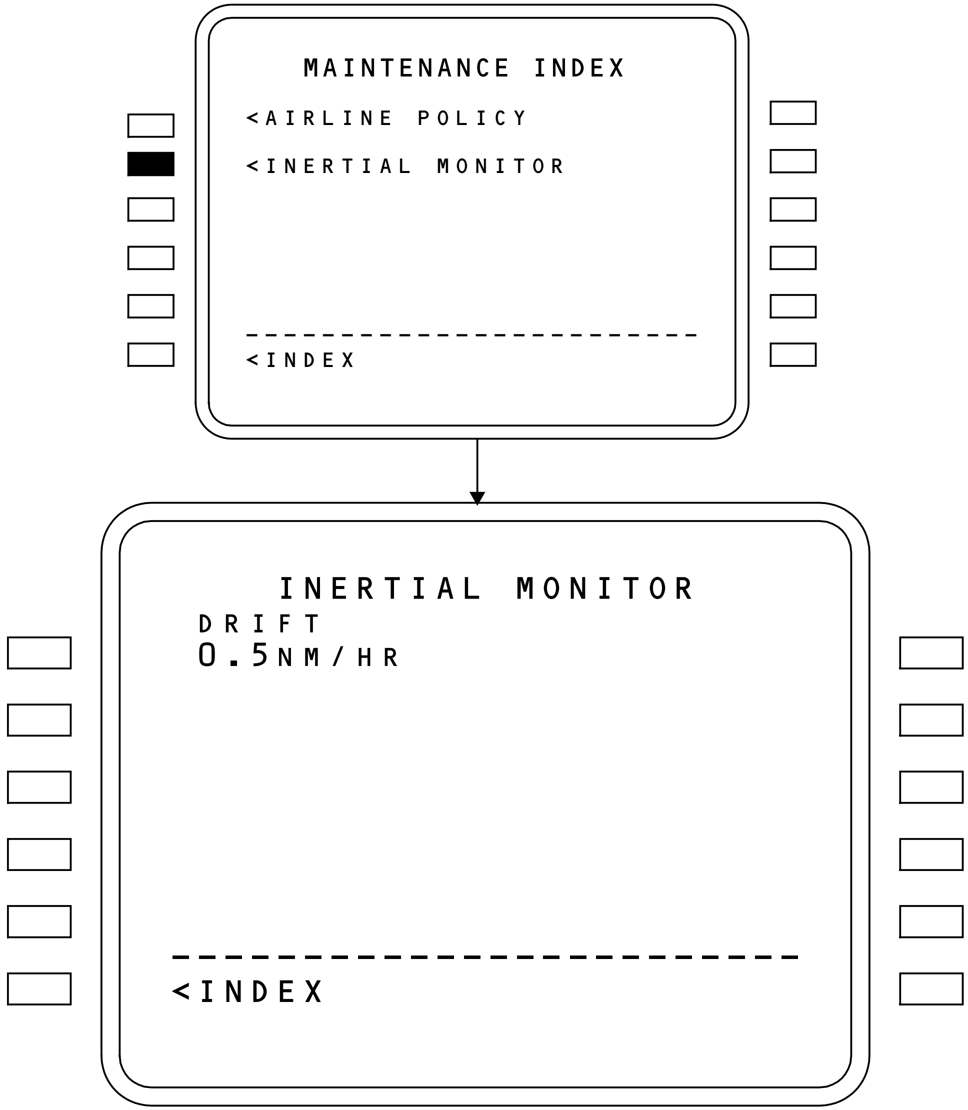
All text on this page is white.

Information

Line 1L is the inertial monitor drift. The drift rate shows for the last completed flight. It cleares at the ground-to-air transition.

Page Selections

Select 6L, <INDEX to show the MAINTENANCE INDEX.



FMCS - INERTIAL MONITOR PAGE

THIS PAGE INTENTIONALLY LEFT BLANK

FMCS - ALTN NAV RADIO PAGE

Purpose

The alternate (back-up) navigation (ALTN NAV) RADIO page gives an alternate means to tune the navigation radios. The left CDU does the alternate tune for the left navigation radios and the center ILS radio. The right CDU does the alternate tune for the right navigation radios.

Page Access

To get access to the ALTN NAV RADIO page, push the NAV RAD mode key when both FMCFs fail.

Color

All text on this page is white except for these indications:

- VOR frequency and course (CRS) entries are green and in large font
- ADF frequency entry is cyan in large font.

Information

Line 1L shows the last FMCF VOR frequency or manual frequency entry for the onside radio. The M shows for both cases.

Line 2L shows the manual CRS entry or dashes with no previous CRS entry. The CRS entry or dashes show when there is a valid frequency in 1L.

Line 3L shows the ADF frequency and tune mode. The tune mode shows next to the ADF frequency, ANT (A) or BFO (B). No show of A or B means that ADF is the active tune mode.

Line 4L shows the ILS title field with L & C for the left CDU and R for the right CDU along with the frequency and course.

Entries and Deletes

Do this to enter a VOR frequency at 1L:

- Type a valid VOR frequency between 108.0 to 117.95 into the scratchpad
- Enter into 1L.

The VOR frequency range does not include the frequencies between 108.0 to 111.95 MHz and frequencies that contain odd tenths. All frequencies from 112 to 117.95 MHz are included.

Line 1L shows dashes with a delete entry.

Line 2L shows dashes with a delete entry.

To enter a VOR course at 2L or 2R when dashes show, do this:

- Type a number between 000 to 360 into the scratchpad
- Enter into 2L.

FMCS - ALTN NAV RADIO PAGE

Dashes show in the VOR course data field and M shows next to the VOR frequency. An entry of 360 shows as 000.

A delete at line 2L with a course present blanks the course data field and dashes show.

Do this to enter an ADF frequency at 3L:

- Type a frequency between 190.0 and 1750 kHz into the scratchpad
- Enter into 3L.

Do this to enter an A (ANT) or B (BFO) ADF tune mode at 3L:

- Type the letter A or B into the scratchpad
- Enter into 3L.

Do this to delete the A or B from an ADF entry at line 3L:

- Push the DEL key. DELETE shows in the scratchpad
- Enter into line 3L.

You can not use the DELETE key to delete an ADF frequency.

Do this to enter an ILS frequency or course at 4L:

- Type an ILS frequency between 108.10 to 111.95 (odd tenths)
- Type a course between 000 to 360 with a leading slash
- Enter into 4L.

A course entry of 360 shows as 000 in the ILS course field at 4L.

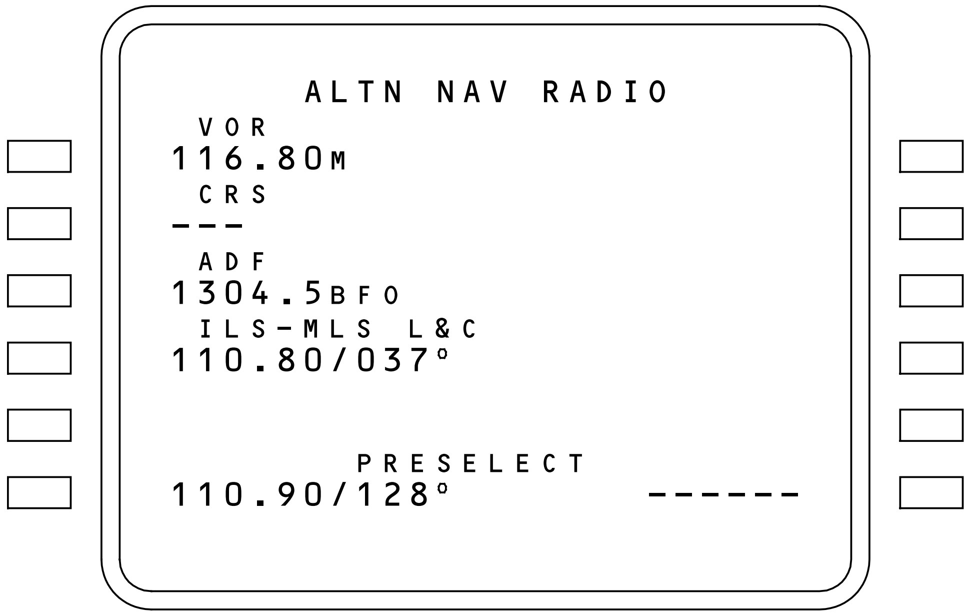
Do this to delete an ILS entry at 4L:

- Push the DEL key
- Enter into 4L.

Line 4L shows dashes with a delete entry.

Line 6L or 6R entries are valid 1L, 2L, 3L, and 4L frequency or course formats.

Line 6L or 6R shows dashes with a delete entry.



34-61-00-049 Rev 2

FMCS - ALTN NAV RADIO PAGE

FMCS - COMM PAGE

Purpose

The FMC communication (COMM) page does these functions:

- Supplies access to FMC CDU pages that have data link information
- Shows which FMC CDU pages have pending uplink information
- Shows the data link status.

Page Access

To see the FMC COMM page, select the FMC COMM mode key.

Color

All text on this page is white.

Information

Line 6R shows the data link status, the possible indications are:

- READY
- NO COMM
- VOICE
- FAIL.

Selections

Push line 1L to access RTE 1 page. If RTE 2 shows on line 1L then you will access the RTE 2 page. The word UPLINK shows in small font above line 1L when there is an uplink pending.

Push line 2L to access the ALTN page. The word UPLINK shows in small font above line 2L when there is an uplink pending.

Push line 3L to access the PERF INIT page. The word UPLINK shows in small font above line 3L when there is an uplink pending.

Push line 4L to access the TAKEOFF REF page 1/2. The word UPLINK shows in small font above line 4L when there is an uplink pending.

Push line 5L to access the ACT RTE X DATA or MOD RTE X DATA. The word UPLINK shows in small font above line 5L when there is an uplink pending.

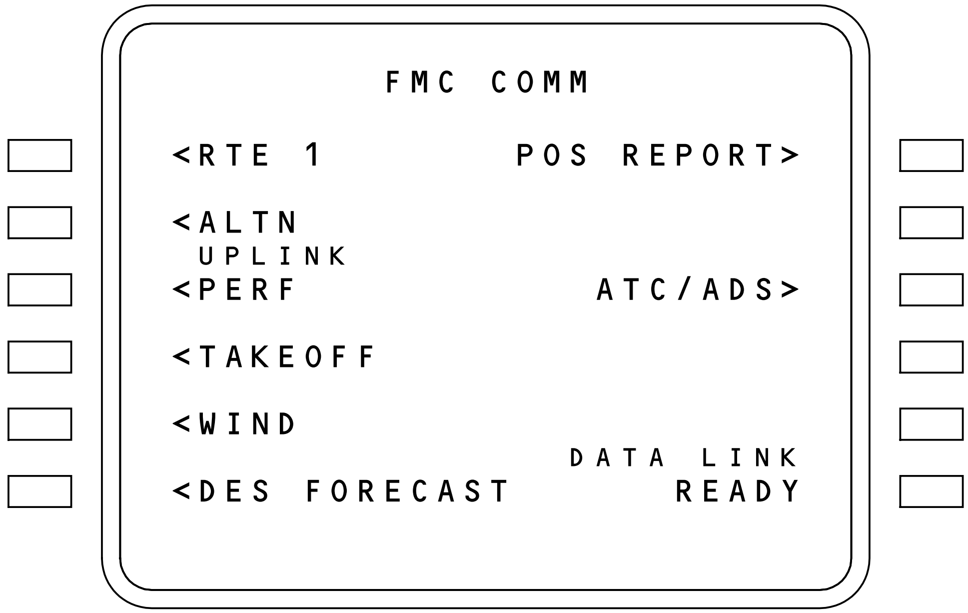
Push line 6L to access the DESCENT FORECAST page. The word UPLINK shows in small font above line 6L when there is an uplink pending.

Push line 1R to access the POS REPORT page.

Push line 3R to access the automatic surveillance/air traffic control (ADS/ATC) status page.

Training Information Point

Refer to the flight operations manual for more information related to this page.



34-61-00-063 Rev 0 03/26/96

FMCS - COMM PAGE

FMCS - FMCF FUNCTIONAL DESCRIPTION - INTRODUCTION

General

There are two FMCFs, one in the CPM/ACMF in the left AIMS cabinet and one in the CPM/Basic in the right AIMS cabinet.

The FMCFs use digital and analog inputs from external sensors and components, flight deck controls, internal AIMS cabinet interfaces, and cross cabinet AIMS interfaces.

Each FMCF has two software partitions. These are:

- Navigation (NAV) partition
- Flight management function (FMF) partition.

The flight management computing function (FMCF) does these sub-functions:

- Lateral navigation (LNAV) - NAV partition
- Nav radio tune - NAV partition
- Vertical nav (VNAV) - FMF partition
- Guidance - FMF partition
- BITE/fault monitoring - FMF partition
- Display control - FMF partition.

The active FMCF sub-function sends this data to these user systems:

- Guidance sub-function sends LNAV and VNAV commands and mode data to the AFDS
- Guidance sub-function sends VNAV thrust commands mode and data to the TMCF
- Radio tune sub-function sends radio tune commands and mode data to the navigation radios
- BITE sub-function sends fault and display data to the PDF and CMCF of AIMS
- Display control sub-function sends page and display data to the CDUs, PDF, and CMCF of AIMS.

NAV - Lateral Navigation Position Calculation

The LNAV sub-function uses these inputs to calculate the current airplane position:

- Air data inertial reference unit (ADIRU) inertial data
- Global position system (GPS) inertial data
- Navigation data base (NDB)
- Nav radio data.

The LNAV sub-function sends these outputs to the VNAV and guidance sub-function for the autopilot flight director system (AFDS):

- Position and velocity data
- Flight path data
- Heading and track data.

NAV - Nav Radio Tune

The nav radio tune sub-function allows autotune and manual tuning of the navigation radios. The FMCF uses the autotuned radios for position update. The flight crew uses the data to verify their position.

The FMCF does not auto tune the ADF radios.

The nav radio tune sub-function receives these inputs to do its calculations:

- Nav radio data
- LNAV data
- NDB
- CDU requests.

The nav radio tune sub-function sends these outputs to the nav radios:

- Tune mode
- Tune frequency
- Identifier
- Course
- ILS course.

FMF - Vertical Navigation

The VNAV sub-function uses these inputs to calculate VNAV (pitch) commands and other display data:

- Airframe and engine performance data from the performance data base (PDB)
- Inertial data from the ADIRU
- LNAV data from the NAV partition
- Engine data from the engine controllers
- Fuel data from the fuel quantity system
- Crew entries from the CDU performance initialization and the takeoff reference page.

The VNAV sub-function sends these outputs to the guidance sub-function for the AFDS and the thrust management computing function (TMCF):

- Altitude
- Vertical track (VTK)
- Cross track (XTK)
- Fuel used
- Thrust limits
- Gross weight
- Takeoff speeds
- Approach speeds.

FMF - Guidance

The guidance sub-function calculates steering and thrust commands. To do this, it looks at inputs from external sensors, components, and internal FMCF interfaces. The guidance sub-function compares the actual position from the LNAV sub-function with the flight plan from the display control sub-function. It compares the VNAV sub-function targets (pitch and thrust) with actual airplane pitch and actual thrust. The guidance sub-function sends roll and pitch steering commands to the AFDS.

The guidance sub-function also supplies these outputs to the AFDS:

- LNAV operate mode
- VNAV operate mode.

It sends this data to the TMCF:

- Thrust commands
- Speed commands
- Thrust limit mode
- Autothrottle mode.

The guidance sub-function also supplies these outputs to the display control sub-function:

- Roll flight path data
- Pitch flight path data.

FMF - BITE/Fault Monitoring

The BITE/fault monitoring sub-function contains hardware monitors, software monitors and fault detection circuits. The BITE/fault monitoring sub-function stores BITE and fault detection information and status for the last ten flight legs in non-volatile memory (NVM). It also records the status of the input source in BITE history. The BITE/fault monitoring sub-function supplies FMCF faults to the display control sub-function.

The BITE/fault monitoring sub-function responds to CMCF test requests when the airplane is on the ground.

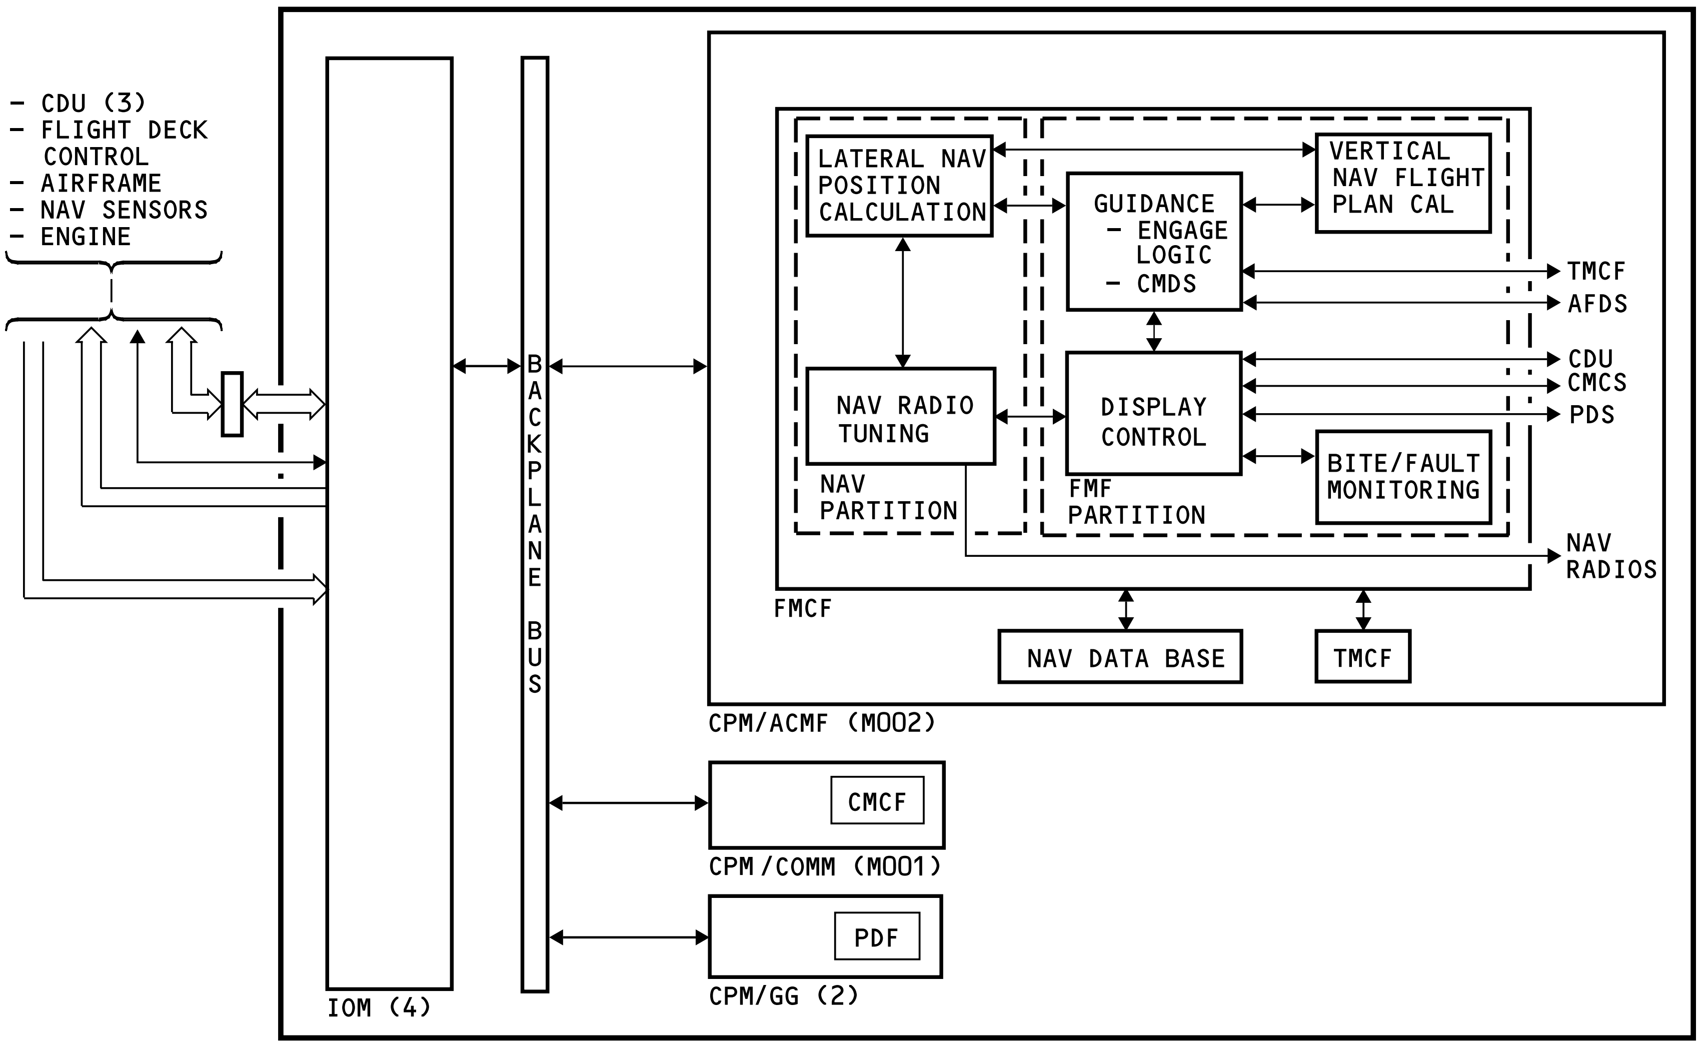
FMF - Display Control

The display control sub-function formats, updates and sends data to the CDU. It sends button push and other flight deck data to the sub-functions. The display control sub-function uses data from the LNAV, VNAV, guidance, and BITE/fault monitoring sub-functions to update and reformat the CDU pages.

The display control sub-function also sends background and dynamic data to the PDF.

The display control sub-function sends alert and advisory messages to the CDU. It also sends the alert message to the PDF for a flight deck annunciation.

The display control sub-function sends fault and display data to the CMCF for display. This occurs during normal FMCF operation and for CMCF test requests.



34-61-00-050 Rev 3 09/22/1997

FMCS - FMCF FUNCTIONAL DESCRIPTION - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

FMCS - FMCF FUNCTIONAL DESCRIPTION - LNAV SUB-FUNCTION

General

The FMCF LNAV sub-function uses data from external systems and internal data from AIMS to calculate navigation data for the performance, guidance, and display control sub-function of the FMCF.

The LNAV sub-function supplies this data:

- Navigation update mode
- Position uncertainty
- Velocity vectors
- Wind data.

The active FMCF display control sub-function sends display data to the CDUs and the primary display function (PDF).

Navigation Update Mode

The FMCF has ten navigation update modes. The navigation update mode determines which sensors the FMCF uses to calculate the airplane position and velocity. These are the ten navigation update modes (not in order of priority):

- No nav - There are no valid FMCF sensors (GPS, radios, or ADIRU) necessary
- GPS only - The FMCF uses global positioning system (GPS) data
- ADIRU only - The FMCF uses ADIRU data
- VOR/DME/ADIRU - The FMCF filters VOR, DME, and ADIRU data
- DME/DME/ADIRU - The FMCF filters DME and ADIRU data
- GPS/ADIRU - The FMCF filters ADIRU data with GPS position data
- LOC/ADIRU - The FMCF filters localizer deviation with ADIRU data
- LOC/VOR/DME/ADIRU - The FMCF filters localizer deviation, collocated VOR/DME, and ADIRU data
- LOC/DME/DME/ADIRU - The FMCF filters localizer deviation, DME/DME, and ADIRU data
- LOC/GPS/ADIRU - The FMCF filters localizer deviation, GPS, and ADIRU data.

Position Uncertainty

The FMCF uses mathematical algorithms to calculate a position uncertainty value for each one of the navigation sensors (GPS, radios, ADIRU).

The FMCF selects only one navigation update mode at a time. The FMCF selects the navigation update mode with the least amount of position uncertainty.

Velocity Vector Calculation

The LNAV sub-function uses north, east, and vertical velocity components from the ADIRU and GPS position bias or radio position bias to calculate the velocity vectors. These are the outputs from the total velocity vector calculations:

- Ground speed
- Distance-to-go to next waypoint

- Cross-track error
- True heading
- Magnetic track
- True track
- Flight path angle
- Magnetic heading
- Altitude.

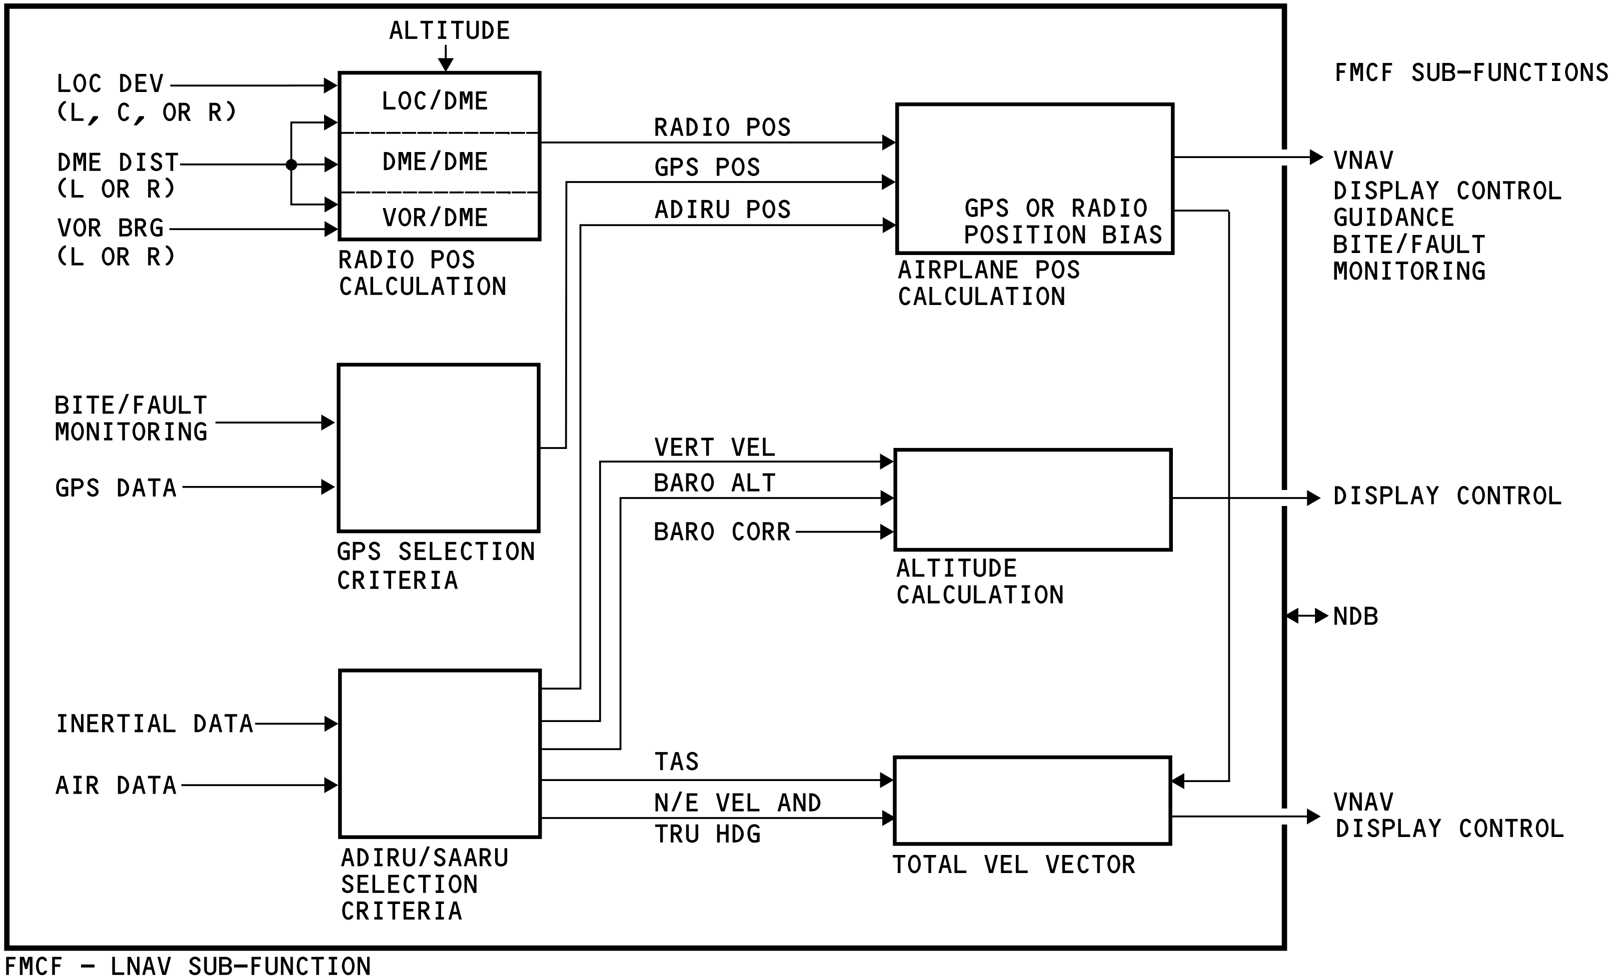
Wind Data Calculation

The LNAV sub-function uses these inputs to calculate wind data:

- Flight path angle
- North and east velocity
- True heading
- ADIRU true airspeed (TAS).

The LNAV sub-function gives wind speed, wind direction, and wind angle. Wind speed is the difference between the track and airplane heading vector.

Wind direction and wind angle is the difference between ground speed and the true airspeed vector.



34-61-00-051 Rev 5 06/20/1997

FMCS - FMCF FUNCTIONAL DESCRIPTION - LNAV SUB-FUNCTION

THIS PAGE INTENTIONALLY LEFT BLANK

FMCS - FMCF FUNCTIONAL DESCRIPTION - RADIO TUNE SUB-FUNCTION

General

Normally, the radio tune commands come from the right FMCF for automatic or manual tune of the navigation radios. If the radio tune sub-function in the right AIMS cabinet fails, the tune commands from the left FMCF are used.

After the FMC autotunes the navigation radios, the radio data goes to the FMCF. If global positioning system (GPS) data in not available, the FMCFs use nav radio data to update the inertial position from the air data inertial reference unit (ADIRU).

Navaid Autotuning

The FMCFs autotune to the best navaids for position updates. The FMCFs autotune to VOR/DME navaids in three different ways. These are the three types and the indications that show on the NAV RADIO page on the CDU:

- The letter P shows for procedure tuning when the FMCF automatically tunes to a navaid that is part of the active departure or arrival procedure.
- The letter R shows for route tuning when the FMCF automatically tunes to a navaid that is the next or last waypoint of the active route.
- Autotune (A) occurs when no procedure (P) or route (R) tune is active. The FMCFs automatically tune to the best navaids.

During autotune (A), the FMCFs use a selection criteria to find the best DME/DME pair to autotune as the navaids. This is the selection criteria:

- Range; the range of navaid station must not be farther than the line-of-sight or closer than 9 nm
- Geometry; the angle between the two stations is between 30 and 150 degrees, with the airplane as the center point
- Raw data availability; when the station is tuned it returns valid data.

The FMCFs make a list of the 20 navaid stations closest to the current FMCF position. The FMCFs update the list every three minutes. The navaid stations are from the navigation data base.

The FMCFs select five navaid stations from the list of 20 to autotune. The FMCFs select the best five navaids that meet the selection criteria. Each DME tunes to those five navaid stations. The FMCFs use two of the five navaid stations for position updates. The FMCFs use two more navaid stations for DME distance display updates in the navigation display. The FMCFs use the last navaid station for co-located ILS/DME distance.

If a DME/DME pair is not available, the FMCFs use the VOR bearing and DME distance from a co-located VOR/DME station.

If the destination runway is a part of the flight plan, the FMCFs autotune to the co-located ILS/DME station for the destination runway. The FMCFs use the ILS localizer deviation and DME slant range distance for FMCF position updates during a landing.

Navaid Manual Tuning

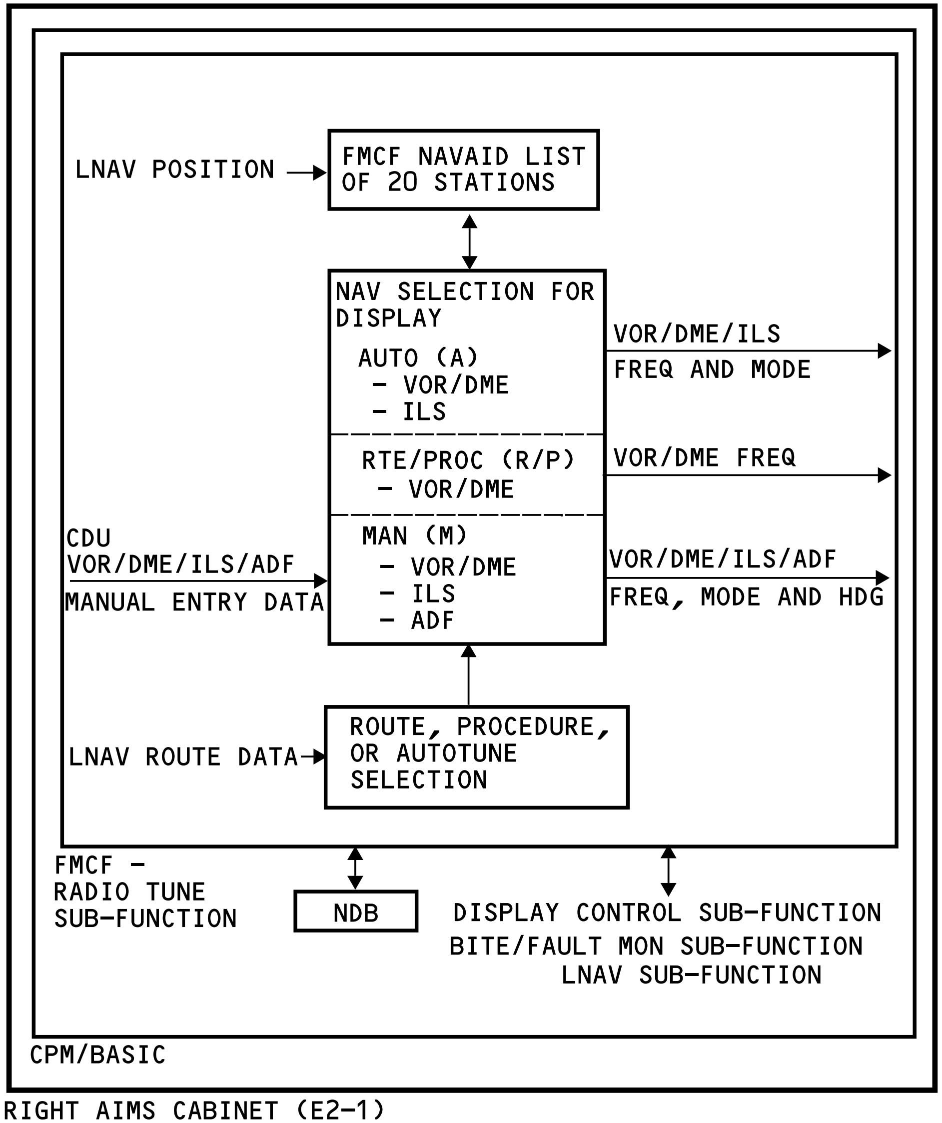
Use the CDU to manually tune the nav radios. To tune to a navaid station, enter a tuning frequency for ILS, VOR, DME or ADF navaids or station identifier for VOR or DME. When you do this, the tuning frequency or identifier goes to the FMCFs. The FMCFs do a check of the validity of the tuning frequency or identifier, and make sure that it is in the navigation data base. If the tuning frequency is valid, the FMCFs send it to the related radio. Then the radio tunes to that station. If you enter a station identifier for VOR or DME, the FMCFs change the station identifier to the related tuning frequency. The FMCFs send the related tuning frequency to the VOR receiver and DME interrogators.

A manual tune entry overrides a P, R, or an A-autotune mode for VOR/DME tuning and an A autotune mode for ILS. This causes the letter M to show between the frequency and identifier on the NAV RADIO page of the CDU. A delete of the manual tune mode causes a P, R or an A to show between the frequency and identifier on the NAV RADIO page.

Navigation Radios Tune Modes

These are the tune modes for the VOR/DME, ILS, and ADF navigation radios:

- VOR/DME - M, P, R, or A
- ILS - M or A, the FMCF auto-tunes the ILS when the airplane is within range of the destination airport and the ILS runway is part of the active flight plan
- ADF - M (manual) tune only.



34-61-00-052 Rev 4 02/11/1998

FMCS - FMCF FUNCTIONAL DESCRIPTION - RADIO TUNE SUB-FUNCTION

FMCS - AUTOMATIC DEPENDENT SURVEILLANCE FUNCTION FUNCTIONAL DESCRIPTION

General

ATC sends automatic dependent surveillance (ADS) requests from the ground to the airplane. The ADSF in the airplane sends airplane data to the ground. ATC uses this data to manage air traffic. The ADSF is automatic and does not require flight crew action.

Functional Description

ATC sends ADS requests from the ground to the airplane. The link between the ground and the airplane is through the ACARS sub-function of the DCMF.

The DCMF sends the request to the ADSF. The ADSF receives inputs from these units and functions:

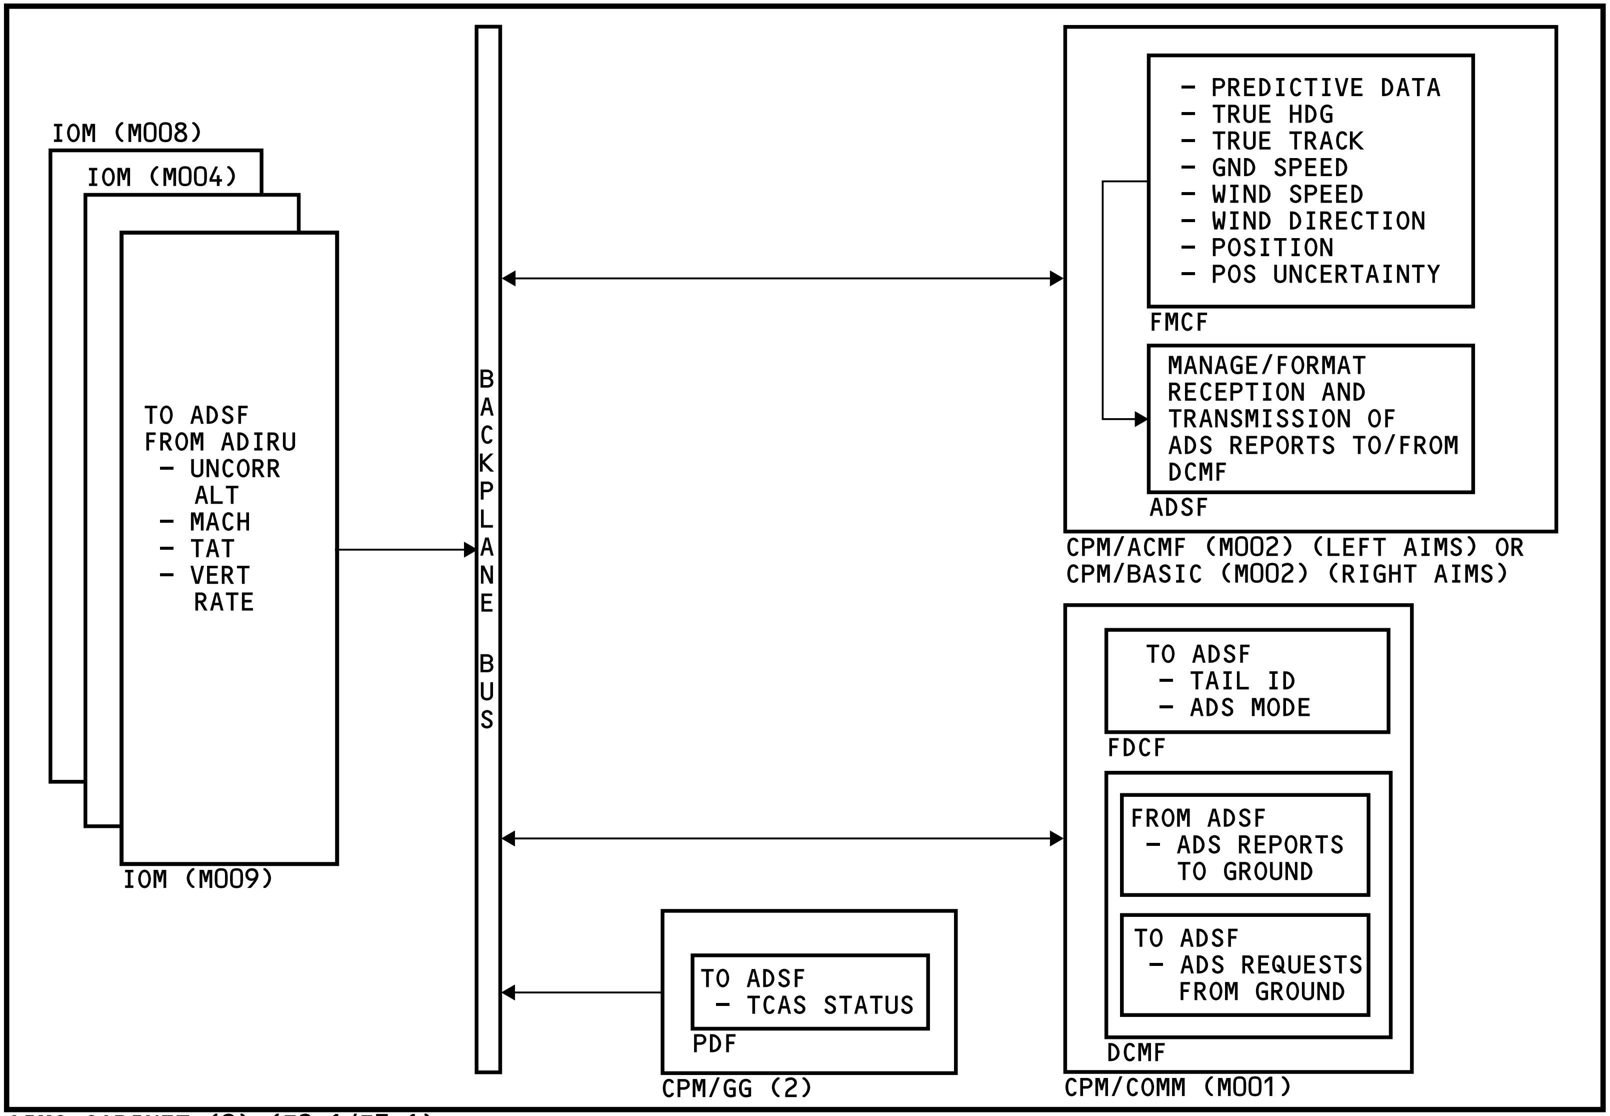
- Air data inertial reference unit (ADIRU)
- Flight management computing function (FMCF)
- Flight deck communication function (FDCF)
- Data communication management function (DCMF)
- Primary display function (PDF).

The ADSF uses these inputs to manage and format the transmission of ADS reports to the ground. The ADSF sends the report to the DCMF. The ACARS sub-function of the DCMF down links the report to the ground.

The reports contain data ATC uses to track the airplane in the air. These are examples of data transmitted to ATC:

- Airplane position
- Flight plan waypoints
- True heading
- True track
- Ground speed
- Wind speed
- Wind direction
- Position uncertainty
- Validity status of the airplane TCAS system
- Aircraft tail identification
- Operational status of the ADSF
- Uncorrected barometric altitude
- Mach number
- Total air temperature (TAT)
- Vertical rate.

The ADS reports occur without any flight crew action.



FMCS - AUTOMATIC DEPENDENT SURVEILLANCE FUNCTION FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

FMCS - FMCF FUNCTIONAL DESCRIPTION - BITE/FAULT MONITORING SUB-FUNCTION

General

The FMCF BITE and fault monitoring sub-function does software and hardware comparisons, input monitoring, and fault recording. The BITE and fault monitoring sub-function uses both external and internal inputs to do:

- Input monitoring
- Power-up checks
- Cross cabinets checks
- Synchronization monitoring
- Software reset.

The BITE and fault monitoring sub-function sends fault display data to the display control sub-function. It also sends fault data to the central maintenance computing function (CMCF) for fault recording.

Input Monitoring

The FMCFs monitor inputs from the CDUs and all the applicable line replaceable units (LRUs). The FMCFs monitor the input buses to find if the input signals are active, not active, valid or invalid.

Power-Up Checks

The FMCF does compatibility and comparison checks during power-up and internal monitoring during normal operation. Power-up checks are done at power-up and at BITE restarts. These are the checks and comparisons that occur:

- Operational program configuration (OPC) check. The FMCF compares the OPC and the FMCF operational software. If they do not agree, the FMCF fails and a maintenance message occurs on the MAT.
- Performance database (PDB) check. The FMCF monitors the airframe/engine identification program pin input and OPS. If they do not agree, the FMCF fails and a maintenance message occurs on the MAT.
- PDB/electronic engine controller (EEC) comparison. The FMCF compares the engine type and thrust rating in the PDB and the engine type and thrust rating from the EEC. If they do not agree, the FMCF stores the EEC data in non-volatile memory then restarts.
- Airline modifiable information (AMI) comparison. The FMCF compares the AMI file with the OPS and the OPC. If they do not agree, the FMCF uses the AMI default values.

Cross Cabinet Checks

The active FMCF compares its OPS, PDB, and navigation data base (NDB) to the inactive FMCF to make sure they agree. If they do not agree, the inactive FMCF fails. A maintenance message goes to the CMCF for display and storage.

Sychronization Monitoring

FMCF synchronization monitoring occurs at power-up and during normal operation. The active FMCF sends flight plan data to the inactive FMCF. This occurs so the inactive FMCF can take over if the active FMCF fails. The active FMCF sends its flight plan data to the inactive FMCF for these conditions:

- Long term power-ups
- BITE induced restart
- Flight plan entries and performance data changes.

When the active FMCF fails, a resychronization (resync) occurs. Resyncs take about 1 second for an entire flight plan update. The active FMCF always resyncs the inactive FMCF. The active FMCF selection is a function of the FMC selector position and FMF partition health.

Software Reset

An AIMS software reset from the MAT does a test of the FMCFs and clears memory buffers, flight plans, and user entered data. Fault data stays in memory over the reset.

FMCS - AIRLINE MODIFIABLE INFORMATION

General

The design of the 777 airplane lets the airlines customize certain default values in the flight management computing system. You customize these functions through airline modifiable information (AMI). You use the ground based software tool (GBST) to make the modifications.

These functions have default values:

- Performance, guidance, and takeoff data
- Alternate function parameters
- Crew alertness monitor
- Request uplink imbedded message identifier (IMI) table
- Datalink option codes
- Downlink trigger parameters.

You can modify any of the default values for these functions. In addition, you can create tables or values for these functions:

- Downlink address table
- Airline ground address table.

There are no default values for these tables.

Performance, Guidance and Takeoff Data

The table shows the default values and the valid range for the performance, guidance and takeoff data.

Parameter	Default Value	Valid Range
All Eng Accel ht	1000 feet	400-9999 feet
Eng out accel ht	1000 feet	400-9999 feet
Speed restriction	none	100-400 knots
Speed transition	250 kts/10000 ft	Spd-100-400 kts Alt-0-40000 ft
Maneuver margin	1.2 FAA 1.3 CAA/JAR	1.2-1.3 FAA 1.3-CAA/JAR
Rate of climb margin for climb	100 ft/min	0-500 ft/min
Rate of climb margin for cruise	100 ft/min	0-500 ft/min
Default thrust rating in cruise	Max cruise thrust	Max climb or max cruise thrust
Minimum cruise time	1 minute	1-20 minutes
Thrust reduction height/flap setting	1000 feet	400-9999 feet
Fuel freeze/min operating temp	-37 deg C	-99to-1 deg C
Takeoff Derate 1	10%	0-30%
Takeoff Derate 2	20%	0-30%
Company speed	Defined in NDB	1-400 KTS CAS .1-.99 MACH
Company speed thrust rating	Max climb thrust	Max climb, Max cruise,Max con

Alternate Function Parameters

The table shows the default values and the valid range for the alternate function parameters.

FMCS - AIRLINE MODIFIABLE INFORMATION

Parameter	Default Value	Valid Range
Altitude	FMCF computed	1500-40000 ft
Min runway length	0 feet	0-15000 ft
Speed mode	ECON	ECON, CAS/ MACH, LRC, EOLRC, COSPD
Speed value	None	1-400 KTS CAS .1-.99 MACH

Crew Alertness Monitor Parameters

The table shows the default values and the valid range for the crew alertness monitor parameters.

Parameter	Default Value	Valid Range
Cruise advisory timer	15 min	15-60 min
Cruise caution timer	20 min	15-75 min
Cruise warning timer	25 min	15-75 min
Descent advisory timer	5 min	5-60 min
Descent caution timer	6 min	5-75 min
Descent warning timer	7 min	5-75 min

Additionally, the default settings for the crew alertness warning, caution and advisory annunciations is disable. You can enable any or all of these annunciations.

Request Uplink IMI Table

The table shows the default IMI values and the associated imbedded element identifier (IEI) values for uplink requests.

IMI Description	IMI	Associated IEI
Flight Plan	FPN	RP, FN
Load information	LDI	RR
Performance initialization	PER	PR
Position	POS	POS
Progress (ETA) report	PRG	DT

Datalink Option Codes

You control the datalink option codes by setting a bit in a data word to a logic 1 or a logic 0. Bits 1-10 are for functions that show on a CDU display. The default value for these functions is set to a logic 0 which causes the function to show on the appropriate display. A logic 1 blanks the function. The functions are:

- Bit 1: Flight plan data request inhibit
- Bit 2: Performance Initialize data request inhibit
- Bit 3: Takeoff data request inhibit
- Bit 4: Enroute wind data request inhibit
- Bit 5: Descent forecast data request inhibit
- Bit 6: Company preferred alternate request inhibit
- Bit 7: Alternate flight list data request inhibit
- Bit 8: Alternate weather data request inhibit
- Bit 9: Flight plan data report inhibit

- Bit 10: Position report inhibit.

Bits 11 through 23 control data that may be added to message content or functions that will be added. These items have a default value of logic 0 which excludes the functionality. The items includes:

- Bit 11: Time stamp IEI enable
- Bit 12: Ground address IEI enable
- Bit 13: Company distribution IEI enable
- Bit 14: Scratchpad IEI enable
- Bit 15: Flight number IEI enable
- Bit 16: Flight plan response enable
- Bit 17: Performance initialize response message enable
- Bit 18: Takeoff response message enable
- Bit 19: Wind response message enable
- Bit 20: Pos report trigger response message enable
- Bit 21: ALTN response message enable
- Bit 22: Change in destination airport trigger enable
- Bit 23: Change in arrival runway trigger enable.

Downlink Trigger Parameters

The table shows the default values and the valid range for the downlink trigger parameters.

Parameter	Default Value	Valid Range
Head wind discrepancy	Disable	0-99 knots
Change in destination ETA	Disable	0-999 min
Time to top of descent 1	Disable	0-999 min
Time to top of descent 2	Disable	0-999 min
Time to top of descent 3	Disable	0-999 min
Time to top of descent 4	Disable	0-999 min
Time to top of descent 5	Disable	0-999 min
Time to destination 1	Disable	0-999 min
Time to destination 2	Disable	0-999 min
Time to destination 3	Disable	0-999 min
Time to destination 4	Disable	0-999 min
Time to destination 5	Disable	0-999 min

Downlink Address Table

The downlink address table has the ground addresses and the company distribution for IMIs. There are no default entries for this table. You may enter a maximum of 20 IMIs in the table.

Airline Ground Address Table

The airline ground address table has the ground addresses with the identification of ADS uplinks that originate with the airline. There are no default entries for this table. You may enter a maximum of 5 ground addresses or 5 groups of addresses in the table.

FMCS - AIRLINE MODIFIABLE INFORMATION

Default Values Summary

Default values are non-modifiable values found in the operational software of the CPM/Basic and the CPM/ACMF. To cause the function to operate with new values you must develop a customized AMI and load that software into the CPMs. These new values do not override the default values but are used instead of the default values. If the AMI fails, FMCFs use the default values.

With the FMCF, you can also use the Airline Policy page to modify the AMI values on a short term basis. You can do this between flights. At power down, the system restores the default values values.

FMCS - SYSTEM TESTS

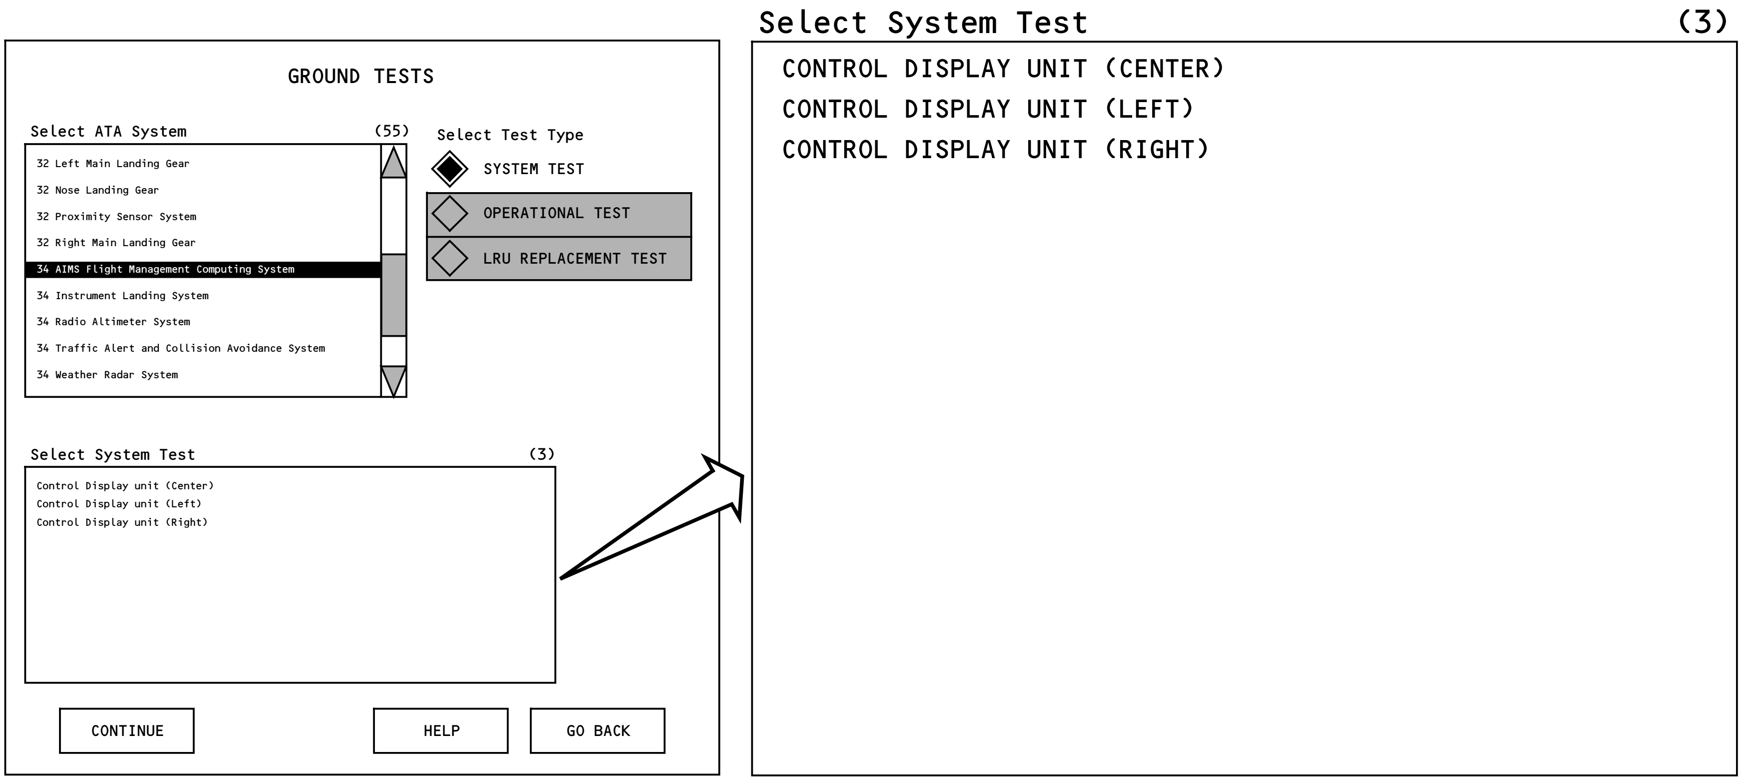
General

These are the system tests for the flight management computing system:

- Control Display Unit (CDU), Center
- Control Display Unit, Left
- Control Display Unit, Right.

CDU System Test

This test makes sure that the center, left, or right CDU operates correctly. The CDU display (screen) goes blank during the test. After you start the test, you can not stop it. This test takes less than one minute.



34-61-00-062 Rev 1 03/02/95

FMCS - SYSTEM TESTS

FMCS - CDU SPECIAL FUNCTIONS

General

The FMCS control display unit (CDU) special function makes sure the internal hardware and software operates correctly. During a special function, the CDU uses it's built in test equipment (BITE) to do a power-up test. The special function also makes a CDU test patterns show on the CDU for operator inspection.

The MAT shows these CDU special function screens/ dialogue boxes:

- Select ATA system
- Select function (left, center, or right CDU)
- CDU center, left, or right special function
- Description (same for all CDUs)
- Special function condition - ready, inhibited, or completed
- Special function instructions - what to look for on the CDU display
- CDU center, left, or right white test pattern
- CDU center, left, or right black test pattern
- CDU center, left, or right checkerboard test pattern.

CDU Display - Special Function Description

The CDU special function permits the operator to look for faults in the CDU LCD glass or drive circuits. Normal operating formats are not on the CDU during this special function.

The approximate time to run a CDU special function is 2-5 minutes.

There are no limitations or special requirements to run a CDU special function.

To do a CDU special function, select a CDU from the MAT select function screen/dialogue box. Next, read and follow the instructions on the MAT screens/dialogue boxes that show.

CDU LCD Test Pattern - White

This special function causes the CDU display to show a white test pattern. Look for defects on the display.

CDU LCD Test Pattern - Black

This special function causes the CDU display to show a black test pattern. Look for defects on the display.

CDU LCD Test Pattern - Checkerboard

This special function causes the CDU display to show a checkerboard test pattern. Look for defects on the display.

TABLE OF CONTENTS

THRUST MANAGEMENT COMPUTING SYSTEM (TMCS) - INTRODUCTION

General

The thrust management computing system (TMCS) is part of the airplane information management system (AIMS). The TMCS controls engine thrust in response to mode requests from the:

- Mode control panel (MCP)
- Flight management computing function (FMCF)
- Flight deck switches.

The TMCS operates in most flight phases.

Abbreviations and Acronyms

A/P	- autopilot
A/T	- autothrottle
ACMF	- airplane condition monitoring function
ADIRU	- air data inertial reference unit
AFDC	- autopilot flight director computer
AFDS	- autopilot flight director system
AGL	- above ground level
AIMS	- airplane information management system
alt	- altitude
app	- approach
ASCPC	- air supply cabin pressure controller
ASG	- ARINC signal gateway
ASIC	- application specific integrated circuit
ASM	- autothrottle servo motor
BARO	- barometric altitude
clb	- climb

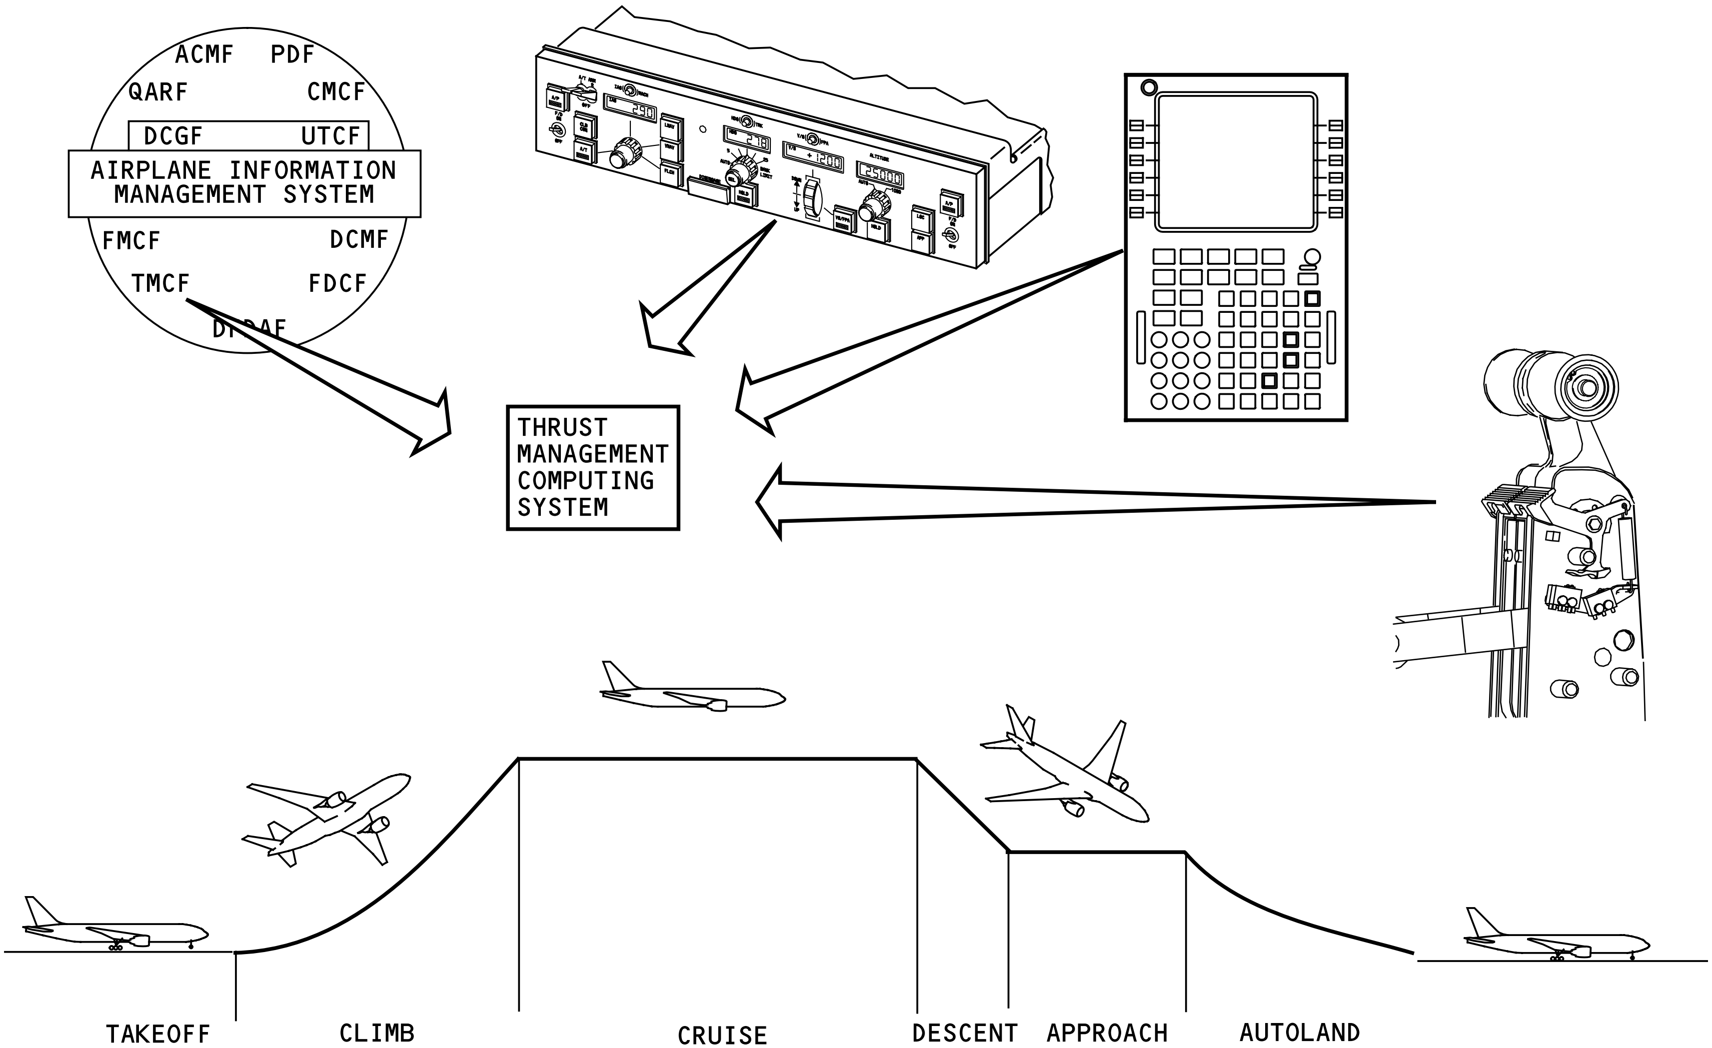
WEU	- warning electronic unit



THRUST MANAGEMENT COMPUTING SYSTEM (TMCS) - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

TMCS - GENERAL DESCRIPTION

General

The operator interface to the TMCS is through the control display units (CDUs) and the mode control panel (MCP). Several airplane systems and components send and receive TMCS information. TMCS information shows on the primary flight display (PFD) and the EICAS display.

TMCS Components

The TMCS has these components:

- TMCF in AIMS cabinets
- Autothrottle servo motors (ASMs)
- A/T disconnect switches
- Takeoff go-around (TO/GA) switches
- A/T arm and mode switches on the MCP.

There are two TMCFs, one in each AIMS cabinet. Each TMCF receives digital and digital discrete data from airframe and engine components. The TMCF also receives flight deck commands (A/T mode requests) and switch position inputs.

The TMCS does these sub-functions:

- Autothrottle (A/T) control laws
- Thrust limit calculation
- Engine trim calculation
- BITE and fault monitoring
- TMCS annunciations.

The ASMs receive digital commands from the TMCF and analog data from the MCP.

The A/T disconnect and TO/GA switches on the center aisle control stand supply disconnect, TO or GA inputs to the TMCF.

The MCP A/T arm and mode switches send digital control and mode data to the TMCF.

The A/T arm switches on the MCP supply analog arm or inhibit signals to the ASMs. They also supply engine trim enable logic to the engine electronic controllers (EECs).

TMCS Interfaces

The TMCF receives data on the flight controls ARINC 629 data buses from these components:

- Autopilot flight director computer (AFDC) (3)
- Air data inertial reference unit (ADIRU)
- Secondary attitude air data reference unit (SAARU)
- Primary flight computer (PFC) (3).

The TMCF receives data on the systems ARINC 629 data buses from these components:

- Air supply cabin pressure controller (ASCPC) (2)
- Cabin temperature controller (CTC) (2)
- Proximity switch electronic units (PSEU) (2)
- Warning electronic units (WEU) (2)
- Engine data interface units (EDIU) (2)

TMCS - GENERAL DESCRIPTION

- Overhead panel bus controller (OPBC) (2)
- Flap slat electronic unit (FSEU) (2)
- ARINC signal gateway (ASG) (2)
- CDU (3).

The TMCF receives ARINC 429 data from these:

- Mode control panel (MCP)
- Radio altimeter (RA) transceiver (xcvr) (3)
- Autothrottle servo motor (ASM) (2).

The TMCF receives analog inputs from these:

- Engine RPM, N1/N2
- Fuel shutoff switch (2)
- Master caution and warning light switch.

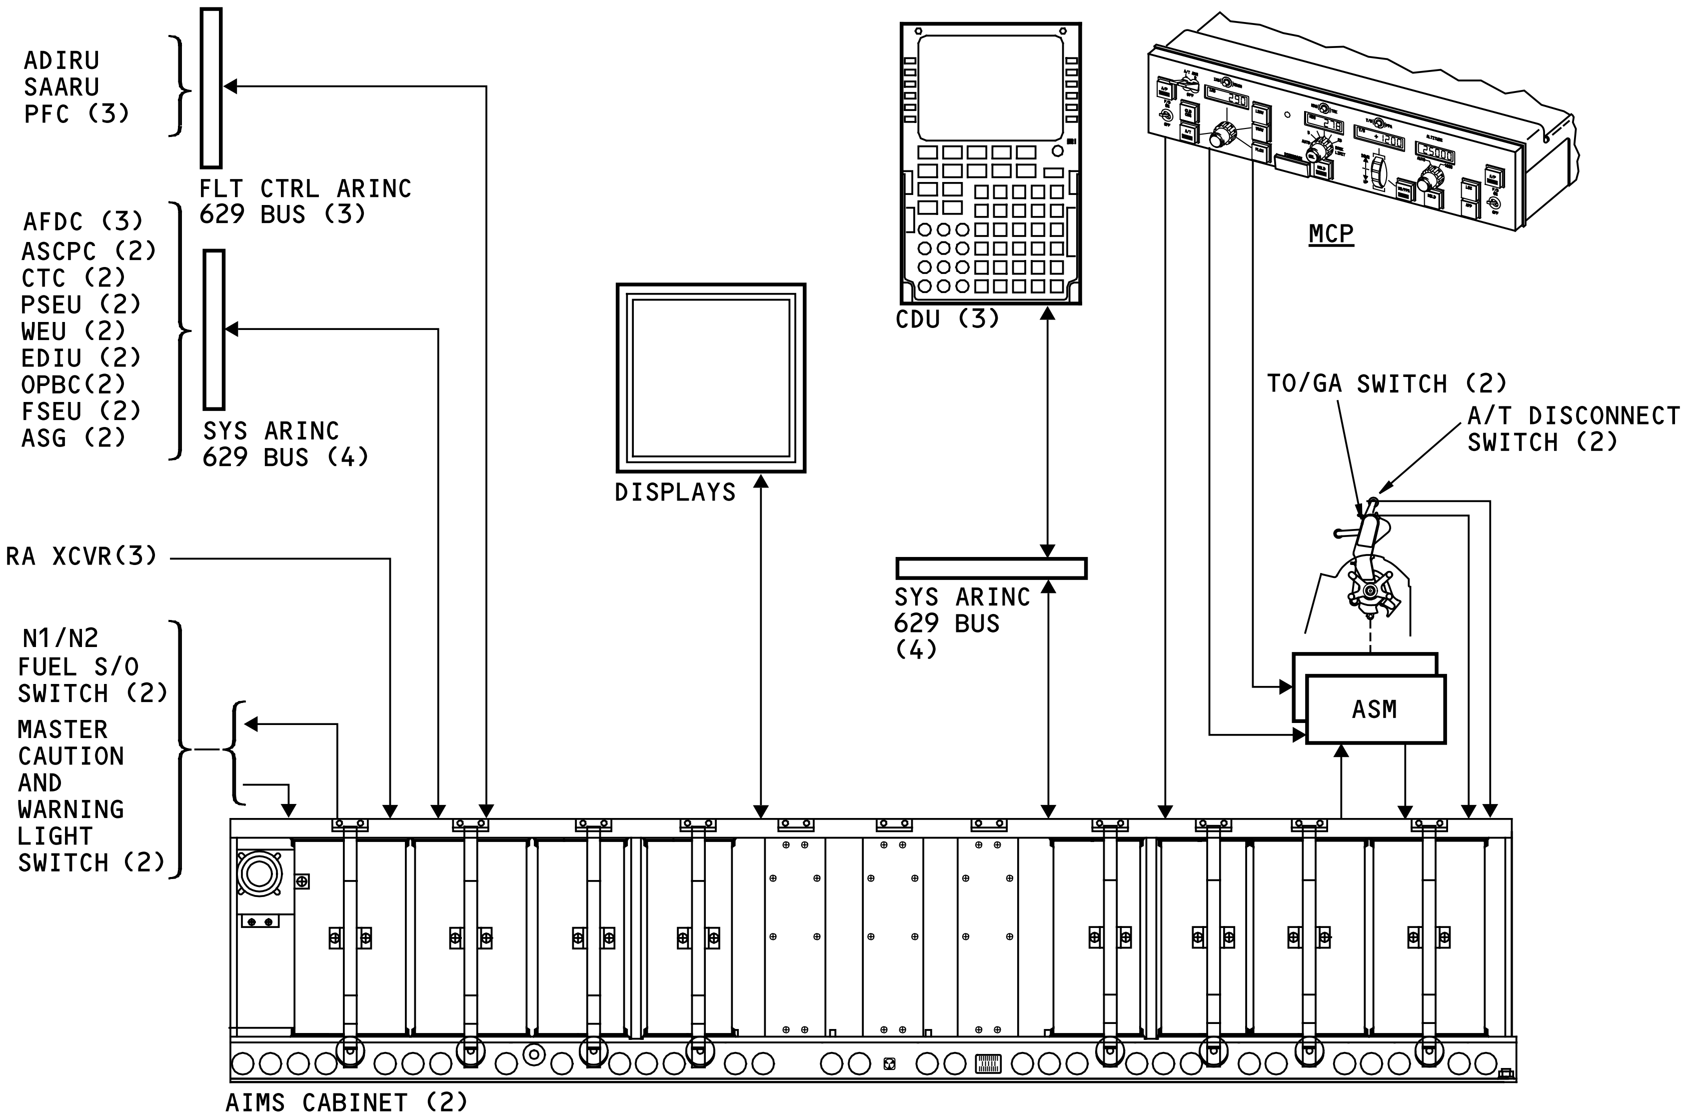
The TMCF also receives analog inputs from these:

- Autothrottle (A/T) disconnect switch (2)
- Takeoff go-around (TO/GA) switch (2)
- Autothrottle servo motor (ASM) (2).

The TMCF sends data to these components and switches:

- WEU (2)
- EDIU (2)
- AFDC (3)
- Primary flight computers (PFC) (3)
- Master caution and warning light switch (2)
- ASM (2).

The TMCF sends display and fault data to the primary display function and the central maintenance computing function in the AIMS cabinets.



TMCS - GENERAL DESCRIPTION

TMCS - FLIGHT DECK COMPONENT LOCATIONS

TMCS Component Locations - P55

These are the components of the TMCS on the P55 glareshield center panel:

- Autothrottle (A/T) mode switch (2) on mode control panel (MCP)
- A/T arm switch (2) on MCP.

TMCS Component Locations - P10

These are the components of the TMCS on the thrust levers and below the control stand:

- Takeoff go-around (TO/GA) switch (2)
- A/T disconnect switch (2)
- A/T servo motor (ASM) (2), one on each side below the control stand.

TMCS - INTERFACES - 1

THIS PAGE INTENTIONALLY LEFT BLANK

TMCS - INTERFACES - 1

General

The left and right AIMS cabinets receive inputs from and send outputs to many components, sensors, and switches for the thrust management computing function (TMCF). These interfaces are on the flight controls ARINC 629 data buses, the systems ARINC 629 data buses or analog discrete signals.

The IOMs show the inputs that come directly from TMCF components.

ADIRU Inputs - Flight Control Bus (L & R)

The air data inertial reference unit (ADIRU) sends these parameters and status to the TMCFs:

- Air data
- Temperature
- Ground speed (G/S).

The TMCFs use this data to calculate the A/T modes and thrust limits.

SAARU Inputs - Flight Control Bus (C)

The secondary attitude air data reference unit (SAARU) sends these backup parameters to the TMCFs:

- Air data
- Temperature
- Ground speed (G/S).

The TMCFs use this data to calculate the A/T modes and thrust limits.

PFC Outputs - Flight Control Bus (L, R, & C)

The PFCs receive this data from the TMCFs:

- Left engine idle discrete
- Right engine idle discrete
- Left engine fail
- Right engine fail
- Speed mode
- Go around mode (GA).

AFDC Inputs - Systems Bus (L, R, & C1)

The AFDCs send a flare retard command to the TMCFs when the airplane is in the final land (autoland) configuration. This causes the TMCF to command the throttles to idle at a set A/T rate. The TMCFs also receive AFDCs status.

The AFDCs also send voted TO/GA to the TMCFs. The AFDCs receive a discrete signal from the TO/GA switch. The AFDCs send a digital voted TO/GA signal to the TMCF. The TMCF uses the voted TO/GA signal to engage take off or go-around modes.

AFDC Outputs - Systems Bus (L, R, & C1)

The TMCF sends this data to the AFDCs:

- A/T engage

TMCS - INTERFACES - 1

- Command altitude rate
- Engine fail and operating discretes
- A/T mode discretes.

CDU Inputs - Systems Bus (L & R)

The CDU sends thrust limit mode and derated thrust limit data and status to the TMCFs.

ASCPC Inputs - Systems Bus (L & R)

The air supply cabin pressure controllers (ASCPCs) sends engine bleed data to the TMCFs to calculate the lower thrust operating limit.

CTC Inputs - Systems Bus (L & R)

The cabin temperature controllers (CTCs) send cabin bleed data to the TMCFs to determine the lower thrust operating limit.

PSEU Inputs - Systems Bus (L & R)

The proximity switch electronic units (PSEUs) send air/ground logic to the TMCFs. The in air logic enables A/T mode operation and inhibits takeoff (TO) mode engage in the air. The on ground logic enables TO mode engage and inhibits all other A/T modes of operation.

WEU Inputs - Systems Bus (L, R, & C1)

The TMCFs receive maximum and minimum speed from the warning electronic units (WEUs).

WEU Outputs - Systems Bus (L, R, & C1)

The TMCFs sends an A/T disengage discrete to the (WEUs) for an automatic or manual A/T disengage. This signal causes the WEUs to sound the caution aural, a four-beep tone in the flight deck speakers. The TMCFs also send engine fail and takeoff thrust limit data to the WEUs.

EDIU Inputs - Systems Bus (L, R, C1, & C2)

The engine data interface units (EDIUs) send engine parameters to help the TMCFs calculate the A/T servo motor commands. The TMCFs also receive status from the EDIUs.

EDIU Outputs - Systems Bus (L, R, C1, & C2)

The TMCFs send this data to the EDIUs:

- Thrust data N1 and N2
- Engine trim commands
- Bleed data (configuration codes).

OPBC Inputs - Systems Bus (L & R)

The overhead panel bus controllers (OPBCs) send this data to the TMCFs:

- FMC selector switch position
- Left and right engine fire handle position
- L/R engine anti-ice switch position
- Wing anti-ice switch position
- L/R engine alternate mode.

TMCS - INTERFACES - 1

FSEU Inputs - Systems Bus (L, R, & C1)

The flap slat electronics units (FSEUs) send flap angle data to the TMCFs.

ASG Inputs - Systems Bus (L & R)

The ASG sends this data to the TMCFs:

- Left and right cowl anti-ice valve position
- Left and right engine anti-ice valve position.

RA RT Inputs - ARINC 429

The radio altimeter (RA) receiver transmitters (RTs) send radio altitude and status to the TMCFs in the AIMS cabinets. This provides A/T flare retard engage or inhibit logic just before touchdown.

Engine RPM (N1 & N2) Analog Inputs

The left and right engine RPM sensors send low (N1) and high (N2) engine RPM to the TMCFs.

Fuel Shutoff (SO) Switches Analog Discrete Inputs

The TMCFs receive the left and right fuel SO switch position as analog discretes. This helps the TMCFs determine engine status along with other inputs.

Master Caution Light Analog Discrete Inputs

The master caution and warning light switch supplies an analog discrete to the TMCFs to reset the caution lights. Push a master caution and warning switch light to reset the A/T disconnect function.

Master Caution Analog Discrete Outputs

The TMCFs send an analog discrete to the master caution and warning light switches. This causes the caution light to come on. This occurs when a manual or an automatic A/T disengage occurs.

A/T Disconnect Switch Analog Discrete Inputs

The autothrottle (A/T) disconnect switch supplies a manual A/T disengage analog discrete to the TMCFs to disengage both A/T servo motors. A second push causes the TMCF to reset both the A/T function and the AUTOTHROTTLE DISC caution message on the EICAS display.

TO/GA Switch Analog Discrete Inputs

The takeoff/go around (TO/GA) switch supplies a TO/GA analog discrete to the TMCFs to start the A/T mode. The TO/GA switch supplies logic to the AFDS for the TO/GA mode. The TO/GA switch analog discrete input is a backup to the voted TO/GA input from the AFDCs. On the ground, the thrust limit mode is TO for the TMCS. In the air the thrust limit mode is GA for the TMCS.

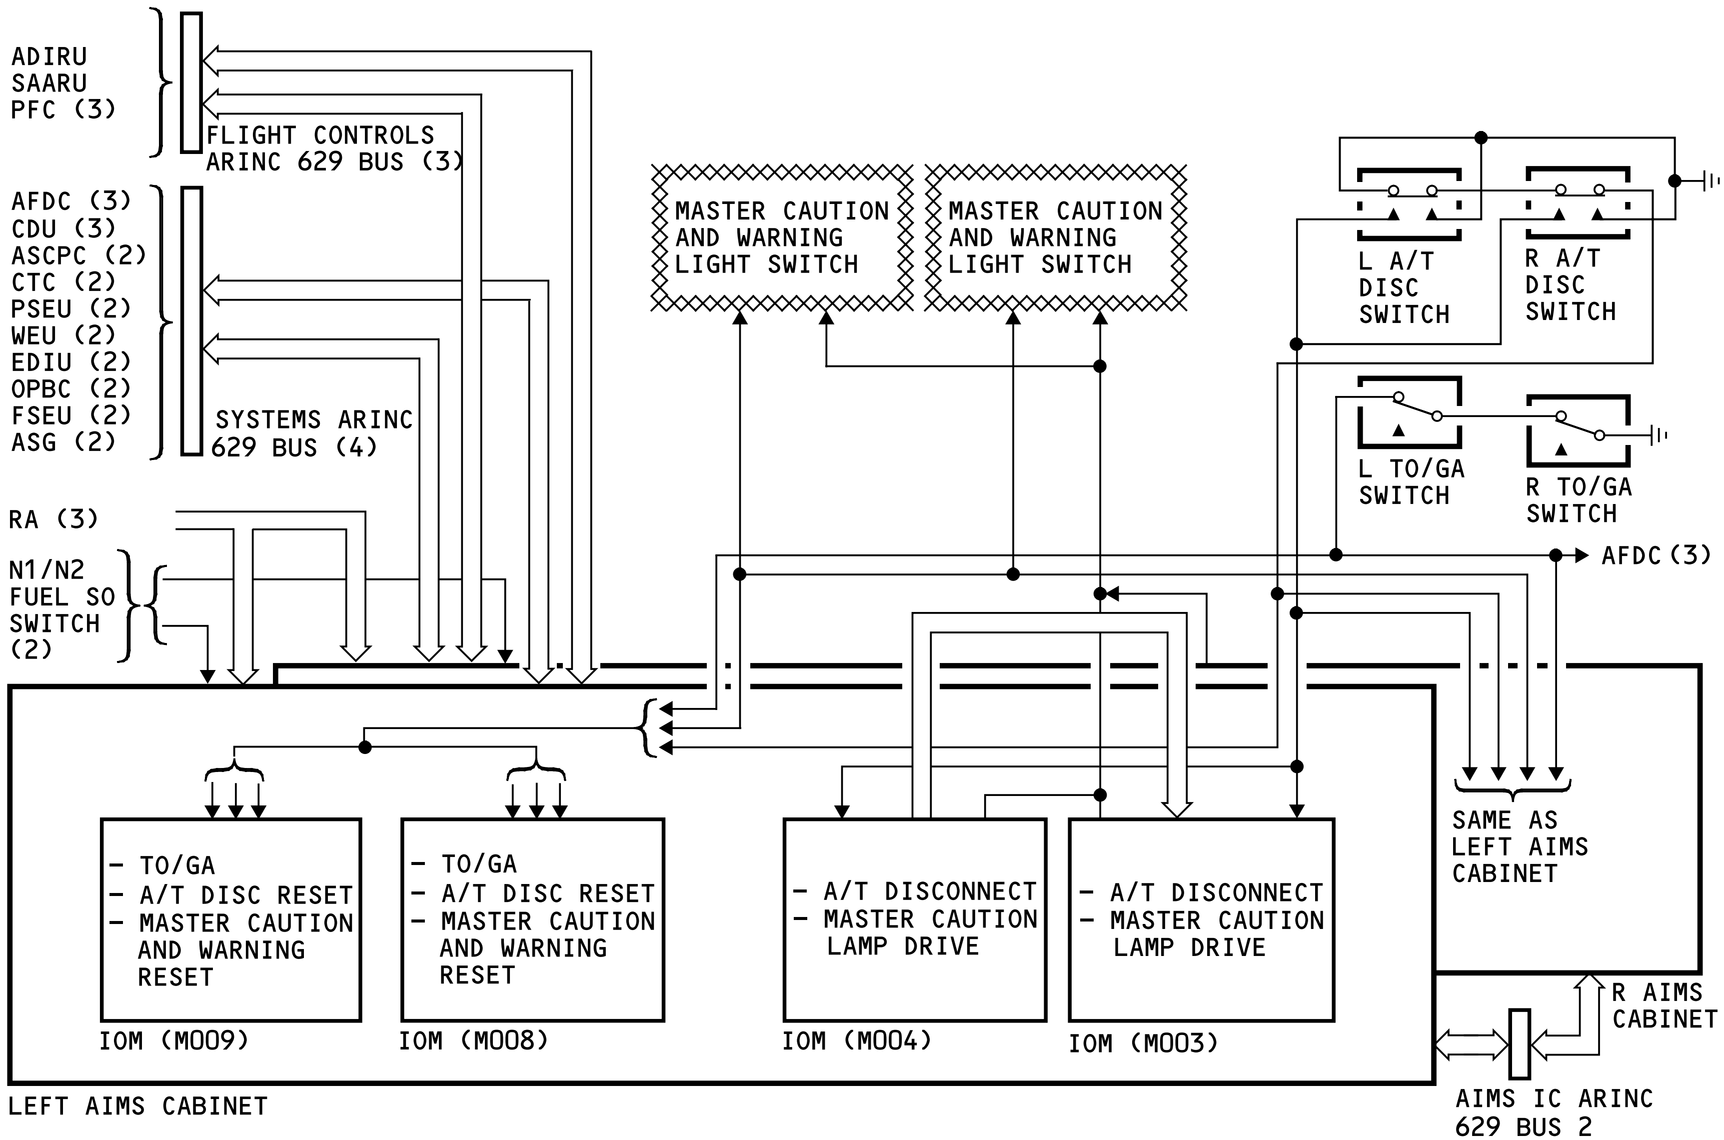
TMCS - INTERFACES - 1

AIMS Intercabinet Bus (ICB) Interfaces

The left and right TMCFs use the ICB to share and compare data.

The left TMCF and right TMCF calculate the same A/T commands. Only one TMCF is active. They compare data bases, input data, sensor status, and BITE results. The active TMCF sends synchronization data to the non-active TMCF at these times:

- When they do not agree
- During power interrupts
- At power up.



TMCS - INTERFACES - 1

22-31-00-005 Rev 6 02/18/1998

TMCS - INTERFACES - 2

General

The active TMCF automatically sets the throttle levers in response to crew or system inputs.

Each autothrottle servo motor (ASM) needs power inputs and control signals from the AIMS cabinets and the mode control panel (MCP).

Power Interface

The P11 overhead circuit breaker panel supplies 28V dc to the left and right ASM for operation. On/off control comes from the mode control panel (MCP). The A/T ARM switches control 28V dc to the ASMs for servo motor operation.

MCP Digital and Analog Discrete Interfaces

The MCP sends this digital discrete data to the TMCFs:

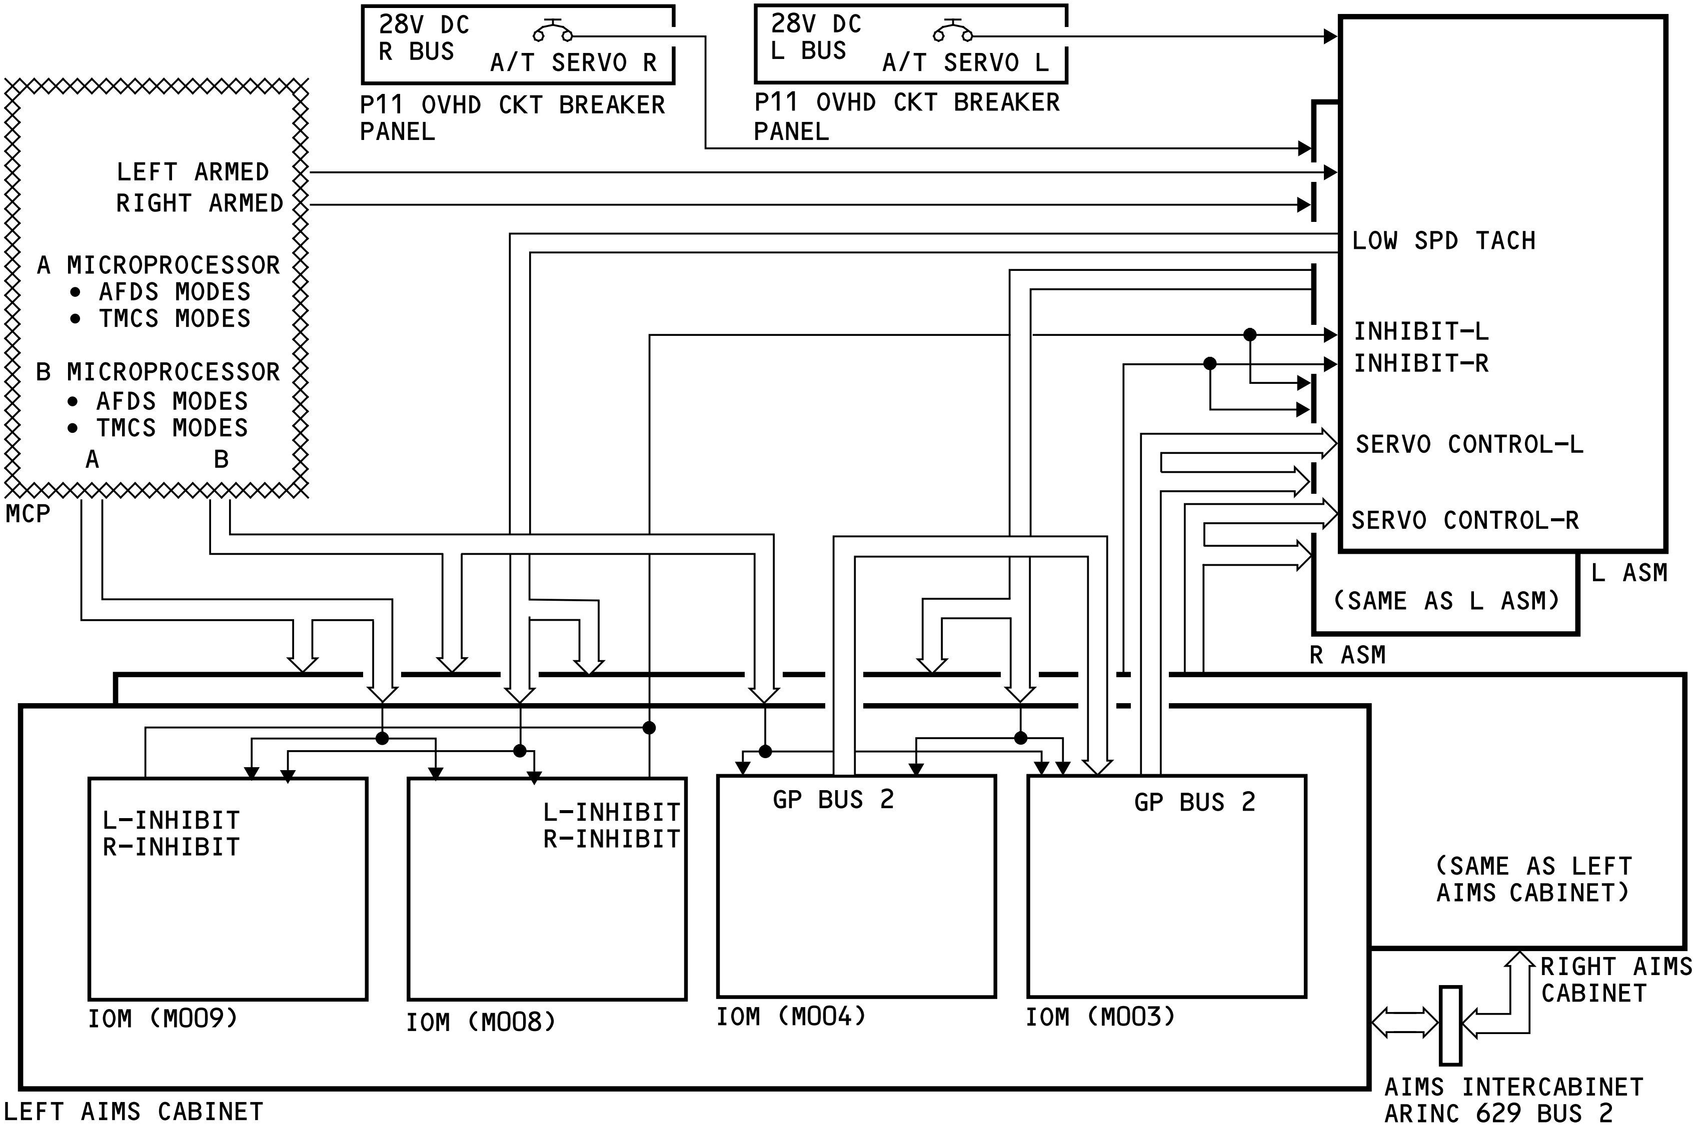
- A/T arm (on/off) - the engine trim function engages when both A/T arm switches are on. Also, single (L or R) or dual (both) autothrottle operation occurs when the appropriate arm switch is in the ARM position
- A/T mode
- AFDS mode
- Parameters for A/T mode logic
- MCP status.

The MCP sends this analog discrete data to the ASMs:

- A/T arm (ON) switch supplies ASM control power in the on position
- A/T arm (OFF) switch removes power (positive disengage) from its ASM in the off position.

ASM Digital Interface

The active TMCF causes the throttles to move forward or aft when it sends the ASMs digital commands. The ASM operation stops with the inhibit input. The A/T servo motors send digital throttle position (low speed tachometer) feedback data to the TMCFs when the servomotor moves. The autothrottle servo motors also send status information to the TMCFs.



22-31-00-006 Rev 3

TMCS - INTERFACES - 2

TMCS - A/T SERVO MOTOR

General

The integrated autothrottle servo motors (ASMs) are below the throttle quadrant (P10). The active TMCF sends servo rate commands to each ASM to move its throttle forward or aft through a separate gear box assembly.

Physical Description

The ASM weighs 1.9 pounds and measures 4.5 inches by 3.26 inches by 4 inches. The electrical power interface is from the bottom of the ASM.

Operation

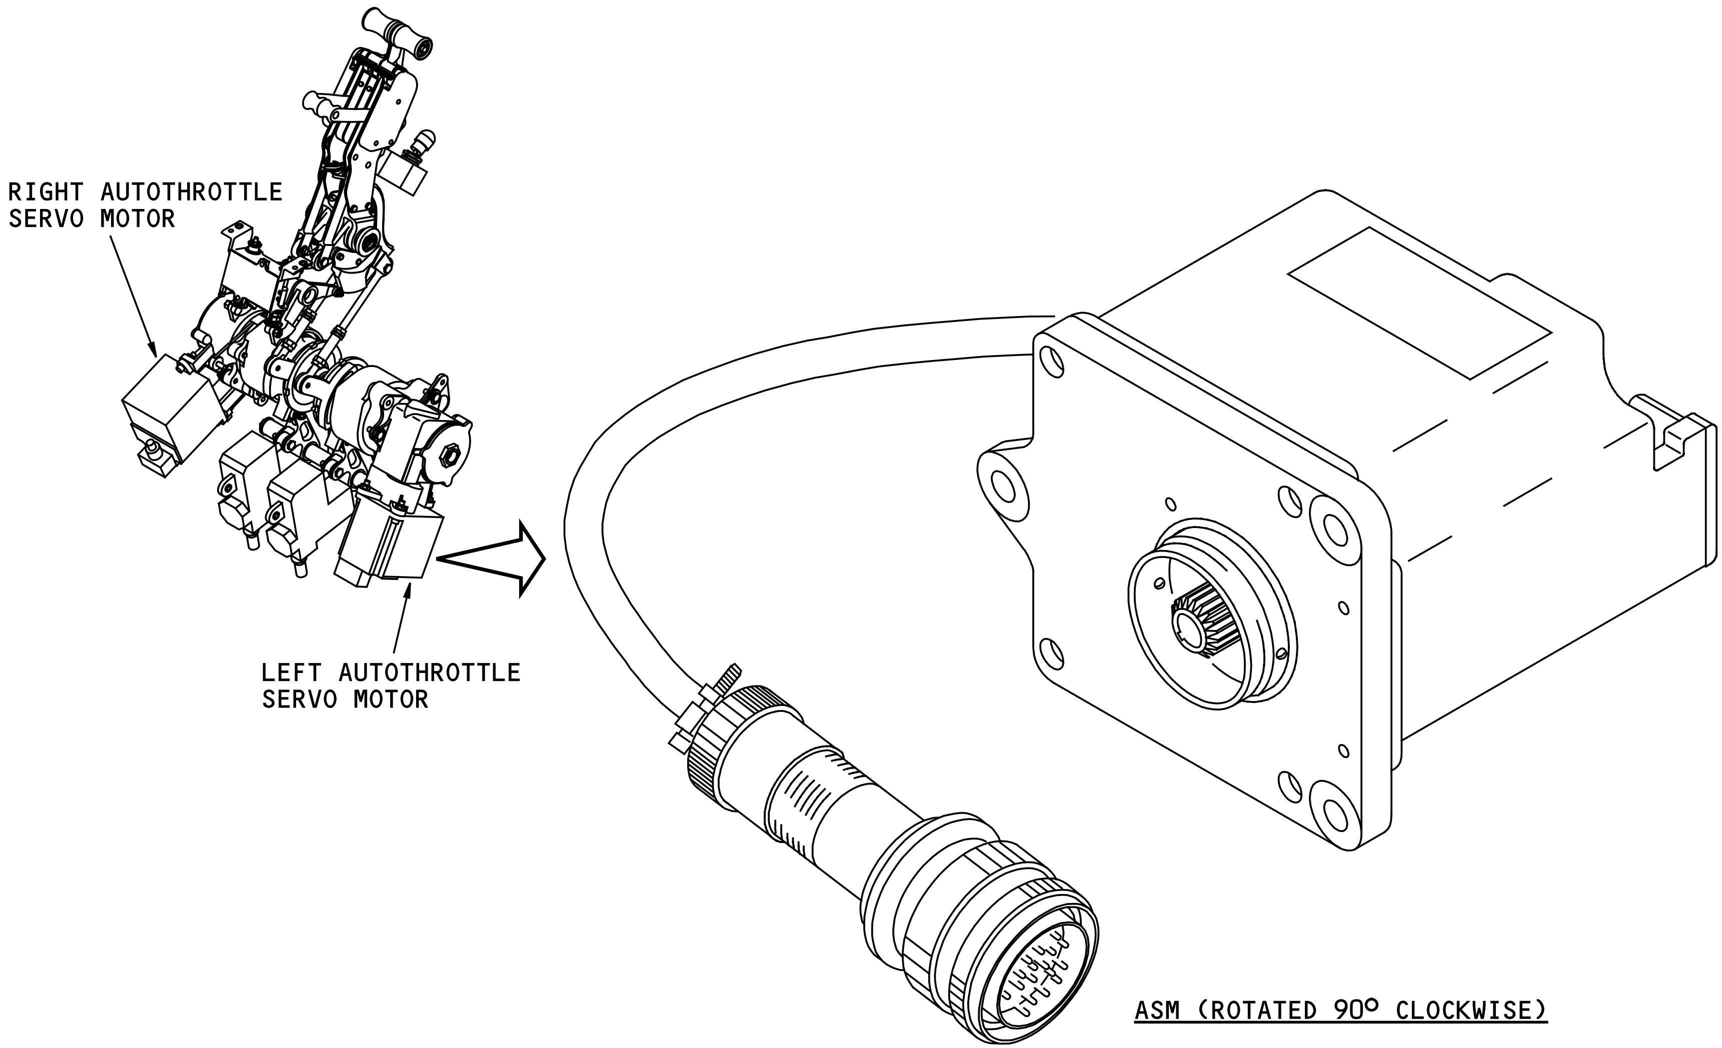
Each ASM consists of these:

- Electronic control module (ECM)
- Power supply unit (PSU)
- Power switching module (PSM)
- Power switching bridge (PSB)
- DC motor with magnetic sensors.

Power to the ASM is 28V dc for excitation and motor control. The ASM pulse modulates and amplifies the digital servo rate commands it receives from the TMCF.

Each ASM receives analog (A/T arm and inhibit L/R) and digital (FMC selector position) discretes to enable its operation. Each ASM sends the TMCF a digital discrete of its state and digital rate feedback.

There are three magnetic pick-off sensors in the DC motor stator that measure rate feedback. These sensors measure the rate between the rotor and stator as the motor moves the throttle forward or aft.



22-31-00-007 Rev 2

TMCS - A/T SERVO MOTOR

TMCS - A/T ARM, A/T MODE AND THROTTLE SWITCHES

General

You use switches on the mode control panel (MCP) and on the thrust levers to arm, select, or disconnect A/T modes.

MCP A/T Arm Switch

The A/T arm switches are on the MCP. You use the A/T arm switches to enable ASM excitation power (28V dc) for operation. The on position (both) also supplies engine trim equalization control from the TMCFs. The off position removes power from that ASM and removes engine trim equalization control.

MCP A/T Mode Switches

The MCP has these A/T mode switches with these functions:

- Climb/continuous (CLB/CON), selects the CLB thrust limit mode in the air or CON thrust limit mode in the air when one engine fails
- A/T, selects the A/T speed (SPD) mode or the thrust reference (THR REF) mode when in the air
- Flight level change (FLCH), gives a thrust command that changes with a small or large altitude change
- Vertical navigation (VNAV), allows the throttles to operate with the autopilot flight director system (AFDS) to control thrust or speed.

To arm the autothrottle, move one or both of the A/T arm switches to the UP position. To engage the A/T, push the A/T switch on the MCP. The autothrottle engages automatically if any of these modes engage:

- VNAV
- FLCH
- TO/GA.

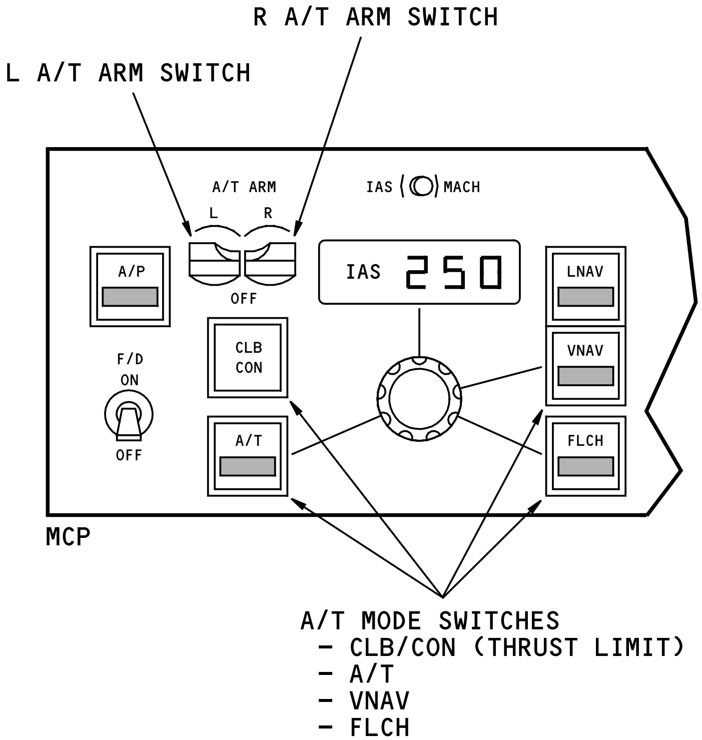
Thrust Lever Switches

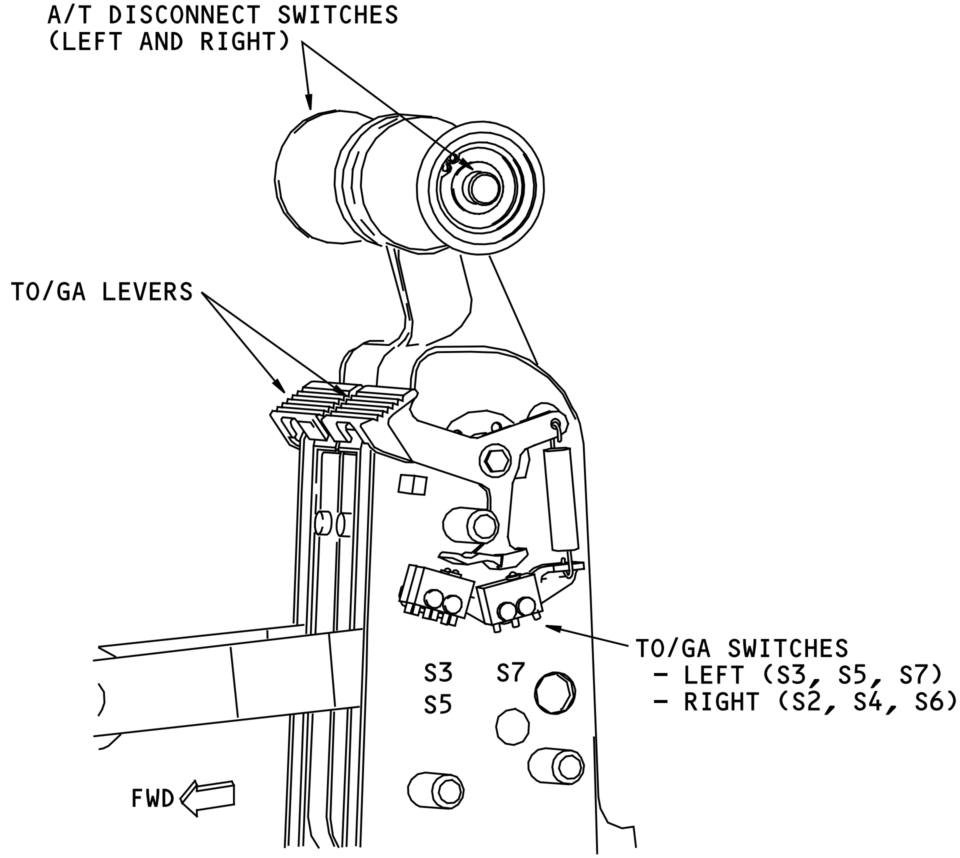
These switches are on the left and right thrust levers:

- Takeoff/go-around (TO/GA), S3, S5 and S7 (left) and S2, S4, and S6 (right)
- A/T disconnect.

Push a TO/GA lever to engage that TO/GA switch. This causes the selected takeoff (TO) thrust mode to operate on the ground. In the air, with a TO/GA request in approach, the go-around (GA) thrust mode operates with less than maximum GA thrust. Push the TO/GA switch twice to move the throttles to the full GA thrust limit when in the air.

An A/T disconnect switch is on the left and right thrust lever. Push an A/T disconnect switch to disconnect the A/T and show the AUTHROTTLE DISC caution message on the EICAS display. To reset the AUTHROTTLE DISC caution message, push the A/T disconnect switch again.





THRUST LEVERS

TMCS - A/T ARM, A/T MODE AND THROTTLE SWITCHES

THIS PAGE INTENTIONALLY LEFT BLANK

TMCS - PRIMARY FLIGHT DISPLAY - OPERATION

General

The autothrottle (A/T) modes show on the primary flight display (PFD) when an A/T mode engages.

A/T Modes

Normal A/T mode annunciation and operation is with both the left and right A/T servo motors (ASM) in operation. A left (L) or right (R) precedes the A/T mode annunciation when only one ASM operates.

These are the A/T modes that show on the PFD:

- Speed (SPD/X SPD)
- Thrust (THR/X THR)
- Thrust reference (THR REF/X THR REF)
- HOLD/X HOLD
- IDLE/X IDLE
- TEST/X TEST.

SPD or X SPD shows when:

- A/T engage conditions are valid and vertical navigation (VNAV) commands the throttles to hold SPD
- VNAV or flight level change (FLCH) mode transitions to another pitch mode, such as vertical speed, altitude hold, capture, or glideslope capture
- The A/T mode on the mode control panel (MCP) is active, the airplane is in the air and the autopilot flight director system (AFDS) is not in a speed mode.

THR or X THR shows when the TMCF receives an A/T mode request and goes into one of these modes:

- VNAV descent
- FLCH
- Go-around (GA) thrust mode.

THR REF or X THR REF shows when the TMCF receives a takeoff (TO) A/T request from the left or right TO/GA switch and the TMCF commands the throttles to full TO thrust. THR REF shows for VNAV CLB or a GA thrust mode.

HOLD or X HOLD shows when the TMCF removes excitation power from the ASMs. HOLD shows in these A/T modes:

- FLCH idle descent (pilot override)
- TO thrust mode when computed air speed (CAS) is more than 80 KTs
- VNAV idle descent.

IDLE or X IDLE show for these A/T modes:

- VNAV descent
- A flare retard idle command from the AFDS.

TEST or X TEST shows when a TMCS ground test is active.

The A/T mode annunciation is blank with one of these:

TMCS - PRIMARY FLIGHT DISPLAY - OPERATION

- No A/T mode requests
- The left and right TMCS invalid.

THIS PAGE INTENTIONALLY LEFT BLANK

TMCS - EICAS DISPLAY - OPERATION

General

The EICAS display shows this TMCF data that relates to engine/thrust performance:

- Thrust limit mode
- Selected temperature
- Thrust limit
- Target N1
- Maximum thrust limit.

Thrust limit Mode

The takeoff (TO) thrust limit mode shows automatically on the ground at power up. Other thrust limit modes show in the automatically or with a manual selection on the CDU THRUST LIMIT page when in flight. It also shows automatically when in flight and VNAV (vertical navigation) engages.

These are the two ways to derate the engine thrust:

- Enter an assumed temperature
- Select CLB 1 or CLB 2.

A temperature derate occurs with a temperature entry on the CDU THRUST LIMIT page. The TMCF uses this value when it is more than the present temperature in use for TO thrust calculation. D shows in front of the TO thrust limit for a temperature derated thrust.

There are two climb derates, CLB 1 and CLB 2. Climb derates are available on the CDU THRUST LIMIT page. CLB 1 derate level is 10% and CLB 2 derate level is 20% of the climb thrust.

Selected Temperature

The TMCF uses temperature (selected) inputs from the CDU THRUST LIMIT page when the input is more than the TAT. The TMCF uses the selected temperature input to calculate temperature derated thrust limits.

Thrust Limit

The TMCF calculates the thrust limit with inputs from the FMCF and other sensors and components. The digital readout shows on the EICAS display.

Maximum Thrust limit

The TMCF calculates the maximum thrust limit. The engine electronic control (EEC) is secondary for maximum thrust limit calculation.

Target N1

The target thrust cursor shows in green when it shows the N1 limit calculated by the TMCF for the active thrust limit mode. The target thrust cursor shows in green for all autothrottle modes other than THR or THR REF when VNAV is engaged.

The target thrust cursor shows in magenta when the TMCF uses a target N1 that the FMCF calculates. The target

TMCS - EICAS DISPLAY - OPERATION

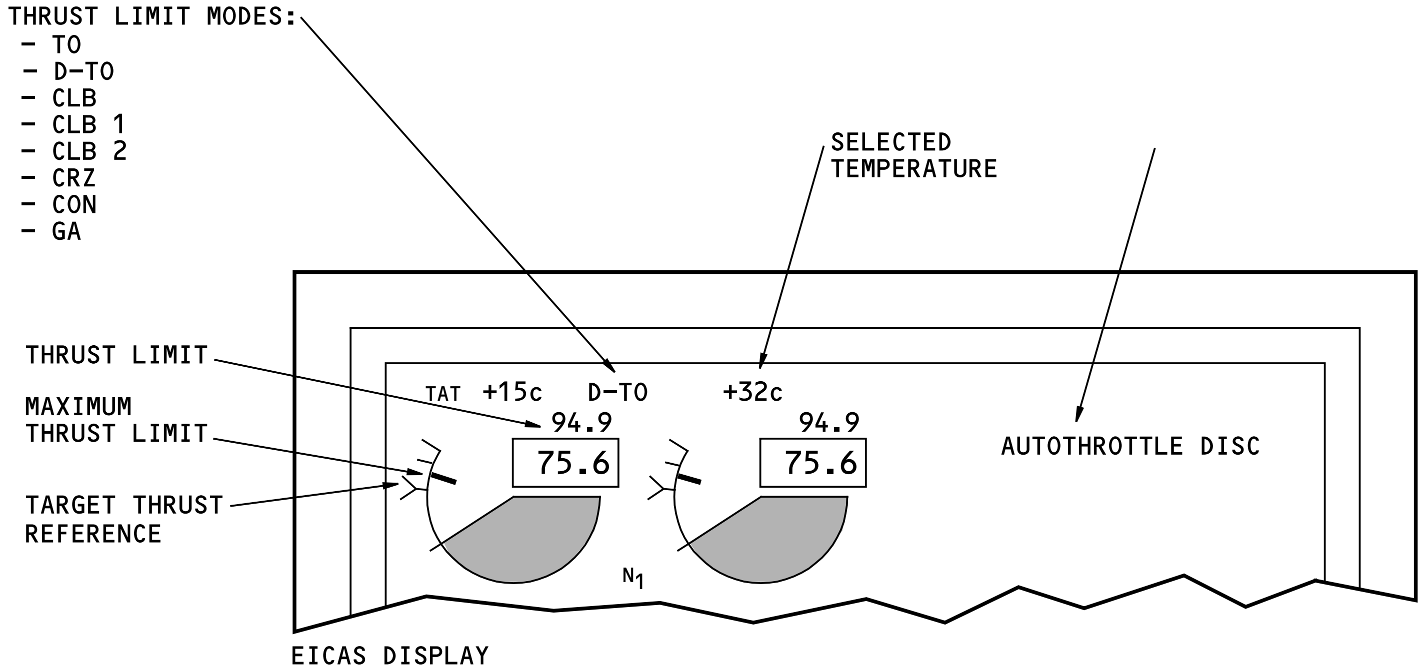
thrust cursor shows in magenta during any of these condtions:

- VNAV is engaged and the autothrottle mode is THR REF. This occurs when VNAV is engaged during climb.
- VNAV is engaged and the autothrottle mode is THR. This occurs when VNAV is engaged during descent and anti-ice is on.
- VNAV is engaged and the autothrottle is off. The pilots can manually set the thrust levers to agreee with the target N1 that shows on EICAS.

Fault Messages

TMCS fault messages show on the EICAS display for these conditions:

- AUTOTHROTTLE DISC, caution occurs when the TMCS detects an automatic or manual disengagement
- AUTOTHROTTLE L and/or AUTOTHROTTLE R, advisory occurs when the TMCS detects an ASM or arm switch failure.



22-31-00-010 Rev 5 10/29/1997

TMCS - EICAS DISPLAY - OPERATION

THIS PAGE INTENTIONALLY LEFT BLANK

TMCS - AUTOTHROTTLE FLIGHT PROFILE

General

During normal flight operations, the flight crew uses the TMCF to perform several routine or normal operations and tasks. These operations or tasks relate to autothrottle modes.

The autothrottle (A/T) modes operate in these flight phases:

- Takeoff (TO)
- Climb (CLB)
- Cruise (CRZ)
- Descent (DES)
- Approach (APP)
- Go-around (GA).

A/T functions that relate to flight phases are flare retard during autoland and A/T disconnect.

A/T thrust mode annunciations relate to pitch mode annunciations on the PFD. Use the MCP to select these modes.

Takeoff

In TO, the A/T controls thrust to the takeoff thrust limit. The A/T mode annunciation on the PFD is thrust reference (THR REF). At 80 knots (KTS) air speed, the A/T mode annunciation changes to HOLD on the PFD.

Climb

These are the three autothrottle mode selections in climb:

- Vertical navigation (VNAV)
- Flight level change (FLCH)
- A/T (MCP) speed mode or thrust mode.

The A/T mode annunciations for these modes are:

- THR REF when VNAV engages
- THR when FLCH engages
- SPD or THR REF when A/T mode engages.

The A/T mode only (MCP) engages when VNAV, FLCH, and TO/GA are not active and the airplane is in the air.

Cruise

These are the two A/T modes in cruise:

- VNAV
- A/T mode only.

These are the A/T mode annunciations in cruise:

- SPD when VNAV engages
- SPD, VNAV is not active.

Descent

These are the three A/T modes in descent:

TMCS - AUTOTHROTTLE FLIGHT PROFILE

- VNAV
- FLCH
- A/T mode only.

These are the A/T mode annunciations in descent:

- IDLE, THR, or HOLD shows for VNAV
- THR, or HOLD shows for FLCH
- SPD.

Approach

SPD is normal mode in approach with glideslope active or in a manual approach.

Go-Around

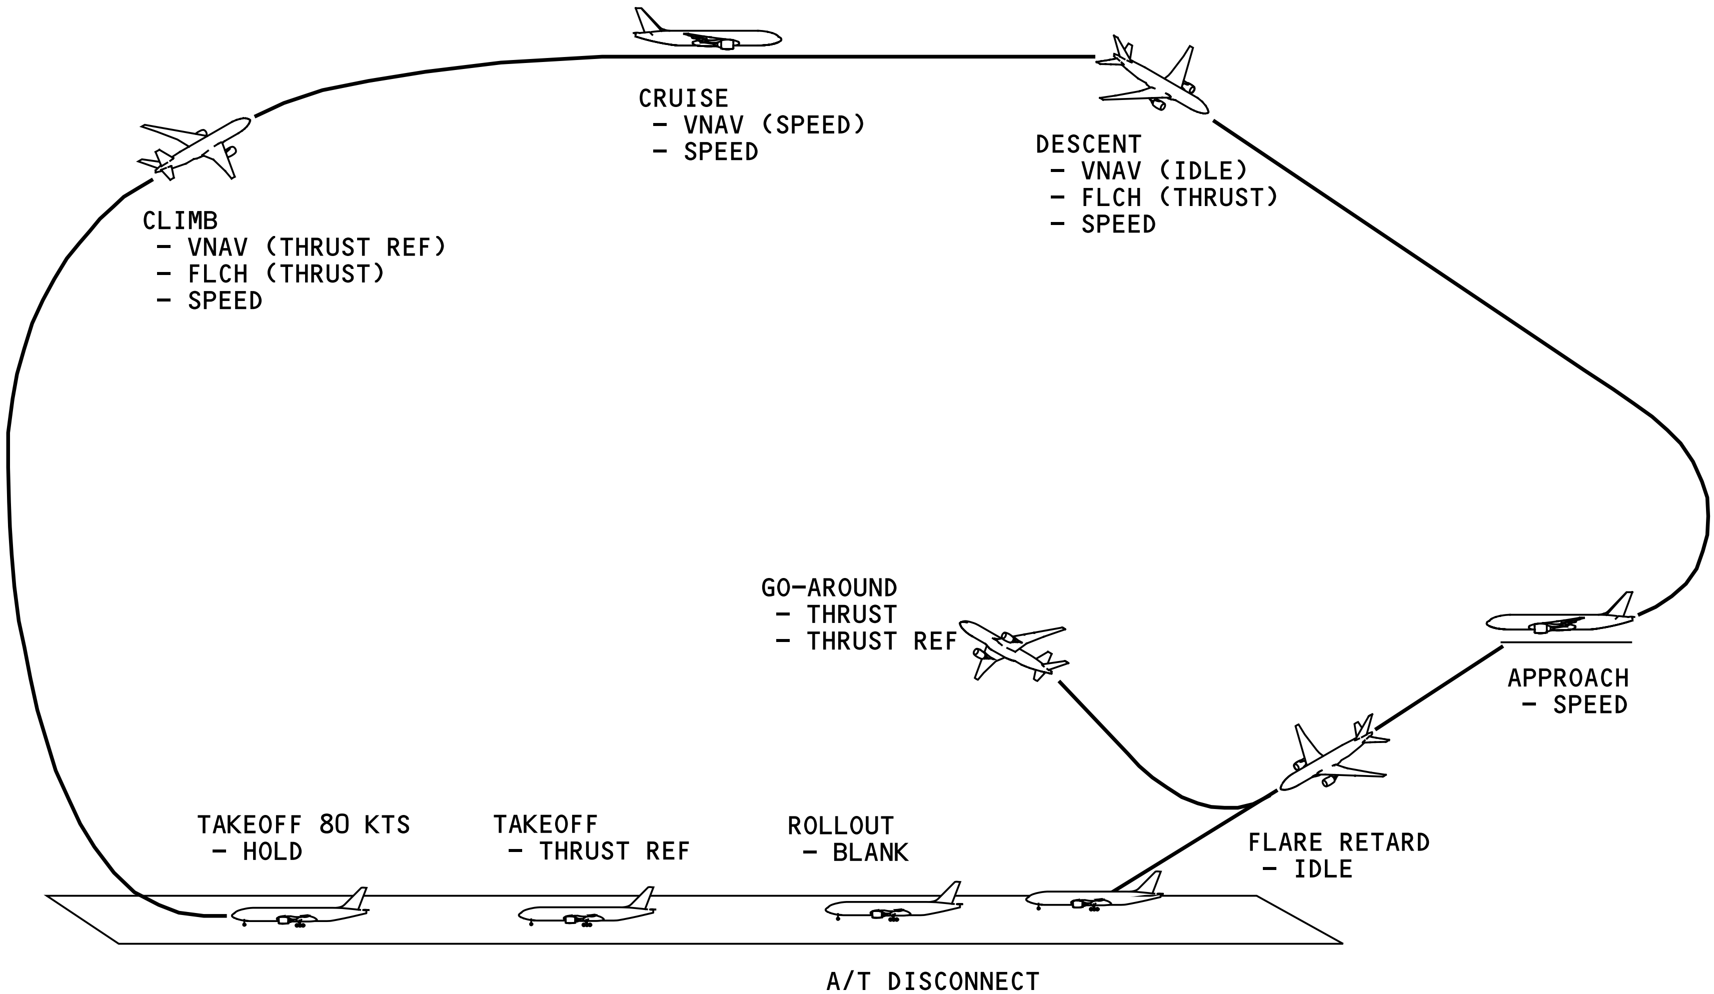
A GA mode request causes the A/T mode to change to THR. A second GA request causes the A/T mode to change to THR REF. You push a TO/GA lever to request GA.

Flare Retard

Flare retard occurs at 25 feet radio altitude during approach with a command from the autopilot flight director system (AFDS). The A/T mode changes to IDLE during a flare retard.

A/T Disconnect

The A/T disconnects with a manual A/T disconnect or with thrust reverser application. This occurs after initial touchdown during rollout.



22-31-00-011 Rev 2 05/14/1997

TMCS - AUTOTHROTTLE FLIGHT PROFILE

TMCS - A/T OPERATION - TAKEOFF

General

To prepare the AFDS and the A/T for the takeoff phase of the flight, use the mode control panel (MCP) to set the necessary parameters. Use the EICAS display and the PFD to see the modes and mode changes.

Before the A/T mode can engage, the system must pass servo motor tests to ensure proper operation.

Mode Selection

The takeoff (TO) mode engages with these conditions:

- Autothrottle (A/T) arm switches on
- Airplane on the ground
- Flap position not zero
- Thrust limit mode takeoff (TO)
- Push a TO/GA lever with less than 50 KTs air speed.

Takeoff Mode Operation

At the start of takeoff, the TMCF does the A/T stopper test. This test does a check for the ability of the TMCF to remove power from the servos.

The TMCF sends ASM commands to move the throttles to the TO thrust limit. The throttles move when the TMCF completes and passes the A/T stopper tests. The A/T mode is thrust reference (THR REF) on the PFD. At more than 80 KTs air speed, the A/T mode changes to HOLD.

During normal operation, as the airplane goes above 400 feet AGL, the A/T mode changes to THR REF.

CONDITION:
- ON THE GROUND
- A/T ARMED
- VNAV ARMED
- TO/GA LEVER PUSHED

TMCS - A/T OPERATION - TAKEOFF

TMCS - A/T OPERATION - VNAV CLIMB

Mode Selection

The VNAV climb mode engages with these conditions:

- Active route
- Performance page complete
- Vertical navigation (VNAV) armed
- VNAV engages when the airplane is 400 feet above ground level (AGL) barometric (BARO) altitude
- A/T armed
- Flight director or A/P active.

Operation

At the thrust reduction altitude, the FMCF sends commands to the TMCF to move the throttles to the climb thrust position. This occurs at or above 400 feet for a flap or an altitude setting. The flap or altitude setting is preset in the airline modifiable information (AMI). Takeoff thrust changes from TO to CLB thrust as the airplane goes through the preset altitude or at a preset flap position. You can change the preset altitude or flap position for a flight on the CDU TAKEOFF REF page 2.

The thrust limit cursor changes from green to magenta on the EICAS display when CLB thrust engages.

The A/T mode changes from HOLD to THR REF at 400 feet (BARO) when VNAV engages.

The FMCF also sends pitch control commands to the autopilot flight director system (AFDS) to control speed on elevator while in climb.

CONDITION:
- IN CLIMB
- > 400 FEET (BARO)
- VNAV ENGAGED

TMCS - A/T OPERATION - VNAV CRUISE

TMCS - A/T OPERATION - VNAV DESCENT

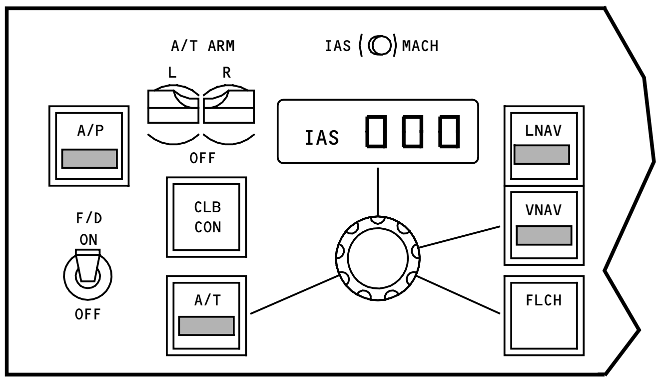
Mode Selection

The VNAV descent (DES) mode engages before the top of descent (T/D). The FMCF causes the A/T to go to the next flight phase, DES. The change from VNAV cruise (CRZ) to VNAV DES is automatic with inputs from the FMCF to the TMCF.

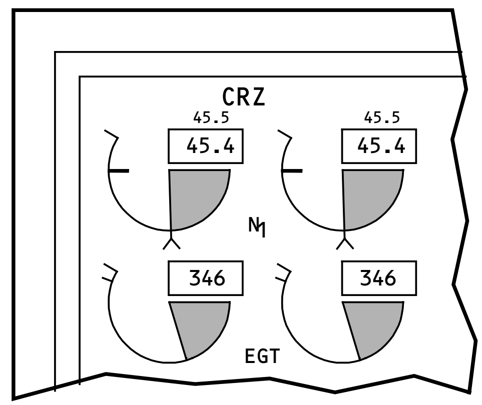
Operation

The TMCF commands the throttles to idle thrust at mode transition. The A/T mode is IDLE or THR in descent. The A/T mode changes to HOLD when a pilot moves the throttles opposite to the throttle command or when the throttles reach the aft mechanical stop.

CONDITION:
- AIRPLANE IN DESCENT
- VNAV ENGAGED



MCP



EICAS DISPLAY

TMCS - A/T OPERATION - VNAV DESCENT

22-31-00-015 Rev 2 05/14/1997

TMCS - A/T OPERATION - FLIGHT LEVEL CHANGE

Mode Selection

The TMCF sends A/T servo motor (ASM) commands to control engine thrust when all these conditions are present:

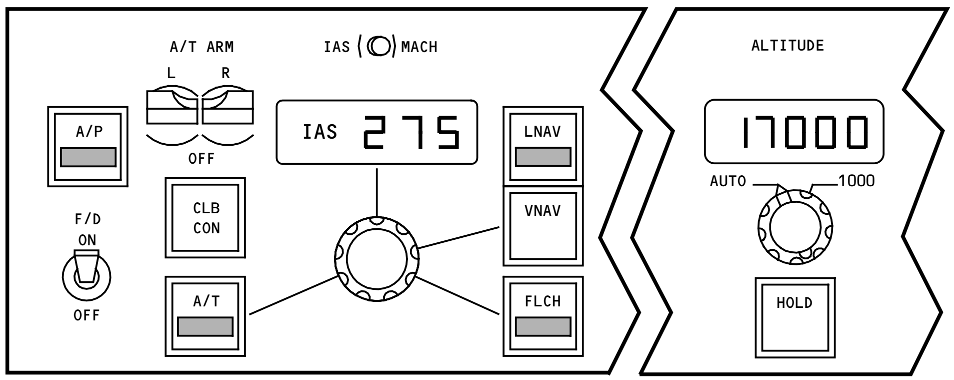
- A/T arm switches are on
- An autopilot (A/P) or flight director (F/D) switch is active
- Flight level change (FLCH) switch is active
- Airplane is in the air.

Operation

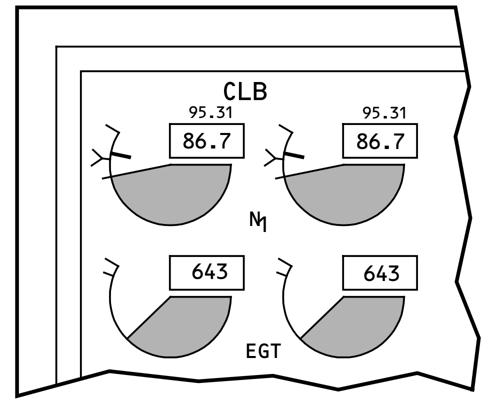
The MCP synchronizes to the current airspeed with a FLCH mode request. The TMCF uses the difference between the present altitude and the MCP altitude to calculate a vertical speed to capture the MCP altitude. The A/T control laws command thrust which produces a vertical speed to complete the altitude change in 125 seconds. The A/T command can not exceed the thrust limit mode.

If an override occurs while in the FLCH mode, the A/T mode goes to HOLD. HOLD shows on the PFD. The thrust limit mode changes to CLB on the engine primary format. An override occurs when throttle position and throttle command differ by more than eight degrees. This may occur when a pilot overrides the throttles. HOLD also shows when the throttle command moves the throttles to the aft mechanical stop and the ASM continues to move.

CONDITION:
- CURRENT ALTITUDE < MCP ALTITUDE
- FLCH ENGAGED



MCP



EICAS DISPLAY

TMCS - A/T OPERATION - FLIGHT LEVEL CHANGE

TMCS - A/T OPERATION - SPEED

Mode Selection

The speed (SPD) mode engages when all these conditions are true:

- Autothrottle arm switches on
- Airplane in the air more than 400 feet above ground level (AGL) BARO altitude
- Takeoff (TO) mode not active
- Go-around (GA) mode not active
- VNAV mode active in cruise
- Flight level change (FLCH) not active
- Select the A/T switch on the mode control panel (MCP)
- Default SPD selection (mode change from FLCH or VNAV).

Operation

The TMCF sends the A/T servo motor commands to move the throttles in the SPD mode to control the airplane speed. The control speed shows in the MCP speed window. The TMCF responds to speed window changes. Thrust limit, speed limit (Vmo/Mmo), and flap speed limit protection is active in this mode. The SPD mode can operate with or without an A/P pitch mode.

SPD shows as the A/T mode on the primary flight display (PFD).

The thrust limit mode climb (CLB) or continuous (CON) shows on the EICAS display when the airplane is in the air. Push the CLB/CON switch on the MCP to get the CLB thrust limit mode. Push the CLB/CON switch on the MCP to get the CON thrust limit mode when one engine fails.

CONDITION:
- MCP A/T SWITCH ACTIVE

22-31-00-017 Rev 2 05/14/1997

TMCS - A/T OPERATION - SPEED

TMCS - A/T OPERATION - GO-AROUND

Mode selection

The go-around (GA) mode engages when all these conditions are true:

- Autothrottle arm switches on
- Airplane in the air
- Glideslope active (engaged) or flaps not zero
- Thrust limit mode not takeoff (TO)
- Push either TO/GA lever.

Operation

The GA mode arms in approach when the flaps are down or glideslope is active. GA shows as the thrust limit mode on the EICAS display. Push any TO/GA lever to start the GA mode. The A/T mode annunciation goes to thrust (THR).

The TMCF commands the A/T servo motors (ASM) to move the throttles and control the airplane to 2000 feet per minute (FPM) vertical speed. Push any TO/GA lever again to start the full thrust GA mode. The A/T mode changes to thrust reference (THR REF). The TMCF commands the ASMs to move the throttles to the full GA thrust limit that shows on the EICAS display.

TMCS - A/T OPERATION - FLARE RETARD

THIS PAGE INTENTIONALLY LEFT BLANK

TMCS - TMCF FUNCTIONAL DESCRIPTION - INTRODUCTION

General

The thrust management computing function (TMCF) controls engine thrust in response to commands from the guidance function of the flight management computing function (FMCF), the mode control panel, and flight deck switches.

The TMCF sub-functions are:

- Thrust limit calculation
- Engine trim equalization
- Autothrottle (A/T)
- BITE and fault monitoring
- TMCF annunciations.

The TMCF uses digital and analog inputs from external sensors, digital and analog inputs from flight deck components, internal AIMS cabinet interface signals, and cross cabinet AIMS interface signals.

Thrust limit Calculation

The TMCF calculates maximum thrust and thrust limits for these thrust limit modes:

- Takeoff (TO) thrust
- Go-around (GA)
- Climb (CLB)
- Continuous (CON)
- Cruise (CRZ)
- Temperature derated TO
- Fixed derated TO and CLB.

The TMCF uses these inputs to calculate thrust limits:

- Temperature
- Barometric altitude
- Barometric pressure
- Engine/airframe data bases
- Thrust model data base
- Flight deck inputs
- Air/ground.

The thrust limits show on the EICAS display.

Engine Trim Equalization

The TMCF calculates engine trim commands to decrease the thrust difference between the engines. The trim function receives actual engine thrust data from each engine to do this. The incremental engine trim command goes to the EECs to change the engine thrust.

Autothrottle (A/T)

The A/T sub-function sets the thrust levers to capture and hold a thrust setting, or to hold a target airspeed.

To calculate the A/T function, the TMCF uses these:

- Engage logic
- Control Laws
- Mode logic.

The A/T uses inputs from these sources:

- External sensor inputs
- Flight deck switches and sensors inputs
- Flight phase logic inputs
- FMCF thrust, mode, and guidance request inputs
- Internal and cross-cabinet AIMS inputs.

The engage logic determines the validity of the control law data and permits the software control laws to operate. The engage logic also sends logic that permits excitation voltage to the A/T servo motor (ASM). This permits the ASM to operate when it receives a command from the TMCF.

The control laws calculate the A/T command. It looks at the desired command and the actual airplane condition for that command. The error from these two is the error command.

The mode logic lets allows manual or automatic selection of the available autothrottle mode, thrust limit mode, and thrust limits. The A/T mode, thrust limit mode, and thrust limits show on the PFD and EICAS display.

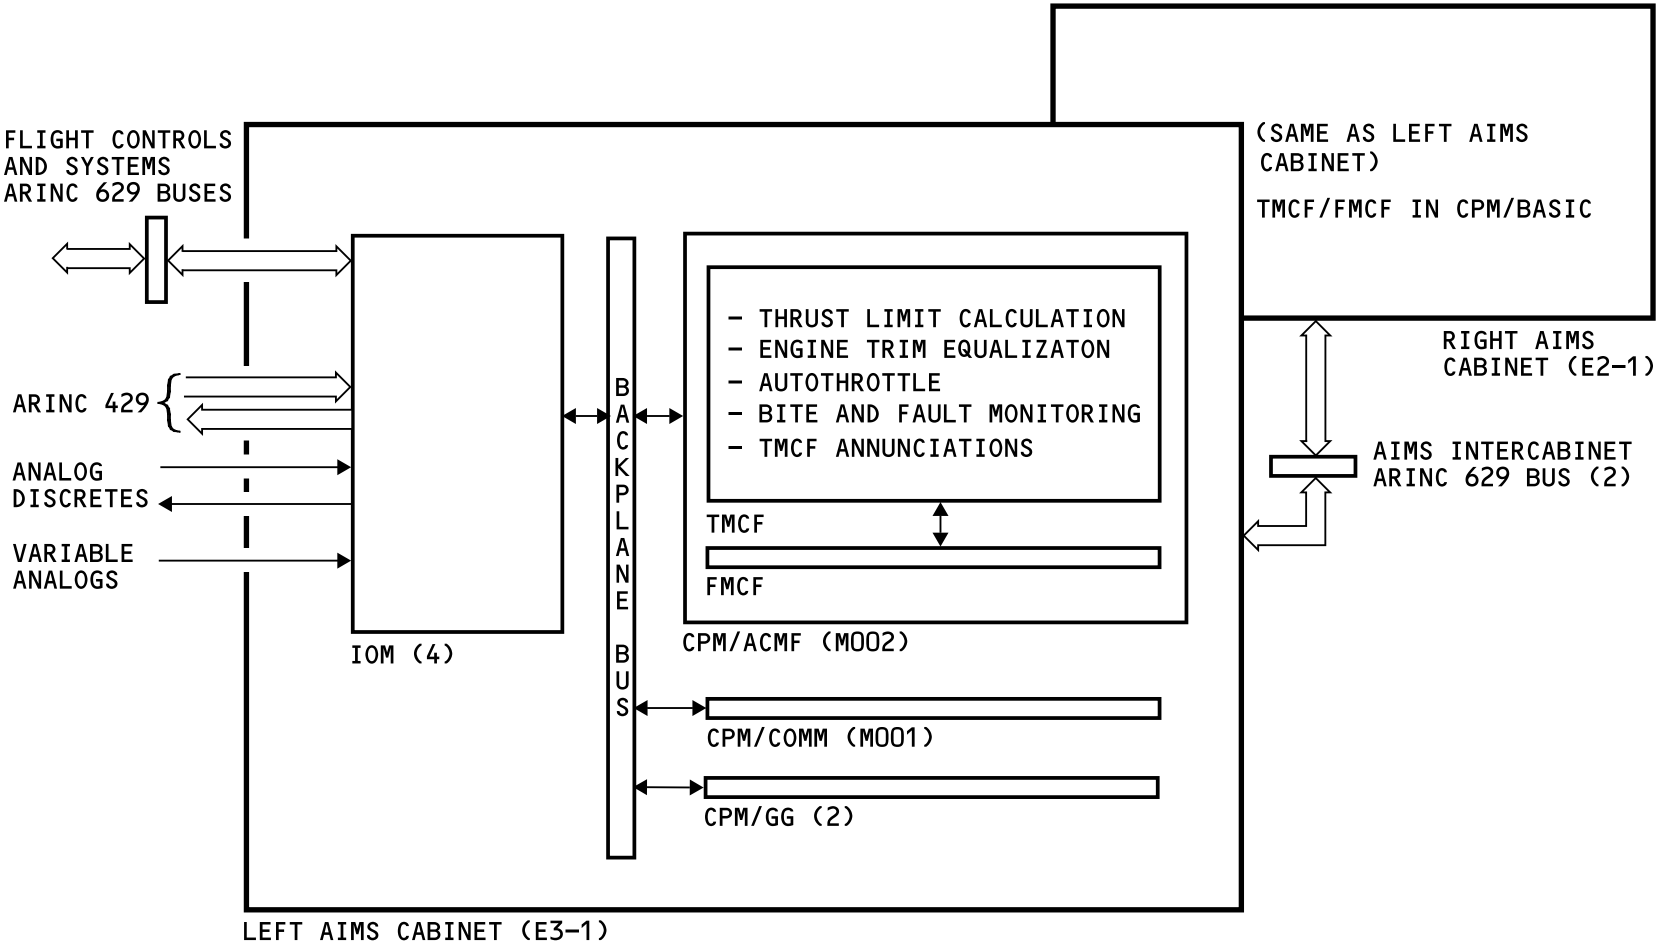
BITE and Fault Monitoring

The TMCF BITE circuits do tests at power-up and throughout the TMCF operation. When the fault monitor circuits receives a test failure from the BITE, it writes the faults in the TMCF memory and sends the faults to the PDF (primary display function) and the central maintenance computing function (CMCF).

TMCF Annunciations

These annunciations go to the primary display function for the PFD and EICAS display:

- A/T modes
- Thrust limits
- Thrust limit modes
- Fault messages.



22-31-00-020 Rev 3 05/14/1997

TMCS - TMCF FUNCTIONAL DESCRIPTION - INTRODUCTION

TMCS - TMCF FUNCTIONAL DESCRIPTION - ENGAGE LOGIC

General

The A/T engage logic process monitors the TMCF parameters for A/T mode engage. The TMCF sends an analog enable discrete to the A/T servo motors (ASM) when conditions are valid. The logic also generates ASM commands and an autothrottle disconnect signal.

Servo Loop Monitor

When the A/T engages, the control law sends rate commands to the ASMs. The ASMs send rate feedback (low speed tachometer data) to the TMCFs. The servo loop monitor compares these two signals and sets the inhibit logic when they do not agree. This causes the ASMs to disconnect. BITE (TMCF and ASM) failures also set the inhibit.

Autothrottle Disconnect

When the A/T disconnects automatically or manually, the AUTHROTTLE DISC caution message shows on the engine primary format display. BITE sets the A/T disconnect. Push an A/T disconnect switch to cause a manual A/T disconnect.

The A/T also disconnects on the ground when the flight crew applies reverse thrust. In this case, there is no A/T disconnect message or caution aural.

The AUTHROTTLE DISC is a caution message that causes the master caution lights to come on and an aural four beep alert to sound in the flight deck.

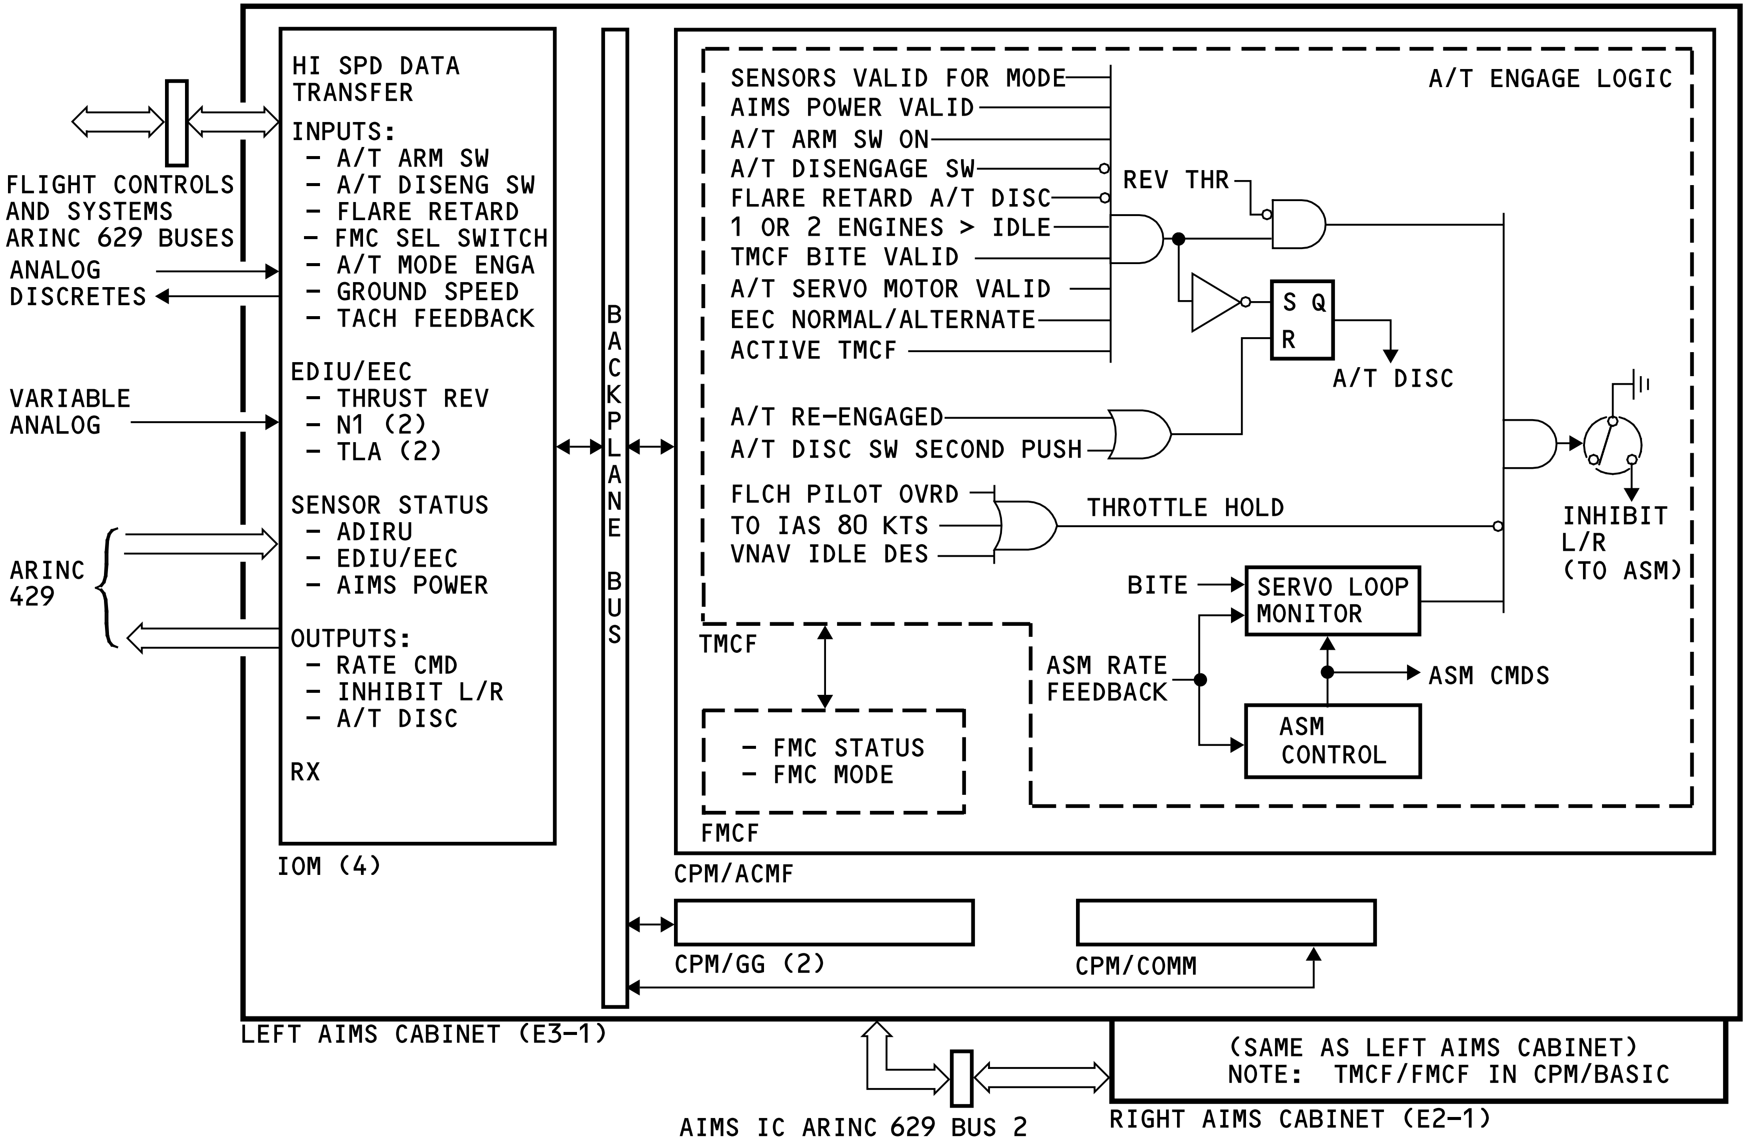
Inhibit L/R

The active TMCF causes the ASMs to disconnect when it sets the left and right inhibit switches.

TMCF Selection

The TMCF selection is similar to the FMCF selection. Use the FMC selector to make the left or right TMCF active.

The FMC selector is a three position switch, LEFT, AUTO and RIGHT. In the LEFT position, the left TMCF and FMCF are active. If the left TMCF fails, then there is no active TMCF. In the AUTO position, a random selection of the active TMCF and FMCF occurs after power is supplied. If the active TMCF fails, then the other TMCF becomes active. In the RIGHT position, the right TMCF and FMCF are active. If the right TMCF fails, then there is no active TMCF.



TMCS - TMCF FUNCTIONAL DESCRIPTION - ENGAGE LOGIC

TMCS - FUNCTIONAL DESCRIPTION - A/T SERVO MOTOR

General

These are the functions of the autothrottle servo motor (ASM):

- ARINC 429 rate command decoding
- Tachometer and power feedback decoding
- Enable/disable logic
- Inner loop servo motor rate control.

The (ASM) has these components:

- Power supply unit (PSU)
- Power Switching Module (PSM)
- Electronic control module (ECM)
- DC motor.

Power Supply Unit

The PSU provides internal power for the ECM and the PSM.

Power Switching Module

The PSM has a series of enable switches that send an output to a power switching bridge. These switch inputs are based on these inputs to the input controller:

- Left and right arm from the MCP
- Left TMCF and right TMCF inhibit
- Left, right or auto from the FMC selector.

The output to the power switching bridge lets the bridge process the drive signals.

The enable switches also send an output to the ECM.

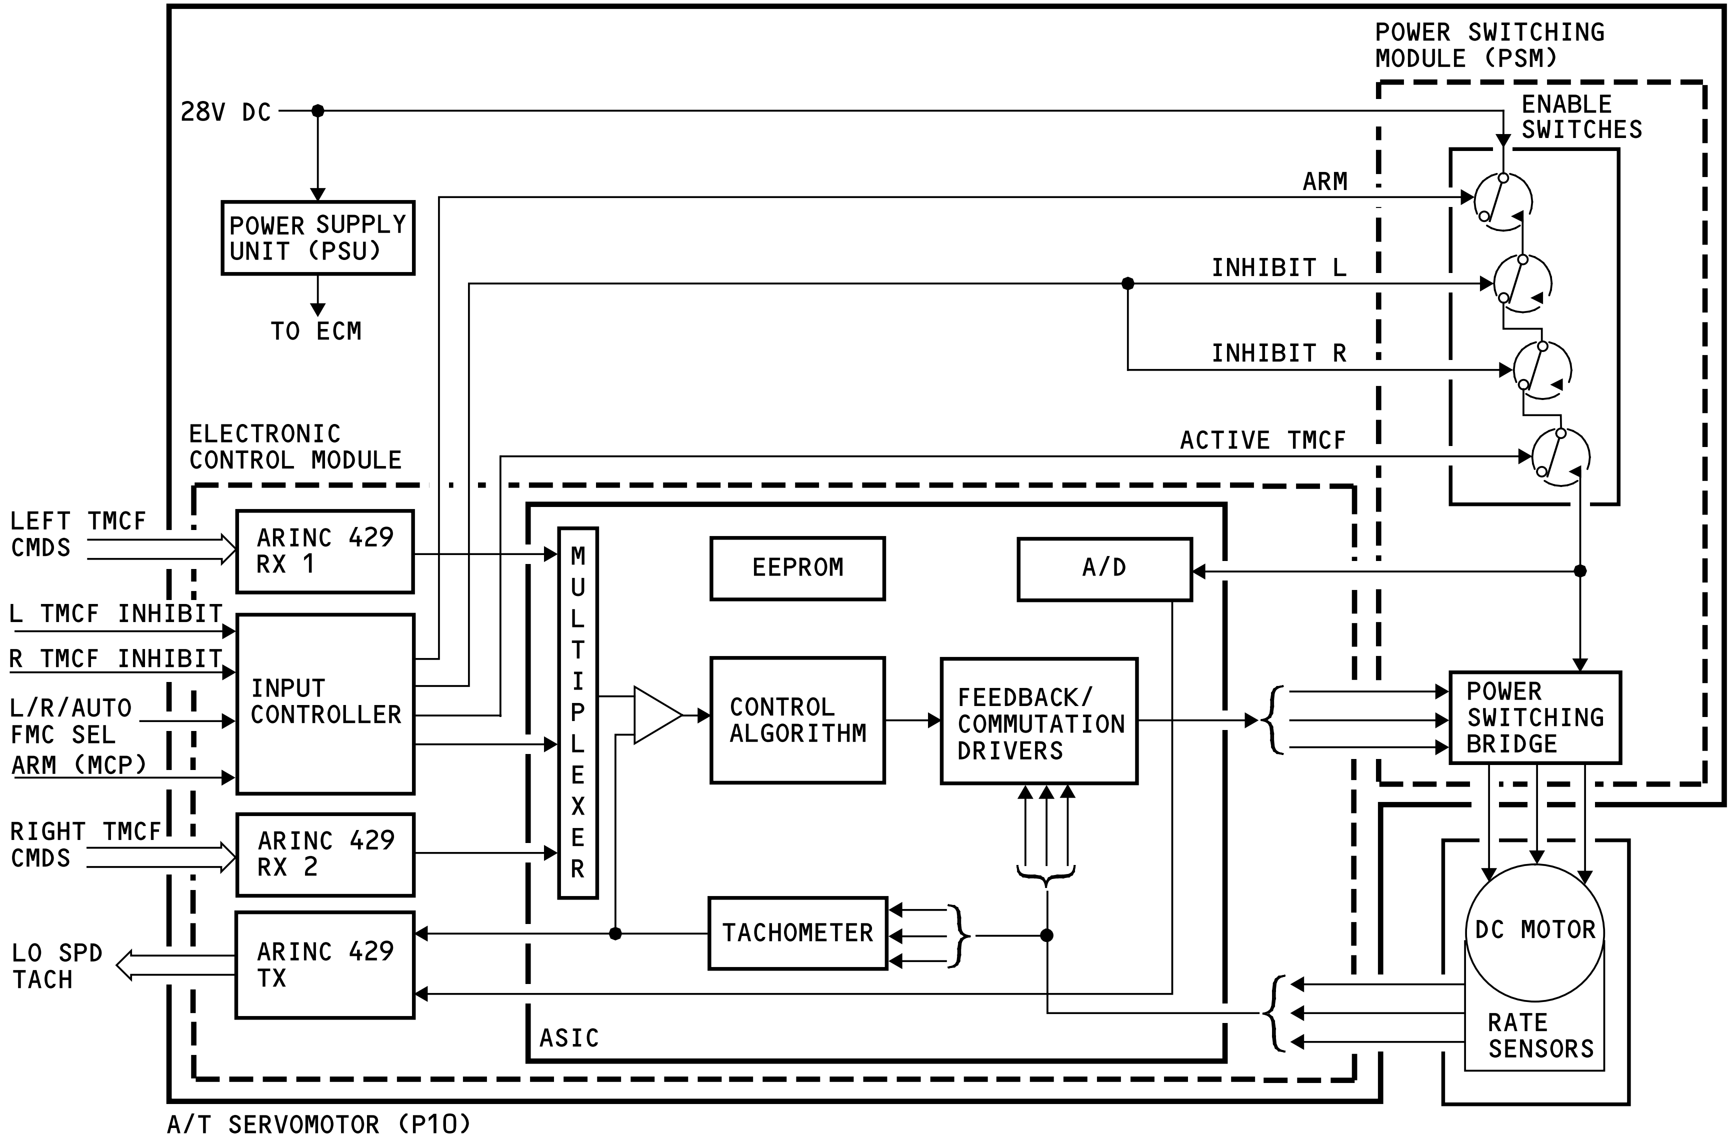
Electronic Control Module

The ECM contains the circuitry to calculate the drive commands for the DC motor. The ECM gets inputs through the ARINC 429 receivers and the input controller and gets feedback signals from the rate sensors of the DC motor.

DC Motor

The DC motor is a 28 VDC brushless motor. The output shaft of the motor connects to a gearbox. The gearbox connects to the throttle lever assembly.

The motor also has a friction brake/clutch assembly that lets a pilot manually override the throttle lever.



TMCS - FUNCTIONAL DESCRIPTION - A/T SERVO MOTOR

22-31-00-024 Rev 4 07/09/1997

THIS PAGE INTENTIONALLY LEFT BLANK

TMCS - TMCF FUNCTIONAL DESCRIPTION - BITE AND FAULT MONITORING

General

The TMCF has internal and external fault monitors. The TMCF records BITE faults into TMCF memory. It sends faults to the central maintenance computing function (CMCF) and causes fault messages to show on the EICAS display. BITE logic removes the A/T and thrust limit modes when TMCF BITE detects an internal or external failure.

Internal Fault Monitors

The TMCF does these checks:

- Compatibility
- Miscomparisons
- Active TMCF selection
- Cross cabinet synchronization checks.

The TMCF does these checks when the core processor module (CPM) and cabinet level BITE is valid, the back plane bus is valid, and the input/output (I/O) modules are valid.

The TMCF does these compatibility checks:

- Operational program software (OPS)/hardware
- Engine/airframe
- Operational program configuration (OPC)/OPS
- Engines/ratings
- Ratings/thrust limit data base (TLDB)
- Left and right engine ratings disagree.

The TMCF stores BITE disagree data into BITE history. With a BITE disagree, the TMCF causes all outputs to go invalid and prevents thrust limit calculation (TLC) and autothrottle engage.

At power up, the TMCF does these cross-cabinet miscomparison checks:

- OPS
- Engine/airframe data bases
- OPC
- TLC database.

When a disagree occurs, the TMCF BITE stores each miscompare in BITE history and the TMCF operation shuts down.

AIMS Cross-Cabinet Synchronization

Continuous cross-cabinet synchronization occurs between the active and inactive TMCF. This ensures common modes of operation, A/T commands, and engine trim commands do not change when there is a master TMCF transfer.

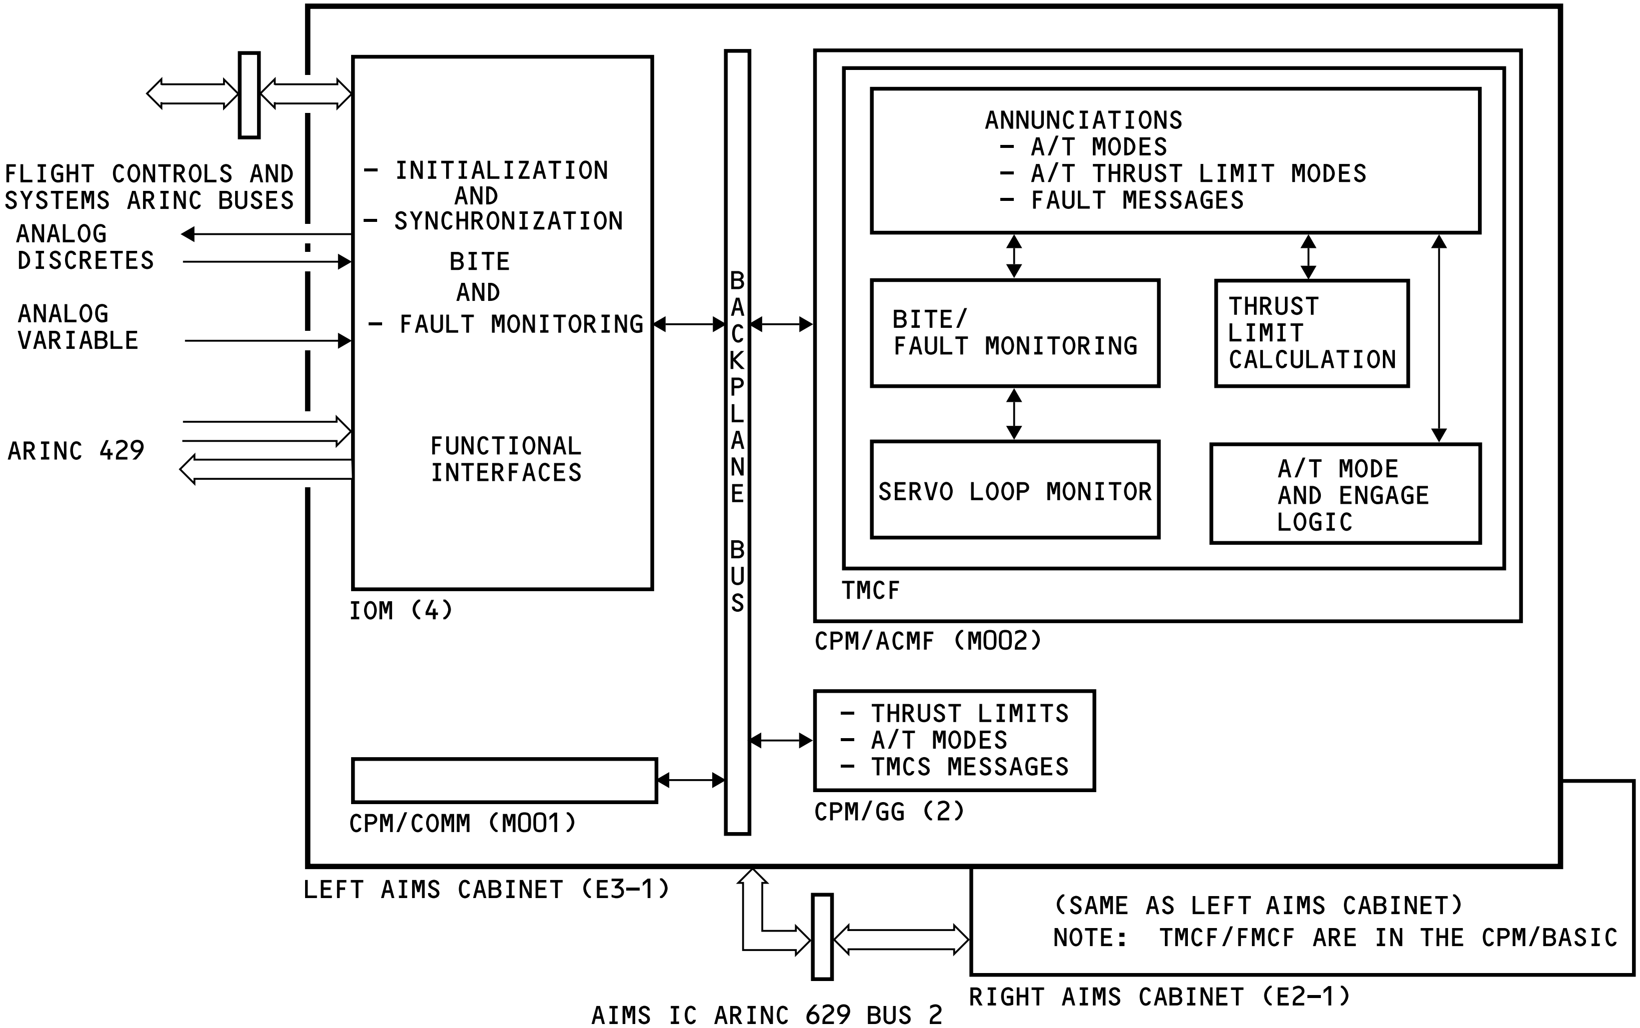
External Fault Monitors

The TMCF also monitors these external interfaces for the autothrottle ASMs:

- Servo
- Power removal or no power
- Tachometer feedback, scheduled or zero
- Servo rate within 2 degrees/second

TMCS - TMCF FUNCTIONAL DESCRIPTION - BITE AND FAULT MONITORING

- Stopper, detects inability to remove power from servo during takeoff less than 50 knots.



TMCS - TMCF FUNCTIONAL DESCRIPTION - BITE AND FAULT MONITORING

TMCS - SYSTEM TESTS

General

These are the servo loop system tests for the left and right TMCF:

- Left cabinet servo loop test
- Right cabinet servo loop test.

Servo Loop Test

The servo loop test makes sure that the TMCF in the left and right AIMS and the autothrottle servomotors operate correctly.

The thrust levers on the P10 control stand move during the test.

This test examines the integrity of each autothrottle servomotor's rate drive. It also tests the ability of the TMCF to remove power from the servos.

The test has four steps. The first step is the initial command. The initial command has a TLA rate of -8 degrees/second for 7 seconds and brings the throttles aft to the mechanical stop. There is no pass/fail.

The second step is the throttle stopper test. This test runs the throttle stopper to verify that the TMCF can remove power from the servos and that the servos do not drive as determined by the tach feedback.

The third step is the forward command. This test has a TLA rate of 8 degrees/second for 5 seconds. During the throttle movement, the average tach feedback for both must be between 6 and 10 degrees/second.

The fourth step is the reverse command. This test has a TLA rate of -8 degrees/second for 5 seconds. During the throttle movement, the average tach feedback for both must be between -6 and -10 degrees/second.

The TMCF provides pass/fail information for each servo to show on the MAT.

Flight Controls - Introduction

WB371

TABLE OF CONTENTS

FLIGHT CONTROLS - INTRODUCTION

General

The flight controls keep the airplane at the desired attitude during flight. They consist of movable surfaces on the wing and the empennage. The flight controls change the lift of the wing and the empennage.

There are two types of flight controls: the primary flight control system and the high lift control system.

Primary Flight Control System

The primary flight control system (PFCS) uses a fly-by-wire control system with digital and analog electronic equipment. It receives commands from the flight crew and the autopilot and causes the control surfaces to move.

The PFCS controls the attitude of the airplane during flight. The control surfaces operated by the PFCS are:

- One aileron on each wing
- One flaperon on each wing
- Seven spoilers on each wing
- One horizontal stabilizer
- One elevator on each side of the horizontal stabilizer
- One tabbed rudder.

High Lift Control System

The high lift control system (HLCS) uses a fly-by-wire control system with digital electronic equipment. It receives commands from the flight crew and causes the flaps and slats to move.

Operation of the HLCS increases the wing lift so the airplane can takeoff and land at lower speed and higher weight. The high lift devices operated by the HLCS are:

- Seven leading edge slats on each wing
- One Krueger flap on each wing
- One single slotted outboard flap on each wing
- One double slotted inboard flap on each wing.

Operation of the HLCS also causes the ailerons and the flaperons to move. They droop on both wings when the high lift devices extend.

Benefits of the Fly-By-Wire System

The fly-by-wire design of the flight controls permits:

- A more efficient structure design
- Increased fuel economy
- A smaller vertical fin
- A smaller horizontal stabilizer
- Reduced weight
- Improved controls and protections.

FLIGHT CONTROLS - INTRODUCTION

PRIMARY FLIGHT CONTROL SYSTEM - INTRODUCTION

Purpose

The primary flight control system (PFCS) controls the airplane flight attitude in relation to the three basic axes:

- Longitudinal
- Lateral
- Vertical.

Roll Control

The roll control uses the ailerons, flaperons, and spoilers to control the airplane attitude about the longitudinal axis. During a bank of the airplane, the aileron and flaperon on one wing move in an opposite direction from the aileron and flaperon on the other wing. The spoilers move up only on the down wing and do not move on the up wing.

Pitch Control

The pitch control uses the horizontal stabilizer and the elevator to control the airplane attitude about the lateral axis. The stabilizer controls long term pitch changes. The elevator supplies short term pitch control.

Yaw Control

The yaw control uses the rudder to control the airplane attitude about the vertical axis. The rudder has a tab which moves to increase the effectiveness of the rudder.

Speedbrakes

The PFCS also includes the speedbrakes. In addition to roll control, the spoilers also act as speedbrakes in the air and on the ground. They deploy on both wings to increase drag and to decrease the amount of lift the wings supply.

PRIMARY FLIGHT CONTROL SYSTEM - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

PFCS - GENERAL DESCRIPTION

General

The pilots or the autopilot commands control the PFCS. The pilots can override the autopilot.

Manual Operation

Position transducers change the pilots' manual commands of the control wheel, the control columns, the rudder pedals, and the speedbrake lever to analog electrical signals. These signals go to the four actuator control electronics (ACEs). The ACEs change the signals to digital format and send them to the three primary flight computers (PFCs).

The PFCs have interfaces with the airplane systems through the three flight controls ARINC 629 buses. In addition to command signals from the ACEs, the PFCs also receive data from:

- The airplane information management system (AIMS)
- The air data inertial reference unit (ADIRU)
- The secondary attitude air data reference unit (SAARU).

The PFCs calculate the flight control commands based on control laws and flight envelope protection functions. The control laws supply stability augmentation in the pitch and yaw axes and flight envelope protections in all three axes. The digital command signals from the PFCs go to the ACEs.

The ACEs change these command signals to analog format and send them to the power control units (PCUs) and the stabilizer trim control modules (STCMs). The ACEs and the PCUs form control loops which control the surfaces based on the PFCs commands.

One, two or three PCUs operate each control surface. One PCU controls each spoiler, two PCUs control each aileron, flaperon, and elevator, and three PCUs control the rudder. The PCUs contain a hydraulic actuator, an electrohydraulic servo valve, and a position feedback transducer.

When commanded, the servo valve causes the hydraulic actuator to move the control surface. The position transducer sends a position feedback signal to the ACEs. The ACEs then stop the PCU command when the position feedback signal equals the commanded position.

Two STCMs control hydraulic power to the motors and brakes of the horizontal stabilizer.

Autopilot Operation

The PFCs receive autopilot commands from all three autopilot flight director computers (AFDCs). The PFCs use the autopilot commands in the same manner as the pilots' manual commands. In addition, the PFCs supply the backdrive signals to the backdrive actuators through the AFDCs. The backdrive actuators move the control wheels, control columns, and rudder pedals in synchronization with the autopilot commands. The movement of the flight deck controls supplies visual indications to the flight crew.

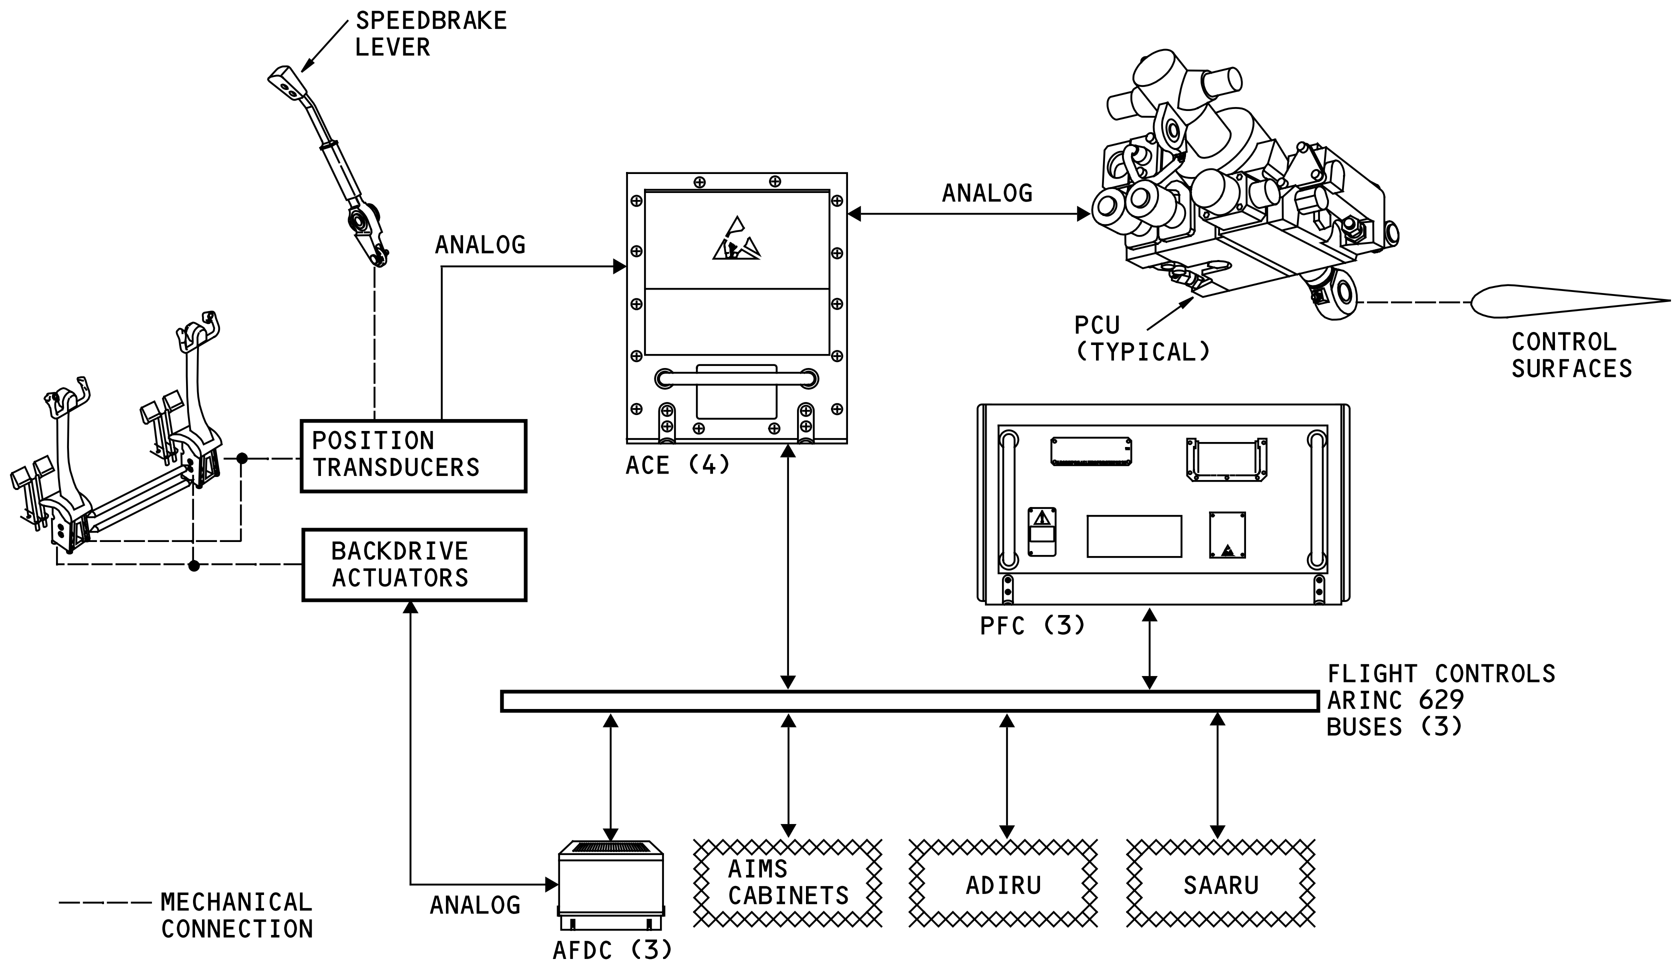
PFCS Modes of Operation

The PFCS has three modes of operation: normal, secondary, and direct.

Normal mode operates when the necessary data are available for the PFCs and the ACEs. All the control laws, protection functions, and the AFDCs operate.

When the PFCS detects the loss of important air and attitude data, the PFCS operation changes to secondary mode. The PFCs and the ACEs operate but the PFC control laws and protection functions downgrade. The autopilot cannot operate in secondary mode.

In direct mode, the PFCs are not used. The ACEs set the position of the control surfaces in direct response to analog pilot control inputs.



27-02-00-002 Rev 4

PFCS - GENERAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

PFCS - PFC CONTROL LAWS - FUNCTIONAL DESCRIPTION

General

The PFCs software includes the flight control laws. They calculate the control surface commands to set the desired airplane stability and control. The calculation uses data inputs from the pilots, the autopilot, and other data from the air and inertial sensing systems.

The PFCs calculate control commands for:

- The ailerons, flaperons and spoilers for roll control
- The ailerons and some spoilers for lockout during cruise
- The ailerons and flaperons for droop control during flap extension
- The spoilers during speedbrake control in flight and on the ground
- The elevators for pitch control
- The elevator feel actuator
- The stabilizer for elevator offload (long term pitch trim), column cutout, and stabilizer auto shutdown
- The rudder for yaw control, yaw damping, rudder ratio, and wheel-rudder cross-tie
- The rudder trim actuator.

The control laws also include stability augmentation and protection functions.

Stability Augmentation

There is a stability augmentation function for the pitch and yaw control. Stability augmentation controls the airplane attitude to simulate the natural reaction of the airplane that the pilots expect.

The control laws calculate yaw damping and turn coordination commands. A gust suppression function makes the ride quality better and reduces the pilots' work load.

In pitch stability augmentation, the PFCs use the control laws to calculate the elevator control commands for speed stability and flare compensation.

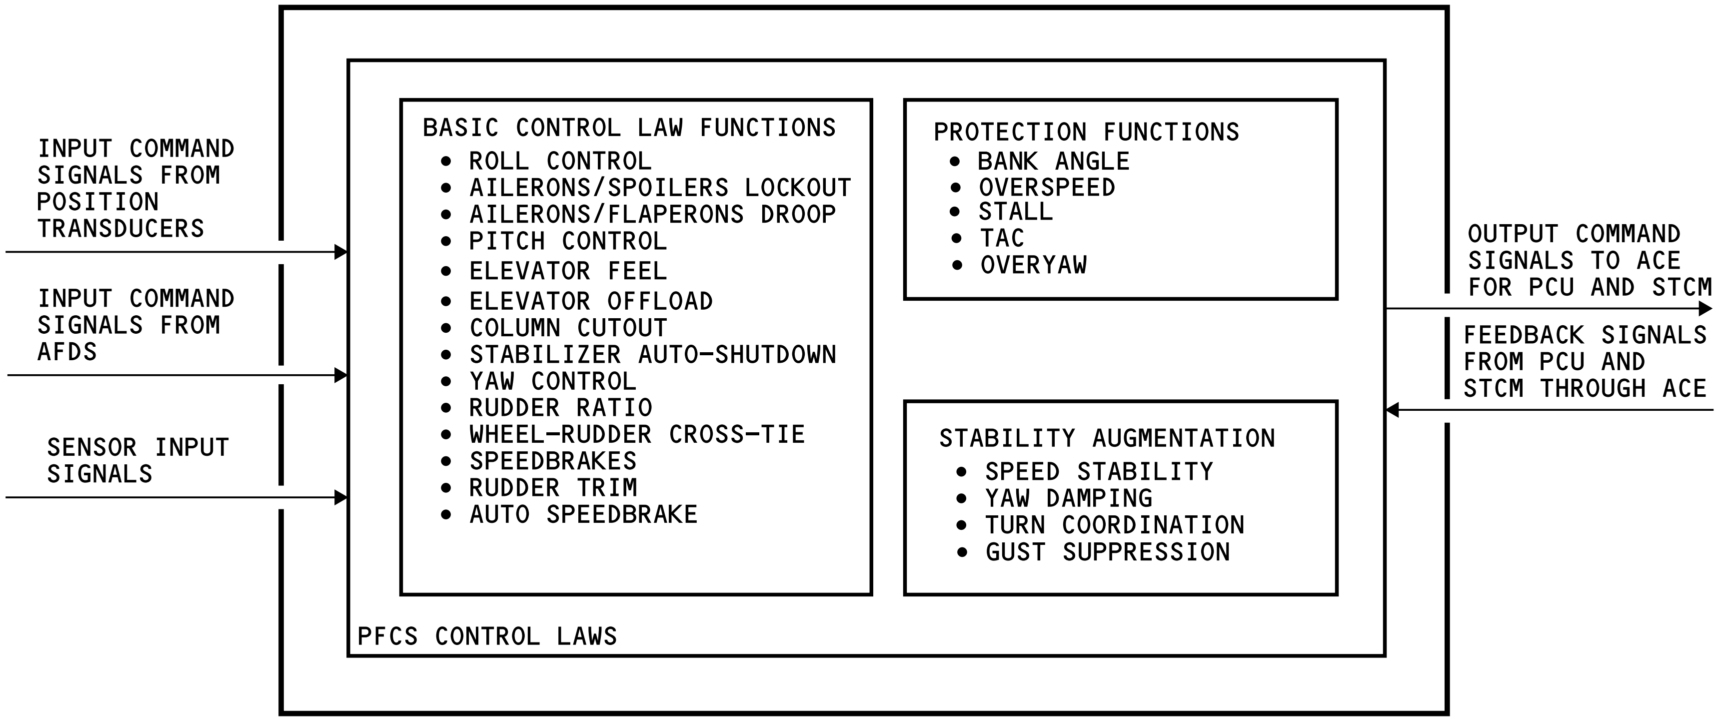
Protection Functions

The control laws contain several different limits to supply flight envelope protection in the three axes of control. The PFCs calculate protection functions for:

- Bank angle
- Overspeed
- Stall
- Thrust asymmetry compensation
- Overyaw.

The bank angle protection supplies a roll command opposite to the bank. The overspeed protection supplies a pitch up command when the speed is more than the maximum. The stall protection supplies a pitch down command. The thrust asymmetry compensation (TAC) automatically controls the rudder movement to make allowance for asymmetrical thrust from the engines. The overyaw protection operates through the wheel-rudder cross-tie function to decrease the yaw command.

The bank angle and the stall protections supply more resistive force to the controls. The pilots can override the protection functions when they move the controls more than the limit. There is no increased force on the controls for the other protection functions.



PRIMARY FLIGHT COMPUTER (TYPICAL)

27-02-00-013 Rev 4

PFCS - PFC CONTROL LAWS - FUNCTIONAL DESCRIPTION

PFCS - OPERATIONAL MODES - FUNCTIONAL DESCRIPTION

General

These are the three modes of PFCS operation:

- Normal
- Secondary
- Direct.

During the PFCS normal and secondary mode operation, both the PFCs and the ACEs are in operation. In the secondary mode, the PFC's operation downgrades. During the direct mode, only the ACEs operate in response to direct analog inputs.

The PFCS selects the mode of operation. On the ground with ground speed less than 40 knots, the PFCs automatically select the highest mode available based on the inputs from the ADIRU and SAARU. In flight, the pilots cycle the PFC disconnect switch on the P5 panel, or move it back to the AUTO position to cause the selection of the highest mode available.

During PFCS mode changes, there is a smooth change to the new commands.

Normal Mode

The PFCS selects the normal mode when all these conditions are met:

- The PFC disconnect switch, on the P5 panel, is in the AUTO position
- The needed input data is available
- At least one PFC and three ACEs are in normal mode.

All the control laws, the protection functions, and the stability augmentation of the PFCs are active in the normal mode. The autopilot operates only in normal mode.

Secondary Mode

The PFCS selects the secondary mode when it detects the loss of important air and attitude sensor data from both the ADIRU and the SAARU. The PFCS also selects the secondary mode when two ACEs are in direct mode.

A simplified set of control laws operate the PFCS in secondary mode. The protection functions are not available. Gain schedules and limits are a function of flap data discretes from the ACEs. Pitch stability augmentation uses pitch rate data from the ACEs. Yaw damper augmentation uses inertial data from the ADIRU and the SAARU if available.

Direct Mode

The PFCS selects the direct mode when there are failures that make the normal and secondary modes unreliable. If three ACEs are in direct mode, the PFCS switches the last ACE to the direct mode. The PFC disconnect switch also causes the selection of the direct mode.

The PFCs do not control the surfaces in the direct mode. Position transducer signals from the control wheels, columns and pedals go directly to the ACEs which use them to control the PCUs. The protection functions are not available.

When the PFCS is in direct mode, whether automatically or manually, the DISC amber light shows next to the PFC disconnect switch.

Manual Switching

The PFCS goes to the direct mode of operation when the pilots move the PFC disconnect switch to the DISC position.

If the pilots cycle the PFC disconnect switch or move it again to the AUTO position, the PFCS goes from the direct mode to the highest mode available. The PFCS selects the mode based on the validity of available data.

If the PFCS is in the secondary or direct modes and the normal mode becomes available, the PFCS may select the normal mode. To do this in the air, you must cycle the PFC disconnect switch. If the airplane is on the ground and ground speed is less than 40 knots, then the PFCS selects the normal mode automatically.

Indications

The EICAS caution message FLIGHT CONTROL MODE shows when the PFCS is in secondary mode.

The EICAS caution message PRI FLIGHT COMPUTERS shows when all ACEs under power are in direct mode and the PFC is not in the hydraulic OFF self-test mode.

On the status display, the status message FLIGHT CONTROL SYS shows when the PFCS does not operate at minimum dispatch requirement levels. This message shows because of one or more of these faults:

- Failure of a column, wheel, pedal, or speedbrake lever position transducer
- Failure of a rudder, elevator, aileron, flaperon, or spoiler PCU
- Failure of a STCM
- Failure of an elevator feel actuator
- Failure of a PFC and at least one lane in another PFC
- Failure of an ACE or at least one ACE is in direct mode
- Failure of the stabilizer control
- Failure of the actuator confidence test
- Failure of a PSA, a flight controls ARINC 629 bus, or a WES channel.

The EICAS caution message FLIGHT CONTROLS shows when the flight control system has lost substantial capabilities. Any one of these faults causes the message to show:

- The stabilizer is not operative
- Two elevator PCUs and one stabilizer path are not operative

PFCS - OPERATIONAL MODES - FUNCTIONAL DESCRIPTION

- The wheel, column, or pedal position transducers for the captain and first officer disagree by more than 15 percent of full range with the airplane on the ground
- The elevator force fight equalization function is defective.

TABLE OF CONTENTS

TABLE OF CONTENTS

AUTOPILOT FLIGHT DIRECTOR SYSTEM - INTRODUCTION

General

The autopilot flight director system (AFDS) has two purposes. These purposes are:

- To automatically control the airplane attitude
- To supply indications so the flight crew can manually control the airplane attitude.

The flight crew uses the mode control panel (MCP) to select a mode of operation.

Autopilot

The autopilot controls the airplane attitude through:

- Takeoff (flight director only)
- Climb
- Cruise
- Descent
- Approach
- Go-around
- Autoland.

The autopilot commands go to the primary flight computers (PFCs) to operate the flight control surfaces.

Flight Director

When the flight director switches are on, the flight director command bars show on the primary flight displays (PFDs). The flight crew uses the flight director bars as guides to control the attitude of the airplane.

AUTOPILOT FLIGHT DIRECTOR SYSTEM - INTRODUCTION

AFDS - GENERAL DESCRIPTION

Pilot Interface

The mode control panel (MCP) is the primary interface between the pilot and the autopilot flight director computers (AFDCs).

Other pilot inputs to the AFDCs are the disconnect switches and the go-around (GA) switches.

Sensors

Sensors supply the AFDCs with this information:

- Transducer positions
- Inertial data
- Atmospheric data
- Ground reference data
- Airplane accelerations
- Velocities
- Attitudes.

These are the types of sensors:

- Airplane sensors
- Navigation sensors
- Air data sensors (ADIRU and SAARU).

Aircraft Information Management System (AIMS) Interface

The flight management computer function (FMCF) sends LNAV and VNAV data to the AFDCs.

The thrust management computer function (TMCF) sends autothrottle data to the AFDCs.

The primary display function receives AFDS display data.

Primary Flight Control System (PFCS)

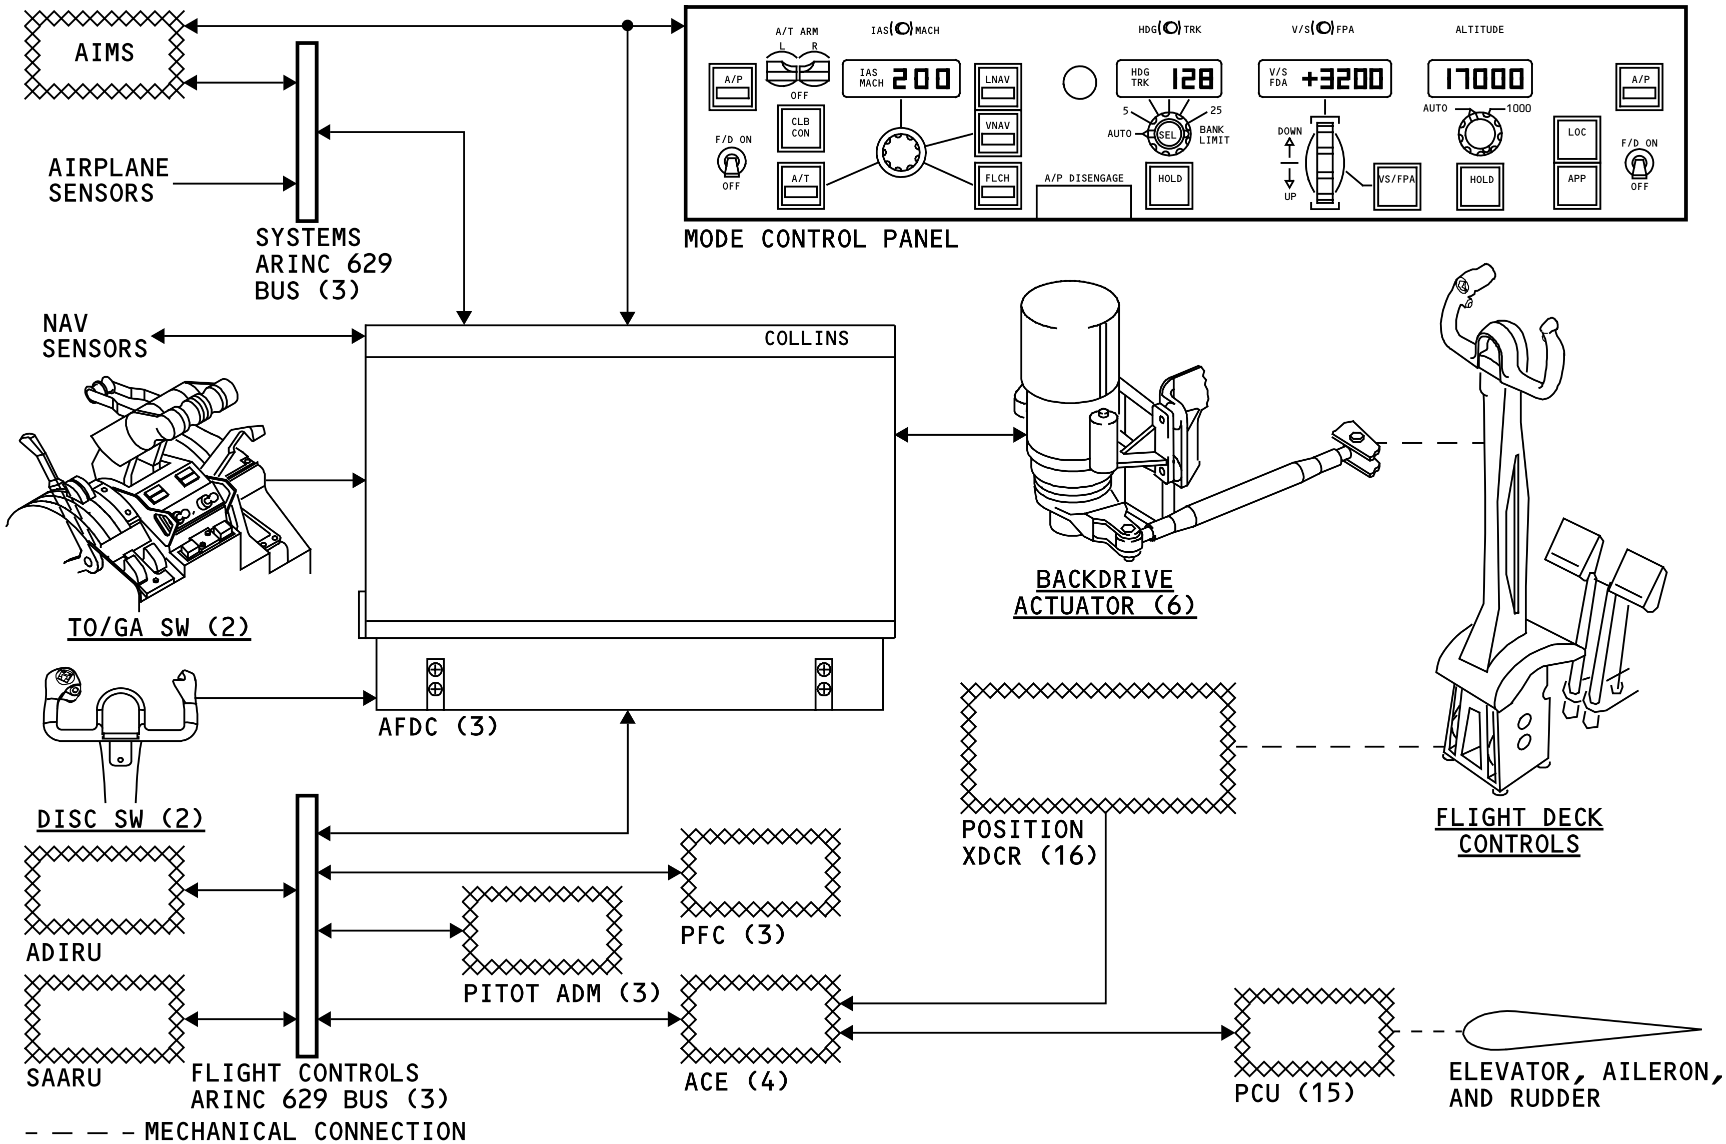
The primary flight computers (PFCs) receive commands from the AFDCs. The PFCs calculate and send surface position commands to the actuator control electronics (ACE).

The ACEs receive surface position commands from the PFCs. The ACEs send commands to the surface power control units (PCU). The PCUs move the surface.

The PFCs also calculate and send backdrive commands to the AFDCs.

Backdrive Actuators

The AFDCs receive backdrive actuator commands from the PFCs. The AFDCs send backdrive commands to the backdrive actuators. The actuators cause the control wheels, control columns, and rudder pedals to move.



AFDS - GENERAL DESCRIPTION

AFDS - FLIGHT DECK COMPONENT LOCATIONS

AFDS Component Locations In The Flight Deck

The AFDS components in the flight deck are:

- The mode control panel (MCP)
- The takeoff/go-around (TO/GA) switches
- The autopilot disconnect switches.

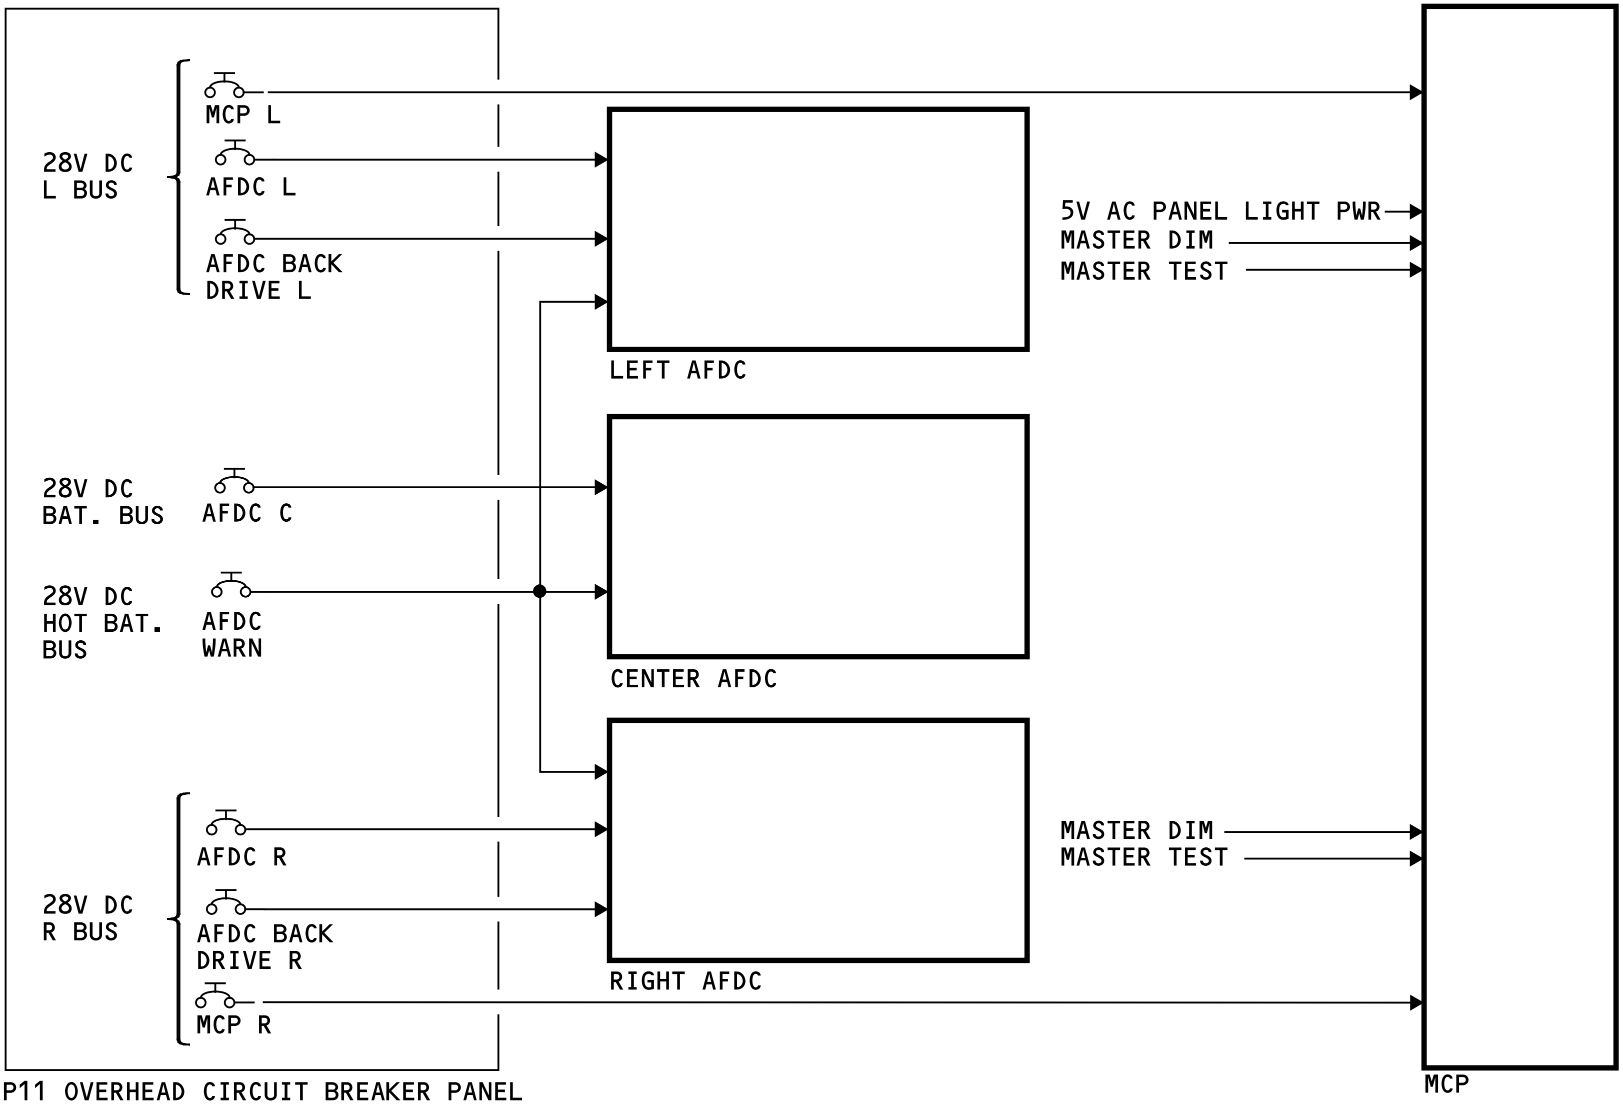
AFDS - POWER INTERFACE

AFDS - Power Distribution

The left and right 28V DC buses supply AFDC and backdrive power to their onside AFDCs and the MCP. The 28V DC battery bus supplies AFDC power to the center AFDC. The hot battery bus supplies a second source of power to the warning function of each AFDC.

The MCP lights receive 5 VAC panel light power. Signals from the master dim and test system control the brightness of the panel lights.



AFDS - POWER INTERFACE

AFDS - SYSTEMS ARINC 629 BUS INTERFACE

Systems ARINC 629 Buses

Each AFDC uses the onside systems bus to transmit and receive data.

AIMS Information

Each AIMS cabinet transmits vertical navigation (VNAV) and lateral navigation (LNAV) data to all three buses.

Each control display unit (CDU) transmits and receives LNAV data from the left and right buses.

Flap Slat Electronics Unit (FSEU)

The FSEUs send flap position and slat position data to the AFDCs. The left FSEU transmits to the left and center buses, the right FSEU transmits to the center and right buses.

Proximity Sensor Electronics Unit (PSEU)

The PSEUs send nose gear and nose gear door position information to the AFDCs. The left PSEU transmits to the left and center buses, the right PSEU transmits to the center and right buses.

Weight-on-Wheels (WOW) Cards

The WOW cards are part of the air/ground system (AGS). They transmit WOW data to the left and right buses. The center AFDC receives WOW data from the AFDC cross channel data buses.

Overhead Panel ARINC 629 System (OPAS)

The OPAS sends heading reference switch data to the AFDCs. The left OPAS controller transmits on the left and right buses. The right OPAS controller transmits on the left and right buses.

Electrical Power System

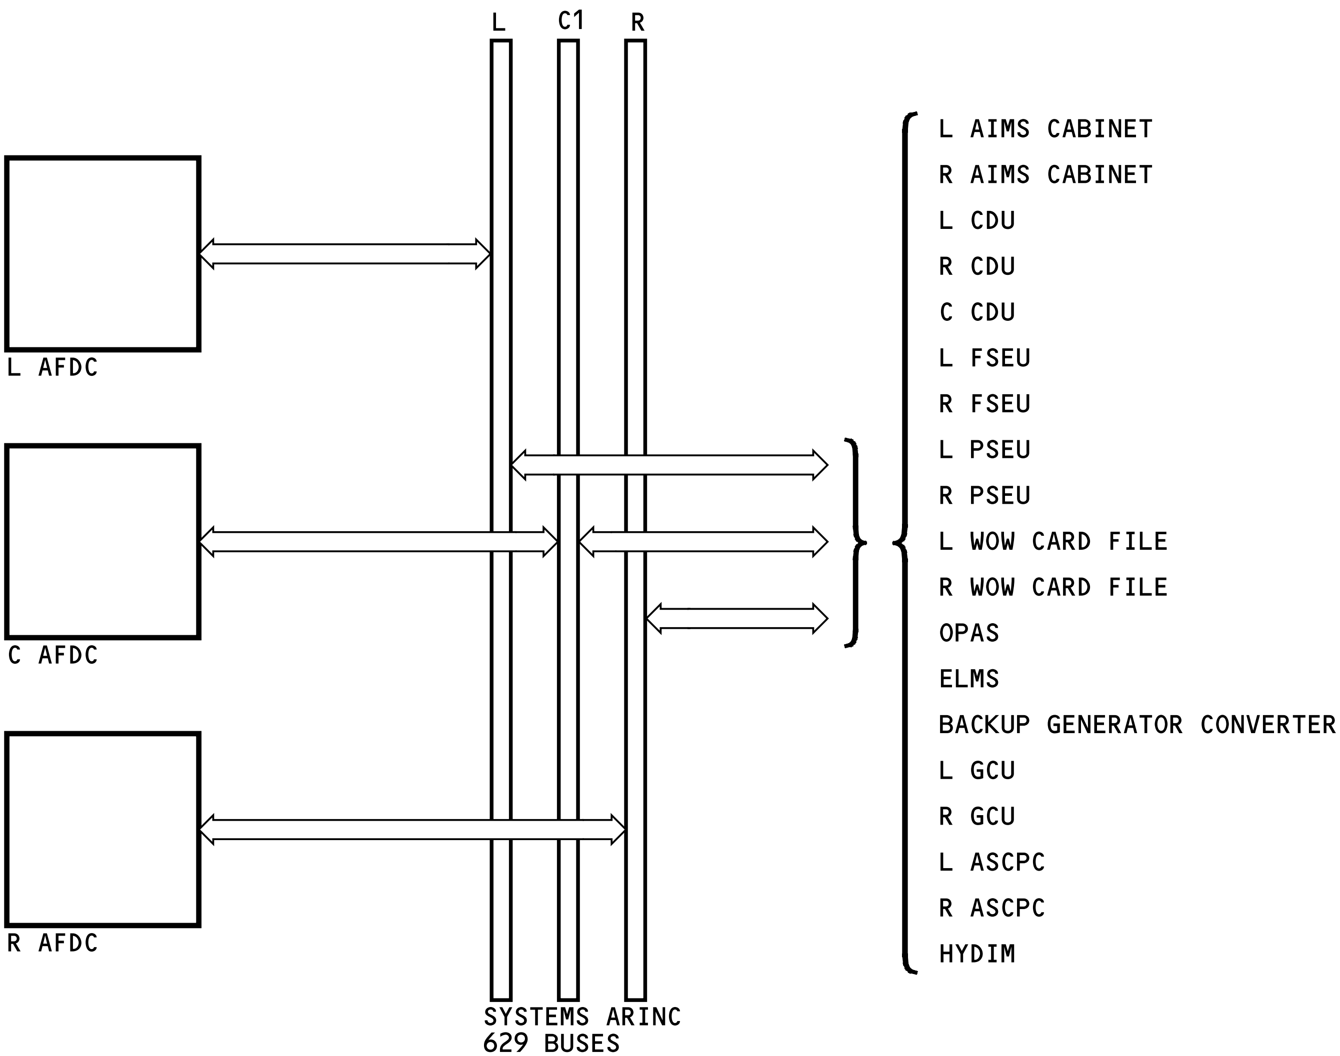
The electrical load management system (ELMS), backup generator converter, and generator control units (GCU) send electrical system status to the left and right AFDCs. They transmit the data to the left and right buses. The center AFDC receives electrical system status from the cross channel data buses. Each AFDC sends bus isolation request to its on-side bus.

Air Supply and Cabin Pressurization Controllers (ASCPC)

Each ASCPC receives AFDC mode status data from the left and right buses.

Hydraulic Interface Modules (HYDIMs)

The HYDIMs send hydraulic system status to the left and right AFDCs. All four HYDIMS transmit to left and right buses. The left and right AFDCs receive the four HYDIMs data on their on-side bus. The center AFDC receives hydraulic status data from the cross channel data buses.



22-11-00-007 Rev 3 08/24/1995

AFDS - SYSTEMS ARINC 629 BUS INTERFACE

AFDC - FLIGHT CONTROLS ARINC 629 BUSES INTERFACE

AFDC

Each AFDC uses the on-side flight controls bus to transmit data. Each AFDC receives data from all three buses.

Primary Flight Control Computers

Each PFC uses the on-side flight controls bus to transmit data. Each PFC receives data from all three buses. Each AFDC receives data from all three PFCs.

The AFDCs send engage requests and autopilot commands to the PFCs. The AFDCs receive backdrive commands, flight deck control input positions, and engagement status.

Air Data Modules (ADMs)

Each ADM receives air/ground and engine running status from their on-side AFDCs.

Air Data Inertial Reference Unit (ADIRU)

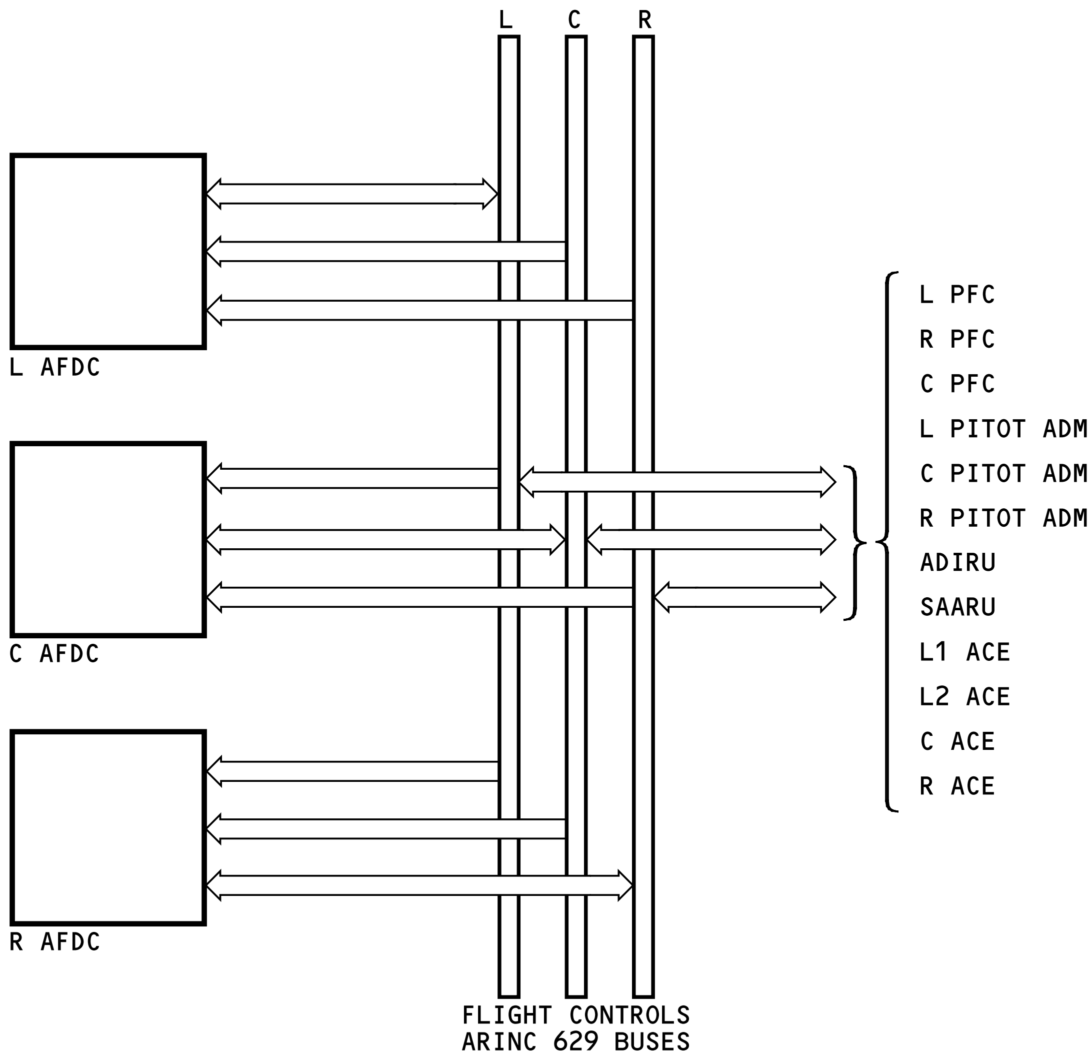
Each AFDC receives attitude and air data from ADIRU on the left and right buses.

Secondary Attitude Air Data Reference Unit (SAARU)

Each AFDC receives attitude and air data from the secondary attitude air data reference unit (SAARU) on the center bus.

Actuator Control Electronics (ACEs)

Each ACE receives flight surface control data from the flight controls bus. Each ACE sends position transducer data from the pilot controls (wheels, columns, pedals) to the PFCS. Each ACE also sends power control unit (PCU) position feedback data to the PFCs.



22-11-00-008 Rev 2 08/24/1995

AFDC - FLIGHT CONTROLS ARINC 629 BUSES INTERFACE

AFDS - ARINC 429 DATA BUS INTERFACE

Mode Control Panel

The mode control panel (MCP) has three 429 input data buses and two 429 output data buses.

The MCP receives mode requests and target values from the three AFDCs on separate data buses.

The MCP sends this information to the three AFDCs:

- Engage requests
- Mode requests
- Target values
- Maintenance data.

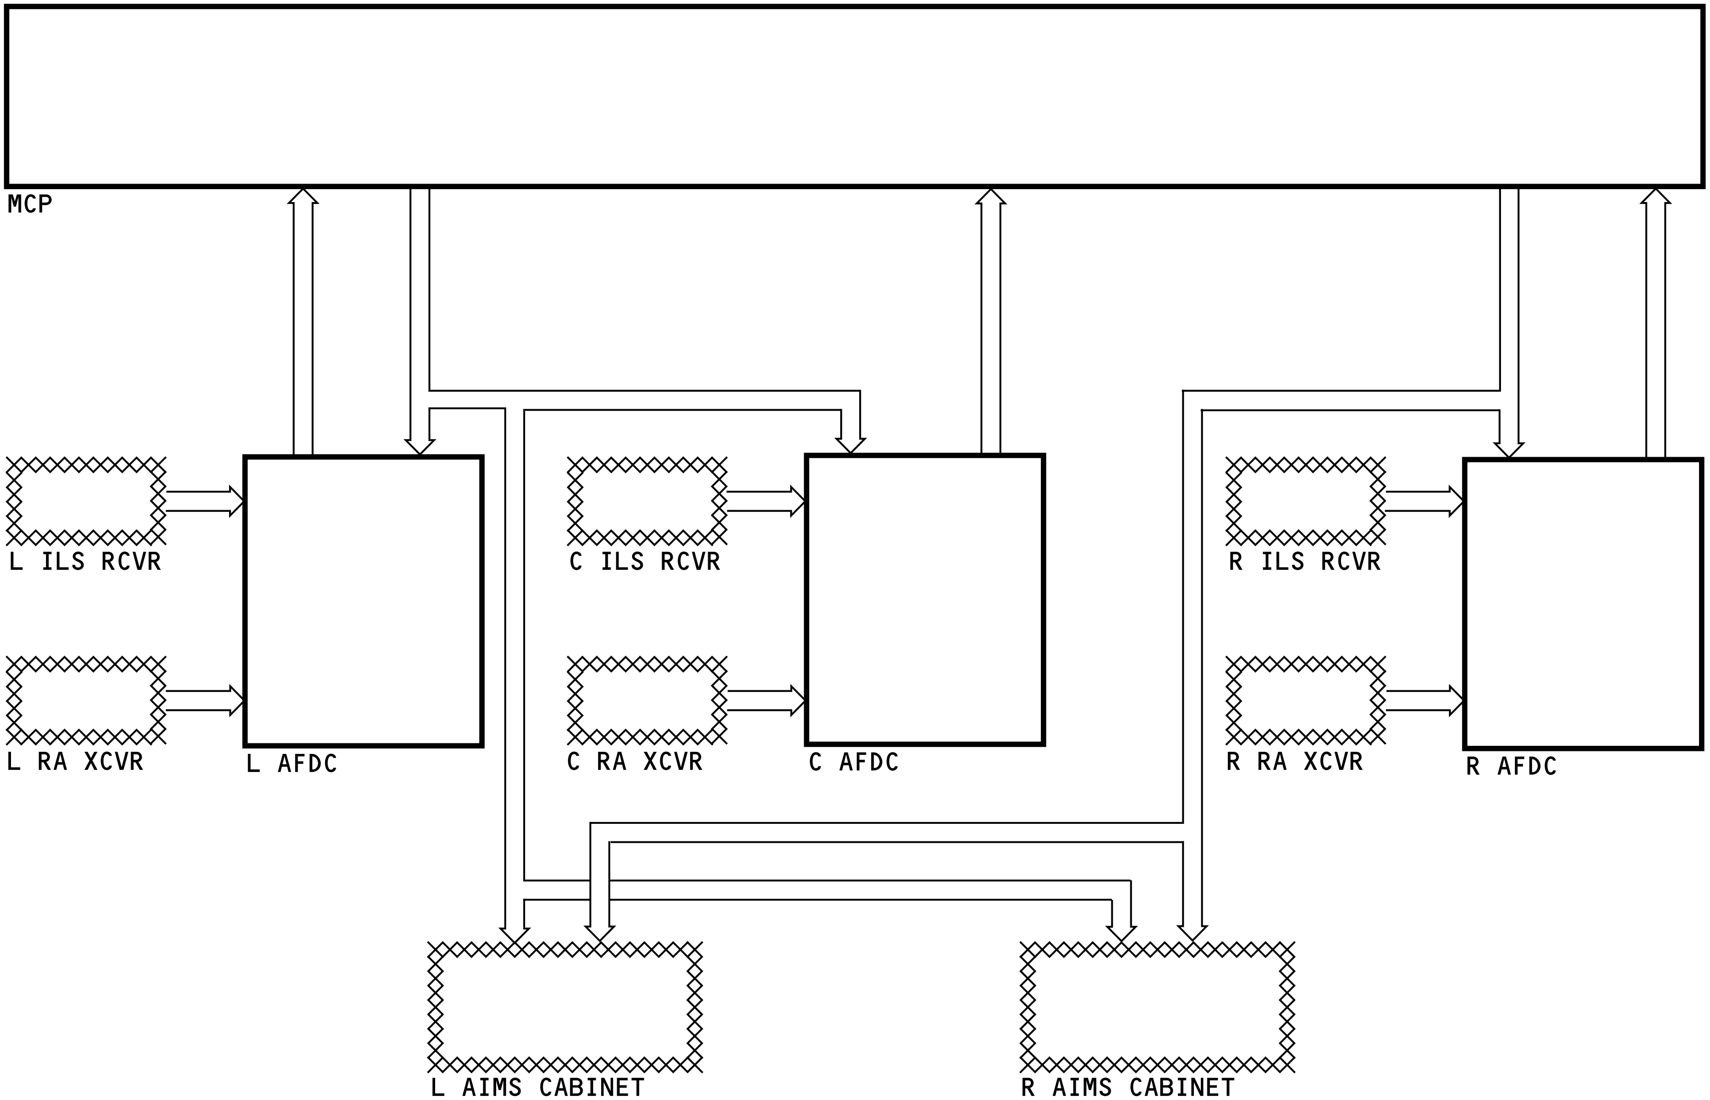
The MCP sends LNAV and VNAV mode requests and maintenance data to the AIMS cabinets.

Instrument Landing System (ILS)

Each ILS receiver sends data to the onside AFDC.

Radio Altimeter Transceiver

Each radio altimeter transceiver sends data to the onside AFDC.



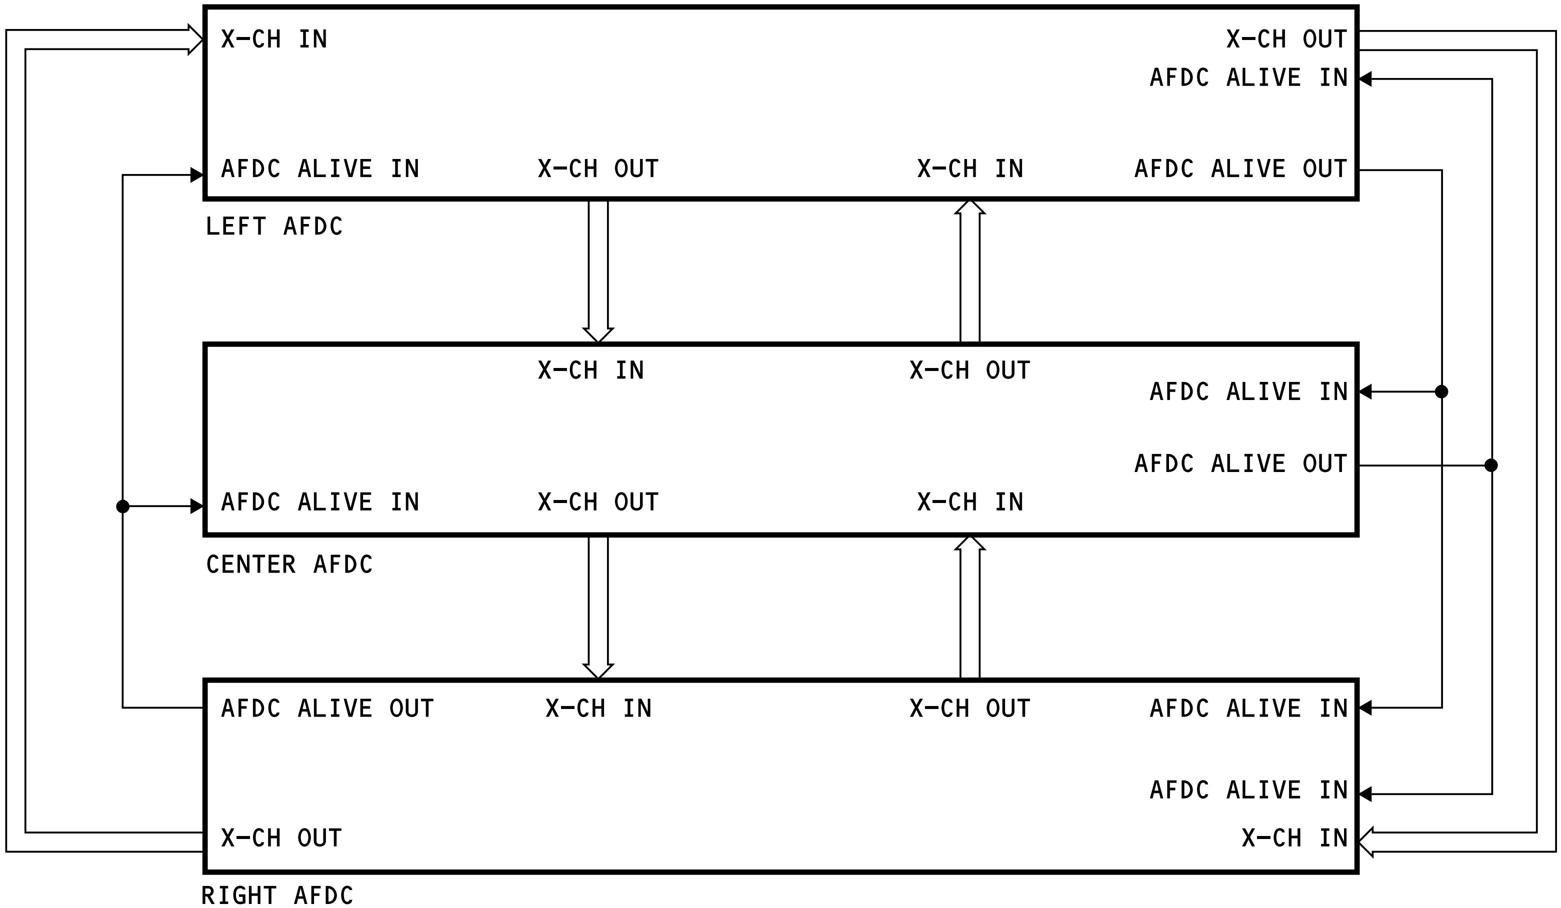
AFDS - ARINC 429 DATA BUS INTERFACE

AFDS - CROSS-CHANNEL DATA INTERFACE

Cross Channel Bus and Discrete Information

Each AFDC receives digital data on cross-channel buses for monitor, signal selection and synchronization functions.

Each AFDC continuously sends an AFDC ALIVE discrete to the other AFDCs if it does not detect any internal faults.



22-11-00-010 Rev 2 08/24/1995

AFDS - CROSS-CHANNEL DATA INTERFACE

AFDS - MISCELLANEOUS ANALOG DISCRETES INTERFACE

General

These discrete inputs to the AFDC are from the:

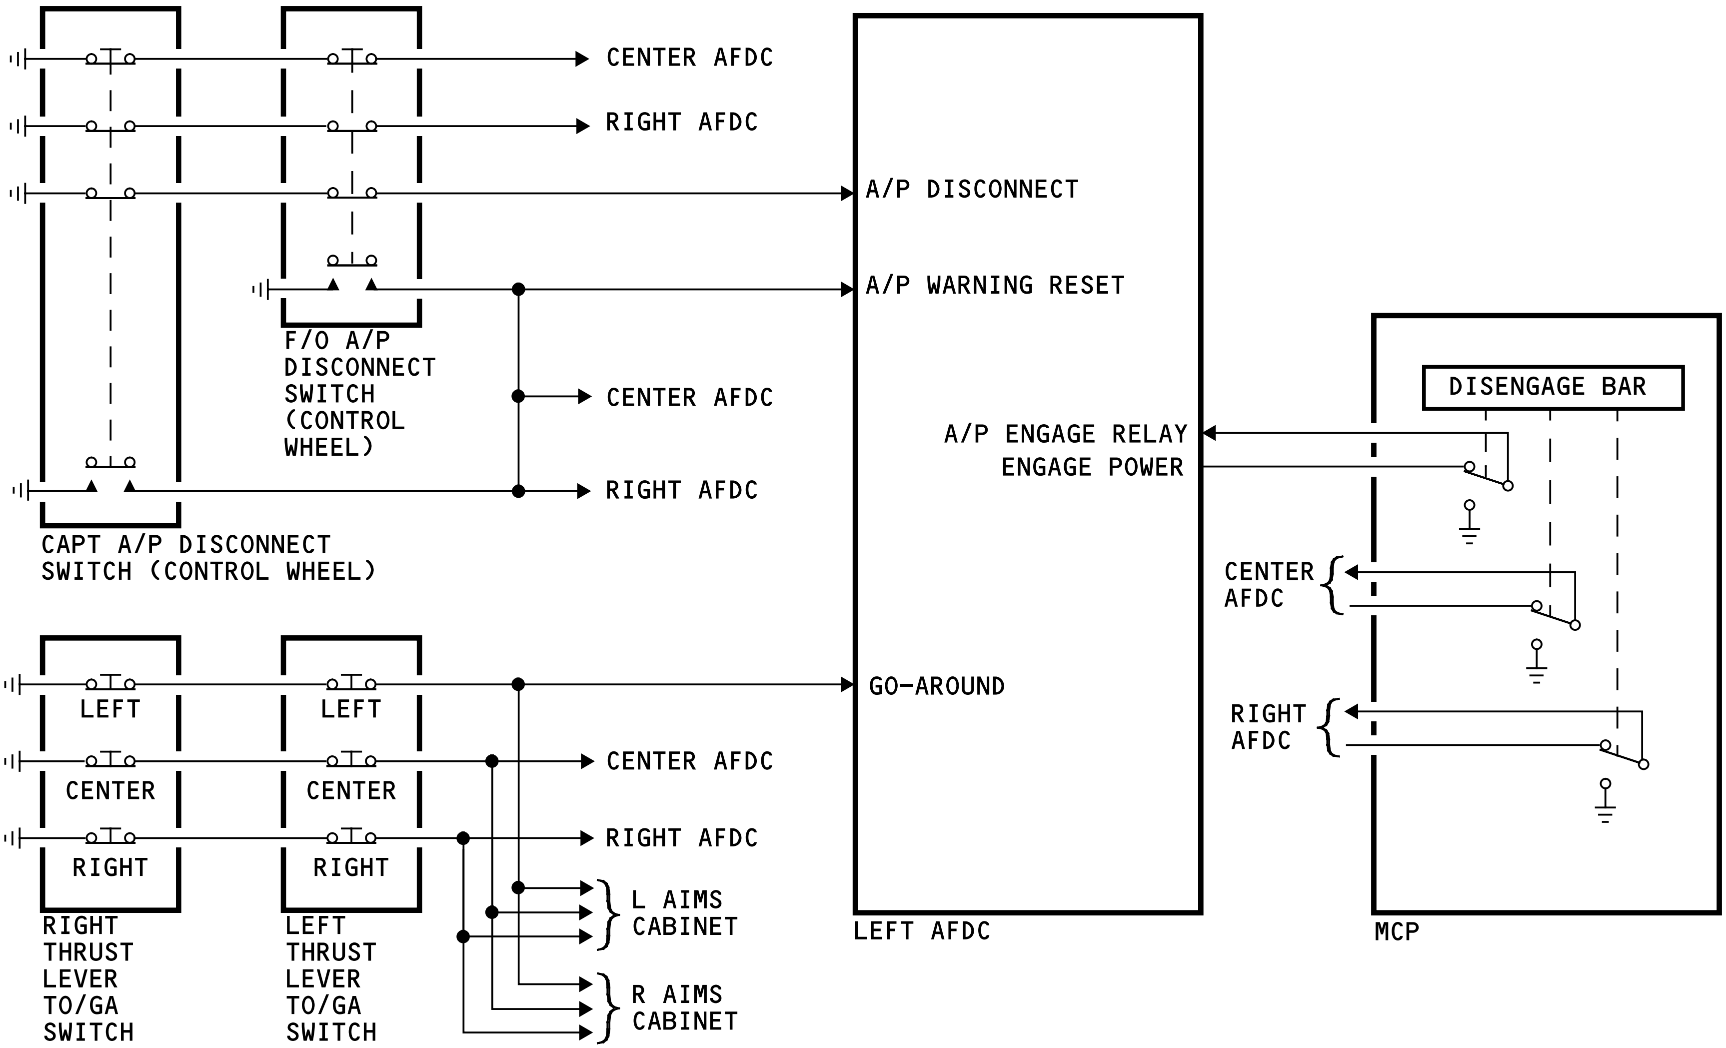
- Autopilot disconnect switches
- Takeoff/go-around (TO/GA) switches
- Autopilot disengage bar.

Interface

Each control wheel has an autopilot disconnect switch. These switches supply the A/P disengage and A/P warning reset discretes to each AFDC.

Two takeoff go-around (TO/GA) switches on the left and right thrust levers supply a discrete to each AFDC. This discrete also goes to both AIMS cabinets.

The disengage bar on the MCP supplies a secondary method to disengage the AFDCs. When the bar is in the up position, the disengage switches supply power to the engage relay in the AFDCs. When the bar is in the down position, the disengage switches supply a ground to this relay.



22-11-00-011 Rev 3 01/14/1998

AFDS - MISCELLANEOUS ANALOG DISCRETES INTERFACE

AFDS - WARNING ANALOG DISCRETES INTERFACE

Warning Electronic System

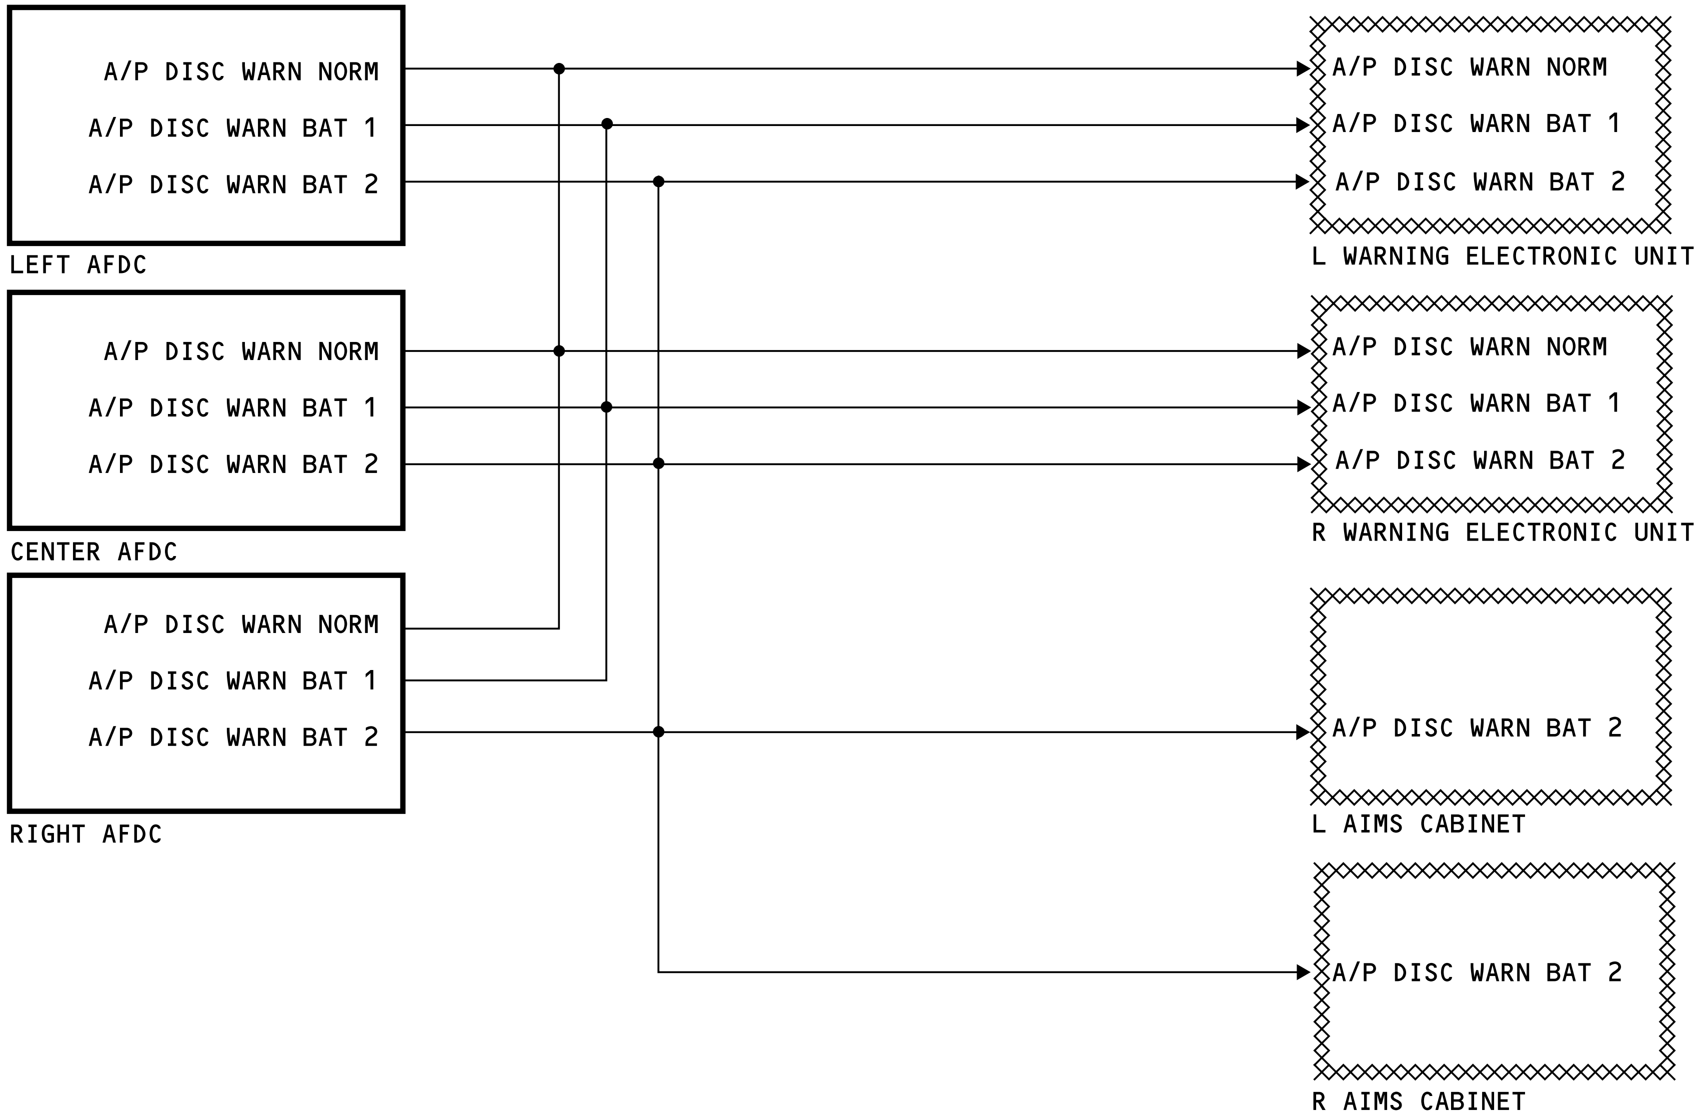
These signals go to the warning electronic units (WEUs) when there is an autopilot disconnect:

- Autopilot disconnect warning normal (A/P DISC WARN NORM)
- Autopilot disconnect warning battery 1 (A/P DISC WARN BAT 1)
- Autopilot disconnect warning battery 2 (A/P DISC WARN BAT 2)

When the WEUs receive at least two of the three warning signals, they make the master warning lights show and the siren sounds.

AIMS

The A/P DISCONNECT WARN BAT 2 discretes are connected together outside of the AFDCs and go to the two AIMS cabinets. The primary display function of AIMS shows a warning message on EICAS.



22-11-00-012 Rev 2 09/22/1997

AFDS - WARNING ANALOG DISCRETES INTERFACE

AFDS - ILS ANALOG DISCRETES INTERFACE

Tune Inhibit Discrete

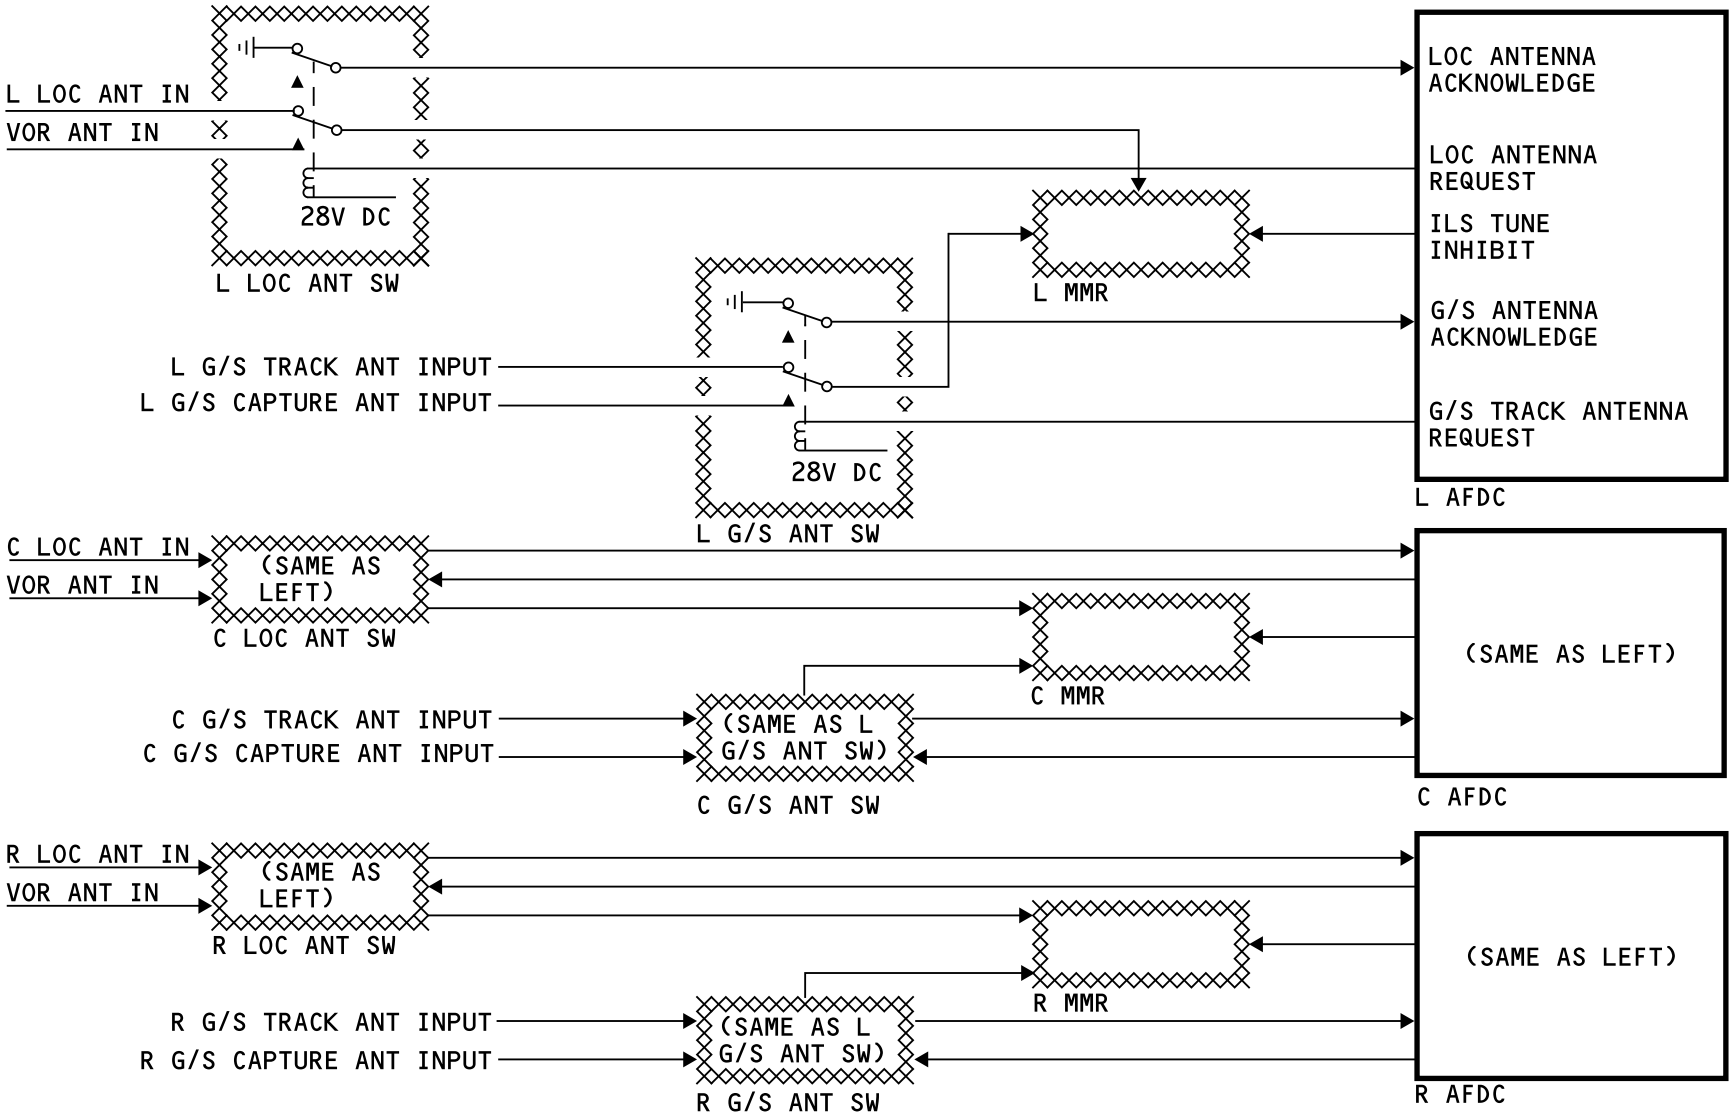
During an approach with the flight director or autopilot engaged, the AFDCs send tune inhibit discretes to the multi-mode receivers (MMRs). The tune inhibit discrete inhibits flight crew from tuning the ILS receivers.

Antenna Switch Interface

Each AFDC controls its antenna switches for the LOC and G/S antennas.

The LOC antenna request discrete signal controls a localizer antenna switch that connects the LOC antenna to the multi-mode receiver (MMR). One set of switch contacts sends feedback to the AFDC to show the position of the relay.

The G/S capture antenna request discrete signal controls a glideslope antenna switch that connects the G/S track antenna to the multi-mode receiver (MMR). One set of switch contacts sends feedback to the AFDC to show the position of the relay.



AFDS - ILS ANALOG DISCRETES INTERFACE

THIS PAGE INTENTIONALLY LEFT BLANK

AFDS - MODE CONTROL PANEL - FUNCTIONAL DESCRIPTION

General

The major components of the MCP are:

- Power supplies (A and B)
- Microprocessors (A and B)
- Fluorescent tube control
- LCDs and encoders
- Push-button and toggle switches.

Power Supplies A and B

Power supplies A and B receive 28v dc from the left and right 28v dc buses. The MCP functions with either source of 28v dc.

Power supplies A and B supply +12v dc, -12v dc and +5v dc to their microprocessors and logic circuits. Power supplies A and B also supply +14v dc to power supply C which is part of the fluorescent tube control.

Microprocessor A and B

The MCP contains two separate microprocessor channels.

Microprocessor A receives data from the Left and center AFDC. Microprocessor B receives data from the right and center AFDC.

Microprocessor A sends data to the left and center AFDCs. Microprocessor B sends data to the right AFDC.

To make sure all three AFDCs use data from one MCP processor, all AFDCs use the microprocessor data sent to the master AFDC.

When the left AFDC is master, microprocessor A writes to the LCD displays. The right and center AFDCs receive microprocessor A data through the AFDC cross-channel buses.

When the right AFDC is master, microprocessor B writes to the LCD displays. The left and center AFDCs receive microprocessor B data through the AFDC cross-channel buses.

Training Information Point

If a microprocessor fails or if its interface to the AFDC fails, the MCP sends a request to the CMCF to make an EICAS status message show. The status message is MCP CTRL PANEL LANE.

Fluorescent Tube Control

The fluorescent tube control circuit supplies current to drive the tube filament and the tube heater.

A heater coil is around the fluorescent tube. A temperature sensor next to the tube operates the heater when the sensor detects a temperature below 40F.

AFDS - MODE CONTROL PANEL - FUNCTIONAL DESCRIPTION

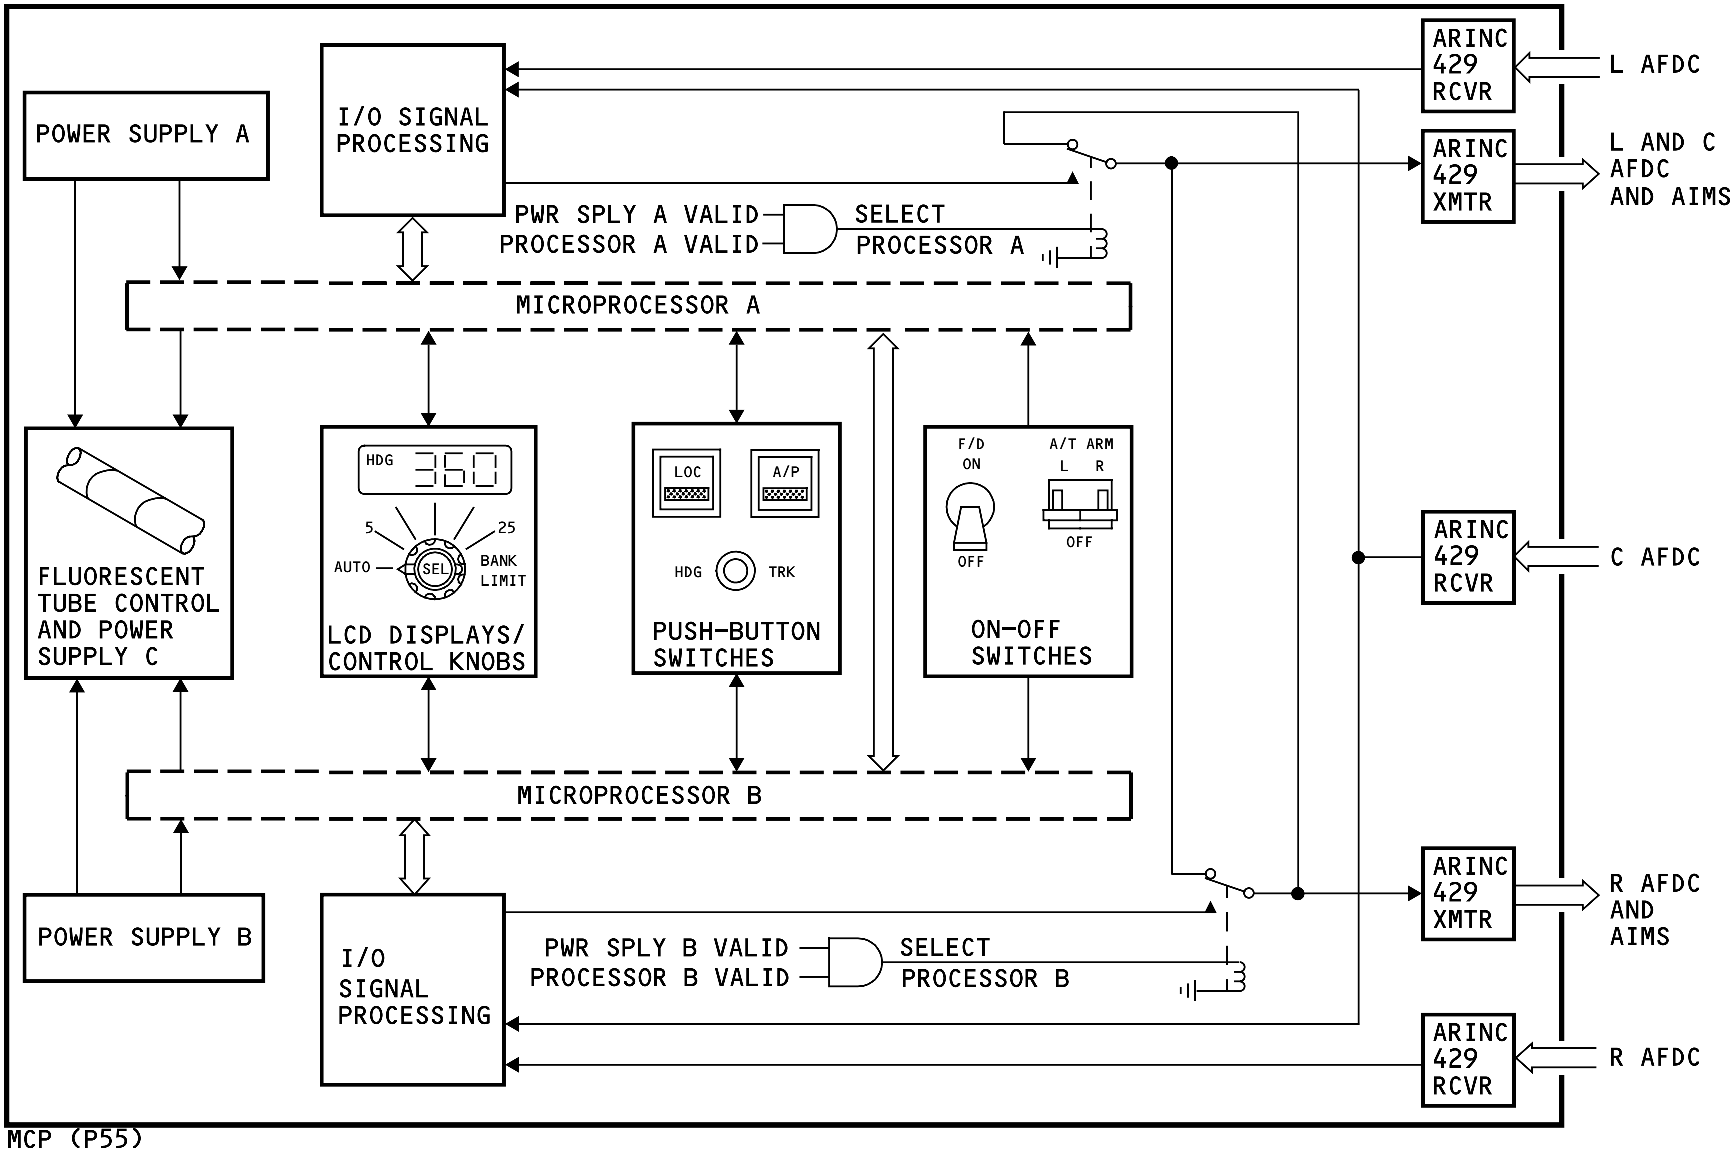
Liquid Crystal Displays (LCD) And Control Knob Encoders

There are four LCDs. They display mode reference values. The values change when you rotate the selector or when the AFDCs command a new reference value.

Microprocessor A and B drive each LCD. Each selector connects to two encoders. Each encoder sends data to the onside microprocessor.

Push-Button And Toggle Switches

Each push-button and toggle switch has two sets of contacts. One set connects to microprocessor A and one set connects to microprocessor B. The LED annunciators in the push-button switches also connect to each microprocessor.



AFDS - MODE CONTROL PANEL - FUNCTIONAL DESCRIPTION

AFDS - MODE CONTROL PANEL - CONTROLS AND DISPLAYS

Autopilot (A/P) Engage Switches

Push either switch to engage all available A/P channels. The LEDs in both switches come on.

Autothrottle (A/T) Arm Switches

The switches arm the A/T and digital trimmer control for each engine. Both switches are normally left in the ARM position. When you set the switches to the OFF position, the A/T disconnects.

IAS/MACH Reference Switch

This switch controls the reference the IAS/MACH window shows.

IAS/MACH Window

The window shows indicated airspeed (IAS) or MACH number. IAS shows from 100 to 399 knots in one knot increments. Mach number shows from 0.400 to 0.900 MACH in increments of 0.001 MACH.

At AFDC power up, the window shows 200 knots. The window is normally blank when VNAV is active. If VNAV is not active, the window shows the current target airspeed/mach.

Mode Switches (8)

These switches request A/P, F/D, and A/T modes.

Light Sensor

A photo diode light sensor on the MCP front panel monitors ambient lighting. It controls the brightness of the LCDs.

Heading/Track (HDG/TRK) Reference Switch

This switch controls the reference for the Heading/ Track window.

Heading/Track Window

The window shows heading or track angle in increments of one degree. The window range is from 001 to 360 degrees.

At AFDC power-up, the window shows 360 degrees. Runway heading shows at localizer capture.

Vertical Speed/Flight Path Angle (V/S/FPA) Reference Switch

This switch controls the reference for the vertical speed/flight path angle window.

Vertical Speed/Flight Path Angle Window

The vertical speed range is +6000 FPM to -8000 FPM. The flight path angle range is +9.9 degrees to -9.9 degrees.

AFDS - MODE CONTROL PANEL - CONTROLS AND DISPLAYS

The window shows four dashes when vertical speed and flight path angle modes are not active.

Altitude Window

The altitude range is from 0 to 50000 feet. The increment is variable.

The altitude in the window is also the altitude alert value for the caution and warning system. At AFDC power-up the display shows 10000 feet.

Flight Director (F/D) Switches

The F/D switches make the F/D displays show on the primary flight displays (PFDs). When the airplane is on the ground and you move a switch to the ON position, the F/D takeoff (TO) mode indications show on the associated PFD.

Altitude Increment Selector (Outer) and Altitude Selector (Inner)

The control has two concentric selectors.

The inner selector changes the reference altitude in the window. If you push the selector while in VNAV, you activate altitude intervention.

The outer selector changes the window increment. With the outer selector in the 1000 position, the inner selector changes the window at 1000 feet/detent.

With the outer selector in the AUTO position, the window change rate is 100 feet/detent. The altitude window also shows the barometric minimums you selected on both EFIS control panels.

For example, you select barometric minimum values of 290 feet on the left EFIS control panel, and 330 feet on the right EFIS control panel. As you rotate the outer selector, the altitude on the window changes as follows:

- 100
- 200
- 290
- 300
- 330
- 400
- 500, etc.

If you select the same barometric minimums value on both EFIS control panels, the MCP shows the value only once.

Once the values from the EFIS control panels show on the MCP, they stay on the MCP even if you change the EFIS control panel barometric minimums.

The MCP rounds up to the next 10 feet. So if you select a barometric minimums value of 181 feet, the MCP shows 190 feet.

AFDS - MODE CONTROL PANEL - CONTROLS AND DISPLAYS

Vertical Speed/Flight Path Angle Selector

Rotate the selector up to decrease the value. Rotate the selector down to increase the value.

Bank Limit Selector (Outer), Heading/Track Selector (Middle), and Heading/Track Select Switch (Inner)

The control has two concentric selectors and one push-button.

The bank limit selector (outer) selects the bank angle limit used in the heading/track select mode.

The heading/track selector (middle) changes the value the window shows.

The heading/track select switch (inner) is a push-button switch. Push this switch to request the heading select or track select mode.

Autopilot Disengage Bar

The bar connects to three toggle switches. The bar is normally in the up position. Push the bar down to disengage all AFDCs.

IAS/MACH Selector

When not in VNAV, the IAS/MACH window shows the current target airspeed. Turn the IAS/MACH selector to change the target airspeed.

In VNAV, the IAS/MACH window is normally blank. If you push the selector, the window unblanks to show the current FMCF target airspeed. You can then turn the IAS/MACH selector to change the target airspeed. This is speed intervention.

Autothrottle (A/T) Engage Switch

This switch engages the autothrottle.

Climb/Continuous (CLB/CON) Thrust Switch

When two engines are in operation, this switch changes the autothrottle thrust reference to climb (CLB). When only one engine is in operation, it changes the thrust reference to maximum continuous (CON).

AFDS - MODE CONTROL PANEL - CONTROLS AND DISPLAYS

AFDS - AUTOPILOT FLIGHT DIRECTOR COMPUTER

Purpose

The autopilot flight director computer (AFDC) calculates:

- Flight director (F/D) commands
- Autopilot commands
- Backdrive actuator commands.

Physical Description

The AFDC has modules, sub-assemblies, and a chassis assembly in an ARINC 600 8 MCU box. The top and bottom covers let cooling air to flow from the bottom to the top. The AFDC is a line replaceable unit (LRU). AFDC internal components are not LRUs.

Software Loading

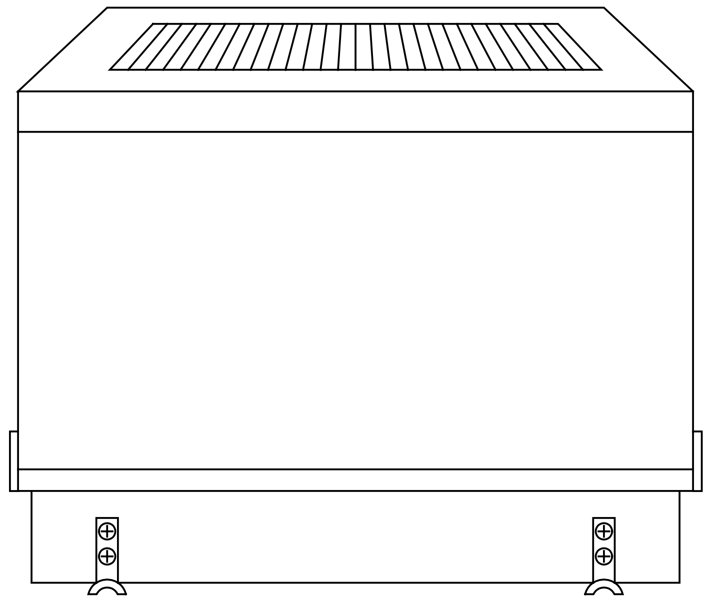
The AFDCs must have operational software loaded in them. Shop personnel can load the software, or you can use the MAT to do a software load.

System Configuration

Use the MAT to monitor the AFDS configuration. You can monitor:

- A/P hardware part number
- A/P software number
- A/P serial number
- A/P configuration pins
- A/P compatibility pins
- A/P interlock pins
- A/P options list.

This information shows for each AFDC.



22-11-00-018 Rev 1

AFDS - AUTOPILOT FLIGHT DIRECTOR COMPUTER

AFDS - AUTOPILOT FLIGHT DIRECTOR COMPUTER - FUNCTIONAL BLOCK DIAGRAM

General

This is a block diagram of the autopilot flight director computer (AFDC).

Input Signal Selection

Each ARINC and discrete input/output (I/O) section monitors and selects input signals. Each I/O section monitors the signal validity first. If the validity check is good, the I/O section selects the signal by one of these methods:

- Mid-value selection which uses the middle value of the three signals. Radio altitude (RA) and instrument landing system (ILS) are examples of signals selected by mid-value.
- Priority selection for signals with two sources (left, right). For example, the air data inertial reference unit (ADIRU) is the normal source of air and inertial reference data. If the ADIRU fails, the AFDC selects the secondary attitude air data reference unit (SAARU).
- Forced selection for airplane information management system (AIMS) data. AIMS tells the AFDC which signal to use.

AFDC Processors

The AFDC has three processors. Processors A and B receive digital backdrive commands from the primary flight computers (PFCs). They convert the digital backdrive commands into analog. Processor C calculates the autopilot and flight director control laws. Processor C also does these functions:

- Test and data load.
- Engage/disengage logic
- Failure detection/fault response monitor

Power Supplies

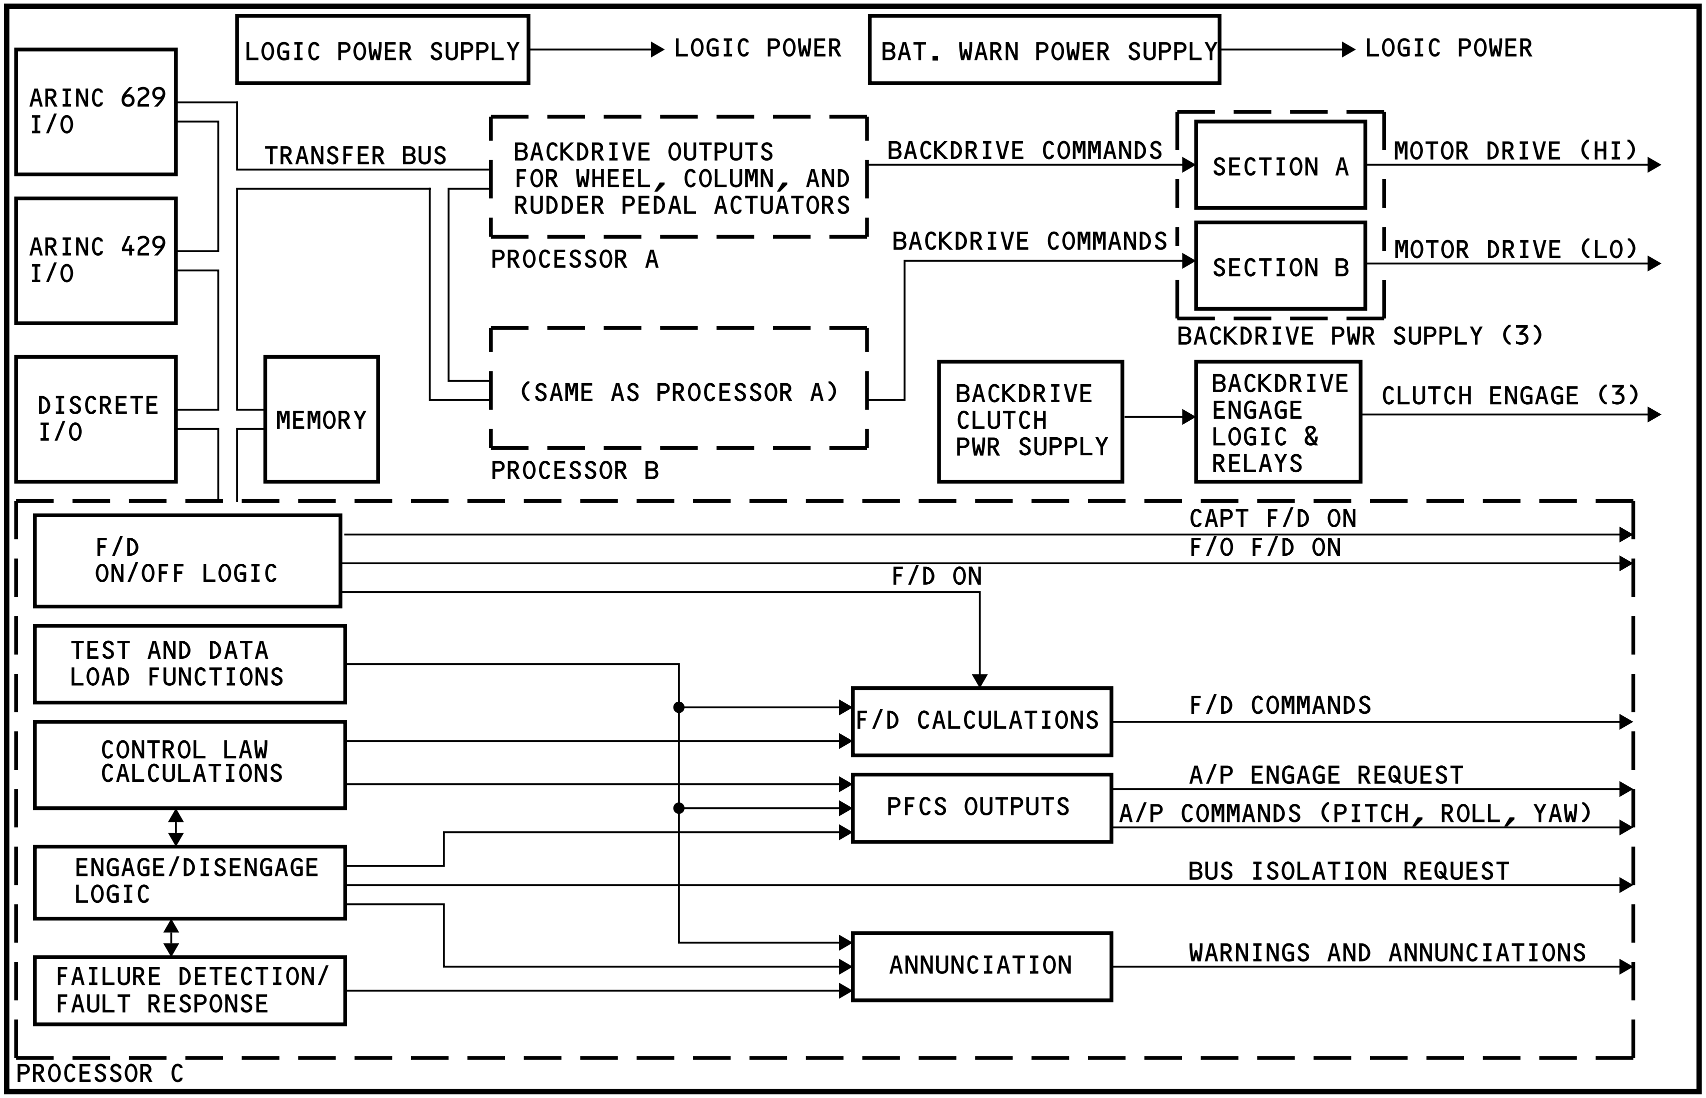
The logic power supply sends +5v dc, +15v dc, -15v dc, and +28v dc to internal components of the AFDC. It also sends +28v dc disengage power to the mode control panel (MCP).

The backdrive clutch power supply sends +28v dc to the backdrive clutch engage logic and relays.

Three backdrive power supplies send drive signals to the wheel, column, and rudder pedal backdrive actuators. Each power supply is a variable voltage push-pull power supply that sends +/-50v dc to each backdrive actuator. Commands from the A and B processors control the variable output of the power supplies.

The center AFDC does not connect to backdrive actuators and does not use its backdrive power supplies.

The battery warning power supply sends +28v dc to the battery warning logic.



AFDC (TYPICAL)

22-11-00-019 Rev 4 04/26/96

AFDS - AUTOPILOT FLIGHT DIRECTOR COMPUTER - FUNCTIONAL BLOCK DIAGRAM

AFDS - BACKDRIVE ACTUATOR INSTALLATION - 1

Purpose

The backdrive actuators are variable torque motors. They move the control columns, control wheels, and rudder pedals during autopilot operation. This movement gives the flight crew an indication of the autopilot commands that go to the primary flight computers (PFCs).

A control wheel backdrive actuator also operates when the bank angle protection (BAP) function operates. The actuator supplies a variable torque to the roll control system if the airplane bank angle exceeds 35 degrees. BAP is available with the autopilot engaged or disengaged.

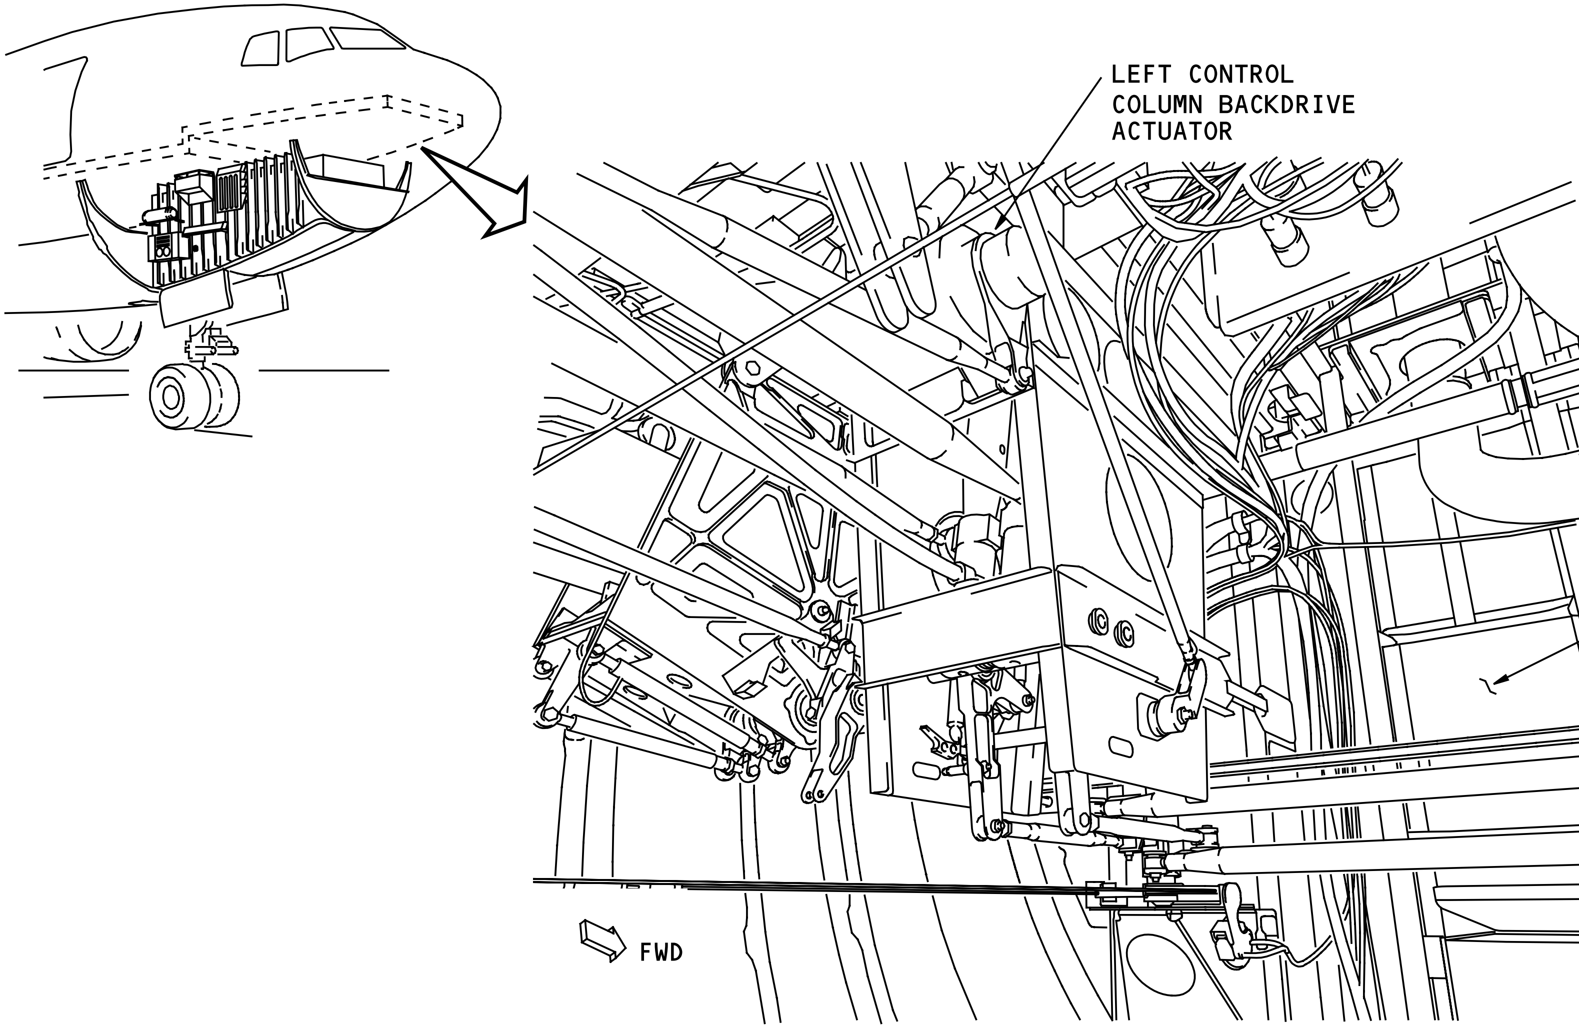
There are two backdrive actuators for each of the control columns, control wheels, and rudder pedals. The backdrive actuators are interchangeable.

Location

The six backdrive actuators are below the floor in the 41 section. Access to the control wheel and rudder pedal backdrive actuators is by the main equipment center access door. Access to the control column backdrive actuators is through the forward equipment center access door.

Physical Description

Each actuator weighs about 8 lbs (3.6 kg) and attaches to the airplane structure with four bolts.



FORWARD EQUIPMENT CENTER BELOW FLIGHT DECK FLOOR

AFDS - BACKDRIVE ACTUATOR - FUNCTIONAL DESCRIPTION

THIS PAGE INTENTIONALLY LEFT BLANK

AFDS - BACKDRIVE ACTUATOR - FUNCTIONAL DESCRIPTION

General

Each backdrive actuator contains:

- Two tachometers
- A DC motor
- An engage clutch
- An override slip clutch.

Tachometers

The two tachometers supply motor rate feedback to the AFDC processors. Tachometer A feedback goes to processor A. Tachometer B feedback goes to processor B.

DC Motor

The AFDC supplies a variable dc current to the motor. The current to the motor limits the motor torque.

Engage Clutch

The AFDC supplies 28v dc to operate the engage clutch. The clutch connects the output crank to the motor and gear train. With the clutch not engaged, the output crank is free to move with the flight controls.

Override Slip Clutch

The override slip clutch lets the pilot override the backdrive actuator if it jams.

Actuator Authority

The AFDC controls the motor current to each backdrive actuator. This limits the force that a backdrive actuator applies to the columns, wheels, and rudder pedals. This force is sufficient for the actuator to overcome the feel and friction forces in the control system. The force is limited so that the pilot can override the backdrive, feel, and centering forces. The autopilot disengages if the pilot overrides the backdrive, feel, and centering forces.

The AFDS engages one control column and one control wheel backdrive actuator in cruise. The override forces necessary to make the autopilot disengage are approximately:

- 50 lbs for the control column
- 27 lbs for the control wheel.

The override forces that show are the sum of the backdrive force and the feel and centering forces from the flight controls system.

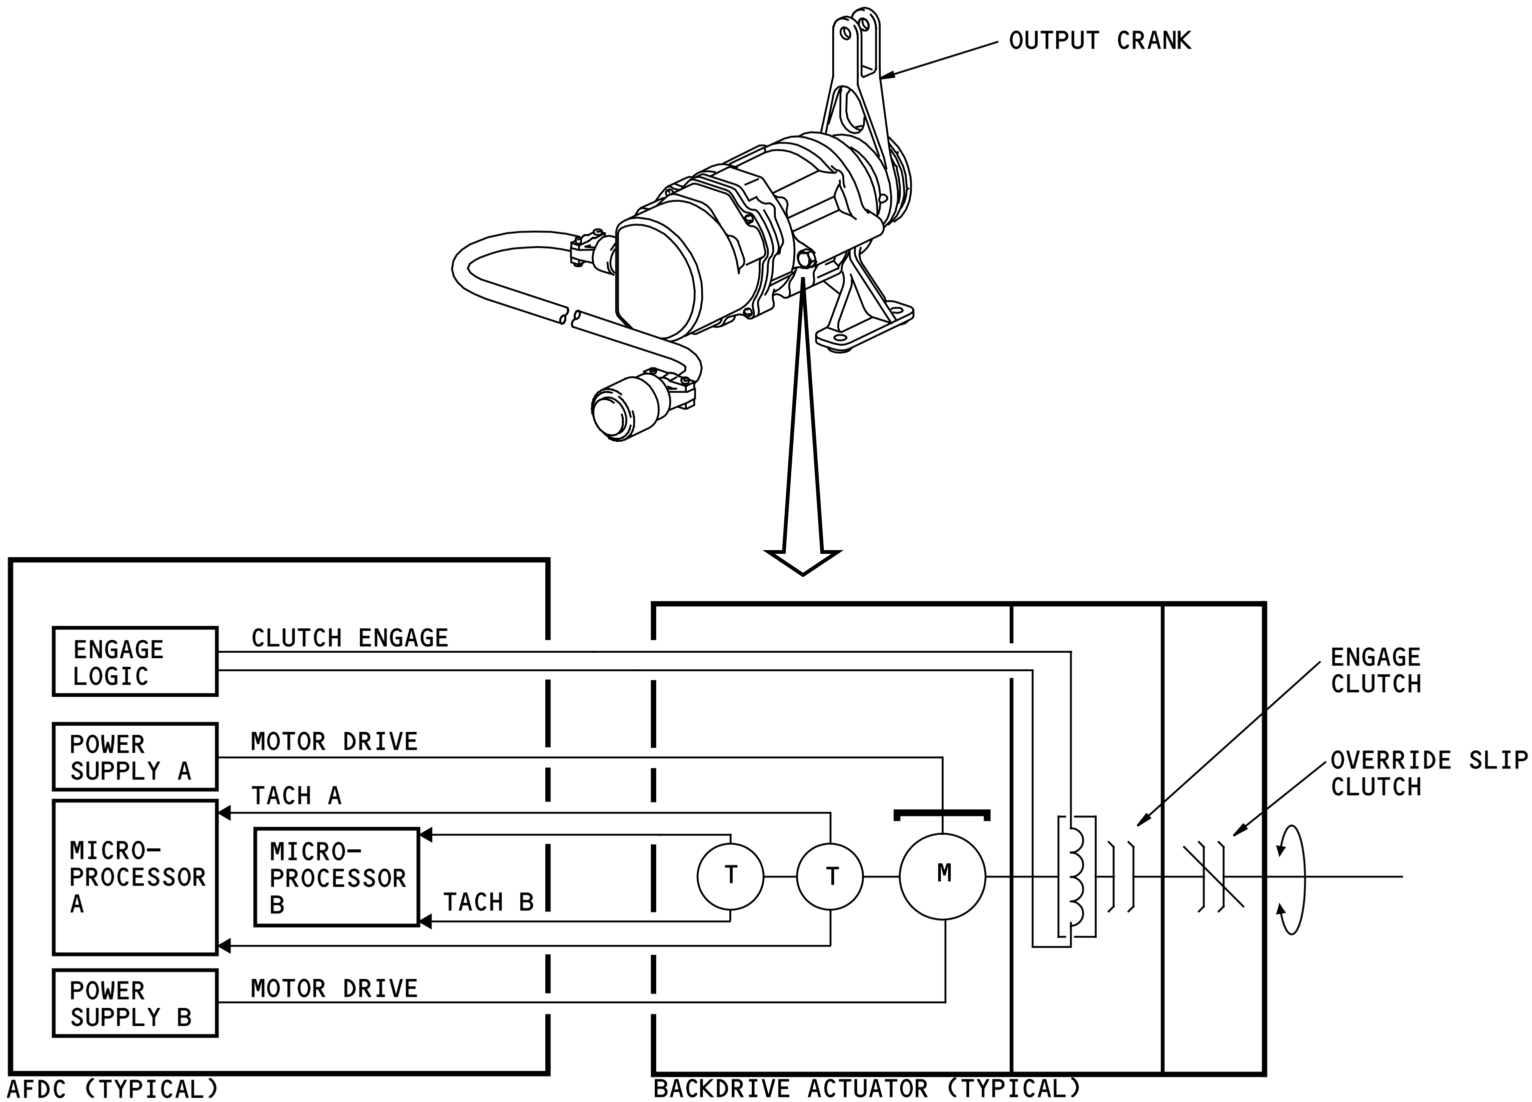
The AFDS engages all six backdrive actuators in autoland. The backdrive forces for this condition are approximately two times the force for a single actuator. The override forces are approximately:

- 81 lbs for the control column
- 49 lbs for the control wheel
- 186 lbs for the rudder pedals.

AFDS - BACKDRIVE ACTUATOR - FUNCTIONAL DESCRIPTION

If one control column actuator fails during autoland, the force limit of the remaining column actuator is two times as high. This makes sure there is enough force to prevent accidental column movement by the pilot during autoland.

If a control wheel or rudder pedal actuator fails during autoland, the force limit of the remaining actuator does not increase.



AFDS - BACKDRIVE ACTUATOR - FUNCTIONAL DESCRIPTION

22-11-00-025 Rev 2

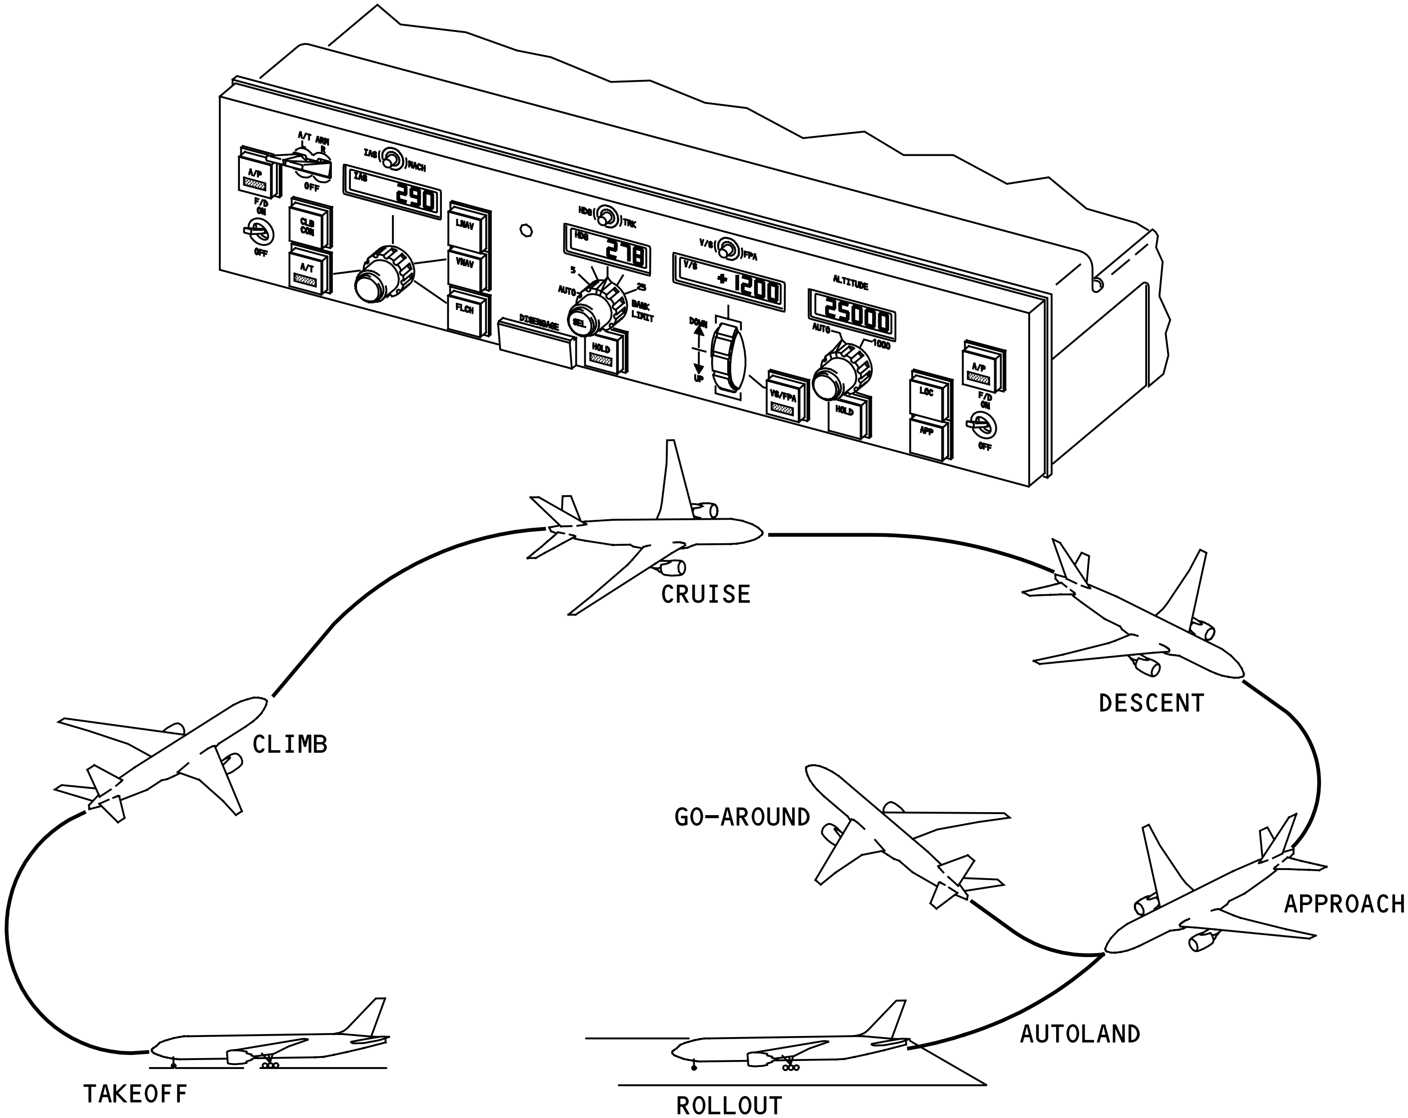
AFDS - OPERATION - OVERVIEW

General

The autopilot flight director system (AFDS) operates on the ground and in flight.

The AFDS calculates commands for these flight sequences:

- Takeoff
- Climb
- Cruise
- Descent
- Approach
- Autoland
- Rollout
- Go-Around.



AFDS - OPERATION - OVERVIEW

22-11-00-026 Rev 0

THIS PAGE INTENTIONALLY LEFT BLANK

AFDS - OPERATION - TAKEOFF

General

The F/D display supplies the pilot with roll and pitch commands during takeoff. After the airplane is off the ground, the pilot can stay in the F/D takeoff mode, or after the airplane passes 50 feet of radio altitude, the pilot can engage the autopilot to the takeoff mode.

Both F/D switches must be set to the OFF position to remove the takeoff mode.

The takeoff mode has this sequence:

- Before takeoff
- Takeoff start
- Lift-off/in air
- Climbout.

Before Takeoff

All of these conditions must be true to put the F/D in the takeoff mode (TO/GA):

- The captain's and/or the first officer's F/D switches are in the ON position
- The autopilot is not engaged
- The airplane is on the ground.

The PFD shows:

- FLT DIR as the AFDS status
- TO/GA as the pitch and roll mode
- The F/D pitch bar shows eight degrees
- The F/D roll bar shows wings level.

The pilot sets an engine-out climb speed (V2) and a clearance altitude on the MCP. The autothrottle (A/T) arm switches are on.

Takeoff Start

The pilot pushes a TO/GA switch on the thrust levers. The autothrottle engages in the takeoff thrust mode and the throttles move forward until the engines reach takeoff thrust. THR REF shows on the PFDs as the active autothrottle mode.

In takeoff, the flight director shows on the PFDs automatically even if the flight director switches are in the OFF position. This is called "auto pop up". It occurs when all these conditions are true:

- A flight director switch is in the OFF position
- The pilot pushes a TO/GA switch
- The trailing edge flaps are not up.

The TMCF removes power from the autothrottle servo motors at 80 knots. Throttle hold (HOLD) shows on the PFDs.

Lift-Off/In Air

For a normal lift-off, the pitch command holds:

- Target airspeed
- Combination of airspeed and pitch attitude

AFDS - OPERATION - TAKEOFF

- Pitch attitude.

If the climb rate is below 600 FPM, the pitch command is to hold attitude. For rates between 600 FPM and 1200 FPM, the pitch command holds a mix of airspeed and attitude. For climb rates above 1200 FPM, the pitch command holds a target airspeed.

If an engine fails during takeoff, the pitch axis command is a mix of airspeed and attitude for climb rates below 1200 FPM. For climb rates above 1200 FPM, the pitch axis holds a target airspeed.

The target airspeed for a normal takeoff is the larger of these two:

- V2 plus 15 knots
- The airspeed at lift-off plus 15 knots.

If the airspeed is more than the target for five seconds, the target airspeed becomes the smaller of the current airspeed or V2 + 25.

This mix of speed and attitude commands gives wind shear protection during takeoff and go-around. The F/D pitch command also keeps the airplane in these limits:

- Flap placard speeds
- Maximum operating velocity and Mach (VMO/MMO)
- Minimum speed.

At five feet radio altitude, the roll command changes to track hold.

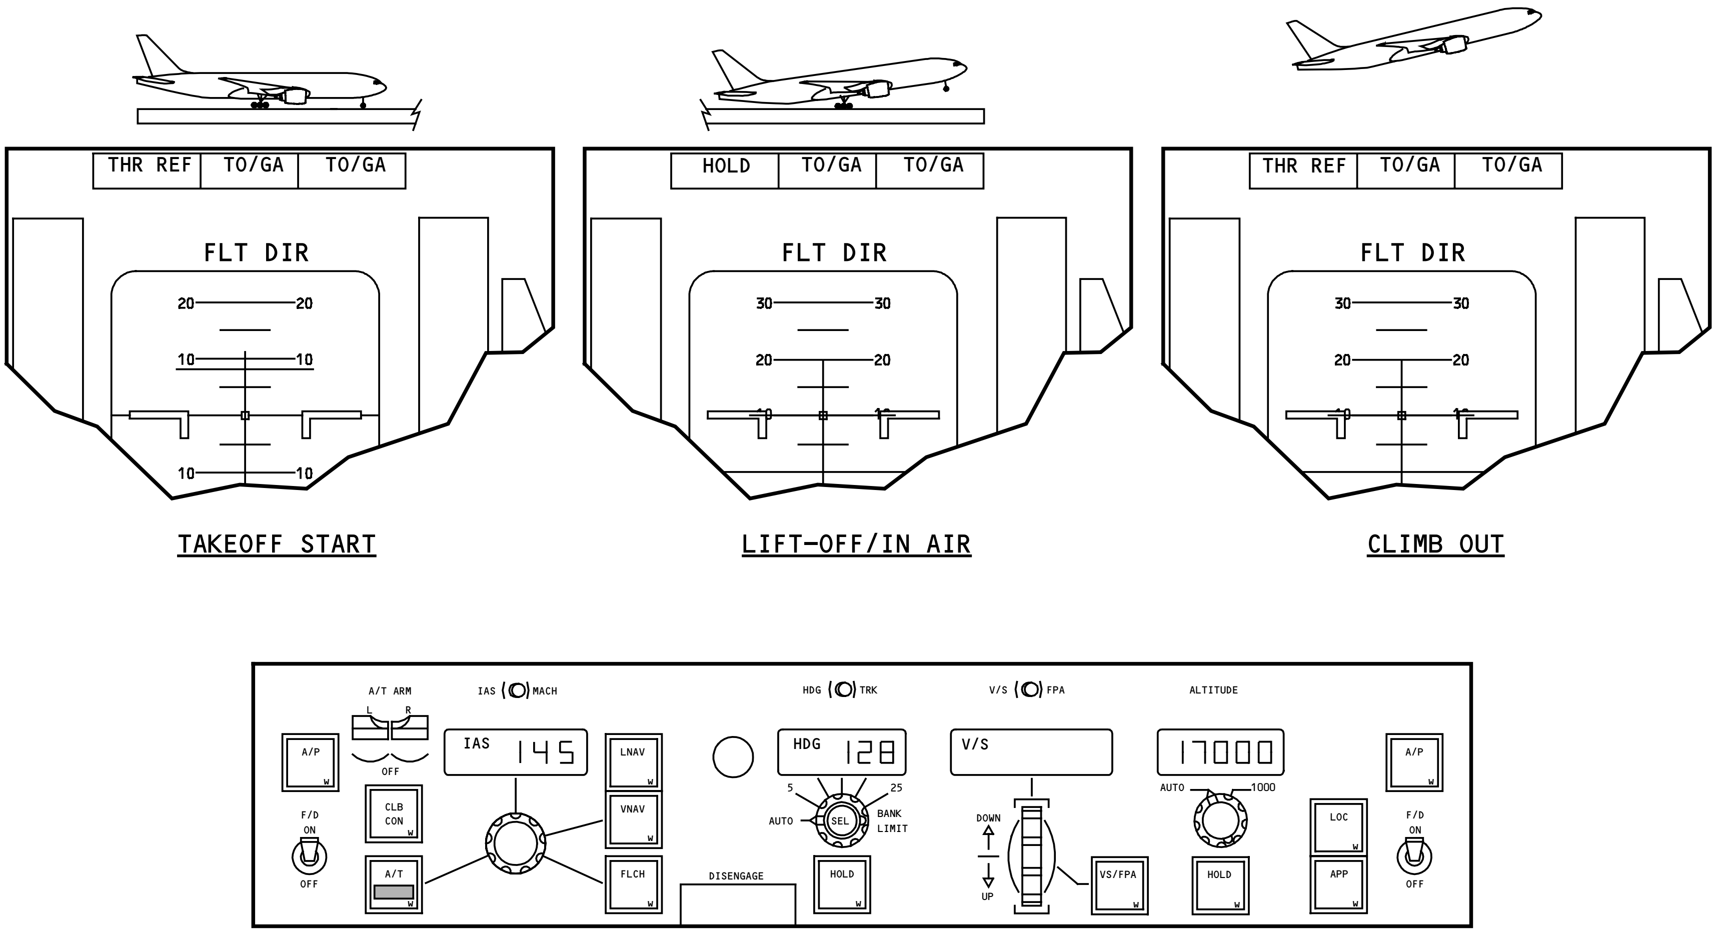
The autothrottle stays in HOLD.

FLT DIR remains the active AFDS status until the pilot engages the autopilot.

The pitch and roll modes remain in TO/GA until the pilot selects another pitch or roll mode.

Climb Out

The roll command continues to hold track. The pitch command continues to hold speed, attitude, or a mix of speed and attitude.



MCP

22-11-00-027 Rev 4 04/26/96

AFDS - OPERATION - TAKEOFF

AFDS - OPERATION - AUTOPILOT ENGAGE

General

Autopilot engagement occurs when the pilot pushes an autopilot (A/P) switch on the MCP. At that time, this happens:

- All available AFDCs and one control wheel and one column backdrive actuator engage
- A/P status shows on the PFDs.

F/D status (on or off) sets the roll and pitch mode selection.

Engage Autopilot With Flight Director On

The AFDS roll and pitch modes stay the same except in these conditions:

- With the LOC mode active, LOC changes to arm and localizer must capture again. The active roll mode is HDG or TRK hold until LOC is captured
- With the G/S mode active, G/S changes to arm and glideslope must capture again. The active pitch mode is V/S or FPA until G/S is captured.

The autopilot will engage in the takeoff mode when all these conditions are true:

- The airplane is on the ground
- A flight director is on
- The mode selected is TO/GA.

Engage Autopilot With Flight Director Off

The active pitch mode is vertical speed or flight path angle.

If the airplane is in a bank of 5 degrees or less, the autopilot commands wings level. When the airplane bank is at 3 degrees or less, the airplane holds the heading or track that is present. The active roll mode is heading or track hold.

The PFDs show the applicable pitch and roll modes and A/P status. The applicable mode select switch LED on the MCP is also on.

Autopilot Engage Inhibit

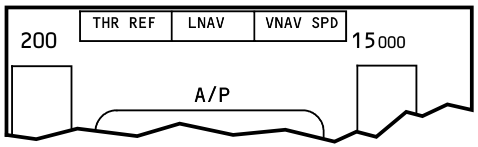
The AFDCs have an inhibit that prevents the engagement of the autopilot during the takeoff roll and immediately after it. You cannot engage the autopilot when all these conditions are true:

- The ground speed is more than 80 knots
- The radio altitude is less 50 feet.

This engage inhibit function does not operate if the airplane takes off with the autopilot already engaged.

Training Information Point

The airplane is not certified for takeoff with the autopilot engaged.

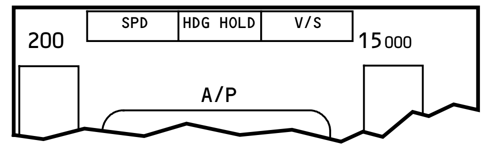


PFD

F/D ON

A/P MODE IS SAME AS
F/D MODE OR:

- HDG HOLD (OR TRK HOLD) IF F/D IN LOC
- V/S (OR FPA) IF F/D IN G/S



PFD

F/D OFF

A/P MODE IS HDG HLD (OR TRK HOLD) AND V/S (OR FPA) IF THE BANK ANGLE IS 5 DEGREES OR LESS:

- A/P COMMAND IS WINGS LEVEL
- AIRPLANE HOLDS HEADING (OR TRACK) WHEN THE BANK IS 3 DEGREES OR LESS

22-11-00-028 Rev 4 04/10/1997

AFDS - OPERATION - AUTOPILOT ENGAGE

AFDS - ROLL ATTITUDE HOLD

General

In this mode, the airplane holds a roll attitude until the pilot selects another roll mode.

Bank Angle More Than Five Degrees

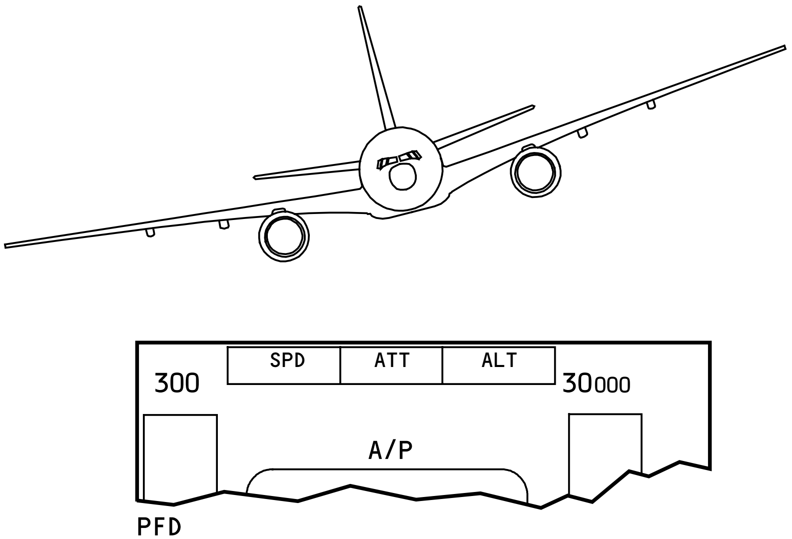
If the pilot engages the autopilot when the bank angle is more than five degrees and the flight director is off, the airplane holds the roll attitude present at that time.

ATT stays as the active roll mode until the pilot selects another roll mode. The PFD shows ATT (roll attitude) for the active roll mode.

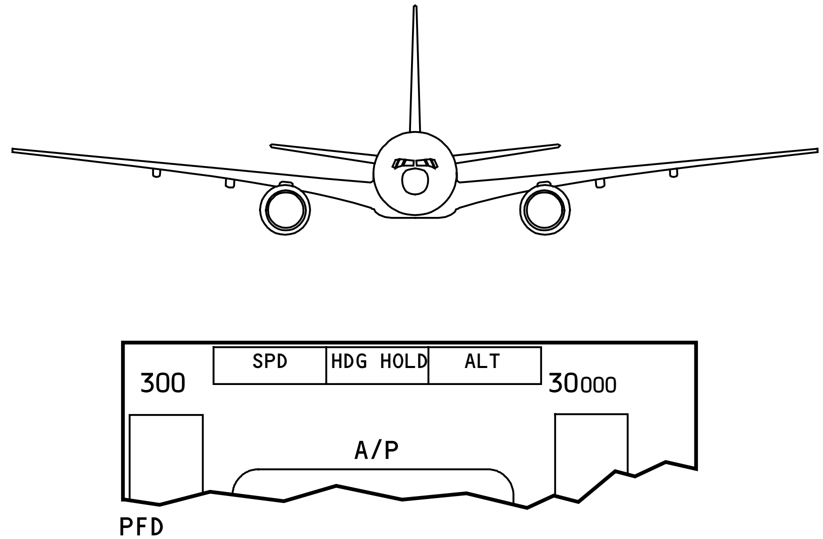
Bank Angle Five Degrees or Less

If the pilot engages the autopilot when the bank angle is five degrees or less and the flight director is off, the airplane will roll to wings level. The active roll mode is heading hold or track hold.

The PFD shows HDG HOLD or TRK HOLD as the active roll mode.



PILOT ENGAGES AUTOPILOT
WITH AIRPLANE IN A BANK
OF MORE THAN FIVE DEGREES AND F/D OFF
- AIRPLANE STAYS ON ROLL ATTITUDE PRESENT
- PFD SHOWS ATT



PILOT ENGAGES AUTOPILOT
WITH AIRPLANE IN A BANK
OF FIVE DEGREES OR LESS AND F/D OFF
- HEADING/TRACK HOLD LIGHT ON
- AIRPLANE HOLDS HEADING
- PFD SHOWS HDG HOLD

22-11-00-060 Rev 2 02/13/1998

AFDS - ROLL ATTITUDE HOLD

AFDS - OPERATION - ROLL INTRODUCTION

General

These AFDS modes are available during climb, cruise and descent:

- Lateral navigation (LNAV)
- Heading hold (HDG HOLD)
- Track hold (TRK HOLD)
- Heading select (HDG SEL)
- Track select (TRK SEL).

LNAV

The commands come from the active FMCF when there is a valid navigation data base and an active flight plan. The CDUs can send LNAV steering commands when there is no active FMCF. The AFDS use this priority to select a CDU command:

- Left if valid
- Center if left not valid
- Right if left and center are not valid.

Heading/Track Hold

In this mode, the airplane holds either heading (HDG) or track (TRK).

If the HDG/TRK display on the MCP shows TRK, the airplane holds track.

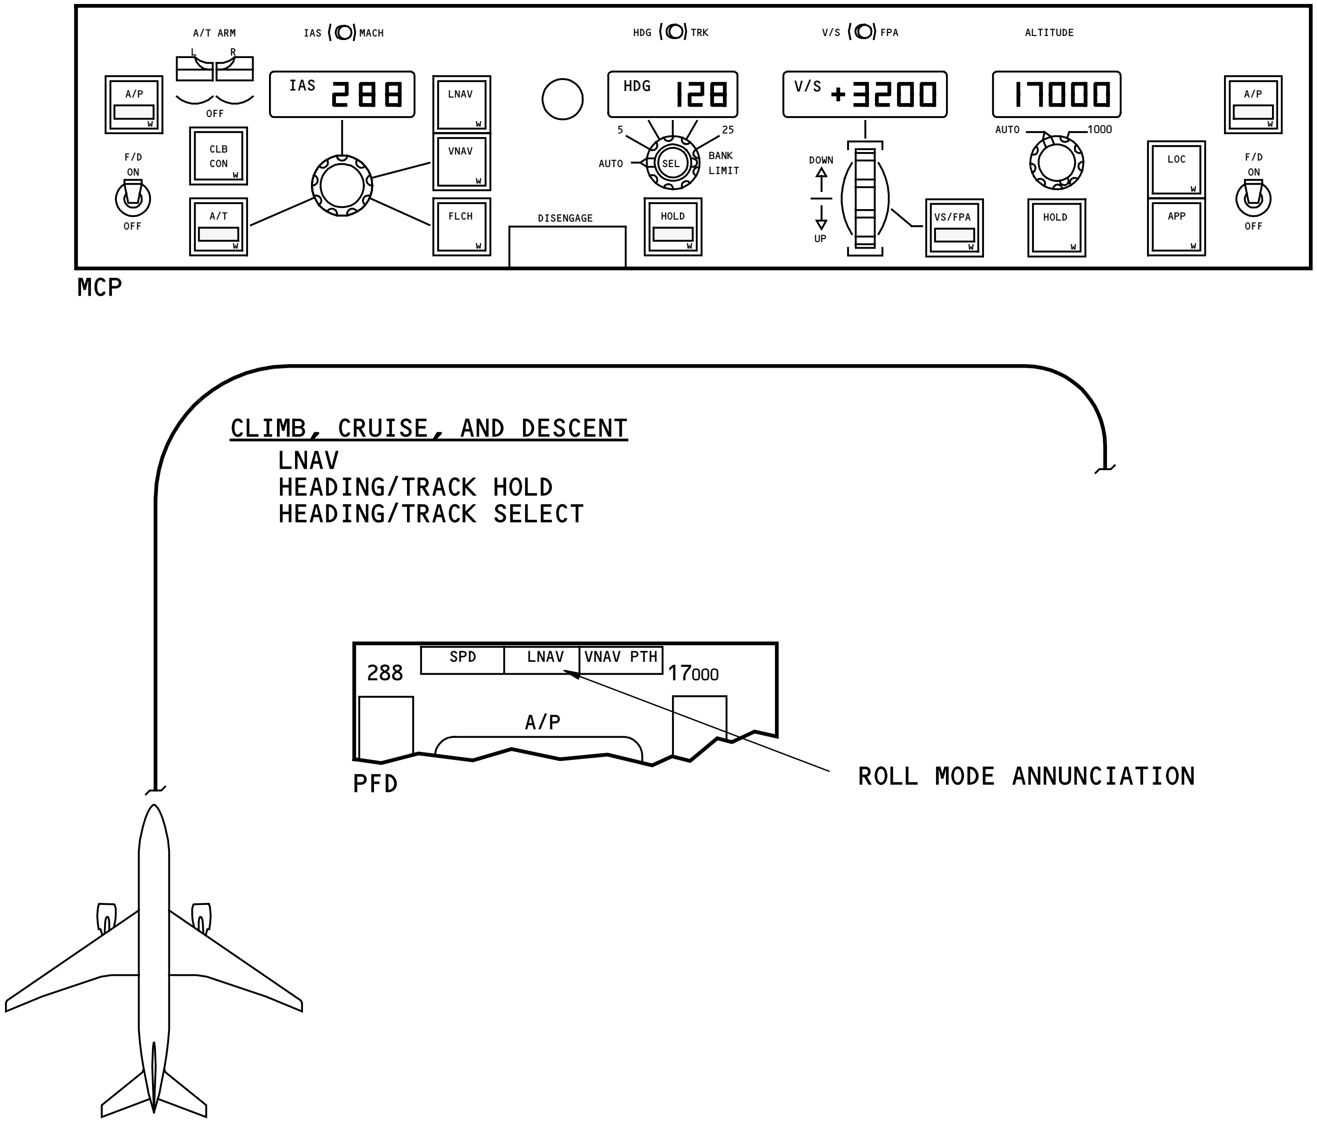
If the HDG/TRK display on the MCP shows HDG, the airplane holds heading.

Heading/Track Select

In this mode, the airplane turns to the heading or track that shows in the heading/track window.

If the HDG/TRK display shows HDG, the airplane goes to and holds the heading that shows in the heading/track window.

If the HDG/TRK display shows TRK, the airplane goes to and holds the track that shows in the heading/track window.



22-11-00-029 Rev 3 08/31/1995

AFDS - OPERATION - ROLL INTRODUCTION

AFDS - OPERATION - LNAV

General

LNAV has two sub modes:

- LNAV arm
- LNAV active.

LNAV Arm

Push the LNAV switch on the MCP to arm LNAV. To remove the LNAV arm status, push the LNAV switch again before LNAV captures or select another roll mode.

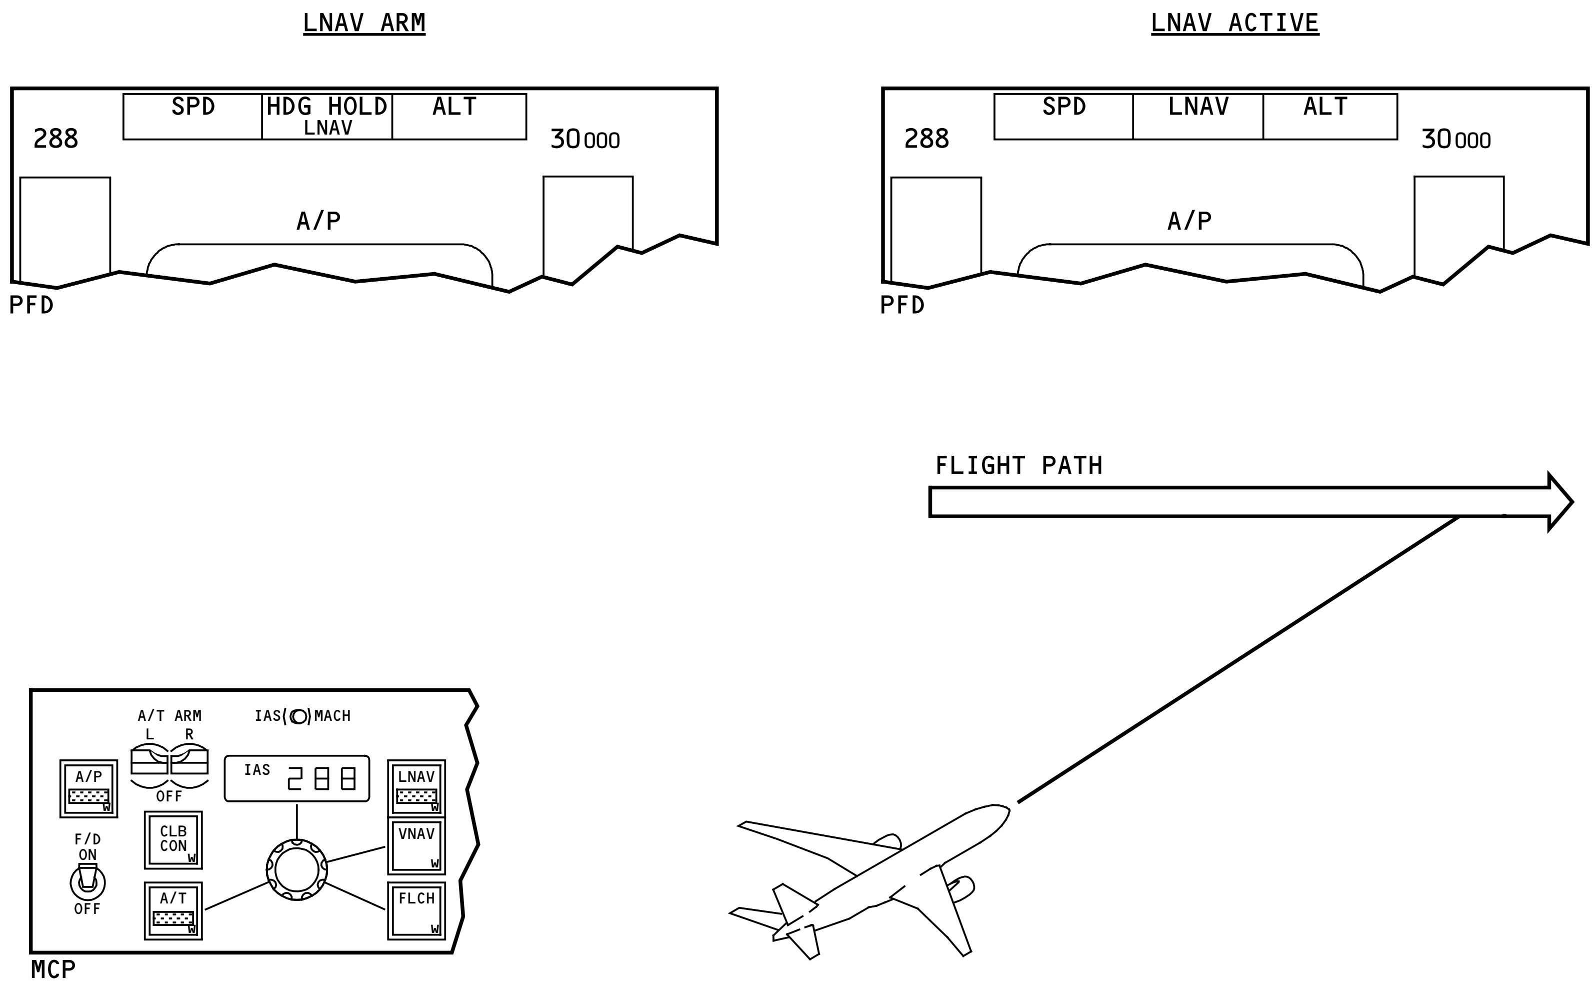
The PFD shows LNAV in white. The LNAV light is on.

You can arm LNAV before takeoff. Also, you can arm LNAV in flight if the LOC mode is not active.

LNAV Active

When active, LNAV on the PFD changes to green. This occurs when all these are true:

- The lateral flight plan is active
- The airplane is greater than 50 feet above the ground
- Data to calculate the lateral guidance command is valid
- Aircraft position is satisfactory for capture.



22-11-00-030 Rev 1

AFDS - OPERATION - LNAV

AFDS - OPERATION - HEADING/TRACK SELECT

General

The pilot uses the HDG/TRK select mode to change the airplane heading.

The select switch (SEL) on the MCP does not have a LED in the switch.

This example shows operation with HDG selected on the heading/track display. Operation with TRK selected is the same except for the display on the PFDs.

There are two ways to use the mode:

- Set heading before the mode is selected
- Select the mode before the heading is set.

Set Heading Before Mode

Set a heading in the heading/track display and push the heading select switch. These things happen:

- HDG SEL shows on the PFD
- The airplane turns in the direction for minimum heading change
- The airplane captures and holds the heading set on the MCP.

Select Mode Before Heading

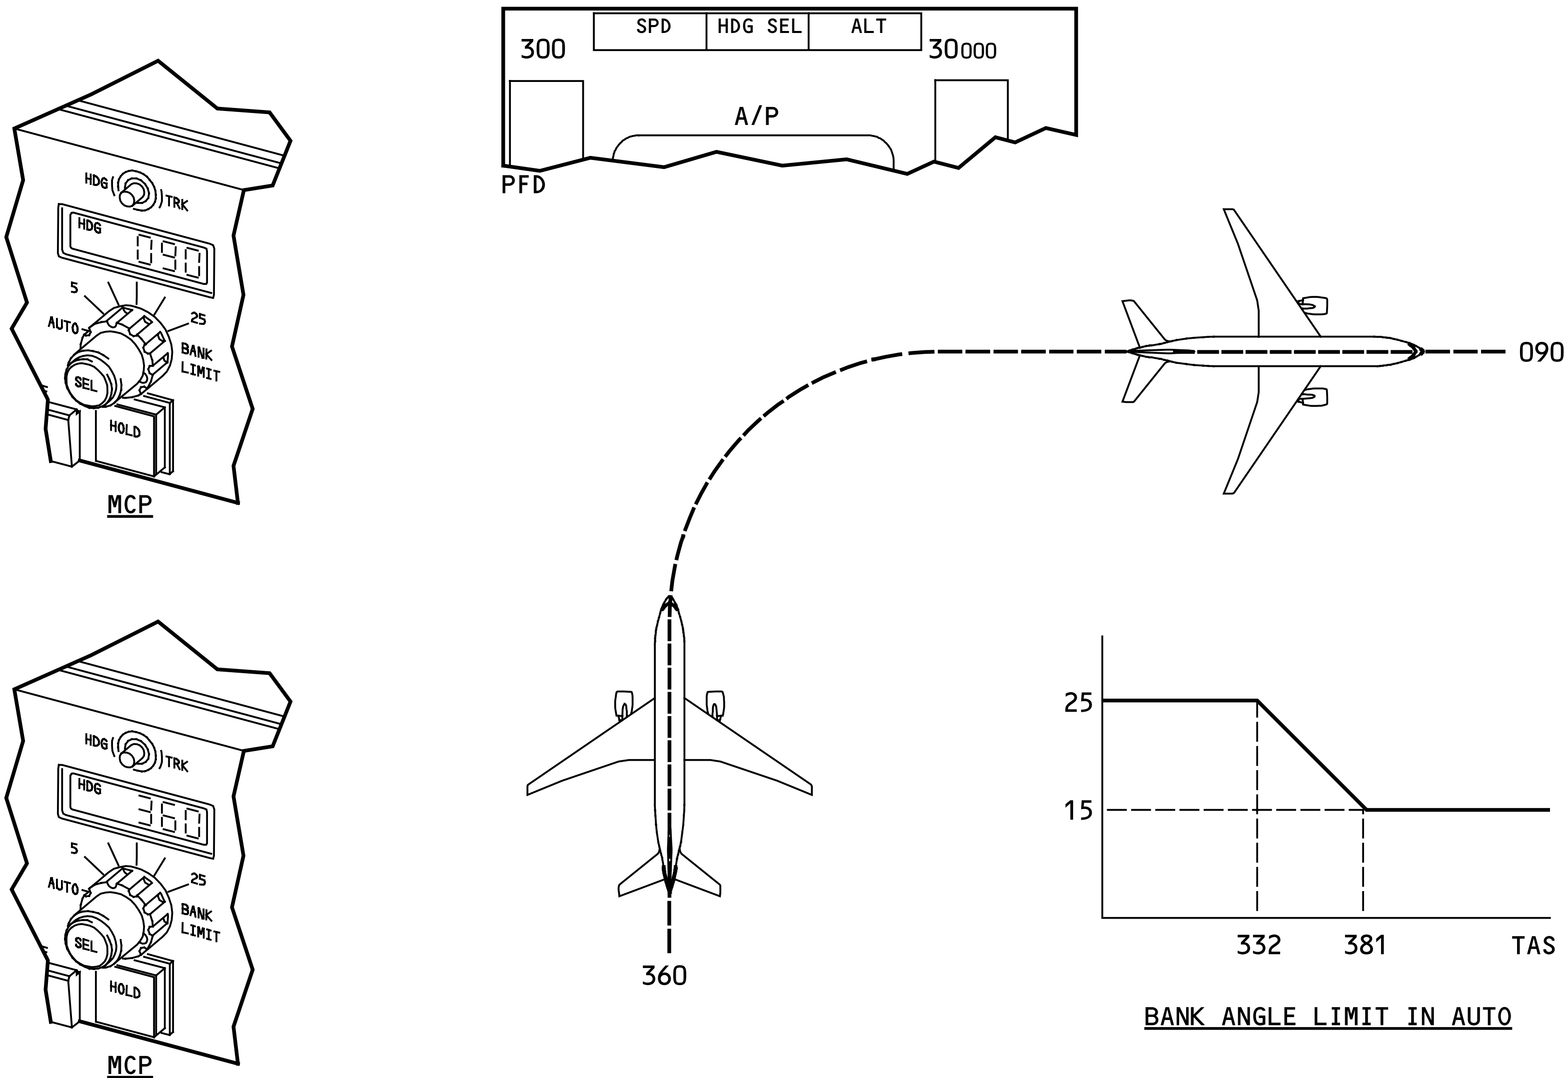
Push the heading select switch and set a heading in the heading/track display. These things happen:

- HDG SEL shows on the PFD
- When the pilot turns the heading knob clockwise, the airplane banks to the right
- When the pilot turns the heading knob counterclockwise, the airplane banks to the left
- The airplane captures and holds the heading set on the MCP.

Heading/Track Select Bank Angle Limit

The pilot uses the bank limit selector on the MCP to limit the airplane bank angle. In the AUTO position, the bank angle limit changes with true airspeed.

Below 200 feet, the bank angle limit is eight degrees.



22-11-00-031 Rev 1

AFDS - OPERATION - HEADING/TRACK SELECT

AFDS - OPERATION - HEADING/TRACK HOLD

General

In this mode the airplane holds a heading or a track angle. The pilot can set a heading or a track in the MCP displays before the mode is set.

This example shows operation with HDG selected. Operation with TRK selected is the same except for the display on the PFDs and MCP.

Airplane In A Bank

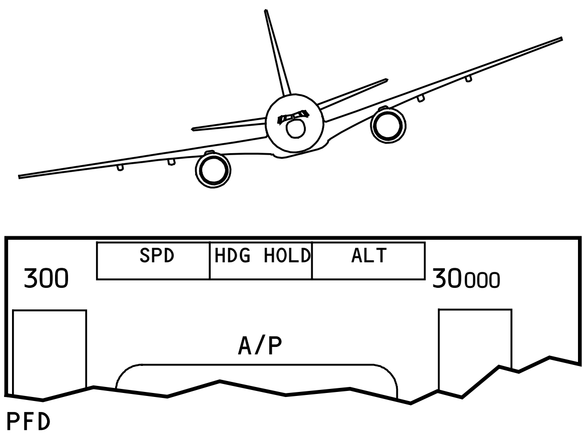
When the pilot pushes the heading/track hold switch:

- The heading/track hold light on the MCP comes on
- The airplane rolls wings level
- HDG HOLD is shown on the PFDs
- The airplane holds the heading present when the bank angle is less than three degrees for two seconds.

Airplane Wings Level

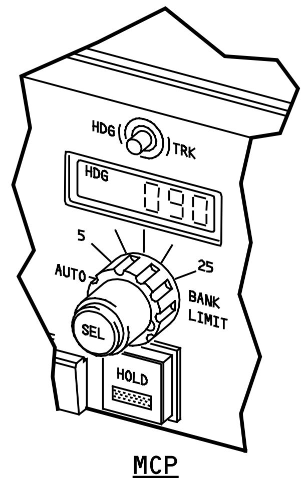
When the pilot pushes the heading/track hold switch:

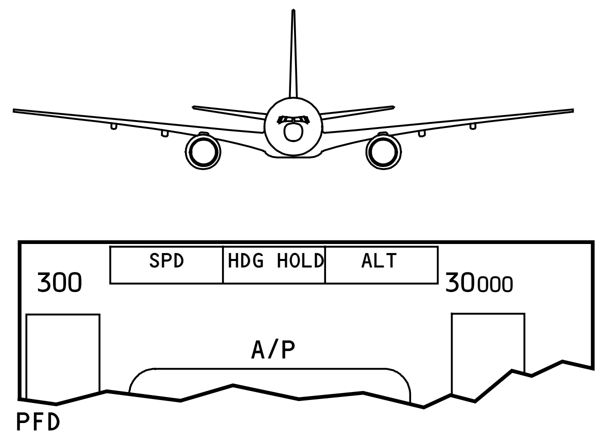
- The heading/track hold light on the MCP comes on
- HDG HOLD shows on the PFDs
- The airplane holds the present heading.



HEADING HOLD SELECTED WITH AIRPLANE IN BANK

- HEADING/TRACK HOLD LIGHT ON
- AIRPLANE ROLLS TO WINGS LEVEL
- PFD SHOWS HDG HOLD
- AIRPLANE HOLDS HEADING WHEN ROLL ATTITUDE LESS THAN 3° FOR 2 SECONDS





HEADING HOLD SELECTED WITH WINGS LEVEL

- HEADING/TRACK HOLD LIGHT ON
- PFD SHOWS HDG HOLD
- AIRPLANE HOLDS HEADING

22-11-00-032 Rev 2 09/22/1997

AFDS - OPERATION - HEADING/TRACK HOLD

AFDS - OPERATION - PITCH INTRODUCTION

General

These AFDS pitch modes are available during climb, cruise and descent:

- Vertical navigation (VNAV)
- Vertical speed (V/S)
- Flight path angle (FPA)
- Flight level change (FLCH)
- Altitude hold (ALT).

VNAV

The VNAV mode is a mix of throttle and elevator commands that control the vertical flight path.

The FMCF vertical steering commands come from the active FMCF based on the navigation data and the active flight plan.

Vertical Speed/Flight Path Angle

The vertical speed or flight path angle command is an elevator command. The pilot uses this mode to change flight levels. The pilot must set the engine thrust necessary to hold the vertical speed or flight path angle command.

When the V/S/FPA display shows V/S, the airplane goes to and holds the vertical speed that shows on the vertical speed/flight path angle window.

When the VS/FPA display shows FPA, the airplane goes to and holds the flight path angle that shows on the vertical speed/flight path angle window.

FLCH

The FLCH command is a mix of thrust and elevator commands to change flight levels.

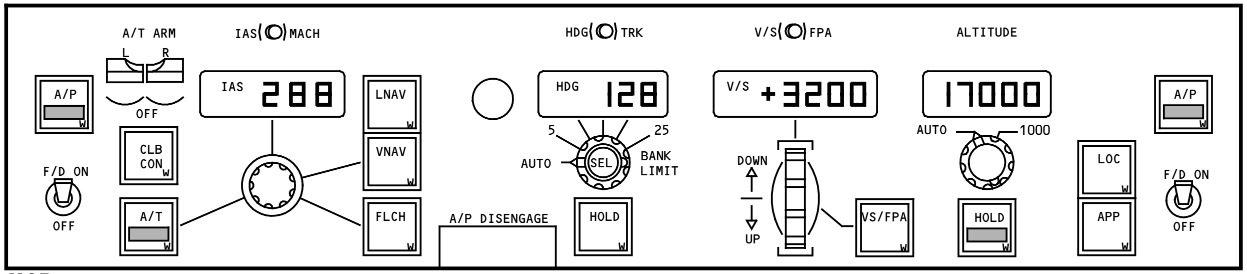
When the IAS/mach display shows IAS, the elevator command holds the speed that shows on the IAS/mach window.

When the IAS/mach display shows MACH, the elevator command holds the mach that shows on the IAS/mach window.

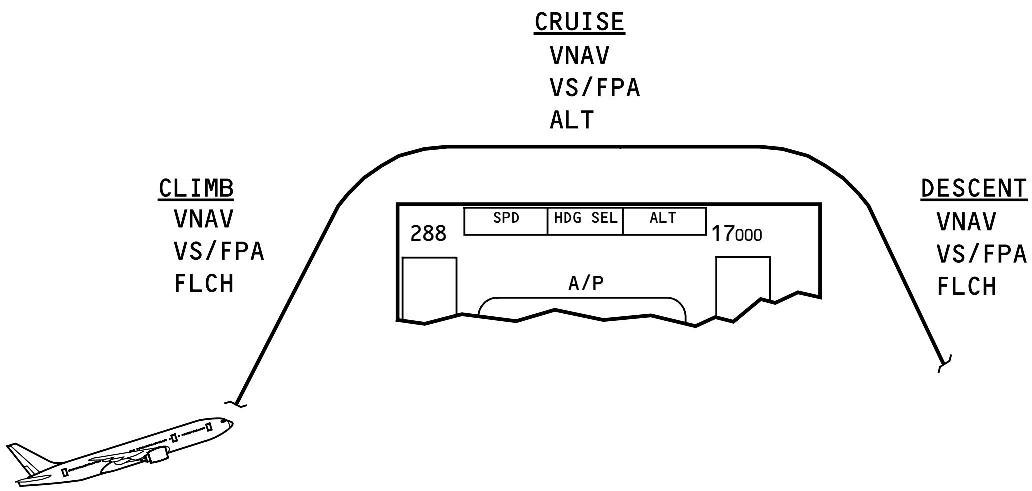
The TMCF supplies the engine thrust commands.

Altitude Hold

In this mode, the airplane holds the barometric altitude present when the pilot pushes the altitude HOLD switch.



MCP



22-11-00-033 Rev 1

AFDS - OPERATION - PITCH INTRODUCTION

AFDS - OPERATION - VNAV

General

Push the VNAV mode select switch to arm VNAV. The PFD shows VNAV in white and the switch LED is on. Push the switch again to remove the arm status.

VNAV can arm before takeoff. Also VNAV can arm in flight with the glideslope mode not active.

When active, VNAV on the PFD changes to green. This occurs when all these conditions are true:

- VNAV flight plan is active
- The airplane is greater than 400 feet above the ground
- Data required to calculate the vertical guidance command is valid.

VNAV active has these three sub-modes:

- VNAV SPD (speed)
- VNAV PTH (path)
- VNAV ALT (altitude).

VNAV SPD

The VNAV SPD mode controls the elevator to hold the FMCF target speed. The mode is active in:

- Climb
- Cruise or descent when the airplane exceeds an FMCF target speed by 5 knots.

VNAV PTH

In climb, VNAV SPD changes to VNAV PTH to capture the FMCF target altitude. In the VNAV PTH mode, the airplane holds the FMCF altitude.

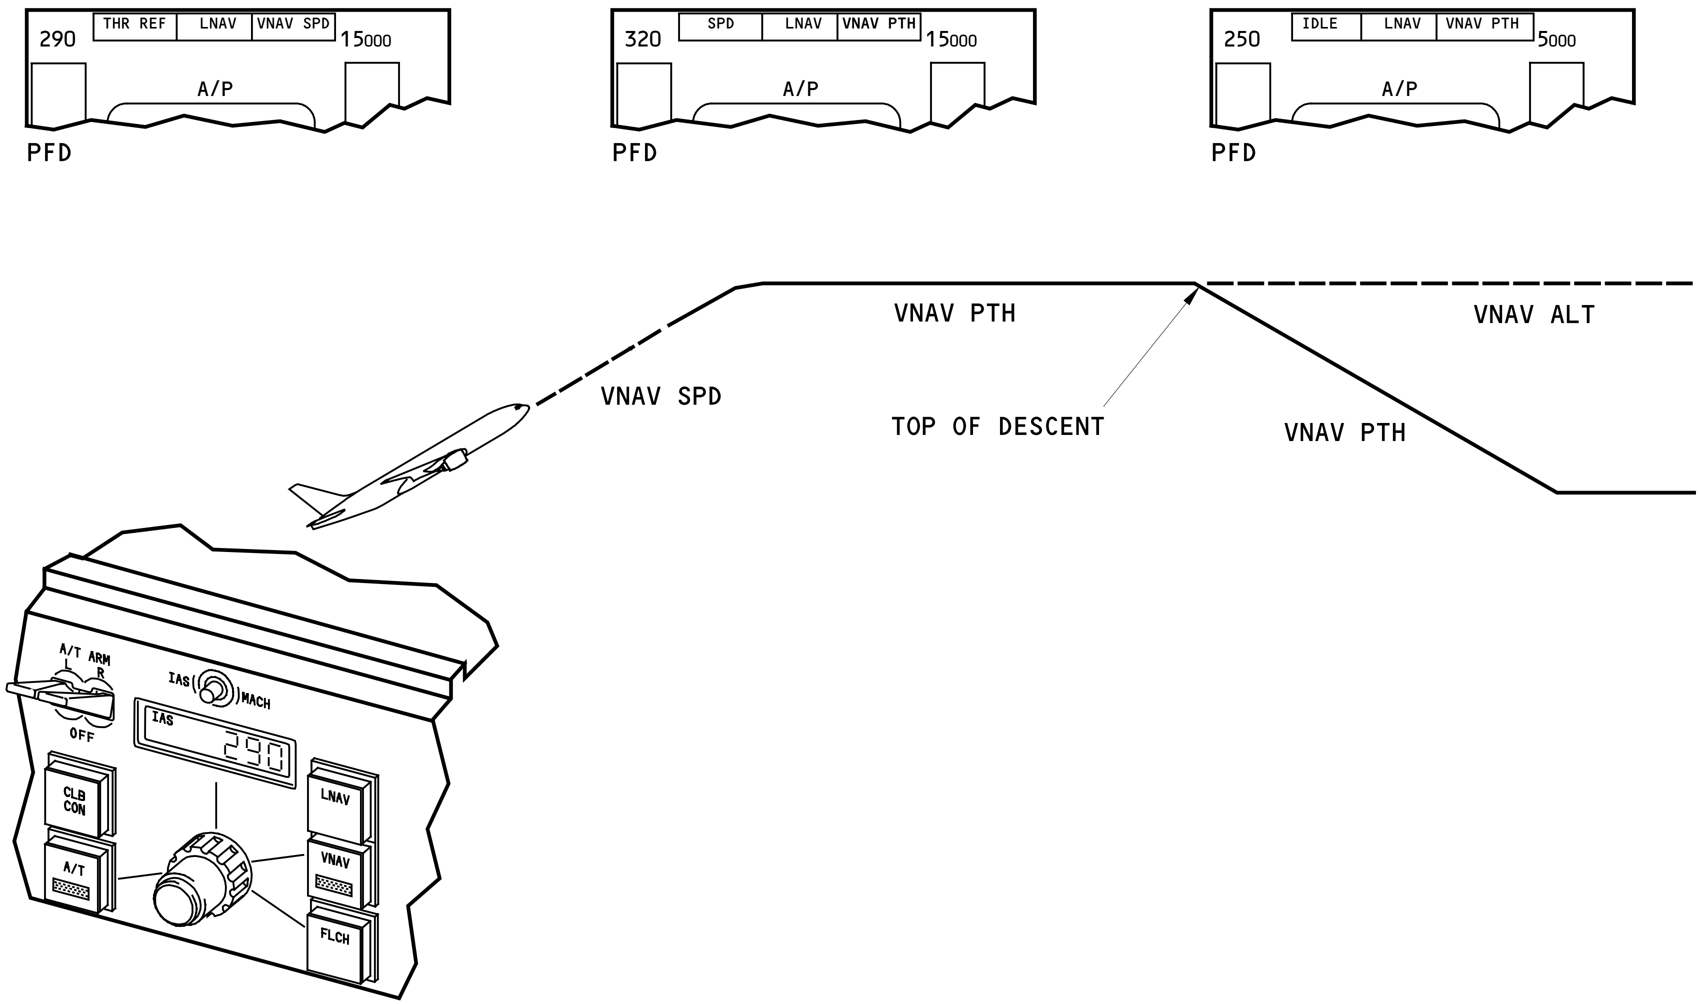
Before descent, the pilot sets an approach altitude on the MCP. At the top of descent, the throttle retards and the PFDs show IDLE. The pitch mode remains in VNAV PTH and the airplane descends.

The VNAV PTH mode continues in descent until the airplane is near the approach altitude. The autothrottle mode returns to SPD. VNAV PTH remains active and holds the approach altitude.

VNAV ALT

The VNAV ALT (altitude) mode occurs when one of these conditions is true:

- When in VNAV SPD and the airplane captures the MCP selected altitude before the FMCF target altitude
- When in VNAV PTH (descent) and the airplane captures the MCP altitude before the FMCF altitude.



22-11-00-034 Rev 1

AFDS - OPERATION - VNAV

AFDS - OPERATION - VERTICAL SPEED/FLIGHT PATH ANGLE

General

The pilot uses the VS/FPA mode to climb or descend to the altitude set in the MCP.

This example shows FPA operation. VS mode operation is the same except for the display on the PFDs.

Climb

These occur when the pilot sets a positive FPA on the MCP and pushes the VS/FPA mode select switch:

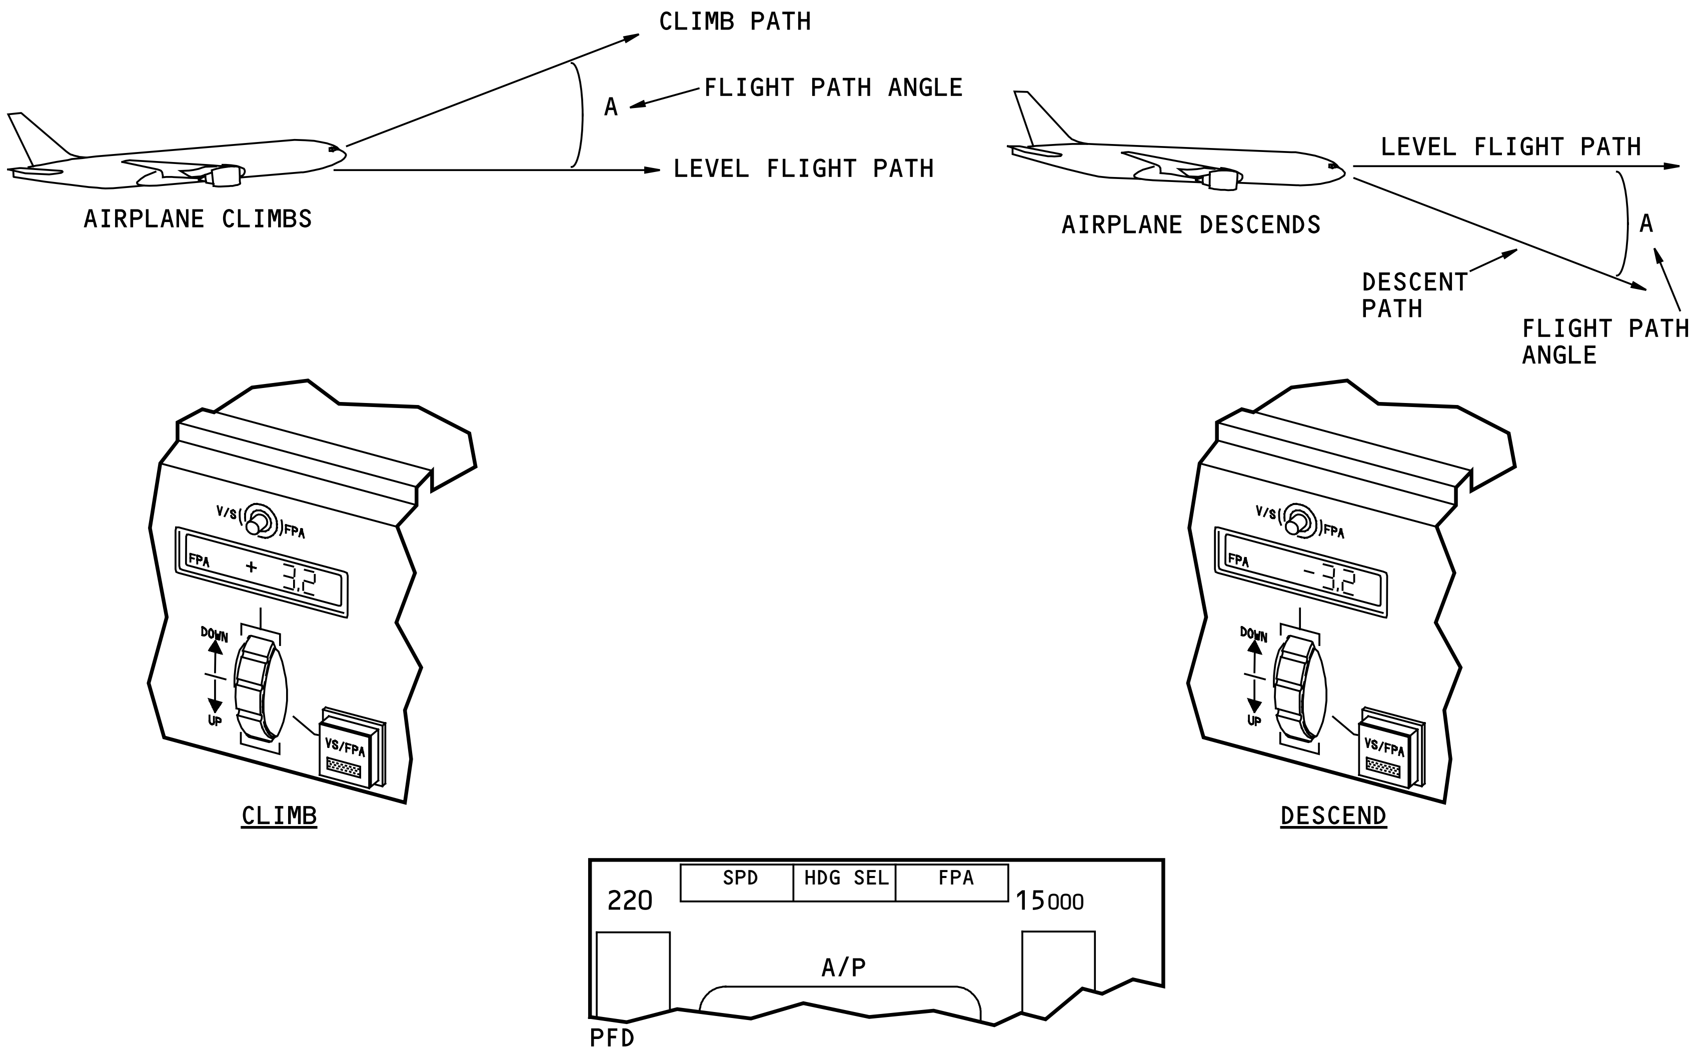
- FPA shows on the PFD
- The switch LED is on
- The airplane holds the selected FPA.

Descend

These occur when the pilot sets a negative FPA on the MCP and pushes the VS/FPA mode select switch:

- FPA shows on the PFD
- The switch LED is on
- The airplane holds the selected FPA.

The AFDS mode changes from FPA to altitude hold (ALT) when the airplane reaches the altitude set on the MCP.



AFDS - OPERATION - VERTICAL SPEED/FLIGHT PATH ANGLE

AFDS - OPERATION - ALTITUDE HOLD

General

Altitude hold is active in any of these conditions:

- Push the altitude hold switch on the MCP
- Select a V/S of 0000 in the V/S mode
- Capture and hold the altitude set on the MCP.

Altitude Hold Switch

These occur when the pilot pushes the altitude hold switch on the MCP:

- The AFDS holds the present barometric altitude
- The altitude hold light is on
- The PFDs show ALT.

Set V/S To 0000

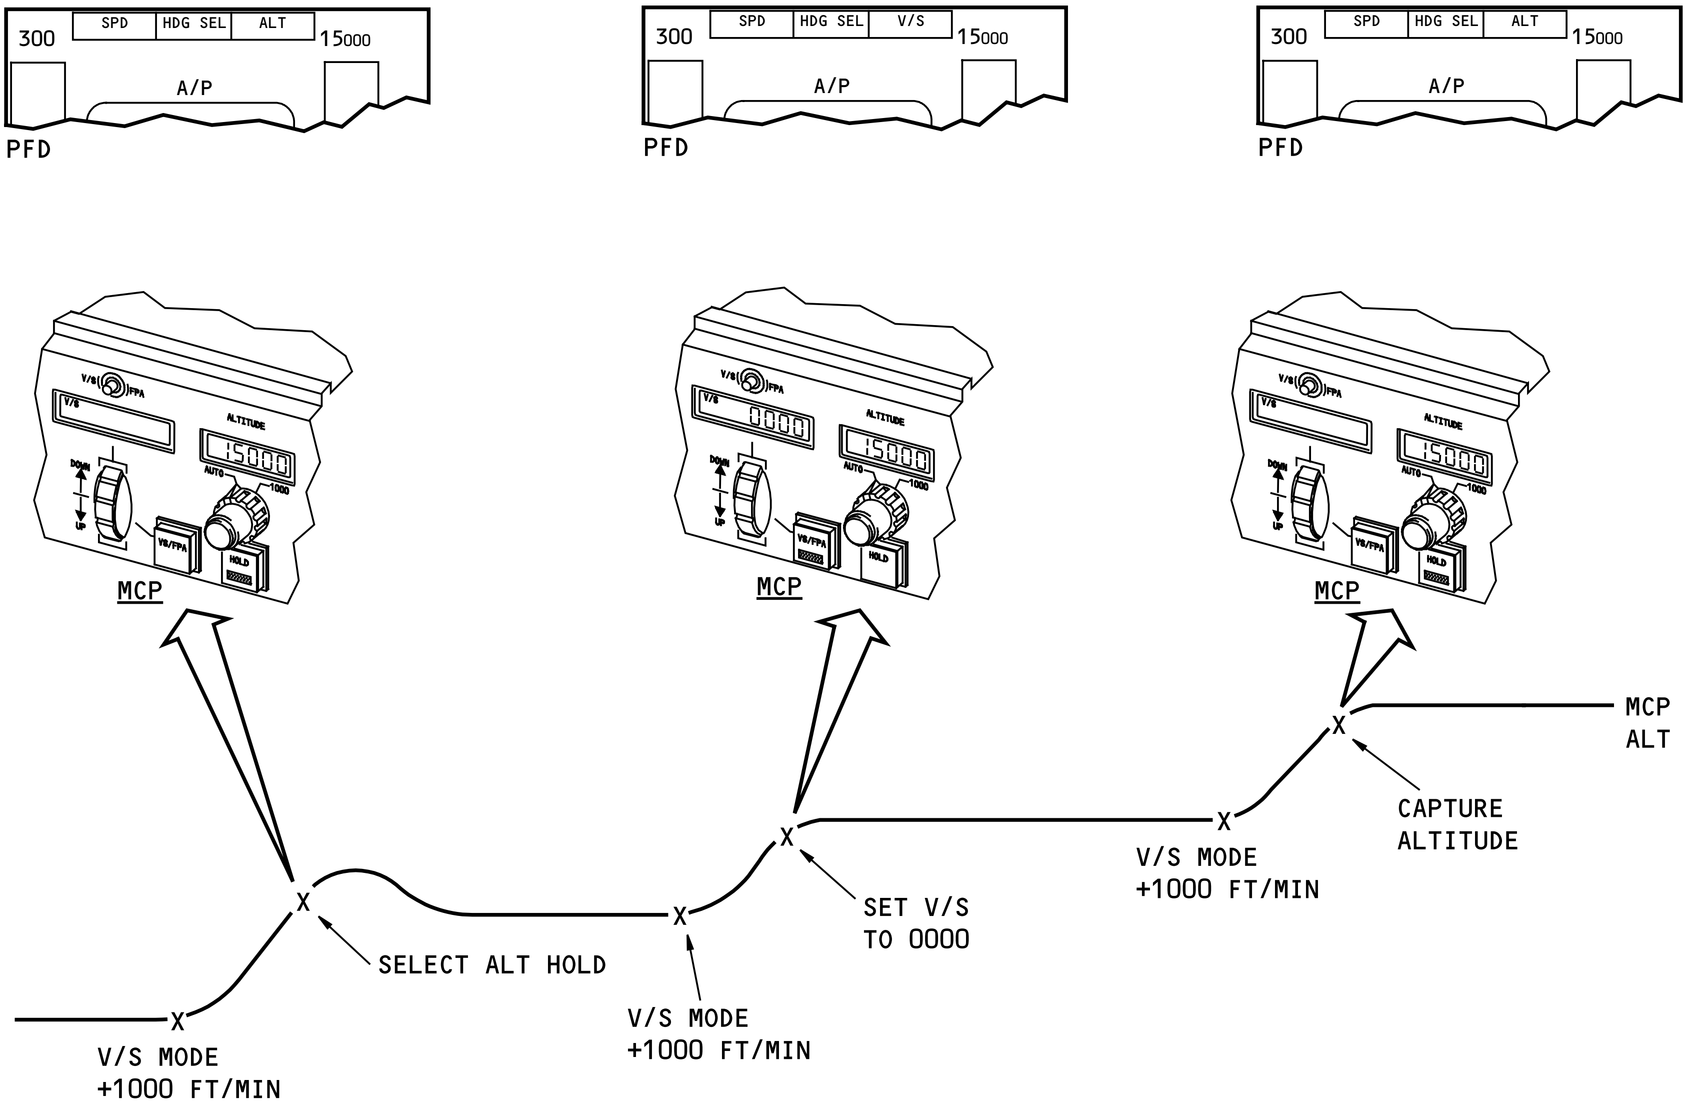
These occur when the pilot sets a vertical speed of 0000:

- The airplane levels and holds the present barometric altitude
- The V/S mode remains active
- The PFDs show V/S.

Capture Altitude

Altitude capture starts as the airplane approaches the MCP selected altitude:

- The PFDs show ALT in green
- The airplane holds the altitude set on the MCP.



22-11-00-036 Rev 1

AFDS - OPERATION - ALTITUDE HOLD

AFDS - OPERATION - FLIGHT LEVEL CHANGE

General

The FLCH mode permits the pilot to change flight levels with the AFDS and the TMCF. The autothrottle controls thrust. The AFDS controls airspeed with the elevator.

FLCH Selection

The pilot must set a target altitude on the MCP before the FLCH mode can be set.

With the FLCH mode active, the flight level change light is on. FLCH SPD is the pitch mode and THR is the autothrottle mode on the PFDs.

If the pilot pushes the FLCH switch with VNAV as the active mode, the MCP IAS/mach window shows the FMCF target speed. The AFDS controls to this speed until the pilot sets a new speed in the window.

When TO/GA is the active pitch mode and the pilot pushes the FLCH switch, the IAS/mach window shows the higher of these:

- Present airspeed
- Speed set in the MCP.

If you push the FLCH switch when the IAS/mach window shows a speed or mach number and the active pitch mode is not TO/GA, the MCP IAS/mach window does not change.

In all cases, the AFDS controls to the speed on the MCP IAS/mach window until the pilot sets a new speed in the window.

The airplane speed stays within these limits:

- Flap placard speeds
- Maximum operating velocity and Mach (VMO/MMO)
- Minimum speed.

Altitude Capture

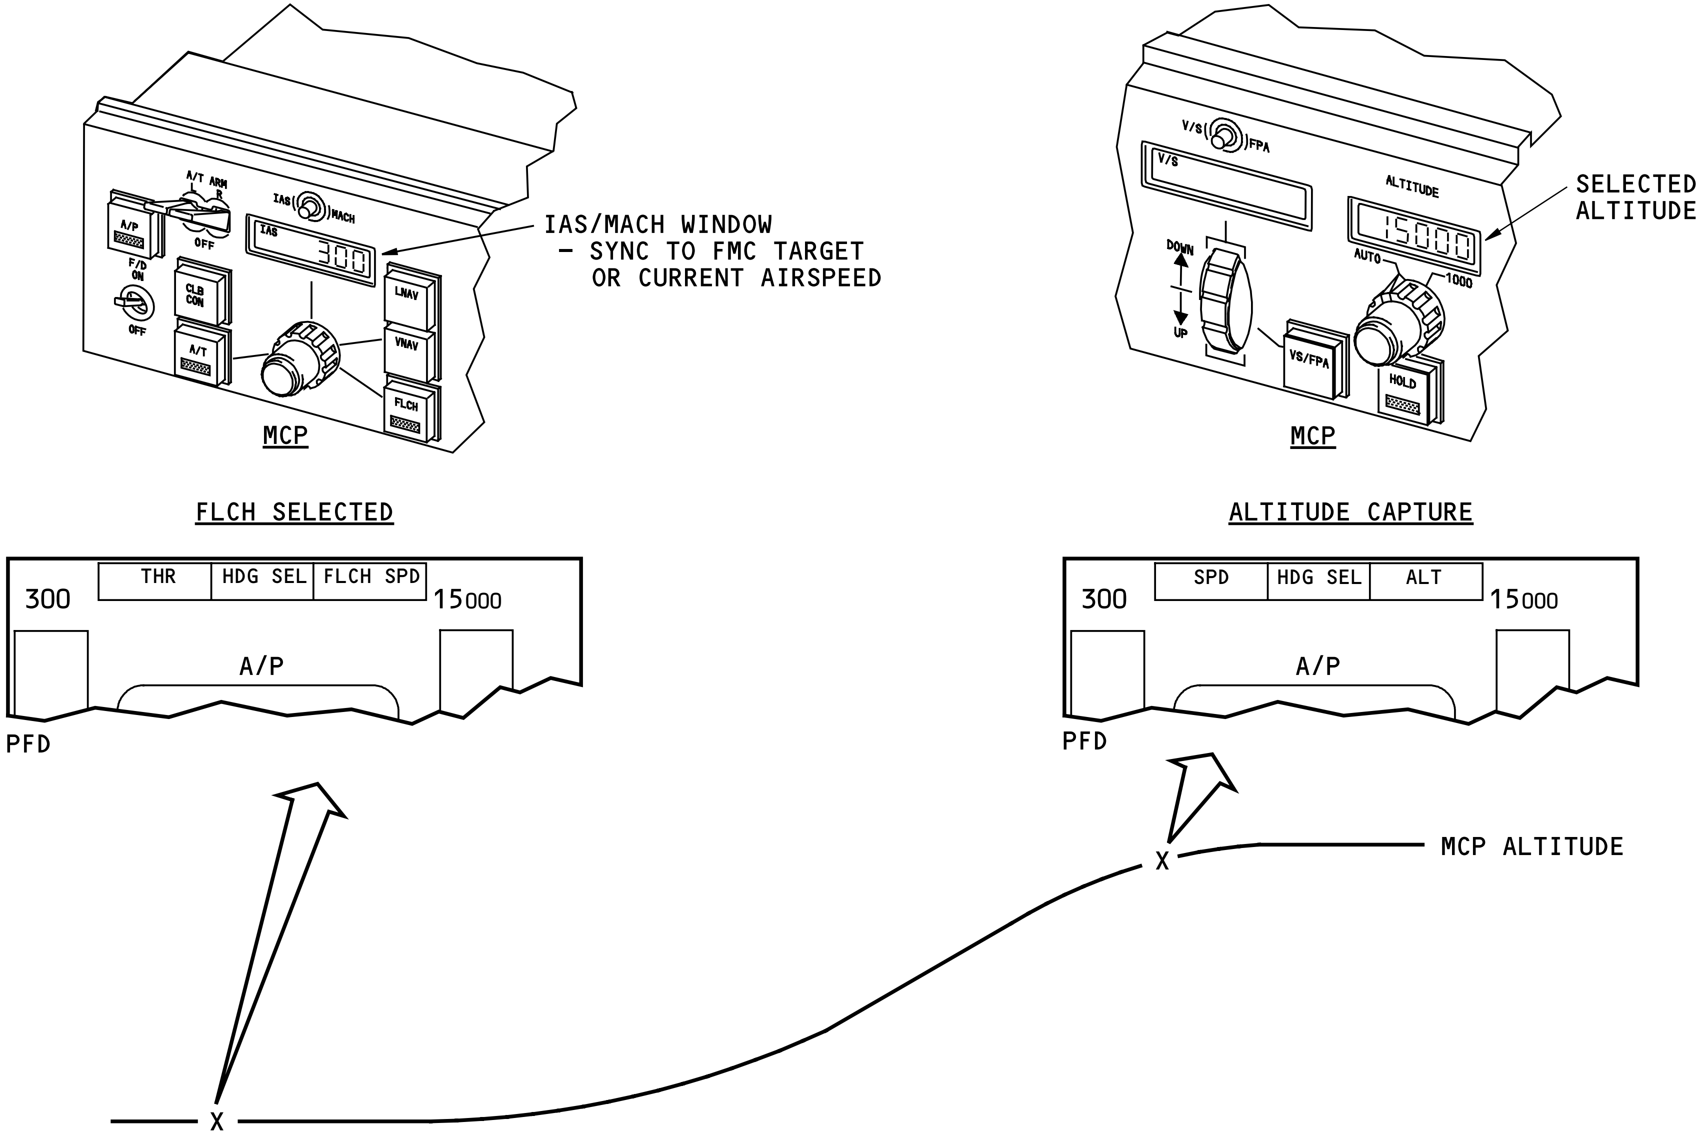
When the airplane is at the altitude set on the MCP, the AFDS pitch mode changes to ALT. The autothrottle mode changes to SPD.

If there is not enough engine thrust to capture the altitude and hold airspeed, the AFDS stays in the speed mode and does not go to the ALT mode.

A/T Modes

These A/T modes can show during FLCH:

- THR
- HOLD
- IDLE.



AFDS - OPERATION - FLIGHT LEVEL CHANGE

AFDS - OPERATION - APPROACH/AUTOLAND INTRODUCTION

General

These AFDS functions are available for landing:

- Localizer (LOC)
- Glideslope (G/S)
- Flare (FLARE)
- Runway Alignment
- Rollout (ROLLOUT)
- Go-Around (TO/GA).

The flight crew pushes the APP switch on the MCP to arm the LOC and G/S modes.

Localizer

The LOC mode captures and holds the airplane to a localizer flight path.

Glideslope

The G/S mode captures and holds the airplane to a vertical descent flight path.

Flare

The flare mode controls the airplane to a smooth touchdown at a point past the glideslope antenna. This is a computed command and is not part of the glideslope mode.

Runway Alignment

In crosswind conditions, the runway alignment mode supplies roll and yaw control to decrease the airplane crab angle for touchdown. The runway alignment mode also includes roll and yaw control for an engine failure in approach during autoland.

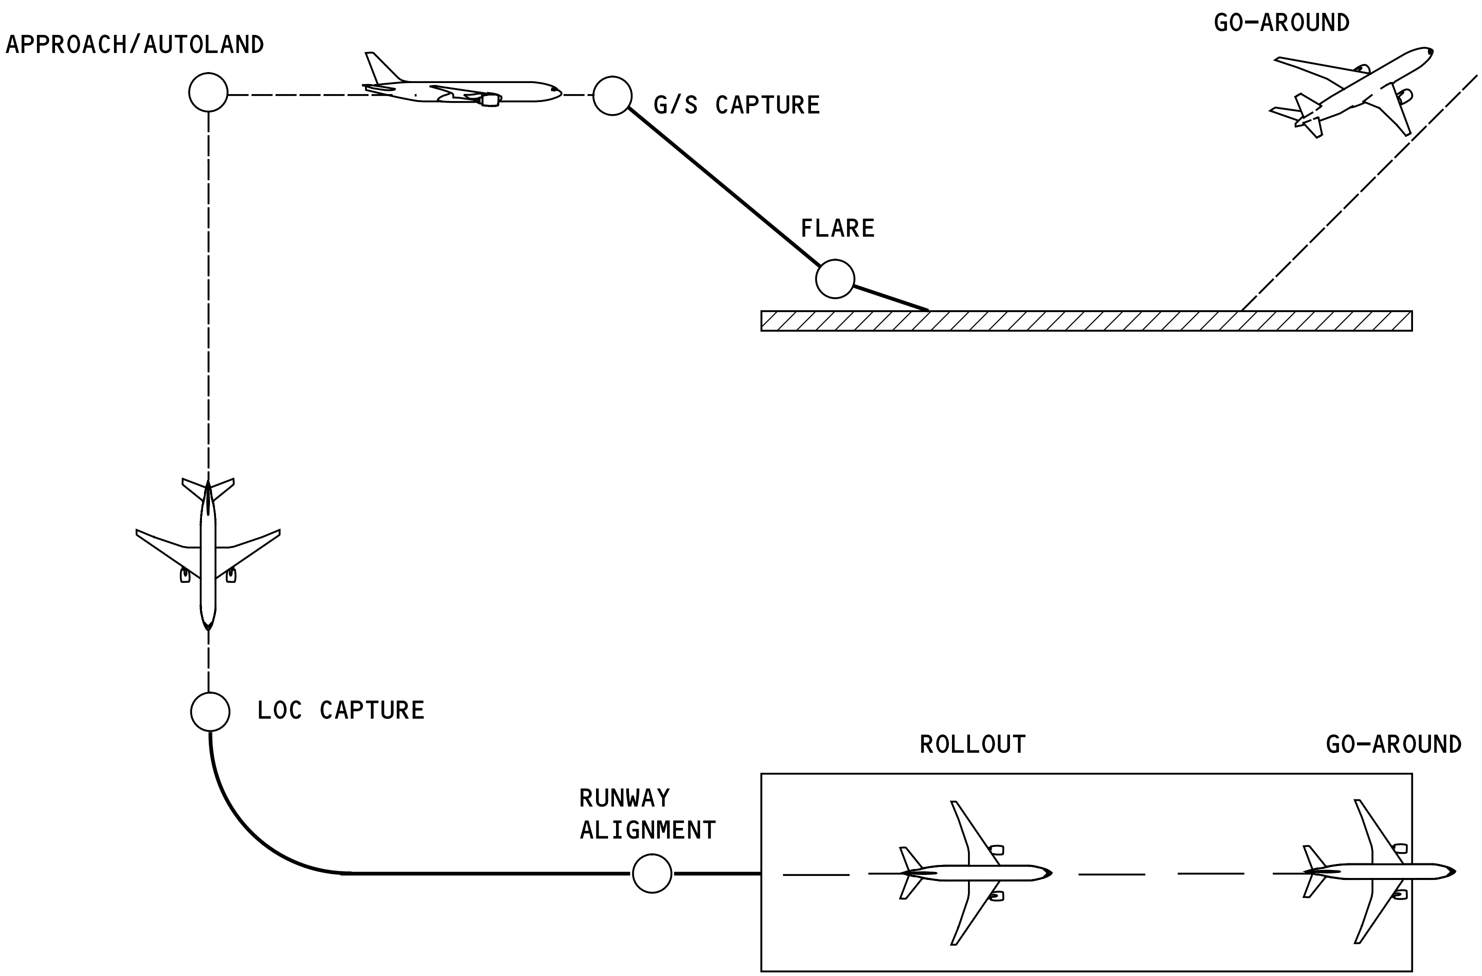
There is no annunciation on the PFD for this mode.

Rollout

After touchdown, the rollout mode controls the airplane to the runway center line. Airplane deviation from the localizer center line supplies rudder and nose wheel steering signals.

Go-Around

The go-around mode controls roll and pitch after an aborted approach. Also, the TMCF controls thrust during go-around.



22-11-00-038 Rev 0

AFDS - OPERATION - APPROACH/AUTOLAND INTRODUCTION

AFDS - OPERATION - LOCALIZER

General

The flight crew uses the localizer switch on the MCP, to select a localizer only approach.

The flight crew uses the localizer only approach when glideslope is not available or uses a different vertical path for descent.

An ILS frequency and course must be set into the FMCF.

The flight crew can use another roll mode to fly the airplane to the localizer. In this example, the flight crew uses the heading select mode.

The LOC mode has these two sub-modes:

- Localizer arm
- Localizer active.

Localizer Arm

The LOC switch on the MCP arms only the localizer mode. The PFD shows LOC in white. The LOC switch light comes on.

To remove the arm status, push the LOC switch again before the localizer captures or select another roll mode.

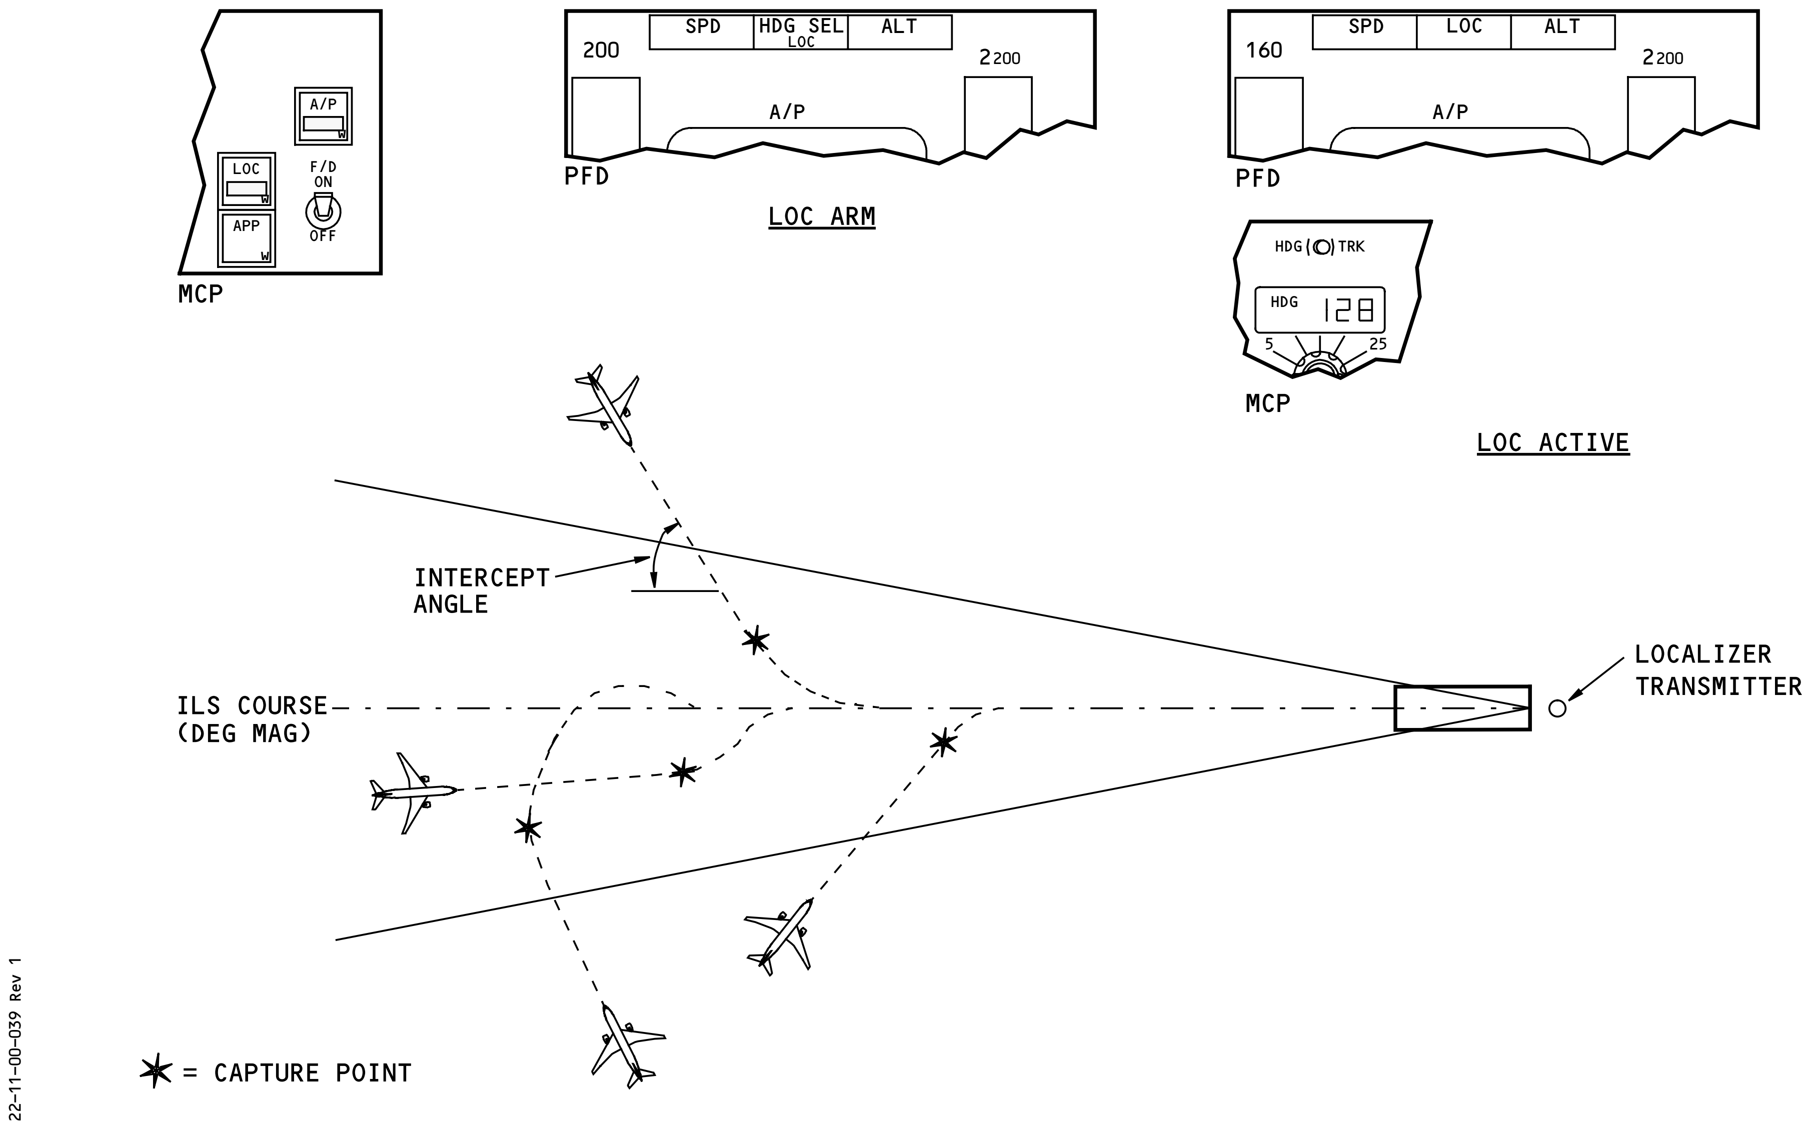
Localizer Active

At LOC capture, the active roll mode changes to LOC. The MCP heading/track window changes to the ILS course.

The localizer capture point is not fixed. The AFDS calculates the localizer capture point as a function of:

- Ground speed
- Localizer deviation
- Intercept angle (must be less than 120 degrees from the selected ILS course).

The AFDS uses the previous data to put the airplane on the localizer beam without large bank angles.



AFDS - OPERATION - LOCALIZER

AFDS - OPERATION - APPROACH

General

In approach (APP), the airplane automatically captures and tracks the localizer and glideslope beams. If an autopilot approach continues, the airplane lands automatically.

The flight crew or the FMCF sets the ILS frequency and the ILS course.

The two sub-modes of APP are:

- LOC and G/S arm
- LOC and G/S capture.

Autoland Status

If the autopilot is engaged in the approach mode below 1500 feet radio altitude, the autoland status shows on the PFD. The autoland status shows LAND 3, LAND 2, or NO AUTOLAND. The autoland status is the level of redundancy in the autoland system.

LAND 3 shows when there are no failures in any part of the autoland system. LAND 2 shows when any part of the autoland system is one failure away from NO AUTOLAND. NO AUTOLAND shows when the autoland system is not available.

There are more than 30 conditions that can cause a change from LAND 3 to LAND 2 or NO AUTOLAND. Refer to the airplane system schematics for a full list of the conditions that change the autoland status to LAND 2 or NO AUTOLAND.

These are some failures that cause a change from LAND 3 to LAND 2:

- Single AFDC failure
- Single backdrive actuator failure
- Single radio altimeter failure
- Single ILS receiver failure
- ADIRU status message.

These are some failures that cause a change from LAND 3 to NO AUTOLAND:

- Two AFDCs fail
- Approach mode not active at 600 feet
- Two radio altimeters fail
- Two ILS receivers fail
- ADIRU failure.

Approach Arm

These occur when the flight crew pushes the approach (APP) switch on the MCP:

- The approach light on the MCP comes on
- LOC and G/S show white on the PFD
- A bus isolation request goes to the electrical power system.

Bus isolation stays active during an autoland until the autopilot disengages or the airplane climbs above 400 feet radio altitude after a go-around starts.

If bus isolation fails, the autoland status changes from LAND 3 to LAND 2.

If you push the APP switch while both LOC and G/S are armed, the approach mode will disarm.

LOC And G/S Capture

The localizer capture point is not fixed. The AFDS calculates the localizer capture point as a function of these data:

- Ground speed
- Localizer deviation
- Intercept angle (must be less than 120 degrees from the selected runway heading).

The glideslope capture point is not fixed. Glideslope capture is a function of these data:

- The airplane distance from the center of the glideslope beam
- Glideslope deviation.

Glide slope capture does not occur until after localizer capture.

At LOC capture, the active roll mode changes to LOC. The MCP heading/track window changes to the ILS course.

At G/S capture, the active pitch mode changes to G/S.

The AFDS supplies an ILS tune inhibit signal when G/S and LOC are active with the autopilot system engaged.

The AFDS also supplies an ILS tune inhibit signal when the autopilot is not engaged and all of these conditions are true:

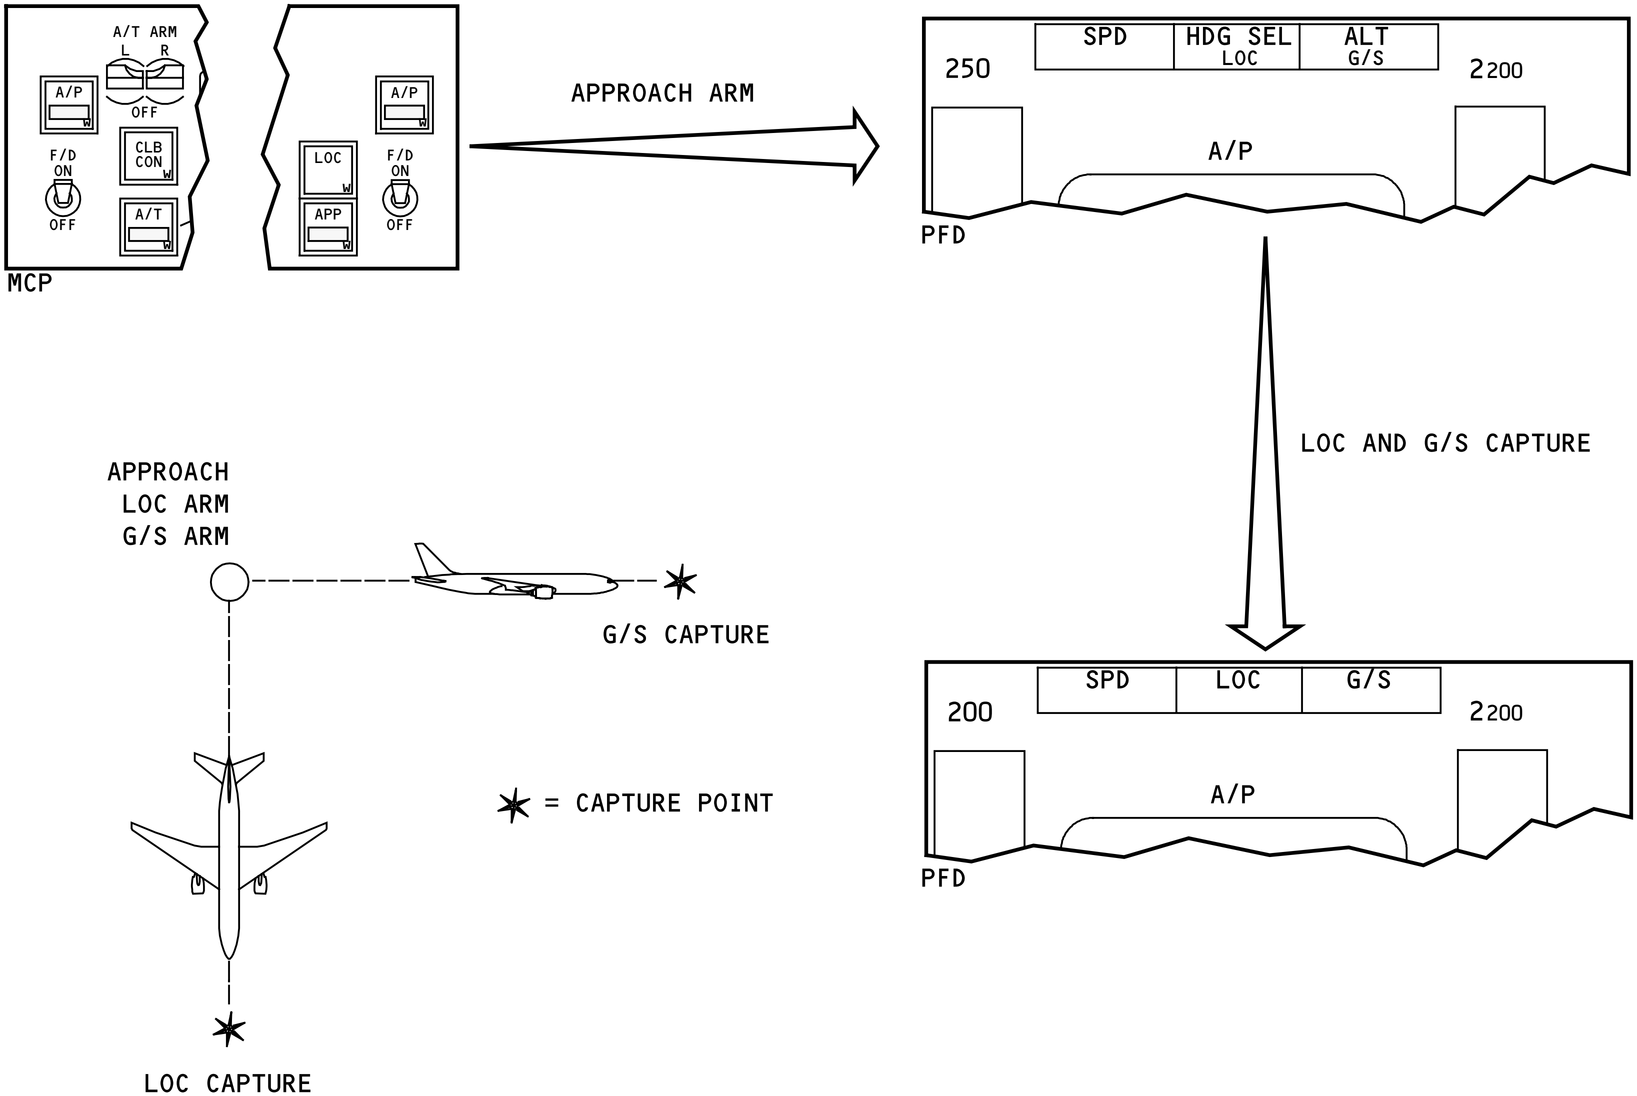
- A flight director is on
- G/S and LOC are active
- The airplane is below 500 feet of radio altitude.

If the autopilot is not engaged and pilot tunes the ILS when the radio altitude is 500 feet or more, the flight director displays go out of view.

With LOC and/or G/S captured, the APP mode goes away by one of these methods:

- Select another pitch mode if only G/S is active
- Select another roll mode including LOC, if only LOC is active
- Push either TO/GA switch if G/S is active, or the trailing edge flaps are not up
- Disengage the autopilot and put the F/D switches in the off position
- Push the APP switch if the airplane is above 1500 feet and both LOC and G/S are active.

The last method lets the flight crew disconnect the APP mode if air traffic control sends the airplane to another runway. The flight crew sets a new ILS frequency and ILS course and pushes the APP switch to arm LOC and G/S again.



22-11-00-040 Rev 3

AFDS - OPERATION - APPROACH

AFDS - OPERATION - AUTOLAND PITCH

General

In autoland, the AFDS controls the elevator for these functions:

- Glideslope (G/S)
- Flare
- Touchdown.

The flare mode and touchdown sub-mode occur when the autopilot is engaged and at least two AFDCs operate.

Glideslope

With the G/S mode active, the AFDS keeps the airplane on the vertical descent flight path.

With the autopilot engaged and G/S and LOC modes active, these events occur as the airplane descends below 1500 feet:

- The other control column and wheel backdrive actuators and both rudder pedal actuators engage. All available backdrive actuators engage.
- LAND 3, LAND 2 or NO AUTOLAND shows on the PFD as the active autoland status
- ROLLOUT and FLARE modes arm and show on the PFD.
- The runway alignment sub-mode is active. There is no added annunciation for runway alignment on the PFD.

Flare/Touchdown

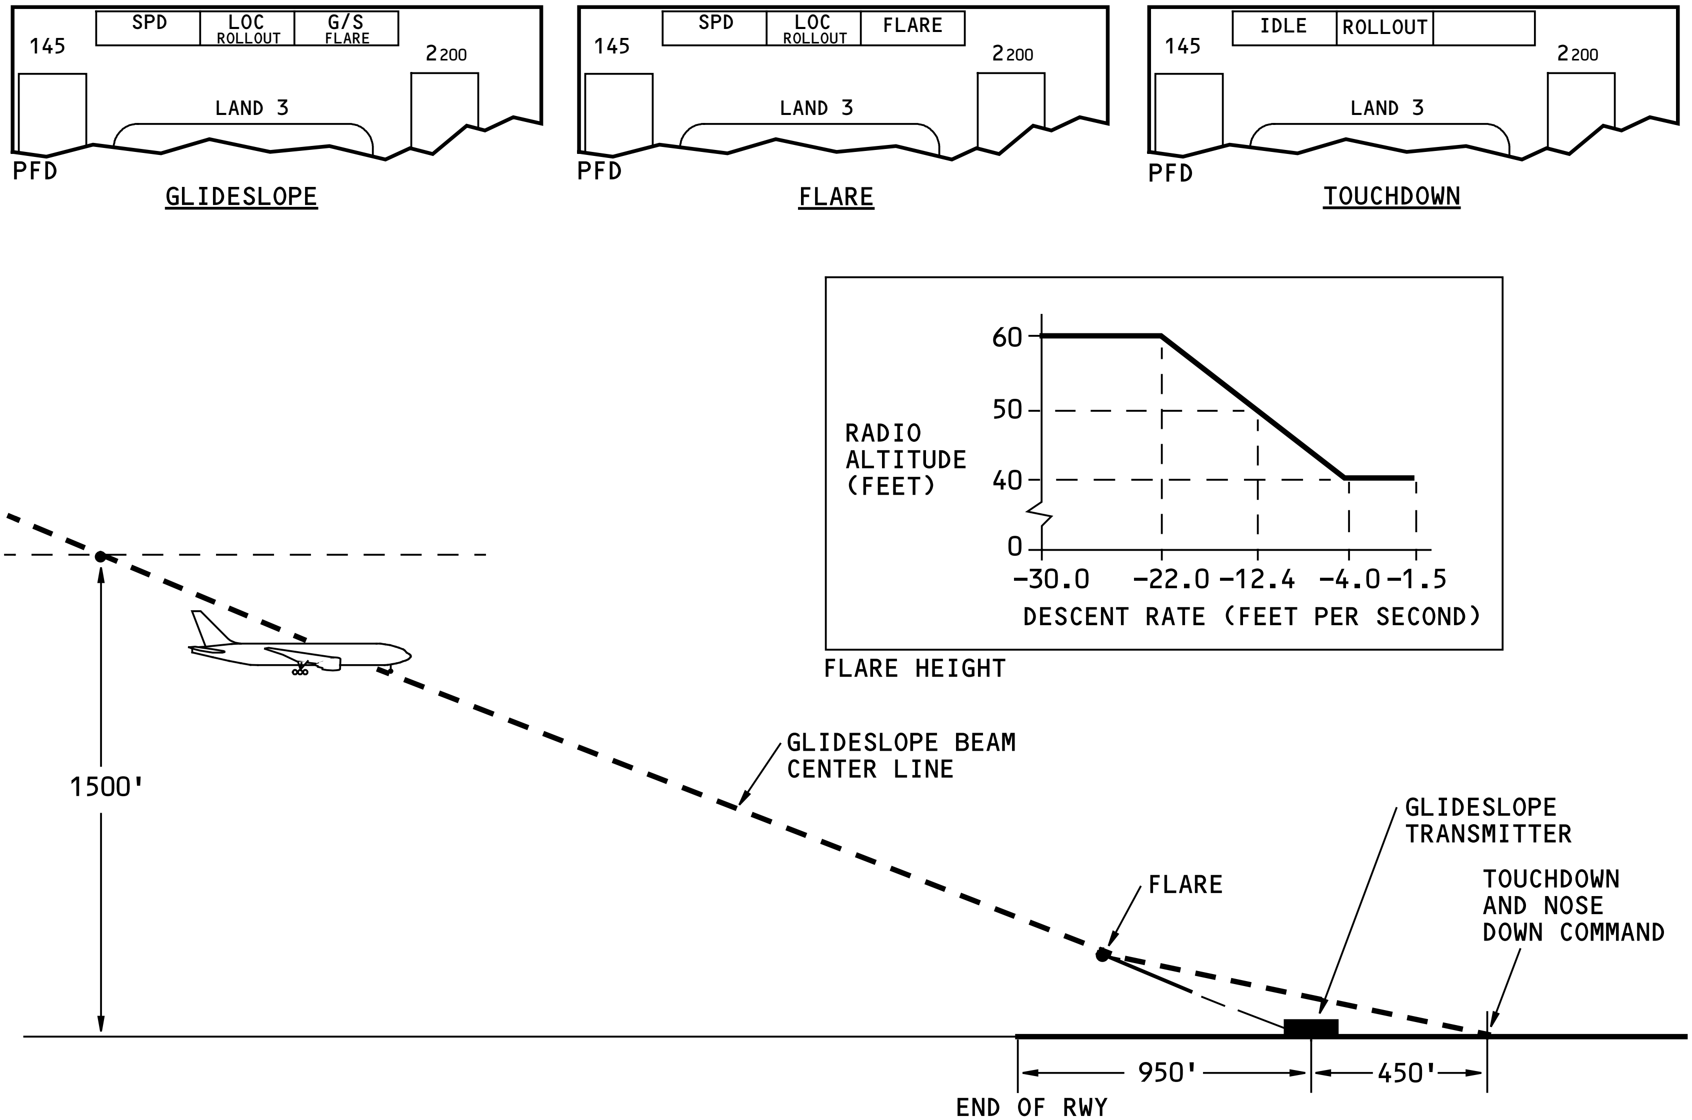
FLARE replaces G/S as the active mode on the PFD.

During flare, airplane touchdown occurs 450 feet past the glideslope transmitter at a descent rate of 1.5 feet/second.

The altitude at which the flare mode becomes active is flare height. The descent rate of the airplane sets this height. An adjustable flare height gives constant touchdown performance for a wide range of approach speeds.

The AFDS sends a throttle idle command to the TMCF at 25 feet radio altitude.

An airplane nose down command brings the nose wheel in contact with the runway. This occurs when the radio altitude is below five feet and the pitch attitude of the airplane is less than two degrees. At this time, the pitch mode goes blank on the PFD.



AFDS - OPERATION - AUTOLAND PITCH

AFDS - OPERATION - AUTOLAND ROLL AND YAW

General

The runway alignment function corrects for engine out and crosswind conditions during an autoland. This is to make sure the wings are level or the upwind wing is low for all possible wind and engine out combinations. The AFDS does this with rudder and aileron commands (sideslip).

At landing, the rollout mode controls rudder and nosewheel steering to keep the airplane on the center line of the runway.

Runway Alignment

Engine out runway alignment occurs at 1300 feet. The speed and the direction of the crosswind sets the amount of sideslip.

Crosswind control occurs at 500 feet or 200 feet.

With a crab angle of more than ten degrees (high crosswinds), the alignment occurs at 500 feet. The AFDS command decreases the crab angle by five degrees.

With a crab angle between five and ten degrees (medium crosswinds), alignment occurs at 500 feet. Another alignment occurs at 200 feet. The total crab angle reduction for both alignments is five degrees.

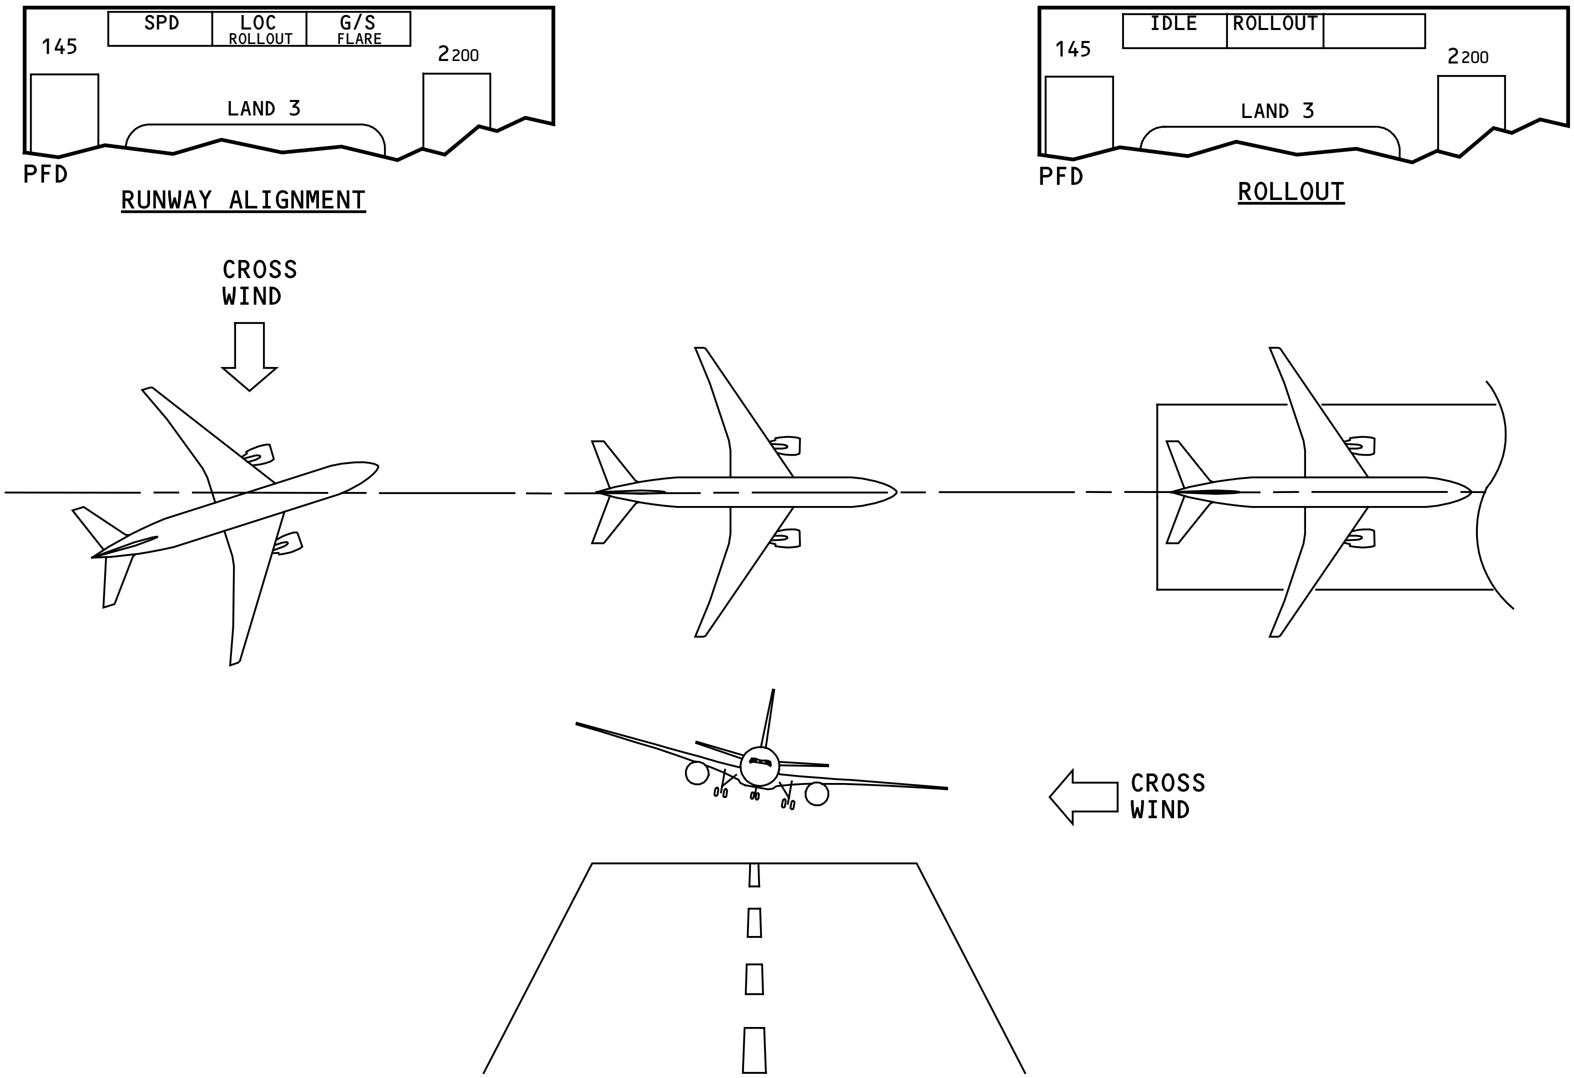
With a crab angle less than five degrees (light crosswinds), alignment occurs at 200 feet. The AFDS removes the crab angle.

Rollout

The rollout mode arms at 1500 feet during an autoland.

As the airplane descends below two feet of radio altitude, the mode is active and ROLLOUT replaces LOC as the active mode on the PFD.

Rollout guidance continues until the flight crew disengages the autopilot and sets the flight director switches to off.



22-11-00-042 Rev 2

AFDS - OPERATION - AUTOLAND ROLL AND YAW

AFDS - OPERATION - GO-AROUND

THIS PAGE INTENTIONALLY LEFT BLANK

AFDS - OPERATION - GO-AROUND

General

Go-around is a combined AFDS and TMCF mode. The pilot uses the mode in these conditions:

- An aborted approach
- Windshear during takeoff or landing.

The pitch command keeps the airplane in these limits:

- Flap placard speeds
- Maximum operating velocity and Mach (VMO/MMO)
- Minimum speed.

The roll command holds the present track of the airplane over the ground.

In go-around, the flight director display on the PFDs automatically comes on even if the flight director switches are off. This is called "auto pop up". It occurs when all these conditions are true:

- A flight director switch is off
- The trailing edge flaps are not up
- The pilot pushes a TO/GA switch.

Go-Around Arm

Go-around arms when the airplane is in the air and, one of these conditions is true:

- Glideslope mode is active
- The trailing edge flaps are not up.

The PFD and MCP continue to show the approach modes.

Go-Around Active

The go-around mode starts when the pilot pushes either TO/GA switch. With one push of the TO/GA switch, the autothrottle controls to a 2000 ft/min climb. With a second push, the autothrottle controls to full go-around thrust.

TO/GA shows on the PFD as the active mode for roll and pitch. The autothrottle mode is thrust (THR).

The AFDS supplies an initial pitch up command to make sure the airplane clears any obstacles. After the pitch up command, the AFDS commands one of these:

- Target airspeed
- A combination of target airspeed and pitch attitude
- Pitch attitude.

If the climb rate is below 600 FPM, the pitch command is to hold attitude. For rates between 600 FPM and 1200 FPM, the pitch axis holds a mixture of airspeed and attitude. For climb rates above 1200 FPM, the pitch axis holds a target airspeed.

For go-around with an engine out, the pitch axis command is a mixture of airspeed and attitude below 1200 FPM. Above 1200 FPM, the pitch axis holds a target airspeed.

AFDS - OPERATION - GO-AROUND

This mix of speed and attitude command gives windshear protection during go-around.

Go-Around Off

Below 400 feet, the AFDS stays in go-around unless the pilot disengages the autopilot and sets the flight director switches to off.

Above 400 feet, the pilot can select another roll or pitch mode.

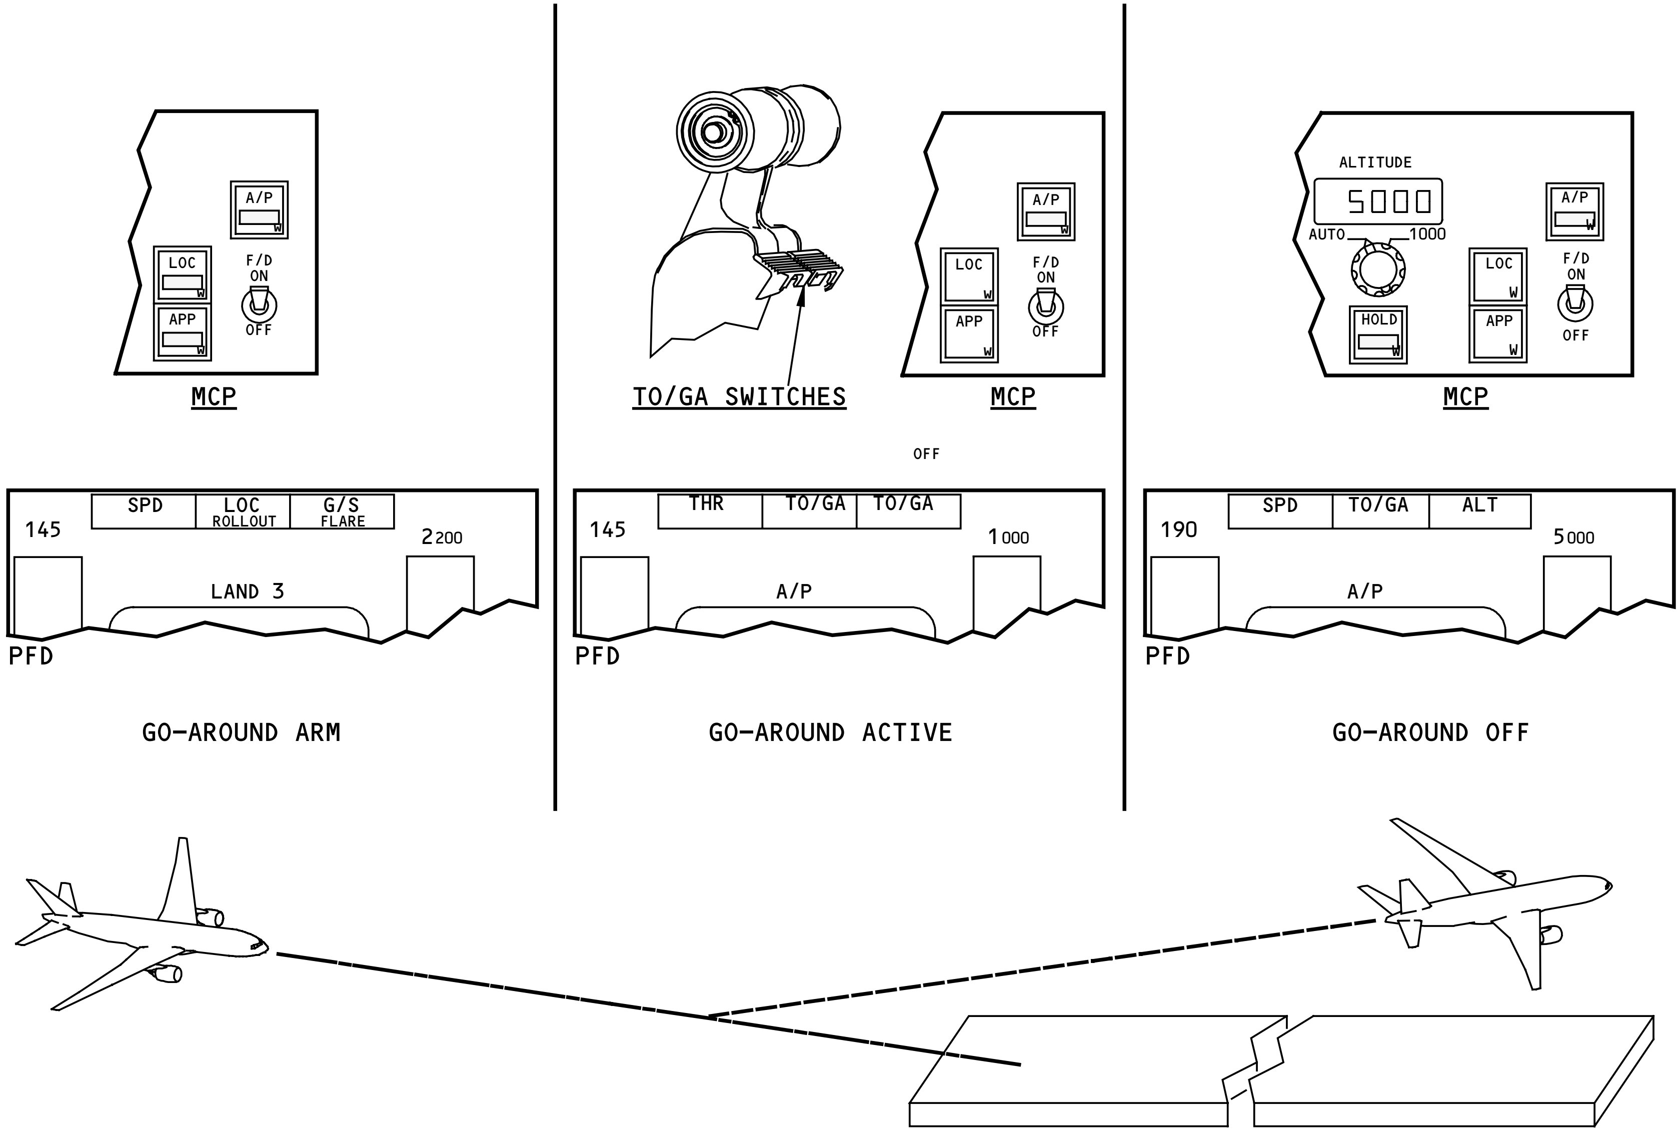
In this example, the AFDS captures the MCP altitude. The PFDs show ALT and the airplane levels off at 5000 feet.

Go-around stays as the active roll mode until the pilot selects another roll mode.

The pitch mode change from TO/GA to ALT makes the autothrottle change to SPD mode at the speed set on the MCP.

When a go-around occurs below 1500 feet during an autoland, all six backdrive actuators remain engaged until a different roll or pitch mode, other than TO/GA, is selected.

When a go-around occurs below 1500 feet during an autoland, bus-isolation remains active until the airplane is above 400 feet.



AFDS - OPERATION - GO-AROUND

AFDS - FUNCTIONAL DESCRIPTION - ENGAGE INTERLOCKS INTRODUCTION

Purpose

The autopilot engage interlock circuits in the AFDCs and PFCs monitor the operation, power, and components of the AFDS and PFCS. With normal conditions, the circuits let the autopilot engage. If conditions are not normal, the autopilot disengages or the autopilot does not engage.

Mode Control Panel

The autopilot engage switches are on the MCP. The flight crew pushes either switch to engage the autopilot.

Usually, all three AFDCs engage when the flight crew pushes either A/P engage switch. If there are faults, it is possible to engage one or two AFDCs. Autoland requires two or three AFDCs engaged.

The disengage bar on the MCP lets the flight crew disengage the autopilot from the MCP. The autopilot cannot engage unless the bar is in the up position.

AFDC

The AFDCs process the engage request from the MCP and send it to the PFCs.

The engage logic and backdrive engage relays in the AFDCs monitor these components, systems, and sensors:

- MCP
- Autopilot disengage switches
- AFDC cross channel data
- PFCS
- ADIRU
- SAARU
- ILS
- RA
- Backdrive actuators.

PFCs

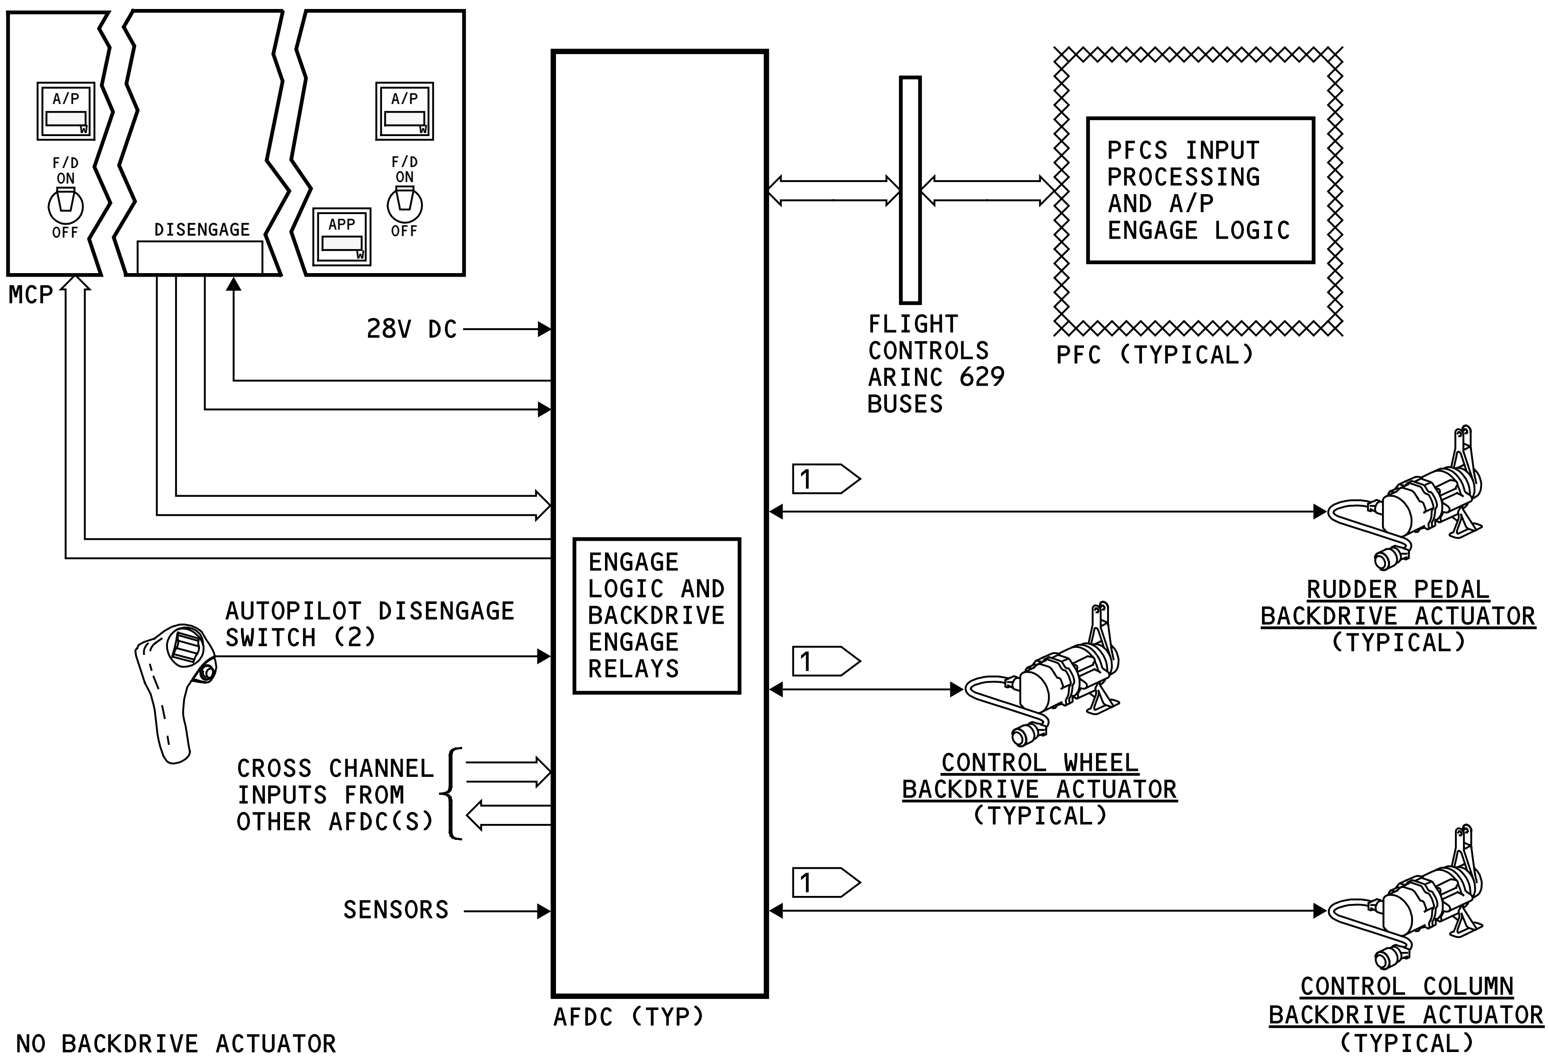
The PFCS controls the elevator, aileron, and rudder. When the PFCs receive valid engage requests from the AFDCs, the PFCs change control of these surfaces from the flight crew to the autopilot. The PFCs also command the AFDCs to engage the backdrive actuators.

Backdrive Actuators

The left and right AFDCs have rudder pedal, control wheel, and control column backdrive actuators. The center AFDC does not control backdrive. For this reason, the autopilot does not engage with only the center AFDC.

The engage relays for the backdrive actuators are in the AFDCs.

Logic in the AFDCs monitor the electrical components in the backdrive actuators.



1 NO BACKDRIVE ACTUATOR CONNECTIONS FOR CENTER AFDC.

AFDS - FUNCTIONAL DESCRIPTION - ENGAGE INTERLOCKS INTRODUCTION

AFDS - FUNCTIONAL DESCRIPTION - ENGAGE INTERLOCKS MASTER/SLAVE SELECTION

General

The AFDCs operate as master or slave when the autopilot engages in cruise. Two or three AFDCs must engage before the master/slave selection occurs.

Only the left or right AFDCs can be master. This is because they operate the backdrive actuators. Any of the three AFDCs can operate as slave.

The master selection changes between the left and right AFDC to:

- Apply equal wear between the backdrive actuators
- Automatically select a good AFDC for master after a failure disengages the autopilot.

The AFDS does not use the master/slave function in autoland.

Selection Process

The AFDCs use these methods to select the master AFDC:

- Random selection of the right or left AFDC when power is applied to the AFDS
- The master AFDC changes each time the autopilot engages.

Master AFDC Function

The master AFDC performs these functions:

- Column and wheel backdrive actuator selection and control in cruise
- Wheel backdrive actuator selection during BAP
- Control of AFDS modes
- Sends AFDS mode data to the slave AFDCs
- Calculate pitch, roll and yaw commands.

If the master AFDC cannot do these functions, the autopilot disengages. You can engage the autopilot again with a different AFDC as the master.

The MCP microprocessor in control follows the master AFDC selection when:

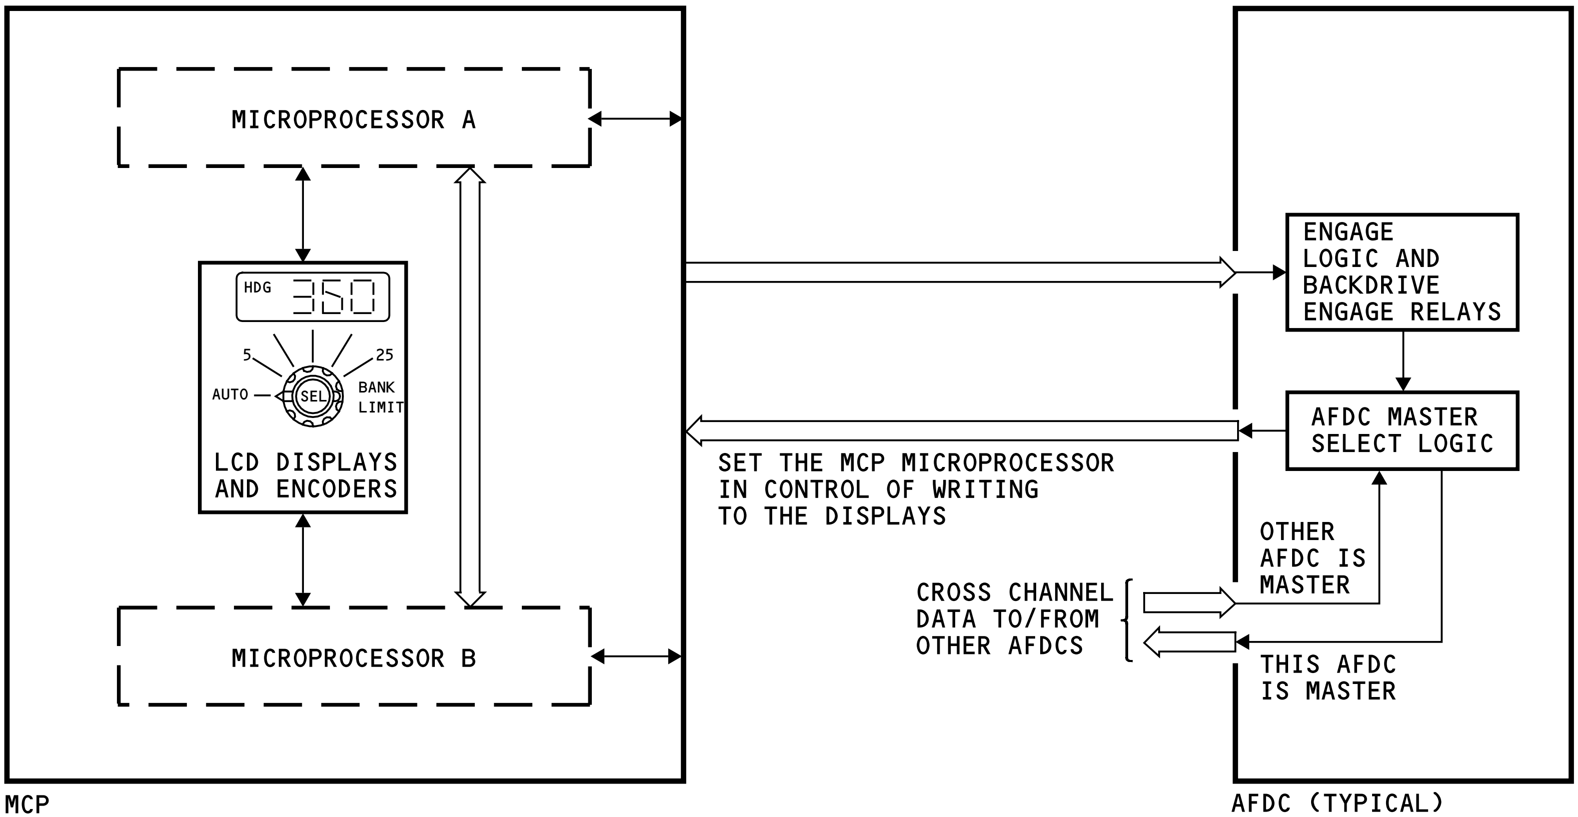
- The left AFDC is the master, MCP microprocessor A writes to all the MCP displays
- The right AFDC is the master, MCP microprocessor B writes to all the MCP displays.

Slave AFDC Function

The slave AFDC does these functions:

- Calculate pitch, roll and yaw commands
- Receives AFDS mode data from the master AFDC
- Limits the AFDS pitch and roll commands to safe values.

If a slave AFDC cannot do its functions, the PFCs do not use autopilot commands from that AFDC.



22-11-00-053 Rev 2

AFDS - FUNCTIONAL DESCRIPTION - ENGAGE INTERLOCKS MASTER/SLAVE SELECTION

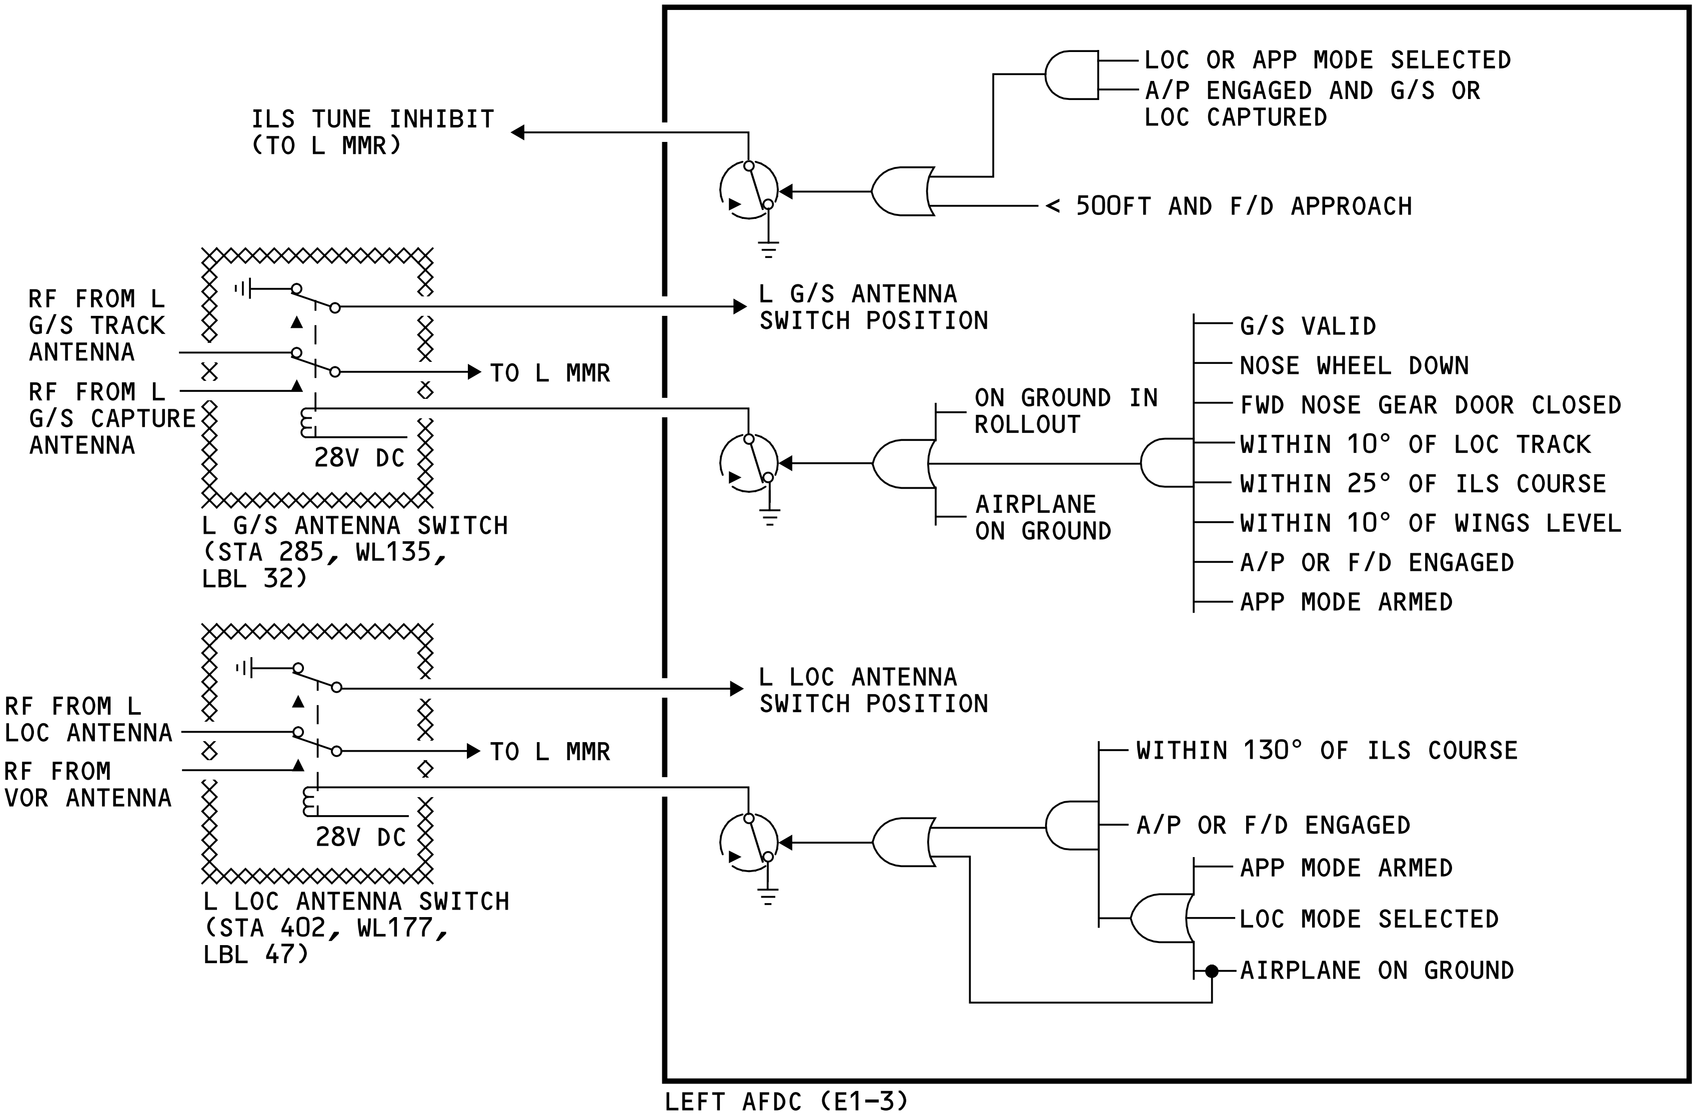
AFDS - ILS ANTENNA SWITCHING LOGIC

ILS Antenna Switching

The autopilot flight director computers (AFDCs) select the position of their onside localizer and glideslope antenna switches.

ILS Tune Inhibit

The AFDCs prevent tuning of the multi-mode receivers (MMRs) when the airplane makes an autopilot engaged approach. The AFDCs also prevent tuning of the MMRs when the pilot makes a flight director only approach and the airplane is below 500 feet of radio altitude.



22-11-00-061 Rev 3 01/14/1998

AFDS - ILS ANTENNA SWITCHING LOGIC

AFDS - FUNCTIONAL DESCRIPTION - WARNING AND ANNUNCIATION INTRODUCTION

General

The AFDCs warning and annunciation functions send normal and non-normal indications of AFDS performance to:

- The AIMS cabinets
- The warning electronic system (WES).

Description

Each AFDC sends this normal data to the AIMS cabinets:

- Mode
- Status
- Flight director commands
- Autoland status.

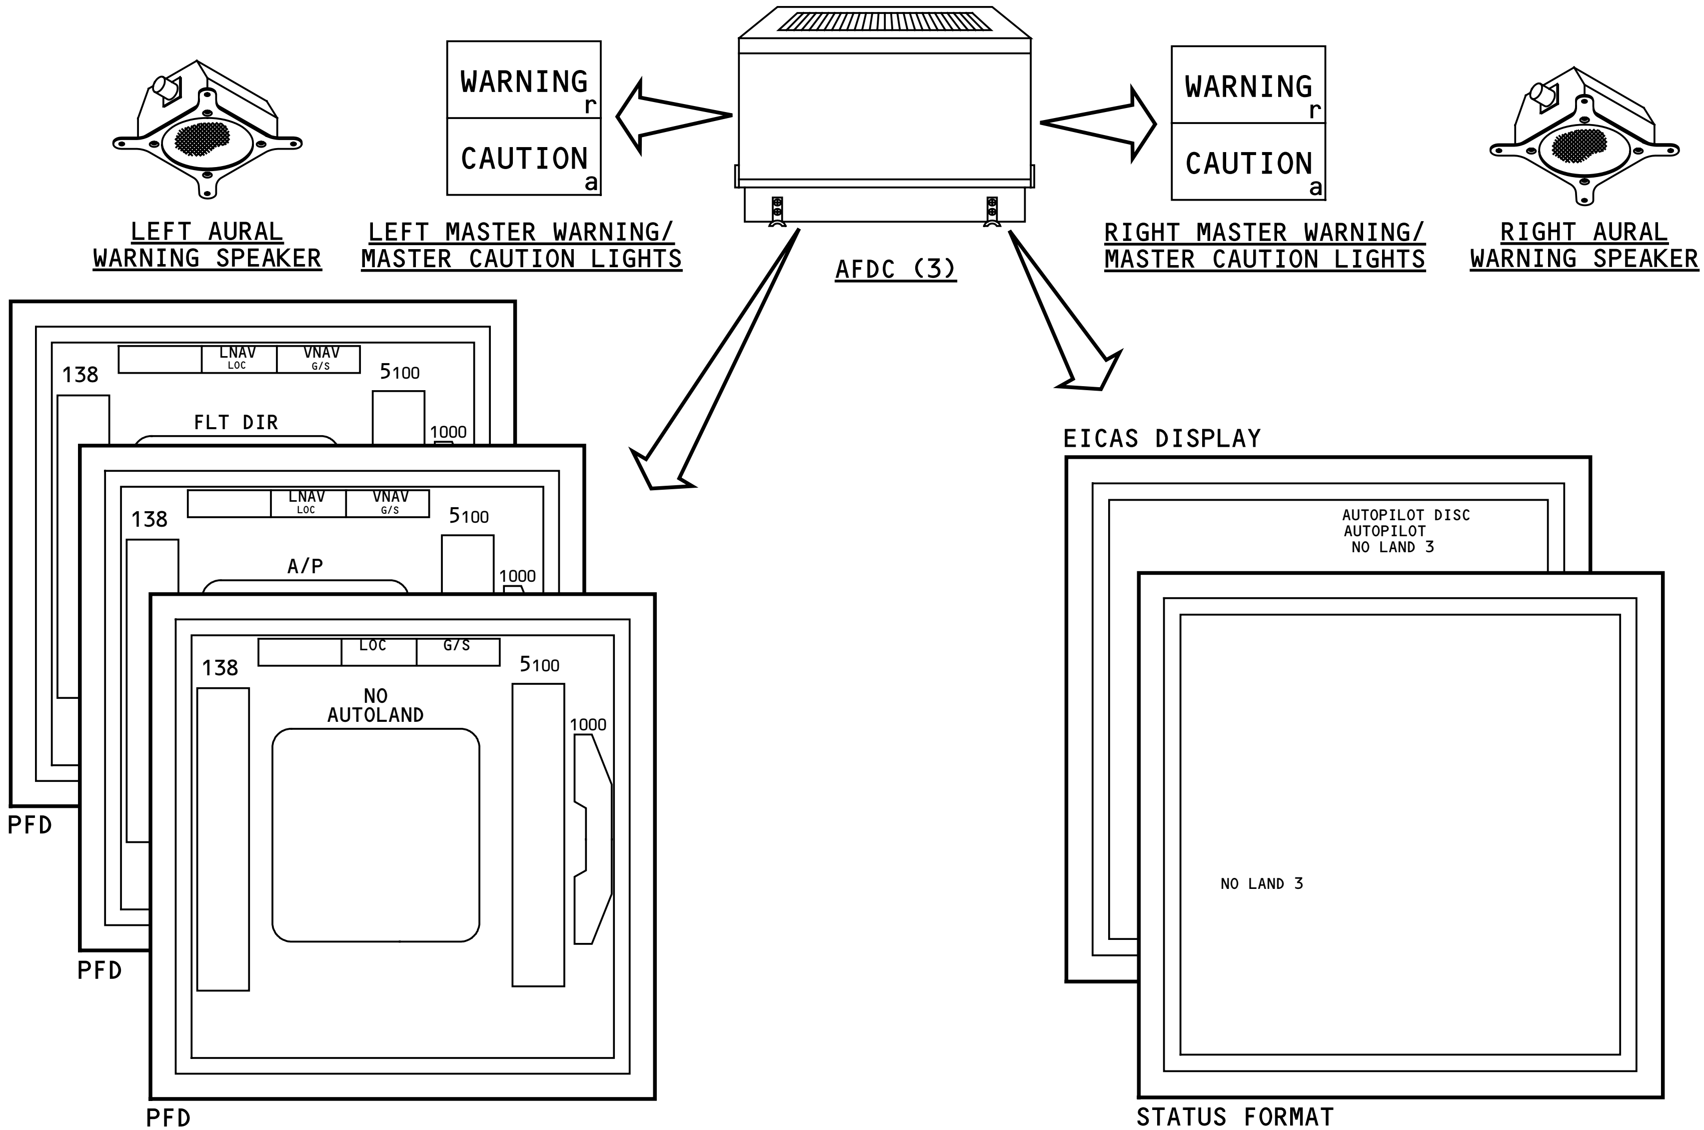
AIMS shows this data on the primary flight displays (PFDs).

Each AFDC sends this non-normal data to AIMS:

- Autopilot disconnect warning
- Autopilot caution
- Autoland status
- Mode fail
- Flight director (F/D) fail.

Each AFDC sends the disconnect warning discrete to the WES. This causes the master warning lights and the siren to come on.

The AIMS also turns on the master caution light and causes the WES to make the caution aural.



22-11-00-054 Rev 3 04/10/1997

AFDS - FUNCTIONAL DESCRIPTION - WARNING AND ANNUNCIATION INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

AFDS - FUNCTIONAL DESCRIPTION - WARNING AND ANNUNCIATION - PFD AND ND DISPLAYS

General

The primary flight displays (PFDs) show AFDS modes, status messages, and flight director (F/D) information. The PFD also shows selected mode control panel (MCP) data.

Display Priority

The AIMS uses the validity of the three AFDCs and the MCP A and B processors to determine the priority for the displays.

This is the AFDC priority for the captain's PFD:

- left AFDC if valid
- Center AFDC if left AFDC is not valid
- Right AFDC if left and center AFDCs are not valid.

This is the AFDC priority for the first officer's PFD:

- Right AFDC if valid
- Center AFDC if right AFDC is not valid
- Left AFDC if right and center AFDCs are not valid.

This is the MCP priority for both PFDs:

- The A microprocessor if valid
- The B microprocessor if the A microprocessor is not valid.

AFDS Modes

The top of the PFD shows the AFDS modes of operation. This is the flight mode annunciator (FMA). Active and arm pitch and roll modes show.

The failure of sensor data necessary for the active pitch or roll mode causes a yellow bar to show through the mode on the FMA. This bar indicates a mode failure. An arm mode will not show the mode fail bar.

Flight Director Commands

Flight director commands show on the PFD as pitch and roll F/D bars. A mode fail will cause the appropriate F/D bar to go out of view.

When the AIMS does not receive any valid F/D data from the AFDCs and either of the F/D switches is on, a F/D failure flag shows on the PFD.

AFDS Engage and Autoland Status Annunciation

The AIMS shows this AFDS status:

- FLT DIR; when in flight director only operation
- A/P; when in autopilot operation
- LAND 3, LAND 2, NO AUTOLAND; when in approach and below 1500 feet radio altitude
- Test; if any AFDC is in test.

This is the autoland status display priority:

- NO AUTOLAND
- LAND 2
- LAND 3.

MCP Selected Data

The AIMS shows this data from the MCP:

- Selected speed
- Selected mach
- Selected altitude
- Selected vertical speed
- Selected flight path angle
- Selected heading
- Selected track.

Selected Flight Path Angle

Selected flight path angle (FPA) shows on the PFD when you select FPA on the MCP. The selected FPA is a target for the flight path vector (FPV) symbol, it is not a target for the flight director pitch bar. If you select FPA on the MCP before you select the FPV on the EFIS control panel, the FPV will show automatically on the PFD.

Navigation Display (ND)

The ND shows the selected track or heading cursors. The AIMS uses the validity of the MCP A and B processors for the priority of the display.

This is the MCP priority for both NDs:

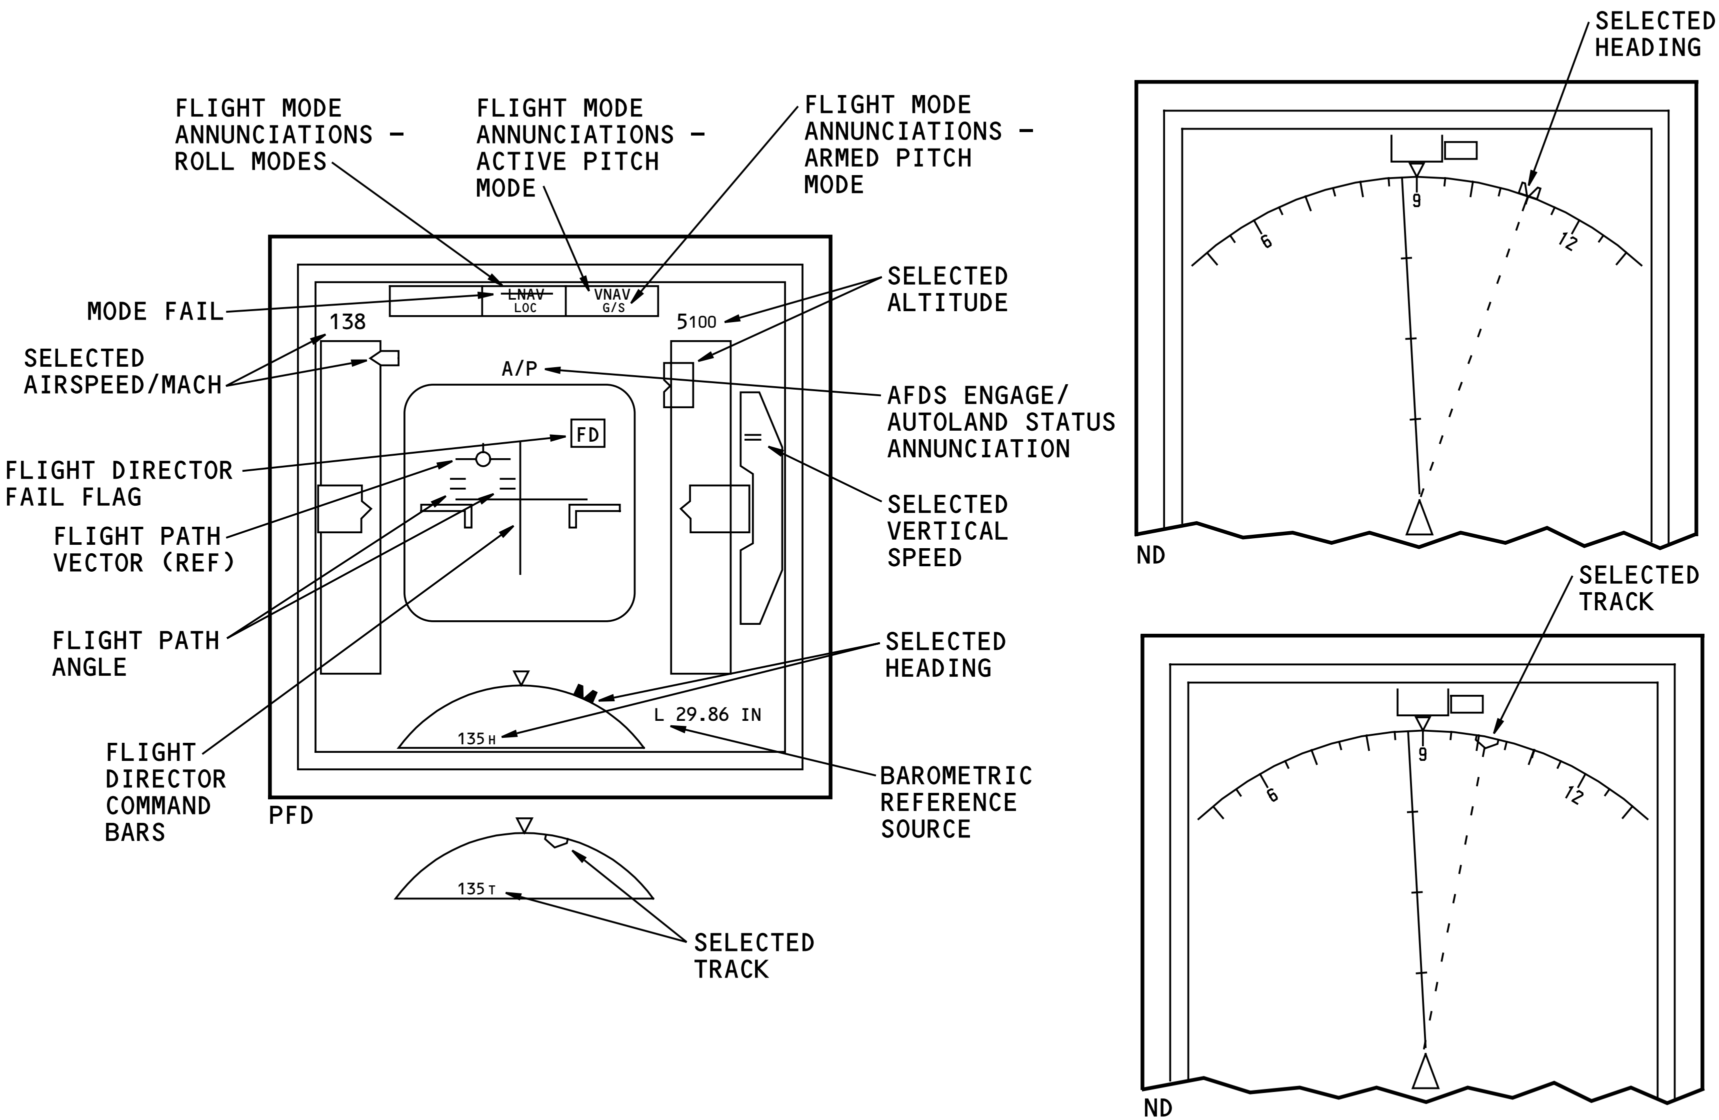
- The A processor
- The B processor.

Barometric Reference Source

The barometric reference source shows which barometric (baro) correction the AFDCs use. An L shows the AFDCs use the captain's baro correction value. An R shows the AFDCs use the first officer's baro correction value. Both PFDs show the same baro reference source.

With no autopilot engagement and with flight director selection only, the AFDCs use the captain's barometric correction when the left flight director switch is on, and both PFDs show the letter L. If you select the ON position for only the right flight director switch, the AFDCs use the first officer's barometric correction and both PFDs show the letter R. If both flight director switches are on, the AFDCs use the captain's barometric correction, and both PFDs show the letter L.

When you engage the autopilot with the left autopilot engage switch, the AFDCs use the captain's baro correction value and both PFDs show the letter L. When you engage the autopilot with the right autopilot engage switch, the AFDCs use the first officer's baro correction value and both PFDs show the letter R.



22-11-00-055 Rev 6 04/26/96

AFDS - FUNCTIONAL DESCRIPTION - WARNING AND ANNUNCIATION - PFD AND ND DISPLAYS

THIS PAGE INTENTIONALLY LEFT BLANK

AFDS - FUNCTIONAL DESCRIPTION - WARNING AND ANNUNCIATIONS - EICAS DISPLAYS

General

The EICAS and MFD displays show messages, warnings, and autoland capability for the autopilot system. The warning electronic units (WEUs) make the master warning lights come on when a warning message shows on the EICAS display. The AIMS makes the master caution lights come on when a caution message shows on the EICAS display.

The AFDCs send data that causes these types of messages to show on the EICAS display and the MFD:

- Warning on the EICAS display
- Caution on the EICAS display
- Advisory on the EICAS display
- Status on the status display.

Warning

The AFDCs send the AUTOPILOT DISC warning message request to the AIMS when either of these happens:

- The flight crew disconnects all engaged AFDCs
- All engaged AFDCs automatically disconnect.

The wheel disconnect switch resets the AUTOPILOT DISCONNECT warning.

The wheel disconnect switch tests the AUTOPILOT DISCONNECT warning if the autopilot is not engaged. The warning resets when the flight crew releases the switch.

Caution

The AFDCs send these autopilot caution messages requests to the AIMS:

- AUTOPILOT, when an autopilot mode fail occurs
- NO LAND 3, when autoland capability degrades while in approach after LAND 3 shows. This only occurs above 200 feet radio altitude
- NO AUTOLAND, when all autoland capability is lost during approach after LAND 2 or LAND 3 has shown. This also occurs during approach if LAND 2 or LAND 3 is not active by 600 feet radio altitude.

Advisory

The AFDCs send these advisory message requests to the AIMS:

- NO LAND 3, when autoland capability degrades before the LAND 3 autoland status annunciation shows
- NO AUTOLAND, when loss of all autoland capability occurs before the LAND 3 or LAND 2 autoland status annunciation shows.

Status

The AFDCs send these autopilot status message requests to the AIMS:

- AFDC L, R, or C; when an AFDC does not operate

- AUTOPILOT BACKDRIVE L or R, when the left or right backdrive system does not operate
- MODE CTRL PANEL LANE, when one of the two lanes in the AFDS MCP or its interface to the AFDC fails
- NO AUTOLAND, when loss of all autoland capability occurs
- NO LAND 3, when the NO LAND 3 caution or advisory message shows
- NO LAND 3, autoland capability degrades during approach when the airplane is below 200 feet radio altitude. There is no caution or advisory message.

AFDS - LRU TESTS

General

The LRU replacement tests verify the correct installation of an LRU.

Autopilot Disconnect Switch LRU Replacement Test

The autopilot disconnect switch LRU replacement test makes sure all contacts of the captain's and first officer's disconnect switches operate correctly.

During the test, the MAT tells you to operate the captain's and first officer's disconnect switches one at a time. The test makes sure all AFDCs receive the correct results.

The autopilot disconnect switch LRU replacement test isolates faults to:

- The AFDC (left, center, or right)
- The captain's disconnect switch
- The first officer's disconnect switch.

AFDC LRU Replacement Tests

The left, right, or center AFDC LRU replacement test causes the AFDC self-test and interface test to start. At the end of the test, the MAT shows AFDC internal and interface faults.

Backdrive Actuator LRU Replacement Tests

All backdrive actuator LRU replacement tests make sure the backdrive electrical signal wires are good. They also make sure the flight deck controls move to the correct position at the correct rate. The left or right AFDC:

- Calculates the backdrive command
- Engages its backdrive actuator
- Drives its backdrive actuator.

The backdrive actuator LRU replacement tests isolate faults to:

- The AFDC (left or right)
- Tachometer A
- Tachometer B
- The engage clutch
- The motor.

Mode Control Panel LRU Replacement Test

The mode control panel LRU replacement test isolates faults to the:

- AFDC (left, center, or right)
- MCP
- MCP/AFDC interface.

AFDS - LRU TESTS

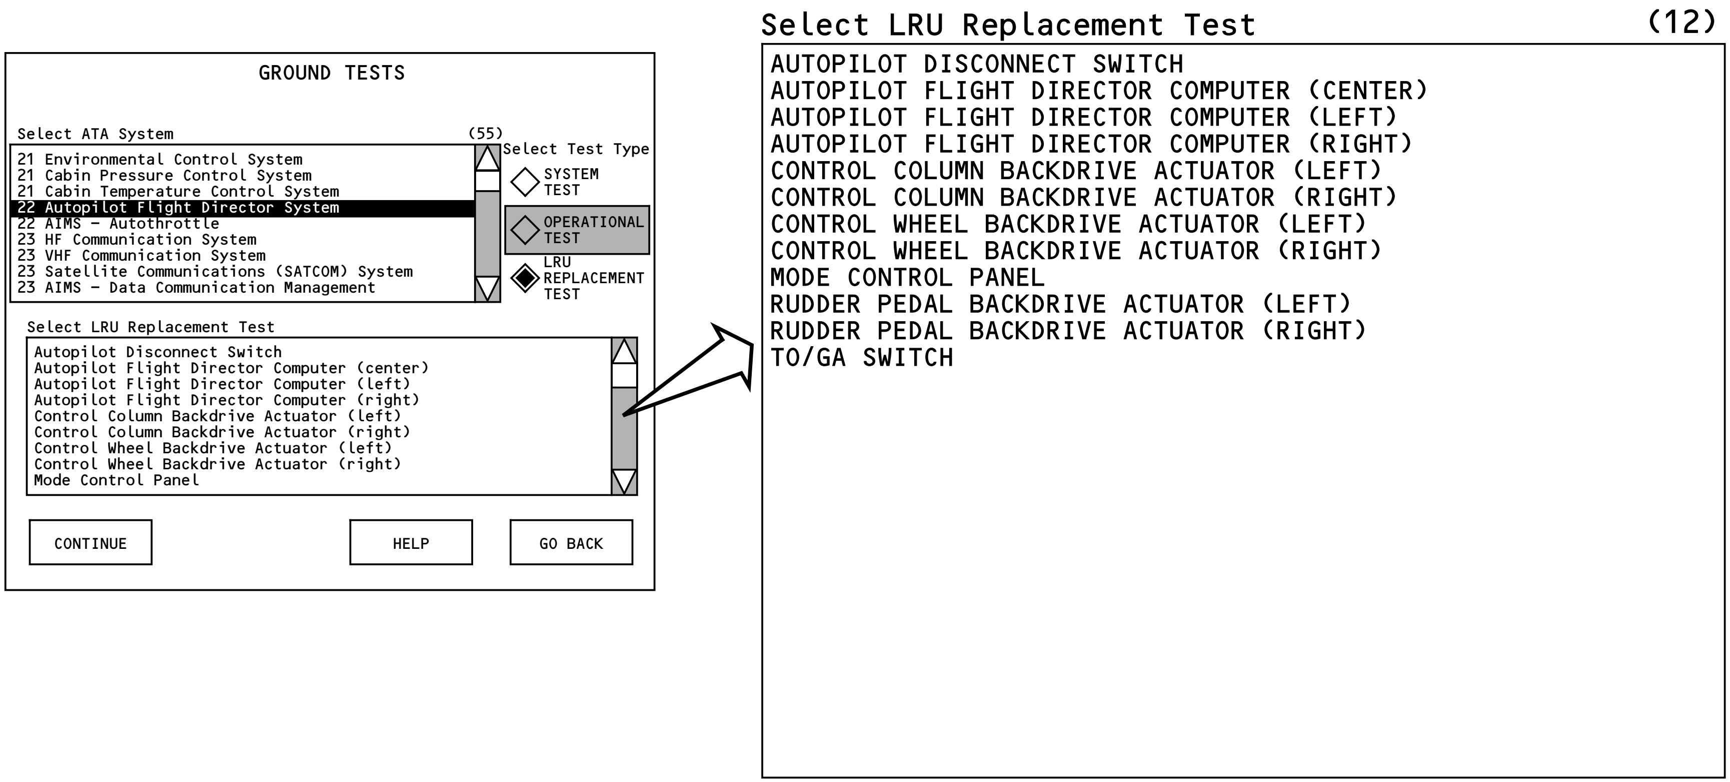
TO/GA Switch LRU Replacement Test

The TO/GA switch LRU replacement test makes sure all contacts of both TO/GA switches operate correctly. The TO/GA switches interface with all AFDCs and AIMS cabinets.

During the test, the MAT tells you to operate the left and right go-around switches one at a time. The test makes sure all AFDCs and AIMS cabinets receive the correct results.

The TO/GA switch LRU replacement test isolates faults to the:

- AFDC (left, center, or right)
- TO/GA switch
- TO/GA switch analog interface with all AFDCs and AIMS cabinets.



22-11-00-058 Rev 1

AFDS - LRU TESTS

THIS PAGE INTENTIONALLY LEFT BLANK

AFDS - SYSTEM TESTS

General

The AFDS system tests verify the correct functionality of the AFDS.

Autopilot Disconnect Warning System Test

The autopilot disconnect warning system test makes sure these functions are correct:

- Installation and operation of the A/P disengage switches
- 28v dc battery power input to the AFDCs
- A/P analog cross-channel discretes
- AFDS-WES analog interfaces
- AFDS-AIMS cabinet analog interfaces
- AFDC disengage warning monitors.

During the test, the MAT tells you to operate the captain's and first officer's disengage switches. You then make sure these functions operate correctly:

- The aural warning
- The master warning lights
- The EICAS messages.

AFDCs System Test

The test program for the AFDCs system test causes all three AFDCs to do a self-test and interface test. This test detects these:

- AFDC internal failures
- Analog signals that are not in their normal state when the airplane is on the ground and is not moving
- ARINC 629 input bus inactivity
- ARINC 429 input bus inactivity
- Incorrect ILS or RA to AFDC connections. For example, left ILS receiver or radio altimeter transceiver not connected to the left AFDC.

Backdrive Actuator System Tests

These tests operate like the LRU replacement tests for the control column, control wheel, or rudder pedal actuators. The tests also do a check of dual backdrive functions.

This test isolates the same faults as the backdrive actuator LRU replacement tests and these:

- Actuator polarity faults
- Single actuator drive faults
- Dual actuator drive faults
- AFDC backdrive monitor faults.

ILS Interface System Test

The ILS interface system test makes sure these functions are correct for all three AFDCs:

- Localizer antenna switches
- Glideslope antenna switches
- ILS tune inhibit.

AFDS - SYSTEM TESTS

During the test, the AFDCs operate these functions to make sure all signal wires are correct:

- Tune inhibit discrete
- Localizer antenna switches
- Glideslope antenna switches.

Mode Control Panel System Test

The MCP system test makes sure these functions are correct:

- All MCP switches, selectors and displays
- MCP panel variable lighting
- MCP configuration pins
- Autothrottle switch discrete output to AIMS
- ARINC 429 bus output to AIMS and the AFDCs
- ARINC 429 inputs from the AFDCs
- Disengage bar discrete outputs to the AFDCs
- Disengage bar discrete inputs from the AFDCs
- Input activity for all buses
- AFDC MCP flight fault monitors.

During the test, the MAT tells you to operate all switches and selectors applicable to the MCP. You also visually monitor the displays on the MCP for correct results.

This MCP system test isolates the same faults as the MCP LRU replacement test and these:

- MCP switch, selector, lights, and display faults
- MCP program pin faults
- MCP/AFDC discrete interface faults
- MCP/AIMS discrete interface faults
- ARINC 429 output bus faults
- Internal MCP monitor faults
- Internal MCP redundant and parallel data path faults.

TO/GA Switch System Test

The TO/GA switch system test is the same as the TO/GA switch LRU replacement test.

PITOT-STATIC/AIR DATA STANDBY INSTRUMENTS - INTRODUCTION

Pitot-Static System

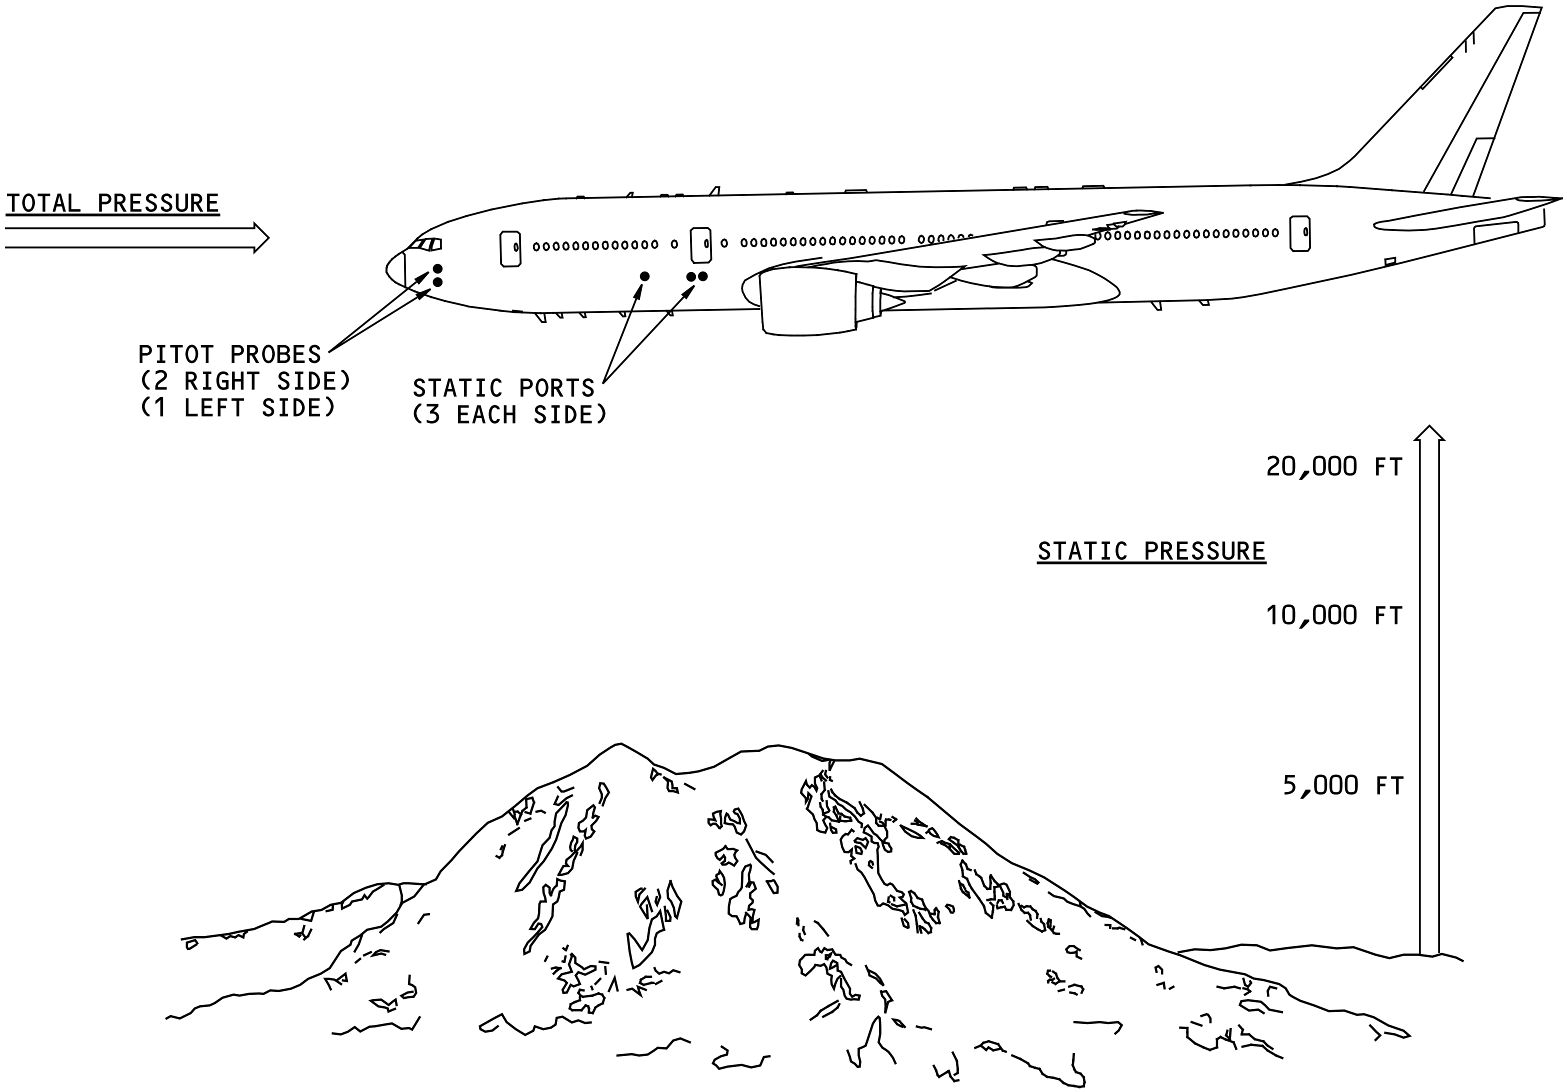
The pitot-static system uses pitot probes and flush static ports to sense total and static air pressures. These pressures go to the air data inertial reference system (ADIRS) to calculate flight parameters such as air speed and altitude.

Air Data Standby Instruments

The air data standby instruments supply the flight crew alternate indications of the airplane altitude and indicated airspeed (IAS).

Abbreviations and Acronyms

ADIRU	- air data inertial reference unit
ADM	- air data module
ALT	- altitude
BITE	- built-in test equipment
CAS	- calibrated air speed
ELMS	- electrical load management system
LCD	- liquid crystal display
IAS	- indicated air speed
SAARU	- secondary attitude air data reference unit
SADM	- standby air data module
SAI	- standby attitude indicator
SALT	- standby altimeter
SASI	- standby airspeed indicator
TYP	- typical



PITOT-STATIC/AIR DATA STANDBY INSTRUMENTS - INTRODUCTION

PITOT-STATIC/AIR DATA STANDBY INSTRUMENTS - GENERAL DESCRIPTION

Pitot-Static System

The pitot-static system gets air pressure inputs from three pitot probes and six flush static ports on the airplane fuselage.

These are the two types of air pressure:

- Static air pressure. This is the ambient air pressure around the airplane
- Pitot air pressure. This is the air pressure on the pitot tube as a result of the forward motion of the airplane.

The pitot-static system has:

- 3 pitot probes
- 6 flush static ports
- Pneumatic lines.
- 6 air data modules (ADMs)
- 2 standby air data modules (SADMs).

The 777 has short flexible hoses that connect pitot probes to the pitot ADMs and pitot SADM. There is cross-fuselage hard tubing that connects pairs of static ports with the static ADMs and static SADM. The static ADMs and static SADM are in the center of the airplane and tubing runs. This reduces the amount of pressure lines and possible leaks from connections that occur in long tubing runs.

The pitot probes and static ports send the air pressures through lines to the ADMs and SADMs. The ADMs change the air pressures to electrical signals and send them to the air data inertial reference unit (ADIRU) and secondary attitude air data reference unit (SAARU) on the flight controls ARINC 629 data buses.

The ADIRU and SAARU use static air pressure and pitot air pressure to calculate airplane altitude and airspeed.

The standby airspeed indicator and standby altimeter get information directly from the SADMs on ARINC 429 data buses.

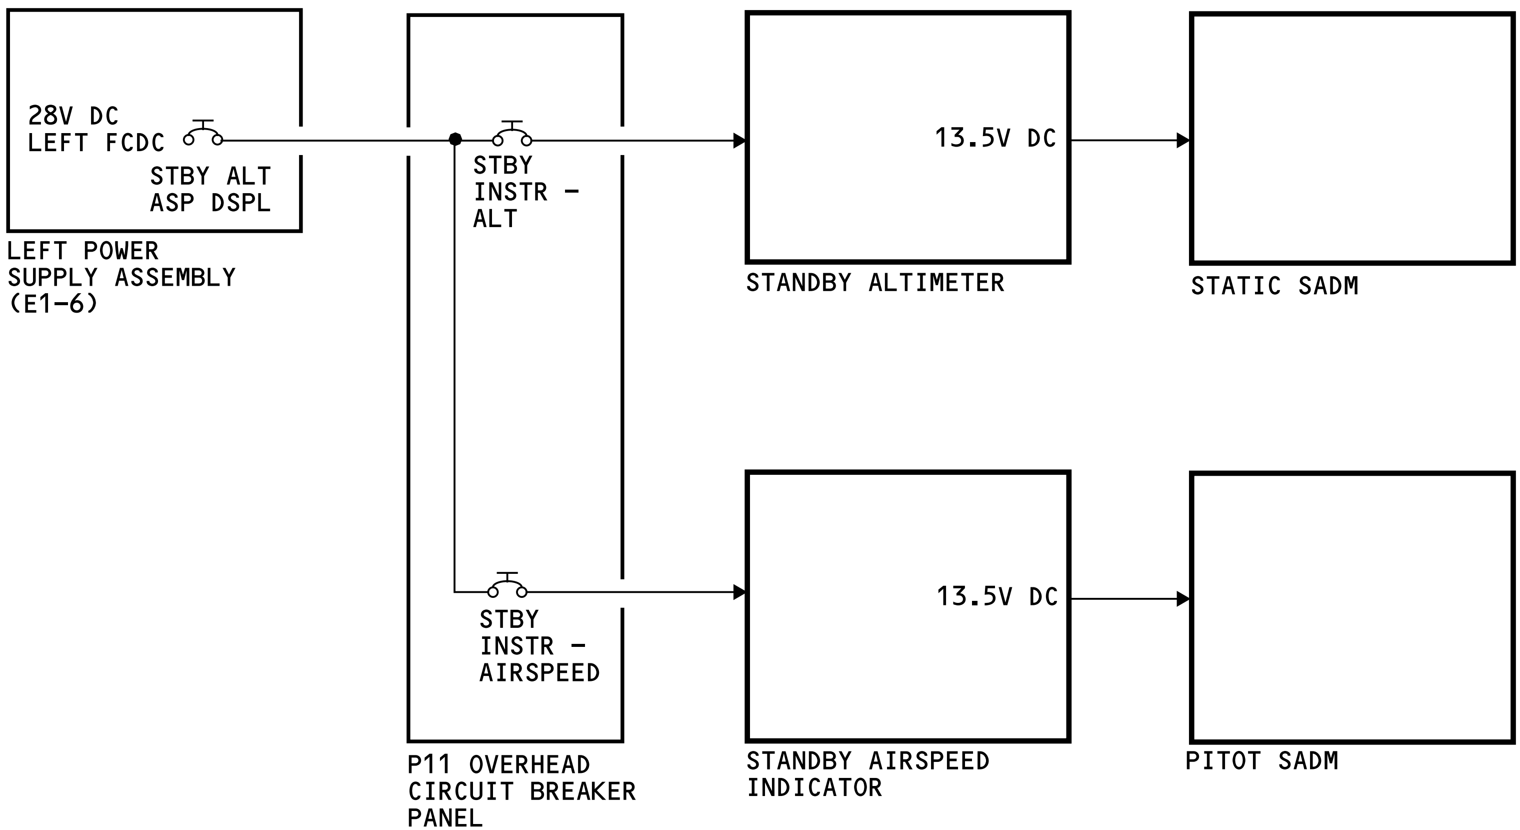
PITOT-STATIC/AIR DATA STANDBY INSTRUMENTS - POWER

Power

28 VDC power comes from the STBY INSTR - ALT and STBY INSTR - AIRSPEED circuit breakers on the P11 panel. Power goes to the air data standby instruments, then to the SADMs.

See the air data inertial reference system section for more information on ADM power (AMM PART I 34-20).



34-11-00-008 Rev 3 08/31/1995

PITOT-STATIC/AIR DATA STANDBY INSTRUMENTS - POWER

PITOT-STATIC/AIR DATA STANDBY INSTRUMENTS - INTERFACE

629 Interfaces

The pitot probes and static ports send air pressure through pressure lines to the ADMs. The ADMs convert the air pressures into ARINC 629 data. The data goes on the flight controls ARINC 629 buses to the ADIRU and SAARU.

The ADMs have interface only with the onside flight control ARINC 629 bus.

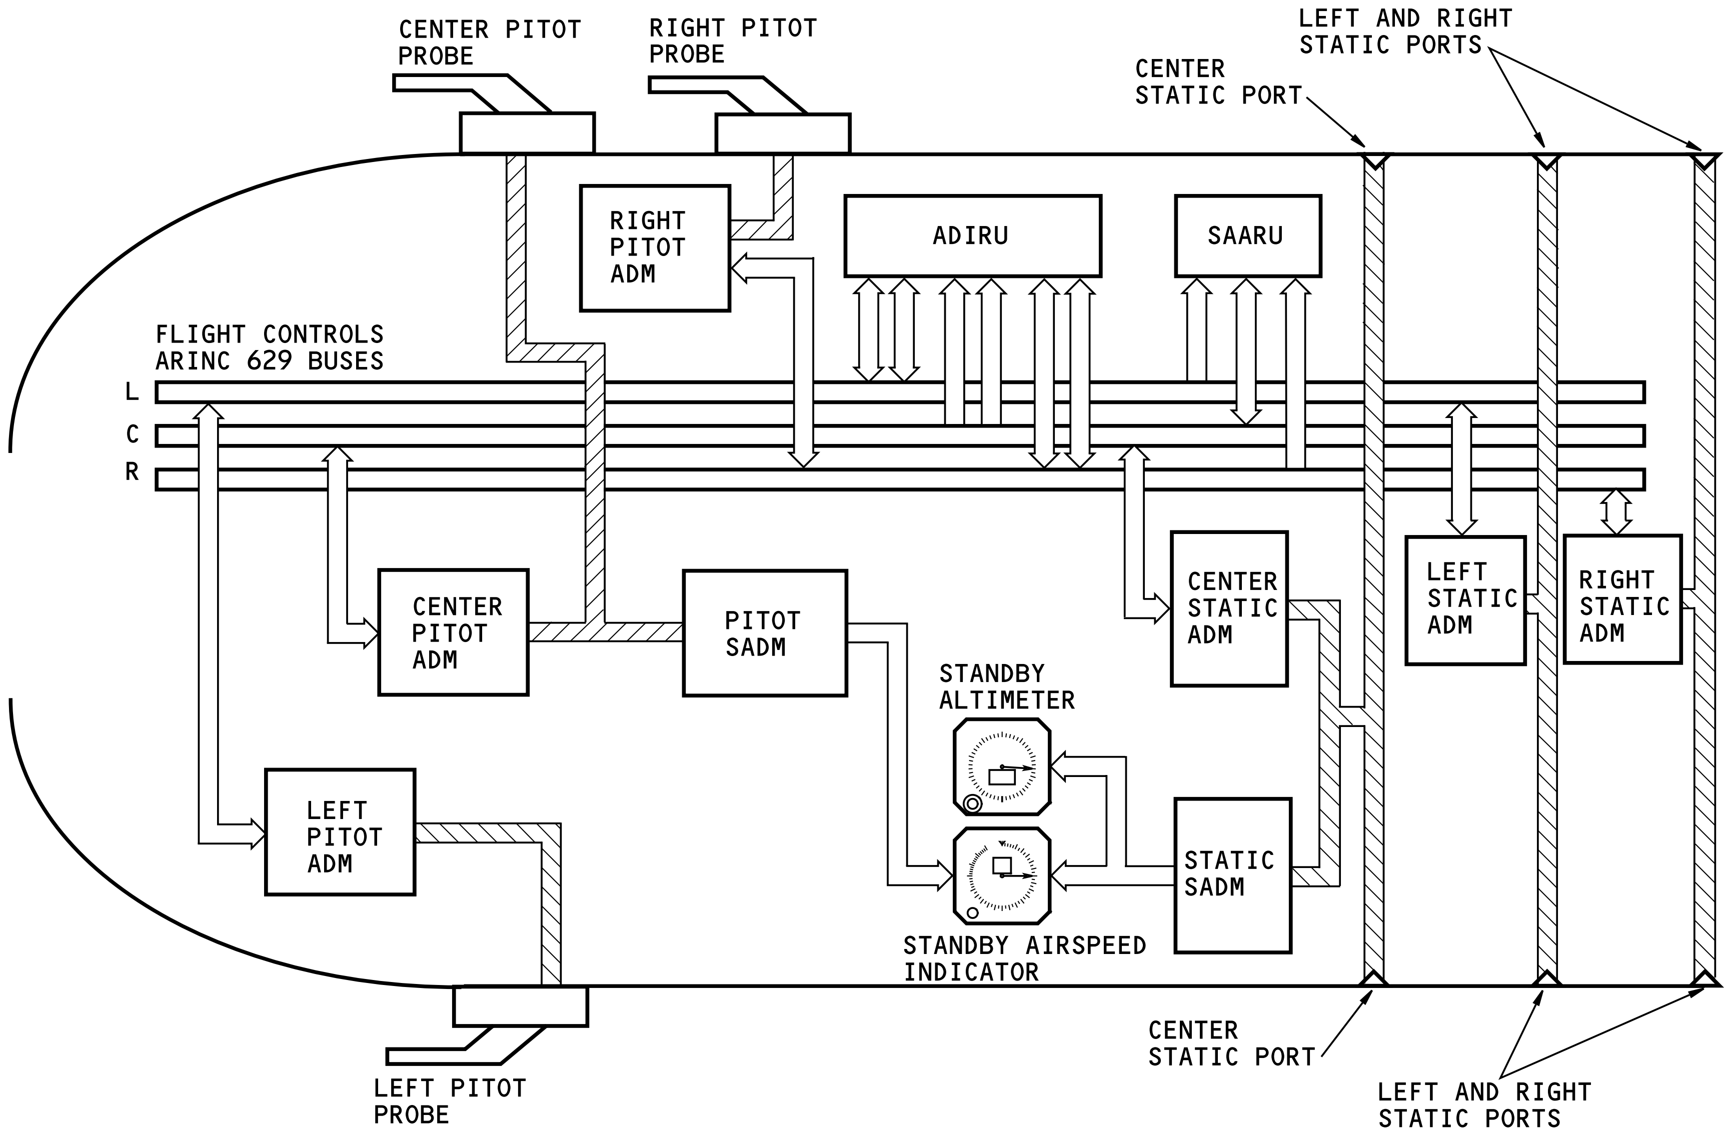
429 Interfaces

The center pitot probe sends pitot pressure to the pitot SADM. The pitot SADM sends the pitot pressure to the standby airspeed indicator on an ARINC 429 bus.

The center static ports send static pressure to the static SADM. The static SADM sends the static pressure to the standby altimeter and the standby airspeed indicator on an ARINC 429 bus.

Pressure lines

The pressure lines go from the pitot tubes and static ports to the ADMs. The static lines average approximately 24 feet long and the pitot lines average approximately 74 inches.



PITOT-STATIC/AIR DATA STANDBY INSTRUMENTS - INTERFACE

PITOT-STATIC/AIR DATA INSTRUMENTS - PITOT PROBES AND STATIC PORTS

Static Ports

The static ports supply static pressure to the static air data modules (ADMs).

Pitot Probes

The pitot probes supply total pressure to the pitot ADMs.

Before you remove a pitot probe, obey this warning.

WARNING: MAKE SURE THAT THE PITOT PROBE HEAT IS OFF. INJURY TO PERSONS CAN OCCUR.

PITOT-STATIC/AIR DATA INSTRUMENTS - PITOT PROBES AND STATIC PORTS

PITOT-STATIC/AIR DATA STANDBY INSTRUMENTS - STANDBY AIR DATA MODULE

General

There are two standby air data modules (SADMs) on the airplane.

The SADMs and the ADMs are different in size and shape. Since they send data on different ARINC formats, they are not interchangeable.

SADM Hardware

The SADM is rectangular, 6 in. deep x 3 in. wide x 2.5 in. tall (15.24 cm. x 7.62 cm. x 6.35 cm.). The SADM mounts directly to the airframe by the two flanges on the sides of the unit. The SADM weighs less than 2 lbs. and it has passive cooling. There is a pitot SADM and a static SADM. There is one electrical and one pneumatic connector on the front of each SADM. The SADMs are interchangeable. The SADMs are higher than the pitot probes and static ports to make sure that moisture does not enter the system.

SADM Data

The SADMs are part of the standby air data system. They are independent of the primary flight instrument system and isolated from all ARINC 629 buses. The SADMs receive pressure inputs from the center static ports or the center pitot probe. It converts these pressures to ARINC 429 data and sends this data to the air data standby instruments.

Training Information Point

The SADM is not software loadable.

PITOT-STATIC/AIR DATA STANDBY INSTRUMENTS - STANDBY AIR DATA MODULE

THIS PAGE INTENTIONALLY LEFT BLANK

PITOT-STATIC/AIR DATA STANDBY INSTRUMENTS - STANDBY AIRSPEED INDICATOR/ALTIMETER

Purpose

The standby airspeed indicator (SASI) and the standby altimeter (SALT) show airspeed and altitude. The standby airspeed indicator and the standby altimeter receive airspeed and altitude information from the standby air data modules (SADMs) through ARINC 429 buses.

Program Pin Configuration

The standby airspeed indicator and the standby altimeter are interchangeable. Program pins determine the function of the air data standby instruments. Install the air data standby instrument in the standby airspeed indicator location to show the standby airspeed indicator format. Install the air data standby instrument in the standby altimeter location to show the standby altimeter format.

The standby airspeed indicator and the standby altimeter can be put in the standby attitude indicator (SAI) position. However, the push button and knob (selector) used on the standby airspeed indicator and standby altimeter have no function when you install the standby instrument in the SAI position. When you put the SAI in the standby altimeter position PROGRAM PIN ERROR shows. When you put the SAI in the standby airspeed indicator position, the airspeed indication shows, but the standby airspeed bug does not show.

Standby Airspeed Bug

Use the standby airspeed bug selector to move the standby airspeed bug. Push the selector to select the airspeed bug on or off. The airspeed bug is off at electrical power-up.

Standby Airspeed Indicator

The standby airspeed indicator range is from 30 to 450 knots. This is the resolution of the indicator:

- 30 to 80 knots in 10 knot increments
- 80 to 250 knots in 5 knot increments
- 250 to 450 knots in 10 knot increments.

Standby Airspeed Indicator NCD

If the standby airspeed indicator detects a no computed data (NCD) condition, the indication is an airspeed of 30 knots. This can occur when the airplane is on the ground and not moving.

Standby Airspeed Indicator Fail

If the standby airspeed indicator or the air data input fails, the indicator goes blank and a fail flag shows in the center of the display. The fail flag is an amber outline box with SPD inside of the box.

Integral Light Sensor

There is an integral light sensor at the lower center of each instrument. The integral light sensor measures the amount of light on the front of the standby instrument. The standby instruments adjust the display brightness to the amount of light available.

The standby instruments send brightness data to each other to adjust their brightness.

Remote Light Sensors

Remote light sensors on the P7 glareshield panel supply brightness signals to the standby instruments. The standby instruments use the average of the integral light sensors and remote light sensors values to adjust the display brightness to the amount of light available.

Standby Altimeter

The standby altimeter shows barometric altitude from 250 to 60000 feet in 100 foot major numerical increments, and 20 foot minor graduation marks. A green hatched box shows in the 10000s digit location for altitude below 10000 feet.

Barometric Reference

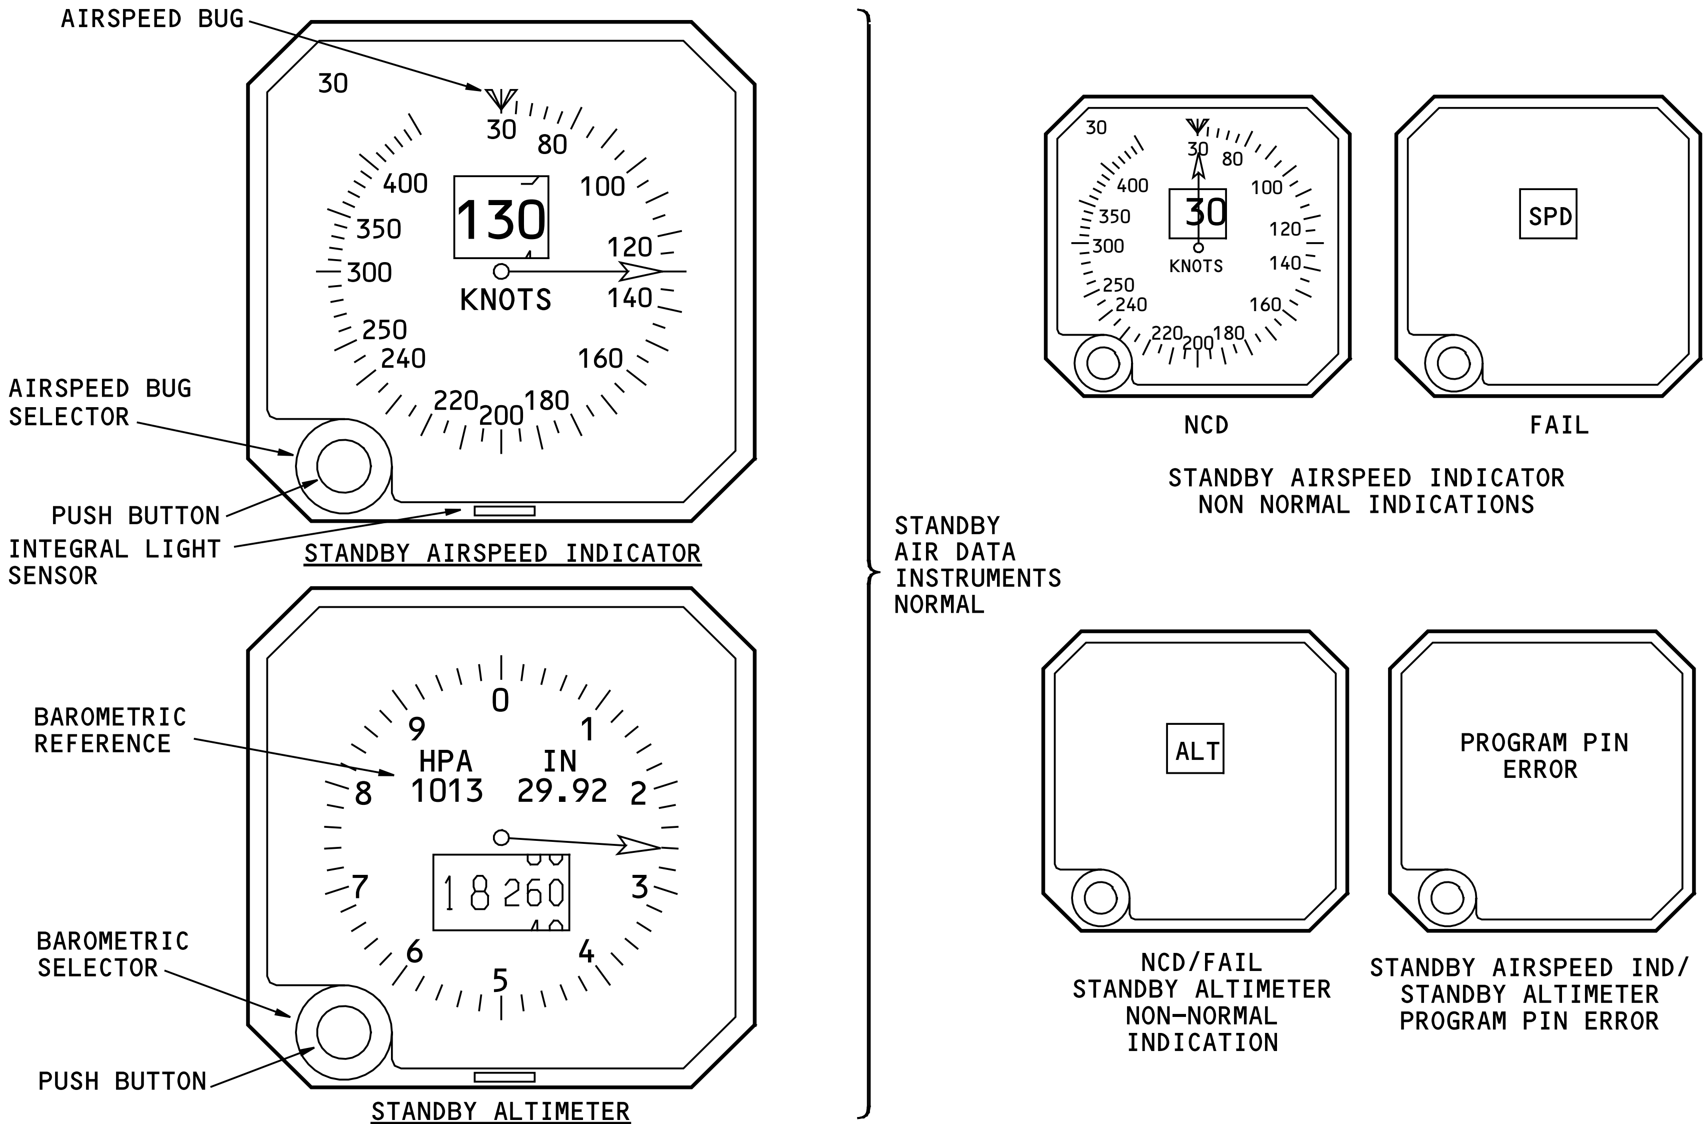
The barometric selector makes corrections to the barometric indication in inches of mercury (HG) and Hectopascal (HPA). The push button toggles the barometric reference between standard barometric pressure (29.92 in. Hg) and the last setting.

Standby Altimeter NCD or Fail

If the standby altimeter detects a NCD or fail condition, the indicator goes blank and a fail flag shows in the center of the display. The fail flag is an amber outline box with ALT inside of the box.

Program Pin Error

If either the standby airspeed indicator or the standby altimeter detects a program pin error, the indicator goes blank and the message PROGRAM PIN ERROR shows.



34-11-00-011 Rev 4

PITOT-STATIC/AIR DATA STANDBY INSTRUMENTS - STANDBY AIRSPEED INDICATOR/ALTIMETER

PITOT-STATIC/AIR DATA STANDBY INSTRUMENTS - FUNCTIONAL DESCRIPTION

Power

The air data standby instruments get power from the standby instrument circuit breakers. The air data standby instruments send 13.5v dc to the SADMs.

SADM Signal Processing

The SADMs receive pressure inputs from a static port or pitot probe. The microprocessor converts this pressure to an ARINC 429 word and sends this data to the standby instruments.

SADM Bite

The SADM built-in-test equipment (BITE) detects internal faults which are in nonvolatile memory that are shop accessible only.

Air Data Standby Instruments Pressure Inputs

SADM data goes to the air data standby instrument ARINC 429 receiver. The receiver sends this data to the microprocessor. The microprocessor supplies display data to the LCD display.

Standby Instruments Brightness Inputs

Brightness data comes from:

- The standby instruments
- Integral light sensor
- Remote light sensor

The microprocessor uses the brightness inputs to adjust the brightness of the LCD display.

Program Pin

Standby altimeter, standby airspeed indicator, and standby attitude indicator program pins select the appropriate standby instrument display format.

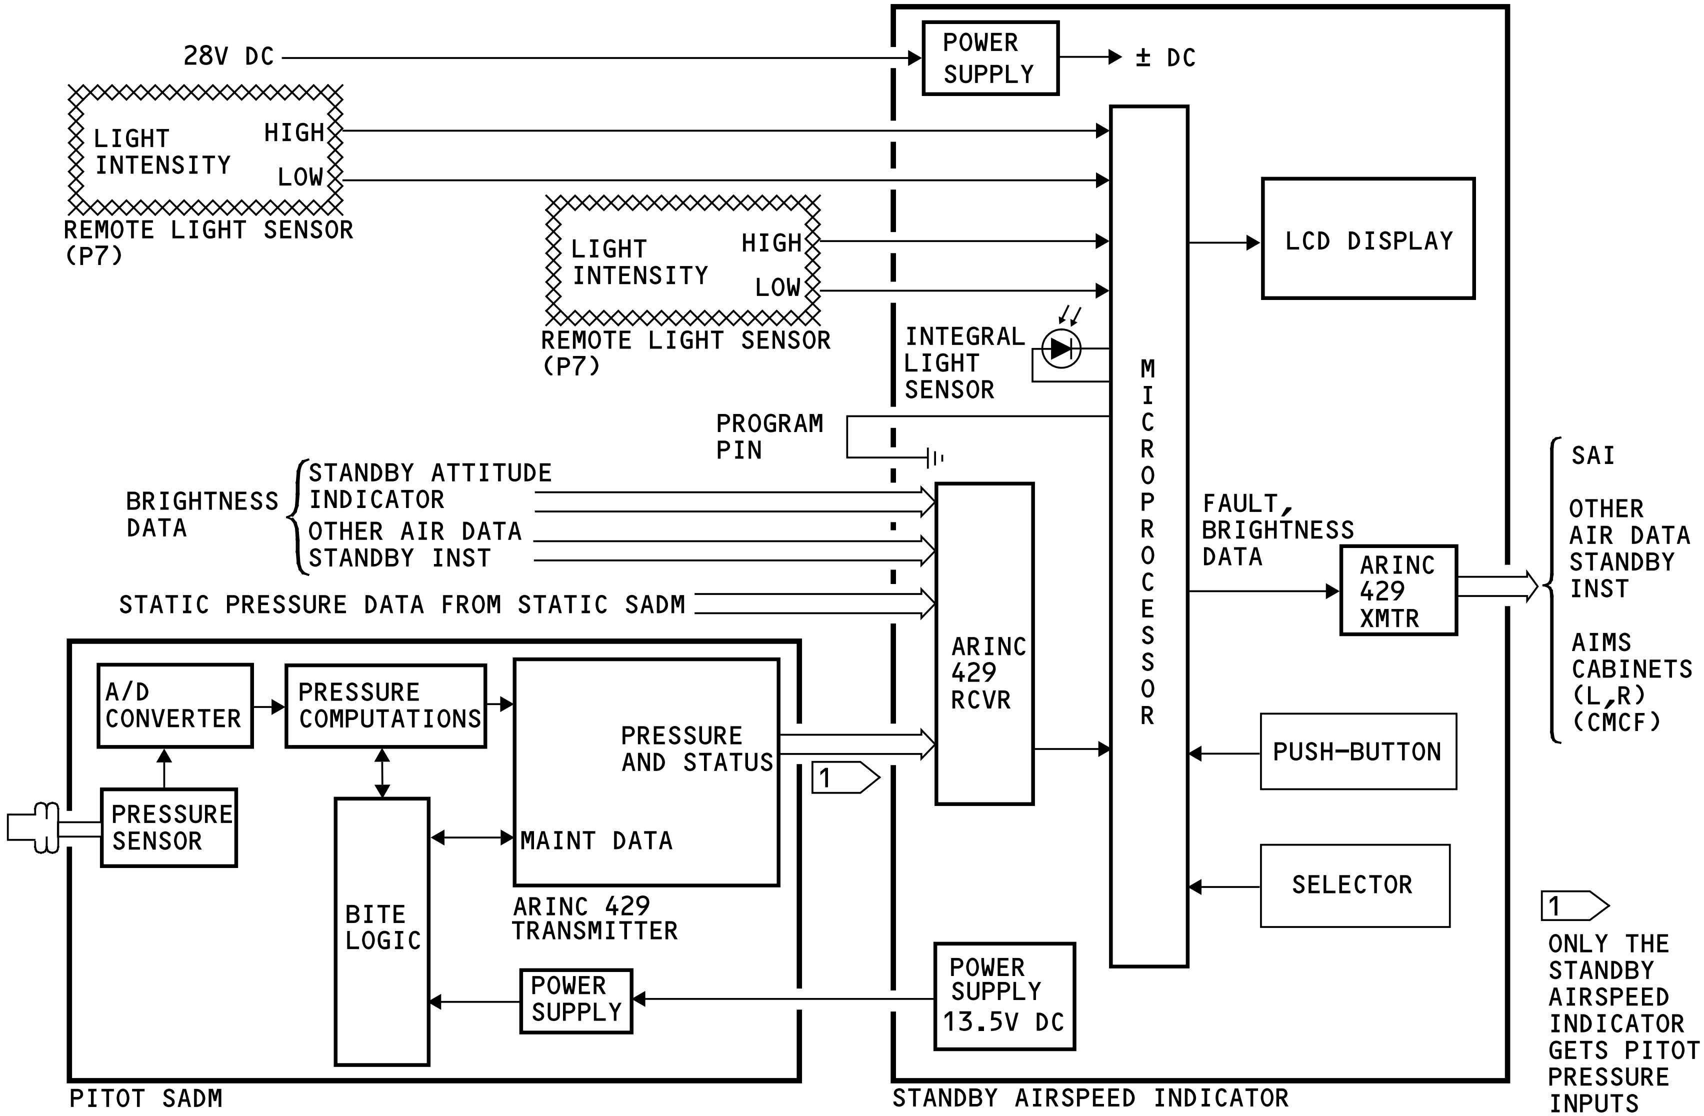
Push-button and Selector

The push-button and selector give the altitude correction value in the standby altimeter, and move the airspeed bug on the standby airspeed indicator.

The push-button and selector does not operate when the standby instrument is in the standby attitude indicator location.

Outputs

Brightness data goes from each standby instrument to the other two standby instruments. Fault data goes to the CMCF in the AIMS cabinets.



34-11-00-012 Rev 3 08/31/1995

PITOT-STATIC/AIR DATA STANDBY INSTRUMENTS - FUNCTIONAL DESCRIPTION

General

The pitot air data modules (ADMs) control the heat control relays in the power management panels. The heat control comes from data the ADMs receive from the primary flight computers (PFCs) through the flight controls ARINC 629 bus. If the PFCs are not valid, the ADMs use data from the autopilot/flight director computers (AFDCs). The AFDC data also comes through the flight controls ARINC 629 bus.

The pitot ADMs control the pitot heaters for the onside pitot probes.

Ground Mode

The ground and the air heat control relays supply 115v ac when the airplane is on the ground and either engine is on.

Air Mode

The air heat control relay supplies 115v ac when any of these conditions are true:

- The computed airspeed (CAS) is more than 50 knots
- The airplane is in the air.

Pitot Heater Current Monitor

The probe heat sensor relay detects current when the pitot probe heat is on, and sends a ground signal to the pitot ADMs. The pitot ADMs send the status of the pitot heat to these units:

- ADIRU
- SAARU
- AIMS cabinets.

Training Information Point

See the ice and rain protection chapter for information on how to do a test of the pitot probe heat (AMM PART I 30).

AIR DATA INERTIAL REFERENCE SYSTEM - INTRODUCTION

General

The air data inertial reference system (ADIRS) has two functions:

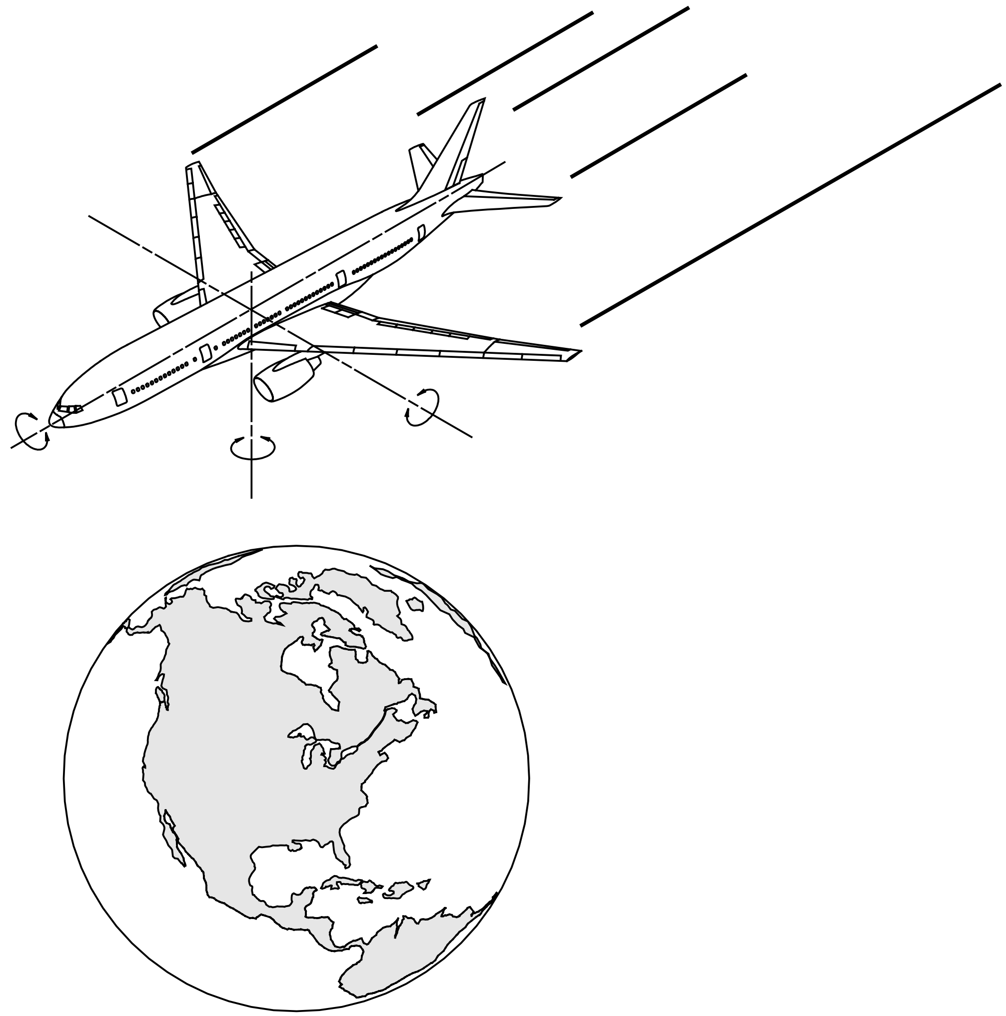
- Air data
- Inertial reference data.

An example of some of the systems that use ADIRS data are the:

- Primary flight control system (PFCS)
- Autopilot flight director system (AFDS)
- Airplane information management system (AIMS).

Abbreviations and Acronyms

ADIRS - air data inertial reference system
ADIRU - air data inertial reference unit
ADM - air data module
AFDC - autopilot flight director computer
AFDS - autopilot flight director system
AIMS - airplane information management system
AOA - angle of attack
ARINC - Aeronautical Radio, inc.
CDU - control display unit
CMCF - central maintenance computing function
CPU - central processing unit
FCA - fault containment area
FCM - fault containment module
FCDC - flight controls direct current
FMCF - flight management computing function
FSEU - flap/slat electronics unit
GPS - global positioning system
LCD - liquid crystal display
MAT - maintenance access terminal
NCD - no computed data
ND - navigation display
NVM - non-volatile memory
OPAS - overhead panel ARINC 629 system
PFC - primary flight computer
PFCS - primary flight control system
PSEU - proximity sensor electronics unit
SAARU - secondary attitude air data reference unit
TAT - total air temperature



34-20-00-001 Rev 1

AIR DATA INERTIAL REFERENCE SYSTEM - INTRODUCTION

ADIRS - GENERAL DESCRIPTION

General

The air data inertial reference system (ADIRS) has these components:

- Pitot probes
- Static port
- Air data modules
- Air data inertial reference unit (ADIRU)
- Total air temperature (TAT) probe
- Angle of attack (AOA) sensors
- Secondary attitude air data reference unit (SAARU)
- Standby attitude indicator.

Air Data Modules

The air data modules (ADMs) get air pressures from the pitot probes or the static ports. The ADMs convert the air pressures into ARINC 629 data. The ADMs send this data to the ADIRU and the SAARU.

Airplane Information Management System

The airplane information management system (AIMS) cabinets receive TAT and AOA analog inputs. The AIMS cabinets change this data to digital and send it to the ADIRU and the SAARU.

The AIMS cabinets receive display data from the ADIRS. The AIMS shows ADIRS data on the primary flight displays (PFDs) and the navigation displays (NDs).

Air Data Inertial Reference Unit

The air data inertial reference unit (ADIRU) uses these inputs to calculate and supply air data to user systems:

- Pitot pressure
- Static pressure
- Total air temperature
- Angle of attack.

The ADIRU uses six ring laser gyros and six accelerometers to calculate and supply inertial reference and navigation data to user systems.

Secondary Attitude Air Data Reference Unit

The secondary attitude air data reference unit (SAARU) is a back-up source of attitude, heading and air data. The SAARU uses these inputs to calculate and supply air data to user systems:

- Pitot pressure
- Static pressure
- Total air temperature
- Angle of attack.

The SAARU uses four fiber optic gyros and four accelerometers to calculate and supply inertial reference data to user systems.

The SAARU supplies attitude data to the standby attitude indicator.

- ADIRU BAT PWR L, C, R circuit breakers
- ADIRU PRI PWR L, C, R circuit breakers.

Other Systems Component Location

The components in the equipment centers that have an interface with the ADIRS are:

- Left power supply assembly
- Center power supply assembly
- Right power supply assembly.

The center power supply assembly has these circuit breakers:

- ADM C ST
- ADM C PT
- Standby attitude display
- SAARU.

The left power supply assembly has these circuit breakers:

- ADM L ST
- ADM L PT.

The right power supply assembly has these circuit breakers:

- ADM R ST
- ADM R PT.

ADIRS - COMPONENT LOCATION - LEFT AND CENTER STATIC ADM

ADIRS - ADIRU, AOA AND SENSOR, SAARU, STANDBY ATTITUDE INDICATOR POWER

ADIRU

The ADIRU gets power from these sources:

- Right 28 volt DC bus
- Left 28 volt DC bus
- Hot battery bus.

The PFC (primary flight computer)/ADIRU panel supplies on/off discretes to the ADIRU. The ADIRU uses these discretes to enable power down.

AOA Sensors

One resolver in each AOA receive 28v ac power from the left (P110) and one resolver in each AOA receive 28v ac from the right (P210). The AIMS cabinets receive the same 28v ac for resolver reference.

SAARU

The secondary attitude air data reference unit (SAARU) gets 28v dc power from the center power supply assembly.

Standby Attitude Indicator

The standby attitude indicator gets 28v dc power through a circuit breaker in the center power supply assembly. The 28v dc goes through a circuit breaker in the P11 overhead circuit breaker panel.

ADIRS - AIR DATA MODULES POWER

THIS PAGE INTENTIONALLY LEFT BLANK

ADIRS - DIGITAL INTERFACES

General

These components send data to the ADIRU and the SAARU through the flight controls ARINC 629 buses:

- Left and right AIMS cabinets
- Left, center, right pitot air data modules (ADMs)
- Left, center, right static ADMs
- Left, center, right PFC.

Total Air Temperature (TAT) Probe

The TAT probe sends analog temperature data to the left and right AIMS cabinets. The AIMS cabinets change the temperature data to ARINC 629 data. The AIMS cabinets send the temperature data to the ADIRU and the SAARU.

Angle of Attack (AOA) Sensors

The AOA sensors send the AOA resolver data to the left and right AIMS cabinets. The AIMS cabinets change the resolver data to ARINC 629 data. The AIMS cabinets send the AOA resolver data to the ADIRU and the SAARU.

FSEU and PSEU Data

The flap/slat electronic units (FSEUs) supply flap data and the proximity sensor electronic units (PSEUs) supply landing gear position to the AIMS cabinets. The AIMS cabinets send this data to the ADIRU and SAARU. The ADIRU and SAARU use this data to calculate corrected AOA data.

Pitot Probes

The pitot probes send total pressure to the pitot air data modules (ADMs). The pitot ADMs change the total pressure to ARINC 629 data. The pitot ADMs send the pitot pressure data to the ADIRU and the SAARU.

Static Ports

The static ports measure the static air pressure and send it through lines to the static ADMs. The static ADMs receive this pressure information and change it to ARINC 629 data. The static ADMs send the static air pressure data to the ADIRU and the SAARU.

PFC Data

The ADIRU and SAARU use speed brake position and air/ground data that comes from the PFCs. The ADIRU and SAARU use this data to calculate corrected AOA data. The AFDCs are the alternate source of air/ground and brake position if the PFCs fail.

ADIRU

The ADIRU receives data on all flight control ARINC 629 buses. The ADIRU has two connections to each flight control ARINC 629 bus.

The ADIRU sends air data and inertial reference data to user systems through the left and right flight control ARINC 629 buses.

ADIRS - DIGITAL INTERFACES

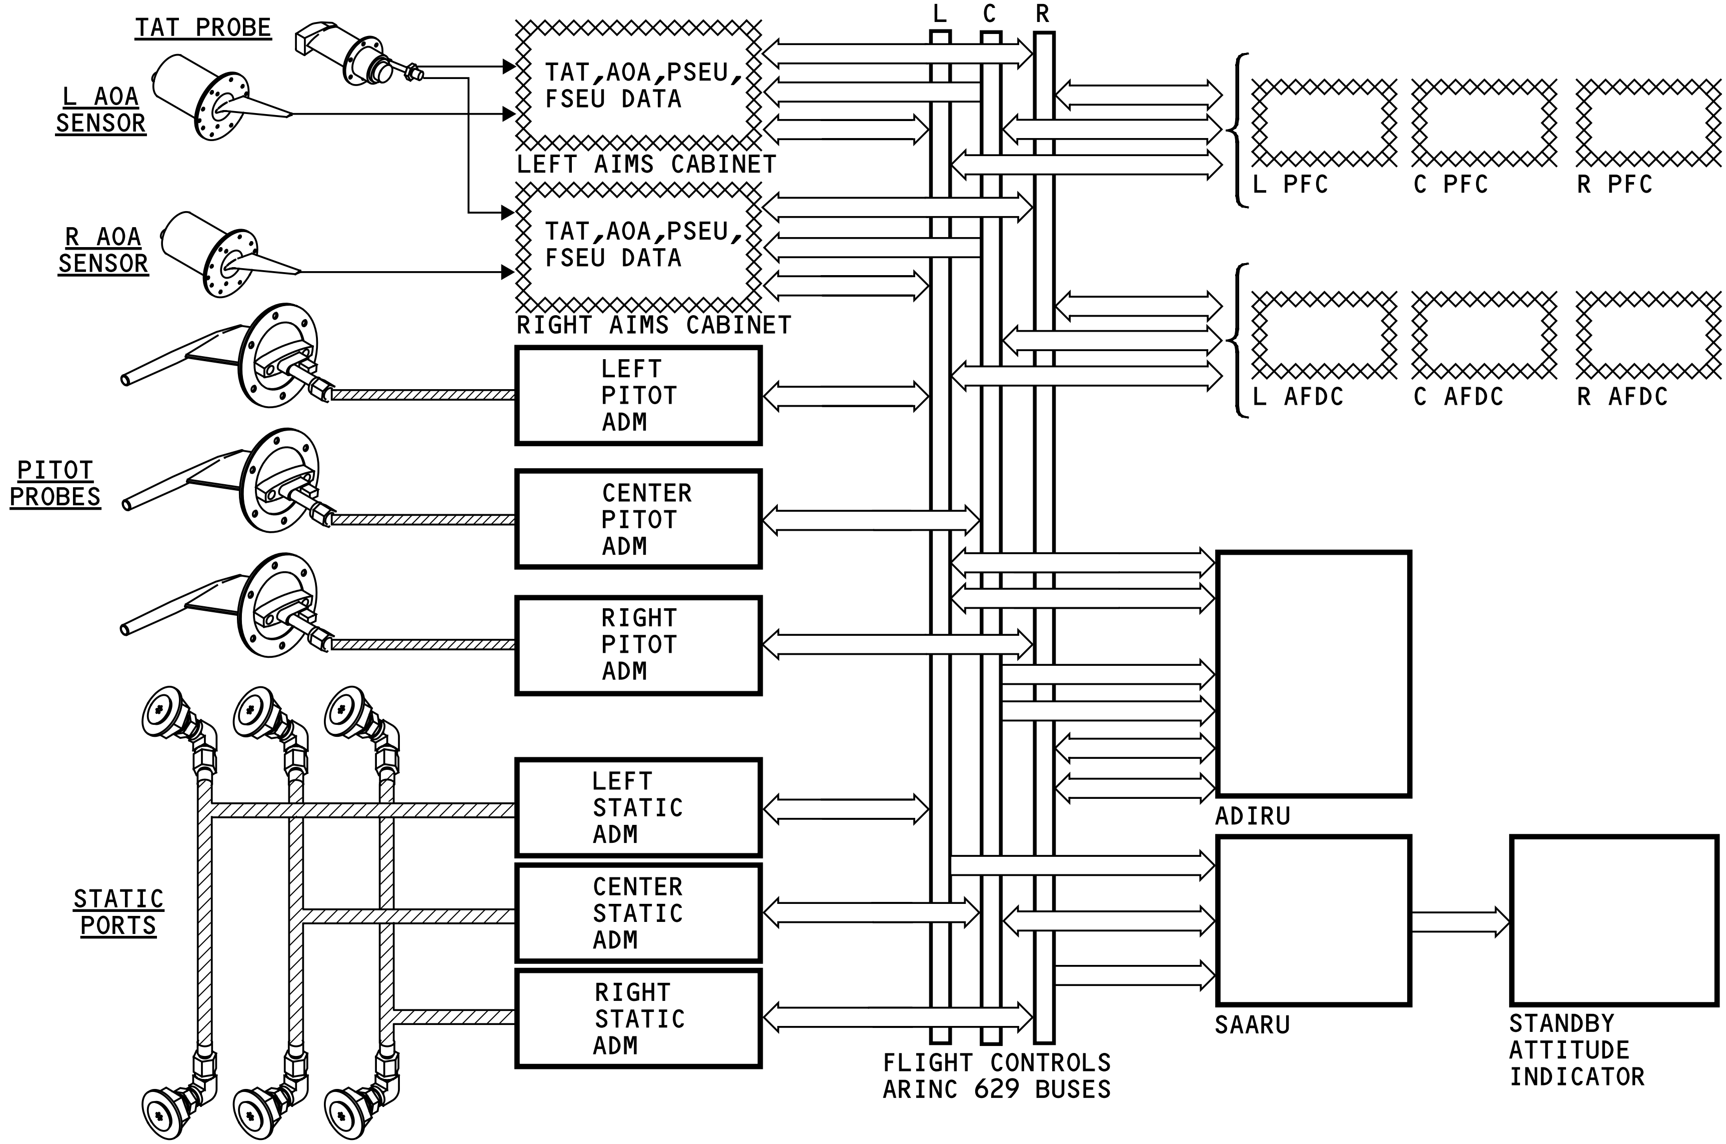
SAARU

The SAARU receives data on all flight control ARINC 629 buses. The SAARU has one connection to each flight control ARINC 629 bus.

The SAARU sends inertial reference and air data to user systems through the center flight control ARINC 629 bus.

Standby Attitude Indicator

The SAARU supplies ARINC 429 attitude data to the standby attitude indicator.



ADIRS - DIGITAL INTERFACES

ADIRS - ADIRU

General

The air data inertial reference unit (ADIRU) has two functions:

- Air data
- Inertial reference data.

The ADIRU has internal redundancy and automatically makes allowances for failures to keep its complete function.

Physical Description

The ADIRU weighs 68 pounds. The ADIRU is 22.75 inches wide, 7.64 inches high, and 13.61 inches deep.

The ADIRU has these features:

- 2 front handles
- Passive cooling fins
- A locking bar
- 2 installation screws
- Installation guide
- 3 ARINC 629 connectors
- 3 power connectors
- 2 side handles.

The ADIRU has these internal components:

- Six laser gyros
- Six linear accelerometers
- Four processors
- Three power supplies
- Three dual channel ARINC 629 input/output interfaces.

Software Loading

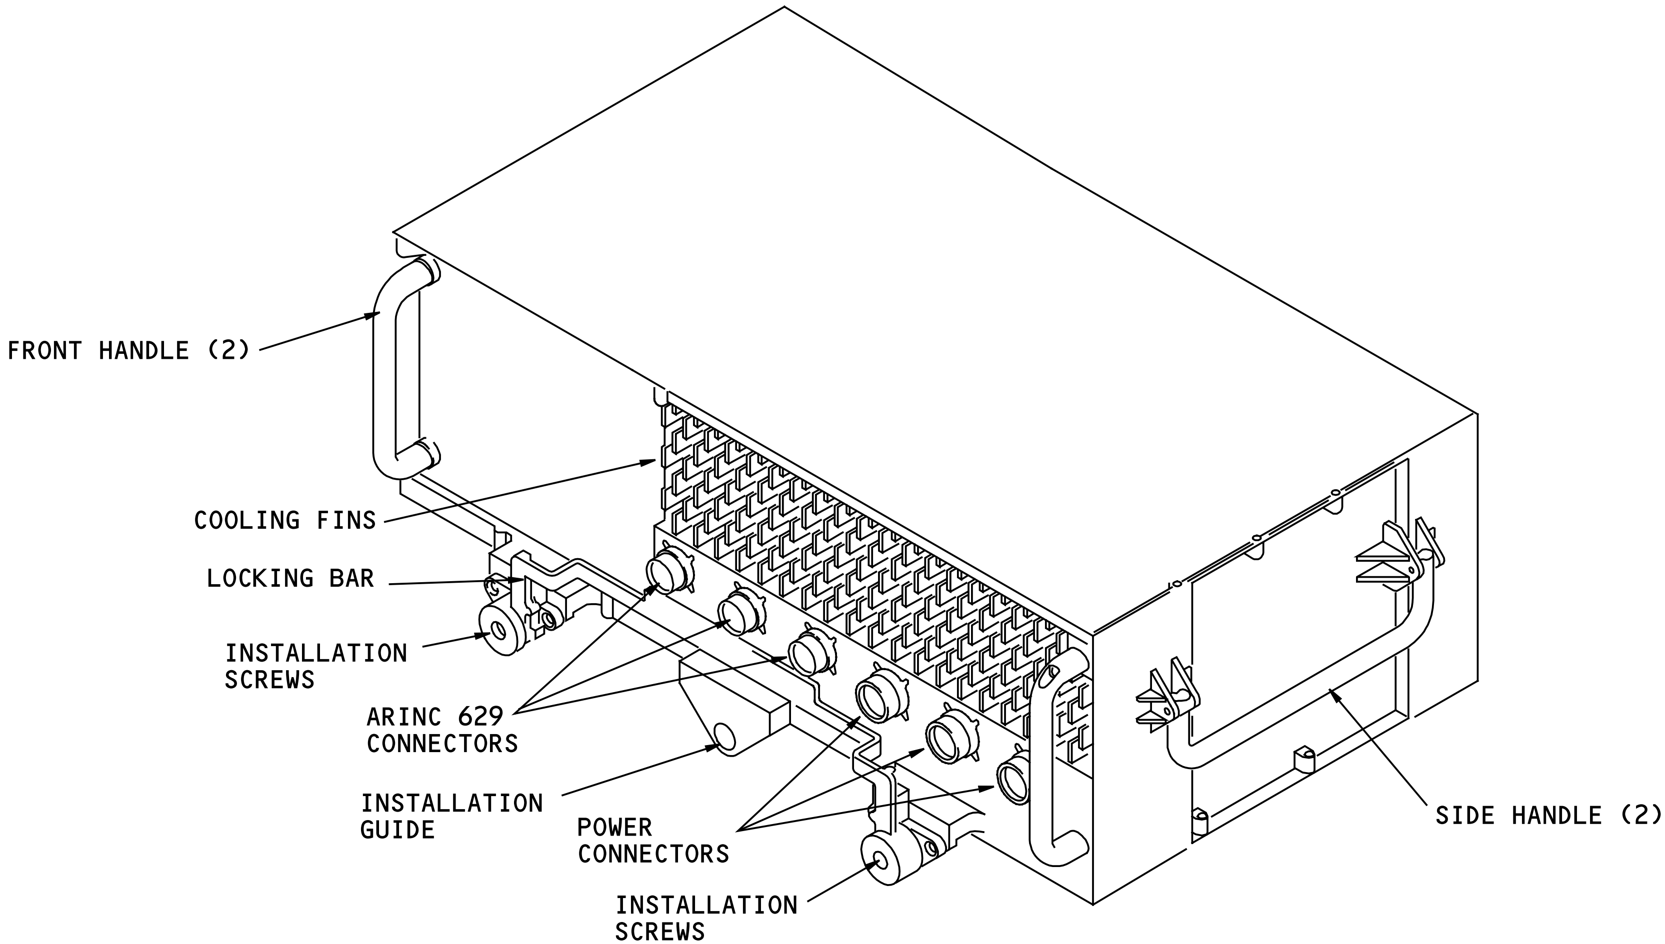
The ADIRU can receive operational program software (OPS) from the AIMS cabinets through the flight controls ARINC 629 buses.

Air Data Function

The ADIRU uses data from the air data sensors to make air data calculations.

Inertial Reference Data Function

The ADIRU uses the data from the accelerometers and gyros to calculate inertial navigation data.



34-20-00-013 Rev 1

ADIRS - ADIRU

ADIRS - ADIRU REMOVAL AND LOCK BAR OPERATION

Locking Bar

The locking bar prevents the:

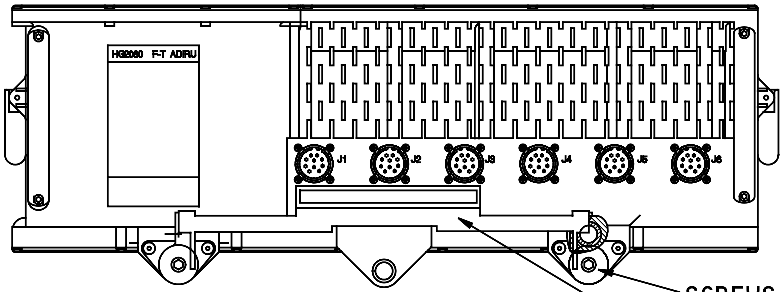
- Removal of the ADIRU until you disconnect the ARINC 629 connections
- Connection of the ARINC 629 interfaces until you install and secure the ADIRU.

Training Information Point

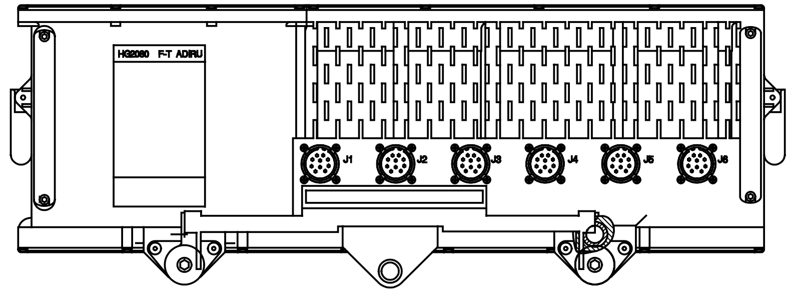
You must use a 1/4 inch hex wrench to turn the ADIRU installation screws.

To remove the ADIRU and operate the locking bar:

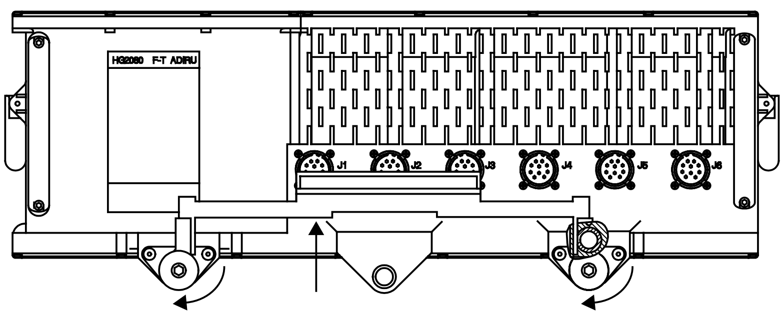
- Remove all six connectors
- Slide the locking bar up until it covers the three connectors
- Use a hex wrench to loosen the installation screws
- After you loosen the screws, a spring moves them out and they hold the locking bar up
- Remove the ADIRU.



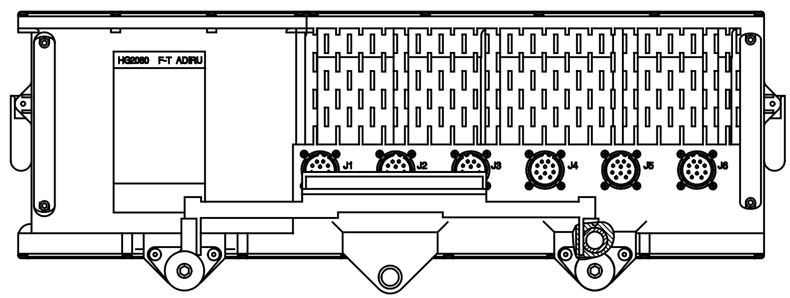
THE ADIRU IS FULLY INSTALLED WITH
SCREWS TIGHT, LOCKING BAR DOWN
AND CONNECTORS IN PLACE



1 ADIRU WITH 6 CONNECTORS REMOVED



2 SLIDE THE LOCKING BAR UP AND LOOSEN THE SCREWS



3 THE LOOSENED SCREWS MOVE OUT
AND HOLD THE LOCKING BAR UP
THE ADIRU IS READY FOR REMOVAL

34-20-00-014 Rev 2

ADIRS - ADIRU REMOVAL AND LOCK BAR OPERATION

ADIRS - ADIRU INSTALLATION

ADIRU Installation

Put the ADIRU on the rack and align the two alignment pins in the back of the ADIRU and one pin in the front of the ADIRU.

To install the ADIRU:

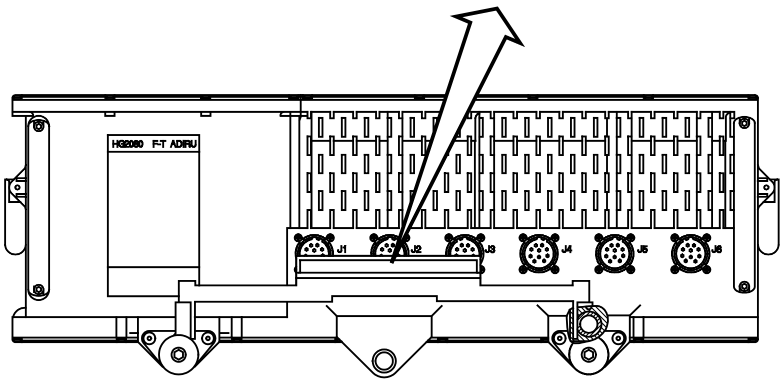
- Install the ADIRU in the rack
- Tighten the screws
- Slide the locking bar down
- Install the six connectors and make sure they are in the full lock position.

Training Information Point

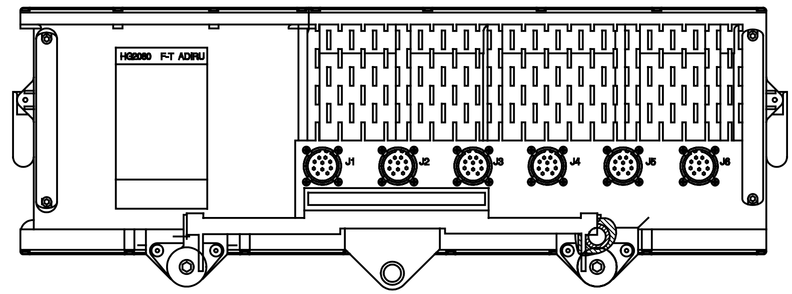
When the ADIRU is secured to the mounting tray, the locking bar is in the down position. Make sure all connectors are in the full lock position before you apply power. You cannot operate the ADIRU if it is not properly installed.

NOTICE: INSTALL THE ADIRU ON THE AIRPLANE MOUNTING SHELF, THEN LOWER THE LOCKING BAR BEFORE YOU ATTACH THE CONNECTORS.

LOCKING BAR NOTICE



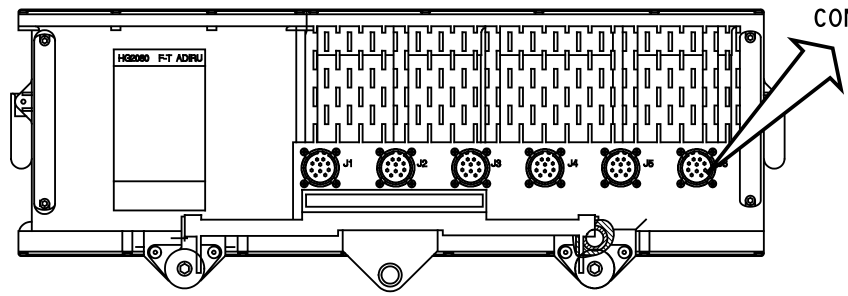
1 INSTALL THE ADIRU ON THE SHELF



2 TIGHTEN THE SCREWS
MOVE THE LOCK BAR DOWN

MAKE SURE ALL CONNECTORS ARE IN THE FULL LOCK POSITION.

CONNECTOR NOTICE



3 INSTALL THE CONNECTORS

ADIRS - ADIRU INSTALLATION

34-20-00-015 Rev 3

ADIRS - ADIRU RELIABILITY AND FAULT TOLERANCE

General

The ADIRU has fault containment areas (FCAs). The FCAs have fault containment modules (FCMs).

The ADIRU has redundancy features that make it more reliable. If a module fails, the ADIRU adjusts itself to use only those components that are good.

Fault Containment Areas and Fault Containment Modules

There are seven FCAs in the ADIRU. In each FCA there are FCMs. These are the FCAs and their FCMs:

- Gyro: 6 laser gyro FCMs
- Accelerometer: 6 accelerometer FCMs
- Power supply: 3 power supply FCMs
- Processor: 4 processor FCMs
- Left, center, and right ARINC 629 interface: 2 ARINC 629 I/O modules in each.

Each FCM is physically and electrically separate from all other like FCMs.

FCMs in the same FCA are the same and interchangeable by shop personnel only.

Single Failures In A Fault Containment Area

If a single FCM fails in one FCA or if there are single FCM failures in more than one FCA, the ADIRU sends data to AIMS to make a maintenance memo show on the maintenance access terminal (MAT). The maintenance memo is ADIRS and it shows on the maintenance planning page.

The flight crew will not see a flight deck effect.

Multiple Failures In The Same FCA

If there are two FCM failures in the same FCA, the ADIRU sends data to AIMS to make a maintenance message show on the MAT, and the status message ADIRU shows on the EICAS display.

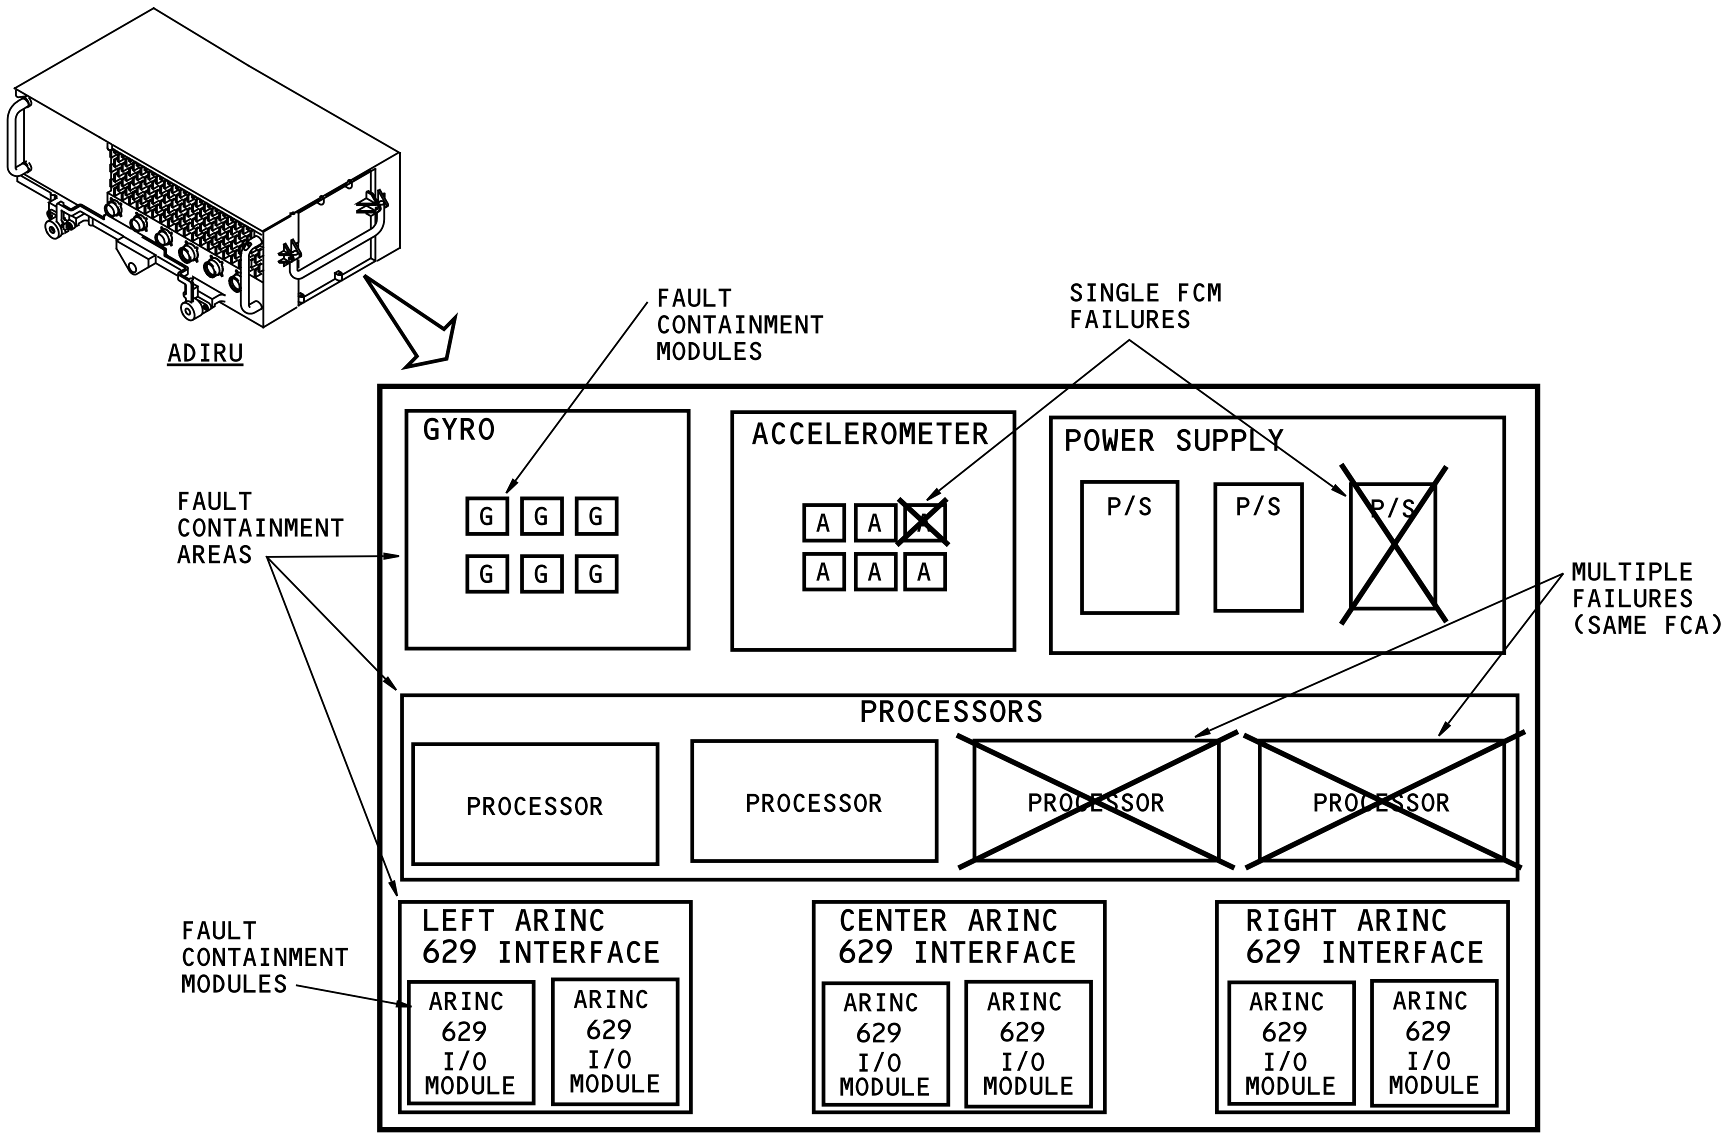
More Failures

The ADIRU must have at least these components in order to supply inertial reference data:

- 4 gyros
- 4 accelerometers
- 1 power supply
- 2 processors
- 1 ARINC 629 I/O module in the left and right FCA.

This happens if there are more than two failures in an FCA:

- The ADIRU does not supply inertial reference data
- The status message ADIRU shows
- The EICAS caution message NAV ADIRU INERTIAL shows
- The ADIRU sends data to AIMS to make a maintenance message show on the MAT.



ADIRS - ADIRU RELIABILITY AND FAULT TOLERANCE

34-20-00-016 Rev 4

ADIRS - ADIRU POWERUP, ON BATTERY, POWERDOWN

PFC/ADIRU Panel

The primary flight computer (PFC)/ADIRU panel has the ADIRU switch and the ADIRU on battery (ON BAT) light.

The ADIRU switch has five sets of contacts. Three of these contacts send discrete inputs to the ADIRU power and monitor circuit. One contact supplies a ground for the ADIRU OFF light, or a ground to energize the relay to make the ground crew call horn come on. The last contact makes the ADIRU ON light come on.

ADIRU Power Source

All the ADIRU power inputs go to the ADIRU power supply. This power goes to the power and I/O (input/output) monitor. The power and I/O monitor verifies the ADIRU switch inputs. If the ADIRU switch is in the on position, the power and I/O monitor permits the power to go to the ADIRU processors.

Ground Crew Alert

If the ADIRU loses primary power, it uses the airplane battery and the ADIRU ON BAT light comes on. The ground crew call horn comes on when the airplane is on the ground and the only source of power for the ADIRU is the hot battery bus. The ground crew call horn comes on to alert the ground crew that the hot battery bus is the only source of power for the ADIRU.

The ADIRU ON BAT light and the ground crew call horn come on if all these conditions are true:

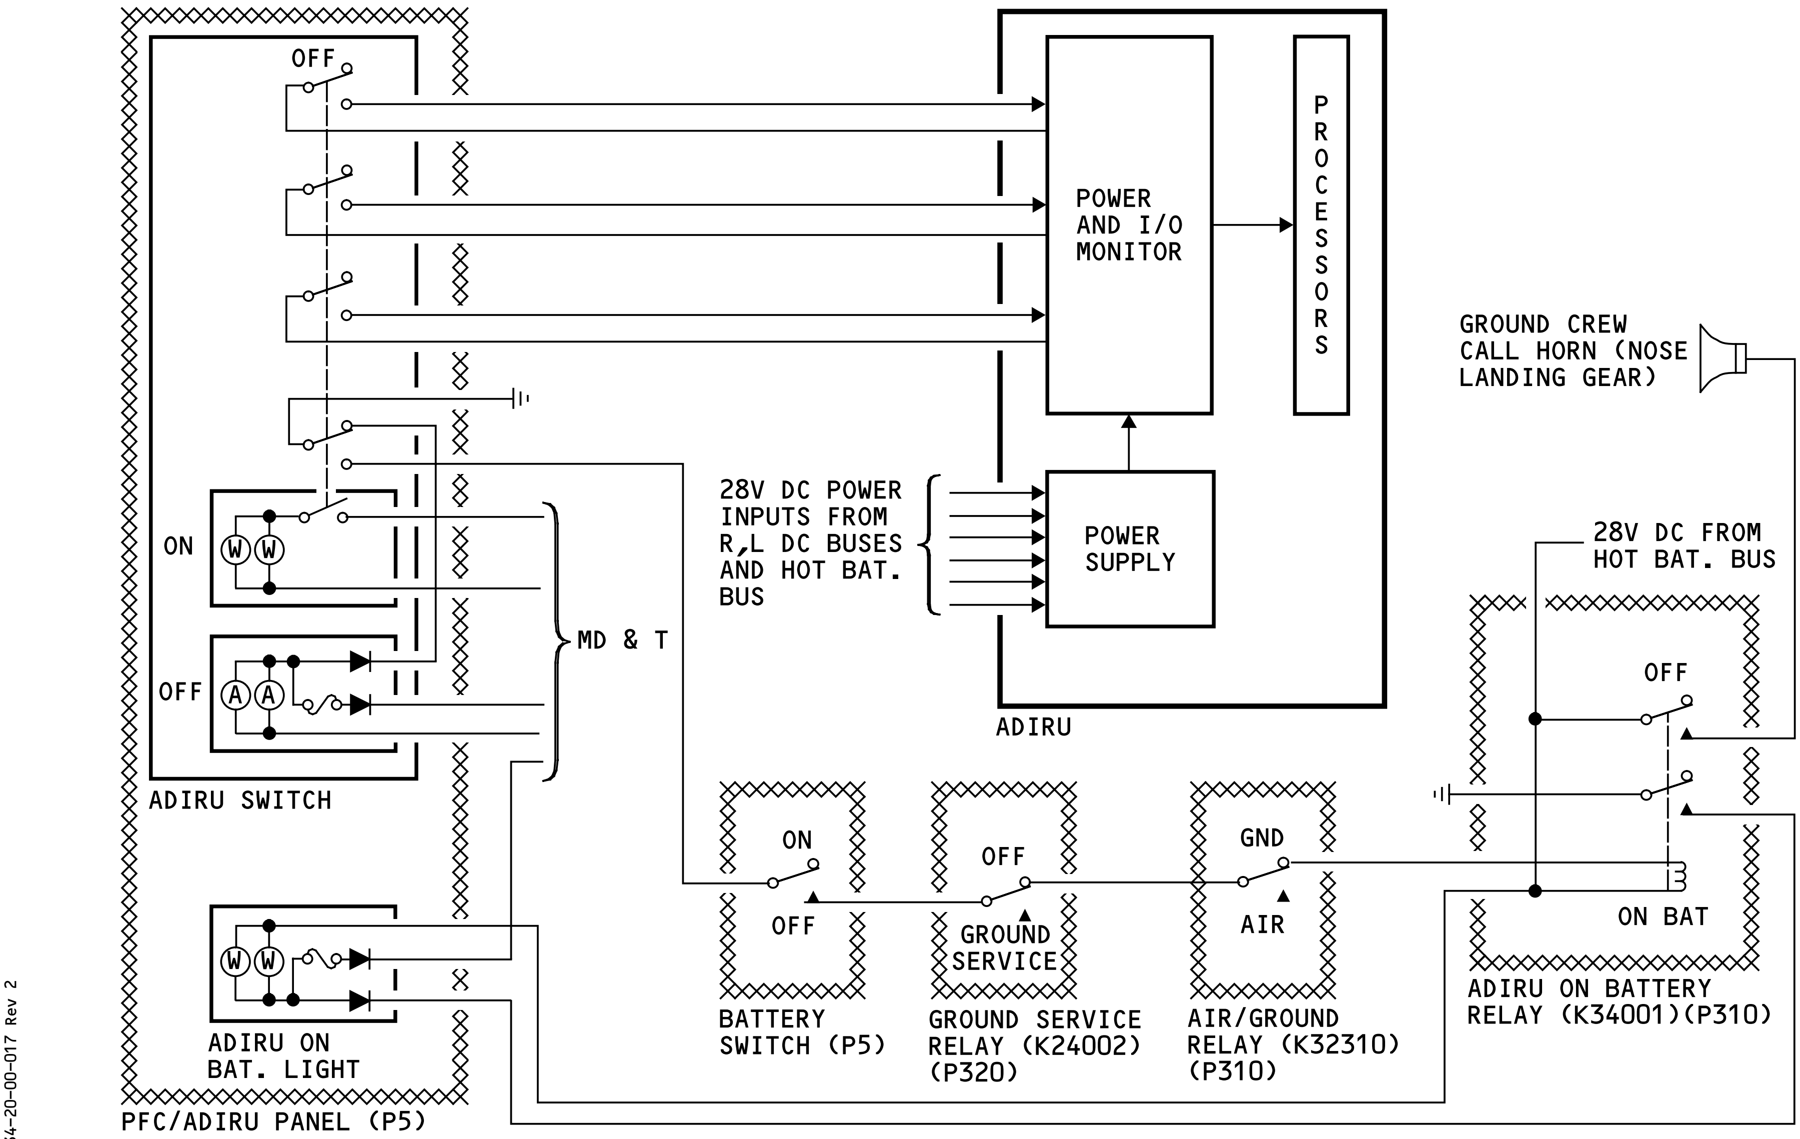
- Battery switch is in the off position
- Ground service relay is in the off position
- Air/ground relay is in the ground position
- The ADIRU switch is in the on position.

Power Down

With the ADIRU switch in the off position, one of these conditions must be present before the ADIRU will power down:

- Ground speed is less than 20 kts
- Computed airspeed is less than 30 kts.

All three power off discretes from the ADIRU on/off switch must be present for shutdown.



ADIRS - ADIRU POWERUP, ON BATTERY, POWERDOWN

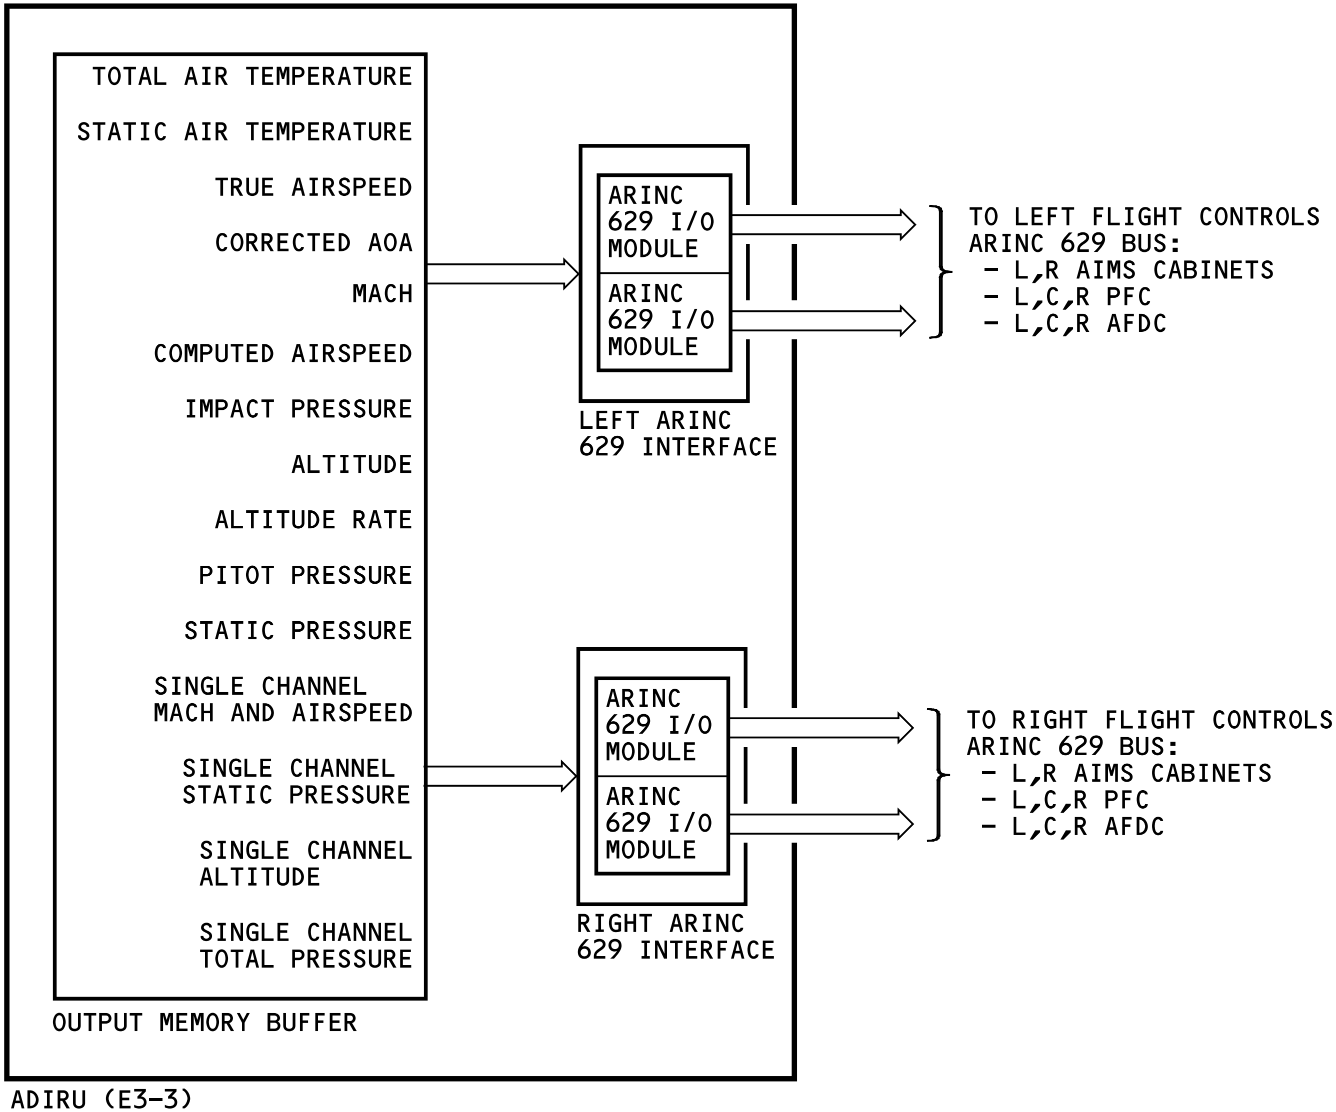
ADIRS - ADIRU AIR DATA FUNCTION - 3

Outputs

The ADIRU transmits air data to the left and right flight controls ARINC 629 buses. The air data goes to these components:

- Left and right AIMS cabinets
- Left, center, and right primary flight computers (PFCs)
- Left, center, and right autopilot flight director computers (AFDCs).

Only one of the two connections to each flight controls ARINC 629 bus is active at a time.



34-20-00-020 Rev 3 05/15/1997

ADIRS - ADIRU AIR DATA FUNCTION - 3

ADIRS - ADIRU INERTIAL REFERENCE DATA FUNCTION - 1

General

The ADIRU uses data from the flight management computing function (FMCF) in the AIMS cabinets to do these functions:

- Initialize the airplane position
- Calibrate the gyros and accelerometers.

Inputs

The FMCF sends this data to the inertial reference function in the ADIRU:

- Initial position
- Airplane type
- Global positioning system (GPS) position (longitude and latitude)
- GPS velocity (north, east, and vertical).

Initial Position

When the flight crew enters the initial position on the control display unit (CDU), the position goes to the FMCF of the AIMS. The AIMS sends the entered initial position to the ADIRU. The ADIRU's initial position validation logic does this:

- Verifies the validity of the entered initial position
- Compares the entered initial position to the global position system (GPS) position or the last ADIRU stored position if GPS data is not available.

If the entered initial position is good, the ADIRU uses it as the initial position for alignment.

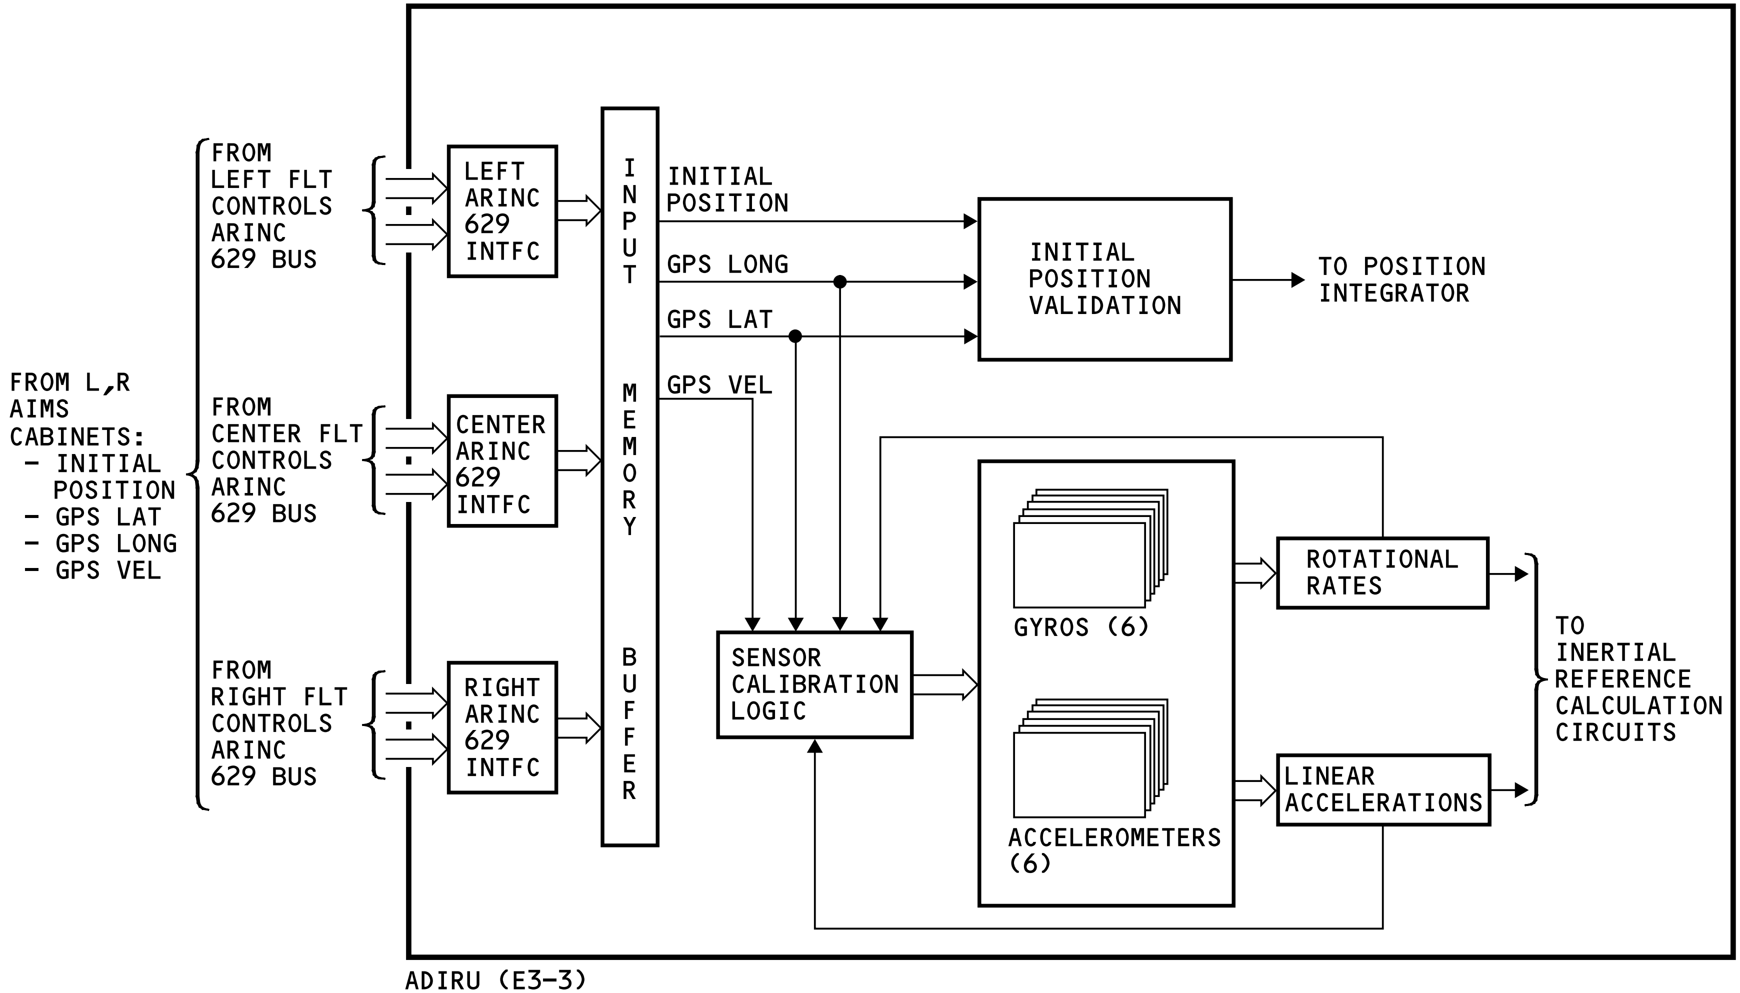
Gyro and Accelerometer Calibration

The GPS position and velocity goes to the sensor calibration logic. The sensor calibration logic supplies calibration data to the gyros and accelerometers. The calibration does not correct the ADIRU errors, it only reduces ADIRU drift errors as the airplane flies.

If the GPS position is not valid, there is no source of calibration data for the gyros and accelerometers.

Gyros and Accelerometers

The gyros send rotational rate data to the inertial reference calculation. The accelerometers send linear accelerations to the inertial reference calculation.



34-20-00-021 Rev 2 05/16/1997

ADIRS - ADIRU INERTIAL REFERENCE DATA FUNCTION - 1

THIS PAGE INTENTIONALLY LEFT BLANK

ADIRS - ADIRU INERTIAL REFERENCE DATA FUNCTION - 2

Wind Speed and Wind Direction

True airspeed data from the ADIRU air data function goes to the calculate wind speed and calculate wind direction function.

Pitch Rate, Roll Rate, Yaw Rate

The ADIRU uses the rotational rates from the six gyros to calculate:

- Pitch rate
- Roll rate
- Yaw rate.

Pitch Angle, Roll Angles, True Heading, Air data Function

The rotational rates from the six gyros go to the angles integrator. The angles integrator function calculates the airplane:

- Pitch angle
- Roll angle
- True heading.

Magnetic Heading And Magnetic Track

Rotational rates and linear accelerations go to the rotate accelerations to earth reference function. The rotate accelerations to earth reference function calculates accelerations in relation to the earth.

The accelerations in relation to the earth go to the velocities integrator. The velocities integrator calculates velocities. The velocities go to the position integrator and the calculate magnetic parameters function.

The position integrator calculates airplane position.

The calculate magnetic parameters uses the following data:

- Position integrator
- Velocities integrator
- Angles integrator.

The magnetic heading and magnetic track go to the output memory buffer only when the magnetic track is valid, and the ground speed is more than 20 knots.

Drift Angle

The velocities integrator sends data to the calculate drift angle circuit.

The drift angle goes to the output memory buffer only when the drift angle is valid and the groundspeed is more than 20 knots.

Latitude and Longitude

The velocities integrator sends velocities to the position integrator. The position integrator sends latitude and longitude to the output memory buffer.

ADIRS - ADIRU INERTIAL REFERENCE DATA FUNCTION - 2

Ground Speed, True Track, and Track Rate

The velocities integrator calculates:

- Ground speed
- True track
- Track rate.

This data goes to the output memory buffer only when the track is valid and the ground speed is more than 20 knots.

Vertical, Along Track, and Cross Track Accelerations

The rotate accelerations to earth reference circuit calculates:

- Vertical acceleration
- Along track acceleration
- Cross track acceleration.

This data goes to the output memory buffer only when the accelerations are valid and the ground speed is more than 20 knots.

Body Normal, Body Longitudinal, and Body Lateral Accelerations

The accelerometers supply these linear accelerations to the output memory buffer:

- Body normal
- Body longitudinal
- Body lateral.

Flight Path Angle

The air data function of the ADIRU supplies barometric altitude to the calculate flight path angle logic through vertical blending filters.

The calculate flight path angle logic also gets data from the velocities integrator.

The flight path angle goes to the output memory buffer only when the flight path is valid and the ground speed is more than 20 knots.

Vertical Speed and Inertial Altitude

Altitude from the ADIRU air data computing function combine with the rotational rates and linear accelerations through vertical blending filters. This data goes to the output buffer as vertical speed and inertial altitude.

ADIRS - AIR DATA MODULE

ADM General

There are 6 air data modules (ADMs) in the air data inertial reference system (ADIRS). Three are for pitot pressure and three are for static pressure. All the ADMs operate in the same manner.

The air data module (ADM) measures absolute pressure. This pressure comes from a pitot probe or static pressure port. The ADM transmits this pressure on a flight controls ARINC 629 bus for use by the ADIRU and SAARU. All ARINC 629 ADMs are interchangeable and can be a pitot or a static ADM.

The pitot ADMs control the heat for the pitot probes and the angle of attack (AOA) sensors.

ARINC 629 Interface

The left ADM transmits and receives on the left flight controls ARINC 629 bus.

The center ADM transmits and receives on the center flight controls ARINC 629 bus.

The right ADM transmits and receives on the right flight controls ARINC 629 bus.

ADM Physical Description

The ADM weighs 2.6 pounds. The ADM has one pneumatic connector and two electrical connectors.

The ADM has a flange on each side. Each flange has two captive screws. The ADM mounts directly to the mounting tray flanges.

The pneumatic connector seals itself when removed from the ADM. You do not need to plug the pneumatic line when you remove the ADM.

One electrical connector is for program pins and power. The other electrical connector is for ARINC 629.

ADM Operation

The ADM gets 28v dc for power.

The ADM receives pneumatic pressure from a pitot probe or static ports. The pressure sensor changes the pressure value to an analog signal. The analog signal goes through an analog to digital converter. The ADM calibrates the pressure and compensates for temperature. The ARINC 629 transmitter/receiver sends the data on a flight controls ARINC 629 bus.

Program pins define the location of the ADM. The input/output decoder logic sends the program pin ADM location data to the processor.

This location information goes to the ADIRU and SAARU on a flight controls ARINC 629 bus.

ADIRS - AIR DATA MODULE

Pitot Probe and AOA Sensor Heat Control

The left pitot ADM controls the heat for the left pitot probe. The center pitot ADM controls the heat for the center pitot probe. The right pitot ADM controls the heat for the right pitot probe.

The left pitot ADM controls the heat for the left AOA sensor. The right pitot ADM controls the heat for the right AOA sensor.

The pitot ADMs control the heat control relays in the power management panels. The heat control comes from data the ADMs receive from the primary flight computers (PFCs) through the flight controls ARINC 629 bus. If the PFCs are not valid, the ADMs use data from the autopilot/flight director computers (AFDCs). The AFDC data also comes through the flight controls ARINC 629 bus.

The ADMs supply a ground heat signal to the power management panels when the PFCs report these two conditions are true:

- The airplane is on the ground
- An engine running.

The ADMs supply an air heat signal to the power management panels when any of these conditions is true:

- The airplane is in the air
- Computed airspeed (CAS) is more than 50 kts.

The power management panels connect the ground heat and the air heat signals to current sense relays to control the voltage to the pitot probes. The ADMs monitor the pitot probe and AOA heaters through three electrical input discretes. The ADM transmits heater fault data on the flight controls bus.

See chapter 30 for information on how to do a test of the pitot probe and the AOA sensor heat operation.

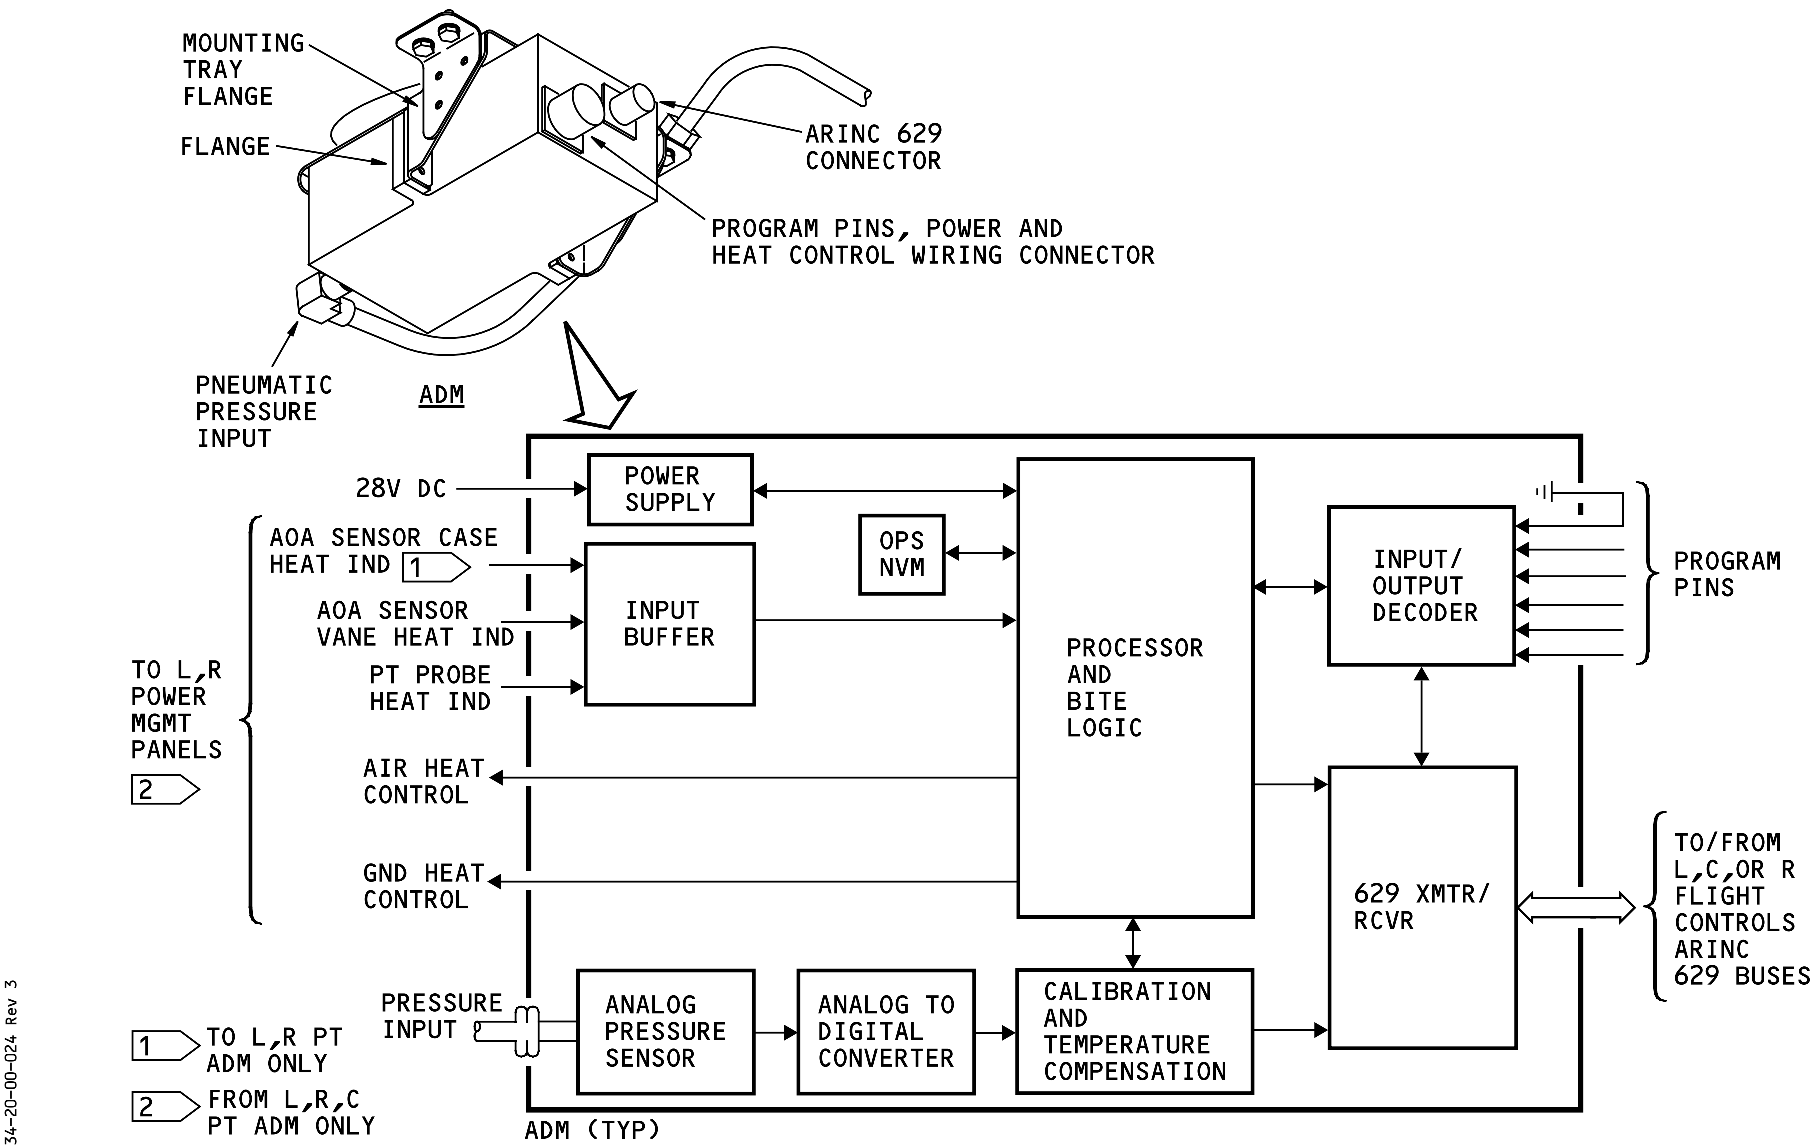
ADM Software Loading

The ADM can receive operational program software (OPS) from the AIMS cabinets through the flight controls ARINC 629 bus. You load the same software for pitot and static ADMs.

The ADM keeps the OPS in non-volatile memory (NVM).

Fault Data

The ADM sends fault and operational status data to the central maintenance computing function (CMCF) of the AIMS. The CMCF can command the ADM to test the pitot heaters and AOA heaters.



ADIRS - AIR DATA MODULE

ADIRS - SECONDARY ATTITUDE AIR DATA REFERENCE UNIT

General

The secondary attitude air data reference unit (SAARU) is a backup source of attitude and air data.

Physical Description

The SAARU weighs 30 pounds. It uses passive cooling. Cooling fins take heat away from the SAARU.

Software Load

The SAARU can receive new software from the flight controls ARINC 629 data bus. The software data modifies the operational program of the SAARU.

Sensors and Circuits

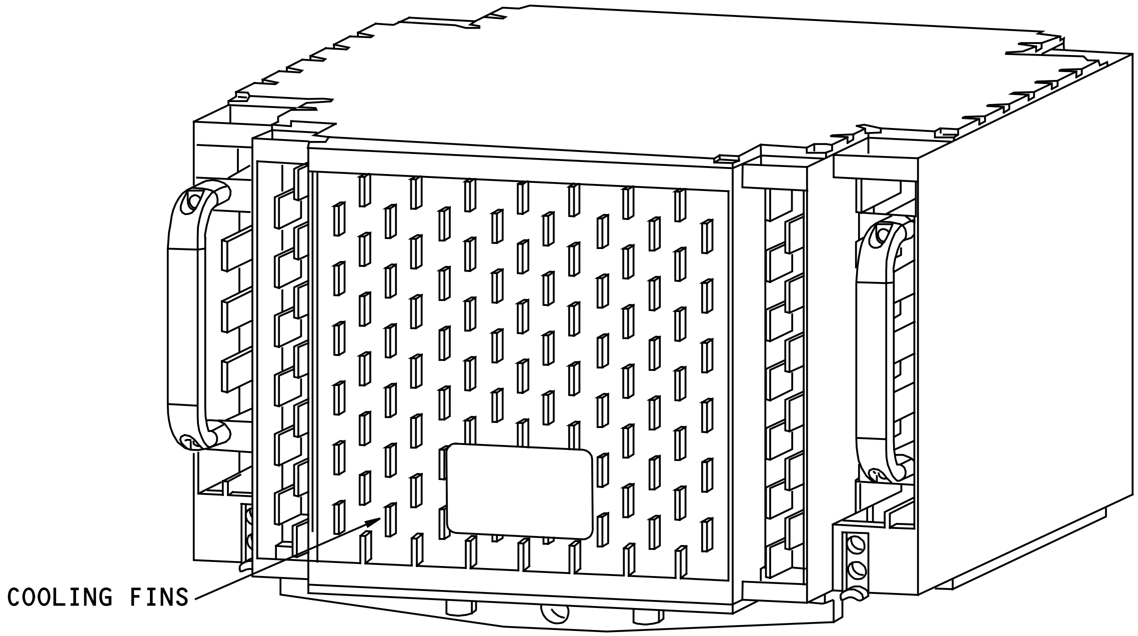
The SAARU has these components:

- Four fiber optic gyros
- Four linear accelerometers
- Two central processing units (CPUs)
- Three ARINC 629 interface modules.
- Two power supplies.

Three fiber optic gyros and three accelerometers are aligned with the roll, pitch, and yaw axis. The fourth fiber optic gyro and fourth accelerometer allow the SAARU to detect any faults in the other three.

Standby Instruments

The SAARU supplies attitude data to the standby attitude indicator through the ARINC 429 bus.



34-20-00-025 Rev 1

ADIRS - SECONDARY ATTITUDE AIR DATA REFERENCE UNIT

ADIRS - SAARU INERTIAL REFERENCE DATA FUNCTION

General

The secondary attitude air data reference unit (SAARU) uses gyros and accelerometers to calculate inertial reference data. The inertial reference data goes to airplane systems.

Power

The SAARU gets power from a circuit breaker in the center power supply assembly. The circuit breaker gets power from the center flight control DC bus.

Gyros and Accelerometers

The gyros and accelerometers measure rotation rates and accelerations. The rotation rates and accelerations go to buffers. The buffers supply the rotation rates and accelerations to the central processing unit which calculate SAARU data.

SAARU Data

The SAARU calculates this inertial reference data:

- Body frame accelerations
- Body frame angular rates
- Attitude (roll and pitch)
- Horizontal and vertical accelerations
- Inertial altitude
- Wander heading
- Vertical speed.

Barometric Altitude Input

The SAARU uses barometric altitude from its air data section to calculate vertical speed. This barometric altitude prevents fast changes in vertical speed.

ARINC 629 Output

The SAARU sends inertial data on the center flight controls ARINC 629 bus. The SAARU data goes to the:

- Left and right AIMS cabinets
- Left, right, and center primary flight computers (PFCs)
- Left, right, and center autopilot flight director computers.

ARINC 429 Output

The SAARU sends attitude data through the output buffer to the standby attitude indicator.

ADIRS - SAARU INERTIAL REFERENCE DATA FUNCTION

THIS PAGE INTENTIONALLY LEFT BLANK

ADIRS - SAARU AIR DATA FUNCTION - 1

General

Redundancy management logic in the SAARU selects or votes a value for the inputs that come from the redundant air data sensors.

Total Air Temperature

The total air temperature (TAT) redundancy management logic calculates an average of the TAT values from TAT inputs 1 and 2.

Pitot Heater Valid

Pitot heater valid signals come from the left, center, and right pitot air data modules (ADMs). The pitot heater valid signals go to the pitot ADM redundancy management logic.

Pitot Pressure

Pitot pressure comes from the left, center, and right pitot air data modules (ADMs). The pitot ADM redundancy management logic calculates an average of the pitot pressures from the ADMs.

AOA Heater Valid

The angle of attack (AOA) heater valid signals go to the AOA redundancy management logic. The AOA redundancy management logic uses the AOA heater valid signal to find out if the AOA sensors are valid.

AOA Input

The AOA values go to the function that calculates the corrected AOA.

Speedbrake Lever Past Arm Signal

The primary flight computers (PFCs) supply the air ground speedbrake lever past arm signals to the SAARU. Input data redundancy management logic selects one of the PFC signals. The speedbrake lever past arm signals go to the AOA redundancy management logic.

Air/Ground, Nose Gear Position, and Flap Position

The proximity sensor electronics units (PSEUs) supply the air/ground and the nose gear position signals to the AIMS cabinets.

The flap/slat electronics units (FSEUs) supply the flap position signals to the AIMS cabinets.

The AIMS cabinets supply the signals to the SAARU. An input data redundancy management logic selects one of the PSEU signals, and one of the FSEU signals.

The air/ground signal, nose gear position, and flap position signals go to the calculate corrected AOA function.

ADIRS - SAARU AIR DATA FUNCTION - 1

Calculate Corrected AOA

The calculate corrected AOA logic calculates the left and right corrected AOA. The calculate corrected AOA function receives these additional signals:

- Mach
- Pitch rate
- True airspeed
- Flap position
- Nose gear position.

The corrected AOAs go to the AOA redundancy management logic.

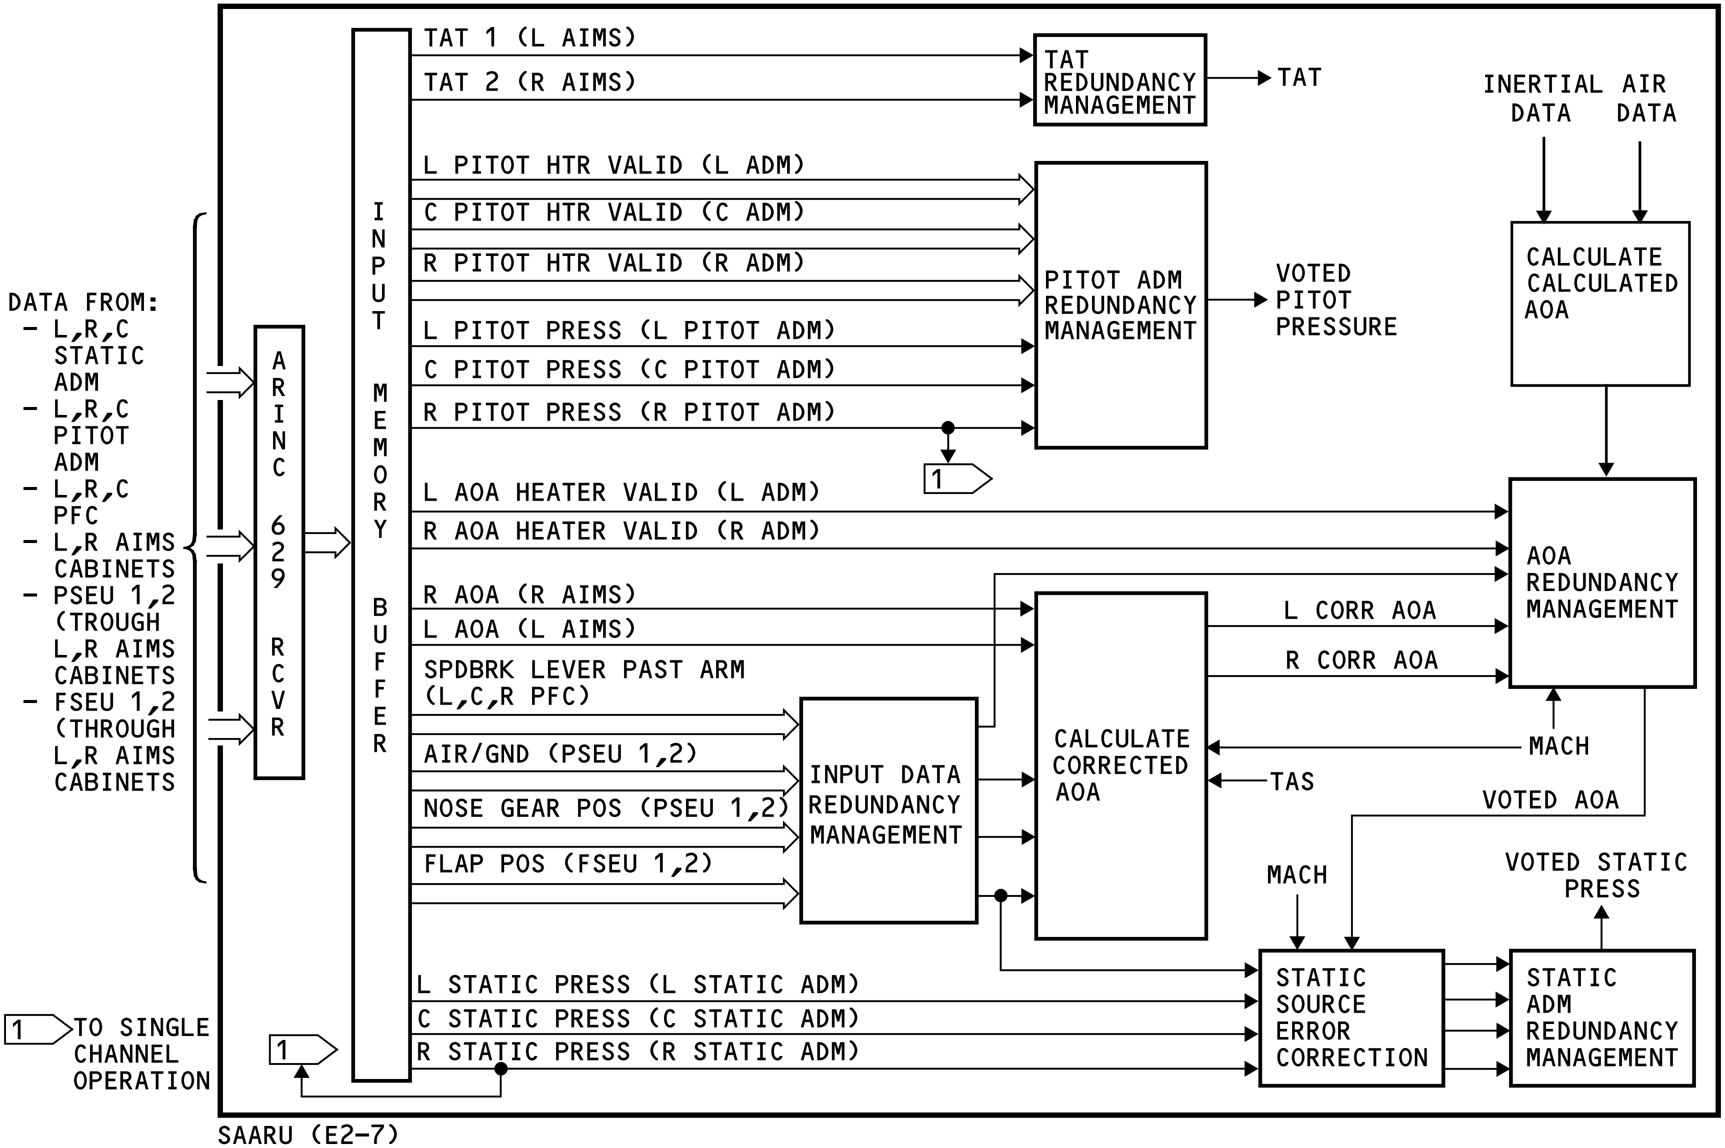
AOA Redundancy Management

The AOA redundancy management logic uses a modified average calculation. The modified average calculation calculates an average of three AOA values, the left corrected AOA, the right corrected AOA, and a calculated AOA. The calculated AOA logic receives inputs from the inertial and air data systems to calculate the calculated AOA.

Static Pressure

Static pressure comes from the left, center, and right static air data modules (ADMs). The static source error correction (SSEC) uses Mach and corrected AOA to compensate for errors in measurement of static pressure. The static pressure goes to the static ADM redundancy management logic.

The static ADM redundancy management logic calculates an average of the static pressures from the ADMs. The static ADM redundancy management logic uses body accelerations from the SAARU inertial reference section to determine error thresholds.



ADIRS - SAARU AIR DATA FUNCTION - 1

34-20-00-027 Rev 4 05/16/1997

THIS PAGE INTENTIONALLY LEFT BLANK

ADIRS - SAARU AIR DATA FUNCTION - 2

Total Air Temperature (TAT)

The TAT signal is corrected for the small temperature rise that occurs when the air flow through the probe slows down.

Static Air Temperature (SAT)

The calculate static air temperature function receives TAT, mach and CAS inputs. The SAT signal goes to the output memory buffer.

True Air Speed (TAS)

The calculate TAS function uses static temperature CAS to calculate TAS. The corrected TAS goes invalid when the CAS is less than 50 knots.

Corrected Angle Of Attack (AOA)

The corrected AOA, from the AOA redundancy management, goes invalid when the CAS is less than 50 knots.

Mach and Computed Air Speed (CAS)

The calculate mach and CAS function uses impact pressure to calculate mach and CAS. The corrected mach goes invalid when the CAS is less than 50 knots.

Impact Pressure

The calculate impact pressure function receives static pressure inputs from the static ADM redundancy management logic. The calculate impact pressure function also receives pitot pressure from the pitot ADM redundancy management. The impact pressure signal goes to the output memory buffer.

Altitude and Altitude Rate.

The calculate altitude and altitude rate function gets signals from the static and pitot ADM redundancy management logic. Altitude and altitude rate signals go to the output memory buffer.

Pitot Pressure and Static Pressure

Pitot and static pressure come directly from the pitot and static ADM redundancy management logic. These pressures go to the output memory buffer.

Single Channel Operation

If the ADIRU and SAARU air data parameters from the redundancy management logic are invalid, the flight deck displays show single channel air data from the ADIRU and SAARU. Single channel air data parameters bypass the redundancy management logic that the flight displays show during normal operation. Air data from the right pitot ADM and right static ADM goes to the the SAARU single channel operation function. This function calculates these single channel quantities:

- Mach
- Airspeed
- Static pressure

ADIRS - SAARU AIR DATA FUNCTION - 2

- Barometric altitude
- Total pressure.

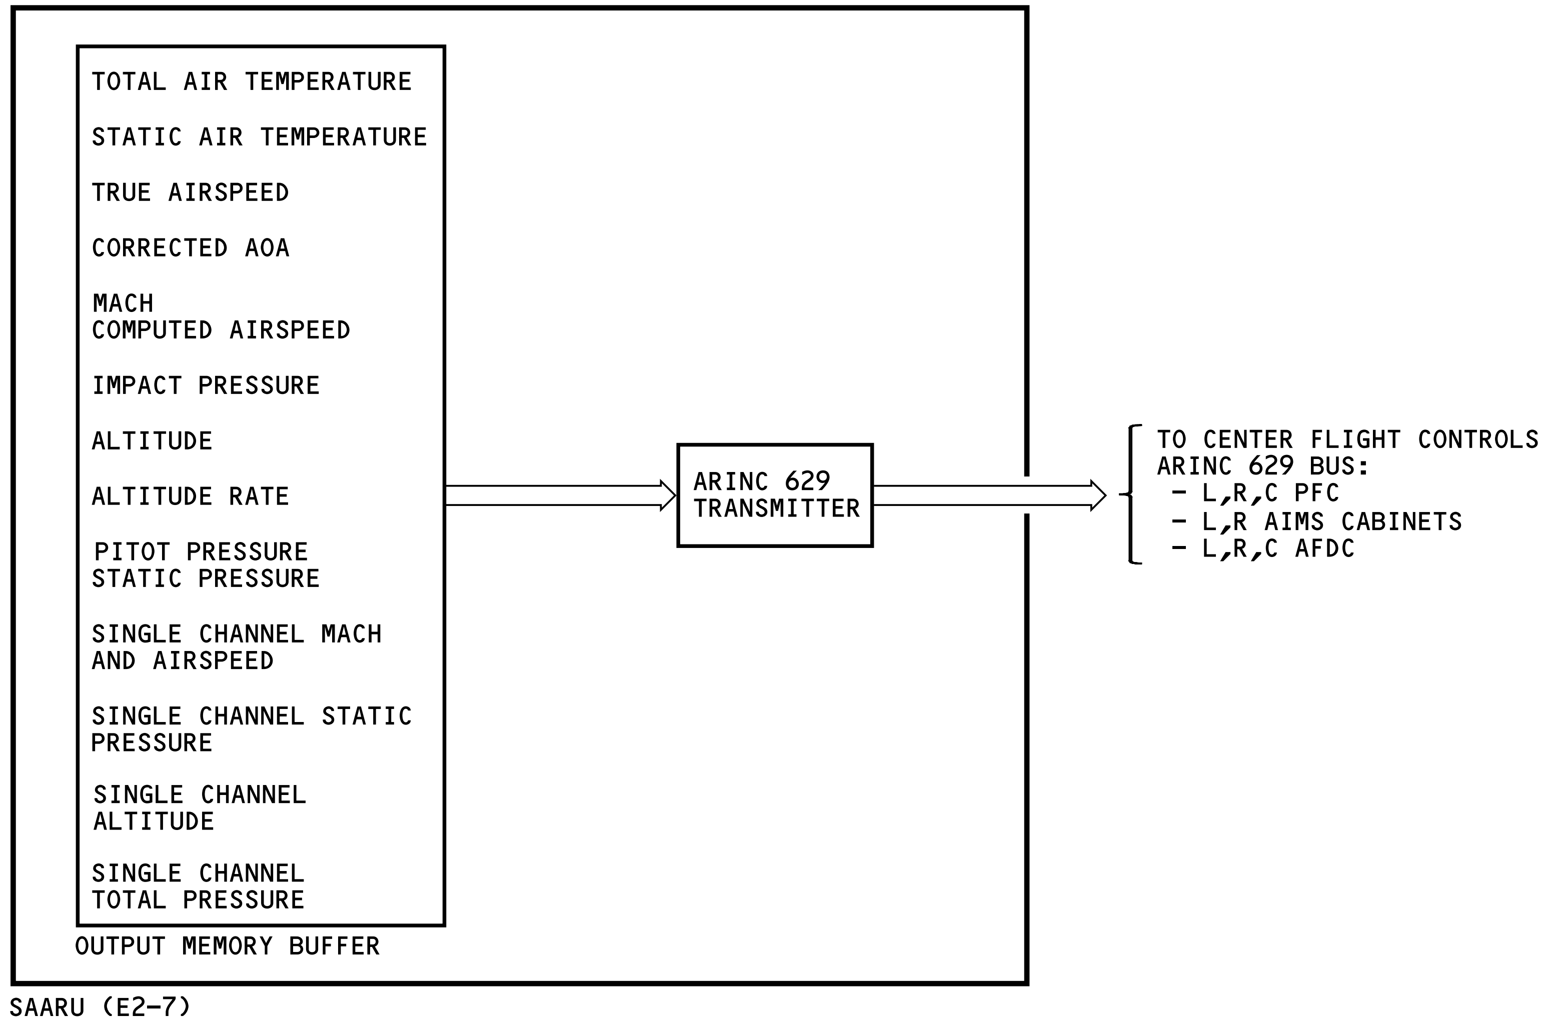
ADIRS - SAARU AIR DATA FUNCTION - 2

ADIRS - SAARU AIR DATA FUNCTION - 3

Air Data Outputs

The secondary attitude air data reference unit (SAARU) sends data on the center flight control ARINC 629 bus. The data goes to the:

- Primary flight computers (PFCs)
- AIMS cabinets
- Autopilot flight director computers (AFDCs).



34-20-00-029 Rev 1 05/15/1997

ADIRS - SAARU AIR DATA FUNCTION - 3

ADIRS - SAARU BACKUP NAVIGATION

General

The ADIRU supplies navigation data to the autopilot flight director system (AFDS) and the primary flight control system (PFCS). The AFDS uses the SAARU backup navigation data if the ADIRU fails.

ADIRU Tracking

When the ADIRU data from the SAARU input memory buffer is valid, the SAARU tracks the ADIRU navigation outputs. This makes the SAARU backup navigation data the same as the ADIRU.

If the ADIRU data goes invalid, the SAARU does not follow the ADIRU outputs. The SAARU continues to calculate backup navigation data independent of the ADIRU. The fiber optic gyros do not supply sufficiently accurate data for autopilot operation for extended periods of time, therefore, the backup navigation function goes invalid after 3 minutes.

ADIRU Inputs

The ADIRU supplies these inputs to the SAARU:

- Roll angle
- Pitch angle
- Magnetic heading
- True heading
- Along-track horizontal acceleration
- Cross-track horizontal acceleration
- North velocity
- East velocity.

The SAARU monitors the ADIRU inputs. If one or more inputs are invalid and the true airspeed (TAS) from the SAARU is more than 80 knots, the SAARU starts to calculate backup navigation data independent of the ADIRU.

Tracking Loops

The tracking loops make the SAARU follow the ADIRU data. If the ADIRU is valid, the SAARU backup navigation data out of the tracking loops and into the output buffer follows the ADIRU data. If the ADIRU fails, the tracking loops let the SAARU data go to the output memory buffer.

Calculate Magnetic Track Angle

The calculate magnetic track angle logic uses magnetic and true heading.

Calculate True Track Angle

The calculate true track angle logic uses north and east velocities.

Calculate Ground Speed

The calculate ground speed logic uses north and east velocities.

Calculate Flight Path Acceleration

The calculate flight path acceleration logic uses these inputs:

- Along track horizontal acceleration
- Ground speed
- Vertical speed
- Vertical acceleration.

SAARU Backup Navigation Outputs

The SAARU backup navigation outputs go to the autopilot flight director computers (AFDCs) and the primary flight computers (PFCs). These are the SAARU backup navigation outputs:

- Roll angle
- Pitch angle
- Magnetic heading
- Magnetic track
- True heading
- Along-track horizontal acceleration
- Cross-track horizontal acceleration
- True track angle
- Ground speed
- Flight path acceleration.

Training Information Point

The autopilot flight director system (AFDS) can use ADIRU or SAARU data. The AFDS uses ADIRU data first. If the ADIRU fails, the AFDS uses SAARU data. Some AFDS modes do not operate when the ADIRU fails and SAARU backup navigation is not available. These are the AFDS modes that do not operate in this condition:

- Approach (APP)
- Flight path angle (FPA)
- Takeoff/go-around (TO/GA)
- Track hold (TRK HLD)
- Track select (TRK SEL)
- Vertical navigation (VNAV)
- Lateral navigation (LNAV).

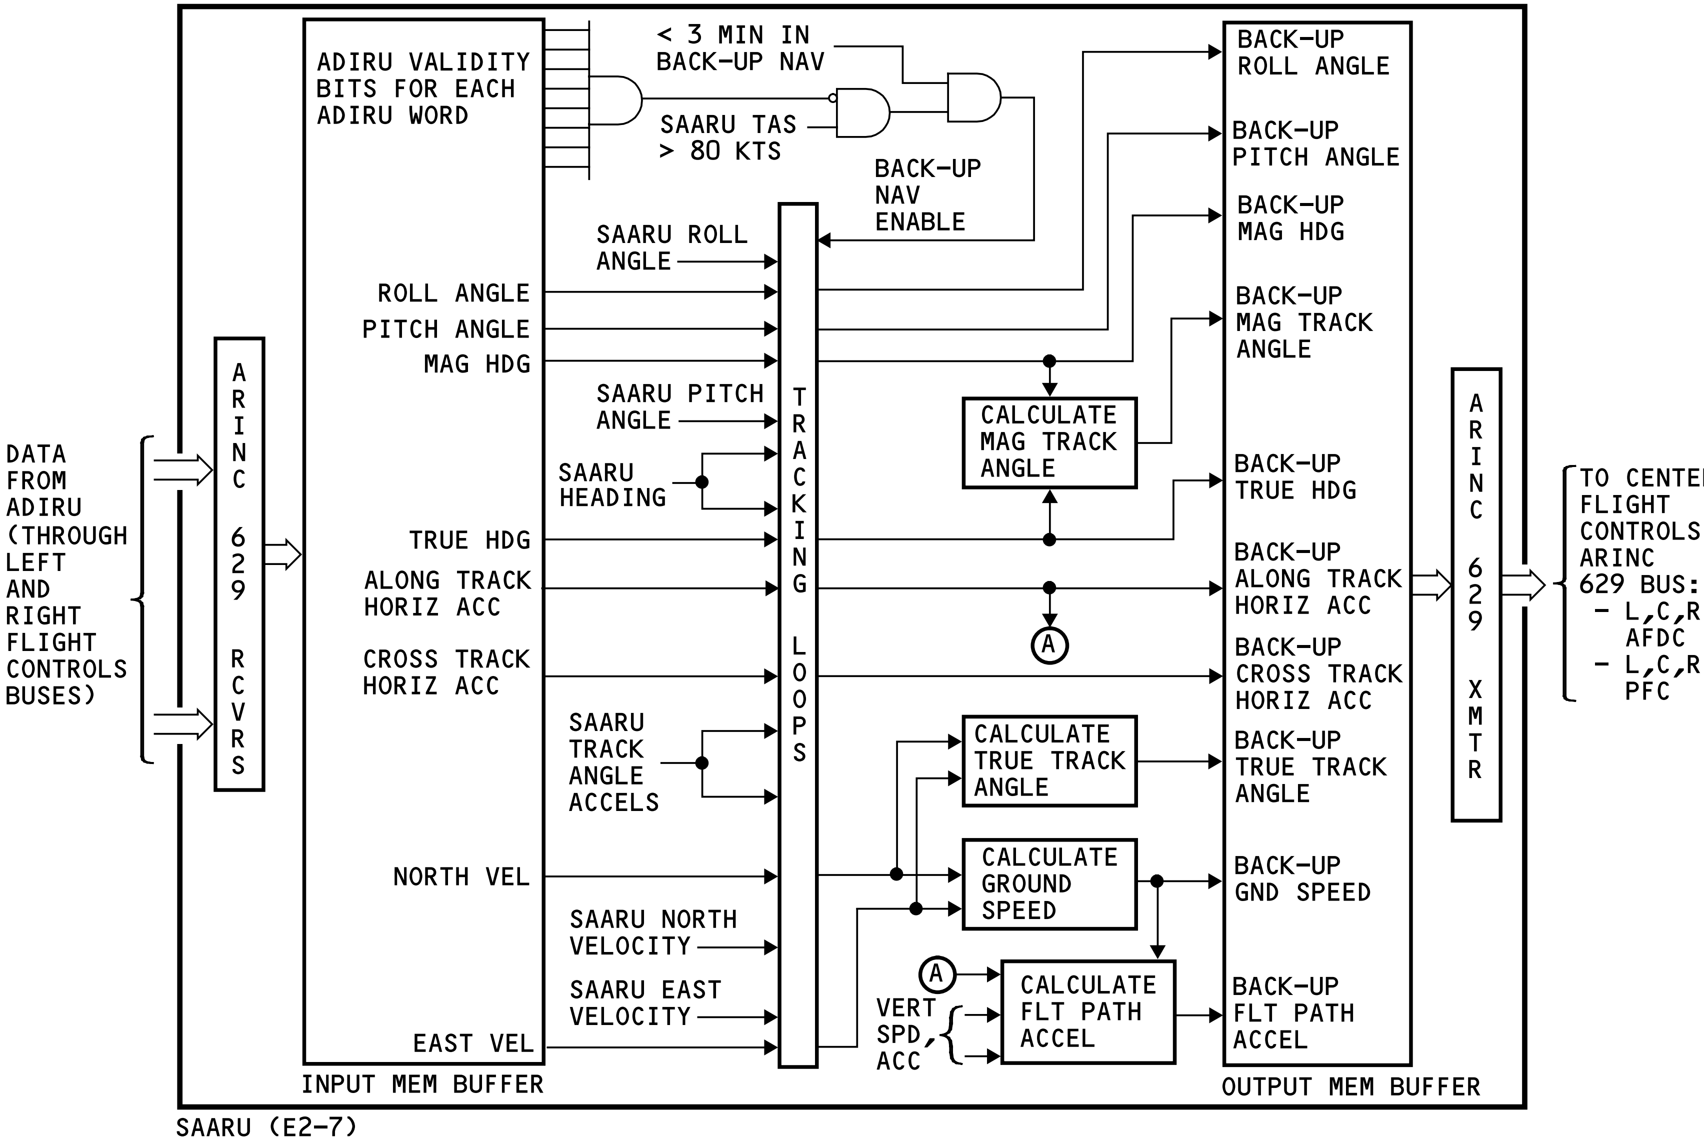
If the ADIRU fails when the APP mode is armed or engaged, the AFDS automatically selects the SAARU backup navigation data. If the airplane does not land within 3 minutes, the autopilot pitch and roll modes fail. The flight crew must select another autopilot mode or disengage the autopilot.

If the ADIRU fails when the FPA mode is engaged, the AFDS will automatically select the SAARU backup navigation data. If the autopilot does not go into another mode or if the flight crew does not select another mode within 3 minutes, the autopilot pitch mode fails. The flight crew must select another autopilot mode or disengage the autopilot.

If the ADIRU fails when the TO/GA mode is engaged, the AFDS will automatically select the SAARU backup navigation data. If the autopilot does not go into another mode or if the flight crew does not select another mode within 3 minutes, the autopilot roll mode fails. The flight crew must select another autopilot mode or disengage the autopilot.

If the ADIRU fails when the TRK HLD or TRK SEL mode is engaged, the AFDS will automatically select the SAARU backup navigation data. If the flight crew does not select another mode within 3 minutes, the autopilot roll mode fails. The flight crew must select another autopilot mode or disengage the autopilot.

VNAV and LNAV are not AFDS modes. VNAV and LNAV are flight management computing system (FMCS) modes that go through the AFDCs. VNAV and LNAV do not operate when the FMCS does not have valid ADIRU data. If the ADIRU fails, the autopilot pitch and roll modes immediately fail. The flight crew must select another autopilot mode or disengage the autopilot.



ADIRS - SAARU BACKUP NAVIGATION

ADIRS - STANDBY ATTITUDE INDICATOR

Purpose

The standby attitude indicator shows attitude data. The attitude data comes from the secondary attitude air data reference unit (SAARU). The standby attitude indicator is a liquid crystal display (LCD).

Program Pin Configuration

Program pins determine the function of the standby instruments. Install the standby instrument in the standby attitude indicator position to show the standby attitude indicator format.

If you replace the normal standby attitude indicator with an indicator that has a push-button and rotating knob, the knob has no function. The push-button and the rotating knob are active only when you install the standby instrument in the standby airspeed indicator position or the standby altimeter position.

Integral Light Sensor

There is an integral light sensor at the lower center of each standby instrument. The integral light sensor measures the amount of light on the front of the standby instrument. The standby instruments adjust the display brightness to the amount of light available.

The standby instruments send brightness data to each other to adjust their brightness.

Remote Light Sensor

Remote light sensors on the glareshield panel (P7) supply brightness signals to the standby instruments. The standby instruments adjust the display brightness to the amount of light available.

NCD Display

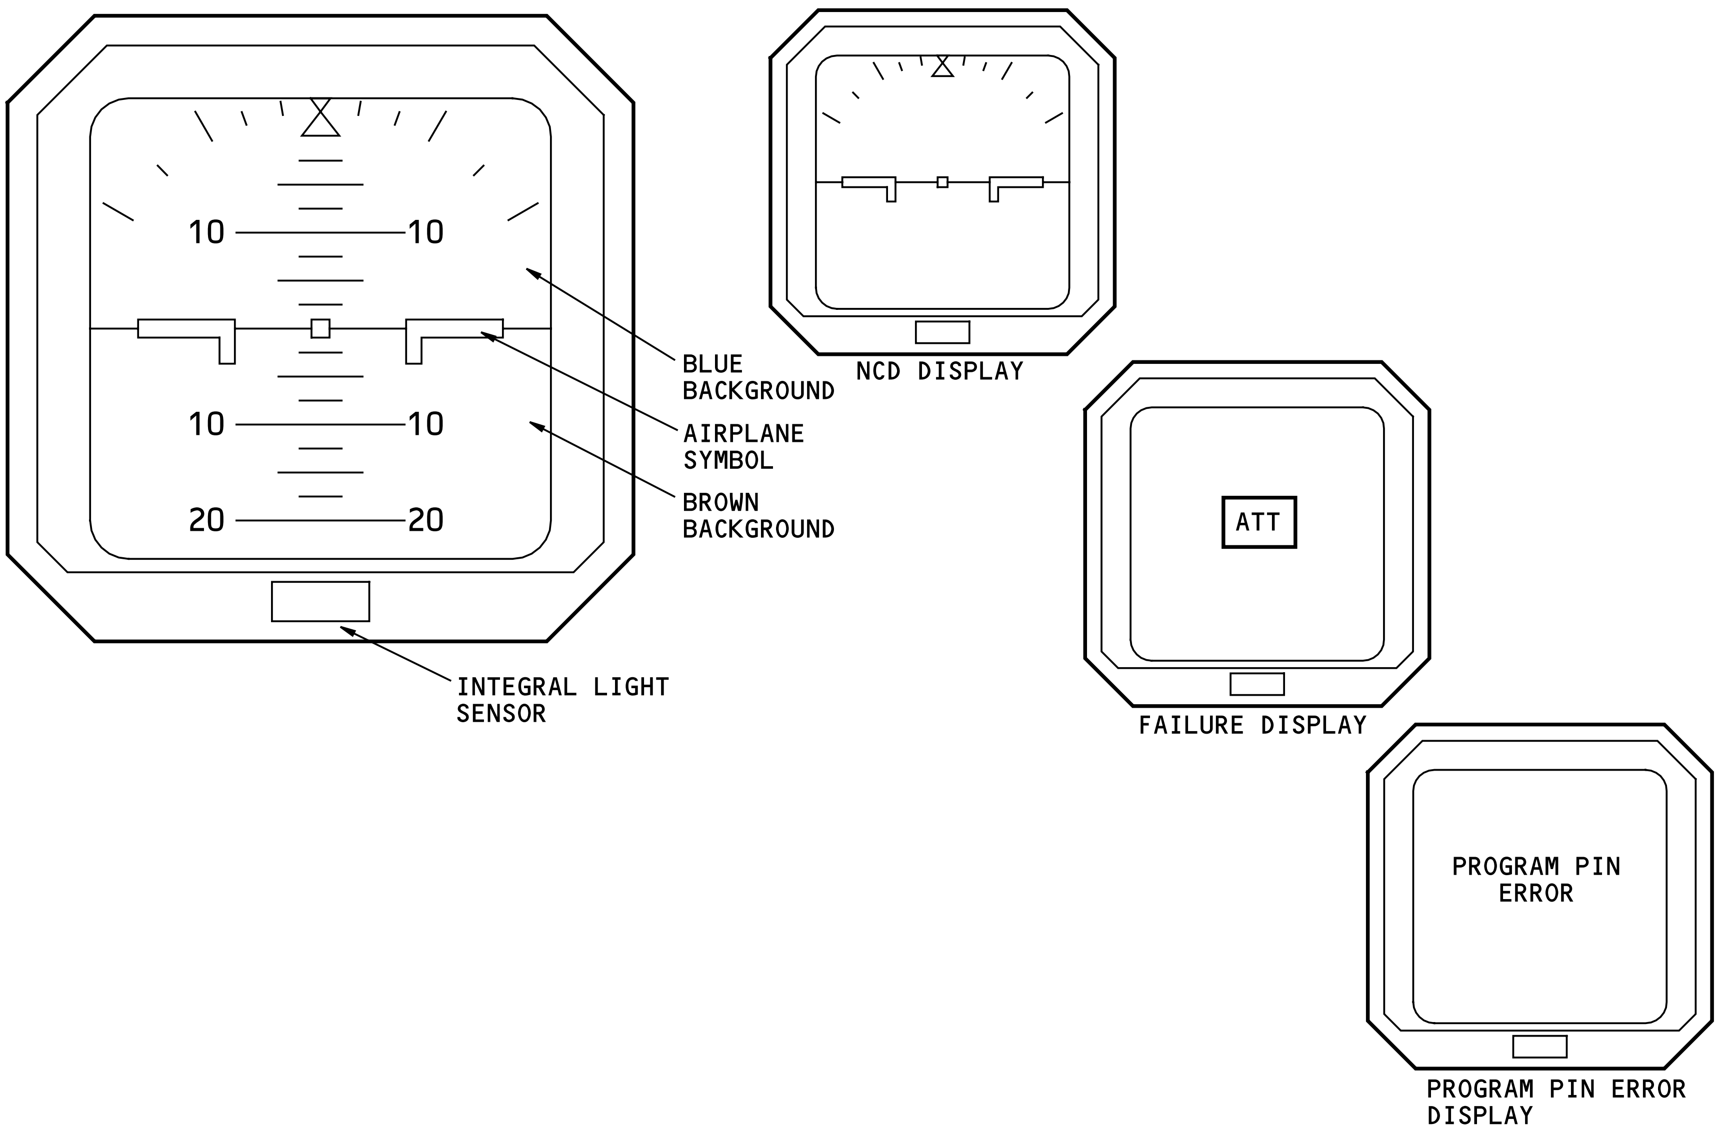
If data from the SAARU is NCD (no computed data), the standby attitude indicator shows only the airplane symbol, roll scale, and zero pitch angle.

Failure Display

If the standby attitude indicator or the data from the SAARU fails, an ATT (attitude) yellow flag shows. A yellow box is around the letters ATT.

Program Pin Error

If the standby attitude indicator finds a program pin error, the yellow message PROGRAM PIN ERROR shows. A program pin error message means the standby instrument finds the program pin connection invalid.



34-20-00-031 Rev 1

ADIRS - STANDBY ATTITUDE INDICATOR

ADIRS - STANDBY ATTITUDE INDICATOR FUNCTIONAL DESCRIPTION

Power

The standby attitude indicator gets 28v dc for power.

Attitude Inputs

The secondary attitude air data reference unit (SAARU) supplies attitude data to the standby attitude indicator. The data goes to a microprocessor. The microprocessor supplies display data to the liquid crystal display (LCD).

Brightness Inputs

Brightness data comes from the:

- Standby altimeter
- Standby airspeed indicator
- Integral light sensor
- Remote light sensors.

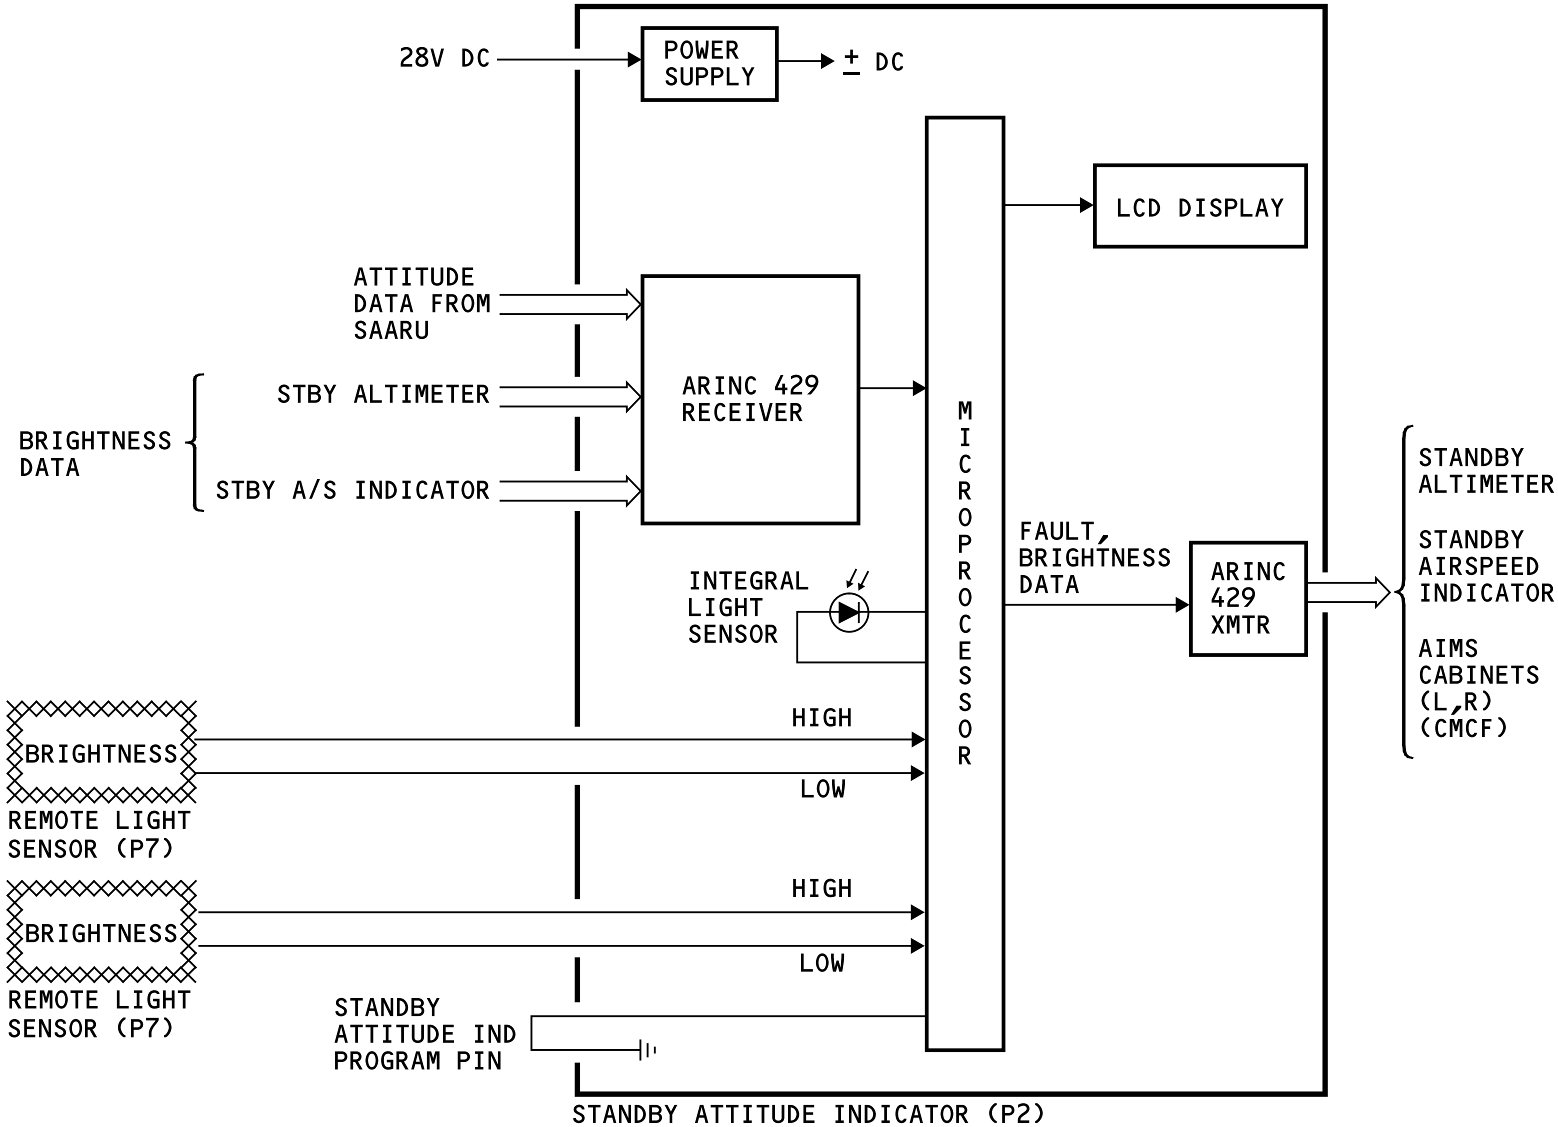
The microprocessor uses the brightness inputs to adjust the brightness of the LCD.

Program Pin

A standby attitude indicator program pin selects the standby attitude indicator display format.

Outputs

Brightness data goes to the standby altimeter and the standby airspeed indicator. Fault data goes to the central maintenance computing function (CMCF) of the AIMS.



34-20-00-032 Rev 0

ADIRS - STANDBY ATTITUDE INDICATOR FUNCTIONAL DESCRIPTION

ADIRS - TOTAL AIR TEMPERATURE PROBE

Purpose

A total air temperature (TAT) probe measures temperature outside the airplane.

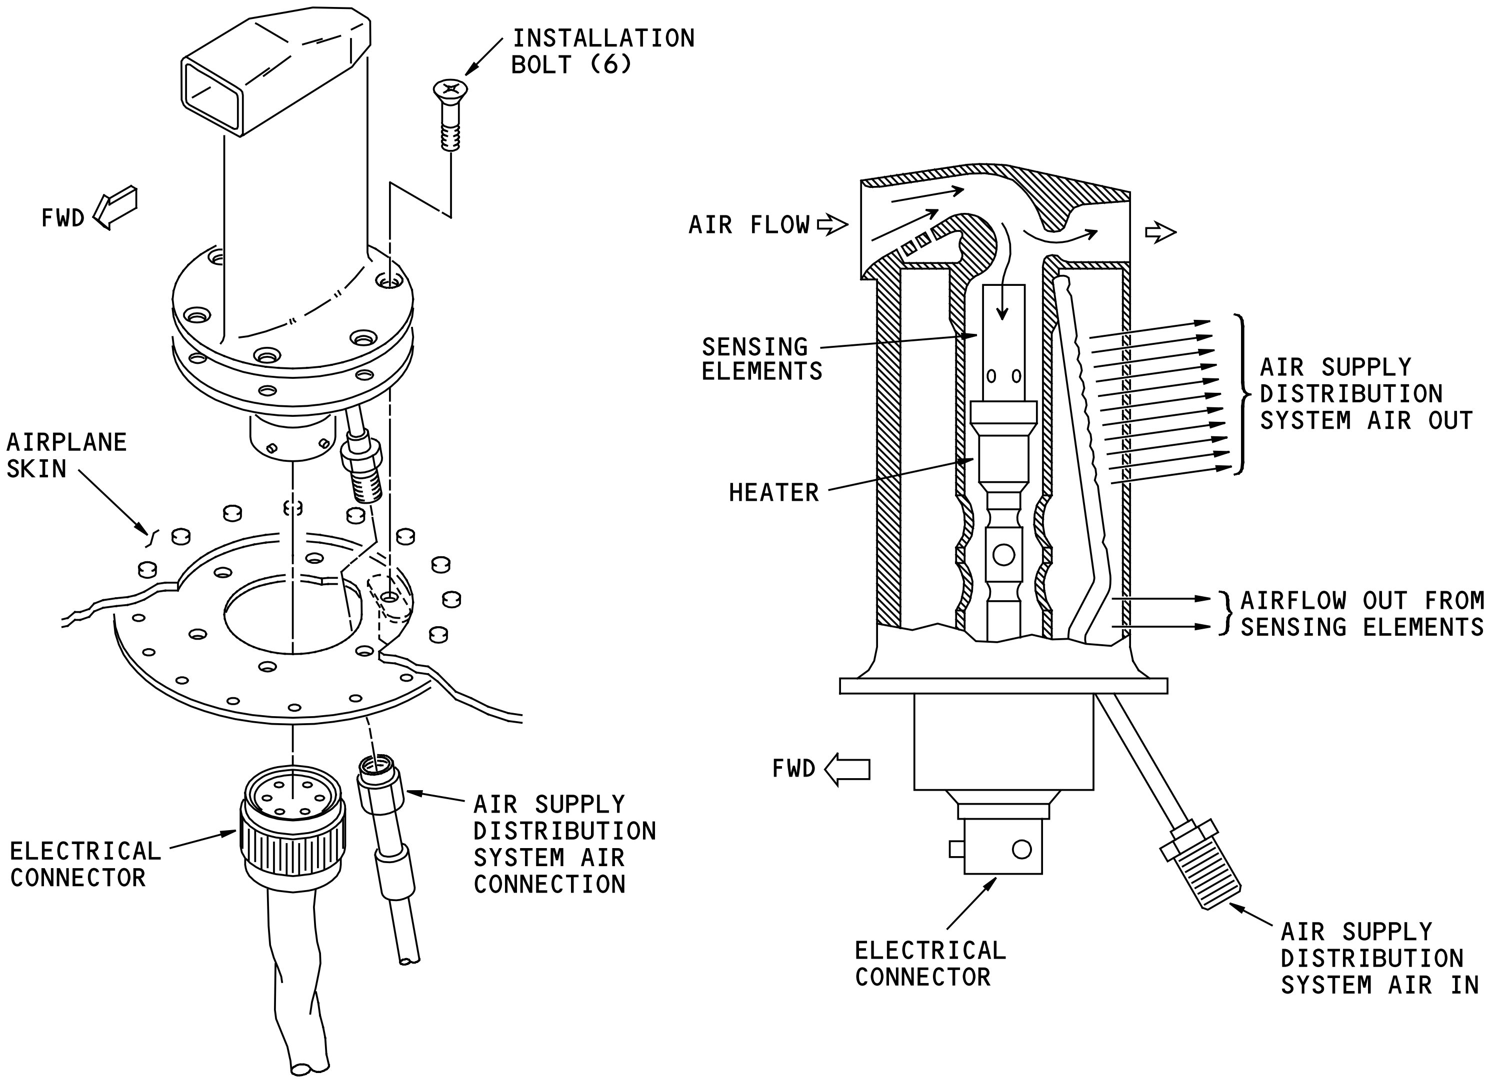
Sensing Elements

There are two sensing elements in a TAT probe. Each sensing element is a resistive element. The value of resistance changes when the temperature of the air flow across the element changes.

Air from the air supply distribution system makes a negative pressure inside the probe. The negative pressure pulls outside air across the sensing elements. This permits accurate temperature measurement when the airplane is on the ground or moving at low speed.

Electrical Connector

The analog connection to AIMS and the heater power connection comes through the electrical connector. The heater in the TAT probe prevents ice buildup.



34-20-00-033 Rev 3 05/06/96

ADIRS - TOTAL AIR TEMPERATURE PROBE

ADIRS - TAT PROBE FUNCTIONAL DESCRIPTION

Probe Heater

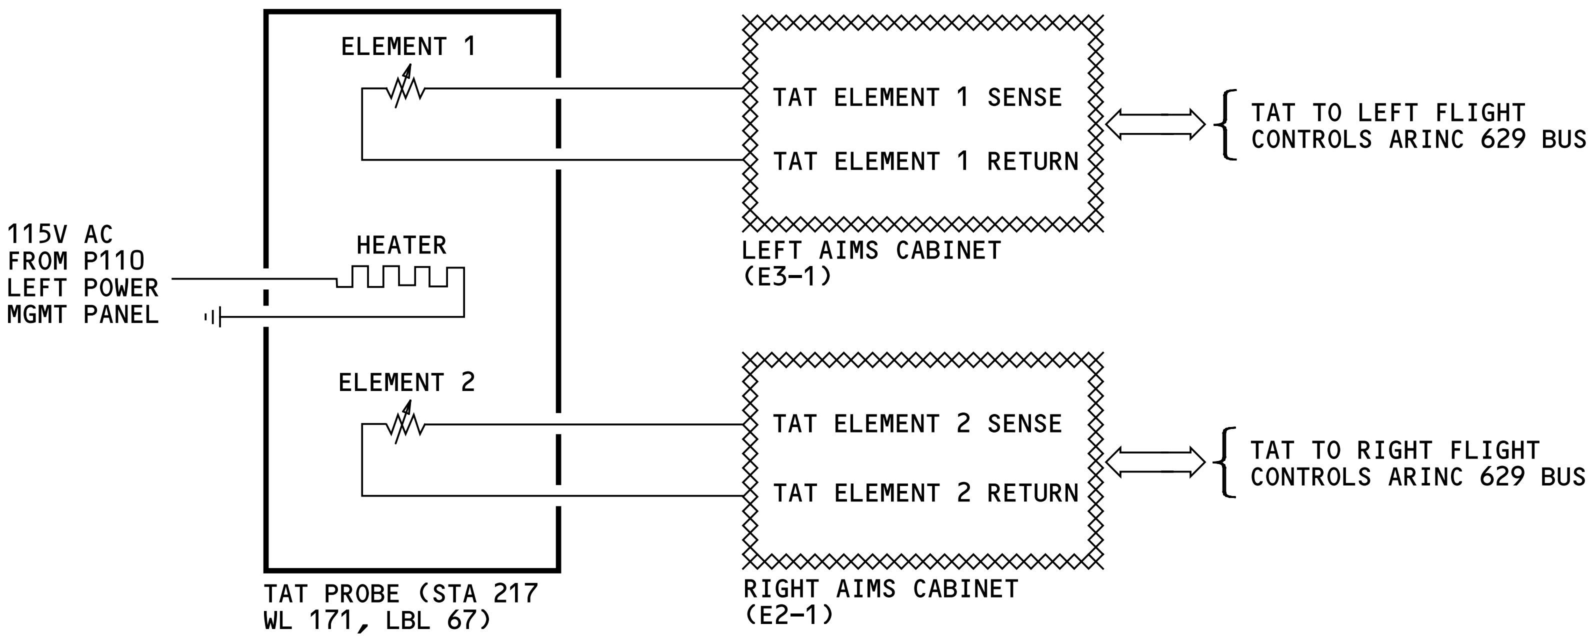
The TAT probe heater gets 115v ac from the P110 left power management panel. The TAT probe has heater power only when the airplane is in the air.

Total Air Temperature (TAT)

TAT element 1 connects to the TAT element 1 sense and return in the left AIMS cabinet. TAT element 2 connects to the TAT element 2 sense and return in the right AIMS cabinet.

The AIMS cabinets change the analog TAT probe data to ARINC 629 data. AIMS sends TAT temperature data from element 1 to the left flight controls ARINC 629 bus. AIMS sends TAT data from element 2 to the right flight controls ARINC 629 bus.

The ADIRU and SAARU receive TAT data to calculate air data.



34-20-00-034 Rev 3 11/29/95

ADIRS - TAT PROBE FUNCTIONAL DESCRIPTION

ADIRS - ANGLE OF ATTACK SENSOR

Electrical Connector

The angle of attack (AOA) sensor sends AOA data to the AIMS cabinet through the electrical connector, and receives heater power through the electrical connector.

Resolvers

There are two resolvers in each AOA sensor.

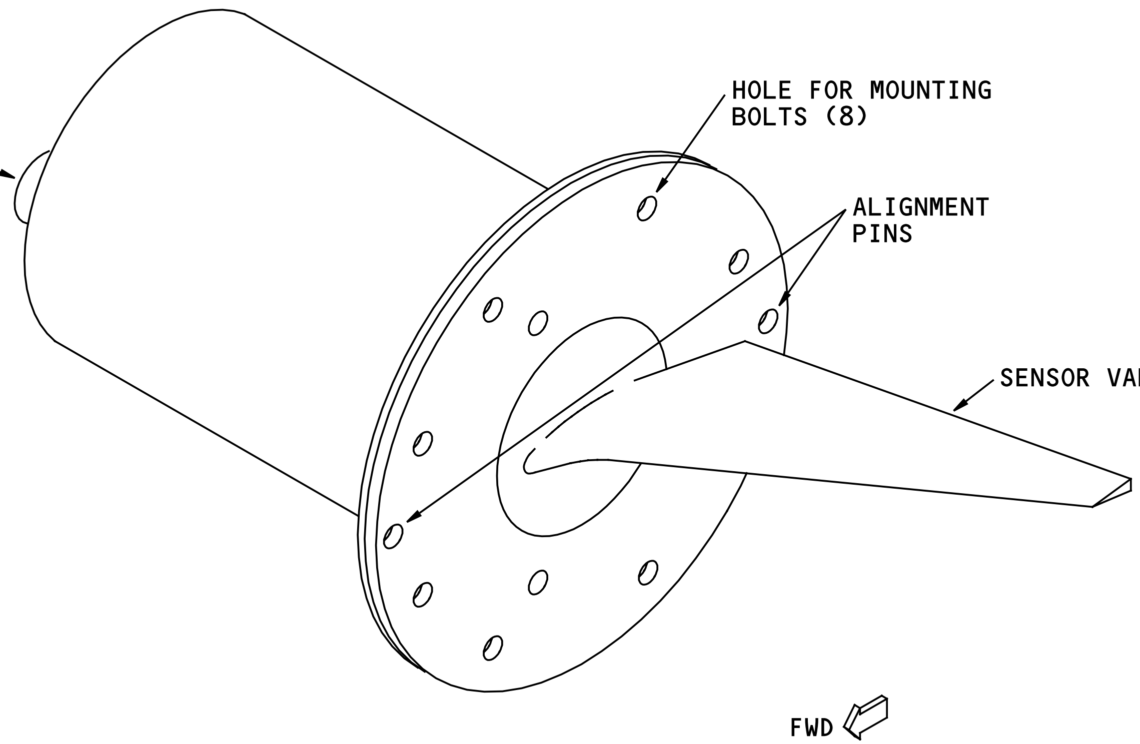
The AOA data from the two resolvers in the left AOA sensor goes to the left AIMS cabinet. The AOA data from the two resolvers in the right AOA sensor goes to the right AIMS cabinet.

Installation and Alignment Pins

You install the AOA sensor from the outside of the airplane.

Training Information Point

There are two alignment pins on the AOA sensor. Make sure the pins fit in their holes when you install the AOA sensor.



34-20-00-035 Rev 1

ADIRS - ANGLE OF ATTACK SENSOR

ADIRS - AOA SENSOR FUNCTIONAL DESCRIPTION

AOA Heaters

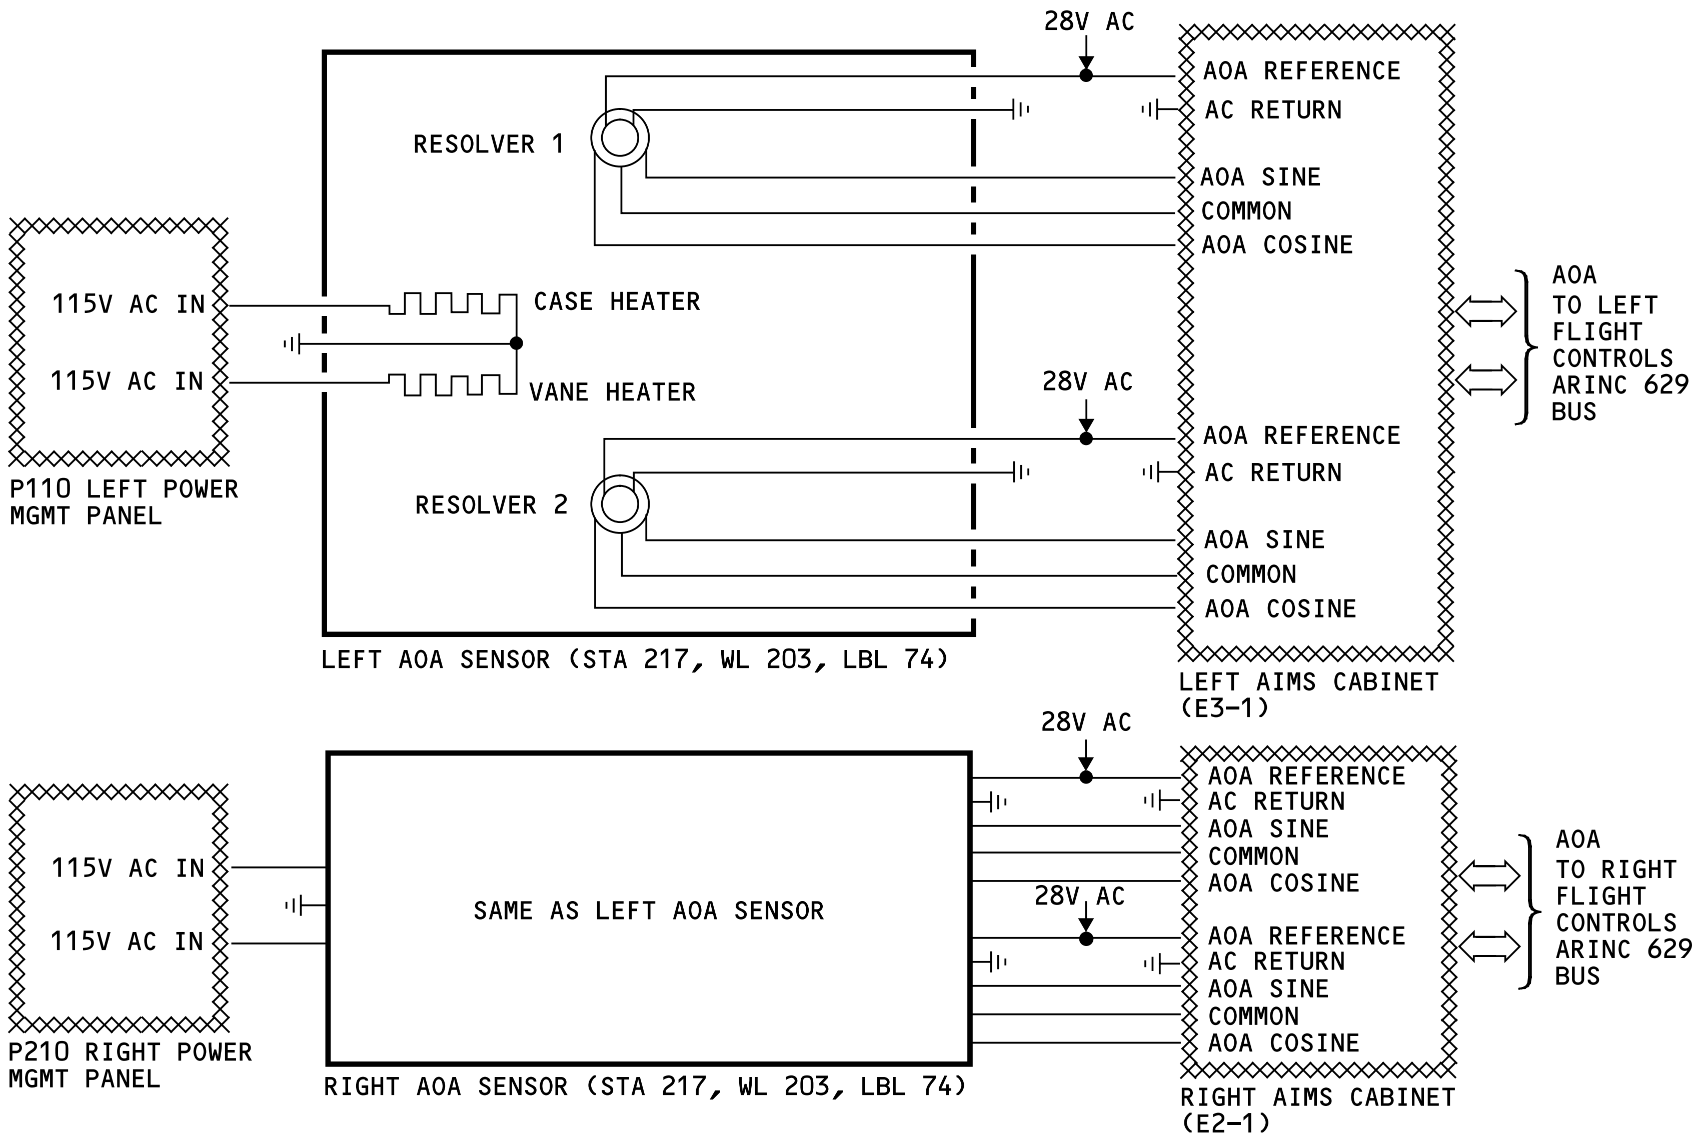
The case and the vane heaters in the angle of attack (AOA) sensors receive 115v ac from the power management panels for power.

AOA Measurement and Transmission

The resolvers in the left AOA sensor send the AOA to the left AIMS cabinet. The resolvers in the right AOA sensor send the AOA to the right AIMS cabinet.

The AIMS cabinets change the AOA sensor data to ARINC 629 format. The AOA sensor data goes to the left and right flight controls ARINC 629 buses.

The air data inertial reference unit (ADIRU) and the secondary attitude air data reference unit (SAARU) use AOA sensor data to calculate the corrected AOA.



34-20-00-036 Rev 2

ADIRS - AOA SENSOR FUNCTIONAL DESCRIPTION

ADIRS - ADM CONTROL OF AOA SENSOR HEAT

Functional Description

The angle of attack (AOA) sensor has two heaters, one for the AOA vane and one for the AOA case. Power for the heaters comes through the ground heat control relay or the air heat control relay.

The pitot air data modules (ADMs) control the relays.

There are two heat sensor relays, one for the vane heater and one for the case heater. The heat sensor relays supply a ground signal to the ADMs when the AOA heat is on.

Power goes through the ground heat control relay when both of these conditions are true:

- The airplane is on the ground
- Left or right engine is running.

Power goes through the air heat control relay when either of these conditions are true:

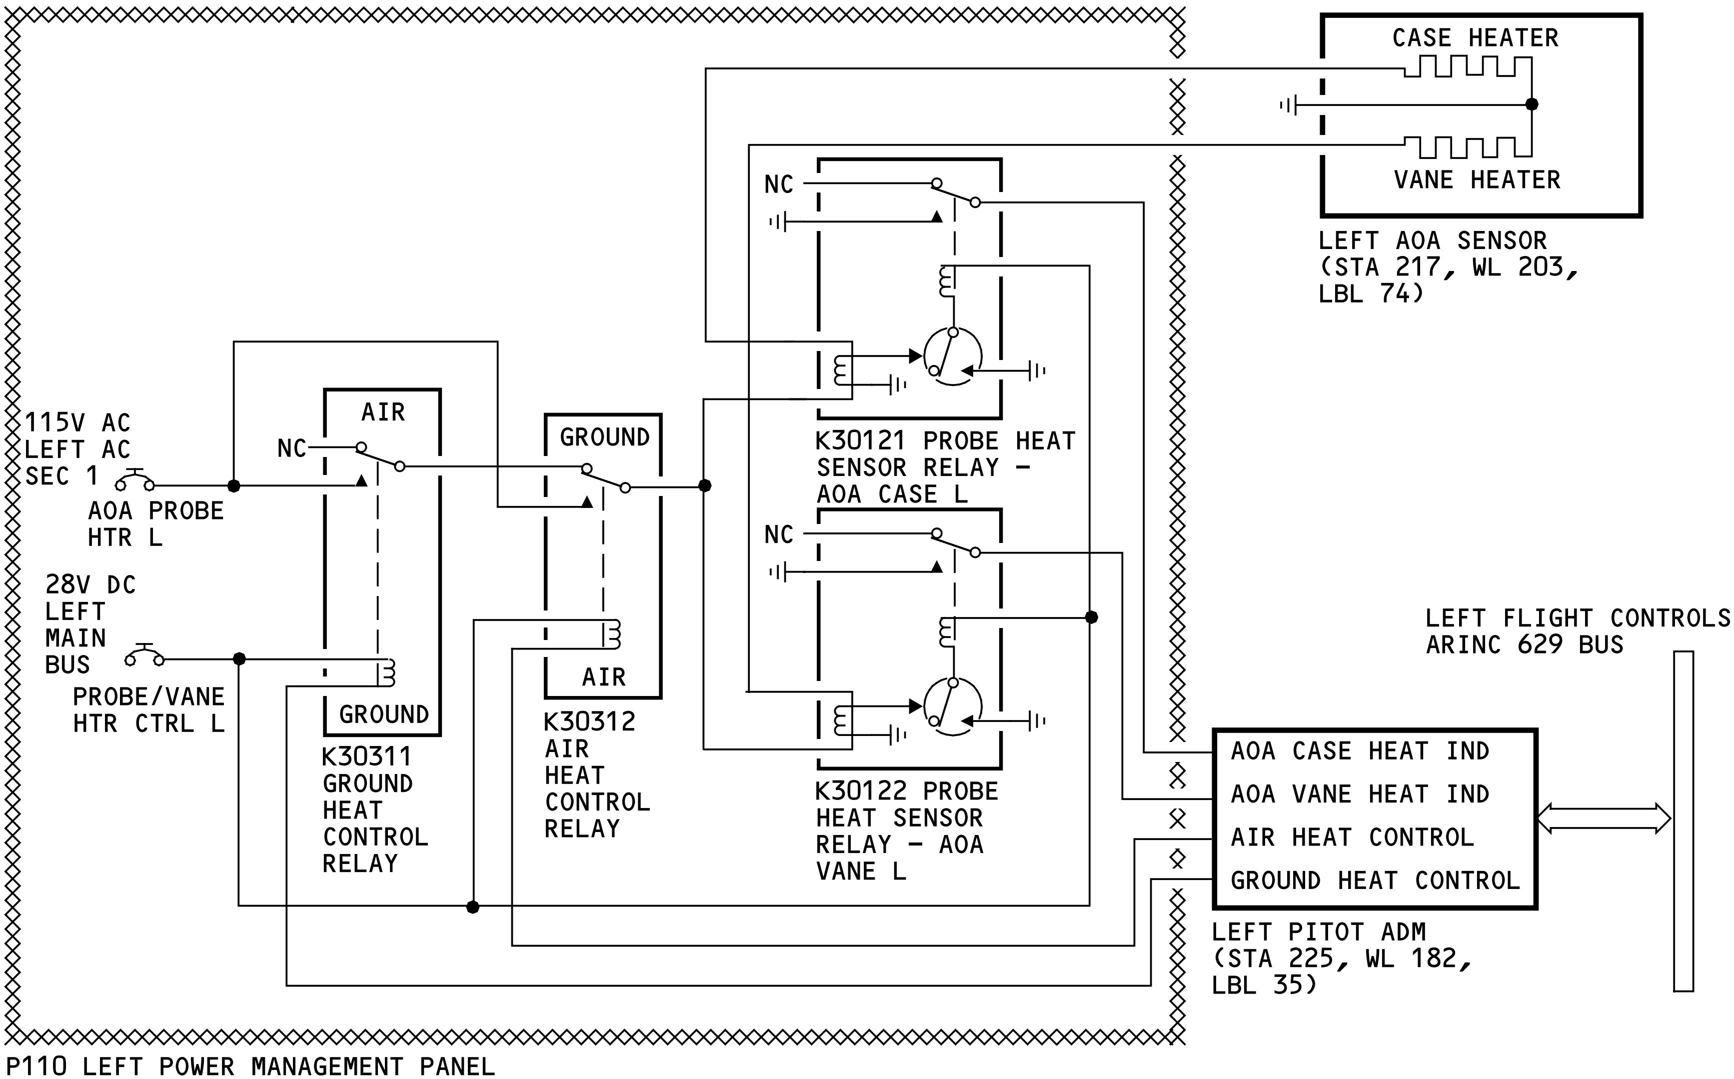
- The airplane is in the air
- CAS is more than 50 kts.

The primary flight computers (PFCs) are the source of air/ground, engine running, and CAS inputs. If the PFCs are not valid, the inputs come from the autopilot flight director computers (AFDCs).

Training Information Point

The air AOA heat and ground AOA heat is 115v ac.

See the ice and rain protection chapter for information on how to do a test of the AOA sensor heat operation (AMM PART I 30).



NOTE: RIGHT AOA SENSOR HEAT IS SIMILAR

ADIRS - ADM CONTROL OF AOA SENSOR HEAT

ADIRS - AIR DATA/ATTITUDE SOURCE SWITCH

General

The captain and first officer air data/attitude switches on the instrument source select panels control the source of air data and attitude data that shows for the onside PFD and ND.

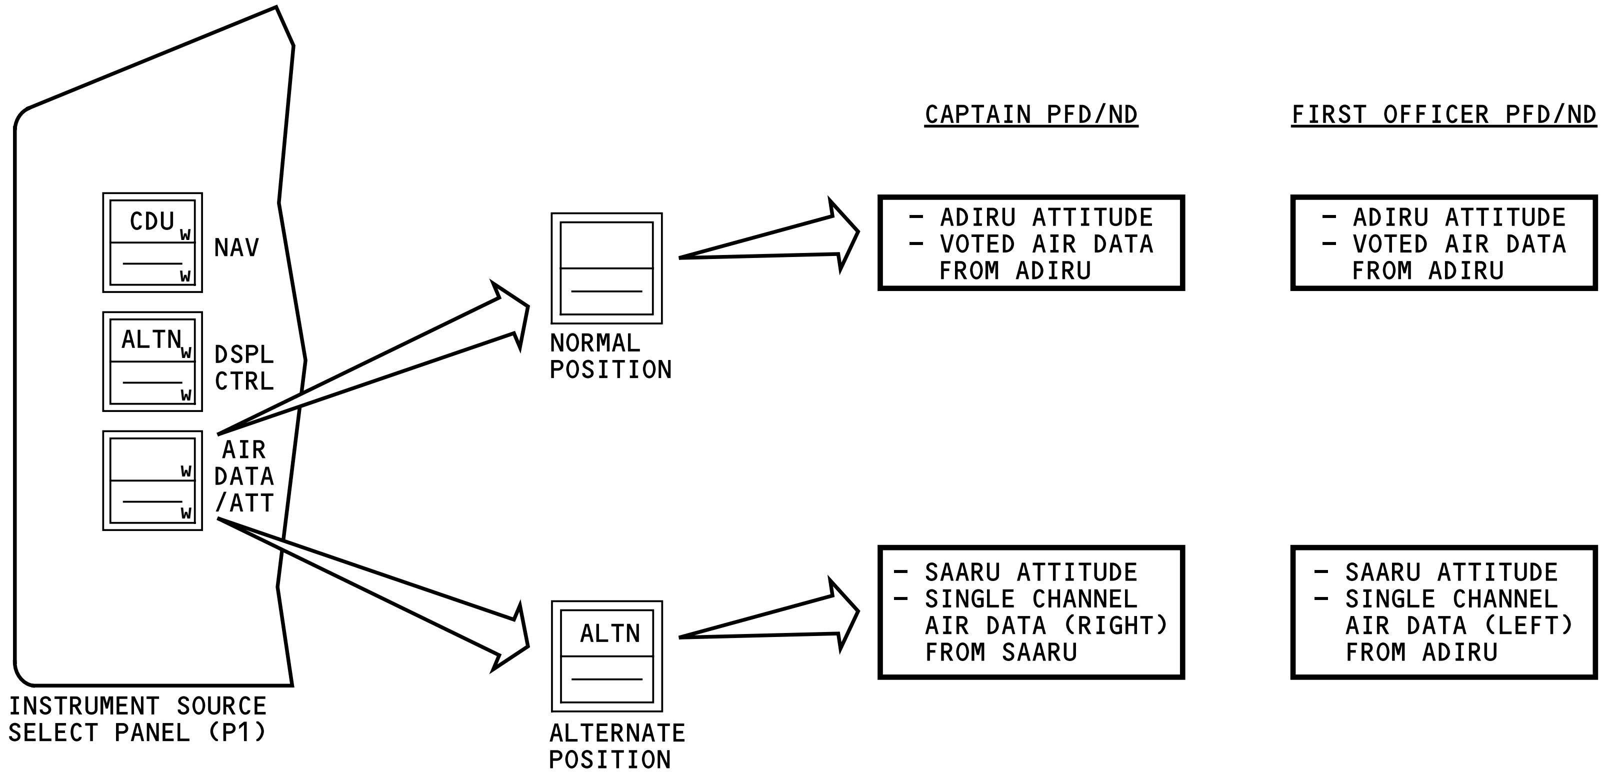
Air Data/Attitude Switch in the Normal Position

When the air data/attitude switches are in the normal position, the ADIRU left bus input to AIMS is the source of display data for the captain PFD and ND. The ADIRU right bus input to AIMS is the source of display data for the first officer PFD and ND. The ADIRU left bus and ADIRU right bus transmit the same data.

Air Data/Attitude Switch in the Alternate (ALTN) Position

When the captain air data/attitude switch is in the ALTN position, the sources for the captain displays are the SAARU for single channel air data and the SAARU for attitude. The ADIRU left bus input to AIMS remains the source for heading and track.

When the first officer air data/attitude switch is in the ALTN position, the sources for the first officer displays are the ADIRU right bus single channel for air data and the SAARU for attitude. The ADIRU right bus input to AIMS remains the source for heading and track.



34-20-00-037 Rev 5 11/06/1997

ADIRS - AIR DATA/ATTITUDE SOURCE SWITCH

ADIRS - AIR DATA/ATTITUDE SOURCE SWITCHING-NON NORMAL

General

The table shows the normal and alternate positions for the captain and first officer air data/attitude switch during normal and non-normal conditions.

The fail condition means that all output data to the buses are invalid.

Display Switching Priorities

These are the priorities for the source of the captain attitude and air data displays:

- ADIRU left flight controls ARINC 629 bus (air data and attitude)
- ADIRU right flight controls ARINC 629 bus (air data and attitude)
- SAARU center flight controls ARINC 629 bus (air data and attitude)
- ADIRU left flight controls ARINC 629 bus (single channel air data)
- ADIRU right flight controls ARINC 629 bus (single channel air data).

These are the priorities for the source of the first officer attitude and air data displays:

- ADIRU right flight controls ARINC 629 bus (air data and attitude)
- ADIRU left flight controls ARINC 629 bus (air data and attitude)
- SAARU center flight controls ARINC 629 bus (air data and attitude)
- ADIRU right flight controls ARINC 629 bus (single channel air data)
- ADIRU left flight controls ARINC 629 bus (single channel air data).

CONDITION / AIR DATA/ATT SWITCH POSITION	ADIRU NORMAL SAARU NORMAL	ADIRU FAIL SAARU NORMAL	ADIRU NORMAL SAARU FAIL	ADIRU FAIL SAARU FAIL
CAPT - NORMAL	ADIRU L BUS ATTITUDE AND VOTED AIR DATA	SAARU C BUS ATTITUDE AND VOTED AIR DATA	SAME AS ADIRU NORMAL SAARU NORMAL	NO DISPLAY DATA AVAIL
CAPT - ALTERNATE	SAARU C BUS SINGLE CHANNEL AIR DATA AND SAARU ATT	SAARU C BUS SINGLE CHANNEL AIR DATA AND SAARU ATT	ADIRU L BUS HEADING AND TRACK DATA ONLY	NO DISPLAY DATA AVAIL
F/O - NORMAL	ADIRU R BUS ATTITUDE AND VOTED AIR DATA	SAARU C BUS VOTED AIR DATA AND SAARU ATT	SAME AS ADIRU NORMAL SAARU NORMAL	NO DISPLAY DATA AVAIL
F/O - ALTERNATE	ADIRU R BUS SINGLE CHANNEL AIR DATA AND SAARU C BUS ATT	SAARU C BUS ATT AND LOSS OF AIR DATA	ADIRU R BUS SINGLE CHANNEL AIR DATA AND LOSS OF ATTITUDE	NO DISPLAY DATA AVAIL

NOTE: VOTED DATA MEANS DATA SELECTED THROUGH THE INPUT DATA REDUNDANCY MANAGEMENT LOGIC.

34-20-00-046 Rev 1 11/06/1997

ADIRS - AIR DATA/ATTITUDE SOURCE SWITCHING-NON NORMAL

ADIRS - ADIRU SWITCH, ADIRU ON BATTERY LIGHT

General

The primary flight computers/ADIRU panel has the ADIRU switch and the ADIRU on battery light.

ADIRU On Battery Light

The ADIRU on battery light comes on when the airplane is on the ground and the only source of power for the ADIRU is the hot battery bus.

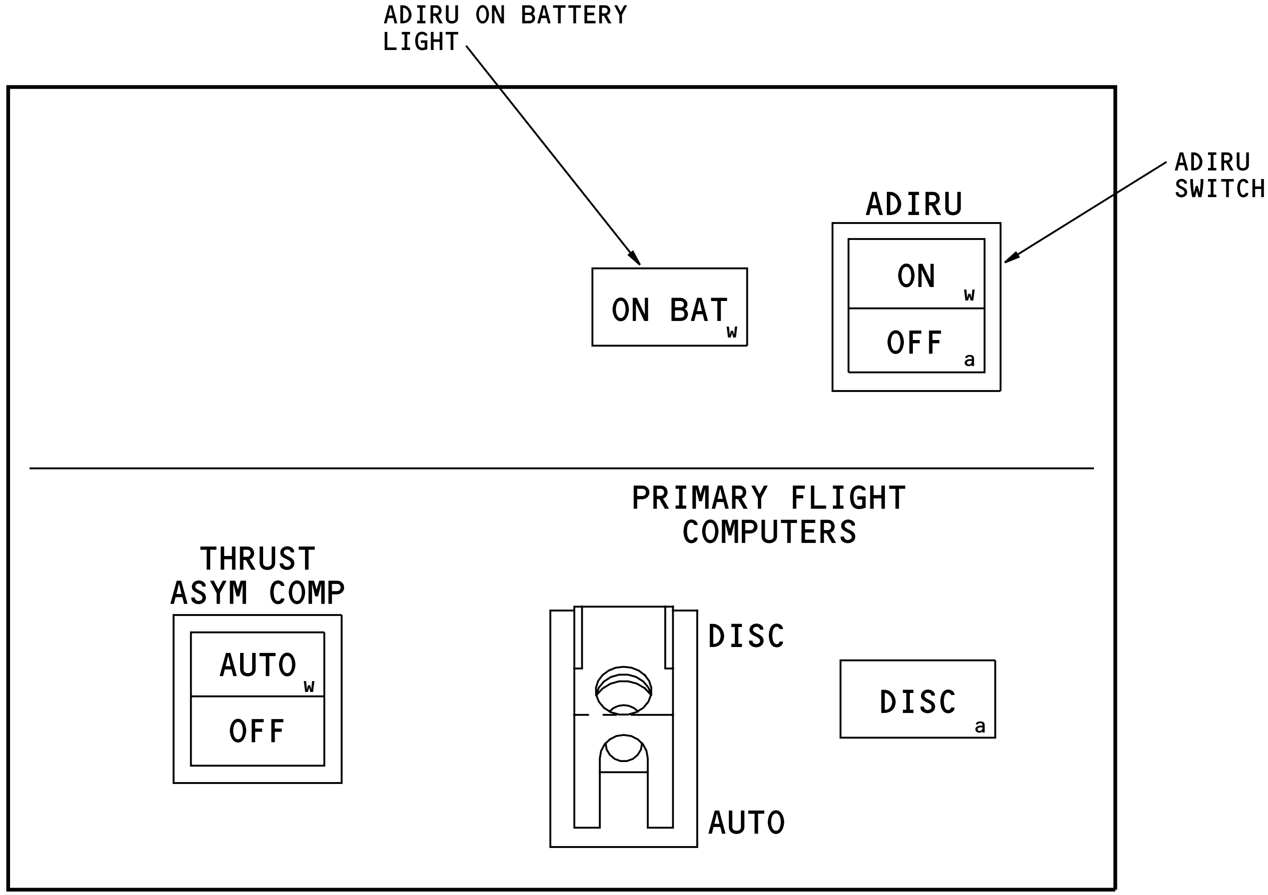
ADIRU Switch

Push the ADIRU switch to make the ADIRU go on. About thirty seconds after you push the ADIRU switch to the ON position, the ADIRU begins alignment. During the initial alignment, the attitude indications on the PFDs show as no computed data (NCD).

Push the ADIRU switch again to make the ADIRU go off.

The ADIRU goes off only when:

- Ground speed (GS) < 20 kts
- Computed airspeed (CAS) < 30 kts.



PRIMARY FLIGHT COMPUTERS/ADIRU PANEL (P5)

34-20-00-038 Rev 2 06/14/96

ADIRS - ADIRU SWITCH, ADIRU ON BATTERY LIGHT

THIS PAGE INTENTIONALLY LEFT BLANK

ADIRS - ALIGNMENT

General

Thirty seconds after you push the ADIRU switch, the ADIRU begins alignment and the position initialization process. Box prompts and a message show on the CDU to show that the ADIRU is ready to accept an inertial position.

Align Mode

For a new alignment, an inertial position compare test does a check of the entered inertial position with the GPS position or last stored position if GPS data is not available. The last stored position comes from the nonvolatile memory of the ADIRU. During a realignment, the test compares the current position calculated by the ADIRU.

The alignment takes between 7.5 minutes and 15 minutes to complete. The time depends on the latitude of the airplane position.

Align Reset Mode

If the airplane moves during the alignment, the align reset mode occurs until there is no movement. The align reset mode detects body rates and accelerations. When the movement stops, the ADIRU returns to the align mode.

GPS Valid Data

When the GPS signal is valid and you enter an inertial position into the CDU, the ADIRU compares the current GPS position to the entered inertial position. If the positions are different by more than 3.5 NM, the position is not accepted and the CDU shows the message ENTER INERTIAL POSITION. When you enter the same inertial position again, the ADIRU accepts the inertial position for alignment.

GPS Data Invalid

If GPS data is not available, the ADIRU uses its last stored position or last calculated position and compares it to the entered inertial position. The entered inertial position must be within the limits defined by the ADIRU. The limits the ADIRU defines depends on the length of the previous flight.

NAV Mode

After alignment, the ADIRU does a latitude compare test. If the ADIRU calculated latitude is the same as the entered inertial position latitude, the ADIRU goes into the NAV mode. If the latitudes are not the same, a latitude miscompare occurs and the CDU shows the ENTER INERTIAL POSITION message.

If you enter a new inertial position that has the same latitude as the ADIRU latitude, the NAV mode starts.

ADIRS - ALIGNMENT

If you enter a new inertial position that is the same as the first inertial position, a full alignment starts and the CDU shows ALIGNMENT REINITIATED.

Auto NAV Realign Mode

The auto nav realign (ANR) mode starts 30 seconds after the airplane stops. The ANR takes 7.5 to 15 minutes to complete.

When the ANR mode starts, dash prompts show on the CDU. The dash prompts show that you may enter a new inertial position. It is not required to enter a new inertial position.

If you do not enter a new position, the ADIRU sets the velocity errors to zero and corrects this data:

- Pitch attitude
- Roll attitude
- Heading.

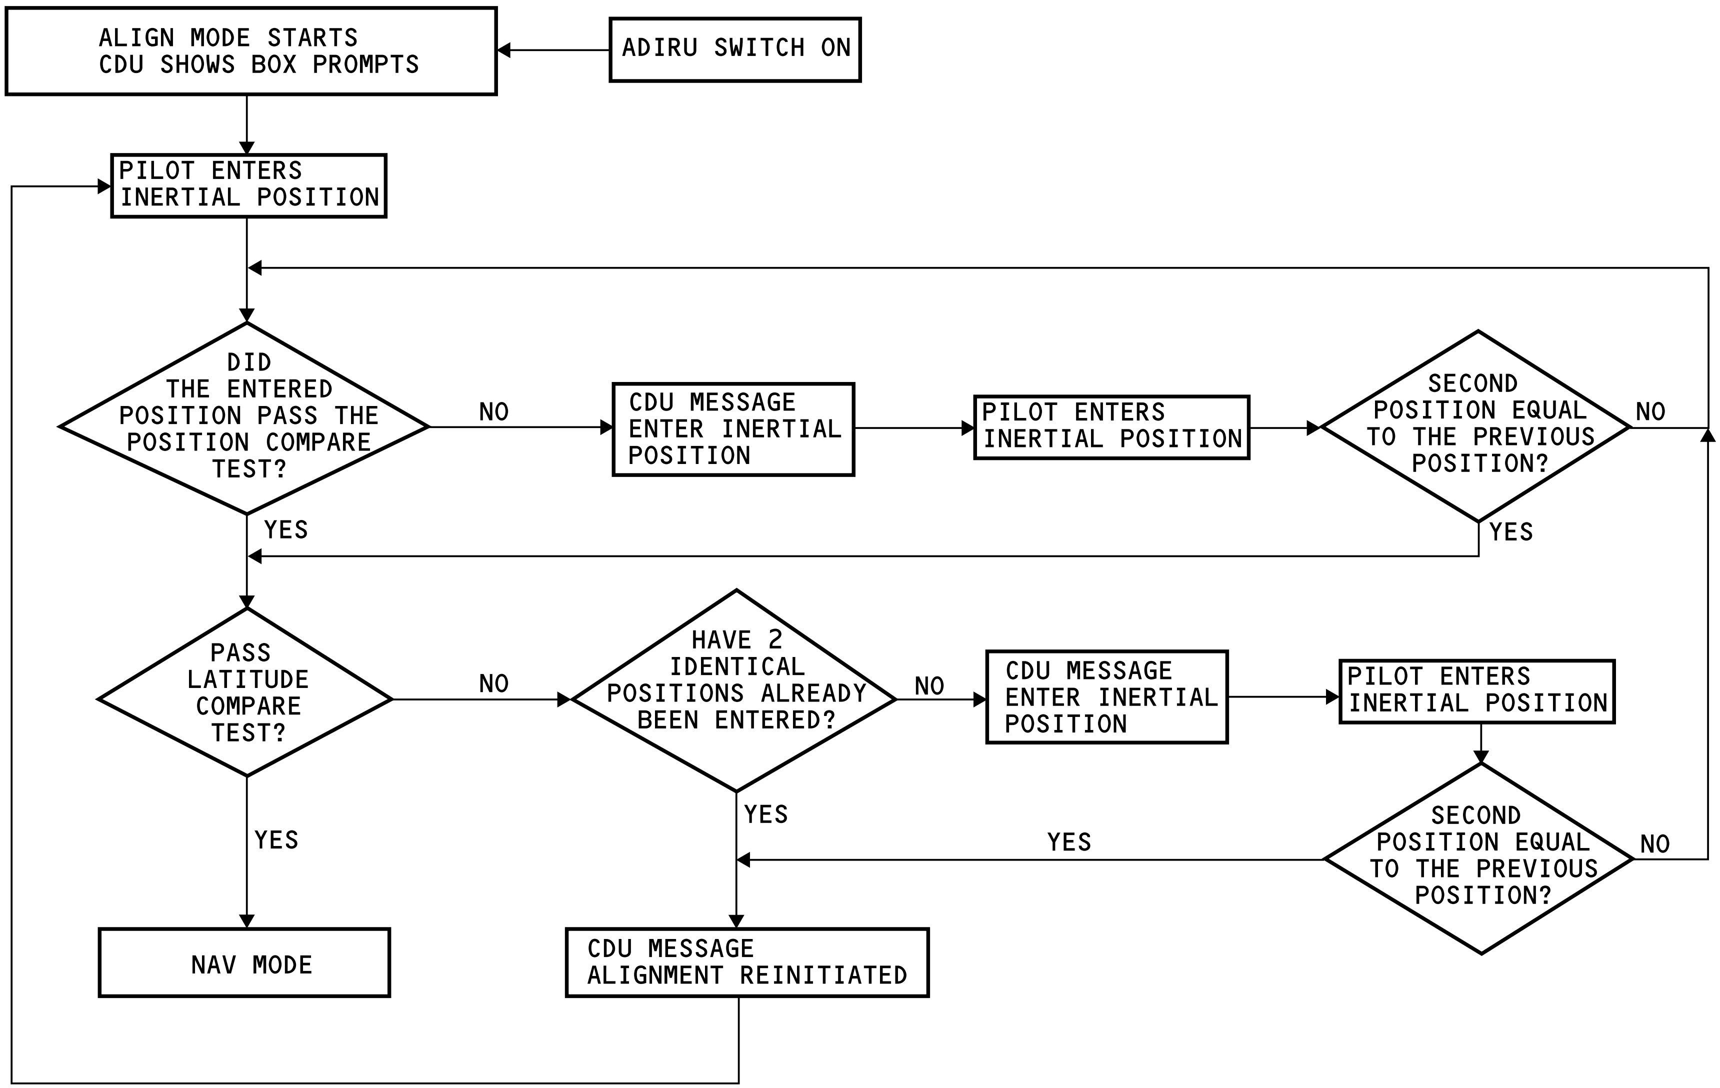
When you enter a new inertial position, the ADIRU does the latitude comparison test with the entered inertial position and the last calculated position.

If the entered position does not pass the latitude test, the CDU shows the ENTER INERTIAL POSITION message. The CDU shows the ALIGNMENT REINITIATED message if the next entered position is the same as the first entered position.

If the test passes, the ADIRU uses the entered position as the start point for the next flight.

If the airplane remains without motion, the ADIRU continues to zero any errors that occur. Also, the dash prompts return on the CDU.

If the ADIRU detects motion during the ANR mode, the ADIRU returns to the NAV mode and uses the last calculated inertial position.



34-20-00-039 Rev 4

ADIRS - ALIGNMENT

ADIRS - ALIGNMENT - POS INIT CDU PAGE

General

To begin alignment, access the POS INIT page on the CDU. Thirty seconds after the ADIRU powers up, the POS INIT page shows box prompts under the SET INERTIAL POS. At this time you can line select an inertial position into the SET INERTIAL POS line. You can use one of these positions:

- The inertial position you entered into the scratchpad
- GPS position
- Last position
- Reference airport
- Gate position.

To get the airport and gate position, line select the airport identifier and gate identifier into the appropriate line and the position shows on that line.

Enter Inertial Position

During alignment, the box prompts show until you enter an inertial position. If there is no entered inertial position when the ADIRU is ready to go into the NAV mode, the CDU shows the ENTER INERTIAL POS message.

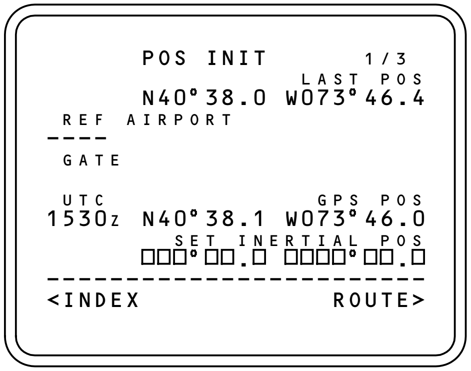
As part of the alignment and when there is an entered inertial position, the ADIRU goes through an inertial position comparison test and the latitude comparison test. If both of the tests pass, the ADIRU can complete the alignment and go into the NAV mode. If either of the tests fail, the CDU shows box prompts and the ENTER INERTIAL POS message. Enter the same inertial position again and the ADIRU uses that position to complete alignment and goes into the NAV mode.

Alignment Reinitiated

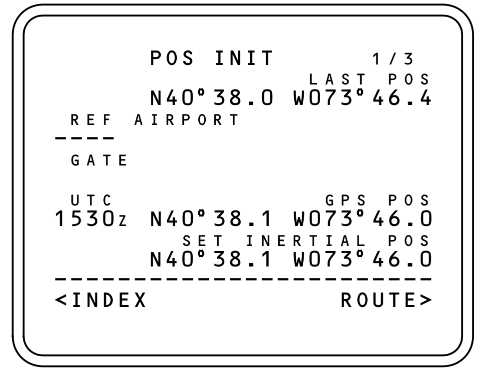
If the alignment cannot finish due to airplane movement or an invalid inertial position entered twice, the CDU shows dashes and the ALIGNMENT REINITIATED message.

Auto Nav Realign Mode

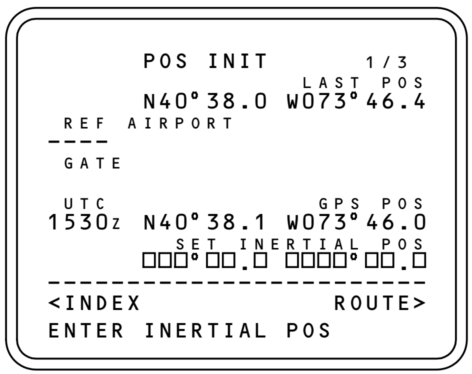
Dash promts show during the auto nav realign (ANR) mode. The dashes tell that the ADIRU is ready to accept an inertial position. Also, the dashes tell that inertial input is optional.



BOX PROMPTS SHOW 30 SECONDS AFTER POWER UP. ENTER THE INERTIAL POSITION ANY TIME.

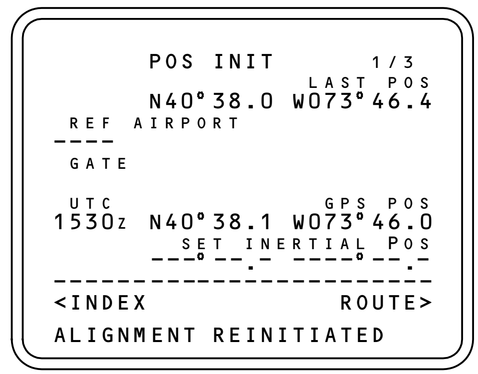


THE INERTIAL POSITION REPLACES THE BOX PROMPTS WHEN YOU LINE SELECT A VALUE INTO THE SET INERTIAL POS LINE.



BOX PROMPTS SHOW AND THE ENTER INERTIAL POS MESSAGE SHOWS WHEN:

- ENTERED POSITION DID NOT PASS THE ENTERED INERTIAL POSITION TEST OR THE LATITUDE COMPARISON TEST
- OR THE ADIRU IS READY TO GO INTO THE NAV MODE BUT AN INERTIAL POSITION IS NOT ENTERED



DASHES REPLACE THE BOX PROMPTS AND ALIGNMENT REINITIATED SHOWS WHEN ALIGNMENT FAILS.

DASHES ALSO SHOW WHEN THE ADIRU IS READY TO ACCEPT A NEW POSITION DURING AUTO NAV REALIGN.

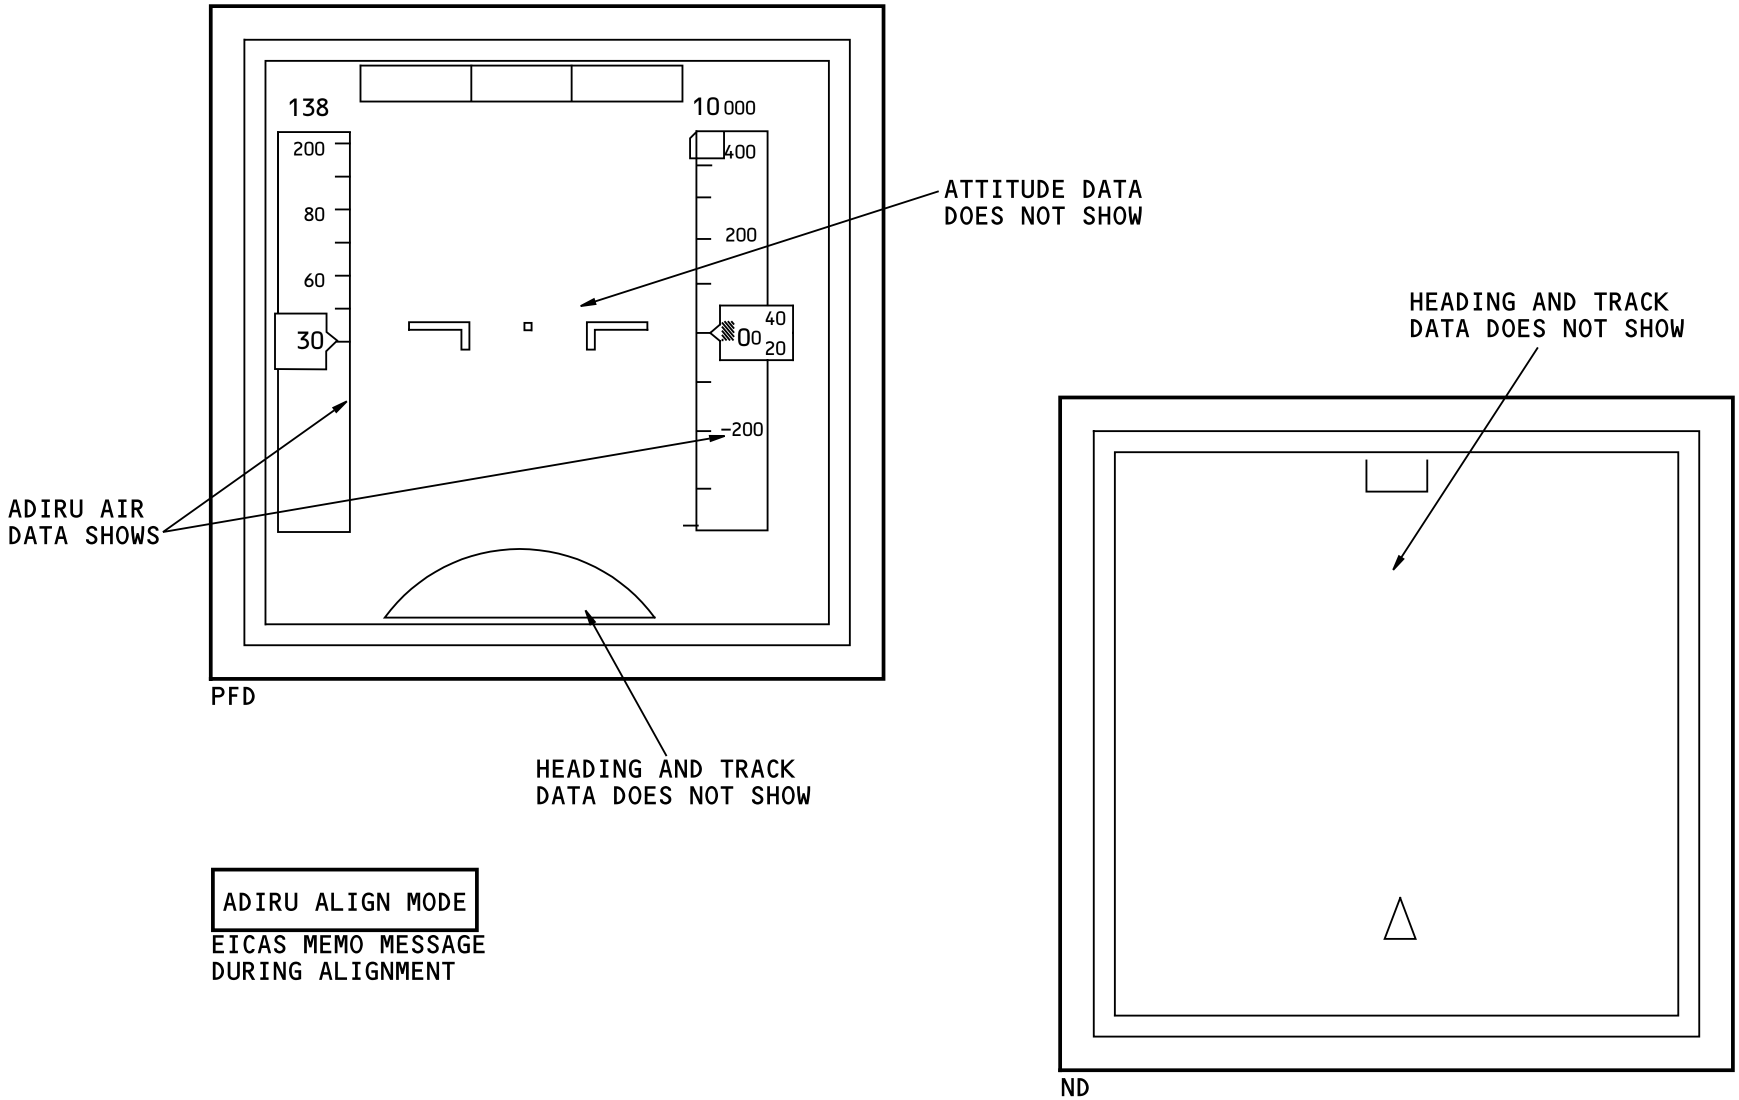
ADIRS - ALIGNMENT - POS INIT CDU PAGE

ADIRS - ND AND PFD INDICATIONS DURING ALIGNMENT

General

These are the indications when the ADIRU is in the align mode:

- The PFDs show no computed data (NCD) attitude, track and heading data
- The PFDs show ADIRU air data
- The NDs show NCD track and heading data
- ADIRU ALIGN MODE memo message shows on the EICAS display.



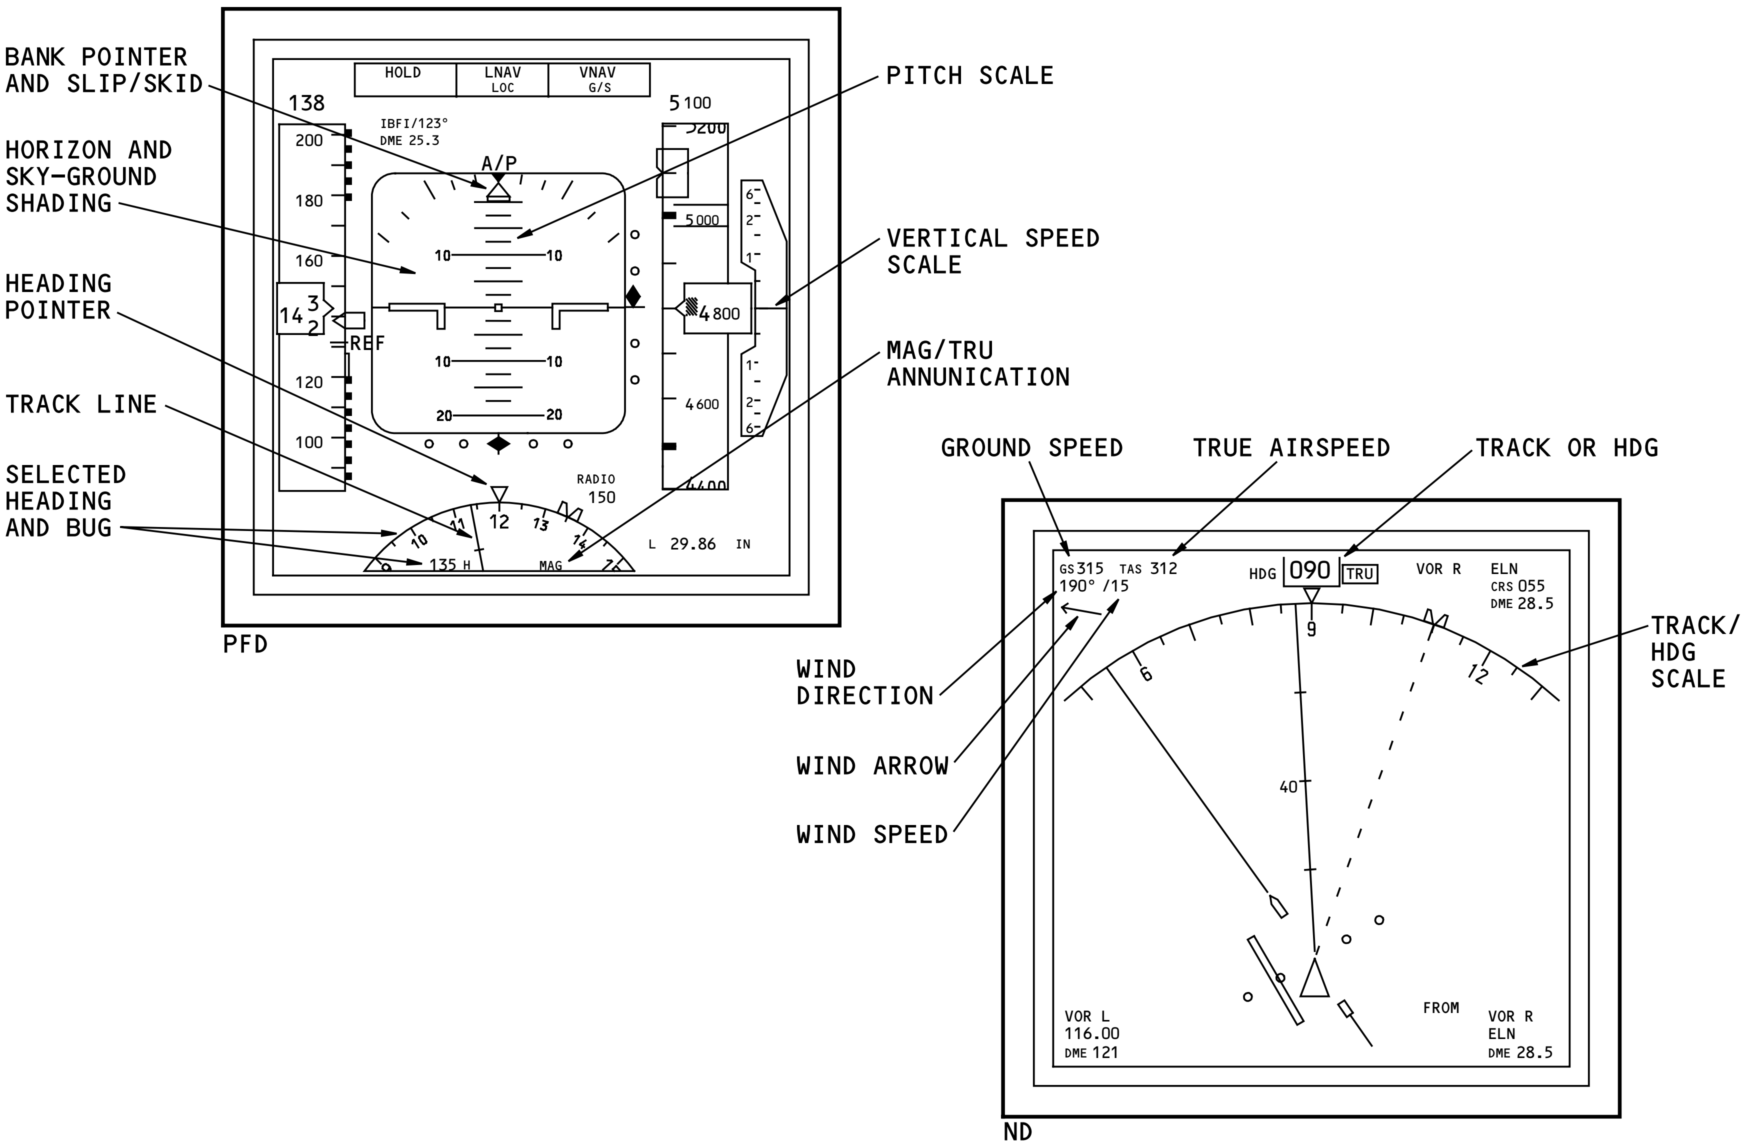
34-20-00-041 Rev 5 04/26/96

ADIRS - ND AND PFD INDICATIONS DURING ALIGNMENT

ADIRS - PFD AND ND INDICATIONS AFTER ALIGNMENT

General

When the ADIRU alignment completes and the ADIRU is in the NAV mode, the PFD AND ND show attitude and air data from the ADIRU.



ADIRS - PFD AND ND INDICATIONS AFTER ALIGNMENT

34-20-00-042 Rev 4 04/26/96

ADIRS - PFD AND ND INVALID IRS DATA

General

The PFD and ND show the invalid attitude and invalid air data indications.

The PFD shows flags for:

- Airspeed
- Attitude
- Altitude
- Vertical speed
- Heading.

The ND shows a heading or track flag.

ADIRS - PFD AND ND INVALID IRS DATA

ADIRS - INERTIAL MONITOR PAGE

Purpose

The inertial monitor page shows the position error rate for the ADIRU.

Page Access

To get access to the INERTIAL MONITOR page, select <INERTIAL MONITOR from the MAINTENANCE INDEX page.

Color

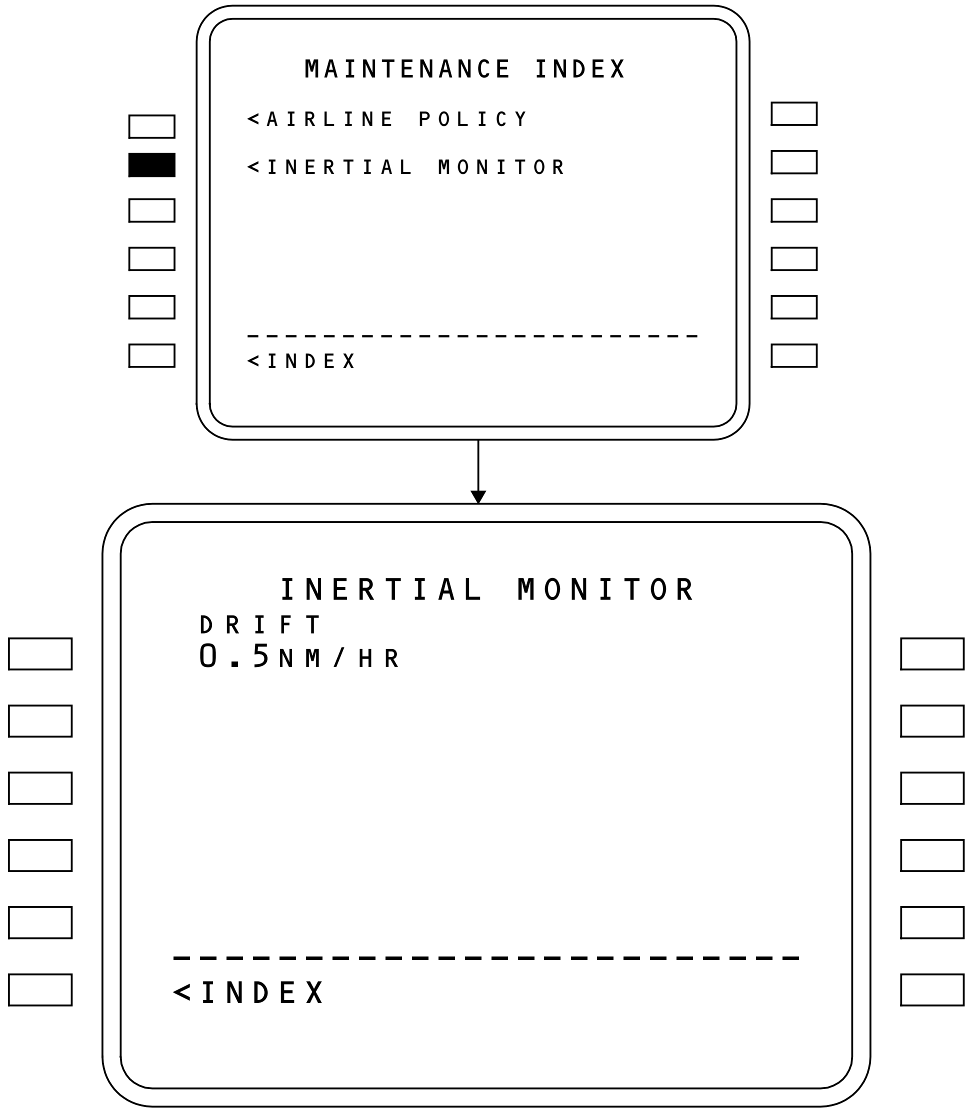
All text on this page is white.

Information

Line 1L is the inertial monitor drift. The drift rate shows for the last completed flight. It clears at the ground-to-air transition.

Page Selections

Select 6L, <INDEX to show the MAINTENANCE INDEX.



34-20-00-048 Rev 1 10/23/95

ADIRS - INERTIAL MONITOR PAGE

ADIRS - FAULT REPORT AND SOFTWARE DATA LOAD

General

These components in the ADIRS report faults and system status to the central maintenance computing function (CMCF) of the AIMS:

- ADIRU
- SAARU
- ADMs.

You can not start any tests for the ADIRU or the SAARU. These components have built-in test equipment (BITE). The BITE automatically detects faults in these ADIRS components. You start a test of the ADM heat control circuit from the ground test menu on the MAT, chapter 30, ice and rain protection.

ADIRU Power-Up Test and Status

The ADIRU does a 30 second test after you put the ADIRU on/off switch in the on position. The results of the test go to the CMCF of the AIMS. The test is automatic and there are no indications for the test.

The ADIRU starts normal operation after the test ends. The air data is valid after the test. The inertial data is invalid until alignment is complete. The ADIRU continuously supplies BITE status data to the CMCF of the AIMS.

SAARU and ADM Status

The SAARU and the ADMs continuously supply BITE status data to the CMCF of the AIMS.

ADIRS Status Monitoring

If there are faults with the ADIRU, SAARU, ADMs and standby attitude display, use the maintenance access terminal (MAT) to monitor the status.

Software Data Load

Use the MAT to load software data into the ADIRU, SAARU, and the ADMs.

Training Information Point

The ADIRU accepts data load software from the left CMCF only.

The SAARU accepts data load software from the left or right CMCF.

The left ADMs accept data load software from the left CMCF only. The center ADMs accept data load software from the left or right CMCF. The right ADMs accept data load software from the right CMCF only.

Use the central maintenance computer switch control selection on the other functions menu from the MAT main menu to select the left or the right CMCF.

Standby Magnetic Compass

WB371

TABLE OF CONTENTS

THIS PAGE INTENTIONALLY LEFT BLANK

STANDBY MAGNETIC COMPASS

Purpose

The standby magnetic compass is a backup magnetic heading reference.

Location

The standby magnetic compass is below the overhead panel (P5).

Power

The standby magnetic compass has a 5v ac light bulb. A lamp access cover permits replacement of the bulb.

Characteristics

The standby magnetic compass has a circular heading indicator card. The card floats in a case filled with liquid. The liquid does not permit the card to move quickly.

There are two magnets in the standby magnetic compass. The magnets are parallel to each other, and they are in the horizontal plane. The magnets align the compass with the magnetic flux lines of the earth.

Adjustment

The standby magnetic compass has N-S (north-south) and E-W (east-west) compensation screws. These screws change the position of the magnets.

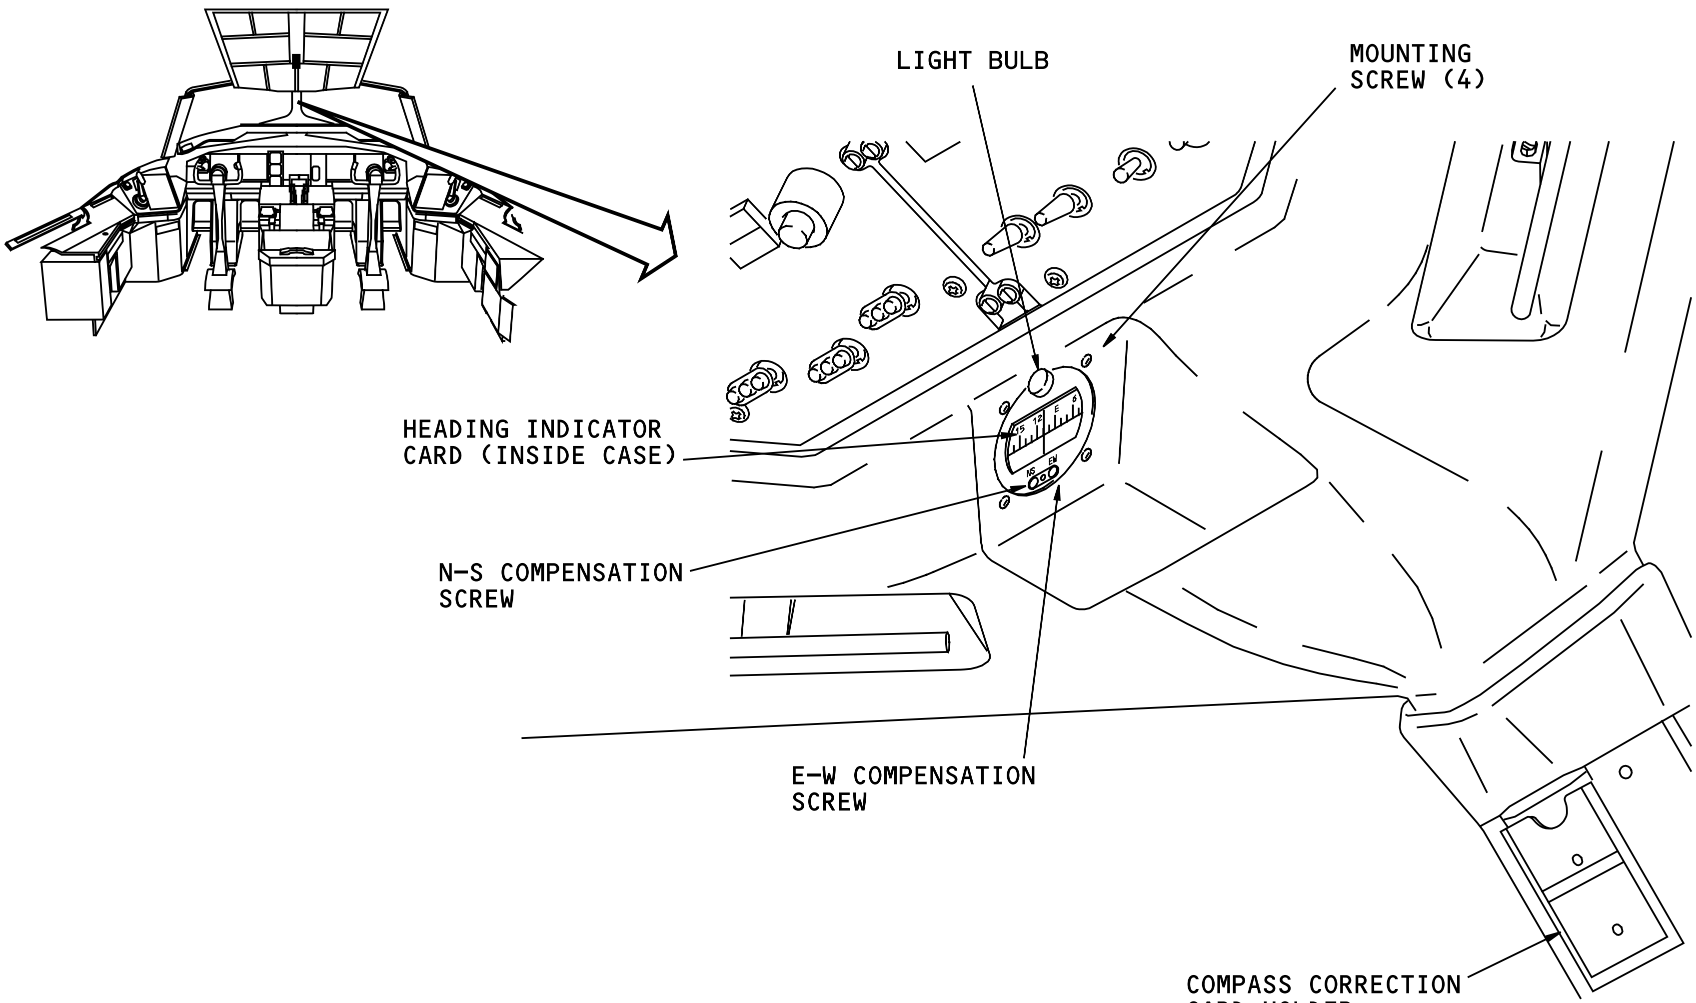
Use the compensation screws to correct for magnetic deviations generated by electrical currents in the flight deck. Use only non-magnetic tools to turn the compensation screws.

There is a compass correction card below the compass. Use this card to write small errors that the compensation screws cannot remove.

Removal/Installation

Four screws hold the standby magnetic compass in place. Use only non-magnetic tools and screws to remove and install the standby magnetic compass.

You must do a compass swing after you replace the standby magnetic compass.



34-23-00-001 Rev 1

Radio Altimeter System

WB371

TABLE OF CONTENTS

THIS PAGE INTENTIONALLY LEFT BLANK

RADIO ALTIMETER SYSTEM - INTRODUCTION

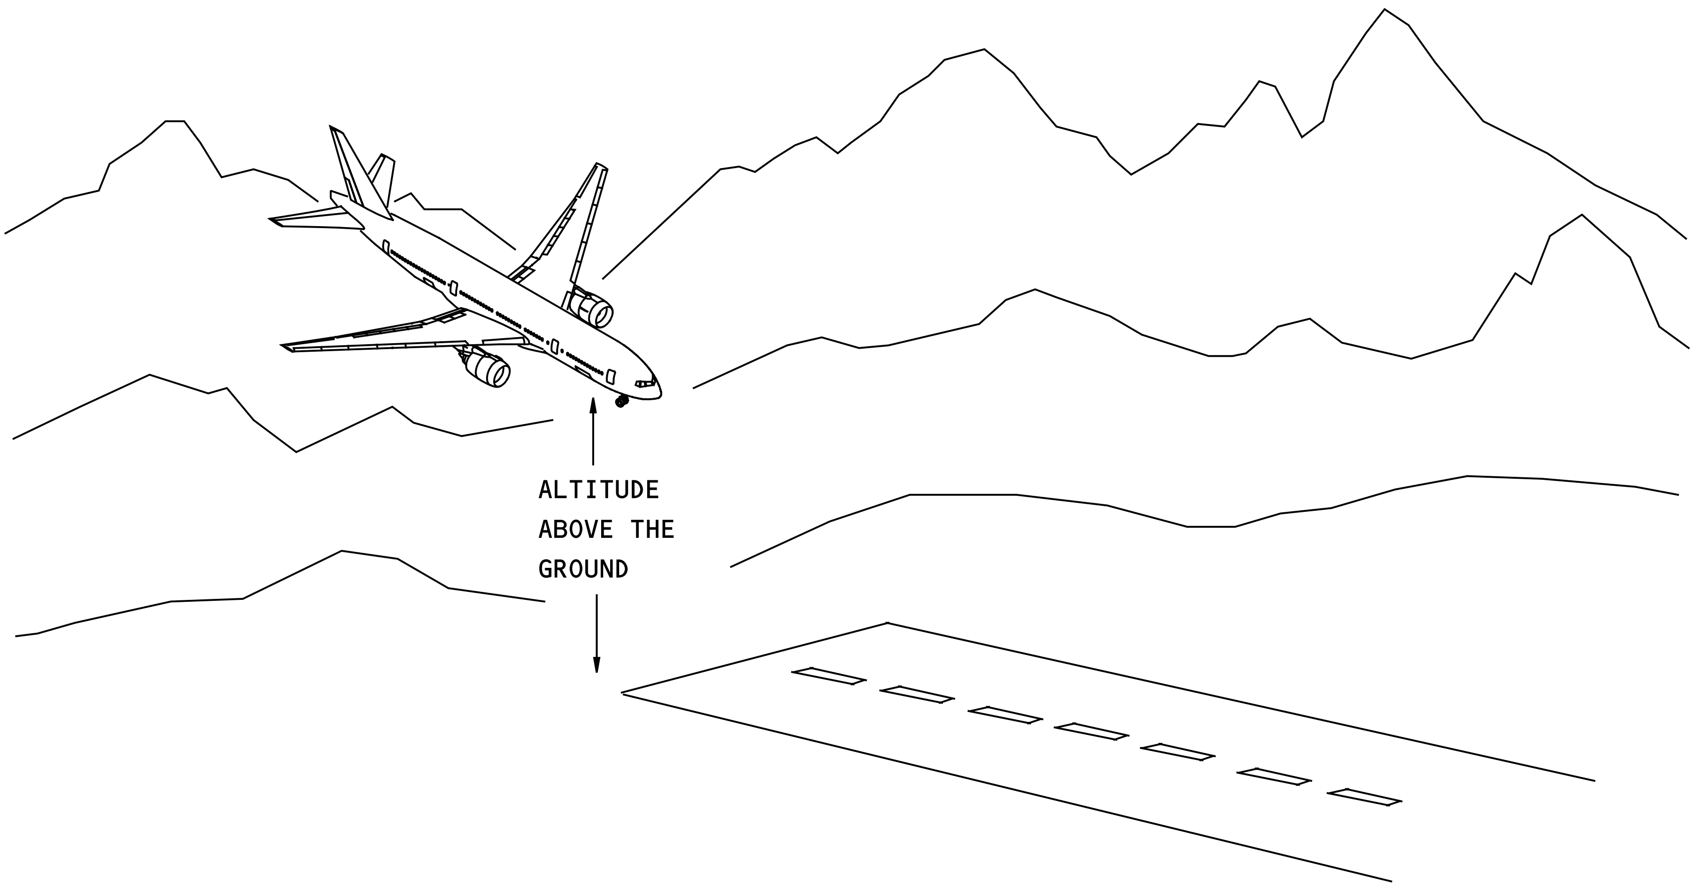
General

The radio altimeter (RA) system measures the distance from the airplane to the ground. The radio altitude shows in the flight deck.

The system has a range of -20 to 2500 feet. The flight crew and other airplane systems use radio altitude during approach and landing.

Abbreviations and Acronyms

AFDC	- autopilot flight director computer
AIMS	- airplane information management system
CMCF	- central maintenance computing function
GPWC	- ground proximity warning computer
PFC	- primary flight computer
PWS	- predictive windshear
RA	- radio altitude
TCAS	- traffic alert and collision avoidance system
WXR	- weather radar
xcvr	- transceiver



34-33-00-001 Rev 2

RADIO ALTIMETER SYSTEM - INTRODUCTION

RA SYSTEM - GENERAL DESCRIPTION

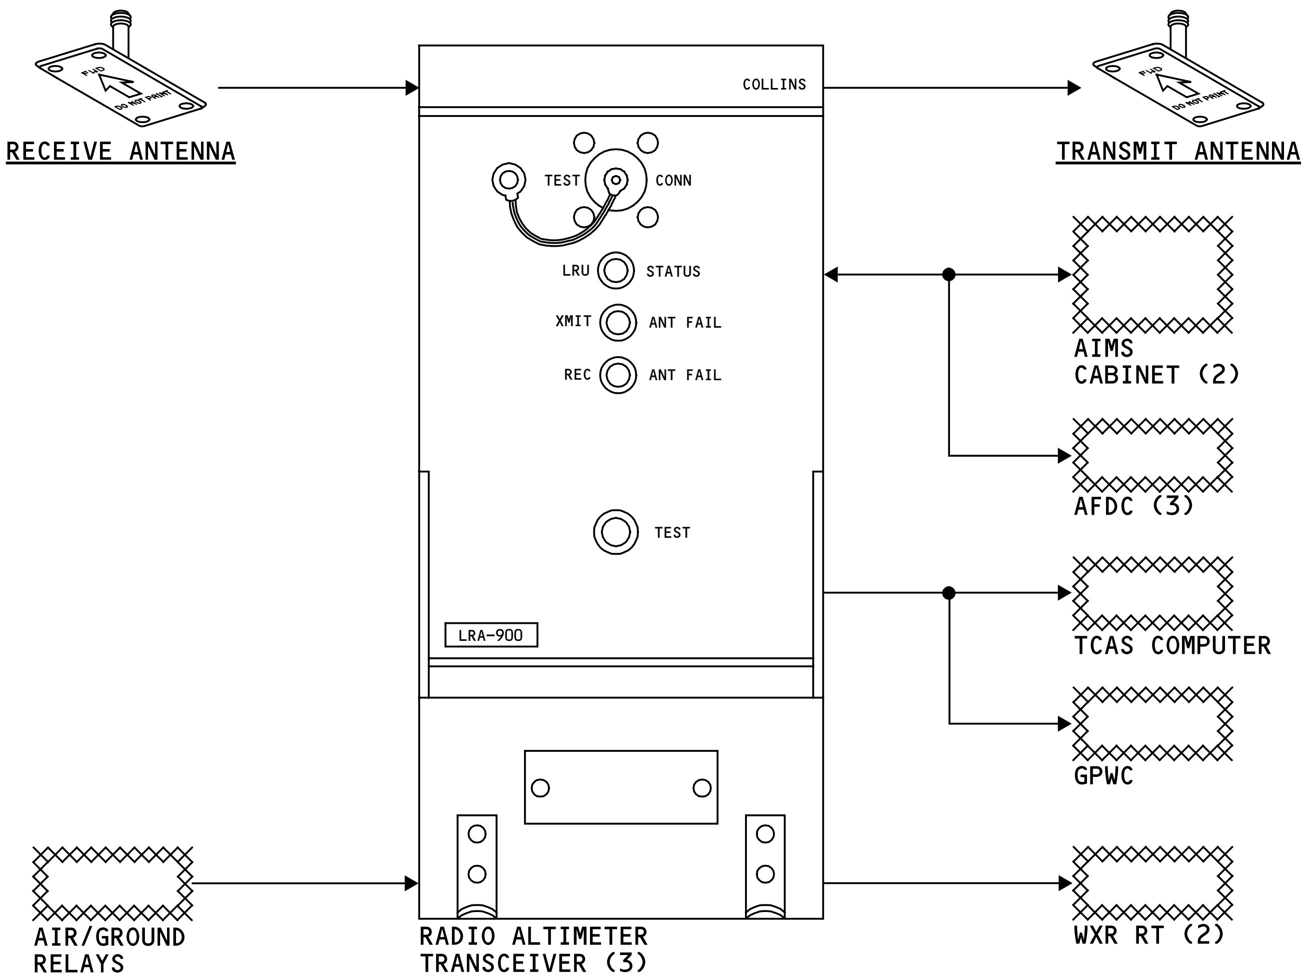
General

The system has three transceivers (xcvr). Each xcvr has a transmit and a receive antenna.

The transceivers get discrete inputs from the air ground relays and from the AIMS cabinets.

Radio altitude data goes on ARINC 429 data buses to the these components:

- Airplane information management system (AIMS) cabinets
- Autopilot flight director computers (AFDCs)
- Traffic alert and collision avoidance system (TCAS) computer
- Ground proximity warning computer (GPWC).
- Weather radar receiver-transmitters.



RA SYSTEM - GENERAL DESCRIPTION

RA SYSTEM - COMPONENT LOCATION - 1

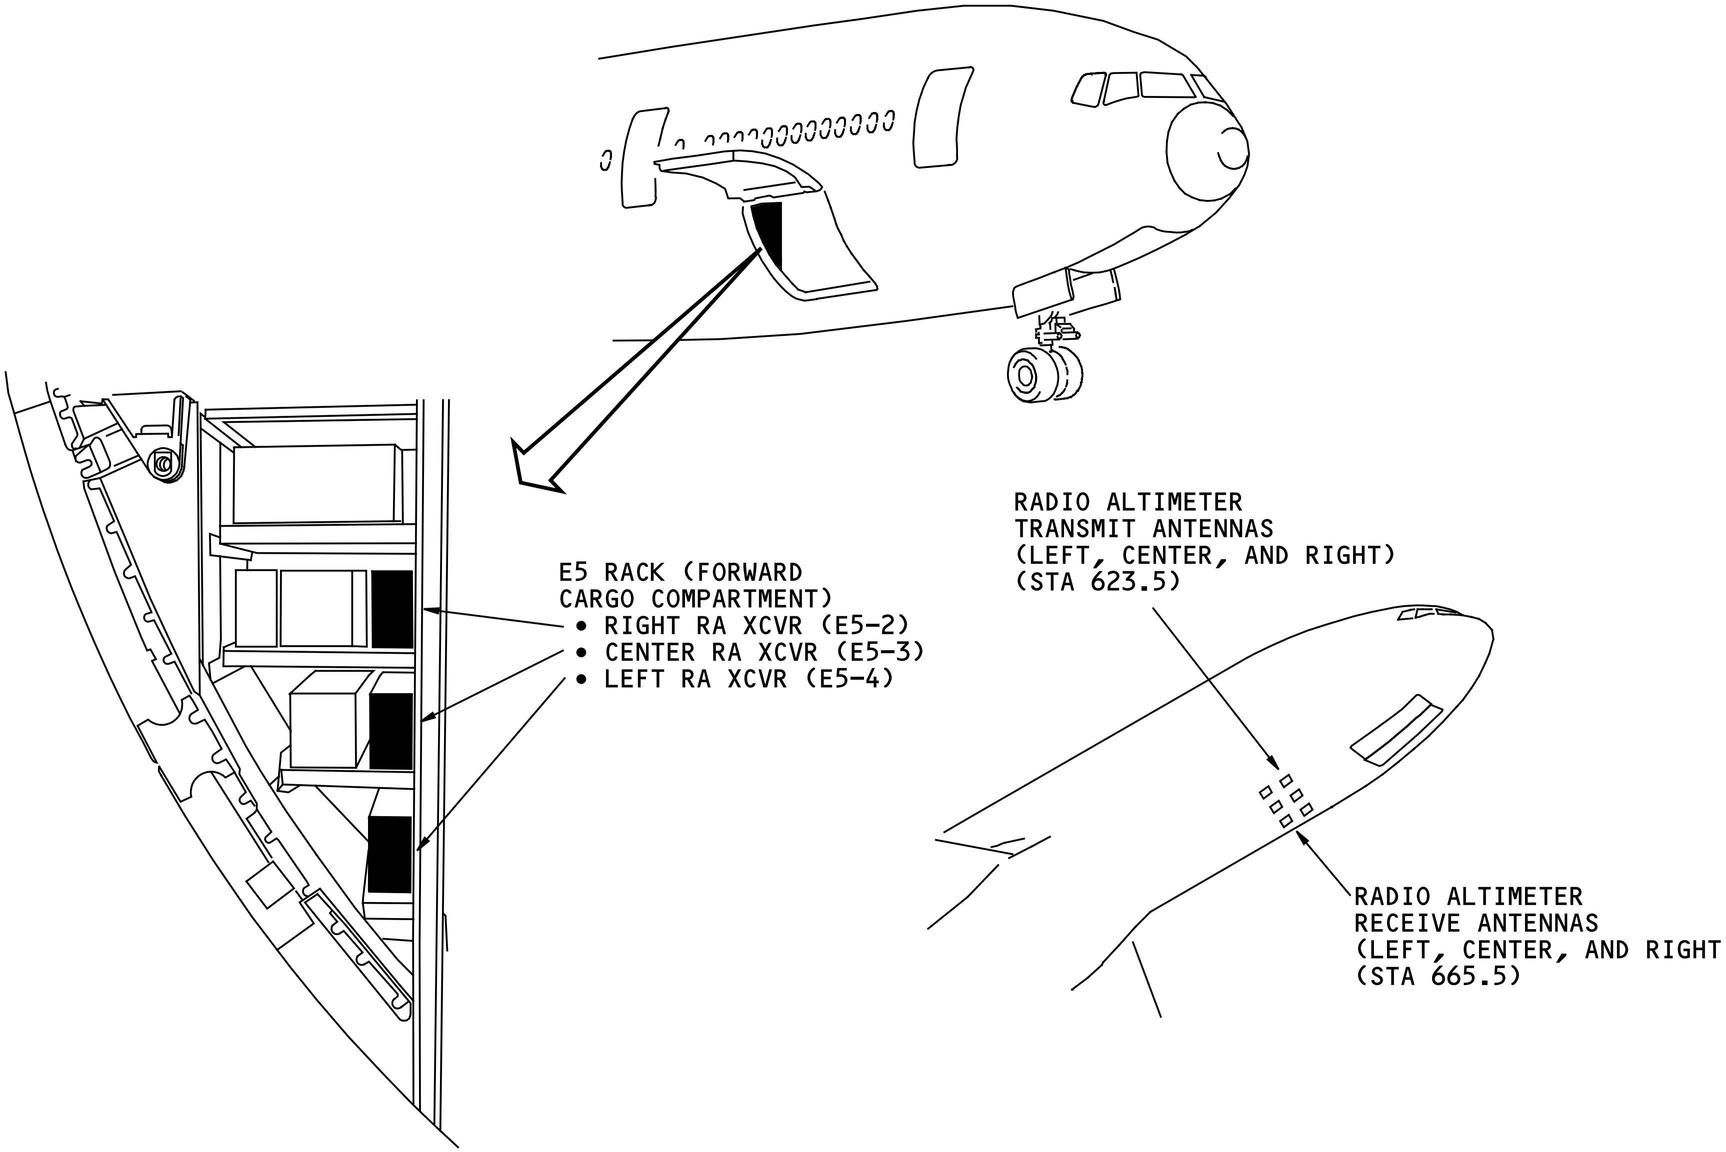
General

These are the RA system components in the E5 rack in the forward cargo compartment:

- Right RA transceiver (xcvr)
- Center RA xcvr
- Left RA xcvr.

These are the RA system components on the bottom of the fuselage:

- Left RA receive antenna
- Center RA receive antenna
- Right RA receive antenna
- Left RA transmit antenna
- Center RA transmit antenna
- Right RA transmit antenna.



34-33-00-003 Rev 1

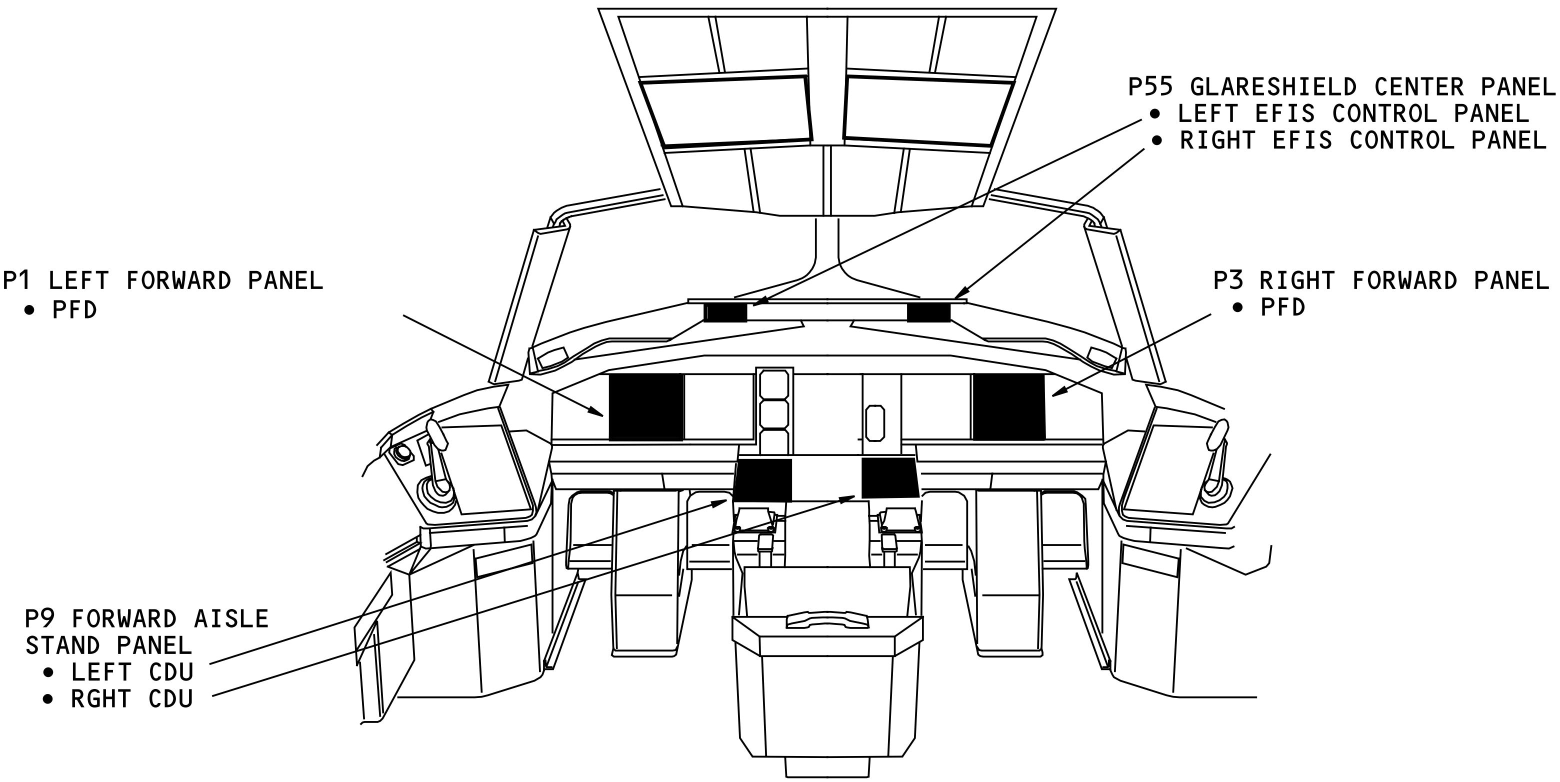
RA SYSTEM - COMPONENT LOCATION - 1

RA SYSTEM - COMPONENT LOCATION - 2

General

These are the RA system components and components that interface with the RA system in the flight deck:

- Primary flight displays (PFD)
- Left and right EFIS control panels
- Left and right control display units (CDU).



34-33-00-004 Rev 1

RA SYSTEM - COMPONENT LOCATION - 2

RA SYSTEM - POWER, ANTENNA, AND DISCRETE INPUTS

Power

Power for the RA xcvrs is 115v ac from:

- 115v ac left transfer bus (left RA)
- 115v ac standby bus (center RA)
- 115v ac right transfer bus (right RA).

Antenna Interfaces

The transmit antennas send radio frequency (RF) signals to the ground. The receive antennas send reflected RF signals to the receiver circuits of the RA xcvr.

AIMS Discrete

The primary flight control computers (PFCs) supply a test inhibit signal to the RA xcvr through the airplane information management system (AIMS) cabinets. This signal prevents a RA test when the primary flight computers detect a ground speed greater than 40 knots, or the airplane is in the air.

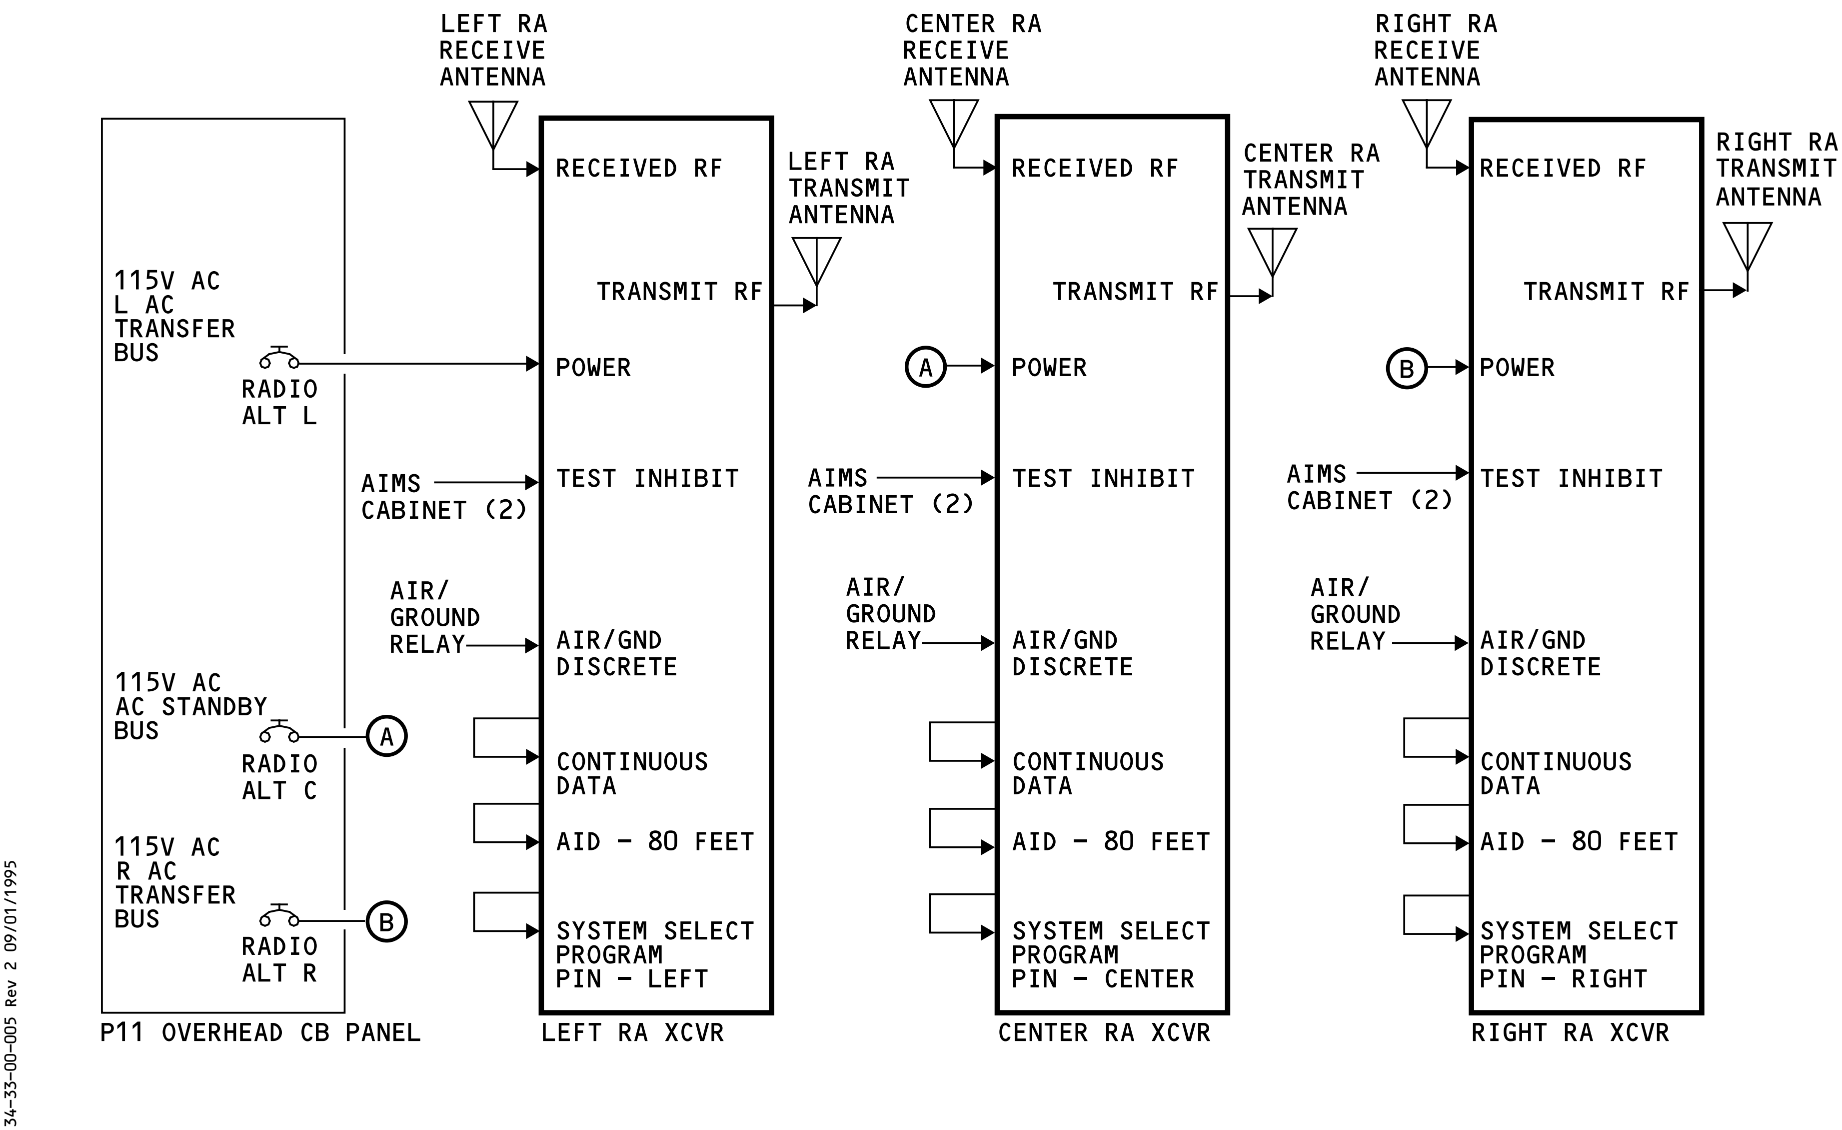
Air/Ground Discrete

The RA xcvr stores internal faults in a nonvolatile fault memory. The RA xcvr stores these faults by flight segments. The central maintenance computing function (CMCF) of the AIMS supplies the primary flight leg start times. The air/ground relay is an alternate way to detect the air/ground condition.

Input Program Pins

The RA xcvr program pins are:

- Continuous data
- Aircraft installation delay (AID) of 80 feet
- System select.



RA SYSTEM - POWER, ANTENNA, AND DISCRETE INPUTS

RA SYSTEM - DATA BUS OUTPUTS, RADIO MINIMUMS INTERFACE

General

The RA system supplies data to the:

- Left, center, and right AFDCs
- TCAS computer
- Left and right weather receiver transmitters
- GPWC
- Left and right AIMS cabinets
- Left, right, and center PFCs (through the AIMS cabinets).

Altitude Data

Radio altitude goes to the AIMS for PFD displays and status messages.

Each AFDC gets radio altitude from its onside RA transceiver. The AFDCs use radio altitude in their approach control calculations.

The GPWC uses radio altitude in its ground proximity alert and warning logic calculations.

The TCAS computer uses radio altitude to set the sensitivity levels and for intruder advisory calculations.

Weather radar (WXR) uses radio altitude data for the following:

- Automatic on/off logic
- Alert and display logic.

Fault Summary Data

Fault data from each radio altimeter goes to the AIMS cabinets. The AIMS cabinets send data to the status page. The status page shows RA status messages.

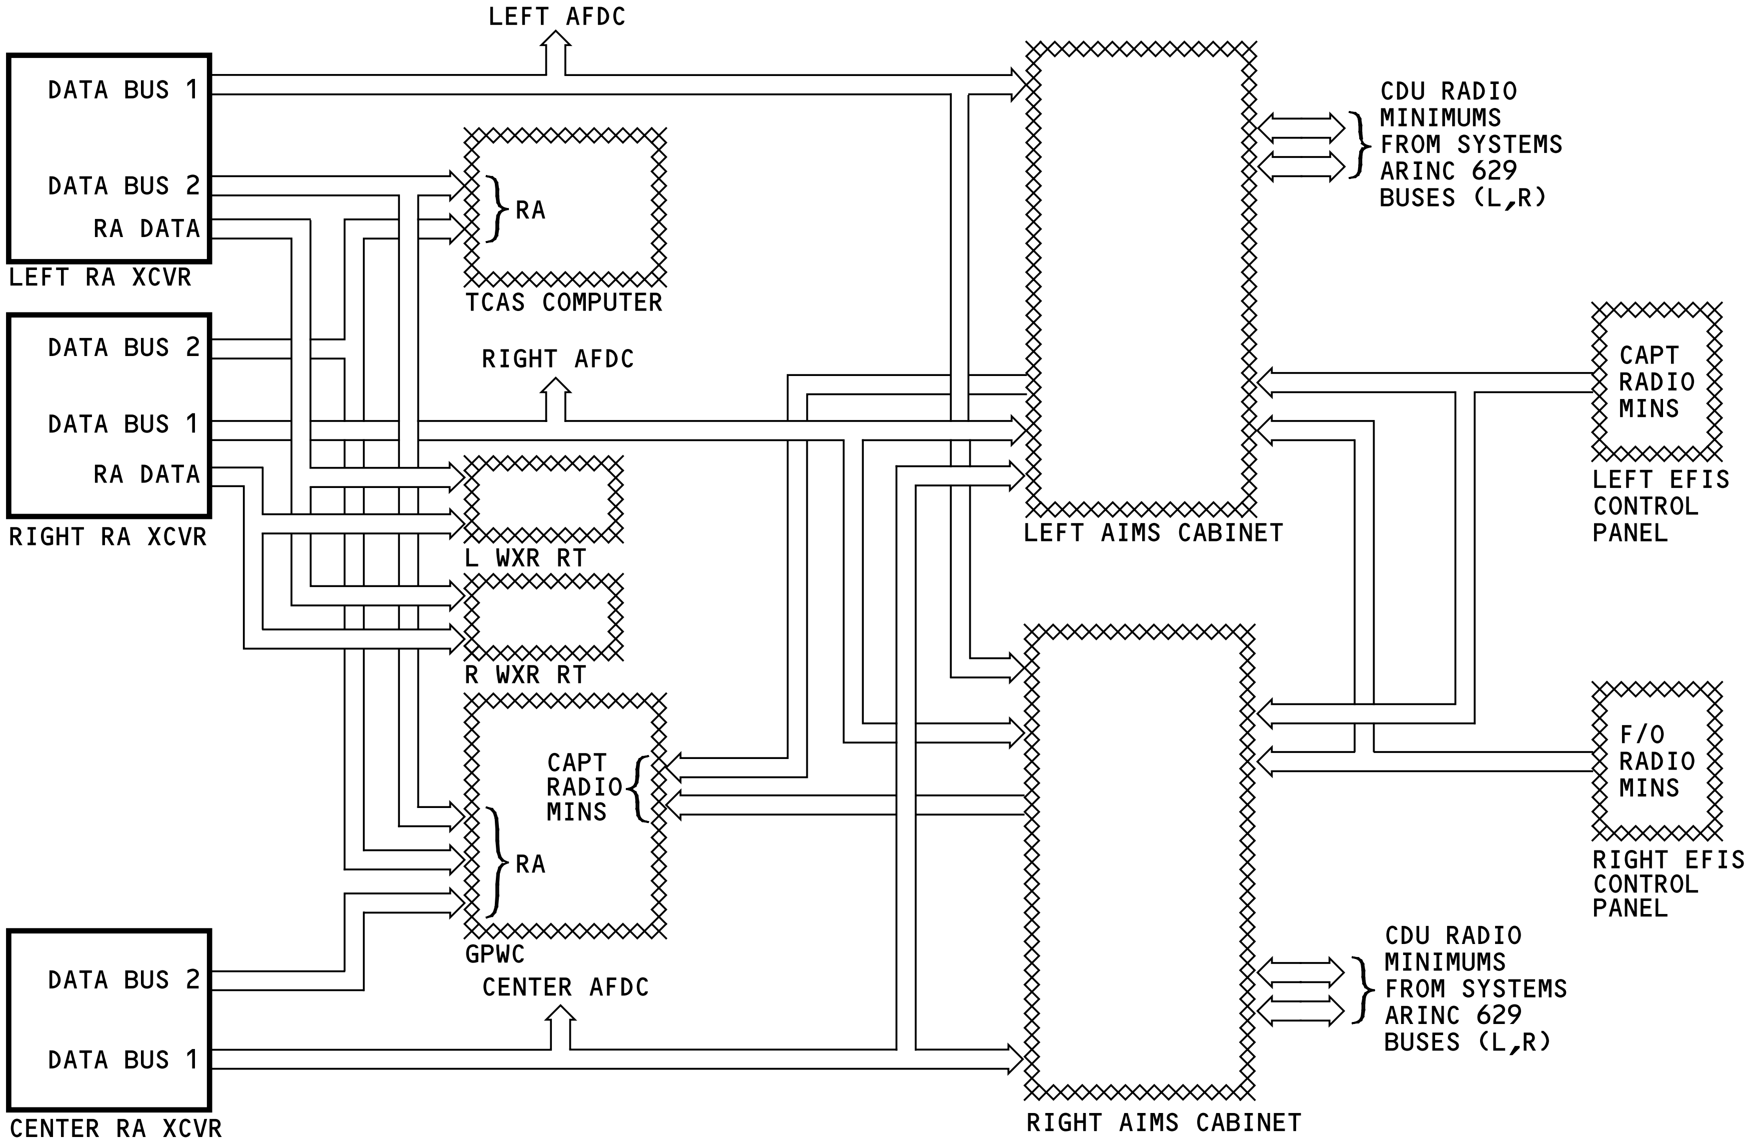
The CMCF of the AIMS cabinets receives and stores RA fault information. Maintenance personnel use the MAT to get fault information.

Radio Minimums GPWC Interface

Radio minimums and radio altitude go to the GPWC for various modes of warning.

Radio Minimums Interface

The EFIS control panels supply radio minimums values to the AIMS. The control display units (CDUs) supply backup radio minimums values to the AIMS.



34-33-00-006 Rev 3 12/01/95

RA SYSTEM - DATA BUS OUTPUTS, RADIO MINIMUMS INTERFACE

RA SYSTEM - RA TRANSCEIVER

Purpose

The RA transceiver calculates radio altitude.

The RA transceiver has a non-volatile memory which stores fault information from the last sixty-three flights. It can store up to thirteen faults per flight. Only shop personnel read the non-volatile memory information.

Operational Characteristics

These are the operational characteristics of the transceiver:

- Frequency = 4235 MHz to 4365 MHz
- Transmit power = 500 mw nominal
- Operating range = -20 to 2500 feet.

A test connector on the front panel connects test equipment for shop tests.

Operation

These are the three LED status indicators on the front panel:

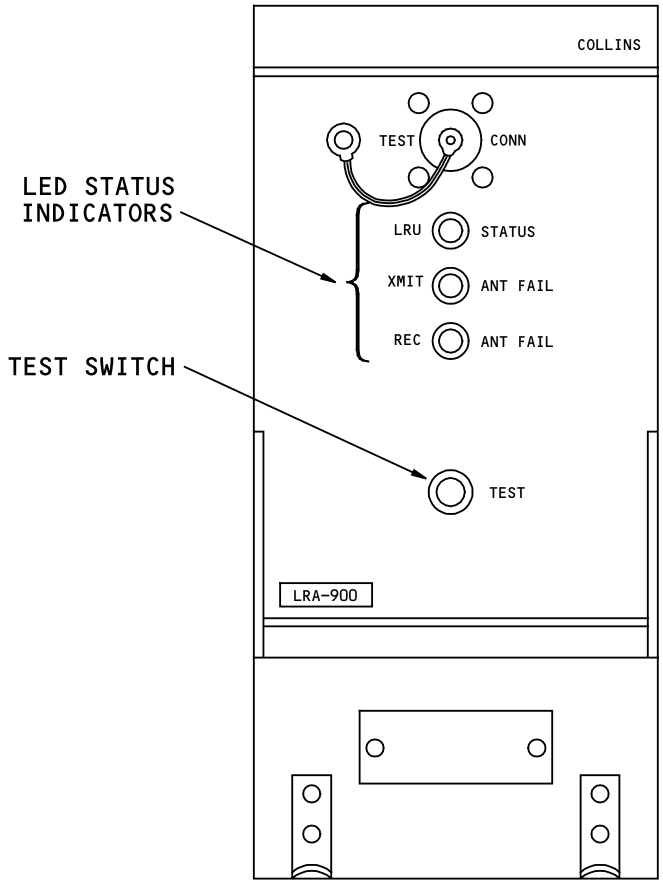
- A red or green LRU STATUS LED shows the transceiver operational status. It comes on green when the transceiver is OK. It comes on red when the transceiver has a fault
- A red XMIT ANT FAIL LED shows a transmission antenna or coax cable fault
- A red REC ANT FAIL LED shows a receive antenna or coax cable fault.

You push the test switch to start a self-test.

Training Information Point

The maintenance manual and the fault isolation manual do not have a task for the line maintenance technician to do a test from the front panel of the RA transceiver. You must do all tests for the RA transceiver from the MAT or a PMAT.

Many LRUs on the 777 are compatible with other model airplanes that do not have a central maintenance computing system (CMCS). For that reason these LRUs have a front panel test feature.



34-33-00-008 Rev 4 10/11/95

RA SYSTEM - RA TRANSCEIVER

RA SYSTEM - RA ANTENNA

Purpose

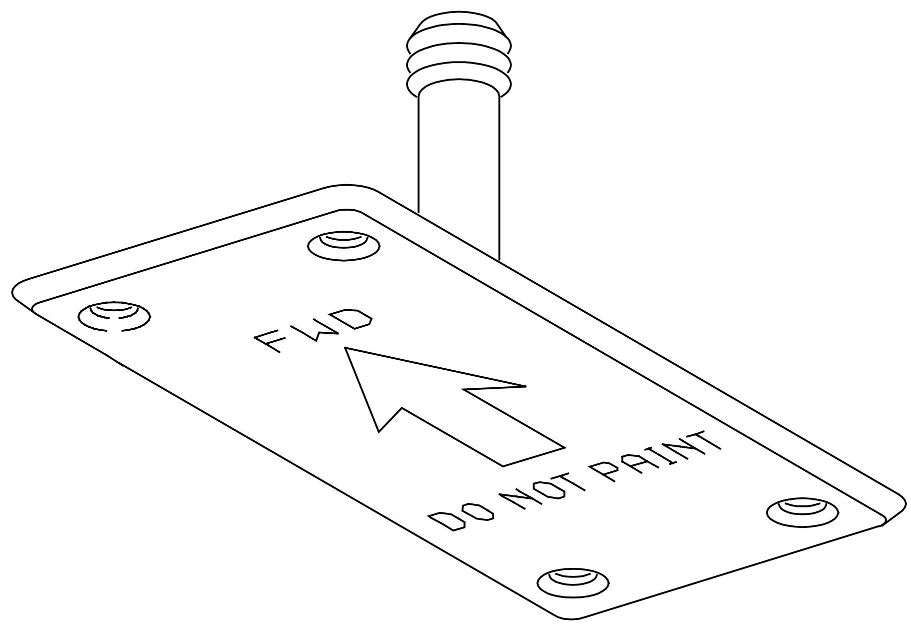
The RA system uses six antennas that transmit and receive RF signals. Each RA xcvr has a transmit and receive antenna. The transmit and receive antenna are the same and interchangeable.

Physical Description

Four screws attach each antenna to the bottom of the fuselage. There is an O-ring seal in a groove around the electrical connector. The O-ring seal supplies moisture protection. The radiation side of the antenna has red markings "FWD" and "DO NOT PAINT".

Training Information Point

Do not paint the radiation surface or the back plate of the antenna. Paint does not permit the antenna to radiate or receive RF signals.



34-33-00-009 Rev 1

RA SYSTEM - RA ANTENNA

THIS PAGE INTENTIONALLY LEFT BLANK

RA SYSTEM - OPERATION - 1

EFIS Control Panel

The EFIS control panel controls the radio minimums and resets the radio minimums alert. The radio minimums show on the captain's and first officer's PFDs. The left EFIS control panel controls the captain's PFD. The right EFIS control panel controls the first officer's PFD.

The RADIO/BARO MINS control has these three concentric controls:

- A two-position rotary switch (minimums reference selector)
- A three-position rotary switch which is spring loaded to center (minimums selector)
- A radio minimums reset switch.

The flight crew uses the minimums reference selector to select either radio minimums or barometric minimums. Radio minimums is the same as decision height (DH). Barometric minimums is the same as minimum descent altitude (MDA).

When the flight crew selects a radio minimums value, the three-position rotary switch, which is spring loaded to center, adjusts the radio minimums between -1 foot and +999 feet.

The flight crew pushes the reset switch to reset the radio minimums alert.

The barometric minimums function does not relate to the radio altimeter operation.

PFD

The PFD shows radio altitude and radio minimums values. The flight crew uses this data during approach and landing.

Radio altitude shows digitally for altitudes between -20 and 2500 feet. The display updates in:

- Two foot increments from -20 to 100 feet
- Ten foot increments from 100 to 500 feet
- Twenty foot increments from 500 to 2500 feet.

The display goes out of view above 2500 feet.

Radio minimums show on the PFD. The radio minimums display has the letters RADIO (radio minimums) and the radio minimums value. If the radio minimums value is less than zero feet or more than 999 feet, the display goes out of view.

Radio Minimums Alert

This happens as the airplane descends through the radio minimums value:

- The radio altitude display changes from white to yellow
- The green letters RADIO and the radio minimums value below it change from green to yellow.

RA SYSTEM - OPERATION - 1

- The radio altitude, the letters RADIO, and the radio minimums value blinks three times at a 4Hz rate.

Each of these resets the radio minimums alert:

- Push the radio minimums reset (RST) switch on the EFIS control panel
- The airplane climbs to 75 feet above the radio minimums value
- The radio minimums alert resets automatically at touchdown.

Reset causes the radio minimums value to go back to green and the radio altitude to go back to white.

RA Data Invalid

Invalid RA data causes a yellow RA flag to show in place of the radio altitude. The invalid occurs when the RA xcvr detects a failure in the RA system.

RA Data NCD

RA NCD causes the RA display to go out of view. The NCD occurs when the return RA signals are too weak or the radio altitude is more than 2500 feet.

Radio Minimums Data Invalid or NCD

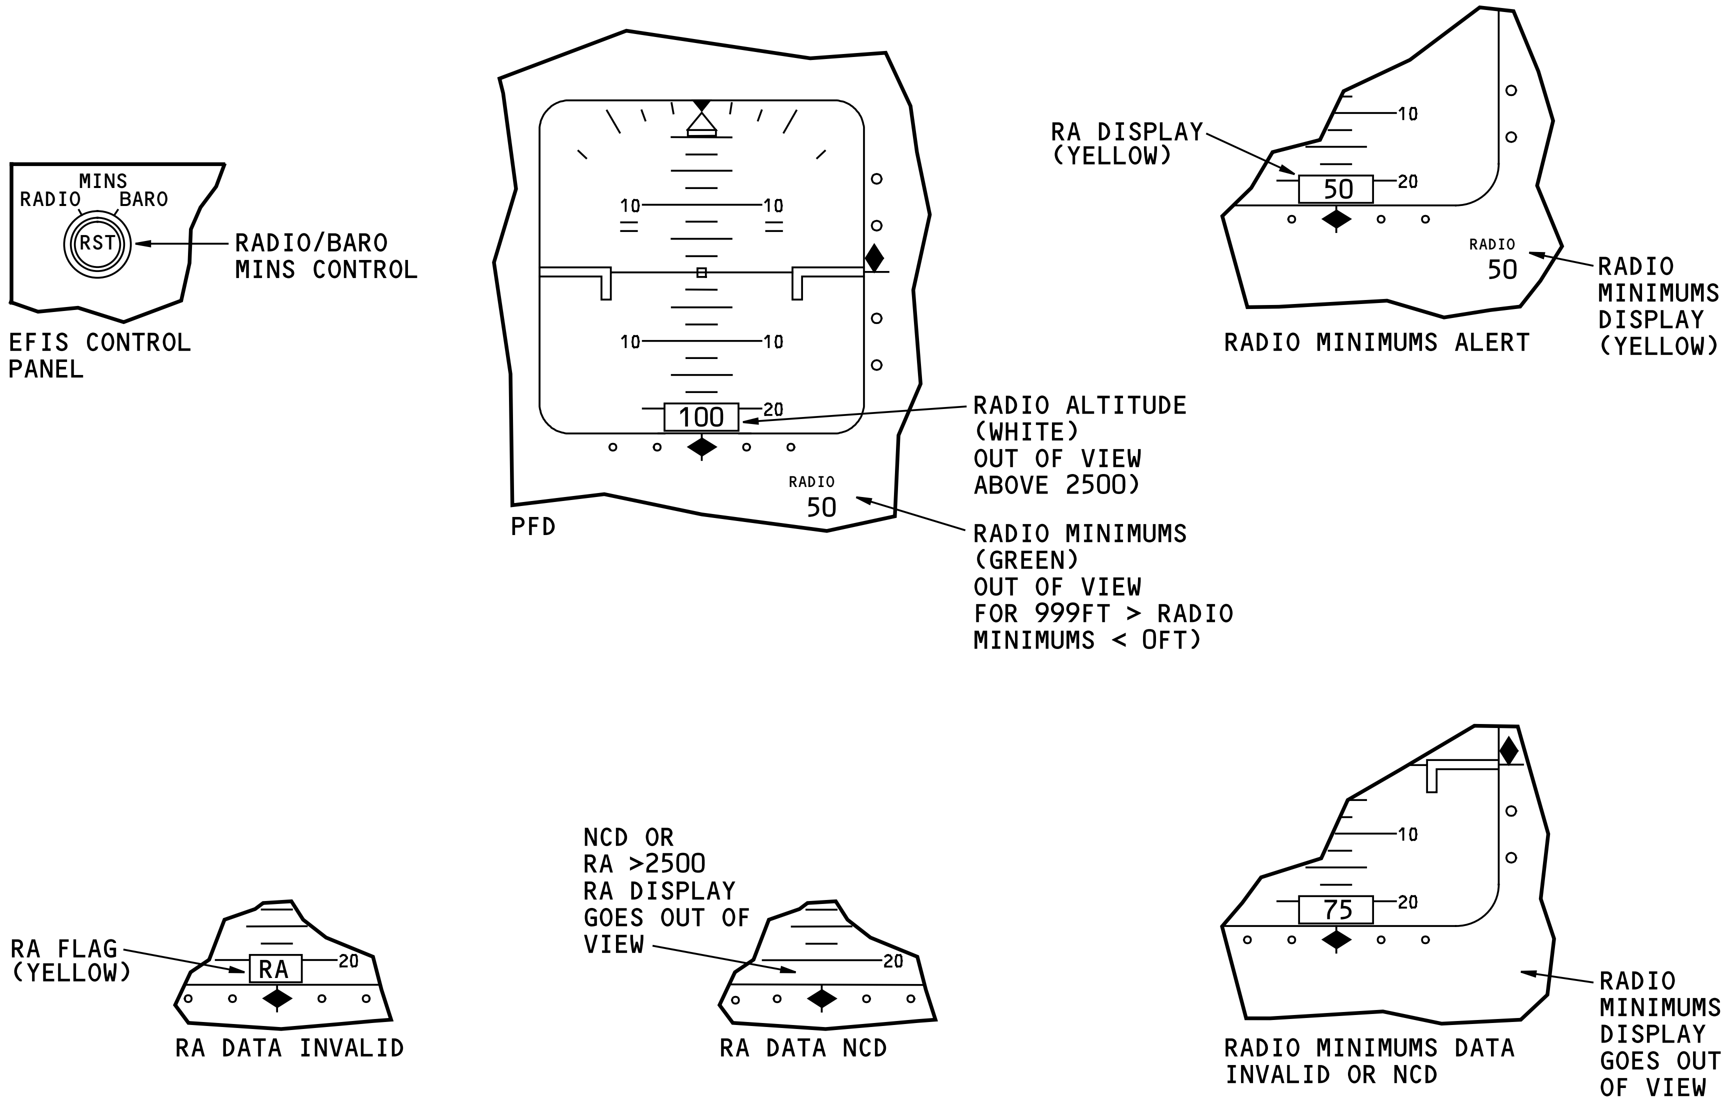
Invalid or NCD EFIS control panel data causes the letters RADIO and the radio minimums value to go out of view. The invalid occurs when the EFIS control panel, the onside CDU, and the center CDU fail.

RA Display Priority

The flight crew cannot manually select a radio altimeter for the PFD. When an RA xcvr fails, the AIMS selects another xcvr to show on the PFD. The selection priority shows below. A RA yellow flag shows on the PFDs only when all radio altimeters fail.

AIMS priority selection of PFD RA display:

Captain's PFD	L,C,R
First Officer's PFD	R,C,L



RA SYSTEM - OPERATION - 1

RA SYSTEM - OPERATION - 2

Purpose

In addition to the EFIS control panels, the flight crew can use the CDUs to select a radio minimums value and to reset a radio minimums alert. When the flight crew uses the CDU, the onside EFIS control panel does not operate.

Operation

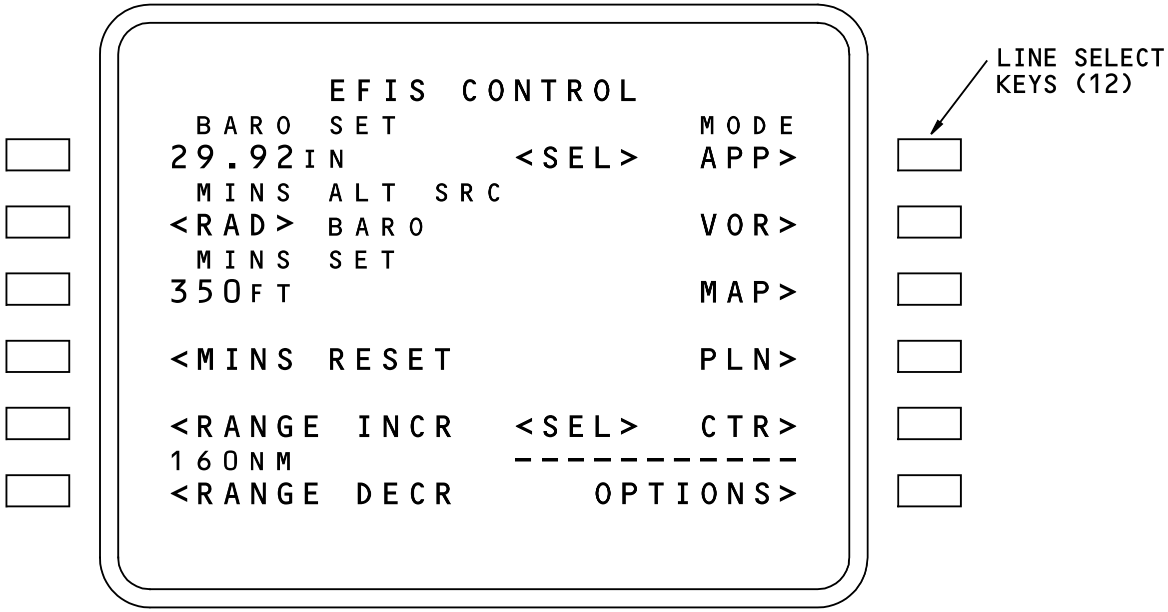
The captain selects a radio minimums value on the left CDU. The captain's radio minimums show on the captain's PFD. The first officer selects a radio minimums value on the right CDU. The first officer's radio minimums show on the first officer's PFD.

When the flight crew selects the EFIS control page on the CDU, the page shows the last radio minimums or barometric minimums of the onside EFIS control panel.

Push the line select key next to <RAD> BARO to make the letters RAD show in green large letters and the letters BARO show in white small letters. This action selects radio minimums in place of barometric minimums.

Type a new radio minimums value into the CDU scratch pad and push the line select key below MINS SET. Valid entries are 0 to 999 feet.

Push the line select key next to MINS RESET to clear a radio minimums alert.



CDU EFIS CONTROL PAGE

34-33-00-011 Rev 1

RA SYSTEM - OPERATION - 2

RA SYSTEM - SELF TEST

Operation

Push and hold the test switch on the front of the RA xcvr to start a self test. All the LED status indicators come on red for a few seconds. After this period, the LRU STATUS LED comes on green, the XMIT ANT FAIL LED and REC ANT FAIL LED go off for a few seconds. After that, all LEDs go off for a few more seconds. Finally, the applicable LEDs come on to show a normal (green) or fault (red) condition.

Test Inhibit

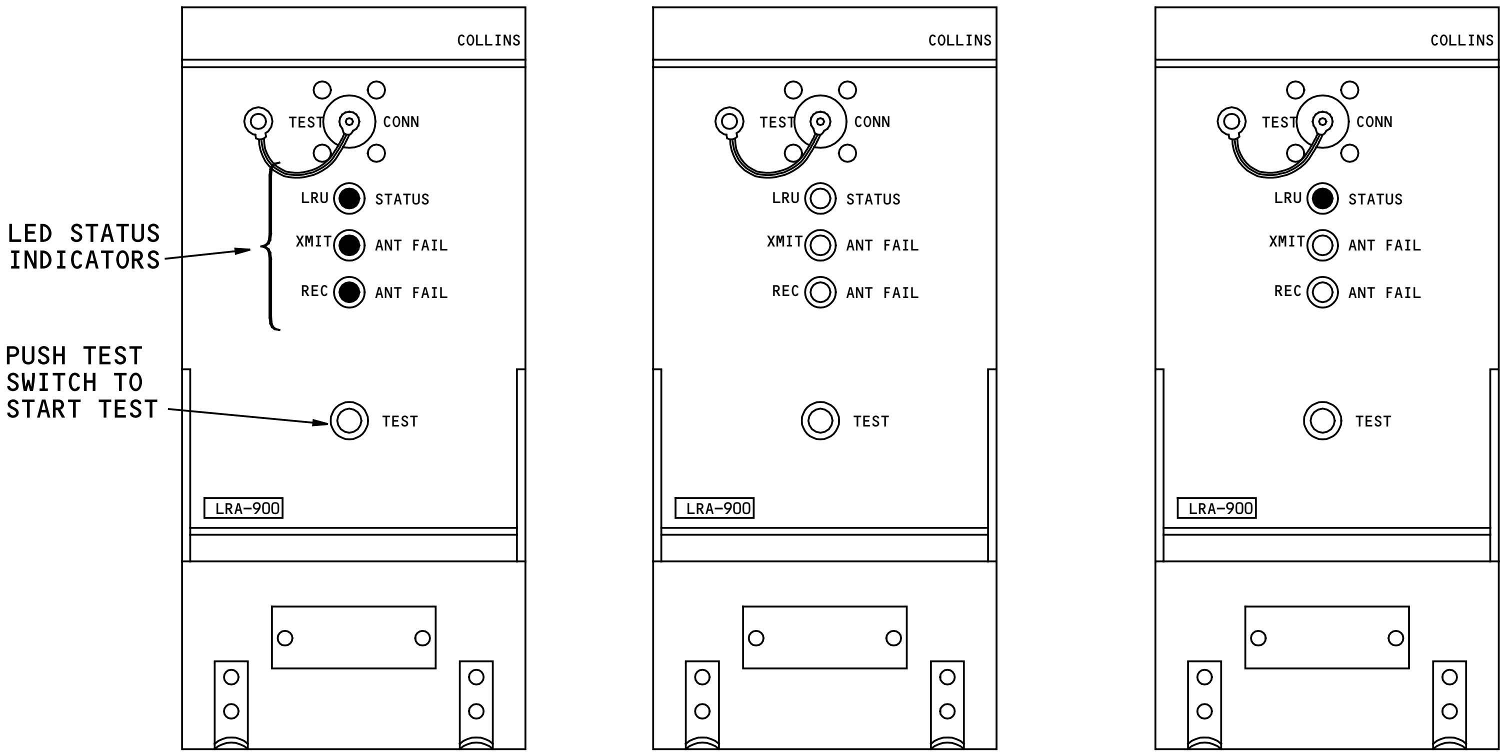
The primary flight control computers supply a test inhibit signal through the AIMS. This signal prevents a self test of the RA xcvr when the airplane is in the air or the ground speed is greater than 40 knots.

A discrete signal from the ground mode relay prevents a self test of the RA xcvr in flight.

Training Information Point

The maintenance manual and the fault isolation manual do not have a task for the line maintenance technician to do a test from the front panel of the RA xcvr. You must do all tests for the RA xcvr from the MAT or a PMAT.

Many LRUs on the 777 are compatible with other model airplanes that do not have a central maintenance computing system (CMCS). For that reason these LRUs have a front panel test feature.



1 ALL LED(S) ON FOR A FEW SECONDS (LRU STATUS COMES ON RED THEN GREEN)

2 ALL LED(S) OFF

3 THE APPLICABLE LED(S) COME ON TO SHOW THE STATUS OF THE RA TRANSCEIVER

34-33-00-014 Rev 3 10/11/95

RA SYSTEM - SELF TEST

RA SYSTEM - GROUND TEST

General

There are only operational tests available for the radio altimeter system. These are the operational tests available:

- Center radio altimeter system
- Left radio altimeter system
- Right radio altimeter system.

Operational Test

The purpose of this test is to verify the operation and function of the radio altimeter transceivers.

This test does a check of the radio altimeter transceiver operation. The test also does a check of the transmission and receive antennas and their coaxial cables.

34-58-00-001 Rev 3

GLOBAL POSITIONING SYSTEM - INTRODUCTION

GPS - GENERAL DESCRIPTION

General

The global positioning system (GPS) calculates:

- Latitude
- Longitude
- Altitude
- Accurate time
- Ground speed.

There are two GPS antennas. The left antenna receives satellite signals and sends them to the left multi-mode receiver (MMR). The right GPS antenna connects to the right MMR. The MMRs calculate the airplane position and accurate time. This data goes to the AIMS cabinets and the ground proximity warning computer (GPWC). The flight management computing function (FMCF) in the AIMS uses GPS data to calculate the airplane position.

The AIMS cabinets send GPS data to the air data inertial reference unit (ADIRU). The ADIRU uses GPS data to calibrate its internal sensors. This decreases inertial reference drift.

GPS time goes to the universal time coordinated function (UTCF) in AIMS. GPS time goes to the clocks in the flight deck through the AIMS cabinets. The clocks can show GPS time.

Power and Antenna Interface

Each multi-mode receiver (MMR) has a circuit breaker. The 115v ac standby and transfer buses supply power to the MMRs.

Each MMR sends 12v dc to its GPS antenna. The power goes through the center conductor of the coaxial cable to each antenna. Amplifiers in the antennas use the power to increase the strength of the received RF signals from the satellites.

Each MMR receives a radio frequency (RF) signal from its GPS antenna.

IRS Data Bus

The MMRs get inertial reference from the flight management computing function (FMCF) in each AIMS cabinet. The MMRs use this data for system initialization and to help system operation during periods of low satellite coverage.

Central Maintenance Data

The left and right MMRs receive central maintenance computing system (CMCS) data from the left AIMS cabinet. The CMCS data supplies airplane ID and flight leg information.

GPS Data Output Bus

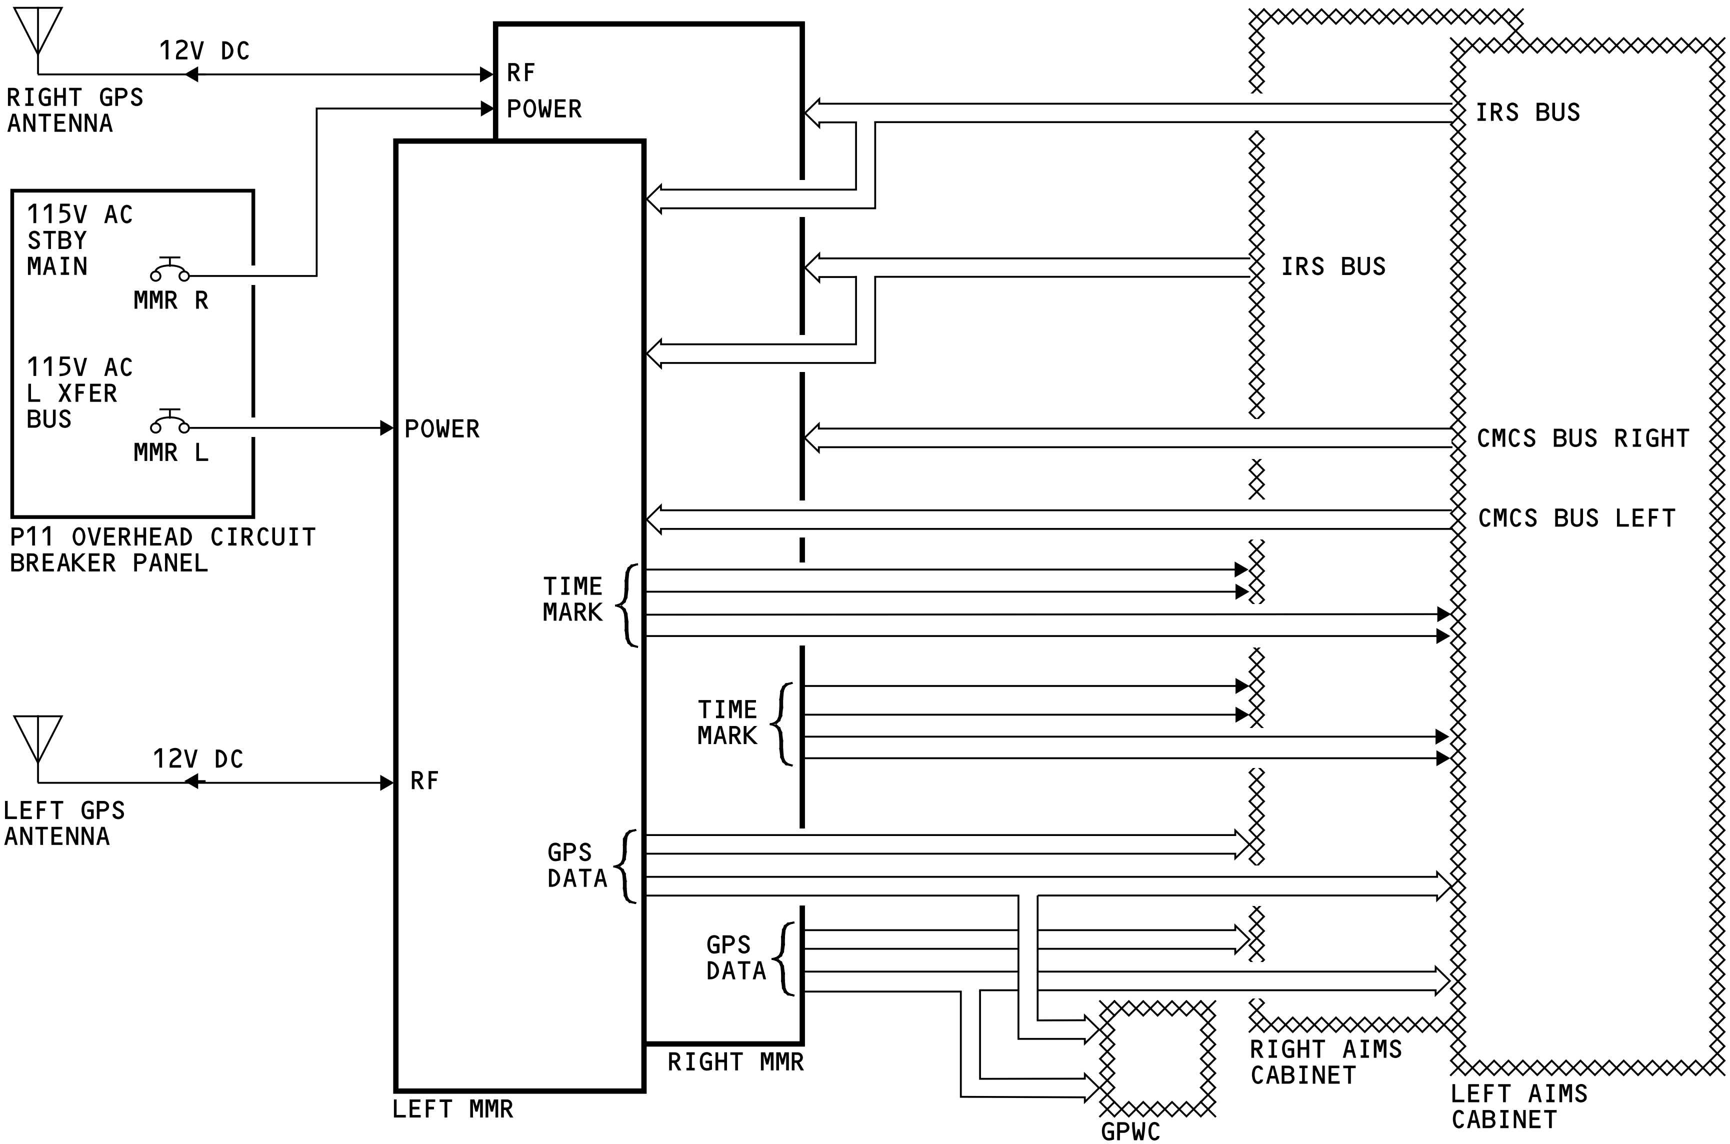
The left and right MMRs send GPS data to both AIMS cabinets. The data is for:

- GPS position reports
- General GPS data reports
- Fault information reports.

The left and right MMRs also send position data to the ground proximity warning computer (GPWC). The GPWC uses this data in its terrain awareness and terrain clearance floor functions.

Time Mark

The left and right MMRs supply time mark pulses to each AIMS cabinet. The pulses occur once per second and have an amplitude of approximately 4 volts. These pulses are the same as accurate universal time (coordinated) (UTC).



GPS - INTERFACES

GPS - GPS ANTENNA

General

The GPS antennas receive L-band frequency signals and send them to the multi-mode receivers (MMRs).

The GPS antenna impedance is 50 ohms.

GPS - GPS ANTENNA

GPS - THEORY OF OPERATION - 1

THIS PAGE INTENTIONALLY LEFT BLANK

GPS - THEORY OF OPERATION - 1

GPS Segments

The GPS has three segments:

- Satellite
- User
- Control.

Satellite Segment

The satellite segment is a group of satellites that orbit approximately 10,900 nautical miles above the earth. Each satellite completes an orbit approximately once every 12 hours. There are 21 operational satellites and 3 spares.

The satellites continuously transmit radio signals with navigation data, range code, and the exact time.

User Segment

The user segment is the multi-mode receiver (MMR) on the airplane. It receives the satellite signals. The MMR uses the satellite data to calculate the airplane position.

Control Segment

The control segment has control and monitor stations on earth that continuously monitor and track the satellites. The purpose of the control segment is to:

- Monitor and correct satellite orbits and clocks
- Calculate and format a satellite navigation message. This message has up-to-date descriptions of the satellites future positions, and a collection of the latest data on all GPS satellites
- Update the satellite navigation message regularly.

The control segment has one master control station and five monitor stations. Three of the monitor stations are also upload stations.

The master control station is in Colorado Springs, USA. The master control station is the operational center of the GPS. The master control station controls all operations in the control segment. The master control station has an atomic clock, this clock is the reference for the GPS.

The monitor stations track the satellites 24 hours a day. The master control station remotely controls the monitor stations through on-line connections. The monitor stations are in:

- Ascension island
- Colorado Springs
- Diego Garcia island
- Hawaii
- Kawajalein island.

The monitor stations receive the same information from the satellites that the MMRs in the airplane receive. The monitor stations:

GPS - THEORY OF OPERATION - 1

- Record the accuracy of the satellite clocks
- Collect and relay to the control station meteorologic data such as barometric pressure, temperature, and dew point. The master control station uses this data to calculate the tropospheric signal delay
- Continuously measure the ranges to all visible satellites. The master control station uses this data to calculate and predict the satellites orbits.

The master control station uses the upload stations to send:

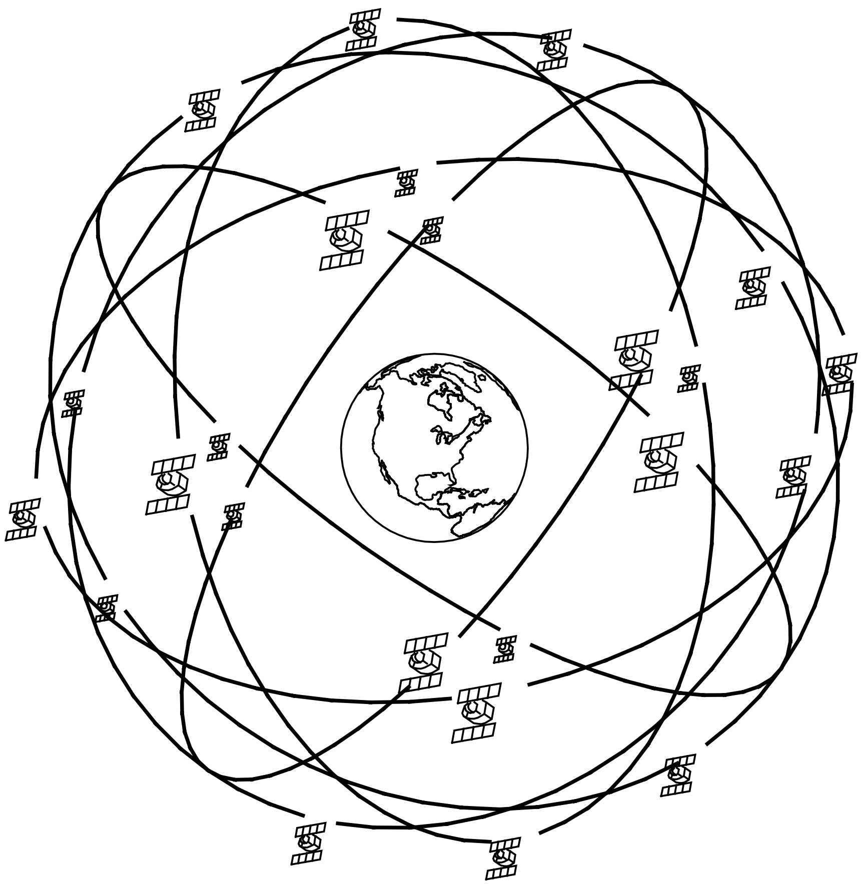
- Orbit correction commands to the satellites. The satellites use control rockets to correct their orbits
- The navigation message to the satellites.

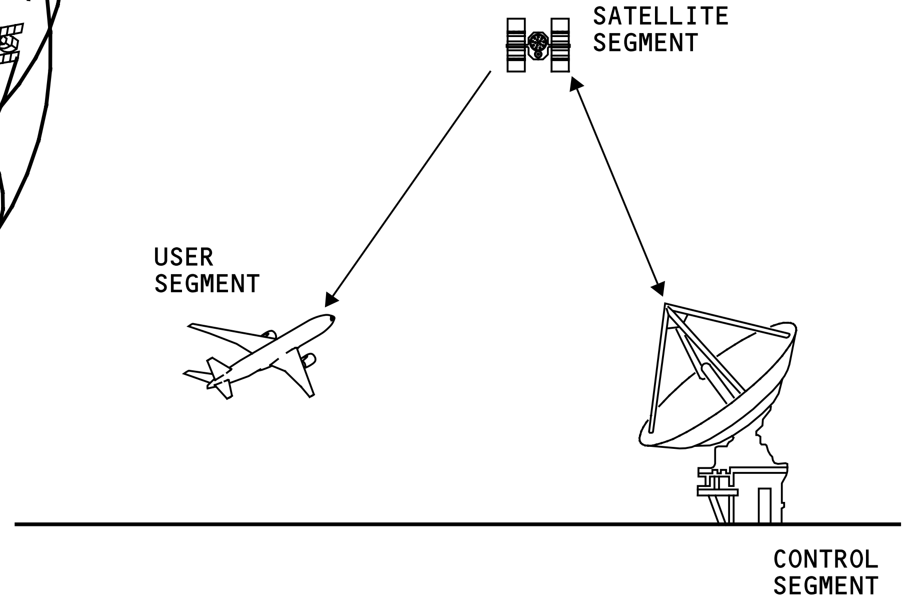
The upload stations are in Ascension island, Diego Garcia island, and Kawajalein island.

GPS Accuracy

Civilian users have access to standard positioning service (SPS). SPS has an accuracy of 15 - 25 meters in 95% of the position fixes. For security reasons, the American Department of Defense intentionally degrades the accuracy for civilian users to 100 meters in 95% of the fixes.

Military users have access to precision positioning service (PPS). PPS has an accuracy of 18 meters or less in 95% of the fixes.





34-58-00-009 Rev 2

GPS - THEORY OF OPERATION - 1

GPS - THEORY OF OPERATION - 2

Ranging

The multi-mode receivers (MMRs) use the principle of ranging to measure the distance between the MMR on earth and the satellites. The MMR has in memory the location of the satellites in their orbits at any time. It is possible for the MMR to know the position of each satellite because they follow a known orbit.

The MMR measures the time it takes for a radio signal to go from a satellite to the airplane. Since the MMR knows the location of the satellite and that the radio signal travels at the speed of light, it can calculate the distance to the satellite.

However since this is one way ranging, the MMR must know exactly at what time the satellite sent the radio signal. The MMR compares the satellite signal to a signal that the MMR makes at the same time as the satellite. The difference between the two signals (Δt) is the time the satellite signal took to get to the MMR.

Each satellite has atomic clocks to keep accurate time. All the satellites have precisely the same time. The MMR in the airplane has an internal clock but it is not atomic, so it is not as accurate. Thus, it is not possible for the MMR to have precisely the same time as the satellite.

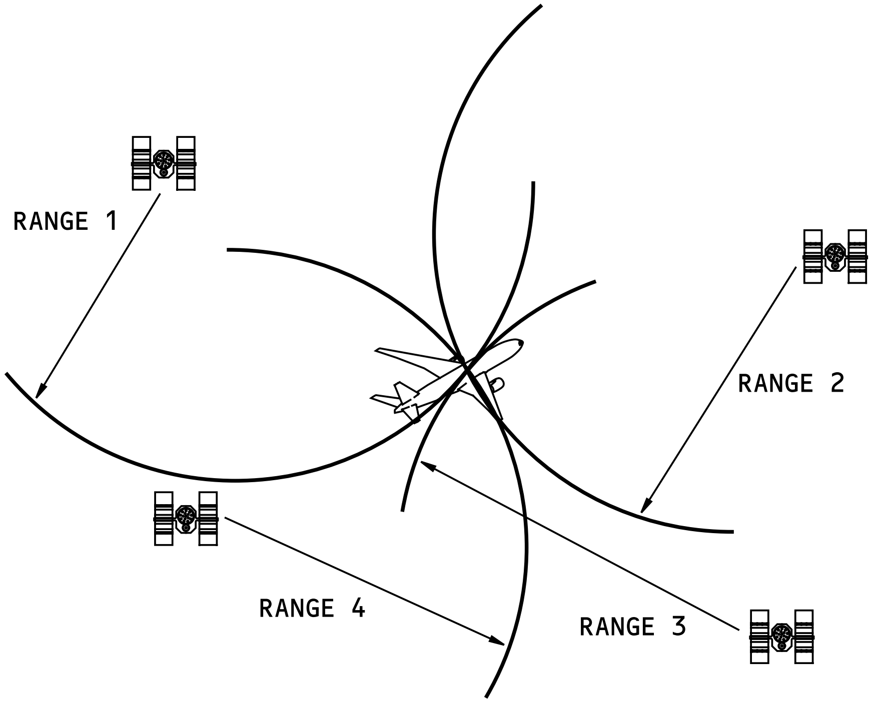
The MMR assumes that its internal clock is off by some clock bias. This clock bias is an unknown that the MMR must calculate. The clock bias is the difference between the MMR time and GPS time.

To calculate the airplane position (latitude, longitude, and altitude) and the clock bias, the MMR must know the position of at least four satellites. The MMR then measures the distances to all the satellites at the same time, and solves for these four unknowns with four range equations:

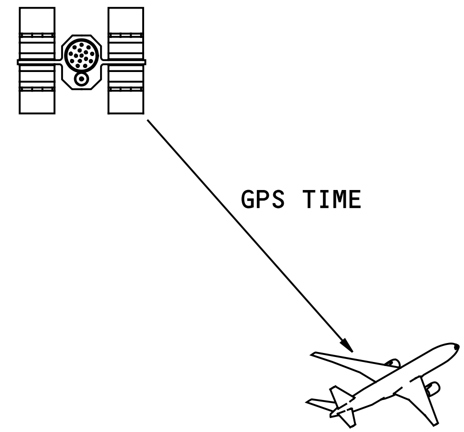
- Latitude
- Longitude
- Altitude
- Clock bias.

GPS Time

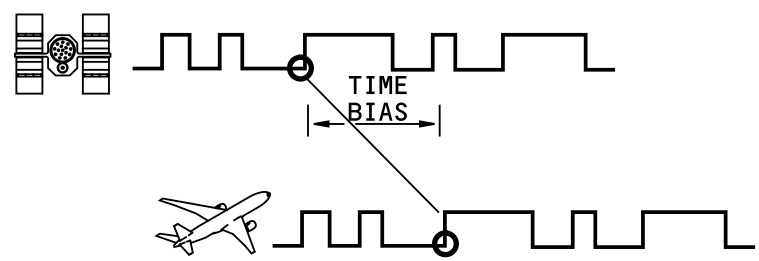
All the satellites synchronize to universal time (coordinated) (UTC). The satellites transmit this time to the MMR. The accuracy of the satellite UTC is approximately 100 nanoseconds. The MMR transmits UTC on an ARINC 429 format. The MMR also transmits a very accurate time mark once per second.



RANGING



GPS TIME



TIME BIAS

GPS - THEORY OF OPERATION - 2

GPS - THEORY OF OPERATION - 3

THIS PAGE INTENTIONALLY LEFT BLANK

GPS - THEORY OF OPERATION - 3

GPS Modes of Operation

The multi-mode receiver (MMR) operates in these modes:

- Acquisition mode
- Navigation mode
- Altitude aided mode
- Aided mode.

Acquisition Mode

The MMR looks for and locks on to the satellite signals. The MMR must find at least 4 satellites before it starts to calculate GPS data. The MMR accepts this data from the flight management computing function (FMCF) in the AIMS when the MMR is in the acquisition mode:

- Position
- Velocity
- Time
- Date.

The MMR uses the FMCF data to calculate which satellites are available at the present airplane position. This helps the MMR get the signals from those satellites available.

If the AIMS data is not available, the MMR can still acquire satellites signals. However, the MMR takes longer to acquire the satellite signals because it has to look for all the satellites. When the MMR finds the satellites, it calculates which it can use.

The MMR takes approximately 75 seconds to acquire the satellite signals when the AIMS data is available. The MMR takes approximately 4 minutes (maximum of 10 minutes) to acquire the satellites when the AIMS data is not available.

Navigation Mode

The MMR enters the navigation mode after it acquires and locks on to at least 4 satellites. When the MMR is in the navigation mode, it computes GPS data. The MMR output goes NCD (no computed data) when the accuracy is not within 16 nautical miles of the actual position.

Altitude Aided Mode

With four satellites available, the MMR stores the difference between the ADIRU inertial altitude and the GPS altitude.

The MMR stores the difference between inertial and GPS altitude so that it can estimate the GPS altitude when only three satellites are available.

In the altitude aided mode, the MMR uses the airplane altitude from the ADIRU and the length of the earth radius as the fourth range.

The MMR enters the altitude aided mode only after these three conditions are true:

- The MMR was in the navigation mode

GPS - THEORY OF OPERATION - 3

- There are only 3 satellites available with good geometry for position fixes
- The MMR stored the difference between inertial and GPS altitude in memory.

The MMR starts normal operation again when a fourth satellite comes into view.

Aided Mode

The MMR enters the aided mode during short periods (less than 30 seconds) of bad satellite coverage. An example of bad satellite coverage is poor satellite geometry, where at least four satellites are available but they are not spread out far enough so the MMR can make an accurate position fix.

In the aided mode, the MMR receives altitude, heading, and speed from the flight management computing function (FMCF) of the AIMS. The MMR uses the FMCF data to go back quickly to the navigation mode when there is good satellite coverage again. The MMR output is NCD in this mode.

GPS Frequencies

The satellites transmit to the MMR in the airplane on the L1 (1575.42 MHz) and L2 (1227.6 MHz) frequencies. The satellites downlink satellite status data to the monitor stations on 1783.74 MHz.

The upload stations send information to the satellites on 2227.5 MHz.

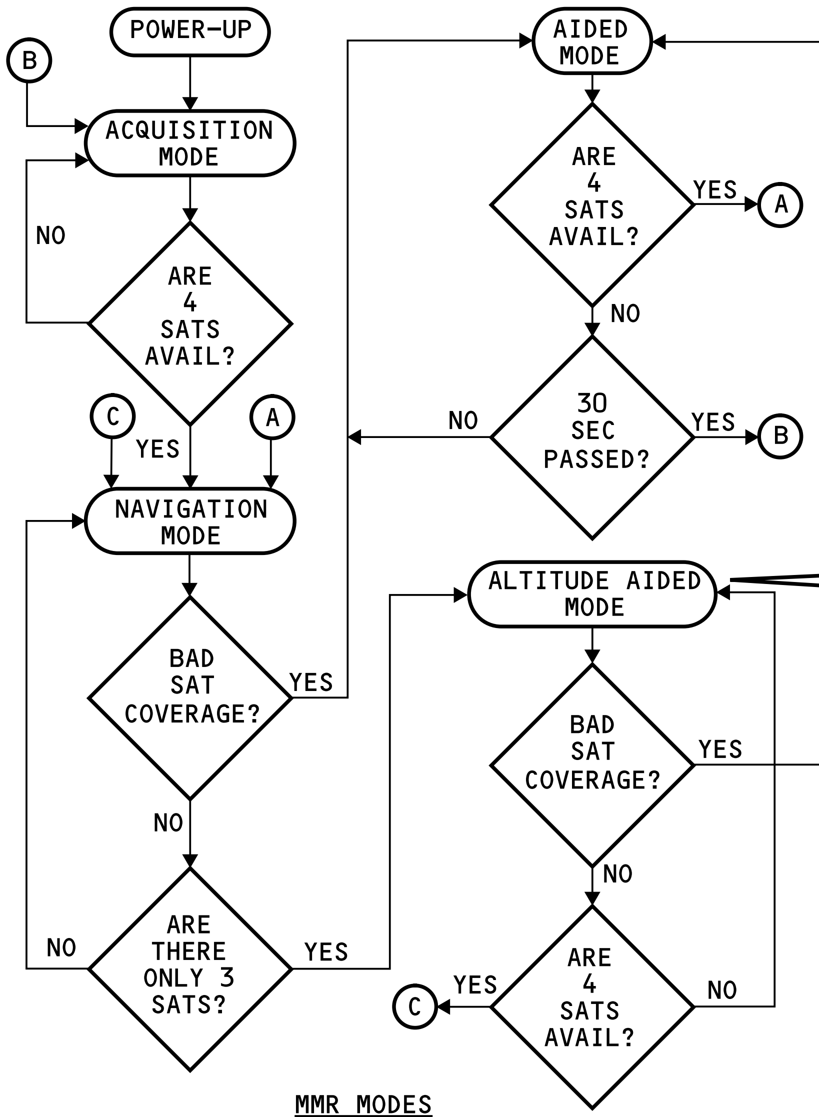
Autonomous Integrity Limit

The MMR has a receiver autonomous integrity monitor (RAIM) function. The RAIM monitors the status of the satellites that the MMR uses for calculations. The output of the RAIM function is an estimate of the GPS position error. The autonomous integrity monitor value goes to the flight management computing function (FMCF) of the AIMS. The FMCF uses the autonomous integrity monitor to determine if it can use GPS data for navigation.

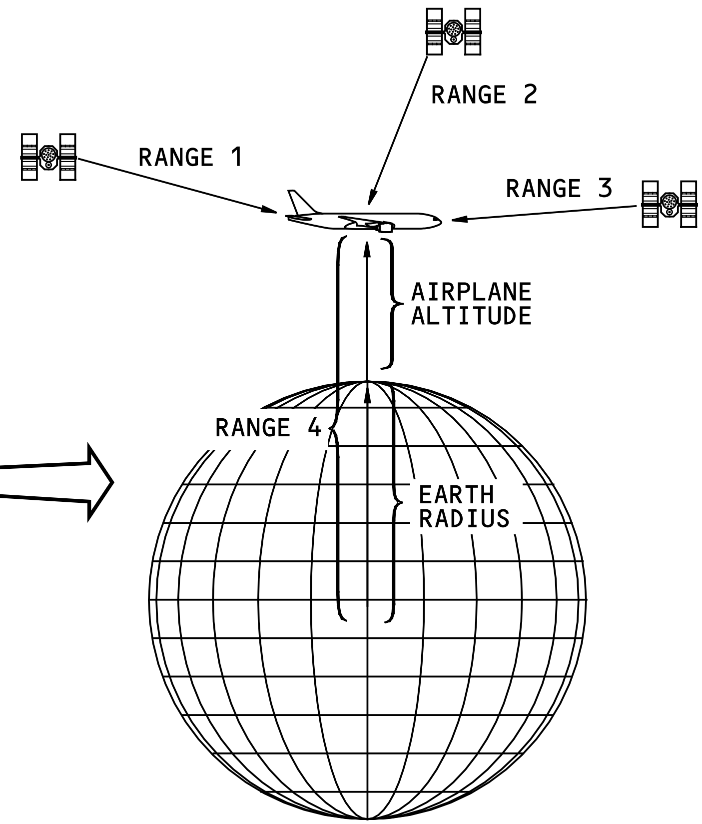
Values Calculated by the MMR

These are some of the values that the MMR calculates:

- Latitude
- Longitude
- Altitude
- Universal time (coordinated) (UTC)
- Date
- North/south velocity
- East/west velocity
- Vertical velocity
- Track angle
- Autonomous integrity limit
- Satellite position
- MMR status.



MMR MODES



ALTITUDE AIDED MODE

GPS - THEORY OF OPERATION - 3

34-58-00-011 Rev 3 09/29/1997

GPS - FUNCTIONAL DESCRIPTION

Power

The power supply makes various dc voltages from the 28v dc input to the multi-mode receiver (MMR).

Satellite Signal Processing

The low noise amplifier (LNA) receives and amplifies the satellite signals from the GPS antenna. The receiver detects the satellite signal and sends it to a digital-to-analog converter (D/A). The D/A sends the digitized signal to the microprocessor. The microprocessor calculates the airplane position and other GPS data. The GPS data goes to the flight management computing function (FMCF) in the left and right AIMS cabinets.

The MMR makes time mark pulses once per second. The time mark pulses goes to the AIMS cabinets.

Inputs

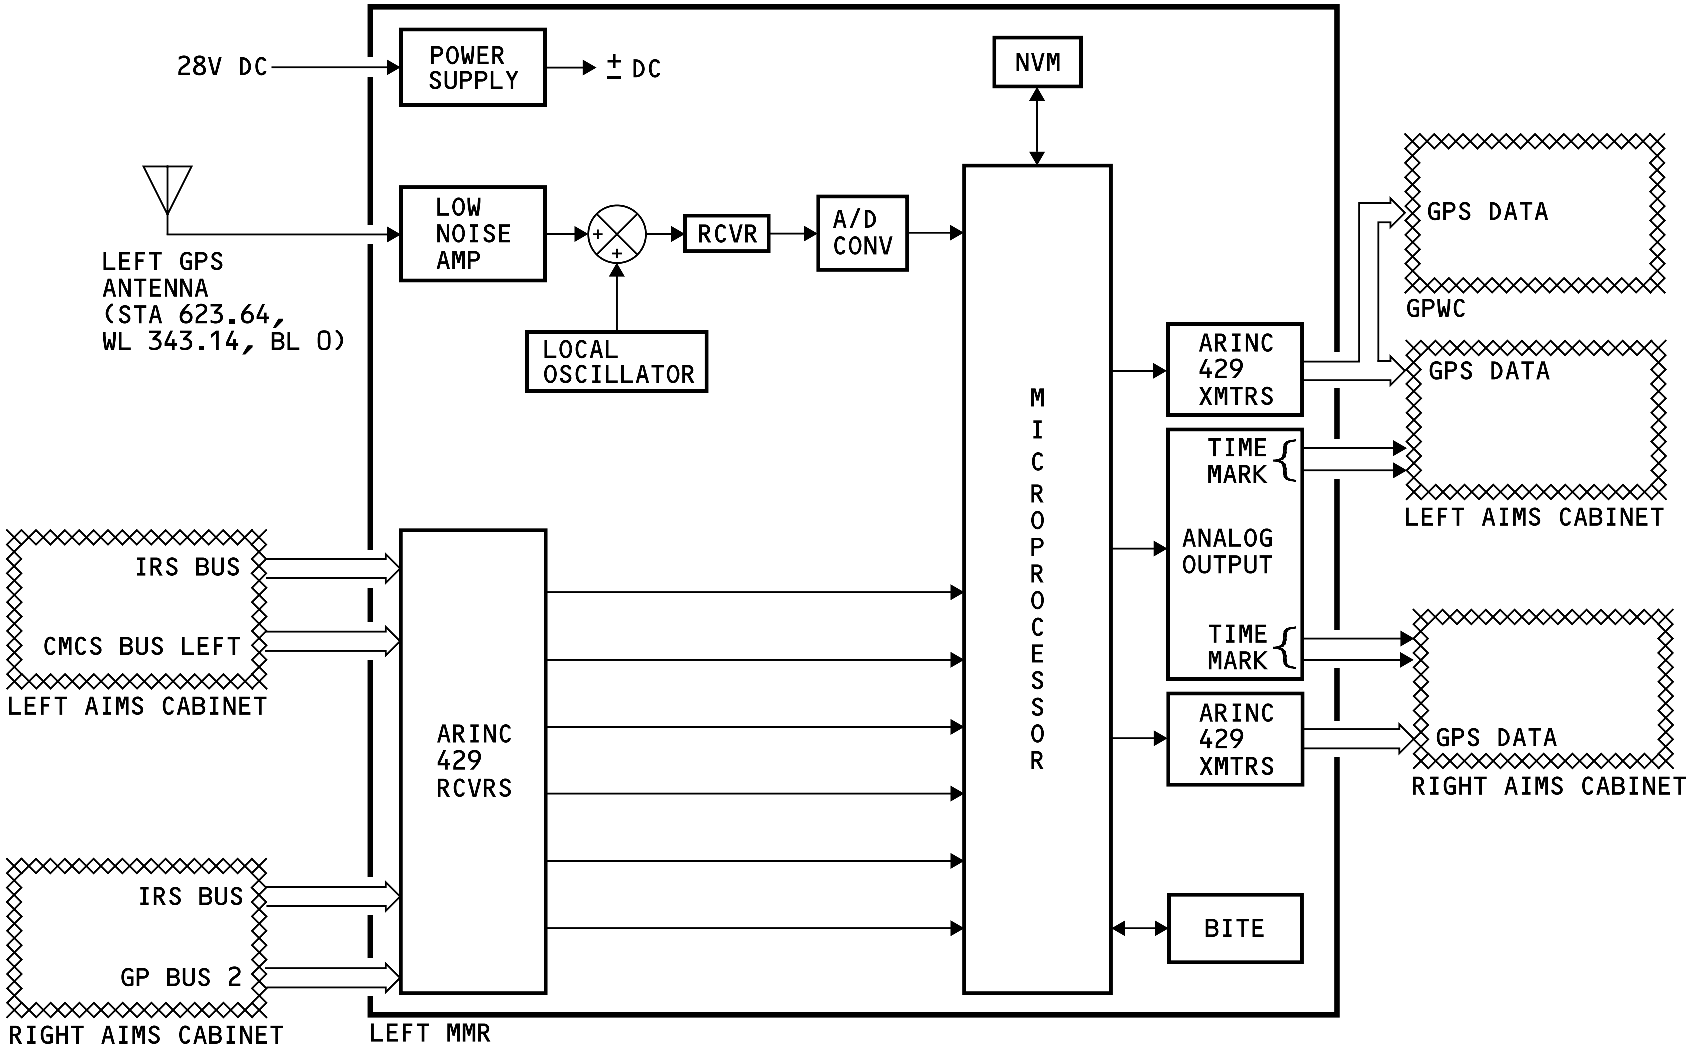
The AIMS cabinets use inertial reference data from the FMCF in the left and right AIMS cabinets during initialization. The MMR also uses this data in the aided and altitude aided modes.

The left MMR receives test and fault report requests on the central maintenance computing system (CMCS) bus from the left AIMS cabinet. Built-in-test equipment (BITE) circuits test and report faults to the AIMS cabinets.

Outputs

The left and right MMRs send position and time mark data to the left and right AIMS cabinets.

The GPSSUs also send position data to the ground proximity warning computer (GPWC). The GPWC uses this data in its terrain awareness and terrain clearance floor functions.



NOTE: LEFT MMR IS SHOWN. RIGHT MMR IS SIMILAR.

GPS - FUNCTIONAL DESCRIPTION

GPS - DISPLAYS - 1

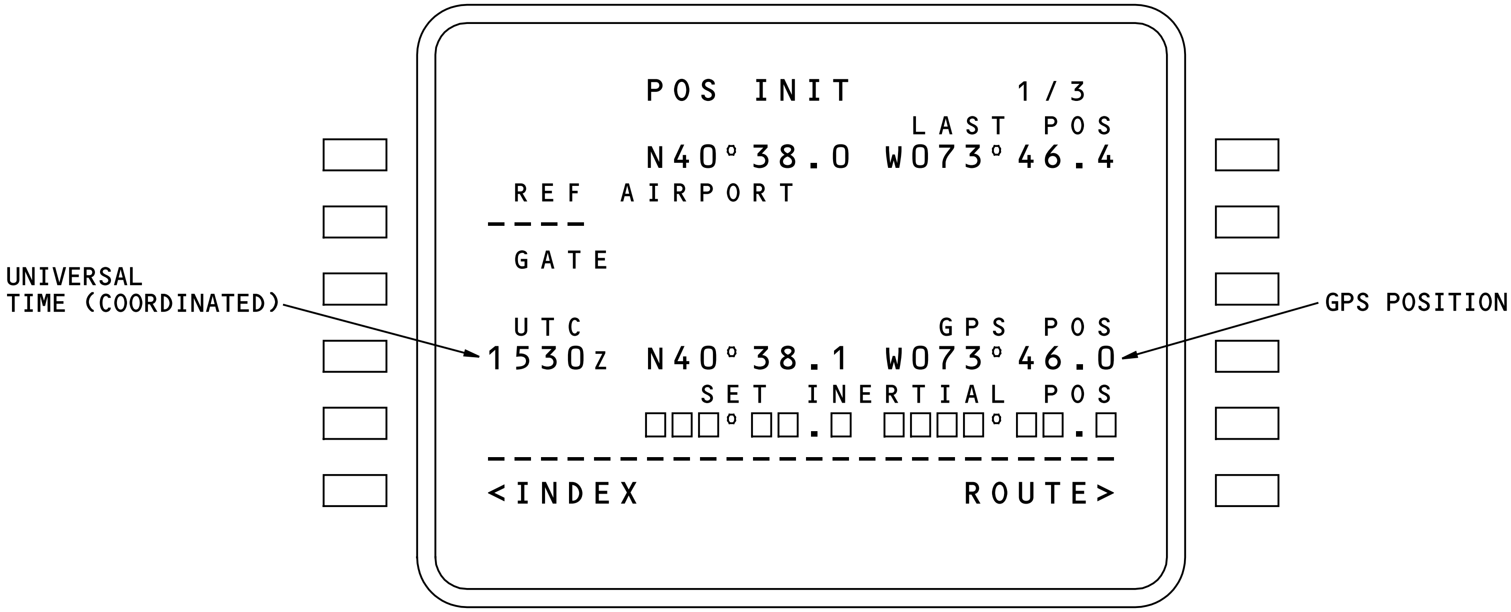
General

The flight management computing function (FMCF) of the AIMS shows position initialization and position reference pages on the control display unit (CDU).

The multi-mode receivers (MMRs) send GPS data to the AIMS cabinets. GPS data shows on the CDU. The position initialization page shows the GPS position and GPS time.

The flight crew can use the GPS position to initialize the air data inertial reference unit (ADIRU) position.

The GPS universal time (coordinated) (UTC) shows on the CDU when the GPS time is valid.



POSITION INITIALIZATION PAGE

34-58-00-013 Rev 1

GPS - DISPLAYS - 1

GPS - DISPLAYS - 2

General

Position reference page two shows the active flight management computing function (FMCF) airplane position.

The FMCF can use GPS position data to calculate the airplane position. The FMCF also uses these other navigation aids to calculate the airplane position:

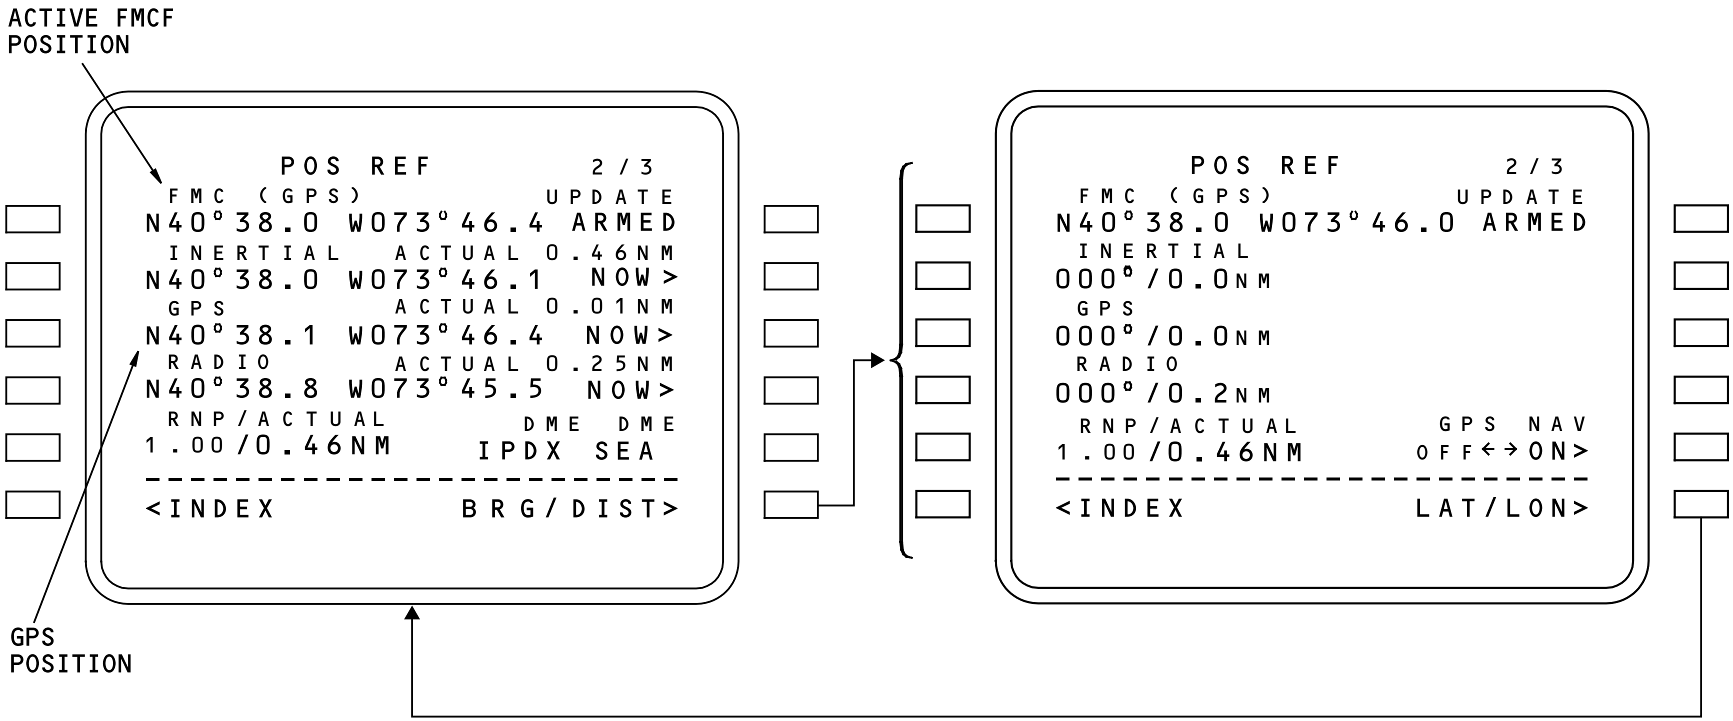
- Air data inertial reference unit (ADIRU)
- Distance measuring equipment (DME)
- Very high frequency omnidirectional ranging (VOR)
- Localizer (LOC).

The FMCF calculates the accuracy of the data from each navigation aid. These calculations show as ACTUAL next to each navigation aid on POS REF page 2 of 3. Accuracy shows in nautical miles.

Use line select keys (LSK) 2R-4R to make the active FMCF use the selected data to update the FMCF position.

The left FMCF uses the left multi-mode receiver (MMR), and the right FMCF uses the right MMR. If the onside MMR fails, the FMCFs use the offside MMR.

Use line select key 6R to see the position reference in bearing/distance format or in latitude/longitude format.



POSITION REFERENCE PAGE 2

GPS - DISPLAYS - 3

General

Position reference page three shows this information:

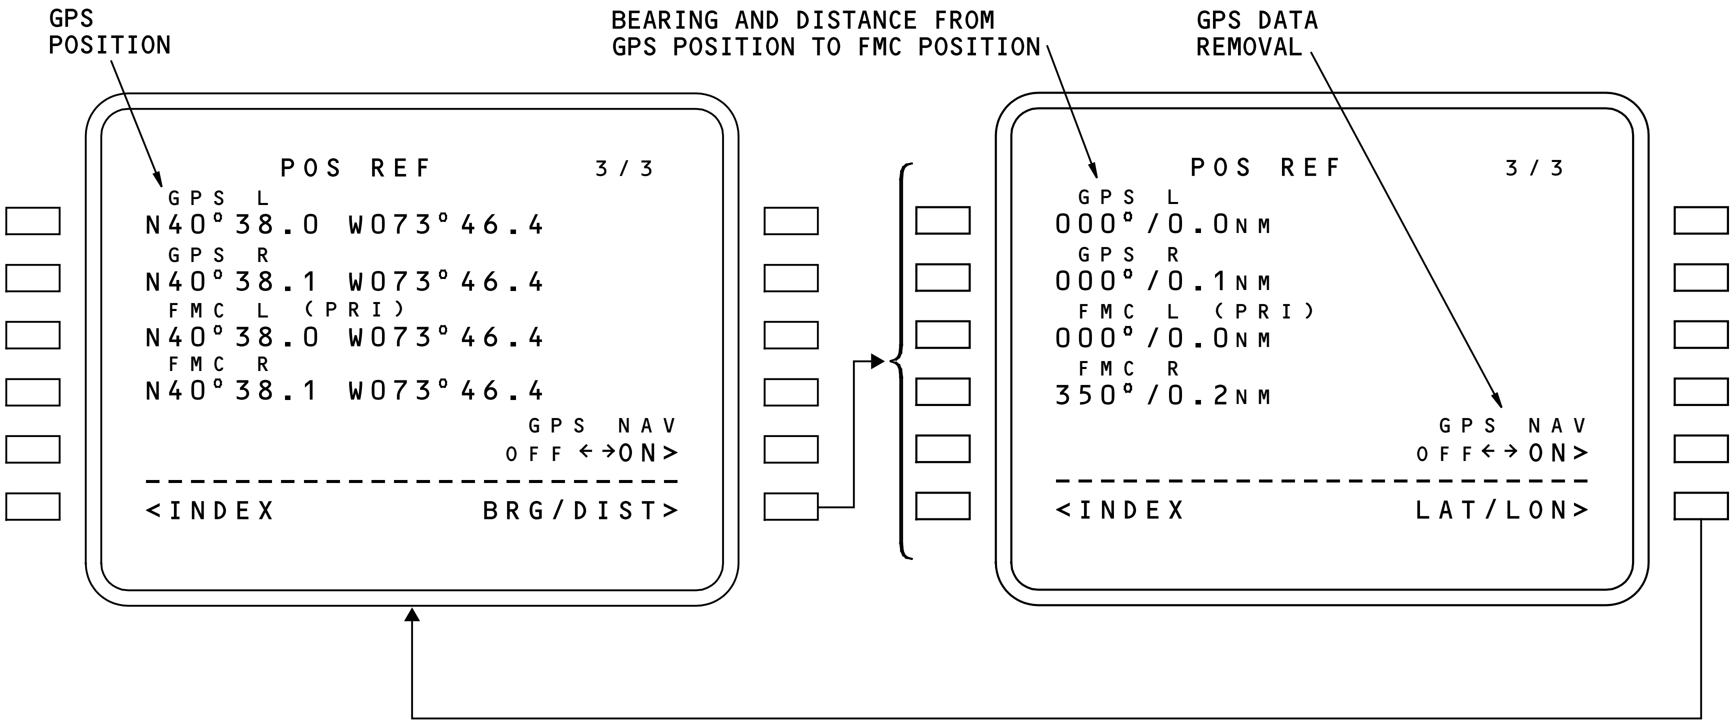
- GPS position
- Bearing and distance to the FMCF airplane position from the GPS position.

GPS Data Elimination

You can remove GPS data from the FMCF position calculation:

- Select line select key (LSK) 5R when ON shows in larger letters to remove GPS data from the FMCF calculation
- Select LSK 5R when OFF shows in larger letters to let the FMCF use GPS data.

Push LSK 6R to see the FMCF airplane position as bearing/distance or latitude/longitude.



POSITION REFERENCE PAGE 3

GPS - DISPLAYS - 3

GPS - GROUND TEST

General

There are only system tests available for the GPS. These are the system tests available:

- Left global positioning system
- Right global positioning system.

System Test

This test lets you verify the operation of the GPS function of the multi-mode receivers (MMRs).

Training Information Point

The MMRs report their operational status to the central maintenance computing system (CMCS) at all times during operation after power-up. The MMRs do not do any additional test when you do a test from the maintenance access terminal (MAT).

During power-up, the MRRs do a test of the antennas. At that time, the MRRs verify continuity on the antenna connections. The MRRs do not do a test of the antennas during operation after power-up.

VHF OMNIDIRECTIONAL RANGING (VOR) SYSTEM

Purpose

The VHF omnidirectional ranging (VOR) system is a navigation aid that gives magnetic bearing data from a VOR ground station to the airplane.

Description

The VOR ground stations transmit an omnidirectional signal and directional signal. Together the signals give magnetic radial information from 000 degrees to 359 degrees. All VOR stations reference the 000 degree to magnetic north.

The VOR system receives the ground station signals and calculates bearing data. The data goes to various systems for display and navigation use.

The VOR system supplies station audio and identifier signals to the flight deck speakers and headsets.

VHF OMNIDIRECTIONAL RANGING (VOR) SYSTEM

VOR - GENERAL DESCRIPTION

General

The VOR system has two VOR/marker beacon (MB) receivers. The receivers have both VOR and marker beacon functions. This section covers only the VOR operation of the VOR/MB receiver. The VOR receivers get RF inputs from one VOR antenna on the vertical stabilizer.

Description

The receivers get manual tune inputs from the left or right CDU or autotune inputs from the airplane information management system (AIMS) cabinets. Manual or autotune inputs both go through the AIMS cabinets, then to the VOR receivers.

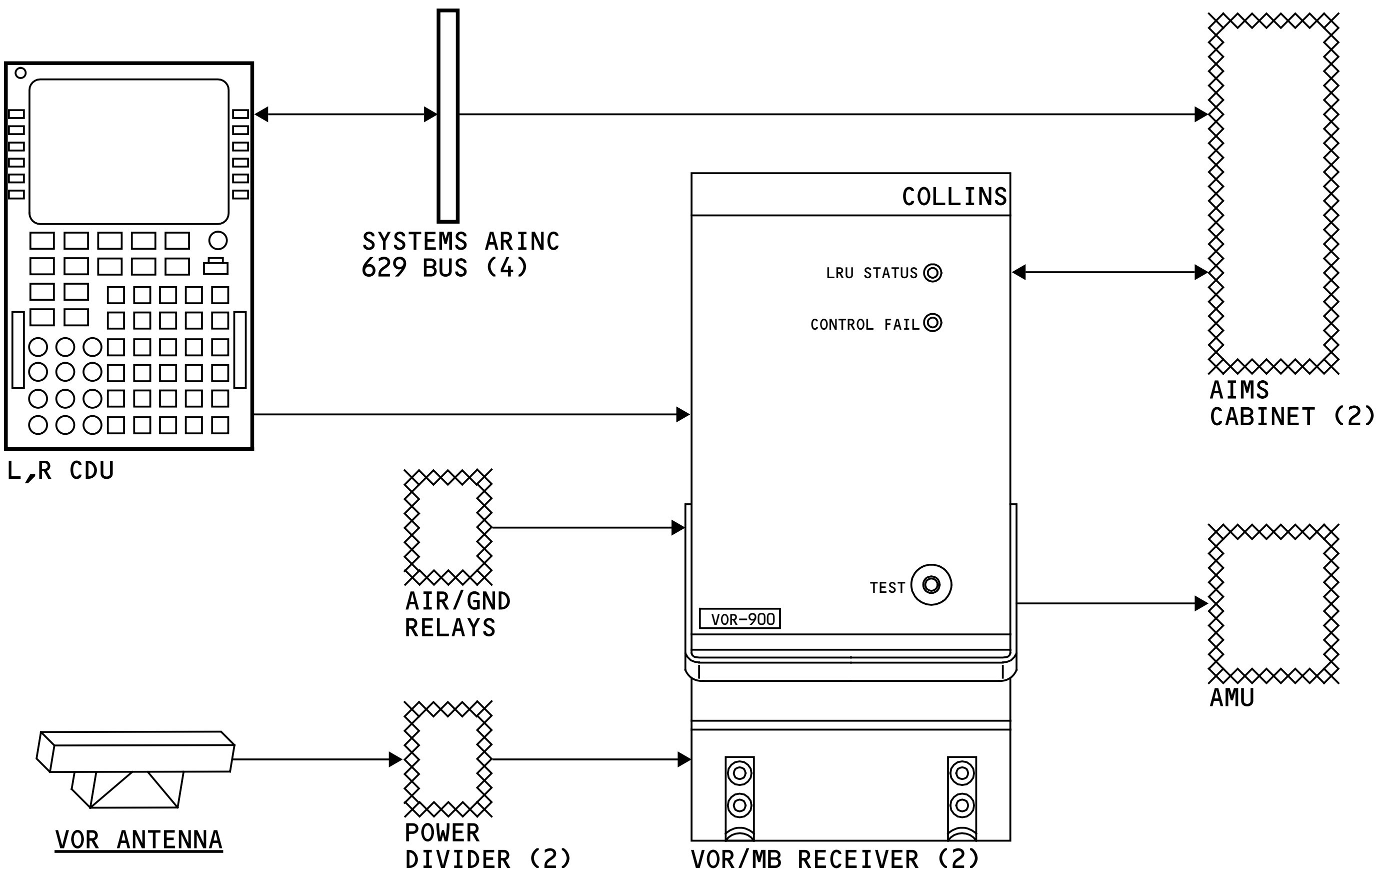
The VOR receivers can get tune inputs directly from the left or right CDU (alternate tune) if the tune inputs from the AIMS cabinets fail.

RF signals from the VOR antenna go through power dividers, then to the VOR receivers. The VOR receivers use the RF signals to calculate station bearing and to decode the Morse code station identifier signal.

The receivers get discretes from the air/ground relays.

The receivers send VOR bearing data to the AIMS cabinets to show on the navigation displays (NDs).

The VOR/MB receivers send station audio and identifier signals to the audio management unit (AMU).



34-51-00-002 Rev 4 11/06/1997

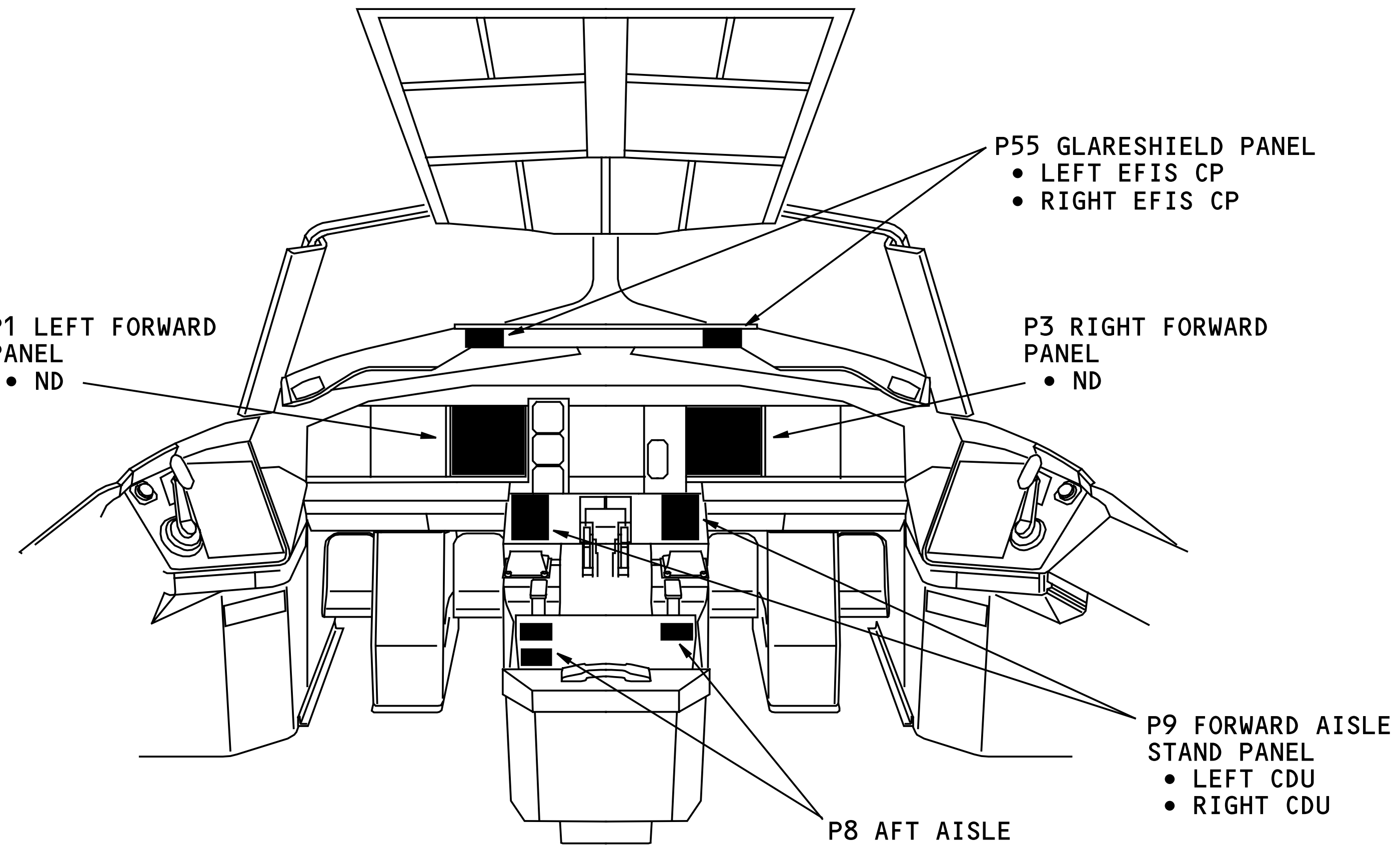
VOR - GENERAL DESCRIPTION

VOR - FLIGHT DECK COMPONENT LOCATION

General

The components on the flight deck that interface with the VOR system are:

- Captain's and first officer's navigation display (ND)
- Left and right EFIS control panel (CP)
- Left and right CDU
- Audio control panels (ACP).



34-51-00-003 Rev 1

VOR - FLIGHT DECK COMPONENT LOCATION

VOR - ANTENNA AND MAIN EQUIPMENT CENTER COMPONENT LOCATION

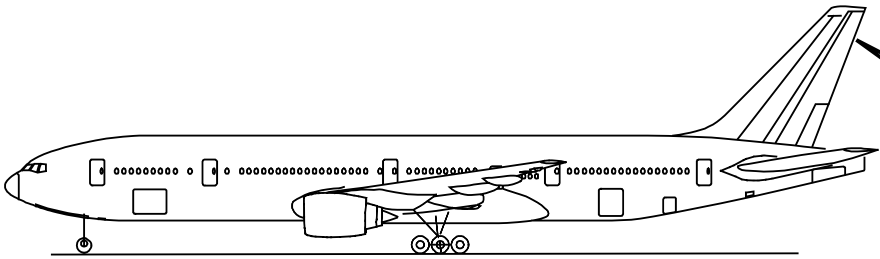
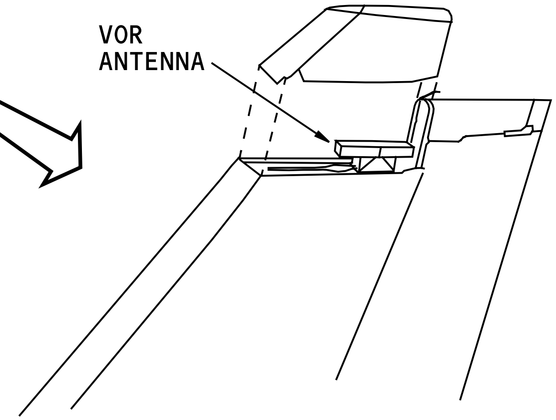
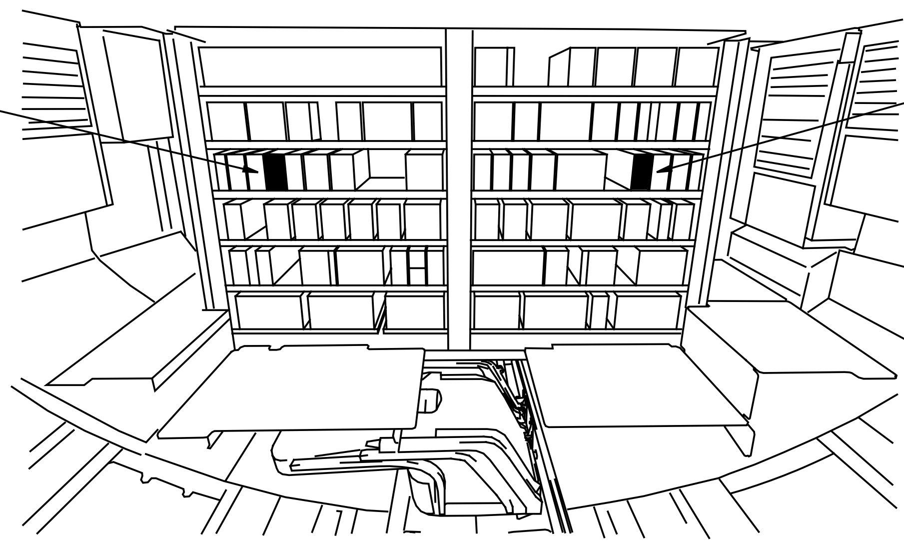
The VOR antenna is at the top of the vertical stabilizer. The left and right VOR/MB receivers are in the main equipment center on the E1 and E2 racks.



ANTENNA LOCATION





MAIN EQUIPMENT CENTER
(LOOKING AFT)

VOR - ANTENNA AND MAIN EQUIPMENT CENTER COMPONENT LOCATION

34-51-00-004 Rev 1

VOR - POWER, ANALOG, AND DISCRETE INTERFACE

General

These are the components that have interface with the VOR system:

- Circuit breakers
- VOR antenna
- Control display units (CDUs)
- AFDCs
- Air/ground relays
- Audio management unit (AMU).

Circuit Breakers

The VOR circuit breakers supply 115v ac power for operation. The left VOR/MB receiver gets power from the ac standby bus and the right VOR/MB receiver gets power from the right ac transfer bus.

CDUs

The CDUs send a frequency source select discrete to cause the VOR receivers to select the tune input from either the CDU or the AIMS cabinets. The resistor assemblies pull up the discretes to 28v dc. The left CDU sends a ground discrete to the left VOR receiver to change the source. The right CDU sends a ground discrete to the right VOR receiver to change the source.

Air/Ground Relay

The air/ground relays supply discrete inputs to the VOR/MB receivers to do these functions:

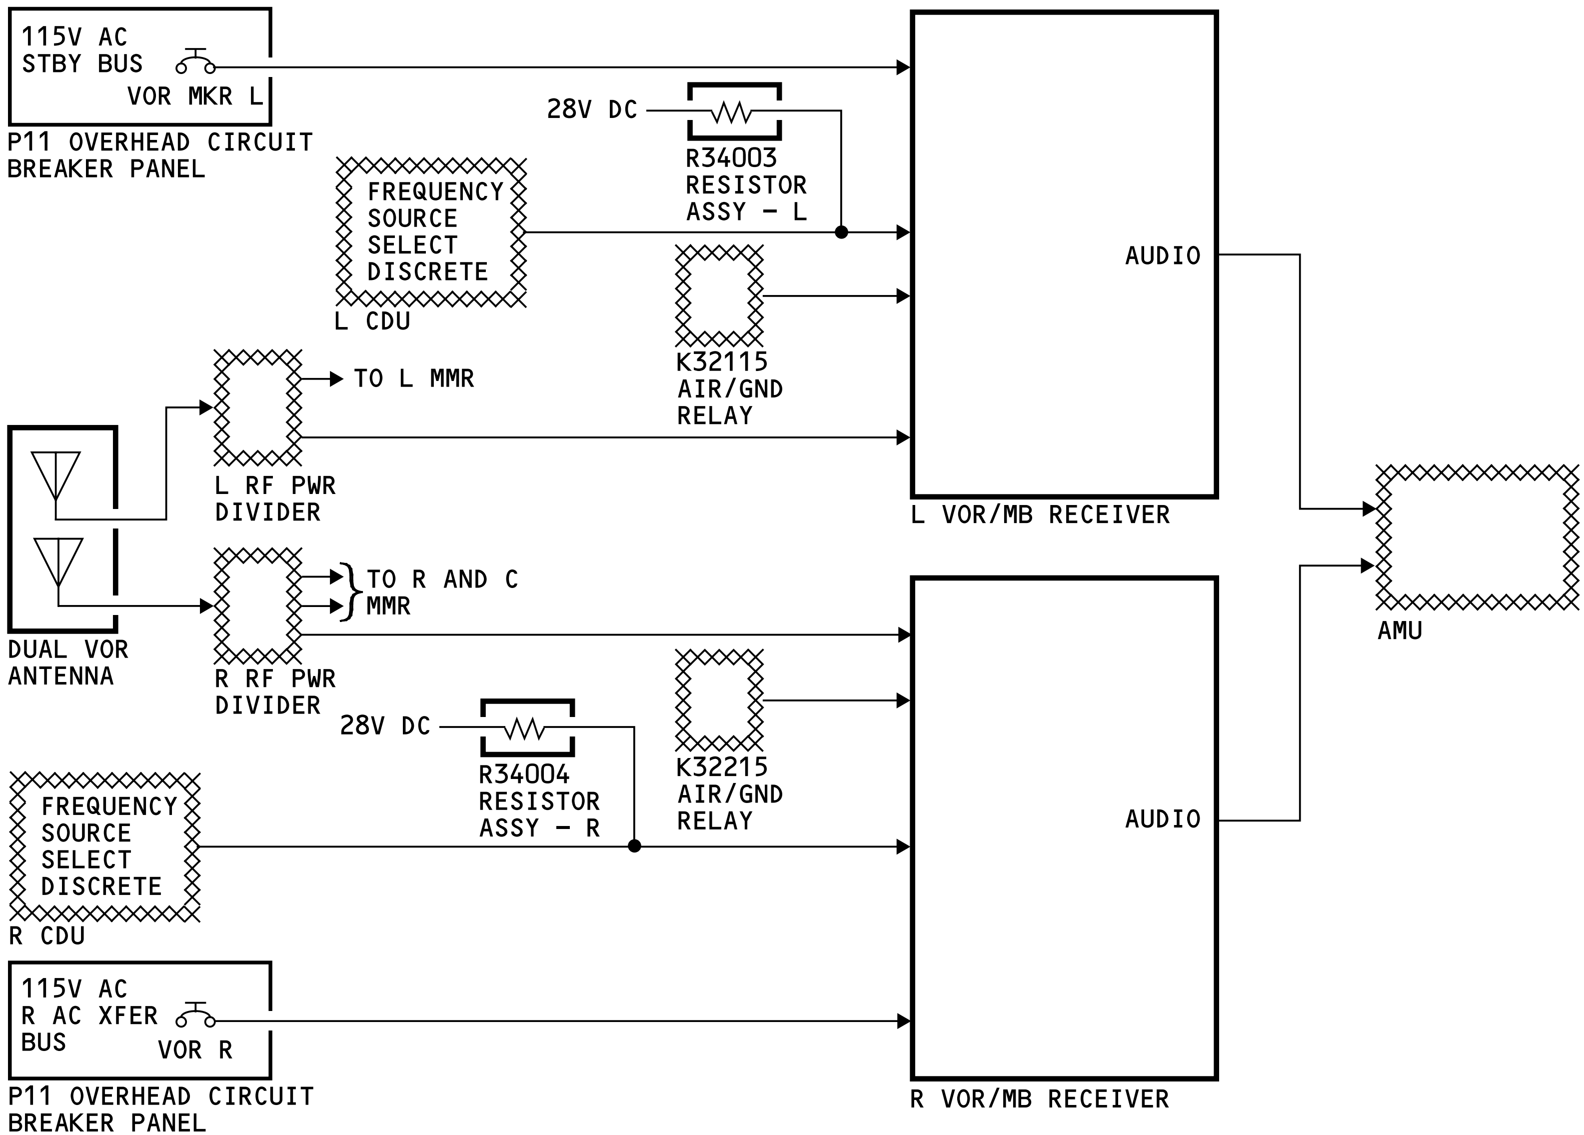
- Set flight legs (as alternate source, primary is from the CMCF of AIMS)
- Inhibit test commands in the air.

VOR Antenna

The VOR antenna sends RF signals through the left and right power dividers to the VOR/MB receivers.

Audio Management Unit

The audio management unit receives Morse code station identifier signals and station audio from the VOR receivers and supplies them to the flight interphone speakers and headsets.



34-51-00-021 Rev 2 02/27/1998

VOR - POWER, ANALOG, AND DISCRETE INTERFACE

VOR - SYSTEM INTERFACE

General

These are the components that interface with the VOR receivers:

- Left and right control display units (CDUs)
- Left and right airplane information management system (AIMS) cabinets.

All digital interfaces are on ARINC 429 data buses.

CDU

The left and right CDUs supply alternate tune inputs directly to the VOR receivers if the AIMS tune inputs fail. The left CDU alternate tunes the left VOR receiver and the right CDU alternate tunes the right VOR receiver.

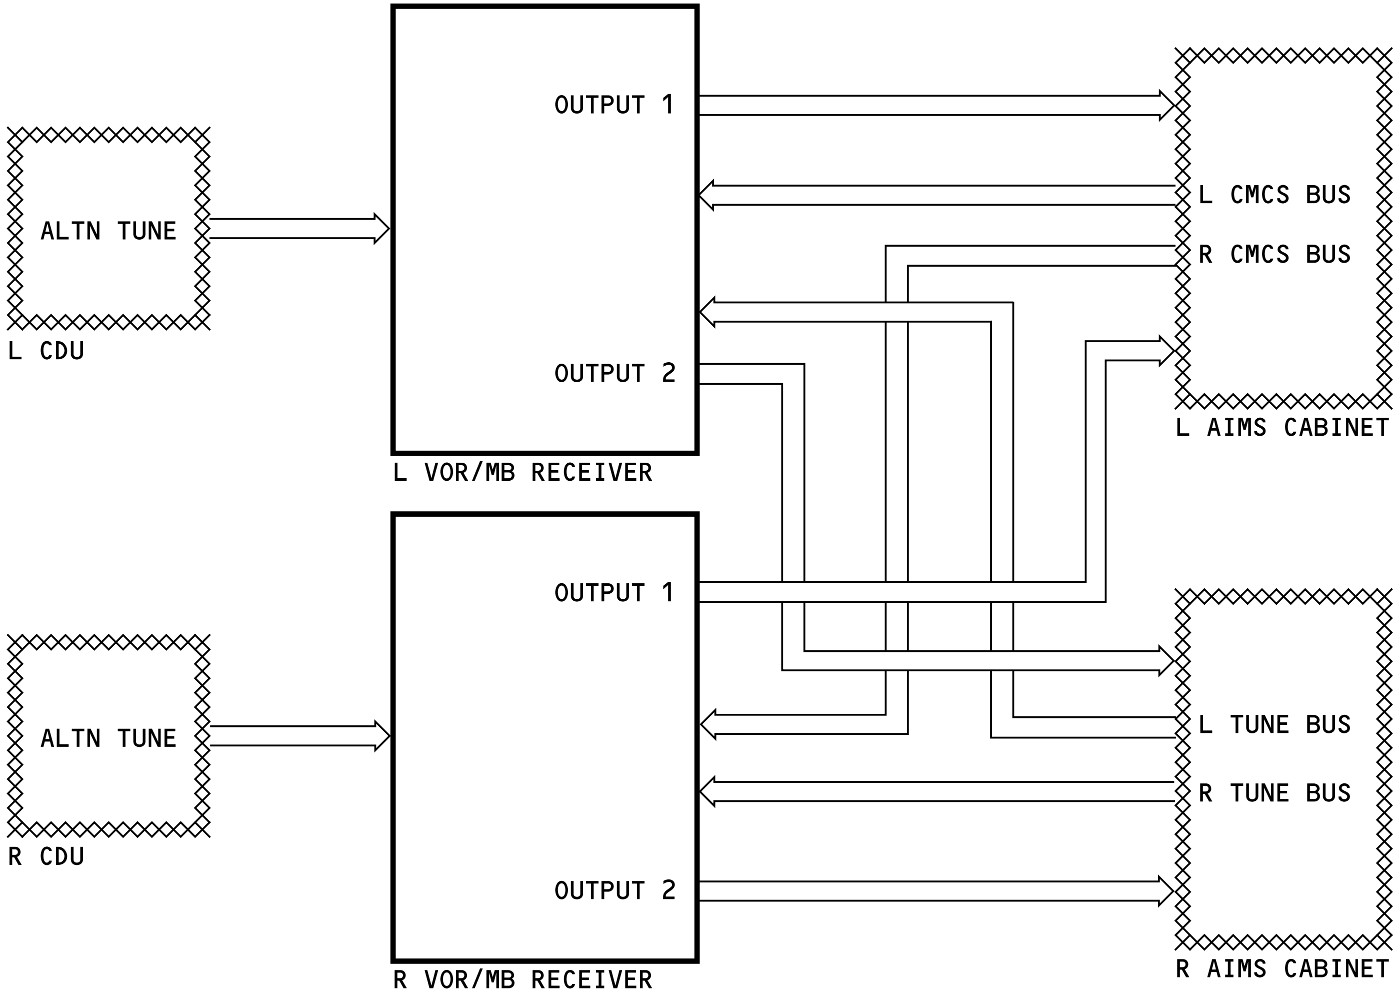
AIMS

The left AIMS cabinet sends test commands and primary flight leg information to the left and right receivers on the Left CMC bus and right CMC bus.

The right AIMS cabinet sends manual tune and autotune inputs to the left and right VOR receivers on the left tune bus and right tune bus.

VOR Outputs

Each VOR receiver has two output buses. One output bus to the left AIMS cabinet and one output bus to the right AIMS cabinet. Output bus one and two from each receiver sends VOR data, test results, and fault information to the left and right AIMS cabinets.



34-51-00-005 Rev 2

VOR - SYSTEM INTERFACE

VOR - VOR/MB RECEIVER

General

The VOR/marker beacon (VOR/MB) receiver has two receivers:

- VOR receiver
- Marker beacon receiver

Test and Indications

There are two light emitting diodes (LEDs) and a test switch on the front panel of the VOR/MB receiver. The LEDs show receiver test status when you do a test of the VOR/MB receiver. The red control fail input LED shows the status of the tune inputs. The green or red LRU status LED shows the status of the receiver test.

You can do a test of the VOR/MB receiver from the maintenance access terminal (MAT) or from the test switch on the VOR/MB receiver front panel. When you do a test of the left VOR/MB receiver, you do a test of the VOR function and the marker beacon function in the left VOR/MB receiver at the same time.

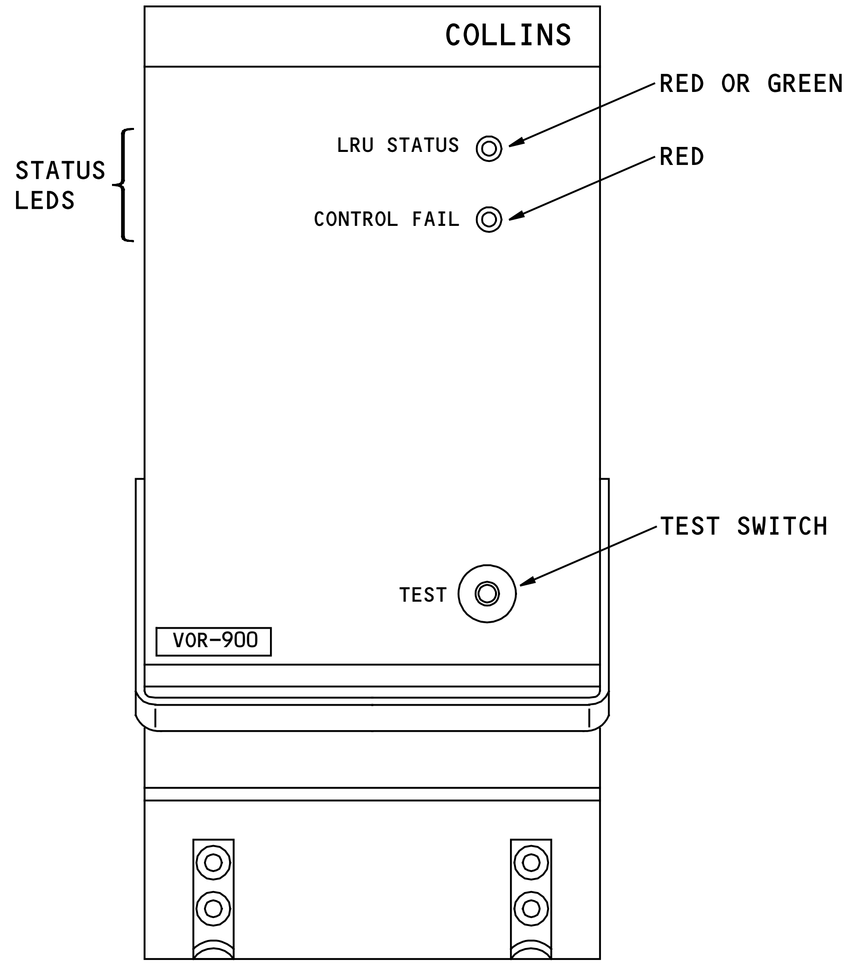
Flight Fault Memory

The VOR/MB receiver has a non-volatile flight fault memory. Only shop personnel can read the memory on the test bench.

Training Information Point

The maintenance manual and the fault isolation manual do not have a task for the line maintenance technician to do a test from the front panel of the VOR/MB receiver. You must do all tests for the VOR/MB receiver from the MAT or a PMAT.

Many LRUs on the 777 are compatible with other model airplanes that do not have a central maintenance computing system (CMCS). For that reason these LRUs have a front panel test feature.



34-51-00-006 Rev 3 05/18/95

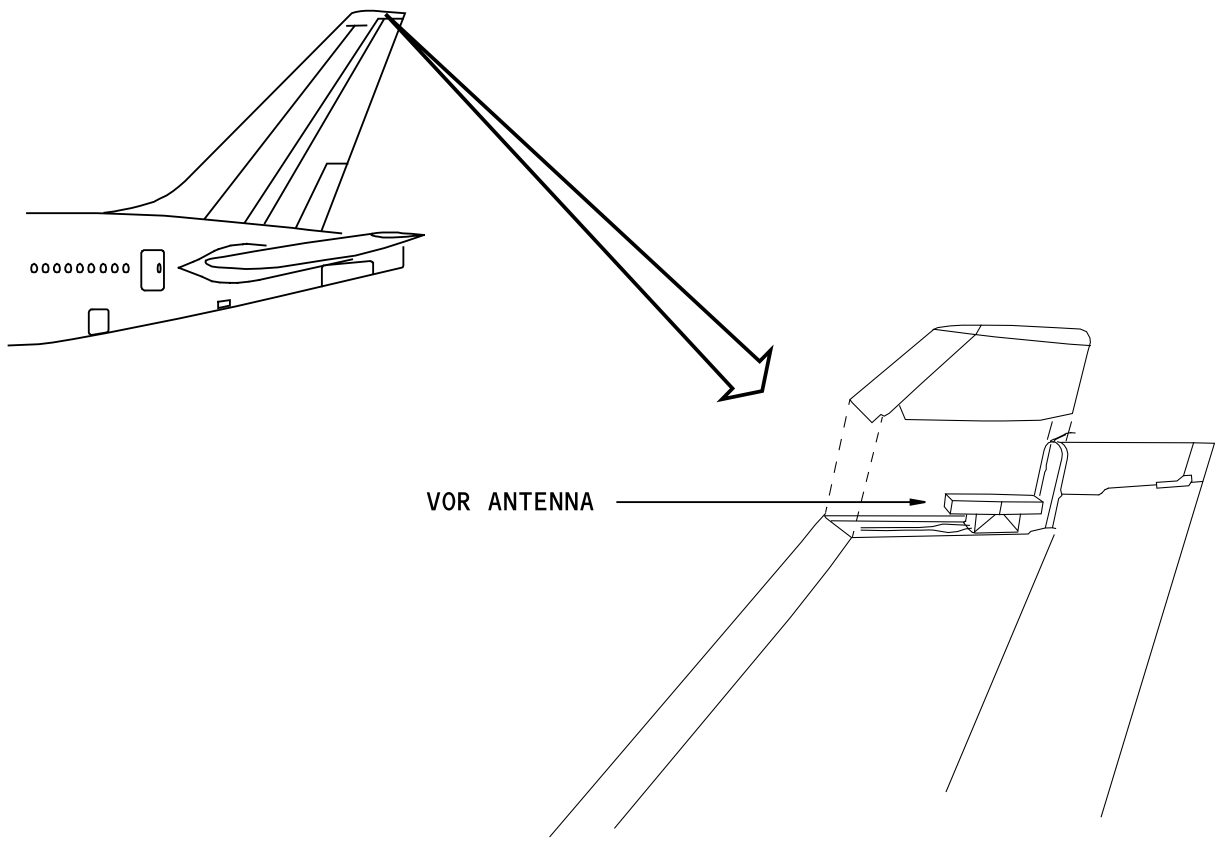
VOR - VOR/MB RECEIVER

VOR - ANTENNA

General

The VOR antenna is on the top of the vertical stabilizer. The VOR antenna receives RF signals in the frequency range of 108 MHz to 117.95 MHz. The antenna receives VOR and ILS frequencies. The VOR antenna sends VOR signals to both VOR/MB receivers.

The VOR antenna has two outputs, one to each VOR receiver.



34-51-00-007 Rev 1

VOR - ANTENNA

VOR - TUNE INPUTS

General

These are the three ways to tune the VOR receivers:

- Manually by the left, center, or right CDU
- Automatically by the AIMS cabinets
- By the CDUs as an alternate tune source.

Manual Tune

You manually tune the VOR receivers from the left or right control display unit (CDU). The center CDU can tune the receivers if the left or right CDU fails. Manual tune inputs from the CDUs go through the left and right systems ARINC 629 buses, then to the left and right AIMS cabinets.

The left AIMS cabinet sends manual and autotune data through the AIMS intercabinet ARINC 629 buses to the right AIMS cabinet.

Manual tune inputs from the left or right AIMS cabinet goes through the right AIMS cabinet to the VOR receivers.

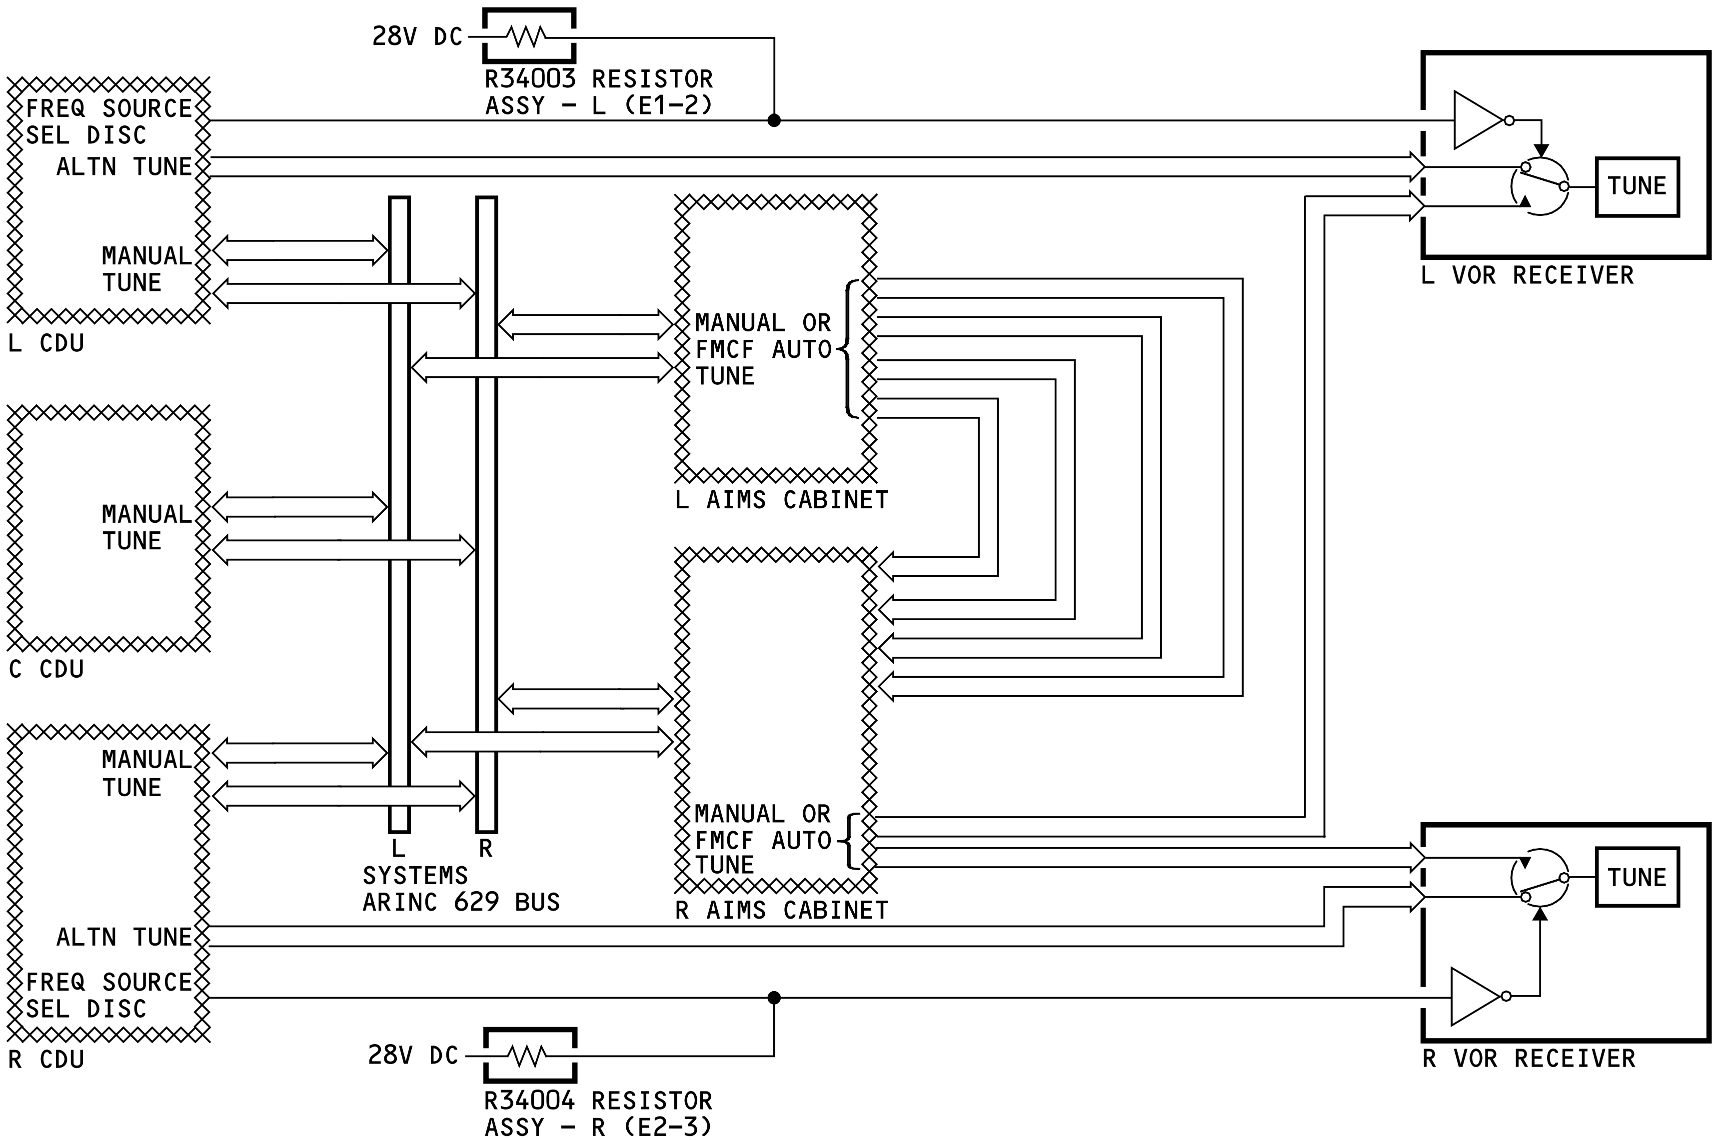
AIMS Autotune

The flight management computing function (FMCF) of the left or right AIMS cabinet can automatically tune (autotune) the VOR receivers. Autotune inputs from the left or right AIMS cabinet go through the right AIMS cabinet, then to the VOR receivers.

Alternate Tune

The CDUs monitor the AIMS cabinets tune functions. If the AIMS tune function fails, the CDUs send a frequency source select discrete to the VOR receivers that changes the tune input from the right AIMS cabinet to the tune input from the left or right CDU. The CDUs use 28v dc from a pull up resistor to set the discrete.

In the alternate tune mode, the left CDU tunes the left VOR receiver and the right CDU tunes the right VOR receiver. The center CDU has no alternate tune function.



VOR - TUNE INPUTS

34-51-00-009 Rev 3 02/06/1998

VOR - AUDIO CONTROLS

General

The audio control panels supply control inputs to the audio management unit. This lets the crew hear audio on the speakers and headsets in the flight deck.

Description

These are the controls on the audio control panel that let you hear VOR audio:

- VOR/ADF receiver selector
- VOR/ADF receiver volume control
- NAV filter selector.

VOR/ADF Receiver Selector

The VOR/ADF receiver selector lets you select ADF or VOR as the source of audio.

VOR/ADF Receiver Volume Control

The VOR/ADF receiver volume control turns on the audio and controls the volume.

NAV Filter Selector

The NAV filter selector lets you select one of these:

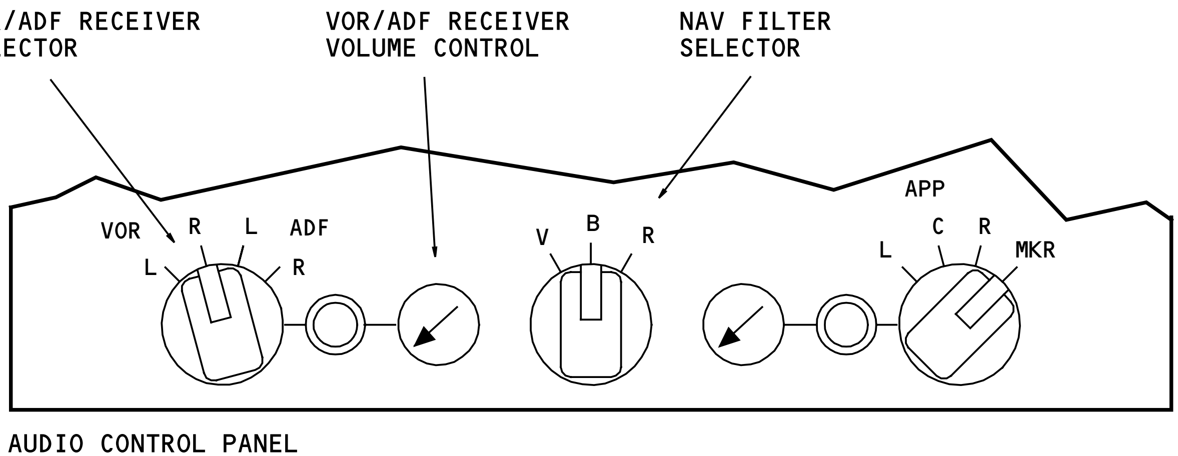
- Voice (V) audio
- Both (B) voice and range audio.
- Range (R) audio

Operation

To hear VOR audio, do this:

- Set the VOR/ADF receiver selector to the left (L) or right (R) VOR position
- Push the VOR/ADF receiver volume control to turn on the ADF audio (turn the control to adjust the volume)
- Set the NAV filter selector to the voice (V) position.

To hear the station identifier, set the NAV filter selector to either the both (B) or the range (R) position.



34-51-00-010 Rev 3 11/07/1997

VOR - AUDIO CONTROLS

VOR - CDU TUNING

General

The CDUs supply manual tune inputs during normal operation and alternate tune inputs when the AIMS tune functions fail.

Operation

To see VOR tune frequencies, push the NAV RAD key on the CDU. The NAV RADIO page shows data for the left and right VOR systems.

To manually tune a VOR receiver, enter a valid VOR frequency or identifier into the CDU scratch pad. Push line select key 1L or 1R to enter the frequency for the left or right VOR receiver.

When you manually enter a VOR frequency, the letter M shows after the frequency.

The letter A shows after the frequency when the FMCF of AIMS autotunes the receivers.

To enter the selected course, enter the course into the CDU scratchpad. Push line select key 2L or 2R to enter the course for the left or right VOR receiver.

To delete the frequency or course, push the delete (DEL) key on the CDU. The delete function shows in the CDU scratchpad. Next, push the line select key (LSK) next to the applicable VOR data line.

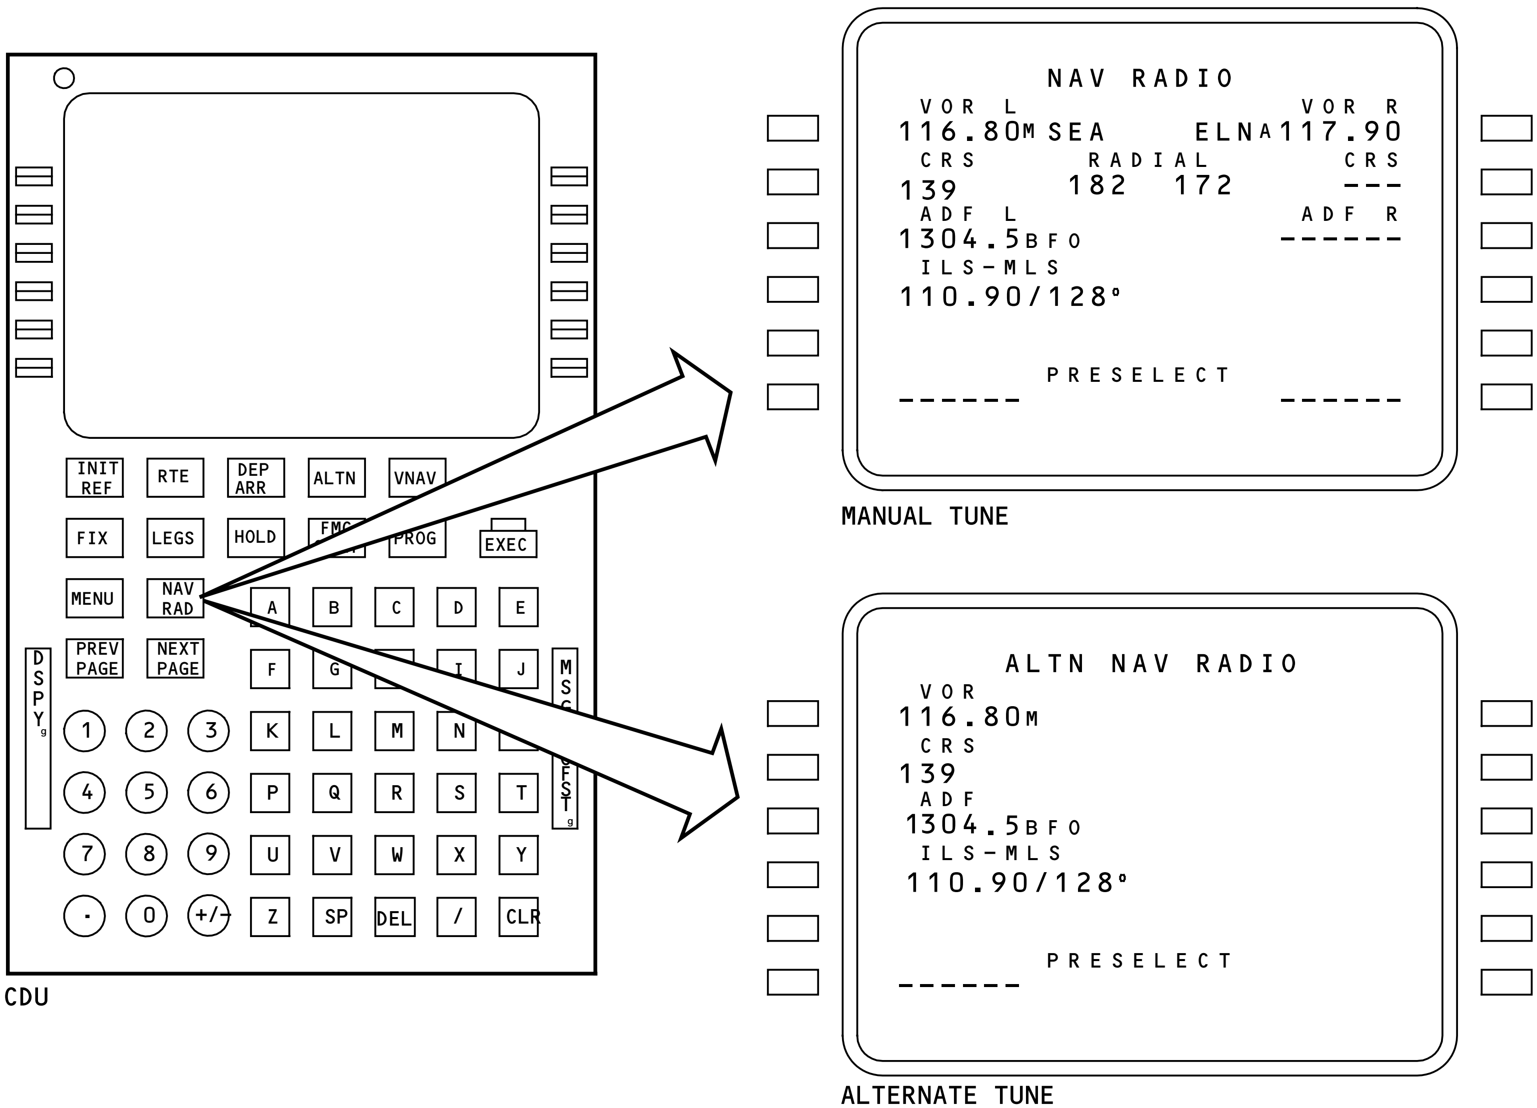
Alternate Tune

The ALTN NAV RADIO page is available only when the tune inputs from the AIMS cabinets fail.

To access the ALTN NAV RADIO page, push the NAV RAD key on the CDU.

The ALTN NAV RADIO page is different than the NAV RADIO page. The ALTN NAV RADIO page shows data for only the onside NAV radio systems. The left CDU ALTN NAV RADIO page controls the left VOR receiver. The right CDU ALTN NAV RADIO page controls the right VOR receiver.

You enter a VOR frequency and selected course the same as you do for normal manual tuning.



VOR - CDU TUNING

VOR - EFIS CONTROLS

General

The EFIS control panel has controls to select the display mode of the ND. These are the EFIS controls that cause VOR displays to show:

- Navigation display mode selector
- Left and right VOR/ADF switches.

Navigation Display Mode Selector

Use the mode selector to select the display mode. To see VOR data, set the mode selector to the VOR position.

VOR/ADF Switch

The VOR/ADF switches select the VOR or ADF receivers as the source of data for the left and right bearing pointers on the ND. There are two switches for the left and right bearing pointers. When the VOR/ADF switches are in the VOR position, VOR data shows in the approach (APP), VOR, and map modes. When the switches are set to the off position, the VOR data goes out of view.

Alternate or Backup EFIS Control Panel

You access the EFIS control page from the MENU page on the control display unit (CDU). The EFIS control page on the CDU permits alternate or backup controls for the VOR system displays.

The left CDU is the alternate or backup control for the left EFIS control panel and the right CDU is the alternate or backup for the right EFIS control panel.

When you select EFIS control from the CDUs, the onside EFIS control panel does not operate.

On the EFIS control page you can select the ND mode display for:

- APP
- VOR
- MAP.

There is no VOR display for PLAN mode. To select VOR data for the bearing pointers, you must push the OPTIONS line select key on the EFIS control page. This brings up the EFIS OPTIONS page.

The line select key next to the OFF-ADF-VOR data line on the EFIS OPTIONS page permits you to toggle between ADF or VOR data as the source of data for the bearing pointers.

OFF selection removes the bearing pointer and data.

VOR - ND VOR DISPLAYS

THIS PAGE INTENTIONALLY LEFT BLANK

VOR - ND VOR DISPLAYS

General

When the navigation display mode selector on the EFIS control panel is in the VOR position and the VOR/ADF switch is set to VOR, these displays show:

- VOR deviation bar and scale
- NAV data source
- VOR frequency or identifier
- Selected course
- Bearing pointers
- To/from pointer and indicator
- VOR data.

VOR displays show in the centered mode or expanded mode.

VOR Display Source

The VOR display source for the VOR mode is the onside VOR receiver only. If the left VOR receiver fails, the captain's VOR mode will not show VOR deviation. If the right VOR receiver fails, the first officer's VOR mode will not show VOR deviation.

VOR Deviation Bar and Scale

The deviation bar and scale shows deviation from the selected course.

NAV Data Source

The NAV data source display shows at the top right corner of the ND. The NAV data source shows which VOR system supplies the navigation data on the ND.

VOR Frequency or Identifier

The frequency or identifier shows at the top right of the ND next to the NAV data source. If the receiver gets a valid VOR ground station signal and the station identifier is present, then the station identifier replaces the frequency.

VOR Selected Course

The VOR selected course shows below the frequency or identifier. Selected course shows when there is a manual selection of the VOR station on the CDUs. The selected course becomes dashes when the AIMS cabinets autotunes the VOR stations.

Bearing Pointers

The left and right pointers show when the VOR/ADF switches are in the VOR or ADF position. The pointers show in APP, VOR, and MAP display modes. The pointers go out of view when the switches are in the off position. The pointers show around the compass arc. In the expanded mode, the pointers show if the bearing of the station is within the range of the compass arc.

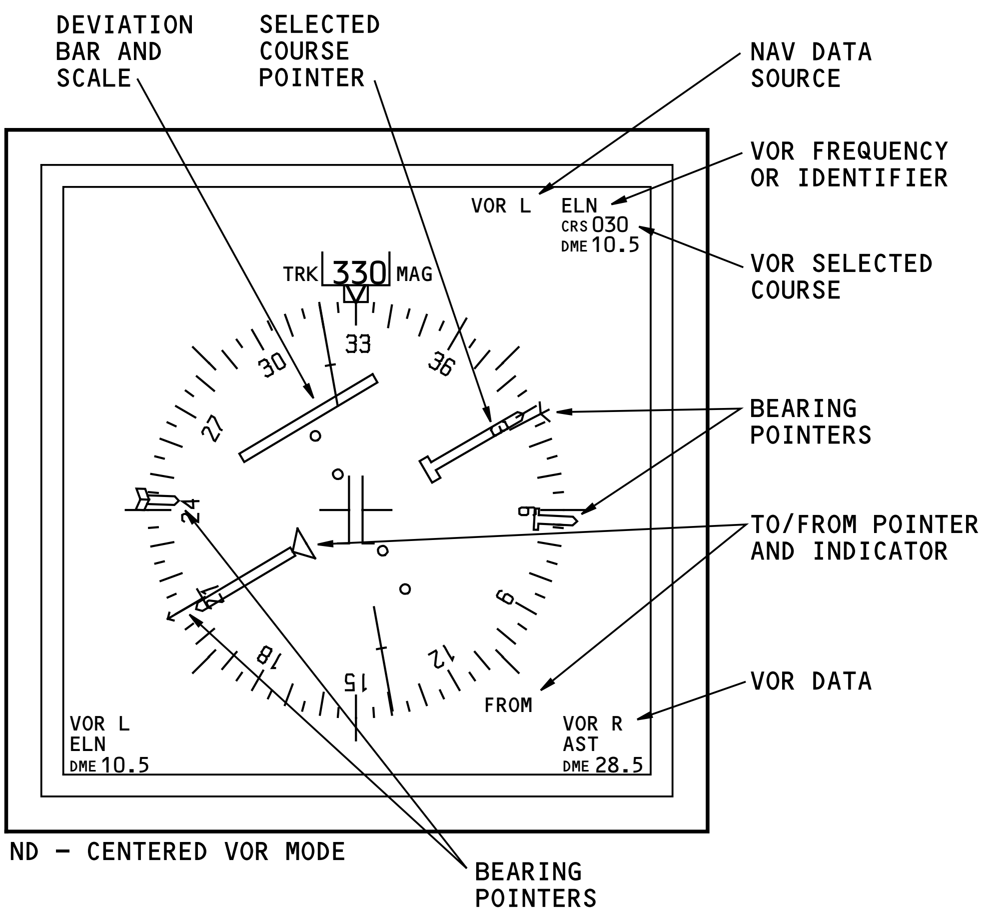
VOR - ND VOR DISPLAYS

To/From Pointer and Indicator

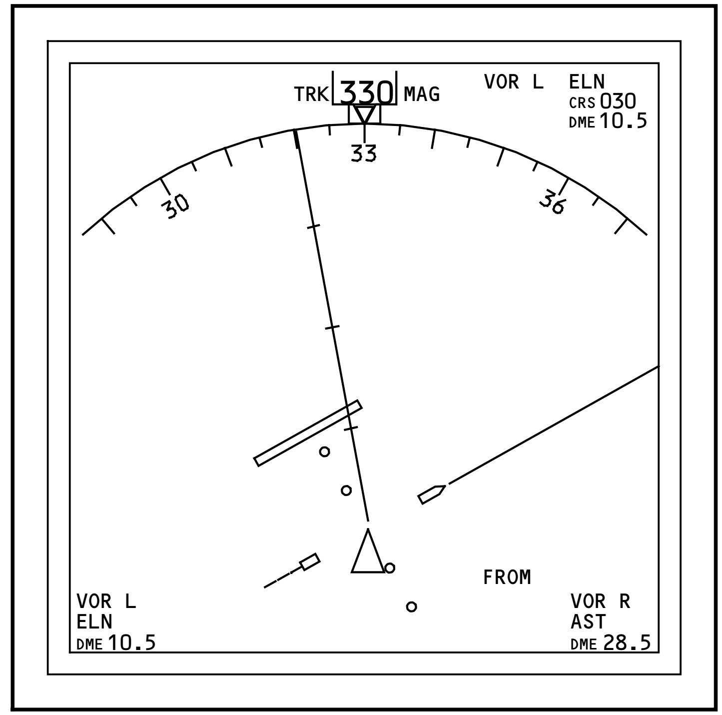
The to/from indications show if the selected course will take the airplane to or from the VOR station.

VOR/ADF Switch Data

The VOR/ADF data shows the data source for the left and right bearing pointers and their frequencies. The data shows at the lower corners of the ND in the APP, VOR, and MAP display modes.



ND - CENTERED VOR MODE



ND - EXPANDED VOR MODE

VOR - ND VOR DISPLAYS

VOR - ND VOR AUTOTUNE DISPLAY

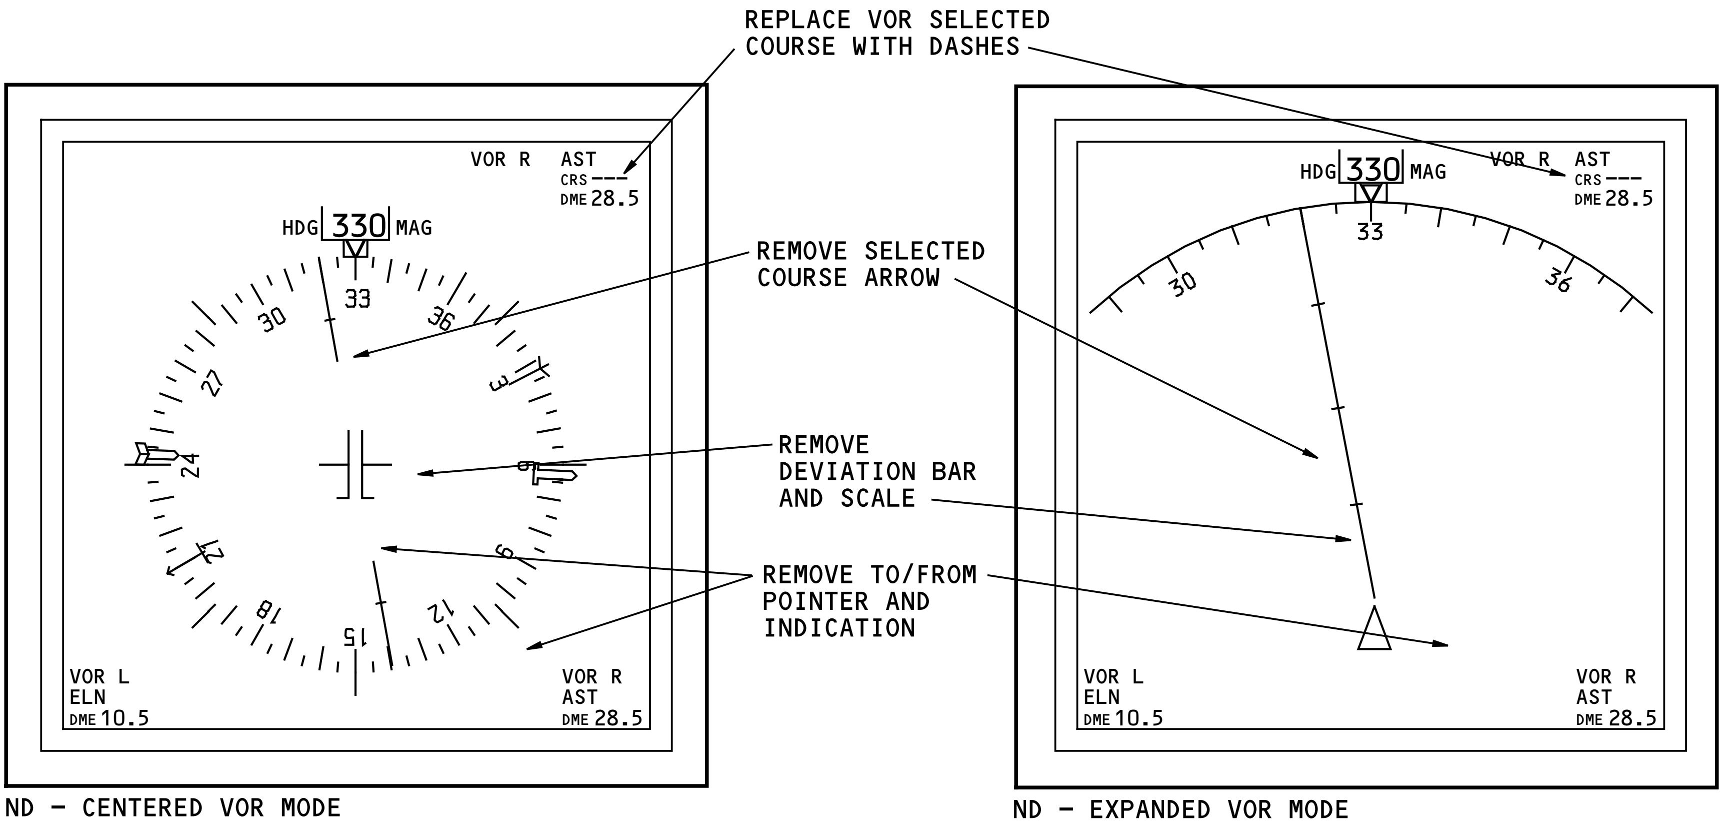
General

In autotune, the flight management computing function (FMCF) of AIMS supplies the VOR frequencies to the VOR/MB receivers.

Autotune Displays

When the FMCF of AIMS autotunes the receivers, these displays change:

- Replace VOR selected course numbers with dashes
- Remove selected course arrow
- Remove deviation bar and scale
- Remove to/from pointer and indication.



34-51-00-014 Rev 2

VOR - ND VOR AUTOTUNE DISPLAY

VOR - ND VOR MAP MODE DISPLAYS

General

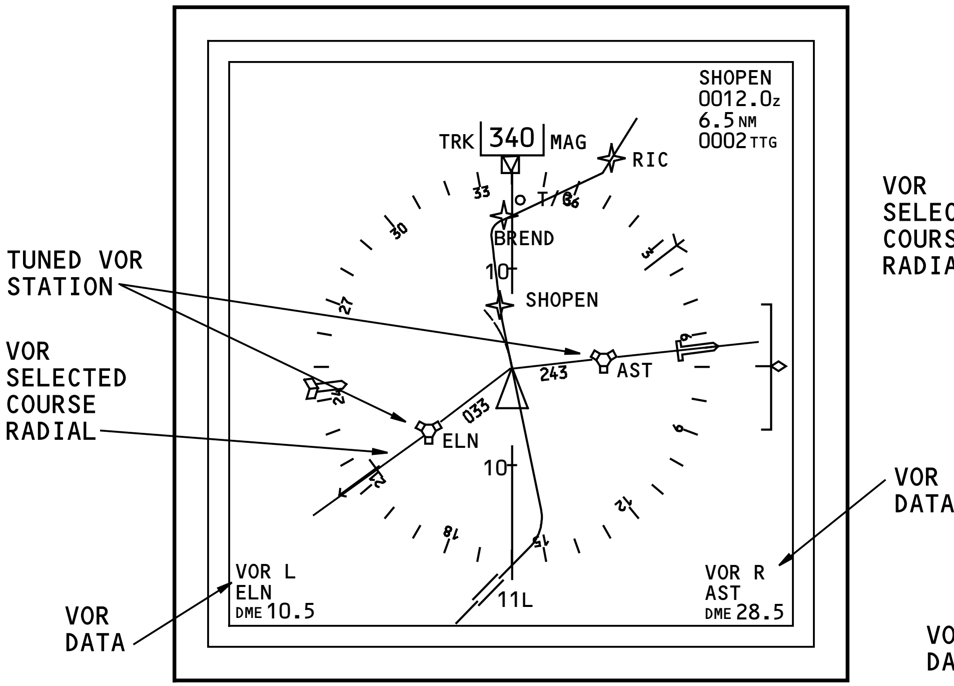
VOR data shows in the ND map mode when the VOR/ADF switches on the EFIS control panels are in the VOR position.

Description

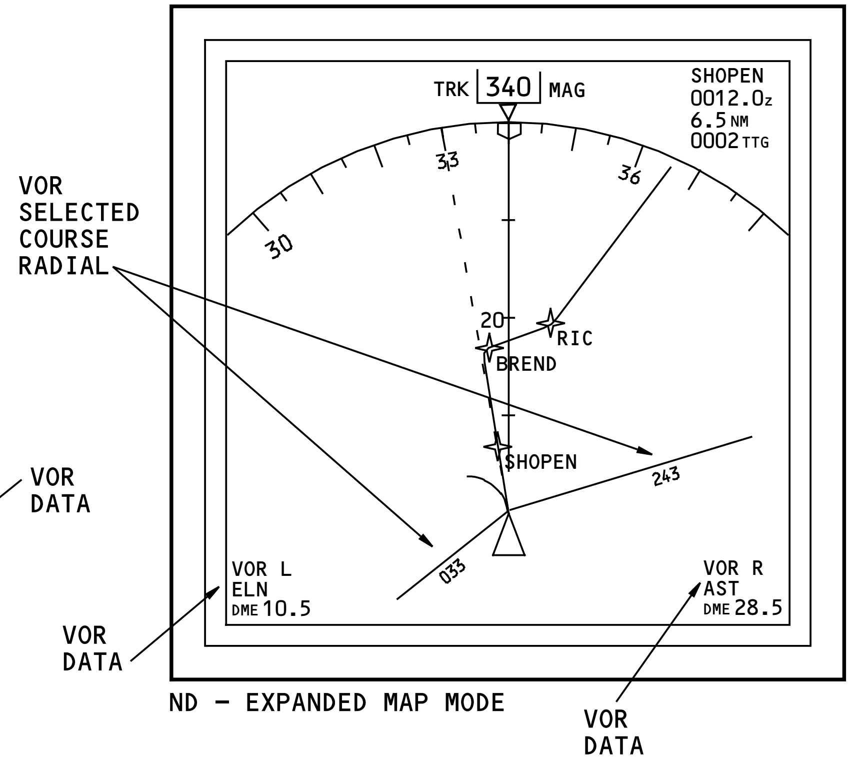
The ND map mode shows in the centered or expanded mode. The map mode shows the tuned VOR stations if they are inside the selected range. When you set the EFIS control panel VOR/ADF switches to the VOR position, the bearing pointers show on the compass scale and the VOR data show at the lower corners of the NDs.

When the VOR/ADF switches are set to the off position, the pointers and VOR data go out of view.

The VOR selected course radial shows on the ND when you push the POS switch on the EFIS control panel. The selected course number shows on the selected course radial with an R before the number to show that it is a radial.



ND – CENTERED MAP MODE



ND – EXPANDED MAP MODE

34-51-00-015 Rev 3 02/12/1998

VOR – ND VOR MAP MODE DISPLAYS

VOR - ND VOR NCD DISPLAYS

General

The inputs that are necessary for VOR displays are:

- Bearing from the VOR/MB receivers
- Frequencies from the CDUs or the AIMS cabinets
- Selected course from the CDUs or the AIMS cabinets.

When one of these inputs change to a no computed data (NCD) condition, some of the displays go out of view.

Bearing NCD

When the VOR bearing output from the VOR/MB receiver goes to an NCD condition, these VOR displays change:

- Remove the deviation bar
- Remove to/from pointer and indication.

Frequency NCD

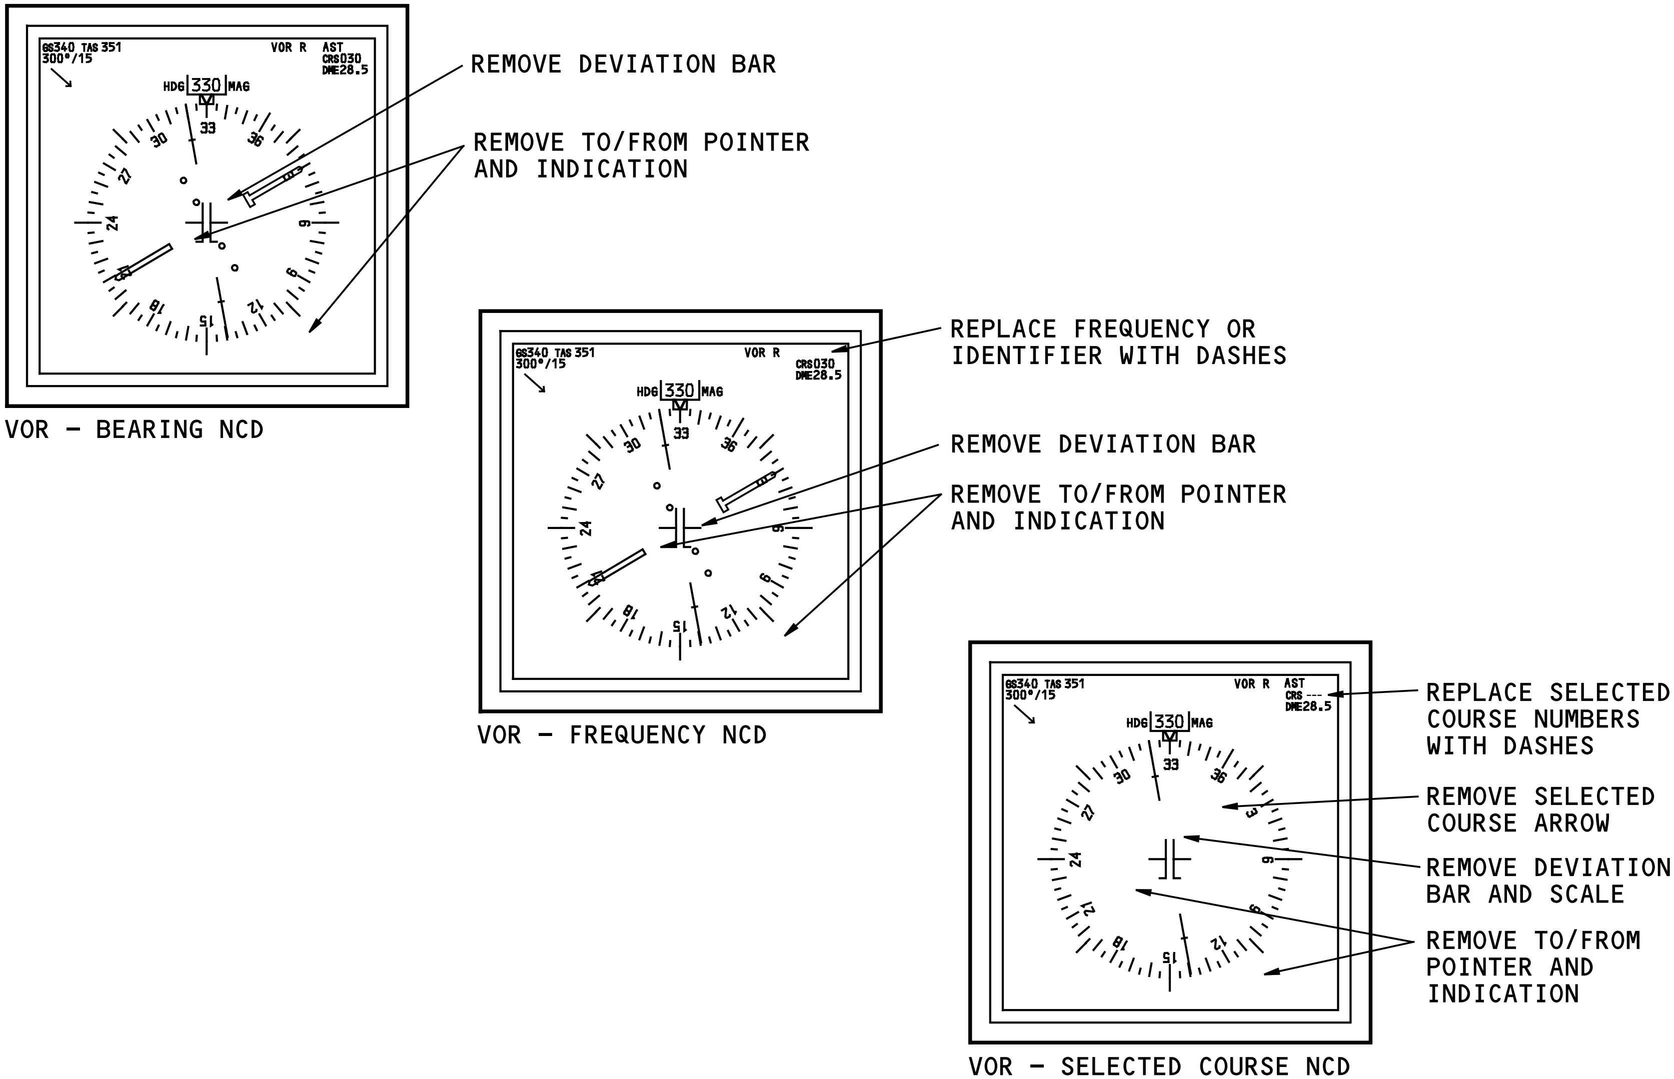
When the frequency input to the VOR/MB receiver goes to an NCD condition, these VOR displays change:

- Replace frequency or identifier with dashes
- Remove the deviation bar
- Remove the to/from pointer and indication.

Selected Course NCD

When the selected course input goes to an NCD condition, these displays change:

- Replace the selected course numbers with dashes
- Remove the selected course arrow
- Remove the deviation bar and scale
- Remove the to/from pointer and indication.



34-51-00-016 Rev 1

VOR – ND VOR NCD DISPLAYS

VOR - ND VOR INVALID DISPLAYS

General

The inputs that are necessary for VOR displays are:

- Bearing from the VOR/MB receivers
- Frequencies from the CDU or the AIMS cabinets
- Selected course from the CDUs or the AIMS cabinets.

When one of these inputs change to an invalid condition, some of the VOR displays change.

Bearing Invalid

When the VOR/MB receiver bearing goes invalid, these changes occur for the VOR displays:

- Show amber VOR flag
- Remove to/from pointer and indication.
- Remove VOR deviation bar and scale

Frequency Invalid

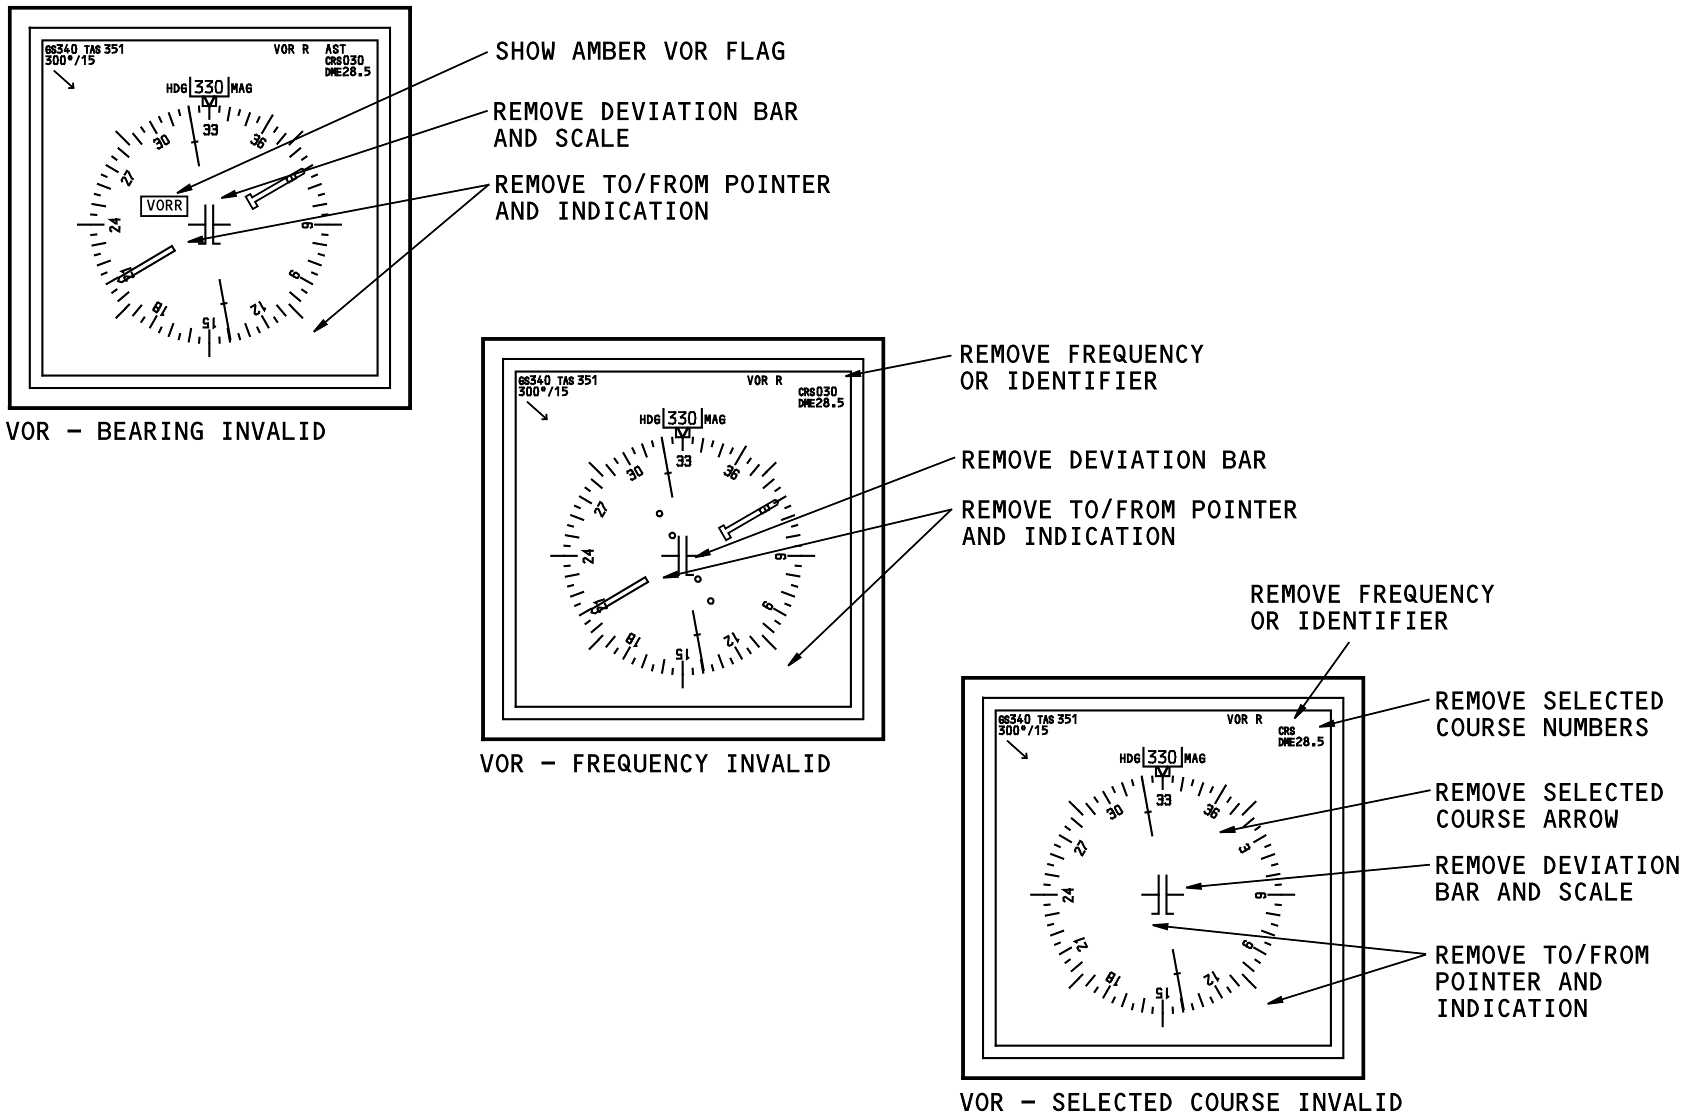
When the frequency input goes invalid, these changes occur for the VOR displays:

- Remove the VOR frequency or identifier
- Remove the to/from pointer and indication
- Remove the VOR deviation bar.

Selected Course Invalid

When the selected course input goes invalid, these changes occur for the VOR display:

- Remove the VOR frequency or identifier
- Remove the selected course number
- Remove the selected course arrow
- Remove the VOR deviation bar and scale
- Remove the to/from pointer and indication.



VOR - ND VOR INVALID DISPLAYS

34-51-00-017 Rev 1

VOR - ND VOR TEST DISPLAYS

General

When you do a test of the VOR/MB receiver, the receiver starts a test sequence that lasts approximately 15 to 20 seconds. During the test sequence, the receiver output changes to these conditions:

- Invalid data for the first three seconds
- NCD for two seconds
- Test display for approximately ten seconds.

Invalid Data Test Display

For the first three seconds of the test, the receiver output goes invalid. These are the ND display changes:

- Remove the selected course arrow
- Remove the deviation bar and scale
- Remove the to/from pointer and indication
- Show the amber VOR flag.

NCD Data Test Display

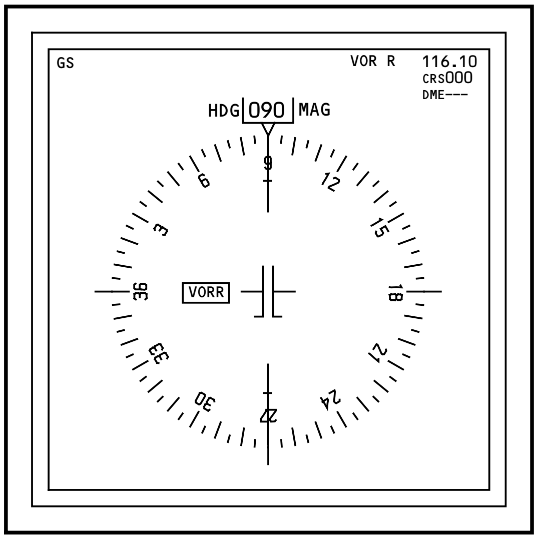
After the first three seconds of invalid data, the receiver output goes to an NCD condition for two seconds. These are the ND display changes:

- Remove the deviation bar
- Remove the to/from pointer and indication
- Show the selected course arrow
- Show the deviation scale.

VOR Test Display

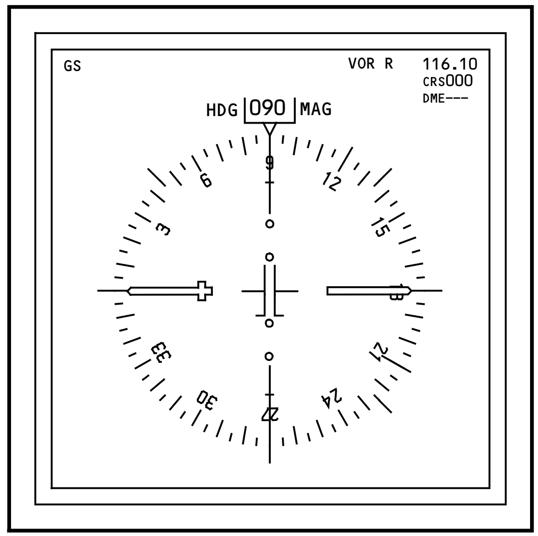
After the NCD condition, the receiver shows a valid test display for approximately ten seconds. These are the VOR test displays:

- Selected course arrow points to 0 degrees on the compass
- The deviation bar is centered if 000 is the selected course during the test
- The to/from pointer and indication show a FROM indication.



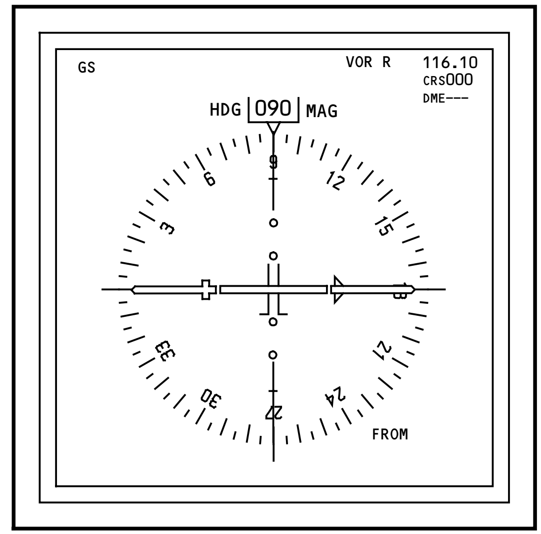
INVALID DATA FIRST 3 SECONDS:

- REMOVE SELECTED COURSE ARROW
- REMOVE DEVIATION BAR AND SCALE
- REMOVE TO/FROM POINTER AND INDICATION
- SHOW AMBER VOR FLAG



NCD DATA FOR 2 SECONDS:

- REMOVE DEVIATION BAR
- REMOVE TO/FROM POINTER AND INDICATION
- SHOW SELECTED COURSE ARROW
- SHOW DEVIATION SCALE



TEST DISPLAY FOR APPROX. 10 SECONDS:

- SELECTED COURSE POINTER AT 0 DEGREES (YOU MUST SELECT A COURSE OF 000)
- DEVIATION BAR CENTERED
- TO/FROM POINTER AND INDICATION SHOWS - FROM

VOR - ND VOR TEST DISPLAYS

VOR - GROUND TEST

General

You can test the VOR/MB system from the MAT. These are the tests that are available from the operational test selection on the MAT:

- Left VOR M/B System
- Right VOR System.

Operational Test

The operational test for the left VOR M/B system does a test of:

- Normal operation of the VOR receiver
- Normal operation of the marker beacon receiver.

The operational test for the right VOR system does a test for normal operation of the right VOR receiver.

The test is the same from the MAT or the receiver front panel test switch. The only difference is that the test from the MAT does not do a lamp test of the receiver front panel LEDs.

ILS - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

ILS - INTRODUCTION

Purpose

The multi-mode receiver (MMR) has these functions:

- Instrument landing system (ILS) function
- Global positioning system (GPS) function.

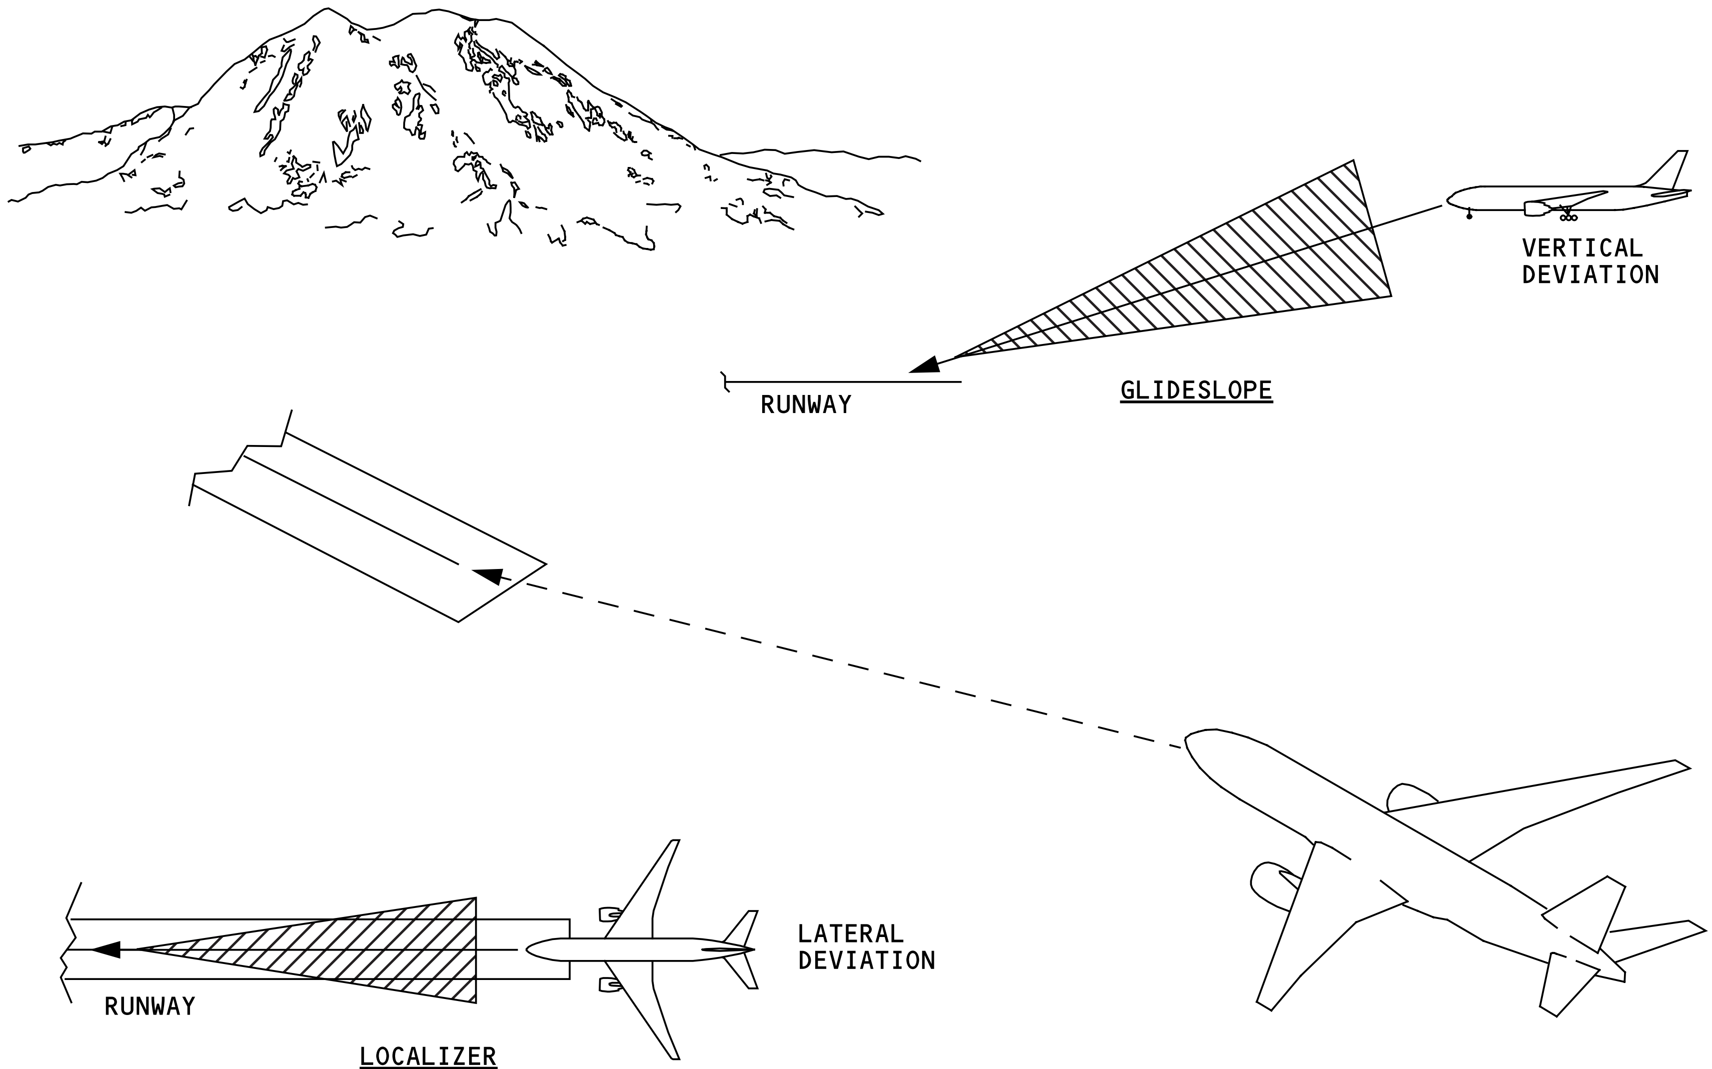
The ILS function provides lateral and vertical guidance to the runway on approach. The system uses signals from a glideslope ground station and a localizer ground station.

The glideslope station transmits signals to give the airplane a descent path to the touchdown point on the runway. The localizer station transmits signals to give a lateral path to keep the airplane centered on the runway.

The ILS system provides station audio and identifier signals to the flight interphone speakers and the headsets.

Abbreviations and Acronyms

ACP - audio control panel
AFDS - autopilot flight director system
AIMS - airplane information management system
AMU - audio management unit
CDU - control display unit
CMCS - central maintenance computing system
GPWC - ground proximity warning computer
ILS - instrument landing system
MMR - multi-mode receiver
ND - navigation display
PFD - primary flight display
VOR - VHF omnidirectional ranging



34-31-00-001 Rev 3

ILS - INTRODUCTION

ILS - GENERAL DESCRIPTION

General

The instrument landing system (ILS) has three multi-mode receivers (MMRs). The ILS system uses inputs from these antennas:

- VOR antenna
- Localizer antennas
- Glideslope capture antennas
- Glideslope track antennas.

Description

The antenna inputs go through localizer and glideslope antenna switches, then to the MMRs.

The receivers get manual tune inputs from the left or right CDU, or autotune inputs from the airplane information management system (AIMS) cabinets. The receivers get tune inputs directly from the left or right CDU (alternate tune) if the tune inputs from AIMS fails.

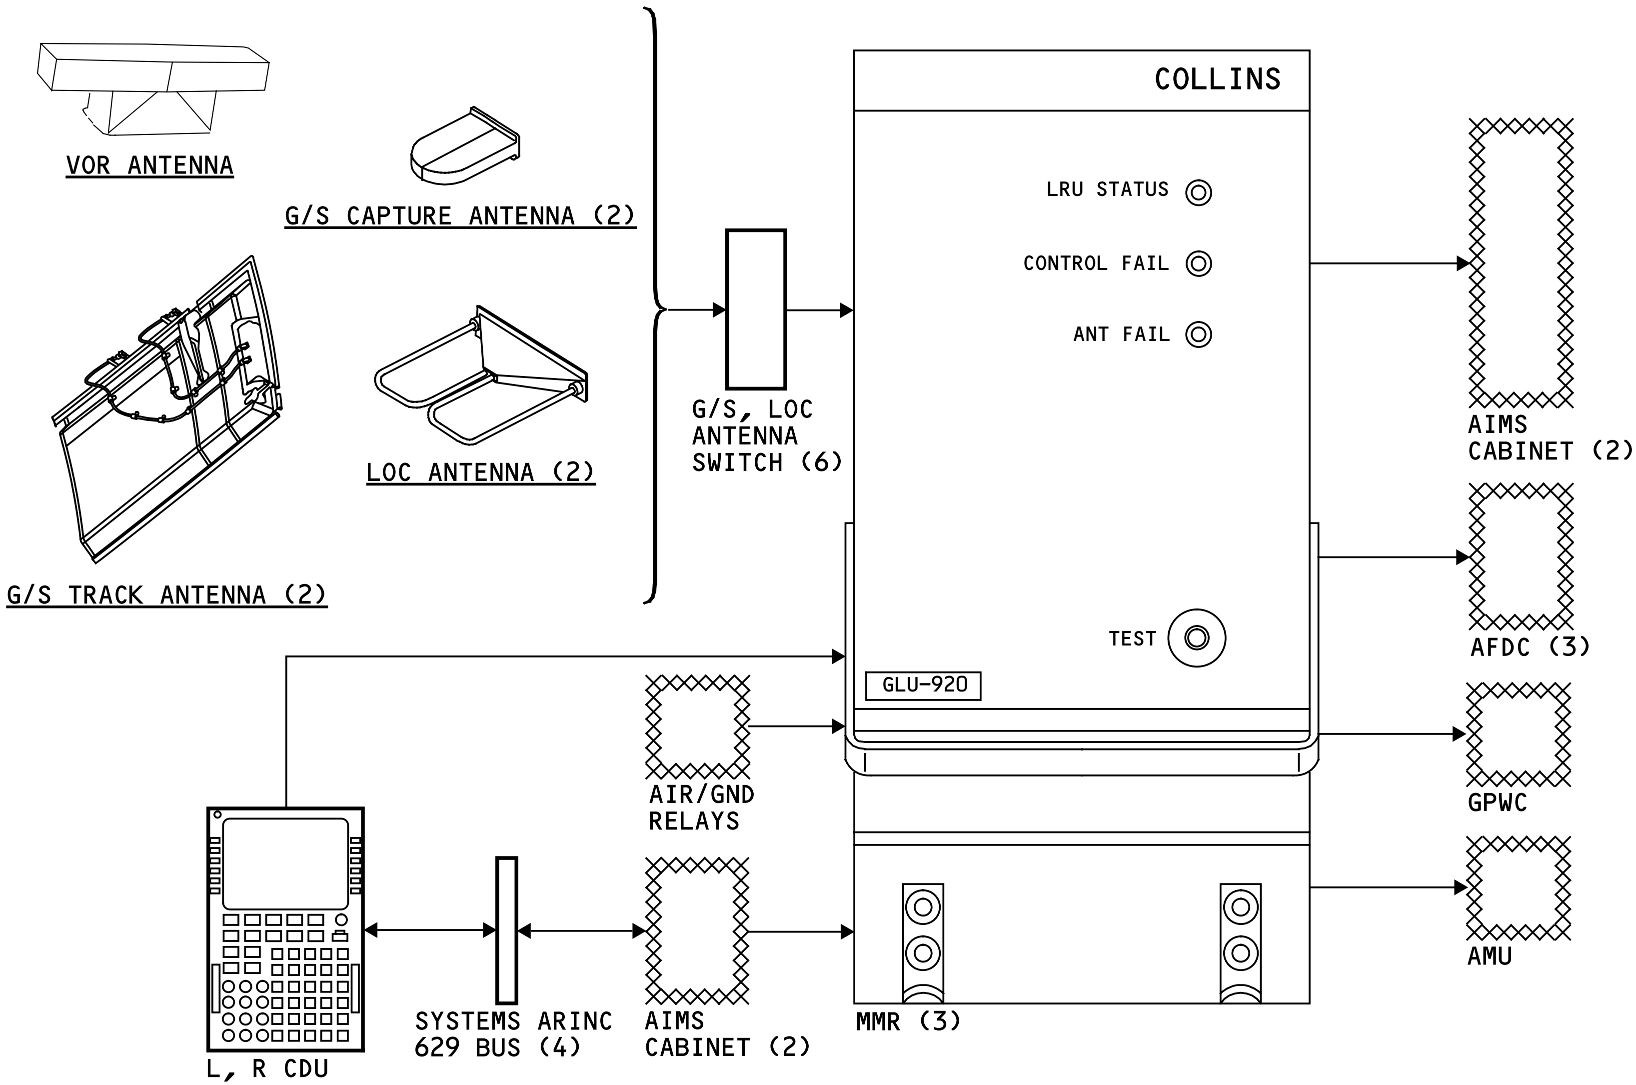
ILS deviations go to both AIMS cabinets to show ILS data on the primary flight displays (PFDs) and navigation displays (NDs).

ILS deviations go to the autopilot flight director computers (AFDCs) for autoland calculations.

The left MMR sends glideslope deviation to the ground proximity warning computer (GPWC) for mode 5 alerts.

The receivers also send station audio and identifier signals to the audio management unit (AMU).

The receivers get discrete inputs from the air/ground relays.



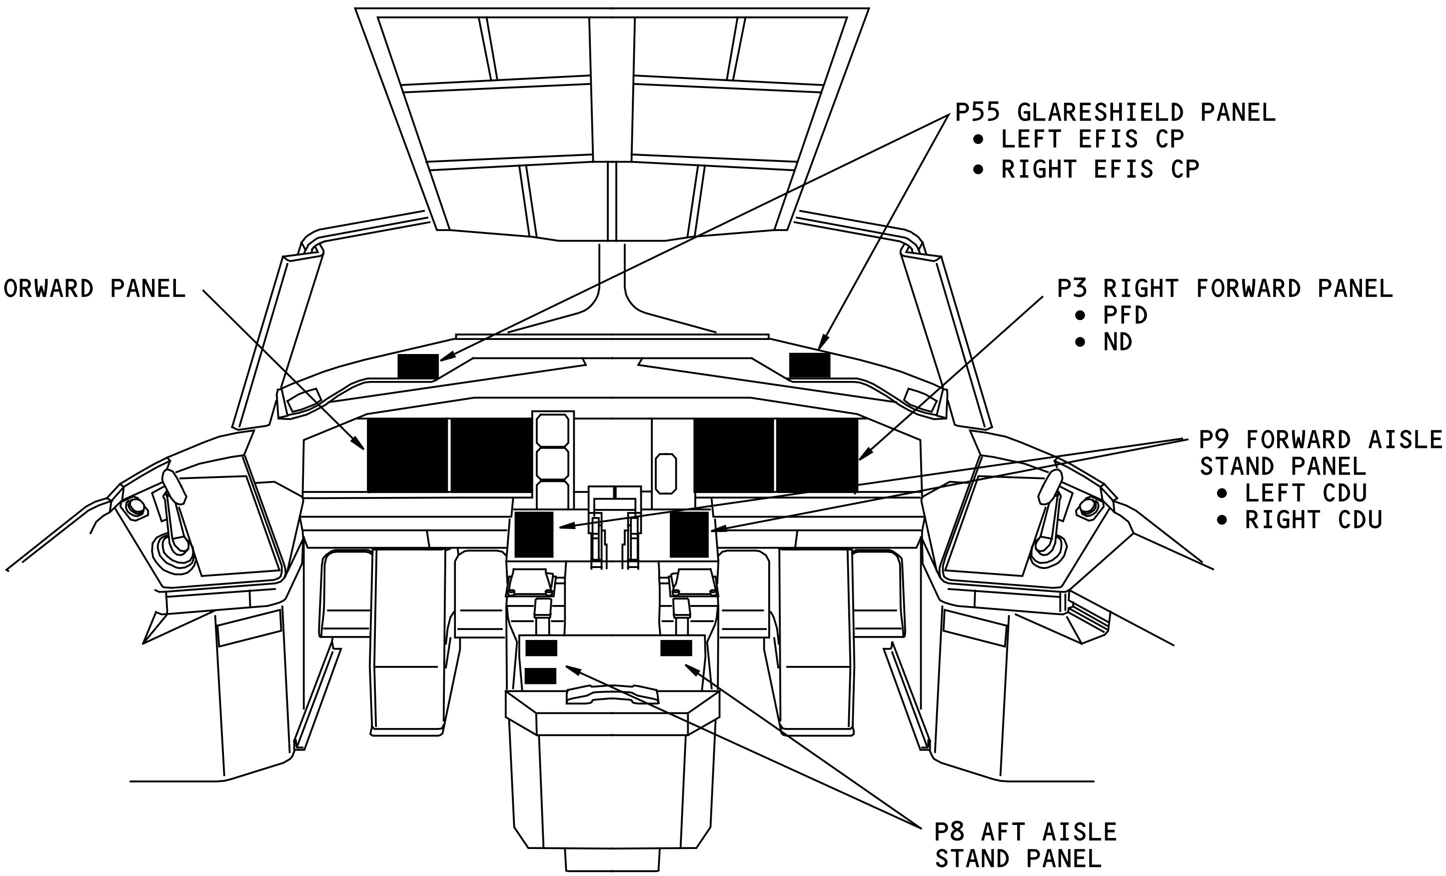
ILS - GENERAL DESCRIPTION

ILS - FLIGHT DECK COMPONENT LOCATION

General

The components on the flight deck that interface with the ILS system are:

- Left and right EFIS control panels (CP)
- Captain's and first officer's primary flight displays (PFD) and navigation displays (ND)
- Left and right CDUs
- Audio control panels (ACP).



34-31-00-003 Rev 2

ILS - FLIGHT DECK COMPONENT LOCATION

ILS - MAIN EQUIPMENT CENTER COMPONENT LOCATIONS

Equipment Center

The ILS components in the main equipment center are:

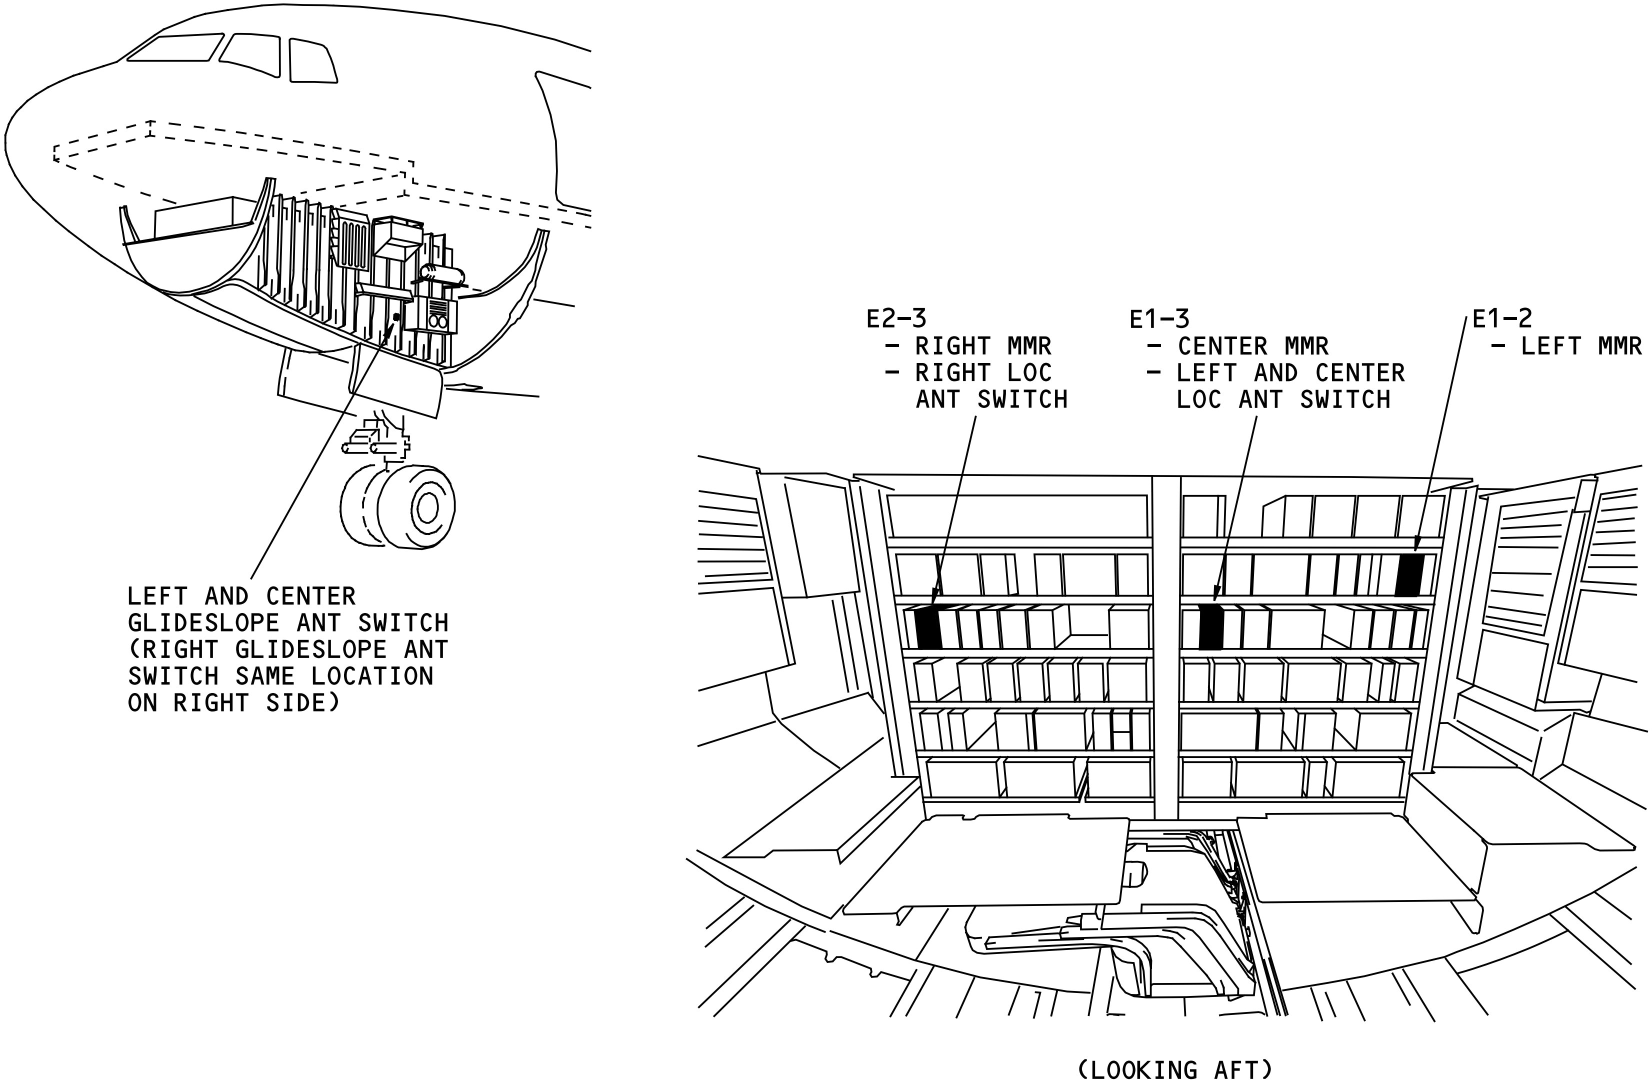
- Left, center, and right glideslope antenna switches
- Left, center, and right multi-mode receivers (MMRs)
- Left, center, and right localizer antenna switches
- Left and right RF power dividers.

The left MMR is on the E1-2 shelf. The center MMR is on the E1-3 shelf. The right MMR is on the E2-3 shelf.

The localizer antenna switches are on the electronic equipment racks (E1 and E2) in the main equipment center. The left localizer antenna switch is on the E1-2 shelf. The center localizer antenna switch is on the E1-3 shelf. The right localizer antenna switch is on the E2-3 shelf.

The glideslope antenna switches are in the forward section of the main equipment center, on the left and right sides of the nose wheel well.

There are two RF power dividers in the main equipment center. The left power divider is on the E1-3 shelf. The right power divider is on the E2-2 shelf.



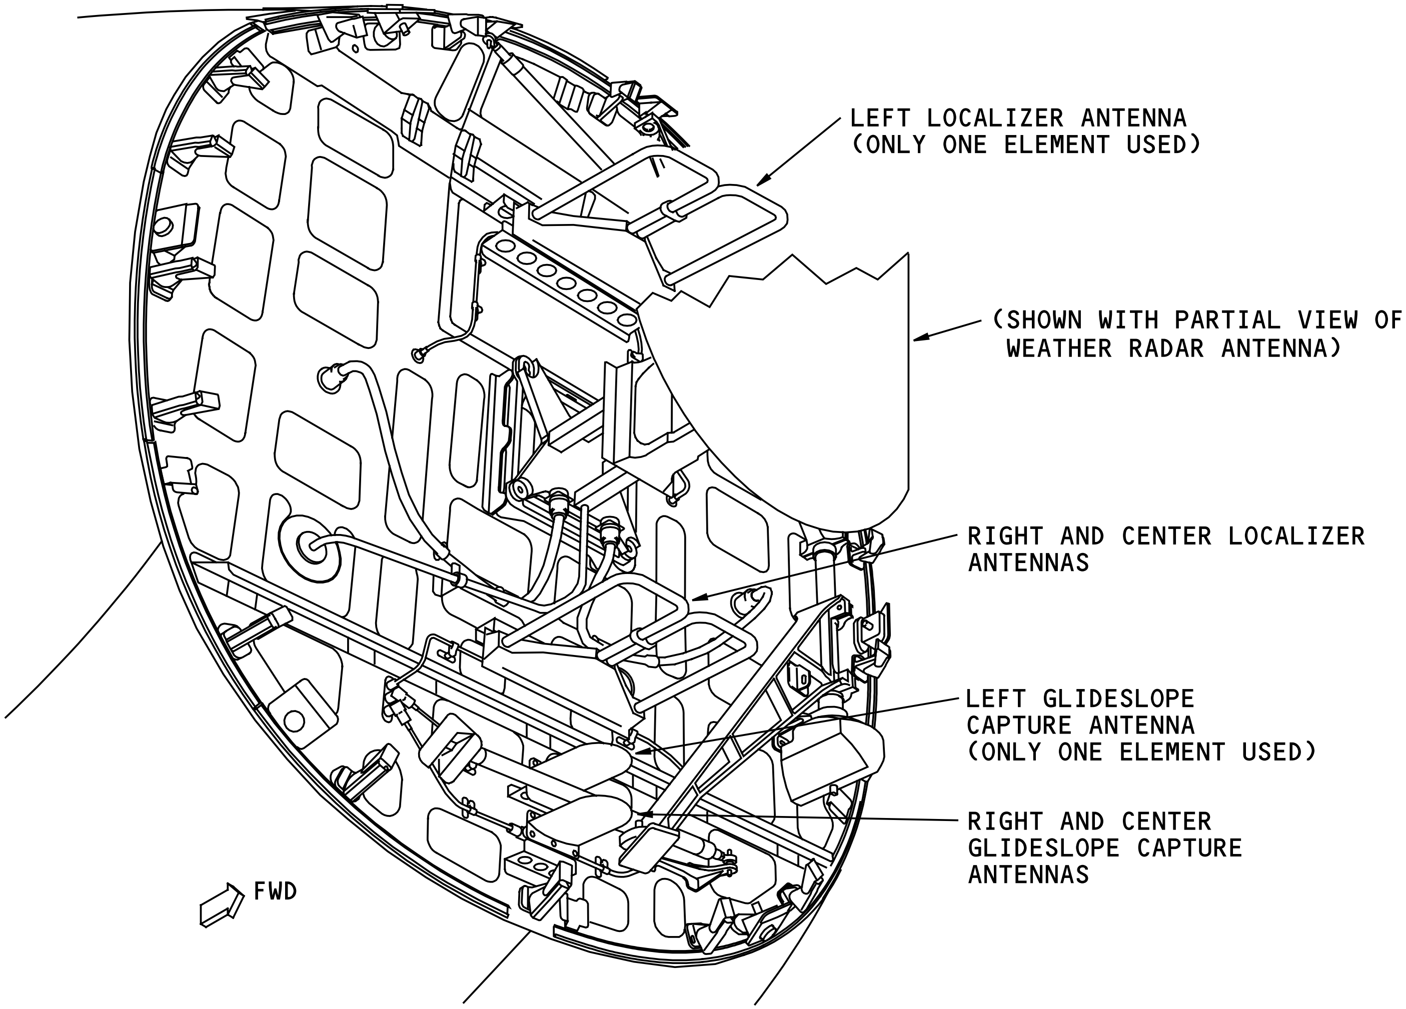
ILS - MAIN EQUIPMENT CENTER COMPONENT LOCATIONS

ILS - NOSE RADOME COMPONENT LOCATIONS

General

The ILS components in the nose radome are:

- Left localizer antenna
- Right and center localizer antennas
- Left glideslope capture antenna
- Right and center glideslope capture antennas.



34-31-00-005 Rev 0

ILS - NOSE RADOME COMPONENT LOCATIONS

ILS - FUSELAGE COMPONENT LOCATIONS

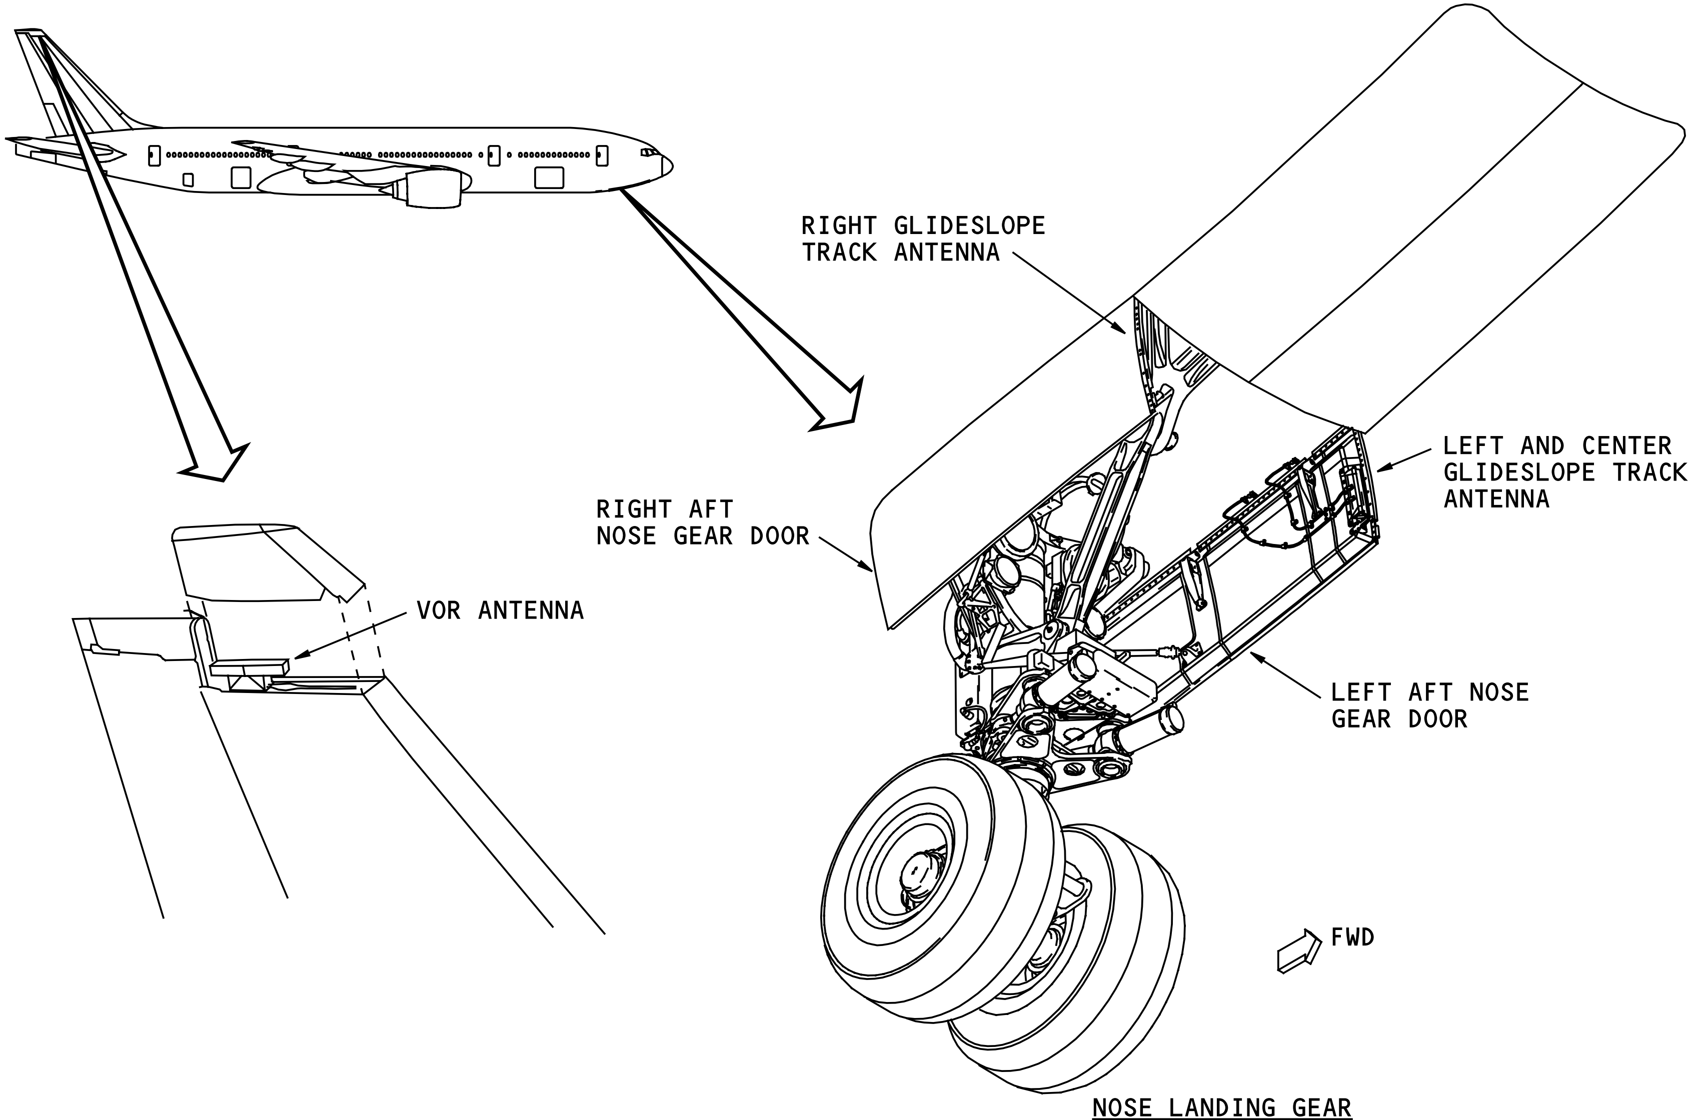
VOR Antenna

The VOR antenna is on top of the vertical stabilizer. The VOR antenna receives VOR and localizer signals.

Glideslope Track Antennas

The glideslope track antennas are on the leading edge of the left and right aft nose gear doors.

The left and center glideslope track antennas are on the left aft nose gear door and the right glideslope track antenna is on the right aft nose gear door.



34-31-00-006 Rev 2 06/17/1996

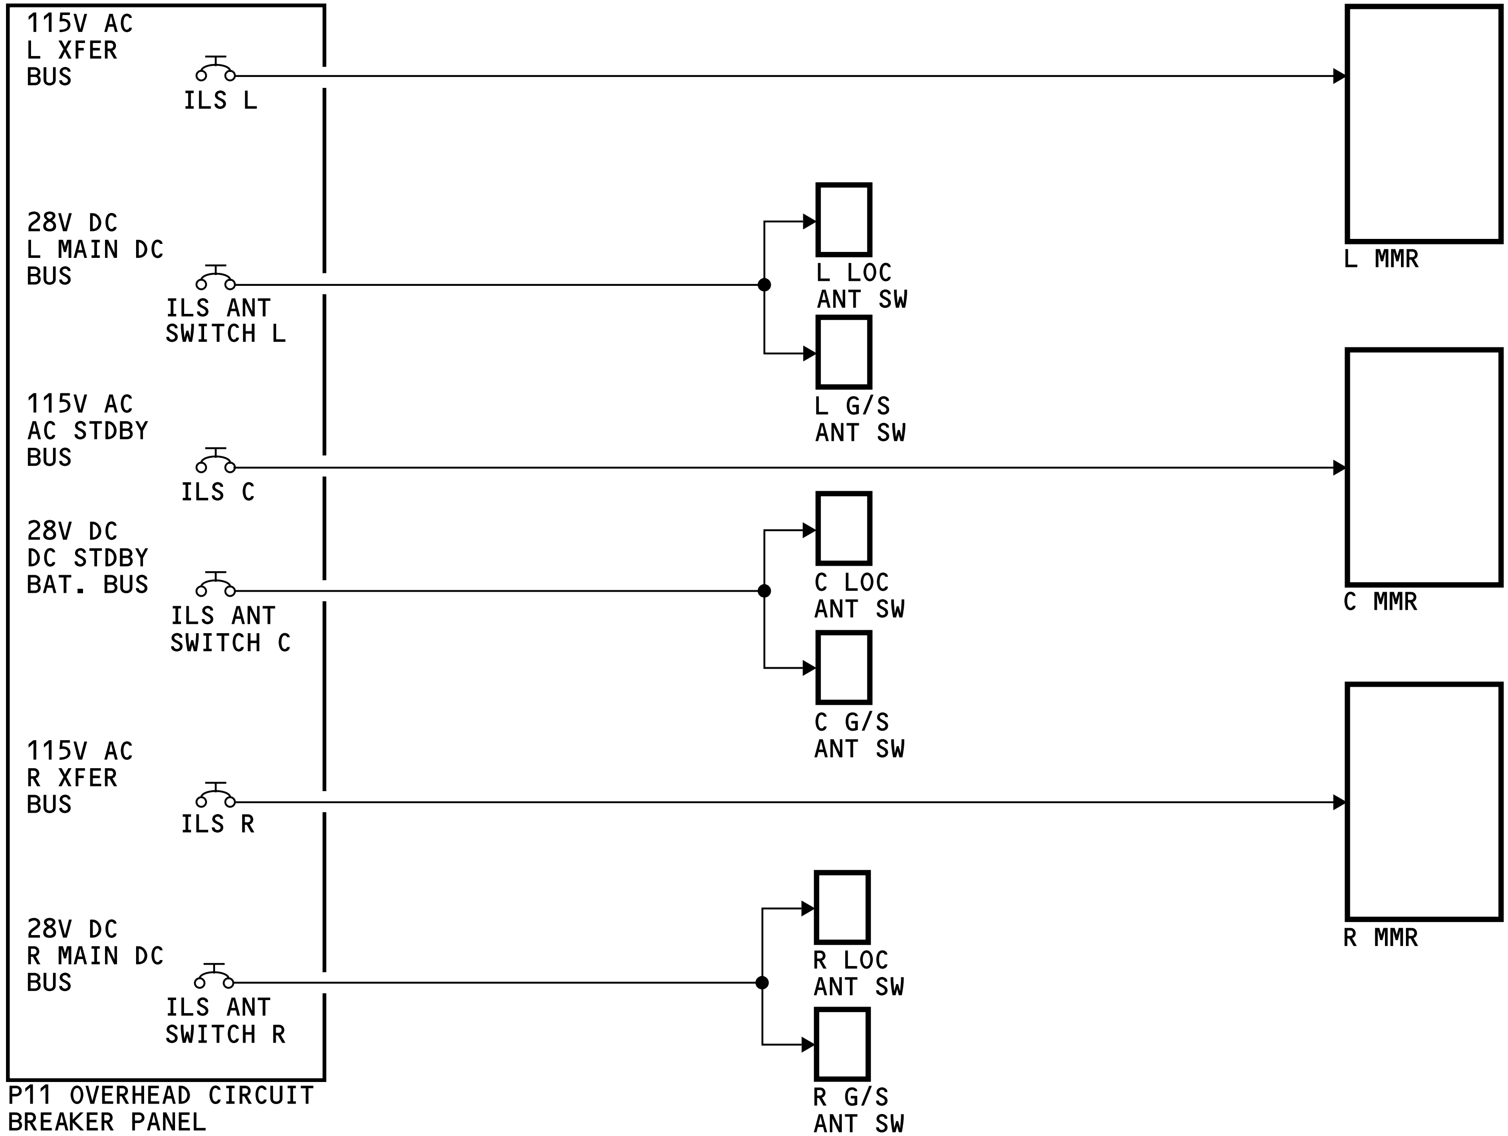
ILS - FUSELAGE COMPONENT LOCATIONS

ILS - POWER INPUTS

Power Inputs

The left and right multi-mode receivers (MMRs) get 115v ac, 400 Hz power from the left and right 115v ac transfer buses. The center MMR gets 115v ac, 400 Hz power from the AC standby bus.

The left and right localizer and glideslope antenna switches get 28v dc from the left and right main DC buses. The center localizer and glideslope antenna switches get 28v dc from the DC standby battery bus.



ILS - POWER INPUTS

ILS - ANALOG AND DISCRETE INTERFACE

General

The LRUs that interface with the multi-mode receivers (MMRs) with analog and discrete signals are:

- Left and right CDUs
- Air/ground relays
- Left, right, and center AFDCs
- Audio management unit (AMU).

Discrete Inputs

The receivers get discrete inputs from these sources:

- CDUs
- Air/ground relays
- AFDCs.

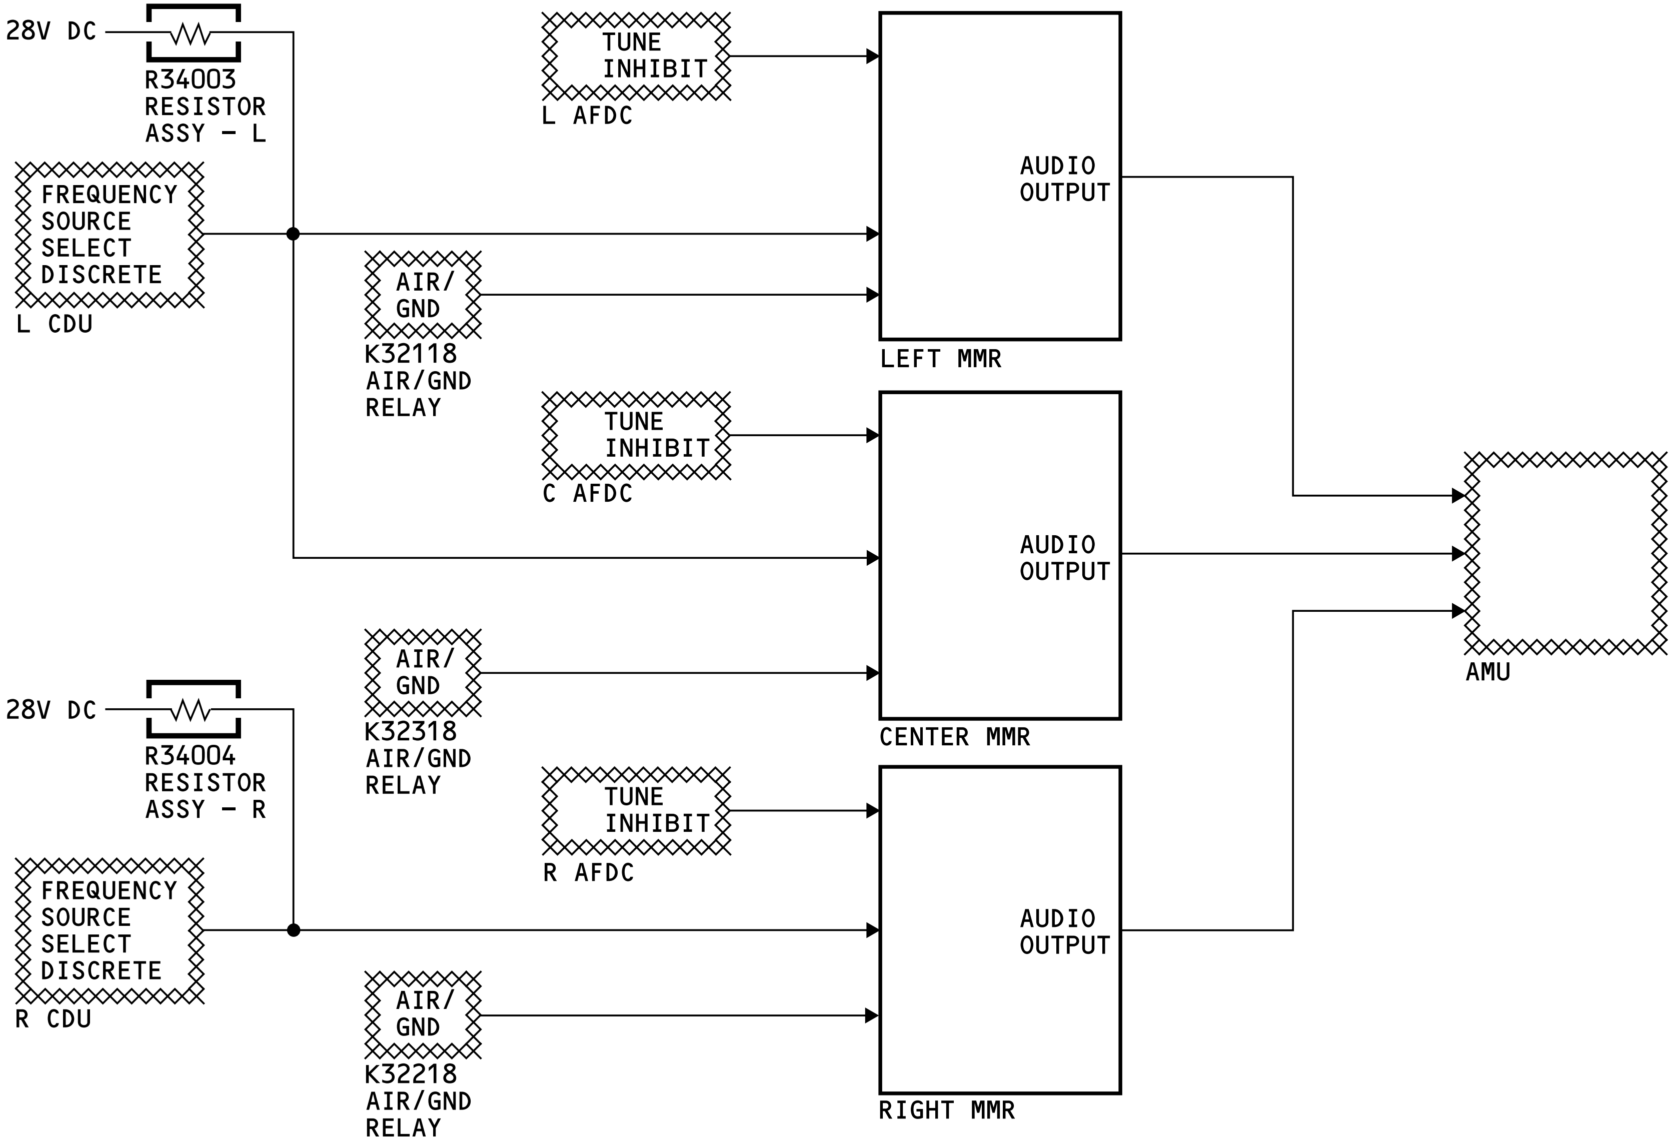
The CDUs send a frequency source select discrete to cause the receiver to select the tune input from either the CDU or the AIMS cabinets. The resistor assemblies pull up the discretes to 28v dc. The left CDU sends a ground discrete to the left and center receivers when the discrete is true. The right CDU sends a ground discrete to the right receiver when the discrete is true.

The air/ground relays send a discrete to the receivers to inhibit tests in the air. The discrete also supplies flight legs data as a backup to the AIMS cabinets flight legs data.

The AFDCs send a discrete to inhibit ILS tune inputs in approach (APP) mode when the airplane is at or below 1500 feet, and there is a localizer or glideslope signal capture. This prevents the flight crew from tuning the receivers.

Analog Outputs

Each receiver sends an audio output to the AMU. The pilots use the audio control panels (ACP) to send ILS audio to the headsets and flight deck speakers.



ILS - ANALOG AND DISCRETE INTERFACE

34-31-00-010 Rev 1 09/25/1997

ILS - ARINC 429 INTERFACE

General

These are the LRUs that have interface with the multi-mode receivers (MMRs) on ARINC 429 data buses:

- Left and right control display units (CDUs)
- Left and right AIMS cabinets
- Left, center, and right autopilot flight director computers (AFDCs)
- Ground proximity warning computer (GPWC).

CDU

The left and right CDUs supply alternate tune inputs directly to the receivers if the AIMS tune inputs fail. The left CDU sends alternate tune signals to the left and center receivers. The right CDU sends alternate tune signals to the right receiver.

AIMS

The right AIMS cabinet sends manual or automatic tune inputs to the receivers on the left, center, and right tune buses.

The left AIMS cabinet sends test commands and flight legs data to the receivers on the left, center, and right CMC buses.

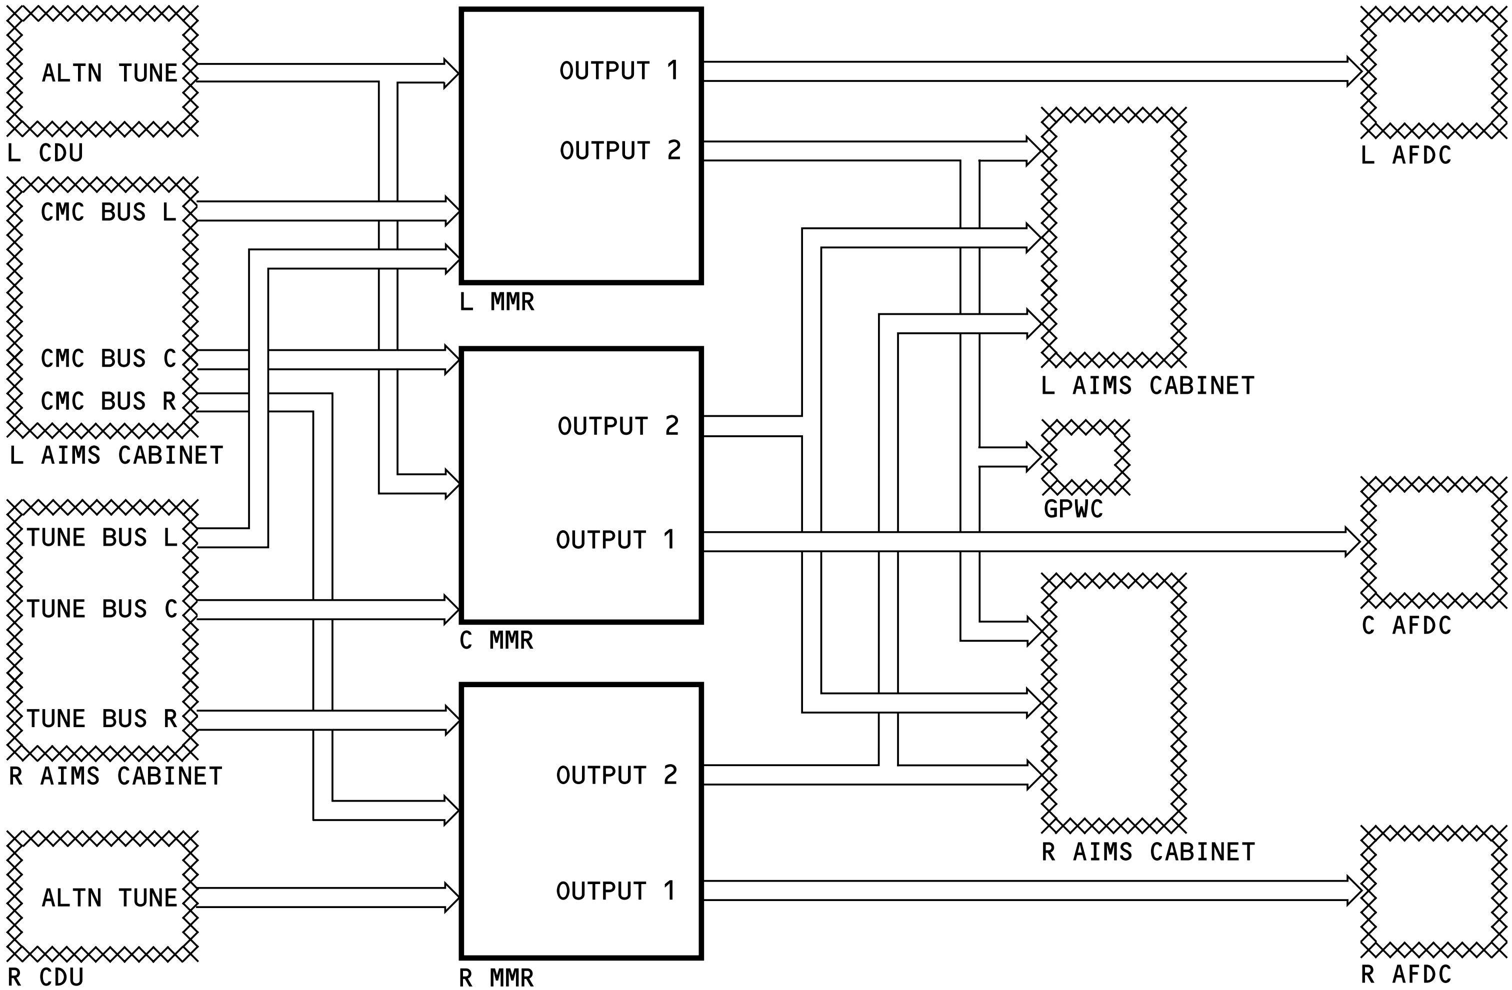
Receiver Outputs

Each receiver has two output buses. Output bus one supplies data to the onside AFDC. Output bus two supplies data to both AIMS cabinets.

Each receiver sends data to both AIMS cabinet to show ILS data on the PFDs and NDs. The receivers also send test status and fault reports.

The left receiver sends ILS data to the GPWC for mode five alerts.

Each receiver sends ILS data to the onside AFDC for autoland functions.



34-31-00-009 Rev 2 09/29/1997

ILS - ARINC 429 INTERFACE

ILS - LOCALIZER ANTENNA INPUTS

General

The multi-mode receivers (MMRs) get localizer signal inputs from the localizer antennas in the nose radome or from the VOR antenna on the vertical stabilizer.

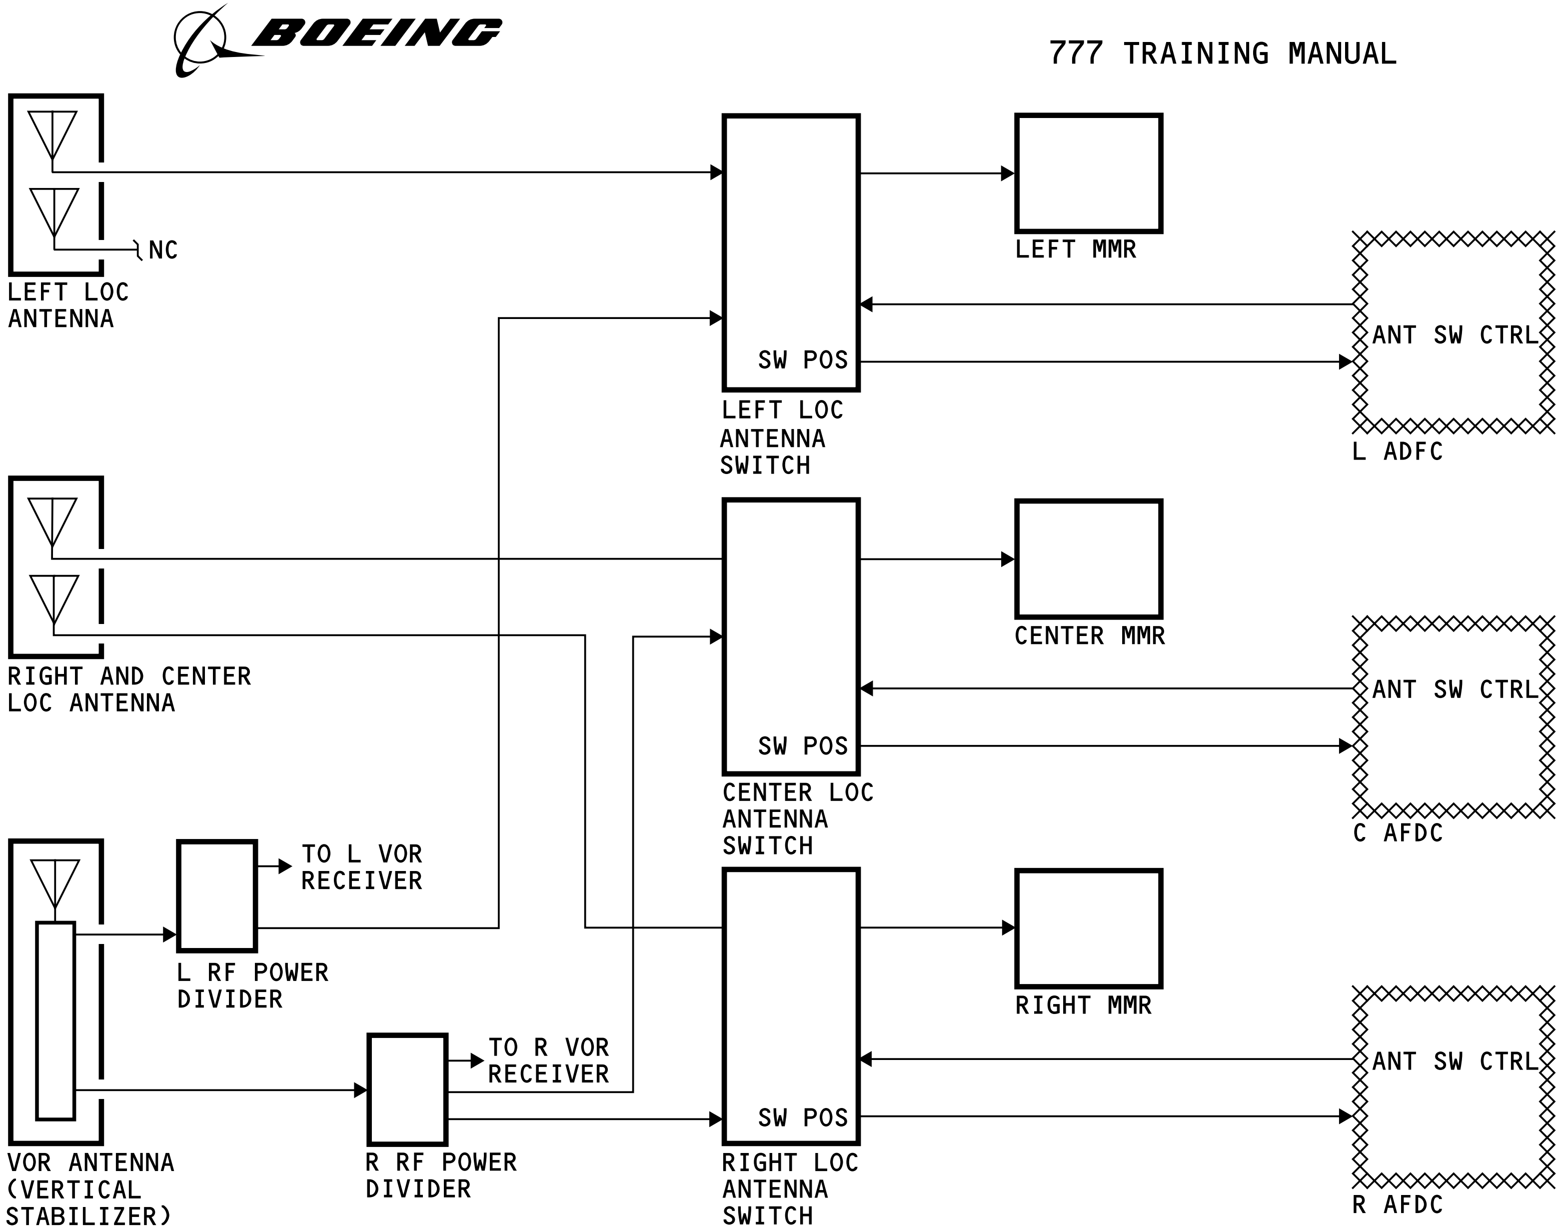
Antenna Inputs

Signal inputs from the VOR antenna on the vertical stabilizer go through the RF power dividers to the localizer antenna switches.

The antenna inputs go through the localizer antenna switches then to the receivers. The switch changes the input from the VOR antenna on the vertical stabilizer to the LOC antennas in the nose radome.

Antenna Switch Control

Each autopilot flight director computer (AFDC) controls its onside localizer antenna switch. Each switch sends antenna switch position feedback to its onside AFDC.



ILS - LOCALIZER ANTENNA INPUTS

ILS - GLIDESLOPE ANTENNA INPUTS

General

The multi-mode receivers (MMRs) get inputs from the glideslope capture antennas in the nose radome, or from the glideslope track antennas on the aft nose gear doors. The antenna inputs go through the glideslope antenna switch, then to the MMRs.

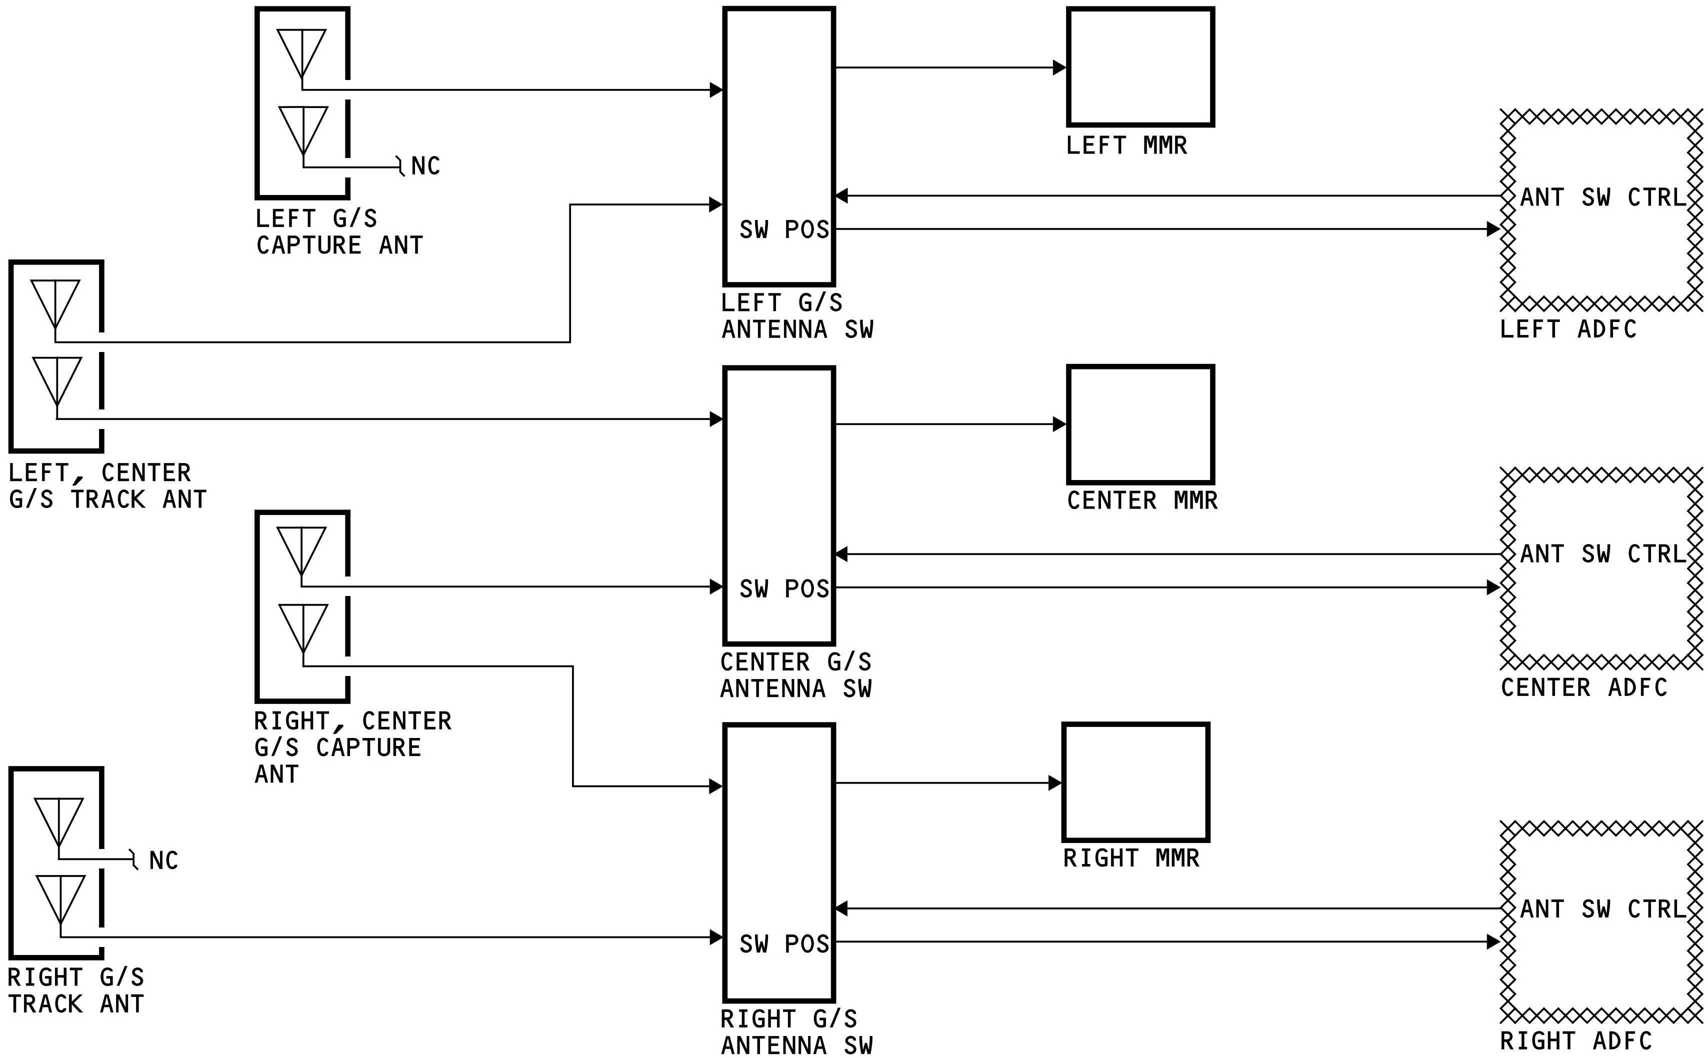
Antenna Inputs

Signal inputs from the glideslope track antenna on the left nose gear door go to the left and center receivers. Signal inputs from the glideslope track antenna on the right aft nose gear door go to the right receiver.

The left capture antenna signals go to the left receiver. The right capture antenna signals go to the center and right receivers.

Antenna Control

Each autopilot flight director computer (AFDC) controls its onside glideslope antenna switch. Each switch sends antenna switch position feedback to its onside AFDC.



34-31-00-012 Rev 2 09/25/1997

ILS - GLIDESLOPE ANTENNA INPUTS

ILS - RECEIVER

Purpose

The multi-mode receiver (MMR) supplies localizer and glideslope deviation to the autopilot flight director computers (AFDCs) and to the AIMS cabinets for display.

Description

Each receiver is a standard ARINC 600 3 MCU unit. The receiver weighs ten pounds and uses 115v ac power for operation.

There are status LEDs on the front panel and a receiver test switch. The ILS status LEDs show either green for a test pass, or red for a test fail.

The receiver has a nonvolatile flight fault memory. Use the ATE connector at the rear of the ILS receiver to access the fault memory. Only shop personnel can use this feature.

Front Panel LEDs

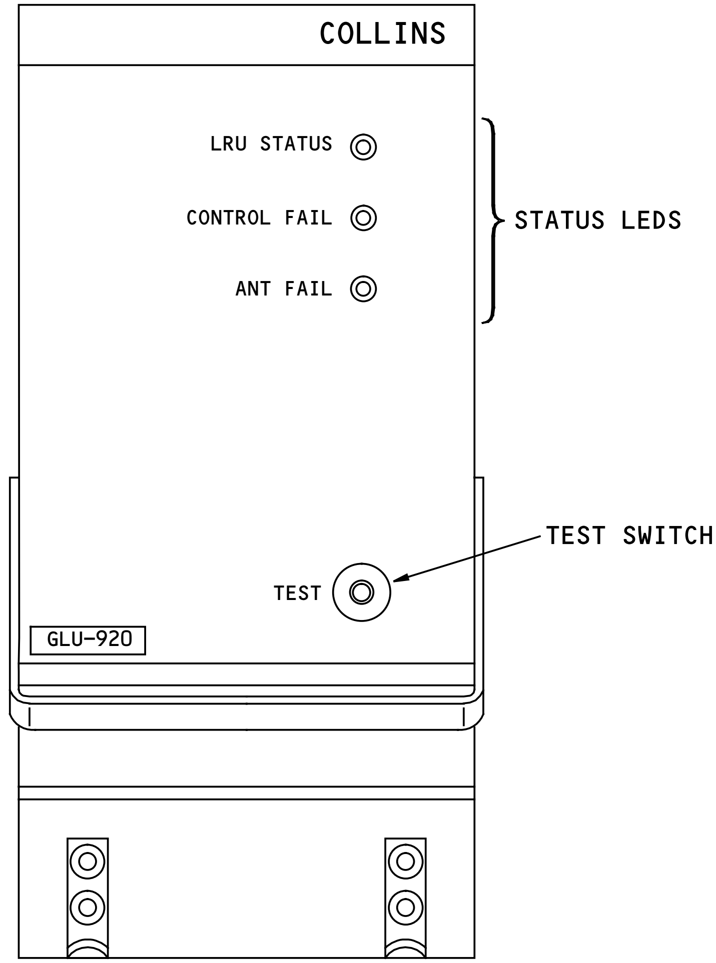
The receiver front panel has these LEDs:

- LRU STATUS - red shows for an internal receiver failure
- CONTROL FAIL - red shows for a control failure
- ANT FAIL - not connected.

Training Information Point

The maintenance manual and the fault isolation manual do not have a task for the line maintenance technician to do a test from the front panel of the receiver. You must do all tests for the receiver from the MAT or a PMAT.

Many LRUs on the 777 are compatible with other model airplanes that do not have a central maintenance computing system (CMCS). For that reason those LRUs have a front panel test feature.



ILS - RECEIVER

ILS - LOCALIZER AND GLIDESLOPE ANTENNAS

Localizer Antennas

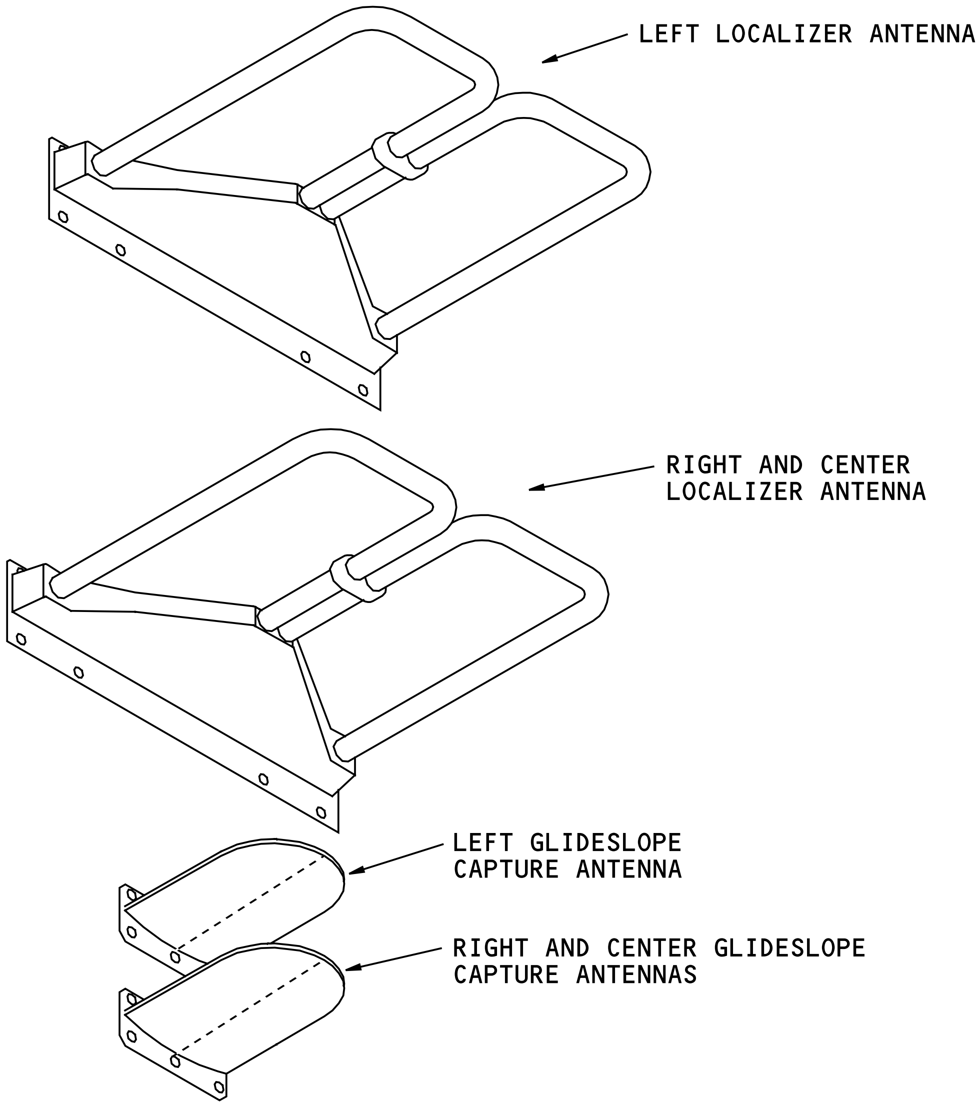
There are two localizer antennas. Each antenna has two elements. The localizer antennas receive frequencies from 108.1 MHz to 111.95 MHz at odd tenths intervals.

The antennas supply signal reception within 90 degrees to the left or right of the airplane centerline.

Glideslope Capture Antennas

There are two glideslope antennas. Each antenna has two elements. The glideslope antennas receive frequencies from 328.6 MHz to 335.4 MHz. The glideslope frequencies are paired with localizer frequencies.

The antennas supply signal reception within 90 degrees above or below the airplane centerline.



34-31-00-015 Rev 1

ILS - LOCALIZER AND GLIDESLOPE ANTENNAS

ILS - GLIDESLOPE TRACK ANTENNA

General

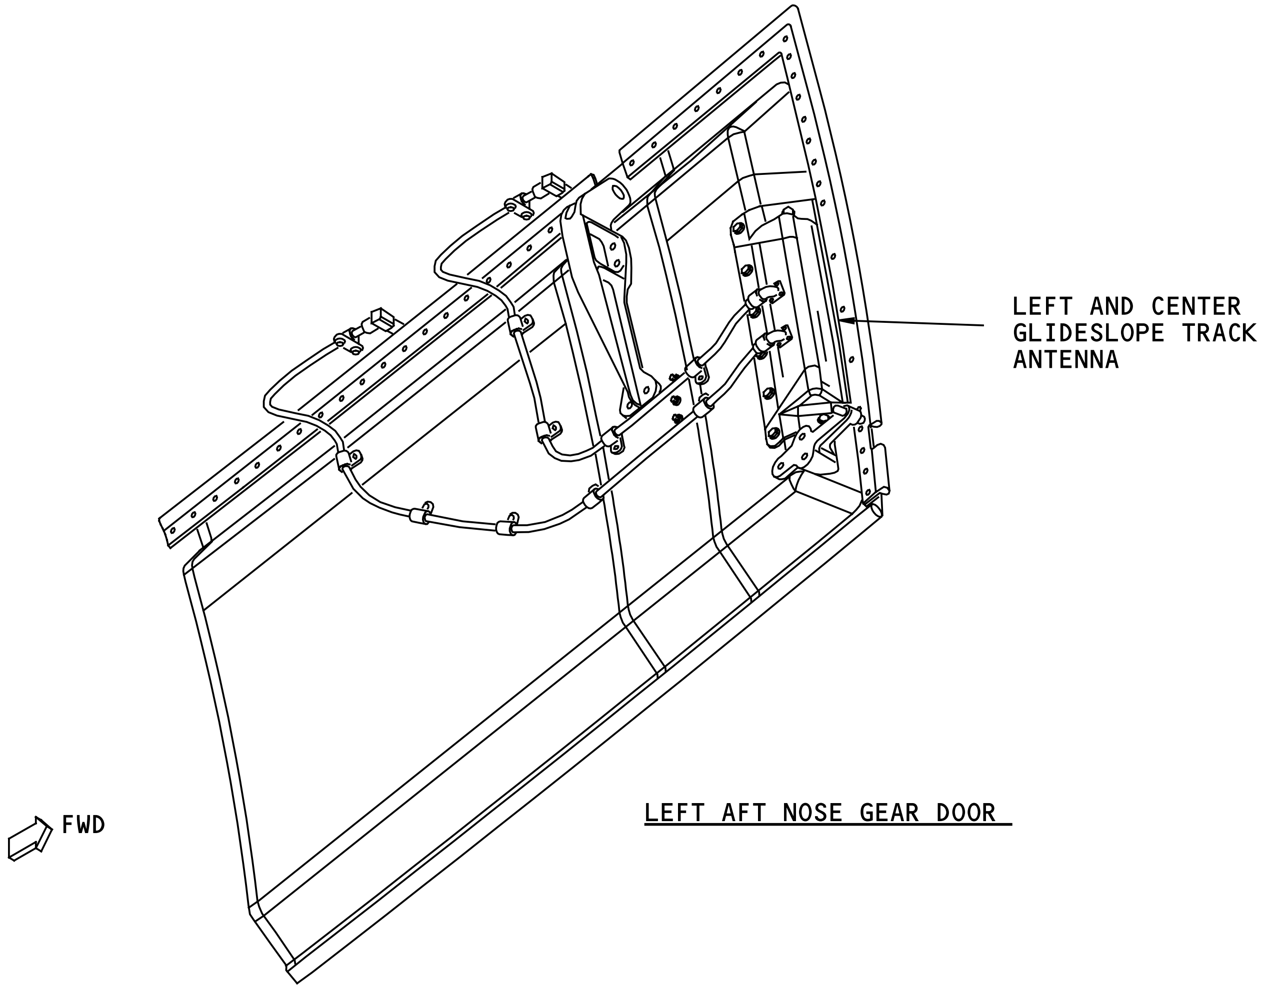
The glideslope track antennas supply final approach and landing glideslope signals. The track antennas are in a position to minimize the vertical distance between the antenna flight path and the main landing gear.

Description

The antennas receive in the frequency range of 328.6 MHz to 335.4 MHz. The glideslope track antennas are on the left and right aft nose gear doors.

Each antenna is a dual element antenna. The left glideslope track antenna on the left aft nose gear door supplies glideslope signals to the left and center ILS receiver. The right glideslope track antenna on the right aft nose gear door supplies glideslope signals to the right ILS antenna.

The graphic below shows the left and center glideslope antenna. The right glideslope antenna looks the same.



34-31-00-016 Rev 1

ILS - GLIDESLOPE TRACK ANTENNA

ILS - TUNING

General

There are three ways to tune the multi-mode receivers (MMRs):

- Automatically by the AIMS cabinets
- Manually by the left, right, or center CDU
- By the CDUs as an alternate tuning source.

AIMS Auto Tune

The flight management computing function (FMCF) of the right AIMS cabinet automatically tunes the receivers when the ILS station is part of the active flight plan. The left AIMS FMCF tunes the receivers through the right AIMS cabinet, if the right FMCF fails.

Manual Tuning

You use the left or right CDUs to manually tune the receivers. When you enter an ILS frequency or identifier into the CDU, the CDU frequency becomes the active frequency. It overrides the AIMS FMCF auto tune input. The CDU delete function deletes the CDU frequency selection and the AIMS FMCF auto tune becomes active. The center CDU tunes the ILS receivers if the left or right CDUs fail.

Alternate Tuning

If the AIMS FMCF tuning functions fail, the CDU sends a frequency source selection discrete to the receiver to select the tuning source. This ground signal to the switch in the receiver changes the tuning input from AIMS to the CDU. You use the right CDU to tune the right receiver. You use the left CDU to tune the left and center receivers. There is no alternate tune function from the center CDU.

ILS - TUNING

ILS - AUDIO CONTROL PANEL ILS AUDIO CONTROLS

General

The audio control panels (ACPs) supply control inputs to the audio management unit. This lets the crew hear audio signals on the speakers and headsets in the flight deck.

Description

These are the controls on the audio control panel that let you hear ILS audio:

- NAV filter selector
- Approach receiver volume control
- Approach receiver selector.

NAV Filter Selector

The NAV filter selector lets you select one of these:

- Voice (V) audio
- Both (B) voice and range audio.
- Range (R) audio

Approach Receiver Volume Control

The approach receiver volume control turns on the audio and controls the volume.

Approach Receiver Selector

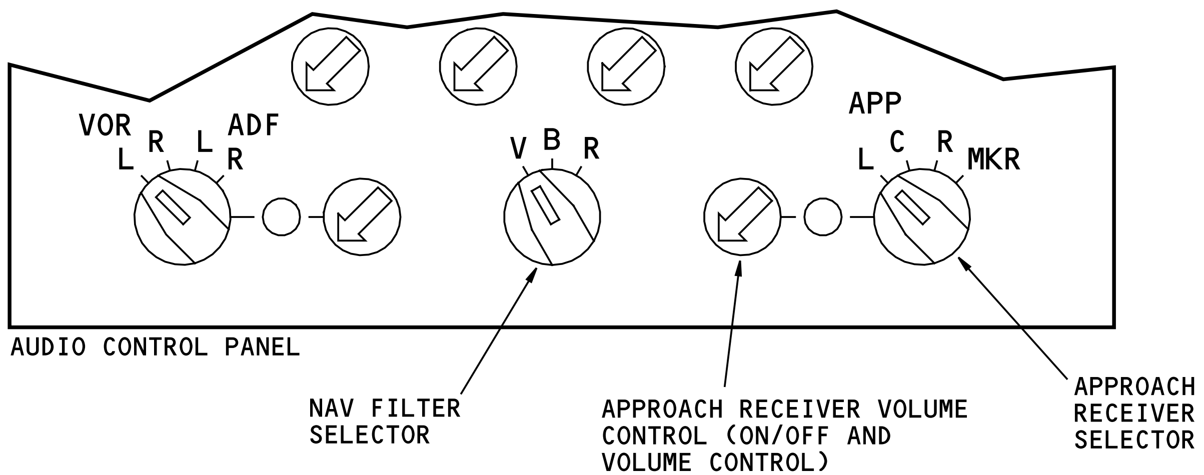
The approach receiver selector lets you select ILS or marker beacon as the source of audio.

Operation

To hear ILS audio, do this:

- Set the approach receiver selector to the left (L), center (C) or right (R) APP position
- Push the approach receiver volume control to turn on the ILS audio (turn the control to adjust the volume)
- Set the NAV filter selector to the voice (V) position.

To hear the station identifier, set the NAV filter selector to either the both (B) or the range (R) position.



34-31-00-020 Rev 2

ILS - AUDIO CONTROL PANEL ILS AUDIO CONTROLS

ILS - CDU ILS TUNING

General

The CDUs supply manual tune inputs during normal operation and alternate tune inputs when the AIMS tune functions fail.

Operation

To see ILS tune frequencies, push the NAV RAD key on the CDU. The NAV RADIO page shows data for the ILS systems.

To manually tune the multi-mode receiver (MMR), enter a valid ILS frequency or identifier and course into the CDU scratch pad and push line select key 4L.

You can enter the frequency and course together or separately. When you enter the course separately, a diagonal slash must be entered first followed by the course.

The PARK display can show on the CDU when the FMCF of AIMS autotunes the receivers. PARK shows for these conditions:

- PARK shows when the ILS is part of the active flight plan and not tuned, and the airplane is more than 200 nm from top of descent, or less than halfway to the destination.
- The frequency and PARK shows when the ILS is part of the active flight plan and not tuned, and the airplane is less than 200 nm from top of descent, or greater than halfway to the destination.

When the FMCF tunes the frequency, only the frequency shows. The PARK display goes out of view when less than 50 nm from top of descent, greater than 150 nm from the runway threshold, or the FMC is in the descent mode.

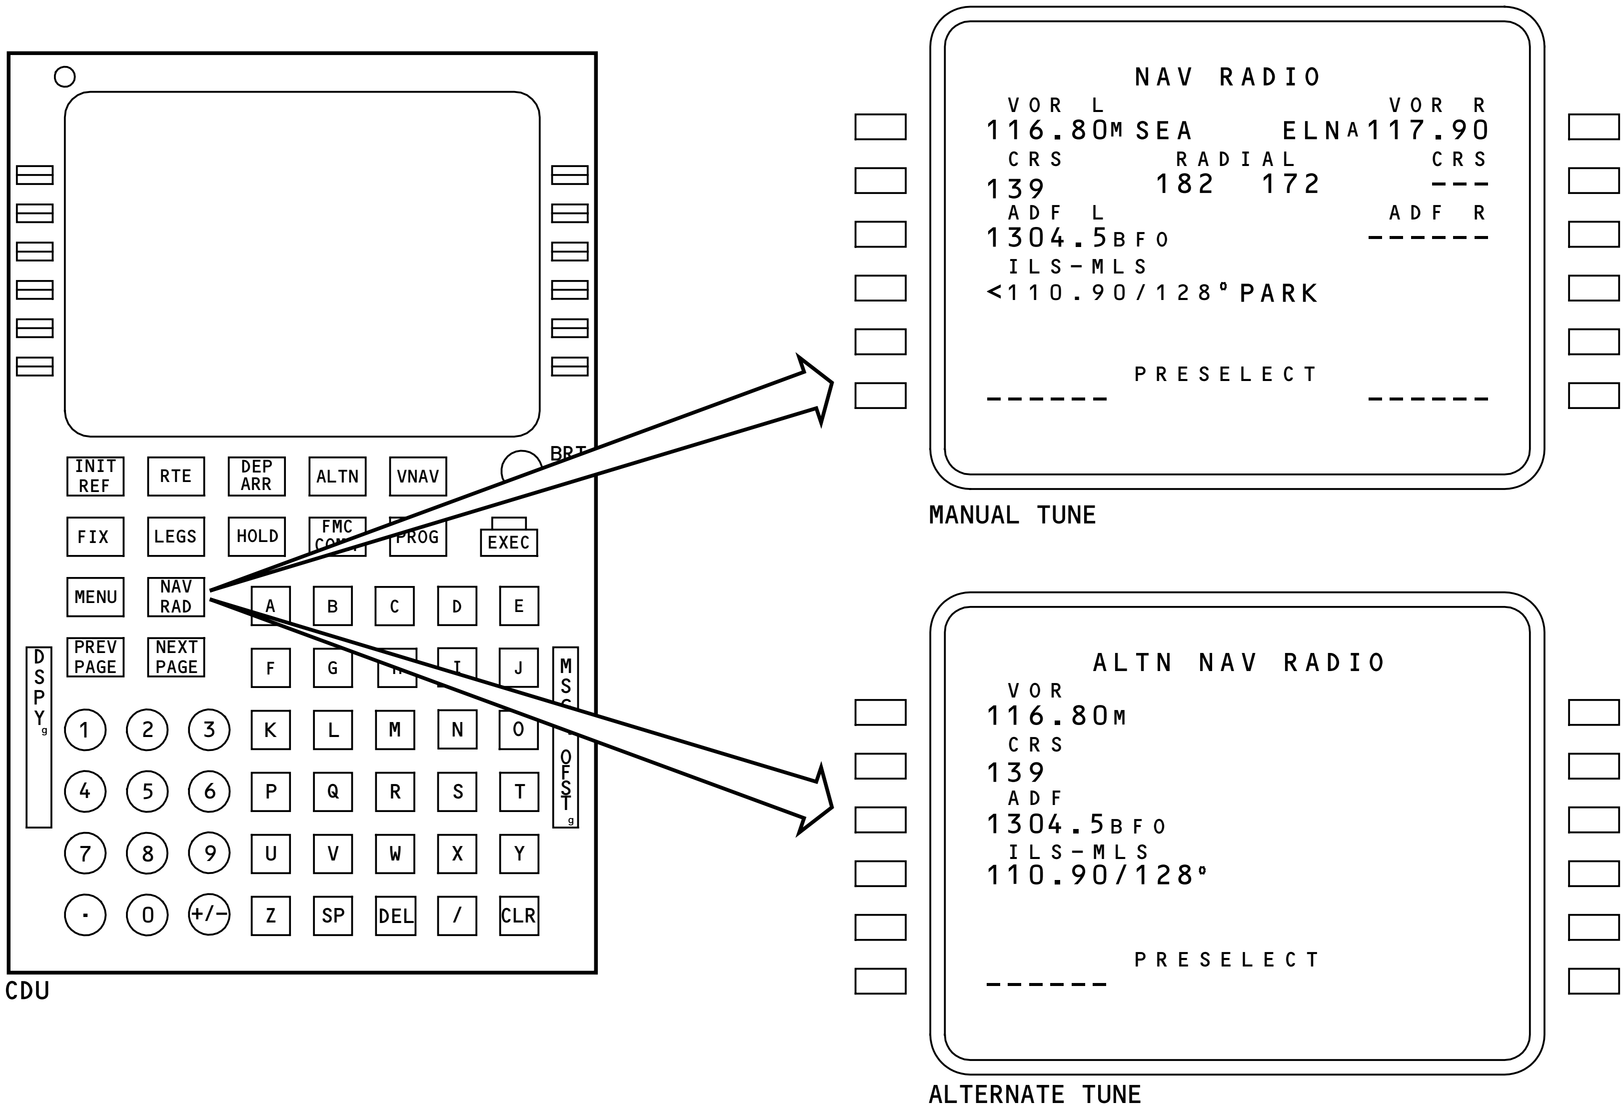
To delete the frequency and course, push the delete (DEL) key on the CDU. The delete function shows in the CDU scratchpad. Next, push the line select key next to the ILS data line to delete the frequency and course.

Alternate Tune

The ALTN NAV RADIO page is available only when the tune inputs from the AIMS cabinets fail.

To get to the ALTN NAV RADIO page, push the NAV RAD key on the CDU.

The ALTN NAV RADIO page is different than the NAV RADIO page. The ALTN NAV RADIO page shows data for the left NAV radio systems. Normally, the left CDU ALTN NAV RADIO page controls the left NAV receivers. The right CDU NAV RADIO page controls the right NAV radio receivers. However, for ILS in alternate tune, the left CDU tunes the left and center MMRs. The right CDU tunes the right MMR.



ILS - CDU ILS TUNING

ILS - EFIS ILS CONTROLS

ILS - PFD DISPLAYS

THIS PAGE INTENTIONALLY LEFT BLANK

ILS - PFD DISPLAYS

ILS Indications

These are the ILS indications on the PFD:

- Localizer frequency or identifier
- ILS course
- Localizer deviation scale and pointer
- Glideslope deviation scale and pointer
- ILS deviation warnings.

Display Source Priority

The flight crew cannot manually select a multi-mode receiver (MMR) for the PFD. When a MMR fails, the AIMS selects another receiver to show on the PFD. LOC and G/S flags show on the PFDs when all MMRs fail.

This is the AIMS priority selection of ILS display data on the PFD:

Captain's PFD	L,C,R
First Officer's PFD	R,C,L

Localizer Frequency and Identifier

The localizer frequency or four letter identifier shows at the top left corner of the PFD in white. The frequency shows until the MMR detects the ILS station Morse code identifier. When the station identifier is present, it replaces the frequency.

ILS Course

The ILS course shows to the right of the localizer frequency or identifier in white. It is a three digit display with a range of 1 to 360 degrees.

Localizer and Glideslope Deviation

The localizer deviation scale and pointer show at the bottom of the attitude display. The scale is a standard four dot scale where one dot equals 1 degree of deviation.

The scale can show in the standard display or the expanded scale where a 2 dot scale replaces the four dot scale. In the expanded scale, each dot equals 0.5 degrees of deviation.

The expanded scale shows when these conditions occur:

- LOC deviation is less than 5/8 dot
- The autopilot or flight director is engaged in the LOC or ROLLOUT mode
- ILS course and airplane track are within 5 degrees of each other
- RA is less than 200 feet.

The glideslope deviation scale and pointer show to the right of the attitude display. The scale is a standard four dot scale where one dot equals 0.35 degrees of deviation. There is no expanded scale for glideslope deviation.

ILS - PFD DISPLAYS

ILS Deviation Warning

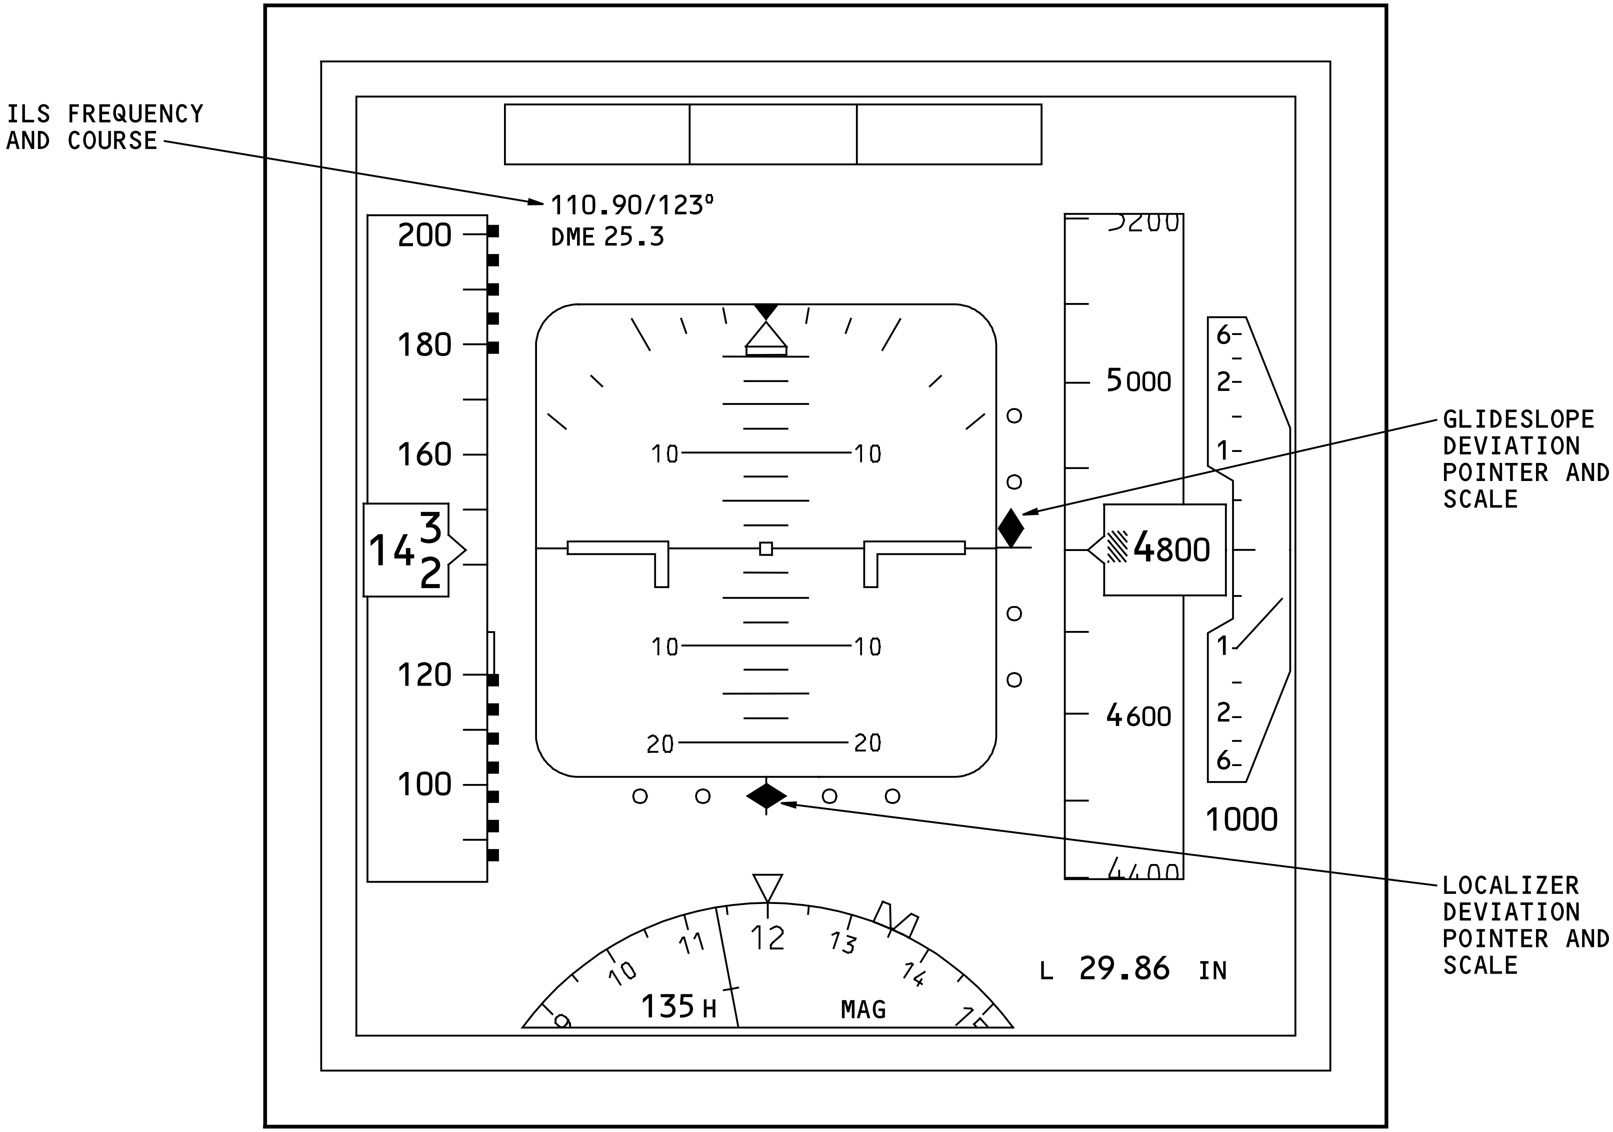
These are the two types of ILS deviation warnings:

- Localizer deviation warnings
- Glideslope deviation warnings.

Localizer deviation warnings occur between 0 and 500 feet RA with localizer captured. Glideslope deviation warnings occur between 100 feet and 500 feet RA with glideslope captured. Localizer deviation warnings occur when deviation is more than 1/4 dot or there is a localizer capture fail. Glideslope deviation warnings occur when the deviation is more than 7/8 dot. The deviation warnings cause the scales and the pointers to turn yellow and blink at a 5Hz rate.

Backcourse Deviation Indications

For backcourse indications, the glideslope pointer goes out of view and the localizer pointer moves in reverse operation. AIMS shows backcourse indications when the ILS course and airplane track is more than 90 degrees apart.



ILS - PFD DISPLAYS

ILS - PFD NCD AND INVALID ILS DISPLAYS

Frequency or Identifier

The ILS frequency or identifier does not show when the ILS input frequency goes invalid or if the selected frequency is not a valid localizer frequency.

ILS course

Dashes replace the ILS course display when the input goes NCD. The course display goes out of view when the course input goes invalid.

Localizer Pointer and Scale

The localizer scale remains in view and the localizer pointer goes out of view if:

- The localizer deviation is NCD
- The ILS course is invalid or NCD
- The airplane track is NCD or invalid.

The amber LOC flag replaces the localizer scale and pointer when the localizer deviation goes invalid.

Glideslope Pointer and Scale

The glideslope scale remains in view and the glideslope pointer goes out of view when the deviation goes NCD or when the airplane is in a backcourse configuration. The amber G/S flag replaces the glideslope scale and pointer when the glideslope deviation goes invalid.

THIS PAGE INTENTIONALLY LEFT BLANK

ILS - ND ILS DISPLAYS

General

Select approach (APP) on the EFIS control panel to show ILS displays on the navigation display (ND). The data shows in both the expanded or center mode formats. Use the mode selector on the EFIS control panel to choose which format shows on the ND.

ILS Displays

These are the ILS displays on the ND:

- Reference receiver for ILS deviation
- ILS frequency or identifier
- ILS course
- Localizer deviation indication
- Localizer deviation scale
- Glideslope deviation pointer
- Glideslope deviation scale.

Display Source Priority

The flight crew cannot manually select a multi-mode receiver (MMR) for the ND. When a MMR fails, the AIMS selects another MMR to show on the ND. LOC and G/S flags show on the NDs when all MMRs fail.

This is the AIMS priority selection of ILS display data on the ND:

Captain's PFD	L,C,R
First Officer's PFD	R,C,L

Reference Receiver for ILS Deviation

The reference receiver for ILS deviation shows to the left of the frequency display. It identifies the left, right, or center receiver as the source for the ILS deviation displays.

ILS frequency or Identifier

The ILS frequency or identifier show at the top right corner of the ND. The frequency shows until the receiver decodes the station identifier. When the receiver decodes the station identifier, the four letter code replaces the frequency.

ILS Course

The ILS course shows below the ILS frequency display at the upper right corner of the ND. The three digit display corresponds to the position of the course arrow. The display range is 1 degree to 360 degrees.

Localizer and Glideslope Deviation

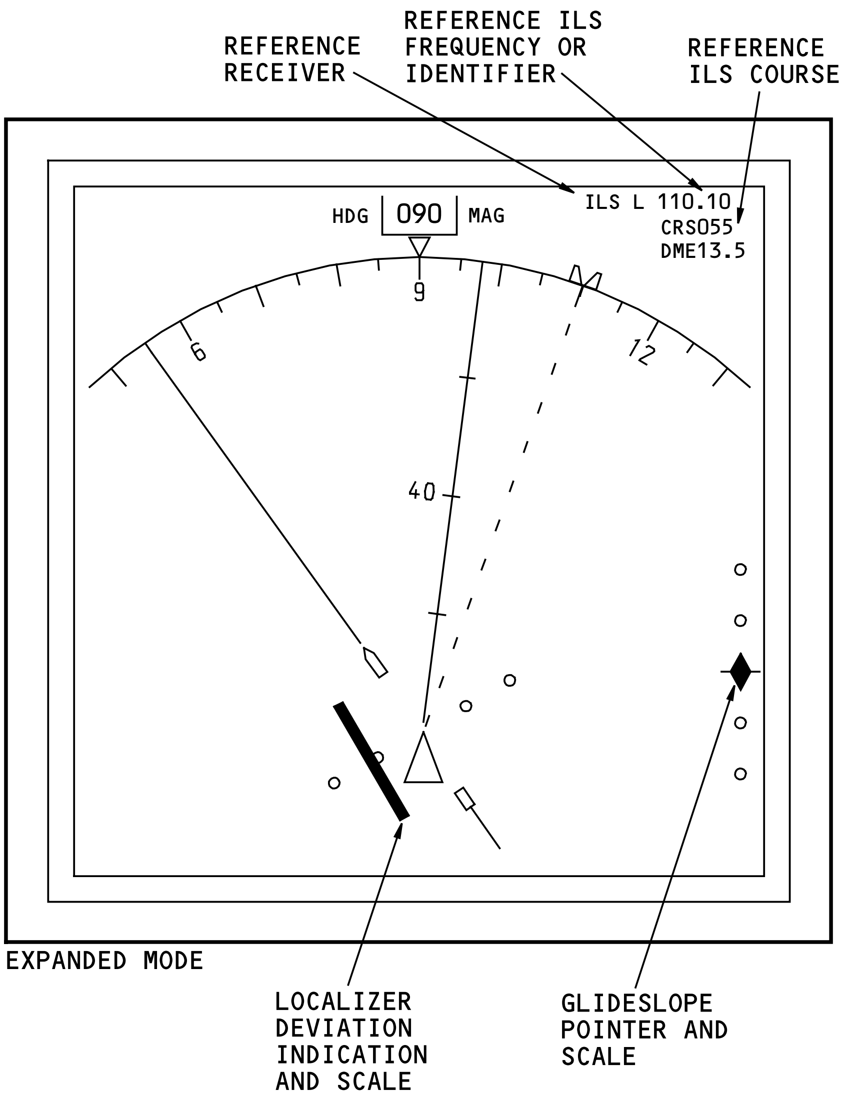
The localizer deviation indication and scale show in the center of the ND. In the expanded ND format, the deviation scale shows at the bottom of the ND. The deviation scale is the standard four dot scale where one dot is equal to 1 degree of deviation. The deviation indication shows deviation to the left or right of the runway centerline.

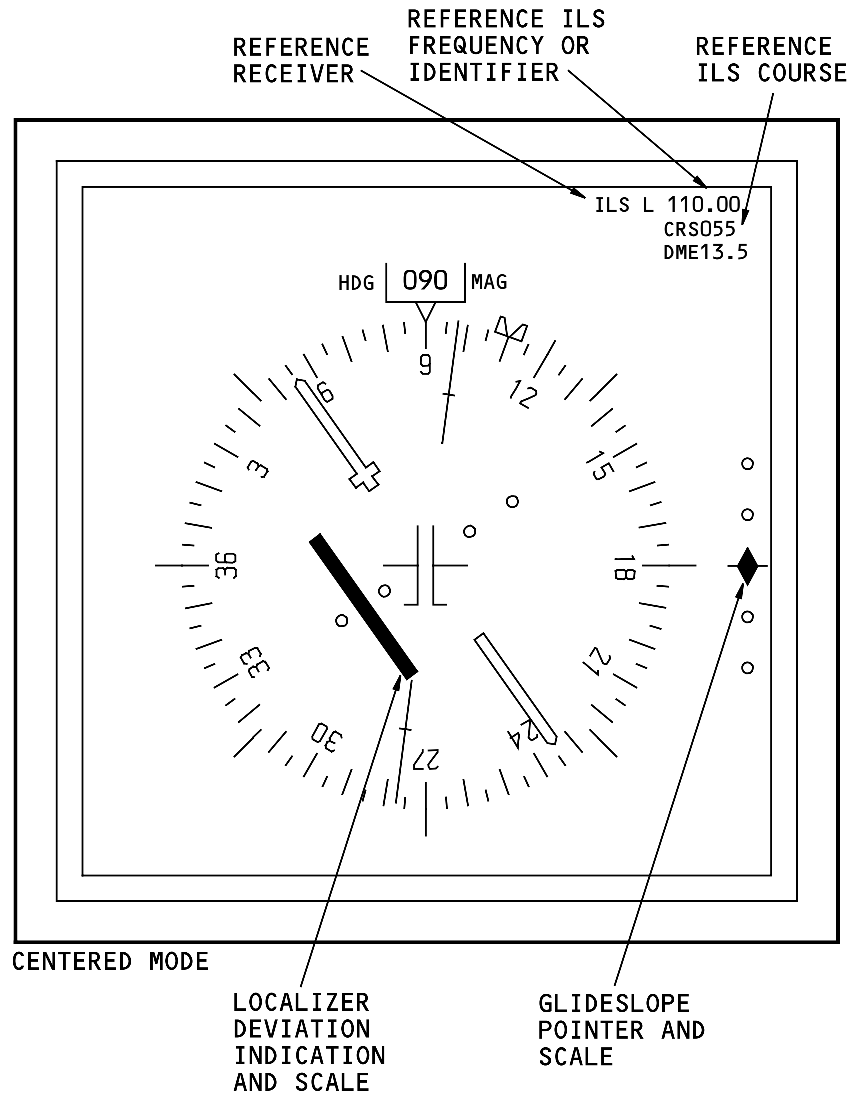
ILS - ND ILS DISPLAYS

The glideslope deviation scale and pointer show at the right side of the ND. The fixed scale is the standard four dot scale where each dot equals 0.35 degrees of deviation. The pointer gives fly to commands to intercept the glideslope beam.

Backcourse

Backcourse happens when the airplane track and runway heading are more than 90 degrees apart. In a backcourse configuration, the glideslope pointer goes out of view.





ILS - ND ILS DISPLAYS

34-31-00-025 Rev 3 10/02/1997

ILS - ND ILS NCD INDICATIONS

ILS Course

When the ILS course input is NCD, dashes replace the three digit course. These are the displays that go out of view:

- Course pointer
- Localizer deviation indication
- Localizer deviation scale
- Glideslope deviation pointer
- Glideslope deviation scale.

ILS Frequency

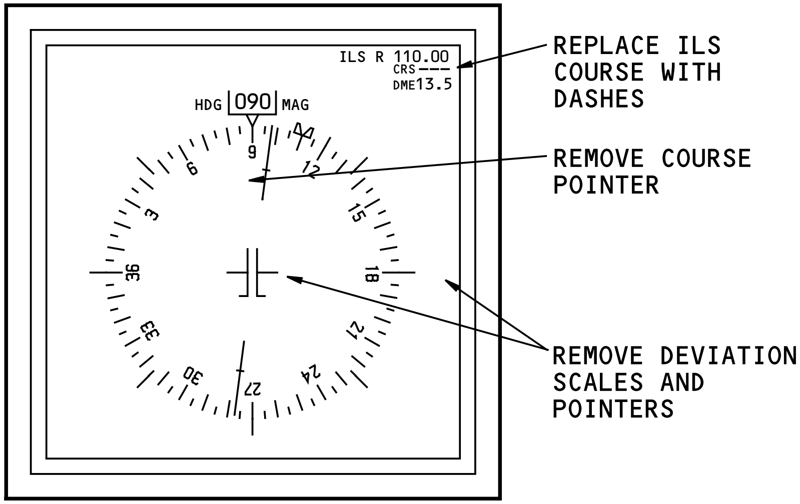
When the ILS frequency is NCD, dashes replace the frequency. These are the displays that go out of view:

- ILS course
- DME
- Localizer deviation indication
- Glideslope deviation pointer.

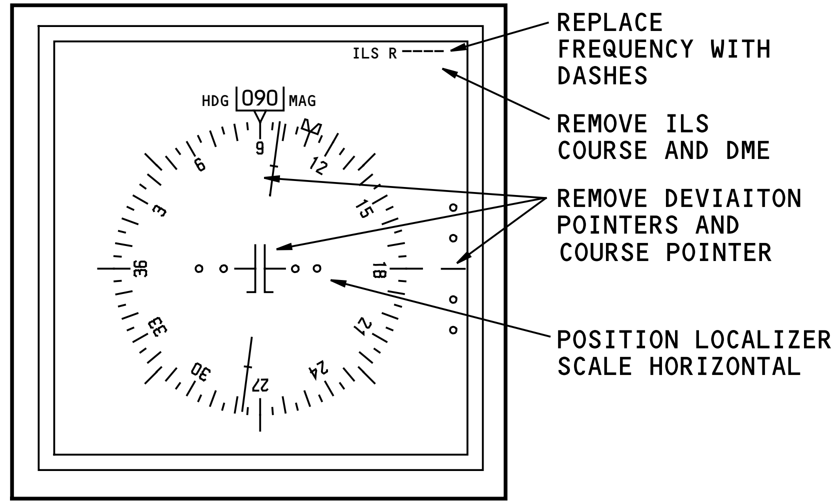
The localizer scale goes to the horizontal position.

ILS Deviation

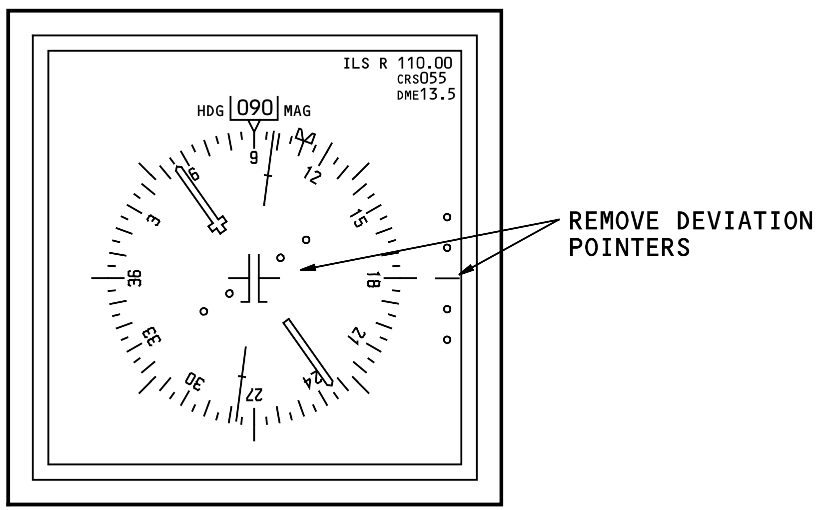
The localizer deviation indication goes out of view when the localizer deviation is NCD. The glideslope deviation pointer goes out of view when the glideslope deviation is NCD.



ILS COURSE NCD



FREQUENCY NCD



LOCALIZER/GLIDESLOPE
DEVIATION NCD

ILS - ND ILS INVALID DISPLAY

ILS - PFD AND ND ILS TEST DISPLAYS

General

Use the maintenance access terminal (MAT) to test the multi-mode receivers (MMRs). The MAT sends the test command to the left AIMS cabinet. The central maintenance computer function of the left AIMS cabinet sends the command to the MMR.

Test Sequence

The receivers start their test sequence when the test command comes from the AIMS cabinet. This is the sequence:

- Invalid data for the first three seconds
- NCD data for approximately two seconds
- Valid data; glideslope pointer up one dot, localizer pointer left one dot for 3 seconds
- Valid data; glideslope pointer down one dot, localizer pointer right one dot for 3 seconds
- Then back to pretest displays.

The AIMS cabinets change the ILS display source when a receiver goes invalid. For this reason, the LOC and G/S flags do not appear while the receiver test sequence goes invalid. To see the flags in the test sequence, the receivers that are not in test must be in a failed condition or power removed.

When the test sequence goes NCD, the localizer pointers and glideslope pointers go out of view.

DISTANCE MEASUREMENT EQUIPMENT SYSTEM - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

DISTANCE MEASUREMENT EQUIPMENT SYSTEM - INTRODUCTION

Purpose

The distance measuring equipment (DME) system supplies slant range (line of sight) distance between the airplane and the ground station.

The DME system supplies station audio and identifier signals to the flight deck speakers and headsets.

Abbreviations and Acronyms

ACP	- audio control panel
AIMS	- airplane information management system
ALTN	- alternate

34-55-00-001 Rev 1

DISTANCE MEASUREMENT EQUIPMENT SYSTEM - INTRODUCTION

DME SYSTEM - GENERAL DESCRIPTION

General

The DME system has two interrogators and two antennas.

The DME interrogator transmits a signal to DME ground stations. The ground stations send a reply signal back to the interrogator. The interrogator measures the time between the transmit signal and the reply signal and calculates distance to the station.

Description

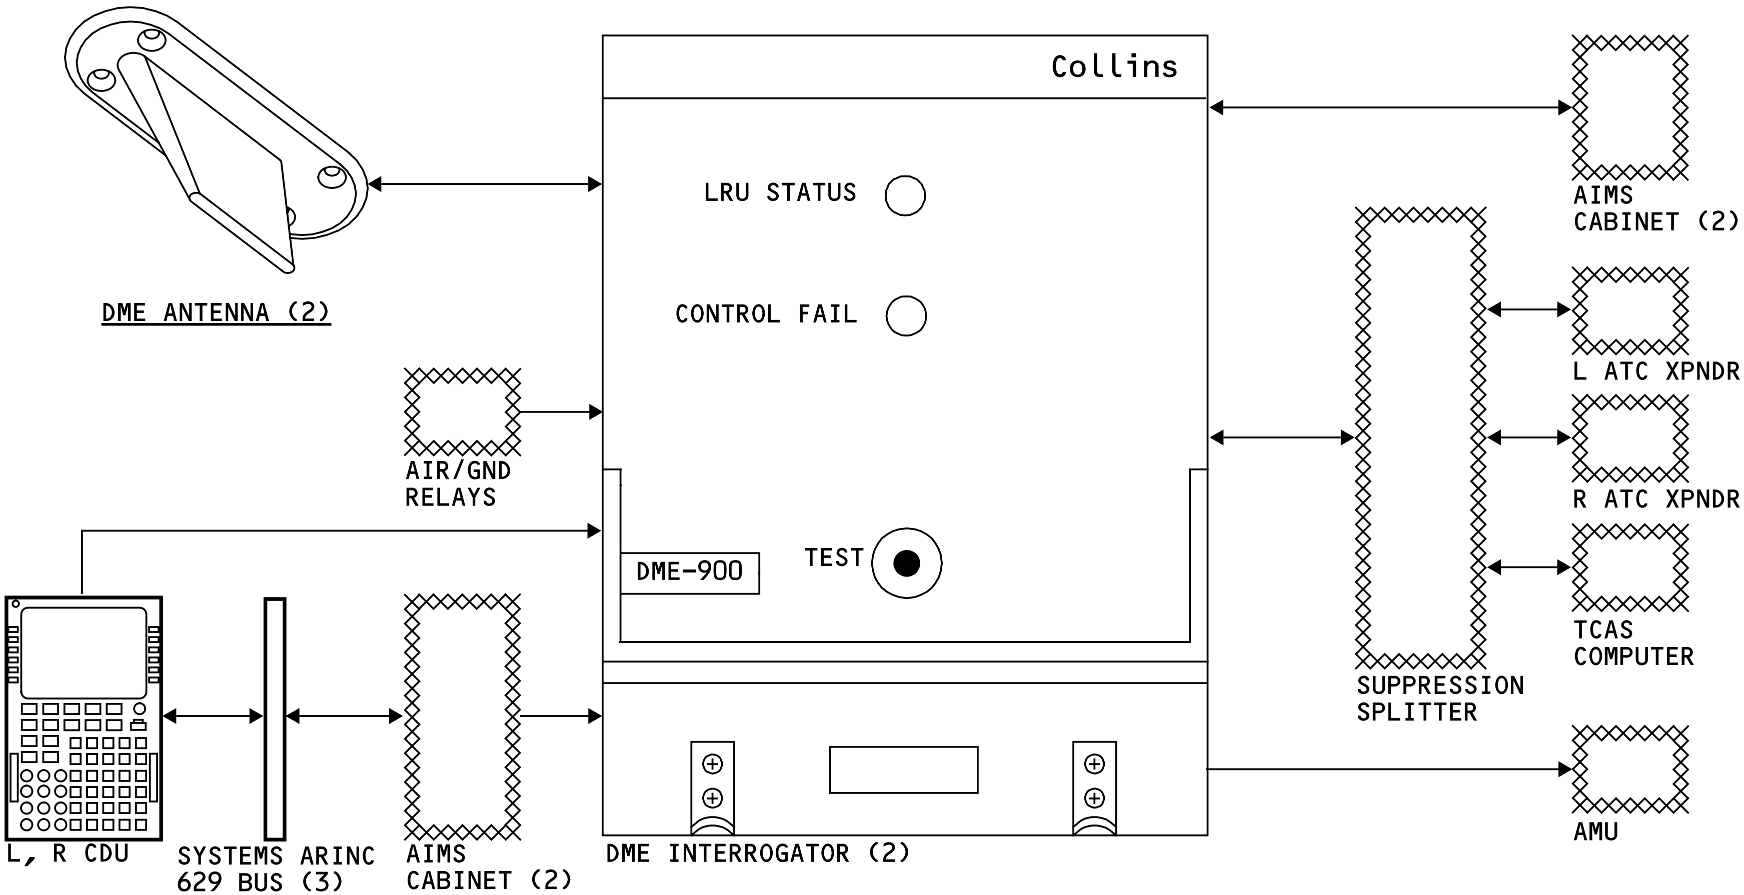
The interrogators get manual tune inputs from the left or right CDU or autotune inputs from the airplane information management system (AIMS) cabinets. The interrogators can get tune inputs directly from the left or right CDU (alternate tune) when the tune inputs from AIMS cabinet fails.

The air/ground relays send discretes to the DME interrogators.

The DME interrogators sends slant range data to the AIMS cabinets to show on the primary flight displays (PFDs) and navigation displays (NDs).

The DME system, air traffic control (ATC) system, and traffic alert and collision avoidance system (TCAS) operate on the same frequency band. When either DME interrogator, or either ATC transponder, or the TCAS computer transmits, that unit sends out a suppression pulse. This pulse goes through a suppression splitter to the other units to inhibit reception in the other units to prevent interference in them.

The DME interrogator receives the station audio identifiers and sends them to the audio management unit (AMU).



34-55-00-002 Rev 4 02/12/1998

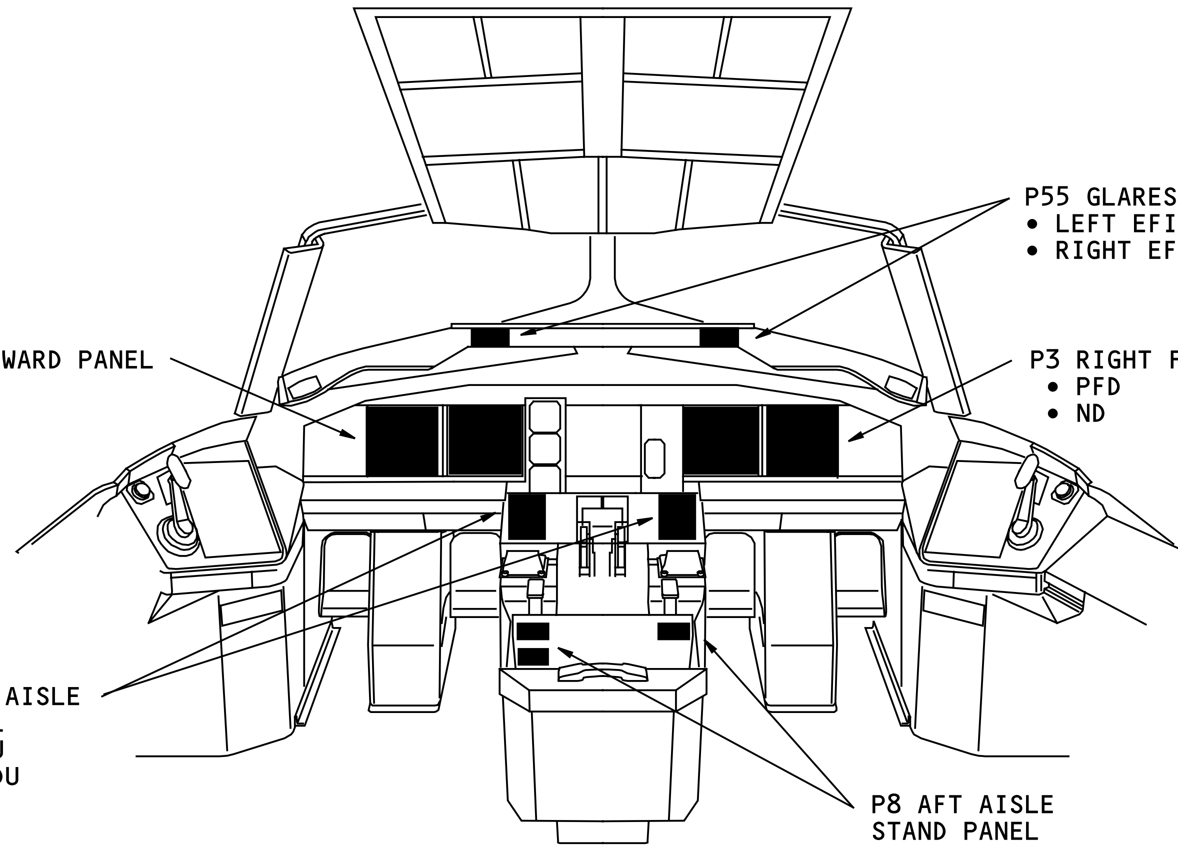
DME SYSTEM - GENERAL DESCRIPTION

DME SYSTEM - COMPONENT LOCATIONS - FLIGHT DECK

DME Component locations - Flight Deck

The components on the flight deck that interface with DME are:

- Left and right EFIS Control Panel (CP)
- Captain's and first officer's primary flight displays (PFDs) and navigation displays (NDs)
- Left and right control display units (CDUs)
- Audio Control Panels (ACPs).



34-55-00-003 Rev 1

DME SYSTEM - COMPONENT LOCATIONS - FLIGHT DECK

DME SYSTEM - COMPONENT LOCATION - MAIN EQUIPMENT CENTER AND ANTENNAS

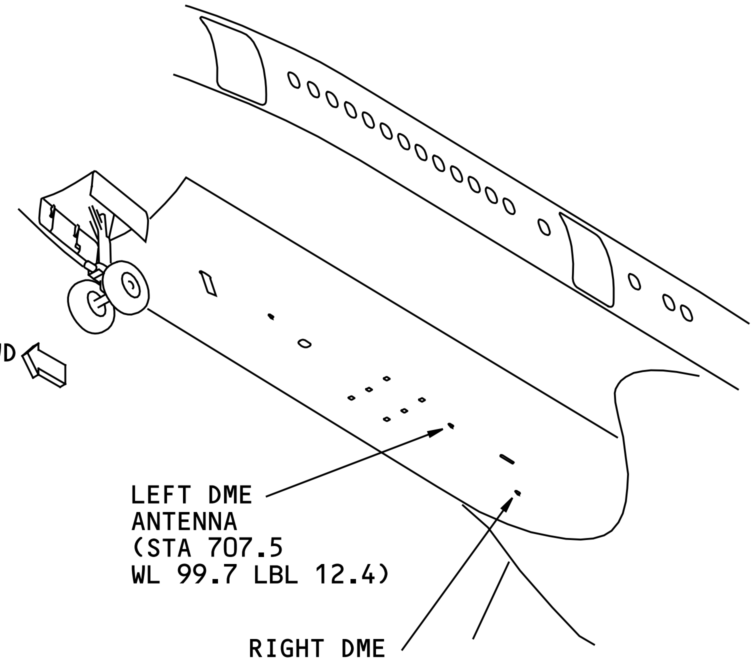
DME Component Locations

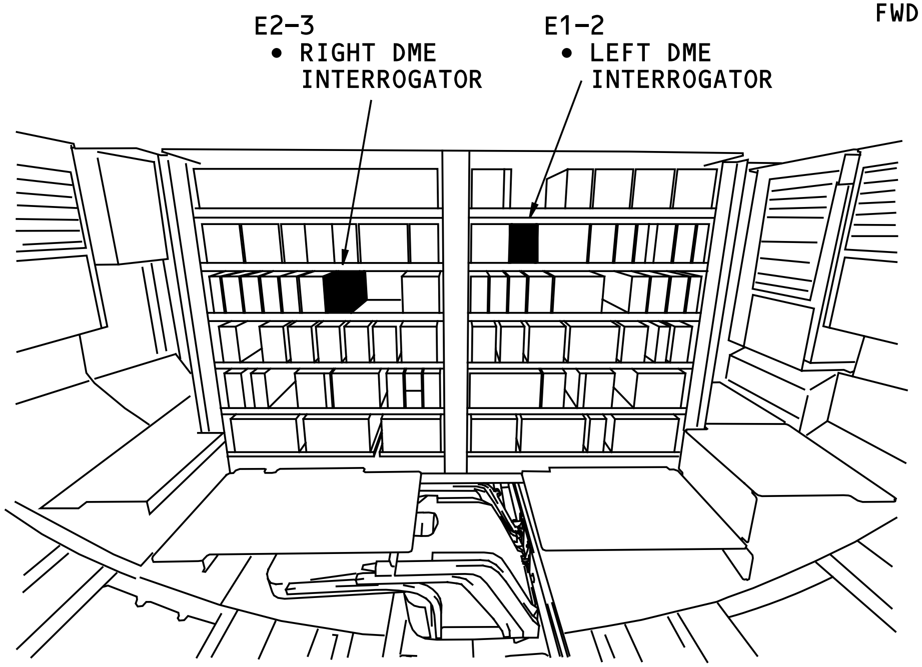
These components are in the main equipment center:

- Left DME interrogator
- Right DME interrogator.

These components are on the exterior of the airplane:

- Left DME antenna
- Right DME antenna.





MAIN EQUIPMENT CENTER

34-55-00-004 Rev 1

DME SYSTEM - COMPONENT LOCATION - MAIN EQUIPMENT CENTER AND ANTENNAS

DME SYSTEM - 429 INTERFACE

CDU

The left and right CDUs supply alternate tune inputs directly to the DME interrogators if the AIMS tune inputs fail. The left CDU alternate tunes the left interrogator and the right CDU alternate tunes the right interrogator.

DME Outputs

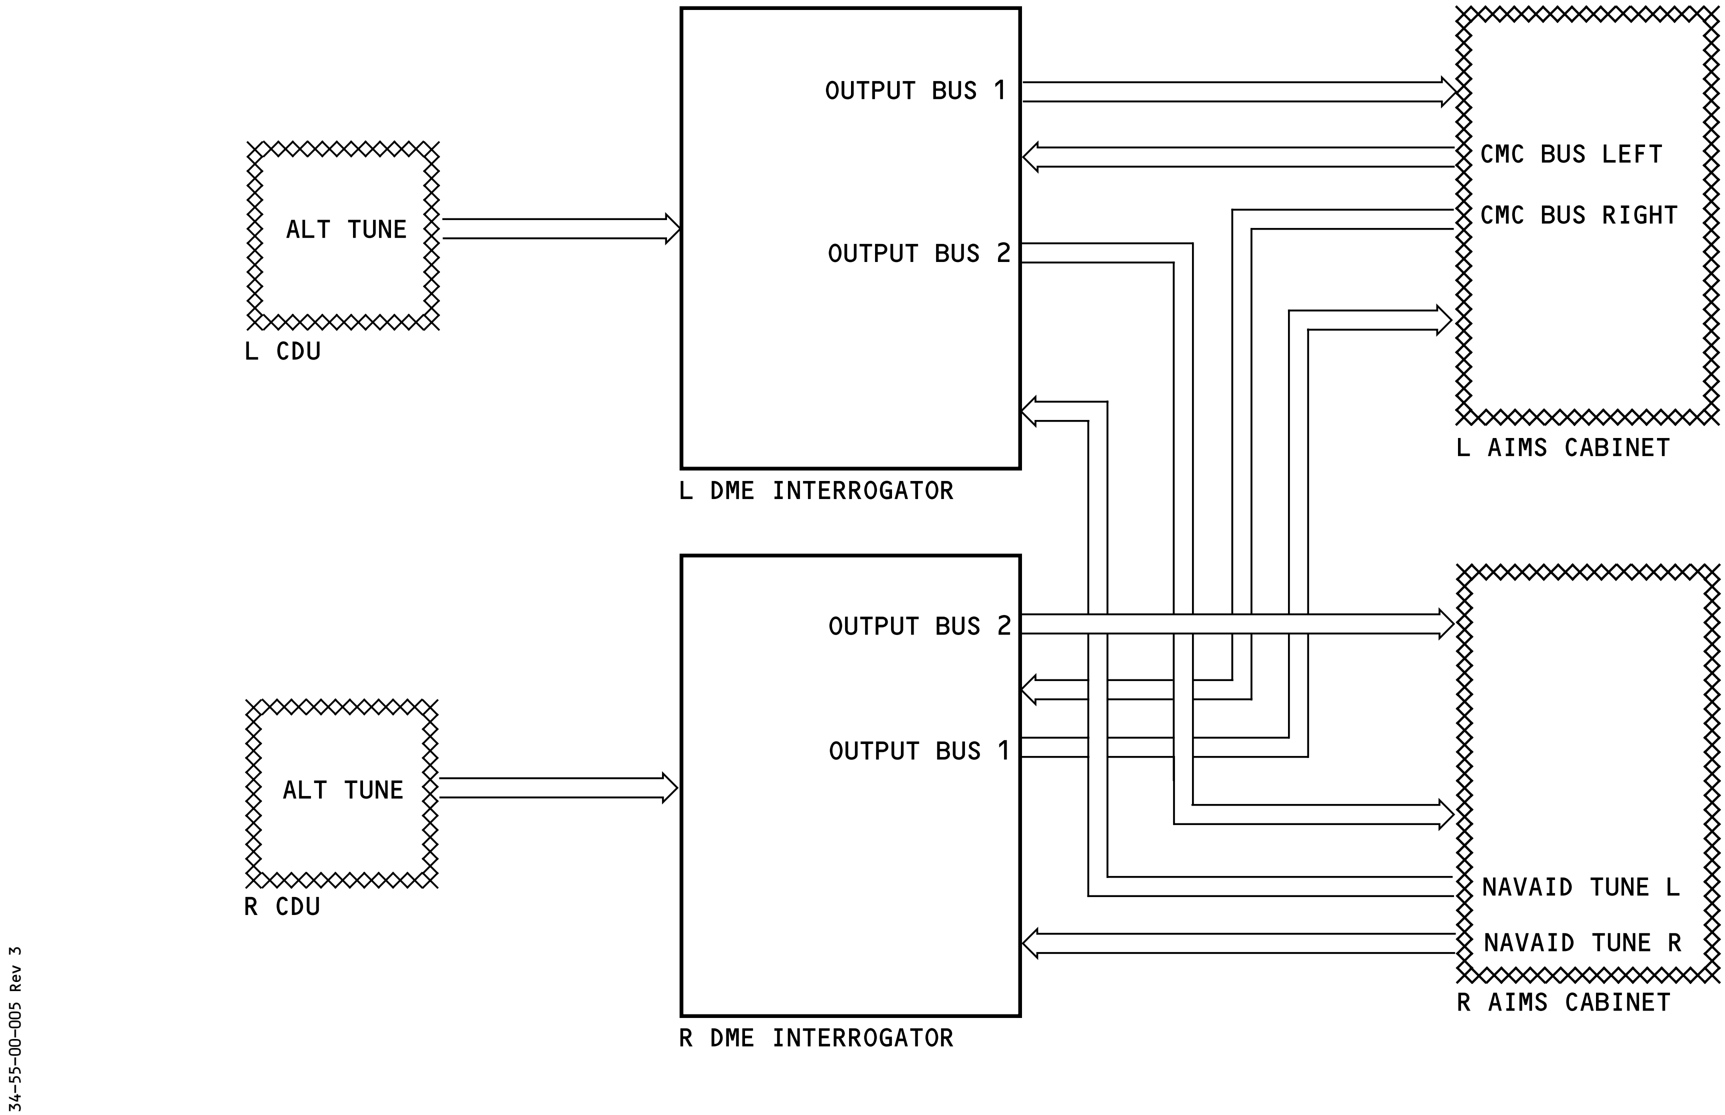
Each DME interrogator has two output buses. The output buses supply data to both AIMS cabinets.

Each DME interrogator sends data to both AIMS cabinet to display DME data on the PFDs and NDs. The interrogators also send test status and fault reports.

AIMS

The left AIMS cabinet sends test commands and flight legs data to the DME interrogators on the left and right CMC buses.

The right AIMS cabinet sends manual or automatic tune inputs to the DME interogators on the left and right tune buses.



DME SYSTEM - 429 INTERFACE

DME SYSTEM - POWER, ANALOG, AND DISCRETE INTERFACE

Power and Antenna Interface

Each DME interrogator receives 115v ac from its circuit breaker.

Air/Ground Relay

The air/ground relays supply discrete inputs to the DME interrogators for these functions:

- Set flight legs (as alternate source, primary is from the CMCF of AIMS)
- Inhibit test commands in the air.

CDU

The CDUs send a frequency source select discrete to cause the interrogator to select the tune input from either the CDU or the AIMS cabinets. The resistor assemblies pull up the discretes to 28v dc. The left CDU sends a ground discrete to the left interrogator when the discrete is true. The right CDU sends a ground discrete to the right interrogator when the discrete is true.

DME Antenna

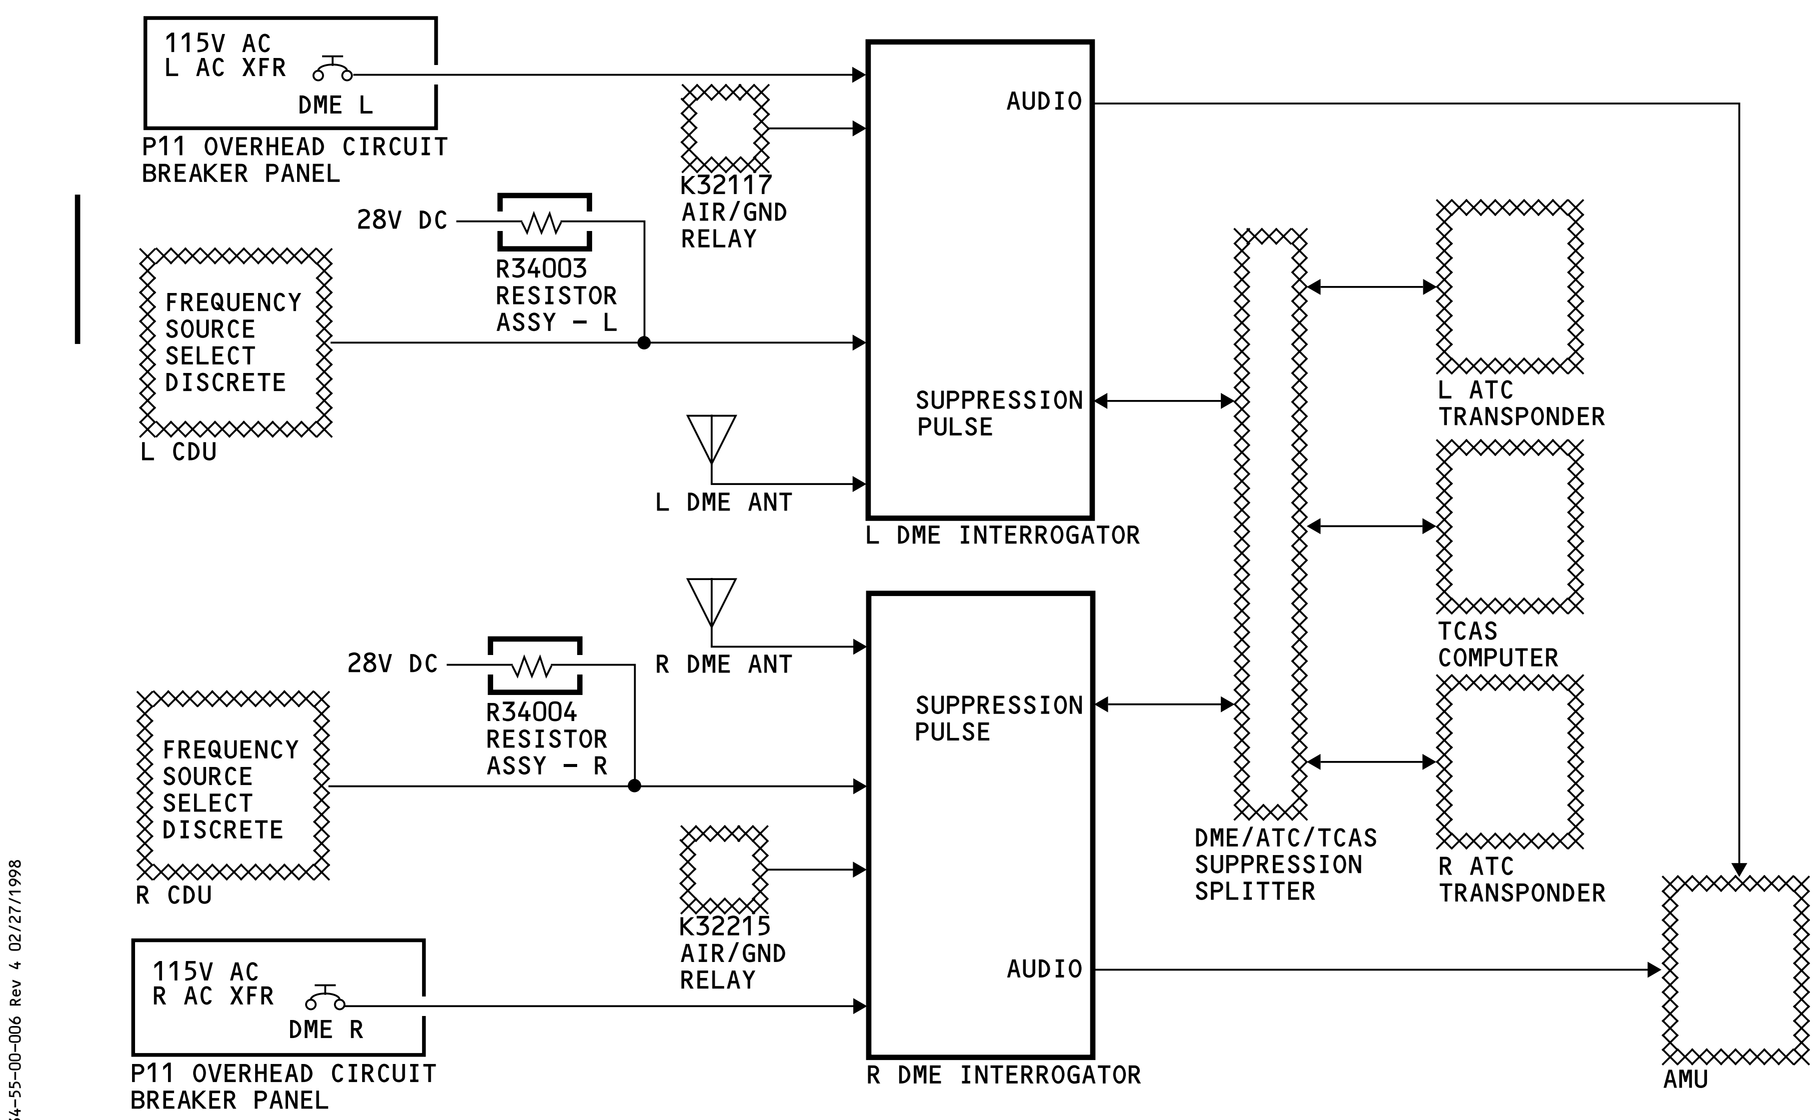
The DME antennas transmit and receive DME signals. The antenna transmits signal pulse pairs to the ground stations then receive the reply signal pulse pairs from the DME ground station and sends them to the interrogator.

DME/ATC/TCAS Suppression

The DME system, the air traffic control (ATC) system, and the traffic alert and collision avoidance system (TCAS) operate in the same frequency band. When a DME interrogator, an ATC transponder or a TCAS computer transmits, it sends a suppression pulse through the suppression splitter. This pulse inhibits reception of the other four units. This prevents damage to the receiver circuits of the other LRUs.

DME Audio

The DME interrogator sends the DME station audio identifier to the audio management unit (AMU). The AMU combines the DME audio with VOR or ILS audio. The audio goes to the headsets and the flight deck speakers.



DME SYSTEM - POWER, ANALOG, AND DISCRETE INTERFACE

DME SYSTEM - INTERROGATOR

General

The DME interrogator scans 252 channels and calculates distance information for all channels in the DME range. There are 200 DME channels paired with the VHF NAV frequencies. The other 52 channels are for military TACAN facilities. The DME receive frequency is 63 MHz above or below the transmit frequency.

Purpose

The purpose of the DME interrogator is to:

- Interrogate DME stations
- Receive the station replys
- Receive audio identifiers
- Calculate slant range distances.

Frequencies

The DME interrogator uses these L-Band frequencies:

- 1025 MHz to 1150 MHz (transmit)
- 962 MHz to 1215 MHz (receive).

These DME tuning frequencies are in the VHF band:

- 108.00 to 117.95 MHz paired VOR or ILS
- 133.30 to 135.95 MHz unpaired.

Front Panel

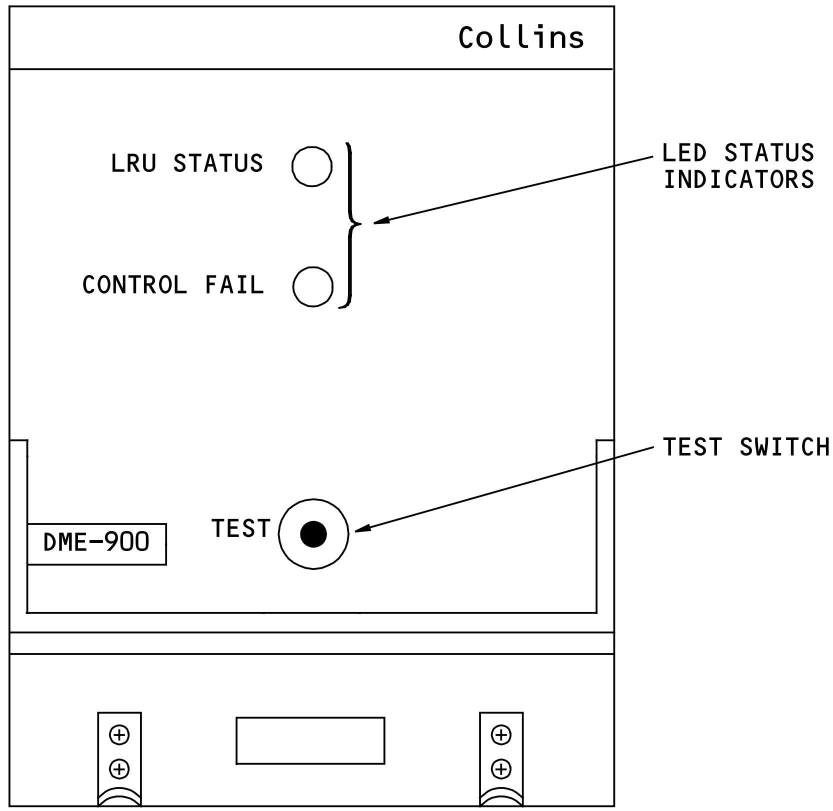
The front panel of the DME interrogator has these features:

-
- LED status indicators
- A self-test switch.

Training Information Point

The maintenance manual and the fault isolation manual do not have a task for the line maintenance technician to do a test from the front panel of the DME interrogator. You must do all tests for the DME interrogator from the MAT or a PMAT.

Many LRUs on the 777 are compatible with other model airplanes that do not have a central maintenance computing system (CMCS). For that reason these LRUs have a front panel test feature.



DME SYSTEM - INTERROGATOR

DME SYSTEM - ANTENNA

General

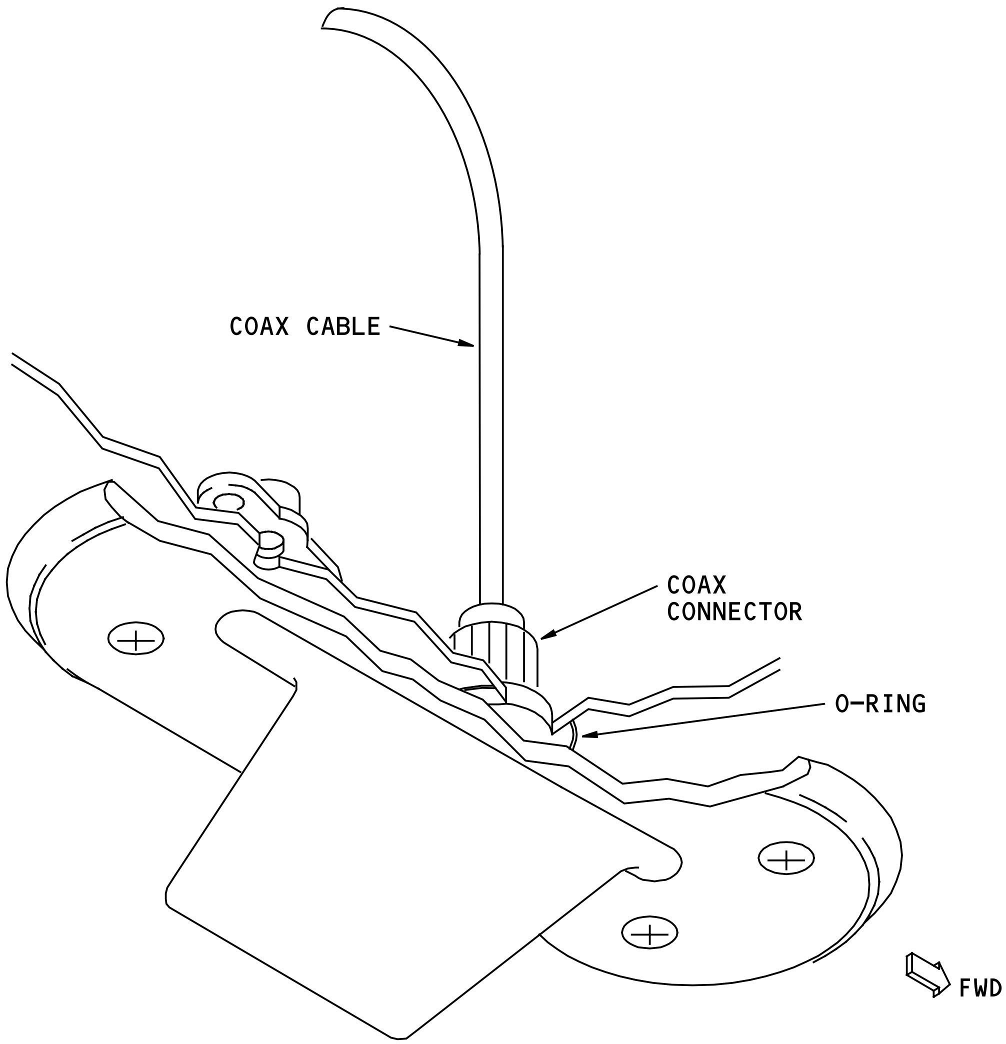
The DME l- band antenna transmits the interrogator output signal and receives the ground station reply signals.

Physical Description

The antenna has an O-ring moisture seal and attaches to the airplane by four screws. The DME and ATC antennas are the same and are interchangeable.

Training Information Point

WARNING: EXTRA FORCE ON THE ANTENNA BASE MAY BE REQUIRED TO BREAK THE WEATHERPROOFING SEAL. TO PREVENT DAMAGE TO AIRPLANE SKIN OR ELECTRICAL CABLE AT THE ANTENNA BASE, CAREFULLY PRY AROUND THE ANTENNA WITH A SEALANT REMOVAL TOOL.



34-55-00-008 Rev 1

DME SYSTEM - ANTENNA

DME SYSTEM - TUNING

General

These are the three ways to tune the DME interrogators:

- Manually by the left, right, or center CDU
- Automatically by the FMCF in the AIMS cabinets
- By the CDUs as an alternate tune source.

Manual Tune

You manually tune the DME interrogators from the left or right control display units (CDUs). The center CDU can tune the interrogators if the left or right CDU fails. Manual tune inputs from the CDUs go through the left and right systems ARINC 629 buses, then to the left and right AIMS cabinets. Manual tune inputs from the left or right AIMS cabinet comes from the right AIMS cabinet and goes to the DME interrogators.

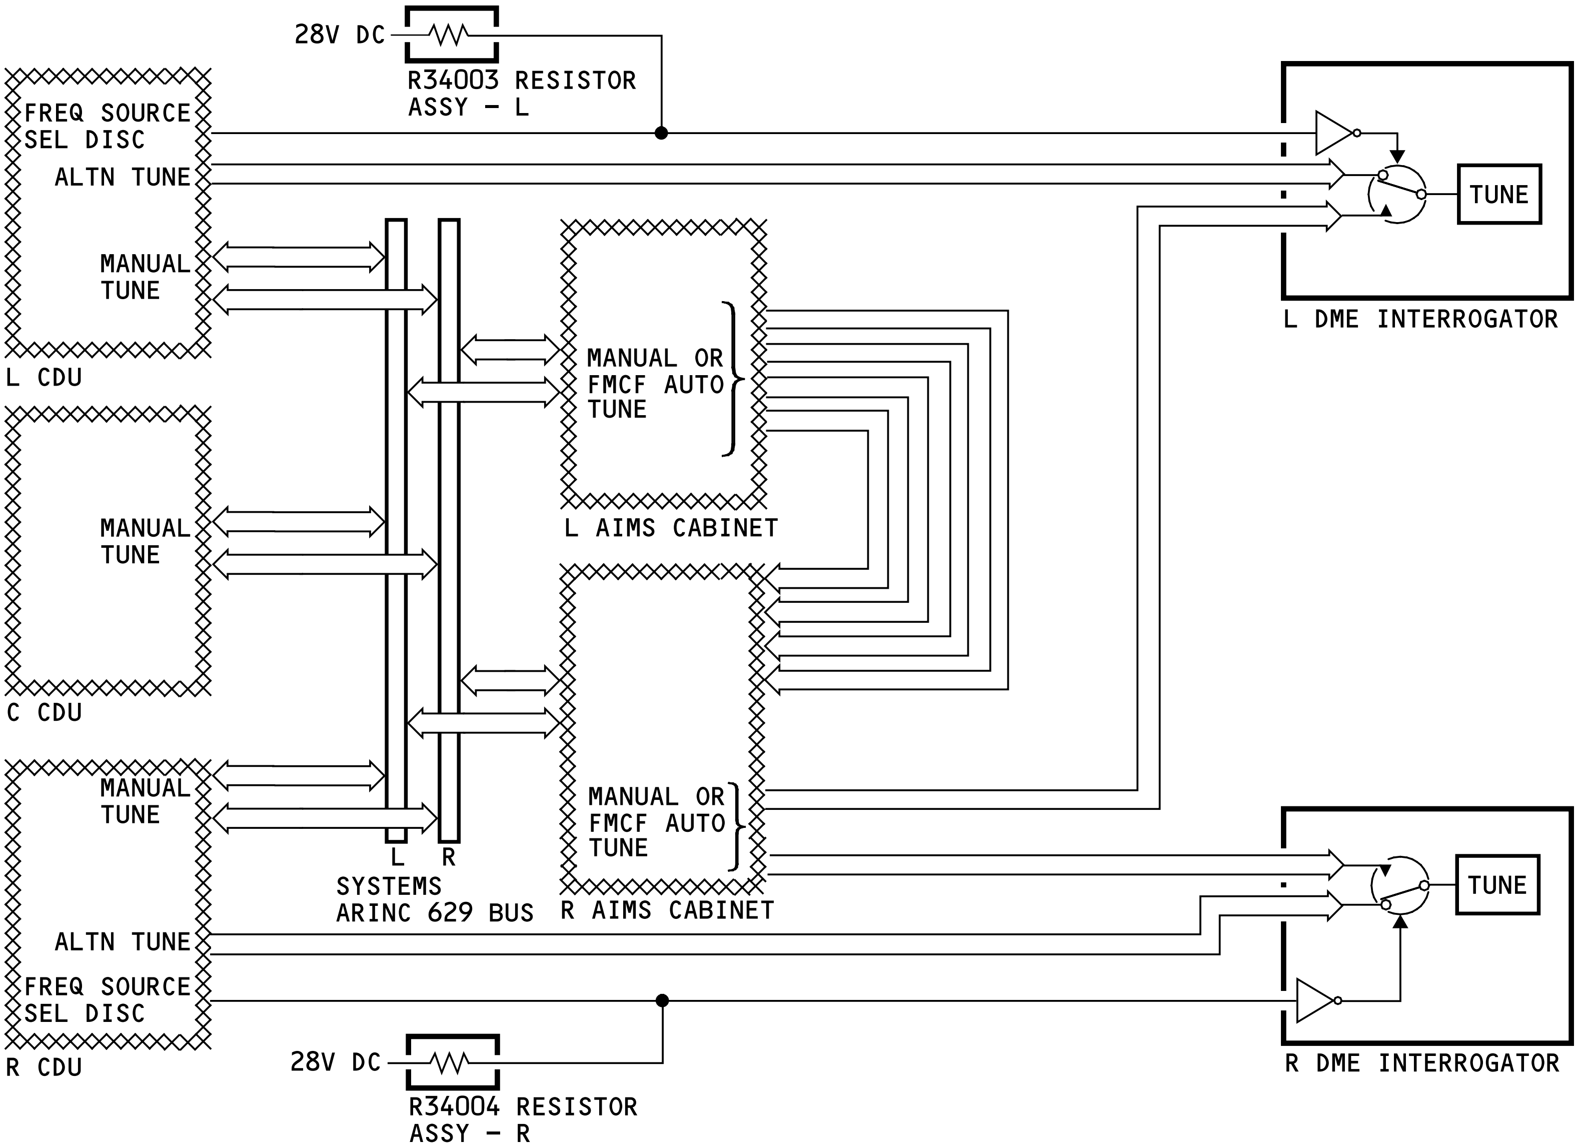
AIMS Autotune

The flight manangement computing function (FMCF) of the left or right AIMS cabinet can automatically tune (autotune) the DME interrogators. Autotune inputs from the left or right AIMS cabinets go through the right AIMS cabinet, then to the DME interrogators.

Alternate Tune

The CDUs monitor the AIMS cabinets tune functions. IF the AIMS tune function fails, the CDUs send a frequency source select discrete to the DME interrogators that changes the inputs from the right AIMS cabinet, to the input that comes directly from the left or right CDU. The CDUs use 28v dc from a pull-up resistor to set the discrete.

In the alternate tune mode, the left CDU alternate tunes the left DME interrogator and the right CDU alternate tunes the right DME interrogator. The center CDU has no alternate tune function.



DME SYSTEM - TUNING

THIS PAGE INTENTIONALLY LEFT BLANK

DME SYSTEM - AUDIO CONTROL PANEL

General

The audio control panels supply control inputs to the audio management unit. This lets the crew hear audio signals on the speakers and headsets in the flight deck.

DME Audio Pairing

The flight management computing function (FMCF) of AIMS can pair the DME station identifier audio with VOR station identifier audio, or with ILS station identifier audio.

The flight crew uses the EFIS control panels or the EFIS CONTROL page on the CDU to determine how to pair the DME audio. The flight crew selections go to the FMCF. The FMCF sends the DME pairing signal to the audio management unit (AMU). The AMU uses the pairing signal to pair the DME audio with ILS or VOR audio.

When the captain selects the approach (APP) ND mode on the left EFIS control panel or on the left CDU EFIS CONTROL page, the AMU pairs the left DME interrogator audio with the left multi-mode receiver (MMR) audio. When the captain selects the VOR, MAP, or PLAN mode, the AMU pairs the left DME interrogator audio with the left VOR receiver audio.

When the first officer selects the approach (APP) ND mode on the right EFIS control panel or on the right CDU EFIS CONTROL page, the AMU pairs the right DME interrogator audio with the right MMR audio. When the first officer selects the VOR, MAP, or PLAN mode, the AMU pairs the right DME interrogator audio with the right VOR receiver audio.

Description

These are the controls on the audio control panel that let you hear DME audio:

- VOR/ADF receiver selector
- VOR/ADF receiver volume control
- NAV filter selector.
- Approach receiver volume control
- Approach receiver selector.

VOR/ADF Receiver Selector

The VOR/ADF receiver selector lets you select VOR or ADF as the source of audio. With the selector in the VOR positions, you can hear DME station identifier audio and VOR station audio.

VOR/ADF Receiver Volume Control

The VOR/ADF receiver volume control turns on the audio and controls the volume.

NAV Filter Selector

The NAV filter selector lets you select one of these:

- Voice (V) audio
- Both (B) voice and range audio.

- Range (R) audio.

Approach Receiver Volume Control

The approach volume control makes the audio come on and controls the volume for the approach (APP) selector.

Approach Receiver Selector

The approach receiver selector lets you select ILS or marker beacon as the source for audio.

With the selector in the left (L) position, you can hear audio from the left DME interrogator. The DME audio you will hear is the DME station identifier audio that is paired with the multi-mode receiver (MMR) audio.

With the selector in the right (R) position, you can hear audio from the right DME interrogator. The DME audio you will hear is the DME station identifier audio that is paired with the right MMR audio.

With the selector in the center (C) position, you will not hear any DME audio. You will only hear ILS station identifier audio from the center MMR.

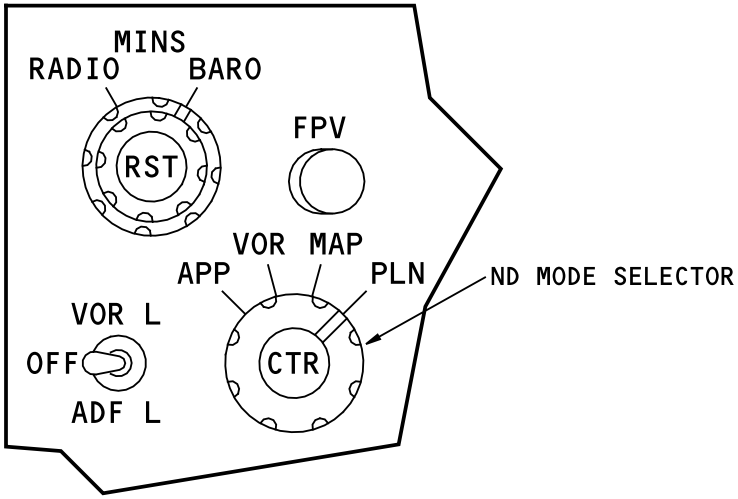
Operation

Do this to hear DME or VOR/DME audio:

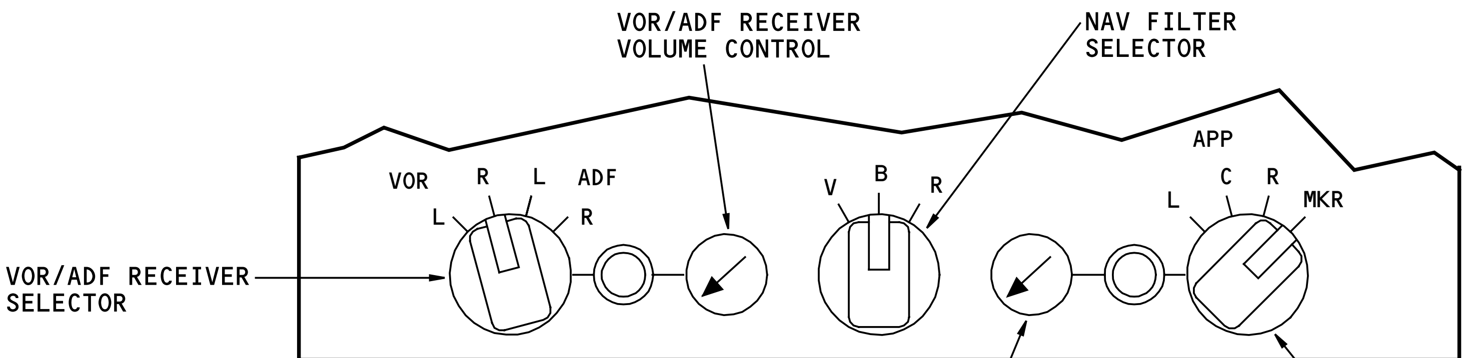
- Set the VOR/ADF receiver selector to the left (L) or right (R) VOR position
- Push the VOR/ADF receiver volume control to make the VOR audio come on (turn the control to adjust the volume)
- Set the NAV filter selector to the both (B) or range (R) position.

Do this to hear ILS/DME audio:

- Set the approach receiver selector to the left (L) or right (R) position
- Push the approach receiver volume control to make the ILS audio come on (turn the control to adjust the volume).



EFIS CONTROL PANEL



AUDIO CONTROL PANEL

34-55-00-010 Rev 4 06/28/96

DME SYSTEM - AUDIO CONTROL PANEL

DME SYSTEM - MANUAL AND ALTERNATE TUNING

General

The CDUs supply manual tune inputs during normal operation and alternate tune inputs when the AIMS tune inputs fail.

Since DME stations are normally paired with VOR or ILS stations, to tune the DME interrogators, you enter a VOR or ILS frequency. You can also tune DME stations that are not paired with VOR or ILS stations.

Operation

To see DME frequencies and DME/VOR or DME/ILS paired frequencies, push the NAV RAD key on the CDU. The NAV RADIO page shows data for the NAV radios.

To manually tune a DME interrogator, enter a valid VOR or ILS frequency or identifier into the scratch pad. Push the line select key to enter the frequency for the applicable data line. To tune an unpaired DME frequency, enter the VOR frequency into the VOR data line for the left or right VOR system.

When you manually enter a VOR frequency, the letter M shows after the frequency.

The letter A shows after the VOR frequency when the FMCF of AIMS autotunes the frequency.

To delete the frequency, push the delete (DEL) key on the CDU. The delete function shows in the CDU scratchpad. Next, line select the delete function to the applicable VOR data line.

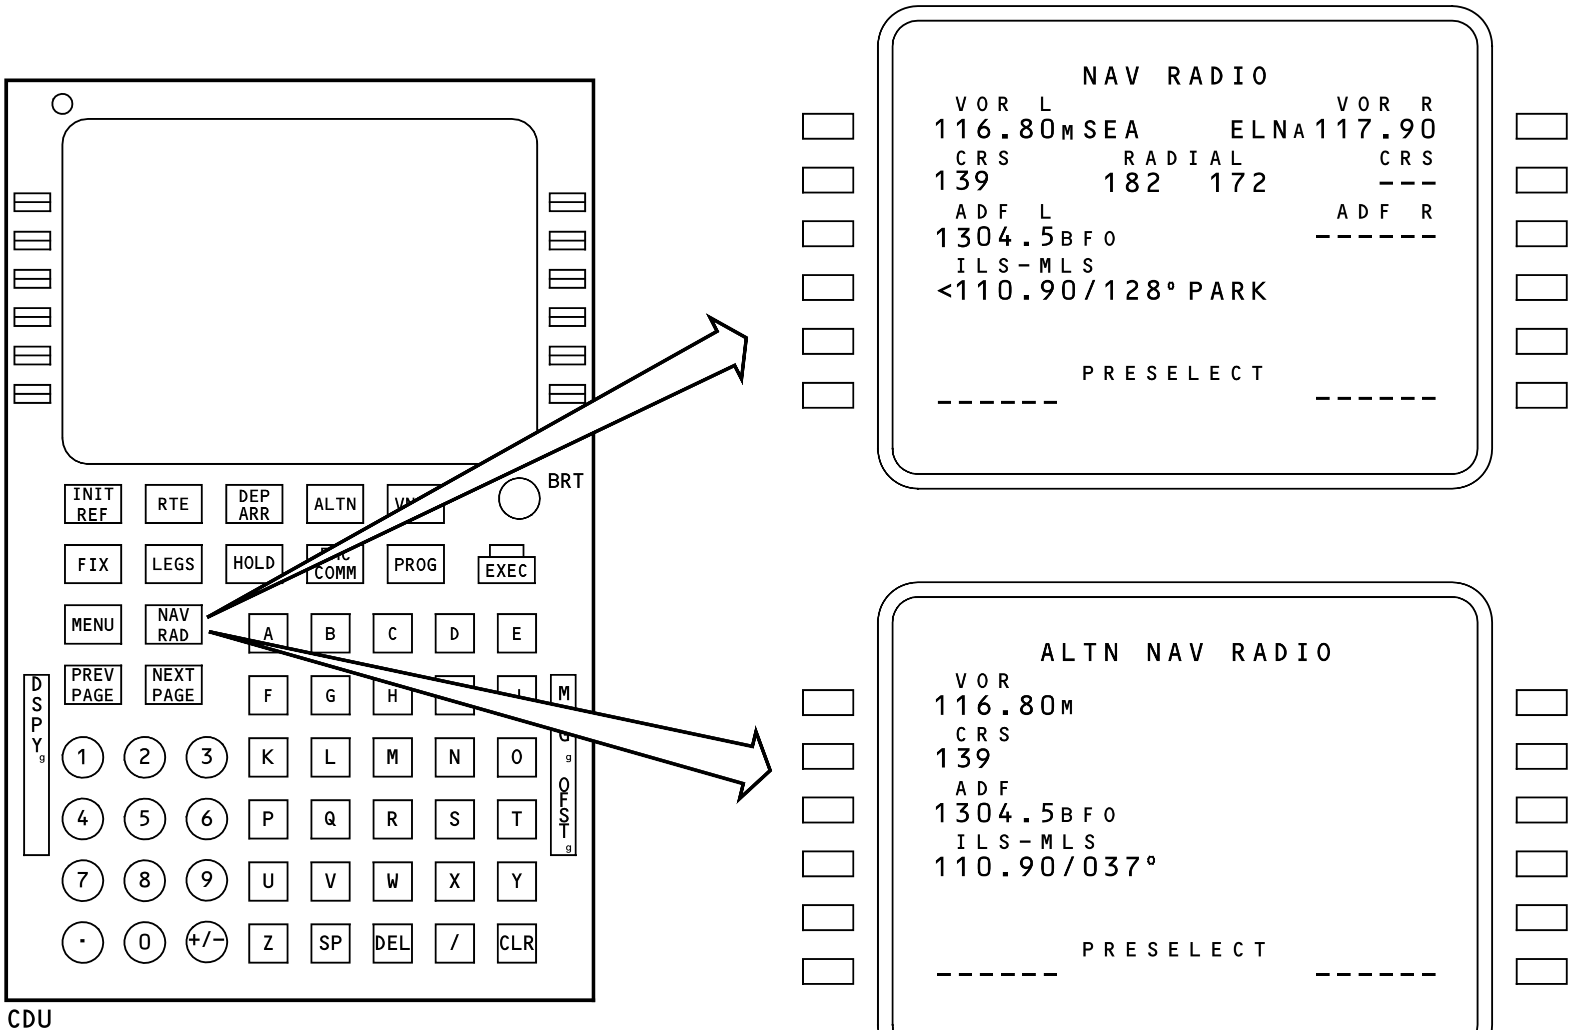
Alternate Tuning

The ALTN NAV RADIO page is available only when the tune inputs from the AIMS cabinets fail.

To get access to the ALTN NAV RADIO page, push the NAV RAD key on the CDU.

The ALTN NAV RADIO page is different from the NAV RADIO page. The ALTN NAV RADIO page shows data for only the left or right NAV radios. The left CDU ALTN NAV RADIO page controls the left NAV receivers and the right CDU ALTN NAV RADIO page controls the right NAV receivers.

You enter a VOR or ILS frequency the same as you do for normal manual tuning.



DME SYSTEM - MANUAL AND ALTERNATE TUNING

DME SYSTEM - EFIS CONTROLS

General

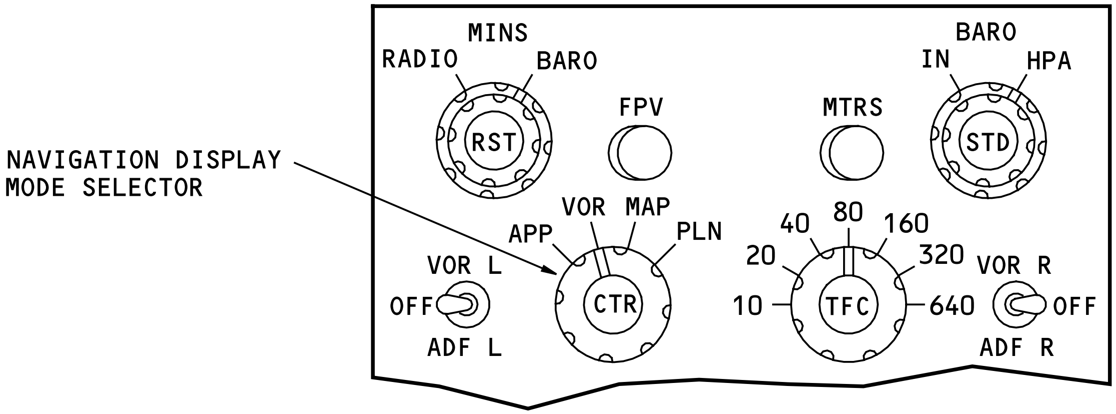
The EFIS control panel has controls to select DME data to show on the navigation displays (NDs).

Navigation Display Mode Selector

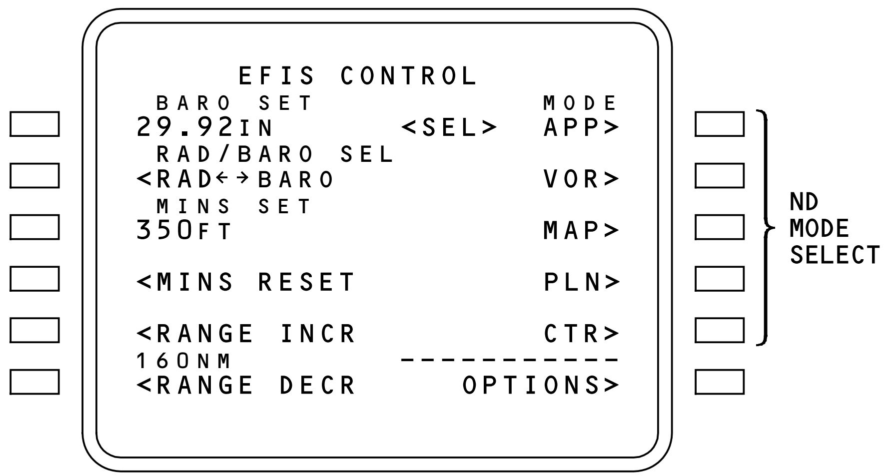
You use the navigation display mode selector to select the display mode on the NDs. DME data shows in all modes except plan (PLN) mode.

Alternate or Backup EFIS Control Panel

The EFIS control page on the CDU supplies backup controls for the EFIS control panel. You can use the EFIS control page to select the display mode for the NDs.



EFIS CONTROL PANEL



EFIS CONTROL PAGE

DME SYSTEM - EFIS CONTROLS

34-55-00-022 Rev 1 11/06/1997

DME SYSTEM - PRIMARY FLIGHT DISPLAY

Normal Display

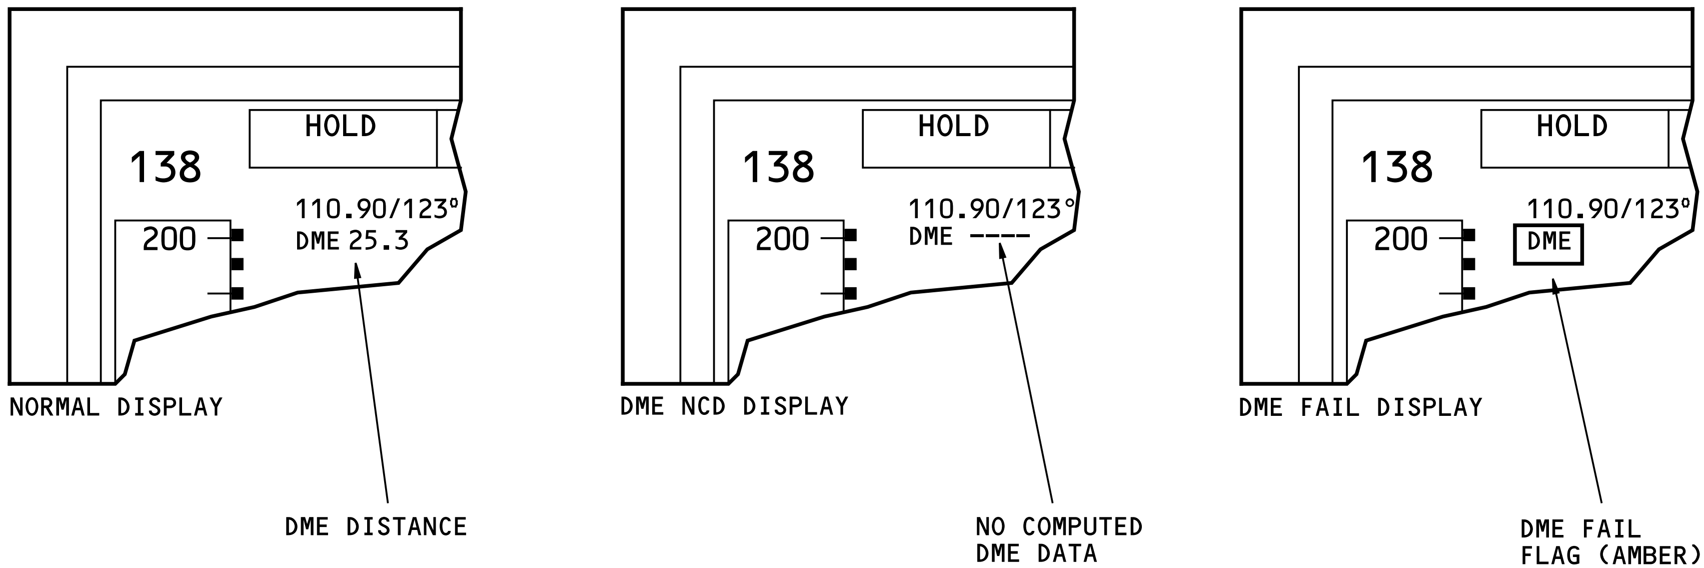
The primary flight display (PFD) format shows the ILS/ DME distance when you tune the onside DME to a paired ILS frequency and when the onside DME distance is valid.

The left PFD shows left DME data. The right PFD shows right DME data. The DME distance display shows in white letters and numbers.

DME NCD and Fail Displays

Dashes replace the DME distance when the DME distance data is no computed data (NCD). If the DME fails, the DME flag replaces the DME distance. Both the NCD and fail flag show in amber.

Only the onside DME distance shows on the PFDs. The left DME distance shows only on the captain's PFD. The right DME distance shows only on the first officer's PFD. If the left DME distance is NCD, dashes shows on the captain's PFD. If the left DME fails, a DME flag shows on the captain's PFD. The same occurs for the first officer's PFD if the right DME is NCD or fails.



34-55-00-011 Rev 2

DME SYSTEM - PRIMARY FLIGHT DISPLAY

DME SYSTEM - ND APPROACH MODE DISPLAY

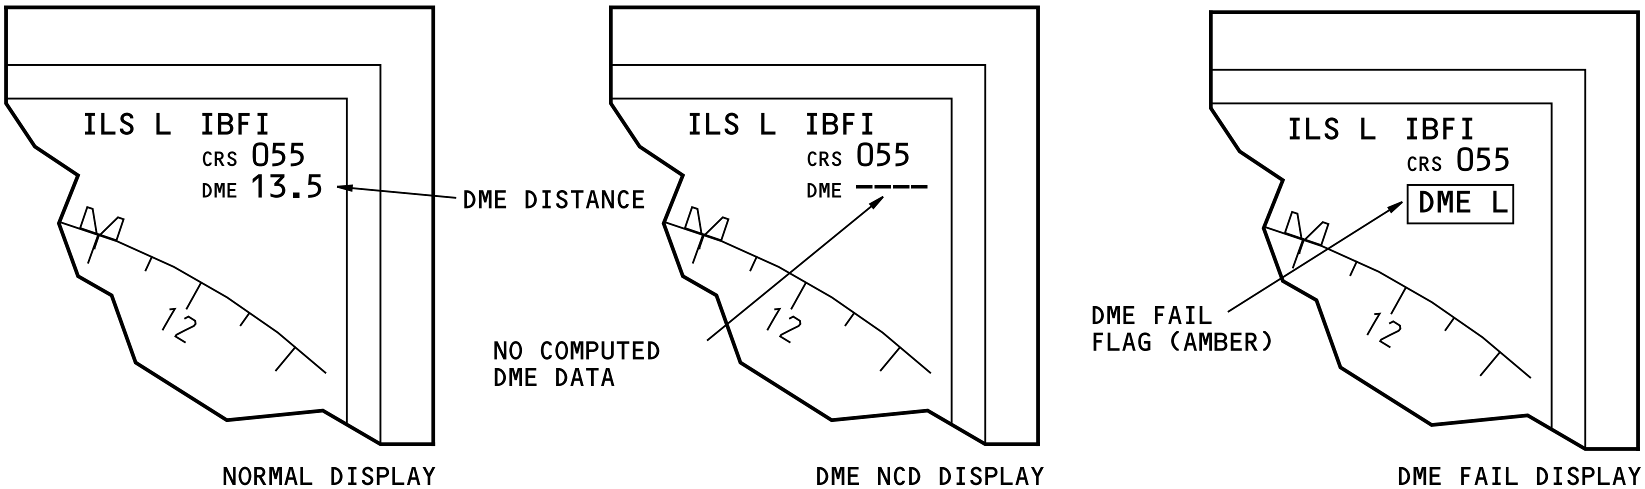
DME Normal Displays

The ILS/DME data shows on the ND in the centered and expanded approach (APP) modes. DME distance shows in the upper right corner of the ILS display when the onside DME is tuned to a paired ILS frequency, and the onside DME distance is valid.

DME NCD or Failed Displays.

Dashes replace digits when the DME distance is NCD. If the DME fails, an amber DME flag replaces the DME distance.

Only onside DME distance shows on the upper right corner of the approach mode. The left DME distance shows only on the captain's approach mode. The right DME distance shows only on the first officer's approach mode. If the left DME distance is NCD, dashes shows on the upper right corner of the captain's approach mode. If the left DME fails, a DME flag shows on the upper right corner of the captain's approach mode. The same occurs for the first officer's approach mode if the right DME is NCD or fails.



34-55-00-012 Rev 2

DME SYSTEM - ND APPROACH MODE DISPLAY

DME SYSTEM - MAP MODE DISPLAY

General

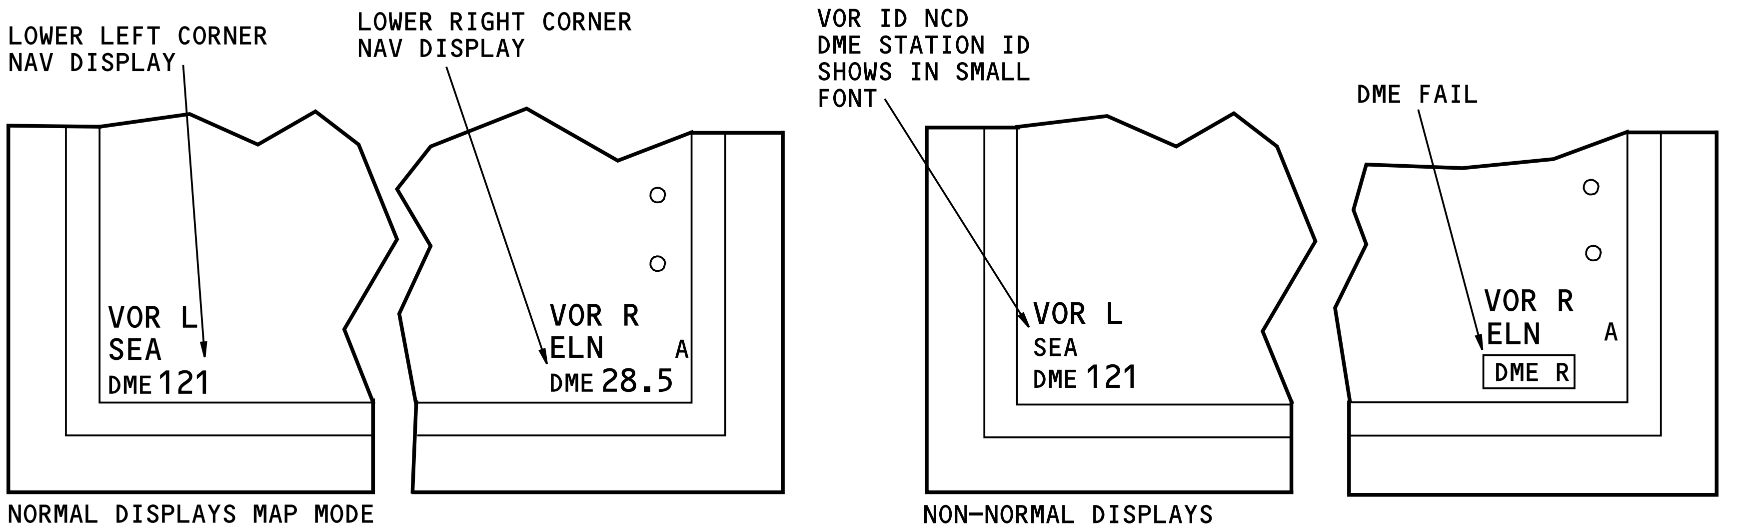
The DME distance shows in all ND modes except PLAN. With the EFIS control panel mode selector set to the MAP mode and the VOR/ADF switches in the VOR position, the ND shows slant range distance of the paired DME stations.

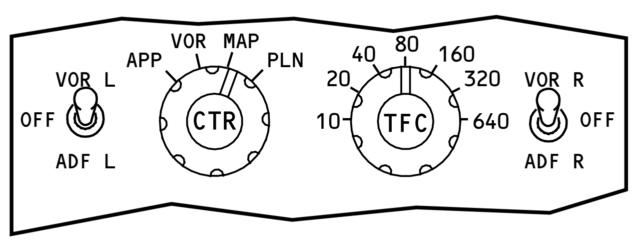
Distance Display

For DME distance less than 99.5 nm, the distance shows in tenths of an nm. For DME distances of 99.5 nautical miles (nm) or greater, the distance shows to the nearest 1 nm.

NCD or Invalid Displays.

Dashes replace digits when the DME distance data is NCD. A DME flag replaces the DME distance when DME fails.





EFIS CONTROL PANEL (P55)

34-55-00-013 Rev 2 02/27/1998

DME SYSTEM - MAP MODE DISPLAY

DME SYSTEM - VOR MODE DISPLAY

DME Normal Displays

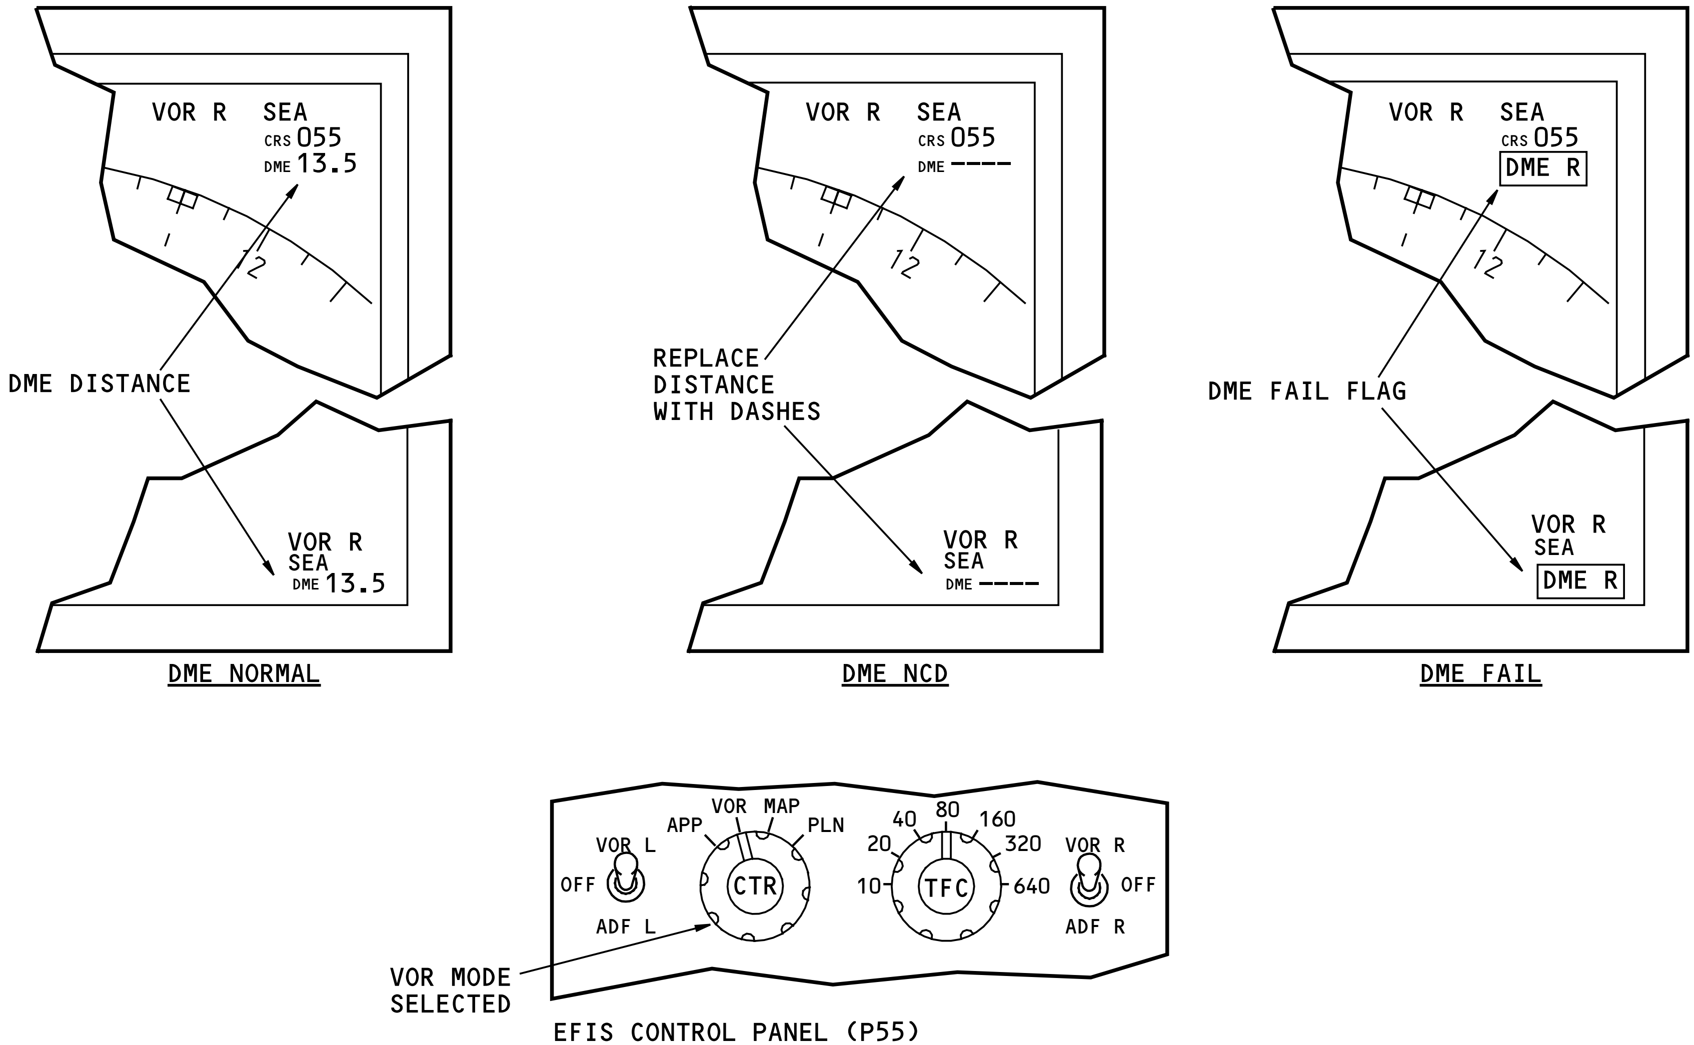
The VOR/DME data shows on the ND in center or expanded VOR modes. DME distance shows in the upper right corner of the VOR display when the onside DME is tuned to a paired VOR frequency, and the onside DME distance is valid.

When the VOR/ADF switches are in the VOR position the DME distance for a paired VOR station shows in the lower corners.

DME NCD or Failed Displays.

Dashes replace digits when the DME distance is NCD. If the DME fails, a DME flag replaces the DME distance.

DME distance shows only on the upper right corner of the onside VOR mode display. The left DME distance shows only on the captain VOR mode. The right DME distance shows only on the first officer VOR mode. If the left DME distance is NCD, dashes shows on the upper right corner captain VOR mode. If the left DME fails, a DME flag shows on the upper right corner of the captain VOR mode. The same occurs for the first officer VOR mode if the right DME is NCD or fails.



34-55-00-014 Rev 3 02/27/1998

DME SYSTEM - VOR MODE DISPLAY

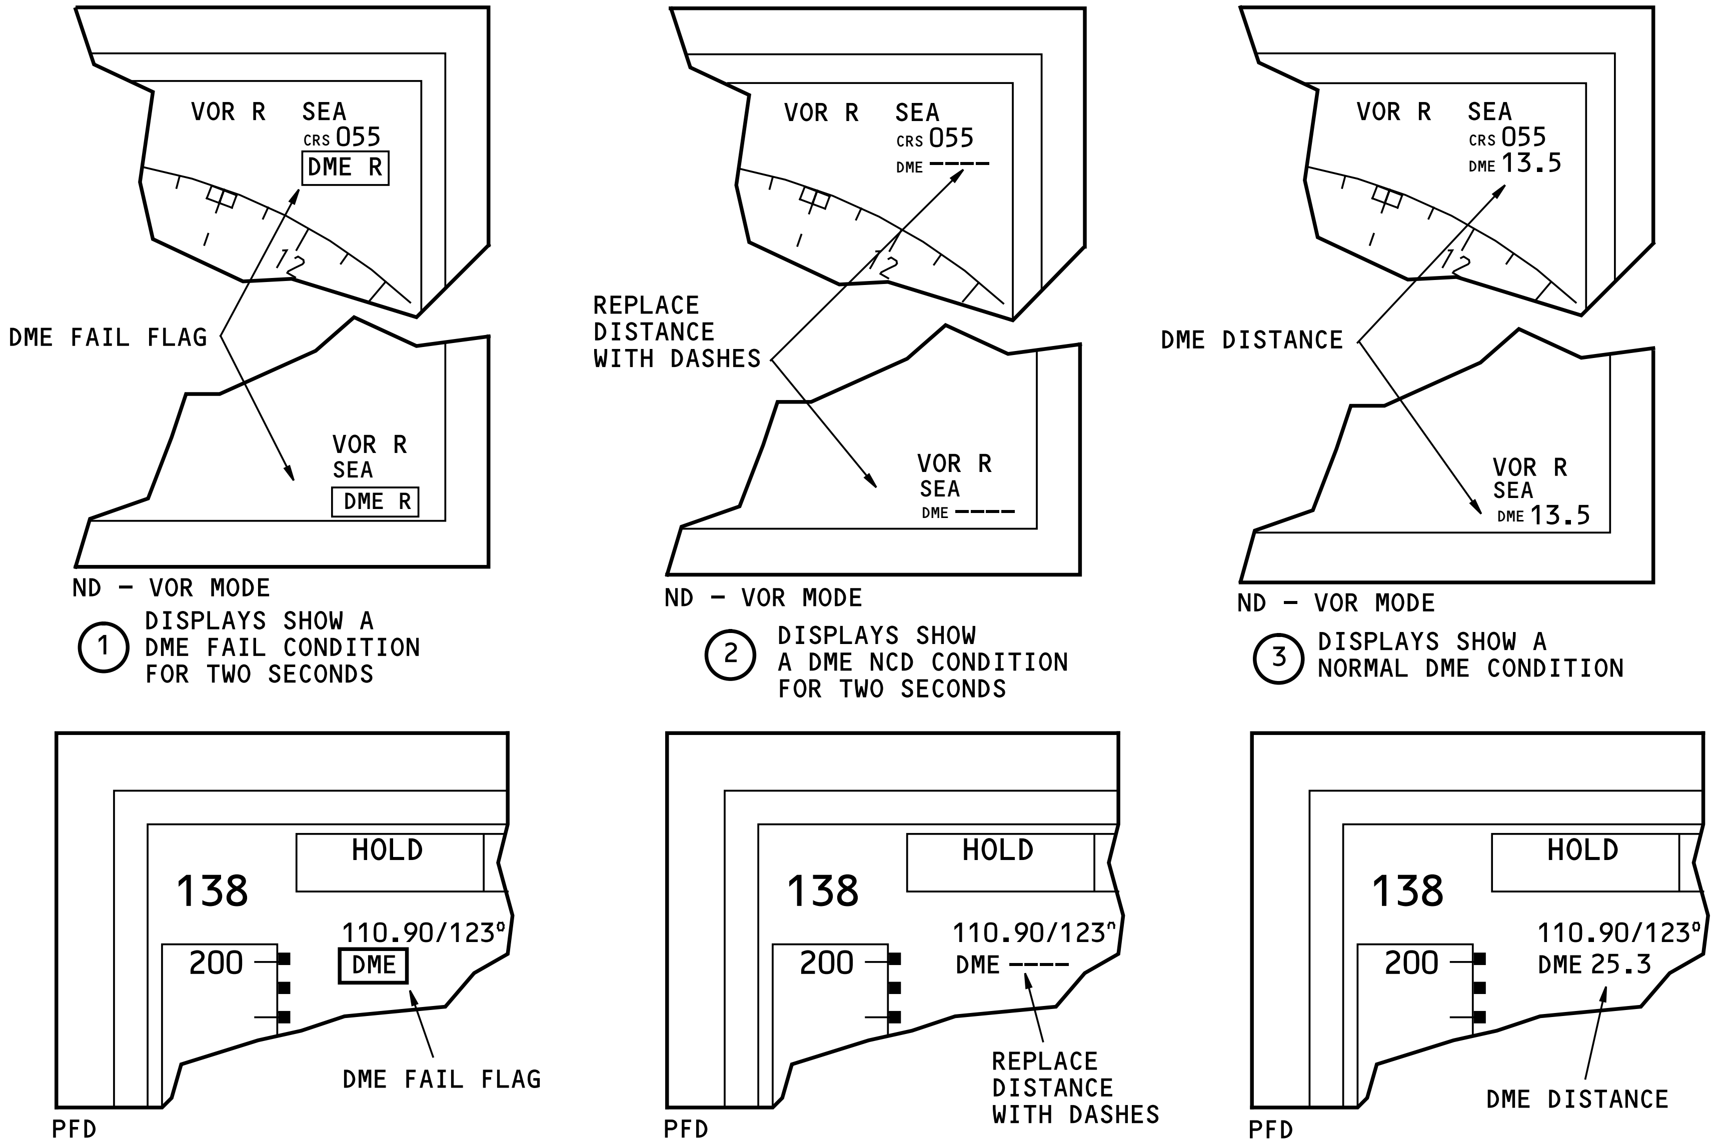
DME SYSTEM - TEST DISPLAYS

General

During a ground test or a self test, the onside PFD and ND show:

- The DME fail condition for two seconds
- The DME NCD condition for the next two seconds
- The DME normal condition to end the test.

The DME normal condition is the distance that shows before the test starts.



DME SYSTEM - TEST DISPLAYS

34-55-00-015 Rev 1

DME SYSTEM - GROUND TEST

General

You can do a test of the DME system from the MAT. These tests are available from the operational test selection on the MAT:

- Left DME System
- Right DME System.

Operational Test

The operational test for the left and right DME systems does a check for normal operation of the DME interrogators and the control inputs to both interrogators.

AUTOMATIC DIRECTION FINDER SYSTEM - INTRODUCTION

ADF SYSTEM - GENERAL DESCRIPTION

General

The ADF system has two receivers and two antennas.

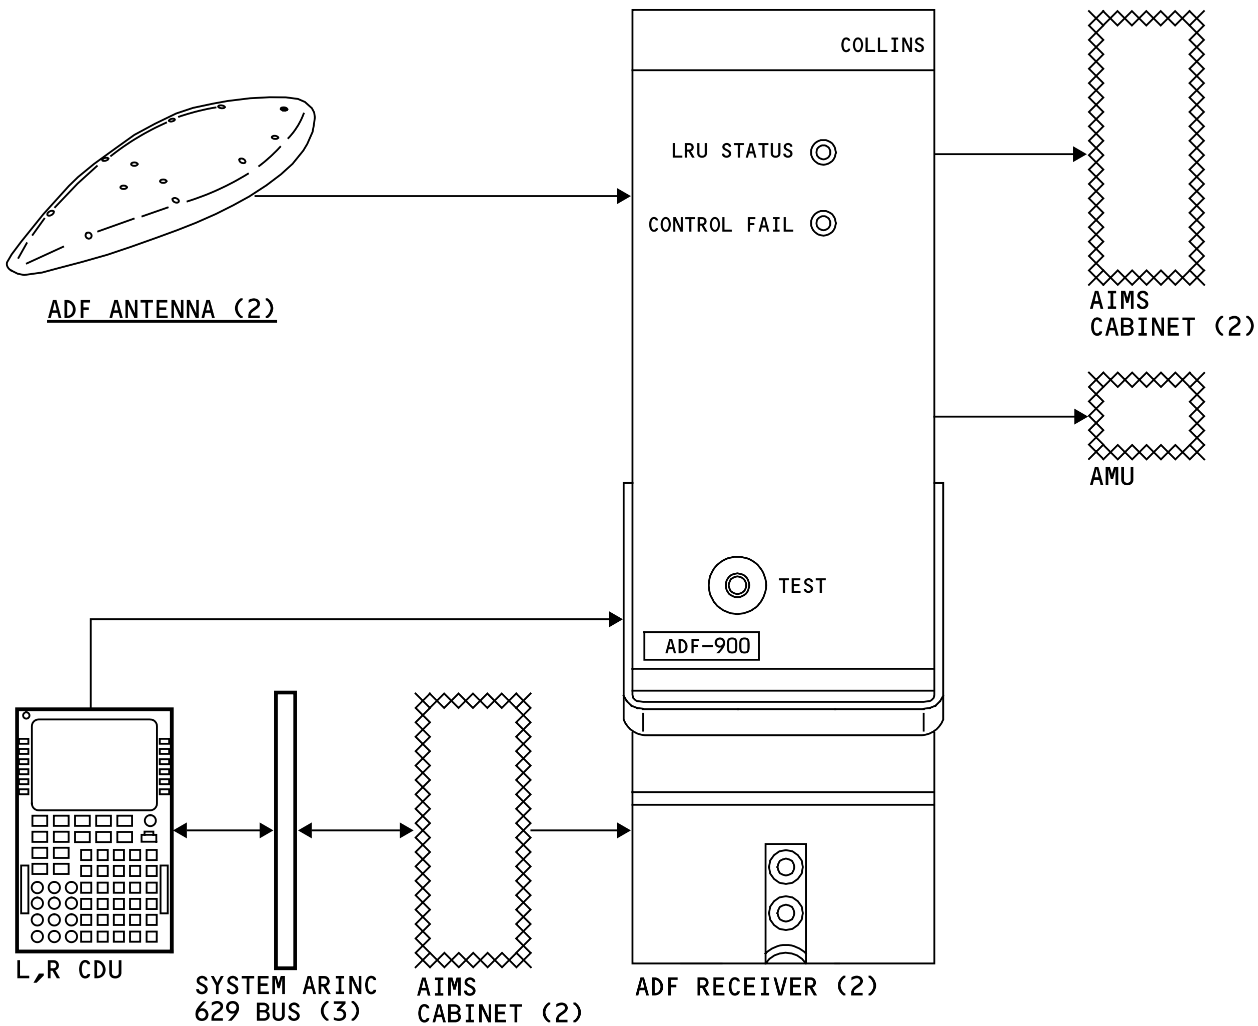
Description

The ADF antenna assembly has both the loop and sense antennas. The antenna receives signals from the ground stations and sends them to the ADF receiver.

The ADF receiver calculates the bearing to the station and sends it to the AIMS cabinets to show on the navigation displays (ND).

You can tune the ADF receivers manually from the left or right CDU. The airplane information management system does not autotune the ADF receivers. The receivers can get tune inputs directly from the left or right CDU (alternate tune) if the tune inputs through the AIMS cabinets fail.

The ADF receiver processes the station audio and sends it to the audio management unit (AMU).



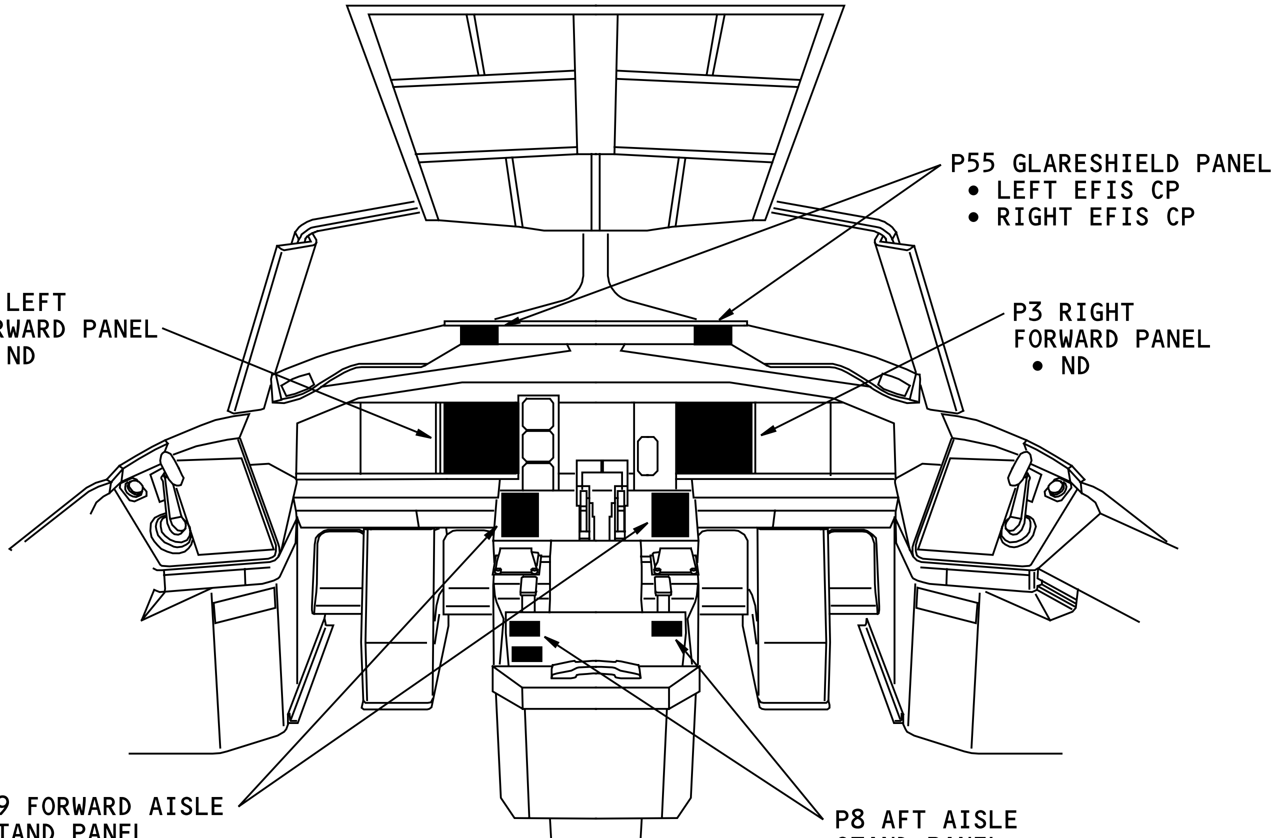
ADF SYSTEM - GENERAL DESCRIPTION

ADF SYSTEM - FLIGHT DECK COMPONENT LOCATION

General

The components on the flight deck that interface with the ADF system are:

- Left and right EFIS control panel (CP)
- Captain's and first officer's navigation display (ND)
- Left and right control display units (CDUs)
- Audio control panels (ACPs).



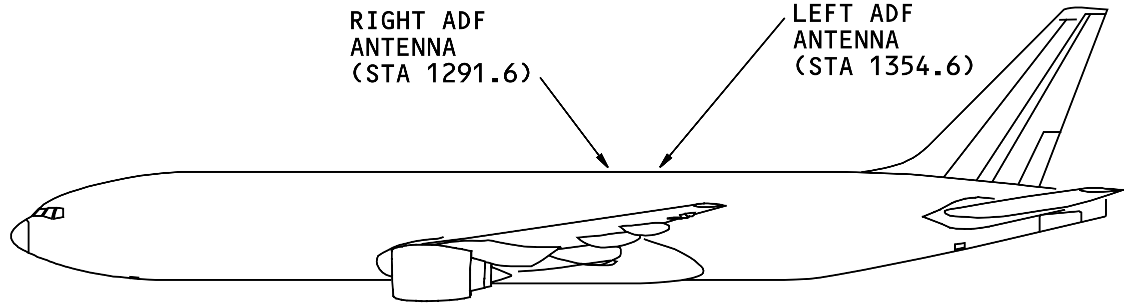
34-57-00-003 Rev 1

ADF SYSTEM - FLIGHT DECK COMPONENT LOCATION

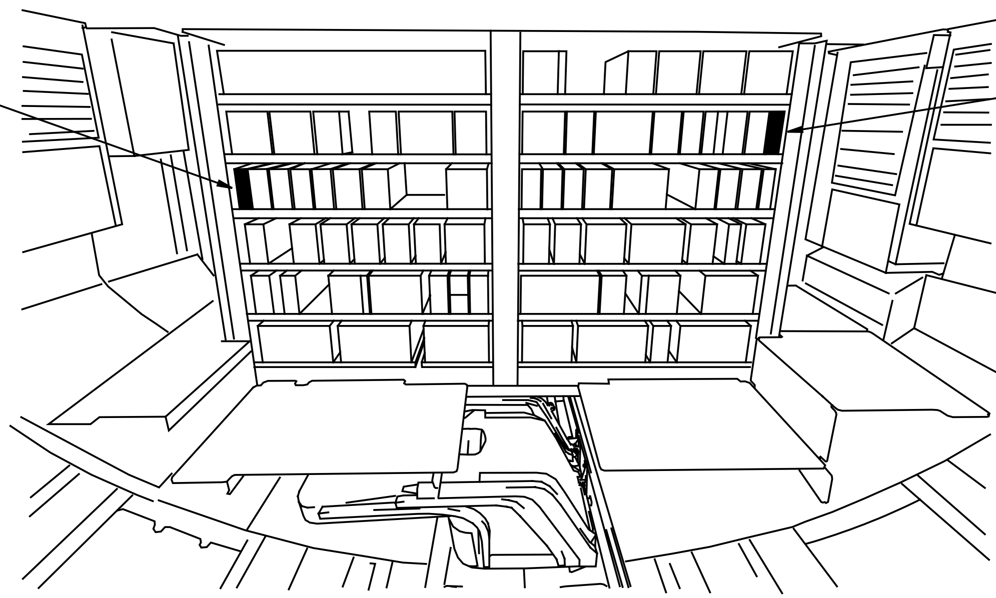
ADF SYSTEM - MAIN EQUIPMENT CENTER AND FUSELAGE COMPONENT LOCATION

General

The ADF antennas are on the top of the fuselage. The left and right ADF receivers are in the main equipment center on the E1 and E2 racks.



FUSELAGE ANTENNA LOCATION



MAIN EQUIPMENT CENTER
(LOOKING AFT)

ADF SYSTEM - MAIN EQUIPMENT CENTER AND FUSELAGE COMPONENT LOCATION

ADF SYSTEM - DIGITAL INTERFACE

General

The components that interface with the ADF receivers on ARINC 429 data buses are the left and right CDUs and the left and right AIMS cabinets.

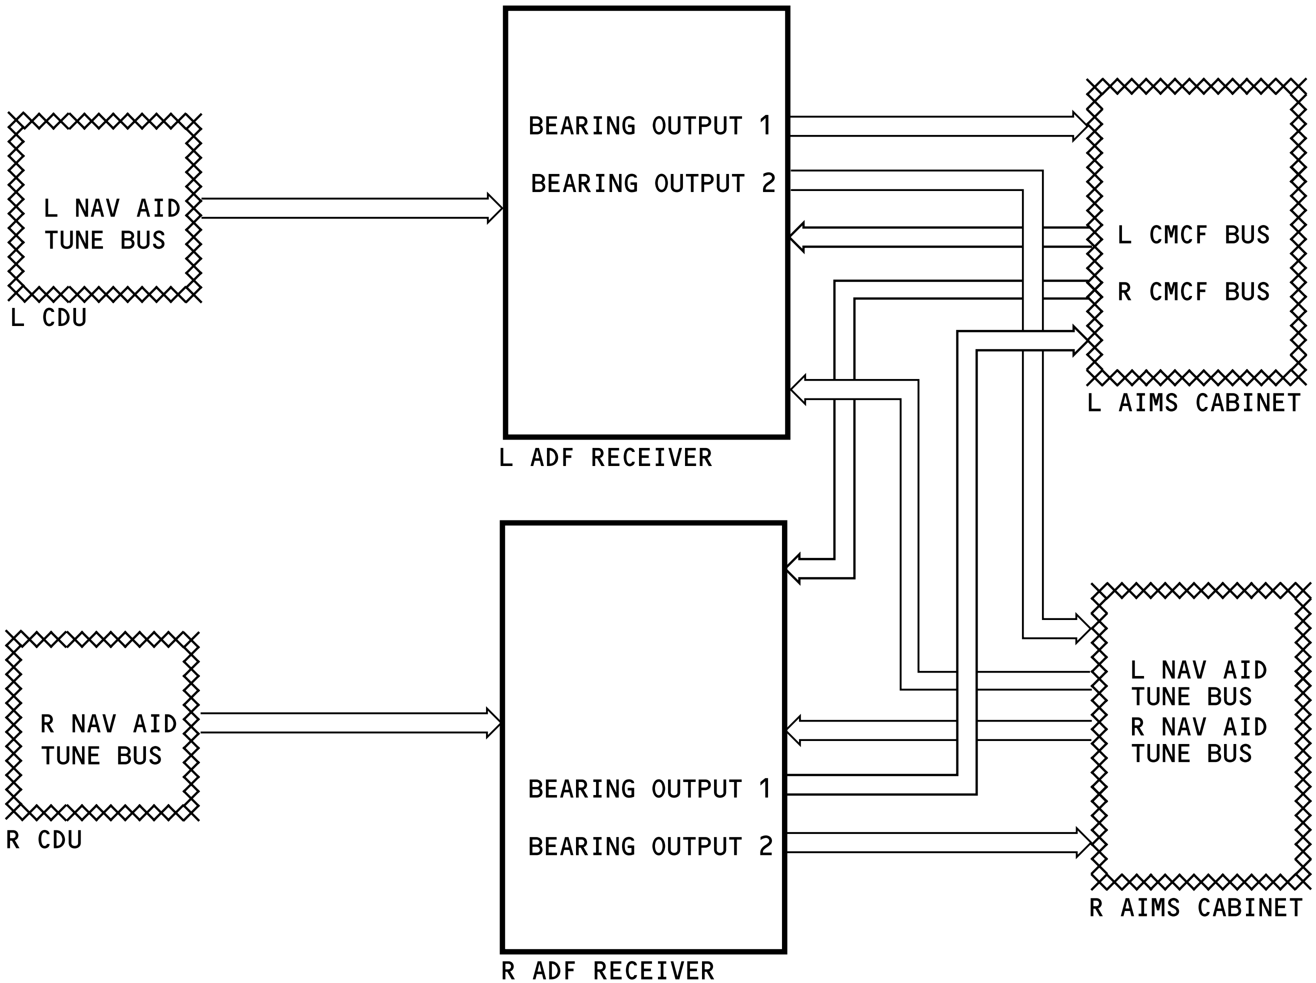
CDU Interfaces

The CDUs supply tune inputs directly to the ADF receivers on the NAV aid tune buses when the tune inputs from the AIMS cabinets fail.

AIMS Cabinet Interfaces

The ADF receivers get tune inputs from the flight management computer function (FMCF) in the right AIMS cabinet. The left and right ADF receivers get tune inputs on the left and right NAV aid tune buses from the right AIMS cabinet.

Test commands come from the central maintenance computer function (CMCF) in the left AIMS cabinet. The left and right ADF receivers get test commands on the left and right CMCF buses from the left AIMS cabinet. The AIMS cabinets also give flight leg data to the ADF receivers.



34-57-00-005 Rev 1

ADF SYSTEM - DIGITAL INTERFACE

ADF SYSTEM - POWER, ANALOG, AND DISCRETE INTERFACES

Power

The left and right ADF receivers get 115v ac from the left and right 115v ac transfer buses.

The ADF receivers send 12v dc to their ADF antennas.

ADF Antennas

The ADF antennas send AM ground station signals to the ADF receivers.

CDUs

The CDUs supply frequency source select discretes to the ADF receivers when the tune inputs from the AIMS fails. The resistor assemblies pull up the discretes to 28v dc. The left CDU sends a ground discrete to the left receiver when the discrete is true. The right CDU sends a ground discrete to the right receiver when the discrete is true.

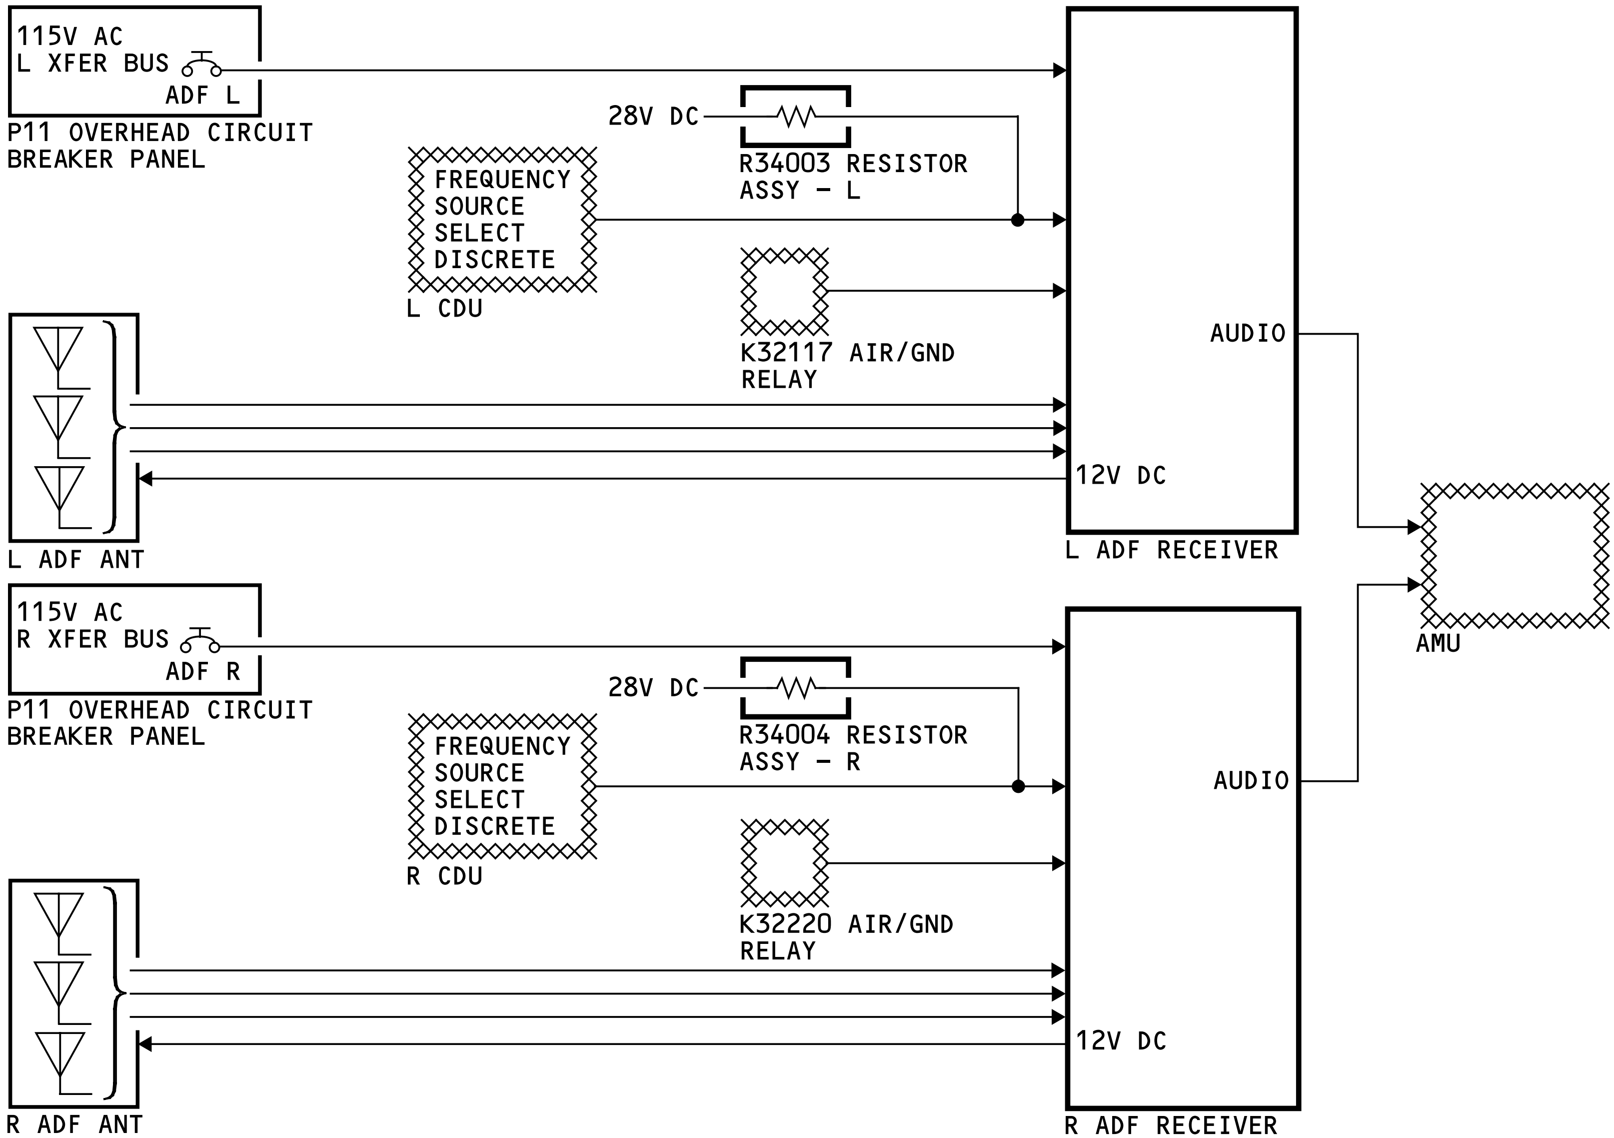
Air/Ground Relay

The air/ground relay supply discrete inputs to the ADF receivers to:

- Set flight legs (as alternate source, primary is from the CMCF of AIMS)
- Inhibit test commands in the air.

AMU

The audio management unit (AMU) receives Morse code station identifier signals and audio from the receivers and sends them to the flight interphone speakers and headsets.



34-57-00-006 Rev 4 02/27/1998

ADF SYSTEM - POWER, ANALOG, AND DISCRETE INTERFACES

ADF SYSTEM - ADF RECEIVER

Purpose

The ADF receiver calculates bearing to a station that transmits in the frequency range of 190 KHz to 1750 KHz. The receiver also receives station identifiers and AM broadcasts.

Description

The ADF receiver operates on 115v ac power. The receiver has built-in test equipment (BITE) that monitors receiver operation and data inputs.

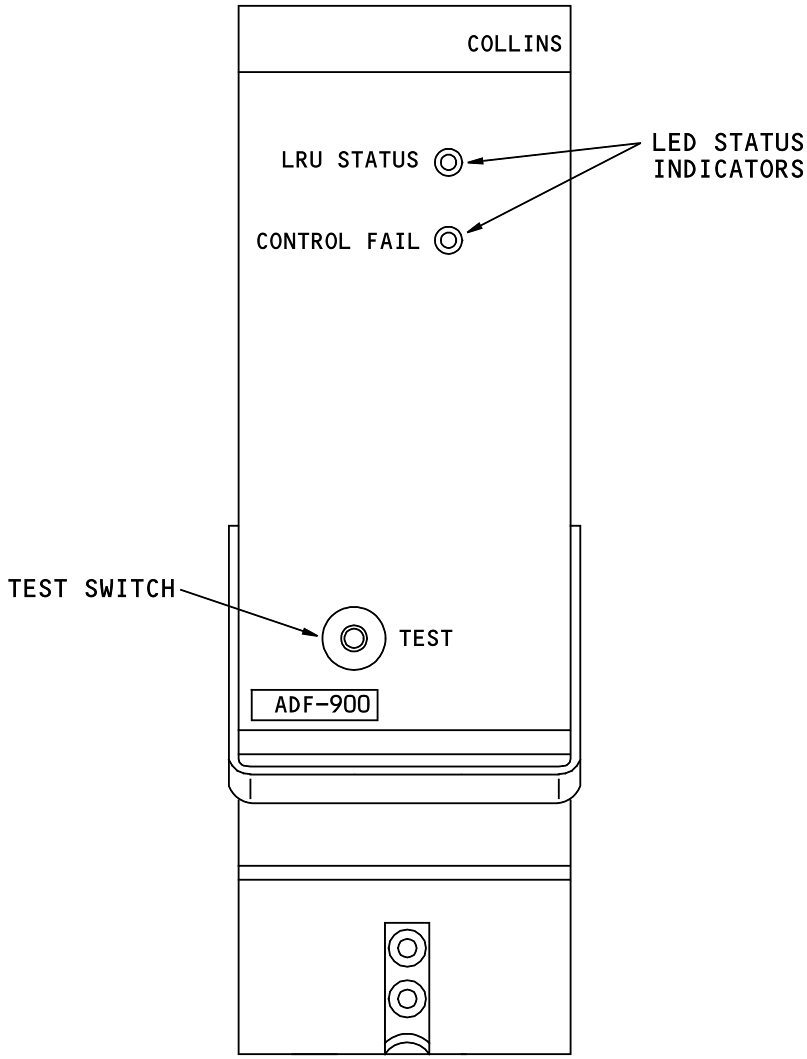
There is a test switch on the front panel of the receiver. When you push the test switch, a self-test begins. At the end of the test, the status of the ADF receiver and tuning inputs shows.

Use the maintenance access terminal (MAT) to do a test of the ADF receiver.

Training Information Point

The maintenance manual and the fault isolation manual do not have a task for the line maintenance technician to do a test from the front panel of the ADF receiver. You must do all tests for the ADF receiver from the MAT or a PMAT.

Many LRUs on the 777 are compatible with other model airplanes that do not have a central maintenance computing system (CMCS). For that reason these LRUs have a front panel test feature.



34-57-00-008 Rev 2 05/18/95

ADF SYSTEM - ADF RECEIVER

ADF SYSTEM - ADF ANTENNA

Purpose

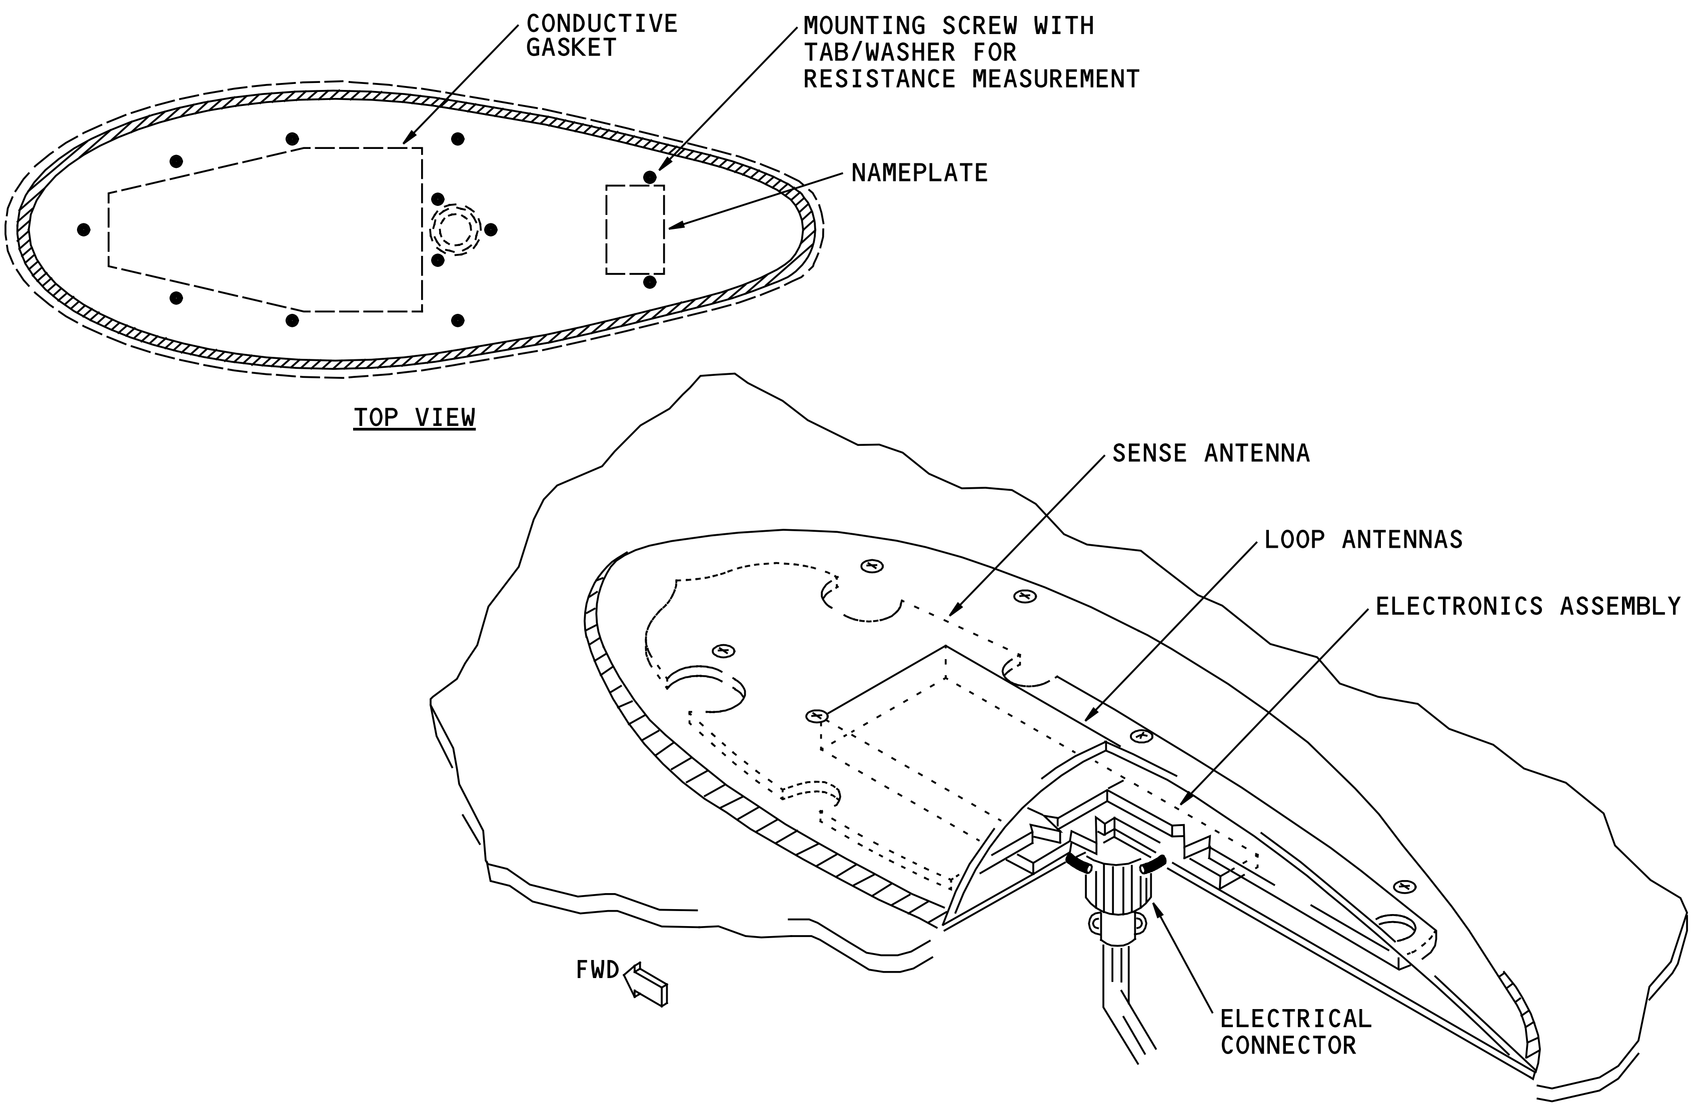
The ADF antenna receives electromagnetic signals from ground stations. The loop antenna receives the magnetic part of the ground station signal, and the sense antenna receives the electrical part of the signal.

Description

The antenna assembly is a one piece molded shell. The antenna assembly has:

- Loop antenna elements (2)
- Sense antenna (1)
- Amplifiers (3), one for each antenna element
- Transformers (3), one for each antenna element.

The ADF antenna elements each have an amplifier and output transformer. The amplifiers receive 12v dc power from the ADF receiver. The left ADF receiver sends power to the left antenna and the right ADF receiver sends power to the right antenna.



ADF SYSTEM - ADF ANTENNA

ADF SYSTEM - TUNING INPUTS

General

These are the two ways to tune the ADF receivers:

- Manually by the left, center, or right CDU
- By the CDUs as an alternate tune source.

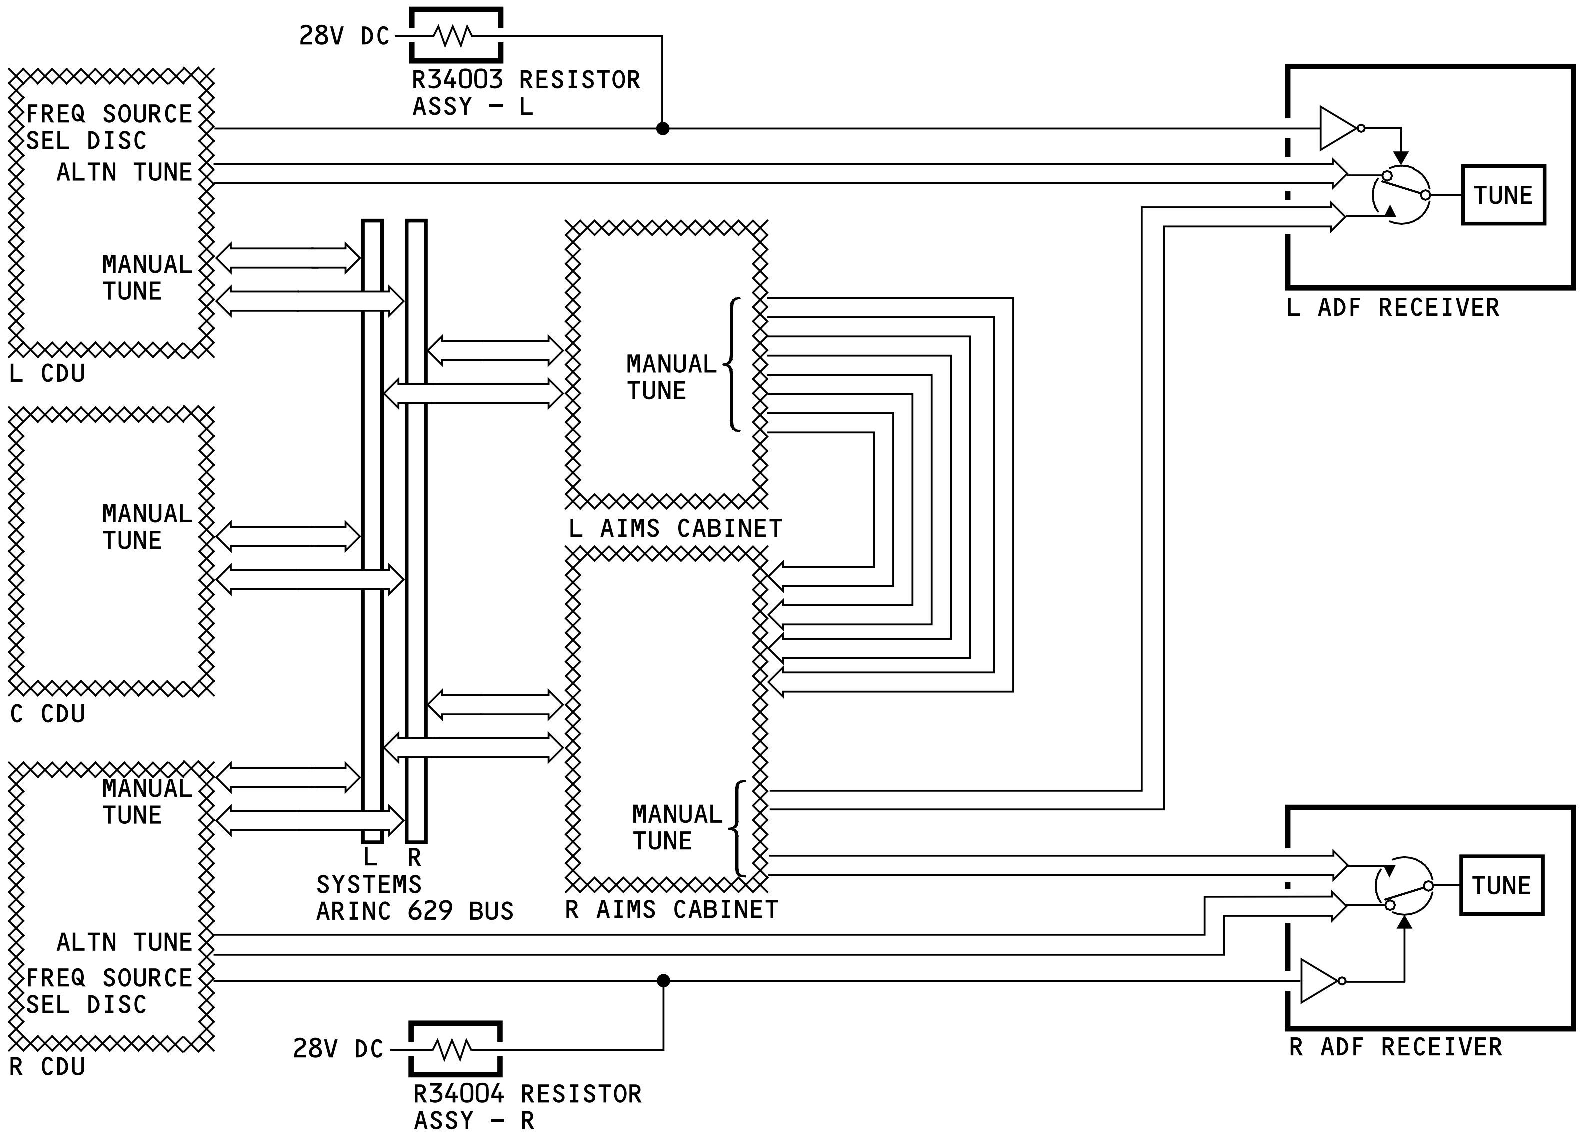
Manual Tuning

You manually tune the ADF receivers from the left or right control display units (CDUs). The center CDU can tune the recievers if the left or right CDU fails. Manual tune inputs from the CDUs go through the left and right systems ARINC 629 buses, then to the left and right AIMS cabinets. Manual tune inputs from the left or right AIMS cabinet goes from the right AIMS cabinet to the ADF receivers.

Alternate Tune

The CDUs monitor the AIMS cabinets tune functions. IF the AIMS tune function fails, the CDUs send a frequency source select discrete to the ADF receivers that changes the inputs from the right AIMS cabinet, to the input that comes directly from the left or right CDU. The CDUs use 28v dc from a pull-up resistor to set the discrete.

In alternate tune mode, the left CDU alternate tunes the left ADF receivers and the right CDU alternate tunes the right ADF receiver. The center CDU has no alternate tune function.



34-57-00-007 Rev 2 02/06/1998

ADF SYSTEM - TUNING INPUTS

ADF SYSTEM - AUDIO CONTROLS

General

The audio control panels supply control inputs to the audio management unit. This permits the crew to hear audio signals on the speakers and headsets in the flight deck.

Description

These are the controls on the audio control panel that let you to hear ADF audio:

- VOR/ADF receiver selector
- VOR/ADF receiver volume control
- NAV filter selector.

VOR/ADF Selector

The VOR/ADF receiver selector lets you select VOR or ADF as the source of audio.

VOR/ADF Receiver Volume Control

The VOR/ADF receiver volume control makes the audio come on and controls the volume.

NAV Filter Selector

The NAV filter selector lets you select one of these:

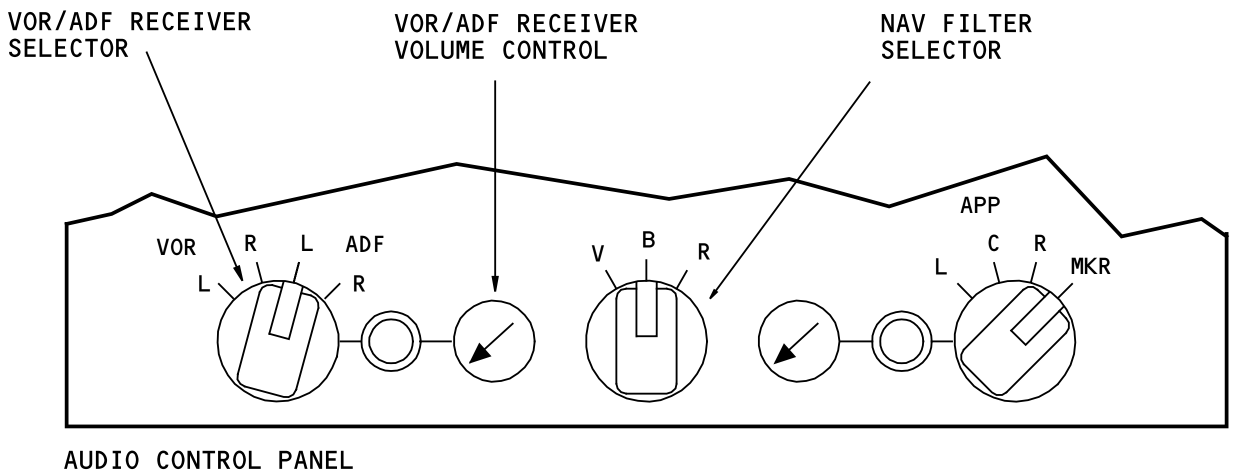
- Voice (V) audio
- Both (B) voice and range audio
- Range (R) audio.

Operation

Do this to hear ADF audio:

- Set the VOR/ADF selector to the left (L) or right (R) ADF position
- Push the VOR/ADF receiver volume control to make the ADF audio come on (turn the control to adjust the volume)
- Set the NAV filter selector to the voice (V) position.

To hear the station identifier, set the NAV filter selector to either the both (B) or the range (R) position.



34-57-00-011 Rev 2

ADF SYSTEM - AUDIO CONTROLS

ADF SYSTEM - CDU ADF TUNING

General

The CDUs supply manual tune inputs during normal operation and alternate tune inputs when the AIMS tune function fails.

Operation

To see ADF tune frequencies, push the NAV RAD key on the CDU. The NAV RADIO page shows data for the left and right ADF systems.

To manually tune an ADF receiver, enter a valid ADF frequency into the scratchpad. Push line select key 3L or 3R to enter the frequency for left or right ADF receiver.

You cannot use the delete key to delete an ADF frequency.

Alternate Tune

The ALTN NAV RADIO page is available only when the tune inputs from the AIMS cabinets fail.

To get to the ALTN NAV RADIO page, push the NAV RAD key on the CDU.

The ALTN NAV RADIO page is different from the NAV RADIO page. The ALTN NAV RADIO page shows data for only the onside NAV radio systems. The left CDU ALTN NAV RADIO page controls the left ADF receiver and the right CDU ALTN NAV RADIO page controls the right ADF receiver.

Antenna (ANT) Mode

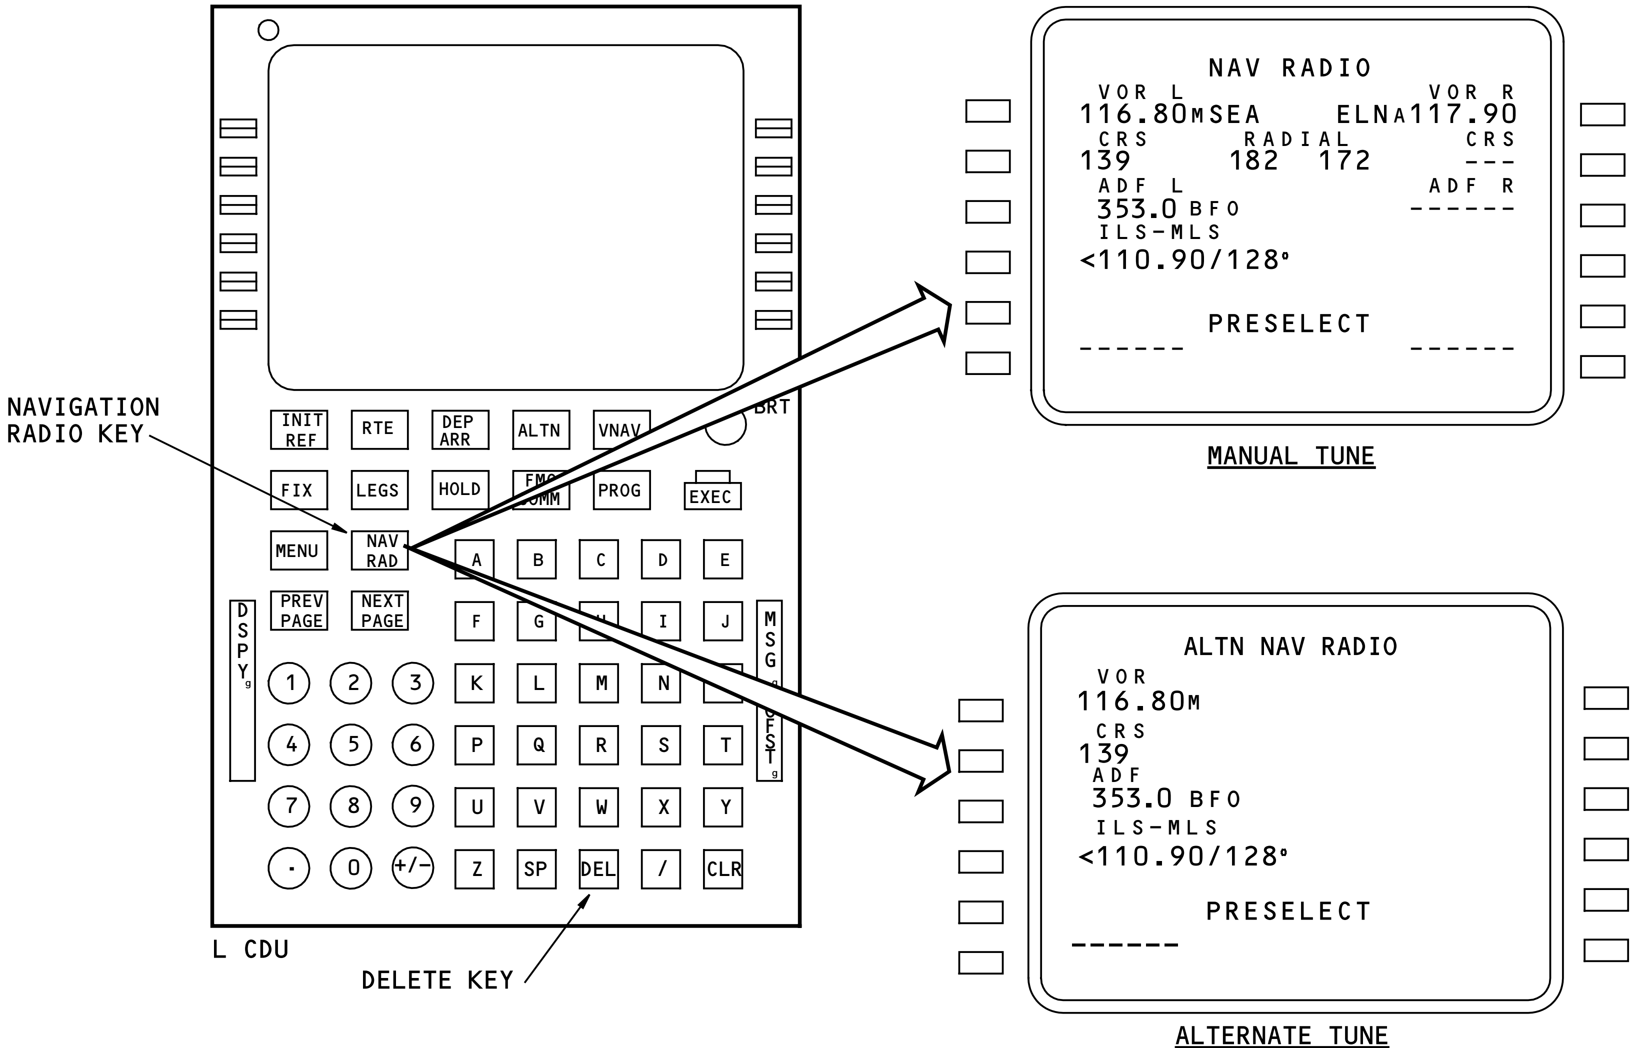
In the antenna (ANT) mode, the ADF receiver uses only the sense antenna to receive station audio broadcasts. To select the ANT mode, enter the letter A after the frequency, then line select the data to the ADF data line. When you enter the frequency, ANT shows after the frequency.

To delete the ANT mode, push the delete key on the CDU. The delete function shows in the CDU. Next, push the line select key next to the ADF line to delete the ANT.

Beat Frequency Oscillator (BFO) Mode

The ADF receivers can detect the station Morse code identifier if the 1020 Hz signal is amplitude modulated with the station audio signal. The ADF receiver can not detect the station Morse code identifier if the signal is a keyed Morse code signal. To hear the station morse code identifier, you must select the BFO mode. To select the BFO mode, type the letter B after the frequency and line select the data to the ADF data line. When you enter the frequency, BFO shows after the frequency.

To delete the BFO mode, push the delete key on the CDU. The delete function shows in the CDU. Next, push the line select key next to the ADF line to delete the BFO.



34-57-00-012 Rev 4 02/09/1998

ADF SYSTEM - CDU ADF TUNING

ADF SYSTEM - EFIS CONTROLS

General

The EFIS control panel has controls to select ADF data to show on the navigation displays (NDs).

VOR/ADF Switch

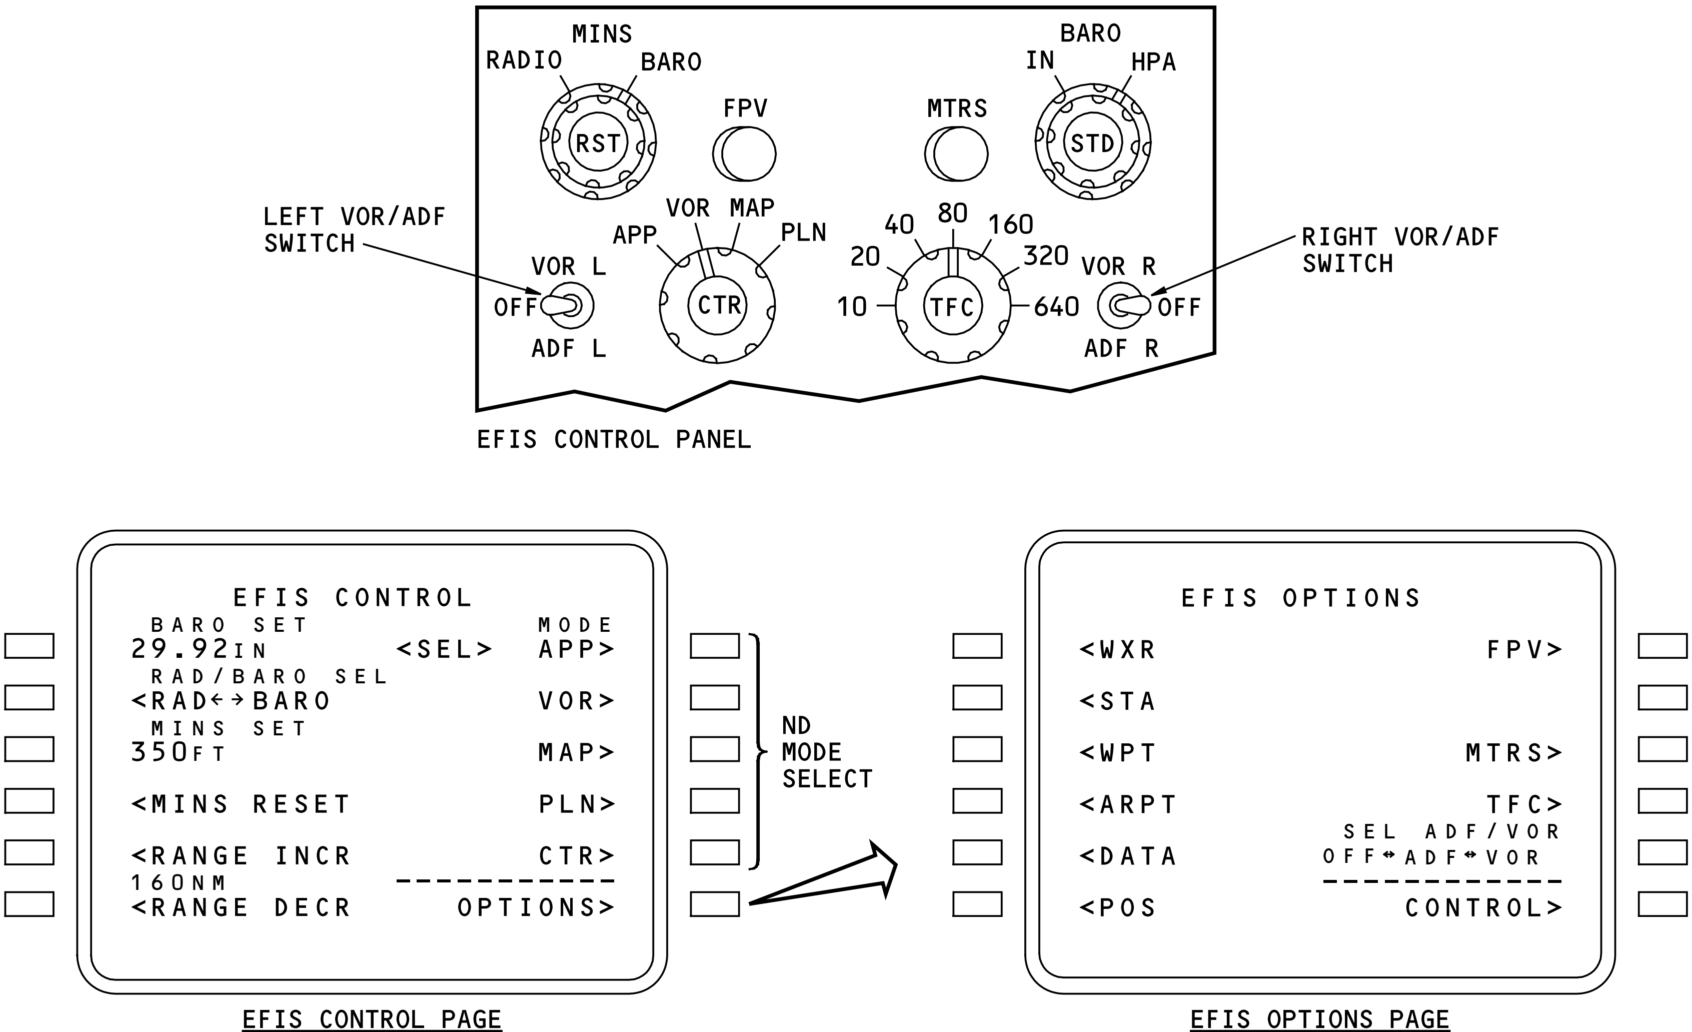
The VOR/ADF switches select the VOR or ADF receivers as the source of data for the left and right bearing pointers on the ND. There are two switches, one for the left bearing pointer and one for the right bearing pointer. When the switches are set to the off position, the bearing pointers and ADF data goes out of view.

Alternate or Backup EFIS Control Panel

The EFIS control page on the CDU supplies backup controls for the EFIS control panel. To select ADF data for the bearing pointers, push the OPTIONS line select key on the EFIS control page. This brings up the EFIS OPTIONS page.

Push the line select key next to the OFF-ADF-VOR data line on the EFIS OPTIONS page to toggle between ADF or VOR data.

The active data shows in large letters.



34-57-00-018 Rev 1 02/27/1998

ADF SYSTEM - EFIS CONTROLS

ADF SYSTEM - DISPLAYS

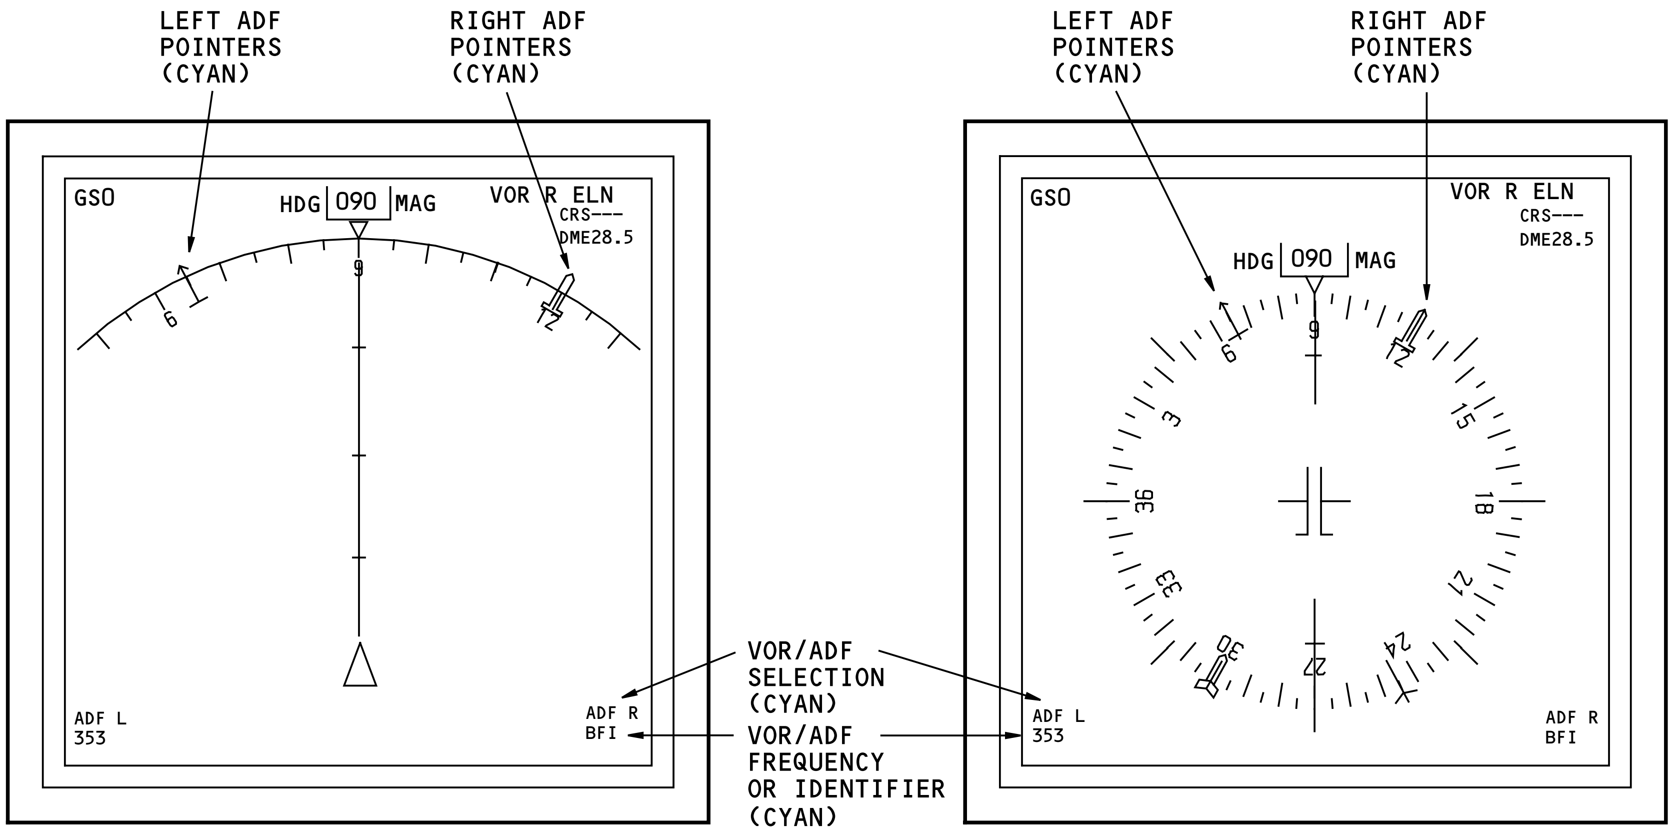
General

ADF pointers show in all EFIS modes but PLN (plan). The pointers are cyan in color. To display the ADF pointers, set the ND mode selector to APP, VOR, or MAP. Set the VOR/ADF switch on the EFIS control panel to the ADF position.

The ADF pointers move around the compass scale. The wide pointer shows the bearing from the right ADF receiver, and the thin pointer shows the bearing from the left ADF receiver.

The ADF source annunciation and frequency or identifier show in cyan at the lower corners of the NDs. The station identifier replaces the frequency when the data is valid from the ADF receiver.

NOTE: The graphic shows the displays for the VOR mode, the displays are the same for the other ND modes except PLN.



ND - EXPANDED MODE

ND - CENTERED MODE

34-57-00-013 Rev 1

ADF SYSTEM - DISPLAYS

ADF SYSTEM - ND NCD AND INVALID DISPLAYS

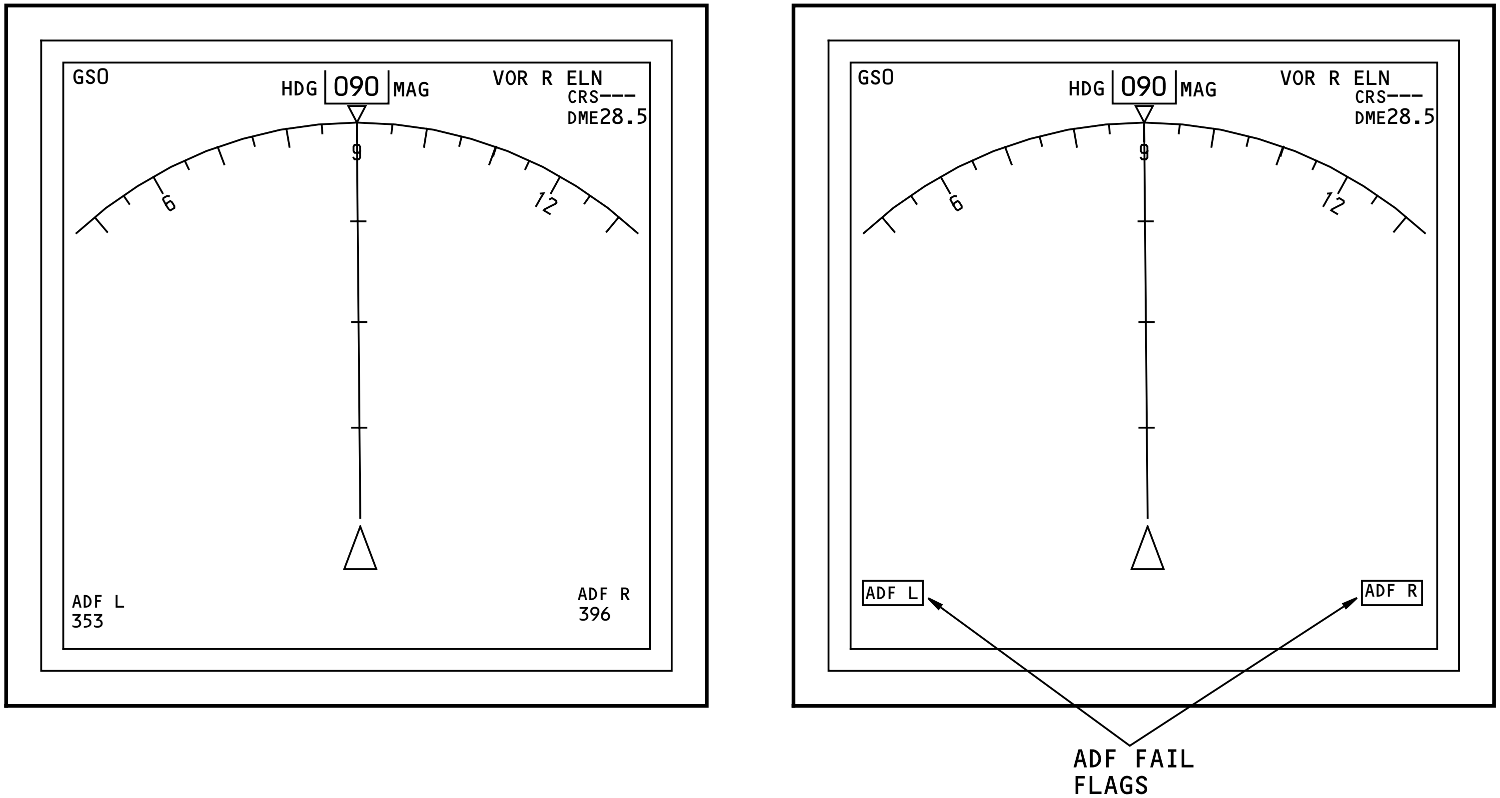
General

When the receiver output is no computed data (NCD), the ADF pointers go out of view. The source annunciation and frequency remain in view.

When the receiver output is invalid, all ADF data goes out of view and the amber ADF flags show.

When you move the VOR/ADF switch on the EFIS control panel from the ADF position, these displays go out of view:

- ADF flags
- Source annunciation
- Frequency
- ADF pointers.



NCD:

REMOVE POINTERS AND SHOW SOURCE ANNUNCIATION AND FREQUENCY.

INVALID:

REMOVE POINTERS, SOURCE ANNUNCIATION, AND FREQUENCY OR IDENTIFIER AND SHOW AMBER ADF FLAGS.

34-57-00-014 Rev 1

ADF SYSTEM - ND NCD AND INVALID DISPLAYS

ADF SYSTEM - TEST DISPLAYS

Test

Use the maintenance access terminal (MAT) to do a test of the ADF receivers. To see the test displays, select APP, VOR, or MAP on the ND mode selector of the EFIS control panel. Set the VOR/ADF switch to ADF.

When you select test on the MAT, the receiver starts a test sequence. The test displays show on the ND.

From one to three seconds, these invalid displays show on the ND:

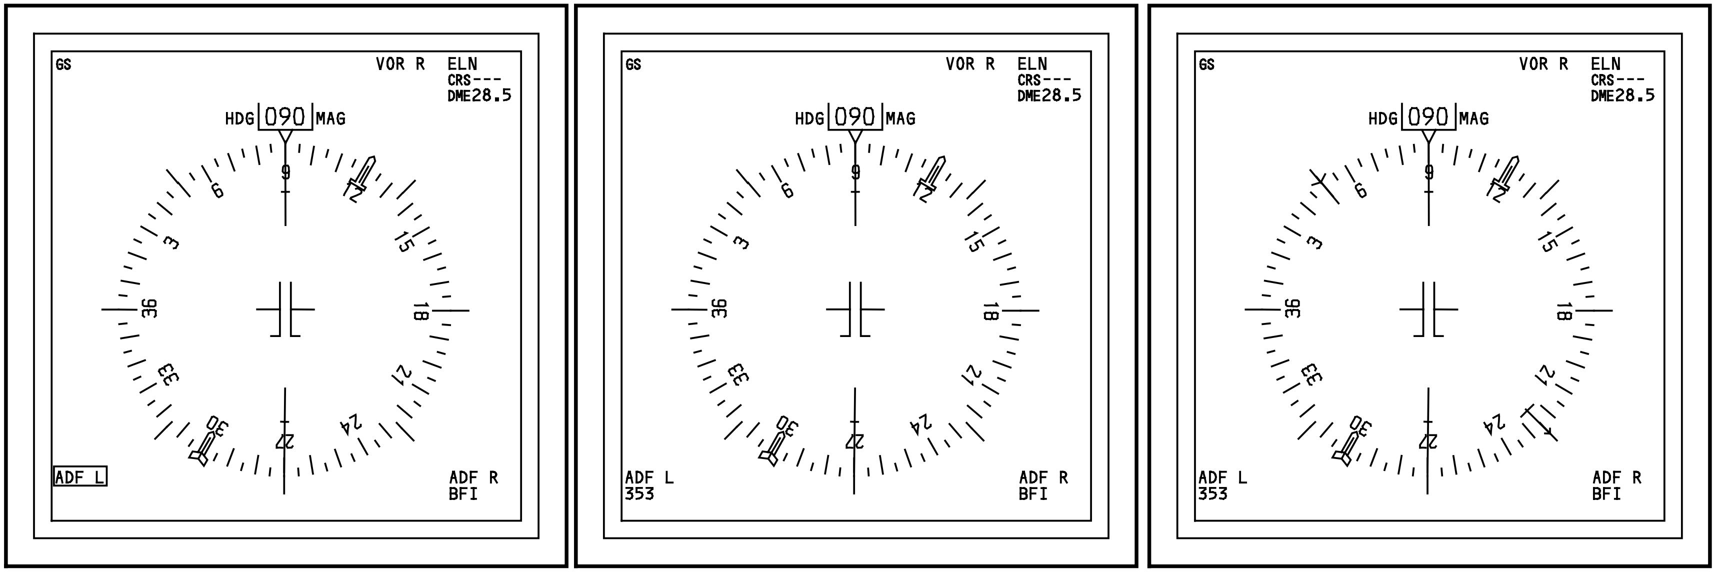
- Remove the ADF source annunciation
- Remove ADF frequency
- Remove ADF pointers
- Show the amber ADF flag.

From three to six seconds, these NCD displays show on the ND:

- Show source annunciation
- Show frequency.
- Remove ADF pointers
- Remove the amber flag.

From six seconds to the end of test, the ND shows the test display with the ADF pointer at 135 degrees in relation to the face of the ND until the end of test.

NOTE: The graphic shows a test of the left ADF receiver. The test is the same for the right ADF system.



1 TO 3 SECONDS:

THE RECEIVER OUTPUT GOES INVALID, ALL ADF DATA GOES OUT OF VIEW, AND THE AMBER ADF FLAG SHOWS.

3 TO 6 SECONDS:

THE RECEIVER OUTPUT GOES TO NO COMPUTED DATA (NCD). THE FLAG GOES OUT OF VIEW, THE SOURCE ANNUNCIATION AND FREQUENCY SHOW AND THE ADF POINTERS STAY OUT OF VIEW.

FROM 6 SECONDS TO END OF TEST:

THE RECEIVER OUTPUT GOES VALID AND THE POINTERS GO TO THE TEST POSITION (APPROX. 135 DEGREES FROM THE CENTER LINE.

34-57-00-015 Rev 3 02/06/1998

NOTE: THESE DISPLAYS ARE FOR THE LEFT ADF TEST.
THE RIGHT ADF TEST IS SIMILAR.

ADF SYSTEM - TEST DISPLAYS

ADF SYSTEM - GROUND TEST

General

You can do a test of the ADF system from the MAT. These are the tests that are available from the operational test selection on the MAT:

- Left ADF System
- Right ADF System.

Operational Test

The operational test for the ADF system makes sure the ADF receiver operates normally.

MARKER BEACONS

34-32-00-001 Rev 1

MARKER BEACON SYSTEM - INTRODUCTION

MARKER BEACON SYSTEM - GENERAL DESCRIPTION

General

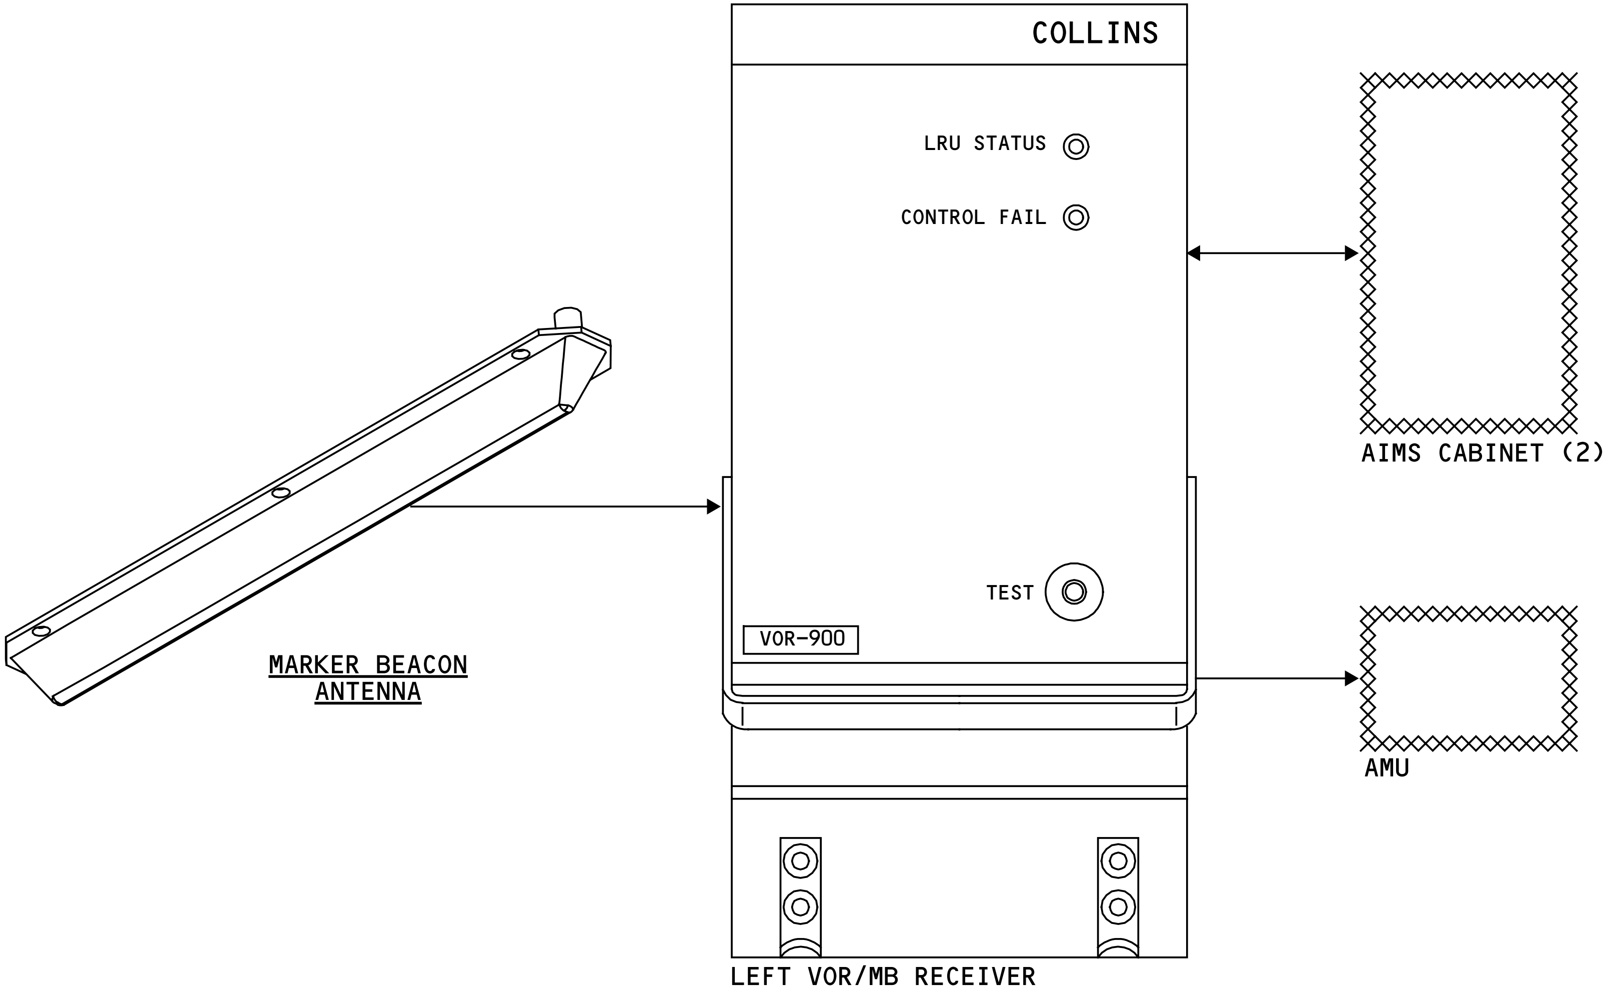
The marker beacon system has an antenna and a VOR/ marker beacon (VOR/MB) receiver. The marker beacon function only operates in the left VOR/MB receiver.

Description

The marker beacon antenna receives the marker beacon signals. The signals go to the left VOR/MB receiver.

The receiver sends marker beacon data to the airplane information management system (AIMS) cabinets to show on the the primary flight displays (PFDs).

The receiver sends marker beacon audio to the audio management unit (AMU).



34-32-00-002 Rev 4 02/12/1998

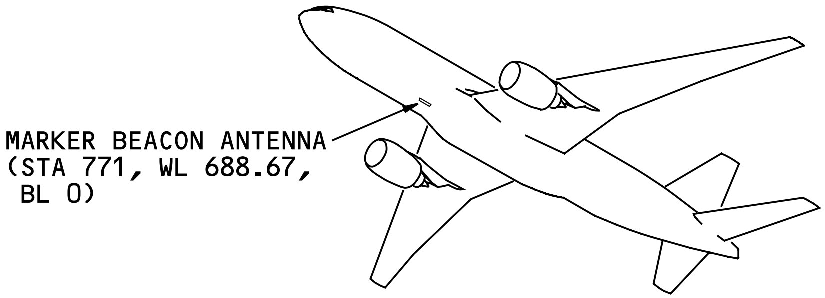
MARKER BEACON SYSTEM - GENERAL DESCRIPTION

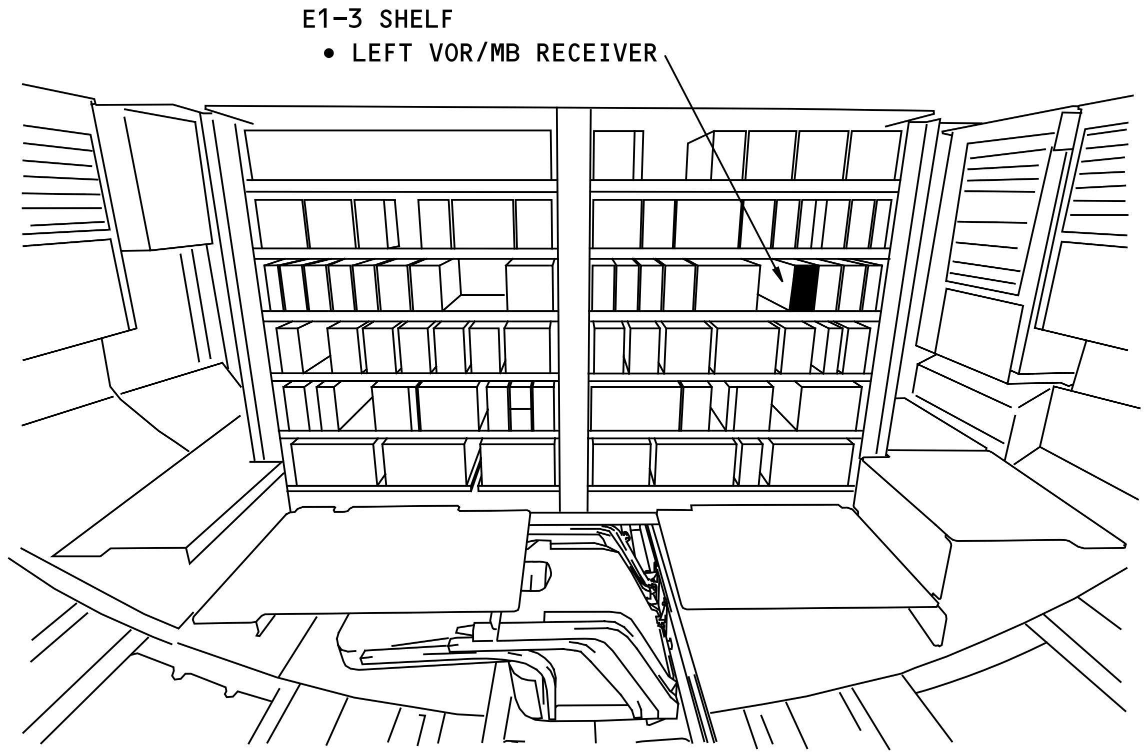
MARKER BEACON SYSTEM - COMPONENT LOCATIONS

General

The marker beacon antenna is on the bottom of the fuselage.

The left VOR/MB receiver is in the main equipment center.





MAIN EQUIPMENT CENTER

34-32-00-003 Rev 1

MARKER BEACON SYSTEM - COMPONENT LOCATIONS

MARKER BEACON SYSTEM - INTERFACES

Power

The left VOR/marker beacon (VOR/MB) receiver uses 115v ac for power.

Antenna Interface

The marker beacon antenna sends radio frequency (RF) signals to the left VOR/marker beacon (VOR/MB) receiver.

Air/Ground Relay

The air/ground relay supplies an air/ground discrete signal to the left VOR/marker beacon (VOR/MB) receiver. The VOR/MB receiver uses this signal:

- To prevent a test in the air
- To count flight legs for an internal nonvolatile fault memory.

Audio Interface

The VOR/MB receiver sends marker beacon audio to the audio management unit (AMU). The AMU supplies marker beacon audio to the flight deck.

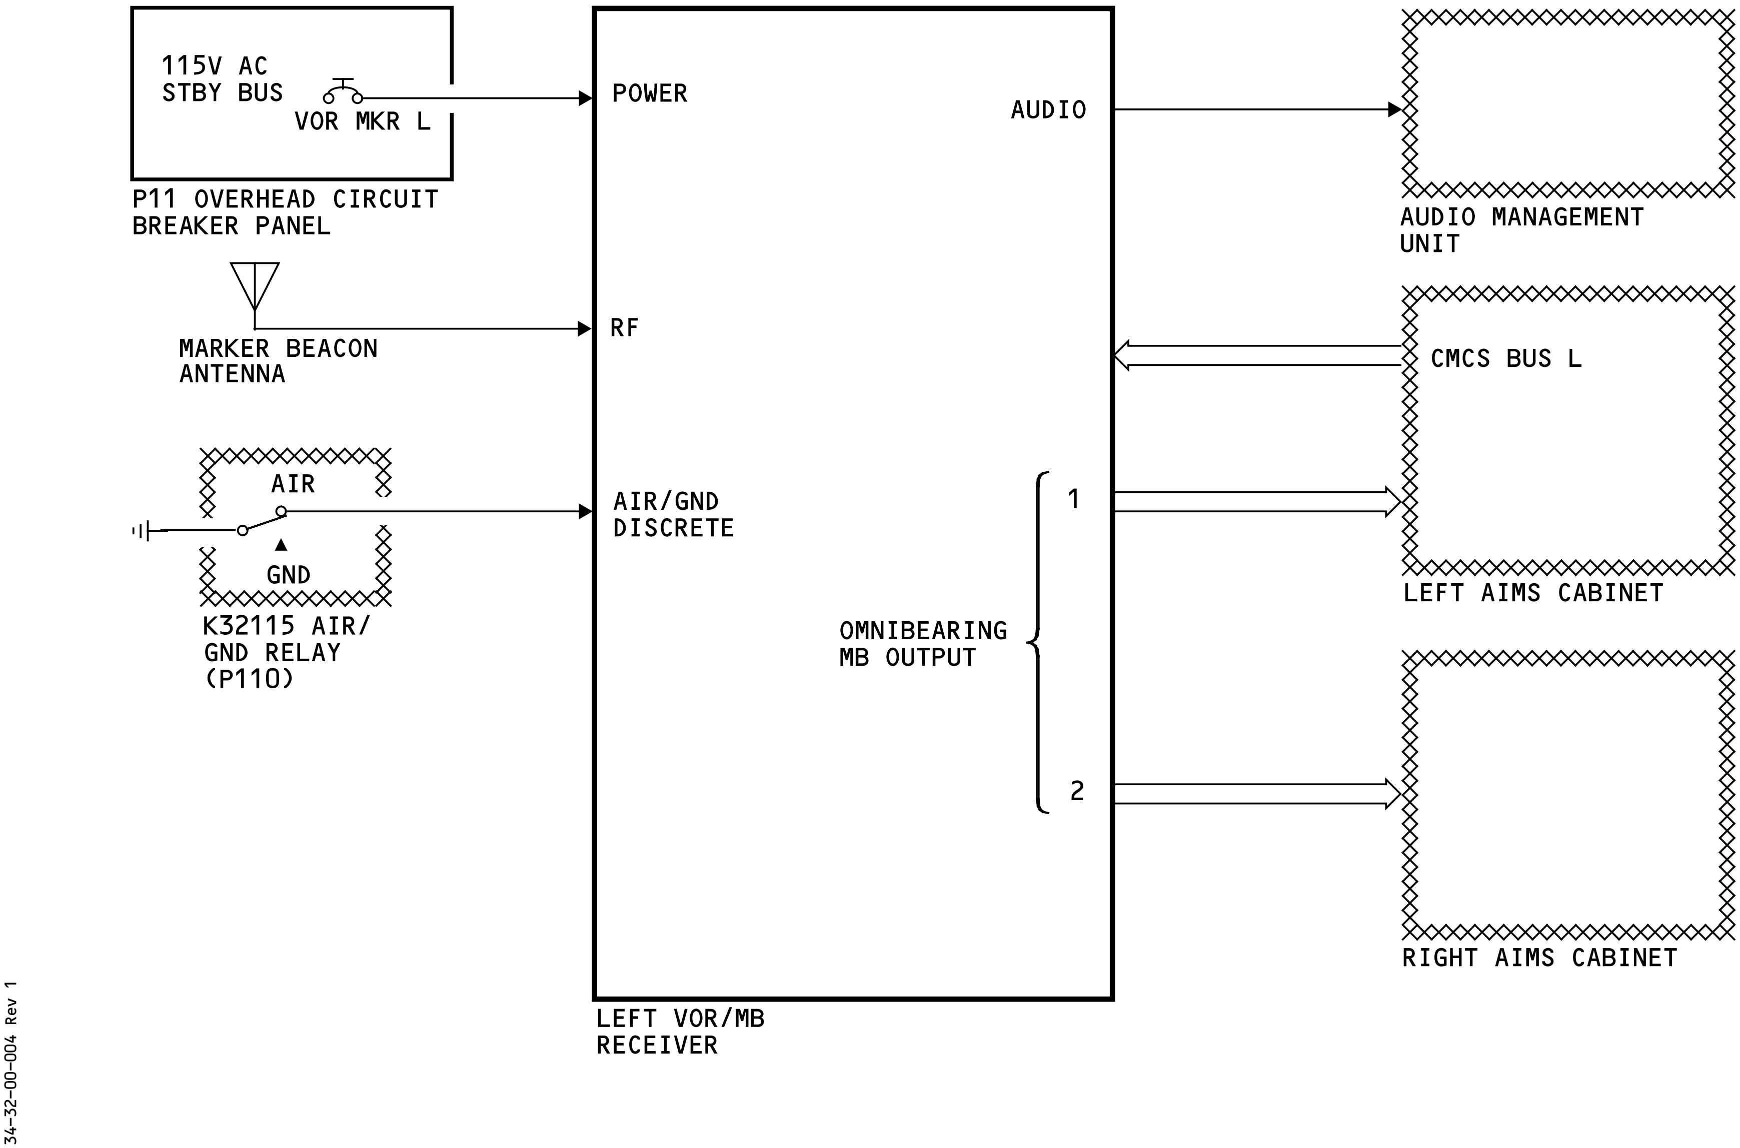
CMCS Interface

The left AIMS cabinet sends central maintenance computing system (CMCS) data to the left VOR/MB receiver. The receiver uses this data to start a test.

Marker Beacon Output

The left VOR/MB receiver supplies marker beacon data to the left and right AIMS cabinets. The AIMS cabinets:

- Supply marker beacon display data to the PFDs
- Receive marker beacon fault and status data.



MARKER BEACON SYSTEM - INTERFACES

MARKER BEACON SYSTEM - DISPLAYS AUDIO OUTPUTS

General

When the airplane passes over a marker beacon transmitter, marker beacon data shows on the primary flight display (PFD).

If you want to listen to marker beacon audio, select the marker beacon audio on the audio control panel (ACP).

Display Types

OM shows when the airplane passes over the outer marker. The OM letters and the circle around them are cyan.

MM shows when the airplane passes over the middle marker. The MM letters and the circle around them are yellow.

IM shows when the airplane passes over the inner marker, backcourse marker, or an airways marker. The letters IM and the circle around them are white.

Audio General

The audio control panel (ACP) supplies control signals to the audio management unit (AMU). The AMU uses the control signals to select the audio that goes to the flight interphone speakers and headsets.

Use the ACP to listen to marker beacon audio.

Audio Operation

To listen to marker beacon audio signals:

- Select marker beacon audio with the approach receiver selector
- Push the approach receiver volume control to make the marker beacon audio come on
- Turn the approach receiver volume control to change the volume level.

Audio Outputs

These are the marker beacon audio outputs:

- Outer marker (OM) is 400 Hz, continuous dashes (- - - -)
- Middle marker (MM) is 1300 Hz, alternate dots and dashes (-.-.-.-.-)
- Inner marker (IM) is 3000 Hz, continuous dots (......)
- Backcourse marker is 3000 Hz, continuous paired dots (.. .. .. ..)
- Airways marker is 3000 Hz with the morse code identifier for that station.

THIS PAGE INTENTIONALLY LEFT BLANK

ADF SYSTEM - FUNCTIONAL DESCRIPTION

Power

The ADF receiver power supply receives 115v ac and supplies all the voltages for the internal circuits.

Antenna Inputs

The receiver circuits get radio frequency (RF) signals from the antenna. The antenna amplifiers receive 12v dc from the antenna control circuits in the ADF receiver. The RF signals from the antenna elements go through amplifiers and transformers then to the receiver circuits.

Tuning Inputs

The ADF receiver input/output data processor receives manual tune inputs from the right AIMS cabinet and alternate tune inputs from the CDUs. If the right AIMS cabinet tune input fails, alternate tune inputs come directly from the onside CDU.

When the AIMS cabinet fails, the CDU sets the frequency source select discrete to ground. This changes the tune input port to the CDU.

Receiver Operation

The data processor sends the tune frequencies to the receiver circuits.

For normal operation, the receiver circuit removes the audio signal from the RF signal and sends it to the audio processor. The audio goes through an audio amplifier then to the AMU.

The audio processor sends the Morse code station identifier to the Morse decoder circuits. when there is an identifier, the Morse decoder sends it to the ARINC 429 transmitter. The identifier replaces the frequency on the NDs.

The receiver circuits send the bearing part of the RF signal to the bearing computer circuit. The bearing circuit compares the inputs of the loop and sense antenna elements to calculate bearing to the ADF station.

Bearing data goes to an ARINC 429 transmitter that has two outputs. For the left ADF receiver, output 1 goes to the left AIMS cabinet and output 2 goes to the right AIMS cabinet. For the right ADF receiver, output 1 goes to the right AIMS cabinet and output 2 goes to the left AIMS cabinet.

If you select the antenna (ANT) mode, the processor sends a signal to the receiver circuit that removes the inputs from the loop antenna elements. In the ANT mode, the receiver circuits use inputs only from the sense antenna.

If you select the beat frequency oscillator (BFO) mode, the processor sends a BFO mode signal to the audio processor to enable a 1020 Hz oscillator. The oscillator permits the audio processor to identify the keyed morse code identifier.

ADF SYSTEM - FUNCTIONAL DESCRIPTION

Built-in-Test Equipment

The ADF receiver contains BITE that monitors ADF receiver operation and signal inputs. A fault memory keeps failures that occur by flight legs. A discrete from the AIMS cabinets sets the flight legs. If the input discrete from the AIMS cabinet fails, the ADF receiver uses the air/ground discrete from the air/ground relay to set the flight legs.

The central maintenance computer function (CMCF) in the left AIMS cabinet sends test signals to the ADF receivers. The processor sends test signals to the antenna control circuit and to a function test RF coupler.

Test

During a test, the antenna control removes power to the antenna amplifiers of the ADF antenna so that no RF signals go to the receiver circuits. A test RF frequency replaces the antenna RF input and the receiver sends the signal through its internal circuits. Test results show on the navigation displays.

Program Pin Inputs

The ADF receivers get discretes from program pin selections.

The bearing computer circuit uses quadrantal error correction (QEC) program pin inputs to adjust for signal distortion caused by airplane structures.

The source destination indicator (SDI) discrete identifies the ADF receiver as the left or right receiver.

A discrete identifies the antenna location as a top mounted antenna.

GPWS - INTRODUCTION

Purpose

The purpose of the ground proximity warning system (GPWS) is to alert the flight crew of an unsafe condition when near the terrain. It also supplies a warning for windshear conditions.

Description

The GPWS uses aural messages, lights, and displays to give alerts and warnings in the flight deck.

GPWS Modes

These are the GPWS modes:

- Mode 1 - Large descent rates
- Mode 2 - Too much of a closure rate when approaching terrain that is rising
- Mode 3 - Too much altitude loss during climbout (at takeoff or in go around) when not in landing configuration
- Mode 4 - Not enough terrain clearance when the airplane is not in landing configuration
- Mode 5 - Too much deviation below the glideslope centerline
- Mode 6 - Aural callouts when descending through selected radio altitudes
- Mode 7 - Warning for windshear conditions.

The GPWS also alerts the flight crew to early descent on approach, or to terrain threats ahead of the airplane.

34-46-00-001 Rev 3

GPWS - INTRODUCTION

GPWS - GENERAL DESCRIPTION

General Description

The main component of the ground proximty warning system (GPWS) is the ground proximity warning computer (GPWC). It uses inputs from other systems to determine if an unsafe condition is present and then gives the proper annunciations.

The GPWS displays terrain forward of the airplane, and also alerts the flight crew of early descent when landing.

Visual annunciations show on the:

- Primary flight displays (PFDs)
- Navigation displays (NDs)
- GND PROX light
- Master warning lights.

Aural annunciations come from the aural warning speakers.

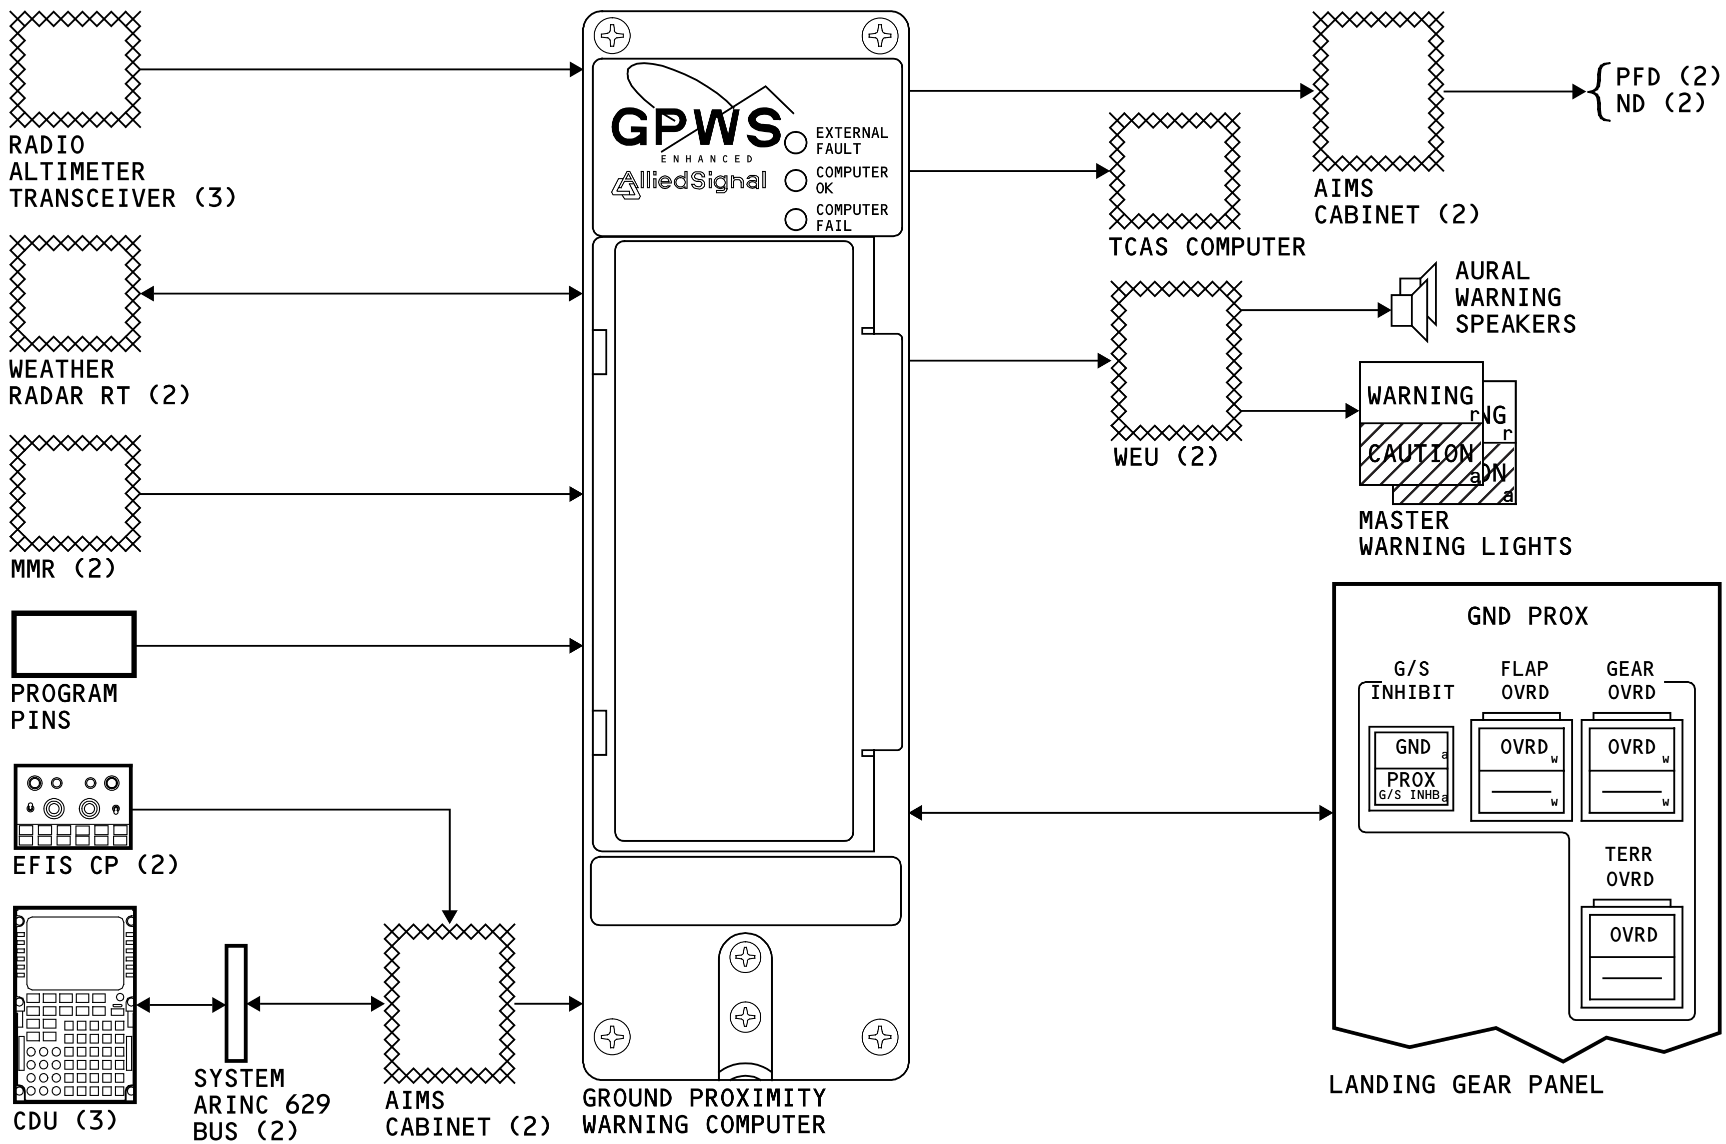
The GPWC sends terrain data to the airplane information management system (AIMS) cabinets to show on the NDs.

These components control GPWS:

- Electronic flight instrument system (EFIS) control panels (CPs)
- Control display units (CDUs)
- Glideslope inhibit switch
- Override switches.

The program pins selects options available for the GPWC.

The GPWC sends discretes to the weather radar (WXR) system and to the traffic alert and collision avoidance system (TCAS).



GPWS - GENERAL DESCRIPTION

GPWS - COMPONENT LOCATIONS - 1

GPWS Component Locations

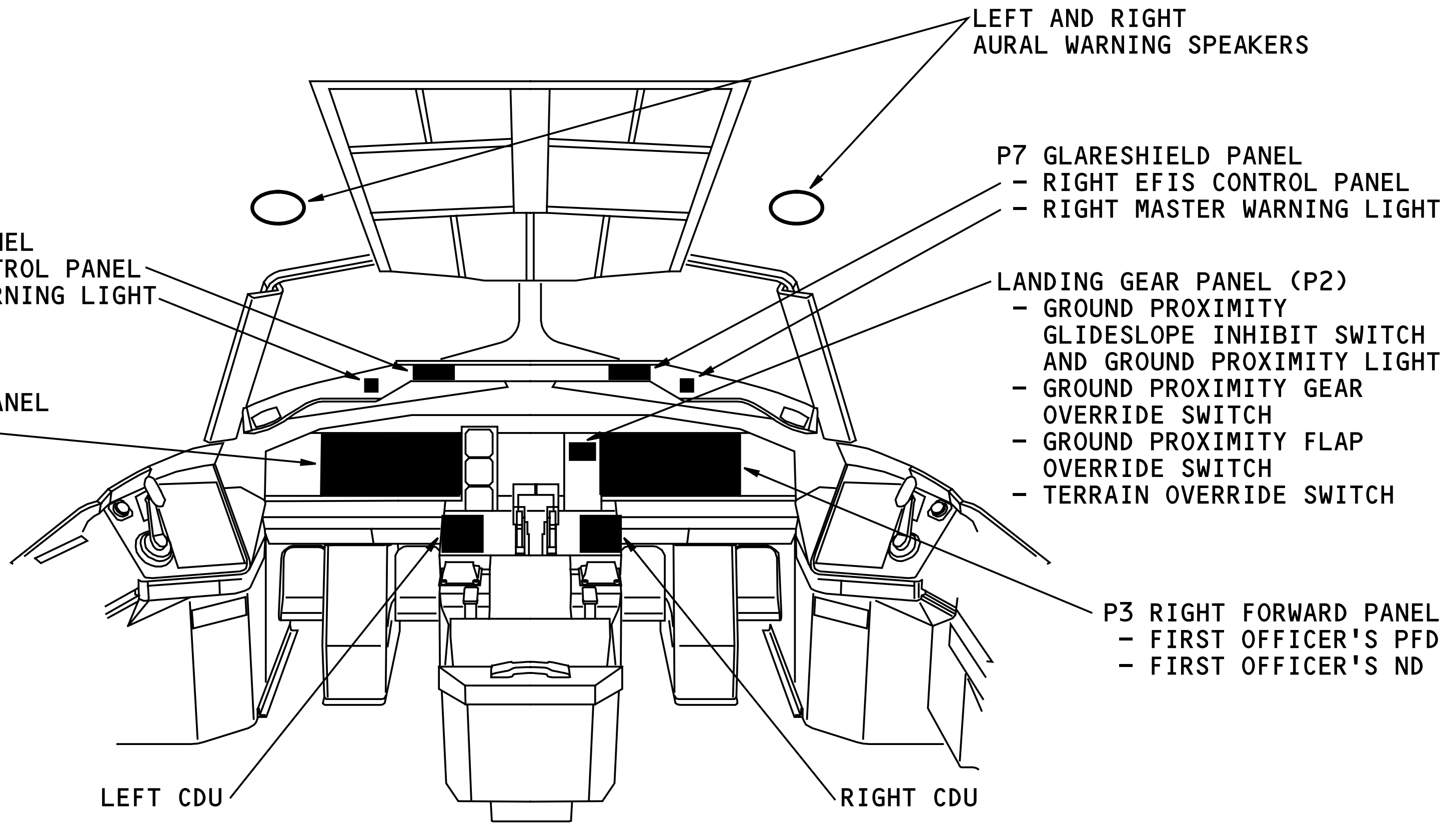
These are the GPWS components in the flight deck:

- Ground proximity glideslope inhibit switch and ground proximity light
- Ground proximity gear override switch
- Terrain override switch
- Ground proximity flap override switch.

Other Systems Component Locations

The components in the flight deck that have an interface with the GPWS are:

- Left and right aural warning speakers
- Left and right master warning lights
- Captain and first officer navigation displays (NDs)
- Left and right electronic flight instrument system (EFIS) control panel (CP)
- Left and right control display units (CDUs)
- Captain and first officer primary flight displays (PFDs).



34-46-00-003 Rev 2 01/23/1998

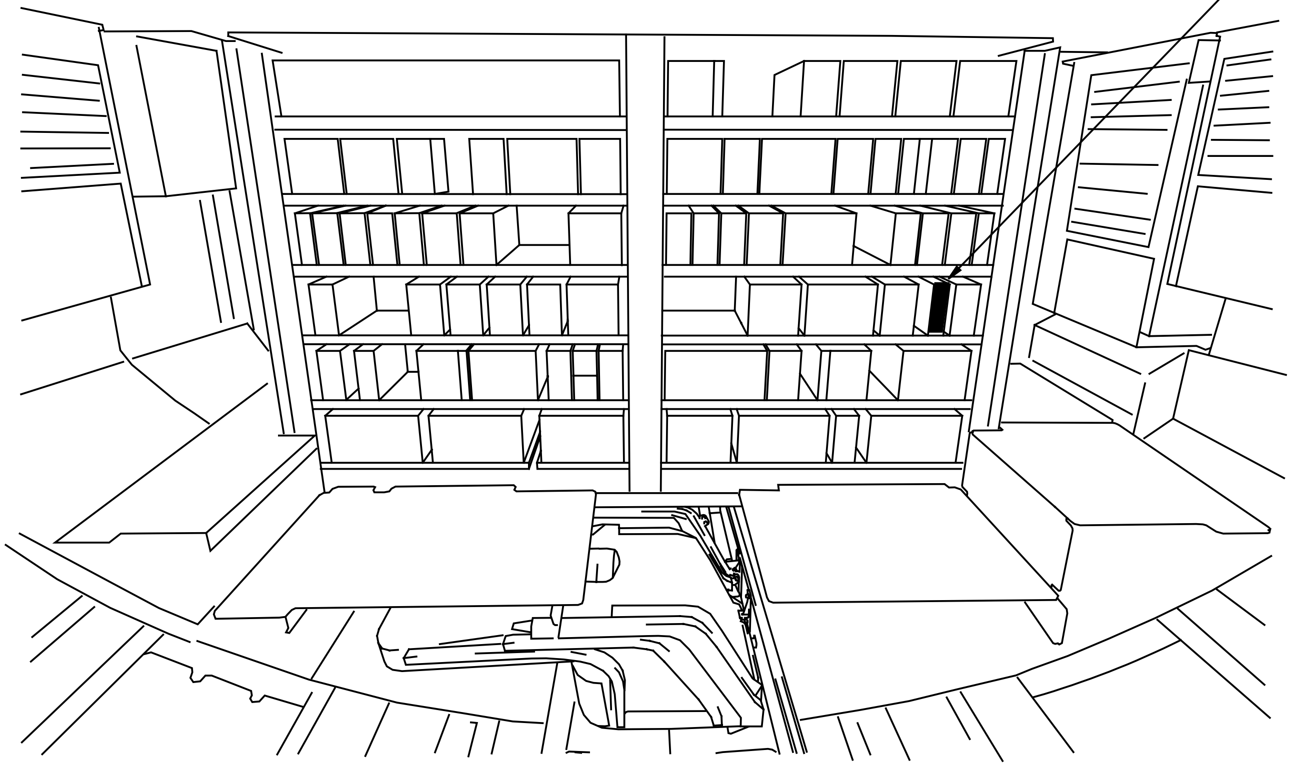
GPWS - COMPONENT LOCATIONS - 1

GPWS - MAIN EQUIPMENT CENTER COMPONENT LOCATIONS

GPWS Component Locations

These components are in the main equipment center:

- Terrain select relays
- Ground proximity warning computer (GPWC).



34-46-00-004 Rev 4 02/03/1998

GPWS - MAIN EQUIPMENT CENTER COMPONENT LOCATIONS

GPWS - INTERFACE

Power

The GPWC gets 115v ac power from the GND PROX circuit breaker on the P11 overhead circuit breaker panel.

General Interface

The ground proximity warning computer (GPWC) has an interface with these:

- Left, right, and center radio altimeter transceivers
- Weather radar (WXR) receiver/transmitters (RTs)
- Left and right AIMS cabinets
- Multi-mode receivers (MMRs)
- Warning electronic units (WEUs)
- Landing gear panel
- Program pins
- TCAS computer.

Radio Altimeter System

The GPWC uses radio altitude from the three radio altimeter transceivers. If the three radio altimeter transceivers are valid, the GPWC selects the left radio altimeter transceiver if the left radio altitude is within 500 feet of the center or right radio altitudes.

If the three radio altimeter transceivers are valid and the left radio altitude is not within 500 feet of the center or right radio altitudes, the GPWC uses the center radio altimeter transceiver provided its altitude is within 500 feet of the right radio altitude.

If the three radio altimeter transceivers are valid and the left, right, and center radio altitudes differ by more than 500 feet between each other, the GPWC uses the left radio altimeter transceiver.

If there are less than three valid radio altimeter transceivers, the GPWC selects one of the radio altimeter transceivers in this order:

- Left
- Center
- Right.

Airplane Information Management System (AIMS)

The GPWC receives data from the left and right AIMS cabinets. The primary input is from the left AIMS cabinet. Both cabinets supply data to the GPWS on three ARINC 429 data buses. A fourth data bus from the left AIMS cabinet supplies CMCF test requests to the GPWC.

IRS data buses supply this data:

- Latitude and longitude (from the ADIRU)
- Magnetic track
- Ground speed
- True heading
- Vertical speed
- True track
- Inertial vertical speed and altitude

GPWS - INTERFACE

- Pitch and roll angle
- Pitch rate
- Normal acceleration
- Longitudinal acceleration
- Vertical acceleration.

The general purpose (GP) data buses supply this data:

- Computed airspeed
- True airspeed
- Barometric altitude
- Baro-corrected altitude
- Barometric altitude rate
- Latitude and longitude (from the FMCF)
- Magnetic track
- Decision height
- Electronic flight instrument system (EFIS) control panel (CP) control data
- Control display unit (CDU) control data (alternate EFIS CP)
- Flap and gear position
- Indicated and corrected AOA
- Stick shaker AOA
- Minimum operating speed
- Air/ground status.

The central maintenance computing (CMC) data bus supplies test commands.

The GPWC sends digital data to the AIMS cabinets on an ARINC 429 data bus. This is the data:

- Windshear warning discrete
- Pull up warning discrete
- Test command reply.

Global Positioning System (GPS)

The GPS receives this data from the multi-mode receivers (MMRs):

- Latitude
- Longitude
- Altitude
- Vertical speed
- Date
- Time (UTC)
- Ground speed
- True track
- Integrity of data
- Sensor status.

Instrument Landing System (ILS)

The GPWC receives this data from the left multi-mode receiver (MMR):

- Glideslope deviation
- Localizer deviation
- Selected runway heading.

Warning Electronic System (WES)

Audio signals from the GPWC go to the warning electronic units (WEUs). The WEUs send the audio to the aural warning speakers.

GPWS - INTERFACE

Landing Gear Panel

The landing gear panel has these functions:

- Terrain override switch
- Ground proximity gear override switch
- Ground proximity flap override switch
- Ground proximity glideslope inhibit switch
- Ground proximity light.

The GPWC sends an alert discrete signal to the GPWS landing gear panel to turn on the GND PROX light.

Traffic Alert and Collision Avoidance System (TCAS)

The GPWC sends alert and warning discretes to the TCAS computer to inhibit TCAS advisories that may conflict with GPWS aural messages.

Program Pins

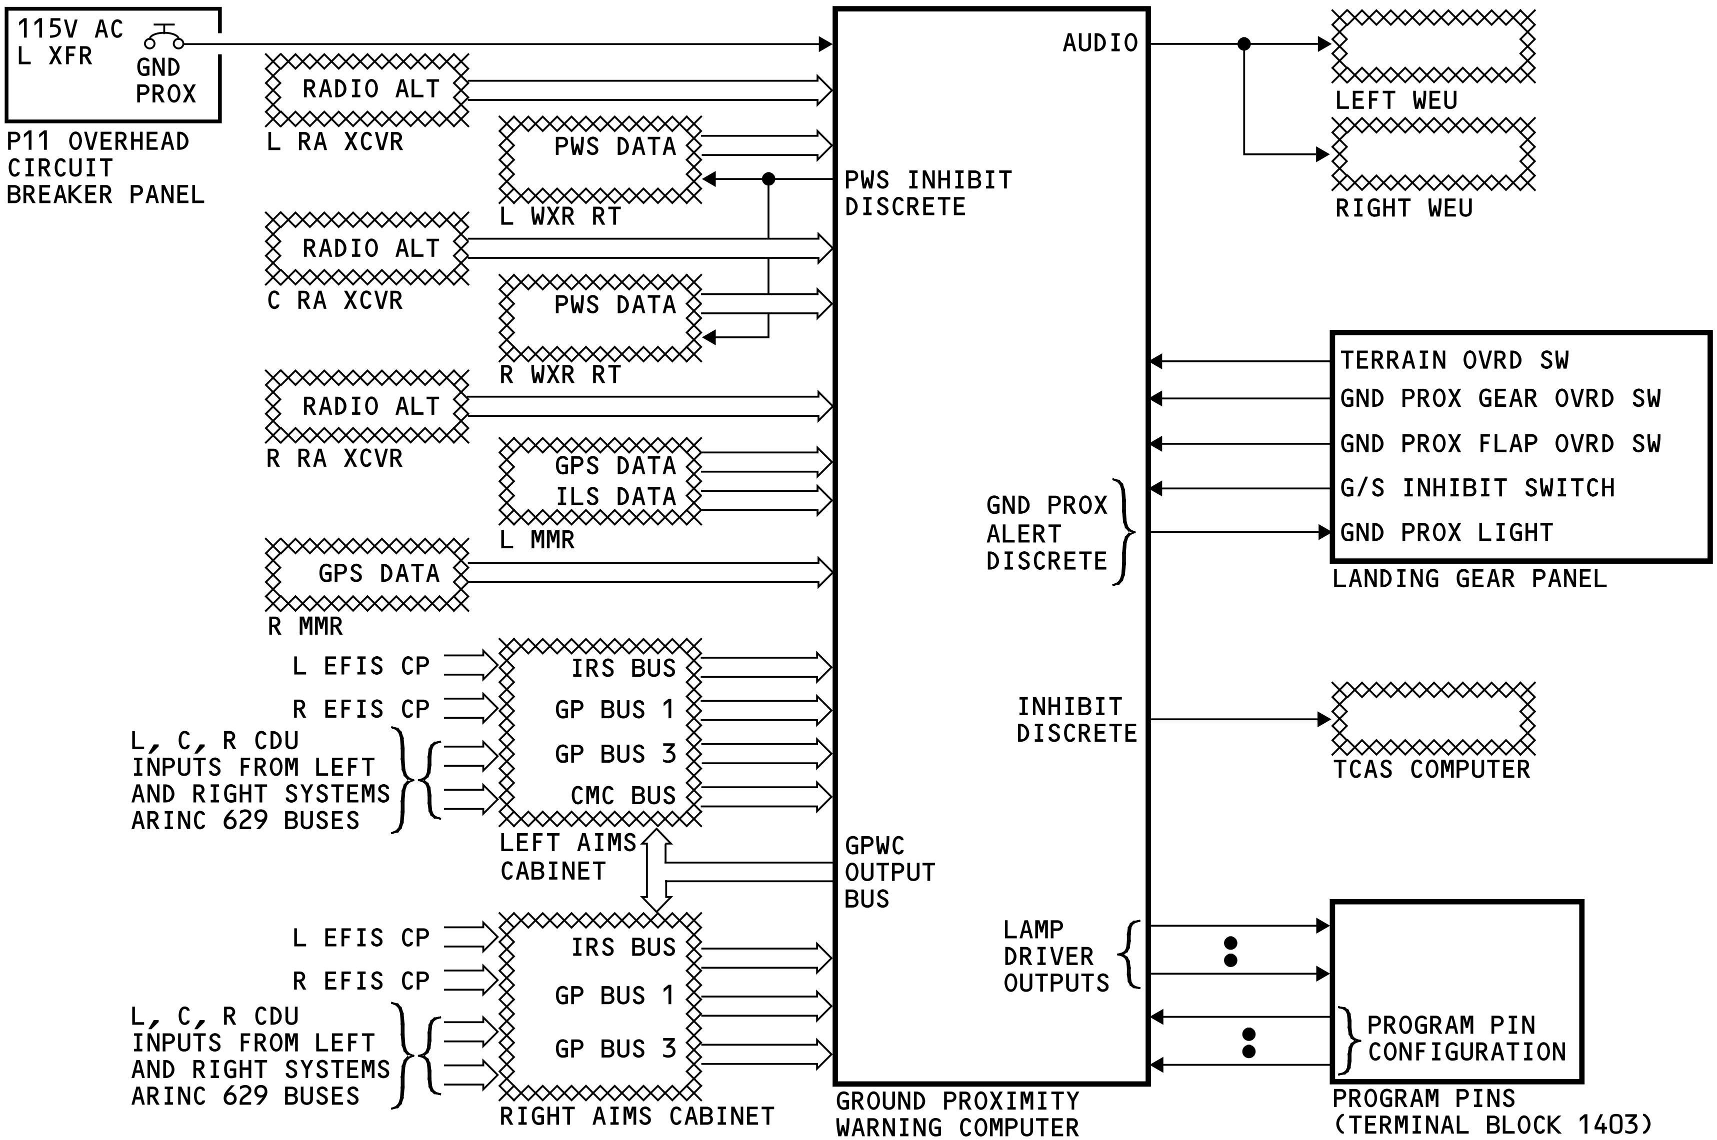
Seventeen program pins connect to six GPWS lamp drivers. The connections are at terminal blocks on the E1-4 shelf in the main equipment center (MEC). When the airplane powers up, the lamp drivers turn on and off one at a time to read the program pin connections. These connections make up the GPWS configuration. The non-volatile memory (NVM) stores this configuration. The configuration determines such parameters as:

- Airplane type
- Mode 6 callouts
- High or low audio volume.

Weather Radar (WXR) System

The WXR receiver-transmitters (RTs) sends predictive windshear (PWS) data to the GPWC to inhibit lower priority GPWS alerts.

The GPWC sends a discrete to the WXR RTs to inhibit lower priority PWS alerts.



GPWS - INTERFACE

GPWS - DISPLAY RELAY INTERFACE

Purpose

The ground proximity warning computer (GPWC) and the weather radar (WXR) receiver-transmitters (RTs) send display data that shows on the navigational displays (NDs). Four terrain select relays control which data shows on each ND.

Relay Power

The terrain select relays gets 28v dc from the TERRAIN DISPLAY circuit breaker on the P11 overhead circuit breaker panel.

Relay Interfaces

The GPWC connects to all terrain select relays with terrain display data buses. The WXR RTs connect to all terrain select relays with weather display data buses.

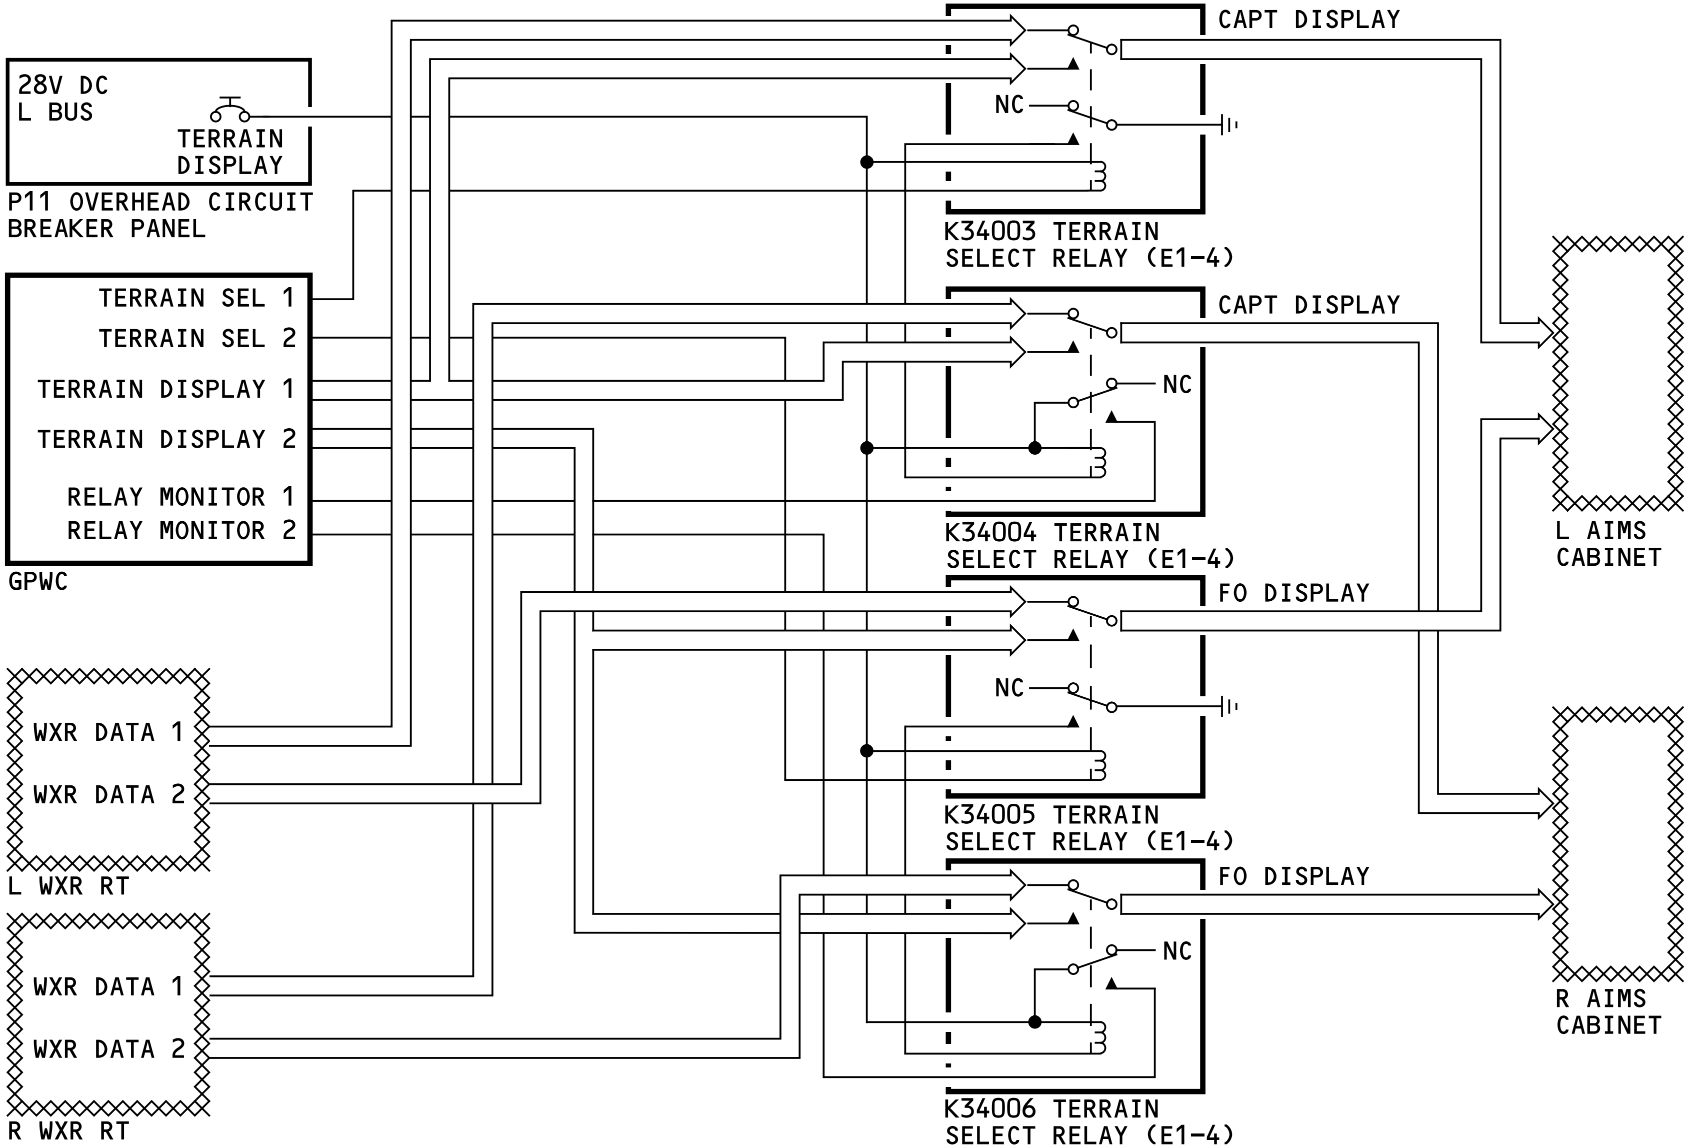
The terrain select relays connect to the AIMS cabinets with data buses. The AIMS cabinets show the data on the NDs.

Relay Control

With weather radar selected, the normal relay position lets weather radar data show on the NDs. When you select TERR on either EFIS control panel (CP), a terrain select ground signal energizes the two on-side terrain select relays. This allows the terrain data to show on the on-side display. Push the TERR switch again and the on-side relays deenergize. The display then shows weather radar data, if selected.

Relay Monitor

The GPWC monitors the terrain select relay positions for faults.



GPWS - DISPLAY RELAY INTERFACE

34-46-00-034 Rev 0 02/03/1998

GPWS - GROUND PROXIMITY WARNING COMPUTER

Purpose

The ground proximity warning computer (GPWC) compares the airplanes flight profile, flap and gear position, and terrain clearance to determine if an alert condition exists.

Description

The enhanced GPWS function contains a worldwide terrain database. It compares airplane position, track and speed with this database to determine if an alert condition exists. Terrain data displays on the navigation displays (NDs).

The enhanced GPWS function also contains an airport database. This database contains terrain information about all hard surface runways 3500 feet or more in length. GPWS compares airplane position and runway location to determine if an alert condition exists.

Physical Description

The ground proximity warning computer (GPWC) is a two MCU chassis and weighs seven pounds. The GPWC requires no forced cooling air.

Front Panel

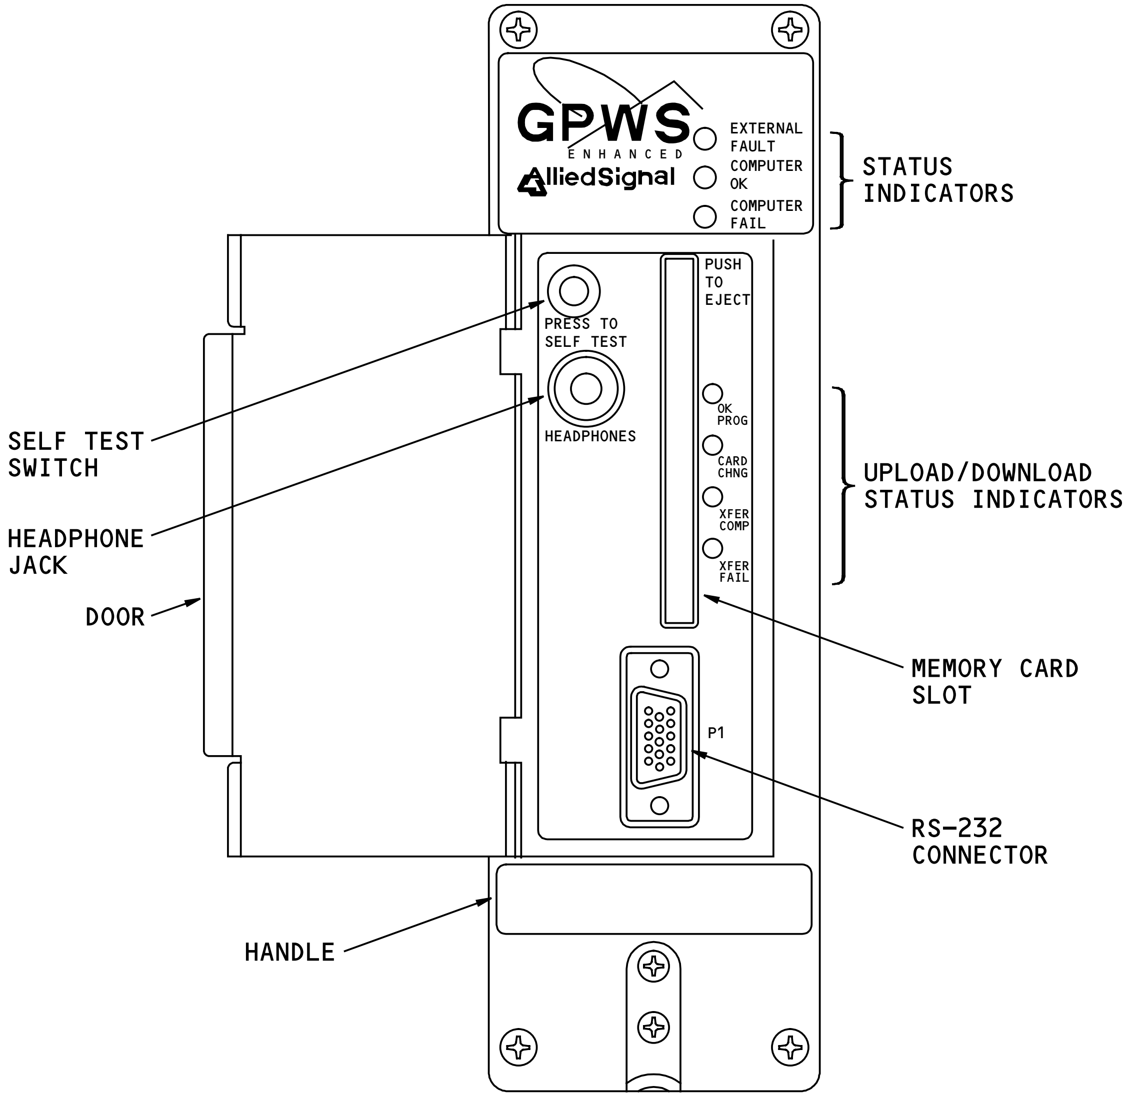
The GPWC front panel has three status LEDs and a door.

These are the three status LEDs on the front panel:

- EXTERNAL FAULT - amber LED turns on for a failure external to the GPWC.
- COMPUTER OK - green LED stays on when GPWC has power and operates normally
- COMPUTER FAIL - red LED turns on when the GPWC has an internal failure.

The front panel door allows access to the following:

- PRESS TO SELF TEST switch - begins a test of the GPWS
- Headphone jack - allows you to hear self test audio
- Memory card slot - allows you to upload software from a memory card, or download fault and warning history data
- Upload/download status indicators - displays conditions of upload or download operation
- RS-232 connector - used for shop test, or for the upload/download of data.



GPWS - GROUND PROXIMITY WARNING COMPUTER

GPWS - CONTROL - EFIS CONTROL PANEL

Description

The EFIS control panel provides these functions:

- Enables the navigation displays (NDs) to show terrain data
- Supplies the selection of different ND modes
- Supplies the selection of different ranges for terrain data to show on the NDs.

TERR Map Switch

When you push the TERR map switch on the EFIS control panel, terrain data shows on the on-side ND. Push the TERR map switch again to remove the display.

ND Mode Selector

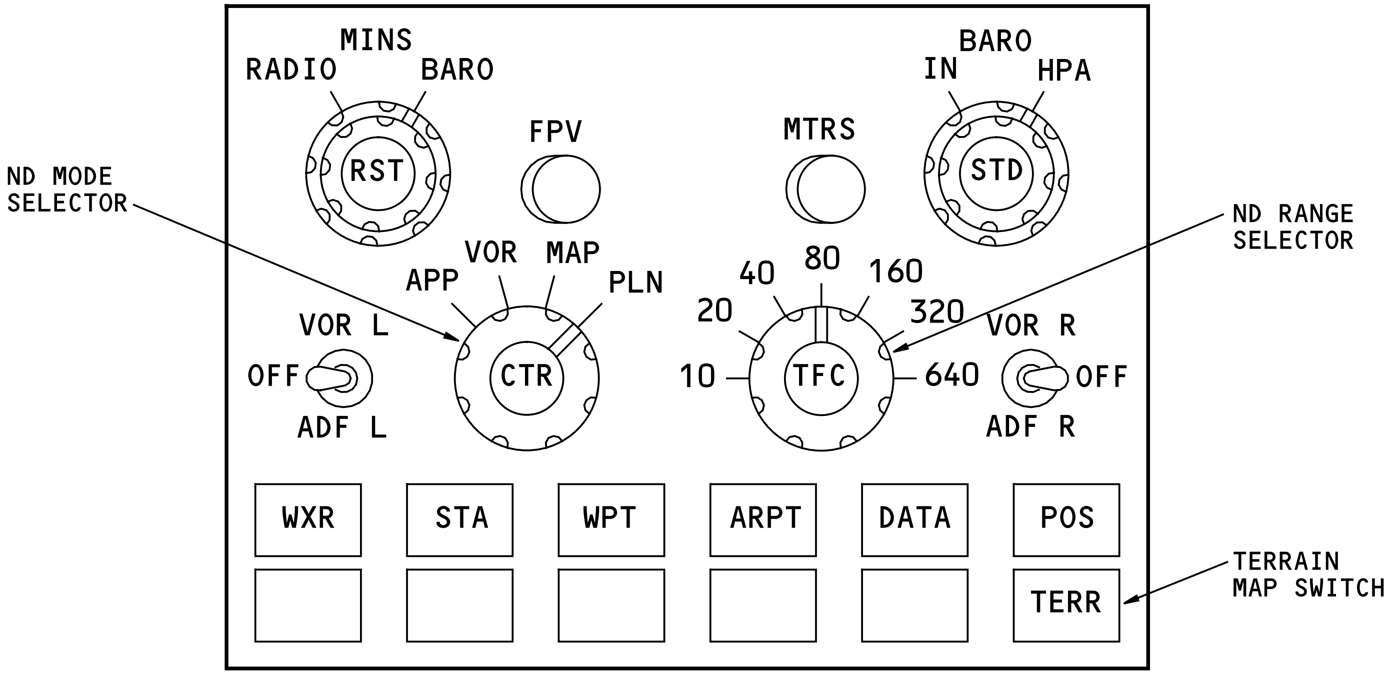
Use the ND mode selector to select an ND mode. The ND modes that show terrain data are:

- Expanded APP (approach) mode
- Expanded VOR mode
- Expanded MAP mode
- Centered MAP mode.

If the mode selector is not in a correct mode when you push the TERR map switch, the terrain display arms. When armed, the terrain display shows as soon as you change the ND selector to a correct mode. The terrain display stays armed even if you push the TERR map switch again. Push the WXR map switch to disarm the terrain display and arm the weather display.

ND Range Selector

The EFIS control panel has a six position range selector. The range selections are 10, 20, 40, 80, 320 and 640 NM. The map mode displays the range at all times. APP and VOR modes display the range only when TERR or WXR data show.



GPWS - CONTROL - EFIS CONTROL PANEL

GPWS - CDU SELECTIONS

Alternate or Backup EFIS Control Panel

The EFIS control page on the control display unit (CDU) permits alternate or backup controls for the ground proximity warning system.

If the EFIS control panel (CP) fails or for alternate operation, use the EFIS control CDU pages on the on-side CDU for:

- On/off control of the on-side terrain display
- Terrain display range selection
- ND mode selection.

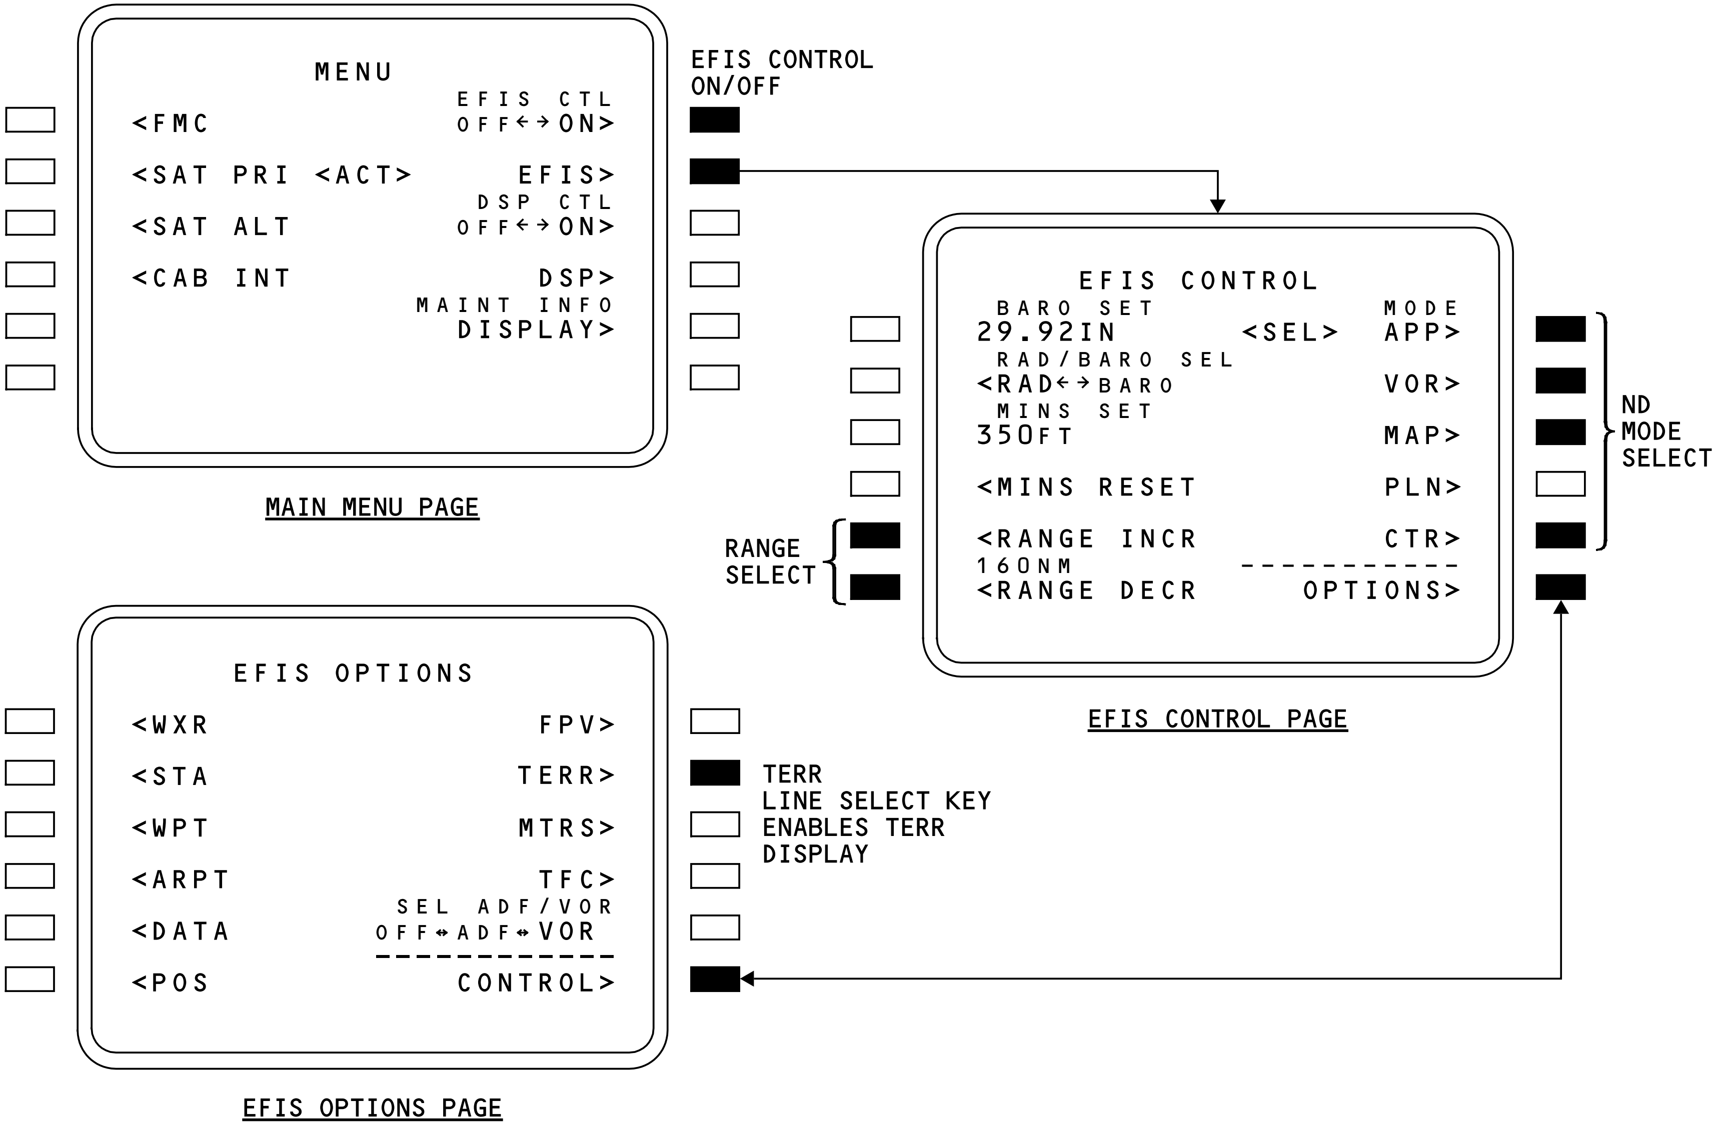
When you select EFIS control to ON from the CDU page, the on-side EFIS CP does not operate.

Access

To get the EFIS control CDU pages on the CDU:

- Push the MENU line select key (LSK) on the CDU to make the MENU page come on
- Push the EFIS CTL LSK on the MENU page and the EFIS prompt comes on
- Push the LSK next to EFIS and the EFIS control page comes on
- Select the ND modes and range From the EFIS CONTROL page
- Push the OPTIONS LSK on the EFIS CONTROL page to go to the EFIS OPTIONS page
- Push the TERR LSK on the EFIS OPTIONS page for ON/OFF control of the GPWS and to enable the terrain display for the on-side ND.
- Push the CONTROL LSK on the EFIS OPTIONS page to return to the EFIS CONTROL page.

You can use the EFIS CP CDU pages on the CDU at any time.



GPWS - CDU SELECTIONS

GPWS - CONTROL COMPONENTS

Description

These are the controls on the landing gear panel:

- Ground proximity light
- Glideslope inhibit switch
- Flap override switch
- Terrain override switch
- Gear override switch.

Ground Proximity Light/Glideslope Inhibit Switch

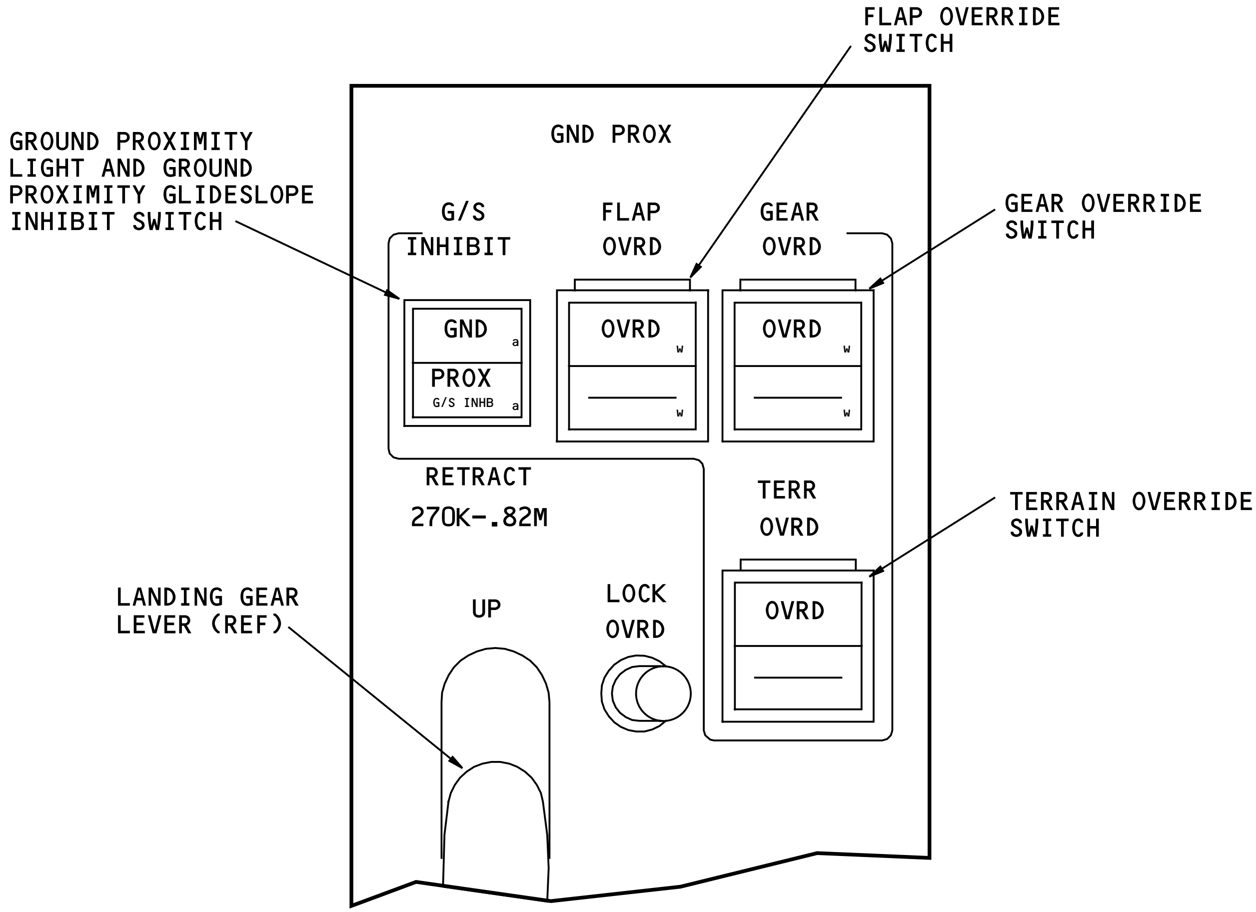
This combination light/switch has two functions. The amber ground proximity light shows ground proximity alerts for modes 1 through 5.

Push the switch to prevent mode 5 (below glideslope) alerts.

Override Switches

The flap override and the gear override switches simulate a flaps down condition and a gear down condition. The use of these switches prevent alerts when the flight crew makes flaps up or gear up approaches intentionally. The flight crew uses the terrain override switch for any of the following conditions:

- The crew determines position data is not valid
- Terrain awareness alerts show when it is obvious no terrain threats exist.



LANDING GEAR PANEL (P2)

34-46-00-007 Rev 2 01/23/1998

GPWS - CONTROL COMPONENTS

GPWS - MODE 1 DESCRIPTION

Purpose

Mode 1 supplies alerts and warnings for large descent rates when the airplane is near the terrain. This mode is independent of flap or gear positions.

Description

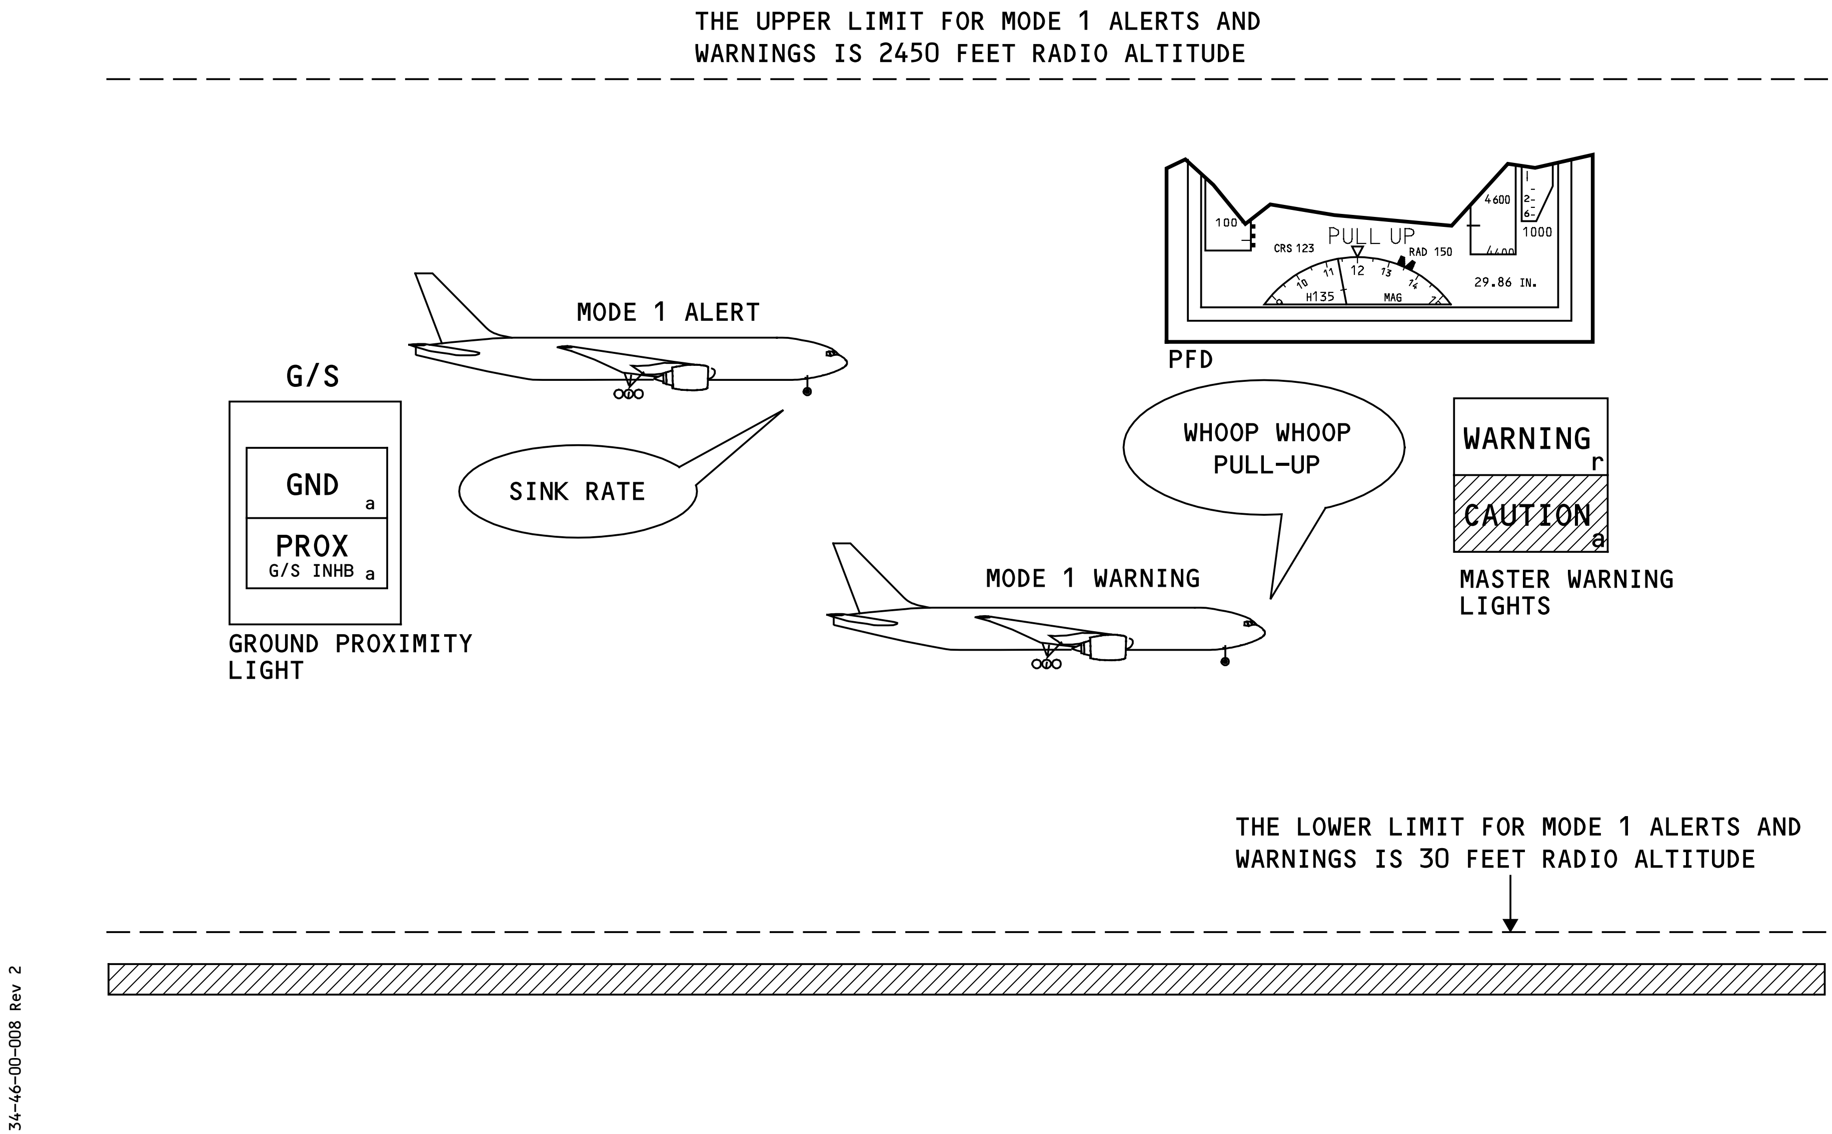
Mode 1 alerts or warnings occur between 2450 feet and 30 feet. The rate of descent sets the point at which mode 1 alerts occur.

The alert consists of these annunciations:

- Aural message SINK RATE
- Ground proximity light on the landing gear panel.

If the descent rate does not decrease, the alert changes to a warning. These are the warning annunciations:

- A red PULL-UP message on the PFD
- Red master warning lights
- The aural message WHOOP, WHOOP, PULL-UP.



GPWS - MODE 1 DESCRIPTION

GPWS - MODE 1 OPERATION

General

Mode 1 alerts and warnings occur at 2450 feet down to 30 feet of radio altitude. The LRUs that supply inputs for mode 1 operation are the left, right, and center radio altimeter transceivers and the AIMS cabinets.

The GPWC uses this data to detect mode 1 alerts and warnings:

- Radio altitude
- Inertial vertical speed
- Barometric altitude.

The mode detector in the GPWC calculates the descent rate from the inertial vertical speed input. If it is not available, the mode detector uses barometric altitude rate.

The type of annunciation depends on the rate of descent and the radio altitude.

The first annunciation is an alert. If the rate of descent does not decrease, the annunciation changes to a warning.

Operation

The mode detector uses the inputs to see if an alert or warning condition is present.

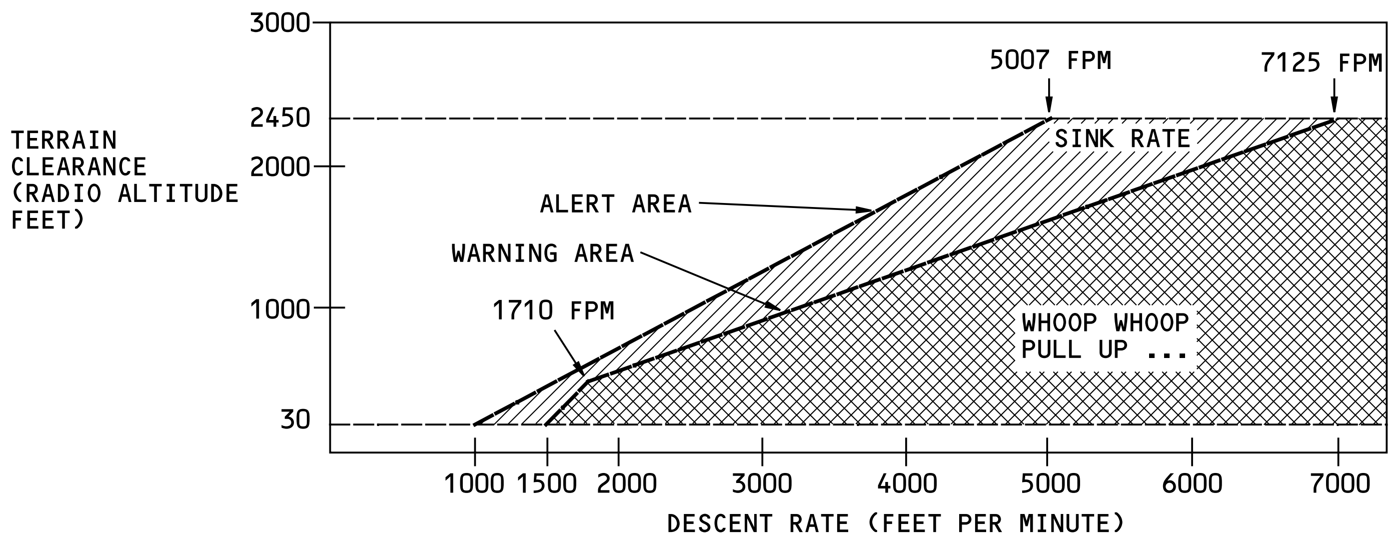
If an alert condition is present, the GPWC sends a discrete to the ground proximity light. The alert discrete goes to the speech prom to make the alert aural. The alert aural goes to the warning electronic units (WEUs) which amplify and send it to the aural warning speakers.

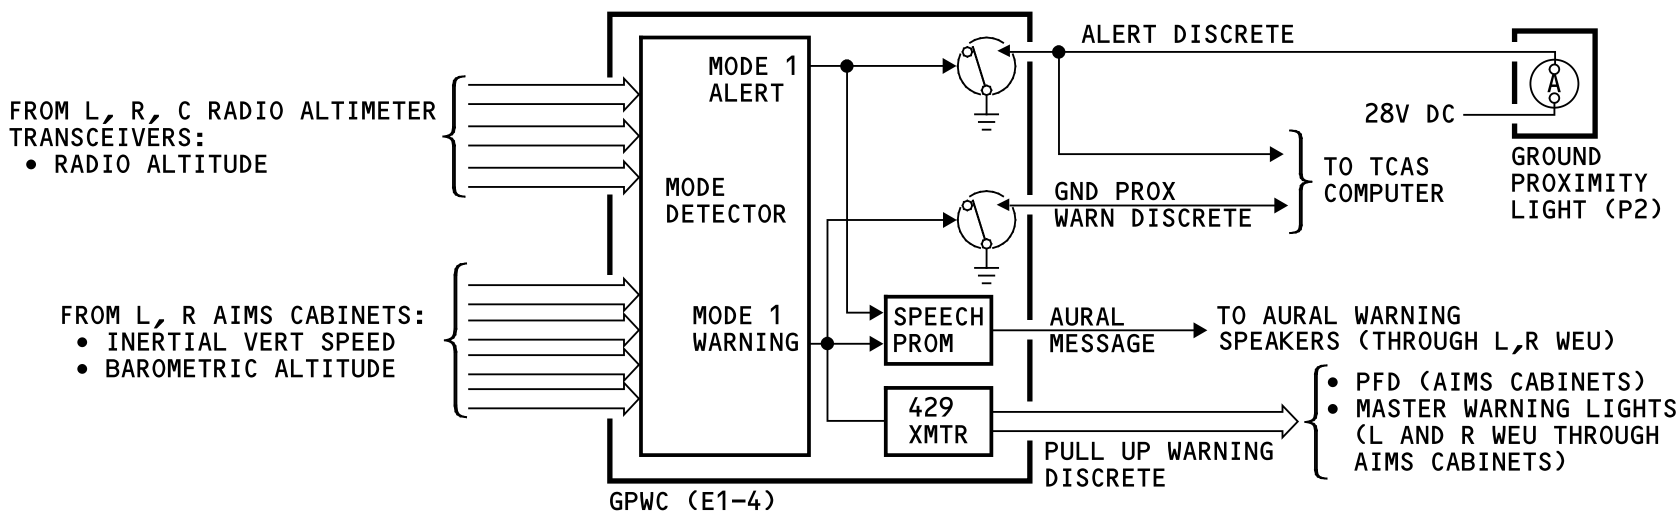
The alert discrete also goes to the TCAS computer to inhibit any TCAS advisory messages.

When a warning condition is present, the GPWC sends a PULL-UP warning discrete to the AIMS cabinets to show the message PULL UP on the PFDs. The warning discrete goes to the speech prom to make the warning aural. The warning aural goes to the warning electronic units (WEUs) which amplify and send it to the aural warning speakers.

The warning discrete also goes to the TCAS computer to inhibit any TCAS advisory messages.

The AIMS cabinets send the warning discretes to the warning electronic units (WEUs) to make the master warning lights come on.





GPWS - MODE 1 OPERATION

GPWS - MODE 2A DESCRIPTION

Purpose

Mode 2 supplies alerts and warnings if the closure rate to the terrain is too large. Mode 2 has two submodes (mode 2A and 2B).

The position of the flaps determine if it is a mode 2A or a mode 2B alert.

Description

Mode 2A gives annunciations for a large closure rate with the flaps up (less than 15 units). Mode 2A gives an alert and a warning. This is the alert:

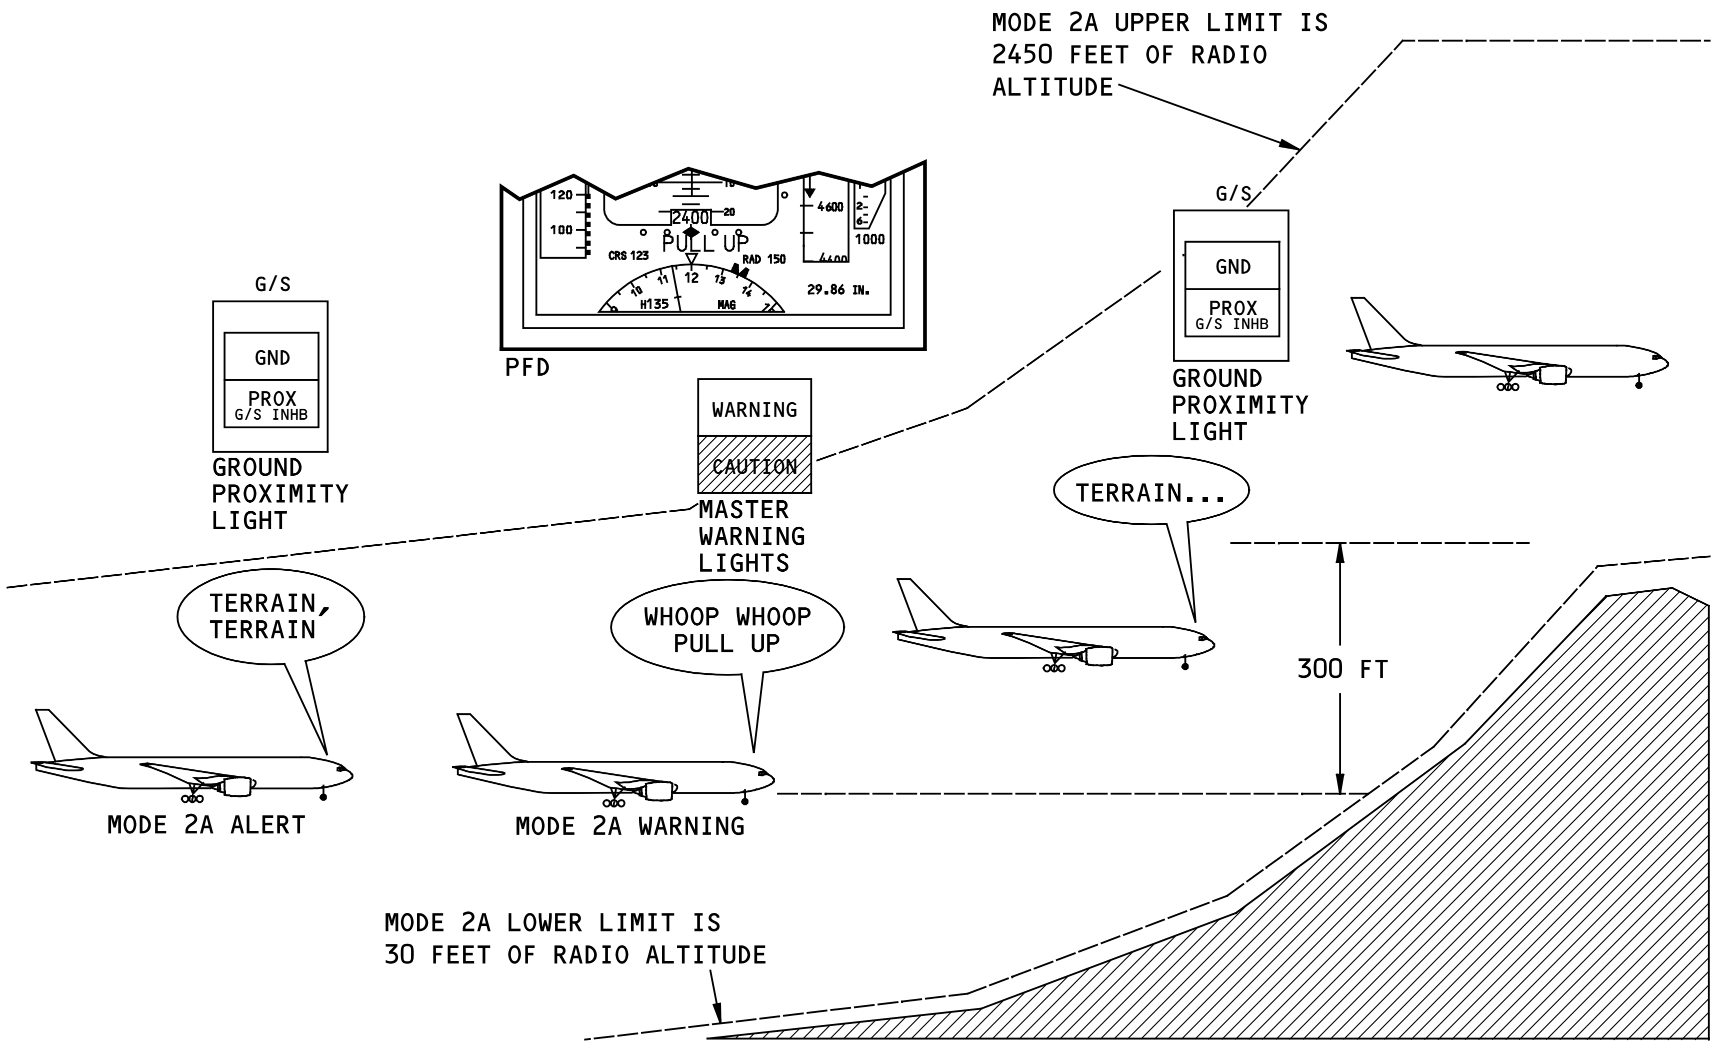
- An aural message TERRAIN, TERRAIN
- The ground proximity light.

This is the warning:

- A red PULL-UP message on the PFDs
- The master warning lights come on
- An aural message WHOOP, WHOOP, PULL-UP.

The warning changes back to the alert annunciation TERRAIN and the ground proximity light on if the closure rate decreases or if the pilot does a pull up maneuver.

The alert annunciation continues until there is a gain of 300 feet of inertial altitude or the gear comes down.



GPWS - MODE 2A DESCRIPTION

34-46-00-010 Rev 2

GPWS - MODE - 2B DESCRIPTION

General

Mode 2B gives annunciations for a large closure rate with the flaps down (greater than 15 units).

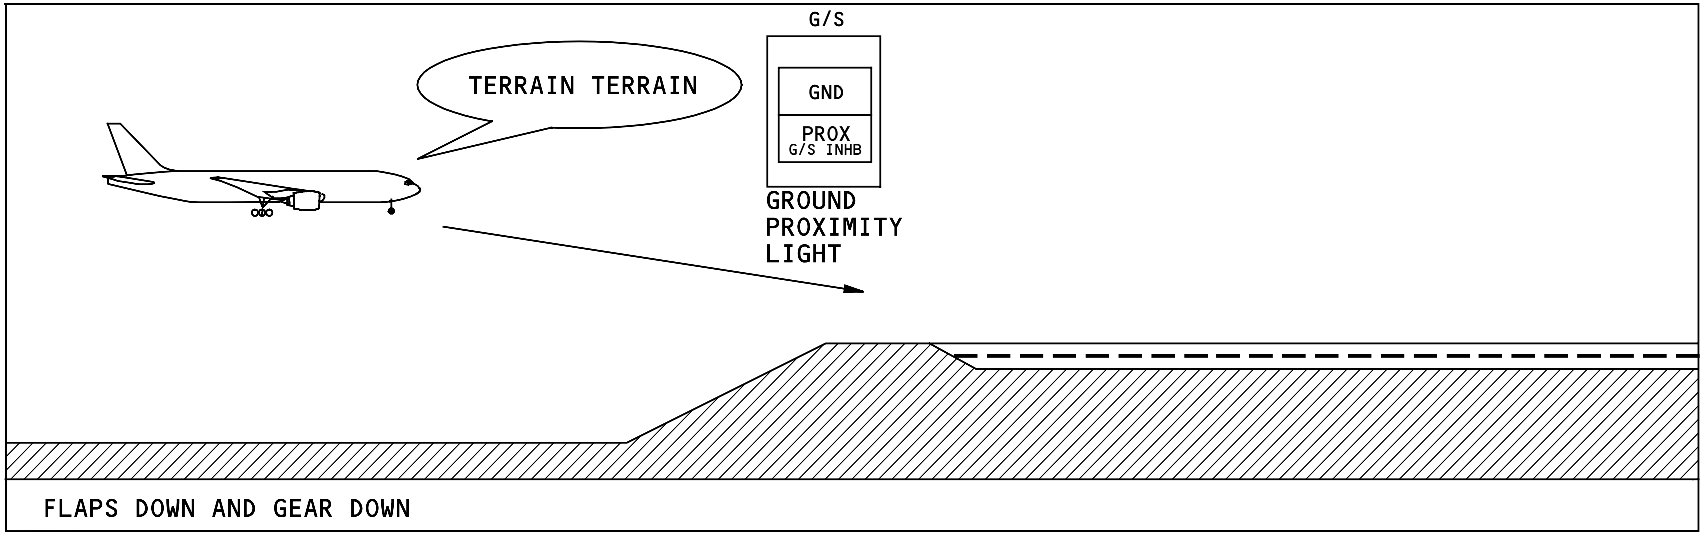
Mode 2B gives two types of annunciations that depend on the position of the landing gear.

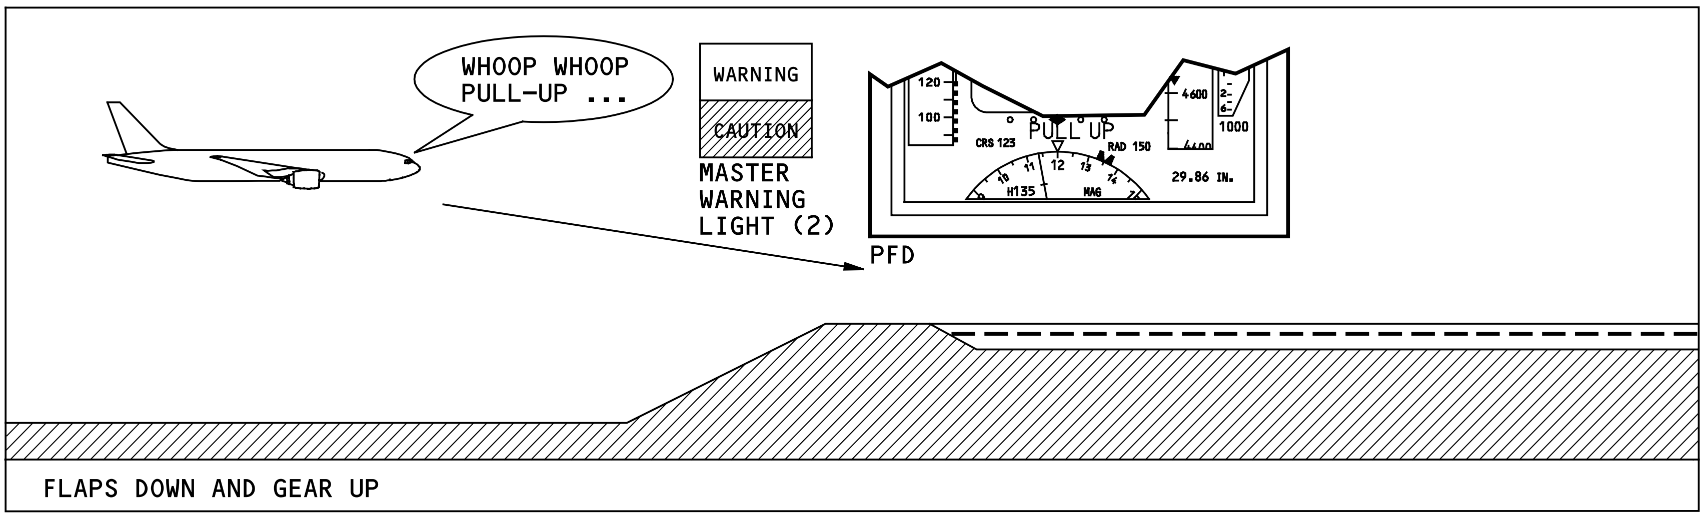
With the landing gear down, the GPWC gives an alert. These are the annunciations:

- The aural message TERRAIN TERRAIN
- The ground proximity light comes on.

With the gear up, the alert is a warning and these are the annunciations:

- The aural message WHOOP, WHOOP, PULL-UP
- Master warning lights come on
- A red PULL-UP message on the PFDs.





34-46-00-011 Rev 2

GPWS - MODE - 2B DESCRIPTION

GPWS - MODE 2 OPERATION

General

Mode 2A annunciations occur at 1650 feet down to 30 feet. The upper limit goes up to 2450 feet for airspeeds above 310 kts.

Mode 2B annunciations occur at 789 feet down to 600 feet. The lower limit goes down to 200 feet for inertial vertical velocity rates less than 400 feet per minute.

The LRUs that supply inputs for mode 2 operation are the left, right, and center radio altimeter transceivers and the AIMS cabinets.

This is the data the GPWC uses to detect mode 2 alerts and warnings:

- Radio altitude
- Inertial vertical speed (IVS)
- Barometric altitude rate
- Barometric altitude
- Computed airspeed
- Flap and gear position.

Operation

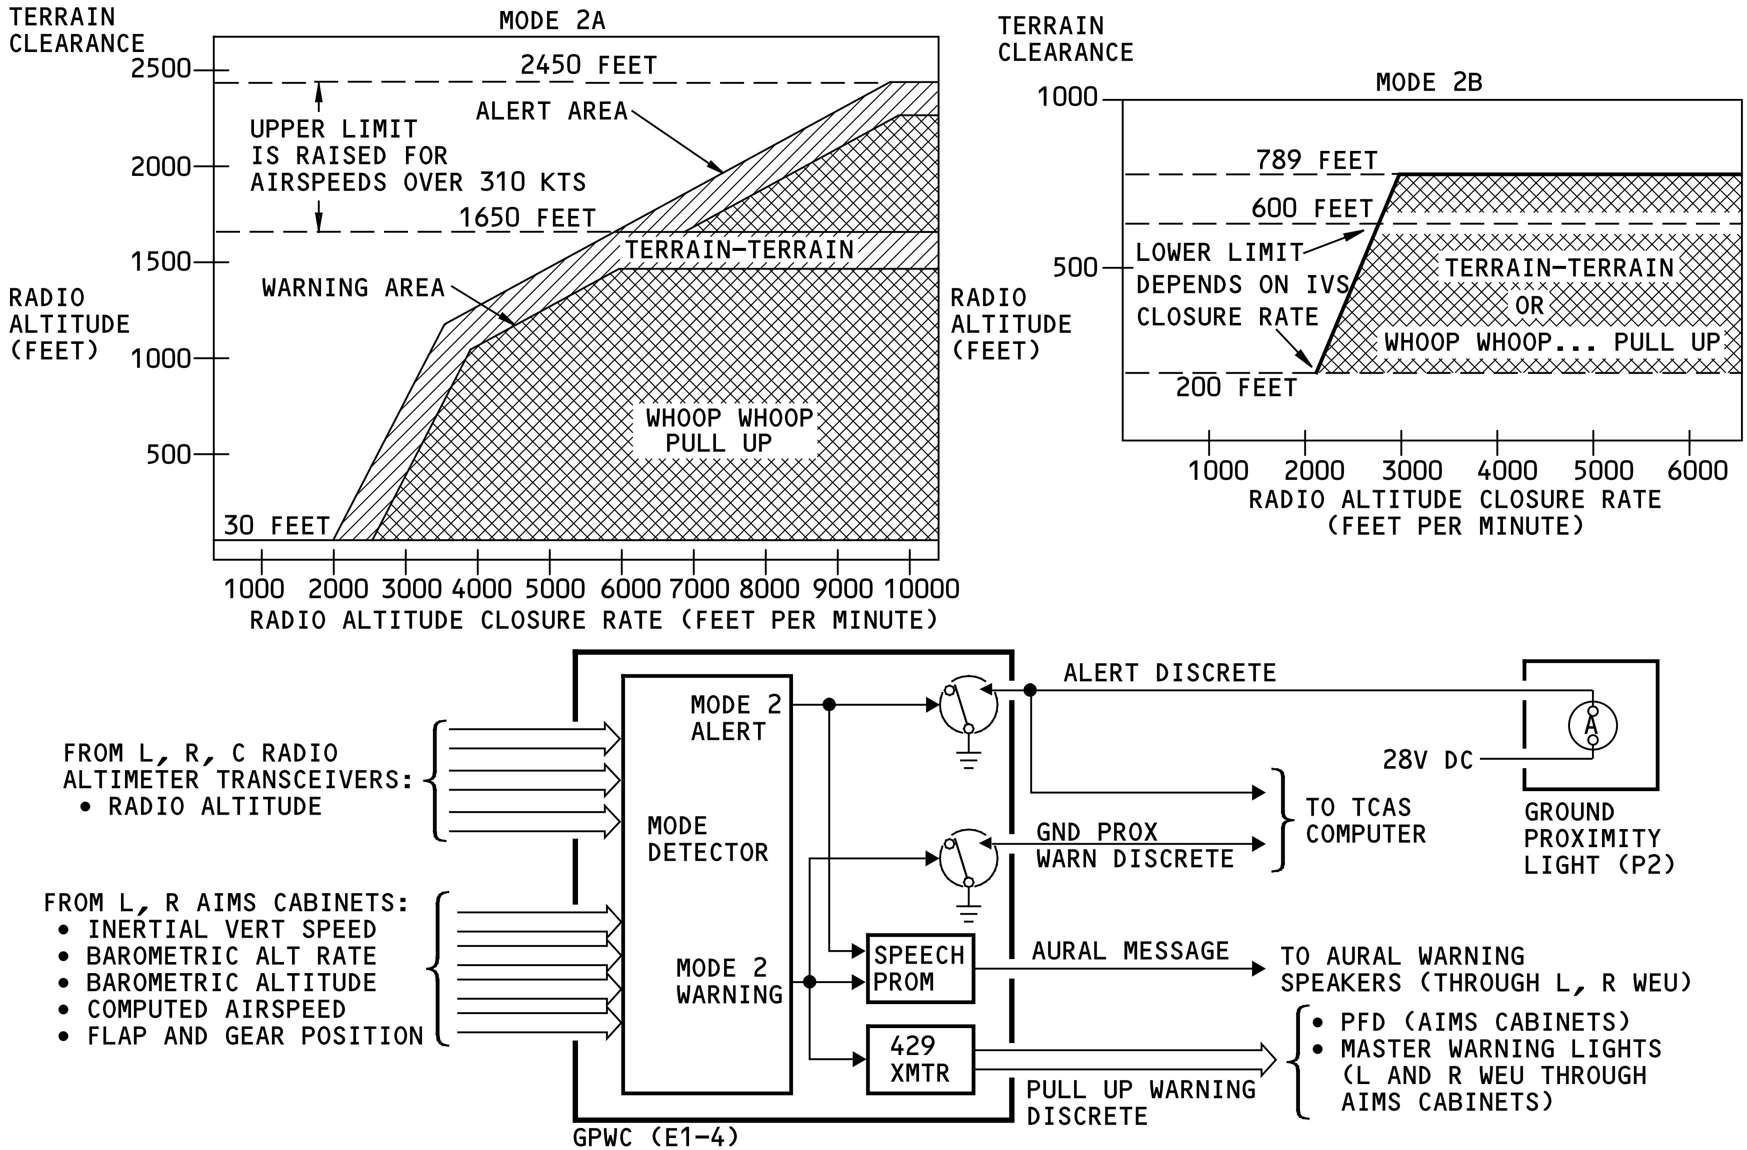
The mode detector uses the inputs to find if there is an alert or warning condition.

If there is an alert condition, the detector sends a discrete to the ground proximity light. The discrete goes to the speech prom to enable the alert aural. The alert aural goes to the WES which sends it to the aural warning speakers in the flight deck.

The alert discrete also goes to the TCAS computer to inhibit any TCAS advisory messages.

If there is a warning condition, the mode detector sends a PULL-UP discrete to the AIMS cabinet to show the message on the PFD's. The AIMS cabinets send the discrete to the WES to turn on the master warning lights. The warning discrete goes to the speech prom to enable the warning aural. The warning aural goes to the WES which sends it to the aural warning speakers in the flight deck.

The ground proximity warning discrete goes to the TCAS computer to inhibit any TCAS advisory messages.



GPWS - MODE 2 OPERATION

GPWS - MODE 3 DESCRIPTION

Purpose

Mode 3 supplies alerts for a large altitude loss during:

- Takeoff
- A missed approach with the gear up and flaps less than 25 units

Mode 3 consists of these two submodes:

- Submode 3A
- Submode 3B.

Submode 3A

Submode 3A gives an alert when the airplane looses too much inertial altitude after takeoff. The amount of inertial loss depends on the climb rate and radio altitude of the airplane.

This is the alert:

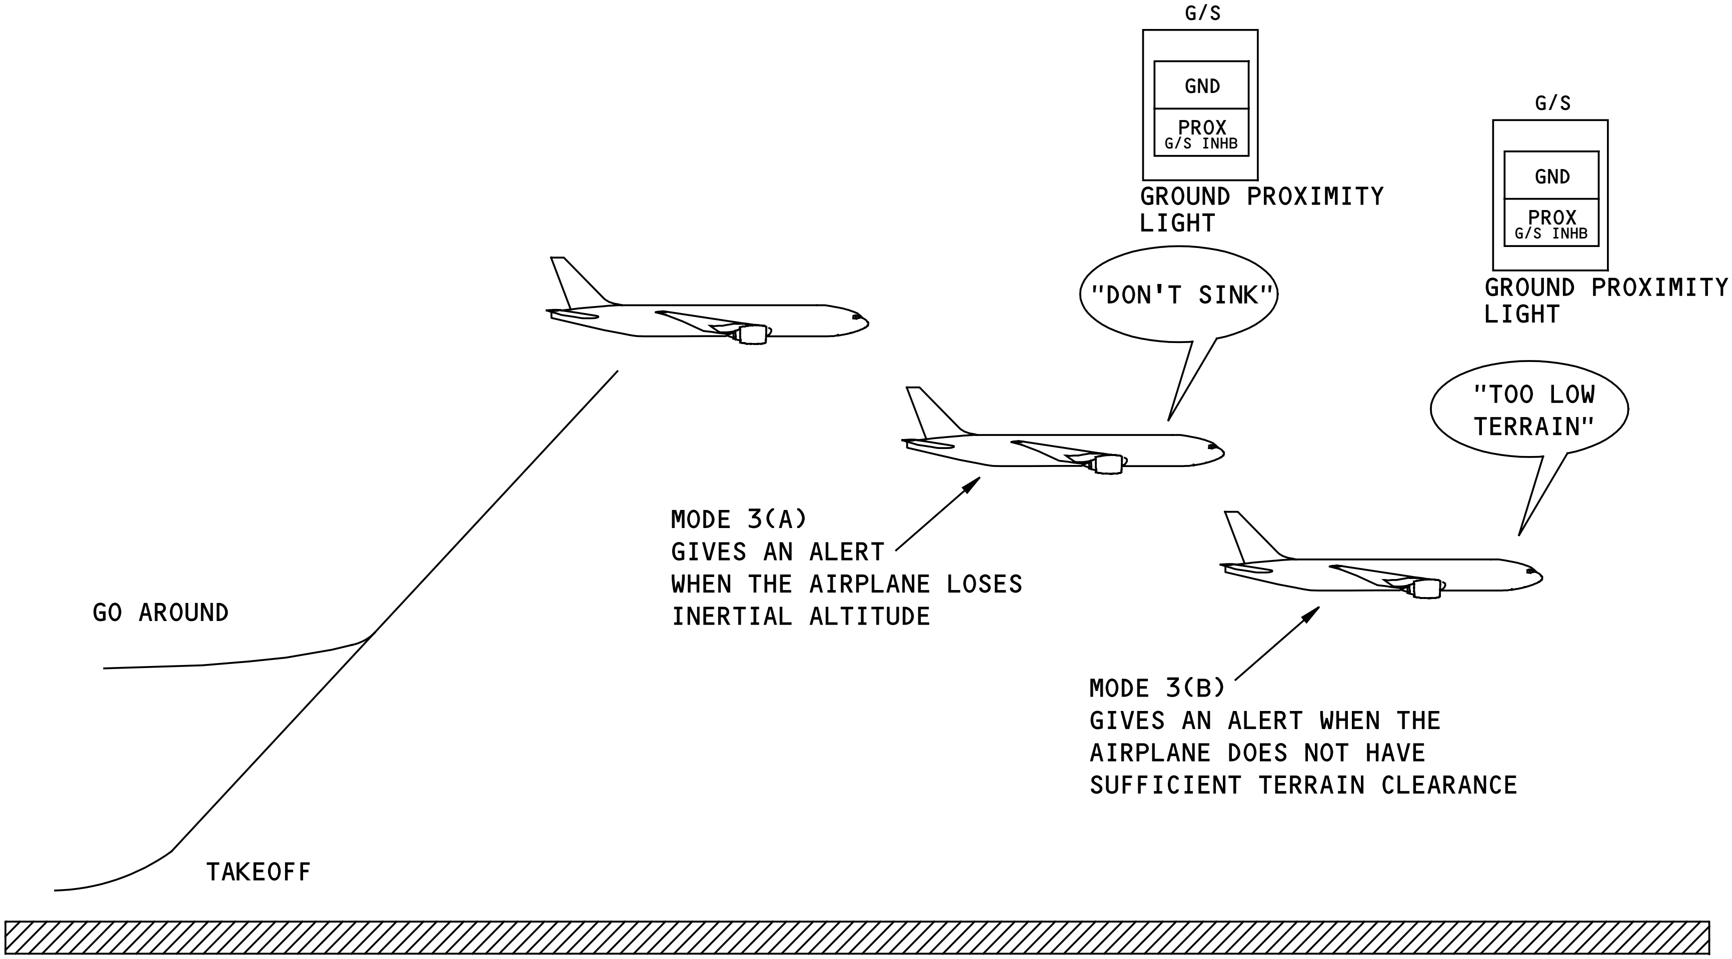
- Ground proximity light comes on
- Aural message DON'T SINK.

Submode 3B

Submode 3B gives an alert if the radio altitude terrain clearance goes below the amount stored in a filter in the GPWC, with the gear up and the flaps up (less than 15 units).

This is the alert:

- Ground proximity light comes on
- Aural message TOO LOW TERRAIN.



34-46-00-013 Rev 1

GPWS - MODE 3 DESCRIPTION

GPWS - MODE 3 OPERATION

General

Mode 3 alerts occur at 1333 feet down to 30 feet. Mode 3 arms when any of these conditions are true:

- Airplane goes below 245 feet in landing configuration (gear down, flaps less than 15 units)
- Airplane goes below 30 feet regardless of flap position.

The LRUs that supply inputs for mode 3 operation are the left, right, and center radio altimeter transceivers and the AIMS cabinets.

The GPWC uses this data to detect mode 3 alerts:

- Radio altitude
- Inertial altitude
- Inertial vertical speed
- Barometric altitude
- Barometric altitude rate
- Flap and gear position.

Mode 3B alerts occur when the altitude drops lower than the value stored in a filter in the GPWC. The filter activates at 150 feet and stores approximately 75% of the actual altitude.

The filter stores up to 500 feet altitude for airspeeds below 190 knots (500 feet in the filter represents an altitude of 667 feet).

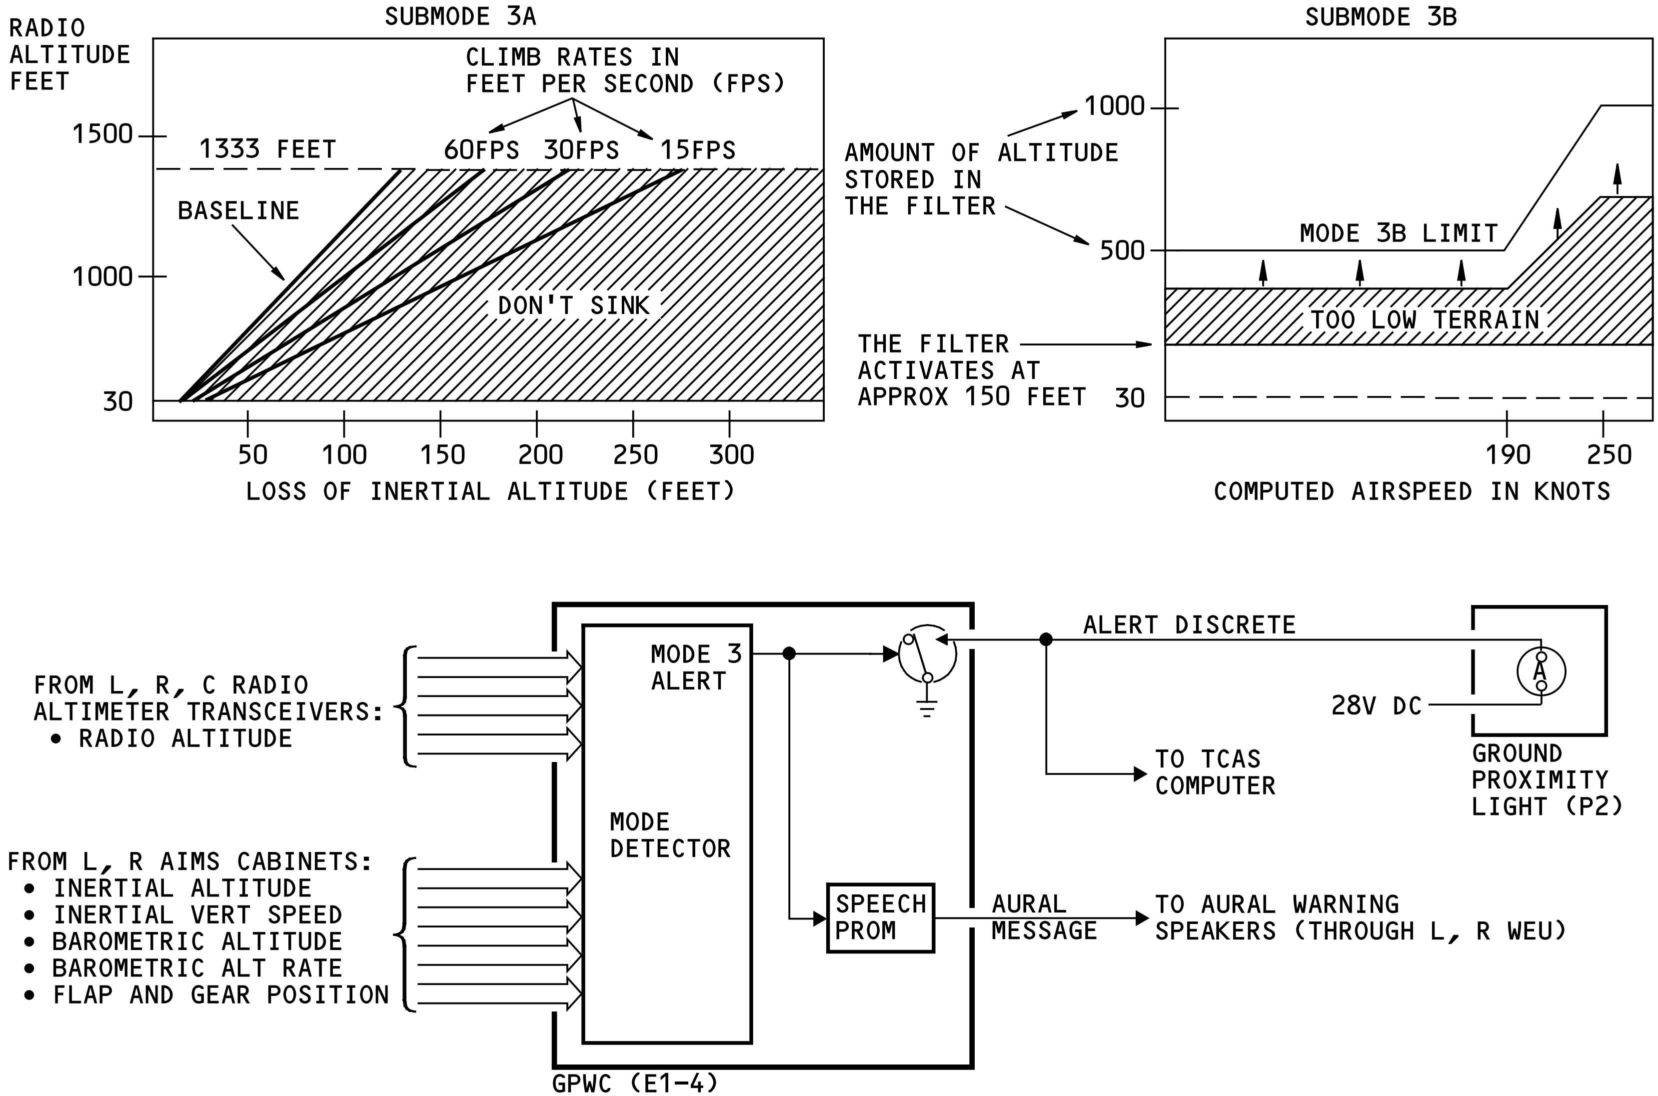
When the airspeed goes above 250 knots, the upper limit goes to 1000 feet (this represents an altitude of 1333 feet).

Mode 3 switches to mode 4 when the altitude gain filter gets to the upper limits.

Operation

The mode detector uses the inputs to determine if an alert condition is present. If present, the mode detector sends a discrete to the ground proximity light. The discrete goes to the speech prom to make the alert aural which goes to the WES. The WES sends the aural to the aural warning speakers.

A discrete also goes to the TCAS computer to inhibit any TCAS advisory messages.



GPWS - MODE 3 OPERATION

GPWS - MODE 4 DESCRIPTION

General

Mode 4 supplies alerts when the airplane is too close to the terrain and the airplane is not in the landing configuration.

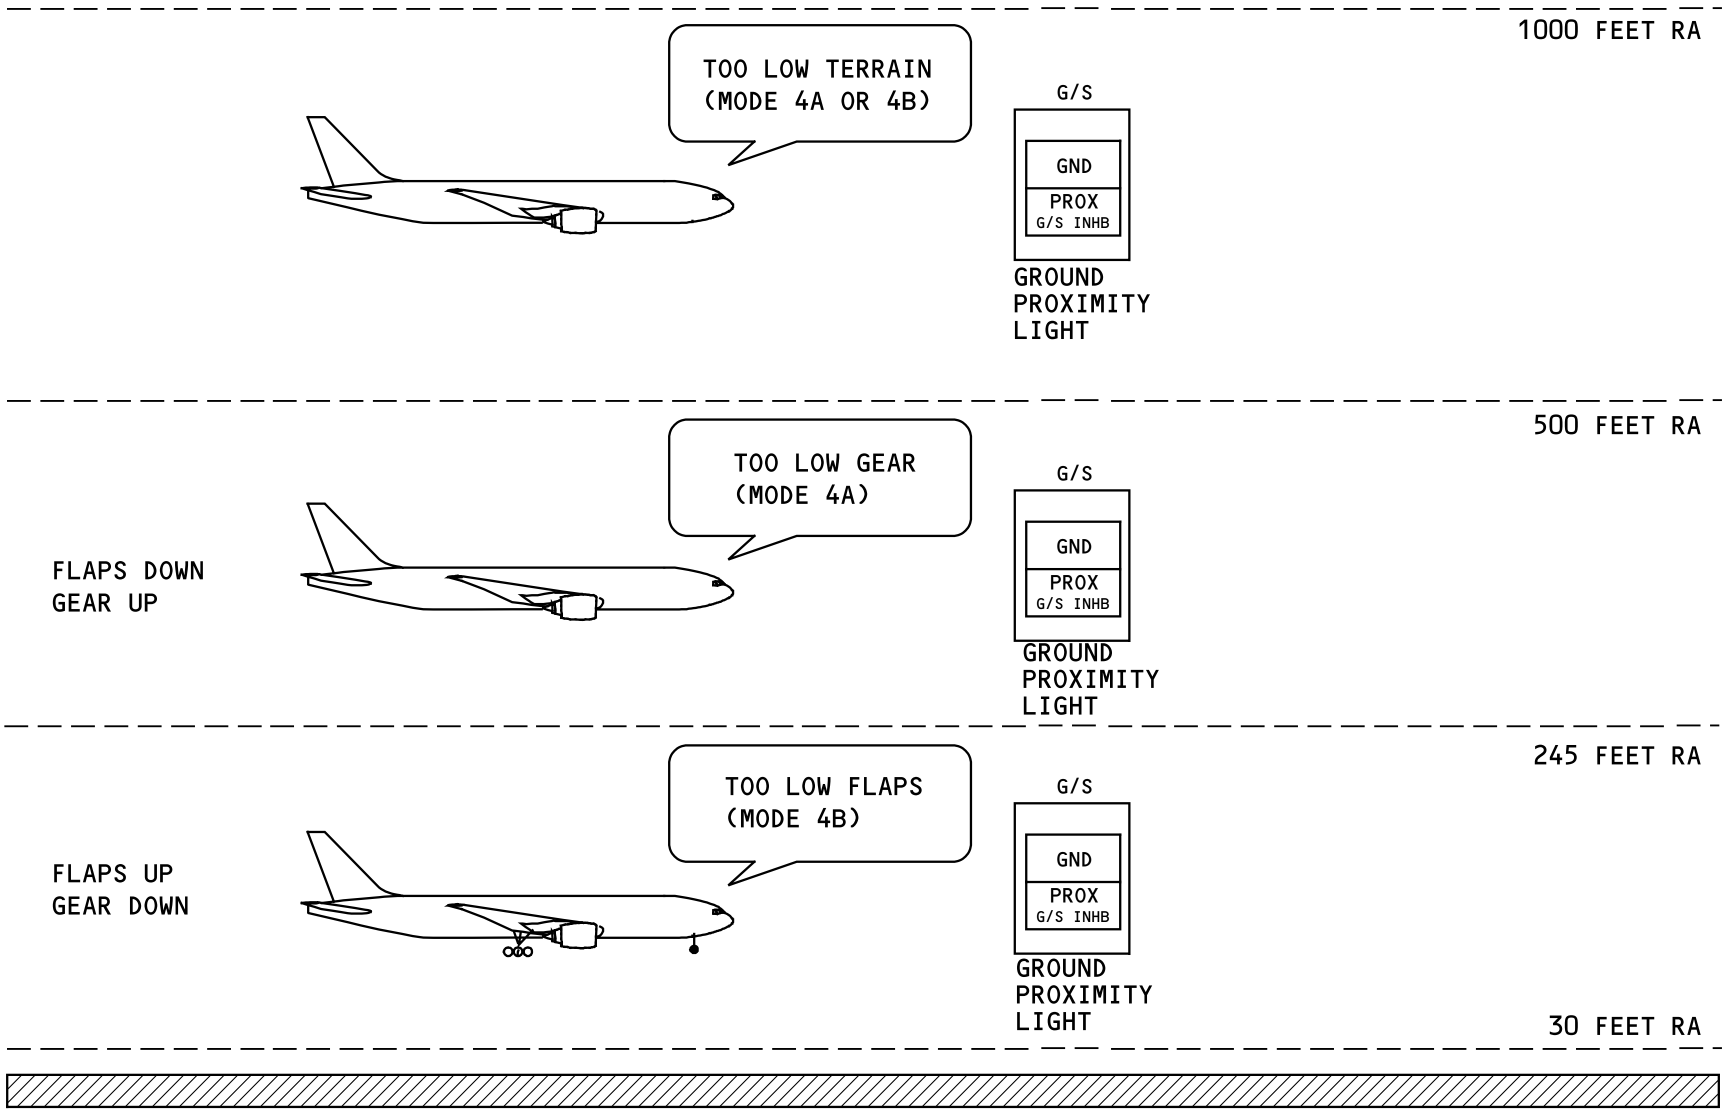
Mode 4 has these two submodes:

- 4A
- 4B

Description

The GPWC gives a mode 4A alert when the landing gear is up. Mode 4A gives different types of aural messages. The aurals are TOO LOW GEAR, and TOO LOW TERRAIN. The ground proximity light will come on for either of these aural messages.

The GPWC gives a mode 4B alert when the gear is down and the flaps are less than 15 units. Mode 4B can have two aural messages depending on airspeed. The aurals are TOO LOW FLAPS, and TOO LOW TERRAIN. The ground proximity light comes on for either of the aural messages.



34-46-00-015 Rev 1

GPWS - MODE 4 DESCRIPTION

GPWS - MODE 4 OPERATION

General

Mode 4 alerts occur at 1000 feet down to 30 feet. The LRUs that supply inputs for mode 4 operation are the left, right, and center radio altimeter transceiver and the AIMS cabinets.

The GPWC uses this data to detect mode 4 alerts:

- Radio altitude
- Computed airspeed
- Flap and gear position.

The mode 4A aural message TOO LOW-GEAR... changes to the aural TOO LOW-TERRAIN... when the airspeed goes above 190 knots with the flaps less than 15 units.

If the flaps are more than 15 units, the aural messages change at 159 knots.

Mode 4B aural message TOO LOW-FLAPS... changes to TOO LOW-TERRAIN...when the airspeed goes above 159 knots.

Mode 4 switches to mode 3 if the airplane goes below 245 feet in landing configuration (flaps and gear down).

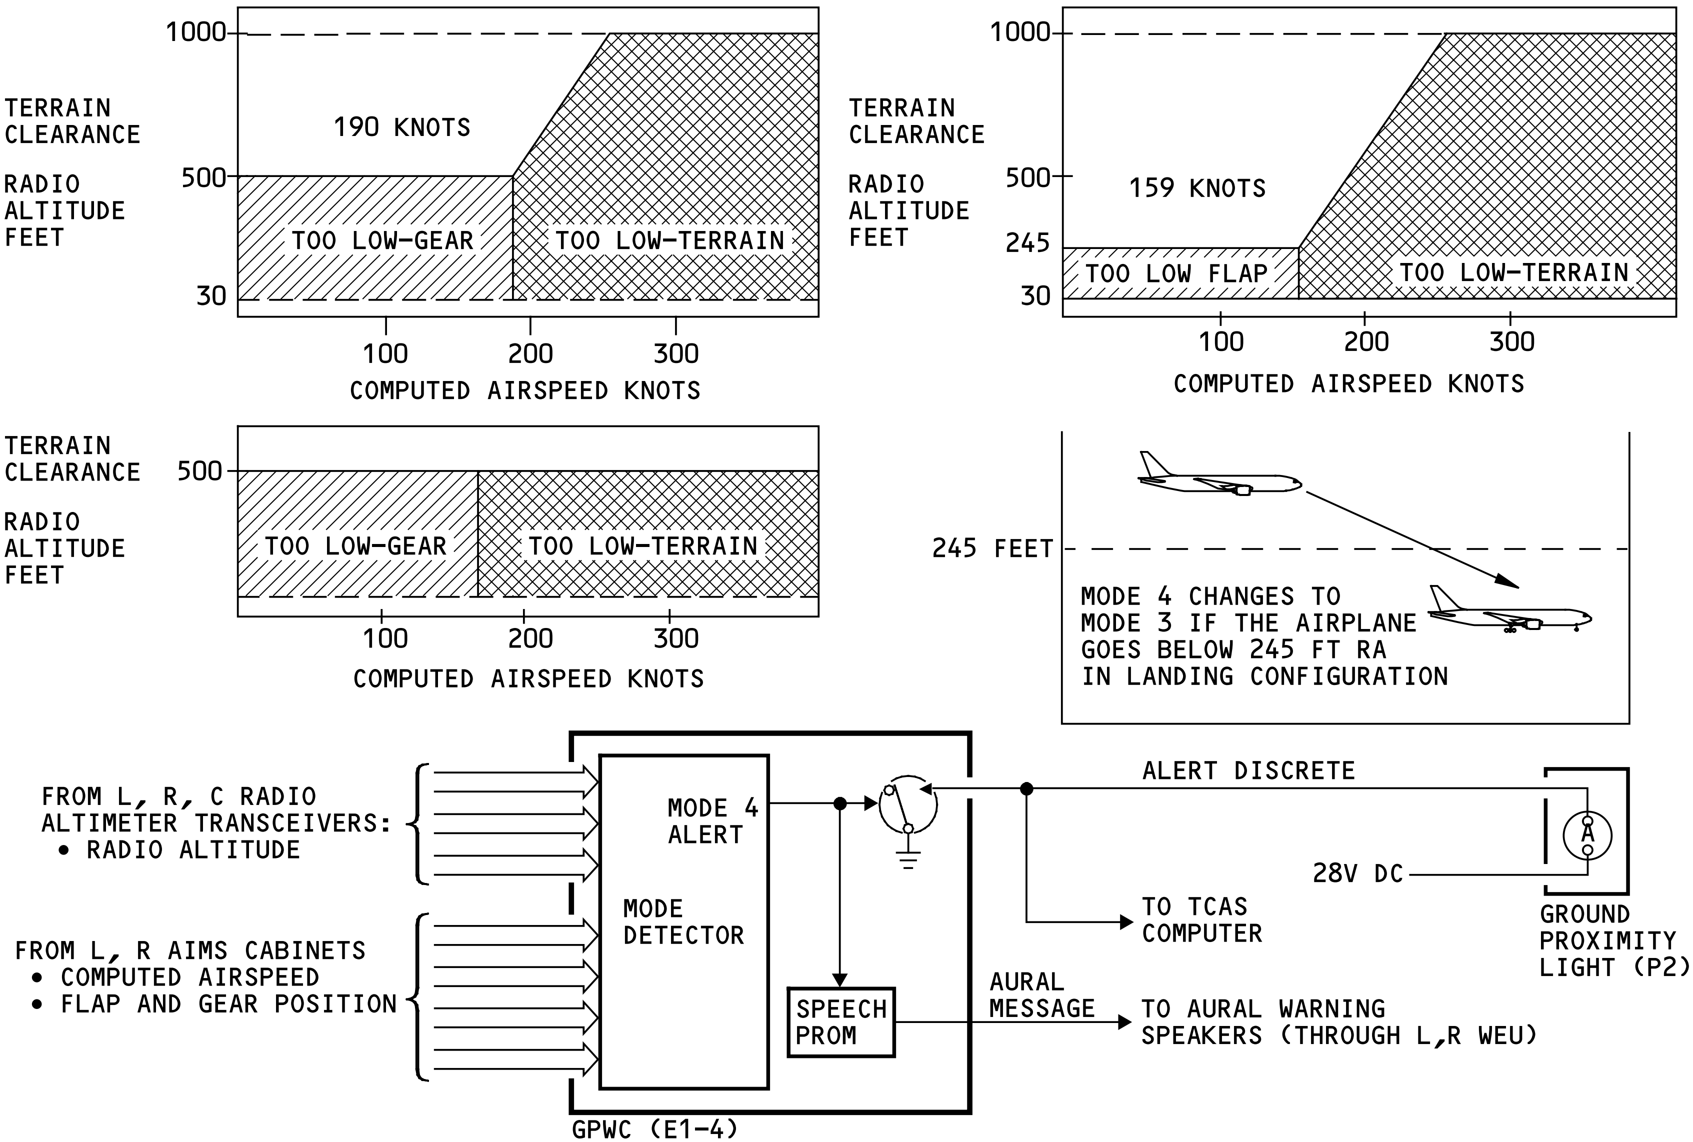
Operation

The mode detector uses the inputs to determine if an alert condition is present.

If present, the mode detector sends a discrete to turn on the ground proximity light. The alert discrete goes to the speech prom to make the alert aural.

The alert aural goes to the WES which sends it to the the aural warning speakers.

The alert discrete also goes to the TCAS computer to inhibit any TCAS advisory messages.



GPWS - MODE 4 OPERATION

GPWS - MODE 5 DESCRIPTION

General

The GPWC gives a mode 5 alert when the airplane is too far below the glideslope during a front course approach with the landing gear down. Mode 5 does not operate during back course approaches.

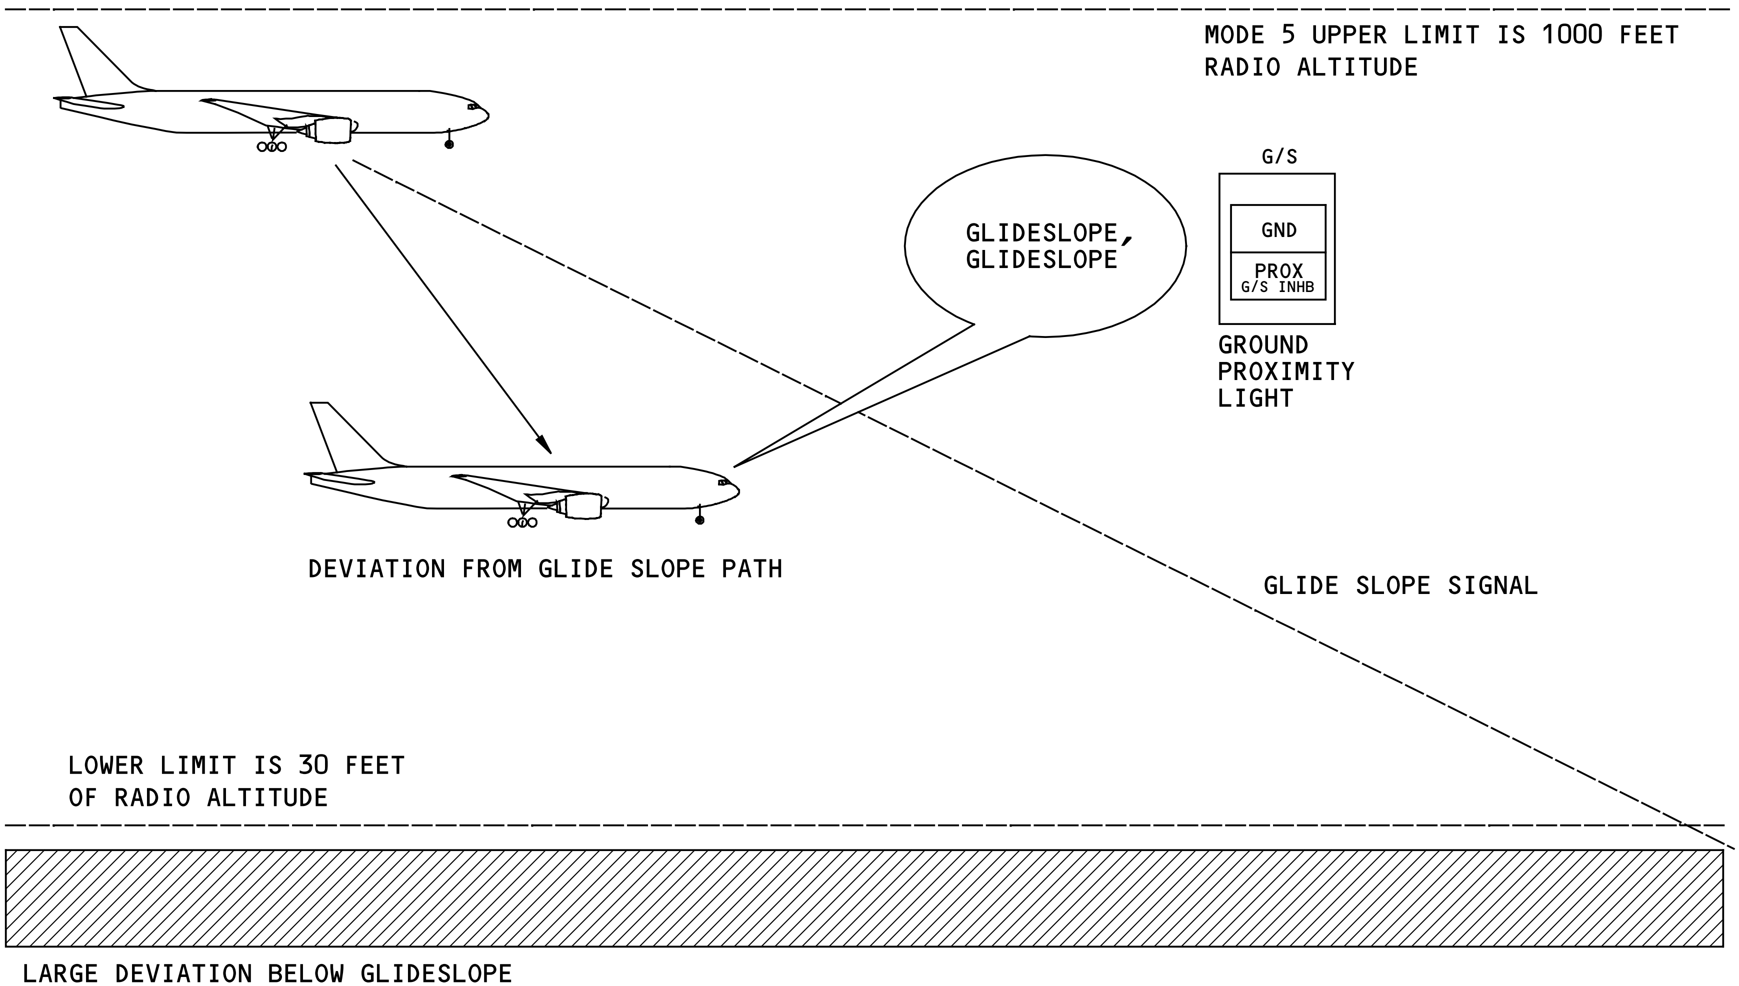
Description

Mode 5 alerts can occur between 30 and 1000 feet. The aural alert message is GLIDESLOPE GLIDESLOPE and the ground proximity light comes on.

The ground proximity glideslope inhibit switch inhibits or cancels mode 5 alerts.

As the deviation below the glideslope increases, the volume of the aural message increases.

The message repeats faster as the terrain gets closer, or if the glideslope deviation increases.



34-46-00-017 Rev 2

GPWS - MODE 5 DESCRIPTION

GPWS - MODE 5 OPERATION

General

Mode 5 alerts can occur between 30 and 1000 feet radio altitude. Mode 5 arms when:

- The airplane terrain clearance is less than 1000 feet
- The gear is down
- The glideslope signal is captured.

These LRUs supply inputs for mode 5 operation:

- Left, right, and center radio altimeter transceivers
- Left ILS receiver
- AIMS cabinets.

The GPWC uses this data to detect mode 5 alerts:

- Glideslope deviation
- Selected runway heading
- Magnetic track
- Gear position.

Low level audio occurs below 1000 feet down to 30 feet when the deviation is more than 1.3 dots.

Normal level audio occurs below 300 feet when the deviation is more than 2 dots.

The interval between messages is normally 5.15 seconds. At 300 feet, the message repeats at a faster rate depending on the glideslope deviation.

Operation

Push the ground proximity glideslope inhibit switch to inhibit or cancel mode 5 aural and visual alerts.

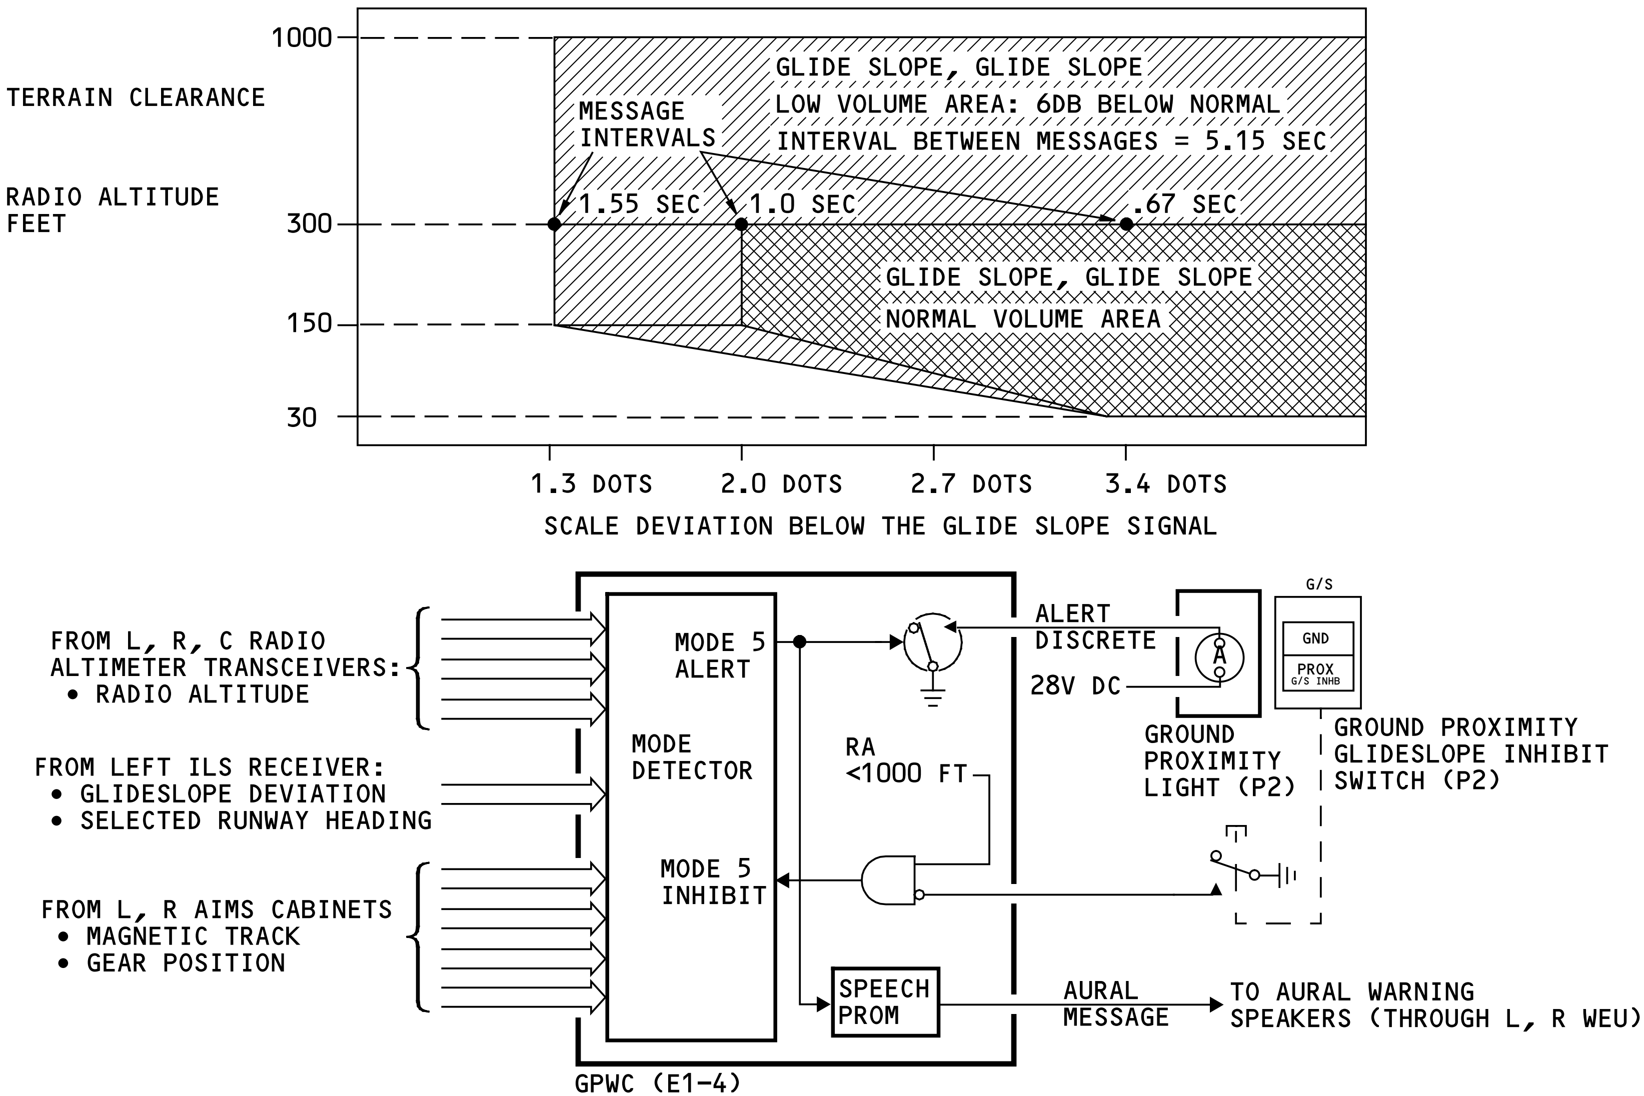
If you push the switch before mode 5 alerts begin, you inhibit the aural and visual annunciations.

If you push the ground proximity glideslope inhibit switch during a mode 5 alert, you cancel the aural and visual annunciations.

When you inhibit or cancel the alert, you cannot activate it again unless the airplane leaves the mode 5 alerting area or you operate the landing gear.

The mode detector uses the inputs to look for an alert condition. If there is an alert condition, the mode detector sends a discrete to turn on the ground proximity light. The discrete goes to the speech prom to make the alert aural.

The alert aural also goes to the WES which sends it to the aural warning speakers.



GPWS - MODE 5 OPERATION

GPWS - MODE 6 DESCRIPTION

General

The GPWC gives mode 6 aural callouts when the airplane descends through selected altitudes with the gear down. A program pin selection determines the callout configuration. Mode 6 supplies only callouts. There are no visual indications.

Description

The GPWC receives inputs from:

- Left, right, or center radio altimeter transceivers
- AIMS cabinets

The GPWC uses this data to determine mode 6 alerts:

- Radio altitude
- Gear position
- Program pin selection.

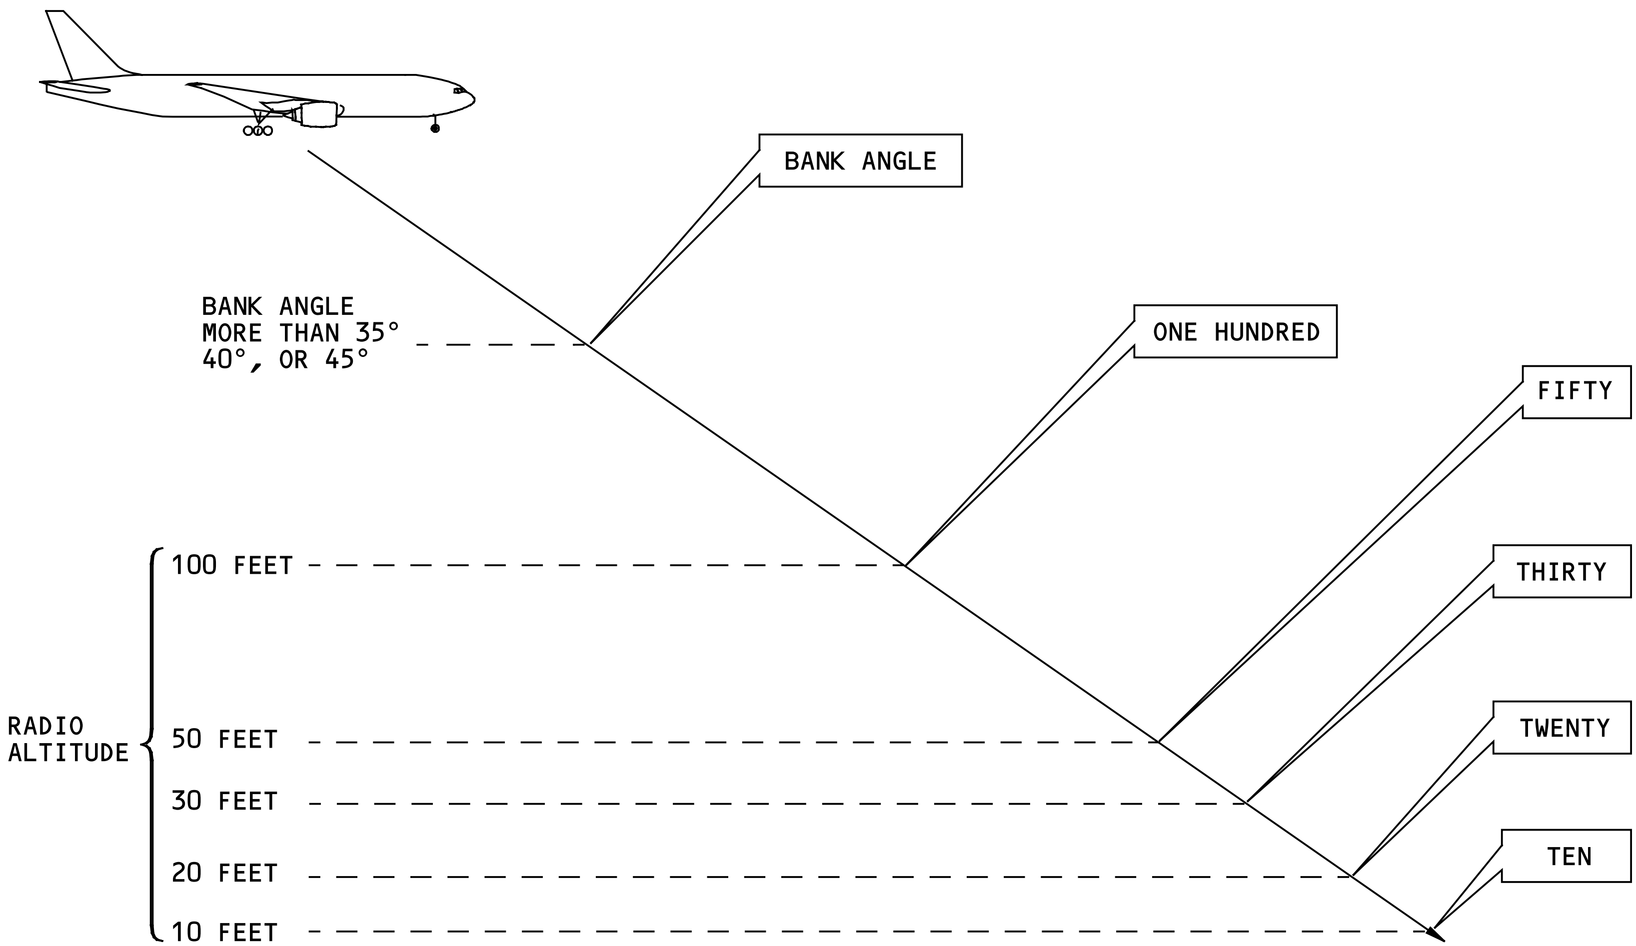
The program program pins do these functions:

- Enable the callouts
- Select the callout configuration
- Select low volume or normal volume for the callouts.

Low volume is one-quarter of the normal audio volume.

Mode 6 callouts come on only once. These are the two ways to reset mode 6 callouts:

- The airplane climbs through 1,000 feet of radio altitude while on approach.
- The airplane goes from takeoff to approach and the radio altitude is higher than an altitude callout. In this case, only those altitude callouts that are lower than the current radio altitude come on as the airplane descends.



34-46-00-019 Rev 15 02/12/1998

GPWS - MODE 6 DESCRIPTION

GPWS - MODE 7 DESCRIPTION

General

The GPWC gives mode 7 warnings when windshear conditions are present in takeoff or approach. The thresholds depend on flap position.

Description

Windshear is the effect of large volumes of air that change direction quickly. The most dangerous type of windshear for airplanes is the microburst. When the airplane is near the terrain, a downward microburst gives a pilot little time to respond to the effects.

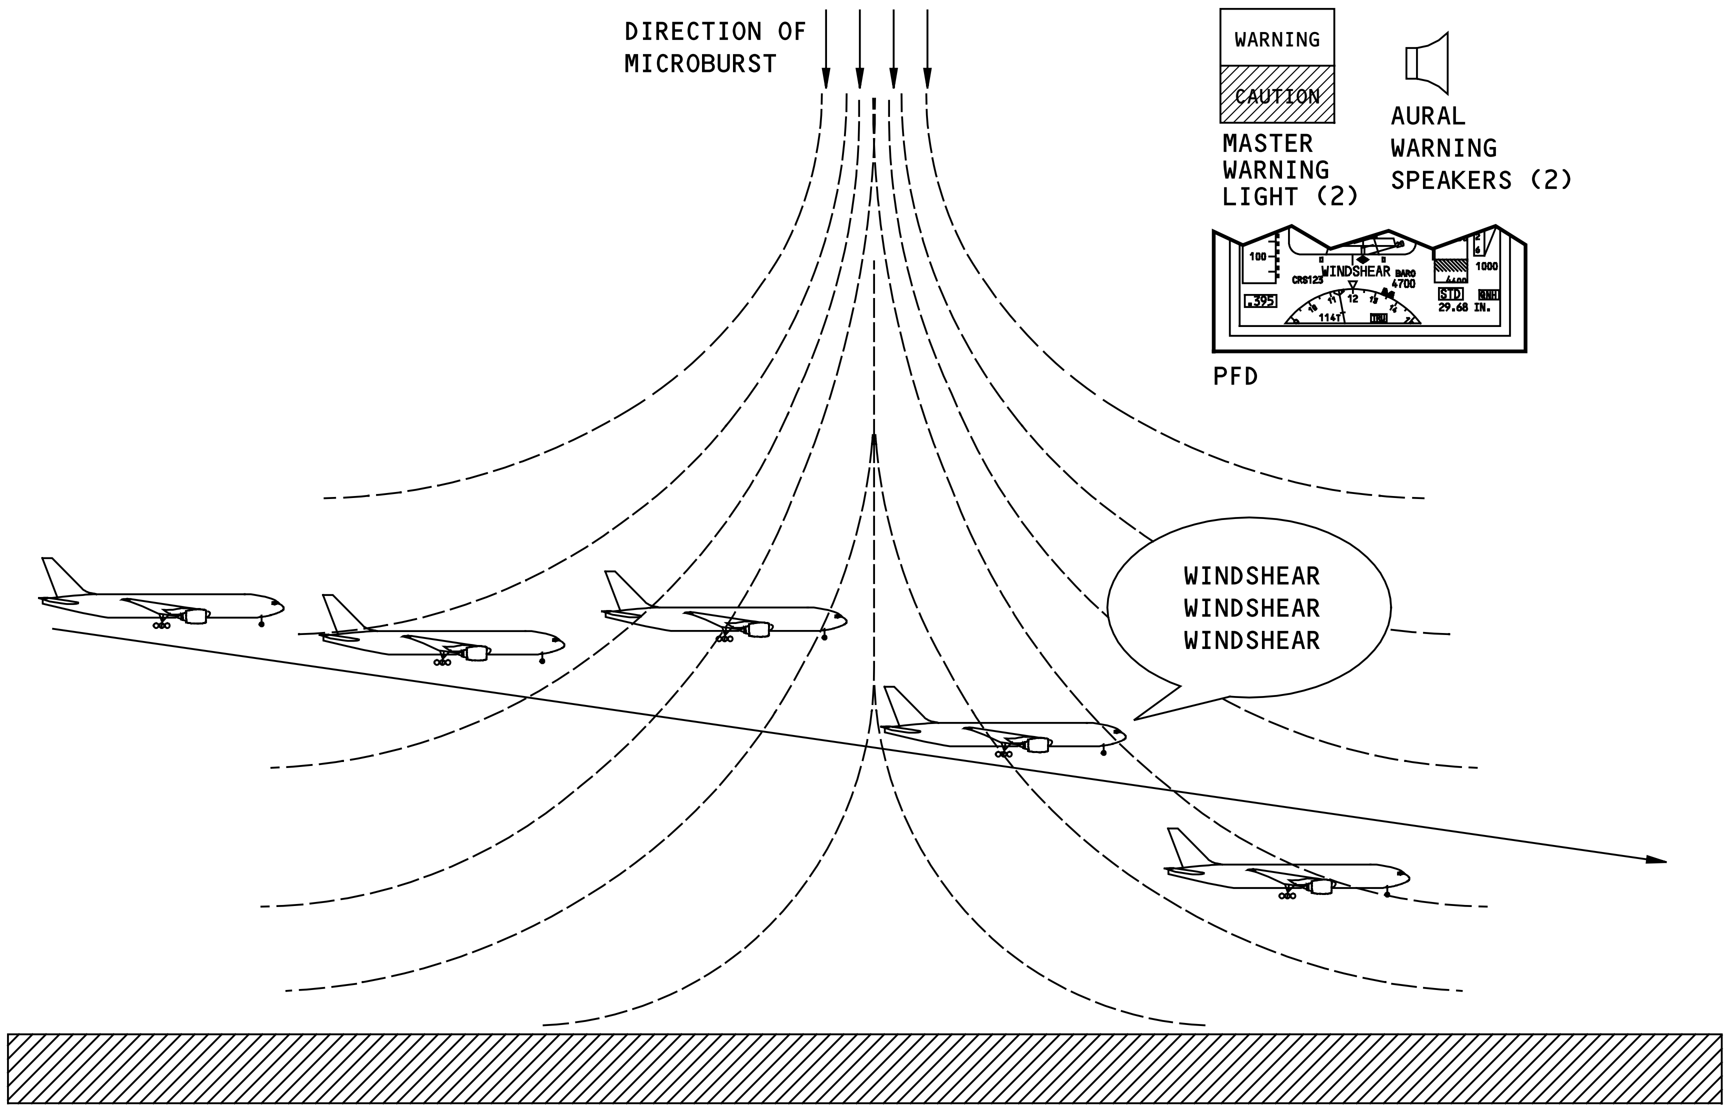
The initial effects on an airplane when it is in a microburst are an increase in airspeed and lift. Because of the increase in lift, the airplane altitude increases.

As the airplane continues through the microburst, the effects quickly change to a loss in airspeed and lift. Because of the decrease in lift, the airplane altitude decreases.

The GPWC uses inputs from airplane systems to detect the changes caused by windshear conditions.

Mode 7 warnings are:

- Master warning lights come on.
- Siren then the aural message WINDSHEAR WINDSHEAR WINDSHEAR from the aural warning speakers
- Red WINDSHEAR message on the PFDs.



GPWS - MODE 7 DESCRIPTION

GPWS - MODE 7 OPERATION

General

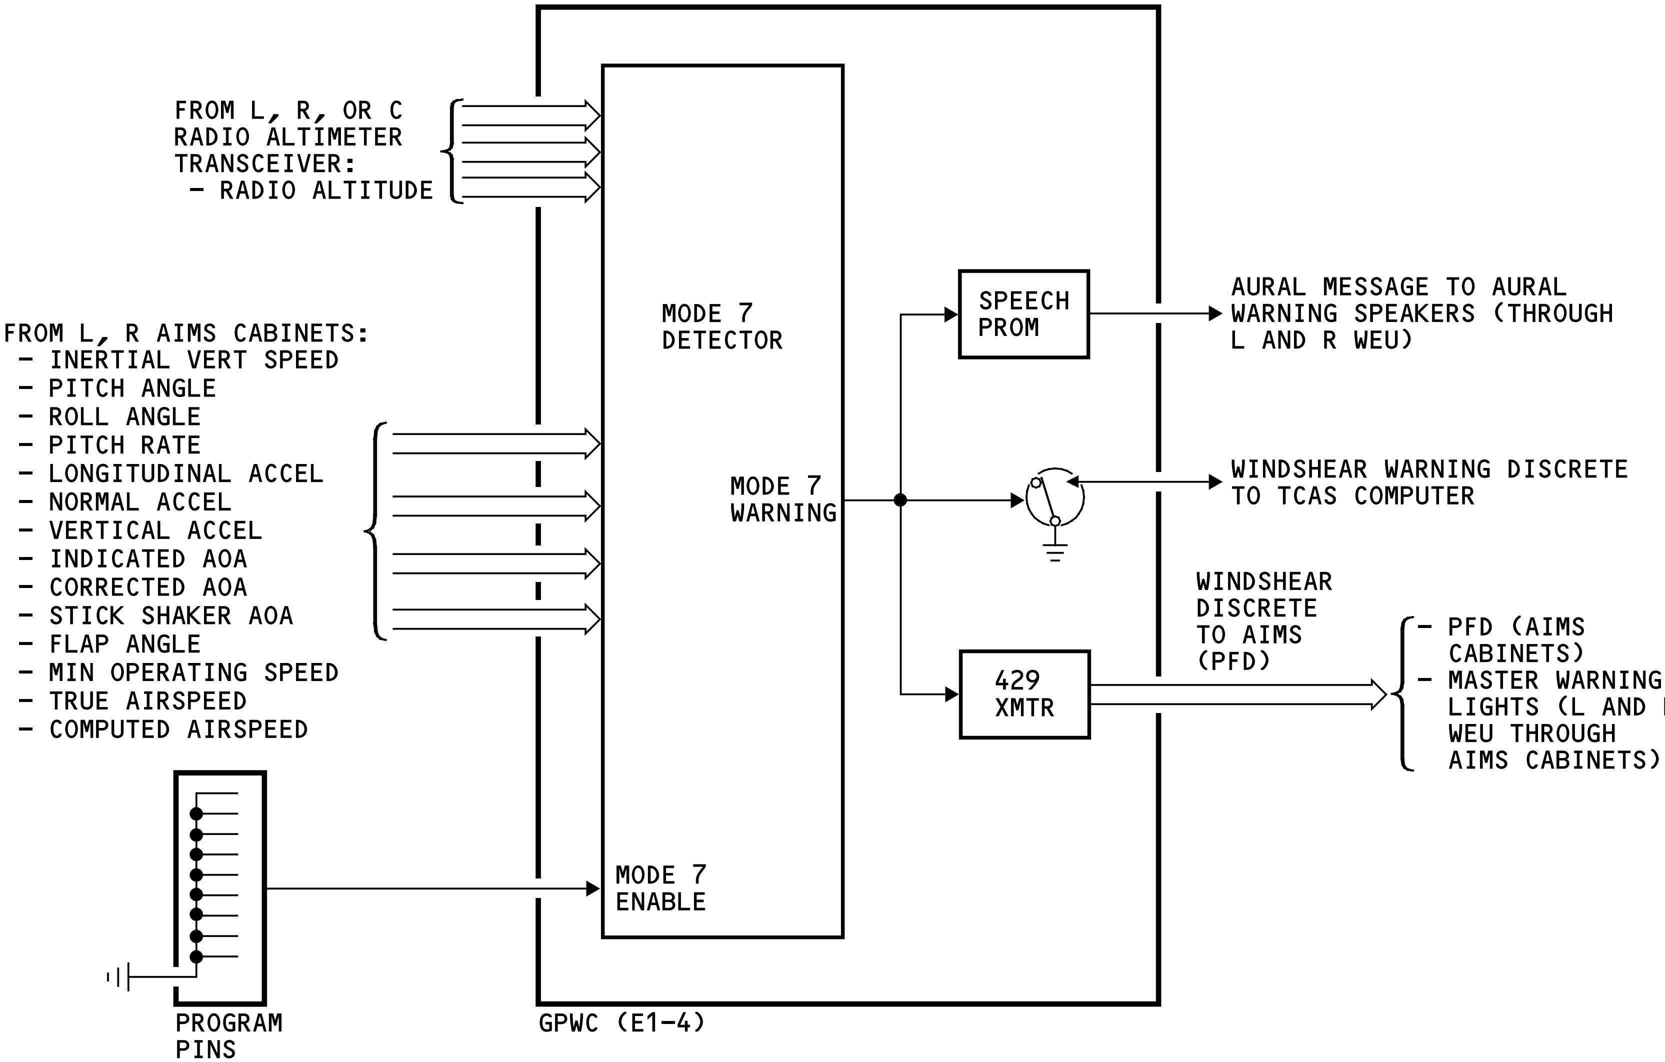
Program pins enable mode 7.

These LRUs supply data for mode 7 operation:

- Left, right, and center radio altimeter transceivers
- AIMS cabinets
- Program pins.

The GPWC uses this data to detect windshear:

- Radio altitude
- Inertial vertical speed
- Pitch and roll angle
- Pitch rate
- Longitudinal acceleration
- Normal acceleration
- Vertical acceleration
- Indicated angle of attack (AOA)
- Corrected AOA
- Stick shaker AOA
- Flap angle
- Minimum operating speed
- True airspeed
- Computed airspeed.



GPWS - MODE 7 OPERATION

THIS PAGE INTENTIONALLY LEFT BLANK

GPWS - TERRAIN AWARENESS

Purpose

The ground proximity warning computer (GPWC) compares the airplane flight profile, flap and gear position, and terrain clearance to determine if an alert or warning condition exists.

Terrain Awareness Inputs

The GPWC receives airplane data from the air data inertial reference system (ADIRS) and the global positioning system (GPS). The terrain awareness function uses this data:

- Latitude
- Longitude
- Barometric altitude
- Ground track
- Ground speed
- Heading
- Roll attitude
- Flight path angle (calculated by GPWC).

Terrain awareness uses GPS for latitude and longitude. It uses flight management computing function (FMCF) data if the GPS data is invalid or not available.

Terrain Awareness Calculation

The GPWC stores a world-wide terrain database in memory. The GPWC looks at airplane position and track, and compares this data to the terrain database. If the GPWC finds there is a terrain threat, it makes an alert.

Terrain Display Output

The GPWC makes a digital map of the terrain forward of the airplane. It sends this digital map to AIMS for display on the navigational displays (NDs). The display uses different colored dots to show terrain altitude relative to airplane altitude.

Terrain Alert Outputs

If the GPWC finds the airplane is about 60 seconds from a terrain conflict, it makes a terrain caution alert. These are the caution alert indications:

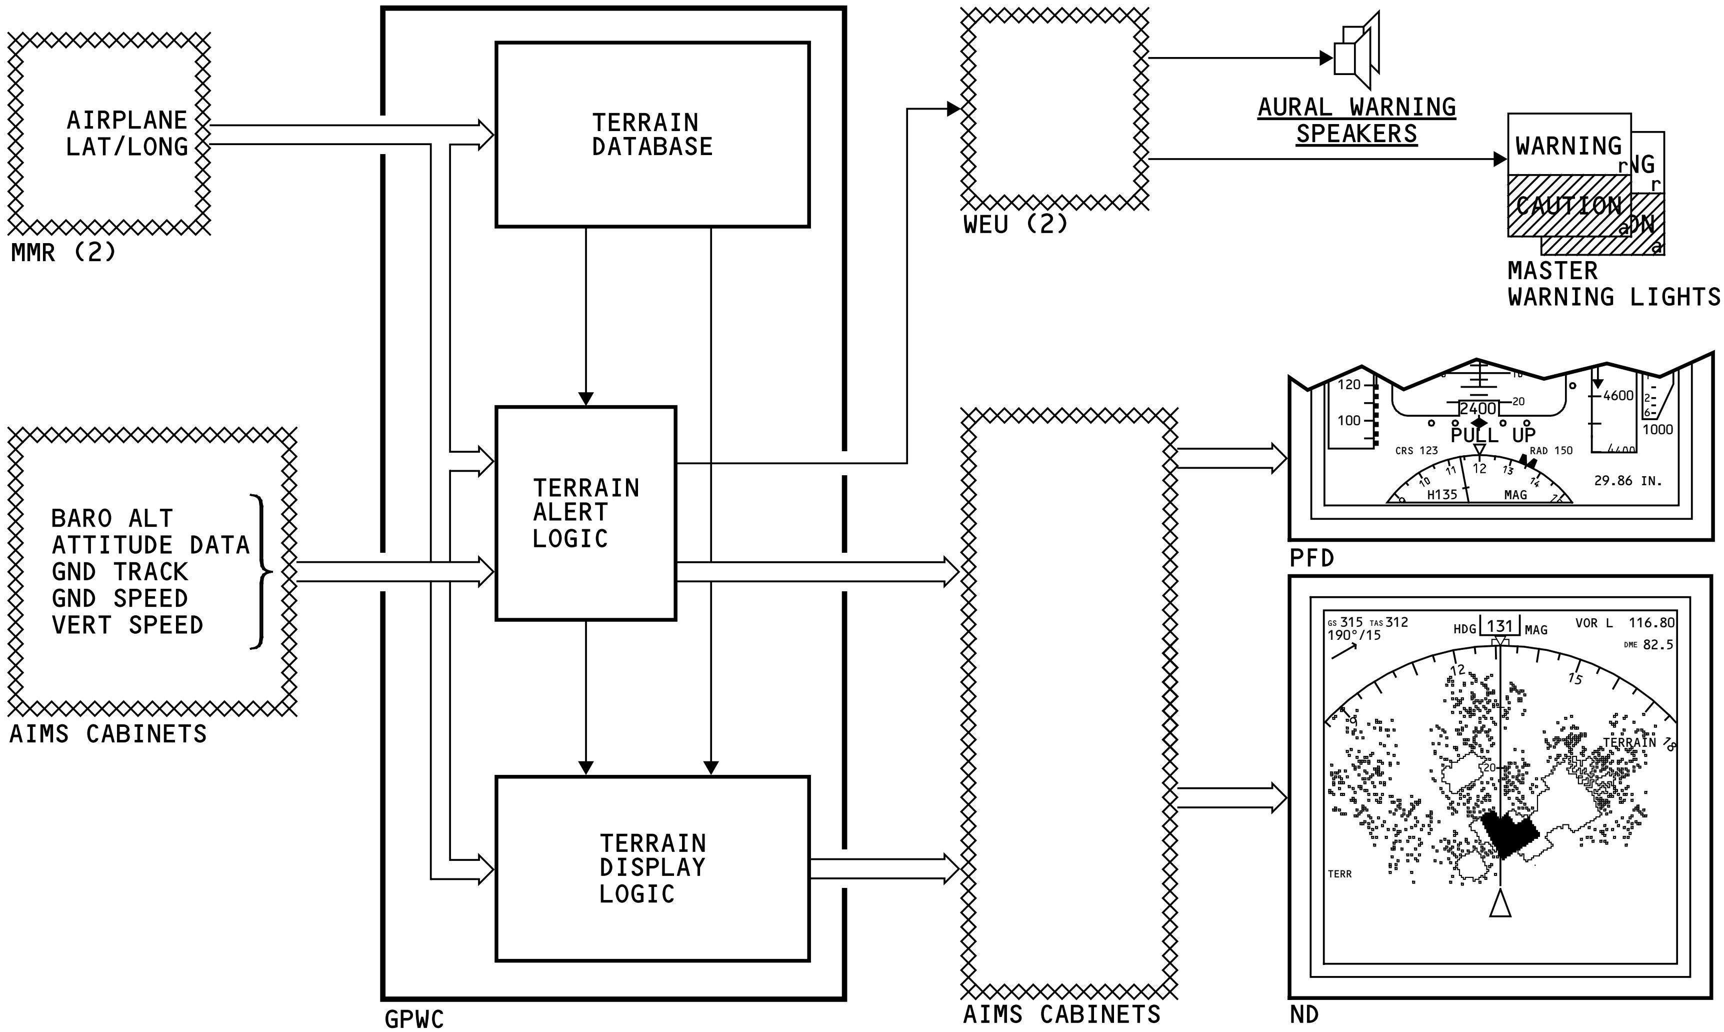
- Alert aural message CAUTION TERRAIN
- Amber message TERRAIN shows on the ND
- The terrain display shows on both NDs if not selected on either one
- The threat terrain on the ND changes from dots to a solid yellow color
- The ground proximity warning light comes on.

If the GPWC finds the airplane is about 30 seconds from a terrain conflict, it makes a terrain warning alert. These are the warning alert indications:

- Aural message TERRAIN, TERRAIN PULL UP
- A red PULL UP message shows on the primary flight display (PFD)
- A red TERRAIN message shows on the ND

GPWS - TERRAIN AWARENESS

- The terrain display shows on both NDs if not selected on either one
- The terrain threat on the ND changes from dots to a solid red color
- The master warning lights come on.



GPWS - TERRAIN AWARENESS

GPWS - TERRAIN CLEARANCE FLOOR

Description

Terrain clearance floor (TCF) alerts the flight crew when the airplane descends too low on approach. TCF uses airplane position and a runway database to determine if an alert condition exists.

Terrain Clearance Floor Inputs

The ground proximity warning system (GPWS) receives airplane data from these systems:

- Global positioning system (GPS)
- Air data inertial reference system (ADIRS)
- Radio altitude (RA) system.

TCF uses this data:

- Latitude
- Longitude
- Radio altitude.

TCF uses GPS for latitude and longitude. It uses flight management computing function (FMCF) data if GPS data is not valid.

Terrain Clearance Floor Logic

The GPWC stores a runway database in memory. This database contains the location of all hard surface runways in the world that are 3,500 feet or more in length. TCF makes a terrain clearance envelope around the runway. The altitude of the envelope increases as the distance from the airport increases. GPWC compares airplane latitude, longitude, and radio altitude with TCF envelope data. If the airplane descends through the floor of the envelope, GPWC makes an alert.

TCF makes an alert even if the airplane is in landing configuration.

Terrain Clearance Floor Caution Alert

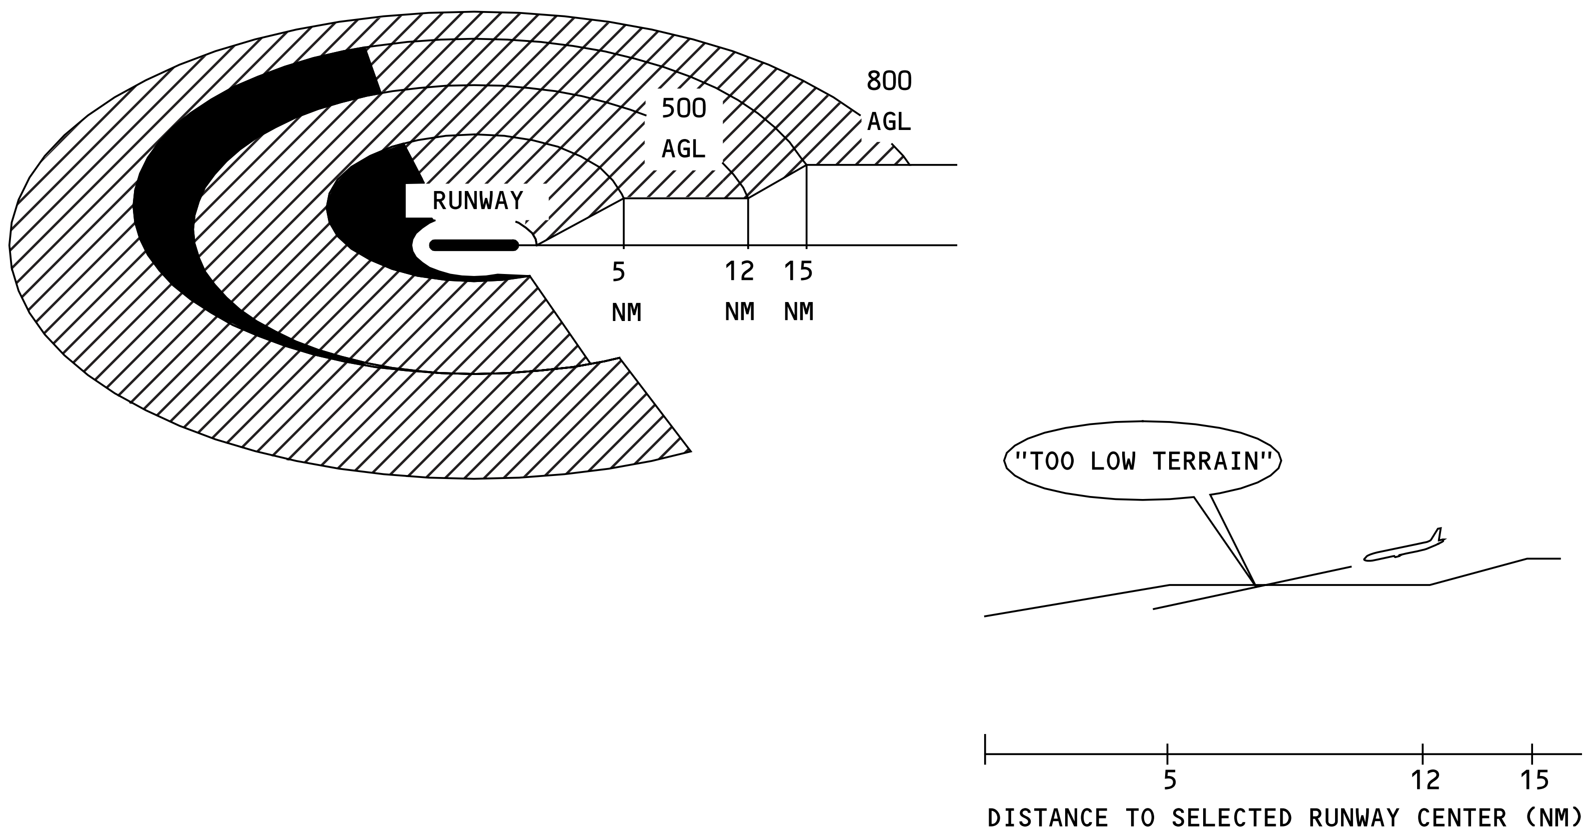
If the GPWC determines the airplane is below the TCF, it makes this caution alert:

- Aural message TOO LOW TERRAIN. This message repeats for each 20 percent loss of altitude.
- The ground proximity warning light comes on and stays on until the airplane climbs above the TCF.

There is no TCF warning alert.

The GPWC inhibits TCF alerts for any of these conditions:

- Airplane is on the ground
- Less than 20 seconds after takeoff
- Less than 30 feet radio altitude.



34-46-00-036 Rev 0 02/03/1998

GPWS - TERRAIN CLEARANCE FLOOR

GPWS - NORMAL DISPLAYS

Terrain Awareness Display Data

The navigational displays (NDs) show this GPWS data:

- Terrain awareness display
- GPWS system messages
- GPWS alert messages.

Terrain Awareness Display

The terrain awareness display on the NDs uses dots to show terrain ahead of the airplane. Dot color and dot pattern density compare terrain altitude with airplane altitude. These are the dot colors and patterns the terrain display uses:

- High density red - Terrain more than 2,000 feet above airplane altitude.
- High density yellow - Terrain 1,000 feet to 2,000 feet above airplane altitude.
- Medium density yellow - Terrain 500 feet below to 1,000 feet above airplane altitude. Gear down changes the 500 feet to 250 feet.
- Medium density green - Terrain 500 feet below to 1,000 feet below airplane altitude. Gear down changes the 500 feet to 250 feet.
- Low density green - Terrain 1,000 feet below to 2,000 feet below airplane altitude.
- Black - Terrain more than 2,000 feet below airplane altitude.
- Magenta - Unknown terrain.

If GPWS detects a terrain caution alert, the threat terrain changes from dots to a solid yellow color. If GPWS detects a terrain warning alert, the threat terrain changes from dots to a solid red color.

On final approach, terrain near the runway does not display.

GPWS System Messages

These GPWS system messages show in cyan on the left side of the ND:

- TERR shows when terrain data displays
- TERR TEST show when the GPWS is in self test mode.

GPWS Alert Messages

These GPWS alert messages show on the right side of the ND:

- WINDSHEAR (red) shows when a mode 7 windshear warning occurs.
- TERRAIN (red) shows when a terrain awareness warning occurs.
- TERRAIN (amber) shows when a terrain awareness caution occurs.

GPWS - MODE DESCRIPTION SUMMARY

GPWS - ENVELOPE MODULATION

General

Some airports have unusual terrain clearances near their runways that cause false messages by the GPWS. Envelope modulation modifies specific alert and warning areas to prevent false messages.

Functional Description

The airports that need envelope modulation are in the GPWC memory and identified by their latitude and longitude. As the airplane approaches one of these airports, the GPWC looks at other airplane parameters to verify if an envelope modulation condition exists. The additional parameters are:

- Radio altitude
- Magnetic track
- Glide slope deviation
- Localizer deviation
- Selected runway heading
- Barometric corrected altitude.

MODE	TYPE OF MODULATION	PURPOSE OF MODULATION
1	RAISES THE DESCENT RATE LIMIT	TO PERMIT GREATER BAROMETRIC DESCENT RATES WITHOUT FALSE ALERTS/WARNINGS
2	LOWERS RADIO ALTITUDE LIMITS	TO PERMIT THE AIRPLANE TO FLY CLOSER TO THE TERRAIN WITHOUT FALSE ALERTS/WARNINGS
4	LOWERS RADIO ALTITUDE LIMITS	TO LOWER THE MINIMUM TERRAIN CLEARANCE DURING HIGH AIRSPEEDS TO PREVENT FALSE ALERTS
5	- RAISES RADIO ALTITUDE LIMITS - REMOVES GEAR DOWN REQUIREMENTS	TO PERMIT MODE 5 ANNUNCIATIONS AT HIGHER ALTITUDES WITHOUT THE GEAR DOWN
6	REMOVES GEAR DOWN REQUIREMENTS	TO PERMIT MODE 6 ANNUNCIATIONS WITHOUT THE GEAR DOWN

34-46-00-023 Rev 1

GPWS - ENVELOPE MODULATION

GPWS - PFD AND MASTER WARNING LIGHT ANNUNCIATIONS

Master Warning Lights

The captain and first officer red master warning lights come on with a PULL UP or WINDSHEAR warning. The AIMS cabinets send a discrete to the warning electronic system (WES) to enable the lights.

PFD Warning Annunciations

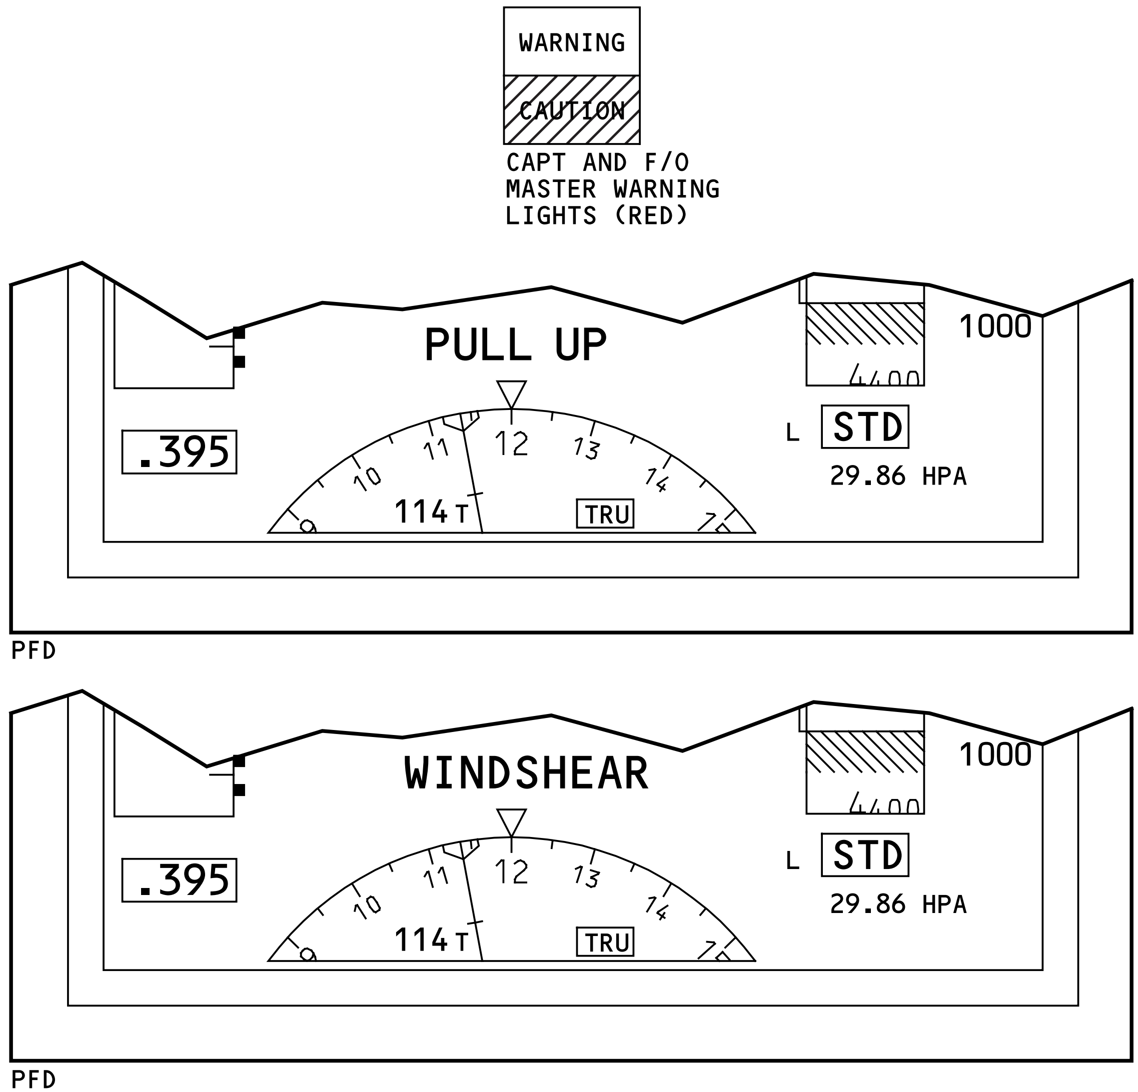
The primary flight displays (PFDs) show these two GPWS messages:

- Red PULL UP
- Red WINDSHEAR.

The red PULL UP message shows for these conditions:

- Mode 1 warnings
- Mode 2 warnings
- Terrain awareness warnings.

The red WINDSHEAR message shows a mode 7 warning.



34-46-00-025 Rev 2 01/19/1998

GPWS - PFD AND MASTER WARNING LIGHT ANNUNCIATIONS

GPWS - NON-NORMAL DISPLAYS

GPWS Non-Normal Messages

These messages show on the navigational display (ND) to alert the flight crew of GPWS non-normal conditions:

- System alert messages
- Range disagree messages.

GPWS System Alert Messages

These messages show in amber on the left side of the ND:

- TERR POS shows when the GPWS determines airplane position data is not valid
- TERR OVRD shows when you push the terrain override switch on the landing gear panel
- TERR FAIL shows when a fault occurs in the GPWS.

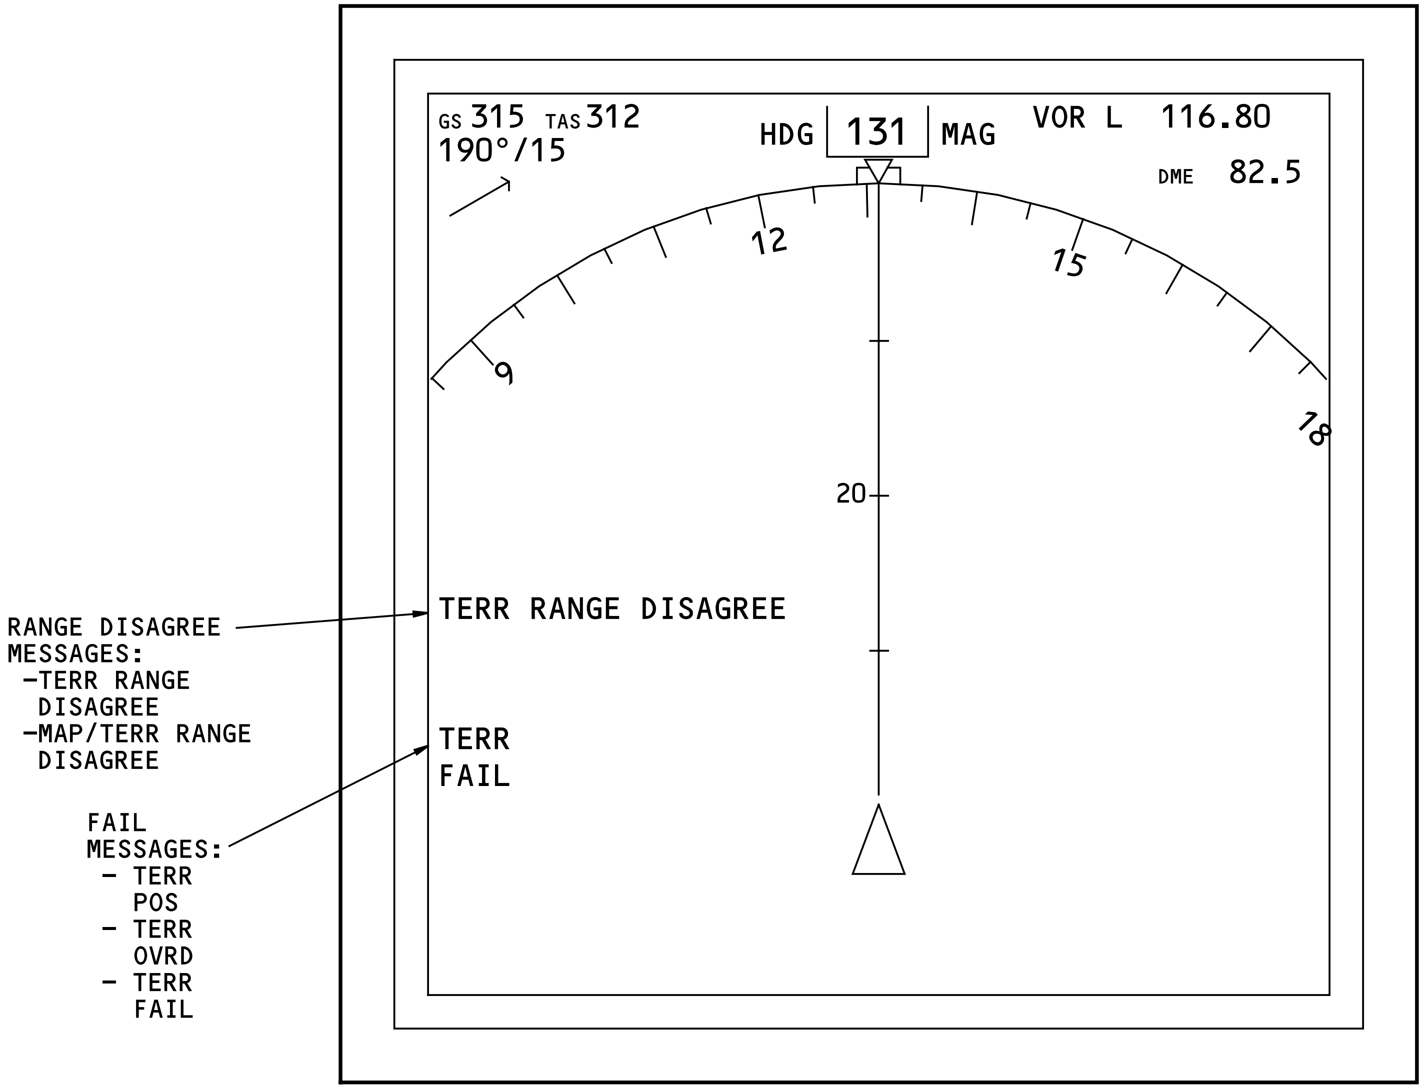
Terrain data does not show on either ND if there is a system alert message.

Range Disagree Messages

These alert messages show in amber on the ND when there is a range disagree fault:

- TERR RANGE DISAGREE shows when the GPWS range disagrees with the range selected on the on-side EFIS control panel
- MAP/TERR RANGE DISAGREE shows when the GPWS range, the on-side EFIS range, and the FMC range disagree.

Terrain data does not show on the ND if there is a range disagree message.



GPWS SYSTEM ALERT MESSAGES AND DISPLAY

GPWS - NON-NORMAL DISPLAYS

GPWS - SELF TEST - LEVEL 1

THIS PAGE INTENTIONALLY LEFT BLANK

GPWS - SELF TEST - LEVEL 1

General

The ground proximity warning system (GPWS) has six levels of self test. Each level provides different information about the GPWS. These are the six levels of self test:

- GO/NO-GO operational test
- Current faults
- System configuration
- Fault history
- Alert/warning history
- Discrete input test.

Level one is a GO/NO-GO operational test. A level one test provides visual and aural annunciations on the flight deck.

Level One Test Preparation

These conditions must be true to do a level one self test of the GPWS:

- Airplane on ground
- GPWS power on
- EFIS ND mode selector in correct mode (expanded VOR, APP, or MAP or centered MAP)
- TERR switch on EFIS control panel (CP) selected.

Level One Test Procedure

Select operational test from the maintenance access terminal (MAT) to begin a level one test. A level one test first does a test of these configuration conditions:

- Program pin parity
- Airplane configuration database validity
- Airplane type.

If the test finds a configuration fault, the self test annunciates the fault and the self test ends. If the GPWS passes the configuration test, the level one test continues.

Training Information Point

You can start a level one self test from the front panel of the GPWC, but you cannot see the flight deck annunciations. Use the MAT to start an operational test of the GPWS.

Level One Test - Normal Indications

These messages will show at some time for a normal Level one self test:

- EICAS Advisory - GROUND PROX SYS
- EICAS Advisory - WINDSHEAR SYS
- EICAS Advisory - ALTITUDE CALLOUTS
- EICAS Advisory - TERR POS
- EICAS Status - GROUND PROX SYS
- EICAS Status - WINDSHEAR REAC
- EICAS Status - TERR SYS
- Amber ND alert message - TERR TEST
- Amber ND alert message - TERR FAIL.

GPWS - SELF TEST - LEVEL 1

These visual and aural annunciations are for a normal level one test:

- ND system message TERR TEST shows in cyan
- Ground proximity warning light on and aural message GLIDESLOPE
- Master warning lights on, PFD message PULL UP (red), and aural message PULL UP
- Master warning lights on, PFD message WINDSHEAR (red), and aural message WINDSHEAR, WINDSHEAR, WINDSHEAR
- Terrain test pattern shows on ND for 12 seconds
- Master warning lights on, PFD message PULL UP (red), TERRAIN alert message (red) on NDs, and aural message TERRAIN, TERRAIN, PULL UP.
- Ground proximity light on and TERRAIN alert message (amber) on NDs
- Aural message SINKRATE
- Aural message PULL UP
- Aural message TERRAIN, TERRAIN
- Aural message PULL UP
- Aural message DONT SINK
- Aural message DONT SINK
- Aural message TOO LOW TERRAIN
- Aural message TOO LOW GEAR
- Aural message TOO LOW FLAPS
- Aural message TOO LOW TERRAIN
- Aural message GLIDESLOPE
- Mode 6 altitude callouts
- Aural message WINDSHEAR, WINDSHEAR, WINDSHEAR
- Aural message TOO LOW TERRAIN
- Aural message CAUTION TERRAIN, CAUTION TERRAIN
- Aural message TERRAIN, TERRAIN, PULL UP.

<u>Level One Self Test - Non-Normal Indications</u>

The GPWS level one test fails for any of these conditions:

- The terrain test pattern does not show
- The TERR FAIL message on the ND stays on
- You do not see and hear all annunciations.

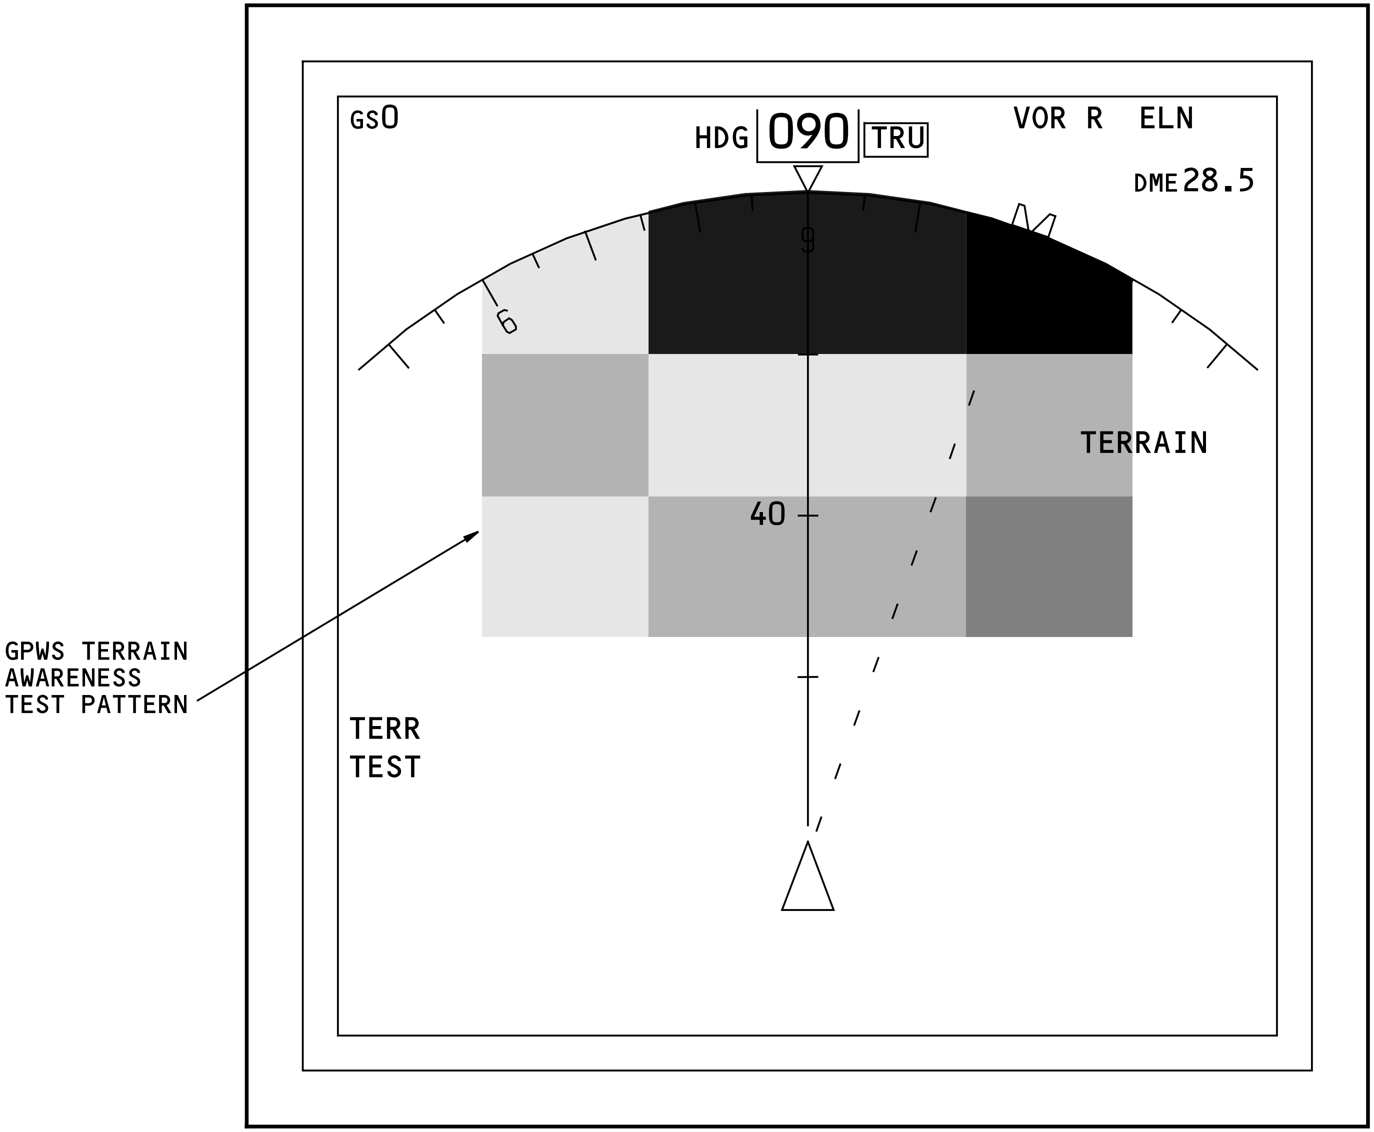
<u>Training Information Point</u>

Some GPWS modes have the same annunciations. If you do not see and hear all annunciations, the test fails.

<u>GPWS Mode Failures</u>

These aural messages annunciate for GPWS modes that do not function:

- GLIDESLOPE INOP
- GPWS INOP
- BANK ANGLE INOP
- CALLOUTS INOP
- WINDSHEAR INOP
- TERRAIN INOP.



GPWS - SELF TEST - LEVEL 1

GPWS - SELF TEST - LEVELS 2-5

THIS PAGE INTENTIONALLY LEFT BLANK

GPWS - SELF TEST - LEVELS 2-5

General Description

The ground proximity warning computer (GPWC) has six levels of self test:

- 1 - GO/NO-GO operational test
- 2 - Current faults
- 3 - System configuration
- 4 - Fault history
- 5 - Alert/warning history
- 6 - Discrete input test.

Self test levels 2-6 access self test information not available through the maintenance access terminal (MAT). Use a 600 ohm headphone to listen to the test information. Plug the headphone into the jack on the front panel of the GPWC.

Use the self test button on the front panel of the GPWC to access levels 2-6. The self test button has these two modes:

- Short cancel - push the button for less than two seconds
- Long cancel - push the button for more than two seconds.

Use the self test button for these functions:

- Start self test level one
- Go to the next item or flight leg within a test
- Go to the next self test level
- End the self test.

When a test level ends, the aural message PRESS TO CONTINUE annunciates. Push the self test button to go to the next test level. If you do not push the self test button within three seconds, self test ends.

Level Two Self Test - Current Faults

A level two test begins with the aural message CURRENT FAULTS. If there are no current faults, you hear the aural message NO FAULTS. If faults exist, the GPWC annunciates the faults one at a time. A short or long cancel ends the level two test.

Level Three Self Test - System Configuration

A level three test annunciates the GPWS configuration. A level three test begins with the aural message SYSTEM CONFIGURATION. A short cancel causes the test to go immediately to the next configuration item. A long cancel ends the level three test. A level three test provides this information:

- GPWC part number
- GPWC modification status
- GPWC serial number
- Application software version
- Configuration software version
- Terrain database version
- Envelope modulation database version
- Boot code version
- Aircraft type
- Audio menu
- Altitude callout menu number

GPWS - SELF TEST - LEVELS 2-5

- Selected options.

Level Four Self Test - Fault History

Level four self test annunciates the GPWS fault history over the last ten flights.

A level four test begins with the aural message FAULT HISTORY. If there are no faults in the flight history memory, you hear the aural message NO FAULTS. If there are faults in the flight history memory, you hear the most recent faults annunciate first. You hear the faults in this order:

- FLIGHT X (X is the most recent flight leg number)
- Internal faults for flight X
- External faults for flight X
- Go to next oldest flight leg and repeat.

A short cancel causes the test to go immediately to the next flight leg. A long cancel ends self test level four.

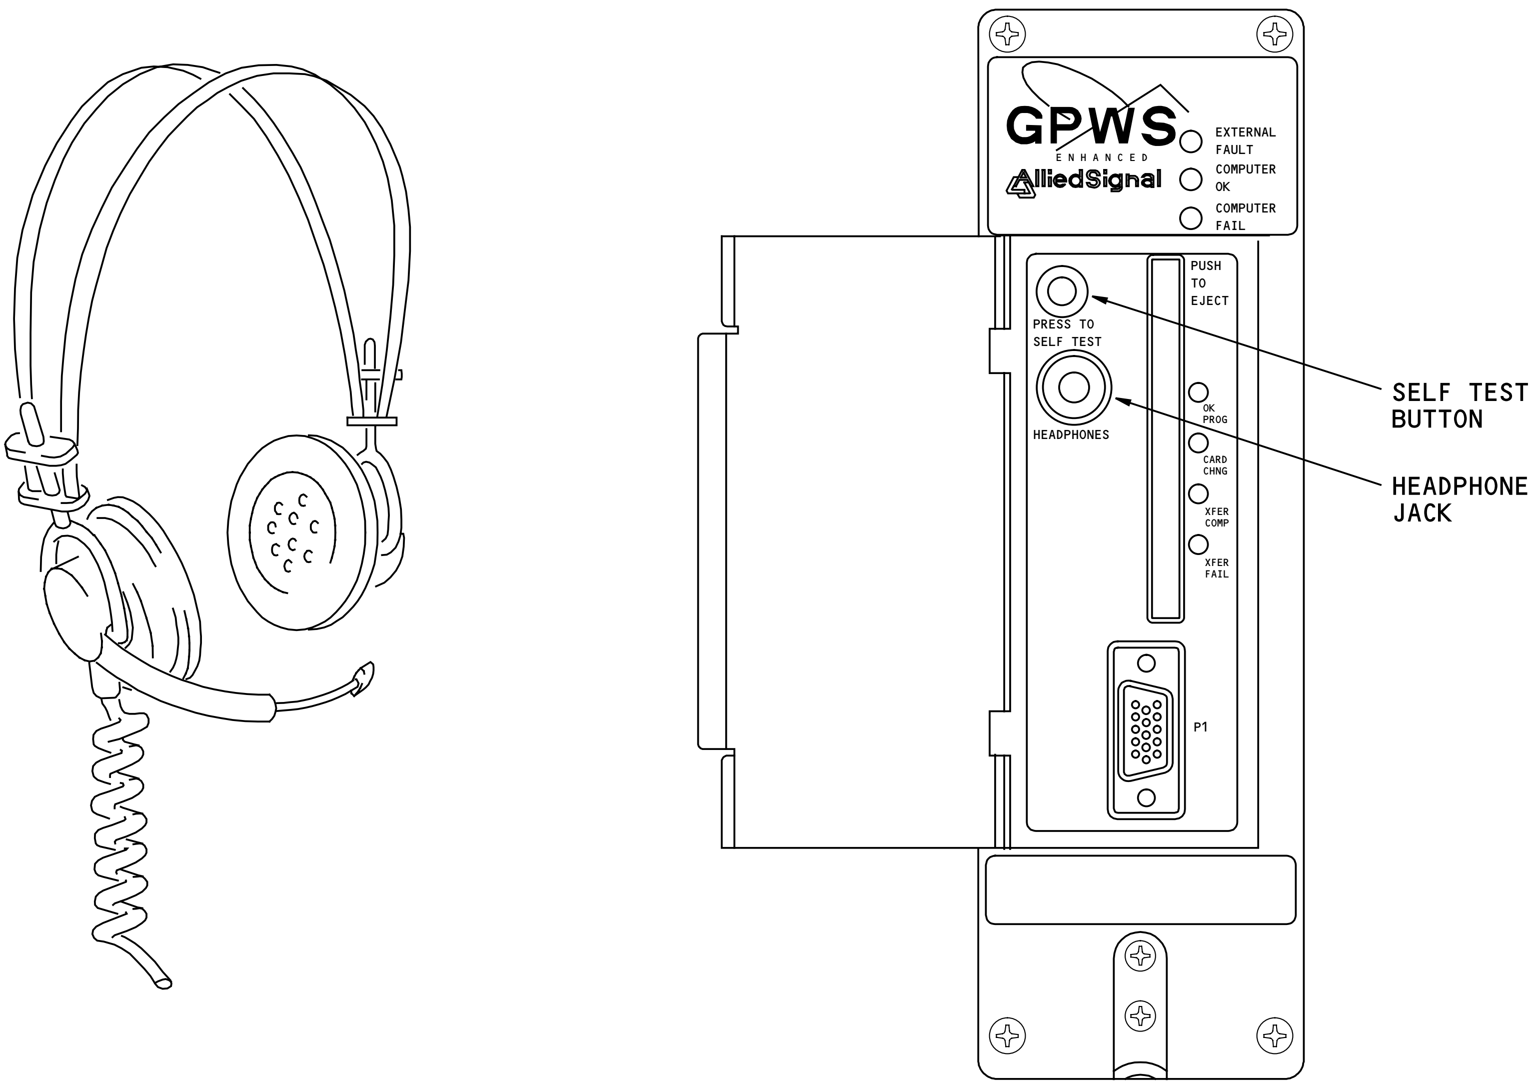
Level Five Self Test - Warning History

Level five self test annunciates GPWS alerts over the last ten flights.

A level five test begins with the aural message WARNING HISTORY. If there are no alerts in the flight history memory, you hear the aural message NO WARNINGS. If there are alerts in the flight history memory, you hear the most recent alerts first. You hear the alerts in this order:

- FLIGHT X (X is the most recent flight leg number)
- GPWS alerts for flight X
- Go to next oldest flight leg and repeat.

A short cancel cause the test to go immediately to the next flight leg. A long cancel ends self test level four.



GPWS - SELF TEST - LEVELS 2-5

GPWS - SELF TEST - LEVEL 6

General Description

The ground proximity warning computer (GPWC) has a level six discrete input test.

This test accesses test information not available from the maintenance access terminal (MAT). Use a 600 ohm headphone to listen to the test information. Plug the headphone into the jack on the front panel of the GPWC.

Use the self test button on the front panel of the GPWC to access level six. The self test button has these two modes:

- Short cancel - push the button for less than two seconds
- Long cancel - push the button for more than two seconds.

Use the self test button for these functions:

- Start self test level one
- Go to the next item or flight leg within a test
- Go to the next self test level
- End the self test.

When a test level ends, the aural message PRESS TO CONTINUE annunciates. Push the self test button to go to the next test level. If you do not push the self test button within three seconds, self test ends.

Level Six Self Test - Discrete Input Test

A level six test checks changes in discrete inputs.

The test starts with the aural message DISCRETE TEST. If the state of a discrete input changes, you hear the new state of the discrete.

You hear the aural message DISCRETE INPUT TEST - PRESS TO CANCEL every 60 seconds. Push a short or long cancel to end the self test.

DISCRETE INPUT	INPUT SOURCE	ANNUNCIATIONS
- GEAR OVERRIDE SWITCH	P2-2 PANEL	LANDING GEAR DOWN LANDING GEAR UP
- FLAP OVERRIDE SWITCH	P2-2 PANEL	LANDING FLAPS NOT LANDING FLAPS
- GLIDESLOPE OVERRIDE SWITCH	P2-2 PANEL	GLIDESLOPE CANCELLED GLIDESLOPE ENABLED
- TERRAIN OVERRIDE SWITCH	P2-2 PANEL	TERRAIN OFF TERRAIN ON
- TERRAIN RELAY 1	LEFT EFIS TERR SWITCH	TERRAIN RELAY 1 ON TERRAIN RELAY 1 OFF
- TERRAIN RELAY 2	RIGHT EFIS TERR SWITCH	TERRAIN RELAY 2 ON TERRAIN RELAY 2 OFF

LEVEL 6 DISCRETE INPUT TEST

34-46-00-043 Rev 0 02/06/1998

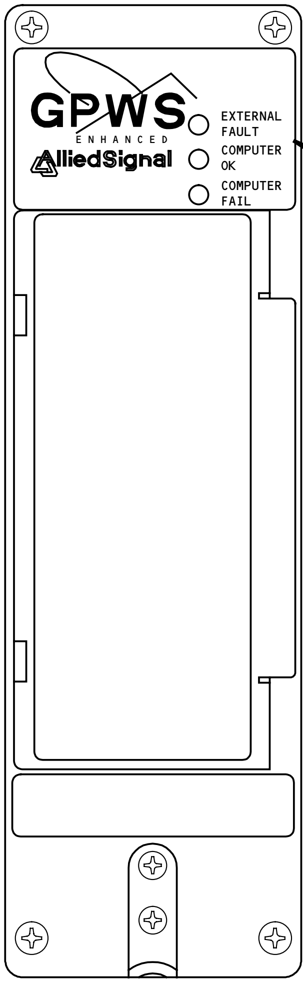
GPWS - SELF TEST - LEVEL 6

GPWS - STATUS LEDS

Purpose

There are three status LEDs on the front panel of the ground proximity warning computer (GPWC). These LEDs turn on when there is power to the GPWC. These LEDs are:

- External fault - yellow
- Computer OK - green
- Computer fail - red.



EXTERNAL FAULT	COMPUTER OK	COMPUTER FAIL	CONDITION
OFF	OFF	OFF	GPWC POWER OFF
OFF	OFF	RED	GPWC INTERNAL FAULT
OFF	GREEN	OFF	NORMAL OPERATION
OFF	GREEN	RED	GPWC INTERNAL FAULT
YELLOW	OFF	OFF	GPWS EXTERNAL FAULT
YELLOW	OFF	RED	BOTH GPWC INTERNAL AND GPWS EXTERNAL FAULTS
YELLOW	GREEN	OFF	GPWS EXTERNAL FAULT
YELLOW	GREEN	RED	GPWC INTERNAL FAULT

34-46-00-044 Rev 0 02/06/1998

GPWS - STATUS LEDS

GPWS - GROUND TESTS

General

You do an operational test of the GPWS from the MAT.

Operational Test

The operational test makes sure the ground proximity warning system operates correctly.

You get these indications when you do an operational test:

- All the GPWS aurals
- The master warning lights come on
- PULL UP and WINDSHEAR messages show on the PFDs
- The ground proximity light comes on.

Training Information Point

If you do not hear all the GPWS aurals and see the master warning lights come on, PFD messages show, and the ground proximity light come on, the operational test failed.

During the test, these aurals do not come on:

- ENGINE FAIL
- V1.

During the test, EICAS shows WINDSHEAR WARNING SYS and GND PROX SYS messages.

Continental Airlines, Inc

Weather Radar System

WB371

TABLE OF CONTENTS

THIS PAGE INTENTIONALLY LEFT BLANK

WEATHER RADAR SYSTEM - INTRODUCTION

Purpose

The weather radar (WXR) system supplies:

- Visual indications of weather conditions
- Visual indications of land contours.

Description

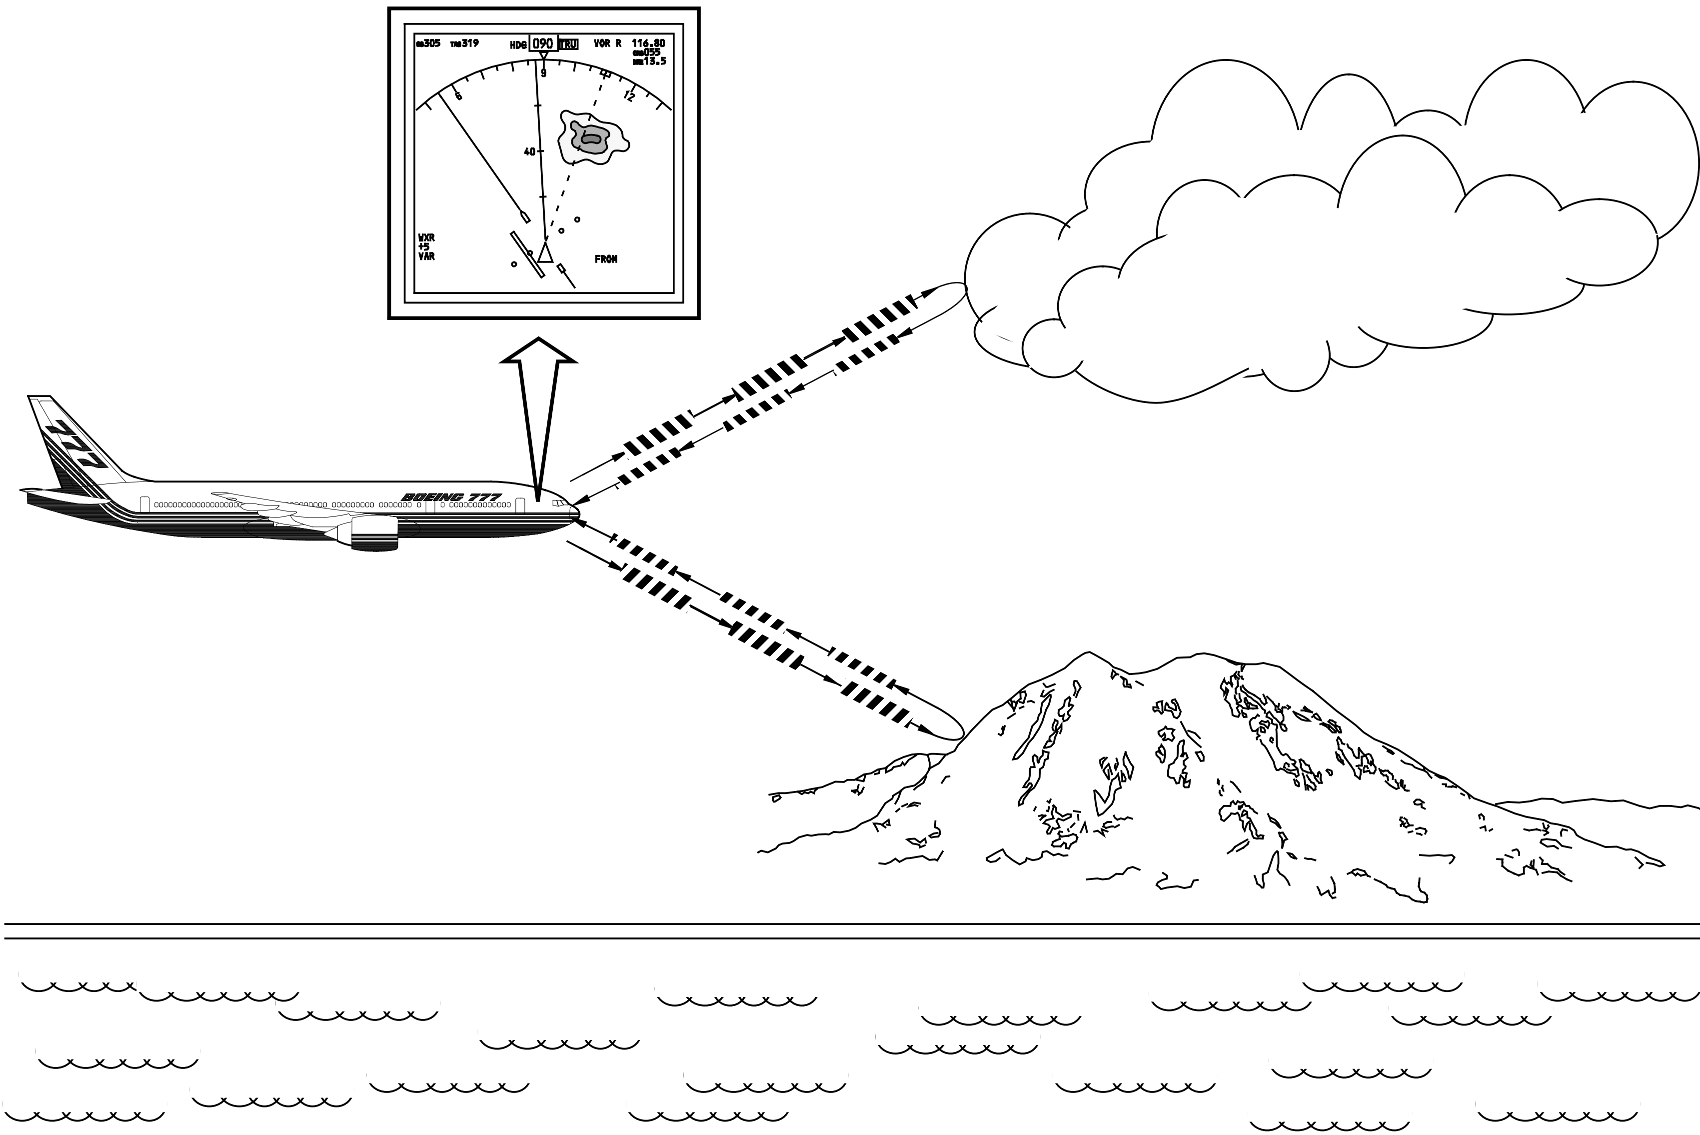
The WXR system transmits radio frequency (RF) pulses in a 180 degree sector forward of the airplane path. Precipitation or terrain contours reflect the pulses back to the airplane.

Display

The WXR returns show in four different colors on the navigation displays (ND). The colors of the indications depend on the intensity of the returns.

Abbreviations and Acronyms

AIMS	- airplane information management system
CMCF	- central maintenance computing function
CDU	- control display unit
CP	- control panel
GPWC	- ground proximity warning computer
MWL	- master warning light
ND	- navigation display
OPAS	- overhead panel ARINC 629 system
PFD	- primary flight display
PRF	- pulse repetition frequency
PWS	- predictive windshear
RA	- radio altimeter
RF	- radio frequency
RT	- receiver-transmitter
TCAS	- traffic and collision avoidance system
WES	- warning electronics system
WEU	- warning electronics unit
WX	- weather
WXR	- weather radar



34-43-00-001 Rev 1

WEATHER RADAR SYSTEM - INTRODUCTION

WXR SYSTEM - GENERAL DESCRIPTION

Control

These components supply weather radar (WXR) system control:

- Left, center, and right control display units (CDUs)
- Left and right EFIS CPs
- WXR panel.

Display

WXR data shows on the navigation displays (NDs). The weather data from the WXR RT goes through the AIMS cabinets then to the NDs.

Antenna

The WXR antenna radiates the RF pulses and receives the RF returns. The RT gets air data inertial reference system (ADIRS) pitch and roll data from the airplane information management system (AIMS) cabinets for antenna stabilization.

Receiver-Transmitter (RT)

The central component of the WXR system is the weather radar receiver-transmitter (RT). The system uses dual RTs with only one RT in operation at a time. The WXR RT does these functions:

- Produces RF pulses
- Transmits RF pulses
- Processes the RF returns
- Supplies the WXR display data.

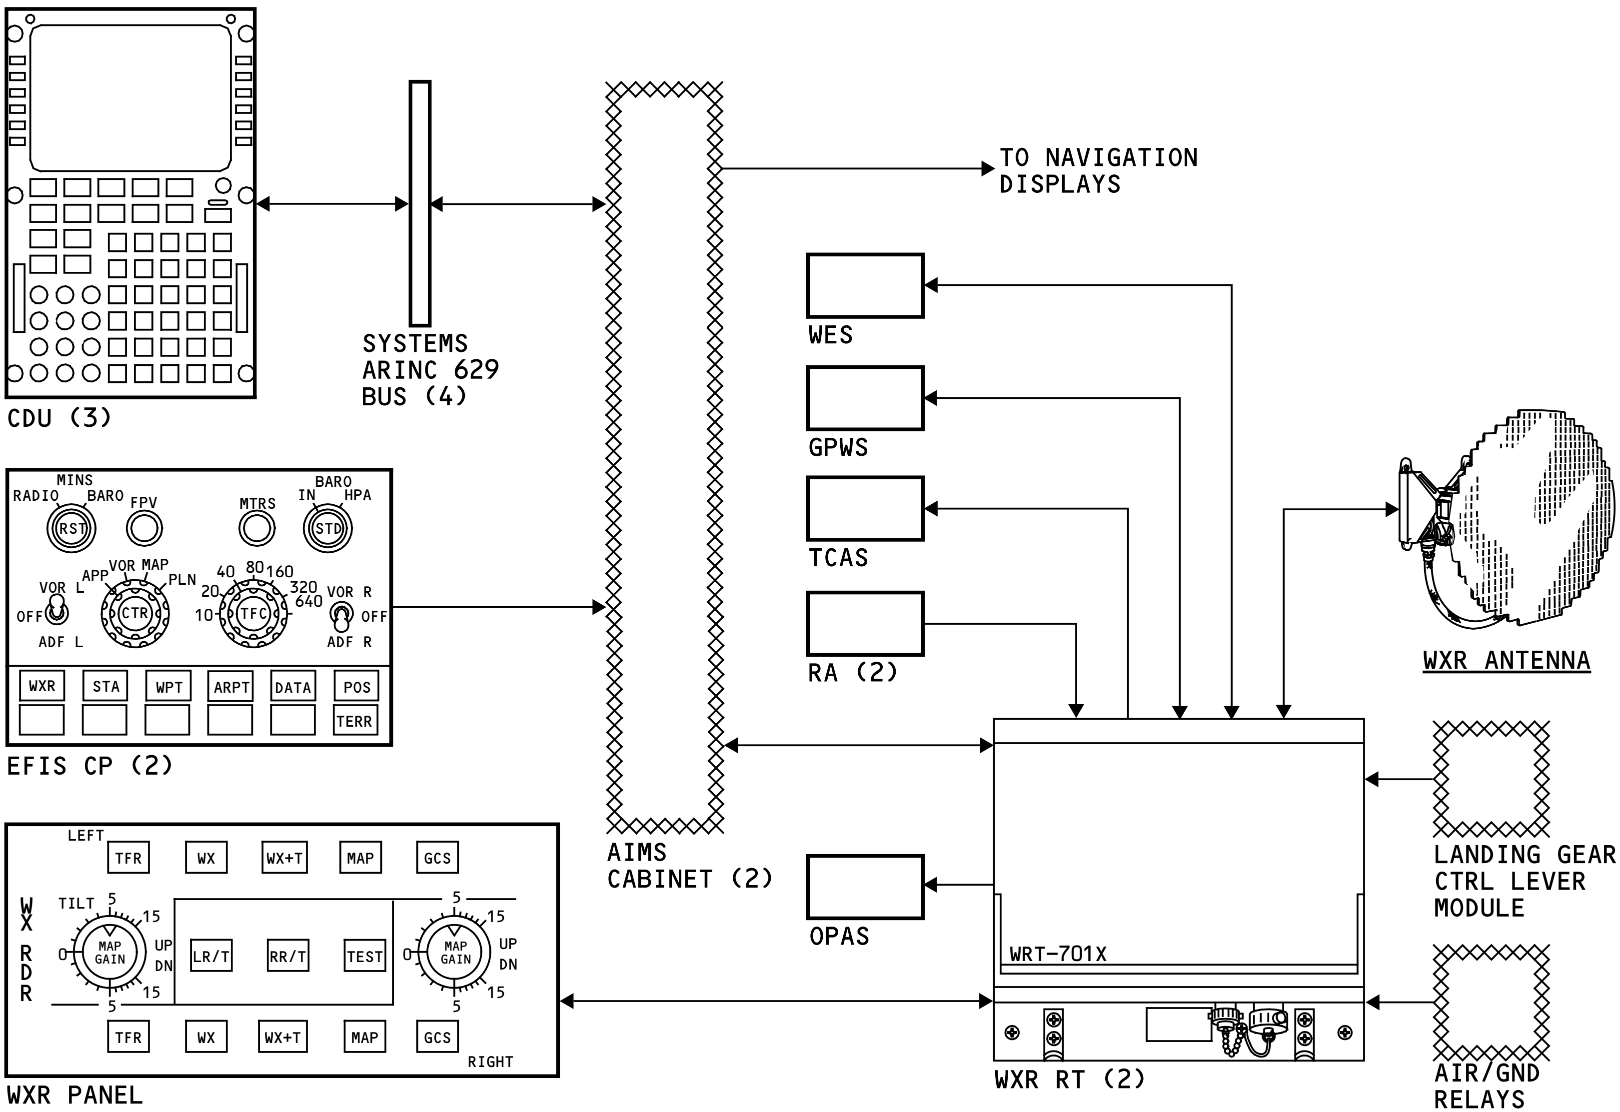
Interfaces

The WXR system interfaces with these systems:

- Warning electronic system (WES)
- Ground proximity warning system (GPWS)
- Traffic alert and collision avoidance system (TCAS)
- Radio altimeter system (RA)
- Overhead panel ARINC 629 system (OPAS).

The WXR system interfaces with these system components:

- Air/ground relay
- Landing gear control lever module.



WXR SYSTEM - GENERAL DESCRIPTION

WXR SYSTEM - COMPONENT LOCATIONS - FLIGHT DECK

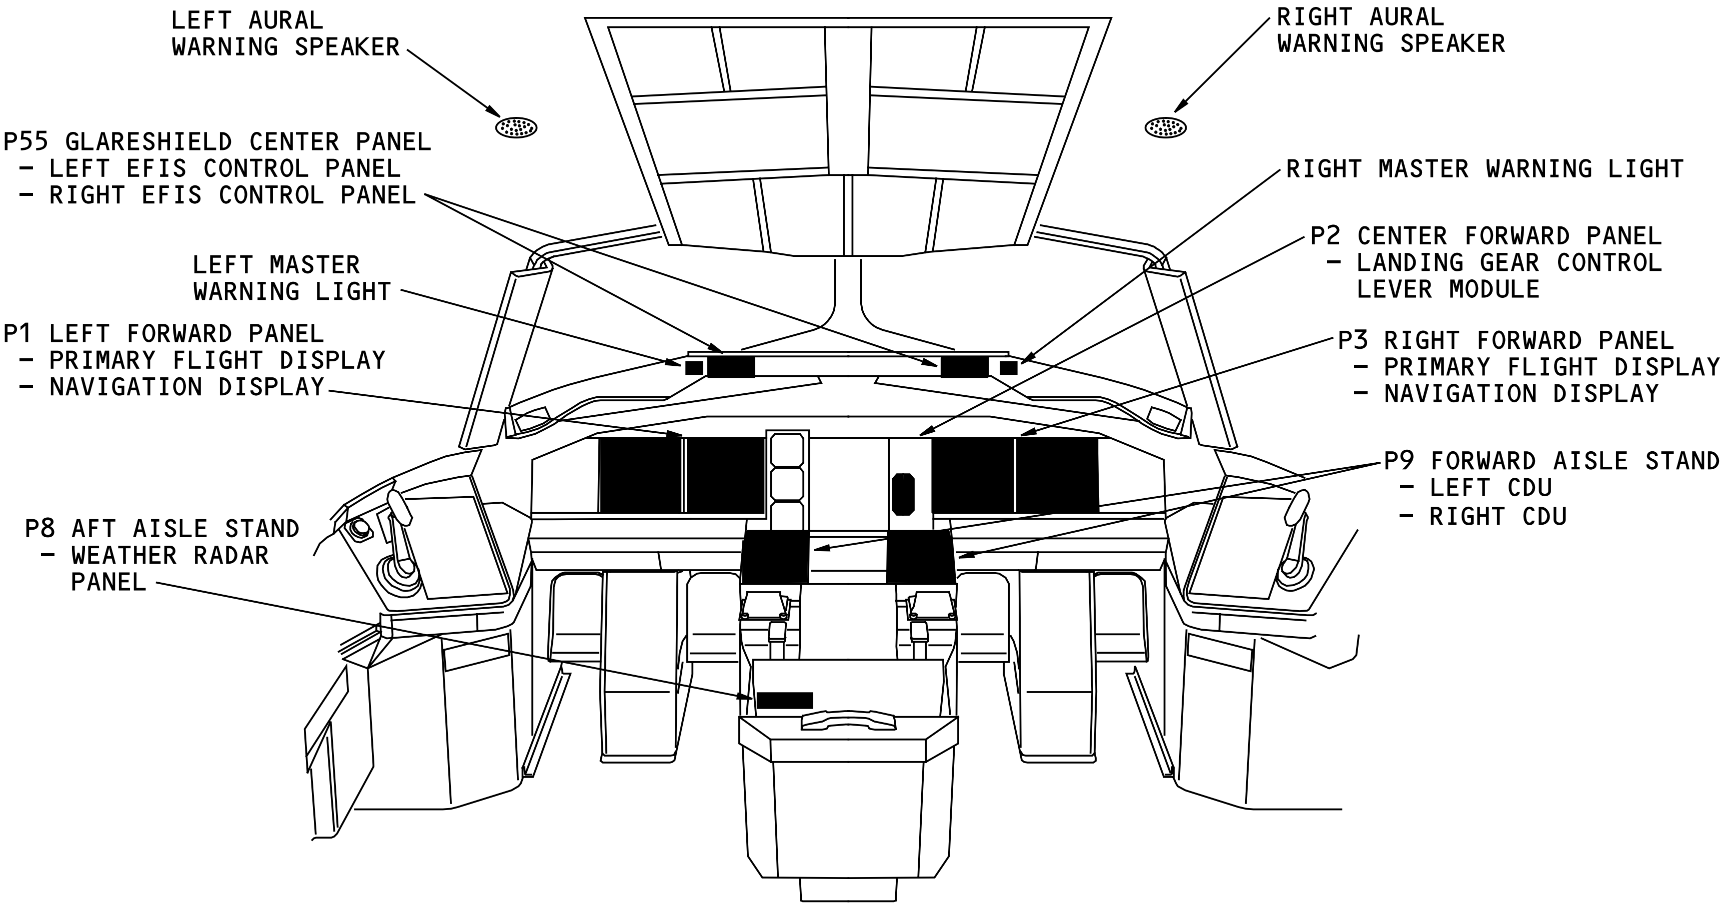
WXR System Components

The WXR system component on the flight deck is the weather radar panel.

WXR System Interface Components

The components that interface with the WXR system are:

- Left EFIS control panel
- Right EFIS control panel
- Left control display unit (CDU)
- Right CDU
- Left navigation display (ND)
- Right ND
- Left primary flight display (PFD)
- Right PFD
- Master warning lights
- Aural warning speakers
- Landing gear control lever module.



34-43-00-003 Rev 2 01/28/1998

WXR SYSTEM - COMPONENT LOCATIONS - FLIGHT DECK

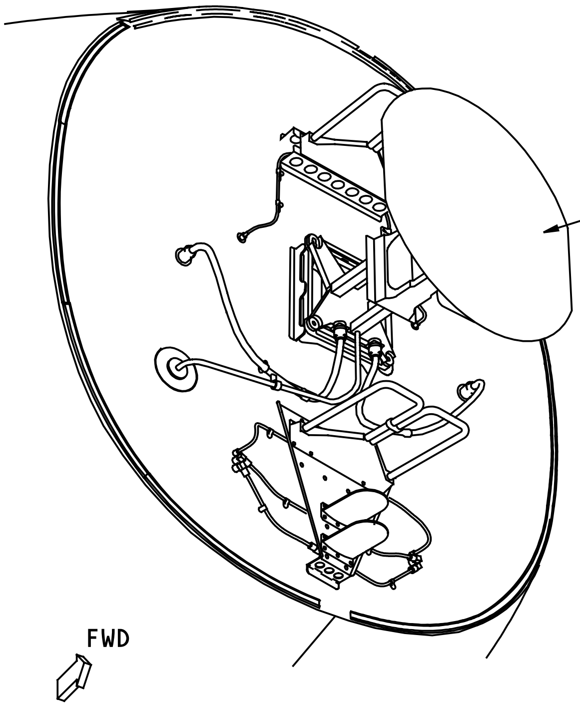
WXR SYSTEM - COMPONENT LOCATIONS - FORWARD EQUIPMENT CENTER AND NOSE RADOME

General

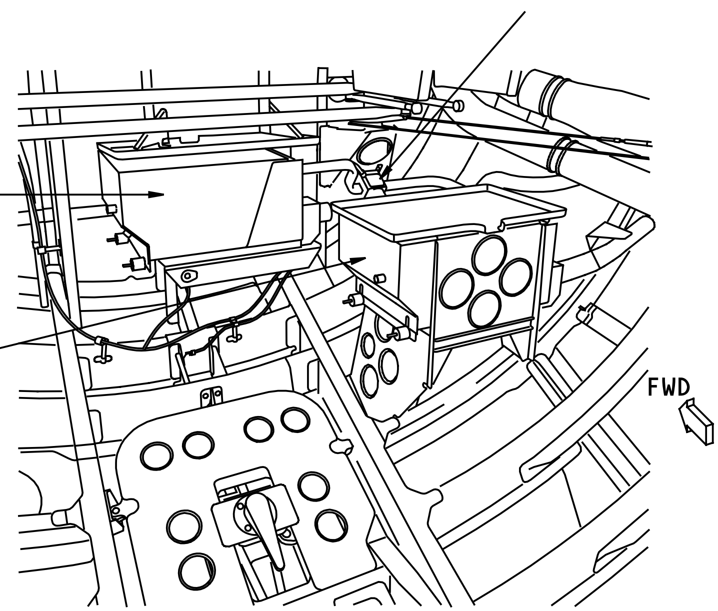
The WXR antenna assembly is in the nose radome.

The WXR system components in the forward equipment center are the:

- Left WXR RT
- Waveguide switch
- Right WXR RT.



NOSE RADOME



FORWARD EQUIPMENT CENTER

34-43-00-004 Rev 2

WXR SYSTEM - COMPONENT LOCATIONS - FORWARD EQUIPMENT CENTER AND NOSE RADOME

WXR SYSTEM - INTERFACE - POWER, INTERLOCKS, ENABLES AND RF TRANSMISSION

System Power

The left WXR RT gets 115v ac through the left WXR circuit breaker from the left ac transfer bus (L AC XFR).

The right WXR RT gets 115v ac through the right WXR circuit breaker from the right ac secondary 2 bus (R AC SEC 2).

The left and right WXR RTs send 28v dc to the onside power supply in the WXR panel.

Interlocks, Enables and RF Transmission

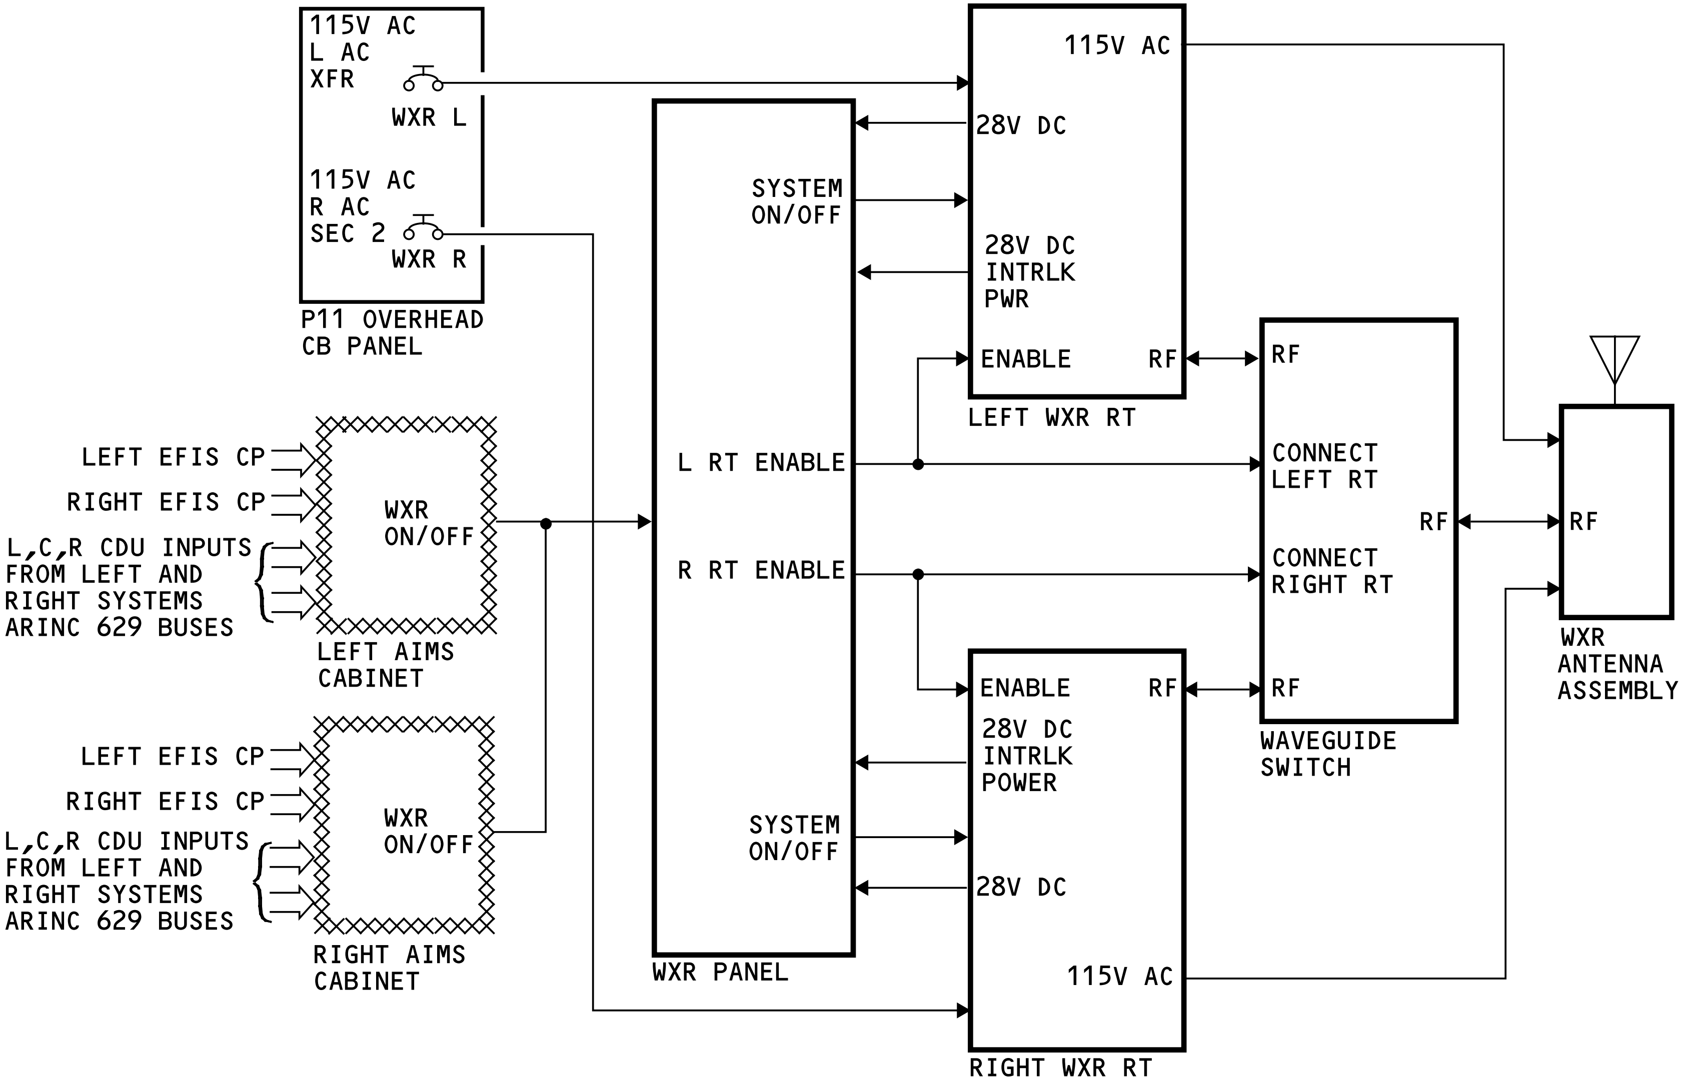
The left and right AIMS cabinets receives WXR on/off discrete inputs from the left and right EFIS CP or left, center, and right CDUs and sends the discrete to the WXR panel.

The WXR panel sends the ON/OFF discrete to the left and right RTs. This discrete permits the selected RT to operate.

The RTs send 28v dc to the WXR control panel for the power interlock (INTRLK) and RT ENABLE. The WXR CP RT ENABLE goes to the WXR RT to enable operation.

The RT ENABLE also causes the waveguide switch to connect the antenna to the selected RT. When the selected RT operates, it sends 28v to the WXR panel power supply to make the WXR panel operate.

The WXR antenna assembly gets 115v ac power from the WXR RTs.



34-43-00-005 Rev 4 01/21/1998

WXR SYSTEM - INTERFACE - POWER, INTERLOCKS, ENABLES AND RF TRANSMISSION

THIS PAGE INTENTIONALLY LEFT BLANK

WXR SYSTEM - CONTROL AND DISPLAY INTERFACE

Control Inputs

The WXR panel supplies this data to the WXR RTs:

- Transmit mode
- Tilt
- Gain control.

Range data and the on/off discretes go from the EFIS control panel or CDU through the AIMS cabinets to the WXR RTs.

WXR Output Data and Display

The selected WXR RT sends WXR display data to the left and right AIMS cabinets.

Display Relays

The weather radar (WXR) receiver-transmitters (RTs) and the ground proximity warning computer (GPWC) send display data that shows on the navigational displays (NDs). Four terrain select relays control which data shows on each ND.

Relay Power

The terrain select relays gets 28v dc from the TERRAIN DISPLAY circuit breaker on the P11 overhead circuit breaker panel.

Relay Interfaces

The WXR RTs connect to the terrain select relays with weather display data buses. The GPWC connects to the terrain select relays with terrain display data buses.

The terrain select relays connect to the AIMS cabinets with data buses. The AIMS cabinets show the data on the NDs.

Relay Control

With weather radar selected, the normal relay position lets weather radar data show on the NDs. When you select TERR on either EFIS control panel (CP), a terrain select ground signal energizes the two on-side terrain select relays. This allows the terrain data to show on the on-side display. Push the TERR switch again and the on-side relays deenergize. The display then shows weather radar data.

Relay Monitor

The GPWC monitors the terrain select relay positions for faults.

Cross Cabinet Bus

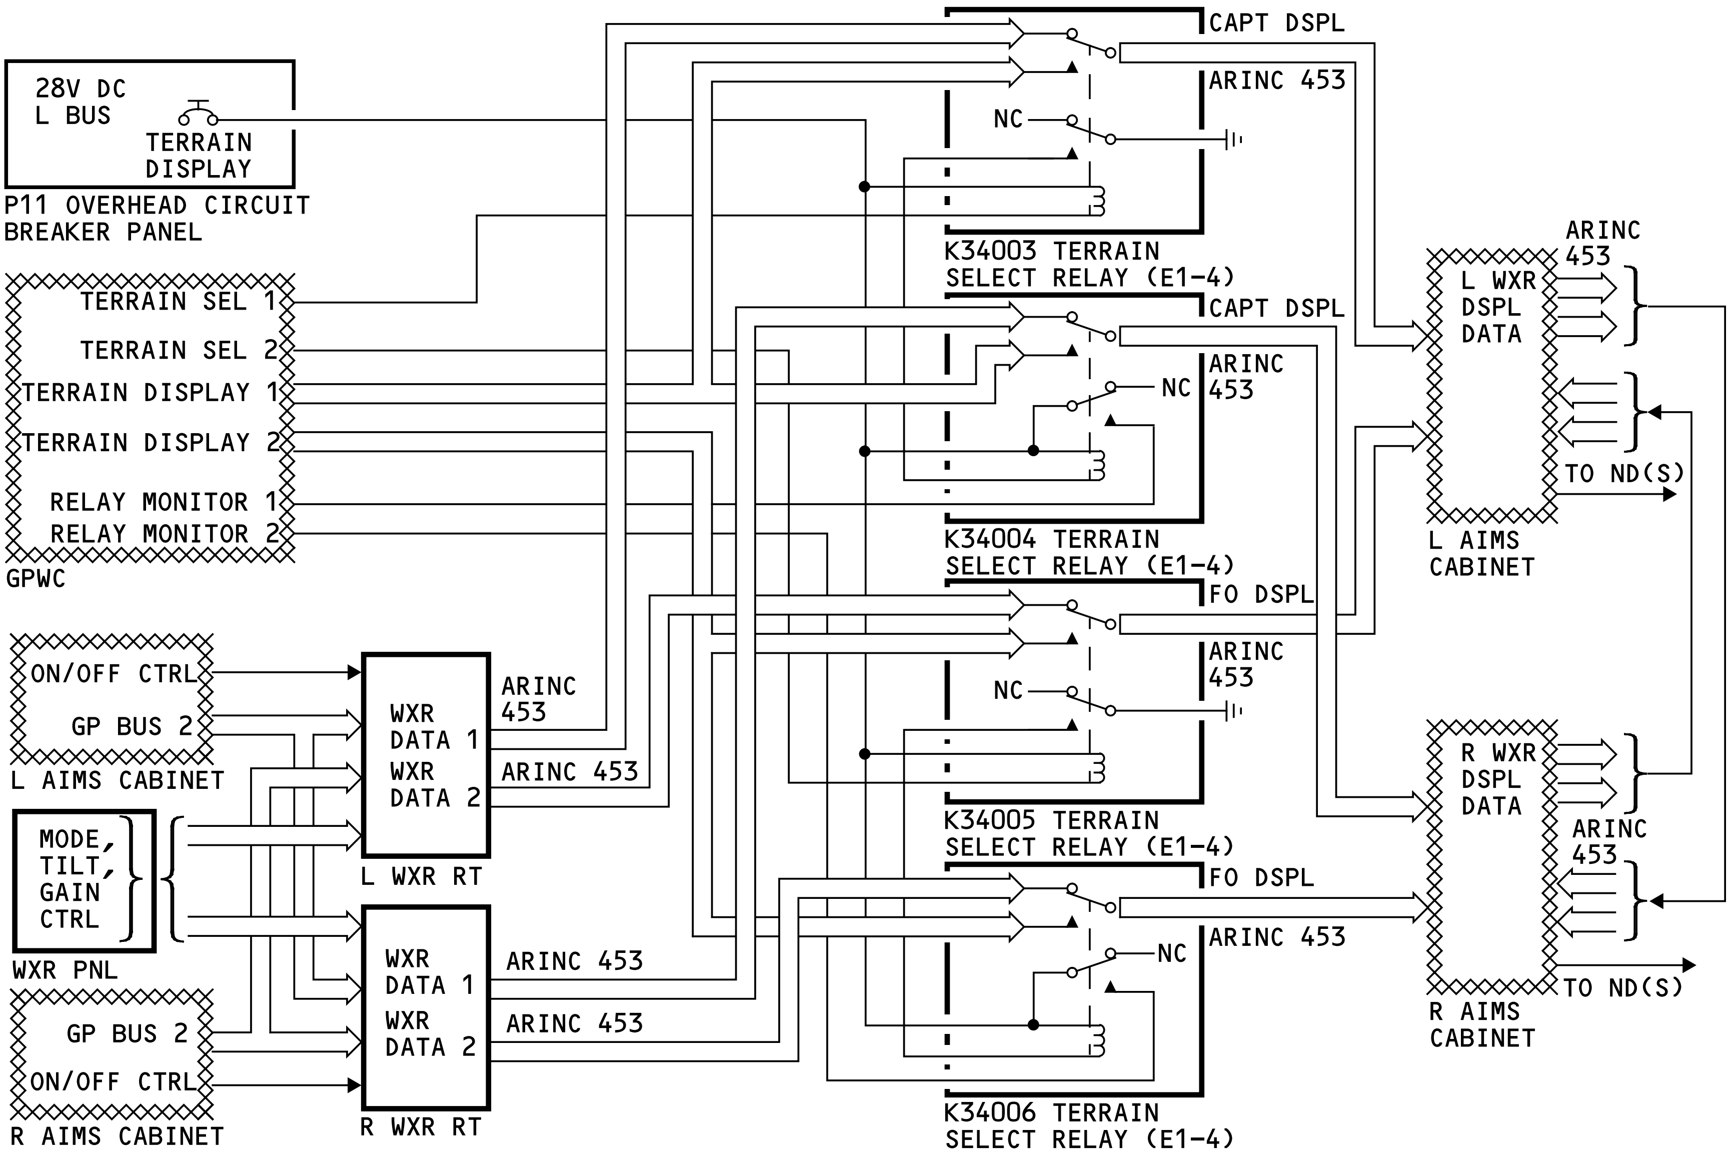
The left AIMS cabinet supplies WXR display data to the right AIMS cabinet and the NDs.

The right AIMS cabinet supplies WXR display data to the left AIMS cabinet and the NDs.

WXR SYSTEM - CONTROL AND DISPLAY INTERFACE

Status Display

The AIMS cabinets get WXR system mode and status data so the NDs can show WXR system mode of operation and system status.



WXR SYSTEM - CONTROL AND DISPLAY INTERFACE

34-43-00-006 Rev 3 02/04/1998

WXR SYSTEM - ANTENNA CONTROL INTERFACE

Antenna Tilt

The WXR panel supplies antenna tilt control signals to the WXR RT.

Attitude Sources

The WXR RT uses ADIRS attitude data from AIMS for antenna stabilization.

The left ADIRS signals from left AIMS cabinet connect to the onside attitude input of the left WXR RT and to the offside attitude input of the right WXR RT. The right ADIRS signals from right AIMS cabinet connect to the onside attitude input of the right WXR RT and to the offside attitude input of the left WXR RT.

Attitude On/Off Discrete

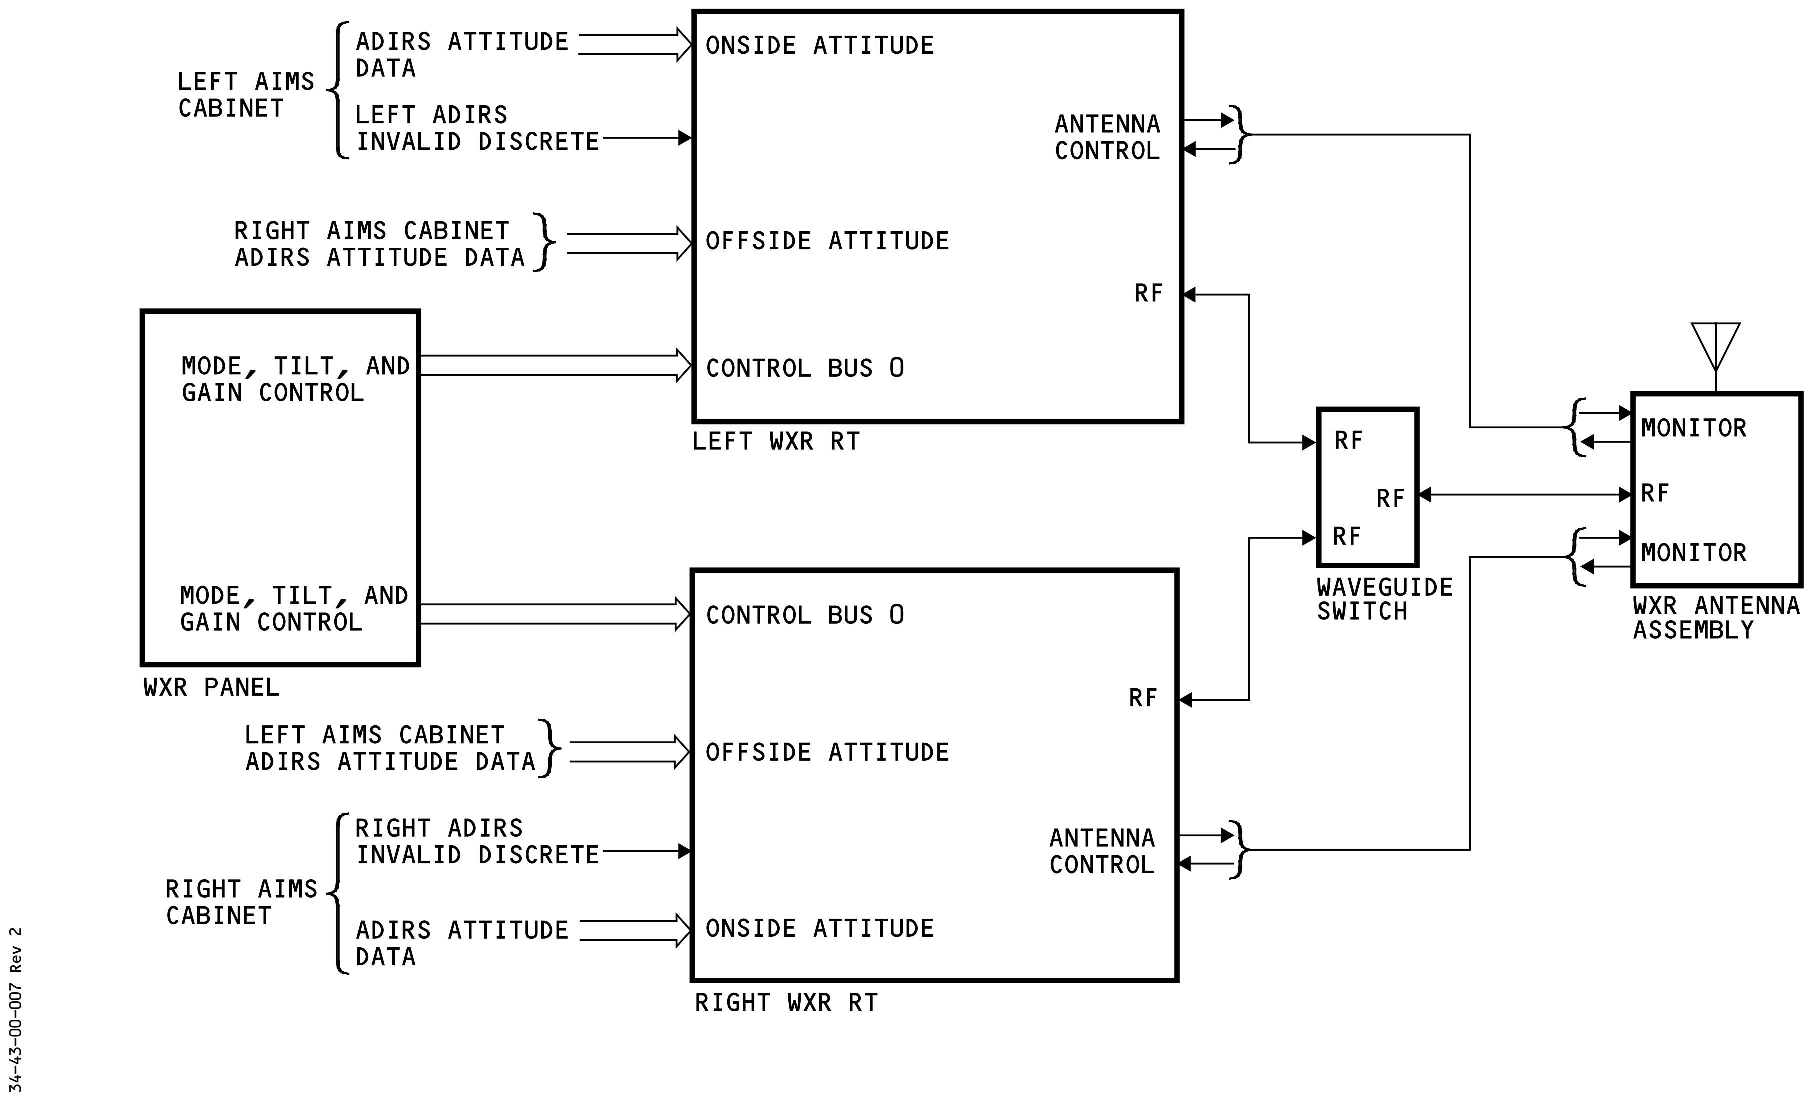
A failed AIMS cabinet supplies an ADIRS invalid discrete to the WXR RT. This permits the RT to use the offside attitude inputs.

WXR RT Antenna Control

The WXR RT sends antenna control and stabilization signals to the WXR antenna assembly.

Antenna Position Monitoring

The WXR antenna sends antenna position feedback to the WXR RT for scan and elevation position monitoring.



WXR SYSTEM - ANTENNA CONTROL INTERFACE

WXR SYSTEM - MAINTENANCE INTERFACES

RT Central Maintenance Computer System Interface

The central maintenance computer system (CMCS) of the left AIMS cabinets sends this data to the left and right WXR RTs:

- Flight legs for the RT nonvolatile memory (NVM)
- Ground test commands to start a WXR system test.

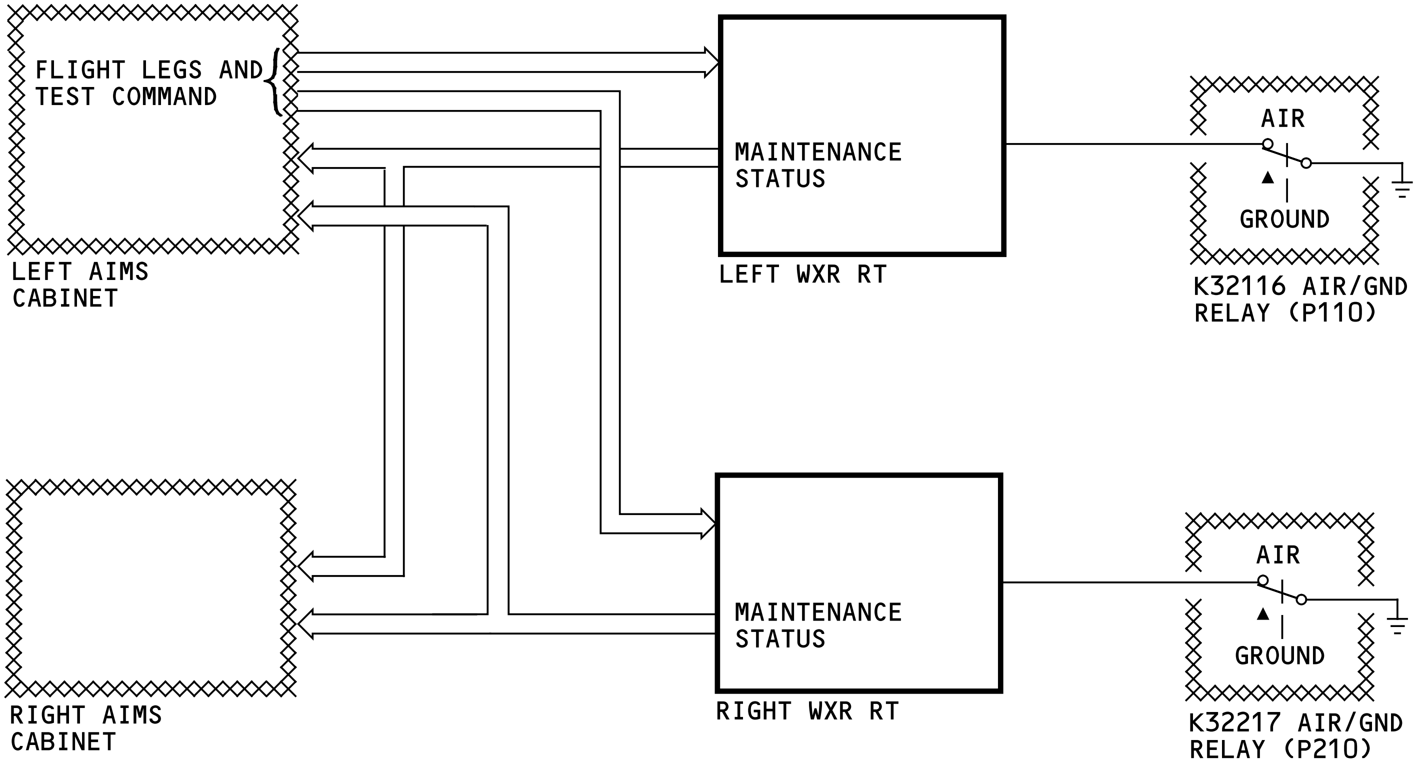
WXR System Maintenance Data

The WXR RTs send WXR system maintenance data to the CMCS in the left AIMS cabinets.

Air/Ground

The air/ground relay input does these functions:

- Inhibits PWS test alerts in the air
- Defines flight legs if the flight legs data from the CMCS fails.



34-43-00-008 Rev 2 01/23/1998

WXR SYSTEM - MAINTENANCE INTERFACES

WXR SYSTEM - WEATHER RADAR PANEL

Purpose

The weather radar (WXR) panel has controls for WXR system operation.

Mode Selector

The left and right alternate action mode select switches have these functions:

- TFR switch causes the RT to use the same mode, tilt, and gain as the other side
- WX/TURB switch selects the weather and turbulence mode (the RT processes turbulence returns for a maximum of 40 nm only)
- WX position selects the weather mode of operation
- MAP position selects the ground map mode
- GCS (ground clutter suppression) switch.

System Select Switch

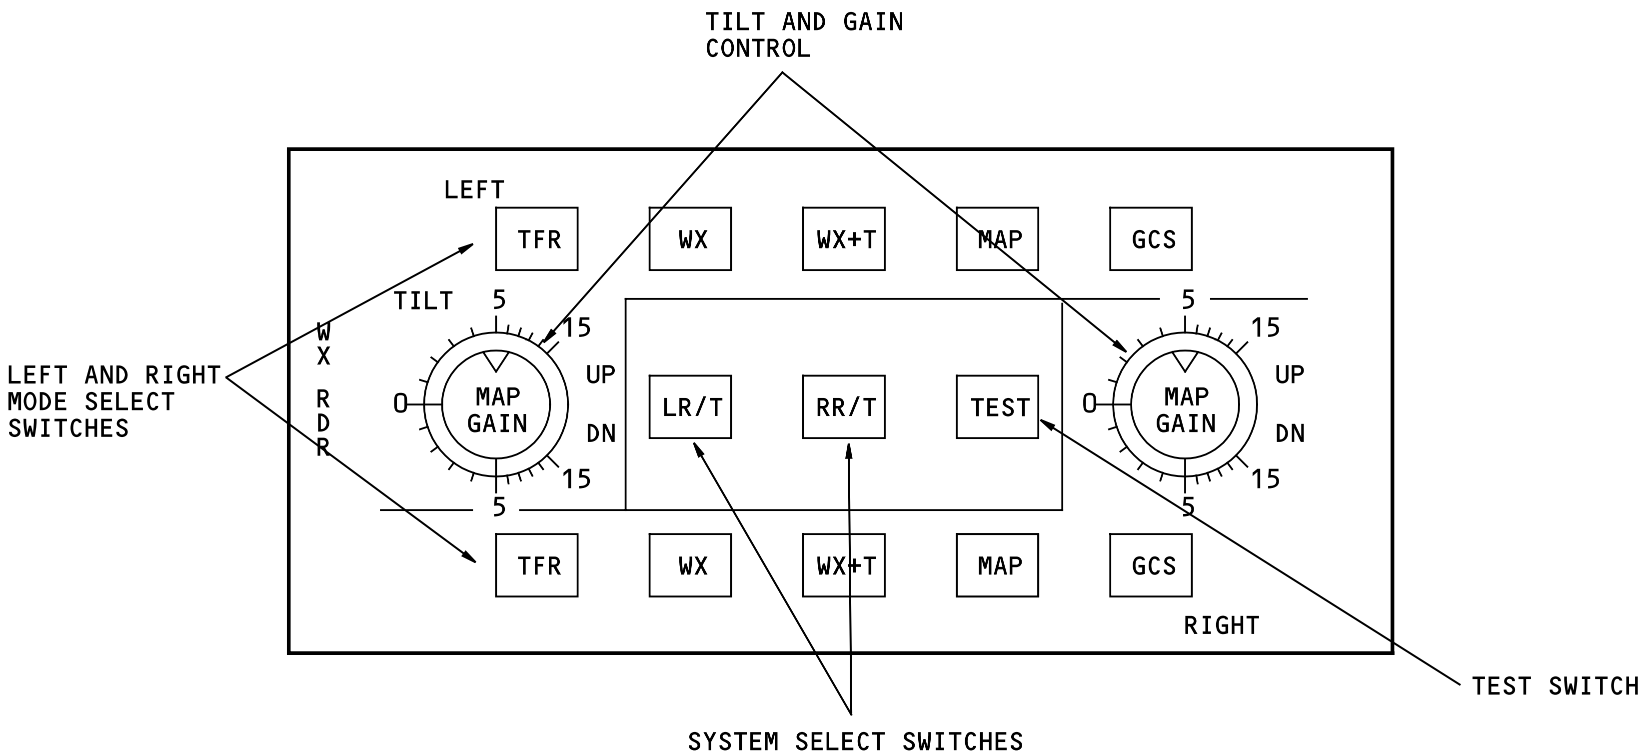
The left (L R/T) and right (R R/T) select switches let you select the left or right WXR RT for operation.

Tilt Control

The left and right antenna tilt controls let you select antenna tilt from +15 degrees to -15 degrees. The tilt controls also have the receiver gain control. The gain control adjusts the system gain in the MAP mode only.

Test

The test switch lets you do a test of the WXR RT that is in operation. The test results show on the NDs.



34-43-00-009 Rev 3

WXR SYSTEM - WEATHER RADAR PANEL

WXR SYSTEM - RECEIVER-TRANSMITTER

Purpose

The purpose of the WXR receiver-transmitter (RT) is to:

- Make and transmit RF pulses
- Process RF return signals
- Make display data
- Send display data to the AIMS
- Supply antenna stabilization
- Monitor and test system operation
- Send and record fault status and test results
- Make WXR display test patterns to show on the display units.

Physical Description

The WXR RT weighs 32 lb (14 kg). Forced air cools the WXR RT.

Front Panel

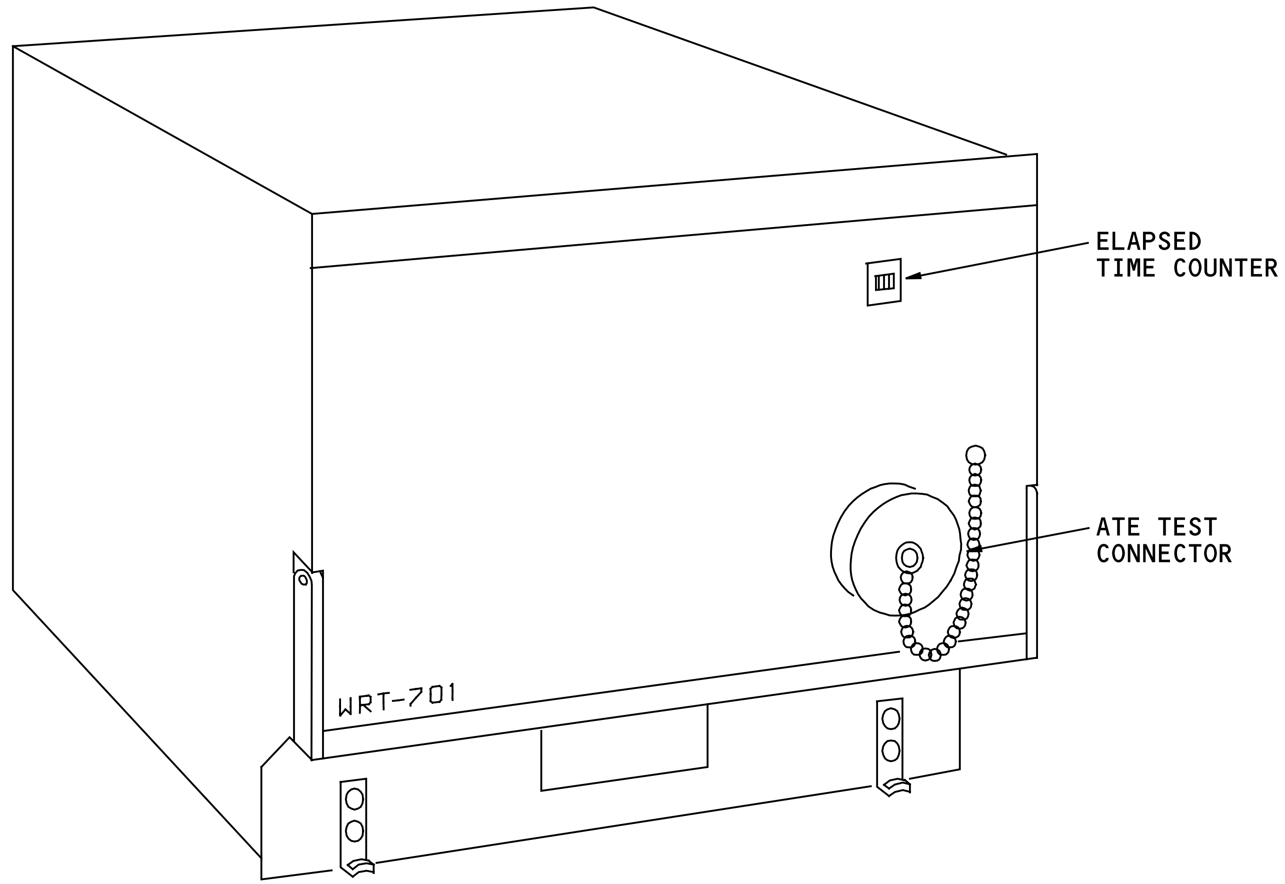
An elapsed time counter records the total hours of operation of the RT.

An ATE test connector supplies a test point to monitor RT operation during bench tests.

Training Information Point

The maintenance manual and the fault isolation manual do not have a task for the maintenance technician to do a test from the front panel of the WXR RT. You must do all tests for the WXR RT from the MAT, PMAT, or from the WXR panel.

Many LRUs on the 777 are compatible with other model airplanes that do not have a central maintenance computing system (CMCS). For that reason, these LRUs have a front panel test feature.



34-43-00-010 Rev 3 06/18/96

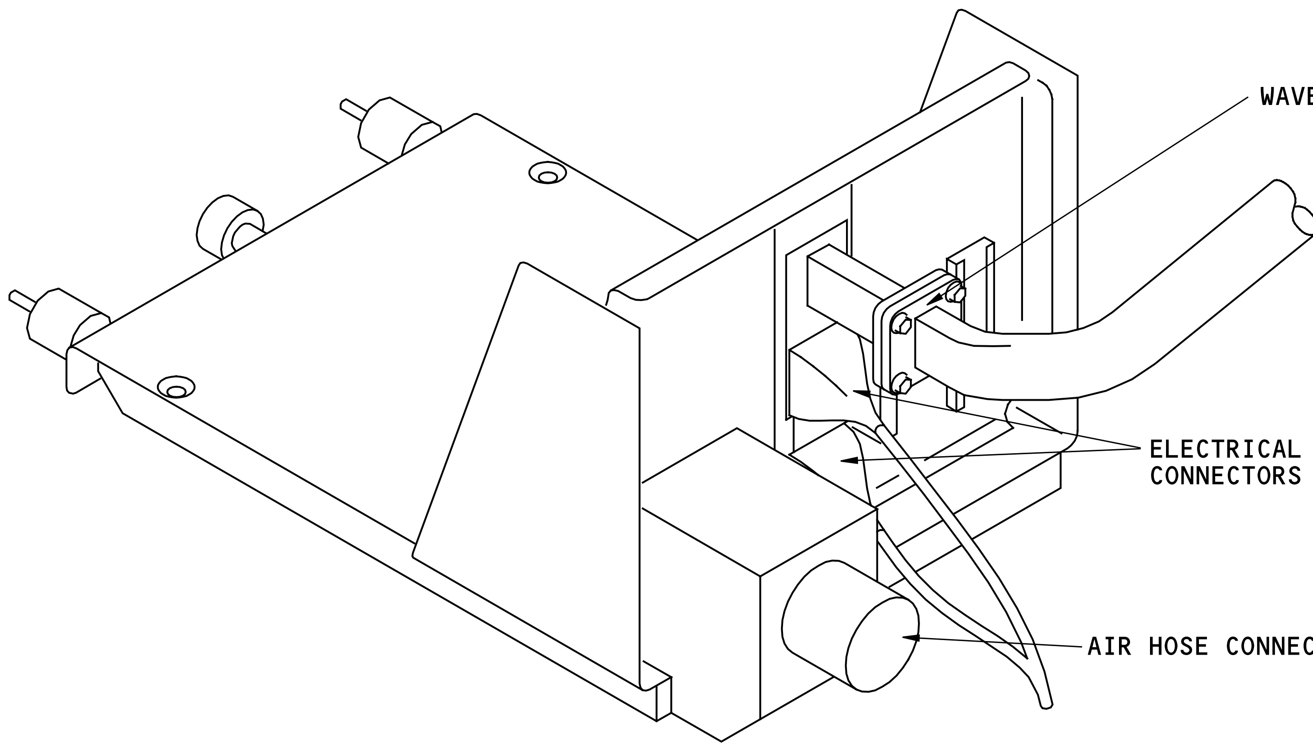
WXR SYSTEM - RECEIVER-TRANSMITTER

WXR SYSTEM - RT MOUNT

Purpose

The purpose of the WXR RT mount is to:

- Hold the RT
- Connect the RT to the airplane wiring
- Connect the RT to the waveguide
- Supply airplane cooling air to the RT.



34-43-00-011 Rev 1

WXR SYSTEM - RT MOUNT

WXR SYSTEM - ANTENNA ASSEMBLY 1

Antenna Assembly

The antenna assembly includes:

- The flat plate WXR antenna
- The antenna pedestal.

Flat Plate Antenna

The flat plate antenna transmits RF pulses from the WXR RT, and receives the pulses as they reflect off precipitation formations.

The flat plate antenna is an array of radiation slots. The RF pulses radiate from each of the slots and combine to make a pencil beam 5.4 degrees high and 5.4 degrees wide. The antenna weighs 6 lb (2.7 kg) and is 23 inches wide.

Antenna Pedestal

The antenna pedestal contains these items:

- Electrical connectors
- Stepper motors to drive the horizontal scan and vertical elevation scan
- Antenna position monitors
- Disable switches.

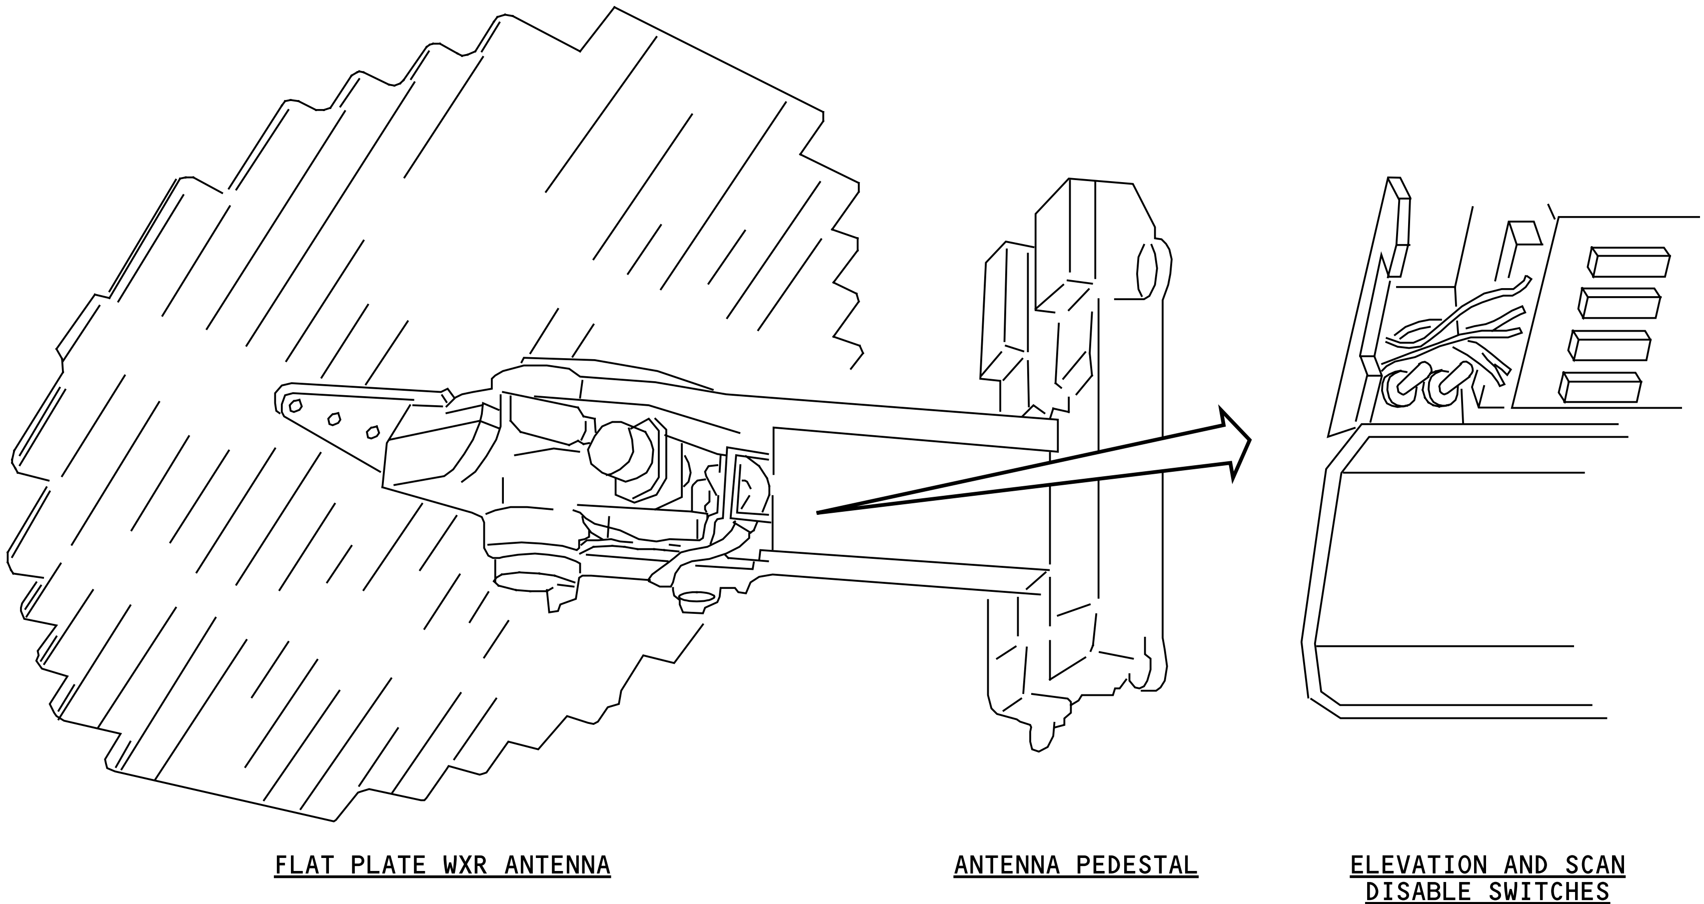
The antenna pedestal receives 115v ac power from the WXR RT. The antenna pedestal has two sets of power supplies and electronics. One set drives the antenna with the left RT selected. The other set drives the antenna with the right RT selected.

There is a horizontal scan stepper motor to drive the antenna +/- 90 degrees of the airplane centerline. There is also a vertical elevation scan stepper motor to drive the antenna +/- 40 degrees up or down (this includes the +/- degrees for manual tilt selection from the WXR control panel). The stepper motors use 26v dc for operation.

There is a zero position monitor and an incremental monitor for each motor. These monitors send antenna horizontal scan and elevation scan position feedback to the WXR RT. There are elevation and azimuth scales that permits a visual measurement of the tilt and scan angles.

There is a horizontal scan and elevation scan disable switch on the antenna pedestal to permit you to remove power to the scan and elevation stepper motors. Use these switches to inhibit movement of the antenna during maintenance. The switches do not stop RF transmissions from the WXR RT.

A torque spring inside the antenna pedestal counter balances the weight of the antenna. When you remove the antenna, the torque spring moves the elevation drive into the upper position.



WXR SYSTEM - ANTENNA ASSEMBLY 1

WXR SYSTEM - ANTENNA MOUNT ASSEMBLY

General

The antenna drive unit attaches to the antenna mount assembly with four antenna mount bolts.

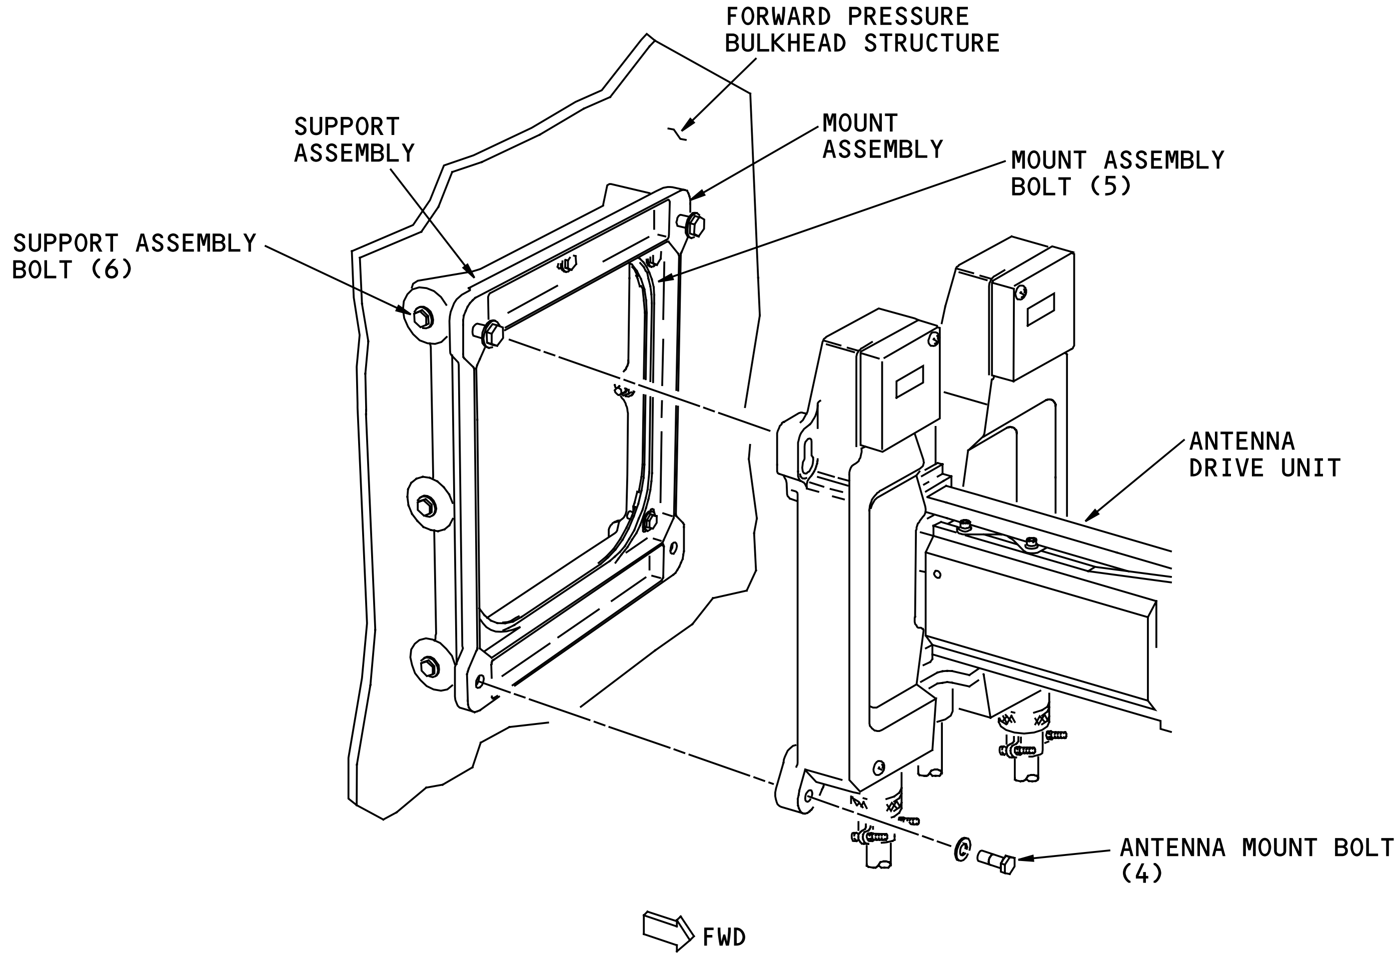
The mount assembly attaches to a support assembly with five mount assembly bolts.

The support assembly attaches to the forward pressure bulkhead with six support assembly bolts.

Training Information Point

The support assembly and mount assembly are aligned at the factory.

NOTE: Do not loosen the mount assembly bolts or the support assembly bolts. The support assembly and mount assembly are aligned at the factory. If the bolts are accidently loosened or if the base is loose or not aligned, special alignment procedures must be done by a Boeing specialty team. Contact Boeing Seattle A.O.G. Office, Technical Assistance Team.



34-43-00-014 Rev 1

WXR SYSTEM - ANTENNA MOUNT ASSEMBLY

WXR SYSTEM - RF SWITCHING

Purpose

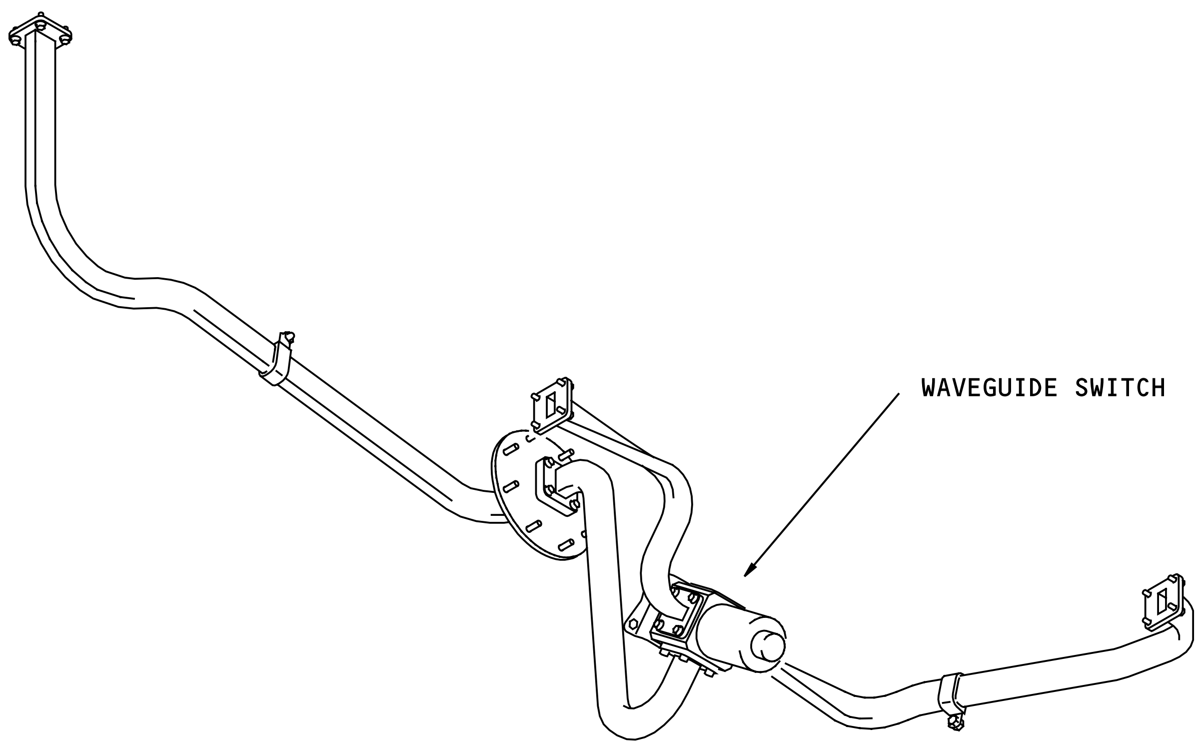
The WXR waveguide switch, switches the WXR antenna between the left and right WXR RTs.

Description

The WXR waveguide switch has three rigid waveguide sections attached to it that go to the:

- Left WXR RT
- Right WXR RT
- WXR antenna pedestal.

The waveguide switch has an electrical connection that enables the switch operation. A discrete signal from the WXR control panel causes the switch to operate.



34-43-00-015 Rev 1

WXR SYSTEM - RF SWITCHING

WXR SYSTEM - CONTROL - EFIS CONTROL PANEL

EFIS Control Panel

These are the functions of the EFIS control panel for WXR control:

- Supplies the on and off control of the WXR RTs
- Enables the NDs to show WXR data
- Supplies the selection of different ND modes
- Supplies the selection of different ranges for WXR data to show on the NDs.

WXR Map Switch

When you push the WXR map switch on the EFIS control panel:

- The WXR RT selected on the WXR panel starts to operate
- The WXR data shows on the onside ND.

To stop the operation of the WXR RT, the WXR switches on both EFIS control panels and the WXR selections on the CDUs must be off.

ND Mode Selector

Use the mode selector switch to select an ND mode. The ND modes that show a WXR display are:

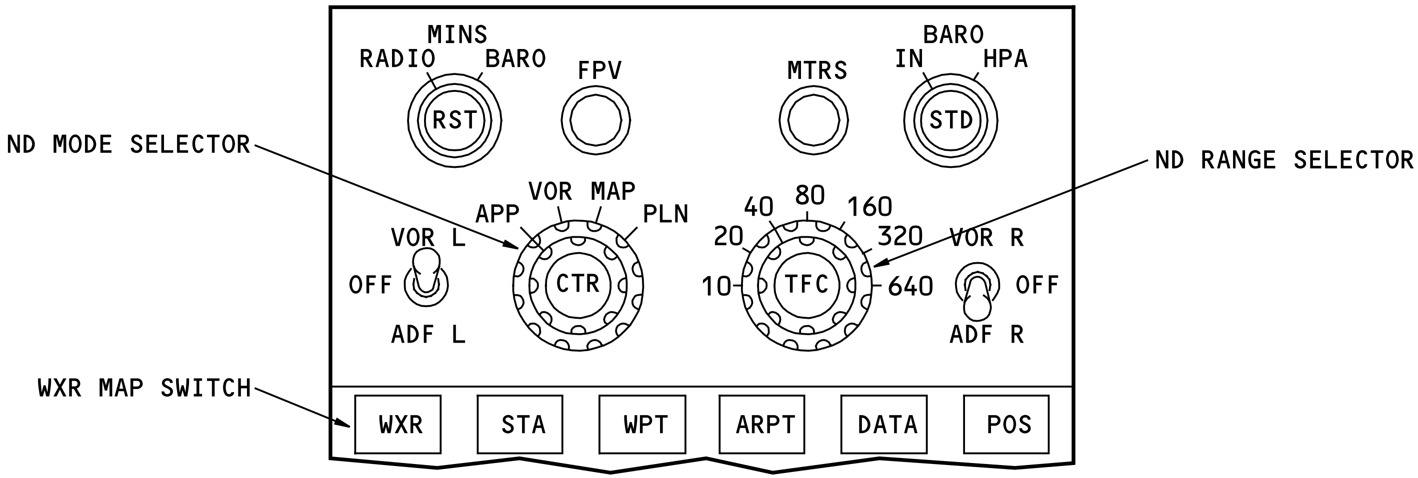
- Expanded APP (approach) mode
- Expanded VOR mode
- Expanded MAP mode
- Centered MAP mode.

If the mode selector is not in a correct mode when you push the WXR map switch, the weather display arms. When armed, the weather display shows as soon as you change the ND selector to a correct mode. The weather display stays armed even if you push the WXR map switch again.

ND Range Selector

The EFIS control panel has a six position range selector. The range selections are 10, 20, 40, 80, 160, 320 and 640 NM. With the 640 NM range selection, the 640 NM range shows on the ND, but the WXR RT only shows weather displays out to its maximum range of 320 NM.

The MAP mode shows the range at all times. The APP and VOR modes show the range only when the WXR is on.



WXR SYSTEM - CONTROL - EFIS CONTROL PANEL

WXR SYSTEM - CDU SELECTIONS

Alternate or Backup EFIS Control Panel

The EFIS control page on the control display unit (CDU) permits alternate or backup controls for the WXR system.

If the EFIS CP fails or for alternate operation, use the EFIS control CDU pages on the onside CDU for:

- On/off power control of the WXR system
- On/off control of the onside WXR display
- WXR range selection
- ND mode selection.

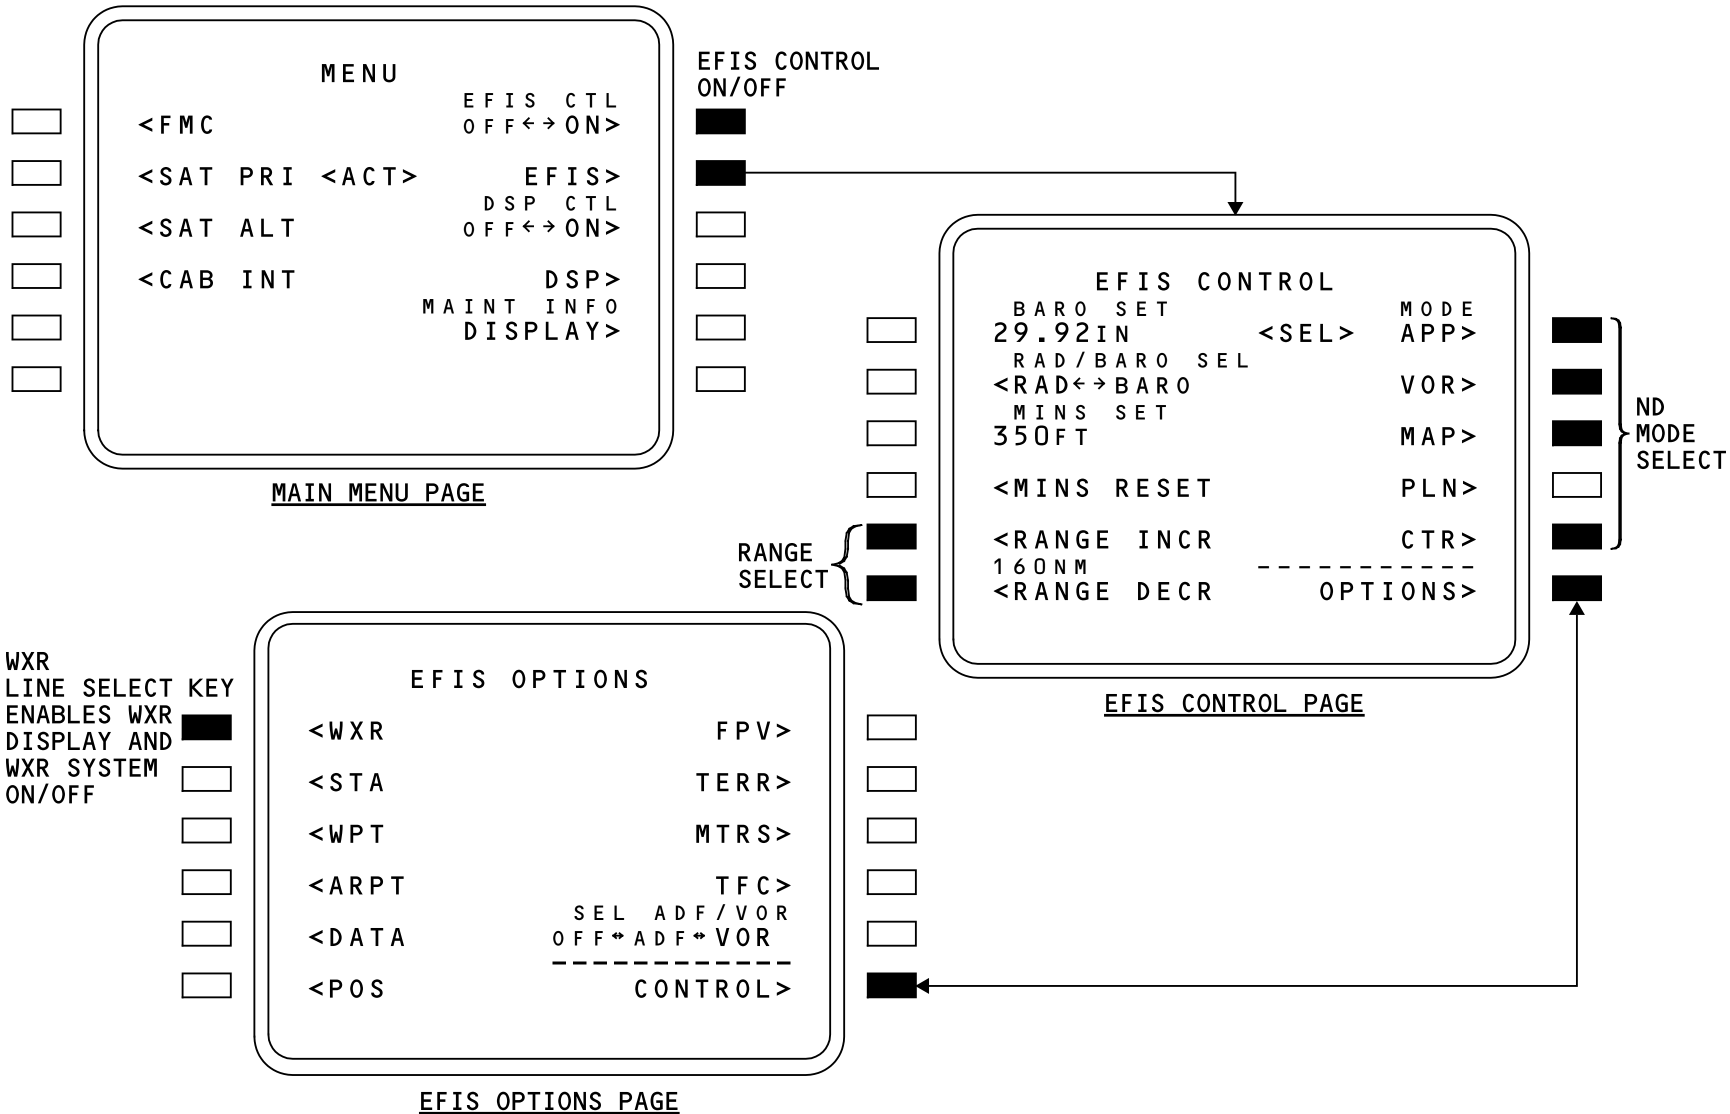
When you select EFIS control to ON from the CDU page, the onside EFIS CP does not operate.

Access

To get the EFIS control CDU pages on the CDU:

- Push the MENU line select key (LSK) on the CDU to make the MENU page come on
- Push the EFIS CTL LSK on the MENU page and the EFIS prompt comes on
- Push the LSK next to EFIS and the EFIS control page comes on
- Select the ND modes and range From the EFIS CONTROL page
- Push the OPTIONS LSK on the EFIS CONTROL page to go to the EFIS OPTIONS page
- Push the WXR LSK on the EFIS OPTIONS page for ON/OFF control of the WXR system and to enable the WXR display for the onside ND.
- Push the CONTROL LSK on the EFIS OPTIONS page to return to the EFIS CONTROL page.

You can use the EFIS CP CDU pages on the CDU at anytime, but normally the EFIS CP supplies the control for the WXR system.



WXR SYSTEM - CDU SELECTIONS

WXR SYSTEM - NORMAL DISPLAYS

Display Modes

The ND shows WXR system data in these modes:

- Expanded approach mode
- Expanded VOR mode
- Centered MAP mode
- Expanded MAP mode.

Each ND mode has a range selection for 10, 20, 40, 80, 160, 320, or 640 NM. Use the EFIS CP to select the mode and range for the ND.

WXR System Display Data

For the WXR system, the ND shows this information:

- WXR displays
- WXR system messages
- WXR alert messages.

WXR Displays

The WXR displays on the ND show the weather in front of the airplane or the terrain below. The WXR display shows in four colors. These colors represent the strength of the RF return signals from the weather or the terrain. These are the four colors for the WXR displays:

- Green shows light weather
- Yellow shows medium weather
- Red shows heavy weather
- Magenta shows turbulence.

The WXR system detects and shows turbulence only to 40 NM.

WXR System Messages

The ND shows WXR system messages on three lines. Line 1 shows WXR mode messages. These are the messages that show on line 1:

- WXR (weather precipitation mode)
- TURB (turbulence mode)
- WX+T (weather and turbulence mode)
- MAP (manual gain)
- TEST (test mode).

Line 2 shows the antenna tilt value set on the WXR panel. The tilt value is +15 degrees to -15 degrees.

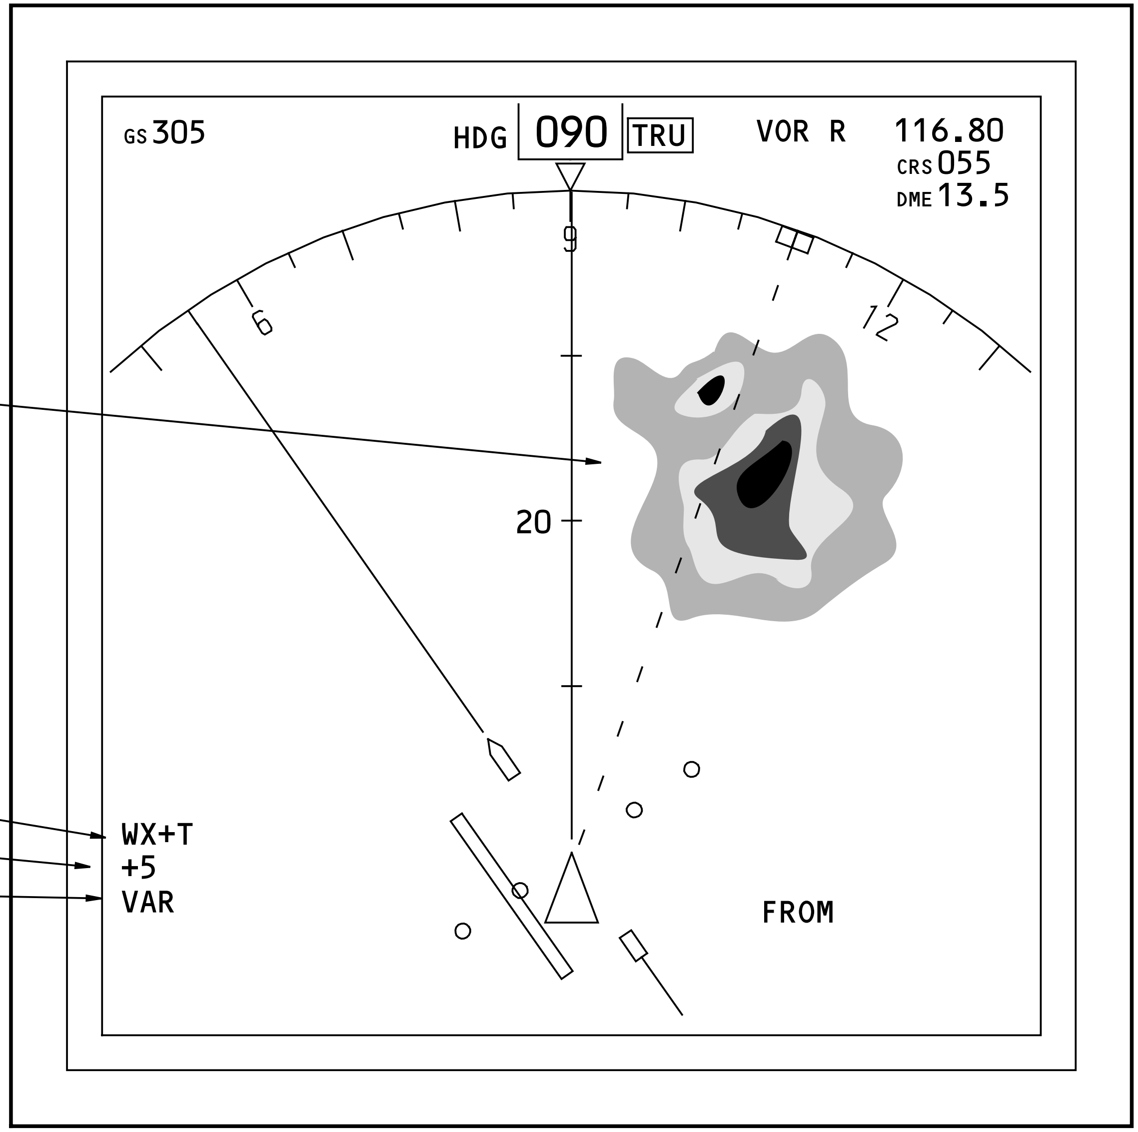
Line 3 shows the manual gain selection made on the WXR panel. The message for manual gain selection is VAR.

When the flight crew does not make a manual gain selection, the WXR RT uses preset calibrated gain and no gain message shows.

All WXR system messages show in the color cyan.

WEATHER DISPLAY:
- GREEN = LIGHT WEATHER
- YELLOW = MEDIUM WEATHER
- RED = HEAVY WEATHER
- MAGENTA = TURBULENCE

WEATHER SYSTEM MESSAGES:
- WEATHER MODE
- ANTENNA TILT
- GAIN VALUE



EXPANDED APPROACH MODE

WXR SYSTEM - NORMAL DISPLAYS

34-43-00-018 Rev 6 02/10/1998

WXR SYSTEM - FAIL MESSAGES AND DISPLAYS

WXR System Alert Messages and Display

When a WXR RT processes data that is not satisfactory, alert messages show on the ND and the WXR display continues to show. These alert messages are:

- WXR WEAK shows for a receiver gain calibration fail
- WXR ATT shows when both attitude inputs fail
- WXR STAB shows when the airplane attitude exceeds stabilization limits.

The alert messages show on these alert-lines:

- Line 1 shows WXR in amber
- line 2 shows WEAK or ATT in amber, WEAK has the highest priority
- Line 3 shows STAB in cyan.

WXR System Fail Messages and Display

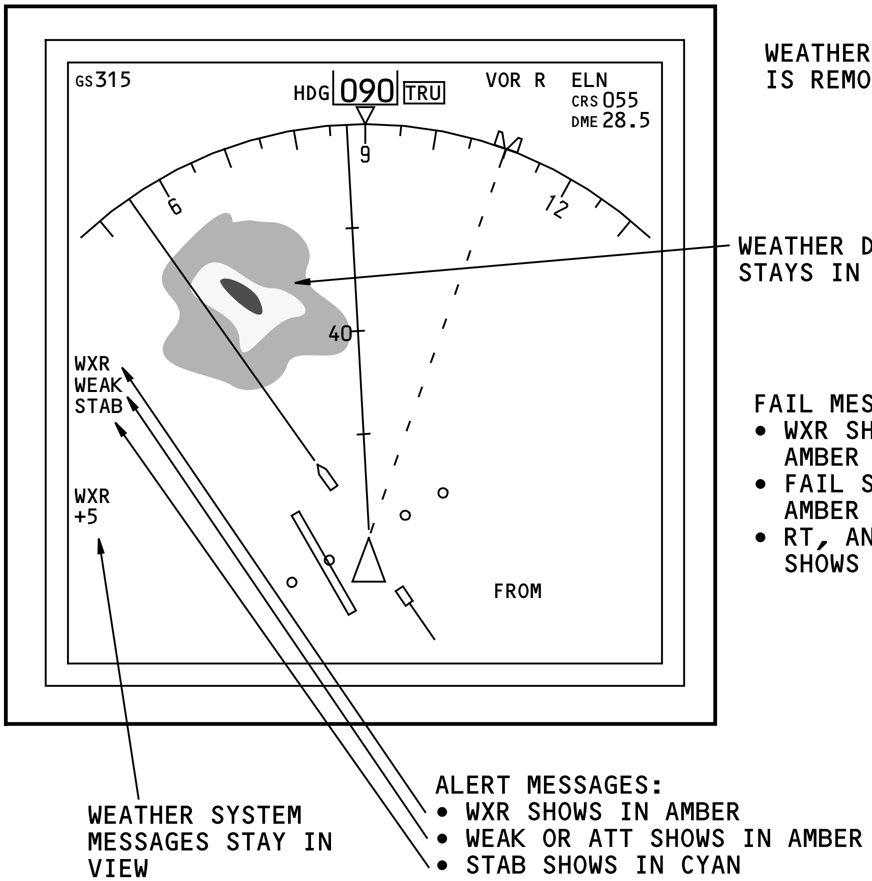
When a failure occurs, a WXR fail message shows and the WXR display does not show.

The fail messages show on these alert-lines:

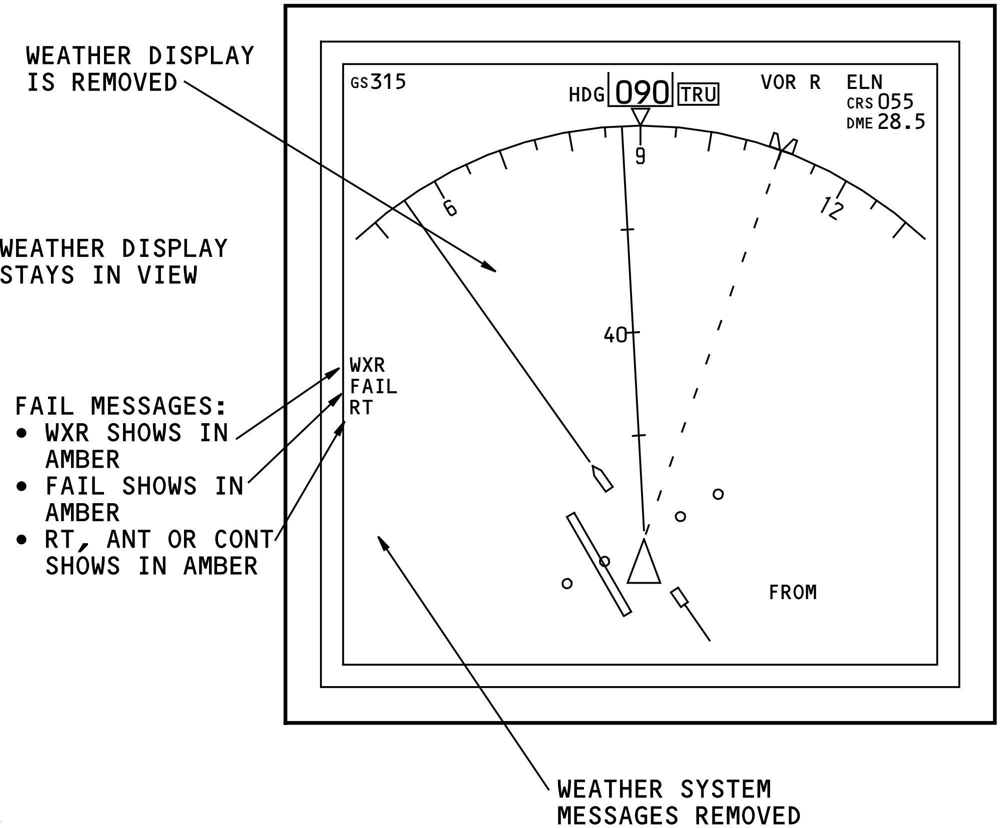
- Line 1 shows WXR in amber
- Line 2 shows FAIL in amber.

These WXR system fail messages show on alert-line 3:

- RT shows for a receiver-transmitter failure
- ANT shows for an antenna failure
- CONT shows for a WXR CP failure.



WXR SYSTEM ALERT MESSAGES AND DISPLAY



WXR SYSTEM FAIL MESSAGES AND DISPLAY

34-43-00-019 Rev 5 07/11/95

WXR SYSTEM - FAIL MESSAGES AND DISPLAYS

WXR SYSTEM - ND RANGE DISAGREEMENT

General

The graphics generators (GGs) in the left and right AIMS cabinets do a comparison of the ranges from these places:

- EFIS CP
- WXR RT
- Flight management computer function (FMCF).

A difference between any of these ranges causes an amber range disagreement message.

These two range disagreement messages are possible:

- WXR RANGE DISAGREE shows when there is a difference between the EFIS CP range and the WXR RT range
- MAP/WXR RANGE DISAGREE shows when there is a difference between the EFIS CP range, the WXR RT range, and the FMCF range.

This happens during a range disagreement:

- The WXR display does not show
- The mode, tilt, and gain messages show
- The FMCF range shows.

34-43-00-020 Rev 0

WXR SYSTEM - ND RANGE DISAGREEMENT

WXR SYSTEM - SYSTEM SELECT AND SYSTEM ON/OFF

System Select

When you select the left or right WXR system at the WXR panel, an RT ENABLE goes to switch S1 in the same WXR RT to enable the RT to operate. 28v dc from the keep-alive power supply goes from the selected RT through the system select switch in the WXR panel to the waveguide switch. The 28v dc energizes the waveguide switch relay to connect the selected RT to the WXR antenna.

System On

To make the WXR system operate, do either of these:

- Push the WXR switch on an EFIS control panel
- Push the LSK for WXR on the EFIS OPTIONS page on the CDU.

When you do this, the AIMS cabinets supply a ground level discrete through the WXR panel through switch S1 of the RTs. This ground level discrete lets 28v dc power go from the keep-alive power supply to energize the relay to close switches S2 and S3 if S1 is energized by the WXR control panel system select switch. The 28v dc keep-alive power supply sends power through switch S2 to energize the WXR CP power supply. 115v ac goes through switch S3 to energize the RT power supply and the WXR antenna drive.

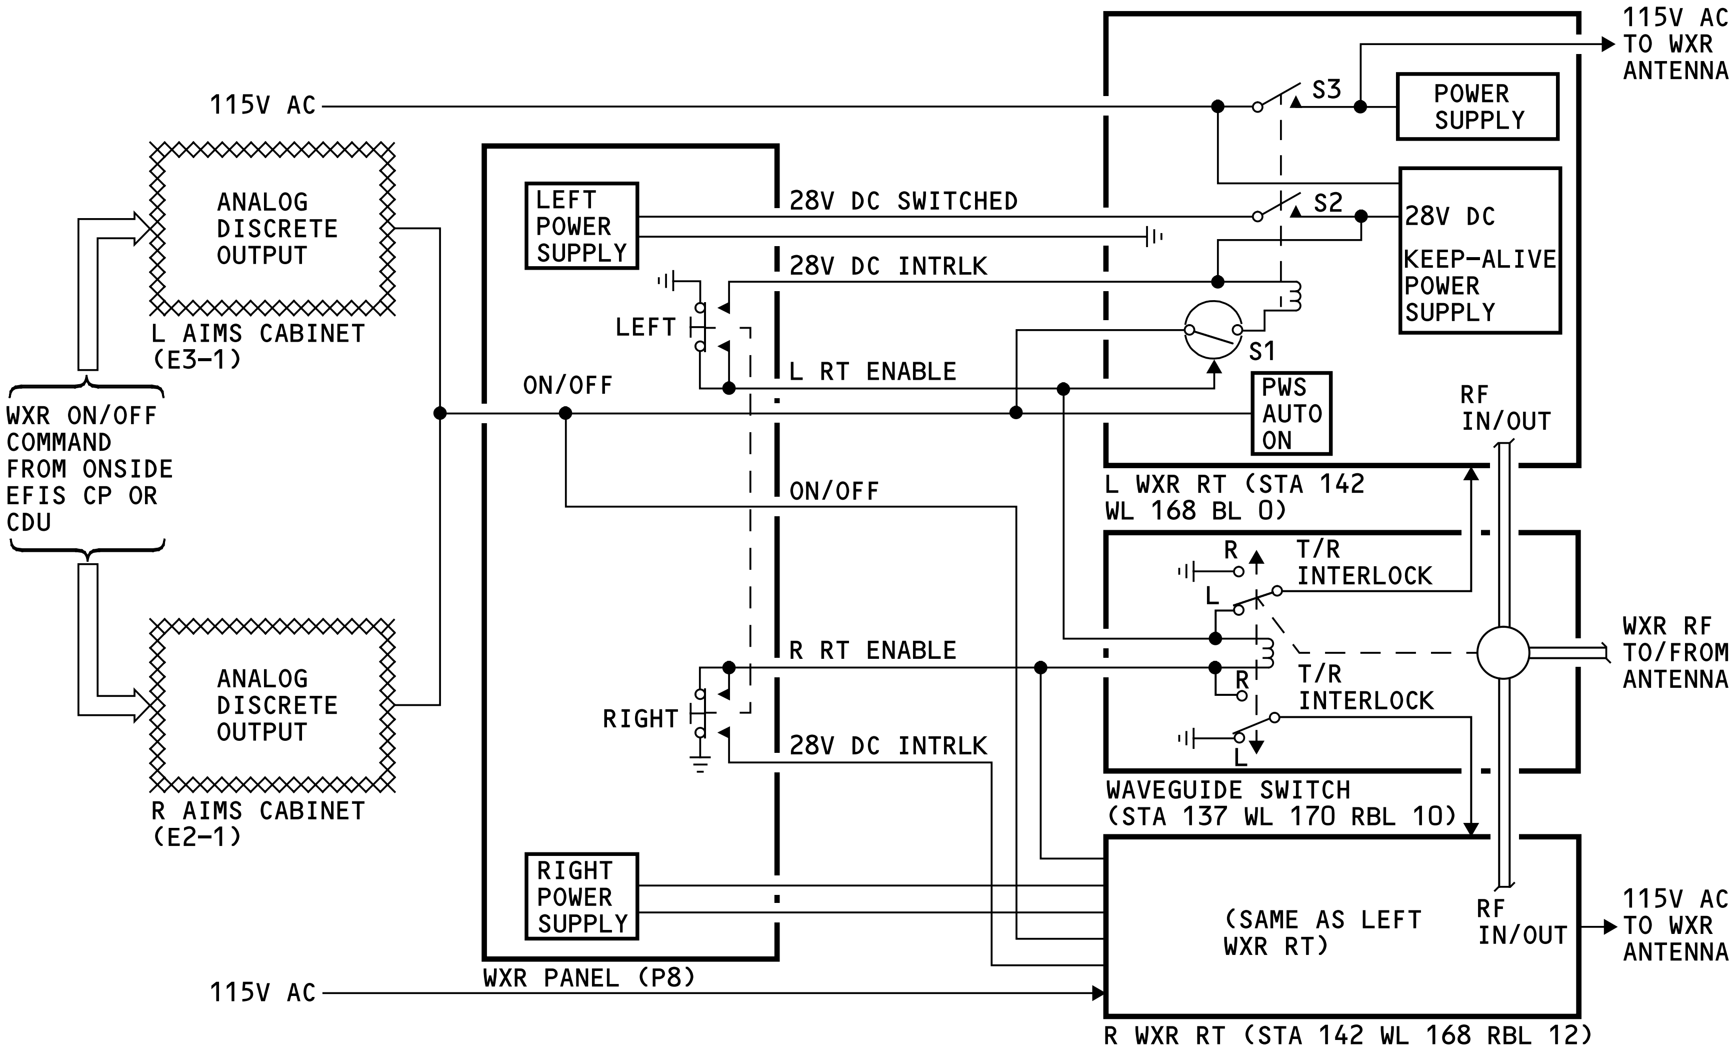
Certain conditions cause the predictive windshear (PWS) function to turn the WXR system on automatically. When this happens, the ground signal to switch S1 comes from the PWS card in the selected RT, instead of the AIMS cabinets.

System Off

To make the WXR system go OFF, do either of these:

- Push the WXR switch again
- Push the WXR LSK on the EFIS OPTIONS page again.

This removes the ground level discrete from the AIMS cabinet. If more than one WXR switch is on, push all of the switches again.



WXR SYSTEM - SYSTEM SELECT AND SYSTEM ON/OFF

THIS PAGE INTENTIONALLY LEFT BLANK

WXR SYSTEM - SELF-TEST

Training Information Point

The weather radar (WXR) system transmits some pulses to let BITE monitor for correct operation. Do not do a test of the WXR system in a hangar. Make sure the nose of the airplane points away from buildings and other aircraft or large metal objects.

Test Preparation

WARNING: DO NOT OPERATE THE WEATHER RADAR WHILE FUEL IS ADDED OR REMOVED FROM THE AIRPLANE. DO NOT TRANSMIT RF ENERGY WHILE FUEL IS ADDED OR REMOVED IN AN AREA 300 FEET OR LESS FROM THE ANTENNA. THIS CAN CAUSE AN EXPLOSION.

WARNING: MAKE SURE NO PERSONS ARE IN THE AREA 15 FEET OR LESS FROM THE ANTENNA WHEN IT TRANSMITS RF ENERGY. RF ENERGY CAN CAUSE INJURIES TO PERSONS.

Use an EFIS control panel or a CDU to:

- Select an ND mode that can show the WXR display
- Apply power to the selected RT
- Enable the WXR display to show on the on-side ND.

Test Start

When you select TEST on the WXR control panel, the WXR self-test starts.

Test Operation

These visual and aural annunciations show for a normal test:

- WXR test pattern and cyan WXR TEST message show on the ND
- Amber WINDSHEAR message on ND
- Aural message - MONITOR WINDSHEAR DISPLAY
- Red WINDSHEAR message on ND and PFD
- Aural message - WINDSHEAR AHEAD, WINDSHEAR AHEAD
- Master warning lights on
- EICAS status messages WINDSHEAR PRED
- EICAS advisory message WINDSHEAR SYS.

The WXR TEST pattern shows until you select another mode on the WXR panel or EFIS control panel.

The TEST pattern shows without any alert annunciations if either of these conditions exist:

- PWS is on
- Airplane is in the air.

The PWS symbol always shows in the TEST pattern. If PWS detects a real windshear threat while in TEST mode, the test stops. PWS then shows the actual display data and alert annunciations.

Test Pass

For a valid self-test, you must see and hear all visual and aural annunciations.

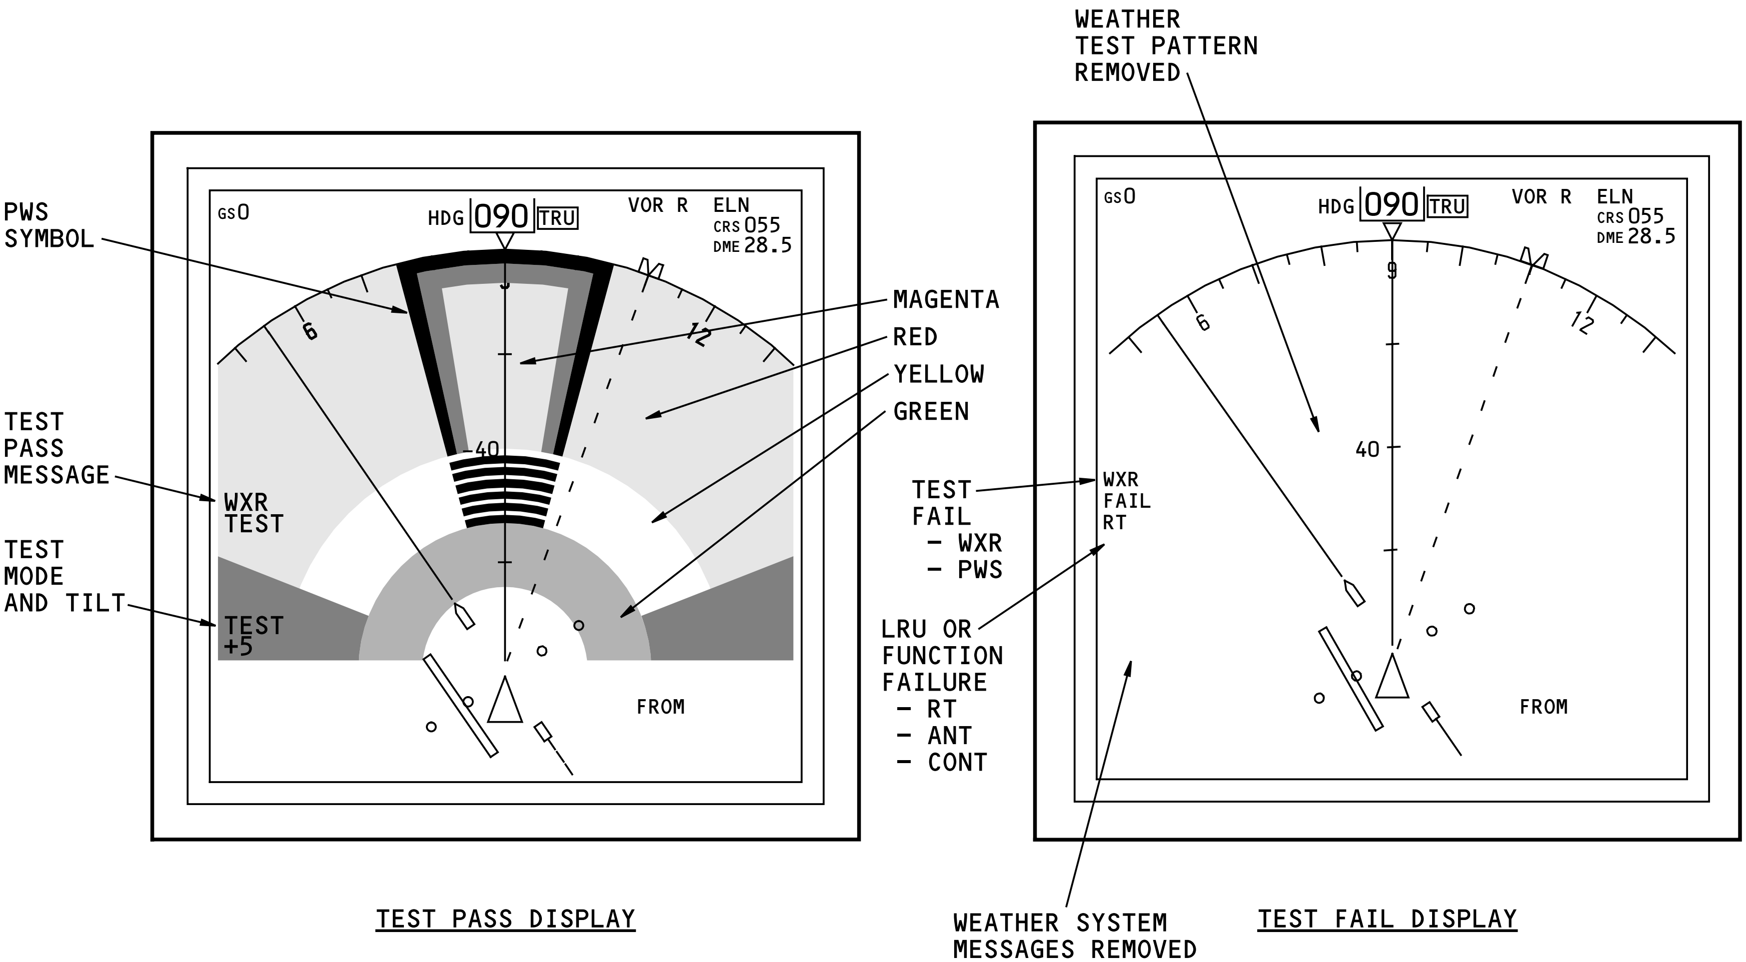
WXR SYSTEM - SELF-TEST

Test Fail

For a self-test that fails, these are the indications:

- For some faults, the WXR test pattern does not show
- WXR or PWS shows in amber on alert message line one
- FAIL shows in amber on alert message line two
- A fail message shows for the WXR system failure.

The windshear symbol shows on the ND, even if PWS fails self-test.



34-43-00-025 Rev 6 02/06/1998

WXR SYSTEM - SELF-TEST

WXR SYSTEM - LRU REPLACEMENT TEST

General

These are the LRU replacement tests for the weather radar system:

- Left WXR system
- Right WXR system.

Weather Radar LRU Replacement Test

The WXR system LRU replacement test causes the WXR RT to do a check of internal WXR RT operations. This test also makes sure the WXR RT connections are good. This test does not do a detailed check of the WXR RT data inputs.

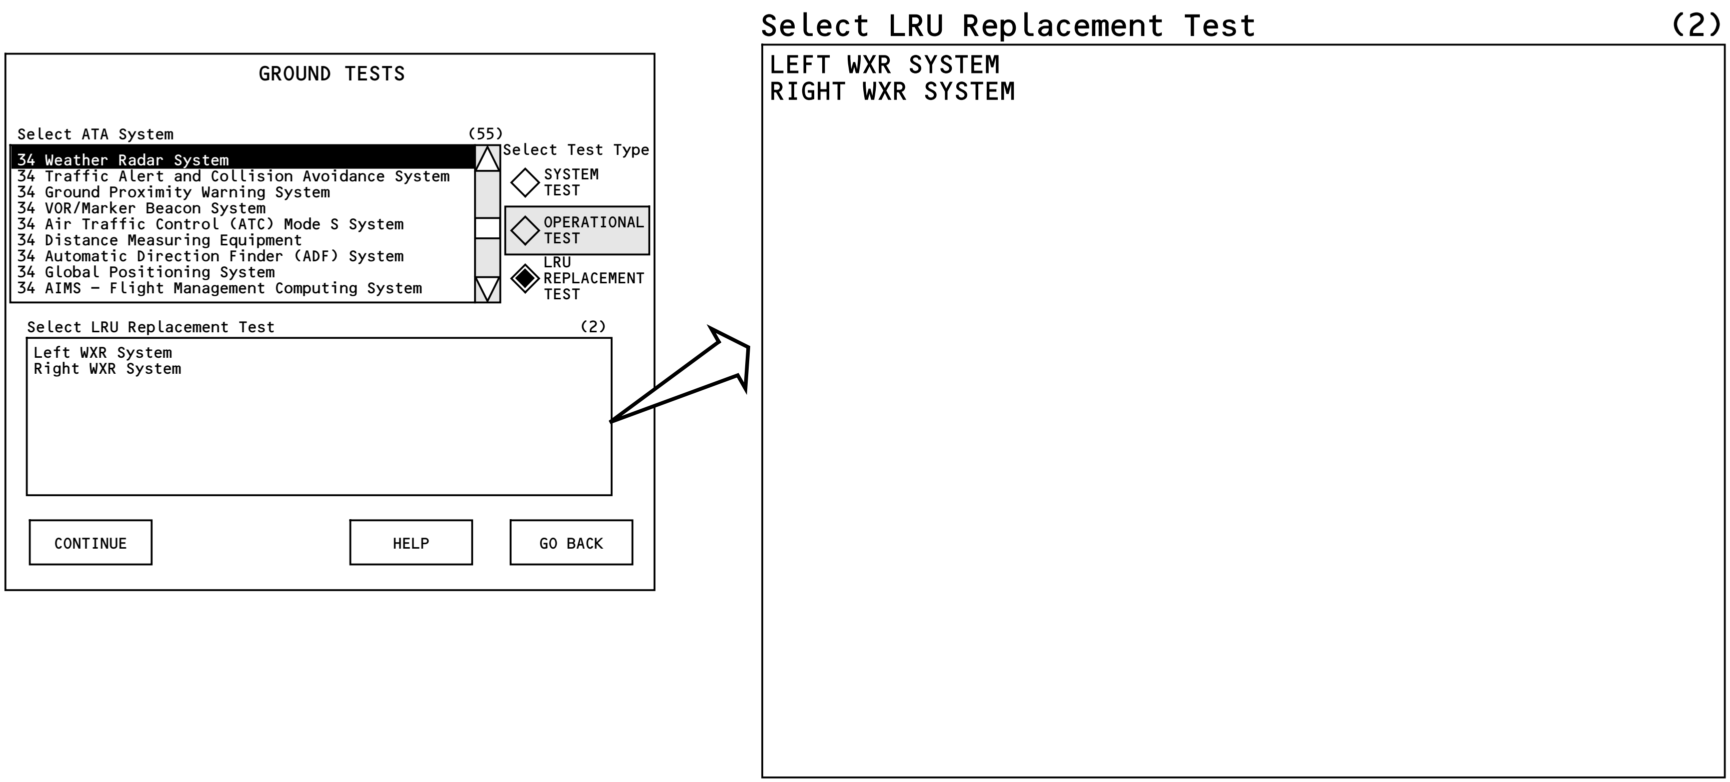
Training Information Point

There are no ND WXR test display patterns when you do a WXR LRU replacement test.

Do not do a WXR system test in a hangar. Make sure the nose of the airplane points away from buildings, other aircraft or large metal objects.

WARNING: DO NOT OPERATE THE WEATHER RADAR WHILE FUEL IS ADDED OR REMOVED FROM THE AIRPLANE. DO NOT TRANSMIT RF ENERGY WHILE FUEL IS ADDED OR REMOVED IN AN AREA 300 FEET OR LESS FROM THE ANTENNA. THIS CAN CAUSE AN EXPLOSION.

WARNING: MAKE SURE NO PERSONS ARE IN THE AREA 15 FEET OR LESS FROM THE ANTENNA WHEN IT TRANSMITS RF ENERGY. RF ENERGY CAN CAUSE INJURIES TO PERSONS.



34-43-00-026 Rev 4

WXR SYSTEM - LRU REPLACEMENT TEST

WXR SYSTEM - SYSTEM TEST

General

These are the system tests for the weather radar system:

- Left WXR system
- Right WXR system.

Weather Radar System Test

You use the WXR system test to verify the correct internal operation of the WXR RT, and to do a detailed check of the WXR RT data inputs.

Training Information Point

There are no ND WXR test display patterns when you do a WXR system test.

Do not test the WXR system in a hangar. Make sure the nose of the airplane points away from buildings and other aircraft or large metal objects.

WARNING: DO NOT OPERATE THE WEATHER RADAR WHILE FUEL IS ADDED OR REMOVED FROM THE AIRPLANE. DO NOT TRANSMIT RF ENERGY WHILE FUEL IS ADDED OR REMOVED IN AN AREA 300 FEET OR LESS OR THE ANTENNA. THIS CAN CAUSE AN EXPLOSION.

WARNING: MAKE SURE NO PERSONS ARE IN THE AREA 15 FEET OR LESS FROM THE ANTENNA WHEN IT TRANSMITS RF ENERGY. RF ENERGY CAN CAUSE INJURIES TO PERSONS.

Continental Airlines, Inc

Air Traffic Control System

WB371

TABLE OF CONTENTS

AIR TRAFFIC CONTROL/MODE S TRANSPONDER SYSTEM

General

The air traffic control (ATC) ground stations interrogate the airborne ATC/Mode S transponder system. The ATC/Mode S transponder replies to the interrogations in the form of coded information that the ground station uses.

The ground station uses a primary surveillance radar (PSR) to get radar returns from airplanes within the radar range. To make a communication link with the airplanes in the radar range, the ground station uses a secondary surveillance radar (SSR) to interrogate the ATC/Mode S transponder. The ground station transmits a side lobe suppression signal to inhibit close ATC replies that come from a SSR side lobe transmission.

On the ground radar display, the ATC operator sees the radar returns, altitude, and a four digit airplane identifier.

The ATC/Mode S transponder also replies to mode S interrogations from the traffic alert and collision avoidance systems (TCAS) of other airplanes.

Abbreviations and Acronymns

AIR TRAFFIC CONTROL/MODE S TRANSPONDER SYSTEM

ATC/MODE S TRANSPONDER SYSTEM - GENERAL DESCRIPTION

General

When a ground station or a TCAS computer from another airplane interrogates the ATC/Mode S transponder system, the transponder transmits a pulse-coded reply signal. The reply signal identifies, and shows the altitude of the airplane.

General Description

The components of the ATC system are:

- Top antenna
- Bottom antenna
- ATC coaxial relay top
- ATC coaxial relay bottom
- Transponder panel
- Two ATC/Mode S transponders
- Two program switch modules.

The two antennas supply transmit and receive signals to the ATC/Mode S transponder through the ATC coax relays.

The transponder panel sends identification and control data to the transponders and control to the ATC coax relays.

The AIMS cabinets supply altitude and central maintenance computing function (CMCF) data to the ATC/ Mode S transponders.

The ATC/Mode S transponders have interface with the TCAS computer.

ATC/MODE S TRANSPONDER SYSTEM - GENERAL DESCRIPTION

ATC/MODE S TRANSPONDER SYSTEM - COMPONENT LOCATION

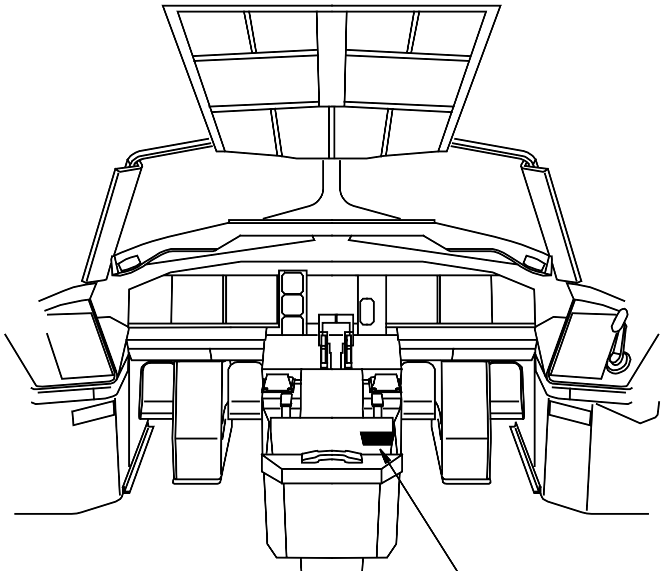
Flight Deck

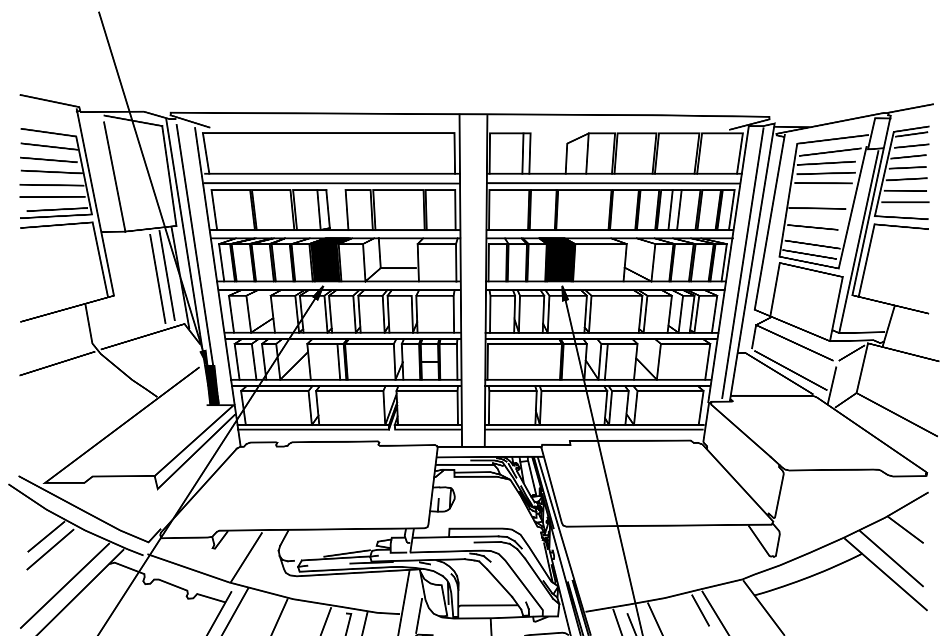
The transponder panel is on the P8 aft aisle stand.

Main Equipment Center

The ATC/Mode S transponder system components in the main equipment center are:

- Left ATC/Mode S transponder
- Right ATC/Mode S transponder
- Program switch modules
- Top ATC coax relay
- Bottom ATC coax relay.





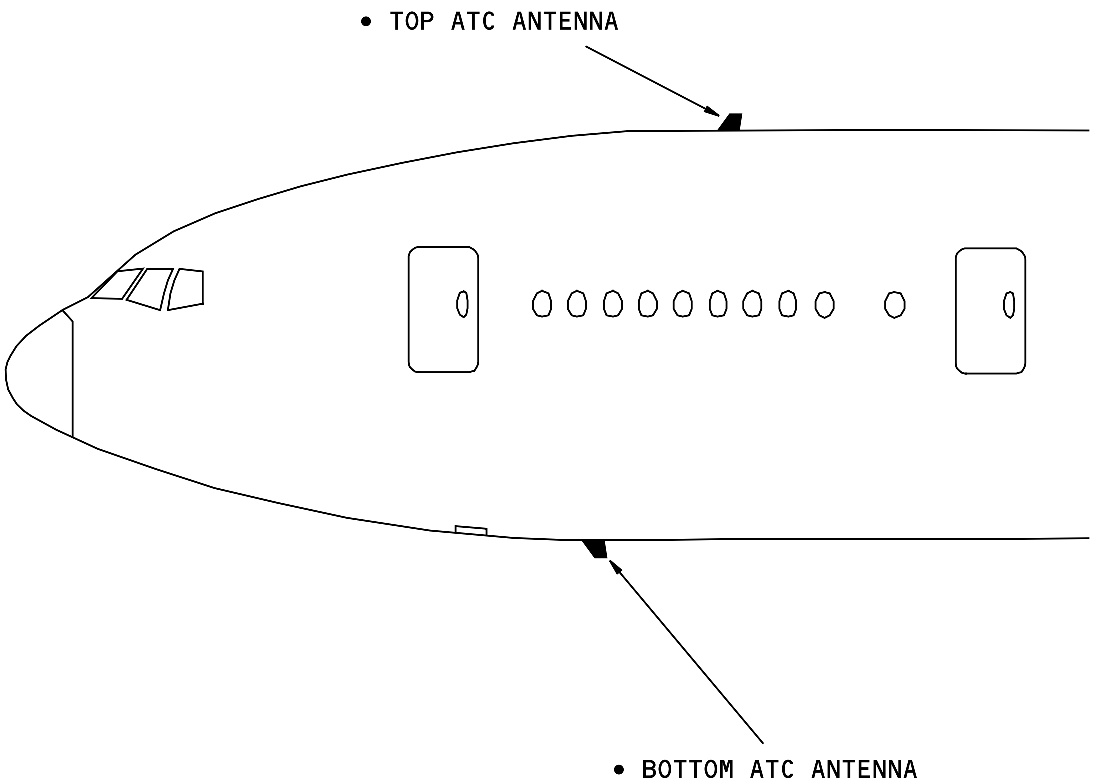
34-53-00-003 Rev 1 02/27/1998

ATC/MODE S TRANSPONDER SYSTEM - COMPONENT LOCATION

ATC/MODE S TRANSPONDER SYSTEM - ANTENNA LOCATION

GENERAL

The top antenna is at station 560.5 and the bottom antenna is at station 480.

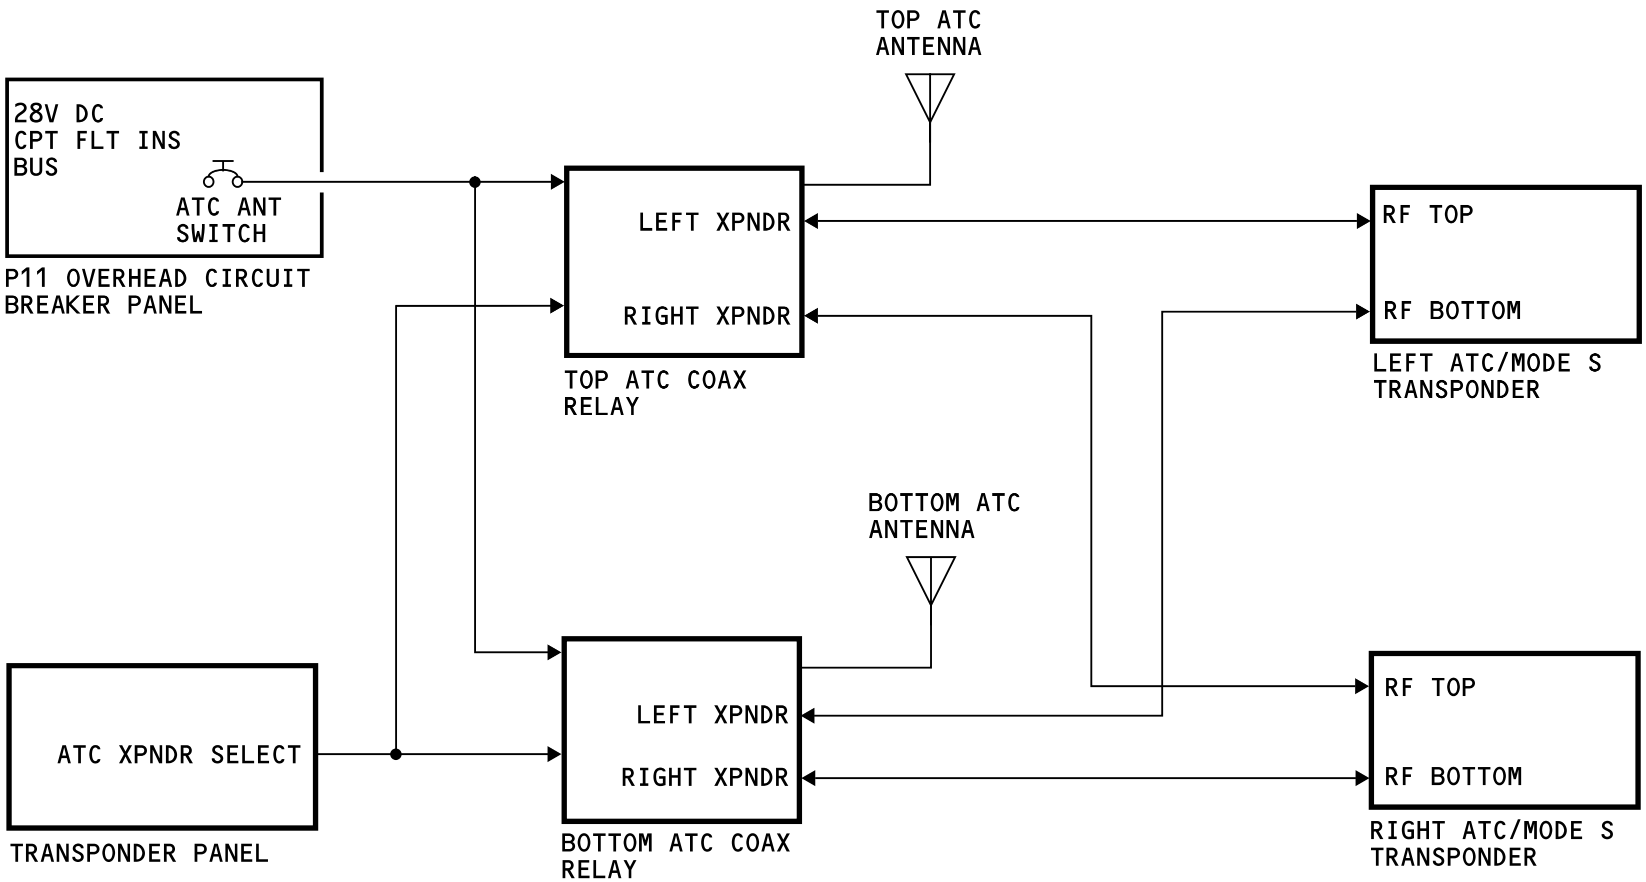


ATC/MODE S TRANSPONDER SYSTEM - ANTENNA LOCATION

ATC/MODE S TRANSPONDER SYSTEM - ANTENNA INTERFACE

General

When you select the left ATC/mode S transponder system, the ATC coax relays do not energize and the antennas connect to the left transponder. When you select the right ATC/mode S transponder system, the transponder panel sends a discrete to the ATC coax relays. This makes the top and bottom antennas connect to the right transponder.



34-53-00-005 Rev 1

ATC/MODE S TRANSPONDER SYSTEM - ANTENNA INTERFACE

ATC/MODE S TRANSPONDER SYSTEM - POWER, IDENTITY, CONTROL, AND AIR DATA INTERFACES

Power

The left ATC/Mode S transponder gets 115v ac power from the ac standby bus. The right ATC/Mode S transponder gets 115v ac power from the right ac transfer bus. The dual transponder panel gets 115v ac power from the ac standby bus.

Standby/On Discrete

The transponder panel sends a (ground) standby discrete to the transponder that is not in use.

Identity Code

The flight crew sets the four digit identity code and it shows on the transponder panel. Both transponders get the identity code from the transponder panel.

Control Data

The transponder panel also sends control data to the transponders. This control data does these functions:

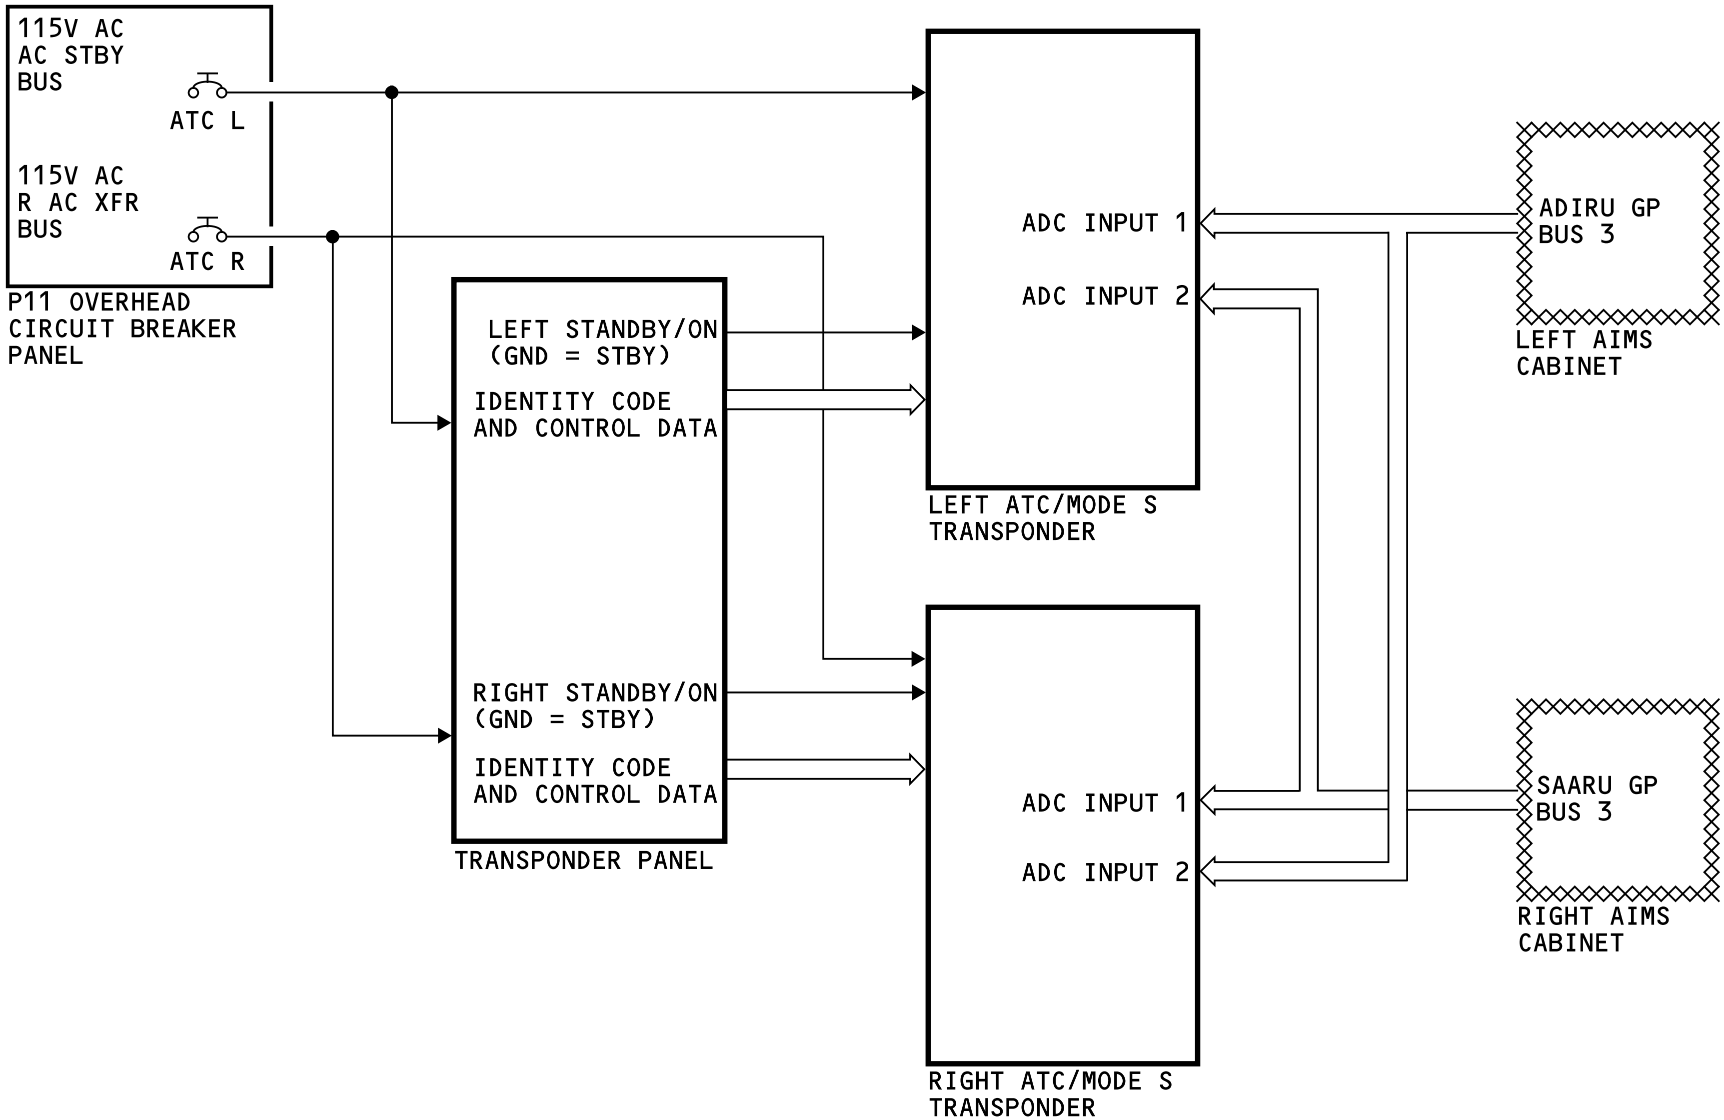
- Permit mode C altitude reporting
- Permit the transponder to send the special position identification (SPI) pulse or airplane identification code.

Air Data

The air data inertial reference unit (ADIRU) and the secondary attitude air data reference unit (SAARU) send air data to the AIMS cabinets. ATC/Mode S transponders receive the air data from both AIMS cabinets.

The left transponder gets air data at ADC input 1 from the ADIRU general purpose (GP) bus 3 from left AIMS cabinet. Air data at ADC input 2 comes from the SAARU GP bus 3 from the right AIMS cabinet.

The right transponder gets air data at ADC input 1 from the SAARU GP bus 3 of the right AIMS cabinet. Air data at ADC input 2 comes from the ADIRU GP bus 3 from the left AIMS cabinet.



34-53-00-007 Rev 2 03/23/1998

ATC/MODE S TRANSPONDER SYSTEM - POWER, IDENTITY, CONTROL, AND AIR DATA INTERFACES

ATC/MODE S TRANSPONDER SYSTEM - MAINTENANCE INTERFACE

Air/Ground

The air/ground discretes go through the transponder panel to the transponders.

The purpose of the air ground relay is to:

- Prevent ground tests of the ATC system in the air
- Define flight legs in the non-volatile memory if the CMCFs fail.

Transponder - Central Maintenance Computing Function Interface

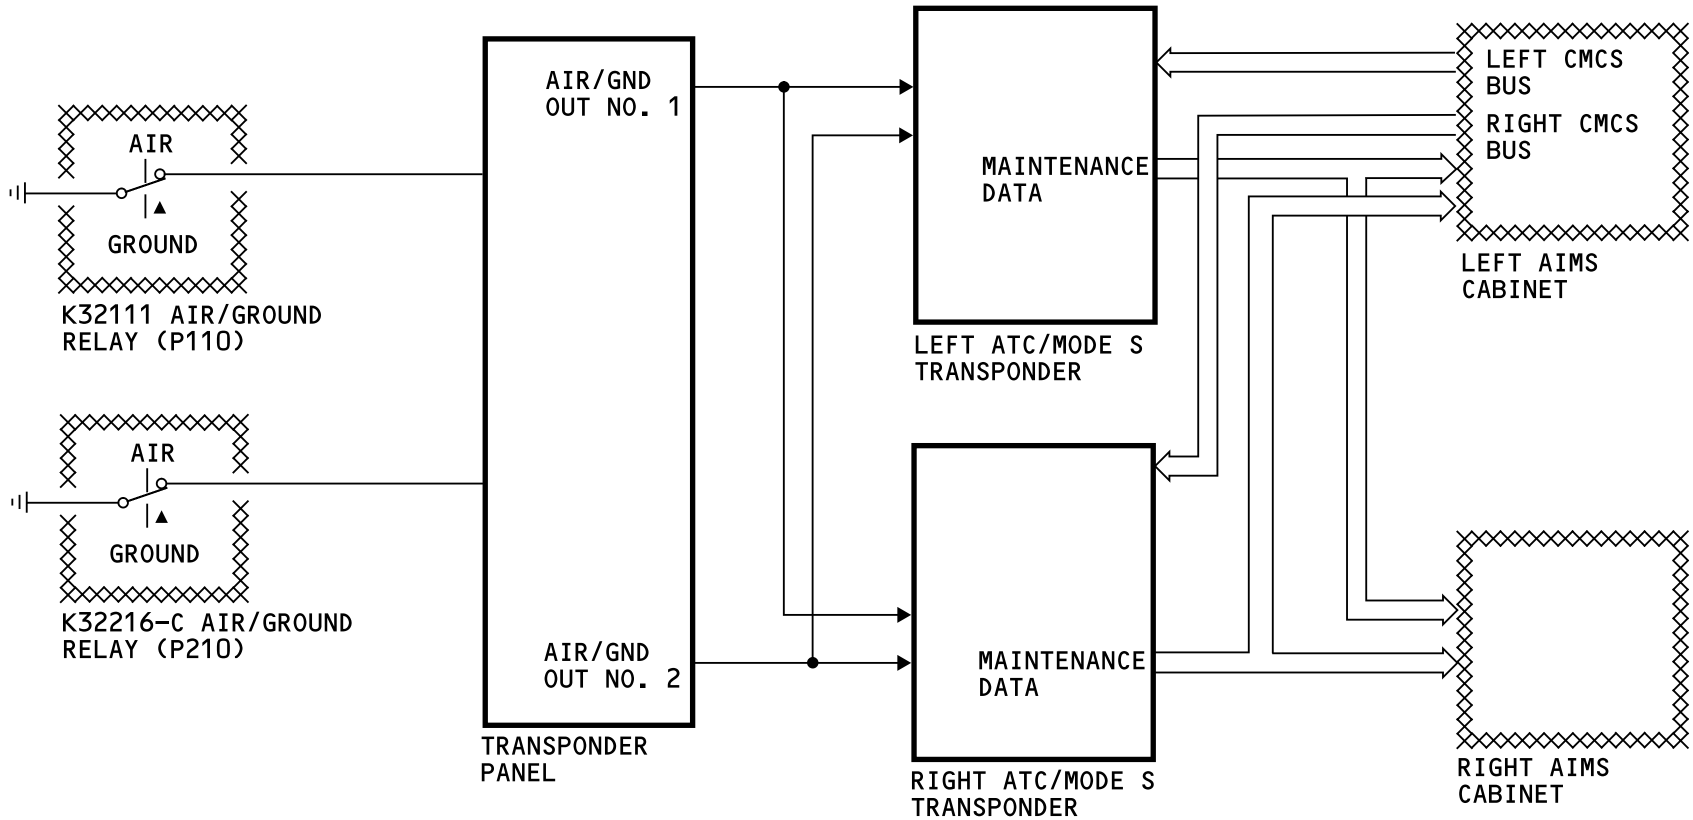
Each transponder has a maintenance interface to the central maintenance computing function (CMCF) of the AIMS cabinets.

The transponders continuously send ATC system maintenance data to the CMCFs in the AIMS cabinets.

The central maintenance computing function (CMCF) in the left AIMS cabinet sends data to both transponders to do these functions:

- Define flight legs for the non-volatile memory (NVM) in the transponder
- Command the ATC/Mode S transponder to start an ATC/Mode S transponder system test.

Use the maintenance access terminal (MAT) to start the ATC system test through the CMCFs.



34-53-00-008 Rev 0

ATC/MODE S TRANSPONDER SYSTEM - MAINTENANCE INTERFACE

ATC/MODE S TRANSPONDER SYSTEM - TCAS INTERFACE AND PROGRAM PINS

Program Pins

Each ATC/Mode S transponder has:

- Airplane mode S address program pins
- Source destination indicator (SDI) program pins
- Maximum true airspeed program pin.

There are 24 airplane address program pins on each transponder. A program switch module connects to the program pins. The program switch module supplies the open and ground connections necessary to make the 24 bit unique airplane identification.

The SDI defines the transponder as a left or right ATC/ Mode S transponder.

The maximum true airspeed pins define the maximum true airspeed for the airframe. The transponder formats and sends the maximum true airspeed to the TCAS computer.

Digital Data to TCAS

The active ATC/Mode S transponder sends this data to the traffic alert and collision avoidance system (TCAS) computer:

- The 24-bit mode S airplane identification. TCAS needs the airplane mode S identification for maneuver coordination
- Barometric altitude
- Maximum true airspeed
- TCAS coordination message data
- ATC/Mode S transponder system failure data.

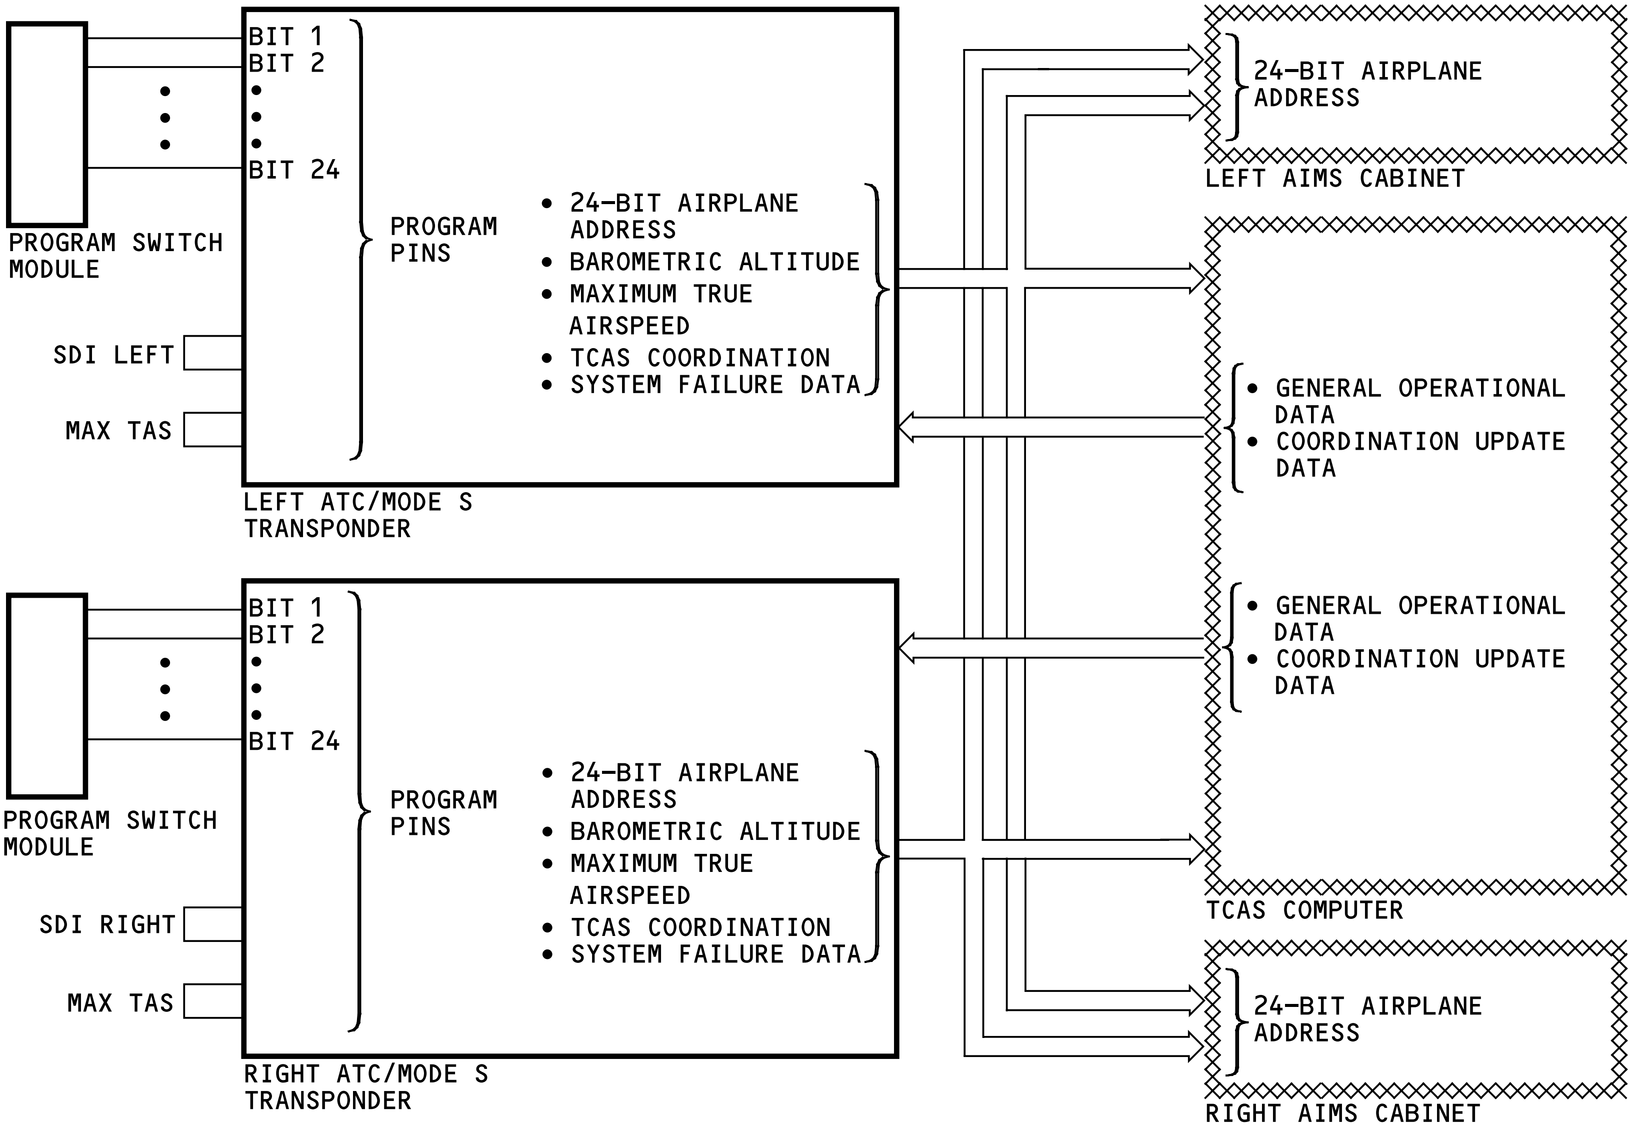
TCAS to Active Transponder

The TCAS computer sends this data to the active transponder:

- General TCAS operational data
- Coordination update data.

Digital Data to the AIMS Cabinets

The ATC/Mode S transponders send the airplane unique 24-bit mode S airplane identification to the AIMS cabinets for use in other systems.



34-53-00-009 Rev 1

ATC/MODE S TRANSPONDER SYSTEM - TCAS INTERFACE AND PROGRAM PINS

ATC/MODE S TRANSPONDER SYSTEM - ATC/MODE S TRANSPONDER

General

The ATC ground station interrogates the ATC/Mode S transponder with a pulse-coded signal at a frequency of 1030 MHz.

The transponder responds with pulse-coded signals at a frequency of 1090 MHz.

Characteristics

The transponder responds to air traffic control radar beacon system (ATCRBS) mode A and mode C interrogations. The transponder also responds to the TCAS computer with the mode select (mode S) format.

The ATC/Mode S transponder has a non-volatile flight-fault memory.

Front Panel Indications

The light emitting diode (LED) status indicators on the front panel show:

- Green PASS LED, if there are no LRU failures
- Red FAIL LED, if there is an LRU failure
- UPPER ANT, if the upper antenna fails
- LOWER ANT, if lower antenna fails
- ALT, if the altitude input from the AIMS cabinets fails
- CTL, if the input from the transponder panel fails.

The test switch starts a self-test.

Training Information Point

The maintenance manual and the fault isolation manual do not have a task for the line maintenance technician to do a test from the front panel of the ATC/mode S transponder. You must do all tests for the ATC/mode S transponder from the MAT or a PMAT.

Many LRUs on the 777 are compatible with other model airplanes that do not have a central maintenance computing system (CMCS). For that reason these LRUs have a front panel test feature.

ATC/MODE S TRANSPONDER SYSTEM - ATC/MODE S TRANSPONDER

THIS PAGE INTENTIONALLY LEFT BLANK

ATC/MODE S TRANSPONDER SYSTEM - TRANSPONDER PANEL

General

The dual transponder panel controls the ATC/Mode S transponder and the TCAS computer.

The ATC controls and displays on the transponder panel are:

- IDENT switch
- Four digit identification code
- Active system display
- Transponder mode selector
- Transponder code selectors
- Altitude source selector
- Transponder selector.

Altitude Source Selector

The altitude source selector has two positions, NORM and ALTN. Each transponder has two ADC inputs. With NORM selected, the active transponder uses the altitude data that comes from ADC input 1. With ALTN selected, the active transponder uses the altitude data that comes from ADC input 2.

Transponder Selector and Active System Display

The transponder selector has a left and a right transponder (XPNDR) position. With the left position selected, the control panel sends a ground standby/on discrete to the right transponder only. Then the right transponder is in standby. The left transponder is active.

With the right position selected, the control panel sends an open standby/on discrete to the right transponder to make it active. A ground standby/on discrete goes to the left transponder and an antenna transfer discrete goes to the ATC coax relays. This puts the left transponder in standby, and makes the relays connect the ATC antennas to the right transponder.

The selected ATC system shows on the LCD active system display.

Identification Code Display and Selection

The flight crew uses the code selectors to set the four digits of the identification code. The four digits show on the liquid crystal display (LCD). Codes are from 0000 to 7777, with 4096 different selections.

CAUTION: DO NOT SELECT CODES 7500, 7600 OR 7700. THESE CODES ARE USED ONLY FOR EMERGENCIES.

Transponder Mode Selector

The transponder mode selector has several positions. These are the functions that the ATC system uses:

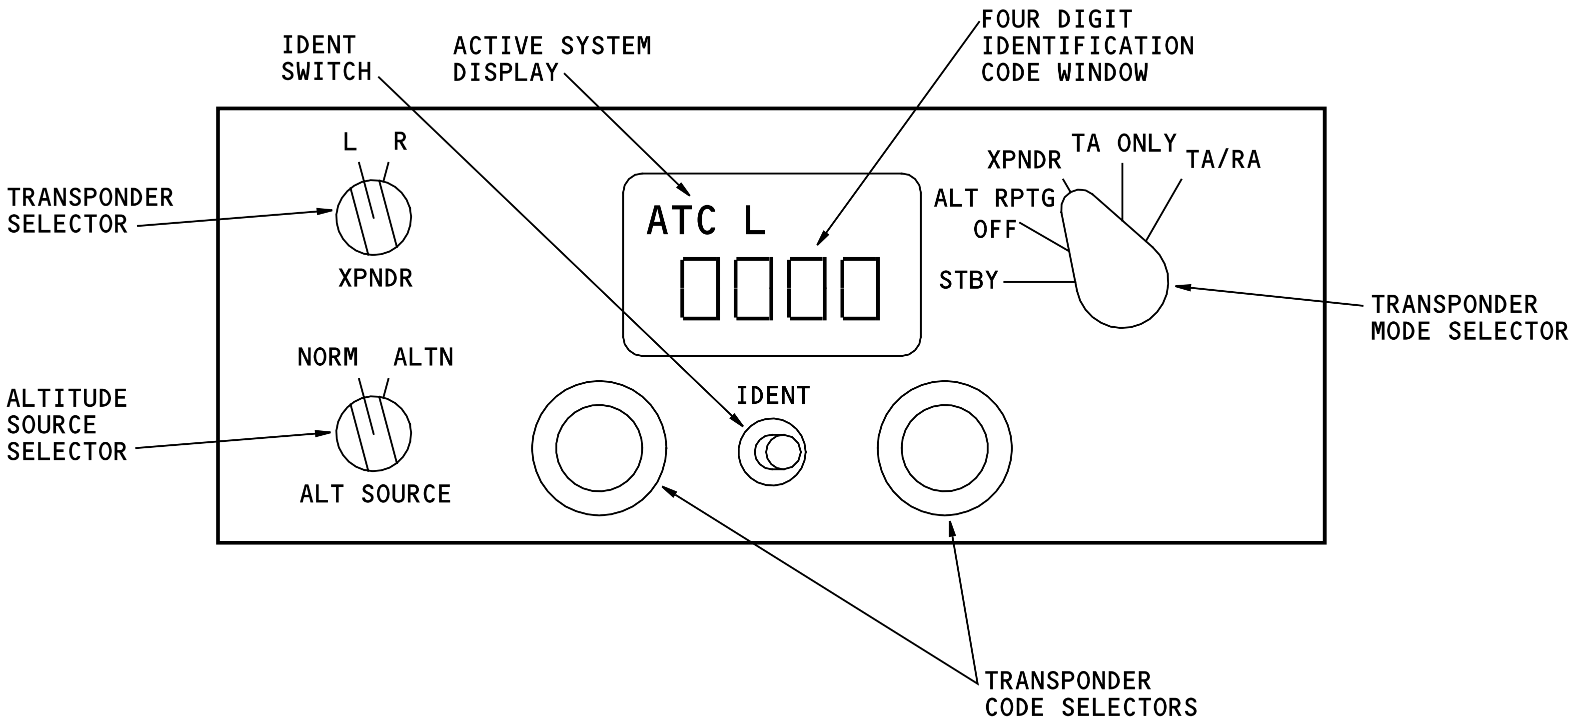
- STBY (standby) - a ground discrete goes to both transponders. This ground discrete prevents operation of the transponder, but does not prevent built-in-test-equipment (BITE) functions.

ATC/MODE S TRANSPONDER SYSTEM - TRANSPONDER PANEL

- ALT RPTG OFF (altitude reporting off) - the active transponder responds to ATC interrogations with mode A replies only.
- XPNDR (transponder) - the active transponder responds to ATC interrogations with mode A and mode C (altitude reporting) replies.

IDENT Switch

When the ATC controller requests the airplane identifier, the pilot pushes the momentary IDENT switch. The transponder adds a special position identification (SPI) pulse to the interrogation reply for the next 18 seconds.



34-53-00-012 Rev 5 09/18/96

ATC/MODE S TRANSPONDER SYSTEM - TRANSPONDER PANEL

ATC/MODE S TRANSPONDER SYSTEM - ATC ANTENNA

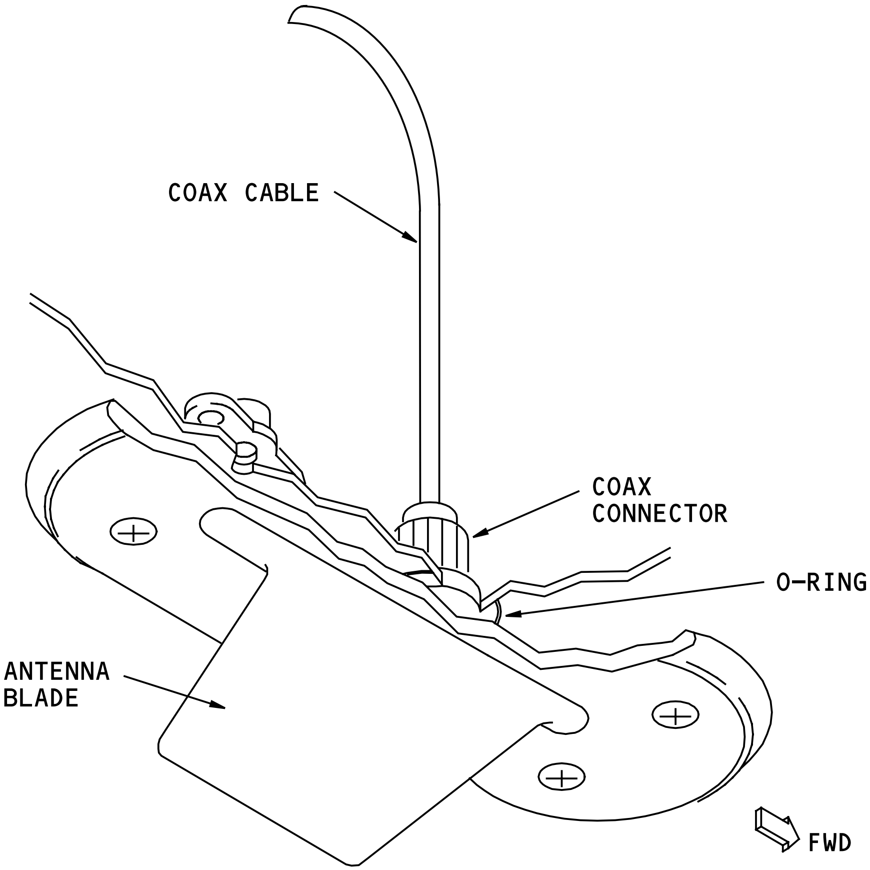
Purpose

The ATC L-band blade antenna receives 1030 MHZ interrogations from ATC ground stations and other airplanes that have TCAS. The ATC/Mode S transponder transmits the reply signals through the L-band antenna.

Physical Description

Connect the coaxial cable connector to the antenna. The antenna has an O-ring moisture seal and attaches to the airplane by four screws. The ATC and DME antennas are the same and are interchangable.

CAUTION: EXTRA FORCE ON THE ANTENNA BASE MAY BE REQUIRED TO BREAK WEATHERPROOFING SEAL. TO PREVENT DAMAGE TO AIRPLANE SKIN OR ELECTRICAL CABLE AT THE ANTENNA BASE, CAREFULLY PRY AROUND THE ANTENNA WITH A SEALANT REMOVAL TOOL.



34-53-00-013 Rev 1

ATC/MODE S TRANSPONDER SYSTEM - ATC ANTENNA

ATC/MODE S TRANSPONDER SYSTEM - ATC COAX RELAY

General

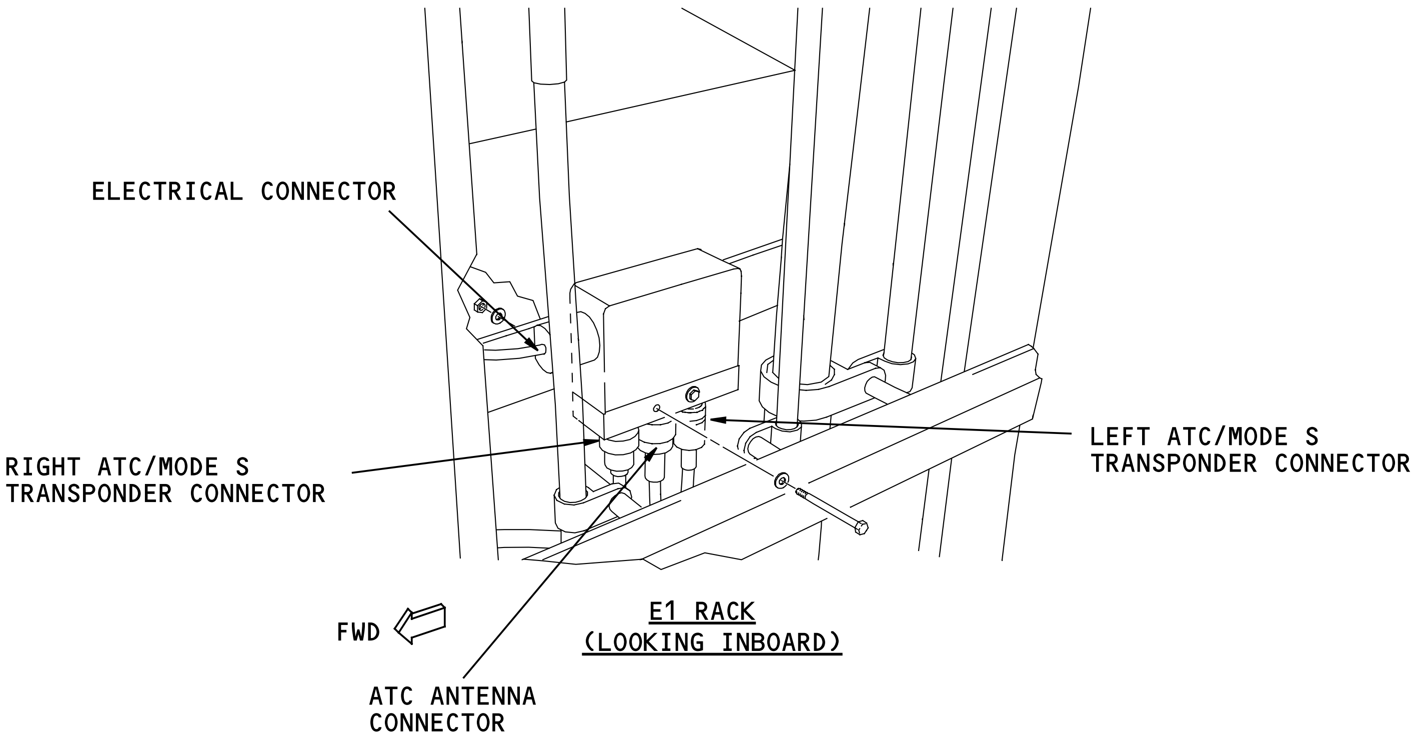
The ATC coax relays connect the active ATC/Mode S transponder to the top and bottom ATC antennas.

The electrical connector has an input from the:

- ATC antenna switch circuit breaker
- ATC control panel.

The ATC coax relays supply an RF interface for the ATC system interrogation and reply signals. These are the connectors:

- Right ATC/mode S transponder connector
- ATC antenna connector
- Left ATC/mode S transponder connector.



34-53-00-014 Rev 1

ATC/MODE S TRANSPONDER SYSTEM - ATC COAX RELAY

ATC/MODE S TRANSPONDER SYSTEM - ANTENNA COAX RELAY CONTROL

General

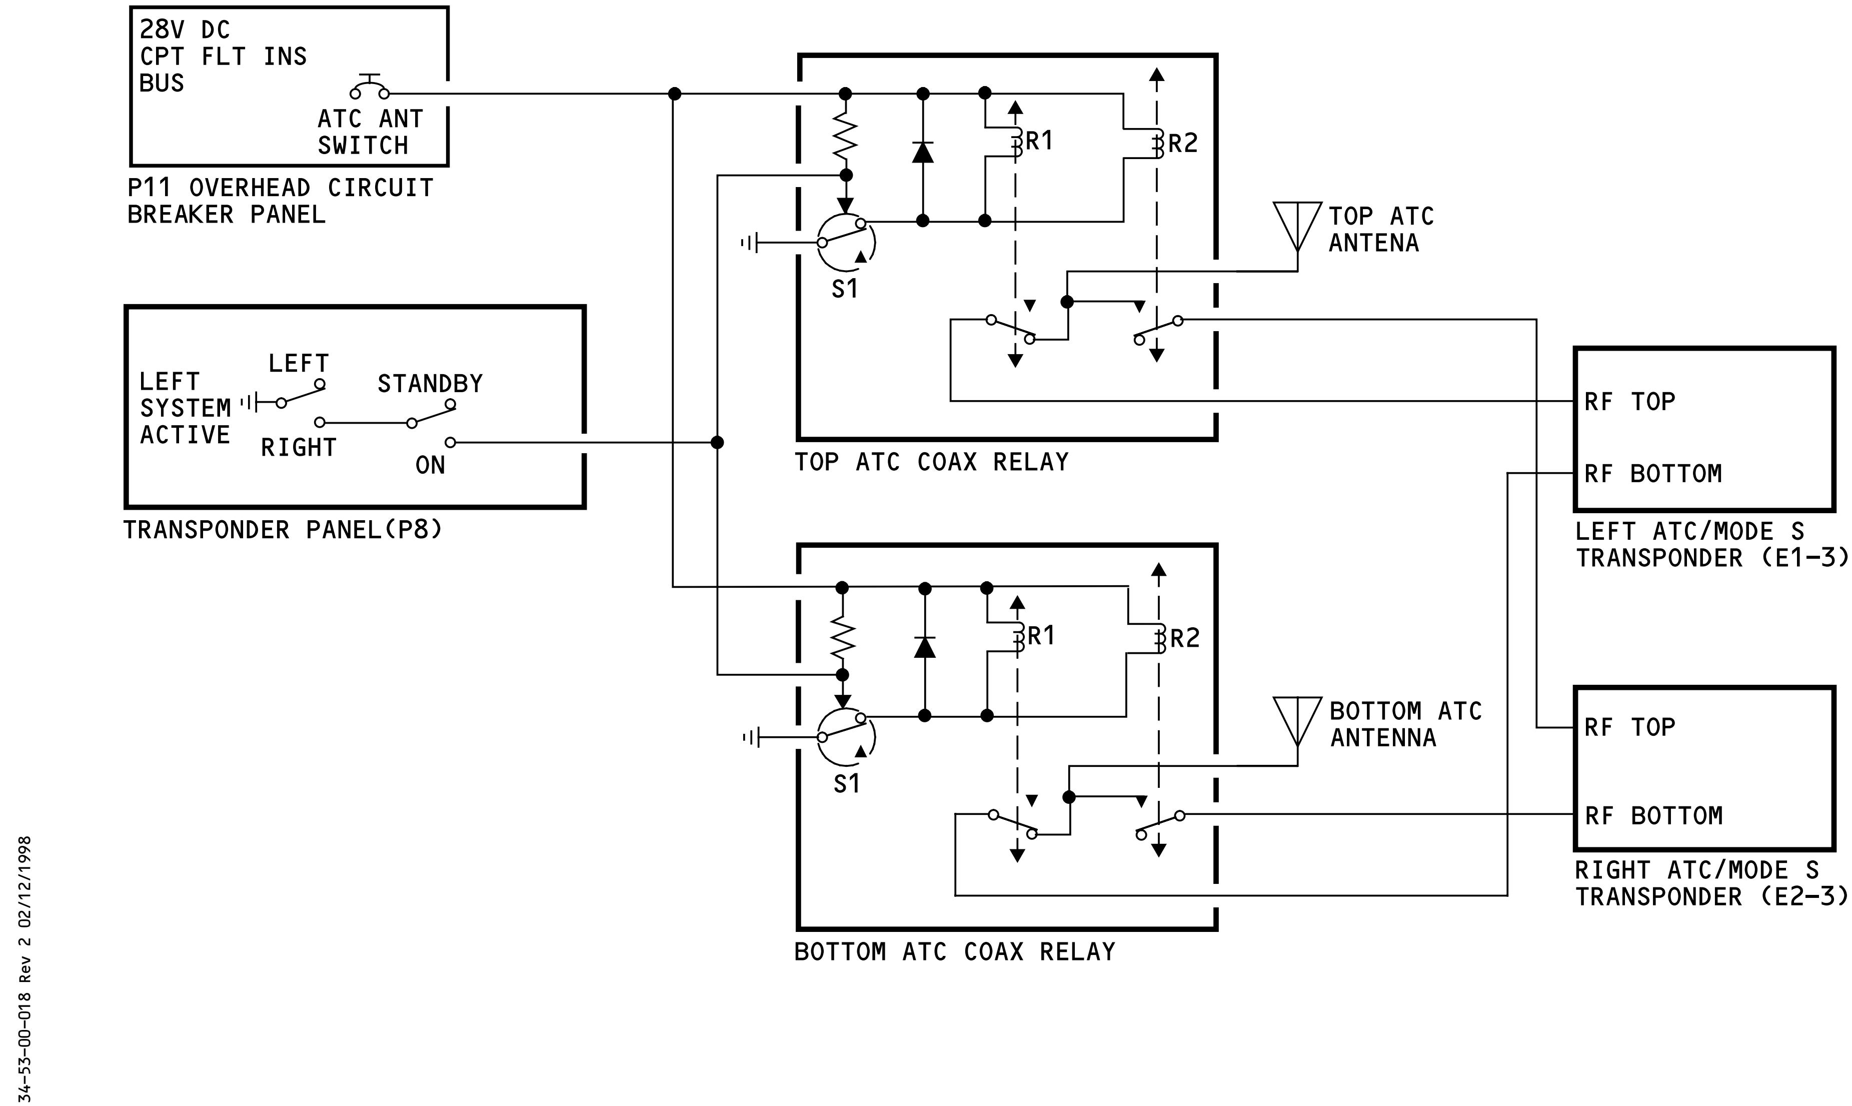
Use the transponder panel to select the active ATC system. When you do this, the transponder panel sends a discrete open or ground to the top and bottom ATC coax relays. This connects the right transponder or left transponder to the top and bottom ATC antennas.

Left System Select or Standby

When the airplane power is on and when the transponder panel has the left transponder or standby selected, the S1 switches open and relays R1 and R2 do not energize. The top and bottom antennas connect to the left ATC/ Mode S transponder.

Right System Select

With the right transponder selected, switch S1 closes to supply a ground to energize relay R1 and R2. The top and bottom antennas connect to the right ATC/Mode S transponder.



ATC/MODE S TRANSPONDER SYSTEM - ANTENNA COAX RELAY CONTROL

ATC/MODE S TRANSPONDER SYSTEM - GROUND TESTS

General

You can do a system test of the ATC/Mode S transponder system from the MAT.

System Test

There is a system test for the left ATC/Mode S transponder system and the right ATC/Mode S transponder system.

The system test for the ATC/Mode S transponder system does a check of these functions:

- Transponder for correct operation
- Transponder panel for correct control data
- Antennas for correct impedance
- Altitude input for correct altitude data.

Traffic Alert and Collision Avoidance System

WB371

TABLE OF CONTENTS

THIS PAGE INTENTIONALLY LEFT BLANK

TRAFFIC ALERT AND COLLISION AVOIDANCE SYSTEM - INTRODUCTION

General

The traffic alert and collision avoidance system (TCAS) helps the flight crew and air traffic control maintain safe air traffic separation. TCAS is an airborne system. TCAS uses an air traffic control radar beacon system (ATCRBS) transponder or an ATC/Mode S transponder to track other airplanes. TCAS also coordinates maneuvers with other airplanes that have TCAS.

TCAS supplies a traffic display and visual and aural vertical commands to the flight crew. All commercial airlines and some general aviation airplanes have TCAS.

TRAFFIC ALERT AND COLLISION AVOIDANCE SYSTEM - INTRODUCTION

TCAS - GENERAL DESCRIPTION

General

The traffic alert and collision avoidance system (TCAS) interrogates other airplanes to get altitude, range, and bearing data. TCAS uses the replies and inputs from other onboard airplanes systems to calculate traffic avoidance data.

General Description

These are the TCAS components:

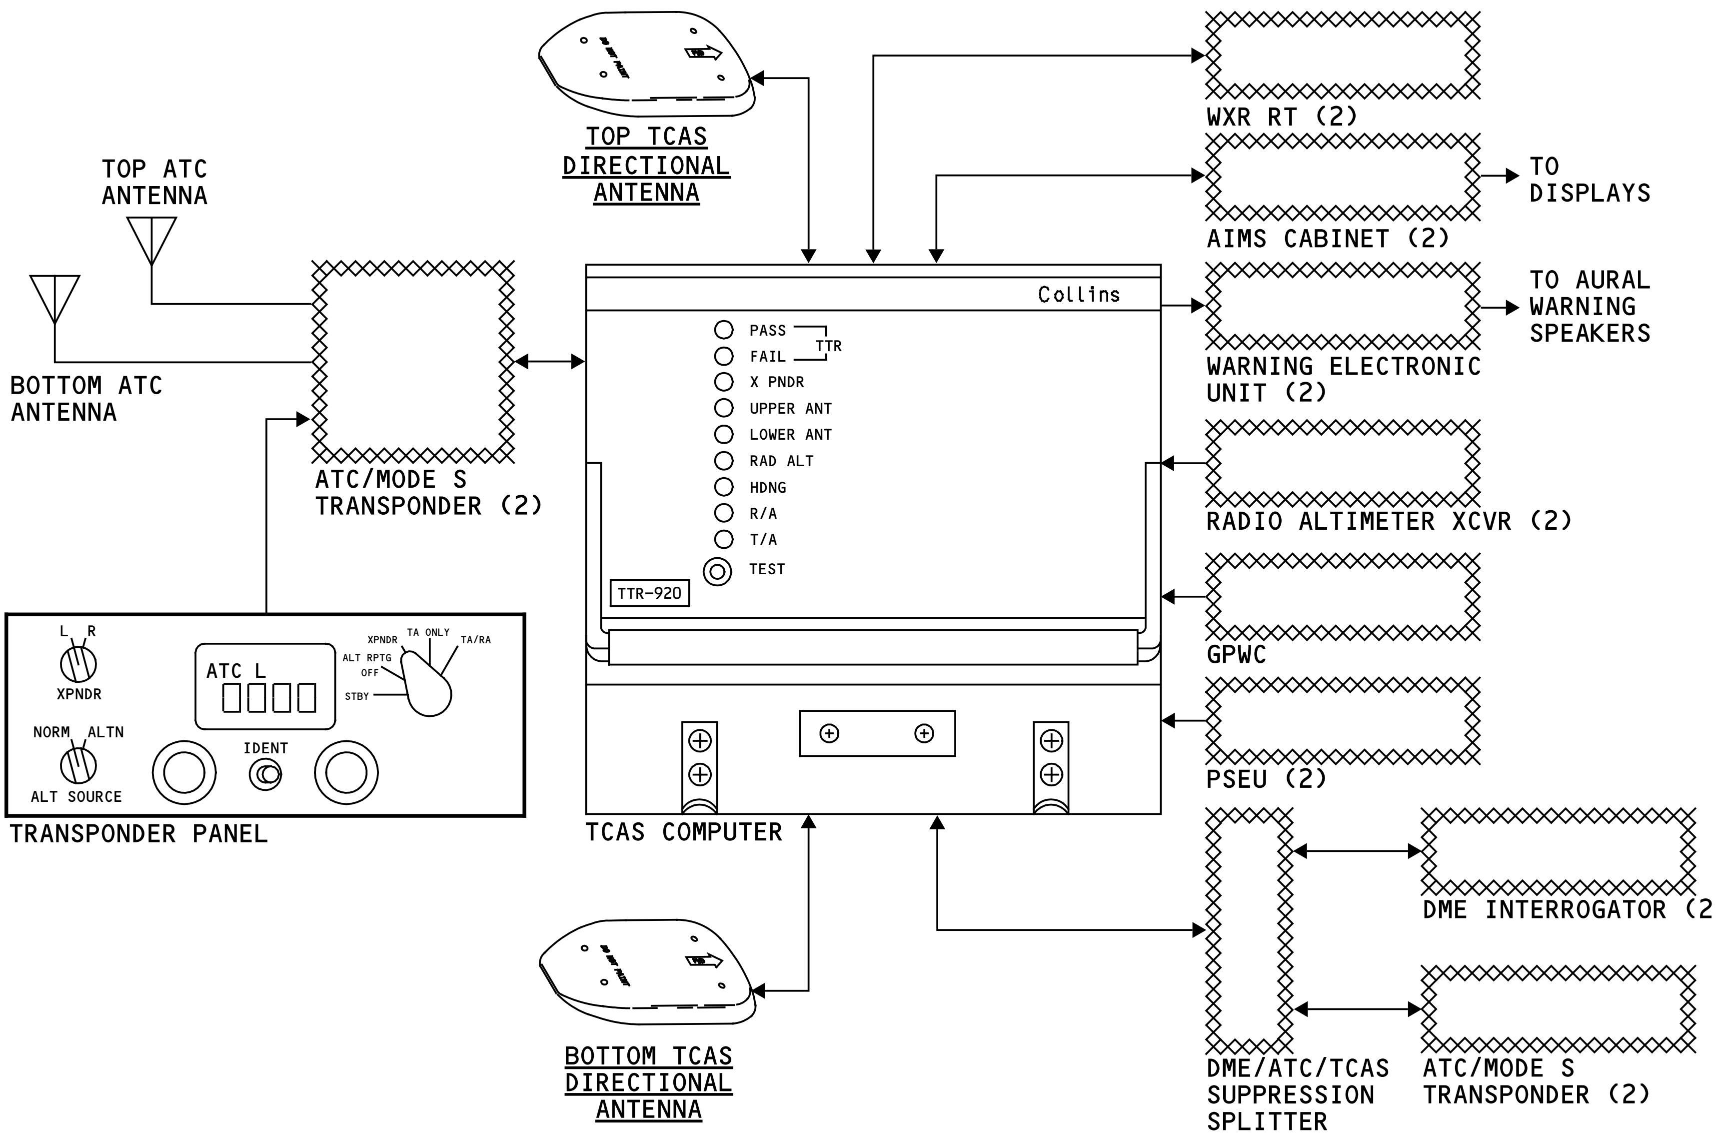
- ATC antennas
- Transponder panel
- TCAS directional antennas
- TCAS computer.

TCAS interfaces with these other system components:

- Left and right airplane information management system (AIMS) cabinets
- Left and right ATC/Mode S transponders
- Left and right warning electronic units (WEUs)
- Left and right radio altimeters
- Ground proximity warning computer (GPWC)
- Left and right weather radar receiver-transmitters (R/Ts)
- Left and right proximity switch electronic units (PSEUs).

Suppression

The TCAS computer connects to the DME interrogators and the ATC transponders through a suppression splitter.



TCAS - GENERAL DESCRIPTION

TCAS - COMPONENT LOCATION

Main Equipment Center

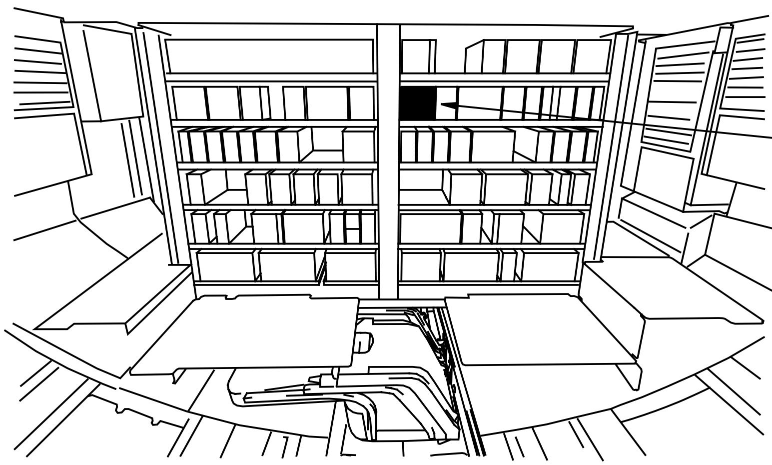
The TCAS computer is in the main equipment center.

Flight Deck

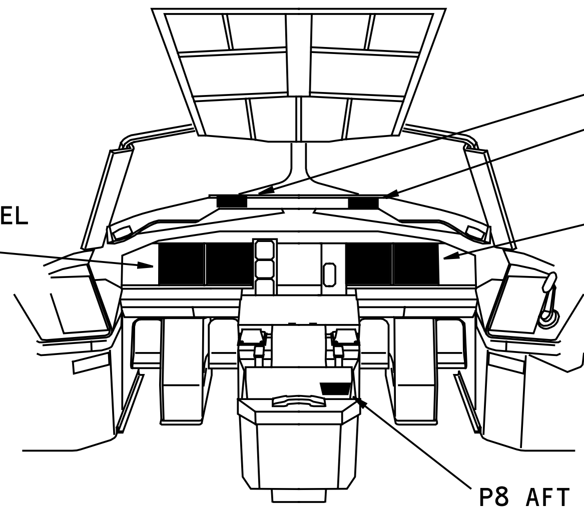
These are the components in the flight deck that interface with TCAS:

- Left EFIS control panel
- Captain's primary flight display (PFD)
- Captain's navigation display (ND)
- Right EFIS control panel
- First officer's PFD
- First officer's ND.

The transponder panel is on the P8 aft aisle stand panel.



MAIN EQUIPMENT CENTER
(LOOKING AFT)

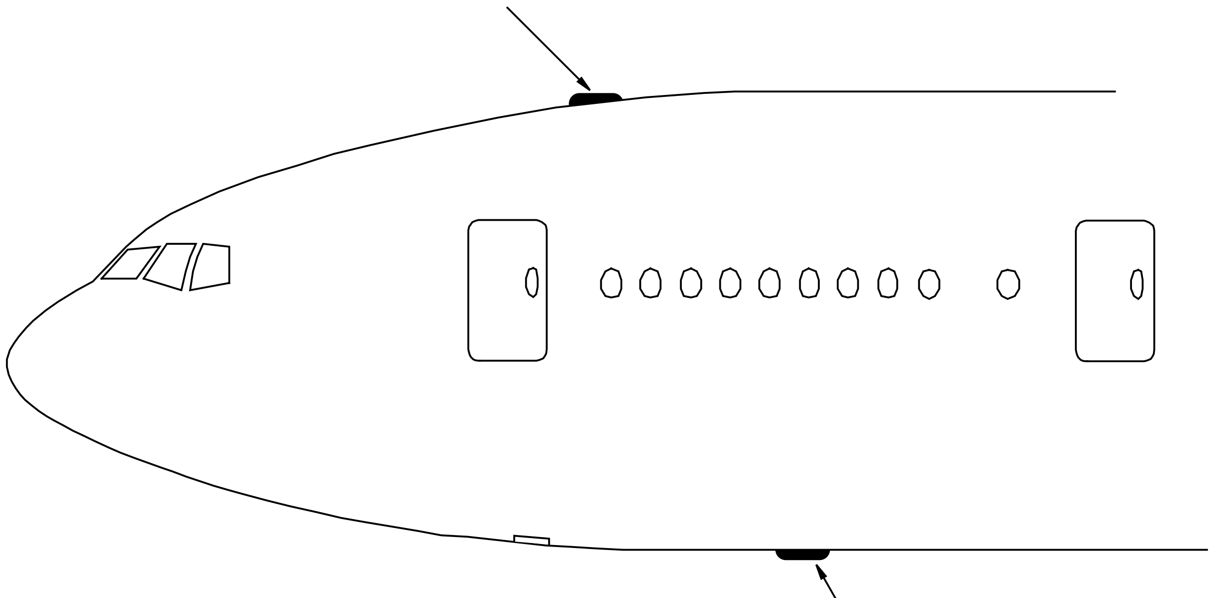


TCAS - COMPONENT LOCATION

TCAS - ANTENNA LOCATION

General

The top TCAS directional antenna is at station 455.5 on top of the fuselage. The bottom TCAS directional antenna is at station 539 and buttock line left 6.3.



TCAS - ANTENNA LOCATION

THIS PAGE INTENTIONALLY LEFT BLANK

TCAS - POWER, ANTENNAS, ANALOG DISCRETE INTERFACES AND PROGRAM PINS

General

The TCAS computer has interfaces with these components:

- Overhead circuit breaker panel
- Top and bottom TCAS directional antennas
- Left AIMS cabinet
- Right AIMS cabinet
- Air/ground relay
- Ground proximity warning computer (GPWC)
- Proximity sensor electronics unit (PSEU) 1
- PSEU 2
- DME/ATC/TCAS suppression splitter
- Left warning electronic unit (WEU)
- Left WXR RT
- Right WXR RT
- Right WEU.

There are program pins to supply control of the TCAS computer.

Power

The TCAS computer gets 115v ac from the left ac secondary 2 bus, through the overhead circuit breaker panel.

Antennas

There are two TCAS directional antennas, one on the top and one on the bottom of the airplane. The TCAS directional antennas receive traffic airplane reply signals. They also transmit the TCAS interrogation signals.

AIMS - Display Status

An analog discrete from either AIMS cabinet goes to the TCAS computer when the display function of AIMS fails. When the TCAS computer gets this discrete, the TCAS computer does not do these functions:

- Send TCAS display outputs to the AIMS
- Send TCAS aurals to the warning electronic system (WES)
- Transmit coordination data to traffic airplanes with TCAS.

Air/Ground Relay

This discrete from the air/ground relay supplies in-air or on-ground status to the TCAS computer. The air/ground discrete inhibits resolution advisories (RAs) when the airplane is on the ground and inhibits tests when in the air. Also, the air/ground discrete increments flight legs in the TCAS nonvolatile memory when the central maintenance computing system (CMCS) fails.

GPWC - Advisory Delay Discretes

The GPWC sends three analog discretes to the TCAS computer. These discretes inhibit advisories during some ground proximity warning and alert conditions.

TCAS - POWER, ANTENNAS, ANALOG DISCRETE INTERFACES AND PROGRAM PINS

PSEU - Landing Gear Position

This analog discrete from the PSEUs supply the TCAS computer with the position of the landing gear. When the TCAS computer gets this discrete, the TCAS computer makes the bottom directional antenna become an omnidirectional antenna.

Suppression Input/Output

The TCAS computer gets a suppression pulse when an ATC transponder or DME interrogator transmits. When the TCAS computer transmits, it sends a suppression pulse to the ATC transponders and the DME interrogators.

WEU - TCAS Aurals - Voice Outputs

The TCAS computer sends RA and TA aural signals to the warning electronic units (WEUs). The WEUs amplify the RA and TA aurals and send them to the aural warning speakers to alert the flight crew.

WXR - TCAS Alert Inhibit

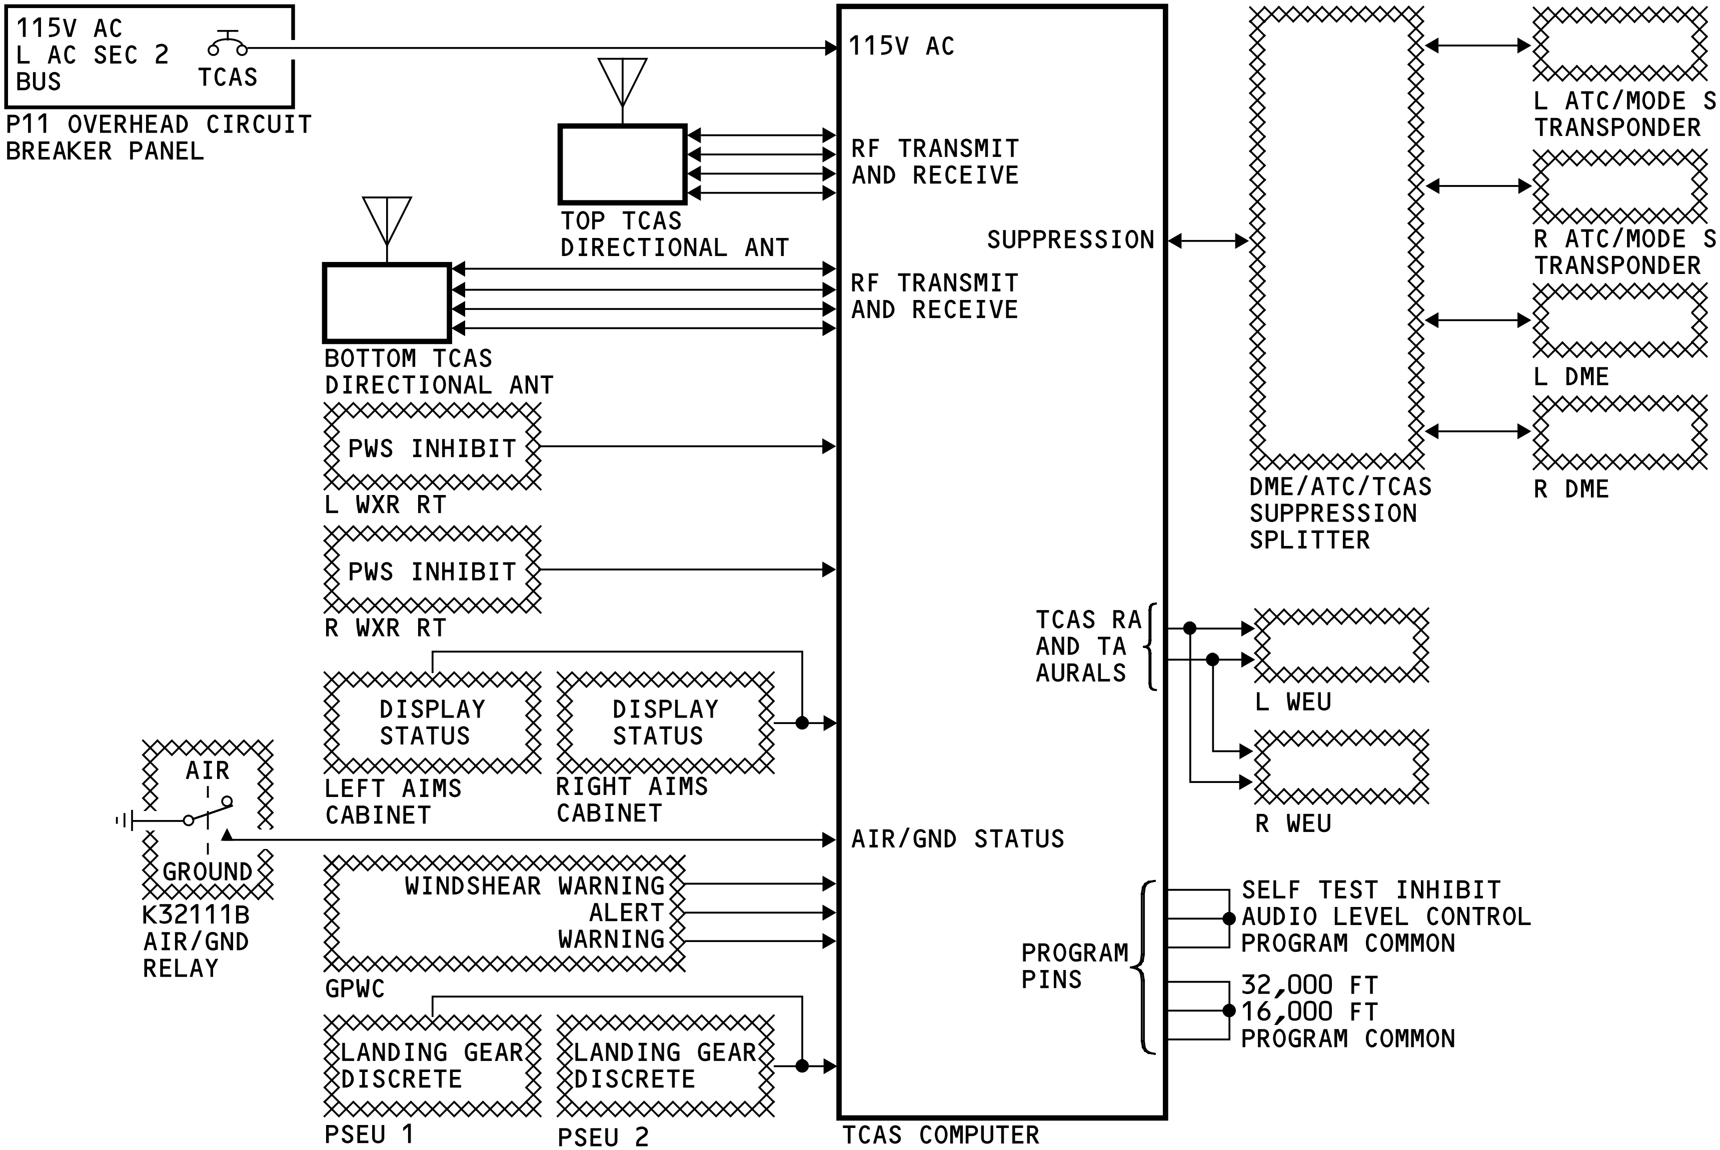
The TCAS computer gets an inhibit discrete from the predictive windshear (PWS) function of WXR. When there is a PWS alert, this discrete does these functions:

- Changes TCAS resolution advisories (RAs) to traffic advisories (TAs)
- Inhibits TCAS aural alerts.

Program Pins

These are the functions that the program pins on the TCAS computer enable:

- A self-test inhibit to prevent self-test in the air
- The audio level of the voice outputs
- The airplane altitude limit of 48,000 feet so TCAS does not command a climb or increase climb above this altitude.



TCAS - POWER, ANTENNAS, ANALOG DISCRETE INTERFACES AND PROGRAM PINS

TCAS - DIGITAL INTERFACES

General

The TCAS computer has digital interfaces with the:

- Left ATC/Mode S transponder
- Right ATC/Mode S transponder
- Left radio altimeter transceiver
- Right radio altimeter transceiver
- Left AIMS cabinet
- Right AIMS cabinet.

ATC/Mode S Transponder - Control and Coordination Data

The dual transponder panel sends this control data through the selected ATC/Mode S transponder to the TCAS computer:

- The TCAS mode selection (TA only or TA/RA)
- Control of the altitude limits for the TCAS display that shows on the ND.

For the TCAS computer to calculate coordination data, ATC transponder sends this to the TCAS computer:

- 24-bit airplane address
- Barometric altitude
- Maximum true airspeed.

The TCAS computer sends this to the transponder:

- General TCAS operational status
- Mode S coordination data.

Radio Altimeter Inputs

The TCAS computer gets radio altitude from the left and right radio altimeter transceivers.

TCAS Inputs from AIMS

The left AIMS cabinet supplies these inputs to the TCAS computer:

- Inertial reference unit (IRU) data from the air data inertial reference system (ADIRS).
- Data loader data
- Data loader enable analog discrete
- Central maintenance computing system (CMCS) data.

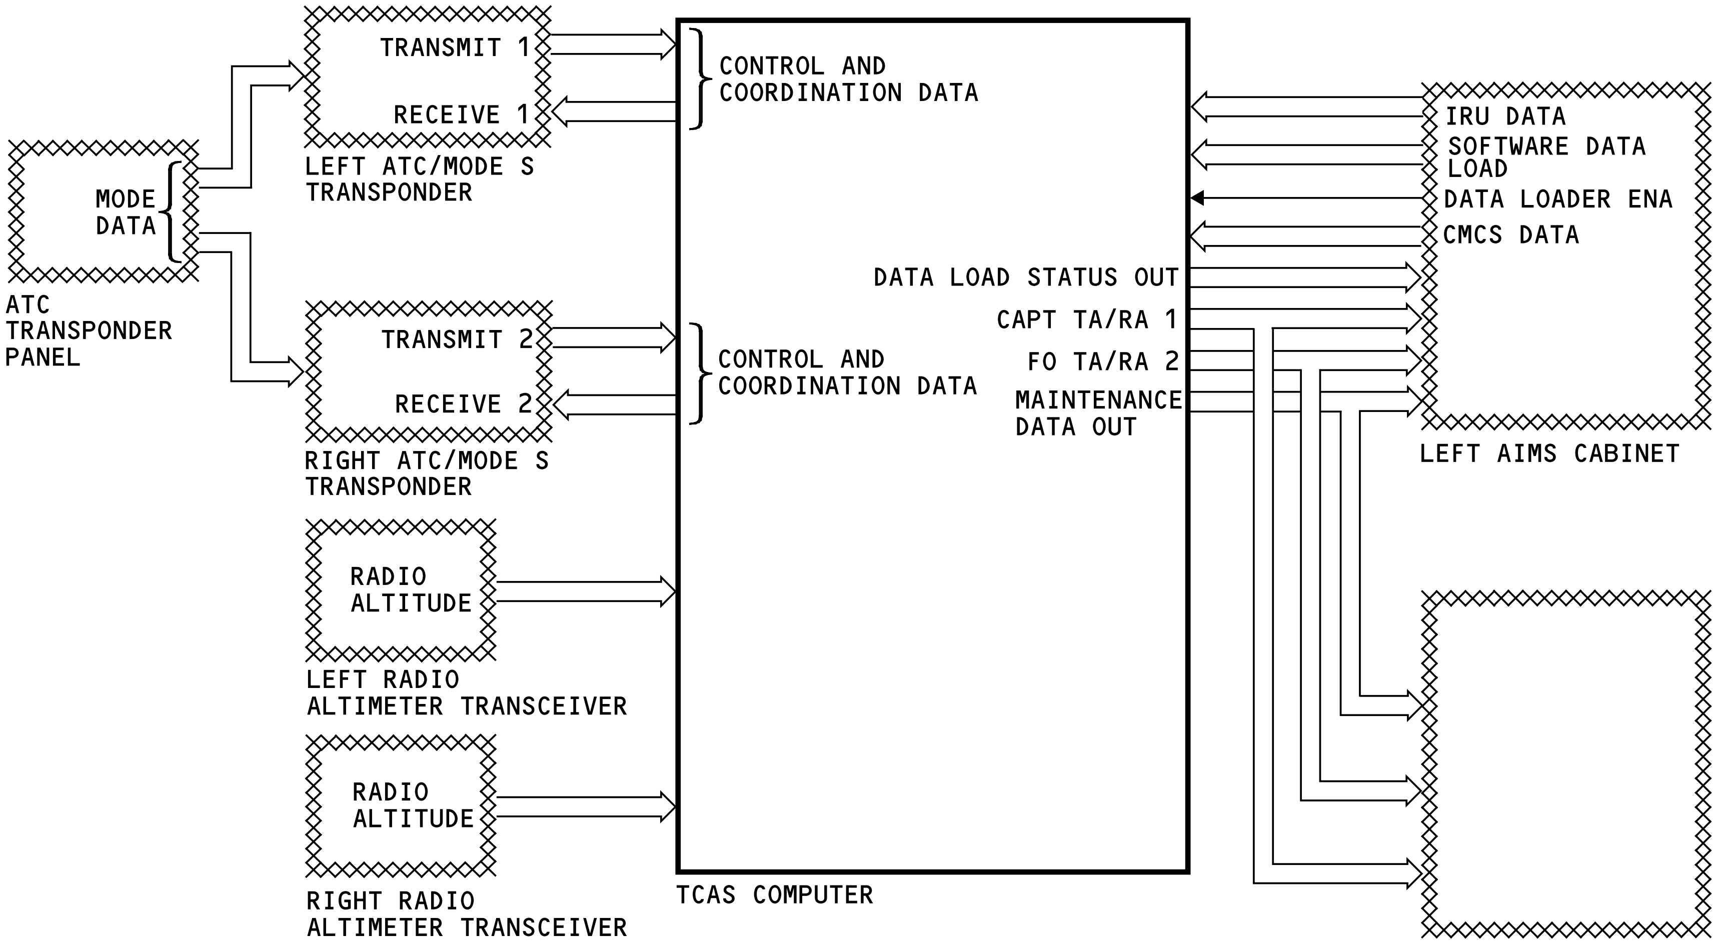
The right AIMS cabinet does not supply any inputs to the TCAS computer.

TCAS Outputs to AIMS

The TCAS computer sends TCAS data load status to the left AIMS cabinet.

The TCAS computer supplies these outputs to both AIMS cabinets:

- Traffic advisory (TA) and resolution advisory (RA) data, which includes all traffic data for TCAS displays
- TCAS maintenance data.



34-45-00-007 Rev 2 01/27/1998

TCAS - DIGITAL INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

TCAS - TCAS COMPUTER

Purpose

The TCAS computer is the main component of the TCAS. It controls these functions:

- Surveillance
- Tracking
- Advisory
- Air-to-air maneuver coordination.

The TCAS computer sends signals alert the flight crew to:

- Maintain the current flight plan
- Make flight maneuvers to avoid a possible collision with other airplanes in the area.

Physical Description

The TCAS computer is a 6 MCU size unit that weighs 28 lbs.

Functional Description

The TCAS computer transmits 1030 MHz pulse-coded interrogation signals. It receives 1090 MHz pulse-coded reply signals from intruder airplanes with a transponder.

Front Panel LED Indications

The status light emitting diodes (LEDs) are:

- A green PASS to show that there is no TCAS computer failures
- A red FAIL to show a TCAS computer failure
- A red XPNDR to show an ATC transponder interface failure
- A red UPPER ANT to show a top TCAS antenna failure
- A red LOWER ANT to show a bottom TCAS antenna failure
- A red RAD ALT to show no radio altitude data from the RA
- A red HDNG to show no heading data from the AIMS
- A red R/A to show an AIMS display function failure
- The red T/A does not operate.

Front Panel Self-Test

Push the test switch on the front panel to start a test of TCAS. The applicable LED indications come on.

Software Loading

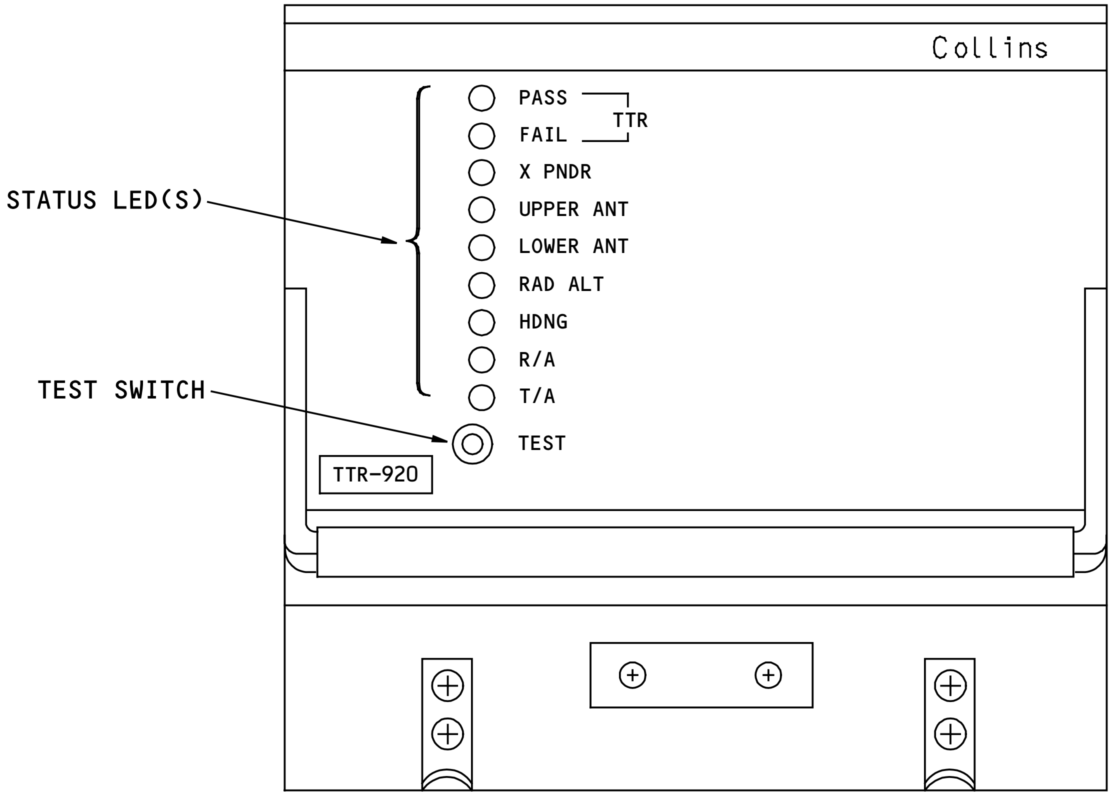
The TCAS computer is software loadable. Use the maintenance access terminal (MAT) to load the operational software into the TCAS computer.

Training Information Point

The TCAS computer receives data load information from the left central maintenance computing function (CMCF) only. You must use the left CMCF when you want to data load the TCAS computer.

TCAS - TCAS COMPUTER

Use the central maintenance computer switch control from the other functions menu on the MAT to select the active CMCF.



34-45-00-008 Rev 3 03/28/96

TCAS - TCAS COMPUTER

TCAS - TRANSPONDER PANEL

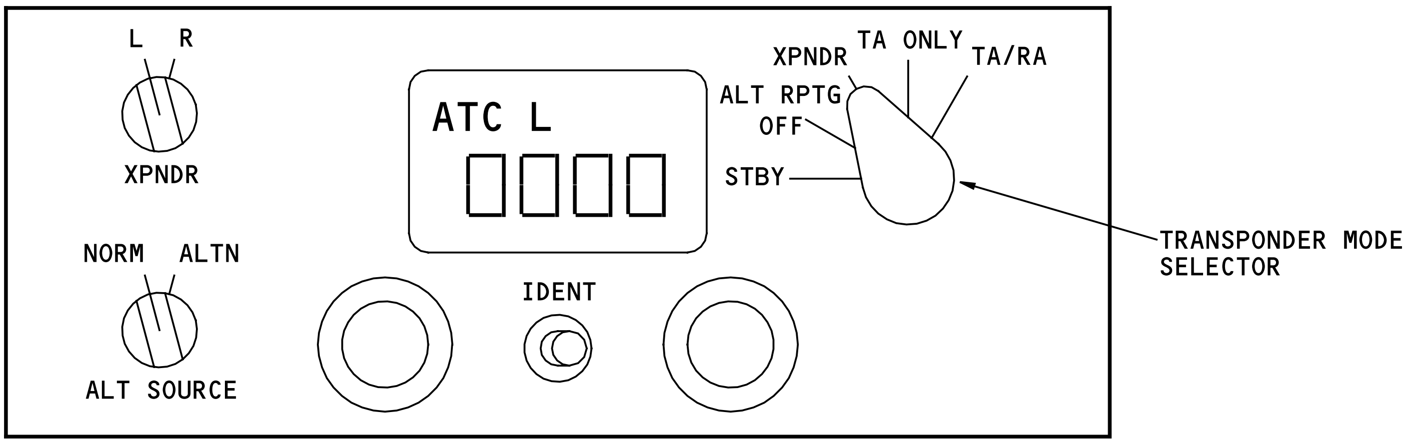
General

The transponder panel controls the TCAS computer to send the selected display data to the AIMS.

Transponder Mode Selector

The transponder mode selector lets the flight crew select one of these two TCAS modes:

- TA ONLY mode. In this mode, all intruder traffic except RAs show
- TA/RA mode. In this mode, all intruder traffic shows. This is the normal mode of operation for TCAS.



34-45-00-009 Rev 4 09/18/96

TCAS - TRANSPONDER PANEL

TCAS - TCAS DIRECTIONAL ANTENNA

General

The TCAS uses a top and bottom directional antenna. The antennas are the same and interchangeable.

Physical Description

The directional antenna is a phased array antenna. Four array elements on the antenna make up the array. Each element has a color coded connector. The TCAS computer sends the array elements transmit interrogation signals with different phases. This makes the interrogation signal directional.

To attach the antenna, match the color of the coaxial cable with the color coded band on the array element connector.

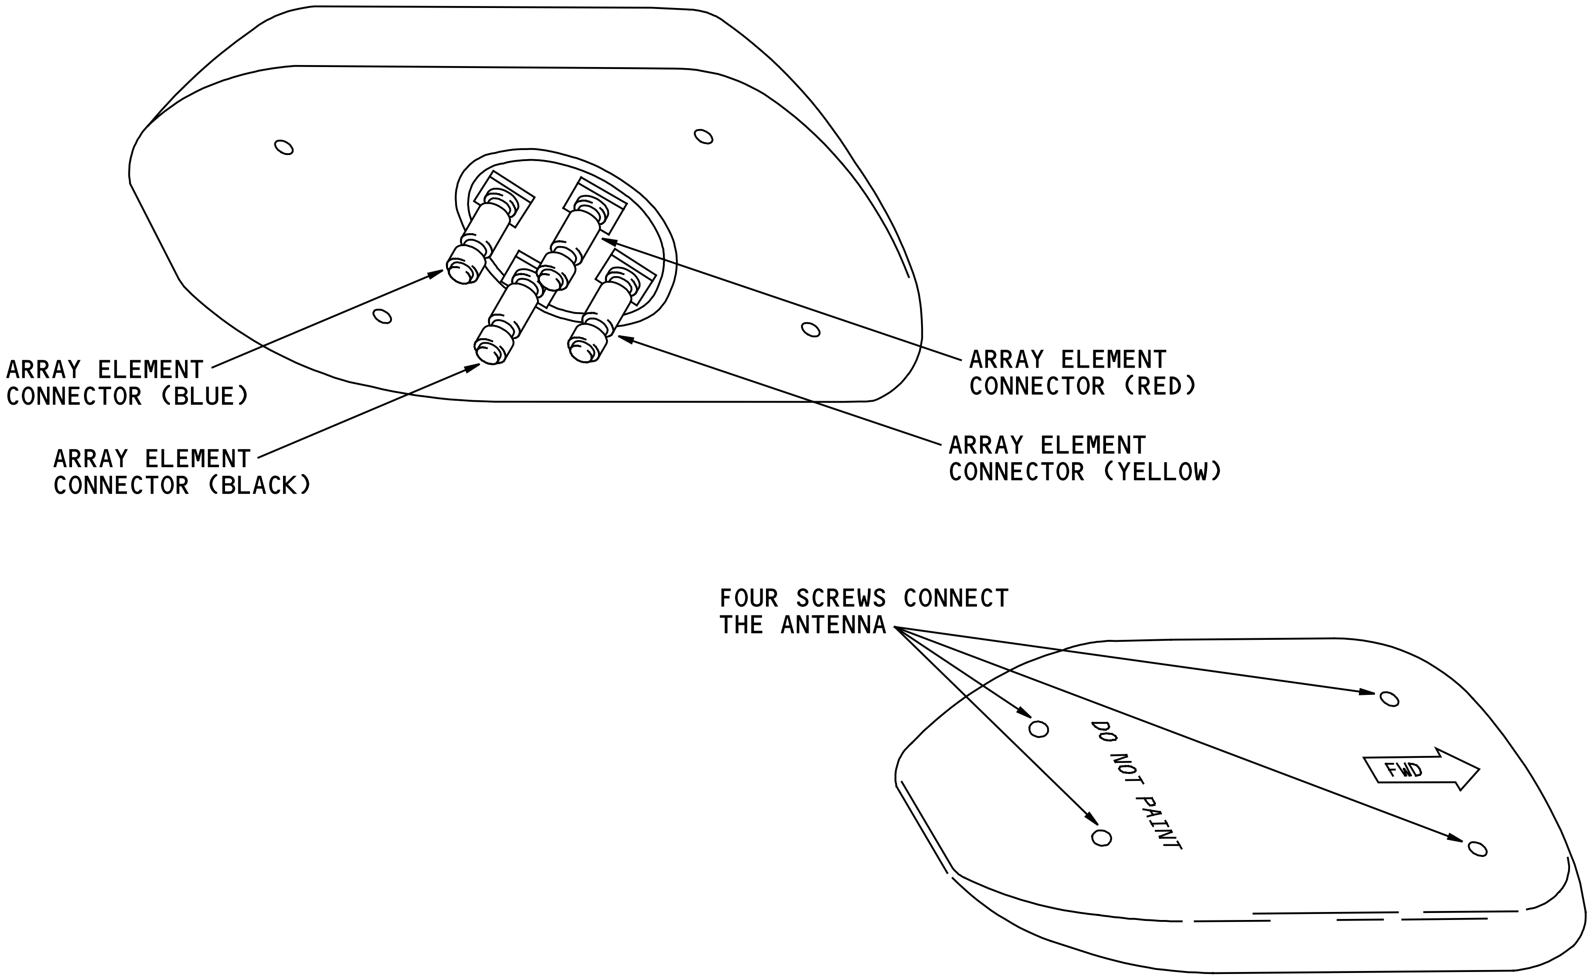
Four screws fasten each antenna to the airplane. The radiation side of the antenna shows "FWD" and "DO NOT PAINT".

CAUTION: DO NOT PAINT THE RADIATION SURFACE OR THE BACKPLATE OF THE ANTENNA. PAINT DOES NOT PERMIT THE ANTENNA TO RADIATE OR RECEIVE RF SIGNALS.

CAUTION: TO PREVENT DAMAGE TO THE ANTENNA CABLES, DO NOT PULL ON THEM.

Training Information Point

An antenna connection includes the coax cable and an antenna element. The TCAS computer checks the resistance of each antenna connection at power-up. The TCAS computer reports an antenna fault when it detects that the resistance of the connection is out of range. If you do not match the coax cable to the correct element, the TCAS computer reports an antenna fault.



34-45-00-010 Rev 3 03/28/96

TCAS - TCAS DIRECTIONAL ANTENNA

THIS PAGE INTENTIONALLY LEFT BLANK

TCAS - OPERATION-SURVEILANCE AREA

General

The TCAS tracks and evaluates the possible threat of up to 30 airplanes that are within the surveillance area.

These four types of traffic airplanes show on the NDs:

- Other traffic are airplanes that have an altitude separation of ±2700 feet and the time until closest point of approach (CPA) is greater than 40 seconds
- Proximate traffic are airplanes that have an altitude separation of ±1200 feet and the time until CPA is greater than 40 seconds
- Intruder traffic which causes a traffic advisory (TA), are airplanes that have an altitude separation of ±1200 feet and the time until closest point of approach (CPA) is between 25 and 40 seconds
- Threat traffic which causes a resolution advisory (RA), are airplanes that have an altitude separation of ±900 feet and the time until CPA is less than 25 seconds.

Surveillance Area

TCAS has a surveillance area that is about 10000 feet above and below the airplane and about 30 nm range in front of the airplane. The surveillance range behind and on the sides of the airplane is not as large as in the front of the airplane.

Within the surveillance area, there are two other areas called traffic advisory (TA) and resolution advisory (RA). To calculate RA and TA, the TCAS computer uses the time until closest point of approach (CPA) and the relative altitude of the traffic airplane.

To calculate CPA and the relative altitude, the TCAS computer uses:

- The TCAS airplane airspeed and altitude
- Range, altitude and airspeed of the traffic airplane.

The RA and TA times change between 20 and 45 seconds with the TCAS airplane altitude. The RA and TA times also change with the airspeed and altitude of the TCAS airplane, and the closure rate of each traffic airplane.

Traffic Advisory

When a traffic airplane is an intruder, the TCAS computer makes a traffic advisory (TA) that shows on the NDs.

Resolution Advisory

When a traffic airplane is a threat, the TCAS computer makes these resolution advisories (RA):

- Indications show on the NDs
- Maneuver indications on the PFDs guide the flight crew to avoid a possible collision

TCAS - OPERATION-SURVEILANCE AREA

- Aurals come from the aural warning speakers.

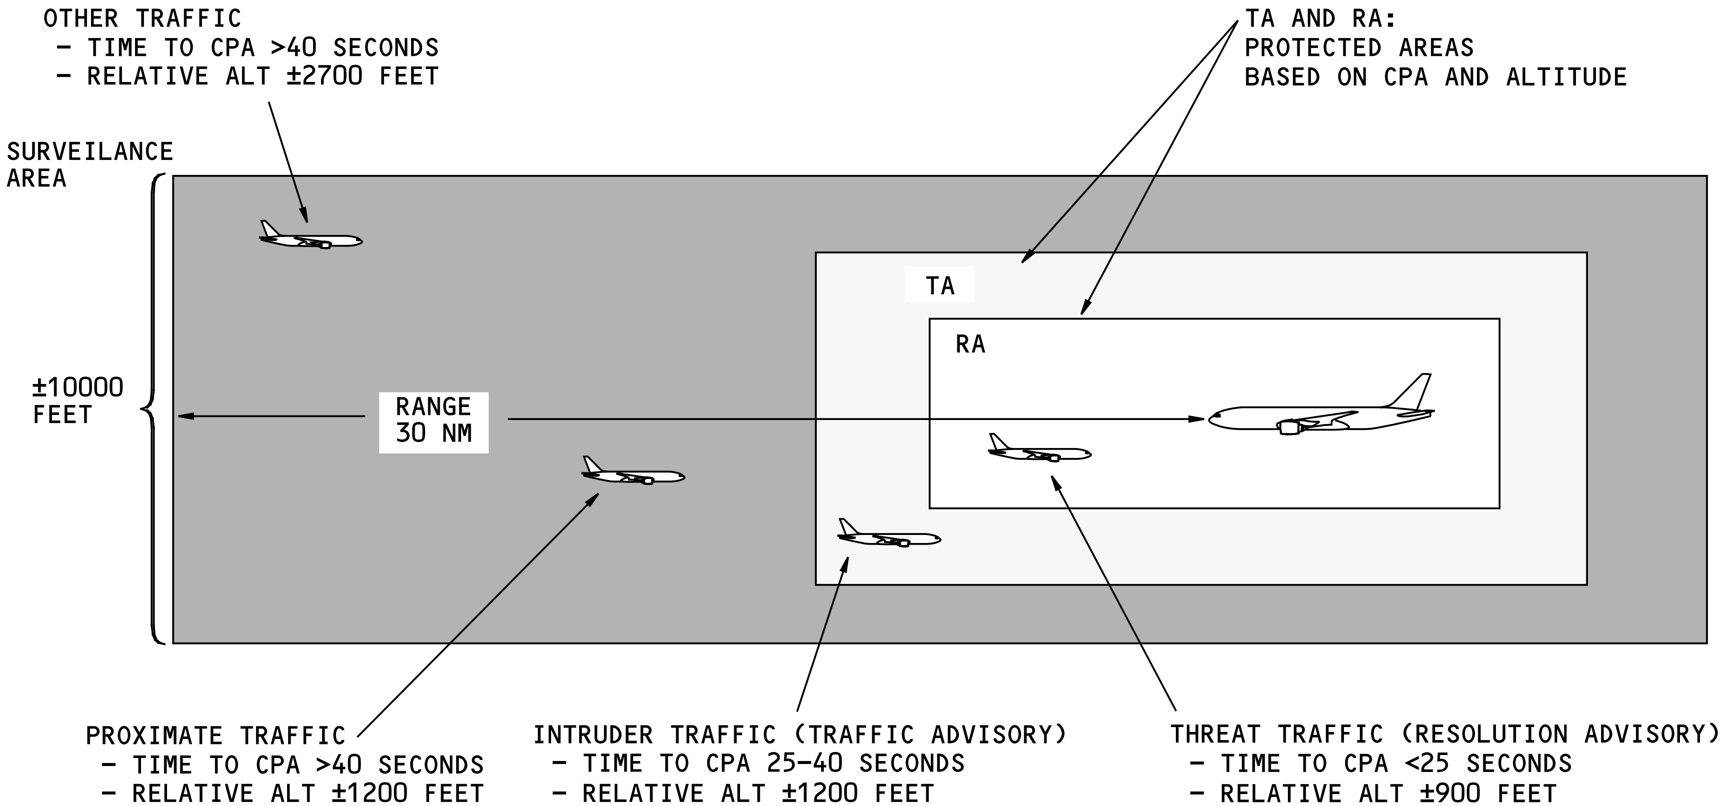
System Inhibits

Inhibits are dependent on the airplane parameters, which include:

- Maximum airplane climb rate
- Radio altitude
- Gear position
- Flap postion.

This table shows the inhibits and the parameters that cause the inhibits.

CONDITION	PARAMETERS
Increased descent RA	Inhibited below 1450ft. AGL
Descend RA	Inhibited below 1000ft. AGL in descent and 1200ft. AGL in climb
Resolution Advisories	Inhibited below 400ft. AGL in descent and below 600ft. AGL in climb.(TCAS automatically goes into TA ONLY)
TA voice message	Inhibited below 400ft. AGL in descent and below 600ft. AGL in climb
Climb or increased climb command	Can be inhibited, based on airplane configuration (flaps, gear, altitude limit, etc.)
Advisory priority	TA/RA goes to TA ONLY or STBY when there are higher priority advisories from GPWS



34-45-00-011 Rev 4

TCAS - OPERATION-SURVEILANCE AREA

TCAS - CONTROL AND DISPLAY

General

The EFIS control panel and the transponder panel control the TCAS data that shows on the PFD and ND.

EFIS Control Panel

To show the TCAS data on the ND, first put the mode control switch on the EFIS control panel in one of these modes:

- Expanded approach
- Expanded VOR
- Expanded map
- Centered map.

Then push the TFC (traffic) switch on the range selector to enable the ND to show the TCAS data. When you do this, the TFC message and all of the TCAS symbols shows on the ND.

To remove all of the TCAS messages and symbols from the ND, push the TFC switch again. To do this, the ND must be in one of these modes:

- Expanded approach
- Expanded VOR
- Expanded map
- Centered map.

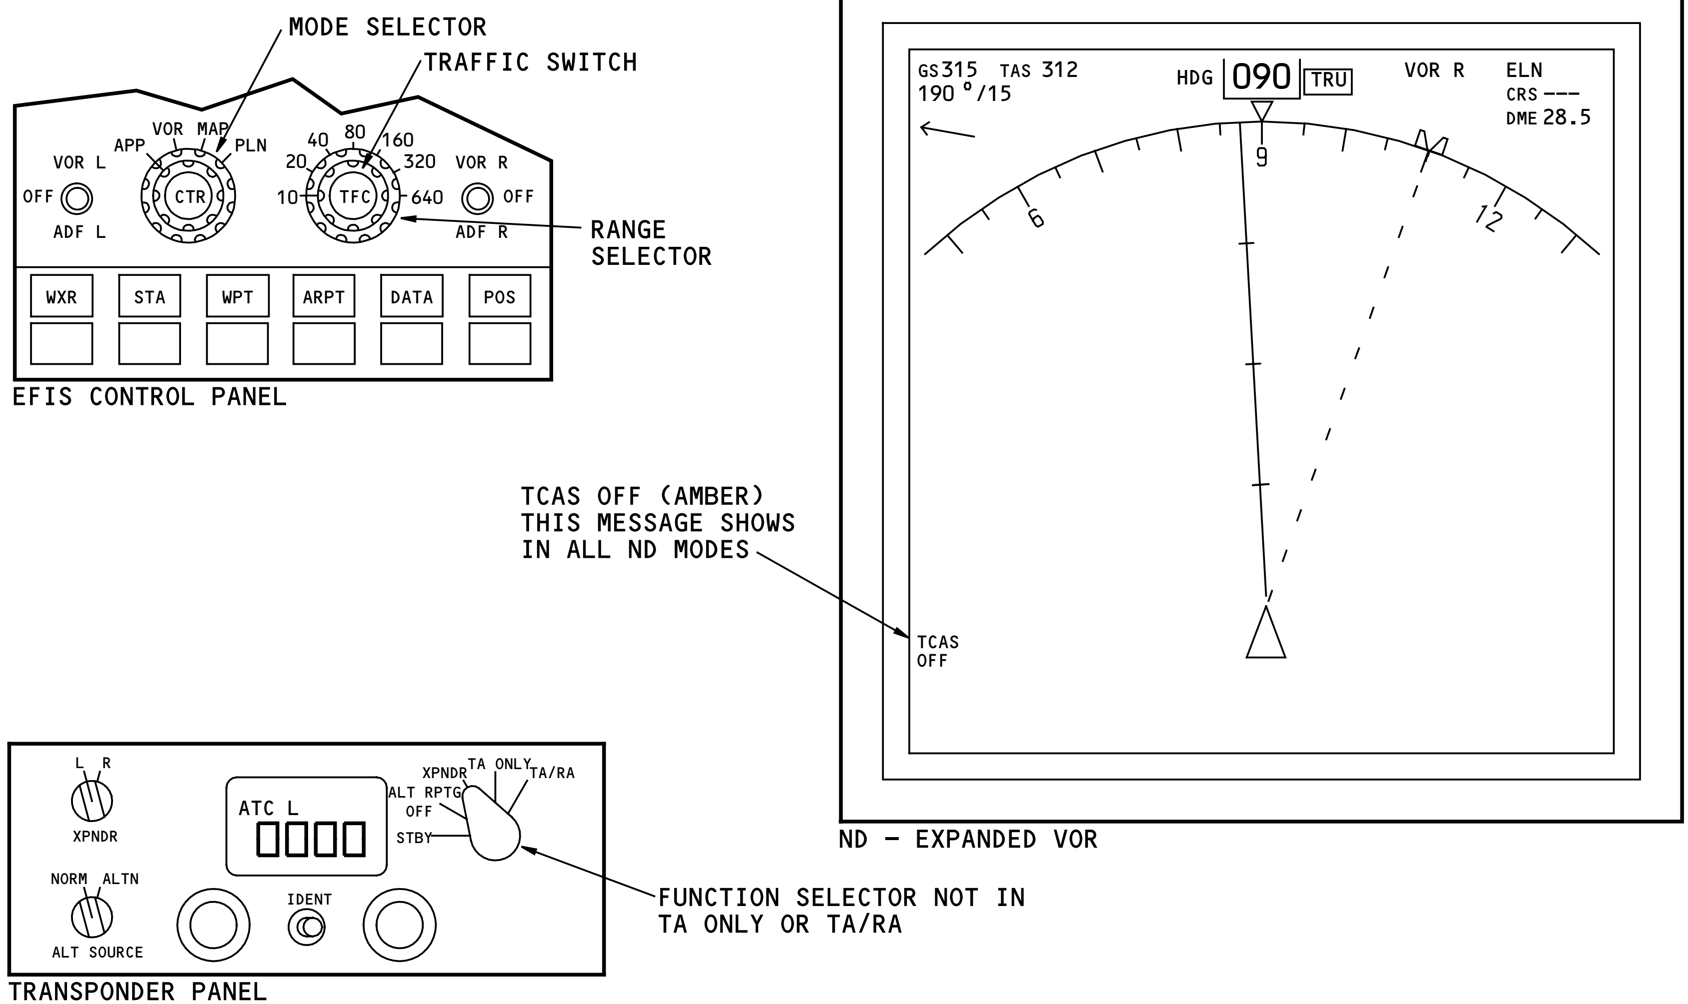
Transponder Panel

The transponder panel sends control data through the selected ATC/Mode S transponder to the TCAS computer.

The TCAS computer sends the selected data to the AIMS for display on the NDs and PFDs.

Push the TFC switch to show TCAS displays. If the function selector is not in the TA ONLY or TA/RA position, the ND:

- Shows a cyan message, TCAS OFF. TCAS OFF shows in all ND modes
- Removes all TCAS symbols.



34-45-00-013 Rev 3 09/18/96

TCAS - CONTROL AND DISPLAY

TCAS - NAVIGATION DISPLAY

THIS PAGE INTENTIONALLY LEFT BLANK

TCAS - NAVIGATION DISPLAY

General

The TCAS computer puts traffic into these four different groups with different symbols to show different types of traffic:

- Other traffic shows as a white open diamond, and the altitude readout is small white text
- Proximate traffic shows as a solid white diamond, and the altitude readout is small white text
- Traffic advisory (TA) shows as a solid amber circle, and the altitude readout is amber text
- Resolution advisory (RA) shows as a solid red square and the altitude readout is red text.

Each traffic symbol has an altitude readout and a vertical motion arrow. The traffic symbols show in one of these modes only:

- Center (CTR) MAP
- Expanded (EXP) MAP
- Expanded (EXP) VOR
- Expanded (EXP) APP.

Range Data

When you push the TFC switch on the EFIS control panel to show TCAS data, the range selected on the EFIS control panel shows on the ND.

TCAS Messages

The ND can show these messages for TCAS:

- TFC shows in cyan in and all modes
- TA ONLY shows in cyan and in all modes
- TCAS TEST shows in cyan and in all modes
- TCAS FAIL shows on two lines in amber, and in the CTR MAP and EXP MAP,VOR and APP modes
- TCAS OFF shows on two lines in amber, and in the CTR MAP and EXP MAP,VOR and APP modes

Altitude Separation

The TCAS computer uses the absolute altitude of the TCAS airplane and the traffic airplane to calculate the altitude separation. The altitude separation shows on the ND in hundreds of feet. If the traffic is above, the digits show above the traffic symbol with a plus (+) sign. If the traffic is below, the digits show below the traffic symbol with a minus (-) sign.

If the altitude separation is less than 100 feet, 00 feet shows.

If the altitude separation is NCD, the altitude readout does not show.

Absolute Altitude

The traffic airplane sends the TCAS computer its absolute altitude. The absolute altitude shows in thousands of feet. If the traffic is above, the digits show above the traffic symbol. If the traffic is below, the digits show below the traffic.

TCAS - NAVIGATION DISPLAY

If the altitude separation is NCD, the altitude readout does not show.

Vertical Motion Arrow

A vertical motion arrow shows on the right side of the traffic symbol. It is the same color as the traffic symbol. If the traffic airplane is in a descent the arrow points down. If the traffic airplane is in a climb the arrow points up.

OFFSCALE

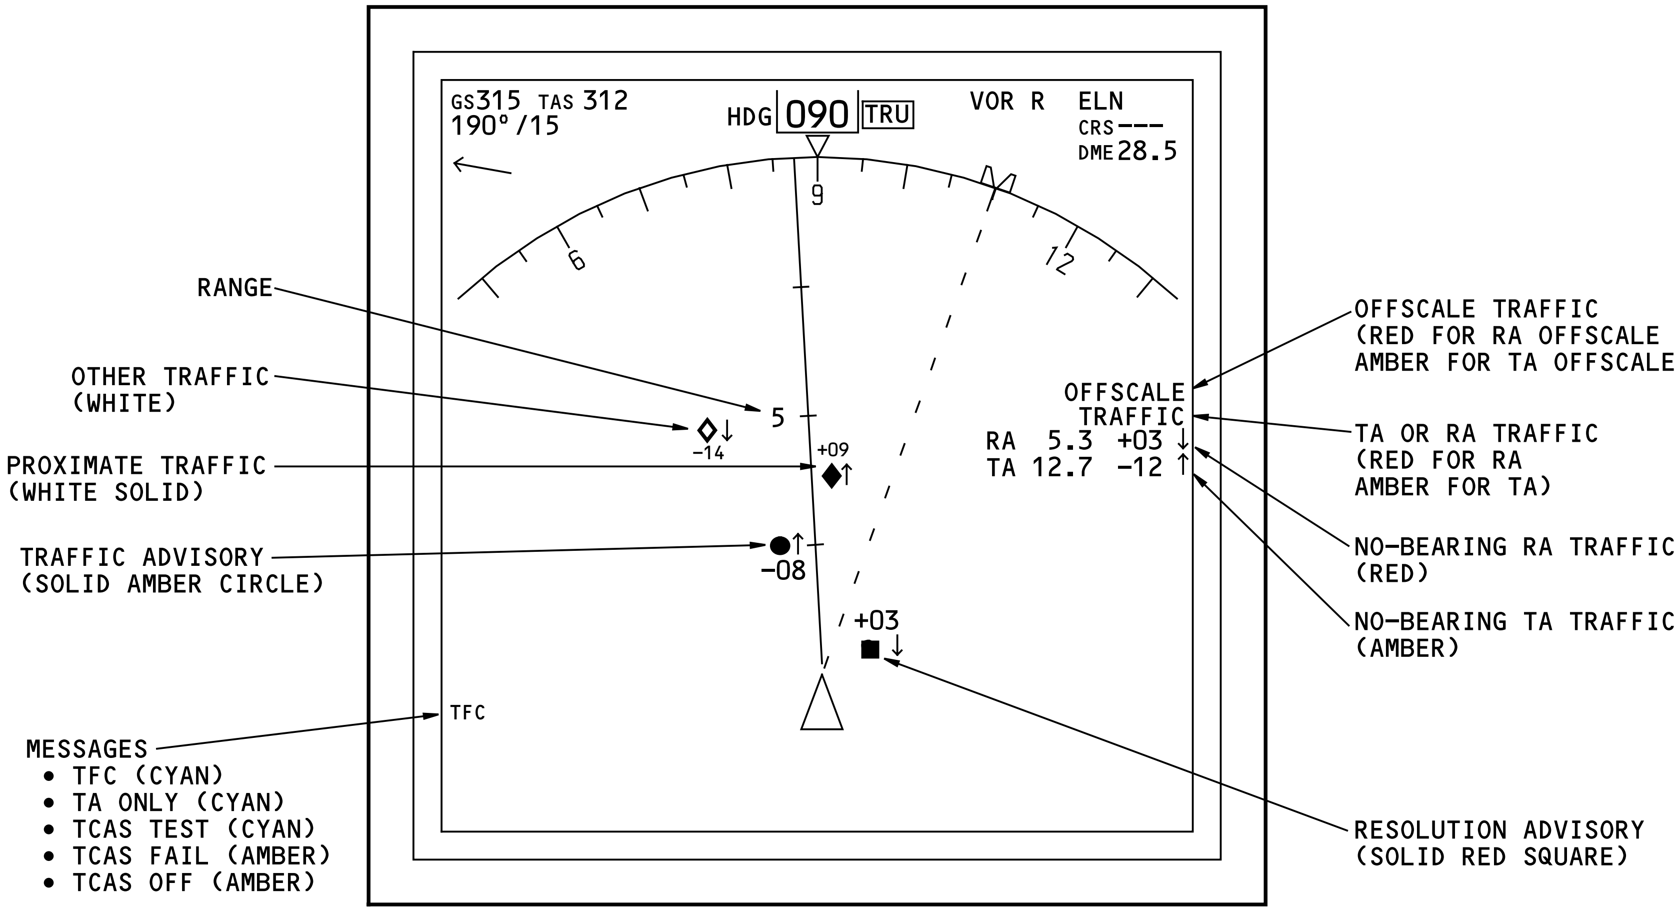
The OFFSCALE message shows on the ND when a RA or TA is outside the ND range. If a RA is outside the ND range, the OFFSCALE message shows in red. If a TA is outside the ND range, the OFFSCALE message shows in amber. If both a TA and RA are outside the ND range, the OFFSCALE message shows in red.

TRAFFIC

The red TRAFFIC message shows any time there is a RA. The amber TRAFFIC message shows any time there is a TA. The TRAFFIC message shows in all ND formats.

RA and TA No-Bearing Traffic

The no-bearing RA and TA messages show on the ND when TCAS loses the bearing of the RA or TA traffic. When the landing gear is down, the bottom directional antenna becomes an omnidirectional antenna. When this happens, the bottom antenna cannot track the bearing of the intruder traffic, thus the bearing is NCD. Because of this, the no-bearing messages show on the ND. If a TA becomes no-bearing traffic, an amber TA with the range, altitude, and vertical motion arrow shows on the ND. If a RA becomes no-bearing traffic, a red RA with the range, altitude, and vertical motion arrow shows on the ND.



ND - EXPANDED VOR MODE

34-45-00-014 Rev 2

NOTE: TCAS FAIL AND TCAS OFF SHOW ON TWO LINES

TCAS - NAVIGATION DISPLAY

TCAS - PRIMARY FLIGHT DISPLAY

General

These are the two types of TCAS advisories that can show on the PFD:

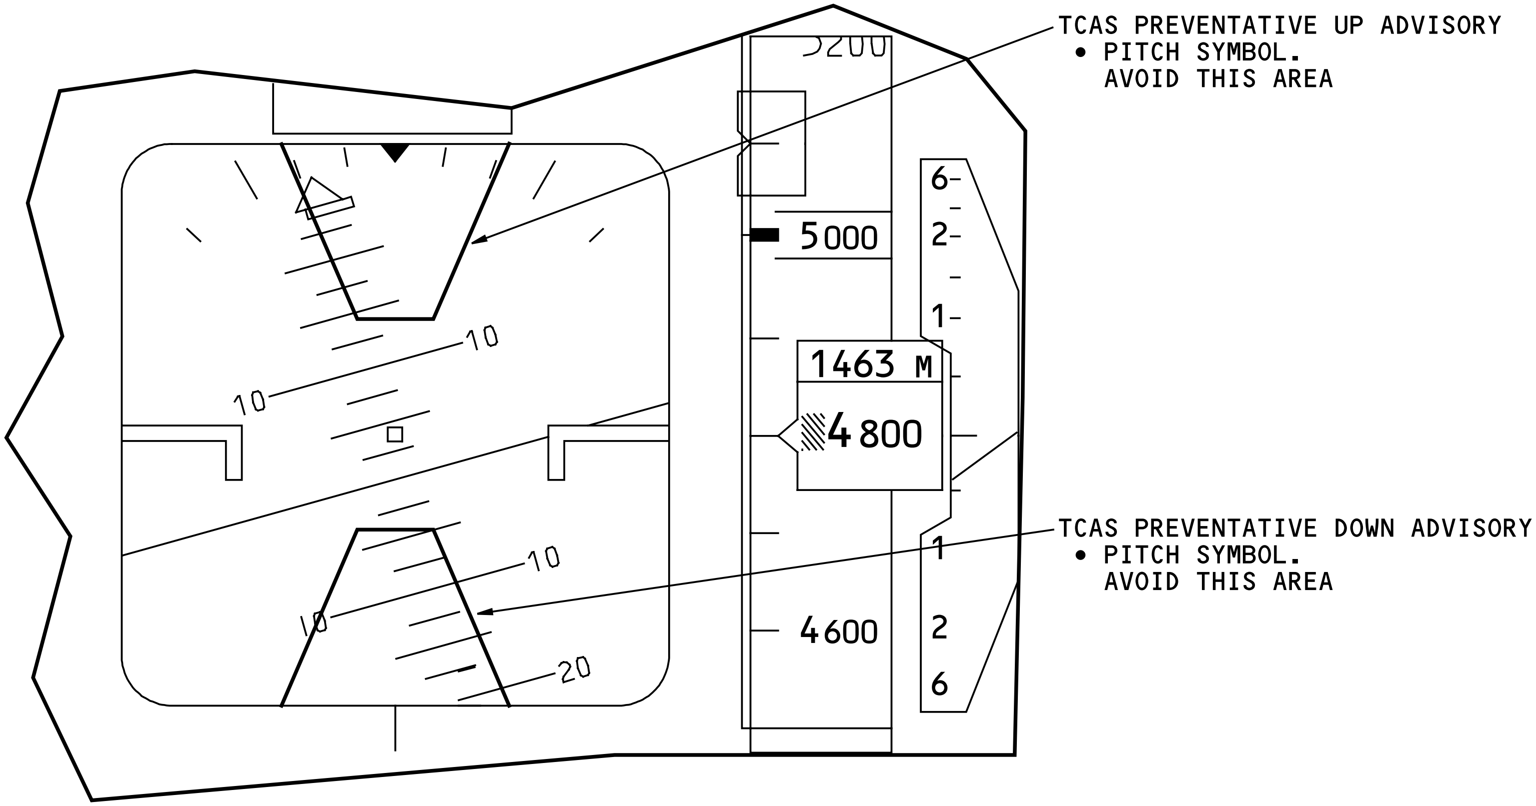
- TCAS preventative down advisory
- TCAS preventative up advisory.

These symbols only show for an RA when the function selector on the transponder panel is in the TA/RA or TA ONLY position and TCAS communicates with threat airplanes that have TCAS.

Description

The red advisories that show on the attitude display tells the flight crew to avoid this area.

The flight crew uses the advisories to avoid a possible collision with threat airplanes.



PRIMARY FLIGHT DISPLAY

34-45-00-015 Rev 3 04/26/96

TCAS - PRIMARY FLIGHT DISPLAY

TCAS - TEST DISPLAYS

General

When a self-test starts, TCAS test indications go to the PFDs, NDs, and the front panel of the TCAS computer. At the end of the test, a TCAS test aural comes on at the aural warning speakers.

There are two ways to start a self-test:

- From the maintenance access terminal (MAT)
- From the front panel test switch.

TCAS Self-Test Indications - ND

During a self-test, the ND shows this data:

- A cyan message, TCAS TEST
- Amber TA traffic symbol at 9 o'clock, -200 feet relative altitude with an up vertical motion arrow and 2 nm distance from the airplane center
- White other traffic symbol at 11 o'clock, +1000 feet relative altitude with no vertical motion arrow and 3.6 nm distance from the airplane center
- White proximate traffic symbol at 1 o'clock, -1000 feet relative altitude with a down vertical motion arrow and 3.6 nm distance from the airplane center
- Red RA traffic symbol at 3 o'clock, +200 feet relative altitude with no vertical motion arrow and 2 nm distance from the airplane center.

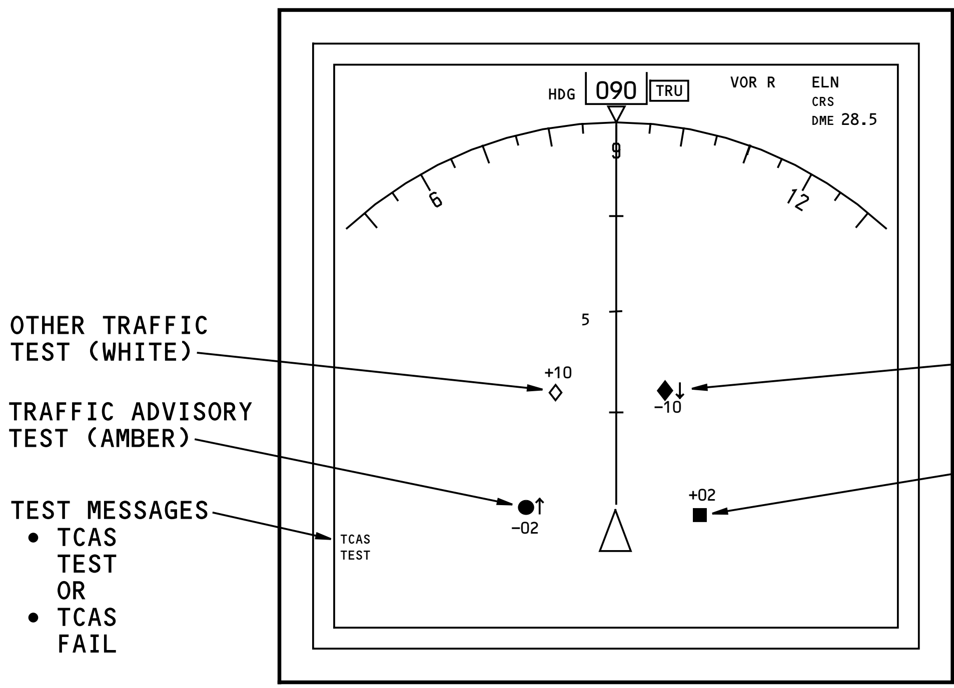
If the test fails, the message TCAS FAIL replaces the TCAS TEST message.

TCAS Self-Test Indications - PFD

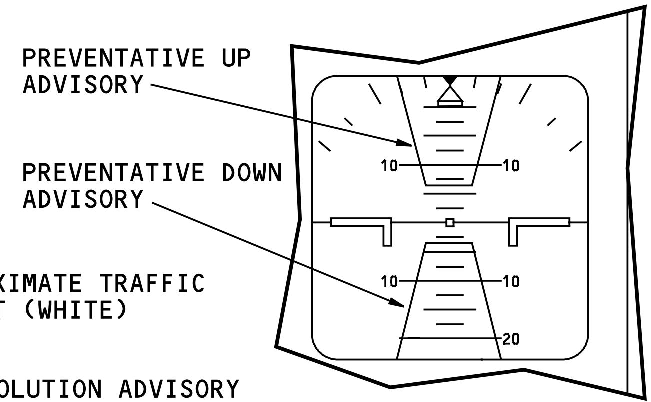
During a self-test, the PFD shows the red RA preventative down advisory and red RA preventative up advisory cues on the attitude display.

TCAS Self-Test Aurals

When the test completes with no faults, the aural message TCAS SYSTEM TEST OK comes on. If the BITE detects a fault during the self-test, the aural message is TCAS SYSTEM TEST FAIL.



ND - EXPANDED VOR



PFD

TCAS - TEST DISPLAYS

TCAS - GROUND TESTS

General

You can do a TCAS system test from the MAT.

TCAS System Test

The TCAS system test makes sure the TCAS computer and its interfaces operate properly.

You get these indications when you do a system test:

- Traffic symbols on the NDs
- Up and down preventative advisories on the PFDs
- TCAS TEST PASS or FAIL aural at the end of the test.

CLOCKS - INTRODUCTION

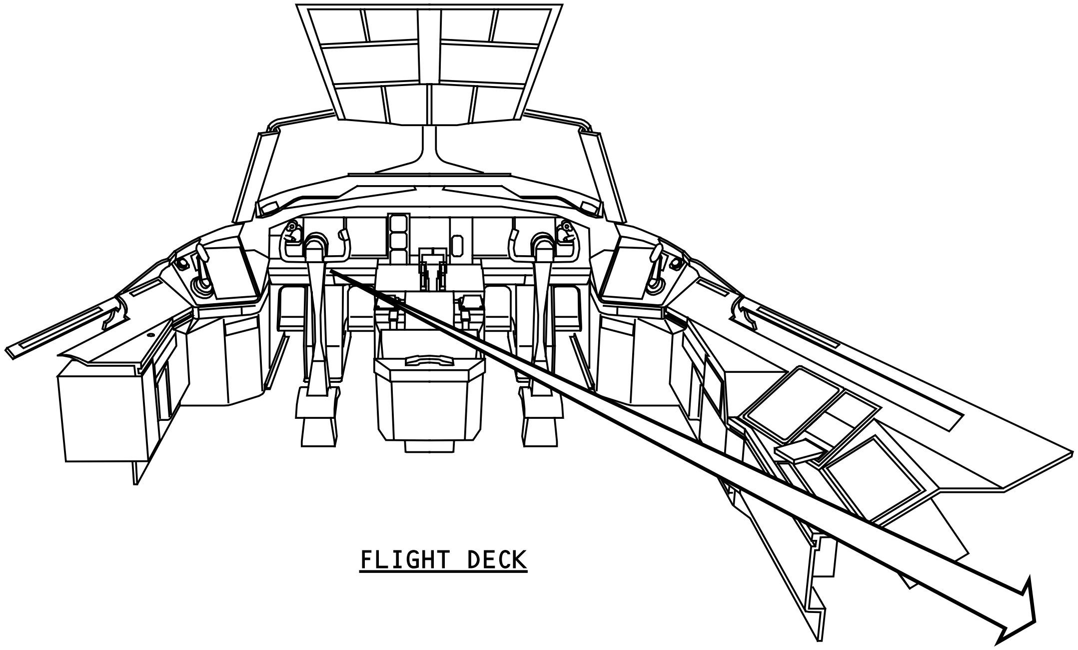
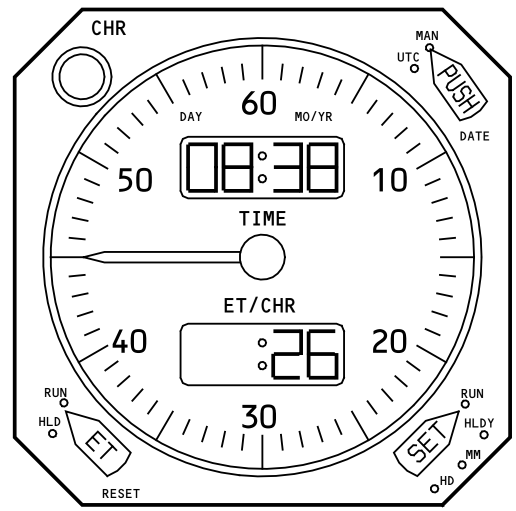
General

The clocks give time reference to the flight crew.

Abbreviations and Acronyms

AIMS	- airplane information management system
ARINC	- aeronautical radio, inc.
CDU	- control display unit
CHR	- chronograph
HD	- hours/days
HLDY	- hold/year
GPS	- global positioning system
GPSSU	- global positioning system sensor unit
LCD	- liquid crystal display
MAN	- manual
MM	- minutes/months
ND	- navigation display
UTC	- universal time (coordinated)
UTCF	- universal time (coordinated) function





31-25-00-001 Rev 1 06/17/96

CLOCKS - INTRODUCTION

CLOCKS - GENERAL DESCRIPTION

General

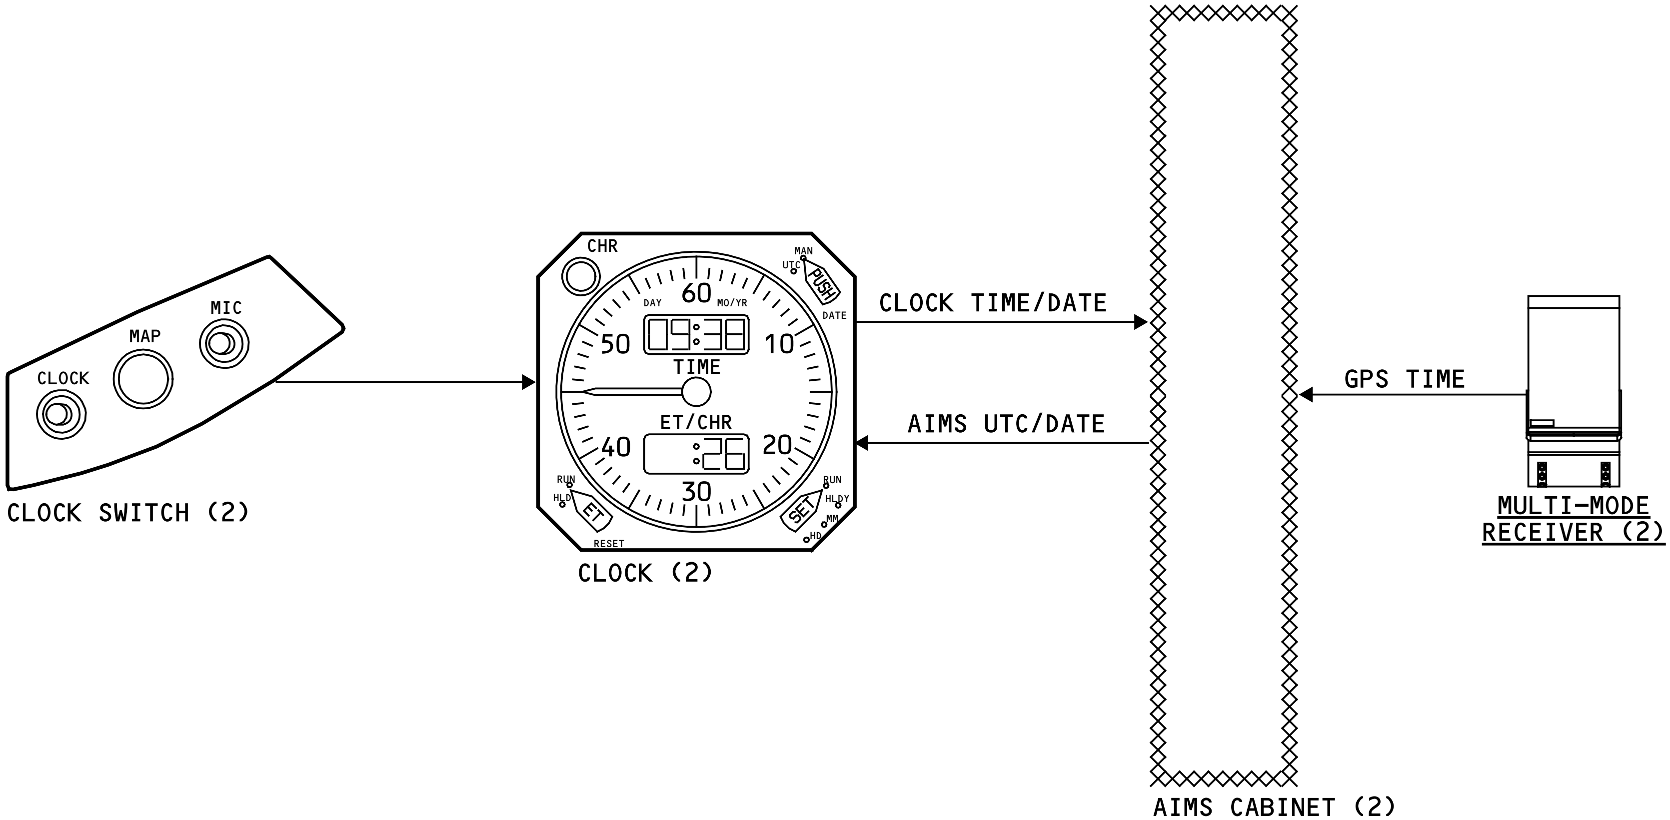
This is the data that the clocks show:

- Time and date set manually from the clock
- Universal time (controlled) (UTC) and date from the airplane information management system (AIMS)
- Elapsed time
- Chronograph time.

Use the clock switches on the glareshield panel to control the chronograph function of the clocks.

The clocks send manually set time and date to the airplane information management system (AIMS) cabinets. However, the AIMS cabinets do not use the clock time and date for any function.

The AIMS cabinets get UTC and date from the the multi-mode receivers (MMRs).



31-25-00-002 Rev 2 01/14/1998

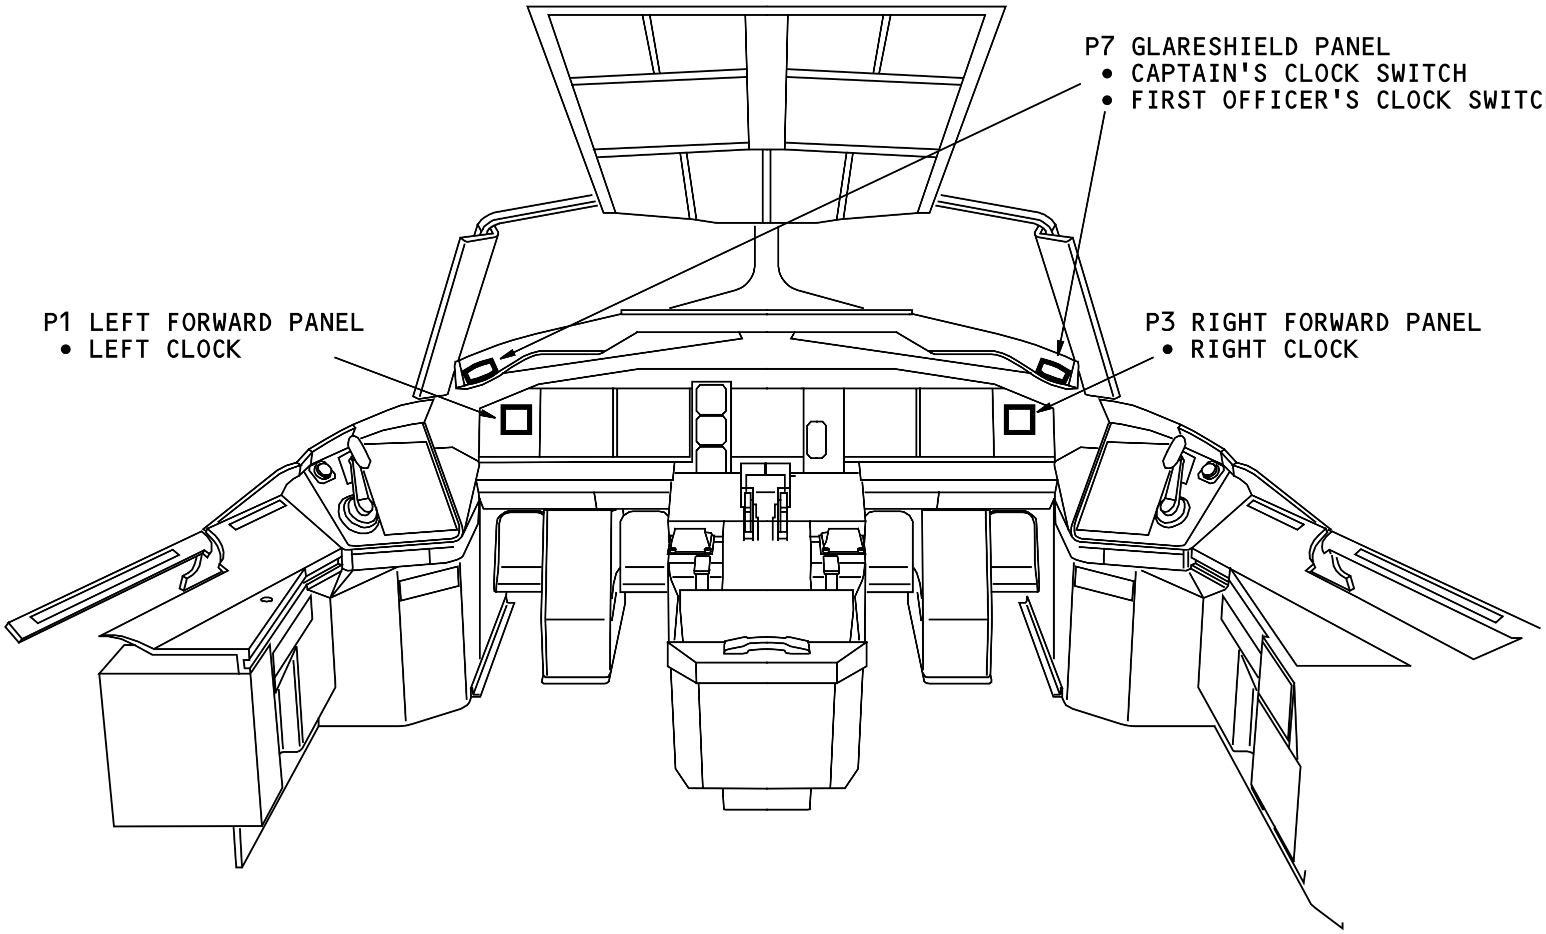
CLOCKS - GENERAL DESCRIPTION

CLOCKS - COMPONENT LOCATIONS

General

The clock system components are:

- Captain's clock
- First Officer's clock
- Captain's clock switch
- First Officer's clock switch.



31-25-00-003 Rev 0

CLOCKS - COMPONENT LOCATIONS

CLOCKS - INTERFACES

Power

Each clock gets 28v dc from a circuit breaker for operation. Each clock gets 5v ac for its internal instrument lights.

Clock Switches

Each clock gets a discrete signal from a clock switch on the glareshield. These discrete signals control the chronograph function of the clock.

Digital Input

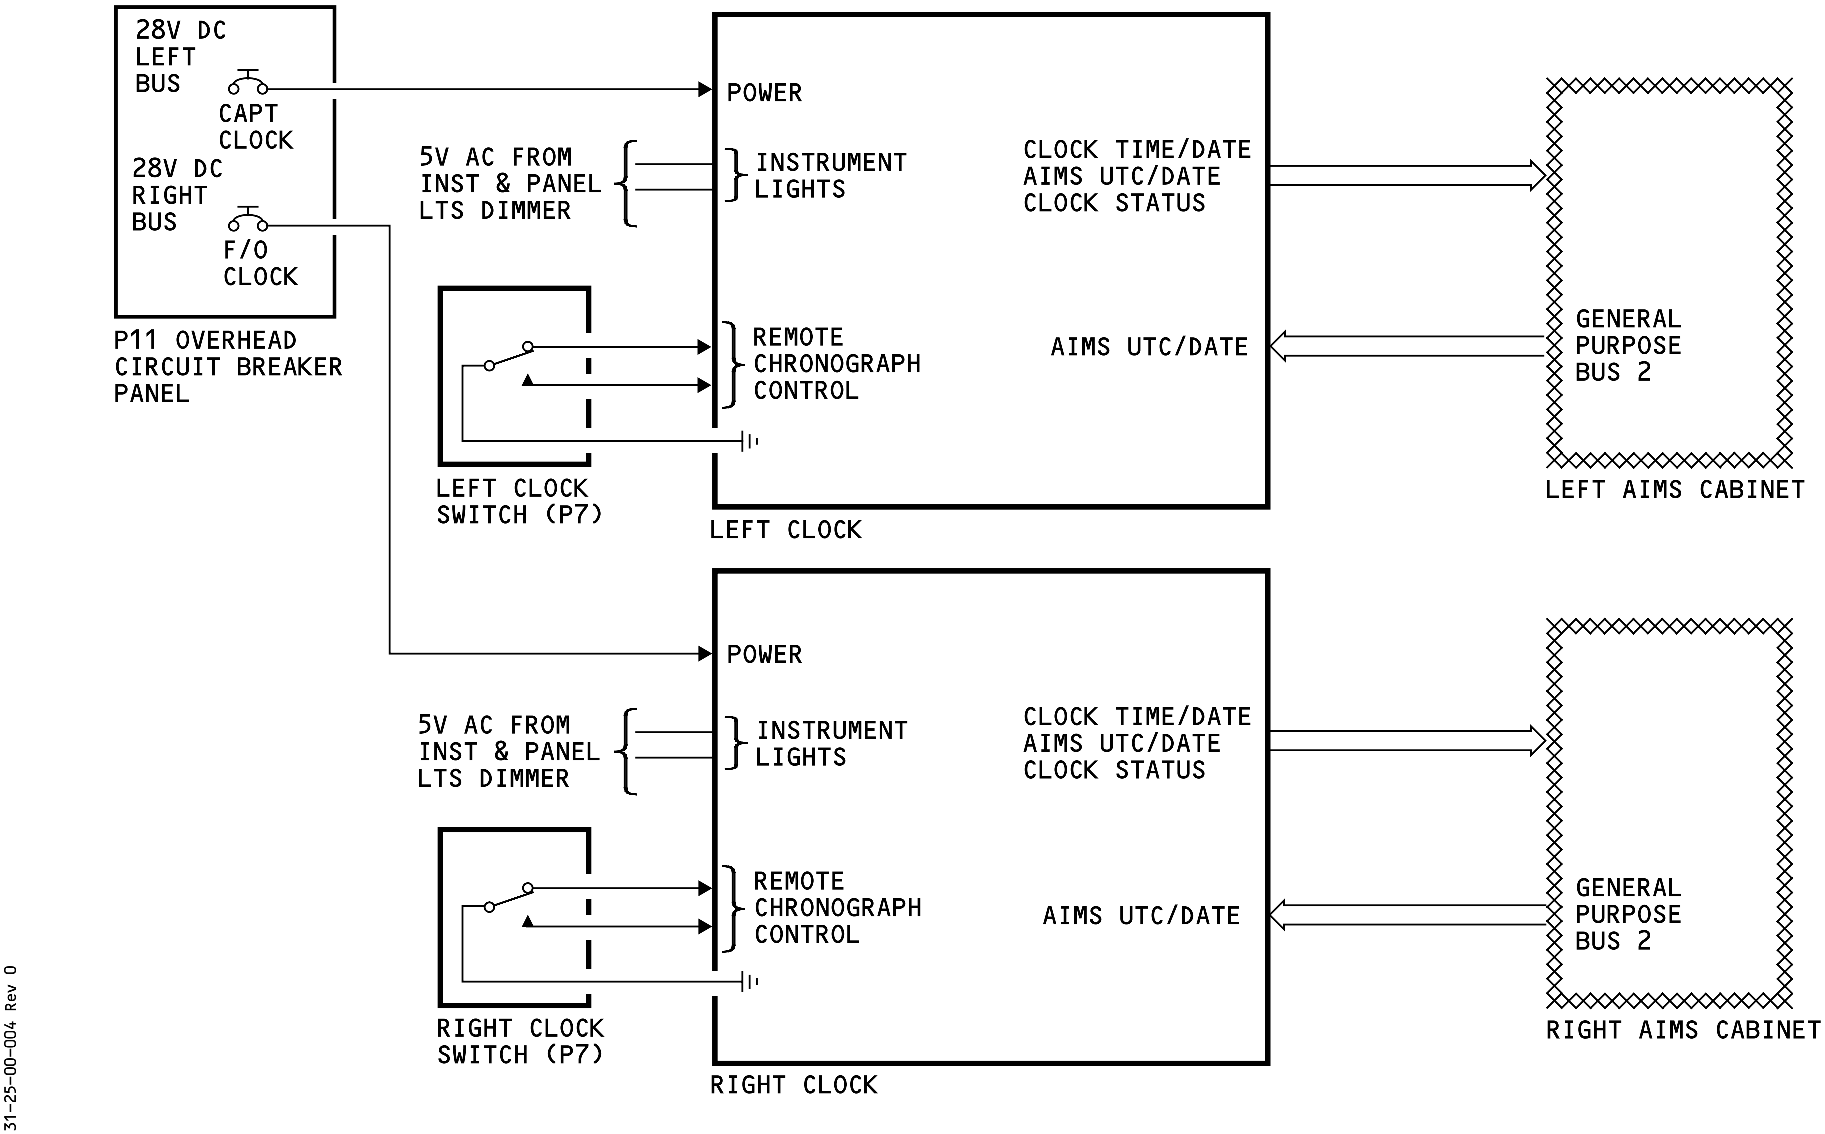
The left clock receives universal time (coordinated) (UTC) and date from the left AIMS cabinet. The right clock receives UTC and date from the right AIMS cabinet.

The clocks show AIMS UTC and date.

Digital Output

The left clock sends data to the left AIMS cabinet when in the manual mode. The right clock sends data to the right AIMS cabinet. The data is:

- UTC and date from the clock
- UTC and date from the AIMS
- Clock status data.



CLOCKS - INTERFACES

CLOCKS - CLOCK

Displays

The clock has a time/date window and an elapsed time/chronograph window. Both are liquid crystal displays (LCDs).

Chronograph Switch

The chronograph switch is a push-button switch. Use this switch to start, stop, and reset the chronograph function.

Sweep Second Hand

The sweep second hand only works with the chronograph function of the clock.

Elapsed Time Selector

The elapsed time selector is a three-position rotary switch. Use this selector to control the elapsed time function of the clock. The elapsed time selector positions are:

- RESET. This is a spring-loaded position. Use this position to reset the elapsed time
- HLD (hold). Use this position to hold the elapsed time
- RUN. Use this position to let the clock start to accumulate elapsed time.

Time/Date Selector

The time/date selector is a push-button rotary two-position switch. In the MAN (manual) position, clock time and date come from the clock. In the UTC position, UTC and date come from the AIMS universal time (coordinated) function (UTCF).

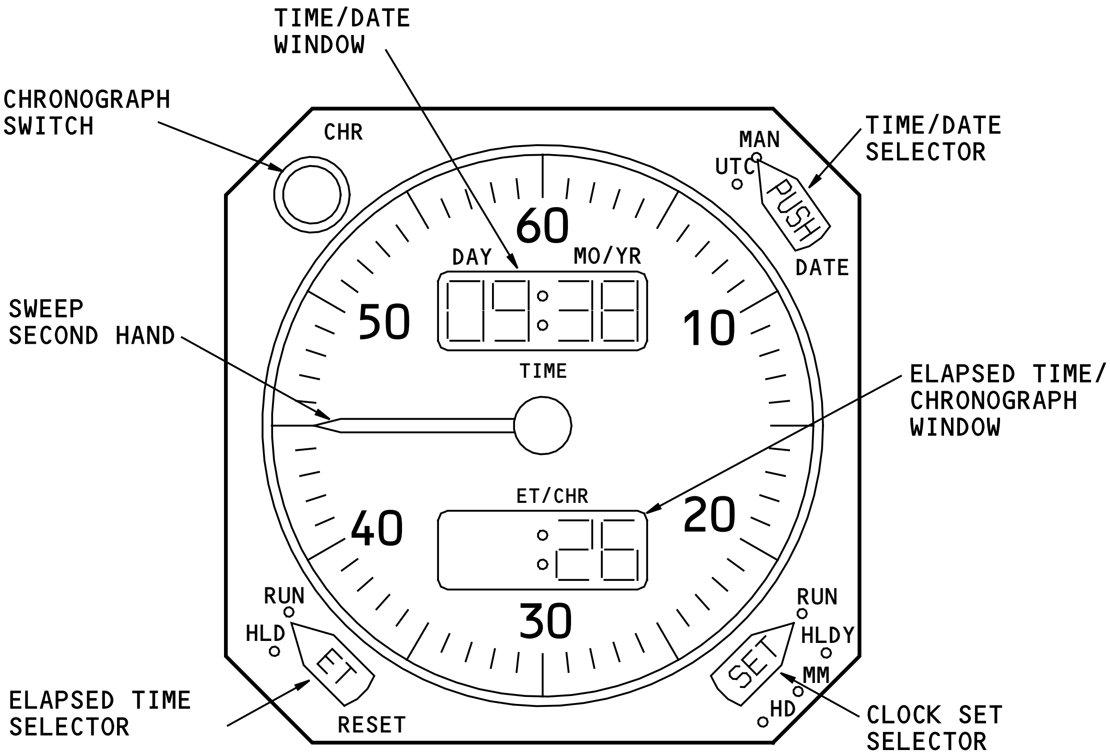
Push the selector once to show the date. Push it again to show the UTC.

Clock Set Selector

The clock set selector is a four-position rotary switch. Use this selector to set or change the clock time and date. You can only change the clock time and date in the manual mode. It is not possible to change the AIMS UTC and date.

The clock set selector positions are:

- HD (hours/date). Use this position to set the hours or the day
- MM (minutes/months). Use this position to set the minutes and the months
- HLDY (hold/year). Use this position to hold the time or set the year
- RUN. Use this position to let the clock begin the time update.



31-25-00-005 Rev 0

CLOCKS - CLOCK

CLOCKS - CLOCK TIME AND DATE SET FROM AIMS

Power-Up

If the time/date control switch is in MAN when the clock first receives power, the clock shows 00 hours, 00 minutes and does not change. You can use the AIMS UTC and date to set the clock time.

Update of Clock Time and Date From AIMS UTCF

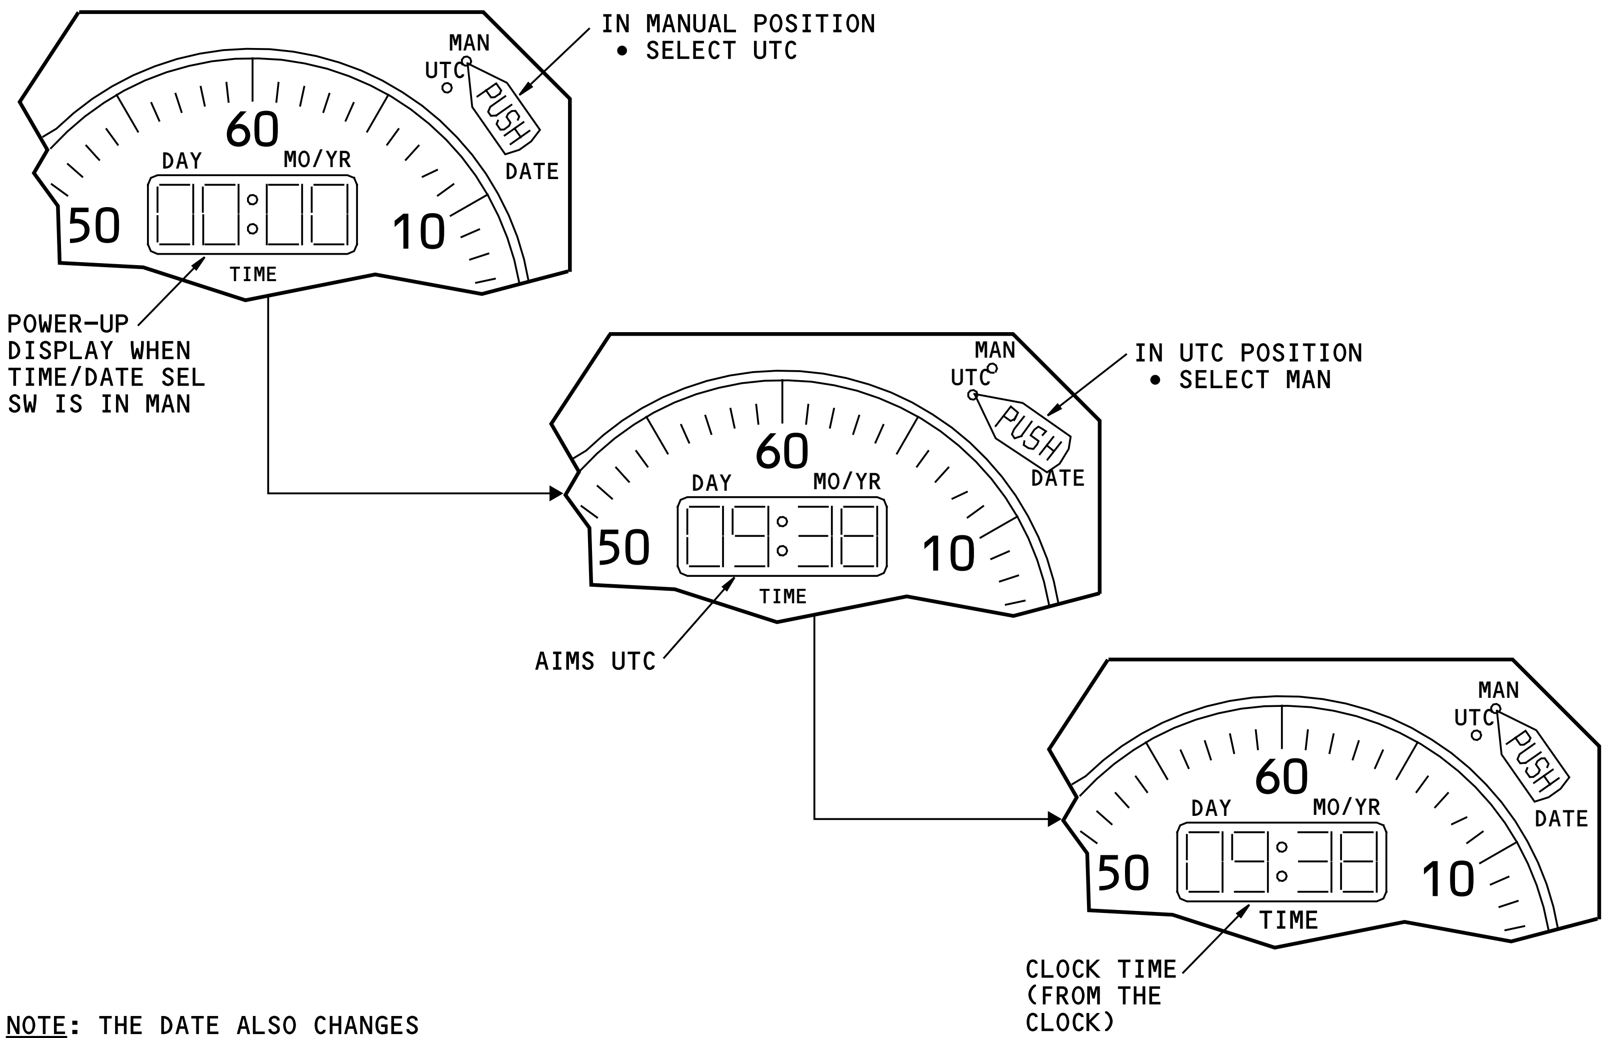
Put the time/date control switch in the UTC position. This causes the clock to:

- Show UTC from the AIMS universal time (coordinated) function (UTCF)
- Use the UTC from the AIMS as a starting point for an internal time accumulator. Once the accumulator starts, it does not look at UTC from the AIMS UTCF.

Put the time/date control switch in MAN. This causes the clock to show UTC and date from its internal time accumulator.

Power-up With Time/Date Control Switch in UTC

If the time/date control switch is in UTC when the clock receives power for the first time, the clock shows the AIMS UTC if it is valid.



NOTE: THE DATE ALSO CHANGES

31-25-00-010 Rev 0

CLOCKS - CLOCK TIME AND DATE SET FROM AIMS

CLOCKS - FUNCTIONAL DESCRIPTION

Inputs

The clock gets 28v dc for power.

The clock receives universal time (coordinated) UTC and date from the AIMS universal time (coordinated) function (UTCF).

A multiplexer senses the position of all the switches on the clock and also the clock switch on the glareshield panel P7.

Calculations and Outputs

A microprocessor does all the time calculations and controls the outputs of the clock.

A stepper motor moves the sweep second hand when the chronograph function is in use.

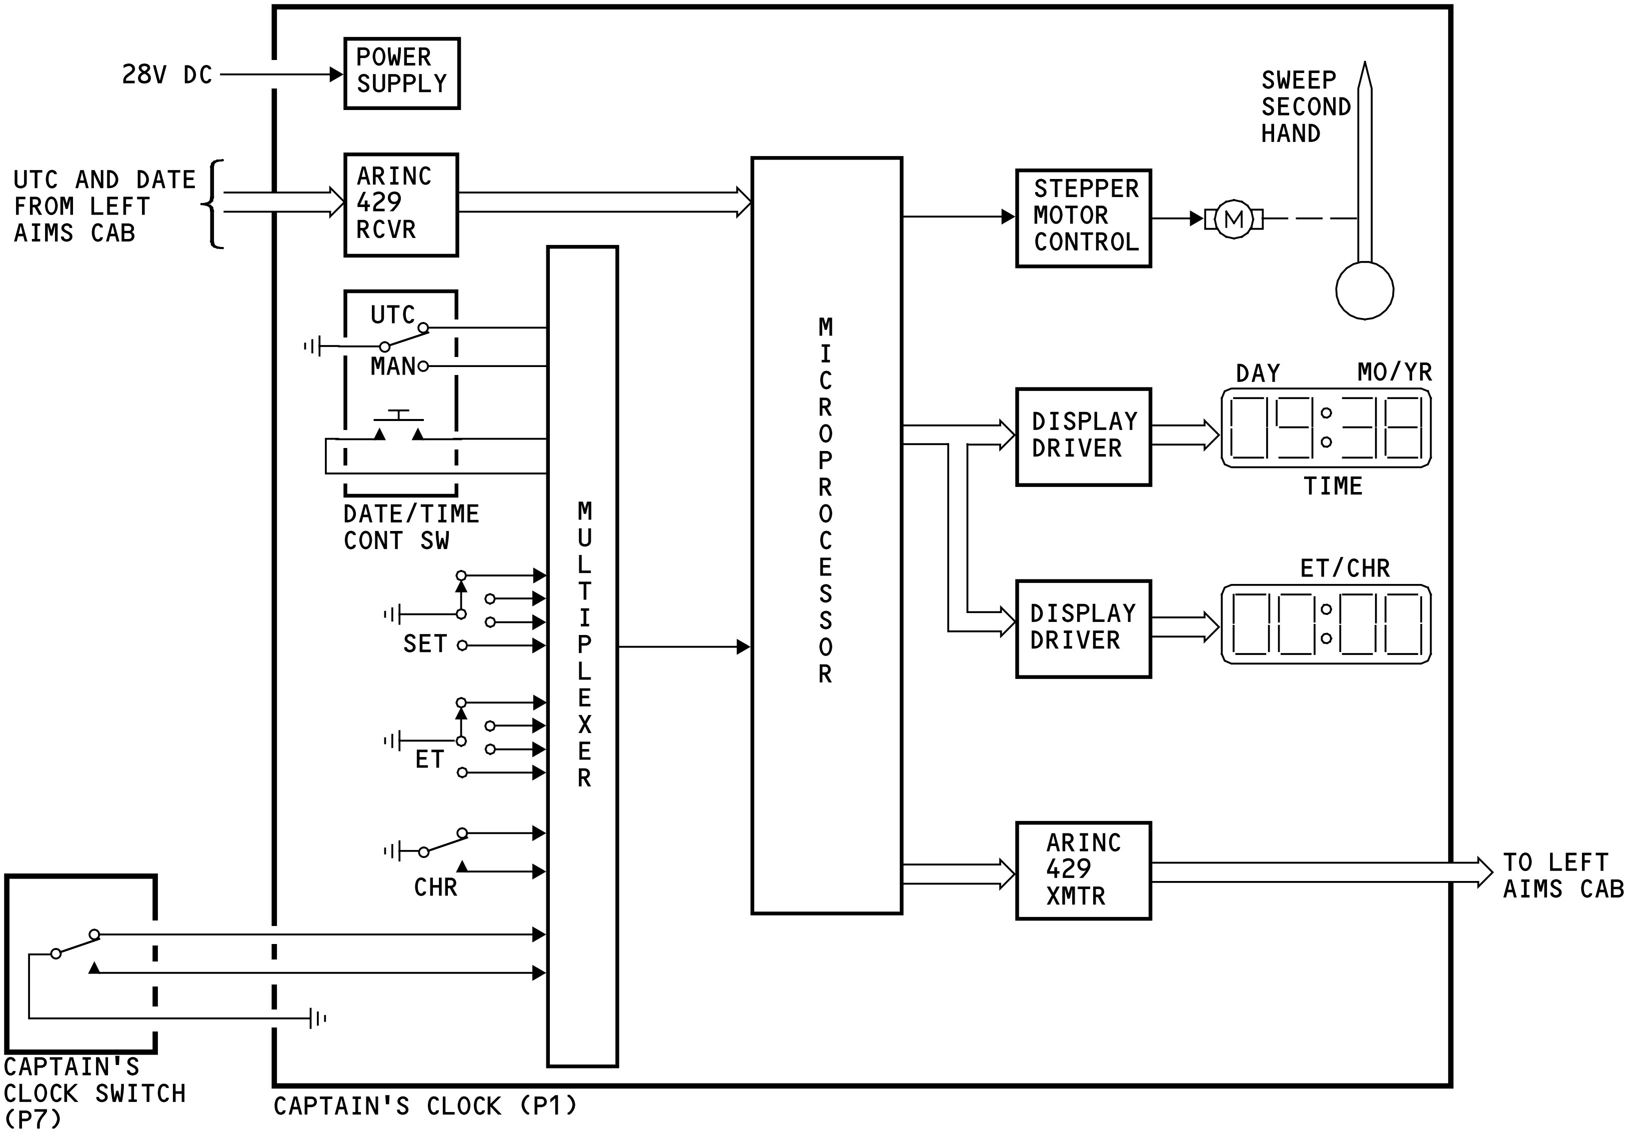
Display drivers supply display information to the clock displays.

ARINC 429 clock data goes to the AIMS cabinet.

Output to AIMS

The clock sends this data to the AIMS UTCF:

- Clock time
- Clock date
- AIMS UTC
- AIMS date
- Clock status data.



CLOCKS - FUNCTIONAL DESCRIPTION

31-51-00-001 Rev 3

WARNING ELECTRONIC SYSTEM - INTRODUCTION

WES - GENERAL DESCRIPTION

General

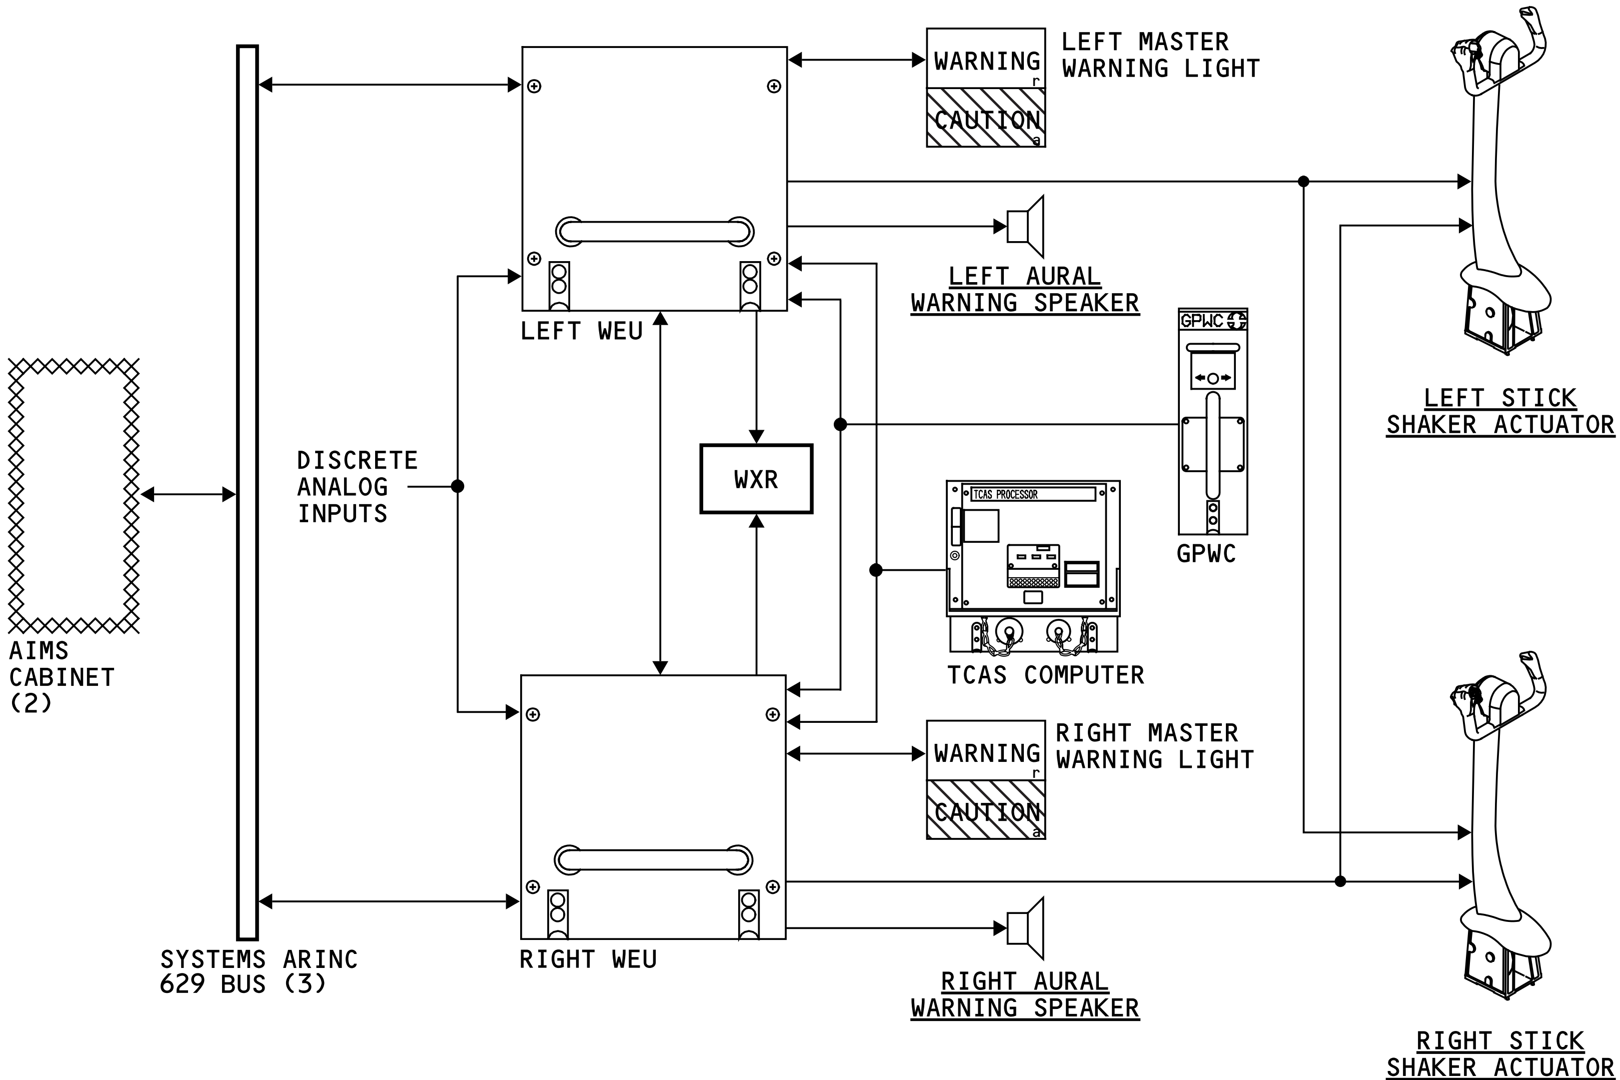
The warning electronic system (WES) has two warning electronic units (WEUs). Each WEU has two internal channels which do the same functions. The WES receives inputs from sensors, airframe, and avionics systems. The systems ARINC 629 buses supply most of the data. Discrete inputs supply the rest of the data.

The WES does these functions:

- Master warning light control
- Alert aurals control and amplification. This includes amplification of alert aurals from the traffic alert and collision avoidance system (TCAS) computer, the ground proximity warning computer (GPWC), and the predictive windshear (PWS) function of the weather radar (WXR).
- Landing and takeoff configuration warning
- Speedbrake alert
- Stabilizer green band
- Altitude alert
- Stall warning
- Auto slat enable
- Speed tape parameter calculation. This includes maximum operating velocity (Vmo), and maximum operating mach (Mmo) indication.

Outputs go to these:

- Master warning lights
- Aural warning speakers
- Stick shaker actuators
- Weather radar (WXR) system
- Airplane information management system (AIMS) for displays, maintenance functions, and data conversion.



31-51-00-002 Rev 2 02/03/1998

WES - GENERAL DESCRIPTION

WES - COMPONENT LOCATIONS 1

General

The warning electronic units (WEUs) are in the main equipment center.

The alternate gear down dispatch switch is on the right side of the lower main equipment access hatch.

WES - COMPONENT LOCATIONS - 2

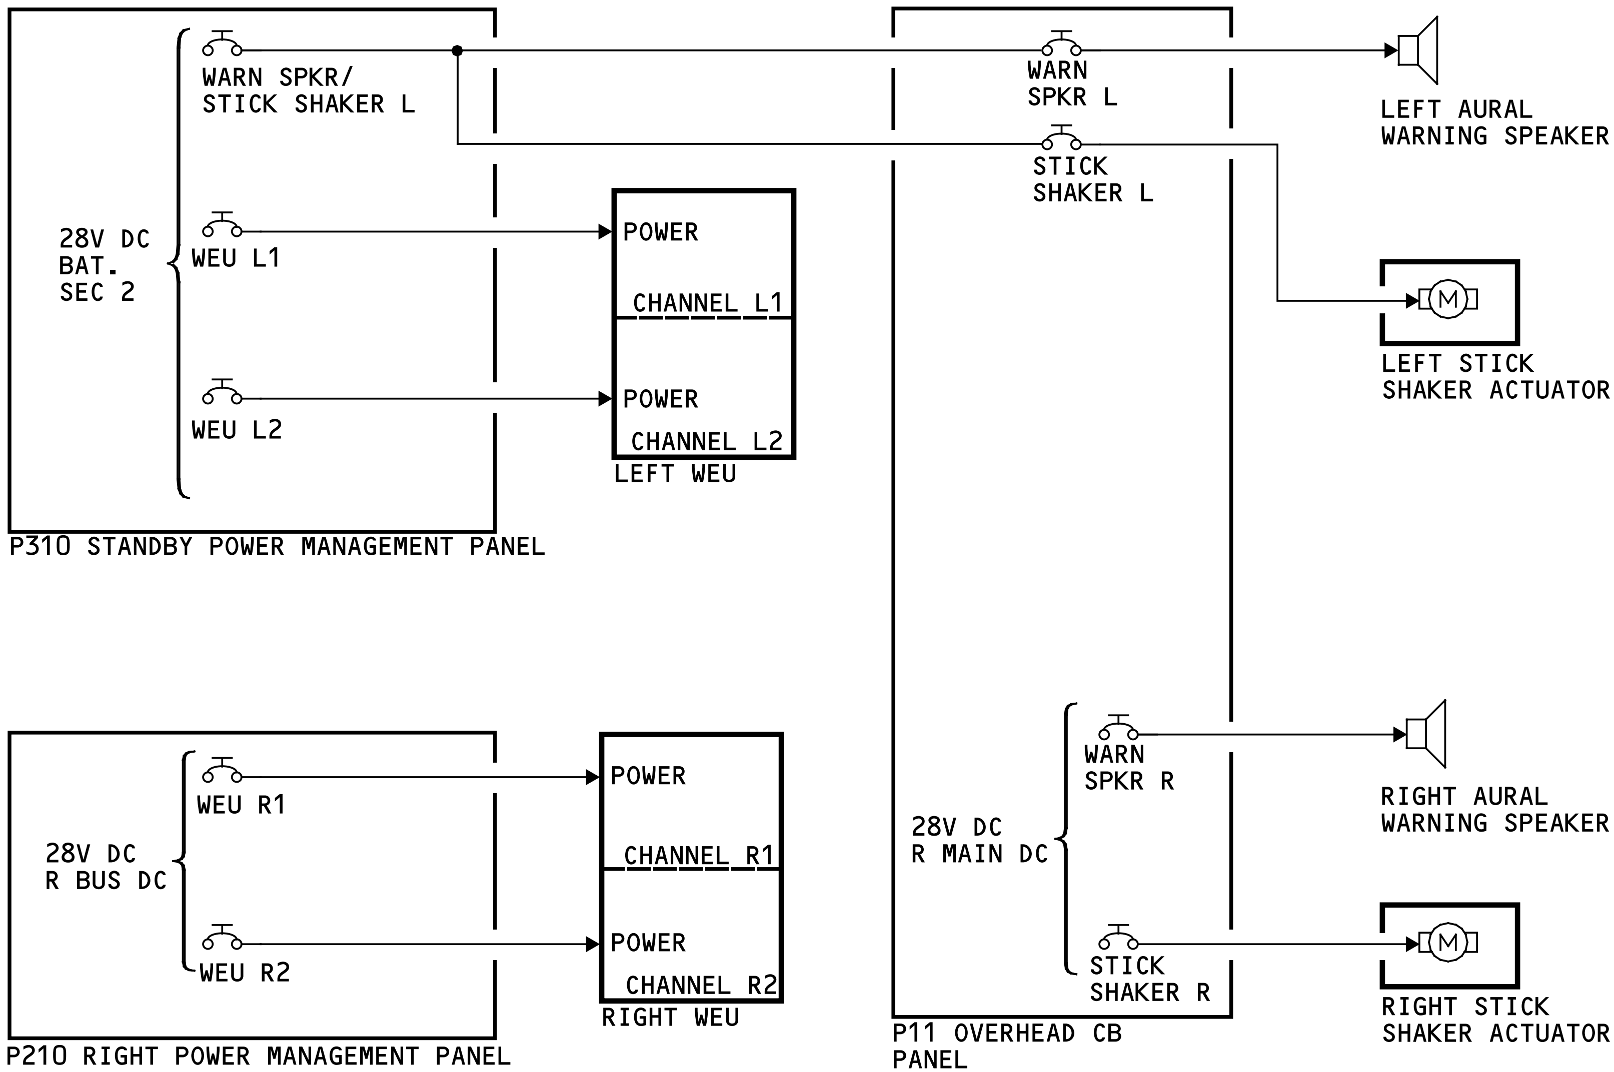
WES - POWER INPUTS

General

Each WEU receives two 28v dc inputs, one for each internal channel.

Each aural warning speaker and each stick shaker actuator receives 28v dc for operation.



31-51-00-005 Rev 0

WES - POWER INPUTS

WES - DIGITAL INTERFACES

ARINC 629 Interface

Each WEU channel connects to two system ARINC 629 buses.

Left WEU channel 1 (L1) transmits to and receives data from the left bus. Channel L1 only receives data from the center 1 bus.

Left WEU channel 2 (L2) transmits to and receives data from the center 1 bus. Channel L2 only receives data from the left bus.

Right WEU channel 1 (R1) transmits to and receives data from the right bus. Channel R1 only receives data from the center 1 bus.

Right WEU channel 2 right (R2) transmits to and receives data from the center 1 bus. Channel R2 only receives data from the right bus.

ARINC 629 Value Selection

One ARINC 629 data bus can have the same data value more than once. For example: radio altitude data from the left, center, and right radio altimeter transceivers is on the left system ARINC 629 bus.

Each WEU channel uses data from one ARINC 629 bus input.

Left WEU channel 1 (L1) uses data from the left bus. If a data value in the left bus fails, channel L1 uses the same data value from the center 1 bus.

Left WEU channel 2 (L2) uses data from the center 1 bus. If a data value in the center 1 bus data fails, channel L2 uses the same data value from the left bus.

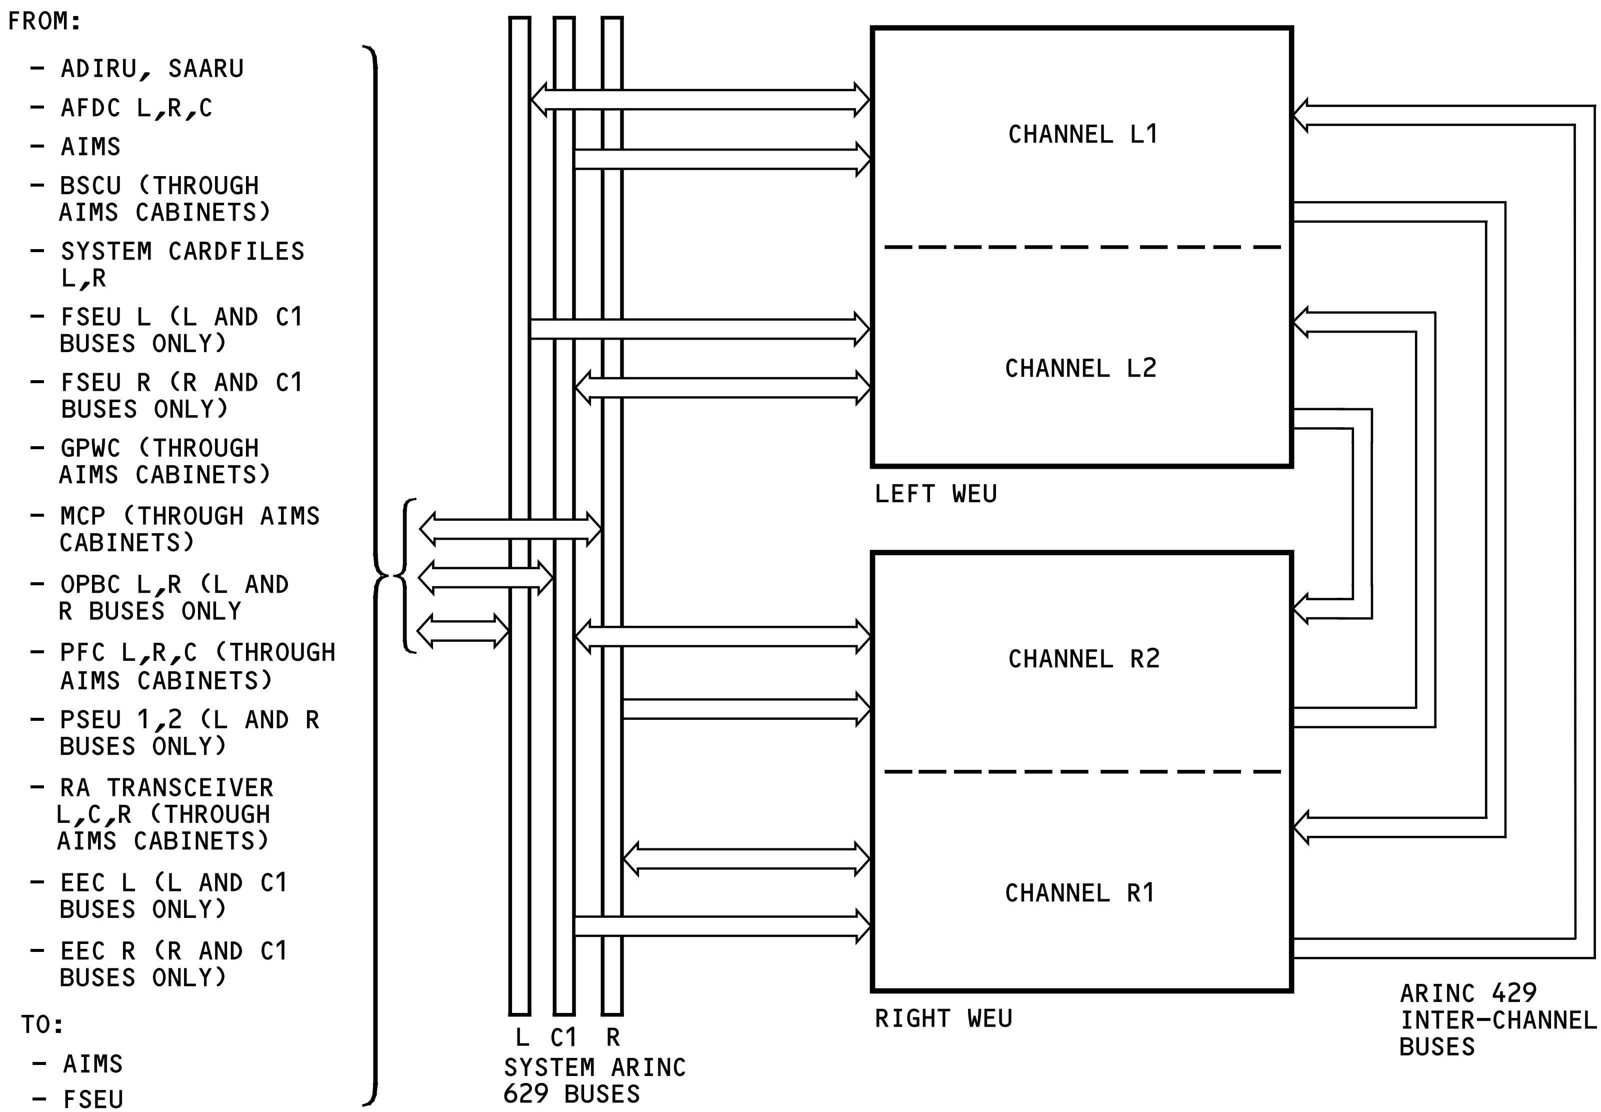
Right WEU channel 1 (R1) uses data from the right bus. If a data value in the right bus fails, channel R1 uses the same data value from the center 1 bus.

Right WEU channel 2 (R2) uses the center 1 bus. If a data value in the center 1 bus fails, channel R2 uses the same data value from the right bus.

Proximity switch electronic unit (PSEU) data selection is also different from the previous explanation. If at least one PSEU supplies a good data value to the WEUs, the WEUs use that data value.

ARINC 429 Inter-Channel Buses

Each WEU channel receives data from the opposite WEU on an ARINC 429 bus. Each WEU channel transmits data to the opposite WEU on an ARINC 429 bus.



WES - DIGITAL INTERFACES

31-51-00-006 Rev 3 01/23/1998

WES - ANALOG INTERFACES - 1

Autopilot Disconnect

The three autopilot flight director computers (AFDCs) supply autopilot disconnect ground signals to the WEUs when the autopilot disconnects. The WEUs use these inputs to make the master warning lights come on and make a siren aural.

Nose Gear Pressure Switch

The nose gear pressure switch supplies an aft or forward center of gravity (CG) signal to the WEUs. The WEUs use this input to verify stabilizer green band calculations.

Alternate Gear Down Dispatch Switch

The alternate gear down dispatch switch supplies three ground discrete signals to each WEU. When the switch is in the maximum operating speed (VMO) position, the WEUs use these signals to modify the maximum operating speed (VMO) and maximum operating mach (MMO).

Ground Proximity Gear Override Switch

The ground proximity gear override switch supplies an on/off signal to the WEUs. The WEUs use this input to inhibit the landing configuration warning siren.

Master Warning Light Interface

The left WEU makes the left master warning light come on. The right WEU makes the right master warning light come on. Each of the two channels in each WEU supplies a master warning arm signal to the opposite WEU. The master warning lights come on when at least two channels generate the master warning light on command.

Push the master warning lights to send a reset ground discrete signal to the WEUs. The reset signal makes the master warning lights go out. The master warning lights also go out when the problem that made them come on goes away.

GPWC,TCAS, and PWS Interface

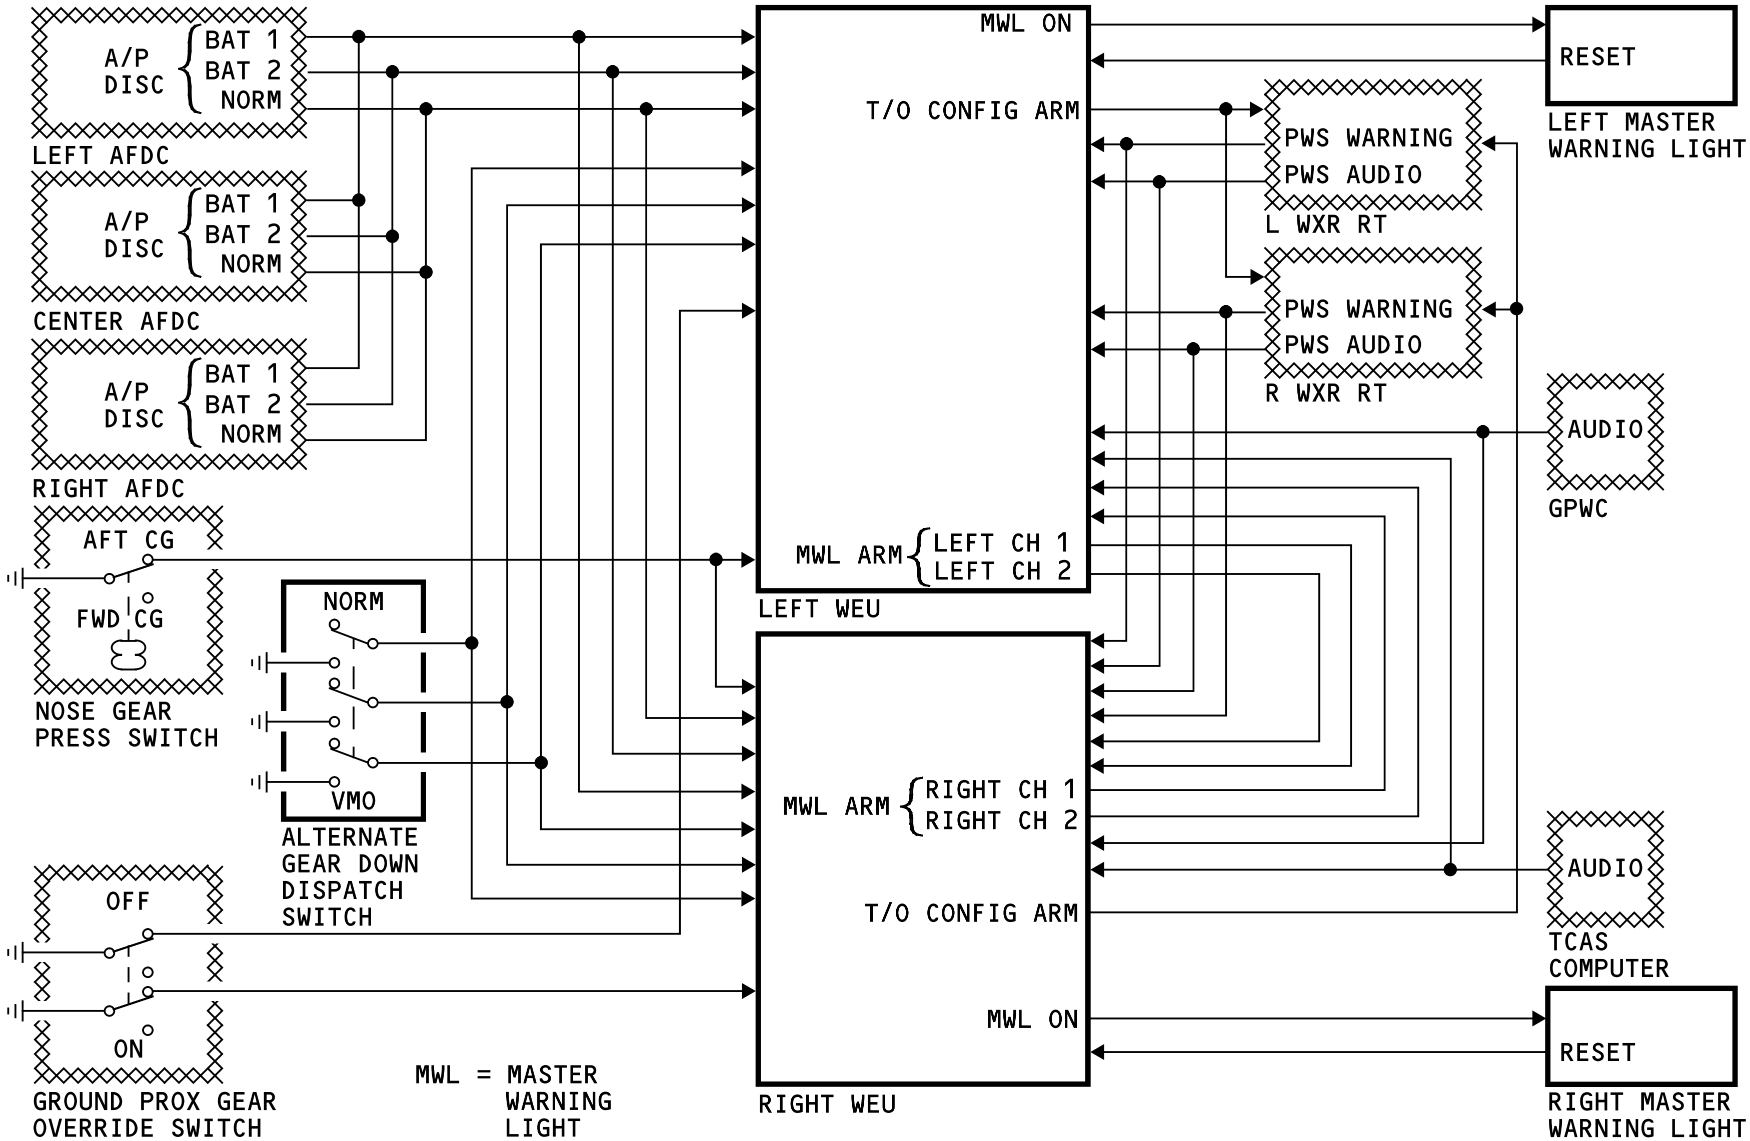
These systems supply analog alert audio to the WEU:

- Ground proximity warning system (GPWS)
- Traffic alert and collision avoidance system (TCAS)
- Weather radar (WXR) - For predictive windshear (PWS) alerts.

The WEUs amplify and send this audio to the aural warning speakers.

PWS Warning Discrete

The predictive windshear function in WXR sends a warning discrete to the WEUs. This discrete causes the master warning lights to come on when there is a PWS warning alert.



WES - ANALOG INTERFACES - 1

WES - ANALOG INTERFACES - 2

Fire Warning Inputs

The warning electronic units (WEUs) receive engine fire and APU fire signals from the engine and APU fire detection cards. The WEUs use these inputs to make a fire bell aural and to make the master warning lights come on.

Hydraulic Interface Modules Interface

The WEUs supply autoslat enable signals to the hydraulic interface modules (HYDIMs). The HYDIMs use these signals to increase available hydraulic flow for the slats.

Main Gear Steering Control Unit Interface

The main gear steering control unit (MGSCU) supplies main landing gear steering signals to the WEUs. The WEUs use these signals for takeoff configuration warning.

Stick Shaker Outputs

The stall warning function of the WEUs makes the stick shaker actuators come on when the airplane is near a stall.

Aural Warning Speaker Interface

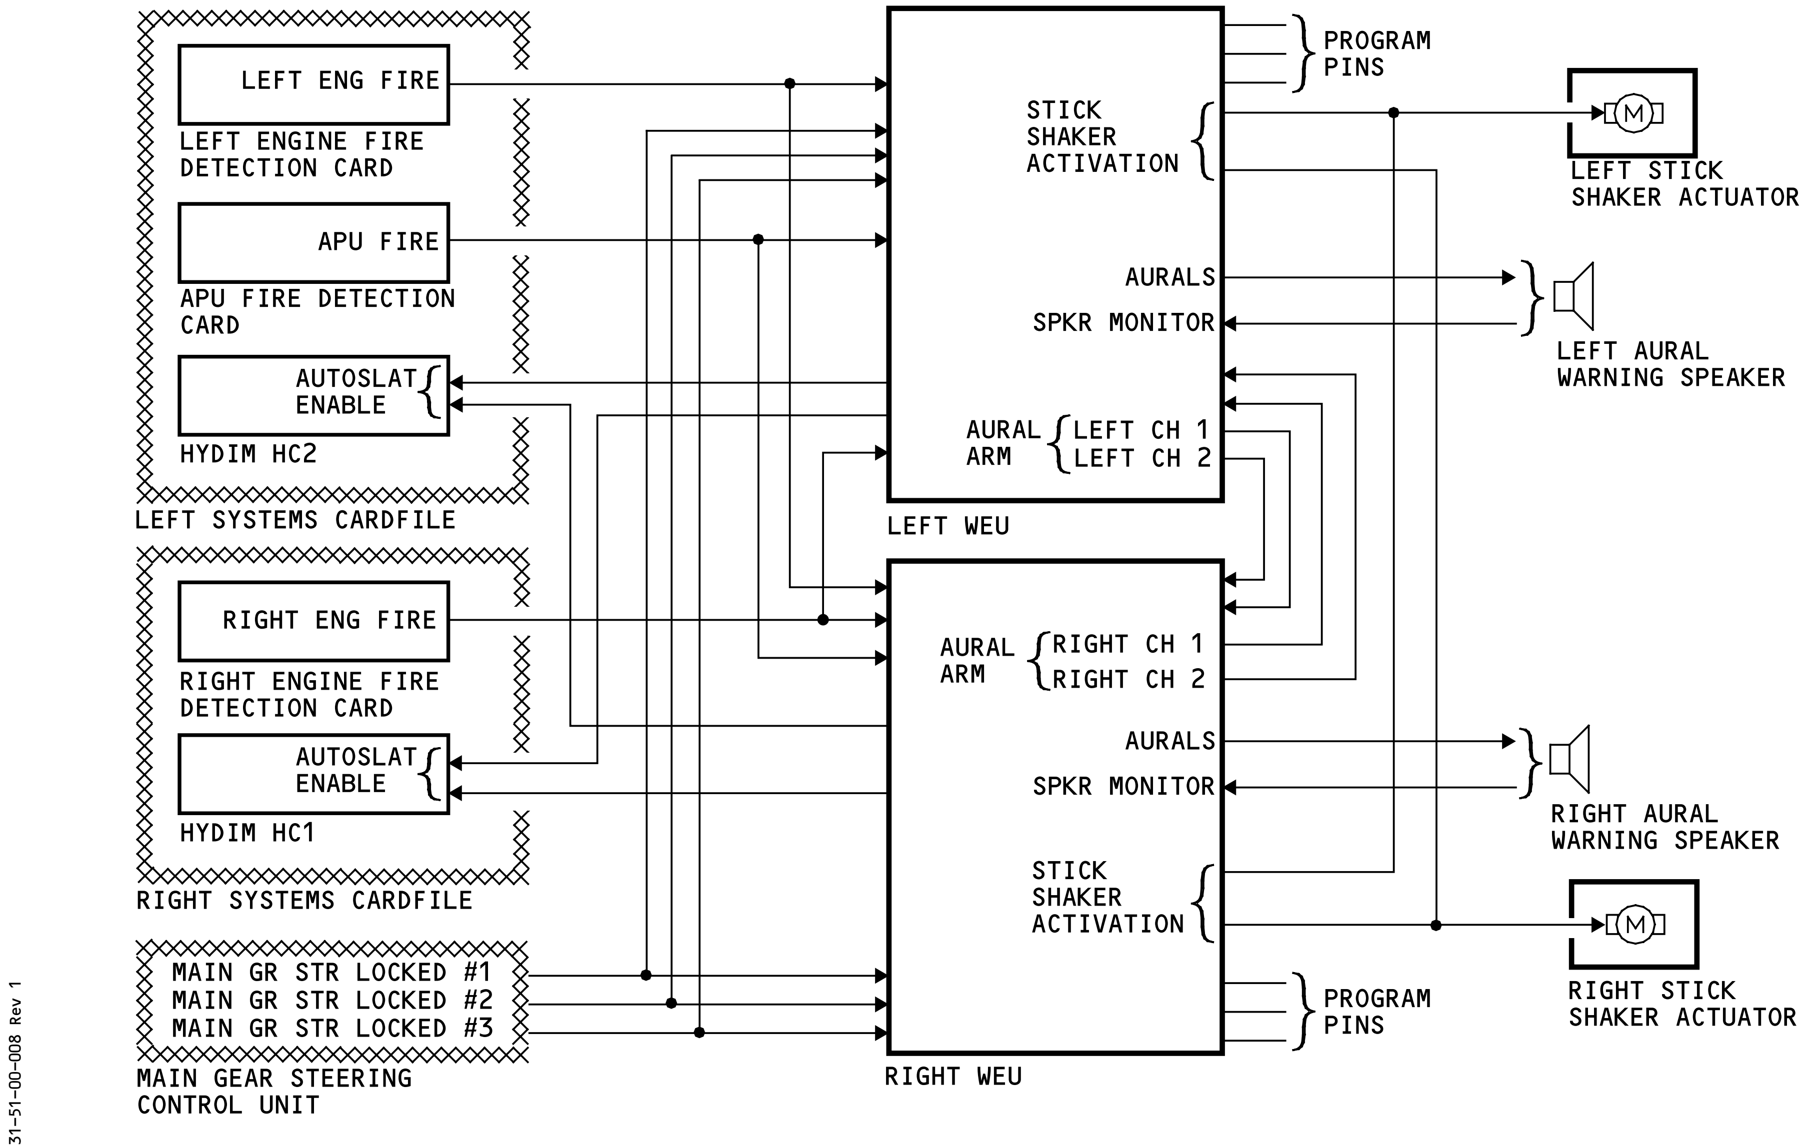
The left WEU supplies alert aurals to the left aural warning speaker. The right WEU supplies alert aurals to the right aural warning speaker.

The two channels in each WEU supplY an aural arm signal to the opposite WEU. An alert aural comes on when at least two channels generate the aural arm command.

The aural warning speakers send speaker monitor signals to the WEUs. The WEUs use these signals to check the speaker status.

Program Pins

Each WEU has program pins. Some program pins identify each WEU (left or right). The WEUs have other program pins, but they are for flight test only.



WES - ANALOG INTERFACES - 2

WES - WARNING ELECTRONIC UNIT

Purpose

The warning electronic unit (WEU) receives inputs from various systems. The WEU uses these inputs to show warning and alert indications to the flight crew.

WEU Channels

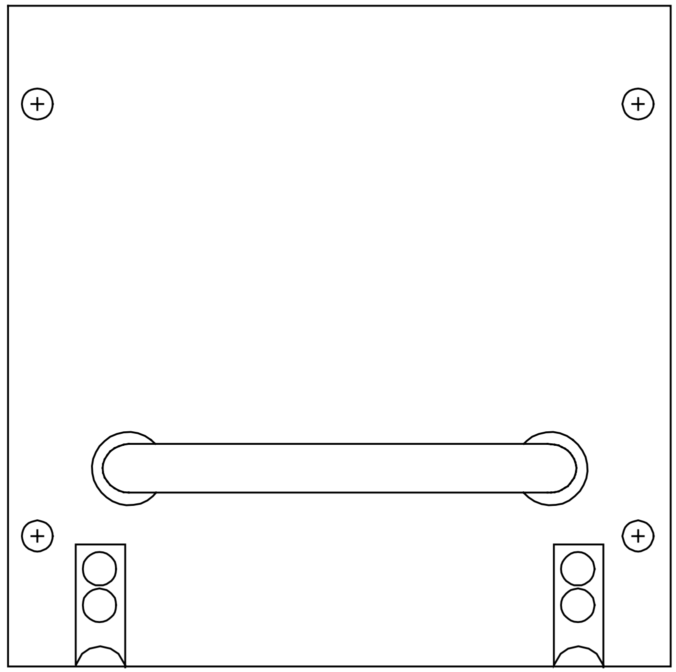
Each WEU has two channels that:

- Make alert aurals
- Do airplane configuration warning
- Do stall warning computations
- Process crew alerting signals.

The WEUs send data to each other. The WEU supplies warning and alerting outputs only when at least two out of the four channels make an output.

Software Loading

The WEUs must have software loaded in them. You use the maintenance access terminal (MAT) to load software into the WEUs.



31-51-00-009 Rev 2

WES - WARNING ELECTRONIC UNIT

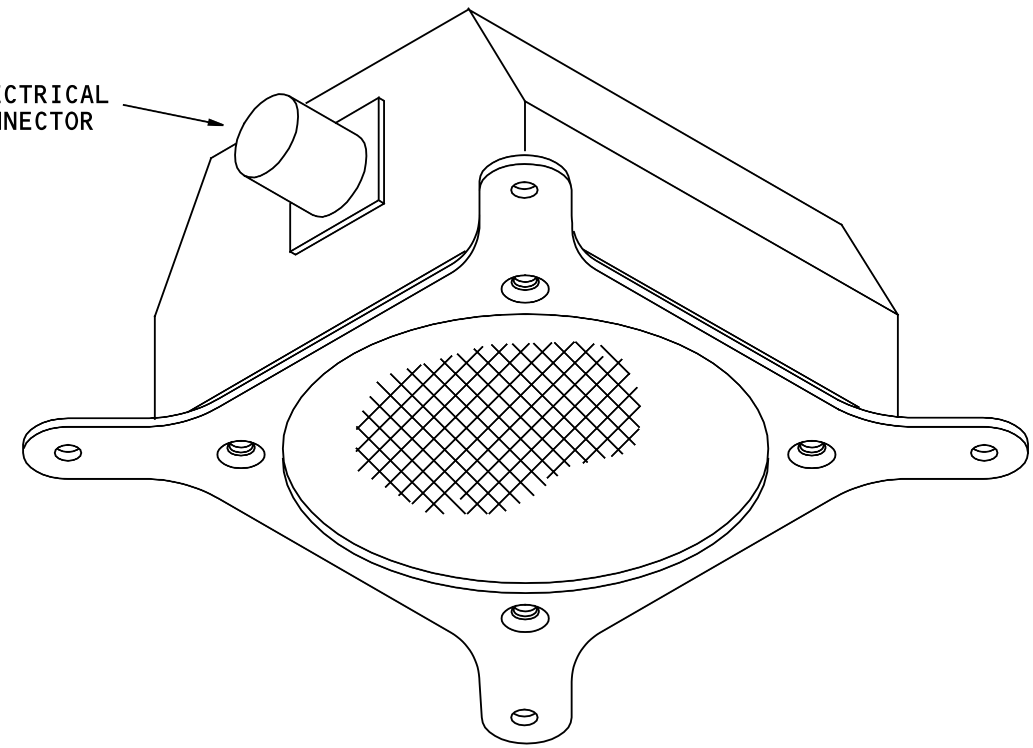
WES - AURAL WARNING SPEAKER

General

The aural warning speakers supply alert aurals to the flight crew.

There are two aural warning speakers. Each speaker gets 28v dc. The 28v dc energizes an amplifier in the speaker.

Each aural warning speaker supplies a speaker monitor signal to its WEU.



31-51-00-010 Rev 0

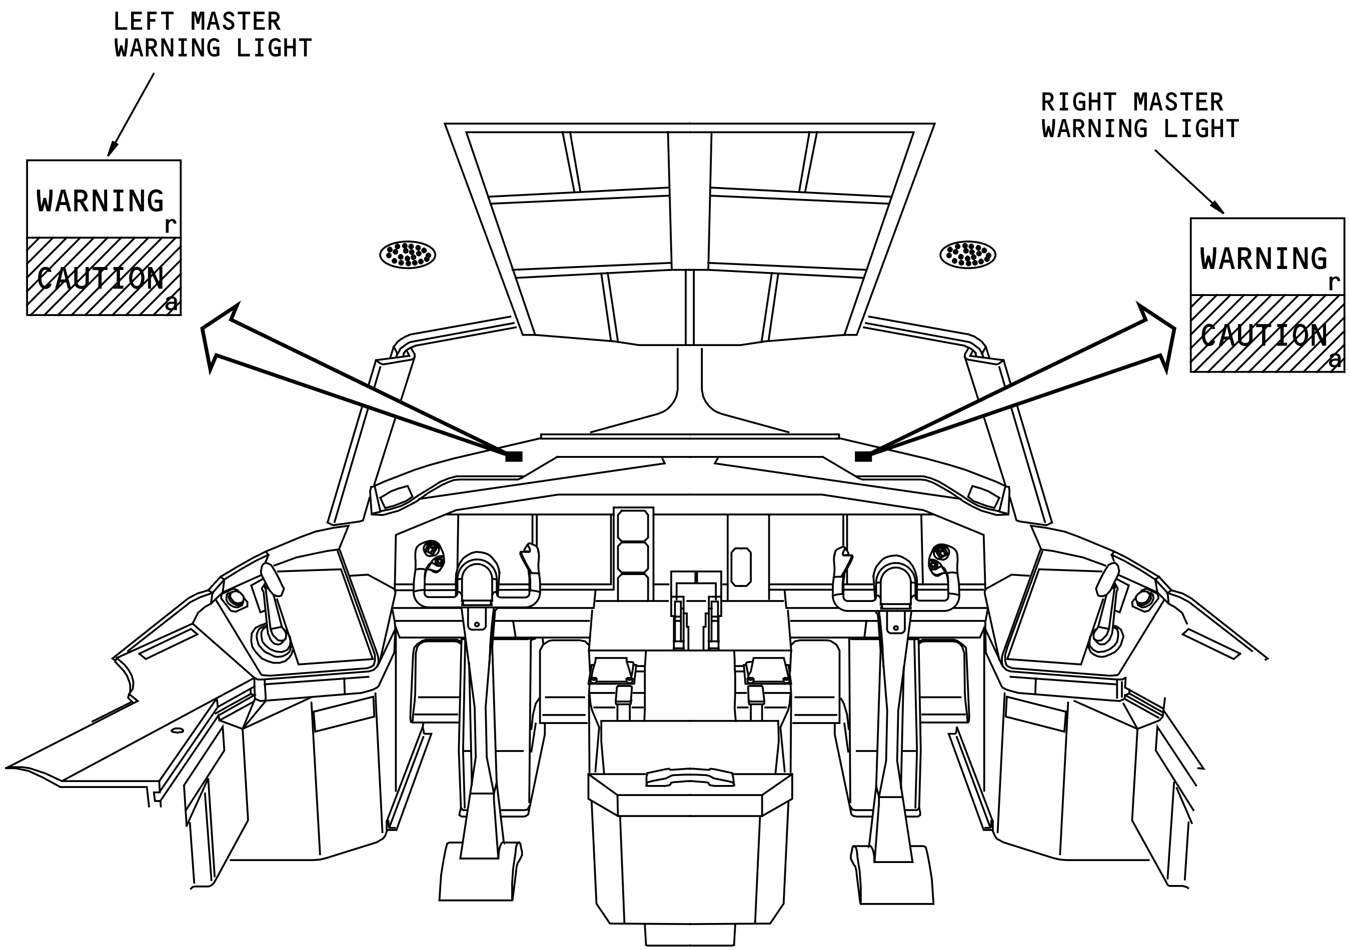
WES - AURAL WARNING SPEAKER

WES - MASTER WARNING LIGHTS

General

The master warning lights come on when the WEU sends a ground signal. The warning lights come on if there is a warning condition.

The master warning lights go out when the warning condition goes out, or when the flight crew pushes the lights.



31-51-00-011 Rev 0

WES - MASTER WARNING LIGHTS

WES - SPEEDBRAKE LEVER, STABILIZER POSITION INDICATOR, FLAP LEVER

General

The speedbrake lever, stabilizer position indicator, and flap lever are not WES components. However, they are critical for WES operation.

Speedbrake Lever

The speedbrake lever moves the speed brakes.

Stabilizer Position Indicator

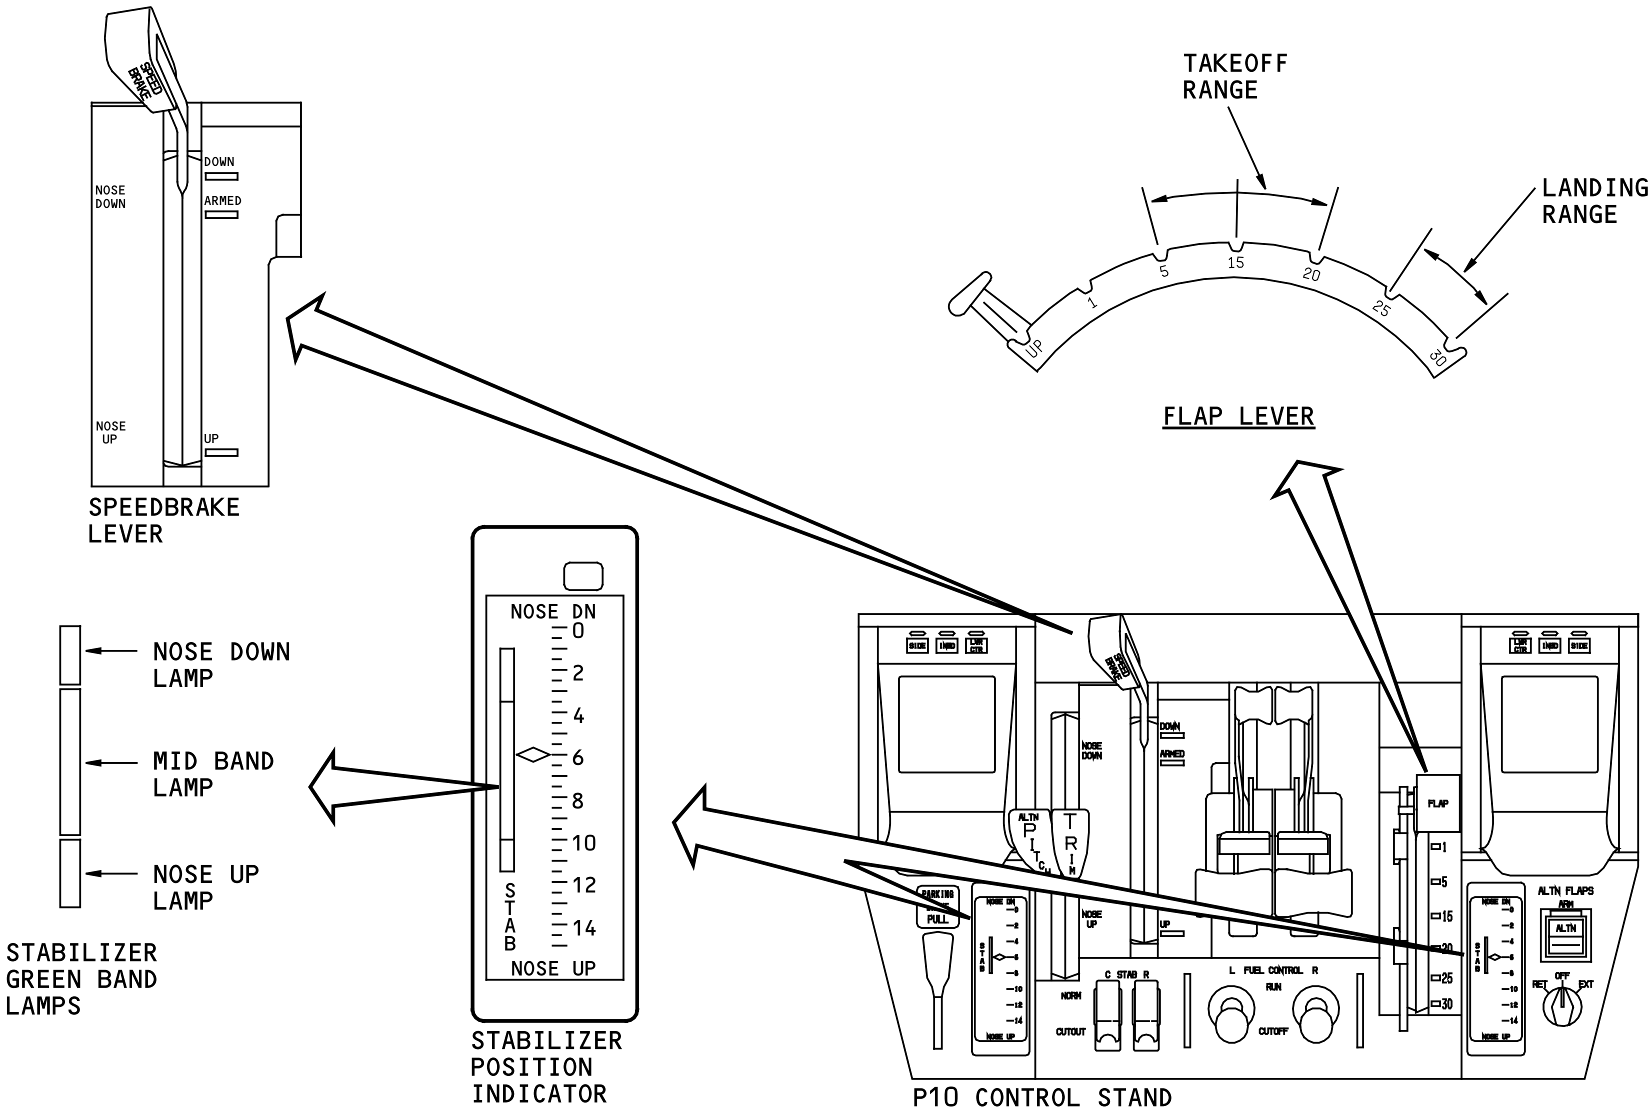
The stabilizer position indicators show the horizontal stabilizer position. Each indicator has three stabilizer green band lamps:

- Nose down
- Mid band
- Nose up.

The stabilizer green band lamps show the correct horizontal stabilizer position range for takeoff. The WEUs makes the stabilizer green band lamps come on.

Flap Lever

The flap lever sets the trailing edge and the leading edge devices position.



WES - SPEEDBRAKE LEVER, STABILIZER POSITION INDICATOR, FLAP LEVER

31-51-00-012 Rev 2 02/27/1998

WES - STICK SHAKER ACTUATOR

General

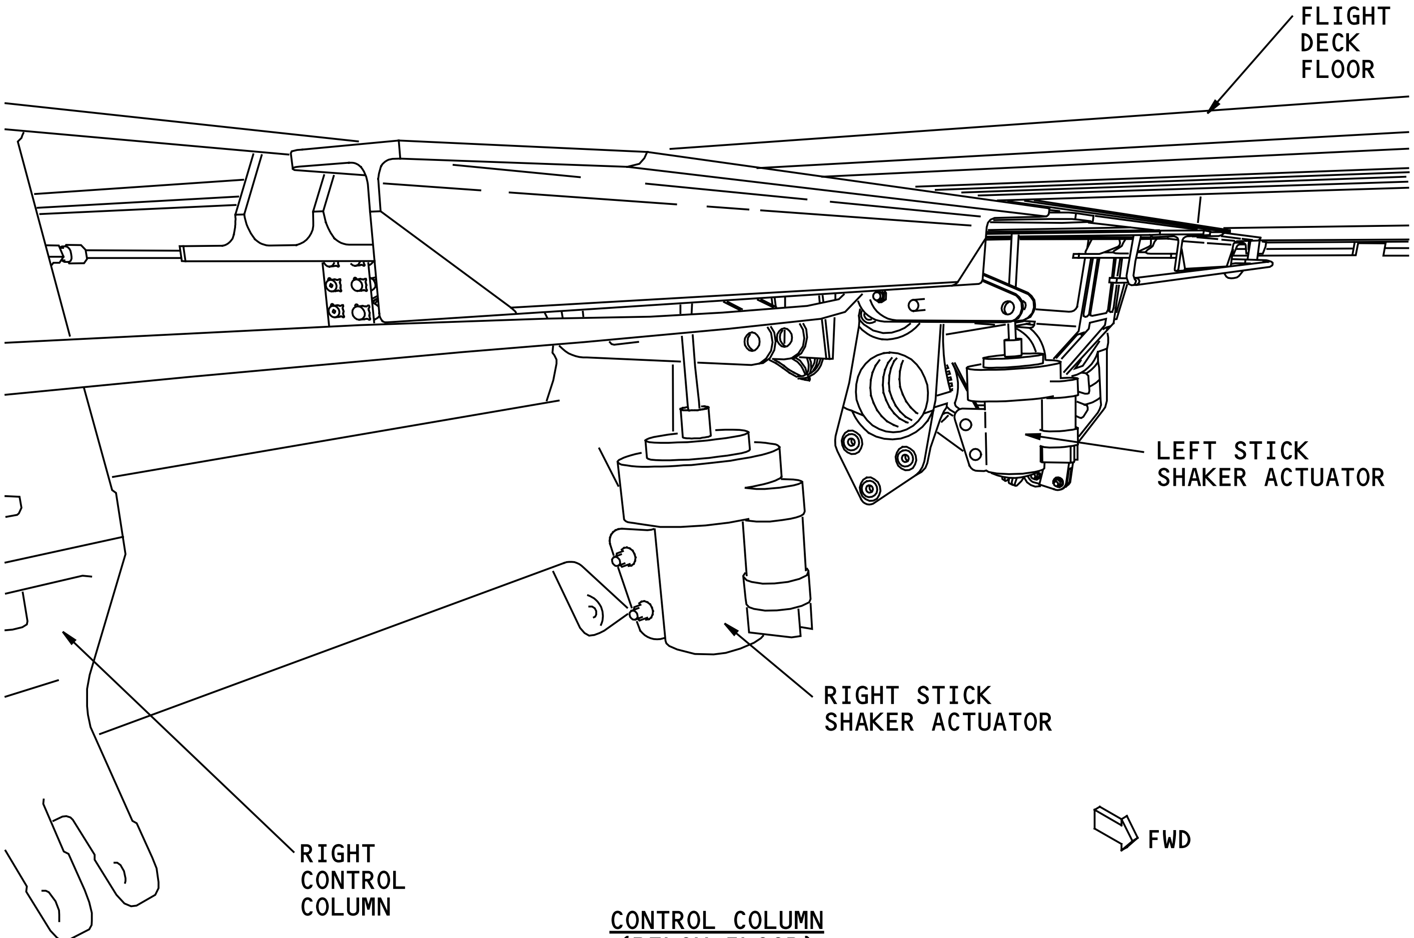
The stick shaker actuators are dc motors that shake the control columns when the airplane is near a stall condition.

The WEUs control the stick shaker actuators.

There are two stick shaker actuators, one below each control column.

Access

Access to the stick shaker actuators is from the forward equipment center.



31-51-00-013 Rev 0

WES - STICK SHAKER ACTUATOR

WES - ALTERNATE GEAR DOWN DISPATCH SWITCH

Description

The alternate gear down dispatch switch has two positions.

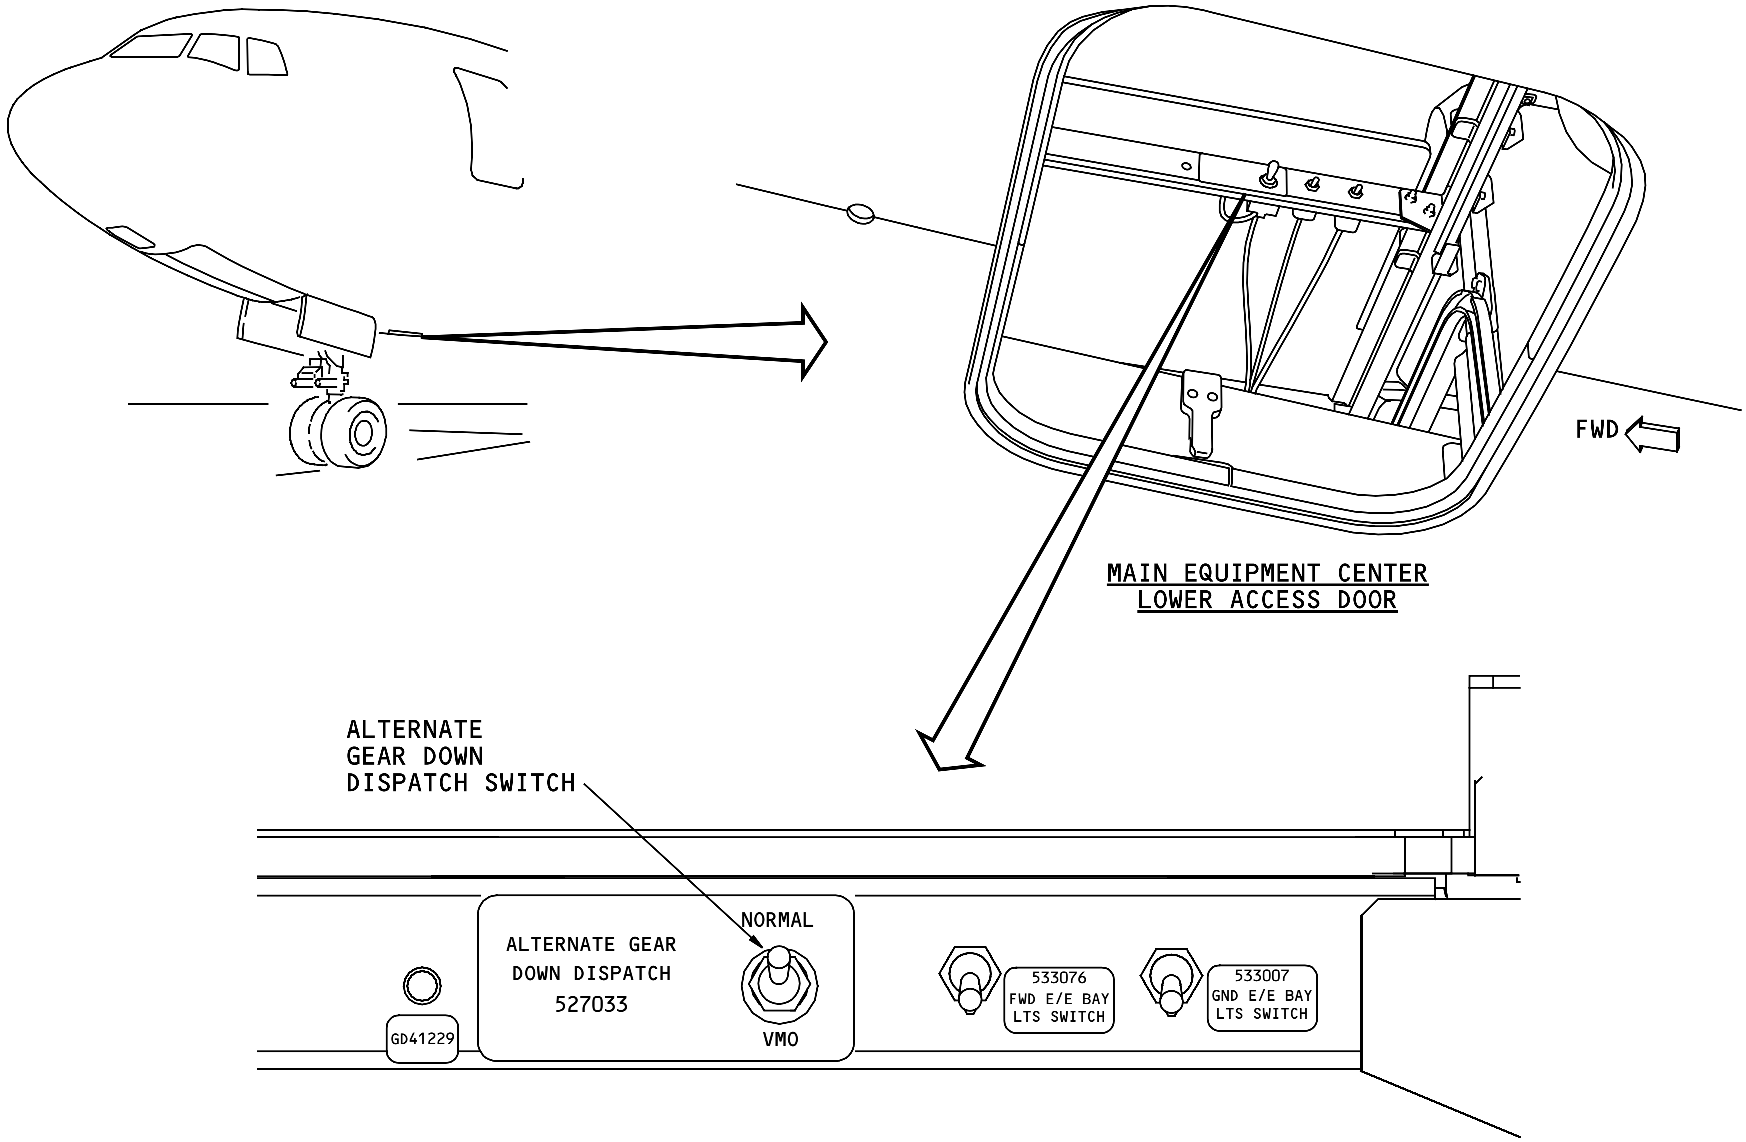
Operation

When the alternate gear down dispatch switch is in the maximum operating speed (VMO) position, the WEU channels use the switch signals to lower the maximum speed limit to 270 knots and the maximum operating mach (MMO) to mach .73.

When the alternate gear down dispatch switch is in the normal position, the VMO is 330 knots. The MMO is .87.

Training Information Point

The memo message VMO GEAR DOWN shows on EICAS when you put the switch in the VMO position.



WES - ALTERNATE GEAR DOWN DISPATCH SWITCH

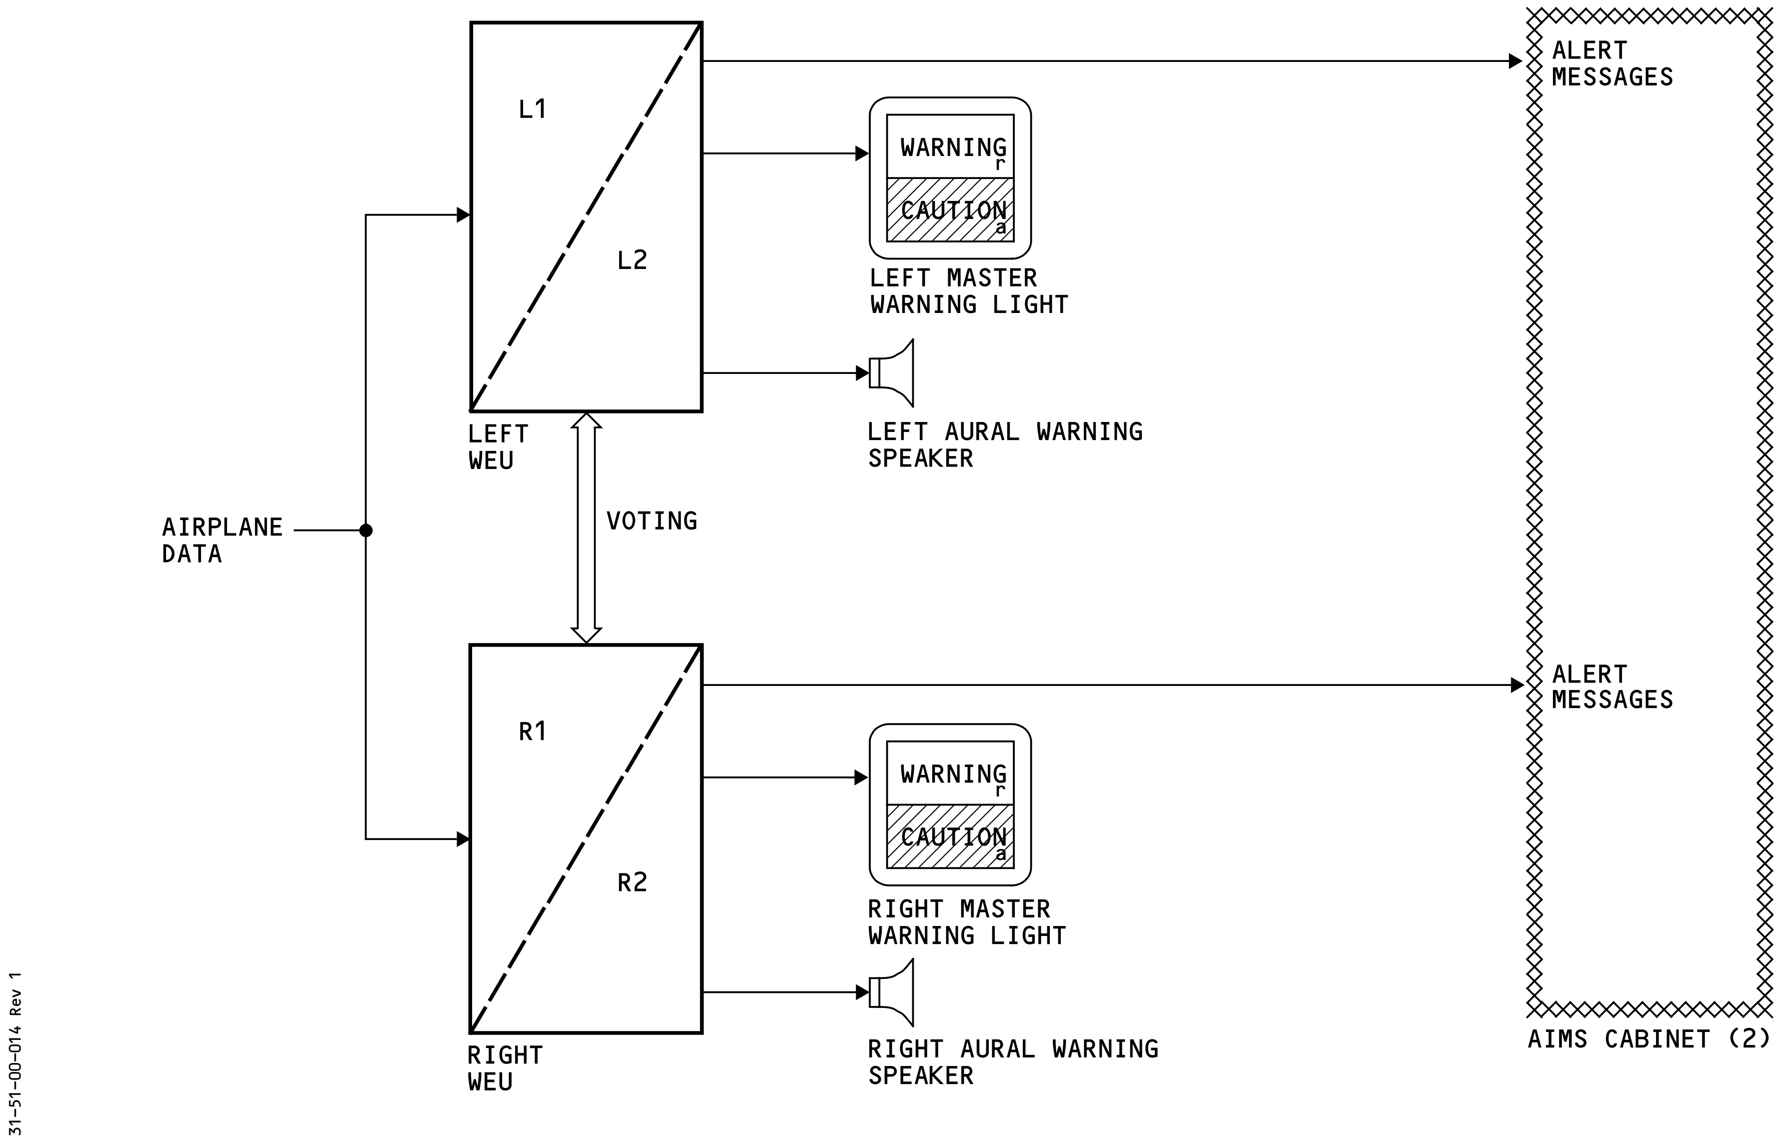
WES - INTERNALLY GENERATED WARNING AND ALERTS

Warning and Alerts

The WEUs receive airplane data to internally calculate and generate warnings and alerts. The four WEU channels vote to produce an alert or a warning. When any 2 out of the 4 channels make the same calculation, the WEUs make a warning or an alert.

These are the indications for warnings and alerts:

- Alert message requests to the AIMS cabinets. The AIMS uses the requests to show alert messages
- Master warning lights on
- Alert aurals.



WES - INTERNALLY GENERATED WARNING AND ALERTS

WES - EXTERNALLY GENERATED WARNING AND ALERTS

Warning and Alerts

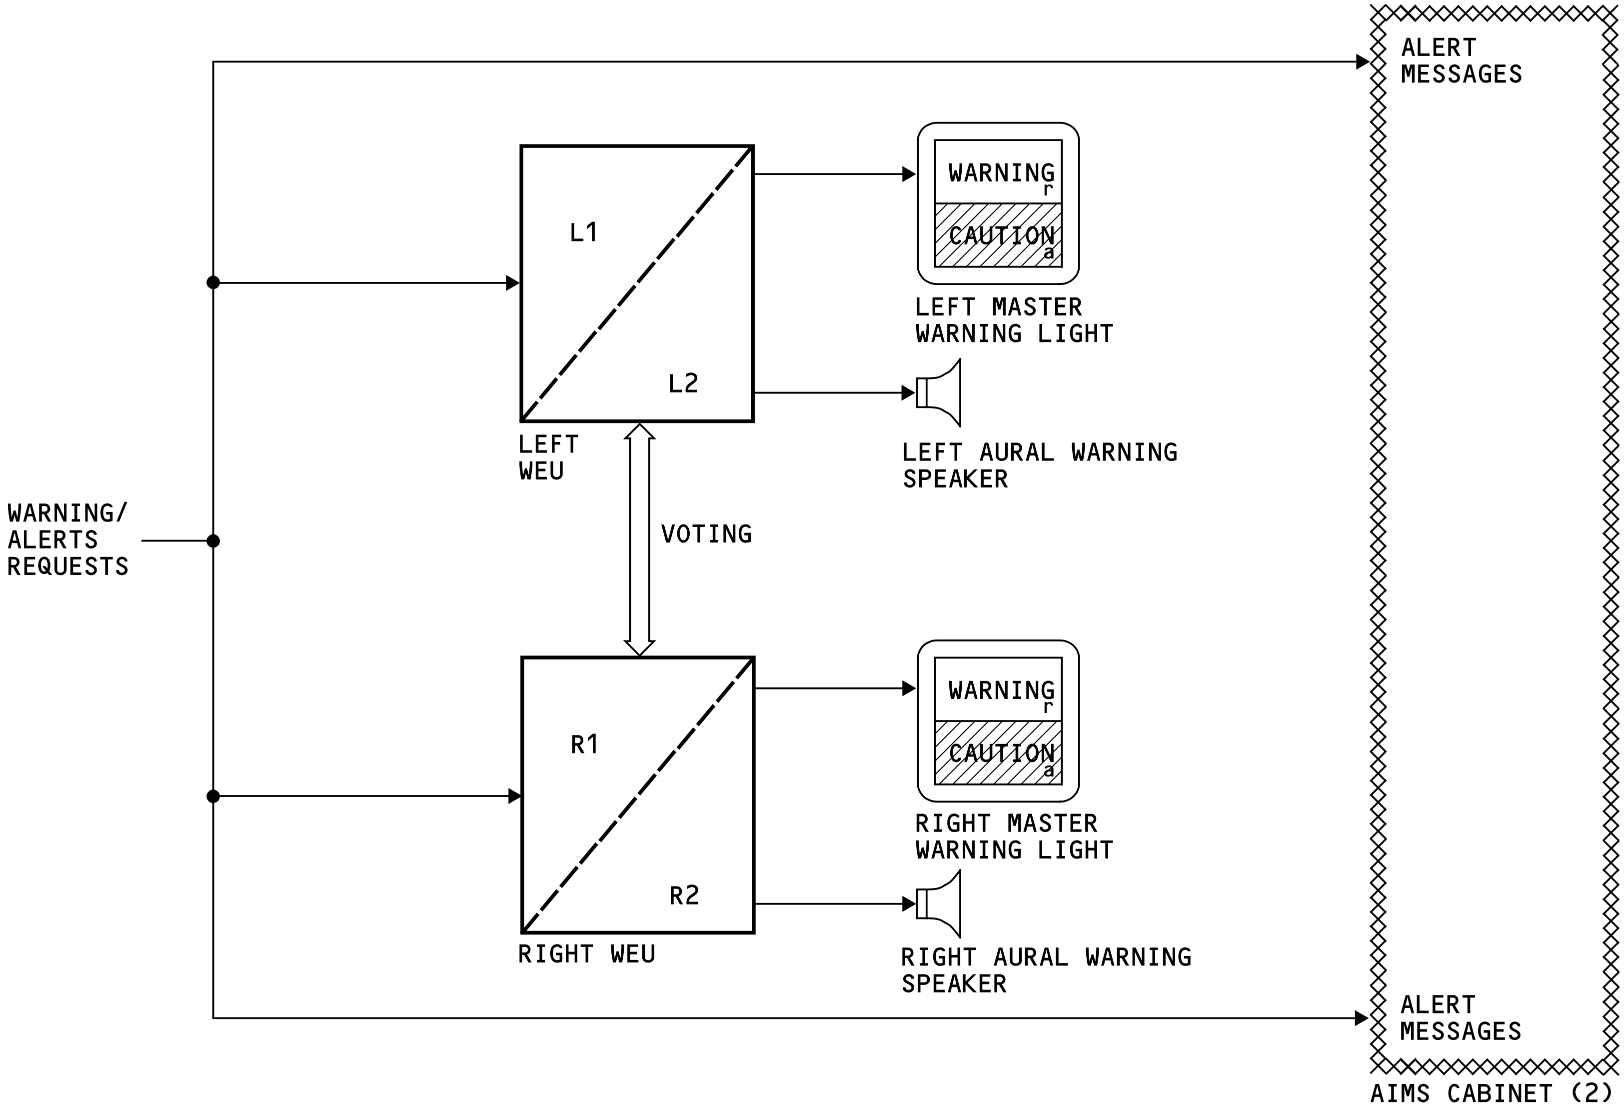
The WEUs receive warning and alert requests from airplane systems. In this case, the WEUs do not calculate an alert or a warning. The four WEU channels only vote to produce the alert or warning. When any 2 out of the 4 channels sense the same request, the WEUs make a warning or an alert.

These are the indications for warnings and alerts:

- Master warning lights on
- Alert aurals.

AIMS

The airplane systems also send warning and alert requests to the AIMS cabinets. The AIMS uses the requests to show alert messages.



31-51-00-015 Rev 1

WES - EXTERNALLY GENERATED WARNING AND ALERTS

WES - STICK SHAKER ACTUATION

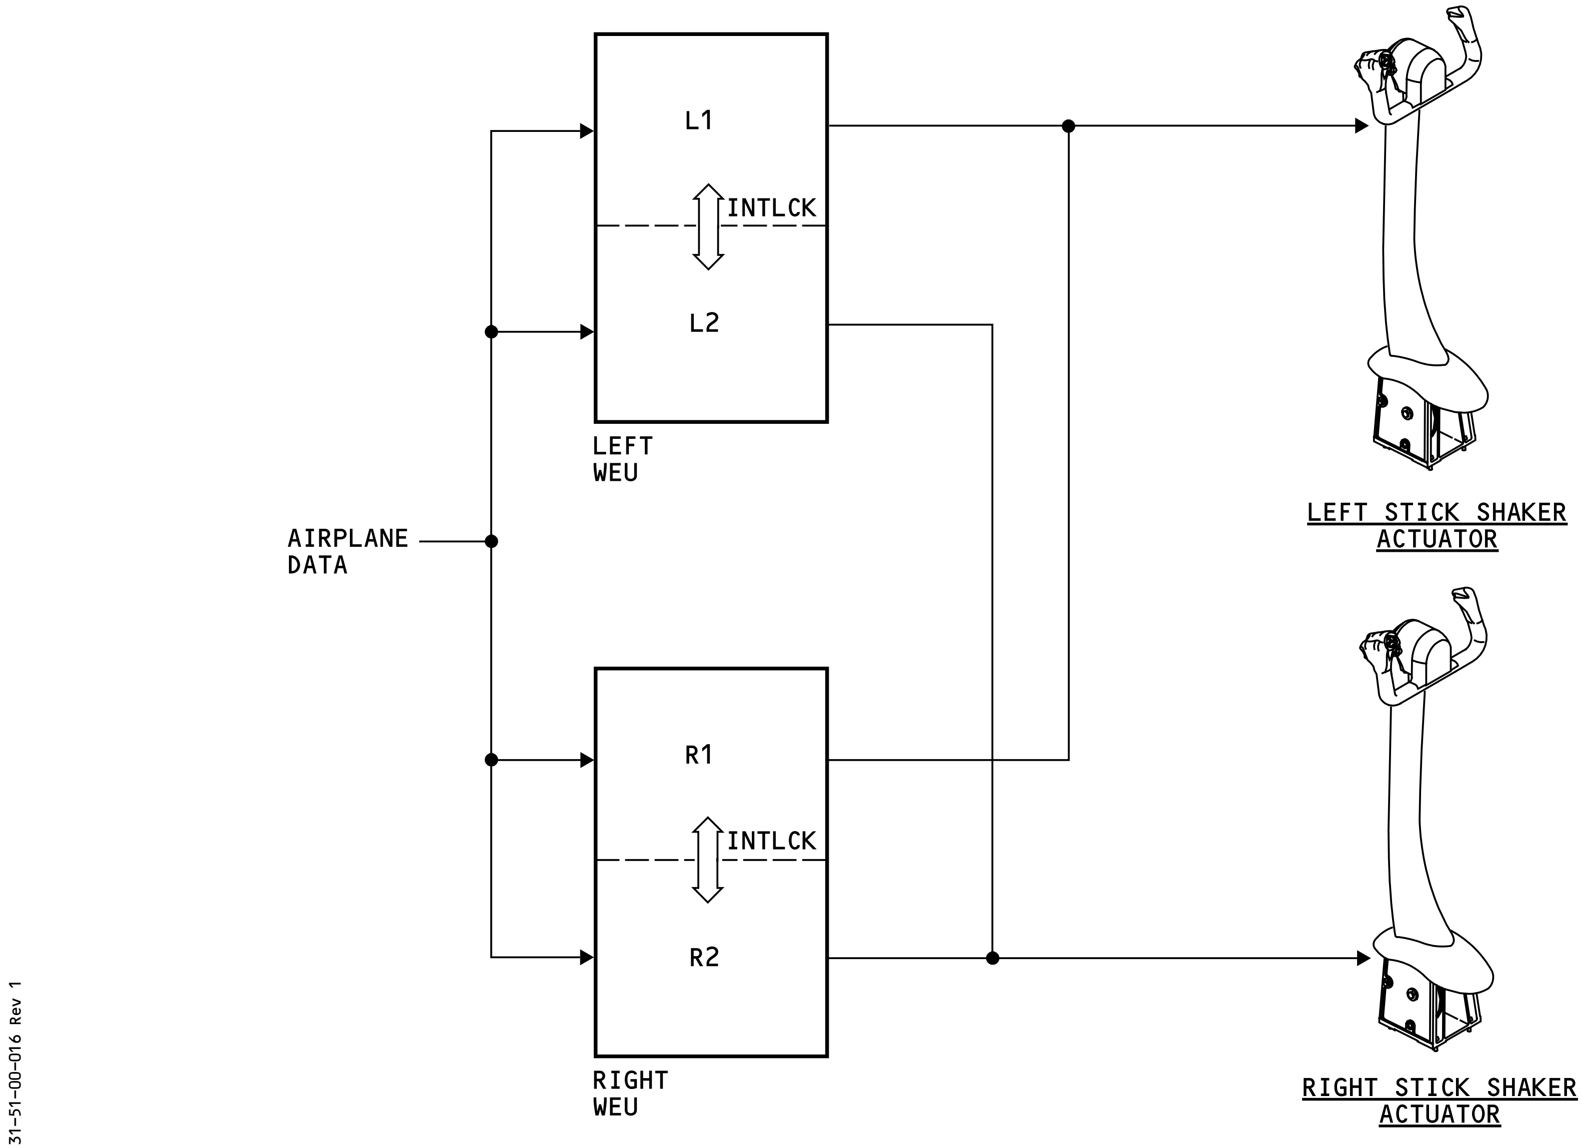
General

Each WEU channel independently calculates stick shaker actuator signals when the airplane is near a stall.

Interlocks

The stick shaker actuators come on only when the two channels inside a WEU produce a stick shaker actuation signal.

Any WEU can turn on both stick shaker actuators.



WES - STICK SHAKER ACTUATION

WES - TAKEOFF WARNING INHIBIT

Purpose and Operation

The takeoff warning inhibit prevents flight crew distractions during takeoff. The takeoff warning inhibit prevents some warning indications and some alert indications.

All channels in each WEU calculate the takeoff warning inhibit.

The takeoff warning inhibit starts when computed airspeed (VCAS) goes to the decision speed (V1), or pitch angle is 5 degrees or more.

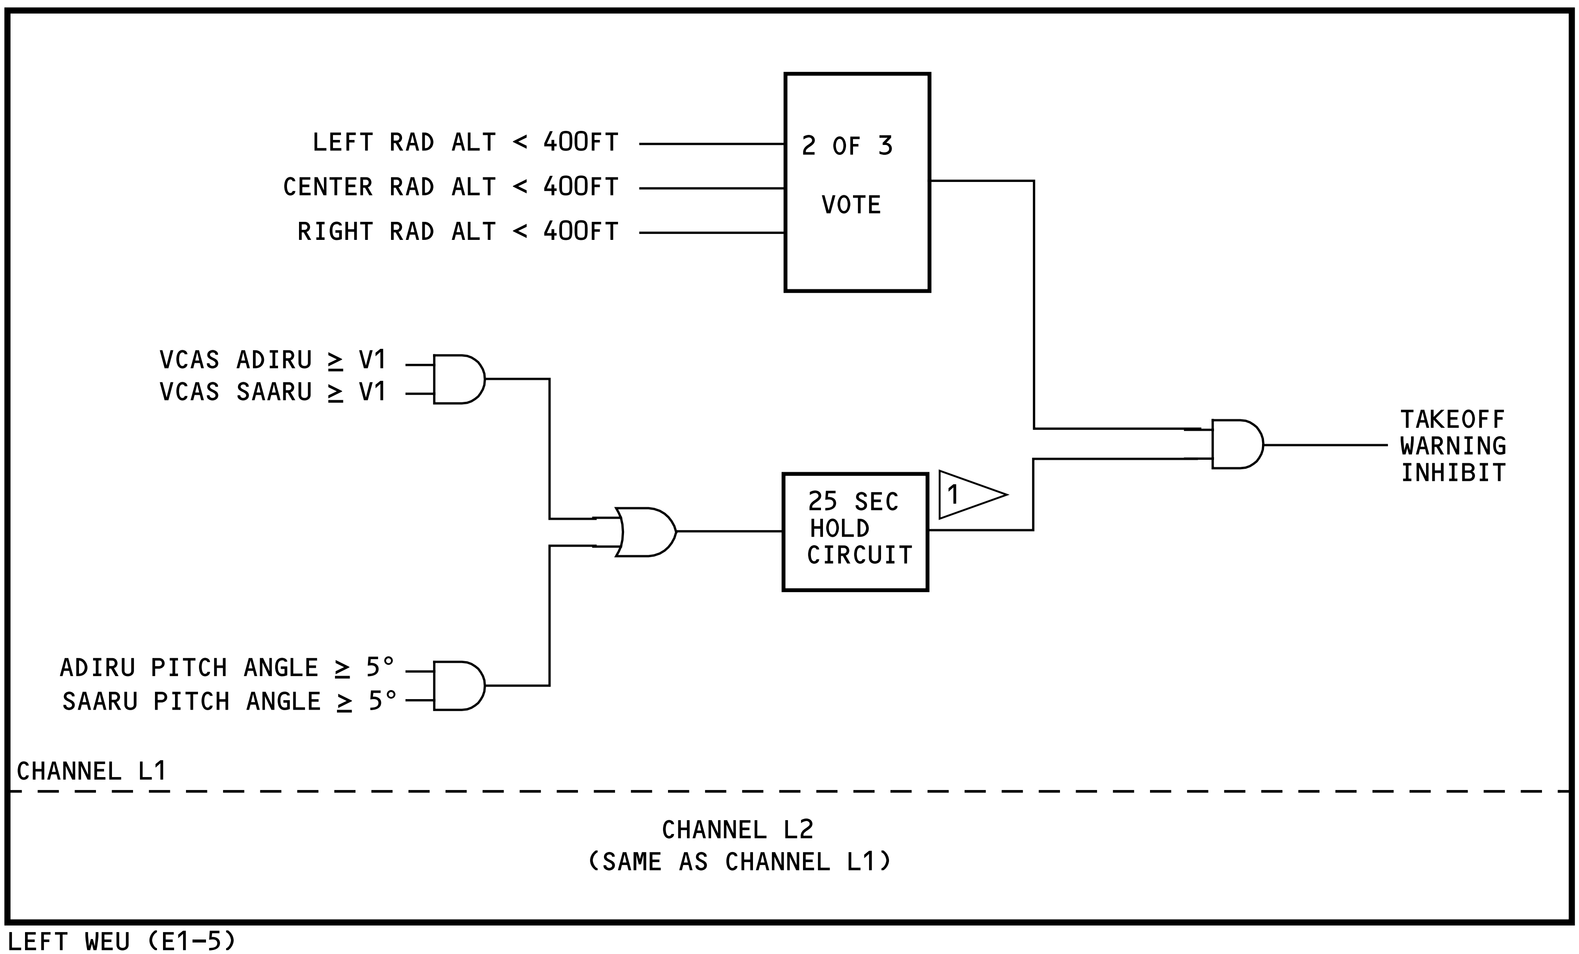
The takeoff warning inhibit stops when the radio altitude goes above 400 feet, or 25 seconds after either the pitch angle was 5 degrees or the airplane reaches V1.

Warnings and Alerts Prevented

The takeoff warning inhibit prevents these warnings and alerts:

- Cabin pressure
- Fire warning
- Altitude alert
- Overspeed
- Takeoff configuration warning.

31-51-00-017 Rev 1



1 WHEN THE INPUT GOES FROM LOW TO HIGH, THE OUTPUT GOES HIGH FOR 25 SECONDS. THEN THE OUTPUT GOES LOW.

31-51-00-017 Rev 1

WES - TAKEOFF WARNING INHIBIT

WES - ALERT AURAL GENERATION

THIS PAGE INTENTIONALLY LEFT BLANK

WES - ALERT AURAL GENERATION

Alert Aurals

The aural synthesizer control function of the WEU gives and amplifies alert aurals. These are the alert aurals, in order of priority:

- Siren
- Fire bell
- Caution
- Chime.

Siren

For all EICAS warning messages, except fire, the WEUs give the siren aural. The siren is a sound that alternates between 250 Hz and 950 Hz. The siren has the highest priority.

Fire Bell

The WEUs give the fire bell aural when there is a fire. The fire bell is a bell sound that is on for 0.85 seconds and off for 9.5 seconds. The fire bell is second in priority.

Caution

The WEUs give the caution aural when there is an EICAS caution message. The caution is four tones one after the other. Each tone is 160 msec long. Each tone has a constant amplitude and a frequency that varies from 20 Hz to 950 Hz. The caution aural is third in priority.

Chime

The WEUs give a high/low chime when there is a call to the flight deck, or when a comm low or medium message shows. The high/low chime is two tones one after the other. The first tone is 1160 Hz with an amplitude that goes down with time. The second tone is 580 Hz with an amplitude that goes down with time. The chime aural is the lowest in priority.

GPWS, PWS and TCAS

The WEUs do not make the GPWS, PWS, and TCAS alert aurals. The GPWS, PWS, and TCAS supply analog alert aurals to the WEUs. The WEUs amplify these alert aurals. The GPWS, PWS, and TCAS alert aurals have no priority. They go on top of other WEU alert aurals.

Alert Aural Logic

Each channel in each WEU makes the same alert aurals.

The alert aural logic makes alert aural requests. The requests are part of the warning and alert conditions for the WEUs.

When the alert aural logic makes an alert aural request, it also makes an aural arm signal. This signal goes to the other three WEU channels. The aural arm signal also permits the WEU channel to make alert aurals.

WES - ALERT AURAL GENERATION

Alert Aural Priority Logic

The alert aural priority logic receives alert aural requests from the alert aural logic.

If there is more than one alert aural request at a time, the alert aural priority logic decides which alert aural has the higher priority.

Only the higher priority alert aural request goes through the alert aural priority logic.

Two of Four Vote

The alert aural requests go to the aural synthesizer only when at least one other WEU channel supplies an aural arm signal.

Aural Synthesizer

The aural synthesizer makes the alert aurals. Gain control circuits set the aural synthesizer audio gain.

TCAS and GPWS Aurals

Each WEU mixes traffic alert and collision avoidance system (TCAS) and ground proximity warning system (GPWS) alert aurals with all other aurals.

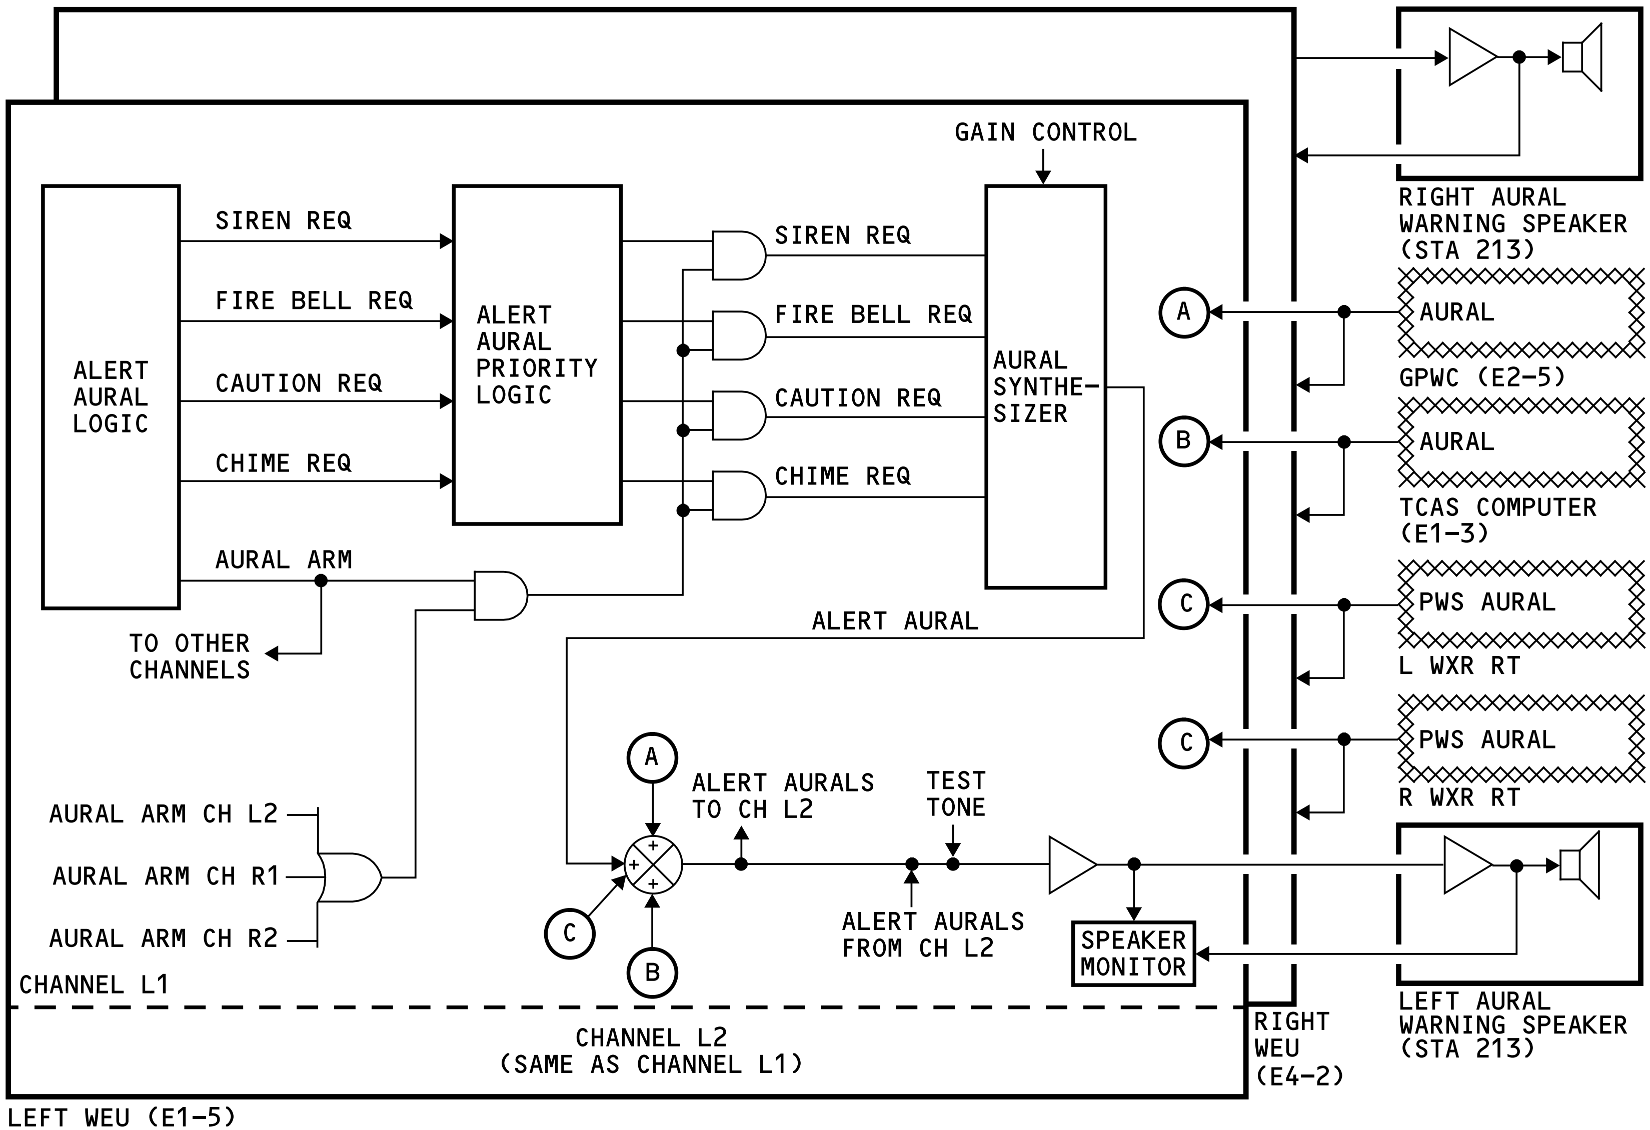
Opposite Channel Aurals, and Aural Warning Speaker Interface

Only channel 1 on each WEU has a direct connection to the aural warning speakers. The left WEU connects to the left aural warning speaker, and the right WEU connects to the right aural warning speaker. Channel 2 on each WEU supplies alert aurals to channel 1.

The aural warning speakers supply audio feedback signals to the WEUs. The WEUs use these signals to check speaker operation.

Test Tone

Each WEU channel makes a test tone during a WES system test.



WES - ALERT AURAL GENERATION

31-51-00-019 Rev 3 02/03/1998

WES - MASTER WARNING LIGHTS ACTIVATION

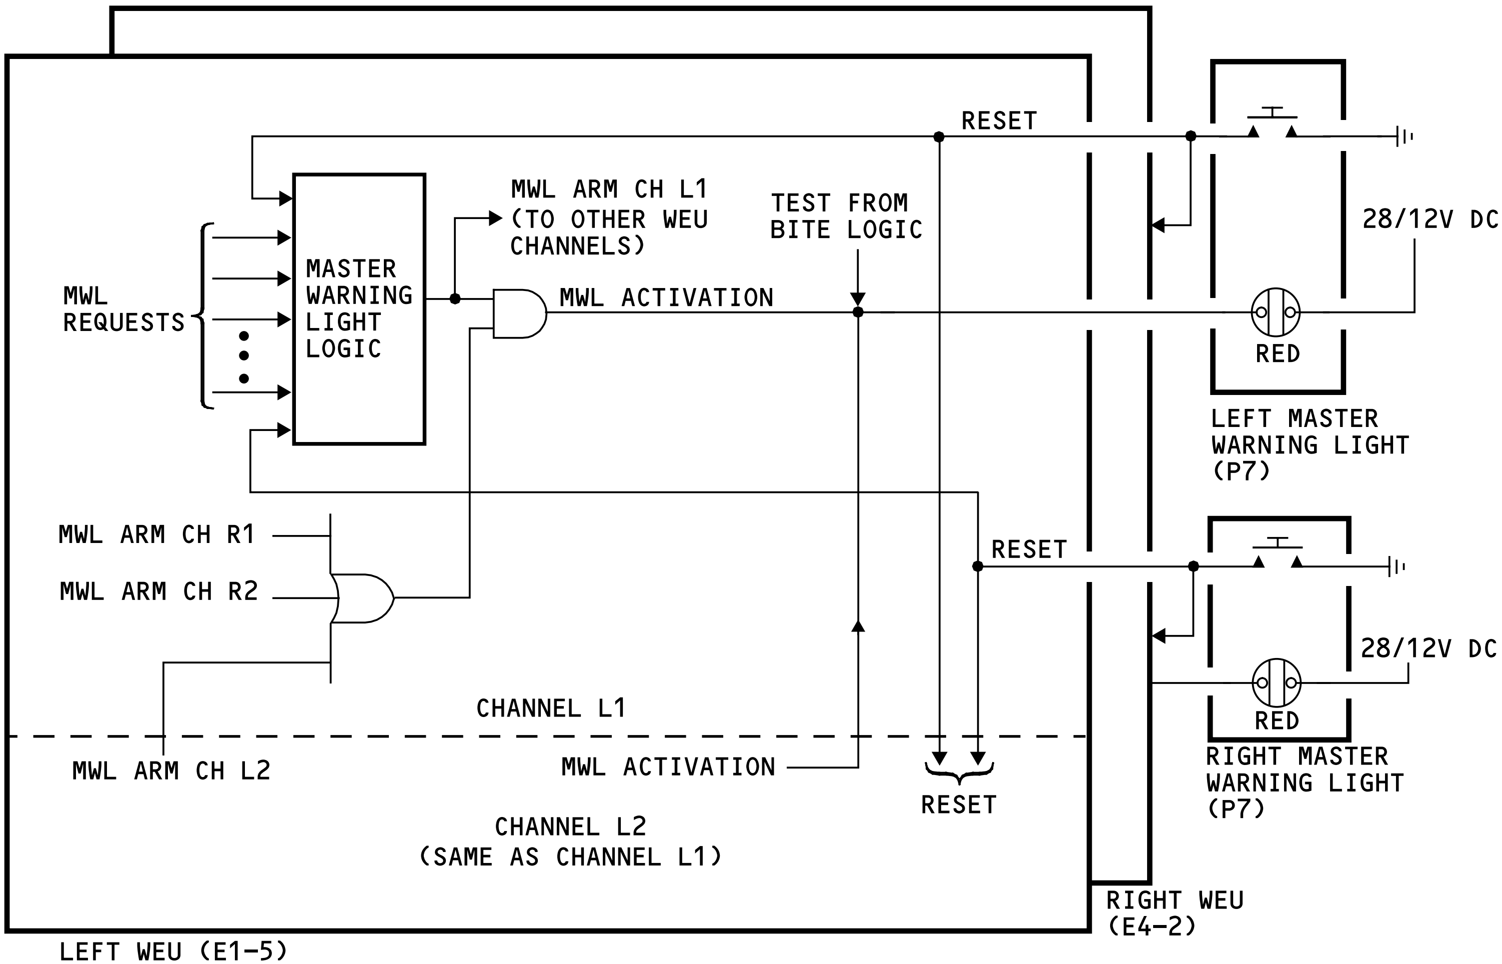
General

The left WEU connects to the left master warning light (MWL). The right WEU connects to the right master warning light.

Each WEU channel makes a MWL arm signal. A WEU channel must receive at least one MWL arm signal from another WEU channel before it makes the MWL activation signal.

The MWL activation signal makes the master warning lights come on.

Push the master warning lights to supply a reset signal to the WEUs. The reset signals make the master warning lights go out. If there is another warning condition, the master warning lights come on again.



31-51-00-021 Rev 1

MWL = MASTER WARNING LIGHT

WES - MASTER WARNING LIGHTS ACTIVATION

WES - FIRE WARNING

Fire Warning Inputs

The fire warning logic gets fire warning inputs from the system cardfiles. These cards supply fire warning inputs to the WEUs:

- Left engine fire detection card
- Right engine fire detection card
- APU fire detection card
- Left and right ARINC signal gateway (ASG) cards.

Each WEU channel inhibits fire warnings when the airplane is in takeoff.

The alert aural logic makes the fire bell alert aural. The master warning light logic makes the master warning lights (MWLs) come on.

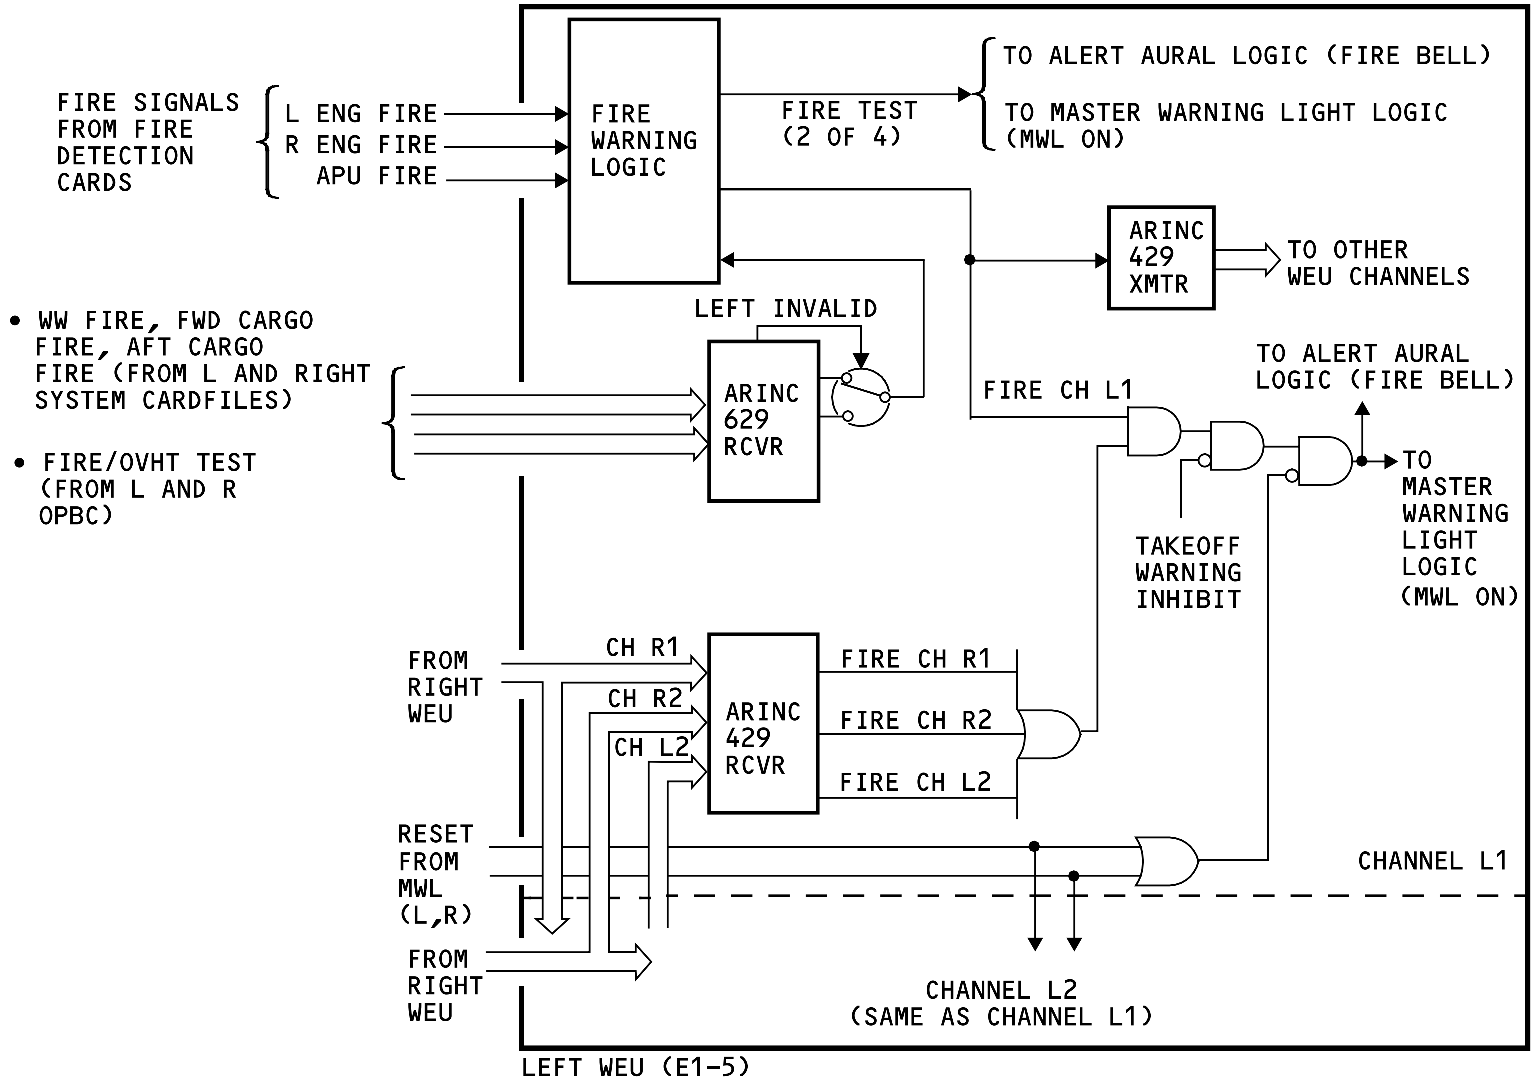
Push any master warning light to make the master warning lights and the fire bell go out.

Fire Test

When you do a fire warning test, the fire warning logic ignores fire warning inputs.

The fire warning logic makes a fire test signal. The fire warning logic makes the fire test signal only when at least one other WEU channel makes the same signal (2 of 4 vote).

The fire warning logic sends the fire test signal to the alert aural logic to make the fire bell and to the master warning light logic to make the master warning lights come on.



WES - FIRE WARNING

WES - AUTOPILOT DISCONNECT WARNING

General

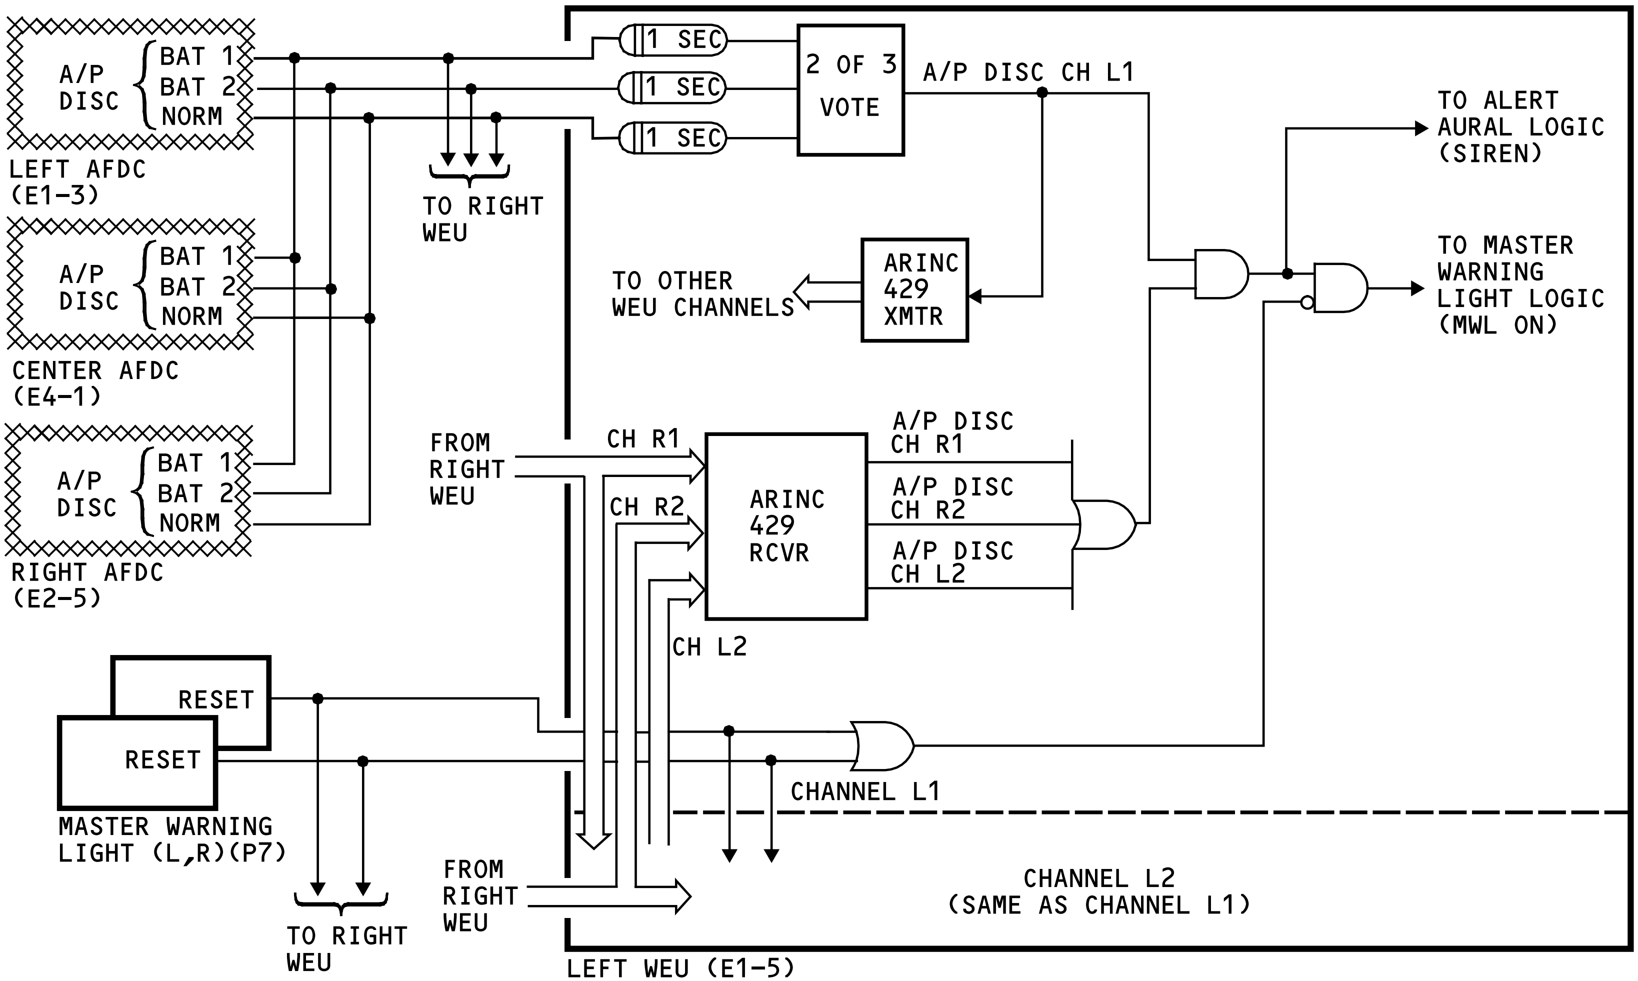
The autopilot flight director computers (AFDCs) supply autopilot disconnect discrete signals to the WEUs when the autopilot disconnects.

If at least two autopilot disconnect discrete signals show for at least one second, the WEUs give an autopilot disconnect warning.

Before a WEU channel gives an autopilot disconnect warning, at least one other WEU channel must give the same warning.

The aural alert logic gives the siren alert aural. The master warning light logic makes the warning lights (MWLs) come on.

Push any master warning light to make the master warning lights go out. The siren continues until the autopilot disconnect signals clear.



31-51-00-023 Rev 2

WES - AUTOPILOT DISCONNECT WARNING

WES - OVERSPEED WARNING

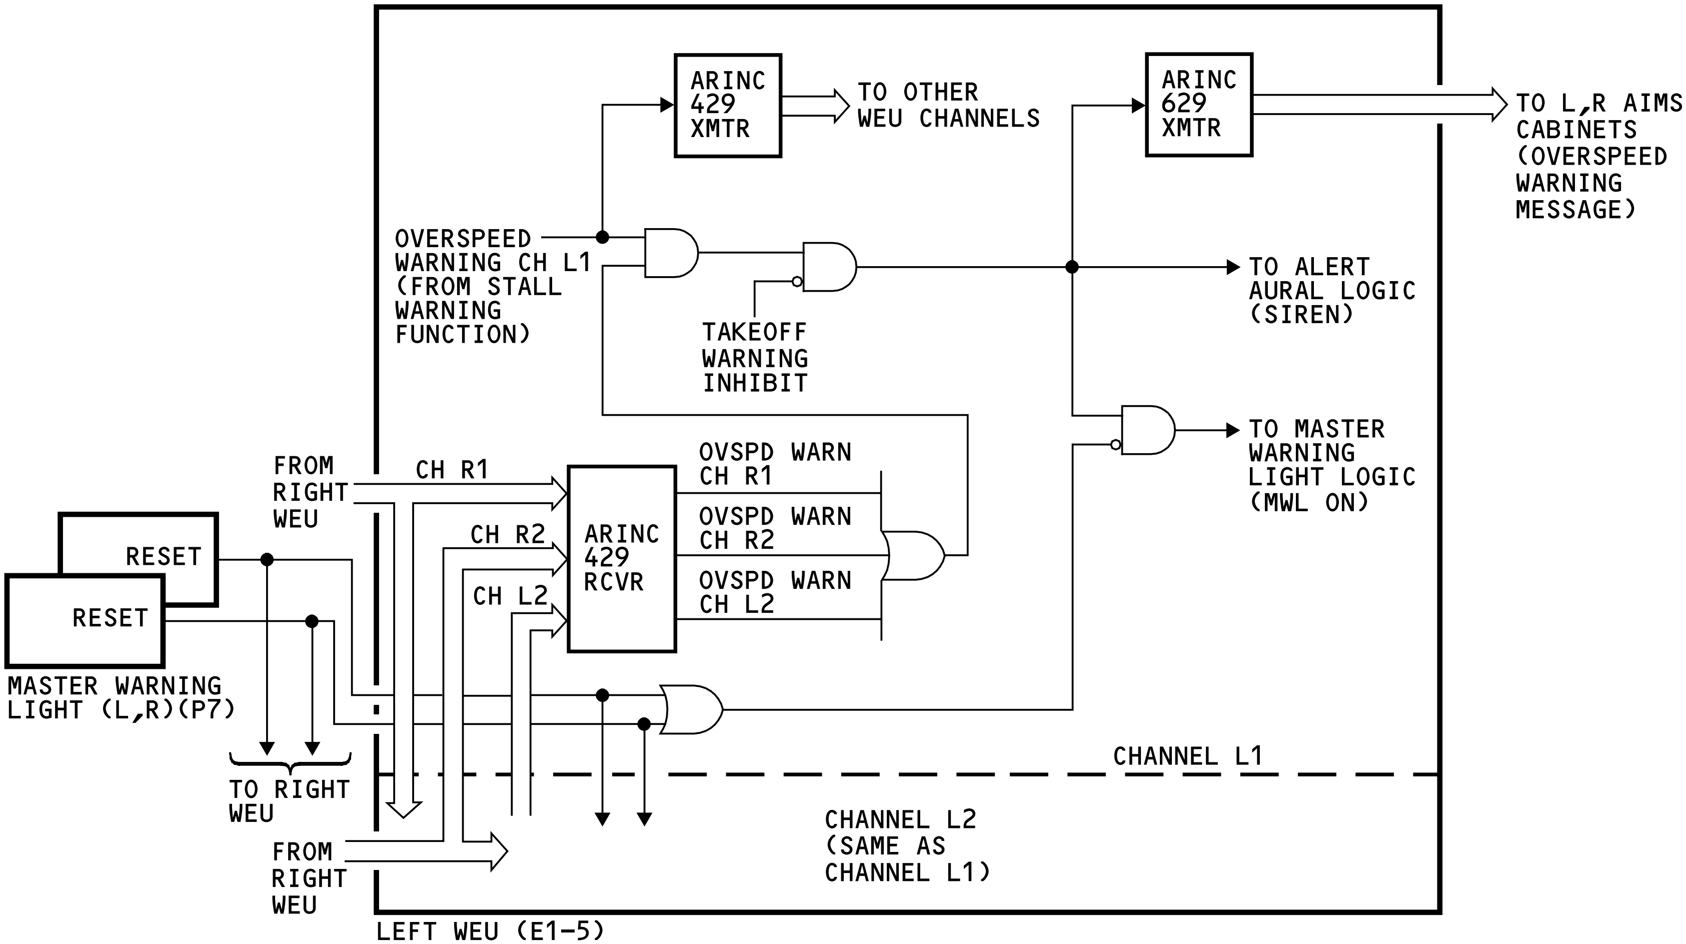
General

The stall warning function of the WEUs makes the overspeed warning signal.

Before a WEU channel gives an overspeed warning, at least one other channel must give the same warning.

If there is a takeoff warning inhibit, the WEUs do not make the overspeed warning signal.

Push any master warning light to make the master warning lights go out and stop the siren.



31-51-00-024 Rev 2 01/19/1998

WES - OVERSPEED WARNING

WES - CABIN PRESSURE WARNING

General

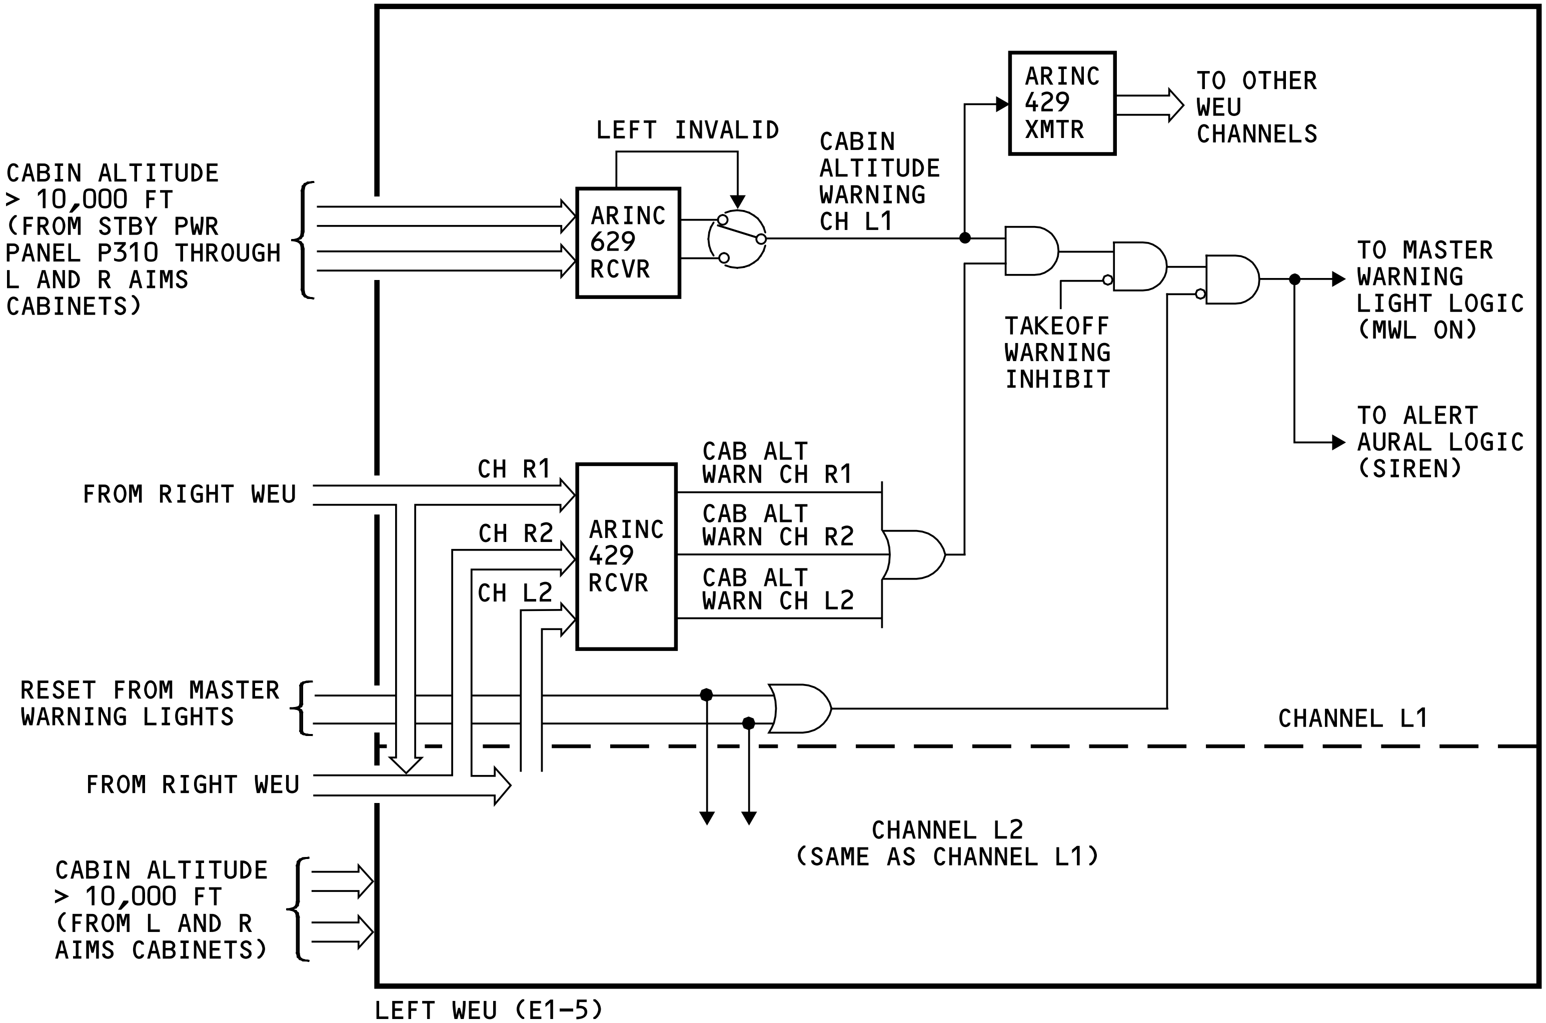
The remote cabin pressure sensor senses cabin pressure. The cabin pressure signal goes to the standby power panel (P310). The standby power panel (P310) supplies the cabin pressure signal to the AIMS cabinets. The AIMS cabinets supply a digital signal for a cabin altitude greater than 10,000 feet to the WEUs.

Before a WEU channel makes a cabin altitude warning, at least another WEU channel must make the same warning.

Each WEU channel inhibits cabin altitude warnings when the airplane is in takeoff.

The master warning light logic makes the master warning lights (MWLs) come on. The alert aural logic makes the siren alert aural.

Push any master warning light to make the master warning lights and the siren go out.



31-51-00-025 Rev 1

WES - CABIN PRESSURE WARNING

WES - UNSCHEDULED STABILIZER MOVEMENT WARNING

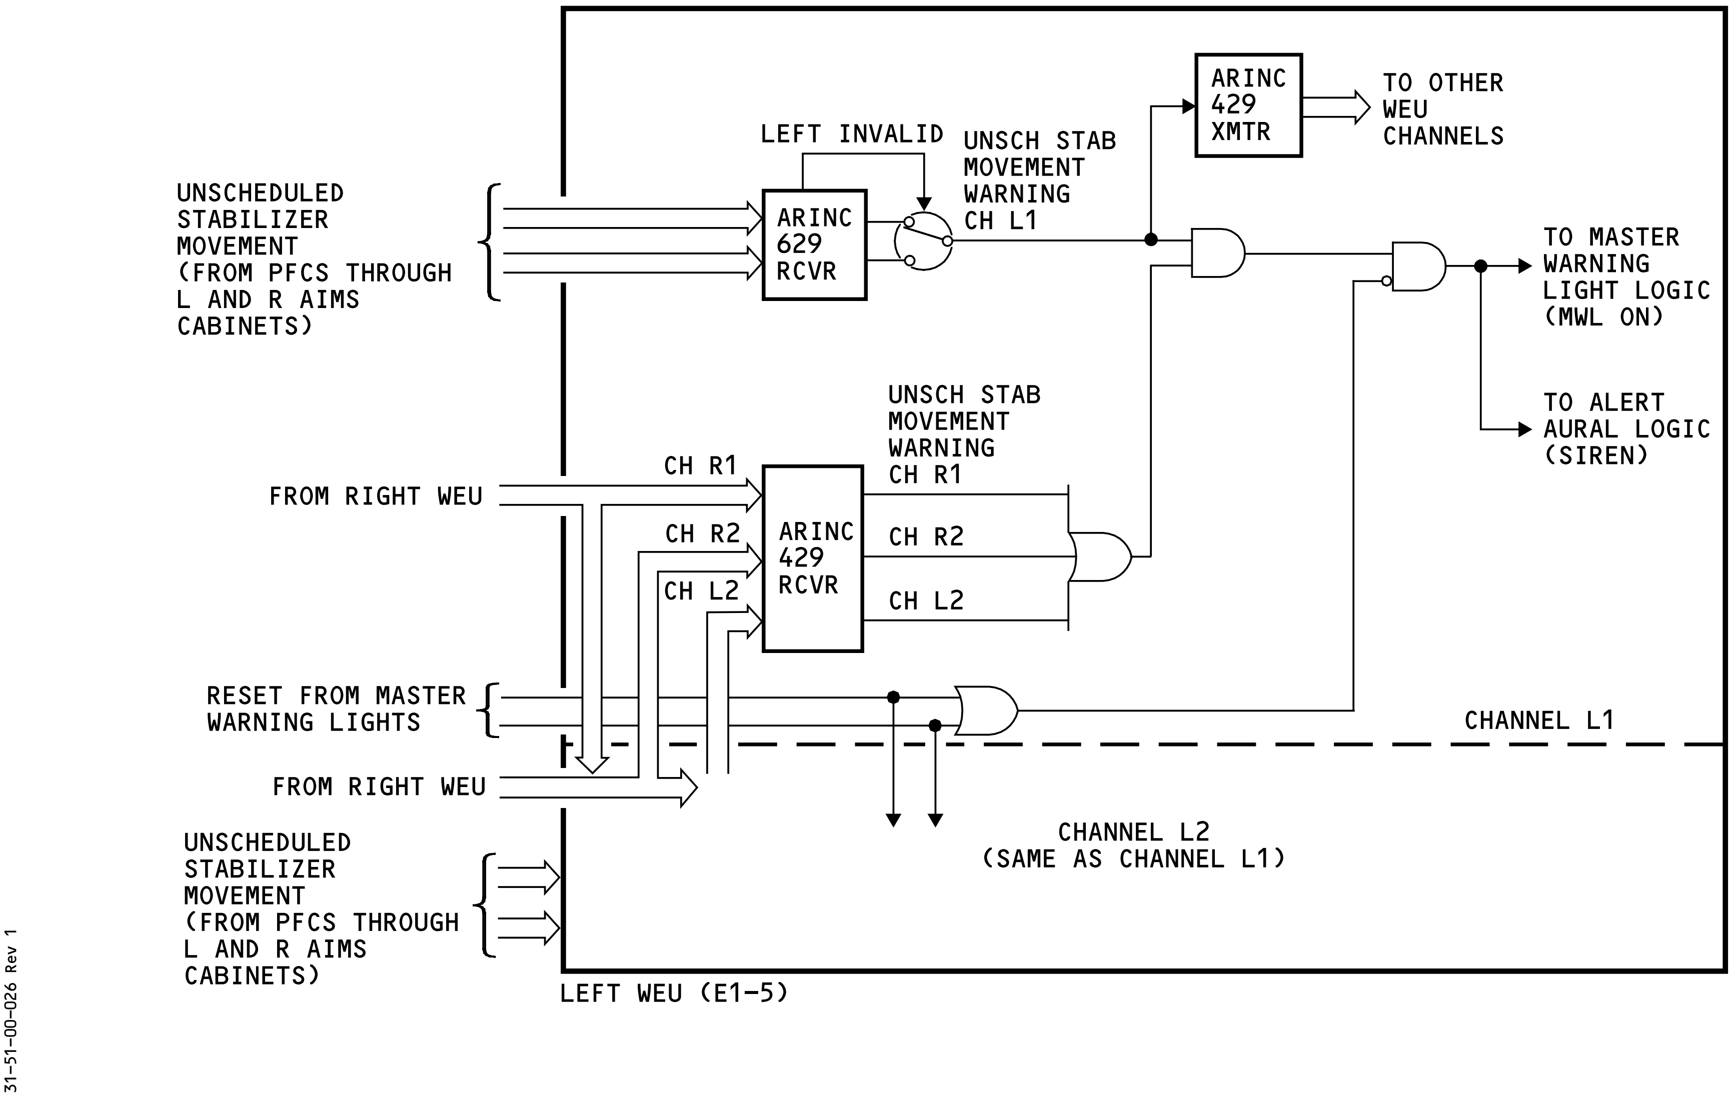
General

The primary flight computers (PFCs) supply a digital signal for unscheduled stabilizer movement to the AIMS cabinets. The AIMS cabinets supply this signal to the WEUs.

Before a WEU channel makes an unscheduled stabilizer movement warning, at least one other WEU channel must make the same warning.

The alert aural logic makes the siren alert aural. The master warning light logic makes the master warning lights (MWLs) come on.

Push any master warning light to make the master warning lights and the siren go out.



WES - UNSCHEDULED STABILIZER MOVEMENT WARNING

WES - ENGINE FAIL WARNING

Operation

The AIMS cabinets supply a digital signal for engine fail warnings.

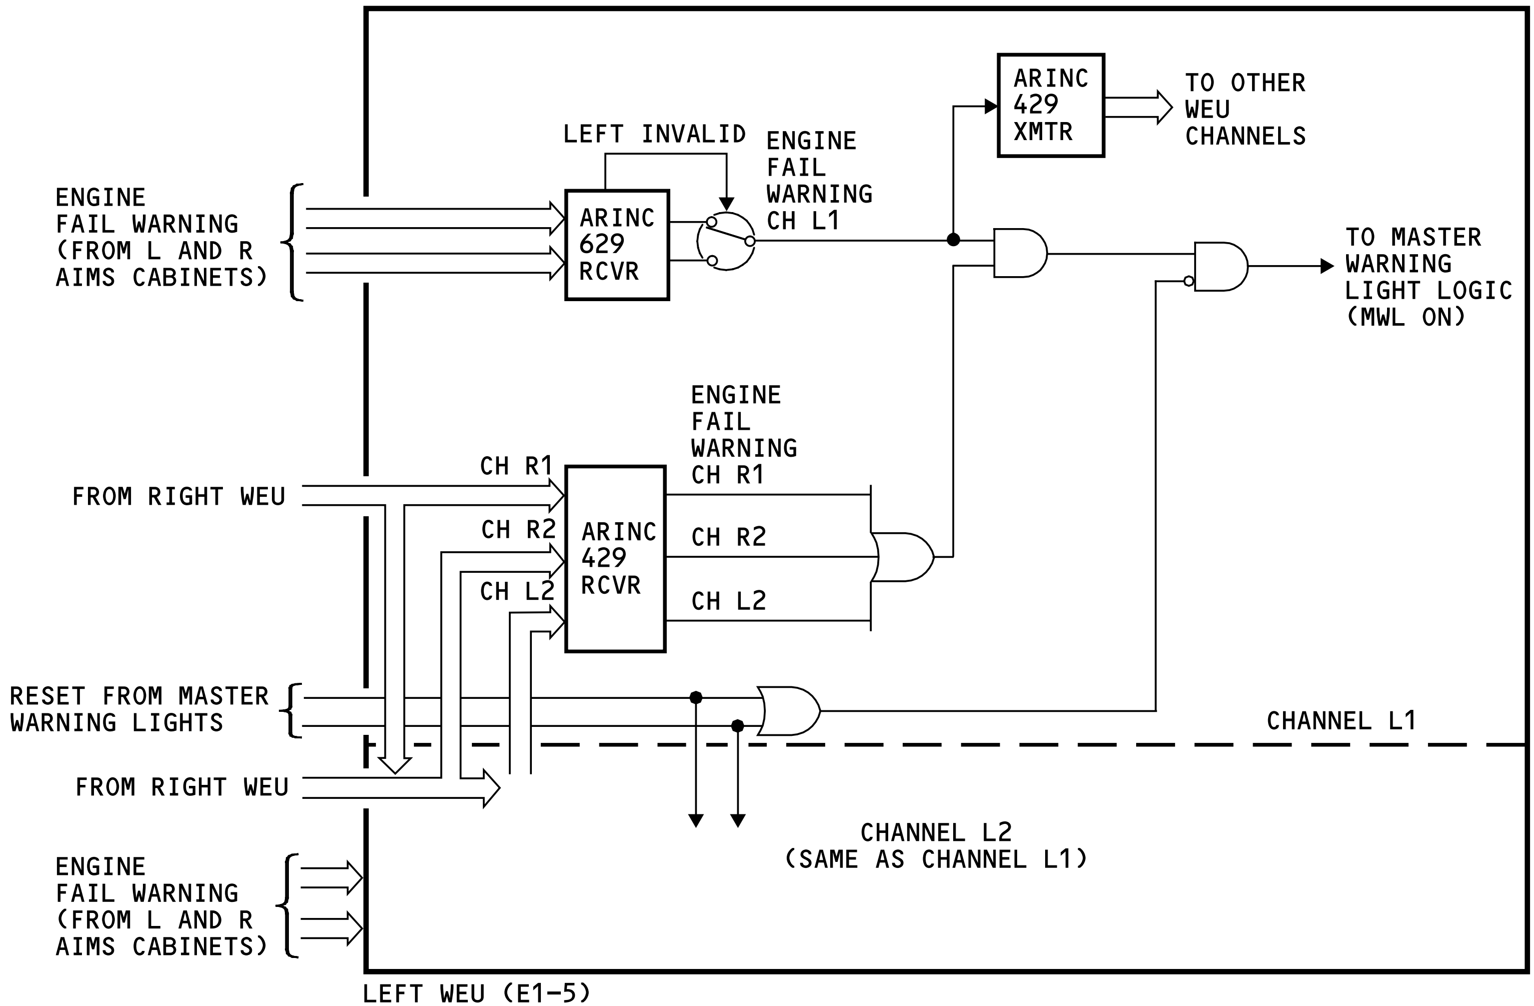
Before a WEU channel makes an engine fail warning, at least one other WEU channel must make the same warning.

The master warning light logic, makes the master warning lights (MWLs) come on.

Push any master warning light to make the master warning lights go out.

Training Information Point

If an engine fails when the airplane is on the ground and the airplane CAS is more than 65 knots but less than 3 knots below V1 (decision speed), the primary display function of AIMS shows the time critical warning message ENGINE FAIL on the PFDs. Also, the master warning lights come on. The AIMS cabinets also send a digital request signal to the ground proximity warning computer (GPWC). The GPWC makes an engine fail aural.



31-51-00-058 Rev 1

WES - ENGINE FAIL WARNING

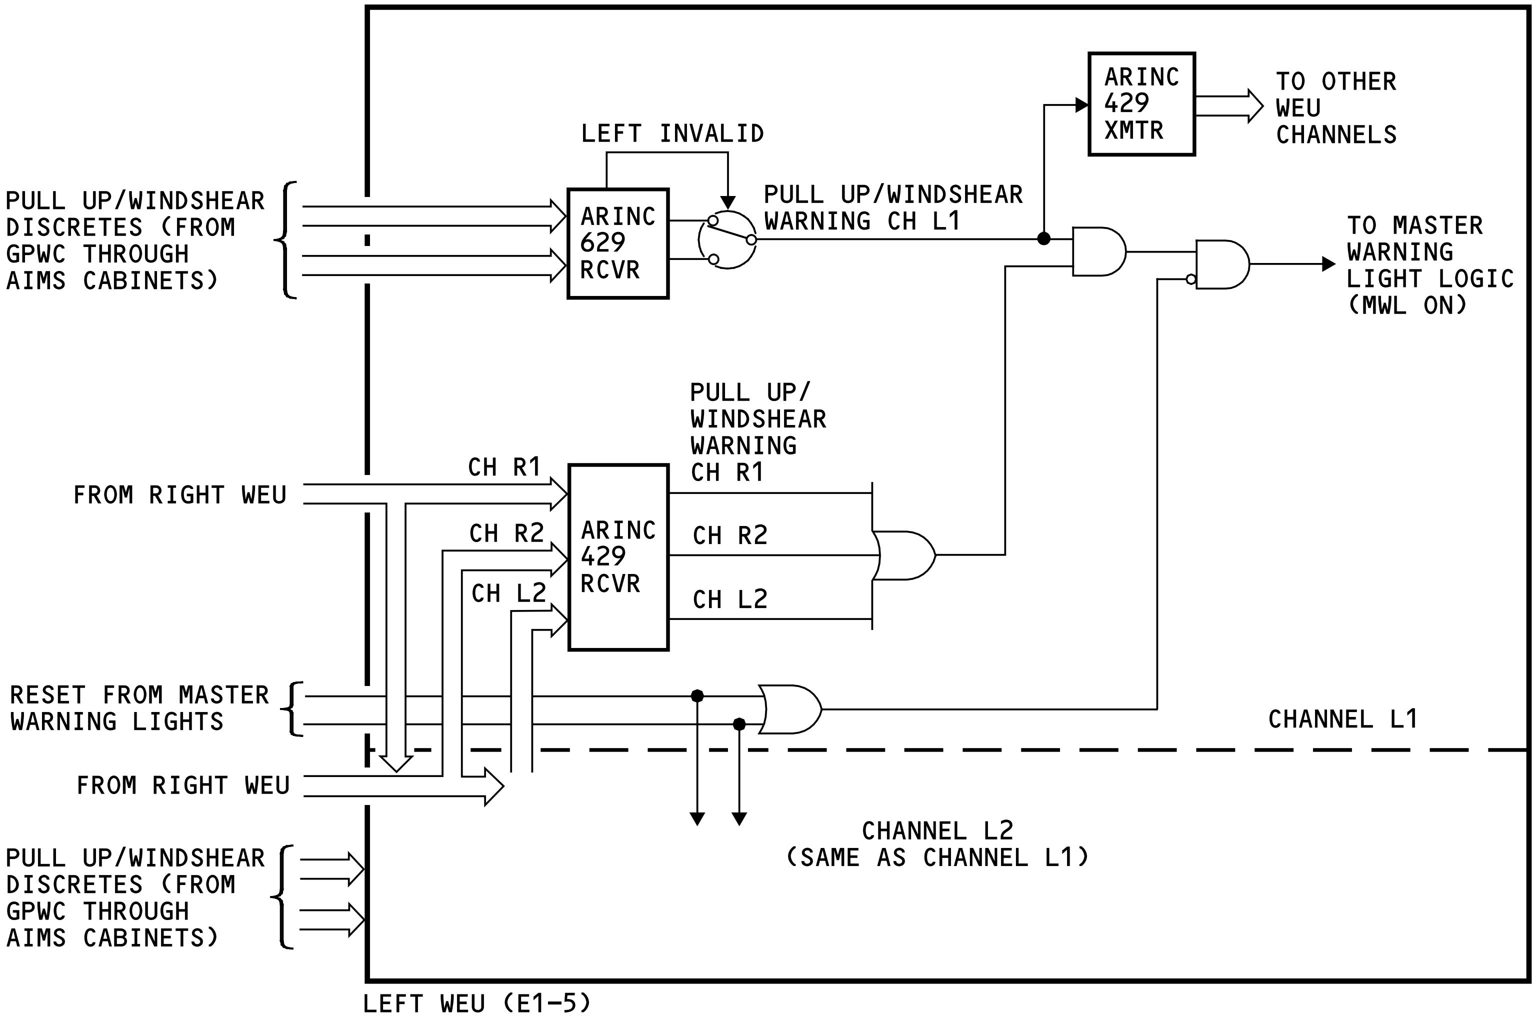
WES - GPWS PULL UP AND WINDSHEAR WARNINGS

General

The ground proximity warning computer (GPWC) supplies pull up and windshear digital discrete signals to the AIMS. The AIMS cabinets supply these signals to the WEUs.

Before a WEU channel makes a pull up or a windshear warning, at least one other WEU channel must make the same warning.

The master warning light logic makes the master warning lights (MWLs) come on. Push any master warning light to make the master warning lights go out.



31-51-00-028 Rev 1

WES - GPWS PULL UP AND WINDSHEAR WARNINGS

WES - TAKEOFF CONFIGURATION WARNING ENABLE

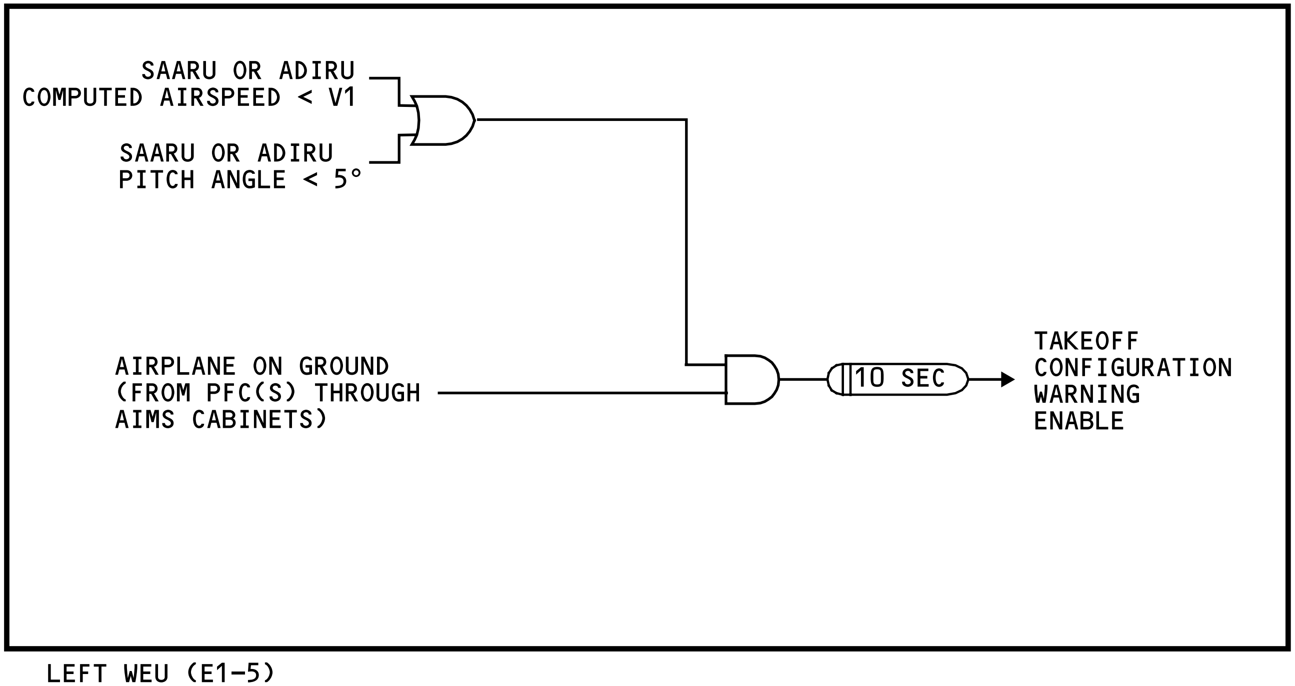
General

The WES makes a takeoff configuration warning when the airplane configuration is not safe for takeoff.

Each WEU has takeoff configuration warning enable logic. The takeoff configuration warning enable permits the WEUs to make takeoff configuration warnings only when it is possible to takeoff.

The WEUs use this data to make the takeoff configuration warning enable:

- Air data inertial reference unit (ADIRU) data
- Secondary attitude air data reference unit (SAARU) data
- Primary Flight Computer (PFC) data.



31-51-00-029 Rev 2 08/31/95

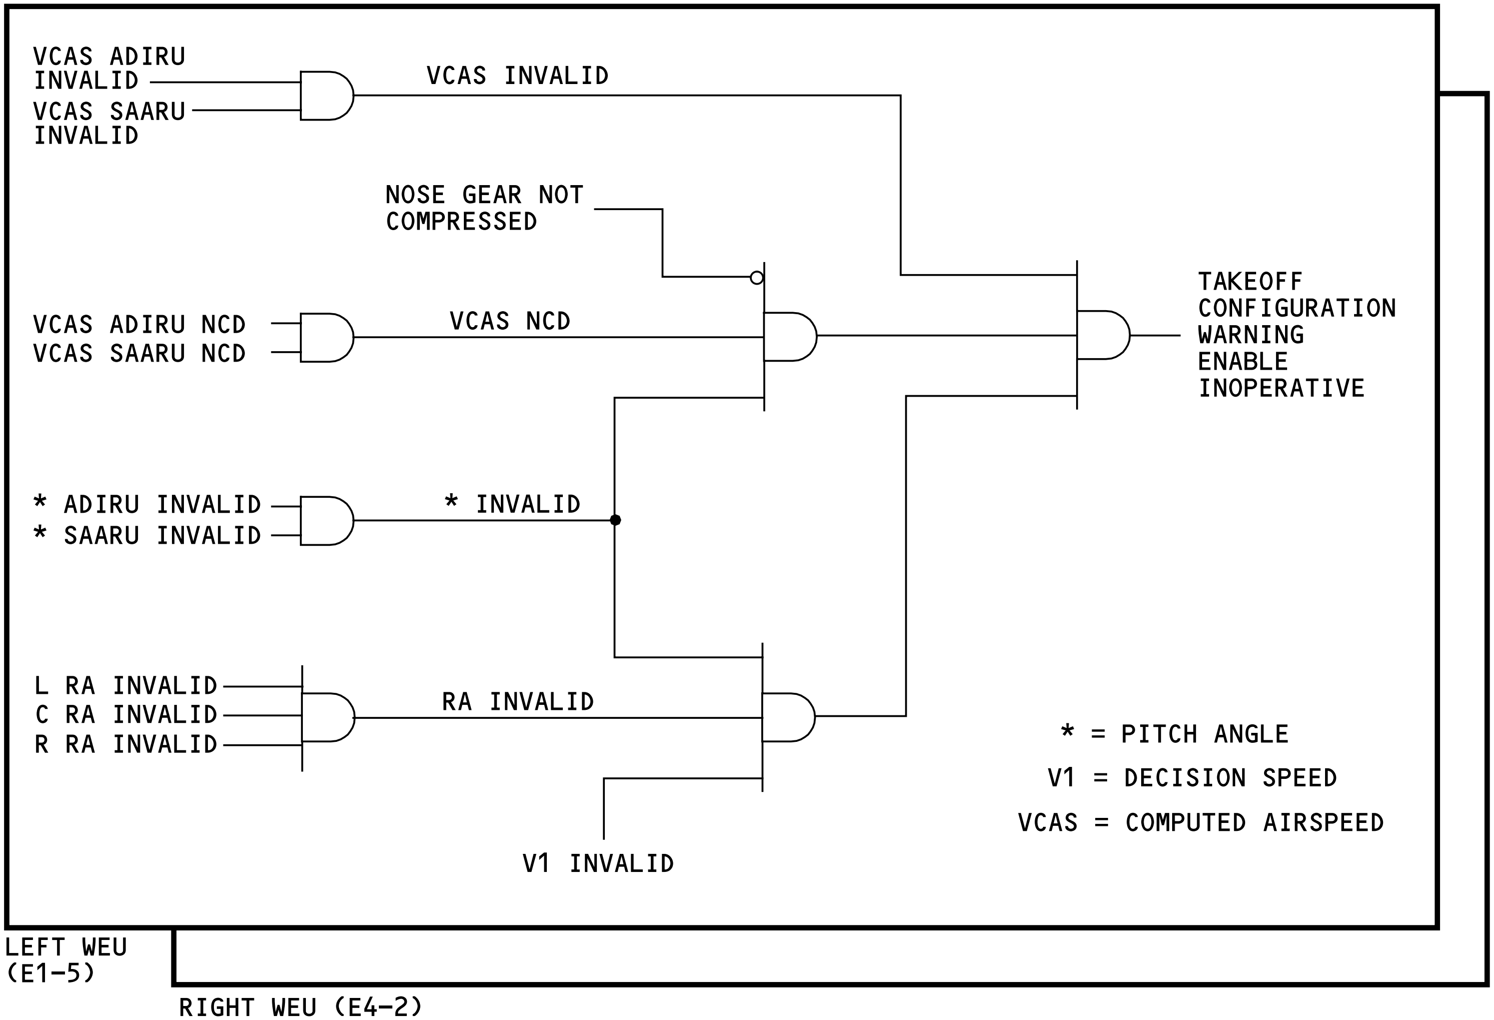
WES - TAKEOFF CONFIGURATION WARNING ENABLE

WES - TAKEOFF CONFIGURATION WARNING ENABLE INOPERATIVE

General

The takeoff configuration warning enable inoperative logic stops the takeoff configuration warning function of each WEU. The WEUs do this when there is not sufficient information from the air data inertial reference system, or the radio altimeter system to make a takeoff configuration warning.

When the takeoff configuration warning enable inoperative is true, the WEUs send a digital signal to the AIMS. The AIMS shows an advisory EICAS message to alert the crew that the takeoff configuration warning function does not operate.



31-51-00-030 Rev 1 02/06/1998

WES - TAKEOFF CONFIGURATION WARNING ENABLE INOPERATIVE

WES - TAKEOFF ATTEMPT AND CONDITIONS MONITORED IN TAKEOFF

Takeoff Attempt

The takeoff attempt signal enable permits the WEU to make a takeoff configuration warning.

The AIMS cabinets supply engine in takeoff thrust signals and the fuel control switch in run signals to the WEUs.

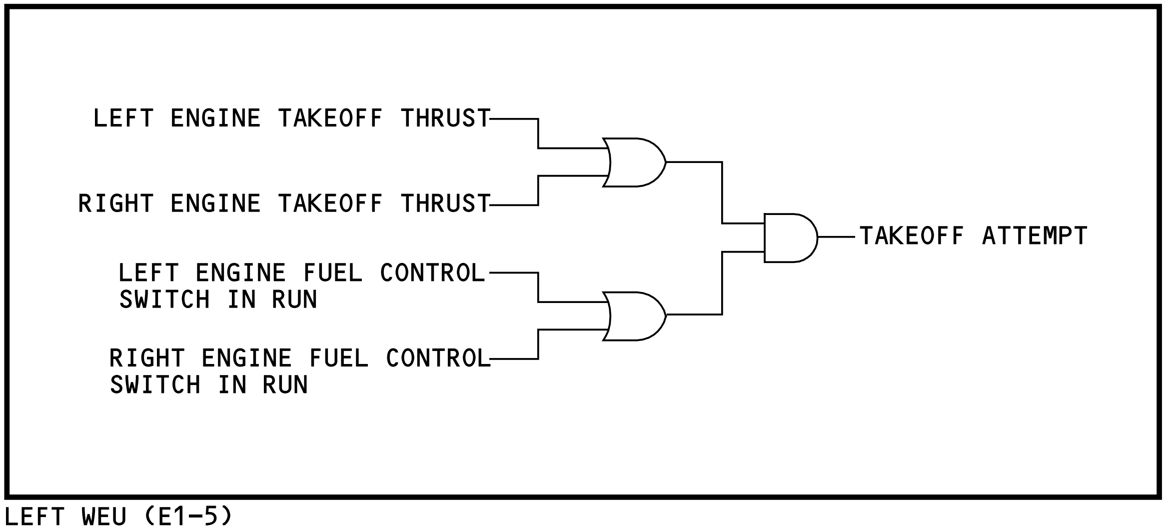
The WEUs make a takeoff attempt signal when a fuel control switch is in the run position and an engine makes takeoff thrust.

Conditions Monitored in Takeoff

The takeoff configuration function of the WEUs monitors these conditions when the flight crew makes a takeoff attempt:

- Flaps and leading edge devices not in takeoff position
- Stabilizer not in takeoff position
- Parking brake set
- Main gear steering not locked
- Rudder not in takeoff trim
- Speed brake lever not down
- Passenger entry and cargo doors closed, latched, and locked.

If any of the above conditions occurs in takeoff, the WEUs supply a takeoff configuration warning to the flight crew.



31-51-00-031 Rev 1

WES - TAKEOFF ATTEMPT AND CONDITIONS MONITORED IN TAKEOFF

WES - TAKEOFF CONFIGURATION WARNING FUNCTION INPUTS - 1

General

The flap slat electronic units (FSEUs) supply flaps and leading edge devices in takeoff position digital signals to the WEUs.

Each WEU channel gets inputs from the two FSEUs. Selection logic on each WEU channel uses one of the FSEUs to set a true output when the flaps or leading edge devices are in the takeoff position.

Each selection logic selects one FSEU input only. The selection priority depends on the WEU channel. This is the selection priority for channel L1:

- Left FSEU through the left bus
- Left FSEU through the center 1 bus
- Right FSEU through the center 1 bus.

This is the selection priority for Channel L2:

- Left FSEU through the center 1 bus
- Right FSEU through the center 1 bus
- Left FSEU through the left bus.

This is the selection priority for Channel R1:

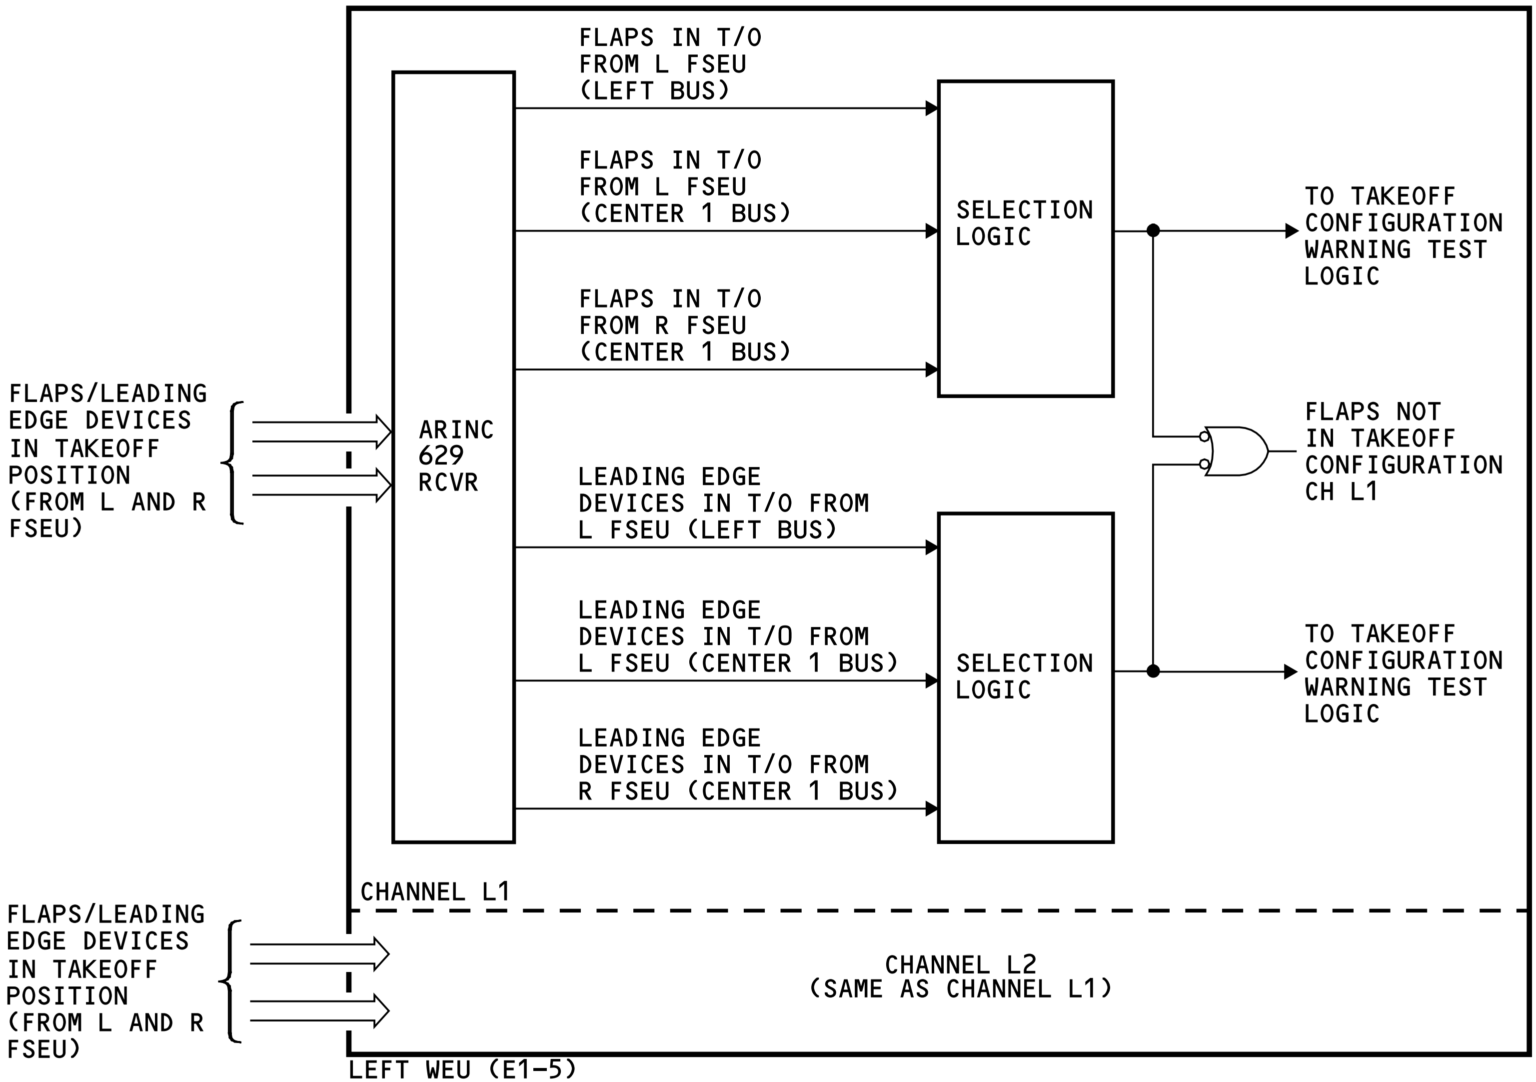
- Right FSEU through the right bus
- Right FSEU through the center 1 bus
- Left FSEU through the center 1 bus.

This is the selection priority for Channel R2:

- Right FSEU through the center 1 bus
- Left FSEU through the center 1 bus
- Right FSEU through the right bus.

Takeoff Configuration Warning Test Logic Interface

Each WEU channel has a takeoff configuration warning test logic. When you do a takeoff configuration warning test, this logic verifies all inputs to the takeoff configuration warning function. The logic checks that all inputs are available and valid.



31-51-00-032 Rev 2 10/23/95

WES - TAKEOFF CONFIGURATION WARNING FUNCTION INPUTS - 1

WES - TAKEOFF CONFIGURATION WARNING FUNCTION INPUTS - 2

Stabilizer Not In Takeoff Position

The primary flight computers (PFCs) supply stabilizer position signals to the AIMS cabinets. The AIMS cabinets supply the signals to the WEUs. The compare logic gets the stabilizer position signals.

The stabilizer green band function of the WEUs supplies stabilizer green band selection to the compare logic. The selection is one of these:

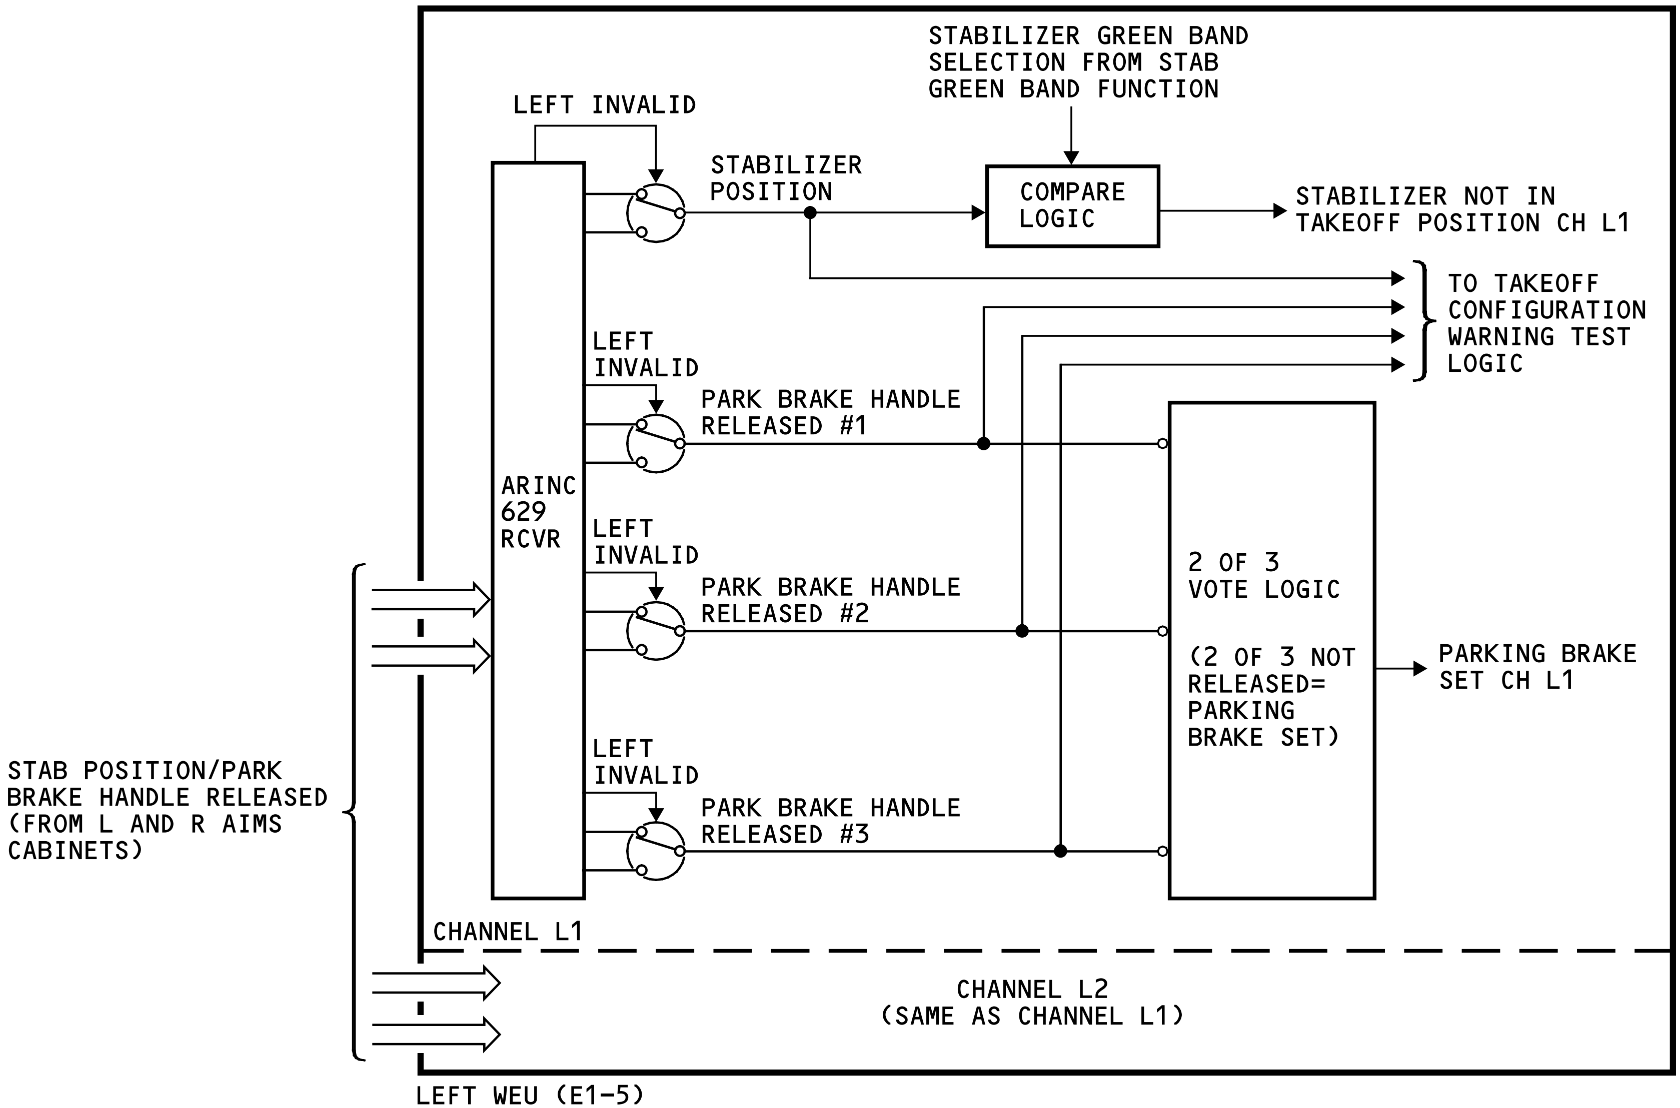
- Nose up band
- Mid band
- Nose down band.

The compare logic compares the stabilizer position and the stabilizer green band selection. If the stabilizer position is not in the green band, the compare logic makes a stabilizer not in takeoff signal.

Parking Brake Set

The parking brake handle has three switches. The switches supply parking brake handle released signals to the AIMS. The AIMS supplies the signals to the WEUs.

Each WEU channel supplies the signals from the three parking brake handle switches to a 2 of 3 vote logic. When at least two signals show the parking brake handle not released, the 2 of 3 vote logic makes a parking brake set signal.



31-51-00-033 Rev 0

WES - TAKEOFF CONFIGURATION WARNING FUNCTION INPUTS - 2

WES - TAKEOFF CONFIGURATION WARNING FUNCTION INPUTS - 3

Speed Brake Lever Not Down

The primary flight computers (PFCs) supply the speed brake lever not down signal to the WEUs.

Rudder Position

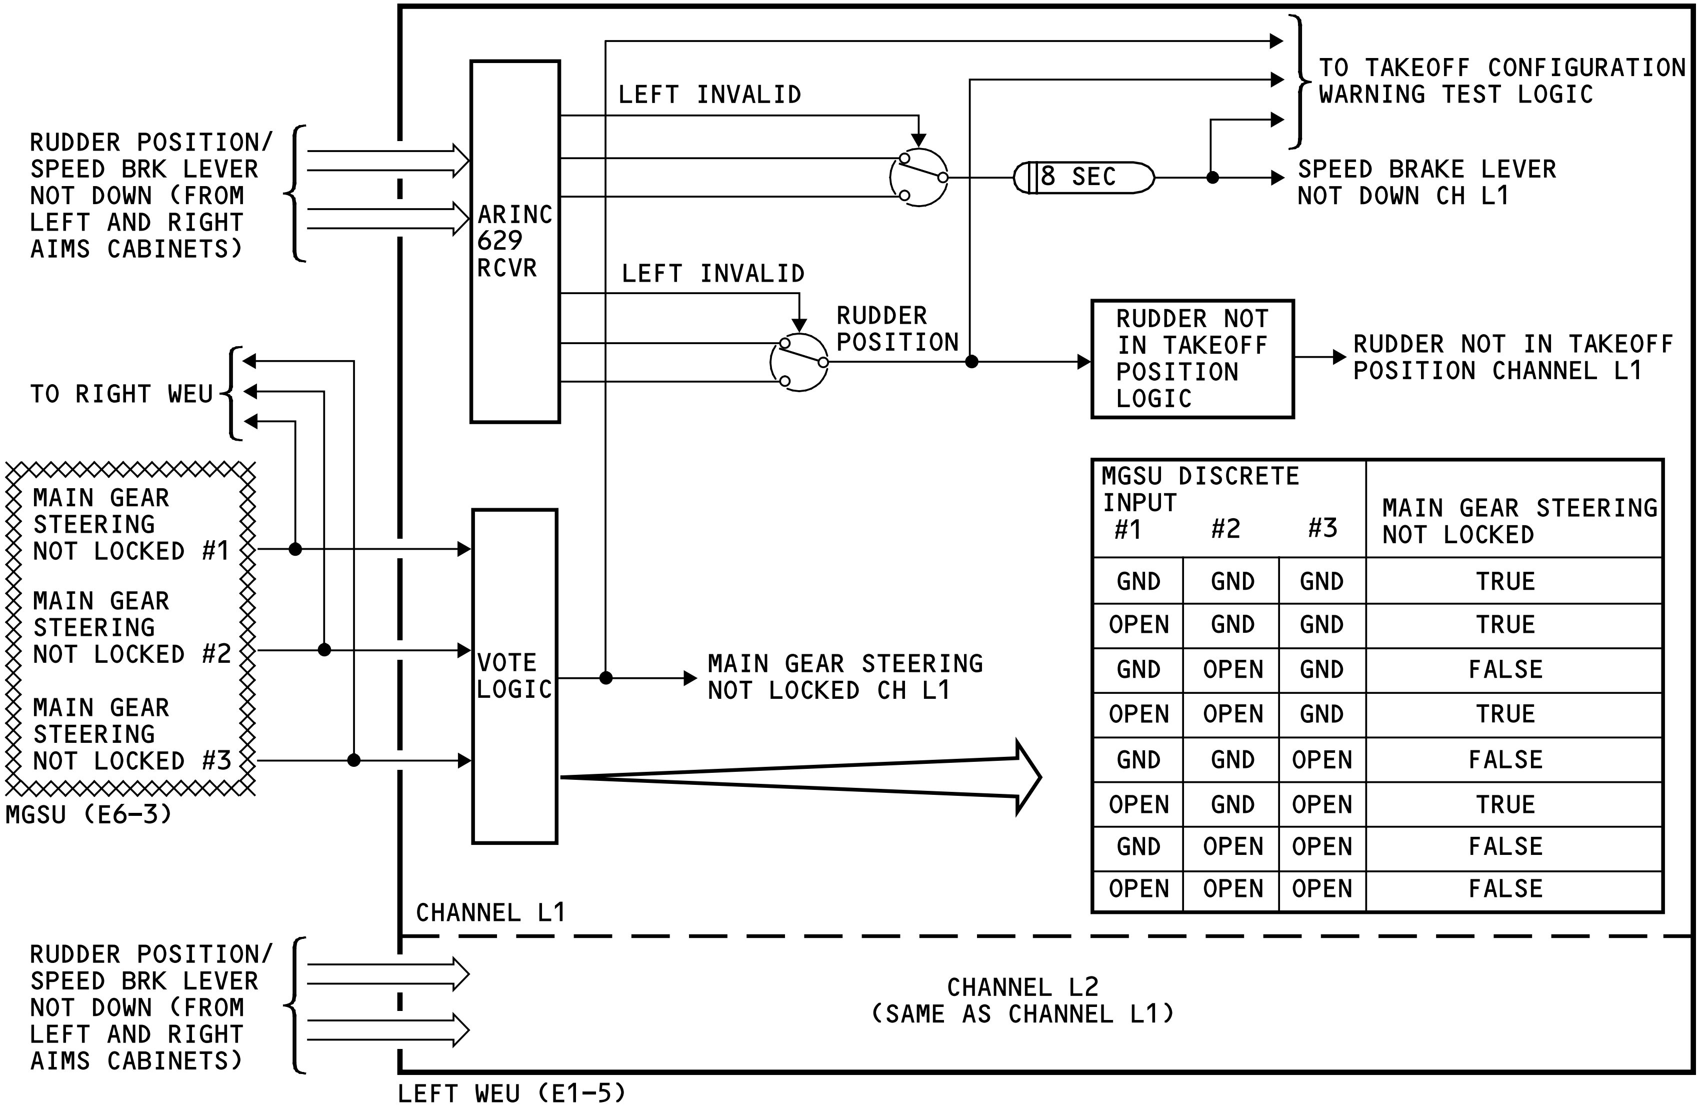
The PFCs supply the rudder position signal to the WEUs.

Each WEU channel has rudder not in takeoff position logic. This logic has the correct rudder position for takeoff. The logic compares the rudder position and the correct rudder position for takeoff. The rudder is in the correct position for takeoff when the trim value is 2 units or less.

If the rudder position is not in the correct takeoff position, the logic makes a rudder not in takeoff position signal.

Main Gear Steering Not Locked

The main gear steering unit (MGSU) supplies three discrete main gear steering not locked signals to the WEUs. Each WEU channel has vote logic. The vote logic makes the main gear steering not locked signal.



MGSU DISCRETE INPUT #1	#2	#3	MAIN GEAR STEERING NOT LOCKED
GND	GND	GND	TRUE
OPEN	GND	GND	TRUE
GND	OPEN	GND	FALSE
OPEN	OPEN	GND	TRUE
GND	GND	OPEN	FALSE
OPEN	GND	OPEN	TRUE
GND	OPEN	OPEN	FALSE
OPEN	OPEN	OPEN	FALSE

31-51-00-034 Rev 2 03/28/95

WES - TAKEOFF CONFIGURATION WARNING FUNCTION INPUTS - 3

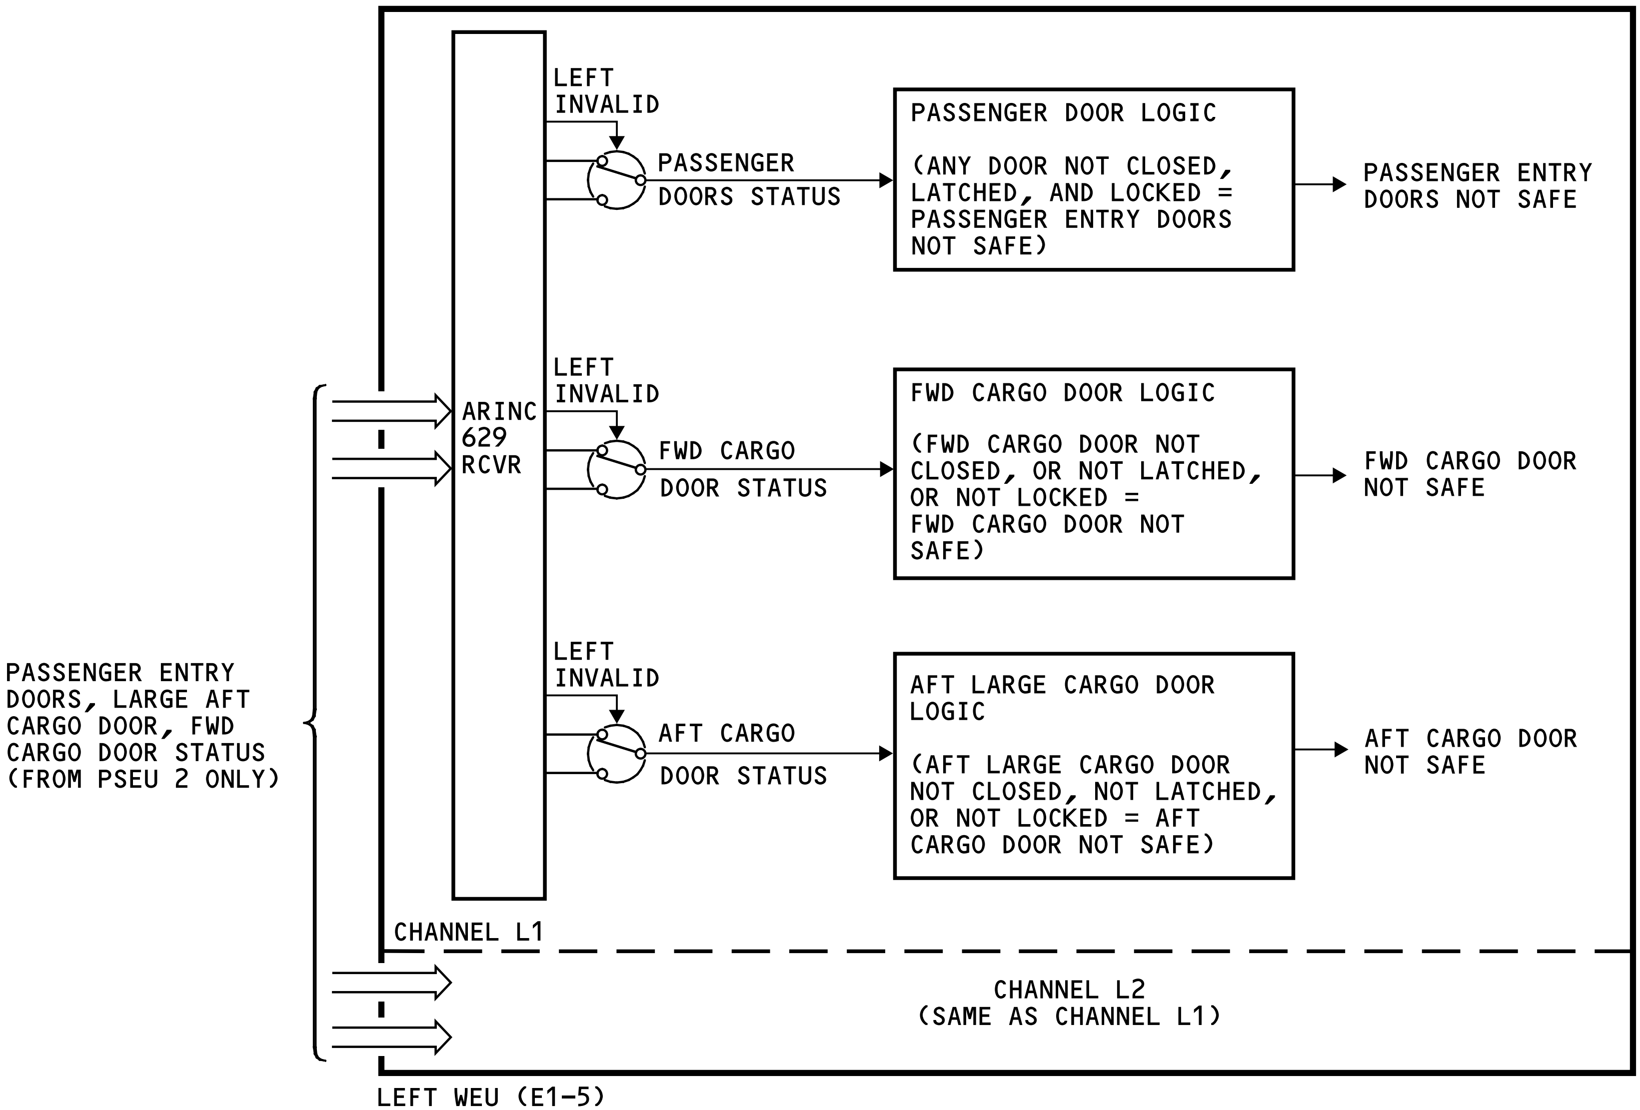
WES - TAKEOFF CONFIGURATION WARNING FUNCTION INPUTS - 4

Airplane Doors Status

The WEUs receive passenger entry and cargo doors status from the proximity switch electronic unit (PSEU) 2.

All doors must be closed, latched and locked before takeoff.

When any door is not closed, latched, and locked, each WEU channel makes doors not safe signals.



31-51-00-035 Rev 0

WES - TAKEOFF CONFIGURATION WARNING FUNCTION INPUTS - 4

WES - TAKEOFF CONFIGURATION WARNING FUNCTION OPERATION

Operation

When the takeoff configuration warning enable is true, and the flight crew makes a takeoff attempt, the WEUs check for correct airplane takeoff configuration.

Before a WEU channel gives a takeoff configuration warning, at least one more channel must give the same warning.

EICAS Warning Messages

The WEUs supply an EICAS message request to the AIMS cabinets. The AIMS shows a warning EICAS message to the flight crew. Before a warning message shows, the AIMS must receive the same message request from at least two WEU channels at the same time.

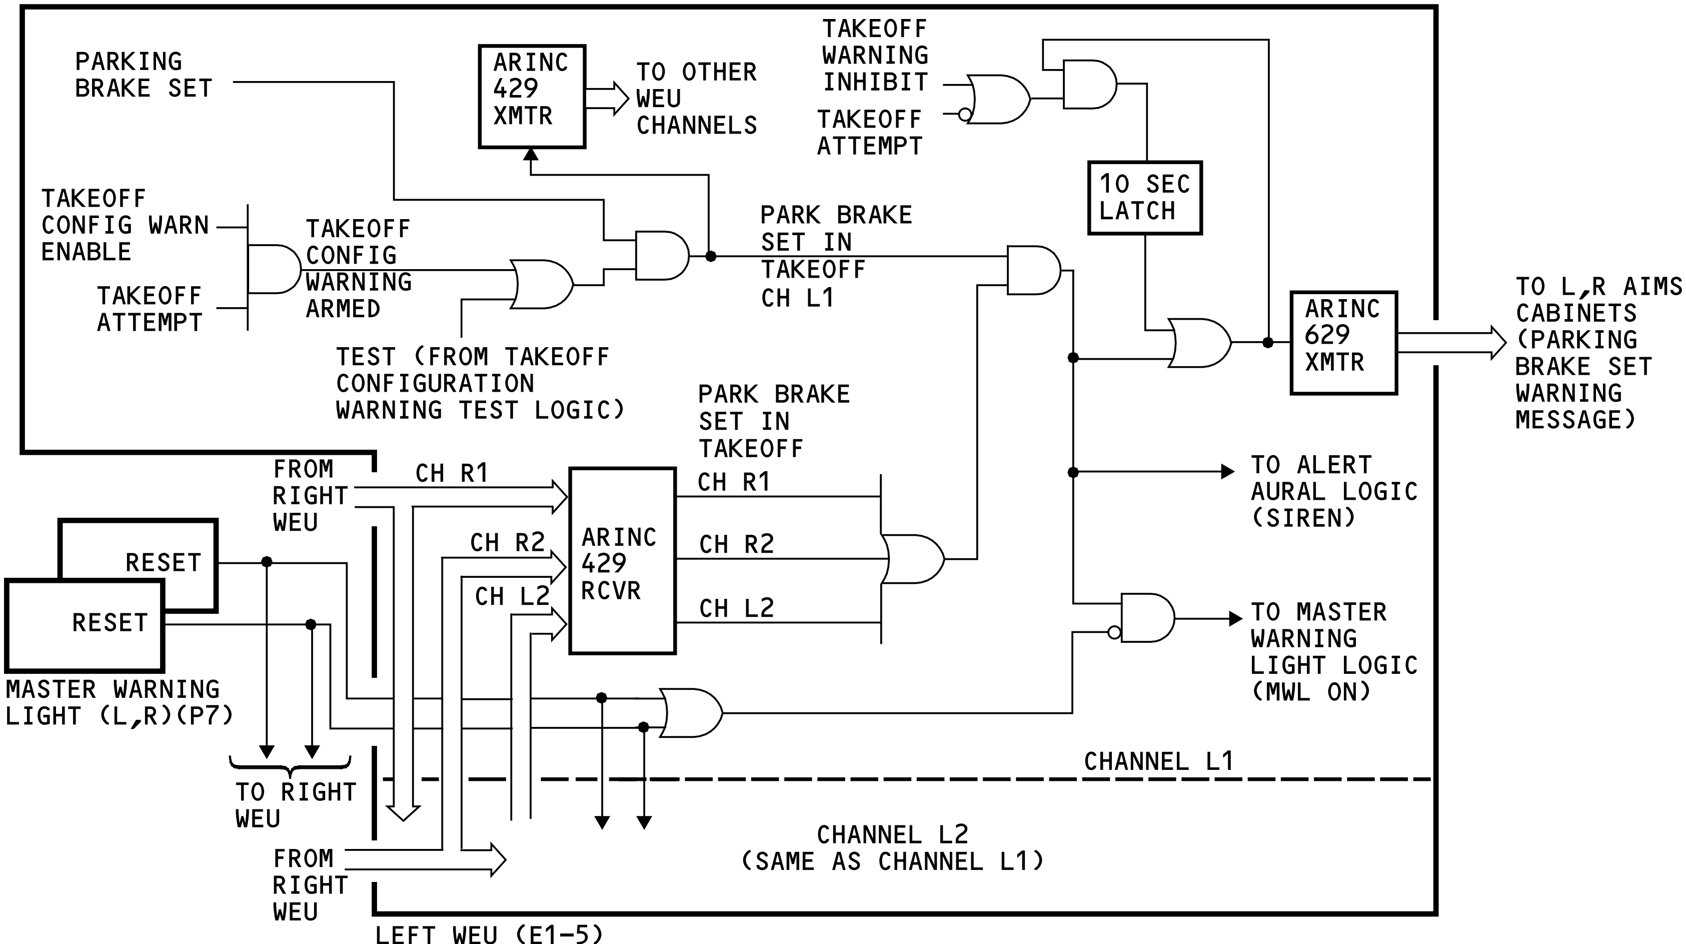
The WEUs latch the digital signal to the AIMS cabinets for 10 seconds after the flight crew stops the takeoff attempt or after the takeoff warning inhibit starts. This is to make sure that the flight crew sees the EICAS message.

Master Warning Lights Reset

Push any master warning light to make the master warning lights go out. The siren continues until the takeoff configuration warning condition is clear.

Test

A test signal comes from the takeoff configuration warning test logic. The test signal arms the takeoff configuration warning function. If the airplane is not in a good takeoff configuration, the WEUs make a takeoff configuration warning.



NOTE: OPERATION IS THE SAME FOR ALL TAKEOFF CONFIGURATION WARNING CONDITIONS

31-51-00-036 Rev 1

WES - TAKEOFF CONFIGURATION WARNING FUNCTION OPERATION

THIS PAGE INTENTIONALLY LEFT BLANK

WES - STABILIZER GREEN BAND FUNCTION

Operation

The stabilizer green band function calculates the correct green band selections for takeoff. These are the three selections:

- Nose up
- Mid band
- Nose down.

The WEUs use this data from the flight management computing function (FMCF) of the AIMS to calculate the green band selection:

- Gross weight (GW)
- Airplane center of gravity (CG)
- Takeoff thrust rating.

The stabilizer green band selection goes to the takeoff configuration warning function.

Green Band Indications

The green band selection logic sends the stabilizer green band selection to the AIMS. The AIMS changes the green band selection into ARINC 429, and sends it to the stabilizer trim position indicators.

An airplane nose down selection makes the mid band lamp and the nose down lamp come on. An airplane nose up selection makes the mid band lamp and the nose up lamp come on. A mid band indication makes only the mid band lamp come on.

If the WEUs get a CG that is more than 44.0 or less than 14.0, the WEUs make all the stabilizer green band lamps go out. The WEUs also supply a STAB GREENBAND advisory EICAS message request to the AIMS.

The green band selection logic changes the stabilizer green band selection only when the takeoff configuration enable is true. When a takeoff attempt is true, the green band selection logic locks the selection in its present condition.

The green band selection logic turns off the green band lamps when the takeoff configuration warning enable is false.

Nose Gear Pressure Switch

The WEUs use the nose gear pressure switch input to do a check of the stabilizer green band selection.

If the WEUs calculate a nose up band, the switch input must be forward CG (fly nose up condition). If the WEUs calculate a nose down band, the switch position must be aft CG (fly nose down condition). If the WEUs calculate a mid band, the WEUs ignore the switch input.

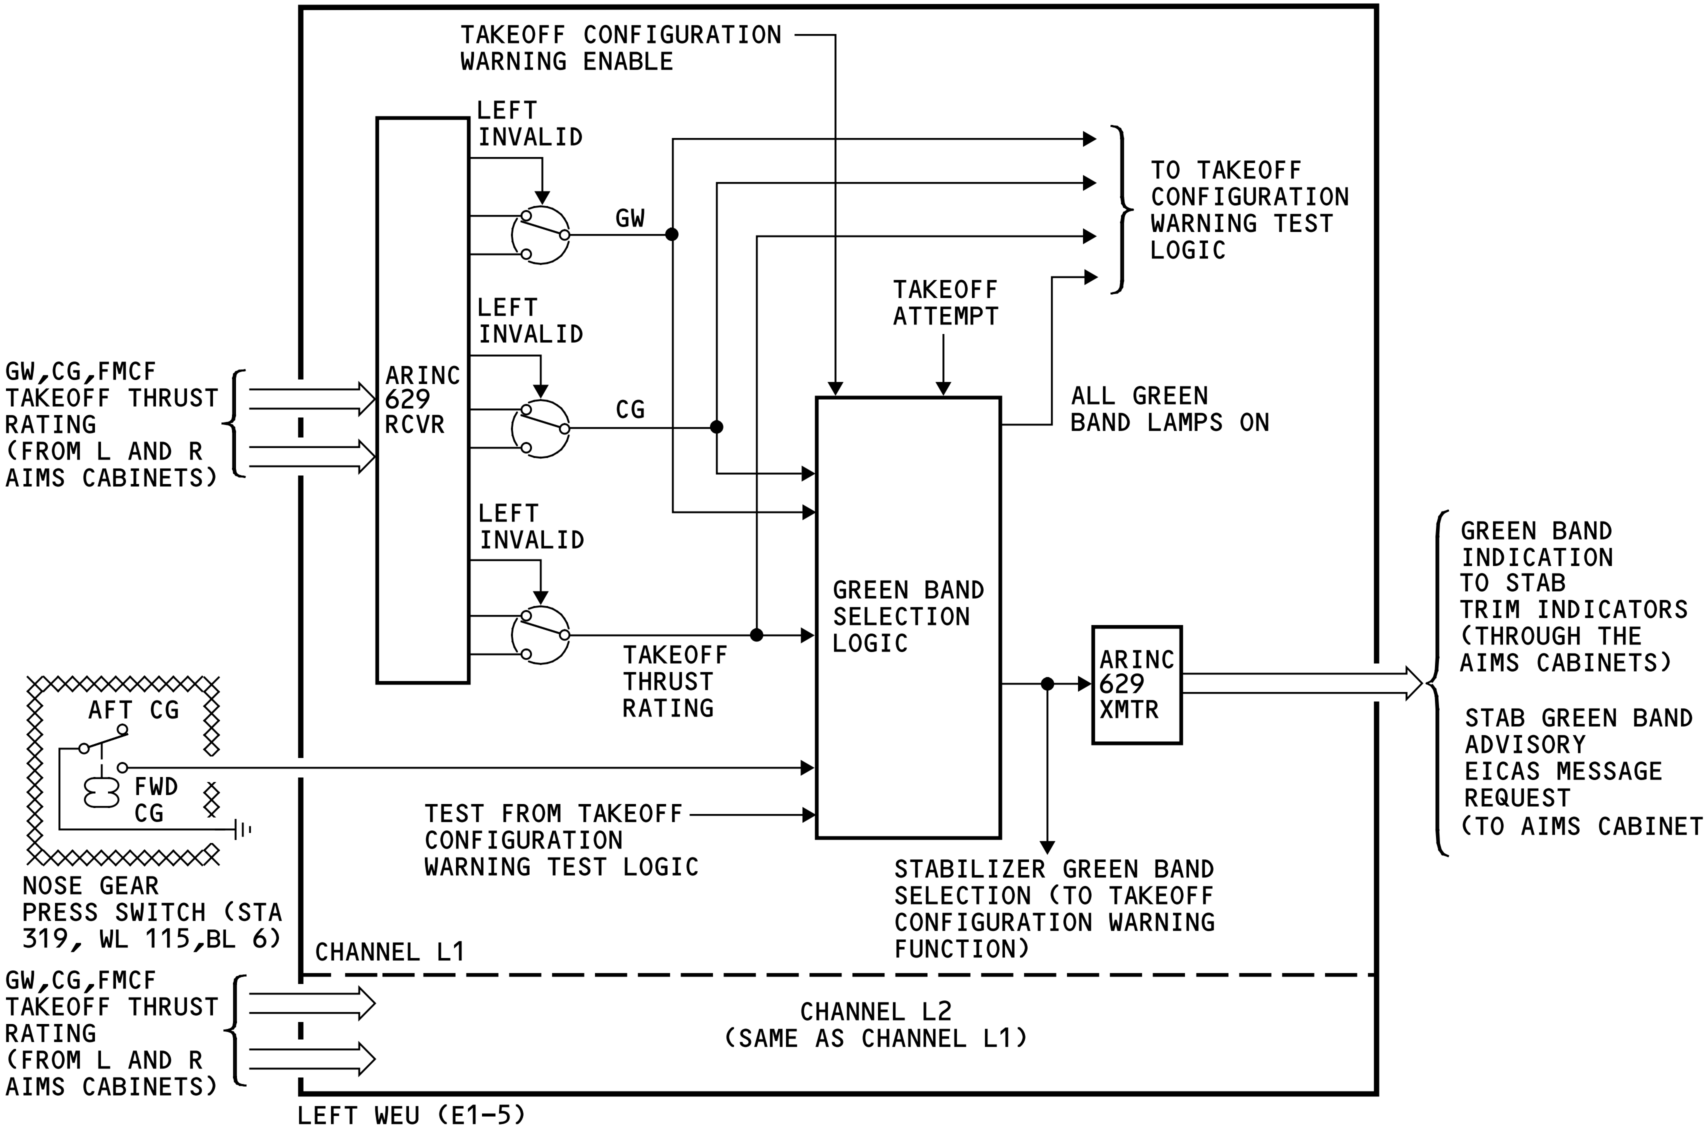
If the nose gear pressure switch input does not agree with the green band calculation, the WEUs supply a STAB GREENBAND advisory EICAS message request to the AIMS.

WES - STABILIZER GREEN BAND FUNCTION

Test

When you do a takeoff configuration warning test from the MAT, you do a test of the stabilizer green band function of the WEUs.

The takeoff configuration warning test logic supplies a test signal to the green band selection logic. The green band selection logic makes all three green band lamps come on each stabilizer trim indicator.



31-51-00-037 Rev 2

WES - STABILIZER GREEN BAND FUNCTION

THIS PAGE INTENTIONALLY LEFT BLANK

WES - TAKEOFF CONFIGURATION WARNING TEST

General

You start a takeoff configuration warning test from the maintenance access terminal (MAT). When you do a takeoff configuration warning test, you also do a stabilizer green band function test.

The takeoff configuration warning test logic checks the condition of the takeoff configuration warning and stabilizer green band function inputs. If any input is not present or is invalid, the test fails.

Initiated Test Inhibit

A WEU channel must make an initiated test inhibit signal as false before a takeoff configuration test can start.

When the initiated test inhibit signal is true, the WEU channels cannot start any test.

The initiated test inhibit signal within a WEU channel is false (a test can start) only when all these conditions are true:

- Both engines are at less than takeoff thrust
- The airplane is on the ground
- The nose gear is compressed
- The ADIRU and the SAARU send incomplete pitot/static data (airplane not moving)
- Three or more WEU channels detect the same previous conditions.

Test Signal

The takeoff configuration warning test logic supplies a test signal that is on for five seconds and then it goes off. The test signal goes to the:

- Takeoff configuration warning function
- Stabilizer green band selection logic
- AIMS.

The test signal arms the takeoff configuration warning function. If the airplane is not in a good takeoff configuration, the WEUs make a takeoff configuration warning. If the airplane is in a good configuration for takeoff, the WEUs do not make a takeoff warning.

The stabilizer green band selection logic supplies an all green band lamps on signal to the takeoff configuration warning test logic. The test signal goes to the AIMS. The AIMS sends the test signal to the stabilizer trim indicators. The indicators make all three green band lamps come on.

CONFIG WARN SYST Advisory Message

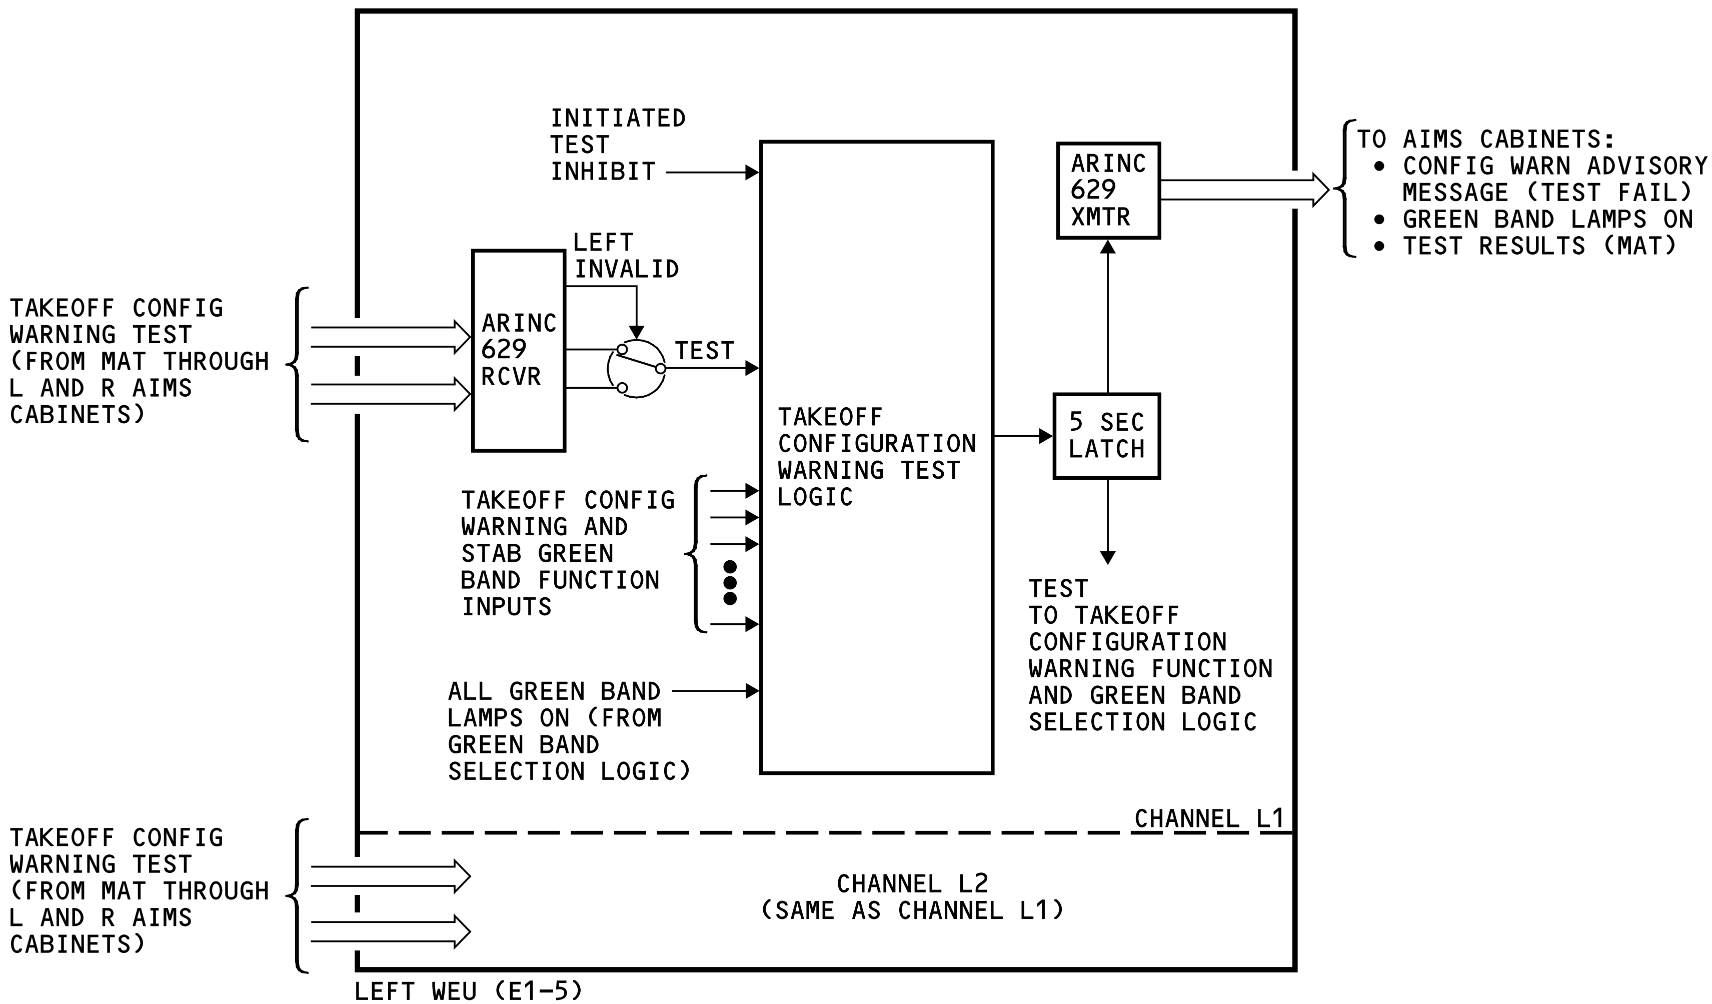
The AIMS shows the CONFIG WARN SYST EICAS advisory if the test fails. Each WEU channel latches the CONFIG WARN SYST message until you do another test or until you remove and reapply power to the WEUs.

The AIMS shows the CONFIG WARN SYST EICAS advisory message only when two or more channels supply a test fail signal.

WES - TAKEOFF CONFIGURATION WARNING TEST

MAT Display

The MAT shows a TAKEOFF CONFIGURATION TEST FAIL message or a TAKEOFF CONFIGURATION TEST COMPLETE message after the test ends.



31-51-00-038 Rev 1

WES - TAKEOFF CONFIGURATION WARNING TEST

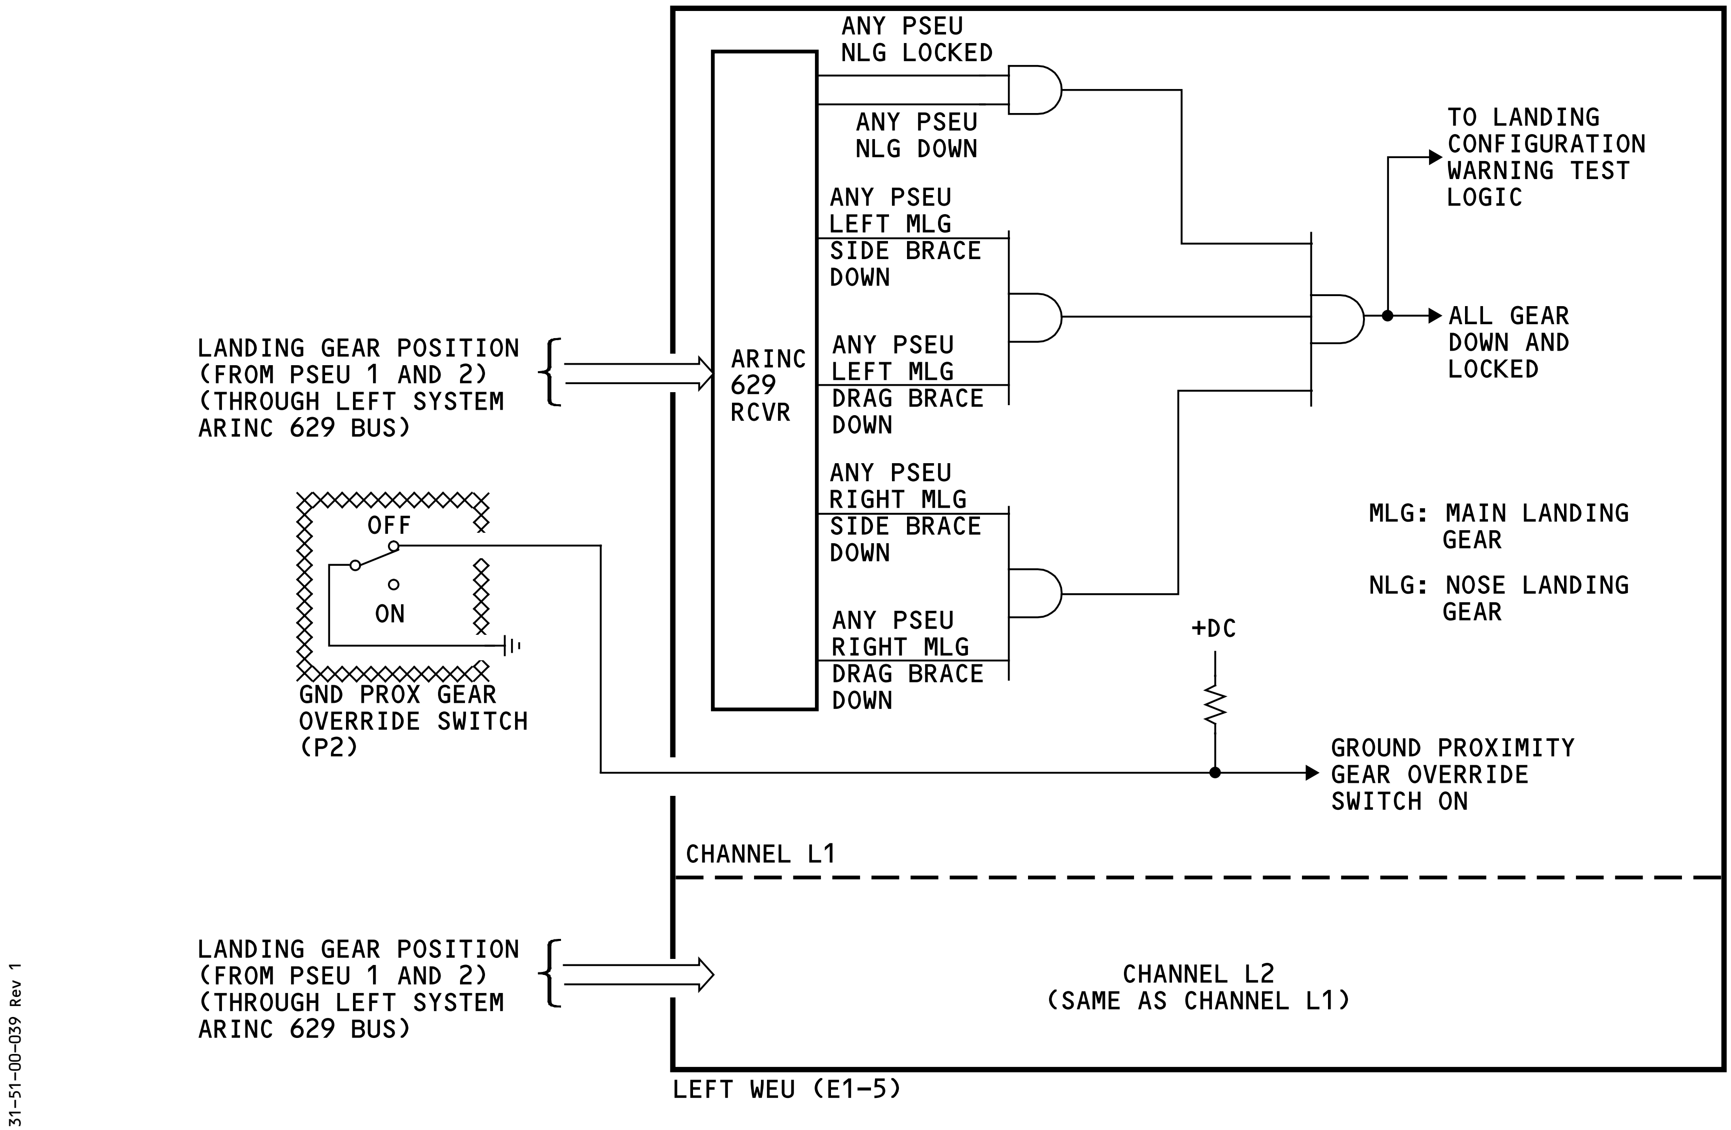
WES - LANDING CONFIGURATION WARNING INPUTS - 1

PSEU Inputs

The proximity switch electronic unit (PSEU) supplies landing gear position to the WEUs. The WEUs make an all gear down and locked signal.

Ground Proximity Gear Override Switch

The ground proximity gear override switch supplies an on signal to the WEUs.



WES - LANDING CONFIGURATION WARNING INPUTS - 1

WES - LANDING CONFIGURATION WARNING INPUTS - 2

Thrust Lever Resolver Angle Input

The electronic engine controls (EECs) supply thrust lever resolver angle (TLRA) to the WEUs. Compare logic in the WEUs make a true output when the TLRA is less than the glideslope power level (GSPL). The WEUs have the GSPL value in memory.

The compare logic also supplies a true output to the speed brake alert logic when the TLRA is greater than the speedbrake power level (SBPL). The WEUs have the SBPL value in memory.

Radio Altitude Input

The AIMS supplies radio altitude to the WEUs. The left WEU uses radio altitude in this priority:

- Left
- Right
- Center.

The right WEU uses radio altitude in this priority:

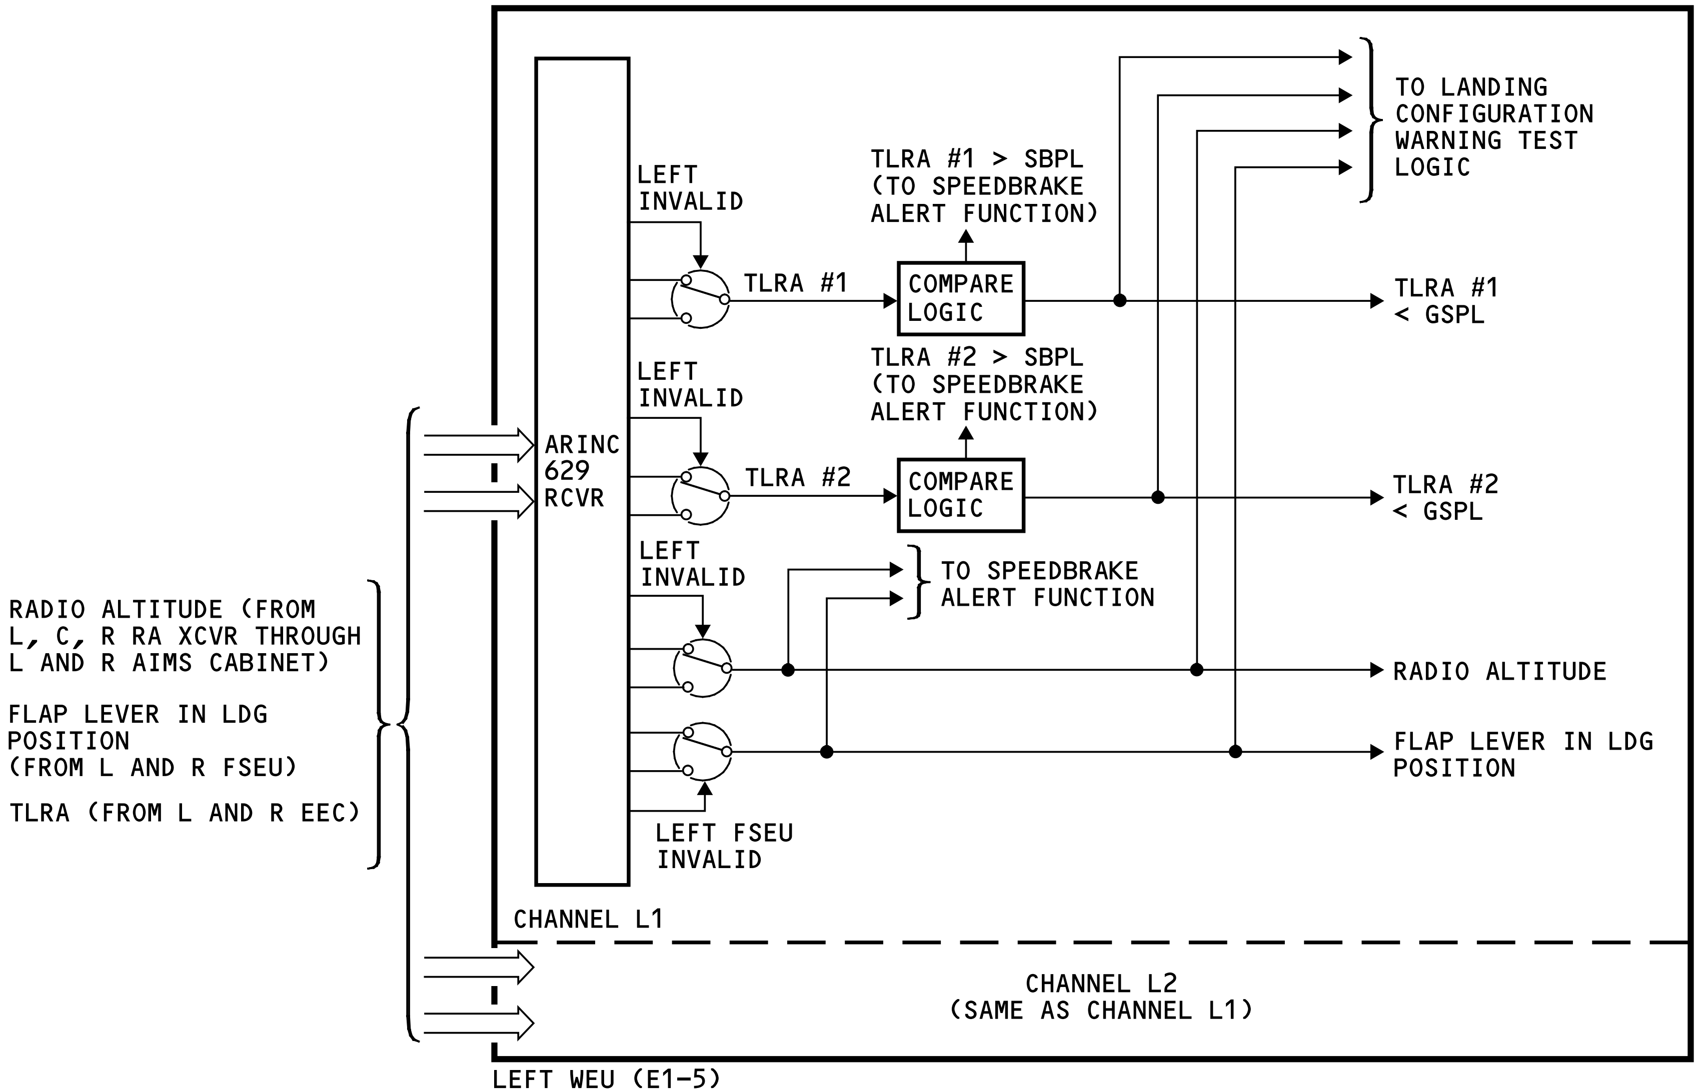
- Right
- left
- Center.

FSEU Inputs

The flap/slat electronic units (FSEUs) supply a flap lever in landing position digital discrete to the WEUs.

Landing Configuration Warning Test Logic Interface

All inputs that the WEUs use for landing configuration warning go to the landing configuration warning test logic.



31-51-00-040 Rev 2 02/12/96

WES - LANDING CONFIGURATION WARNING INPUTS - 2

WES - LANDING CONFIGURATION WARNING OPERATION

General

The WEUs make a landing configuration warning when the airplane is on approach and the landing gear is not down and locked.

There are two types of landing configuration warnings: resetable and non-resetable. Both types of warnings show the same indications. The indications are:

- CONFIG GEAR level A message shows on the EICAS primary display.
- Siren aural comes on
- Master warning lights come on

Resetable Landing Configuration Warning

During a resetable landing configuration warning, the CONFIG GEAR warning message stays until you lower the landing gear. Push any master warning light to stop the siren aural and to make the warning lights go out. The siren also stops when the ground proximity gear override switch is on.

Non-resetable Landing Configuration Warning

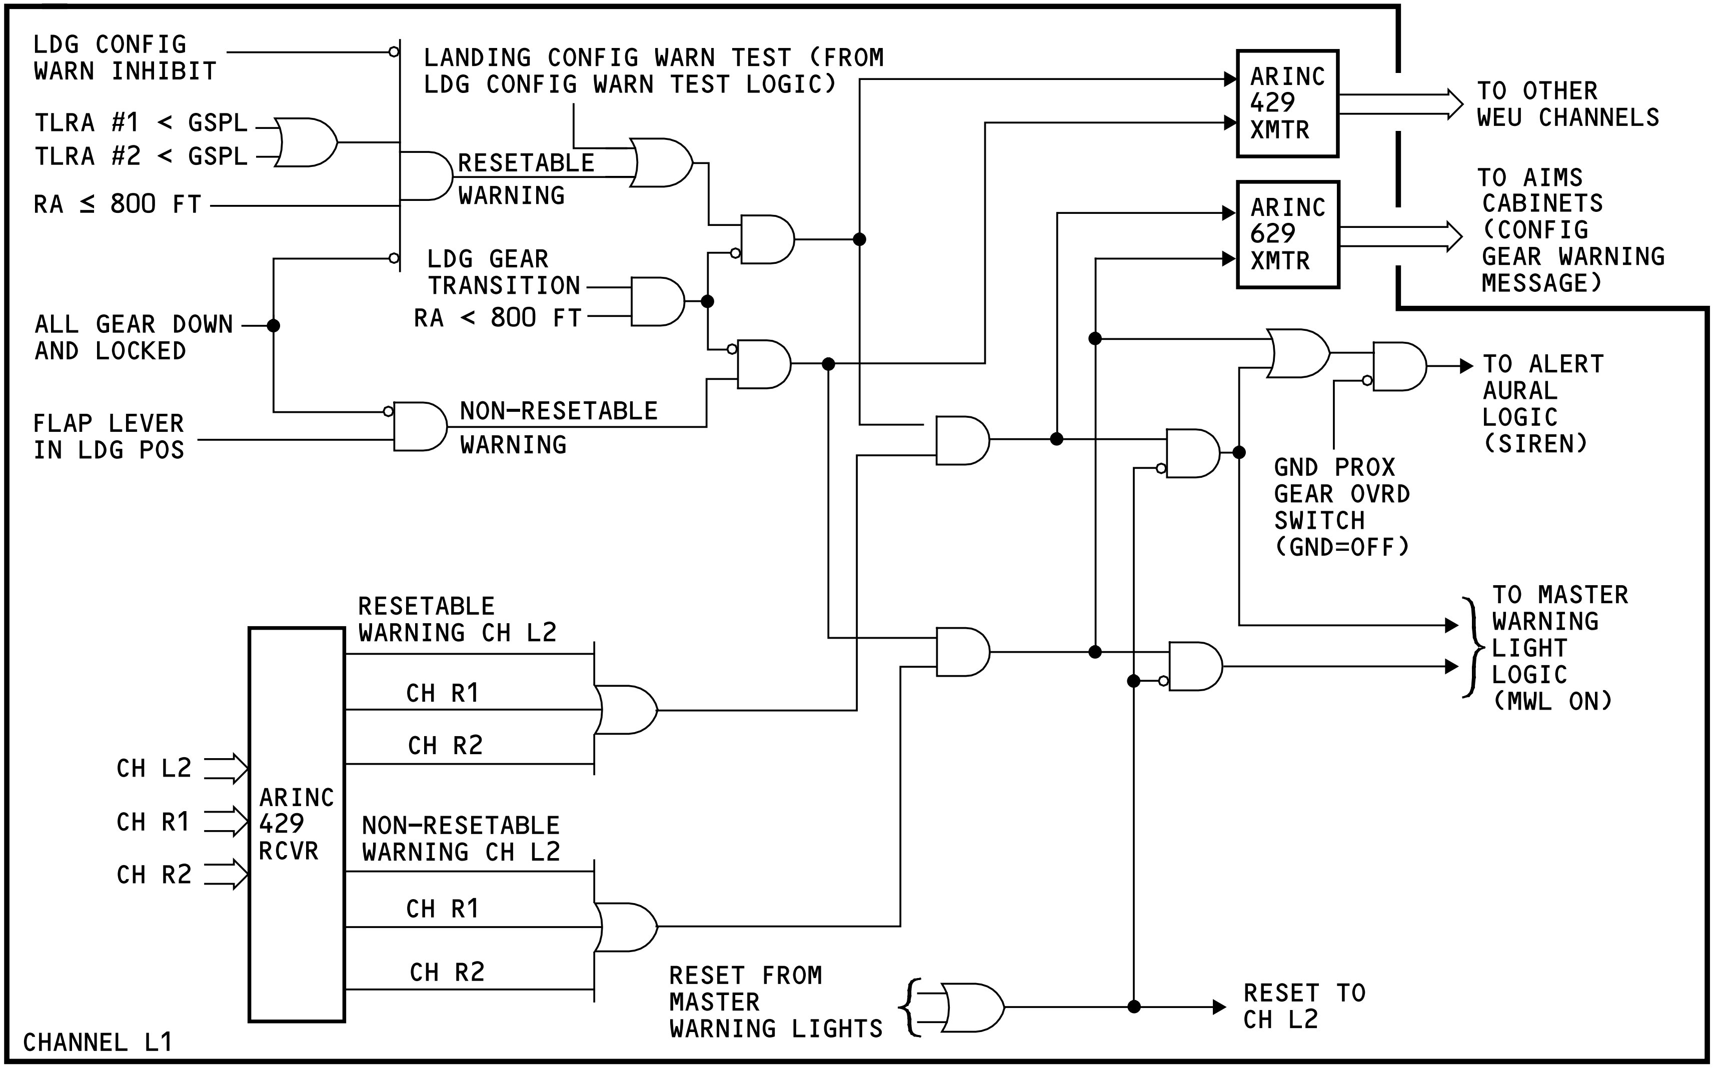
During a non-resetable landing configuration warning, the CONFIG GEAR warning message and the siren aural stay until you lower the landing gear. Push any master warning light to make the warning lights go out. The siren also stops when the ground proximity gear override switch is on.

Landing Configuration Warning Inhibit

The landing configuration warning inhibit prevents false resetable landing configuration warnings. The inhibit starts when the nose gear not compressed signal from the PSEU goes from false to true. The inhibit stops when the airplane goes above 800 feet of radio altitude, or 140 seconds after the nose gear not compressed signal was true.

Total Inhibit

The landing configuration warning function does not operate when the landing gear goes from all gear down and locked to all gears not down and locked (landing gear transition), and the radio altitude is below 800 feet. This is to prevent false warnings when the flight crew aborts a landing below 800 feet of radio altitude.



LEFT WEU (E1-5)

31-51-00-041 Rev 1

WES - LANDING CONFIGURATION WARNING OPERATION

WES - SPEEDBRAKE ALERT

General

The speedbrake alert function tells the flight crew when it is not safe to extend the speedbrakes.

Conditions Monitored

The WEUs make a speedbrake alert when the speedbrake handle is past the arm position, and any of these conditions is present:

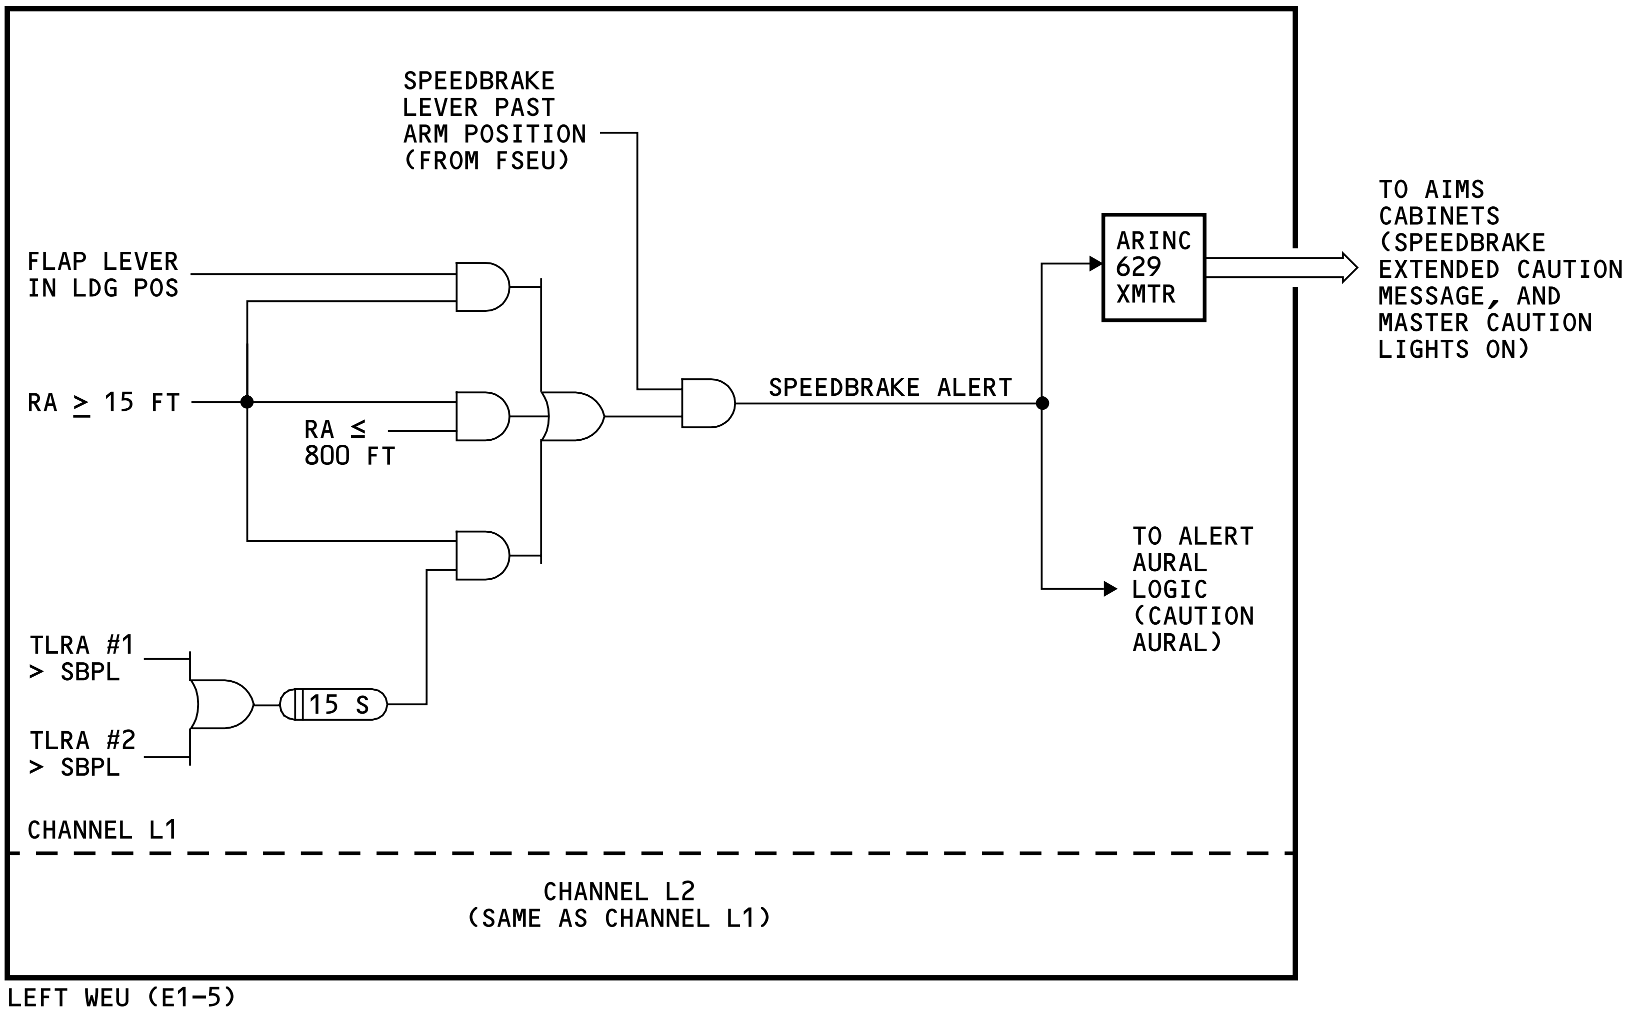
- Flaps lever in landing position with a radio altitude of 15 feet or more
- Radio altitude is between 15 and 800 feet
- 15 seconds after any thrust lever resolver angle (TLRA) is more than the speedbrake power level (SBPL) and the radio altitude is 15 feet or more.

Speedbrake Alert Indications

A speedbrake alert has these indications:

- A SPEEDBRAKE EXTENDED caution message shows on the EICAS display
- The master caution lights come on
- A caution aural comes on.

The AIMS shows the caution message and makes the master caution lights come on. The AIMS does this only when at least two WEU channels supply a speedbrake alert digital signal.



31-51-00-042 Rev 2 10/23/95

WES - SPEEDBRAKE ALERT

THIS PAGE INTENTIONALLY LEFT BLANK

WES - LANDING CONFIGURATION WARNING TEST

General

You start a landing configuration warning test from the maintenance access terminal (MAT). When you do a landing configuration warning test, you also do a test of the speedbrake alert function at the same time.

When the test passes, the WEUs make a landing configuration warning.

The landing configuration warning test logic checks the condition of the landing configuration warning and speedbrake alert function inputs. If any input is not present or is invalid, the test fails and you will not see a landing configuration warning.

Initiated Test Inhibit

A WEU channel must make an initiated test inhibit signal as false before a landing configuration warning test can start.

When the initiated test inhibit signal is true, the WEU channels cannot start any test.

The initiated test inhibit signal within a WEU channel is false (a test can start) only when all these conditions are true:

- Both engines are at less than takeoff thrust
- The airplane is on the ground
- The nose gear is compressed
- The ADIRU and the SAARU send incomplete pitot/static data (airplane not moving)
- Three or more WEU channels detect the same previous conditions.

Test Signal

The landing configuration warning test logic supplies a test signal that is on for 5 seconds and then it goes off. The test signal goes to the:

- Landing configuration warning function
- AIMS cabinets.

The landing configuration warning function makes a resetable landing configuration warning if all inputs to the landing configuration are valid.

CONFIG WARN SYST Advisory Message

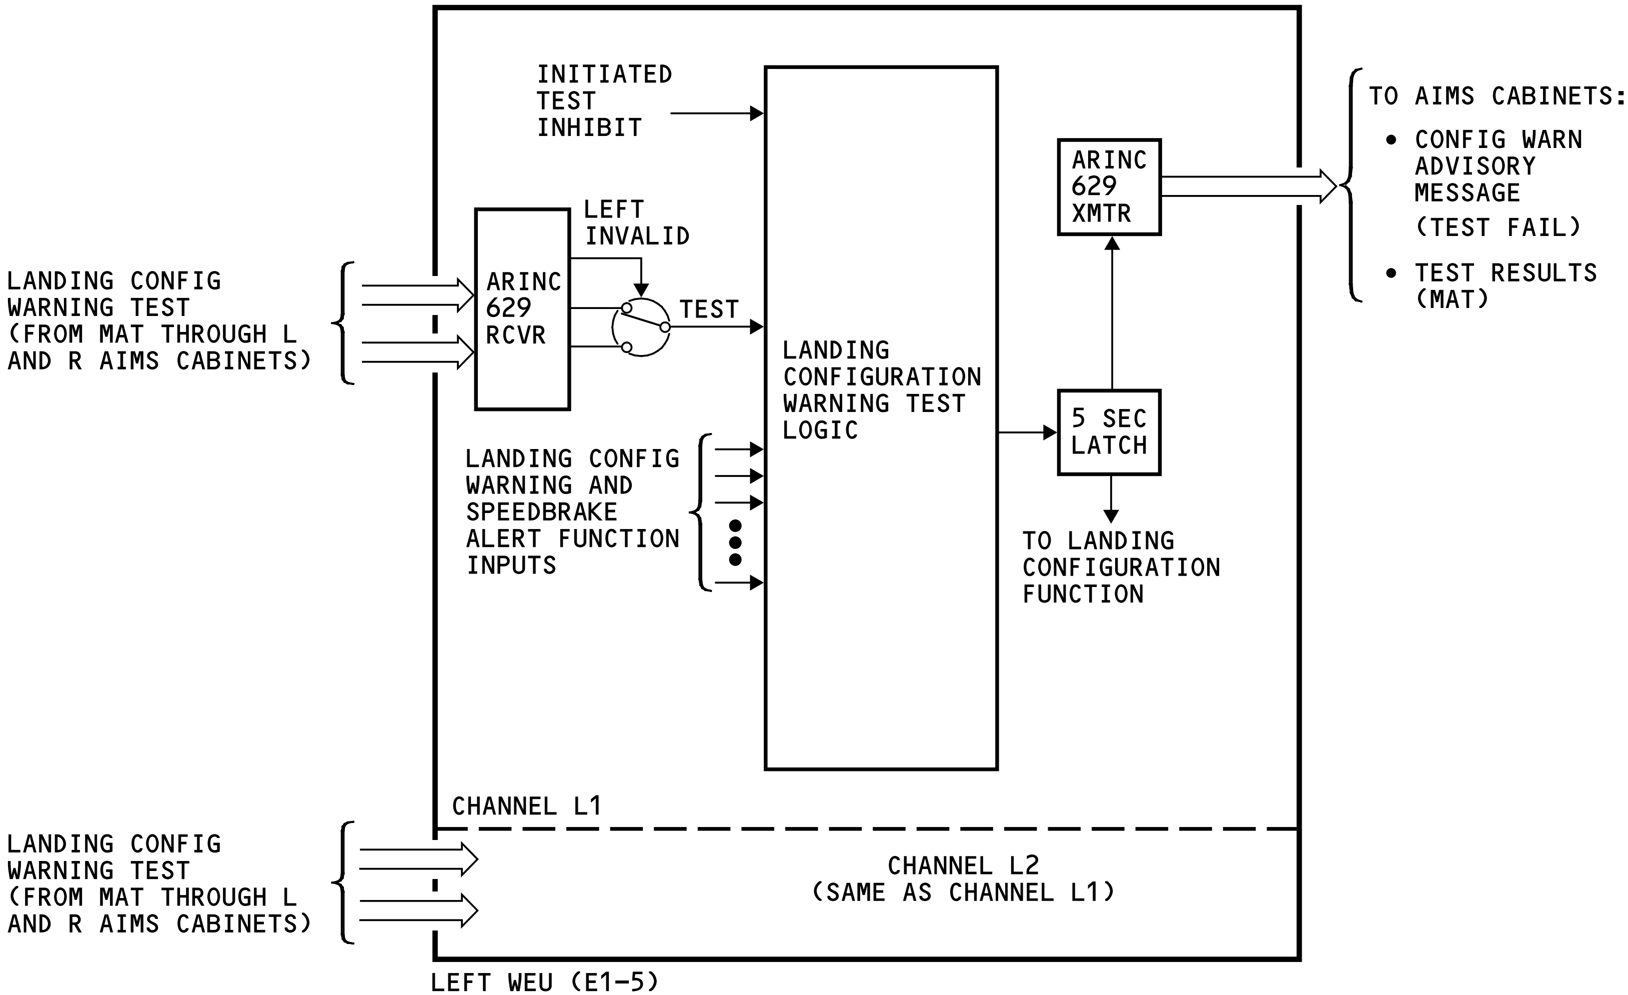
The AIMS shows the CONFIG WARN SYST EICAS advisory if the test fails. Each WEU channel latches the CONFIG WARN SYST message until you do another test or until you remove and reapply power to the WEUs.

The AIMS shows the CONFIG WARN SYST EICAS advisory message only when two or more channels supply a test fail signal.

WES - LANDING CONFIGURATION WARNING TEST

MAT Display

The MAT shows a LANDING CONFIGURATION TEST FAIL message or a LANDING CONFIGURATION TEST COMPLETE message after the test ends.



31-51-00-043 Rev 1

WES - LANDING CONFIGURATION WARNING TEST

WES - ALTITUDE ALERT FUNCTION

Purpose

The altitude alert function of the WEUs tells the pilots when the airplane approaches or deviates from the mode control panel (MCP) selected altitude.

Altitude Approach Point

The altitude approach point is 900 feet from the selected altitude.

Altitude Approach

Altitude approach indications show on the PFD when the airplane is less than 900 feet and more than 200 feet from the selected altitude.

Altitude Capture Point

The altitude capture point is 200 feet from the selected altitude.

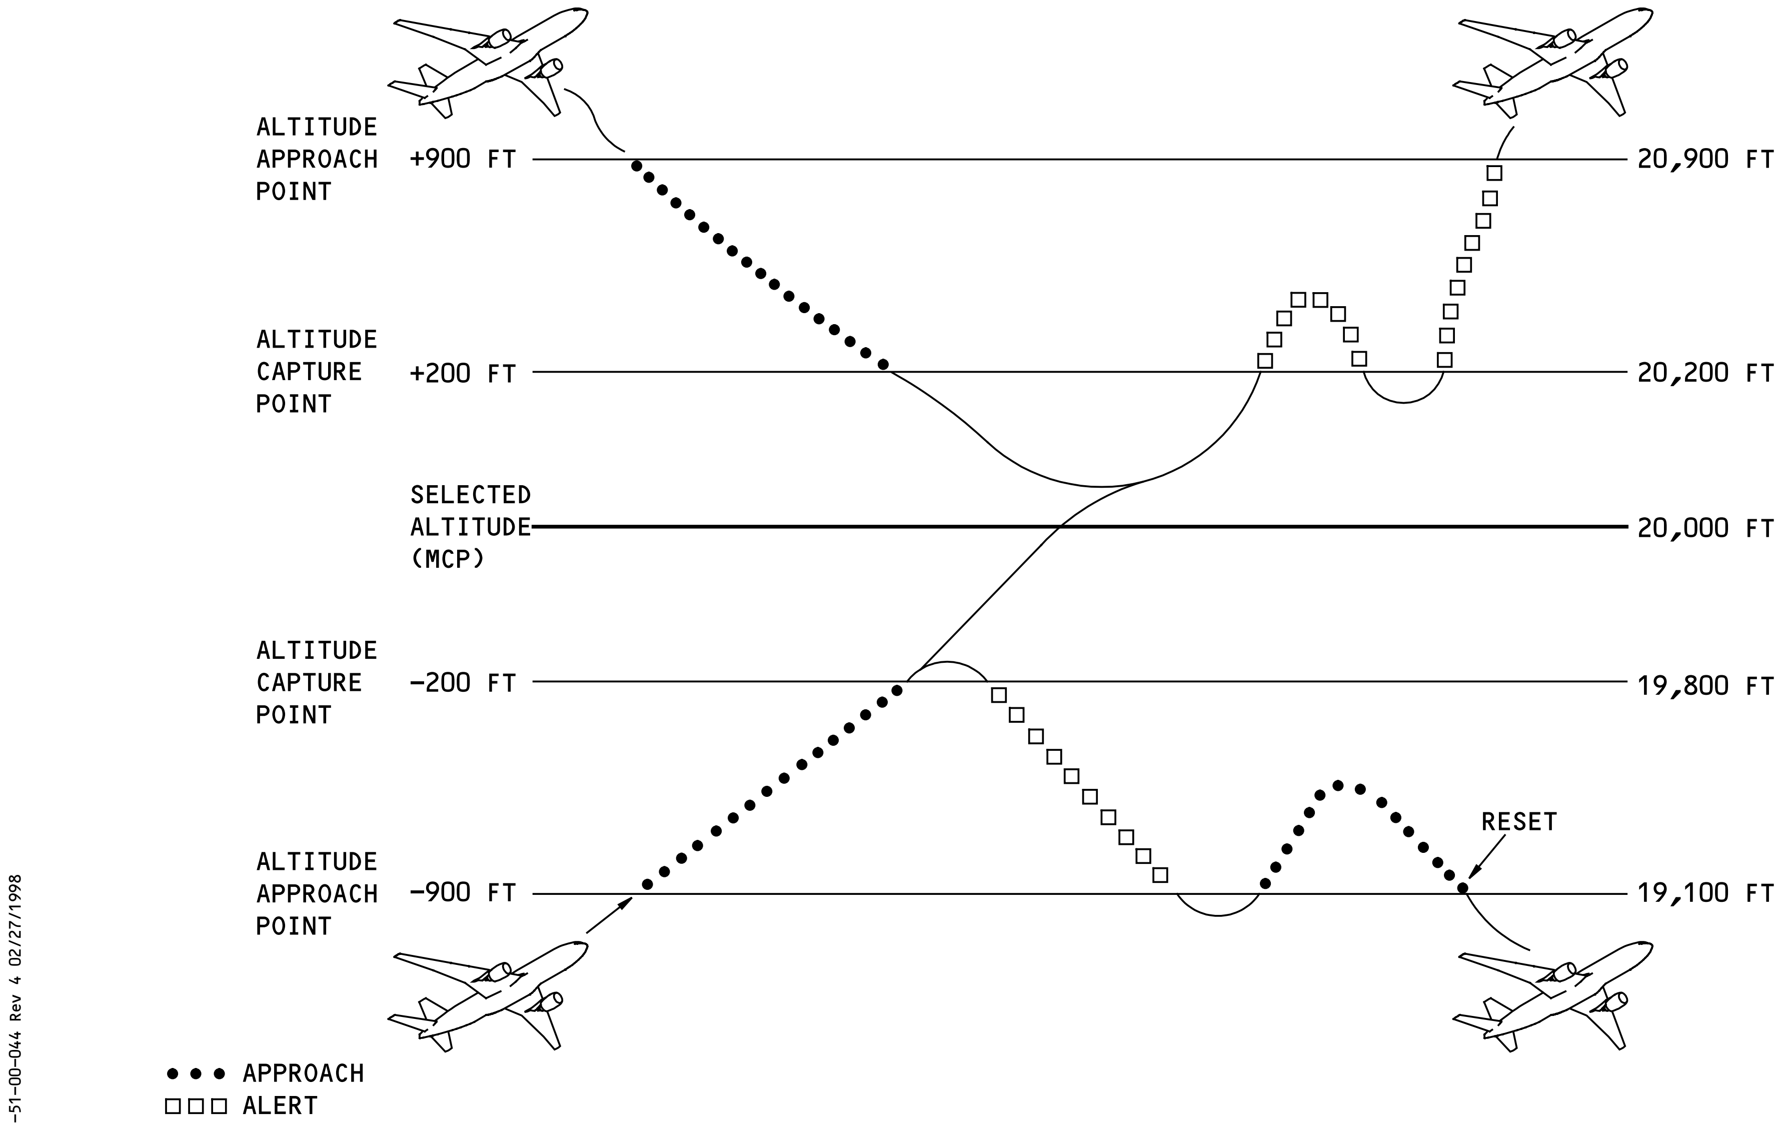
Altitude Alert

An altitude alert occurs when the airplane goes more than 200 feet away from the selected altitude.

Reset

An altitude alert reset occurs when one of these happens:

- The airplane goes 900 feet away from the selected altitude
- The flight crew changes the selected altitude on the mode control panel
- The airplane returns to within 200 feet of the selected altitude.



WES - ALTITUDE ALERT FUNCTION

WES - ALTITUDE ALERT PFD INDICATIONS AND CONTROL

General

The primary flight display (PFD) shows altitude alert indications.

Selected Altitude Display and Bug

The selected altitude from the mode control panel (MCP) shows above the altitude indication. The color of the selected altitude display is magenta.

The selected altitude bug is magenta. The bug points to the selected altitude when the selected altitude is on the PFD barometric altitude scale. If the selected altitude is not on the scale, the bug is at the top or bottom of the scale.

Selected Altitude Highlight Box

An altitude alert box is around the selected altitude when the airplane gets to the altitude capture point. This box stays when the airplane is less than 900 feet but more than 200 feet from the selected altitude (altitude approach).

Current Altitude Box

The box around the current altitude is usually white. The box is thicker when the airplane gets to the altitude capture point. The box stays thicker when the airplane is less than 900 feet but more than 200 feet from the selected altitude (altitude approach).

The box is yellow when the airplane goes more than 200 feet but less than 900 feet from the selected altitude (altitude alert).

MCP

The altitude selector is on the MCP. The selected altitude shows in the altitude window above the altitude selector.

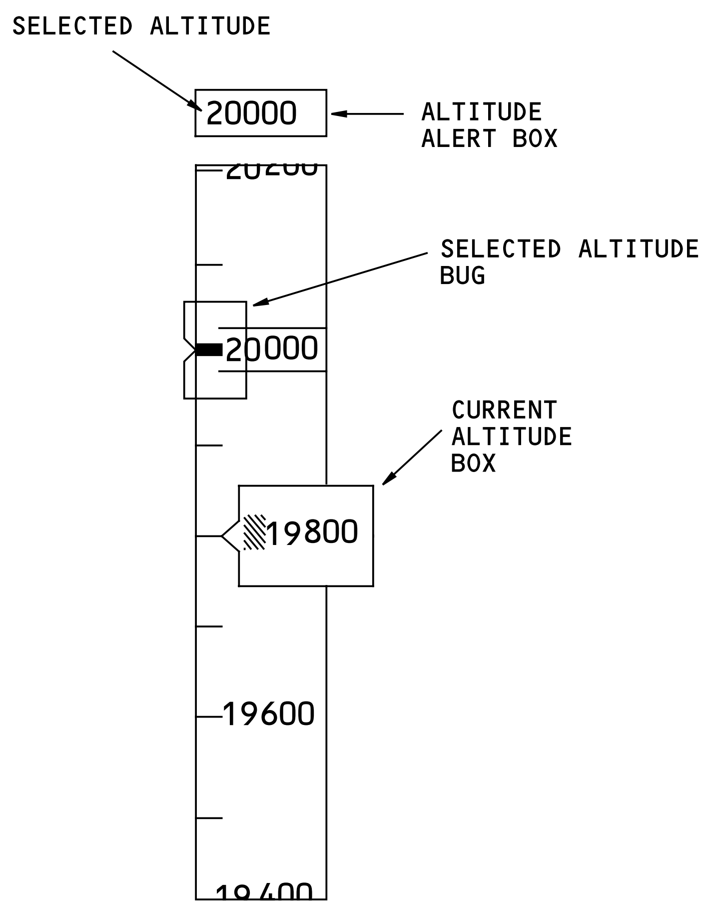
Rotate the altitude selector to change the selected altitude.

Caution Aural

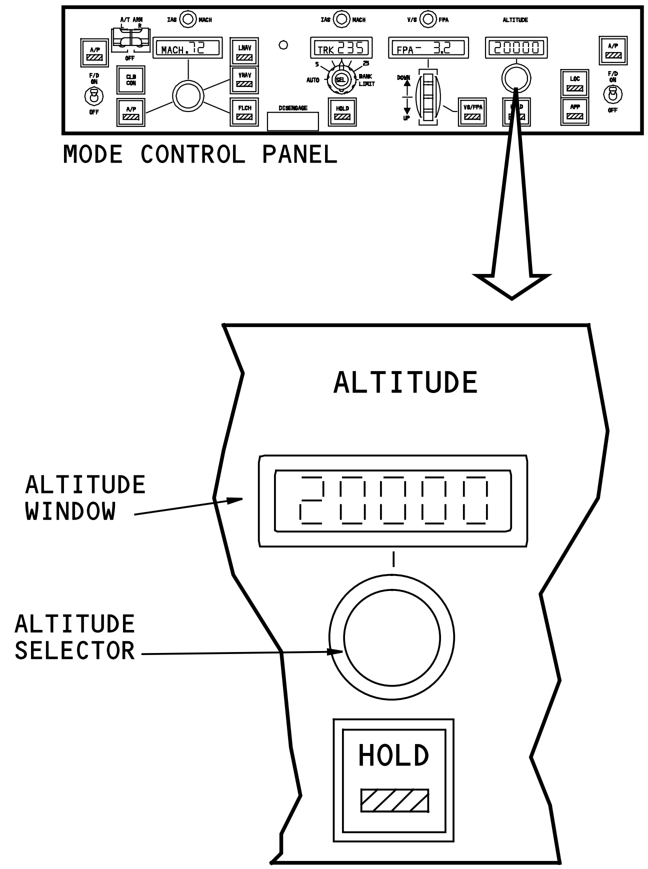
The WEUs make a caution aural when an altitude alert occurs.

EICAS Message and Master Caution Lights

The WEUs send a digital signal to the AIMS cabinets when an altitude alert occurs. The AIMS shows an ALTITUDE ALERT EICAS caution message. The AIMS also makes the master caution lights come on.



ALTITUDE INDICATION
ON PFD



SELECTED ALTITUDE CONTROLS

31-51-00-045 Rev 6

WES - ALTITUDE ALERT PFD INDICATIONS AND CONTROL

WES - ALTITUDE ALERT OPERATION

Altitude Comparator

The altitude comparator compares the selected altitude with the barometric altitude. The altitude comparator supplies these outputs:

- More than or equal to 200 feet from the selected altitude
- Less than or equal to 900 feet from the selected altitude
- Less than or equal to 200 feet from the selected altitude.

Alert/Approach Logic

The alert/approach logic calculates when the airplane approaches the selected altitude, or when it moves away from the selected altitude.

The alert/approach logic makes an altitude approach signal when the airplane is 200 feet or more, and 900 feet or less from the selected altitude. The altitude approach signal goes to the AIMS cabinets. The AIMS shows altitude approach indications on the primary flight displays (PFDs).

The alert/approach logic makes an altitude alert signal when the airplane goes 200 feet or more from the selected altitude. The altitude alert signals go to the aural alert logic and the AIMS cabinets.

The aural alert logic makes the caution aural.

The AIMS cabinets must receive an altitude alert signal from at least two WEU channels. The AIMS does these functions:

- Shows the ALTITUDE ALERT caution message
- Shows the altitude alert indications on the PFDs
- Makes the master caution lights come on.

Altitude Alert Inhibit

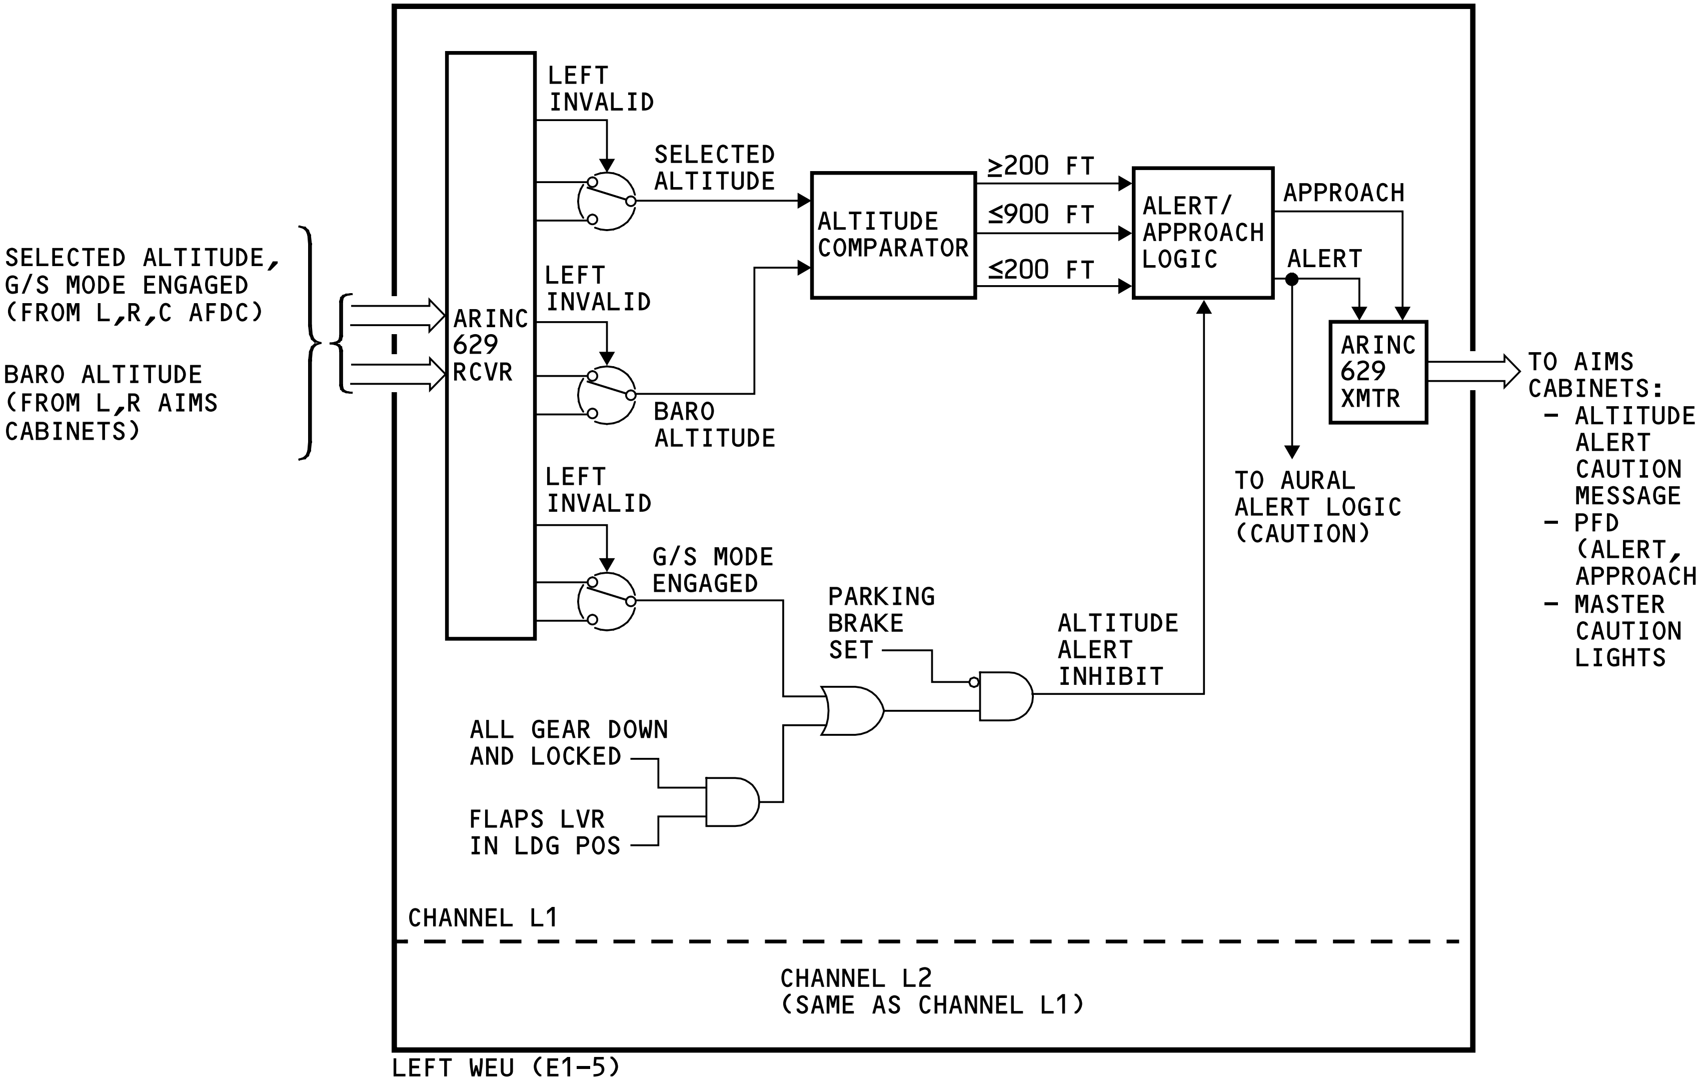
The altitude alert inhibit signal stops the operation of the altitude alert/approach logic. The WEUs use these signals to make an altitude alert inhibit signal:

- Glideslope (G/S) mode engaged
- Parking brake set
- All gear down and locked
- Flaps in landing position.

Operational Check

With the parking brake set, the altitude alert inhibit signal is false. This permits an operational check of the altitude alert function on the ground.

Move the altitude selector on the mode control panel (MCP). You will see altitude approach indications when the difference between the selected altitude and the barometric altitude is 900 feet or less. After that, you will see altitude alert indications when the difference between selected altitude and barometric altitude is 200 feet or more.



31-51-00-046 Rev 5 02/27/1998

WES - ALTITUDE ALERT OPERATION

WES - STALL WARNING FUNCTION

General

The stall warning function has these four functions:

- Stick shaker activation
- Pitch limit indication (PLI) calculation
- Speed tape parameter calculation
- Auto slat enable.

Stick Shaker Activation

The WEUs make the stick shaker actuators come on when the airplane has a corrected angle of attack (AOA) (alpha) that is too high.

The stick shaker trip point (AOA STRIP) logic calculates the AOA STRIP. The logic uses these inputs:

- Mach number from the air data inertial reference unit (ADIRU). Channels L1 and R1 use the ADIRU as the primary source and the SAARU as the secondary source. Channels L2 and R2 use the SAARU as the primary source and the ADIRU as the secondary source
- Nose gear down and locked from the proximity switch electronic unit (PSEU)
- Speedbrake lever position (SBLP) from the primary flight computers (PFCs)
- Flap and slat position from the flap/slat electronics units (FSEUs).

The WEUs compare the AOA STRIP and the AOA. If the AOA is equal to or higher than the AOA STRIP, each WEU channel makes a stick shaker actuator enable signal. This will happen only if the airplane is in the air.

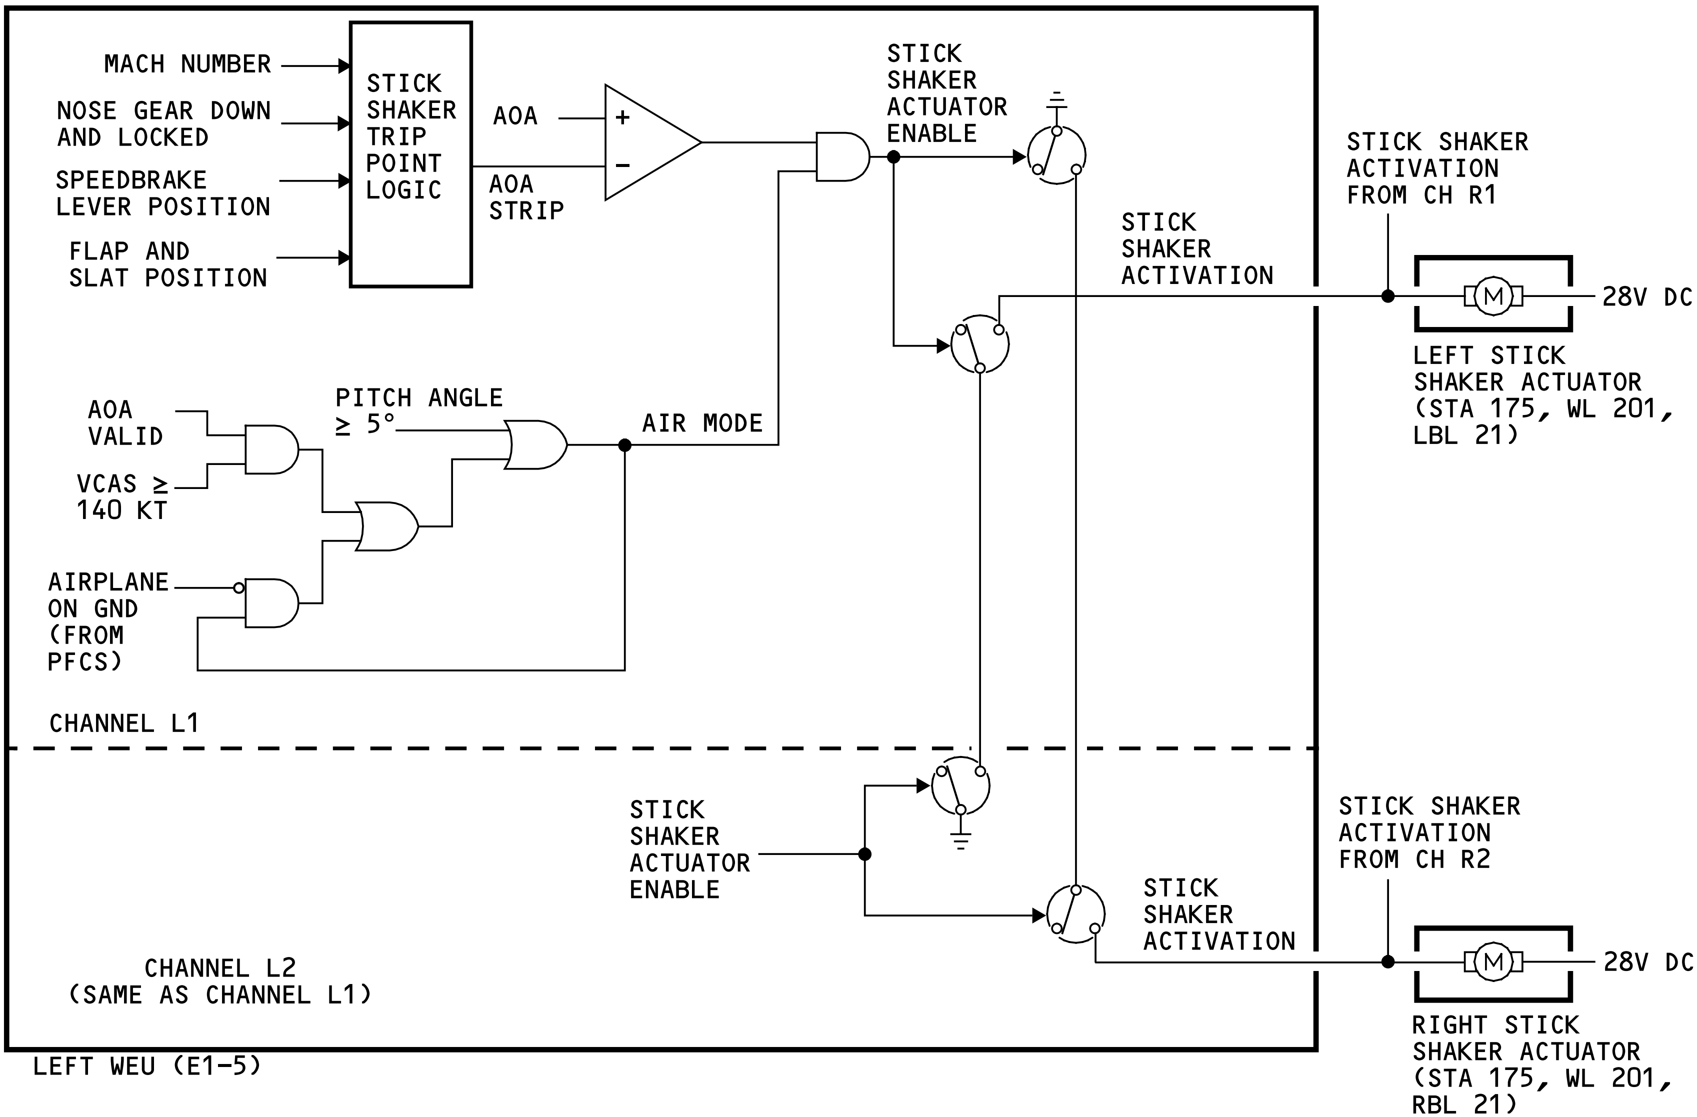
The stick shaker actuators come on only when at least two channels in the same WEU make a stick shaker actuator enable signal.

Air Mode

The WEUs make the stick shaker actuators come on only when the air mode signal is true. The WEUs use these inputs to calculate the air mode signal:

- Angle of attack (AOA)
- Computed airspeed
- Pitch angle.

All these signals come from the ADIRU. If the ADIRU fails, the WEUs use the SAARU.



31-51-00-047 Rev 4 02/09/1998

WES - STALL WARNING FUNCTION

WES - PITCH LIMIT INDICATION

General

The WEUs calculate and show the flight crew the maximum pitch limit. The maximum pitch limit is the number of degrees the airplane can pitch up from the current pitch angle before the stick shaker actuators come on.

PLI Logic

The pitch limit indication (PLI) logic in each WEU channel uses these inputs to calculate the maximum pitch limit:

- Active control minimum speed (VCMIN). VCMIN comes from the flight management computing function (FMCF) of AIMS
- Stick shaker speed (VSS). VSS comes from the VSS logic in each WEU
- Stick shaker trip point (AOA STRIP)
- Corrected angle of attack (AOA)
- Air mode signal
- Computed airspeed (VCAS)
- Flaps up. This signal comes from the flap slat electronic units (FSEUs)
- Leading edge devices retracted. This signal comes from the FSEUs.

PLI Data

The PLI logic sends the PLI data to the AIMS cabinets. The AIMS cabinets send the data to the primary flight displays (PFDs). The PFDs show the pitch limit indicator symbol.

The WEUs send valid PLI data to the AIMS only when any of these conditions is present:

- VCAS is less than the upper limit of the FMCF minimum maneuver speed (amber band) on the PFD speed tape
- VCAS is 1.44(VSS) or less
- The flaps are not up.

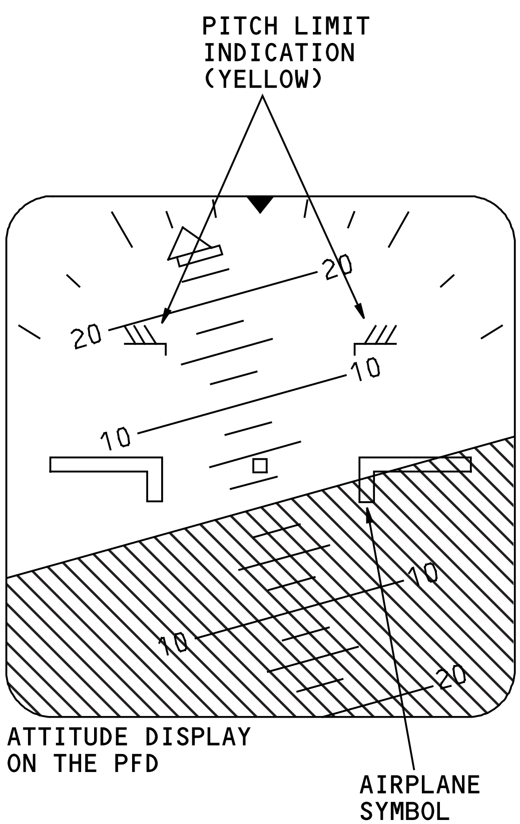
At any other time the data is no computed data (NCD).

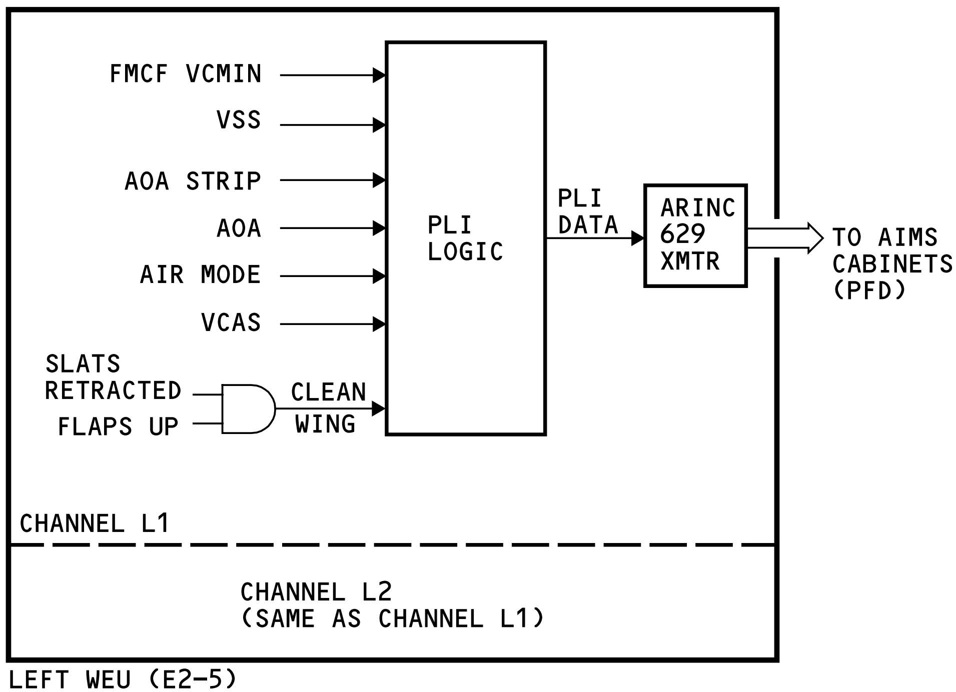
Pitch Limit Indications

When the airplane is on the ground, the pitch limit indicator shows 15 degrees pitch up attitude.

The maximum pitch limit indication at any time is 30 degrees minus the actual pitch angle.

The stick shaker actuators come on when the airplane symbol reaches the same pitch as the pitch limit indicator symbol.





31-51-00-048 Rev 3 04/26/96

WES - PITCH LIMIT INDICATION

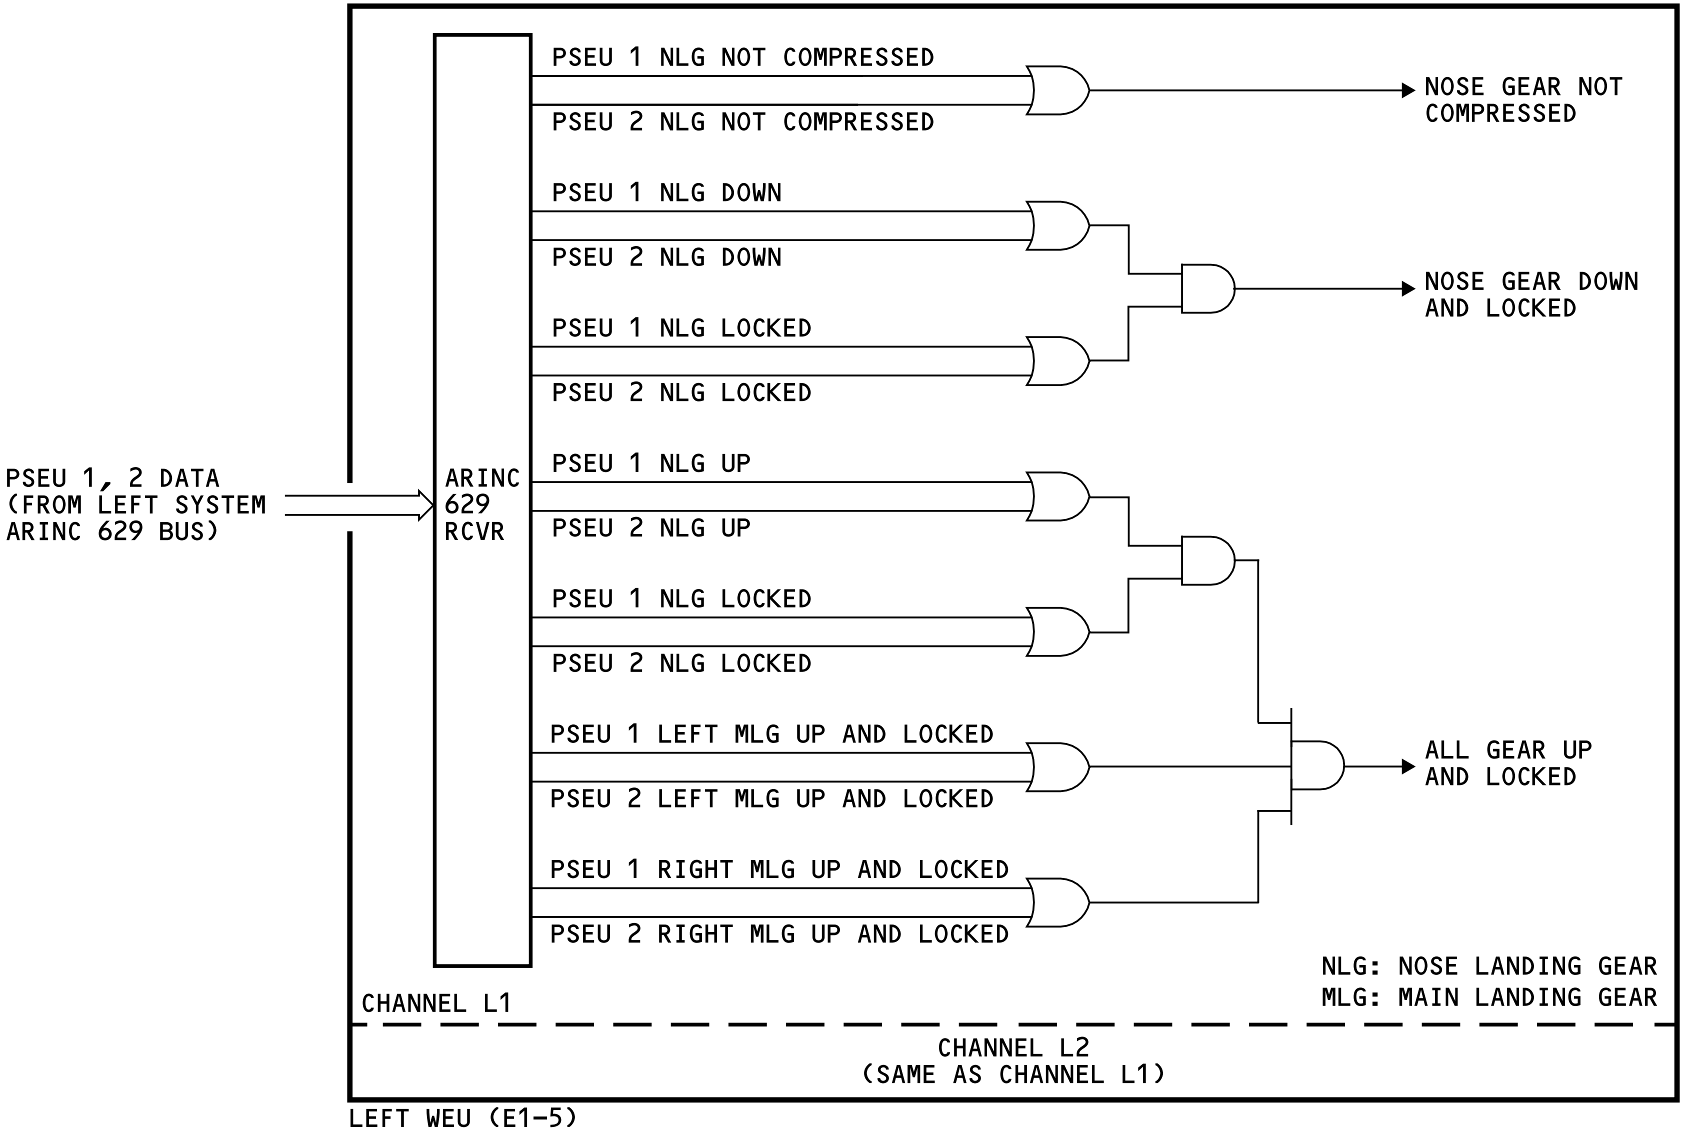
WES - SPEED TAPE PARAMETER CALCULATION - 1

General

The WEUs use proximity switch electronic unit (PSEU) data to make these signals:

- All gear up and locked
- Nose gear not compressed signal
- Nose gear down and locked.

The WEUs use those signals to make speed tape parameters.



31-51-00-049 Rev 0

WES - SPEED TAPE PARAMETER CALCULATION - 1

WES - SPEED TAPE PARAMETER CALCULATION - 2

THIS PAGE INTENTIONALLY LEFT BLANK

WES - SPEED TAPE PARAMETER CALCULATION - 2

Speed Tape Parameters

The WEUs calculate these speed tape parameters:

- Maximum operating speed and the maximum operating mach number (VMO/MMO)
- Maximum flaps extended/maximum gear extended speed (VFE/VLE)
- Maximum speed (VMAX)
- Minimum speed (VMIN)
- Maneuver margin above stick shaker speed (VSSNG).

Inputs

The air data inertial reference unit (ADIRU) supplies these inputs for speed tape parameter calculation:

- Corrected angle of attack (AOA)
- Barometric altitude
- Body longitudinal acceleration (AL)
- Body normal acceleration (AN)
- Computed airspeed (VCAS)
- Mach number (MACH NO)
- Static pressure.

If the ADIRU fails, the secondary attitude air data reference unit (SAARU) supplies the same inputs.

The primary flight computers (PFCs) supply the PFCS in secondary or direct mode of operation signal, and speedbrake lever position (SBLP).

The proximity switch electronic units (PSEU) supply these inputs:

- All gear up and locked
- Nose gear down and locked
- Nose gear not compressed.

The flap slat electronic units (FSEUs) supply flap and slat position.

The alternate gear down dispatch switch supplies three identical ground signals when the switch is in the VMO position. When the alternate gear down dispatch switch is in the VMO position, the WEUs send a memo message request to the AIMS cabinets. The primary display function of the AIMS shows the memo message VMO GEAR DOWN.

Speed Tape

The primary flight display (PFD) shows the speed tape. The maximum speed (VMAX) and minimum speed (VMIN) show on the speed tape.

VMO/MMO Logic

The VMO/MMO logic calculates the maximum operating speed (VMO) and the maximum operating mach number (MMO).

The VMO and MMO are normally 330 knots and mach .87. When at least two of the three ground signals from the alternate gear down dispatch switch show the switch is

WES - SPEED TAPE PARAMETER CALCULATION - 2

in the VMO position, the VMO/MMO logic changes the VMO and MMO to 270 knots and mach .73.

The VMO/MMO goes to the maximum operating speed (VMAX) logic. When the computed airspeed (VCAS) or the mach number (MACH NO) is more than the limit calculated by the VMO/MMO logic, the VMO/MMO logic makes an overspeed warning.

VFE/VLE Logic

The VFE/VLE logic calculates VFE/VLE.

When the flaps and slats are up and the gear not clean signal is false, VFE/VLE is no computed data. When the flaps are not up, VFE/VLE is the same as VFE. When the flaps are up and the gear not clean signal is true, VFE/VLE is the same as VLE.

VFE/VLE goes to the VMAX logic. VFE/VLE also goes to the AIMS cabinets for FMCF calculations.

VMAX Logic

The VMAX logic calculates the VMAX. If the wing is clean and the gear not clean signal is false, VMAX is the same as the VMO/MMO. VMAX is the same as VFE/VLE for any other condition.

VMAX goes to the AIMS cabinets for display on the PFD and for FMCF calculations.

VSS Logic

The stick shaker speed (VSS) logic calculates VSS. VSS goes to the VMIN logic.

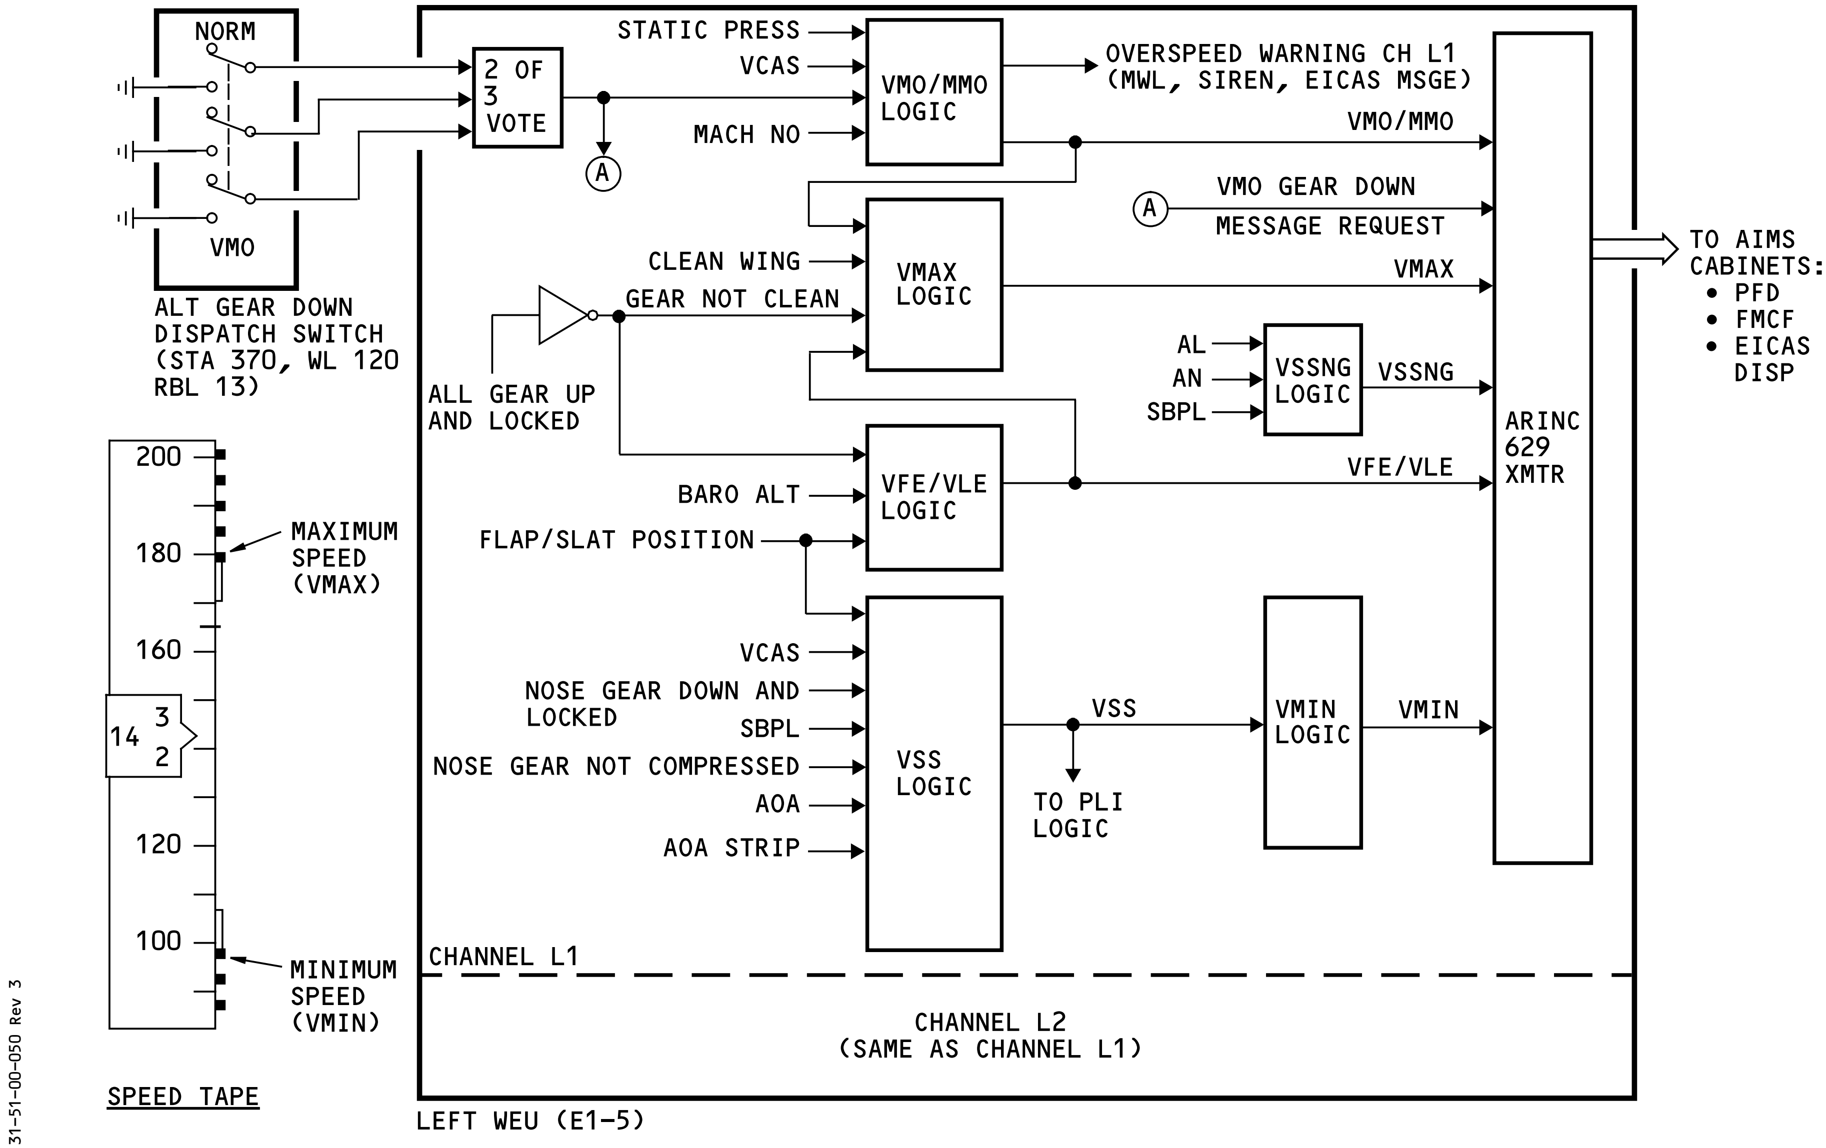
VMIN Logic

The VMIN logic calculates VMIN. VMIN is the same as VSS.

VMIN goes to the AIMS cabinets for display on the PFD and for FMCF calculations.

VSSNG Logic

The VSSNG logic calculates VSSNG. VSSNG goes the AIMS cabinets for FMCF calculations.



WES - SPEED TAPE PARAMETER CALCULATION - 2

WES - AUTO SLAT ENABLE

General

The auto slat enable function extends the leading edge slats automatically when the airplane is near a stall. The slats extend from the sealed position to the gapped position. This action gives more lift.

The auto slat enable function only operates when the flaps are 1 to 20 units, and the airplane is in the air.

Operation

If the corrected angle of attack (AOA) is more than the auto slat trip point (AOA AS), the WEUs make an auto slat enable signal.

The auto slat enable signal goes to the flap slat electronic units (FSEUs) and to the hydraulic interface modules (HYDIMs).

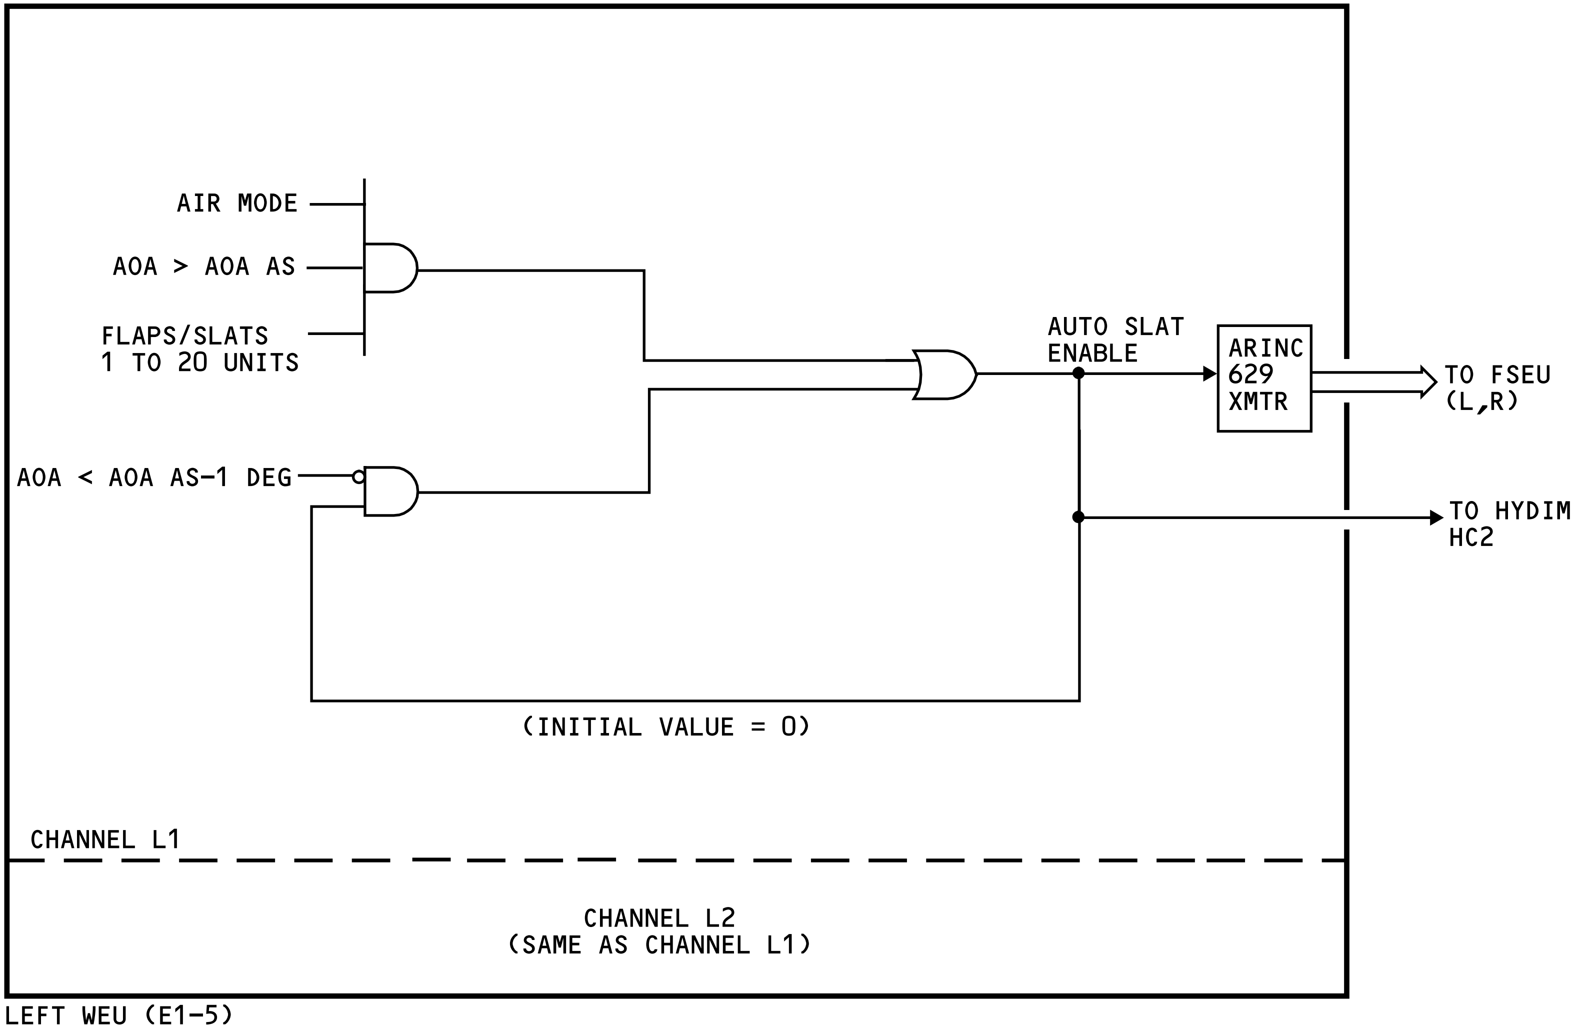
The FSEUs extend the slats from the sealed to the gapped position.

The HYDIMs increase available hydraulic flow for the slats. Because of the WEU signals to the HYDIMs, the slats move from the sealed position to the gapped position faster than normal.

When the auto slat enable signal is true, it stays true until the AOA is one degree below the AOA AS.

HYDIM Interfaces

Channels L1 and R1 auto slat enable signals go to HYDIM HC2. Channels L2 and R2 auto slat enable signals go to HYDIM HC1.



31-51-00-051 Rev 3 02/12/1998

WES - AUTO SLAT ENABLE

WES - STALL WARNING FUNCTION TEST

General

Start a stall warning function test from the maintenance access terminal (MAT).

The stall warning function test does a check of the stall warning function in each WEU channel. The stall warning function test also verifies the condition of the stall warning function inputs. If any input is not present or is invalid, the test fails.

Initiated Test Inhibit

A WEU channel must make an initiated test inhibit signal as false before a stall warning function test can start.

When the initiated test inhibit signal is true, the WEU channels cannot start any test.

The initiated test inhibit signal within a WEU channel is false (a test can start) only when all these conditions are true:

- Both engines are at less than takeoff thrust
- The airplane is on the ground
- The nose gear is compressed
- The ADIRU and the SAARU send incomplete pitot/static data (airplane not moving)
- Three or more WEU channels detect the same previous conditions.

Stall Warning Function Test Logic

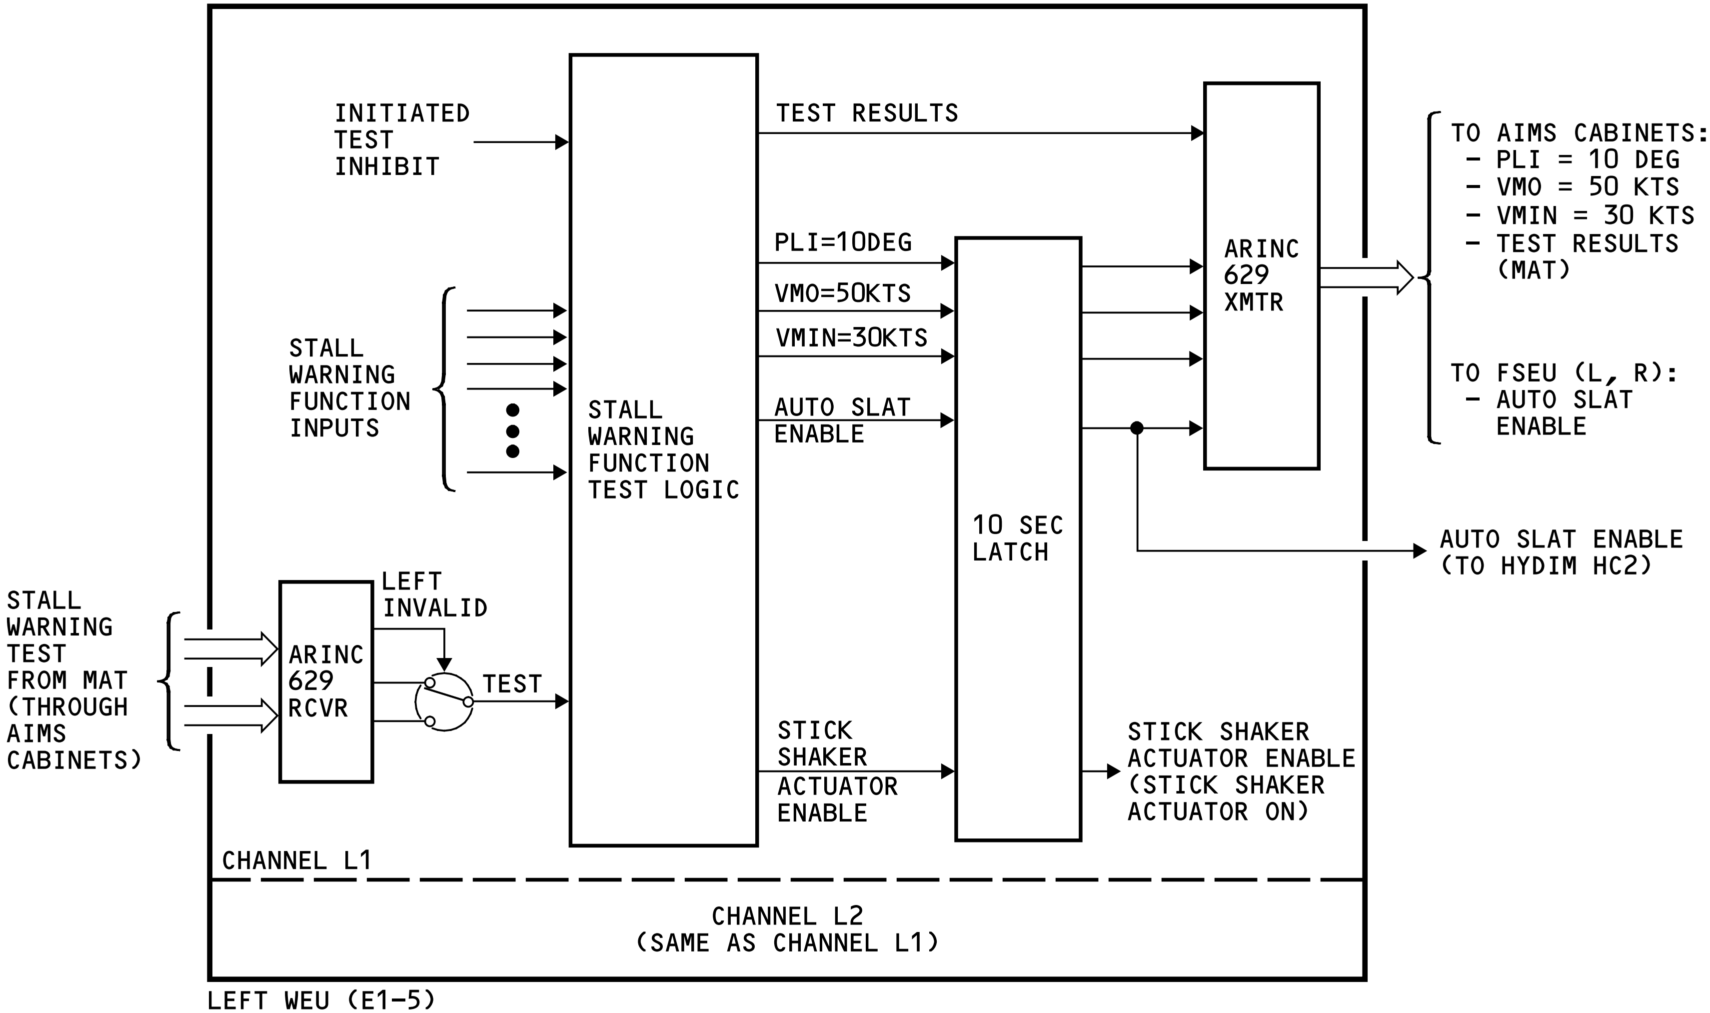
The stall warning function test logic receives the stall warning test signal from the AIMS cabinets. The stall warning function test logic supplies test signals that are on for 2 seconds and then go off. The stall warning function test logic does these functions:

- Makes the pitch limit indicators on the PFD go to 10 degrees
- The PFD speed tape shows a maximum operating speed (Vmo) of 50 knots, and a minimum speed limit of 30 knots
- Makes an auto slat enable signal that goes to a hydraulic interface module (HYDIM) and the flap slat electronic units (FSEUs)
- Makes the stick shaker actuators come on
- Verifies the condition of the stall warning function inputs
- Supplies test results to the MAT.

WARNING: IF THE FLAP LEVER IS AT 1,5,15, OR 20 AND HYDRAULIC POWER IS APPLIED TO THE AIRPLANE, THIS TEST WILL CAUSE THE LE SLATS TO MOVE FROM SEALED TO GAPPED. THIS LE SLAT MOVEMENT CAN BE PREVENTED BY SETTING BOTH THE C1 AND C2 AIR SWITCHES (P5 HYDRAULIC PANEL) TO THE OFF POSITIONS.

MAT Display

The MAT shows a STALL WARNING TEST FAIL message or a STALL WARNING TEST PASS message after the test ends.



31-51-00-052 Rev 3 02/13/1998

WES - STALL WARNING FUNCTION TEST

THIS PAGE INTENTIONALLY LEFT BLANK

WES - SYSTEM TEST

General

Use the MAT to start a WES system test. During the WES system test, each channel verifies:

- Its internal status
- The ARINC 629 inputs
- The ARINC 429 inputs
- All analog discrete inputs
- That all WEU channels have the same software
- Correct operation of the master warning lights and the aural warning speakers.

Each channel does the first five operations independent of each other. The four channels operate synchronously during the last operation.

The system test lasts approximately 20 seconds.

Initiated Test Inhibit

When the initiated test inhibit signal is true, the WEU channels cannot start any test.

These conditions must be true before you can do any WES test:

- Both engines are at less than takeoff thrust
- The airplane is on the ground
- The nose gear is compressed
- The ADIRU and the SAARU send incomplete pitot/ static data (airplane not moving)
- Three or more WEU channels detect the same previous conditions.

Initiated Test Enable, WES System Test Enable

Each WEU channel must make an initiated test enable signal and a WES system test enable signal before a WES system test can start.

The initiated test enable signal within a WEU channel is true only when all these conditions are true:

- Both engines are at less than takeoff thrust
- The airplane is on the ground
- The nose gear is compressed
- The ADIRU and the SAARU send incomplete pitot/ static data (airplane not moving).

The WES system test enable signal is true when all these conditions are present:

- Both engines fuel control switches are in the cut-off position (engines are not running)
- Initiated test enable signal is true.

Master Warning lights

Each WEU channel verifies its ability to make the master warning lights come on. Each WEU channel must receive at least one master warning light (MWL) arm signal from one other channel, before it makes a master warning light come on. Each WEU channel verifies all MWL arm combinations.

WES - SYSTEM TEST

The master warning lights will come on and then go out as each of the 4 WEU channels verifies its master warning light. You will see the master warning lights flash 4 times during the WES system test.

Each WEU channel verifies the status of a master warning light. If current flow is not present when a channel makes the master warning light come on, or if current flow is present when a channel makes the master warning light go off, the channel considers the light failed.

A MWL-L or R status message shows when a master warning light fails.

<u>Aural Warning Speakers</u>

Channel L1 does a test of the left aural warning speaker. Channel L1 must receive at least one aural arm signal from one other channel, before it sends a test tone for approximately 100 ms to the left aural warning speaker. Channel R1 does the same with the right aural warning speaker. You will hear a short test tone two times during the WES system test.

If a return voltage from the aural warning speaker is not present when a channel makes the test tone, or if a return voltage is present when a WEU channel makes the test tone, the channel considers the speaker failed.

A WARNING SPEAKER-L or R status message shows when an aural warning speaker fails.

<u>Test Status</u>

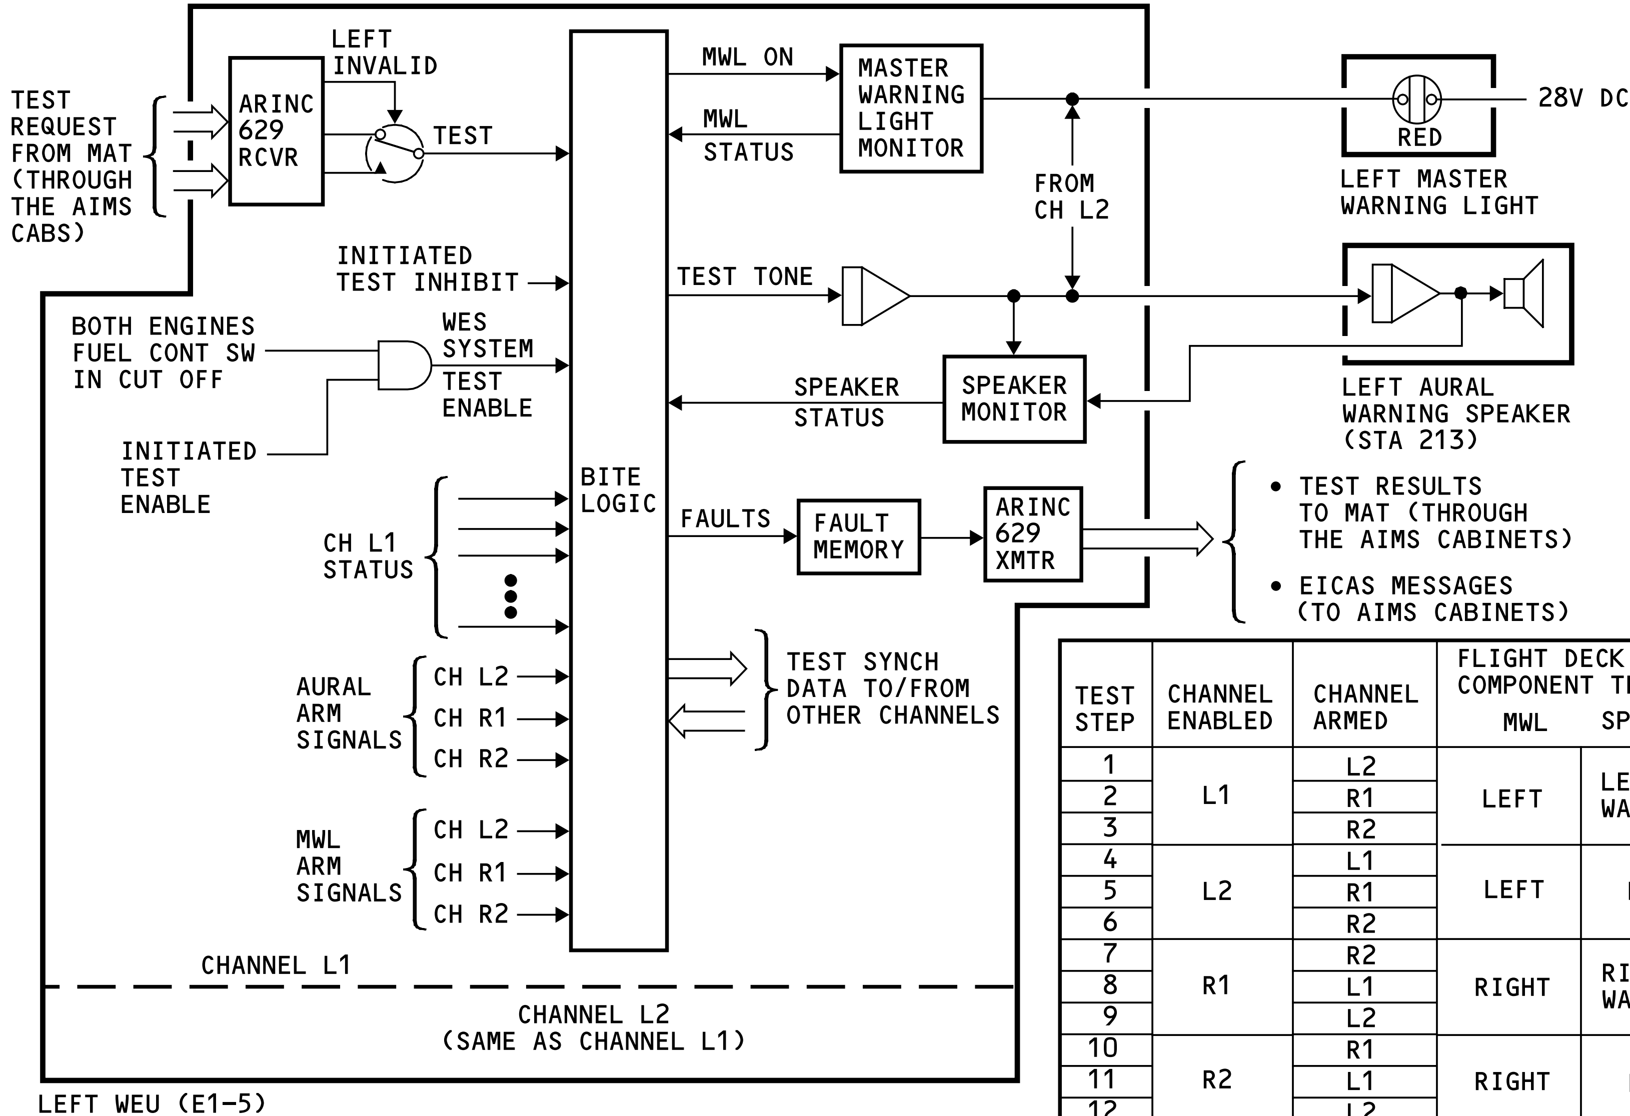
The MAT shows a WES SYSTEM TEST PASS message or a WES SYSTEM TEST FAIL after the WES system test ends.

<u>Channel Failure</u>

If a WEU channel fails during a system test, a WEU L1, L2, R1, or R2 EICAS status message shows.

<u>Automatic WES System Test</u>

The WEUs start a WES system test automatically when you apply power to the WEUs. However, the automatic test will start only if the WES system test enable signal is true.



TEST STEP	CHANNEL ENABLED	CHANNEL ARMED	FLIGHT DECK COMPONENT TESTED MWL	SPEAKER
1	L1	L2	LEFT	LEFT WARNING
2		R1		
3		R2		
4	L2	L1	LEFT	N/A
5		R1		
6		R2		
7	R1	R2	RIGHT	RIGHT WARNING
8		L1		
9		L2		
10	R2	R1	RIGHT	N/A
11		L1		
12		L2		

31-51-00-053 Rev 2

WES - SYSTEM TEST

WES - DATA LOAD

Software Loading

It is necessary to load software into the WEUs. The WEU software files are:

- WEU OPC (operational program codes)
- WEU OPS (operational program system)
- WEU DB (data base).

The WEU OPC file supplies the warning electronics system (WES) customer options.

The WEU OPS file supplies the WEU operational software system.

The WEU DB file supplies the WEU data bases. Examples of the WEU data bases are stabilizer green band look-up tables, and stall warning function limits.

Software Interlock and ARINC 629 Input Port

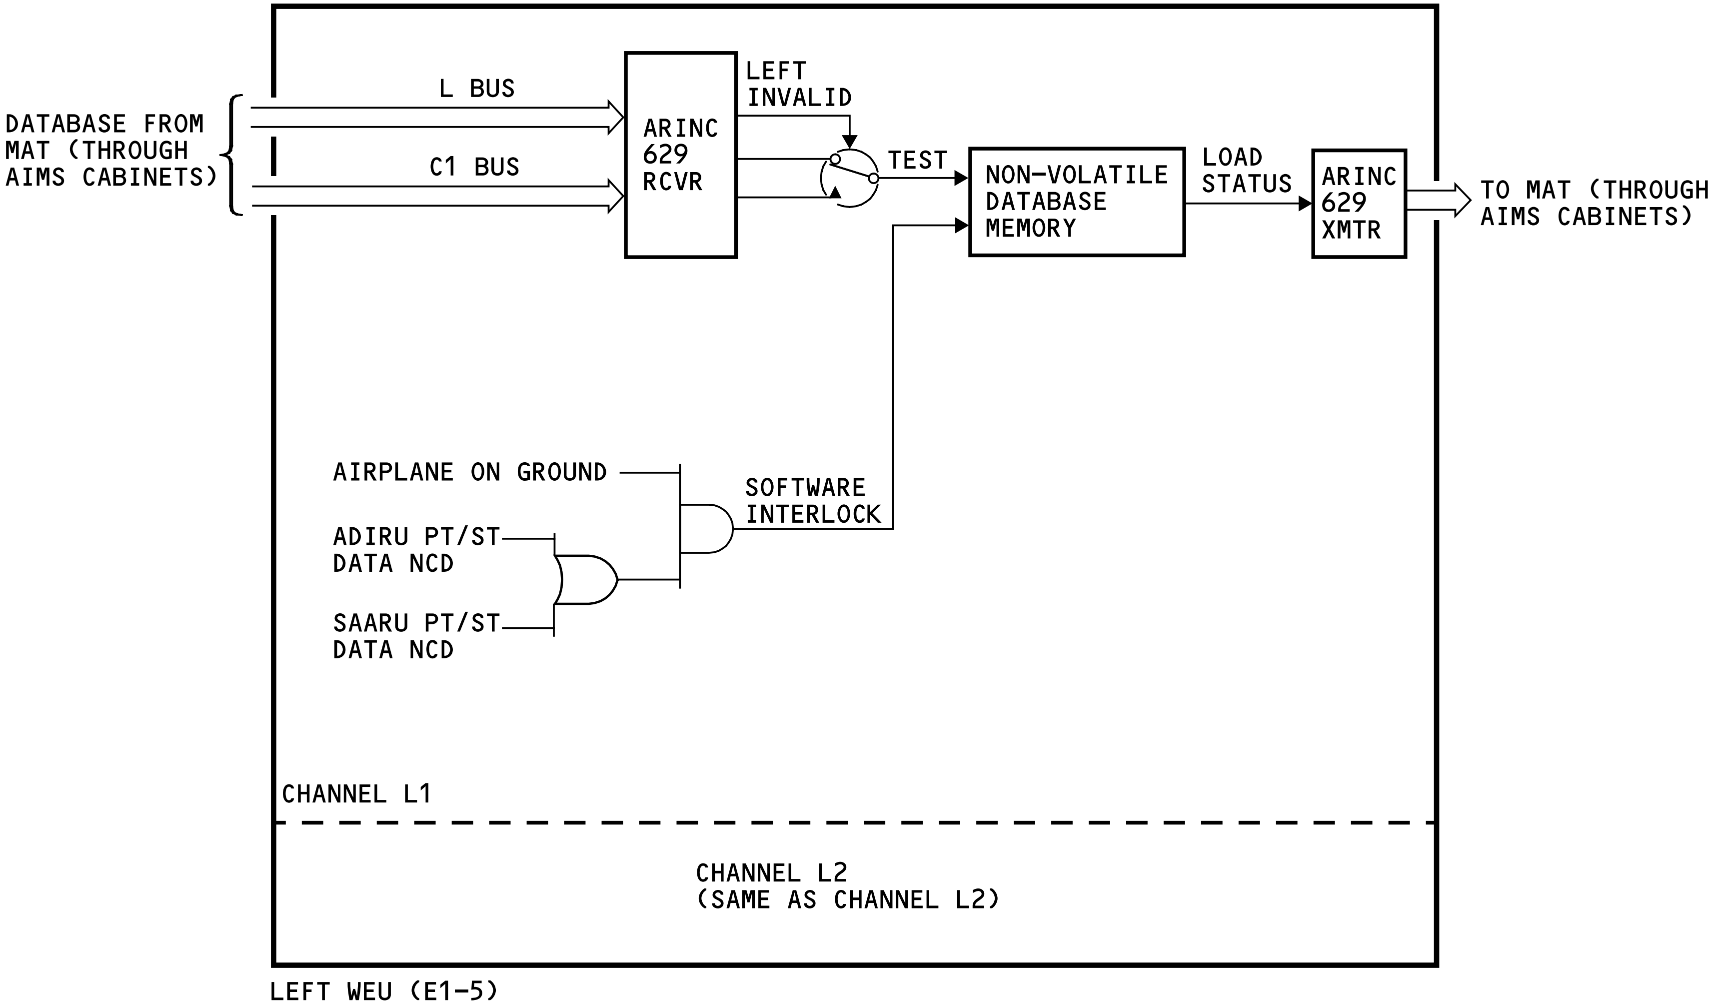
A software interlock must be present before a channel accepts a software data load.

Each channel accepts software data loads through only one ARINC 629 input port. If that input fails the channel switches to its other ARINC 629 input port.

Maintenance Practices

Each WEU must have software files. Use the MAT to make sure each WEU has software files loaded. All channels must have the same software.

If the WEUs do not have software files in them, use the MAT to load the WEU software files.



31-51-00-054 Rev 3 11/06/1997

WES - DATA LOAD

WES - GROUND TESTS - 1

General

These are the WES tests you can do from the MAT:

- WES system test
- Takeoff configuration warning test
- Landing configuration warning test.

Landing Configuration Warning Test

The landing configuration warning test verifies the operation of the landing configuration warning function and the speedbrake alert function. You will notice a landing configuration warning when you do this test.

Takeoff Configuration Warning Test

The takeoff configuration warning test verifies the operation of the takeoff configuration warning function. This test simulates takeoff thrust and looks for proper takeoff configuration warning function response.

When you do a takeoff configuration warning test, you also do a stabilizer green band test. You will see the green band lamps on the stabilizer trim indicators come on.

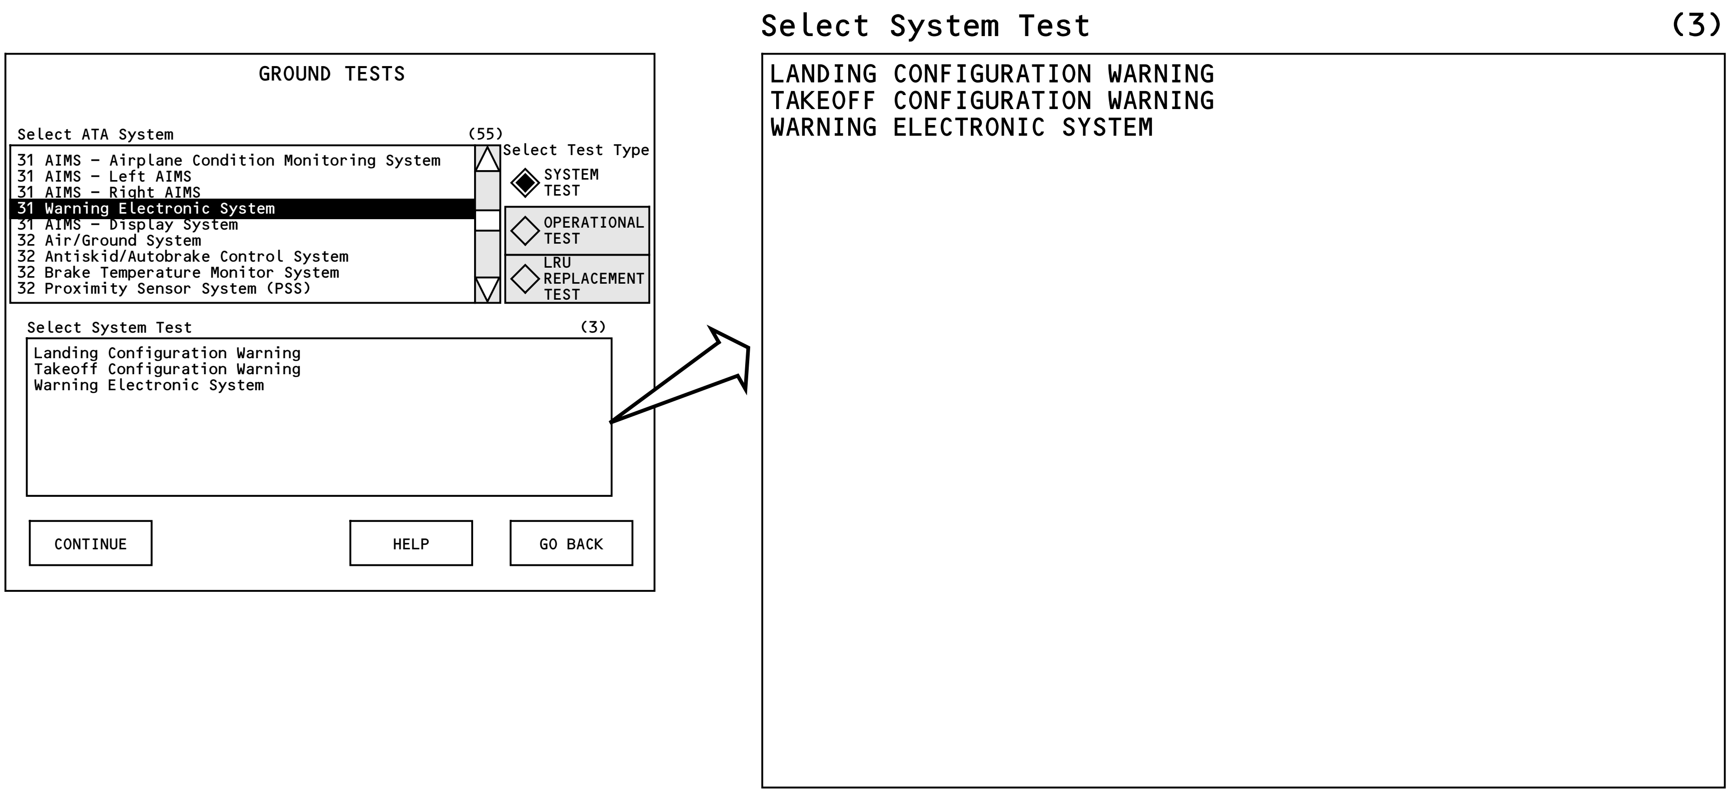
Training Information Point

The takeoff configuration warning test will supply a takeoff configuration warning only if the airplane is not in the proper configuration for takeoff.

WES System Test

The WES system test verifies the status of each one of the WES channels. The test also verifies the operation of these:

- Master warning lights
- Aural warning speakers
- Stick shaker actuators.



31-51-00-055 Rev 3

WES - GROUND TESTS - 1

WES - GROUND TESTS - 2

General

You do the stall warning test from the MAT.

Training Information Point

The WES is in ATA chapter 31. However, you must select ATA System 27 Stall Warning Management to do a stall warning test.

Stall Warning Test

The stall warning test verifies the operation of the stall warning function. This test will activate the stick shaker actuators momentarily. You will also see some speed tape parameters on the PFD.

CABIN SERVICES SYSTEM - INTRODUCTION

General

The cabin services system (CSS) is an integrated system that combines these systems:

- Passenger address
- Cabin interphone
- Passenger service
- Cabin lighting
- Monitor and control.

Passenger Address System

The flight crew and cabin attendants use the passenger address system (PAS) to make announcements to the passengers. The PA audio goes to speakers in the passenger cabin.

Cabin Interphone System

The flight crew and cabin attendants use the cabin interphone system (CIS) to speak with each other. They use handsets in the cabin and flight deck.

Passenger Service System

Passengers use the passenger service system (PSS) to control reading lights and to call attendants. The PSS also controls the passenger information signs.

Cabin Lighting System

The cabin lighting system (CLS) controls the passenger cabin illumination.

Monitor and Control Functions

The CSS has interfaces with other airplane systems for different functions. Flight attendants use CSS control panels to select monitor and control functions. These are some of the CSS monitor and control functions:

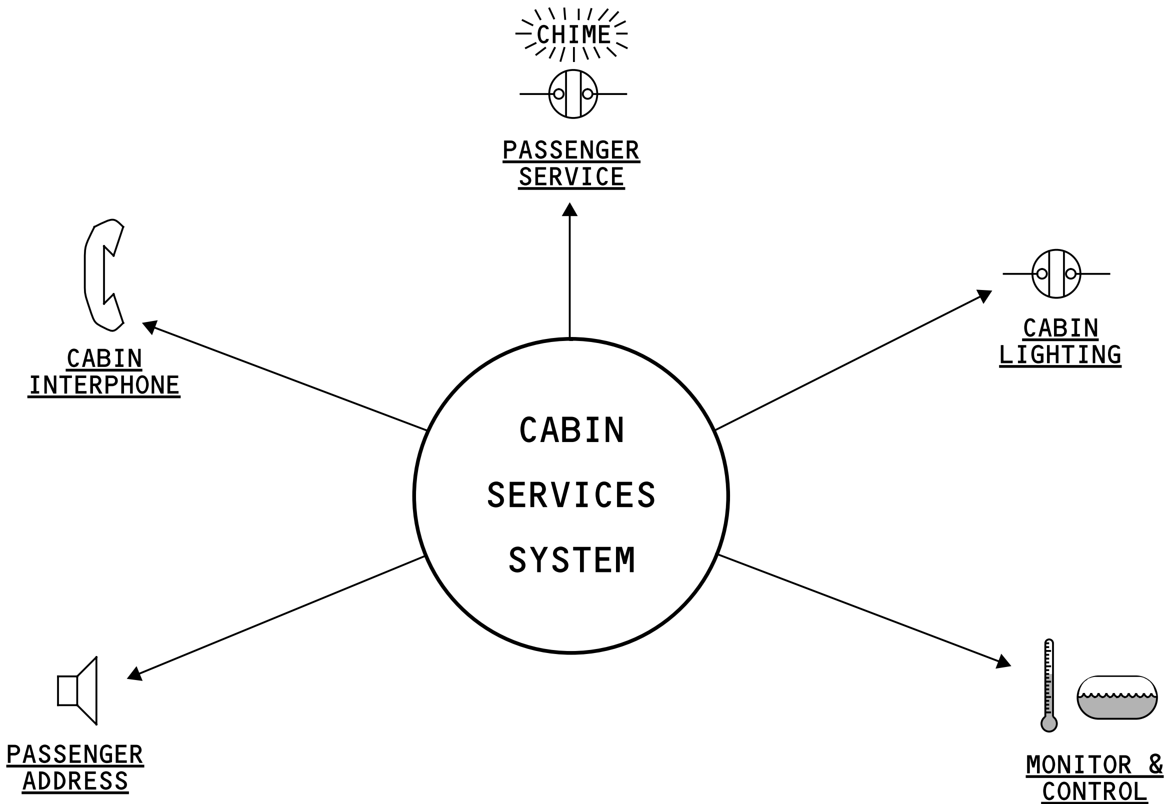
- Cabin temperature selection
- Potable water status
- Cabin door status.

Abbreviations and Acronyms

AIMS	- airplane information management system
AMU	- audio management unit
annct	- announcement
ANS	- ambient noise sensor
ASG	- ARINC signal gateway
ASP	- attendant switch panel
BFE	- buyer furnished equipment
CACP	- cabin area control panel
CAH	- cabin attendant handset
CCP	- cabin control panel
CDG	- configuration database generator
CDU	- control display unit
CIC	- cabin interphone controller

CABIN SERVICES SYSTEM - INTRODUCTION

CIS	- cabin interphone system
CLS	- cabin lighting system
CSCP	- cabin system control panel
CSMU	- cabin system management unit
CSS	- cabin services system
ECS	- environmental control system
ELMS	- electrical load management system
FDH	- flight deck handset
FSEU	- flap/slat electronics unit
IFE	- in-flight entertainment
LLAR	- lower lobe attendants rest
MCU	- modular concept unit
MMC	- mass memory card
OEU	- overhead electronics unit
OPAS	- overhead panel ARINC 629 system
PA	- passenger address
PA/CI	- passenger address/cabin interphone
PAC	- passenger address controller
PAS	- passenger address system
pax	- passenger
PRAM	- prerecorded announcement machine
PSEU	- proximity sensor electronics unit
PSS	- passenger service system
PTT	- push to talk
RF	- radio frequency
SDM	- speaker drive module
SFE	- seller furnished equipment
WES	- warning electronic system
ZMU	- zone management unit



CABIN SERVICES SYSTEM - INTRODUCTION

THIS PAGE INTENTIONALLY LEFT BLANK

CSS GENERAL - INTRODUCTION TO ARINC 628

General

ARINC 628 gives design guidance for the development, installation, and certification of new cabin systems.

The cabin system has two parts, the cabin services system (CSS) and the in-flight entertainment (IFE) system.

The CSS has these basic systems and functions:

- Cabin interphone system (CIS)
- Passenger address system (PAS)
- Passenger service system (PSS)
- Cabin lighting system (CLS)
- Monitor and control functions (MCF).

The IFE system provides passenger entertainment and other optional capabilities including passenger telephone.

ARINC 628 has four parts. Each part gives design guidance in a different part of the cabin system.

ARINC 628 Part 1 - Peripherals

Part 1 of the ARINC 628 specification defines standards for the interfaces between the IFE systems main controller(s) and the head-end equipment. These are examples of head-end equipment:

- Audio entertainment player (AEP)
- Video entertainment player (VEP)
- Passenger in-flight information computer (PIIC)
- Prerecorded announcement machine (PRAM).

ARINC 628 Part 2 - Seat Interfaces

Part 2 of the ARINC 628 specification defines standards for the interfaces between the seat peripherals and the seat-end equipment. These are examples of seat peripherals:

- Passenger control units (PCU)
- Passenger headphones
- Seat video displays (SVD)
- Passenger telephone handsets.

Seat-end equipment are equipment installed on the bottom of the seat group such as a seat electronics box (SEB).

ARINC 628 Part 3 - In-Flight Entertainment Interfaces

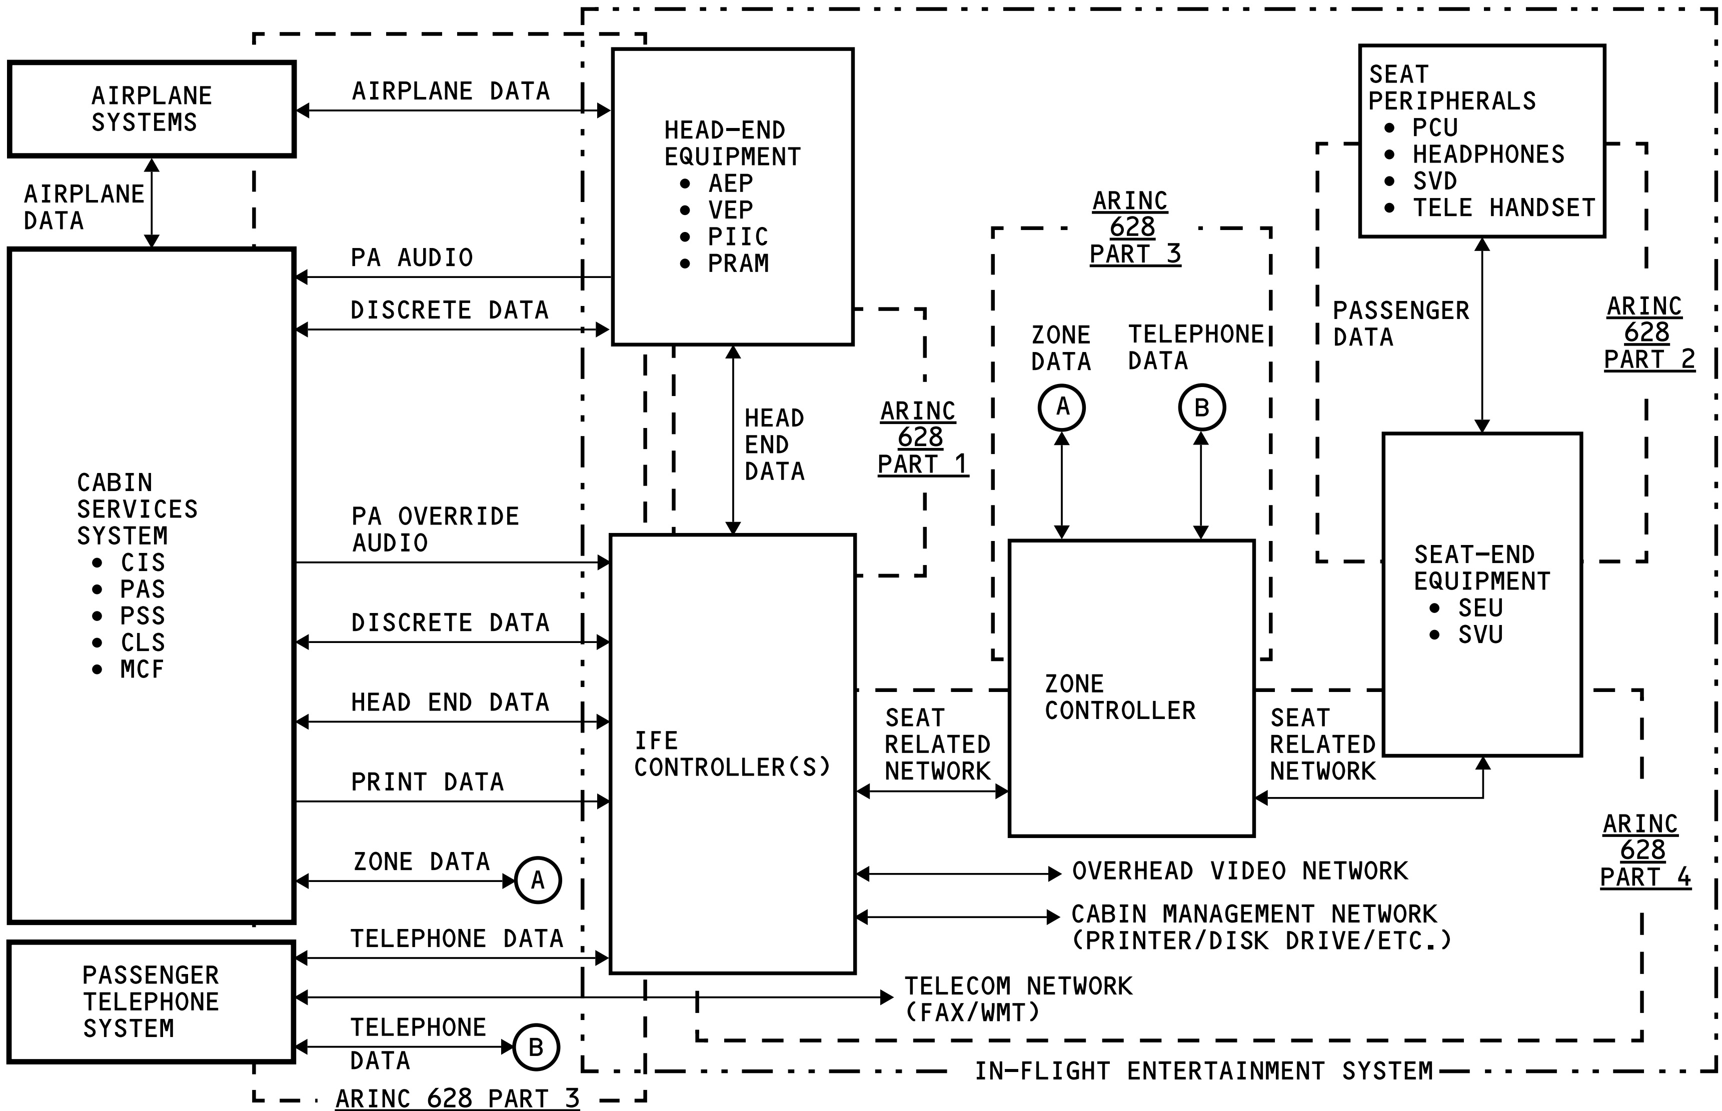
Part 3 of the ARINC 628 specification defines standards for the interfaces between the IFE system and other airplane systems.

ARINC 628 Part 4 - Cabin Distribution System

Part 4 of the ARINC 628 specification defines standards for an in-flight entertainment cabin distribution system (CDS). The CDS consists of some or all of these networks:

CSS GENERAL - INTRODUCTION TO ARINC 628

- A seat related network. This network distributes audio and video signals to each passenger seat and handles all passenger service functions. The network can also distribute data for functions like passenger telephone, games, and interactive services.
- An overhead video network. This network distributes video signals and control data such as monitor on/off and video select commands to the overhead display units.
- A cabin management network. This network provides a connection to printers, fixed or handheld terminals, data storage units, etc.
- A telecom network. This network provides for bidirectional voice and fax communication. The network is used for dedicated telephone/fax stations which are not integrated into the seat related network.



CSS GENERAL - INTRODUCTION TO ARINC 628

CABIN SERVICES SYSTEM - GENERAL DESCRIPTION

General

You use cabin control panels (CCPs) to operate the CSS. The hardware configuration of a CCP tells it to operate as a cabin area control panel (CACP) or a cabin system control panel (CSCP).

The CSS uses a configuration database to define the cabin interior. You change the configuration database to agree with changes in the cabin interior.

Operation

Maintenance personnel use the CSCP to test and to program the CSS. Flight attendants use the CSCP and the CACPs to select light settings and other monitor and control functions. The CSCP also has a mass storage device to keep program data and test results.

The cabin system management unit (CSMU) sends test commands. It also has interfaces with other airplane systems for some CSS functions.

The passenger address/cabin interphone (PA/CI) controller controls the passenger address and cabin interphone functions. It controls routing of cabin interphone calls. The PA/CI controller gets passenger address audio inputs and sends them through the speaker drive modules (SDMs) to cabin speakers. The ambient noise sensors (ANSs) supply cabin noise levels for automatic volume adjustment.

There are three zone management units (ZMUs). The ZMUs control these zones:

- ZMU 1 controls zone 1
- ZMU 2 controls zone 2
- ZMU 3 controls zone 3.

In each zone, the ZMUs connect to these three types of LRUs:

- Overhead electronics units (OEUs)
- Cabin attendant handsets (CAHs)
- Cabin control panels (CCPs).

The OEUs control lights and passenger information signs. They also receive inputs from other cabin systems.

Flight attendants use CAHs to talk on the cabin interphone and to make passenger address announcements.

Flight attendants use the CACPs to select cabin light settings, set some passenger service functions and operate the monitor and control functions.

The ZMUs also have an interface with the in-flight entertainment system. The passengers use controls at the passenger seat to control reading lights and make attendant calls.

The CSS components operate together in five subsystems.

CABIN SERVICES SYSTEM - GENERAL DESCRIPTION

Passenger Address System (PAS)

The PA/CI controller gets audio inputs from different sources. It selects the highest priority audio, digitizes it and sends it to the SDMs and the in-flight entertainment system. The SDMs change the signal back to analog and send it to one or two speakers. The inflight entertainment system overrides entertainment audio at the passenger seat with PA audio.

The PAS also supplies chimes to the cabin.

Cabin Interphone System (CIS)

CAHs connect to ZMUs to send and receive audio and dial codes. The ZMUs have a digital interface with the PA/CI controller. The PA/CI controller makes the connection between attendant stations.

When a station gets a call, the PAS makes a chime and the ZMU makes a master call light come on.

The flight crew interface to the CIS is almost the same, except the flight interphone system and flight deck handset connect directly to the PA/CI controller.

Passenger Service System (PSS)

Passengers use controls at the passenger seat to control reading lights and to call attendants. The passenger selections go to the ZMU over an ARINC 628 zone interface. The ZMU sends the data to an OEU. The OEU makes a reading light or row call light come on.

For an attendant call, the ZMU also makes a master call light come on. The PAS makes a chime sound.

Cabin Lighting System (CLS)

The CLS uses these four types of lights:

- Sidewall wash lights
- Indirect ceiling lights
- Direct ceiling lights
- Night lights.

Flight attendants use the CACPs to select light settings. The CACPs send the selection to the ZMUs. The ZMUs send signals to the OEUs which make the applicable lights go on or off.

Monitor and Control Functions

The CSS monitors many other cabin systems. This gives the flight attendants a central location to select cabin controls. Attendants use the CSCP and CACPs for monitor and control functions.

The monitor function shows information only. These are some of the monitored systems:

- Potable water status
- Waste tank status
- Cabin door status
- Smoke detectors.

CABIN SERVICES SYSTEM - GENERAL DESCRIPTION

The control function permits both display and selection. These are some of the systems controlled by the CSS:

- Cabin temperature selection
- Air/ground communication.

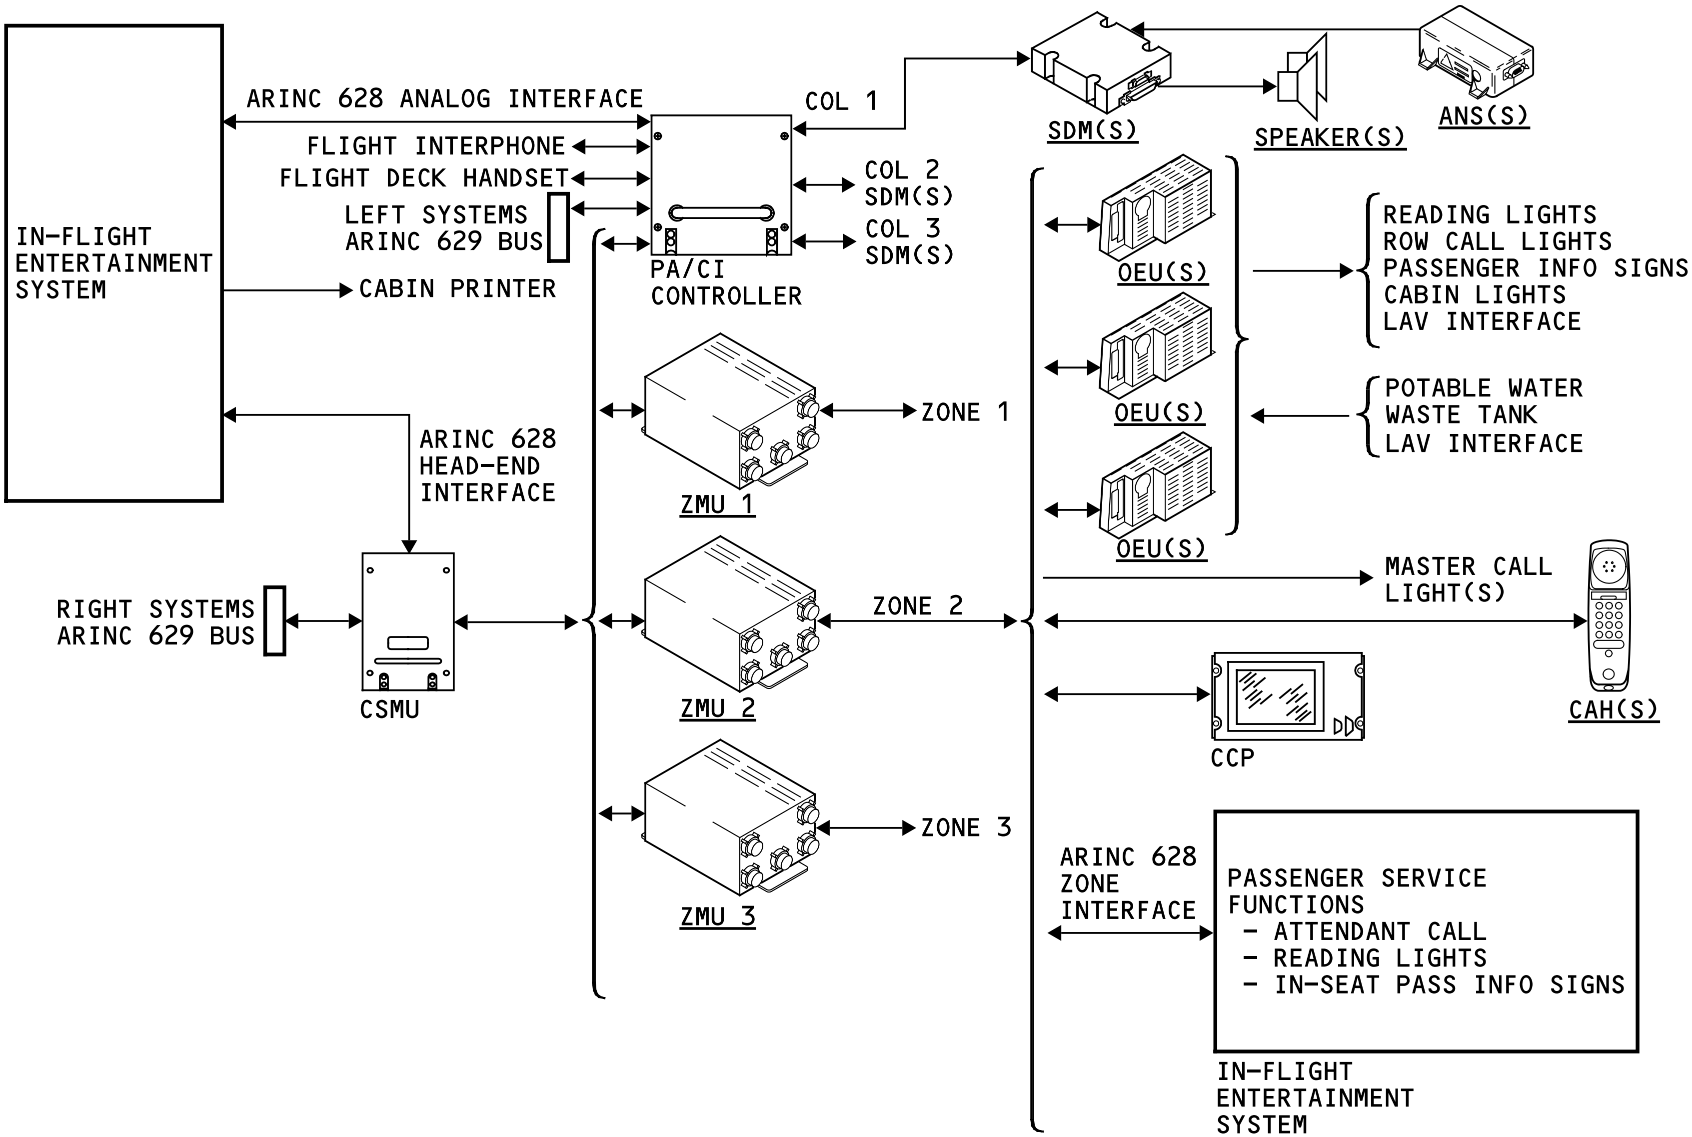
CSS Maintenance

Maintenance personnel use the cabin system control panel (CSCP) to test and to install software in the CSS. The CSCP has a touch sensitive screen for selections.

The CSCP sends test selections to the CSMU. The CSMU sends the test selection to the CSS components. The CSCP keeps test results in memory and shows them on the screen.

The CSCP also sends failure data through the in-flight entertainment system to the cabin printer for a paper copy.

The CSCP has a disk drive. You use the CSCP to install software for the configuration database and LRU operational programs.



CABIN SERVICES SYSTEM - GENERAL DESCRIPTION

CSS GENERAL - COMPONENT LOCATIONS

General

CSS components are in the main equipment center and the cabin area. The cabin diagram shows a typical configuration.

A typical passenger cabin has three zones:

- Zone 1 starts at the forward part of the cabin and ends at door 2
- Zone 2 is between doors 2 and 3
- Zone 3 is from door 3 to the aft end of the cabin.

Cabin Components

These components are above the cabin ceiling panels:

- Zone management units (ZMUs)
- Speaker drive modules (SDMs)
- Ambient noise sensors (ANSs).

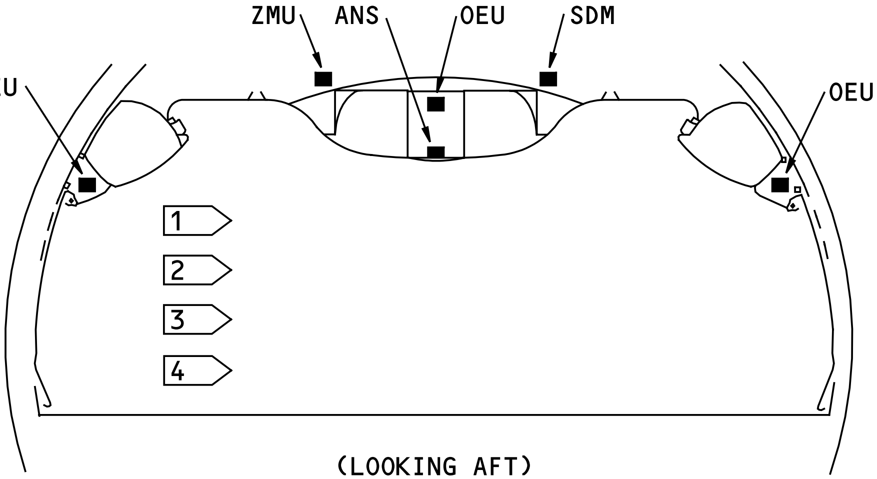
These components are in the passenger cabin:

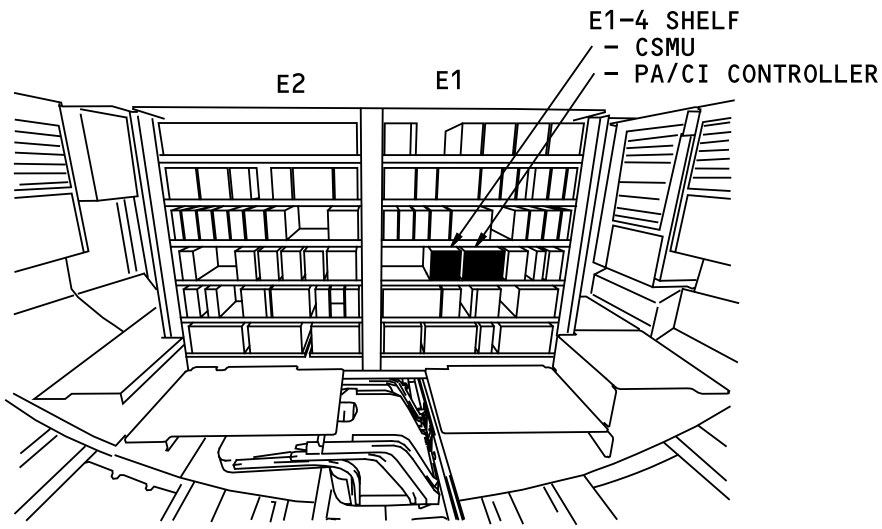
- Overhead electronics units (OEUs) (in the passenger service units)
- A cabin system control panel (CSCP)
- Cabin area control panels (CACP)
- Cabin printer
- Cabin attendant handsets (CAHs) (at each door).

Main Equipment Center Components

These components are in the main equipment center:

- Cabin system management unit (CSMU)
- Passenger address/cabin interphone (PA/CI) controller.





MAIN EQUIPMENT CENTER
(LOOKING AFT)

1 THE CSCP IS IN THE PASSENGER CABIN NEAR DOOR 2 LEFT.

2 THE CACP(S) ARE AT DOOR 1 LEFT AND DOOR 4 RIGHT.

3 THE FAX MACHINE IS IN THE PURSER STATION NEAR DOOR 2 LEFT.

4 THE CABIN PRINTER IS IN THE PURSER STATION NEAR DOOR 2 LEFT.

CSS GENERAL - COMPONENT LOCATIONS

CSS GENERAL - COMPONENT LOCATIONS 2

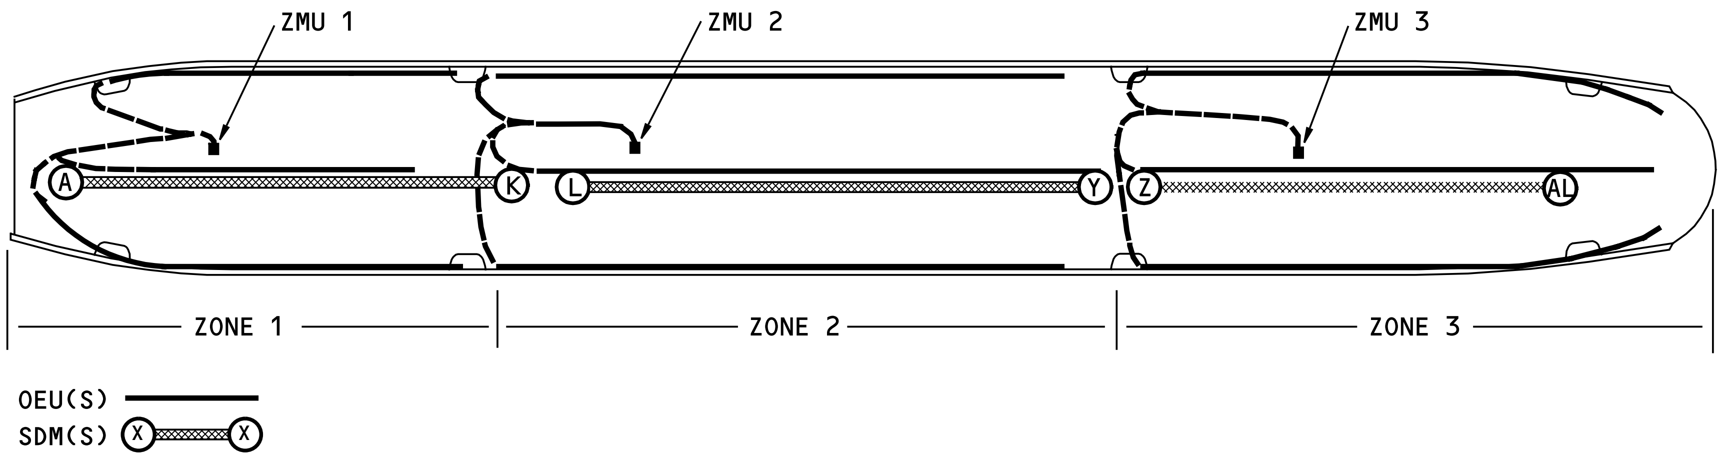
General

CSS components are in the main equipment center and the cabin area. The cabin diagram shows a typical configuration.

The passenger cabin has three zones:

- Zone 1 starts at the forward part of the cabin and ends at door 2
- Zone 2 is between doors 2 and 3
- Zone 3 is from door 3 to the aft end of the cabin.

Each zone has three columns of overhead electronics units (OEUs) and one column of speaker driver modules (SDMs).



23-39-00-535 Rev 0 10/29/1997

CSS GENERAL - COMPONENT LOCATIONS 2

CSS GENERAL - CONFIGURATION DATABASE GENERATOR

General

The CSS uses a database to identify the interior configuration and optional features of the system. The database software has programmable selections that permit changes to the interior configuration and optional features.

Many CSS components keep configuration data in nonvolatile memory. If you replace a component, you must install the configuration database.

The database controls many functions, including:

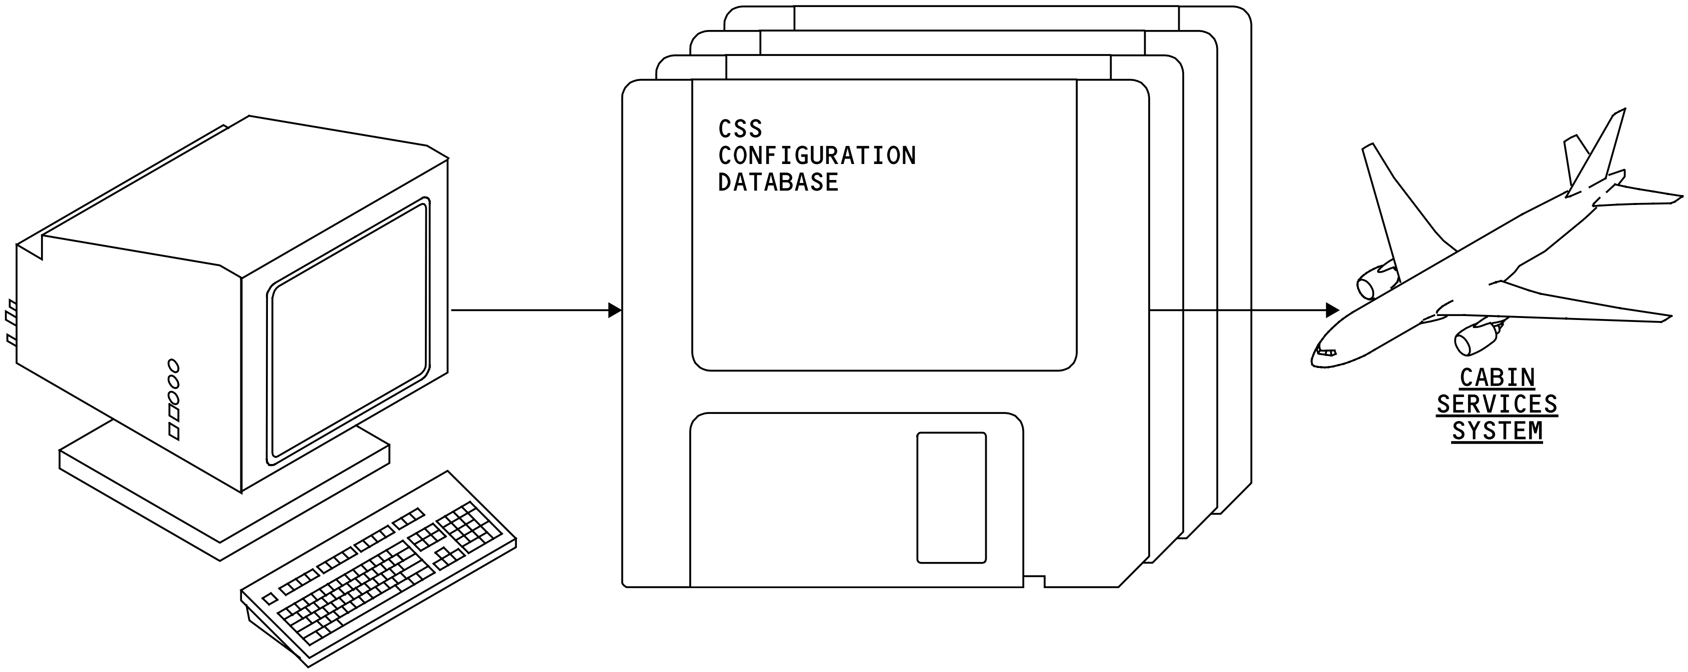
- Passenger seating area
- Cabin light levels
- Passenger address areas
- Cabin interphone handset locations and dial codes
- CSCP and CACP screen selections.

Configuration Database Generator

The configuration database generator (CDG) is a software tool that operates on a personal computer. Boeing uses the CDG to write the original configuration database.

Boeing copies the database onto 3 1/2 inch floppy diskettes and carries them to the airplane to install into the CSS.

The airline engineering organization also has a copy of the Boeing CDG. If the airline chooses to change the interior configuration or change an optional feature, they change the configuration database using the CDG. They copy the new database to a floppy disk and carry it to the airplane to install it into the CSS.



23-39-00-504 Rev 0 07/12/96

CSS GENERAL - CONFIGURATION DATABASE GENERATOR

CSS GENERAL - INSTALL CONFIGURATION DATABASE

General

Boeing engineering writes and loads the initial configuration database. Airline engineering may change the configuration database using the configuration database generator (CDG). The engineers copy the database to floppy diskettes.

You must load the diskettes to install the new database.

Disk Loading (Phase 1 Load)

The cabin system control panel (CSCP) has a disk drive. Put a floppy diskette in the disk drive to load it into the CSCP. The CSCP keeps the configuration database on a mass storage device.

Installation of data to the CSCP mass storage is called a phase 1 load.

Database Installation (Phase 2 load)

When the configuration database is in the CSCP, you use selections on the CSCP screen to install it in the CSS.

Many CSS components use the configuration database to operate. If you replace a component, you must use the CSCP to send database information to the new component. Because the configuration database is normally in CSCP memory, you only need to use a CSCP screen selection to install the database.

Installation of data to the CSS components is called a phase 2 load.

CSS GENERAL - INSTALL CONFIGURATION DATABASE

CSS GENERAL - OPERATIONAL PROGRAMS

General

The CSS components use special software for internal operation. The operational program controls the basic functions of the LRU. The LRU operational programs are not part of the configuration database.

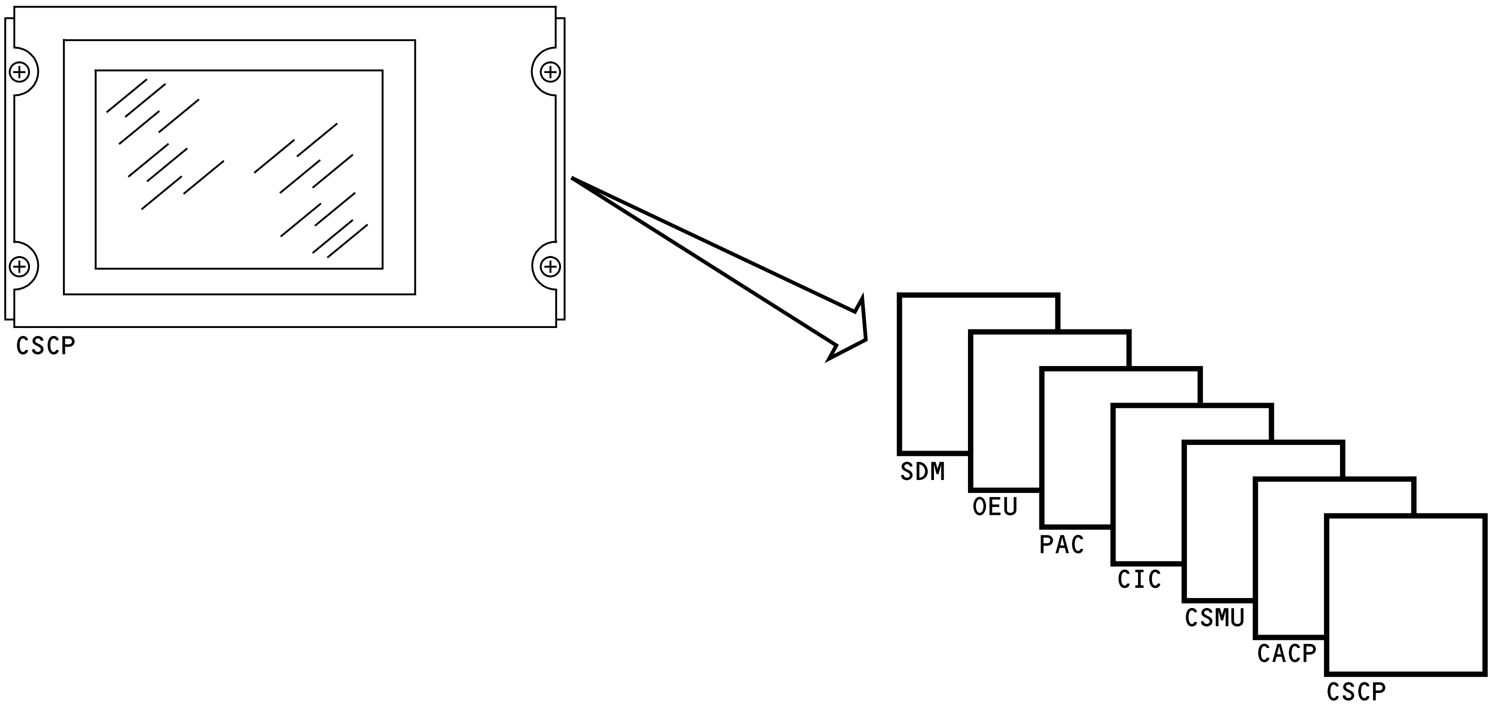
Operational Software Installation

The LRU manufacturer normally installs the operational program. A service bulletin may require you to install new operational programs.

You can select an LRU operational program from CSCP memory and install it in the LRU.

These LRUs have operational programs:

- Cabin system management unit (CSMU)
- Cabin system control panel (CSCP)
- Passenger address controller (PAC) - part of the passenger address/cabin interphone (PA/CI) controller
- Cabin interphone controller (CIC) - part of the PA/CI controller
- Zone management units (ZMUs)
- Cabin area control panels (CACPs)
- Overhead electronics units (OEUs)
- Speaker drive modules (SDMs).



CSS GENERAL - OPERATIONAL PROGRAMS

CSS GENERAL - POWER INTERFACE

General

Power for the cabin services system (CSS) comes through these three power management panels:

- P110 left power management panel
- P210 right power management panel
- P310 standby power management panel.

Circuit breakers control power to these CSS core components:

- Cabin system management unit (CSMU)
- Cabin system control panel (CSCP)
- Cabin area control panels (CACPs)
- Cabin printer
- Passenger address/cabin interphone (PA/CI) controller.

P110 Left Power Management Panel

The CAB SYS MGMT UNIT circuit breaker connects 115v ac power to the CSMU and the CSCP.

P210 Right Power Management Panel

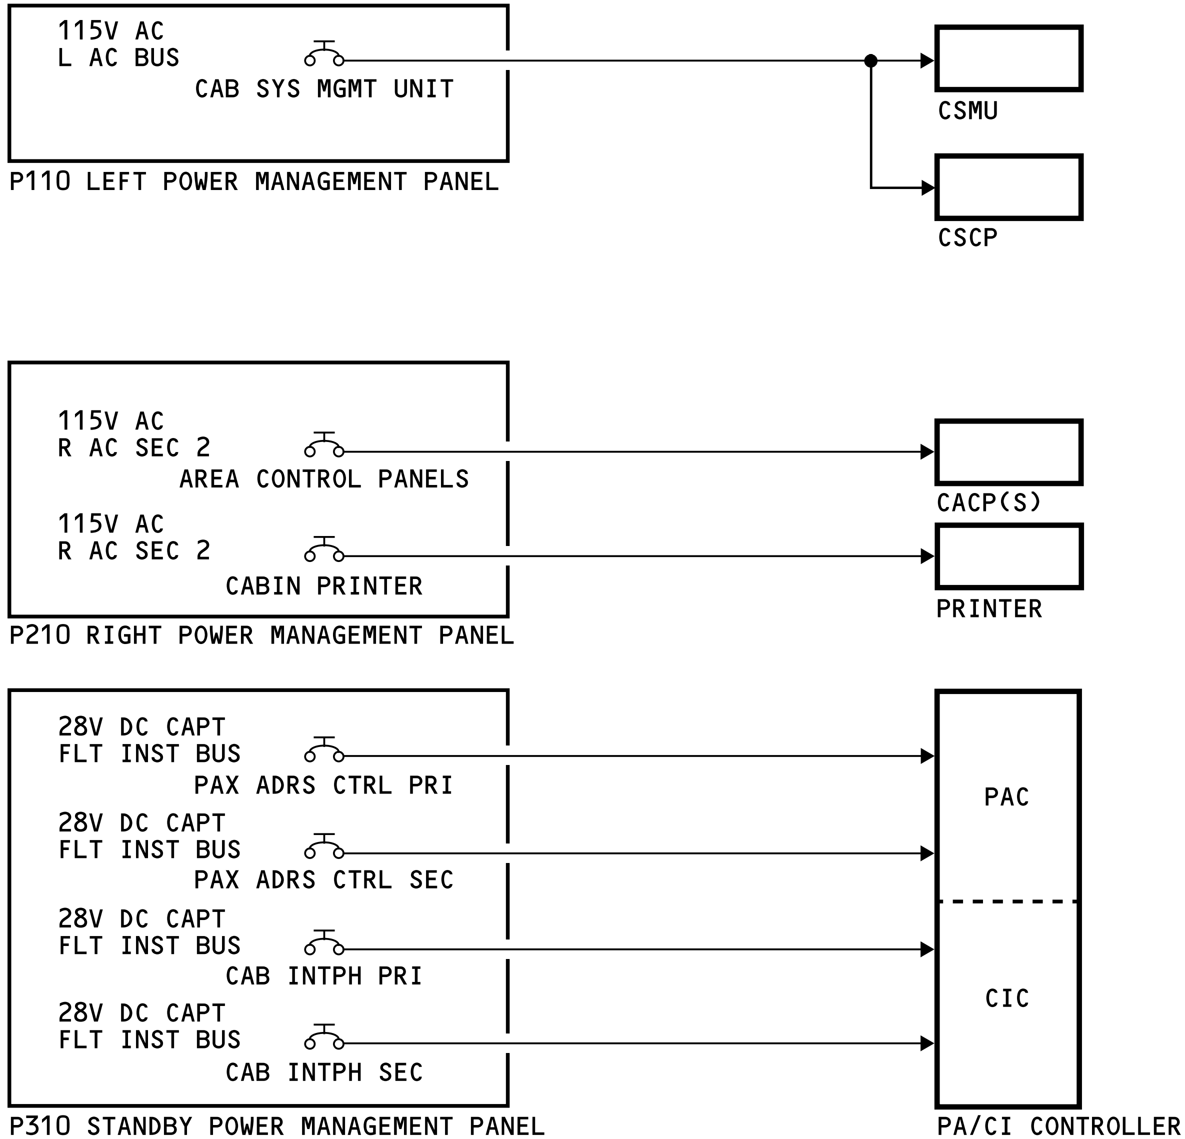
The AREA CONTROL PANELS circuit breaker connects 115v ac power to all CACPs.

The CABIN PRINTER circuit breaker connects 115v ac power to the cabin printer.

P310 Standby Power Management Panel

These circuit breakers connect 28v dc to the PA/CI controller:

- PAX ADRS CTRL PRI
- PAX ADRS CTRL SEC
- CAB INTPH PRI
- CAB INTPH SEC.



CSS GENERAL - POWER INTERFACE

CSS GENERAL - POWER INTERFACE - ZONE 1

General

Components on the left, right, and standby power management panels control power to these zone 1 LRUs:

- Left, center, and right overhead electronics units (OEUs)
- Zone management unit (ZMU) 1
- Speaker drive modules (SDMs).

Components

The P110 left power management panel has these components:

- OEU ZONE1 MAIN BUS circuit breaker
- OEU ZONE1 XFER BUS circuit breaker
- ZONE MGMT 1 circuit breaker.

The P210 right power management panel has the PAX MASTER CALL LT circuit breaker.

The P310 standby power management panel has these components:

- PA DIR ACCESS circuit breaker
- CAB INTPH ZMUS circuit breaker
- SDM COL 1 circuit breaker.

Overhead Electronics Unit Power

The OEU ZONE 1 MAIN and OEU ZONE 1 XFER circuit breakers connect 115v ac power to the left, center and right OEUs.

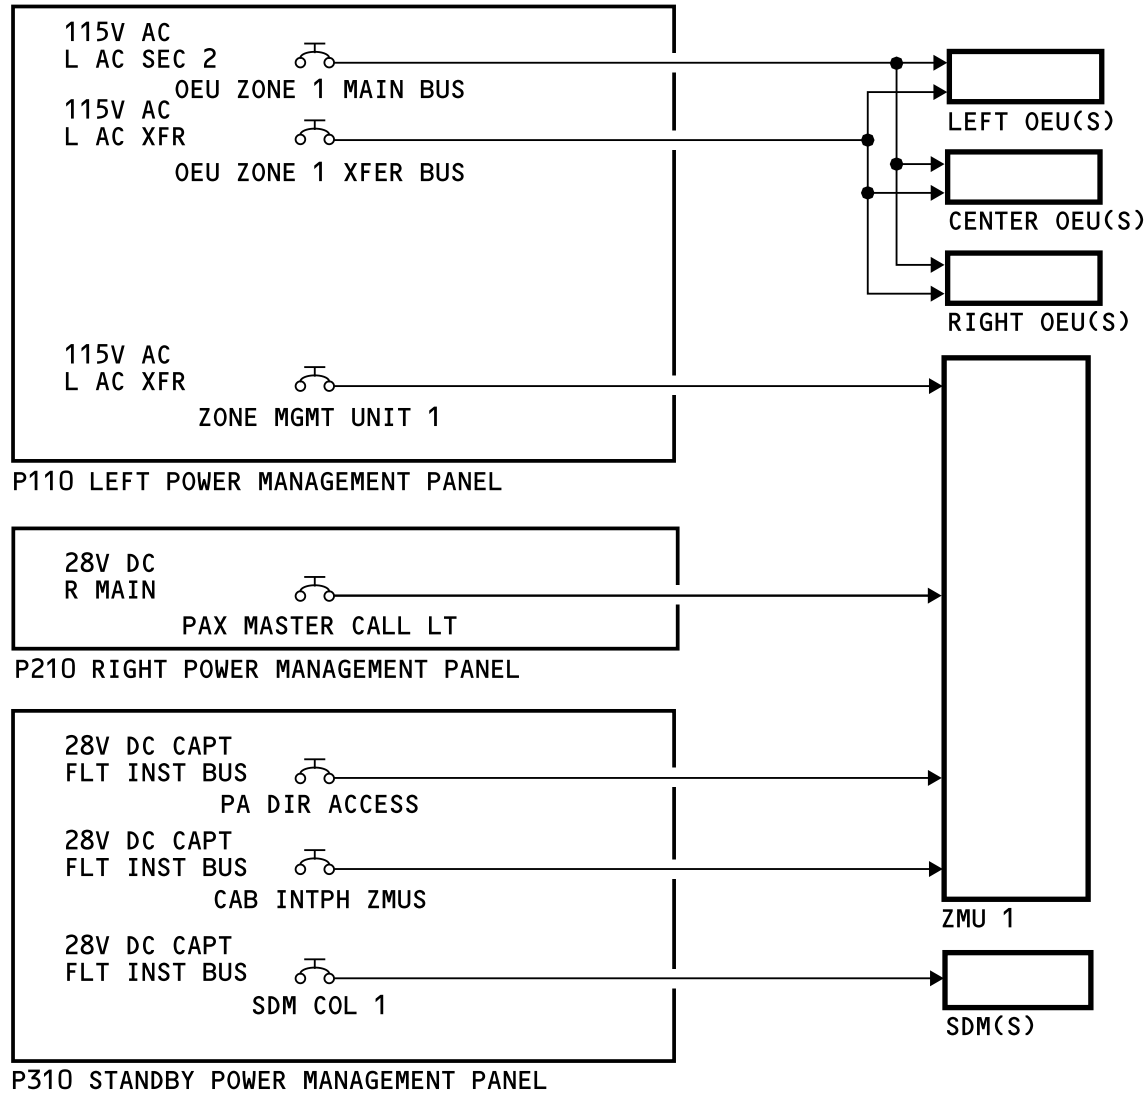
Zone Management Unit Power

These circuit breakers connect power to ZMU 1:

- ZONE MGMT UNIT 1 - 115v ac
- PA DIR ACCESS - 28v dc
- CAB INTPH ZMUS - 28v dc
- PAX MASTER CALL LT - 28v dc.

Speaker Drive Module Power

The SDM COL 1 circuit breaker connects 28v dc to all SDMs in zone 1.



23-39-00-512 Rev 0 07/12/96

CSS GENERAL - POWER INTERFACE - ZONE 1

CSS GENERAL - POWER INTERFACE - ZONE 2

General

Components on the right and standby power management panels control power to these zone 2 LRUs:

- Left, center, and right overhead electronics units (OEUs)
- Zone management (ZMU) unit 2
- Speaker drive modules (SDMs).

Components

The P210 right power management panel has these components:

- OEU ZONE2 LEFT MAIN BUS circuit breaker
- OEU ZONE2 CENTER MAIN BUS circuit breaker
- OEU ZONE2 RIGHT MAIN BUS circuit breaker
- OEU ZONE2 XFER BUS circuit breaker
- ZONE MGMT UNIT 2 circuit breaker
- PAX MASTER CALL LT circuit breaker.

The P310 standby power management panel has these components:

- PA DIR ACCESS circuit breaker
- CAB INTPH ZMUS circuit breaker
- SDM COL 2 circuit breaker.

Overhead Electronics Unit Power

These circuit breakers connect 115v ac to the OEUs:

- OEU ZONE2 LEFT MAIN BUS to the left column of OEUs
- OEU ZONE2 CENTER MAIN BUS to the center column of OEUs
- OEU ZONE2 RIGHT MAIN BUS to the right column of OEUs
- OEU ZONE2 XFER BUS to all OEUs.

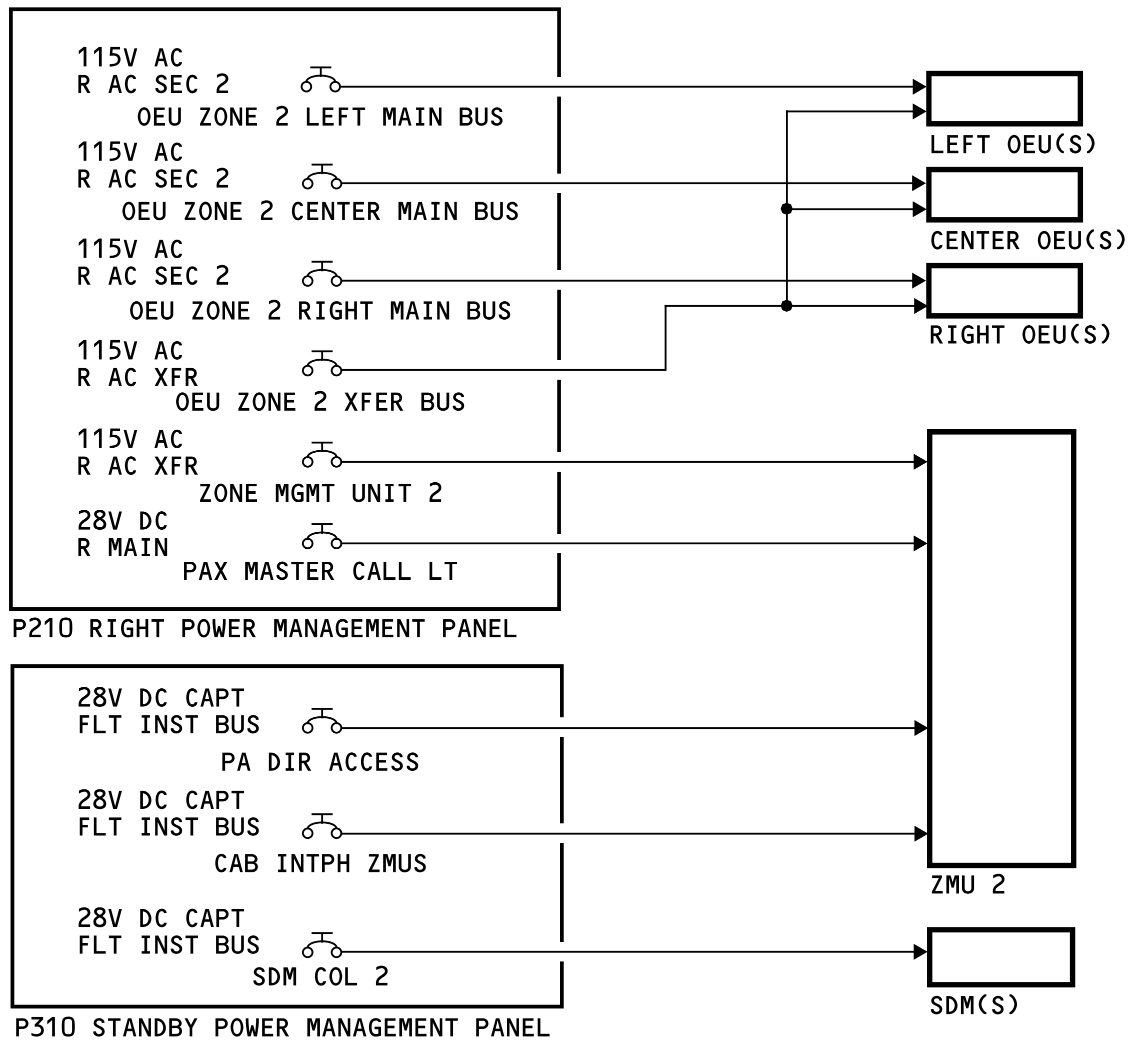
Zone Management Unit Power

These circuit breakers connect power to ZMU 2:

- ZONE MGMT UNIT 2 - 115v ac
- PAX MASTER CALL LT - 28v dc
- PA DIR ACCESS - 28v dc
- CAB INTPH ZMUS - 28v dc.

Speaker Drive Module Power

The SDM COL 2 circuit breaker connects 28v dc to all SDMs in zone 2.



23-39-00-513 Rev 0 07/12/96

CSS GENERAL - POWER INTERFACE - ZONE 2

CSS GENERAL - POWER INTERFACE - ZONE 3

General

Components on the left, right, and standby power management panels control power to these zone 3 LRUs:

- Left, center, and right overhead electronics units (OEUs)
- Zone management unit (ZMU) 3
- Speaker drive modules (SDMs).

Components

The P110 left power management panel has these components:

- OEU ZONE3 LEFT MAIN BUS circuit breaker
- OEU ZONE3 CENTER MAIN BUS circuit breaker
- OEU ZONE3 RIGHT MAIN BUS circuit breaker
- OEU ZONE3 XFER BUS circuit breaker
- ZONE MGMT UNIT 3 circuit breaker.

The P210 right power management panel has the PAX MASTER CALL LT circuit breaker.

The P310 standby power management panel has these components:

- PA DIR ACCESS circuit breaker
- CAB INTPH ZMUS circuit breaker
- SDM COL 3 circuit breaker.

Overhead Electronics Unit Power

These circuit breakers connect 115v ac to the OEUs:

- OEU ZONE3 LEFT MAIN BUS to the left column of OEUs
- OEU ZONE3 CENTER MAIN BUS to the center column of OEUs
- OEU ZONE3 RIGHT MAIN BUS to the right column of OEUs
- OEU ZONE3 XFER BUS to all OEUs.

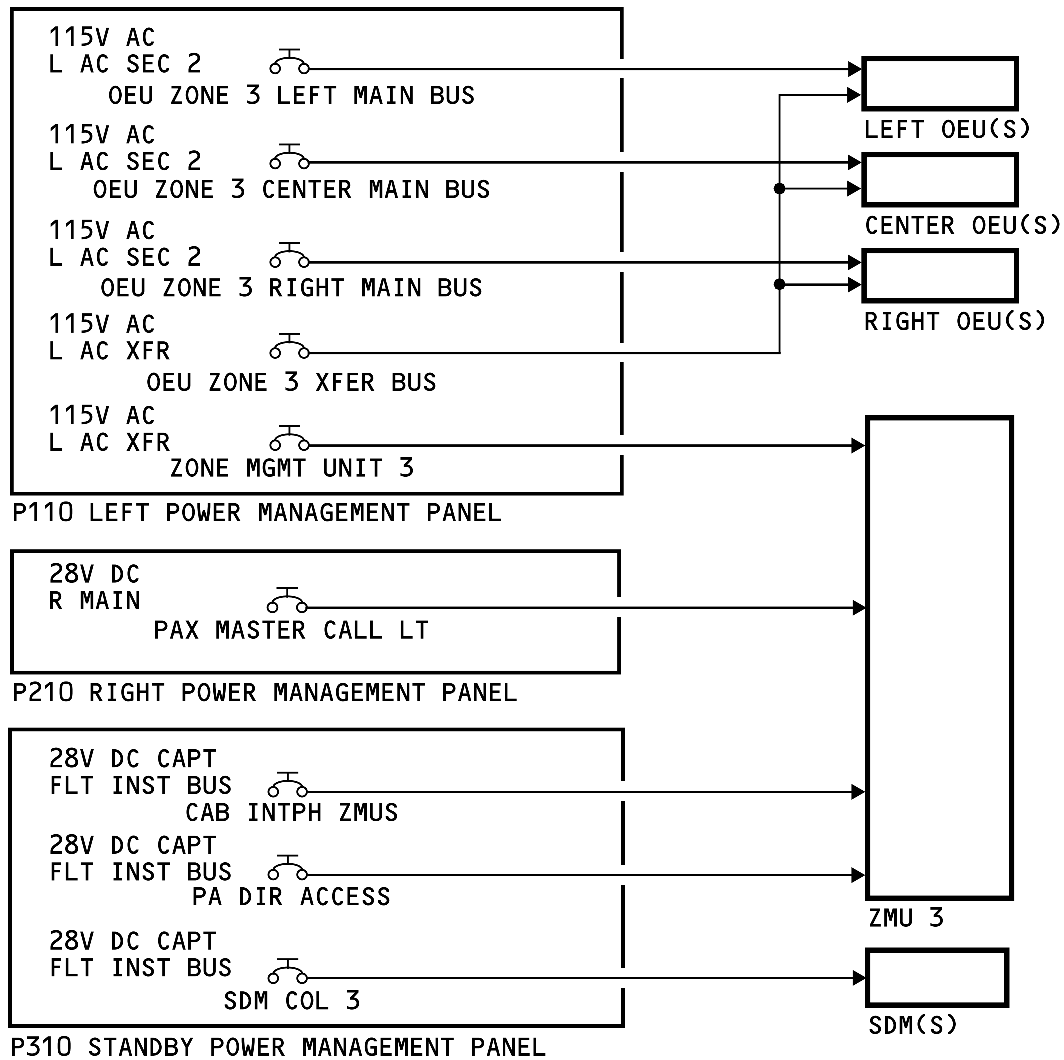
Zone Management Unit Power

These circuit breakers connect power to ZMU 3:

- ZONE MGMT UNIT 3 - 115v ac
- PAX MASTER CALL LT - 28v dc
- PA DIR ACCESS - 28v dc
- CAB INTPH ZMUS - 28v dc.

Speaker Drive Module Power

The SDM COL 3 circuit breaker connects 28v dc to all SDMs in zone 3.



CSS GENERAL - POWER INTERFACE - ZONE 3

CSS GENERAL - SYSTEM INTERFACES

General

The CSS uses different buses and interfaces to send data between the CSS components. These are the interfaces with the main CSS components:

- Intersystem (I/S) bus
- Cabin interphone (CI) bus
- Passenger address/cabin interphone (PA/CI) bus.

Intersystem Bus

The intersystem bus is the primary bus the CSS uses to send and get data.

The CSMU, passenger address/cabin interphone (PA/CI) controller, and zone management units (ZMUs) all send and receive data on the intersystem bus.

The intersystem bus passes through the components it connects. Thus, a failure of a component does not cause a failure of the bus.

The intersystem bus uses the IEEE 802.3 10 base 2 data standard for data transfer.

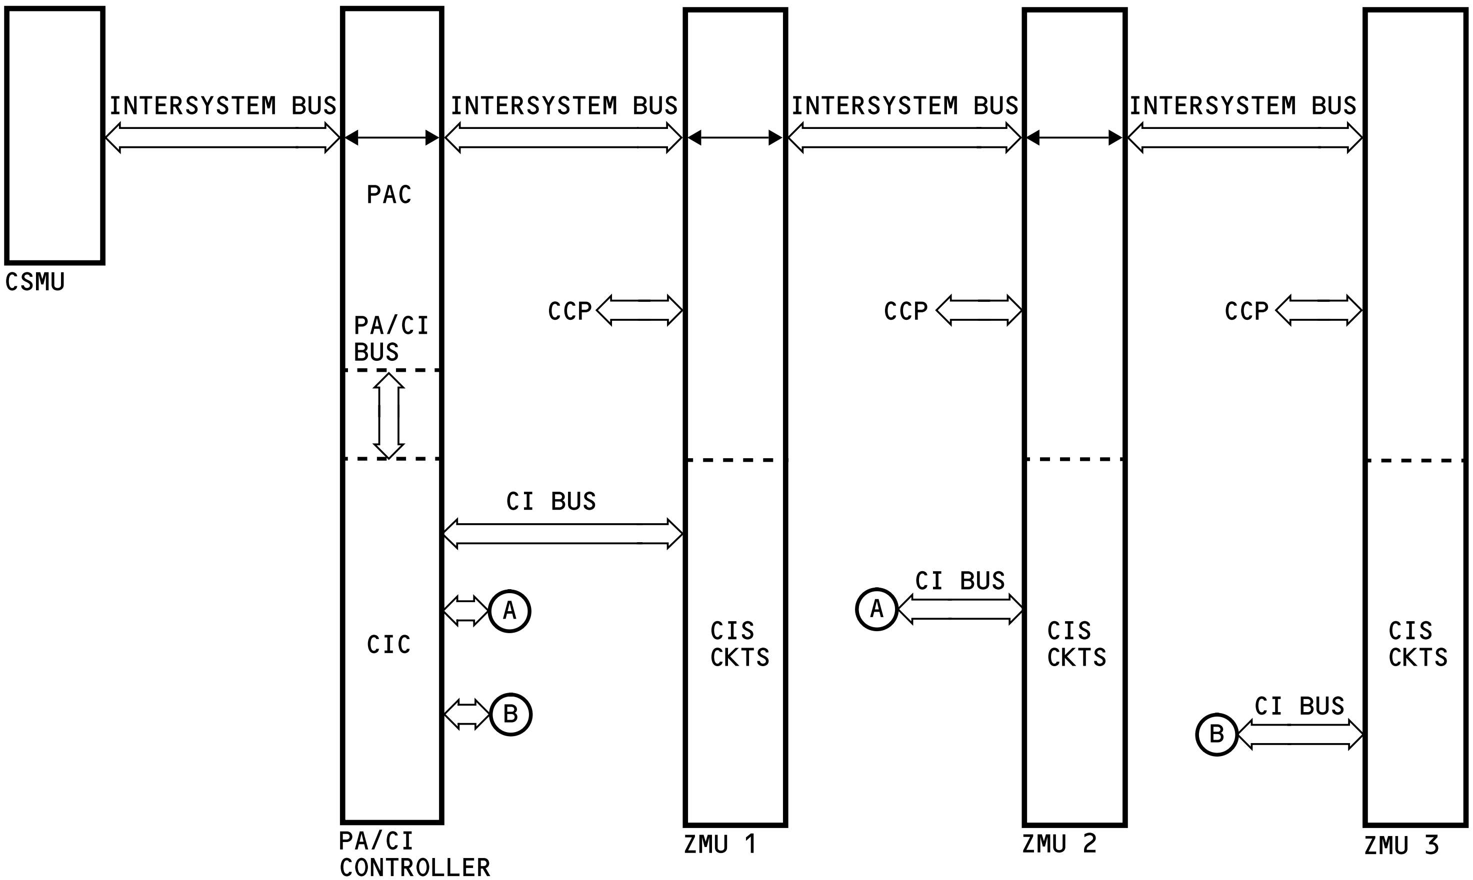
Each cabin control panel (CCP) can send and get commands and data from a related ZMU. The ZMUs change 10 base 2 data from the intersystem bus and send it to the CCP.

Passenger Address/Cabin Interphone (PA/CI) Bus

The passenger address controller gets and sends data on the intersystem bus. The cabin interphone controller does not have an interface with the intersystem bus. Any information the CIC needs from the intersystem bus is sent over the PA/CI bus from the PAC.

Cabin Interphone (C/I) Bus

A cabin interphone bus goes from the CIC to each of the ZMUs. These are the main communication busses for the cabin interphone system. A failure of the intersystem bus would have very little effect on the cabin interphone system. Likewise, a failure of a cabin interphone bus would have very little effect on the passenger address system.



23-39-00-515 Rev 3 07/08/1997

CSS GENERAL - SYSTEM INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

CSS GENERAL - PASSENGER ADDRESS/CABIN INTERPHONE CONTROLLER INTERFACES

General

The passenger address/cabin interphone (PA/CI) controller connects to other CSS components and audio systems to control passenger address and cabin interphone audio. It also controls call indications.

The PA/CI controller has two passenger address controllers (normal and alternate) and two cabin interphone controllers (normal and alternate). Only one passenger address controller and one cabin interphone controller operate at a time.

CSMU

The cabin system management unit (CSMU) selects which controller is operational. If a normal controller fails, you select the alternate controller from a switch on an attendant switch panel (ASP). The ASP sends a signal to the CSMU. The CSMU sends the signal to the PA/CI controller.

The PA/CI controller sends cabin interphone controller (CIC) BITE status to the CSMU using a health discrete. The PA/CI controller sends passenger address controller (PAC) BITE status to the CSMU using the intersystem bus.

The PA/CI controller and CSMU send data on the intersystem bus.

Airplane Systems Interfaces

The PA/CI controller has interfaces with airplane systems on the left system ARINC 629 bus. The system interfaces are:

- Environmental control system (ECS)
- ARINC signal gateway (ASG) card
- Proximity sensor electronics unit (PSEU)
- Overhead panel ARINC 629 system (OPAS)
- Flap/slat electronics unit (FSEU)
- Electrical load management system (ELMS)
- Warning electronic system (WES)
- Airplane information management system (AIMS).

CDU, AMU, and FDH Interfaces

The flight crew uses the flight interphone system to talk on the passenger address system and cabin interphone system. The audio management unit (AMU) supplies the interface to the PA/CI controller. The center control display unit (CDU) sends dial data and shows call information. The flight crew uses the flight deck handset (FDH) to talk.

AIMS Interfaces

The PA/CI controller sends call signals to the AIMS for these four conditions:

- Cabin call
- Cabin ready
- Cabin alert

- Ground call.

IFE System Interfaces

The in-flight entertainment system sends these signals to the passenger address/cabin interphone (PA/CI) controller:

- Boarding music
- Prerecorded announcements
- Video entertainment audio
- Video in use.

The IFE system also sends keylines to tell the PAC when an audio signal is present.

The PA/CI controller sends these signals to the IFE system:

- PA override audio
- PA override keylines
- Prerecorded announcement machine pause
- PA-All keyline
- Decompression.

Speaker Drive Module Interfaces

There are three columns of speaker drive modules (SDMs), one column for each zone. The PA/CI controller sends digitized passenger address audio to the SDMs. The data format uses the EIA-485 data standard. Another EIA-485 bus is for data between the SDMs and PA/CI controller.

The PA/CI controller sends a token signal during configuration database installation.

Zone Management Unit Interfaces

The PA/CI controller receives mic audio and a PTT signal from zone management unit (ZMU) 1 for the passenger address direct access input. It sends and receives digital audio for the cabin interphone system. The cabin interphone bus uses the EIA-485 data format. The passenger address controller and cabin interphone controller send these signals to each other. The cabin interphone controller gets attendant announcements and sends them to the passenger address controller.

The PA/CI controller also connects to the other ZMUs on the cabin interphone buses.

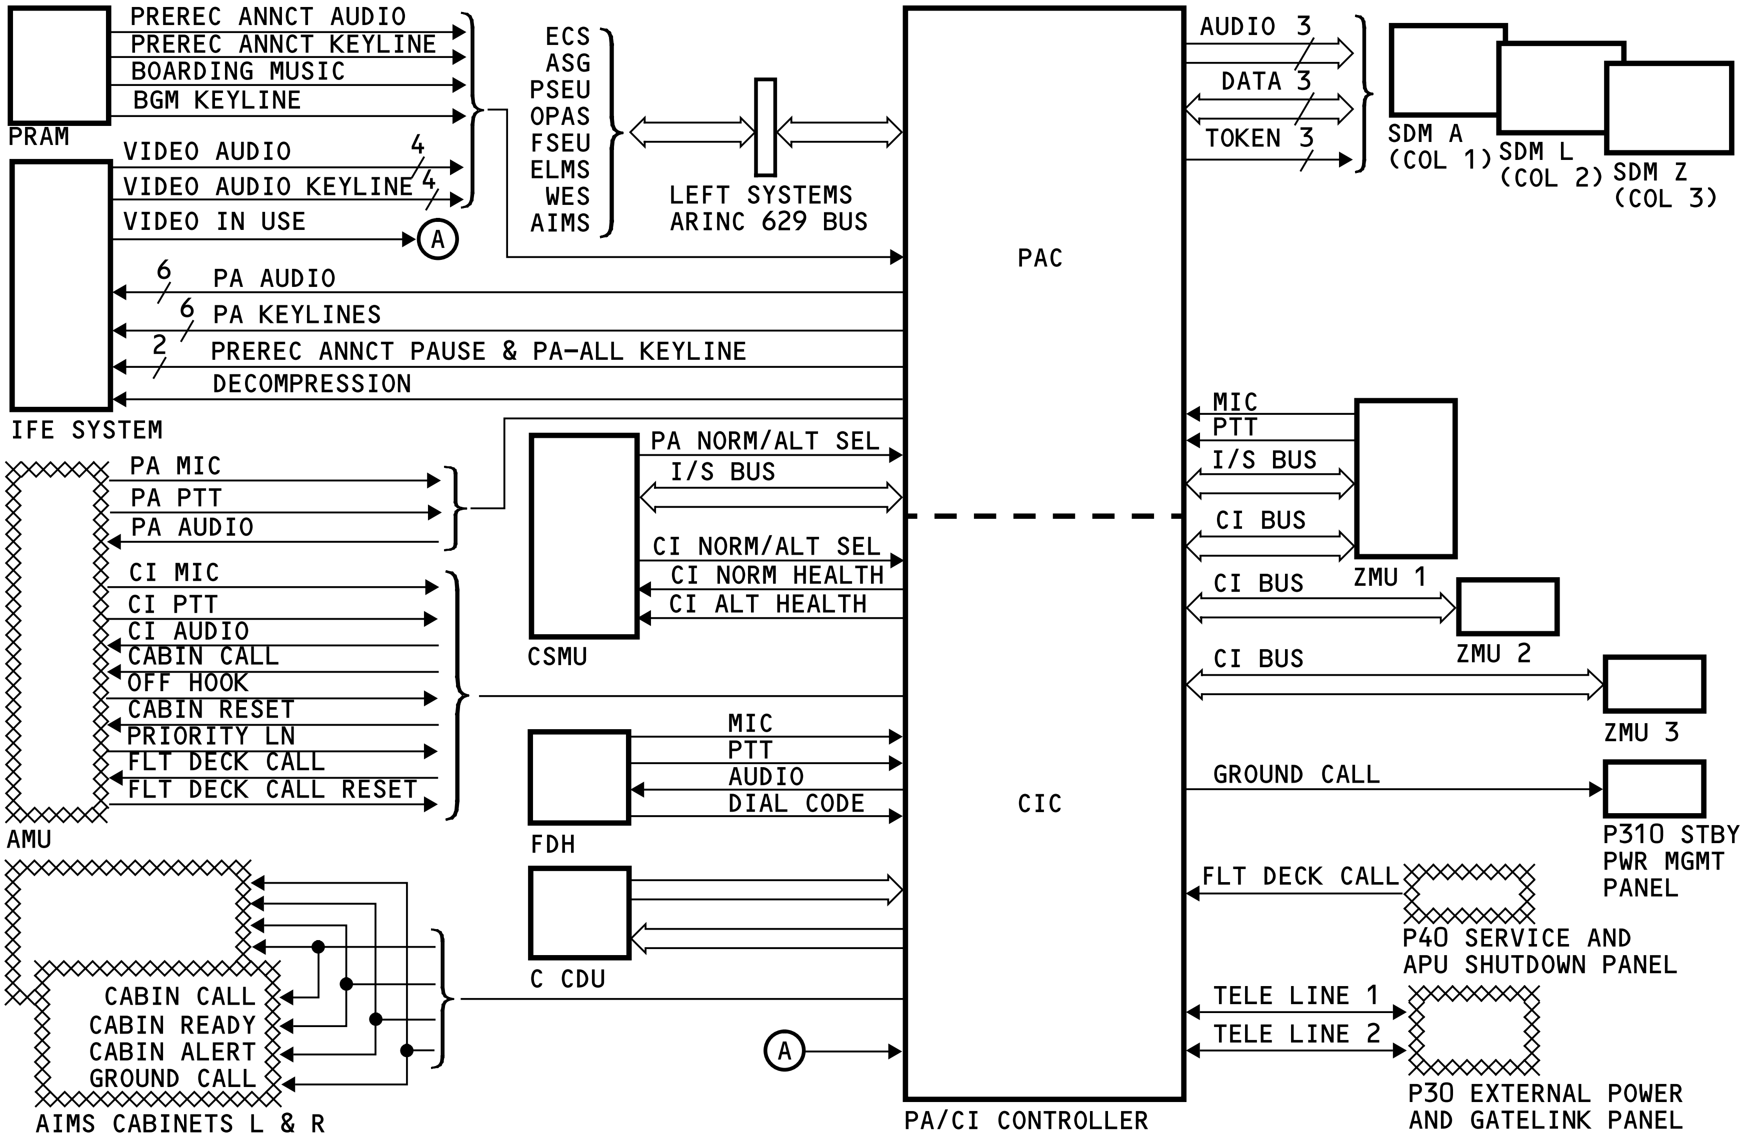
The PA/CI controller uses the intersystem bus between the CSMU and ZMU 1.

Panel Interfaces

The PA/CI controller sends a signal to the P310 standby power management panel for a ground crew call.

The P40 service and APU shutdown panel sends a signal to the PA/CI controller when the ground crew calls the flight deck.

The P30 external power and gatelink panel has two telephone jacks. They connect to the PA/CI controller.



CSS GENERAL - PASSENGER ADDRESS/CABIN INTERPHONE CONTROLLER INTERFACES

THIS PAGE INTENTIONALLY LEFT BLANK

CSS GENERAL - ZONE MANAGEMENT UNIT 1 INTERFACES

General

The zone management unit (ZMU) controls the cabin components connected to it. It is also an interface between cabin components and other main controllers.

Passenger Address/Cabin Interphone Controller Interfaces

The bus interfaces between the passenger address/cabin interphone (PA/CI) controller and ZMU 1 are the intersystem bus and the cabin interphone bus. The intersystem bus supplies a data interface for primary CSS components. It uses a 10 base 2 data format. The cabin interphone bus is for the cabin interphone function. It uses an EIA-485 data format.

ZMU 1 sends analog audio and a PTT signal to the PA/CI controller for the passenger address direct access function.

Zone Management Unit Interfaces

The intersystem bus from ZMU 1 connects to ZMU 2 which also connects to ZMU 3. Each ZMU uses the data from this bus to control their related zone components.

The ARINC 628 zone interface bus provides an interface with the in-flight entertainment system for passenger service functions.

ZMU 2 sends analog microphone audio and a PTT signal to ZMU 1 for the passenger address direct access function.

ZMU 2 also gets audio and a PTT signal from ZMU 3 to send to ZMU 1. ZMU 1 sends the signals to the PA/CI controller.

Cabin Attendant Handset Interfaces

Attendants use the cabin attendant handsets (CAHs) for cabin interphone calls and passenger address announcements. Each ZMU connects to as many as five CAHs. The CAH sends microphone audio, a PTT, and dialing signals to the ZMU. The ZMU sends receive audio to the CAH.

Each ZMU can have only one passenger address direct access interface. Attendants use the CAH that has a direct access button on the handset cradle to energize a relay in the ZMU. The interface between the cradle and the ZMU is a power signal, set signal, and reset signal.

Master Call Light Interfaces

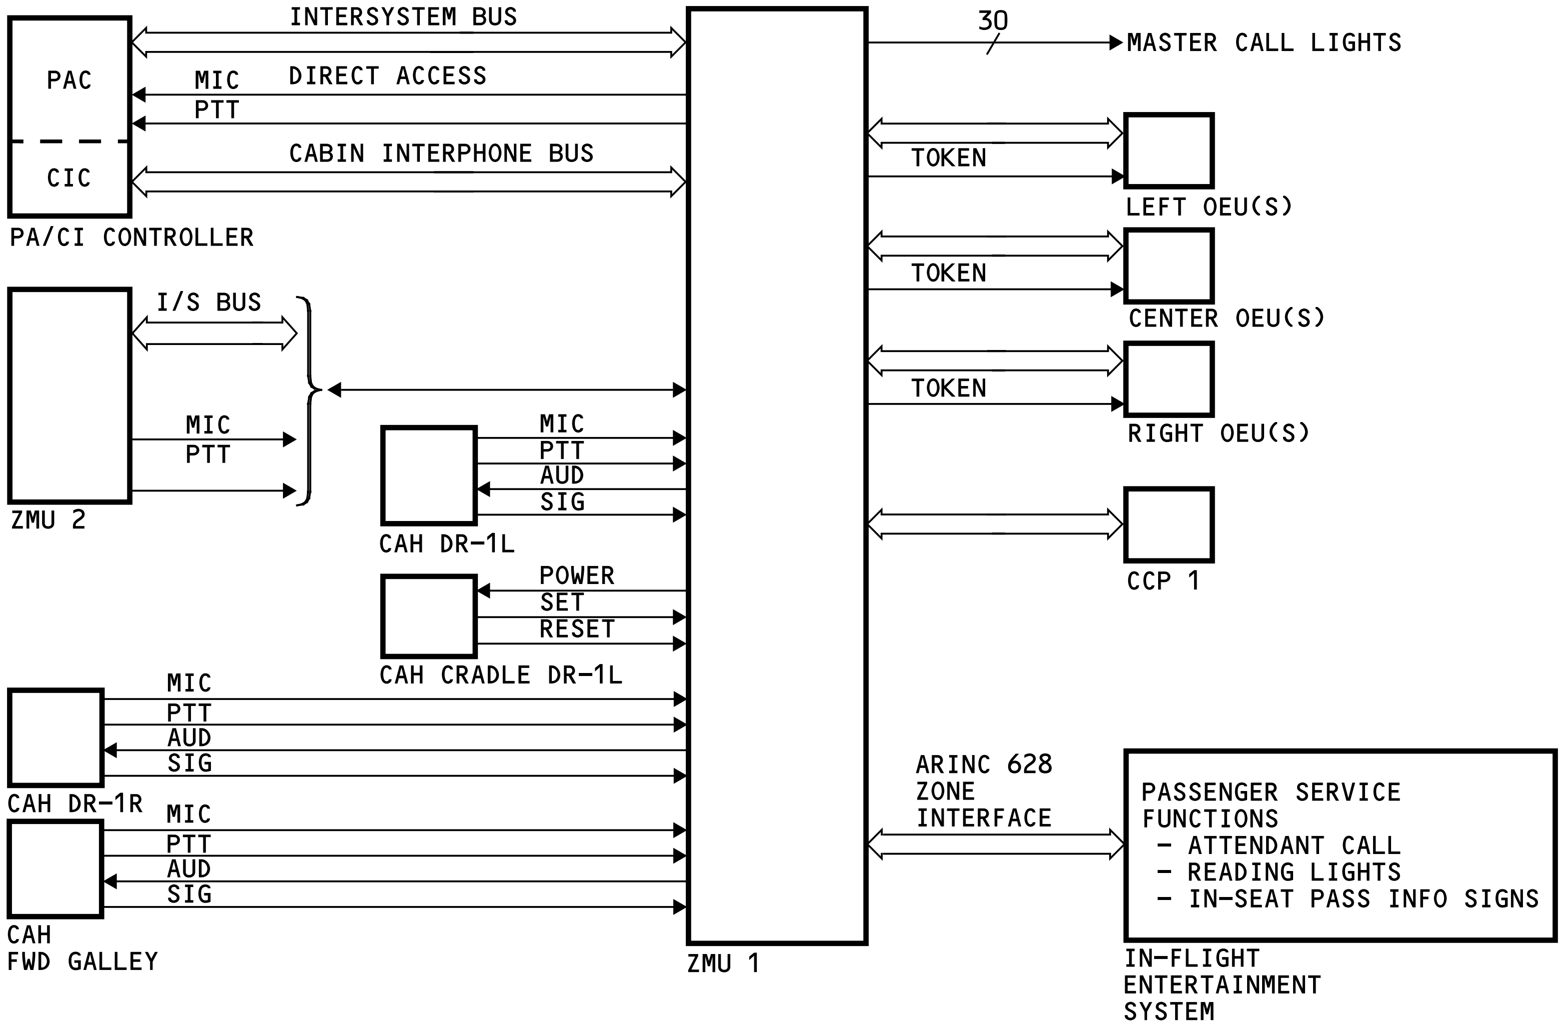
Each ZMU controls as many as 30 master call lights. Ten master call lights are for cabin interphone calls. Twenty master call lights are for passenger to attendant calls.

Overhead Electronics Unit Interfaces

Each ZMU connects to three columns of overhead electronics units (OEUs). The data bus uses an EIA-485 type of data format.

CSS GENERAL - ZONE MANAGEMENT UNIT 1 INTERFACES

OEUs control lights and passenger information signs. They also monitor different inputs. The token signal is for test and software installation.



23-39-00-518 Rev 12 02/25/1998

CSS GENERAL - ZONE MANAGEMENT UNIT 1 INTERFACES

CSS GENERAL - CABIN CONTROL PANEL

Purpose

You use the cabin control panels (CCPs) to operate the CSS. The hardware configuration of a CCP tells it to operate as a cabin area control panel (CACP) or a cabin system control panel (CSCP).

Flight attendants use the the CSCP or the CACPs to control CSS functions. Maintenance personnel use the CSCP to do tests and to install software.

Physical Description

The CCP weighs 13 pounds. These are the dimensions:

- Length - 16.5inches
- Width - 10.4inches
- Height - 3.3inches.

The front panel has these items:

- A touch-sensitive flat panel screen to select all functions
- Connector J1 for 115v ac power input and connection to the zone management unit (ZMU) panel bus
- Connector J2 for an RS-232 interface jack for shop maintenance functions
- Connector J3 for 10-base-T network interface.

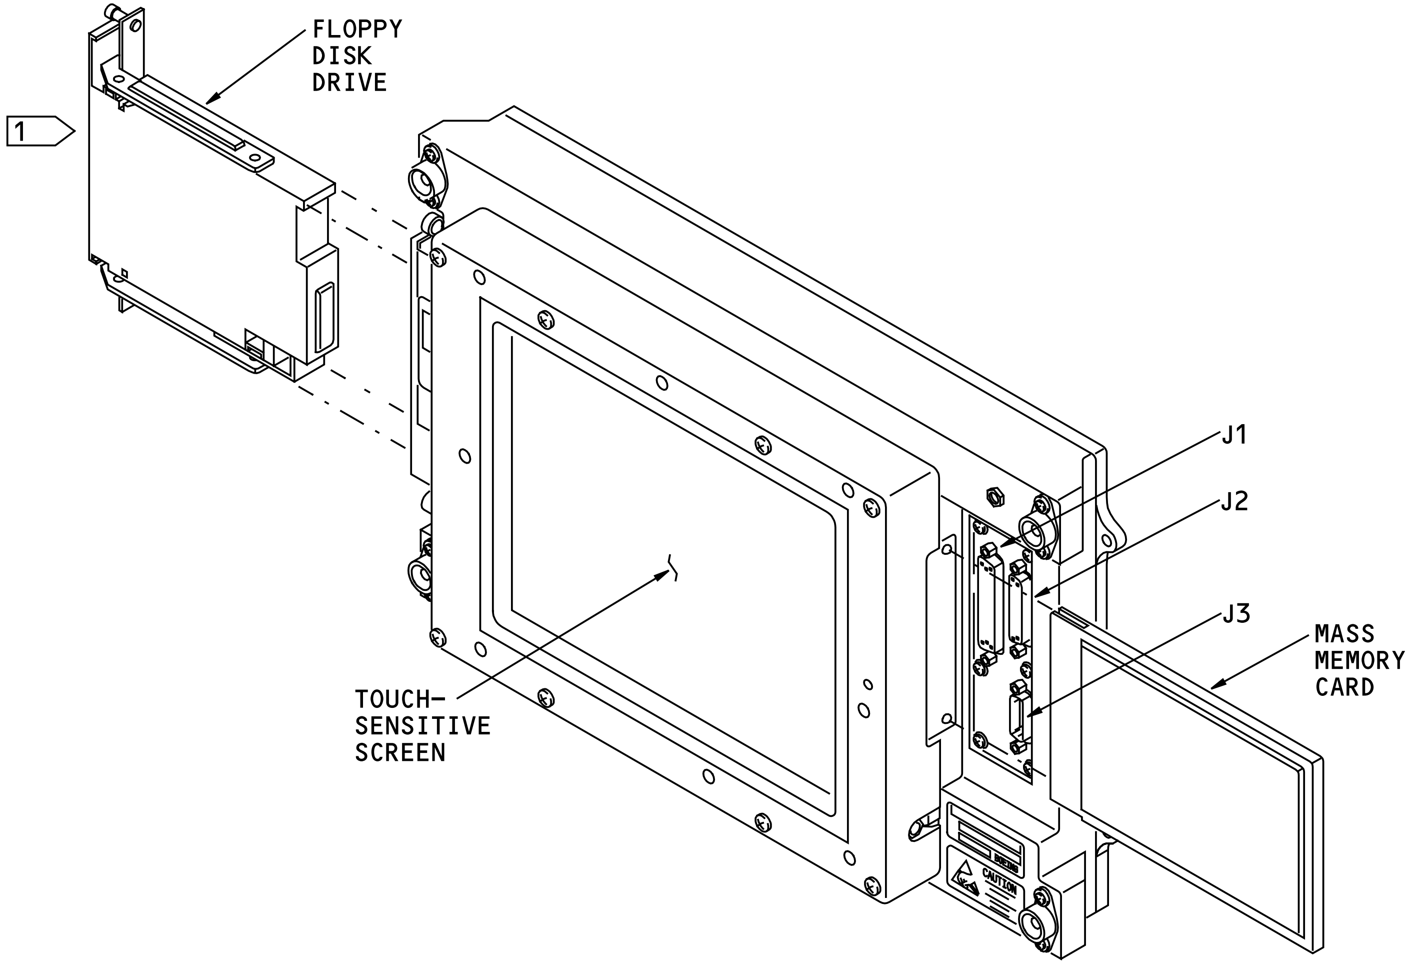
Functional Description

Attendants make selections on the touch screen to control these CSS functions:

- Cabin lighting
- Passenger services
- Cabin environment.

Training Information Point

The mass memory card and the floppy disk drive are line replaceable.



1 FLOPPY DISK DRIVE FOR
CSCP CONFIGURATION ONLY.

23-39-00-532 Rev 1 09/16/1997

CSS GENERAL - CABIN CONTROL PANEL

CSS GENERAL - CABIN SYSTEM MANAGEMENT UNIT

Purpose

The cabin system management unit (CSMU) supplies an interface between CSS LRUs and other airplane systems.

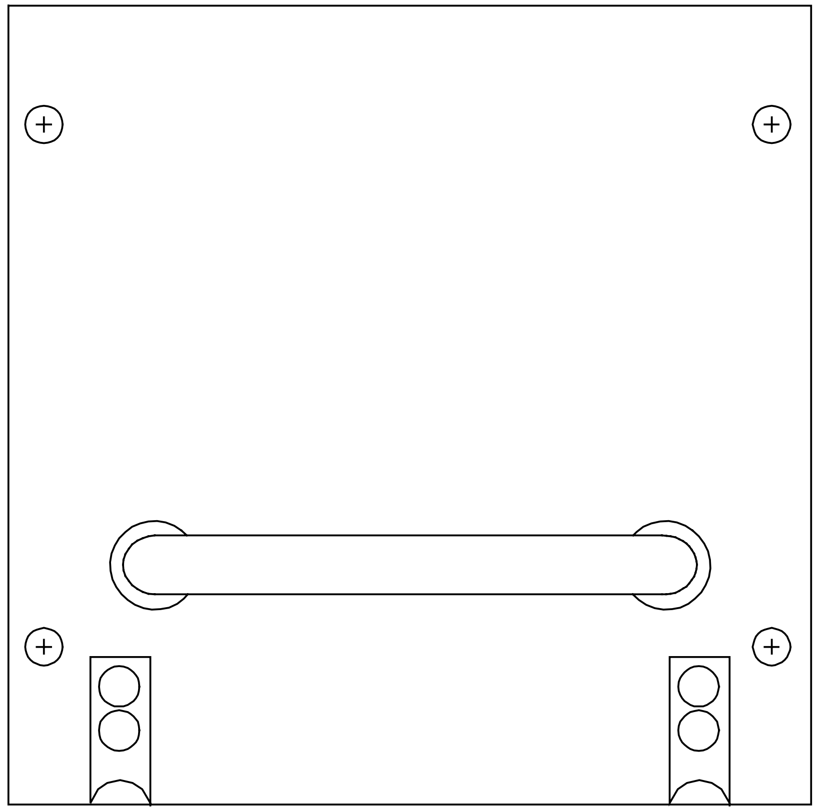
Physical Description

The CSMU is a 6 MCU LRU and weighs approximately 12 pounds.

Functional Description

The CSMU has these functions:

- Gets CSS database and operational program software from the cabin system control panel (CSCP) and sends it to other CSS LRUs
- Sends data to and gets data from the right systems ARINC 629 bus (temperature control, maintenance information, etc.)
- Does data bus conversion to and from the CSCP.



23-39-00-522 Rev 0 07/24/96

CSS GENERAL - CABIN SYSTEM MANAGEMENT UNIT

CSS GENERAL - PASSENGER ADDRESS/CABIN INTERPHONE CONTROLLER

Purpose

The passenger address/cabin interphone (PA/CI) controller permits announcements on the passenger address system. It also permits attendants to make station to station calls and calls to the flight deck.

Physical Description

The PA/CI controller is an 8 MCU LRU and weighs 21 pounds.

Functional Description

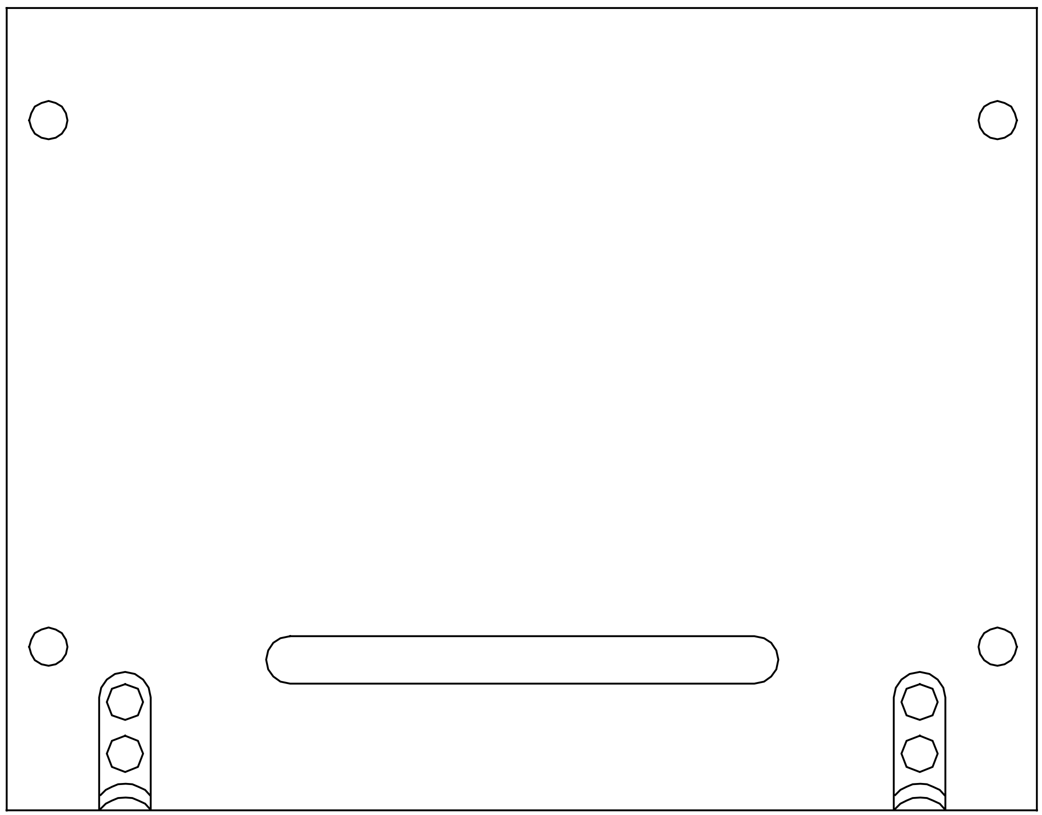
The PA/CI controller has two passenger address controllers and two cabin interphone controllers. Each controller uses different circuits in the LRU. Only one passenger address controller and one cabin interphone controller operates at a time. If a controller fails, you can select the alternate controller.

The PA controller does these functions:

- Digitizes six PA channels for audio output
- Sends PA override signals to the in-flight entertainment (IFE) system (overrides passenger entertainment audio when necessary)
- Calculates the volume for each speaker
- Receives audio inputs from the flight interphone system, direct access, cabin interphone controller, and IFE system (prerecorded announcements, video audio, boarding music)
- Controls the logic for the passenger information signs
- Has an interface with the left systems ARINC 629 bus.

The cabin interphone controller does these functions:

- Makes digital connections between stations
- Sends audio tones to off-hook handsets
- Sends audio sidetone to the flight deck
- Processes ground crew calls
- Has interfaces with the flight deck, flight interphone system, and AIMS.



23-39-00-523 Rev 0 07/15/96

CSS GENERAL - PASSENGER ADDRESS/CABIN INTERPHONE CONTROLLER

CSS GENERAL - ZONE MANAGEMENT UNIT

Purpose

The zone management units (ZMUs) primarily control passenger service and cabin lighting. They have interfaces with these components:

- Passenger address/cabin interphone (PA/CI) controller
- Cabin area control panels (CACPs)
- Cabin attendant handsets (CAHs)
- Overhead electronics units (OEUs).

Physical Description

The ZMU weighs 12 pounds. These are the dimensions:

- Length - 10.3 inches
- Width - 8 inches
- Height - 5.8 inches.

Functional Description

Each ZMU does these functions:

- Does bus conversion from 10 base 2 to 10 base T for as many as three cabin area control panels
- Has interfaces for as many as five handsets and three columns of OEUs
- Controls as many as 30 master call lights
- Routes PA direct access signals.

CSS GENERAL - ZONE MANAGEMENT UNIT

CSS GENERAL - ZONE MANAGEMENT UNIT INSTALLATION

General

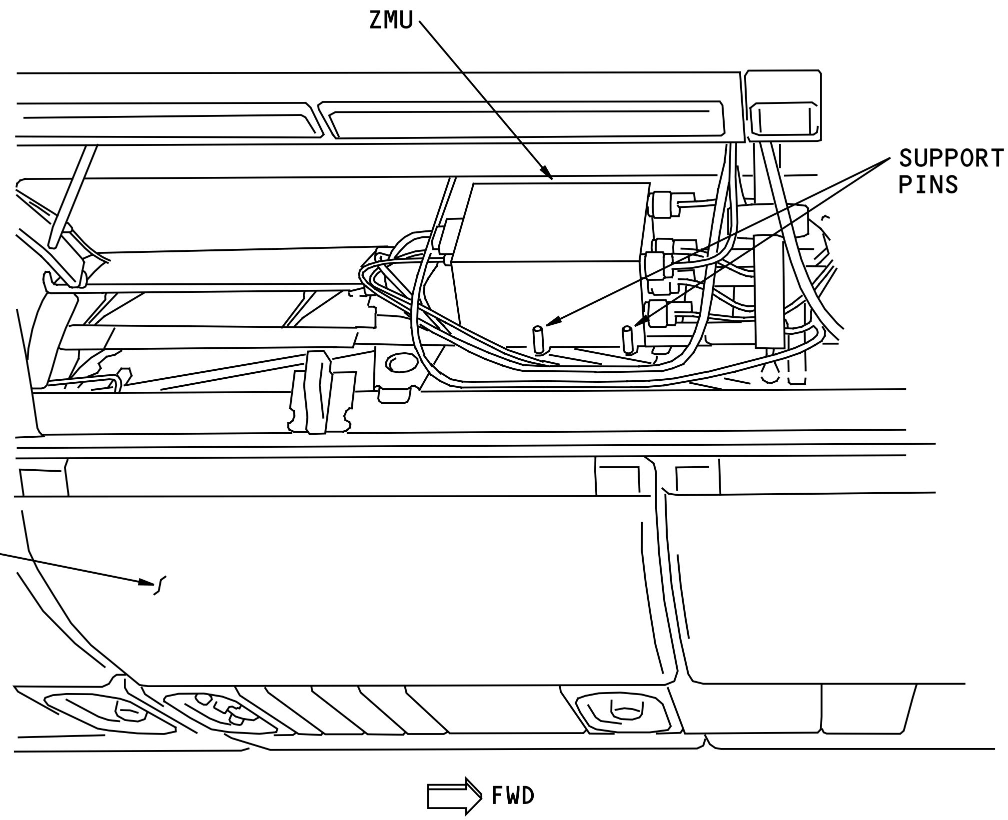
The ZMUs are above the cabin ceiling on the right side of the stow bin ladder assembly. Four screws attach the ZMU to the ladder assembly.

Training Information Point

You remove ceiling panels to get access to a ZMU.

Training Information Point

There are support pins to hold the ZMU during removal and installation.



(LOOKING INBOARD FROM RIGHT SIDE)
(TYPICAL INSTALLATION)

23-39-00-525 Rev 0 07/15/96

CSS GENERAL - ZONE MANAGEMENT UNIT INSTALLATION

CSS GENERAL - CABIN PRINTER

Purpose

The cabin printer makes reports of CSS data.

Physical Description

The printer has these characteristics:

- Weight - 12 pounds with a full roll of paper loaded
- Width - 5 inches
- Height - 9.75 inches
- Depth - 10.25 inches.

Controls and Indications

Push the PWR switch to enable the printer. When you enable the printer, an indicator on the switch comes on.

The FAULT indicator comes on for any of these reasons:

- A failure condition occurs
- The door is open
- There is no paper in the printer.

Push the momentary TEST button to do a test of the printer. During the test, a test pattern prints and an indicator on the TEST button comes on to show that a test is in progress.

Push the PPR ADV button to advance the paper.

The LOW PPR shows when the paper supply is less than 10 feet. There is also a low paper stripe on the paper for the last 6 feet of paper.

Push the momentary ALRT RST switch to cause a power-on reset of the electronic circuitry of the printer. Printing will stop. This reset does not erase any messages in the printer memory.

Functional Description

The cabin printer is a thermal dot matrix printer. The printer paper is 8.5 inches wide in a roll 125 feet long. You open the printer door to load the paper. During print operation, a friction feed moves paper through the printer at the rate of 4 pages per minute. At the paper exit there is a cutting edge to help tear paper from the roll.

CSS GENERAL - CABIN PRINTER

CSS GENERAL - CABIN CONTROL PANEL FUNCTIONAL DESCRIPTION

General

You use the cabin control panels (CCPs) to operate the CSS. The hardware configuration of a CCP tells it to operate as a cabin area control panel (CACP) or a cabin system control panel (CSCP).

The CSCP configuration has a floppy disk drive (FDD) and an 85 megabyte mass memory card (MMC). The CACP configuration has a 20 megabyte MMC and no FDD.

Controller

The controller controls CSS functions.

It controls tests and software installation in the CSS components. It also controls selection of normal CSS functions such as lighting, monitor and control, and passenger services.

Display

The CCP display is a touch-sensitive screen. The display shows menus for control of the CSS.

Mass Memory Card

The CCP uses a mass memory card (MMC) to keep software. The mass memory card is a solid state data storage device. The MMC keeps operational software and data from the configuration database (CDB). The CDB data in the CCP tells the CCP which screen selections it may show. The mass memory card is line replaceable.

Floppy Disk Drive

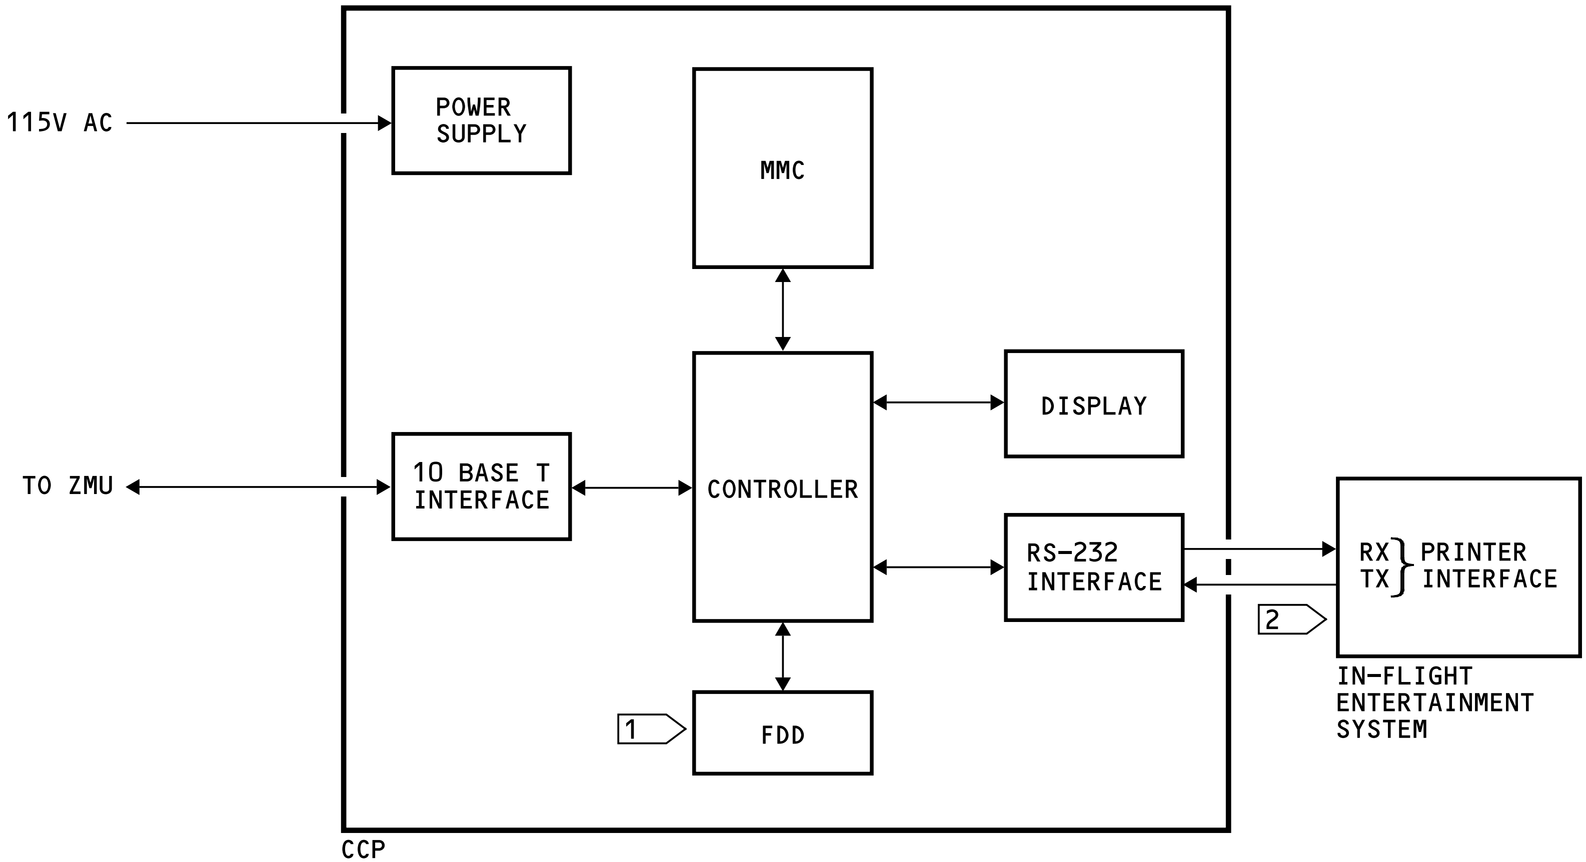
The FDD is only used in the CSCP . You use the FDD to install the database software and operational software into the MMC. The FDD also saves report data from the CSS on to a floppy disk.

Interfaces

The CCP sends and receives data on the intersystem bus. This includes these functions:

- Test commands
- Programming
- Normal CSS selections.

The CSCP sends report data to the in-flight entertainment (IFE) system. The IFE system sends the report data to a cabin printer to make printouts of CSS data.



1 FLOPPY DISK DRIVE FOR CSCP CONFIGURATION ONLY.

2 PRINTER INTERFACE FOR CSCP CONFIGURATION ONLY.

CSS GENERAL - CSCP/CACP SCREENS MENU TREE

THIS PAGE INTENTIONALLY LEFT BLANK

CSS GENERAL - CSCP/CACP SCREENS MENU TREE

General

The cabin system control panel (CSCP) and cabin area control panels (CACPs) selection screens are menu driven. To access a control screen, you may have to use one or more menu screens.

Because of selections made in the configuration database generator or airline equipment options, some menu selections will not operate.

Main Menu

The main menu shows only on the CSCP. You can select CABIN CONTROLS or CABIN MAINTENANCE from this screen.

The CABIN CONTROLS selection permits you to monitor and control cabin functions.

The CABIN MAINTENANCE selection shows the cabin maintenance menu. See the CSS test and software installation section for additional data.

Cabin Controls Main Menu

The cabin controls main menu shows on both the CSCP and CACPs. The cabin controls main menu is the highest level menu on the CACPs. It shows when power is supplied to the CSS.

Most selections on the cabin controls main menu cause a control screen to show. These are the control screen selections:

- CABIN TEMPERATURE
- BOARDING MUSIC
- PASSENGER ADDRESS
- SMOKING ASSIGNMENTS
- CABIN DOOR STATUS
- SPECIAL FUNCTIONS
- DISPLAY CONTROLS.

Other selections cause a sub-menu to show. These are the selections that have sub-menus:

- LIGHTING
- SERVICE CALL/CHIME CONTROL
- WATER/WASTE TANK STATUS.

Sub-menus

The lighting menu selections are:

- CABIN LIGHTING
- ENTRY WAY LIGHTS
- READING LIGHTS.

The service call/chime control menu selections are:

- SERVICE CALL
- AREA CHIME CONTROL
- SEAT CHIME CONTROL.

The water/waste tank status menu selections are:

- LAVATORY/WASTE TANK STATUS
- LAVATORY INOPERABLE CONTROL

CSS GENERAL - CSCP/CACP SCREENS MENU TREE

- POTABLE WATER STATUS.

CSS GENERAL - MAIN MENU

CSS GENERAL - CABIN CONTROLS MAIN MENU

General

Attendants use the cabin controls main menu to select CSS core functions.

Access

Touch CABIN CONTROLS on the cabin system control panel (CSCP) main menu to show this screen.

On the cabin area control panels (CACPs), the cabin controls main menu is the highest level menu. It shows automatically when you apply power to the CSS.

The CACPs do not have the EXIT selection.

Controls and Indications

The cabin controls screens on the CSCP and CACPs may be different. Some selections may be available on one panel but not on another. The configuration database controls the selections that show on each screen.

Normally, the CACPs control only given seating areas of the cabin. The configuration database identifies the areas each CACP controls. The PANEL OVERRIDE selection lets all CACPs control any area.

The LIGHTING selection controls cabin illumination and reading lights.

The SERVICE CALL/CHIME CONTROL selection gives information on passenger-to-attendant calls. It also permits the attendants to disable the passenger-to-attendant chimes.

Use the CABIN TEMPERATURE selection to control the cabin temperature.

The WATER/WASTE TANK STATUS selection supplies data on potable water level status and waste tank status. It also gives selection for lavatory inoperable controls.

Attendants use the BOARDING MUSIC selection to control boarding music.

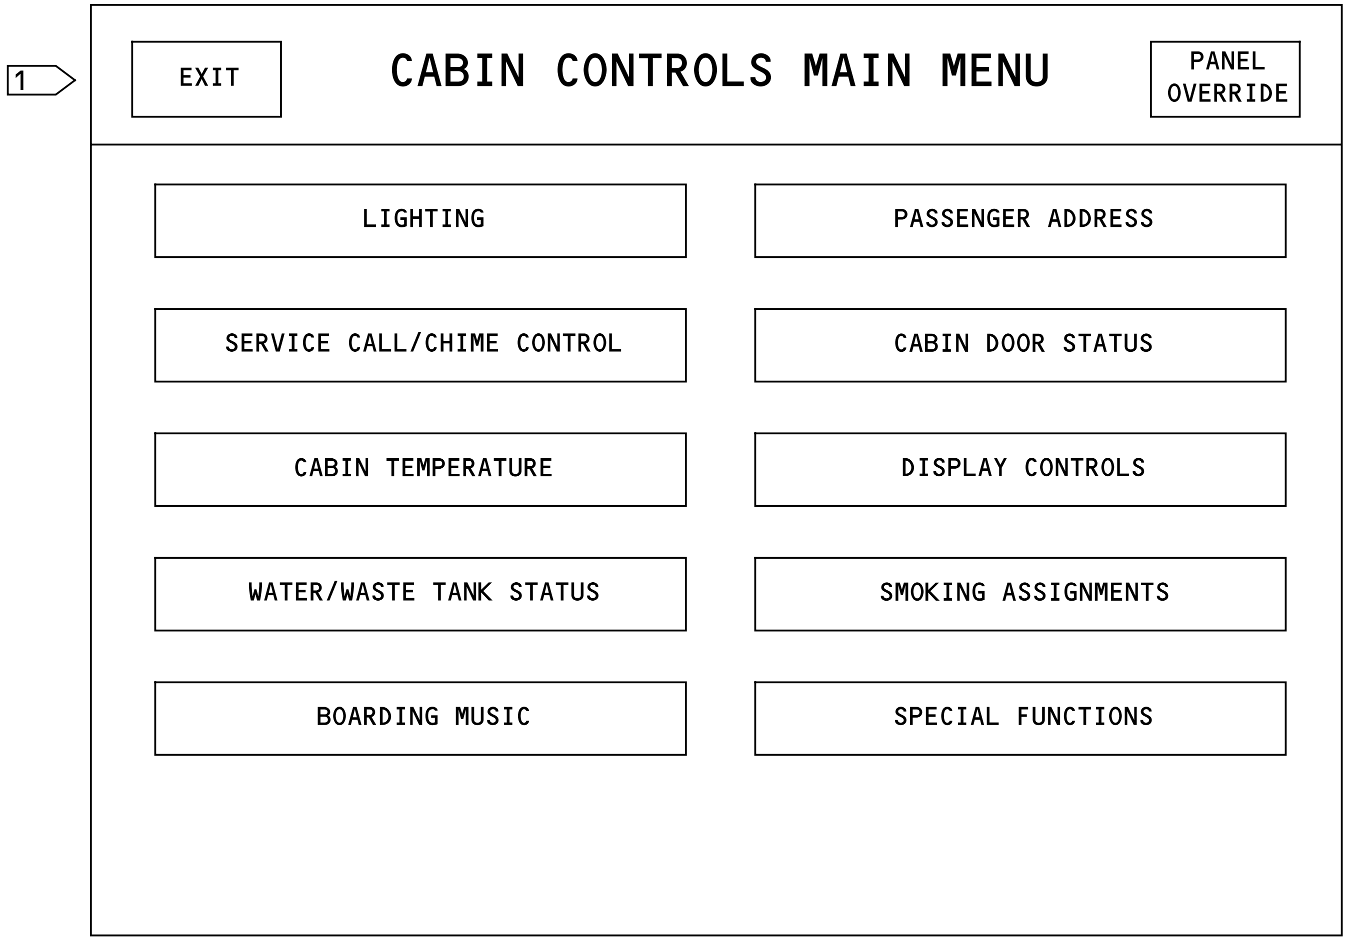
The PASSENGER ADDRESS selection supplies passenger address volume control and ambient noise sensor on/off control.

The CABIN DOOR STATUS supplies data for door positions (open or closed).

The DISPLAY CONTROLS selection supplies panel brightness controls and panel lockout control.

Use the SMOKING ASSIGNMENTS selection to control smoking area selections.

The SPECIAL FUNCTIONS selection gives on/off control of items identified by the configuration database.



CSCP/CACP SCREEN

CSS GENERAL - PASSENGER ADDRESS SCREEN

General

Attendants use the passenger address screen to adjust the passenger address volume and to control the ambient noise sensors.

Access

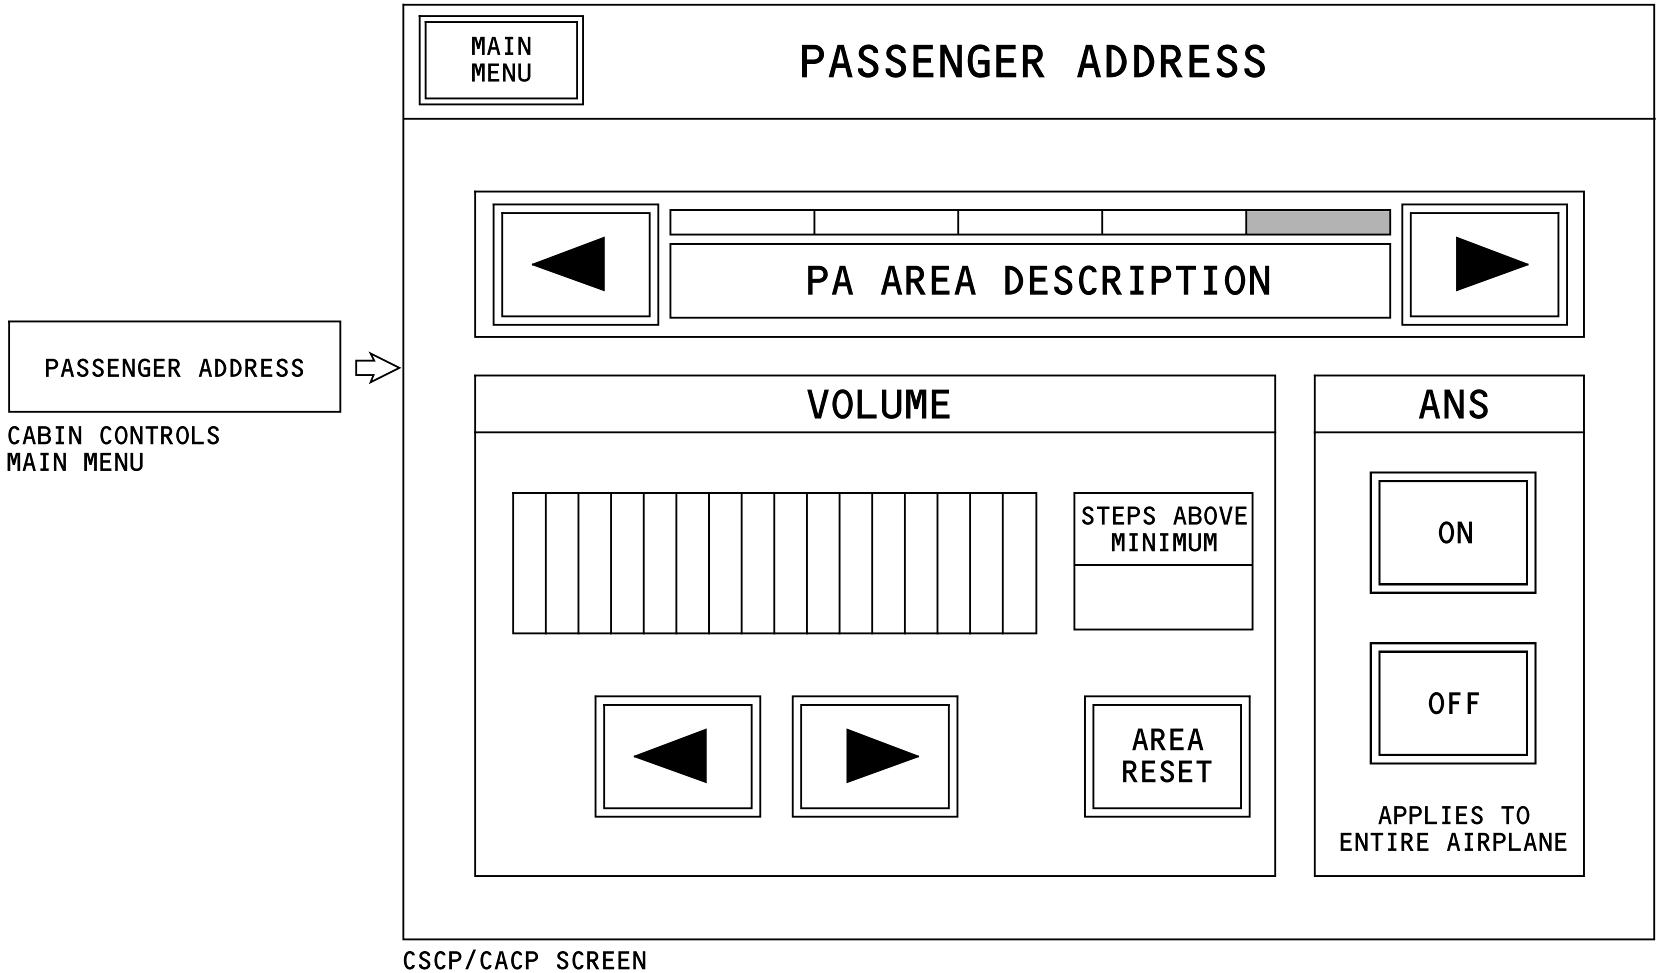
Touch PASSENGER ADDRESS on the cabin controls main menu to show this screen.

Controls and Indications

Use the left and right arrows to select the cabin areas. The space between the arrows shows the selected cabin area description.

Use the left and right arrows in the volume area to control the amount of increase in volume above the reference level. The number of steps above minimum you select shows in the steps above minimum area. Touch AREA RESET to return the volume to the reference level.

Use the ambient noise sensor (ANS) controls to enable or disable the ambient noise sensors.



23-39-00-618 Rev 0 06/17/96

CSS GENERAL - PASSENGER ADDRESS SCREEN

CSS GENERAL - CABIN DOOR STATUS SCREEN

General

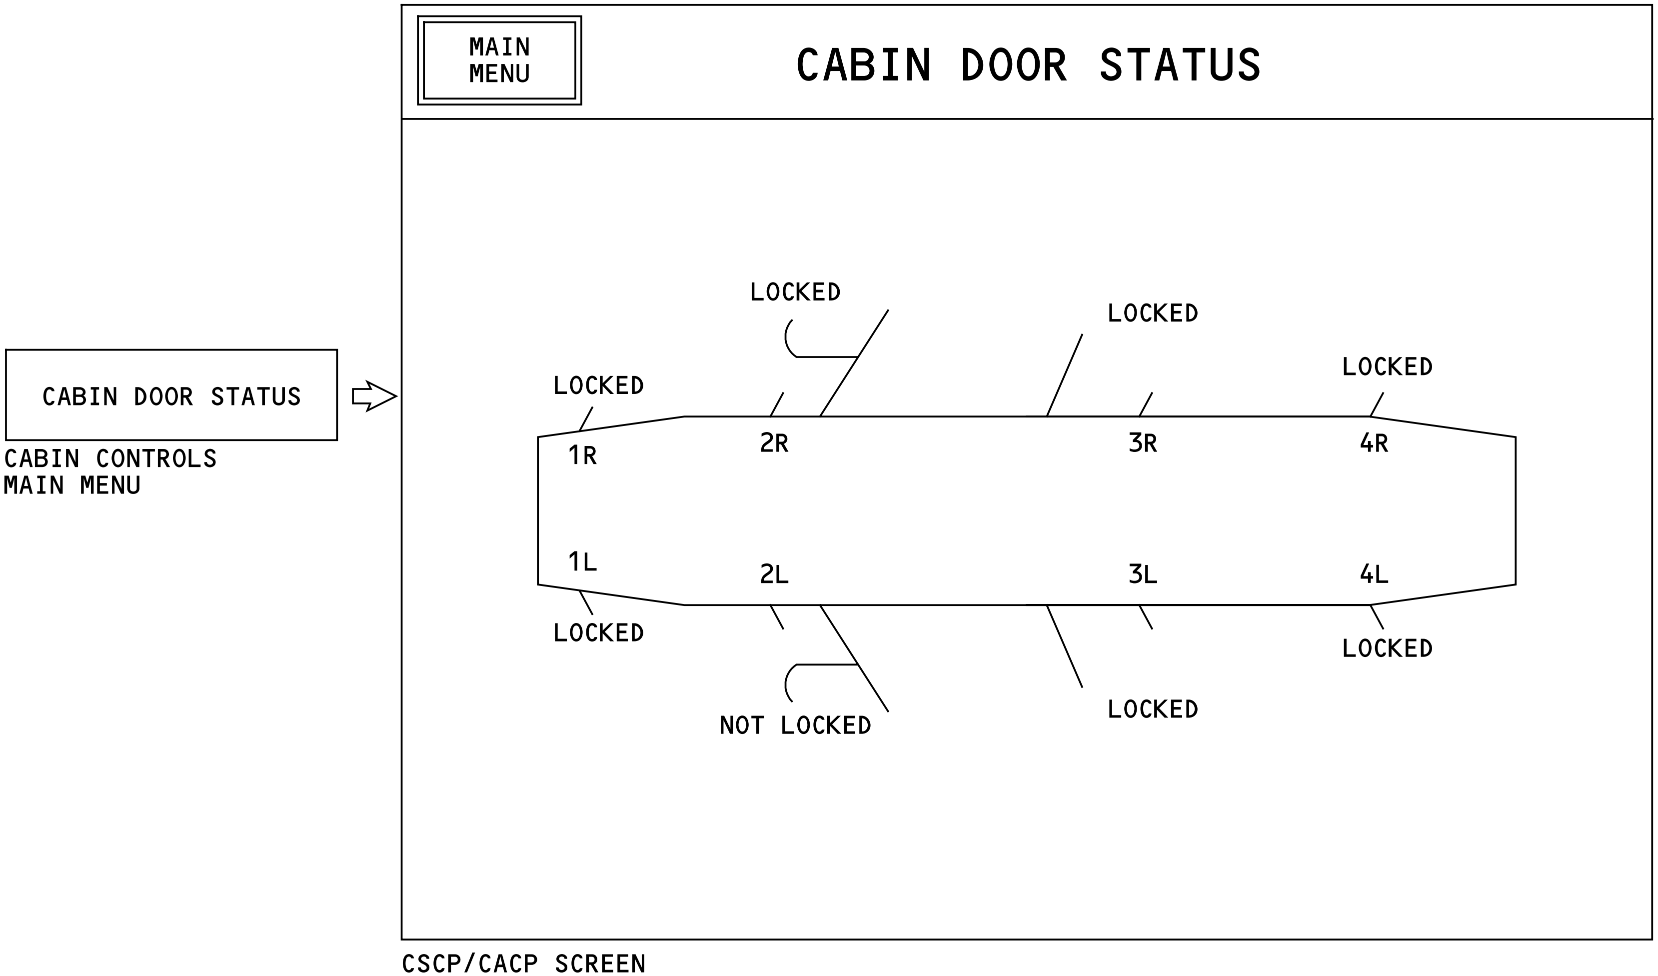
Attendants use the cabin door status screen to see if the doors are locked or not locked.

Access

Touch CABIN DOOR STATUS on the cabin controls main menu to show this screen.

Controls and Indications

The cabin door status screen shows the locked/not locked status of the cabin doors.



23-39-00-619 Rev 1 07/08/1997

CSS GENERAL - CABIN DOOR STATUS SCREEN

CSS GENERAL - DISPLAY CONTROLS SCREEN

General

You use the display controls screen to adjust the panel brightness and clean the display.

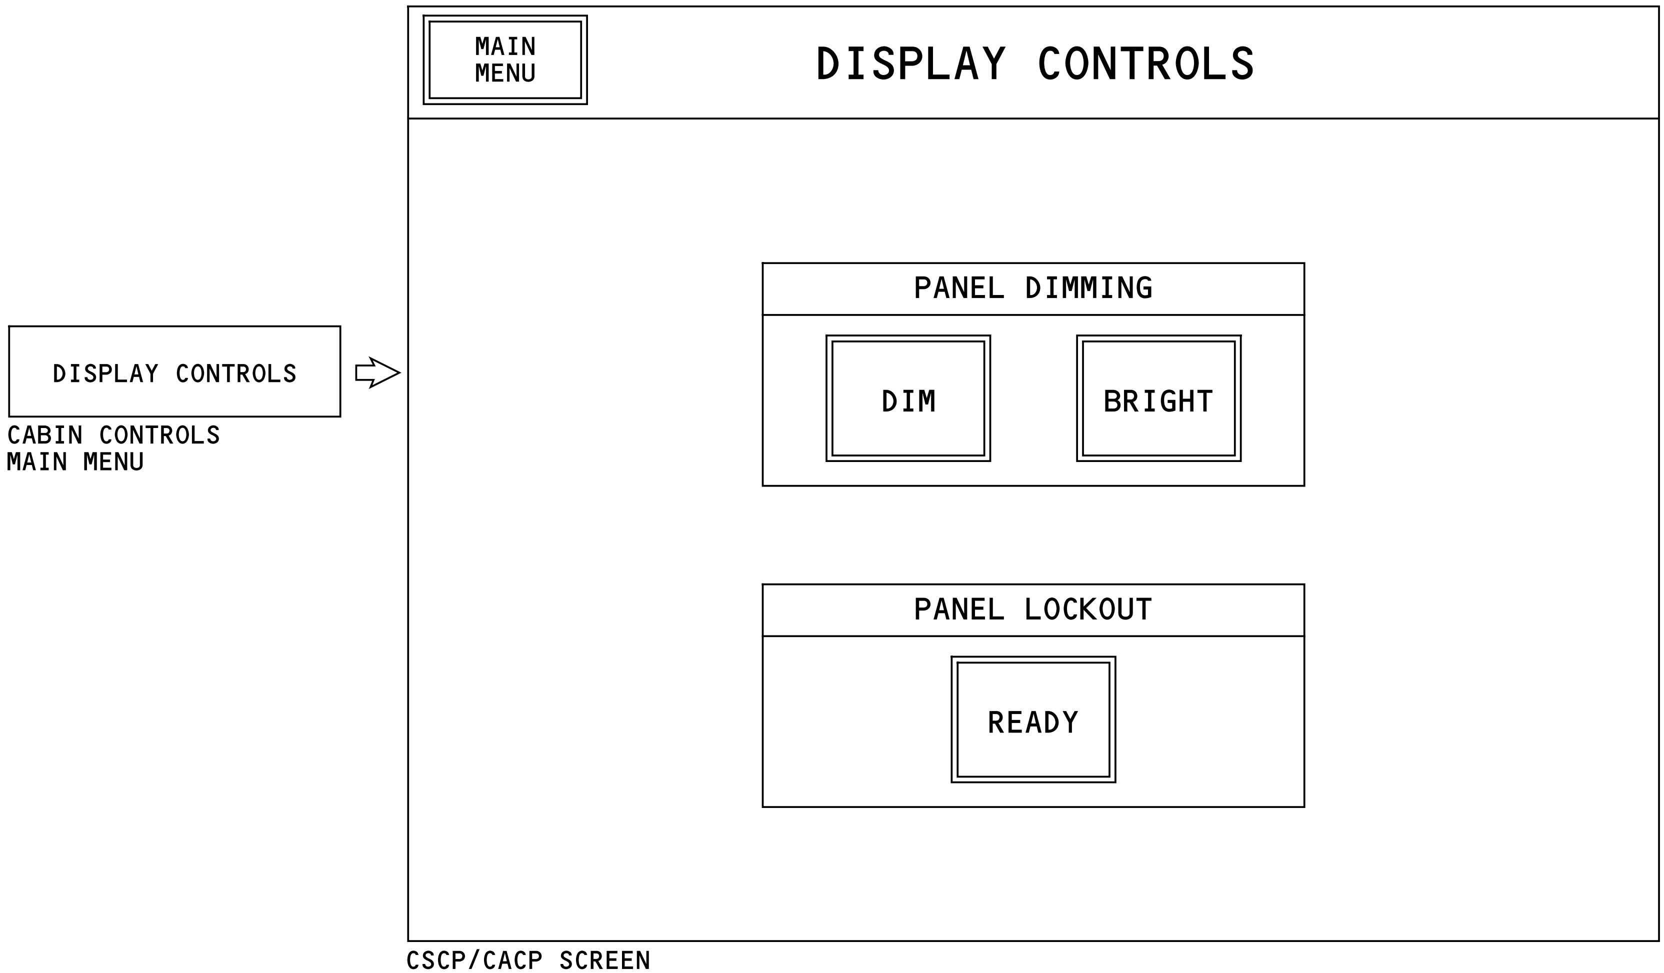
Access

Touch DISPLAY CONTROLS on the cabin controls main menu to show the display controls screen.

Controls

The panel dimming selections control the screen brightness. Touch DIM to decrease the brightness. Touch BRIGHT to increase the brightness.

Touch the panel lockout selection to stop panel operation for 30 seconds. A 30 second timer shows on the screen. You can not make screen selections while the panel is locked out. You can clean the screen while the panel is locked out.



23-39-00-620 Rev 0 06/17/96

CSS GENERAL - DISPLAY CONTROLS SCREEN

CSS GENERAL - POP-UP WINDOWS

General

The CMS shows pop-up windows on the CSCP and CACPs for important system messages. These windows show on top of the active window.

There are three types of pop-up windows:

- Alert messages
- Function lockout messages
- Error messages.

Alert Messages

The alert messages tell the flight attendants that a condition requires action. These conditions cause alert messages:

- Lavatory smoke detection
- Passenger address controller failures
- Cabin interphone controller failures
- Waste tank full
- Less than 1/4 tank of potable water.

Function Lockout Messages

Function lockout messages tell the flight attendants some functions may not operate because of system conditions. These conditions cause function lockout messages:

- Cabin decompression
- Loss of ground service bus power
- Loss of data from the environmental control system.

Error Messages

When a system does not respond to a selection, an applicable message shows.

Clearing Pop-up Windows

Touch CLEAR to remove the pop-up window from the display.

CSS GENERAL - POP-UP WINDOWS

CSS TEST AND SOFTWARE INSTALLATION - INTRODUCTION

General

You do most cabin services system (CSS) maintenance functions from the cabin system control panel (CSCP).

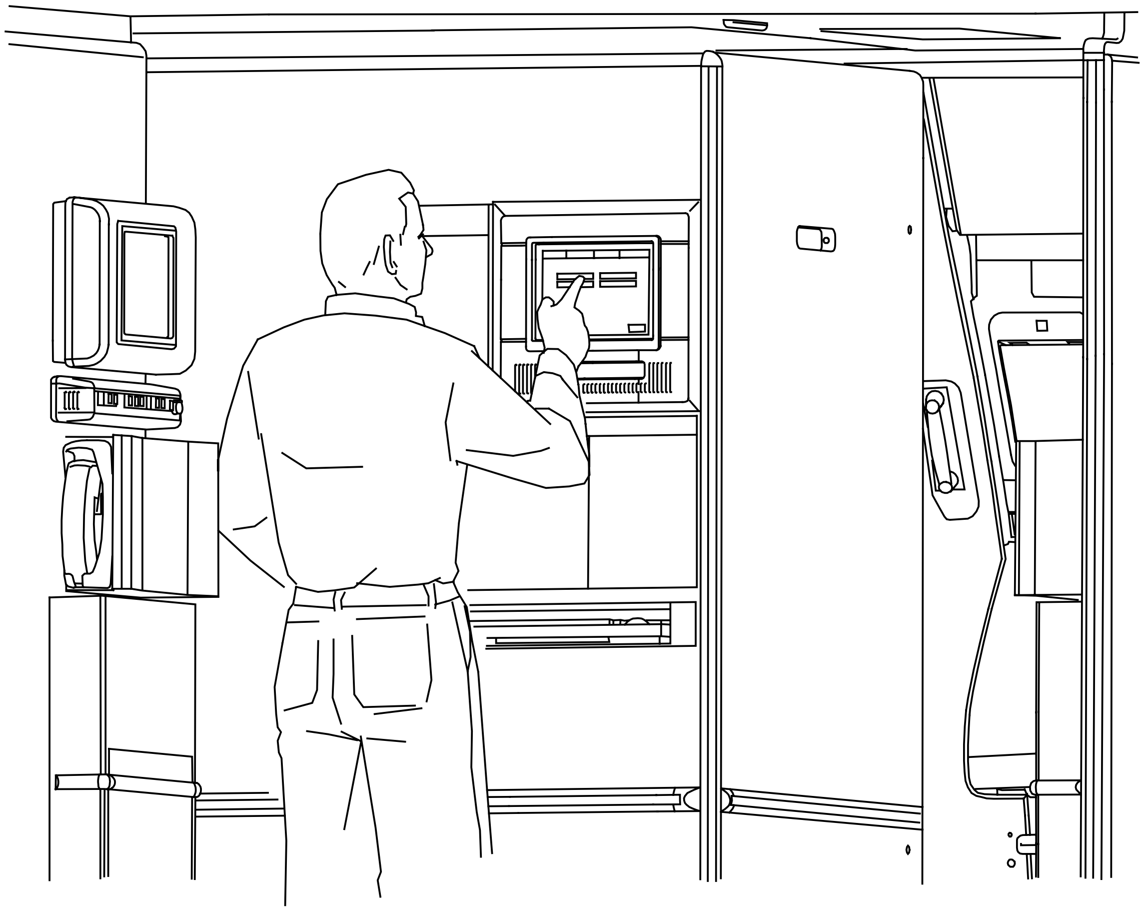
CSS maintenance includes two general areas; tests and software installation.

Tests

You use the CSCP to do tests and review failure data. BITE and continuous fault monitor are the two primary types of tests.

Software Installation

You use the CSCP to install software in the CSS. Software operation functions include software installation and configuration checks.



23-39-00-650 Rev 0 06/17/96

CSS TEST AND SOFTWARE INSTALLATION - INTRODUCTION

CSS TEST AND SOFTWARE INSTALLATION - REQUEST FOR PASSWORD DIALOGUE WINDOW

General

For some CSS maintenance functions, you may need to enter a password. The configuration database controls which functions require passwords.

A dialogue window shows automatically when you make a selection that requires a password.

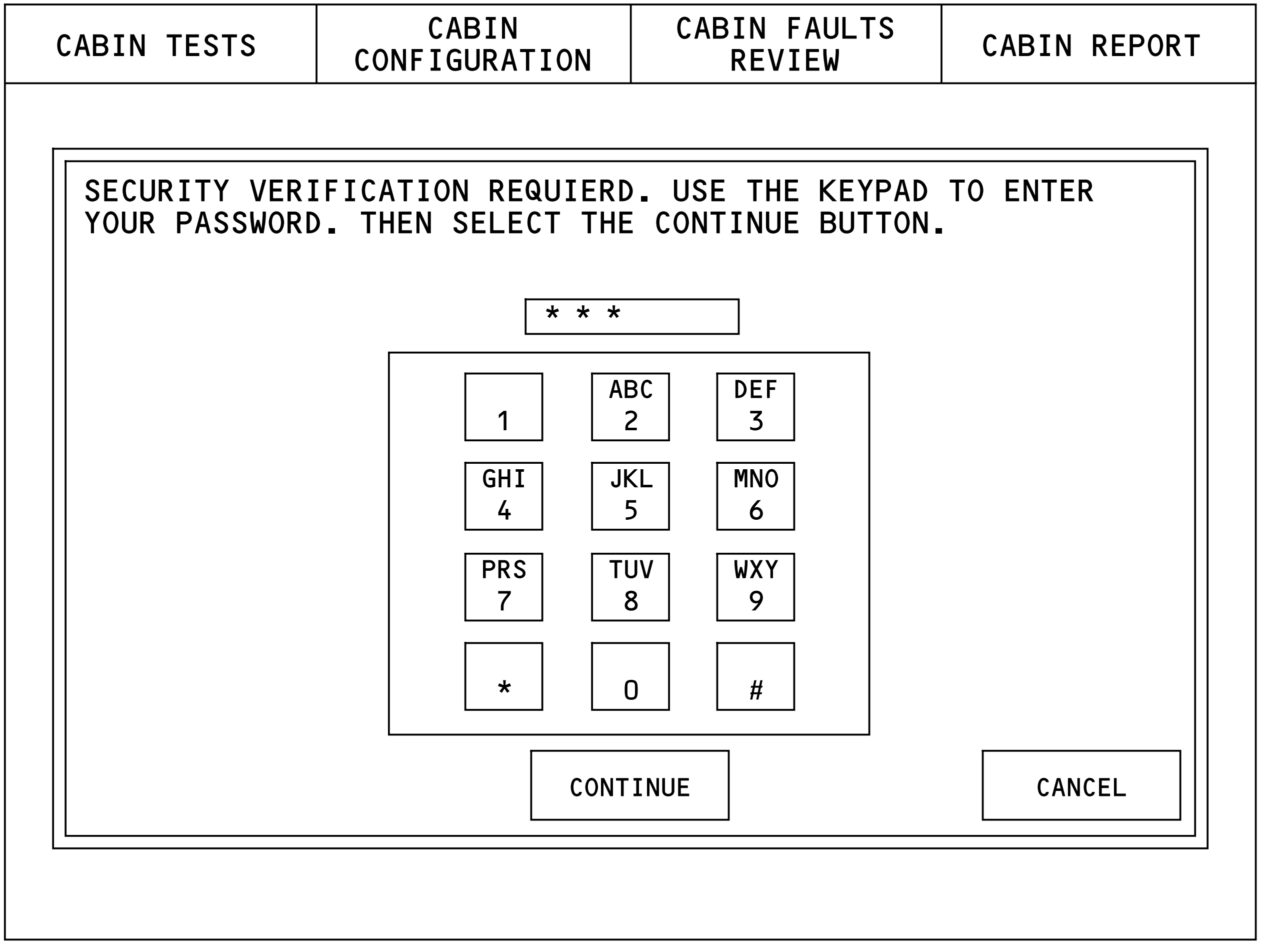
Controls and Indications

The request for password dialogue window tells you to enter a password for a selection you made on a previous screen. It also shows a keypad that looks like telephone keys.

Use the keys on the keypad to enter your password. An asterisk shows in the area above the keypad for each key you select.

After you enter your password, touch CONTINUE to go to the function you selected. If you enter a wrong password, an access denied dialogue window shows.

Touch CANCEL to stop password selections and return to the previous screen.



CSCP SCREEN

23-39-00-651 Rev 0 06/17/96

CSS TEST AND SOFTWARE INSTALLATION - REQUEST FOR PASSWORD DIALOGUE WINDOW

CSS TEST AND SOFTWARE INSTALLATION - CABIN MAINTENANCE MAIN MENU

General

You use the cabin system control panel (CSCP) cabin maintenance main menu to select all maintenance functions.

Access

Touch CABIN MAINTENANCE on the CSCP main menu to show the cabin maintenance main menu.

Controls

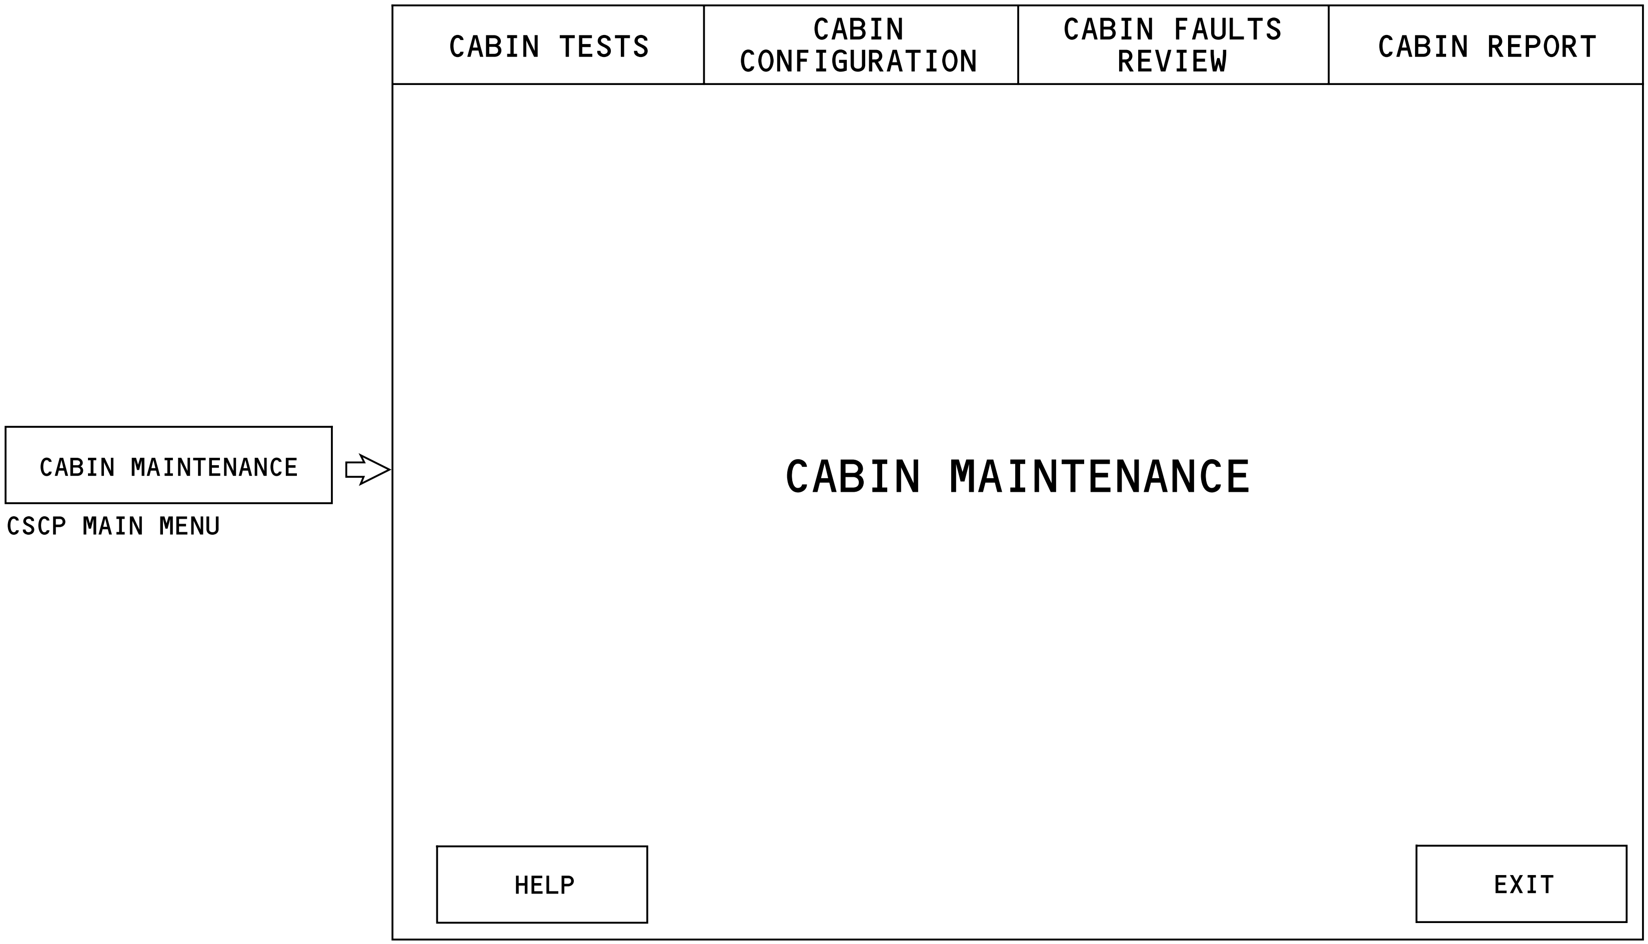
Touch any of these four selections at the top of this screen to do the related function:

- CABIN TESTS - start CSS tests and monitor test results
- CABIN CONFIGURATION - install software and see LRU hardware and software part numbers
- CABIN FAULTS REVIEW - review failure data including faults related to CSS flight deck effects
- CABIN REPORT - send fault and part number data to a cabin printer.

The four selections show at the top of all maintenance screens. You can select any of the four selections from any maintenance screen (except for dialogue windows).

Touch these selections at the bottom of the screen to do the related function:

- HELP - to go to the cabin maintenance menu tree. The menu tree shows cabin maintenance selections and gives access to additional data on cabin maintenance functions
- EXIT - to go back to the CSCP main menu.



CSCP SCREEN

23-39-00-652 Rev 0 06/17/96

CSS TEST AND SOFTWARE INSTALLATION - CABIN MAINTENANCE MAIN MENU

CSS TEST AND SOFTWARE INSTALLATION - CABIN MAINTENANCE MENU TREE

THIS PAGE INTENTIONALLY LEFT BLANK

CSS TEST AND SOFTWARE INSTALLATION - CABIN MAINTENANCE MENU TREE

General

The cabin maintenance menu tree gives you data for all the available selections on the maintenance menus.

Because of selections made in the configuration database generator or airline equipment options, some menu selections will not operate.

Access

To show the cabin maintenance menu tree, touch HELP on the cabin maintenance main menu.

Controls and Indications

The selections at the top of the menu tree show general data about these four top-level selections available on all maintenance screens:

- Cabin Tests
- Cabin Configuration
- Cabin Faults Review
- Cabin Report.

Cabin Tests

The Cabin Tests selection shows you general data about the different tests of the CSS. Touch any of the four selections below Cabin Tests to see the help screen for that function.

These are the four cabin tests:

- Quick test; collects real-time failures for 20 seconds and shows them on the screen.
- All test; starts a full BITE of the CSS. The CSCP shows all failures the BITE finds.
- Engineering tests have a special use. Different functions have different engineering tests.
- Lamps test; lets you control cabin lights. It lets you visually check the operation of the lamps.

Cabin Configuration

The Cabin Configuration selection shows you general data about software installation and configuration checks of the CSS. Touch any of the three selections below Cabin Configuration to see the help screen for that function.

These are the three cabin configuration functions:

- You can select and install a configuration database in the CSS components.
- A software management menu lets you install operational programs in CSS LRUs and remove and load software programs in the CSCP memory.
- Use the configuration check to see the LRU part number data of CSS components installed in the airplane.

Cabin Faults Review

This selection shows you general data about faults review screens. Touch any of the six selections below

CSS TEST AND SOFTWARE INSTALLATION - CABIN MAINTENANCE MENU TREE

Cabin Faults Review to see the help screen for that function.

These are the different types of review screens:

- The quick test faults review shows the results of the last quick test.
- The all test faults review shows the results of the last all test.
- A data installation faults review screen shows the results of the last software installation.
- The flight deck effects faults (active) screen shows active CSS related flight deck effects (FDEs). The CSCP shows all active CSS related FDEs and the failure that caused the FDE.
- The flight deck effects faults (history) screen shows CSS related flight deck effects (FDEs) in memory. The CSCP shows as many as 99 of the last CSS related FDEs and the failures that caused each FDE.

Cabin Report Menu

This selection tells you how to make a paper copy of the faults results and configuration data. Touch any of the eight selections below cabin report to see the help screen for that function.

These are the different reports:

- A fault summary report that shows maintenance message numbers and the number of times they have occurred.
- A quick test faults report that shows the results of the last quick test.
- A report of the results of the last all test.
- A data installation report that contains failure descriptions from the last configuration database or operational program installation.
- A list of active CSS related FDEs and maintenance messages.
- A list all CSS related FDEs and maintenance messages in memory (history).
- A CSS configuration report that lists the hardware and software part numbers of the CSS related items installed in the airplane.
- The CSS configuration summary report shows part number data for CSS components.

CSS TEST AND SOFTWARE INSTALLATION - CABIN MAINTENANCE MENU TREE

CSS TEST AND SOFTWARE INSTALLATION - CABIN MAINTENANCE MENU TREE HELP WINDOW

General

The help menu tree dialogue windows give you data for the selection that was made on the cabin maintenance menu tree help window.

Access

To show the help menu tree dialogue window:

- Touch HELP on the cabin maintenance main menu
- Make a selection on the cabin maintenance menu tree.

Controls and Indications

The screen shows data for the selected function. If there is more data than fits in the window, use the up and down arrows at the right of the display to show more. The square in the scroll bar between the arrows shows the location of the displayed data in the data field.

Touch MENU TREE to return to the menu tree.

Touch MAIN MENU to show the cabin maintenance main menu.

Flight Deck Effects Faults (Active)

CABIN MAINTENANCE MENU TREE

HELP FOR Flight Deck Effects Faults (Active)

FLIGHT DECK EFFECT FAULTS (ACTIVE) shows fault information for failures that cause Cabin Services System-related EICAS messages. Active EICAS messages are messages that currently exist. Touch this selection to show the active FLIGHT DECK EFFECTS FAULTS.

The FLIGHT DECK EFFECTS FAULTS (ACTIVE) Screen has two parts: fault conditions and maintenance message data.

The top part of the screen shows the part number of the currently installed configuration database for the current leg.

The top part of the screen also shows, for each fault in the list of active Flight Deck Effects Faults, the date and the time of the faults occurrence.

The main part of the screen shows the maintenance message data. One maintenance message shows for each fault. The sequence number of each maintenance message

CSS TEST AND SOFTWARE INSTALLATION - CABIN MAINTENANCE MENU TREE HELP WINDOW

CSS TEST AND SOFTWARE INSTALLATION - CABIN TESTS MENU

General

You use the cabin tests menu to start tests of the CSS. There are four selections on the cabin tests menu:

- START QUICK TEST
- START ALL TEST
- ENGINEERING TESTS
- LAMPS TEST.

Access

Touch CABIN TESTS on any maintenance screen to go directly to the cabin tests menu.

Quick Test

You use a quick test to find major faults or during a turn-around. To start a quick test, touch START QUICK TEST. The test may operate for as long as 20 seconds and then shows the results.

All Test

You use an all test for a more complete test. Normally you use an all test when the airplane is in for overnight service. To start an all test, touch START ALL TEST. The test operates for approximately two minutes then shows the results.

Engineering Tests

Touch ENGINEERING TESTS to show the engineering tests menu.

Lamps Test

Touch LAMPS TEST to show the lamps test control screens.

CSS TEST AND SOFTWARE INSTALLATION - QUICK TEST FAULT RESULTS SCREEN

THIS PAGE INTENTIONALLY LEFT BLANK

CSS TEST AND SOFTWARE INSTALLATION - QUICK TEST FAULT RESULTS SCREEN

General

You use the quick test fault results screen to see failures found during the last quick test.

Access

You can select this screen from the quick test faults review screen. The faults review screen shows at the end of a quick test. To start a quick test:

- Touch CABIN TESTS on any maintenance screen
- Touch START QUICK TEST on the cabin tests menu
- Touch CONTINUE TEST on the quick test explanation window
- Touch ALL UNITS or an LRU type and then touch CONTINUE on the faults review screen.

You can also select the quick test fault results screen from the cabin faults review menu. To show the quick test faults review screen:

- Touch CABIN FAULTS REVIEW at the top of any maintenance screen
- Touch QUICK TEST FAULTS REVIEW on the cabin faults review menu
- Touch ALL UNITS or touch an LRU type on the quick test faults review screen
- Touch CONTINUE on the quick test faults review screen.

Controls and Indications

These are the three parts of the screen:

- Test conditions
- Maintenance message data
- Selection controls.

Test Conditions

The test conditions part of the screen shows this test data:

- Test type (quick test or all test)
- The configuration database part number installed at the time of the test.
- The date and time of the test
- The type of LRUs selected from the faults review screen
- The sequence of each maintenance message in the list of messages for the selected LRU type.

There is a HELP selection on the left. Touch HELP for data on how to use the screen.

Maintenance Message Data

Each page shows one maintenance message. The maintenance message shows data about each failure. There are three parts to the message:

- Fault description
- Maintenance message number

CSS TEST AND SOFTWARE INSTALLATION - QUICK TEST FAULT RESULTS SCREEN

- Recommended maintenance action.

The fault description identifies the failure condition detected by the test. It also identifies the component that found the fault.

You use the maintenance message number to find the corrective action in the fault isolation manual (FIM).

Some faults show as Latched. Most Latched faults are faults the system detects at power up. Some major faults are also latched during continuous monitor. Latched means the fault will stay in system memory until you take corrective action.

The recommended maintenance action identifies all the possible components or conditions that could cause the fault. The most probable cause shows first and the least probable cause shows last.

Each screen shows one maintenance message. Touch the down arrow to access additional messages. Touch the up arrow to return through the message list. The square on the scroll bar shows your position in the message list.

Selection Controls

Touch PREVIOUS MENU to show the cabin tests menu.

Touch PREVIOUS SCREEN to show the quick test faults review screen.

Touch SHOW LOCATION to show a visual reference of a defective component. If there is more than one defective component in the list of possible causes, another screen shows to let you select a component. Another screen will then show you the location of the component you selected.

Touch UNIT USAGE to show the components controlled by the defective component. If there is more than one defective component in the list of possible causes, another screen shows to let you select a component. Another screen will then show you the unit usage of the component you selected.

Touch SAVE to send the data to a diskette in the CSCP disk drive.

Touch PRINT to send the data to the printer for a paper copy.

Touch MAIN MENU to show the cabin maintenance menu.

Training Information Point

To determine if a fault is still active you must do a new test.

23-39-00-669 Rev 0 06/17/96

CSS TEST AND SOFTWARE INSTALLATION - ALL TEST FAULT RESULTS SCREEN

THIS PAGE INTENTIONALLY LEFT BLANK

CSS TEST AND SOFTWARE INSTALLATION - ALL TEST FUNCTIONAL DESCRIPTION

General

The all test does a complete check of the CSS. You use the cabin system control panel (CSCP) to start the test and see the results.

To do an all test, at least one of these conditions must be true:

- Airplane is on ground
- Parking brake is set
- At least one passenger door is open.

Components

All the CSS components that use microprocessors have BITE circuits. These components use microprocessors:

- Cabin system control panel (CSCP)
- Cabin system management unit (CSMU)
- Passenger address/cabin interphone (PA/CI) controller
- Speaker drive modules (SDMs)
- Zone management units (ZMUs)
- Overhead electronics units (OEUs)
- Cabin area control panels (CACPs)

Operation

The BITE circuits check system operation. They do a complete test of internal operation and check interfaces. The BITE circuits also do a test of connected components that do not have a microprocessor.

The CSMU sends BITE commands to the PA/CI controller and ZMUs on the intersystem (I/S) bus. The CSMU gets failure data from the LRUs and sends them to the CSCP. The CSCP processes the data and keeps it in nonvolatile memory (NVM). You review the failure data at the CSCP on the all test fault results screen.

The PA/CI controller sends BITE commands to its SDMs. It sends failure data from SDMs and its own internal failures to the CSMU on the I/S bus. If the PA/CI does not get data from the SDM or it is out of tolerance, the PA/CI sends a failure message for that SDM.

Each ZMU sends BITE commands to its connected components. A ZMU sends its own internal failures and failure data from its OEUs and CACP to the CSMU on the I/S bus. The ZMUs also check the cabin attendant handsets (CAHs) and master call lights. If a ZMU does not get data from one of its LRUs or the data is out of tolerance, the ZMU sends a failure message for that LRU.

The SDMs do a test of the speakers and the ambient noise sensors (ANSs). The SDMs send failure data to the PA/CI controller.

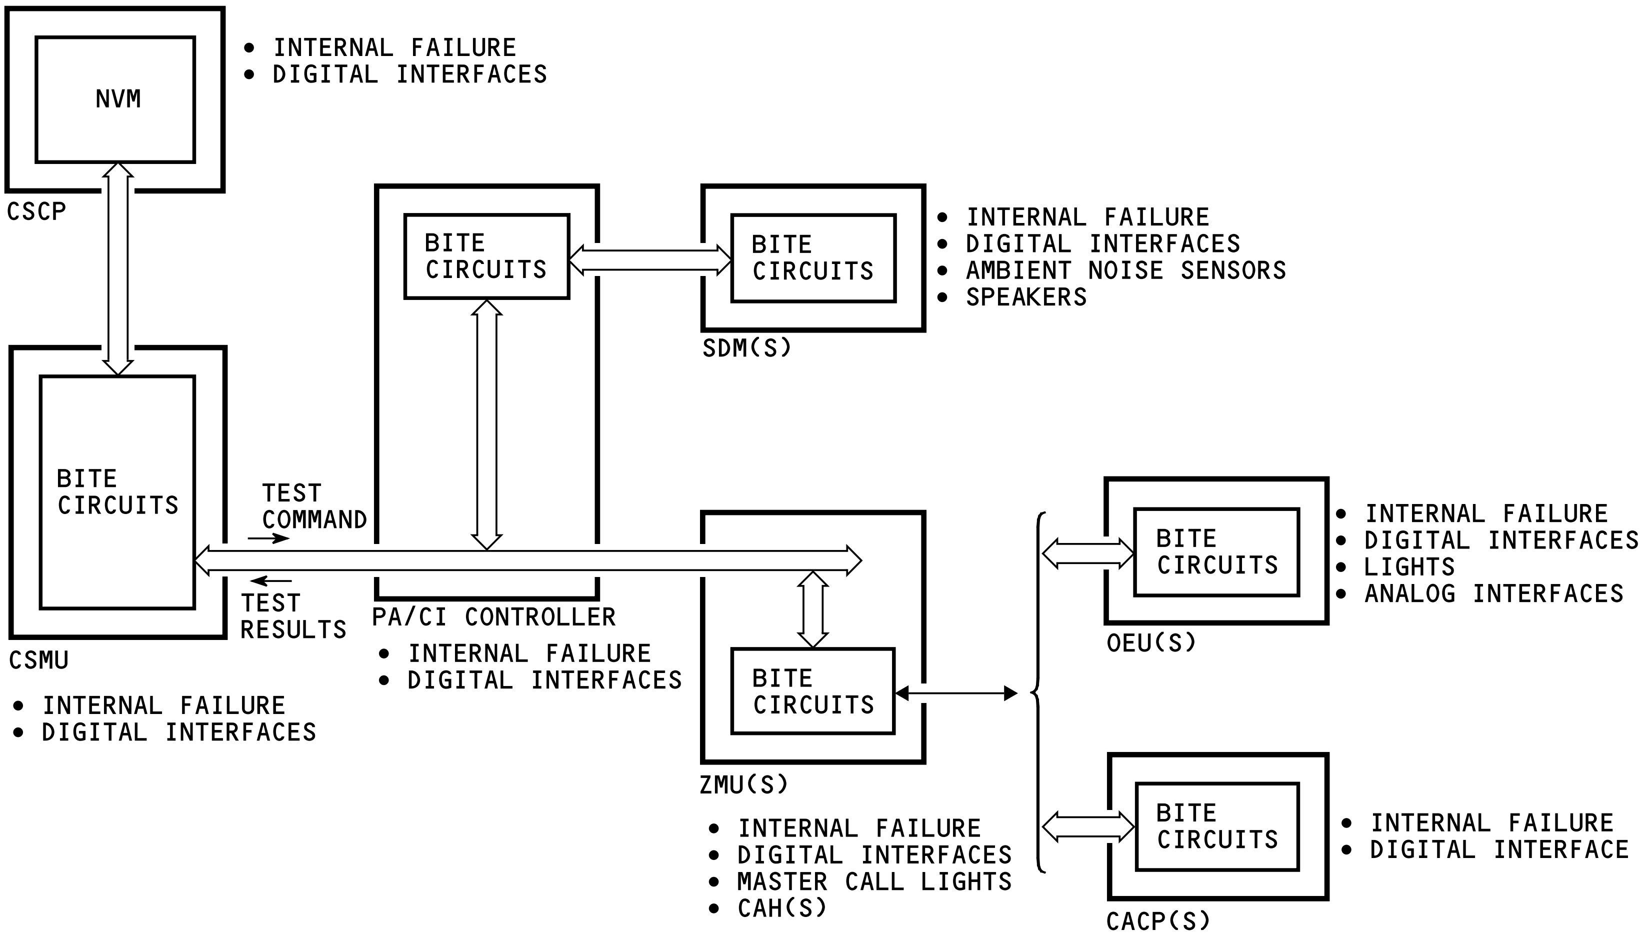
The OEUs do a test of all lights and ballasts they control. They also check their discrete and analog inputs such as smoke detectors and tank sensors.

CSS TEST AND SOFTWARE INSTALLATION - ALL TEST FUNCTIONAL DESCRIPTION

Fault Processing

The CSMU sends all fault data to the CSCP. The CSCP processes all fault data and stores it in memory.

The CSCP looks at the fault data to identify if multiple fault indications can be from one failure. If it is, the CSCP combines the fault indications into one maintenance message. This procedure is called fault consolidation.



23-39-00-670 Rev 0 06/17/96

CSS TEST AND SOFTWARE INSTALLATION - ALL TEST FUNCTIONAL DESCRIPTION

CSS TEST AND SOFTWARE INSTALLATION - LAMPS TEST SCREEN - PAGE 1

General

The lamps test screen lets you control lights controlled by the CMS. You use this to see the operation of the lamps. There are two pages to the lamps test screen.

Access

To show the page one of the lamps test screen, touch CABIN TESTS at the top of any maintenance screen, then touch LAMPS TEST on the cabin tests menu.

Controls and Indications

Touch ON next to ALL to set all lights controlled by the CSS to on. The selection shows green. Touch OFF to set them all to off.

To check a type of light, touch one of the selections next to the name of a light type. All of the selected lights change to the set condition. The selection shows green.

Touch NEXT PAGE to show page two of the lamps test screen.

When you touch RESET ALL, it shows green. Then touch any other screen selection, except NEXT PAGE, to put all lights back to their initial condition.

Touch PREVIOUS MENU to show the cabin tests menu.

Touch MAIN MENU to show the cabin maintenance menu.

CSS TEST AND SOFTWARE INSTALLATION - LAMPS STATES RESET WINDOW

CSS TEST AND SOFTWARE INSTALLATION - ENGINEERING TESTS MENU TREE

General

Each engineering test is for a special use. You normally use engineering tests for detailed troubleshooting.

The engineering tests menu has these selections:

- INPUT/OUTPUT MONITOR
- COMMAND OUTPUT
- SHOP FAULTS
- INSTALL ADDRESSES
- EXTENDED CABIN FAULTS REVIEW.

Sub-Menus

These four selections have sub-menus:

- INPUT/OUTPUT MONITOR
- COMMAND OUTPUT
- SHOP FAULTS
- EXTENDED CABIN FAULTS REVIEW.

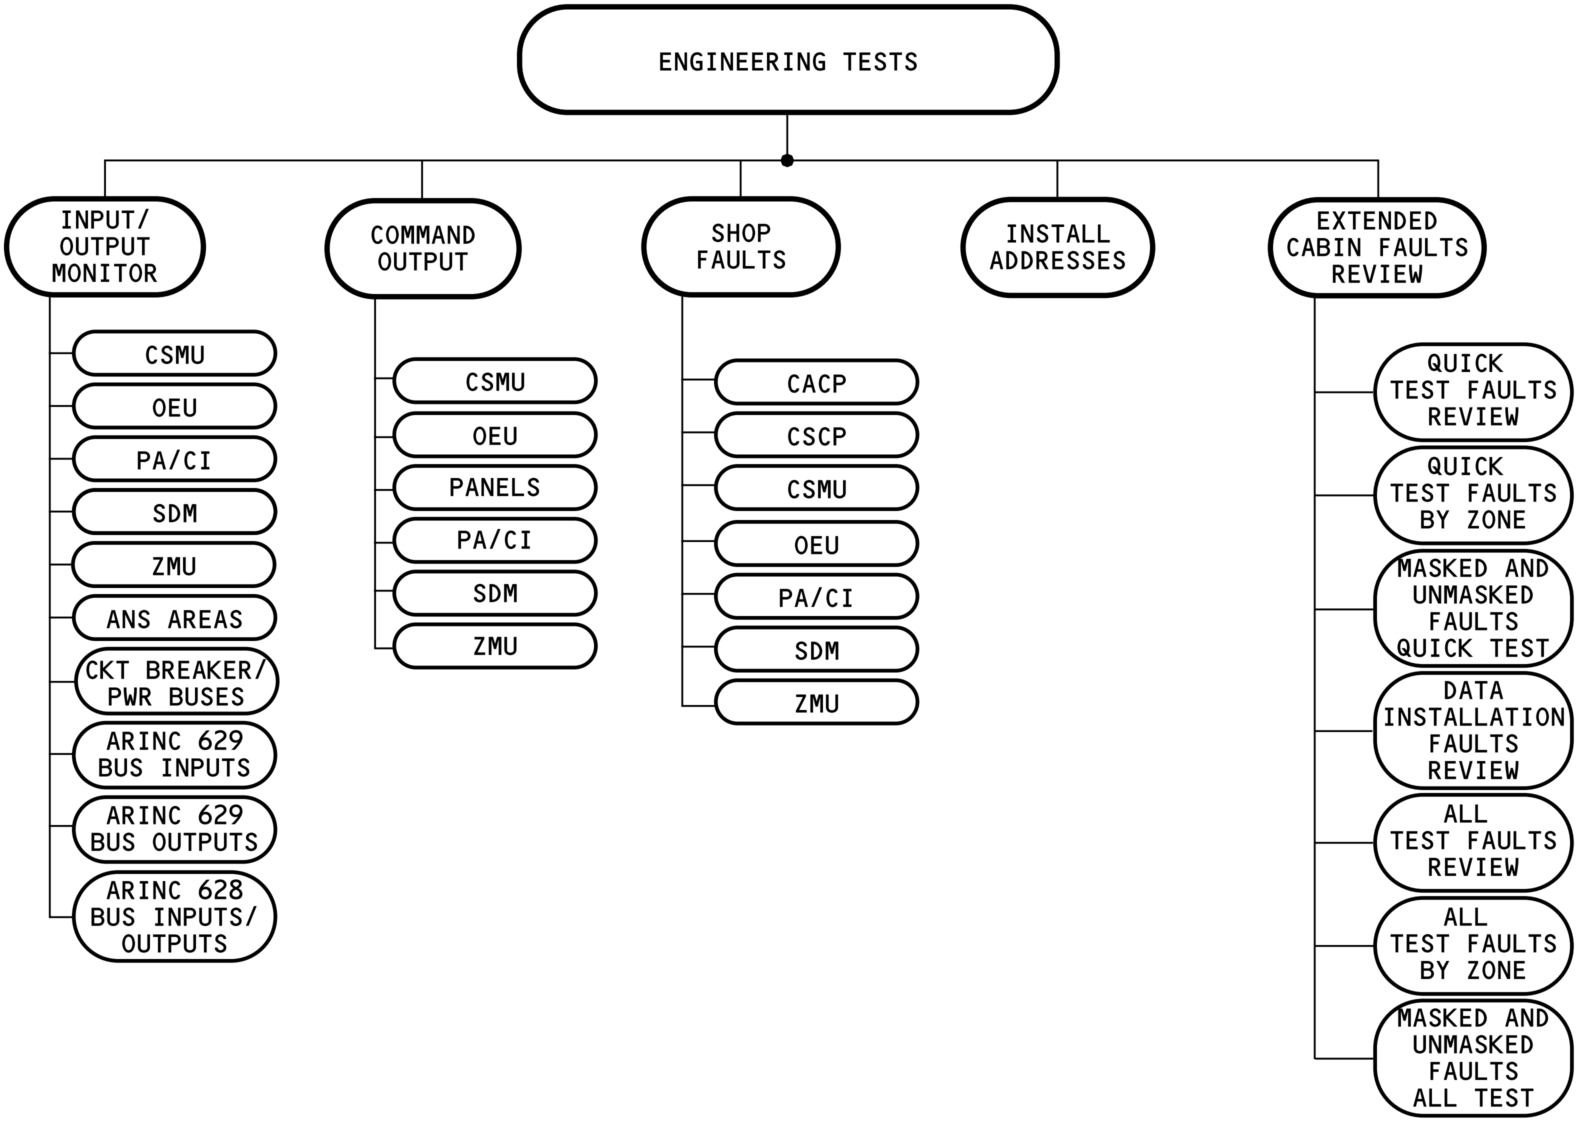
You use the input/output monitor to examine the condition of all the interfaces to a selected LRU. The input/output monitor menu gives selections for the LRUs you can monitor.

You use command output to set an output from an LRU. This lets you make sure the output is operational. The command output menu shows the LRUs for which you can set outputs.

You use shop faults to show the details of LRU internal failures. The shop faults menu shows from which LRU you can get shop fault data.

You use the extended cabin faults review to review test and installation faults. The menu gives selections for the tests and installation fault screens you can see.

You use install addresses to do engineering tests without a configuration database installed.



23-39-00-674 Rev 0 06/17/96

CSS TEST AND SOFTWARE INSTALLATION - ENGINEERING TESTS MENU TREE

CSS TEST AND SOFTWARE INSTALLATION - ENGINEERING TESTS MENU

General

You use the engineering tests menu for detailed trouble-shooting.

Access

To show the engineering test menu, touch CABIN TESTS at the top of any maintenance screen, then touch ENGINEERING TESTS on the cabin tests menu.

Controls and Indications

These selections cause other menus to show:

- INPUT/OUTPUT MONITOR
- COMMAND OUTPUT
- SHOP FAULTS
- EXTENDED CABIN FAULTS REVIEW.

Touch PREVIOUS MENU to show the cabin maintenance menu.

Touch MAIN MENU to show the cabin maintenance menu.

CSS TEST AND SOFTWARE INSTALLATION - ENGINEERING TESTS MENU

CSS TEST AND SOFTWARE INSTALLATION - INPUT/OUTPUT MONITOR MENU

General

You use the input/output monitor tests to examine the condition of the interfaces to a CSS component. You use the input/output monitor menu to select the type of component.

Access

To show the input/output monitor menu:

- Touch CABIN TESTS on any maintenance screen
- Touch ENGINEERING TESTS on the cabin test menu
- Touch INPUT/OUTPUT MONITOR on the engineering tests menu.

Controls and Indications

You can monitor the interfaces to these components:

- Cabin system management unit (CSMU)
- Overhead electronics units (OEUs)
- Passenger address/cabin interphone (PA/CI) controller
- Speaker drive modules (SDMs)
- Zone management units (ZMUs)
- Ambient noise sensors (ANSs).

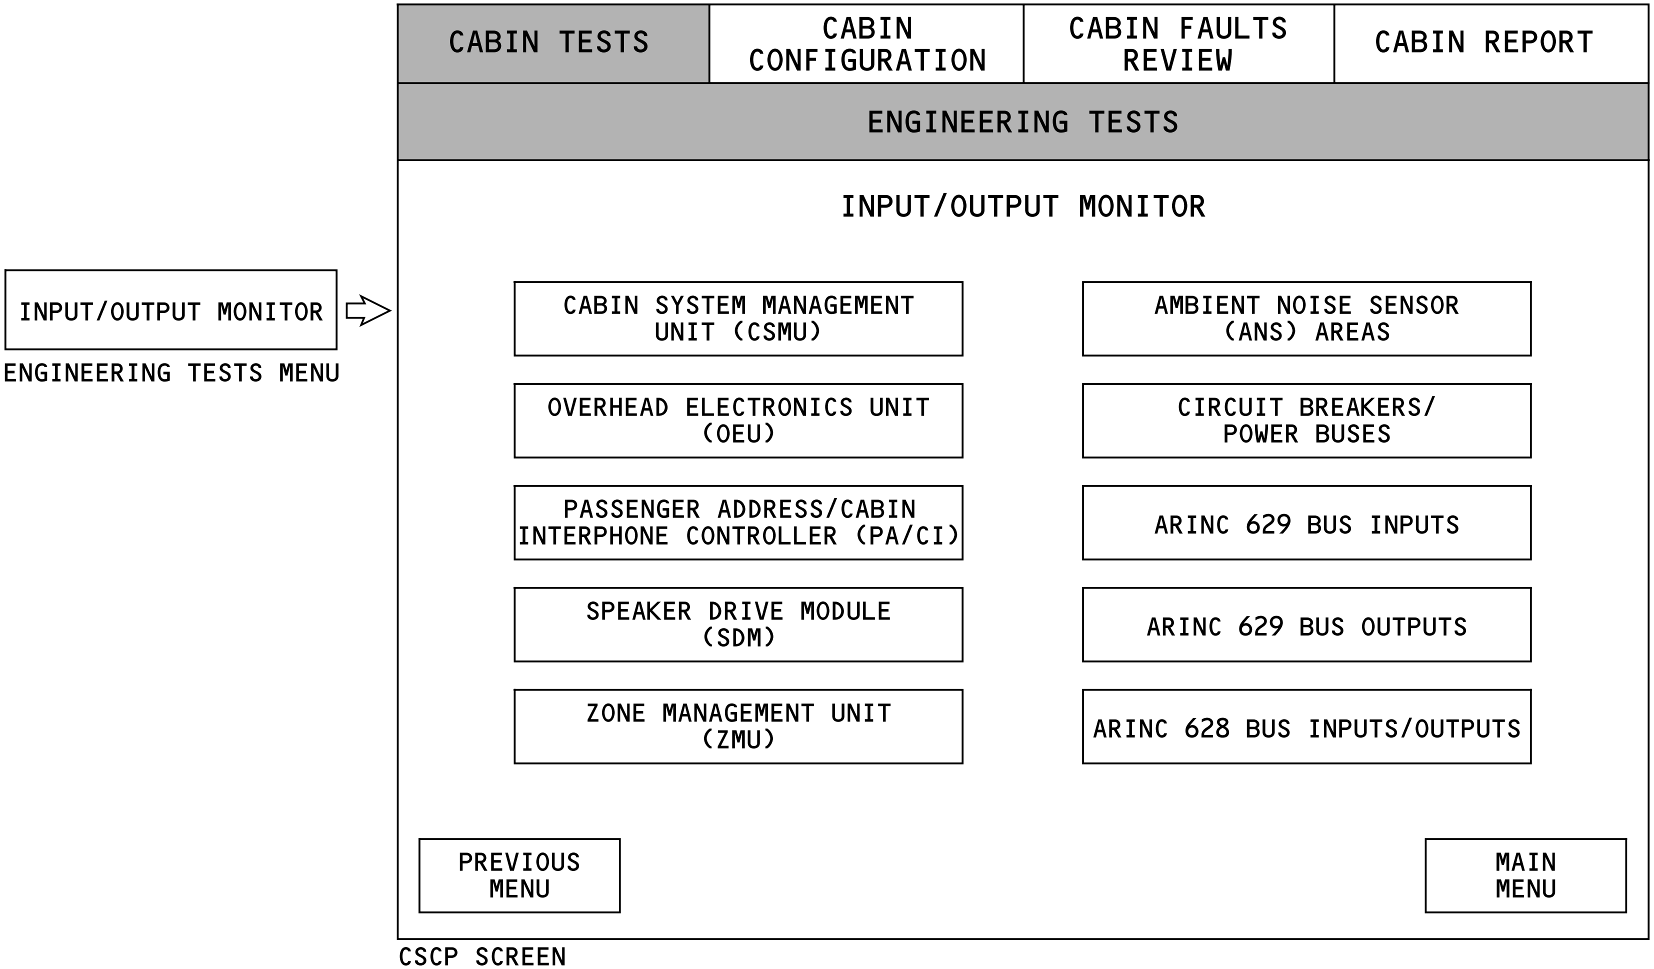
To select a component, touch the applicable selection.

You can also monitor the position of CSS circuit breakers and the condition of the connected power bus.

You can also monitor the inputs and outputs of the ARINC 629 and ARINC 628 data buses.

Touch PREVIOUS MENU to show the engineering tests menu.

Touch MAIN MENU to show the cabin maintenance menu.



23-39-00-676 Rev 0 06/17/96

CSS TEST AND SOFTWARE INSTALLATION - INPUT/OUTPUT MONITOR MENU

CSS TEST AND SOFTWARE INSTALLATION - INPUT MONITOR - ANS AREA SELECTION

General

You use the input monitor - ANS area selection to monitor the input levels of ambient noise sensors (ANSs) in an area of the cabin.

Access

To show this screen:

- Touch CABIN TESTS on any maintenance screen
- Touch ENGINEERING TESTS on the cabin test menu
- Touch INPUT/OUTPUT MONITOR on the engineering tests menu
- Touch AMBIENT NOISE SENSOR (ANS) AREA on the input/output monitor menu.

Controls and Indications

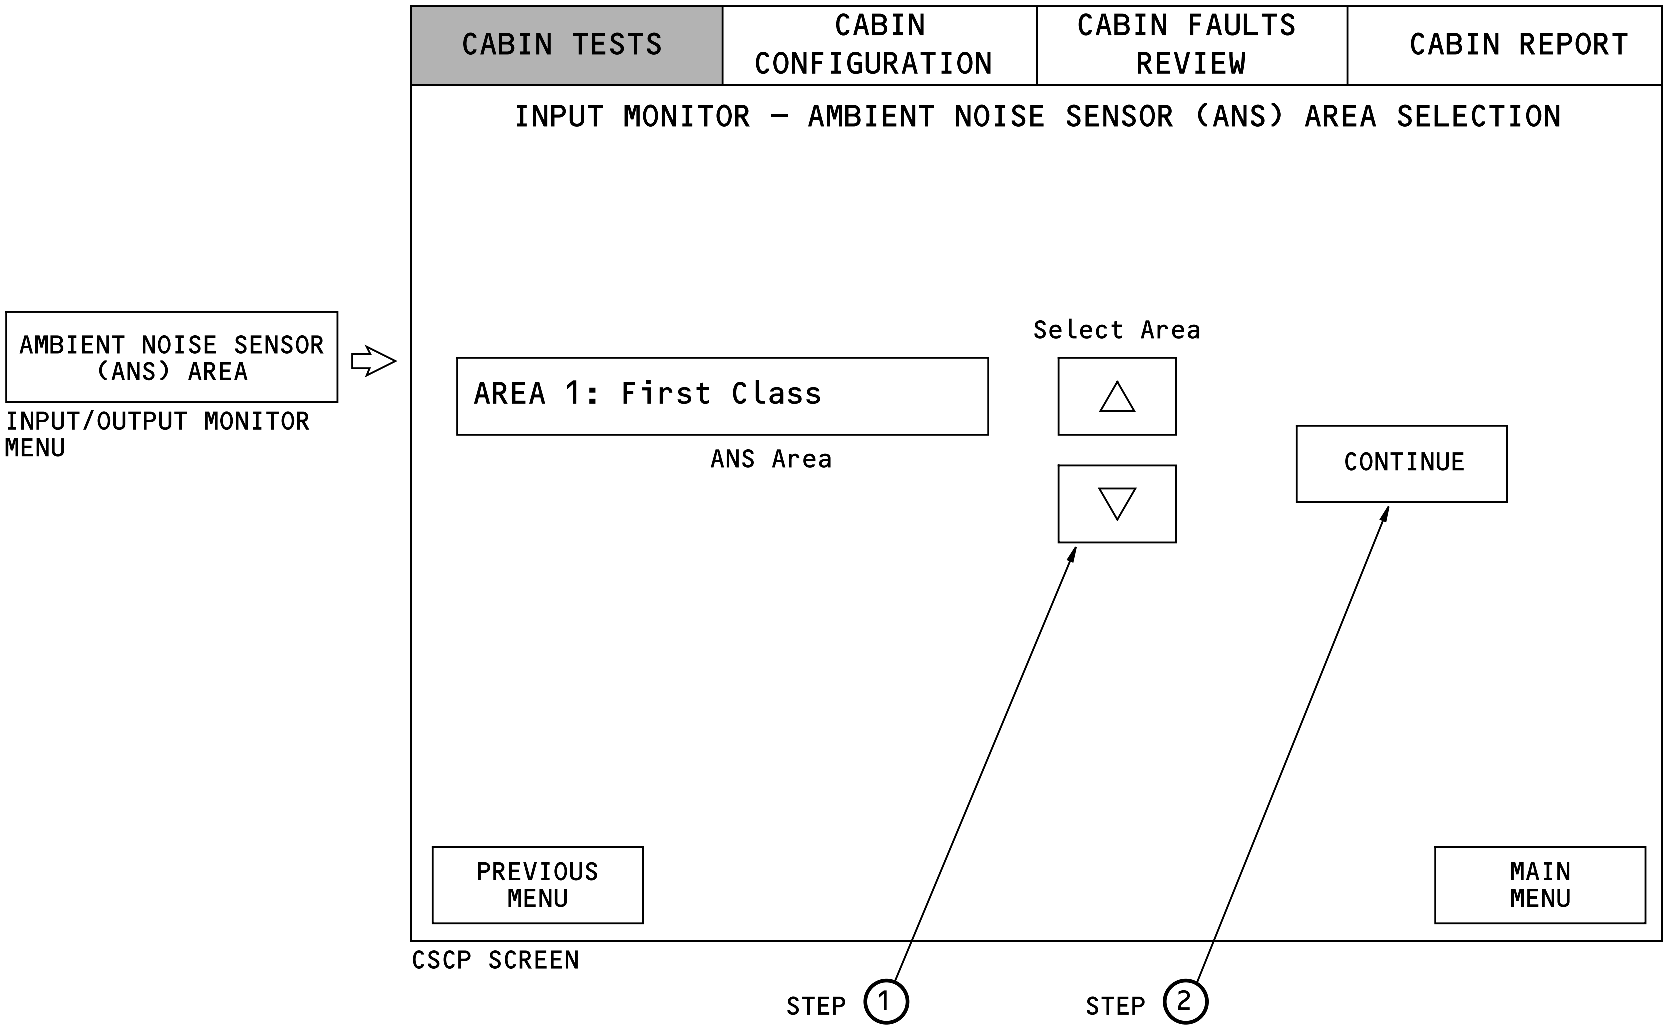
To select an ANS area, use the up or down arrow below Select Area. The CSS can have as many as 16 volume control areas. The configuration database defines the number of areas.

The area you select shows at the left of the arrows above ANS area.

After you select an area, touch CONTINUE to show the input monitor - ANS area screen.

Touch PREVIOUS MENU to show the input/output monitor menu.

Touch MAIN MENU to show the cabin maintenance menu.



23-39-00-677 Rev 0 06/18/96

CSS TEST AND SOFTWARE INSTALLATION - INPUT MONITOR - ANS AREA SELECTION

CSS TEST AND SOFTWARE INSTALLATION - INPUT MONITOR - ANS AREA SCREEN

General

You use this screen to examine the inputs from ambient noise sensors (ANSs) in an area.

Access

To show the input monitor - ANS area screen:

- Touch CABIN TESTS on any maintenance screen
- Touch ENGINEERING TESTS on the cabin test menu
- Touch INPUT/OUTPUT MONITOR on the engineering tests menu
- Touch AMBIENT NOISE SENSOR (ANS) AREAS on the input/output monitor menu
- Select an area and touch CONTINUE on the ANS area selection screen.

Controls and Indications

The screen shows the time at the top.

A window below the time shows the average value of the ANS inputs for the area.

Another window shows each speaker drive module (SDM) in the area that has an ANS connected to it. This window gives the address and location of each SDM. It also shows the input of the related ANS.

Touch PREVIOUS MENU to show the input/output monitor menu.

Touch PREVIOUS SCREEN to show the ANS area selection screen.

Touch FREEZE so the screen does not change if the condition of an interface changes.

Touch SAVE to send the data to a floppy diskette in the cabin system control panel (CSCP) disk drive.

Touch PRINT to send the data to the cabin printer.

Touch MAIN MENU to show the cabin maintenance menu.

CSS TEST AND SOFTWARE INSTALLATION - INPUT MONITOR - ANS AREA SCREEN

CSS TEST AND SOFTWARE INSTALLATION - INPUT/OUTPUT MONITOR - OEU SELECTION

General

You use the input/output monitor - OEU test to examine the condition of the interfaces to an overhead electronics unit (OEU). You use the input/output monitor - OEU selection screen to select the OEU.

Access

To show this screen:

- Touch CABIN TESTS on any maintenance screen
- Touch ENGINEERING TESTS on the cabin test menu
- Touch INPUT/OUTPUT MONITOR on the engineering tests menu
- Touch OVERHEAD ELECTRONICS UNIT (OEU) on the input/output monitor menu.

Controls and Indications

To select an OEU, first select a zone with the up or down arrow below Select Zone. The CSS can have as many as five zones (one for each zone management unit).

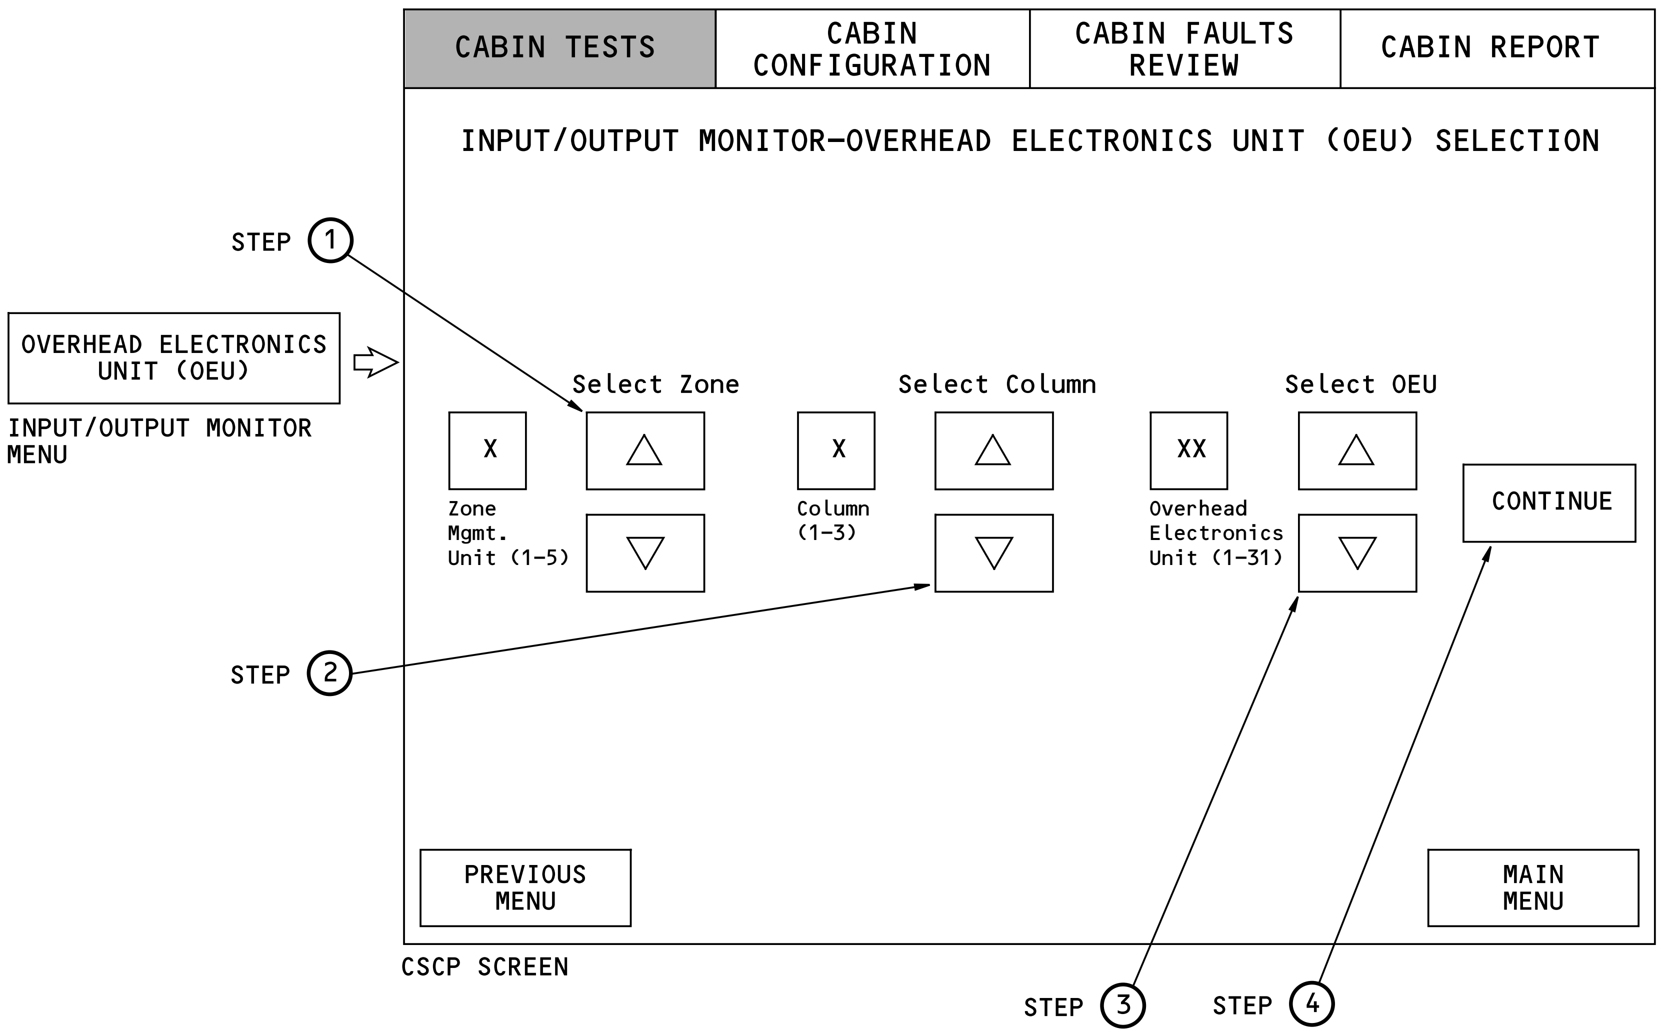
After you select a zone, select a column. Each zone has three columns (1 for left, 2 for center, and 3 for right). To select a column, touch the up or down arrows under Select Column.

After you select a column, select an OEU. The OEU number relates to the sequence in the column. The first OEU in a column is number one, the second is number two. To select an OEU, touch the up or down arrows under Select OEU. The CSS can have as many as 31 OEUs in a column.

After you select an OEU, touch CONTINUE to show the input/output monitor - OEU screen.

Touch PREVIOUS MENU to show the input/output monitor menu.

Touch MAIN MENU to show the cabin maintenance menu.



23-39-00-679 Rev 0 06/17/96

CSS TEST AND SOFTWARE INSTALLATION - INPUT/OUTPUT MONITOR - OEU SELECTION

CSS TEST AND SOFTWARE INSTALLATION - INPUT/OUTPUT MONITOR - OEU SCREEN

General

You use this screen to examine the condition of the interfaces of an overhead electronics unit (OEU).

Access

To show the input/output monitor - OEU screen:

- Touch CABIN TESTS on any maintenance screen
- Touch ENGINEERING TESTS on the cabin test menu
- Touch INPUT/OUTPUT MONITOR on the engineering tests menu
- Touch OVERHEAD ELECTRONICS UNIT (OEU) on the input/output monitor menu
- Select an OEU and touch CONTINUE on the OEU selection screen.

Controls and Indications

The screen shows the time at the top.

The OEU data window show the OEU address and location.

The OEU data window gives this data for each OEU interfaces:

- Input (IN) or output (OUT)
- Connector pin number
- Type of interface (analog, discrete, shop, token, or lamp control)
- The condition of the interface (voltage, ground or open, active or not active).

Touch PREVIOUS MENU to show the input/output monitor menu.

Touch PREVIOUS SCREEN to show the OEU selection screen.

Touch FREEZE so the screen does not change if the condition of an interface changes.

Touch SAVE ALL to send the data to a floppy diskette in the cabin system control panel (CSCP) disk drive.

Touch PRINT ALL to send the data to the cabin printer.

Touch MAIN MENU to show the cabin maintenance menu.

CSS TEST AND SOFTWARE INSTALLATION - INPUT MONITOR - CKT BREAKER/POWER BUS

General

You use this screen to examine the position of CSS circuit breakers and the condition of the power buses.

Access

To show the input monitor-circuit breaker/power buses screen:

- Touch CABIN TESTS on any maintenance screen
- Touch ENGINEERING TESTS on the cabin test menu
- Touch INPUT/OUTPUT MONITOR on the engineering tests menu
- Touch CIRCUIT BREAKER/POWER BUSES on the input/output monitor menu.

Controls and Indications

The screen shows the time at the top.

The power buses off data window shows the electrical power buses that have no power. The scroll bar shows on the right of the window when the number of buses off is more than the window can show.

The circuit breakers off data window shows the CSS circuit breakers that are out. The scroll bar shows on the right of the window when the number of circuit breakers out is more than the window can show.

The passenger entertainment/service power shows OFF when the seat power is off.

Touch PREVIOUS MENU to show the input/output monitor menu.

Touch FREEZE so the screen does not change when the condition of an interface changes.

Touch SAVE ALL to send the data to a floppy diskette in the cabin system control panel (CSCP) disk drive.

Touch PRINT ALL to send the data to the cabin printer.

Touch MAIN MENU to show the cabin maintenance menu.

CSS TEST AND SOFTWARE INSTALLATION - INPUT MONITOR - CKT BREAKER/POWER BUS

CSS TEST AND SOFTWARE INSTALLATION - INPUT MONITOR - ARINC 629 INPUTS

General

You use the input monitor-ARINC 629 inputs screen to examine the data on the left and right systems ARINC 629 data buses.

Access

To show this screen:

- Touch CABIN TESTS on any maintenance screen
- Touch ENGINEERING TESTS on the cabin test menu
- Touch INPUT/OUTPUT MONITOR on the engineering tests menu
- Touch INPUTS next to ARINC 629 BUS on the input/ output monitor menu.

Controls and Indications

The screen shows the time at the top.

Touch HELP for more information on this screen.

The data window shows CSS related data on the left and right systems ARINC 629 buses.

Each row shows data for one ARINC 629 word. The word label shows at the left in hexadecimal format. The signal name shows adjacent to the label. The bus name shows adjacent to the signal name (LEFT for left systems ARINC 629 bus, RIGHT for right systems ARINC 629 bus). The word data shows on the right.

To show more data, touch the up or down arrow. The box shows your position in the data list.

Touch PREVIOUS MENU to show the input/output monitor menu.

Touch FREEZE so the screen does not change when the condition of the data changes.

Touch SAVE ALL to send the data to a floppy diskette in the cabin system control panel (CSCP) disk drive.

Touch PRINT ALL to send the data to the cabin printer for a paper report.

Touch MAIN MENU to show the cabin maintenance menu.

23-39-00-686 Rev 0 06/17/96

CSS TEST AND SOFTWARE INSTALLATION - COMMAND OUTPUT MENU

CSS TEST AND SOFTWARE INSTALLATION - COMMAND OUTPUT - OEU

General

You use the command output - OEU screen to set outputs of an overhead electronics unit (OEU).

Access

To show the command output menu:

- Touch CABIN TESTS on any maintenance screen
- Touch ENGINEERING TESTS on the cabin test menu
- Touch COMMAND OUTPUT on the engineering tests menu
- Touch OVERHEAD ELECTRONICS UNIT (OEU) on the command output menu.

Controls and Indications

You use the upper section of the screen to select an OEU.

To select an OEU, first select a zone with the up or down arrow below Select Zone. The CSS can have as many as five zones (one for each zone management unit).

After you select a zone, select a column. Each zone has three columns (1 for left, 2 for center, and 3 for right). To select a column, touch the up or down arrows under Select Column.

After you select a column, you select an OEU. The OEU number is its sequence in the column. The first OEU in a column is number 1, the second is number two. To select an OEU, touch the up or down arrows under Select OEU. The CSS can have as many as 31 OEUs in a column.

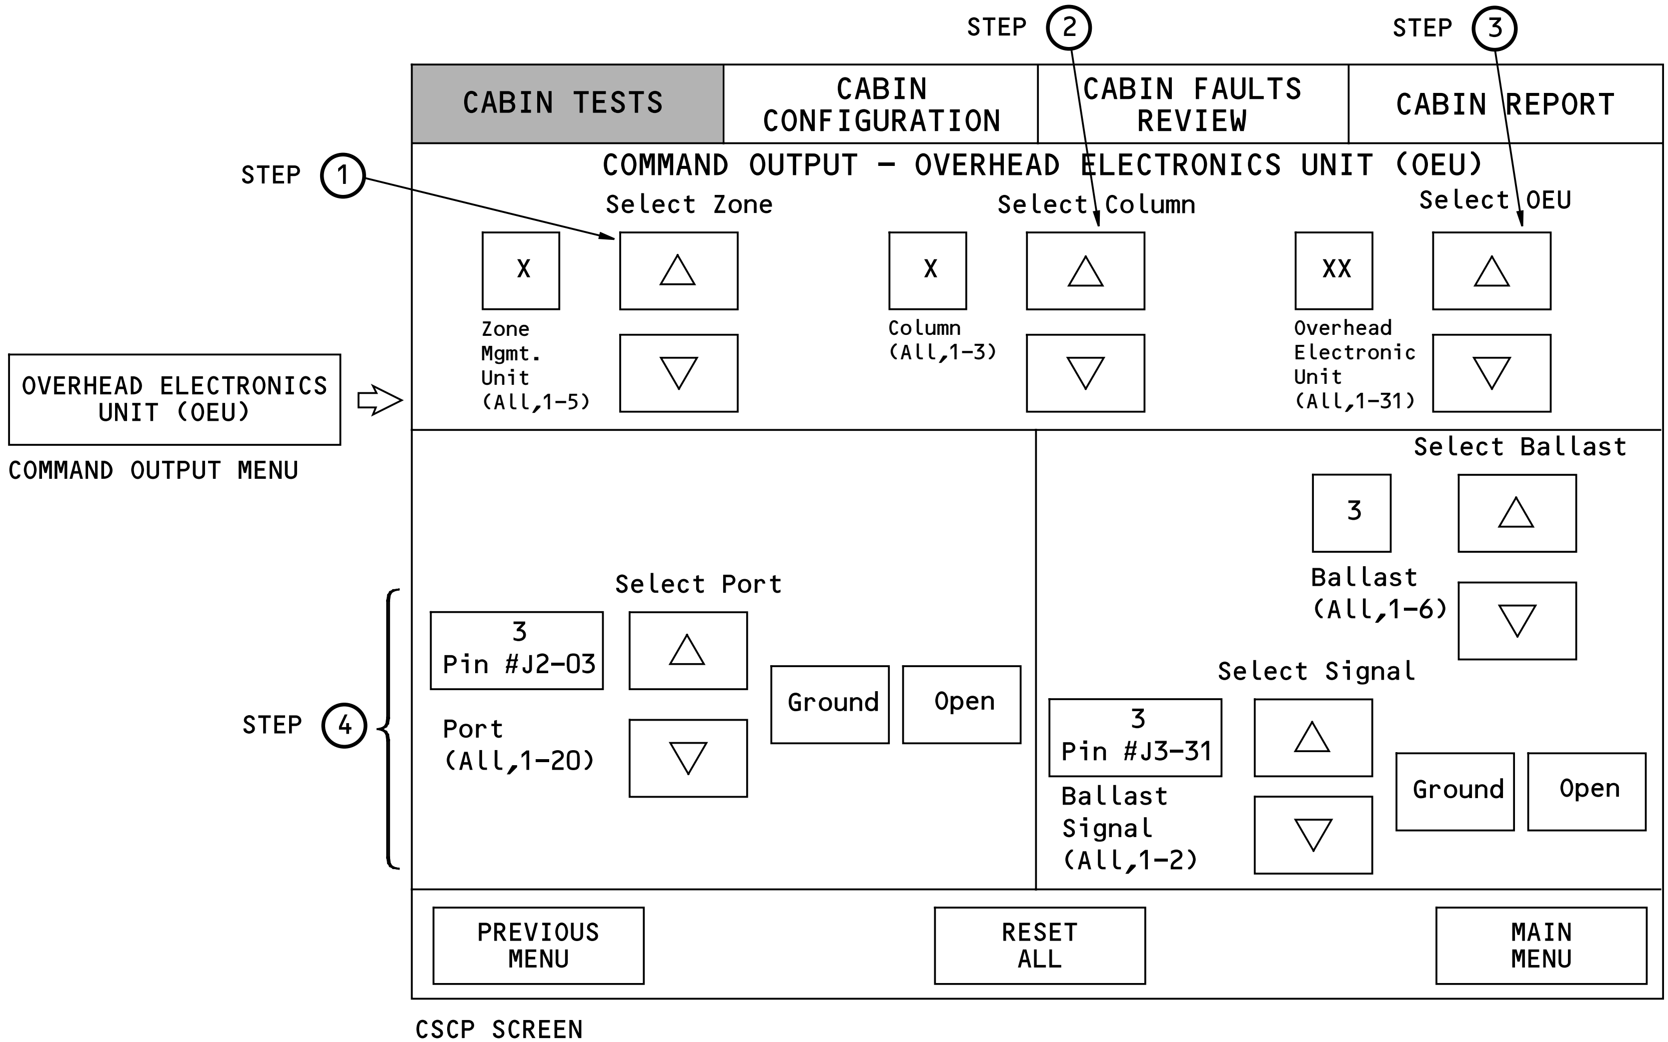
You use the lower left section of the screen to set a port output. There are twelve ports on an OEU. Touch the up or down arrows to select a port. The selected port number and connector pin number show next to the arrows. If you select all ports, ALL shows. After you select a port, touch either GROUND or OPEN to set the output.

You use the lower right section of the screen to set a ballast output. There are four ballasts to an OEU. You select a ballast in the same way that you select a port.

Touch PREVIOUS MENU to show the command output menu.

Touch RESET ALL to set the ports and ballasts back to their initial condition.

Touch MAIN MENU to show the cabin maintenance menu.



23-39-00-687 Rev 0 06/17/96

CSS TEST AND SOFTWARE INSTALLATION - COMMAND OUTPUT - OEU

CSS TEST AND SOFTWARE INSTALLATION - COMMAND OUTPUT - SDM

General

You use the command output - SDM screen to cause the speaker drive modules (SDMs) to make noise.

Access

To show the command output menu:

- Touch CABIN TESTS on any maintenance screen
- Touch ENGINEERING TESTS on the cabin test menu
- Touch COMMAND OUTPUT on the engineering tests menu
- Touch SPEAKER DRIVE MODULE (SDM) on the command output menu.

Controls and Indications

Touch the column select arrows to select one or all columns (zones). There can be as many as five columns.

Touch the SDM select arrows to select one or more SDMs. There can be as many as 25 SDMs in a column.

Touch SPEAKER 1 ON and SPEAKER 2 ON to cause the SDMs to make noise. Each SDM has one or two speakers.

Touch RESET ALL to stop the random noise.

Touch PREVIOUS MENU to show the command output menu.

Touch MAIN MENU to show the cabin maintenance menu.

CSS TEST AND SOFTWARE INSTALLATION - EXTENDED CABIN FAULTS REVIEW MENU

THIS PAGE INTENTIONALLY LEFT BLANK

CSS TEST AND SOFTWARE INSTALLATION - EXTENDED CABIN FAULTS REVIEW MENU

General

You use the extended cabin faults review menu to show failure data for the CSS. These are the seven selections on the extended cabin faults review menu:

- QUICK TEST FAULTS REVIEW
- QUICK TEST FAULTS REVIEW BY ZONE
- MASKED AND UNMASKED FAULTS REVIEW (QUICK TEST)
- DATA INSTALLATION FAULTS REVIEW
- ALL TEST FAULTS REVIEW
- ALL TEST FAULTS REVIEW BY ZONE
- MASKED AND UNMASKED FAULTS REVIEW (ALL TEST).

Access

To show the extended cabin faults review menu, do this:

- Touch CABIN TESTS on any maintenance screen
- Touch ENGINEERING TESTS
- Touch EXTENDED CABIN FAULTS REVIEW.

Quick Test Faults Review

Touch QUICK TEST FAULTS REVIEW to show the faults review screen from the last quick test. See the quick test description for more information.

Quick Test Faults Review by Zone

Quick test faults review by zone is the same as quick test faults review but you can look at faults for a specified zone. You use this when you do trouble-shooting within a cabin zone.

Masked and Unmasked Faults Review (Quick Test)

Normally, quick test only shows unmasked faults. Masked faults are faults that do not normally show because the configuration database prevents them. Touch MASKED AND UNMASKED FAULTS REVIEW (QUICK TEST) to show both masked and unmasked faults from the last quick test.

Data Installation Faults Review

Touch DATA INSTALLATION FAULTS REVIEW to show an installation fault results screen from the last database or operational program installation. For more information on data installation, see the database or operational program installation description.

All Test Faults Review

Touch ALL TEST FAULTS REVIEW to show the faults review screen from the last all test. See the all test description for more information.

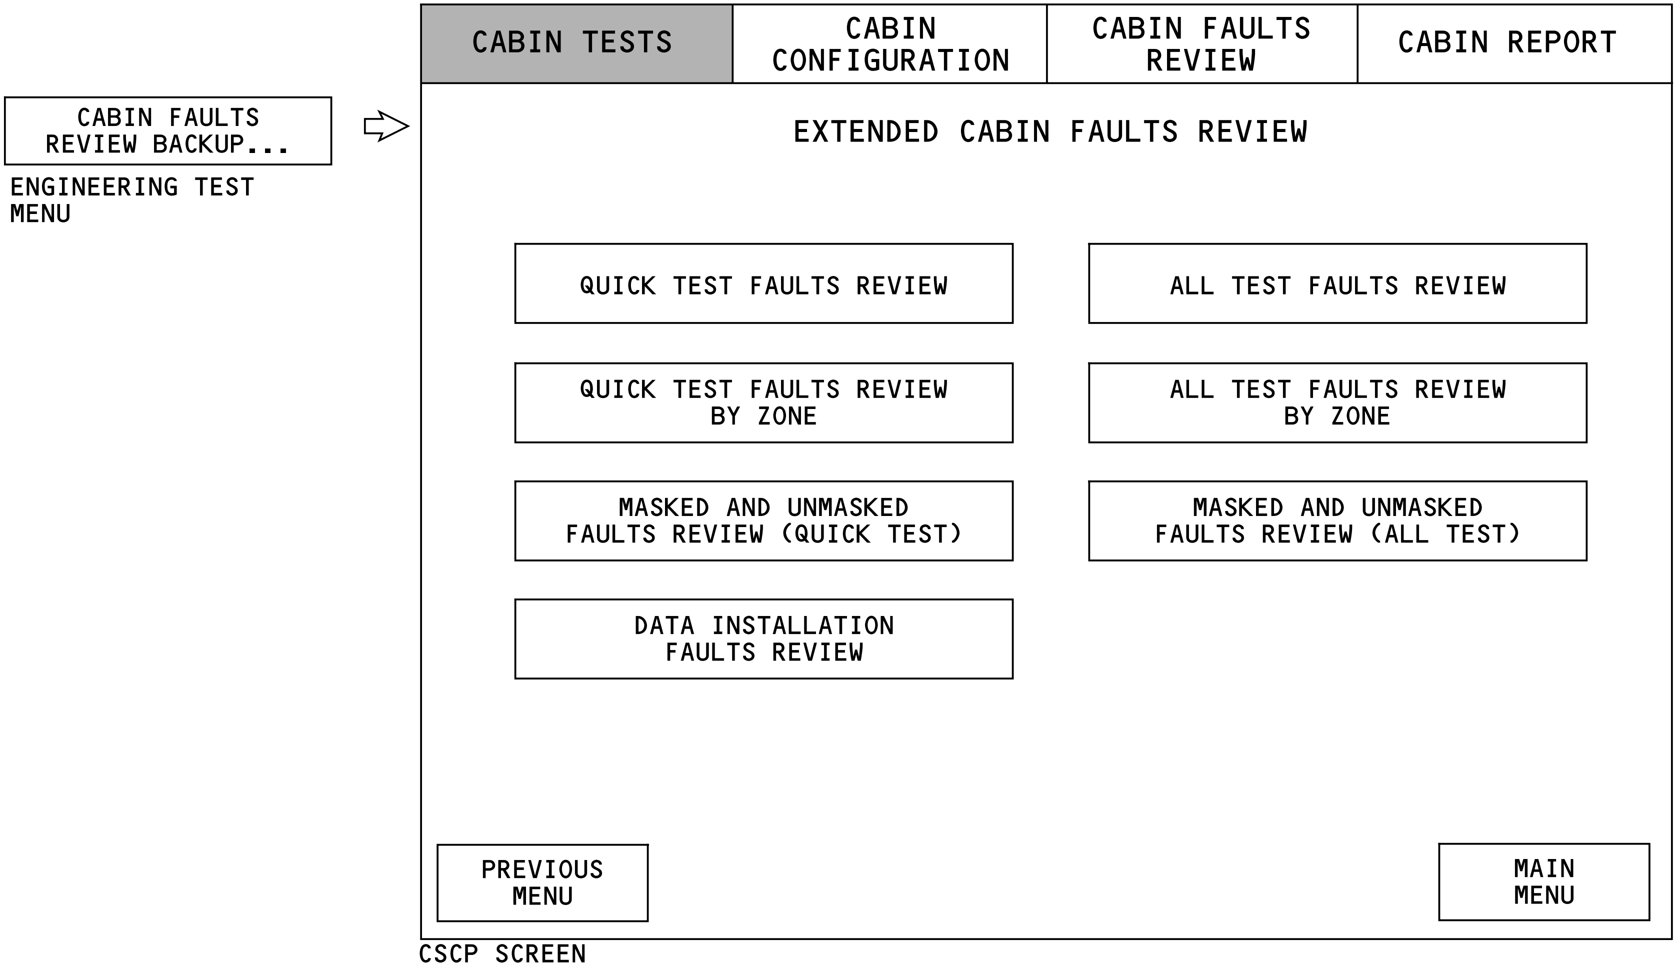
All Test Faults Review by Zone

All test faults review by zone is the same as all test faults review but you can look at faults for a specific zone. You use this when you do trouble-shooting within a cabin zone.

CSS TEST AND SOFTWARE INSTALLATION - EXTENDED CABIN FAULTS REVIEW MENU

Masked and Unmasked Faults Review (All Test)

Normally, all test only shows unmasked faults. Masked faults are faults that do not normally show because the configuration database prevents them. Touch MASKED AND UNMASKED FAULTS REVIEW (ALL TEST) to show both masked and unmasked faults from the last all test.



23-39-00-696 Rev 0 06/17/96

CSS TEST AND SOFTWARE INSTALLATION - EXTENDED CABIN FAULTS REVIEW MENU

CSS TEST AND SOFTWARE INSTALLATION - QUICK TESTS FAULTS REVIEW BY ZONE

General

You use quick test faults review by zone to show failures from the last quick test for each cabin zone.

An equivalent function is available for all test review when you select all test review by zone.

Access

To show this screen:

- Touch CABIN TESTS on any maintenance screen
- Touch ENGINEERING TESTS on the cabin test menu
- Touch QUICK TEST FAULTS REVIEW BY ZONE on the engineering tests menu.

Controls and Indications

You use the upper selections to select a zone. The selection shows green.

After you select a zone and an LRU type, touch CONTINUE to show the quick test fault results screens for the selected cabin zone.

Touch PREVIOUS MENU to show the engineering tests menu.

Touch MAIN MENU to show the cabin maintenance menu.

23-39-00-697 Rev 0 06/17/96

CSS TEST AND SOFTWARE INSTALLATION - CABIN CONFIGURATION MENU TREE

THIS PAGE INTENTIONALLY LEFT BLANK

CSS TEST AND SOFTWARE INSTALLATION - CABIN CONFIGURATION MENU TREE

General

You use the cabin system control panel (CSCP) for CSS maintenance procedures.

Use the cabin configuration menu to install software and check the configuration of components in the CSS. The cabin configuration menu has three selections:

- CONFIGURATION DATABASE INSTALLATION
- SOFTWARE MANAGEMENT
- CONFIGURATION CHECK.

Configuration Database Installation

Touch CONFIGURATION DATABASE INSTALLATION to install a configuration database.

The configuration database installation window shows the part number and version number of the active database. It also gives you alternative selections for installing the database.

After you install a database, one of two screens shows on the CSCP. Installation complete with no faults shows if the installation is good. If there are faults, a faults results screen shows them.

Software Management

You use the SOFTWARE MANAGEMENT selection to install operational programs. The SOFTWARE MANAGEMENT selection shows the software management menu. It has four selections:

- OPERATIONAL PROGRAM SOFTWARE INSTALLATION
- INSTALL DATA FROM FLOPPY DISK DRIVE
- LIST OF FILES ON FLOPPY DISKETTE
- DISK MAINTENANCE
- SOFTWARE IN MASS STORAGE.

Select OPERATIONAL PROGRAM SOFTWARE INSTALLATION to install software in selected LRUs. Installation of operational program software is almost the same as the configuration database installation.

LIST OF FILES ON FLOPPY DISKETTE shows you all of the software files on any disk you have in the CSCP disk drive.

Select INSTALL DATA FROM CSCP DISK DRIVE to install configuration database or operational software from a floppy disk in the CSCP disk drive.

DISK MAINTENANCE lets you remove database or operational programs from the system.

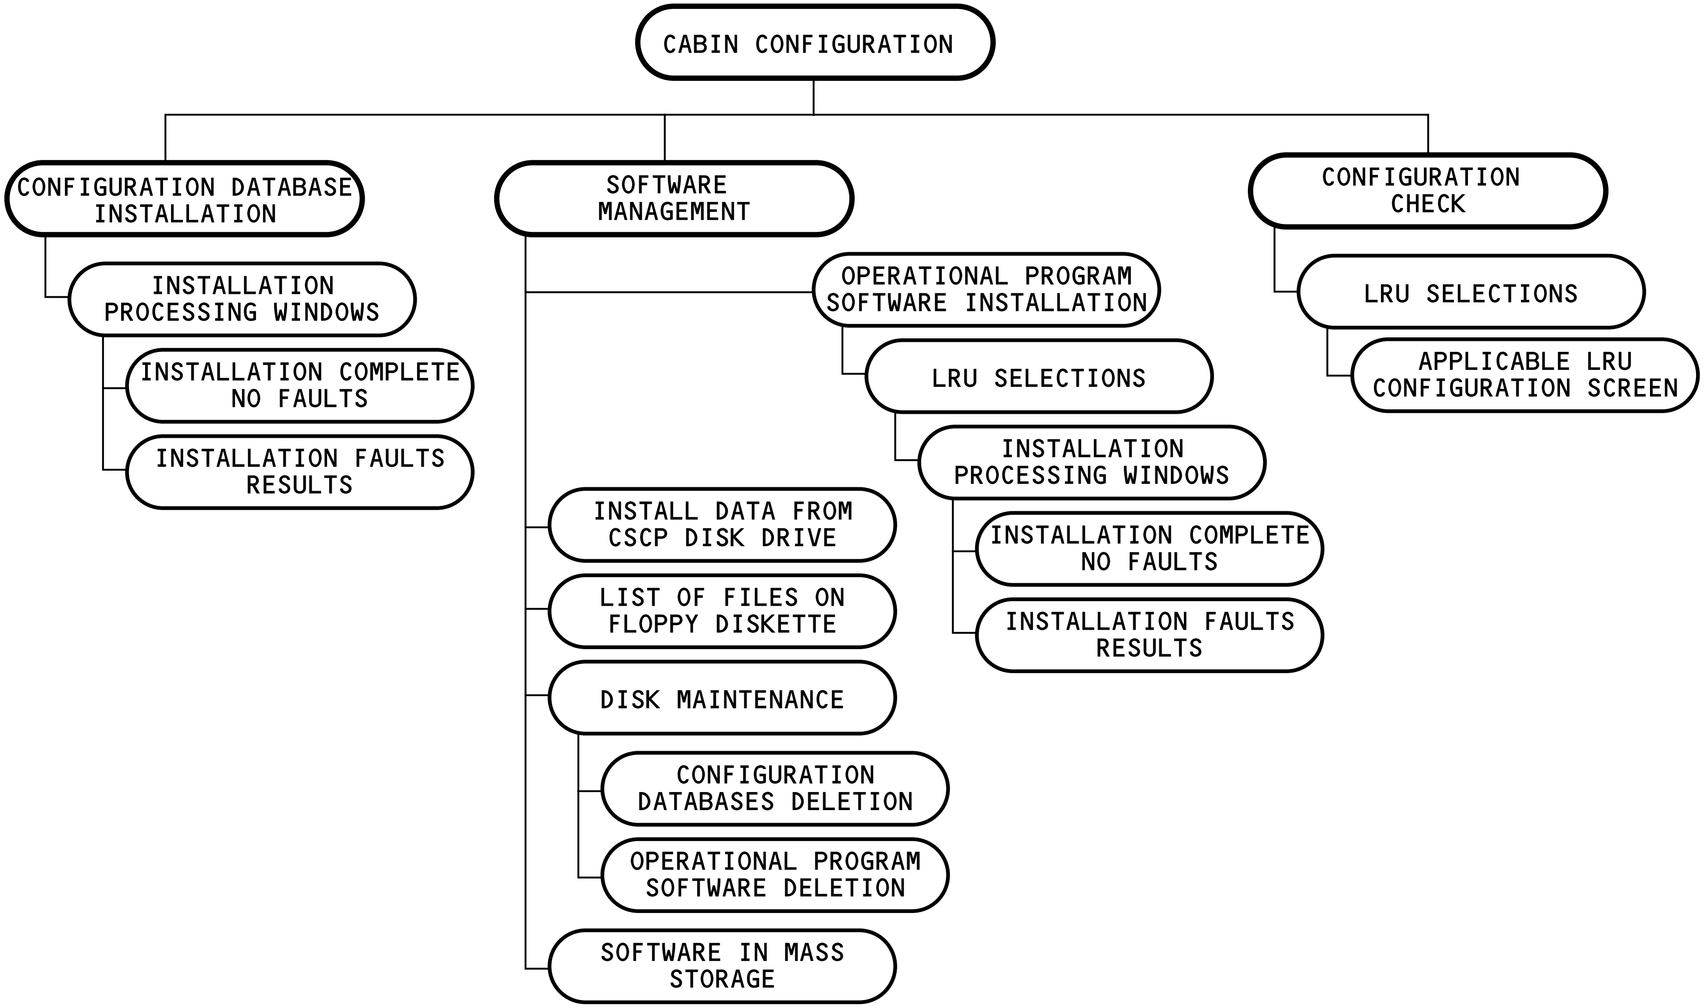
SOFTWARE IN MASS STORAGE lets you see the software files in the CSCP mass storage.

Configuration Check

The configuration check lets you see the current configuration of selected LRUs installed in the airplane.

CSS TEST AND SOFTWARE INSTALLATION - CABIN CONFIGURATION MENU TREE

You can use the configuration check to see all hardware/software part numbers related to a selected LRU.



23-39-00-698 Rev 0 06/17/96

CSS TEST AND SOFTWARE INSTALLATION - CABIN CONFIGURATION MENU TREE

CSS TEST AND SOFTWARE INSTALLATION - CABIN CONFIGURATION MENU

General

You use the cabin configuration menu to install software and check the configuration of components in the CSS. These are the three selections:

- CONFIGURATION DATABASE INSTALLATION
- SOFTWARE MANAGEMENT
- CONFIGURATION CHECK.

Access

Touch CABIN CONFIGURATION on any maintenance screen to show the cabin configuration menu.

Configuration Database Installation

When you touch CONFIGURATION DATABASE INSTALLATION, a processing screen shows while the CMS installs addresses to the core components. Then the configuration database installation screen shows.

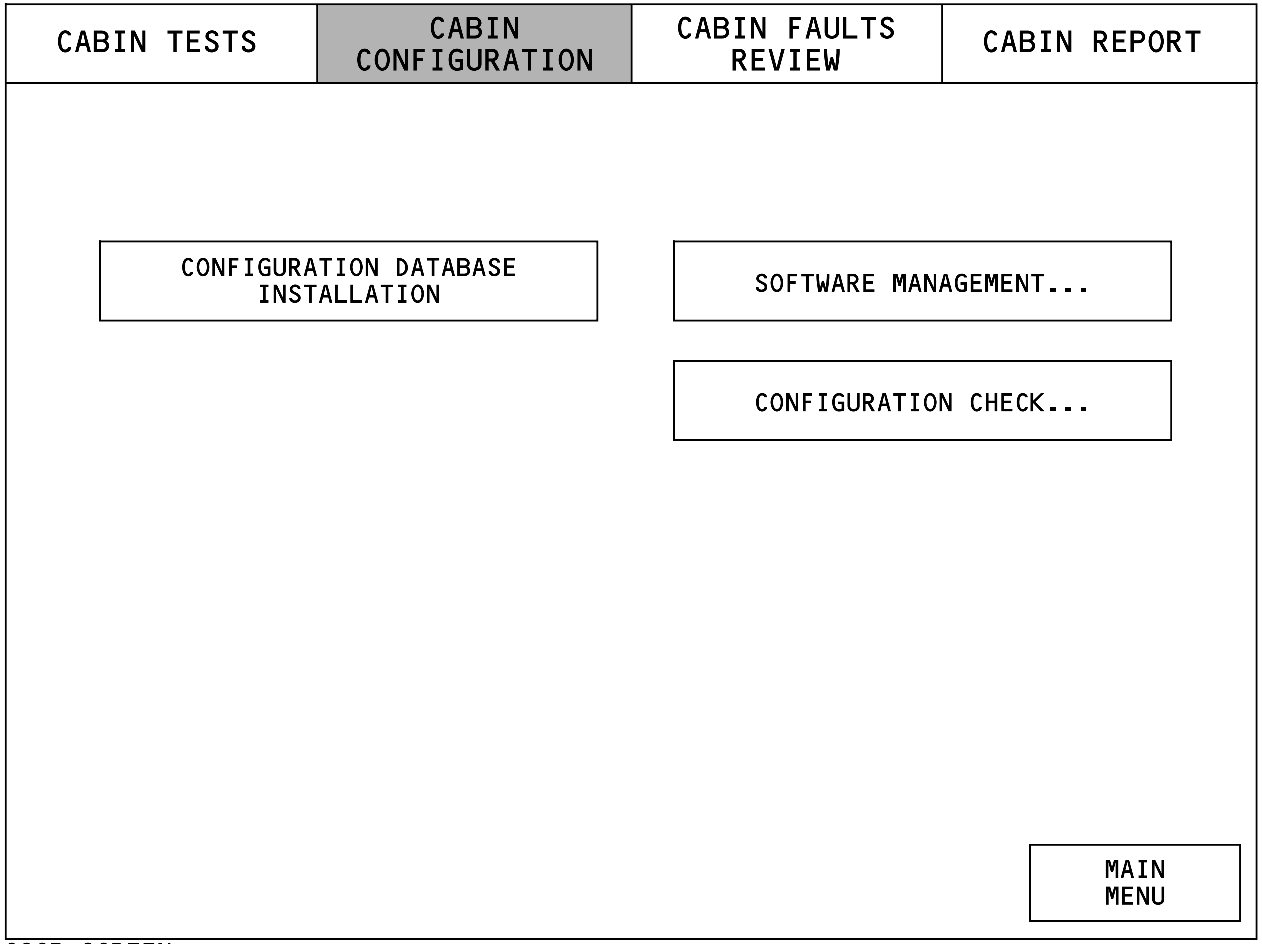
The configuration database installation screen shows the part number and version number of the active database. It gives you selections you use to install a configuration database.

Software Management

Software management lets you install operational programs in selected LRUs. You can also list disk files and control database and operational software programs installed in the cabin system control panel (CSCP).

Configuration Check

The configuration check lets you see the current LRU configuration of the CSS. It also shows you if the installed LRUs can operate with each other.



CSCP SCREEN

CSS TEST AND SOFTWARE INSTALLATION - CABIN CONFIGURATION MENU

CSS TEST AND SOFTWARE INSTALLATION - CONFIGURATION DATABASE INSTALLATION

General

The configuration database installation window shows the active CSS database. It also gives you selections to install a database.

Access

Touch these selections to show the configuration database installation screen:

- CABIN CONFIGURATION on any maintenance screen
- CONFIGURATION DATABASE INSTALLATION on the cabin configuration menu.

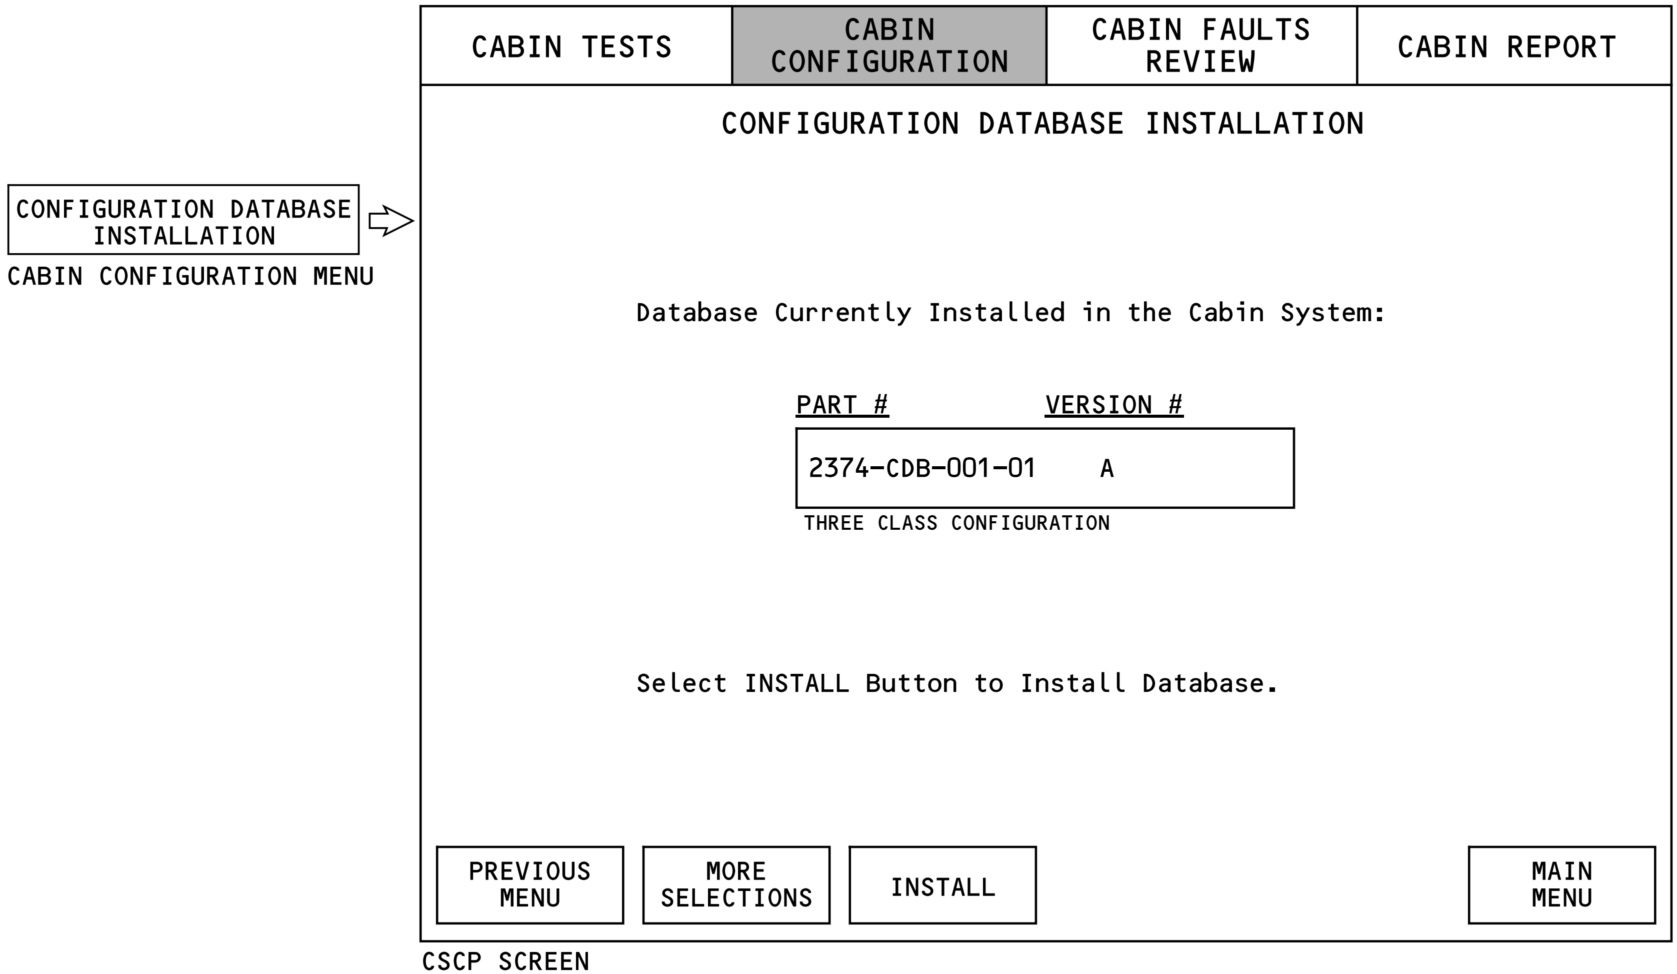
Controls and Indications

This window shows the part number and version of the database installed. Below the part number is the title of the database.

Touch INSTALL to install the database shown on the screen. After you touch INSTALL, a dialogue window shows to tell you that the database installation is operating.

You can not select INSTALL if the current database is not in the cabin system control panel (CSCP) mass storage.

Touch MORE SELECTIONS to see other databases that may be available.



23-39-00-700 Rev 0 06/18/96

CSS TEST AND SOFTWARE INSTALLATION - CONFIGURATION DATABASE INSTALLATION

CSS TEST AND SOFTWARE INSTALLATION - CONFIGURATION DATABASE INSTALLATION - MULTIPLE DATABASES

General

This configuration database installation screen shows as many as six databases in the cabin system control panel (CSCP) memory.

Access

Touch one of these to show the configuration database installation screen for multiple databases:

- CABIN CONFIGURATION on any maintenance screen
- CONFIGURATION DATABASE INSTALLATION on the cabin configuration menu
- MORE SELECTIONS on the first configuration database installation screen.

Controls and Indications

This screen shows the part numbers and versions of all databases stored in memory in the CSCP. Below each part number is the database type.

In this example, the upper left database area shows that the active database is not in the CSCP memory. You use other screens to delete programs from memory.

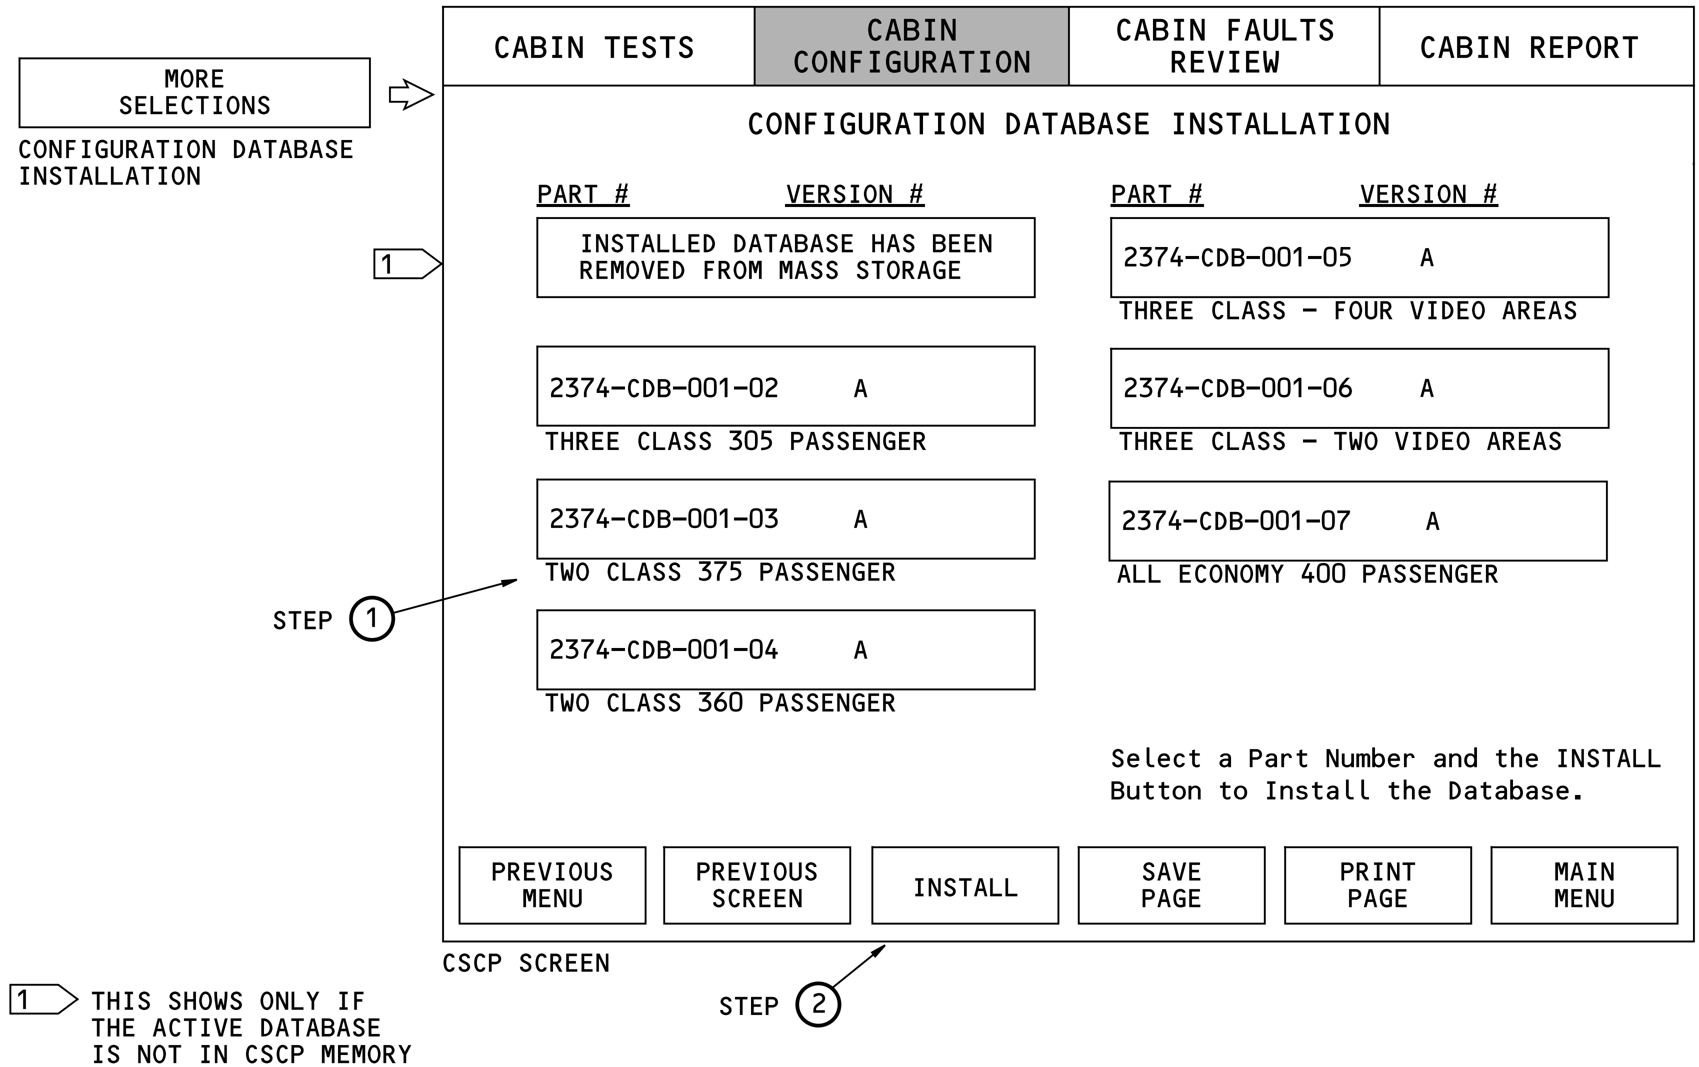
Touch any of these selections at the bottom of the screen to do the related function:

- PREVIOUS MENU - go to the cabin configuration menu
- INSTALL - install the selected database
- SAVE PAGE - save the contents of this screen to a floppy diskette in the CSCP disk drive
- PRINT PAGE - print the contents of this screen on the cabin printer
- MAIN MENU - return to the cabin maintenance main menu.

Database Installation

Touch the database part number on the screen to select it. The part number you select changes to green and the INSTALL selection at the bottom of the screen becomes active.

Touch INSTALL to install the database. After you touch INSTALL, a screen shows to tell you that the configuration database installation is operating.



23-39-00-701 Rev 0 06/18/96

CSS TEST AND SOFTWARE INSTALLATION - CONFIGURATION DATABASE INSTALLATION - MULTIPLE DATABASES

CSS TEST AND SOFTWARE INSTALLATION - DATABASE DISCREPANCY DIALOGUE WINDOW

General

The database discrepancy dialogue window tells you that the database you selected is different from the active one.

Access

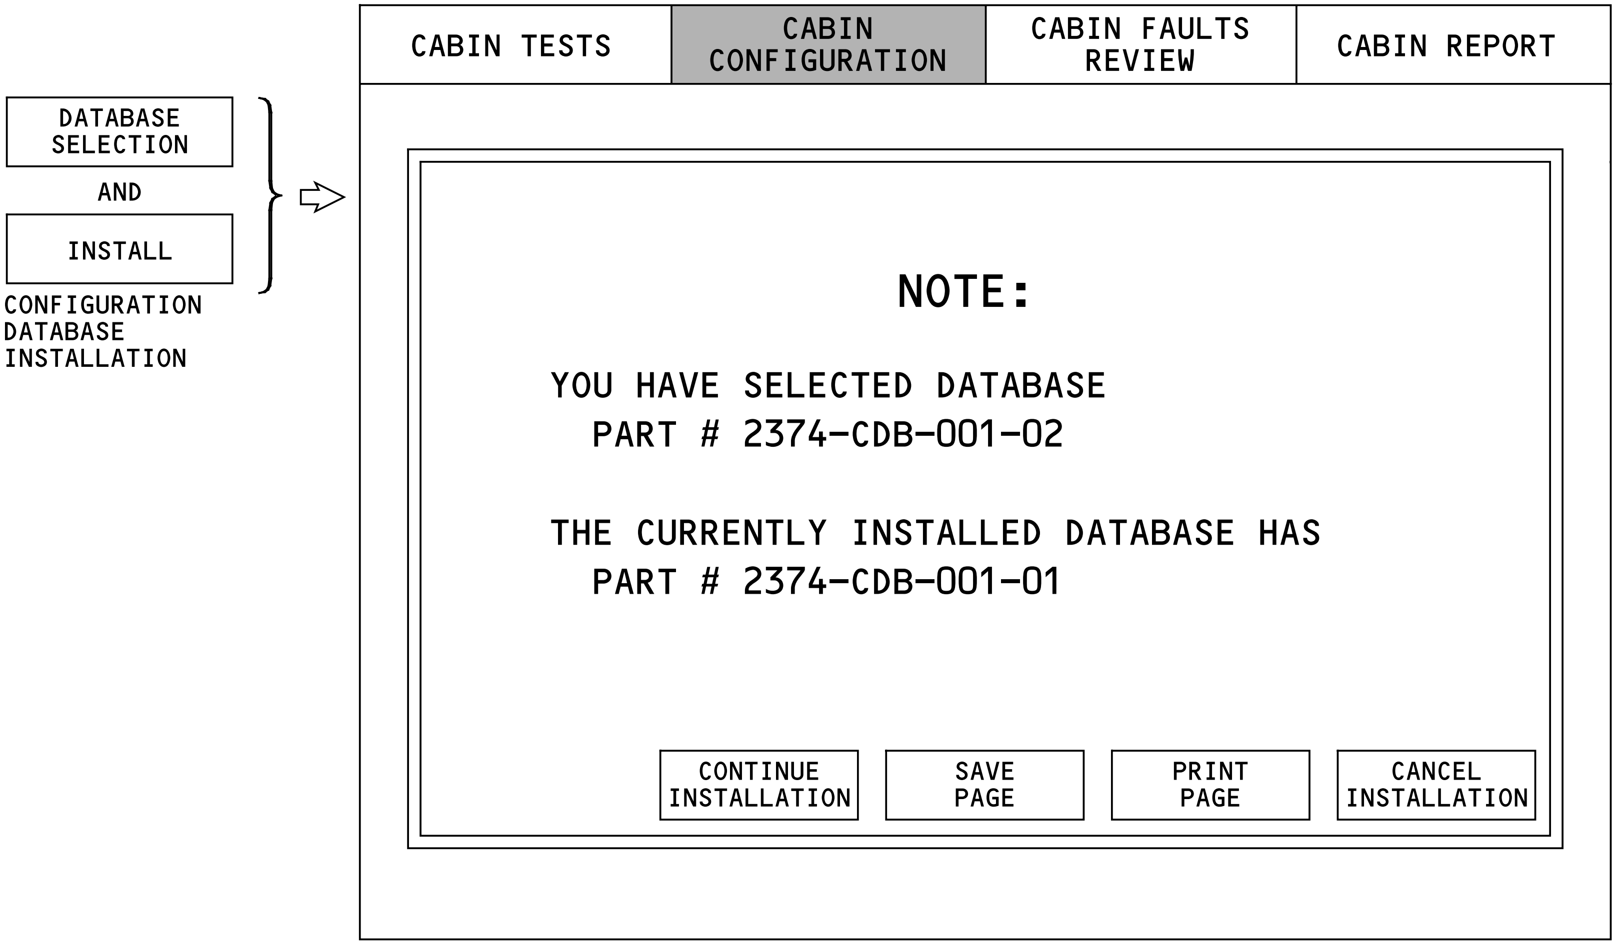
This screen shows automatically when you select a database different from the one installed in the cabin system control panel (CSCP) memory. It shows after you touch INSTALL on the configuration database installation screen.

Controls and Indications

This screen shows the part number of the database you selected. It also shows the part number of the active database.

Touch any of these selections at the bottom of the screen to do the related function:

- CONTINUE INSTALLATION - to install the database
- SAVE PAGE - to save the contents of this screen to a floppy diskette in the CSCP disk drive
- PRINT PAGE - to print the contents of this screen on the cabin printer
- CANCEL INSTALLATION - to cancel installation and return to the configuration database installation screen.



CSCP SCREEN

CSS TEST AND SOFTWARE INSTALLATION – DATABASE DISCREPANCY DIALOGUE WINDOW

CSS TEST AND SOFTWARE INSTALLATION - CONFIGURATION DATABASE INSTALLATION IS OPERATING

General

The configuration database installation is operating screen shows when you install a configuration database.

Access

This screen shows automatically when you select a database and touch INSTALL on the configuration database installation screen.

It also shows if you touch CONTINUE INSTALLATION on the database discrepancy screen.

Controls and Indications

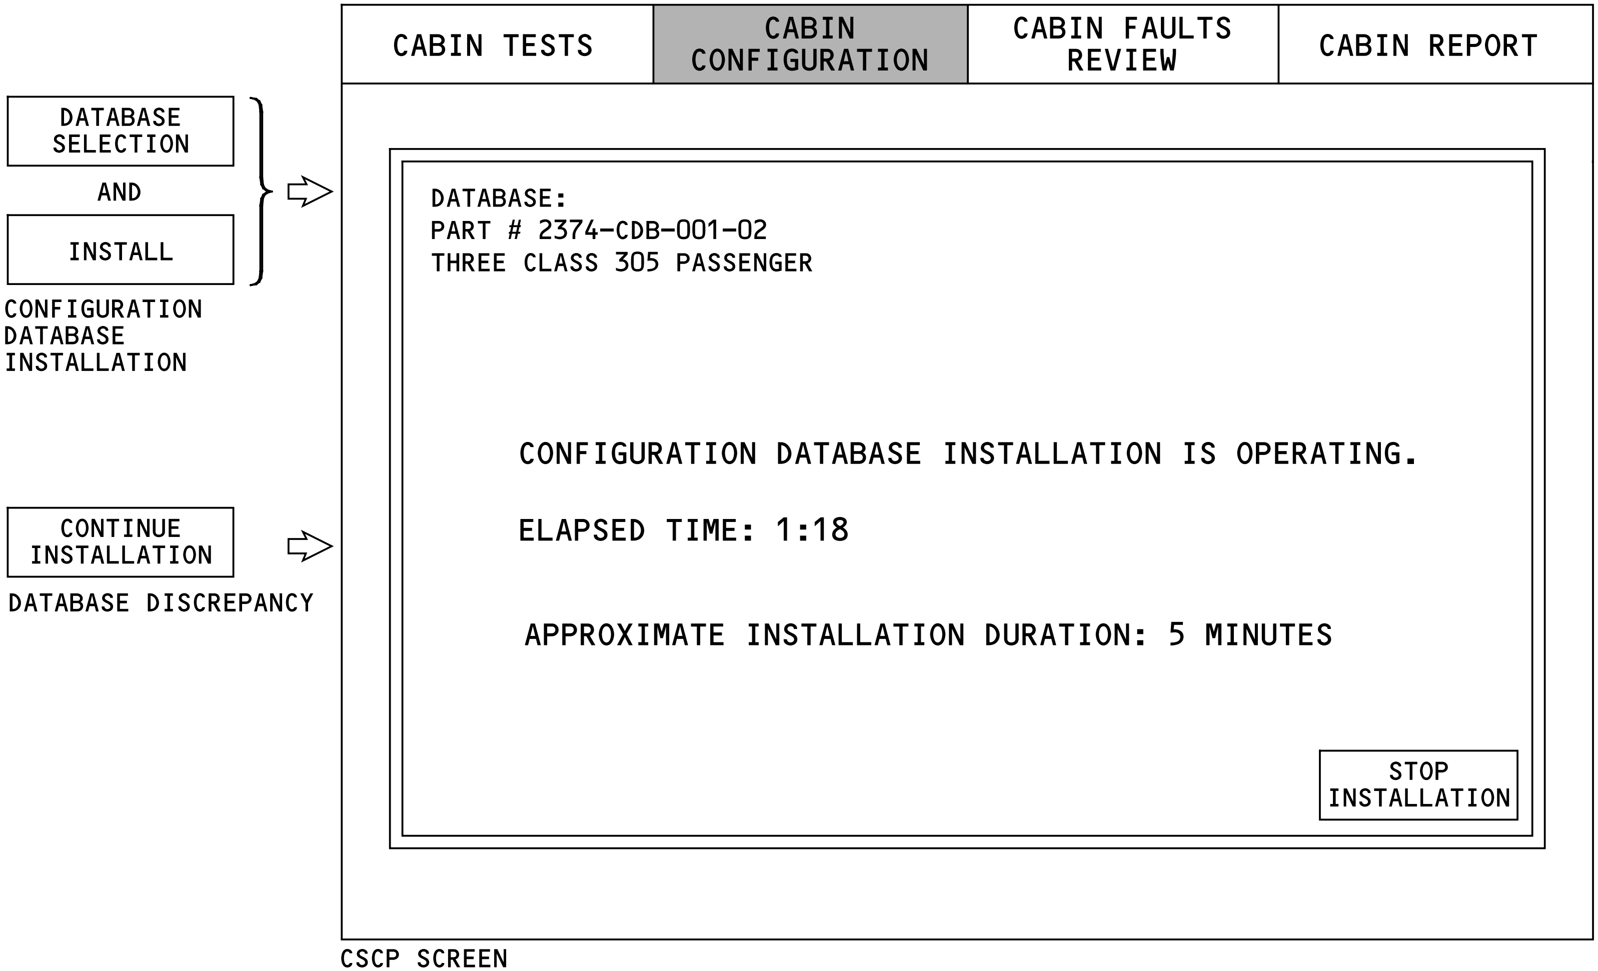
The part number and description of the database show in the top-left part of the window.

The center of the window shows you that the database is being installed and the elapsed time. This area also shows the approximate installation time.

Touch STOP INSTALLATION to cancel the database installation. When you stop in the middle of the installation, only some of the CSS components may get the database. A window shows you that stopping the installation may make the system not operate.

When the installation is done, one of two screen will show. The configuration database installation complete screen shows if there are no faults. The database installation fault results screen shows if there are faults.

All of the faults results screens work in the same way as in the CSS test section.



23-39-00-703 Rev 0 06/18/96

CSS TEST AND SOFTWARE INSTALLATION - CONFIGURATION DATABASE INSTALLATION IS OPERATING

CSS TEST AND SOFTWARE INSTALLATION - CONFIGURATION DATABASE INSTALLATION STOP

General

The configuration database installation stop screen shows when you cancel a configuration database installation.

Access

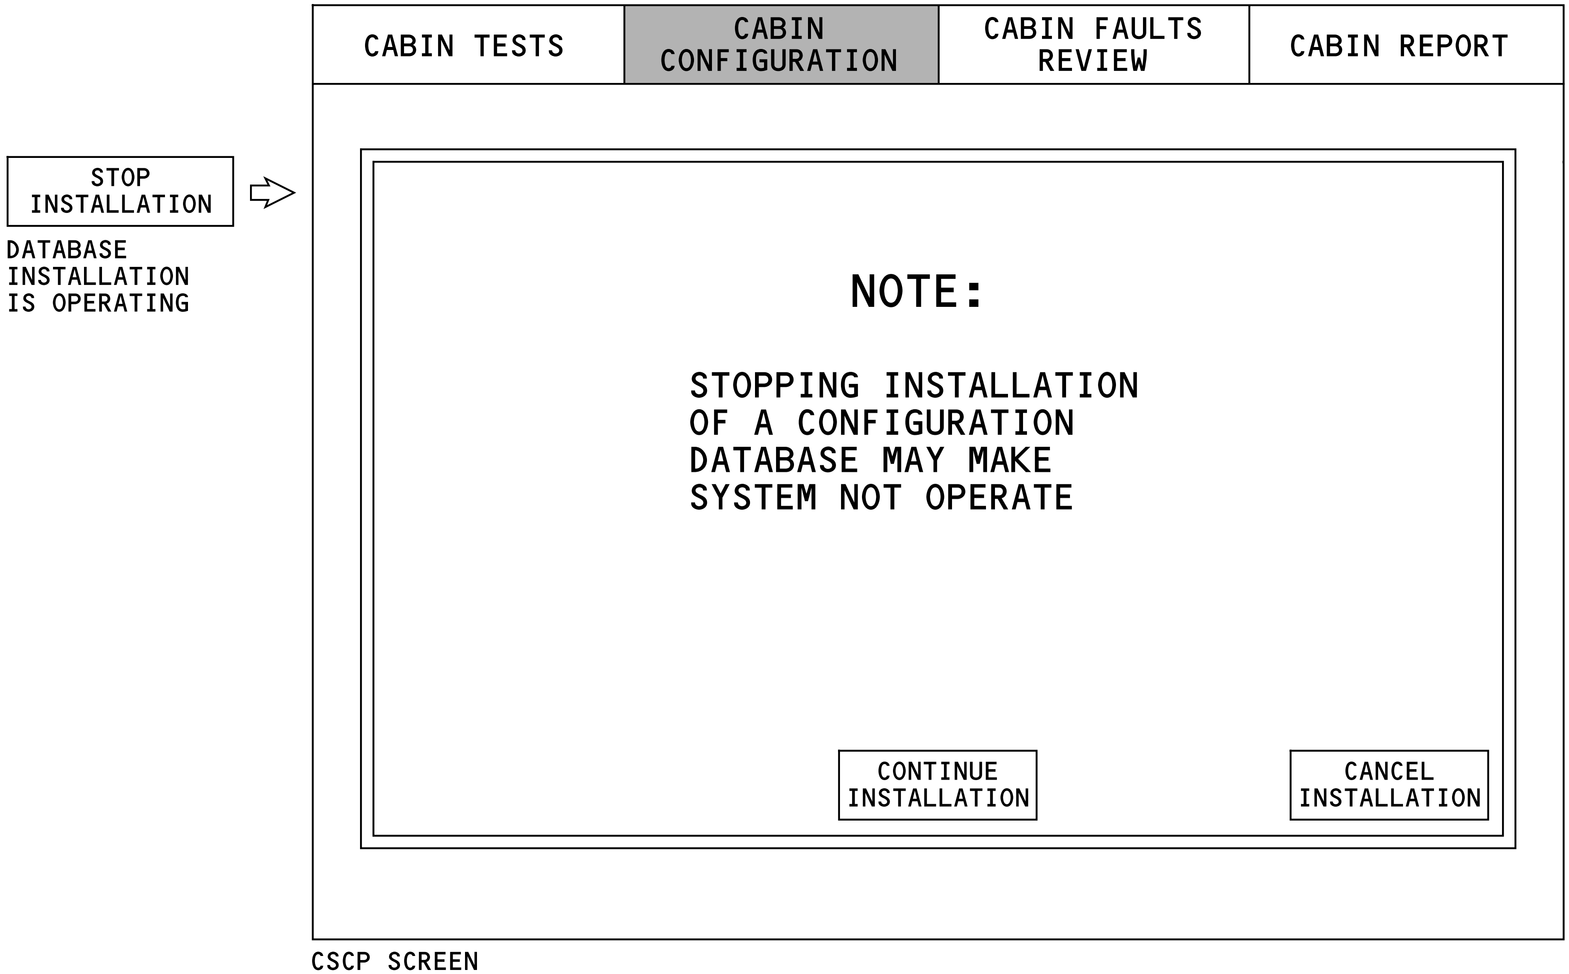
This screen shows when you touch STOP INSTALLATION on the database installation is operating screen.

Controls and Indications

The message tells you that if you cancel the installation, the CSS may not operate.

Touch CONTINUE INSTALLATION to install the remaining part of the database and show the database installation is operating screen.

Touch CANCEL INSTALLATION to stop the installation. A screen shows to tell you that the installation is being stopped. After the installation stops, the cabin configuration menu shows.



23-39-00-704 Rev 0 06/18/96

CSS TEST AND SOFTWARE INSTALLATION - CONFIGURATION DATABASE INSTALLATION STOP

CSS TEST AND SOFTWARE INSTALLATION - CONFIGURATION DATABASE INSTALLATION COMPLETE

General

The configuration database installation complete screen automatically shows at the end of a database installation.

Access

This screen shows when you select a database and touch INSTALL on the configuration database installation screen.

It also shows if you touch CONTINUE INSTALLATION on the database discrepancy screen.

Controls and Indications

The part number and description of the database show in the top-left part of the window.

The center of the window shows you that the database is complete and there were no faults.

Touch PREVIOUS MENU to show the cabin configuration menu.

Touch MAIN MENU to show the cabin maintenance main menu screen.

This screen automatically shows when you install a configuration database and there are failures.

Access

Touch these selections to show the configuration database installation fault results screen:

- CABIN CONFIGURATION on any maintenance screen
- CONFIGURATION DATABASE INSTALLATION on the cabin configuration menu
- Select a database on the configuration database installation screen and touch INSTALL.

This screen shows automatically at the end of the installation. It also shows after you touch CLEAR SCREEN on the operational program software conflict screen.

Controls and Indications

These are the three parts of the screen:

- Installation conditions
- Maintenance message data
- Selection controls.

Installation Conditions

The test conditions part of the screen shows this test data:

- The configuration database part number installed at the time of the installation.
- The date and time of the installation.
- The sequence of each maintenance message in the list of messages.

There is a HELP selection on the left. Touch HELP for information on how to use the screen.

Maintenance Message Data

Each page shows one maintenance message. The maintenance message shows data about each failure. There are three parts to the maintenance message:

- Fault description
- Maintenance message number
- Recommended maintenance action.

The fault description identifies the failure condition detected by the installation. It also identifies the component that found the fault.

You use the maintenance message number to find the corrective action in the fault isolation manual (FIM).

The recommended maintenance action identifies all the possible components or conditions that could cause the fault. The most probable cause shows first and the least probable cause shows last.

Each screen shows one maintenance message. Use the up and down arrows at the far right of the screen to show the previous or next message. The square on the scroll bar shows your position in the message list.

Selection Controls

To show a visual reference of the defective component, touch SHOW LOCATION.

To show the components controlled by the defective component, touch UNIT USAGE.

Touch PREVIOUS MENU to show the cabin configuration menu.

Touch SAVE to send the data to a diskette in the CSCP disk drive.

Touch PRINT to send the data to the printer for a paper copy.

Touch MAIN MENU to show the cabin maintenance menu.

CSS TEST AND SOFTWARE INSTALLATION - INSTALLATION FAULT RESULTS

CSS TEST AND SOFTWARE INSTALLATION - SOFTWARE MANAGEMENT MENU

General

You use this screen to install and remove software programs from the cabin system control panel (CSCP) memory. You also use it to install operational data in LRUs.

Access

Touch these selections to show the software management menu:

- CABIN CONFIGURATION on any cabin maintenance screen
- SOFTWARE MANAGEMENT on the cabin configuration menu.

Controls and Indications

Touch OPERATIONAL PROGRAM SOFTWARE INSTALLATION to install LRU operational programs from the CSCP memory. One of these screens shows after you touch the selection:

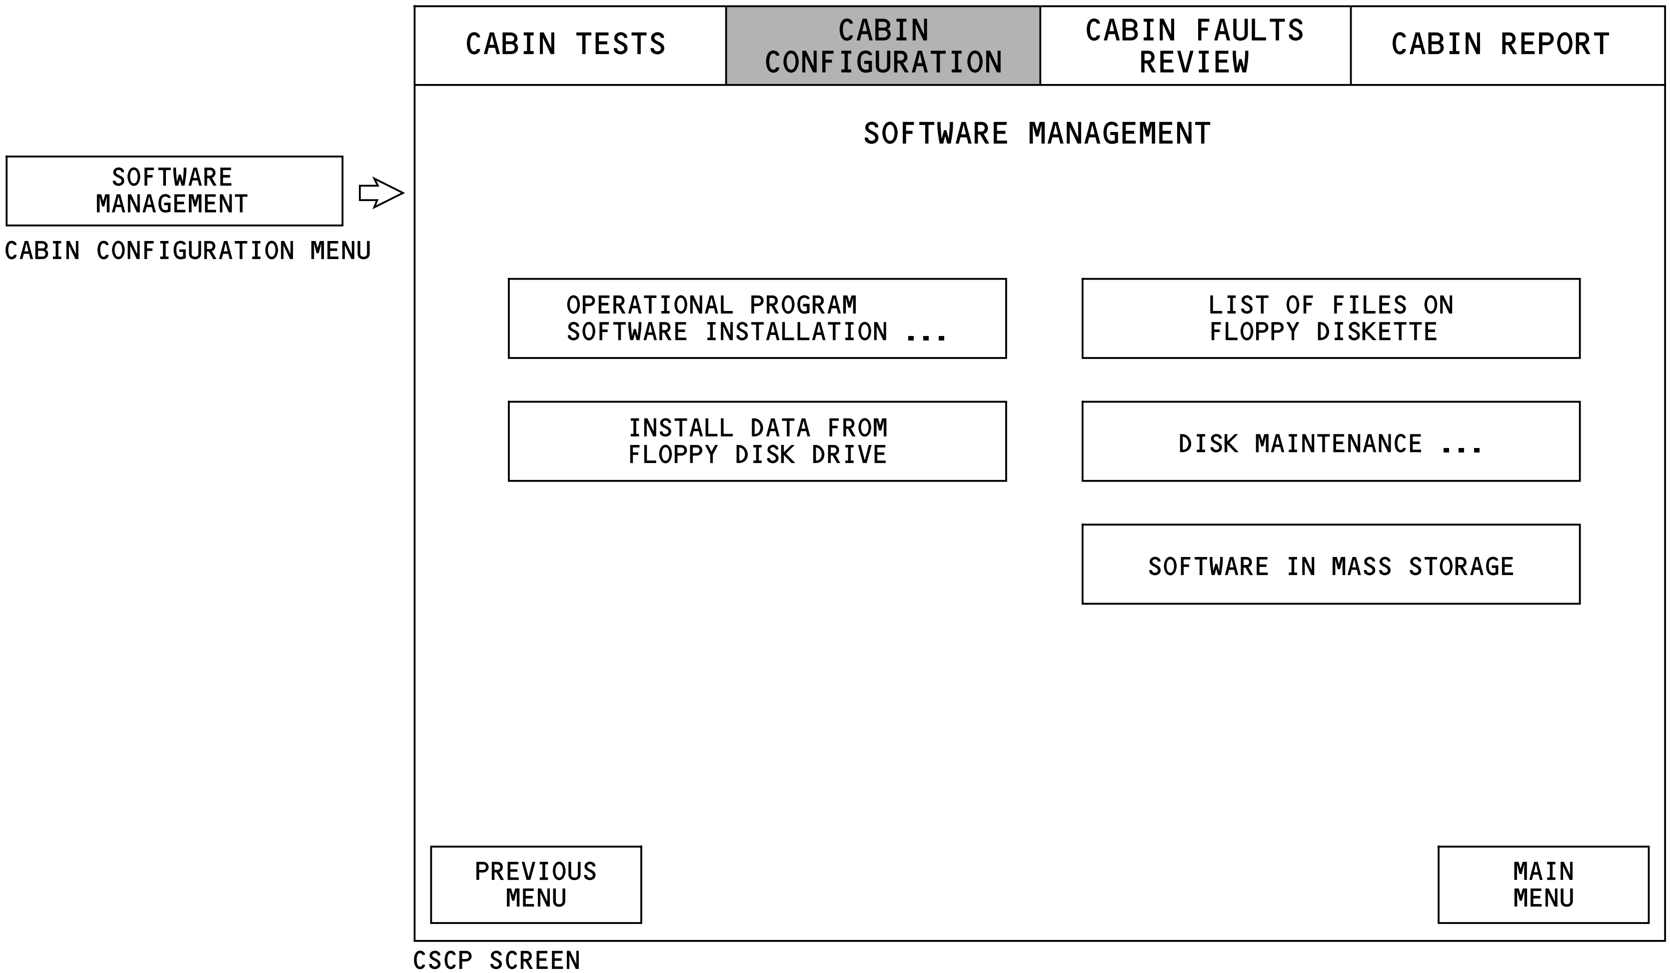
- The operational program software installation menu if there are no failures
- An intrusive function not available dialogue window if the airplane is not in the correct condition for an installation
- A breakers/buses off dialogue window to show any open CSS circuit breakers or power buses that are off
- A function not available dialogue window when a data load from a maintenance access terminal (MAT) is in progress.

Touch LIST OF FILES ON FLOPPY DISKETTE to show a list of the files on a floppy diskette in the CSCP disk drive. If you did not put the diskette in the disk drive, a dialogue window will tell you to do so.

Touch INSTALL DATA FROM FLOPPY DISK DRIVE to install a configuration database or operational program software from a diskette into CSCP memory. A screen shows to tell you that the data installation is operating.

Touch DISK MAINTENANCE to show a disk maintenance menu This lets you remove configuration databases or operational program software from the CSCP memory.

Touch PREVIOUS MENU at the bottom of the screen to return to the cabin configuration menu. Touch MAIN MENU to return to the cabin maintenance menu.



23-39-00-707 Rev 0 06/18/96

CSS TEST AND SOFTWARE INSTALLATION - SOFTWARE MANAGEMENT MENU

CSS TEST AND SOFTWARE INSTALLATION - OPERATIONAL PROGRAM SOFTWARE INSTALLATION MENU

General

You use the operational program software installation menu to install operational program software in CSS LRUs. The cabin system control panel (CSCP) mass storage keeps the operational programs.

Access

Touch these selections to show this menu:

- Touch CABIN CONFIGURATION on any maintenance screen
- Touch SOFTWARE MANAGEMENT on the cabin configuration menu
- Touch OPERATIONAL PROGRAM SOFTWARE INSTALLATION on the software management menu.

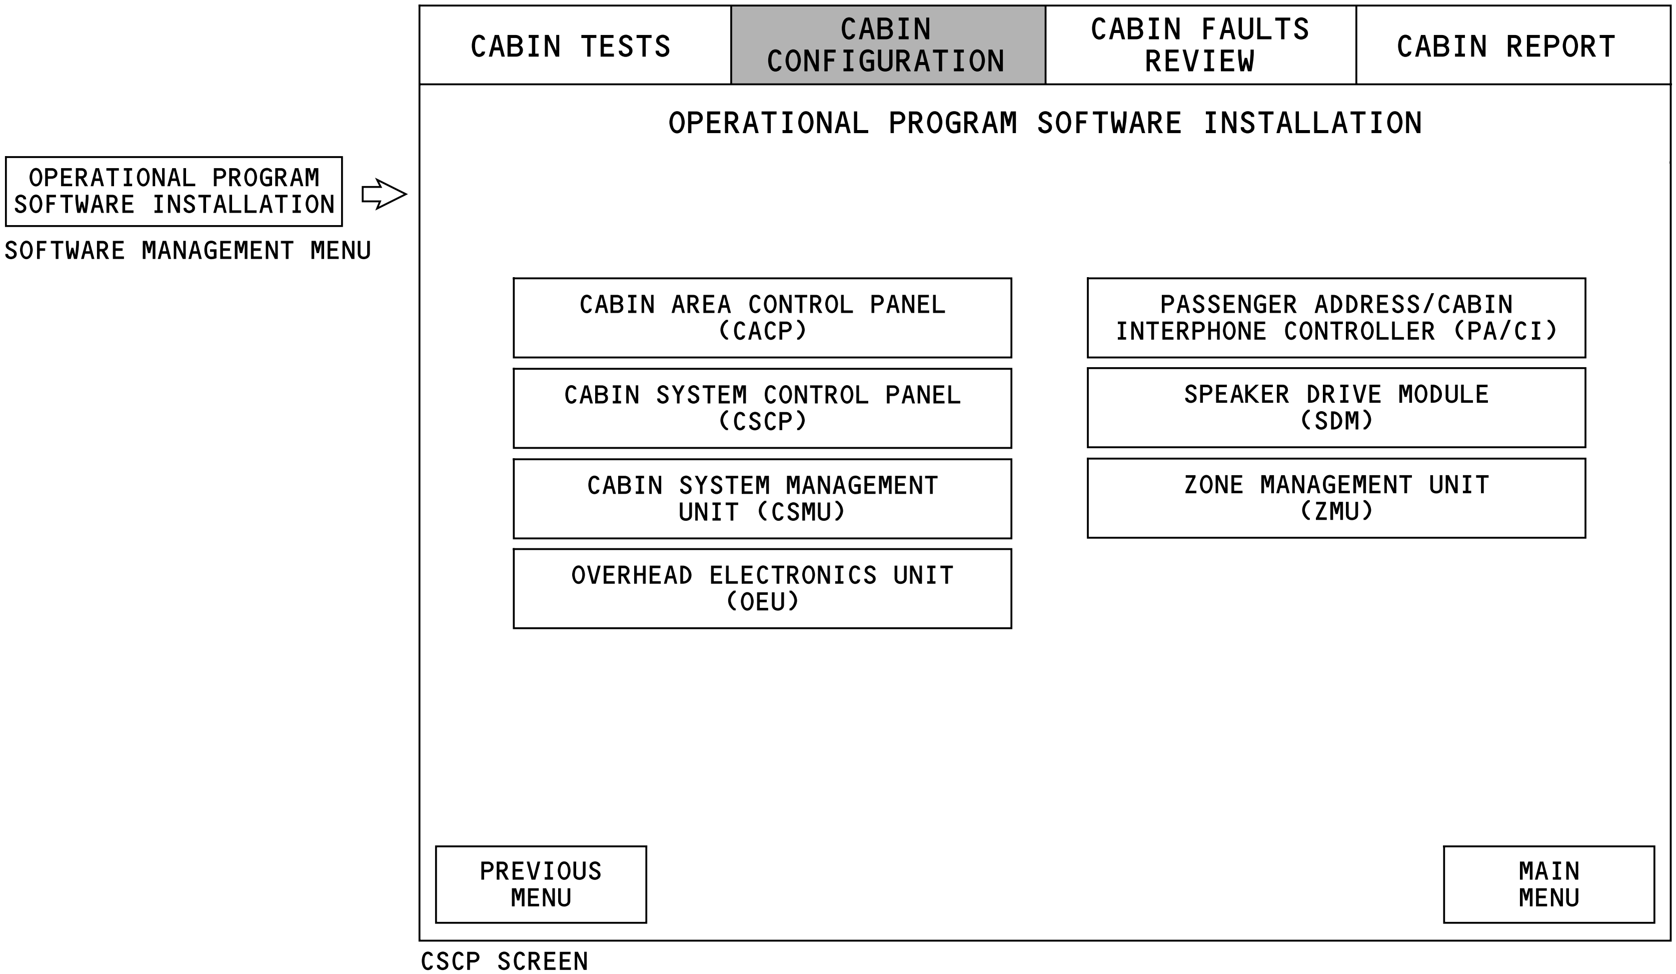
Controls and Indications

Touch any one of the LRU selections to start installation of the related operational software. The operational program software installation screen for that LRU will show to let you install the program.

A screen may show to tell you that an LRU that controls the LRU you selected does not have its operational software installed.

Touch PREVIOUS MENU to go to the software management menu.

Touch MAIN MENU to go to the cabin maintenance main menu.



23-39-00-708 Rev 0 06/18/96

CSS TEST AND SOFTWARE INSTALLATION - OPERATIONAL PROGRAM SOFTWARE INSTALLATION MENU

CSS TEST AND SOFTWARE INSTALLATION - OPERATIONAL PROGRAM SOFTWARE INSTALLATION SCREEN

General

Use this screen to select and install operational program software in LRUs. The diagram shows a typical installation screen for an overhead electronics unit (OEU). Other LRU screens are similar.

Access

Touch these selections to show the operational program software installation screen:

- CABIN CONFIGURATION on any maintenance screen
- SOFTWARE MANAGEMENT on the cabin configuration menu
- OPERATIONAL PROGRAM SOFTWARE INSTALLATION on the software management menu.
- Touch any LRU selection on the operational program software installation menu.

Controls and Indications

The selected LRU shows in the screen title.

Use the up and down arrows on the left side of the screen to select applicable hardware part numbers.

Each hardware part number has a list of related software part numbers. The recommended software part number for the LRU automatically shows green when the screen first comes on. Touch any of the software part numbers to select them. You can select only one software part number for each LRU part number.

Use the up and down arrows on the right side of the screen to scroll through the software part numbers.

Touch any of these selections at the bottom of the screen to do the related function:

- PREVIOUS MENU - to return to the operational program software installation menu
- INSTALL - to install the operational program software you selected on the screen
- SAVE - to save the entire list of hardware and software part numbers to a CSCP floppy diskette
- PRINT - to print the entire list of hardware and software part numbers to the cabin printer
- MAIN MENU - to return to the cabin maintenance main menu.

If the software you select is not the recommended part number, a preferred software dialogue window shows when you touch INSTALL. If there are no problems, a normal installation dialogue window shows.

CSS TEST AND SOFTWARE INSTALLATION – OPERATIONAL PROGRAM SOFTWARE INSTALLATION SCREEN

CSS TEST AND SOFTWARE INSTALLATION - PREFERRED SOFTWARE DIALOGUE WINDOW

General

This screen shows if you install operational software and did not select the recommended software part numbers for an LRU.

Access

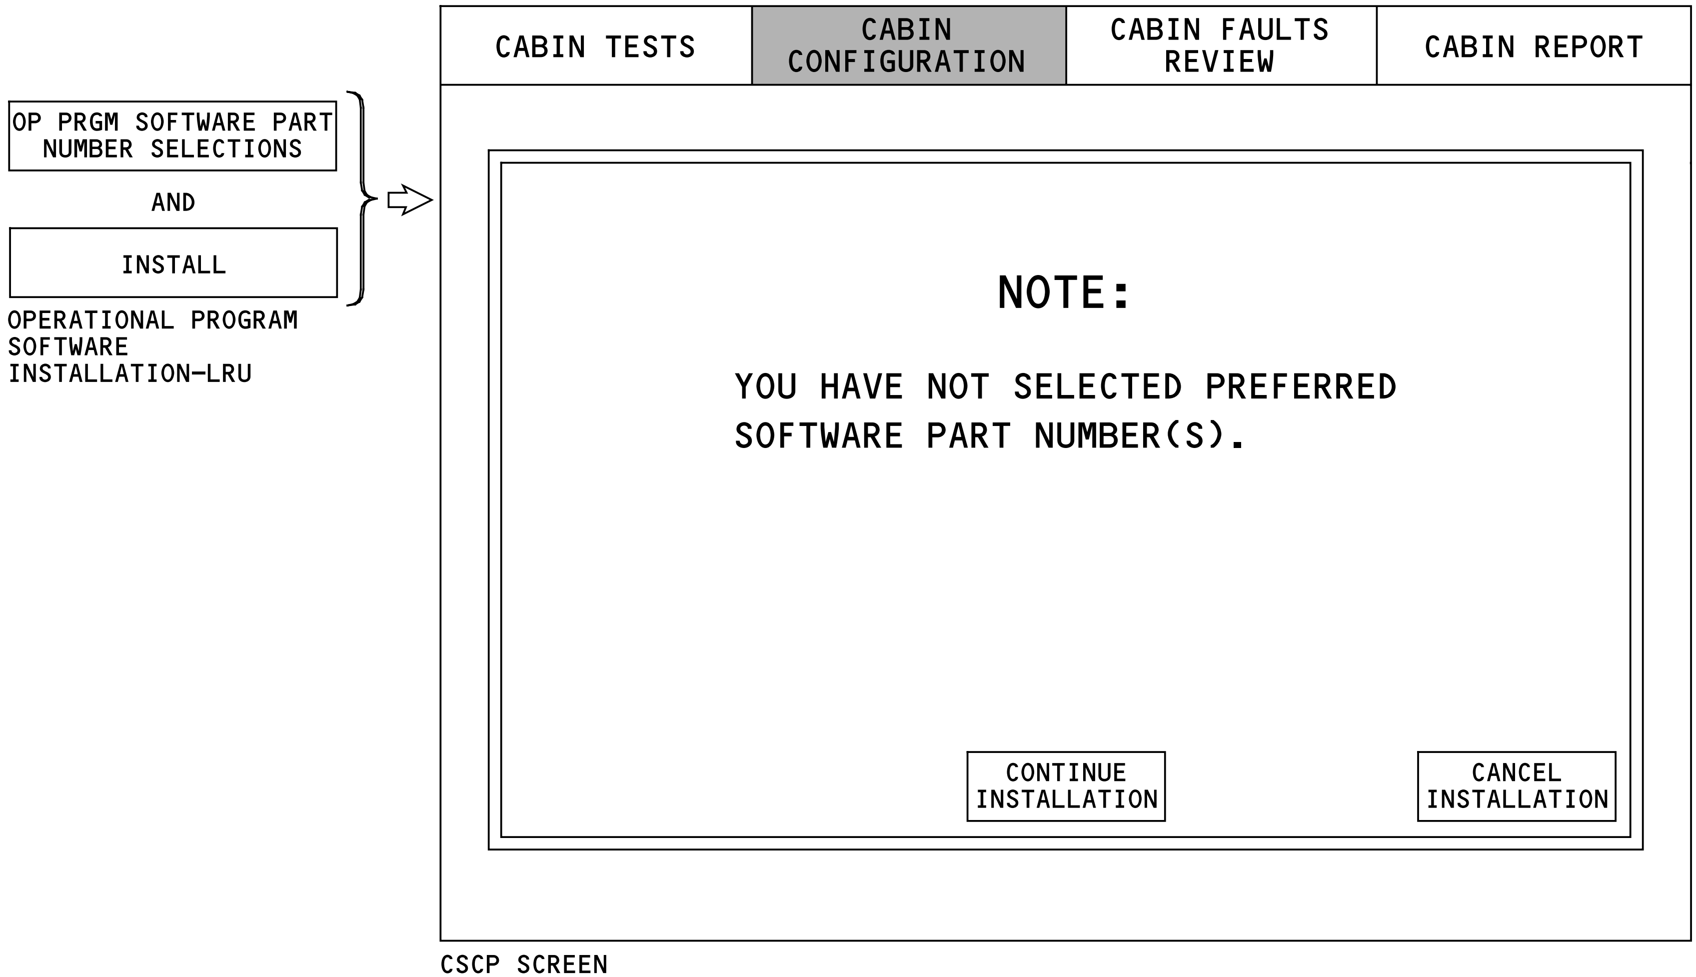
This screen shows if you make these selections:

- Touch CABIN CONFIGURATION on any maintenance screen
- Touch SOFTWARE MANAGEMENT on the cabin configuration menu
- Touch OPERATIONAL PROGRAM SOFTWARE INSTALLATION on the software management menu.
- Touch any LRU selection on the operational program software installation menu
- Select any software part number on the operational program software installation screen that does not show green when the screen first comes into view and touch INSTALL.

Controls and Indications

Touch CONTINUE INSTALLATION to install the operational program software. A window shows to tell you that the software installation is operating.

Touch CANCEL INSTALLATION to stop the installation and return to the operational program software installation screen for the LRU.



23-39-00-710 Rev 0 06/18/96

CSS TEST AND SOFTWARE INSTALLATION - PREFERRED SOFTWARE DIALOGUE WINDOW

CSS TEST AND SOFTWARE INSTALLATION - OPERATIONAL PROGRAM SOFTWARE INSTALLATION IS OPERATING

General

This screen shows when you install operational software.

Access

This screen shows when you make these selections:

- Touch CABIN CONFIGURATION on any maintenance screen
- Touch SOFTWARE MANAGEMENT on the cabin configuration menu
- Touch OPERATIONAL PROGRAM SOFTWARE INSTALLATION on the software management menu.
- Touch any LRU selection on the operational program software installation menu
- Select the software part number on the operational program software installation screen and touch INSTALL.

This screen also shows when you select the recommended software part numbers and touch INSTALL on the operational program software installation screen for an LRU.

This screen will show when you select CONTINUE INSTALLATION from the preferred software dialogue window.

Controls and Indications

The center of the window shows you that the operational software is being installed and the elapsed time.

Touch STOP INSTALLATION to cancel the operational program software installation. A window shows you that stopping the installation may stop the system operation.

When the installation is done, one of two screens shows. The operational program software installation complete screen shows if there were no faults. The database installation fault results screen shows if there were faults. The installation fault results screen is the same as the one for the configuration database installation.

This screen automatically shows when you install operational software and there are no failures.

Access

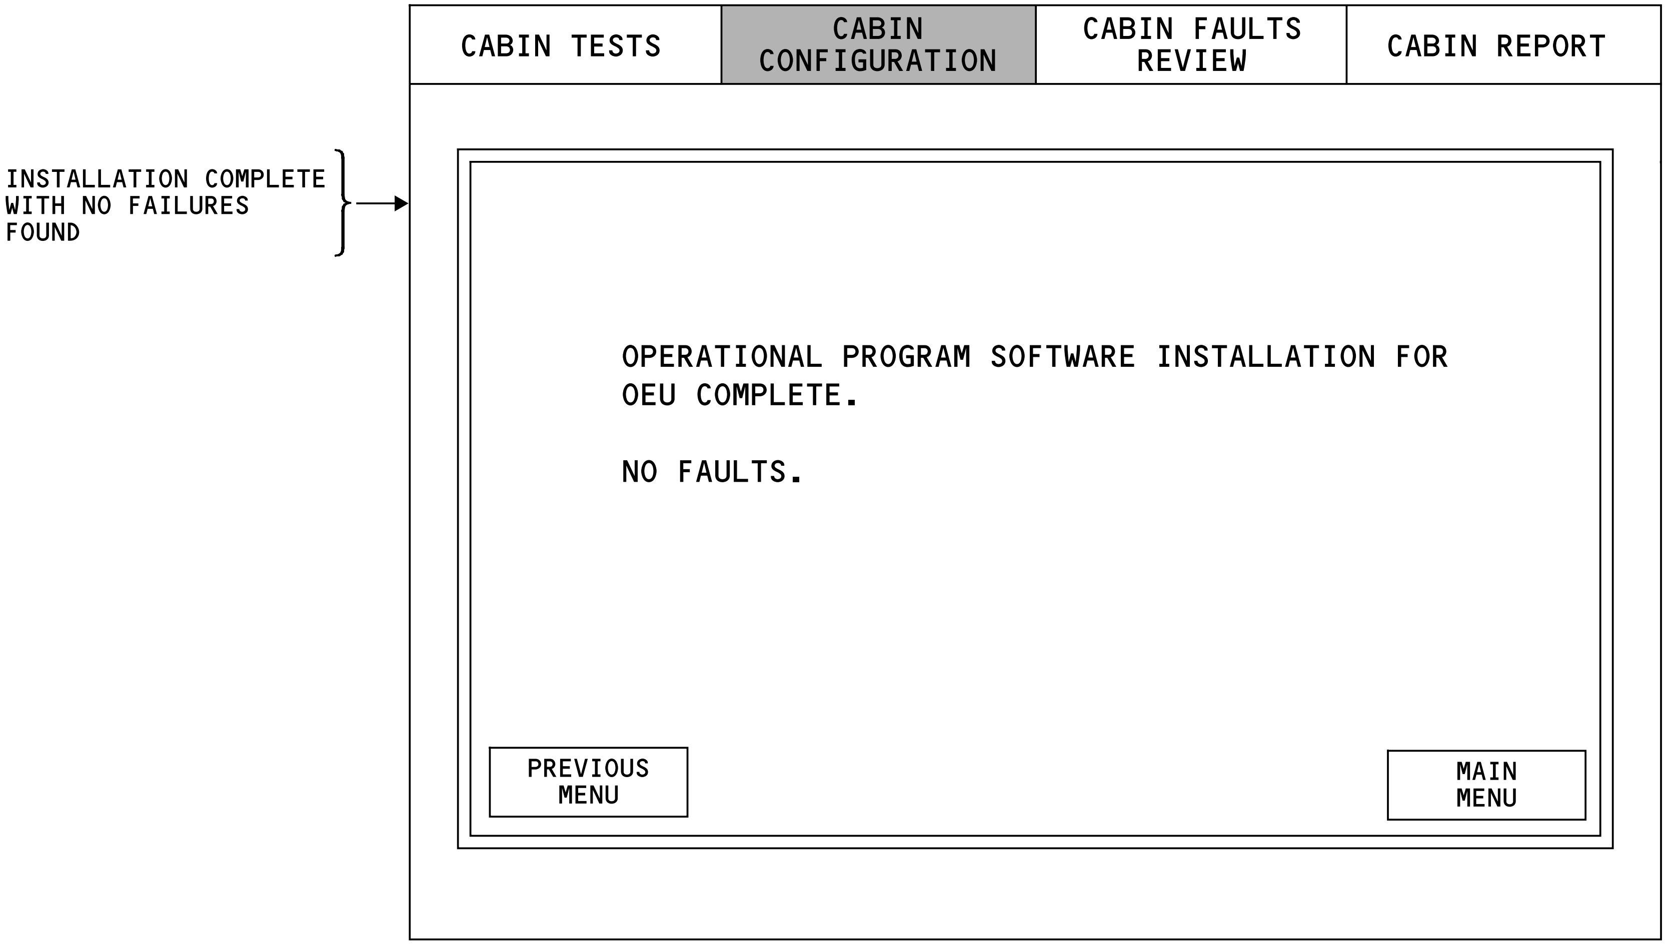
This screen shows when you make these selections:

- Touch CABIN CONFIGURATION on any maintenance screen
- Touch SOFTWARE MANAGEMENT on the cabin configuration menu
- Touch OPERATIONAL PROGRAM SOFTWARE INSTALLATION on the software management menu
- Touch any LRU selection on the operational program software installation menu
- Select the software part number on the operational program software installation screen and touch INSTALL.

This screen shows automatically at the end of the installation.

Controls and Indications

When you touch PREVIOUS MENU or MAIN MENU, another dialogue window shows to tell you to install the configuration database.



CSCP SCREEN

23-39-00-713 Rev 0 06/18/96

CSS TEST AND SOFTWARE INSTALLATION - OPERATIONAL PROGRAM SOFTWARE INSTALLATION IS COMPLETE

CSS TEST AND SOFTWARE INSTALLATION - INSTALL DATABASE DIALOGUE WINDOW

General

The install database dialogue window tells you to install the configuration database after you have installed any necessary operational program software.

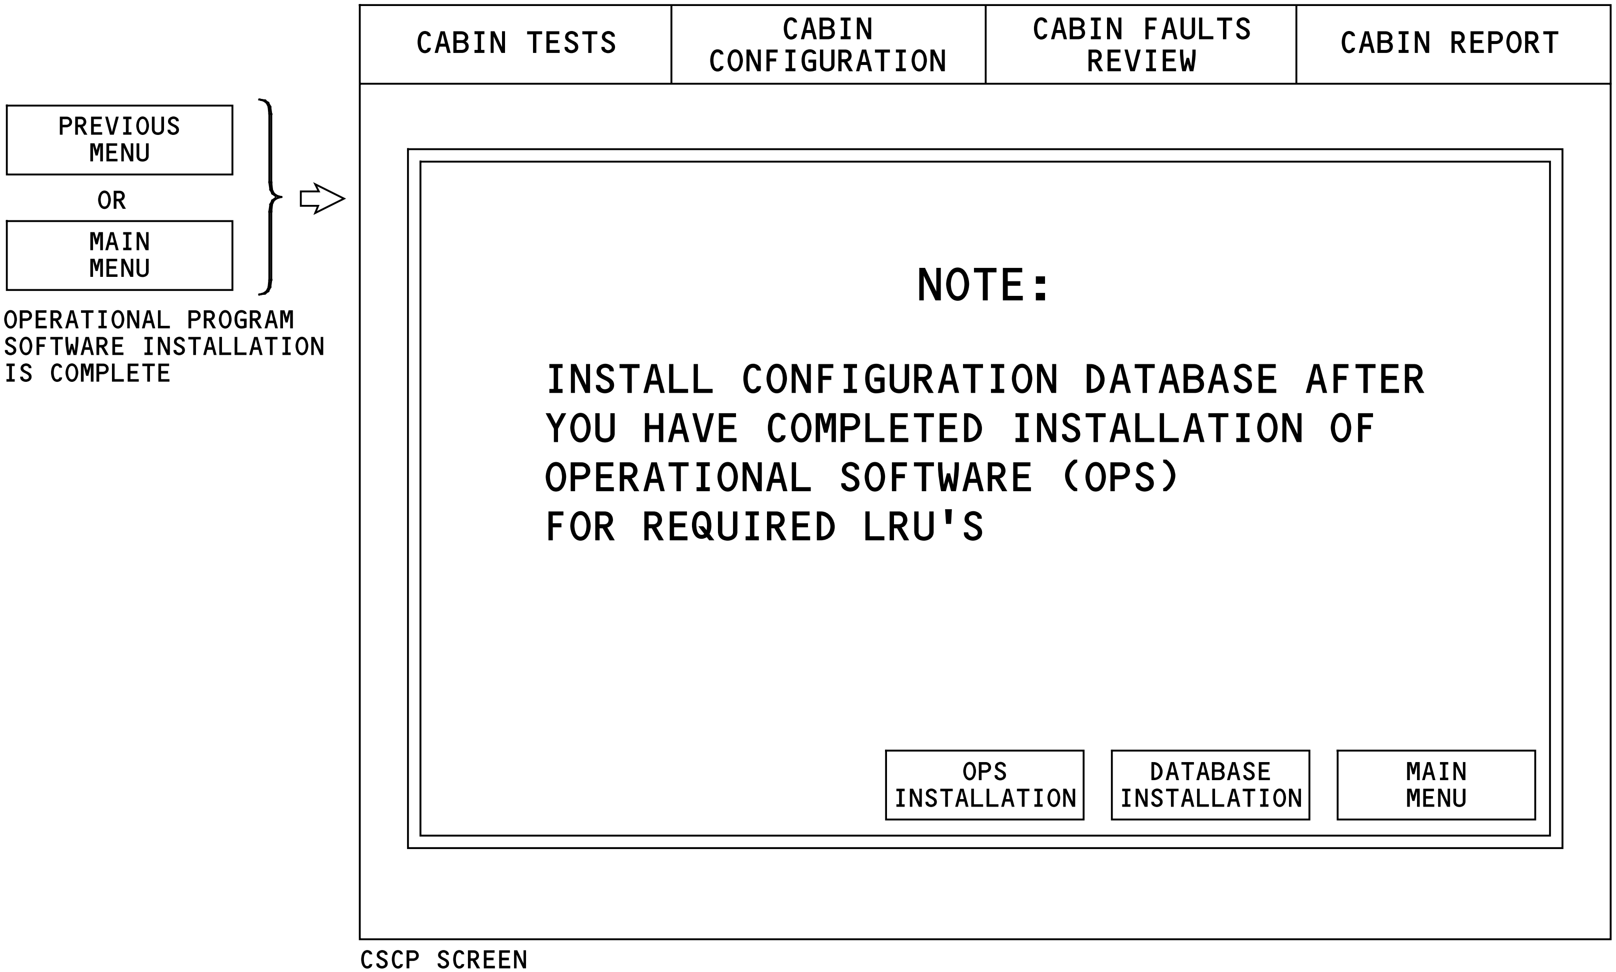
Access

This screen shows automatically when you select PREVIOUS MENU or MAIN MENU on the operational program software installation is complete screen.

Controls and Indications

Touch any of these selections at the bottom of the screen to do the related function:

- OPS INSTALLATION - to return to the operational program software installation menu
- DATABASE INSTALLATION - to show the configuration database installation screen
- MAIN MENU - to return to the cabin maintenance main menu.



23-39-00-714 Rev 0 06/18/96

CSS TEST AND SOFTWARE INSTALLATION - INSTALL DATABASE DIALOGUE WINDOW

THIS PAGE INTENTIONALLY LEFT BLANK

General

Software controls all cabin services system (CSS) functions. A configuration database and operational program software for the LRUs control the different systems that use the CSS.

The configuration database tells the CSS the cabin layout and customer options. Programmers use a configuration database generator on a computer to write this software. These are some of the items the configuration database identifies:

- Call light assignments
- Passenger information sign control
- The number and configuration of LRUs in the CSS
- Passenger address configuration
- Chime types and assignments
- Cabin interphone configuration.

Software Installation

The mass memory card in the cabin system control panel (CSCP) has all of the software programs. You use screens on the CSCP to install the configuration database and operational program software in CSS LRUs. These CSS components require the configuration database for operation:

- Cabin system control panel (CSCP)
- Cabin system management unit (CSMU)
- Passenger address/cabin interphone (PA/CI) controller
- Speaker drive modules (SDMs)
- Cabin area control panel (CACP)
- Zone management units (ZMUs)
- Overhead electronics units (OEUs).

Token Process

The PA/CI controller and ZMUs each use a data bus to load the SDMs, OEUs, and SEUs. The PA/CI controller and the ZMUs use a token signal to begin the sequence of data installation to these LRUs.

The token process enables each LRU to accept the data it needs. You start the token process when you install a configuration database or operational program software from the CSCP.

The PA/CI controller and the ZMUs send a token to the first LRU in each column. When the first LRU reads and accepts its data, it passes the token to the second LRU. When all the LRUs receive the token and accept their data, the token process is complete.

Configuration Database

You must install the configuration database after you replace any of these LRUs:

- CSCP
- CACPs
- CSMU
- ZMUs
- PA/CI controller

- SDMs
- OEUs.

You also install the configuration database if you install operational program software. Use screens on the CSCP to start the configuration database installation.

The CSCP sends configuration data to these components in this order:

- CSCP
- CSMU
- ZMUs (in sequence)
- PAC (normal)
- SDMs
- CIC (normal)
- PAC (alternate)
- CIC (alternate)
- CACPs (in sequence)
- OEUs (by zone).

Operational Program Software

Use the CSCP to start the operational program software installation. You can install data in only one LRU type at a time. Each LRU type has its own screen for you to select software part numbers.

The CSCP uses a panel bus to send data to the CSMU. The CSMU checks the operational program software to see where to send it. The CSMU puts it on the intersystem (I/S) bus for the other LRUs.

The PA/CI controller looks at the data on the bus to see if it is for itself or for the SDMs. If the data is for any of the SDMs, the PA/CI controller temporarily keeps the data in its random access memory (RAM). The PA/CI controller uses a data bus to send operational program software to all SDMs in a column at the same time. Each SDM makes a decision to install the data in its non-volatile memory (NVM).

Each ZMU does a check of the data to see if it is for itself or any of its OEUs or the CACP. Data loads to the OEUs or the CACP are almost the same as for the SDMs.

At the start of the installation, each LRU of the type you select does a check of its software part number to see if it already has the software in NVM. If it does not or if the software is failed, the LRU puts the data in NVM.

The LRU sends failure data back to the CSMU. The CSMU sends the failure data to the CSCP display.

After the data load, the LRU re-initializes itself and returns to normal operations.

CSS TEST AND SOFTWARE INSTALLATION - SOFTWARE INSTALLATION FUNCTIONAL DESCRIPTION

CSS TEST AND SOFTWARE INSTALLATION - DATA INSTALLATION IS OPERATING FROM DISK DRIVE

General

This screen shows automatically when you install data from a floppy diskette to the cabin system control panel (CSCP) memory.

Access

Touch these selections to show the data installation is operating from disk drive screen:

- CABIN CONFIGURATION on any maintenance screen
- SOFTWARE MANAGEMENT on the cabin configuration menu
- INSTALL DATA FROM FLOPPY DISK DRIVE on the software management menu.

Controls and Indications

The screen shows you the part number of the diskette in the disk drive. It also shows if the diskette is one of a number of diskettes in a set.

The elapsed time shows during the installation.

Touch STOP INSTALLATION to stop the installation of the data and return to the software management menu.

When the installation is complete, an insert next diskette dialogue window may show if it is necessary to use more than one diskette to install the data.

After you load all of the necessary data, a screen shows to tell you the installation is complete.

CSS TEST AND SOFTWARE INSTALLATION - DISK MAINTENANCE

CSS TEST AND SOFTWARE INSTALLATION - CONFIGURATION DATABASES IN MASS STORAGE

General

This screen gives you selections to remove configuration databases from the cabin system control panel (CSCP) memory.

Access

Touch these selections to show the configuration databases in mass storage screen:

- CABIN CONFIGURATION on any maintenance screen
- SOFTWARE MANAGEMENT on the cabin configuration menu
- DISK MAINTENANCE on the software management menu
- CONFIGURATION DATABASES DELETION on the disk maintenance menu.

Controls and Indications

The screen shows as many as six database selections. If the operating database is not in the CSCP memory, the first selection on the top left of the screen shows you that it was removed.

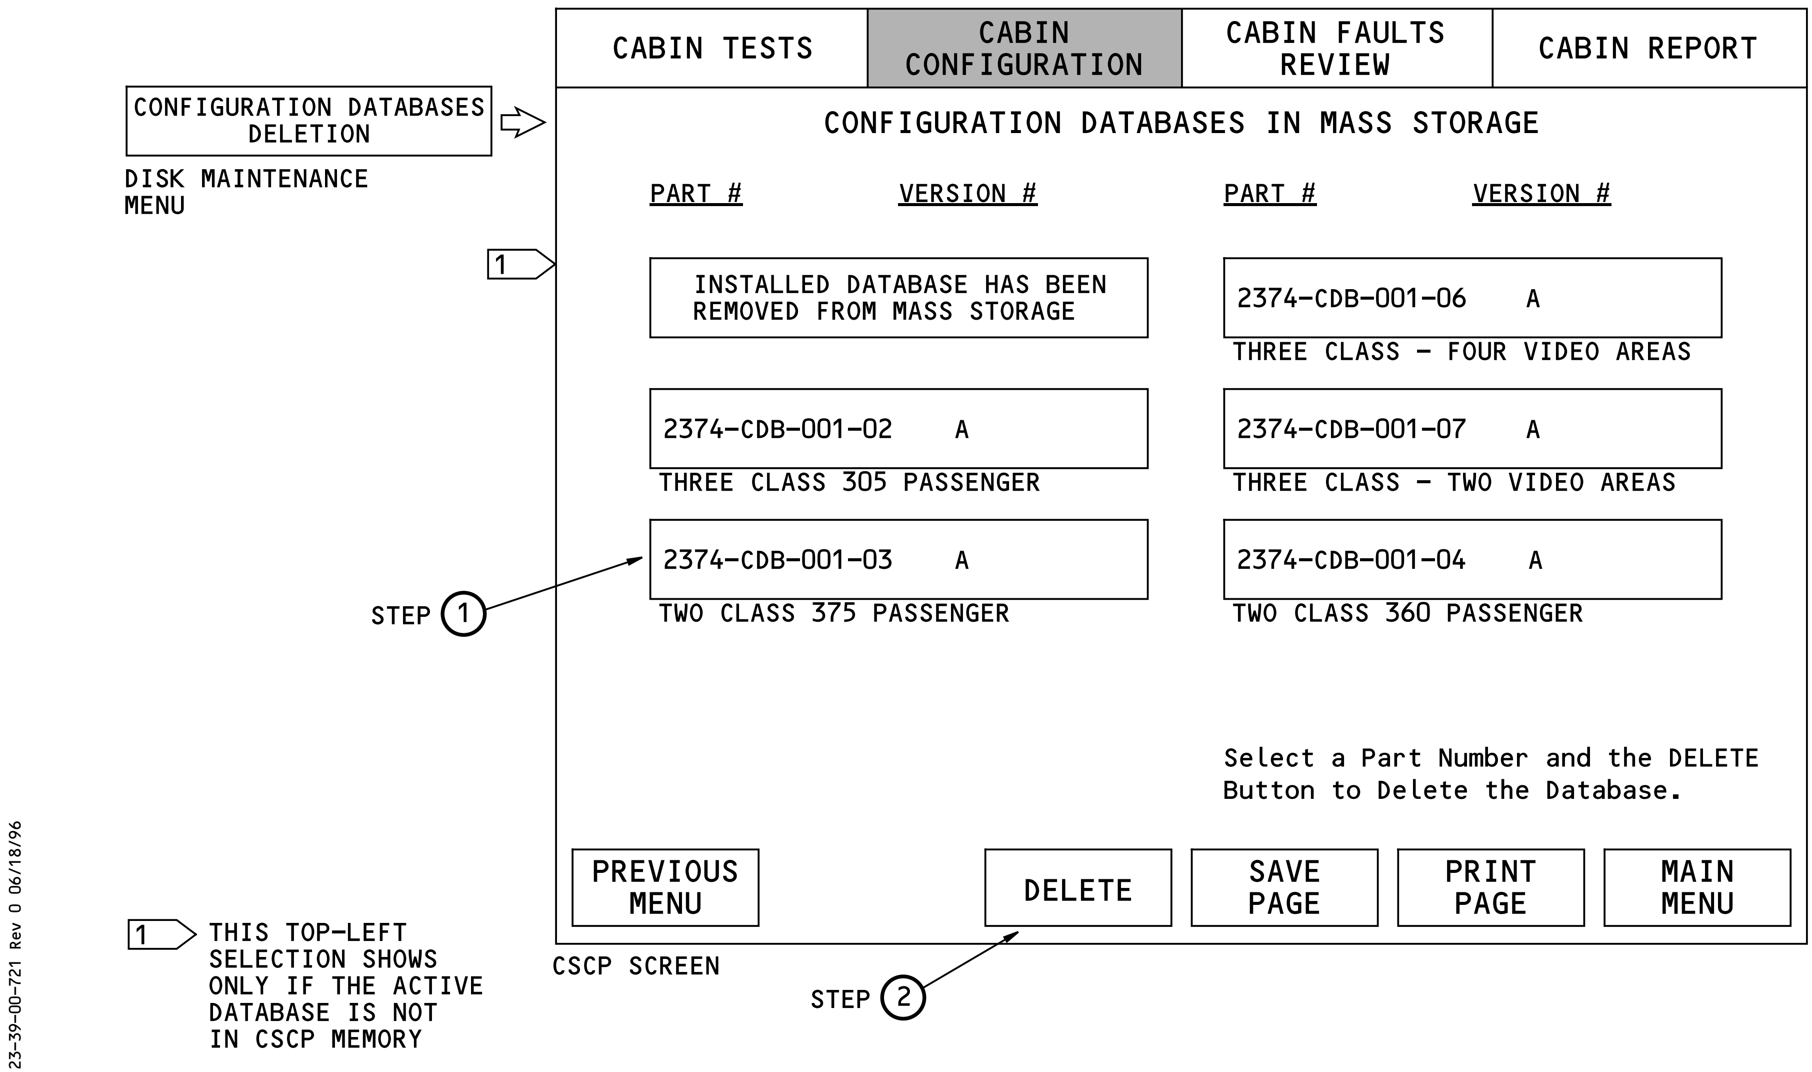
To remove a database from memory, first touch the database selection and then touch DELETE at the bottom of the screen. You can select only one database at a time.

After you touch DELETE, one of two screens will show. If you selected the active database, a dialogue window warns you that you are deleting the current database.

If you select any other database, a dialogue window asks you if you want to delete the database.

Touch any of these other selections at the bottom of the screen to do the related function:

- PREVIOUS MENU - to return to the disk maintenance menu
- SAVE PAGE - to save the screen data to a floppy diskette
- PRINT PAGE - to print the screen data to the cabin printer
- MAIN MENU - to return to the cabin maintenance menu.



CSS TEST AND SOFTWARE INSTALLATION - CONFIGURATION DATABASES IN MASS STORAGE

CSS TEST AND SOFTWARE INSTALLATION - CURRENT CONFIGURATION DATABASE DELETION

General

This screen shows automatically when you want to remove the operating database from the cabin system control panel (CSCP) memory.

Access

This screen shows if you make these selections:

- Touch CABIN CONFIGURATION on any maintenance screen
- Touch SOFTWARE MANAGEMENT on the cabin configuration menu
- Touch DISK MAINTENANCE on the software management menu
- Touch CONFIGURATION DATABASES DELETION on the disk maintenance menu
- Select the currently installed database on the configuration databases in mass storage screen and touch DELETE.

Controls and Indications

The screen shows the part number of the database you selected on the configuration databases in mass storage screen.

Touch one of these selections at the bottom of the screen to do the related function:

- CONTINUE DELETION - to delete the selection and show the deleting configuration database window
- SAVE PAGE - to store the screen data to floppy diskette
- PRINT PAGE - to print the screen data on the cabin printer
- CANCEL DELETION - to cancel deleting and return to the configuration databases in mass storage screen.

CSS TEST AND SOFTWARE INSTALLATION - CONFIGURATION CHECK MENU

CSS TEST AND SOFTWARE INSTALLATION - CONFIGURATION CHECK - LRU SELECTION SCREEN

General

This configuration check - LRU selection screen is applicable to multiple-LRU types. It permits you to select any or all LRUs of a single type and get configuration data.

Access

Touch these selections to show a configuration check screen for an LRU:

- CABIN CONFIGURATION on any maintenance screen
- CONFIGURATION CHECK on the cabin configuration menu
- Touch an LRU selection on the configuration check menu.

Controls and Indications

This screen shows the overhead electronics unit (OEU) selection. Screens for other LRUs are almost the same.

The controls on the screen permit you to make any of these selections:

- One OEU in a column of a zone
- All OEUs in a column of a zone
- All OEUs in a zone
- All OEUs in the system.

Use the up and down arrows on the left side of the screen to select any one or all of the CSS zones. The zone number you select shows to the left of the arrows.

Use the up and down arrows in the center of the screen to select any one or all of the columns of the selected zone. The column number you select shows to the left of the arrows.

Use the up and down arrows on the right side of the screen to select any one or all of the OEUs in the selected column. The OEU you select shows to the left of the arrows.

After you make the selections, touch CONTINUE to get the configuration. If any LRU does not respond, a dialogue window shows you which ones. If all LRUs are active, the configuration check screen for the LRU type shows.

Touch any of these selections at the bottom of the screen to do the related function:

- PREVIOUS MENU - to return to the configuration check menu
- LRU SUMMARY - to see a screen that shows the number of OEUs in each column and zone
- MAIN MENU - to return to the cabin maintenance menu.

This screen shows the configuration of the LRUs of the type you selected with other screens.

Access

To show the LRU configuration check screen:

- Touch CABIN CONFIGURATION on any maintenance screen
- Touch CONFIGURATION CHECK on the cabin configuration menu
- Touch an LRU selection on the configuration check menu
- Make the necessary selections for the LRU and touch CONTINUE on the configuration check - LRU selection screen.

Controls and Indications

The screen shows each LRU of the type you selected on the configuration check selection screen. It shows these items for each LRU:

- The LRU name
- The address assigned by the configuration database
- LRU location
- The serial number of the unit
- The hardware part number
- The software part number of the operation program software installed
- The database part number and version number of the configuration database installed.

Use the up and down arrows at the right of the window to scroll through the data.

Touch any of these selections at the bottom of the screen to do the related function:

- PREVIOUS MENU - to return to the configuration check menu
- PREVIOUS SCREEN - to return to the configuration check - LRU selection screen
- SAVE - to save the data to a cabin system control panel (CSCP) floppy diskette
- PRINT - to print the data to the cabin printer
- MAIN MENU - to return to the cabin maintenance menu.

CSS TEST AND SOFTWARE INSTALLATION - CONFIGURATION CHECK - LRU SCREEN

CSS TEST AND SOFTWARE INSTALLATION - CABIN FAULTS REVIEW MENU

General

You use the cabin faults review menu to show failure data for the CSS. These are the five selections on the cabin faults review menu:

- QUICK TEST FAULTS REVIEW
- ALL TEST FAULTS REVIEW
- DATA INSTALLATION FAULTS REVIEW
- FLIGHT DECK EFFECTS FAULTS (ACTIVE)
- FLIGHT DECK EFFECTS FAULTS (HISTORY)

Access

Touch CABIN FAULTS REVIEW on any maintenance screen to show the cabin faults review menu.

Quick Test Faults Review

Touch QUICK TEST FAULTS REVIEW to show the faults review screen from the last quick test. See the quick test description for more information.

All Test Faults Review

Touch ALL TEST FAULTS REVIEW to show the faults review screen from the last all test. See the all test description for more information.

Data Installation Faults Review

Touch DATA INSTALLATION FAULTS REVIEW to show an installation fault results screen from the last database or operational program installation. For more information on data installation see the database or operational program installation description.

Flight Deck Effects Faults (Active)

Touch FLIGHT DECK EFFECTS FAULTS (ACTIVE) to show CSS failures that cause EICAS messages. The screen shows all active CSS related EICAS messages and related maintenance messages.

Flight Deck Effects Faults (History)

The flight deck effects faults (history) screen is the same as flight deck effects faults (active) screen except it also has EICAS related failures kept in memory. It can keep as many as 99 failures in non-volatile memory.

CSS TEST AND SOFTWARE INSTALLATION - FLIGHT DECK EFFECTS FAULTS (ACTIVE) SCREEN

General

You use the flight deck effects faults (active) screen to show failures that cause CSS related EICAS messages. Active EICAS messages are messages that currently show on EICAS.

Access

To show the flight deck effects faults (active) screen:

- Touch CABIN FAULTS REVIEW on any maintenance screen
- Touch FLIGHT DECK EFFECTS FAULTS (ACTIVE) on the cabin faults review menu.

Controls and Indications

These are the three parts of the screen:

- Fault conditions
- Maintenance message data
- Selection controls.

Fault Conditions

The fault conditions part of the screen shows this fault data:

- Screen title - FLIGHT DECK EFFECTS (FDE) FAULTS (ACTIVE)
- The configuration database part number currently installed
- The date and time of the fault
- The sequence of each maintenance message in the list of messages.

Flight Deck Effects

The data window shows maintenance messages for each flight deck effect. The bottom line of the data window shows the EICAS message. These are the two EICAS status messages that can occur because of CSS failures:

- PASSENGER ADDRESS - Caused by a failure of the active passenger address controller. It can also occur if two adjacent speaker drive modules have a failure.
- CABIN INTERPHONE - Caused by a failure of the active cabin interphone controller. It can also occur if a zone management unit fails, or if two cabin attendant handsets fail in the same zone.

Maintenance Message Data

Each page shows one maintenance message. The maintenance message shows data about each failure. These are the three parts to the maintenance message:

- Fault description
- Maintenance message number/fault activity level
- Recommended maintenance action.

The fault description identifies the failure condition detected by the continuous BITE. It also identifies the component that found the fault.

CSS TEST AND SOFTWARE INSTALLATION - FLIGHT DECK EFFECTS FAULTS (ACTIVE) SCREEN

There is one maintenance message number for every maintenance message. You use the maintenance message number to find the corrective action in the fault isolation manual (FIM). Some maintenance messages show Latched. latched means the fault will stay in the system until you take corrective action.

The recommended maintenance action identifies all the possible components or conditions that could cause the fault. The most probable cause shows first and the least probable cause shows last.

Each screen shows one maintenance message. Use the up or down arrow at the right of the screen to scroll through the messages. The square on the scroll bar shows your position in the message list.

Selection Controls

Touch PREVIOUS MENU to show the cabin faults review menu.

Touch SHOW LOCATION to show a visual reference of the defective component.

Touch UNIT USAGE to show the components controlled by the defective component.

Touch SAVE to send the data to a floppy diskette in the CSCP.

Touch PRINT to send the data to the printer for a paper copy.

Touch MAIN MENU to show the cabin maintenance menu.

CSS TEST AND SOFTWARE INSTALLATION - FLIGHT DECK EFFECTS FAULTS (ACTIVE) SCREEN

THIS PAGE INTENTIONALLY LEFT BLANK

CSS TEST AND SOFTWARE INSTALLATION - FLIGHT DECK EFFECTS FAULTS (HISTORY) SCREEN

General

You use the flight deck effects faults (history) screen to show failures that cause CSS related EICAS messages.

The flight deck effects faults (history) is the same as flight deck effects faults (active) except that it shows all faults in memory. The CSS can keep as many as 99 faults in non-volatile memory.

Access

To show the flight deck effects faults (history) screen, do this:

- Touch CABIN FAULTS REVIEW on any maintenance screen
- Touch FLIGHT DECK EFFECTS FAULTS (HISTORY) on the cabin faults review menu.

Controls and Indications

These are the three parts of the screen:

- Fault conditions
- Maintenance message data
- Selection controls.

Fault Conditions

The fault conditions part of the screen shows this fault data:

- Screen title - FLIGHT DECK EFFECTS (FDE) FAULTS (HISTORY)
- PRESENT LEG shows if the fault occurred on the current flight leg
- The configuration database part number installed at the time of the fault
- The date and time of the fault
- The number of times the fault occurred during the flight leg. If the number of occurrences is more than one, the fault is an intermittent fault
- The flight phase when the fault occurred
- The sequence of each maintenance message in the list of messages.

The flight phase shows the part of flight in which the fault first occurred. These are the possible flight phases:

- Power on
- Engine start
- Taxi out
- Takeoff
- Initial climb
- Climb
- Enroute
- Descent
- Approach
- Go around
- Flare
- Rollout
- Taxi in
- Shutdown
- Maintenance.

CSS TEST AND SOFTWARE INSTALLATION - FLIGHT DECK EFFECTS FAULTS (HISTORY) SCREEN

Flight Deck Effects

The data window shows maintenance messages for each flight deck effect. The bottom line of the data window shows the EICAS message. These are the two EICAS status messages that can occur because of CSS failures:

- PASSENGER ADDRESS - Caused by a failure of the active passenger address controller. It can also occur if two adjacent speaker drive modules have a failure.
- CABIN INTERPHONE - Caused by a failure of the active cabin interphone controller. It can also occur if a zone management unit fails or if two cabin attendant handsets fail in the same zone.

Maintenance Message Data

Each page shows one maintenance message. The maintenance message shows data about each failure. These are the three parts to the maintenance message:

- Fault description
- Maintenance message number
- Recommended maintenance action.

The fault description identifies the failure condition detected by the continuous BITE. It also identifies the component that found the fault.

There is one maintenance message number for every maintenance message. You use the maintenance message number to find the corrective action in the fault isolation manual (FIM). Some maintenance messages show Latched. latched means the fault will stay in the system until you take corrective action.

The recommended maintenance action identifies all the possible components or conditions that could cause the fault. The most probable cause shows first and the least probable cause shows last.

Each screen shows one maintenance message. Touch the down arrow to access additional messages. Touch the up arrow to return through the message list. The square on the scroll bar shows your position in the message list.

Selection Controls

Touch PREVIOUS MENU to show the cabin faults review menu.

Touch SHOW LOCATION to show a visual reference of the defective component.

Touch UNIT USAGE to show the components controlled by the defective component.

Touch SAVE to send the data to a floppy diskette in the CSCP.

Touch PRINT to send the data to the printer for a paper copy.

Touch MAIN MENU to show the cabin maintenance menu.

CSS TEST AND SOFTWARE INSTALLATION - CABIN REPORT MENU

General

You use the cabin report menu to make a paper copy or digital copy of fault results and configuration data. For a paper copy, the CSS sends the data to the cabin printer. For a digital copy, the CSS sends the data to a diskette in the cabin system control panel (CSCP).

Access

Touch CABIN REPORT on any maintenance screen to show the cabin report menu.

Fault Summary

The fault summary report shows maintenance message numbers and the number of times they have occurred.

Quick Test Faults

The quick test faults report contains test data and all maintenance messages from the last quick test.

All Test Faults

The all test faults report contains test data and all maintenance messages from the last all test.

Data Installation Faults

The data installation report contains failure descriptions from the last configuration database installation or operational program installation.

Flight Deck Effects-Active Faults-Report

The flight deck effects-active report contains CSS EICAS messages and related maintenance messages for active EICAS messages.

Flight Deck Effects-Fault History-Report

The flight deck effects-fault history report contains CSS EICAS messages and their related maintenance message for EICAS messages stored in non-volatile memory.

CSS Configuration All

The CSS configuration report shows part number data for CSS components. The list includes these items for each component:

- Hardware part number
- Software part number
- Database part number
- Database version number
- Serial number
- Name, address, and location
- Report date, time, and title.

CSS Configuration Summary

The CSS configuration summary report shows part number data for CSS components. The list includes these items for each component:

- Hardware part number
- Software part number
- LRU type name
- Report date, time, and title.

Cabin Report Menu Controls

To select a report, touch the report selection. The selection becomes green and the SAVE ALL and PRINT ALL selection show in dark print. Touch SAVE ALL to send the data to a diskette in the CSCP. Touch PRINT ALL to send the report to the cabin printer.

Touch MAIN MENU to show the cabin maintenance menu.

CABIN INTERPHONE SYSTEM - INTRODUCTION

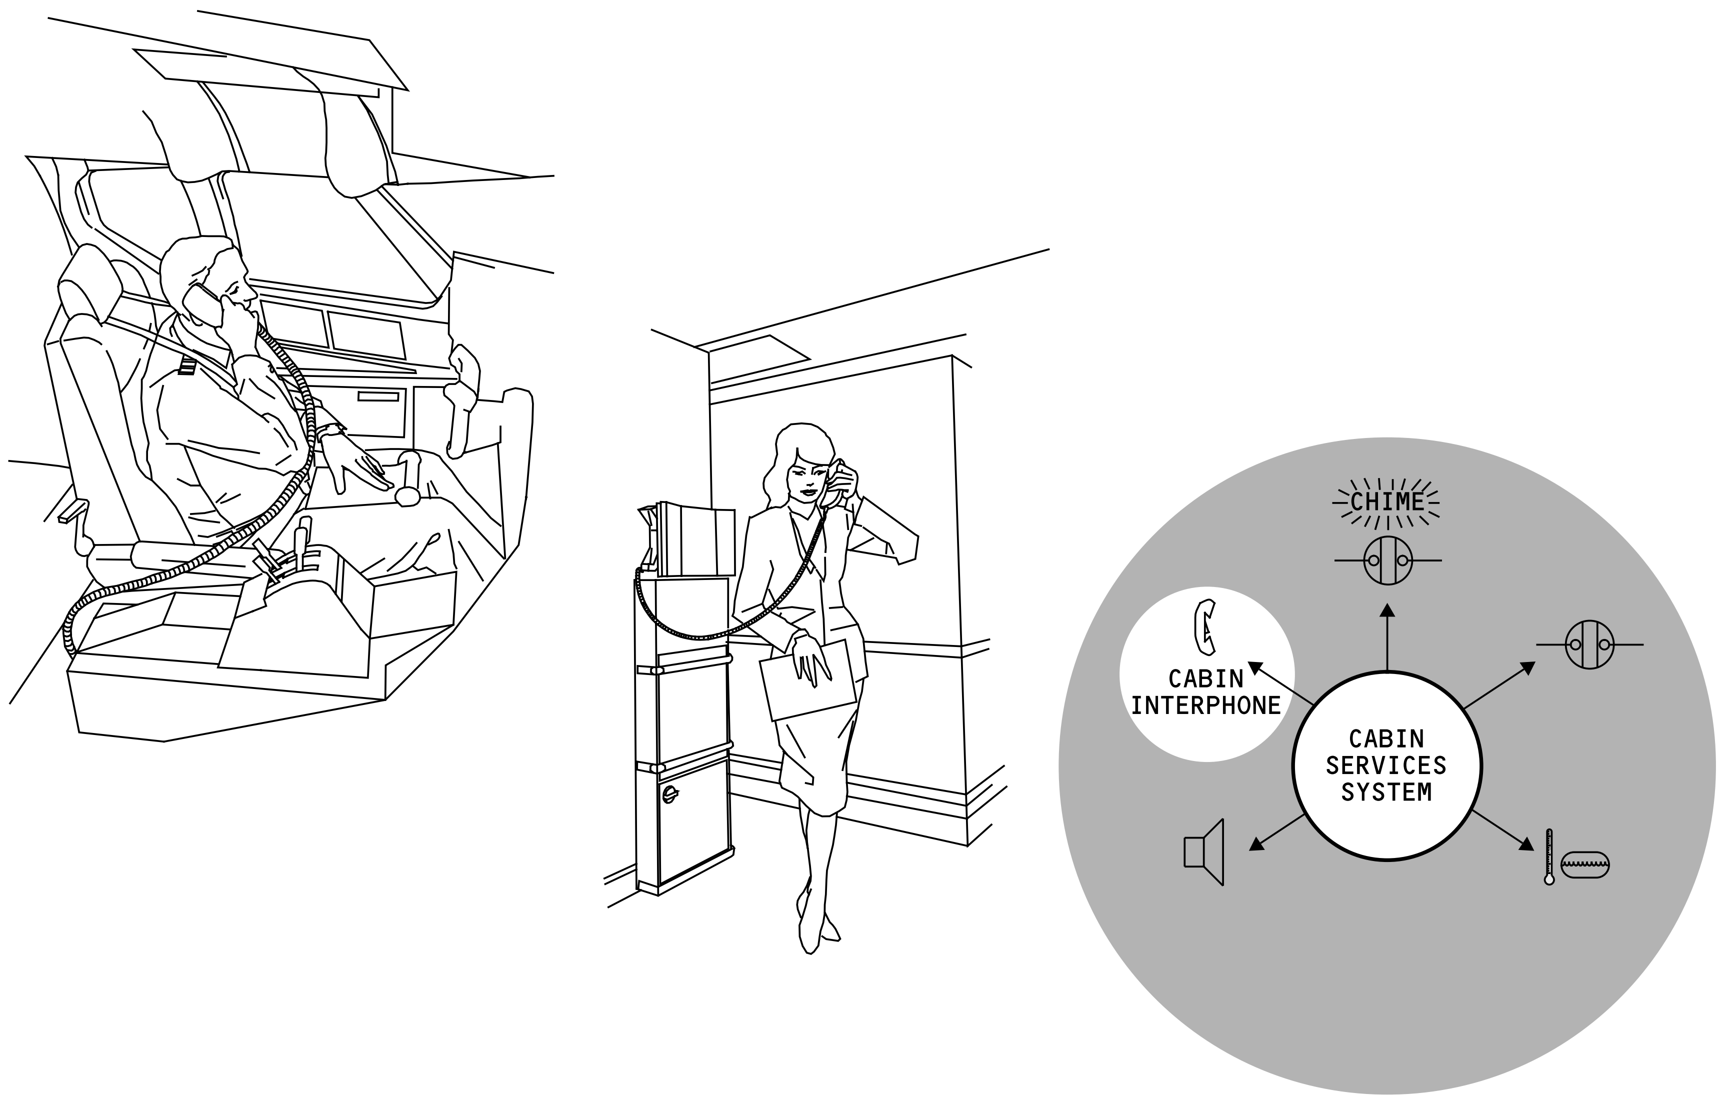
Purpose

Flight attendants use the cabin interphone system (CIS) to speak with each other and the pilots.

The CIS is like a telephone system which uses handsets and dial codes.

Abbreviations and Acronyms

AMU	- audio management unit
ASP	- attendant switch panel
alt	- alternate
aud	- audio
CACP	- cabin area control panel
CAH	- cabin attendant handset
CCP	- cabin control panel
CIC	- cabin interphone controller
CIS	- cabin interphone system
CDU	- control display unit
CSCP	- cabin system control panel
CSMU	- cabin system management unit
CSS	- cabin services system
dr	- door
FCR	- flight crew rest
FDH	- flight deck handset
FSEU	- flap/slat electronics unit
LLAR	- lower lobe attendants rest
PA/CI	- passenger address/cabin interphone
PAC	- passenger address controller
PAS	- passenger address system
PTT	- push to talk
ZMU	- zone management unit



23-42-00-001 Rev 5 08/07/96

CABIN INTERPHONE SYSTEM - INTRODUCTION

CIS - GENERAL DESCRIPTION

General

Flight attendants and the flight crew speak with each other on the CIS.

All audio signals go through the passenger address/ cabin interphone (PA/CI) controller. The PA/CI controller is the primary component of the CIS.

Flight Deck

The flight deck has a flight deck handset (FDH) that connects to the PA/CI controller. The flight crew uses the FDH to dial flight attendant stations and to talk to flight attendants.

The flight crew can also use the flight interphone system to talk on the CIS. They use the center control display unit (CDU) to call the attendant station. The audio management unit (AMU) connects the PA/CI controller to the flight crew headsets. The center CDU also shows incoming call information.

The PA/CI sends call alert signals to the AIMS cabinets. The AIMS shows EICAS messages for calls to the flight deck.

Cabin

Each attendant station has a cabin attendant handset (CAH). The flight attendants use the CAHs to talk to each other and the flight crew. They use dial code keys on the CAH to call other stations.

The CAHs connect to zone management units (ZMUs) for audio and dial codes. The ZMUs have a digital interface with the PA/CI controller. The ZMUs digitize the signal from the CAH and send it to the PA/CI controller. The PA/CI controller makes the connection between stations. The ZMU changes the signal back to analog and sends it to the CAH.

When an attendant station gets a call, the passenger address system (PAS) makes a chime. The ZMU causes a master call light to come on at the attendant station.

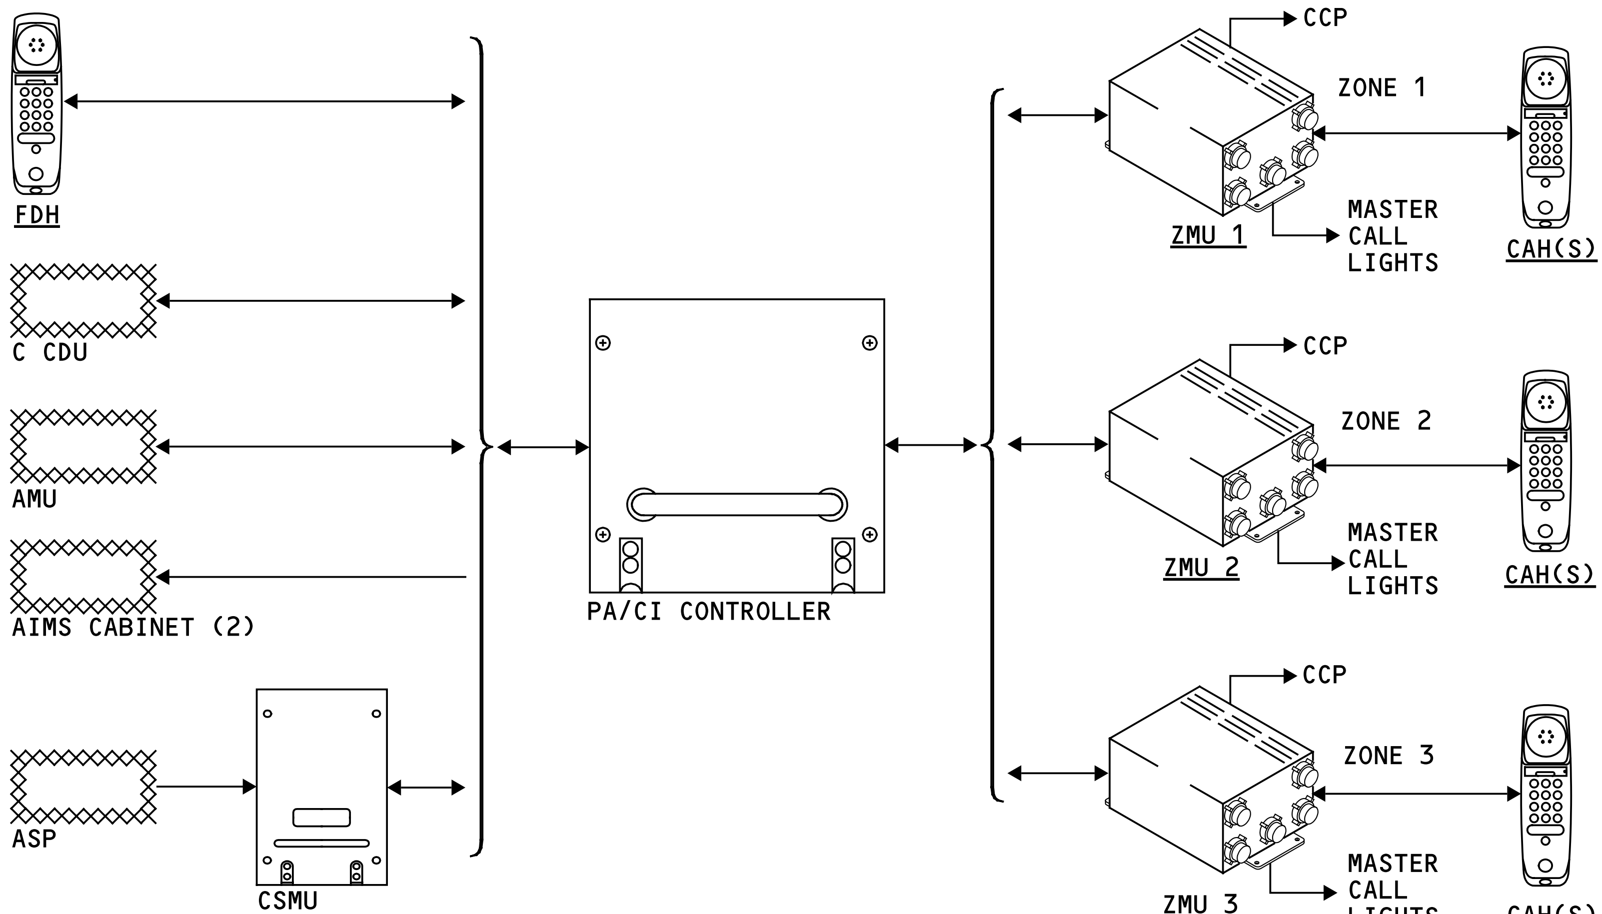
Other Interfaces

The PA/CI controller sends fault information on the left systems ARINC 629 bus. It also uses airplane systems information for some functions.

You use the cabin control panels (CCPs) to control the CIS. A CCP operates as a cabin area control panel (CACP) or as a cabin system control panel (CSCP), depending upon its configuration.

The PA/CI controller has two cabin interphone controllers, normal and alternate. If the normal cabin interphone controller fails, the flight attendants get a message on the cabin control panels (CCPs). The flight attendants use the attendant switch panel (ASP) to select the alternate controller.

You use the cabin system control panel (CSCP) to test and install software into the CIS.



CIS - GENERAL DESCRIPTION

CIS - COMPONENT LOCATIONS - CABIN AND MAIN EQUIPMENT CENTER

Cabin

The cabin attendant handsets (CAHs) are at each attendant seats station. The CI NORM/ALT switch is on the attendant switch panel (ASP) at door 2 left.

There is one CAH in the flight crew rest (FCR).

The zone management units (ZMUs) are above the passenger cabin area on the stow bin ladder assembly.

The passenger address/cabin interphone (PA/CI) controller is in the main equipment center (MEC).
